Note: S-TYPE-3, P-TYPE-3
Note: This register is accessed by the clock of PCLKB/64 to reduce current consumption in Deep Software Standby mode1.
Note 1. OVRCURA or OVRCURB can not be used. Only OVRCURA-DS or OVRCURB-DS can be used in Deep Software Standby mode1.

DPINTE0 bit (USB DP Interrupt Enable/Clear)

The DPINTE0 bit enables or disables triggering of recovery from Deep Software Standby mode 1 by the DP input of the USBFS. Writing 0 to this bit while the DPINT0 bit is 1 sets the DPINT0 bit to 0.

DMINTE0 bit (USB DM Interrupt Enable/Clear)

The DMINTE0 bit enables or disables triggering of recovery from Deep Software Standby mode 1 by the DM input of the USBFS. Writing 0 to this bit while the DMINT0 bit is 1 clears the DMINT0 bit to 0.

DOVRCRAE0 bit (USB OVRCURA-DS Interrupt Enable/Clear)

The DOVRCRAE0 bit enables or disables triggering of recovery from Deep Software Standby mode 1 by the OVRCURA-DS input of the USBFS. Writing 0 to this bit while the DOVRCRA0 bit is 1 clears the DOVRCRA0 bit to 0.

DOVRCRBE0 bit (USB OVRCURB-DS Interrupt Enable/Clear)

The DOVRCRBE0 bit enables or disables triggering of recovery from Deep Software Standby mode 1 by the OVRCURB-DS input of the USBFS. Writing 0 to this bit while the DOVRCRB0 bit is 1 clears the DOVRCRB0 bit to 0.

DVBSE0 bit (USB VBUS Interrupt Enable/Clear)

The DVBSE0 bit enables or disables triggering of recovery from Deep Software Standby mode 1 by the VBUS input of the USBFS. Writing 0 to this bit while the DVBINT0 bit is 1 clears the DVBINT0 bit to 0.

DPINT0 bit (USB DP Interrupt Source Recovery)

The DPINT0 bit indicates that the system has returned from Deep Software Standby mode 1 because of the DP input of the USBFS. This recovery is only enabled when the DPINTE0 bit is 1. Writing 0 to the DPINTE0 bit while this bit is 1 clears this bit to 0.

DMINT0 bit (USB DM Interrupt Source Recovery)

The DMINT0 bit indicates that the system has returned from Deep Software Standby mode 1 because of the DM input of the USBFS. This recovery is only enabled when the DMINTE0 bit is 1. Writing 0 to the DMINTE0 bit while this bit is 1 clears this bit to 0.

DOVRCRA0 bit (USB OVRCURA-DS Interrupt Source Recovery)

The DOVRCRA0 bit indicates that the system has returned from Deep Software Standby mode 1 because of the OVRCURA-DS input of the USBFS. This recovery is only enabled when the DOVRCRAE0 bit is 1. Writing 0 to the DOVRCRAE0 bit while this bit is 1 clears this bit to 0.

DOVRCRB0 bit (USB OVRCURB-DS Interrupt Source Recovery)

The DOVRCRB0 bit indicates that the system has returned from Deep Software Standby mode 1 because of the OVRCURB-DS input of the USBFS. This recovery is only enabled when the DOVRCRBE0 bit is 1. Writing 0 to the DOVRCRBE0 bit while this bit is 1 clears this bit to 0.

DVBINT0 bit (USB VBUS Interrupt Source Recovery)

The DVBINT0 bit indicates that the system has returned from Deep Software Standby mode 1 because of the VBUS input of the USBFS. This recovery is only enabled when the DVBSE0 bit is 1. Writing 0 to the DVBSE0 bit while this bit is 1 clears this bit to 0.

27.3 Operation

27.3.1 System Control

This section describes register settings required for initializing the USBFS and controlling power consumption.

27.3.1.1 Setting data to the USBFS registers

Setting the SYSCFG.USBE bit to 1 after starting the clock supply (SYSCFG.SCKE bit = 1) enables and starts USBFS operation.

27.3.1.2 Selecting the controller function

The USBFS can operate as either a host or device controller.

Use the SYSCFG.DCFM bit to select one of these USBFS functions. The DCFM bit must be changed in the initial settings immediately after a reset or in the D+ pull-up-disabled state (SYSCFG.DPRPU bit = 0) and D+ and D– pull-down-disabled state (SYSCFG.DRPD bit = 0).

27.3.1.3 Controlling the USB data bus using resistors

The USBFS provides pull-up and pull-down resistors for the D+ and D– lines. Pull these lines up or down by setting the SYSCFG.DPRPU and DRPD bits.

In device controller mode, confirm that connection to the USB host is made, and then set the SYSCFG.DPRPU bit to 1 and pull up the D+ line (in full-speed communication).

When the SYSCFG.DPRPU bit is set to 0 during communication with a PC, the USBFS disables the pull-up resistor of the USB data line, thereby notifying the USB host of disconnection.

In host controller mode, set the SYSCFG.DRPD bit to 1 to pull down the D+ and D– lines.

Table 27.14 USB data bus resistor control

SYSCFG register settings		USB data bus control		
DRPD bit	DPRPU bit	D–	D+	Function
0	0	Open	Open	When resistors not used
0	1	Open	Pull-up	When operating as a device controller at full-speed
1	0	Pull-down	Pull-down	When operating as a host controller
1	1	—	—	Setting prohibited

27.3.1.4 Example external connection circuits

Figure 27.2 shows an example OTG connection in the self-powered system. The USBFS controls the pull-up resistor of the D+ line and the pull-down resistor of D+ and D- lines. Select pull-up and pull-down for the lines in the SYSCFG.DPRPU and SYSCFG.DRPD bits. In device controller mode, the pull-up resistor of USB data line is disabled if SYSCFG.DPRPU bit is set to 0 while communicating with the USB host. The USBFS can use this to notify the USB host of a device disconnect.

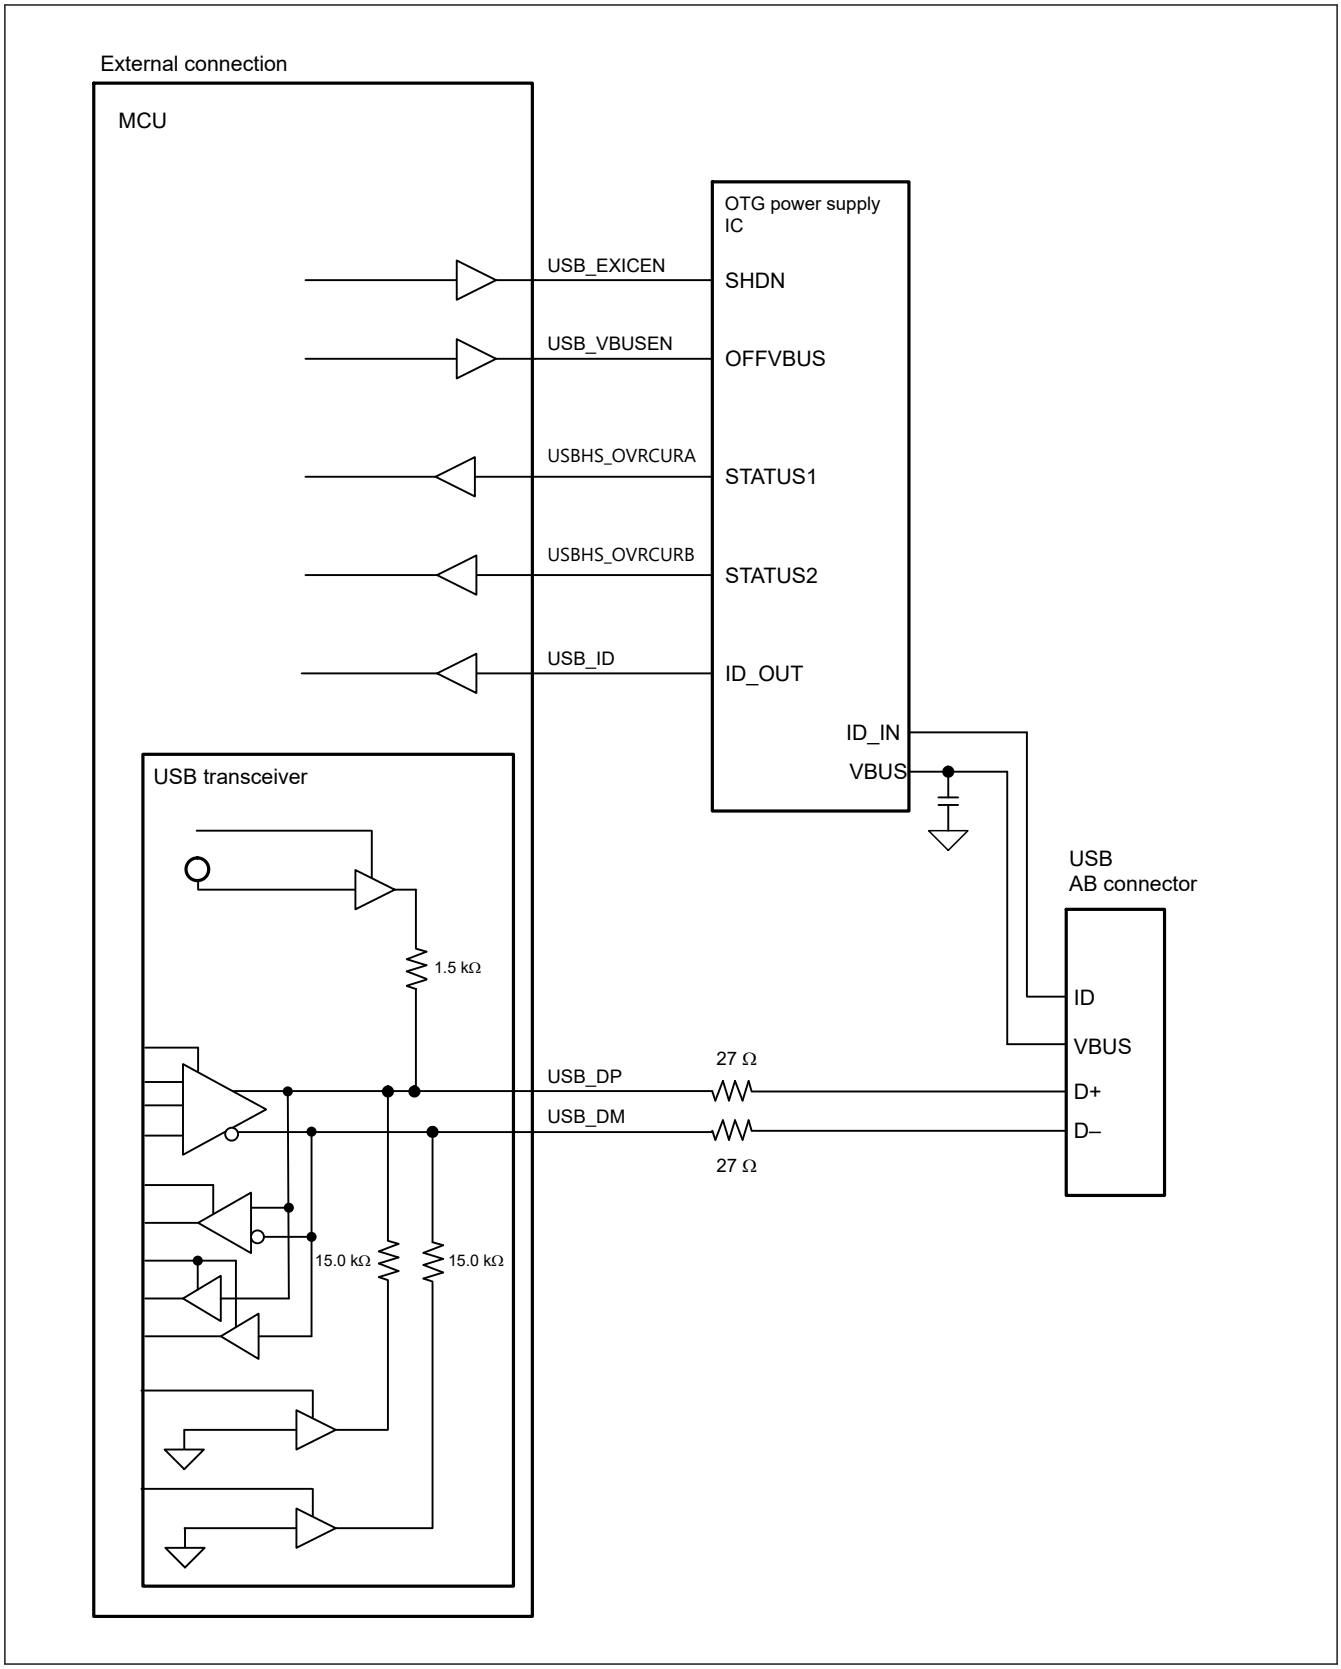

Figure 27.2 Example OTG connection in a self-powered system

Figure 27.3 shows an example device connection in a self-powered system.

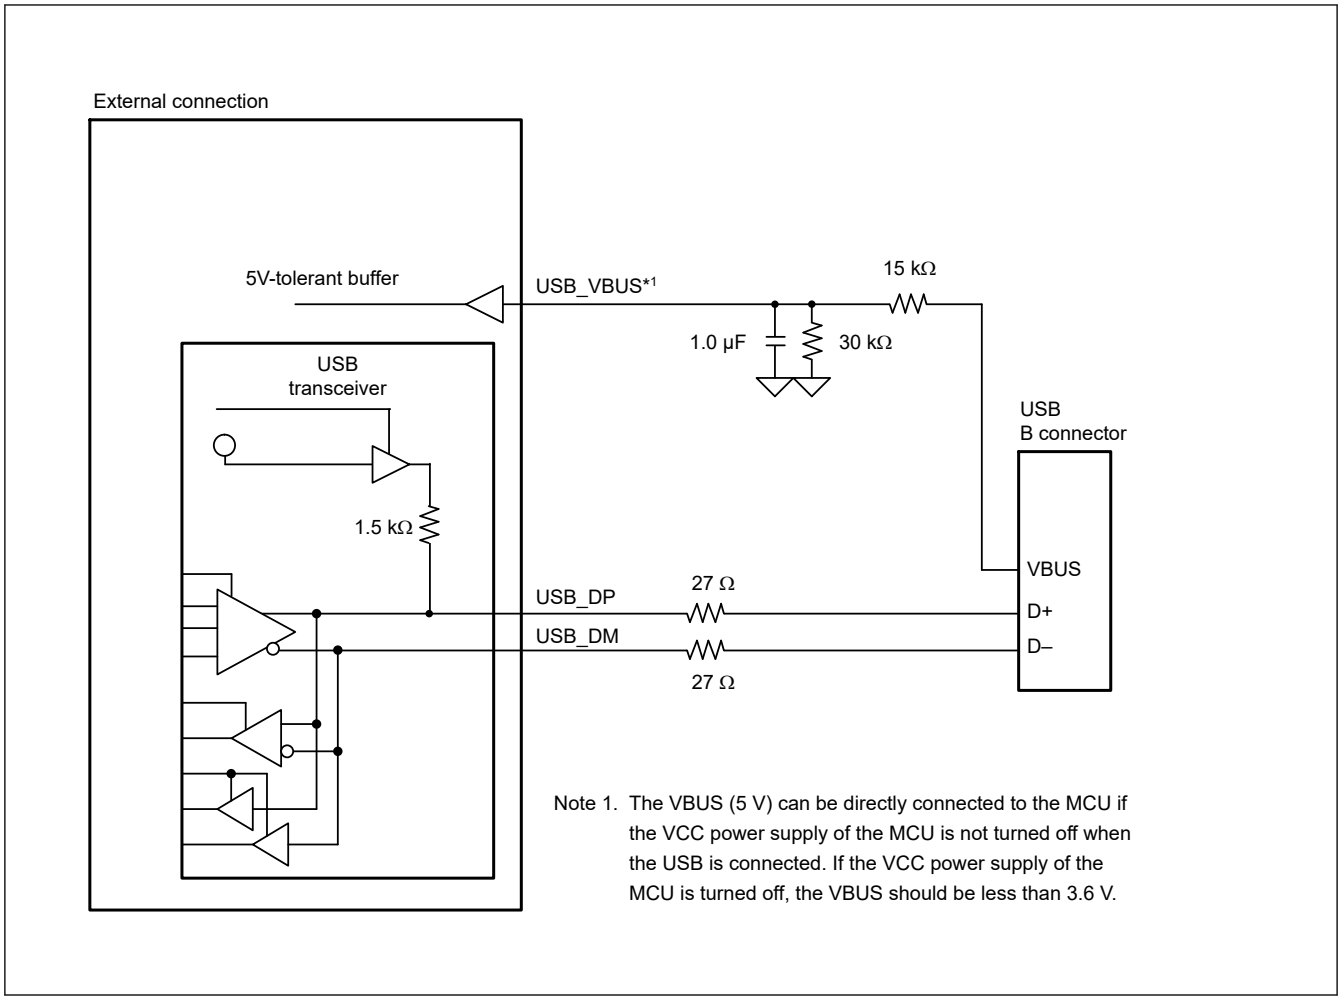

Figure 27.3 Example device connection in a self-powered system

Figure 27.4 shows an example host connection.

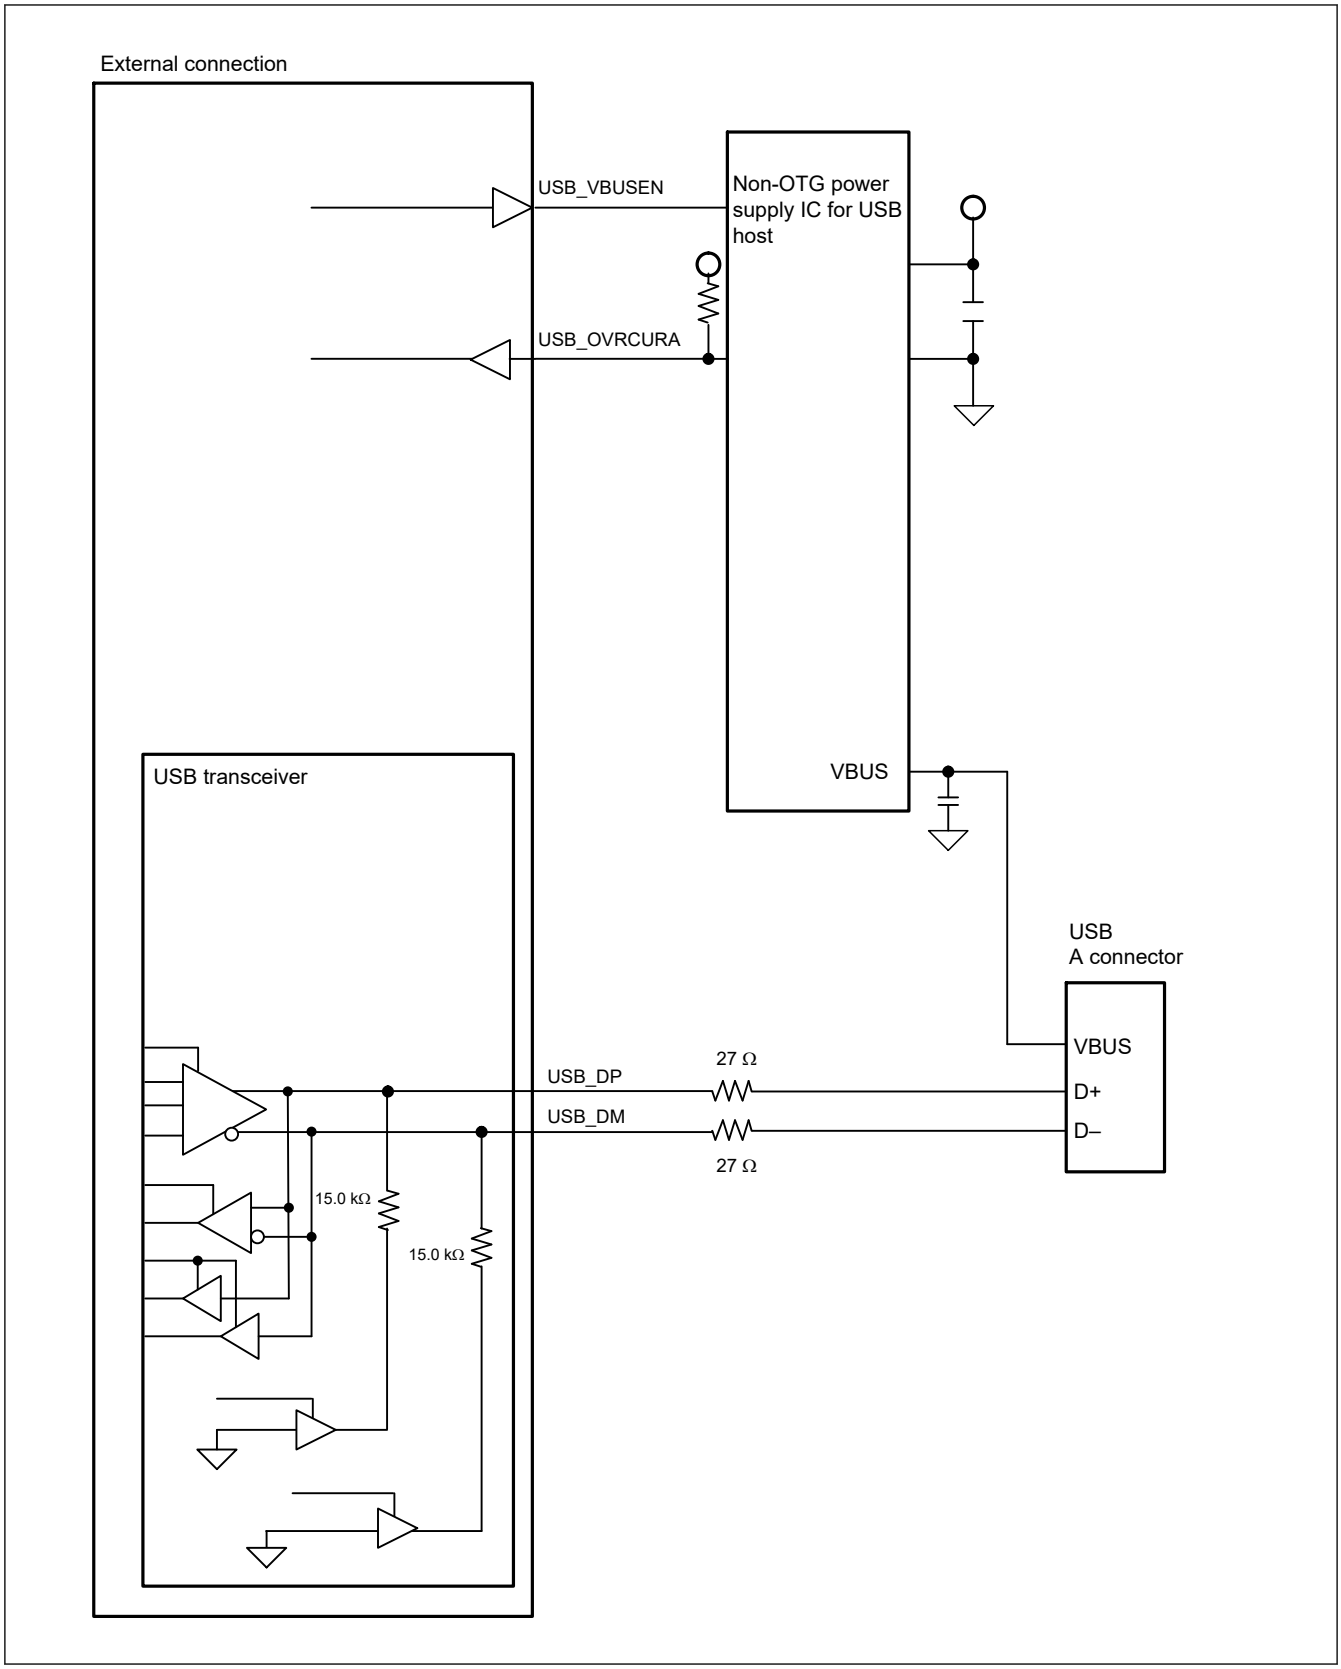

Figure 27.4 Example host connection

Figure 27.5 shows an example device connection in a bus-powered system.

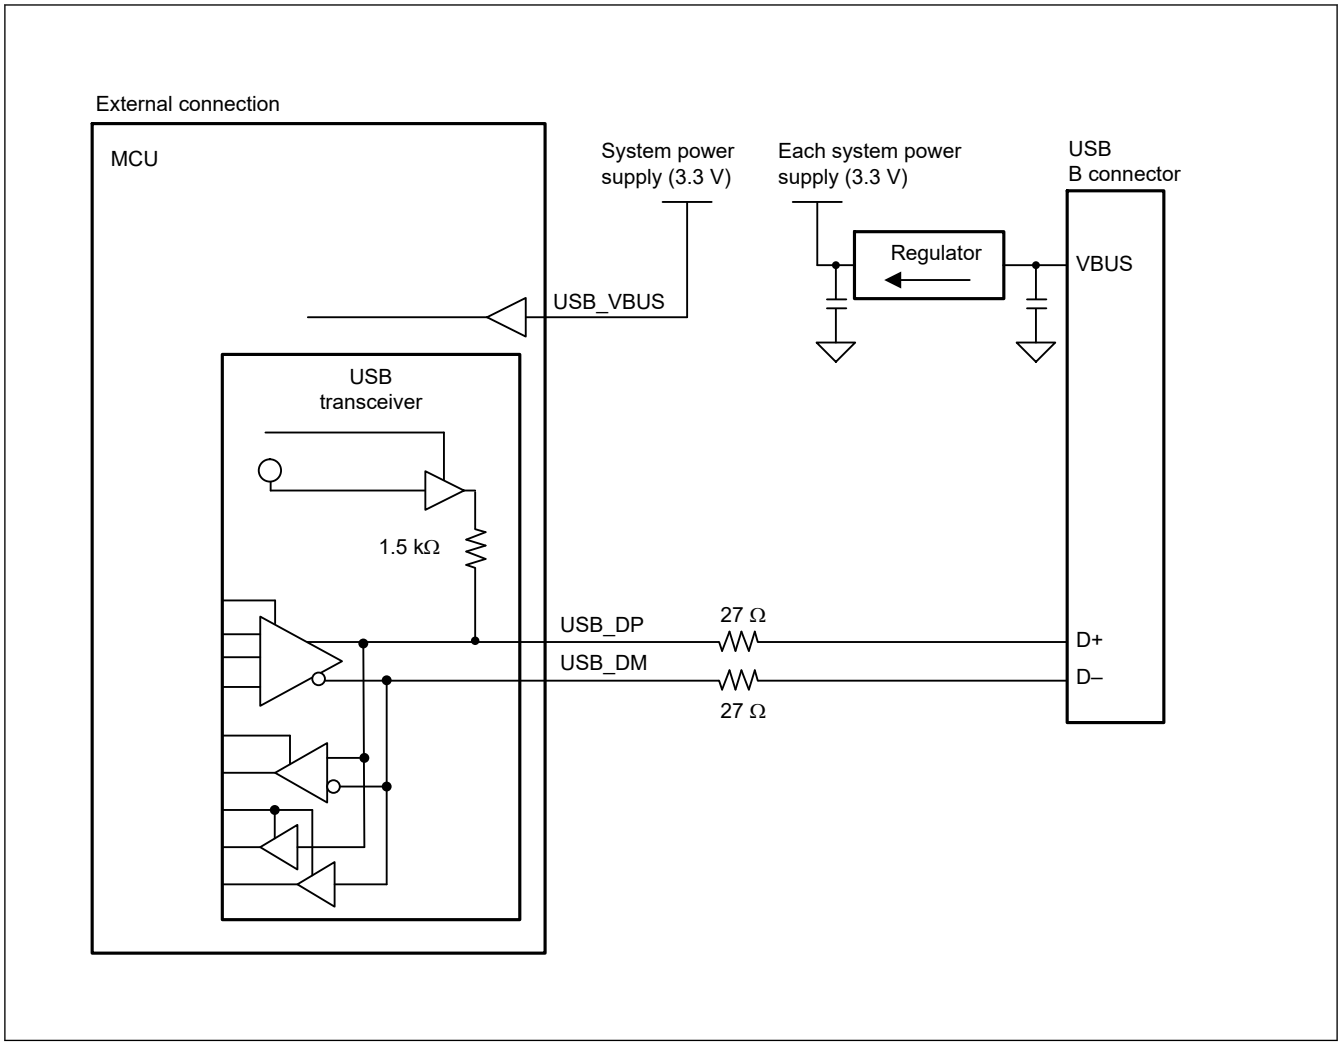

Figure 27.5 Example device connection in a bus-powered state

The examples of external circuits given in this section are simplified circuits, and their operation in every system is not guaranteed.

27.3.1.5 Release from Deep Software Standby mode1 because of USB suspend/resume interrupts

Deep Software Standby mode1 can be canceled by a USB suspend/resume interrupt. USB suspend/resume interrupts are detected by the USB resume detecting unit, which controls and monitors the USB I/O pins to detect the interrupts.

Figure 27.6 shows a schematic diagram of the connection between the USB resume detecting unit and the USB I/O pins.

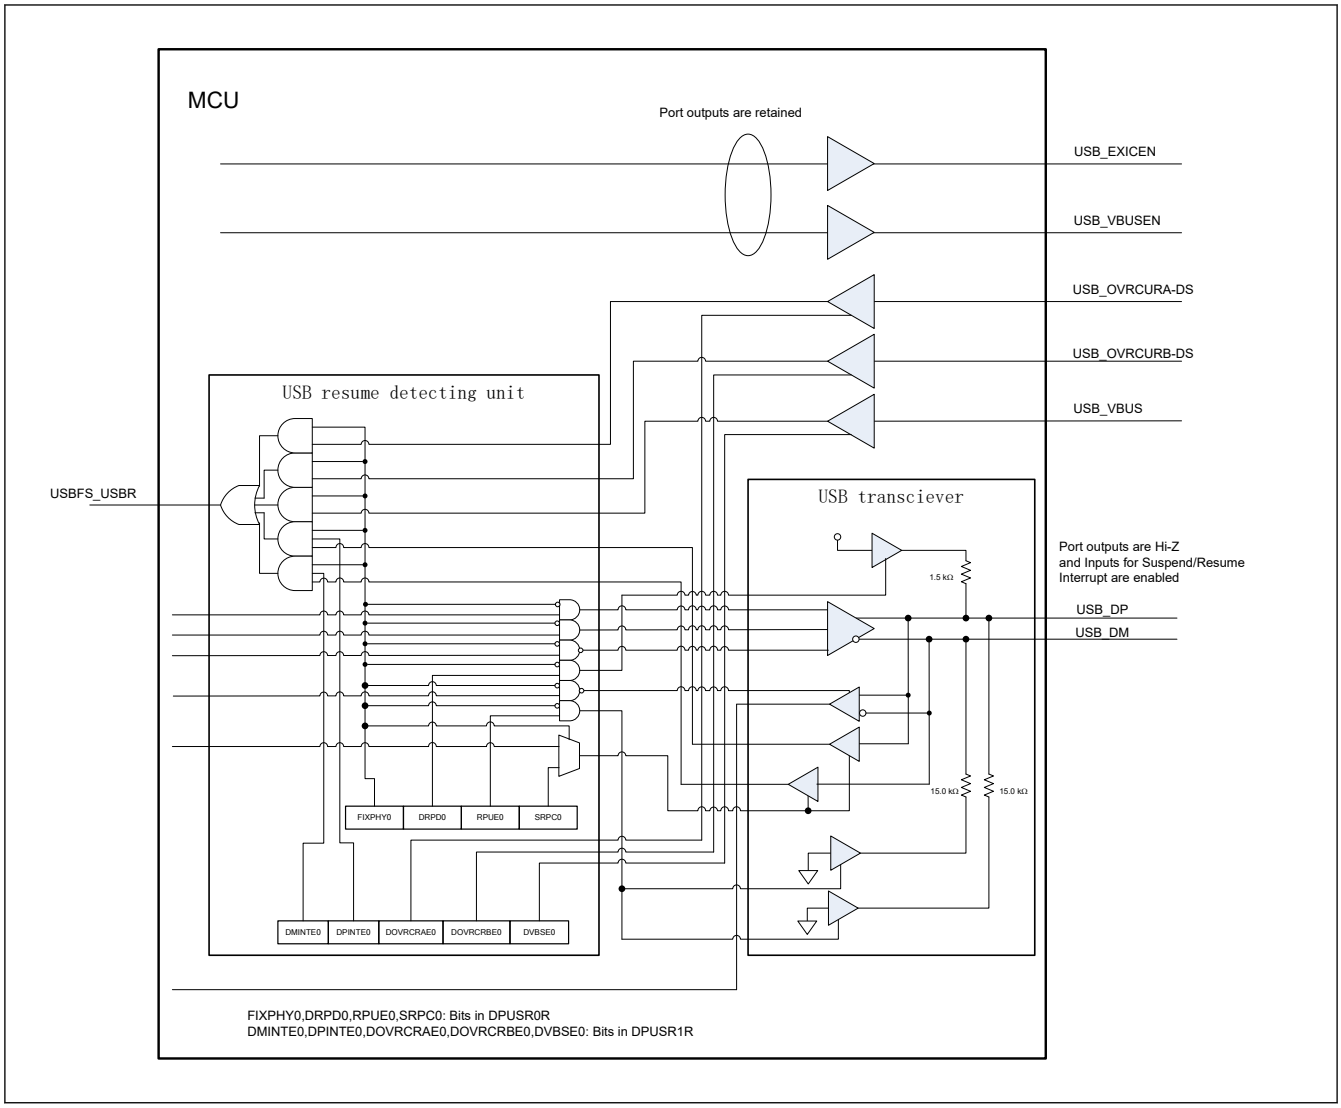

Figure 27.6 Connection between the USB resume detecting unit and the USB I/O pins

Table 27.15 shows the USB suspend and resume interrupt sources and their associated I/O pins.

Table 27.15 USB suspend and resume interrupt sources and their associated I/O pins

USB operating mode	Source	Pin name
Device, OTG	Resume	USB_DP
Host, OTG	Attach or detach	USB_DP, USB_DM
Device	Attach or detach	USB_VBUS
Host	Overcurrent detection	USB_OVRCURA-DS
OTG	Overcurrent detection	USB_OVRCURA-DS, USB_OVRCURB-DS

Figure 27.7 shows the flow for setting the USBFS when entering Deep Software Standby mode 1 from either host or device controller mode. Figure 27.8 shows the flow for setting the USBFS when canceling Deep Software Standby mode 1 from host controller mode. Figure 27.9 shows the flow for setting the USBFS when canceling Deep Software Standby mode 1 from device controller mode.

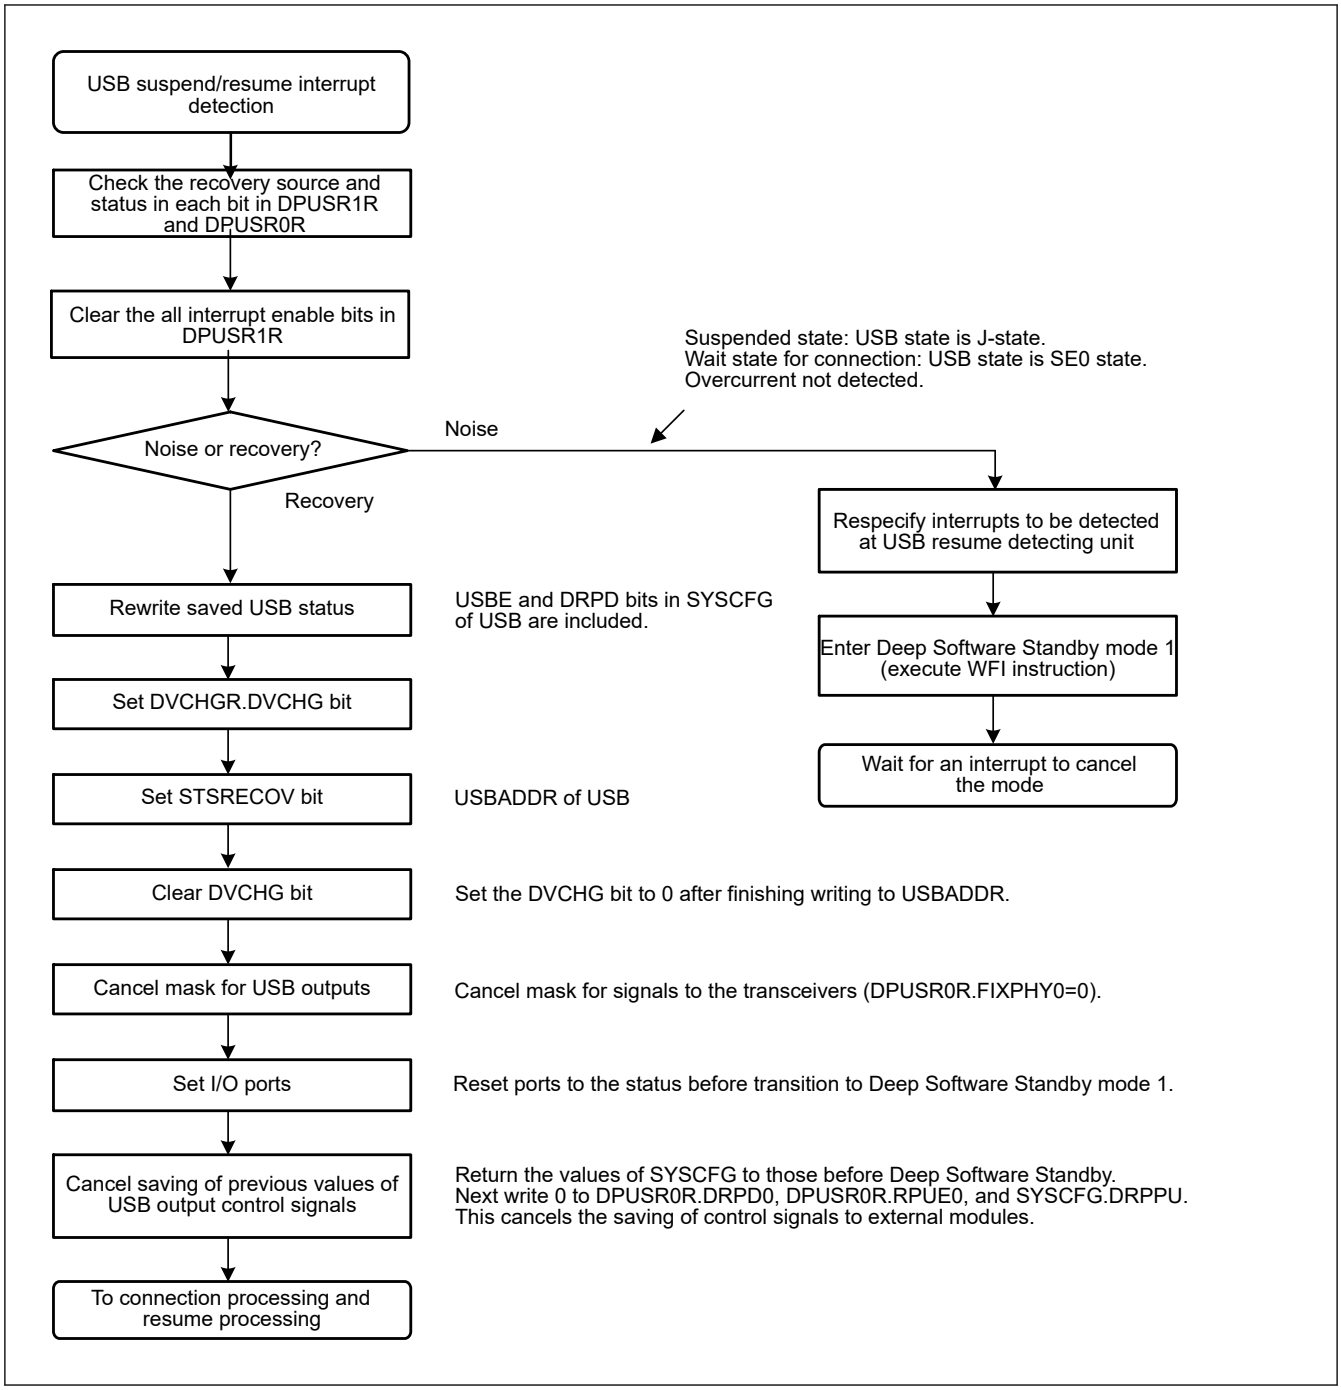

Figure 27.8 USBFS setup flow for canceling Deep Software Standby mode 1 as host controller

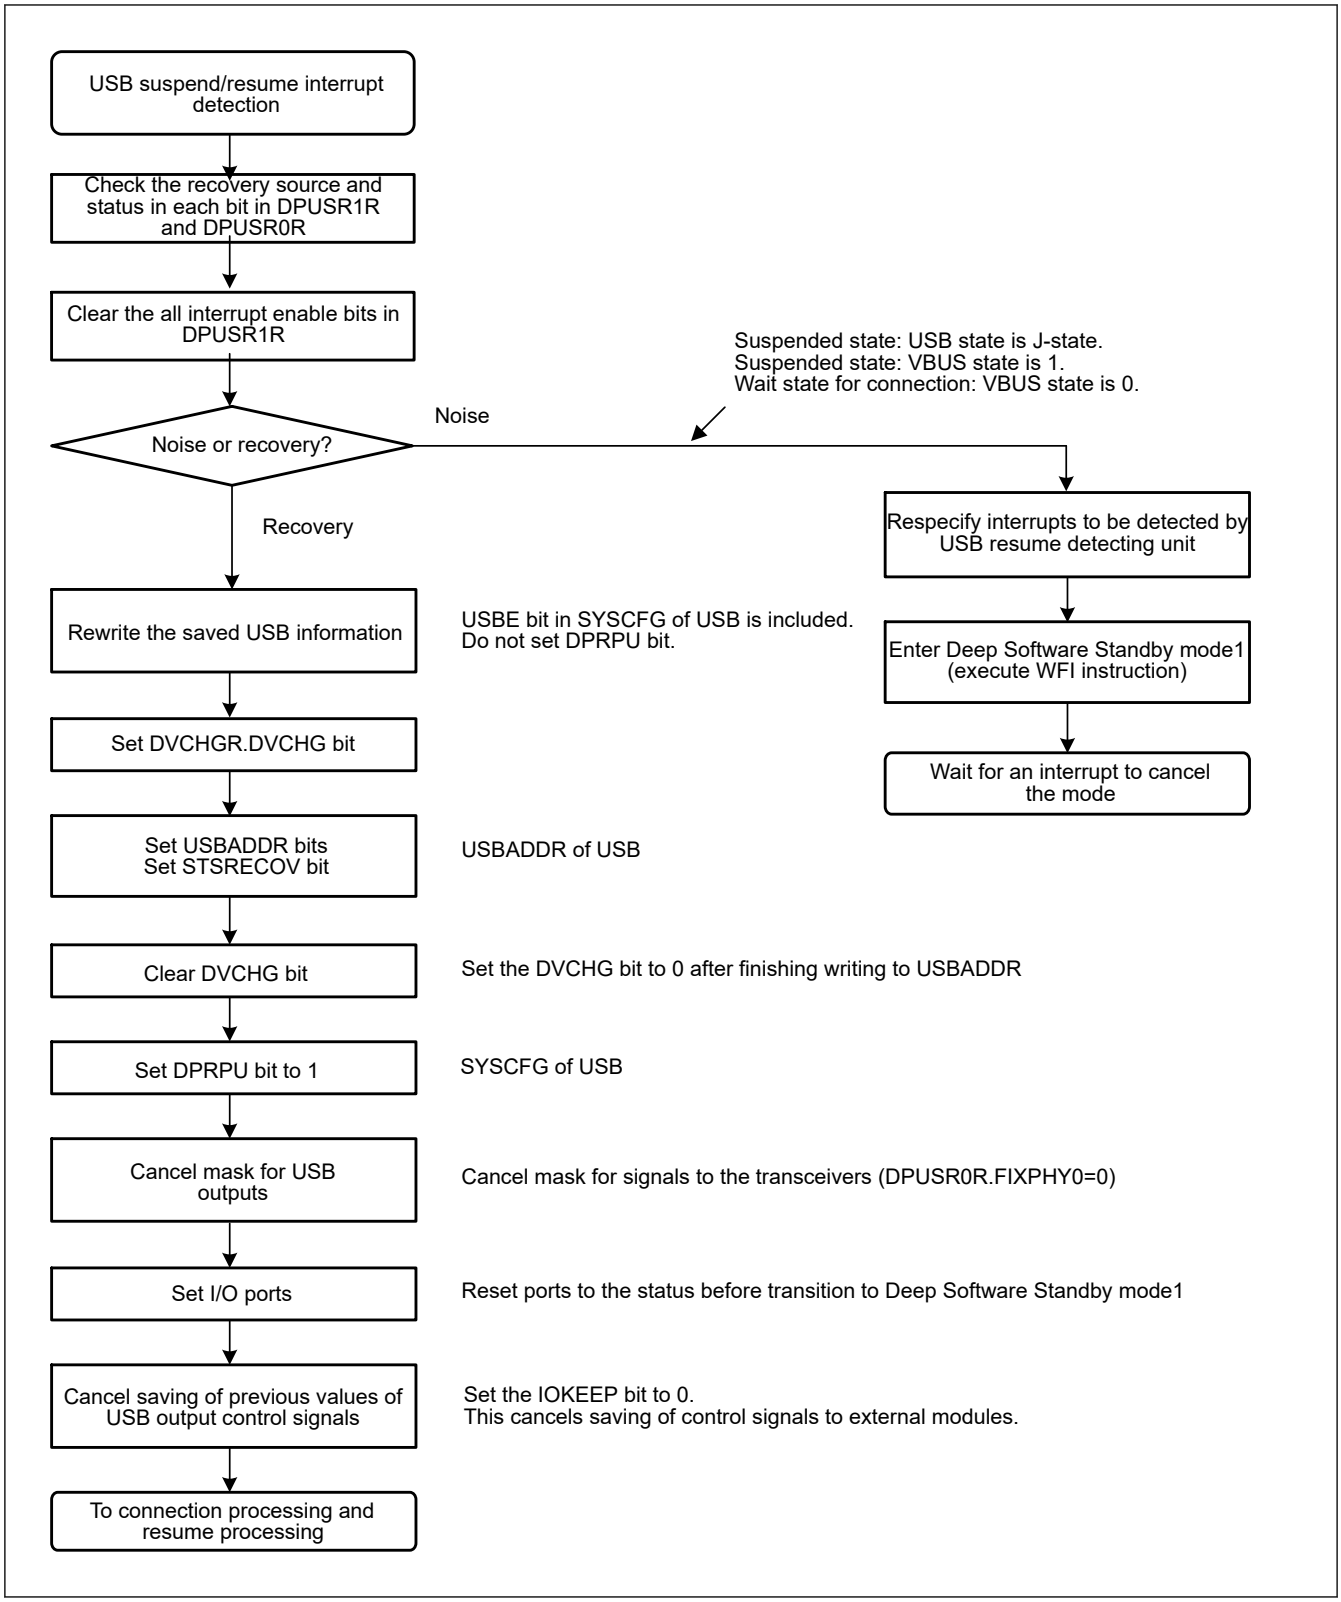

Figure 27.9 USBFS setup flow for canceling Deep Software Standby mode 1 as device controller

27.3.2 Interrupts

Table 27.16 lists the interrupt sources in the USBFS. When an interrupt generation condition is satisfied and the interrupt output is enabled using the associated interrupt enable register, a USBFS interrupt request is issued to the Interrupt Controller Unit (ICU) and an USBFS interrupt is generated.

Table 27.16 Interrupt sources (1 of 2)

Bit to be set to 1	Name	Interrupt source	Applicable controller function	Status flag
VBINT	VBUS interrupt	• A change in the state of the USB_VBUS input pin was detected (low to high or high to low)	Host or device*1	INTSTS0.VBSTS
RESM	Resume interrupt	• A change in the state of the USB bus was detected in the Suspend state (J-state to K-state or J-state to SE0)	Device	—
SOFR	Frame number update interrupt	In host controller mode: • An SOF packet with a different frame number was transmitted In device controller mode: • An SOF packet with a different frame number was received	Host or device	—
DVST	Device state transition interrupt	• One of the following device state transitions was detected: – USB bus reset was detected – Suspend state was detected – SET_ADDRESS request was received – SET_CONFIGURATION request was received	Device	INTSTS0.DVSQ[2:0]
CTRT	Control transfer stage transition interrupt	• A control transfer stage transition was detected because of one of the following: – Setup stage completed – Control write transfer status stage transition occurred – Control read transfer status stage transition occurred – Control transfer completed – Control transfer sequence error occurred	Device	INTSTS0.CTSQ[2:0]
BEMP	Buffer empty interrupt	• The buffer is empty after all FIFO buffer data was transmitted • A packet larger than the maximum packet size was received	Host or device	BEMPSTS.PIPEnBEMP
NRDY	Buffer not ready interrupt	In host controller mode • A STALL response was received from the peripheral device in response to the issued token • The response from the peripheral device in response to the issued token was not received successfully (no response three times consecutively or packet reception error three times consecutively) • An overrun or underrun error occurred during isochronous transfer In device controller mode • NAK was returned for an IN or OUT token while the PID [1:0] bits were set to 01b (BUF) • A CRC error or bit stuffing error occurred during data reception in isochronous transfer • An overrun or underrun occurred during data reception in isochronous transfer	Host or device	NRDYSTS.PIPEnNRDY
BRDY	Buffer ready interrupt	• The buffer is ready (readable or writable state)	Host or device	BRDYSTS.PIPEnBRDY
OVRCR	Overcurrent input change interrupt	• USB_OVRCURA, USB_OVRCURA-DS, USB_OVRCURB or USB_OVRCURB-DS input pin state change was detected (low to high or high to low)	Host	INTSTS1.OVRCR
BCHG	Bus change interrupt	• USB bus state change was detected	Host or device	SYSSTS0.LNST[1:0]
DTCH	Disconnect detection during full-speed operation	Peripheral device disconnect was detected in full-speed operation	Host	DVSTCTR0.RHST[2:0]
ATTCH	Device connect detection interrupt	• J-state or K-state was detected on the USB bus for 2.5 µs continuously This interrupt can be used to check whether peripheral devices are connected	Host	—

Table 27.16 Interrupt sources (2 of 2)

Bit to be set to 1	Name	Interrupt source	Applicable controller function	Status flag
EOFERR	EOF error detection interrupt	• An EOF error was detected for a peripheral device	Host	—
SACK	Setup normal interrupt	• A setup transaction normal response (ACK) was received	Host	—
SIGN	Setup error interrupt	• A setup transaction error (no response or ACK packet corruption) was detected three consecutive times	Host	—

Note 1. Although this interrupt can be generated in host controller mode, it is not usually used in this mode.

Figure 27.10 shows the circuits related to the USBFS interrupts.

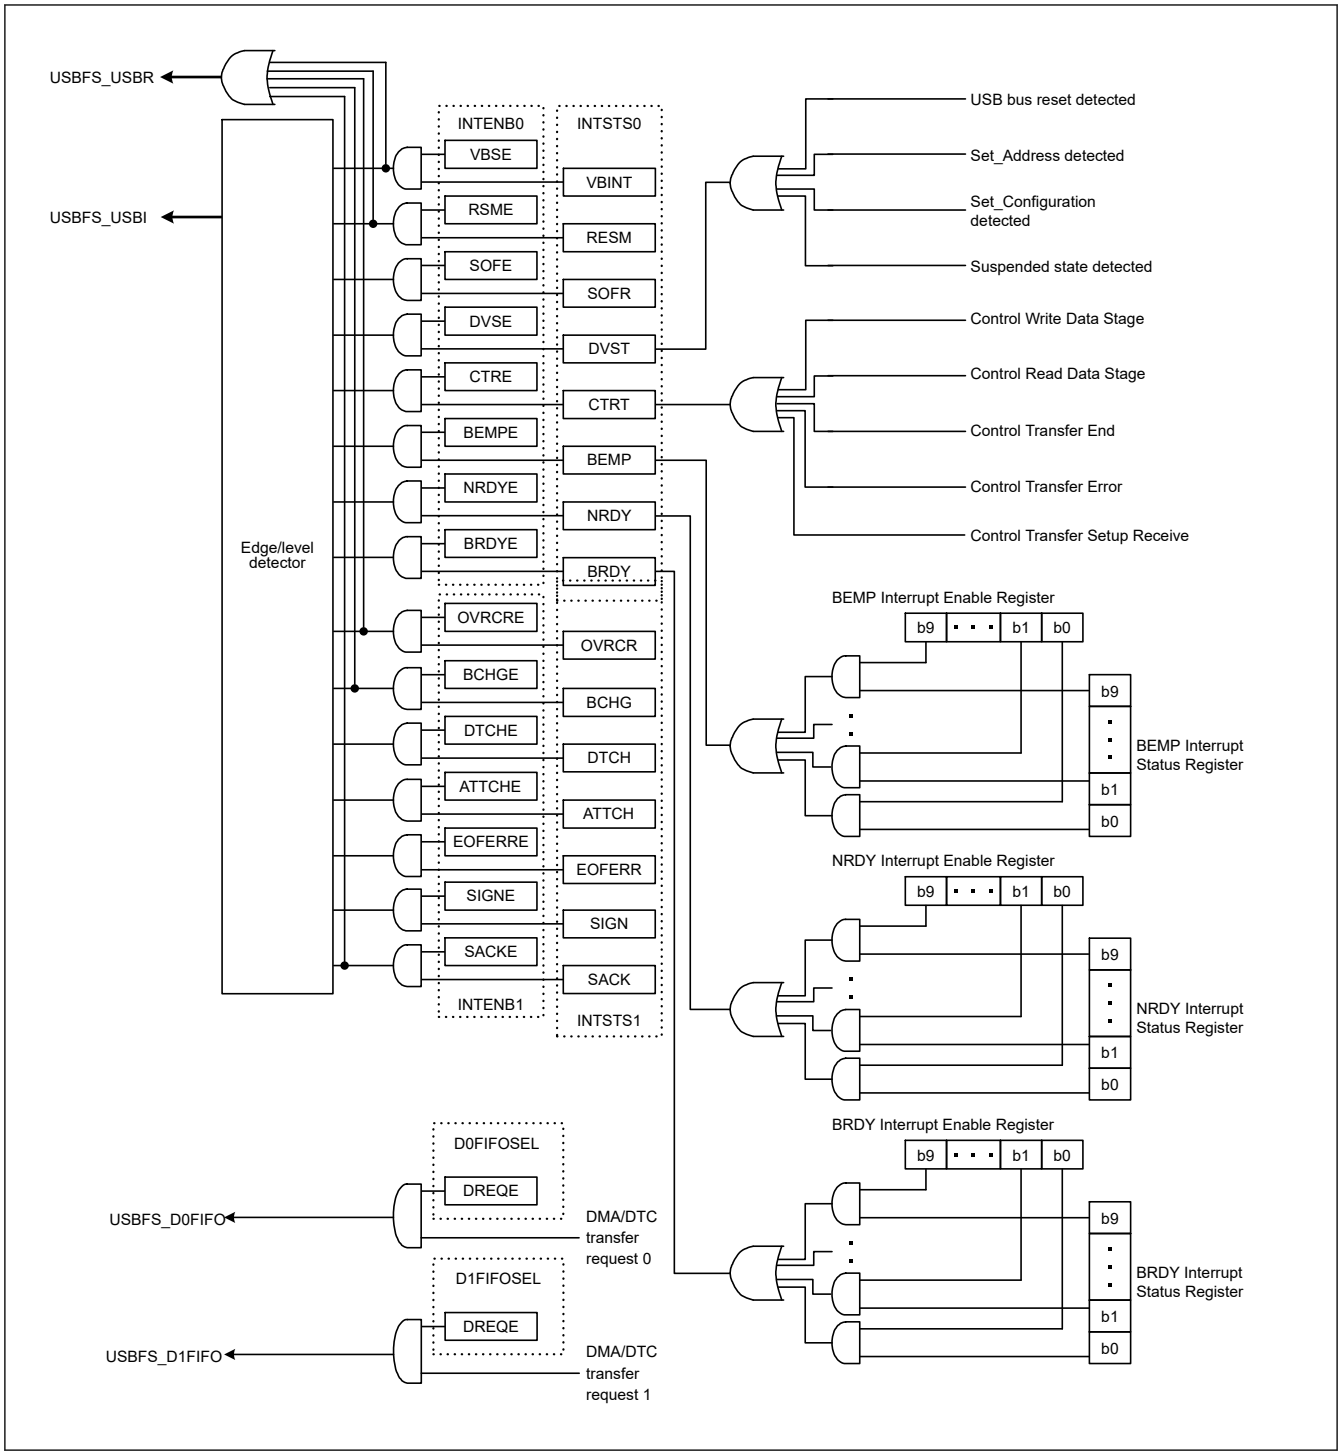

Figure 27.10 USBFS interrupt-related circuits

Table 27.17 shows the interrupts generated by the USBFS.

Table 27.17 USBFS interrupts

Interrupt name	Interrupt status flag	DTC activation	DMAC activation	Priority
USBFS_D0FIFO	DMA transfer request 0	Possible	Possible	High
USBFS_D1FIFO	DMA transfer request 1	Possible	Possible	↑
USBFS_USBI	VBUS interrupt, resume interrupt, frame number update interrupt, device state transition interrupt, control transfer stage transition interrupt, buffer empty interrupt, buffer not ready interrupt, buffer ready interrupt, overcurrent input change interrupt, bus change interrupt, disconnect detection interrupt during full-speed operation, device connect detection interrupt, EOF error detection interrupt, normal setup operation interrupt, and setup error interrupt	Not possible	Not possible	Low
USBFS_USBR*1	VBUS interrupt, resume interrupt, overcurrent input change interrupt and setup error interrupt	Not possible	Not possible	—

Note 1. Software Standby mode can be canceled. And Deep Software Standby mode 1 also can be canceled, but only dedicated pin (OVRCURA-DS, OVRCURB-DS) can be used for overcurrent pins.

27.3.3 Interrupt Descriptions

27.3.3.1 BRDY interrupt

The BRDY interrupt is generated in both host and device controller modes. This section describes the conditions in which the USBFS sets the associated bit in BRDYSTS to 1. Under these conditions, the USBFS generates a BRDY interrupt if the software has set the bit in BRDYENB associated with the given pipe to 1 and the INTENB0.BRDYE bit to 1.

The conditions for generating and clearing the BRDY interrupt depend on the SOFCFG.BRDYM and PIPECFG.BFRE settings for each pipe as follows:

(1) When SOFCFG.BRDYM = 0 and PIPECFG.BFRE = 0

With these settings, the BRDY interrupt indicates that the FIFO port is accessible.

On any of the following conditions, the USBFS generates an internal BRDY interrupt request trigger and sets the BRDYSTS.PIPEnBRDY bit associated with the selected pipe to 1.

For transmitting pipes

- When the DIR bit is changed from 0 to 1 by software
- When packet transmission is complete for a pipe while write-access from the CPU to the FIFO buffer for the pipe is disabled (when the BSTS bit is read as 0)
- When one FIFO buffer is empty on completion of writing data to the other FIFO buffer in double buffer mode
- No request trigger is generated until completion of writing data to the currently-written FIFO buffer even if transmission to the other FIFO buffer is complete
- When the hardware flushes the buffer of the pipe for isochronous transfers
- When 1 is written to the PIPEnCTR.ACLRM bit, which causes the FIFO buffer to transition from the write-disabled to write-enabled state

No request trigger is generated for the DCP, that is, during data transmission for control transfers.

For receiving pipes

- When packet reception is successfully complete, enabling the FIFO buffer to be read while read-access from the CPU to the FIFO buffer for the given pipe is disabled (when the BSTS bit is read as 0). No request trigger is generated for transactions in which a DATA-PID mismatch has occurred.
- When one FIFO buffer is read-enabled on completion of reading data from the other FIFO buffer in double buffer mode. No request trigger is generated until completion of reading data from the currently-read FIFO buffer, even if reception by the other FIFO buffer is complete.

In device controller mode, the BRDY interrupt is not generated in the status stage of control transfers. The PIPEBRDY interrupt status of the selected pipe can be set to 0 by writing 0 to the associated PIPEnBRDY bit through software. In this case, the other PIPEBRDY bit should be set to 1.

Clear the BRDY status before accessing the FIFO buffer.

(2) When SOFCFG.BRDYM = 0 and PIPECFG.BFRE = 1

With these settings, the USBFS generates a BRDY interrupt on completion of reading all data for a single transfer using the receiving pipe, and sets the bit in BRDYSTS associated with the pipe to 1.

On any of the following conditions, the USBFS determines that the last data for a single transfer was received.

- When a short packet including a zero-length packet is received
- When the PIPEn transaction counter register (PIPEnTRN) is used and the number of packets specified in the PIPEnTRN.TRNCNT[15:0] bits are completely received

When the data is completely read after any of these conditions is satisfied, the USBFS determines that all data for a single transfer is completely read.

When a zero-length packet is received while the FIFO buffer is empty, the USBFS determines that all data for a single transfer is completely read when the FRDY bit in the FIFO port control register is 1 and the DTLN[8:0] bits are 0. In this case, to start the next transfer, write 1 to the BCLR bit in the associated port control register through the software. With these settings, the USBFS does not detect a BRDY interrupt for the transmitting pipe.

The PIPEBRDY interrupt status of a pipe can be set to 0 by writing 0 to the associated BRDYSTS.PIPEnBRDY bit through the software. In this case, 1 must be written to the PIPEBRDY bits for the other pipes.

In this mode, do not change the PIPECFG.BFRE bit setting until all data for a single transfer is processed. When it is necessary to change the PIPECFG.BFRE bit before completion of processing, all FIFO buffers for the pipe must be cleared using the PIPEnCTR.ACLRM bit.

(3) When SOFCFG.BRDYM = 1 and PIPECFG.BFRE = 0

With these settings, the BRDYSTS.PIPEnBRDY values are linked to the BSTS bit setting for each pipe. In other words, the BRDY interrupt status bits (PIPEBRDY) are set to 1 or 0 by the USB depending on the FIFO buffer status.

For transmitting pipes

The BRDY interrupt status bits are set to 1 when the FIFO buffer is ready for write access, and are set to 0 when it is not ready. The BRDY interrupt is not generated for the DCP in the transmitting direction even when it is ready for write access.

For receiving pipes

The BRDY interrupt status bits set to 1 when the FIFO buffer is ready for read access, and set to 0 when all data is read (not ready for read access).

When a zero-length packet is received while the FIFO buffer is empty, the associated bit is set to 1 and the BRDY interrupt is continuously generated until the software writes 1 to BCLR. With this setting, the PIPEnBRDY bit cannot be set to 0 by software.

When the SOFCFG.BRDYM bit is set to 1, set the PIPECFG.BFRE bit for all pipes to 0.

Figure 27.11 shows the timing of BRDY interrupt generation.

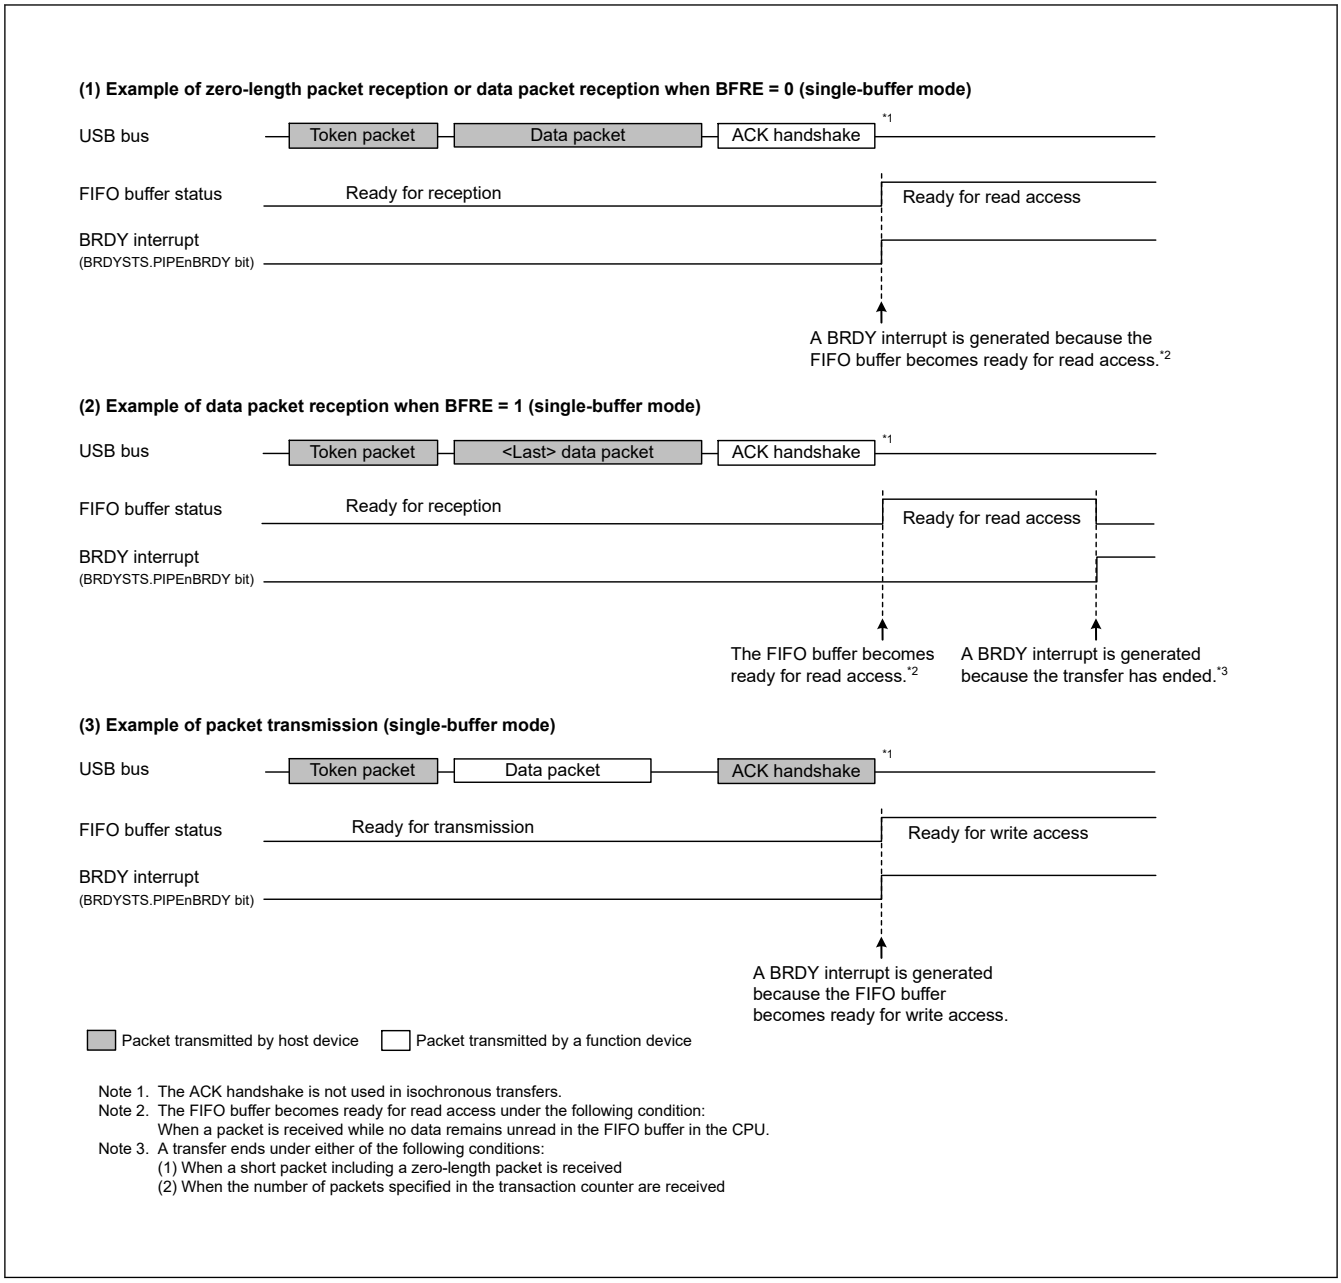

Figure 27.11 Timing of BRDY interrupt generation

The condition for clearing the INTSTS0.BRDY bit depends on the SOFCFG.BRDYM bit setting, as shown in Table 27.18.

Table 27.18 Conditions for clearing the BRDY bit

BRDYM bit	Condition for clearing BRDY bit
0	The USBFS clears the BRDY bit to 0 when all bits in BRDYSTS are set to 0 by software.
1	The USBFS clears the BRDY bit to 0 when the BSTS bits for all pipes have cleared to 0.

27.3.3.2 NRDY interrupt

On generating an internal NRDY interrupt request for the pipe whose PID bits are set to BUF by software, the USBFS sets the associated PIPEnNRDY bit in NRDYSTS to 1. If the associated bit in NRDYENB is set to 1 by software, the USBFS sets the INTSTS0.NRDY bit to 1 and generates a USBFS interrupt.

This section describes the conditions in which the USBFS generates the internal NRDY interrupt request for a given pipe.

The internal NRDY interrupt request is not generated during setup transaction execution in host controller mode. During setup transactions in host controller mode, the SACK or SIGN interrupt is detected.

The internal NRDY interrupt request is not generated during status stage execution of the control transfer in device controller mode.

(1) In host controller mode

For transmitting pipes

On any of the following conditions, the USBFS detects an NRDY interrupt:

- For isochronous transfer pipes, when the time to issue an OUT token comes while there is no data to be transmitted in the FIFO buffer. In this case, the USBFS transmits a zero-length packet following the OUT token and sets the associated NRDYSTS.PIPEnNRDY bit and the FRMNUM.OVRN bit to 1.
- During communications other than setup transactions on pipes not used for isochronous transfers, when any combination of the following two cases occur three consecutive times:
  - No response is returned from the peripheral device (when timeout is detected before detection of the handshake packet from the peripheral device
  - An error is detected in the packet from the peripheral device. In this case, the USBFS sets the associated PIPEnNRDY bit to 1 and changes the associated PID[1:0] setting for the pipe to NAK
- During communications other than setup transactions, when the STALL handshake is received from the peripheral device. In this case, the USBFS sets the associated PIPEnNRDY bit to 1 and changes the PID[1:0] setting for the associated pipe to STALL (11b).

For receiving pipes

- For isochronous transfer pipes, when the time to issue an IN token comes but there is no space available in the FIFO buffer. In this case, the USBFS discards the received data for the IN token and sets the PIPEnNRDY bit associated with the pipe and the OVRN bit to 1. When a packet error is detected in the received data for the IN token, the USBFS also sets the FRMNUM.CRCE bit to 1.
- For non-isochronous transfer pipes, when any combination of the following two cases occur three consecutive times:
  - No response is returned from the peripheral device for the IN token issued by the USBFS (when timeout is detected before detection of the DATA packet from the peripheral device)
  - An error is detected in the packet from the peripheral device. In this case, the USBFS sets the associated PIPEnNRDY bit to 1 and changes the associated PID[1:0] setting for the pipe to NAK
- For isochronous transfer pipes, when no response is returned from the peripheral device for the IN token (when timeout is detected before detection of the DATA packet from the peripheral device) or an error is detected in the packet from the peripheral device. In this case, the USBFS sets the PIPEnNRDY bit associated with the pipe to 1. The PID[1:0] setting for the pipe is not changed.
- For isochronous transfer pipes, when a CRC error or a bit stuffing error is detected in the received data packet. In this case, the USBFS sets the PIPEnNRDY bit associated with the pipe and the CRCE bit to 1.
- When the STALL handshake is received. In this case, the USBFS sets the PIPEnNRDY bit associated with the pipe to 1 and changes the PID[1:0] setting for the associated pipe to STALL.

(2) In device controller mode

For transmitting pipes

- When an IN token is received while there is no data to be transmitted in the FIFO buffer. In this case, the USBFS generates a NRDY interrupt request on reception of the IN token and sets the NRDYSTS.PIPEnNRDY bit to 1. For an isochronous transfer pipe in which an interrupt is generated, the USBFS transmits a zero-length packet and sets the FRMNUM.OVRN bit to 1.

For receiving pipes

- When an OUT token is received but there is no space available in the FIFO buffer. For an isochronous transfer pipe in which an interrupt is generated, the USBFS generates a NRDY interrupt request on reception of the OUT token and sets the PIPEnNRDY bit to 1 and OVRN bit to 1. For a non-isochronous transfer pipe in which an interrupt is generated, the USBFS generates a NRDY interrupt request when a NAK handshake is transferred after the data following the OUT token is received, and sets the PIPEnNRDY bit to 1. The NRDY interrupt request is not generated during retransmission

because of a DATA-PID mismatch. In addition, the NRDY interrupt request is not generated if an error occurs in the DATA packet.

- For isochronous transfer pipes, when a token is not received successfully within an interval frame. In this case, the USBFS generates an NRDY interrupt request when the SOF is received, and sets the PIPEnNRDY bit to 1.

Figure 27.12 shows the timing of NRDY interrupt generation in device controller mode.

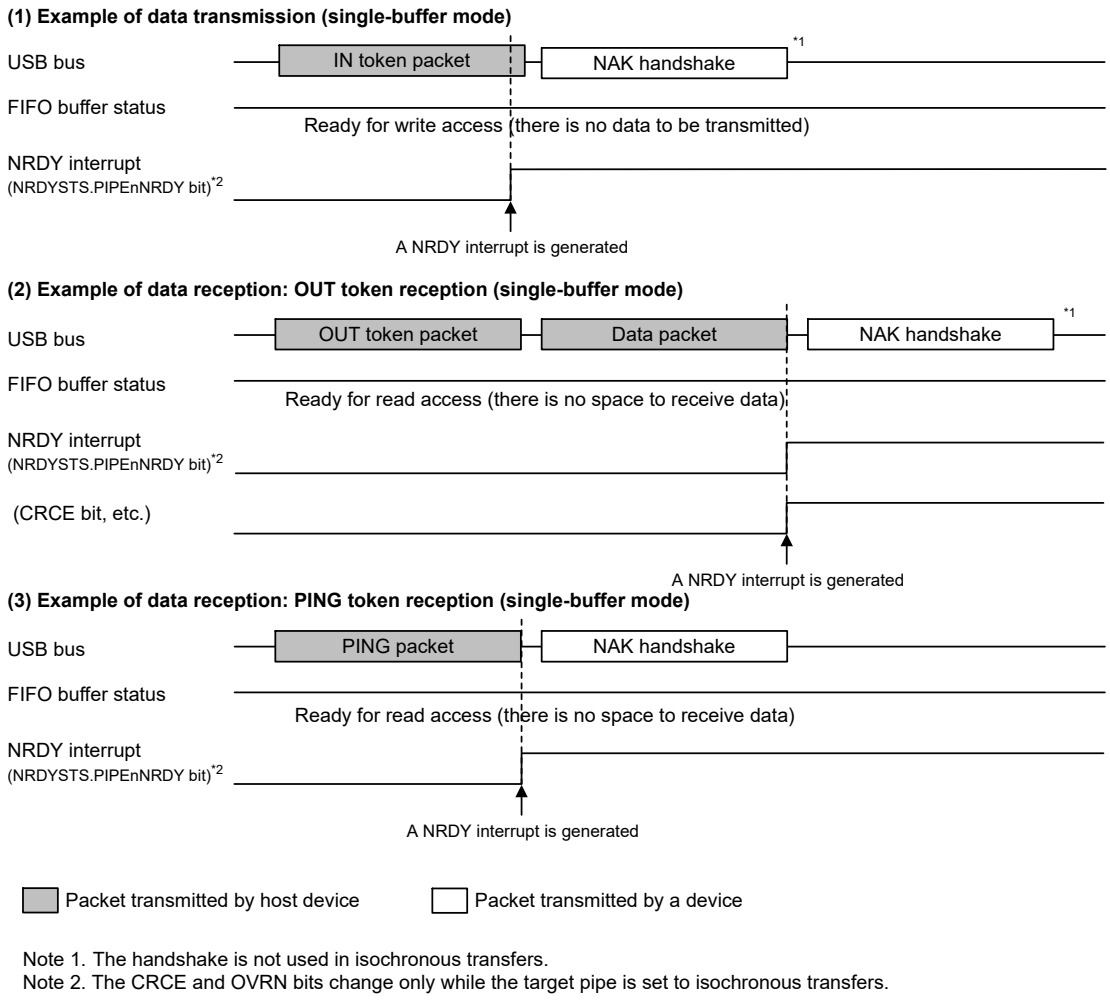

Figure 27.12 Timing of NRDY interrupt generation in device controller mode

27.3.3.3 BEMP interrupt

On detecting a BEMP interrupt for the pipe whose PID bits are set to BUF by software, the USBFS sets the associated BEMPSTS.PIPEnBEMP bit to 1. If the associated bit in BEMPENB is set to 1 by software, the USBFS sets the INTSTS0.BEMP bit to 1 and generates a USBFS interrupt. This section describes the conditions in which the USBFS generates an internal BEMP interrupt request.

(1) For transmitting pipes

When the FIFO buffer of the associated pipe is empty on completion of transmission, including zero-length packet transmission, and in single buffer mode, an internal BEMP interrupt request is generated simultaneously with the BRDY interrupt for a non-DCP pipe. The internal BEMP interrupt request is not generated in any of the following conditions:

- When the CPU or DMA/DTC has already started writing data to the FIFO buffer of the CPU on completion of transmitting data from one FIFO buffer in double buffer mode
- When the buffer is cleared (emptied) by setting the PIPEnCTR.ACLRM or the BCLR bit to 1 in the port control register
- When an IN transfer (zero-length packet transmission) is performed during the control transfer status stage in device controller mode

(2) For receiving pipes

When a successfully-received data packet size exceeds the specified maximum packet size. In this case, the USBFS generates a BEMP interrupt request, sets the associated BEMPSTS.PIPEnBEMP bit to 1, discards the received data, and changes the associated PID[1:0] setting for the pipe to STALL (11b). The USBFS returns no response in host controller mode, and returns STALL response in device controller mode.

The internal BEMP interrupt request is not generated in any of the following conditions:

- When a CRC error or a bit stuffing error is detected in the received data
- When a setup transaction is being performed:
  - Writing 0 to the BEMPSTS.PIPEnBEMP bit clears the status
  - Writing 1 to the BEMPSTS.PIPEnBEMP bit has no effect

Figure 27.13 shows the timing of BEMP interrupt generation in device controller mode.

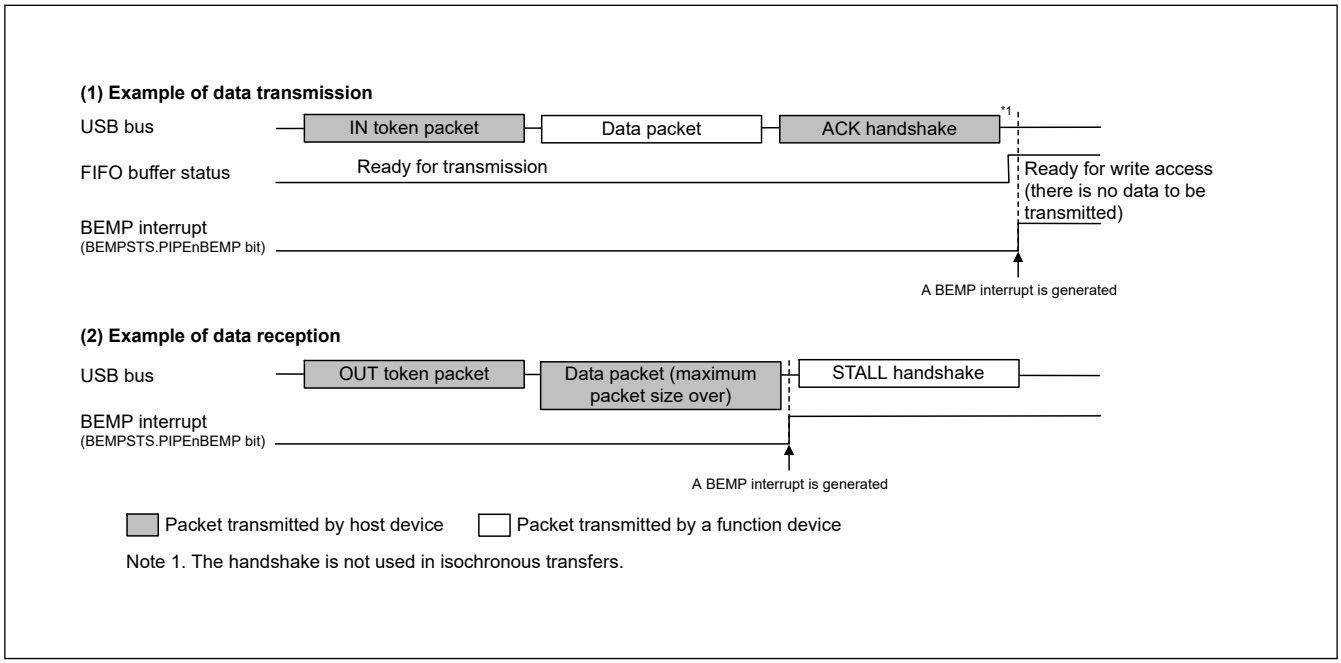

Figure 27.13 Timing of BEMP interrupt generation in device controller mode

27.3.3.4 Device state transition interrupt (device controller mode)

Figure 27.14 shows a diagram of the USBFS device state transitions. The USBFS controls device states and generates device state transition interrupts. However, recovery from the Suspend state (resume signal detection) is detected by means of the resume interrupt. Device state transition interrupts can be enabled or disabled independently in INTENB0. Devices whose states have changed can be checked in the INTSTS0.DVSQ[2:0] bits.

When a transition is made to the default state, a device state transition interrupt is generated after a USB bus reset is detected.

The USBFS controls device states, and device state transition interrupts can be generated, only in device controller mode.

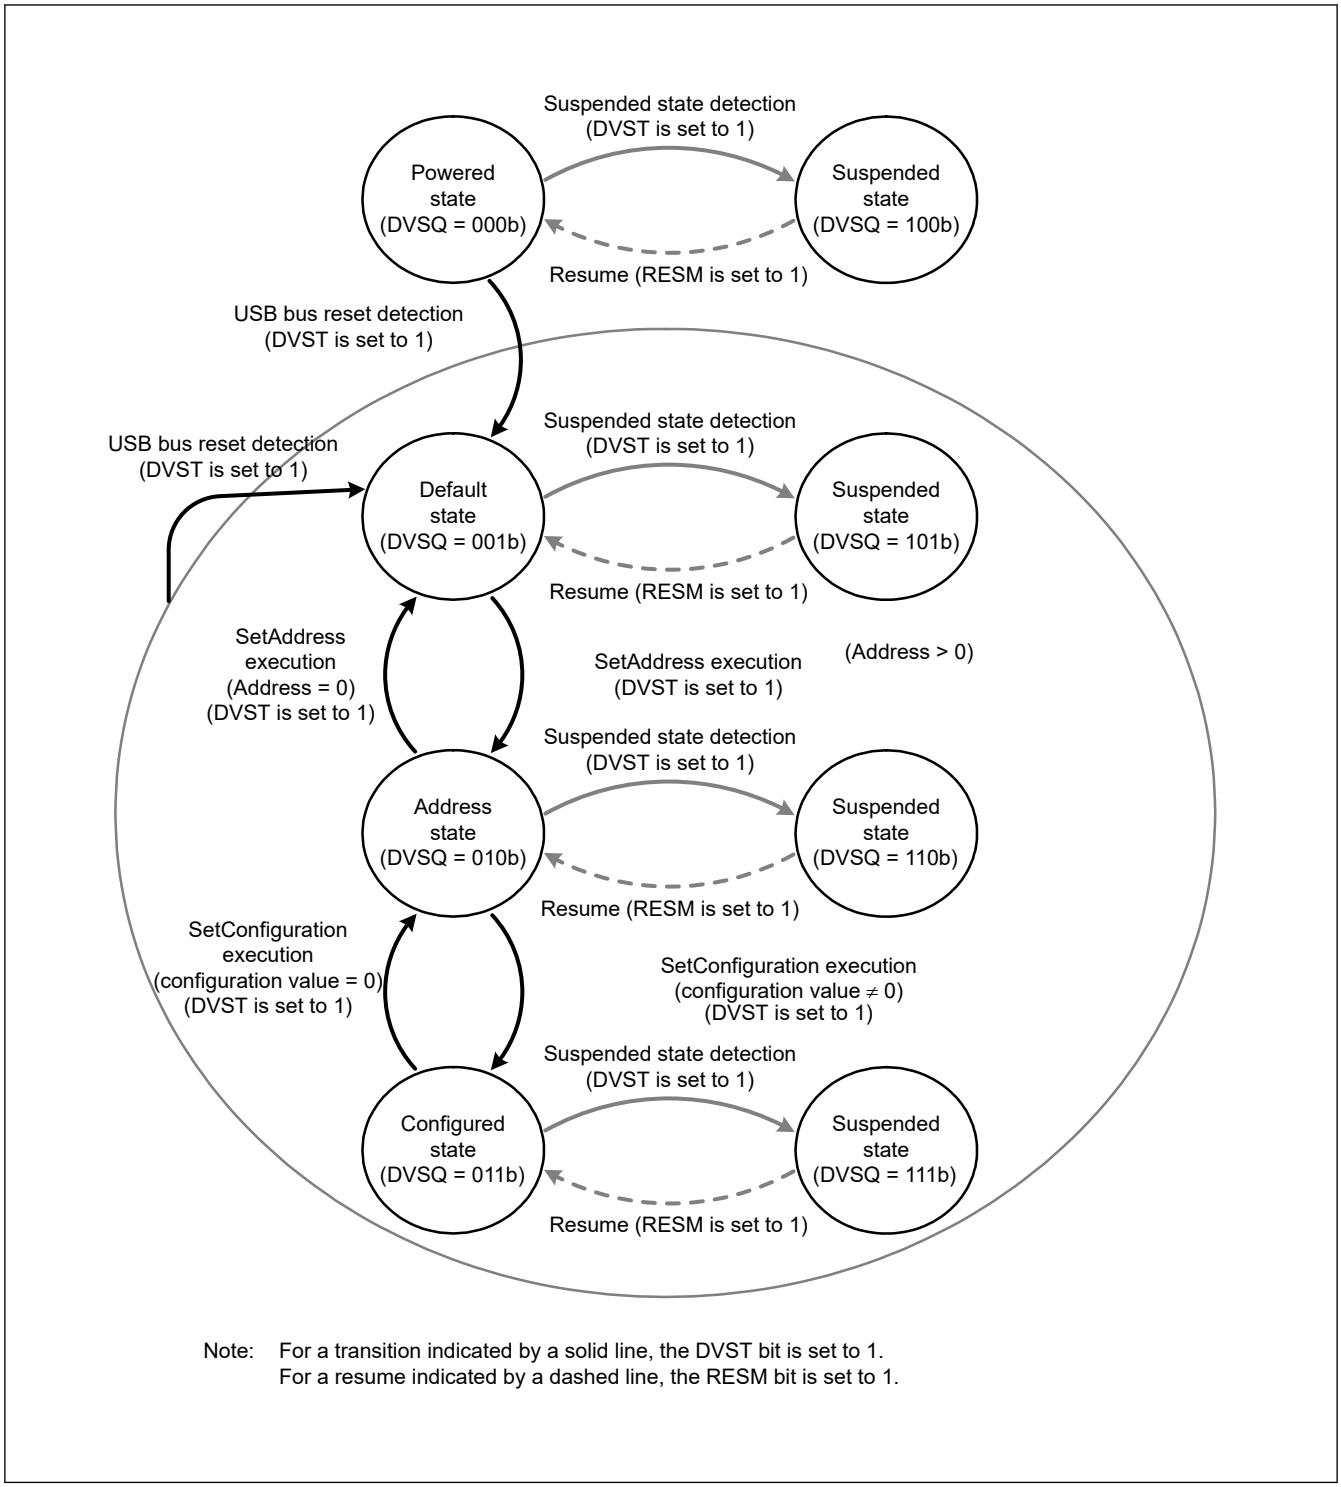

Figure 27.14 Device state transitions

27.3.3.5 Control transfer stage transition interrupt (device controller mode)

Figure 27.15 shows a diagram of the control transfer stage transitions of the USBFS. The USBFS controls the control transfer sequence and generates control transfer stage transition interrupts. Control transfer stage transition interrupts can be enabled or disabled independently in INTENB0. Transfer stages that have transitioned can be checked in the INTSTS0.CTSQ[2:0] bits.

Control transfer stage transition interrupts are generated only in device controller mode. This section describes control transfer sequence errors. If an error occurs, the DCPCTR.PID[1:0] bits are set to 1xb (STALL response).

(1) Control read transfer errors

- An OUT token is received but no data is transferred in response to the IN token at the data stage
- An IN token is received at the status stage
- A data packet with DATAPID = DATA0 is received at the status stage

(2) Control write transfer errors

- An IN token is received but no ACK is returned in response to the OUT token at the data stage
- A data packet with DATAPID = DATA0 is received as the first data packet at the data stage
- An OUT token is received at the status stage

(3) Control write no data transfer errors

- An OUT token is received at the status stage

At the control write transfer data stage, if the receive data length exceeds the wLength value of the USB request, it is not recognized as a control transfer sequence error. At the control read transfer status stage, packets other than zero-length packets are received by an ACK response and the transfer ends normally.

When a CTRT interrupt occurs in response to a sequence error (INTSTS0.CTRT = 1), the CTSQ[2:0] = 110b value is saved until the CTRT bit is set to 0, clearing the interrupt status. While CTSQ[2:0] = 110b is being saved, no CTRT interrupt for ending the setup stage is generated, even if a new USB request is received. The USBFS saves the setup stage completion status, and it generates a CTRT interrupt after the interrupt status is cleared by software.

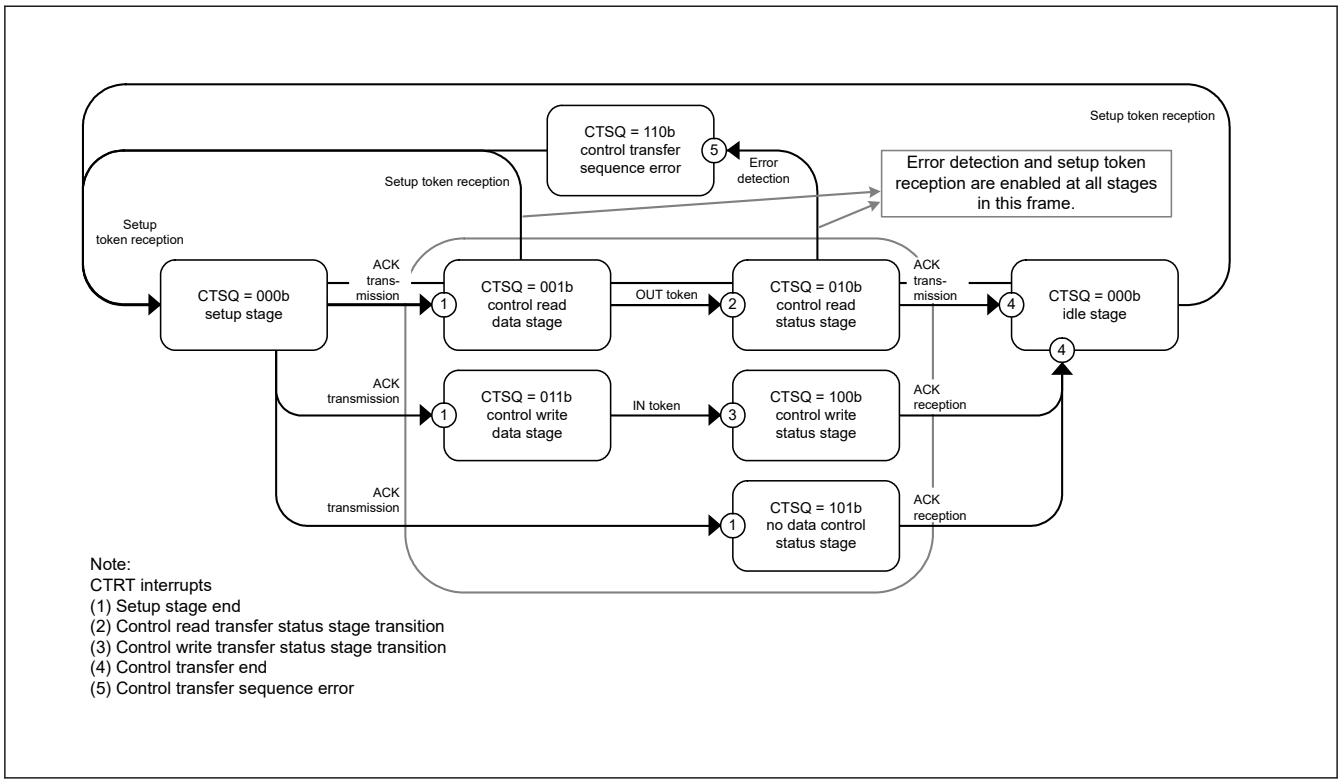

Figure 27.15 Control transfer stage transitions

27.3.3.6 Frame update interrupt

In host controller mode, an interrupt is generated when the frame number is updated.

In device controller mode, an SOFR interrupt is generated when the frame number is updated. The USBFS updates the frame number and generates an SOFR interrupt if it detects a new SOF packet during full-speed operation.

27.3.3.7 VBUS interrupt

When the USB_VBUS pin level changes, a VBUS interrupt is generated. The level of the USB_VBUS pin can be checked with the INTSTS0.VBSTS bit. Whether the host controller is connected or disconnected can be confirmed using the VBUS interrupt. If the system is activated with the host controller connected, the first VBUS interrupt is not generated, because there is no change in the USB_VBUS pin level.

27.3.3.8 Resume interrupt

In device controller mode, a resume interrupt is generated when the device state is the Suspend state and the USB bus state has changed (from J-state to K-state, or from J-state to SE0). Recovery from the Suspend state is detected by means of the resume interrupt.

In host controller mode, no resume interrupt is generated. Use the BCHG interrupt to detect a change in the USB bus state.

27.3.3.9 OVRCR interrupt

An OVRCR interrupt is generated when the USB_OVRCURA, USB_OVRCURA-DS, USB_OVRCURB or USB_OVRCURB-DS pin level has changed. The levels of the USB_OVRCURA, USB_OVRCURA-DS, USB_OVRCURB and USB_OVRCURB-DS pins can be checked in the SYSSTS0.OVCMON[1:0] flags. The external power supply IC can check whether overcurrent is detected using the OVRCR interrupt.

For OTG connections, the OVRCR interrupt allows you to check whether a change is detected in the VBUS comparator.

27.3.3.10 BCHG interrupt

A BCHG interrupt is generated when the USB bus state has changed. The BCHG interrupt can be used to detect whether a peripheral device is connected and can also be used to detect a remote wakeup in host controller mode. The BCHG interrupt is generated in both host and device controller modes.

27.3.3.11 DTCH interrupt

A DTCH interrupt occurs when a USB bus disconnect is detected in host controller mode. The USBFS detects bus disconnects in compliance with the USB 2.0 specification.

On interrupt detection, all pipes in which communications are being carried out for the relevant port must be terminated by software. The pipes enter the wait state for a bus connection to the port, waiting for an ATTCH interrupt to occur. Regardless of the value set in the associated interrupt enable bit, the USBFS hardware:

- Sets the DVSTCTR0.UACT bit for the port in which the DTCH interrupt is detected to 0
- Puts the port in which the DTCH interrupt occurred into the idle state

27.3.3.12 SACK interrupt

A SACK interrupt is generated when an ACK response for the transmitted setup packet is received from the peripheral device in host controller mode. The SACK interrupt can be used to confirm that the setup transaction is successfully complete.

27.3.3.13 SIGN interrupt

A SIGN interrupt is generated when an ACK response for the transmitted setup packet is not correctly received from the peripheral device three consecutive times in host controller mode. The SIGN interrupt can be used to detect no ACK response transmitted from the peripheral device or corruption of an ACK packet.

27.3.3.14 ATTCH interrupt

An ATTCH interrupt is generated when J-state or K-state of the full-speed signal level is detected on the USB port for 2.5 µs in host controller mode. To be more specific, an ATTCH interrupt is detected on any of the following conditions:

- When K-state, SE0, or SE1 changes to J-state, and J-state continues 2.5 µs
- When J-state, SE0, or SE1 changes to K-state, and K-state continues 2.5 µs

27.3.3.15 EOFERR interrupt

An EOFERR interrupt occurs when the USBFS detects that communication is not complete at the EOF2 timing defined in the USB 2.0 specification.

On interrupt detection, all pipes in which communications are being carried out for the relevant port must be terminated by software, and the port must be re-enumerated. Regardless of the value set in the associated interrupt enable bit, the USBFS hardware:

- Sets the DVSTCTR0.UACT bit for the port in which the EOFERR interrupt is detected to 0
- Puts the port in which the EOFERR interrupt is generated into the idle state

27.3.4 Pipe Control

Table 27.19 lists the pipe settings for the USBFS. USB data transfer is performed through logical pipes that the software associates with endpoints. The USBFS provides 10 pipes that are used for data transfer. Set up the pipes based on your system specifications.

Table 27.19 Pipe settings

Register name	Bit name	Setting	Notes
DCPCFG PIPECFG	TYPE	Transfer type	Pipes 1 to 9: Settable
	BFRE	BRDY interrupt mode	Pipes 1 to 5: Settable
	DBLB	Double buffer select	Pipes 1 to 5: Settable
	DIR	Transfer direction select	IN or OUT settable
	EPNUM	Endpoint number	Pipes 1 to 9: Settable A value other than 0000b must be set when the pipe is used.
	SHTNAK	Selects disabled state for pipe when transfer ends	Pipes 1 and 2: Settable only for bulk transfers Pipes 3 to 5: Settable
DCPMAXP PIPEMAXP	DEVSEL	Device select	Referenced only in host controller mode.
	MXPS	Maximum packet size	Compliant with the USB 2.0 specification.
PIPEPERI	IFIS	Buffer flush	Pipes 1 and 2: Settable only for isochronous transfers Pipes 3 to 9: Setting disabled
	IITV	Interval counter	Pipes 1 and 2: Settable only for isochronous transfers Pipes 3 to 5: Setting disabled Pipes 6 to 9: Settable only in host controller mode
DCPCTR PIPEnCTR	BSTS	Buffer status	For the DCP, receive buffer status and transmit buffer status are switched with the ISEL bit.
	INBUFM	IN buffer monitor	Available only for pipes 1 to 5.
	SUREQ	Setup request	Settable only for the DCP and controlled in host controller mode
	SUREQCLR	SUREQ clear	Settable only for the DCP and controlled in host controller mode
	ATREPM	Auto response mode	Pipes 1 to 5: Settable only in device controller mode
	ACLRM	Auto buffer clear	Pipes 1 to 9: Settable
	SQCLR	Sequence clear	Clears the data toggle bit
	SQSET	Sequence set	Sets the data toggle bit
	SQMON	Sequence monitor	Monitors the data toggle bit
	PBUSY	Pipe busy status	—
	PID	Response PID	See section 27.3.4.6. Response PID.
PIPEnTRE	TRENB	Transaction counter enable	Pipes 1 to 5: Settable
	TRCLR	Current transaction counter clear	Pipes 1 to 5: Settable
PIPEnTRN	TRNCNT	Transaction counter	Pipes 1 to 5: Settable

27.3.4.1 Pipe control register switching procedures

The following bits in the pipe control registers can be changed only when USB communication is prohibited (PID = NAK).

Do not change the following registers and bits when USB communication is enabled (PID = BUF):

- Bits in DCPCFG and DCPMAXP
- SQCLR and SQSET bits in DCPCTR
- Bits in PIPECFG, PIPEMAXP, and PIPEPERI
- ATREPM, ACLRM, SQCLR, and SQSET bits in PIPEnCTR
- Bits in PIPEnTRE and PIPEnTRN

To set these bits when USB communication is enabled (PID = BUF):

1. A request to change the bits in the pipe control register occurs.
2. Set the PID[1:0] bits associated with the pipe to NAK.
3. Wait until the associated PBUSY bit clears to 0.
4. Set the bits in the pipe control register.

The following bits in the pipe control registers can be changed only when the selected pipe information is not set in the CURPIPE[3:0] bits in CFIFOSEL, D0FIFOSEL, and D1FIFOSEL.

Do not set the following registers when the CURPIPE[3:0] bits are set:

- Bits in DCPCFG and DCPMAXP
- Bits in PIPECFG, PIPEMAXP and PIPEPERI

To change pipe information, you must set the CURPIPE[3:0] bits in the port select registers to a pipe other than the one to be changed. For the DCP, the buffer must be cleared using the BCLR bit in the Port Control Register after the pipe information is changed.

27.3.4.2 Transfer types

The PIPECFG.TYPE[1:0] bits specify the following transfer types for each pipe:

- DCP: No setting is necessary (fixed at control transfer)
- Pipes 1 and 2: Set to bulk or isochronous transfer
- Pipes 3 to 5: Set to bulk transfer
- Pipes 6 to 9: Set to interrupt transfer

27.3.4.3 Endpoint number

The PIPECFG.EPNUM[3:0] bits are used to set the endpoint number for each pipe. The DCP is fixed at endpoint 0. The other pipes can be set from endpoint 1 to 15.

- DCP: No setting is necessary (fixed at endpoint 0)
- Pipes 1 to 9: Select and set the endpoint numbers from 1 to 15 so that the combination of the PIPECFG.DIR and EPNUM[3:0] bits is unique

27.3.4.4 Maximum packet size setting

Specify the maximum packet size for each pipe in the DCPMAXP.MXPS[6:0] and PIPEMAXP.MXPS[9:0] bits. The DCP and pipes 1 to 5 can be set to any of the maximum pipe sizes defined in the USB 2.0 specification. For pipes 6 to 9, the maximum packet size is 64 bytes. Set the maximum packet size as follows before starting a transfer (PID = BUF):

- DCP: Set to 8, 16, 32, or 64
- Pipes 1 to 5: Set to 8, 16, 32, or 64 for bulk transfers
- Pipes 1 and 2: Set between 1 and 256 for isochronous transfers
- Pipes 6 to 9: Set between 1 and 64

27.3.4.5 Transaction counter for pipes 1 to 5 in the receiving direction

When the specified number of transactions is complete in the data packet receiving direction, the USBFS recognizes that the transfer ended. Two transaction counters are provided: one is the PIPEnTRN register, which specifies the number of transactions to be executed, and the other is the current counter, which internally counts the number of executed transactions. If the PIPECFG.SHTNAK bit is set to 1, when the current counter value matches the specified number of transactions, the associated PIPEnCTR.PID[1:0] bits are set to NAK and the subsequent transfer is disabled. The transactions can be counted again from the beginning by initializing the current counter of the transaction counter function through the PIPEnTRE.TRCLR bit. The data read from PIPEnTRN differs depending on the PIPEnTRE.TRENB setting as follows:

- The TRENB bit = 0: Specified transaction counter value can be read
- The TRENB bit = 1: Current counter value indicating the internally counted number of executed transactions can be read

The following constraints apply when working with the TRCLR bit:

- If the transactions are being counted and PID = BUF, the current counter cannot be cleared
- If there is any data left in the buffer, the current counter cannot be cleared

27.3.4.6 Response PID

Specify the response PID for each pipe in the PID[1:0] bits in DCPCTR and PIPEnCTR. This section describes the USBFS operation with different response PID settings.

(1) Software response PID settings in host controller mode

Select the response PID to specify the execution of transactions as follows:

- NAK setting: Using pipes is disabled and no transactions are executed
- BUF setting: Transactions are executed based on the FIFO buffer state:
  - OUT direction: An OUT token is issued if the FIFO buffer contains transmit data.
  - IN direction: An IN token is issued if the FIFO buffer is not full and can receive data.
- STALL setting: Using pipes is disabled and no transactions are executed

Note: Use the DCPCTR.SUREQ bit to execute setup transactions for the DCP.

(2) Software response PID settings in device controller mode

Select the response PID to respond as follows to transactions from the host:

- NAK setting: A NAK response is returned to all generated transactions
- BUF setting: A response is returned to transactions based on the FIFO buffer
- STALL setting: A STALL response is returned to all generated transactions

Note: For setup transactions, an ACK response is always returned, regardless of the PID[1:0] bits setting, and the USB request is stored in the register.

Sections (3) and (4) describe situations in which the USBFS writes to the PID[1:0] bits because of specific transaction results.

(3) Hardware response PID settings in host controller mode

- NAK setting: PID = NAK is set in the following cases, and issuing of tokens is automatically stopped:
  - When a non-isochronous transfer is performed and an NRDY interrupt is generated

    (For details, see section 27.3.3.2. NRDY interrupt.)
  - If a short packet is received when the PIPECFG.SHTNAK bit is set to 1 for bulk transfers
  - If transaction counting ends when the SHTNAK bit is set to 1 for bulk transfers
- BUF setting: The USBFS does not write this setting.

- STALL setting: PID = STALL is set in the following cases, and issuing of tokens is automatically stopped:
  - When STALL is received in response to a transmitted token
  - When a received data packet exceeds the maximum packet size

(4) Hardware response PID settings in device controller mode

- NAK setting: PID = NAK is set in the following cases, and a NAK response is returned to transactions:
  - When the setup token is received normally (DCP only)
  - If transaction counting ends or a short packet is received when the PIPECFG.SHTNAK bit is set to 1 for bulk transfers
- BUF setting: There is no BUF writing by the USBFS.
- STALL setting: PID = STALL is set in the following cases, and a STALL response is returned to transactions:
  - When a received data packet exceeds the maximum packet size
  - When a control transfer sequence error is detected (DCP only)

27.3.4.7 Data PID sequence bit

The USBFS automatically toggles the sequence bit in the data PID when data is transferred successfully in the control transfer data stage, bulk transfer, and interrupt transfer. The sequence bit of the next data PID to be transmitted can be confirmed with the SQMON bit in DCPCTR and PIPEnCTR. When data is transmitted, the sequence bit toggles on ACK handshake reception. When data is received, the sequence bit toggles on ACK handshake transmission. The SQCLR bit in DCPCTR and the SQSET bit in PIPEnCTR can be used to change the data PID sequence bit.

In device controller mode when control transfers are used, the USBFS automatically sets the sequence bit for stage transitions. DATA1 is returned when the setup stage ends. The sequence bit is not referenced and PID = DATA1 is returned in the status stage. Therefore, no software settings are required. However, in host controller mode when control transfers are used, the sequence bit must be set by software for the stage transitions.

For ClearFeature requests for transmission or reception, the data PID sequence bit must be set by software in both host and device controller modes.

27.3.4.8 Response PID = NAK function

The USBFS provides a function for disabling pipe operation (PID response = NAK) when the final data packet of a transaction is received. The USBFS automatically distinguishes this based on reception of a short packet or the transaction counter. Enable this function by setting the PIPECFG.SHTNAK bit to 1.

When the double buffer mode is being used for the FIFO buffer, using this function enables reception of data packets in transfer units. If pipe operation is disabled, the software must enable the pipe again (PID response = BUF).

The response PID = NAK function can be used only for bulk transfers.

27.3.4.9 Auto response mode

For bulk transfer pipes (1 to 5), when the PIPEnCTR.ATREPM bit is set to 1, a transition is made to auto response mode. During an OUT transfer (PIPECFG.DIR = 0), OUT-NAK mode is invoked, and during an IN transfer (DIR = 1), null auto response mode is invoked.

27.3.4.10 OUT-NAK mode

For bulk OUT transfer pipes, NAK is returned in response to an OUT token, and an NRDY interrupt is output when the PIPEnCTR.ATREPM bit is set to 1. To transition from normal mode to OUT-NAK mode, specify OUT-NAK mode while pipe operation is disabled (PID[1:0] = 00b for NAK response). Next enable pipe operation (PID[1:0] = 01b for BUF response), on which OUT-NAK mode becomes valid. If an OUT token is received immediately before pipe operation is disabled, the token data is normally received, and an ACK is returned to the host.

To transition from OUT-NAK mode to normal mode, cancel OUT-NAK mode while pipe operation is disabled (NAK). Next enable pipe operation (BUF). In normal mode, reception of OUT data is enabled.

27.3.4.11 Null auto response mode

For bulk IN transfer pipes, zero-length packets are continuously transmitted when the PIPEnCTR.ATREPM bit is set to 1.

To transition from normal mode to null auto response mode, specify null auto response mode while pipe operation is disabled (response PID = NAK). Next enable pipe operation (response PID = BUF) on which null auto response mode becomes valid. Before setting null auto response mode, check that PIPEnCTR.INBUFM = 0, because the mode can be set only when the buffer is empty. If the INBUFM bit is 1, empty the buffer using the PIPEnCTR.ACLRM bit. Do not write data from the FIFO port while a transition to null auto response mode is being made.

To transition from null auto response mode to normal mode, keep pipe operation disabled (response PID = NAK) for the period of the zero-length packet transmission (about 10 µs) before canceling the null auto response mode. In normal mode, data can be written from the FIFO port, so packet transmission to the host is enabled by enabling pipe operation (response PID = BUF).

27.3.5 FIFO Buffer

The USBFS provides a FIFO buffer for data transfers, and it manages the memory area used for each pipe. The FIFO buffer has two states depending on whether the access right is assigned to the system (CPU side) or the USBFS (SIE side).

(1) Buffer status

Table 27.20 and Table 27.21 show the buffer status in the USBFS. The FIFO buffer status can be confirmed using the DCPCTR.BSTS and PIPEnCTR.INBUFM bits. The transfer direction for the FIFO buffer can be specified in either the PIPECFG.DIR or CFIFOSEL.ISEL bit (when DCP is selected).

The INBUFM bit is valid for pipes 1 to 5 in the transmitting direction.

When a transmitting pipe uses double buffering, the software can read the BSTS bit to monitor the FIFO buffer status on the CPU side and the INBUFM bit to monitor the FIFO buffer status on the SIE side. When write access to the FIFO port by the CPU or DMA/DTC is slow and the buffer empty status cannot be determined using the BEMP interrupt, the software can use the INBUFM bit to confirm the end of transmission.

Table 27.20 Buffer status indicated in the BSTS bit

ISEL or DIR	BSTS	FIFO buffer status
0 (receiving direction)	0	There is no received data, or data is being received. Reading from the FIFO port is disabled.
0 (receiving direction)	1	There is received data, or a zero-length packet is received. Reading from the FIFO port is allowed. When a zero-length packet is received, reading is not possible and the buffer must be cleared.
1 (transmitting direction)	0	Transmission has not completed. Writing to the FIFO port is disabled.
1 (transmitting direction)	1	Transmission is complete. CPU write is allowed.

Table 27.21 Buffer status indicated in the INBUFM bit

DIR	INBUFM	FIFO buffer status
0 (receiving direction)	Invalid	Invalid
1 (transmitting direction)	0	Transmission is complete. There is no data waiting to be transmitted.
1 (transmitting direction)	1	The FIFO port has written data to the buffer. There is data to be transmitted.

27.3.6 FIFO Buffer Clearing

Table 27.22 shows the methods for clearing the FIFO buffer. The FIFO buffer can be cleared using BCLR bit in the port control register, DnFIFOSEL.DCLRM, or the PIPEnCTR.ACLRM bit.

Single or double buffering can be selected for pipes 1 to 5 in the PIPECFG.DBLB bit.

Table 27.22 Buffer clearing methods

FIFO buffer clearing mode	Clearing FIFO buffer on the CPU side	Mode for automatically clearing the FIFO buffer after reading the specified pipe data	Auto buffer clear mode for discarding all received packets
Register used	CFIFOCTR DnFIFOCTR	DnFIFOSEL	PIPEnCTR
Bit used	BCLR	DCLRM	ACLRM
Clearing condition	Cleared by writing 1	1: Mode valid 0: Mode invalid	1: Mode valid 0: Mode invalid

(1) Auto buffer clear mode function

The USBFS discards all received data packets if the PIPEnCTR.ACLRM bit is set to 1. If a correct data packet is received, the ACK response is returned to the host controller. The auto buffer clear mode function can only be set in the FIFO buffer reading direction.

Setting the ACLRM bit to 1 and then to 0 clears the FIFO buffer of the selected pipe regardless of the access direction. An access cycle of at least 100 ns is required for the internal hardware sequence processing between ACLRM = 1 and ACLRM = 0.

27.3.7 FIFO Port Functions

Table 27.23 shows the settings for the FIFO port functions. In write access, writing data until the maximum packet size is reached automatically enables transmission of the data. To enable transmission before the maximum packet size is reached, set the BVAL flag in the port control register to end writing. To send a zero-length packet, use the BCLR bit to clear the buffer, and then set the BVAL flag to end writing.

In reading, reception of new packets is automatically enabled when all data is read. Data cannot be read when a zero-length packet is received (DTLN[8:0] = 0), so the buffer must be cleared with the BCLR bit. The length of the receive data can be confirmed in the DTLN[8:0] bits in the port control register.

Table 27.23 FIFO port function settings

Register name	Bit name	Description
CFIFOSEL, DnFIFOSEL (n = 0, 1)	RCNT	Selects DTLN[11:0] read mode
	REW	FIFO buffer rewind (re-read, rewrite)
	DCLRM	Automatically clears receive data for a specified pipe after the data is read (only for DnFIFO)
	DREQE	Enables DMA/DTC transfers (only for DnFIFO)
	MBW	FIFO port access bit width
	BIGEND	Selects FIFO port endian
	ISEL	FIFO port access direction (only for DCP)
	CURPIPE	Selects the current pipe
CFIFOCTR, DnFIFOCTR (n = 0, 1)	BVAL	Ends writing to the FIFO buffer
	BCLR	Clears the FIFO buffer on the CPU side
	DTLN	Checks the length of receive data

(1) FIFO port selection

Table 27.24 shows the pipes that can be selected with the different FIFO ports. The pipe to be accessed must be selected in the CURPIPE[3:0] bits in the port select register. After the pipe is selected, the software must check whether the written value can be read correctly from the CURPIPE[3:0] bits. (If the previous pipe number is read, it indicates that the USBFS is modifying the pipe.) Next, the software checks that the FRDY bit in the port control register is 1.

In addition, the software must specify the bus width to be accessed in the MBW bit in the port select register. The FIFO buffer access direction conforms to the PIPECFG.DIR setting. For the DCP only, the ISEL bit in the port select register determines the direction.

Table 27.24 FIFO port access by pipe

Pipe	Access method	Ports that can be used
DCP	CPU access	CFIFO port register
Pipes 1 to 9	CPU access	• CFIFO port register • D0FIFO/D1FIFO port register
	DMA/DTC access	D0FIFO/D1FIFO port register

(2) REW bit

It is possible to temporarily stop access to a pipe currently being accessed, access a different pipe, and then continue processing for the first pipe again. The REW bit in the port select register is used for this processing.

If a pipe is selected in the CURPIPE[3:0] bits in the port select register with the REW bit set to 1, the pointer used for reading from and writing to the FIFO buffer is reset, and reading or writing can be carried out from the first byte. If a pipe is selected with 0 set for the REW bit, data can be read and written in continuation from the previous selection, without the pointer being reset.

To access the FIFO port, the software must check that the FRDY bit in the port control register is 1 after selecting a pipe.

27.3.8 DMA Transfers (D0FIFO and D1FIFO Ports)

(1) Overview of DMA transfers

For pipes 1 to 9, the FIFO port can be accessed using the DMAC. When buffer access for a pipe targeted for DMA transfer is enabled, a DMA transfer request is issued.

Select the unit of transfer to the FIFO port in the DnFIFOSEL.MBW bit, and select the pipe targeted for the DMA transfer in the DnFIFOSEL.CURPIPE[3:0] bits. Do not change the selected pipe during the DMA transfer.

(2) DnFIFO auto clear mode (D0FIFO and D1FIFO port reading direction)

If 1 is set in the DnFIFOSEL.DCLRM bit, the USBFS automatically clears the FIFO buffer of the selected pipe when reading of data from the FIFO buffer is complete.

Table 27.25 shows the packet reception and FIFO buffer clearing processing by software for each of the settings.
As shown in the table, the buffer clearing conditions depend on the value set in the PIPECFG.BFRE bit. Using the DnFIFOSEL.DCLRM bit eliminates the need for the buffer to be cleared by software in any situation that requires buffer clearing. This enables DMA transfers without involving software.

The DnFIFO auto clear mode can only be set in the FIFO buffer reading direction.

Table 27.25 Packet reception and FIFO buffer clearing processing by software

Buffer status when packet is received	Register setting			
	DCLRM = 0		DCLRM = 1	
	BFRE = 0	BFRE = 1	BFRE = 0	BFRE = 1
Buffer full	No clearing required	No clearing required	No clearing required	No clearing required
Zero-length packet reception	Clearing required	Clearing required	No clearing required	No clearing required
Normal short packet reception	No clearing required	Clearing required	No clearing required	No clearing required
Transaction count end	No clearing required	Clearing required	No clearing required	No clearing required

27.3.9 Control Transfers Using the DCP

The DCP is used for data transfers in the control transfer data stage. The FIFO buffer of the DCP is a 64-byte single buffer with a fixed area for both control reads and control writes. The FIFO buffer can be accessed only through the CFIFO port.

27.3.9.1 Control transfers in host controller mode

(1) Setup stage

The USQREQ, USBVAL, USBINDX, and USBLENG registers are used to transmit USB requests for setup transactions. Writing the setup packet data to the registers and then writing 1 to the DCPCTR.SUREQ bit transmits the specified data for the setup transaction. On completion of the transaction, the SUREQ bit clears to 0. Do not change these USB request registers while SUREQ = 1.

When an attached function device is detected, the software must issue the first setup transaction for the device using this sequence with the DCPMAXP.DEVSEL[3:0] bits cleared to 0 and the DEVADD0.USBSPD[1:0] bits set appropriately.

When an attached function device is shifted to the Address state, the software must issue setup transactions using this sequence with the assigned USB address set in the DEVSEL[3:0] bits and the bits in DEVADDn corresponding to the specified USB address set appropriately. For example, when PIPEMAXP.DEVSEL[3:0] = 0010b, make appropriate settings in DEVADD2. When PIPEMAXP.DEVSEL[3:0] = 0101b, make appropriate settings in DEVADD5.

When the setup transaction data is sent, an interrupt request is generated based on the response from the peripheral device (SIGN or SACK bit in INTSTS1). This interrupt request allows the software to check the setup transaction result.

A DATA0 data packet (USB request) for the setup transaction is always transmitted regardless of the status of the DCPCTR.SQMON bit.

(2) Data stage

The data stage is used to transfer data using the DCP FIFO buffer.

Before accessing the DCP FIFO buffer, specify the access direction in the CFIFOSEL.ISEL bit. Specify the transfer direction in the DCPCFG.DIR bit.

For the first data packet of the data stage, the data PID must be transferred as DATA1. Set data PID = DATA1 in the DCPCTR.SQSET bit and set the PID bits = BUF. Completion of data transfer is detected using the BRDY or BEMP interrupt.

For control write transfers, when the number of data bytes to be sent is an integer multiple of the maximum packet size, the software must send a zero-length packet at the end.

(3) Status stage

The status stage is used for zero-length packet data transfers in the reverse direction of the data stage. As in the data stage, data is transferred using the DCP FIFO buffer. Transactions are executed using the same procedure as the data stage.

Data packets in the status stage must be transmitted and received with the data PID set to DATA1 using the DCPCTR.SQSET bit.

When a zero-length packet is received, check the receive-data length in the CFIFOCTR.DTLN[8:0] bits after a BRDY interrupt is generated, and then clear the FIFO buffer using the BCLR bit.

27.3.9.2 Control transfers in device controller mode

(1) Setup stage

The USBFS sends an ACK response to a normal setup packet for the USBFS. The USBFS operates in the setup stage as follows:

On receiving a new setup packet, the USBFS sets the following bits:

- Sets the INTSTS0.VALID bit to 1
- Sets the DCPCTR.PID[1:0] bits to NAK
- Sets the DCPCTR.CCPL bit to 0

When the USBFS receives a data packet following a setup packet, it stores the USB request parameters in USBREQ, USBVAL, USBINDX, and USBLENG.

Before performing the response processing for a control transfer, set the VALID flag to 0. When the VALID bit = 1, PID = BUF cannot be set, and the data stage cannot be terminated.

Using the VALID bit function, the USBFS can suspend a request being processed when it receives a new USB request during a control transfer and return a response to the latest request.

In addition, the USBFS automatically detects the direction bit (bmRequestType bit [8]) and the request data length (wLength) in the received USB request. It distinguishes between control read transfers, control write transfers, and no-data control transfers, and it controls stage transitions. For an incorrect sequence, a sequence error occurs in the control transfer stage transition interrupt, and the interrupt is reported to the software. For a diagram of the stage control by the USBFS, see Figure 27.15.

(2) Data stage

The DCP must be used to execute data transfers for received USB requests. Before accessing the DCP FIFO buffer, specify the access direction in the CFIFOSEL.ISEL bit.

If the transfer data is larger than the size of the DCP FIFO buffer, execute the data transfer using the BRDY interrupt for control write transfers and the BEMP interrupt for control read transfers.

(3) Status stage

Control transfers are terminated by setting the DCPCTR.CCPL bit to 1 while the DCPCTR.PID[1:0] bits are set to BUF.

After this setting is made, the USBFS automatically executes the status stage based on the data transfer direction determined at the setup stage. The procedure is as follows:

- For control read transfers

  The USBFS receives a zero-length packet from the USB host and transmits an ACK response.
- For control write transfers and no-data control transfers

  The USBFS transmits a zero-length packet and receives an ACK response from the USB host.

(4) Control transfer auto response function

The USBFS automatically responds to a correct SET_ADDRESS request. If any of the following errors occurs in the SET_ADDRESS request, a response from the software is necessary.

- bmRequestType is not 0x00: Any transfer other than a control write transfer
- wIndex is not 0x00: Request error
- wLength is not 0x00: Any transfer other than a no-data control transfer
- wValue is larger than 0x7F: Request error
- INTSTS0.DVSQ[2:0] are 011b (Configured state): Control transfer of a device state error

For all requests other than the SET_ADDRESS request, a response is required from the corresponding software.

27.3.10 Bulk Transfers (Pipes 1 to 5)

The FIFO buffer usage (single/double buffer setting) is configurable for bulk transfers. The USBFS provides the following functions for bulk transfers:

- BRDY interrupt function (PIPECFG.BFRE bit), see section 27.3.3.1. BRDY interrupt
- Transaction count function (PIPEnTRE.TRENB, TRCLR, and PIPEnTRN.TRNCNT[15:0] bits), see section 27.3.4.5. Transaction counter for pipes 1 to 5 in the receiving direction
- Response PID = NAK function (PIPECFG.SHTNAK bit), see section 27.3.4.8. Response PID = NAK function
- Auto response mode (PIPEnCTR.ATREPM bit), see section 27.3.4.9. Auto response mode

27.3.11 Interrupt Transfers (Pipes 6 to 9)

In device controller mode, the USBFS performs interrupt transfers based on the timing dictated by the host controller.

In host controller mode, the software can set the timing for issuing tokens using the interval counter.

27.3.11.1 Interval counter for interrupt transfers in host controller mode

Specify the transaction interval for interrupt transfers in the PIPEPERI.IITV[2:0] bits. The USBFS issues interrupt transfer tokens based on this interval.

(1) Counter initialization

The USBFS initializes the interval counter under the following conditions:

- Power-on reset

  This initializes the IITV[2:0] bits.
- FIFO buffer initialization using the PIPEnCTR.ACLRM bit:

  This does not initialize the IITV[2:0] bits, but does initialize the count value. Setting the PIPEnCTR.ACLRM bit to 0 starts counting from the value set in IITV[2:0].

The interval counter is not initialized in the following case:

- USB bus reset or USB suspended

  The IITV[2:0] bits are not initialized. Setting 1 to the DVSTCTR0.UACT bit starts counting from the value saved before entering the USB bus reset state or USB suspend state.

(2) Operation when tokens cannot be transmitted or received even on token generation

No token is generated in the following cases even at token generation time. In these cases, the USBFS tries to execute the transaction in the next interval.

- When the PID is set to NAK or STALL
- When the FIFO buffer is full at token transmit time in the receiving (IN) direction
- When there is no data to be transmitted in the FIFO buffer at token transmit time in the transmitting (OUT) direction

27.3.12 Isochronous Transfers (Pipes 1 and 2)

The USBFS provides the following functions for isochronous transfers:

- Notification of isochronous transfer error
- Interval counter specified in the PIPEPERI.IITV[2:0] bits
- Isochronous IN transfer data setup control (IDLY function)
- Isochronous IN transfer buffer flush function specified in the PIPEPERI.IFIS bit

27.3.12.1 Error detection in isochronous transfers

The USBFS provides a function for detecting the errors described in this section, so that when errors occur in isochronous transfers, they can be controlled by software. Table 27.26 and Table 27.27 show the priority order for errors detected by the USBFS and the associated interrupts.

PID errors

- The PID value of the received packet is invalid.

CRC errors and bit stuffing errors

- A CRC error is found in a received packet or the bit stuffing is illegal.

Maximum packet size exceeded

- The data size of the received packet exceeds the specified maximum packet size.

Overrun and underrun errors

In host controller mode:

- The FIFO buffer is full at token transmit time in the IN (receiving) direction
- There is no data to be sent in the FIFO buffer at token transmit time in the OUT (transmitting) direction

In device controller mode:

- There is no data to be sent in the FIFO buffer at token receive time in the IN (transmitting) direction
- The FIFO buffer is full at token receive time in the OUT (receiving) direction

Interval errors

In device controller mode, the following cases are treated as an interval error:

- Failure to receive an IN token in the interval frame during an isochronous IN transfer
- Failure to receive an OUT token in the interval frame during an isochronous OUT transfer

Table 27.26 Error detection for token transmission and reception

Detection priority	Error	Generated interrupt and status
1	PID error	No interrupts are generated in either host or device controller mode (ignored as a corrupted packet)
2	CRC or bit stuffing error	No interrupts are generated in either host or device controller mode (ignored as a corrupted packet)
3	Overrun or underrun error	An NRDY interrupt is generated to set the FRMNUM.OVRN bit to 1 in both host and device controller modes. In device controller mode, a zero-length packet is transmitted in response to an IN token. No data packets are received in response to OUT token.
4	Interval error	An NRDY interrupt is generated in device controller mode. No interrupt is generated in host controller mode.

Table 27.27 Error detection for data packet reception

Detection priority	Error	Generated interrupt and status
1	PID error	No interrupts are generated (ignored as a corrupted packet)
2	CRC or bit stuffing error	An NRDY interrupt is generated and the FRMNUM.CRCE bit sets to 1 in both host and device controller modes
3	Maximum packet size exceeded error	A BEMP interrupt is generated and the PID[1:0] bits set to STALL in both host and device controller modes

27.3.12.2 DATA-PID

In device controller mode, the USBFS responds to a received PID as follows:

(1) IN direction

- DATA0: Transmitted as data packet PID
- DATA1: Not transmitted
- DATA2: Not transmitted
- mDATA: Not transmitted

(2) OUT direction

- DATA0: Received normally as data packet PID
- DATA1: Received normally as data packet PID
- DATA2: Packets ignored
- mDATA: Packets ignored

27.3.12.3 Interval counter

The isochronous transfer interval can be set in the PIPEPERI.IITV[2:0] bits. In device controller mode, the interval counter enables the functions as shown in Table 27.28. In host controller mode, the USBFS generates the token issuance timing, and the interval counter operation is the same as that for interrupt transfers.

Table 27.28 Interval counter functions in device controller mode

Transfer direction	Function	Conditions for detection
IN	Transmit buffer flush	Failure to receive an IN token successfully in the interval frame during an isochronous IN transfer.
OUT	Notification of no reception of token	Failure to receive an OUT token successfully in the interval frame during an isochronous OUT transfer.

The interval count is performed when an SOF is received or for interpolated SOFs, so the isochronism can be maintained even if an SOF is corrupt. The frame interval can be set to 2^{IITV} frames.

(1) Counter initialization in device controller mode

The USBFS initializes the interval counter under the following conditions:

- Power-on reset

  This initializes the PIPEPERI.IITV[2:0] bits.
- FIFO buffer initialization using the ACLRM bit

  This does not initialize the IITV[2:0] bits, but does initialize the count value.

After the interval counter is initialized, the interval count starts under one of the following conditions when a packet is transferred successfully:

- An SOF is received after data is transmitted in response to an IN token when PID = BUF
- An SOF is received after data is received in response to an OUT token when PID = BUF

The interval counter is not initialized in the following conditions:

- When the PID[1:0] bits are set to NAK or STALL

  This does not stop the interval timer. The USBFS attempts the transaction in the next interval.
- When the USB bus is reset or USBFS is suspended

  This does not initialize the IITV[2:0] bits. When an SOF is received, the interval counter starts counting from the value set before SOF was received.

(2) Interval counting and transfer control in host controller mode

The USBFS controls the interval between token issuance operations based on the PIPEPERI.IITV[2:0] bits settings. Specifically, the USBFS issues a token for a selected pipe once every 2^{IITV} frames.

The USBFS starts counting the token issuance interval at the frame following the frame in which the PID[1:0] bits are set to BUF by software.

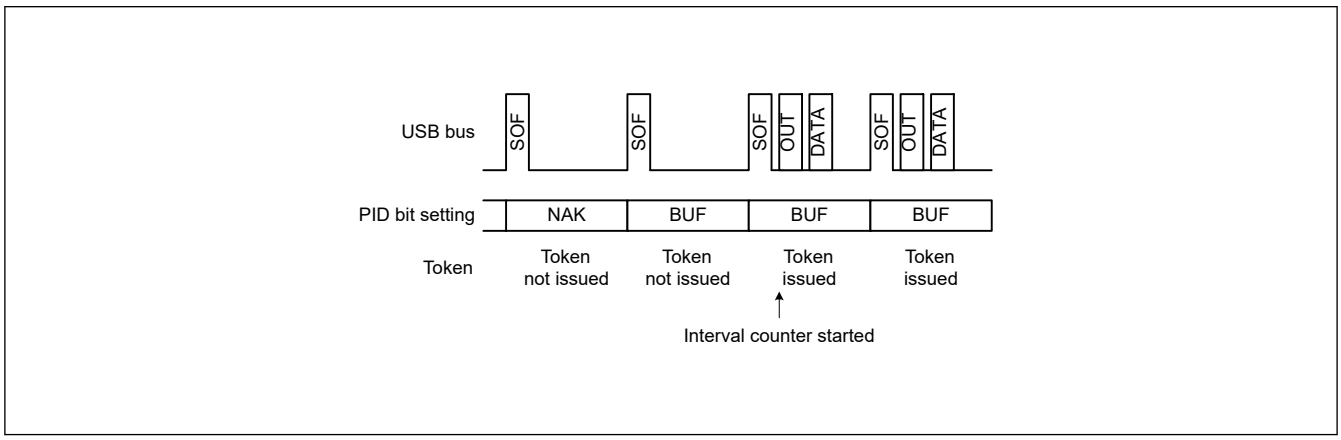

Figure 27.16 Token issuance when IITV = 0

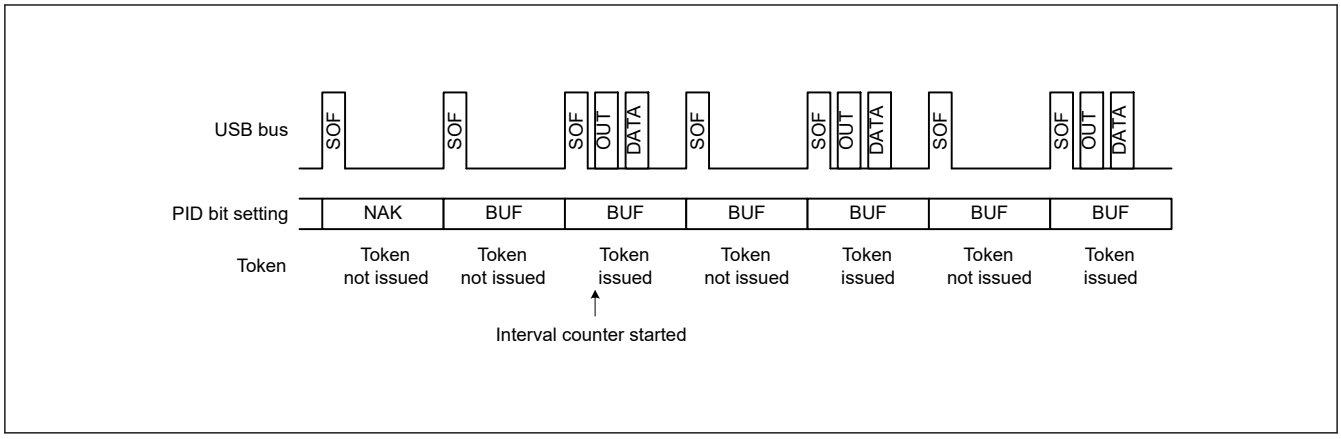

Figure 27.17 Token issuance when IITV = 1

When the selected pipe is set for isochronous transfers, the USBFS performs the following operation in addition to controlling the token issuance interval. The USBFS issues a token even when the NRDY interrupt generation condition is satisfied.

When the selected pipe is for isochronous IN transfers

The USBFS generates an NRDY interrupt when the USBFS issues an IN token but does not successfully receive a packet from a peripheral device (no response or packet error).

The USBFS sets the FRMNUM.OVRN bit to 1, generating an NRDY interrupt, when the time to issue an IN token occurs while the USBFS cannot receive data because the FIFO buffer is full, because the CPU or DMAC/DTC is too slow in reading data from the FIFO buffer.

When the selected pipe is for isochronous OUT transfers

The USBFS sets the OVRN bit to 1, generating an NRDY interrupt and transmitting a zero-length packet, when the time to issue an OUT token comes while there is no data to be transmitted in the FIFO buffer, or because the CPU or DMAC/DTC is too slow in writing data to the FIFO buffer.

The token issuance interval is reset on any of the following conditions:

- When the USBFS is reset through a reset pin

  This initializes the IITV[2:0] bits.
- When the PIPEnCTR.ACLRM bit is set to 1 by software

(3) Interval counting and transfer control in device controller mode

When the selected pipe is for isochronous OUT transfers

The USBFS generates an NRDY interrupt when it fails to receive a data packet within the interval set in the PIPEPERI.IITV[2:0] bits.

The USBFS also generates an NRDY interrupt when it fails to receive data because of a CRC error or other errors contained in the data packet or because the FIFO buffer is full.

The NRDY interrupt is generated on SOF packet reception. Even if the SOF packet is corrupted, internal interpolation allows the interrupt to be generated when the SOF packet is received. However, when the IITV bits are set to a value other than 0, the USBFS generates an NRDY interrupt on receiving an SOF packet for every interval after interval counting starts.

When the PID[1:0] bits are set to NAK by software after starting the interval timer, the USBFS does not generate an NRDY interrupt on receiving an SOF packet.

The timing for starting interval counting depend on the IITV[2:0] setting as follows:

- When the IITV[2:0] bits = 0:

  Interval counting starts at the next frame after the software changes the PID[1:0] bits of the selected pipe to BUF.
- When the IITV[2:0] bits ≠ 0:

  Interval counting starts on completion of successful reception of the first data packet after the PID[1:0] bits for the selected pipe are changed to BUF.

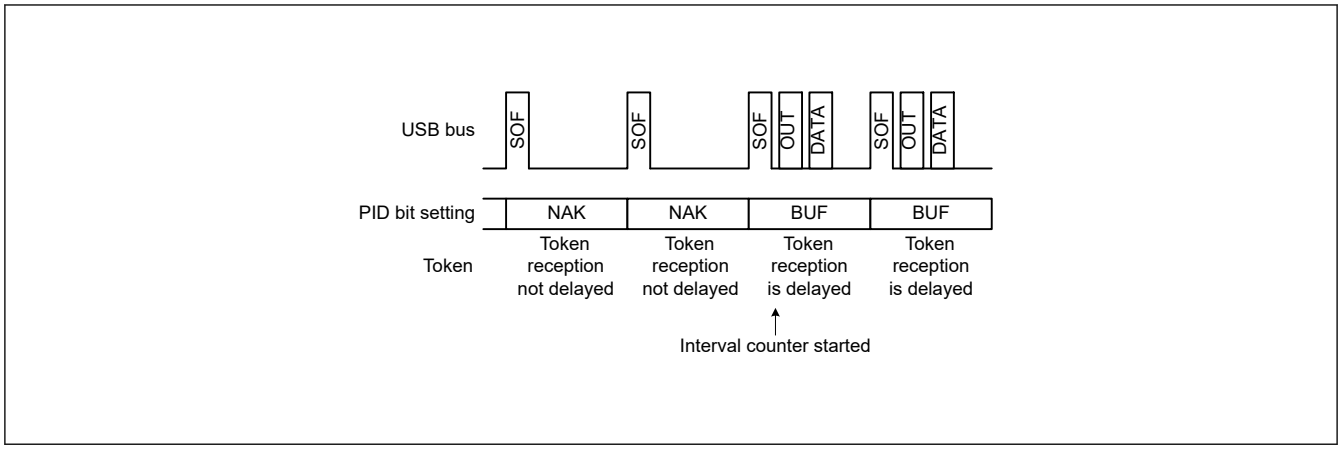

Figure 27.18 Relationship between frames and expected token reception when IITV[2:0] = 0

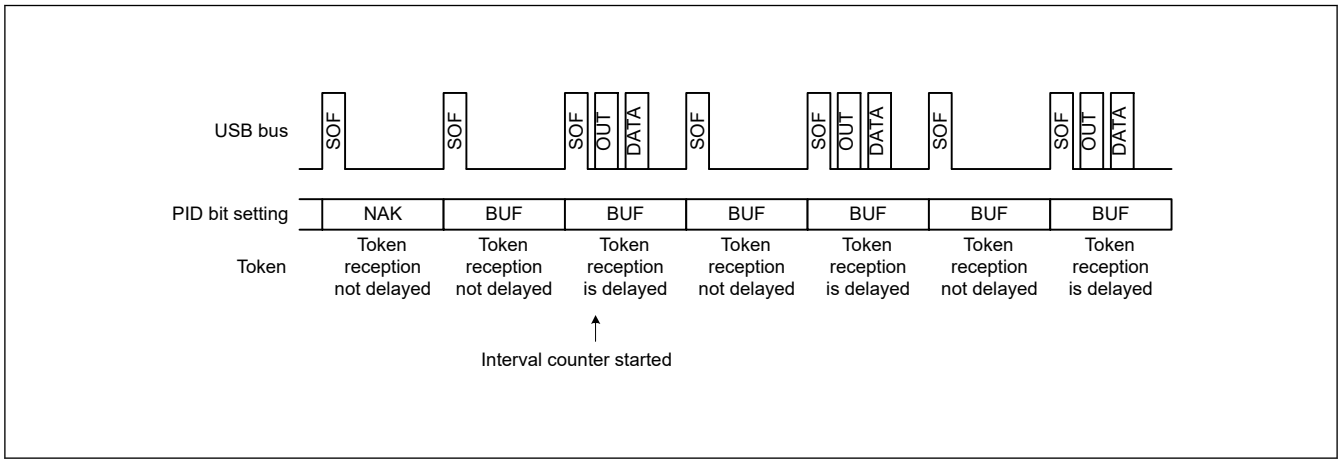

Figure 27.19 Relationship between frames and expected token reception when IITV[2:0] ≠ 0

When the selected pipe is for isochronous IN transfers

The PIPEPERI.IFIS bit must be 1 for this use case. When IFIS = 0, the USBFS transmits a data packet in response to a received IN token regardless of the PIPEPERI.IITV[2:0] setting.

When IFIS is 1 and there is data to be transmitted in the FIFO buffer, the USBFS clears the FIFO buffer when it fails to receive an IN token in the frame at the interval set in the IITV[2:0] bits.

The USBFS also clears the FIFO buffer when it fails to receive an IN token successfully because of a bus error, such as a CRC error, contained in the IN token.

The FIFO buffer is cleared on SOF packet reception. Even if the SOF packet is corrupted, the internal interpolation allows the FIFO buffer to be cleared when the SOF packet is received.

The timing to start interval counting depends on the IITV[2:0] setting, as with OUT transfers.

The interval is counted on any of the following conditions in device controller mode:

- When a hardware reset is applied to the USBFS (which also sets the IITV[2:0] bits to 000b)
- When the PIPEnCTR.ACLRM bit is set to 1 by software
- When the USBFS detects a USB bus reset

(4) Transmit data setup for isochronous transfers in device controller mode

With isochronous data transmission using the USBFS in device controller mode, after data is written to the FIFO buffer, a data packet can be transmitted in the first frame after the SOF packet is detected. This isochronous transfer transmit data setup function can identify the frame that started transmission.

When the double buffering is used, transmission is only enabled for the buffer where data writing was completed first, even after the data write to both buffers is complete. Accordingly, even if multiple IN tokens are received, only the one packet of FIFO buffer data is transmitted.

When the FIFO buffer is ready to transmit data when an IN token is received, the data is transferred and a normal response is returned. However, if the FIFO buffer cannot transmit data, a zero-length packet is transmitted and an underrun error occurs.

Figure 27.20 shows an example transmission using the isochronous transfer transmission data setup function when IITV = 0 (every frame) is set.

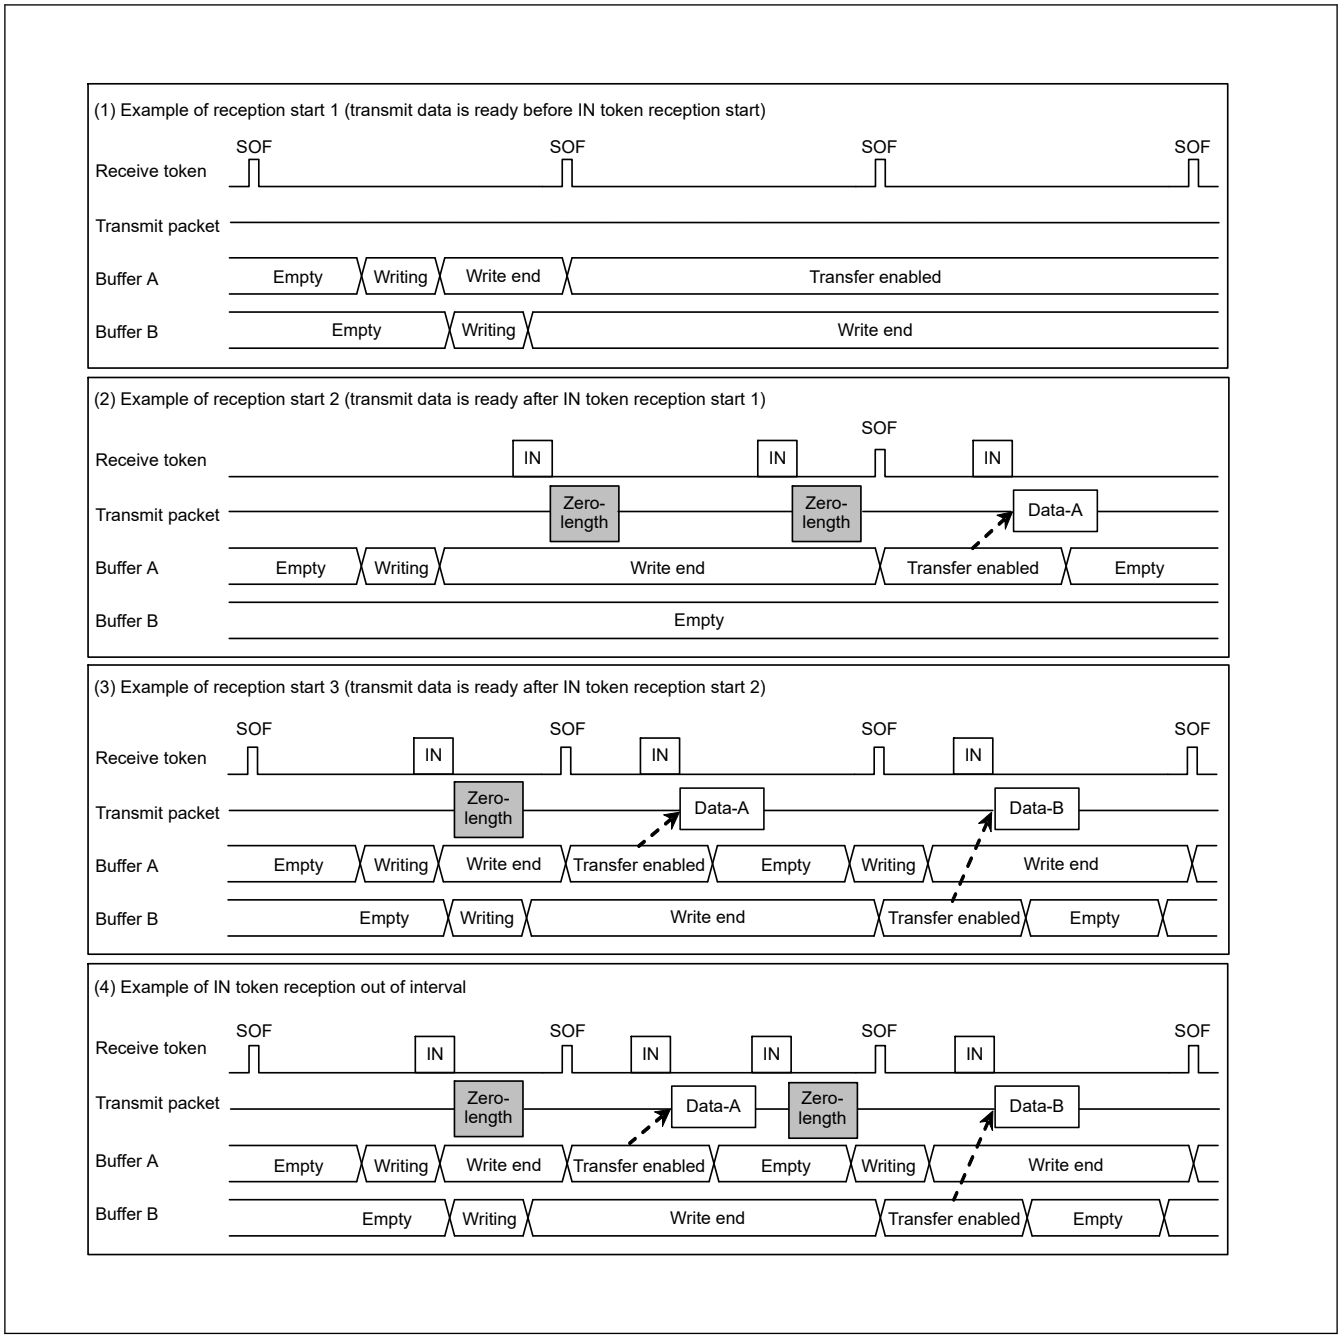

Figure 27.20 Example data setup operation

(5) Transmit buffer flush for isochronous transfers in device controller mode

In device controller mode during isochronous data transmission, if the USBFS receives an SOF packet for the next frame without receiving an IN token in the interval frame, it operates as if the IN token is corrupt and clears the buffer that is enabled for transmission, putting that buffer in the writing enabled state.

When double buffering is used and writing to both buffers is complete, the cleared FIFO buffer is assumed to be the one where the data was transmitted in the interval frame, and transmission is enabled for the FIFO buffer that was not cleared on SOF packet reception.

The timing of the buffer flush function depends on the PIPEPERI.IITV[2:0] setting as follows:

- When IITV = 0:

  The buffer flush operation starts from the first frame after the pipe is enabled.

- When IITV ≠ 0:

  The buffer flush operation starts after the first normal transaction.

Figure 27.21 shows an example buffer flush. When an unanticipated token is received before the interval frame, the USBFS sends the write data or a zero-length packet as an underrun error, depending on the data setup status.

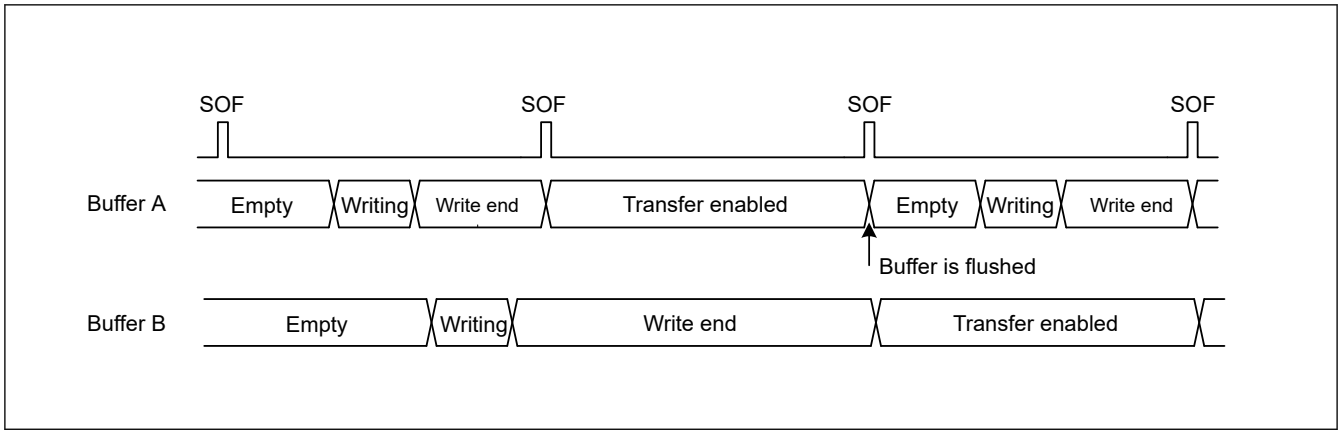

Figure 27.21 Example buffer flush operation

Figure 27.22 shows an example interval error occurrence. There are five types of interval errors, as shown in the figure. An interval error occurs at timing (A), and the buffer flush function is activated.

If an interval error occurs during an IN transfer, the buffer flush function is activated. If it occurs during an OUT transfer, an NRDY interrupt is generated. Use the FRMNUM.OVRN bit to distinguish between this and NRDY interrupts triggered by received packet errors and overrun errors.

For tokens that are shaded in the figure, responses are returned based on the FIFO buffer status.

- IN direction:
  - If the buffer is ready to transfer data, the data is transferred and a normal response is returned
  - If the buffer is not ready to transfer data, a zero-length packet is transmitted and an underrun error occurs
- OUT direction:
  - If the buffer is ready to receive data, the data is received and a normal response is returned
  - If the buffer is not ready to receive data, the received data is discarded and an overrun error occurs

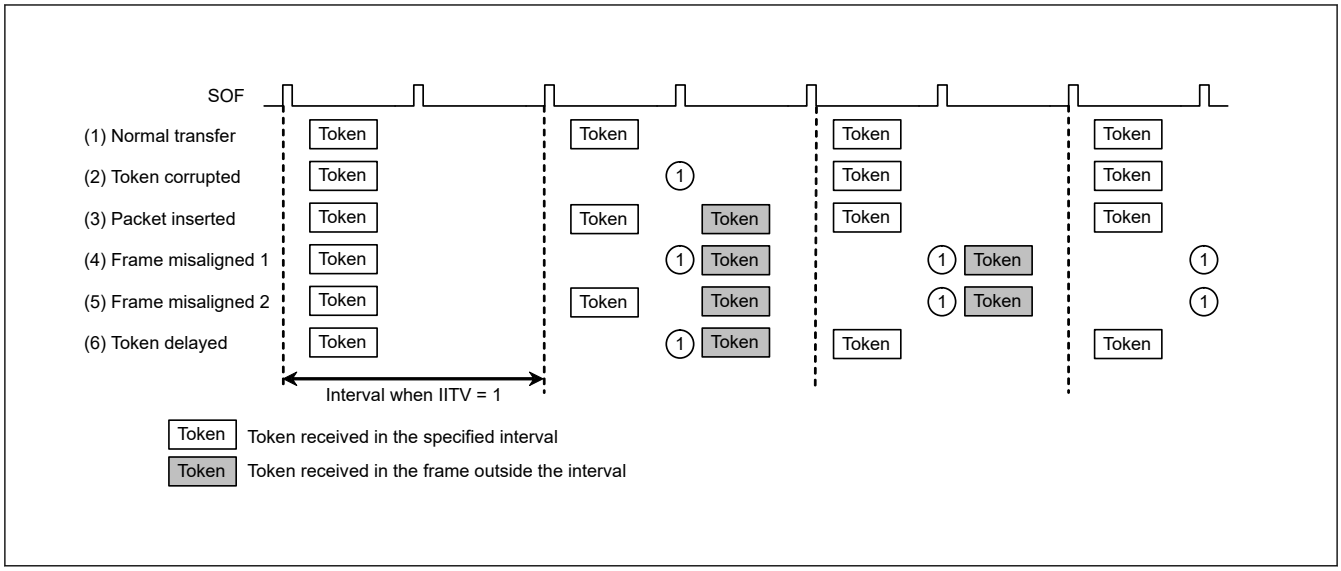

Figure 27.22 Example interval error occurrence when IITV = 1

27.3.13 SOF Interpolation Function

In device controller mode, if packet reception is disabled at intervals of 1 ms because the SOF packet is corrupted or missing, the USBFS interpolates the SOF. SOF interpolation begins when the USBE and SCKE bits in SYSCFG are set to 1 and an SOF packet is received.

The interpolation function is initialized under the following conditions:

- MCU reset
- USB bus reset
- Suspend state detection

The SOF interpolation operates as follows:

- The interpolation function is not activated until an SOF packet is received
- When the first SOF packet is received, interpolation is performed by counting 1 ms on the 48-MHz internal clock
- When the second and subsequent SOF packets are received, interpolation is performed at the previous reception interval
- Interpolation is not performed in the Suspend state or on reception of a USB bus reset

The USBFS supports the following functions controlled by SOF packet reception. These functions operate normally with SOF interpolation if the SOF packet is missing:

- Updating of the frame number
- SOFR interrupt timing
- Isochronous transfer interval count

If an SOF packet is missing during full-speed operation, the FRMNUM.FRNM[10:0] bits are not updated.

27.3.14 Pipe Schedule

27.3.14.1 Conditions for generating transactions

In host controller mode and when the DVSTCTR0.UACT bit is set to 1, the USBFS generates transactions under the conditions shown in Table 27.29.

Table 27.29 Conditions for generating transactions

Transaction	Conditions for generation				
	DIR	PID	IITV0	Buffer state	SUREQ
Setup	—*1	—*1	—*1	—*1	1 setting
Control transfer data stage, status stage, bulk transfer	IN	BUF	Invalid	Receive area exists	—*1
	OUT	BUF	Invalid	Transmit data exists	—*1
Interrupt transfer	IN	BUF	Valid	Receive area exists	—*1
	OUT	BUF	Valid	Transmit data exists	—*1
Isochronous transfer	IN	BUF	Valid	*2	—*1
	OUT	BUF	Valid	*3	—*1

Note 1. An em dash (—) in the table indicates that the condition is unrelated to the generating of tokens. “Valid” indicates that, for interrupt transfers and isochronous transfers, a transaction is generated only in transfer frames that are based on the interval counter. “Invalid” indicates that a transaction is generated regardless of the interval counter.

Note 2. This indicates that a transaction is generated regardless of whether there is a receive area. If there is no receive area, however, the received data is discarded.

Note 3. This indicates that a transaction is generated regardless of whether there is any data to be transmitted. If there is no data to be transmitted, however, a zero-length packet is transmitted.

27.3.14.2 Transfer schedule

This section describes the transfer scheduling within a frame of the USBFS. After the USBFS sends an SOF, the transfer is carried out in the following sequence:

1. Execution of periodic transfers:

   A pipe is searched for in the order of pipe 1 → pipe 2 → pipe 6 → pipe 7 → pipe 8 → pipe 9, and then if there is a pipe for which an isochronous or interrupt transfer transaction can be generated, the transaction is generated.

2. Setup transactions for control transfers:

   The DCP is checked, and if a setup transaction is possible, it is sent.

3. Execution of bulk transfers, control transfer data stages, and control transfer status stages:

   A pipe is searched for in the order of DCP → pipe 1 → pipe 2 → pipe 3 → pipe 4 → pipe 5, and then if there is a pipe for which a transaction for a bulk transfer, a control transfer data stage, or a control transfer status stage can be generated, the transaction is generated.

   When a transaction is generated, processing moves to the next pipe transaction regardless of whether the response from the peripheral device is ACK or NAK. If there is time for transfer within the frame, step 3 is repeated.

27.3.14.3 Enabling USB communication

Setting the DVSTCTR0.UACT bit to 1 initiates an SOF transmission, and transaction generation is enabled. Setting the UACT bit to 0 stops SOF transmission and the Suspend state is invoked. If the UACT setting is changed from 1 to 0, processing stops after the next SOF is sent.

27.4 Usage Notes

27.4.1 Settings for the Module-Stop State

USBFS operation can be disabled or enabled using Module Stop Control Register B (MSTPCRB). The USBFS is initially stopped after reset. Releasing the module-stop state enables access to the registers. For details, see section 10, Low Power Modes.

27.4.2 Clearing the Interrupt Status Register on Canceling Software Standby Mode

Because the input buffer is always enabled in Software Standby mode, an unexpected interrupt might occur under the following conditions:

- When the interrupt is enabled in Normal mode
- When the interrupt is disabled in Software Standby mode
- When the input level of the pin that cancels software standby mode is changed in Software Standby mode

These conditions might cause the associated interrupt flag in the Interrupt Status Register to set unexpectedly. After the MCU cancels the Software Standby mode, the unexpected interrupt might be sent to the interrupt controller. To avoid this, always clear the INTSTS0 and INTSTS1 registers in the canceling sequence.

27.4.3 Clearing the Interrupt Status Register after Setting Up the Port Function

The input buffer is disabled before the PmnPFS.PSEL and PmnPFS.PMR port is set up, so the internal signal is fixed high or low. The input buffer is enabled after the port is set so that the external pin state is propagated to the MCU. An unexpected interrupt might occur at this time, causing the VBINT and OVRCR bits in INTSTS0 and INTSTS1, or other interrupt status flags to set to 1. To avoid a malfunction, always clear the INTSTS0 and INTSTS1 registers after setting up the port.

27.4.4 Setting Up the Port Function before setting USB function

USB_DP, USB_DM pins are compatible with P814, P815 I/O ports. So before setting USBFS registers to enable USBFS function, set register bit P814PFS.PMR and P815PFS.PMR to 1.

28. Serial Communications Interface (SCI)

This is the SCI_B version of the SCI peripheral module.

SCI_B is referred to as SCI in this chapter.

28.1 Overview

The Serial Communications Interface (SCI) × 6 channels have asynchronous and synchronous serial interfaces:

- Asynchronous interfaces (UART and Asynchronous Communications Interface Adapter (ACIA))
- 8-bit clock synchronous interface
- Simple IIC (master-only)
- Simple SPI
- Simple LIN
- Smart card interface
- Manchester interface

The smart card interface complies with the ISO/IEC 7816-3 standard for electronic signals and transmission protocol. SCIn (n = 0 to 4, 9) has FIFO buffers to enable continuous and full-duplex communication, and the data transfer speed can be configured independently using an on-chip baud rate generator.

In this section, PCLK refers to PCLKA.

Table 28.1 lists the SCI specifications, Table 28.2 shows the functions of each SCI channel, Figure 28.1 shows a block diagram of SCI, Figure 28.2 shows a clock source selector block diagram, and Table 28.3 lists the I/O pins.

Table 28.1 SCI specifications (1 of 4)

Parameter	Specifications
Number of modules	6 (SCIn (n = 0 to 4, 9))
Serial communication modes	• Asynchronous • Clock synchronous • Simple IIC • Simple SPI • Simple LIN (SCIn (n = 0, 1)) • Smart card interface • Manchester interface (SCIn (n = 0))
Operation clock (TCLK)	Synchronized clock (PCLK) or independent clock (SCICLK) can be selected
Transfer speed	Bit rate specifiable with the on-chip baud rate generator
Full-duplex communications	• Transmitter: Continuous transmission possible using double-buffering • Receiver: Continuous reception possible using double-buffering
Half-duplex communications	Half-duplex communication is possible by using only TXDn pins
Data transfer	Selectable as LSB-first or MSB-first transfer
Inverter for communication pins (RXDn, TXDn)	Selectable inverter for each pins (RXDn, TXDn)
Interrupt sources	Transmit end, transmit data empty, receive data full, receive error, receive data ready, address match. Break Field detection/output, Bus collision detection, Active edge detection. (SCIn (n = 0, 1)). Completion of generation of a start condition, restart condition, or stop condition. (for simple IIC mode)
Loop Back function	Self-diagnosis of communication function by SCI internal transmission / reception is possible
Synchronizer Bypass function	Ability to bypass synchronization circuit between bus clock (PCLK) and operation clock (TCLK)
Module-stop function	Module-stop state can be set for each channels to reduce power consumption
Reception in Software Standby mode	Only SCI0 is available

Table 28.1 SCI specifications (2 of 4)

Parameter		Specifications
Clock synchronous mode	Data length	8 bits
	Adjustment of receive sampling timing	Adjustable receive sampling timing after the default timing in master mode only when using internal clock
	Receive error detection	Overrun error
	Clock source	Selectable to internal clock (master mode) or external clock (slave mode)
	Double-speed mode	Baud rate generator double-speed mode is selectable
	Hardware flow control	Transmission and reception controllable with CTSn_RTSn pins
	Transmission and reception	Selectable to 1-stage register or 16-stage FIFO
Asynchronous mode	Data length	7, 8, or 9 bits
	Transmission stop bit	1 or 2 bits
	Adjustment of receive sampling timing	Adjustable receive sampling timing before/after the default timing
	Adjustment of transmit timing	Adjustable edge timing of transmit waveform controlled by the setting value of registers.
	Parity	Even parity, odd parity, or no parity
	Receive error detection	• Parity error • Overrun error • Framing error
	Hardware flow control	Transmission and reception controllable with CTSn_RTSn pin and CTSn pin
	Transmission and reception	Selectable to 1-stage register or 16-stage FIFO
	Address match	Interrupt request/event output can be issued upon detecting a match between received data and the value in the compare match register
	Start-bit detection	Selectable to low level or falling edge detection
	Break detection	Breaks from framing errors detectable by read from CSR register
	Clock source	Selectable to internal or external clock. Transfer rate clock input from the GPT can be used. (SCIn (n = 1, 2))
	Double-speed mode	Baud rate generator double-speed mode is selectable
	Multi-processor communications function	Serial communication enabled among multiple processors
	RS-485 driver control function	Output DEn signal to enable external transceiver transmit mode
	Noise cancellation	Digital noise filters included on signal paths from the RXDn pin inputs
Smart card interface mode	Error processing	Error signal can be automatically transmitted upon detecting a parity error during reception
		Data can be automatically retransmitted upon receiving an error signal during transmission
	Data type	Both direct and inverse convention supported
Manchester mode	Communication format	Manchester code with the preface and the Start Bit added
	Data length	7, 8, or 9 bits
	Transmission stop bit	1 or 2 bits
	Parity function	Even parity, odd parity, or no parity
	Receive error detection	Parity, overrun, framing, Manchester errors
	Hardware flow control	Transmission and reception controllable with CTSn_RTSn pin and CTSn pin
	Clock source	Only internal clock can be used.

Table 28.1 SCI specifications (3 of 4)

Parameter		Specifications
	Double-speed mode	Baud rate generator double-speed mode is selectable
	Multi-processor communication function	Serial communication among multiple processors
	Manchester encoding / decoding function	Function to perform Manchester encoding / decoding of transmission / reception data and communicate using Manchester code
	Noise cancellation	The signal paths from input on the RXDn pins incorporate digital noise filters
	Preface setting / detection function	The function outputs the configured the preface pattern and detects it.
	Start Bit setting / detection function	The function outputs the configured the Start Bit pattern and detects it.
	Reception retiming function	Timing correction is performed for each bit of the received signal
Simple IIC mode	Transfer format	I^2C bus format (MSB-first only)
	Operating mode	Master (single-master operation only)
	Transfer rate	Up to 400 kbps
	Noise cancellation	The signal paths from input on the SCLn and SDAn pins incorporate digital noise filters and provide an adjustable interval for noise cancellation
Simple SPI mode	Data length	8 bits
	Error detection	Overrun error
	Clock source	Selectable to internal clock (master mode) or external clock (slave mode)
	Double-speed mode	Baud rate generator double-speed mode is selectable
	Transmission / Reception	Selectable either 1 stage register or 16-stage FIFO
	Adjustment of receive sampling timing	Adjustable receive sampling timing after the default timing in master mode only when using internal clock
	SSn input pin function	High impedance state can be invoked on the output pins by driving the SSn pin high.
	Clock settings	Configurable among four clock phase and clock polarity settings
Simple LIN mode	Start Frame Transmission	• Break Field output possible, Break Field output complete interrupt output possible • Bus collision detection possible, bus collision detection interrupt output possible
	Start Frame Reception	• Break Field detectable, Break Field detected interrupt output possible • Control Field 0/1 data comparison function • Control Field 1 can set two types of comparison data of primary and secondary • Priority interrupt bit can be set in Control Field 1 • Handling of Start Frames that do not include a Break Field • Handling of Start Frames that do not include a Control Field 0 • Bit rate measurement function
	Input/Output control function	• Selectable polarity for TXDn and RXDn signals • Selection of a digital filter for the RXDn signal • Half-duplex operation employing RXDn and TXDn signals multiplexed on the same pin • Selectable timing for the sampling of data received through RXDn
Bit rate modulation function		Error reduction through correction of outputs from the on-chip baud rate generator
Event link function		Error event output for receive error or error signal detection (SCIn_ERI) (n = 0 to 4, 9)
		Receive data full event output (SCIn_RXI) (n = 0 to 4, 9)
		Transmit data empty event output (SCIn_TXI) (n = 0 to 4, 9)
		Address match event output (SCIn_AM) (n = 0 to 4, 9)

Table 28.1 SCI specifications (4 of 4)

Parameter	Specifications
	Active edge detection event output (SCIn_AED) (n = 0, 1)
	Transmit end event output (SCIn_TEI) (n = 0 to 4, 9)
TrustZone Filter	Security and Privilege attribution can be set for each channels

28.2 Register Descriptions

28.2.1 RSR : Receive Shift Register

RSR is a shift register that receives serial data input from the RXDn pin and converts it into parallel data. When one frame of data is received, the data is automatically transferred to the RDR register. The RSR register cannot be directly accessed by the CPU.

28.2.2 RDR/RDR_BY : Receive Data Register

Base address: SCIn_B = 0x4035_8000 + 0x0100 × n (n = 0 to 4, 9)
SCIn_B_NS = 0x5035_8000 + 0x0100 × n (n = 0 to 4, 9)

Offset address: 0x00

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	FER	PER	—	—	ORER	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	FFER	FPER	DR	MPB	RDAT[8:0]								
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
8:0	RDAT[8:0]	Serial receive data RDAT is a 9-bit register for storing received data. Received data is stored in [6:0] when 7-bit data is selected, in [7:0] when 8-bit data is selected, and in [8:0] when 9-bit data is selected. And 0 is stored in the unused bit. Use RDR_BY for byte access to RDR[7:0].	R
9	MPB	Multi-processor flag 0: Data transmission cycles 1: ID transmission cycles	R
10	DR	Receive data ready flag FRSR.DR can be read.	R
11	FPER	FIFO parity error flag Valid only in Asynchronous mode 0: There is no parity error in the data read from the receive-FIFO 1: There is parity error in the data read from the receive-FIFO	R
12	FFER	FIFO framing error flag Valid only in Asynchronous mode 0: There is no framing error in the data read from the receive-FIFO 1: There is framing error in the data read from the receive-FIFO	R
23:13	—	These bits are read as 0.	R
24	ORER	Overrun Error flag CSR.ORER can be read.	R
26:25	—	These bits are read as 0.	R
27	PER	Parity error flag CSR.PER can be read.	R
28	FER	Framing error flag CSR.FER can be read.	R
31:29	—	These bits are read as 0.	R

Note: S-TYPE-3, P-TYPE-3

In FIFO mode (CCR3.FM = 1), the RDR/RDR_BY is 16-stage FIFO buffer configuration.

When using FIFO mode, use RDR for 32-bit access.

RDAT[8:0] bits (Serial receive data)

After one frame of data is received, the received data is transferred from the RSR register to this register, thus allowing the RSR register to receive the next data.

The RSR and RDR registers have a double-buffered construction to enable continuous reception.

For Non-FIFO mode, read RDR only once when a receive data full interrupt (SCIn_RXI) request is issued. Without reading received data from RDR, if the next one frame is received, an overrun error occurs.

For FIFO mode, continuous reception is executed until 16 stages are stored. If data is read when there is no received data in the receive-FIFO(RDR), the value is undefined. When the receive-FIFO (RDR) are full of received data, subsequent serial receive data is lost.

The CPU cannot write to RDR.

0 is stored in the bit position which isn't received (RDR.bit8 or RDR.bit7) at the time of 7bit or 8bit communication of Asynchronous and Manchester mode.

MPB bit (Multi-processor flag)

In Asynchronous mode and Manchester mode, during multi-processor communication (CCR3.MP = 1), the value of the multi-processor bit corresponding to the received data (RDAT[8:0]) can be read.

FPER bit (FIFO parity error flag)

Indicates whether the data read from the receive-FIFO has a parity error.

0 is stored for non-FIFO mode.

FFER bit (FIFO framing error flag)

Indicates whether the data read from receive-FIFO has a framing error.

0 is stored for non-FIFO mode.

28.2.3 TDR/TDRLL/TDRLH : Transmit Data Register

Base address: SCIn_B = 0x4035_8000 + 0x0100 × n (n = 0 to 4, 9)
SCIn_B_NS = 0x5035_8000 + 0x0100 × n (n = 0 to 4, 9)

Offset address: 0x04(TDR/TDRLL)
0x05(TDRLH)

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	TSYNC	—	—	MPBT	TDAT[8:0]								
Value after reset:	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

Bit	Symbol	Function	R/W
8:0	TDAT[8:0]	Serial transmit data TDAT is a 9-bit register for setting transmit data. Transmit data is set in [6:0] when 7-bit data is selected, in [7:0] when 8-bit data is selected, and in [8:0] when 9-bit data is selected. When byte access, write TDR [15:8] and then write TDR [7:0]. Use TDRLL for byte access to TDR[7:0], TDRLH for byte access to TDR[15:8].	R/W
9	MPBT	Multi-processor transfer bit flag Value of the multi-processor bit in the transmission frame. This bit is use in Asynchronous and Manchester mode. When writing to this bit when not used, write the initial value. 0: Data transmission cycles 1: ID transmission cycles	R/W
11:10	—	These bits are read as 1. The write value should be 1.	R/W
12	TSYNC	Transmit SYNC data It is valid when MCR.SBSEL = 1 and MCR.SYNSEL = 1 in Manchester mode. When this bit is not used, write the initial value. 0: The Start Bit is transmitted as DATA SYNC. 1: The Start Bit is transmitted as COMMAND SYNC.	R/W
31:13	—	These bits are read as 1. The write value should be 1.	R/W

Note: S-TYPE-3, P-TYPE-3

In FIFO mode (CCR3.FM = 1), the TDR/TDRLL/TDRLH is 16-stage FIFO buffer configuration.

When using FIFO mode, use TDR for 32-bit access.

TDAT[8:0] bits (Serial transmit data)

The is a 9-bit register for storing transmit data.

When empty space is detected in the TSR register, the transmit data stored in the TDR/TDRLL/TDRLH registers is transferred to TSR, and transmitting is started.

The TSR and TDR/TDRLL/TDRLH registers have a double-buffered construction to realize continuous transmission. When the next data to be transmitted is stored in TDR/TDRLL/TDRLH after one frame of data has been transmitted, the transmitting operation is continued by transfer to the TSR register.

When the SCI detects that the transmit shift register (TSR) is empty, it transmits data written in the transmit-FIFO (TDR/TDRLL/TDRLH) into TSR and starts serial transmission. Continuous serial transmission is executed until there is no transmit data left in the transmit-FIFO (TDR/TDRLL/TDRLH).

For non-FIFO mode, when a transmit data empty interrupt (SCIn_TXI) request is issued and CCR0.TE is 1, write transmit data to the TDR only once.

For FIFO mode, when transmit-FIFO is full of transmit data 16 frames, no more data can be written. If writing of new data is attempted, the data is ignored.

The TDR/TDRLL/TDRLH register can always be read / written from the CPU. And when byte access, write TDR/TDRLL/TDRLH[15:8] and then write TDR/TDRLL/TDRLH[7:0].

MPBT bit (Multi-processor transfer bit flag)

Selects the multi processor bit of transmit frame.

TSYNC bit (Transmit SYNC data)

When Manchester mode and MCR.SBSEL = 1 and MCR.SYNSEL = 1, the type of SYNC selected according to the TSYNC bit becomes the Start Bit of the transmission frame.

28.2.4 TSR : Transmit Shift Register

TSR is a shift register that transmits serial data. To perform serial data transmission, the SCI first automatically transfers transmit data from TDR to TSR, then sends the data to the TXDn pin. The CPU cannot directly access the TSR.

28.2.5 CCR0 : Common Control Register 0

Base address: SCIn_B = 0x4035_8000 + 0x0100 × n (n = 0 to 4, 9)
SCIn_B_NS = 0x5035_8000 + 0x0100 × n (n = 0 to 4, 9)

Offset address: 0x08

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	SSE	—	—	TEIE	TIE	—	—	—	RIE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	IDSEL	DCME	MPIE	—	—	—	TE	—	—	—	RE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	RE	Receive Enable 0: Serial reception is disabled 1: Serial reception is enabled	R/W*1 *3
3:1	—	These bits are read as 0. The write value should be 0.	R/W
4	TE	Transmit Enable 0: Serial transmission is disabled 1: Serial transmission is enabled	R/W*1

Bit	Symbol	Function	R/W
7:5	—	These bits are read as 0. The write value should be 0.	R/W
8	MPIE	Multi-Processor Interrupt Enable Valid in Asynchronous mode and Manchester mode when CCR3.MP is 1. This bit should set 0 in Smart card interface mode. 0: Non-multi-processor reception 1: Multi-processor reception When the data with the multi-processor bit set to 0 is received, the data is not read, and setting the status flags to 1 is disabled. When the data with the multi-processor bit set to 1 is received, the MPIE bit is automatically cleared to 0, and non-multi-processor reception is resumed. If you want to continue receiving operation using the multiprocessor function, set this bit to 1 sufficiently earlier than receiving the STOP bit of the next received frame (consider the synchronization delay time).	R/W*2
9	DCME	Data Compare Match Enable Valid only in Asynchronous mode 0: Address match function is disabled 1: Address match function is enabled	R/W*2
10	IDSEL	ID Frame Select Valid only in Asynchronous mode with multi-processor 0: Compare data irrespective of the value of the MPB bit 1: Compare data only when the MPB bit is 1 (ID frame)	R/W
15:11	—	These bits are read as 0. The write value should be 0.	R/W
16	RIE	Receive Interrupt Enable 0: SCIn_RXI and SCIn_ERI interrupt requests are disabled 1: SCIn_RXI and SCIn_ERI interrupt requests are enabled	R/W
19:17	—	These bits are read as 0. The write value should be 0.	R/W
20	TIE	Transmit Interrupt Enable 0: SCIn_TXI interrupt request is disabled 1: SCIn_TXI interrupt request is enabled	R/W
21	TEIE	Transmit End Interrupt Enable This bit should set 0 in Smart card interface mode. 0: SCIn_TEI interrupt request is disabled 1: SCIn_TEI interrupt request is enabled	R/W
23:22	—	These bits are read as 0. The write value should be 0.	R/W
24	SSE	SSn Pin Function Enable Valid in Simple SPI mode. In slave mode (CCR3.CKE[1:0] = 1x), set 1 to this bit. 0: SSn pin function is disabled 1: SSn pin function is enabled	R/W
31:25	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

Note 1. In Clock synchronous mode (CCR3.MOD[2:0] = 010b), Simple SPI mode (CCR3.MOD[2:0] = 011b), and Simple IIC mode (CCR3.MOD[2:0] = 100b), 1 can be written only when TE = 0 and RE = 0. After setting TE or RE to 1, only 0 can be written in TE and RE. In other mode, writing is enabled under any condition.

Note 2. This bit is a bit that is cleared by hardware. Note that writing to a bit other than this bit with a bit manipulation instruction may cause this bit to be unintentionally set to 1 by a read-modify-write operation.

Note 3. In Clock synchronous mode or Simple SPI mode, and internal clock (master mode), receive-only setting is prohibited in the internal clock (master mode) (TE = 0 and RE = 1 setting prohibited).

RE bit (Receive Enable)

Enables or disables serial receive operation.

When the RE bit is set to 1, serial reception becomes possible after the synchronization delay time has elapsed in Asynchronous mode or the synchronous clock input in Clock synchronous mode or the neg-edge of RXDn in Manchester mode or start bit in Smart card interface mode.

Note that CCR3 should be set prior to setting the RE bit to 1 in order to designate the reception format.

Except Smart card interface mode, even if reception is halted by setting the RE bit to 0, the CSR. RDRF, FER, PER, ORER, MSR.MER, SBER, SYER, PFER, FRSR. DR flags are not affected, and the previous values is retained. In Smart card interface mode, even if reception is halted by setting the RE bit to 0, the CSR.FER, PER, ORER flags are not affected and

the previous value is retained. Also, to stop the reception operation, synchronization delay time is required from when the RE bit is set to 0 until the reception operation is stopped.

TE bit (Transmit Enable)

Enables or disables serial transmission.

When the TE bit is set to 1, serial transmission becomes possible after the synchronization delay time has elapsed. After the synchronization delay time, transmission is started by writing transmit data to TDR. Note that CCR3 should be set prior to setting the TE bit to 1 in order to designate the transmission format. In addition, the synchronization delay time is required until the transmission control circuit is stopped after the TE bit is set to 0.

MPIE bit (Multi-Processor Interrupt Enable)

When the MPIE bit is set to 1 and data with the multi-processor bit set to 0 is received, the data is not read and setting the status flags (CSR.RDRF, ORER, FER, FRSR, DR, MSR.MER, SYER, PFER, SBER) are disabled.

When data with the multi-processor bit set to 1 is received, the MPIE is automatically cleared to 0, and normal reception is resumed. For details, see section 28.4. Multi-Processor Communication Function. If you want to continue receiving operation using the multi-processor function, set this bit to 1 sufficiently earlier than receiving the STOP bit of the next received frame.

When the receive data includes the MPB bit set to 0, the receive data is not transferred from the RSR to the RDR, a receive error is not detected, and setting the flags ORER, FER, MER, SYER, PFER, and SBER to 1 is disabled.

When the receive data includes the MPB bit set to 1, the MPIE bit is automatically cleared to 0, the SCIn_RXI and SCIn_ERI interrupt requests are enabled (if CCR0.RIE is set to 1), and setting the flags ORER, FER, MER, SYER, PFER, and SBER to 1 is enabled.

MPIE should be set to 0 if multi-processor communications function is not to be used.

DCME bit (Data Compare Match Enable)

The DCME bit selects whether the address match function (data compare match function) is enabled or not.

When DCME is 1, if SCI detects the match to the comparison data (CCR4.CMPD) with receive data, DCME is cleared automatically, and after that, SCI operation mode is in receive mode without data compare match function.

See section 28.3.6. Address Match (Receive Data Match Detection) Function.

The write value should be 0 other than Asynchronous mode.

IDSEL bit (ID Frame Select)

The IDSEL bit selects whether to compare data irrespective of the value of MPB bit or to compare data only when the MPB bit = 1 (ID frame) when the address match function is valid. Set at the same time as DCME.

RIE bit (Receive Interrupt Enable)

Enables or disables SCIn_RXI and SCIn_ERI interrupt requests.

SCIn_RXI and SCIn_ERI interrupt request is disabled by setting the RIE bit to 0.

An SCIn_ERI interrupt request can be canceled by reading 1 from the CSR.ORER, FER, or PER and then setting the flag to 0 or setting the RIE bit to 0.

In Manchester mode, the MER, SYER, PFER and SBER flags are also the cause of SCIn_ERI interrupt request, so the same processing is necessary. For details of these flags, see section 28.2.12. MCR : Manchester Control Register and section 28.2.21. MSR : Manchester Status Register.

TIE bit (Transmit Interrupt Enable)

Enables or disables SCIn_TXI interrupt request.

An SCIn_TXI interrupt request is disabled by setting the TIE bit to 0. At the beginning of transmission, set 1 to CCR0.TE and CCR0.TIE simultaneously. The SCIn_TXI interrupt request is then generated.

TEIE bit (Transmit End Interrupt Enable)

Enables or disables a SCIn_TEI interrupt request. A SCIn_TEI interrupt request is disabled by setting the TEIE bit to 0.

In simple IIC mode, the SCIn_TEI is allocated to the interrupt on completion of issuing a start, restart, or stop condition (STIn). In this case, the TEIE bit can be used to enable or disable the STIn.

SSE bit (SSn Pin Function Enable)

Set the SSE bit to 1 if the SSn pin is to be used in control of transmission and reception (in simple SPI mode).

Set the SSE bit to 0 in any other mode. Do not set both the SSE and CTSE bits to enabled (even if this setting is made, operation is the same as that when these bits are set to 0).

In the slave mode (CCR3.CKE[1:0] = 10 or 11), SSE should be set 1.

In the master mode (CCR3.CKE[1:0] = 00 or 01) and single-master, the SSn pin on the master side is not required to control reception and transmission, so SSE should be set 0.

28.2.6 CCR1 : Common Control Register 1

Base address: SCIn_B = 0x4035_8000 + 0x0100 × n (n = 0 to 4, 9)
SCIn_B_NS = 0x5035_8000 + 0x0100 × n (n = 0 to 4, 9)

Offset address: 0x0C

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	NFM	NFEN	—	NFCS[2:0]			—	—	—	SHARPS	—	—	—	SPLP
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	RINV	TINV	—	—	PM	PE	—	—	SPB2IO	SPB2DT	—	—	CTSPEN	CTSE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0

Bit	Symbol	Function	R/W
0	CTSE	CTS Enable 0: CTS function is disabled (RTS output function is enabled) 1: CTS function is enabled	R/W
1	CTSPEN	CTS External Pin Enable 0: Alternate setting to use CTS and RTS functions as either 1 pin 1: Dedicated setting for separately using CTS and RTS functions with 2 pins	R/W
3:2	—	These bits are read as 0. The write value should be 0.	R/W
4	SPB2DT	Serial Port Break Data Select The output level of TXDn pin is selected when CCR0.TE = 0 and SPB2IO = 1.*1 0: When TINV is 0, low level is output in TXDn pin. When TINV is 1, high level is output in TXDn pin. 1: When TINV is 0, high level is output in TXDn pin. When TINV is 1, low level is output in TXDn pin.	R/W
5	SPB2IO	Serial Port Break I/O This bit selects whether the value of SPB2DT is output to TXDn pin when CCR0.TE = 0.*1 0: The value of SPB2DT bit is not output in TXDn pin 1: The value of SPB2DT bit is output in TXDn pin	R/W
7:6	—	These bits are read as 0. The write value should be 0.	R/W
8	PE	Parity Enable Valid only in Asynchronous mode and Manchester mode. In Smart Card Interface mode, set 1 to this bit. 0: When transmitting: Do not add parity bit When receiving: Do not check parity bit 1: When transmitting: Add parity bit When receiving: Check parity bit	R/W
9	PM	Parity Mode Valid only when the PE bit is 1 0: Selects even parity 1: Selects odd parity	R/W

Bit	Symbol	Function	R/W
11:10	—	These bits are read as 0. The write value should be 0.	R/W
12	TINV	TXD Invert 0: Transmit data is not inverted and output to TXDn*2 1: Transmit data is inverted and output to TXDn	R/W
13	RINV	RXD Invert 0: Received data from RXDn is not inverted and input*2 1: Received data from RXDn is inverted and input	R/W
15:14	—	These bits are read as 0. The write value should be 0.	R/W
16	SPLP	Loopback Control This bit can be used for internal clock operation in Asynchronous mode, internal mode operation in Manchester mode, internal clock operation in Clock synchronous mode. 0: Normal mode 1: Loopback mode	R/W
19:17	—	These bits are read as 0. The write value should be 0.	R/W
20	SHARPS	Half-Duplex Communication Select In Simple IIC mode, Smart Card Interface mode, or Simple SPI mode, this bit should be set to 0. 0: TXDn pin, RXDn pin independent 1: TXDn/RXDn pin combination use (half-duplex communication using TXDn pin)	R/W
23:21	—	These bits are read as 0. The write value should be 0.	R/W
26:24	NFCS[2:0]	Noise Filter Clock Select Valid in Asynchronous mode and Manchester mode, Simple LIN mode, and Simple IIC mode. In Simple IIC mode, 000 setting is prohibited. The on-chip baud rate generator source clock means the clock selected by CCR2.CKS [1:0]. Select for the clock source of the noise filter. 0 0 0: The base clock signal divided by 1 0 0 1: The on-chip baud rate generator source clock divided by 1 0 1 0: The on-chip baud rate generator source clock divided by 2 0 1 1: The on-chip baud rate generator source clock divided by 4 1 0 0: The on-chip baud rate generator source clock divided by 8 others: Setting prohibited	R/W
27	—	This bit is read as 0. The write value should be 0.	R/W
28	NFEN	Digital Noise Filter Function Enable Valid in Asynchronous mode, Manchester mode, Simple LIN mode, and Simple IIC mode 0: In Asynchronous, Manchester, Simple LIN modes: Disable noise cancellation function for RXDn input signal In Simple IIC mode: Disable noise cancellation function for SCLn and SDAn input signals 1: In Asynchronous, Manchester, Simple LIN modes: Enable noise cancellation function for RXDn input signal In Simple IIC mode: Enable noise cancellation function for SCLn and SDAn input signals	R/W
29	NFM	Noise Filter Mode Valid in asynchronous mode and ABCSE2 = 1 0: 3-point matching mode 1: Majority vote mode	R/W
31:30	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3
Note 1. Use this bit in Asynchronous mode and Manchester mode only. Operation in other mode is not guaranteed.
Note 2. RINV/TINV should be set to 0 in Smart card interface mode and Simple IIC mode.

CTSE bit (CTS Enable)

Set the CTSE bit to 1 if the SSn pin is to be used for inputting of the CTSn control signal to control of transmission and reception. The RTSn signal is output when this bit is set to 0. Set this bit to 0 in smart card interface mode, simple SPI mode, Simple LIN mode, and simple IIC mode. Do not set both the CTSE and SSE bits to enabled (even if this setting is made, operation is the same as that when these bits are set to 0).

CTSPEN bit (CTS External Pin Enable)

When CTSE is 1, select the pins usage method when using the CTS and RTS functions. Set this bit to 1 when assigning the CTS/RTS function to 2 pins and using them at the same time. Set it to 0 except in Asynchronous and Manchester modes.

Table 28.4 shows the relationship between the CTSE bit and CTSPEN bit settings and the functions of the CTSn_RTSn pin and CTSn pin.

Table 28.4 CTSE bit and CTSPEN bit settings and pin functions

CTSE bit	CTSPEN bit	CTSn_RTSn pin	CTSn pin
0	0	RTSn signal output	Not use
1	0	CTSn signal input	Not use
1	1	RTSn signal output	CTSn signal input
0	1	prohibition	prohibition

SPB2DT bit (Serial Port Break Data Select), SPB2IO bit (Serial Port Break I/O)

The TXDn pin status determined by combination of CCR0.TE bit, CCR1.SPB2IO bit, and CCR1.SPB2DT bit is indicated in Table 28.5.

Table 28.5 TXDn pin status

Value of CCR0.TE	Value of CCR1.SPB2IO	Value of CCR1.SPB2DT	TXDn pin status (when TINV is 0)
0	0	—	Hi-Z (initial value)
0	1	0	Low level output
0	1	1	High level output
1	—	—	Serial transmission data is output

Note: —: Don't care

PE bit (Parity Enable)

When the PE bit to 1, the parity bit is added to transmit data before transmission, and the parity bit is checked in reception.

In the multi-processor format, the parity bit is not added or checked regardless of the PE bit setting.

PM bit (Parity Mode)

The PM bit selects the parity mode for transmission and reception (even or odd). In Multi-processor mode, the PM bit is invalid.

For details on the usage of this bit in Smart card interface mode, see section 28.7.2. Data Format (Except in Block Transfer Mode).

TINV bit (TXD Invert), RINV bit (RXD Invert)

The data of RDR is controlled by RINV and CCR3.SINV. And the data from TXDn pin is controlled by TINV and CCR3.SINV. The control by RINV/TINV are done to communication pins (RXDn / TXDn), so they can control not only data-bits but also other bits (start bit, stop bit, parity bit). For details, see Figure 28.3.

During half-duplex communication and slave operation in Simple SPI mode, use the TXDn pin for reception, so set the inversion control of the received data with the TINV bit.

Note: Description and a timing chart of the SCI operation are provided when TINV = 0 and RINV = 0 (when the value of TINV and the value of RINV are not specified).

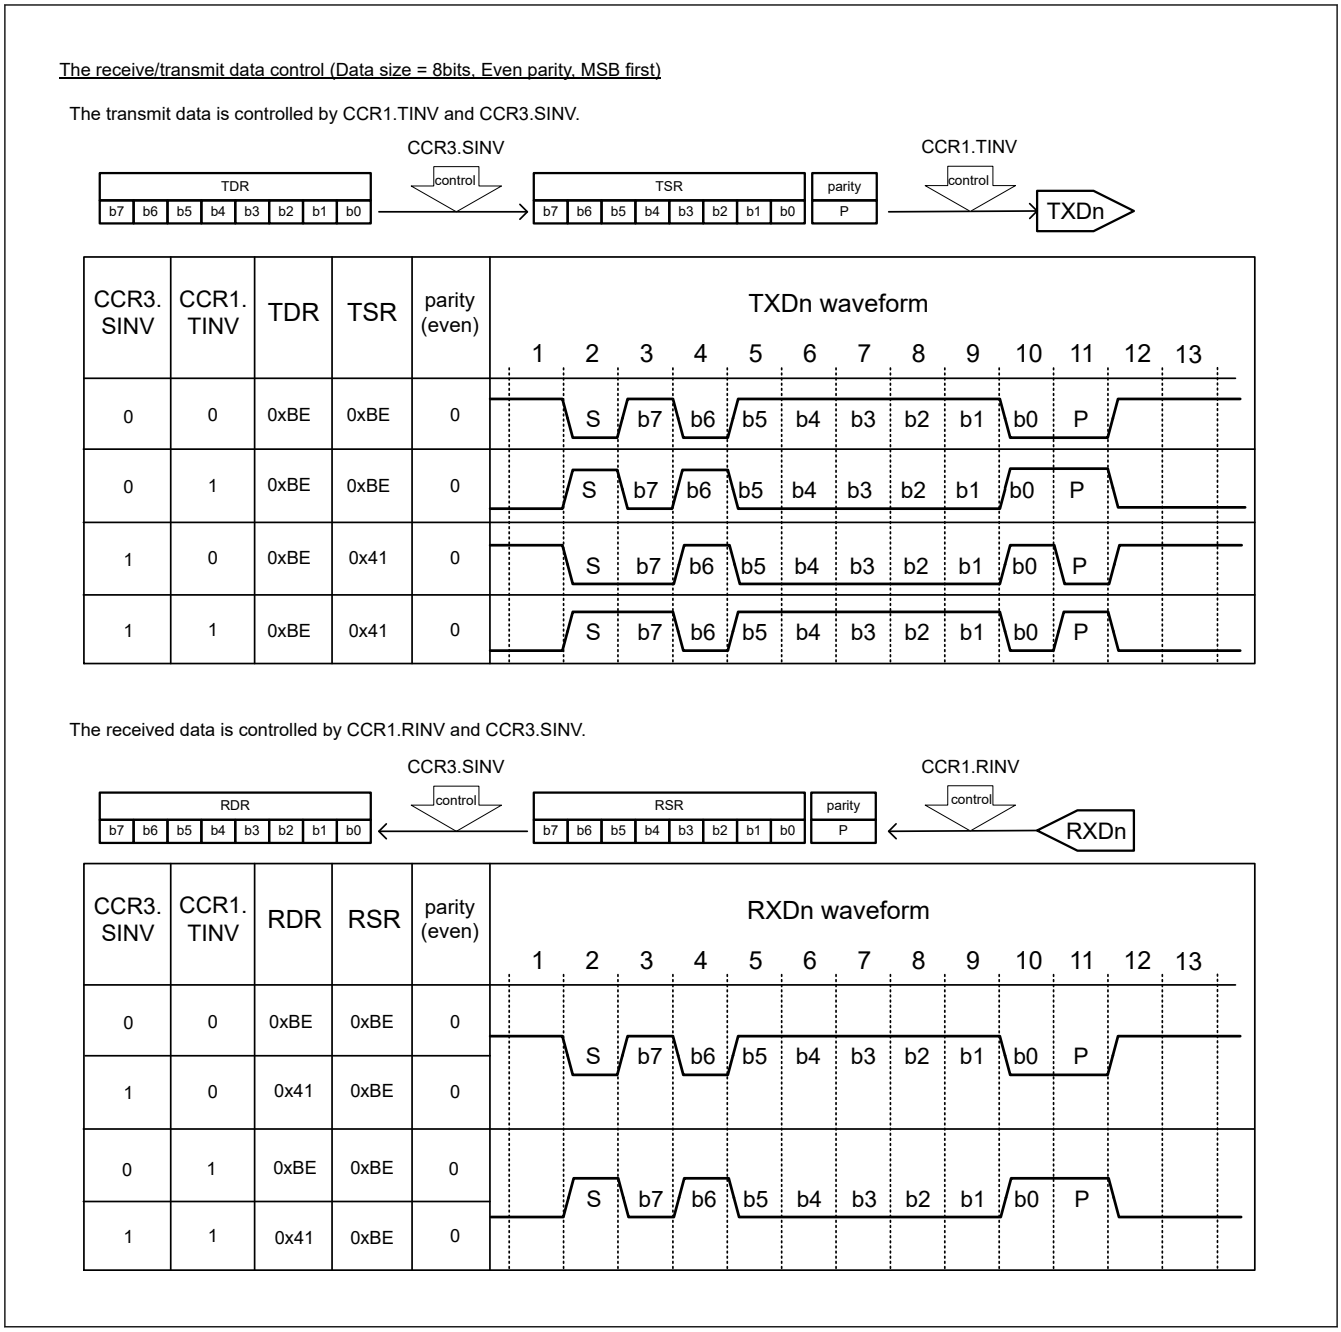

Figure 28.3 Example of receive or transmit data control

SPLP bit (Loopback Control)

When the SPLP bit is 1, SCI blocks the input path from RXDn and connects the output path to TXDn to the reception data register.

Transmit data can be inverted and received by combining it with TINV bit.

Set this bit to 0 for slave operation in Clock synchronous mode, when using an external clock in Asynchronous mode, and when in Simple LIN mode.

SHARPS bit (Half-Duplex Communication Select)

Setting the SHARPS bit to 1 enables half-duplex communication using the TXDn pin. However, the SHARPS bit cannot be used in Simple SPI mode, Simple IIC mode and Smart card interface mode.

If the SHARPS bit is set to 1 and CCR0.TE = 1, CCR0.RE = 0, the TXDn pin becomes the communication output. If this bit is set to 1 and CCR0.TE = 0, CCR0.RE = 1, the TXDn pin becomes the communication input. For details, see section 28.17. Half-Duplex communication Function.

NFCS[2:0] bits (Noise Filter Clock Select)

The NFCS[2:0] bits select the sampling clock for the digital noise filter.

To use the noise filter in Asynchronous mode, Manchester mode, and Simple LIN mode set the NFCS[2:0] bits from 000b to 100b. In Simple IIC mode, set the bits to a value in the range from 001b to 100b. In particular, if the ABCSE or ABCSE2 bit is set to 1 in asynchronous mode, set it to 000b or 001b.

NFEN bit (Digital Noise Filter Function Enable)

The NFEN bit enables or disables the digital noise filter function. When the function is enabled, noise cancellation is applied to the RXDn input signal in Asynchronous mode, Manchester mode, Simple LIN mode, and noise cancellation is applied to the SDAn and SCLn input signals in Simple IIC mode. In any mode other than above, set the NFEN bit to 0 to disable the digital noise filter function. When the function is disabled, input signals are transferred as is, as internal signals.

NFM bit (Noise Filter Mode)

The NFM bit selects the operation mode of the digital noise filter function. For details, see section 28.14. Noise Cancellation Function.

28.2.7 CCR2 : Common Control Register 2

Base address: SCIn_B = 0x4035_8000 + 0x0100 × n (n = 0 to 4, 9)
SCIn_B_NS = 0x5035_8000 + 0x0100 × n (n = 0 to 4, 9)

Offset address: 0x10

23:22	—	These bits are read as 0. The write value should be 0.	R/W
31:24	MDDR[7:0]	Modulation Duty Setting MDDR corrects the bit rate adjusted by the BRR[7:0] bits.	R/W

Note: S-TYPE-3, P-TYPE-3
Note 1. S is the value of S in BRR[7:0] bits explanation.
Note 2. n is the decimal notation of the value of n in BRR[7:0] bits explanation.

BCP[2:0] bits (Base Clock Pulse)

The BCP[2:0] bits select the number of base clock cycles in a 1-bit data transfer time in smart card interface mode.

For details, see section 28.7.4. Receive Data Sampling Timing and Reception Margin.

BGDM bit (Baud Rate Generator Double-Speed Mode Select)

The BGDM bit is valid when the on-chip baud rate generator is selected as the clock source (CCR3.CKE[1] = 0) in Asynchronous mode, Manchester mode, Clock synchronous mode, Simple SPI mode. When external clock is selected (CCR3.CKE[1] = 1), set it to 0. For the clock output from the baud rate generator, either single or doubled frequency can be selected. The base clock is generated by the clock output from the baud rate generator. When the BGDM bit is set to 1, the base clock cycle is halved, and the bit rate is doubled.

Set this bit to 0 in modes other than Asynchronous mode, Manchester mode, Clock synchronous mode, or Simple SPI mode.

ABCS bit (Asynchronous Mode Base Clock Select)

Selects the clock cycles for 1-bit period.

Set the ABCS bit to 0 in modes other than Asynchronous mode, Manchester mode, or Simple LIN mode.

ABCSE bit (Asynchronous Mode Extended Base Clock Select)

The pulse number for a base clock at 1-bit period is 6 and the clock of a double frequency is output from baud rate generator. Only when the bit rate is set to 6 dividing frequency of the bus clock can this bit be used to set CCR2.CKS [1:0] = 00b and BRR[7:0] = 0x00.

Set it to 0 in modes other than Asynchronous mode. Even in Asynchronous mode, set it to 0 when using external clock.

ABCSE2 bit (Asynchronous Mode Extended Base Clock Select 2)

The pulse number for a base clock at 1-bit period is 4 and the clock of a double frequency is output from baud rate generator. Only when the bit rate is set to 4 dividing frequency of the bus clock, please use this bit and set CCR2.CKS [1:0] = 00 and BRR[7:0] = 0.

Set it to 0 in modes other than asynchronous mode. Even in asynchronous mode, set it to 0 when using external clock.

Table 28.6 Base clock cycle number per 1-bit

ABCSE2	ABCSE	ABCS	BGDM	The base clock cycles /1bit	The frequency of the baud rate generator
0	0	0	0	16	×1
0	0	0	1	16	×2
0	0	1	0	8	×1
0	0	1	1	8	×2
0	1	— (don't care)	— (don't care)	6	×2
1	0	— (don't care)	— (don't care)	4	×2

BRR[7:0] bit (Bit Rate Setting)

BRR is an 8-bit register that adjusts the bit rate.

SCI has independent baud rate generator control, different bit rates can be set for each. Table 28.7 shows the relation-ship between the setting (N) in the BRR and the bit rate (B) for Asynchronous mode, multiprocessor transfer, Manchester mode, clock synchronous mode, smart card interface mode, simple SPI mode, and simple IIC mode.

Table 28.7 Relationship between N Setting in BRR and Bit Rate B

Mode	CCR2 settings				BRR[7:0] setting	Error*4
	BGDM bit	ABCS bit	ABCSE bit	ABCSE 2 bit		
Asynchronous, multi-processor, Manchester*2, Simple-LIN*3	0	0	0	0	$N = \frac{TCLK \times 10^6}{64 \times 2^{2n-1} \times B} - 1$	$Error\ (\%) = \left\{\frac{TCLK \times 10^6}{B \times 64 \times 2^{2n-1} \times (N+1)} - 1\right\} \times 100$
	1	0	0	0	$N = \frac{TCLK \times 10^6}{32 \times 2^{2n-1} \times B} - 1$	$Error\ (\%) = \left\{\frac{TCLK \times 10^6}{B \times 32 \times 2^{2n-1} \times (N+1)} - 1\right\} \times 100$
	0	1	0	0		
	1	1	0	0	$N = \frac{TCLK \times 10^6}{16 \times 2^{2n-1} \times B} - 1$	$Error\ (\%) = \left\{\frac{TCLK \times 10^6}{B \times 16 \times 2^{2n-1} \times (N+1)} - 1\right\} \times 100$
	Don't care	Don't care	1	0	$N = \frac{TCLK \times 10^6}{12 \times 2^{2n-1} \times B} - 1$	$Error\ (\%) = \left\{\frac{TCLK \times 10^6}{B \times 12 \times 2^{2n-1} \times (N+1)} - 1\right\} \times 100$
	Don't care	Don't care	0	1	$N = \frac{TCLK \times 10^6}{8 \times 2^{2n-1} \times B} - 1$	$Error\ (\%) = \left\{\frac{TCLK \times 10^6}{B \times 8 \times 2^{2n-1} \times (N+1)} - 1\right\} \times 100$
Clock synchronous, simple SPI	0	0 (Initial value)	0 (Initial value)	0 (Initial value)	$N = \frac{TCLK \times 10^6}{8 \times 2^{2n-1} \times B} - 1$	—
	1	0 (Initial value)	0 (Initial value)	0 (Initial value)	$N = \frac{TCLK \times 10^6}{4 \times 2^{2n-1} \times B} - 1$	—
Smart card interface					$N = \frac{TCLK \times 10^6}{S \times 2^{2n+1} \times B} - 1$	$Error\ (\%) = \left\{\frac{TCLK \times 10^6}{B \times S \times 2^{2n+1} \times (N+1)} - 1\right\} \times 100$
Simple IIC*1					$N = \frac{TCLK \times 10^6}{64 \times 2^{2n-1} \times B} - 1$	—

Note: B: Bit rate (bps)
N: BRR setting for on-chip baud rate generator (0 ≤ N ≤ 255)
TCLK: Operating frequency (MHz)
n and S: Determined by the settings of the CCR2 registers as listed in the Table 28.9 and Table 28.10. Please be careful about $2^{(2n+1)}$ is used in the expression for Smart card interface, $2^{(2n-1)}$ is used in other mode.
Note 1. Adjust the bit rate so that the widths at high and low level of the SCL output in simple IIC mode satisfy the IIC standard.
Note 2. In Manchester mode, only ABCSE = 0 and ABCSE2 = 0 can be selected.
Note 3. In Simple-LIN mode, BGDM = 0, ABCSE = 0 and ABCSE2 = 0 can be selected.
Note 4. Error means that if the N value calculated by the above formula is not an integer for the baud rate value B to be set, the BRR is set to an approximate integer value in which case it represents the error between the baud rate value and B.

Table 28.8 Calculating widths at high and low Level for SCL

Mode	SCLn	Formula (result in seconds)
IIC	Width at high level (minimum value)	$(N+1) \times 4 \times 2^{2n-1} \times 7 \times \frac{1}{TCLK \times 10^6}$
	Width at low level (minimum value)	$(N+1) \times 4 \times 2^{2n-1} \times 8 \times \frac{1}{TCLK \times 10^6}$

Table 28.9 Clock source settings

CCR2 setting		
CKS[1:0] bit	Clock source	n
00	TCLK clock	0
01	TCLK/4 clock	1
10	TCLK/16 clock	2
11	TCLK/64 clock	3

Table 28.10 Base clock settings in Smart card interface mode

CCR2 setting		
BCP[2:0] setting	Base clock cycles for 1-bit period	S
0 0 0	93 clock cycles	93
0 0 1	128 clock cycles	128
0 1 0	186 clock cycles	186
0 1 1	512 clock cycles	512
1 0 0	32 clock cycles	32
1 0 1	64 clock cycles	64
1 1 0	372 clock cycles	372
1 1 1	256 clock cycles	256

Table 28.11 and Table 28.12 list examples of N settings in BRR in Asynchronous mode and Manchester mode. Table 28.13 lists the maximum bit rate settable for each operating frequency. Examples of BRR (N) settings in Clock synchronous mode and Simple SPI mode are listed in Table 28.16. Examples of BRR (N) settings in Smart card interface mode are listed in Table 28.18. Examples of BRR (N) settings in Simple IIC mode are listed in Table 28.20. In Smart card interface mode, the number of base clock cycles S in a 1-bit data transfer time can be selected. For details, see section 28.7.4. Receive Data Sampling Timing and Reception Margin. Table 28.14 and Table 28.17 list the maximum bit rates with external clock input. Table 28.15 lists the maximum bit rates with GPT clock input.

When either the Asynchronous mode base clock select bit (ABCS) or the baud rate generator double-speed mode select bit (BGDM) is set to 1 in Asynchronous mode and Manchester mode, the bit rate becomes twice that listed in Table 28.11 and Table 28.12. When both of those registers are set to 1, the bit rate becomes four times the listed value.

BRME bit (Bit Rate Modulation Enable)

Enables and disables the bit rate modulation function. The bit rate generated by on-chip baud rate generator is evenly corrected when this function is enabled.

Set to 0 in Clock-synchronous mode, Simple SPI mode, Smart Card Interface mode, Manchester mode and Simple LIN mode.

Even in asynchronous mode, set this bit to 0 when ABCSE2 = 1.

CKS[1:0] bits (Clock Select)

The CKS[1:0] bits select the clock source for the on-chip baud rate generator.

For the relationship between the settings of the CKS[1:0] bits and the baud rate, see BRR[7:0] bits explanation.

MDDR[7:0] bits (Modulation Duty Setting)

When the BRME bit is set to 1, the bit rate generated by the on-chip baud rate generator is evenly corrected according to the settings of MDDR (M/256). The relationship between the MDDR setting (M) and the bit rate (B) is given in Table 28.22.

The initial value of MDDR is FFh. Bit 7 in the CCR2 is fixed to 1.

Table 28.22 Relationship between MDDR Setting (M) and Bit Rate (B) When Bit Rate Modulation Function is Used

Mode*1	CCR2 settings			BRR setting	Error
	BGDM bit	ABCS bit	ABCSE bit		
Asynchronous, Multiprocessor transfer	0	0	0	$N = \frac{TCLK \times 10^6}{64 \times 2^{2n-1} \times (256/M) \times B} - 1$	$Error\ (\%) = \left\{\frac{TCLK \times 10^6}{B \times 64 \times 2^{2n-1} \times (256/M) \times (N+1)} - 1\right\} \times 100$
	1	0	0	$N = \frac{TCLK \times 10^6}{32 \times 2^{2n-1} \times (256/M) \times B} - 1$	$Error\ (\%) = \left\{\frac{TCLK \times 10^6}{B \times 32 \times 2^{2n-1} \times (256/M) \times (N+1)} - 1\right\} \times 100$
	0	1	0		
	1	1	0	$N = \frac{TCLK \times 10^6}{16 \times 2^{2n-1} \times (256/M) \times B} - 1$	$Error\ (\%) = \left\{\frac{TCLK \times 10^6}{B \times 16 \times 2^{2n-1} \times (256/M) \times (N+1)} - 1\right\} \times 100$
	x (Arbitrarily)	x (Arbitrarily)	1*2	$N = \frac{TCLK \times 10^6}{12 \times 2^{2n-1} \times (256/M) \times B} - 1$	$Error\ (\%) = \left\{\frac{TCLK \times 10^6}{B \times 12 \times 2^{2n-1} \times (256/M) \times (N+1)} - 1\right\} \times 100$
Simple IIC*2	$N = \frac{TCLK \times 10^6}{64 \times 2^{2n-1} \times (256/M) \times B} - 1$				

Note: B: Bit rate (bps)
M: MDDR setting (128 ≤ M ≤ 255)
N: BRR setting for bound rate generator (0 ≤ N ≤ 255)
TCLK: Operating frequency (MHz)
n: Determined by the settings of the CKS[1:0] as listed in Table 28.9.

Note 1. Do not use this function in Clock-synchronous mode, Simple SPI mode, Smart card Interface mode, Manchester mode and Simple LIN mode.

Note 2. Adjust the bit rate so that the widths at high and low level of the SCL output in simple IIC mode satisfy the I2C standard.

Table 28.23 and Table 28.24 list examples of N settings in BRR and M settings in MDDR in Asynchronous mode.

Table 28.23 Examples of BRR and MDDR Settings for Various Bit Rates (Asynchronous Mode) (1) (1 of 3)

Note: This is an example when the CCR2.ABCS = 0 and CCR2.ABCSE = 0.
Note 1. It means that the bit rate modulation function is disable. (CCR2.BRME = 0, M = 256)

28.2.8 CCR3 : Common Control Register 3

Base address: SCIn_B = 0x4035_8000 + 0x0100 × n (n = 0 to 4, 9)
SCIn_B_NS = 0x5035_8000 + 0x0100 × n (n = 0 to 4, 9)

Offset address: 0x14

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	BLK	GM	—	ACS0	CKE[1:0]		—	—	DEN	FM	MP	MOD[2:0]		
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	RXDESEL	STP	SINV	LSBF	—	—	CHR[1:0]		BPEN	—	—	—	—	—	CPOL	CPHA
Value after reset:	0	0	0	1	0	0	1	0	0	0	0	0	0	0	1	1

Bit	Symbol	Function	R/W
0	CPHA	Clock Phase Select Valid in Clock synchronous mode and Simple SPI mode. Set this bit only when CCR0.TE = 0 and RE = 0. 0: Data is sampled at an odd edge and changes at an even edge (clock is delayed) 1: Data changes at an odd edge and is sampled at an even edge (clock is not delayed)	R/W
1	CPOL	Clock Polarity Select Valid in Clock synchronous mode and Simple SPI mode. Set this bit only when CCR0.TE = 0 and RE = 0. 0: SCKn in idle state is 0 1: SCKn in idle state is 1	R/W
6:2	—	These bits are read as 0. The write value should be 0.	R/W
7	BPEN	Synchronizer Bypass Enable This bit controls whether to bypass the synchronizer circuit between the bus clock and operation clock. 0: Synchronizer circuit is not bypassed 1: Synchronizer circuit is bypassed	R/W
9:8	CHR[1:0]	Character Length Valid in Asynchronous mode and Manchester mode[*1] Select the data length for transmission and reception. 0 0: Transmit/receive in 9-bit data length 0 1: Transmit/receive in 9-bit data length 1 0: Transmit/receive in 8-bit data length (initial value) 1 1: Transmit/receive in 7-bit data length[*2]	R/W
11:10	—	These bits are read as 0. The write value should be 0.	R/W

Bit	Symbol	Function	R/W
12	LSBF	LSB First select Set this bit to 0 in Simple IIC mode. Set this bit to 1 in Simple LIN mode. 0: MSB-first 1: LSB-first	R/W
13	SINV	Transmitted/Received Data Invert Set this bit to 0 in Simple IIC mode. The level of communication pins (RXDn/TXDn) are controlled by combination of this bit and CCR1.TINV/RINV. For details, see Figure 28.3. 0: TDR contents are transmitted to TSR as is. RSR contents are stored to RDR as is. 1: TDR contents are inverted before being transmitted to TSR. RSR contents are inverted and stored to RDR.	R/W
14	STP	Stop Bit Length Valid in Asynchronous mode, Manchester mode, and Simple LIN mode 0: 1 stop bit/break delimiter length is 1-bit 1: 2 stop bits/break delimiter length is 2-bit	R/W
15	RXDESEL	Asynchronous Start Bit Edge Detection Select Valid only in Asynchronous mode Set this bit to 1 in Simple LIN mode. 0: The low level on the RXDn pin is detected as the start bit 1: A falling edge on the RXDn pin is detected as the start bit	R/W
18:16	MOD[2:0]	Communication Mode Select Select the SCI communication mode. 0 0 0: Asynchronous mode (multi-processor mode) 0 0 1: Smart card interface mode 0 1 0: Clock synchronous mode 0 1 1: Simple SPI mode 1 0 0: Simple IIC mode 1 0 1: Manchester mode 1 1 0: Simple LIN mode 1 1 1: Setting prohibited	R/W
19	MP	Multi-Processor Mode Valid in Asynchronous mode and Manchester mode 0: Multi-processor communications function is disabled 1: Multi-processor communications function is enabled	R/W
20	FM	FIFO Mode Select Valid in Asynchronous mode (including Multi-processor mode), Clock synchronous mode, and Simple SPI mode 0: TDR register and RDR register are non-FIFO buffer configuration 1: TDR register and RDR register are FIFO buffer configuration	R/W
21	DEN	Driver Enable 0: RS-485 driver control function disabled 1: RS-485 driver control function enabled	R/W
23:22	—	These bits are read as 0. The write value should be 0.	R/W
25:24	CKE[1:0]	Clock Enable See Table 28.26 for details.	R/W
26	ACS0	Asynchronous Mode Clock Source Select Valid only in Asynchronous mode. These bits for SCI channels other than SCIn (n = 1, 2) are reserved. 0: External clock input 1: Logical AND of compare matches output from the internal GPT	R/W
27	—	This bit is read as 0. The write value should be 0.	R/W
28	GM	GSM Mode Valid only in Smart card interface mode. 0: Non-GSM mode operation 1: GSM mode operation	R/W

Bit	Symbol	Function	R/W
29	BLK	Block Transfer Mode Valid only in Smart card interface mode. 0: Non-block transfer mode operation 1: Block transfer mode operation	R/W
31:30	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3
Note 1. In other than Asynchronous mode and Manchester mode, this bit setting is invalid and a fixed data length of 8 bits is used. In the Simple LIN mode, only the data length of 8 bits can be used, so set it to the initial value.
Note 2. LSB first is fixed and the MSB (bit 7) in TDR is not transmitted in transmission.
Note 3. GPT clock is selectable for SCI1 and SCI2.

CPHA bit (Clock Phase Select)

The CPHA bit selects the phase of the clock signal output through the SCKn pin. For details, see Figure 28.99.

Set the bit to 1 in other than Simple SPI mode and Clock synchronous mode.

CPOL bit (Clock Polarity Select)

The CPOL bit selects the polarity of the clock signal output through the SCKn pin. For details, see Figure 28.99.

Set the bit to 1 in other than Simple SPI mode and Clock synchronous mode.

BPEN bit (Synchronizer Bypass Enable)

The BPEN bit selects whether to enable or disable the synchronization bypass function. Set this bit to 1 when the bus clock (PCLK) is also used as operation clock (TCLK). For details, see Figure 28.2 and section 28.18. Synchronizer Bypass Function.

Note: For details of this bit setting, see section 28.19.17. Notes on CCR3.BPEN bit setting.

CHR[1:0] bits (Character Length)

Selects the data length for transmission and reception.

Except for Asynchronous mode and Manchester mode, a fixed data length of 8 bits is used.

LSBF bit (LSB First select)

Select whether to transmit/receive data in MSB-first or LSB-first.

SINV bit (Transmitted/Received Data Invert)

SINV can invert the transmit data bit from TDR to TSR, and can invert the received data from RSR to RDR. The SINV bit does not affect the logic level of the parity bit. To invert the parity bit, invert the CCR1.PM.

STP bit (Stop Bit Length)

Selects the stop bit length in transmission.

In reception, only the first stop bit is checked regardless of the STP bit setting. If the second stop bit is 0, it is treated as the start bit of the next transmit frame.

In addition, it is used as the break delimiter length setting when sending start frame in Simple LIN mode.

RXDESEL bit (Asynchronous Start Bit Edge Detection Select)

Selects the detection method of the start bit for reception in Asynchronous mode. When a break occurs, data receiving operation depends on the settings of the RXDESEL bit. Set this bit to 1 when reception should be stopped while a break occurs or when reception should be started without retaining the RXDn pin input at high level for the period of one data frame or longer after completion of the break.

Set this bit to 1 in Simple LIN mode. Set this bit to 0 in modes except of Asynchronous mode and Simple LIN mode.

MOD[2:0] bits (Communication Mode Select)

Selects the SCI communication mode.

Table 28.25 Relationship between communication mode selection bits (MOD[2:0]) and other operation mode setting bits

Communication mode	Asynchronous								Smart card interface	Clock synchronous	Simple SPI				Simple IIC	Manchester		Simple LIN
CCR3.MOD[2:0]	000b								001b	010b	011b				100b	101b		110b
CCR3.MP	0				1				—	—	—				—	0	1	—
CCR3.FM	0		1		0		1		—	0	1	0		1	—	—		—
CCR3.DEN	0	1	0	1	0	1	0	1	—	—	—				—	—		—
CCR0.SSE	—								—		0	1	0	1	—	—		—

Note: — is prohibited setting.

MP bit (Multi-Processor Mode)

Disables/enables multi-processor communications function. The settings of the PE bit and PM bit are invalid in multi-processor mode.

FM bit (FIFO Mode Select)

When the FM bit is set to 1, the TDR register / RDR register switches to FIFO configuration, and transmit FIFO (TDR register) / receive FIFO (RDR register) can be used for serial transmission/reception.

DEN bit (Driver Enable)

Select RS-485 driver control function disabled or enabled.

CKE[1:0] bits (Clock Enable)

Table 28.26 Association between Clock Enable bits CKE[1:0] and operation mode (1 of 2)

CKE[1:0]	Function
00b	In Asynchronous mode: On-chip baud rate generator The SCKn pin is available for use as an I/O port in accord with the I/O port settings. In Manchester mode and Simple LIN mode: On-chip baud rate generator The SCKn pin functions as I/O port. In Clock synchronous mode and Simple SPI mode: Internal clock (master operation) The SCKn pin functions as the clock output pin. In Smart card interface mode and when CCR3.GM = 0: Output disabled (the SCKn pin is available for use as an I/O port in accord with the I/O port settings). In Smart card interface mode and when CCR3.GM = 1: Output fixed low
01b	In Asynchronous mode: On-chip baud rate generator The clock with the same frequency as the bit rate is output from the SCKn pin. In Manchester mode and Simple LIN mode: Prohibited In Clock synchronous mode and Simple SPI mode: Internal clock (master operation) The SCKn pin functions as the clock output pin. In Smart card interface mode and when CCR3.GM = 0: Clock output In Smart card interface mode and when CCR3.GM = 1: Clock output

Table 28.26 Association between Clock Enable bits CKE[1:0] and operation mode (2 of 2)

CKE[1:0]	Function
10b	In Asynchronous mode: External clock or GPT clock ● When using the external clock 16 times the bit rate should be input from the SCKn pin when CCR2.ABCS bit is 0. Input a clock signal with a frequency 8 times the bit rate when the CCR2.ABCS bit is 1. ● When using the GPT clock*3 The SCKn pin is available for use as an I/O port in accord with the I/O port settings when the GPT clock is used. In Manchester mode and Simple LIN mode: Prohibited In Clock synchronous mode and Simple SPI mode: External clock (slave operation) The SCKn pin functions as the clock input pin. In Smart card interface mode and when CCR3.GM = 0: Prohibited In Smart card interface mode and when CCR3.GM = 1: Output fixed high
11b	In Asynchronous mode: External clock or GPT clock ● When using the external clock 16 times the bit rate should be input from the SCKn pin when CCR2.ABCS bit is 0. Input a clock signal with a frequency 8 times the bit rate when the CCR2.ABCS bit is 1. ● When using the GPT clock *3 The SCKn pin is available for use as an I/O port in accord with the I/O port settings when the GPT clock is used. In Manchester mode and Simple LIN mode: Prohibited In Clock synchronous mode and Simple SPI mode: External clock (slave operation) The SCKn pin functions as the clock input pin. In Smart card interface mode and when CCR3.GM = 0: Prohibited In Smart card interface mode and when CCR3.GM = 1: Clock output

The CKE[1:0] bits select the clock source and SCKn pin function.

The combination of these bit settings and of the CCR3.ACS0 bit sets the internal GPT clock.

In Smart card interface mode, these bits control the clock output from the SCKn pin.

In GSM mode, clock output can be dynamically switched. For details, see section 28.7.8. Clock Output Control.

GM bit (GSM Mode)

Setting the GM bit to 1 allows GSM mode operation.

In GSM mode, the CSR.TEND flag set timing is put forward to 11.0 etu (elementary time unit = 1-bit transfer time) from the start and the clock output control function is appended. For details, see section 28.7.6. Serial Data Transmission (Except in Block Transfer Mode), section 28.7.8. Clock Output Control.

ACS0 bit (Asynchronous Mode Clock Source Select)

Selects the clock source in the Asynchronous mode.

The ACS0 bit is valid in Asynchronous mode (CCR3.MOD[2:0] = 000b) and when an external clock input is selected (CCR3.CKE[1:0] = 10b or 11b). This bit is used to select an external clock input or the logical AND of compare matches output from the internal GPT.

Set the ACS0 bit to 0 in other than Asynchronous mode.

For SCI1 and SCI2, the GTIOCmA output (m = 3, 4, 6, 7) of GPT can be set as the serial transfer base clock. See Table 28.27 for details.

These bits for SCI channels other than SCI1 and SCI2 are reserved. The write values to these bits for other than SCI1 and SCI2 should be 0.

Table 28.27 Association between SCI channels and compare match outputs

SCI	GPT	Compare match output
SCI1	GPT3	GTIOC3A
	GPT4	GTIOC4A
SCI2	GPT6	GTIOC6A
	GPT7	GTIOC7A

Figure 28.4, Figure 28.5 show a setting example of when GTIOC3A and GTIOC4A are selected for output. This figure shows an example when GPT clock is input to SCI1.

When generating 187.5 kbps of GPT average transfer rate for PCLKD = 32 MHz:

1. Generate a frequency of 4 MHz using GTIOC3A as the base clock.
2. Generate 3/4 clock enable of base clock to set an average transfer rate of 3 MHz/16 = 187.5 kbps using GTIOC4A.

Setting examples of GPT and SCI

- GPT3.GTSSR = 0x80000000, GPT4.GTSSR = 0x80000000 (enable software counter start)
- GPT3.GTPR = 0x00000007, GPT4.GTPR = 0x0000001F (maximum count value of GTCNT)
- GPT3.GTCCRA = 0x00000003, GPT4.GTCCRA = 0x00000007 (compare match value)
- GPT3.GTCR = 0x00000000, GPT4.GTCR = 0x00000000 (Saw-wave PWM mode, timer prescaler is PCLKD)
- GPT3.GTIOR = 0x00000306, GPT4.GTIOR = 0x00000306
  (initial output low, output high at GTCCRA compare match, output low at cycle end)
- CCR3.CKE[1:0] = 10b (external clock input or GPT clock input is selected)
- CCR3.ACS0 = 1, CCR2.ABCSE = 1, CCR2.ABCS=0 (GPT clock input is selected with 16 base clock cycles for 1-bit period)
- GPT3.GTSTR = 0x00000018 (software start GTCNT counter)

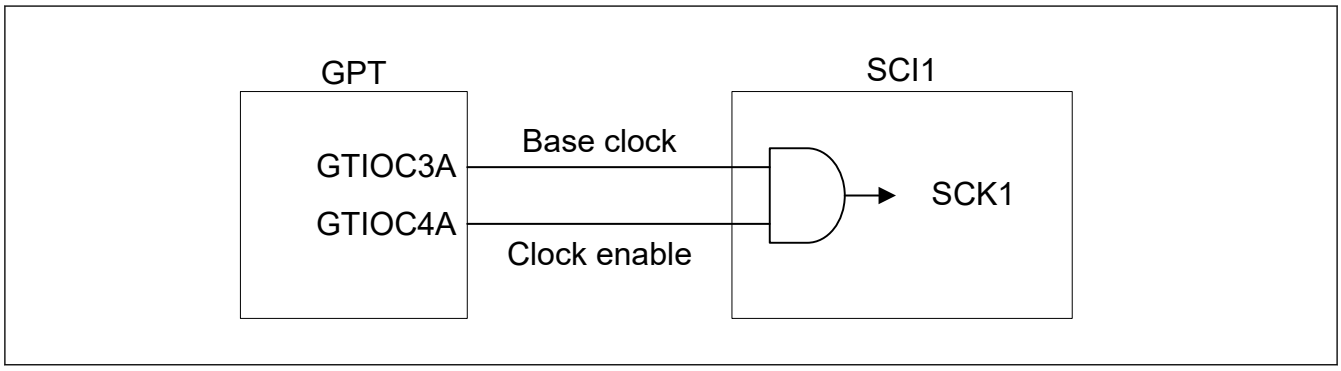

Figure 28.4 Example of GPT and SCI connection

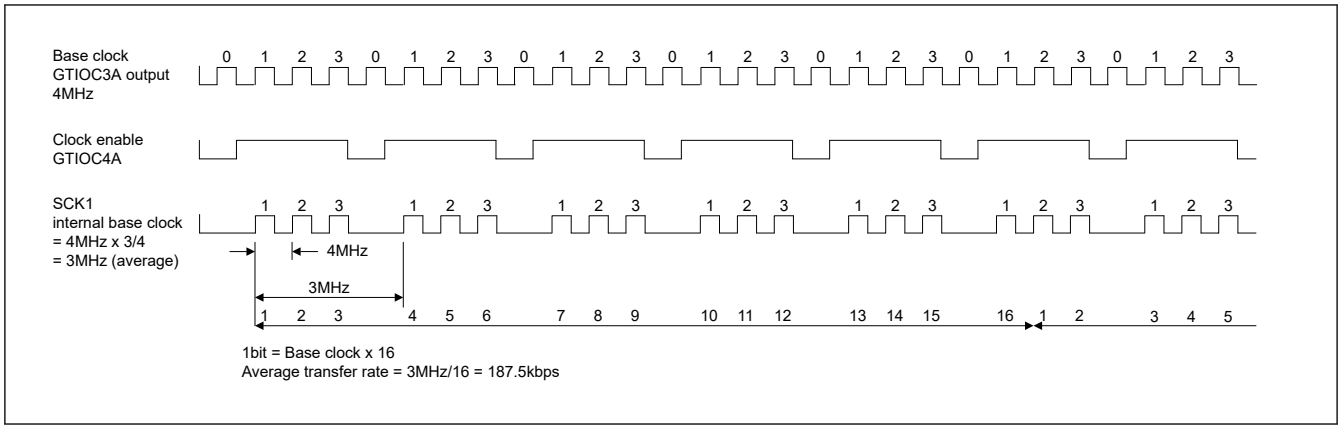

Figure 28.5 Example of average transfer rate setting when GPT clock is input

BLK bit (Block Transfer Mode)

Setting the BLK bit to 1 allows block transfer mode operation.

For details, see section 28.7.3. Block Transfer Mode.

28.2.9 CCR4 : Common Control Register 4

Base address: SCIn_B = 0x4035_8000 + 0x0100 × n (n = 0 to 4, 9)
SCIn_B_NS = 0x5035_8000 + 0x0100 × n (n = 0 to 4, 9)

Bit	Symbol	Function	R/W
26:24	AST[2:0]	Adjustment Value for Receive Sampling Timing This bit enables only when ASEN is 1. In Asynchronous mode and Simple LIN mode using internal clock: The sampling timing of RXDn pin is adjusted from the middle of bit by the following formula. Adjustment sampling timing = base clock × the setting value of AST[2:0]. In Clock synchronous mode and Simple SPI mode using internal clock: The RXDn sampling timing can be adjusted by delaying 1 to 4 TCLK 0 0 0: 1-TCLK delay 0 0 1: 2-TCLK delay 0 1 0: 3-TCLK delay 0 1 1: 4-TCLK delay Others: Setting prohibited	R/W
27	AJD	Adjustment Direction for Receive Sampling Timing Valid in Asynchronous mode using internal clock and Simple LIN mode using internal clock. This bit enables only when ASEN is 1. Adjustment direction for RXDn receive sampling timing is determined by this bit. For details, see section 28.3.10. The function of adjust receive sampling timing (Asynchronous Mode). 0: The sampling timing is adjusted backward to the middle of bit. 1: The sampling timing is adjusted forward to the middle of bit.	R/W
30:28	ATT[2:0]	Adjustment Value for Transmit Timing Valid in Asynchronous mode using internal clock and Simple LIN mode using internal clock. This bit enables only when ATEN is 1. The selected edge timing of TXDn is adjusted by the following formula. Adjustment edge timing = base clock × the setting value of ATT[2:0] This setting timing is limited by setting the base clock cycles. For details, see section 28.3.11. The function of adjust transmit timing (Asynchronous Mode).	R/W
31	AET	Adjustment Edge for Transmit Timing Valid in Asynchronous mode using internal clock and Simple LIN mode using internal clock. The adjustable edge is set by this bit. This bit enables only when ATEN is 1. For details, see section 28.3.11. The function of adjust transmit timing (Asynchronous Mode). 0: When CCR1.TINV is 0, adjust the rising edge timing. When CCR1.TINV is 1, adjust the falling edge timing. 1: When CCR1.TINV is 0, adjust the falling edge timing. When CCR1.TINV is 1, adjust the rising edge timing.	R/W

Note: S-TYPE-3, P-TYPE-3

CMPD[8:0] bits (Compare Match Data)

Set the comparison data for receive data when address match function is enabled (CCR0.DCME = 1). CCR4.CMPD[8:0] should be written while CCR0.DCME is 0.

For the comparison data, it can select length from three types, they are CMPD[6:0] with 7-bit length, CMPD[7:0] with 8-bit length, and CMPD[8:0] with 9-bit length.

Note: If the description in this document and the timing chart do not specify the ASEN / ATEN setting value, it means that the reception sampling adjustment function/transmission timing adjustment function are OFF (CCR4.ASEN = 0, CCR4.ATEN = 0).

ASEN bit (Adjust Receive Sampling Timing Enable)

When the ASEN bit is 1, the receive sampling timing adjustment function is enabled. Control is different in Asynchronous mode, Simple LIN mode, Clock-synchronous mode, and Simple SPI mode.

For details of using internal clock in Asynchronous mode, see section 28.6.7. Reception Sampling Timing Adjustment Function in Clock Synchronous Mode with internal clock used. The operation when the Simple LIN mode internal clock is selected is the same as when the Asynchronous mode internal clock is selected.

For details of Clock synchronous mode operating as master and Simple SPI mode operating as master, see section 28.6.6. Simultaneous Serial Data Transmission and Reception in Clock Synchronous Mode. Only the digital delay of the master mode receive sampling clock can be controlled by this bit.

ATEN bit (Adjust Transmit Timing Enable)

When the ATEN bit is 1, the transmission timing adjustment function is enabled. The transmission timing adjustment function can adjust the edge timing of the waveform output from the TXDn pin. For details, see section 28.3.11. The function of adjust transmit timing (Asynchronous Mode).

SCKSEL bit (Master receive clock selection)

In Clock synchronous or Simple-SPI mode, SCKSEL bit selects whether to enable or disable the internal clock for master reception.

AST[2:0] bits (Adjustment Value for Receive Sampling Timing)

When the ASEN bit is 1, the receive sampling timing can be adjusted according to this bit setting value.

In Asynchronous mode and Simple LIN mode using internal clock.

The sampling timing of RXDn pin is adjusted from the middle of bit by the following formula. This setting value is limited by setting the base clock cycles. For details, see section 28.3.10. The function of adjust receive sampling timing (Asynchronous Mode).

Adjustment sampling timing = base clock × the setting value of AST[2:0].

In Clock-synchronous mode and Simple SPI mode using internal clock

The sampling timing of RXDn pin can be adjusted by delaying 1 to 4 TCLK. For details, see section 28.6.7. Reception Sampling Timing Adjustment Function in Clock Synchronous Mode with internal clock used.

000: 1-TCLK delay

001: 2-TCLK delay

010: 3-TCLK delay

011: 4-TCLK delay

1xx: Setting prohibited

Note: In Clock-synchronous mode and Simple SPI mode, it is recommended to set delay time within half the period of the SCK clock cycle.

AJD bit (Adjustment Direction for Receive Sampling Timing)

Set the RXDn pin sampling timing adjustment direction from the bit center to the rear or front. For details, see section 28.3.10. The function of adjust receive sampling timing (Asynchronous Mode).

ATT[2:0] bits (Adjustment Value for Transmit Timing)

The edge timing of the TXDn pin specified by the AET bit is adjusted by the base clock × ATT[2:0] setting value. The upper limit of the adjustment time that can be set is limited by the number of base clock cycles. For details, see section 28.3.11. The function of adjust transmit timing (Asynchronous Mode).

AET bit (Adjustment Edge for Transmit Timing)

Set the TXDn pin edge for timing adjustment. For details, see section 28.3.11. The function of adjust transmit timing (Asynchronous Mode).

28.2.10 ICR : Simple IIC Control Register

Base address: SCIn_B = 0x4035_8000 + 0x0100 × n (n = 0 to 4, 9)
SCIn_B_NS = 0x5035_8000 + 0x0100 × n (n = 0 to 4, 9)

Offset address: 0x20

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit field:	—	—	IICACKT	—	—	—	IICCSC	IICINTM	—	—	—	IICDL[4:0]				
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
4:0	IICDL[4:0]	SDA Delay Output Select The following cycles are of the clock signal from the on-chip baud rate generator: 0x00: No output delay 0x01: 0 to 1 cycle 0x02: 1 to 2 cycles 0x03: 2 to 3 cycles 0x04: 3 to 4 cycles 0x05: 4 to 5 cycles ⋮ 0x1E: 29 to 30 cycles 0x1F: 30 to 31 cycles	R/W
7:5	—	These bits are read as 0. The write value should be 0.	R/W
8	IICINTM	IIC Interrupt Mode Select 0: Use ACK/NACK interrupts 1: Use reception and transmission interrupts	R/W
9	IICCSC	Clock Synchronization 0: No synchronization with the clock signal 1: Synchronization with the clock signal	R/W
12:10	—	These bits are read as 0. The write value should be 0.	R/W
13	IICACKT	ACK Transmission Data 0: ACK transmission 1: NACK transmission and reception of ACK/NACK	R/W
15:14	—	These bits are read as 0. The write value should be 0.	R/W
16	IICSTAREQ	Start Condition Generation 0: A start condition is not generated 1: A start condition is generated *1 *3 *4 *5	R/W
17	IICRSTAREQ	Restart Condition Generation 0: A restart condition is not generated 1: A restart condition is generated *2 *3 *4 *5	R/W
18	IICSTPREQ	Stop Condition Generation 0: A stop condition is not generated. 1: A stop condition is generated *2 *3 *4 *5	R/W
19	—	This bit is read as 0. The write value should be 0.	R/W
21:20	IICSDAS[1:0]	SDA Output Select 0 0: Serial data output 0 1: Generate a start, restart, or stop condition 1 0: Output the low level on the SDAn pin 1 1: Place the SDAn pin in the high-impedance state	R/W

Bit	Symbol	Function	R/W
23:22	IICSCLS[1:0]	SCL Output Select 0 0: Serial clock output 0 1: Generate a start, restart, or stop condition 1 0: Output the low level on the SCLn pin 1 1: Place the SCLn pin in the high-impedance state	R/W
31:24	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3
Note 1. In bus free state, perform the start condition generation.
Note 2. In bus busy state, perform restart or stop condition generation when the SCLn pin after acknowledgment described in Figure 28.86 and Figure 28.87 is low level.
Note 3. Do not set more than one from among the IICSTAREQ, IICRSTAREQ, and IICSTPREQ bits to 1 at a given time.
Note 4. Execute the generation of a condition after the value of the IICSTIF flag is 0.
Note 5. Do not write 0 to this bit while it is 1. Generation of a condition is suspended by writing 0 to this bit while it is 1.

IICDL[4:0] bits (SDA Delay Output Select)

The IICDL[4:0] bits are used to set a delay for output on the SDAn pin relative to the falling edge of the output on the SCLn pin. The available delay settings range from no delay to 31 cycles, with the clock signal from the on-chip baud rate generators the base. The signal obtained by frequency-dividing TCLK by the divisor set in CCR2.CKS[1:0] is supplied as the clock signal from the on-chip baud rate generator.

Set these bits to 00000b unless operation is in simple IIC mode. In simple IIC mode, set the bits to a value in the range from 00001b to 11111b.

IICINTM bit (IIC Interrupt Mode Select)

The IICINTM bit selects the sources of interrupt requests in Simple IIC mode.

IICCSC bit (Clock Synchronization)

Set the IICCSC bit to 1 if the internally generated SCLn clock signal is to be synchronized when the SCLn pin is placed at the low level and when a wait is inserted by other device, for example.

The SCLn clock signal is not synchronized if the IICCSC bit is 0. The SCLn clock signal is generated in accord with the rate selected in the BRR regardless of the level being input on the SCLn pin.

Set the IICCSC bit to 1 except during debugging.

IICACKT bit (ACK Transmission Data)

Transmitted data contains ACK bits. Set this bit to 1 when ACK and NACK bits are received.

IICSTAREQ bit (Start Condition Generation)

When a start condition is to be generated, set both the IICSDAS[1:0] and IICSCLS[1:0] bits to 01b as well as setting the IICSTAREQ bit to 1.

To generate the start condition after generating the stop condition, start the generation of the start condition with a half cycle period of the bit rate from the stop condition generation interrupt (STI) request output.

[Setting condition]

- Writing 1 to the bit

[Clearing condition]

- Completion of generation of the start condition

IICRSTAREQ bit (Restart Condition Generation)

When a restart condition is to be generated, set both the IICSDAS[1:0] and IICSCLS[1:0] bits to 01b as well as setting the IICRSTAREQ bit to 1.

[Setting condition]

- Writing 1 to the bit

[Clearing condition]

- Completion of generation of the restart condition

IICSTPREQ bit (Stop Condition Generation)

When a stop condition is to be generated, set both the IICSDAS[1:0] and IICSCLS[1:0] bits to 01b as well as setting the IICSTPREQ bit to 1.

[Setting condition]

- Writing 1 to the bit

[Clearing condition]

- Completion of generation of the stop condition

IICSDAS[1:0] bits (SDA Output Select)

The IICSDAS[1:0] bits control output from the SDAn pin.

IICSCLS[1:0] bits (SCL Output Select)

The IICSCLS[1:0] bits control output from the SCLn pin.

28.2.11 FCR : FIFO Control Register

Base address: SCIn_B = 0x4035_8000 + 0x0100 × n (n = 0 to 4, 9)
SCIn_B_NS = 0x5035_8000 + 0x0100 × n (n = 0 to 4, 9)

Offset address: 0x24

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	RSTRG[4:0]					RFRST	—	—	RTRG[4:0]				
Value after reset:	0	0	0	1	1	1	1	1	0	0	0	1	1	1	1	1

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	TFRST	—	—	TTRG[4:0]					—	—	—	—	—	—	—	DRES
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	DRES	Receive Data Ready Error Select Bit Valid in Asynchronous mode. This bit selects the interrupt request for a reception data ready detection. 0: Reception data full interrupt (SCIn_RXI) 1: Receive error interrupt (SCIn_ERI)	R/W
7:1	—	These bits are read as 0. The write value should be 0.	R/W
12:8	TTRG[4:0]	Transmit FIFO Data Trigger Number Valid in Asynchronous mode (including Multiprocessor mode), Clock synchronous mode, and Simple SPI mode. Trigger number must be set to 15 or less. 0x00: Trigger number 0 ⋮ 0x1F: Trigger number 31	R/W
14:13	—	These bits are read as 0. The write value should be 0.	R/W
15	TFRST	Transmit FIFO Data Register Reset This bit enables only when CCR3.FM is 1. The read value is always 0. 0: When set, this bit is invalid and does not affect operation 1: The number of data stored in Transmit-FIFO (TDR register) is 0	W

Bit	Symbol	Function	R/W
20:16	RTRG[4:0]	Receive FIFO Data Trigger Number Valid in Asynchronous mode (including Multi processor mode), Clock synchronous mode, and Simple SPI mode. Trigger number must be set to 15 or less. 0x00: Trigger number 0 ⋮ 0x1F: Trigger number 31	R/W
22:21	—	These bits are read as 0. The write value should be 0.	R/W
23	RFRST	Receive FIFO Data Register Reset This bit enables only when CCR3.FM is 1. The read value is always 0. 0: When set, this bit is invalid and does not affect operation 1: The number of data stored in Receive-FIFO(RDR register) is 0	W
28:24	RSTRG[4:0]	RTS Output Active Trigger Number Select Valid in Asynchronous mode (including Multi processor mode) and Clock synchronous mode. This bit enables only when CCR3.FM = 1 and CCR1.CTSE = 0 and CCR0.SSE = 0. Trigger number must be set to 15 or less. 0x00: Trigger number 0 ⋮ 0x1F: Trigger number 31	R/W
31:29	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

DRES bit (Receive Data Ready Error Select Bit)

Select whether the detection of receive data ready (FRSR.DR flag = 1) is the cause of SCIn_RXI interrupt request or the cause of SCIn_ERI interrupt request.

TTRG[4:0] bits (Transmit FIFO Data Trigger Number)

The TDRE flag is set to 1 when the quantity of transmit data in the transmit-FIFO(TDR register) is equal to or less than the specified transmit triggering number. If CCR0.TIE = 1, SCIn_TXI interrupt request occurs.

Note: Trigger number must be set to 15. When the trigger number is set to 16 or more, unexpected SCIn_TXI interrupt occurs.

TFRST bit (Transmit FIFO Data Register Reset)

When the TFRST bit is set to 1, the number of the transmission data stored in Transmit-FIFO(TDR register) is 0.

RTRG[4:0] bits (Receive FIFO Data Trigger Number)

The CSR.RDRF flag is set to 1 when the quantity of receive data in the receive-FIFO(RDR register) is equal to or greater than the specified receive triggering number. If CCR0.RIE = 1, SCIn_RXI interrupt request occurs. When FCR.RTRG is set to 0, RDRF bit is set if the quantity of data in receive-FIFO is greater than or equal to 1.

Note: Trigger number must be set to 15. When the trigger number is set to 16 or more, unexpected SCIn_RXI interrupt occurs.

RFRST bit (Receive FIFO Data Register Reset)

When the RFRST bit is set to 1, the number of the reception data stored in Receive-FIFO(RDR register) is 0.

RSTRG[4:0] bits (RTS Output Active Trigger Number Select)

When the quantity of receive data stored in the receive-FIFO (RDR register) is equal to or greater than this number, the RTSn signal is in the High state. When FCR.RSTRG is set to 0, RTSn is in the high state if the quantity of data in receive FIFO is greater than or equal to 1.

Note: Trigger number must be set to 15. When the trigger number is set to 16 or more, RTSn goes to a high state at unexpected timing.

28.2.12 MCR : Manchester Control Register

Base address: SCIn_B = 0x4035_8000 + 0x0100 × n (n = 0)
SCIn_B_NS = 0x5035_8000 + 0x0100 × n (n = 0)

Offset address: 0x2C

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	SBERE N	SYERE N	PFERE N	—	—	RPPAT[1:0]		RPLEN[3:0]			
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	TPPAT[1:0]		TPLEN[3:0]				—	SBSEL	SYNSEL	SYNVAL	—	ERTEN	TMPOL	RMPOL
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	RMPOL	Polarity of Received Manchester Code Sets the polarity of the received Manchester code. 0: Logic 0 is coded as a zero-to-one transition in Manchester code Logic 1 is coded as a one-to-zero transition in Manchester code 1: Logic 0 is coded as a one-to-zero transition in Manchester code Logic 1 is coded as a zero-to-one transition in Manchester code	R/W
1	TMPOL	Polarity of Transmit Manchester Code Sets the polarity of the transmit Manchester code 0: Logic 0 is coded as a zero-to-one transition in Manchester code Logic 1 is coded as a one-to-zero transition in Manchester code 1: Logic 0 is coded as a one-to-zero transition in Manchester code Logic 1 is coded as a zero-to-one transition in Manchester code	R/W
2	ERTEN	Manchester Edge Retiming Enable Sets the receive retiming function. 0: Disables the receive retiming function 1: Enables the receive retiming function	R/W
3	—	This bit is read as 0. The write value should be 0.	R/W
4	SYNVAL	SYNC value Setting Sets the SYNC type of the start bit(s) in the Manchester code. When the start bit area consists of one bit (SBSEL = 0) ● When transmitting: 0: The start bit is added as a zero-to-one transition 1: The start bit is added as a one-to-zero transition ● When receiving: 0: Only when the start bit is a zero-to-one transition, the data is received. Other cases are determined as an error. 1: Only when the start bit is a one-to-zero transition, the data is received. Other cases are determined as an error. When the start bit area consists of three bits (SBSEL = 1) ● When transmitting: 0: The start bits are added as a zero-to-one transition (DATA SYNC) 1: The start bits are coded as a one-to-zero transition (COMMAND SYNC) ● When receiving: When the start bit area consists of three bits, data is received regardless of the value of this bit.	R/W
5	SYNSEL	SYNC Select 0: The start bit pattern is set with the SYNVAL bit 1: The start bit pattern is set with the TSYNC bit	R/W
6	SBSEL	Start Bit Select 0: The start bit area consists of one bit 1: The start bit area consists of three bits (COMMAND SYNC or DATA SYNC)	R/W
7	—	This bit is read as 0. The write value should be 0.	R/W

Bit	Symbol	Function	R/W
11:8	TPLEN[3:0]	Transmit Preface Length Set the preface length of the transmit data in Manchester mode. 0x0: Disables the transmit preface generation Others: Transmit preface length (bit length)	R/W
13:12	TPPAT[1:0]	Transmit Preface Pattern Set the preface pattern of the transmit data. 0 0: ALL ZERO 0 1: ZERO ONE 1 0: ONE ZERO 1 1: ALL ONE	R/W
15:14	—	These bits are read as 0. The write value should be 0.	R/W
19:16	RPLEN[3:0]	Receive Preface Length Set the preface length in received frames when Manchester mode is enabled. 0x0: Disables the receive preface generation Others: Receive preface length (bit length)	R/W
21:20	RPPAT[1:0]	Receive Preface Pattern Set the preface pattern of received frames 0 0: ALL ZERO 0 1: ZERO ONE 1 0: ONE ZERO 1 1: ALL ONE	R/W
23:22	—	These bits are read as 0. The write value should be 0.	R/W
24	PFEREN	Preface Error Enable Specifies whether to handle a preface error as an interrupt source. 0: Does not handle a preface error as an interrupt source 1: Handles a preface error as an interrupt source	R/W
25	SYEREN	Receive SYNC Error Enable Specifies whether to handle a receive SYNC error as an interrupt source. 0: Does not handle a receive SYNC error as an interrupt source 1: Handles a receive SYNC error as an interrupt source	R/W
26	SBEREN	Start Bit Error Enable Specifies whether to handle a start bit error as an interrupt source. 0: Does not handle a start bit error as an interrupt source 1: Handles a start bit error as an interrupt source	R/W
31:27	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

RMPOL bit (Polarity of Received Manchester Code)

The RMPOL bit sets the polarity of the received Manchester code. For details, see section 28.5.7. Serial Data Reception in Manchester Mode.

TMPOL bit (Polarity of Transmit Manchester Code)

The TMPOL bit sets the polarity of the transmit Manchester code. For details, see section 28.5.6. Serial data transmission in Manchester mode.

ERTEN bit (Manchester Edge Retiming Enable)

The ERTEN bit sets the receive retiming function in Manchester mode.

For information on the receive retiming function, see section 28.5.9. Receive Retiming.

SYNVAL bit (SYNC value Setting)

The SYNVAL bit is valid when the SYNSEL bit of the MCR is set to 0.

The SYNC type can be set by combining this bit and the SBSEL bit.

For the start bit area determined by the combination of this bit and the SBSEL bit, see Figure 28.54 and Figure 28.55.

SYNSEL bit (SYNC Select)

The SYNSEL bit is valid when the SBSEL bit of the MCR is set to 1. This bit determines the destination to be referred to for setting the SYNC type of the start bit area added to Manchester frames.

When this bit is set to 0, the SYNVAL bit of the MCR is referred to.

When this bit is set to 1, the TSYNC bit in the TDR register is referred to.

SBSEL bit (Start Bit Select)

The SBSEL bit sets the start bit area in Manchester frames.

When this bit is set to 1, the start bit area added to each frame consists of three bits, and the SYNSEL and SYNVAL bits in this register are valid.

When this bit is set to 0, the start bit area added to each frame consists of one bit.

TPLEN[3:0] bits (Transmit Preface Length)

The TPLEN[3:0] bits set the preface bit length of the transmit data in Manchester mode.

The settable range is 0x0 to 0xF (0d to 15d). The setting of 0x0 disables the transmit preface, which is not added.

TPPAT[1:0] bits (Transmit Preface Pattern)

The TPPAT[1:0] bits set one of the four preface patterns in Manchester mode. For the transmit data when the TPPAT[1:0] bits are set, see Figure 28.53.

When these bits are set to 00b, the preface area is set to all 0s.

When these bits are set to 01b, the preface area is set to the zero-one-zero-one pattern.

When these bits are set to 10b, the preface area is set to the one-zero-one-zero pattern.

When these bits are set to 11b, the preface area is set to all 1s.

RPLEN[3:0] bits (Receive Preface Length)

The RPLEN[3:0] bits set the preface bit length of the received frames in Manchester mode.

The settable range is 0x0 to 0xF (0d to 15d). The setting of 0x0 disables the receive preface, which is not added. When 0x1 to 0xF is set, the set value is handled as the receive preface bit length.

RPPAT[1:0] bits (Receive Preface Pattern)

The RPPAT[1:0] bits set one of the four preface patterns in Manchester mode. For the transmit and receive data when the RPPAT[1:0] bits are set, see Figure 28.53.

When these bits are set to 00b, the preface area is handled as all 0s.

When these bits are set to 01b, the preface area is handled as the zero-one-zero-one pattern.

When these bits are set to 10b, the preface area is handled as the one-zero-one-zero pattern.

When these bits are set to 11b, the preface area is handled as all 1s.

PFEREN bit (Preface Error Enable)

The PFEREN bit specifies whether to handle a preface error as an interrupt source.

When it is set to 0, a preface error is not handled as an interrupt source. When it is set to 1, a preface error is handled as an interrupt source.

SYEREN bit (Receive SYNC Error Enable)

The SYEREN bit specifies whether to handle a receive SYNC error as an interrupt source.

When it is set to 0, a receive SYNC error is not handled as an interrupt source. When it is set to 1, a receive SYNC error is handled as an interrupt source.

SBEREN bit (Start Bit Error Enable)

The SBEREN bit specifies whether to handle a start bit error as an interrupt source.

When it is set to 0, a start bit error is not handled as an interrupt source. When it is set to 1, a start bit error is handled as an interrupt source.

28.2.13 DCR : Driver Control Register

Base address: SCIn_B = 0x4035_8000 + 0x0100 × n (n = 0 to 4, 9)
SCIn_B_NS = 0x5035_8000 + 0x0100 × n (n = 0 to 4, 9)

Offset address: 0x30

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	DEAST[4:0]					—	—	—	—	—	—	—	DEPOL
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	DEPOL	Driver Effective Polarity Select Valid only in Asynchronous mode. 0: The DEn signal is active-high 1: The DEn signal is active-low	R/W
7:1	—	These bits are read as 0. The write value should be 0.	R/W
12:8	DEAST[4:0]	Driver Assertion Time Valid only in Asynchronous mode. Set the driver assertion time. When DEN = 1, the driver assertion time is inserted in addition to the normal transmission waiting time. Setting DEAST[4:0] = 0x00 is prohibited.	R/W
15:13	—	These bits are read as 0. The write value should be 0.	R/W
20:16	DENGT[4:0]	Driver Negate Time Valid only in Asynchronous mode. Set the driver negation time. When DEN = 1, the driver negate time is inserted after STOP bit transmission end. Setting DENGT[4:0] = 0x00 is prohibited.	R/W
31:21	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

DEPOL bit (Driver Effective Polarity Select)

Select the active level of the DEn signal.

DEAST[4:0] bits (Driver Assertion Time)

Set the driver assertion time (= time from the activation of the DEn (Driver Enable) signal to the start of the start bit). It is expressed in base clock period.

Driver assertion time

= DEAST [4:0] set value × base clock period + transmission waiting time

DENGT[4:0] bits (Driver Negate Time)

Set the driver negation time (= time from the end of the last stop bit of the transmitted message until the DEn (Driver Enable) signal is disabled). It is expressed in base clock period.

Driver negate time

= DENGT[4:0] set value × base clock period

If the transmission data is written during the driver negate time, transmit starting operation is different depends on the writing timing. The DEn signal remains valid, and transmission of the start bit may start after the transmission wait time has

elapsed. Also, the DEn signal may become invalid once, and start bit transmission may start after the Driver assertion time has elapsed.

28.2.14 XCR0 : Simple LIN Control Register 0

Base address: SCIn_B = 0x4035_8000 + 0x0100 × n (n = 0, 1)
SCIn_B_NS = 0x5035_8000 + 0x0100 × n (n = 0, 1)

Offset address: 0x34

16	BFOIE	Break Field Output Completion Interrupt Enable Select whether to include Break Field output completion as a SCIn_TXI interrupt factor. 0: Break Field output completion is not included in SCIn_TXI interrupt factor 1: Break Field output completion is included in SCIn_TXI interrupt factor	R/W

Bit	Symbol	Function	R/W
17	BCDIE	Bus Conflict Detection Interrupt Enable Select whether to output an SCIn_ERI interrupt when a bus collision is detected. 0: Bus conflict detection is not included in SCIn_ERI interrupt factor 1: Bus conflict detection is included in SCIn_ERI interrupt factor	R/W
19:18	—	These bits are read as 0. The write value should be 0.	R/W
20	BFDIE	Break Field Detection Interrupt Enable Select whether to output a SCIn_BFD interrupt when a Break Field is detected. 0: Break Field detection interrupt disabled 1: Break Field detection interrupt enabled	R/W
21	COFIE	Counter Overflow Interrupt Enable Select whether to include counter overflow as an SCIn_ERI interrupt factor. 0: Counter overflow is not included in SCIn_ERI interrupt factor 1: Counter overflow is included in SCIn_ERI interrupt factor	R/W
22	AEDIE	Active Edge Detection Interrupt Enable Select whether to output an SCIn_AED interrupt when a valid edge is detected. 0: Active edge detection interrupt disabled 1: Active edge detection interrupt enabled	R/W
23	—	This bit is read as 0. The write value should be 0.	R/W
25:24	BCCS[1:0]	Bus Conflict Detection Clock Selection Select the sampling clock for the bus conflict detection circuit. When CCR2.ABCS = 1, setting BCCS[1] = 1 is prohibited. 0 0: Base clock*2 0 1: Base clock/2 1 0: Base clock/4 1 1: Setting prohibited	R/W
31:26	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3
Note 1. You can rewrite TCSS[1:0] only when the timer is stopped (TCST = 0 and SDST = 0 and BMEN = 0)
Note 2. Base clock: 1/16 period of 1 bit period when CCR2.ABCS = 0, 1/8 period of 1 bit period when CCR2.ABCS = 1.
Note 3. This bit is a setting bit required for the start frame reception operation. Rewrite this bit when the start frame reception or transmission is not in progress (XCR1.SDST = 0 and XCR1.TCST = 0).

TCSS[1:0] bits (Timer Count Clock Source Selection)

Select clock source of timer in Simple LIN module.

BFE bit (Break Field Enable)

Set the presence or absence of Break Field of Start Frame.

CF0RE bit (Control Field 0 Enable)

Set the presence or absence of Control Field 0 of Start Frame.

CF1DS[1:0] bits (Control Field1 Compare Data Select)

Select the compare data for Control Field 1.

PIBE bit (Priority Interrupt Bit Enable)

Select whether to enable priority interrupt bit comparison of Control Field 1. When the PIBE bit is 1, regardless of the XCR1.CF1CE [7:0] setting value, the bit specified in PIBS [2:0] is compared with the primary comparison data for Control Field 1 (XCR1.PCF1D [7:0]).

PIBS[2:0] bits (Priority Interrupt Bit Select)

Specify bit N (N = 0-7) of Control Field 1 as the priority interrupt bit.

BFOIE bit (Break Field Output Completion Interrupt Enable)

Select whether to include Break Field output completion as a SCIn_TXI interrupt factor. Set CCR0.TIE = 1 and CCR3.MOD [1: 0] = 110b, to output SCIn_TXI upon completion of Break Field output.

BCDIE bit (Bus Conflict Detection Interrupt Enable)

Select whether to output an SCIn_ERI interrupt when a bus collision is detected. In Simple LIN mode (CCR3.MOD [1:0] = 110b), SCIn_ERI output control is performed with the BCDIE bit. When CCR3.MOD [1:0] = 110b and BCDIE = 1, an SCIn_ERI interrupt is issued when a bus collision is detected even if CCR0.RIE = 0.

COFIE bit (Counter Overflow Interrupt Enable)

Select whether to include counter overflow as an SCIn_ERI interrupt factor. Set CCR0.RIE = 1 and CCR3.MOD [1:0] = 110b are required to output SCIn_ERI upon counter overflow.

AEDIE bit (Active Edge Detection Interrupt Enable)

Select whether to output an SCIn_AED interrupt when a valid edge is detected. To output SCIn_AED with valid edge detection, XCR1.BMEN = 1 and CCR3.MOD [1:0] = 110b must be set.

BCCS[1:0] bits (Bus Conflict Detection Clock Selection)

Select the sampling clock for the bus conflict detection circuit.

28.2.15 XCR1 : Simple LIN Control Register 1

Base address: SCIn_B = 0x4035_8000 + 0x0100 × n (n = 0, 1)
SCIn_B_NS = 0x5035_8000 + 0x0100 × n (n = 0, 1)

Offset address: 0x38

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	CF1CE[7:0]								SCF1D[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	PCF1D[7:0]								—	—	BMEN	SDST	—	—	—	TCST
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	TCST	Break Field Output Timer Count Start Trigger 0: Break Field output timer count stopped 1: Break Field output timer count start	R/W
3:1	—	These bits are read as 0. The write value should be 0.	R/W
4	SDST	Start Frame Detection Enable 0: Start Frame/Break Field detection disabled 1: Start Frame/Break Field detection enabled Do not set this bit and TCST bit to 1 at the same time.	R/W
5	BMEN	Bit Rate Measurement Enable Set this bit to 1 simultaneously with the SDST bit. This bit can be set to 0 at any timing. 0: Bit rate measurement disabled 1: Bit rate measurement enabled	R/W
7:6	—	These bits are read as 0. The write value should be 0.	R/W
15:8	PCF1D[7:0]	Priority Compare Data for Control Field 1 The priority compare data for Control Field 1.	R/W
23:16	SCF1D[7:0]	Secondary Compare Data for Control Field 1 The secondary compare data for Control Field 1.	R/W
31:24	CF1CE[7:0]	Control Field 1 Compare Bit Enable Select whether to compare bit N of Control Field 1. (N = 0 -7) 0: Control Field 1 bit N compare disabled 1: Control Field 1 bit N compare enabled	R/W

Note: S-TYPE-3, P-TYPE-3

TCST bit (Break Field Output Timer Count Start Trigger)

[Clearing condition]

- When 0 is written to TCST. Break Field output timer count is stopped and TXDn output becomes idle level.
- When Break Field output for the period set in XCR2.BFLW [15: 0] is completed.

[Setting condition]

- When 1 is written to TCST. Start Break Field output from TXDn. Holds 1 during Break Field output.

SDST bit (Start Frame Detection Enable)

When 1 is written to the SDST bit, Start Frame detection starts. When XCR0.BFE = 1 is set, Break Field can be detected during Start Frame is detected and after Start Frame is detected. When XCR0.BFE = 0 is set, Break Field is not detected.

When 0 is written to the SDST bit, Start Frame detection and Break Field detection are stopped. However, if XSR0.RXDSF = 0 at the time of stop, it is not possible to stop data reception of the SCI core with this bit. Write 0 to CCR0.RE to stop the reception operation or perform reception completion processing (CSR.RDRF clear or RDR read) after reception is completed.

BMEN bit (Bit Rate Measurement Enable)

Set this bit to 1 simultaneously with the SDST bit. When the BMEN bit is set to 1, the valid edge interval of Control Field 0 and Control Field 1 data is measured.

PCF1D[7:0] bits (Priority Compare Data for Control Field 1)

Set the priority compare data for Control Field 1.

SCF1D[7:0] bits (Secondary Compare Data for Control Field 1)

Set the secondary compare data for Control Field 1.

CF1CE[7:0] bits (Control Field 1 Compare Bit Enable)

Select whether to compare bit N of Control Field 1. (N = 0 - 7)

When all of the CF1CE[7:0] bits are set to 0 (CF1CE[7:0] = 0x00), it is always determined that Control Field 1 matches when reception is completed, and XSR0.CF1MF is set. This bit is a comparison enable with PCF1D[7:0] or SCF1D[7:0], and is not a priority interrupt bit comparison enable.

28.2.16 XCR2 : Simple LIN Control Register 2

Base address: SCIn_B = 0x4035_8000 + 0x0100 × n (n = 0, 1)
SCIn_B_NS = 0x5035_8000 + 0x0100 × n (n = 0, 1)

Offset address: 0x3C

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	BFLW[15:0]															
Value after reset:	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	CF0CE[7:0]								CF0D[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	CF0D[7:0]	Control Field 0 Compare Data The compare data for Control Field 0.	R/W
15:8	CF0CE[7:0]	Control Field 0 Compare Bit Enable Select whether to compare bit N of Control Field 0. (N = 0 - 7) 0: Control Field 0 bit N compare disabled 1: Control Field 0 bit N compare enabled	R/W

Bit	Symbol	Function	R/W
31:16	BFLW[15:0]	Break Field Length Setting This register sets the Break Field length. The Break Field length is (BFLW [15:0] setting value + 1) × clock of the timer. The upper limit for setting this register is 0xFFFE. Setting is prohibited for 0xFFFF.	R/W

Note: S-TYPE-3, P-TYPE-3

CF0D[7:0] bits (Control Field 0 Compare Data)

The compare data for Control Field 0.

CF0CE[7:0] bits (Control Field 0 Compare Bit Enable)

Select whether to compare bit N of Control Field 0. (N = 0 - 7)

When all of the CF0CE[7:0] bits are set to 0 (CF0CE[7:0] = 0x00), it is always determined that Control Field 0 matches when reception is completed, and XSR0.CF0MF is set.

BFLW[15:0] bits (Break Field Length Setting)

BFLW[15:0] are 16-bit Break Field length setting bits and the initial value is 0xFFFE.

Set the Break Field length to 1 frame or more. The LIN standard stipulates that the Break Field length is 13 bits or more.

When the Break Field is sending, writing 1 to TCST causes SCI to output the Break Field on TXDn. Up-counting is performed with the clock of the timer selected by XCR0.TCSS[1:0]. When the count value matches the value set in this register, up-counting is stopped and Break Field output from TXDn is also stopped.

When the Break Field is receiving, writing 1 to SDST enables Start Frame detection. SCI starts counting from the negative edge of RXDn. The clock of the timer is selected by XCR0.TCSS[1:0].

When the count value matches the value set in the XCR2, a Break Field has been detected. Up-counting continues until the next valid edge or counter overflow.

28.2.17 CSR : Common Status Register

Base address: SCIn_B = 0x4035_8000 + 0x0100 × n (n = 0 to 4, 9)
SCIn_B_NS = 0x5035_8000 + 0x0100 × n (n = 0 to 4, 9)

Offset address: 0x48

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

18	DFER	Data Compare Match Framing Error Flag Valid only in Asynchronous mode. 0: No framing error occurred at address match detection 1: A framing error has occurred at address match detection	R
23:19	—	These bits are read as 0.	R
24	ORER	Overrun Error Flag 0: No overrun error occurred 1: An overrun error has occurred	R
25	—	This bit is read as 0.	R
26	MFF	Mode Fault Error Flag Valid only in Simple SPI mode. 0: No mode fault error 1: Mode fault error	R
27	PER	Parity Error Flag 0: Non-FIFO selected (CCR3.FM = 0): No parity error occurred FIFO selected (CCR3.FM = 1): No parity error in all received data in receive-FIFO 1: Non-FIFO selected (CCR3.FM = 0): A parity error has occurred FIFO selected (CCR3.FM = 1): One or more parity errors occurred in received data in receive-FIFO	R
28	FER	Framing Error Flag 0: Non-FIFO selected (CCR3.FM = 0): No framing error occurred FIFO selected (CCR3.FM = 1): No framing error in all received data in receive-FIFO 1: Non-FIFO selected (CCR3.FM = 0): A framing error has occurred FIFO selected (CCR3.FM = 1): One or more framing errors occurred in received data in receive-FIFO	R
29	TDRE	Transmit Data Empty Flag 0: Non-FIFO selected (CCR3.FM = 0): Transmit data is in TDR register FIFO selected (CCR3.FM = 1): The quantity of transmit data written in transmit-FIFO exceeds the specified transmit triggering number. 1: Non-FIFO selected (CCR3.FM = 0): No transmit data is in TDR register FIFO selected (CCR3.FM = 1): The quantity of transmit data written in transmit-FIFO is equal to or less than the specified transmit triggering number.	R
30	TEND	Transmit End Flag 0: A character is being transmitted or standing by for transmission. 1: Character transfer has been completed, or sending Break Field.	R
31	RDRF	Receive Data Full Flag 0: Non-FIFO selected (CCR3.FM = 0): No received data is in RDR register FIFO selected (CCR3.FM = 1): The quantity of receive data written in receive-FIFO falls below the specified receive triggering number. 1: Non-FIFO selected (CCR3.FM = 0): Received data is in RDR register FIFO selected (CCR3.FM = 1): The quantity of receive data written in receive-FIFO is equal to or greater than the specified receive triggering number.	R

Note: S-TYPE-3, P-TYPE-3

ERS bit (Error Signal Status Flag)

[Setting condition]

- When an error signal low is sampled.

[Clearing condition]

- When write 1 to CFCLR.ERSC.

DCMF bit (Data Compare Match Flag)

The DCMF bit indicates that SCI detects the match to the comparison data (CCR4.CMPD) with receive data.

Clearing the CCR0.RE bit to 0 does not affect the DCMF flag, which retains its previous state.

[Setting condition]

- Matched to the comparison data (CCR4.CMPD) with receive data, while CCR0.DCME = 1.

[Clearing condition]

- When write 1 to CFCLR.DCMFC.

DPER bit (Data Compare Match Parity Error Flag)

The DPER bit indicates that a parity error occurred at address match detection (reception data match detection).

Clearing the CCR0.RE bit to 0 does not affect the DPER flag, which retains its previous state.

[Setting condition]

- When a parity error is detected by the frame in which an address match was detected.

[Clearing condition]

- When writing 1 to CFCLR.DPERC.

DFER bit (Data Compare Match Framing Error Flag)

The DFER bit indicates that a framing error occurred at address match detection (reception data match detection).

Clearing the CCR0.RE bit to 0 does not affect the DFER flag, which retains its previous state.

[Setting condition]

- When a stop bit of the frame in which an address match was detected is 0.
  When it is a 2-stop mode, the 1st bit of the stop bit only determines whether it is 1 and does not check the 2nd bit of the stop bit.

[Clearing condition]

- When writing 1 to CFCLR.DFERC.

ORER bit (Overrun Error Flag)

The ORER bit indicates that an overrun error has occurred during reception and the reception ends abnormally.

Clearing the CCR0.RE bit to 0 does not affect the ORER flag, which retains its previous state. In Simple IIC mode, the ORER bit is not used.

[Setting condition with non-FIFO mode (CCR3.FM = 0)]

- When the next data is received before reading out RDR with no-error reception data stored in RDR.
  In RDR, receive data prior to an overrun error occurrence is retained, but data received after the overrun error occurrence is lost. When the ORER flag is set to 1, reception data is not forwarded to RDR register.

  Note: In Clock synchronous mode and Simple SPI mode, serial reception is stopped.

[Setting condition with FIFO mode (CCR3.FM = 1)]

- When the next serial reception is completed while the receive FIFO is full of 16 receive data.

[Clearing condition]

- When write 1 to CFCLR.ORERC.

MFF bit (Mode Fault Error Flag)

The MFF bit indicates mode fault errors. In a multi-master configuration, determine the mode fault error occurrence by reading the MFF flag.

[Setting condition]

- Input on the SSn pin being at the low level during master operation (CCR3.CKE[1:0] = 00 or 01) in Simple SPI mode.

[Clearing condition]

- When writing 1 to CFCLR.MFFC.

PER bit (Parity Error Flag)

The PER bit indicates that a parity error has occurred during reception and the reception ends abnormally.

Clearing the CCR0.RE bit to 0 does not affect the PER flag, which retains its previous state.

In Clock synchronous mode, Simple SPI mode, and Simple IIC mode, the PER bit is not used.

[Setting condition]

- When a parity error is detected during reception. In FIFO select mode, when one or more parity error is detected in receive-FIFO data.
  In non-FIFO mode, although receive data when the parity error occurs is transferred to RDR, no SCIn_RXI interrupt request occurs. Note that when the PER flag is set to 1, the subsequent receive data is not transferred to RDR.

[Clearing condition]

- When writing 1 to CFCLR.PERC.

FER bit (Framing Error Flag)

The FER bit indicates that a framing error has occurred during reception and the reception ends abnormally.

Clearing the CCR0.RE bit to 0 does not affect the FER flag, which retains its previous state.

In Clock synchronous mode, Simple SPI mode, and Simple IIC mode, the FER bit is not used.

[Setting condition]

- When 0 is sampled as the stop bit during reception. In FIFO select mode, when one or more framing error is detected in receive-FIFO data. In Manchester mode, when both sampling results (1⁄4 and 3⁄4 sampling points) are not 1 for 1 stop bit. In Simple LIN mode, even if a condition that changes to 1 occurs when XCR1.SDST = 1, the FER set timing is delayed up to the Break Field evaluation timing at the longest, since it may be a Break Field. If an edge is detected on the RXDn signal before the Break Field evaluation timing, FER is detected. If no edge is detected in the RXDn signal before the Break Field evaluation timing, Break Field is detected.
  In 2-stop-bit mode, only the first stop bit is checked whether it is 1 but the second stop bit is not checked. In non-FIFO mode, although receive data when the framing error occurs is transferred to RDR, no SCIn_RXI interrupt request occurs. In addition, when the FER flag is being set to 1, the subsequent receive data is not transferred to RDR.

[Clearing condition]

- When writing 1 to CFCLR.FERC.

TDRE bit (Transmit Data Empty Flag)

[Non-FIFO selected (CCR3.FM = 0)]

The TDRE bit indicates the presence of transmit data in the TDR register.

The condition of CCR0.TE = 0 has priority over the condition of 0.

If other conditions that become 1 and conditions that become 0 are satisfied at the same time, the TDRE flag is set to 0.

[Setting condition]

- When CCR0.TE is 0.
- When data is transmitted from the TDR register to the TSR register.

[Clearing condition]

- When writing 1 to CFCLR.TDREC.
- When the transmission data is written to the TDR register during CCR0.TE = 1.

[FIFO selected (CCR3.FM = 1)]

The TDRE bit indicates that data has been transferred from the transmit-FIFO (TDR) into the transmit shift register (TSR), the quantity of data in transmit-FIFO has fallen below the specified transmit triggering number.

When the condition which becomes 1 and the condition which becomes 0 are formed at the same time, TDRE flag is 0. After that, when the number of data stored in transmit-FIFO is evaluated, and if that is equal to or less than TTRG value, TDRE is set to 1 after 1 PCLK.

[Setting condition]

- When the quantity of transmit data written in transmit-FIFO is equal to or less than the specified transmit triggering number*1.

Note 1. The transmit-FIFO is FIFO register of 16 stages, the maximum number of data that can be written when the TDRE flag is 1 is indicated in 0x10 - FTSR.T[5:0]. Even if more data is written, data is discarded.

[Clearing condition]

- When writing 1 to CFCLR.TDREC.
- When the transmission data is written to transmit-FIFO by the DTC or DMAC (the last block transfer of block transfer).

TEND bit (Transmit End Flag)

[Non-FIFO selected (CCR3.FM = 0), and not Smart card interface mode (CCR3.MOD[2:0] ≠ 001)]

The TEND bit indicates completion of transmission.

[Setting condition]

- When CCR0.TE is 0.
- When the CCR0.TE bit is changed from 0 to 1, the TEND flag is not affected and retains the value 1.
- When the TDR register is not updated at the time of transmission of the tail-end bit of a character being transmitted.
- When the TDR register is not updated at the end of DE negate time with DE control function enable (CCR3.DEN = 1).
- When Break Field is sending.

[Clearing condition]

- After the synchronization delay time has elapsed since the transmission data was written to the TDR register during CCR0.TE = 1.
- When writing 1 to CFCLR.TDREC during CCR0.TE = 1.

[Non-FIFO selected (CCR3.FM = 0), and Smart card interface mode (CCR3.MOD [2:0] = 001)]

With no error signal from the receiving side, this bit is set to 1 when additional data for transfer is ready to be transferred to the TDR register.

[Setting condition]

- When CCR0.TE is 0.
- When the CCR0.TE bit is changed from 0 to 1, the TEND flag is not affected and retains the value 1.
- When a specified period has elapsed after the latest transmission of 1 byte, the ERS flag is 0, and the TDR register is not updated. The set timing is determined by register settings as listed below.1
  When GM = 0 and BLK = 0, 12.5etu after the start of transmission
  When GM = 0 and BLK = 1, 11.5etu after the start of transmission
  When GM = 1 and BLK = 0, 11.0etu after the start of transmission
  When GM = 1 and BLK = 1, 11.0etu after the start of transmission

[Clearing condition]

- After the synchronization delay time has elapsed since the transmission data was written to the TDR register during CCR0.TE = 1.
- When writing 1 to CFCLR.TDREC during CCR0.TE = 1.

[FIFO selected (CCR3.FM = 1)]

The TEND bit indicates that the transmit-FIFO does not contain valid data when transmitting the last bit of a serial character, so the transmission is halted.

[Setting condition]

- TEND is set to 1 when transmit-FIFO does not contain transmit data when the last bit of a one-byte serial character is transmitted.
- When the TDR register is not updated at the end of DE negate time with DE control function enable (CCR3.DEN = 1).

[Clearing condition]

- After the synchronization delay time has elapsed since the transmission data was written to the TDR register during CCR0.TE = 1.

RDRF bit (Receive Data Full Flag)

[Non-FIFO selected (CCR3.FM = 0)]

The RDRF bit indicates the presence of receive data in the RDR register.

[Setting condition]

- When the reception ends normally, and receive data is forwarded from the RSR register to the RDR register.

[Clearing condition]

- When writing 1 to CFCLR.RDRFC.
- When the read data is read from the RDR register.

[FIFO selected (CCR3.FM = 1)]

The RDRF bit indicates that receive data has been transferred to the receive FIFO data register (RDR), and the quantity of data in receive-FIFO is equal to or greater than the specified receive triggering number. When FCR.RTRG is set to 0, RDRF is set if the quantity of data in receive-FIFO is greater than or equal to 1.

[Setting condition]

- RDRF is set to 1 when the quantity of receive data in receive-FIFO is equal to or greater than the specified receive triggering number*1.

Note 1. Since the receive-FIFO is 16 stage FIFO register, the maximum quantity of data that can be read when RDRF is 1 is equivalent to the specified receive data count number (FDR.R[5:0]). If an attempt is made to read after all the data in receive-FIFO has been read, the data is undefined.

[Clearing condition]

- When writing 1 to CFCLR.RDRFC.
- When the reception data is read form receive-FIFO by the DTC or DMAC (the last block transfer of a block transfer).

When the condition which becomes 1 and the condition which becomes 0 are formed at the same time, RDRF flag is 0. After that, when the number of stored data in receive-FIFO is evaluated, and if that is equal to or greater than RTRG value, RDRF is set to 1 after 1 PCLK.

Note: When Non-FIFO is selected, except when interruption communication, RDRF and TDRE should not be cleared by CFCLR register.

28.2.18 ISR : Simple IIC Status Register

Base address: SCIn_B = 0x4035_8000 + 0x0100 × n (n = 0 to 4, 9)
SCIn_B_NS = 0x5035_8000 + 0x0100 × n (n = 0 to 4, 9)

Offset address: 0x4C

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	IICSTIF	—	—	IICACKR
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	IICACKR	ACK Reception Data Flag 0: ACK received 1: NACK received	R
1	—	This bit is read as 0.	R
2	—	The read value is undefined.	R
3	IICSTIF	Issuing of Start, Restart, or Stop Condition Completed Flag 0: There are no requests for generating conditions or a condition is being generated. 1: A start, restart, or stop condition is completely generated.	R
5:4	—	The read value is undefined.	R
31:6	—	These bits are read as 0.	R

Note: S-TYPE-3, P-TYPE-3

IICACKR bit (ACK Reception Data Flag)

Received ACK and NACK bits can be read from this bit.

The IICACKR flag is updated at the rising of SCLn clock for the ACK/NACK receiving bit.

IICSTIF bit (Issuing of Start, Restart, or Stop Condition Completed Flag)

After generating a condition, this bit indicates that the generation is completed. When using the IICSTAREQ, IICRSTAREQ, or IICSTPREQ bit to cause generation of a condition, do so after setting the IICSTIF flag to 0.

When the IICSTIF flag is 1 while an interrupt request is enabled by setting the CCR0.TEIE bit, an STIn request is output.

[Setting condition]

- Completion of the generation of a start, restart, or stop condition (however, in cases where this conflicts with any of the conditions for the flag becoming 0 listed below, the clearing condition takes precedence)

[Clearing condition]

- Writing 1 to ICFCLR.IICSTIFC bit
- When operation is not in Simple IIC mode
- Writing 0 to CCR0.TE bit

28.2.19 FRSR : FIFO Receive Status Register

Base address: SCIn_B = 0x4035_8000 + 0x0100 × n (n = 0 to 4, 9)
SCIn_B_NS = 0x5035_8000 + 0x0100 × n (n = 0 to 4, 9)

Offset address: 0x50

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	FNUM[5:0]						—	—	PNUM[5:0]					
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	R[5:0]						—	—	—	—	—	—	—	DR
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	x	0

Bit	Symbol	Function	R/W
0	DR	Receive Data Ready Flag 0: Receiving is in progress, or no received data remains in the receive-FIFO after a successful reception (receive-FIFO is empty) 1: The following receive data is not received for a fixed period after storing data under the threshold in the receive-FIFO	R
1	—	The read value is undefined.	R
7:2	—	These bits are read as 0.	R
13:8	R[5:0]	Receive-FIFO Data Count Valid in Asynchronous mode (including Multiprocessor mode), Clock synchronous mode, and Simple SPI mode, when CCR3.FM is 1. Indicate the quantity of receive data stored in receive-FIFO	R
15:14	—	These bits are read as 0.	R
21:16	PNUM[5:0]	Parity Error Count Valid only in Asynchronous mode Indicates the quantity of data with a parity error for the receive data stored in the Receive FIFO Data register.	R
23:22	—	These bits are read as 0.	R
29:24	FNUM[5:0]	Framing Error Count Valid only in Asynchronous mode. Indicates the quantity of data with a framing error for the receive data stored in the Receive FIFO Data register.	R
31:30	—	These bits are read as 0.	R

Note: S-TYPE-3, P-TYPE-3

DR bit (Receive Data Ready Flag)

The DR bit indicates that the quantity of data stored in the Receive FIFO Data register (RDR) falls below the specified receive triggering number, and that no next data has been received yet after the elapse of 15 etu from the last stop bit in Asynchronous mode. This bit is valid only Asynchronous mode (including Multiprocessor mode) and FIFO selected. In other mode, this bit does not set to 1.

[Setting conditions]

- DR is set to 1 when the following conditions are met:
  - After receive FIFO Data register (RDR) receives less data than the specified receive triggering number, no next data has been received yet after the elapse of 15 etu*1 from the last stop bit
  - CSR.FER, PER flags are 0.

Note 1. This is equivalent to one and a half (1.5) frames in the 8-bit format with one stop bit (etu: elementary time unit).

[Clearing conditions]

- When all receive data in the receive FIFO Data (RDR register) is read and 1 is written to FFCLR.DRC.

- When CCR3.FM bit is 0.

R[5:0] bits (Receive-FIFO Data Count)

The R[5:0] bits indicate the quantity of receive data stored in the Receive FIFO Data register.

0x00 means no receive data. 0x10 means receive-FIFO is full.

PNUM[5:0] bits (Parity Error Count)

The value indicates the quantity of data stored in the Receive FIFO Data register with a parity error.

FNUM[5:0] bits (Framing Error Count)

The value indicates the quantity of data stored in the Receive FIFO Data registers with a framing error.

28.2.20 FTSR : FIFO Transmit Status Register

Base address: SCIn_B = 0x4035_8000 + 0x0100 × n (n = 0 to 4, 9)
SCIn_B_NS = 0x5035_8000 + 0x0100 × n (n = 0 to 4, 9)

Offset address: 0x54

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	T[5:0]					
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
5:0	T[5:0]	Transmit-FIFO Data Count Valid in Asynchronous mode (including Multiprocessor mode), Clock synchronous mode, and Simple SPI mode, when CCR3.FM is 1. Indicate the quantity of non-transmit data stored in transmit-FIFO	R
31:6	—	These bits are read as 0.	R

Note: S-TYPE-3, P-TYPE-3

T[5:0] bits (Transmit-FIFO Data Count)

The T[5:0] bits indicate the quantity of non-transmitted data stored in transmit-FIFO.

0x00 means no non-transmit data. 0x10 means transmit-FIFO is full.

28.2.21 MSR : Manchester Status Register

Base address: SCIn_B = 0x4035_8000 + 0x0100 × n (n = 0)
SCIn_B_NS = 0x5035_8000 + 0x0100 × n (n = 0)

Offset address: 0x58

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	RSYNC	—	MER	—	SBER	SYER	PFER
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	PFER	Preface Error Flag This bit is set when a preface error (pattern mismatch) is detected 0: No preface error detected 1: Preface error detected	R
1	SYER	SYNC Error Flag This bit is set when no edge is detected in the adjustable range during receive retiming 0: No receive SYNC error detected 1: Receive SYNC error detected	R
2	SBER	Start Bit Error Flag This bit is set when a pattern mismatch in the start bit area is detected 0: No start bit error detected 1: Start bit error detected	R
3	—	This bit is read as 0.	R
4	MER	Manchester Error Flag Valid for Manchester mode only 0: No Manchester error occurred 1: Manchester error has occurred	R
5	—	This bit is read as 0.	R
6	RSYNC	Receive SYNC Data Bit It is valid when MCR.SBSEL = 1 in Manchester mode, 0 is read otherwise. 0: The received start bit is DATA SYNC 1: The received start bit is COMMAND SYNC	R
31:7	—	These bits are read as 0.	R

Note: S-TYPE-3, P-TYPE-3

PFER bit (Preface Error Flag)

The PFER bit indicates that a preface error was detected when receiving frames in Manchester mode.

Even when the RE bit in CCR0 is set to 0 (serial reception is disabled), the PFER flag is not affected and retains its previous value.

[Setting condition]

- When detecting a preface error when receiving frames in Manchester mode
  The following operations are performed when a preface error occurs.
  - When MCR.PFEREN = 1
    The received data is not transferred to the RDR register and no SCIn_RXI interrupt request occurs. Instead, an SCIn_ERI interrupt request occurs. Note that when the PFER flag is set to 1, the subsequently received data is not transferred to the RDR register.
  - When MCR.PFEREN = 0
    The received data is transferred to the RDR register and an SCIn_RXI interrupt request occurs. An SCIn_ERI interrupt request is not generated. The subsequent receive operations are not affected even with the PFER flag is set to 1.

[Clearing condition]

- Writing 1 to MFCLR.PFERC.

SYER bit (SYNC Error Flag)

The SYER bit indicates that a receive SYNC error was detected when receiving frames in Manchester mode with MCR.ERTEN = 1 (Manchester edge retiming enabled).

Even when the RE bit in CCR0 is set to 0 (serial reception is disabled), the SYER flag is not affected and retains its previous value.

[Setting condition]

- When detecting a receive SYNC error when receiving frames in Manchester mode
  The following operations are performed when a receive SYNC error occurs.

– When MCR.SYEREN = 1
Although the received data is transferred to the RDR register, no SCIn_RXI interrupt request occurs. Instead, an SCIn_ERI interrupt request occurs. Note that when the SYER flag is set to 1, the subsequently received data is not transferred to the RDR register.

– When MCR.SYEREN = 0
The received data is transferred to the RDR register and an SCIn_RXI interrupt request occurs. An SCIn_ERI interrupt request is not generated. The subsequent receive operations are not affected even with the SYER flag is set to 1.

[Clearing condition]

- Writing 1 to MFCLR.SYERC.

SBER bit (Start Bit Error Flag)

The SBER bit indicates that a start bit error was detected when receiving frames in Manchester mode.

Even when the RE bit in CCR0 is set to 0 (serial reception is disabled), the SBER flag is not affected and retains its previous value.

[Setting condition]

- When detecting a start bit error when receiving frames in Manchester mode
The following operations are performed when a start bit error occurs.
  – When MCR.SBEREN = 1
  The received data is not transferred to the RDR register and no SCIn_RXI interrupt request occurs. Instead, an SCIn_ERI interrupt request occurs. Note that when the SBER flag is set to 1, the subsequently received data is not transferred to the RDR register.
  – When MCR.SBEREN = 0
  The received data is transferred to the RDR register and an SCIn_RXI interrupt request occurs. An SCIn_ERI interrupt request is not generated. The subsequent receive operations are not affected even with the SBER flag is set to 1.

[Clearing condition]

- Writing 1 to MFCLR.SBERC.

MER bit (Manchester Error Flag)

When data is received in Manchester mode, Manchester error is detected and displayed. Even when the RE bit in CCR0 is set to 0 (serial reception is disabled), the MER flag is not affected and retains its previous value.

[Setting conditions]

- When receiving in Manchester mode and detecting Manchester code error in data area of received frame.
Received data when an error occurs is transferred to the RDR register, but the SCIn_RXI interrupt request is not generated and the SCIn_ERI interrupt request is generated.
When the Manchester error flag is set to 1, subsequent receive data is not transferred to the RDR register.
For details on Manchester error, section 28.5.11. Errors in Manchester Mode.

[Clearing condition]

- Writing 1 to MFCLR.MERC.

RSYNC bit (Receive SYNC Data Bit)

When Manchester mode (CCR3.MOD[2:0] = 101b) and MCR.SBSEL = 1, this bit indicates the type of SYNC of the received start bit. For other settings, it is fixed to 0.

28.2.22 XSR0 : Simple LIN Status Register 0

Base address: SCIn_B = 0x4035_8000 + 0x0100 × n (n = 0, 1)
SCIn_B_NS = 0x5035_8000 + 0x0100 × n (n = 0, 1)

Offset address: 0x5C

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	CF1RD[7:0]								CF0RD[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	AEDF	COF	PIBDF	CF1MF	CF0MF	BFDF	BCDF	BFOF	—	—	—	—	—	—	RXDSF	SFSF
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	SFSF	Start Frame Status Flag 0: Start Frame detection disabled or Start Frame detection complete 1: Before Start Frame detection or during detection	R*1
1	RXDSF	RXDn Input Status Flag 0: RXDn input to SCI is enabled 1: RXDn input to SCI is disabled	R*1
7:2	—	These bits are read as 0.	R
8	BFOF	Break Field Output Completion Flag 0: Break Field is being output or is not being output 1: Completed BF output	R
9	BCDF	Bus Conflict Detection Flag 0: No bus collision detected 1: Detected a bus collision	R
10	BFDF	Break Field Detection Flag 0: Break Field is not detected 1: Break Field is detected	R
11	CF0MF	Control Field 0 Compare Match Flag 0: Control Field 0 received data does not match the setting data 1: Control Field 0 received data matches the setting data	R
12	CF1MF	Control Field 1 Compare Match Flag 0: Control Field 1 received data does not match the setting data 1: Control Field 1 received data matches the setting data	R
13	PIBDF	Priority Interrupt Bit Detection Flag 0: Priority interrupt bit is not detected 1: Priority interrupt bit is detected	R
14	COF	Counter Overflow Flag 0: Break Field detection counter has not overflowed 1: Break Field detection counter overflowed	R
15	AEDF	Active Edge Detection Flag 0: No valid edge detected 1: Detected a valid edge	R
23:16	CF0RD[7:0]	Control Field 0 received data Control Field 0 received data.	R
31:24	CF1RD[7:0]	Control Field 1 received data Control Field 1 received data.	R

Note: S-TYPE-3, P-TYPE-3

Note 1. When PCLK is faster than TCLK, the flag set timing is delayed from the receive data full interrupt (SCIn_RXI) output. To see this flag under these conditions, wait at least 1 TCLK cycle after the receive data full interrupt (SCIn_RXI) before reading this register.

SFSF bit (Start Frame Status Flag)

Indicates whether detect Start Frame is being detected.

[Setting condition]

- When 1 is written to XCR1.SDST.
- When a Break Field is detected in the Control Field 0/Control Field 1/Information Field phase and the transition to the Control Field 0 or Control Field 1 reception state occurs.

[Clearing condition]

- When XCR1.SDST is 0.
- When Start Frame detection is completed.

RXDSF bit (RXDn Input Status Flag)

Indicates the RXDn input status to the SCI core. When the RXDSF bit is 1, RXDn input is received only by the simple LIN module and the Break Field is detected and is not input to the SCI core.

BFOF bit (Break Field Output Completion Flag)

Indicates the completion of Break Field output.

The BFOF bit can be cleared to 0 by writing 1 to XFCLR.BFOC.

BCDF bit (Bus Conflict Detection Flag)

Indicates the detection of bus conflict in Simple LIN transmit operation.

The BCDF bit can be cleared to 0 by writing 1 to XFCLR.BCDC.

BFDF bit (Break Field Detection Flag)

Indicates Break Field detection.

The BFDF bit can be cleared to 0 by writing 1 to XFCLR.BFDC.

CF0MF bit (Control Field 0 Compare Match Flag)

Indicates compare match of Control Field 0 and compare data.

The CF0MF bit can be cleared to 0 by writing 1 to XFCLR.CF0MC.

CF1MF bit (Control Field 1 Compare Match Flag)

Indicates compare match detection of Control Field 1 and compare data.

The CF1MF bit can be cleared to 0 by writing 1 to XFCLR.CF1MC.

PIBDF bit (Priority Interrupt Bit Detection Flag)

Indicates compare match detection of Control Field 1 and priority interrupt bit.

The PIBDF bit can be cleared to 0 by writing 1 to XFCLR.PIBDC.

COF bit (Counter Overflow Flag)

Indicates that the 16-bit counter in the simple LIN module has overflowed.

The COF bit can be cleared to 0 by writing 1 to XFCLR.COFC.

AEDF bit (Active Edge Detection Flag)

Indicates active edge detection.

The AEDF bit can be cleared to 0 by writing 1 to XFCLR.AEDC and when read out XSR1.TCNT[15:0].

CF0RD[7:0] bits (Control Field 0 received data)

Stores the received data with a Control Field 0 match detected.

CF1RD[7:0] bits (Control Field 1 received data)

Stores the received data with a Control Field 1 match detected.

28.2.23 XSR1 : Simple LIN Status Register 1

Base address: SCIn_B = 0x4035_8000 + 0x0100 × n (n = 0, 1)
SCIn_B_NS = 0x5035_8000 + 0x0100 × n (n = 0, 1)

Offset address: 0x60

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	TCNT[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	TCNT[15:0]	Timer Count Capture Value Stores the 16-bit counter capture value. The initial value is 0000.	R
31:16	—	These bits are read as 0.	R

Note: S-TYPE-3, P-TYPE-3

TCNT[15:0] bits (Timer Count Capture Value)

Stores the capture value of the 16-bit counter of the Simple LIN module.

- When sending Start Frame
  The XSR1 holds the previous value.
- When receiving Start Frame with bit rate measurement disabled
  If a Break Field is detected in the Break Field detection state (see Figure 28.81), the Break Field length is captured and held (counter value is captured at the rising edge of RXDn). If a Break Field is detected in a state other than the Break Field detection state, the previous value is retained.
  If the counter overflows, it is not captured.
- When receiving Start Frame with bit rate measurement enabled
  The count value is captured and held at the valid edge (both RXDn edges). However, in the Break Field detection state, the count value is not captured even if a valid edge occurs. Counter capture value retention is canceled by the XSR1 read. Even if a valid edge occurs before reading, the counter value is not captured.

28.2.24 CFCLR : Common Flag Clear Register

Base address: SCIn_B = 0x4035_8000 + 0x0100 × n (n = 0 to 4, 9)
SCIn_B_NS = 0x5035_8000 + 0x0100 × n (n = 0 to 4, 9)

Offset address: 0x68

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	RDRFC	—	TDREC	FERC	PERC	MFFC	—	ORERC	—	—	—	—	—	DFERC	DPERC	DCMFC
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	ERSC	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
3:0	—	The write value should be 0.	W
4	ERSC	ERS Clear Bit Setting this bit to 1 clears the CSR.ERS bit. The read value is always 0.	W
15:5	—	The write value should be 0.	W
16	DCMFC	DCMF Clear Bit Setting this bit to 1 clears the CSR.DCMF bit. The read value is always 0.	W
17	DPERC	DPER Clear Bit Setting this bit to 1 clears the CSR.DPER bit. The read value is always 0.	W
18	DFERC	DFER Clear Bit Setting this bit to 1 clears the CSR.DFER bit. The read value is always 0.	W
23:19	—	The write value should be 0.	W
24	ORERC	ORER Clear Bit Setting this bit to 1 clears the CSR.ORER bit. The read value is always 0.	W
25	—	The write value should be 0.	W
26	MFFC	MFF Clear Bit Setting this bit to 1 clears the CSR.MFF bit. The read value is always 0.	W
27	PERC	PER Clear Bit Setting this bit to 1 clears the CSR.PER bit. The read value is always 0.	W
28	FERC	FER Clear Bit Setting this bit to 1 clears the CSR.FER bit. The read value is always	W
29	TDREC	TDRE Clear Bit Setting this bit to 1 clears the CSR.TDRE bit. The read value is always 0.	W
30	—	The write value should be 0.	W
31	RDRFC	RDRF Clear Bit Setting this bit to 1 clears the CSR.RDRF bit. The read value is always 0.	W

0	RIST	RE Internal Status 0: RE signal internal state value 0 1: RE signal internal state value 1	R
3:1	—	These bits are read as 0.	R

Bit	Symbol	Function	R/W
4	TIST	TE Internal Status 0: TE signal internal state value 0 1: TE signal internal state value 1	R
7:5	—	These bits are read as 0.	R

Note: S-TYPE-3, P-TYPE-3

The operation clocks of the communication module and control register can be used asynchronously. Since some control register values are transmitted internally through the synchronization circuit so that they operate correctly even if they are asynchronous, it takes some time for the state to be reflected internally after rewriting the control register.

Communication enable CCR0.TE and CCR0.RE correspond to this register, and when these control bits change from 1 to 0 to rewrite the control bits for the next communication, the TE and RE bits signal it is necessary to rewrite the next control bit after the internal state becomes 0. If a very slow clock is used for the communication module clock, the TE and RE bit states are not reflected internally. At this time, you can check the internal status using this register.

28.3 Operation in Asynchronous Mode

Figure 28.6 shows the general format for asynchronous serial communications. One frame consists of a start bit (low level), transmit or receive data, a parity bit, and stop bits (high level). In asynchronous serial communications, the communications line is usually held in the mark state (high level).

The SCI monitors the communications line. When the SCI detects a start bit, it starts serial communication. The detection condition of the start bit changes according to the CCR3.RXDESEL setting. SCI regards space (Low level) as a start bit when CCR3.RXDESEL is 0. SCI regards a fall edge as a start bit when RXDESEL is 1.

Inside the SCI, the transmitter and receiver are independent units, enabling full-duplex communications. Both the transmitter and receiver have a double-buffered structure in addition to FIFO mode, so that data can be read or written during transmission or reception, enabling continuous data transmission and reception.

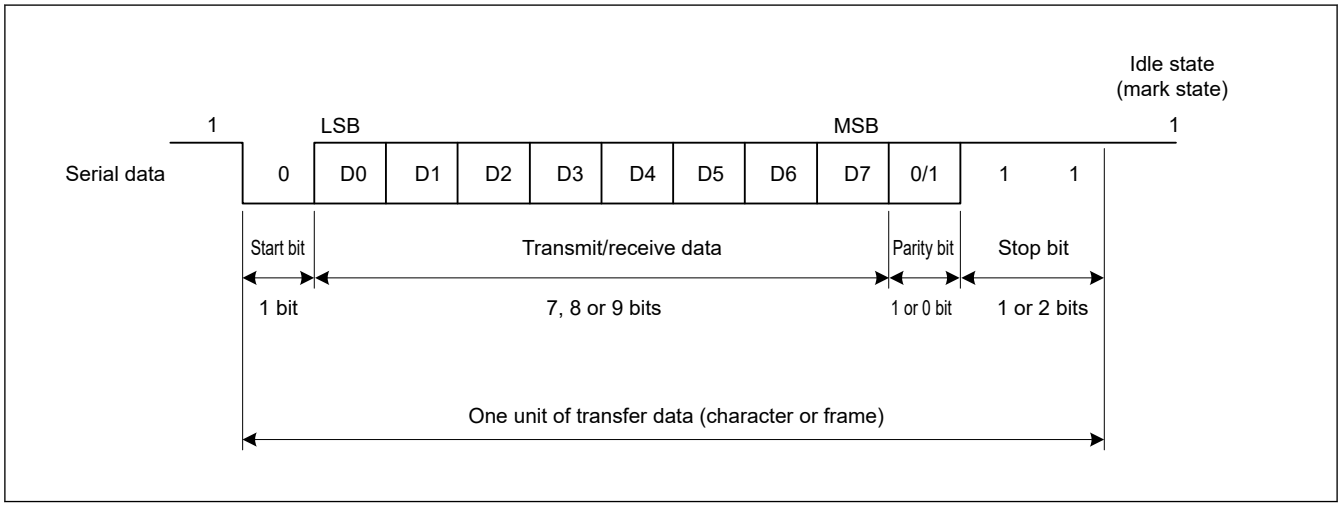

Figure 28.6 Data format in asynchronous serial communications with 8-bit data, parity bit, and 2 stop bits

28.3.1 Serial Data Transfer Format

Table 28.28 lists the serial data transfer formats that can be used in Asynchronous mode. Any of 18 transfer formats can be selected with the CCR1 and CCR3 settings. For details on the multi-processor function, see section 28.4. Multi-Processor Communication Function.

Table 28.28 Serial transfer formats in Asynchronous mode

CCR3		CCR1		CCR3	Serial transfer format and frame length
CHR[1:0]		PE	MP	STP	1 2 3 4 5 6 7 8 9 10 11 12 13
0	0	0	0	0	ST 9-bit data SP
0	0	0	0	1	ST 9-bit data SP SP
0	0	1	0	0	ST 9-bit data P SP
0	0	1	0	1	ST 9-bit data P SP SP
1	0	0	0	0	ST 8-bit data SP
1	0	0	0	1	ST 8-bit data SP SP
1	0	1	0	0	ST 8-bit data P SP
1	0	1	0	1	ST 8-bit data P SP SP
1	1	0	0	0	ST 7-bit data SP
1	1	0	0	1	ST 7-bit data SP SP
1	1	1	0	0	ST 7-bit data P SP
1	1	1	0	1	ST 7-bit data P SP SP
0	0	—	1	0	ST 9-bit data MPB SP
0	0	—	1	1	ST 9-bit data MPB SP SP
1	0	—	1	0	ST 8-bit data MPB SP
1	0	—	1	1	ST 8-bit data MPB SP SP
1	1	—	1	0	ST 7-bit data MPB SP
1	1	—	1	1	ST 7-bit data MPB SP SP

ST: Start bit
SP: Stop bit
P: Parity bit
MPB: Multi-processor bit

28.3.2 Receive Data Sampling Timing and Reception Margin in Asynchronous Mode

In Asynchronous mode, the SCI operates on a base clock with a frequency of 16 times[*1] the bit rate.

In reception, the SCI samples the falling edge of the start bit using the base clock, and performs internal synchronization.[*2]

Because receive data is sampled on the rising edge of the 8th pulse[*1] of the base clock, data is latched at the middle of each bit (when sampling timing does not adjust (CCR4.ASEN = 0 or CCR4.ASEN = 1 and CCR4.AST[2:0] = 000b)), as shown in Figure 28.7 The reception margin in Asynchronous mode is determined by the following formula (1):

$$M = \left|\left(0.5 - \frac{1}{2N}\right) - (L - 0.5)F - \frac{|D - 0.5|}{N}(1 + F)\right| \times 100\ [\%] \quad \ldots \quad \text{Formula (1)}$$

Note: M: Reception margin

N: Ratio of bit rate to clock

See Table 28.6 for bit rate to basic clock ratios.

D: Duty cycle of clock (D = 0.5 to 1.0)

L: Frame length (L = 9 to 13)

F: Absolute value of clock frequency deviation

Assuming values of F = 0 and D = 0.5 in formula (1), the reception margin is determined using the following formula:
$M = \{0.5 - 1/(2 \times 16)\} \times 100\ (\%) = 46.875\ \%$

This represents the computed value. Renesas recommends a margin of 20% to 30% in system design.

Note 1. This is an example when CCR2.ABCS is 0, CCR2.ABCSE is 0 and CCR2.ABCSE2 is 0. When CCR2.ABCS is 1, CCR2.ABCSE is 0 and CCR2.ABCSE2 is 0, a frequency of 8 times the bit rate is used as a base clock and receive data is sampled at the rising edge of the 4th pulse of the base clock. When CCR2.ABCSE is 1 and CCR2.ABCSE2 is 0, a frequency of 6 times the bit rate is used as a bas clock and receive data is sampled at the rising edge of the 3rd pulse of the base clock. When CCR2.ABCSE is 0 and CCR2.ABCSE2 is 1, a frequency of 4 times the bit rate is used as a base clock and receive data is sampled at the rising edge of the 2nd pulse of the base clock.

Note 2. The determination condition of the start bit is as follows.

The function of adjust sampling timing is OFF (ASEN = 0):

The determination condition of a start bit is that Low beyond half bit length continues. It is same as the sampling timing. In Figure 28.7, Low period should be kept over 8-cycles to detect a start bit. If Low period does not keep over 8-cycles, the SCI judges this as a noise. So, the SCI does not start reception and wait start bit.

The function of adjust sampling timing is ON (ASEN = 1):

The determination condition of a start bit is that Low keeps up until the sampling timing. Adjusting the sampling timing forward (AJD = 1) increases the possibility of erroneously determining a noise as the start bit.

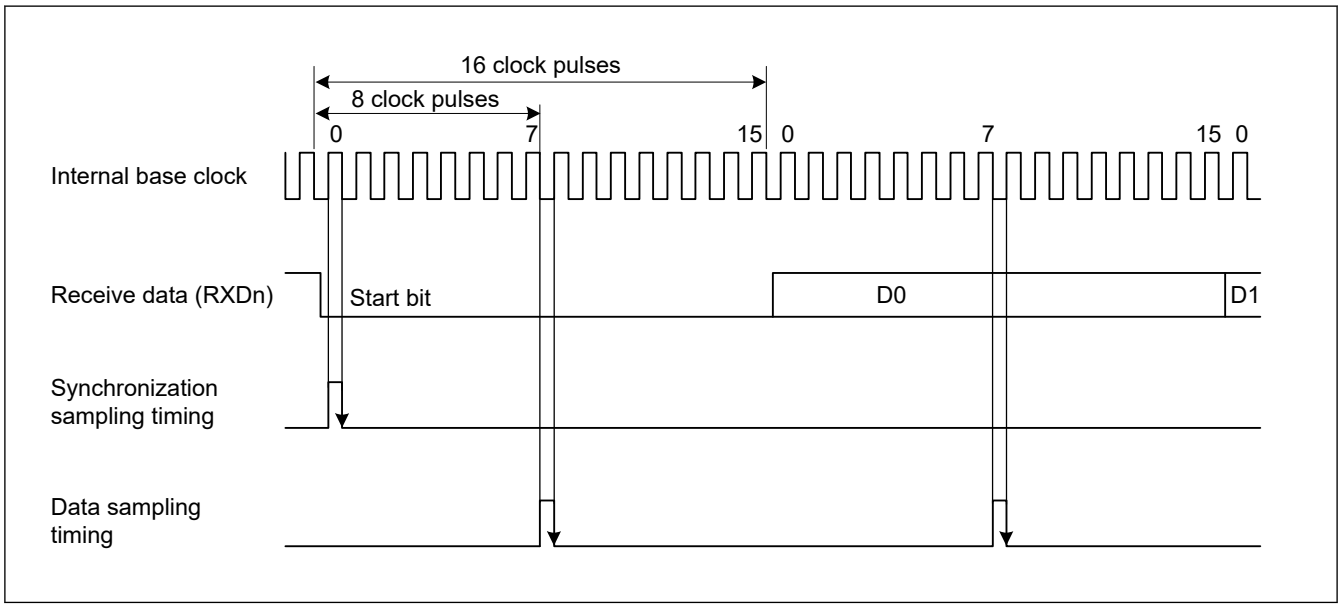

Figure 28.7 Receive data sampling timing in Asynchronous mode

28.3.3 Clock

Either an internal clock generated by the on-chip baud rate generator or an external clock input to the SCKn pin can be selected as the transfer clock of the SCI, based on the CCR3.CKE[1:0] settings.

When an external clock is input to the SCKn pin, the clock frequency must be 16 times the bit rate (when CCR2.ABCS = 0) or 8 times the bit rate (when CCR2.ABCS = 1).

In addition, when an external clock is specified, the base clock of GPTn (n = 3, 4, 6, 7) can be selected by the CCR2.ACS0.

When the SCI uses its internal clock, the clock can be output from the SCKn pin. The frequency of the clock output in this case is equal to the bit rate, and the phase is configured so that the rising edge of the clock is in the middle of the transmit data, as shown in Figure 28.8.

When the internal clock is selected, the SCKn pin is outputted after setting the CCR0.TE or CCR0.RE bit to 1.

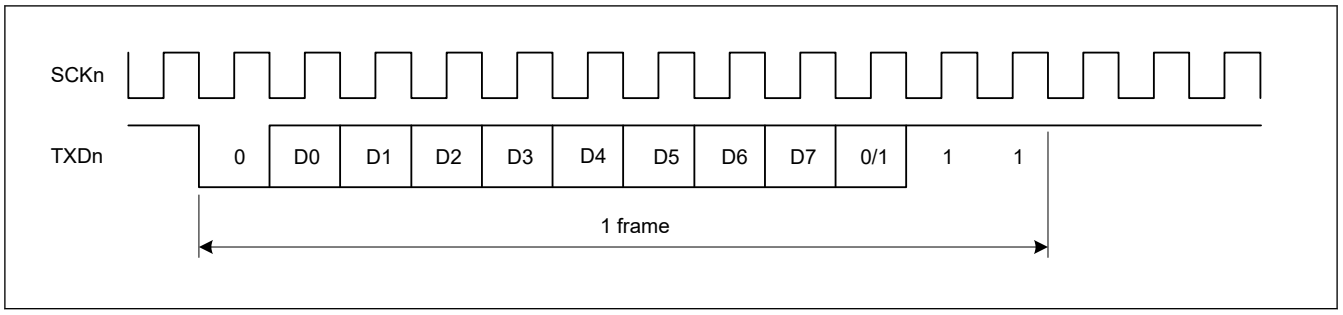

Figure 28.8 Phase relationship between output clock and transmit data in Asynchronous mode when CCR1.PE = 1, CCR3.CHR[1:0] = 10b, MP = 0, and STP = 1

28.3.4 Double-Speed Operation and Frequency of 6 or 4 Times the Bit Rate

When the CCR2.ABCS bit is set to 1, the SCI operates on the bit rate twice that of when ABCS is set to 0. When the CCR2.BGDM bit is set to 1, the cycle of the base clock is half and the bit rate is double that of when BGDM is set to 0. When the CCR3.CKE[1] bit is set to 0 and the on-chip baud rate generator is selected, setting the ABCS and BGDM bits to 1 allows the SCI to operate at a bit rate four times that when the ABCS and BGDM bits are set to 0.

When CCR2.ABCSE is set to 1 and CCR2.ABCSE2 is set to 0, the number of base clock pulses are 6 during a period of 1 bit, and the base clock frequency is half. And RSCI works 16/3 times of bit rate compared with a case of CCR2.ABCS = 0, CCR2.BGDM = 0, CCR2.ABCSE = 0 and CCR2.ABCSE2 = 0.

When CCR2.ABCSE is set to 1 and CCR2.ABCSE2 is set to 1, the number of base clock pulses are 4 during a period of 1 bit, and the base clock frequency is half. And RSCI works 8 times of bit rate compared with a case of CCR2.ABCS = 0, CCR2.BGDM = 0, CCR2.ABCSE = 0 and CCR2.ABCSE2 = 0.

As shown by Formula (1) in section 28.3.2. Receive Data Sampling Timing and Reception Margin in Asynchronous Mode, the reception margin decreases when CCR2.ABCS is set to 1, CCR2.ABCSE is set to 1 or CCR2.ABCSE2 is set to 1. Therefore, if the desired bit rate can be obtained, it is recommended to use the RSCI with CCR2.ABCS set to 1, CCR2.ABCSE set to 1 and CCR2.ABCSE2 set to 1.

28.3.5 CTS and RTS Functions

The CTS function controls transmission using the CTSn pin input. Setting the CCR1.CTSE bit to 1 enables the CTS function. For the functions of CTS and RTS, you can select the alternate setting to set CTSn_RTSn pin as a multiplexed pin that uses either function with one pin or the dedicated setting that uses each function independently with two pins at CTSn pin for CTSn signal and CTSn_RTSn pin for RTSn signal. This setting is done with the CCR1.CTSPEN bit.

When the CTS function is enabled, placing a low level on the CTSn_RTSn pin causes transmission to start.

If FIFO is used and CTSn_RTSn signal is held high before transmission, transmission will not start, so the number of TDR registers written, and the number of data stored are the same (unlike using clock synchronous FIFO).

Driving the CTSn_RTSn pin high while transmission is in progress does not affect transmission of the current frame.

In the RTS function, which uses output on the CTSn_RTSn pin, a low level is output when reception becomes possible. Conditions for output of the low and high levels are shown in this section.

[Conditions for low level output]

Satisfaction of all conditions are listed in this section.

Non-FIFO selected

- The value of the CCR0.RE bit is 1
- When the next reception is possible
  - There are no received data yet to be read and not receiving.
  - CSR.ORER, FER, PER flags are all 0

FIFO selected

- The value of the CCR0.RE bit is 1
- When the next reception is possible
  - When the quantity of receive data written in receive-FIFO(RDR) are less than the setting value of FCR.RSTRG[4:0]
  - CSR.ORER(RDR.ORER) is 0

[Condition for high level output]

- The conditions for low-level output are not satisfied

28.3.6 Address Match (Receive Data Match Detection) Function

The address match function can be used only in Asynchronous mode.

If the CCR0.DCME bit is set to 1[*2], when one frame of data is received, the SCI compares that received data with the data set in CCR4.CMPD. If the SCI detects a match to the comparison data (CCR4.CMPD[*1]) with the received data, the SCI can issue the SCIn_RXI interrupt request.

If the CCR3.MP bit is set to 0, comparison occurs only for valid data in receive format. In multi-processor mode (CCR3.MP bit = 1), if the CCR0.IDSEL bit is set to 1, receive data where the MPB bit is 1 is subject to comparison for address match and receive data where the MPB bit is 0 is always treated as a non-match.

If the CCR0.IDSEL bit is set to 0, SCI performs address match detection regardless of the MPB bit value of the received data.

Until SCI detects a match to the comparison data (CCR4.CMPD[*1]) with receive data, received data is skipped (discarded), and the SCI cannot detect a parity error or framing error.

When SCI detects a match, the CCR0.DCME bit is automatically cleared, and the CSR.DCMF flag is set to 1. If the CCR0.IDSEL bit is set to 1, the CCR0.MPIE bit is automatically cleared. If CCR0.IDSEL is set to 0, the value of the CCR0.MPIE bit is retained. If the CCR0.RIE bit is set to 1, the SCI issues an SCIn_RXI interrupt request.

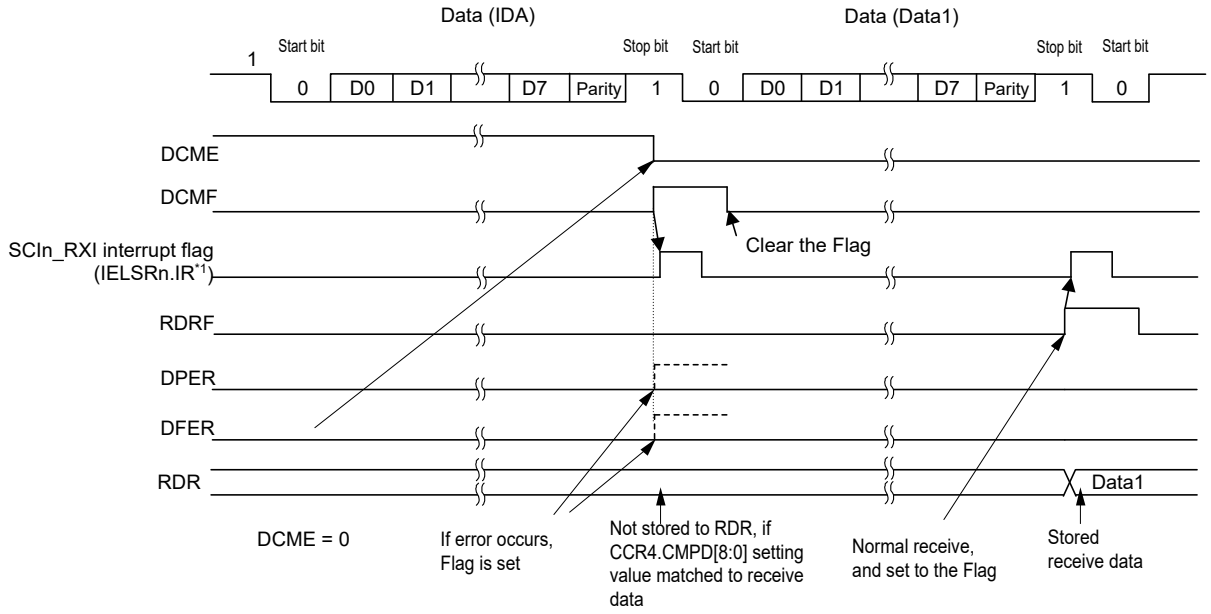
If the SCI detects a framing error in the receive data for which a match is detected, the CSR.DFER flag is set to 1, and if the SCI detects a parity error in that frame, the CSR.DPER flag is set to 1. The compared receive data and MPB bit is not stored in the RDR register, and CSR.RDRF remains 0.

After the SCI detects a match, and CCR0.DCME is automatically cleared, the SCI receives the next data continuously based on the current register setting.

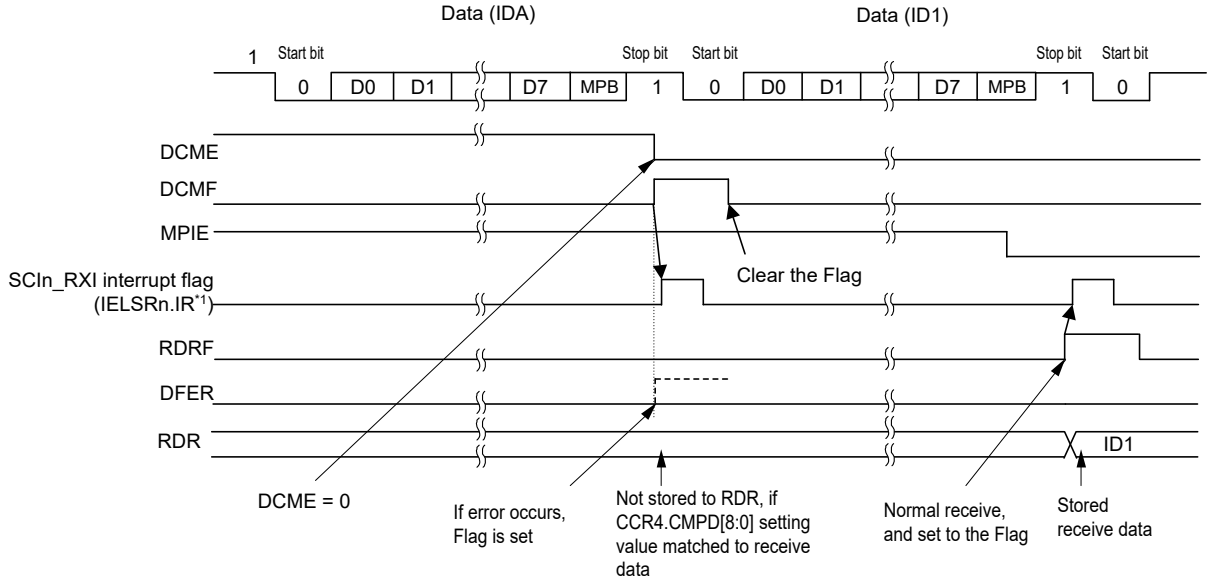
When the CSR.DFER or CSR.DPER flag is set, the address match is not performed. Before enabling the address match function, set the CSR.DFER and CSR.DPER flags to 0.

Examples of the address match function are shown in Figure 28.9 and Figure 28.10.

Note 1. This comparative target can select one length of 3 types: CMPD[6:0] with 7-bit length, CMPD[7:0] with 8-bit length, and CMPD[8:0] with 9-bit length.
Note 2. Set the CCR0.DCME bit to 1 before receiving the start bit of the received frame that performs address matching.



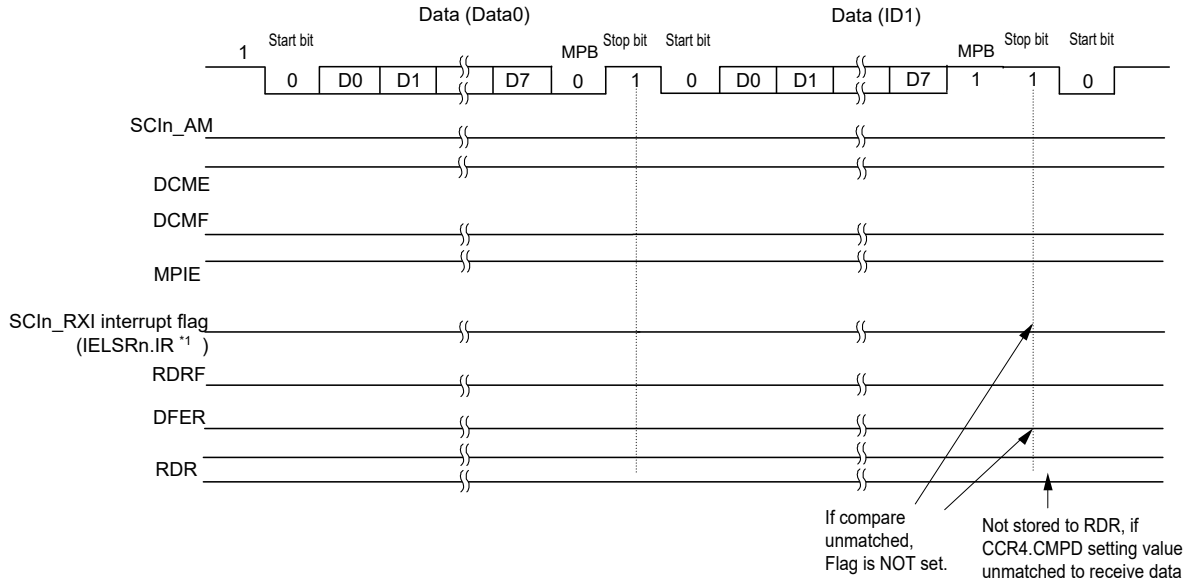
(a) Example of Compare matched between receive data and CCR4.CMPD[8:0] (8bit length/parity/Normal mode)



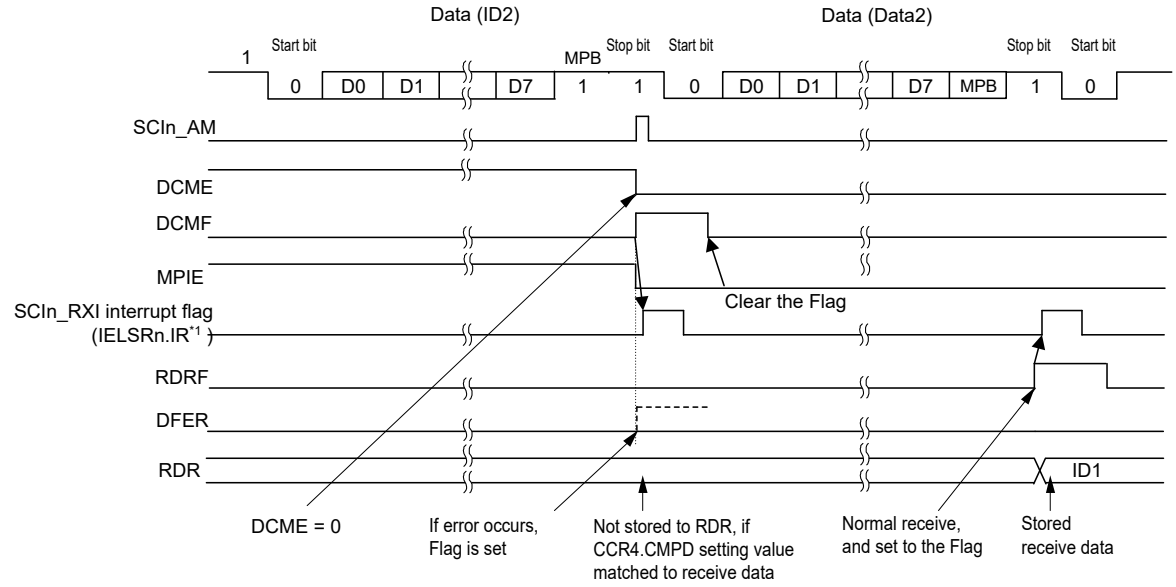
(b) Example of Compare matched between receive data and CCR4.CMPD[8:0] (8bit length/Multi-processor mode)

Note 1. See section 12, Interrupt Controller Unit (ICU) for information on the corresponding interrupt event number.

Figure 28.9 Example of address match (1) normal mode and multi-processor mode



(a) Example of Compare unmatched between receive data and CCR4.CMPD (8bit length/IDSEL = 1/Multi-processor mode)



(b) Example of Compare matched between receive data and CCR4.CMPD (8bit length/IDSEL = 1/Multi-processor mode)

Note 1. See section 12, Interrupt Controller Unit (ICU) for information on the corresponding interrupt event number.

Figure 28.10 Example of address match (2) multi-processor mode

28.3.7 SCI Initialization in Asynchronous Mode

Before transmitting and receiving data, start by writing the initial value 0 to the CCR0.TE and CCR0.RE (or writing the initial value to CCR0), then continue through the SCI initialization procedure (select non-FIFO or FIFO) shown in Table 28.29 and Table 28.30. Whenever the operating mode or transfer format is to be changed, the CCR0.TE and CCR0.RE bits must be initialized before the change is made.

When the external clock is used in Asynchronous mode, ensure that the clock signal is supplied during initialization.

Note: Setting the CCR0.RE bit to 0 initializes neither the ORER, FER, RDRF, RDAT, PER, and DR flags in CSR nor RDR. When FIFO selected, even if the TE bit is set as 0, the TEND flag for the selected FIFO buffer is not initialized.

Please be also careful at the time of change in the operation mode.

Note: Switching the value of the CCR0.TE bit from 0 to 1 while the CCR0.TIE bit is 1 leads to the generation of an SCIn_TXI interrupt request.

Table 28.29 Example flow of SCI initialization in Asynchronous mode with non-FIFO selected

No.	Step Name	Description
1	Start initialization	—
2	Set CCR0	Set CCR0.TEIE, TIE, RIE, TE, RE to 0. If you have not changed from the initial settings, you can skip this step.
3	Set CCR3	Set up following function and communication mode. Driver control function for RS-485, FIFO no-use, Multi-Processor mode, Communication mode (MOD[2:0] = 000b) Transmission / reception format Clock enable (Leave the initial value when outputting the clock) Leave unused bits at their initial values.
4	Set CCR2	Set up the bit-rate-modulation function*1 *2, select clock, set bit rate*2
5	Set CCR1	Set up the Noise-filter function, the loop-back function, communication pin status, the parity check function, and the CTSn_RTSn function.
6	Set CCR4	Set up the adjust sampling timing function and the adjust transmit timing function.
7	Set the I/O port functions	Make I/O port settings to enable input and output functions as required for TXDn, RXDn, and SCKn pins.
8	Set CCR3	Set clock enable bit (CKE[1:0]) at this step when outputting the clock. After this register setting, the clock pin will be in the output state immediately.
9	Set CFCLR	Write 1 to the following bits and clear the corresponding flag. CFCLR.RDRFC, FERC, PERC, MFFC, ORERC, DFERC, DPERC, DCMFC, ERSC If it's initialization flow after a reset, you can skip this step.
10	Set CCR0	Set the TE or RE bit to 1. To enable interrupts, set the TE bit and TIE bit, and the RE bit and RIE bit to 1 with one instruction at the same time. Setting the TE and RE bits allows TXDn and RXDn to be used.
11	Initialization completed	—

Note 1. If you do not use the bit rate modulation function, you do not need to set it.
Note 2. If you use an external clock, you do not need to set it.

Table 28.30 Example flow of SCI initialization in Asynchronous mode with FIFO selected (1 of 2)

No.	Step Name	Description
1	Start initialization	—
2	Set CCR0	Set CCR0.TEIE, TIE, RIE, TE, RE to 0. If you have not changed from the initial settings, you can skip this step.
3	Set CCR3	Set up following function and communication mode. Driver control function for RS-485, FIFO use, Multi-Processor mode, Communication mode (MOD[2:0] = 000b) Transmission / reception format Clock enable (Leave the initial value when outputting the clock) Leave unused bits at their initial values.
4	Set CCR2	Set up the bit-rate-modulation function*1 *2, select clock, set bit rate*2
5	Set CCR1	Set up the Noise-filter function, the loop-back function, communication pin status, the parity check function, and the CTSn_RTSn function.
6	Set CCR4	Set up the adjust sampling timing function and the adjust transmit timing function.
7	Set FCR	Set the TFRST and RFRST to 1 to empty FIFO. Set the DRES, TTRG[4:0], RTRG[4:0], and RSTRG[4:0] bits

Table 28.30 Example flow of SCI initialization in Asynchronous mode with FIFO selected (2 of 2)

No.	Step Name	Description
8	Set the I/O port functions	Make I/O port settings to enable input and output functions as required for TXDn, RXDn, and SCKn pins.
9	Set CCR3	If you select a clock output in Asynchronous mode, set the CKE[1:0] bit here. After setting the register, the clock pin will be in the output state immediately. But the clock operates after setting TE or RE to 1.
10	Set CFCLR	Write 1 to the following bits and clear the corresponding flag. CFCLR.RDRFC, FERC, PERC, MFFC, ORERC, DFERC, DPERC, DCMFC, ERSC If it's initialization flow after a reset, you can skip this step.
11	Set FFCLR	Write 1 to The FFCLR.BRKC, DRC and clear the corresponding flag. If it's initialization flow after a reset, you can skip this step.
12	Set CCR0	Set the TE or RE bit to 1. To enable interrupts, set the TE bit and TIE bit, and the RE bit and RIE bit to 1 with one instruction at the same time. Setting the TE and RE bits allows TXDn and RXDn to be used.
13	Initialization completed	—

Note 1. If you do not use the bit rate modulation function, you do not need to set it.
Note 2. If you use an external clock, you do not need to set it.

Figure 28.11 shows an example of the timing when data is transmitted after reset is released, and SCI is set to Asynchronous mode according to Table 28.29 or Table 28.30. As shown in the figure, when the pin function is set to the TXDn pin, the CCR0.TE bit is 0, so the pin is high impedance. When transmit data is written after setting the CCR0.TE bit to 1, data transmission starts. There is a transmission wait time from writing TDR to data transmission starts. In Asynchronous mode, TXDn is high during this period.

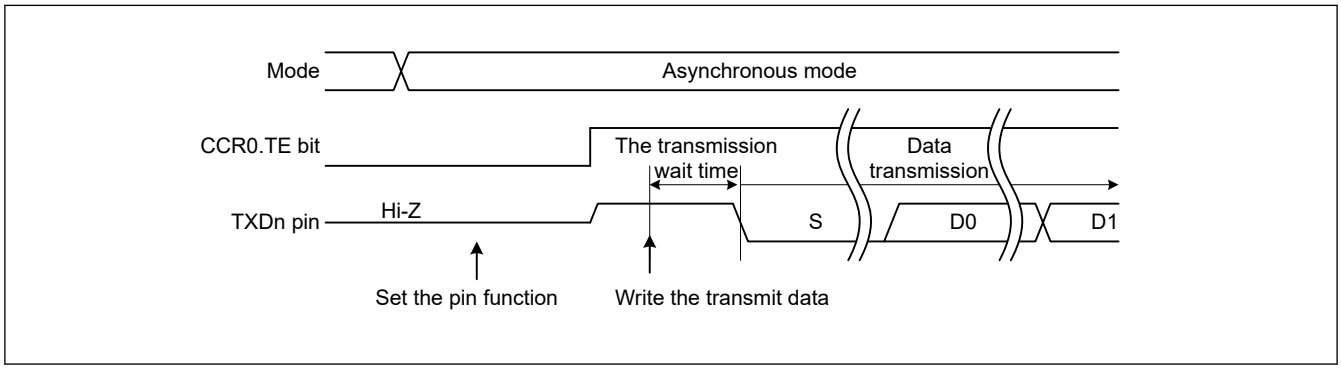


Figure 28.11 Data transmission timing example in Asynchronous mode

28.3.8 Serial Data Transmission in Asynchronous Mode

(1) Non-FIFO selected

Figure 28.12, Figure 28.13, Figure 28.14 and Figure 28.15 show examples of serial transmission in Asynchronous mode.

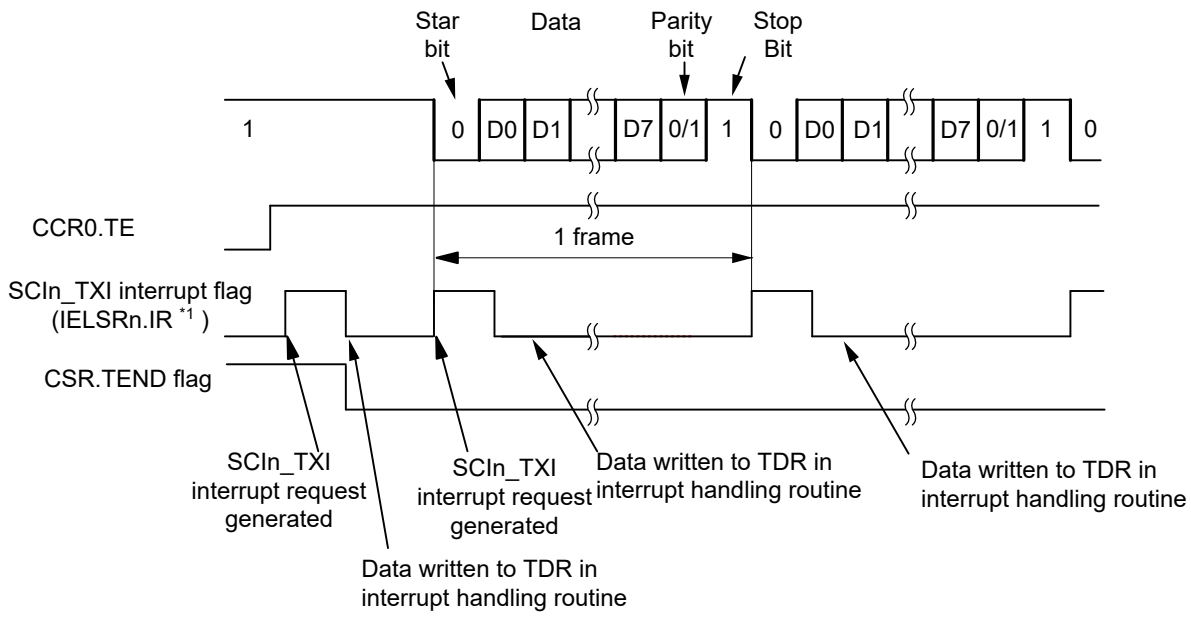
In serial transmission, the SCI operates as described in this section.

1. The SCI transfers data from the TDR register to the TSR register when data is written to TDR in the SCIn_TXI interrupt handling routine.
   The SCIn_TXI interrupt request at the beginning of transmission is generated when the CCR0.TE and CCR0.TIE bits are set to 1 simultaneously by a single instruction.
2. Transmission starts after the CCR1.CTSE bit is set to 0 (CTS function is disabled) or a low level on the CTSn_RTSn pin causes data transfer from the TDR register to the TSR register. If the CCR0.TIE bit is 1, an SCIn_TXI interrupt request is generated. Continuous transmission is possible by writing the next transmit data to the TDR register in the SCIn_TXI interrupt handling routine before transmission of the current transmit data is complete. When SCIn_TEI interrupt requests are in use, set the CCR0.TIE bit to 0 (SCIn_TXI interrupt requests are disabled) and the CCR0.TEIE bit to 1 (an SCIn_TEI interrupt request is enabled) after the last of the data to be transmitted is written to the TDR register from the handling routine for SCIn_TXI requests.
3. Data is sent from the TXDn pin in the following order:
   - Start bit

- Transmit data
- Parity bit or multi-processor bit (can be omitted depending on the format)
- Stop bit

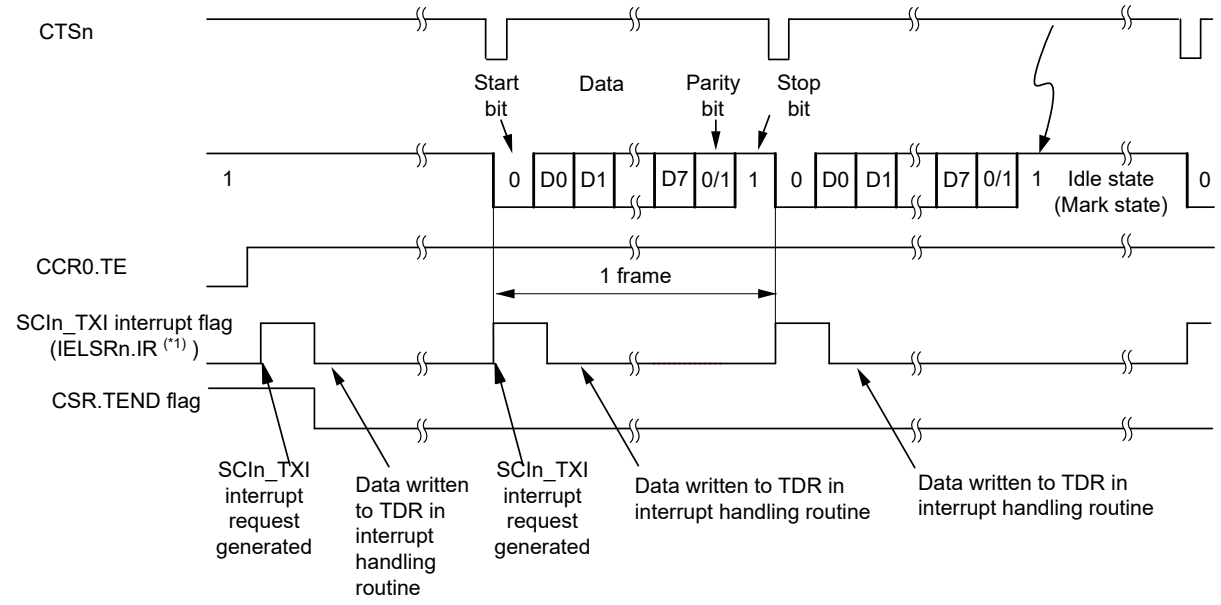
4. The SCI checks for update of the TDR register on output of the stop bit.
5. When the TDR register is updated, setting the CCR1.CTSE bit to 0 (CTS function is disabled) or a low level input on the CTSn_RTSn pin causes transfer of the next transmit data from the TDR register to the TSR register and transmission of the stop bit, after which serial transmission of the next frame starts.
6. If the TDR register is not updated, the CSR.TEND flag is set to 1, the stop bit is sent, and the mark state is entered, in which 1 is output. If the CCR0.TEIE bit is 1, the CSR.TEND flag is set to 1 and an SCIn_TEI interrupt request is generated.

Figure 28.12, Figure 28.13, Figure 28.14 and Figure 28.15 show examples of serial transmission in Asynchronous mode.



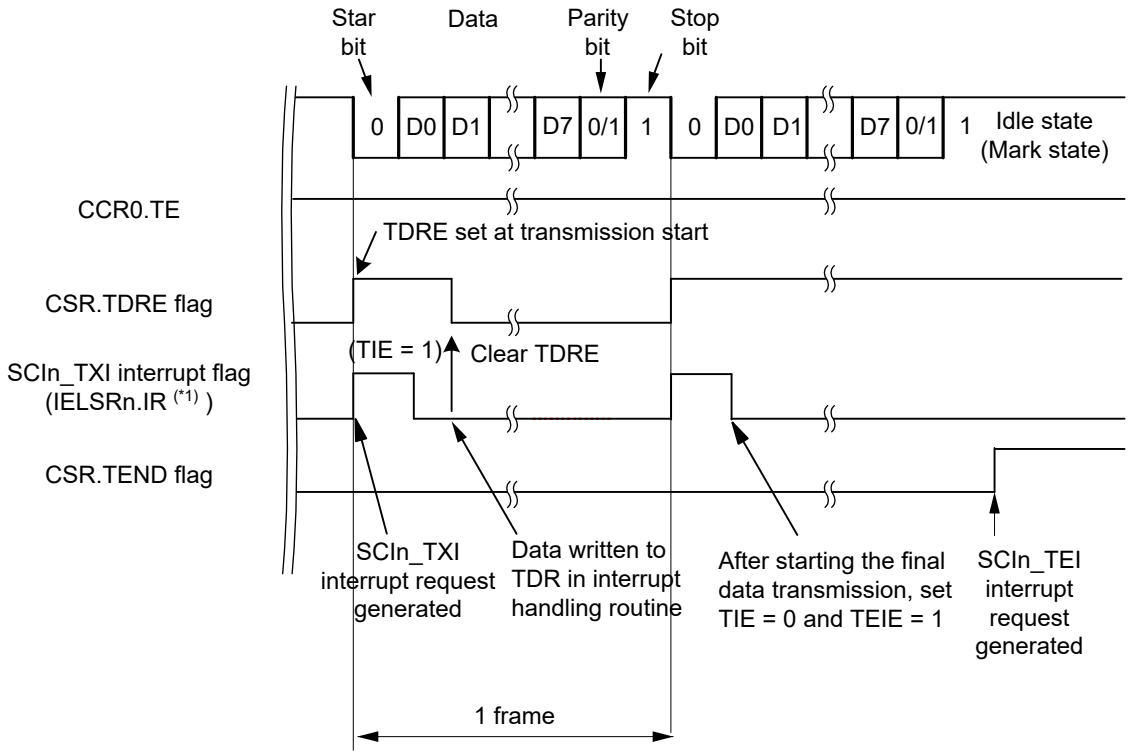
Note 1. See section 12, Interrupt Controller Unit (ICU) for information on the corresponding interrupt event number.

Figure 28.12 Example operation for serial transmission in Asynchronous mode (1) with 8-bit data, parity bit, 1 stop bit, CTS function not used, and at the beginning of transmission



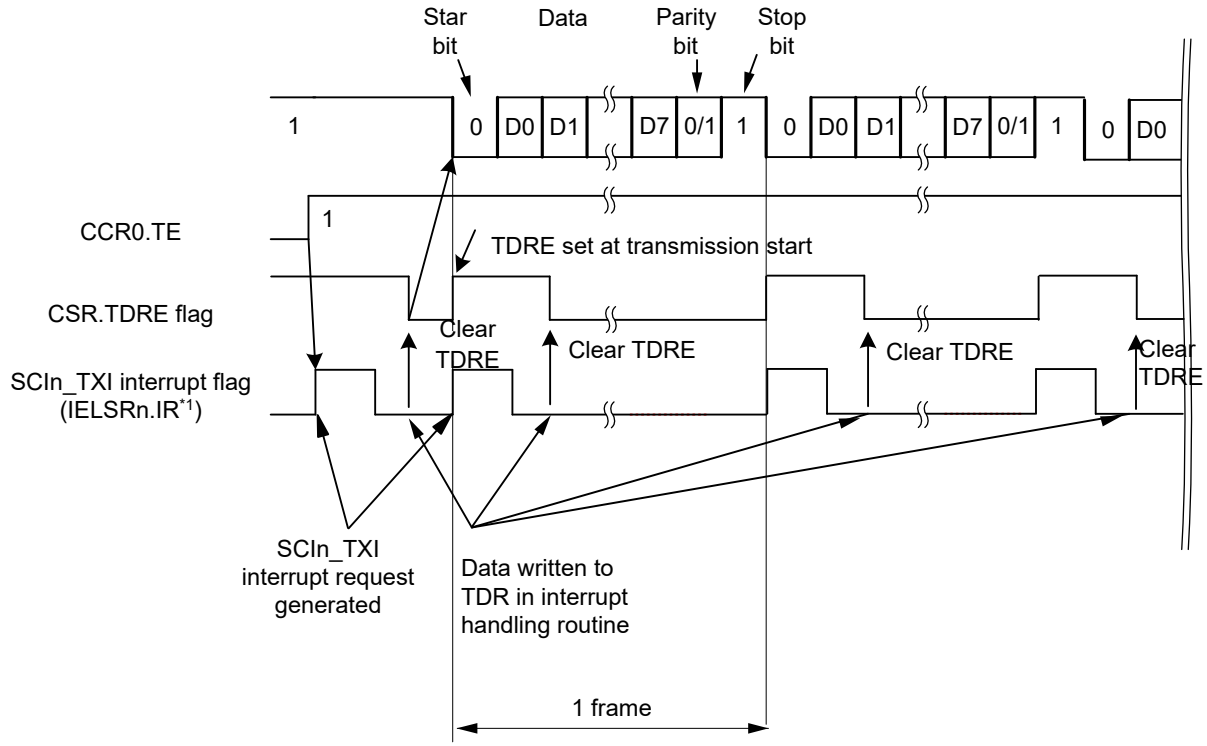
Note 1. See section 12, Interrupt Controller Unit (ICU) for information on the corresponding interrupt event number.

Figure 28.13 Example operation for serial transmission in Asynchronous mode (2) with 8-bit data, parity bit, one stop bit, CTS function used, and at the beginning of transmission



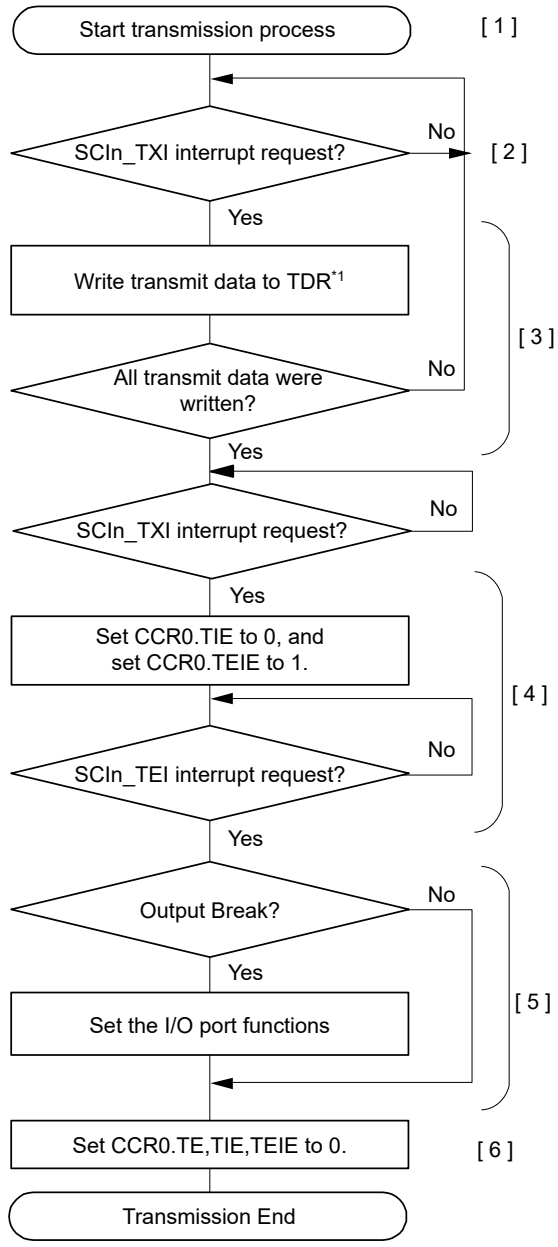
Note 1. See section 12, Interrupt Controller Unit (ICU) for information on the corresponding interrupt event number.

Figure 28.14 Example operation for serial transmission in Asynchronous mode (3) with 8-bit data, parity bit, one stop bit, CTS function not used, and from the middle of transmission until transmission completion



Note 1. See section 12, Interrupt Controller Unit (ICU) for information on the corresponding interrupt event number.

Figure 28.15 Example of Operation for Serial Transmission in Asynchronous Mode (4)(with 8-Bit Data, Parity, 1 Stop Bit, CTS Function Not Used, from the Middle of Transmission until Transmission Completion)



[1] Start transmission process

[2] SCIn_TXI interrupt request:
The transmit-data-empty-interrupt(SCIn_TXI) is generated at following conditions.
When set TE and TIE to 0 at same time.
When transmission-data forwards to TSR from TDR.

[3] Serial transmission continuation procedure:
To continue serial transmission write transmit data to TDR*1 once by using a SCIn_TXI.
Transmit data can also be written by activating the DMAC or DTC.

[4] If you use TEI, set TIE = 0 and TEIE = 1 after writing the last-transmit-data to TDR*1 and transmission is started.

[5] Break output at the end of serial transmission:
To output a break, it is necessary to set SPB2IO and SPB2DT, for output status setting when TE is 0.
(If you set these bits at initialization, you can skip this step.)

[6] Set CCR0.TE,TIE,TEIE to 0.

Note 1. In case of byte access with data length 9 bits, write transmit data in order of TDR[15:8] and TDR[7:0].

Figure 28.16 Example flow of serial transmission in Asynchronous mode with non-FIFO selected

(2) FIFO selected

Figure 28.17 shows an example of a data format that is written to TDR register in asynchronous mode with FIFO selected.

Data corresponding to the data length is set to TDR[8:0]. Write 0 for unused bits. Write in order from TDR[15:8] to TDR[7:0].

Data Length	Register setting		Transmit data in TDR[15:0]															
	CCR3.CHR[1:0]		b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
7 bit	1	1	–	–	–	–	–	–	MPBT	–	–	TDAT[6:0]						
8 bit	1	0	–	–	–	–	–	–	MPBT	–	TDAT[7:0]							
9 bit	0	Don't Care	–	–	–	–	–	–	MPBT	TDAT[8:0]								

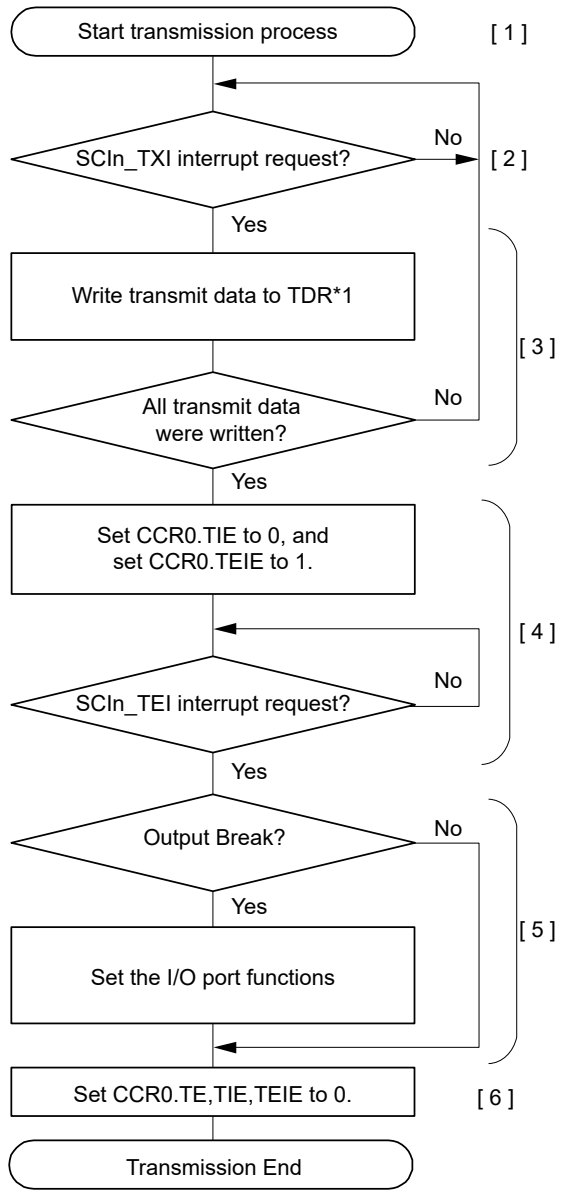
Note: —: Invalid. The write value should be 0.

Figure 28.17 Data format written to transmit-FIFO(TDR) with FIFO selected

In serial transmission, the SCI operates as described in this section.

1. The SCI transfers data from the TDR register to the TSR register when data is written to TDR in the SCIn_TXI interrupt handling routine. The amount of data that can be written to TDR is 16 minus FTSR.T[5:0] bytes. The SCIn_TXI interrupt request at the beginning of transmission is generated when the CCR0.TE and CCR0.TIE bits are set to 1 simultaneously by a single instruction.
2. Transmission starts after the CCR1.CTSE bit is set to 0 (CTS function is disabled) or a low level on the CTSn_RTSn pin causes data transfer from the TDR register to the TSR register. When the amount of transmit data written in TDR is equal to or less than the specified transmit triggering number, CSR.TDRE is set to 1. If the CCR0.TIE bit is 1, an SCIn_TXI interrupt request is generated. Continuous transmission is possible by writing the next transmit data to TDR in the SCIn_TXI interrupt handling routine before transmission of the current transmit data is complete. When SCIn_TEI interrupt requests are in use, set the CCR0.TIE bit to 0 (SCIn_TXI interrupt requests are disabled) and the CCR0.TEIE bit to 1 (an SCIn_TEI interrupt request is enabled) after the last of the data to be transmitted is written to the TDR register from the handling routine for SCIn_TXI requests.
3. Data is sent from the TXDn pin in the following order:
   - Start bit
   - Transmit data
   - Parity bit or multi-processor bit (can be omitted depending on the format)
   - Stop bit
4. On output of the stop bit, the SCI checks whether non-transmitted data remains in the TDR register.
5. When data is set to transmit-FIFO (TDR), setting the CCR1.CTSE bit to 0 (CTS function is disabled) or a low level input on the CTSn_RTSn pin causes transfer of the next transmit data from TDR to TSR and transmission of the stop bit, after which serial transmission of the next frame starts.
6. If data is not set in transmit-FIFO (TDR), the TEND flag in CSR is set to 1, the stop bit is sent, and the mark state is entered in which 1 is output. If the CCR0.TEIE bit is 1, an SCIn_TEI interrupt request is generated.

Figure 28.18 shows an example flow of serial transmission in Asynchronous mode with FIFO selected.



[1] Start transmission process

[2] SCIn_TXI interrupt request:
The transmit-data-empty-interrupt(SCIn_TXI) is generated when transmission-data forwards to TSR from the transmit-FIFO(TDR) and the number of transmit-data written in the transmit-FIFO is equal to or less than the transmit-FIFO threshold.

[3] Serial transmission continuation procedure:
To continue serial transmission, write all transmit data to the transmit-FIFO(TDR) by using a SCIn_TXI interrupt and clear TDRE flag to 0. (Transmit data can also be written to the transmit-FIFO(TDR) by activating the DMAC or DTC. In this case, the TDRE flag is cleared automatically, so please don't operate the TDRE flag.)
The number of transmission data it's possible to write in is 16 - (the number of stored transmit FIFO data).

[4] If you use SCIn_TEI, set TIE = 0 and TEIE = 1 after writing the last-transmit-data to TDR*1.

[5] Break output at the end of serial transmission:
To output a break, it is necessary to set SPB2IO and SPB2DT, for output status setting when TE is 0.
(If you set these bits at initialization, you can skip this step.)

[6] Set CCR0.TE,TIE,TEIE to 0.

Note 1. In case of byte access with data length 9 bits, write transmit data in order of TDR[15:8] and TDR[7:0].

Figure 28.18 Example flow of serial transmission in Asynchronous mode with FIFO selected

28.3.9 Serial Data Reception in Asynchronous Mode

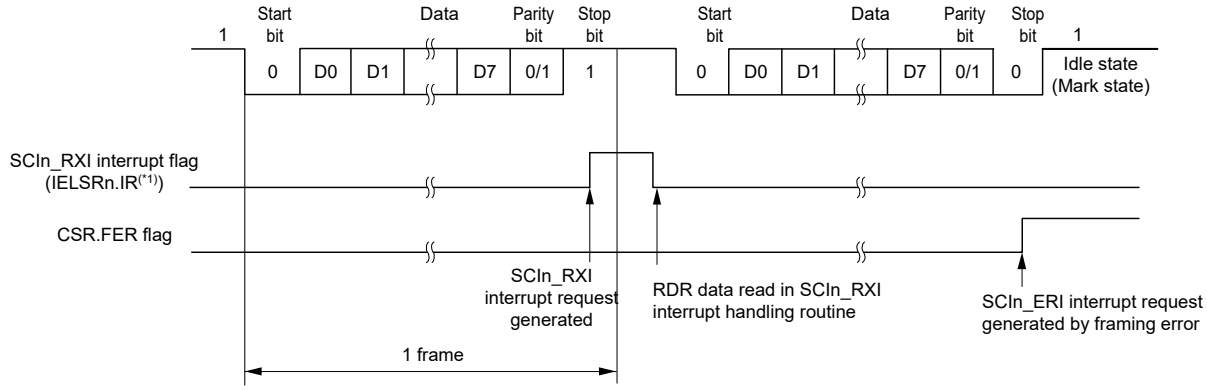
(1) Non-FIFO selected

Figure 28.19 and Figure 28.20 show an example of the operation for serial data reception in Asynchronous mode.

In serial data reception, the SCI operates as follows:

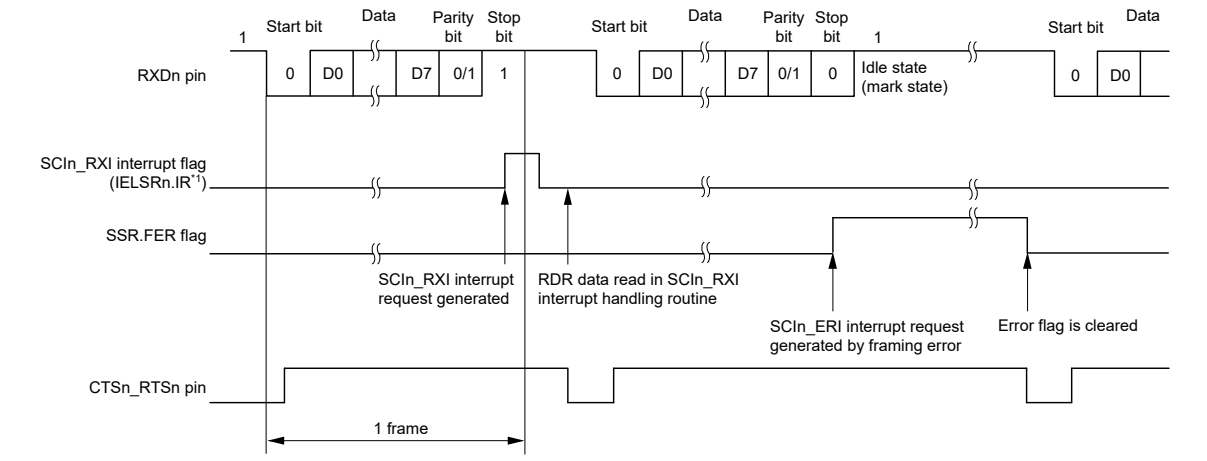
1. When the value of the CCR0.RE bit becomes 1, the output signal on the CTSn_RTSn pin goes low.
2. The SCI monitors the communications line and when it detects a start bit, the SCI performs internal synchronization, stores receive data in RSR, and checks the parity bit and stop bit.
3. If an overrun error occurs, the CSR.ORER flag is set to 1. If the CCR0.RIE bit is 1, an SCIn_ERI interrupt request is generated. Receive data is not transferred to the RDR register.
4. If a parity error is detected, the CSR.PER flag is set to 1 and receive data is transferred to the RDR register. If the SCR.RIE bit is 1, an SCIn_ERI interrupt request is generated.

5. If a framing error is detected, the CSR.FER flag is set to 1 and receive data is transferred to the RDR register. If the CCR0.RIE bit is 1, an SCIn_ERI interrupt request is generated.
6. When reception finishes successfully, receive data is transferred to the RDR register. If the CCR0.RIE bit is 1, an SCIn_RXI interrupt request is generated. Continuous reception is enabled by reading the receive data transferred to the RDR register in the SCIn_RXI interrupt handling routine before reception of the next receive data is complete. Reading the received data that was transferred to the RDR register causes the CTSn_RTSn pin to output low.



Note 1. See section 12, Interrupt Controller Unit (ICU) for information on the corresponding interrupt event number.

Figure 28.19 Example of SCI operation for serial reception in Asynchronous mode (1) when the RTS function is not used, and with 8-bit data, parity bit, and 1 stop bit



Note 1. See section 12, Interrupt Controller Unit (ICU) for information on the corresponding interrupt event number.

Figure 28.20 Example of SCI operation for serial reception in Asynchronous mode (2) when RTS function is used, and with 8-bit data, parity bit, and 1 stop bit

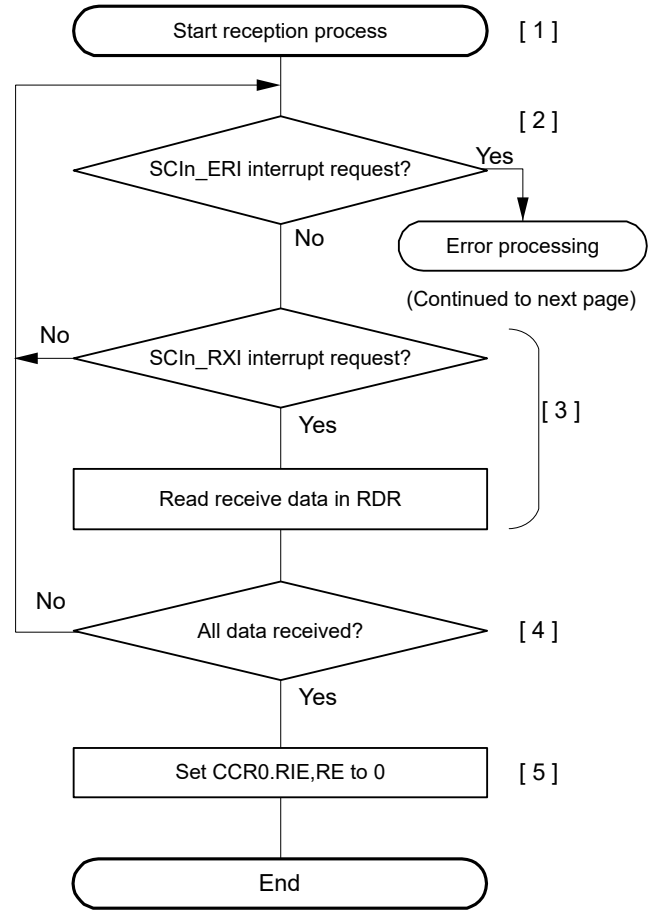
Table 28.31 lists the states of the flags in the CSR status register and receive data handling when a receive error is detected.

If a receive error is detected, an SCIn_ERI interrupt request is generated but an SCIn_RXI interrupt request is not generated. Data reception cannot be resumed while the receive error flag is 1. Accordingly, set the ORER, FER, and PER bits to 0 before resuming reception. In addition, be sure to read the RDR register during overrun error processing. When a reception is forced to terminate by setting the CCR0.RE bit to 0 during operation, read the RDR register because received data that is not yet read might be left in the RDR.

Figure 28.21 and Figure 28.22 show example flows of serial data reception.

Table 28.31 Flags in CSR Status Register and receive data handling

Flags in the CSR Status Register			Receive data	Receive error type
ORER	FER	PER		
1	0	0	Lost	Overrun error
0	1	0	Transferred to RDR	Framing error
0	0	1	Transferred to RDR	Parity error
1	1	0	Lost	Overrun error + framing error
1	0	1	Lost	Overrun error + parity error
0	1	1	Transferred to RDR	Framing error + parity error
1	1	1	Lost	Overrun error + framing error + parity error



[1] Start reception process

[2] Receive error processing and break detection: If a receive error occurs, an SCIn_ERI interrupt is generated. After performing the appropriate error processing, be sure to set the ORER, PER, and FER flags to 0. Reception cannot be resumed if any of these flags is set to 1. In the case of a framing error, a break can be detected by reading the value of the input port corresponding to the RXDn pin.

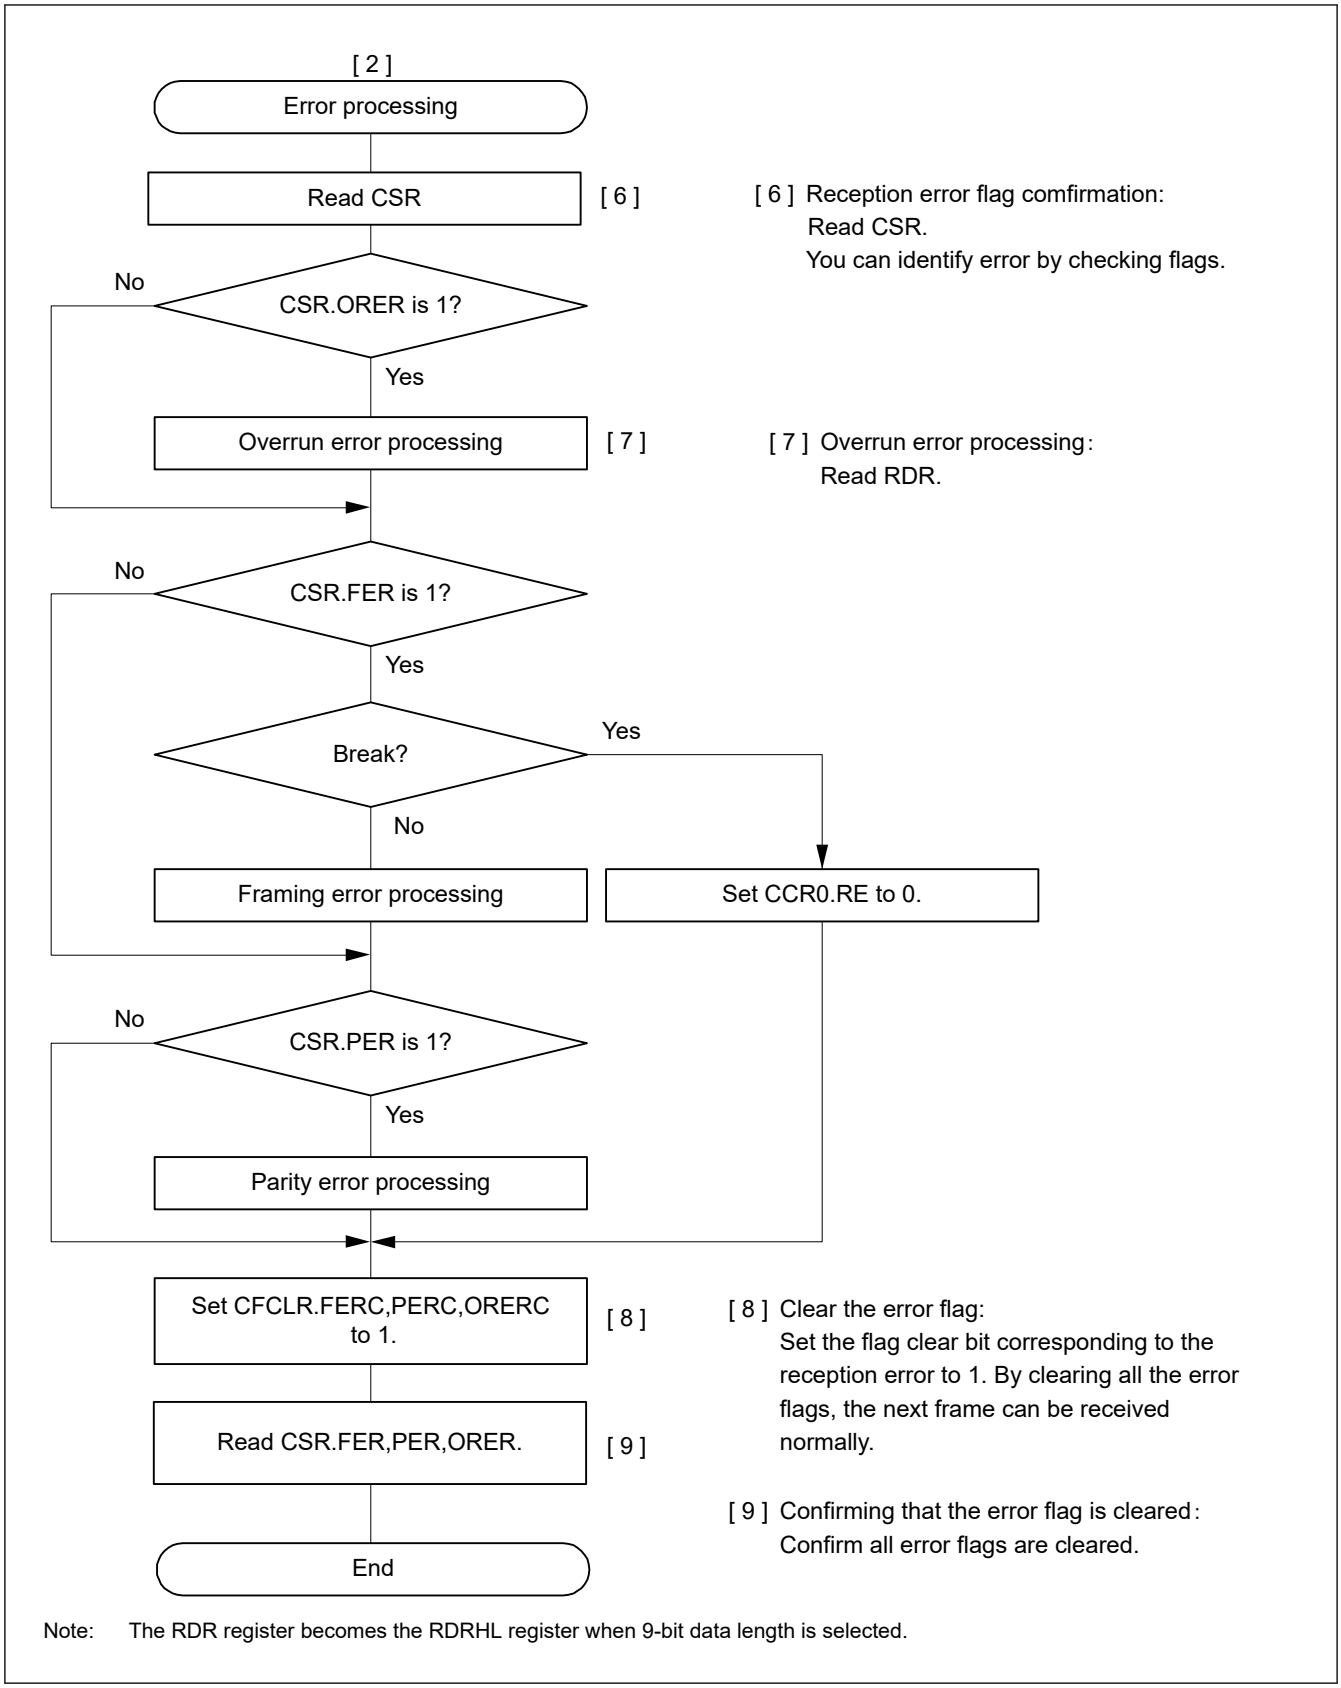
[3] Read the receive data in RDR*1 once in the SCIn_RXI interrupt handling routine.

[4] Serial reception continuation procedure: To continue serial reception, before the stop bit of the current frame is received, read data from RDR in the SCIn_RXI interrupt handling routine. The RDR data can also be read by activating the DMAC or DTC.

[5] Set CCR0.RIE,RE to 0.

Note 1. Do not set RE to 0 before reading RDR.

Figure 28.21 Example flow of serial reception in Asynchronous mode with non-FIFO selected and Address Matching Disabled (1)



Note: The RDR register becomes the RDRHL register when 9-bit data length is selected.

Figure 28.22 Example flow of serial reception in Asynchronous mode with non-FIFO selected and Address Matching Disabled (2)

(2) FIFO selected

Figure 28.23 shows an example of a data format that is written to Receive-FIFO(RDR) register in Asynchronous mode.

In Asynchronous mode, 0 is written to the MPB bit in the RDR register. Data that corresponds to the data length is written to RDR. Unused bits are written as 0. If software reads RDR, the SCI updates FER, PER, and receive data (RDAT[8:0]) in the RDR register with the next data. The flags ORER, and DR in the RDR register always reflect the associated flags in the CSR register.

Data Length	Register Setting		Receive flag in RDR[31:0], MPB, RDAT[8:0]															
	CCR3.CHR[1:0]		b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
7bit	1	1	-	-	-	FFER	FPER	DR	MPB	0	0	RDAT[6:0]						
8bit	1	0	-	-	-	FFER	FPER	DR	MPB	0	RDAT[7:0]							
9bit	0	Don't care	-	-	-	FFER	FPER	DR	MPB	RDAT[8:0]								
	CCR3.CHR[1:0]		b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
7bit	1	1	-	-	-	FER	PER	-	-	ORER	-	-	-	-	-	-	-	-
8bit	1	0	-	-	-	FER	PER	-	-	ORER	-	-	-	-	-	-	-	-
9bit	0	Don't care	-	-	-	FER	PER	-	-	ORER	-	-	-	-	-	-	-	-

Note: 0 is always read from the MPB flag (RDR [9] bit).
When a 7-bit data length is selected, 0 is read from the RDAT [8:7] bits.
When 8-bit data length is selected, 0 is read from the RDAT [8] bit.

Figure 28.23 Data format stored in receive-FIFO(RDR) with FIFO selected

Table 28.32 lists the states of the flags in CSR status register and receive data handling when a receive error is detected with FIFO selected. Figure 28.24 and Figure 28.25 show samples of flowcharts for serial data reception with FIFO selected.
In serial data reception, the SCI operates as follows:

1. When the value of the CCR0.RE bit becomes 1, the output signal on the CTSn_RTSn pin goes low.
2. The SCI monitors the communications line and, when it detects a start bit, the SCI performs internal synchronization, stores receive data in the RSR register.
3. If an overrun error occurs during normal communications, the CSR.ORER flag is set to 1. If the CCR0.RIE bit is 1, an SCIn_ERI interrupt request is generated. Receive data is not transferred to the RDR register.
4. If a parity error is detected, the PER flag and receive data are transferred to the RDR register. If the CCR0.RIE bit is set to 1, an SCIn_ERI interrupt request is generated.
5. If a framing error is detected, the FER flag and receive data are transferred to the RDR register. If the CCR0.RIE bit is set to 1, an SCIn_ERI interrupt request is generated.
6. After a framing error is detected and when SCI detects that the continuous receive data is zero for one frame, reception stops.
7. When the amount of data stored in the RDR register falls below the specified receive triggering number, and the next data is not received after 15 etus from the last stop bit in Asynchronous mode, the FRSR.DR flag is set to 1. When the CCR0.RIE bit is 1 and the FCR.DRES bit is 0, the SCI generates an SCIn_RXI interrupt request. When the FCR.DRES bit is 1, SCI generates an SCIn_ERI interrupt request.
8. When reception finishes successfully, receive data is transferred to the RDR register. The RDRF bit is set to 1 when the amount of receive data written to RDR is equal to or greater than the specified receive triggering number. If the CCR0.RIE bit is 1, an SCIn_RXI interrupt request is generated. Continuous reception is enabled by reading the receive data transferred to the RDR register in the SCIn_RXI interrupt handling routine, before an overrun error occurs. If the received data that is transferred to RDR is less than the RTS trigger number, the CTSn_RTSn pin outputs low.

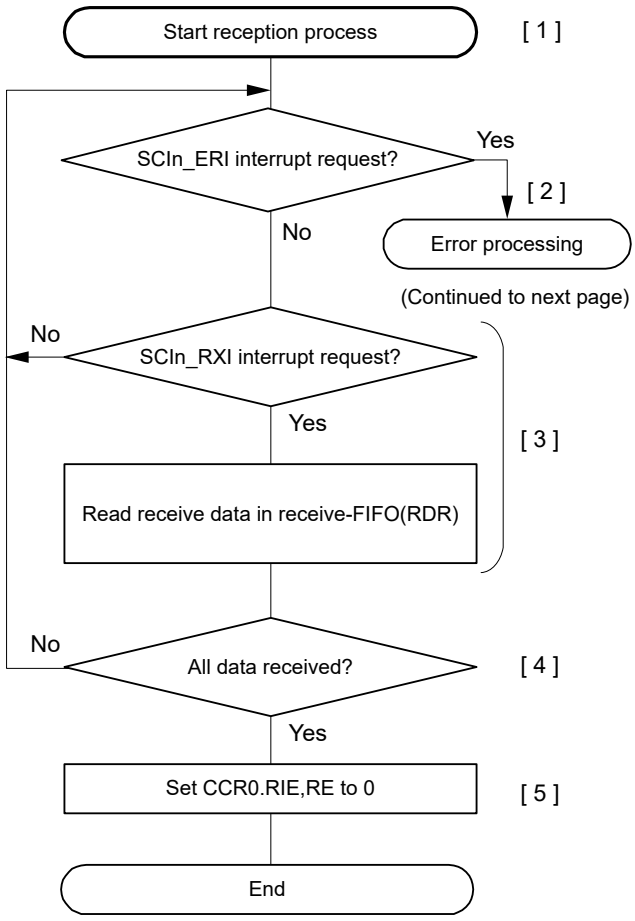
Table 28.32 Flags in the CSR Status Register and Receive Data Handling (FIFO selected) (1 of 2)

CSR value			Receive-FIFO (RDR)	Receive Error Type
ORER	FER*1	PER*1	RDAT[8:0]	
1	0	0	Lost	Overrun error
0	1	0	Transferred RDR	Framing error
0	0	1	Transferred RDR	Parity error

Table 28.32 Flags in the CSR Status Register and Receive Data Handling (FIFO selected) (2 of 2)

CSR value			Receive-FIFO (RDR)	Receive Error Type
ORER	FER*1	PER*1	RDAT[8:0]	
1	1	0	Lost	Overrun error + Framing error
1	0	1	Lost	Overrun error + Parity error
0	1	1	Transferred RDR	Framing error + Parity error
1	1	1	Lost	Overrun error + Framing error + Parity error

Note 1. This flag indicates whether there is an error in received data when reception is completed.



[1] Start reception process

[2] Receive error processing and break detection: If a receive error occurs, an SCIn_ERI interrupt is generated. After performing the appropriate error processing, be sure to set the ORER flag*1 to 0. Reception cannot be resumed if ORER is set to 1. Reception can continue even if PER,FER,DR flags*1 are 1.

[3] Read the receive data in the receive-FIFO(RDR) in the SCIn_RXI interrupt handling routine. The reception data stored in the receive-FIFO(RDR) is read until the number of stored data will be below the FCR.RTRG value at least. You can confirm the number of the reception data in the FIFO by FRSR.R[5:0].

[4] Serial reception continuation procedure: To continue serial reception, before an overrun error occurs, please read data from the receive-FIFO(RDR) in the SCIn_RXI interrupt handling routine and clear CSR.RDRF flag and FRSR.DR flag to 0. The receive-FIFO data can also be read by activating the DMA or DTC. The RDRF flag is cleared automatically in this case, so please don't operate the RDRF flag.

[5] Set CCR0.RIE,RE to 0.

Note 1. Can be read in the RDR.ORER, PER, FER and DR flags.

Figure 28.24 Example flow of serial reception in Asynchronous mode with FIFO selected and Address Matching Enabled (1)

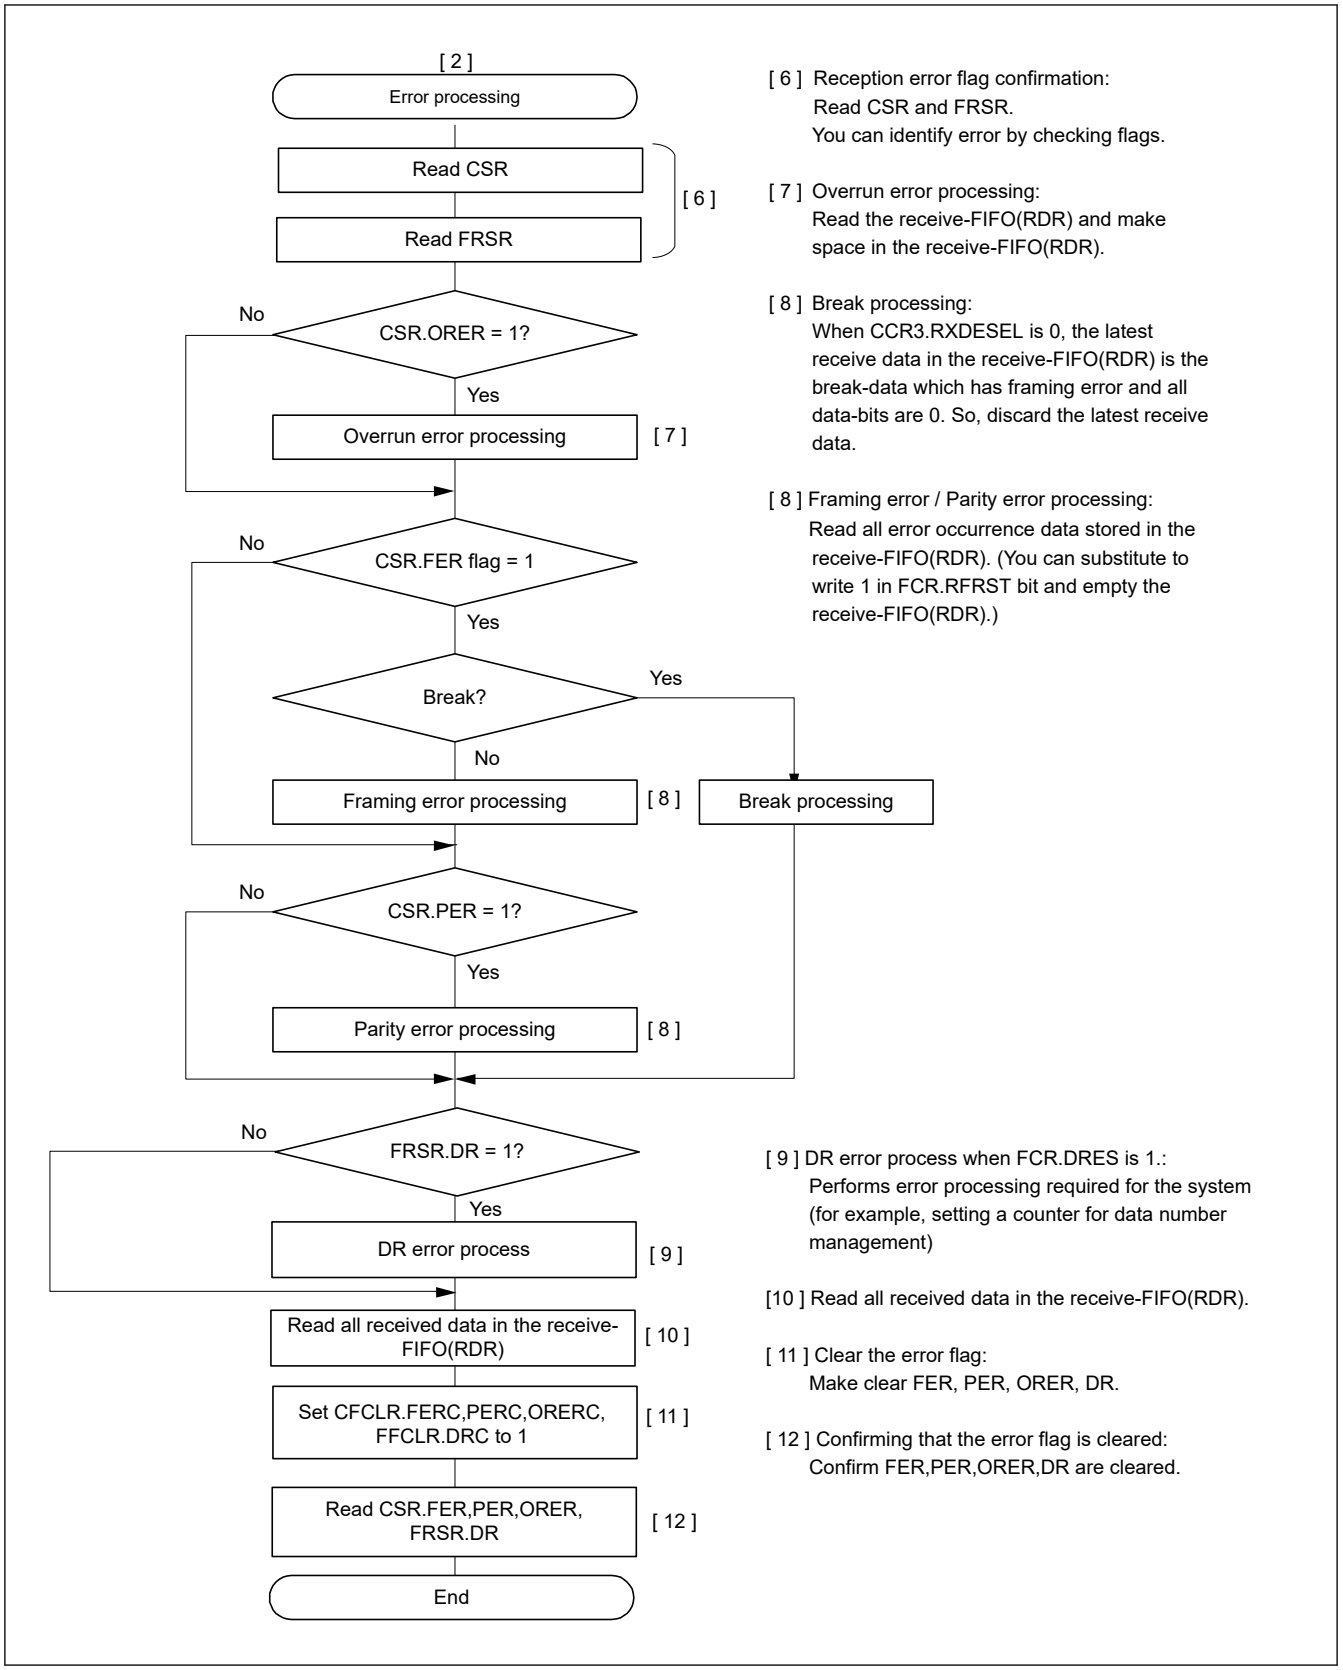


Figure 28.25 Example flow of serial reception in Asynchronous mode with FIFO selected Address Matching Disabled (2)

28.3.10 The function of adjust receive sampling timing (Asynchronous Mode)

When there is the difference between the rising transfer time and the falling transfer time through a photo coupler, the receive sampling timing at middle of bit affects the reception margin. In this case, the receive sampling timing is able to adjust from the middle of bit to the optimum timing by using this function.

The receive sampling timing is adjusted from the middle of bit by following formula. The adjustable direction is set by CCR4.AJD. When adjusting backward (CCR4.AJD = 0), substitute AJD = +1 and substitute AJD = −1 when adjusting forward (CCR4.AJD = 1).

Adjusted sampling timing = the middle of bit + AJD × (base clock × the setting value of CCR4.AST[2:0])

The setting timing is limited by base clock cycles per 1 bit. For details, see Table 28.33.

An overview of reception operation of the communication through a photo coupler with this function is shown in Figure 28.26, Figure 28.27 and Figure 28.28, the explanation of operation with this function is shown in Figure 28.29.

Do not use this function when there is no difference between the rising transfer time and the falling transfer time, because there is a possibility of deteriorating the reception margin.

Table 28.33 The acceptable value of setting register (Asynchronous mode using internal clock)

CCR2.ABCSE2	CCR2.ABCSE	CCR2.ABCS	The number of base cycles/1bit	The acceptable value	
				CCR4.AJD	CCR4.AST*1
1	0	x	4	0	000 to 011
				1	(Note1)
0	1	x	6	0	000 to 010
				1	(Note1)
0	0	1	8	0	000 to 011
				1	(Note1)
0	0	0	16	0	000 to 111
				1	

Note: x: Don't care
Note 1. When the value of CCR4.AST exceeds the acceptable value, sampling is done at default timing. (Adjustment of sampling is not done.)

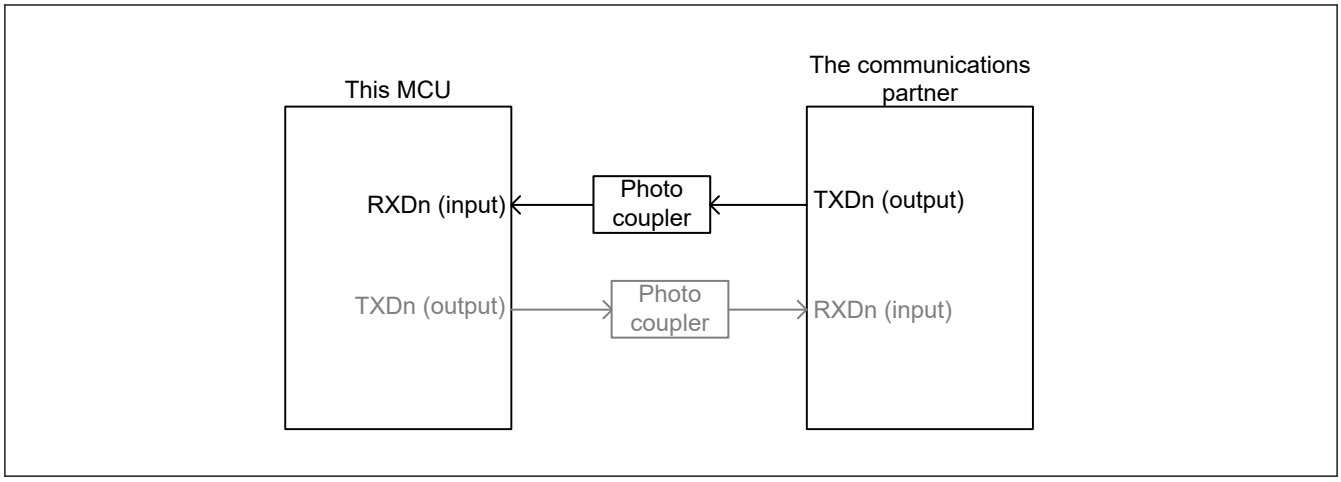

Figure 28.26 block diagram image of the reception through a photo couple

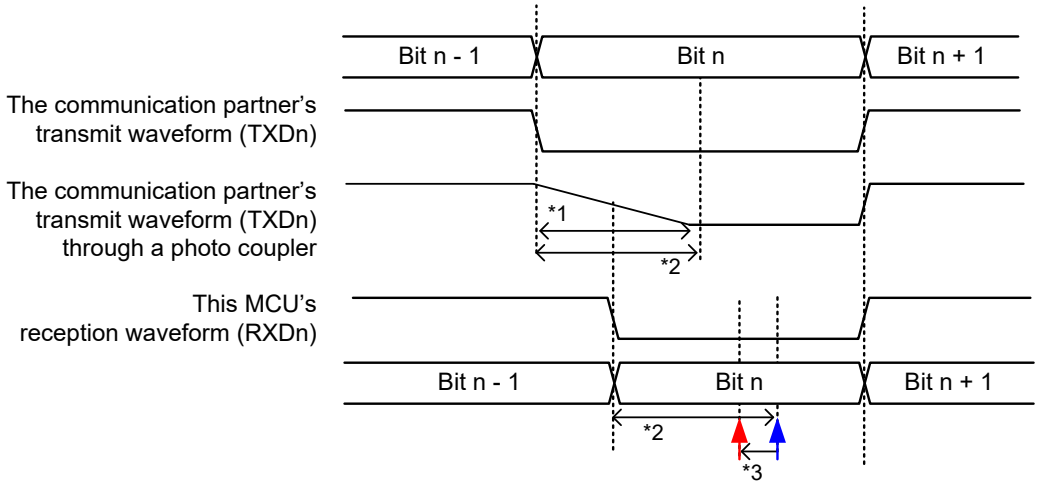
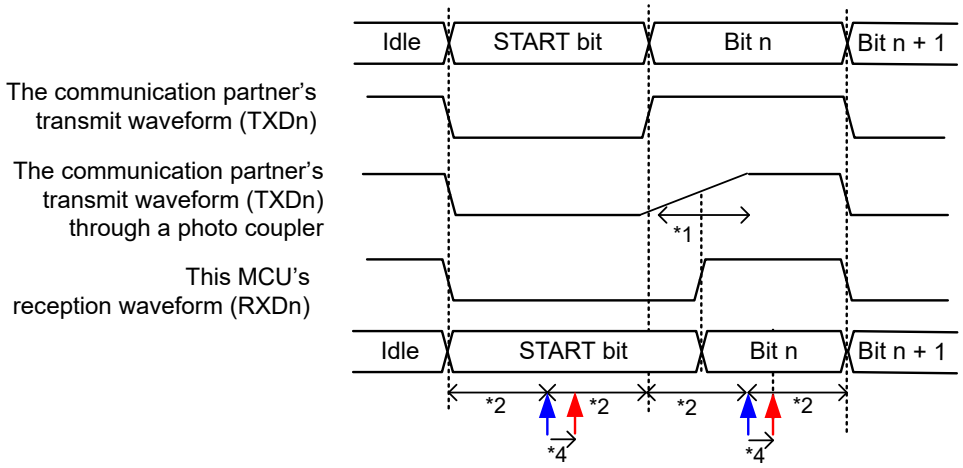
(a) In the case of the falling transfer time >> rising transfer time

The falling edge of reception waveform is made dull like following chart.
In this case, you can sampling at the middle of bit if you adjust the receive sampling timing to forward (AJD = 1).



(b) In the case of the falling transfer time << rising transfer time

The rising edge of reception waveform is made dull like following chart.
So, the reception margin of communications partner will be bad. In this case, you can improve the reception margin if you adjust the receive sampling timing to back.



The receive sampling timing when unadjusted (middle of bit)
The adjusted receive sampling timing

Note: This waveform shows the operation image of adjustment in reception sampling timing.
Note 1. The dull period by a photo coupler
Note 2. Bit center timing at set communication rate
Note 3. When CCR4.AJD is 1, the receive sampling timing is shifted to forward by the setting value of CCR4.AST[2:0].
Note 4. When CCR4.AJD is 0, the Receive sampling timing is shifted to backward by the setting value of CCR4.AST[2:0].

Figure 28.27 Overview of reception operation of the communication through a photo coupler

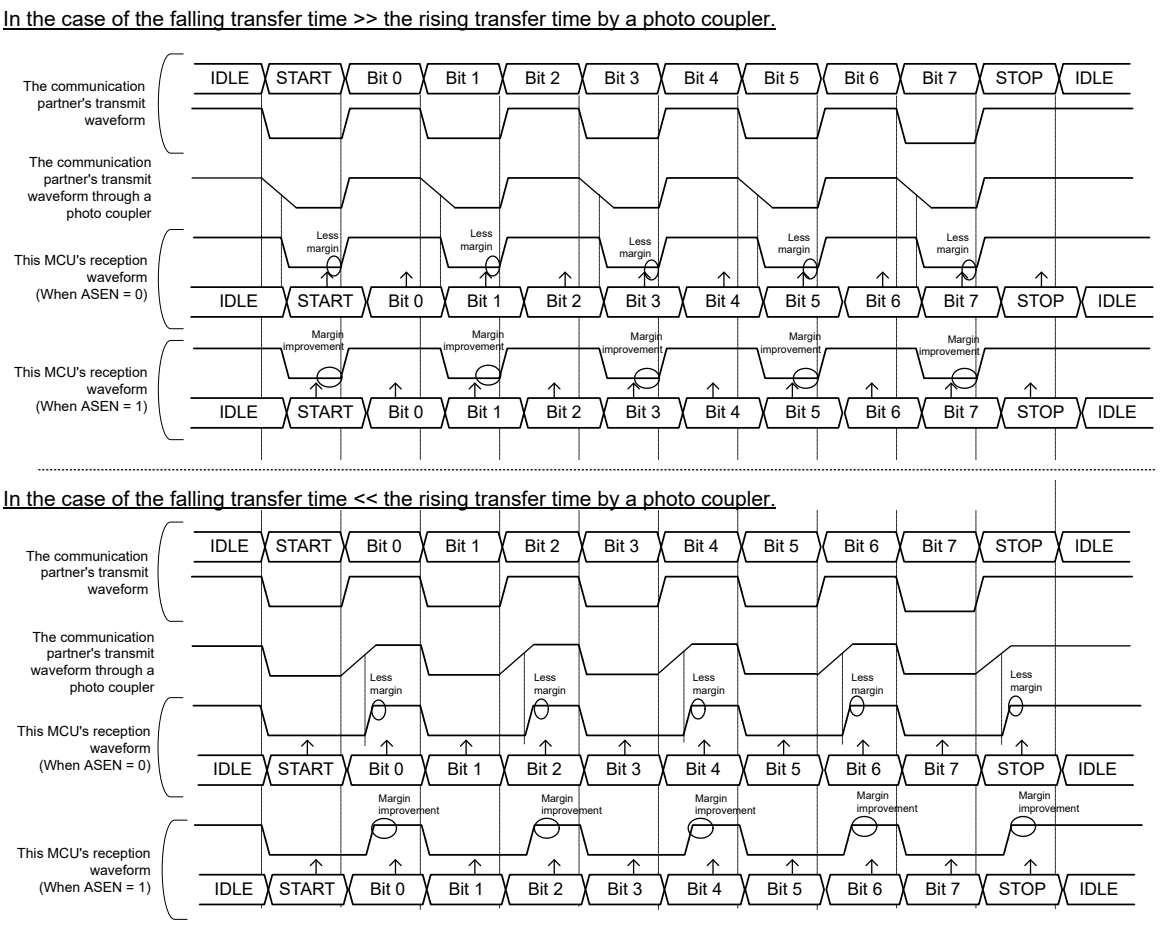


Figure 28.28 Example of improvement in reception margin by the reception sampling timing adjustment function

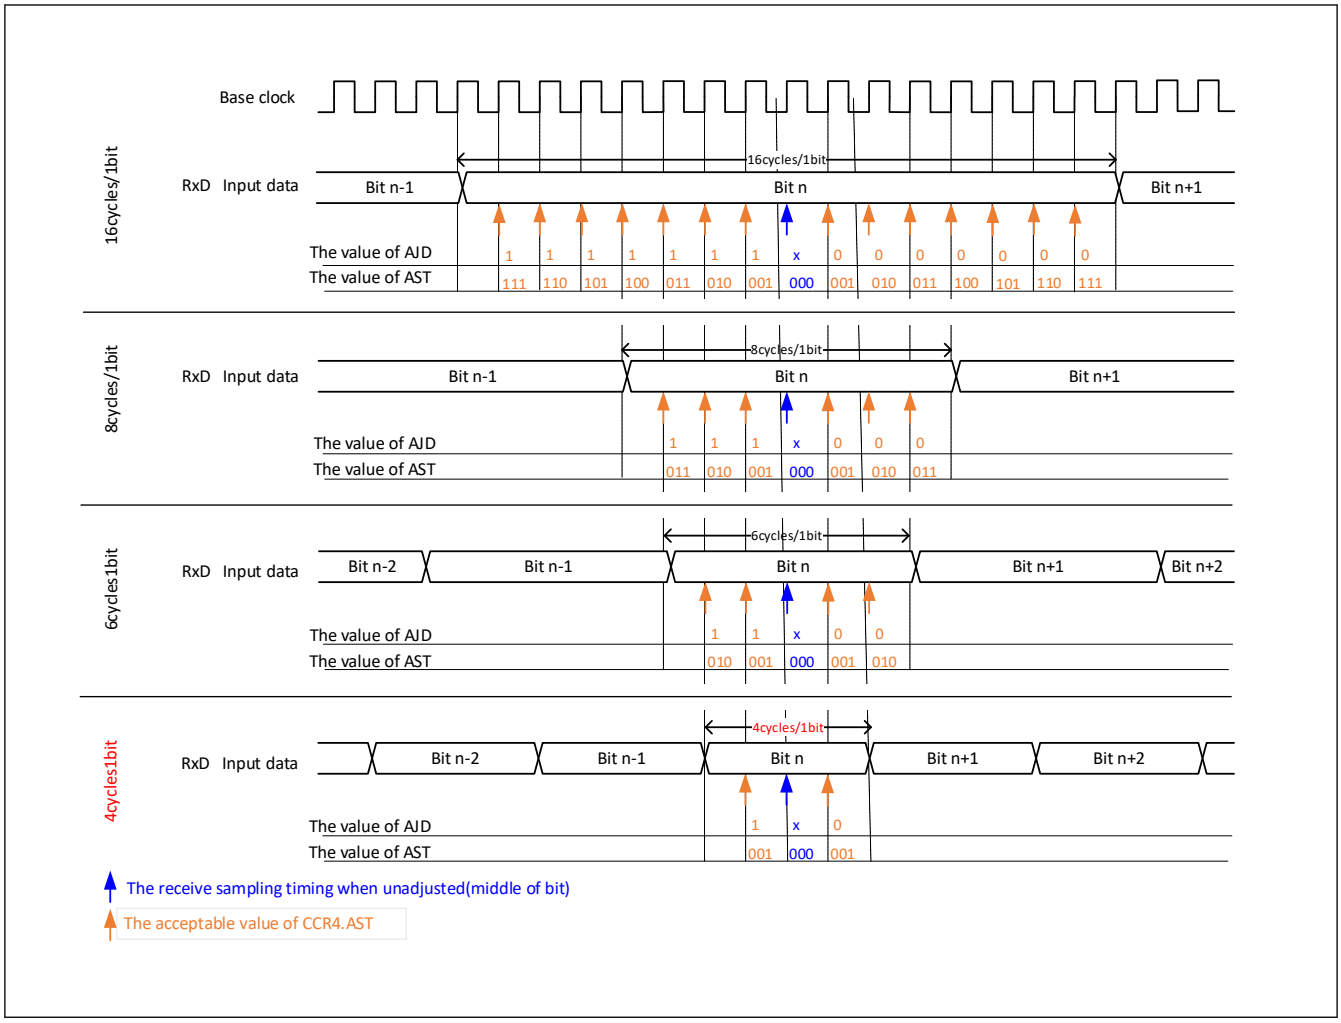

Figure 28.29 Overview of the adjustment operation for the reception sampling timing (Asynchronous mode using internal clock)

28.3.11 The function of adjust transmit timing (Asynchronous Mode)

In communication via a photo coupler or the like, when either the rising or falling transition time of the TXDn output signal is long, then a communication partner receive dulled waveform. In this case, the reception margin may be affected.

In these cases, make a communication partner to be sampling at middle of bit using the function of adjust transmit timing.

When CCR4.ATEN is 1, this function can adjust the edge timing at the timing calculated by the following formula for the edge set with CCR4.AET.

The adjustment edge timing = the base clock × CCR4.ATT[2:0]

In addition, the upper limit of the adjustment edge timing is limited by setting the base clock cycles. For details, see Table 28.34.

A transmission movement image figure of the communication through a photo coupler with this function is shown in Figure 28.30, Figure 28.31 and Figure 28.32, the overview of operation with this function is shown in Figure 28.33 and Figure 28.34.

Do not use this function when there is not the difference between the rising transfer time and the falling transfer time, there is a possibility of deteriorating the reception margin of a communication partner.

Table 28.34 The acceptable value of CCR4.AET and CCR4.ATT (Asynchronous mode using internal clock)

ABCSE2	ABCSE	ABCS	The number of base clock cycles/1bit	The acceptable value	
				AET	ATT [2:0]
1	0	x	4	0	000 to 011
				1	
0	1	x	6	0	000 to 101
				1	
0	0	1	8	0	000 to 111
				1	
0	0	0	16	0	000 to 111
				1	

Note: x: Don’t care
Note: When the value of ACTR.AET/ATT is out of the acceptable value, this SCI module doesn’t adjust transmit timing.

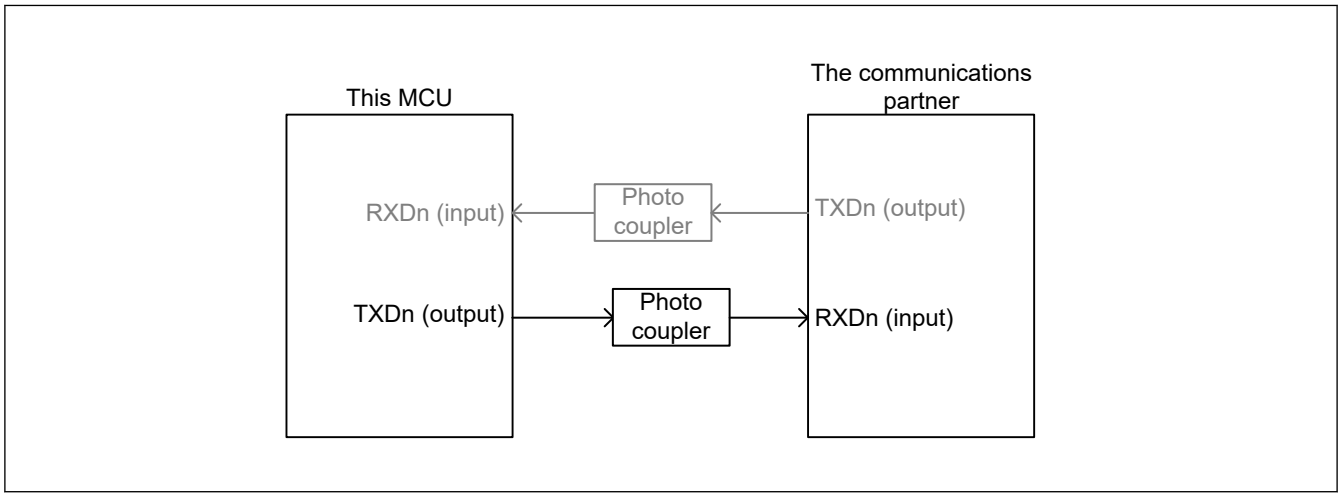

Figure 28.30 block diagram image of the transmission through a photo coupler

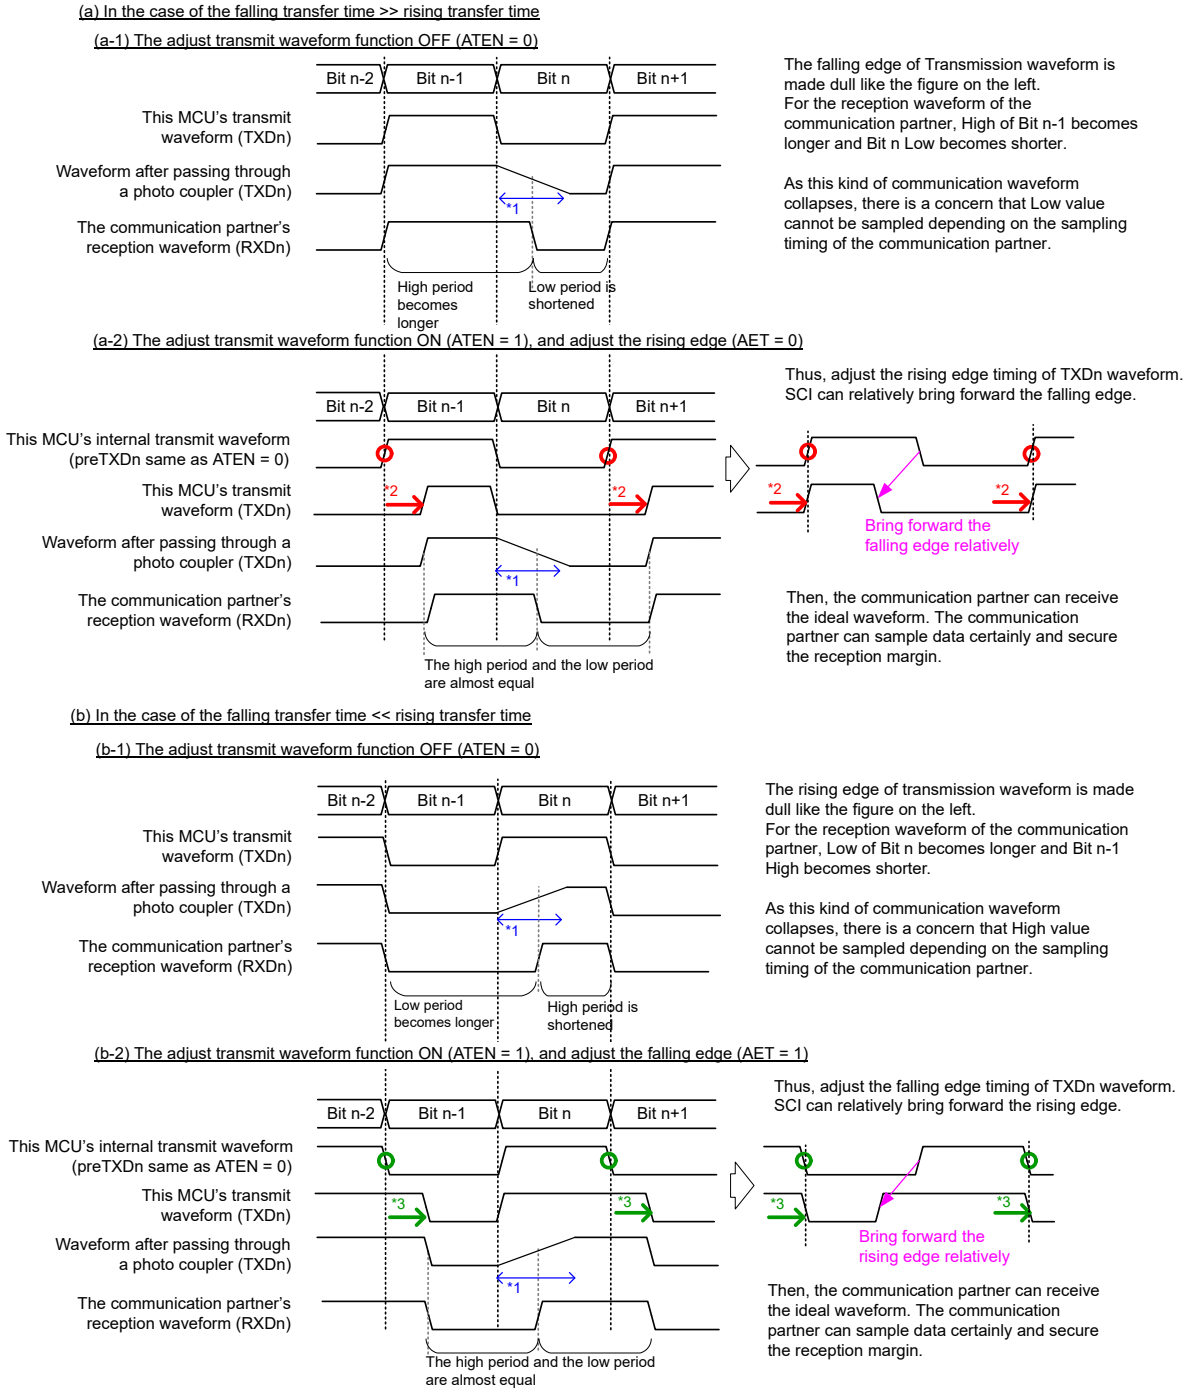

Note: This waveform shows the operation image of adjustment transmit waveform.
Note 1. The dull period by a photo coupler
Note 2. When CCR4.AET is 0, the rising edge of transmit waveform timing is shifted to back by the setting value of CCR4.ATT[2:0]. This MCU transmit waveform bringing forward the falling edge relatively.
Note 3. When CCR4.AET is 1, the falling edge of transmit waveform timing is shifted to back by the setting value of CCR4.ATT[2:0]. This MCU transmit waveform bringing forward the rising edge relatively.

Figure 28.34 The adjustment operation explanation for the transmit timing when AET is 1

28.4 Multi-Processor Communication Function

The multi-processor communication function enables the SCI to transmit and receive data between multiple processors by sharing an asynchronous serial communication line that has an added multi-processor bit. In multi-processor communication, a unique ID code is allocated to each receiving station. Serial communication cycles consist of an ID transmission cycle to specify the receiving station and a data transmission cycle to transmit data to the specified receiving station.

The multi-processor bit is used to distinguish between the ID transmission cycle and the data transmission cycle:

- When the multi-processor bit is set to 1, the transmission cycle is the ID transmission cycle
- When the multi-processor bit is set to 0, the transmission cycle is the data transmission cycle

Figure 28.35 shows an example of communication between processors using a multi-processor format. First, a transmitting station transmits communication data in which the multi-processor bit set to 1 is added to the ID code of the receiving station. Next, the transmitting station transmits communication data in which the multi-processor bit set to 0 is added to the transmit data. After receiving communication data with the multi-processor bit set to 1, the receiving station compares the received ID with the ID of the receiving station itself. If the two match, the receiving station receives communication data that is subsequently transmitted. If the received ID does not match with the ID of the receiving station, the receiving station skips the communication data until it receives data in which the multi-processor bit is set to 1.

RTS control cannot be used at the time of multi-processor communication function use because this is a function corresponding to one-to-many communications.

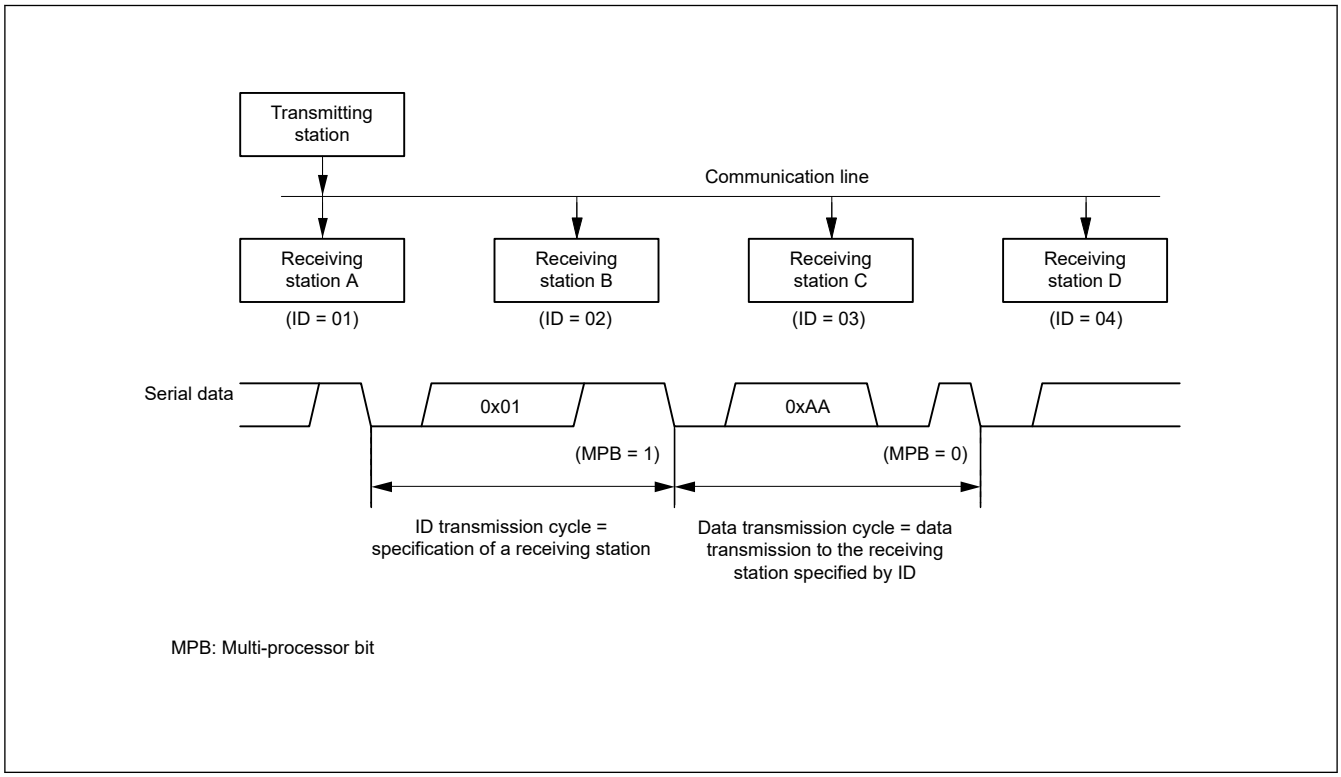

Figure 28.35 Example of communication using multi-processor format with transmission of data 0xAA to receiving station A

(1) Non-FIFO selected

To support this function, the SCI provides the CCR0.MPIE bit. When the MPIE bit is set to 1, the following operations are disabled until the reception of data in which the multi-processor bit is set to 1:

- Transfer of receive data from the RSR register to the RDR register
- Detection of a receive error
- Setting of the respective RDRF, ORER, and FER status flags in the CSR register

When the SCI receives a character in which the multi-processor bit is set to 1, the RDR.MPB bit is set to 1 and the CCR0.MPIE bit is automatically cleared, returning the SCI to non-multi-processor reception operation. If the CCR0.RIE bit is set to 1, an SCIn_RXI interrupt is generated.

When the multi-processor format is specified, the parity bit function is disabled. Apart from this, there is no difference from operation in non-multi-processor Asynchronous mode. The clock used for the multi-processor communication is the same as the clock used in non-multi-processor Asynchronous mode.

(2) FIFO selected

For data transmission, software must write data to TDR.MPBT (Multi-Processor Bit Transfer) that corresponds to transmit data in TDR.TDAT. For data reception, the multi-processor bit that is part of the receive data is written to RDR.MPB and receive data is written to RDR.RDAT.

When the MPIE bit is set to 1, the following operations are disabled until reception of data in which the multi-processor bit is set to 1:

- Transfer of receive data from the RSR register to the RDR.RDAT register
- Detection of a receive error
- Detection of DR
- Setting of the respective RDRF, ORER, and FER status flags in the CSR register

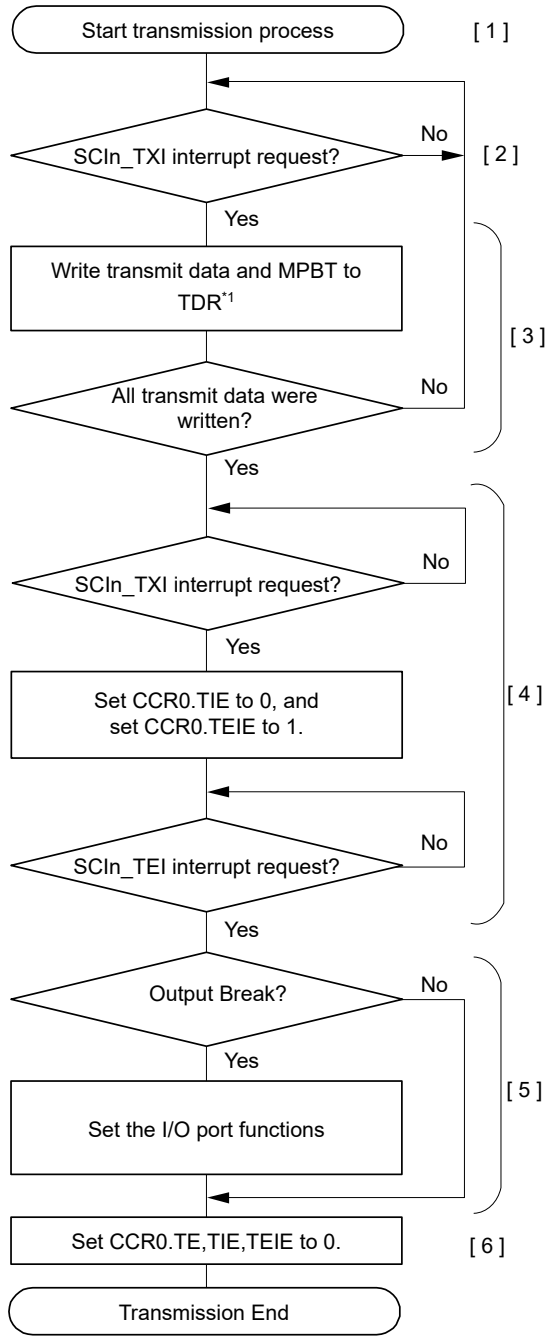
When the SCI receives a character in which the multi-processor bit is set to 1, the RDR.MPB bit is set to 1 and receive data is written to receive-FIFO(RDR.RDAT). The CCR0.MPIE bit is automatically cleared, returning the SCI to normal reception operation. If the CCR0.RIE bit is set to 1, an SCIn_RXI interrupt is generated.

When the multi-processor format is specified, the parity bit function is disabled. Apart from this, there is no difference from operation in normal Asynchronous mode with FIFO selected.

28.4.1 Multi-Processor Serial Data Transmission

(1) Non-FIFO selected

Figure 28.36 shows an example flow of multi-processor data transmission. In the ID transmission cycle, the ID must be transmitted with the TDR.MPBT bit set to 1. In the data transmission cycle, the data must be transmitted with the MPBT bit set to 0. The rest of the operations are the same as operations in Asynchronous mode.



[1] Start transmission process

[2] SCIn_TXI interrupt request:
The transmit-data-empty-interrupt(SCIn_TXI) is generated at following conditions.
When set TE and TIE to 0 at same time.
When transmission-data forwards to TSR from TDR.

[3] Serial transmission continuation procedure:
To continue serial transmission write transmit data and MPBT setting value to TDR*1 once by using a SCIn_TXI. Transmit data and MPBT setting value can also be written by activating the DMAC or DTC.

[4] If you use SCIn_TEI, set TIE = 0 and TEIE = 1 after writing the last-transmit-data to TDR*1 and transmission is started.

[5] Break output at the end of serial transmission:
To output a break, it is necessary to set SPB2IO and SPB2DT, for output status setting when TE is 0.
(If you set these bits at initialization, you can skip this step.)

[6] Set CCR0.TE,TIE,TEIE to 0.

Note 1. In case of byte access with data length 9 bits or to write MPBT bit, write transmit data in order of TDR[15:8] and TDR[7:0].

Figure 28.36 Example flow of multi-processor serial transmission with non-FIFO selected

(2) FIFO selected

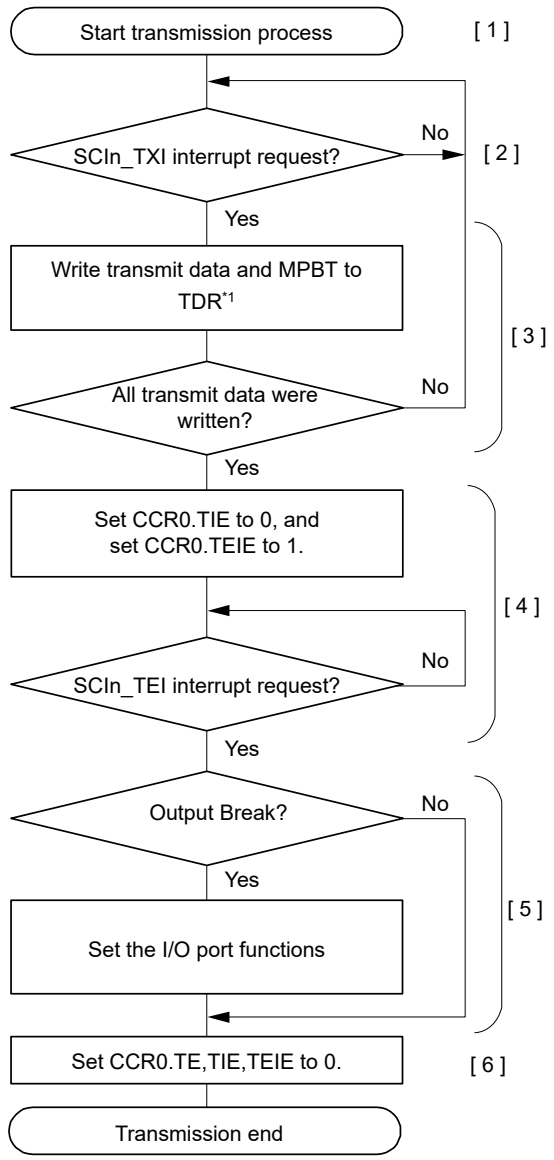
Figure 28.37 shows an example of data format that is written to transmit-FIFO (TDR) in multi-processor mode. The TDR.MPBT bit is set to 1. Data is set to transmit-FIFO (TDR) with the correct data length. Write 0 for unused bits.

Data Length	Register setting		Transmit data in TDR[15:0]															
	CCR3. CHR[1:0]		b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
7 bit	1	1	–	–	–	–	–	–	MPBT	–	–	TDAT[6:0]						
8 bit	1	0	–	–	–	–	–	–	MPBT	–	TDAT[7:0]							
9 bit	0	Don't Care	–	–	–	–	–	–	MPBT	TDAT[8:0]								

Note: —: Invalid. The write value should be 0.

Figure 28.37 Data format written to transmit-FIFO (TDR) in multi-processor mode with FIFO selected

Figure 28.38 shows an example flow of multi-processor serial transmission with FIFO selected. In the ID transmission cycle, the ID must be transmitted with the TDR.MPBT bit set to 1. In the data transmission cycle, the data must be transmitted with the MPBT bit set to 0. The rest of the operations are the same as operations in Asynchronous mode with FIFO selected.



[1] Start transmission process
To enable SCIn_TXI interrupt at he start of transmission, set TE and TIE to 1 with one instructions at the same time. And set CCR3.FM,MP to 1.

[2] SCIn_TXI interrupt request:
The transmit-data-empty-interrupt(SCIn_TXI) is generated when transmission-data forwards to TSR from the transmit-FIFO(TDR) and the number of transmit-data written in the transmit-FIFO is equal to or less than the transmit-FIFO threshold.

[3] Serial transmission continuation procedure:
To continue serial transmission, write all transmit data and MPBT setting value to the transmit-FIFO(TDR) by using a SCIn_TXI interrupt. Transmit data and MPBT setting value can also be written to the transmit- FIFO(TDR) by activating the DMAC or DTC.

[4] If you use SCIn_TEI, set TIE = 0 and TEIE = 1 after writing the last-transmit-data to TDR*1.

[5] Break output at the end of serial transmission:
To output a break, it is necessary to set SPB2IO and SPB2DT, for output status setting when TE is 0.
(If you set these bits at initialization, you can skip this step.)

[6] Set CCR0.TE,TIE,TEIE to 0.

Note 1. In case of byte access with data length 9 bits or to write MPBT bit, write transmit data in order of TDR[15:8] and TDR[7:0].

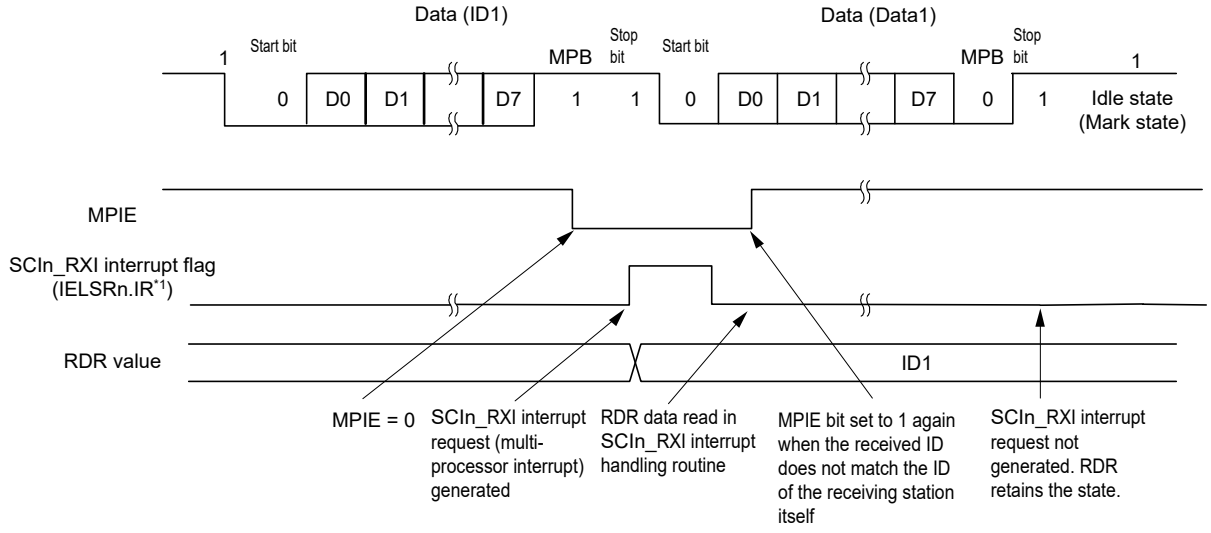
Figure 28.38 Example flow of serial transmission in multi-processor mode with FIFO selected

28.4.2 Multi-Processor Serial Data Reception

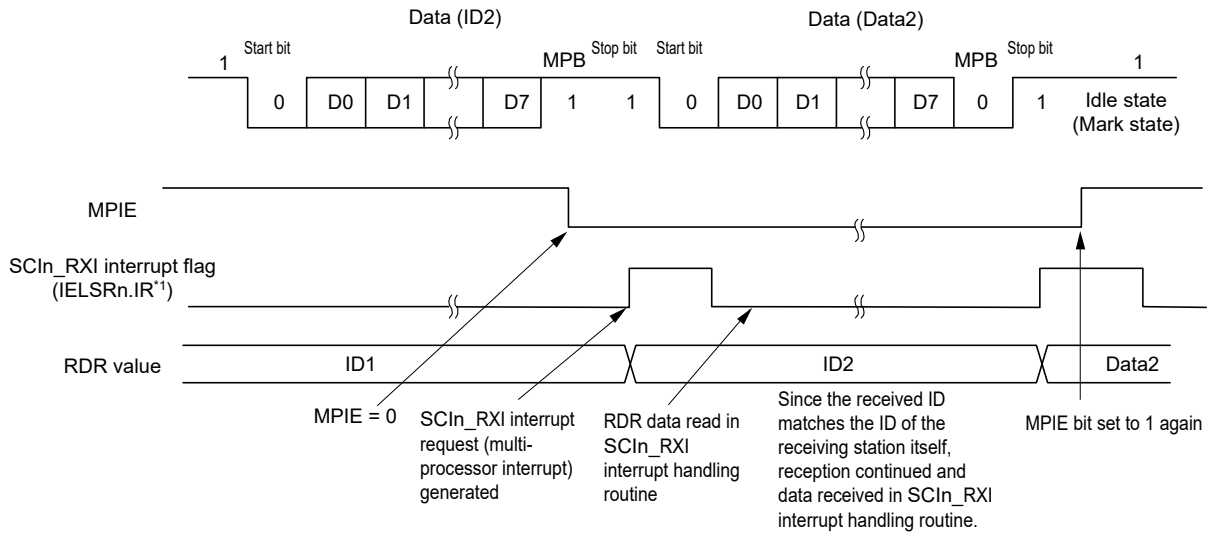
(1) Non-FIFO selected

Figure 28.40 and Figure 28.41 are example flows of multi-processor serial reception. When the CCR0.MPIE bit is set to 1, reading communication data is skipped until reception of communication data in which the multi-processor bit is set to 1. When communication data in which the multi-processor bit is set to 1 is received, the received data is transferred to the RDR register, and the SCIn_RXI interrupt request is generated. The rest of the operations are the same as operations in Asynchronous mode.

Figure 28.39 shows an example operation for data reception.



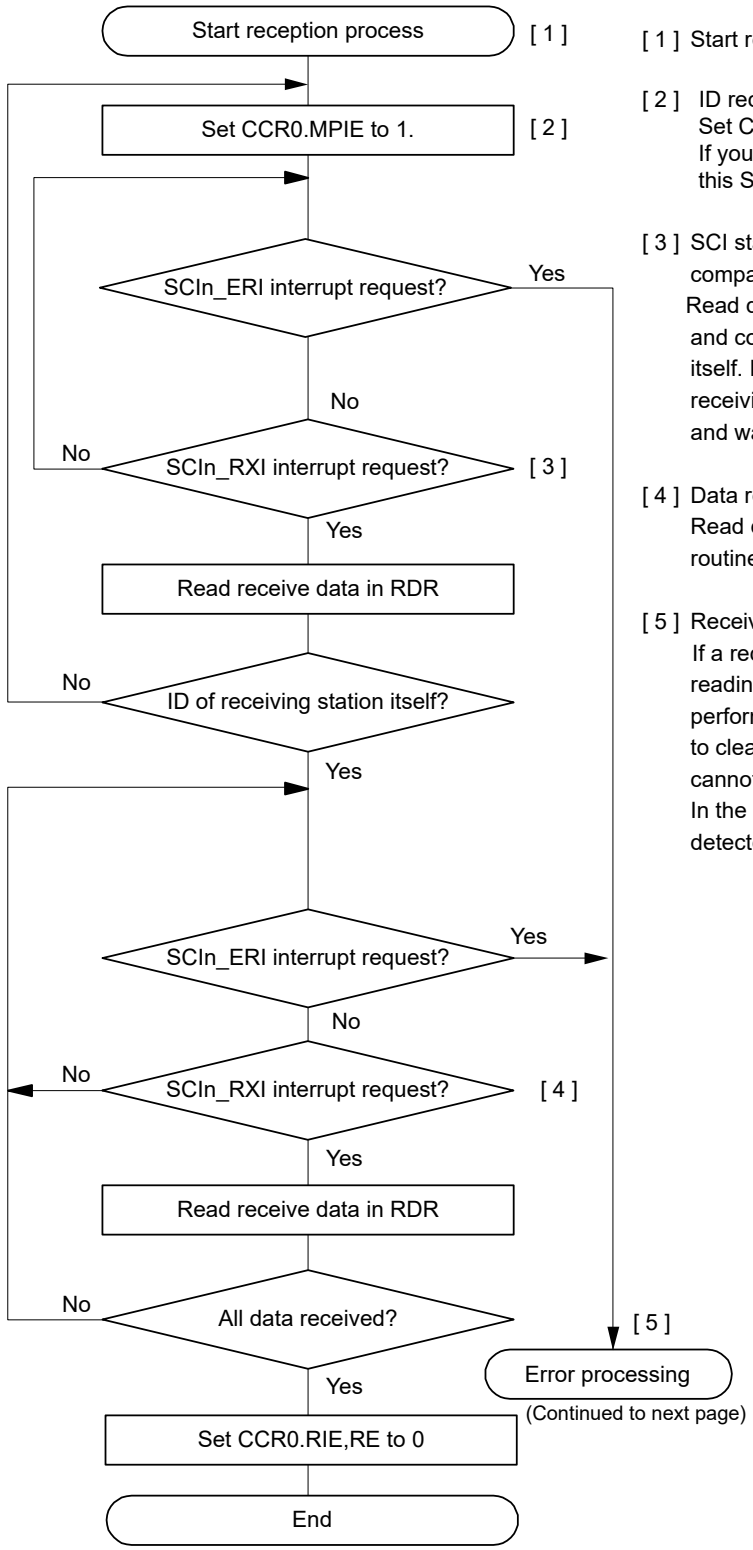
(a) When the received ID does not match the ID of the receiving station itself



(b) When the received ID matches the ID of the receiving station itself

Note 1. See section 12, Interrupt Controller Unit (ICU) for information on the corresponding interrupt event number.

Figure 28.39 Example of SCI reception with 8-bit data, multi-processor bit, and 1 stop bit



[1] Start reception process

[2] ID reception cycle:
Set CCR0.MPIE to 1. and wait for ID reception.
If you set this bits at initialization([1]), you can skip this Step.

[3] SCI status confirmation and reception and comparison of ID:
Read data in RDR at the first SCIn_RXI interrupt and compare it with the ID of the receiving station itself. If the ID does not match the ID of the receiving station itself, set the MPIE bit to 1 again, and wait for another SCIn_RXI interrupt request.

[4] Data reception at an SCIn_RXI interrupt:
Read data in RDR once in the SCIn_RXI interrupt routine.

[5] Receive error processing and break detection:
If a receive error occurs, an error is identified by reading ORER and FER flags in CSR. After performing the appropriate error processing be sure to clear the ORER and FER flags. Reception cannot be resumed if any of these flags is set to 1. In the case of a framing error, a break can be detected by reading CSR.RXDMON bit.

Figure 28.40 Example flow of multi-processor serial reception with non-FIFO selected (1)

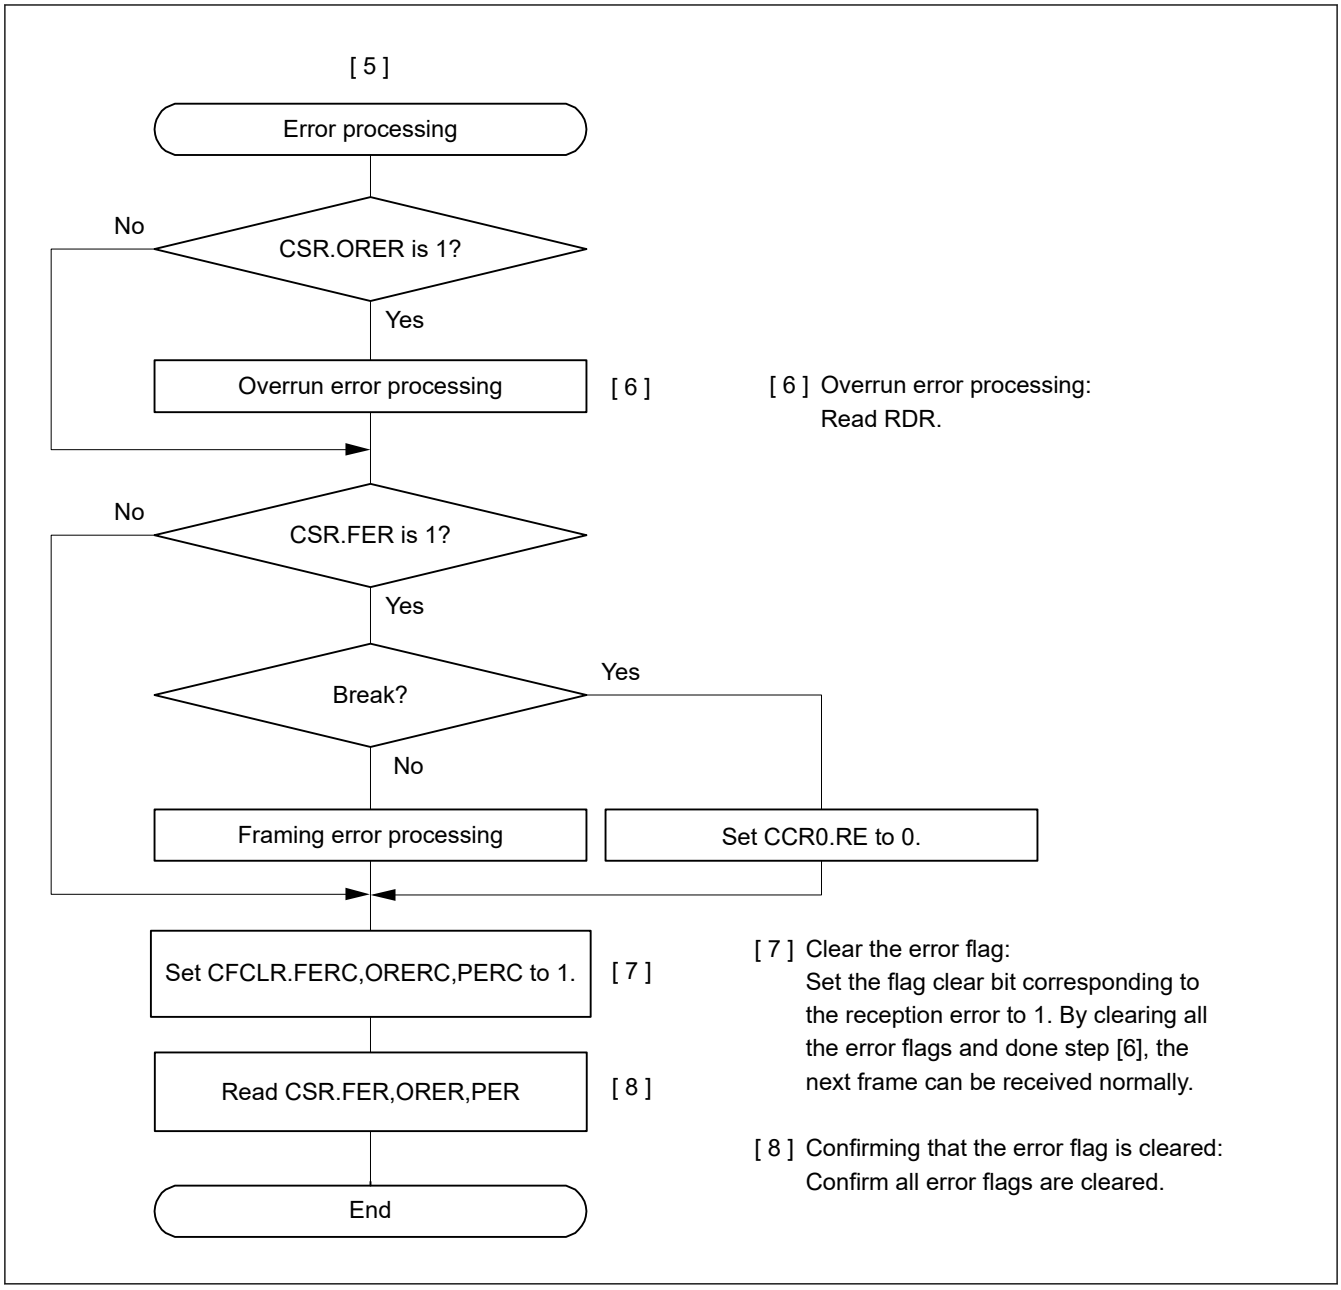


Figure 28.41 Example flow of multi-processor serial reception with non-FIFO selected (2)

(2) FIFO selected

Figure 28.42 shows an example of a data format that is written to receive-FIFO (RDR) in multi-processor mode.

In multi-processor mode, the MPB value that is a part of the receive data is written to the RDR.MPB bit. A value of 0 is written to the RDR.FPER and PER flags. Data is written to receive-FIFO (RDR) with the correct data length. Unused bits are written with 0. When software reads the receive-FIFO (RDR) register, the SCI updates RDR.FFER, FPER, and MPB flags, and receive data (RDAT[8:0]) in receive-FIFO (RDR) with the next data. The FER, PER, and ORER flags in the receive-FIFO (RDR) register always reflect the associated flags in the CSR and FRSR registers.

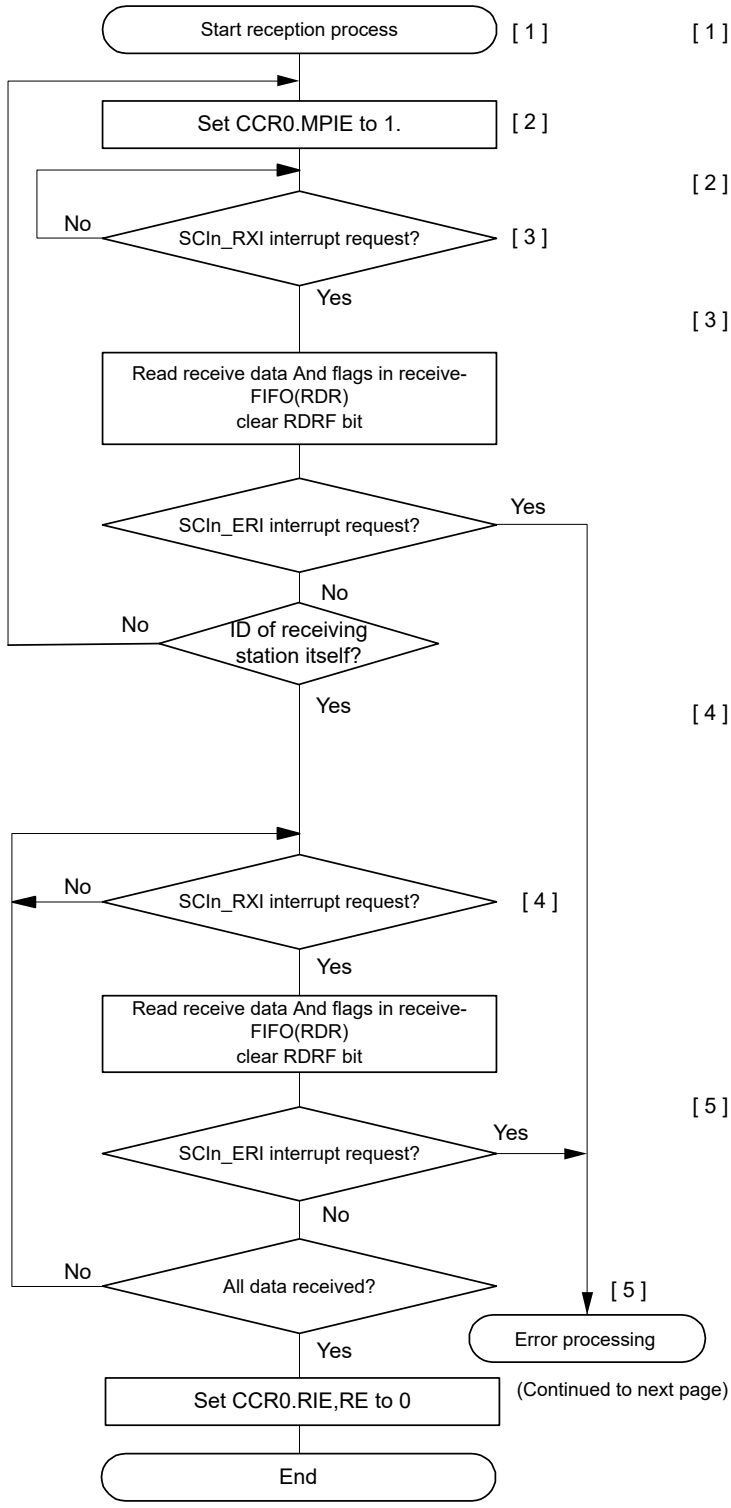
Data Length	Register Setting CCR3.CHR[1:0]		Receive data in RDR[31:0] b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
7bit	1	1	0	0	0	FFER	FPER	DR	MPB	0	0	RDAT[6:0]						
8bit	1	0	0	0	0	FFER	FPER	DR	MPB	0	RDAT[7:0]							
9bit	0	Don't Care	0	0	0	FFER	FPER	DR	MPB	RDAT[8:0]								
Data Length	CCR3.CHR[1:0]		b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
7bit	1	1	0	0	0	FER	PER	0	0	ORER	0	0	0	0	0	0	0	0
8bit	1	0	0	0	0	FER	PER	0	0	ORER	0	0	0	0	0	0	0	0
9bit	0	Don't Care	0	0	0	FER	PER	0	0	ORER	0	0	0	0	0	0	0	0

Note: When data length is 7bit, it can read always 0 in RDAT[8:7].
When data length is 8bit, it can read always 0 in RDAT[8].

Figure 28.42 Data format stored in receive-FIFO (RDR) in multi-processor mode with FIFO selected

Figure 28.43 shows an example flow of multi-processor data reception with FIFO selected. When the CCR0.MPIE is set to 1, reading communication data is skipped until reception of communication data in which the multi-processor bit is set to 1. When communication data in which the multi-processor bit is set to 1 is received, the received data, MPB and associated errors are transferred to the receive-FIFO (RDR) register. The CCR0.MPIE bit is automatically cleared and normal reception continues.

If a framing error occurs and the CSR.FER flag is set to 1, the SCI continues data reception. The rest of the operations are the same as operations in Asynchronous mode with FIFO selected.



[1] Start reception process
To generate an SCIn_RXI interrupt request with MP detection, please set FCR.RTRG = 1 and FCR.DRES = 0.

[2] ID reception cycle:
Set CCR0.MPIE to 1. and wait for ID reception. If you set this bits at initialization([1]), you can skip this Step.

[3] SCI status confirmation and reception and comparison of ID:
Skip the communication data until the MPB bit receives data 1. When the MPB bit receives data 1, an SCIn_XRI interrupt request is generated. When an SCIn_RXI interrupt request is received, read the data in the receiving FIFO (RDR register) and compare it to the ID of my station. If it is not my station's ID, set the MPIE bit to 1 again and wait for the SCIn_RXI interrupt request. For my station's ID, set the received FIFO threshold to the necessary value.

[4] Data reception at an SCIn_RXI interrupt:
When the number of received data stored in the received FIFO (RDR register) exceeds the received FIFO threshold, the CSR.RDRF bit becomes 1 and an SCIn_RXI interrupt request is generated. In addition, if the number of received data stored in the received FIFO (RDR register) is 1 or more and less than the received FIFO threshold, the FRSR.DR bit becomes 1 after 15 etus, and an SCIn_RXI interrupt request is generated. The SCIn_RXI interrupt routine reads the data from the received FIFO (RDR register).

[5] Receive error processing and break detection:
If a receive error occurs, an error is identified by reading ORER and FER flags in CSR. After performing the appropriate error processing be sure to clear the ORER and FER flags. In the case of a framing error, a break can be detected by reading the value of the RXDn pin.

Figure 28.43 Example flow of serial reception in multi-processor mode with FIFO selected

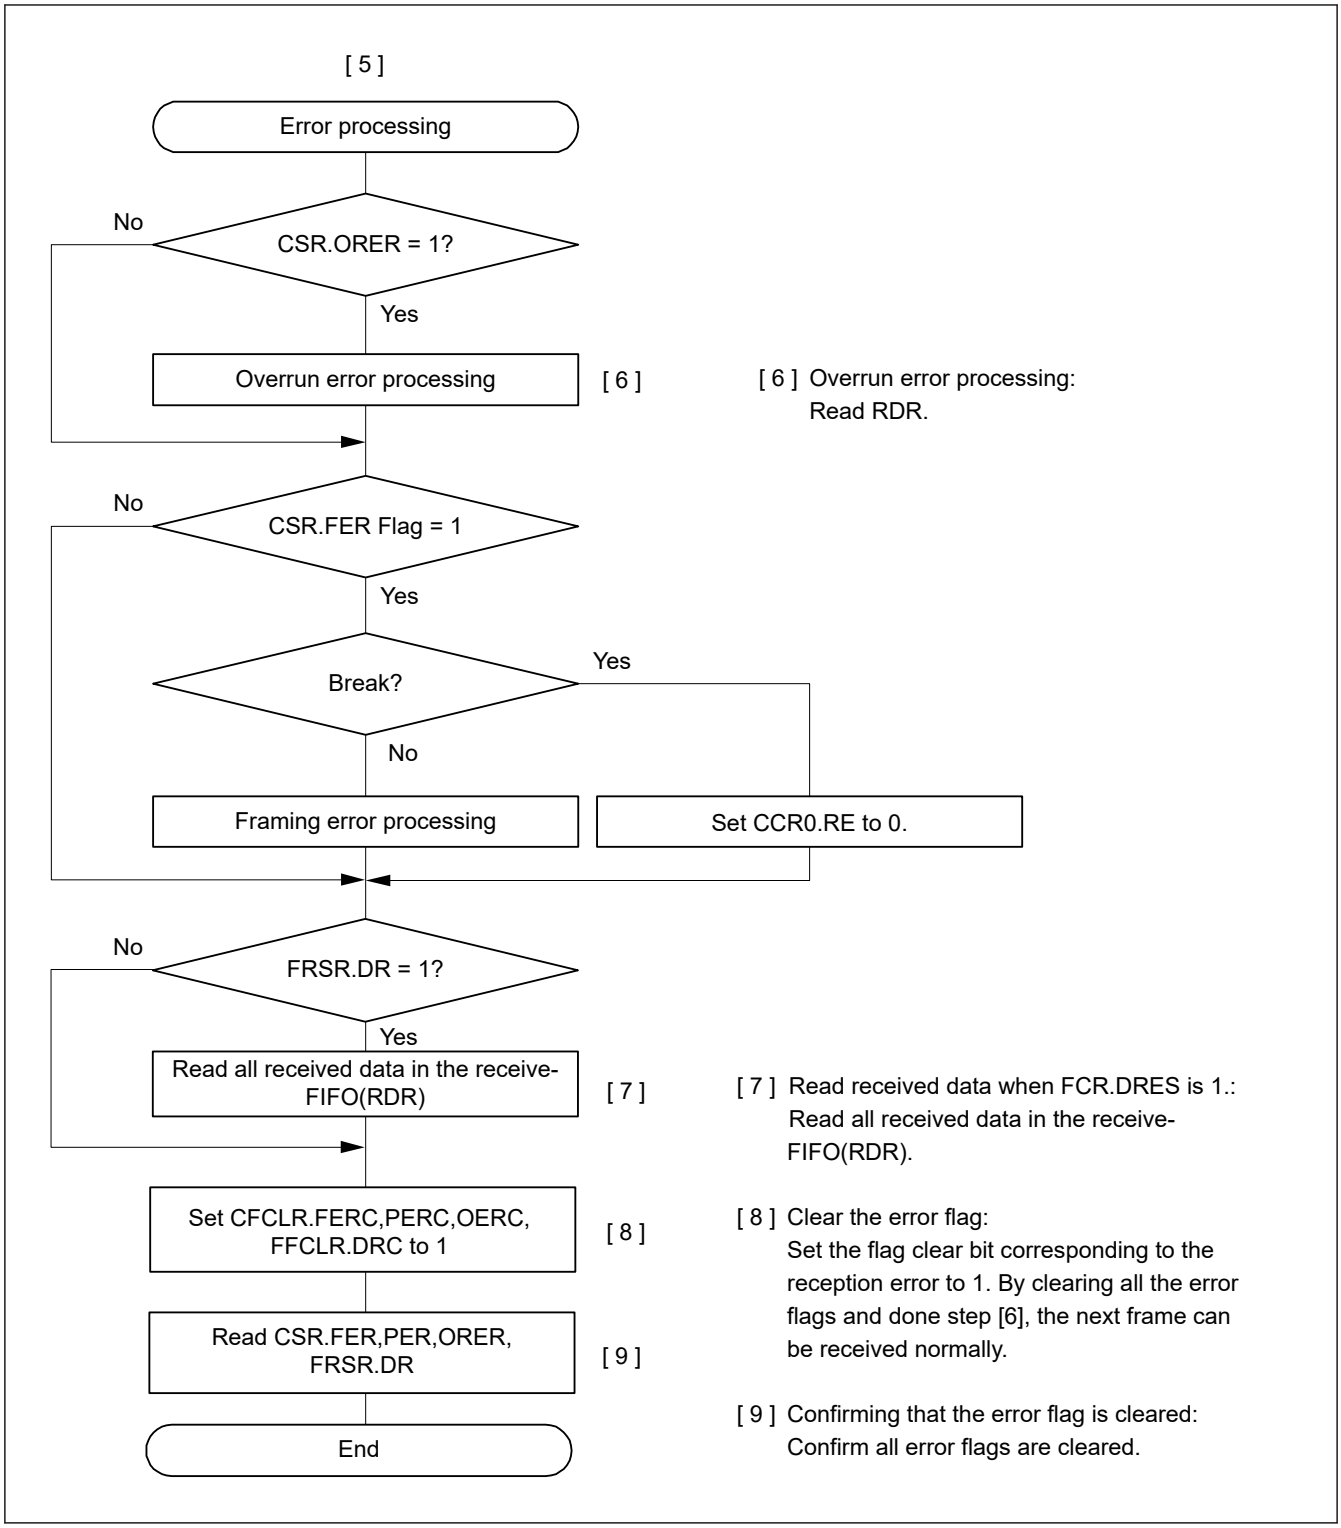


Figure 28.44 Example Flowchart of Serial Reception in Multi-Processor Mode (2) (FIFO selected)

28.5 Operation in Manchester mode

In Manchester mode, the transmit or receive serial data is coded in Manchester encoding.

Figure 28.45 shows the conceptual image of Manchester encoding.

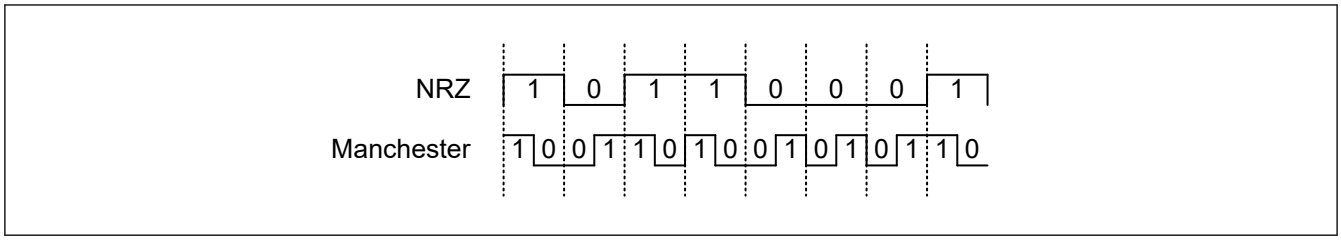

Figure 28.45 Example of Manchester Encoding

In Manchester mode, a preface and a start bit area are added to the transmit data in the register to configure a transmit frame. For transmission, data is encoded in Manchester encoding. When data is received, frames having the same format as transmitted frames are detected and Manchester decoding is performed.

For details on the frame format, see section 28.5.1. Frame Format.

28.5.1 Frame Format

Figure 28.46 shows the frame format in Manchester mode.

In the upper half of the figure, relevant setting registers are shown.

The preface area and the data area are encoded in Manchester encoding.

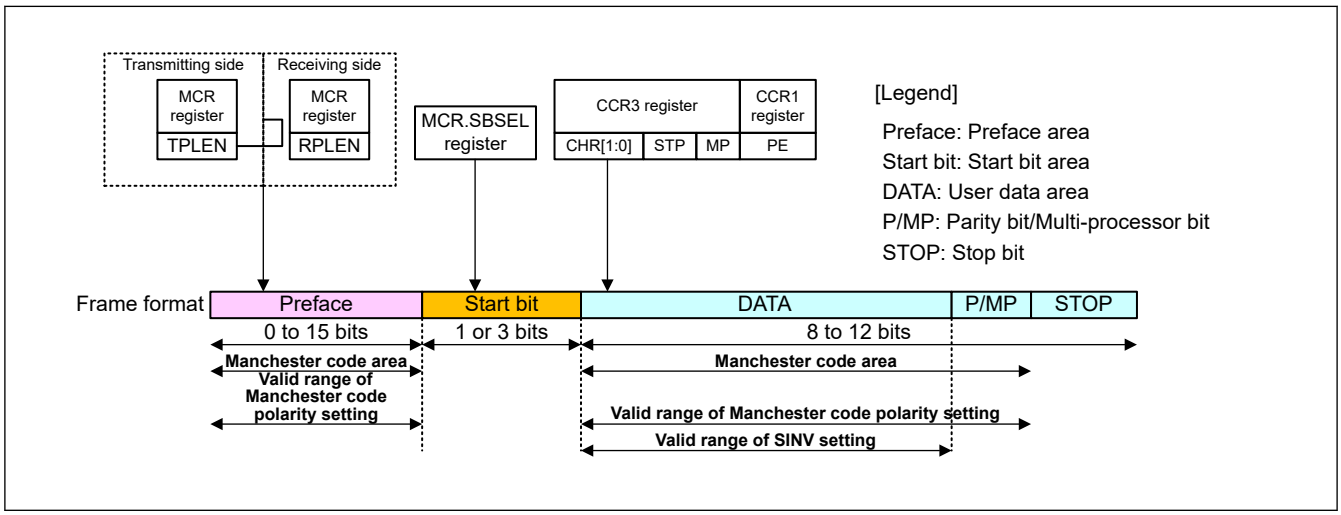

Figure 28.46 Frame Format in Manchester Mode

(1) Preface area

This is a fixed pattern area located at the beginning of each frame.

Different registers are used to set the preface area for transmission and reception. The preface length is determined by setting MCR.TPLEN[3:0] for transmission. It is determined by setting MCR.RPLEN[3:0] for reception.

If it is set to 0, the transmit preface is disabled and is not added.

If it is set to 1d to 15d, a preface whose length is determined by this setting is added.

(For example, if it is set to 1d, a 1-bit preface is added. If it is set to 15d, a 15-bit preface is added.)

The preface pattern is set with MCR.TPPAT[1:0] for transmission and MCR.RPPAT[1:0] for reception, and is selected from four types of patterns.

Figure 28.47 shows how the preface pattern is set. The preface area and the start bit area are added for each communication frame.

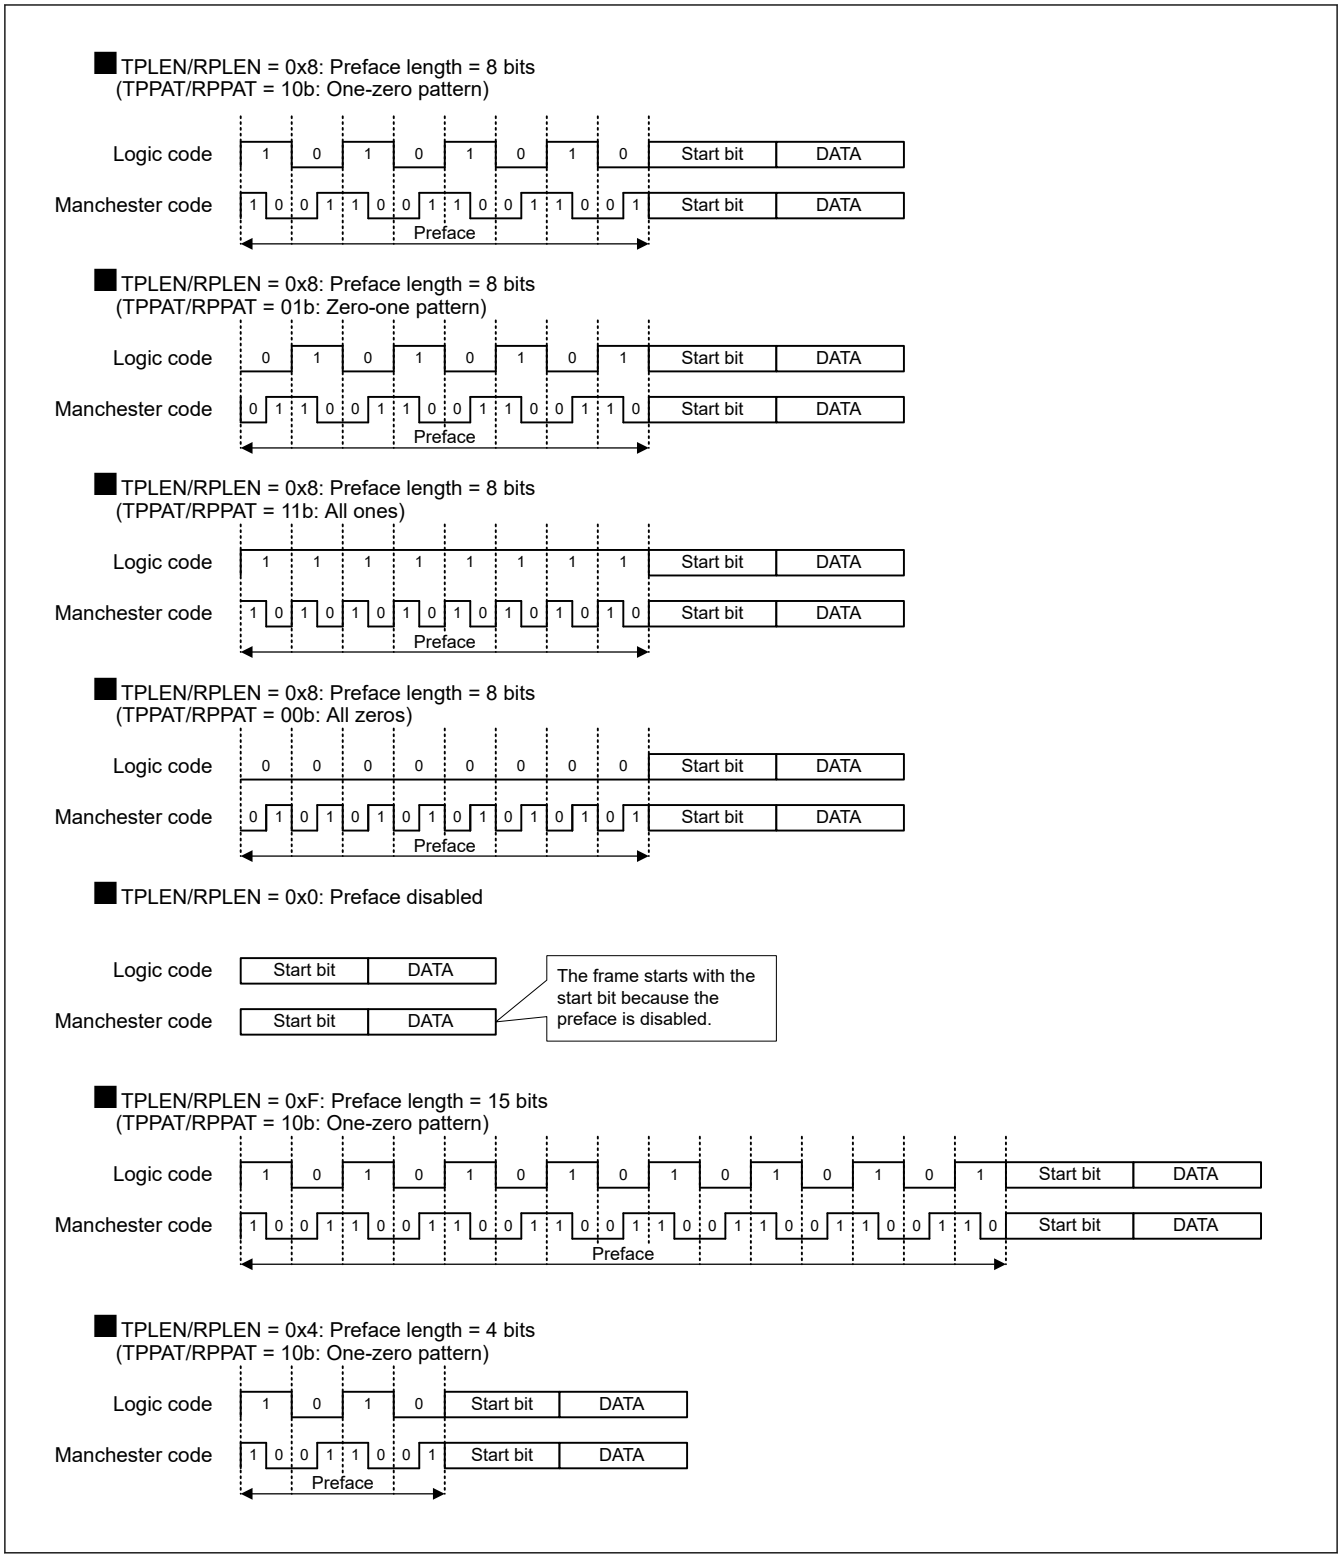

Figure 28.47 Preface Pattern Setting Example

(2) Start bit area

This is an area indicating the start of valid data in a frame. It is added after the preface area.

The start bit length is determined by MCR.SBSEL setting. When MCR.SBSEL = “0”, the start bit length is 1 bit.

When MCR.SBSEL = “1”, the start bit length is 3 bits.

When MCR.SBSEL = “1”, the SYNC type can be selected from command SYNC and data SYNC.

Command SYNC means the three start bits are added as a one-to-zero transition.

Data SYNC means the three start bits are added as a zero-to-one transition.

The SYNC type is determined by the MCR.SYNSEL, MCR.SYNVAL and TDR.TSYNC settings.

(When receiving, the received result is applied to MSR.RSYNC.)

When MCR.SBSEL = “0”, the start bit is added as a zero-to-one or one-to-zero transition.

The selection is determined by the MCR.SYNVAL setting.

The MCR.SYNSEL bit specifies the destination to be referred to when setting for transmission.

When the MCR.SYNSEL bit is set to 1, the MCR.SYNVAL setting is referred to. When the MCR.SYNSEL bit is set to 0, the TDR.TSYNC setting is referred to.

Figure 28.48 shows the state of the start bit area according to the settings in the MCR.SYNSEL, MCR.SYNVAL and TDR.TSYNC registers in the case of transmission. Figure 28.49 shows that in the case of reception.

The start bit(s) is not affected by the MCR.TMPOL or MCR.RMPOL setting.

*d.c. = don’t care, Preface = preface area, START = start bit area, Data = user data area,
P = parity bit, MP = multi-processor bit, STOP = stop bit

Register setting				Output signal	Output Start bit
MCR			TDR	Output TXDn waveform	
SBSEL	SYNSEL	SYNVAL	TSYNC		
0	d.c.	0	d.c.		1bit 0 to 1 transition
0	d.c.	1	d.c.		1bit 1 to 0 transition
1	0	0	d.c.		3bit 0 to 1 transition (DATA SYNC)
1	0	1	d.c.		3bit 1 to 0 transition (COMMAND SYNC)
1	1	d.c.	0		3bit 0 to 1 transition (DATA SYNC)
1	1	d.c.	1		3bit 1 to 0 transition (COMMAND SYNC)

Figure 28.48 Settings Related to and Format of the Start Bit Area at Transmission

d.c. = don't care, Preface = Preface area, START = Start bit area, Data = Data area
P = Parity bit, MP = Multi-processor bit, STOP = Stop bit

Register setting				Input signal	Start bit detection result*1	Register indication
MCR			TDR	RXDn input waveform		MSR.RSYNC
SBSEL	SYNSEL	SYNVAL	TSYNC			
0	d.c.	0	d.c.		Normal start bit (1 bit: 0-to-1 transition)	0
					Start bit error	0
					Start bit error	0
					Start bit error	0
0	d.c.	1	d.c.		Start bit error	0
					Normal start bit (1 bit: 1-to-0 transition)	0
					Start bit error	0
					Start bit error	0
1	d.c.	d.c.	d.c.		Start bit error	0
					Start bit error	0
					Data SYNC	0
					Command SYNC	1

Note 1. Data other than the start bit is assumed to be normal.

Figure 28.49 Settings Related to and Judgment of the Start Bit Area at Reception

(3) DATA

Since the format of the data area is the same as that of the Asynchronous mode, see section 28.3.1. Serial Data Transfer Format.

As shown in Figure 28.45, Frame Format in Manchester Mode, the stop bit is not included in the Manchester encoding range.

28.5.2 Clock

As the transfer clock in Manchester mode, the clock generated by the on-chip baud rate generator is used by setting the CCR2.CKS[1:0] bit.

Also it is possible to set the oversampling (transfer rate of one-bit period) by CCR2.ABCS bit.

When the CCR2.ABCS bit is set to 0, oversampling x16 is selected with the one-bit period being 16 cycles of the base clock. When the CCR2.ABCS bit is set to 1, oversampling x8 is selected with the one-bit period being 8 cycles of the base clock.

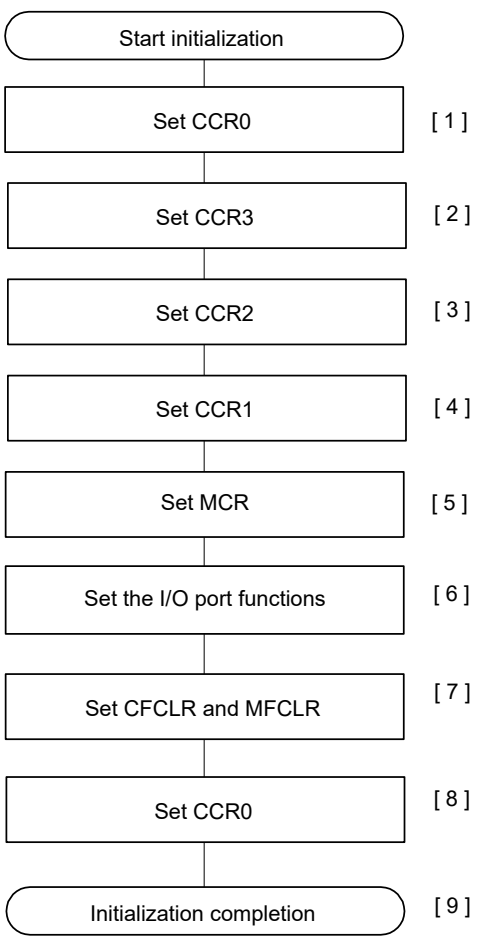
28.5.3 Initialization of the SCI in Manchester Mode

Before transferring data, write 0 to CCR0.TE and CCR0.RE (or write the initial value to CCR0 register) and initialize the SCI following the example of flowchart shown in Figure 28.50.

Whenever the operating mode or transfer format is changed, the CCR0 register must be initialized before the change is made.

Note that setting the CCR0.RE bit to 0 initializes none of the ORER, FER, PER, MER, RDRF, SYER, PFER and SBER flags, and the RDR registers.

Note also that switching the value of CCR0.TE from 0 to 1 when CCR0.TIE is 1 generates a SCIn_TXI interrupt request.



[1] Set the following bits of CCR0 to 0.
TEIE, TIE, RIE, TE, RE
If you have not changed from the initial settings, you can skip this step.

[2] Set the driver control, Multi-processor communication, the communication mode, transmission/reception format, and Clock enable.
Do not use function bits such as CPOL and CPHA at the initial value.

[3] Set the clock selection, Bit rate setting.
Leave unused function bits at their initial values.(ex. BRME)

[4] Set the noise filter, loopback control, communication pin status, parity check, and CTS / RTS function.

[5] Set Manchester transmission / reception setting.
Start bit setting, retiming setting, Manchester polarity setting, transmission preface setting, reception preface setting.

[6] Set the I / O port so that the required pin function is valid among the TXDn, RXDn, and SCKn pins.

[7] Set 1 to the following clear bits in the CFCLR and MFCLR registers to clear the target flag.
CFCLR.RDRFC, FERC, PERC, MFFC, ORERC, DFERC, DPERC, DCMFC, ERSC
MFCLR.MERC, SBERC, SYERC, PFERC
This procedure can be omitted for the initial setting after reset.

[9] Set the TE bit or RE bit to 1.
To enable interrupts, set the TE bit and TIE bit, and the RE bit and RIE bit to 1 with one instruction at the same time, and multiprocessor function. The TXDn and RXDn pins can be used by setting the TE and RE bits.

Figure 28.50 SCI Initialization Flow in Manchester Mode

28.5.4 Double-speed operation

When the ABCS bit in CCR2 is set to 1 and eight pulses of the base clock for a 1-bit period is selected, the SCI operates on the bit rate twice that of when ABCS is set to 0.

When the BGDM bit in CCR2 is set to 1, the cycle of the base clock is reduced to half and the SCI operates on the bit rate twice that of when ABCS is set to 0.

When the ABCS and the BGDM bits in CCR2 are set to 1, the SCI operates on the bit rate four times that of when the ABCS and the BGDM bits in CCR2 are set to 0.

28.5.5 CTS and RTS functions

The CTS function uses input on the CTSn pin in transmission control. Setting the CTSE bit in CCR1 to 1 enables the CTS function. The CTSn_RTSn pin can be set as a multiplexed pin which allows one pin to be used for either CTS or RTS function, or as dedicated pins with each pin at CTSn pin for CTS function and CTSn_RTSn pin for RTS function. Use the CTSPEN bit in CCR1 for this setting.

When the CTS function is enabled, reception starts only when the CTSn pin is at the low level.

Applying a high level to the CTSn pin after transmission starts does not affect transmission of the current frame, which continues.

The RTS function uses output on the CTSn_RTSn pin to request transmission. When the SCI is ready to receive, it outputs a low level to the CTSn_RTSn pin, Conditions for output of the low level and high level are as follows:

[Conditions for low-level output]

When all conditions listed below are satisfied:

- The value of the RE bit in CCR0 is 1.
- When The SCI is ready to receive next.
  - When there is no received data yet to be read and not receiving
  - All of the following flags are set to 0: CSR.ORER, FER, and PER, MSR.MER, SYER (when SYEREN = 1), PFER (when PFEREN = 1) and SBER flags (when SBEREN = 1).

[Conditions for high-level output]

- When the conditions for low output are not satisfied

28.5.6 Serial data transmission in Manchester mode

The SCI encodes data in Manchester encoding and sends the resultant data in Manchester mode.

When the polarity setting (MCR.TMPOL) set to 0, logic 0 is coded as a zero-to-one transition in Manchester code and logic 1 is coded as a one-to-zero transition in Manchester code.

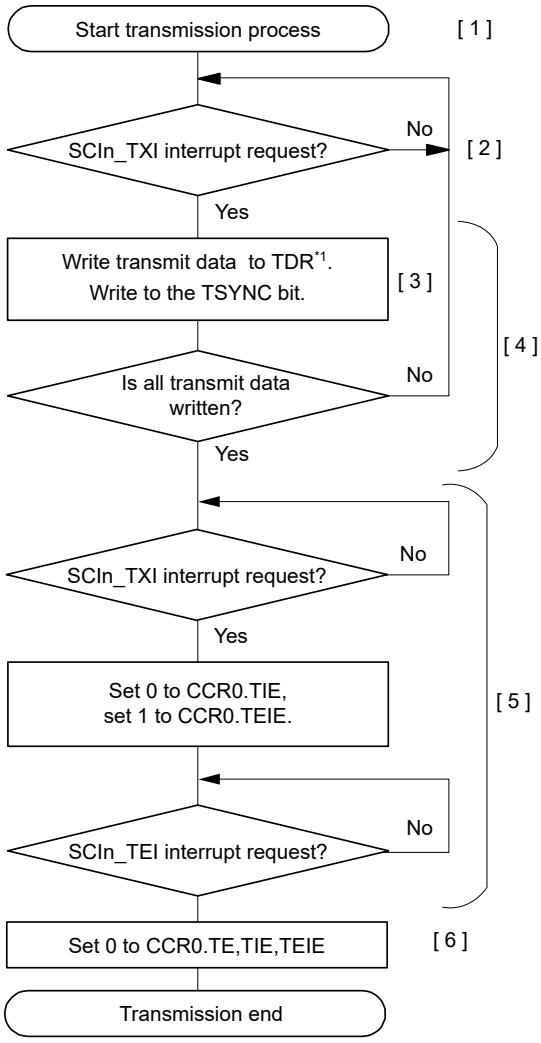
When the polarity setting (MCR.TMPOL) set to 1, logic 0 is coded as a one-to-zero transition in Manchester code and logic 1 is coded as a zero-to-one transition in Manchester code.

For this reason, a level transition occurs with the Manchester encoded data in the middle of individual logic data. (See Figure 28.45).

The transmitter constructs transmit frames in a specific format by adding a preface area to data and setting the start bit(s) according to the polarity setting and sends resultant serial data.

For details on the frame format, see section 28.5.1. Frame Format.

Figure 28.51 shows the flowchart in transmission. At transmission starts, set the CCR0.TIE and CCR0.TE bits to 1 simultaneously with one instruction. Then, a SCIn_TXI interrupt request is generated. Figure 28.52, Figure 28.53, and Figure 28.54 show examples of the operation for serial transmission in Manchester mode.



[1] Start transmission process

[2] SCIn_TXI interrupt:
A transmit data empty interrupt (SCIn_TXI) request is generated when CCR0.TIE = 1 and TE = 0->1, and when transmit data is transferred from TDR to TSR.

[3] TDR setting:
Write the transmit data to TDR.
When TSYNC is used, also set TDR.TSYNC.

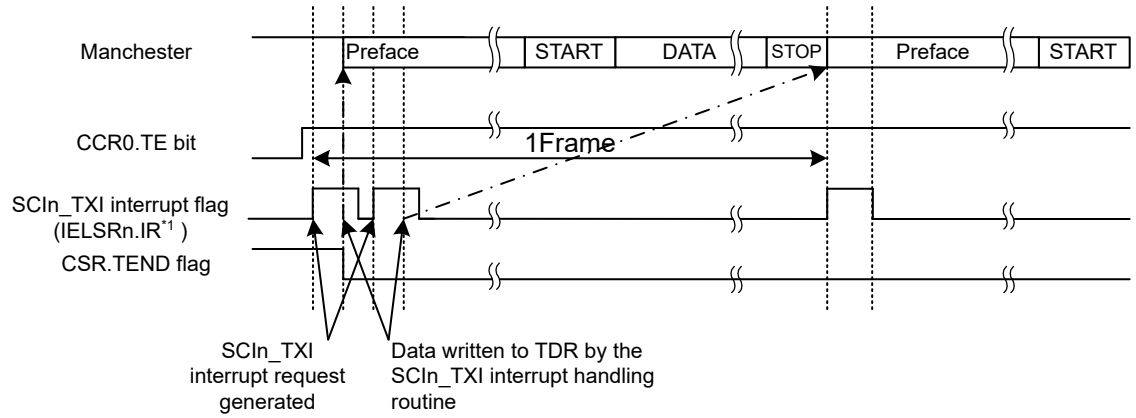
[4] Serial transmission continuation procedure:
To continue serial transmission, write the transmit data to TDR*1 once by using an SCIn_TXI interrupt.
The transmit data can also be written to TDR*1 by activating the DMAC or DTC in the SCIn_TXI interrupt request.

[5] When SCIn_TEI interrupt requests are used, set the CCR0.TIE bit to 0 and the CCR0.TEIE bit to 1 after the last of the data to be transmitted is written to TDR and it's transmission is started.

[6] Set 0 to CCR0.TE, TIE and TEIE.

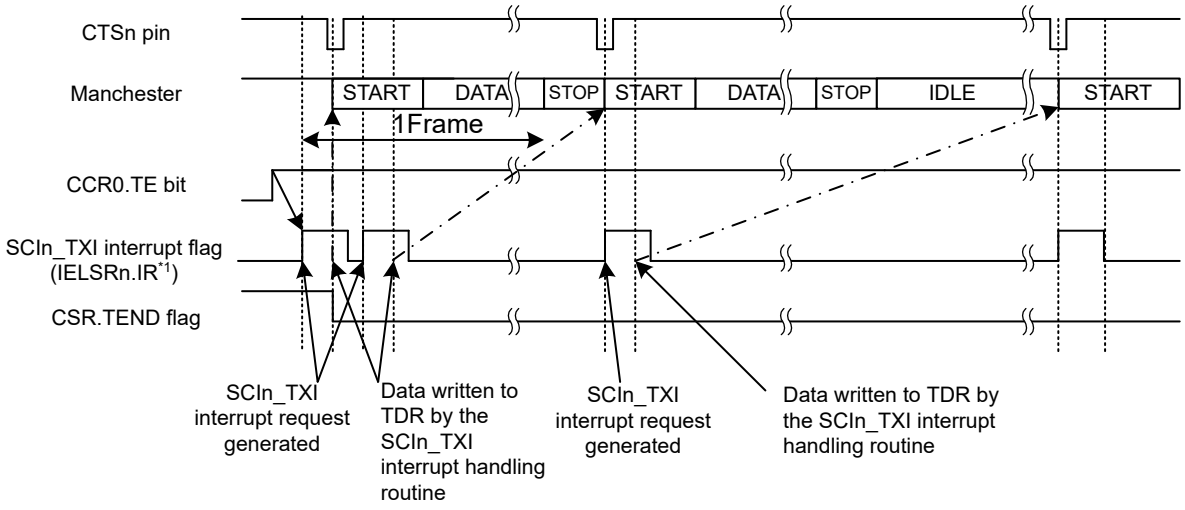
Note 1. If TDR[15:8] requires data write and byte access is required, write the transmit data in the order of TDR [15:8] and TDR [7:0].

Figure 28.51 Example of Serial Transmission Flowchart in Manchester Mode



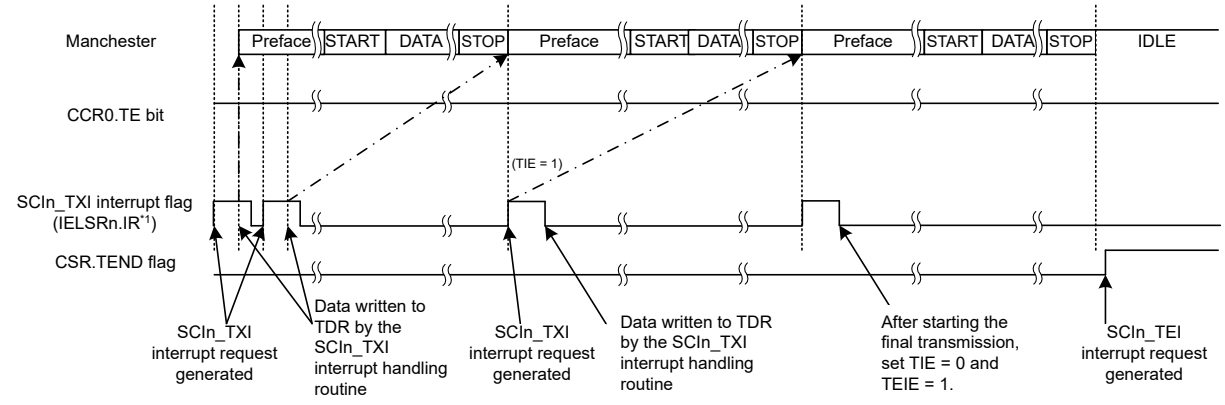
Note 1. For corresponding interrupt numbers, see section 12, Interrupt Controller Unit (ICU)

Figure 28.52 Example of Start-of-Transmission Operation for Serial Transmission in Manchester mode (with Preface but Without the CTS Function)



Note 1. For corresponding interrupt numbers, see section 12, Interrupt Controller Unit (ICU)

Figure 28.53 Example of Start-of-Transmission Operation for Serial Transmission in Manchester Mode (Without Preface but with the CTS Function)



Note 1. For corresponding interrupt numbers, see section 12, Interrupt Controller Unit (ICU)

Figure 28.54 Example of End-of-Transmission Operation for Serial Transmission in Manchester Mode (with Preface but Without the CTS Function)

28.5.7 Serial Data Reception in Manchester Mode

In Manchester mode, the SCI operates on a base clock with a frequency of 16 times*1 the bit rate. Reception starts by sampling the falling edges of received data at the base clock. As shown in Figure 28.55, reception starts at a falling edge of the received data and it continues if the received data keeps low for the duration of 1/4 bit. If the received data goes high within the duration of 1/4 bit, the SCI judges it as an error and waits for a falling edge again.

If a high level is expected in the first half of a bit in the received data, the SCI judges a low level that continues for one base clock cycle as an error and ignores the change to the low level.

Note 1. This is the case when CCR2.ABCS = 0. When CCR2.ABCS = 1, the SCI operates on a base clock with a frequency of 8 times the bit rate.

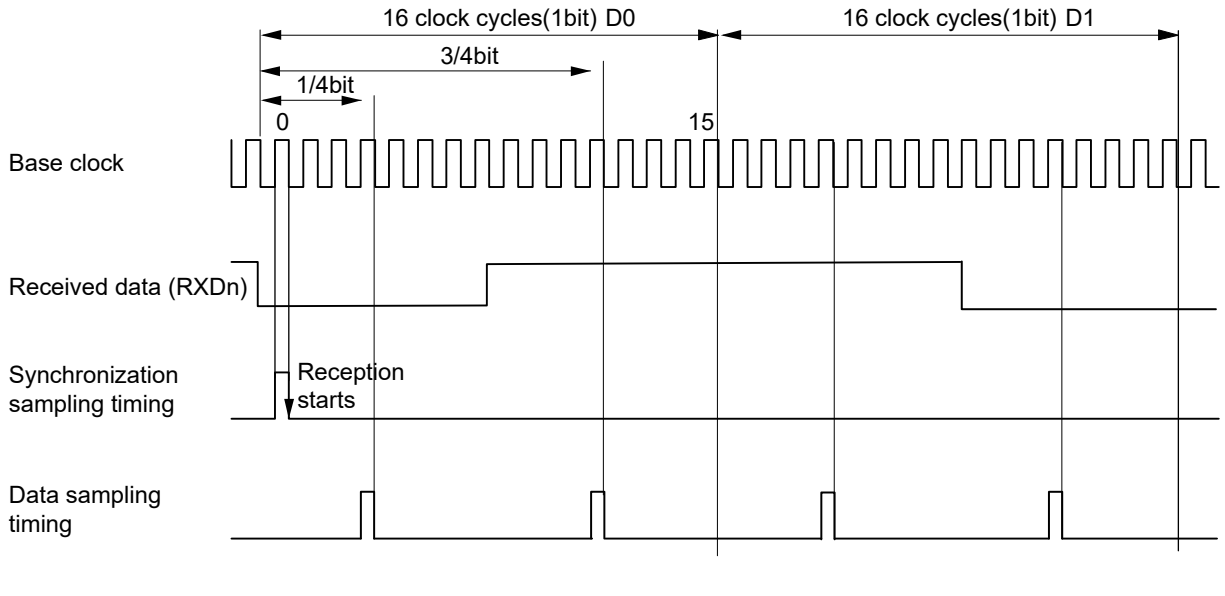


Figure 28.55 Data Reception Sampling Timing in Manchester Mode

In Manchester mode, data reception starts with detection of a preface and start bit area.

The SCI checks the input from the RXDn pin to see whether a preface is added based on the value of MCR.RPLEN.

If the preface is disabled (MCR.RPLEN = 0), it moves on to the detection of a start bit area without detecting a preface.

When a preface is enabled, it identifies a preface pattern setting according to the set value in MCR.RPPAT, and compares it with the RXDn input for a pattern match to detect a preface pattern.

Upon detection of a preface pattern match, it judges it as a normal preface and moves on to the detection of a start bit area.

If detecting a preface pattern mismatch or a Manchester code error in the preface area, it judges it as a preface error and asserts a preface error (PFER).

For start bit detection, the SCI selects an expected value based on the register settings (MCR.SBSEL and SYNVAL), compares it with the RXDn input for a pattern match to detect a start bit area. Upon detection of a start bit pattern match, it judges it as a normal start bit area and moves on to the data processing.

Only when a preface and a start bit area are detected normally, it moves on to the next phase of data reception.

Upon detection of a start bit pattern mismatch, it asserts a start bit error flag (SBER).

In data processing, the SCI shifts the data by the expected received data length based on the register settings (CCR3.CHR[1:0]) through the RSR register. If two sampling points in a bit of the received data are identical, the SCI judges this as a Manchester code error.

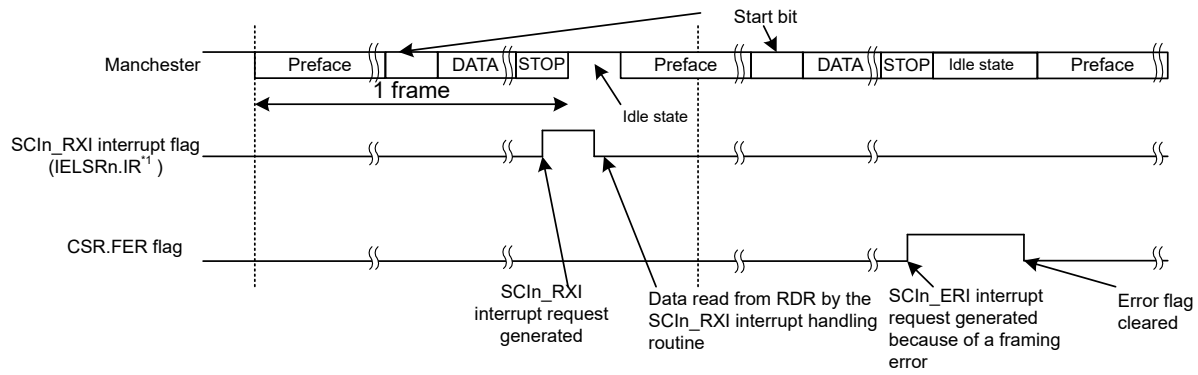
For details, see section 28.5.11. Errors in Manchester Mode (4).

When the parity function is disabled (CCR1.PE = 0), the SCI moves on to the next phase of stop bit detection. When the parity function is enabled (CCR1.PE = 1), the SCI performs parity checking. If detecting a parity error, it asserts a parity error flag (PER), and then moves on to stop bit detection.

In stop bit detection, the SCI checks the following in the stop bit area of the received frame:

It has two sampling points in a bit. If both points are at the high level, the bit is recognized as a normal stop bit and the data is stored in the RDR register. At least one low-level point is judged as an abnormal stop bit, causing a framing error flag (FER) to be set. Even when an error is detected, the received data is stored in the RDR register as abnormal data.

Figure 28.56 shows an example of the operation for serial data reception in Manchester mode.



Note 1. For corresponding interrupt numbers, see section 12, Interrupt Controller Unit (ICU).

Figure 28.56 Example of Operation for Serial Data Reception in Manchester mode (with a Preface)

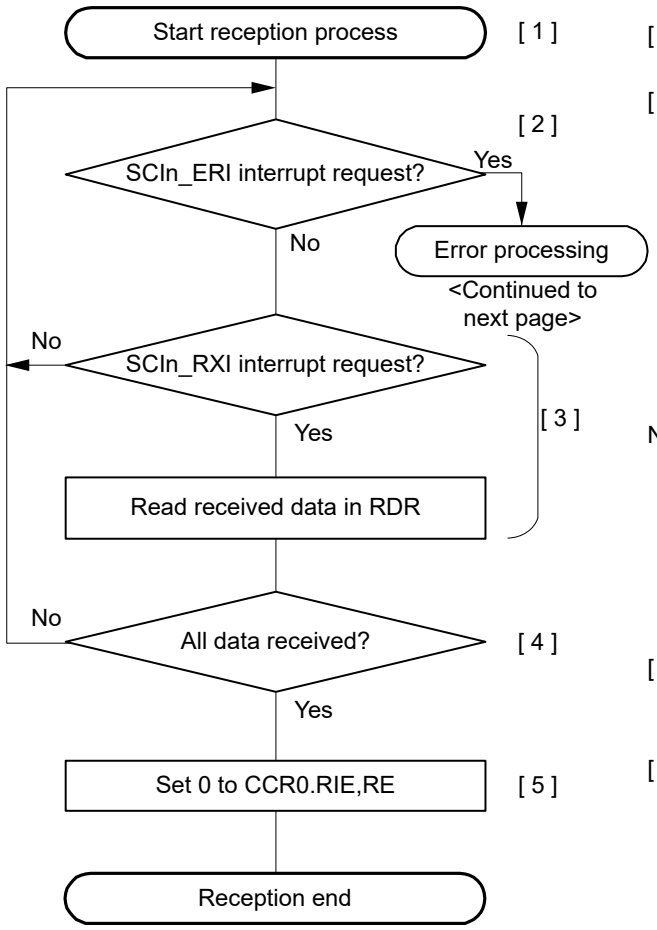
For the state of each status flag in the CCR0 register and RXDn input processing when a receive error is detected, see section 28.5.11. Errors in Manchester Mode.

If a receive error is detected, an SCIn_ERI interrupt request is generated but an SCIn_RXI interrupt request is not generated.

Data reception cannot be resumed while the receive error flag is 1. Accordingly, set the ORER, FER, PER, MER, SYER*1, PFER*1, and SBER*1 flags to 0 before resuming reception. Also, be sure to read the RDR register during overrun error processing. When a reception is forcibly terminated by setting the CCR0.RE bit to 0 during operation, read the RDR register because received data which has not yet been read may be left in the RDR register.

Figure 28.57 and Figure 28.58 show examples of serial data reception flowchart in Manchester mode.

Note 1. Effective when the corresponding bit is enabled.



[1] Start reception process

[2] Receive error processing:
When a receive error occurs, SCI generates an SCIn_ERI interrupt . An error is identified by reading the ORER, PER, FER in CSR and MER, SBER, SYER, PFER in MSR. After performing the appropriate error processing, always set the ORER, PER, FER, MER, SBER, SYER, PFER flags to 0. Reception cannot be resumed if any of these flags is set to 1.

Note: Each of the PFER, SYER, SBER bits in MSR has an enable bit (PFEREN, SYEREN, and SBEREN in MECR). If the corresponding enable bit is set to 0 (disable), the flag value does not affect the communication. Perform error processing as required.

[3] Read the received data in RDR once in the SCIn_RXI interrupt handling routine.

[4] Serial reception continuation procedure:
To continue serial reception, before the stop bit of a frame is received, read data from RDR in the SCIn_RXI interrupt handling routine. The RDR data can also be read by activating the DMAC or DTC.

[5] Write 0 to CCR0.RIE and RE.

Figure 28.57 Example of Serial Data Reception Flowchart in Manchester Mode (Normal Reception)

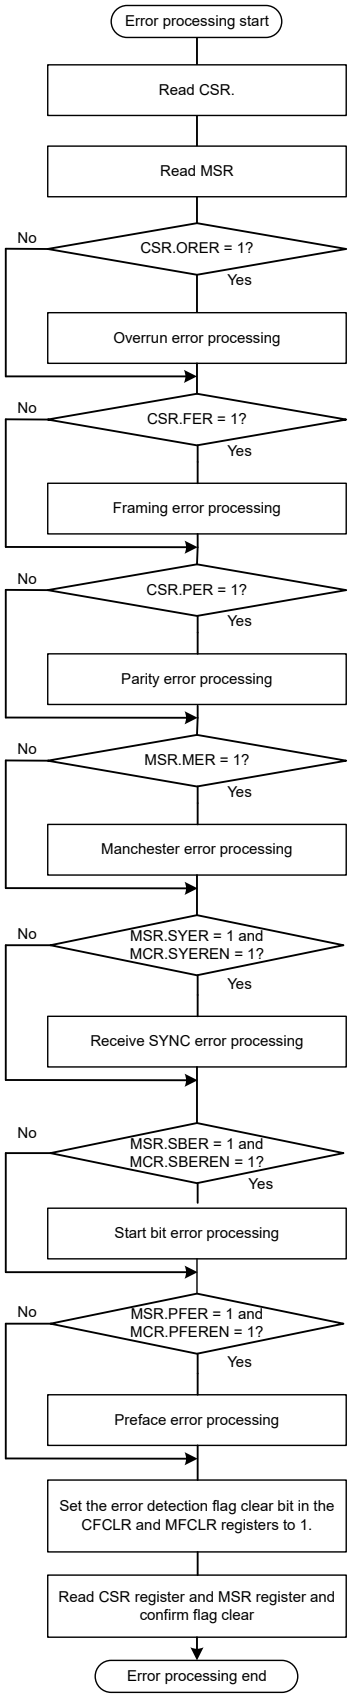


Figure 28.58 Example of Serial Reception Flowchart in Manchester Mode (Error Processing)

28.5.8 Operation When Multi-Processor Bit Is Used

See section 28.4. Multi-Processor Communication Function (1) for the operation in Manchester mode when using multi-processor mode because the operation is the same.

A preface and a start bit area are added to the frame format in Manchester mode. See Figure 28.58 for error processing in Manchester mode for the reception flowchart (Figure 28.41). See Table 28.37 for the operation status when detecting various errors.

28.5.9 Receive Retiming

This function corrects the timing for each central edge of the bit, taking advantage of the fact that each bit has an edge in the center in Manchester code.

The receive retiming function can be turned on or off by setting the ERTEN bit in the MCR register.

When the receive retiming function is turned off (MCR.ERTEN = 0), retiming is not performed, causing misalignment between the internal clock and the RXDn input to be accumulated and the receive margin to be reduced.

When the receive retiming function is turned on (MCR.ERTEN = 1), retiming is performed for the preface area, the start bit area*1, and the data area (excluding the stop bit).

Note 1. Retiming is not performed for the start bit area if the preface length is 0 and the start bit length is 3.

As an example, the receive retiming when oversampling x16 is selected is shown below.

When detecting an RXDn input edge two to four cycles before the expected receive cycle, the receive processing is shortened by one sampling CLK cycle.

When detecting a RXDn input edge two to three cycles after the expected receive cycle, the receive processing is extended by one sampling CLK cycle.

(Even if the clock is misaligned with the data by more than two cycles, one cycle is corrected for each bit.)

Figure 28.59 shows the conceptual image of receive retiming range.

When detecting an edge in the tolerance area in the figure, data is received as is without making correction.

When detecting an edge in the SyncJump area in the figure, data is corrected for reception.

When detecting an edge in the SyncError area in the figure, data is received as abnormal data with no correction made.

For a Manchester code error (data matches at the 1/4-phase and 3/4-phase sampling points), the SCI reports a code error.

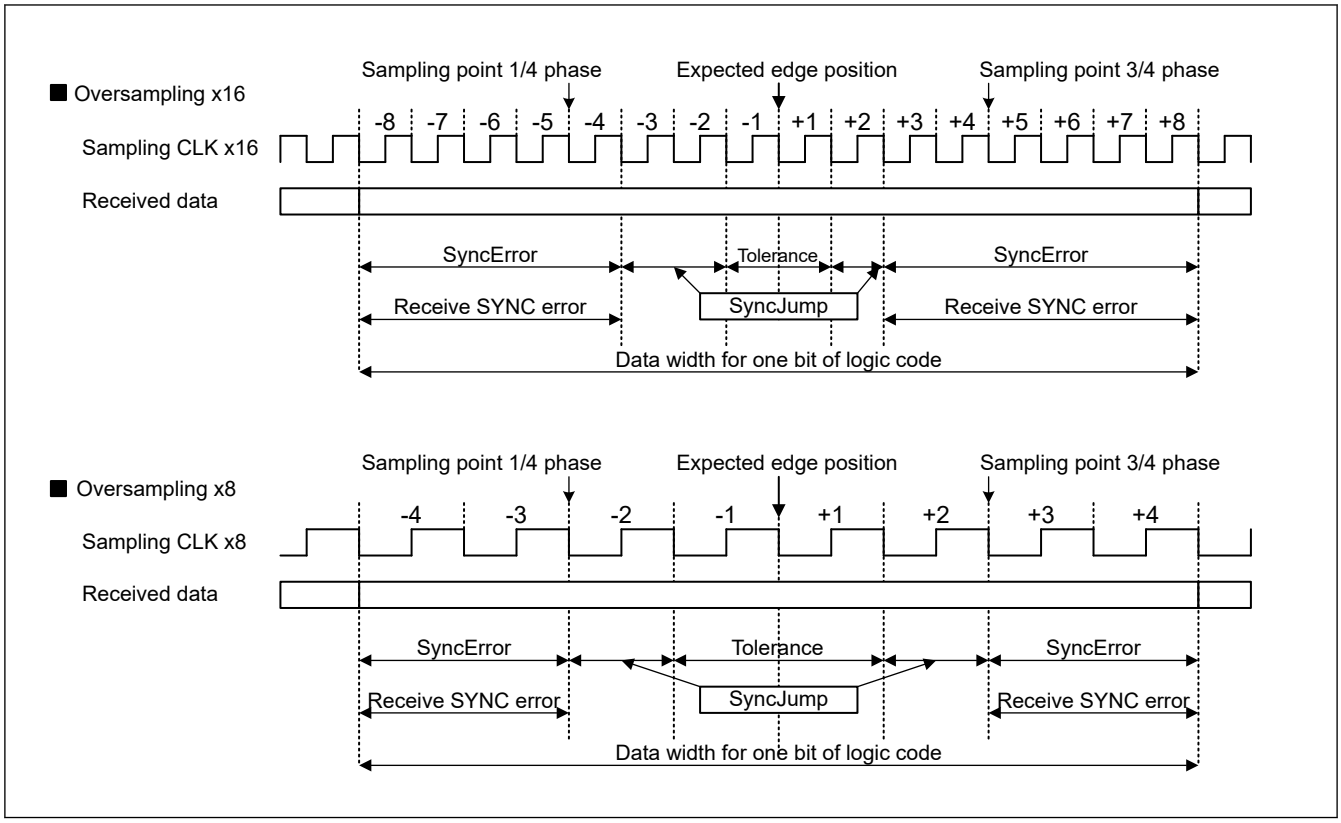

Figure 28.59 Conceptual Image of Reception Retiming Range

28.5.10 Polarity Setting for Manchester Code

The polarity of the Manchester code can be set with the Manchester Control Register (MCR).

It can be set separately for transmission and reception. Use the MCR.TMPOL bit to set the polarity for transmission and the MCR.RMPOL bit to set the polarity for reception.

The Manchester code polarity setting is valid for the preface area, the data area, and the parity or multi-processor area.

When the initial settings (TMPOL/RMPOL = 0) are used for the polarity of Manchester code, logic 0 is encoded as a zero-to-one transition in Manchester code and logic 1 is encoded as a one-to-zero transition in Manchester code. If the settings are changed to TMPOL/RMPOL = 1, logic 0 is encoded as a one-to-zero transition in Manchester code and logic 1 is encoded as a zero-to-one transition in Manchester code. Figure 28.60 shows the conceptual image of the settings and operation.

Separately from the function above, the transmitted and received data in the data area can be inverted by the transmitted/received data inversion function (CCR3.SINV). Since the polarity of Manchester code (MCR.TMPOL/RMPOL) can be set separately from the transmitted/received data invert function (CCR3.SINV), if both are set to inversion (MCR.TMPOL/RMPOL = 1 and CCR3.SINV = 1), the transmitted and received data are set to initial state (inversion + inversion = normal).

The polarity of the start bit area can be set by a register different from the ones mentioned above.

Since a different register is used, the polarity of the start bit area is not affected by the polarity setting for Manchester code mentioned above.

For details on the setting for the start bit area, see section 28.5.1. Frame Format (2).

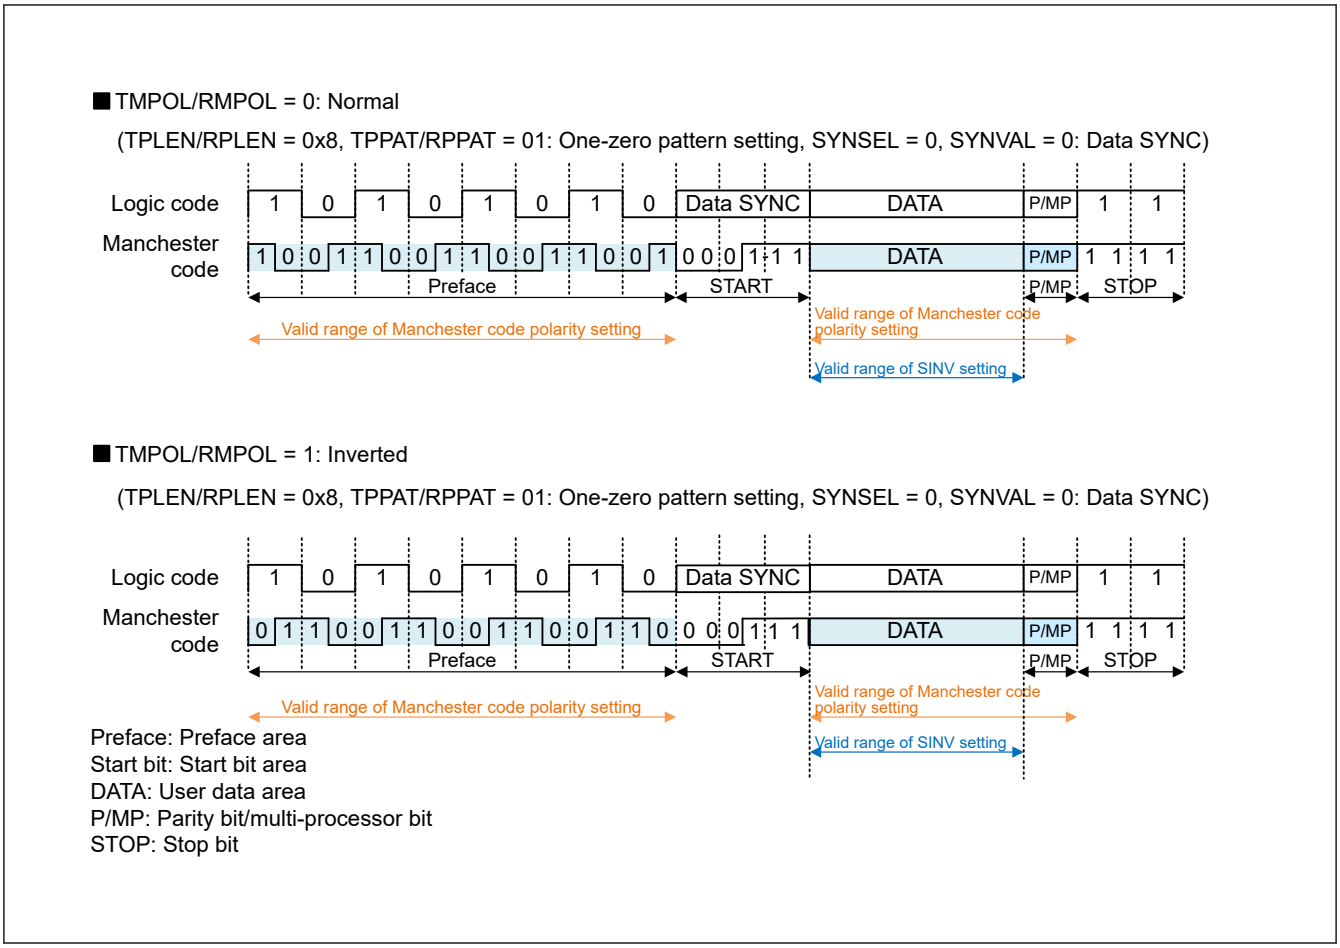

Figure 28.60 Valid Range of the Manchester Code Polarity Setting

28.5.11 Errors in Manchester Mode

There are the following errors in Manchester mode:

1. Parity error
2. Over run error
3. Framing error
4. Manchester error
5. Preface error
6. Start Bit error
7. Receive SYNC error

For errors (1) to (3), see section 28.3.9. Serial Data Reception in Asynchronous Mode (1) because they are the same as in Asynchronous mode.

Each errors are judged in each area, but they are reflected on flags and operations at the timing of 3/4-bit sampling of the STOP bit area. If a preface error or start bit error is detected, subsequent data will not be received. Therefore, no other error detection is performed, and the error flag holds the previous information.

Table 28.35 lists the states of the serial status register when detecting errors and judgment about whether to store data in the RDR.

Table 28.36 lists the errors that can be detected in each area of a Manchester frame.

If a Preface error or Start bit error is detected, subsequent data will not be received. Therefore, no other error detection is performed, and the error flag holds the result of the previous frame reception. Also, if an error is detected in the previous

frame, data will not be received, but errors in the pre-face area and start bit area will update that flag. Table 28.37 shows the flags and actions in this case.

(4) Manchester error

A Manchester error is generated when a Manchester code error is detected.

In Manchester code, there must be an edge (transition) in the center of the bit.

In the data area of a received frame (including the parity/multi-processor bit), the values of the 1/4-bit and 3/4-bit sampling points are checked in each received 1-bit data, and a Manchester code error is determined if these two values match.

If a Manchester code error is detected, the Manchester error flag (MSR.MER) is asserted.

If a Manchester error occurs, it is handled as an interrupt source and event source. If a Manchester error is detected, the next reception is not performed until the corresponding error flag is cleared.

(5) Preface error

A preface error is generated when the preface pattern does not match or a Manchester code error is detected in the preface area. If a preface error is detected, the preface error flag (MSR.PFER) is asserted.

It is possible to set whether to use this error flag as an interrupt source with the setting of the MCR register.

When MCR.PFEREN = 1, a preface error is handled as an interrupt source or event source. If a preface error is detected, the next reception is not performed until the corresponding error flag is cleared.

When MCR.PFEREN = 0, a preface error is not handled as an interrupt source or event source, and the next reception is not halted. However, a preface error is notified to MSR.PFER.

(6) Start bit error

A start bit error is generated when a mismatch is detected between the start bit area in the received frame and the preset start bit pattern. Upon detection of a start bit error, a start bit error flag (MSR.SBER) is asserted.

It is possible to set whether to use the start bit error as an interrupt source with the setting of the MCR register.

When MCR.SBEREN = 1, a start bit error is handled as an interrupt source or event source. If a start bit error is detected, the next reception is not performed until the corresponding error flag is cleared.

When MCR.SBEREN = 0, a start bit error is not handled as an interrupt source or event source, and the next reception is not halted. However, a start bit error is notified to MSR.SBER.

(7) Receive SYNC error

When the receive retiming function described in section 28.5.9. Receive Retiming is enabled, the receive retiming operation is performed.

If no edges are detected within the receive retiming range (SyncError area in Figure 28.59) when receive timing operation is being performed, a receive SYNC error is generated. Upon detection of a receive SYNC error, a receive SYNC error flag (MSR.SYER) is asserted. In areas not subject to retiming, receive SYNC errors are not detected.

The preface area[*1], the start bit area[*1],[*2], and the data area (excluding the stop bit) for which receive retiming operation is performed are checked.

It is possible to set whether to use the receive SYNC error as an interrupt source with the setting of the MCR register.

When MCR.SYEREN = 1, a receive SYNC error is handled as an interrupt source or event source. If a receive SYNC error is detected, the next reception is not performed until the corresponding error flag is cleared.

When MCR.SYEREN = 0, a receive SYNC error is not handled as an interrupt source or event source, and the next reception is not halted. However, a receive SYNC error is notified to MSR.SYER.

Note 1. In the case of a frame that starts with a pattern that expects the first half of the bit to be High, it is excluded from retiming.

Note 2. In the start bit area, when there is no preface length and 3 bit start bit is set, it is not subject to retiming.

Also, the 1st bit and the 2nd bit in the start bit area when 3 bit start bit is set are not subject to retiming.

Table 28.35 Flags in the CSR Register and Receive Data Handling in Manchester Mode

Flag in the CSR register			Flag in the MRS register				Received data	Received error status (SCIn_ERI interrupt / event generation)
ORER	FER	PER	MER	SBER*1	PFER*1	SYER		
0	0	0	0	0	0	0	transfer to RDR	No error
0	1	0	0	0	0	0	transfer to RDR	Framing error
0	0	1	0	0	0	0	transfer to RDR	Parity error
0	1	1	0	0	0	0	transfer to RDR	Framing error + Parity error
0	0	0	1	0	0	0	transfer to RDR	Manchester error
0	1	0	1	0	0	0	transfer to RDR	Framing error + Manchester error
0	0	1	1	0	0	0	transfer to RDR	Parity error + Manchester error
0	1	1	1	0	0	0	transfer to RDR	Framing error + Parity error + Manchester error
1	0	0	0	0	0	0	Lost	Overrun error
1	1	0	0	0	0	0	Lost	Overrun error + Framing error
1	0	1	0	0	0	0	Lost	Overrun error + Parity error
1	1	1	0	0	0	0	Lost	Overrun error + Framing error + Parity error
1	0	0	1	0	0	0	Lost	Overrun error + Manchester error
1	1	0	1	0	0	0	Lost	Overrun error + Framing error + Manchester error
1	0	1	1	0	0	0	Lost	Overrun error + Parity error + Manchester error
1	1	1	1	0	0	0	Lost	Overrun error + Framing error + Parity error + Manchester error
0	Combination of above			0	0	1	transfer to RDR	Errors above + Receive SYNC error*2
1				0	0	1	Lost	Errors above + Receive SYNC error*2
hold	hold	hold	hold	0	1	0	Lost	Preface error*3
hold	hold	hold	hold	1	0	0	Lost	Start bit error*3
hold	hold	hold	hold	0	1	1	Lost	Preface error*3 + Receive SYNC error*2
hold	hold	hold	hold	1	0	1	Lost	Start bit error*3 + Receive SYNC error*2

Note 1. Start bit error and Preface error never become 1 at the same time.
Note 2. When MCR.SYEREN = 1, SCIn_ERI interrupt / event is generated by SYER factor.
Note 3. If MCR.PFEREN = 1 or MCR.SBEREN = 1, an SCIn_ERI interrupt / event is generated when the corresponding flag is set.

Table 28.36 Errors Detectable in Each Area

	Preface error (PFER)	Start Bit error (SBER)	Manchester error (MER)	Receive SYNC error (SYER)	Parity error (PER)	Framing error (FER)
Preface area	✓	—	—*1	✓*2	—	—
Start Bit area	—	✓	—	✓*2	—	—
Data area	—	—	✓	✓	—	—
Parity area	—	—	✓	✓	✓	—
Multi-processor area	—	—	✓	✓	—	—
Stop Bit area	—	—	—	—	—	✓

Note: ✓: Detected, —: Not detected
Note 1. When an Manchester code error occurs in the preface area, it is defined as a preface error.
Note 2. It may not be subject to Receive SYNC error detection. For details see the text section 28.5.11. Errors in Manchester Mode (7)

Table 28.37 Operation status due to presence / absence of error in previous frame and operation status list in multiprocessor mode (1 of 2)

Previous frame	Each area of the Frame					PFEREN	SBEREN	SYEREN	received data	Error flag	Interrupt request	Event signal
	preface	start bit	data	parity	stop							
No Error	PFER	No Error	Don't Care	Don't Care	Don't Care	0	Don't Care	Don't Care	Lost	set PFER*1	not output	not output
	No SYER*1					1					output	output

		No SYER*1					1				output	output
	SYER	No Error	Don't Care	Don't Care	Don't Care	Don't Care	Don't Care	0	transfer to RDR	set SYER	not output	not output
	No PFER							1	Lost		output	output
	No Error	SYER	Don't Care	Don't Care	Don't Care	Don't Care	Don't Care	0	transfer to RDR	set SYER	not output	not output
		No SBER						1	Lost		output	output
	No Error	No Error	SYER		No Error	Don't Care	Don't Care	0	transfer to RDR	set SYER	not output	not output
								1			output	output
	No Error	No Error	MER		No Error	Don't Care	Don't Care	Don't Care	transfer to RDR	set MER	output	output
	No Error	No Error	Don't Care	PER	No Error	Don't Care	Don't Care	Don't Care	transfer to RDR	set PER	output	output
	No Error	No Error	Don't Care	Don't Care	FER	Don't Care	Don't Care	Don't Care	transfer to RDR	set FER	output	output
	There is some error ORER					Don't Care	Don't Care	Don't Care	Lost	set some flags*2	output	output
	No Error	No Error	No Error	No Error	No Error ORER	Don't Care	Don't Care	Don't Care	Lost	set ORER	output	output

Table 28.37 Operation status due to presence / absence of error in previous frame and operation status list in multiprocessor mode (2 of 2)

Previous frame	Each area of the Frame					PFEREN	SBEREN	SYEREN	received data	Error flag	Interrupt request	Event signal
	preface	start bit	data	parity	stop							
some error*3 *6	PFER No SYER*1	No Error	Don't Care	Don't Care	Don't Care	0	Don't Care	Don't Care	Lost	set PFER*1	output*4	not output*5
						1						
	No Error	SBER No SYER*1	Don't Care	Don't Care	Don't Care	Don't Care	0	Don't Care		set SBER*1		
							1					
	SYER No PFER	No Error	Don't Care	Don't Care	Don't Care	Don't Care	Don't Care	0		set SYER		
								1				
	No Error	SYER No SBER	Don't Care	Don't Care	Don't Care	Don't Care	Don't Care	0		set SYER		
								1				
	No Error	No Error	SYER		No Error	Don't Care	Don't Care	0		don't set any flags		
								1				
	No Error	No Error	MER		No Error	Don't Care	Don't Care	Don't Care				
	No Error	No Error	Don't Care	PER	No Error	Don't Care	Don't Care	Don't Care				
	No Error	No Error	Don't Care	Don't Care	FER	Don't Care	Don't Care	Don't Care				
	There is some error ORER					Don't Care	Don't Care	Don't Care				
	No Error	No Error	No Error	No Error	No Error ORER	Don't Care	Don't Care	Don't Care				

Note 1. If SYER is detected, the SYER flag is also set. Other operations are as shown in this table.
Note 2. Other detected error flags including ORER are also set.
Note 3. If all the error flags are cleared before the STOP bit is judged, the operation will be the same as the case where there is no error in the previous frame of this table.
Note 4. Since the SCIn_ERI interrupt request is level output, it remains active due to errors in the previous frame regardless of the presence or absence of error in the relevant frame.
Note 5. Since the error cause is continuously detected, the SCIn_ERI event is not newly output regardless of the presence or absence of errors in the relevant frame.
Note 6. For PFER, SBER, and SYER, when each enable bit is set to disable, it is treated as no error.

Table 28.38 Operation when MPIE = 1 in multi-processor mode (MPIE = 0)

MPB*1	Each area of the frame					PFEREN	SBEREN	SYEREN	received data	Error flag	Interrupt request	Event signal
	preface	start bit	data	parity	stop							
1	No Error	No Error	Don't Care	Don't Care	Don't Care	Don't Care	Don't Care	Don't Care	transfer to RDR	set some flags	output*2	output*2
	No PFER	No SBER	Don't Care	Don't Care	Don't Care	Don't Care	Don't Care	0				
	SYER*3	SYER*3						1	Lost	don't set any flags	not output	not output
	PFER	No Error	Don't Care	Don't Care	Don't Care	Don't Care	Don't Care	Don't Care				
	No Error	SBER	Don't Care	Don't Care	Don't Care	Don't Care	Don't Care					

Note 1. If the received MPB bit is 0, it is not received the frame, and the operation is the same as lost of the reception data of this table.
Note 2. If no error is detected, SCIn_RXI interrupt request or event is output, and if it is detected, SCIn_ERI interrupt request or event is output.

Note 3. When SYER is detected in the preface area or the start bit area, the behavior of handling as an error depending on the SYEREN bit changes.

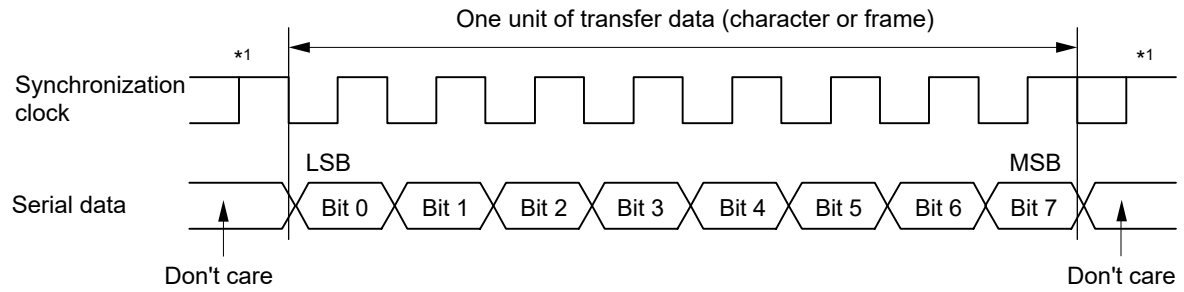
28.6 Operation in Clock Synchronous Mode

Figure 28.61 shows the data format for clock synchronous serial data communications.

In clock synchronous mode, data is transmitted or received in synchronization with clock pulses. For single-character data transfer, data consists of 8-bit. In clock synchronous mode, no parity bit can be added.

In data transmission when CPHA = 1 and CPOL = 1, the SCI outputs data from one falling edge of the synchronization clock to the next falling edge. In data reception, the SCI receives data in synchronization with the rising edge of the synchronization clock. After 8-bit data is output, the transmission line holds the last bit as output state. When the CPHA bit is 0 in slave mode, the transmission line holds the first bit output state.

Within the SCI, the transmitter and receiver are independent units, enabling full-duplex communications by using a shared communication clock of the transmitter and the receiver. Furthermore, because both the transmitter and the receiver also have a double-buffered structure, so that the next transmit data can be written during transmission or the previous receive data can be read during reception, enabling continuous data transfer.



Note 1. Holds a high level except during continuous transfer.

Figure 28.61 Data format in clock synchronous serial communications with LSB-first order

28.6.1 Clock

If the maximum speed of SCK = 1/2TCLK is set in Clock Synchronous and Simple SPI mode, Do not make PCLK less than half the speed of TCLK. If PCLK is made slower than this, malfunction may occur.

1. When the internal clock is selected
   When the SCI operates on an internal clock (CCR3.CKE[1:0] bits are set to 00b or 01b (master mode)), the synchronization clock is output from the SCKn pin. Eight synchronization clock pulses are output during single-character transmission/reception. When no data transfer is performed, the clock is held at high level.*1 In transmission-only or transmission/reception, the synchronization clock is not output unless transmit data is prepared.
   When the internal clock is selected, the clock with a delay from the SCKn signal is used for the master reception sampling clock. This ensures the data setup time and hold time for high-speed communication.

   Note 1. The signal is held high while (CCR3.CPHA = 0 and CCR3.CPOL = 1) or (CCR3.CPHA = 1 and CCR3.CPOL = 1). It is held low while (CCR3.CPHA = 0 and CCR3.CPOL = 0) or (CCR3.CPHA = 1 and CCR3.CPOL = 0).

2. When the external clock is selected
   When the CCR3.CKE[1:0] bits are set to 10b or 11b (slave mode), data is transmitted and received using the external clock that is input from the SCKn pin.

28.6.2 CTS and RTS Functions

In the CTS function, the CTSn_RTSn pin input controls the start of data reception or transmission when the clock source is the internal clock. Setting the CCR1.CTSE bit to 1 enables the CTS function. In clock synchronous communication, the CTS function can be used for the internal clock and the RTS function can be used for the external clock, so the CTS function and RTS function cannot be used at the same time. When the CTS function is enabled, setting the CTSn_RTSn pin low causes data reception or transmission to start.

Setting the CTSn_RTSn pin high while the data transmission or reception is in progress does not affect transmission or reception of the current frame.

In the RTS function, the CTSn_RTSn pin output is used to request the start of data reception or transmission when the clock source is an external synchronizing clock. The CTSn_RTSn output goes low when serial communication is enabled. Conditions for output of the CTSn_RTSn low and high are shown as follows:

[Conditions for low output]

Satisfaction of all the following conditions:

Non-FIFO selected when all of the following conditions are satisfied

- The value of the CCR0.RE bit or the CCR0.TE bit is 1
- Next serial communication is enabled.
  - No receive data is present before reading and not receiving. (when CCR0.RE bit = 1)
  - When the transmission data written in TDR is ready for transmission.*1 (when CCR0.TE bit = 1)
- The CSR.ORER flag is 0

Note 1. The CTSn_RTSn pin will be High after starting transmission.

FIFO selected when all of the following conditions are satisfied

- The value of the CCR0.RE bit or the CCR0.TE bit is 1
- Next serial communication is enabled.
  - The number of receive data stored in the receive FIFO (RDR register) is less than the value set in FCR.RSTRG[4:0] (when CCR0.RE bit = 1)
  - When the transmission data written in the transmission FIFO (TDR register) is ready for transmission.*1 (when CCR0.TE bit = 1)
- The CSR.ORER flag is 0

Note 1. The CTSn_RTSn pin will be High after the last data transmission starts.

[Condition for high output]

- The conditions for low output are not satisfied

28.6.3 SCI Initialization in Clock Synchronous Mode

Before transmitting and receiving data, start by writing the initial value 0x00 to the CCR0 register, then continue through the SCI initialization procedure given in the sections describing non-FIFO and FIFO selection in section 28.6.2. CTS and RTS Functions. Anytime the operating mode or transfer format is to be changed, the CCR0.TE and CCR0.RE must write to 0 before the change can be made.

Note: Setting the CCR0.RE bit to 0 initializes neither the ORER, FER, PER, and RDRF flags in CSR nor the RDR register. When the TE bit is set to 0, the TEND flag for the selected FIFO buffer is not initialized.

Note: Switching the value of the CCR0.TE bit from 1 to 0 when the CCR0.TIE bit is 1 generates an SCIn_TXI interrupt request.

Table 28.39 Example flow of SCI initialization in clock synchronous mode with non-FIFO selected (1 of 2)

No.	Step Name	Description
1	Start initialization	—
2	Set CCR0	Set the CCR0.TEIE, TIE, RIE, TE, and RE bits to 0*1. If you have not changed from the initial settings, you can skip this step.
3	Set FCR	Set the TFRST and RFRST to 1 to empty FIFO. Set the TTRG[4:0], RTRG[4:0], and RSTRG[4:0] bits.

Table 28.39 Example flow of SCI initialization in clock synchronous mode with non-FIFO selected (2 of 2)

No.	Step Name	Description
4	Set CCR3 except MOD[2:0]	Set CCR3 except of communication mode. ● FIFO use/no-use ● Transmission/reception format ● Clock setting ● Leave unused bits (CHR[1:0], STP, RXDSEL, MP, DE, ACS0, GM, BLK) at their initial values.
5	Set CCR3.MOD[2:0]	Set communication mode (MOD[2:0] = 010b)*2.
6	Set CCR2	Select clock, set bit rate *3. Leave unused bits (BCP[2:0], ABCS, ABCSE, BRME, MDDR[7:0]) at their initial values.
7	Set CCR1	Set up the loop-back function, communication pin status and the CTS/RTS function.
8	Set CCR4	Set up the adjust sampling timing function. Leave unused bits (CMPD[8:0]) at their initial values.
9	Set the I/O port functions	Make I/O port settings to enable input and output functions as required for TXDn, RXDn, and SCKn pins.
10	Set CFCLR, FFCLR	Write 1 to the following bits and clear the corresponding flag. CFCLR.RDRFC, FERC, PERC, MFFC, ORERC, DFERC, DPERC, DCMFC, ERSC FFCLR.BRKC, DRC
11	Set CCR0	Set the TE or RE bit to 1.*1 *4 To enable interrupts, set the TE bit and TIE bit, and the RE bit and RIE bit to 1 with one instruction at the same time. Setting the TE and RE bits allows TXDn and RXDn to be used.
12	Initialization completion	—

Note 1. In simultaneous transmit and receive operations, the TE and RE bits in CCR0 should both be to 0 or set to 1 simultaneously.
Note 2. Set CPOL and CPHA before setting the communication mode.
Note 3. If you use an external clock, you do not need to set it.
Note 4. When using the internal clock (master), the setting of reception only is prohibited.

28.6.4 Serial Data Transmission in Clock Synchronous Mode

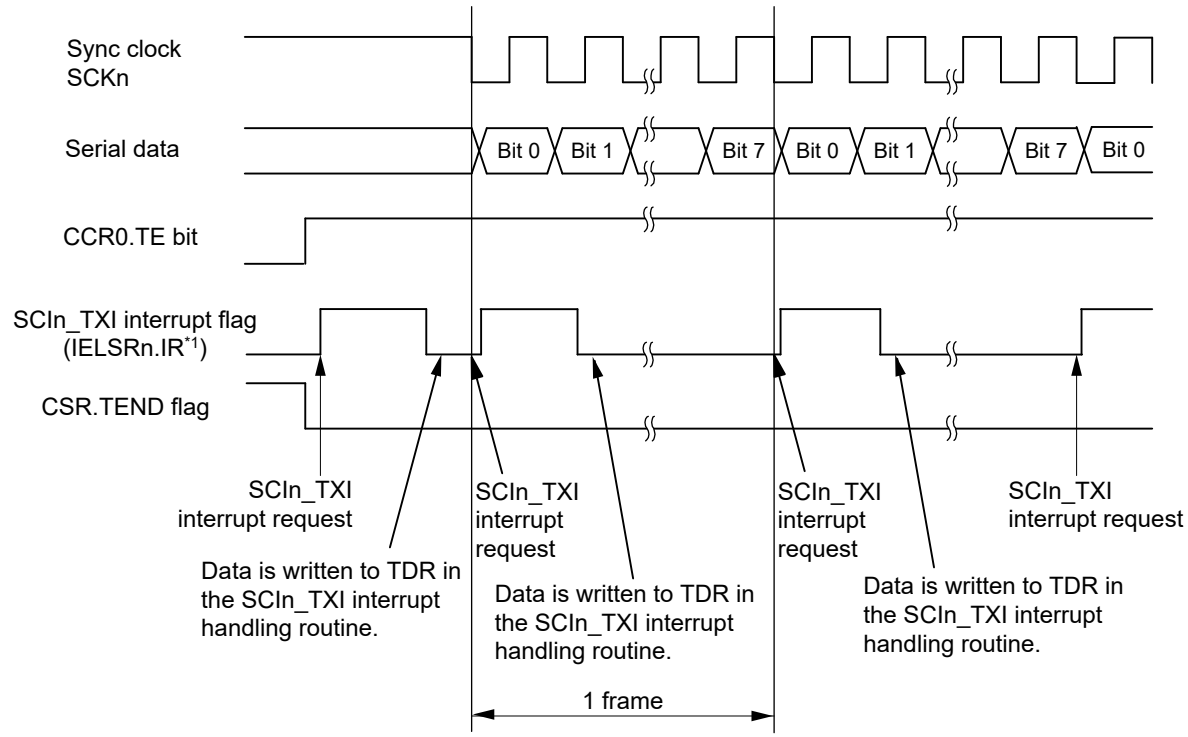
(1) Non-FIFO selected

Figure 28.62, Figure 28.63, and Figure 28.64 show examples of serial transmission in clock synchronous mode.

In serial data transmission, the SCI operates as follows:

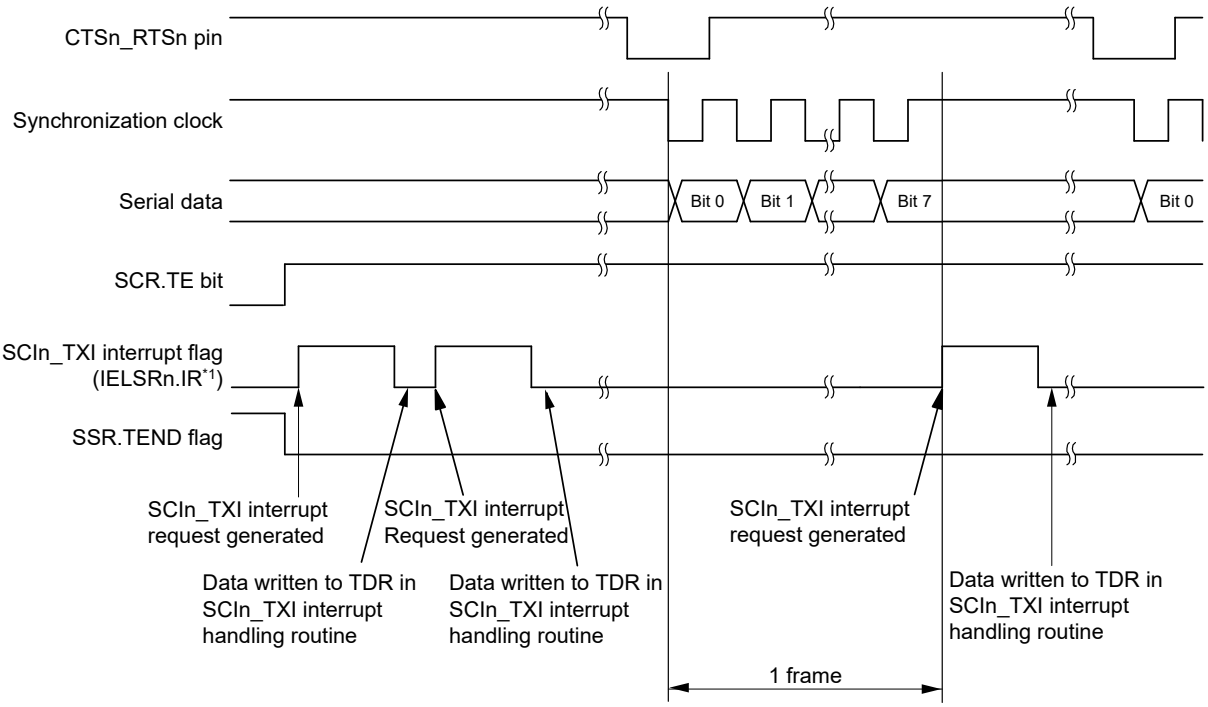
1. The SCI transfers data from the TDR register to the TSR register when data is written to TDR in the SCIn_TXI interrupt handling routine. When starting data transmission, set the CCR0.TIE bit and the CCR0.TE bit to 1 simultaneously by a single instruction. Then a SCIn_TXI interrupt request is generated.
2. After transferring data from TDR to TSR, the SCI starts transmission. When the CCR0.TIE bit is set to 1, an SCIn_TXI interrupt request is generated. Continuous transmission is enabled by writing the next transmit data to TDR in the SCIn_TXI interrupt handling routine before transmission of the current transmit data finishes. When SCIn_TEI interrupt requests are in use, set the CCR0.TIE bit to 0 and the CCR0.TEIE bit to 1 after the last of the data to be transmitted is written to the TDR register from the handling routine for SCIn_TXI requests.
3. 8-bit data is sent from the TXDn pin in synchronization with the output clock when the clock output mode is specified and in synchronization with the input clock when the use of an external clock is specified. Output of the clock signal is suspended until the input CTS signal is low when the CCR1.CTSE bit is 1 (CTS function enabled).
4. The SCI checks for update to the TDR register on output of the last bit.
5. When the TDR register is updated, the next transmit data is transferred from TDR to TSR, and serial transmission of the next frame starts.
6. If TDR is not updated, the CSR.TEND flag is set to 1. The TXDn pin retains the output state of the last bit. If the CCR0.TEIE bit is 1, an SCIn_TEI interrupt request is generated and the SCKn pin is held high.

Figure 28.62, Figure 28.63, and Figure 28.64 show examples of serial data transmission.



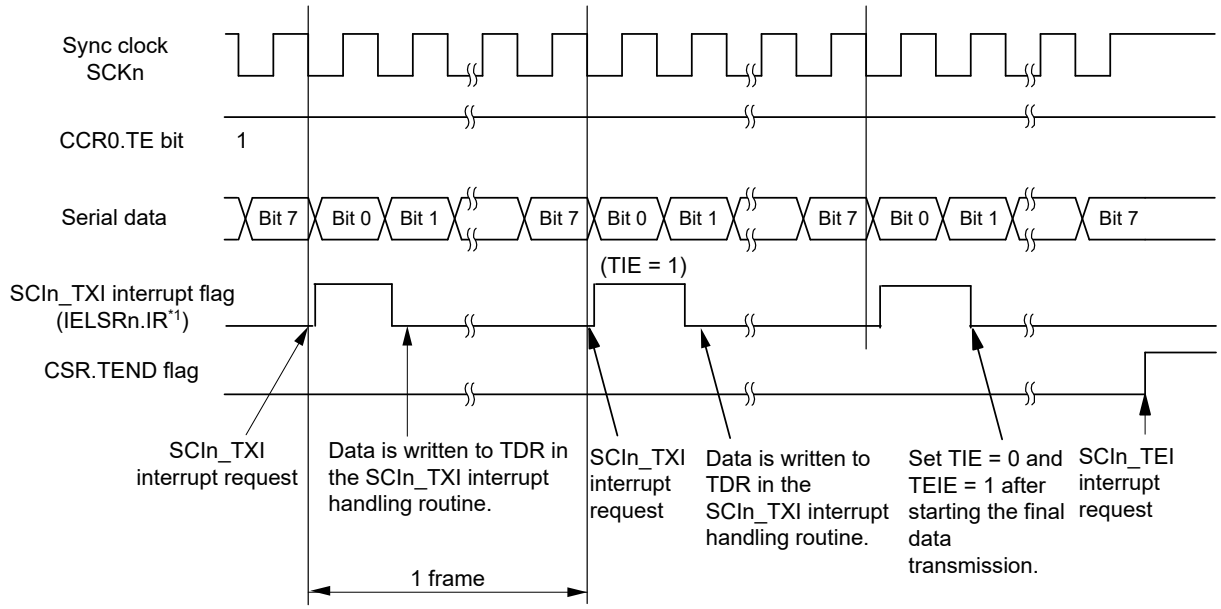
Note 1. See section 12, Interrupt Controller Unit (ICU) for information on the corresponding interrupt event number.

Figure 28.62 Example of serial data transmission in clock synchronous mode when the CTS function is not used at the beginning of transmission



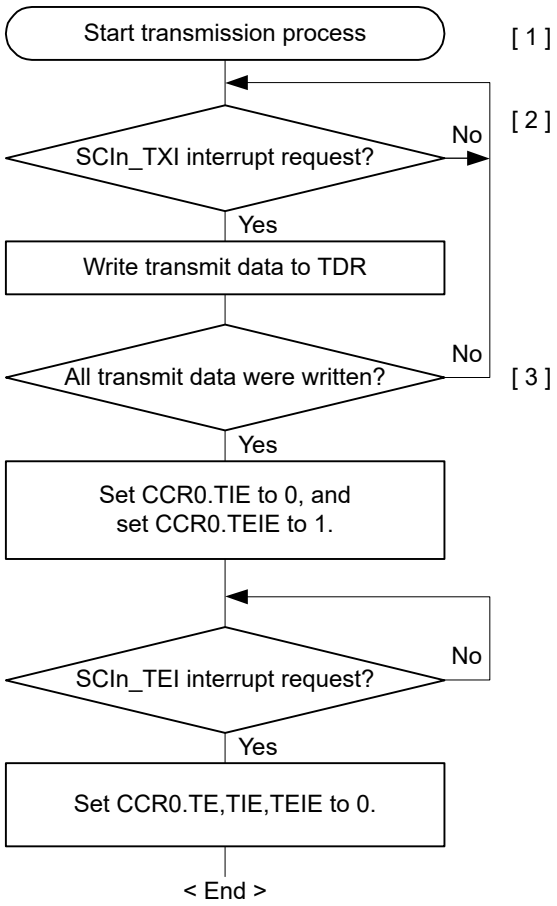
Note 1. See section 12, Interrupt Controller Unit (ICU) for information on the corresponding interrupt event number.

Figure 28.63 Example of serial data transmission in clock synchronous mode when the CTS function is used at the beginning of transmission



Note 1. See section 12, Interrupt Controller Unit (ICU) for information on the corresponding interrupt event number.

Figure 28.64 Example of serial data transmission in clock synchronous mode from the middle of transmission until transmission completion



[1] Start transmission process

[2] Write transmit data to TDR by using SCIn_TXI:
The transmit-data-empty-interrupt(SCIn_TXI) is Generated when transmission-data forwards to TSR from TDR. Write transmit data to TDR once by using a SCIn_TXI.

[3] Serial transmission continuation procedure:
To continue serial transmission write transmit data to TDR by using a SCIn_TXI.
Transmit data can also be written by activating the DMAC or DTC.
If you use SCIn_TEI, set CCR0.TIE = 0 and CCR0.TEIE = 1 after writing the last-transmit-data to TDR.

Note: When the external clock is in use (the value of the CCR3.CKE[1:0] is 10b or 11b), the rising edge on the SCK pin for the last bit sets the CSR.TEND flag to 1. Setting TE to 0 immediately after this, then it may lead to insufficient received data hold time on the receiver side.

Figure 28.65 Example flow of serial transmission in clock synchronous mode with non-FIFO selected

(2) FIFO selected

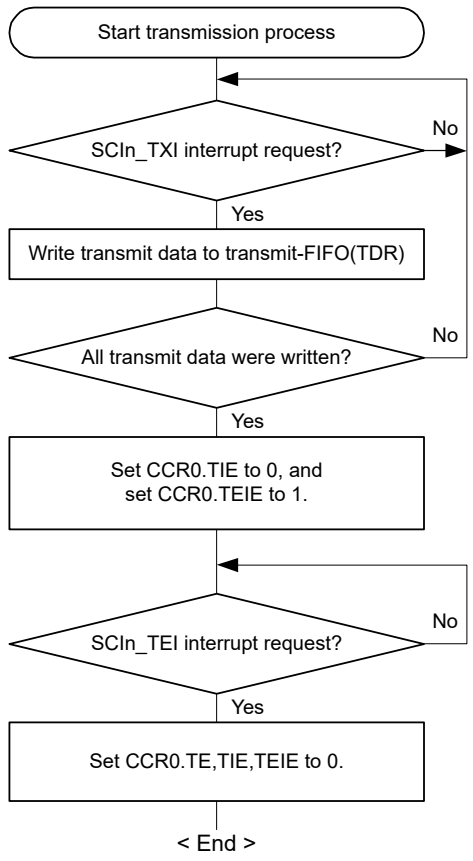
Figure 28.66 shows an example of serial transmission in clock synchronous mode with FIFO selected.

In serial data transmission, the SCI operates as follows:

1. The SCI transfers data from the transmit-FIFO (TDR register) to the TSR register when data is written to transmit-FIFO (TDR register) in the SCIn_TXI interrupt handling routine. The amount of data that can be written to transmit-FIFO (TDR register) is 16 - FTSR.T[5:0] bytes. In addition, when starting data transmission, set the CCR0.TIE bit and the CCR0.TE bit to 1 simultaneously by a single instruction. Then a SCIn_TXI interrupt request is generated.
2. After transferring data from transmit-FIFO (TDR register) to TSR, the SCI starts transmission. When the amount of transmit data written in transmit-FIFO (TDR register) is equal to or less than the specified transmit triggering number, the CSR.TDRE is set to 1. When the CCR0.TIE bit is set to 1, an SCIn_TXI interrupt request is generated. Continuous transmission is enabled by writing the next transmit data to transmit-FIFO (TDR register) in the SCIn_TXI interrupt handling routine before transmission of the current transmit data has finished. When SCIn_TEI interrupt requests are in use, set the CCR0.TIE bit to 0 and the CCR0.TEIE bit to 1 after the last of the data to be transmitted is written to the transmit-FIFO (TDR register) from the handling routine for SCIn_TXI requests.
3. 8-bit data is sent from the TXDn pin in synchronization with the output clock when the clock output mode is specified and in synchronization with the input clock when the use of an external clock is specified. Output of the clock signal is suspended until the input CTS signal is low when the CCR1.CTSE bit is 1 (CTS function enabled).
4. The SCI checks whether non-transmitted data remains in transmit-FIFO (TDR register)*1 on output of the stop bit.
5. When data is remaining in the transmit-FIFO (TDR register), the next transmit data is transferred from transmit-FIFO (TDR register) to TSR and serial transmission of the next frame starts.

6. If no data is remaining in the transmit FIFO (TDR register), the CSR.TEND flag is set to 1. The TXDn pin retains the output state of the last bit. If the CCR0.TEIE bit is 1, an SCIn_TEI interrupt request is generated and the SCKn pin is held high.

Note 1. The number of unsent transmit data stored in the TDR register (transmit FIFO) can be monitored by reading the FTSR.T[5:0] bits.



[1] [1] Start transmission process

[2] [2] Write transmit data to transmit-FIFO(TDR) by using SCIn_TXI: The transmit-data-empty-interrupt(SCIn_TXI) is generated when transmission-data forwards to TSR from the transmit-FIFO(TDR) and the number of transmit-data written in the transmit-FIFO is equal to or less than the transmit-FIFO threshold.

[3] [3] Serial transmission continuation procedure: To continue serial transmission, write transmit data to the transmit-FIFO(TDR) by using a SCIn_TXI interrupt and clear CSR.TDRE flag to 0. Transmit data can also be written to the transmit- FIFO(TDR) by activating the DMAC or DTC. In this case, the TDRE flag is cleared automatically, so please don't operate the TDRE flag. If you use SCIn_TEI, set CCR0.TIE = 0 and CCR0.TEIE = 1 after writing the last-transmit-data to TDR.

Note: When the external clock is in use (the value of the CCR3.CKE[1:0] is 10b or 11b), the rising edge on the SCK pin for the last bit sets the CSR.TEND flag to 1. Setting CCR0.TE to 0 immediately after this, then it may lead to insufficient received data hold time on the receiver side.

Figure 28.66 Example flow of serial transmission in clock synchronous mode with FIFO selected

28.6.5 Serial Data Reception in Clock Synchronous Mode

(1) Non-FIFO selected

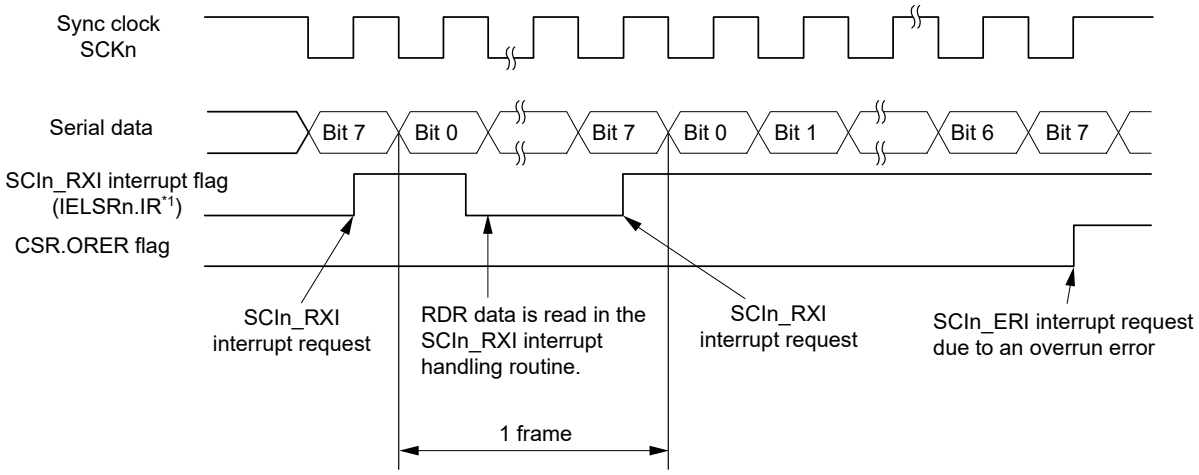
Figure 28.67 and Figure 28.68 show examples of SCI operation for serial reception in clock synchronous mode.

In serial data reception, the SCI operates as follows during serial data reception. Reception-only operation is possible only in slave mode. (In master mode, reception-only operation is prohibited.)

1. When the value of the CCR0.RE bit becomes 1, the CTSn_RTSn pin goes low (when the RTS function is used).
2. The SCI performs internal initialization and starts receiving data in synchronization with a synchronization clock input or output, and stores the receive data in the RSR register.
3. If an overrun error occurs, the CSR.ORER flag is set to 1. If the CCR0.RIE bit is 1, an SCIn_ERI interrupt request is generated. Receive data is not transferred to the RDR register.
4. When reception completes successfully, receive data is transferred to the RDR register. If the CCR0.RIE bit is 1, an SCIn_RXI interrupt request is generated. Continuous reception is enabled by reading the received data transferred to the

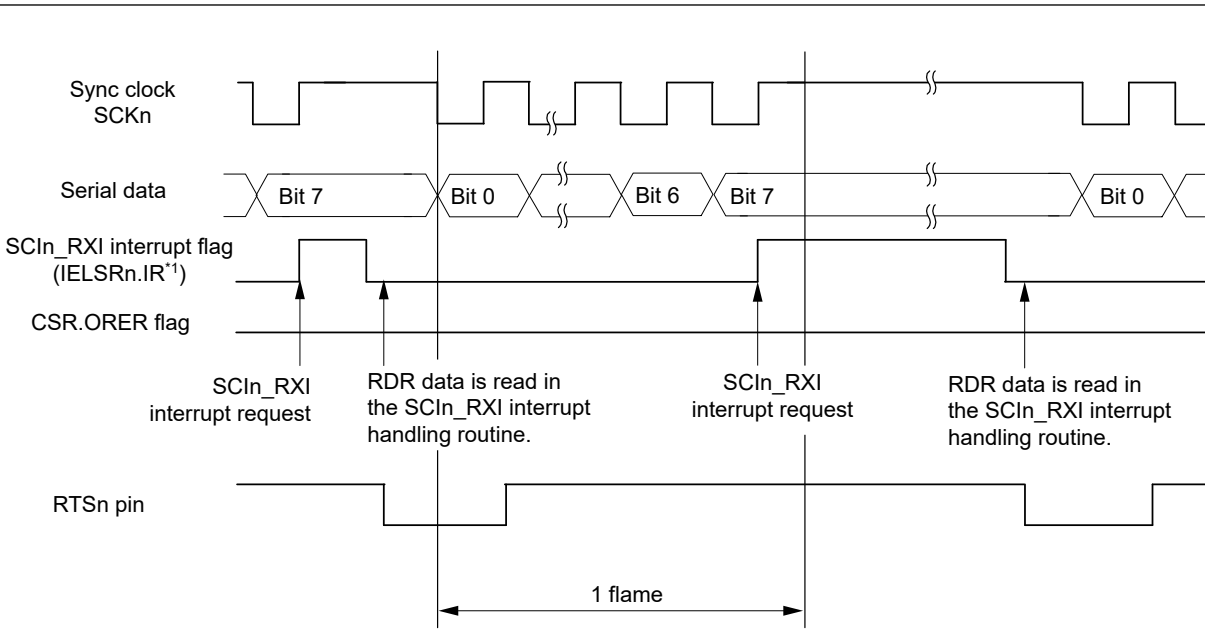
RDR register in the SCIn_RXI interrupt handling routine before reception of the next receive data completes. Reading the received data that is transferred to RDR causes the CTSn_RTSn pin to output low (when the RTS function is used).

If you want to prevent the CTSn_RTSn pin output from turning low level after the final data is received, clear the CCR0.RE bit to 0 and then read the RDR register.



Note 1. See section 12, Interrupt Controller Unit (ICU) for information on the corresponding interrupt event number.

Figure 28.67 Example operation for serial reception in clock synchronous mode (1) when the RTS function is not used

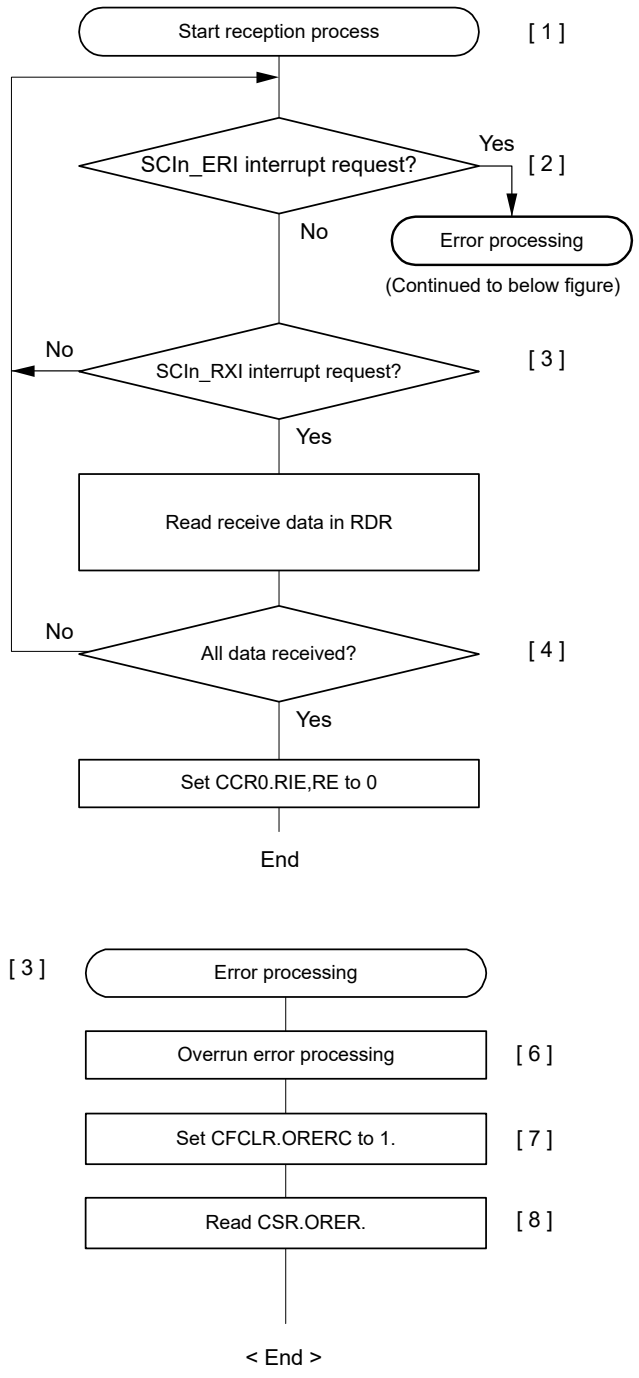


Note 1. See section 12, Interrupt Controller Unit (ICU) for information on the corresponding interrupt event number.

Figure 28.68 Example operation for serial reception in clock synchronous mode (2) when RTS function is used

Data transfer cannot resume while the receive error flag is 1. Therefore, clear the ORER, FER, and PER flags in the CSR register to 0 before resuming data reception. Additionally, always read the RDR register during overrun error processing. When a data reception is forced to terminate by a 0 write to the CCR0.RE bit during operation, read the RDR register because received data that is not yet read might be left in the RDR register.

Figure 28.69 shows an example flow of serial data reception.



[1] Start reception process

[2] Receive error processing:
If a receive error occurs, after performing the appropriate error processing, be sure to CSR.ORER is 0. Reception cannot be resumed if ORER is 1.

[3] Read the receive data in RDR once in the SCIn_RXI interrupt handling routine.

[4] Serial reception continuation procedure:
To continue serial reception, before the MSB bit (bit7) of the current frame is received, read data from RDR in the SCIn_RXI interrupt handling routine. The RDR data can also be read by activating the DMAC or DTC.

[6] Overrun error processing:
Read RDR.

[7] Clear the error flag:
Set the flag clear bit corresponding to the reception error to 1. Done this step and step [6], the next frame can be received normally.

[8] Confirming that the error flag is cleared:
Confirm all error flags are cleared.

Figure 28.69 Example flow of serial reception in clock synchronous mode with non-FIFO selected

(2) FIFO selected

Figure 28.70 shows an example of serial reception in clock synchronous mode with FIFO selected.

In serial data reception, the SCI operates as follows during serial data reception. Reception-only operation is possible only in slave mode. (In master mode, reception-only operation is prohibited.)

1. When the value of the CCR0.RE bit becomes 1, the CTSn_RTSn pin goes low (when the RTS function is used).
2. The SCI performs internal initialization and starts receiving data in synchronization with a synchronization clock input or output, and transfers the received data to the receive-FIFO (RDR register).
3. If an overrun error occurs, the CSR.ORER flag is set to 1. If the CCR0.RIE bit is 1, an SCIn_ERI interrupt request is generated. Received data is not transferred to the receive-FIFO (RDR register)*1.

4. When data reception completes successfully, the receive data is transferred to the receive-FIFO (RDR register)*1. The CSR.RDRF flag is set to 1 when the amount of the receive data stored in receive-FIFO (RDR register) is equal to or greater than the specified receive triggering number. If the CCR0.RIE bit is 1, an SCIn_RXI interrupt request is generated. Continuous data reception is enabled by reading the receive data transferred to receive-FIFO (RDR register)*1 in the SCIn_RXI interrupt handling routine before an overrun error occurs. If the amount of received data that is transferred to receive-FIFO (RDR register) is less than the specified receive triggering number, the CTSn_RTSn pin goes low (when the RTS function is used).

Note 1. In clock synchronous mode, RDR.RDAT[8] is not used.

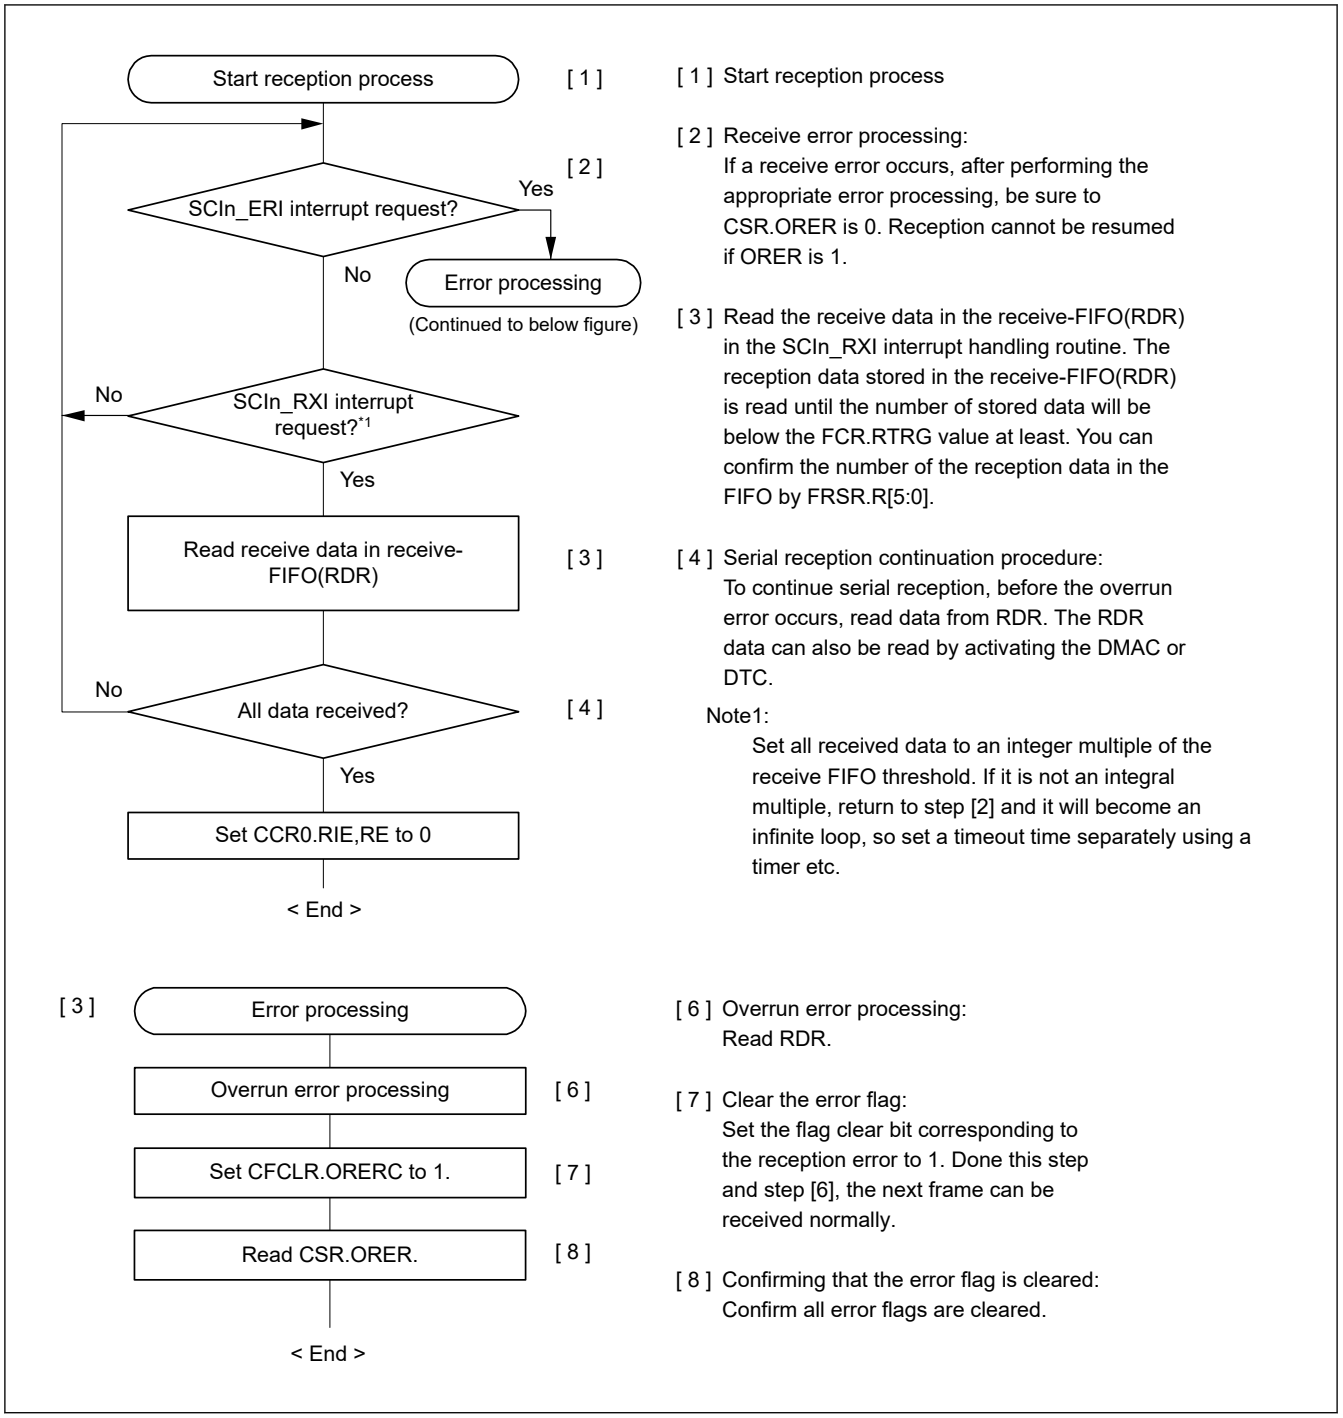


Figure 28.70 Example flow of serial reception in clock synchronous mode with FIFO selected

28.6.6 Simultaneous Serial Data Transmission and Reception in Clock Synchronous Mode

(1) Non-FIFO selected

Figure 28.71 shows an example flow of simultaneous serial transmit and receive operations in clock synchronous mode. After initializing the SCI, use the following procedure for simultaneous serial data transmit and receive operations.

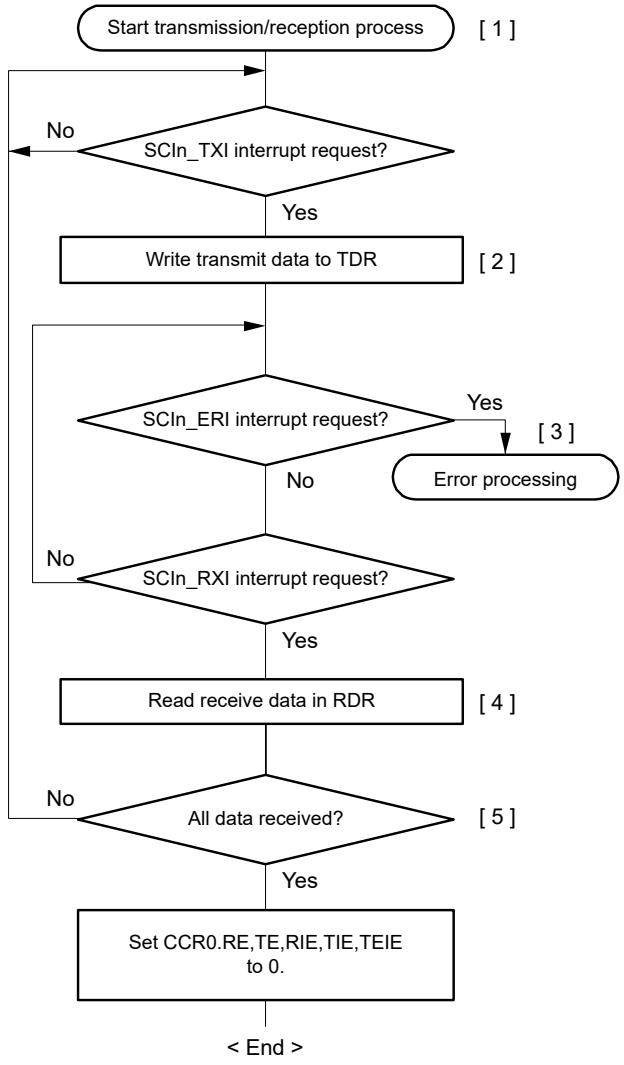
To switch from transmit mode to simultaneous transmit and receive mode:

1. Check that the SCI completes the data transmission by verifying that the CSR.TEND flag is set to 1.
2. Initialize the CCR0 register, and then set the TIE, RIE, TE, and RE bits in the CCR0 register to 1 simultaneously by a single instruction.

To switch from receive mode to simultaneous transmit and receive mode:

1. Check that the SCI completes the data reception.
2. Set the CCR0.TE and RE bits to 0, and then check that the receive error flag (ORER, FER, and PER) in the CSR register is 0.
3. Set the TIE, RIE, TE, and RE bits in the CCR0 register to 1 simultaneously by a single instruction.

When the RTS function is used in the concurrent transmission/reception operation, if you want to prevent the CTSn_RTSn pin output from turning to low after the final data is received as in the reception operation, clear the RE and TE bits in CCR0 to 0 simultaneously, and then read the RDR register.



[1] Start transmission/reception process

[2] Transmit data write:
Write transmit data to TDR in the SCIn_TXI Interrupt request handling routine.

[3] Receive error processing:
If a receive error occurs, after performing the appropriate error processing, be sure to CSR.ORER is 0. Reception cannot be resumed if ORER is 1.

[4] Reading receive data:
The reception data stored in RDR once in the SCIn_RXI interrupt request handling routine.

[5] Serial transmission/reception continuation procedure
To continue serial reception, before the MSB bit (bit7) of the current frame is received, read data from RDR in the SCIn_RXI interrupt handling routine. And before the MSB(bit7) of the current frame is transmitted, write transmit data to TDR in the SCIn_TXI interrupt handling. Transmit data can also be written by activating the DMAC or DTC. And the RDR data can also be read by activating the DMAC or DTC.

Figure 28.71 Example flow of simultaneous serial transmission and reception in clock synchronous mode with non-FIFO selected

(2) FIFO selected

Figure 28.72 shows an example flow of simultaneous serial transmit and receive operations in clock synchronous mode with FIFO selected.

After initializing the SCI, use the following procedure for simultaneous serial data transmit and receive operations.

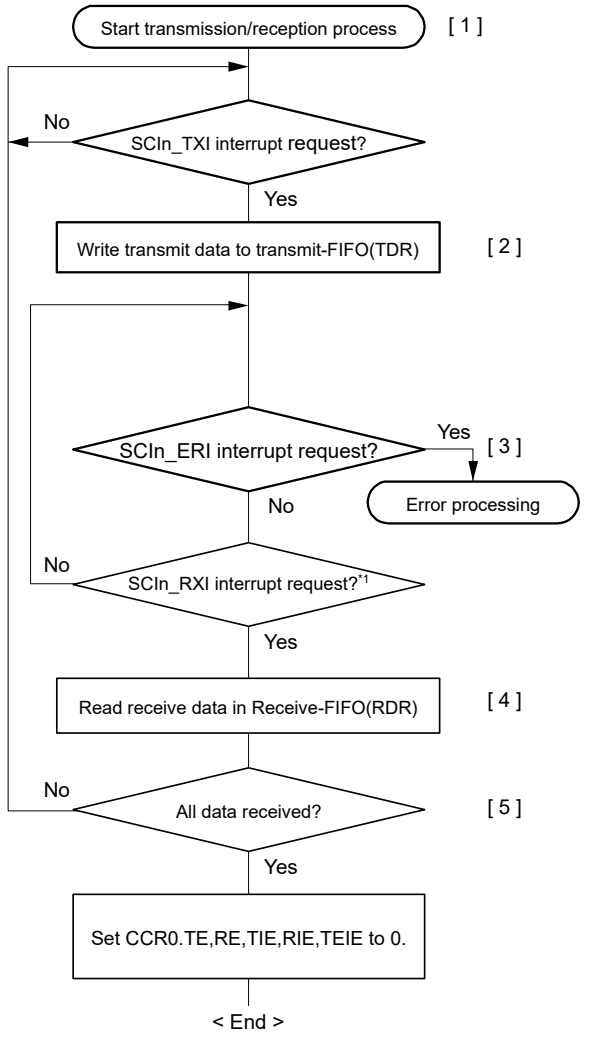
To switch from transmit mode to simultaneous transmit and receive mode:

1. Check that the SCI completes the transmission by verifying that the CSR.TEND flag is set to 1.
2. Initialize the CCR0 register, then set the TIE, RIE, TE, and RE bits in the CCR0 register to 1 simultaneously by a single instruction.

To switch from receive mode to simultaneous transmit and receive mode:

1. Check that the SCI completes the reception.
2. Set the CCR0.TE and RE bits to 0.
3. Check that the receive error flags (ORER, FER, and PER) in the CSR register are 0, and then set the TIE, RIE, TE, and RE bits in the CCR0 register to 1 simultaneously by a single instruction.

Since clock synchronous communication performs transmission and reception at the same time, make sure that the number of data to be transmitted and received is the same.



[1] Start transmission / reception process

[2] Transmit data write:
Write transmit data to Transmit-FIFO(TDR) in the SCIn_TXI Interrupt request handling routine.
Match the number of transmitted data with the FCR.RTRG.

[3] Receive error processing:
If a receive error occurs, after performing the appropriate error processing (Initialization such as stopping communication, reading all received data, clearing CSR.RDRF, etc.), be sure to ORER is 0. Reception cannot be resumed if ORER is 1.

[4] Read receive data:
Read the received data stored in receive-FIFO(RDR) for the number of the FCR.RTRG in the SCIn_RXI interrupt handling routine.

[5] Serial transmission/reception continuation procedure
To continue serial reception, before the overrun error occurs, read data from RDR and clear CSR.RDRF.
To continue serial transmission, write transmit data to the transmit-FIFO(TDR) by using a SCIn_TXI interrupt and clear TDRE flag to 0.
Transmit data can also be written to the transmit- FIFO(TDR) by activating the DMAC or DTC. And The RDR data can also be read by activating the DMAC or DTC. In this case, the TDRE and RDRF are cleared automatically, so please don't operate the TDRE And RDRF.

Note 1. Set all received data to an integer multiple of the receive FIFO threshold. If it is not an integral multiple, return to step [2] and it will become an infinite loop, so set a timeout time separately using a timer etc.

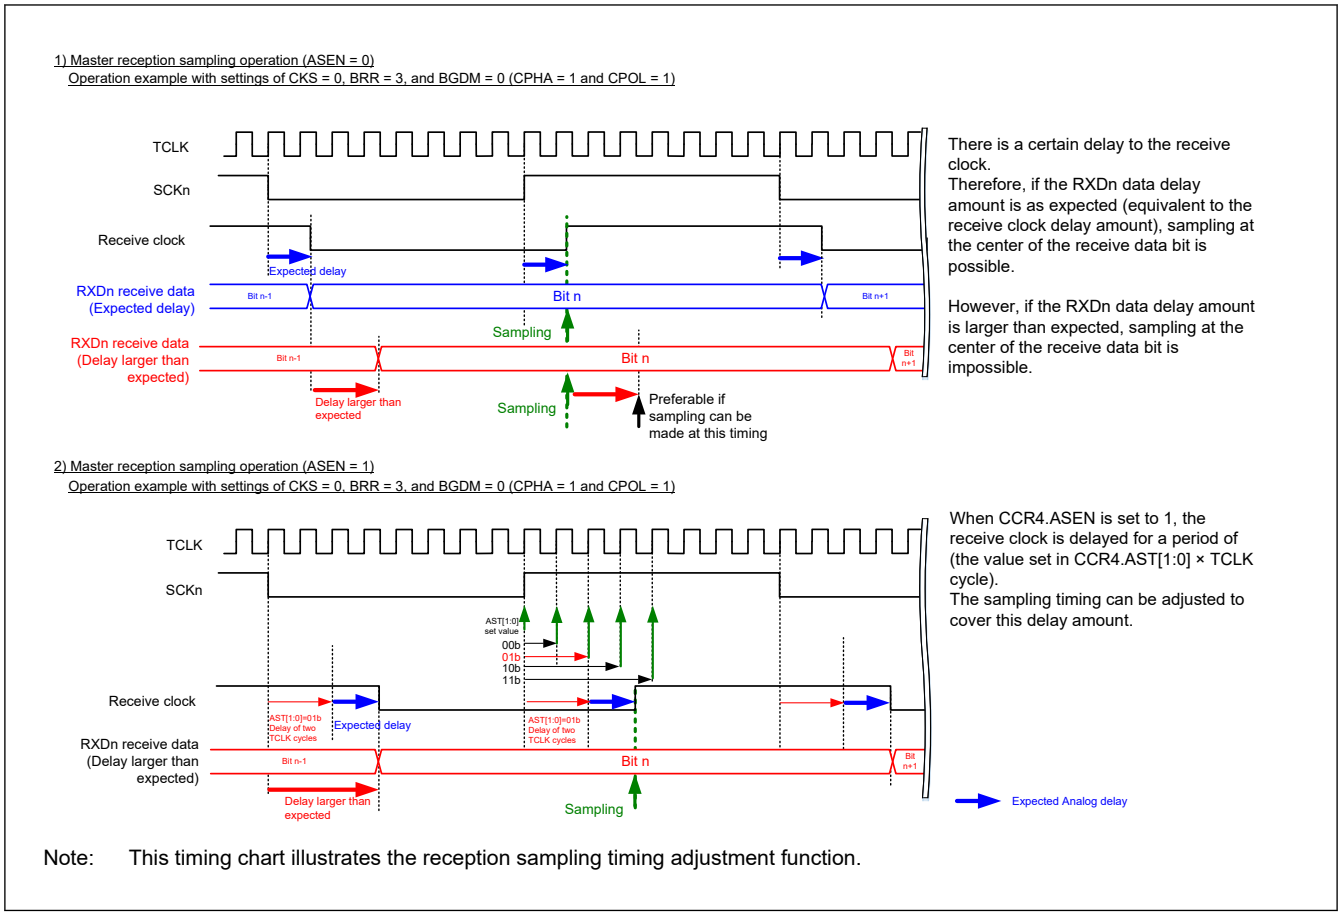
Figure 28.72 Example flow of simultaneous serial transmission and reception in clock synchronous mode with FIFO selected

28.6.7 Reception Sampling Timing Adjustment Function in Clock Synchronous Mode with internal clock used

When the clock synchronous internal clock is used (master mode), the clock enabled by CCR4.SCKSEL bit is used as a reception sampling clock.

This function adjusts the reception sampling timing by delaying the clock by 1 to 4 TCLK and adding a digital delay.

Setting the CCR4.ASEN bit to 1 enables this function. The delay value is set in CCR4.AST[1:0].



Note: This timing chart illustrates the reception sampling timing adjustment function.

Figure 28.73 Reception Sampling Timing Adjustment Operation in Clock Synchronous Mode (Master)

28.7 Operation in Smart Card Interface Mode

The SCI supports smart card (IC card) interfaces conforming to ISO/IEC 7816-3 (standard for Identification Cards), as an extended function of the SCI.

Smart card interface mode can be selected using the appropriate register.

28.7.1 Example Connection

Figure 28.74 shows an example connection between a smart card (IC card) and the MCU. As shown in Figure 28.74, because the MCU communicates with an IC card using a single transmission line, interconnect the TXDn and RXDn pins and pull up the data transmission line to VCC using a resistor.

Setting the CCR0.TE and CCR0.RE bits to 1 with an IC card disconnected enables closed-loop transmission or reception, allowing self-diagnosis. To supply an IC card with the clock pulses generated by the SCI, input the SCKn pin output to the CLK pin of an IC card.

An output port of the MCU can be used to output a reset signal.

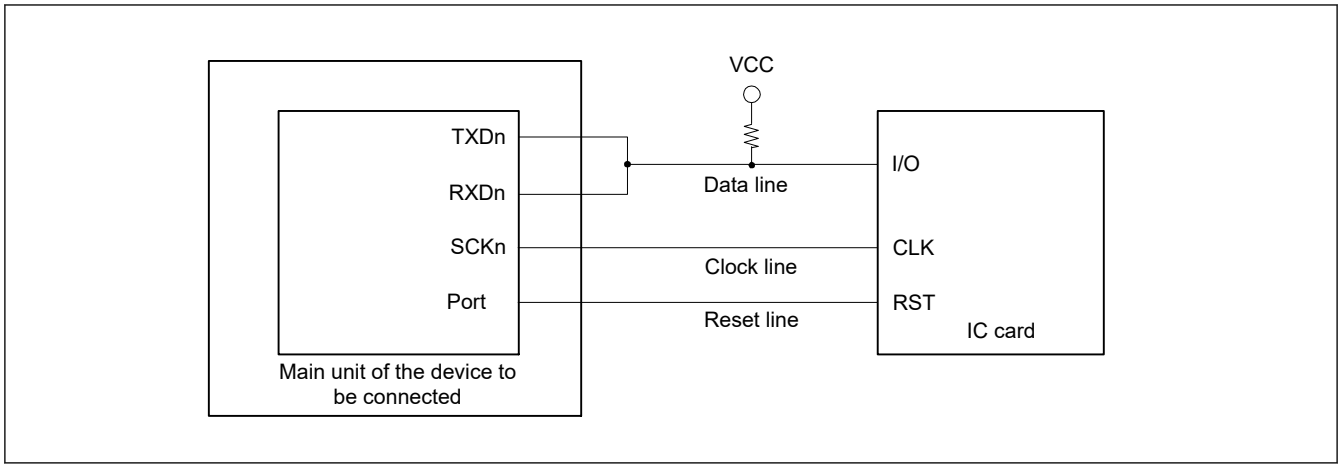


Figure 28.74 Example connection with a smart card (IC card)

28.7.2 Data Format (Except in Block Transfer Mode)

Figure 28.75 shows the data transfer formats in smart card interface mode:

- One frame consists of 8-bit data and a parity bit in Asynchronous mode.
- During transmission, at least 2 etus (elementary time unit – the time required for transferring 1 bit) is set as a guard time from the end of the parity bit until the start of the next frame.
- If a parity error is detected during reception, a low error signal is output for 1 etu after 10.5 etus elapse from the start bit.
- If an error signal is sampled during transmission, the same data is automatically retransmitted after at least 2 etus.

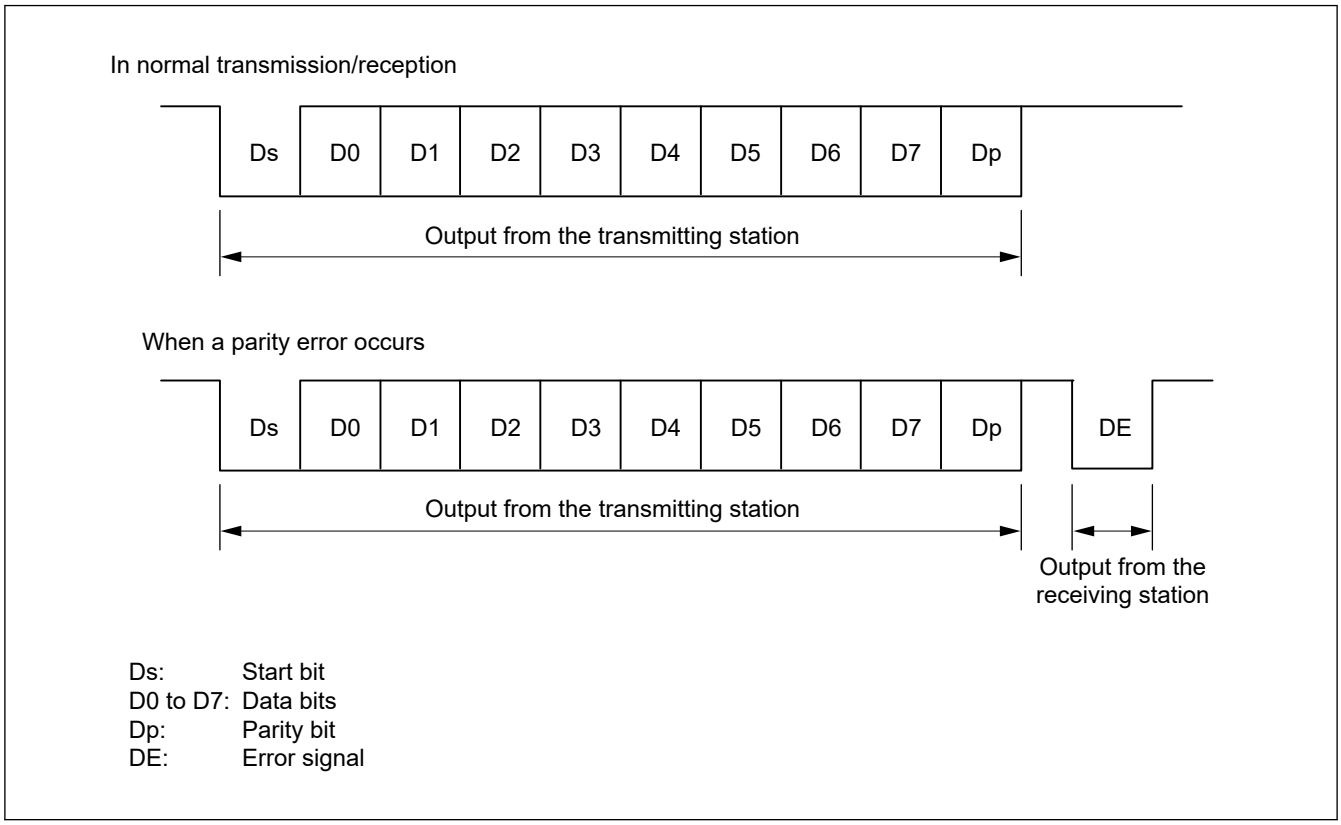

Figure 28.75 Data formats in smart card interface mode

For communications with IC cards of the direct convention type and inverse convention type, follow the procedures in this section.

(1) Direct Convention Type

For the direct convention type, logic levels 1 and 0 indicate the Z and A states, respectively, and data is transferred with LSB-first for the start character, as shown in Figure 28.76. Therefore, data in the start character in the figure is 0x3B.

When using the direct convention type, write 1 to the CCR3.LSBF and write 0 to the CCR3.SINV. Write 0 to the CCR1.PM bit to use even parity, which is prescribed by the smart card standard.

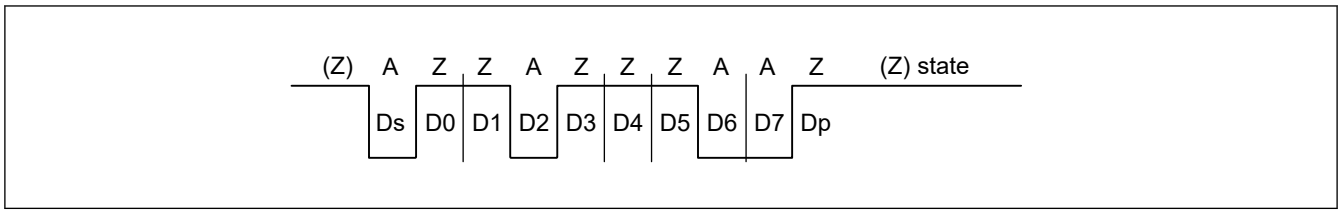

Figure 28.76 Direct convention with LSBF in CCR3 = 1, SINV in CCR3 = 0, and PM in CCR1 = 0

(2) Inverse Convention Type

For the inverse convention type, logic levels 1 and 0 indicate the A and Z states, respectively, and data is transferred with MSB-first for the start character, as shown in Figure 28.77. Therefore, data in the start character in the figure is 0x3F.

When using the inverse convention type, write 0 to the CCR3.LSBF and write 1 to the CCR3.SINV. The parity bit is logic level 0 to produce even parity, which is prescribed by the smart card standard, and corresponds to the Z state. Because the SINV bit of the MCU only inverts data bits D7 to D0, write 1 to the PM bit in CCR1 to invert the parity bit for both transmission and reception.

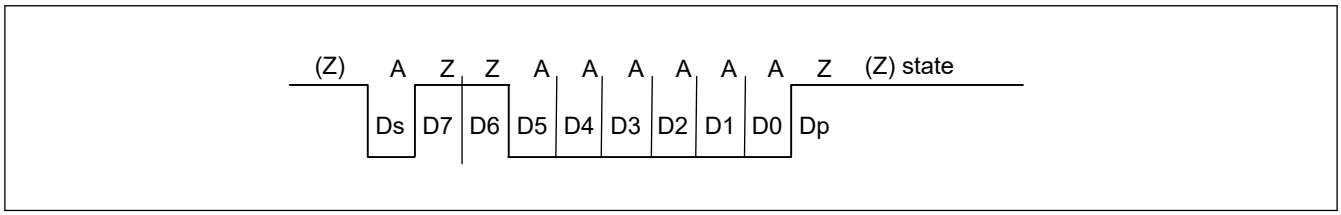

Figure 28.77 Inverse convention with LSBF in CCR3 = 0, SINV in CCR3 = 1, and PM in CCR1 = 1

28.7.3 Block Transfer Mode

Block transfer mode differs from normal smart card interface mode as follows:

- Even if a parity error is detected during reception, no error signal is output. Because the PER flag in CSR is set by error detection, clear the PER flag before receiving the parity bit of the next frame.
- During transmission, at least 1 etu is set as a guard time from the end of the parity bit until the start of the next frame
- Because the same data is not retransmitted, the TEND flag in CSR is set to 11.5 etus after transmission starts
- In block transfer mode, the ERS flag in CSR indicates the error signal status as in normal smart card interface mode, but the flag is read as 0 because no error signal is transferred

28.7.4 Receive Data Sampling Timing and Reception Margin

Only the internal clock generated by the on-chip baud rate generator can be used as a transfer clock in smart card interface mode.

In this mode, the SCI can operate on a base clock with a frequency of 32, 64, 372, 256, 93, 128, 186, or 512 times the bit rate set up in the CCR2.BCP[2:0] bits. The frequency is always 16 times the bit rate in normal Asynchronous mode.

For data reception, the falling edge of the start bit is sampled with the base clock to perform internal synchronization.

Receive data is sampled on the 16th, 32nd, 186th, 128th, 46th, 64th, 93rd, and 256th rising edges of the base clock so that it can be latched at the middle of each bit as shown in Figure 28.78. The reception margin is determined by the following formula:

$$M = \left|\left(0.5 - \frac{1}{2N}\right) - (L - 0.5)F - \frac{|D - 0.5|}{N}(1 + F)\right| \times 100\ [\%]$$

M: Reception margin (%)

N: Ratio of bit rate to clock (N = 32, 64, 372, 256)

D: Duty cycle of clock (D = 0 to 1.0)

L: Frame length (L = 10)

F: Absolute value of clock frequency deviation

Assuming values of F = 0, D = 0.5, and N = 372 in the specified formula, the reception margin is determined using the following formula:

$$M = \{0.5 - 1/(2 \times 372)\} \times 100\ [\%] = 49.866\ \%$$

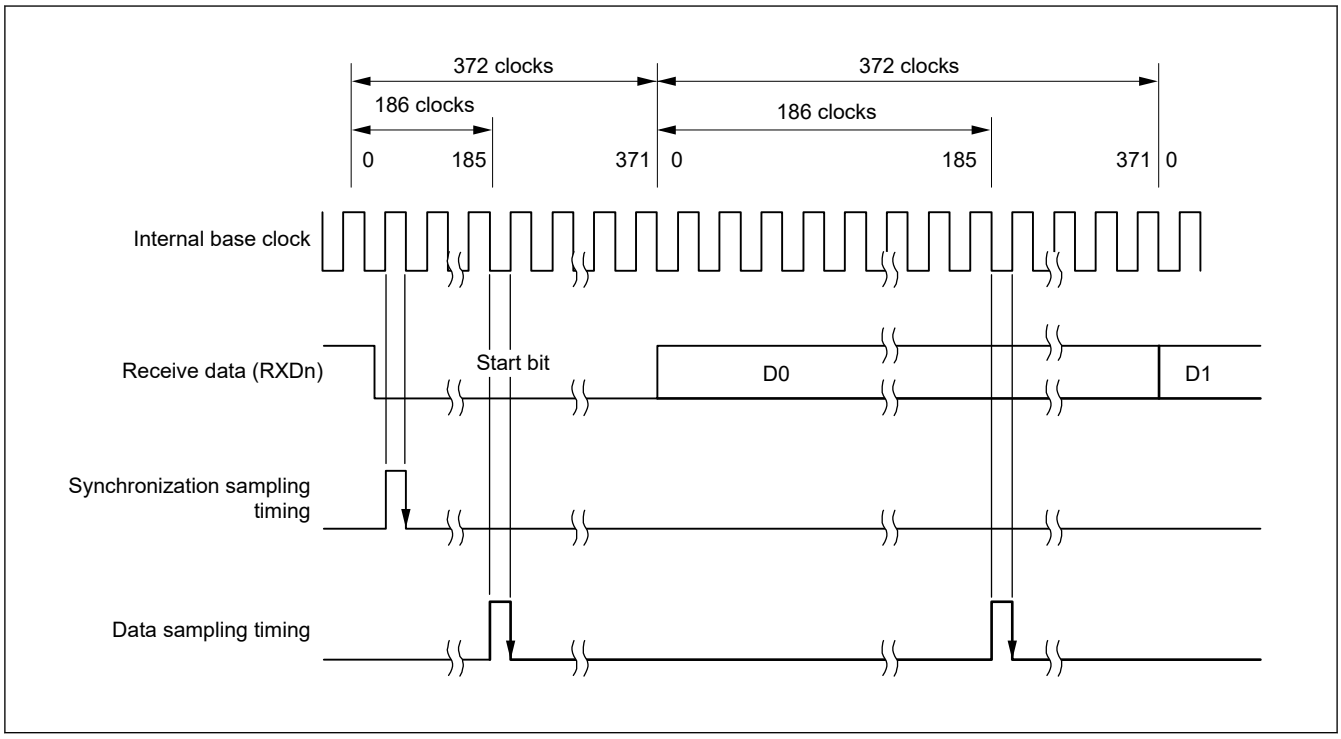

Figure 28.78 Receive data sampling timing in smart card interface mode when the clock frequency is 372 times the bit rate

28.7.5 SCI Initialization (Smart Card Interface Mode)

Before transmitting and receiving data, write the initial value 0x00 in the CCR0 register and initialize the SCI following the example flow shown in Table 28.40.

Always set the initial value in the TIE, RIE, TE, RE, TEIE bits in the CCR0 register before switching from transmission to reception mode or from reception to transmission mode. When CCR0.RE is set to 0, the RDR register is not initialized.

In transmission mode, set 1 to the CCR0.TE bit and CCR0.TIE bit simultaneously, then the SCIn_TXI interrupt request is generated.

To change from reception mode to transmission mode, first check that reception has completed, then initialize the SCI. At the end of initialization, set CCR0.TE = 1 and CCR0.RE = 0. Reception completion can be verified by reading the SCIn_RXI request, ORER, or PER flag in CSR.

To change transmission mode to reception mode, first check that transmission has completed, then initialize the SCI. At the end of initialization, set CCR0.TE = 0 and CCR0.RE = 1. Transmission completion can be verified by reading the TEND flag in CSR.

Table 28.40 Example flow of SCI initialization in smart card interface mode

No.	Step Name	Description
1	Start initialization	—
2	Set CCR0	Set CCR0.TEIE, TIE, RIE, TE, RE to 0. If you have not changed from the initial settings, you can skip this step.
3	Set CCR3	Set communication mode (MOD[2:0] = 001b), BLK, GM, and SINV. Leave other bits at their initial values.
4	Set CCR2	Set clock-select and bit-rate. Set BRME to 0.
5	Set CCR1	Set up the Noise filter function, communication terminal status. Set NFEN, PE, CTSE to 0 and set PE to 1.
6	Set the I/O port functions	Make I/O port settings to enable input and output functions as required for TXDn, RXDn, and SCKn pins.
7	Set CCR3	Set CKE[1:0]. When the CKE[0] bit is set to “1” due on GM setting value, the clock is output from the SCKn pin.
8	Set CFCLR	Write 1 to the following bits and clear the corresponding flag. CFCLR.RDRFC, FERC, PERC, MFFC, ORERC, DFERC, DPERC, DCMFC, ERSC
9	Set CCR0	Set the TE or RE to 1. And set the TIE and RIE. Do not simultaneously set the TE and RE bits to 1 if self-diagnosis in not used.
10	Initialization completed	—

Figure 28.79 is a timing chart when data transmission is performed by making transition to the Smart Card Interface mode according to the above flow chart. The figure shows the case when CCR3.GM bit is 0. As shown in the figure, when the pin function is set to the SCKn pin, the SCKn pin is high impedance because the CCR3.CKE [0] bit is 0. When the TXDn pin is set, the TXDn pin is high impedance because the CCR0.TE bit is 0. Start clock output to the SCKn pin with the clock output setting CCR3.CKE [0] to 1, start data transmission by writing transmit data after setting CCR0.TE to 1.

In the smart card interface mode, even if not communicating at CCR0.TE = 0 and CCR0.RE = 0, the clock is continuously output if the clock output setting is used.

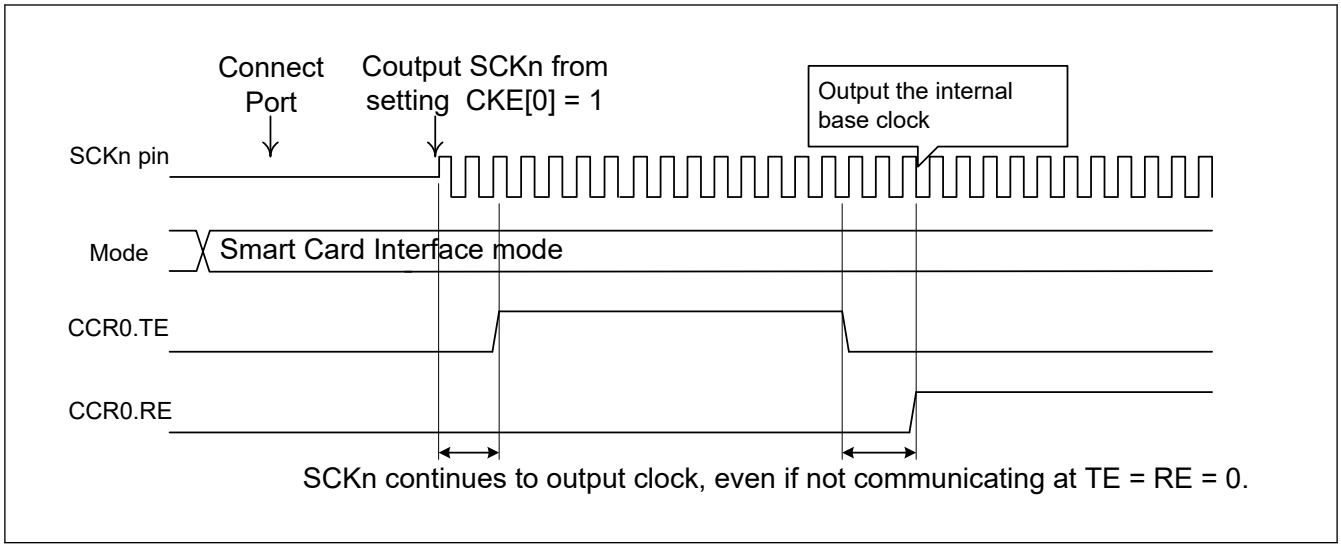

Figure 28.79 Example of Timing chart of data transmission in Smart Card Interface Mode

28.7.6 Serial Data Transmission (Except in Block Transfer Mode)

Serial data transmission in smart card interface mode (except in block transfer mode) is different from that in non-smart card interface mode, in that an error signal is sampled and data can be re-transmitted in smart card mode. Figure 28.80 shows the data re-transfer operation during transmission.

1. When an error signal from the receiver end is sampled after 1-frame data is transmitted, the CSR.ERS flag is set to 1. If the CCR0.RIE bit is 1, an SCIn_ERI interrupt request is generated. Clear the ERS flag to 0 before the next parity bit is sampled.

2. For a frame in which an error signal is received, the CSR.TEND flag is not set. Data is re-transferred from TDR to TSR, allowing automatic data retransmission.
3. If no error signal is returned from the receiver, the ERS flag is not set to 1.
4. In this case, the SCI determines that transmission of 1-frame data, including the re-transfer, is complete, and the TEND flag is set. If the CCR0.TIE bit is 1, an SCIn_TXI interrupt request is generated. Write transmit data to the TDR to start transmission of the next data.

Figure 28.82 shows an example flow of serial transmission. All the processing steps are automatically performed using an SCIn_TXI interrupt request to activate the DTC or DMAC.

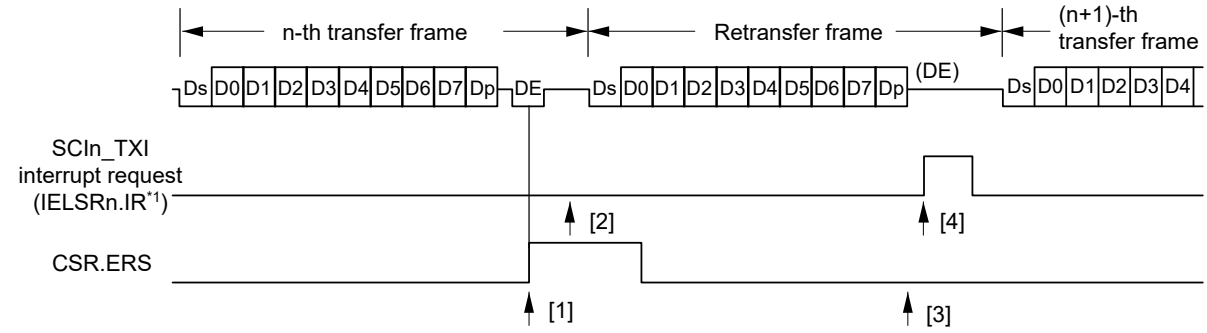
When the CSR.TEND flag is set to 1 in transmission and when the CCR0.TIE bit is 1, an SCIn_TXI interrupt request is generated.

The DTC or DMAC is activated by an SCIn_TXI interrupt request if the SCIn_TXI interrupt request is previously specified as a source of DTC or DMAC activation, allowing the transfer of transmit data. The TEND flag is automatically set to 0 when the DTC or DMAC transfers the data.

If an error occurs, the SCI automatically retransmits the same data. During this retransmission, the TEND flag is kept at 0 and the DTC or DMAC is not activated. Therefore, the SCI and DTC or DMAC automatically transmit the specified number of bytes, including retransmission when an error occurs. Because the ERS flag is not automatically cleared, set the RIE bit to 1 before enabling an SCIn_ERI interrupt request to be generated if an error occurs, and clear the ERS flag to 0.

When transmitting or receiving data using the DTC or DMAC, always enable the DTC or DMAC before making the SCI settings.

For DTC or DMAC settings, see section 16, Data Transfer Controller (DTC), section 15, DMA Controller (DMAC).



Note 1. See section 12, Interrupt Controller Unit (ICU) for information on the corresponding interrupt event number.

Figure 28.80 Data re-transfer operation in smart card interface transmission mode

The CSR.TEND flag is set at different timings depending on the CCR3.GM bit setting. Figure 28.81 shows the TEND flag generation timing.

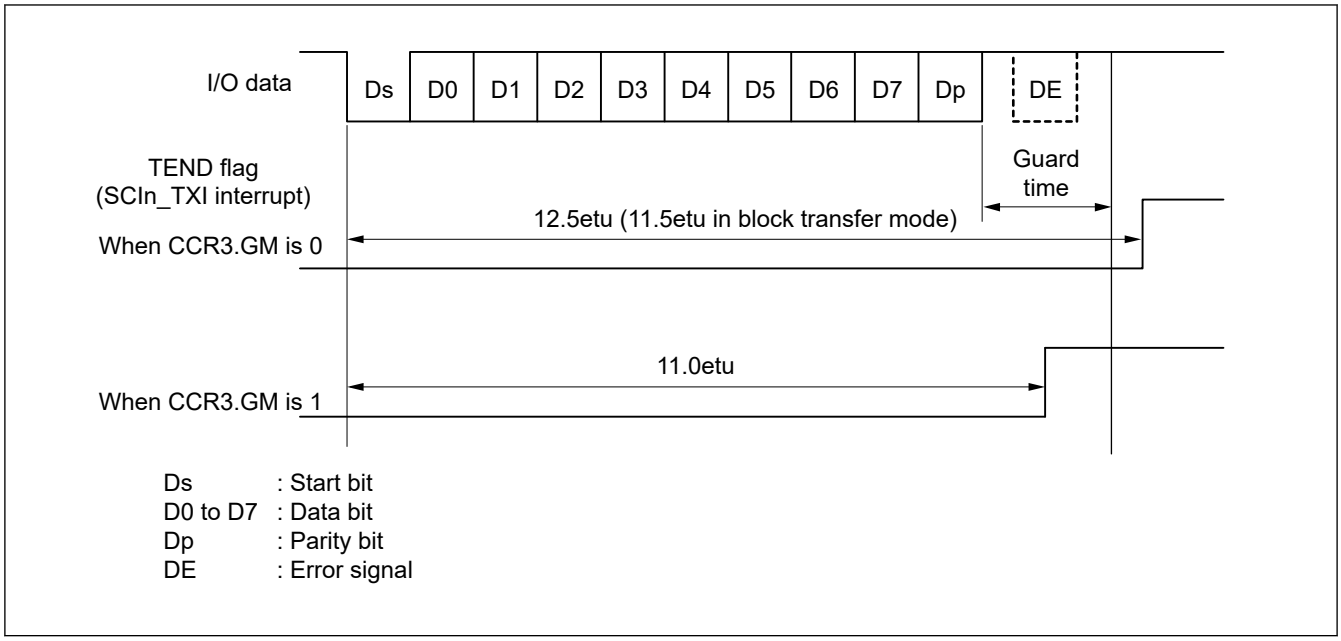


Figure 28.81 CSR.TEND flag generation timing during transmission

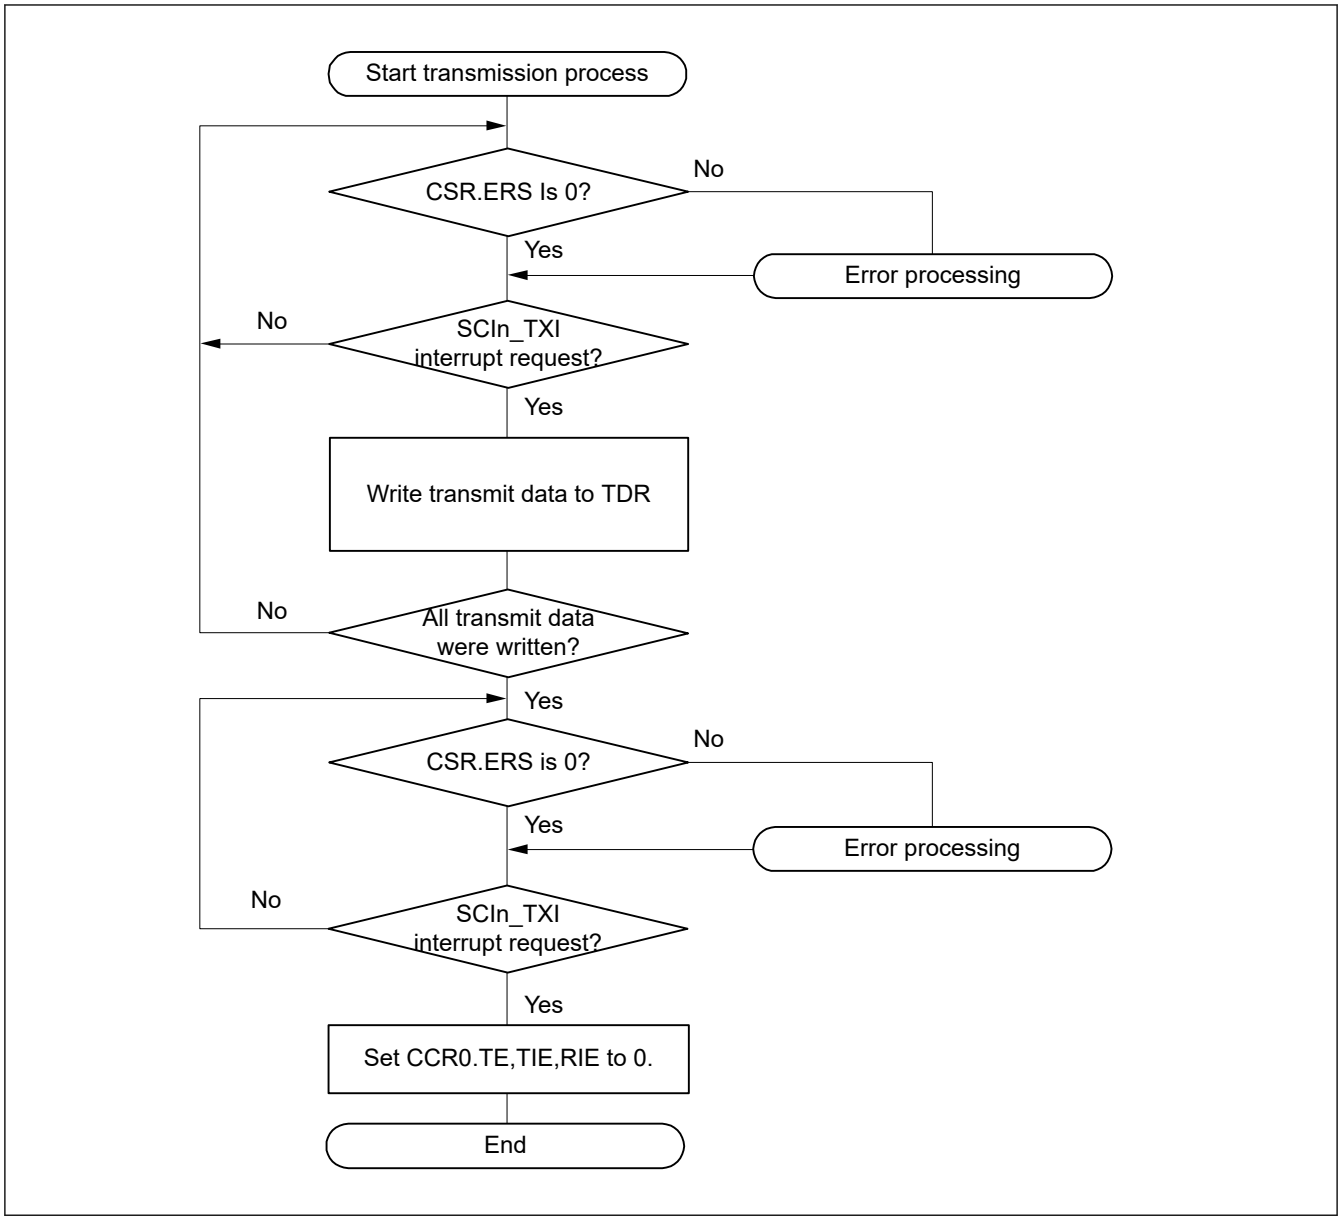

Figure 28.82 Example flow of smart card interface transmission

28.7.7 Serial Data Reception (Except in Block Transfer Mode)

Serial data reception in smart card interface mode is similar to that in non-smart card interface mode. Figure 28.83 shows the data re-transfer operation in reception mode.

1. If a parity error is detected in the receive data, the CSR.PER flag is set to 1. When the CCR0.RIE bit is 1, an SCIn_ERI interrupt request is generated. Clear the PER flag to 0 before the next parity bit is sampled.
2. For a frame in which a parity error is detected, no SCIn_RXI interrupt is generated.
3. When no parity error is detected, the CSR.PER flag is not set to 1.
4. In this case, data is determined to be received successfully. When the CCR0.RIE bit is 1, an SCIn_RXI interrupt request is generated.

Figure 28.84 shows an example flow of serial data reception. All the processing steps are automatically performed using an SCIn_RXI interrupt request to activate the DTC or DMAC.

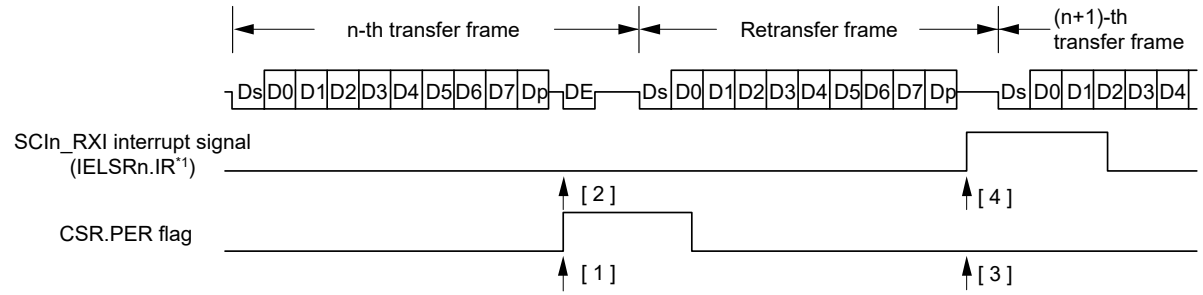
In reception, setting the RIE bit to 1 allows an SCIn_RXI interrupt request to be generated. The DTC or DMAC is activated by an SCIn_RXI interrupt request if the SCIn_RXI interrupt request is previously specified as a source of DTC or DMAC activation, allowing the transfer of receive data.

If an error occurs during reception and either the ORER or PER flag in CSR is set to 1, a receive error interrupt (SCIn_ERI) request is generated. Clear the error flag after the error occurrence. If an error occurs, the DTC or DMAC is not activated and receive data is skipped. Therefore, the number of bytes of receive data specified in the DTC or DMAC is transferred.

If a parity error occurs and the PER flag is set to 1 during reception, the receive data is transferred to RDR, allowing the data to be read.

When a reception is forced to terminate by setting CCR0.RE to 0 during operation, read the RDR register because the received data that is not yet read might be left in the RDR.

Note: For operations in block transfer mode, see section 28.3.9. Serial Data Reception in Asynchronous Mode.



Note 1. See section 12, Interrupt Controller Unit (ICU) for information on the corresponding interrupt event number.

Figure 28.83 Data re-transfer operation in smart card interface reception mode

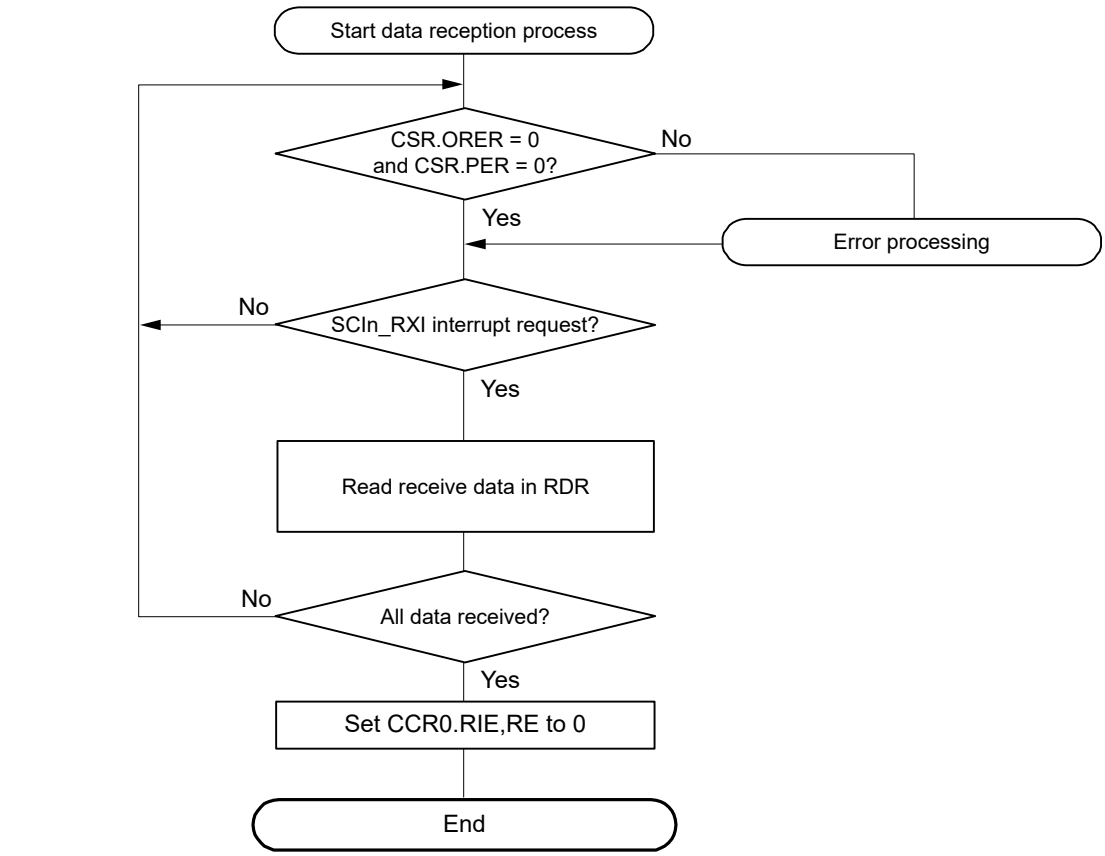


Figure 28.84 Example flow of smart card interface reception

28.7.8 Clock Output Control

When the GM bit in CCR3 is set to 1, the clock output can be controlled by the CKE[1:0] bits in CCR3. For details on the CKE[1:0] bits, see section 28.2.8. CCR3 : Common Control Register 3. When setting the clock output, the base clock described in section 28.7.4. Receive Data Sampling Timing and Reception Margin the bit rate is set by CCR2.CKS, CCR2.BCP[2:0] and BRR[7:0].

Figure 28.85 shows an example timing for the clock output control when the CKE[1] bit in CCR3 is set to 0 and the CKE[0] bit in CCR3 is controlled.

When the GM bit in CCR3 is 0, output control by the CKE[0] bit in CCR3 is immediately reflected on the SCKn pin, so there is a possibility that pulses with an unintended width may be output from the SCKn pin.

When the GM bit in CCR3 is 1, the output pulse control by the CCR3.CKE [0] controls the pulse width set to be based on the state of the base clock.

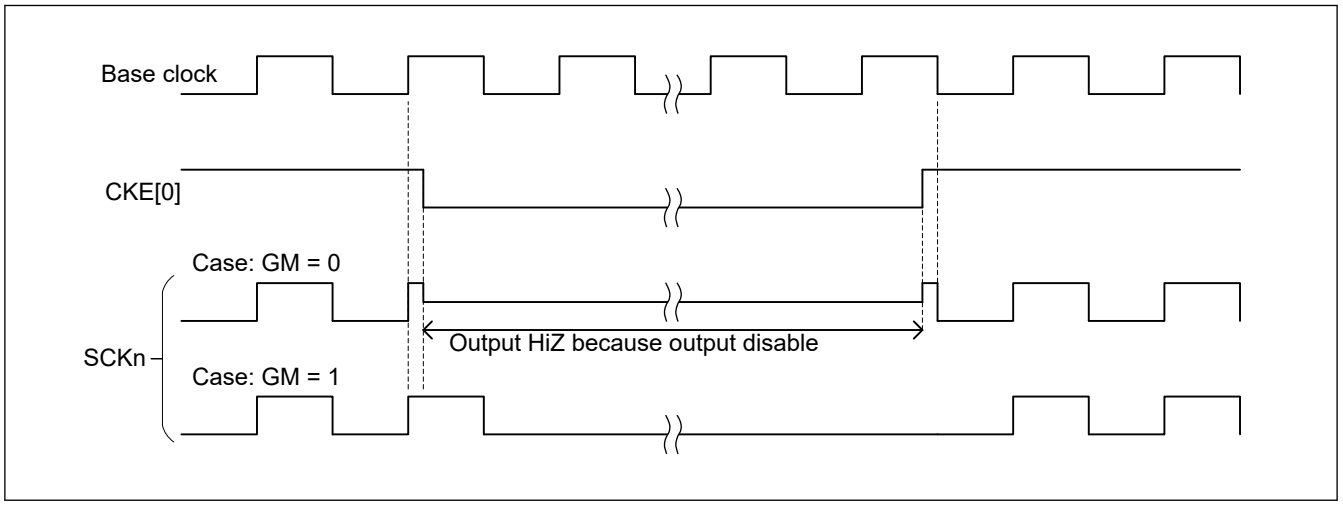

Figure 28.85 Clock Output timing

28.8 Operation in Simple IIC Mode

Simple IIC mode format is composed of 8 data bits and an acknowledge bit. By continuing into a slave-address frame after a start condition or restart condition, a master device can specify a slave device as the partner for communications. The currently specified slave device remains valid until a new slave device is specified or a stop condition is satisfied. The 8 data bits in all frames are transmitted in order from the MSB.

The I^2C bus format and timing of the I^2C bus are shown in Figure 28.86 and Figure 28.87.

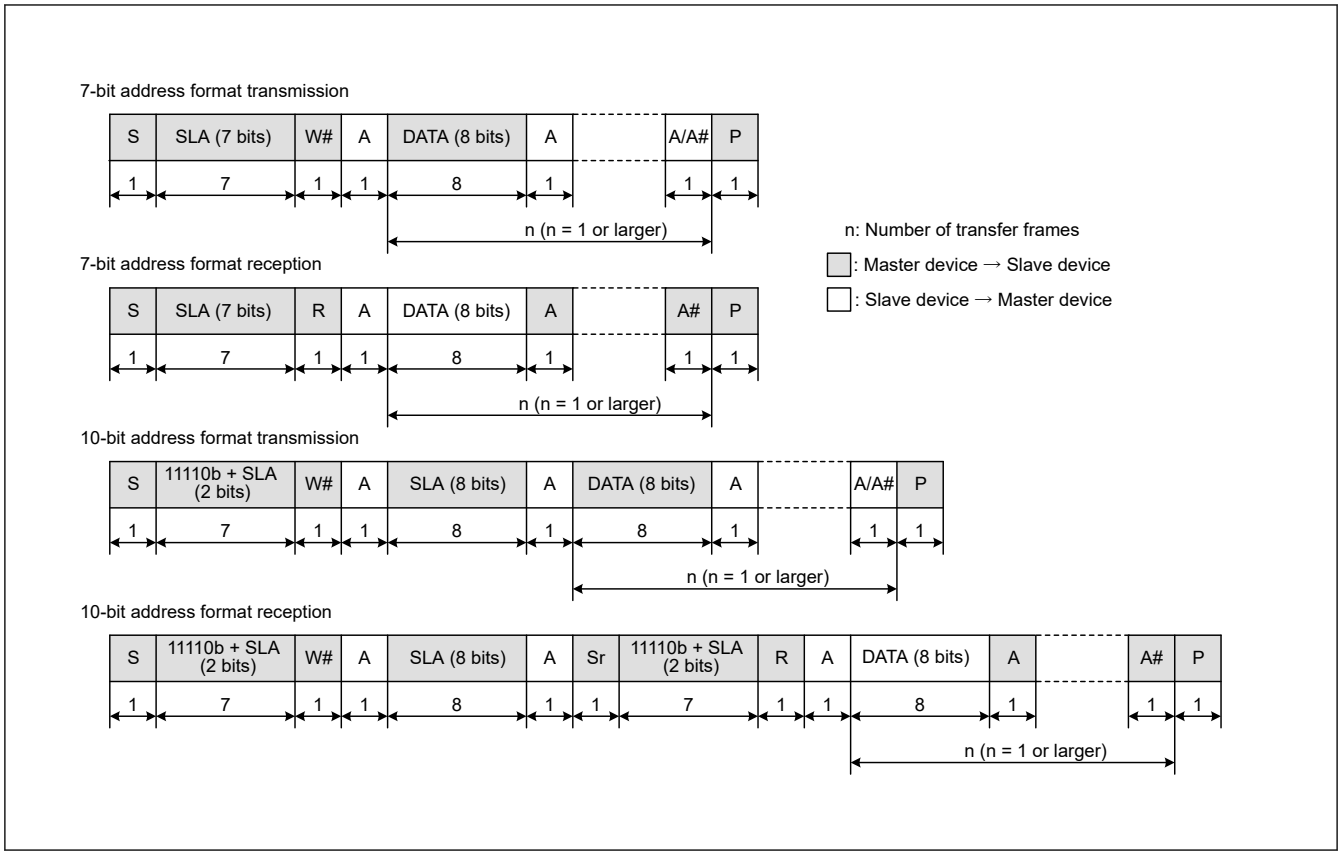

Figure 28.86 **I²C bus format**

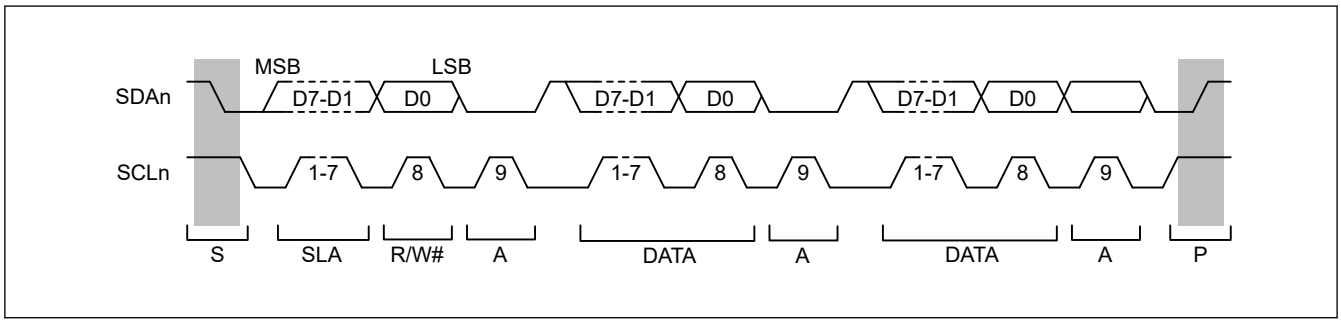

Figure 28.87 **I²C bus timing when SLA is 7 bits**

- S: Indicates a start condition, when the master device changes the level on the SDAn line from high to low while the SCLn line is high
- SLA: Indicates a slave address, by which the master device selects a slave device
- R/W#: Indicates the direction of transfer (reception or transmission). The value 1 indicates transfer from the slave device to the master device and 0 indicates transfer from the master device to the slave device.
- A/A#: Indicates an acknowledge bit. This is returned by the slave device for master transmission and by the master device for master reception. Return low indicates ACK and return high indicates NACK.
- Sr: Indicates a restart condition, when the master device changes the level on the SDAn line from high to low while the SCLn line is high and after the setup time elapses
- DATA: Indicates the data being received or transmitted
- P: Indicates a stop condition, when the master device changes the level on the SDAn line from low to high while the SCLn line is high

28.8.1 Generation of Start, Restart, and Stop Conditions

Writing 1 to the ICR.IICSTAREQ bit causes the generation of a start condition. The generation of a start condition proceeds through the following operations:

- The level on the SDAn line falls (from the high level to the low level) and the SCLn line is kept in the released state
- The hold time for the start condition is set as half of a bit period at the bit rate determined by the CCR2.BRR setting
- The level on the SCLn line falls (from the high level to the low level), the IICSTAREQ bit in ICR is set to 0, and a start-condition generated interrupt is output

Writing 1 to the IICRSTAREQ bit in ICR causes the generation of a restart condition. The generation of a restart condition proceeds through the following operations:

- The SDAn line is released and the SCLn line is kept at the low level
- The period at low level for the SCLn line is set as half of a bit period at the bit rate determined by the CCR2.BRR setting
- The SCLn line is released (transition from the low to the high level)
- When a high level is detected on the SCLn line, the setup time for the restart condition is set as half of a bit period at the bit rate determined by the CCR2.BRR setting
- The level on the SDAn line falls (from the high level to the low level)
- The hold time for the restart condition is set as half of a bit period at the bit rate determined by the CCR2.BRR setting
- The level on the SCLn line falls (from the high level to the low level), the ICR.IICRSTAREQ bit is set to 0, and a restart-condition generated interrupt is output

Writing 1 to the ICR.IICSTPREQ bit causes the generation of a stop condition. The generation of a stop condition proceeds through the following operations:

- The level on the SDAn line falls (from the high level to the low level) and the SCLn line is kept at the low level
- The period at low level for the SCLn line is set as half of a bit period at the bit rate determined by the CCR2.BRR setting
- The SCLn line is released (transition from the low to the high level)
- When a high level is detected on the SCLn line, the setup time for the stop condition is set as half of a bit period at the bit rate determined by the CCR2.BRR setting
- The SDAn line is released (transition from the low to the high level), the ICR.IICSTPREQ bit is set to 0, and a stop-condition generated interrupt is output

Figure 28.88 shows the timing of operations in the generation of start, restart, and stop conditions.

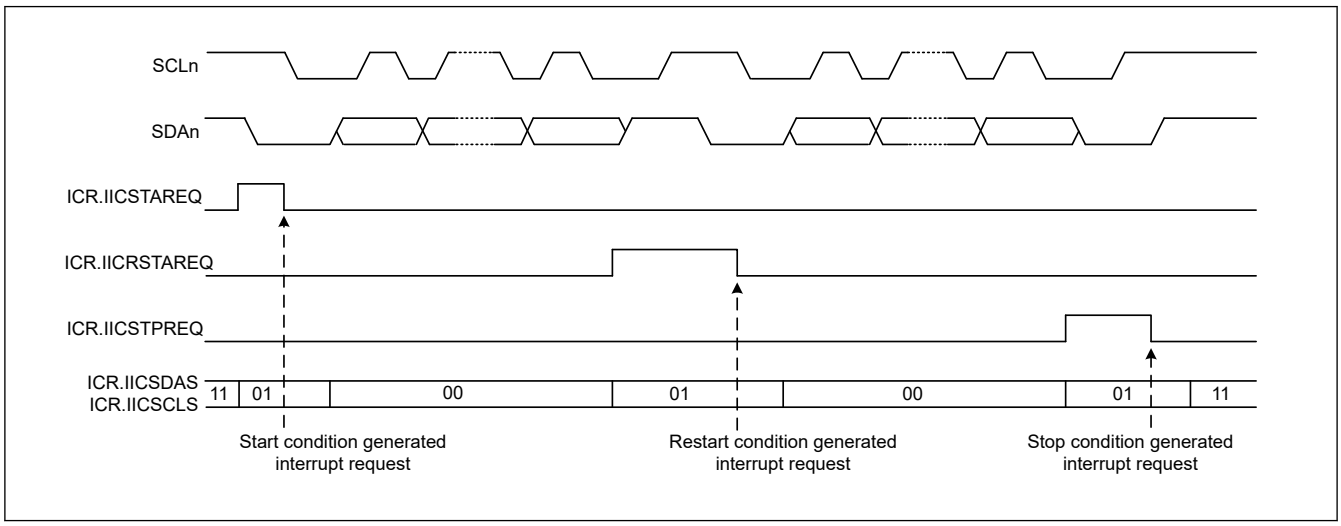

Figure 28.88 Timing of operations in generation of start, restart, and stop conditions

28.8.2 Clock Synchronization

The SCLn line can be driven low if a wait is inserted by a slave device at the other side of the transfer. Setting the ICR.IICCSC bit to 1 applies control to obtain synchronization when a difference arises between the levels of the internal SCLn clock signal and the level being input on the SCLn pin.

When the ICR.IICCSC bit is set to 1, the level of the internal SCLn clock signal changes from low to high. Counting to determine the period at a high level stops while the low level is being input on the SCLn pin. Counting to determine the period at a high level starts after the transition of the input on the SCLn pin to the high level.

The interval from this time until counting to determine the period at high level starts on the transition of the SCLn pin to the high level, is the total time which contains the SCLn input delay, delay for noise filtering of the input on the SCLn pin (2 or 3 cycles of sampling clock for the noise filter), and delay for internal processing (1 or 2 cycles of PCLK). The period at high level of the internal SCLn clock is extended even when other devices do not place the low level on the SCLn line.

If the ICR.IICCSC bit is 1, synchronization is obtained for the transmission and reception of data by taking the logical AND of the input on the SCLn pin and the internal SCLn clock. If the ICR.IICCSC bit is 0, synchronization with the internal SCLn clock is obtained for the transmission and reception of data.

If a slave device inserts a wait period into the interval until the transition of the internal SCLn clock signal from the low to the high level after a request for the generation of a start, restart, or stop condition is issued, the time until generation is prolonged by that period.

If a slave device inserts a wait period after the transition of the internal SCLn clock signal from the low to the high level, although the generation-completed interrupt is issued without stopping the waiting period, generation of the condition itself is not guaranteed.

Figure 28.89 shows an example operation for synchronizing the clocks.

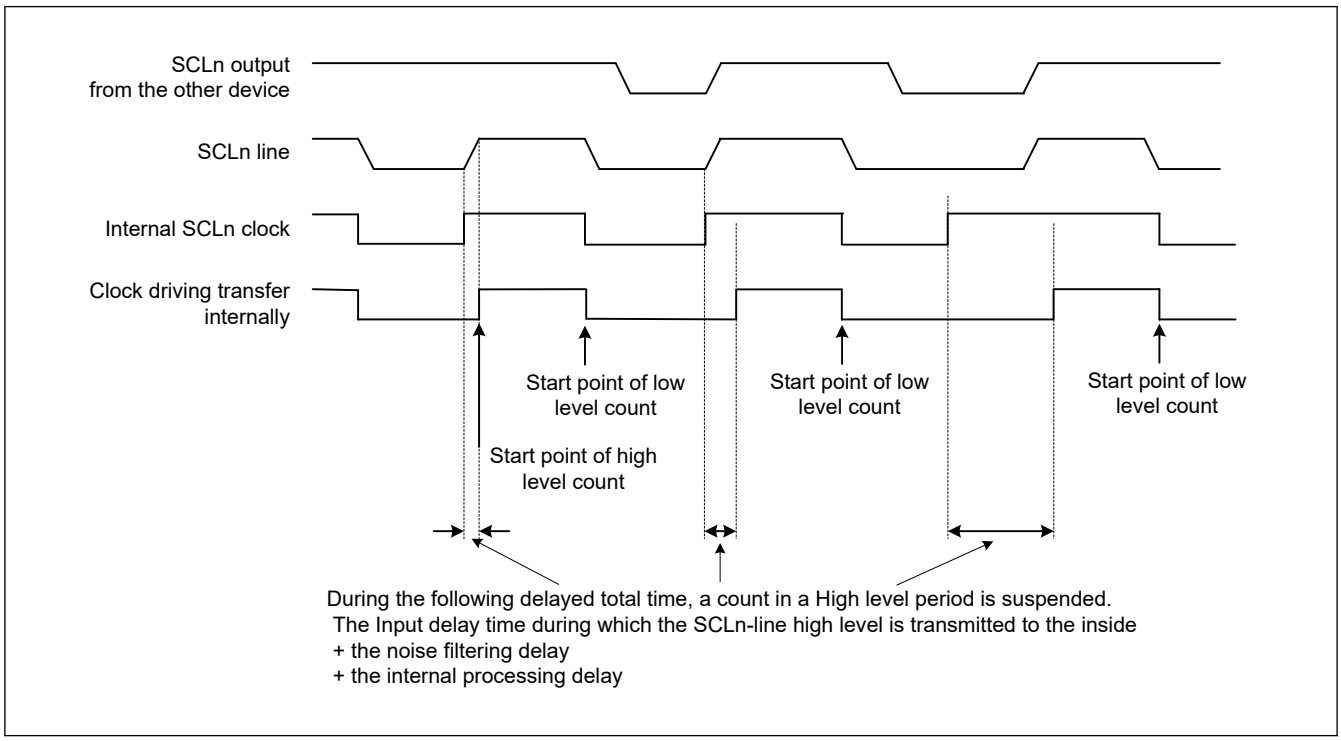

Figure 28.89 Example operations for clock synchronization

28.8.3 SDAn Output Delay

The ICR.IICDL[4:0] bits can be used to set a delay for output on the SDAn pin relative to falling edges of output on the SCLn pin. Delay settings from 0 to 31 are selectable, representing periods of the corresponding numbers of cycles of the clock signal from the on-chip baud rate generator (derived by frequency-dividing the base clock, TCLK, by the divisor selected in the CCR2.CKS[1:0] bits). A delay for output on the SDAn pin applies to the start condition/restart condition/stop condition signal, 8-bit transmit data, and acknowledge bit.

If the SDAn output delay is shorter than the time for the level on the SCLn pin to fall, the change of the output on the SDAn pin starts while the output level on the SCLn pin is falling, creating a possibility of erroneous operation for slave devices. Ensure that settings for the delay of output on the SDAn pin specify times greater than the time output on the SCLn pin takes to fall (300 ns for IIC in normal mode and fast mode).

Figure 28.90 shows the timing of delays in SDAn output.

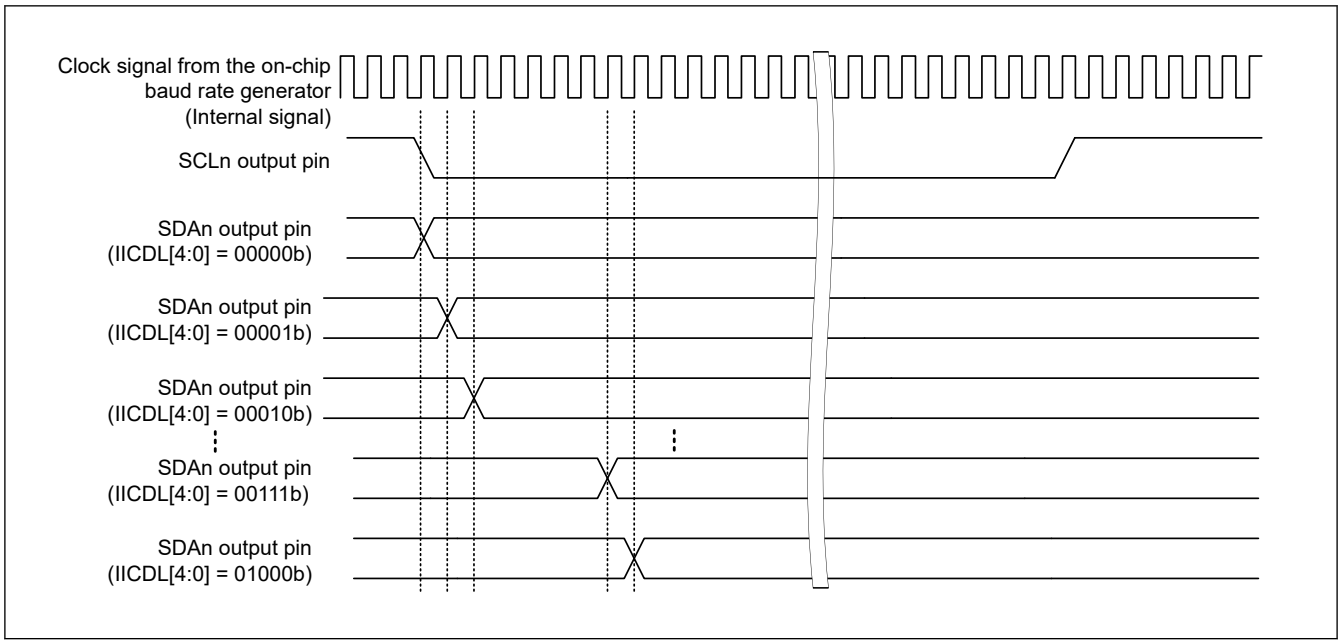

Figure 28.90 Timing of delays in SDAn output

28.8.4 SCI Initialization in Simple IIC Mode

Before transferring data, write the initial value 0x00 to CCR0 and initialize the interface following the example shown in Table 28.41.

Before making any changes to the operating mode or transfer format, be sure to set CCR0 to its initial value. In simple IIC mode, the open-drain setting for the communication ports should be made on the port side.

Table 28.41 Example flow of SCI initialization in simple IIC mode

No.	Step Name	Description
1	Start initialization	—
2	Set CCR0	Set CCR0.TEIE, TIE, RIE, TE, RE to 0. If you have not changed from the initial settings, you can skip this step.
3	Set ICR	Set the IICSDAS[1:0] and IICSCLS[1:0] to 11b. Set the IICDL[4:0] and IICINTM as required. Set the IICACKT and the IICCSC bits to 1.
4	Set CCR3	Set the transmission / reception format as the communication mode (MOD [2:0] = 100b) and CKE [1:0] = 00b.
5	Set CCR2	Set the bit rate modulation function*1, the clock selection, and the bit rate.
6	Set CCR1	Set noise filter, communication pin status, parity check, and CTSn / RTSn function.
7	Set the I/O port functions	Set I/O port settings that allow use (on NMOS open-drain output pins and Hi-Z) of the SCLn and SDAn pin functions.
8	Set CFCLR, ICFCLR	Write 1 to the following bits and clear the corresponding flag. CFCLR.RDRFC, FERC, PERC, MFFC, ORERC, DFERC, DPERC, DCMFC, ERSC ICFCLR.IICSTIFC
9	Set CCR0 (TE, RE, TIE, RIE)	Set the TE and RE bits to 1. To enable interrupts, set the TE, TIE, RE and RIE bits to 1 with one instruction at the same time (for transmission and when the IICINTM bit is 1, clear the RIE bit). Setting the TE and RE bits to 1 makes the SCLn and SDAn pins functions available.
10	Initialization completed	—

Note: Set the CCR0.TE and RE bits to 0 or 1 at the same time.

Note 1. If you do not use the bit rate modulation function, you do not need to set it.

28.8.5 Operation in Master Transmission in Simple IIC Mode

Figure 28.91 and Figure 28.92 show examples of master transmission and Figure 28.93 shows an example flow of data transmission.

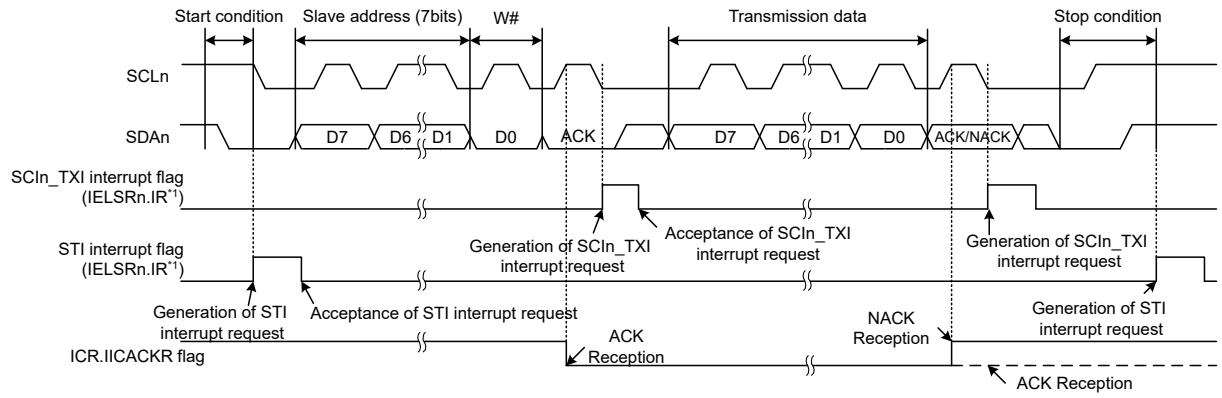
Figure 28.91 shows the operation example when ICR.IICINTM bit is 1 (use reception and transmission interrupts). In this case, you can start DMAC or DTC by SCIn_TXI interrupt. However, if use DMAC or DTC, ACK/NACK cannot be confirmed. If you want to confirm ACK/NACK, prepare the transmit data by CPU.

In simple IIC mode, SCIn_TXI interrupt is generated when communication of one frame is completed. And it is not used SCIn_RXI interrupt in master transmission, so the CCR0.RIE set to 0.

See Table 28.46 for more information on the STI interrupt.

Figure 28.93 shows a flow chart in the case of ICR.IICINTM is 1 and address transmission by CPU and data transmission by DTC or DMAC. When 10-bit slave addresses are in use, steps [3] and [4] are repeated twice.

In simple IIC mode, the transmit data empty interrupt (SCIn_TXI) is generated when communication of one frame is complete, unlike the SCIn_TXI interrupt request generation timing during clock synchronous transmission.



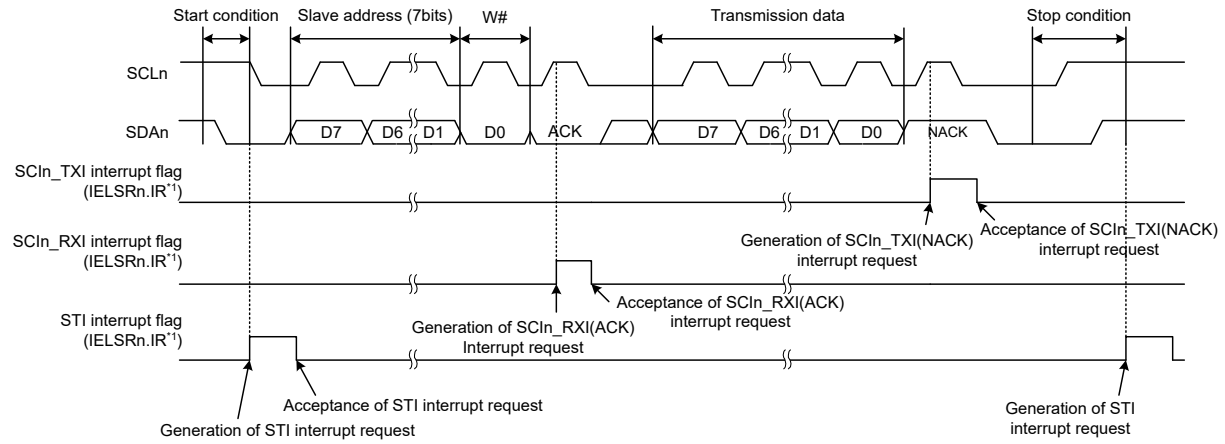
Note 1. See section 12, Interrupt Controller Unit (ICU) for information on the corresponding interrupt event number.

Figure 28.91 Example 1 of operations for master transmission in simple IIC mode with 7-bit slave addresses, transmission interrupts, and reception interrupts (ICR.IICINTM = 1)

When the ICR.IICINTM bit is set to 0 (use ACK/NACK interrupts) during master transmission, the DTC or DMAC is activated by the ACK interrupt as the trigger and required number of data bytes are transmitted. When the NACK is received, error processing such as transmission stop and retransmission is performed using the NACK interrupt as the trigger.

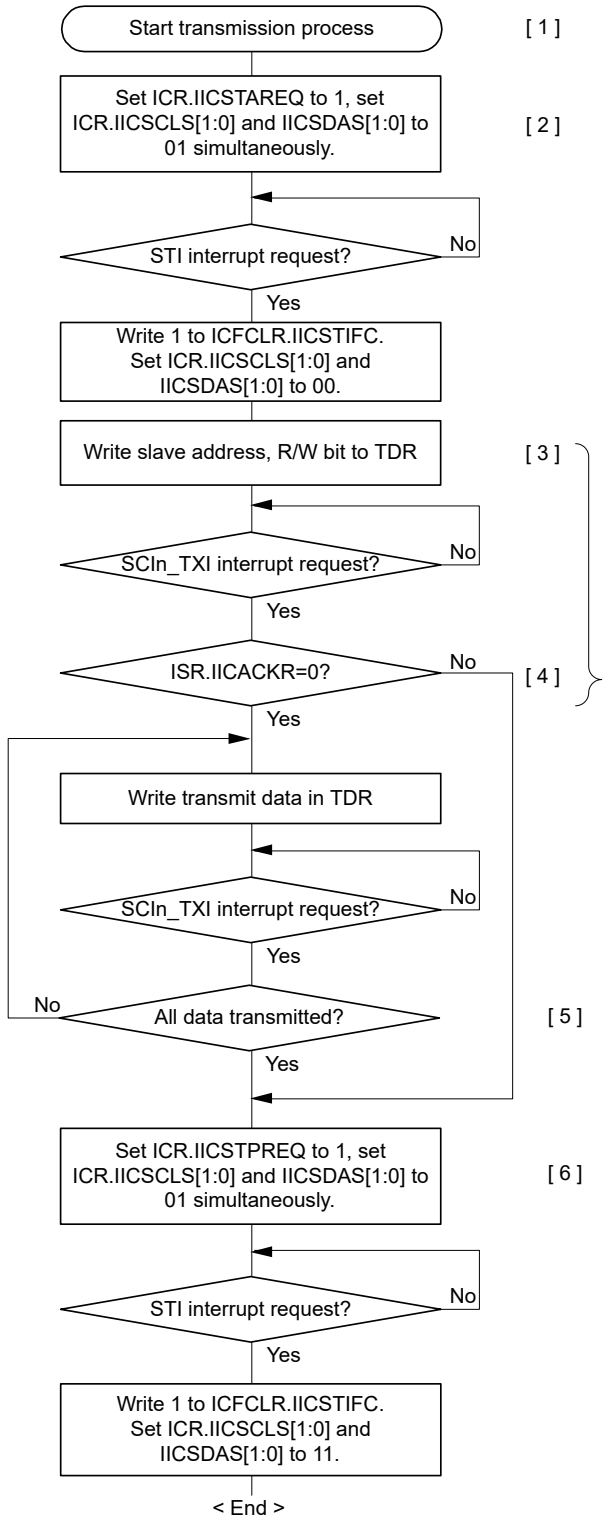
To restart communication for some reason after writing data in the TDR register, use the following procedure:

1. Set the TE and RE bits in the CCR0 register to 0 to stop communication.
2. Set ICR.IICSCLS[1:0] and ICR.IICSDAS[1:0] bits to 11b, release the I^2C bus, and clear the generation of a condition.
3. If the RDRF flag in the CSR register is set to 1, the RDR register is read by dummy and the RDRF bit is set to 0.
4. Set the TE and RE bits in the CCR0 register to 1 and start the next communication.



Note 1. See section 12, Interrupt Controller Unit (ICU) for information on the corresponding interrupt event number.

Figure 28.92 Example 2 of operations for master transmission in simple IIC mode with 7-bit slave addresses, ACK interrupts, and NACK interrupts (ICR.IICINTM = 0)



[1] Start transmission process
For transmission, set the CCR0.RIE to 0.
(SCIn_RXI and SCIn_ERI interrupts requests are disabled)

[2] Generate a start condition.

[3] Writing to TDR:
Writing the slave address and value for the R/W bit to TDR.

[4] Confirm ACK response from the slave device:
Check the ISR.IICACKR bit. If its value is 0, it is indicated that the slave device responded with ACK and operations proceed. If its value is 1, it is indicated that there was no response from a slave device so the next transition is to generation of the stop condition.

[5] Steps for continuing with serial transmission:
When transmission is to continue, write further transmit data to TDR. Except for the first data to be transmitted, a SCIn_TXI interrupt request can activate the DMAC or DTC to handle writing of data to TDR.
But it cannot be confirmed status of ACK or NACK in this case.

[6] Generation of a stop condition.

If 10-bits slave address are in use, processing from [3] to [4] is repeated twice.

Note: In simple IIC mode, the SCIn_TXI interrupt request is generated when communication is completed.

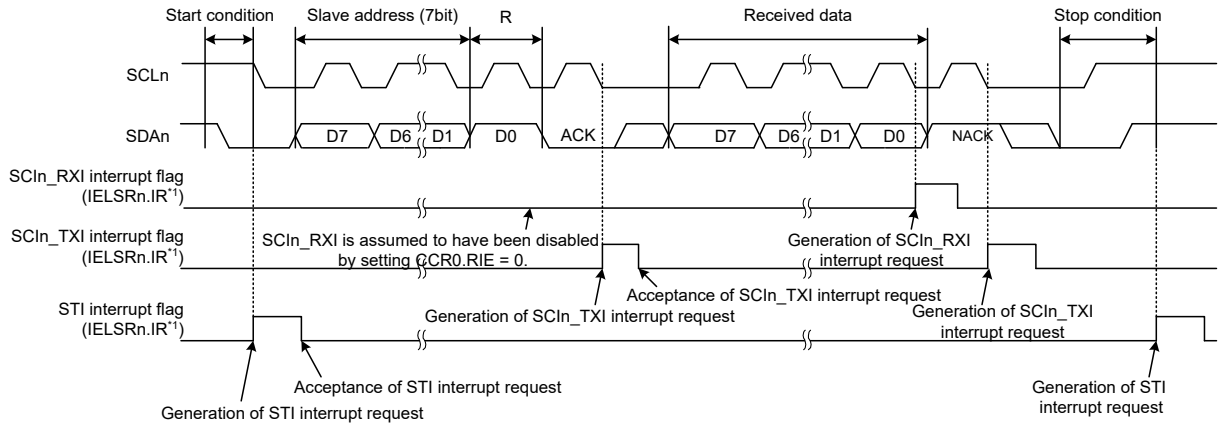
Figure 28.93 Example flow of master transmission in simple IIC mode with transmission interrupts and reception interrupts

28.8.6 Master Reception in Simple IIC Mode

Figure 28.94 shows an example operation in simple IIC mode master reception and Figure 28.96 shows an example flow of master reception.

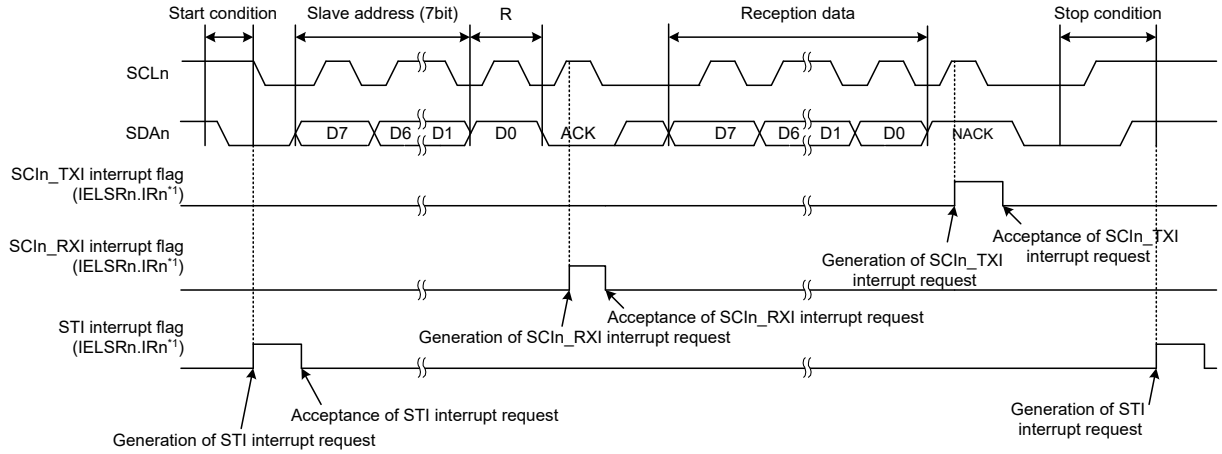
The value of the ICR.IICINTM bit is assumed to be 1 (use reception and transmission interrupts) and 0 (use ACK and NACK interrupts).

In simple IIC mode, the transmit data empty interrupt (SCIn_TXI) is generated when communication of one frame is complete, unlike the SCIn_TXI interrupt request generation timing during clock synchronous transmission.



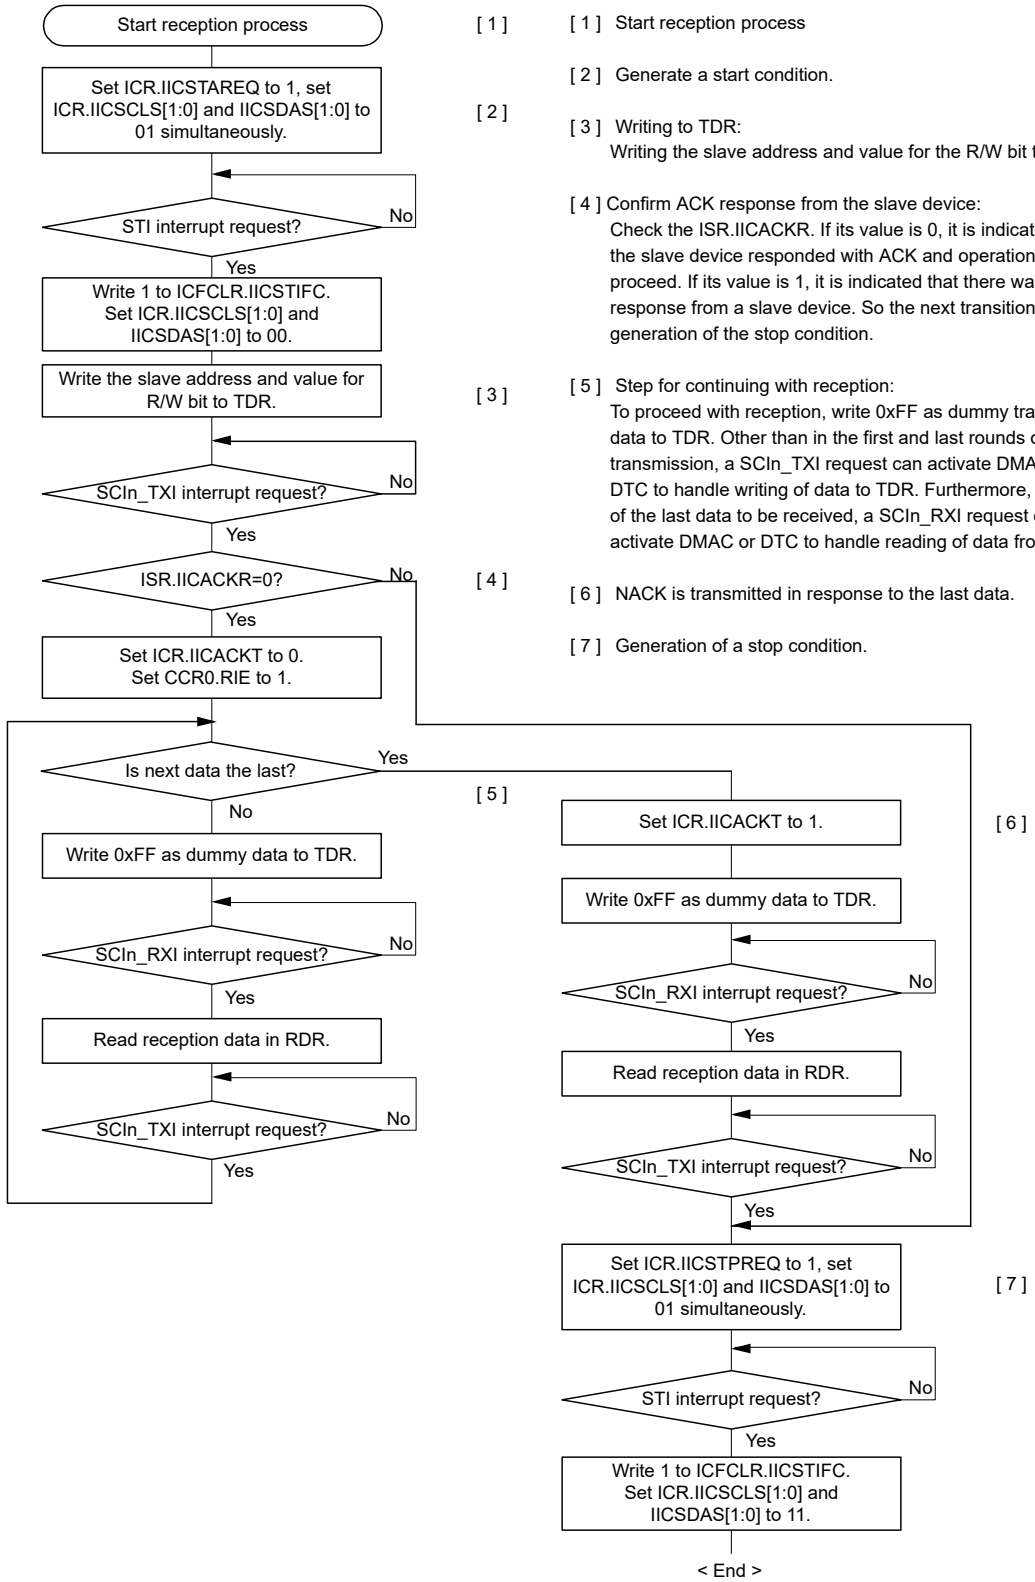
Note 1. See section 12, Interrupt Controller Unit (ICU) for information on the corresponding interrupt event number.

Figure 28.94 Example operations for master reception in simple IIC mode with 7-bit slave addresses, transmission interrupts, and reception interrupts (ICR.IICINTM = 1)



Note 1. See section 12, Interrupt Controller Unit (ICU) for information on the corresponding interrupt event number.

Figure 28.95 Example of Operations for Master Reception in Simple IIC Mode (7bit Slave address, ACK and NACK interrupt in use (ICR.IICINTM = 0))



[1] Start reception process

[2] Generate a start condition.

[3] Writing to TDR:
Writing the slave address and value for the R/W bit to TDR.

[4] Confirm ACK response from the slave device:
Check the ISR.IICACKR. If its value is 0, it is indicated that the slave device responded with ACK and operations proceed. If its value is 1, it is indicated that there was no response from a slave device. So the next transition is to generation of the stop condition.

[5] Step for continuing with reception:
To proceed with reception, write 0xFF as dummy transmit data to TDR. Other than in the first and last rounds of transmission, a SCIn_TXI request can activate DMAC or DTC to handle writing of data to TDR. Furthermore, except of the last data to be received, a SCIn_RXI request can activate DMAC or DTC to handle reading of data from RDR.

[6] NACK is transmitted in response to the last data.

[7] Generation of a stop condition.

Note: In simple IIC mode, the SCIn_TXI interrupt request is generated when communication is completed.

Figure 28.96 Example flow of master reception in simple IIC mode with transmission interrupts and reception interrupts (ICR.IICINTM = 1)

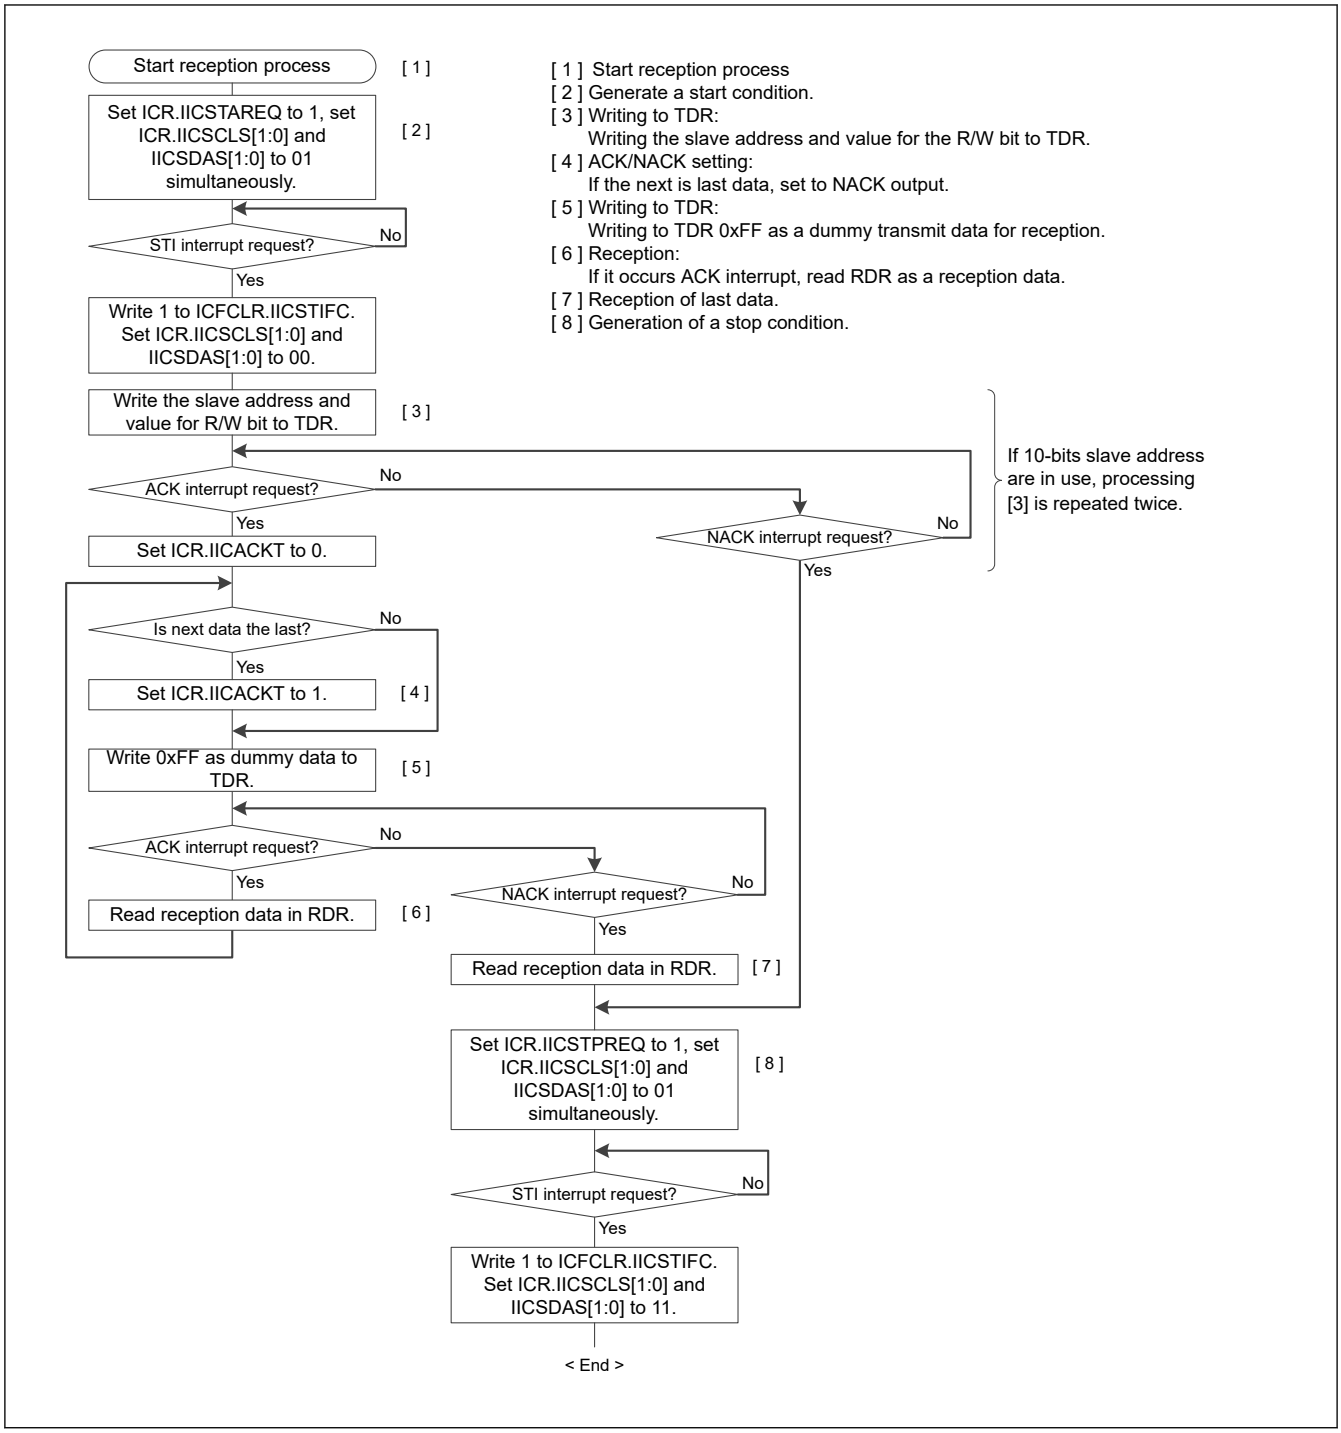


Figure 28.97 Example flow of master reception in simple IIC mode with ACK Interrupts and NACK Interrupts (ICR.IICINTM = 0)

28.9 Operation in Simple SPI Mode

As an extended function, the SCI supports a simple SPI mode that handles transfer among one or multiple master devices and multiple slave devices.

Using the settings for Simple SPI mode setting (CCR3.MOD[2:0] bit = 011b) and setting the CCR0.SSE bit to 1 place the SCI in simple SPI mode. However, the SSn pin function on the master side is not required for connection of the device used as the master in simple SPI mode when the configuration only has a single master. Therefore, set the CCR0.SSE bit to 0 in such cases.

Figure 28.98 shows an example of connections for simple SPI mode. Control a general port pin to produce the SSn output signal from the master.

In simple SPI mode, data is transferred in synchronization with clock pulses in the same way as in clock synchronous mode. One character of data for transfer consists of 8 bits of data, and parity bits cannot be appended. The data can be inverted by setting the CCR3.SINV bit to 1.

Because the receiver and transmitter are independent of each other within the SCI module, full-duplex communications are possible, with a shared clock signal. Additionally, because both the transmitter and receiver have a buffered structure, writing the next transmit data while transmission is in progress and reading previously received data while reception is in progress are both possible. This enables continuous transfer.

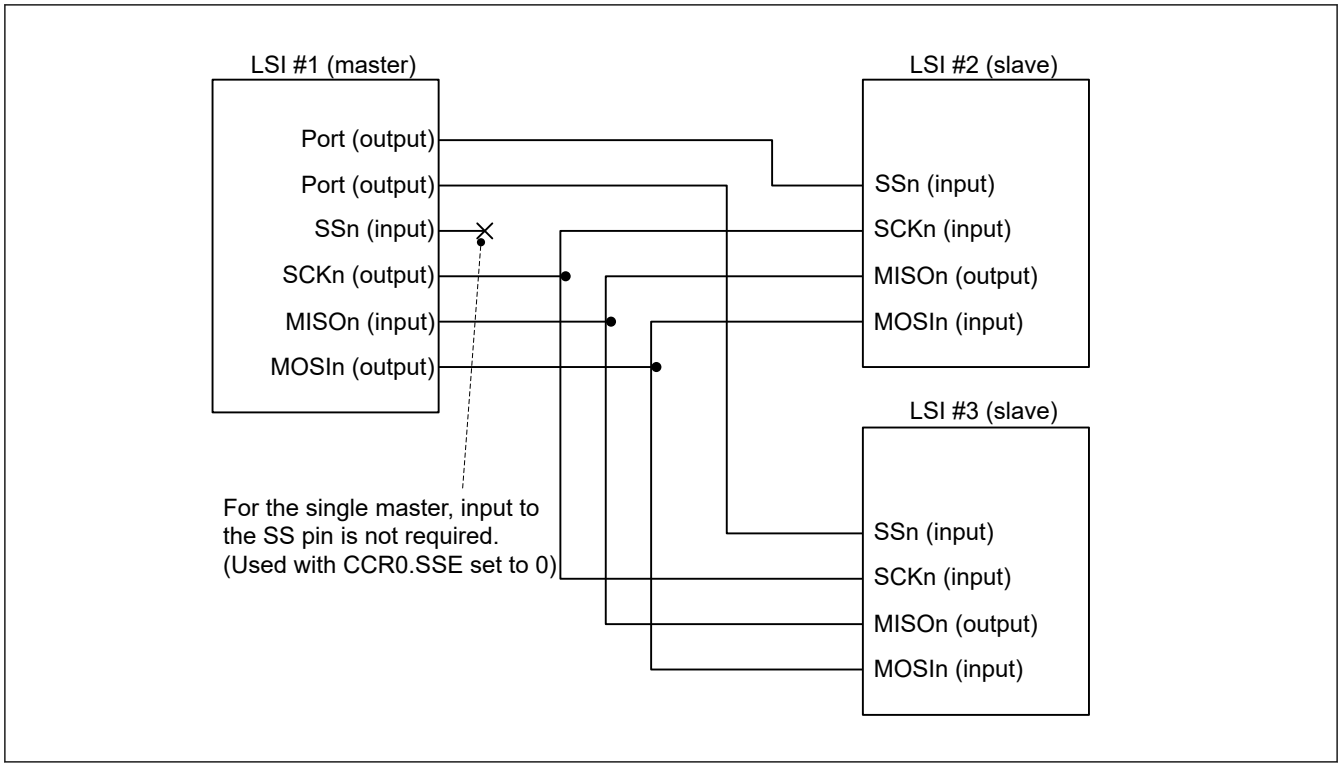

Figure 28.98 Example connections using simple SPI mode in single master mode with CCR0.SSE bit = 0

28.9.1 States of Pins in Master and Slave Modes

The direction (input or output) of pins for the simple SPI mode interface differs according to whether the device is a master (CCR3.CKE[1:0] = 00b or 01b) or slave (CCR3.CKE[1:0] = 10b or 11b).

Table 28.42 lists the relationship between the pin states, mode, and level on the SSn pin.

Table 28.42 States of pins by mode and input level on SSn pin

Mode	Input on SSn pin	State of MOSIn pin	State of MISOn pin	State of SCKn pin
Master mode*1	High level (transfer can proceed)	Output for data transmission*2	Input for received data	Clock output*3
	Low level (transfer cannot proceed)	High-impedance	Input for received data (but disabled)	High-impedance
Slave mode	High level (transfer cannot proceed)	Input for received data (but disabled)	High-impedance	Clock input (but disabled)
	Low level (transfer can proceed)	Input for received data	Output for data transmission	Clock input

Note 1. When there is only a single master (CCR0.SSE = 0), transfer is possible regardless of the input level on the SSn pin. This is equivalent to input of a high level on the SSn pin. The SSn pin is not used and is available for other purposes.
Note 2. The MOSIn pin output is in the high-impedance state when serial transmission is disabled (CCR0.TE bit = 0).
Note 3. The SCKn pin output is in the high-impedance state when serial transmission is disabled (CCR0.TE = 0 and CCR0.RE = 0) in a multi-master configuration (CCR0.SSE = 1).

28.9.2 SS Function in Master Mode

Setting the CKE[1:0] bits in the CCR3 to 00b or 01b selects master mode operation. The SSn pin is not used in single-master configurations (CCR0.SSE = 0), so transmission or reception can proceed regardless of the value of the SSn pin.

When the level on the SSn pin is high in a multi-master configuration (CCR0.SSE = 1), a master device outputs clock signals from the SCKn pin before starting transmission or reception to indicate that there are no other masters or another master is performing reception or transmission.

When the level on the SSn pin is low in a multi-master configuration (CCR0.SSE = 1), there are other masters, and a transmission or reception is in progress. The MOSIn output and SCKn pins are placed in the high-impedance state and starting transmission or reception is not possible. In addition, the value of the CSR.MFF bit is 1, indicating a mode fault error. In a multi-master configuration, start error processing by reading CSR.MFF flag. If a mode fault error occurs while transmission or reception is in progress, transmission or reception does not stop, but the MOSIn and SCKn outputs are in the high-impedance state after completion of the transfer. When the SSn pin input becomes high level, the SCKn pin outputs a clock signal and the MOSIn outputs data. Even if the SCKn pin and the MOSIn pin are in the high impedance state, internal transmission or reception operation continues, but it stops after transmission or reception of a single character is complete. In this case, any of SCIn_TXI, SCIn_RXI, and SCIn_TEI interrupts occurs.

Use a general port pin to produce the SS output signal from the master.

28.9.3 SS Function in Slave Mode

Setting the CCR3.CKE[1:0] bits to 10b or 11b selects slave operation. When the SSn pin is high, the MISOn output pin is in the high-impedance state and clock input through the SCKn pin is ignored. When the SSn pin is low, clock input through the SCKn pin is valid and transmission or reception can proceed.

If the input on the SSn pin changes from low to high during transmission or reception, the MISOn output pin is placed in the high-impedance state. Transmission / reception operation is immediately suspended. If the transmission is in progress, the CSR.TEND flag will not be set, a transmit end interrupt will not be output, and an abnormal stop status will occur. So, do not negate the SSn pin during slave transmission / reception. If an abnormal stop occurs, set CCR0.RE and CCR0.TE to 0 to stop transmission / reception. To resume transmission / reception, set CCR0.RE and CCR0.TE to 1 after at least TCLK × 3 cycles + PCLK × 3 cycles.

28.9.4 Relationship between Clock and Transmit/Receive Data

The CPOL and CPHA bits in the CCR3 register can be used to set up the clock for use in transmission and reception in four different ways. The relation between the clock signal and the transmission and reception of data is shown in Figure 28.99. The relation is the same for both master and slave operation. This is the same as when the level on the SSn pin is high.

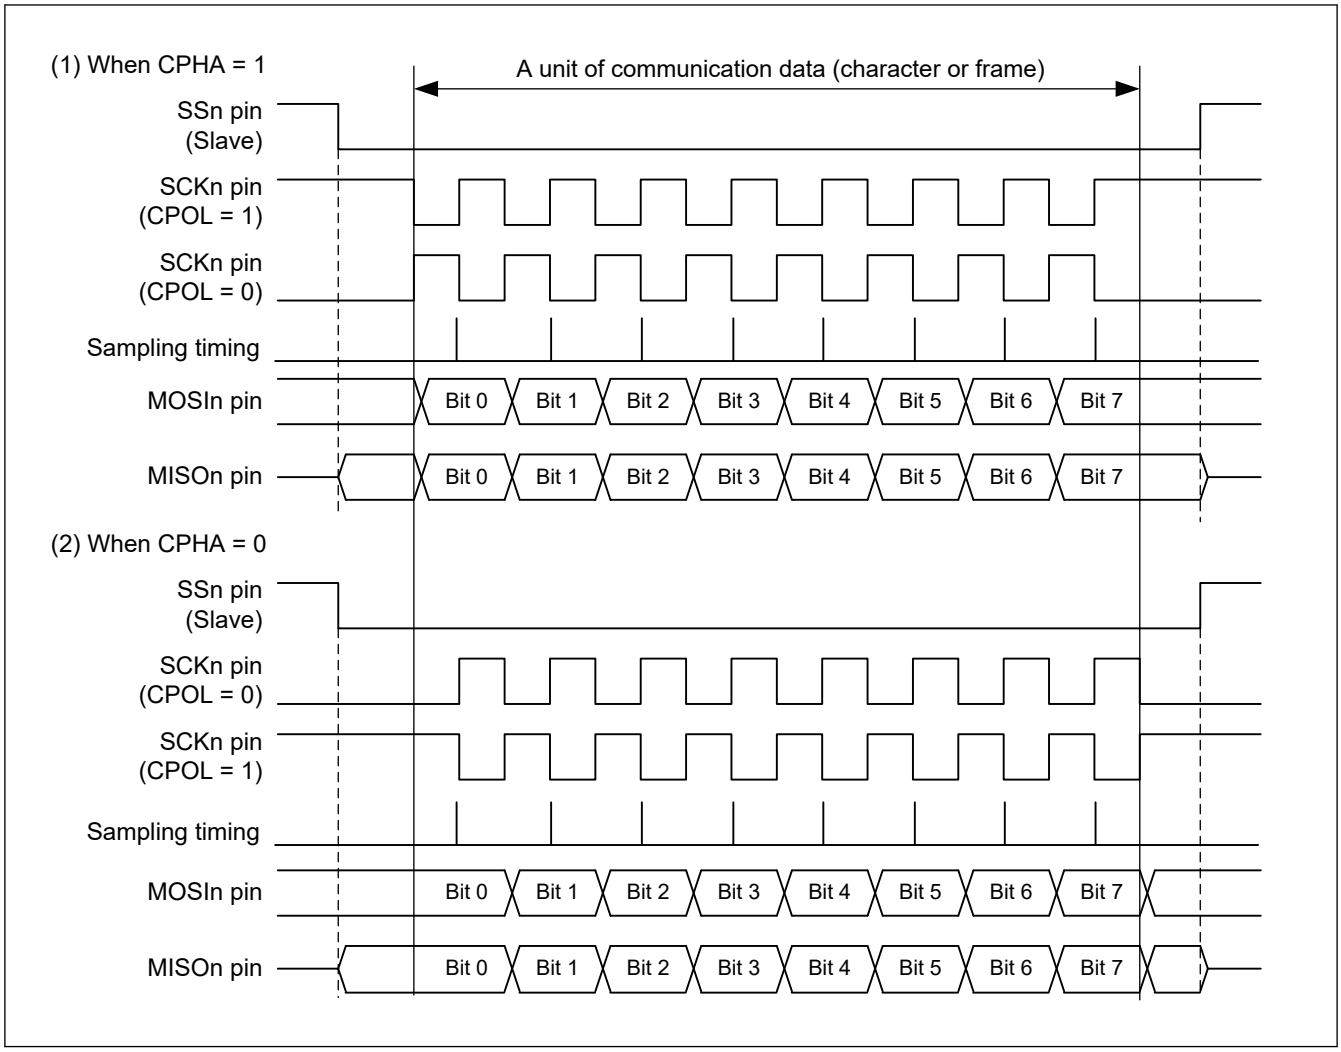

Figure 28.99 Relation between clock signal and transmit or receive data in simple SPI mode

28.9.5 SCI Initialization in Simple SPI Mode

Initialization in simple SPI mode is the same as in clock synchronous mode. See section 28.6.3. SCI Initialization in Clock Synchronous Mode for an example initialization flow. The CPOL and CPHA bits in the CCR3 register must be set to ensure that the clock signal is suitable for both master and slave devices.

Always initialize the CCR0 register before making any changes to the operating mode or transfer format.

Note: Only the RE bit is set to 0. The CSR.ORER, FER, PER, and RDR flags are not initialized.

Changing the value of the TE bit from 1 to 0 or from 0 to 1 when the TIE bit in the CCR0 register is 1 at the same time, leads to the generation of a transmit data empty interrupt (SCIn_TXI).

28.9.6 Transmission and Reception of Serial Data in Simple SPI Mode

In master operation, ensure that the SSn pin of the slave device on the other side of the transfer is at the low level before starting the transfer and at the high level on completion of the transfer. In multiple master operation with CCR0.SSE = 1 even in master mode, a mode fault error will occur if the SSn pin goes low. Therefore, make sure that no mode fault error has occurred before starting communication, and start communication, and make sure that no mode fault error has occurred even after communication ends. If a mode fault error has occurred, communication may be incomplete, so measures such as retransmission are required. Otherwise, the procedures are the same as in clock synchronous mode.

In slave mode, it operates according to the SSn pin input level. Other steps are the same as those of clock synchronous mode.

28.9.7 Reception Sampling Timing Adjustment Function in Simple SPI Mode with internal clock used

The reception sampling timing adjustment function in simple SPI mode is the same as the reception sampling timing adjustment function in clock synchronous mode. For the description of operation, see section 28.6.7. Reception Sampling Timing Adjustment Function in Clock Synchronous Mode with internal clock used.

28.10 Bit Rate Modulation Function

Using the bit rate modulation function, the bit rate can be evenly corrected using the number specified in the MDDR register among 256 clock cycles of internal clocks which is selected by the CKS[1:0] bits in CCR2.

Figure 28.100 shows an example where the PCLK is selected in the CKS[1:0] bits in CCR2, the BRR bit is set to 0, and the MDDR is set to 160 in Asynchronous mode. In this example, the cycle of the base clock is evenly corrected (256/160) and the bit rate is also corrected (160/256).

Note: Enabling an internal clock causes bias, and expansion and contraction are generated in the pulse width of the internal base clock.

Do not use this function in clock synchronous mode, simple SPI mode, Smart Card Interface mode, Manchester mode and Simple LIN mode.

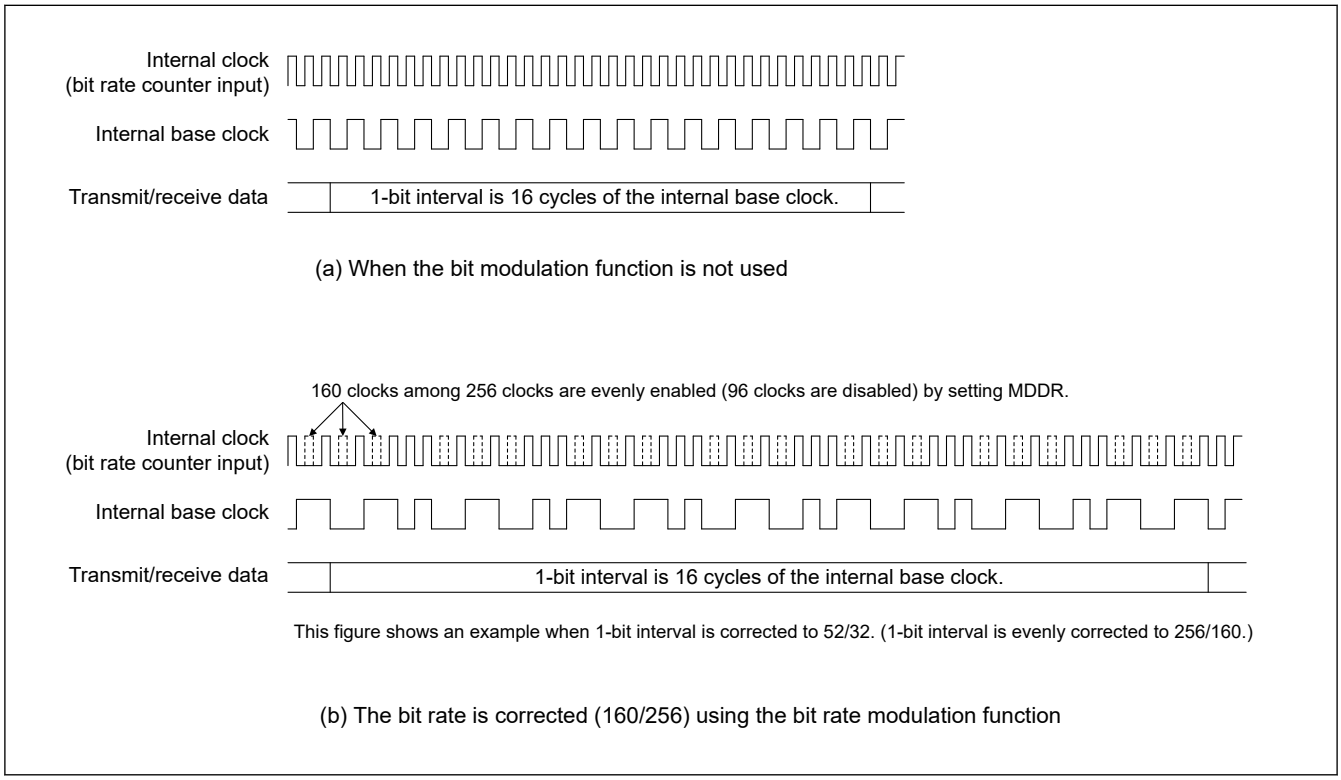

Figure 28.100 Example internal base clock when bit rate modulation function is used

28.11 Simple LIN mode

As an extended function of the SCI, the SCI supports the serial communication protocol (Figure 28.101) consisting of a Start Frame and an Information Frame as Simple LIN. Simple LIN mode is enabled by the CCR3.MOD[2:0] = 110b. Since the Simple LIN mode uses the same circuit as the Asynchronous mode for transmission / reception control other than Break Field, the basic communication settings required for the Asynchronous mode are also required for the Simple LIN mode.

(For the setting value when using simple LIN, see the explanation in section 28.2. Register Descriptions. In particular, note that CCR3.RXDESEL needs to be changed from the initial value and set to 1.)

The Start Frame consists of a Break Field, Control Field 0, and Control Field 1. The Information Frame can be configured with some Data Fields, a Checksum Field.

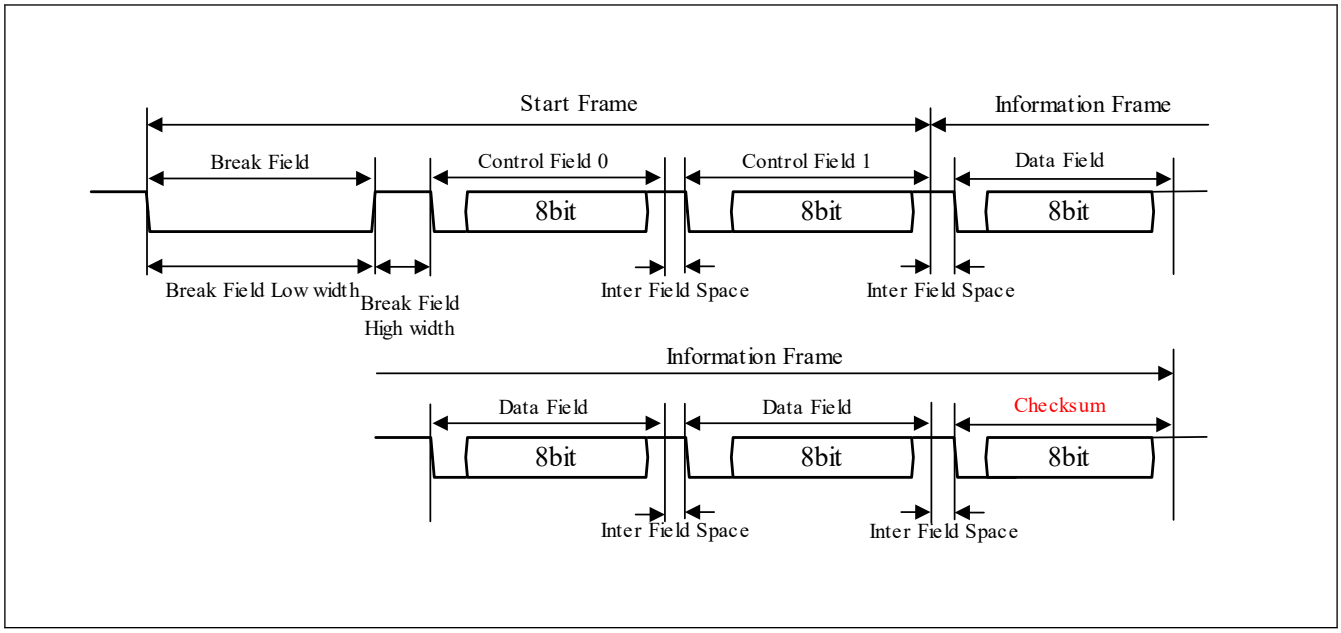

Figure 28.101 Simple LIN Protocol Example

The following describes operations when the Simple LIN is used. In this section, operations are described with the following conditions:

Communication pin (RXDn / TXDn) level inversion function: OFF (RINV = TINV = 0)

When using the simple LIN with the communication pin (RXDn / TXDn) level inversion function enabled, replace the RXDn and TXDn signal levels with their inverted levels.

28.11.1 Simple LIN Start Frame Transmission

Figure 28.102 shows an example of transmission of the Start Frame consisting of a Break Field, Control Field0, and Control Filed1. (Omit Break Field and Control Field0 according to the Start Frame configuration.)

Figure 28.103 shows a flowchart for Start Frame transmission.

The SCI operates as follows during Start Frame transmission.

1. Make the initial settings for the SCI according to the SCI initialization flow (Figure 28.68) in Asynchronous mode. In Simple LIN mode, do not set CCR0.TE and TIE to 1 at the same time to avoid SCIn_TXI output before the Break Field. Therefore, perform the following two steps sequentially to set the SCI initialization flow (Asynchronous mode) procedure [9].
   - Set the bits except CCR0.TIE. (CCR0.TIE = 0, CCR0.TE = 1, and CCR0.RE = 0)
   - Set CCR0.TIE to 1.
2. When 1 is written to TCST, the Break Field output timer starts counting and outputs a low level (Break Field) from the TXDn pin for the period set in XCR2.BFLW[15:0]. A timer count clock source can be selected by XCR0.TCSS[1:0]. Writing 0 to XCR1.TCST suspends output of the Break Field. After the suspension, set CCR0.TE = 0 and turn off the transmission.
3. When the Simple LIN module timer count value matches the set XCR2.BFLW[15:0] value, the timer stops counting and inverts the TXDn pin output level, and the XSR0.BFOF flag is set to 1[*1]. Furthermore, if XCR0.BFOIE has been set to 1 at this time, a SCIn_TXI interrupt is generated.
4. After the SCIn_TXI interrupt and confirming XSR0.BFOF = 1, write the transmitted data then the Control Field 0 data is transmitted using the SCI[*2].
5. After the Control Field 0 data has been transmitted, write the Control Field 1 data to TDR. And it is transmitted.
6. After the Control Field 1 data has been transmitted, the Information Frame data is transmitted.

Note 1. After XSR0.BFOF is set to 1, if 1 is written to XCR1.TCST without clearing it, no SCIn_TXI interrupt is output at the end of Break Field transmission. Clear XSR0.BFOF before writing 1 to XCR1.TCST.

Note 2. LIN communication requires a Break Delimiter (IDLE period) of 1 bit or more from the end of Break Field output until the next data transmission starts. For this reason, the Break Delimiter length is counted upon completion of Break Field output. If transmit data is written while the Break Delimiter length is being counted, transmission does not start until the Break Delimiter length counting is completed. When transmit data is written after the Break Delimiter length has been counted, transmission starts at the same timing as normal data transmission.

Break Delimiter length count time after Break Field output:

1-bit to 2-bit length (CCR3.STP = 0)

2-bit to 3-bit length (CCR3.STP = 1)

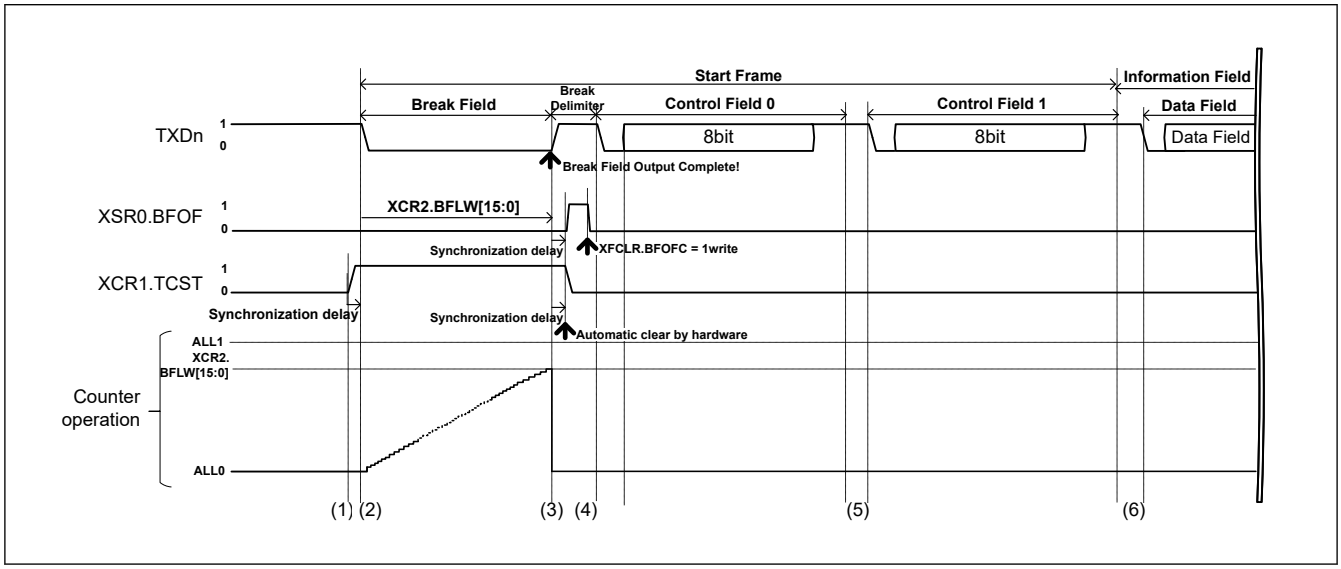

Figure 28.102 Start Frame Transmission Example

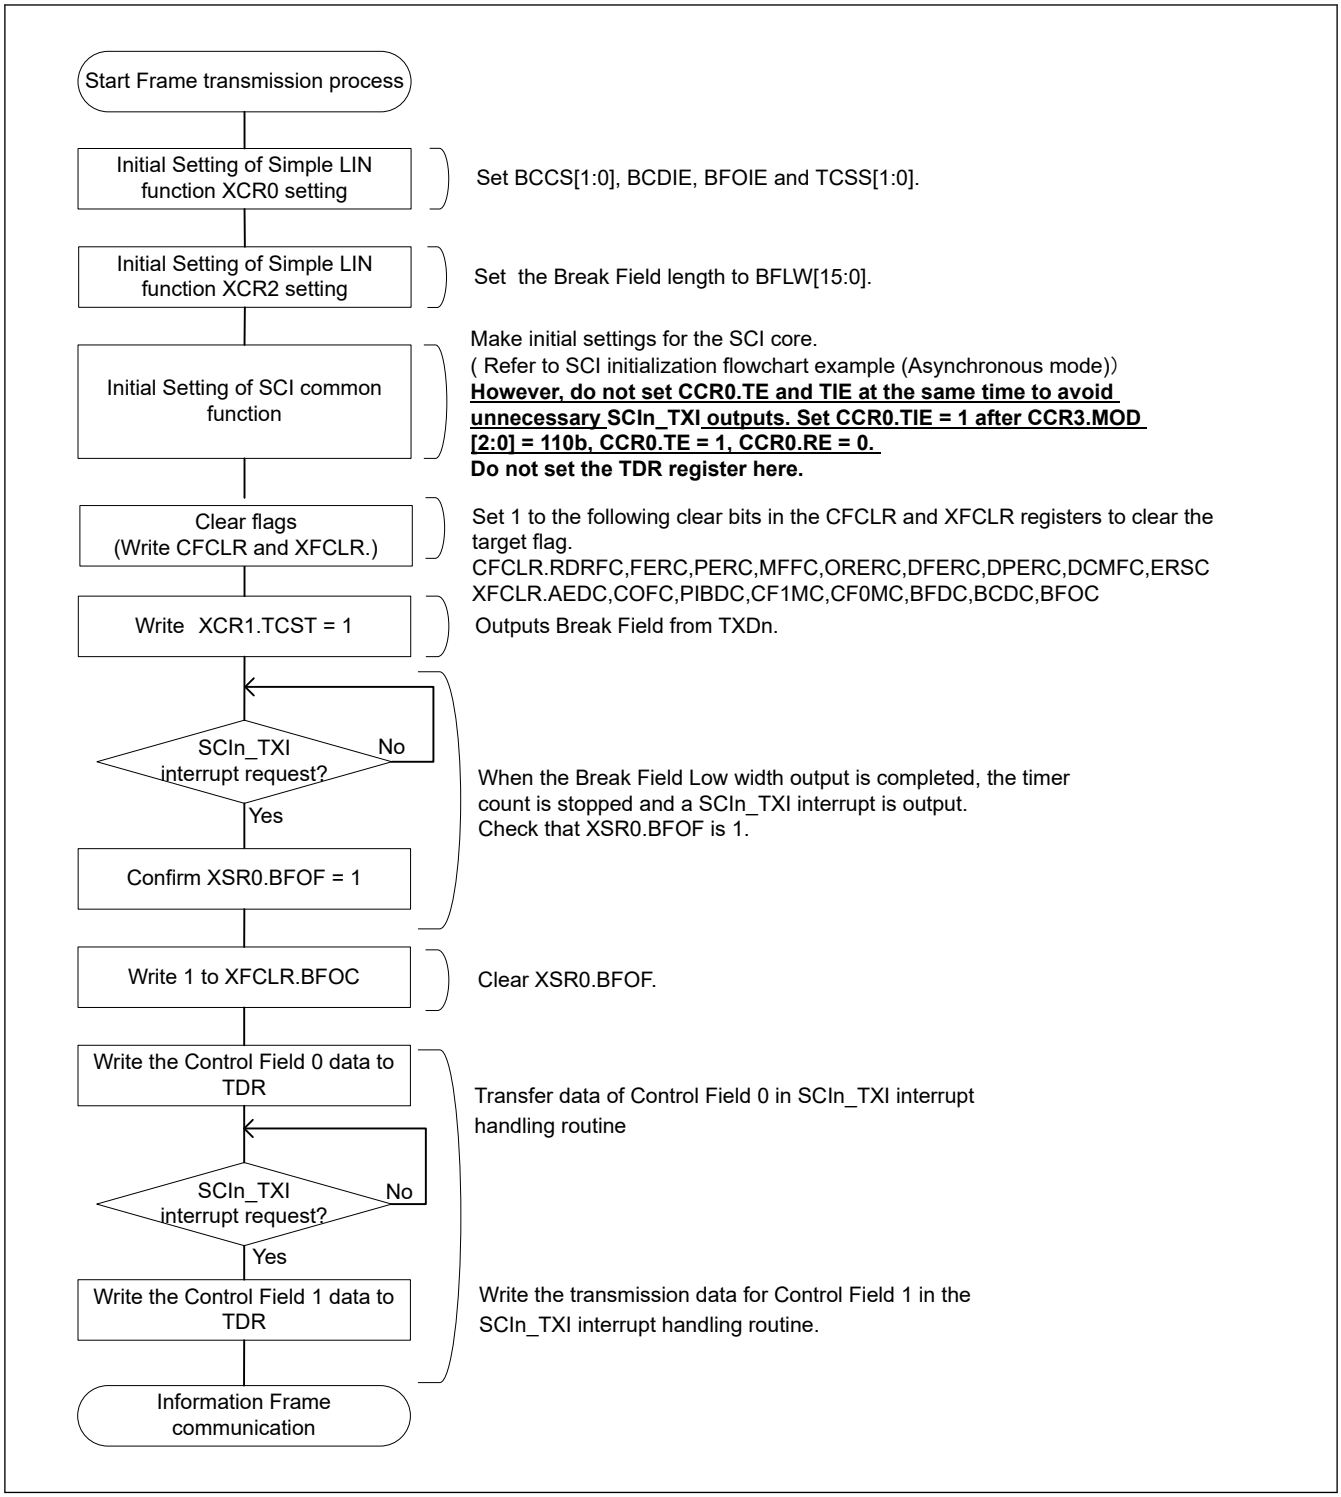

Figure 28.103 Start Frame Transmission Flowchart Example

28.11.2 Simple LIN Start Frame Reception

The SCI can detect Start Frames configured as shown in Figure 28.104.

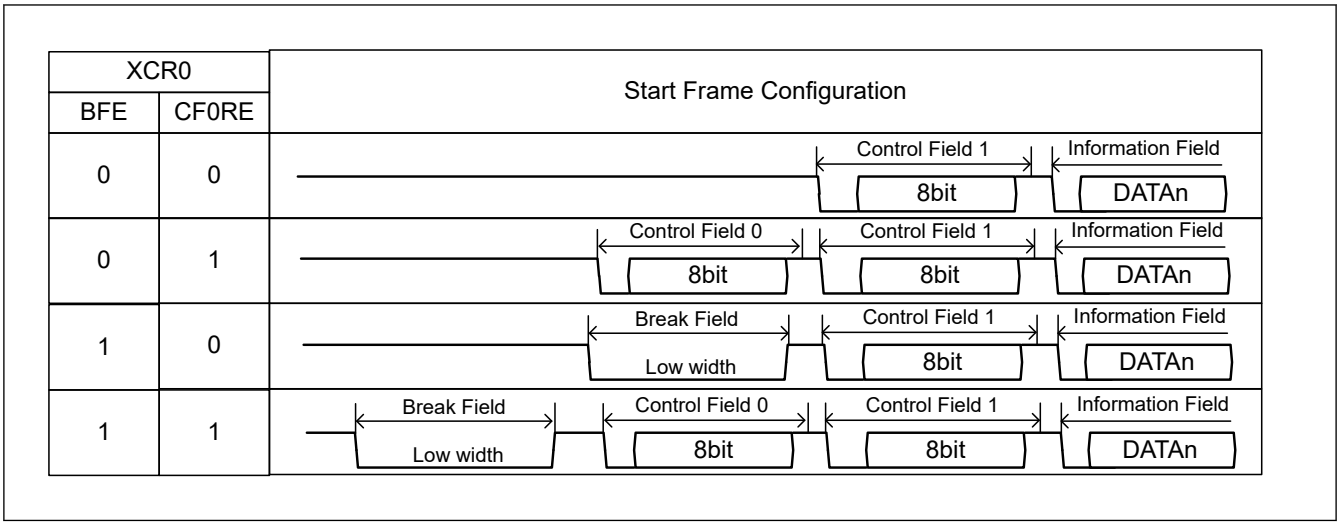

Figure 28.104 Start Frame Configuration

(1) Simple LIN normal reception of Start Frame (PIB not used)

Figure 28.105 shows an example of normal reception of the Start Frame consisting of a Break Field, Control Field0, and Control Field1. Figure 28.106 shows an example of reception to detect the Break Field during Control Field 1. Figure 28.107 shows a flowchart to receive the Start Frame, and Figure 28.108 shows a state transition diagram.

When receiving the Start Frame, the SCI operates as follows. Omit the processing of Break Field and Control Field0 according to the Start Frame configuration.

1. Writing 1 to XCR1.SDST makes it possible to detect the Start Frame. When XCR0.BFE = 1, RXDn input to the SCI core is disabled until the Break Field is detected (because XSR0.RXDSF is set to 1). Once the Break Field is detected, RXDn input can be received to the SCI core (XSR0.RXDSF = 0).
2. When a low level is input from the RXDn pin, the Break Field detection count starts. A timer count clock source can be selected by XCR0.TCSS[1:0].
3. When a low level that is equal to or longer than the period set in XCR2.BFLW[15:0] is input from the RXDn pin, it is determined as Break Field. At this time, XSR0.BFDF is set to 1. If XCR0.BFDIE has been set to 1 at this time, a SCIn_BFD interrupt is generated.
   The timer continues counting until the RXDn rising edge or counter overflow.
4. After the Break Field is detected, when the input level from the RXDn pin becomes high, the count value is captured to XSR1.TCNT[15:0] when BMEN = 0. At this time, XSR0.RXDSF is cleared to 0 and the SCI core starts receiving the RXDn input.
5. The SCI core starts receiving Control Field 0. Because the simple LIN continuously counts the edge interval, it determines a low level that is equal to or longer than the period set in XCR2.BFLW[15:0] as detection of the Break Field. When the Break Field is detected in the Control Field 0 phase, the SCI core waits for reception of Control Field 0 again (Figure 28.106).
6. When Control Field 0 has been received, an SCIn_RXI interrupt is generated and the Control Field 0 data is stored in XSR0.CF0RD[7:0]. When the received data matches the set XCR2.CF0D[7:0] value, XSR0.CF0MF is set to 1. If the received data differs from the set XCR2.CF0D[7:0] value, the SCI transitions to the state before the Break Field is detected.
7. The SCI core starts receiving Control Field 1. When BFE = 1, the Break Field detection function is continuously enabled while SDST = 1 as in the case of Control Field 0. When the Break Field is detected in the Control Field 1 phase, the SCI core waits for reception of Control Field 0 again.
8. When Control Field 1 has been received, an SCIn_RXI interrupt is generated and the Control Field 1 data is stored in XSR0.CF1RD[7:0]. When the received data matches the set XCR1.PCF1D[7:0] value or the set XCR1.SCF1D[7:0] value, XSR0.CF1MF is set to 1. If the received Control Field 1 data matches neither the set XCR1.PCF1D[7:0] value nor the set XCR1.SCF1D[7:0] value, the SCI transitions to the state before the Break Field is detected.
9. The SCI core performs Information Frame communication.
10. When communication is completed, write 0 to XCR1.SDST and 0 to CCR0.RE to stop reception.

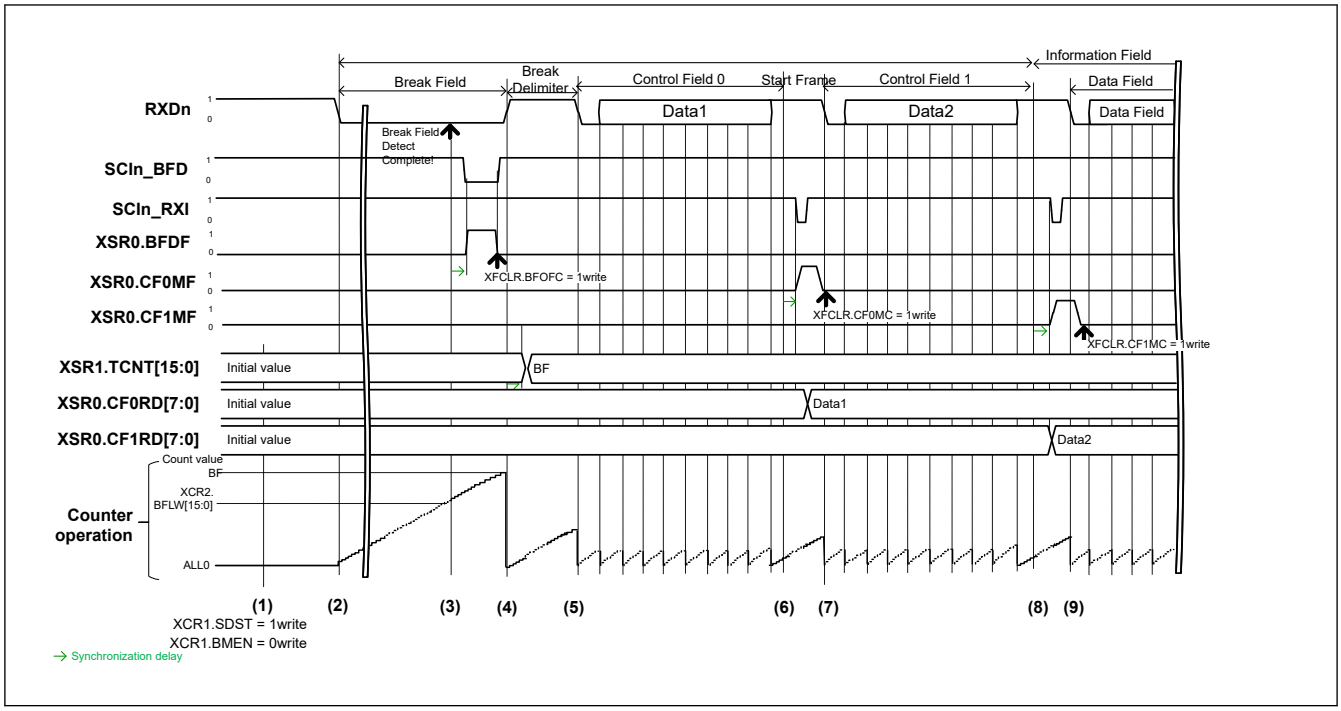

Figure 28.105 Normal Reception Example of Start Frame (PIB Not Used)

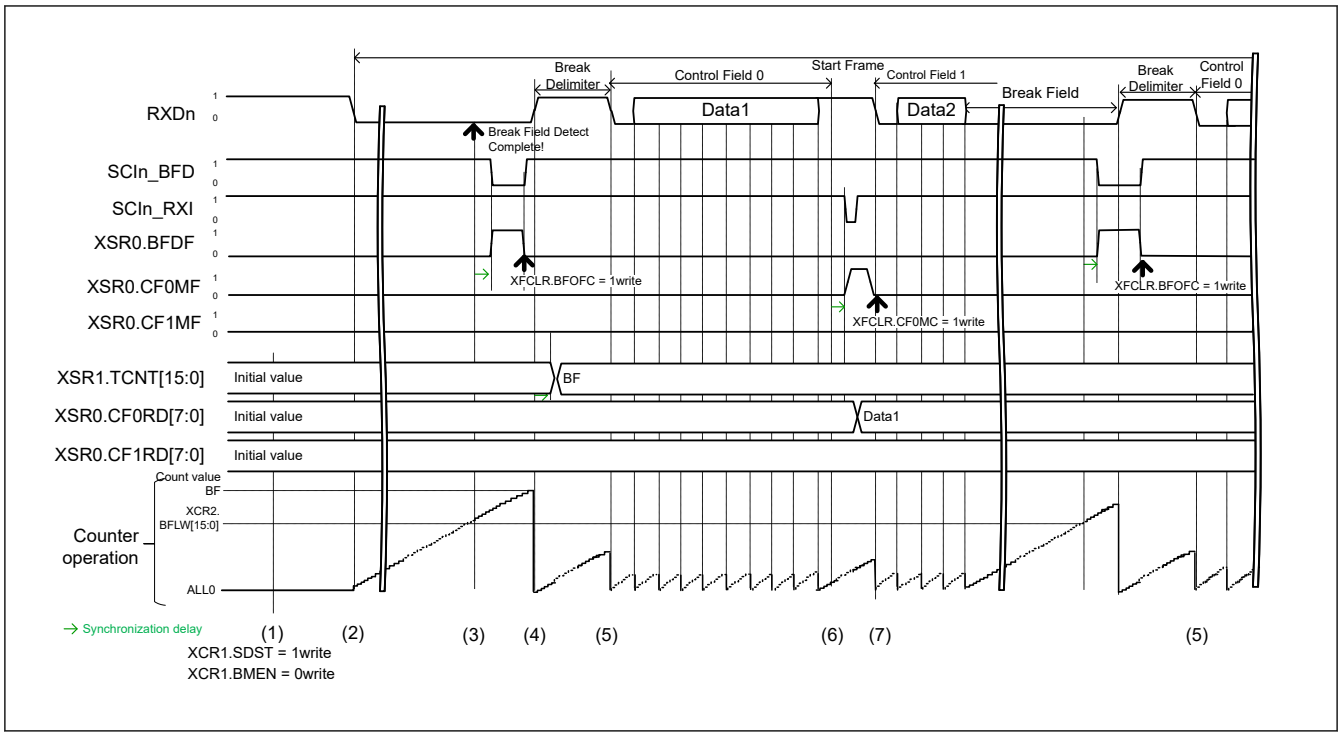

Figure 28.106 Start Frame Reception Example (PIB Not Used) Break Field Detected during Control Field 1

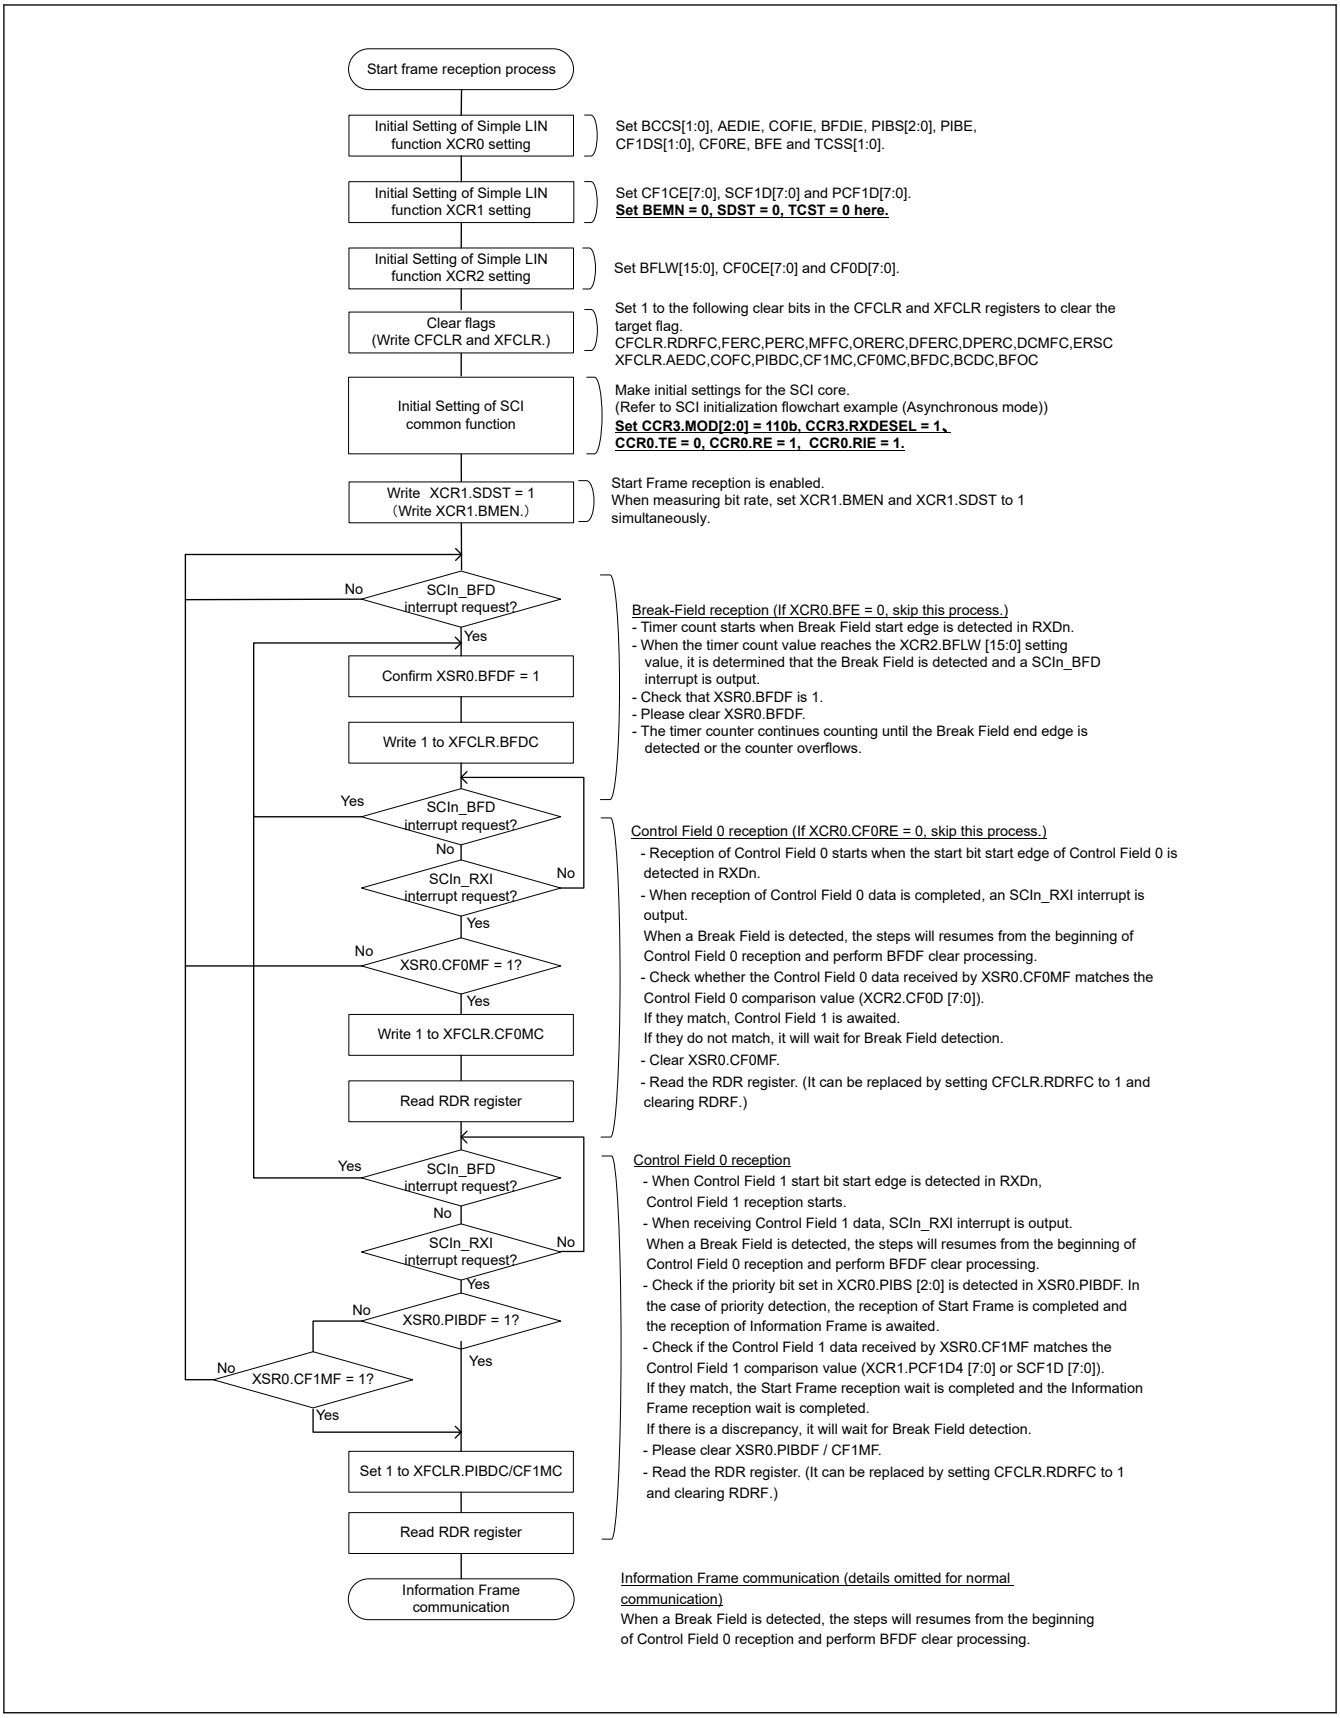

Figure 28.107 Example of Start Frame Reception Flowchart

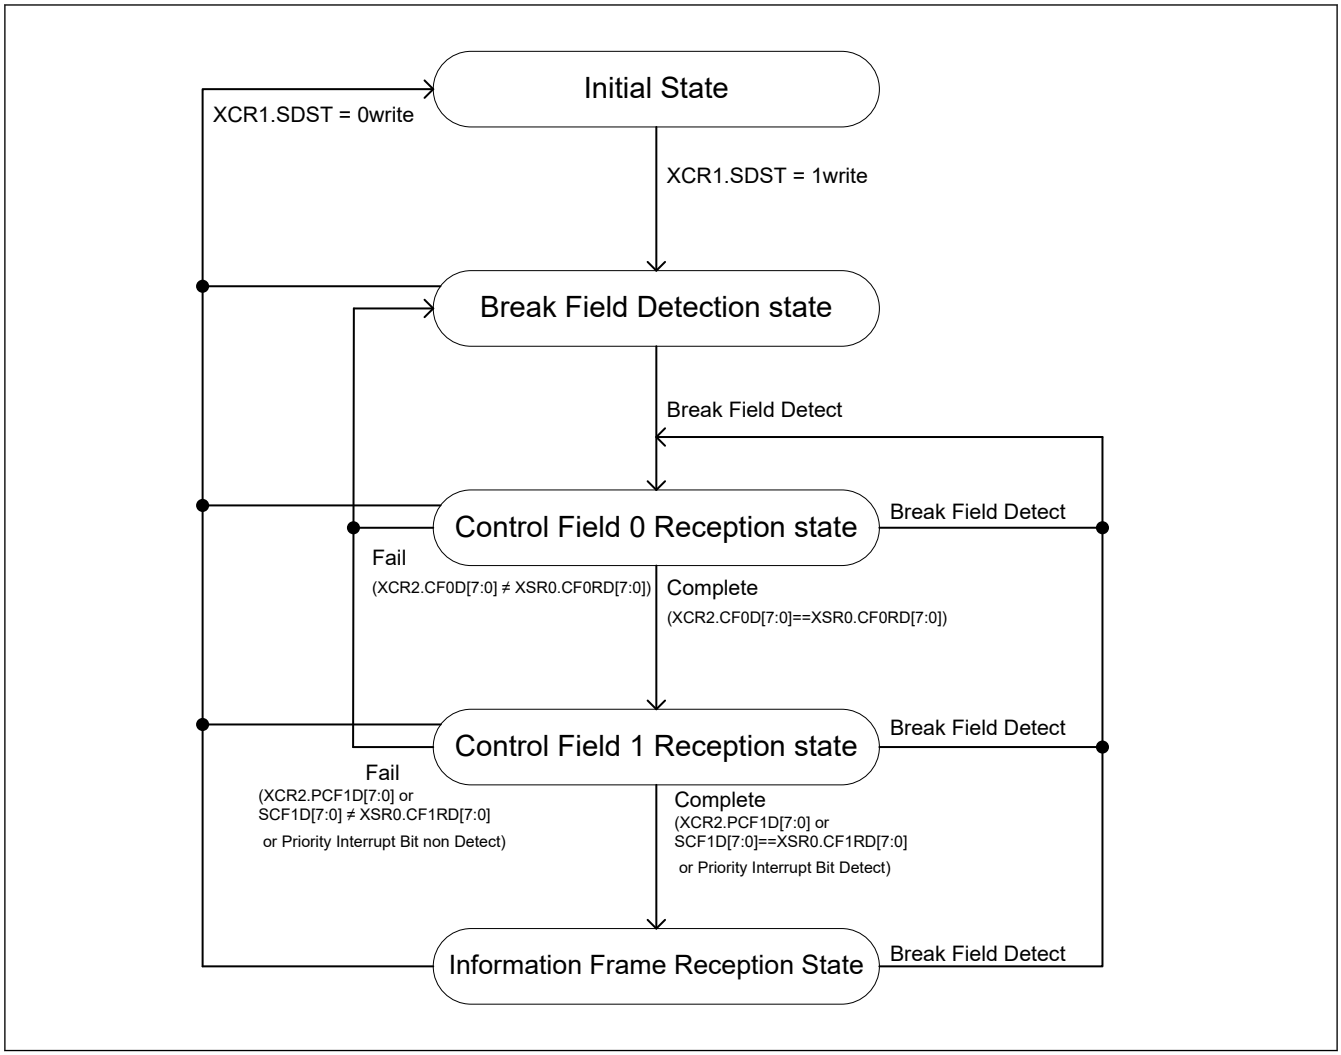

Figure 28.108 State Transition Diagram of Start Frame Reception

(2) Simple LIN Start Frame reception (using the priority interrupt bit)

Figure 28.109 shows an example of Start Frame reception using the priority interrupt bit. The priority interrupt bit is enabled by setting XCR0.PIBE to 1.

The SCI operates as follows during Start Frame reception using the priority interrupt bit.

Steps (1) to (7) are the same as steps (1) to (7) in the Start Frame reception example in Figure 28.105.

(8) When the value specified in the XCR0.PIBS[2:0] bits matches the set XCR1.PCF1D[7:0] value, XSR0.PIBDF is set to 1 and the SCI core performs communication of the Information Frame. If the data received in Control Field 1 matches neither the set XCR1.PCF1D[7:0] value nor the set XCR1.SCF1D[7:0] value and the priority interrupt bit is not detected, the SCI transitions to the state before the Break Field is detected.

(9) Communicate information frame at the SCI core.

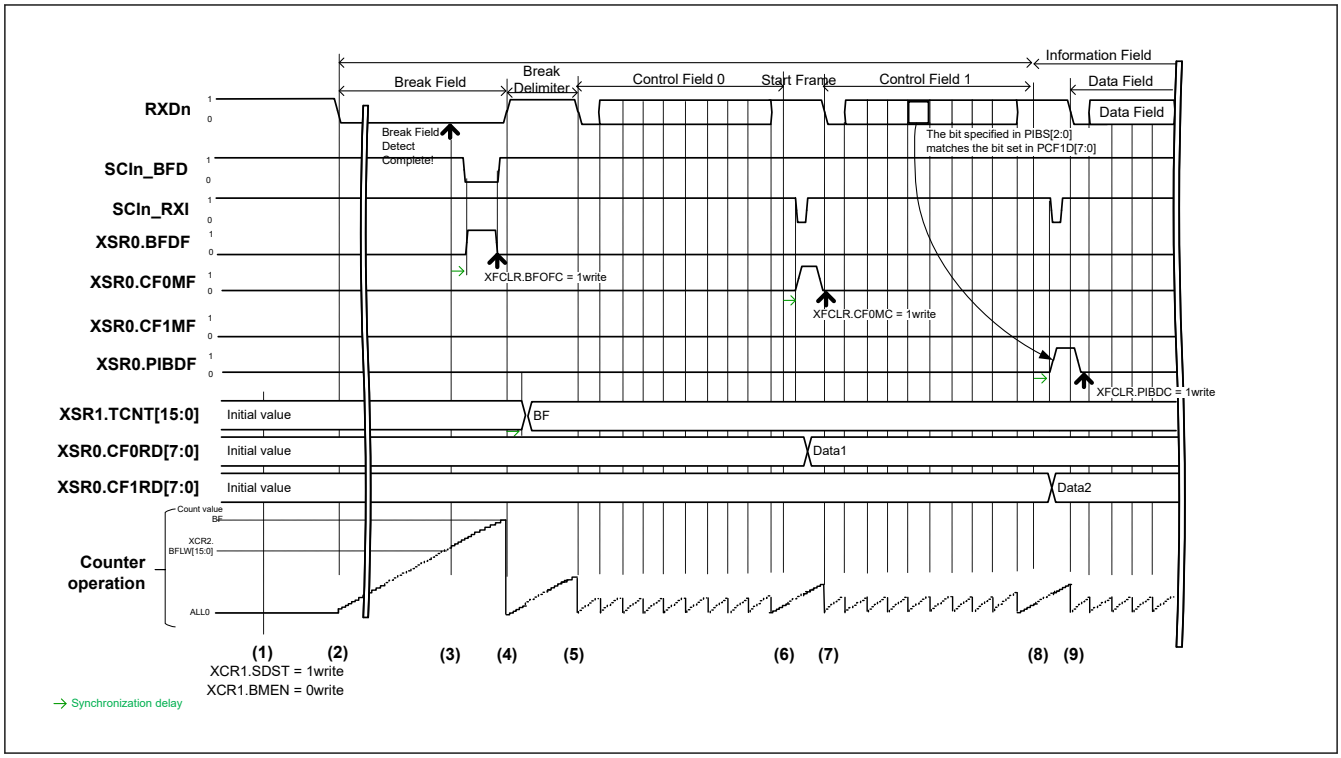

Figure 28.109 Start Frame Reception Example (Priority Interrupt Bit Used)

28.11.3 Simple LIN Bus Conflict Detection Function

In Simple LIN mode (CCR3MOD[2:0] = 110) when TE = 1, the bus conflict detection function works during Break Field output and during data transmission.

Figure 28.110 shows an operation example of the bus conflict detection function. The TXDn pin output and the RXDn pin input are sampled by the bus conflict detection clock set in XCR0.BCCS[1:0]. When a mismatch occurs three times in a row, XSR0.BCDF is set to 1, and if XCR0.BCDIE has been set to 1 at this time, an SCIn_ERI interrupt is generated.

When an SCIn_ERI interrupt is generated, stop transmission according to Figure 28.111. Check the bus state to decide whether to resume transmission.

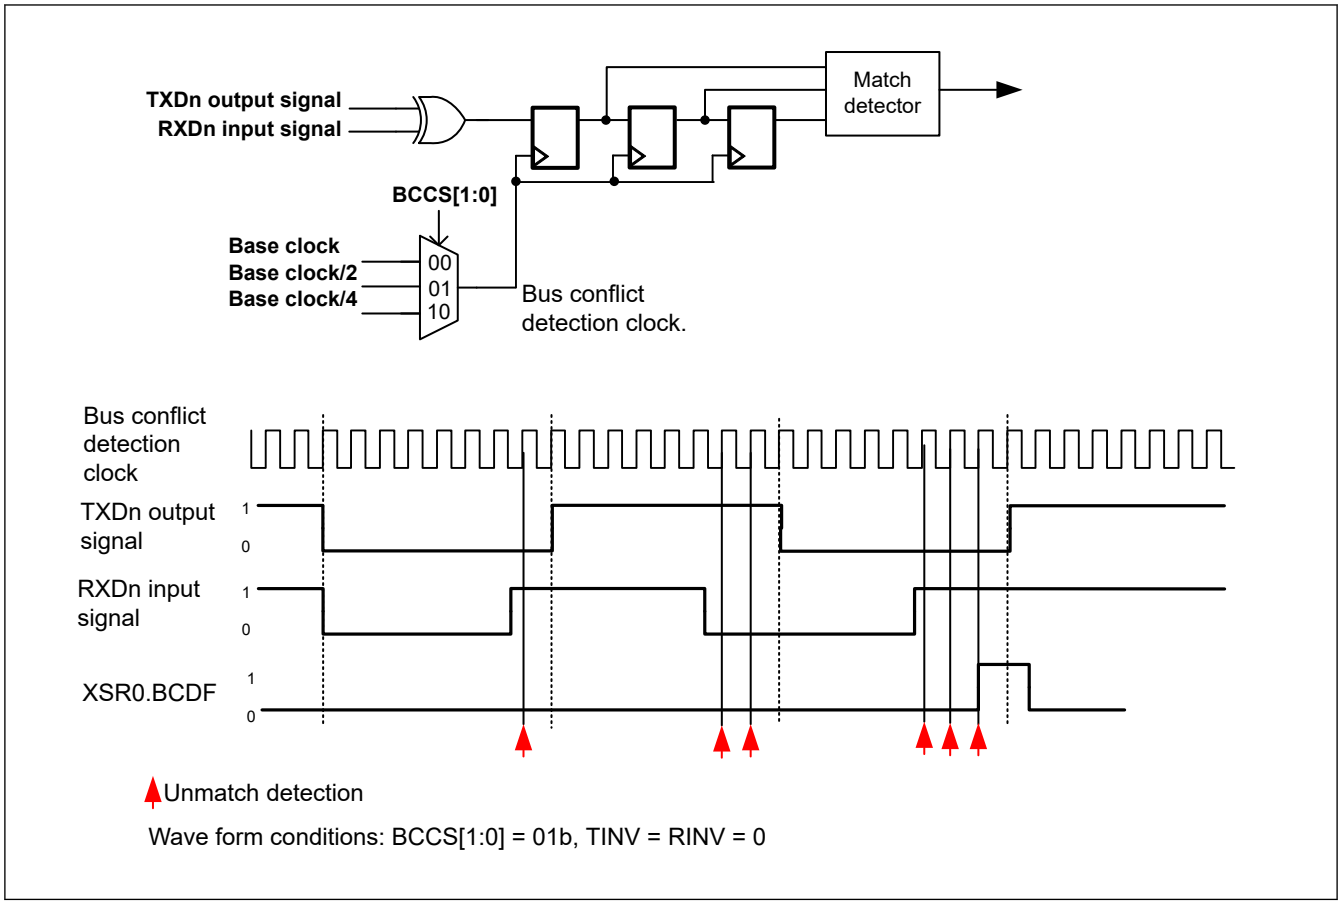

Figure 28.110 Operation Example of the Bus Conflict Detection Function

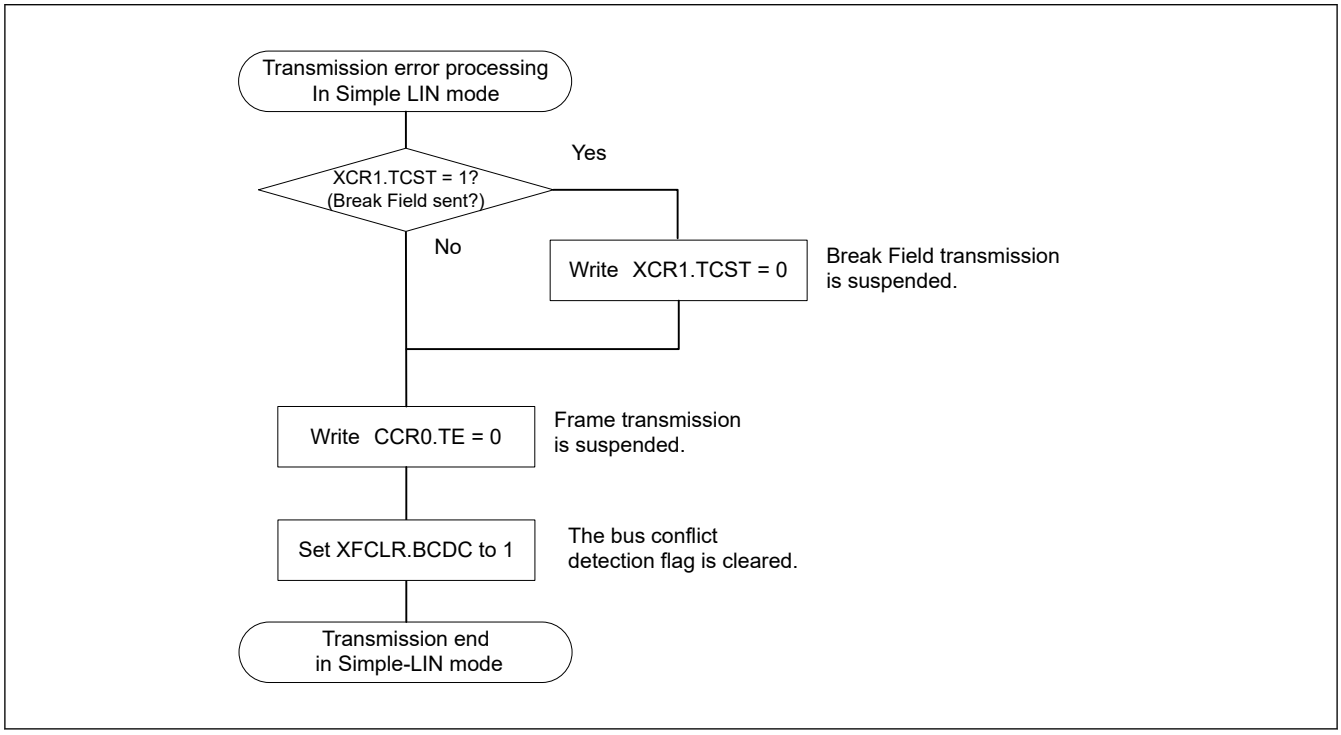

Figure 28.111 SCIn_ERI Interrupt handling flow at transmission in Simple LIN mode

28.11.4 Simple LIN Bit Rate Measurement Function

This function measures a bit rate between the effective edges of the input signal from the RXDn pin. Figure 28.112 shows an operation example of the bit rate measurement function.

1. Writing 1 to XCR1.SDST and XCR1.BMEN enables bit rate measurement. When this bit is set to 1, the valid edge interval of Control Field 0 and Control Field 1 data is measured. However, bit rate is not measured between the Break Field and the Break Delimiter. Set XCR1.BMEN and XCR1.SDST to 1 simultaneously, only when measuring bit rate.
2. Because bit rate is not measured in the Break Field, the effective edge detection flag is not set to 1 at the rising edge at the end of the Break Field, and the counter capture value is not stored in XSR1.TCNT[15:0].
3. The counter starts counting from the falling edge of the start bit in Control Field 0. The Break Delimiter count value is not captured in XSR1.TCNT[15:0].
4. The rising edge of the start bit is detected as an effective edge, and then the XSR0.AEDF flag is set to 1. If XCR0.AEDIE has been set to 1 at this time, an SCIn_AED interrupt is output. The start bit count value is stored in XSR1.TCNT[15:0]. The XSR1.TCNT[15:0] value is retained until the effective capture value is read.
5. Even if an effective edge is input from the RXDn input pin, the count value of this effective edge timing is not captured because the XRS1.TCNT[15:0] value has not been read and retention has not been released. In this case, an SCIn_AED interrupt is not output.
6. The XSR1.TCNT[15:0] value is read. Then the retention of XSR1.TCNT[15:0] is released and the XSR0.AEDF flag is cleared by hardware.
7. Because the retention of XSR1.TCNT[15:0] has been released, the count value is captured at the effective edge and is retained. At the same time, the XSR0.AEDF flag is set to 1, and if XCR0.AEDIE has been set to 1, an SCIn_AED interrupt is output. The bit rate can be adjusted by calculating it from the count value between effective edges by software and by changing the SCI settings.
8. To disable bit rate measurement, write 0 to XCR1.BMEN.
9. The XSR0.AEDF value and the XSR1.TCNT[15:0] value remain unchanged at the effective edge timing because the bit rate measurement function is disabled.

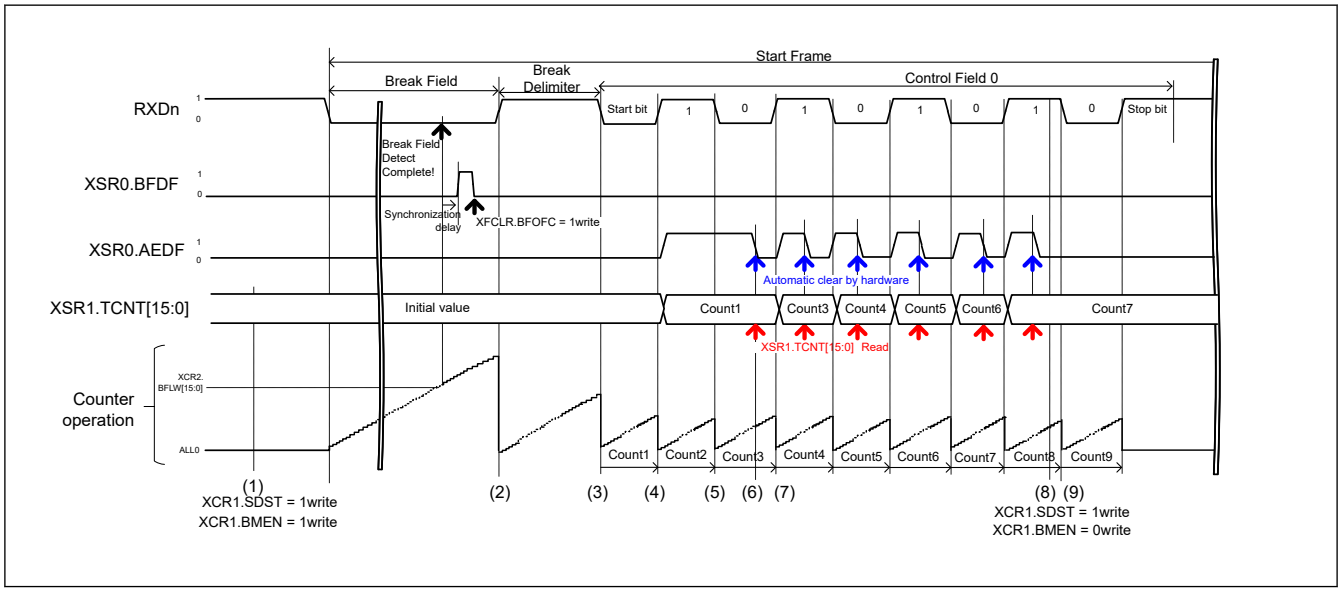

Figure 28.112 Operation Example of the Bit Rate Measurement Function

28.12 Interrupt Sources

28.12.1 Buffer Operation for SCIn_TXI and SCIn_RXI Interrupts

If the conditions for an SCIn_TXI and SCIn_RXI interrupt are satisfied while the interrupt status flag in the ICU is 1, the ICU does not output the interrupt request but saves it internally with a capacity for retention of one request per source.

28.12.2 Interrupts in Asynchronous, Manchester, Clock Synchronous, and Simple SPI Modes

(1) Non-FIFO selected

Table 28.43 lists interrupt sources in Asynchronous mode, Manchester mode, clock synchronous mode, and simple SPI mode.

A different interrupt vector can be assigned to each interrupt source. Individual interrupt sources can be enabled or disabled with the enable bits in the CCR0 register.

If the CCR0.TIE bit is 1, an SCIn_TXI interrupt request is generated when transmit data is transferred from the TDR register to the TSR register. An SCIn_TXI interrupt request can also be generated by using a single instruction to set the CCR0.TE and CCR0.TIE bits to 1 at the same time. An SCIn_TXI interrupt request can activate the DTC or DMAC to handle data transfer.

An SCIn_TXI interrupt request is not generated by setting the CCR0.TE bit to 1 when CCR0.TIE is 0 or by setting the CCR0.TIE bit to 1 when the CCR0.TE is 1.*1

When new data is not written by the time of transmission of the last bit of the current transmit data and CCR0.TEIE is 1, the CSR.TEND flag is set to 1 and an SCIn_TEI interrupt request is generated. Additionally, when CCR0.TE is 1, the CSR.TEND flag retains the value 1 until more transmit data is written to the TDR register, and setting CCR0.TEIE to 1 leads to the generation of an SCIn_TEI interrupt request.

Writing data to the TDR register leads to clearing of the CSR.TEND flag and, after a certain time, discarding of the SCIn_TEI interrupt request.

If the CCR0.RIE bit is 1, an SCIn_RXI interrupt request is generated when received data is stored in the RDR register. An SCIn_RXI interrupt request can activate the DTC or DMAC to handle data transfer.

Setting any of the CSR.ORER, FER, PER or MSR.MER*2, SYER*2, PFER*2, and SBER*2 flags to 1 when the CCR0.RIE bit is 1 leads to the generation of an SCIn_ERI interrupt request.

An SCIn_RXI interrupt request is not generated in this case. Clearing all these flags (ORER, FER, PER, MER*2, SYER*2, PFER*2 and SBER*2) leads to discarding of the SCIn_ERI interrupt request.

Note 1. To temporarily prohibit SCIn_TXI interrupts on transmission of the last of the data when a new round of transmission is to be started, after handling the transmission-completed interrupt, control activation of the interrupt by using the interrupt request enable bit in the ICU rather than using the CCR0.TIE bit. This approach can prevent the suppression of SCIn_TXI interrupt requests in the transfer of new data.

Note 2. MER, SYER, PFER, and SBER work as a factor of SCIn_ERI interrupt only in Manchester mode. SYER, PFER, and SBER also only work if its enable bits (SYEREN, PFEREN, SBEREN in MECR) are set to "1".

(2) FIFO selected

Table 28.44 lists interrupt sources in FIFO selected mode.

If the CCR0.TIE bit is 1, an SCIn_TXI interrupt request is generated when the stored amount of data in the transmit-FIFO (TDR) register becomes the threshold value indicated in FCR.TTRG or below. An SCIn_TXI interrupt request can also be generated by using a single instruction to set the CCR0.TIE and CCR0.TE bits to 1 simultaneously or by setting CCR0.TIE to 1 when CCR0.TE is 1.

An SCIn_TXI interrupt request is not generated by setting CCR0.TE to 1 when CCR0.TIE is 0 or by setting the CCR0.TIE bit to 1 while the setting of the CCR0.TE bit is 1.

If CCR0.TEIE is 1 and if the next data is not written to the transmit-FIFO (TDR) register by the time the last bit of the transmit data is sent, the CSR.TEND flag is set to 1 and the SCIn_TEI interrupt request is generated.

If CCR0.RIE is 1, the SCIn_RXI interrupt request is generated when the stored amount of data in the transmit-FIFO (TDR) register is equal to or greater than the threshold value indicated in FCR.RTRG. When RTRG is 0, an SCIn_RXI interrupt does not occur even when the amount of data in the receive FIFO is equal to 0.

If the CCR0.RIE bit is 1, when the CSR.ORER flag is set to 1 or data with a framing error or a parity error is stored in the transmit-FIFO (TDR) register, the SCIn_ERI interrupt request is generated. When the amount of data stored in the transmit-FIFO (TDR) register is at the threshold value or above, the SCIn_RXI interrupt request is also generated. The SCIn_ERI interrupt request can be canceled, in which case CSR.ORER, FER, and PER flags are all cleared.

Table 28.43 SCI interrupt sources with non-FIFO selected

Name	Interrupt source	Interrupt flag	Interrupt enable	DTC or DMAC activation
SCIn_ERI (n = 0 to 4, 9)	Receive error	CSR.ORER, CSR.FER, CSR.PER, CSR.DFER, CSR.DPER, (MSR.MER, MSR.SYER, MSR.PFER, MSR.SBER)*1	CCR0.RIE	Not possible
SCIn_RXI (n = 0 to 4, 9)	Receive data full	CSR.RDRF	CCR0.RIE	Possible
	Address match	CSR.DCMF	CCR0.RIE	Possible
SCIn_TXI (n = 0 to 4, 9)	Transmit data empty	CSR.TDRE	CCR0.TIE	Possible
	TE = 0->1 detection			
SCIn_TEI (n = 0 to 4, 9)	Transmit end	CSR.TEND	CCR0.TEIE	Not possible

Note: Only SCI0 supports Manchester mode.
Note 1. MER, SYER, PFER, and SBER work as a factor of SCIn_ERI interrupt only in Manchester mode. SYER, PFER, and SBER also only work if its enable bits (SYEREN, PFEREN, SBEREN in MCR) are set to 1.

Table 28.44 SCI interrupt sources with FIFO selected

Name	Interrupt source	Interrupt flag	Interrupt enable	DTC or DMAC activation
SCIn_ERI (n = 0 to 4, 9)	Receive error	CSR.ORER, CSR.FER, CSR.PER, CSR.DFER, CSR.DPER	CCR0.RIE	Not possible
		FRSR.DR (when FCR.DRES = 1)	CCR0.RIE	Not possible
SCIn_RXI (n = 0 to 4, 9)	Receive data full	CSR.RDRF	CCR0.RIE	Possible
	Receive data ready	FRSR.DR (when FCR.DRES = 0)	CCR0.RIE	Possible
	Address match	CSR.DCMF	CCR0.RIE	Possible
SCIn_TXI (n = 0 to 4, 9)	Transmit data empty	CSR.TDRE	CCR0.TIE	Possible
	TE=0->1 detection			
SCIn_TEI (n = 0 to 4, 9)	Transmit end	CSR.TEND	CCR0.TEIE	Not possible

Note: Only SCI0 supports Manchester mode.

28.12.3 Interrupts in Smart Card Interface Mode

Table 28.45 lists interrupt sources in smart card interface mode. A transmit end interrupt (SCIn_TEI) request and an address match (SCIn_AM) request cannot be used in this mode.

Table 28.45 SCI Interrupt sources in Smart Card Interface Mode

Name	Interrupt source	Interrupt flag	Interrupt enable	DTC or DMAC activation
SCIn_ERI (n = 0 to 4, 9)	Receive error or error signal detection	CSR.ORER, CSR.PER, CSR.ERS	CCR0.RIE	Not possible
SCIn_RXI (n = 0 to 4, 9)	Receive data full	CSR.RDRF	CCR0.RIE	Possible
SCIn_TXI (n = 0 to 4, 9)	Transmit data empty	CSR.TEND	CCR0.TIE	Possible
	When set TE = 0->1			

Data transmission or reception using the DTC or DMAC is also possible in smart card interface mode, similar to normal SCI mode. In transmission, when the CCR0.TEND flag is set to 1, an SCIn_TXI interrupt request is generated. This SCIn_TXI interrupt request activates the DTC or DMAC, allowing transfer of transmit data if the SCIn_TXI request is previously specified as a source of DTC or DMAC activation. The TEND flag is automatically set to 0 when the DTC or DMAC transfers the data.

If an error occurs, the SCI automatically retransmits the same data. During the retransmission, the TEND flag is kept at 0 and the DTC or DMAC is not activated. Therefore, the SCI and DTC or DMAC automatically transmit the specified

number of bytes, including retransmission after an error occurrence. However, the CSR.ERS flag is not automatically set to 0 at error occurrence. Therefore, the ERS flag must be cleared by previously setting the CCR0.RIE bit to 1 to enable an SCIn_ERI interrupt request to be generated at error occurrence.

When transmitting or receiving data using the DTC or DMAC, always enable the DTC or DMAC before making the SCI settings. For DTC or DMAC settings, see section 16, Data Transfer Controller (DTC), section 15, DMA Controller (DMAC).

In reception, an SCIn_RXI interrupt request is generated when receive data is set to the RDR register. This SCIn_RXI interrupt request activates the DTC or DMAC, allowing transfer of the receive data if the SCIn_RXI request is previously specified as a source of DTC or DMAC activation. If an error occurs, the error flag is set. Therefore, the DTC or DMAC is not activated and an SCIn_ERI interrupt request is issued to the CPU instead. The error flag must be cleared.

28.12.4 Interrupts in Simple IIC Mode

Table 28.46 lists the interrupt sources in simple IIC mode. The STI interrupt is allocated to the transmit end interrupt (SCIn_TEI) request. The receive error interrupt (SCIn_ERI) and the address match (SCIn_AM) request cannot be used.

The DTC or DMAC can also be used to handle transfer in simple IIC mode.

When the ICR.IICINTM bit is 1:

- An SCIn_RXI request is generated on the falling edge of the SCLn signal for the 8th bit. If SCIn_RXI is previously set up as an activation source for the DTC or DMAC, the SCIn_RXI request activates the DTC or DMAC to handle transfer of the received data.
- An SCIn_TXI request is generated on the falling edge of the SCLn signal for the 9th bit (acknowledge bit). If SCIn_TXI is previously set up as an activation source for the DTC or DMAC, the SCIn_TXI request activates the DTC or DMAC to handle transfer of the transmit data.

When the ICR.IICINTM bit is 0:

- An SCIn_RXI request (ACK detection) is generated if the input on the SDAn pin is low on the rising edge of the SCLn signal for the 9th bit (acknowledge bit)
- An SCIn_TXI request (NACK detection) is generated if the input on the SDAn pin is high on the rising edge of the SCLn signal for the 9th bit (acknowledge bit)
- If SCIn_RXI is previously set up as an activation source for the DTC or DMAC, the SCIn_RXI request activates the DTC or DMAC to handle transfer of the received data.

If the DTC or DMAC is used for data transfer in reception or transmission, always set up and enable the DTC or DMAC before setting up the SCI.

When the IICSTAREQ, IICRSTAREQ, and IICSTPREQ bits in ICR are used to generate a start condition, restart condition, or stop condition, the STI request is issued when generation is complete.

Table 28.46 SCI interrupt sources in Simple IIC Mode

Name	Interrupt source		Interrupt flag	Interrupt enable	DTC or DMAC activation
	ICR.IICINTM = 1	ICR.IICINTM = 0			
SCIn_RXI (n = 0 to 4, 9)	Reception end	—	—	CCR0.RIE	Possible*1
	—	ACK detection	—		Possible
SCIn_TXI (n = 0 to 4, 9)	Transmission end		—	CCR0.TIE	Possible*1
	—	NACK detection	—		Possible
SCIn_TEI(STIn) (n = 0 to 4, 9)	Completion of generation of a start, restart, or stop condition		ICR.IICSTIF	CCR0.TEIE	Not possible

Note 1. If the DMAC or DTC are being used, you cannot confirm whether ACK or NACK.

28.12.5 Interrupts in Simple LIN mode

Table 28.47 lists interrupt sources in Simple LIN mode.

Table 28.47 SCI interrupt sources in Simple LIN mode

Name	Interrupt Sources	Interrupt Flag	Flag the needs to be confirmed	Interrupt Enable	DTC/DMAC Activation
SCIn_ERI (n = 0, 1)	Receive error	CSR.ORER, CSR.FER, CSR.PER	—	CCR0.RIE	Not Possible
		XSR0.BCDF		XCR0.BCDIE	
		XSR0.COF		CCR0.RIE, XCR0.COFIE	
SCIn_RXI(n = 0, 1)	Receive data full flag	CSR.RDRF	XSR0.CF0MF XSR0.CF1MF XSR0.PIBDF	CCR0.RIE	XSR0.SFSF = 0: Possible XSR0.SFSF = 1: Not Possible
SCIn_AED (n = 0, 1)	Active edge detection	XSR0.AEDF	—	XCR0.AEDIE	Possible
SCIn_TXI(n = 0, 1)	Transmit data empty interrupt	CSR.TDRE	—	CCR0.TIE	Possible
	When set TE = 0->1				
	Break Field output completion	XSR0.BFOF		CCR0.TIE, XCR0.BFOIE	
SCIn_TEI(n = 0, 1)	Transmit end	CSR.TEND	—	CCR0.TEIE	Not Possible
SCIn_BFD(n = 0, 1)	Break Field Detection	XSR0.BFDF	—	XCR0.BFDIE	Not Possible (Unnecessary)

In Simple LIN mode, in addition to reception errors (ORER, FER, PER), an SCIn_ERI interrupt request is output when a bus conflict is detected during transmission, or when a counter overflow of the Simple LIN module occurs. At this time, a SCIn_RXI interrupt request is not output. The SCIn_ERI interrupt request can be canceled by clearing all the flags.

When transmitting Start Frame, if CCR0.TIE = 1 and XCR0.BFOIE = 1, a SCIn_TXI interrupt request is output when Break Field transmission is completed. When Control Field 0 data is written to the TDR register, data transmission starts. Therefore, transmission using DTC or DMAC is possible.

Set CCR0.TEIE = 1 after writing the last transmit data to the TDR register and transmission starts.

During Start Frame reception (XSR0.SFSF = 1), reception using DTC or DMAC by SCIn_RXI interrupt is not possible. Check the CSR register and XSR0 register, check the reception status (See Figure 28.83), and then clear the flag. Also read the RDR register (if you do not need to check the received data value, clear the RDRF flag without reading the RDR register). When reception of Control Field 1 is completed (XSR0.CF1MF = 1), Start Frame detection is disabled (XSR0.SFSF = 0) and reception using DTC or DMAC is possible. Be sure to read the RDR register.

When Start Frame / Break Field detection is enabled (XCR1.SDST = 1), if a Break Field longer than the period set in XCR2.BFLW [15:0] is received, the BFDF flag is set and a SCIn_BFD interrupt request is output. Then SCI becomes the Start Frame reception state. Clear the BFDF flag.

When Start Frame / Break Field detection is enabled (XCR1.SDST = 1) and the bit rate measurement function is enabled (XCR1.BMEN = 1), an SCIn_AED interrupt factor is output when an active edge is detected. Read the timer count capture value (XSR1.TCNT [15:0]).

28.13 Event Linking

By using interrupt request signals as event signals, the SCIn can provide linked operation through the ELC for modules selected in advance.

Event signals can be output regardless of the values of the associated interrupt request enable bits.

(1) Error event output (receive error or error signal detected) (SCIn_ERI, n = 0 to 4, 9)

- Indicates abnormal termination because of a parity error during reception in Asynchronous mode
- Indicates abnormal termination because of a framing error during reception in Asynchronous mode
- Indicates abnormal termination because of an overrun error during reception
- Indicates abnormal termination due to a Manchester error during reception (Only in Manchester mode).

- Indicates that a preface error occurred upon reception and abnormal termination occurred (only in Manchester mode and MCR.PFEREN = 1).
- Indicates that a start bit error occurred during reception and abnormal termination occurred (only in Manchester mode and MCR. SBEREN = 1).
- Indicates that a reception sync error occurred during reception and abnormal termination occurred (only in Manchester mode and only when MCR.SYEREN = 1).
- Indicates detection of the error signal during transmission in smart card interface mode
- The CSR.FER and PER flags are 0, and receive data less than the receive FIFO data trigger number is set in a reception FIFO buffer, and it indicates that 15 etus elapse when FIFO is selected and the FCR.DRES bit is 1
- In Simple LIN mode, indicates that the 16-bit counter in the Simple LIN module has overflowed.
- In Simple LIN mode, a bus collision is detected during transmission (CCR0.TE = 1).

(2) Receive data full event output (SCIn_RXI, n = 0 to 4, 9)

- Indicates that ACK is detected if the ICR.IICINTM bit is 0 in simple IIC mode
- Indicates that the 8th-bit SCLn falling edge is detected if the ICR.IICINTM bit is 1 in simple IIC mode
- When the ICR.IICINTM bit is 1 during master transmission in simple IIC mode, set the ELC so that receive data full events are not used

Non-FIFO selected

- Indicates that received data is set in the Receive Data Register (RDR).

FIFO selected

- Using this event output is prohibited.

(3) Transmit data empty event output (SCIn_TXI, n = 0 to 4, 9)

- Indicates that the CCR0.TE bit is changed from 0 to 1
- Indicates that transmission is complete in smart card interface mode
- Indicates that NACK is detected if the ICR.IICINTM bit is 0 in simple IIC mode
- Indicates that the 9th-bit SCLn falling edge is detected if the ICR.IICINTM bit is 1 in simple IIC mode
- In Simple LIN mode, indicates that Break Field output is complete.

Non-FIFO selected

- Indicates that transmit data is transferred from the Transmit Data Register (TDR) to the Transmit Shift Register (TSR).

FIFO selected

- Using this event output is prohibited.

(4) Transmit end event output (SCIn_TEI, n = 0 to 4, 9)

- Indicates the completion of transmission
- Indicates that the starting condition, resumption condition, or termination condition is generated in simple IIC mode
- In Smart Card mode, the transmit end event is not output.

Note: When FIFO is selected, using this event output is prohibited

(5) Address match event output (SCIn_AM, n = 0 to 4, 9)

- Indicates a match of the comparison data (CCR4.CMPD) with one frame of receive data when CCR0.DCME is set to 1 in Asynchronous mode, including multi-processor mode.

(6) Active edge detection event output (SCIn_AED, n= 0, 1)

- In Simple LIN mode, when CCR1.BMEN is 1, it indicates that a valid edge has been detected in the RXD input signal.

28.14 Noise Cancellation Function

Figure 28.113 shows the configuration of the noise filter used for noise cancellation. The noise filter consists of a 2-stage flip-flop circuit and a match detection circuit. When the input signals of the noise filter and the output signals of the 2-stage flip-flop circuits completely match, the matched level is conveyed as an internal signal. Unless otherwise matched, the previous value is retained. When the same level is retained for 3 cycles or longer on the sampling clock of the noise filter, it is considered as a valid receive signal. A change in pulse for 3 cycles or shorter is considered as noise, not as a receive signal. (When CCR1.NFM = 0)

When CCR2.ABCSE2 = 1 in asynchronous mode, the above noise cancellation cannot be used because one bit has only 4 base clocks. Therefore, only in this case, set the noise cancellation mode to transmit the majority value internally by a majority vote of 3 sampling values instead of matching 3 consecutive sampling values. (CCR1.NFM = 1)

In Asynchronous mode, Manchester and Simple LIN modes, the noise cancellation function can be applied to the receive signal input to the RXDn pin. The sampling period of the noise filter can be selected from the base clock period and the divided clock of the baud rate generator clock source by CCR1.NFCS[2:0].

- When CCR1.NFCS[2:0] = 000b, CCR2.ABCS = 0 and CCR2.ABCSE = 0, the cycle is 1/16 of a 1-bit period.
- When CCR1.NFCS[2:0] = 000b, CCR2.ABCS = 1 and CCR2.ABCSE = 0, the cycle is 1/8 of a 1-bit period.
- When CCR1.NFCS[2:0] = 000b, CCR2.ABCSE = 1, the cycle is 1/6 of a 1-bit period.
- When CCR1.NFCS[2:0] = 000b, CCR2.ABCSE2 = 1, the cycle is 1/4 of a period 1 transfer bit.
- For the CCR1.NFCS value, select “000b” or “001b” if ABCSE = 1 or ABCSE2 = 1. At least, the sampling period of Noise Filter should not be greater than the base clock due to the CCR2.BRR setting value.

In simple IIC mode, this function can be used for each input on SDAn and SCLn. The sampling clock is selected from divided clock of baud rate generator settings by CCR1.NFCS[2:0].

If the base clock is stopped once with the noise filter enabled and then the base clock input is restarted again, the noise filter operation resumes from the state where the clock was stopped. When CCR0.TE and CCR0.RE are set to 0 during base clock input, all of the noise filter flip-flop values are initialized to 1. Accordingly, if the input data is 1 when reception operation resumes, the function determines that a level match is detected and the result is conveyed as an internal signal. If the input data is 0, the Noise Filter output holds its initial value until all three sampled pin levels match (CCR1.NFM = 0) or two or more match (CCR1.NFM = 1).

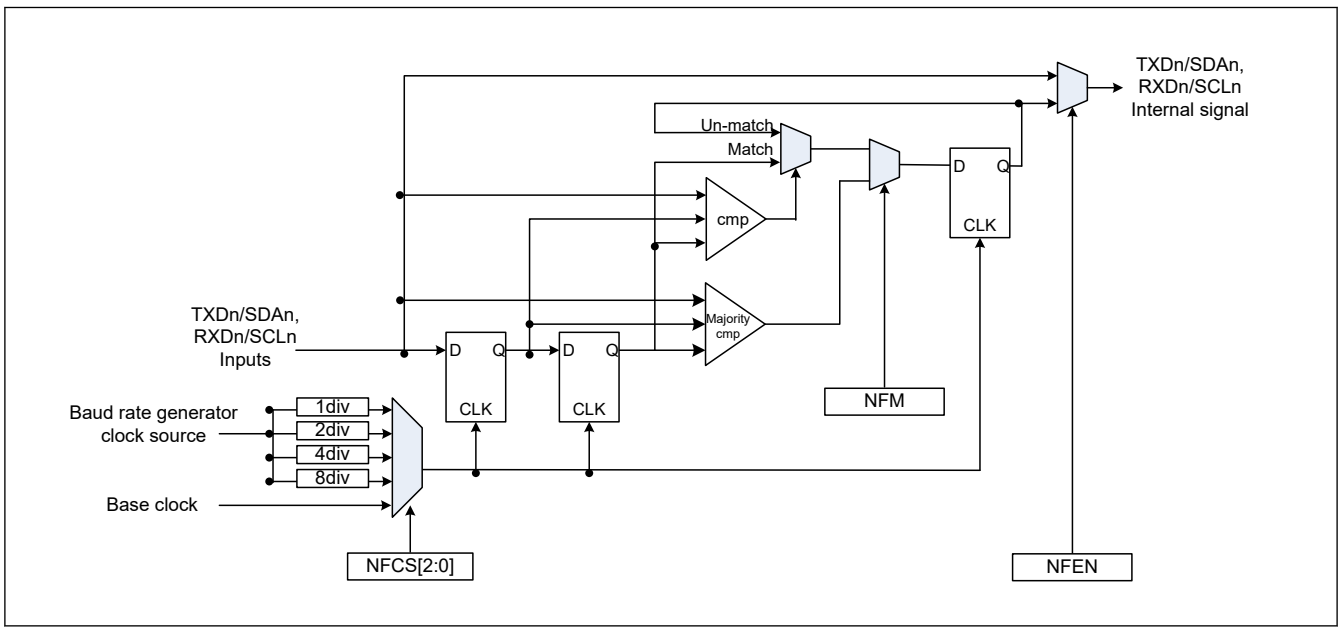

Figure 28.113 Digital noise filter circuit block diagram

28.15 RS-485 Driver Control Function

Setting the DEN bit in the SCI common control register3 (CCR3) to 1 enables the RS-485 driver control function and generates a DEn (Driver Enable) signal that enables the external transceiver transmission mode. The DEn signal outputs a valid level for the period with driver assertion time and driver negate time added before and after data transmission. The DEn signal valid level is set by the DEPOL bit in the driver control register (DCR).

The driver assertion time is the time from when the DEn signal is valid until the start bit starts. Set by DEAST [4:0] of driver control register (DCR).

The driver negate time is the time from the end of the last stop bit of the transmitted message to the invalidation of the DEn signal. Set with DENGT [4:0] of the driver control register (DCR).

DEAST and DENGT are expressed in base clock period (1/4, 1/6, 1/8, or 1/16 bit period, see Table 28.6). For details, see section 28.2.13. DCR : Driver Control Register.

When this function is used (CCR3.DEN = 1), the CSR.TEND set timing and SCIn_TEI interrupt output timing are at the end of the driver negation time.

When transmission is completed and the next transmission data is not written before the DEn signal is negated, the DEn signal is negated once. If the timing for writing the next transmit data is not in time, assert the DEn signal after negating it again, insert the driver assertion time, and transmit the next data. If you want to perform the next transmission with the DEn signal asserted, write the next transmission data to the TDR quickly enough in consideration of the synchronization delay time of the register.

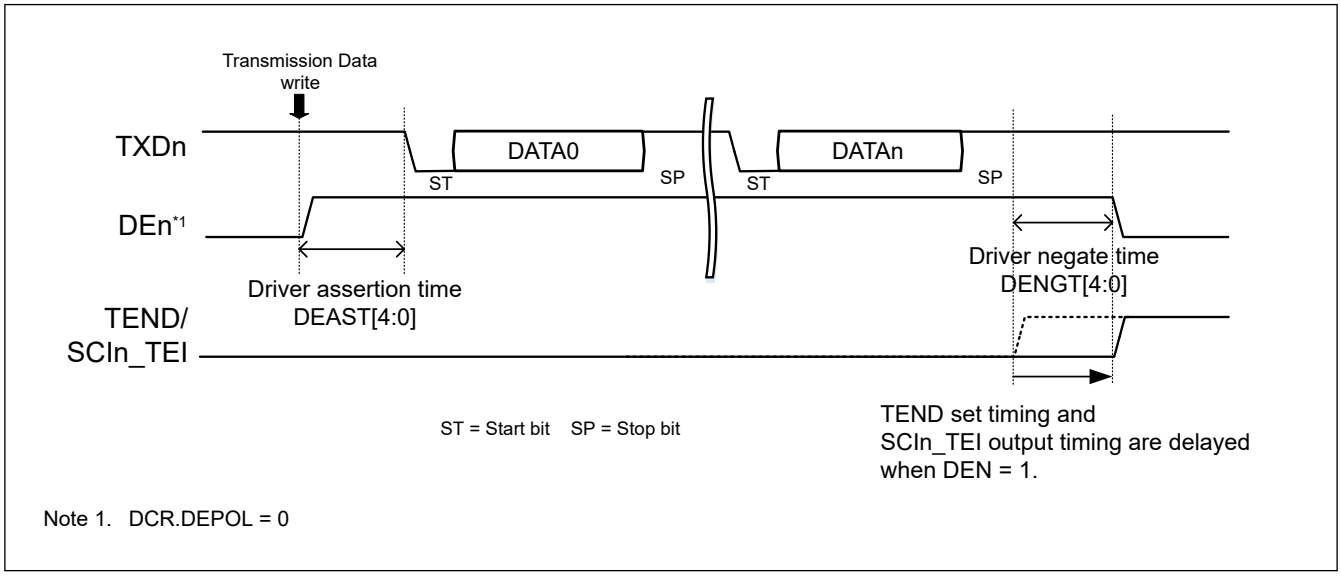

Figure 28.114 The image waveform for RS-485 driver control DE signal output

28.16 Loopback Function

The loopback function can be used in Asynchronous mode with the internal clock, and Manchester mode with the internal clock, and Clock synchronous mode with the internal clock.

When 1 is written to the SPLP bit in the CCR1 register, SCI blocks the external input (RXDn) path and connects the output path of the transmit data register and the input path of the receive data register.

When this function is used with TINV bit = 1, inversion of transmission data becomes reception data. However, this function can be used with TINV = 1 only when operating in clock synchronous mode internal clock.

Table 28.48 shows the relationship between the TINV and SPLP bit settings and the received data.

Table 28.48 TINV and SPLP bit settings and received data

CCR1.TINV	CCR1.SPLP	Receive Data	Communication mode		
			Asynchronous	Manchester	Clock synchronous
			internal clock	internal clock	internal clock
—	0	Receive Data from RXDn pin	Possible	Possible	Possible
0	1	Transmit Data	Possible	Possible	Possible
1	1	Inverted transmit data	Impossible	Impossible	Possible

Note: —: don't care

Figure 28.115 shows the configuration of the shift register input / output path in loopback mode.

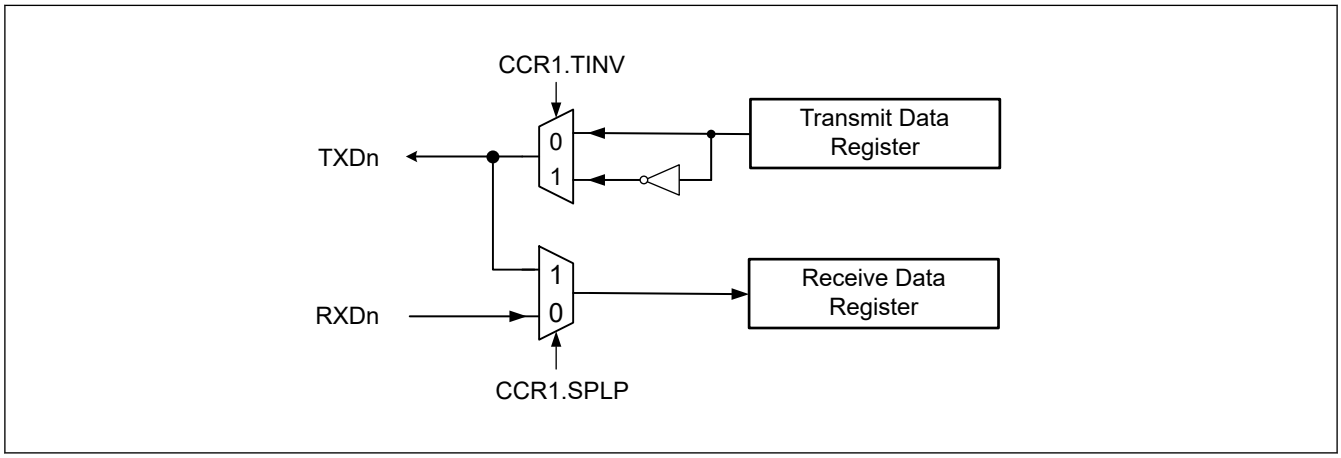

Figure 28.115 Shift register input output configuration image in loopback mode

28.17 Half-Duplex communication Function

Do not use the half-duplex communication function in Simple IIC, Simple SPI and Smart Card Interface modes.

In other communication modes, if the CCR1.SHARPS bit is set to 1, half-duplex communication using the TXDn pin is possible. When half-duplex communication is used, transmission and reception must be performed exclusively. Transmission and reception settings (CCR0.TE = 1 and CCR0.RE = 1) is prohibited.

However, if half-duplex communication is performed as the master reception in clock synchronous mode, perform transmission / reception settings (CCR0.TE = 1 and CCR0.RE = 1) and perform dummy transmission. By dummy transmission (arbitrary transmission data is written to TDR), SCKn is output and reception is enabled. The dummy transmission data is discarded inside the SCI and is not actually transmitted.

During half-duplex communication, only the TXDn pin is used as the communication pin. Output when CCR0.TE = 1, input when CCR0.TE = 0.

28.18 Synchronizer Bypass Function

The SCI has a bus clock (PCLK) and the operation clock (TCLK). And these have each operating circuit. Therefore, there is a synchronization circuit for signal transfer between different clocks, and synchronization delay time is required for signal propagation between different clocks.

However, the synchronization circuit can be bypassed by the CCR3.BPEN bit only when the same clock is input to the bus clock and the operation clock. In this case, eliminates synchronization delay time and improves responsiveness. Figure 28.116 shows the image waveform of the bypass function.

The SCI also has a synchronization circuit between the communication clock (SCKn) and the operation clock (TCLK), but this synchronization circuit cannot be bypassed.

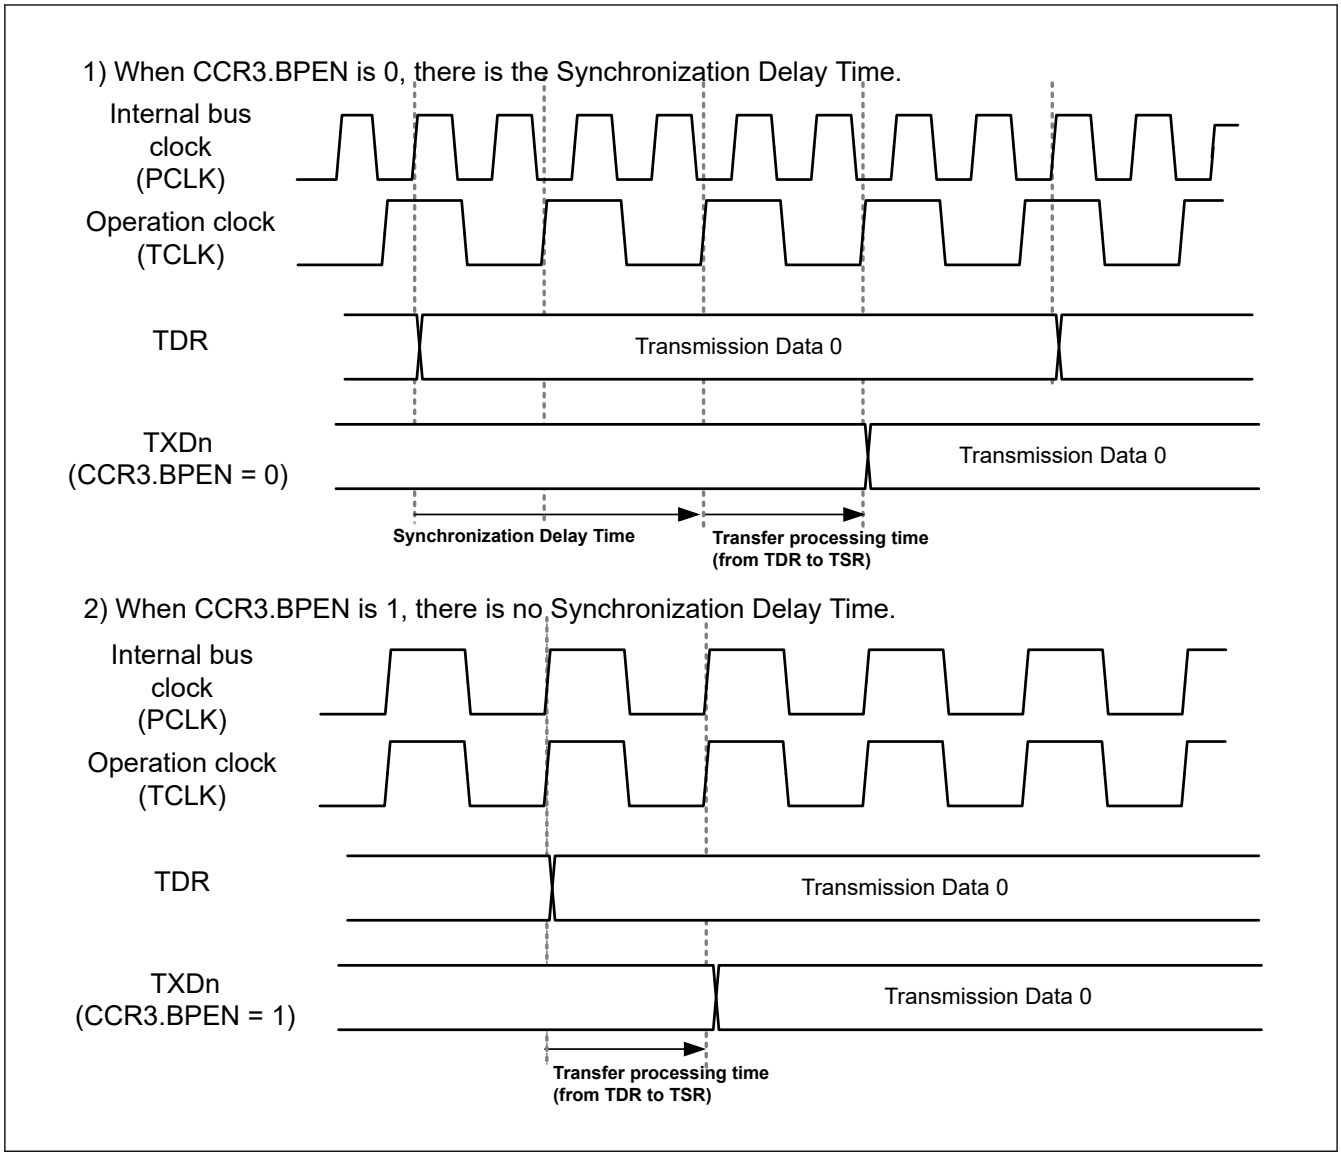

Figure 28.116 Image waveform of Synchronizer bypass function

28.19 Usage Notes

28.19.1 Settings for the Module-Stop Function

The Module Stop Control Register B (MSTPCRB) can enable or disable SCI operation. The SCI is initially stopped after reset. Releasing the module-stop state enables access to the registers. For details, see section 10, Low Power Modes.

28.19.2 SCI Operation during Low Power State

(1) Transmission

Before using the power consumption reduction function to reduce SCI's power consumption, do the following to confirm transmission end (CSR.TEND = 1):

- Set the output pin state after transmission operation is stopped by CCR1.SPB2DT, SPB2IO.
- Stop the transmission (CCR0.TIE = 0, TE = 0, TEIE = 0)

When transitions to these states are made during transmission, the data being transmitted become indeterminate.

To transmit data in the same operation mode after cancellation of the low power consumption state, set the TE bit to 1, read CSR, and write data to TDR sequentially to start data transmission. To transmit data with a different operation mode, initialize the SCI first.

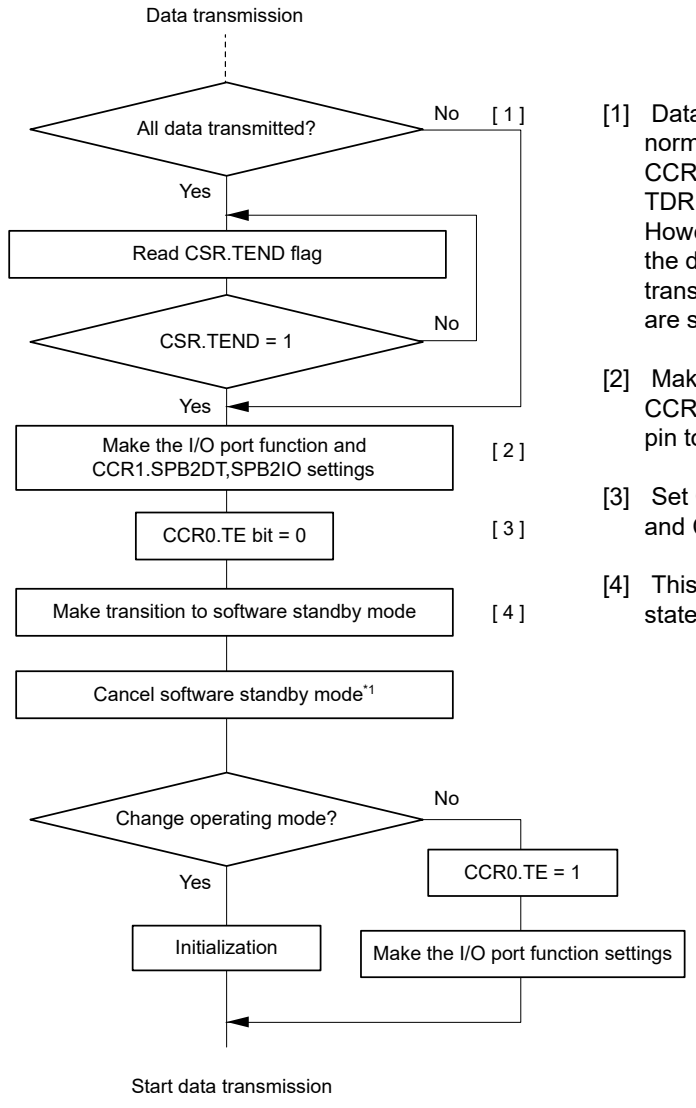
To start transmission using the DMAC or DTC after cancellation from software standby mode, set the CCR0.TE and CCR0.TIE bit to at the same time. Then SCIn_TXI interrupt flag is generated, which causes the DMAC or DTC to write the transmit data, which starts transmission.

Figure 28.117 shows a sample flowchart for transition to software standby mode during transmission. Figure 28.118 and Figure 28.119 show the port pin states during transition to software standby mode.

(2) Reception

Before specifying the module stop state or making a transition to software standby mode, stop the receive operations (CCR0.RE = 0). If transition is made during data reception, the data being received will be invalid.

Figure 28.120 shows a sample flowchart for reception to software standby mode during reception.



[1] Data being transmitted is lost halfway. Data can be normally transmitted from the CPU by setting the CCR0.TE to “1”, reading CSR, and writing data to TDR after canceling software stand by mode. However, if the DMAC or DTC has been activated, the data remaining in the DMAC or DTC will be transmitted when both the TE and TIE bits in CCR0 are set to “1”.

[2] Make the I/O port function and CCR1.SPB2DT,SPB2IO settings to switch the TxDn pin to operate as a general I/O port.

[3] Set CCR0.TE bit to “0”. Set also 0 to CCR0.TIE and CCR0.TEIE if you set these bits were 1.

[4] This includes the setting for the module stopped state.

Note 1. The registers of channels other than SCI0 are initialized in Software Standby mode. So they need to be set again

Figure 28.117 Example of Flowchart for Transition to Software Standby Mode during Transmission

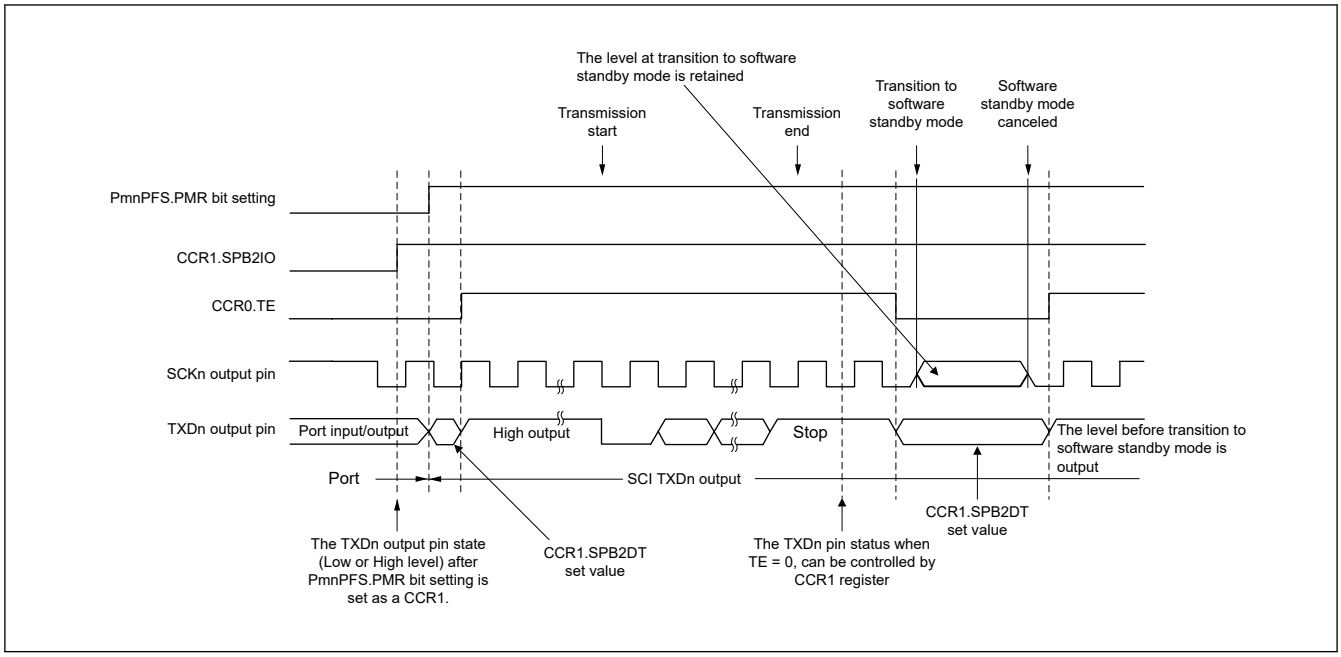


Figure 28.118 Port Pin States during Transition to Software Standby Mode (Internal Clock, Asynchronous Transmission)

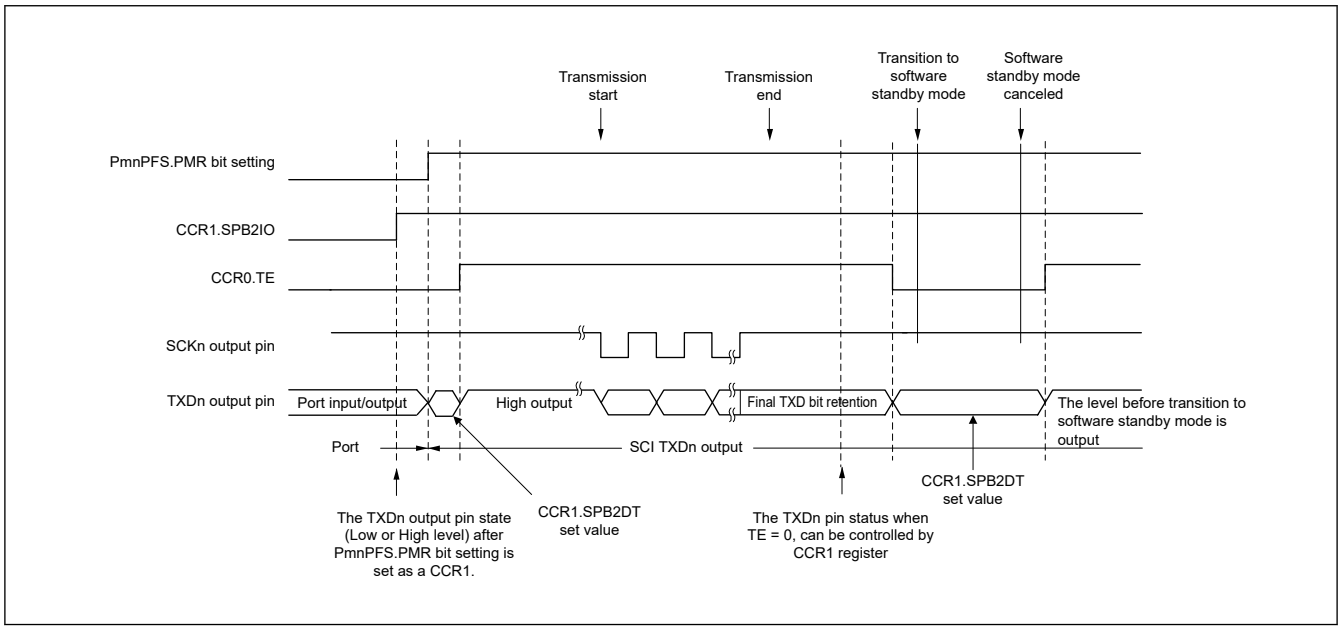

Figure 28.119 Port Pin States during Transition to Software Standby Mode (Internal Clock, Clock Synchronous Transmission)

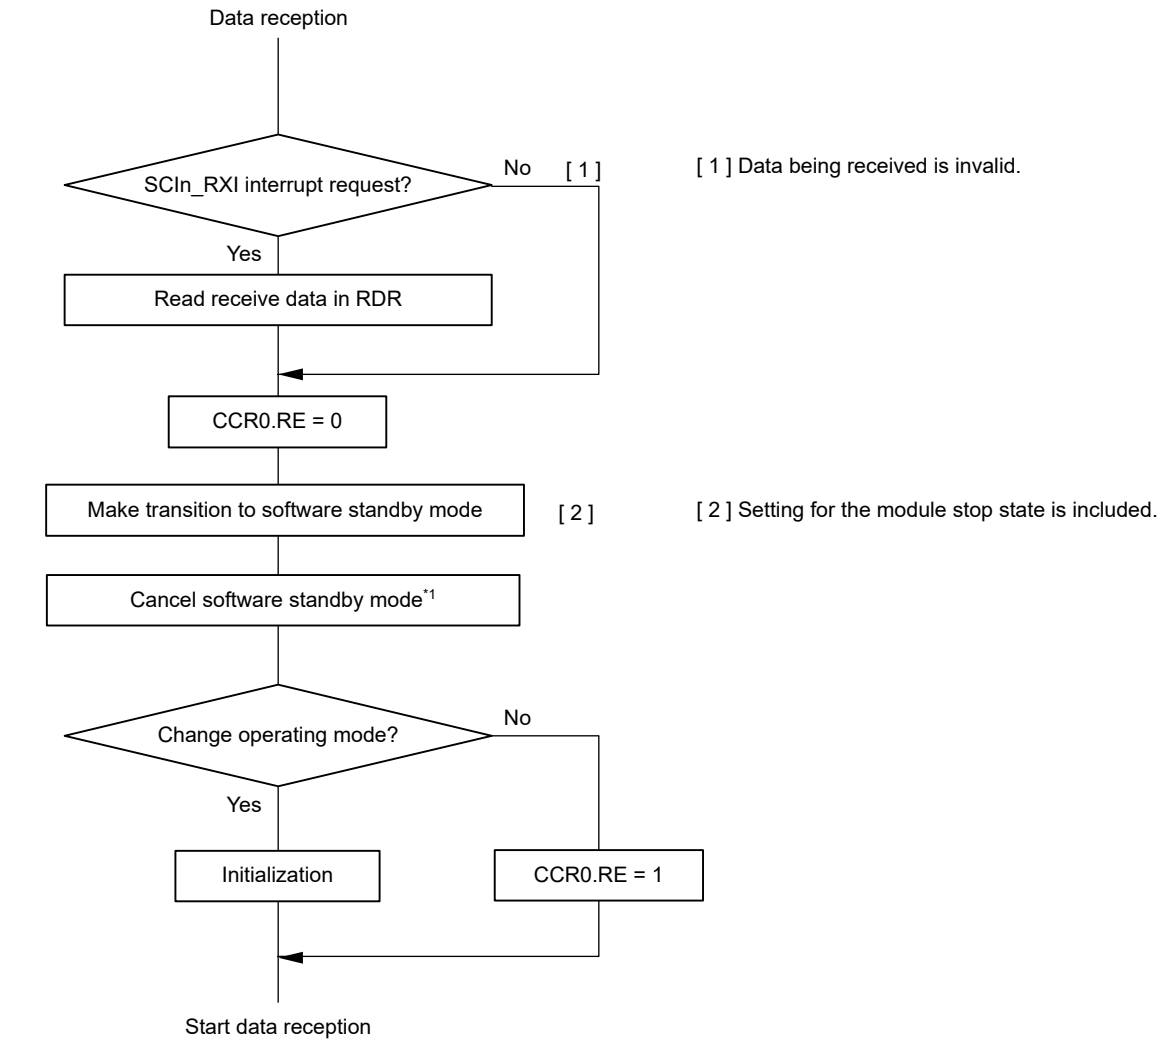


Note 1. The registers of channels other than SCI0 are initialized in Software Standby mode. So they need to be set again

Figure 28.120 Example of Flowchart for Reception to Software Standby Mode during Reception

28.19.3 Break Detection and Processing

(1) Non-FIFO selected

When a framing error is detected, a break can be detected by reading CSR.RXDMON bit value. In a break, the input from the RXDn pin becomes all 0s, and the CSR.FER flag is set to 1 to indicate a framing error, and the CSR.PER flag might also be set to 1 to indicate a parity error. The SCI continues the receive operation even after a break is received. Therefore, even if the FER flag is 0, indicating that no framing error occurred, it is set to 1 again. When the CCR3.RXDESEL bit is 1, the SCI sets the CSR.FER flag to 1 and stops receiving operations until a start bit of the next data frame is detected. If the CSR.FER flag is set to 0, the CSR.FER flag retains 0 during the break.

When the RXDn pin is set to 1 and the break ends, detecting the beginning of the start bit on the first falling edge of the RXDn pin allows the SCI to start the receiving operation.

(2) FIFO selected

After a framing error is detected and when the SCI detects that continuous receive data is 0 for 1 frame, reception stops. When a framing error is detected, a break can be detected by reading the CSR.RXDMON flag value. After the RXDn signal is in high and the break is finished, data reception to the receive-FIFO (RDR) register resumes.

28.19.4 Mark State and Production of Breaks

When the CCR0.TE bit is 0, disabling serial transmission, the state of the TXDn pin can be set using the CCR1.SPB2IO and CCR1.SPB2DT bits. With this approach, a TXDn pin can be placed in the mark state to transmit a break.

Before setting the CCR0.TE bit to 1, enabling serial transmission, set the SPB2IO and SPB2DT bits to put the communication line in the mark state (the state of 1), and change the TXDn pin using I/O port function. To output a break on data transmission, after setting the TXDn pin to output 0 by setting the SPB2IO and SPB2DT bits, change the TXDn pin using the I/O port function and set the CCR0.TE bit to 0. When the CCR0.TE bit is set to 0, the transmitter is initialized regardless of the current state of transmission.

28.19.5 Receive Error Flags and Transmit Operations (Clock Synchronous Mode and Simple SPI Mode)

Transmission can be start by writing transmit-data to TDR even if CSR.ORER is 1. However, reception cannot be started. Note also that the receive error flags cannot be set to 0 even if the CCR0.RE is set to 0 (serial reception is disabled).

28.19.6 Writing Data to TDR

(1) Non-FIFO selected

Data can be written to TDR anytime when CCR0.TE is 1. However, if new data is written to TDR when transmit data is remaining in TDR, the previous data in TDR is lost because it has not been transferred to TSR yet. If you use DTC or DMAC, be sure to write transmit data to TDR in the SCIn_TXI interrupt request handling routine.

(2) FIFO selected

Data can be written to transmit-FIFO(TDR) when CCR0.TE is 1. Check the number of writable data with the FTSR.T [5:0] bit.

28.19.7 Restrictions on Clock Synchronous Transmission (Clock Synchronous Mode and Simple SPI Mode)

When the external clock source is used as a synchronization clock, the following restrictions apply.

(1) Start of transmission

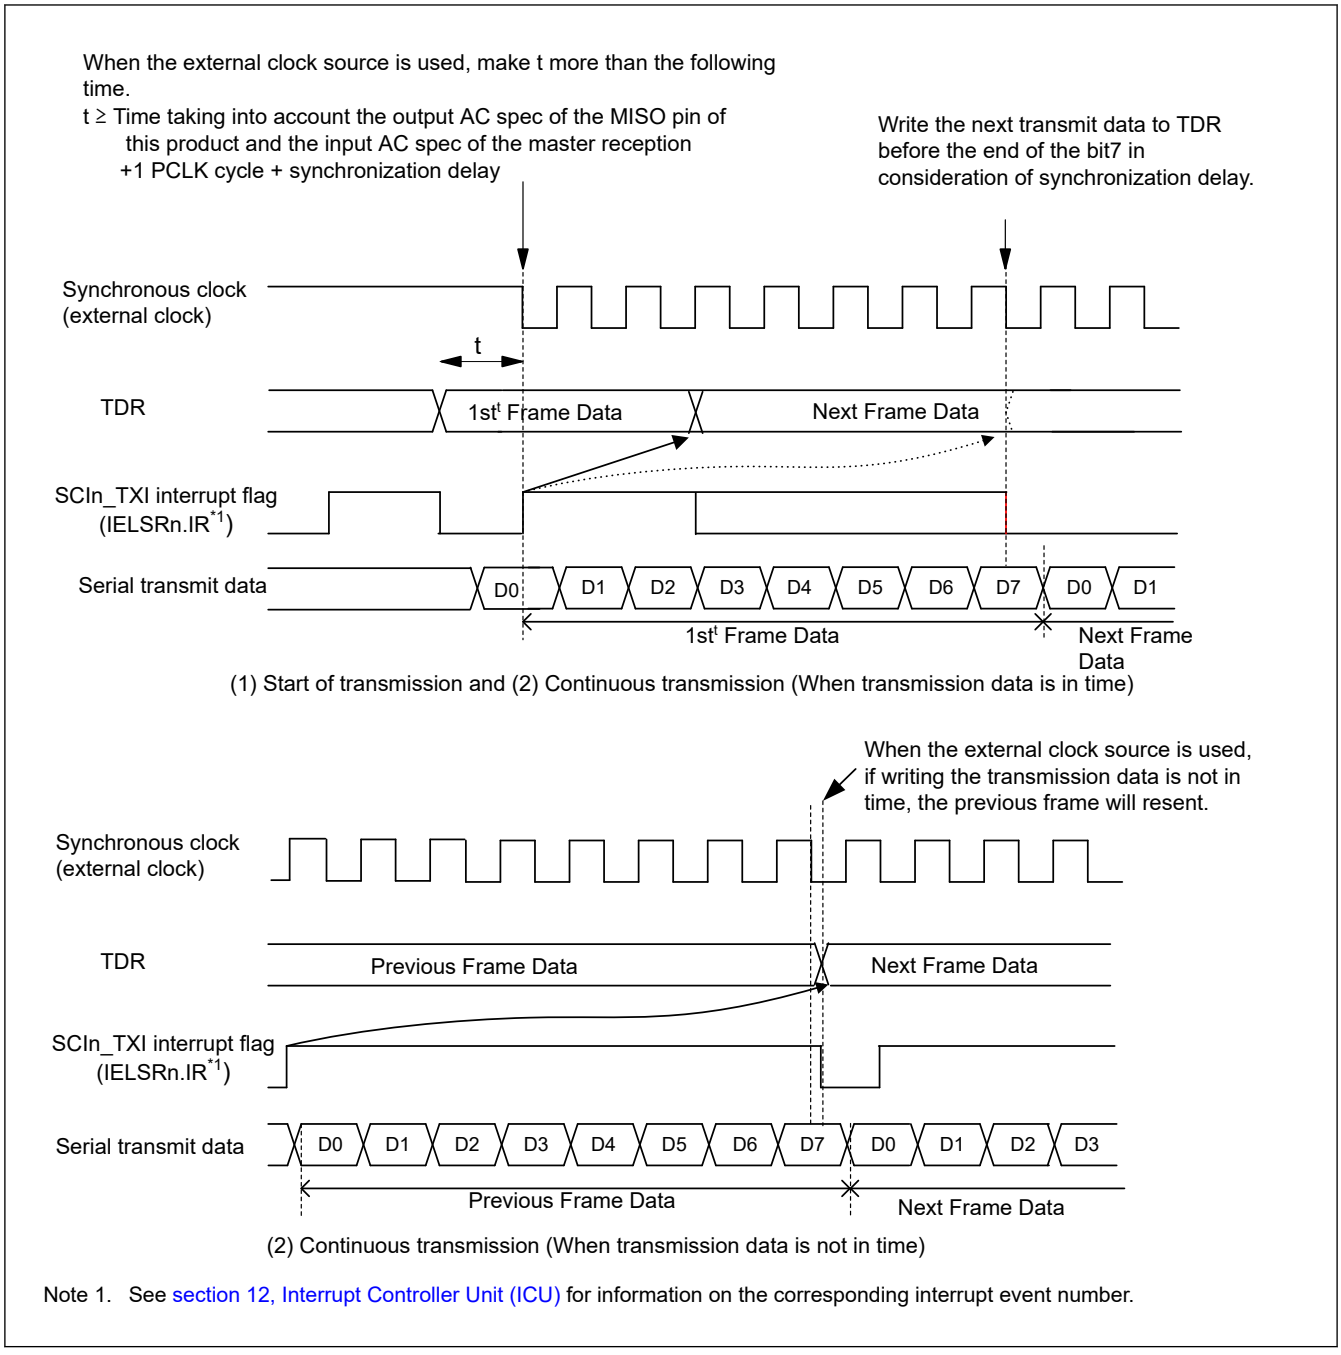
Update TDR by the CPU, DMAC, or DTC and wait at least the following time until the start of the external clock input: (See Figure 28.121)

Take the following time into account: the output AC spec of the MISO pin of this product and the input AC spec of the master reception + 1 PCLK cycle + synchronization delay.

(2) Continuous transmission

Write the next transmit data to TDR before the falling edge[*1] of the transmit clock for bit 7. Write the transmit data to TDR in consideration of synchronization delay. If the transmit data cannot be written in time, the previous frame data is resent. (See Figure 28.121)

Note 1. When CCR3.CPOL = 1 and CCR3.CPHA = 0, or CCR3.CPOL = 0 and CCR3.CPHA = 1. In the case of CCR3.CPOL = 0 and CCR3.CPHA = 0, or CCR3.CPOL = 1 and CCR3.CPHA = 1, it's the rising edge.



Note 1. See section 12, Interrupt Controller Unit (ICU) for information on the corresponding interrupt event number.

Figure 28.121 Restrictions on Use of External Clock in Clock Synchronous Transmission

28.19.8 Restrictions on Using DMAC or DTC

When using the DMAC or DTC to read RDR, be sure to set the receive data full interrupt (SCIn_RXI) as the activation source of the relevant SCI.

During the operation in transmission / reception using the DMAC or DTC, it should not set transfer information of DMAC or DTC.

28.19.9 Notes on Starting Transfer

At the point where transfer starts when the interrupt status flag (IELSRn.IR flag) in the ICU is 1, follow the procedure in this section to clear interrupt requests before permitting operations (by setting the CCR0.TE or CCR0.RE bit to 1). For details on the interrupt status flag, see section 12, Interrupt Controller Unit (ICU).

1. Confirm that transfer has stopped (the CCR0.TE or CCR0.RE bit is 0)

2. Set the associated interrupt enable bit (CCR0.TIE or CCR0.RIE bit) to 0
3. Read the associated interrupt enable bit (CCR0.TIE or CCR0.RIE bit) to check that it actually becomes 0
4. Set the interrupt status flag, IELSRn.IR, in the ICU to 0

28.19.10 Limitations on Simple SPI Mode

(1) Master mode

- Use a resistor to pull up or pull down the clock line matching the initial settings for the transfer clock set in the CCR3.CPHA and CPOL bits when the CCR0.SSE bit is 1.

  This prevents the clock line from being placed in the high-impedance state when the CCR0.TE bit is set to 0 or unexpected edges from being generated on the clock line when the CCR0.TE bit changes from 0 to 1. When the CCR0.SSE bit is 0 in single master mode, pulling up or pulling down the clock line is not required because the clock line is not placed in the high-impedance state even when the SCR.TE bit is set to 0.
- For the clock delay setting (CCR3.CPHA bit is 0), the receive data full interrupt (SCIn_RXI) is generated before the final clock edge on the SCKn pin as indicated in Figure 28.122. If the TE and RE bits in the CCR0 register become 0 before the final edge of the clock signal on the SCKn pin, the SCKn pin is placed in the high-impedance state, so the width of the last clock pulse of the transfer clock is shortened. Additionally, an SCIn_RXI interrupt might lead to the input signal on the SSn pin of a connected slave going to the high level before the final edge of the clock signal on the SCKn pin, leading to incorrect operation of the slave.
- In a multi-master configuration, the SCKn pin output goes to high-impedance while the input on the SSn pin is at the low level if a mode fault error occurs while a character is being transferred, stopping supply of the clock signal to the connected slave. Reset the connected slave to avoid misaligned bits when transfer is restarted.

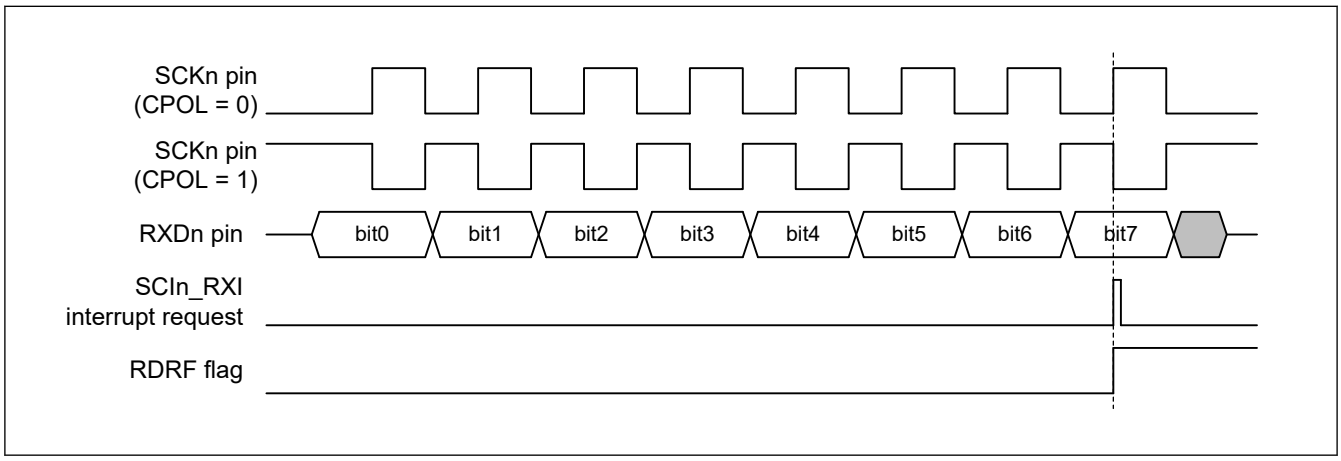


Figure 28.122 Timing of SCIn_RXI interrupt in simple SPI mode with clock delay

(2) Slave mode

- It takes 1PCLK + synchronization delay time + data output delay time (AC spec) from writing the transmit data to the TDR register until the data is output to the RXDn pin. Take these into account when starting external clock input.
- Provide an external clock signal to the master the same as the data length for transfer
- Secure the SSn input setup time (AC spec) from the SSn low-level input to the start of external clock input.
- Control the input on the SSn pin before the start and after the end of data transfer
- When the input level on the SSn pin is to be changed from low to high while a character is being transferred, set the TE and RE bits in the CCR0 register to 0 and, after restoring the settings, restart transfer of the first byte

28.19.11 Notes on Transmit Enable bit (CCR0.TE)

In initial register value, when CCR0.TE = 0, the state of the TXDn pin is high impedance. The TXDn line should not be high impedance by the following one of ways.

1. The pull-up or pull-down resistance is connected to the TXDn line.

2. Set CCR1 and decided level of TXDn terminal during TE is 0.

28.19.12 Notes on Simple LIN mode

In Simple LIN mode (CCR3.MOD[2:0] = 110), the following functions cannot be used.

- Multi-processor communication function
- Bit Rate Modulation function
- Loopback function
- FIFO buffer

28.19.13 Notes on RS-485 Driver Control function

RS-485 Driver control function is valid only in Asynchronous mode.

When RS-485 Driver control function is active (CCR3.DEN = 1), the CSR.TEND set timing / SCIn_TEI output timing changes as follows. Wait for the SCIn_TEI interrupt and set the CCR0.TE bit in SCI to 0.

When RS-485 Driver control function is inactive: When STOP bit output is completed.

When RS-485 Driver control function is active: At the end of DEn negation time.

28.19.14 Notes on Loopback function

The Loopback function is valid in Asynchronous mode with internal clock, in Manchester mode with internal clock and Clock synchronous mode with internal clock.

28.19.15 Notes regarding register access when operation clock (TCLK) is slower than bus clock (PCLK)

If the operating clock (TCLK) is slower than the bus clock (PCLK), the time until this information is transmitted internally after writing to the CCR0.TE and CCR0.RE registers is slower than the bus access time. In particular, when trying to change the setting register after writing 0 and interrupting communication, do not change the setting register before the signal inside the SCI is in the communication stopped state. To prevent this, after setting CCR0.TE and CCR0.RE to 0, check the CESR.TIST and CESR.RIST bits until they are 0 before setting the next register.

28.19.16 Notes on interrupting operation

If 0 is written to CCR0.RE during data reception and the reception operation is interrupted, there is a possibility of an invalid state, do not use the received data (RDR register stored value) and the flag value of each status register. To interrupt the reception operation, stop the interrupt or event link reception side and then write 0 to the CCR0.RE bit.

28.19.17 Notes on CCR3.BPEN bit setting

Set the BPEN bit only once when setting the CCR3 register in the SCI initialization flow.

This bit cannot be changed after the initialization.

When this bit setting is changed, start from the SCI initialization flow again.

29. I2C Bus Interface (IIC)

29.1 Overview

The I2C bus interface (IIC) has 2 channels. The IIC module conforms with and provides a subset of the NXP I2C (Inter-Integrated Circuit) bus interface functions.

Table 29.1 lists the IIC specifications, Figure 29.1 shows a block diagram, and Figure 29.2 shows an example of I/O pin connections to external circuits, with an I2C bus configuration. Table 29.2 lists the I/O pins.

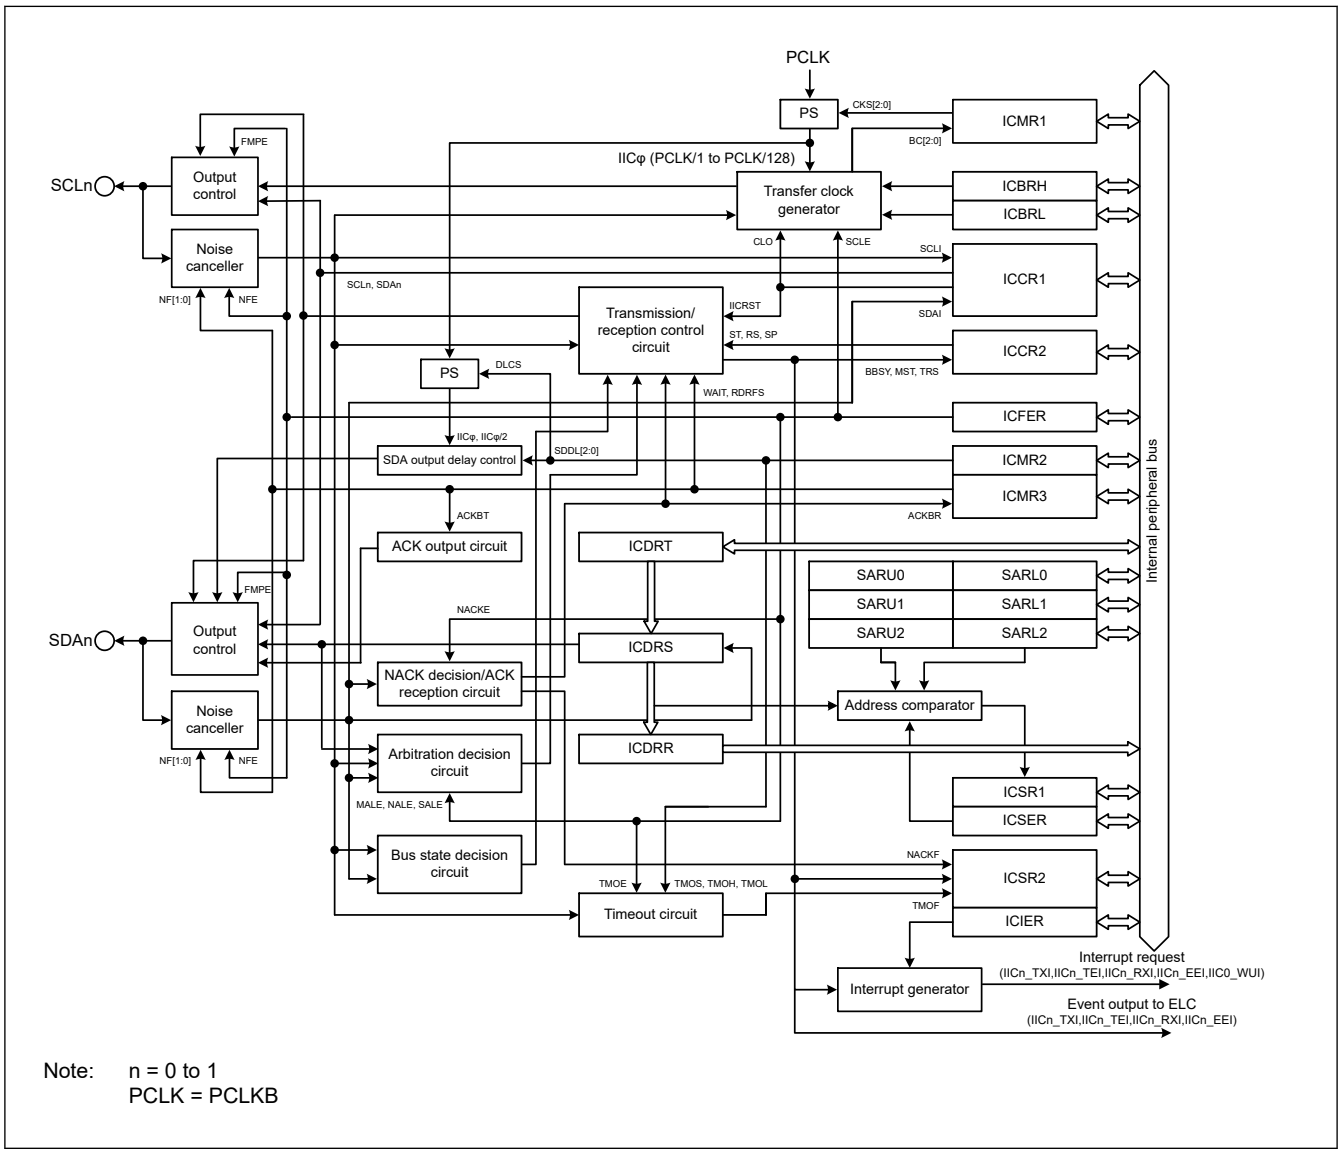
Table 29.1 IIC specifications (1 of 2)

Parameter	Specifications
Communications format	• I2C-bus format or SMBus format • Master or slave mode selectable • Automatic securing of the setup times, hold times, and bus-free times for the transfer rate
Transfer rate	• Fast-mode Plus supported, up to 1 Mbps
SCL clock	For master operation, the duty cycle of the SCL clock is selectable in the range from 4% to 96%
Issuing and detecting conditions	• Start, restart, and stop conditions are automatically generated • Start conditions (including restart conditions) and stop conditions are detectable
Slave address	• Configurable for up to three different slave addresses • 7- and 10-bit address formats supported, including simultaneous use • General call addresses, device ID addresses, and SMBus host addresses detectable
Acknowledgment	• For transmission, automatic loading of the acknowledge bit Transfer of the next transmit data can be automatically suspended on detection of a not-acknowledge bit. • For reception, automatic transmission of the acknowledge bit If a wait between the 8th and 9th clock cycles is selected, the software can control the value in the acknowledge field in response to the received value.
Wait function	During reception, the following wait periods are available by holding the SCL clock low: • Waiting between the eighth and ninth clock cycles • Waiting between the ninth clock cycle and the 1st clock cycle of the next transfer
SDA output delay function	Output timing of transmitted data, including the acknowledge bit, can be delayed
Arbitration	• For multi-master operation: – SCL clock synchronization is possible when conflict occurs with the SCL signal from another master – When issuing the start condition creates conflict on the bus, loss of arbitration is detected by testing for a mismatch between the internal signal for the SDA line and the level on the SDA line – In master operation, loss of arbitration is detected by testing for non-matching between the signal on the SDA line and the internal signal for the SDA line • Loss of arbitration because the start condition occurs while the bus is busy is detectable, to prevent the issuing of double start conditions • Loss of arbitration is detectable on transfer of a not-acknowledge bit because the internal signal for the SDA line and the level on the SDA line do not match • Loss of arbitration because a mismatch of internal and line levels for data is detectable in slave transmission
Timeout function	Internal detection of long-interval stops of the SCL clock
Noise cancellation	• Digital noise filters for both the SCL and SDA signals • Programmable window for noise cancellation by the filters
Interrupt sources	• Transfer error or event occurrence (arbitration-lost, NACK, timeout, start or restart condition, or stop condition) • Receive data full, including matching with a slave address • Transmit data empty, including matching with a slave address • Transmit end
Module-stop function	Module-stop state can be set for each channel to reduce power consumption.
IIC operating modes	• Master transmit • Master receive • Slave transmit • Slave receive

Table 29.1 IIC specifications (2 of 2)

Parameter	Specifications
Event link function (output)	• Transfer error or event occurrence (arbitration-lost, NACK, timeout, start or restart condition, or stop condition) • Receive data full, including matching with a slave address • Transmit data empty, including matching with a slave address • Transmit end
Wakeup function*1	CPU can return from Software Standby mode using a wakeup event
TrustZone Filter	Security and Privilege attribution can be set for each channels

Note 1. This function is only available for IIC channel IIC0. IIC1 is not supported.



Note: n = 0 to 1
PCLK = PCLKB

Figure 29.1 IIC block diagram

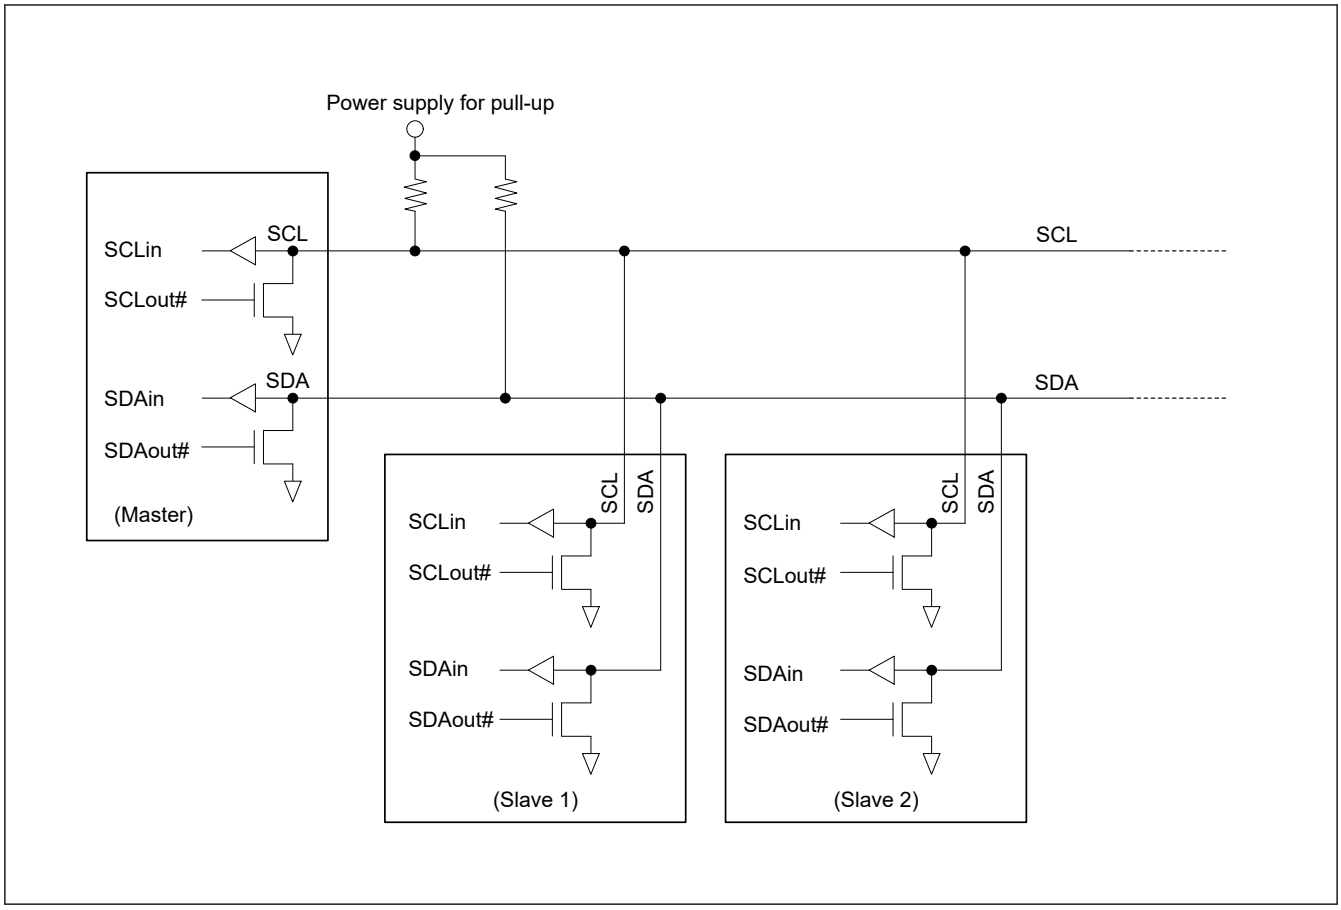


Figure 29.2 I/O pin connection to an external circuit (I^2C bus configuration example)

The input level of the signals for IIC is CMOS when I^2C bus is selected (ICMR3.SMBS = 0), or TTL when SMBus is selected (ICMR3.SMBS = 1).

Table 29.2 IIC I/O pins

Channel	Pin name	I/O	Function
IICn	SCLn	I/O	IICn serial clock I/O pin
	SDAn	I/O	IICn serial data I/O pin

Note: n = 0 to 1

29.2 Register Descriptions

29.2.1 ICCR1 : I^2C Bus Control Register 1

Base address: IICn = 0x4025_E000 + 0x0100 × n (n = 0 to 1)
IICn_NS = 0x5025_E000 + 0x0100 × n (n = 0 to 1)

Offset address: 0x00

Bit position:	7	6	5	4	3	2	1	0
Bit field:	ICE	IICRST	CLO	SOWP	SCLO	SDAO	SCLI	SDAI
Value after reset:	0	0	0	1	1	1	1	1

Bit	Symbol	Function	R/W
0	SDAI	SDA Line Monitor 0: SDAn line is low 1: SDAn line is high	R

Bit	Symbol	Function	R/W
1	SCLI	SCL Line Monitor 0: SCLn line is low 1: SCLn line is high	R
2	SDAO	SDA Output Control/Monitor 0: Read: IIC drives SDAn pin low Write: IIC drives SDAn pin low 1: Read: IIC releases SDAn pin Write: IIC releases SDAn pin	R/W
3	SCLO	SCL Output Control/Monitor Use an external pull-up resistor to drive the signal high. 0: Read: IIC drives SCLn pin low Write: IIC drives SCLn pin low 1: Read: IIC releases SCLn pin Write: IIC releases SCLn pin	R/W
4	SOWP	SCLO/SDAO Write Protect This bit is read as 1. 0: Write enable SCLO and SDAO bits 1: Write protect SCLO and SDAO bits	W
5	CLO	Extra SCL Clock Cycle Output This bit clears automatically after 1 clock cycle is output. 0: Do not output extra SCL clock cycle (default) 1: Output extra SCL clock cycle	R/W
6	IICRST	I2C Bus Interface Internal Reset This setting clears the bit counter and the SCLn/SDAn output latch. 0: Release IIC reset or internal reset 1: Initiate IIC reset or internal reset	R/W
7	ICE	I2C Bus Interface Enable Used in combination with the IICRST bit to select either IIC or internal reset. 0: Disable (SCLn and SDAn pins in inactive state) 1: Enable (SCLn and SDAn pins in active state)	R/W

Note: S-TYPE3, P-TYPE3

SDAO bit (SDA Output Control/Monitor) and SCLO bit (SCL Output Control/Monitor)

The SDAO and SCLO bits directly control the SDAn and SCLn signals output from the IIC. When writing to these bits, also write 0 to the SOWP bit. Setting these bits results in input to the IIC by the input buffer. When slave mode is selected, a start condition might be detected and the bus might be released, depending on the bit settings.

Do not rewrite these bits during a start condition, stop condition, restart condition, transmission, or reception. Operation after rewriting under these conditions is not guaranteed. When reading these bits, the state of signals output from the IIC can be read.

CLO bit (Extra SCL Clock Cycle Output)

The CLO bit allows output of an extra SCL clock cycle for debugging or error processing. Normally, set this bit to 0. Setting the bit to 1 in a normal communication state causes a communication error. For details on this function, see section 29.12.2. Extra SCL Clock Cycle Output Function.

IICRST bit (I2C Bus Interface Internal Reset)

The IICRST bit initiates an internal state reset of the IIC. Setting this bit to 1 initiates an IIC reset or internal reset. Whether an IIC reset or internal reset is initiated is determined by the settings of this bit in combination with the ICE bit. Table 29.3 lists the IIC resets.

The IIC reset initializes all registers except ICCR1.ICE and ICCR1.IICRST bits and internal states of the IIC. In addition to the internal states of the IIC, the internal reset initializes the following:

- Bit counter (ICMR1.BC[2:0] bits)
- I2C Bus Shift Register (ICDRS)
- I2C Bus Status Registers (ICSR1 and ICSR2)
- SDAO and SCLO Output Control/Monitor (ICCR1.SDAO and ICCR1.SCLO bits)

- I²C Bus Control Register 2 (except ICCR2.BBSY bit)

For the reset conditions for each register, see section 29.15. State of Registers When Issuing Each Condition.

An internal reset initiated with the IICRST bit set to 1 during operation (with the ICE bit set to 1) resets the internal states of the IIC without initializing the port settings and the control and setting registers of the IIC. If the IIC hangs in a low-level output state, resetting the internal states cancels the low-level output state and releases the bus with the SCLn pin and SDAn pin at high impedance.

Note: If an internal reset is initiated using the IICRST bit for a bus hang-up that occurs during communication with the master device in slave mode, the slave and master devices might enter different states, because the bit counter information differs. For this reason, do not initiate an internal reset in slave mode. Initiate recovery processing from the master device. If an internal reset is required because the IIC hangs with the SCLn line in a low-level output state in slave mode, initiate an internal reset, then issue a restart condition from the master device, or issue a stop condition and resume communication from the start condition. If communication is restarted by initiating a reset solely in the slave device without issuing a start or restart condition from the master device, synchronization is lost because the master and slave devices operate asynchronously.

Table 29.3 IIC resets

IICRST	ICE	State	Specifications
1	0	IIC reset	Resets all registers except ICCR1.IICRST and ICCR1.ICE bits, and the internal states of the IIC
	1	Internal reset	Reset the following: • ICMR1.BC[2:0] bits • ICSR1, ICSR2, ICDRS registers • SDAO and SCLO Output Control/Monitor (ICCR1.SDAO and ICCR1.SCLO bits) • I²C Bus Control Register 2 (except ICCR2.BBSY bit) • Internal states of the IIC

ICE bit (I²C Bus Interface Enable)

The ICE bit selects the active or inactive state of the SCLn and SDAn pins. It can also be combined with the IICRST bit to initiate two types of resets. See Table 29.3 for the reset descriptions.

Set the ICE bit to 1 when using the IIC. The SCLn and SDAn pins are placed in the active state when the ICE bit is set to 1. Set the ICE bit to 0 when the IIC is not used. The SCLn and SDAn pins are placed in the inactive state when the ICE bit is set to 0. Do not assign the SCLn or SDAn pin to the IIC when setting up the pin function control. Slave address comparison is performed if the pins are assigned to the IIC.

29.2.2 ICCR2 : I²C Bus Control Register 2

Base address: IICn = 0x4025_E000 + 0x0100 × n (n = 0 to 1)
IICn_NS = 0x5025_E000 + 0x0100 × n (n = 0 to 1)

Offset address: 0x01

Bit position:	7	6	5	4	3	2	1	0
Bit field:	BBSY	MST	TRS	—	SP	RS	ST	—
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	—	This bit is read as 0. The write value should be 0.	R/W
1	ST	Start Condition Issuance Request 0: Do not issue a start condition request 1: Issue a start condition request	R/W
2	RS	Restart Condition Issuance Request 0: Do not issue a restart condition request 1: Issue a restart condition request	R/W

Bit	Symbol	Function	R/W

4	—	This bit is read as 0. The write value should be 0.	R/W
5	TRS	Transmit/Receive Mode 0: Receive mode 1: Transmit mode	R/W*1
6	MST	Master/Slave Mode 0: Slave mode 1: Master mode	R/W*1
7	BBSY	Bus Busy Detection Flag 0: I2C bus released (bus free state) 1: I2C bus occupied (bus busy state)	R

Note: S-TYPE3, P-TYPE3
Note 1. The MST and TRS bits can be written to when the ICMR1.MTWP bit is set to 1.

ST bit (Start Condition Issuance Request)

The ST bit requests transition to master mode and triggers a start condition. When this bit is set to 1, a start condition is issued when the BBSY flag is set to 0 (bus free state). For details on this function, see section 29.11. Start, Restart, and Stop Condition Issuing Function.

[Setting condition]

- When 1 is written to the ST bit.

[Clearing conditions]

- When 0 is written to the ST bit
- When a start condition is issued (a start condition is detected)
- When the AL (arbitration-lost) flag in ICSR2 is set to 1
- When 1 is written to the IICRST bit in ICCR1 to apply an IIC reset or an internal reset.

Note: Only set the ST bit to 1 (start condition request) when the BBSY flag is set to 0 (bus free state). Arbitration might be lost if the ST bit is set to 1 (start condition request) when the BBSY flag is 1 (bus busy state).

RS bit (Restart Condition Issuance Request)

The RS bit requests that a restart condition be issued in master mode. When this bit is set to 1 to request a restart condition, a restart condition is issued when the BBSY flag is set to 1 (bus busy state) and the MST bit is set to 1 (master mode). For details on this function, see section 29.11. Start, Restart, and Stop Condition Issuing Function.

[Setting condition]

- When 1 is written to the RS bit with the BBSY flag in ICCR2 set to 1.

[Clearing conditions]

- When 0 is written to the RS bit
- When a restart condition is issued (a start condition is detected)
- When the AL (arbitration-lost) flag in ICSR2 is set to 1
- When 1 is written to the IICRST bit in ICCR1 to apply an IIC reset or an internal reset.

Note: Do not set the RS bit to 1 while issuing a stop condition.
Note: If 1 (restart condition request) is written to the RS bit in slave mode, the restart condition is not issued, but the RS bit remains set to 1. If the operating mode changes to master mode without the bit being cleared, a restart condition might be issued.

SP bit (Stop Condition Issuance Request)

The SP bit requests that a stop condition be issued in master mode. When this bit is set to 1, a stop condition is issued when the BBSY flag is set to 1 (bus busy state) and the MST bit is set to 1 (master mode). For details on this function, see section 29.11. Start, Restart, and Stop Condition Issuing Function.

[Setting condition]

- When 1 is written to the SP bit with both the BBSY flag and the MST bit in ICCR2 set to 1.

[Clearing conditions]

- When 0 is written to the SP bit
- When a stop condition is issued (a stop condition is detected)
- When the AL (arbitration-lost) flag in ICSR2 is set to 1
- When a start condition and a restart condition are detected
- When 1 is written to the IICRST bit in ICCR1 to apply an IIC reset or an internal reset.

Note: Writing to the SP bit is not possible while the BBSY flag is 0 (bus free state).
Note: Do not set the SP bit to 1 while a restart condition is being issued.

TRS bit (Transmit/Receive Mode)

The TRS bit indicates transmit or receive mode. The IIC is in receive mode when the TRS bit is 0 and in transmit mode when the bit is 1. The combination of this bit and the MST bit indicates the IIC operating mode.

The value of the TRS bit automatically changes to 1 for transmit mode or 0 for receive mode when a start condition is issued or detected and the R/W# bit is set. Although writing to the TRS bit is possible when the MTWP bit in ICMR1 is set to 1, writing to this bit is not required during normal usage.

[Setting conditions]

- When a start condition is issued normally because of a start condition request (when a start condition is detected with the ST bit set to 1)
- When a restart condition is issued normally because of a restart condition request (when a restart condition is detected with the RS bit set to 1)
- When the R/W# bit appended to the slave address is set to 0 in master mode
- When the address received in slave mode matches the address enabled in ICSER, with the R/W# bit set to 1
- When 1 is written to the TRS bit with the MTWP bit in ICMR1 set to 1.

[Clearing conditions]

- When a stop condition is detected
- When the AL (arbitration-lost) flag in ICSR2 is set to 1
- When the R/W# bit appended to the slave address is set to 1 in master mode
- In slave mode, on a match between the received address and the address enabled in ICSER when the value of the received R/W# bit is 0, including when the received address is the general call address
- In slave mode, when a restart condition is detected (a restart condition is detected with ICCR2.BBSY = 1 and ICCR2.MST = 0)
- When 0 is written to the TRS bit with the MTWP bit in ICMR1 set to 1
- When 1 is written to the IICRST bit in ICCR1 to apply an IIC reset or an internal reset.

MST bit (Master/Slave Mode)

The MST bit indicates master or slave mode. The IIC is in slave mode when the MST bit is 0 and is in master mode when the bit is 1. The combination of this bit and the TRS bit indicates the IIC operating mode.

The value of the MST bit automatically changes to 1 for master mode or 0 for slave mode when a start condition is issued or a stop condition is issued or detected. Although writing to the MST bit is possible when the MTWP bit in ICMR1 is set to 1, writing to this bit is not required during normal usage.

[Setting conditions]

- When a start condition is issued normally because of a start condition request (when a start condition is detected with the ST bit set to 1)
- When 1 is written to the MST bit with the MTWP bit in ICMR1 set to 1.

[Clearing conditions]

- When a stop condition is detected
- When the AL (arbitration-lost) flag in ICSR2 is set to 1
- When 0 is written to the MST bit with the MTWP bit in ICMR1 set to 1
- When 1 is written to the IICRST bit in ICCR1 to apply an IIC reset or an internal reset.

BBSY flag (Bus Busy Detection Flag)

The BBSY flag indicates whether the I^2C bus is occupied (bus busy state) or released (bus free state). The flag is set to 1 when the SDAn line changes from high to low when the SCLn line is high, assuming that a start condition was issued. The flag is set to 0 if a start condition is not detected for the bus free time (ICBRL setting), assuming that a stop condition was issued.

[Setting condition]

- When a start condition is detected.

[Clearing conditions]

- When a start condition is not detected for the bus free time (ICBRL setting) after detecting a stop condition
- When 1 is written to the IICRST bit in ICCR1 with the ICE bit in ICCR1 set to 0 (IIC reset).

29.2.3 ICMR1 : I^2C Bus Mode Register 1

Base address: IICn = 0x4025_E000 + 0x0100 × n (n = 0 to 1)
IICn_NS = 0x5025_E000 + 0x0100 × n (n = 0 to 1)

Offset address: 0x02

Bit position:	7	6	5	4	3	2	1	0
Bit field:	MTWP	CKS[2:0]			BCWP	BC[2:0]		
Value after reset:	0	0	0	0	1	0	0	0

Bit	Symbol	Function	R/W
2:0	BC[2:0]	Bit Counter 0 0 0: 9 bits 0 0 1: 2 bits 0 1 0: 3 bits 0 1 1: 4 bits 1 0 0: 5 bits 1 0 1: 6 bits 1 1 0: 7 bits 1 1 1: 8 bits	R/W*1
3	BCWP	BC Write Protect This bit is read as 1. 0: Write enable BC[2:0] bits 1: Write protect BC[2:0] bits	W*1
6:4	CKS[2:0]	Internal Reference Clock Select Select the internal reference clock source (IICφ) for the IIC. IICφ = (PCLKB / $2^{CKS[2:0]}$) clock	R/W
7	MTWP	MST/TRS Write Protect 0: Write protect MST and TRS bits in ICCR2 1: Write enable MST and TRS bits in ICCR2	R/W

Note: S-TYPE3, P-TYPE3

Note 1. Rewrite the BC[2:0] bits and set the BCWP bit to 0 at the same time.

BC[2:0] bits (Bit Counter)

The BC[2:0] bits function as a counter indicating the number of bits remaining to be transferred on detection of a rising edge on the SCLn line. Although BC[2:0] are read/write bits, it is not required to access these bits under normal conditions.

To write to these bits, specify the number of bits to be transferred plus one, for an additional acknowledge bit, between transferred frames when the SCLn line is at a low level. The value in the BC[2:0] bits returns to 000b at the end of a data transfer, including the acknowledge bit, or when a start or restart condition is detected.

29.2.4 ICMR2 : I2C Bus Mode Register 2

Base address: IICn = 0x4025_E000 + 0x0100 × n (n = 0 to 1)
IICn_NS = 0x5025_E000 + 0x0100 × n (n = 0 to 1)

Offset address: 0x03

Bit position:	7	6	5	4	3	2	1	0
Bit field:	DLCS	SDDL[2:0]			—	TMOH	TMOL	TMOS
Value after reset:	0	0	0	0	0	1	1	0

Bit	Symbol	Function	R/W
0	TMOS	Timeout Detection Time Select 0: Select long mode 1: Select short mode	R/W
1	TMOL	Timeout L Count Control 0: Disable count while SCLn line is low 1: Enable count while SCLn line is low	R/W
2	TMOH	Timeout H Count Control 0: Disable count while SCLn line is high 1: Enable count while SCLn line is high	R/W
3	—	This bit is read as 0. The write value should be 0.	R/W
6:4	SDDL[2:0]	SDA Output Delay Counter 0 0 0: No output delay 0 0 1: 1 IICφ cycle (When ICMR2.DLCS = 0 (IICφ)) 1 or 2 IICφ cycles (When ICMR2.DLCS = 1 (IICφ/2)) 0 1 0: 2 IICφ cycles (When ICMR2.DLCS = 0 (IICφ)) 3 or 4 IICφ cycles (When ICMR2.DLCS = 1 (IICφ/2)) 0 1 1: 3 IICφ cycles (When ICMR2.DLCS = 0 (IICφ)) 5 or 6 IICφ cycles (When ICMR2.DLCS = 1 (IICφ/2)) 1 0 0: 4 IICφ cycles (When ICMR2.DLCS = 0 (IICφ)) 7 or 8 IICφ cycles (When ICMR2.DLCS = 1 (IICφ/2)) 1 0 1: 5 IICφ cycles (When ICMR2.DLCS = 0 (IICφ)) 9 or 10 IICφ cycles (When ICMR2.DLCS = 1 (IICφ/2)) 1 1 0: 6 IICφ cycles (When ICMR2.DLCS = 0 (IICφ)) 11 or 12 IICφ cycles (When ICMR2.DLCS = 1 (IICφ/2)) 1 1 1: 7 IICφ cycles (When ICMR2.DLCS = 0 (IICφ)) 13 or 14 IICφ cycles (When ICMR2.DLCS = 1 (IICφ/2))	R/W
7	DLCS	SDA Output Delay Clock Source Select 0: Select internal reference clock (IICφ) as the clock source for SDA output delay counter 1: Select internal reference clock divided by 2 (IICφ/2) as the clock source for SDA output delay counter*1	R/W

Note: S-TYPE3, P-TYPE3
Note 1. The setting DLCS = 1 (IICφ/2) is only valid when SCL is low. When SCL is high, the DLCS = 1 setting becomes invalid and the clock source becomes the internal reference clock (IICφ).

TMOS bit (Timeout Detection Time Select)

The TMOS bit selects long or short mode for the timeout detection time when the timeout function is enabled (ICFER.TMOE = 1). When this bit is set to 0, long mode is selected. When it is set to 1, short mode is selected. In long mode, the timeout detection internal counter functions as a 16 bit-counter. In short mode, the counter functions as a

14- bit counter. While the SCLn line is in the state that enables this counter as specified in the TMOH and TMOL bits, the counter counts up in synchronization with the internal reference clock (IICφ) as a count source. For details on this function, see section 29.12.1. Timeout Function.

TMOL bit (Timeout L Count Control)

The TMOL bit enables or disables up-counting on the internal counter of the timeout function while the SCLn line is held low and the timeout function is enabled (ICFER.TMOE = 1).

TMOH bit (Timeout H Count Control)

The TMOH bit enables or disables up-counting on the internal counter of the timeout function while the SCLn line is held high and the timeout function is enabled (ICFER.TMOE = 1).

SDDL[2:0] bits (SDA Output Delay Counter)

The SDDL[2:0] bits can be used to delay the SDA output. This counter works with the clock source selected in the DLCS bit. This setting can be used for all types of SDA output, including transmission of the acknowledge bit.

Set the SDA output delay to meet the I2C bus standard for the data enable time/acknowledge enable time,*1 or the SMBus standard, within [data hold time (300 ns or more + the SCL clock low-level period) - the data setup time (250 ns)]. If a value outside the standard is set, communication between devices might malfunction or falsely indicate a start or stop condition, depending on the bus state.

For details on this function, see section 29.5. SDA Output Delay Function.

Note 1. Data enable time/acknowledge enable time.
3,450 ns for up to 100 kbps: Standard mode (Sm)
900 ns for up to 400 kbps: Fast mode (Fm)
450 ns for up to 1 Mbps: Fast-mode Plus (Fm+)

29.2.5 ICMR3 : I2C Bus Mode Register 3

Base address: IICn = 0x4025_E000 + 0x0100 × n (n = 0 to 1)
IICn_NS = 0x5025_E000 + 0x0100 × n (n = 0 to 1)

Offset address: 0x04

Bit position:	7	6	5	4	3	2	1	0
Bit field:	SMBS	WAIT	RDRFS	ACKWP	ACKBT	ACKBR	NF[1:0]	
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
1:0	NF[1:0]	Noise Filter Stage Select 0 0: Filter out noise of up to 1 IICφ cycle (single-stage filter) 0 1: Filter out noise of up to 2 IICφ cycles (2-stage filter) 1 0: Filter out noise of up to 3 IICφ cycles (3-stage filter) 1 1: Filter out noise of up to 4 IICφ cycles (4-stage filter)	R/W
2	ACKBR	Receive Acknowledge 0: 0 received as the acknowledge bit (ACK reception) 1: 1 received as the acknowledge bit (NACK reception)	R
3	ACKBT	Transmit Acknowledge 0: Send 0 as the acknowledge bit (ACK transmission) 1: Send 1 as the acknowledge bit (NACK transmission)	R/W*1
4	ACKWP	ACKBT Write Protect 0: Write protect ACKBT bit 1: Write enable ACKBT bit	R/W

Bit	Symbol	Function	R/W
5	RDRFS	RDRF Flag Set Timing Select Low-hold is released by writing to ACKBT. 0: Set the RDRF flag on the rising edge of the 9th SCL clock cycle. The SCLn line is not held low on the falling edge of the 8th clock cycle. 1: Set the RDRF flag on the rising edge of the 8th SCL clock cycle. The SCLn line is held low on the falling edge of the 8th clock cycle.	R/W*2
6	WAIT	Low-hold is released by reading ICDRR. 0: No wait (The SCLn line is not held low during the period between the 9th clock cycle and the 1st clock cycle.) 1: Wait (The SCLn line is held low during the period between the 9th clock cycle and the 1st clock cycle.)	R/W*2
7	SMBS	SMBus/I2C Bus Select 0: Select I2C Bus 1: Select SMBus	R/W

Note: S-TYPE3, P-TYPE3
Note 1. Write to the ACKBT bit only while the ACKWP bit is already 1. If the application writes 1 to the ACKWP and ACKBT bits at the same time, the ACKBT bit is not set to 1.
Note 2. The WAIT and RDRFS bits are only valid in receive mode (invalid in transmit mode).

NF[1:0] bits (Noise Filter Stage Select)

The NF[1:0] bits select the number of stages in the digital noise filter. For details on this function, see section 29.6. Digital Noise Filter Circuits

Note: Set the noise range to be filtered within a range less than the SCLn line high- or low-level period. If the noise range is set to a value of [SCL clock width: high- or low-level period, whichever is shorter] - [1.5 internal reference clock (IICφ) cycles + analog noise filter: 120 ns (reference values)] or more, the SCL clock is regarded as noise, which might prevent the IIC from operating normally.

ACKBR bit (Receive Acknowledge)

The ACKBR bit stores the acknowledge bit information received from the receive device in transmit mode.

[Setting condition]

- When 1 is received as the acknowledge bit with the TRS bit in ICCR2 set to 1.

[Clearing conditions]

- When 0 is received as the acknowledge bit with the TRS bit in ICCR2 set to 1
- When 1 is written to the IICRST bit in ICCR1 while the ICE bit in ICCR1 is 0 (IIC reset).

ACKBT bit (Transmit Acknowledge)

The ACKBT bit sets the acknowledge bit to be sent in receive mode

[Setting condition]

- When 1 is written to this bit with the ACKWP bit set to 1.

[Clearing conditions]

- When 0 is written to this bit with the ACKWP bit set to 1
- When stop condition request is detected with the SP bit in ICCR2 set to 1
- When 1 is written to the IICRST bit in ICCR1 while the ICE bit in ICCR1 is 0 (IIC reset).

ACKWP bit (ACKBT Write Protect)

The ACKWP bit controls write enabling of the ACKBT bit.

RDRFS bit (RDRF Flag Set Timing Select)

The RDRFS bit selects the RDRF flag set timing in receive mode and also selects whether to hold the SCLn line low on the falling edge of the 8th SCL clock cycle.

When the RDRFS bit is 0, the SCLn line is not held low on the falling edge of the 8th SCL clock cycle, and the RDRF flag is set to 1 on the rising edge of the 9th SCL clock cycle.

When the RDRFS bit is 1, the RDRF flag is set to 1 on the rising edge of the 8th SCL clock cycle, and the SCLn line is held low on the falling edge of the 8th SCL clock cycle. The low-hold of the SCLn line is released by a write to the ACKBT bit.

After data is received with this setting, the SCLn line is automatically held low before the acknowledge bit is sent. This enables processing to send ACK (ACKBT = 0) or NACK (ACKBT = 1), based on the receive data.

WAIT bit (WAIT)

The WAIT bit controls whether to force a low-hold between the ninth SCL clock cycle and the first SCL clock cycle, until the receive data buffer (ICDRR) is completely read each time single-byte data is received in receive mode.

When the WAIT bit is 0, the receive operation continues without a low-hold between the ninth and the first SCL clock cycle. When both the RDRFS and WAIT bits are 0, continuous receive operation is enabled with the double buffer.

When the WAIT bit is 1, the SCLn line is held low from the falling edge of the ninth clock cycle until the ICDRR value is read each time single-byte data is received. This enables receive operation in byte units.

Note: When the value of the WAIT bit is to be read, always read ICDRR first.

SMBS bit (SMBus/I2C Bus Select)

Setting the SMBS bit to 1 selects the SMBus and enables the HOAE bit in ICSER.

29.2.6 ICFER : I2C Bus Function Enable Register

Base address: IICn = 0x4025_E000 + 0x0100 × n (n = 0 to 1)
IICn_NS = 0x5025_E000 + 0x0100 × n (n = 0 to 1)

Offset address: 0x05

Bit position:	7	6	5	4	3	2	1	0
Bit field:	FMPE	SCLE	NFE	NACKE	SALE	NALE	MALE	TMOE
Value after reset:	0	1	1	1	0	0	1	0

Bit	Symbol	Function	R/W
0	TMOE	Timeout Function Enable 0: Disable 1: Enable	R/W
1	MALE	Master Arbitration-Lost Detection Enable 0: Disable the arbitration-lost detection function and disable automatic clearing of the MST and TRS bits in ICCR2 when arbitration is lost 1: Enable the arbitration-lost detection function and enable automatic clearing of the MST and TRS bits in ICCR2 when arbitration is lost	R/W
2	NALE	NACK Transmission Arbitration-Lost Detection Enable 0: Disable 1: Enable	R/W
3	SALE	Slave Arbitration-Lost Detection Enable 0: Disable 1: Enable	R/W
4	NACKE	NACK Reception Transfer Suspension Enable 0: Do not suspend transfer operation during NACK reception (disable transfer suspension) 1: Suspend transfer operation during NACK reception (enable transfer suspension)	R/W
5	NFE	Digital Noise Filter Circuit Enable 0: Do not use the digital noise filter circuit 1: Use the digital noise filter circuit	R/W
6	SCLE	SCL Synchronous Circuit Enable 0: Do not use the SCL synchronous circuit 1: Use the SCL synchronous circuit	R/W

Bit	Symbol	Function	R/W
7	FMPE*1	Fast-Mode Plus Enable 0: Do not use the Fm+ slope control circuit for the SCLn and SDAn pins 1: Use the Fm+ slope control circuit for the SCLn and SDAn pins.	R/W

Note: S-TYPE3, P-TYPE3
Note 1. The Fast-mode Plus enable bit (FMPE) is supported by IIC0 (SCL0_A, SDA0_A) and IIC1(SCL1_A, SDA1_A). Bit [7] is the reserved bit in the not supported channel.

TMOE bit (Timeout Function Enable)

The TMOE bit enables or disables the timeout function. For details on this function, see section 29.12.1. Timeout Function.

MALE bit (Master Arbitration-Lost Detection Enable)

The MALE bit specifies whether to use the arbitration-lost detection function in master mode. Normally, set this bit to 1.

NALE bit (NACK Transmission Arbitration-Lost Detection Enable)

The NALE bit specifies whether to cause arbitration to be lost when ACK is detected during transmission of NACK in receive mode, for example when slaves with the same address exist on the bus or when two or more masters select the same slave device simultaneously with a different number of receive bytes.

SALE bit (Slave Arbitration-Lost Detection Enable)

The SALE bit specifies whether to cause arbitration to be lost when a value different from the value being transmitted is detected on the bus in slave transmit mode, for example when slaves with the same address exist on the bus or when a mismatch with the transmit data occurs because of noise.

NACKE bit (NACK Reception Transfer Suspension Enable)

The NACKE bit specifies whether to continue or discontinue the transfer operation when NACK is received in transmit mode. Normally, set this bit to 1.

When NACK is received with the NACKE bit set to 1, the next transfer operation is suspended. When the NACKE bit is 0, the next transfer operation continues regardless of the received acknowledge content.

For details, see section 29.9.2. NACK Reception Transfer Suspension Function.

SCLE bit (SCL Synchronous Circuit Enable)

The SCLE bit specifies whether to synchronize the SCL clock with the SCL input clock. Normally, set this bit to 1.

When the SCLE bit is set to 0 (no SCL synchronous circuit used), the IIC does not synchronize the SCL clock with the SCL input clock. With this setting, the IIC outputs the SCL clock at the transfer rate set in ICBRH and ICBRL, regardless of the SCLn line state. For this reason, if the bus load of the I^2C bus line is much larger than the specification value, or if the SCL clock output overlaps in multiple masters, a short-cycle SCL clock that does not meet the specification might be output. When no SCL synchronous circuit is used, it also affects the issuing of the start, restart, and stop conditions, and the continuous output of extra SCL clock cycles.

Do not set this bit to 0 except when checking the output of the set transfer rate.

FMPE bit (Fast-Mode Plus Enable)

The FMPE bit specifies whether to use a slope control circuit for Fast-mode Plus (Fm+).

When this bit is set to 1, a slope control circuit conforming to the I^2C bus Fast-mode Plus (Fm+) standard (tof) is selected. When this bit is set to 0, a slope control circuit conforming to the I^2C bus Standard-mode (Sm) and Fast-mode (Fm) standards (tof) is selected.

Set this bit to 1 when using transmission rates up to 1 Mbps (Fast-mode Plus (Fm+) standard). Set it to 0 when using other transmission rates (up to 100 kbps (Sm) or up to 400 kbps (Fm)) or for SMBus (10 to 100 kbps).

29.2.7 ICSER : I²C Bus Status Enable Register

Base address: IICn = 0x4025_E000 + 0x0100 × n (n = 0 to 1)
IICn_NS = 0x5025_E000 + 0x0100 × n (n = 0 to 1)

Offset address: 0x06

Bit position:	7	6	5	4	3	2	1	0
Bit field:	HOAE	—	DIDE	—	GCAE	SAR2E	SAR1E	SAR0E
Value after reset:	0	0	0	0	1	0	0	1

Bit	Symbol	Function	R/W
0	SAR0E	Slave Address Register 0 Enable 0: Disable slave address in SARL0 and SARU0 1: Enable slave address in SARL0 and SARU0	R/W
1	SAR1E	Slave Address Register 1 Enable 0: Disable slave address in SARL1 and SARU1 1: Enable slave address in SARL1 and SARU1	R/W
2	SAR2E	Slave Address Register 2 Enable 0: Disable slave address in SARL2 and SARU2 1: Enable slave address in SARL2 and SARU2	R/W
3	GCAE	General Call Address Enable 0: Disable general call address detection 1: Enable general call address detection	R/W
4	—	This bit is read as 0. The write value should be 0.	R/W
5	DIDE	Device-ID Address Detection Enable 0: Disable device-ID address detection 1: Enable device-ID address detection	R/W
6	—	This bit is read as 0. The write value should be 0.	R/W
7	HOAE	Host Address Enable 0: Disable host address detection 1: Enable host address detection	R/W

Note: S-TYPE3, P-TYPE3

SARyE bit (Slave Address Register y Enable) (y = 0 to 2)

The SARyE bit enables or disables the received slave address and the slave address set in SARLy and SARUy.

When this bit is set to 1, the slave address set in SARLy and SARUy is enabled and is compared with the received slave address. When this bit is set to 0, the slave address set in SARLy and SARUy is disabled and is ignored even if it matches the received slave address.

GCAE bit (General Call Address Enable)

The GCAE bit specifies whether to ignore the general call address (0000 000b + 0 [W]: All 0) when it is received.

When this bit is set to 1, if the received slave address matches the general call address, the IIC recognizes the received slave address as the general call address independently of the slave addresses set in SARLy and SARUy (y = 0 to 2) and performs the data receive operation. When this bit is set to 0, the received slave address is ignored even if it matches the general call address.

DIDE bit (Device-ID Address Detection Enable)

The DIDE bit specifies whether to recognize and execute the device-ID address when a device ID (1111 100b) is received in the first frame after a start or restart condition is detected.

When this bit is set to 1, if the received first frame matches the device ID, the IIC recognizes that the device-ID address was received. When the next R/W# bit is 0 (W), the IIC recognizes the second and the subsequent frames as slave addresses and continues the receive operation. When this bit is set to 0, the IIC ignores the received first frame even if it matches the device-ID address, and it recognizes the first frame as a normal slave address.

For details on this function, see section 29.7.3. Device-ID Address Detection.

HOAE bit (Host Address Enable)

The HOAE bit specifies whether to ignore the received host address (0001 000b) when the SMBS bit in ICMR3 is 1.

When this bit is set to 1 while the SMBS bit in ICMR3 is 1, if the received slave address matches the host address, the IIC recognizes the received slave address as the host address independently of the slave addresses set in SARLy and SARUy (y = 0 to 2) and performs the receive operation.

When the SMBS bit in ICMR3 or the HOAE bit is set to 0, the received slave address is ignored even if it matches the host address.

29.2.8 ICIER : I²C Bus Interrupt Enable Register

Base address: IICn = 0x4025_E000 + 0x0100 × n (n = 0 to 1)
IICn_NS = 0x5025_E000 + 0x0100 × n (n = 0 to 1)

Offset address: 0x07

Bit position:	7	6	5	4	3	2	1	0
Bit field:	TIE	TEIE	RIE	NAKIE	SPIE	STIE	ALIE	TMOIE
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	TMOIE	Timeout Interrupt Request Enable 0: Disable timeout interrupt (TMOI) request 1: Enable timeout interrupt (TMOI) request	R/W
1	ALIE	Arbitration-Lost Interrupt Request Enable 0: Disable arbitration-lost interrupt (ALI) request 1: Enable arbitration-lost interrupt (ALI) request	R/W
2	STIE	Start Condition Detection Interrupt Request Enable 0: Disable start condition detection interrupt (STI) request 1: Enable start condition detection interrupt (STI) request	R/W
3	SPIE	Stop Condition Detection Interrupt Request Enable 0: Disable stop condition detection interrupt (SPI) request 1: Enable stop condition detection interrupt (SPI) request	R/W
4	NAKIE	NACK Reception Interrupt Request Enable 0: Disable NACK reception interrupt (NAKI) request 1: Enable NACK reception interrupt (NAKI) request	R/W
5	RIE	Receive Data Full Interrupt Request Enable 0: Disable receive data full interrupt (IICn_RXI) request 1: Enable receive data full interrupt (IICn_RXI) request	R/W
6	TEIE	Transmit End Interrupt Request Enable 0: Disable transmit end interrupt (IICn_TEI) request 1: Enable transmit end interrupt (IICn_TEI) request	R/W
7	TIE	Transmit Data Empty Interrupt Request Enable 0: Disable transmit data empty interrupt (IICn_TXI) request 1: Enable transmit data empty interrupt (IICn_TXI) request	R/W

Note: S-TYPE3, P-TYPE3

TMOIE bit (Timeout Interrupt Request Enable)

The TMOIE bit enables or disables timeout interrupt (TMOI) requests when the TMOF flag in ICSR2 is 1. To cancel a TMOI interrupt request, set the TMOF flag or the TMOIE bit to 0.

ALIE bit (Arbitration-Lost Interrupt Request Enable)

The ALIE bit enables or disables arbitration-lost interrupt (ALI) requests when the AL flag in ICSR2 is 1. To cancel an ALI interrupt request, set the AL flag or the ALIE bit to 0.

STIE bit (Start Condition Detection Interrupt Request Enable)

The STIE bit enables or disables start condition detection interrupt (STI) requests when the START flag in ICSR2 is 1. To cancel an STI interrupt request, set the START flag or the STIE bit to 0.

SPIE bit (Stop Condition Detection Interrupt Request Enable)

The SPIE bit enables or disables stop condition detection interrupt (SPI) requests when the STOP flag in ICSR2 is 1. To cancel an SPI interrupt request, set the STOP flag or the SPIE bit to 0.

NAKIE bit (NACK Reception Interrupt Request Enable)

The NAKIE bit enables or disables NACK reception interrupt (NAKI) requests when the NACKF flag in ICSR2 is 1. To cancel an NAKI interrupt request, set the NACKF flag or the NAKIE bit to 0.

RIE bit (Receive Data Full Interrupt Request Enable)

The RIE bit enables or disables receive data full interrupt (IICn_RXI) requests when the RDRF flag in ICSR2 is 1.

TEIE bit (Transmit End Interrupt Request Enable)

The TEIE bit enables or disables transmit end interrupt (IICn_TEI) requests when the TEND flag in ICSR2 is 1. To cancel an IICn_TEI interrupt request, set the TEND flag or the TEIE bit to 0.

TIE bit (Transmit Data Empty Interrupt Request Enable)

The TIE bit enables or disables transmit data empty interrupt (IICn_TXI) requests when the TDRE flag in ICSR2 is 1.

29.2.9 ICSR1 : I2C Bus Status Register 1

Base address: IICn = 0x4025_E000 + 0x0100 × n (n = 0 to 1)
IICn_NS = 0x5025_E000 + 0x0100 × n (n = 0 to 1)

Offset address: 0x08

Bit position:	7	6	5	4	3	2	1	0
Bit field:	HOA	—	DID	—	GCA	AAS2	AAS1	AAS0
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	AAS0	Slave Address 0 Detection Flag 0: Slave address 0 not detected 1: Slave address 0 detected	R/(W)*1
1	AAS1	Slave Address 1 Detection Flag 0: Slave address 1 not detected 1: Slave address 1 detected	R/(W)*1
2	AAS2	Slave Address 2 Detection Flag 0: Slave address 2 not detected 1: Slave address 2 detected	R/(W)*1
3	GCA	General Call Address Detection Flag 0: General call address not detected 1: General call address detected	R/(W)*1
4	—	This bit is read as 0. The write value should be 0.	R/W
5	DID	Device-ID Address Detection Flag This bit is set to 1 when the first frame received immediately after a start condition is detected matches a value of (device ID (1111 100b) + 0[W]). 0: Device-ID command not detected 1: Device-ID command detected	R/(W)*1
6	—	This bit is read as 0. The write value should be 0.	R/W

Bit	Symbol	Function	R/W
7	HOA	Host Address Detection Flag This bit is set to 1 when the received slave address matches the host address (0001 000b). 0: Host address not detected 1: Host address detected	R/(W)*1

Note: S-TYPE3, P-TYPE3
Note 1. Only 0 can be written to clear the flag.

AASy flag (Slave Address y Detection flag) (y = 0 to 2)

The AASy flag indicates whether slave address y was detected.

[Setting conditions]

For 7-bit address format (SARUy.FS = 0):

- When the received slave address matches the SVA[6:0] value in SARLy, with the SARyE bit in ICSER set to 1 (slave address y detection enabled).
  The AASy flag is set to 1 on the rising edge of the ninth SCL clock cycle in the frame.

For 10-bit address format: (SARUy.FS = 1):

- When the received slave address matches a value of (11110b + SVA[1:0] in SARUy), and the subsequent address matches the SARLy value, with the SARyE bit in ICSER set to 1 (slave address y detection enabled).
  The AASy flag is set to 1 on the rising edge of the ninth SCL clock cycle in the frame.

[Clearing conditions]

- When 0 is written to the AASy flag after reading AASy = 1
- When a stop condition is detected
- When 1 is written to the IICRST bit in ICCR1 to apply an IIC reset or an internal reset.

For 7-bit address format (SARUy.FS = 0):

- When the received slave address does not match the SVA[6:0] value in SARLy, with the SARyE bit in ICSER set to 1 (slave address y detection enabled).
  The AASy flag is set to 0 on the rising edge of the ninth SCL clock cycle in the frame.

For 10-bit address format (SARUy.FS = 1):

- When the received slave address does not match a value of (11110b + SVA[1:0] in SARUy), with the SARyE bit in ICSER set to 1 (slave address y detection enabled)
  The AASy flag is set to 0 on the rising edge of the ninth SCL clock cycle in the frame.
- When the received slave address matches a value of (11110b + SVA[1:0] in SARUy), and the subsequent address does not match the SARLy value, with the SARyE bit in ICSER set to 1 (slave address y detection enabled).
  The AASy flag is set to 0 on the rising edge of the ninth SCL clock cycle in the frame.

GCA flag (General Call Address Detection Flag)

The GCA flag indicates whether the general call address was detected.

[Setting condition]

- When the received slave address matches the general call address (0000 000b + 0 [W]), with the GCAE bit in ICSER set to 1 (general call address detection enabled).
  The GCA flag is set to 1 on the rising edge of the ninth SCL clock cycle in the frame.

[Clearing conditions]

- When 0 is written to the GCA flag after reading GCA = 1
- When a stop condition is detected
- When the received slave address does not match the general call address (0000 000b + 0 [W]), with the GCAE bit in ICSER set to 1 (general call address detection enabled)
  The GCA flag is set to 0 on the rising edge of the ninth SCL clock cycle in the frame.

- When 1 is written to the IICRST bit in ICCR1 to apply an IIC reset or an internal reset.

DID flag (Device-ID Address Detection Flag)

The DID flag indicates whether the device-ID address was detected.

[Setting condition]

- When the first frame received immediately after a start or restart condition is detected matches a value of (device ID (1111 100b) + 0 [W]), with the DIDE bit in ICSER set to 1 (device-ID address detection enabled).
  The DID flag is set to 1 on the rising edge of the ninth SCL clock cycle in the frame.

[Clearing conditions]

- When 0 is written to the DID flag after reading DID = 1
- When a stop condition is detected
- When the first frame received immediately after a start or restart condition is detected does not match a value of (device ID (1111 100b)), with the DIDE bit in ICSER set to 1 (device-ID address detection enabled)
  The DID flag is set to 0 on the rising edge of the ninth SCL clock cycle in the frame.
- When the first frame received immediately after a start or restart condition is detected matches a value of (device ID (1111 100b) + 0 [W]), and the second frame does not match any slave address from 0 to 2, with the DIDE bit in ICSER set to 1 (device-ID address detection enabled)
  The DID flag is set to 0 on the rising edge of the ninth SCL clock cycle in the frame.
- When 1 is written to the IICRST bit in ICCR1 to apply an IIC reset or an internal reset.

HOA flag (Host Address Detection Flag)

The HOA flag indicates whether the host address was detected.

[Setting condition]

- When the received slave address matches the host address (0001 000b), with the HOAE bit in ICSER set to 1 (host address detection enabled).
  The HOA flag is set to 1 on the rising edge of the ninth SCL clock cycle in the frame.

[Clearing conditions]

- When 0 is written to the HOA flag after reading HOA = 1
- When a stop condition is detected
- When the received slave address does not match the host address (0001 000b), with the HOAE bit in ICSER set to 1 (host address detection enabled)
  The HOA flag is set to 0 on the rising edge of the ninth SCL clock cycle in the frame.
- When 1 is written to the IICRST bit in ICCR1 to apply an IIC reset or an internal reset.

29.2.10 ICSR2 : I²C Bus Status Register 2

Base address: IICn = 0x4025_E000 + 0x0100 × n (n = 0 to 1)
IICn_NS = 0x5025_E000 + 0x0100 × n (n = 0 to 1)

Offset address: 0x09

Bit position:	7	6	5	4	3	2	1	0
Bit field:	TDRE	TEND	RDRF	NACKF	STOP	START	AL	TMOF
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	TMOF	Timeout Detection Flag 0: Timeout not detected 1: Timeout detected	R/(W)*1

Bit	Symbol	Function	R/W
1	AL	Arbitration-Lost Flag 0: Arbitration not lost 1: Arbitration lost	R/(W)*1
2	START	Start Condition Detection Flag 0: Start condition not detected 1: Start condition detected	R/(W)*1
3	STOP	Stop Condition Detection Flag 0: Stop condition not detected 1: Stop condition detected	R/(W)*1
4	NACKF	NACK Detection Flag 0: NACK not detected 1: NACK detected	R/(W)*1
5	RDRF	Receive Data Full Flag 0: ICDRR contains no receive data 1: ICDRR contains receive data	R/(W)*1
6	TEND	Transmit End Flag 0: Data being transmitted 1: Data transmit complete	R/(W)*1
7	TDRE	Transmit Data Empty Flag 0: ICDRT contains transmit data 1: ICDRT contains no transmit data	R

Note: S-TYPE3, P-TYPE3
Note 1. Only 0 can be written, to clear the flag.

TMOF flag (Timeout Detection Flag)

The TMOF flag is set to 1 when the IIC detects a timeout because the SCLn line state remains unchanged for the set period.

[Setting condition]

- When the SCLn line state remains unchanged for the period specified in the ICMR2.TMOH, TMOL, and TMOS bits while the ICFER.TMOE bit is 1 (timeout function enabled) in master or in slave mode and the received slave address matches.

[Clearing conditions]

- When 0 is written to the TMOF flag after reading TMOF = 1
- When 1 is written to the IICRST bit in ICCR1 to apply an IIC reset or an internal reset.

AL flag (Arbitration-Lost Flag)

The AL flag indicates that bus mastership was lost in arbitration because of a bus conflict or some other reason when a start condition was issued or an address and data was transmitted. The IIC monitors the level on the SDAn line during transmission and, if the level on the line does not match the value of the bit being output, is set the value of the AL flag to 1 to indicate that the bus is occupied by another device.

The IIC can also set the AL flag to indicate the detection of arbitration loss during NACK transmission or during data transmission.

[Setting conditions]

When master arbitration-lost detection is enabled (ICFER.MALE = 1):

- When the internal SDA output state does not match the SDAn line level on the rising edge of the SCL clock except for the ACK period during data transmission in master transmit mode
- When a start condition is detected while the ST bit in ICCR2 is 1 (start condition requested) or the internal SDA output state does not match the SDAn line level
- When the ST bit in ICCR2 is 1 (start condition requested), with the BBSY flag in ICCR2 set to 1.

When NACK arbitration-lost detection is enabled (ICFER.NALE = 1):

- When the internal SDA output state does not match the SDAn line level on the rising edge of the SCL clock in the ACK period during NACK transmission in receive mode.

When slave arbitration-lost detection is enabled (ICFER.SALE = 1):

- When the internal SDA output state does not match the SDAn line level on the rising edge of the SCL clock, except for the ACK period during data transmission in slave transmit mode.

[Clearing conditions]

- When 0 is written to the AL flag after reading AL = 1
- When 1 is written to the IICRST bit in ICCR1 to apply an IIC reset or an internal reset.

Table 29.4 Relationship between arbitration-lost generation sources and arbitration-lost enable functions

ICFER			ICSR2		
MALE	NALE	SALE	AL	Error	Arbitration-lost generation source
1	x	x	1	Start condition issuance error	When internal SDA output state does not match SDAn line level when a start condition is detected, while the ST bit in ICCR2 is 1
					When ST in ICCR2 is set to 1 while BBSY in ICCR2 is 1
			1	Transmit data mismatch	When transmit data (including slave address) does not match the bus state in master transmit mode
x	1	x	1	NACK transmission mismatch	When ACK is detected during transmission of NACK in master or slave receive mode
x	x	1	1	Transmit data mismatch	When transmit data does not match the bus state in slave transmit mode

x: Don’t care

START flag (Start Condition Detection Flag)

The START flag indicates whether a start or restart condition was detected.

[Setting condition]

- When a start or restart condition is detected.

[Clearing conditions]

- When 0 is written to the START flag after reading START = 1
- When a stop condition is detected
- When 1 is written to the IICRST bit in ICCR1 to apply an IIC reset or an internal reset.

STOP flag (Stop Condition Detection Flag)

The STOP flag indicates whether a stop condition was detected.

[Setting condition]

- When a stop condition is detected.

[Clearing conditions]

- When 0 is written to the STOP flag after reading STOP = 1
- When 1 is written to the IICRST bit in ICCR1 to apply an IIC reset or an internal reset.

NACKF flag (NACK Detection Flag)

The NACKF flag indicates whether a NACK was detected.

[Setting condition]

- When acknowledge is not received (NACK received) from the receive device in transmit mode, with the NACKE bit in ICFER set to 1 (transfer suspension enabled).

[Clearing conditions]

- When 0 is written to the NACKF flag after reading NACKF = 1
- When 1 is written to the IICRST bit in ICCR1 to apply an IIC reset or an internal reset.

Note: When the NACKF flag is set to 1, the IIC suspends data transmission and reception. Writing to ICDRT in transmit mode or reading from ICDRR in receive mode with the NACKF flag set to 1 does not enable data transmit or receive operation. To restart data transmission or reception, set the NACKF flag to 0.

RDRF flag (Receive Data Full Flag)

The RDRF flag indicates whether the ICDRR contains receive data.

[Setting conditions]

- When receive data is transferred from ICDRS to ICDRR
  The RDRF flag is set to 1 on the rising edge of the eighth or ninth SCL clock cycle (selected in the RDRFS bit in ICMR3).
- When the received slave address matches after a start or restart condition is detected with the TRS bit in ICCR2 set to 0.

[Clearing conditions]

- When 0 is written to the RDRF flag after reading RDRF = 1
- When data is read from ICDRR
- When 1 is written to the IICRST bit in ICCR1 to apply an IIC reset or an internal reset.

TEND flag (Transmit End Flag)

The TEND flag indicates completion of transmission.

[Setting condition]

- On the rising edge of the ninth SCL clock cycle while the TDRE flag is 1.

[Clearing conditions]

- When 0 is written to the TEND flag after reading TEND = 1
- When data is written to ICDRT
- When a stop condition is detected
- When 1 is written to the IICRST bit in ICCR1 to apply an IIC reset or an internal reset.

TDRE flag (Transmit Data Empty Flag)

The TDRE flag indicates whether the ICDRT contains transmit data.

[Setting conditions]

- When data is transferred from ICDRT to ICDRS and ICDRT becomes empty
- When the TRS bit in ICCR2 is set to 1
- When the received slave address matches while the TRS bit is 1.

[Clearing conditions]

- When data is written to ICDRT
- When the TRS bit in ICCR2 is set to 0
- When 1 is written to the IICRST bit in ICCR1 to apply an IIC reset or an internal reset.

Note: When the NACKF flag is set to 1 while the NACKE bit in ICFER is 1, the IIC suspends data transmission and reception. In this case, if the TDRE flag is 0 (next transmit data written), data is transferred to the ICDRS register and the ICDRT register becomes empty on the rising edge of the 9th clock cycle, but the TDRE flag does not set to 1.

29.2.11 ICWUR : I2C Bus Wakeup Unit Register

Base address: IIC0WU = 0x4025_E014
IIC0WU_NS = 0x5025_E014

Offset address: 0x02

Bit position:	7	6	5	4	3	2	1	0
Bit field:	WUE	WUIE	WUF	WUACK	—	—	—	WUAFA
Value after reset:	0	0	0	1	0	0	0	0

Bit	Symbol	Function	R/W
0	WUAFA	Wakeup Analog Filter Additional Selection 0: Do not add the wakeup analog filter 1: Add the wakeup analog filter	R/W
3:1	—	These bits are read as 0. The write value should be 0.	R/W
4	WUACK	ACK Bit for Wakeup Mode Choice of four response modes in combination with ICCR1.IICRST and WUACK. See Table 29.5.	R/W
5	WUF	Wakeup Event Occurrence Flag 0: Slave address not matching during wakeup 1: Slave address matching during wakeup	R/W
6	WUIE	Wakeup Interrupt Request Enable 0: Disable wakeup interrupt request (IIC0_WUI) 1: Enable wakeup interrupt request (IIC0_WUI)	R/W
7	WUE	Wakeup Function Enable 0: Disable wakeup function 1: Enable wakeup function	R/W

Note: S-TYPE3, P-TYPE3

Table 29.5 Wakeup mode

IICRST	WUACK	Operation mode	Description
0	0	Normal wakeup mode 1	ACK response on 9th SCL, and SCL low-hold after 9th SCL.
0	1	Normal wakeup mode 2	No ACK response immediately and SCL low-hold between 8th and 9th SCL. SCL low-hold release and ACK response on 9th SCL.
1	0	Command recovery mode	ACK response on 9th SCL and no SCL low-hold.
1	1	EEP response mode	NACK response on 9th SCL and no SCL low-hold.

WUF flag (Wakeup Event Occurrence Flag)

The WUF flag indicates whether the slave address is matching during wakeup.

[Setting condition]

- When PCLKB is supplied after the slave address of I2C bus is matched with the address whose enable bits of ICSER (except Device ID address) are set to 1 (enable), the bit is set.

[Clearing conditions]

- When 0 is written to the WUF flag after reading WUF = 1 (when WUSYF flag is set to 1).
- When ICCR1.ICE = 0 and IICRST = 1.

29.2.12 ICWUR2 : I2C Bus Wakeup Unit Register 2

Base address: IIC0WU = 0x4025_E014
IIC0WU_NS = 0x5025_E014

Offset address: 0x03

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	WUSYF	WUASYF	WUSEN
Value after reset:	1	1	1	1	1	1	0	1

Bit	Symbol	Function	R/W
0	WUSEN	Wakeup Function Synchronous Enable 0: IIC asynchronous circuit enable 1: IIC synchronous circuit enable	R/W
1	WUASYF	Wakeup Function Asynchronous Operation Status Flag 0: IIC synchronous circuit enable condition 1: IIC asynchronous circuit enable condition	R
2	WUSYF	Wakeup Function Synchronous Operation Status Flag 0: IIC asynchronous circuit enable condition 1: IIC synchronous circuit enable condition	R
7:3	—	These bits are read as 1. The write value should be 1.	R/W

Note: S-TYPE3, P-TYPE3

WUSEN bit (Wakeup Function Synchronous Enable)

The WUSEN bit is used in combination with the WUASYF flag (or WUSYF flag) to switch between the PCLKB synchronous and asynchronous operation, when the wakeup effective function is enabled (ICWUR.WUE = 1).

The PCLKB operation switches from synchronous to asynchronous operation:

When the ICCR2.BBSY flag is 0, if 0 is written to the WUSEN bit while the WUASYF flag is 0, the reception occurs independently of the operation of PCLKB (with PCLKB stopped) after it switches to the PCLKB asynchronous operation, on wakeup event detection.

The PCLKB operation switches from asynchronous to synchronous operation:

- When 1 is written to the WUSEN bit, with the WUASYF flag at 1, when a wakeup event is detected. After writing 1, the WUASYF flag immediately becomes 0.
- When the stop condition is detected with a wakeup event undetected.

[Setting condition]

- When 1 is written to the WUSEN bit.
- ICCR1.ICE = 0 and IICRST = 1 (IIC reset)
- ICWUR.WUE = 0

[Clearing conditions]

- When 0 is written to the WUSEN bit.

WUASYF flag (Wakeup Function Asynchronous Operation Status Flag)

The WUASYF flag can place the IIC in PCLKB asynchronous operation when the wakeup effective function is enabled (ICWUR.WUE = 1).

[Setting condition]

- When the ICCR2.BBSY flag is 0, and the WUSEN bit is set to 0 with the ICWUR.WUE bit set to 1.

[Clearing conditions]

- When 1 is written to the WUSEN bit after detecting the wake-up event with ICWUR.WUE bit set to 1.

- When a stop condition is detected with WUSEN bit set to 1 before detecting the wake-up event with WUASY flag set to 1 with ICWUR.WUE bit set to 1.
- When you write 1 in the WUSEN bit with the WUASYF flag detected 1 and the wake-up event in the state of ICWUR.WUE = 1.
- ICCR1.ICE = 0 and ICCRST = 1 (ICC reset)
- ICWUR.WUE = 0.

WUSYF flag (Wakeup Function Synchronous Operation Status Flag)

It is shown that IIC is in the PCLKB synchronous operation at wake-up effective function (ICWUR.WUE = 1). This flag is a value in which the WUASYF flag is always reserved.

[Setting conditions]

- When 1 is written to the WUSEN bit after detecting the wake-up event with ICWUR.WUE bit set to 1 with WUSYF flag set to 0 with ICWUR.WUE bit set to 1.
- When a stop condition is detected with WUSEN bit set to 1 before detecting the wake-up event with WUSYF flag set to 0 with ICWUR.WUE bit set to 1.
- ICCR1.ICE = 0 and ICCRST = 1 (ICC reset)
- ICWUR.WUE = 0.

[Clearing condition]

- When the ICCR2.BBSY flag is 0 with the ICWUR.WUE bit set to 1 after writing 0 to the WUSEN bit.

29.2.13 SARLy : Slave Address Register Ly (y = 0 to 2)

Base address: IICn = 0x4025_E000 + 0x0100 × n (n = 0 to 1)
IICn_NS = 0x5025_E000 + 0x0100 × n (n = 0 to 1)

Offset address: 0x0A + 0x02 × y

Bit position:	7	6	5	4	3	2	1	0
Bit field:	SVA[6:0]							SVA0
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	SVA0	10-bit Address LSB Slave address setting.	R/W
7:1	SVA[6:0]	7-bit Address/10-bit Address Lower Bits Slave address setting.	R/W

Note: S-TYPE3, P-TYPE3

SVA0 bit (10-bit Address LSB)

When the 10-bit address format is selected (SARUy.FS = 1), the SVA0 bit functions as the LSB of a 10-bit address and is combined with the SVA[6:0] bits to form the lower 8 bits of a 10-bit address.

This bit is valid when the SARyE bit in ICSER is set to 1 (SARLy and SARUy enabled) and the SARUy.FS bit is 1. When the SARUy.FS or SARyE bit is 0, the setting in this bit is ignored.

SVA[6:0] bits (7-bit Address/10-bit Address Lower Bits)

When the 7-bit address format is selected (SARUy.FS = 0), the SVA[6:0] bits function as a 7-bit address. When the 10-bit address format is selected (SARUy.FS = 1), these bits combine with the SVA0 bit to form the lower 8 bits of a 10-bit address.

When the SARyE bit in ICSER is 0, the setting in these bits is ignored.

29.2.14 SARUy : Slave Address Register Uy (y = 0 to 2)

Base address: IICn = 0x4025_E000 + 0x0100 × n (n = 0 to 1)
IICn_NS = 0x5025_E000 + 0x0100 × n (n = 0 to 1)

Offset address: 0x0B + 0x02 × y

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	SVA[1:0]		FS
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	FS	7-bit/10-bit Address Format Select 0: Select 7-bit address format 1: Select 10-bit address format	R/W
2:1	SVA[1:0]	10-bit Address Upper Bits Slave address setting.	R/W
7:3	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE3, P-TYPE3

FS bit (7-bit/10-bit Address Format Select)

The FS bit selects 7- or 10-bit format for slave address y (in SARLy and SARUy).

When the SARyE bit in ICSER is set to 1 (SARLy and SARUy enabled) and the SARUy.FS bit is 0, the 7-bit address format is selected for slave address y, the SVA[6:0] setting in SARLy is valid, and the SVA[1:0] and SVA0 settings in SARLy are ignored.

When the SARyE bit in ICSER is set to 1 (SARLy and SARUy enabled) and the SARUy.FS bit is 1, the 10-bit address format is selected for slave address y and the SVA[1:0] and SARLy settings are valid.

When the SARyE bit in ICSER is 0 (SARLy and SARUy disabled), the SARUy.FS setting is invalid.

SVA[1:0] bits (10-bit Address Upper Bits)

When the 10-bit address format is selected (FS = 1), the SVA[1:0] bits function as the upper 2 bits of a 10-bit address.

These bits are valid when the SARyE bit in ICSER is set to 1 (SARLy and SARUy enabled) and the SARUy.FS bit is 1. When the SARUy.FS or SARyE bit is 0, the setting in these bits is ignored.

29.2.15 ICBRL : I2C Bus Bit Rate Low-Level Register

Base address: IICn = 0x4025_E000 + 0x0100 × n (n = 0 to 1)
IICn_NS = 0x5025_E000 + 0x0100 × n (n = 0 to 1)

Offset address: 0x10

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	BRL[4:0]				
Value after reset:	1	1	1	1	1	1	1	1

Bit	Symbol	Function	R/W
4:0	BRL[4:0]	Bit Rate Low-Level Period Low-level period of SCL clock.	R/W
7:5	—	These bits are read as 1. The write value should be 1.	R/W

Note: S-TYPE3, P-TYPE3

BRL[4:0] bits (Bit Rate Low-Level Period)

The BRL[4:0] bits set the low-level period of the SCL clock. ICBRL counts the low-level period with the internal reference clock source (IICφ) specified by the CKS[2:0] bits in ICMR1. ICBRL also generates the data setup time for automatic SCL

low-hold operation, see section 29.9. Automatic Low-Hold Function for SCL. When the IIC is used in slave mode, the BRL[4:0] bits must be set to a value longer than the data setup time*1.

If the digital noise filter is enabled (NFE bit in ICFER is 1), set the BRL[4:0] bits to a value at least one greater than the number of stages in the noise filter. For details on the number of stages, see the description of the NF[1:0] bits in section 29.2.5. ICMR3 : I2C Bus Mode Register 3.

Note 1. Data setup time (t_{SU}: DAT)

250 ns for up to 100 kbps: Standard-mode (Sm)

100 ns for up to 400 kbps: Fast-mode (Fm)

50 ns for up to 1 Mbps: Fast-mode Plus (Fm+)

29.2.16 ICBRH : I2C Bus Bit Rate High-Level Register

Base address: IICn = 0x4025_E000 + 0x0100 × n (n = 0 to 1)
IICn_NS = 0x5025_E000 + 0x0100 × n (n = 0 to 1)

Offset address: 0x11

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	BRH[4:0]				
Value after reset:	1	1	1	1	1	1	1	1

Bit	Symbol	Function	R/W
4:0	BRH[4:0]	Bit Rate High-Level Period High-level period of SCL clock.	R/W
7:5	—	These bits are read as 1. The write value should be 1.	R/W

Note: S-TYPE3, P-TYPE3

BRH[4:0] bits (Bit Rate High-Level Period)

The BRH[4:0] bits set the high-level period of SCL clock. BRH[4:0] bits are valid in master mode. If the IIC is used only in slave mode, do not set the BRH[4:0] bits.

ICBRH counts the high-level period with the internal reference clock source (IICφ) specified in the CKS[2:0] bits in ICMR1.

If the digital noise filter is enabled (the NFE bit in ICFER is 1), set these bits to a value at least one greater than the number of stages in the noise filter. For the number of stages in the noise filter, see the description of the NF[1:0] bits in section 29.2.5. ICMR3 : I2C Bus Mode Register 3.

The IIC transfer rate and the SCL clock duty are calculated using the following expressions (1) to (5):

1. ICFER.SCLE = 0
   Transfer rate = 1/[{(BRH + 1) + (BRL + 1)}/IICφ*1 + tr*2 + tf*2]
   Duty cycle = [tr + {(BRH + 1)/IICφ}]/[tr + tf + {(BRH + 1) + (BRL + 1)}/IICφ]
2. ICFER.SCLE = 1 and ICFER.NFE = 0 and CKS[2:0] = 000b (IICφ = PCLKB)
   Transfer rate = 1/[{(BRH + 3) + (BRL+ 3)}/IICφ + tr + tf]
   Duty cycle = [tr + {(BRH + 3)/IICφ}]/[tr + tf + {(BRH + 3) + (BRL + 3)}/IICφ]
3. ICFER.SCLE = 1 and ICFER.NFE = 1 and CKS[2:0] = 000b (IICφ = PCLKB)
   Transfer rate = 1/[{(BRH + 3 + nf*3) + (BRL + 3 + nf)}/IICφ + tr + tf]
   Duty cycle = [tr + {(BRH + 3 + nf)/IICφ}]/[tr + tf + {(BRH + 3 + nf) + (BRL + 3 + nf)}/IICφ]
4. ICFER.SCLE = 1 and ICFER.NFE = 0 and CKS[2:0] ≠ 000b
   Transfer rate = 1/[{(BRH + 2) + (BRL + 2)}/IICφ + tr + tf]
   Duty cycle = [tr + {(BRH + 2)/IICφ}]/[tr + tf + {(BRH + 2) + (BRL + 2)}/IICφ]
5. ICFER.SCLE = 1 and ICFER.NFE = 1 and CKS[2:0] ≠ 000b
   Transfer rate = 1/[{(BRH + 2 + nf) + (BRL + 2 + nf)}/IICφ + tr + tf]
   Duty cycle = [tr + {(BRH + 2 + nf)/IICφ}]/[tr + tf + {(BRH + 2 + nf) + (BRL + 2 + nf)}/IICφ]

Note 1. IICφ = PCLKB × division ratio
Note 2. The SCLn line rise time (tr) and SCLn line fall time (tf) depend on the total bus line capacitance (Cb) and the pull-up resistor (Rp). For details, see the I2C bus standard from NXP Semiconductors.
Note 3. nf = Number of digital noise filters selected in the ICMR3.NF bit.

Table 29.6 Example of ICBRH/ICBRL Settings for Transfer Rate IIC when SCLE = 0

Transfer rate (kbps)	CKS[2:0] (ICMR1)	BRH[4:0] (ICBRH)	BRL[4:0] (ICBRL)	PCLKB (MHz)	NF[1:0]	Computation expression
100	100b	14 (0xEE)	17 (0xF1)	60	—	(1)
400	010b	8 (0xE8)	19 (0xF3)	60	—	(1)
1000	000b	15 (0xEF)	29 (0xFD)	60	—	(1)

Table 29.7 Example of ICBRH/ICBRL Settings for Transfer Rate when SCLE = 1 and NFE = 0

29.2.17 ICDRT : I2C Bus Transmit Data Register

Base address: IICn = 0x4025_E000 + 0x0100 × n (n = 0 to 1)
IICn_NS = 0x5025_E000 + 0x0100 × n (n = 0 to 1)

Offset address: 0x12

Bit position:	7	6	5	4	3	2	1	0
Bit field:								
Value after reset:	1	1	1	1	1	1	1	1

When ICDRT detects a space in the I2C Bus Shift Register (ICDRS), it transfers the transmit data that was written to ICDRT to ICDRS and starts transmitting data in transmit mode. The double-buffer structure of ICDRT and ICDRS allows continuous transmit operation if the next transmit data is written to ICDRT while the ICDRS data is being transmitted.

ICDRT can always be read and written to. Write transmit data to ICDRT once when a transmit data empty interrupt (IICn_TXI) request is generated.

29.2.18 ICDRR : I2C Bus Receive Data Register

Base address: IICn = 0x4025_E000 + 0x0100 × n (n = 0 to 1)
IICn_NS = 0x5025_E000 + 0x0100 × n (n = 0 to 1)

Offset address: 0x13

Bit position:	7	6	5	4	3	2	1	0
Bit field:								
Value after reset:	0	0	0	0	0	0	0	0

When 1 byte of data is received, the received data is transferred from the I2C Bus Shift Register (ICDRS) to ICDRR to enable the next data to be received. The double-buffer structure of ICDRS and ICDRR allows continuous receive operation if the received data is read from ICDRR while ICDRS is receiving data. ICDRR cannot be written to. Read data from ICDRR once when a receive data full interrupt (IICn_RXI) request is generated.

If ICDRR receives the next receive data before the current data is read from ICDRR (while the RDRF flag in ICSR2 is 1), the IIC automatically holds the SCL clock low 1 cycle before the RDRF flag is set to 1 next.

29.2.19 ICDRS : I2C Bus Shift Register

Base address: n/a

Offset address: n/a

Bit position:	7	6	5	4	3	2	1	0
Bit field:								
Value after reset:	—	—	—	—	—	—	—	—

ICDRS is an 8-bit shift register for data transmit and receive. During transmission, transmit data is transferred from ICDRT to ICDRS and is transmitted from the SDAn pin. During reception, data is transferred from ICDRS to ICDRR after 1 byte of data is received. ICDRS cannot be accessed directly.

29.3 Operation

29.3.1 Communication Data Format

The I2C bus format consists of 8-bit data and 1-bit acknowledge. The frame following a start or restart condition is an address frame that specifies a slave device with which the master device communicates. The specified slave is valid until a new slave is specified or a stop condition is issued.

Figure 29.3 shows the I2C bus format, and Figure 29.4 shows the I2C bus timing.

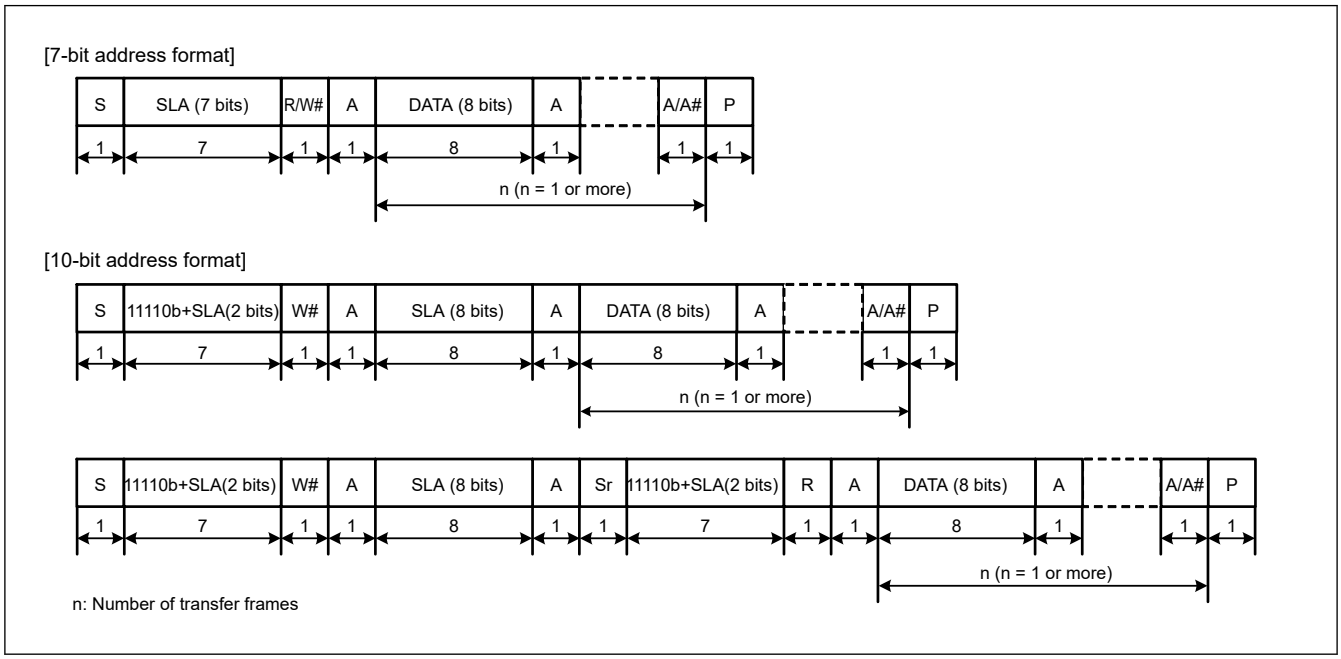

Figure 29.3 I2C bus format

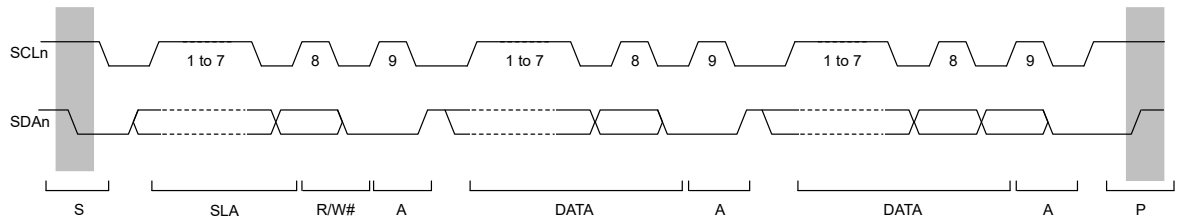


Note: n = 0, 1

Figure 29.4 I²C bus timing when the SLA setting = 7 bits

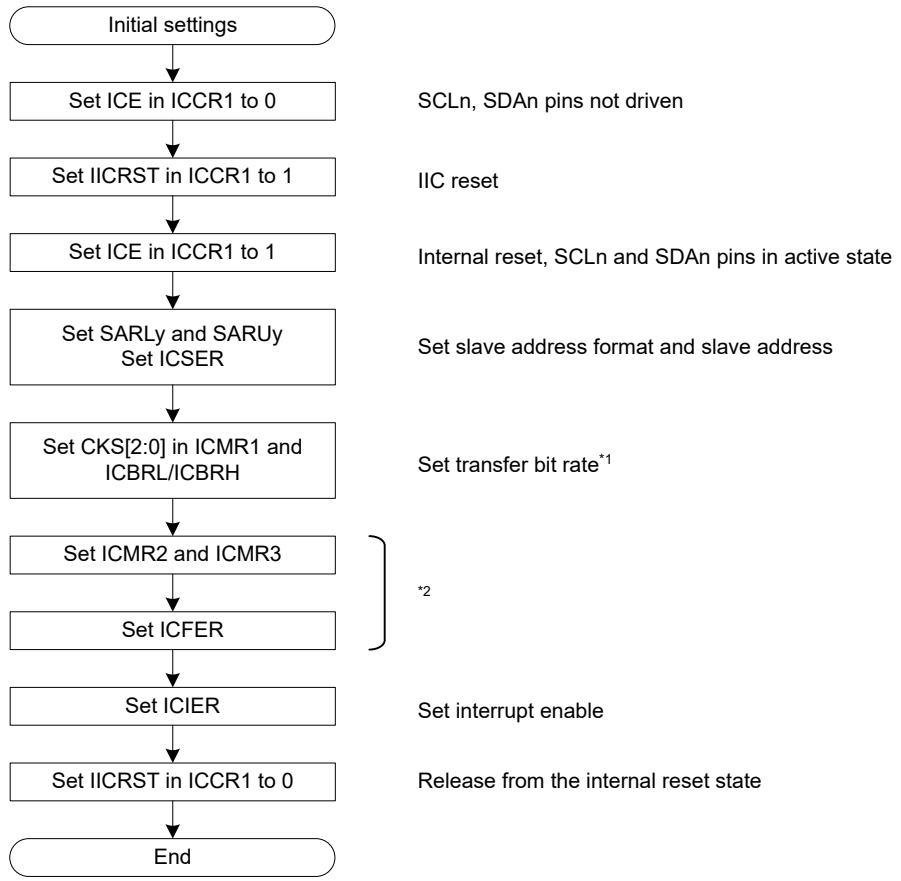
S:	Start condition. The master device drives the SDAn line low from high while the SCLn line is high.
SLA:	Slave address, by which the master device selects a slave device.
R/W#:	Indicates the direction of data transfer: from the slave device to the master device when R/W# is 1, or from the master device to the slave device when R/W# is 0.
A:	Acknowledge. The receive device drives the SDAn line low. In master transmit mode, the slave device returns acknowledge. In master receive mode, the master device returns acknowledge.
A#:	Not Acknowledge. The receive device drives the SDAn line high.
Sr:	Restart condition. The master device drives the SDAn line low from the high level after the setup time has elapsed with the SCLn line high.
DATA:	Transmitted or received data.
P:	Stop condition. The master device drives the SDAn line high from low while the SCLn line is high.

29.3.2 Initial Settings

Before starting data transmission or reception, initialize the IIC using the procedure shown in Figure 29.5.

1. Set the ICCR1.ICE bit to 0 to set the SCLn and SDAn pins to the inactive state.
2. Set the ICCR1.IICRST bit to 1 to initiate IIC reset.
3. Set the ICCR1.ICE bit to 1 to initiate internal reset.
4. Set the SARLy, SARUy, ICSER, ICMR1, ICBRH, and ICBRL registers (y = 0 to 2), and set the other registers as required. For initial settings of the IIC, see Figure 29.5.
5. When the required register settings are complete, set the ICCR1.IICRST bit to 0 to release the IIC reset.

This procedure is not required if the IIC initialization is already complete.



Note: n = 0, 1, y = 0 to 2
Note 1. When the IIC is used only in slave mode, set the ICBRL register to a value longer than the data setup time.
Note 2. Set these registers as required.

Figure 29.5 Example IIC initialization flow

29.3.3 Master Transmit Operation

In master transmit operation, the IIC outputs the SCL clock and transmitted data signals as the master device, and the slave device returns acknowledgments. Figure 29.6 shows an example of master transmission, and Figure 29.7 to Figure 29.9 show the operation timing in master transmission.

To set up and perform master transmission:

1. Process initial settings. For details, see section 29.3.2. Initial Settings.
2. Read the BBSY flag in ICCR2 to check that the bus is free, and then set the ST bit in ICCR2 to 1 (start condition request). On receiving the request, the IIC issues a start condition. At the same time, the BBSY and START flags in ICSR2 automatically set to 1 and the ST bit automatically is set to 0. At this time, if the start condition is detected and the internal levels for the SDA output state and the levels on the SDAn line match while the ST bit is 1, the IIC recognizes that issuance of the start condition as requested by the ST bit is successfully complete, and the MST and TRS bits in ICCR2 automatically set to 1, placing the IIC in master transmit mode. The TDRE flag in ICSR2 also automatically is set to 1 in response to the setting of the TRS bit to 1.
3. Check that the TDRE flag in ICSR2 is 1, and then write the value for transmission (the slave address and the R/W# bit) to ICDRT. When the transmit data is written to ICDRT, the TDRE flag automatically is set to 0, the data is transferred from ICDRT to ICDRS, and the TDRE flag again is set to 1. After the byte containing the slave address and R/W# bit is transmitted, the value of the TRS bit automatically updates to select master transmit or master receive mode based on the value of the transmitted R/W# bit. If the value of the R/W# bit was 0, the IIC continues in master transmit mode.

Because the ICSR2.NACKF flag being 1 at this time indicates that no slave device recognized the address or there was an error in communications, write 1 to the ICCR2.SP bit to issue a stop condition.
For data transmission with an address in the 10-bit format, start by writing 11110b, the 2 higher-order bits of the slave address, and W to ICDRT as the first address transmission. For the second address transmission, write the 8 lower-order bits of the slave address to ICDRT.

4. Check that the TDRE flag in ICSR2 is 1, and then write the transmit data to the ICDRT register. The IIC automatically holds the SCLn line low until the transmit data is ready or a stop condition is issued.
5. After all bytes of transmit data are written to the ICDRT register, wait until the value in the TEND flag in ICSR2 returns to 1, and then set the SP bit in ICCR2 to 1 (stop condition requested). On receiving a stop condition request, the IIC issues the stop condition. Regarding issuing a stop condition, see section 29.11.3. Issuing a Stop Condition.
6. On detecting the stop condition, the IIC automatically sets the MST and TRS bits in ICCR2 to 00b and enters slave receive mode. Additionally, it automatically sets the TDRE and TEND flags to 0, and sets the STOP flag in ICSR2 to 1.
7. Check that the ICSR2.STOP flag is 1, and then set the ICSR2.NACKF and STOP flags to 0 for the next transfer operation.

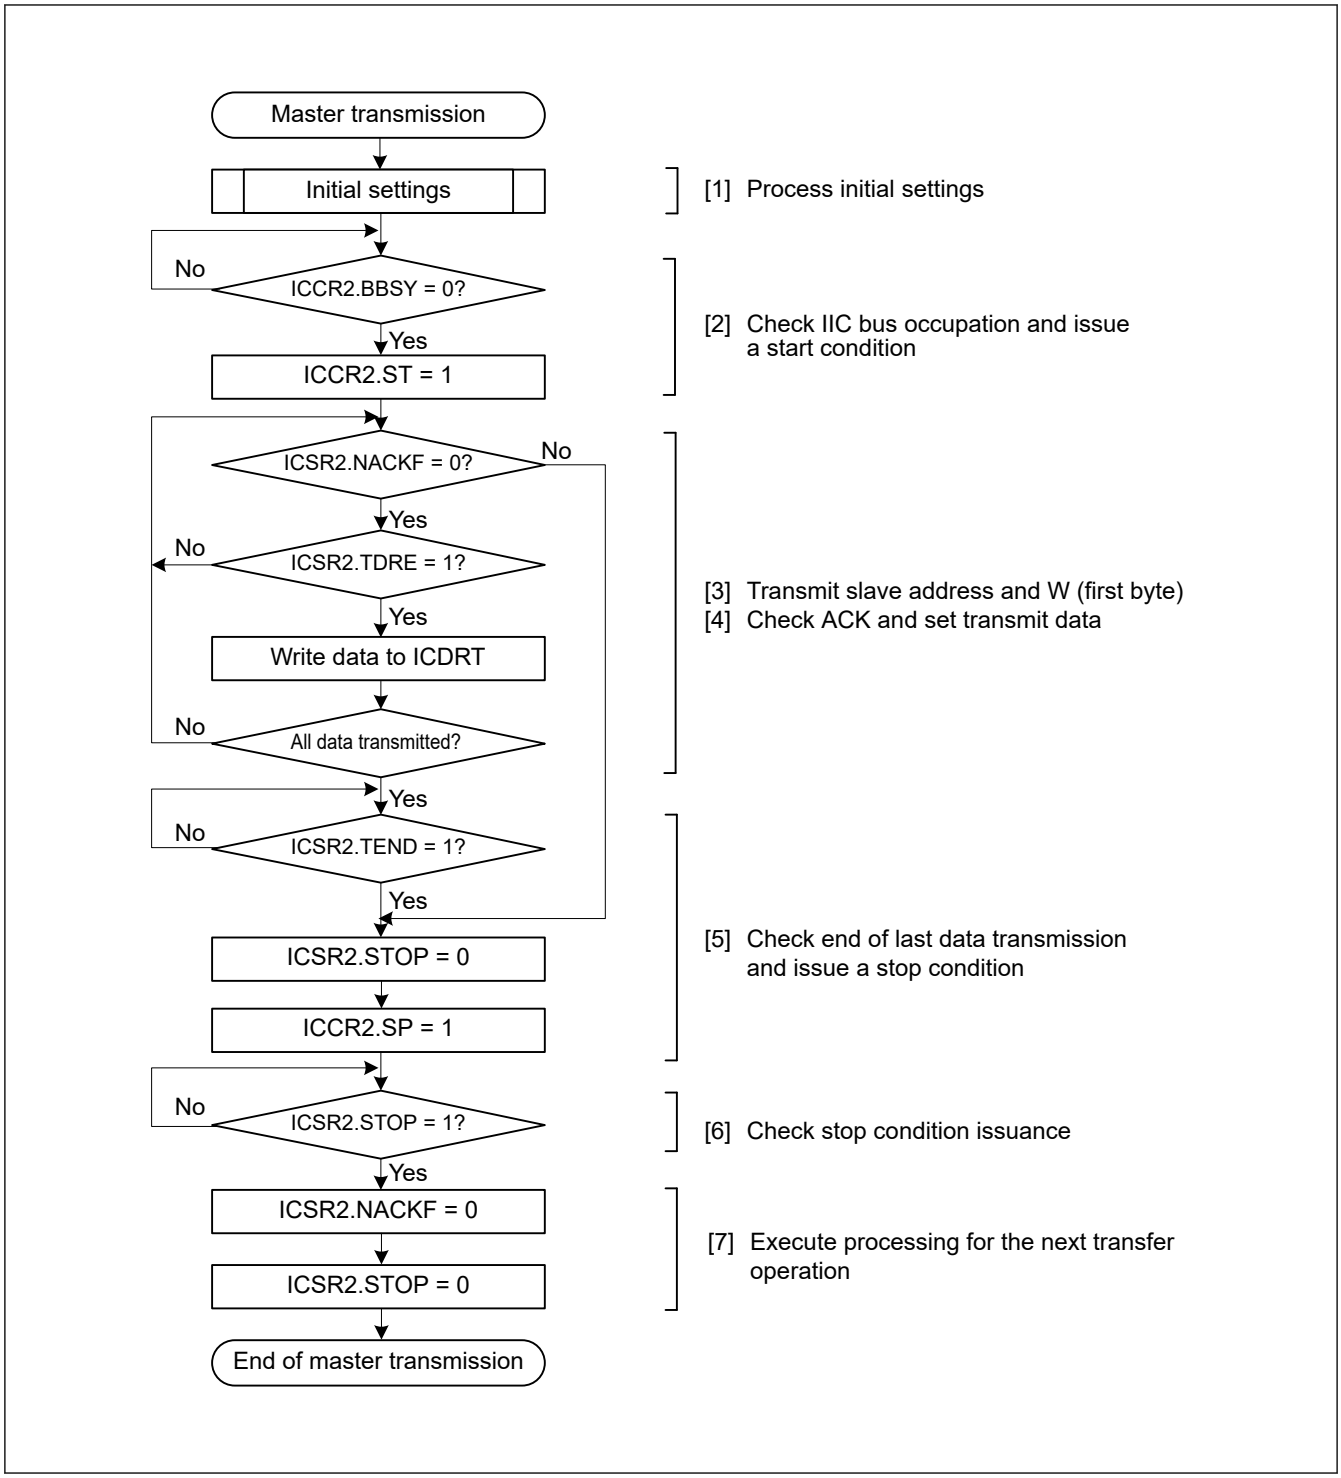


Figure 29.6 Example master transmission flow

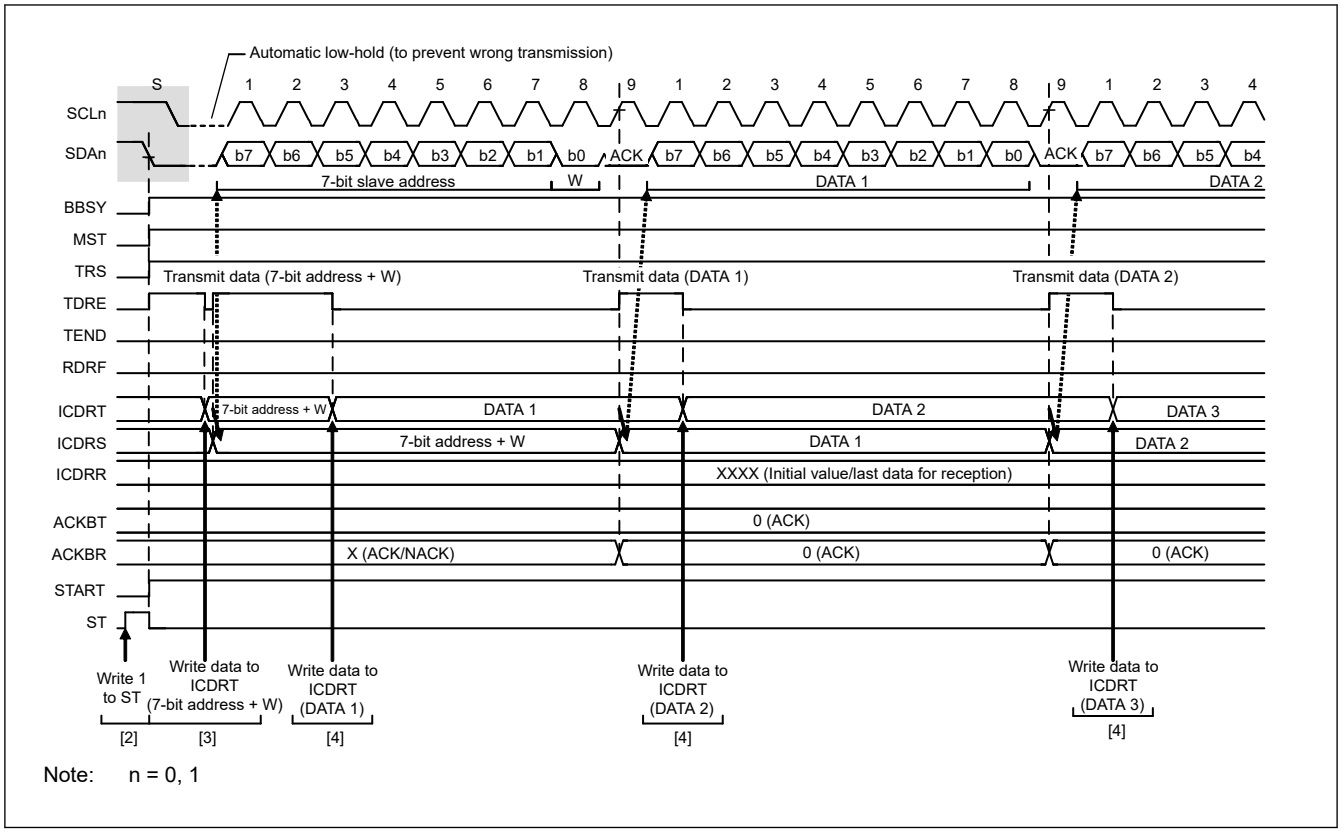

Figure 29.7 Master transmit operation timing (1) with 7-bit address format

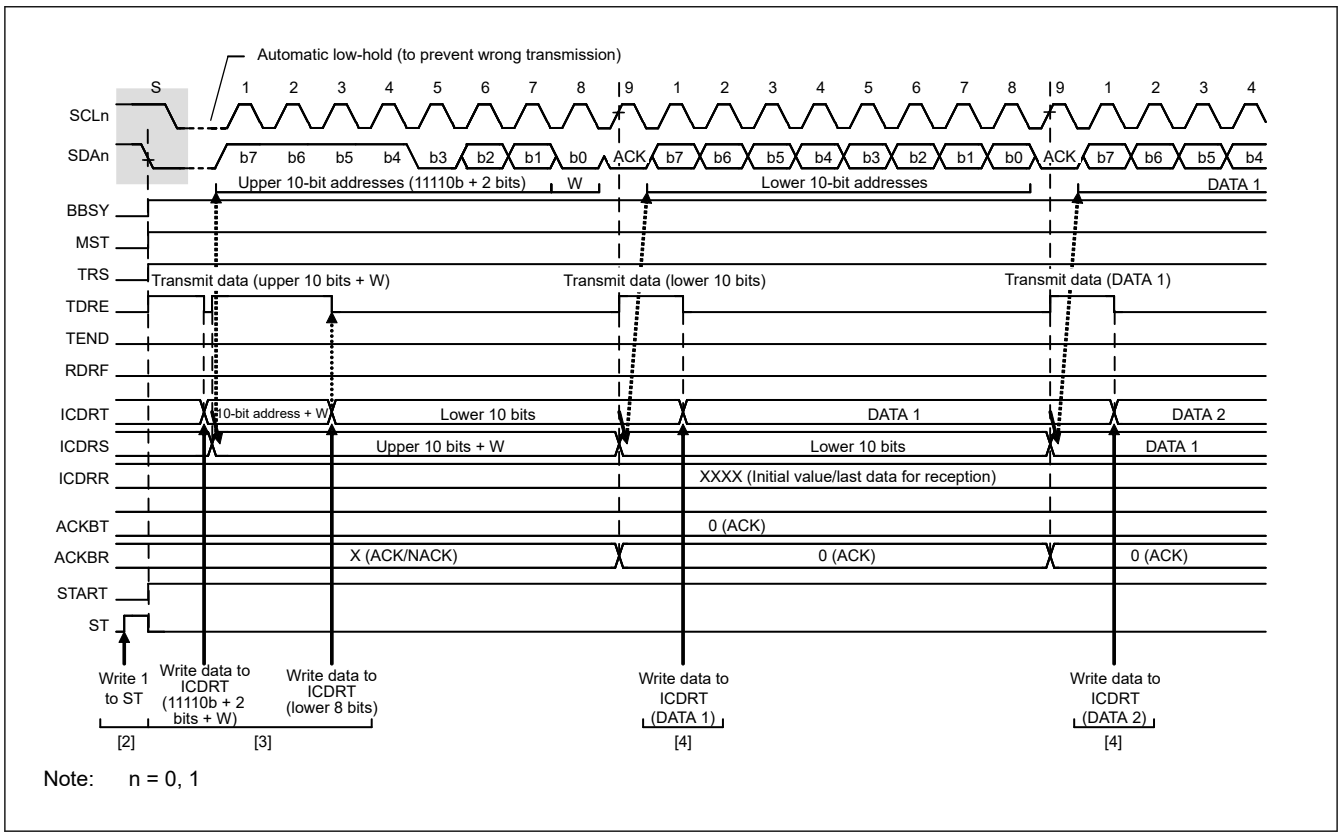

Figure 29.8 Master transmit operation timing (2) with 10-bit address format

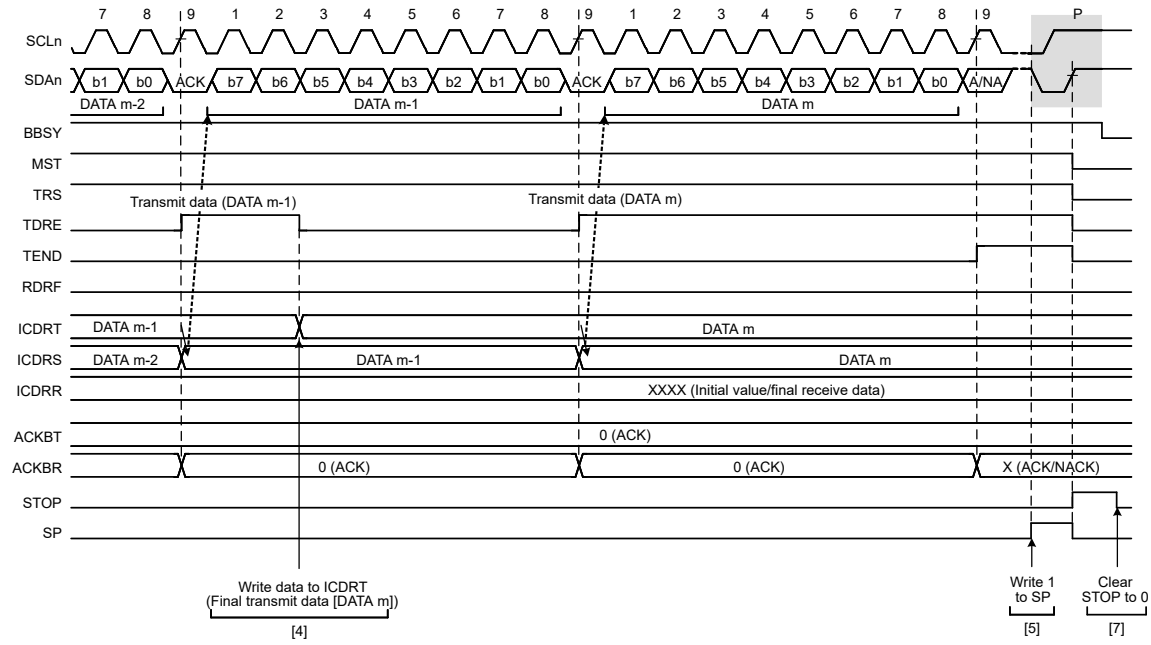

Note: n = 0, 1

Figure 29.9 Master transmit operation timing (3)

29.3.4 Master Receive Operation

In master receive operation, the IIC as a master device outputs the SCL clock, receives data from the slave device, and returns acknowledgments. Because the IIC must start by sending a slave address to the associated slave device, this part of the procedure is performed in master transmit mode, but the subsequent steps are in master receive mode.

Figure 29.10 and Figure 29.11 show examples of master reception (7-bit address format), and Figure 29.12 to Figure 29.14 show the operation timing in master reception.

To set up and perform master reception:

1. Process initial settings. For details, see section 29.3.2. Initial Settings.
2. Read the BBSY flag in ICCR2 to check that the bus is free, and then set the ST bit in ICCR2 to 1 (start condition request). On receiving the request, the IIC issues a start condition. When the IIC detects the start condition, the BBSY and START flags in ICSR2 automatically set to 1, and the ST bit automatically is set to 0. At this time, if the start condition is detected and the levels for the SDA output and the levels on the SDAn line match while the ST bit is 1, the IIC recognizes that issuance of the start condition as requested by the ST bit is successfully complete, and the MST and TRS bits in ICCR2 automatically set to 1, placing the IIC in master transmit mode. The TDRE flag in ICSR2 also automatically is set to 1 in response to the setting of the TRS bit to 1.
3. Check that the TDRE flag in ICSR2 is 1, and then write the value for transmission (the first byte indicates the slave address and value of the R/W# bit) to ICDRT. When the transmit data is written to ICDRT, the TDRE flag automatically is set to 0, the data is transferred from ICDRT to ICDRS, and the TDRE flag again is set to 1. When the byte containing the slave address and R/W# bit is transmitted, the value of the ICCR2.TRS bit automatically updates to select transmit or receive mode based on the value of the transmitted R/W# bit. If the value of the R/W# bit is 1, the TRS bit is set to 0 on the rising edge of the ninth cycle of the SCL clock, placing the IIC in master receive mode. At this time, the TDRE flag is set to 0 and the ICSR2.RDRF flag automatically is set to 1.
   Because the ICSR2.NACKF flag being 1 at this time indicates that no slave device recognized the address or there was an error in communications, write 1 to the ICCR2.SP bit to issue a stop condition.
   For master reception from a device with a 10-bit address, start by using master transmission to issue the 10-bit address, and then issue a restart condition. After that, transmitting 11110b, the two higher-order bits of the slave address, and the R bit places the IIC in master receive mode.

4. Dummy read ICDRR after confirming that the RDRF flag in ICSR2 is 1. This makes the IIC start output of the SCL clock and start data reception.
5. After 1 byte of data is received, the RDRF flag in ICSR2 is set to 1 on the rising edge of the 8th or 9th cycle of the SCL clock, as selected in the RDRFS bit in ICMR3. Reading ICDRR at this time produces the received data, and the RDRF flag is automatically set to 0 at the same time. Additionally, the value of the acknowledgment field received during the ninth cycle of the SCL clock is returned as the value set in the ICMR3.ACKBT bit. If the next byte to be received is the second-to-last byte, set the ICMR3.WAIT bit to 1 for wait insertion before reading ICDRR, containing the second-to-last byte. In addition to enabling NACK output, even when interrupts or other operations result in delays in setting the ICMR3.ACKBT bit to 1 (NACK) in step (6), this fixes the SCLn line to the low level on the rising edge of the ninth clock cycle in reception of the last byte, which enables the issuing of a stop condition.
6. When the ICMR3.RDRFS bit is 0, and the slave device must be notified that it is to end transfer for data reception after transfer of the next and final byte, set the ICMR3.ACKBT bit to 1 (NACK).
7. After reading the second-to-last byte from the ICDRR register, if the value of the ICSR2.RDRF flag is 1, write 1 to the SP bit in ICCR2 (stop condition requested), and then read the last byte from ICDRR. When ICDRR is read, the IIC is released from the wait state and issues the stop condition after low-level output in the ninth clock cycle is complete or the SCLn line is released from the low-hold state.
8. On detecting the stop condition, the IIC automatically sets the MST and TRS bits in ICCR2 to 00b and enters slave receive mode. Additionally, detection of the stop condition sets the ICSR2.STOP flag to 1.
9. Check that the ICSR2.STOP flag is 1, then set the ICSR2.NACKF and STOP flags to 0 for the next transfer operation.

29.3.5 Slave Transmit Operation

In slave transmit operation, the master device outputs the SCL clock, the IIC transmits data as a slave device, and the master device returns acknowledgments.

Figure 29.15 shows an example of slave transmission, and Figure 29.16 and Figure 29.17 show the operation timing in slave transmission.

To set up and perform slave transmission:

1. Initialize the IIC using the procedure in section 29.3.2. Initial Settings.
   After initialization, the IIC stays in the standby state until it receives a slave address that matches.
2. After receiving a matching slave address, the IIC sets one of the associated ICSR1.HOA, GCA, and AASy flags (y = 0 to 2) to 1 on the rising edge of the ninth cycle of the SCL clock and outputs the value set in the ICMR3.ACKBT bit to the acknowledge bit on the ninth cycle of the SCL clock. If the value of the R/W# bit is 1, the IIC automatically places itself in slave transmit mode by setting both the ICCR2.TRS bit and the ICSR2.TDRE flag to 1.
3. Check that the ICSR2.TDRE flag is 1, then write the transmit data to the ICDRT register. If the IIC receives no acknowledge from the master device (receives an NACK signal) while the ICFER.NACKE bit is 1, the IIC suspends transfer of the next data.
4. Wait until the ICSR2.TEND flag is set to 1 while the ICSR2.TDRE flag is 1, after the ICSR2.NACKF flag is set to 1 or the last byte for transmission is written to the ICDRT register. When the ICSR2.NACKF flag or the TEND flag is 1, the IIC drives the SCLn line low on the ninth falling edge of the SCL clock.
5. When the ICSR2.NACKF or ICSR2.TEND flag is 1, dummy read ICDRR to complete the processing. This releases the SCLn line.
6. On detecting the stop condition, the IIC automatically sets the ICSR1.HOA, GCA, and AASy flags (y = 0 to 2), the ICSR2.TDRE and TEND flags, and the ICCR2.TRS bit to 0, and enters slave receive mode.
7. Check that the ICSR2.STOP flag is 1, then set the ICSR2.NACKF and STOP flags to 0 for the next transfer operation.

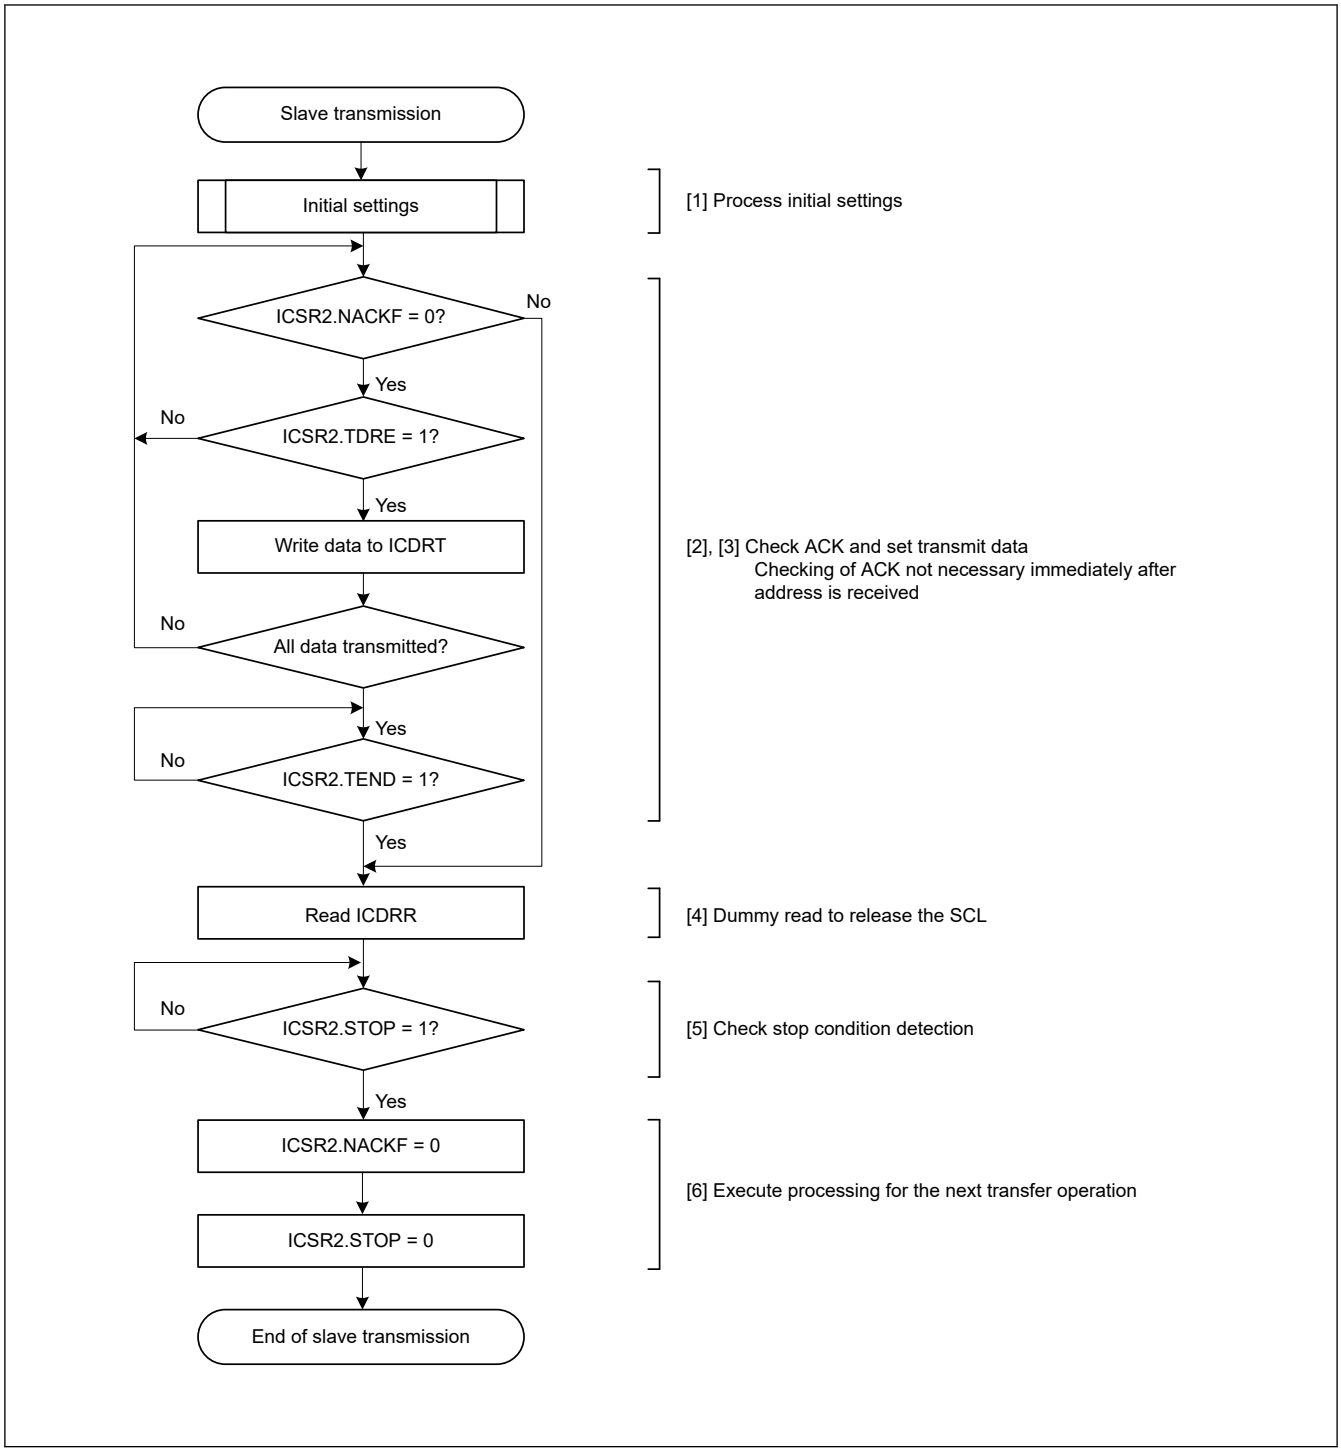

Figure 29.15 Example slave transmission flow

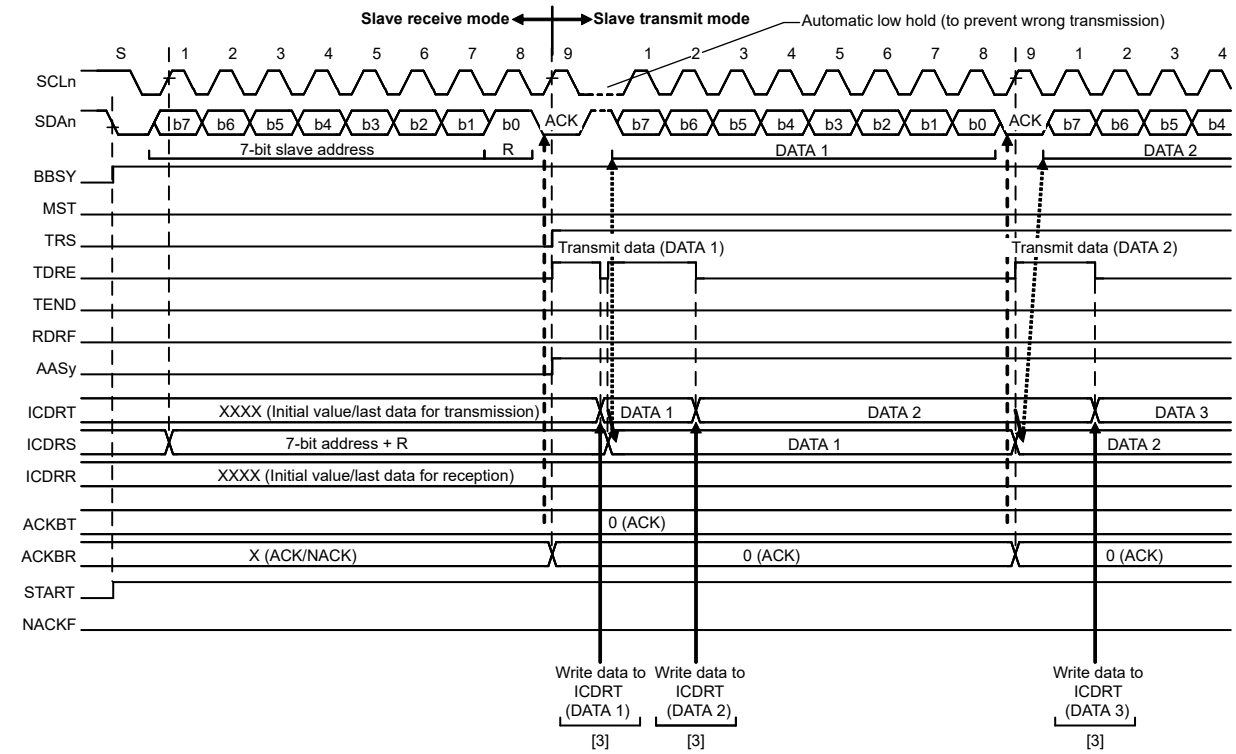
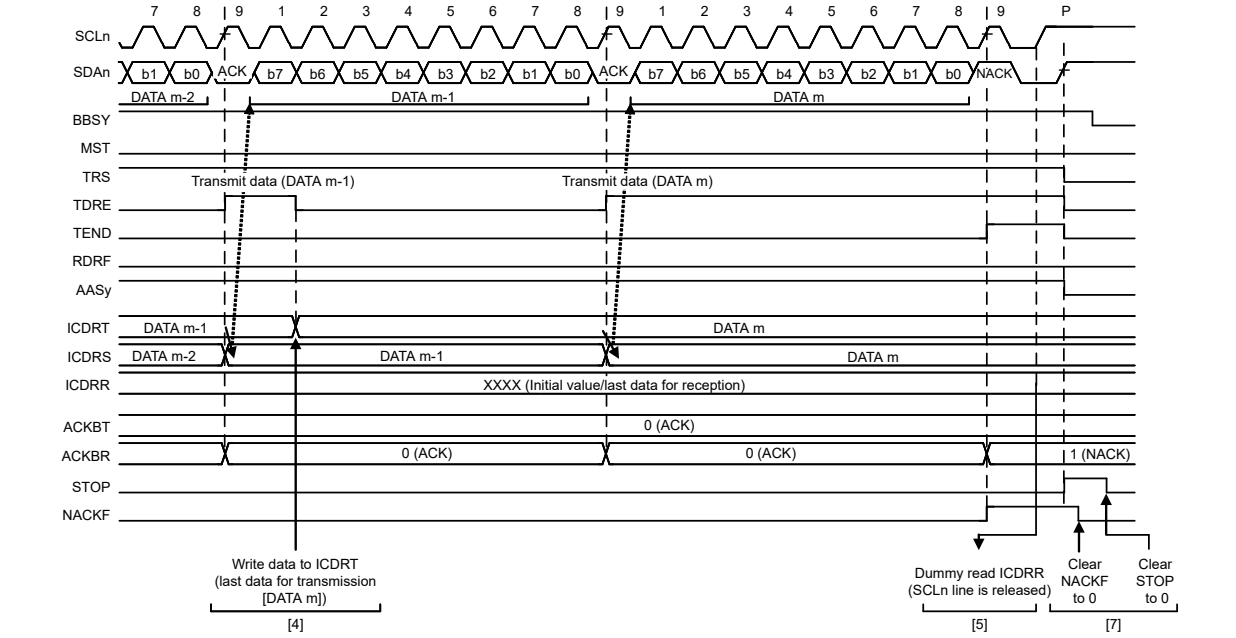


Note: n = 0, 1, y = 0 to 2

Figure 29.16 Slave transmit operation timing (1) with 7-bit address format



Note: n = 0, 1, y = 0 to 2

Figure 29.17 Slave transmit operation timing (2)

29.3.6 Slave Receive Operation

In slave receive operation, the master device outputs the SCL clock and transmit data, and the IIC returns acknowledgments as a slave device.

Figure 29.18 shows an example of slave reception, and Figure 29.19 and Figure 29.20 show the operation timing in slave reception.

To set up and perform slave reception:

1. Initialize the IIC using the procedure in section 29.3.2. Initial Settings.
   After initialization, the IIC stays in the standby state until it receives a slave address that matches.
2. After receiving a matching slave address, the IIC sets one of the associated ICSR1.HOA, GCA, and AASy flags (y = 0 to 2) to 1 on the rising edge of the ninth cycle of the SCL clock and outputs the value set in the ICMR3.ACKBT bit to the acknowledge bit on the ninth cycle of the SCL clock. If the value of the R/W# bit is 0, the IIC continues to place itself in slave receive mode and sets the RDRF flag in ICSR2 to 1.
3. Check that the ICSR2.STOP flag is 0 and the ICSR2.RDRF flag is 1, then dummy read ICDRR. The dummy value consists of the slave address and R/W# bit when the 7-bit address format is selected, or the lower 8 bits when the 10-bit address format is selected.
4. When ICDRR is read, the IIC automatically sets the ICSR2.RDRF flag to 0. If reading of ICDRR is delayed and a next byte is received while the RDRF flag is still set to 1, the IIC holds the SCLn line low at the SCL clock one cycle before the point where the RDRF is set. In this case, reading ICDRR releases the SCLn line from being held low.
   When the ICSR2.STOP flag is 1 and the ICSR2.RDRF flag is also 1, read ICDRR until all the data is completely received.
5. On detecting the stop condition, the IIC automatically clears the ICSR1.HOA, GCA, and AASy flags (y = 0 to 2) to 0.
6. Check that the ICSR2.STOP flag is 1, then set the ICSR2.STOP flag to 0 for the next transfer operation.

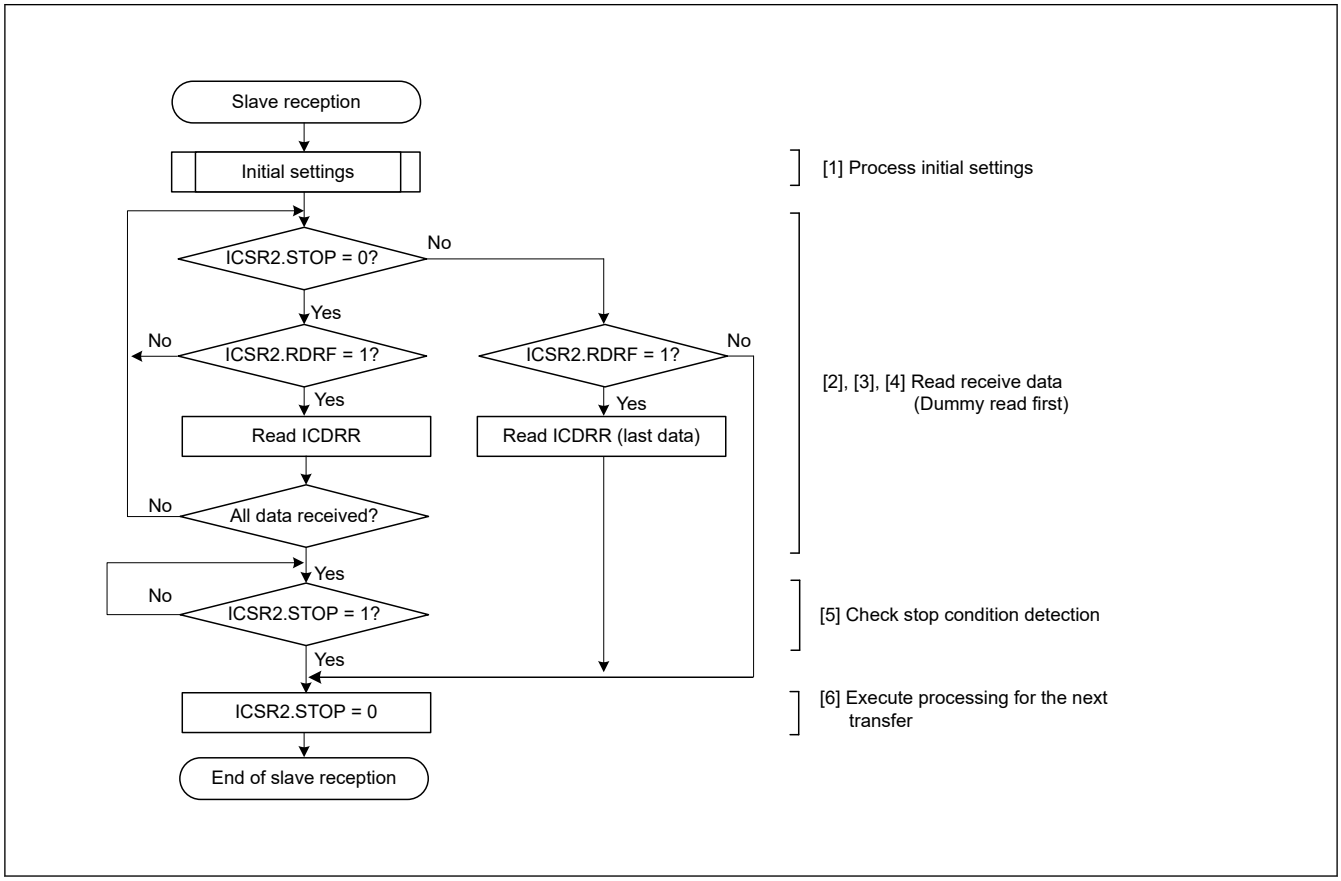


Figure 29.18 Example slave reception flow

29.4 SCL Synchronization Circuit

For generation of the SCL clock, the IIC starts counting the value for the high-level period specified in ICBRH when it detects a rising edge on the SCLn line, and it drives the SCLn line low when it completes counting. When the IIC detects the falling edge of the SCLn line, it starts counting the value for the low-level period specified in ICBRL, and then it stops driving the SCLn line, releasing the line, when it completes counting. The IIC repeats this process to generate the SCL clock.

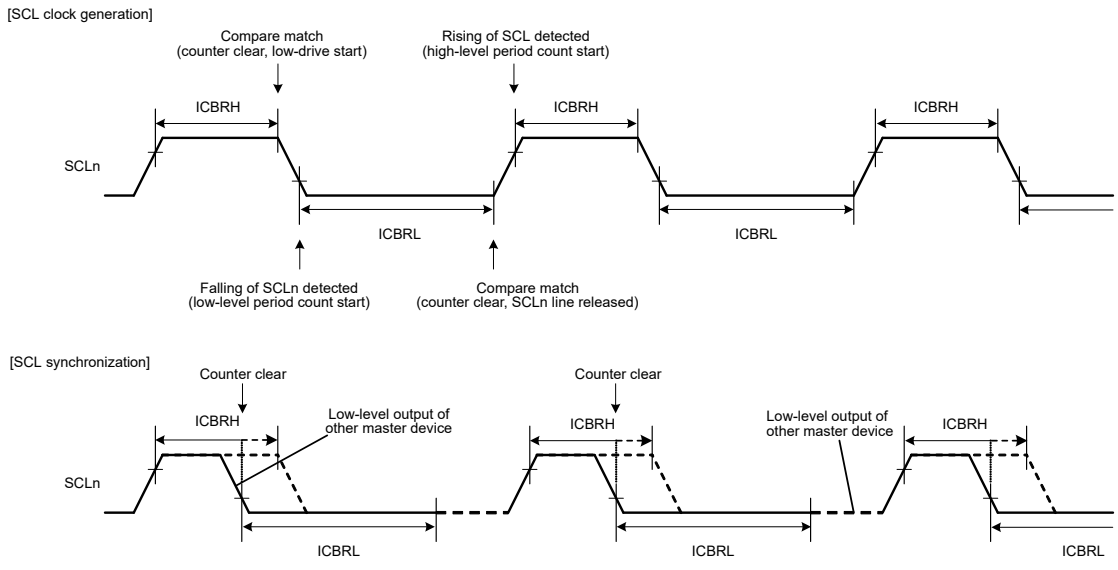
If multiple master devices are connected to the I^2C bus, a collision of SCL signals might arise because of contention with another master device. In such cases, the master devices must synchronize their SCL signals. Because this synchronization of SCL signals must be bit-by-bit, the IIC is equipped with an SCL synchronization circuit to obtain bit-by-bit synchronization of the SCL clock signals by monitoring the SCLn line while in master mode.

When the IIC detects a rising edge on the SCLn line and starts counting the high-level period specified in ICBRH.BRH[4:0], and the level on the SCLn line falls because an SCL signal is being generated by another master device, the IIC performs the following:

1. Stops counting when it detects the falling edge.
2. Drives the level on the SCLn line low.
3. Starts counting the low-level period specified in ICBRL.BRL[4:0].

When the IIC finishes counting the low-level period, it stops driving the SCLn line low to release the line. If the low-level period of the SCL clock signal from the other master device is longer than the low-level period set in the IIC, the low-level period of the SCL signal is extended. When the low-level period for the other master device ends, the SCL signal rises because the SCLn line is released.

When the IIC finishes outputting the low-level period of the SCL clock, the SCLn line is released and the SCL clock rises. That is, when SCL signals from more than one master are contending, the high-level period of the SCL signal is synchronized with that of the clock with the narrower period, and the low-level period of the SCL signal is synchronized with that of the clock with the broader period. However, such synchronization of the SCL signal is only enabled when the SCLE bit in ICFER is set to 1.



ICBRH: IIC-Bus Bit Rate High-Level Register (SCL clock high-level period counter)
ICBRL: IIC-Bus Bit Rate Low-Level Register (SCL clock low-level period counter)

Note: n = 0, 1

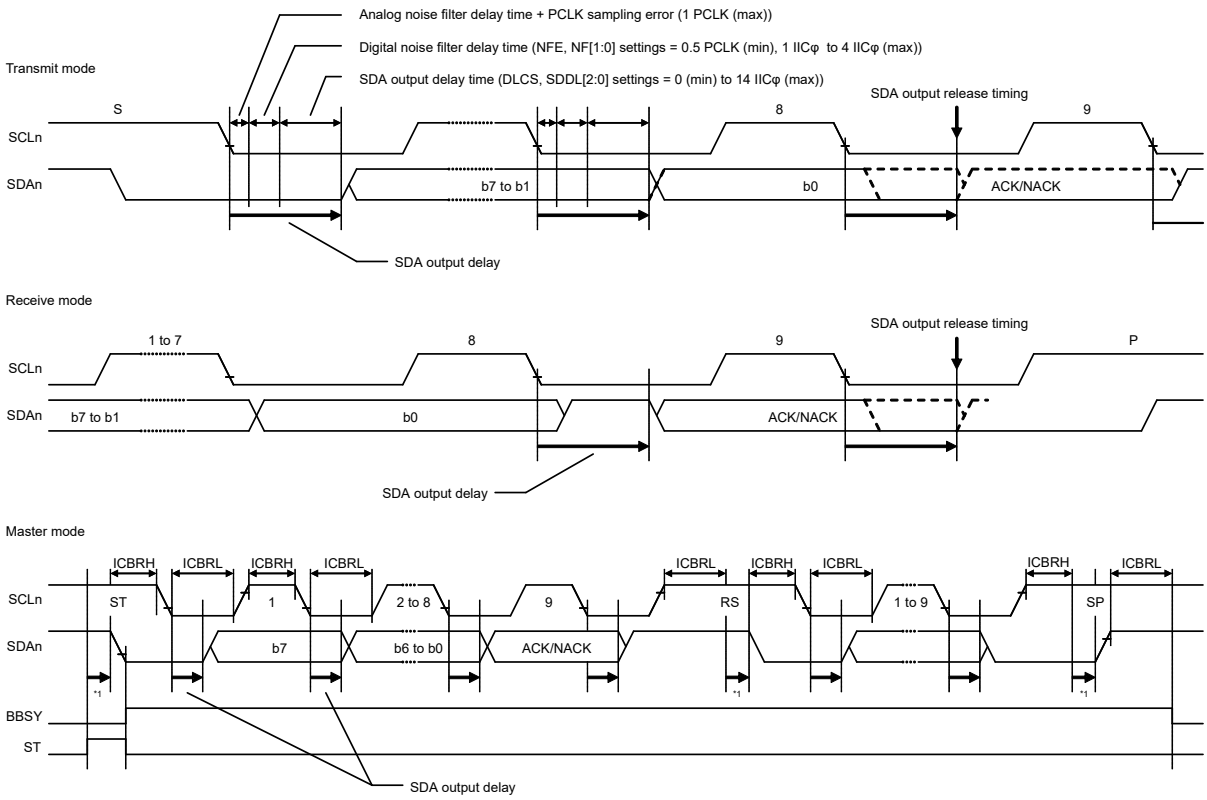
Figure 29.21 Generation and synchronization of SCL signal from IIC

29.5 SDA Output Delay Function

The IIC module incorporates a function for delaying output on the SDA line. The delay can be applied to all output on the SDA line, including issuing of the start, restart, and stop conditions, data, and the ACK and NACK signals.

With this function, SDA output is delayed from the detection of a falling edge of the SCL signal to ensure that the SDA signal is output within the interval during which the SCL clock is low. This approach helps prevent erroneous operation of communications devices, with the aim of satisfying the 300-ns minimum data-hold time requirement of the SMBus specification. The output delay function is enabled by setting the SDDL[2:0] bits in ICMR2 to a value other than 000b, and disabled by setting the same bits to 000b.

When the SDA output delay function is enabled, for example, the DLCS bit in ICMR2 selects the clock source for the SDA output delay counter, either as the internal base clock (IICφ) for the IIC module or as the internal base clock divided by 2 (IICφ/2). The counter counts the number of cycles set in the SDDL[2:0] bits in ICMR2. When the delay cycles count is reached, the IIC module places the required output (start, restart, or stop condition, data, or an ACK or NACK signal) on the SDA line.



Note: PCLK = PCLKB
Note: n = 0, 1
Note 1. The output delay function is set by the DLCS and SDDL[2:0] bits when a start (ST), restart (RS), or stop (SP) condition is issued.

Figure 29.22 SDA output delay function

29.6 Digital Noise Filter Circuits

The internal circuitry sees the states of the SCLn and SDAn pins through analog and digital noise-filter circuits. Figure 29.23 shows a block diagram of the digital noise-filter circuit.

The on-chip digital noise-filter circuit of the IIC consists of four flip-flop circuit stages connected in series and a match-detection circuit. The number of valid stages in the digital noise filter is selected in the NF[1:0] bits in ICMR3. The selected number of valid stages determines the noise-filtering capability as a period from 1 to 4 IICφ cycles.

The input signal to the SCLn pin (or SDAn pin) is sampled on falling edges of the IICφ signal. When the input signal level matches the output level of the number of valid flip-flop circuit stages as selected in the NF[1:0] bits in ICMR3, the signal level is seen in the subsequent stage. If the signal levels do not match, the previous value is saved.

If the ratio between the frequency of the internal operating clock (PCLKB) and the transfer rate is small, for example, if data transfer is 400 kbps with PCLKB = 4 MHz, the characteristics of the digital noise filter might lead to the elimination of required signals as noise. In such cases, it is possible to disable the digital noise-filter circuit by setting the ICFER.NFE bit to 0, and use only the analog noise filter circuit.

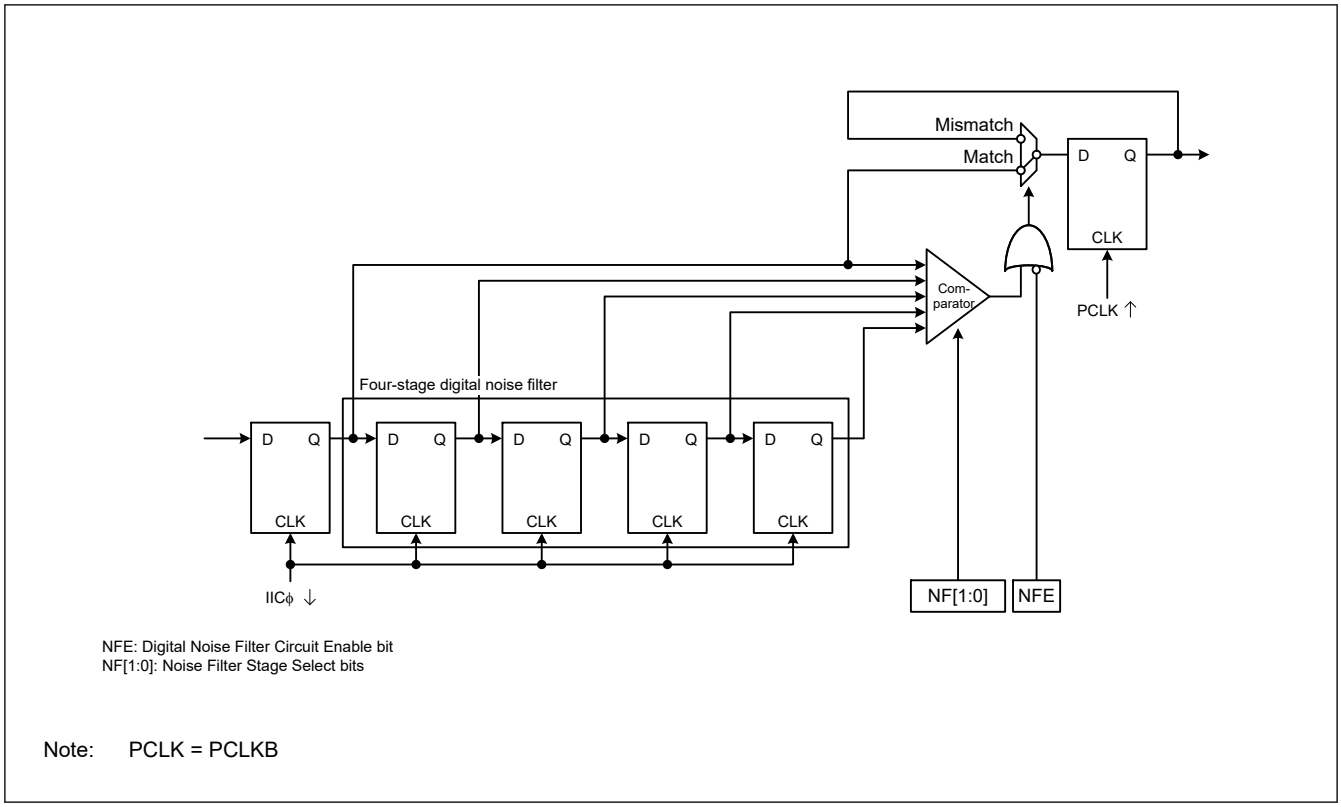


Figure 29.23 Digital noise filter circuit block diagram

29.7 Address Match Detection

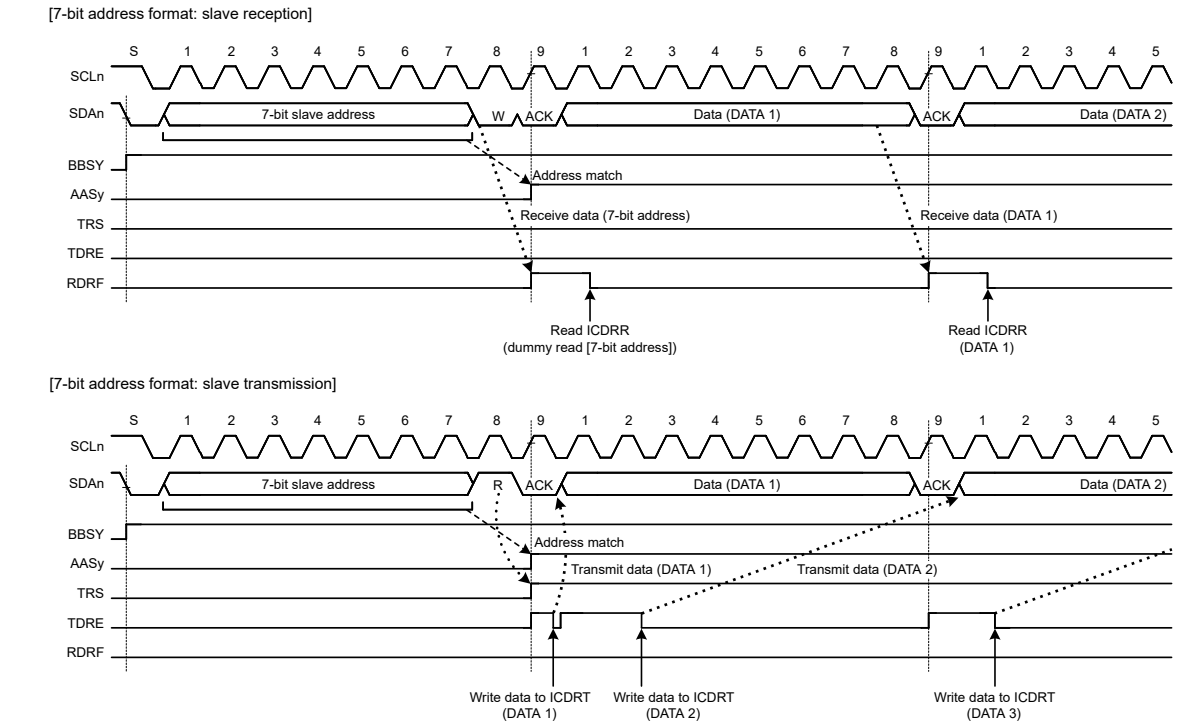
The IIC can set three unique slave addresses in addition to the general call address and host address. The slave addresses can be 7-bit or 10-bit slave addresses.

29.7.1 Slave-Address Match Detection

The IIC can set three unique slave addresses and has a slave address detection function for each unique slave address. When the SARyE bit (y = 0 to 2) in ICSER is set to 1, the slave addresses set in SARUy and SARLy (y = 0 to 2) can be detected.

When the IIC detects a match of the set slave address, the associated AASy flag (y = 0 to 2) in ICSR1 is set to 1 on the rising edge of the ninth SCL clock cycle, and the RDRF flag in ICSR2 or the TDRE flag in ICSR2 is set to 1 by the subsequent R/W# bit. This causes a receive data full interrupt (IICn_RXI) or transmit data empty interrupt (IICn_TXI) to be generated. The AASy flag identifies which slave address is specified.

Figure 29.24 to Figure 29.26 show the AASy flag set timing in three cases.



Note: n = 0, 1, y = 0 to 2

Figure 29.24 AASy flag set timing with 7-bit address format

Figure 29.25 AASy flag set timing with 10-bit address format

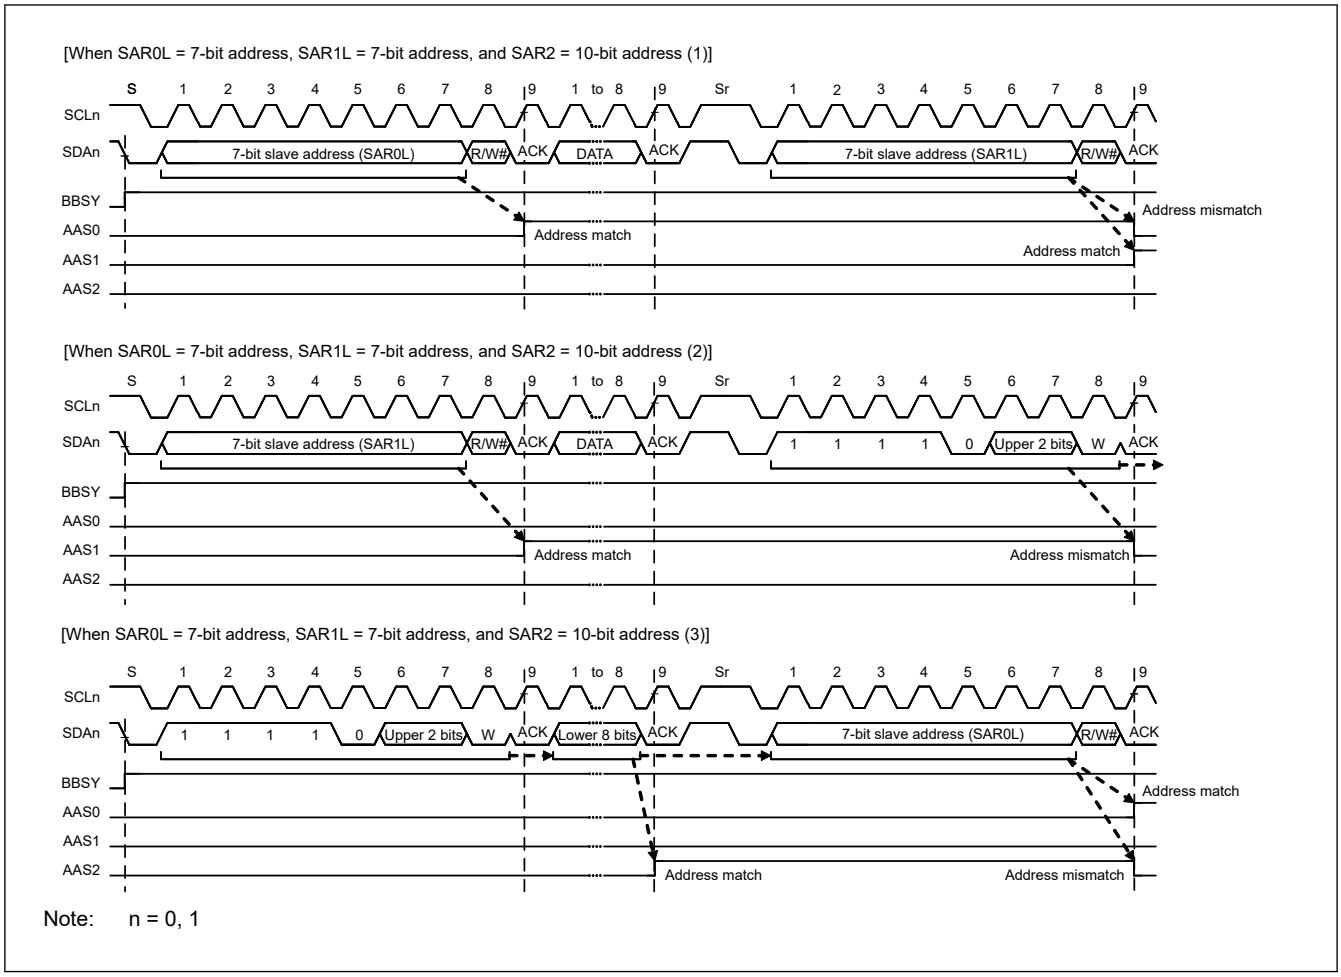

Figure 29.26 AASy flag set and clear timing with mixed 7-bit and 10-bit address formats

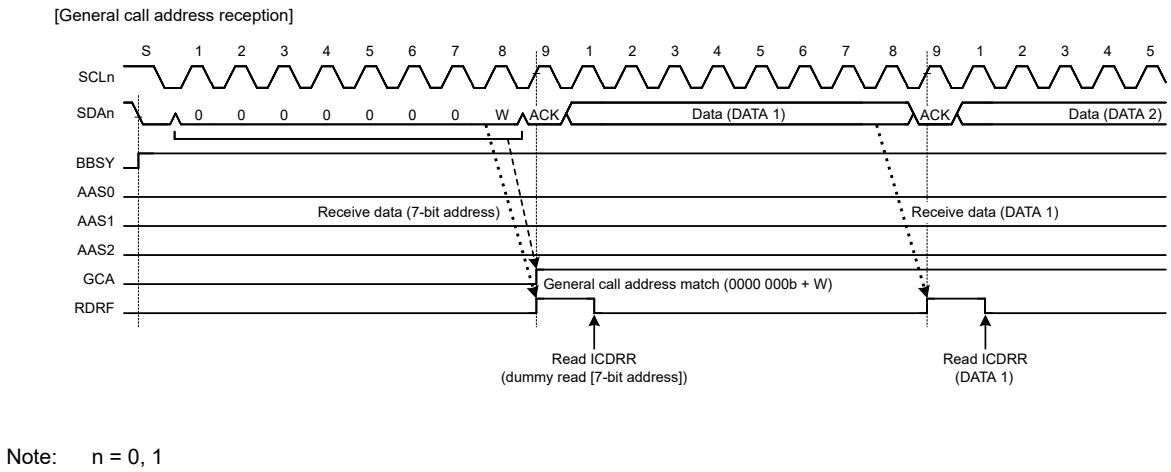
29.7.2 Detection of General Call Address

The IIC provides detection of the general call address (0000 000b + 0 [W]). This is enabled by setting the GCAE bit in ICSER to 1.

If the address received after a start or restart condition is issued is 0000 000b + 1[R] (start byte), the IIC recognizes this as the address of a slave device with an all-zero address, but not as the general call address.

When the IIC detects the general call address, both the GCA flag in ICSR1 and the RDRF flag in ICSR2 set to 1 on the rising edge of the ninth cycle of the SCL clock. This leads to the generation of a receive data full interrupt (IICn_RXI). The value of the GCA flag can be checked to confirm that the general call address was transmitted.

Operation after detection of the general call address is the same as normal slave receive operation.



Note: n = 0, 1

Figure 29.27 Timing of GCA flag setting during reception of general call address

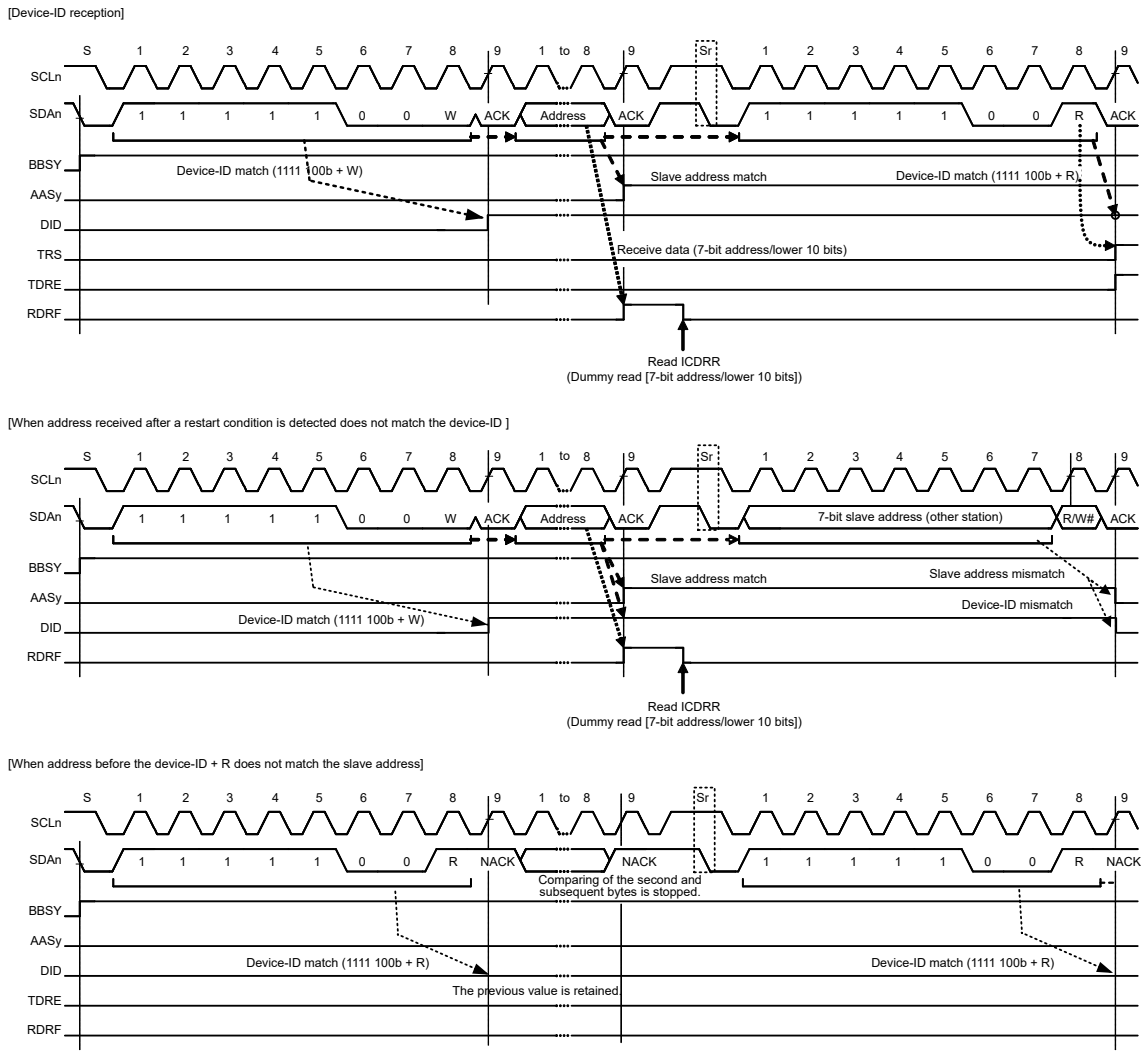
29.7.3 Device-ID Address Detection

The IIC module provides detection of device-ID address compliant with the I^2C bus specification (revision 03). When the IIC receives 1111 100b as the first byte after a start or restart condition is issued with the DIDE bit in ICSER set to 1, it recognizes the address as a device ID, sets the DID flag in ICSR1 to 1 on the rising edge of the ninth SCL clock cycle when the subsequent R/W# bit is 0, then compares the second and subsequent bytes with its own slave address. If the address matches the value in the slave address register, the IIC sets the associated AASy flag (y = 0 to 2) in ICSR1 to 1.

When the first byte received after the issue of a start or restart condition matches the device ID address (1111 100b) again and the subsequent R/W# bit is 1, the IIC does not compare the second and subsequent bytes and sets the ICSR2.TDRE flag to 1.

In the device ID address detection function, the IIC sets the DID flag to 0 if a match with the IIC slave address is not obtained or a match with the device ID address is not obtained after a match with the IIC slave address and a restart condition is not detected. If the first byte after detection of a start or restart condition matches the device ID address (1111 100b), and the R/W# bit is 0, the IIC sets the DID flag to 1 and compares the second and subsequent bytes with the slave address of the IIC. If the R/W# bit is 1, the DID flag holds the previous value and the IIC does not compare the second and subsequent bytes. Therefore, the reception of a device ID address can be checked by reading the DID flag after confirming that TDRE = 1.

Additionally, prepare the device ID fields (3 bytes: 12 bits indicating the manufacturer + 9 bits identifying the part + 3 bits indicating the revision) that must be sent to the host after reception of a continuous device-ID field as normal transmit data. For details on the information that must be included in device ID fields, contact NXP Semiconductors.



Note: n = 0, 1, y = 0 to 2

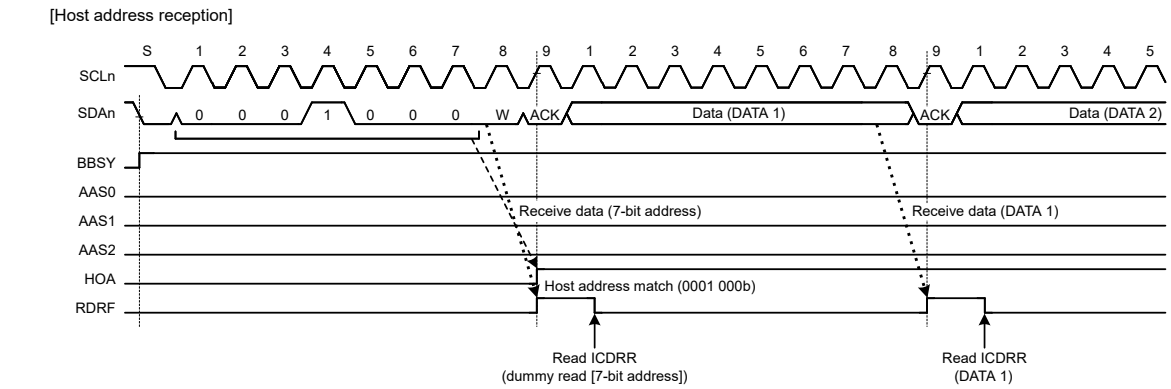
Figure 29.28 AASy and DID flag set and clear timing during reception of device ID

29.7.4 Host Address Detection

The IIC provides host address detection when operating in SMBus. When the HOAE bit in ICSER is set to 1 while the SMBS bit in ICMR3 is 1, the IIC can detect the host address (0001 000b) in slave receive mode (MST and TRS bits = 00b in ICCR2).

When the IIC detects the host address, the HOA flag in ICSR1 is set to 1 on the rising edge of the 9th SCL clock cycle, and at the same time, the RDRF flag in ICSR2 is set to 1 when the R/W# bit is 0 (Wr bit). This causes a receive data full interrupt (IICn_RXI) to be generated. The HOA flag indicates that the host address was sent from another device.

If the bit following the host address (0001 000b) is an Rd bit (R/W# bit = 1), the IIC can also detect the host address. After the host address is detected, the IIC operates in the same manner as in normal slave operation.



Note: n = 0, 1

Figure 29.29 HOA flag set timing during reception of host address

29.8 Wakeup Function

The IIC provides a wakeup function that causes the MCU to transition from Software Standby mode to normal operation. The wakeup function enables the reception of data when the peripheral module clock (PCLKB) is stopped, and generates a wakeup interrupt signal on a match of the slave address of the received data. This wakeup interrupt signal triggers the return to normal operation. After the wakeup interrupt occurs, switch the IIC to PCLKB synchronous operation so that communication can continue.

The wakeup function has four operation modes:

- Normal wakeup mode 1
- Normal wakeup mode 2
- Command recovery mode
- EEP response mode

Table 29.9 describes the behavior in these modes.

Table 29.9 Wakeup operation modes

Operation mode	ACK response timing	ACK response before wakeup to PCLKB synchronous operation	SCL state during wakeup to PCLKB synchronous operation
Normal wakeup mode 1	Before wakeup to PCLKB synchronous operation*1	ACK	Fixed low
Normal wakeup mode 2	After wakeup to PCLKB synchronous operation*2	Before wakeup: no response (NACK level retained) After wakeup: ACK response	Fixed low
Command recovery mode	Before wakeup to PCLKB synchronous operation*1	ACK	Open
EEP response mode	Before recovery to PCLKB synchronous operation*1	NACK	Open

Note 1. Switching timing from PCLKB asynchronous operation to PCLKB synchronous operation is the falling edge of the 9th clock of the SCL.
Note 2. Switching timing from PCLKB asynchronous operation to PCLKB synchronous operation is the falling edge of the 8th clock of the SCL.

The following can be selected as wakeup interrupt sources:

- Host address detection (valid when ICSER.HOAE = 1)
- General call address detection (valid when ICSER.GCAE = 1)

- Slave address 0[*1] detection (valid when ICSER.SAR0E = 1)
- Slave address 1[*1] detection (valid when ICSER.SAR1E = 1)
- Slave address 2[*1] detection (valid when ICSER.SAR2E = 1)

Note 1. Only 7-bit address can be set. Set the FS bit in SARUy (y = 0 to 2) to 0.

Precautions on the use of the wakeup function

- Do not change the content of the IIC registers except the ICIER register and WUSEN bit in ICWUR2 while the WUASYF flag in ICWUR2 is 1 (during PCLKB asynchronous operation).
- Set ICWUR.WUE and ICWUR.WUIE to 1, and ICCR2.MST and ICCR2.TRS to 0 (slave reception mode) before switching to PCLKB asynchronous mode.
- The device ID and the 10-bit slave address cannot be selected for the wakeup interrupt source. Set the DIDE bit in ICSER and FS bit in SARUy (y = 0 to 2) to 0.
- Set bits TIE, TEIE, RIE, NAKIE, SPIE, STIE, ALIE, and TMOIE in the ICIER register to 0 (interrupt disabled) after switching to PCLKB asynchronous operation (ICWUR2.WUASYF = 1).
- When the wakeup function is enabled, do not use the timeout function (ICWUR.WUE = 1)
- Even when a wakeup interrupt is generated during PCLKB asynchronous operation (when ICWUR2.WUASYF = 1), if the slave addresses match in PCLKB synchronous mode (ICWUR2.WUASYF = 0), the wakeup interrupt does not occur and the WUF flag is not set.
- If the timing of writing 0 to the ICWUR2.WUSEN bit and the timing of detecting a start condition conflict, the IIC might start the next reception in PCLKB synchronous operation mode. In this case, ICWUR2.WUASYF flag becomes 1 (switch to PCLKB asynchronous mode) when data communication is complete, a stop condition is detected, and detection of a wakeup event starts.
- If you want to switch from PCLKB asynchronous operation to PCLKB synchronous operation without address match detection, it will switch in the stop condition detection. When the ICWUR2.WUSEN bit was set to 1 in a bus free state, it is continued PCLKB asynchronous operation (Reception operation: waiting communication frame). ICWUR2.WUSYF flag becomes to 1 when IIC detect the stop condition of the next communication frame, and IIC switches to PCLKB synchronous operation.
- After writing 0 to the WUSEN bit in ICWUR2, do not change registers relate to the IIC operation mode setting (ICMR3, ICSER, and SARLy) until the mode is switched to PCLKB asynchronous operation from PCLKB synchronous operation (while the ICWUR2.WUASYF flag is 1). If the register value changes during this period by an interrupt handling or another factor, the IIC might malfunction before switching to the asynchronous operation.
- During PCLKB asynchronous operation (ICWUR2.WUSYF = 0 (or WUASYF = 1)), do not refer to each flag of ICSR1, ICSR2 register and ICCR2.BBSY flag.

29.8.1 Normal Wakeup Mode 1

This section describes the behavior, the timing, and an example operation of normal wakeup mode 1.

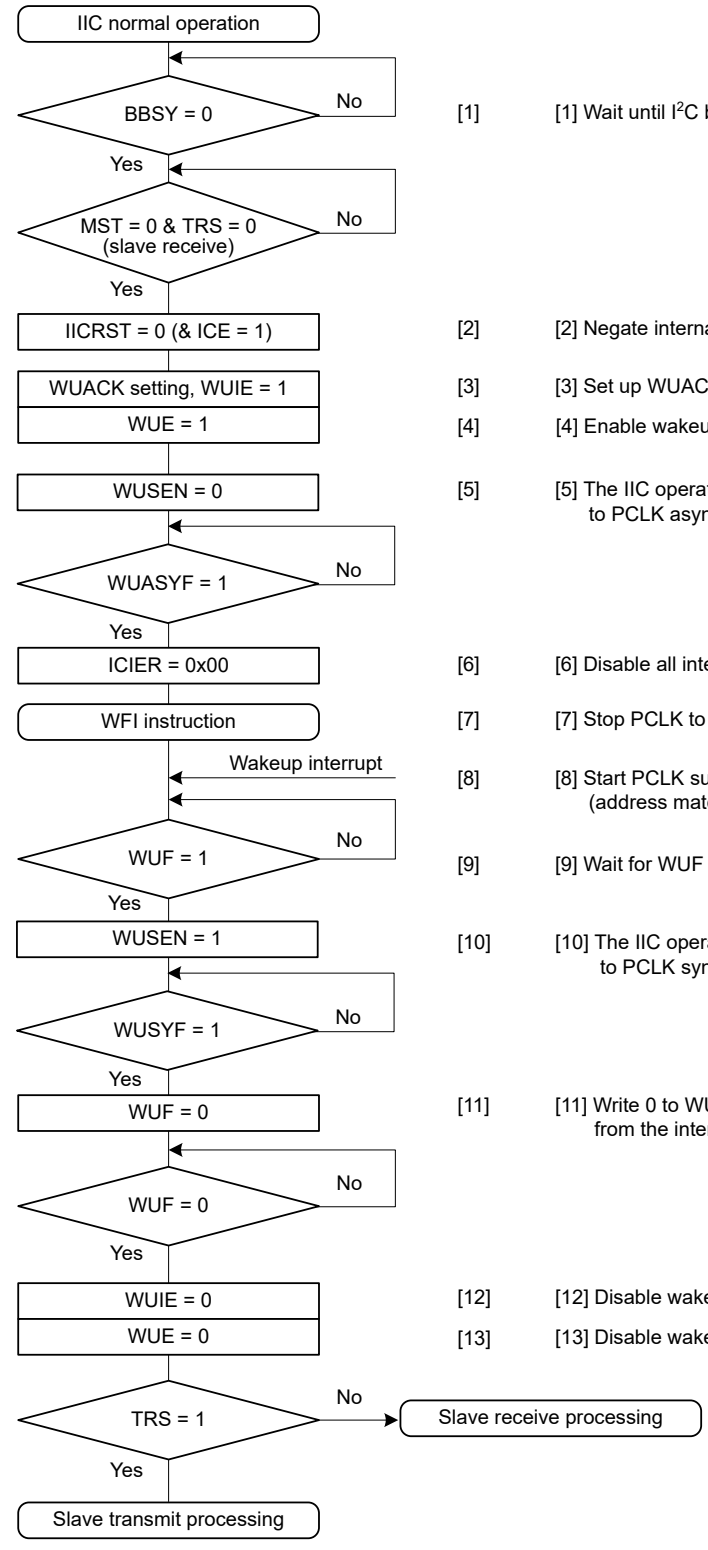
In normal wakeup mode 1, a wakeup interrupt triggered by the match of the slave address initiates the transition to normal operation as follows:

Before wakeup:	ACK is sent in response to the data received with its own slave address of the IIC.
During wakeup:	ACK response is made on the 9th clock cycle of SCL, after which SCL is held low[*1].
After wakeup:	Normal operation continues.

Note 1. Between the 9th clock cycle and 1st clock cycle during wakeup, ICMR1.WAIT = 1 is invalid.

If the slave address does not match, the SCL line is not held low after the 9th clock cycle of SCL, and the slave operation continues. Figure 29.30 shows an operation example, and Figure 29.32 shows the detailed timing.

If the transition from Software Standby mode is triggered by an interrupt other than a wakeup interrupt, for example the IRQn, the WUF flag is not set to 1. Figure 29.31 shows an operation example.



[1] [1] Wait until I^2C bus is open and stay in standby state.

[2] [2] Negate internal reset (if asserted).

[3] [3] Set up WUACK for the desired wakeup mode. Enable wakeup interrupt.

[4] [4] Enable wakeup function.

[5] [5] The IIC operating state is changed from PCLK synchronous to PCLK asynchronous.

[6] [6] Disable all interrupt requests except WUI.

[7] [7] Stop PCLK to IIC. IIC continues to receive.

[8] [8] Start PCLK supply to IIC on wakeup interrupt (address match).

[9] [9] Wait for WUF = 1.

[10] [10] The IIC operating state is changed from PCLK asynchronous to PCLK synchronous.

[11] [11] Write 0 to WUF. Read and check that WUF = 0 before returning from the interrupt handling.

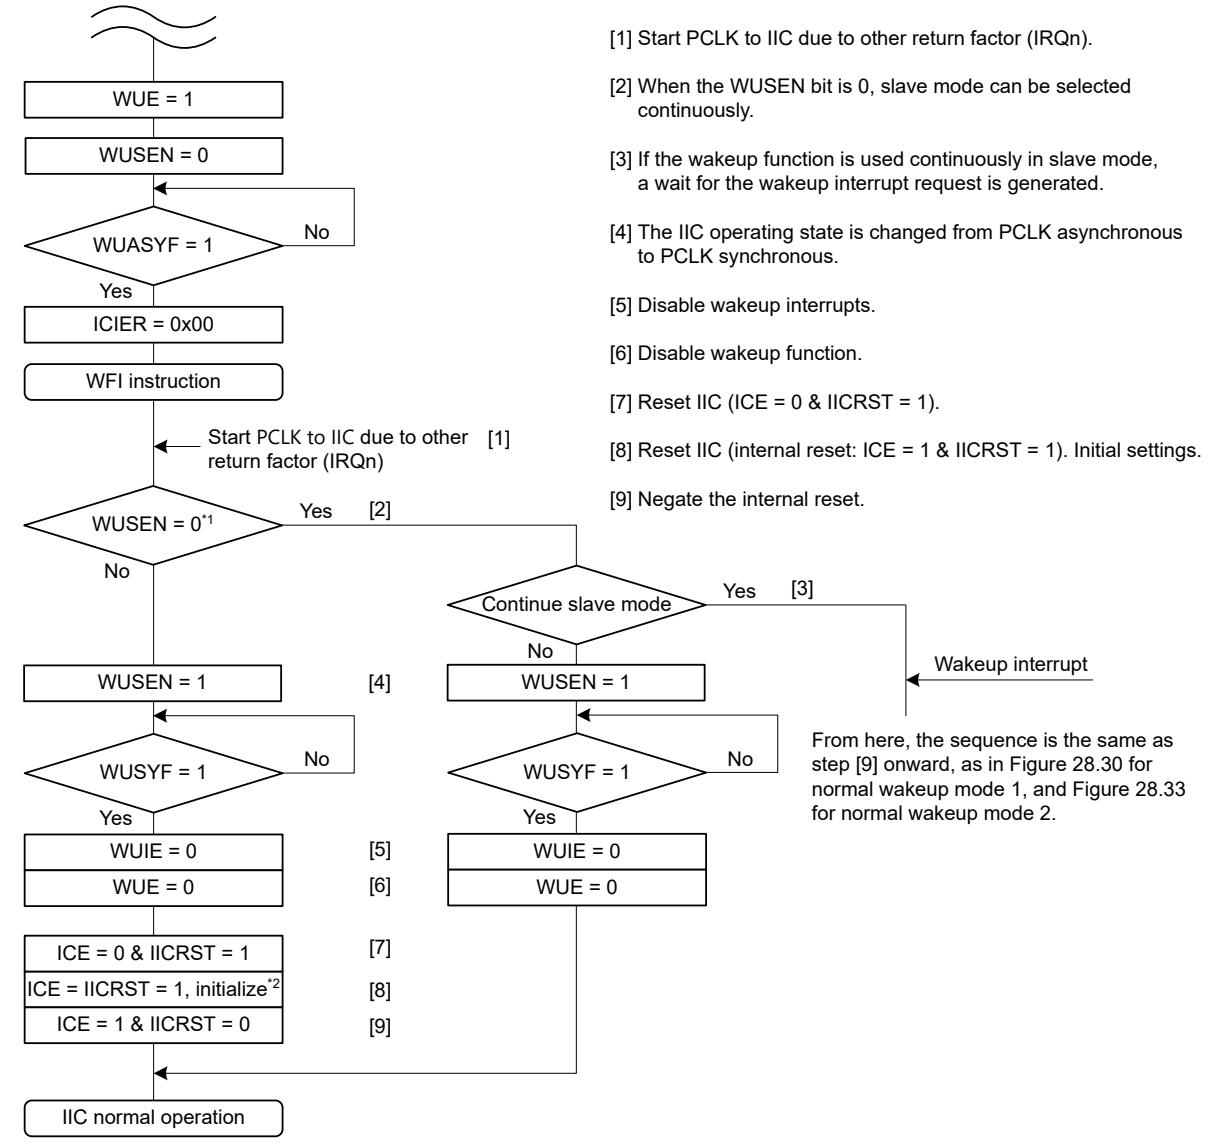
[12] [12] Disable wakeup Interrupt.

[13] [13] Disable wakeup function.

Note: PCLK = PCLKB

Figure 29.30 Example operation of normal wakeup mode 1 when wakeup is triggered by a wakeup interrupt on match of the slave address

Note: See Precautions on the use of the wakeup function.



Note: PCLK = PCLKB
Note 1. In the MCU, WUSEN bit is always 0 in the IIC.
Note 2. For details on the IIC initial settings, see section 29.3.2. Initial Settings.

Figure 29.31 Example operation of normal wakeup modes 1 and 2 when wakeup is triggered by an interrupt other than IIC wakeup interrupt, for example, the IRQn

Note: For details on the IIC initial settings, see section 29.3.2. Initial Settings.

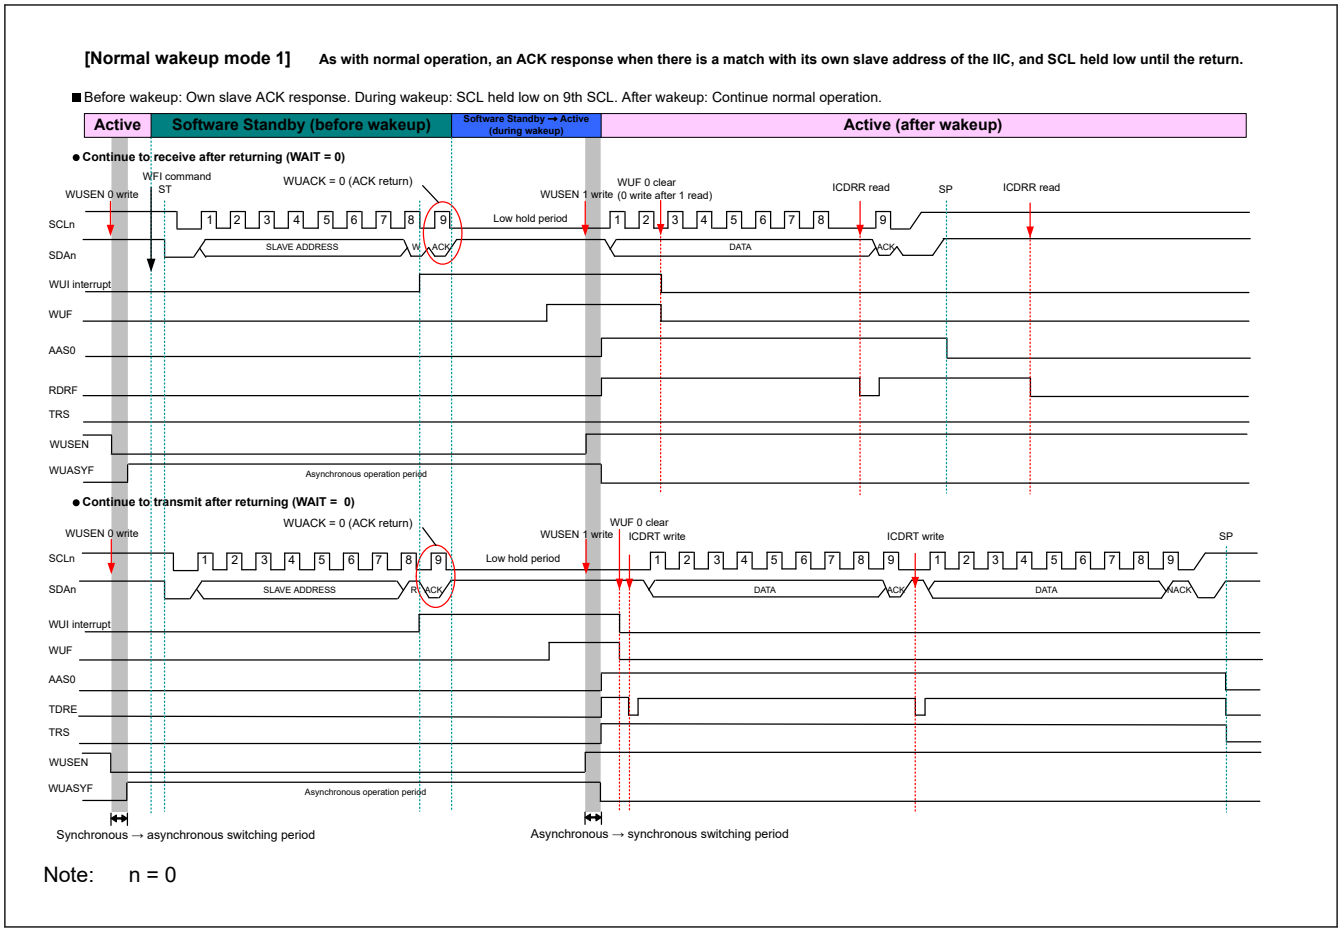


Figure 29.32 Timing of normal wakeup mode 1

29.8.2 Normal Wakeup Mode 2

This section describes the behavior, the timing, and an example operation of normal wakeup mode 2.

In normal wakeup mode 2, a wakeup interrupt triggered by a match of the slave address initiates the transition to normal operation as follows:

Before wakeup:	No response to data received with its own slave address until the end of the 8th SCL cycle.
During wakeup:	SCL line held low during the 8th and 9th clock cycles.
After wakeup:	ACK returns on the 9th clock cycle of SCL, and normal operation continues.

If the slave address does not match, the SCL line is not held low after the 8 th SCL clock cycle, and the slave operation continues. Figure 29.33 shows an example operation, and Figure 29.34 shows the detailed timing.

If the transition from Software Standby mode is triggered by an interrupt other than a wakeup interrupt, such as the IRQn, for example, the WUF flag is not set to 1. Figure 29.31 shows an operation example.

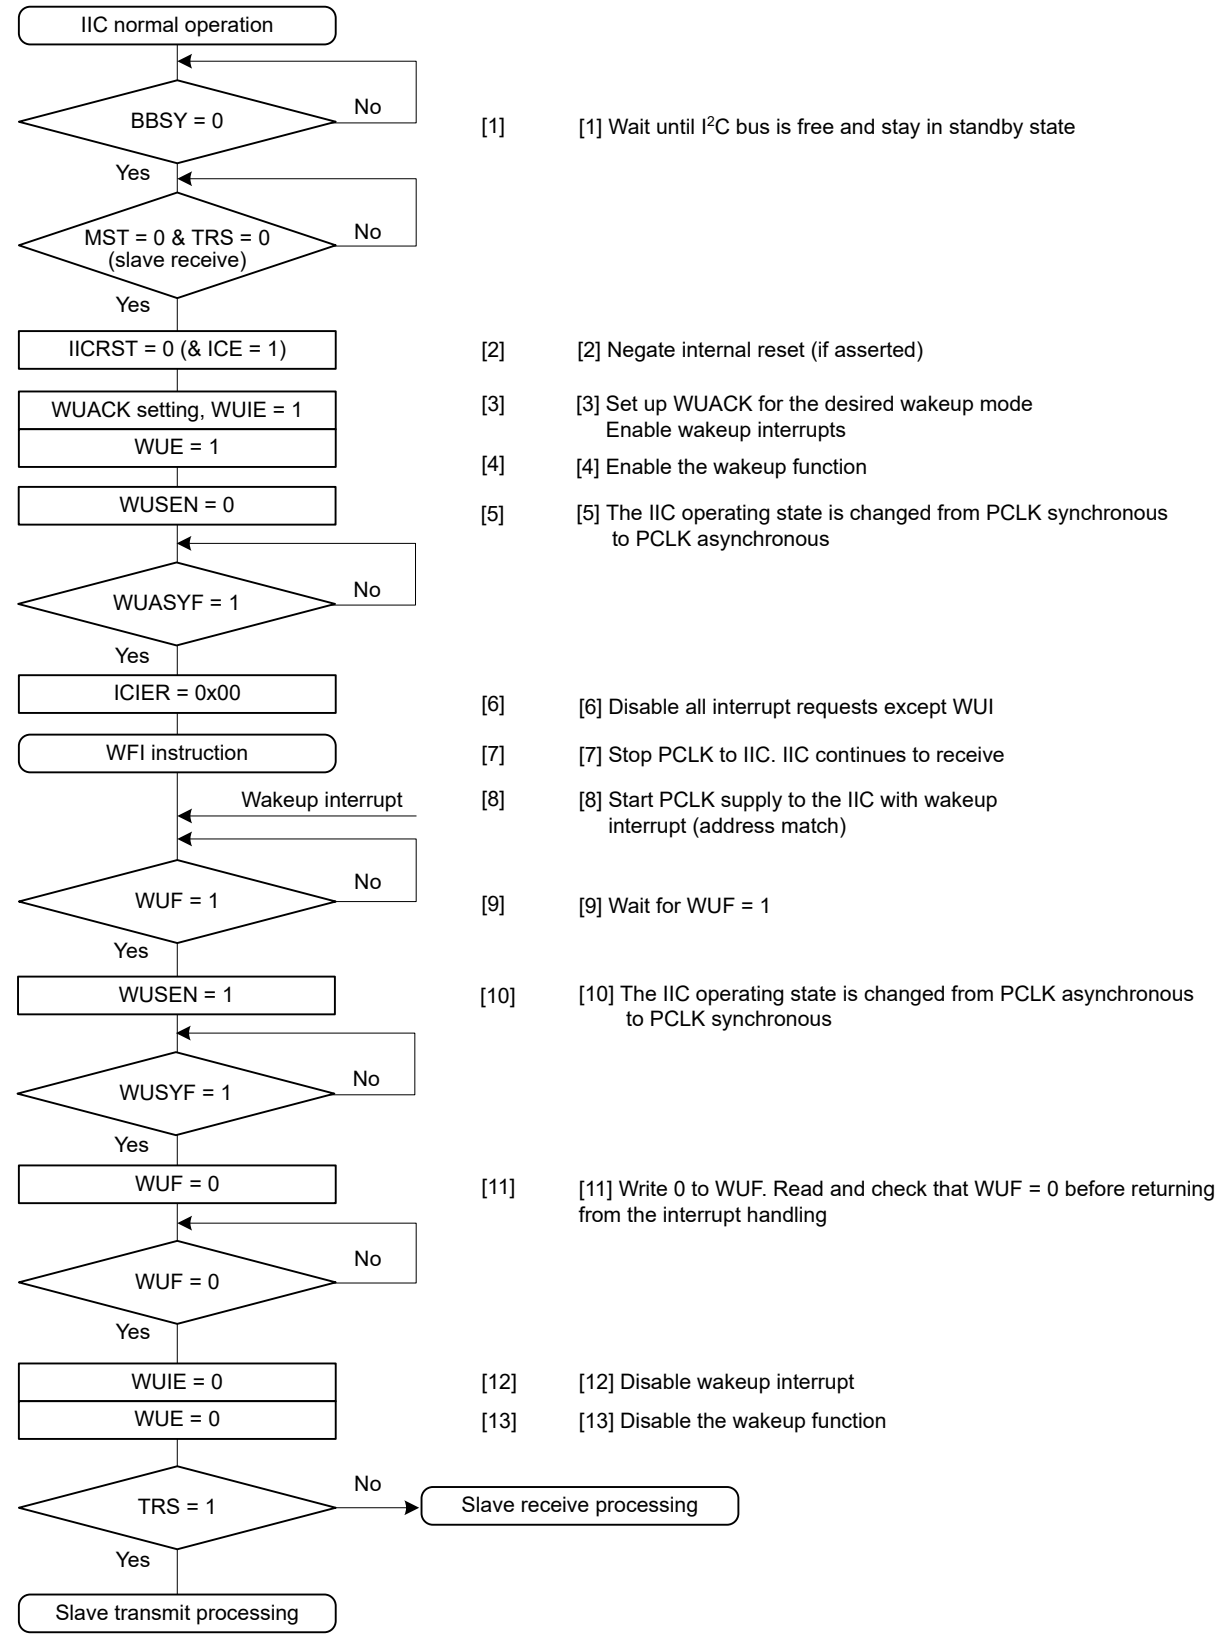

Figure 29.33 Example operation of normal wakeup mode 2 when wakeup is triggered by a wakeup interrupt on match of the slave address

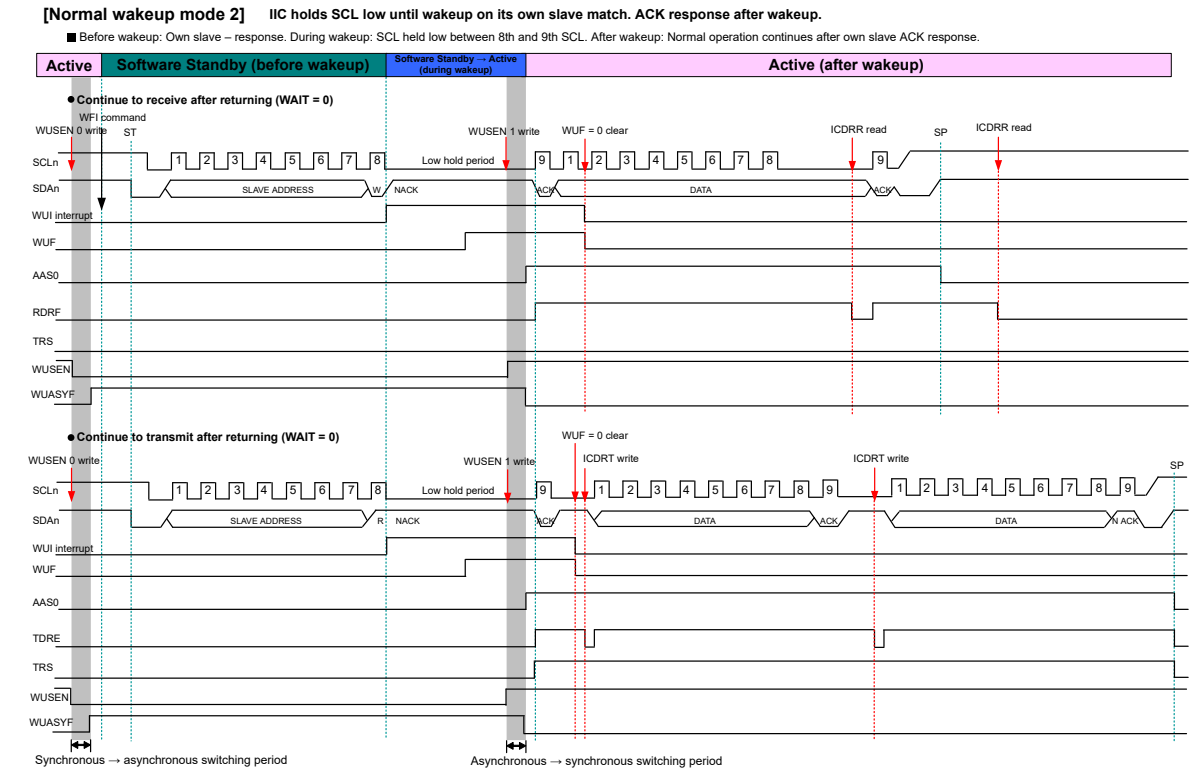
Note: See Precautions on the use of the wakeup function.



Note: n = 0

Figure 29.34 Timing of normal wakeup mode 2

29.8.3 Command Recovery Mode and EEP Response Mode (Special Wakeup Modes)

This section describes the behavior, the timing, and example operations of the command recovery and EEP response modes.

In the command recovery and EEP response modes, the SCL line is not held low during the wakeup period (after the rise of the 9th clock cycle of SCL). Therefore, other IIC devices can use the I^2C bus during this period.

A wakeup interrupt triggered by a match of the slave address initiates the transition to normal operation as follows:

Before wakeup:	In response to the data received with its own slave address, the IIC returns ACK (command recovery mode) or NACK (EEP response mode).
During wakeup:	The SCL line is not held low.
After wakeup:	Normal operation continues after IIC initialization.

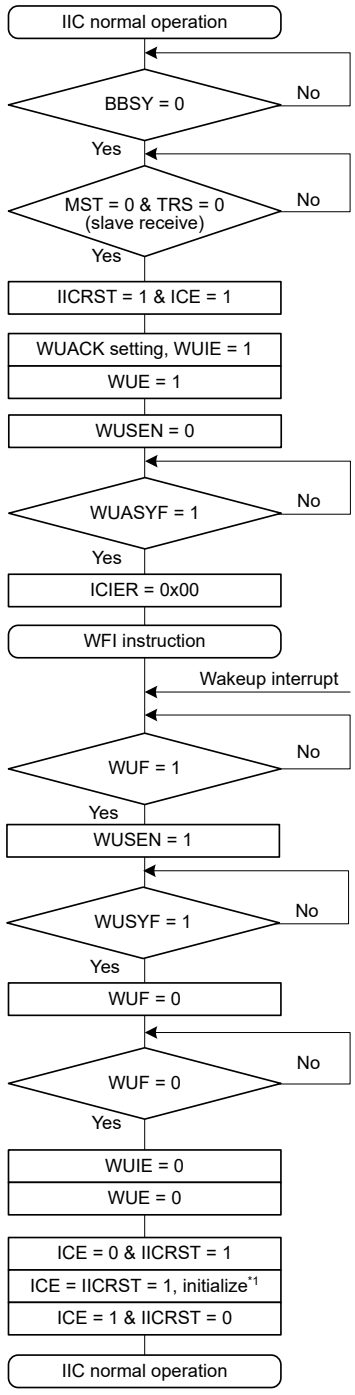
If the slave address does not match, the slave operation continues.

Note: Because the SCL line is not held low during wakeup, transmission or reception of the data that follows the slave address is not possible.

Note: The command recovery and EEP response modes are internal reset states (ICE = IICRST = 1). Therefore, the match of the slave address does not set the flags, HOA, GCA, ASS0, ASS1, and ASS2 in the ICSR1 register.

Figure 29.35 shows an example operation in recovery and EEP response modes. Figure 29.37 shows the detailed timing.

If the transition from Software Standby mode is triggered by an interrupt other than a wakeup interrupt, such as IRQn for example, the WUF flag is not set to 1. Follow the processing shown in Figure 29.36.



[1] [1] Wait until I^2C bus is open and stay in standby state.

[2] [2] Internal reset is asserted.

[3] [3] Set up WUACK for the desired wakeup mode. Enable wakeup interrupt.

[4] [4] Enable wakeup function.

[5] [5] The IIC operating state is changed from PCLK synchronous to PCLK asynchronous.

[6] [6] Disable all interrupt requests except WUI.

[7] [7] Stop PCLK to IIC. IIC continues to receive.

[8] [8] Start PCLK supply to the IIC with wakeup interrupt (address match).

[9] [9] Wait for WUF = 1.

[10] [10] The IIC operating state is changed from PCLK asynchronous to PCLK synchronous.

[11] [11] Write 0 to WUF. Read and check that WUF = 0 before returning from the interrupt handling.

[12] [12] Disable wakeup interrupt.

[13] [13] Disable wakeup function.

[14] [14] Reset IIC (ICE = 0 & IICRST = 1).

[15] [15] Reset IIC (internal reset: ICE = 1 & IICRST = 1). Initial settings.

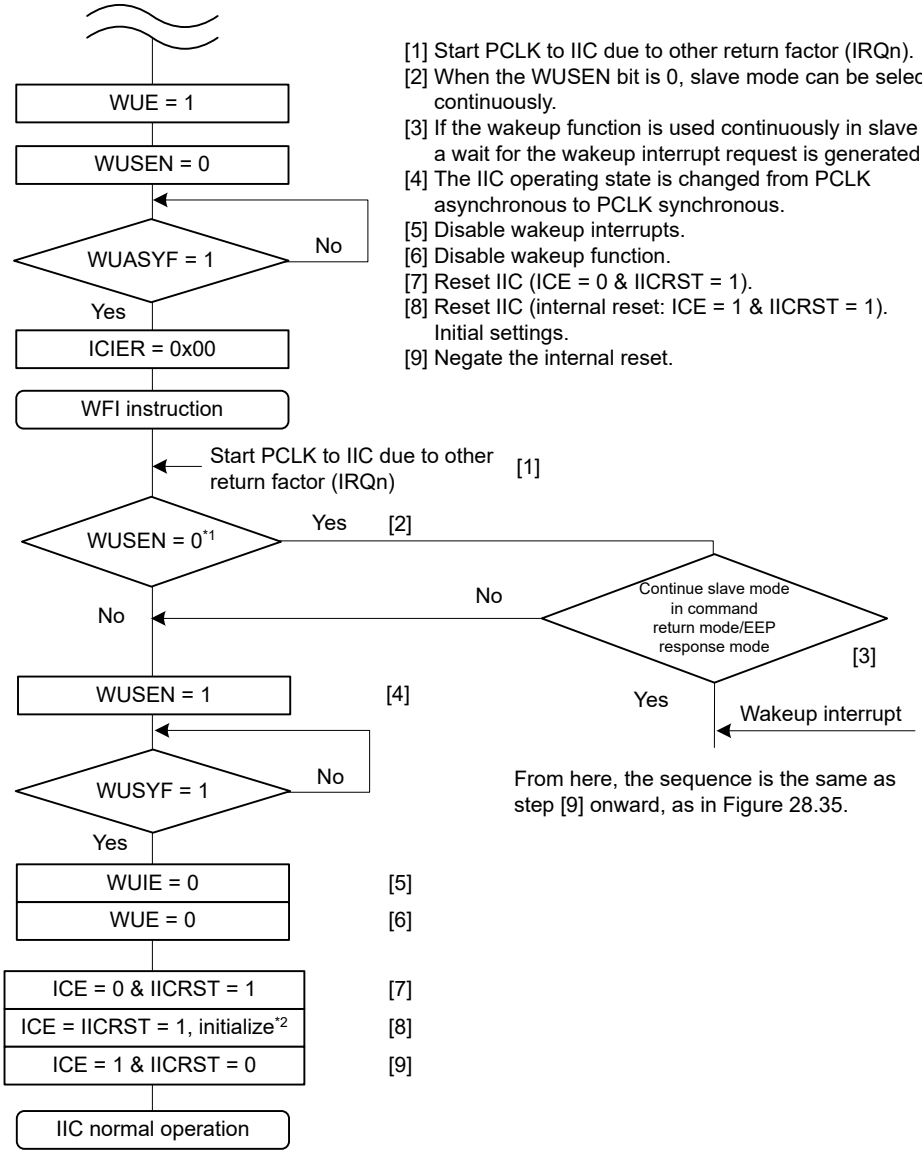
[16] [16] Negate the internal reset.

Note: PCLK = PCLKB

Note 1. For details on IIC initialization, see section 29.3.2. Initial Settings.

Figure 29.35 Example operation of command recovery mode and EEP response mode when wakeup is triggered by a wakeup interrupt on match of the slave address

Note: See Precautions on the use of the wakeup function.



Note: PCLK = PCLKB
Note 1. In the MCU, WUSEN bit is always 0 in the IIC.
Note 2. For details on IIC initialization, see section 29.3.2. Initial Settings.

29.9 Automatic Low-Hold Function for SCL

29.9.1 Function to Prevent Wrong Transmission of Transmit Data

If the I^2C Bus Shift Register (ICDRS) is empty and data has not been written to the I^2C Bus Transmit Data Register (ICDRT) with the IIC in transmission mode (TRS bit = 1 in ICCR2), the SCLn line is automatically held low over the subsequent intervals. This low-hold period is extended until the transmit data is written, which prevents the unintended transmission of erroneous data.

Master transmit mode:

- Low-level interval after a start or restart condition is issued
- Low-level interval between the 9th clock cycle of one transfer and the 1st clock cycle of the next.

Slave transmit mode:

- Low-level interval between the 9th clock cycle of one transfer and the 1st clock cycle of the next.

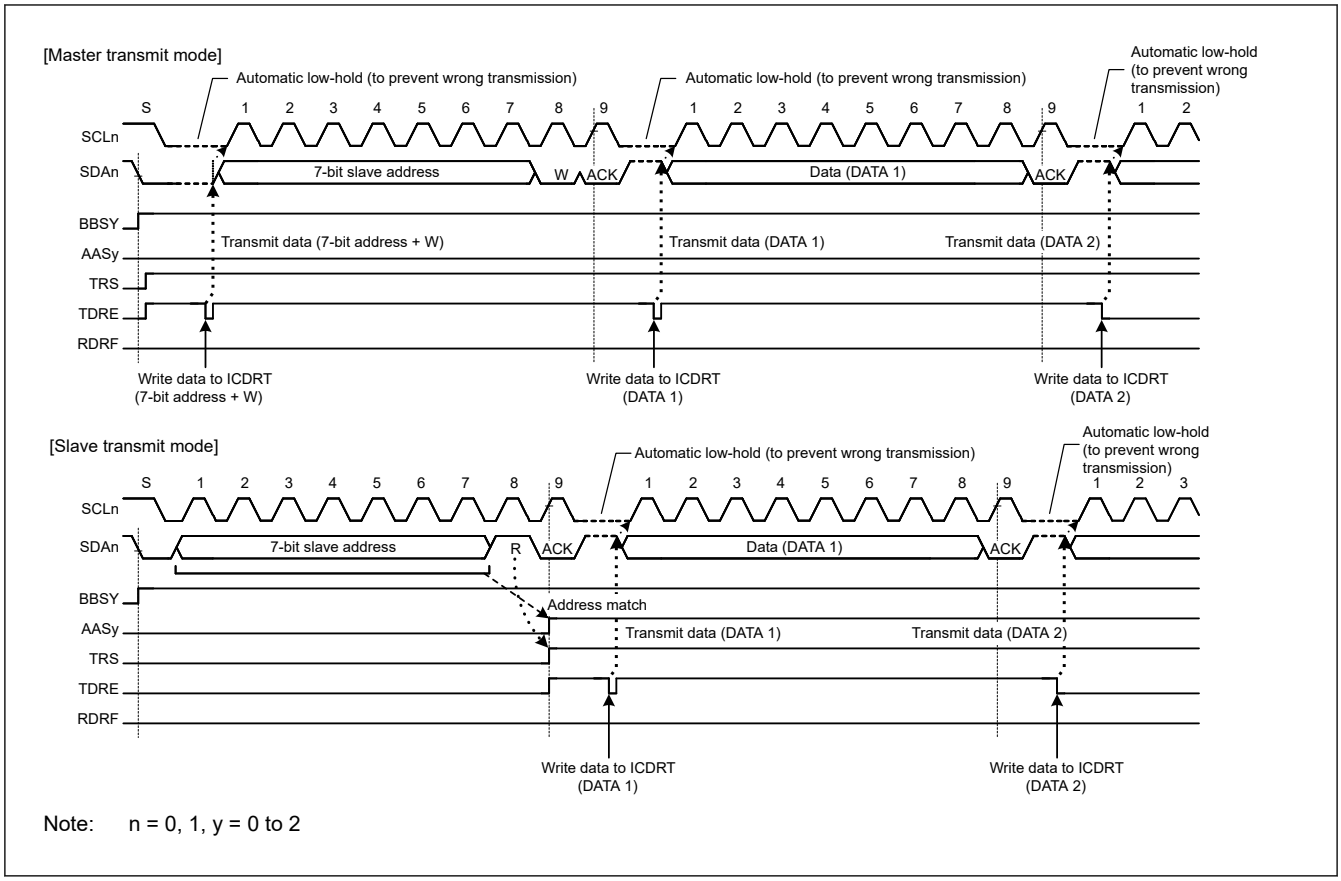

Figure 29.38 Automatic low-hold operation in transmit mode

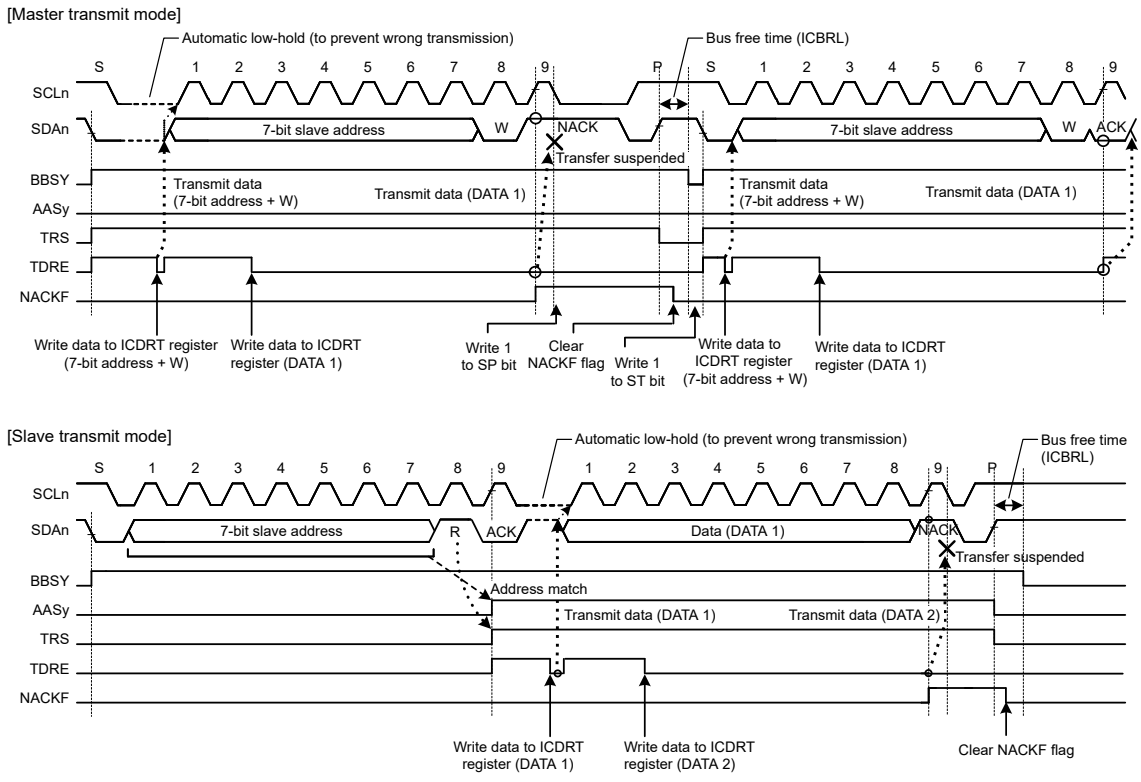
29.9.2 NACK Reception Transfer Suspension Function

This function suspends transfer operation when NACK is received in transmit mode (TRS bit = 1 in ICCR2). This function is enabled when the NACKE bit in ICFER is set to 1. If the next transmit data is already written (TDRE flag = 0 in ICSR2) when NACK is received, the next data transmission on the falling edge of the 9th SCL clock cycle is automatically suspended. This prevents the SDAn line output level from being held low when the MSB of the next transmit data is 0.

If the transfer operation is suspended by this function (NACKF flag = 1 in ICSR2), transmit and receive operations are discontinued. To restore transmit or receive operation, after issuing the restart condition, you need to set the NACKF flag to 0 and try again, or set the NACKF flag to 0 after issuing the stop condition and then start again from issuing the start condition.



Note: n = 0, 1, y = 0 to 2

Figure 29.39 Suspension of data transfer when NACK is received, when NACKE = 1

29.9.3 Function to Prevent Failure to Receive Data

If response processing is delayed when receive data (ICDRR) read is delayed for a period of one transfer frame or more with receive data full (RDRF flag = 1 in ICSR2) in receive mode (TRS = 0 in ICCR2), the IIC holds the SCLn line low automatically immediately before the next data is received to prevent a failure to receive data.

This function is enabled even if the read processing of the final receive data is delayed and, in the meantime, the IIC slave address is designated after a stop condition is issued. This function does not interfere with other communication because the IIC does not hold the SCLn line low when a mismatch with its own slave address occurs after a stop condition is issued.

Periods in which the SCLn line is held low can be selected with a combination of the WAIT and RDRFS bits in ICMR3.

(1) 1-byte receive operation and automatic low-hold function using the WAIT bit

When the WAIT bit in ICMR3 is set to 1, the IIC performs a 1-byte receive operation using the WAIT bit function. Additionally, when the ICMR3.RDRFS bit is 0, the IIC automatically sends the ACKBT bit value in ICMR3 for the acknowledge bit in the period from the falling edge of the 8th SCL clock cycle to the falling edge of the 9th SCL clock cycle, and automatically holds the SCLn line low on the falling edge of the 9th SCL clock cycle using the WAIT bit function. This low-hold is released by reading data from ICDRR, which enables byte-wise receive operation.

The WAIT bit function is enabled for receive frames after a match with the IIC slave address, including the general call address and host address, is obtained in master or slave receive mode.

(2) 1-byte receive operation (ACK/NACK transmission control) and automatic low-hold function using the RDRFS bit

When the RDRFS bit in ICMR3 is set to 1, the IIC performs a 1-byte receive operation using the RDRFS bit function. When the RDRFS bit is set to 1, the RDRF flag in ICSR2 is set to 1 (receive data full) on the rising edge of the eighth SCL clock cycle, and the SCLn line is automatically held low on the falling edge of the eighth SCL clock cycle. This low-hold

is released by writing a value to the ACKBT bit in ICMR3, but cannot be released by reading data from ICDRR, which enables receive operation through the ACK or NACK transmission control based on the data received in byte units.

The RDRFS bit function is enabled for receive frames after a match with the IIC slave address, including the general call address and host address, is obtained in master or slave receive mode.

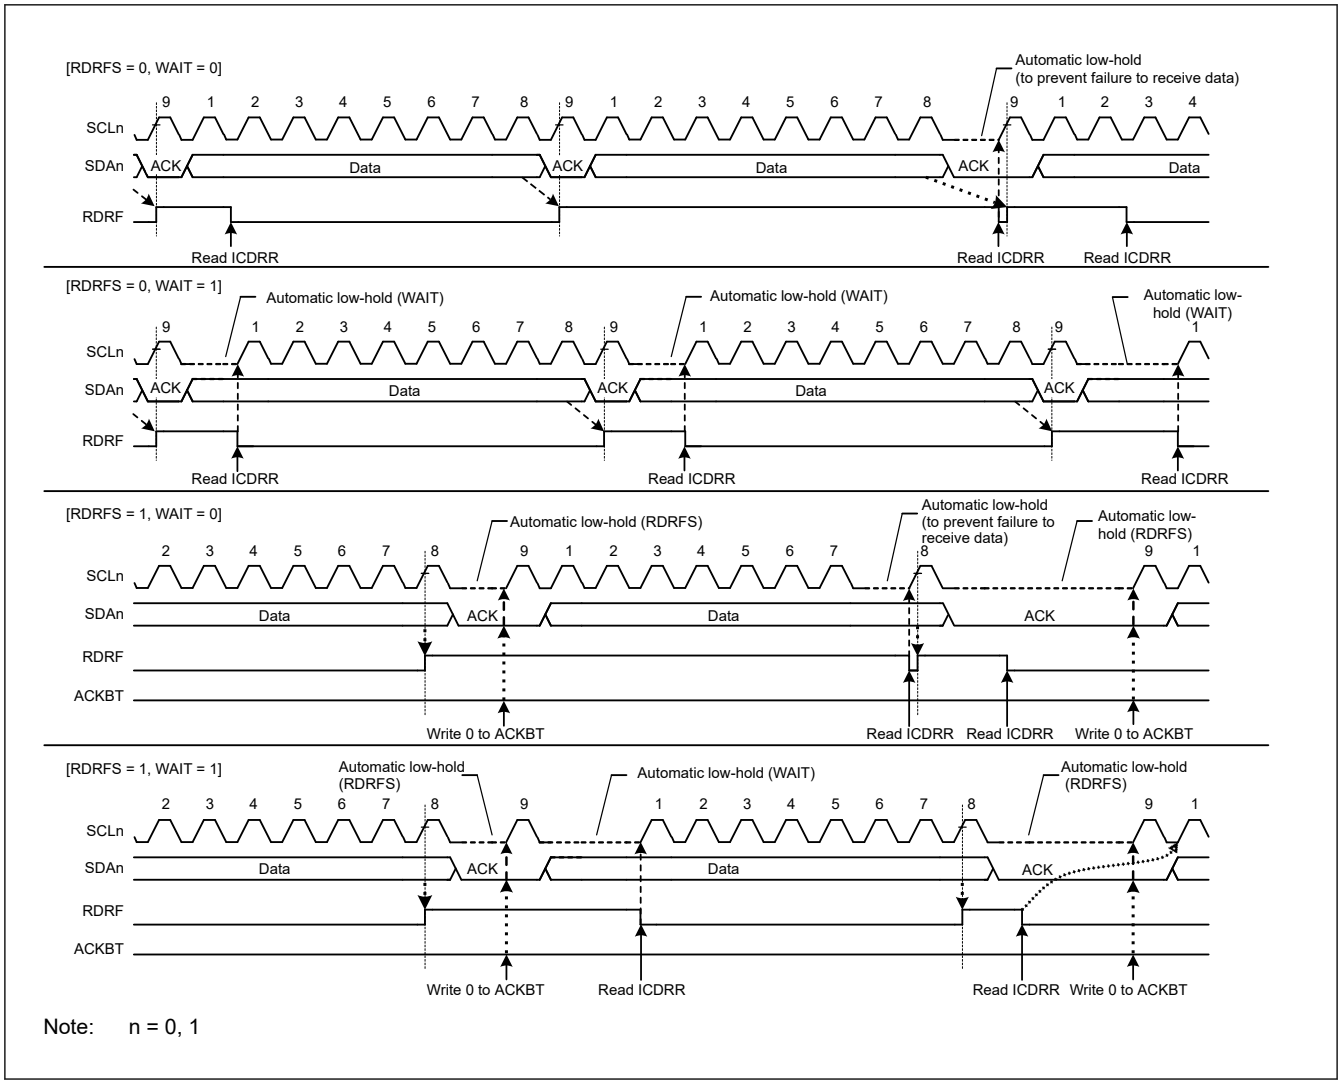


Figure 29.40 Automatic low-hold operation in receive mode using the RDRFS and WAIT bits

29.10 Arbitration-Lost Detection Functions

In addition to the normal arbitration-lost detection function defined by the I^2C bus standard, the IIC provides functions to prevent double-issue of a start condition, detect arbitration-lost during transmission of NACK, and detect arbitration-lost in slave transmit mode.

29.10.1 Master Arbitration-Lost Detection (MALE Bit)

The IIC drives the SDAn line low to issue a start condition. However, if the SDAn line was already driven low by another master device issuing a start condition, the IIC regards its own start condition as an error and considers this a loss in arbitration. Priority is given to transfer by the other master device. Similarly, if a request to issue a start condition is made by setting the ST bit in ICCR2 to 1 while the bus is busy (BBSY flag = 1 in ICCR2), the IIC regards this as a double-issuing-of-start-condition error and considers itself to have lost in arbitration. This prevents a failure of transfer resulting from a start condition being issued while transfer is in progress.

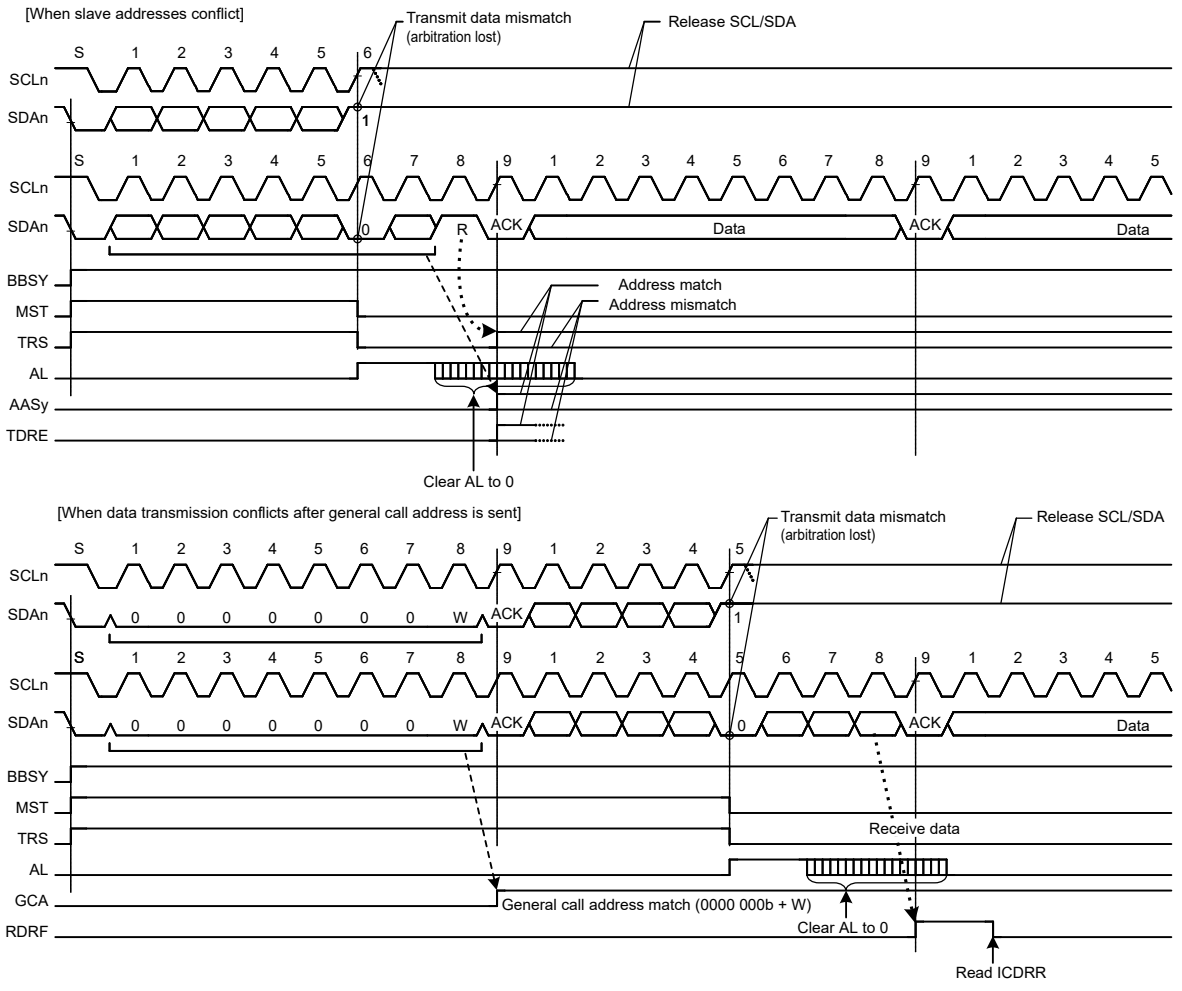
When a start condition is issued successfully, if the transmit data including the address bits (internal SDA output level) and the level on the SDAn line do not match (high output as the internal SDA output, meaning the SDAn pin is in the high-impedance state and a low level is detected on the SDAn line), the IIC loses in arbitration.

After a loss in arbitration of mastership, the IIC immediately enters slave receive mode. If a slave address, including the general call address, matches its own address at this time, the IIC continues in slave operation.

A loss in arbitration of mastership is detected when the following conditions are met while the MALE bit in ICFER is 1 (master arbitration-lost detection enabled).

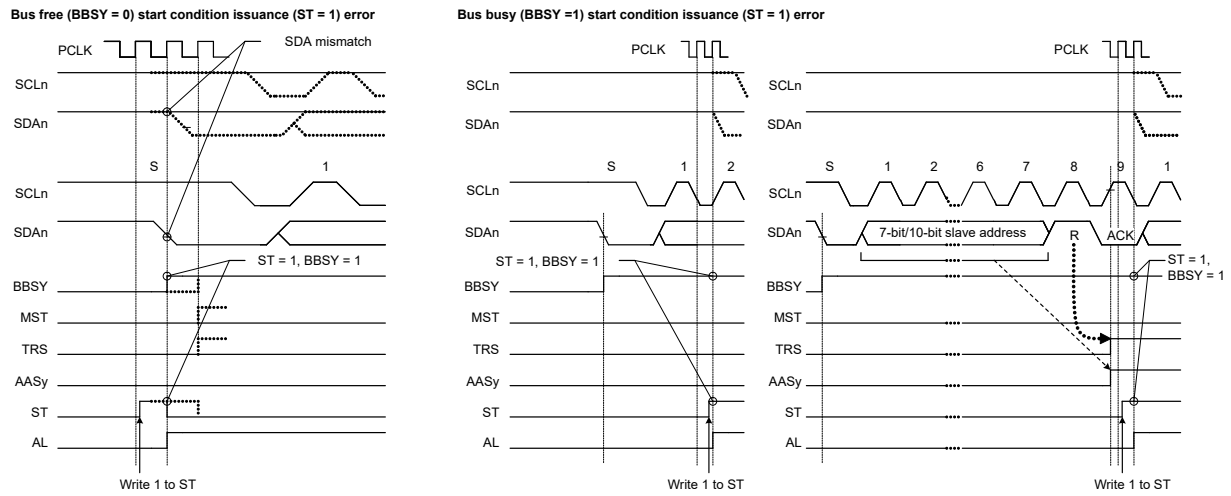
[Master arbitration-lost conditions]

- Mismatching of the internal level for output on SDA and the level on the SDAn line after a start condition was issued by setting the ST bit in ICCR2 to 1 while the BBSY flag in ICCR2 is set to 0 (erroneous issuing of a start condition)
- Setting of the ST bit in ICCR2 to 1 (start condition double-issue error) while the BBSY flag is 1
- When the transmit data excluding acknowledge (internal SDA output level) does not match the level on the SDAn line in master transmit mode (MST and TRS bits = 11b in ICCR2).



Note: n = 0, 1

Figure 29.41 Examples of master arbitration-lost detection when MALE = 1

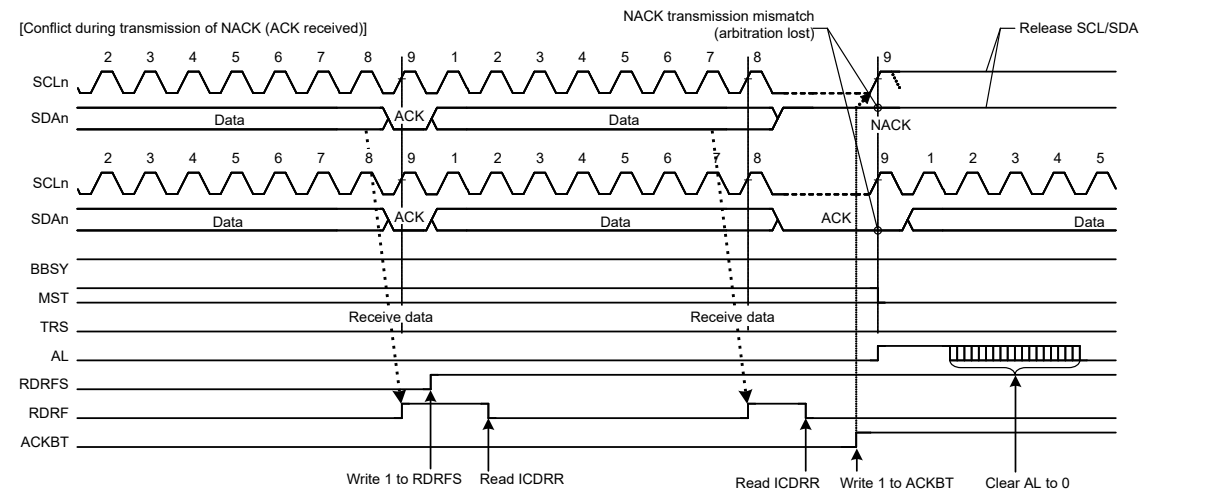


Note: PCLK = PCLKB
Note: n = 0, 1, y = 0 to 2

Figure 29.42 Arbitration-lost when start condition is issued when MALE = 1

29.10.2 Function to Detect Loss of Arbitration during NACK Transmission (NALE Bit)

This function causes arbitration to be lost if the internal SDA output level does not match the level on the SDAn line (high output as the internal SDA output, meaning the SDAn pin is in the high-impedance state) and the low level is detected on the SDAn line during transmission of NACK in receive mode. Arbitration is lost because of a conflict between NACK and ACK transmissions when two or more master devices receive data from the same slave device simultaneously in a multi-master system. Such a conflict occurs when multiple master devices send or receive the same information through a single slave device. Figure 29.43 shows an example of arbitration-lost detection during transmission of NACK.



Note: n = 0, 1

Figure 29.43 Example of arbitration-lost detection during transmission of NACK when NALE = 1

The following explains arbitration-lost detection using an example in which two master devices (master A and master B) and a single slave device are connected through the bus. In this example, master A receives 2 bytes of data from the slave device, and master B receives 4 bytes of data from the slave device.

If master A and master B access the slave device simultaneously, because the slave address is identical, arbitration is not lost in either master A or master B during access to the slave device. Therefore, both master A and master B recognize that they have obtained the bus mastership and operate as such. Master A sends NACK when it has received 2 final bytes of

data from the slave device. Meanwhile, master B sends ACK because it has not received the required 4 bytes of data. At this time, the NACK transmission from master A and the ACK transmission from master B conflict. In general, if a conflict like this occurs, master A cannot detect the ACK transmitted by master B and issues a stop condition. The stop condition issue conflicts with the SCL clock output of master B, which disrupts communication.

When the IIC receives ACK during transmission of NACK, it detects a defeat in conflict with other master devices and causes arbitration to be lost. If arbitration is lost during transmission of NACK, the IIC immediately cancels the slave match condition and enters slave receive mode. This prevents a stop condition from being issued, preventing a communication failure on the bus.

Similarly, in the ARP command processing of SMBus, the function to detect loss of arbitration during transmission of NACK is also available for eliminating the extra clock cycle processing, such as 0xFF transmission processing, which is required if the UDID (Unique Device Identifier) of the assigned address does not match in the Get UDID general processing after the Assign Address command.

The IIC detects arbitration-lost during transmission of NACK when the following condition is met with the NALE bit in ICFER set to 1 (arbitration-lost detection during NACK transmission enabled).

[Condition for arbitration-lost during NACK transmission]

- When the internal SDA output level does not match the SDAn line (ACK is received) during transmission of NACK (ACKBT bit = 1 in ICMR3).

29.10.3 Slave Arbitration-Lost Detection (SALE Bit)

This function causes arbitration to be lost if the transmit data (internal SDA output level) and the level on the SDAn line do not match (high output as the internal SDA output, meaning the SDAn pin is in the high-impedance state), and the low level is detected on the SDAn line in slave transmit mode. This arbitration-lost detection function is mainly used when transmitting a UDID (Unique Device Identifier) over an SMBus.

When the IIC loses slave arbitration, the IIC is immediately released from the slave-matched state and enters slave receive mode. This function can detect conflicts of data during transmission of UDIDs over an SMBus and eliminates subsequent redundant processing for the transmission of 0xFF.

The IIC detects slave arbitration-lost when the following condition is met with the SALE bit in ICFER set to 1 (slave arbitration-lost detection enabled).

[Condition for slave arbitration-lost]

- When transmit data excluding acknowledge (internal SDA output level) does not match the SDAn line in slave transmit mode (MST and TRS bits = 01b in ICCR2).

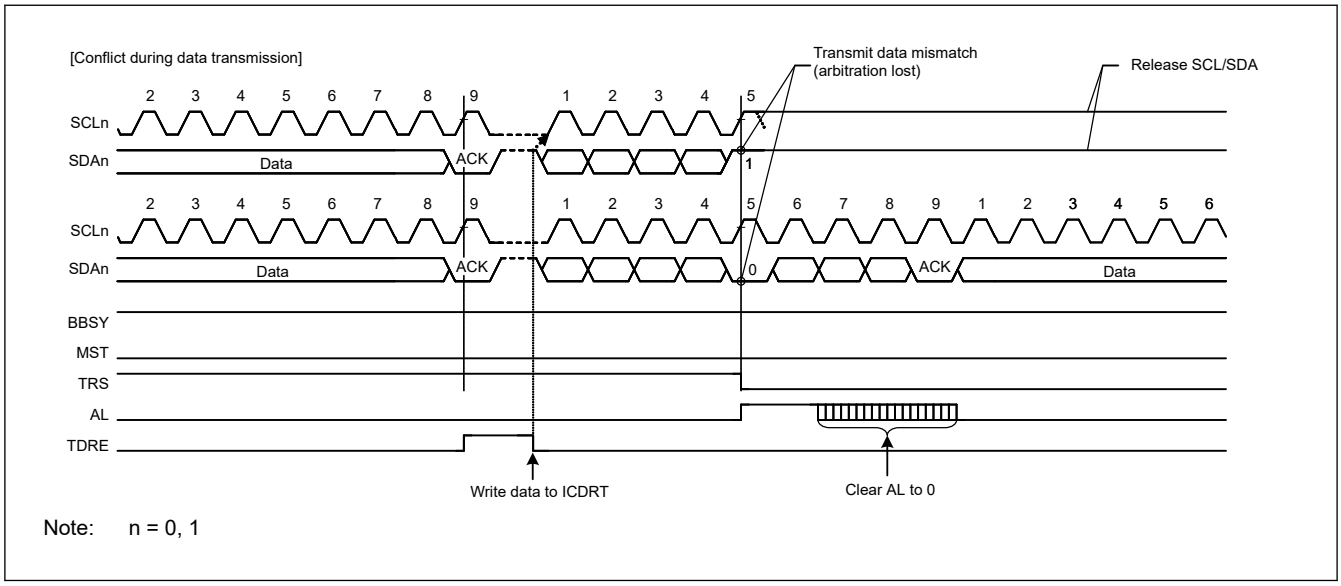


Figure 29.44 Example of slave arbitration-lost detection when SALE = 1

29.11 Start, Restart, and Stop Condition Issuing Function

29.11.1 Issuing a Start Condition

The IIC issues a start condition when the ST bit in ICCR2 is set to 1. When the ST bit is set to 1, a start condition request is made, and the IIC issues a start condition when the BBSY flag in ICCR2 is 0 (bus free state). When a start condition is issued normally, the IIC automatically shifts to the master transmit mode.

To issue a start condition:

1. Drive the SDAn line low (high level to low level).
2. Ensure that the time set in ICBRH and the start condition hold time elapse.
3. Drive the SCLn line low (high level to low level).
4. Detect low level on the SCLn line and ensure the low-level period of the SCLn line set in ICBRL elapses.

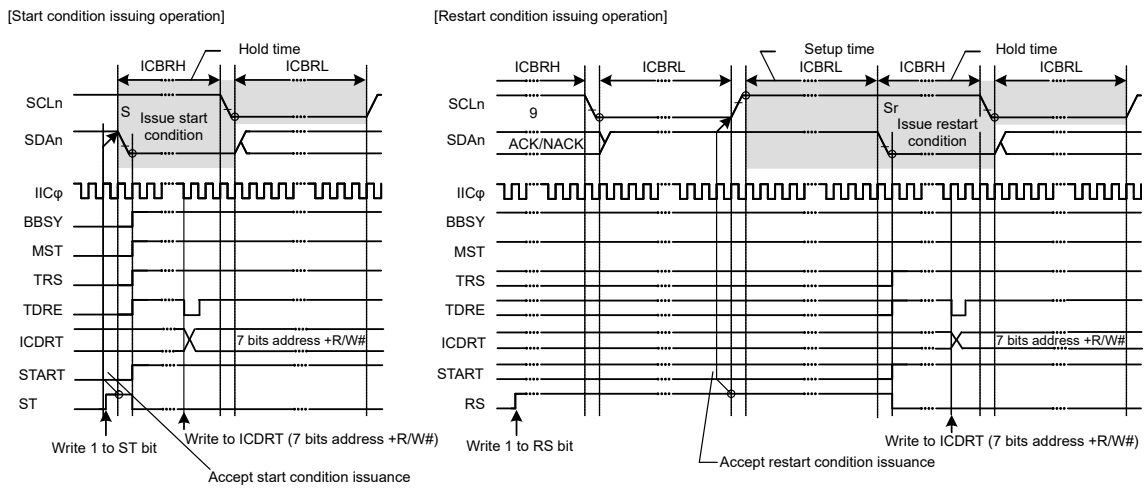
29.11.2 Issuing a Restart Condition

The IIC issues a restart condition when the RS bit in ICCR2 is set to 1. When the RS bit is set to 1, a restart condition request is made, and the IIC issues a restart condition when the BBSY flag in ICCR2 is 1 (bus busy state) and the MST bit in ICCR2 is 1 (master mode).

To issue a restart condition:

1. Release the SDAn line.
2. Ensure the low-level period of the SCLn line set in ICBRL elapses.
3. Release the SCLn line (low level to high level).
4. Detect a high level on the SCLn line and ensure the time set in ICBRL and the restart condition setup time elapse.
5. Drive the SDAn line low (high level to low level).
6. Ensure the time set in ICBRH and the restart condition hold time elapse.
7. Drive the SCLn line low (high level to low level).
8. Detect a low level on the SCLn line and ensure the low-level period of the SCLn line set in ICBRL elapses.

Note: When issuing restart condition requests, write the slave address to ICDRT after confirming that ICCR2.RS = 0. Data written while ICCR2.RS = 1 is not forwarded because of the retransmission condition before the occurrence.



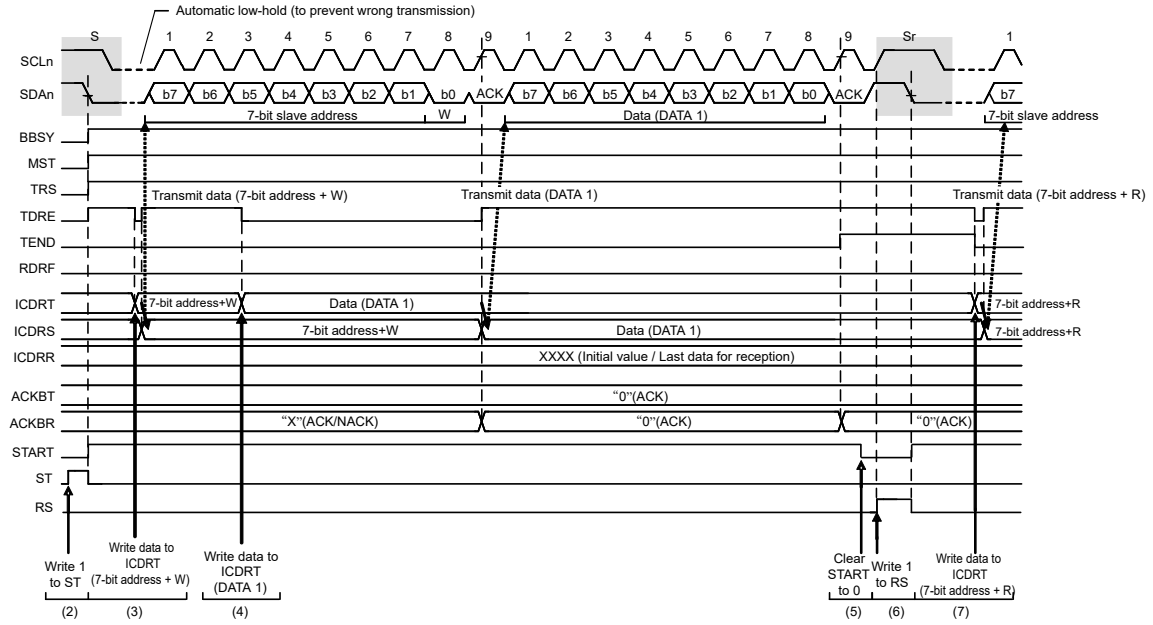
Note: n = 0, 1

Figure 29.45 Start and restart condition issue timing using the ST and RS bits

Figure 29.46 shows the operation timing when a restart condition is issued after the master transmission.

[To issue a restart condition after the master transmission:]

1. Initialize the IIC using the procedure in section 29.3.2. Initial Settings.
2. Read the BBSY flag in ICCR2 to check that the bus is open, then set the ST bit in ICCR2 to 1 (start condition issuance request). On receiving the request, the IIC issues a start condition. At the same time, the BBSY and the START flags in ICSR2 are automatically set to 1 and the ST bit is automatically set to 0. If the start condition is detected and the internal levels for the SDA output state and the levels on the SDAn line match while the ST bit is 1, the IIC recognizes that a start condition is successfully issued as requested by the ST bit has been successfully completed. The MST and TRS bits in ICCR2 are automatically set to 1, placing the IIC in master transmit mode. The TDRE flag in ICSR2 is also automatically set to 1 when the TRS bit is set to 1.
3. Check that the TDRE flag in ICSR2 is 1, and then write the value for transmission (the slave address and the R/W# bit) to ICDRT. After the data for transmission is written to ICDRT, the TDRE flag is automatically set to 0, data is transferred from ICDRT to ICDRS, and the TDRE flag is again set to 1. After the byte containing the slave address and R/W# bit has been transmitted, the value of the TRS bit is automatically updated to select master transmit or master receive mode according to the value of the transmitted R/W# bit. If the value of the R/W# bit is 0, the IIC continues in master transmit mode. If the ICSR2.NACKF flag is 1 at this time, indicating that no slave device recognized the address or that there was an error in communications, write 1 to ICCR2.SP bit to issue a stop condition. To transmit data with an address in the 10-bit format, start by writing 1111 0b, the 2 upper bits of the slave address, and W to ICDRT as the first address transmission. Then, as the second address transmission, write the 8 lower bits of the slave address to ICDRT.
4. After confirming that the TDRE flag in ICSR2 is 1, write data for transmission to the ICDRT register. The IIC automatically holds the SCLn line low until data for transmission is ready, a restart condition is issued or a stop condition is issued.
5. After all bytes of data for transmission are written to the ICDRT register, wait until the value of the TEND flag in ICSR2 returns to 1. Then after checking that the START flag in ICSR2 is 1, set the START flag in ICSR2 to 0.
6. Set the RS bit in ICCR2 to 1 (restart condition issue request). On receiving the request, the IIC issues a restart condition.
7. After checking that the START flag in ICSR2 is 1, write the value for transmission (the slave address and the R/W# bit) to ICDRT.



Note: n = 0, 1

Figure 29.46 Restart condition issue timing after master transmission.

29.11.3 Issuing a Stop Condition

The IIC issues a stop condition when the SP bit in ICCR2 is set to 1. When the SP bit is set to 1, a stop condition request is made, and the IIC issues a stop condition when the BBSY flag in ICCR2 is 1 (bus busy state) and the MST bit in ICCR2 is 1 (master mode).

To issue a stop condition:

1. Drive the SDAn line low (high level to low level).
2. Ensure the low-level period of the SCLn line set in ICBRL elapses.
3. Release the SCLn line (low level to high level).
4. Detect a high level on the SCLn line and ensure the time set in ICBRH and the stop condition setup time elapse.
5. Release the SDAn line (low level to high level).
6. Ensure the time set in ICBRL and the bus free time elapse.
7. Clear the BBSY flag to 0 to release the bus mastership.

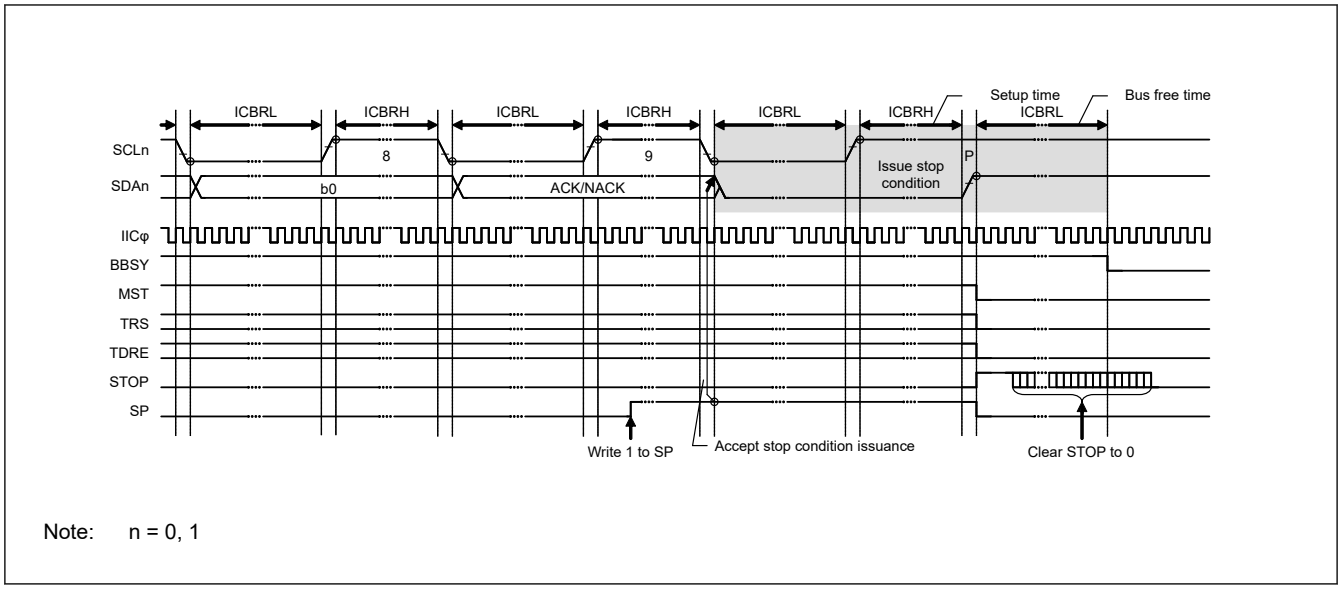


Figure 29.47 Stop condition issue timing using the SP bit

29.12 Bus Hanging

If the clock signals from the master and slave devices are out of synchronization because of noise or other factors, the I^2C bus might hang with a fixed level on the SCLn line or SDAn line.

To manage bus hanging, the IIC has a timeout function to detect hanging by monitoring the SCLn line, and a function for outputting an extra SCL clock cycle to release the bus from:

- A timeout function to detect hanging by monitoring the SCLn line
- The IIC reset function
- An internal reset function.

By checking the SCLO, SDAO, SCLI, and SDAI bits in ICCR1, it is possible to see whether the IIC or its communicating partner is placing the low level on the SCLn or SDAn line.

29.12.1 Timeout Function

The timeout function can detect when the SCLn line is stuck longer than the predetermined time. The IIC can detect an abnormal bus state by monitoring that the SCLn line is stuck low or high for a predetermined time.

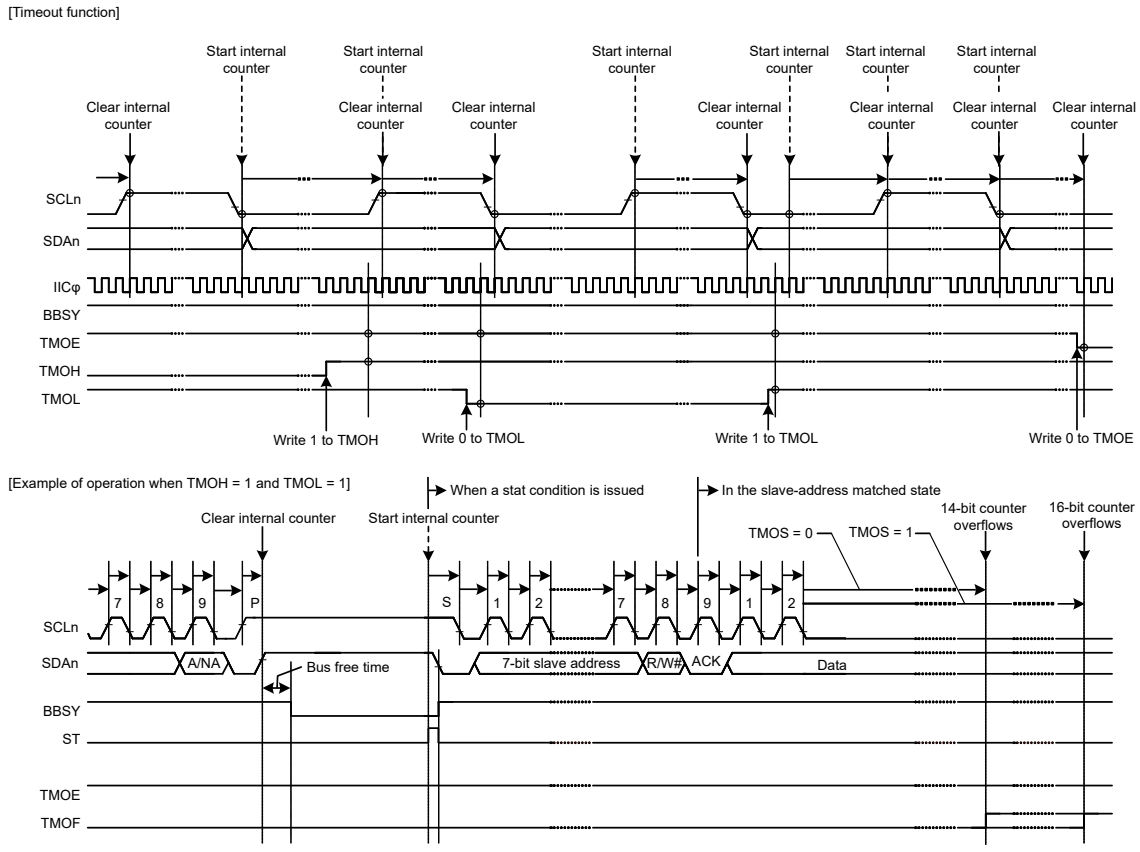
The timeout function monitors the SCLn line state and counts the low- or high-level period using the internal counter. The timeout function resets the internal counter each time the SCLn line changes (rises or falls), but continues to count unless the SCLn line changes. If the internal counter overflows because no SCLn line changes, the IIC can detect the timeout and report the bus hung state.

This timeout function is enabled when the ICFER.TMOE bit is 1. It detects a hung state when the SCLn line is stuck low or high during the following conditions:

- The bus is busy (ICCR2.BBSY flag is 1) in master mode (ICCR2.MST bit is 1)
- The IIC slave address is detected (ICSR1 register is not 0x00) and the bus is busy (ICCR2.BBSY flag is 1) in slave mode (ICCR2.MST bit is 0)
- The bus is open (ICCR2.BBSY flag is 0) while a start condition is requested (ICCR2.ST bit is 1).

The internal counter of the timeout function uses the internal reference clock (IICφ) set in the CKS[2:0] bits in ICMR1 as a count source. It functions as a 16-bit counter when long mode is selected (TMOS bit = 0 in ICMR2) or a 14-bit counter when short mode is selected (TMOS bit = 1).

The SCLn line level (low, high, or both levels) during which this counter is activated can be selected in the TMOH and TMOL bits in ICMR2. If both TMOL and TMOH bits are set to 0, the internal counter is disabled.



Note: n = 0, 1

Figure 29.48 Timeout function using the TMOE, TMOS, TMOH, and TMOL bits

29.12.2 Extra SCL Clock Cycle Output Function

In master mode, this function outputs extra SCL clock cycles to release the SDAn line of the slave device from being held low because the master is out of synchronization with the slave device. This function is mainly used in master mode to release the SDAn line of the slave device from being fixed low by including extra cycles of SCL output from the IIC. It uses single cycles of the SCL clock for a bus error where the IIC cannot issue a stop condition because the slave device is holding the SDAn line at the low level. Do not use this function in normal situations. Using it when communications are proceeding correctly leads to malfunctions.

When the CLO bit in ICCR1 is set to 1 in master mode, a single cycle of the SCL clock at the frequency specified in the CKS[2:0] bits in ICMR1, and in the ICBRH and ICBRL registers, is output as an extra clock cycle. After output of this single cycle of the SCL clock, the CLO bit is automatically set to 0. At this time, if ICCR2.BBSY = 1, the SCL pin goes low, and when ICCR2.BBSY = 0, the SCL pin goes high. After confirming that the CLO bit is 0 by software, write 1 to the CLO bit to output the additional clock continuously.

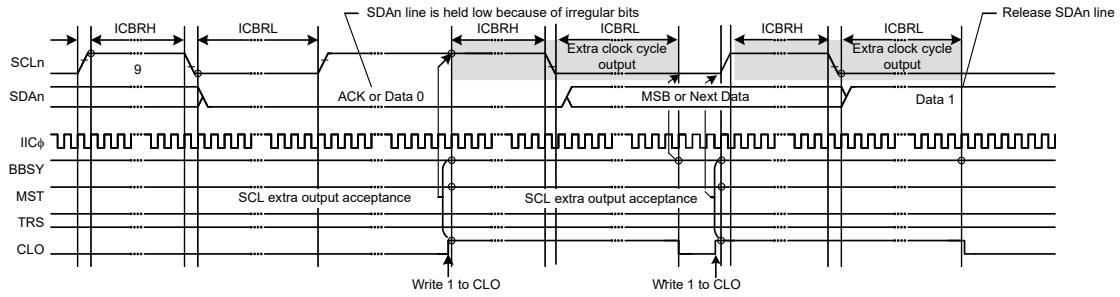
When the IIC module is in master mode and the slave device is holding the SDAn line low because synchronization with the slave device is lost because of effects like noise, the output of a stop condition is not possible. This function can be used to output extra cycles of SCL one by one to make the slave device release the SDAn line from being held low, and so recover the bus from an unusable state. Release of the SDAn line by the slave device can be monitored by reading the SDAI bit in ICCR1. After confirming the release of the SDAn line by the slave device, complete communications by reissuing the stop condition.

[Output conditions for using the CLO bit in ICCR1]

- When the bus is open (BBSY flag in ICCR2 = 0) or in master mode (MST bit = 1 and BBSY flag = 1 in ICCR2)

- When the communication device does not hold the SCLn line low.

Figure 29.49 shows the operation timing of the extra SCL clock cycle output function (CLO bit).



Note: n = 0, 1

Figure 29.49 Extra SCL clock cycle output function using the CLO bit

29.12.3 IIC Reset and Internal Reset

The IIC module incorporates a function for resetting itself. It uses two types of resets:

- An IIC reset, which initializes all registers, including the BBSY flag in ICCR2.
- An internal reset, which releases the IIC from the slave-address matched state and initializes the internal counter while saving other settings.

After issuing a reset, always set the IICRST bit in ICCR1 to 0. Both types of resets are valid for release from bus-hung states, because both restore the output state of the SCLn and SDAn pins to the high-impedance state.

Issuing a reset during slave operation might lead to a loss of synchronization between the master device clock and the slave device clock, so avoid this when possible. In addition, monitoring of the bus state, such as for the presence of a start condition, is not possible during an IIC reset (ICE and IICRST bits = 01b in ICCR1).

For a detailed description of the IIC and internal resets, see section 29.15. State of Registers When Issuing Each Condition.

29.13 SMBus Operation

The IIC supports data communication conforming to the SMBus Specification (version 2.0). To perform SMBus communication, set the SMBS bit in ICMR3 to 1. To use the transfer rate within a range of 10 to 100 kbps of the SMBus standard, set the CKS[2:0] bits in ICMR1, the ICBRH, and ICBRL registers. In addition, specify the values in the DLCS bit in ICMR2 and the SDDL[2:0] bits in ICMR2 to meet the data hold time specification of 300 ns or more. When the IIC is used only as a slave device, the transfer rate setting is not required, but ICBRL must be set to a value longer than the data setup time (250 ns).

For the SMBus device default address (1100 001b), use one of the slave address registers L0 to L2 (SARL0, SARL1, and SARL2), and set the associated FS bit (7- or 10-bit address format select) in SARUy (y = 0 to 2) to 0 (7-bit address format).

When transmitting the UDID (Unique Device Identifier), set the SALE bit in ICFER to 1 to enable the slave arbitration-lost detection function.

29.13.1 SMBus Timeout Measurement

(1) Measuring slave device timeout

The following period (timeout interval: $T_{LOW:\ SEXT}$) must be measured for slave devices in SMBus communication:

- From start condition to stop condition.

To measure timeout for slave devices, measure the period from start condition detection to stop condition detection with the GPT using the IIC start condition detection interrupt (STIn) and stop condition detection interrupt (SPIn). The measured timeout period must be within the total clock low-level period [slave device] $T_{LOW:\ SEXT}$: 25 ms (maximum) of the SMBus standard.

If the time measured with the GPT exceeds the clock low-level detection timeout $T_{TIMEOUT}$: 25 ms (minimum) of the SMBus standard, the slave device must release the bus by writing 1 to the IICRST bit in ICCR1 to issue an internal reset of the IIC. When an internal reset is issued, the IIC stops driving the bus for the SCLn and SDAn pins, making them output high-impedance, which releases the bus.

(2) Measuring master device timeout

The following periods (timeout interval: $T_{LOW:\ MEXT}$) must be measured for master devices in SMBus communication:

- From start condition to acknowledge bit
- Between acknowledge bits
- From acknowledge bit to stop condition.

To measure timeout for master devices, measure these periods with the GPT using the IIC start condition detection interrupt (STIn), stop condition detection interrupt (SPIn), transmit end interrupt (IICn_TEI), or receive data full interrupt (IICn_RXI). The measured timeout period must be within the total clock low-level extended period (master device) $T_{LOW:\ MEXT}$: 10 ms (maximum) of the SMBus standard, and the total of all $T_{LOW:\ MEXT}$ values from start condition to stop condition must be within $T_{LOW:\ SEXT}$: 25 ms (maximum).

For the ACK receive timing (rising edge of the 9th SCL clock cycle), monitor the TEND flag in ICSR2 in master transmit mode (master transmitter) and the RDRF flag in ICSR2 in master receive mode (master receiver). Perform byte-wise transmit operations in master transmit mode, and hold the RDRFS bit in ICMR3 at 0 until the byte immediately before reception of the final byte in master receive mode. While the RDRFS bit is 0, the RDRF flag is set to 1 on the rising edge of the 9th SCL clock cycle.

If the period measured with the GPT exceeds the total clock low-level extended period (master device) $T_{LOW:\ MEXT}$: 10 ms (maximum) of the SMBus standard or the total of measured periods exceeds the clock low-level detection timeout $T_{TIMEOUT}$: 25 ms (minimum) of the SMBus standard, the master device must stop the transaction by issuing a stop condition. In master transmit mode, immediately stop the transmit operation (stop writing data to ICDRT).

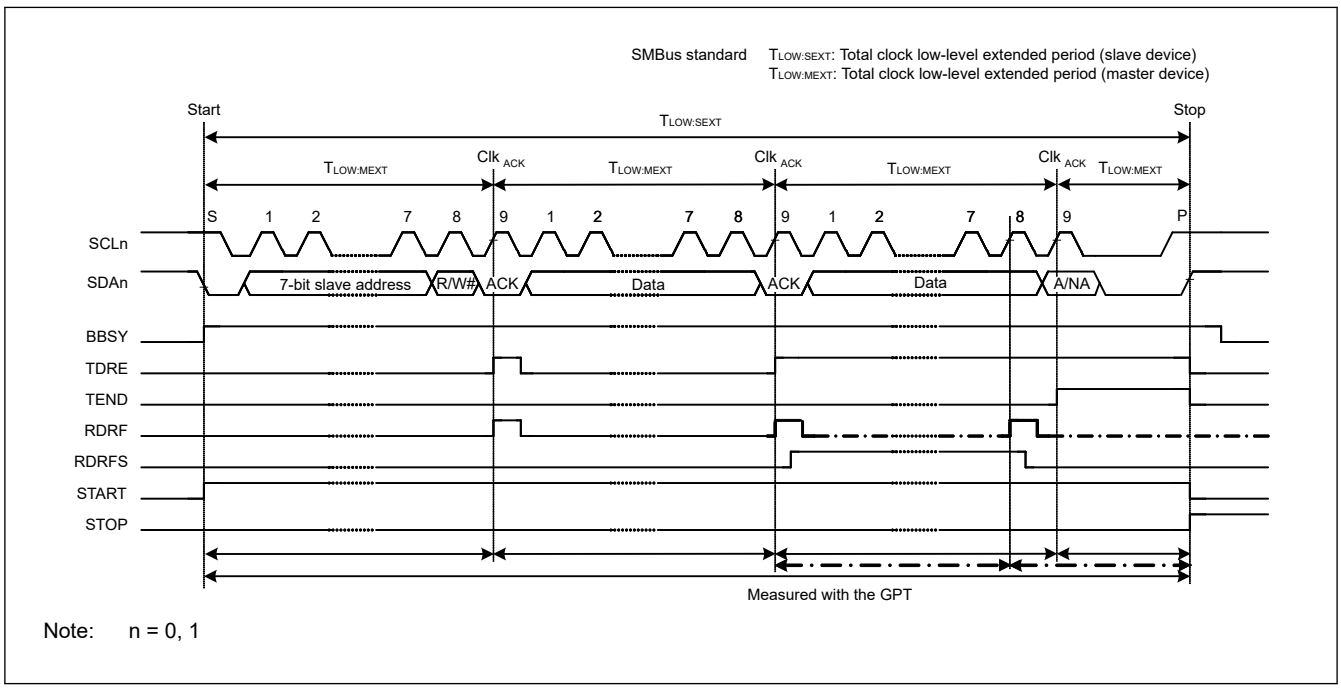


Figure 29.50 SMBus timeout measurement

29.13.2 Packet Error Code (PEC)

The MCU provides a CRC calculator that enables transmission of a Packet Error Code (PEC) or allows checking of the received data in SMBus data communication for the IIC. For the CRC-generating polynomials of the CRC calculator, see section 35, Cyclic Redundancy Check (CRC).

In master transmit mode, the PEC data can be generated by writing all transmit data to the CRC Data Input Register (CRCDIR) in the CRC calculator.

In master receive mode, the PEC data can be checked by writing all receive data to CRCDIR in the CRC calculator and comparing the obtained value in the CRC Data Output Register (CRCDOR) with the received PEC data.

To send ACK or NACK based on the match or mismatch result when the final byte is received as a result of the PEC code check, set the RDRFS bit in ICMR3 to 1 before the rising edge of the 8th SCL clock cycle during reception of the final byte, and hold the SCLn line low on the falling edge of the 8th clock cycle.

29.13.3 SMBus Host Notification Protocol (Notify ARP Master Command)

In communicating over an SMBus, a slave device can temporarily act as a master device to notify the SMBus host (or ARP master) of its own slave address, or to request its own slave address from the SMBus host.

For a product using the MCU to operate as an SMBus host or ARP master, the host address (0001 000b) sent from the slave device must be detected as a slave address, and so the IIC provides a function for detecting the host address. To detect the host address as a slave address, set the SMBS bit in ICMR3 and the HOAE bit in ICSER to 1. Operation after the host address is detected is the same as normal slave operation.

29.14 Interrupt Sources

The IIC issues five types of interrupt requests:

- Transfer error or event generation (arbitration-lost, NACK detection, timeout detection, start condition detection, and stop condition detection)
- Receive data full
- Transmit data empty
- Transmit end
- Address match during wakeup function

Table 29.10 lists details about the interrupt requests. The receive data full and transmit data empty interrupts can activate data transfer by the DTC or DMAC.

Table 29.10 Interrupt sources

Symbol	Interrupt source	Interrupt flag	DTC or DMAC activation	Interrupt condition
IICn_EEI*5	Transfer error or event occurrence	AL	Not possible	AL = 1, ALIE = 1
		NACKF		NACKF = 1, NAKIE = 1
		TMOF		TMOF = 1, TMOIE = 1
		START		START = 1, STIE = 1
		STOP		STOP = 1, SPIE = 1
IICn_RXI*2 *5	Receive data full	RDRF	Possible	RDRF = 1, RIE = 1
IICn_TXI*1 *5	Transmit data empty	RDRF	Possible	TDRE = 1, TIE = 1
IICn_TEI*3 *5	Transmit end	TEND	Not possible	TEND = 1, TEIE = 1
IIC0_WUI*4	Slave address match during wakeup function	WUF	Not possible	Slave address match Slave receive complete RWAK operation ASY0 = 1 WUIE = 1

Note: There is a delay between the execution of a write instruction for a peripheral module by the CPU and the actual writing to the module. When an interrupt flag is cleared or masked, read the relevant flag again to check whether clearing or masking is complete, then return from interrupt handling. Not doing so creates the possibility of repeated processing of the same interrupt.

Note 1. Because IICn_TXI is edge-detected, it does not require clearing. Additionally, the TDRE flag in ICSR2 (condition for IICn_TXI) is automatically set to 0 when transmit data is written to the ICDRT register or a stop condition is detected (STOP flag = 1 in ICSR2).
Note 2. Because IICn_RXI is edge-detected, it does not require clearing. Additionally, the RDRF flag in ICSR2 (condition for IICn_RXI) is automatically set to 0 when data is read from ICDRR.
Note 3. When using the IICn_TEI interrupt, clear the TEND flag in ICSR2 in the IICn_TEI interrupt handling. The TEND flag in ICSR2 automatically is set to 0 when transmit data is written to the ICDRT register or a stop condition is detected (STOP flag = 1 in ICSR2).
Note 4. Only channel 0 has a wakeup function, so IIC0_WUI is for channel 0 only.
Note 5. Channel number (n = 0 to 1).

Clear or mask each flag during interrupt handling.

29.14.1 Buffer Operation for IICn_TXI and IICn_RXI Interrupts

If the conditions for generating an IICn_TXI or IICn_RXI interrupt are satisfied while the associated IR flag is 1, the interrupt request is not output for the ICU but is saved internally. One request per source can be saved internally.

An interrupt request that is saved in the ICU is output when the ICU.IELSRn.IR flag becomes 0. Internally saved interrupt requests are automatically cleared under normal conditions. They can also be cleared by writing 0 to the interrupt enable bit within the associated peripheral module.

29.15 State of Registers When Issuing Each Condition

The IIC has two dedicated resets, IIC reset and Internal reset. Table 29.11 lists the registers states when issuing each condition.

Table 29.11 Register states when issuing each condition (1 of 2)

Registers		Reset	IIC reset (ICE = 0, IICRST = 1)	Internal reset (ICE = 1, IICRST = 1)	Start or restart condition detection	Stop condition detection
ICCR1	ICE, IICRST	In reset	Saved	Saved	Saved	Saved
	SCLO, SDAO		In reset	In reset

29.16 Event Link Output

The IIC0 module handles the event output for the Event Link Controller (ELC) for the following sources:

(1) Transfer error event

When a transfer error event occurs, the associated event signal can be output to another module by the ELC.

(2) Receive data full

When a receive data register becomes full, the associated event signal can be output to another module by the ELC.

(3) Transmit data empty

When a transmit data register becomes empty, the associated event signal can be output to another module by the ELC.

(4) Transmit end

On completion of the transfer, the associated event signal can be output to another module by the ELC.

29.16.1 Interrupt Handling and Event Linking

Each of the IIC interrupt types (see Table 29.10) has an enable bit to control enabling and disabling of the associated interrupt signal. An interrupt request signal is output to the CPU when an interrupt source condition is satisfied while the associated enable bit is set.

The associated event link output signals are sent to other modules as event signals by the ELC when the interrupt source conditions are satisfied, regardless of the interrupt enable bit settings. For details on interrupt sources, see Table 29.10.

29.17 Usage Notes

29.17.1 Settings for the Module-Stop Function

The Module Stop Control Register B (MSTPCRB) can enable or disable IIC operation. The IIC is initially stopped after reset. Releasing the module-stop state enables access to the registers. For details, see section 10, Low Power Modes.

29.17.2 Notes on Starting Transfer

If the IR flag associated with the IIC interrupt is 1 when transfer is started (ICCR1.ICE bit = 1), follow the procedure in this section to clear the interrupts before enabling operations. Starting transfer with the IR flag set to 1 while the ICCR1.ICE bit is 1 leads to an interrupt request being internally saved after transfer starts, and this can lead to unexpected behavior of the IR flag.

To clear interrupts before starting transfer operation:

1. Confirm that the ICCR1.ICE bit is 0.

2. Set the relevant interrupt enable bits, such as ICIER.TIE to 0.
3. Read the relevant interrupt enable bits, such as ICIER.TIE, and confirm that the value is 0.
4. Set the IR flag to 0.

30. I3C Bus Interface (I3C)

Specific HDR Modes are not covered by conformance test suite (CTS).

When CTS for HDR Modes is available, Renesas will confirm CTS tests.

30.1 Overview

30.1.1 Functional Overview

The I3C bus interface (I3C) has one channel. The I3C module conforms with and provides a subset of the NXP I^2C (Inter-Integrated Circuit) bus interface functions and a subset of the MIPI I3C.

In this section, PCLK refers to PCLKA, TCLK refers to I3CCLK.

Table 30.1 lists the I^2C specifications and Table 30.2 lists the I3C specifications.

Table 30.1 I^2C specifications (1 of 2)

Parameter	Specifications
Operation mode	Master mode and slave mode selectable
Data handler	Single buffer transfer
Communication protocol	• I^2C bus format – Standard-mode (Sm) : 0 to 100 kbps – Fast-mode (Fm) : 0 to 400 kbps – Fast-mode Plus (Fm+) : 0 to 1 Mbps – High-speed mode (Hs-mode) : 0 to 3.4 Mbps • SMBus format : 10 to 100 kbps
Address format	• 7-bit address • 10-bit address
Address detection	• Slave address (static address) (max 3 address) • General call address • Hs-mode master code • Device ID • Host address • 10-bit slave addressing
Clock stretching	Clock stretching capability
Noise-filter	• Analog noise-filter • Digital noise-filter
Interrupt source	• Normal Rx data buffer full • Normal Tx data buffer empty • START condition detection • STOP condition detection • Transmit end • NACK detection • Arbitration lost • Timeout detection • Wake-up condition detection
Error detection	• Non-recoverable internal error • NACK received • Receive overflow or transfer underflow error • Arbitration lost error • Timeout error
Event link output	• Normal Rx data buffer full event • Normal Tx data buffer empty event • START condition event • STOP condition event • Transmit end event • NACK event • Arbitration lost event • Timeout event
Wake-up source	Address detection of slave address

Table 30.1 I^2C specifications (2 of 2)

Parameter	Specifications
Module-stop function	Module-stop state can be set to reduce power consumption
Trust Zone Filter	Security and Privilege attribution can be set

Table 30.2 I3C specifications (1 of 2)

Parameter	Specifications
Operation mode	Master (main master/secondary master) mode and slave mode selectable
Data handler	• Master : – High priority FIFO buffer transfer – Normal FIFO buffer transfer • Slave : – Normal FIFO buffer transfer
Communication protocol	• SDR (I3C Single Data Rate) mode : up to 12.5 Mbps – Private message – Broadcast message (common command code) – Direct message (common command code) • HDR (I3C High Data Rate) mode – HDR-DDR (Dual Data Rate) mode : up to 25 Mbps – HDR-TSL (Ternary Symbol Legacy) mode : up to 27.5 Mbps – HDR-TSP (Ternary Symbol Pure-bus) mode : up to 39.5 Mbps • Legacy I^2C message – Fast-mode (Fm) : 0 to 400 kbps – Fast-mode Plus (Fm+) : 0 to 1 Mbps
In-band interrupt	• Slave interrupt request • Master ship request (secondary master only)
Address format	7-bit address
Address detection	• Slave address (static address or dynamic address) • Broadcast address (0x7E)
Clock stalling	Clock stalling capability
Timing control	• Synchronous timing control – Sync mode : Synchronous basic mode • Asynchronous timing control – Async mode 0 : Asynchronous basic mode – Async mode 1 : Asynchronous advanced mode
Interrupt source	• Non-recoverable internal error • Normal Transfer error • Normal Transfer abort • Normal Response queue full • Normal Command queue empty • Normal IBI Queue Empty/Full • Normal Rx Data buffer full • Normal Tx Data buffer empty • Normal Receive status queue full • High Priority Response queue full • High Priority Command queue empty • High Priority Rx Data buffer full • High Priority Tx Data buffer empty • High Priority Transfer Error • High Priority Transfer Abort • START condition detection • STOP condition detection • HDR exit pattern detection • Timeout detection • Synchronous Timing • MREF Counter Overflow • MREF Capture • Additional Master-initiated bus Event • Wake-up condition detection

Table 30.2 I3C specifications (2 of 2)

Parameter	Specifications
Error detection	• Non-recoverable internal error • CRC error • Parity error • Frame error • Address header error • Address NACKed or dynamic address assignment NACKed • Receive overflow or transfer underflow error • Aborted • NACK received for the I^2C write data transfer • Timeout error
Event link output	• Normal Response queue full event • Normal Command queue empty event • Normal IBI Queue Empty/Full • Normal Rx data buffer full event • Normal Tx data buffer empty event • Normal Receive Status queue full event • High Priority Response queue full event • High Priority Command queue empty event • High Priority Rx Data buffer full event • High Priority Tx Data buffer empty event • Non-recoverable internal error event • Normal Transfer Error event • Normal Transfer Abort event • High Priority Transfer Error event • High Priority Transfer Abort event • START condition event • STOP condition event • HDR exit pattern event • Timeout event • Synchronous timing event • MREF counter overflow event • MREF capture event • Additional master-initiated bus Event
Wake-up source	• Master : SDA assert of IBI (START condition detection) • Slave : Address detection of broadcast address (0x7E) and slave address
Module-stop function	Module-stop state can be set to reduce power consumption
TrustZone Filter	Security and Privilege attribution can be set

Table 30.3 I3C I/O pins

Channel	Pin name	I/O	Function
I3C	I3C_SCL0	I/O	I3C serial clock I/O pin
	I3C_SDA0	I/O	I3C serial data I/O pin

Note: In this section, I3C_SCL refers to I3C_SCL0, I3C_SDA refers to I3C_SDA0.

30.1.2 Block Diagram

Figure 30.1 shows the main components of this I3C.

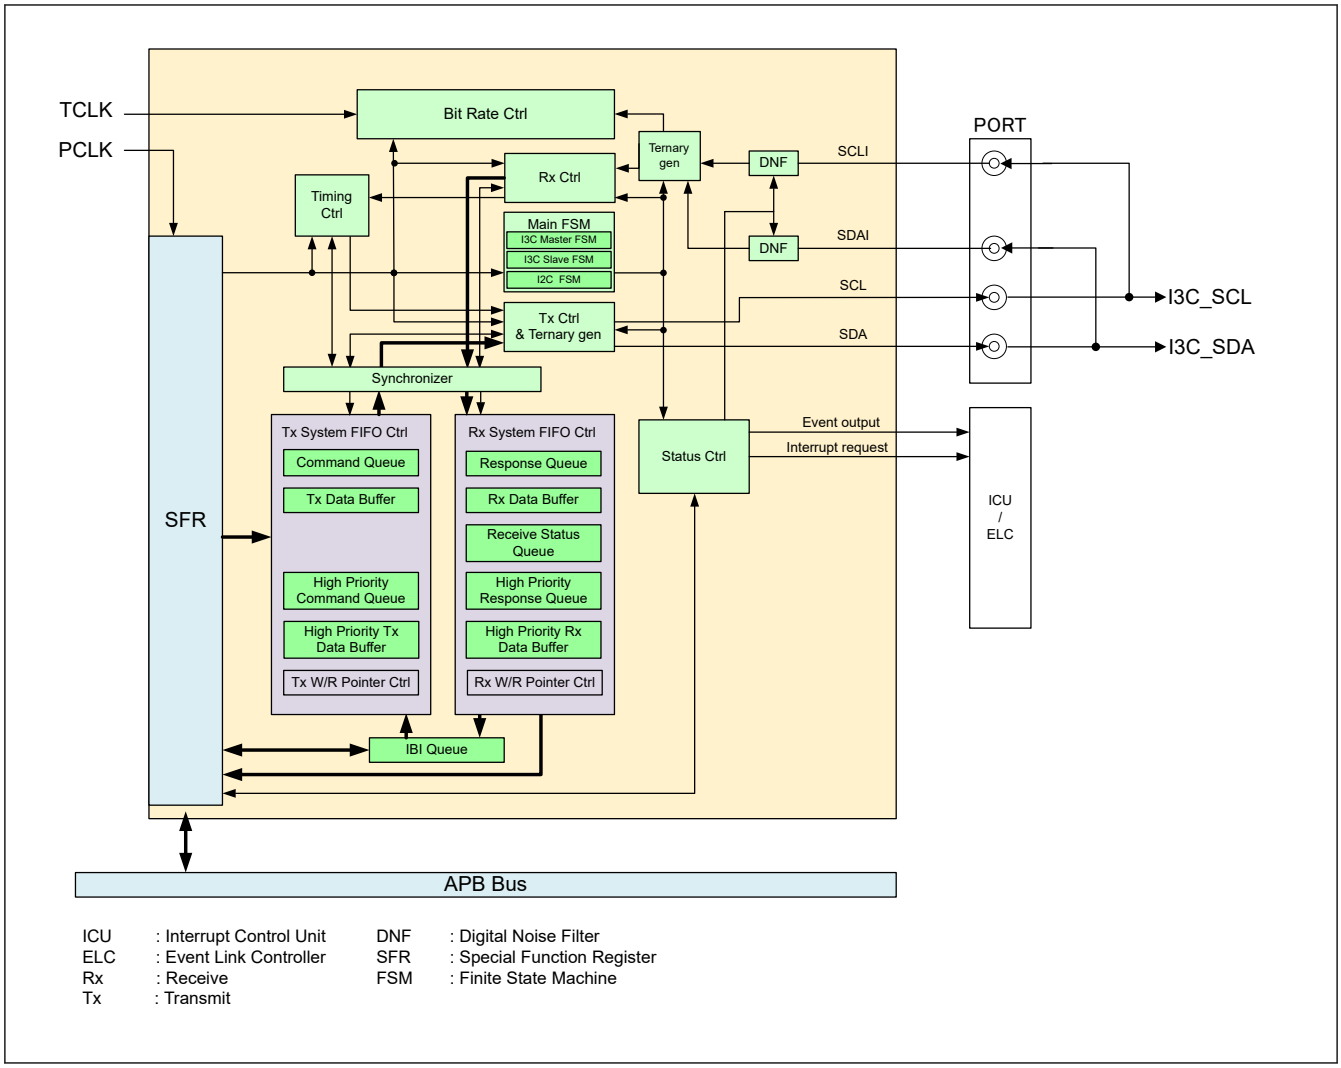

Figure 30.1 I3C block diagram

30.2 Registers

30.2.1 PRTS : Protocol Selection Register

Base address: I3C = 0x4035_F000
I3C_NS = 0x5035_F000

Offset address: 0x000

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	PRTMD
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

Bit	Symbol	Function	R/W
0	PRTMD	Protocol Mode 0: I3C protocol mode 1: I^2C protocol mode	R/W

Bit	Symbol	Function	R/W
31:1	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE3, P-TYPE3

PRTMD bit (Protocol Mode)

PRTMD = 0 : I3C FIFO buffer transfer (Equivalent to HCI)

PRTMD = 1 : I^2C single buffer transfer

There are notes about rewriting the PRTS.PRTMD bit, see .

30.2.2 BCTL : Bus Control Register

Base address: I3C = 0x4035_F000
I3C_NS = 0x5035_F000

Offset address: 0x014

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	BUSE	RSM	ABT	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	BMDS	—	—	—	—	—	—	INCBA
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	INCBA	Include I3C Broadcast Address*1 0: Do not include I3C broadcast address for private transfers 1: Include I3C broadcast address for private transfers	R/W
6:1	—	These bits are read as 0. The write value should be 0.	R/W
7	BMDS	Bus Mode Selection*1 0: Legacy inclusive Bus mode disabled 1: Legacy inclusive (mix) Bus mode enabled	R/W
28:8	—	These bits are read as 0. The write value should be 0.	R/W
29	ABT	Abort*1 0: I3C is running. 1: I3C has aborted a transfer.	R/W
30	RSM	Resume*2 Values when read: 0: I3C is running. 1: I3C is suspended.	R/W
31	BUSE	Bus Enable 0: I3C bus operation is disabled. 1: I3C bus operation is enabled.	R/W

Note: S-TYPE3, P-TYPE3
Note 1. This bit supports I3C master mode and I3C secondary master mode.
Note 2. This bit supports all I3C mode.

INCBA bit (Include I3C Broadcast Address)

This bit controls whether the I3C broadcast address (0x7E) is included for private transfers.

If the I3C broadcast address is not included for private transfers, then IBIs driven from Slaves might not win the arbitration, potentially delaying acceptance of the IBIs.

BMDS bit (Bus Mode Selection)

Indicates whether or not any Legacy I^2C Devices are present on the I3C Bus. Whenever this bit is set, I3C shall use the HDR-TSL protocol (Ternary Symbol Legacy Inclusive Bus) for HDR-TS Transfers.

The specific mode of the transfer (SDR, DDR, HDRTS) is controlled on a per-Command basis.

I3C shall use this field to select either TSL (1) or TSP (0) for HDR-TS transfers.

ABT bit (Abort)

When set to 1, this bit allows I3C to relinquish control of the I3C Bus before completing the currently issued transfer.

In response to an ABORT request, I3C issues the STOP condition on the I3C Bus after the complete data byte is transferred or received.

The Driver shall clear the ABT bit to allow operation on the Bus.

If BCTL.ABT is set and ABORT processing is performed, please ignore ERR_STATUS of Response Descriptor.

RSM bit (Resume)

This bit is used to resume I3C operation following the Halt state.

I3C enters the Halt state (as indicated in register PRSTDBG) as a result of any type of error occurring in a transfer.

The error type is indicated by the field ERR_STATUS in register NRSPQP, HRSPQP, NRSQP and NIBIQP).

After I3C has entered the Halt state, the application must write the value 1 to the RSM bit to resume I3C operation. I3C shall auto-clear the RSM bit once it has resumed making transfers (it has initiated the next Command).

BUSE bit (Bus Enable)

Enables or disables the operation on the I3C Bus by I3C.

Set the BUSE bit to 1 when using I3C. The I3C_SCL and I3C_SDA pins are placed in the active state when the BUSE bit is set to 1. Set the BUSE bit to 0 when I3C is not to be used. The I3C_SCL and I3C_SDA pins are placed in the inactive state when the BUSE bit is set to 0.

If the software sets this bit, then it also confirms that initialization is done, and that I3C can use the programmed register values (for example, generation of SCL on IBI detection, etc.). If this bit is not set, then I3C shall not generate SCL for incoming IBI.

Software may disable I3C bus operation while it is active, However:

- If a disable request occurs while receiving IBI, the actual disabling will not occur until reception of the IBI is complete.
- When the software reads the value 0 from this field, this indicates that I3C bus operation disable operation has completed.
  If commands remain in the command queue, do not set BUSE = 0.

30.2.3 MSDVAD : Master Device Address Register

Base address: I3C = 0x4035_F000
I3C_NS = 0x5035_F000

Offset address: 0x018

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	MDYADV	—	—	—	—	—	—	—	—	MDYAD[6:0]						
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	—	These bits are read as 0. The write value should be 0.	R/W

Bit	Symbol	Function	R/W
22:16	MDYAD[6:0]	Master Dynamic Address	R/W
30:23	—	These bits are read as 0. The write value should be 0.	R/W
31	MDYADV	Master Dynamic Address Valid 0: The master dynamic address field is not valid. 1: The master dynamic address field is valid.	R/W

Note: S-TYPE3, P-TYPE3
Note: This register supports I3C master mode.

MDYAD[6:0] bits (Master Dynamic Address)

This field is used to program I3C master dynamic address. I3C uses this address to respond to master transactions in I3C interface mode (slave or secondary master role).

In I3C main master mode, the software shall program the dynamic address as it self-assigns its dynamic address.

MDYADV bit (Master Dynamic Address Valid)

This bit indicates whether or not the value in the MDYAD field is valid.

In I3C main master mode, the user sets this bit to 1 as it self-assigns its dynamic address.

Note: After setting MSDVAD, and setting BCTL. BUSE = 1, the device will act as main master.

Without setting MSDVAD, setting SVDCT.TBCR76[1:0] = 00b (Device Role Slave), and setting BCTL.BUSE = 1, the device will act as slave.

Without setting MSDVAD, setting MSDCTm.RBCR76[1:0] = 01b (Device Role Master), and setting BCTL.BUSE = 1, the device will act as slave.

30.2.4 RSTCTL : Reset Control Register

Base address: I3C = 0x4035_F000
I3C_NS = 0x5035_F000

Offset address: 0x020

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	INTLRST
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	HRDBRST	HTDBRST	HRSPQRST	HCMDQRST	—	—	RSQRST	IBIQRST	RDBRST	TDBRST	RSPQRST	CMDQRST	RI3CRST
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	RI3CRST	I3C Software Reset 0: Release I3C reset. 1: Initiate I3C reset.	R/W
1	CMDQRST	Normal Command Queue Software Reset*1 0: The Normal Command Queues in I3C is not flushed. 1: The Normal Command Queues in I3C is flushed.	R/W
2	RSPQRST	Normal Response Queue Software Reset*1 0: The Normal Response Queues in I3C is not flushed. 1: The Normal Response Queues in I3C is flushed.	R/W
3	TDBRST	Normal Tx Data Buffer Software Reset*1 0: The Normal Tx Data buffers in I3C is not flushed. 1: The Normal Tx Data buffers in I3C is flushed.	R/W

Bit	Symbol	Function	R/W
4	RDBRST	Normal Rx Data Buffer Software Reset*1 0: The Normal Rx Data buffers in I3C is not flushed. 1: The Normal Rx Data buffers in I3C is flushed.	R/W
5	IBIQRST	Normal IBI Queue Software Reset*1 0: The Normal IBI Queues in I3C is not flushed. 1: The Normal IBI Queues in I3C is flushed.	R/W
6	RSQRST	Normal Receive Status Queue Software Reset*2 0: The Normal Receive Status Queue in I3C is not flushed. 1: The Normal Receive Status Queue in I3C is flushed.	R/W
8:7	—	These bits are read as 0. The write value should be 0.	R/W
9	HCMDQRST	High Priority Command Queue Software Reset*3 0: The High Priority Command Queues in I3C is not flushed. 1: The High Priority Command Queues in I3C is flushed.	R/W
10	HRSPQRST	High Priority Response Queue Software Reset*3 0: The High Priority Response Queues in I3C is not flushed. 1: The High Priority Response Queues in I3C is flushed.	R/W
11	HTDBRST	High Priority Tx Data Buffer Software Reset*3 0: The High Priority Tx Data buffers in I3C is not flushed. 1: The High Priority Tx Data buffers in I3C is flushed.	R/W
12	HRDBRST	High Priority Rx Data Buffer Software Reset*3 0: The High Priority Rx Data buffers in I3C is not flushed. 1: The High Priority Rx Data buffers in I3C is flushed.	R/W
15:13	—	These bits are read as 0. The write value should be 0.	R/W
16	INTLRST	Internal Software Reset 0: Releases of some registers and internal state. 1: Resets of some registers and internal state.	R/W
31:17	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE3, P-TYPE3
Note 1. This bit supports all I3C mode.
Note 2. This bit supports I3C secondary master mode and I3C slave mode.
Note 3. This bit supports I3C master mode and I3C secondary master mode.

For details on reset for each register, see section 30.6. Reset Descriptions.

RI3CRST bit (I3C Software Reset)

On Driver setting this bit to 1, I3C shall be reset and disabled.

All registers shall return to their reset values, and the software shall re-initialize I3C.

This field is cleared automatically upon I3C reset completion. This field also resets all Queues in I3C.

Note: Programming this field while it contains a value of 1 may result in undefined behavior.

CMDQRST bit (Normal Command Queue Software Reset)

On software setting this bit to 1, the Normal Command Queues in I3C shall be flushed.

This field shall be cleared automatically upon Normal Command Queue reset completion.

RSPQRST bit (Normal Response Queue Software Reset)

On software setting this bit to 1, the Normal Response Queues in I3C shall be flushed.

This field shall be cleared automatically upon Normal Response Queue reset completion.

TDBRST bit (Normal Tx Data Buffer Software Reset)

On software setting this bit to 1, the Normal Tx Data Buffers in I3C shall be flushed.

This field shall be cleared automatically upon Normal Tx Data Buffer reset completion.

RDBRST bit (Normal Rx Data Buffer Software Reset)

On software setting this bit to 1, the Normal Rx Data Buffers in I3C shall be flushed.

This field shall be cleared automatically upon completion of Normal Rx Data Buffer reset.

IBIQRST bit (Normal IBI Queue Software Reset)

On software setting this bit to 1, the Normal IBI Queues in I3C shall be flushed.

This field shall be cleared automatically upon completion of Normal IBI Queue reset.

RSQRST bit (Normal Receive Status Queue Software Reset)

On software setting this bit to 1, the Normal Receive Status Queues in I3C shall be flushed.

This field shall be cleared automatically upon Normal Receive Status Queue reset completion.

HCMDQRST bit (High Priority Command Queue Software Reset)

On software setting this bit to 1, the High Priority Command Queues in I3C shall be flushed.

This field shall be cleared automatically upon High Priority Command Queue reset completion.

HRSPQRST bit (High Priority Response Queue Software Reset)

On software setting this bit to 1, the High Priority Response Queues in I3C shall be flushed.

This field shall be cleared automatically upon High Priority Response Queue reset completion.

HTDBRST bit (High Priority Tx Data Buffer Software Reset)

On software setting this bit to 1, the High Priority Tx Data Buffers in I3C shall be flushed.

This field shall be cleared automatically upon High Priority Tx Data Buffer reset completion.

HRDBRST bit (High Priority Rx Data Buffer Software Reset)

On software setting this bit to 1, the High Priority Rx Data Buffers in I3C shall be flushed.

This field shall be cleared automatically upon completion of High Priority Rx Data Buffer reset.

INTLRST bit (Internal Software Reset)

When set to 1, some of registers is reset. For details on the registers to be reset, see section 30.6. Reset Descriptions.

Note: When set internal software reset during bus operation enable, use DISEC CCC in advance to disable IBI transmission to I3C Slave in order to avoid conflict with IBI from I3C Slave connected to I3C Bus.

30.2.5 PRSST : Present State Register

Base address: I3C = 0x4035_F000
I3C_NS = 0x5035_F000

Offset address: 0x024

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	PRSS TWP	—	—	TRMD	—	CRMS	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
1:0	—	These bits are read as 0. The write value should be 0.	R/W

Bit	Symbol	Function	R/W
2	CRMS	Current Master*2 0: The Master is not the Current Master, and must request and acquire bus ownership before initiating any transfer. 1: The Master is the Current Master, and as a result can initiate transfers.	R/W*1
3	—	This bit is read as 0. The write value should be 0.	R/W
4	TRMD	Transmit/Receive Mode*3 0: Receive mode 1: Transmit mode	R
6:5	—	These bits are read as 0. The write value should be 0.	R/W
7	PRSSTWP	Present State Write Protect*2 0: CRMS bit is protected. 1: CRMS bit can be written when writing simultaneously with the value of the target bit.	W
31:8	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE3, P-TYPE3
Note 1. When the PRSSTWP bit is set to 1, the CRMS bit can be written to.
Note 2. This bit supports I2C, I3C master, and I3C secondary master mode.
Note 3. This bit supports I2C mode.

CRMS bit (Current Master)

Indicates the set condition and reset condition of each operation mode.

Operation Mode [I2C/I3C common]

[Clearing conditions]

- When 0 written to the PRSST.CRMS by the software.

[Setting conditions]

- When 1 written to the PRSST.CRMS by the software.

Operation Mode [I2C]

[Clearing conditions]

- When STOP is issued.
- When Master Arbitration-Lost.

[Setting conditions]

- When START is issued.

Operation Mode [I3C Main Master]

[Clearing conditions]

- When 0 written to the MSDVAD.MDYADV by the software.
- When GETACCMST transmission is successfully completed by issuing STOP, after responding ACK to the Mastership-Request received from the Secondary Master.

[Setting conditions]

- When 1 written to the MSDVAD.MDYADV by the software.
- When GETACCMST reception is successfully completed by issuing STOP, after the ACK is responded to the Mastership-Request transmitted to the Secondary Master.

Operation Mode [I3C Secondary Master]

[Clearing condition]

- When GETACCMST transmission is successfully completed by issuing STOP, after responding ACK to the Mastership-Request received from the Non-Current Master.

[Setting condition]

- When GETACCMST reception is successfully completed by issuing STOP, after the ACK is responded to the Mastership-Request transmitted to the Current Master.

The PRSST register returns I3C current state.

State has two parts: this register which is mandatory, and an additional optional PRSST_DEBUG register intended for debug purposes (see the Debug Capability registers in the Extended Capabilities list).

TRMD bit (Transmit/Receive Mode)

This bit indicates transmit or receive mode.

I3C is in receive mode when the TRMD bit is set to 0 and is in transmit mode when the bit is set to 1. Combination of this bit and the CRMS bit indicates the operating mode of I3C.

The value of TRMD bit is automatically changed to 1 for transmit mode or 0 for receive mode by issuing or detection of a START condition and setting of the R/W# bit.

[Setting conditions]

- When a START condition is issued normally according to the START condition issuance request (when a START condition is detected with the CNDCTL.STCND bit set to 1).
- When a Repeated START condition is issued normally according to the Repeated START condition issuance request (when a Repeated START condition is detected with the CNDCTL.SRCND bit set to 1).
- When the R/W# bit added to the slave address is set to 0 in master mode.
- When the address received in slave mode matches the address enabled in SVCTL, with the R/W# bit set to 1.

[Clearing conditions]

- When a STOP condition is detected.
- The ALF (arbitration-lost) flag in BST being set to 1.
- In master mode, reception of a slave address to which an R/W# bit with the value 1 is appended.
- In slave mode, a match between the received address and the address enabled in SVCTL when the value of the received R/W# bit is 0 (including cases where the received address is the general call address).
- In slave mode, a Repeated START condition is detected (a Repeated START condition is detected with BCST.BFREF = 0 and CRMS = 0).

PRSSTWP bit (Present State Write Protect)

PRSSTWP is always 0 when reading.

When writing to PRSST, writing 1 to this bit at the same time enables writing to CRMS bit.

30.2.6 INST : Internal Status Register

Base address: I3C = 0x4035_F000
I3C_NS = 0x5035_F000

Offset address: 0x030

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	INEF	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
9:0	—	These bits are read as 0. The write value should be 0.	R/W
10	INEF	Internal Error Flag 0: I3C Internal Error has not detected. 1: I3C Internal Error has detected.	R/W*1
31:11	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE3, P-TYPE3
Note: This register supports all I3C mode.
Note 1. Clearing (to 0) condition : Writing 0 after the 1 state is read.

The Interrupt Status register reflects the status of outstanding interrupts.

The status fields are either write 0 to clear, or else are cleared based on queue operations.

INEF bit (Internal Error Flag)

When this bit is 1, it indicates that I3C Internal Error has detected.

When this bit is 0, it indicates that I3C Internal Error has not detected.

[Setting conditions]

- The following 1 is satisfied and any of the following 2 to 9 are satisfied.
  1. The INSTE.INEE bit = 1
  2. When transmit data is written to the Tx Data Buffer that is completely full.
  3. When received data is read from the Rx Data Buffer that is completely empty.
  4. When Command Descriptor is written to the Command Queue that is completely full.
  5. When Response Descriptor is read from the Response Queue that is completely empty.
  6. When Receive Status Descriptor is read from the Receive Status Queue that is completely empty.
  7. When IBI Status Descriptor is read from the IBI Queue under the condition that the IBI Queue is completely empty and PRSST.CRMS = 1.
  8. When IBI Data is written to the IBI Queue under the condition that the IBI Queue is completely full and PRSST.CRMS = 0.
  9. When the Response Queue, IBI Queue or Receive Status Queue overflows.

[Clearing condition]

- When 0 is written to the INEF bit after reading INEF bit = 1.

30.2.7 INSTE : Internal Status Enable Register

Base address: I3C = 0x4035_F000
I3C_NS = 0x5035_F000

Offset address: 0x034

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	INEE	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
9:0	—	These bits are read as 0. The write value should be 0.	R/W

Bit	Symbol	Function	R/W
10	INEE	Internal Error Enable 0: Disable INST.INEF 1: Enable INST.INEF	R/W
31:11	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE3, P-TYPE3
Note: This register supports all I3C mode.

INEE bit (Internal Error Enable)

When this bit set to 1, it enables detection of I3C Internal Error.

When this bit set to 0, it disables detection of I3C Internal Error.

30.2.8 INIE : Internal Interrupt Enable Register

Base address: I3C = 0x4035_F000
I3C_NS = 0x5035_F000

Offset address: 0x038

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit field:	—	—	—	—	—	INEIE	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
9:0	—	These bits are read as 0. The write value should be 0.	R/W
10	INEIE	Internal Error Interrupt Enable 0: Disables Non-recoverable Internal Error Interrupt Signal. 1: Enables Non-recoverable Internal Error Interrupt Signal.	R/W
31:11	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE3, P-TYPE3
Note: This register supports all I3C mode.

INEIE bit (Internal Error Interrupt Enable)

When set to 1 and register INEF is set, the hardware Controller asserts an interrupt to the Host.

30.2.9 INSTFC : Internal Status Force Register

Base address: I3C = 0x4035_F000
I3C_NS = 0x5035_F000

Offset address: 0x03C

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	INEFC	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
9:0	—	The write value should be 0.	W
10	INEFC	Internal Error Force 0: Not force a specific interrupt 1: Force a specific interrupt	W
31:11	—	The write value should be 0.	W

Note: S-TYPE3, P-TYPE3
Note: This register supports all I3C mode.

INEFC bit (Internal Error Force)

For debug, helps to force this interrupt.

30.2.10 DVCT : Device Characteristic Table Register

Base address: I3C = 0x4035_F000
I3C_NS = 0x5035_F000

Offset address: 0x044

Bit position:	31	30	29	28	27	26	25	24	23				19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	IDX[4:0]					—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
18:0	—	These bits are read as 0.	R
23:19	IDX[4:0]	DCT Table Index Current index of the DCT, which is used as the starting index for the I3C ENTDAA CCC.	R
31:24	—	These bits are read as 0.	R

Note: S-TYPE3, P-TYPE3
Note: This register supports I3C master mode and I3C secondary master mode.

IDX[4:0] bits (DCT Table Index)

Once the complete characteristics of device that won the arbitration are written to the DCT (during ENTDAA using Address Assignment Command) this index is incremented by 1.

Note: How to check the progress of ENTDAA using this bit:

1. Read the value of this bit before setting the Command Descriptor for issuing the ENTDAA command.
2. After starting the ENTDAA command, until the value of this bit is updated (that is, it changes from the value read in advance), it indicates that the Dynamic Address is being assigned to the device specified by the first index value (value set in DEV_INDEX[4:0] of Command Descriptor).
3. After the value of this bit is updated, it indicates that Dynamic Address is being assigned according to the value set in DEV_INDEX[4:0] and DEV_COUNT[3:0] of Command Descriptor to the device of the first index value or later.

30.2.11 IBINCTL : IBI Notify Control Register

Base address: I3C = 0x4035_F000
I3C_NS = 0x5035_F000

Offset address: 0x058

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	NRSIRCTL	—	NRMRCTL	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	—	This bit is read as 0. The write value should be 0.	R/W
1	NRMRCTL	Notify Rejected Master Request Control 0: Do not pass rejected IBI Status to the Normal IBI Queue, if the incoming Master Request is NACKed and is auto-disabled based on DVMRRJ field in relevant DAT entry. 1: Pass rejected IBI Status to the Normal IBI Queue if the incoming Master Request is NACKed and is autodisabled based on DVMRRJ field in relevant DAT entry.	R/W
2	—	This bit is read as 0. The write value should be 0.	R/W
3	NRSIRCTL	Notify Rejected Slave Interrupt Request Control 0: Do not pass rejected IBI Status to the Normal IBI Queue, if the incoming SIR is NACKed and is auto-disabled based on DVSIRRJ field in relevant DAT entry. 1: Pass rejected IBI Status to the Normal IBI Queue, if the incoming SIR is NACKed and is auto-disabled based on DVSIRRJ field in relevant DAT entry.	R/W
31:4	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE3, P-TYPE3
Note: This register supports I3C master mode and I3C secondary master mode.

NRMRCTL bit (Notify Rejected Master Request Control)

Enables or disables reporting rejection of individual Master Requests.

NRSIRCTL bit (Notify Rejected Slave Interrupt Request Control)

Enables or disables reporting rejection of individual Slave Interrupt Requests (SIR).

30.2.12 BFCTL : Bus Function Control Register

Base address: I3C = 0x4035_F000
I3C_NS = 0x5035_F000

Offset address: 0x060

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	HSME	FMPE	—	SMBS	—	—	—	SCSYNE	—	—	—	—	—	SALE	NALE	MALE
Value after reset:	0	0	0	0	0	0	0	1	0	0	0	0	0	0	0	1

Bit	Symbol	Function	R/W
0	MALE	Master Arbitration-Lost Detection Enable 0: Master arbitration-lost detection disables. Disables the arbitration-lost detection function and does not clear the CRMS and TRMD bits in PRSST automatically when arbitration is lost. 1: Master arbitration-lost detection enables. Enables the arbitration-lost detection function and clears the CRMS and TRMD bits in PRSST automatically when arbitration is lost.	R/W
1	NALE	NACK Transmission Arbitration-Lost Detection Enable 0: NACK transmission arbitration-lost detection disables. 1: NACK transmission arbitration-lost detection enables.	R/W
2	SALE	Slave Arbitration-Lost Detection Enable 0: Slave arbitration-lost detection disables. 1: Slave arbitration-lost detection enables.	R/W
7:3	—	These bits are read as 0. The write value should be 0.	R/W
8	SCSYNE	SCL Synchronous Circuit Enable 0: No SCL synchronous circuit uses. 1: An SCL synchronous circuit uses.	R/W
11:9	—	These bits are read as 0. The write value should be 0.	R/W
12	SMBS	SMBus/I^2C Bus Selection 0: The I^2C bus select. 1: The SMBus select.	R/W
13	—	This bit is read as 0. The write value should be 0.	R/W
14	FMPE	Fast-mode Plus Enable 0: No Fm+ slope control circuit uses for the I3C_SCL pin and I3C_SDA pin. (n = 0) 1: An Fm+ slope control circuit uses for the I3C_SCL pin and I3C_SDA pin. (n = 0)	R/W
15	HSME	High Speed Mode Enable 0: Disable High Speed Mode. 1: Enable High Speed Mode.	R/W
31:16	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE3, P-TYPE3
Note: This register supports for I2C mode.

MALE bit (Master Arbitration-Lost Detection Enable)

This bit is used to specify whether to use the arbitration-lost detection function in master mode. Normally, set this bit to 1.

NALE bit (NACK Transmission Arbitration-Lost Detection Enable)

This bit is used to specify whether to cause arbitration to be lost when ACK is detected during transmission of NACK in receive mode (such as when slaves with the same address exist on the bus or when two or more masters select the same slave device simultaneously with different number of receive bytes).

SALE bit (Slave Arbitration-Lost Detection Enable)

This bit is used to specify whether to cause arbitration to be lost when a value different from the value being transmitted is detected on the bus in slave transmit mode (such as when slaves with the same address exist on the bus or when a mismatch with the transmit data occurs due to noise).

SCSYNE bit (SCL Synchronous Circuit Enable)

This bit is used to specify whether to synchronize the SCL clock with the SCL input clock. Normally, set this bit to 1.

When the SCSYNE bit set to 0 (no SCL synchronous circuit used), I3C does not synchronize the SCL clock with the SCL input clock. In this setting, I3C outputs the SCL clock with the transfer rate set in STDBR and EXTBR regardless of the I3C_SCL line state. For this reason, if the bus load of the I^2C bus line is much larger than the specification value or if the SCL clock output overlaps in multiple masters, the short-cycle SCL clock that does not meet the specification may be output. When no SCL synchronous circuit uses, it also affects the issuance of a START condition, Repeated START condition, and STOP condition, and the continuous output of extra SCL clock cycles.

This bit must not be set to 0 except for checking the output of the set transfer rate.

FMPE bit (Fast-mode Plus Enable)

This bit is used to specify whether to use a slope control circuit for Fast-mode Plus [Fm+].

When this bit is set to 1, a slope control circuit conforming to the Fast-mode Plus [Fm+] slope control specification (tof) of the I3C-bus is selected. When this bit is set to 0, a slope control circuit conforming to the Standard-mode [Sm] and Fast-mode [fm] slope control specification (tof) of the I3C-bus is selected.

Set this bit to 1 when using the transmission rate within a range up to 1 Mbps (Fast-mode Plus [Fm+]) of the I3C-bus specification. Set this bit to 0 when using the transmission rate at other rates (up to 100 kbps [Sm], up to 400 kbps [Fm]) or for SMBus (10 to 100 kbps).

Note: When communicating in Hs-mode, set as follows.
- Set FMPE to 0 when sending Hs-mode master code (0000 1XXXb) with Fast-mode.
- Set FMPE to 1 when sending Hs-mode master code (0000 1XXXb) with Fast-mode Plus.

HSME bit (High Speed Mode Enable)

This bit is used for communicating in Hs-mode.

When this bit is set to 1, the Hs-mode master code is recognized and Hs-mode communication is possible.

After the START condition is detected, if Hs-mode master code (0000 1XXXb) transmission is recognized, Hs-mode communication starts from Repeated START after receiving the NACK response.

It communicates at the bit rate set in STDBR until the NACK response, and automatically switches from Repeated START condition issuance after receiving the NACK response to the bit rate set in EXTBR.

Hs-mode continues until a STOP condition is detected.

When the STOP condition is detected, the bit rate is automatically switched to the bit rate set in STDBR.

Note: When this bit is set to 1, the BST.NACKDF bit will not be set even if a NACK response is received after sending the Hs-mode master code.

30.2.13 SVCTL : Slave Control Register

Base address: I3C = 0x4035_F000
I3C_NS = 0x5035_F000

Offset address: 0x064

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18		16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	SVAE[2:0]		
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	HOAE	—	—	—	—	—	—	—	—	DVIDE	HSMCE	—	—	—	—	GCAE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	GCAE	General Call Address Enable*1 0: General call address detection disables. 1: General call address detection enables.	R/W
4:1	—	These bits are read as 0. The write value should be 0.	R/W
5	HSMCE	Hs-mode Master Code Enable*1 0: Hs-mode Master Code Detection disables. 1: Hs-mode Master Code Detection enables.	R/W
6	DVIDE	Device-ID Address Enable*1 0: Device-ID address detection disables. 1: Device-ID address detection enables.	R/W
14:7	—	These bits are read as 0. The write value should be 0.	R/W

Bit	Symbol	Function	R/W
15	HOAE	Host Address Enable*1 0: Host address detection disables. 1: Host address detection enables.	R/W
18:16	SVAE[2:0]	Slave Address Enable n (n = 0 to 2)*2 0: Slave n disables 1: Slave n enables	R/W
31:19	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE3, P-TYPE3
Note 1. This bit supports I2C mode.
Note 2. These bits support I2C, I3C secondary master, and I3C slave mode.

GCAE bit (General Call Address Enable)

This bit is used to specify whether to ignore the general call address (0000 000 + 0 (write): All 0) when it is received. When this bit is set to 1, if the received slave address matches the general call address, I3C recognizes the received slave address as the general call address independently of the slave addresses set in the SVDVADn.SVAD[9:0] bits (n = 0 to 2) and performs data receive operation.

When this bit is set to 0, the received slave address is ignored even if it matches the general call address.

HSMCE bit (Hs-mode Master Code Enable)

This bit is used to specify whether to recognize and execute the Hs-mode master code (00001xxxb) is received in the first byte after a START condition is detected.

When this bit is set to 1, if the received first byte matches the Hs-mode master code, I3C recognizes that the Hs-mode master code has been received.

The first byte after Repeated START after NACK response to Hs-mode master code is recognized as a slave address and compared with the slave address set by SVDVADn.SVAD[9:0]bits (n = 0 to 2).

If the addresses match, the transmission / reception operation continues according to the R/W# bit value.

Hs-mode continues until a STOP condition is detected.

When this bit is set to 0, I3C will ignore the pattern until a STOP condition is detected, even if it matches the Hs-mode master code.

Note: When this bit is set to 1, SCSTRCTL.ACKTWE bit must be set to 0 and SCSTRCTL.RWE bit must be set to 1.

DVIDE bit (Device-ID Address Enable)

This bit is used to specify whether to recognize and execute the Device-ID address when a device ID (1111 100) is received in the first byte after a START condition or Repeated START condition is detected.

When this bit is set to 1, if the received first byte matches the Device-ID, I3C recognizes that the Device-ID address has been received. When the following R/W# bit is 0 (write), I3C recognizes the second and the following bytes as slave addresses and continues the receive operation.

When this bit is set to 0, I3C ignores the received first byte even if it matches the Device ID address and recognizes the first byte as a normal slave address.

For details on the Device-ID address detection, see (3) Device-ID Address Detection [I2C mode].

HOAE bit (Host Address Enable)

This bit is used to specify whether to ignore received host address (0001 000) when the BFCTL.SMBS bit = 1.

When this bit is set to 1 while the SMBS bit = 1, if the received slave address matches the host address, I3C recognizes the received slave address as the host address independently of the slave addresses set in the SVDVADn.SVAD[9:0] bits (n = 0 to 2) and performs the receive operation.

When the SMBS bit or the HOAE bit is set to 0, the received slave address is ignored even if it matches the host address.

SVAE[2:0] bits (Slave Address Enable n (n = 0 to 2))

This bit is used to enable or disable the slave address set in the SVDVADn.SVAD[9:0] bits.

When this bit is set to 1, the slave address set in the SVAD[9:0] bits is enabled and is compared with the received slave address.

When this bit is set to 0, the slave address set in the SVAD[9:0] bits is disabled and is ignored even if it matches the received slave address.

30.2.14 REFCKCTL : Reference Clock Control Register

Base address: I3C = 0x4035_F000
I3C_NS = 0x5035_F000

Offset address: 0x070

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	IREFCKS[2:0]		
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
2:0	IREFCKS[2:0]*1	Internal Reference Clock Selection Selects the internal reference clock source (I3Cφ) for I3C. 0 0 0: TCLK/1 clock 0 0 1: TCLK/2 clock 0 1 0: TCLK/4 clock 0 1 1: TCLK/8 clock 1 0 0: TCLK/16 clock 1 0 1: TCLK/32 clock 1 1 0: TCLK/64 clock 1 1 1: TCLK/128 clock	R/W
31:3	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE3, P-TYPE3
Note 1. Set the IREFCKS[2:0] bit to 000 in I3C mode.

30.2.15 STDBR : Standard Bit Rate Register

Base address: I3C = 0x4035_F000
I3C_NS = 0x5035_F000

Offset address: 0x074

Bit position:	31	30	29	24	23	22	21	16
Bit field:	DSBRPO	—	SBRHP[5:0]		—	—	SBRLP[5:0]	
Value after reset:	0	0	1 1 1 1 1 1		0	0	1 1 1 1 1 1	

Bit position:	15	8	7	0
Bit field:	SBRHO[7:0]		SBRLO[7:0]	
Value after reset:	1 1 1 1 1 1 1 1		1 1 1 1 1 1 1 1	

Bit	Symbol	Function	R/W
7:0	SBRLO[7:0]	Standard Bit Rate Low-Level Period Open-Drain Count value of the low-level period of SCL clock*1	R/W
15:8	SBRHO[7:0]	Standard Bit Rate High-Level Period Open-Drain Count value of the high-level period of SCL clock*1	R/W

Bit	Symbol	Function	R/W
21:16	SBRLP[5:0]	Standard Bit Rate Low-level Period Push-Pull*2 Count value of the low-level period of SCL clock	R/W
23:22	—	These bits are read as 0. The write value should be 0.	R/W
29:24	SBRHP[5:0]	Standard Bit Rate High-Level Period Push-Pull*3 Count value of the high-level period of SCL clock	R/W
30	—	This bit is read as 0. The write value should be 0.	R/W
31	DSBRPO	Double the Standard Bit Rate Period for Open-Drain*4 0: The time period set for SBRHO[7:0] and SBRLO[7:0] is not doubled. 1: The time period set for SBRHO[7:0] and SBRLO[7:0] is doubled.	R/W

Note: S-TYPE3, P-TYPE3
Note 1. These bits support I2C, I3C master, and I3C secondary master mode.
Note 2. These bits support I3C master mode and I3C secondary master mode.
Note 3. These bits support all I3C mode.
Note 4. This bit supports I2C, I3C master, and I3C secondary master mode.

The STDBR register sets the bit rate according to the operating speed.

- I2C mode: Bit rate setting when communicating with Standard-mode / Fast-mode / Fast-mode plus
- I3C master mode: Bit rate setting selected by MODE bit of command descriptor
- I3C slave mode: I3C bit rate setting

The I2C transfer rate and the SCL clock duty are calculated using the following expression.

Transfer rate = 1 / {[(High-Level Period + α*1) + (Low-Level Period + α)] / I3Cφ*2 + I3C_SCL line rising time [tr]*3 + I3C_SCL line falling time [tf]*3}

Duty cycle = {I3C_SCL line rising time [tr] + (High-Level Period + α) / I3Cφ} / {I3C_SCL line falling time [tf] + (Low- Level Period + α) / I3Cφ}

Note 1. α depend on the number of stages in the noise filter.
Note 2. I3Cφ = TCLK × Division ratio
Note 3. The I3C_SCL line rising time [tr] and I3C_SCL line falling time [tf] depend on the total bus line capacitance [Cb] and the pull-up resistor [Rp]. For details, see the I2C-bus specification from NXP Semiconductors.

The I3C transfer rate and the SCL clock duty are calculated using the following expression.

Transfer rate = 1 / [(High-Level Period + Low-Level Period) / I3Cφ + I3C_SCL line rising time [tr] + I3C_SCL line falling time [tf]]

Duty cycle = [I3C_SCL line rising time [tr] + High-Level Period / I3Cφ] / [I3C_SCL line falling time [tf] + Low-Level Period / I3Cφ]

SBRLO[7:0] bits (Standard Bit Rate Low-Level Period Open-Drain)

The SBRLO[7:0] bits are used to set the low-level period of SCL clock in Open-Drain mode.

I3C counts the low-level period with the internal reference clock source (I3Cφ) specified by the REFCKCTL.IREFCKS[2:0] bits. It also works to generate the data setup time for automatic SCL low-hold operation (see section 30.3.2.3.6. Clock Stretching [I2C mode]); when I3C is used in I2C slave mode, these bits need to be set to a value longer than the data setup time*1.

If the digital noise filter is enabled (INCTL.DNFE = 1), set the SBRLO[7:0] bits to a value at least one greater than the number of stages in the noise filter. Regarding the number of stages in the noise filter, see the description of the INCTL.DNFS[3:0] bits.

Note 1. Data setup time (tSU: DAT)
250 ns (up to 100 kbps: Standard-mode [Sm])
100 ns (up to 400 kbps: Fast-mode [Fm])
50 ns (up to 1 Mbps: Fast-mode plus [Fm+])
10 ns (up to 3.4 Mbps: Hs-mode [HS])

SBRHO[7:0] bits (Standard Bit Rate High-Level Period Open-Drain)

The SBRHO[7:0] bits use to set the high-level period of SCL clock in Open-Drain mode. SBRHO[7:0] bits are valid in master mode. If I3C is used only in I^2C slave mode, these bits need not to set the high-level period.

I3C counts the high-level period with the internal reference clock source (I3Cφ) specified by the REFCKCTL.IREFCKS[2:0] bits.

If the digital noise filter is enabled (the INCTL.DNFE bit = 1), set the SBRHO[7:0] bits to a value at least one greater than the number of stages in the noise filter. Regarding the number of stages in the noise filter, see the description of the INCTL.DNFS[3:0] bits.

SBRLP[5:0] bits (Standard Bit Rate Low-level Period Push-Pull)

SBRLP[5:0] bits are used to set the low-level period of SCL clock in Push-Pull.

I3C counts the low-level period with the internal reference clock source (I3Cφ) specified by the REFCKCTL.IREFCKS[2:0] bits.

If the digital noise filter is enabled (the INCTL.DNFE bit = 1), set the SBRLP[5:0] bits to a value at least one greater than the number of stages in the noise filter. Regarding the number of stages in the noise filter, see the description of the INCTL.DNFS[3:0] bits.

SBRHP[5:0] bits (Standard Bit Rate High-Level Period Push-Pull)

SBRHP[5:0] bits is used to set the high-level period of SCL clock in Push-Pull mode.

SBRHP[5:0] bits are valid in master mode. If I3C is used only in I^2C slave mode, these bits need not to set the high-level period.

I3C counts the high-level period with the internal reference clock source (I3Cφ) specified by the REFCKCTL.IREFCKS[2:0] bits.

If the digital noise filter is enabled (the INCTL.DNFE bit = 1), set the SBRHP[5:0] bits to a value at least one greater than the number of stages in the noise filter. Regarding the number of stages in the noise filter, see the description of the INCTL.DNFS[3:0] bits.

DSBRPO bit (Double the Standard Bit Rate Period for Open-Drain)

When DSBRPO = 1, double the high-level period that is set in SBRHO[7:0] and double the low-level period that is set in SBRLO[7:0].

Table 30.4 Requirement and usage of setting in each mode

Bit name	Device mode				
	I^2C master	I^2C slave	I3C Master	I3C Secondary Master	I3C Slave
SBRHP[5:0]	do not use	do not use	Setting required*3	Setting required*4	Setting required*6
SBRLP[5:0]	do not use	do not use	Setting required*3	Setting required*5	do not use
SBRHO[7:0]	Setting required*1	do not use	Setting required*3	Setting required*5	do not use
SBRLO[7:0]	Setting required*1	Setting required*2	Setting required*3	Setting required*5	do not use

Note 1. The setting value is used for the data rate of ST, FM, and FM+ mode.
Note 2. The setting value is used for the data setup time of automatic SCL low-hold operation.
Note 3. The setting value is used for the data rate of each communication.
Note 4. When operating with I3C Master, the setting value is used for the data rate of each communication.
When operating with I3C Slave, the setting value is used for the data rate of HDR-TSP/TSL mode.
Note 5. When operating with I3C Master, the setting value is used for the data rate of each communication.
When operating with I3C Slave, do not use.
Note 6. The setting value is used for the data rate of HDR-TSP/TSL mode.

30.2.16 EXTBR : Extended Bit Rate Register

Base address: I3C = 0x4035_F000
I3C_NS = 0x5035_F000

Offset address: 0x078

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	EBRHP[5:0]						—	—	EBRLP[5:0]						EBRHO[7:0]								EBRLO[7:0]							
Value after reset:	0	0	1	1	1	1	1	1	0	0	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

Bit	Symbol	Function	R/W
7:0	EBRLO[7:0]	Extended Bit Rate Low-Level Period Open-Drain*1 Count value of the low-level period of SCL clock	R/W
15:8	EBRHO[7:0]	Extended Bit Rate High-Level Period Open-Drain*1 Count value of the high-level period of SCL clock	R/W
21:16	EBRLP[5:0]	Extended Bit Rate Low-Level Period Push-Pull*2 Count value of the low-level period of SCL clock	R/W
23:22	—	These bits are read as 0. The write value should be 0.	R/W
29:24	EBRHP[5:0]	Extended Bit Rate High-Level Period Push-Pull*2 Count value of the high-level period of SCL clock	R/W
31:30	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE3, P-TYPE3
Note 1. These bits support I2C, I3C master, and I3C secondary master mode.
Note 2. These bits support I3C master mode and I3C secondary master mode.

The EXTBR register sets the bit rate according to the operating speed.

- I2C mode: Bit rate setting for communicating in high-speed mode
- I3C master mode: Bit rate setting selected by MODE bit of command descriptor
- I3C slave mode: unused

EBRLO[7:0] bits (Extended Bit Rate Low-Level Period Open-Drain)

See SBRLO[7:0] bits of section 30.2.15. STDBR : Standard Bit Rate Register for details. Watch SBRHO, SBRLO as EBRHO[7:0], EBRLO[7:0].

EBRHO[7:0] bits (Extended Bit Rate High-Level Period Open-Drain)

See SBRHO[7:0] bits of section 30.2.15. STDBR : Standard Bit Rate Register for details. Watch SBRHO, SBRLO as EBRHO[7:0], EBRLO[7:0].

EBRLP[5:0] bits (Extended Bit Rate Low-Level Period Push-Pull)

See SBRLP[5:0] bits of section 30.2.15. STDBR : Standard Bit Rate Register for details. Watch SBRHP, SBRLP as EBRHP[5:0], EBRLP[5:0].

EBRHP[5:0] bits (Extended Bit Rate High-Level Period Push-Pull)

See SBRHP[5:0] bits of section 30.2.15. STDBR : Standard Bit Rate Register for details. Watch SBRHP, SBRLP as EBRHP[5:0], EBRLP[5:0].

Table 30.5 Requirement and usage of setting in each mode (1 of 2)

Bit name	Device mode				
	I2C master	I2C slave	I3C Master	I3C Secondary Master	I3C Slave
EBRHP[5:0]	do not use	do not use	Setting required*3	Setting required*4	do not use
EBRLP[5:0]	do not use	do not use	Setting required*3	Setting required*4	do not use

Table 30.5 Requirement and usage of setting in each mode (2 of 2)

Bit name	Device mode				
	I²C master	I²C slave	I3C Master	I3C Secondary Master	I3C Slave
EBRHO[7:0]	Setting required*1	do not use	Setting required*3	Setting required*4	do not use
EBRLO[7:0]	Setting required*1	Setting required*2	Setting required*3	Setting required*4	do not use

Note 1. The setting value is used for the data rate of High-Speed mode.
Note 2. The setting value is used for the data setup time of automatic SCL low-hold operation in Hs-mode.
Note 3. The setting value is used for the data rate of each communication.
Note 4. When operating with I3C Master, the setting value is used for the data rate of each communication.
When operating with I3C Slave, do not use.

30.2.17 BFRECDT : Bus Free Condition Detection Time Register

Base address: I3C = 0x4035_F000
I3C_NS = 0x5035_F000

Offset address: 0x07C

Bit position:	31																						9	8									0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	FRECYC[8:0]									
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
8:0	FRECYC[8:0]	Bus Free Condition Detection Cycle The count value is a period for detecting the Bus free condition.	R/W
31:9	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE3, P-TYPE3

FRECYC[8:0] bits (Bus Free Condition Detection Cycle)

I3C counts the period for detecting the Bus free condition with the I3Cφ.

These bits set the Bus Free period. This Bus Free period is counted by the internal reference clock (I3Cφ) selected by the REFCKCTL.IREFCKS[2:0] bits. See the BCST.BFREF flag for Bus Free detection behavior.

30.2.18 BAVLCDT : Bus Available Condition Detection Time Register

Base address: I3C = 0x4035_F000
I3C_NS = 0x5035_F000

Offset address: 0x080

Bit position:	31																						9	8									0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	AVLCYC[8:0]									
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
8:0	AVLCYC[8:0]	Bus Available Condition Detection Cycle The count value is a period for detecting the Bus available condition.	R/W
31:9	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE3, P-TYPE3
Note: This register supports all I3C mode.

AVLCYC[8:0] bits (Bus Available Condition Detection Cycle)

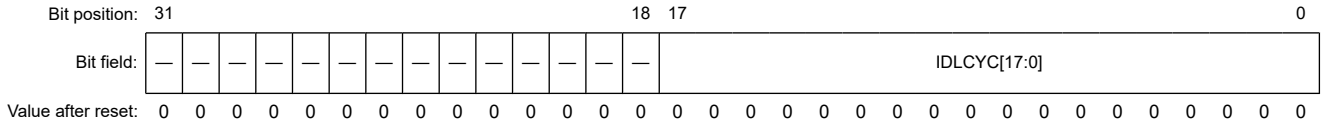
I3C counts the period for detecting the Bus available condition with the I3Cφ.

These bits set the Bus Available period. This Bus Available period is counted by the internal reference clock (I3Cφ) selected by the REFCKCTL.IREFCKS[2:0] bits. See the BCST.BAVLF flag for Bus Available detection behavior.

30.2.19 BIDLCDT : Bus Idle Condition Detection Time Register

Base address: I3C = 0x4035_F000
I3C_NS = 0x5035_F000

Offset address: 0x084



Bit	Symbol	Function	R/W
17:0	IDLCYC[17:0]	Bus Idle Condition Detection Cycle The count value is a period for detecting the Bus idle condition.	R/W
31:18	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE3, P-TYPE3
Note: This register supports all I3C mode.

IDLCYC[17:0] bits (Bus Idle Condition Detection Cycle)

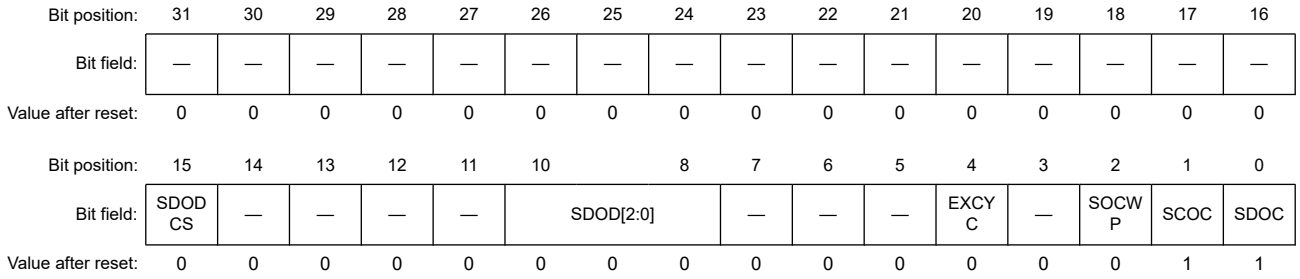
I3C counts the period for detecting the Bus idle condition with the I3Cφ.

These bits set the Bus Idle period. This Bus Idle period is counted by the internal reference clock (I3Cφ) selected by the REFCKCTL.IREFCKS[2:0] bits. See the BCST.BIDLF flag for Bus Available detection behavior.

30.2.20 OUTCTL : Output Control Register

Base address: I3C = 0x4035_F000
I3C_NS = 0x5035_F000

Offset address: 0x088



Bit	Symbol	Function	R/W
0	SDOC	SDA Output Control*1 0: I3C drives the I3C_SDA pin low. 1: I3C releases the I3C_SDA pin.	R/W
1	SCOC	SCL Output Control*1 High level output is achieved through an external pull-up resistor. 0: I3C drives the I3C_SCL pin low. 1: I3C releases the I3C_SCL pin.	R/W
2	SOCWP	SCL/SDA Output Control Write Protect*1 0: Bits SCOC and SDOC are protected. 1: Bits SCOC and SDOC can be written (When writing simultaneously with the value of the target bit). This bit is read as 0.	W
3	—	This bit is read as 0. The write value should be 0.	R/W

Bit	Symbol	Function	R/W
4	EXCYC	Extra SCL Clock Cycle Output*3 The EXCYC bit is cleared automatically after one clock cycle is output. 0: Does not output an extra SCL clock cycle (default). 1: Outputs an extra SCL clock cycle.	R/W
7:5	—	These bits are read as 0. The write value should be 0.	R/W
10:8	SDOD[2:0]	SDA Output Delay*2 0 0 0: No output delay 0 0 1: 1 I3Cφ cycle (When OUTCTL.SDODCS = 0 (I3Cφ)) 1 or 2 I3Cφ cycles (When OUTCTL.SDODCS = 1 (I3Cφ/2)) 0 1 0: 2 I3Cφ cycles (When OUTCTL.SDODCS = 0 (I3Cφ)) 3 or 4 I3Cφ cycles (When OUTCTL.SDODCS = 1 (I3Cφ/2)) 0 1 1: 3 I3Cφ cycles (When OUTCTL.SDODCS = 0 (I3Cφ)) 5 or 6 I3Cφ cycles (When OUTCTL.SDODCS = 1 (I3Cφ/2)) 1 0 0: 4 I3Cφ cycles (When OUTCTL.SDODCS = 0 (I3Cφ)) 7 or 8 I3Cφ cycles (When OUTCTL.SDODCS = 1 (I3Cφ/2)) 1 0 1: 5 I3Cφ cycles (When OUTCTL.SDODCS = 0 (I3Cφ)) 9 or 10 I3Cφ cycles (When OUTCTL.SDODCS = 1 (I3Cφ/2)) 1 1 0: 6 I3Cφ cycles (When OUTCTL.SDODCS = 0 (I3Cφ)) 11 or 12 I3Cφ cycles (When OUTCTL.SDODCS = 1 (I3Cφ/2)) 1 1 1: 7 I3Cφ cycles (When OUTCTL.SDODCS = 0 (I3Cφ)) 13 or 14 I3Cφ cycles (When OUTCTL.SDODCS = 1 (I3Cφ/2))	R/W
14:11	—	These bits are read as 0. The write value should be 0.	R/W
15	SDODCS	SDA Output Delay Clock Source Selection*3 0: The internal reference clock (I3Cφ) is selected as the clock source of the SDA output delay counter. 1: The internal reference clock divided by 2 (I3Cφ/2) is selected as the clock source of the SDA output delay counter.*4	R/W
31:16	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE3, P-TYPE3
Note 1. This bit supports I^2C, I3C master, and I3C secondary master mode.
Note 2. These bits support I^2C mode.
Note 3. This bit supports I^2C mode.
Note 4. The setting SDODCS = 1 (I3Cφ/2) only becomes valid when SCL is at the low level. When SCL is at the high level, the setting SDODCS = 1 becomes invalid and the clock source becomes the internal reference clock (I3Cφ).

SDOC bit (SDA Output Control) and SCOC bit (SCL Output Control)

These bits are used to directly control the I3C_SDA and I3C_SCL signals output from this I3C.

When writing to these bits, also write 1 to the SOCWP bit at the same time.

The result of setting these bits is input to I3C through the input buffer. When slave mode is selected, a START condition may be detected and the bus may be released depending on the bit settings.

Do not rewrite these bits during a START condition, STOP condition, Repeated START condition, or during transmission or reception. Operation after rewriting under the above conditions is not guaranteed.

EXCYC bit (Extra SCL Clock Cycle Output)

This bit is used to output an extra SCL clock cycle for debugging or error processing.

Normally, set the bit to 0. Setting the bit to 1 in a normal communication state causes a communication error.

For details on this function, see section 30.3.2.3.11. Port Control , (1) Extra SCL Clock Cycle Output Function.

30.2.21 INCTL : Input Control Register

Base address: I3C = 0x4035_F000
I3C_NS = 0x5035_F000

Offset address: 0x08C

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3			0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	DNFE	DNFS[3:0]			
Value after reset:	0	0	0	0	0	0	0	0	1	1	0	1	0	0	0	0

Bit	Symbol	Function	R/W
3:0	DNFS[3:0]	Digital Noise Filter Stage Selection 0x0: Noise of up to one I3Cφ cycle is filtered out (single-stage filter). 0x1: Noise of up to two I3Cφ cycles is filtered out (2-stage filter). 0x2: Noise of up to three I3Cφ cycles is filtered out (3-stage filter). 0x3: Noise of up to four I3Cφ cycles is filtered out (4-stage filter). 0x4: Noise of up to five I3Cφ cycles is filtered out (5-stage filter). ⋮ 0xF: Noise of up to sixteen I3Cφ cycles is filtered out (16-stage filter).	R/W
4	DNFE	Digital Noise Filter Circuit Enable 0: No digital noise filter circuit is used. 1: A digital noise filter circuit is used.	R/W
5	—	This bit is read as 0. The write value should be 0.	R/W
7:6	—	These bits are read as 1. The write value should be 1.	R/W
31:8	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE3, P-TYPE3
Note: This register supports I^2C mode.

DNFS[3:0] bits (Digital Noise Filter Stage Selection)

These bits are used to select the number of stages in the digital noise filter.

For details on the digital noise filter function, see section 30.3.2.6.3. Digital Noise-Filter Circuits [I^2C mode].

In I^2C High Speed mode, I3C changes the number of noise filter stage to a quarter of the number of noise filter stage automatically.

Note:
- Set the noise range to be filtered out by the noise filter within a range less than the I3C_SCL line high-level period or low-level period. If the noise range is set to a value of (SCL clock width: high-level period or lowlevel period, whichever is shorter) - [1.5 internal reference clock (I3Cφ) cycles] or more, the SCL clock is regarded as noise by the noise filter function of I3C, which may prevent I3C from operating normally.
- In I^2C High Speed mode, the lower 2 bits of the DNFS [3:0] bits are ignored, and the number of filter stages for 1 to 4 stages is selected by the upper 2 bits.

30.2.22 TMOCTL : Timeout Control Register

Base address: I3C = 0x4035_F000
I3C_NS = 0x5035_F000

Offset address: 0x090

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	TOMDS[1:0]		TOHCTL	TOLCTL	—	—	TODTS[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	1	1	0	0	0	0

Bit	Symbol	Function	R/W
1:0	TODTS[1:0]	Timeout Detection Time Selection 0 0: 16bit-timeout 0 1: 14bit-timeout 1 0: 8bit-timeout 1 1: 6bit-timeout	R/W
3:2	—	These bits are read as 0. The write value should be 0.	R/W
4	TOLCTL	Timeout L Count Control 0: Count is disabled while the I3C_SCL line is at a low level. 1: Count is enabled while the I3C_SCL line is at a low level.	R/W
5	TOHCTL	Timeout H Count Control 0: Count is disabled while the I3C_SCL line is at a high level. 1: Count is enabled while the I3C_SCL line is at a high level.	R/W
7:6	TOMDS[1:0]	Timeout Operation Mode Selection 0 0: Timeout is detected during the following conditions: • The bus is busy (BCST.BFREF = 0) in master mode. • I3C's own slave address is detected and the bus is busy in slave mode. • The bus is free (BCST.BFREF = 1) while generation of a START condition is requested (CNDCTL.STCND = 1). 0 1: Timeout is detected while the bus is busy. 1 0: Timeout is detected while the bus is free. 1 1: Setting prohibited	R/W
31:8	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE3, P-TYPE3

TODTS[1:0] bits (Timeout Detection Time Selection)

These bits are used to select for the timeout detection time when the timeout function is enabled (BSTE.TODE bit = 1).

When these bits are set to 00b, the timeout detection internal counter functions as a 16-bit counter.

When these bits are set to 01b, the counter functions as a 14-bit counter.

When these bits are set to 10b, the counter functions as a 8-bit counter.

When these bits are set to 11b, the counter functions as a 6-bit counter.

While the I3C_SCL line is in the state that enables this counter as specified by bits TOHCTL and TOLCTL, the counter counts up in synchronization with the internal reference clock (I3Cφ) as a count source.

For details on the timeout function, see section 30.3.2.4.5. Timeout Error Detection .

TOLCTL bit (Timeout L Count Control)

This bit is used to enable or disable the internal counter of the timeout function to count up while the I3C_SCL line is held low when the timeout function is enabled (BSTE.TODE = 1).

TOHCTL bit (Timeout H Count Control)

This bit is used to enable or disable the internal counter of the timeout function to count up while the I3C_SCL line is held high when the timeout function is enabled (BSTE.TODE = 1).

TOMDS[1:0] bits (Timeout Operation Mode Selection)

These bits are used to select the detection condition for timeout when the timeout function is enabled.

Note: When working with I²C Slave, during 10-bit address communication, the timeout count starts when the upper address match is detected.

30.2.23 WUCTL : Wake Up Unit Control Register

Base address: I3C = 0x4035_F000
I3C_NS = 0x5035_F000

Offset address: 0x098

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	WUFE	WUFSYNE	—	WUANFS	—	—	—	WUACKS
Value after reset:	0	0	0	0	0	0	0	0	0	1	0	0	0	0	0	1

Bit	Symbol	Function	R/W
0	WUACKS	Wake-Up Acknowledge Selection*1 Choice of four response mode with a combination of RSTCTL.INTLRST bit and WUACKS bit. Shown in Table 30.6.	R/W
3:1	—	These bits are read as 0. The write value should be 0.	R/W
4	WUANFS	Wake-Up Analog Noise Filter Selection*1 0: Do not add the Wake Up analog filter. 1: Add the Wake Up analog filter.	R/W
5	—	This bit is read as 0. The write value should be 0.	R/W
6	WUFSYNE	Wake-Up function PCLK Synchronous Enable 0: I3C asynchronous circuit enable 1: I3C synchronous circuit enable	R/W
7	WUFE	Wake-Up function Enable Do not set WUFE = 0 during Wake-Up operation. 0: Wake-up function disables 1: Wake-up function enables	R/W
31:8	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE3, P-TYPE3
Note 1. This bit supports I²C mode.

Table 30.6 Wake-Up Mode

INTLRST	WUACKS	Operation mode	Description
0	0	Normal Wake-Up mode 1	ACK response at 9th SCL and SCL low hold after at 9th SCL.
0	1	Normal Wake-Up mode 2	No ACK response immediately and SCL low hold between 8th and 9th SCL. Release SCL low hold and ACK response at 9th SCL.
1	0	Command recovery mode	ACK response at 9th SCL and not SCL low hold.
1	1	EEP response mode	NACK response at 9th SCL and not SCL low hold.

Note: In WakeUp mode 2, HS mode cannot be used.

WUFSYNE bit (Wake-Up function PCLK Synchronous Enable)

This bit is used to switch between the PCLK synchronous operation and the PCLK asynchronous operation.

The bit is used in combination with the WUASYNF flag at Wake-Up effective function (WUCTL.WUFE bit = 1).

[When switching from the PCLK synchronous operation to the PCLK asynchronous operation]

I3C operation changes into the PCLK asynchronous operation during BCST.BFREF flag = 1, when the WUASYNF flag set to 1 during WUFSYNE = 0.

The reception can operate without depending on the state of operation of PCLK (With PCLK stopped) after it switches to the PCLK asynchronous operation (Wake-Up event detection operation).

[When switching from the PCLK asynchronous operation to the PCLK synchronous operation]

I3C operation changes into the PCLK synchronous operation at the following conditions. (At the same timing when WUFSYNE flag becomes 0)

In the case Wake-Up event detects : right after WUFSYNE bit is set to 1.

In the case Wake-Up event does not detect : when STOP condition is detected after WUFSYNE bit is set to 1.

[Setting condition]

- When 1 is written to the WUFSYNE bit.
- WUCTL.WUFE = 0

[Clearing conditions]

- When 0 is written to the WUFSYNE bit.

30.2.24 ACKCTL : Acknowledge Control Register

Base address: I3C = 0x4035_F000
I3C_NS = 0x5035_F000

Offset address: 0x0A0

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	ACKTWP	ACKT	ACKR
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	ACKR	Acknowledge Reception 0: A 0 is received as the acknowledge bit (ACK reception). 1: A 1 is received as the acknowledge bit (NACK reception).	R
1	ACKT	Acknowledge Transmission 0: A 0 is sent as the acknowledge bit (ACK transmission). 1: A 1 is sent as the acknowledge bit (NACK transmission).	R/W
2	ACKTWP	ACKT Write Protect 0: The ACKT bit are protected. 1: The ACKT bit can be written (when writing simultaneously with the value of the target bit). This bit is read as 0.	W
31:3	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE3, P-TYPE3
Note: This register supports I^2C mode.

ACKR bit (Acknowledge Reception)

This bit is used to store the acknowledge bit information received from the receive device in transmit mode.

[Setting condition]

- When 1 is received as the acknowledge bit with the PRSST.TRMD bit set to 1.

[Clearing condition]

- When 0 is received as the acknowledge bit with the PRSST.TRMD bit set to 1.

ACKT bit (Acknowledge Transmission)

[Setting condition]

- When 1 is written to the ACKT bit and 1 is written to the ACKTWP bit at the same time.

[Clearing conditions]

- When 0 is written to the ACKT bit and 1 is written to the ACKTWP bit at the same time.
- When a STOP condition is detected. (when a STOP condition is detected with the CNDCTL.SPCND bit set to 1.)

Note: Set the ACKT bit to 0 in I^2C Slave mode.

ACKTWP bit (ACKT Write Protect)

This bit is used to control the modification of the ACKT bit.

When changing the ACKT bit, setting this bit to 1 at the same time can change the ACKT bit.

When this bit is read, 0 is always read.

30.2.25 SCSTRCTL : SCL Stretch Control Register

Base address: I3C = 0x4035_F000
I3C_NS = 0x5035_F000

Offset address: 0x0A4

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	RWE	ACKTWE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	ACKTWE	Acknowledge Transmission Wait Enable 0: NTST.RDBFF0 is set at the rising edge of the ninth SCL clock cycle. (The I3C_SCL line is not held low at the falling edge of the eighth clock cycle.) 1: NTST.RDBFF0 is set at the rising edge of the eighth SCL clock cycle. (The I3C_SCL line is held low at the falling edge of the eighth clock cycle.) Low-hold is released by writing a value to the ACKCTL.ACKT bit.	R/W
1	RWE	Receive Wait Enable 0: No WAIT (The period between ninth clock cycle and first clock cycle is not held low.) 1: WAIT (The period between ninth clock cycle and first clock cycle is held low.) Low-hold is released by reading NTDTBP0.	R/W
31:2	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE3, P-TYPE3
Note: This register supports I^2C mode.

ACKTWE bit (Acknowledge Transmission Wait Enable)

This bit is used to select the NTST.RDBFF0 flag set timing in receive mode and also to select whether to hold the I3C_SCL line low at the falling edge of the eighth SCL clock cycle.

When ACKTWE = 0, the I3C_SCL line is not held low at the falling edge of the eighth SCL clock cycle, and the NTST.RDBFF0 flag is set to 1 at the rising edge of the ninth SCL clock cycle.

When ACKTWE = 1, the NTST.RDBFF0 flag is set to 1 at the rising edge of the eighth SCL clock cycle and the I3C_SCL line is held low at the falling edge of the eighth SCL clock cycle. The low-hold of the I3C_SCL line is released by writing a value to the ACKCTL.ACKT bit.

After data is received with this setting, the I3C_SCL line is automatically held low before the acknowledge bit is sent. This enables processing to send ACK (ACKCTL.ACKT = 0) or NACK (ACKCTL.ACKT = 1) according to receive data.

RWE bit (Receive Wait Enable)

This bit is used to control whether to hold the period between the ninth SCL clock cycle and the first SCL clock cycle low until the receive data buffer (NTDTBP0) is completely read each time single-byte data is received in receive mode.

When RWE = 0, the receive operation is continued without holding the period between the ninth and the first SCL clock cycle low. When both the ACKTWE and RWE bits = 0, continuous receive operation is enabled with the double buffer.

When RWE = 1, the I3C_SCL line is held low from the falling edge of the ninth clock cycle until the NTDTBP0 value is read each time single-byte data is received.

This enables receive operation in byte units.

Note: When the value of the RWE bit is to be read, be sure to read the NTDTBP0 beforehand.

30.2.26 SCSTLCTL : SCL Stalling Control Register

Base address: I3C = 0x4035_F000
I3C_NS = 0x5035_F000

Offset address: 0x0B0

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	ACKPE	PARPE	—	AAPE	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	0
Bit field:	STLCYC[15:0]	
Value after reset:	0 0 0 0 0 0 0 0	0 0 0 0 0 0 0 0

Bit	Symbol	Function	R/W
15:0	STLCYC[15:0]	Stalling Cycle Counter setting of stall period (I3Cφ cycle). Common use for each phase.	R/W
27:16	—	These bits are read as 0. The write value should be 0.	R/W
28	AAPE	Assigned Address Phase Enable Enable bit that allows stall by the first bit at address assignment 0: Does not stall the SCL clock during the address assignment phase. 1: Stall the SCL clock during address assignment phase.	R/W
29	—	This bit is read as 0. The write value should be 0.	R/W
30	PARPE	Parity Phase Enable Stall enable bit in parity bit period 0: Does not stall the SCL clock during the parity bit period. 1: Stall the SCL clock during the parity bit period.	R/W
31	ACKPE	ACK phase Enable Stall enable bit during ACK/NACK phase 0: Does not stall the SCL clock during the ACK/NACK phase. 1: Stall the SCL clock during the ACK/NACK phase.	R/W

Note: S-TYPE3, P-TYPE3
Note: This register supports I3C master mode and I3C secondary master mode.

When setting this register, follow Chapter 5.1.2.5 Master Clock Stalling of MIPI I3C Spec V1.0, and use it only when necessary because of its negative impacts on bus performance.

STLCYC[15:0] bits (Stalling Cycle)

These bits set the SCL stall period. The SCL stall period is counted by the internal reference clock (I3Cφ). This is a counter common to the enable bits of each phase.

AAPE bit (Assigned Address Phase Enable)

The master can stall SCL during the low period of the first bit of the assigned address phase of the Enter Dynamic Address Assignment CCC command. It can gain time in assigning dynamic address to the device based on the BCR and DCR of the slave. However, because the Dynamic Address Assignment procedure sends the dynamic address set in the DATBASm (m = 0 to 7) register in sequence, it is not necessary to set this bit and it is prohibited.

PARPE bit (Parity Phase Enable)

The parity bit of the transmission data of I3C write transfer can be used for SCL stalling to avoid underrun of the transmission data FIFO. However, when the transmission data FIFO of the I3C master becomes empty, SCL stalling is performed regardless of the setting of this bit, it is not necessary to set this bit and it is prohibited. It is necessary to set this bit when the I3C slave requires preparation time to receive data.

ACKPE bit (ACK phase Enable)

Determine the need to perform SCL stalling in the ACK/NACK phase based on the following criteria:

- It is necessary to set this bit when the I3C and I2C slaves connected to the bus require preparation time to receive or transmit data.
- In legacy I^2C communication, if there is a possibility that the data FIFO of the I3C master might underrun or overflow, it is not necessary to set this bit because SCL Stalling is performed by FIFO Empty or Full regardless of the setting of this bit.
- Other than legacy I^2C communication, the data FIFO of I3C master might underrun or overflow, and if SCL stalling is required in ACK phase, this bit can be set. However, it is necessary to build the software so that the FIFO does not underrun or overflow due to the interrupt generated according to the FIFO threshold setting (NQTHCTL, NTBTHCTL0, NRQTHCTL, HQTHCTL, HTBTHCTL).
- When I3C master responds ACK/NACK to IBI, it is not necessary to set this bit because ACK/NACK response can be set in advance by BCTL.HJACK, DATBASm.DVMRRJ and DATBASm.DVS IRRJ (m = 0 to 7).
- It is necessary to set this bit when the I3C slave connected to the bus requires preparation time to transmit data for Direct GET CCC.

30.2.27 SVTDLG0 : Slave Transfer Data Length Register 0

Base address: I3C = 0x4035_F000
I3C_NS = 0x5035_F000

Offset address: 0x0C0

Bit position:	31															16	15													0
Bit field:	STDLG[15:0]																—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	—	These bits are read as 0. The write value should be 0.	R/W
31:16	STDLG[15:0]	Slave Transfer Data Length Indicates the number of bytes to be transferred.	R/W

Note: S-TYPE3, P-TYPE3
Note: This register supports I3C secondary master mode and I3C slave mode.

30.2.28 STCTL : Synchronous Timing Control Register

Base address: I3C = 0x4035_F000
I3C_NS = 0x5035_F000

Offset address: 0x120

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	STOE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	STOE	Synchronous Timing output Enable 0: Disable 1: Enable	R/W
31:1	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE3, P-TYPE3
Note: This register supports all I3C mode.

30.2.29 ATCTL : Asynchronous Timing Control Register

Base address: I3C = 0x4035_F000
I3C_NS = 0x5035_F000

Offset address: 0x124

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	CDIV[7:0]								—	—	—	—	—	AMEOE	MREFOE	ATTRGS
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	ATTRGS	Asynchronous Timing Trigger Select*1 0: Software trigger 1: Hardware trigger	R/W
1	MREFOE	MREF Output Enable (Capture Event / Counter Overflow)*2 0: Disable 1: Enable	R/W
2	AMEOE	Additional Master-initiated bus Event Output Enable*2 0: Disable 1: Enable	R/W
7:3	—	These bits are read as 0. The write value should be 0.	R/W
15:8	CDIV[7:0]	TCLK Counter Divide Setting*3	R/W
31:16	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE3, P-TYPE3
Note 1. This bit supports I3C secondary master mode and I3C slave mode.
Note 2. This bit supports I3C master mode and I3C secondary master mode.
Note 3. These bits support all I3C mode.

30.2.30 ATTRG : Asynchronous Timing Trigger Register

Base address: I3C = 0x4035_F000
I3C_NS = 0x5035_F000

Offset address: 0x128

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	ATSTRG
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	ATSTRG	Asynchronous Timing Software Trigger 0: Do nothing 1: Software trigger (one-shot pulse) output This bit is always read as 0.	W
31:1	—	These bits are read as 0.	R

Note: S-TYPE3, P-TYPE3
Note: This register supports I3C secondary master mode and I3C slave mode.

30.2.31 ATCCNTE : Asynchronous Timing Control Counter Enable Register

Base address: I3C = 0x4035_F000
I3C_NS = 0x5035_F000

Offset address: 0x12C

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	ATCE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	ATCE	Asynchronous Timing Counter Enable for MREF, MC2, SC1, SC2. 0: Disable 1: Enable	R/W
31:1	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE3, P-TYPE3
Note: This register supports all I3C mode.

30.2.32 CNDCTL : Condition Control Register

Base address: I3C = 0x4035_F000
I3C_NS = 0x5035_F000

Offset address: 0x140

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	SPCND	SRCND	STCND
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	STCND	START (S) Condition Issuance 0: Does not request to issue a START condition. 1: Requests to issue a START condition.	R/W
1	SRCND	Repeated START (Sr) Condition Issuance 0: Does not request to issue a Repeated START condition. 1: Requests to issue a Repeated START condition.	R/W
2	SPCND	STOP (P) Condition Issuance 0: Does not request to issue a STOP condition. 1: Requests to issue a STOP condition.	R/W
31:3	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE3, P-TYPE3
Note: This register supports I^2C mode.

STCND bit (START (S) Condition Issuance)

This bit is used to request transition to master mode and issuance of a START condition.

For details on the START condition issuance, see section 30.3.2.3.3. START Condition / Repeated START Condition / STOP Condition Issuing Function .

[Setting condition]

- When 1 is written to the STCND bit

[Clearing conditions]

- When 0 is written to the STCND bit
- When a START condition has been issued (A START condition is detected)
- When the BST.ALF (arbitration-lost) flag is set to 1

Note: Set the STCND bit to 1 (START condition issuance request) when the BCST.BFREF flag is set to 1 (bus free state).
Note that arbitration may be lost due to a START condition issuance error if the STCND bit is set to 1 (START condition issuance request) when the BFREF flag is set to 0 (bus busy state).

SRCND bit (Repeated START (Sr) Condition Issuance)

This bit is used to request that a Repeated START condition be issued in master mode.

When this bit is set to 1 to request to issue a Repeated START condition, a Repeated START condition is issued when the BFREF flag is set to 0 (bus busy state) and the PRSST.CRMS bit is set to 1 (master mode).

For details on the Repeated START condition issuance, see section 30.3.2.3.3. START Condition / Repeated START Condition / STOP Condition Issuing Function .

[Setting condition]

- When 1 is written to the SRCND bit with the BCST.BFREF flag set to 0

[Clearing conditions]

- When 0 is written to the SRCND bit
- When a Repeated START condition has been issued (A Repeated START condition is detected)
- When the BST.ALF (arbitration-lost) flag is set to 1

Note: Do not set the SRCND bit to 1 while issuing a STOP condition.

Note: If 1 (requests to issue a Repeated START condition) is written to the SRCND bit in slave mode, the Repeated START condition is not issued but the SRCND bit remains set to 1.

If the operating mode changes to master mode with the bit not being cleared, note that the Repeated START condition may be issued.

SPCND bit (STOP (P) Condition Issuance)

This bit is used to request that a STOP condition be issued in master mode.

When this bit is set to 1 to request to issue a STOP condition, a STOP condition is issued when the BCST.BFREF flag is set to 0 (bus busy state) and the PRSST.CRMS bit is set to 1 (master mode).

For details on the STOP condition issuance, see section 30.3.2.3.3. START Condition / Repeated START Condition / STOP Condition Issuing Function .

[Setting condition]

- When 1 is written to the SPCND bit with the BCST.BFREF flag set to 0 and the PRSST.CRMS bit set to 1

[Clearing conditions]

- When 0 is written to the SPCND bit
- When a STOP condition has been issued (A STOP condition is detected)
- When the BST.ALF (arbitration-lost) flag is set to 1
- When a START condition and a Repeated START condition are detected

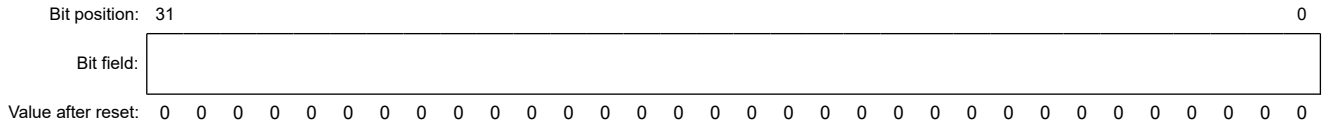
Note: Writing to the SPCND bit is not possible while the setting of the BCST.BFREF flag = 1 (bus free state).

Note: Do not set the SPCND bit to 1 while a Repeated START condition is being issued.

30.2.33 NCMDQP : Normal Command Queue Port Register

Base address: I3C = 0x4035_F000
I3C_NS = 0x5035_F000

Offset address: 0x150



Bit	Symbol	Function	R/W
31:0	n/a	Normal Command Queue Port	W

Note: S-TYPE3, P-TYPE3
Note: This register supports all I3C mode.

32-bit mailbox register NCMDQP contains a command descriptor structure that depends on the requested transfer type:

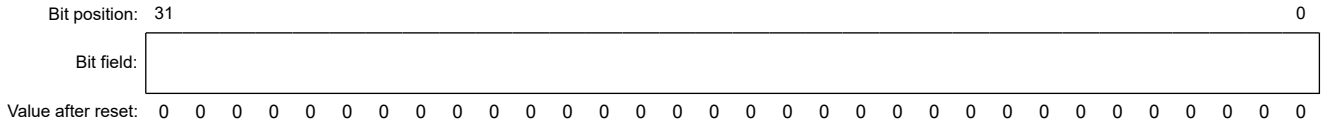
1. Address Assignment Command (see section 30.3.1.1.1. Address Assign Command)
2. Immediate Data Transfer (see section 30.3.1.1.2. Immediate Transfer Command)
3. Regular Data Transfer (see section 30.3.1.1.3. Regular Transfer Command)
4. Write + Write/Read Combo Transfer (see section 30.3.1.1.4. Combo Transfer Command)
5. Internal Control Command (see section 30.3.1.1.5. Internal Control Command)

Within the command descriptor, DWORDs appear starting with the Least Significant DWORD, in order until the Most Significant DWORD.

30.2.34 NRSPQP : Normal Response Queue Port Register

Base address: I3C = 0x4035_F000
I3C_NS = 0x5035_F000

Offset address: 0x154



Bit	Symbol	Function	R/W
31:0	n/a	Normal Response Queue Port	R

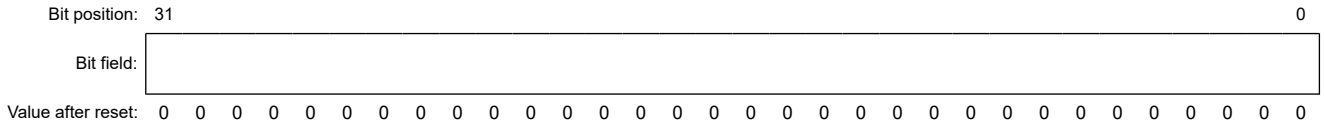
Note: S-TYPE3, P-TYPE3
Note: This register supports all I3C mode.

32-bit mailbox register NRSPQP contains a response structure (see section 30.3.1.4. Receive Status Descriptor).

30.2.35 NTDTBP0/NTDTBP0_BY : Normal Transfer Data Buffer Port Register 0

Base address: I3C = 0x4035_F000
I3C_NS = 0x5035_F000

Offset address: 0x158



Bit	Symbol	Function	R/W
31:0	n/a	Normal Transfer Data Buffer Port NTDTBP0 is a 32-bit read/write register. NTDTBP0_BY (NTDTBP0[7:0]) is a 8-bit read/write register.	R/W

Note: S-TYPE3, P-TYPE3

Note: NTDTBP0 is 32-bit access in I3C mode.
NTDTBP0_BY is 8-bit access in I^2C mode.

32-bit mailbox register NTDTBP0 is a 32-bit bi-directional data transfer register which is used both to read from the Normal Rx Data Buffer, and to write to the Normal Tx Data Buffer.

In other words, the Normal Rx Data Buffer and the Normal Tx Data Buffer have the same offset, forming a single bidirectional port for transmitting or receiving I3C data.

Read Operations:

[I3C protocol mode]

Data Read from the Normal Rx Data Buffer. Its should be read based on Normal Queue Status Level indications. The Rx data is always aligned to a 4-byte boundary, and stored in the Normal Rx Data Buffer. If the length of the data transfer is not aligned to a 4-byte boundary, then there will be extra (unused) bytes at the end of the transferred data. The valid data must be identified using the DATA_LENGTH field in the Response Descriptor.

[I2C protocol mode]

When 1 byte of data has been received, the received data is transferred from the internal shift register to NTDTBP0 to enable the next data to be received. The double-buffer structure of the internal shift register and NTDTBP0 allows continuous receive operation if the received data has been read from NTDTBP0 while the internal shift register is receiving

data. Read data from NTDTBP0 once when a Normal Rx Data buffer full interrupt (I3C_RX) request is generated. If NTDTBP0 receives the next Rx data before the current data is read from NTDTBP0 (while the RDBFF0 flag in NTST is 1), this module automatically holds the SCL clock low one cycle before the RDBFF0 flag is set to 1 next. The lower 8 bits of the read 32-bit data are valid as received data.

Write Operations:

[I3C protocol mode]

Data Written to the Normal Tx Data Buffer. Data DWORDs written to the Normal Tx Data Buffer are placed onto the I3C bus one byte at a time, with the DWORD LSB first. Within each byte, bits are placed onto the I3C bus in big-endian order, with bit 7 going out first on the bus. The Tx data should always start aligned to a 4-byte boundary, and written to the NTDTBP0 register. If the length of the transfer is not aligned to a 4-byte boundary, then there will be extra (unused) bytes at the end of the transferred data. I3C shall only send the valid number of bytes indicated in the DATA_LENGTH field of the Command Descriptor.

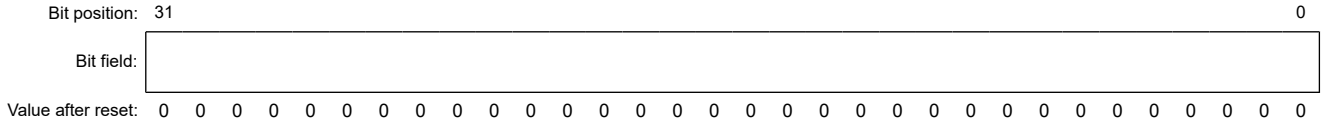
[I2C protocol mode]

When NTDTBP0 detects a space in the internal shift register, it transfers the Tx data that has been written to NTDTBP0 to the internal shift register and starts transmitting data in transmit mode. The double-buffer structure of NTDTBP0 and the internal shift register allows continuous transmit operation if the next Tx data has been written to NTDTBP0 while the internal shift register data is being transmitted. Write Tx data to NTDTBP0 once when a Normal Tx Data buffer empty interrupt (I3C_TX) request is generated. The lower 8 bits of the written 32-bit data are valid as transmission data.

30.2.36 NIBIQP : Normal IBI Queue Port Register

Base address: I3C = 0x4035_F000
I3C_NS = 0x5035_F000

Offset address: 0x17C



Bit	Symbol	Function	R/W
31:0	n/a	Normal IBI Queue Port	R/W

Note: S-TYPE3, P-TYPE3
Note: This register supports all I3C mode.

When receiving an IBI, 32-bit mailbox register NIBIQP is used for both:

- Read the IBI status descriptor (see section 30.3.1.3. IBI Status Descriptor)
- Read the IBI data (which is raw/opaque data).

The IBI status descriptor is a read-only structure describing an IBI event received from a Slave device on the I3C bus.

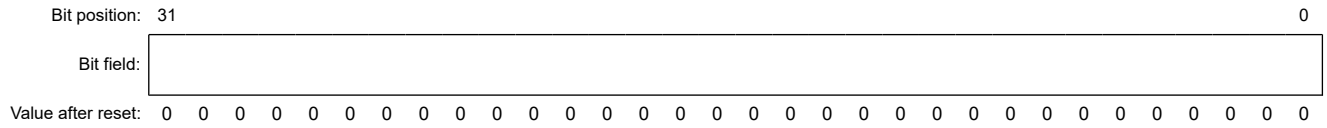
Note: If the I3C HCI auto-read feature is used, then the IBI data includes the data received from the auto-generated private read operation.

Even if LAST_STATUS is set to 0, the driver software still evaluates the data payload length by examining the CHUNKS field.

30.2.37 NRSQP : Normal Receive Status Queue Port Register

Base address: I3C = 0x4035_F000
I3C_NS = 0x5035_F000

Offset address: 0x180



Bit	Symbol	Function	R/W
31:0	n/a	Normal Receive Status Queue Port	R

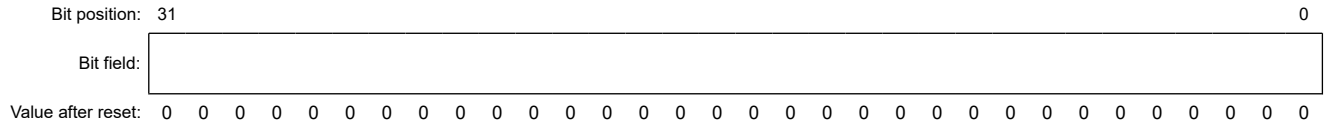
Note: S-TYPE3, P-TYPE3
Note: This register supports I3C secondary master mode and I3C slave mode.

32-bit mailbox register NRSQP contains a receive status structure (see section 30.3.1.4. Receive Status Descriptor).

30.2.38 HCMDQP : High Priority Command Queue Port Register

Base address: I3C = 0x4035_F000
I3C_NS = 0x5035_F000

Offset address: 0x184



Bit	Symbol	Function	R/W
31:0	n/a	High Priority Command Queue Port	W

Note: S-TYPE3, P-TYPE3
Note: This register supports I3C master mode and I3C secondary master mode.

32-bit mailbox register HCMDQP contains a command descriptor structure that depends on the requested transfer type:

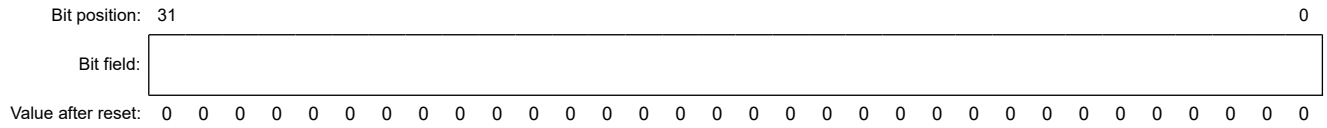
1. Address Assignment Command (see section 30.3.1.1.1. Address Assign Command)
2. Immediate Data Transfer (see section 30.3.1.1.2. Immediate Transfer Command)
3. Regular Data Transfer (see section 30.3.1.1.3. Regular Transfer Command)
4. Write + Write/Read Combo Transfer (see section 30.3.1.1.4. Combo Transfer Command)
5. Internal Control Command (see section 30.3.1.1.5. Internal Control Command)

Within the command descriptor, DWORDs appear starting with the least significant DWORD, in order until the most significant DWORD.

30.2.39 HRSPQP : High Priority Response Queue Port Register

Base address: I3C = 0x4035_F000
I3C_NS = 0x5035_F000

Offset address: 0x188



Bit	Symbol	Function	R/W
31:0	n/a	High Priority Response Queue Port	R

Note: S-TYPE3, P-TYPE3
Note: This register supports I3C master mode and I3C secondary master mode.

32-bit mailbox register HRSPQP contains a response structure. (see section 30.3.1.2. Response Descriptor)

30.2.40 HTDTBP : High Priority Transfer Data Buffer Port Register

Base address: I3C = 0x4035_F000
I3C_NS = 0x5035_F000

Offset address: 0x18C

Bit position:	31																												0
Bit field:																													
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	n/a	High Priority Transfer Data Buffer Port	R/W

Note: S-TYPE3, P-TYPE3
Note: This register supports I3C master mode and I3C secondary master mode.

The HTDTBP register is a 32-bit bi-directional data transfer register which is used both to read from the high priority Rx data, and to write to the high priority Tx data.

For Read Operation:

To receive data from the High Priority Rx Data Buffer, read from the HTDTBP register. It should be read based on queue status indication.

The Rx data is always aligned to a 4-byte boundary, and stored in the High Priority Rx Data Buffer.

If the length of the data transfer is not aligned to a 4-byte boundary, then there will be extra (unused) bytes at the end of the transferred data.

The valid data must be identified using the DATA_LENGTH field in the response descriptor.

For Write Operation:

To send data to the High Priority Tx Data Buffer, write to the HTDTBP register. Data DWORDs written to the Data port are placed onto the I3C bus one byte at a time, with the DWORD's LSB first. Within each byte, bits are placed onto the I3C bus in big-endian order, with bit 7 going out first on the bus.

The High Priority Tx Data Buffer Port is mapped to the High Priority Tx Data Buffer.

The Tx data should always start aligned to a 4byte boundary, and written to the Tx data port register.

If the length of the transfer is not aligned to a 4-byte boundary, then there will be extra (unused) bytes at the end of the transferred data.

I3C shall only send the valid number of bytes indicated in the DATA_LENGTH field of the command descriptor.

30.2.41 NQTHCTL : Normal Queue Threshold Control Register

Base address: I3C = 0x4035_F000
I3C_NS = 0x5035_F000

Offset address: 0x190

Bit position:	31							24	23							16	15							8	7							0
Bit field:	IBIQTH[7:0]								IBIDSSZ[7:0]								RSPQTH[7:0]								CMDQTH[7:0]							
Value after reset:	0	0	0	0	0	0	0	1	0	0	0	0	0	0	0	1	0	0	0	0	0	0	0	1	0	0	0	0	0	0	0	1

Bit	Symbol	Function	R/W
7:0	CMDQTH[7:0]	Normal Command Queue Threshold*1 0x00: Interrupt is issued when Normal Command Queue is completely empty. Others: Interrupt is issued when Normal Command Queue contains N empties. (N = CMDQTH[7:0])	R/W
15:8	RSPQTH[7:0]	Normal Response Queue Threshold*1 0x00: Interrupt is issued when Normal Response Queue contains 1 entry (DWORD). Others: Interrupt is triggered when Normal Response Queue contains N+1 entries (DWORD). (N = CMDQTH[7:0])	R/W
23:16	IBIDSSZ[7:0]	Normal IBI Data Segment Size*2 Supported Values: Minimum: 1 (4 bytes) Maximum: 63 (252 bytes), provided that the configured IBI Queue depth is 64 or more. When ATCCNTE.ATCE = 1, restrict to the number of slices ≥ 2.	R/W
31:24	IBIQTH[7:0]	Normal IBI Queue Threshold*1 0x00: I3C Protocol mode (Master): Interrupt is generated when the Outstanding IBI Status count is 1 or more. I3C Protocol mode (Slave): Interrupt is issued when IBI Data Buffer is completely empty. Others: I3C Protocol mode (Master): Interrupt is generated when the Outstanding IBI Status count is N + 1 or more. (N = CMDQTH[7:0]) I3C Protocol mode (Slave): Interrupt is issued when IBI Data Buffer contains N empties.	R/W

Note: S-TYPE3, P-TYPE3
Note 1. These bits support all I3C mode.
Note 2. These bits support I3C master mode and I3C secondary master mode.

The Queue Threshold Control register controls the interrupt trigger thresholds for the Command Queue, the Response Queue, and the IBI Queue.

The specific reset values are indicative, and could be hardware implementation specific.

CMDQTH[7:0] bits (Normal Command Queue Threshold)

Controls the minimum number of Normal Command Queue empties needed to trigger the I3C_CMD interrupt.

If this field is greater than (Normal Command Queue size*1 – 1), then only the number of bits required to address the full buffer depth will be considered.

RSPQTH[7:0] bits (Normal Response Queue Threshold)

Controls the minimum number of Normal Response Queue entries needed to trigger the I3C_RESP interrupt.

If this field is greater than (Normal Response Queue size*2 – 1), then only the number of bits required to address the full buffer depth will be considered.

IBIDSSZ[7:0] bits (Normal IBI Data Segment Size)

This is the IBI data segment size, in DWORDs (4 bytes).

In PIO mode, this field allows the incoming Normal IBI data to be sliced into multiple segments generating status individually, to support cutthrough readout of a long IBI payload data.

When Asynchronous Timing Control mode is supported, this field should be set to a value other than 1 or 3 to allow the single data segment to contain the entire Master time-stamp value (for example, both MREF and MC2).

IBIQTH[7:0] bits (Normal IBI Queue Threshold)

For I3C protocol mode (Master): PRTS.PRTMD = 0 and PRSST.CRMS = 1.

Controls generation of the I3C_IBI interrupt, based on the value of the Normal IBI Queue's Outstanding IBI status count.

Each IBI status entry can represent either the complete IBI payload (if the IBI payload byte size is 4 × IBIDSSZ or less), or a segment of the IBI payload (if the IBI payload byte size is more than 4 × IBIDSSZ).

For I3C protocol mode (Slave) : PRTS.PRTMD bit = 0, PRSST.CRMS bit = 0.

Controls the minimum number of IBI Data Buffer empties needed to trigger the I3C_IBI interrupt.

If this field is greater than (IBI Data Buffer size[*3] – 1), then only the number of bits required to address the full buffer depth will be considered.

Note 1. Normal Command Queue size is 4.
Note 2. Normal Response Queue size is 4.
Note 3. IBI Data Buffer size is 8.

Note: It is assumed that I3C has exactly one Command Queue, exactly one Response Queue, and exactly one IBI Queue.

30.2.42 NTBTHCTL0 : Normal Transfer Data Buffer Threshold Control Register 0

Base address: I3C = 0x4035_F000
I3C_NS = 0x5035_F000

Offset address: 0x194

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

26:24	RXSTTH[2:0]	Normal Rx Start Threshold[*2] 0 0 0: Wait for 2 empty DWORDs 0 0 1: Wait for 4 empty DWORDs 0 1 0: Wait for 8 empty DWORDs 0 1 1: Wait for 16 empty DWORDs Others: Setting prohibited	R/W
31:27	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE3, P-TYPE3
Note 1. These bits support all I3C mode.
Note 2. These bits support I3C master mode and I3C secondary master mode.

The Data Buffer Control register controls the interrupt trigger thresholds for the Rx Data Buffer Queue and the Tx Data Buffer Queue.

TXDBTH[2:0] bits (Normal Tx Data Buffer Threshold)

Minimum number of Tx Data Buffer empties, in DWORDs, that will trigger the I3C_TX interrupt.

The software must program a value less than Tx Data Buffer size in this register.

RXDBTH[2:0] bits (Normal Rx Data Buffer Threshold)

Minimum number of Rx Data Buffer entries in DWORDs that will trigger the I3C_RX interrupt.

The software must program a value less than Rx Data Buffer size in this register.

TXSTTH[2:0] bits (Normal Tx Start Threshold)

When preparing to initiate a Write Transfer on the I3C Bus, I3C shall wait until the Transmit Buffer has at least the indicated number of locations available.

Two optional configurable Modes are available:

1. Store and Forward Mode
   If the TXSTTH[2:0] field is set to the Transmit Buffer size, then I3C shall delay initiation of the Write Command as follows:
   - If the data length to be transferred is more than the Transmit Buffer size, then this module shall wait until the Tx Data Buffer is completely full.
   - If the data length to be transferred is less than the Transmit Buffer size, then I3C shall wait until enough Tx Data Buffer locations are available to store the data to be transferred.
2. Threshold Mode
   If the TXSTTH[2:0] field value is less than the Transmit Buffer size, then I3C shall initiate the Write Command as soon as the indicated number of Tx Data Buffer locations are entries.

RXSTTH[2:0] bits (Normal Rx Start Threshold)

When preparing to initiate a Read Transfer on the I3C bus, I3C shall wait until the Receive Buffer has at least the indicated number of empty locations in DWORDs.

Two optional configurable Modes are available:

1. Store and Forward Mode
   If the RXSTTH[2:0] field is set to the Receive Buffer size, then I3C shall delay initiation of the Read Command as follows:
   - If the data length to be transferred is more than the Receive Buffer size, then this module shall wait until the Rx Data Buffer is completely empty.
   - If the data length to be transferred is less than the Receive Buffer size, then I3C shall wait until enough Rx Data Buffer locations are available to store the data to be transferred.
2. Threshold Mode
   If the RXSTTH[2:0] field value is less than the Receive Buffer size, then I3C shall initiate the Read Command as soon as the indicated number of Rx Data Buffer locations are empty.

30.2.43 NRQTHCTL : Normal Receive Status Queue Threshold Control Register

Base address: I3C = 0x4035_F000
I3C_NS = 0x5035_F000

Offset address: 0x1C0

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	RSQTH[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

Bit	Symbol	Function	R/W
7:0	RSQTH[7:0]	Normal Receive Status Queue Threshold 0x00: Interrupt is issued when Normal Receive Status Queue contains 1 entry (DWORD). Others: Interrupt is triggered when Normal Receive Status Queue contains N+1 entries (DWORD). (N = RSQTH[7:0])	R/W
31:8	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE3, P-TYPE3
Note: This register supports I3C secondary master mode and I3C slave mode.

RSQTH[7:0] bits (Normal Receive Status Queue Threshold)

Controls the minimum number of normal receive status queue entries needed to trigger the I3C_RCV interrupt.

If this field is greater than (Normal Receive Status Queue size[*1] – 1), then only the number of bits required to address the full buffer depth will be considered.

Note 1. Normal Receive Status Queue size is 2.

30.2.44 HQTHCTL : High Priority Queue Threshold Control Register

Base address: I3C = 0x4035_F000
I3C_NS = 0x5035_F000

Offset address: 0x1C4

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	RSPQTH[7:0]								CMDQTH[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0	0	0	0	1

Bit	Symbol	Function	R/W
7:0	CMDQTH[7:0]	High Priority Command Queue Threshold 0x00: Interrupt is issued when High Priority Command Queue is completely empty. Others: Interrupt is issued when High Priority Command Queue contains N entries. (N = CMDQTH[7:0])	R/W
15:8	RSPQTH[7:0]	High Priority Response Queue Threshold 0x00: Interrupt is issued when High Priority Response Queue contains 1 entry (DWORD). Others: Interrupt is triggered when High Priority Response Queue contains N+1 entries (DWORD). (N = RSPQTH[7:0])	R/W
31:16	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE3, P-TYPE3
Note: This register supports I3C master mode and I3C secondary master mode.

The High Priority Queue Threshold Control register controls the interrupt trigger thresholds for the High Priority Command Queue, the High Priority Response Queue, and the IBI Queue.

The specific reset values are indicative, and could be hardware implementation specific.

CMDQTH[7:0] bits (High Priority Command Queue Threshold)

Controls the minimum number of empty High Priority Command Queue entries needed to trigger the I3C_HCMD interrupt.

If this field is greater than (High Priority Command Queue size[*1] – 1), then only the number of bits required to address the full buffer depth will be considered.

RSPQTH[7:0] bits (High Priority Response Queue Threshold)

Controls the minimum number of High Priority Response Queue entries needed to trigger the I3C_HRESP interrupt.

If this field is greater than (High Priority Response Queue size[*2] – 1), then only the number of bits required to address the full buffer depth will be considered.

Note 1. High Priority Command Queue size is 2.
Note 2. High Priority Response Queue size is 2.

Note: It is assumed that I3C has exactly one High Priority Command Queue, exactly one High Priority Response Queue, and exactly one IBI Queue.

30.2.45 HTBTHCTL : High Priority Transfer Data Buffer Threshold Control Register

Base address: I3C = 0x4035_F000
I3C_NS = 0x5035_F000

Offset address: 0x1C8

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	RXSTTH[2:0]			—	—	—	—	—	TXSTTH[2:0]		
Value after reset:	0	0	0	0	0	0	0	1	0	0	0	0	0	0	0	1

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	RXDBTH[2:0]			—	—	—	—	—	TXDBTH[2:0]		
Value after reset:	0	0	0	0	0	0	0	1	0	0	0	0	0	0	0	1

Bit	Symbol	Function	R/W
2:0	TXDBTH[2:0]	High Priority Tx Data Buffer Threshold 0 0 0: Interrupt triggers at 2 High Priority Tx Buffer empties, DWORDs 0 0 1: Reserved Others Setting prohibited	R/W
7:3	—	These bits are read as 0. The write value should be 0.	R/W
10:8	RXDBTH[2:0]	High Priority Rx Data Buffer Threshold 0 0 0: Interrupt triggers at 2 High Priority Rx Buffer entries, DWORDs 0 0 1: Reserved Others Setting prohibited	R/W
15:11	—	These bits are read as 0. The write value should be 0.	R/W
18:16	TXSTTH[2:0]	High Priority Tx Start Threshold 0 0 0: Wait for 2 entry DWORDs 0 0 1: Reserved Others Setting prohibited	R/W
23:19	—	These bits are read as 0. The write value should be 0.	R/W
26:24	RXSTTH[2:0]	High Priority Rx Start Threshold 0 0 0: Wait for 2 empty DWORDs 0 0 1: Reserved Others Setting prohibited	R/W
31:27	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE3, P-TYPE3
Note: This register supports I3C master mode and I3C secondary master mode.

TXDBTH[2:0] bits (High Priority Tx Data Buffer Threshold)

Minimum number of High Priority Tx Data Buffer empties, in DWORDs, that will trigger the I3C_HTX interrupt. The software must program a value less than High Priority Tx Data Buffer size in this register.

RXDBTH[2:0] bits (High Priority Rx Data Buffer Threshold)

Minimum number of High Priority Rx Data Buffer entries in DWORDs that will trigger the I3C_HRX interrupt. The software must program a value less than High Priority Rx Data Buffer size in this register.

TXSTTH[2:0] bits (High Priority Tx Start Threshold)

When preparing to initiate a Write Transfer on the I3C bus, I3C shall wait until the High Priority Transmit Buffer has at least the indicated number of locations available.

Two optional configurable modes are available:

1. Store and Forward Mode

If the TXSTTH[2:0] field is set to the High Priority Transmit Buffer size, then I3C shall delay initiation of the write command as follows:

- If the data length to be transferred is more than the High Priority Transmit Buffer size, then I3C shall wait until the High Priority Tx Data Buffer is completely full.
- If the data length to be transferred is less than the High Priority Transmit Buffer size, then I3C shall wait until enough High Priority Tx Data Buffer locations are available to store the data to be transferred.

2. Threshold mode
If the TXSTTH[2:0] field value is less than the High Priority Transmit Buffer size, then I3C shall initiate the write command as soon as the indicated number of High Priority Tx Data Buffer locations are empty.

RXSTTH[2:0] bits (High Priority Rx Start Threshold)

When preparing to initiate a Read Transfer on the I3C bus, I3C shall wait until the High Priority Receive Buffer has at least the indicated number of empty locations in DWORDs.

Two optional configurable modes are available:

1. Store and forward mode
If the RXSTTH[2:0] field is set to the High Priority Receive Buffer size, then I3C shall delay initiation of the read command as follows:

- If the data length to be transferred is more than the High Priority Receive Buffer size, then I3C shall wait until the High Priority Rx Data Buffer is completely empty.
- If the data length to be transferred is less than the High Priority Receive Buffer size, then I3C shall wait until enough High Priority Rx Data Buffer locations are available to store the data to be transferred.

2. Threshold mode
If the RXSTTH[2:0] field value is less than the High Priority Receive Buffer size, then I3C shall initiate the read command as soon as the indicated number of High Priority Rx Data Buffer locations are empty.

30.2.46 BST : Bus Status Register

Base address: I3C = 0x4035_F000
I3C_NS = 0x5035_F000

Offset address: 0x1D0

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	WUCNDDF	—	—	—	TODF	—	—	—	ALF
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	TENDF	—	—	—	NACKDF	—	HDREXDF	SPCNDDF	STCNDDF
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	STCNDDF	START Condition Detection Flag 0: START condition is not detected. 1: START condition is detected.	R/W*3
1	SPCNDDF	STOP Condition Detection Flag 0: STOP condition is not detected. 1: STOP condition is detected.	R/W*3
2	HDREXDF	HDR Exit Pattern Detection Flag*1 0: HDR Exit Pattern is not detected 1: HDR Exit Pattern is detected.	R/W*3
3	—	This bit is read as 0. The write value should be 0.	R/W

Bit	Symbol	Function	R/W
4	NACKDF	NACK Detection Flag*2 0: NACK is not detected. 1: NACK is detected.	R/W*3
7:5	—	These bits are read as 0. The write value should be 0.	R/W
8	TENDF	Transmit End Flag*2 0: Data is being transmitted. 1: Data has been transmitted.	R/W*3
15:9	—	These bits are read as 0. The write value should be 0.	R/W
16	ALF	Arbitration Lost Flag*2 0: Arbitration is not lost 1: Arbitration is lost.	R/W*3
19:17	—	These bits are read as 0. The write value should be 0.	R/W
20	TODF	Timeout Detection Flag 0: Timeout is not detected. 1: Timeout is detected.	R/W*3
23:21	—	These bits are read as 0. The write value should be 0.	R/W
24	WUCNDDF	Wake-Up Condition Detection Flag 0: Wake-Up is not detected. 1: Wake-Up is detected.	R/W*3
31:25	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE3, P-TYPE3
Note 1. This bit supports all I3C mode.
Note 2. This bit supports I^2C mode.
Note 3. Clearing (to 0) condition : Writing 0 after 1 is read.

STCNDDF bit (START Condition Detection Flag)

[Setting conditions]

- All of the followings are satisfied:
  1. The BSTE.STCNDDE bit = 1.
  2. When a START condition (or a Repeated START condition) is detected.

[Clearing conditions]

- When 0 is written to the STCNDDF flag after reading STCNDDF flag = 1.
- When a STOP condition is detected.

SPCNDDF bit (STOP Condition Detection Flag)

[Setting conditions]

- All of the followings are satisfied:
  1. The BSTE.SPCNDDE bit = 1.
  2. When a STOP condition is detected.

[Clearing condition]

- When 0 is written to the SPCNDDF flag after reading SPCNDDF flag = 1.

HDREXDF bit (HDR Exit Pattern Detection Flag)

[Setting conditions]

- All of the followings are satisfied:
  1. The BSTE.HDREXDE bit = 1.
  2. When a HDR EXIT pattern is detected.

[Clearing condition]

- When 0 is written to the HDREXDF flag after reading HDREXDF flag = 1.

NACKDF bit (NACK Detection Flag)

[Setting conditions]

- All of the followings are satisfied:
  1. The PRTS.PRTMD bit = 1 (I^2C protocol mode).
  2. The BSTE.NACKDE bit = 1 (Enables NACK detection interrupt status logging).
  3. When acknowledge is not received (NACK is received) from the receive device in transmit mode.

[Clearing condition]

- When 0 is written to the NACKDF flag after reading NACKDF flag = 1.

TENDF bit (Transmit End Flag)

[Setting conditions]

- All of the followings are satisfied:
  1. The PRTS.PRTMD bit = 1 (I^2C protocol mode).
  2. The BSTE.TENDE bit = 1 (Enables Transmit End Interrupt Status logging).
  3. At the rising edge of the ninth SCL clock cycle while the NTST.TDBEF0 flag = 1.
     Excluding when sending an address.

[Clearing conditions]

- When 0 is written to the TENDF flag after reading TENDF flag = 1.
- When data is written to the NTDTBP0 register.
- When a STOP condition is detected.

ALF bit (Arbitration Lost Flag)

[Setting conditions]

When master arbitration-lost detection is enabled: BSTE.ALE bit = 1, BFCTL.MALE = 1.

- When the internal SDA output state does not match the I3C_SDA line level at the rising edge of SCL clock except for the ACK period during data (including slave address) transmission in master transmit mode (when the I3C_SDA line is driven low while the internal SDA output is at a high level (the I3C_SDA pin is in the highimpedance state)).
- All of the followings are satisfied.
  1. When the START condition is detected while the CNDCTL.STCND bit = 1.
  2. When the internal SDA output state does not match the I3C_SDA line level.
- When the CNDCTL.STCND bit is set to 1 (START condition issuance request) while the BCST.BFREF flag = 0.

When NACK arbitration-lost detection is enabled: BSTE.ALE bit = 1, BFCTL.NALE = 1.

- When the internal SDA output state does not match the I3C_SDA line level at the rising edge of SCL clock in the ACK period during NACK transmission in receive mode.

When slave arbitration-lost detection is enabled: BSTE.ALE bit = 1, BFCTL.SALE = 1.

- When the internal SDA output state does not match the I3C_SDA line level at the rising edge of SCL clock except for the ACK period during data transmission in slave transmit mode.

[Clearing condition]

- When 0 is written to the ALF flag after reading ALF flag = 1.

TODF bit (Timeout Detection Flag)

[Setting conditions]

- All of the followings are satisfied.
  1. The BSTE.TODE bit = 1 (Enables Timeout Detection Interrupt Status logging).
  2. When the master mode or the received slave address matches the slave address n (n = 0 to 2) in Slave mode.
  3. When the I3C_SCL line state remains unchanged for the period specified by TMOCTL register.

[Clearing condition]

- When 0 is written to the TODF flag after reading TODF flag = 1.

WUCNDDF bit (Wake-Up Condition Detection Flag)

[Setting condition]

For I^2C protocol mode: PRTS.PRTMD bit = 1

- When PCLK and TCLK are supplied after all of the followings are satisfied.
  1. The WUCTL.WUFE bit = 1 (Wake-up function is enabled).
  2. The BSTE.WUCNDDE bit = 1 (Enables Wake-up Condition Detection Status logging).
  3. The WUST.WUASYNF flag = 1.
  4. When the address received in slave mode matches the address of slave enabled in the SVCTL.SVAE[2:0] bit (except for the Device-ID address).

For I3C Protocol mode (Master): PRTS.PRTMD bit = 0, PRSST.CRMS bit = 1.

- When PCLK and TCLK are supplied after all of the followings are satisfied.
  1. The WUCTL.WUFE bit = 1 (Wake-up function is enabled).
  2. The BSTE.WUCNDDE bit = 1 (Enables Wake-up Condition Detection Status logging).
  3. The WUST.WUASYNF flag = 1.
  4. When low level of the I3C_SDA line is detected (When the START condition is detected).

For I3C Protocol mode (Slave) : PRTS.PRTMD bit = 0, PRSST.CRMS bit = 0.

- When PCLK and TCLK are supplied after all of the followings are satisfied.
  1. The WUCTL.WUFE bit = 1 (Wake-up function is enabled).
  2. The BSTE.WUCNDDE bit = 1 (Enables Wake-up Condition Detection Status logging).
  3. The WUST.WUASYNF flag = 1.
  4. When the broadcast address (0x7E) is detected after a START (or Repeated START) condition and the own dynamic address is detected after the Repeated START condition following the broadcast address.

[Clearing condition]

- When 0 is written to the WUCNDDF flag after reading WUCNDDF flag = 1 while the WUST.WUASYNF flag = 0.

30.2.47 BSTE : Bus Status Enable Register

Base address: I3C = 0x4035_F000
I3C_NS = 0x5035_F000

Offset address: 0x1D4

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

19:17	—	These bits are read as 0. The write value should be 0.	R/W
20	TODE	Timeout Detection Enable 0: Disables Timeout Detection Interrupt Status logging. 1: Enables Timeout Detection Interrupt Status logging.	R/W
23:21	—	These bits are read as 0. The write value should be 0.	R/W
24	WUCNDDE	Wake-up Condition Detection Enable 0: Disables Wake-up Condition Detection Status logging. 1: Enables Wake-up Condition Detection Status logging.	R/W
31:25	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE3, P-TYPE3
Note 1. This bit supports all I3C mode.
Note 2. This bit supports I^2C mode.

STCNDDE bit (START Condition Detection Enable)

When this bit is 1, operation of BST.STCNDDF is enabled. For the setting conditions and clearing conditions of the BST.STCNDDF flag, see the details of BST.STCNDDF.

SPCNDDE bit (STOP Condition Detection Enable)

When this bit is 1, operation of BST.SPCNDDF is enabled. For the setting conditions and clearing conditions of the BST.SPCNDDF flag, see the details of BST.SPCNDDF.

HDREXDE bit (HDR Exit Pattern Detection Enable)

When this bit is 1, the operation of BST.HDREXDF is enabled. For the setting conditions and clearing conditions of the BST.HDREXDF flag, see the details of BST.HDREXDF.

NACKDE bit (NACK Detection Enable)

When this bit is 1, the operation of BST.NACKDF is enabled. This bit is used to specify whether to continue or discontinue the transfer operation when NACK is received from the slave device in transmit mode. Normally, set this bit to 1. For the setting conditions and clearing conditions of the BST.NACKDF flag, see the details of BST.NACKDF.

TENDE bit (Transmit End Enable)

When this bit is 1, the operation of BST.TENDF is enabled. For the setting conditions and clearing conditions of the BST.TENDF flag, see the details of BST.TENDF.

ALE bit (Arbitration Lost Enable)

When this bit is 1, the operation of BST.ALF is enabled. For the setting conditions and clearing conditions of the BST.ALF flag, see the details of BST.ALF.

TODE bit (Timeout Detection Enable)

When this bit is 1, the operation of BST.TODF is enabled. For the setting conditions and clearing conditions of the BST.TODF flag, see the details of BST.TODF.

WUCNDDE bit (Wake-up Condition Detection Enable)

When this bit is 1, the operation of BST.WUCNDDF is enabled. For the setting conditions and clearing conditions of the BST.WUCNDDF flag, see the details of BST.WUCNDDF.

30.2.48 BIE : Bus Interrupt Enable Register

Base address: I3C = 0x4035_F000
I3C_NS = 0x5035_F000

Offset address: 0x1D8

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	WUCNDDIE	—	—	—	TODIE	—	—	—	ALIE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	STCNDDIE	START Condition Detection Interrupt Enable 0: Disables START condition Detection Interrupt Signal. 1: Enables START condition Detection Interrupt Signal.	R/W
1	SPCNDDIE	STOP Condition Detection Interrupt Enable 0: Disables STOP condition Detection Interrupt Signal. 1: Enables STOP condition Detection Interrupt Signal.	R/W
2	HDREXDIE	HDR Exit Pattern Detection Interrupt Enable*1 0: Disables HDR Exit Pattern Detection Interrupt Signal. 1: Enables HDR Exit Pattern Detection Interrupt Signal.	R/W
3	—	This bit is read as 0. The write value should be 0.	R/W

Bit	Symbol	Function	R/W
4	NACKDIE	NACK Detection Interrupt Enable*2 0: Disables NACK Detection Interrupt Signal. 1: Enables NACK Detection Interrupt Signal.	R/W
7:5	—	These bits are read as 0. The write value should be 0.	R/W
8	TENDIE	Transmit End Interrupt Enable*2 0: Disables Transmit End Interrupt Signal. 1: Enables Transmit End Interrupt Signal.	R/W
15:9	—	These bits are read as 0. The write value should be 0.	R/W
16	ALIE	Arbitration Lost Interrupt Enable*2 0: Disables Arbitration Lost Interrupt Signal. 1: Enables Arbitration Lost Interrupt Signal.	R/W
19:17	—	These bits are read as 0. The write value should be 0.	R/W
20	TODIE	Timeout Detection Interrupt Enable 0: Disables Timeout Detection Interrupt Signal. 1: Enables Timeout Detection Interrupt Signal.	R/W
23:21	—	These bits are read as 0. The write value should be 0.	R/W
24	WUCNDDIE	Wake-Up Condition Detection Interrupt Enable 0: Disables Wake-Up Condition Detection Interrupt Signal. 1: Enables Wake-Up Condition Detection Interrupt Signal.	R/W
31:25	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE3, P-TYPE3
Note 1. This bit supports all I3C mode.
Note 2. This bit supports I^2C mode.

The BIE register enables signaling of outstanding bus interrupts received by I3C.

STCNDDIE bit (START Condition Detection Interrupt Enable)

This bit enables or disables the START Condition Detection interrupt requests when the BST.STCNDDF flag is set to 1.

SPCNDDIE bit (STOP Condition Detection Interrupt Enable)

This bit enables or disables the STOP Condition Detection interrupt requests when the BST.SPCNDDF flag is set to 1.

HDREXDIE bit (HDR Exit Pattern Detection Interrupt Enable)

This bit enables or disables the HDR Exit Pattern Detection interrupt requests when the BST.HDREXDF flag is set to 1.

NACKDIE bit (NACK Detection Interrupt Enable)

This bit enables or disables the NACK Detection interrupt requests when the BST.NACKDF flag is set to 1.

TENDIE bit (Transmit End Interrupt Enable)

This bit enables or disables the Transmit End interrupt (I3C_TEND) requests when the BST.TENDF flag is set to 1.

ALIE bit (Arbitration Lost Interrupt Enable)

This bit enables or disables the Arbitration lost interrupt requests when the BST.ALF flag is set to 1.

TODIE bit (Timeout Detection Interrupt Enable)

This bit enables or disables the Timeout Detection interrupt requests when the BST.TODF flag is set to 1.

WUCNDDIE bit (Wake-Up Condition Detection Interrupt Enable)

This bit enables or disables the Wake-up Condition Detection interrupt (I3C_WU) requests when the BST.WUCNDDF flag is set to 1.

30.2.49 BSTFC : Bus Status Force Register

Base address: I3C = 0x4035_F000
I3C_NS = 0x5035_F000

Offset address: 0x1DC

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	WUCNDDFC	—	—	—	TODFC	—	—	—	ALFC
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	TENDFC	—	—	—	NACKDFC	—	HDREXDFC	SPCNDDFC	STCNDDFC
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	STCNDDFC	START condition Detection Force 0: Not Force START condition Detection Interrupt for software testing. 1: Force START condition Detection Interrupt for software testing.	W
1	SPCNDDFC	STOP condition Detection Force 0: Not Force STOP condition Detection Interrupt for software testing. 1: Force STOP condition Detection Interrupt for software testing.	W
2	HDREXDFC	HDR Exit Pattern Detection Force*1 0: Not Force HDR Exit Pattern Detection Interrupt for software testing. 1: Force HDR Exit Pattern Detection Interrupt for software testing.	W
3	—	This bit is read as 0.	R
4	NACKDFC	NACK Detection Force*2 0: Not Force NACK Detection Interrupt for software testing. 1: Force NACK Detection Interrupt for software testing.	W
7:5	—	These bits are read as 0.	R
8	TENDFC*3	Transmit End Force*2 0: Not Force Transmit End Interrupt for software testing. 1: Force Transmit End Interrupt for software testing.	W
15:9	—	These bits are read as 0.	R
16	ALFC	Arbitration Lost Force*2 0: Not Force Arbitration Lost Interrupt for software testing. 1: Force Arbitration Lost Interrupt for software testing.	W
19:17	—	These bits are read as 0.	R
20	TODFC	Timeout Detection Force 0: Not Force Timeout Detection Interrupt for software testing. 1: Force Timeout Detection Interrupt for software testing.	W
23:21	—	These bits are read as 0.	R
24	WUCNDDFC	Wake-Up Condition Detection Force 0: Not Force Wake-Up Condition Detection Interrupt for software testing. 1: Force Wake-Up Condition Detection Interrupt for software testing.	W
31:25	—	These bits are read as 0.	R

Note: S-TYPE3, P-TYPE3
Note 1. This bit supports all I3C mode.
Note 2. This bit supports I^2C mode.
Note 3. TENDFC does not work unless TDBEF0 = 1.

30.2.50 NTST : Normal Transfer Status Register

Base address: I3C = 0x4035_F000
I3C_NS = 0x5035_F000

Offset address: 0x1E0

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	RSQFF	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit field:	—	—	—	—	—	—	TEF	—	—	—	TABTF	RSPQFF	CMDQEF	IBIQEFF	RDBFF0	TDBEF0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	TDBEF0	Normal Tx Data Buffer Empty Flag 0 0: For I2C protocol mode: PRTS.PRTMD bit = 1. Normal Tx Data Buffer contains transmit data. For I3C protocol mode: PRTS.PRTMD bit = 0. The number of empties in the Normal Tx Data Buffer is less than the NTBTHCTL0.TXDBTH[2:0] threshold. 1: For I2C protocol mode: PRTS.PRTMD bit = 1. Normal Tx Data Buffer contains no transmit data. For I3C protocol mode: PRTS.PRTMD bit = 0. The number of empties in the Normal Tx Data Buffer is the NTBTHCTL0.TXDBTH[2:0] threshold or more.	R/W*3
1	RDBFF0	Normal Rx Data Buffer Full Flag 0 0: For I2C protocol mode: PRTS.PRTMD bit = 1. Normal Rx Data Buffer contains no receive data. For I3C Protocol mode: PRTS.PRTMD bit = 0. The number of entries in the Normal Rx Data Buffer is less than the NTBTHCTL0.RXDBTH[2:0] threshold. 1: For I2C protocol mode: PRTS.PRTMD bit = 1. Normal Rx Data Buffer contains receive data. For I3C Protocol mode: PRTS.PRTMD bit = 0. The number of entries in the Normal Rx Data Buffer is the NTBTHCTL0.RXDBTH[2:0] threshold or more.	R/W*3
2	IBIQEFF	Normal IBI Queue Empty/Full Flag*1 0: For I3C protocol mode (Master): PRTS.PRTMD bit = 0, PRSST.CRMS bit = 1. The number of Normal IBI Queue entries is the NQTHCTL.IBIQTH threshold or less. For I3C protocol mode (Slave) : PRTS.PRTMD bit = 0, PRSST.CRMS bit = 0. If the NQTHCTL.IBIQTH = 0: The number of IBI Data Buffer empties is less than the IBI Data Buffer size. If the NQTHCTL.IBIQTH is other than 0: The number of IBI Data Buffer empties is less than the NQTHCTL.IBIQTH threshold. 1: For I3C protocol mode (Master): PRTS.PRTMD bit = 0, PRSST.CRMS bit = 1. The number of Normal IBI Queue entries is more than the NQTHCTL.IBIQTH threshold. For I3C protocol mode (Slave) : PRTS.PRTMD bit = 0, PRSST.CRMS bit = 0. If the NQTHCTL.IBIQTH = 0: The number of IBI Data Buffer empties is the IBI Data Buffer size. If the NQTHCTL.IBIQTH is other than 0: The number of IBI Data Buffer empties is the NQTHCTL.IBIQTH threshold or more.	R/W*3

Bit	Symbol	Function	R/W
3	CMDQEF	Normal Command Queue Empty Flag*1 0: If the NQTHCTL.CMDQTH = 0: The number of Normal Command Queue empties is less than the Normal Command Queue size. If the NQTHCTL.CMDQTH is other than 0: The number of Normal Command Queue empties is less than the NQTHCTL.CMDQTH threshold. 1: If the NQTHCTL.CMDQTH = 0: The number of Normal Command Queue empties is the Normal Command Queue size. If the NQTHCTL.CMDQTH is other than 0: 1: The number of Normal Command Queue empties is the NQTHCTL.CMDQTH threshold or more.	R/W*3
4	RSPQFF	Normal Response Queue Full Flag*1 0: The number of Normal Response Queue entries is the NQTHCTL.RSPQTH threshold or less. 1: The number of Normal Response Queue entries is more than the NQTHCTL.RSPQTH threshold.	R/W*3
5	TABTF	Normal Transfer Abort Flag*1 0: Normal Transfer Abort does not occur. 1: Normal Transfer Abort occur. To clear, write 0 to this bit after 1 state is read.	R/W*3
8:6	—	These bits are read as 0. The write value should be 0.	R/W
9	TEF	Normal Transfer Error Flag*1 0: Normal Transfer Error does not occur. 1: Normal Transfer Error occurs. To clear, write 0 to this bit after 1 state is read.	R/W*3
19:10	—	These bits are read as 0. The write value should be 0.	R/W
20	RSQFF	Normal Receive Status Queue Full Flag*2 0: The number of Normal Receive Status Queue entries is the NRQTHCTL.RSQTH threshold or less. 1: The number of Normal Receive Status Queue entries is more than the NRQTHCTL.RSQTH threshold.	R/W*3
31:21	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE3, P-TYPE3
Note 1. This bit supports all I3C mode.
Note 2. This bit supports I3C secondary master mode and I3C slave mode.
Note 3. Clearing (to 0) condition : Writing 0 after the 1 state is read.

TDBEF0 bit (Normal Tx Data Buffer Empty Flag 0)

[Setting conditions]

For I^2C Protocol mode: PRTS.PRTMD bit = 1.

The following condition 1 is satisfied and any of the following conditions 2 to 4 are satisfied:

1. The NTSTE.TDBEE0 bit = 1 (enables Normal Tx Data Buffer Empty Interrupt Status logging).
2. When data has been transferred from the Normal Tx Data Buffer to the Shift Register and the Normal Tx Data Buffer becomes empty*1.
3. When the PRSST.TRMD bit is set to 1.
4. When the received slave address matches while the TRMD bit = 1.

For I3C Protocol mode: PRTS.PRTMD bit = 0.

The following conditions 1 and 2 are satisfied:

1. The NTSTE.TDBEE0 bit = 1 (enables Normal Tx Data Buffer Empty Interrupt Status logging).
2. When the number of empties in the Normal Tx Data Buffer is the NTBTHCTL0.TXDBTH[2:0] threshold or more (see NTBTHCTL0 register).

[Clearing conditions]

For I2C Protocol mode: PRTS.PRTMD bit = 1.

- When data is written to NTDTBP0.
- When the TRMD bit in PRSST is set to 0.

For I3C protocol mode: PRTS.PRTMD bit = 0.

- Write 0 to this bit after 1 is read.
- On completion of the last write access to Normal Tx Data by DMAC/DTC.

Note 1. When the BST.NACKDF flag is set to 1 while the BSTE.NACKDE bit = 1, I3C aborts data transmission/reception. If the TDBEF0 flag = 0 (next transmit data has been written), data is transferred to the Shift Register and the Normal Tx Data Buffer register becomes empty at the rising edge of the 9th clock cycle, but the TDBEF0 flag is not set to 1.

RDBFF0 bit (Normal Rx Data Buffer Full Flag 0)

[Setting conditions]

For I2C Protocol mode: PRTS.PRTMD bit = 1.

The following condition 1 is satisfied and any of the following condition 2 or 3 is satisfied:

1. The NTSTE.RDBFE0 bit = 1 (enables Normal Rx Data Buffer Full Interrupt Status logging).
2. When Rx data is transferred from Shift Register to Normal Rx Data Buffer.
   The RDBFF0 flag is set to 1 on the rising edge of the 8th or 9th SCL clock cycle (selected in the ACKTWE bit in SCSTRCTL).
3. When the received slave address matches after a START (or Repeated START) condition is detected with the TRMD bit in PRSST set to 0.

For I3C Protocol mode: PRTS.PRTMD bit = 0.

The following conditions 1 and 2 are satisfied:

1. The NTSTE.RDBFE0 bit = 1 (enables Normal Rx Data Buffer Full Interrupt Status logging).
2. When the number of Normal Rx Data Buffer entries is the NTBTHCTL0.RXDBTH[2:0] threshold or more (see NTBTHCTL0 register).

[Clearing conditions]

For I2C Protocol mode: PRTS.PRTMD bit = 1.

- When data is read from NTDTBP0.

For I3C Protocol mode: PRTS.PRTMD bit = 0.

- Write 0 to this bit after 1 is read.
- On completion of the last read access to Normal Rx Data by DMAC/DTC.

IBIQEFF bit (Normal IBI Queue Empty/Full Flag)

[Setting conditions]

The following 2 conditions are satisfied:

1. The NTSTE.IBIQEFE bit = 1 (enables Normal IBI Queue Empty/Full Interrupt Status logging)
2. For I3C protocol mode (master): PRTS.PRTMD bit = 0, PRSST.CRMS bit = 1.
   - When the number of Normal IBI Queue entries is more than the NQTHCTL.IBIQTH threshold (see NQTHCTL register).

   For I3C protocol mode (slave) : PRTS.PRTMD bit = 0, PRSST.CRMS bit = 0.
   If the NQTHCTL.IBIQTH = 0:
   - When IBI Data Buffer is completely empty.

If the NQTHCTL.IBIQTH is other than 0:

- When the number of IBI Data Buffer empties is the NQTHCTL.IBIQTH threshold or more (see NQTHCTL register).

[Clearing conditions]

For I3C protocol mode (master): PRTS.PRTMD bit = 0, PRSST.CRMS bit = 1.

- Write 0 to this bit after 1 is read.
- On completion of the last read access to IBI Status by DMAC/DTC.

For I3C protocol mode (slave): PRTS.PRTMD bit = 0, PRSST.CRMS bit = 0.

- Write 0 to this bit after 1 is read.
- On completion of the last write access to IBI Status by DMAC/DTC.

CMDQEF bit (Normal Command Queue Empty Flag)

[Setting conditions]

The following 2 conditions are satisfied:

1. The NTSTE.CMDQEE bit = 1 (enables Normal Command Queue Empty Interrupt Status logging).
2. If the NQTHCTL.CMDQTH = 0:
   - When Normal Command Queue is completely empty.

   If the NQTHCTL.CMDQTH is other than 0:
   - When the number of Normal Command Queue empties is the NQTHCTL.CMDQTH threshold or more (see NQTHCTL register).

[Clearing conditions]

- Write 0 to this bit after 1 is read.
- On completion of the last write access to Normal Command by DMAC/DTC.

RSPQFF bit (Normal Response Queue Full Flag)

[Setting conditions]

The following 2 conditions are satisfied:

1. The NTSTE.RSPQFE bit = 1 (enables Normal Response Queue Full Interrupt Status logging).
2. When the number of Normal Response Queue entries is more than the NQTHCTL.RSPQTH threshold (see NQTHCTL register).

[Clearing conditions]

- Write 0 to this bit after 1 is read.
- On completion of the last read access to Normal Receive Status by DMAC/DTC.

TABTF bit (Normal Transfer Abort Flag)

[Setting conditions]

The following 2 conditions are satisfied:

1. The NTSTE.TABTE bit = 1 (enables Normal Transfer Abort Interrupt Status logging).
2. When any transfer is aborted.

[Clearing condition]

- Write 0 to this bit after 1 is read.

TEF bit (Normal Transfer Error Flag)

[Setting conditions]

The following 2 conditions are satisfied:

1. The NTSTE.TEE bit = 1 (enables Normal Transfer Error Interrupt Status logging).
2. When any transfer error occurs on the I3C bus. The Error type for this error is available in the Response or Receive Status structure corresponding to the Transfer command.

[Clearing condition]

- Write 0 to this bit after 1 is read.

RSQFF bit (Normal Receive Status Queue Full Flag)

[Setting conditions]

The following 2 conditions are satisfied:

1. The NTSTE.RSQFE bit = 1 (Normal Receive Status Queue Full Enable).
2. When the number of Normal Receive Status Queue entries is more than the NRQTHCTL.RSQTH threshold (see NRQTHCTL register).

[Clearing conditions]

- Write 0 to this bit after 1 is read.
- On completion of the last read access to Normal Receive Status by DMAC/DTC.

30.2.51 NTSTE : Normal Transfer Status Enable Register

Base address: I3C = 0x4035_F000
I3C_NS = 0x5035_F000

4	RSPQFE	Normal Response Queue Full Enable*1 0: Disables Normal Response queue Full Interrupt Status logging. 1: Enables Normal Response queue Full Interrupt Status logging.	R/W

Bit	Symbol	Function	R/W
5	TABTE	Normal Transfer Abort Enable*1 0: Disables Normal Transfer Abort Interrupt Status logging. 1: Enables Normal Transfer Abort Interrupt Status logging.	R/W
8:6	—	These bits are read as 0. The write value should be 0.	R/W
9	TEE	Normal Transfer Error Enable*1 0: Disables Normal Transfer Error Interrupt Status logging. 1: Enables Normal Transfer Error Interrupt Status logging.	R/W
19:10	—	These bits are read as 0. The write value should be 0.	R/W
20	RSQFE	Normal Receive Status Queue Full Enable*2 0: Disables Normal Receive Status Queue Full Interrupt Status logging. 1: Enables Normal Receive Status Queue Full Interrupt Status logging.	R/W
31:21	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE3, P-TYPE3
Note 1. This bit supports all I3C mode.
Note 2. This bit supports I3C secondary master mode and I3C slave mode.

TDBEE0 bit (Normal Tx Data Buffer Empty Enable 0)

When this bit is 1, the operation of NTST.TDBEF0 is enabled.

For the setting conditions and clearing conditions of the NTST.TDBEF0 flag, see the details of NTST.TDBEF0.

RDBFE0 bit (Normal Rx Data Buffer Full Enable 0)

When this bit is 1, the operation of NTST.RDBFF0 is enabled.

For the setting conditions and clearing conditions of the NTST.RDBFF0 flag, see the details of NTST.RDBFF0.

IBIQEFE bit (Normal IBI Queue Empty/Full Enable)

When this bit is 1, the operation of NTST.IBIQEFF is enabled.

For the setting conditions and clearing conditions of the NTST.IBIQEFF flag, see the details of NTST.IBIQEFF.

CMDQEE bit (Normal Command Queue Empty Enable)

When this bit is 1, the operation of NTST.CMDQEF is enabled.

For the setting conditions and clearing conditions of the NTST.CMDQEF flag, see the details of NTST.CMDQEF.

RSPQFE bit (Normal Response Queue Full Enable)

When this bit is 1, the operation of NTST.RSPQFF is enabled.

For the setting conditions and clearing conditions of the NTST.RSPQFF flag, see the details of NTST.RSPQFF.

TABTE bit (Normal Transfer Abort Enable)

When this bit is 1, the operation of NTST.TABTF is enabled.

For the setting conditions and clearing conditions of the NTST.TABTF flag, see the details of NTST.TABTF.

TEE bit (Normal Transfer Error Enable)

When this bit is 1, the operation of NTST.TEF is enabled.

For the setting conditions and clearing conditions of the NTST.TEF flag, see the details of NTST.TEF.

RSQFE bit (Normal Receive Status Queue Full Enable)

When this bit is 1, the operation of NTST.RSQFF is enabled.

For the setting conditions and clearing conditions of the NTST.RSQFF flag, see the details of NTST.RSQFF.

30.2.52 NTIE : Normal Transfer Interrupt Enable Register

Base address: I3C = 0x4035_F000
I3C_NS = 0x5035_F000

Offset address: 0x1E8

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	RSQFIE	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	TDBEIE0	Normal Tx Data Buffer Empty Interrupt Enable 0 0: Disables Normal Tx Data Buffer Empty Interrupt Signal. 1: Enables Normal Tx Data Buffer Empty Interrupt Signal.	R/W
1	RDBFIE0	Normal Rx Data Buffer Full Interrupt Enable 0 0: Disables Normal Rx Data Buffer Full Interrupt Signal. 1: Enables Normal Rx Data Buffer Full Interrupt Signal.	R/W
2	IBIQEFIE	Normal IBI Queue Empty/Full Interrupt Enable*1 0: Disables Normal IBI Queue Empty/Full Interrupt Signal. 1: Enables Normal IBI Queue Empty/Full Interrupt Signal.	R/W
3	CMDQEIE	Normal Command Queue Empty Interrupt Enable*1 0: Disables Normal Command Queue Empty Interrupt Signal. 1: Enables Normal Command Queue Empty Interrupt Signal.	R/W
4	RSPQFIE	Normal Response Queue Full Interrupt Enable*1 0: Disables Normal Response Queue Full Interrupt Signal. 1: Enables Normal Response Queue Full Interrupt Signal.	R/W
5	TABTIE	Normal Transfer Abort Interrupt Enable*1 0: Disables Normal Transfer Abort Interrupt Signal. 1: Enables Normal Transfer Abort Interrupt Signal.	R/W
8:6	—	These bits are read as 0. The write value should be 0.	R/W
9	TEIE	Normal Transfer Error Interrupt Enable*1 0: Disables Normal Transfer Error Interrupt Signal. 1: Enables Normal Transfer Error Interrupt Signal.	R/W
19:10	—	These bits are read as 0. The write value should be 0.	R/W
20	RSQFIE	Normal Receive Status Queue Full Interrupt Enable*2 0: Disables Normal Receive Status Queue Full Interrupt Signal. 1: Enables Normal Receive Status Queue Full Interrupt Signal.	R/W
31:21	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE3, P-TYPE3
Note 1. This bit supports all I3C mode.
Note 2. This bit supports I3C secondary master mode and I3C slave mode.

The PIO Interrupt Signal Enable register enables signaling of outstanding interrupts received by I3C.

TDBEIE0 bit (Normal Tx Data Buffer Empty Interrupt Enable 0)

This bit is used to enable or disable the Normal Tx Data buffer empty interrupt (I3C_TX) requests when the NTST.TDBEF0 flag is set to 1.

RDBFIE0 bit (Normal Rx Data Buffer Full Interrupt Enable 0)

This bit is used to enable or disable the Normal Rx Data buffer full interrupt (I3C_RX) requests when the NTST.RDBFF0 flag is set to 1.

IBIQEFIE bit (Normal IBI Queue Empty/Full Interrupt Enable)

This bit is used to enable or disable the Normal IBI Queue Empty/Full interrupt (I3C_IBI) requests when the NTST.IBIQEFF flag is set to 1.

CMDQEIE bit (Normal Command Queue Empty Interrupt Enable)

This bit is used to enable or disable the Normal Command queue empty interrupt (I3C_CMD) requests when the NTST.CMDQEF flag is set to 1.

RSPQFIE bit (Normal Response Queue Full Interrupt Enable)

This bit is used to enable or disable the Normal Response queue full interrupt (I3C_RESP) requests when the NTST.RSPQFF flag is set to 1.

TABTIE bit (Normal Transfer Abort Interrupt Enable)

This bit is used to enable or disable the Normal Transfer Abort interrupt (I3C_EEI) requests when the NTST.TABTF flag is set to 1.

TEIE bit (Normal Transfer Error Interrupt Enable)

This bit is used to enable or disable the Normal Transfer Error interrupt (I3C_EEI) requests when the NTST.TEF flag is set to 1.

RSQFIE bit (Normal Receive Status Queue Full Interrupt Enable)

This bit is used to enable or disable the Normal Receive Status queue full interrupt (I3C_RCV) requests when the NTST.RSQFF flag is set to 1.

30.2.53 NTSTFC : Normal Transfer Status Force Register

Base address: I3C = 0x4035_F000
I3C_NS = 0x5035_F000

Offset address: 0x1EC

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	RSQFFC	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	TEFC	—	—	—	TABTFC	RSPQFFC	CMDQEFC	IBIQEFFC	RDBFFC0	TDBEFC0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	TDBEFC0	Normal Tx Data Buffer Empty Force 0 0: Not Force Normal Tx Data Buffer Empty Interrupt for software testing. 1: Force Normal Tx Data Buffer Empty Interrupt for software testing.	W
1	RDBFFC0	Normal Rx Data Buffer Full Force 0 0: Not Force Normal Rx Data Buffer Full Interrupt for software testing. 1: Force Normal Rx Data Buffer Full Interrupt for software testing.	W
2	IBIQEFFC	Normal IBI Queue Empty/Full Force*1 0: Not Force Normal IBI Queue Empty/Full Interrupt for software testing. 1: Force Normal IBI Queue Empty/Full Interrupt for software testing.	W
3	CMDQEFC	Normal Command Queue Empty Force*1 0: Not Force Normal Command Queue Empty Interrupt for software testing. 1: Force Normal Command Queue Empty Interrupt for software testing.	W
4	RSPQFFC	Normal Response Queue Full Force*1 0: Not Force Normal Response Queue Full Interrupt for software testing. 1: Force Normal Response Queue Full Interrupt for software testing.	W

Bit	Symbol	Function	R/W
5	TABTFC	Normal Transfer Abort Force*1 0: Not Force Normal Transfer Abort Interrupt for software testing. 1: Force Normal Transfer Abort Interrupt for software testing.	W
8:6	—	These bits are read as 0.	R
9	TEFC	Normal Transfer Error Force*1 0: Not Force Normal Transfer Error Interrupt for software testing. 1: Force Normal Transfer Error Interrupt for software testing.	W
19:10	—	The write value should be 0.	W
20	RSQFFC	Normal Receive Status Queue Full Force*2 0: Not Force Normal Receive Status Queue Full Interrupt for software testing. 1: Force Normal Receive Status Queue Full Interrupt for software testing.	W
31:21	—	The write value should be 0.	W

Note: S-TYPE3, P-TYPE3
Note 1. This bit supports all I3C mode.
Note 2. This bit supports I3C secondary master mode and I3C slave mode.

The PIO Interrupt Force register is used to force specific interrupt. It can be used for debug purposes.

TDBEFC0 bit (Normal Tx Data Buffer Empty Force 0)

For software testing, when set to 1, forces the corresponding interrupt, subject to TDBEE0 and TDBEIE0 configuration.

RDBFFC0 bit (Normal Rx Data Buffer Full Force 0)

For software testing, when set to 1, forces the corresponding interrupt, subject to RDBFE0 and RDBFIE0 configuration.

IBIQEFFC bit (Normal IBI Queue Empty/Full Force)

For software testing, when set to 1, forces the corresponding interrupt, subject to IBIQEFE and IBIQEFIE configuration.

CMDQEFC bit (Normal Command Queue Empty Force)

For software testing, when set to 1, forces the corresponding interrupt, subject to CMDQEE and CMDQEIE configuration.

RSPQFFC bit (Normal Response Queue Full Force)

For software testing, when set to 1, forces the corresponding interrupt, subject to RSPQFE and RSPQFIE configuration.

TABTFC bit (Normal Transfer Abort Force)

For software testing, forces the corresponding interrupt, subject to TABTE and TABTIE configuration.

TEFC bit (Normal Transfer Error Force)

For software testing, when set to 1, forces the corresponding interrupt, subject to TEE and TEIE configuration.

RSQFFC bit (Normal Receive Status Queue Full Force)

For software testing, when set to 1, forces the corresponding interrupt, subject to RSQFE and RSQFIE configuration.

30.2.54 HTST : High Priority Transfer Status Register

Base address: I3C = 0x4035_F000
I3C_NS = 0x5035_F000

Offset address: 0x200

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	TEF	—	—	—	TABTF	RSPQFF	CMDQEF	—	RDBFF	TDBEF
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	TDBEF	High Priority Tx Data Buffer Empty Flag 0: The number of empties in the High Priority Tx Data Buffer is less than the HTBTHCTL.TXDBTH[2:0] threshold. 1: The number of empties in the High Priority Tx Data Buffer is or more than the HTBTHCTL.TXDBTH[2:0] threshold.	R/W*1
1	RDBFF	High Priority Rx Data Buffer Full Flag 0: The number of entries in the High Priority Rx Data Buffer is less than the HTBTHCTL.RXDBTH[2:0] threshold. 1: The number of entries in the High Priority Rx Data Buffer is or more than the HTBTHCTL.RXDBTH[2:0] threshold.	R/W*1
2	—	This bit is read as 0. The write value should be 0.	R/W
3	CMDQEF	High Priority Command Queue Empty Flag 0: If HQTHCTL.CMDQTH is 0, the number of High Priority Command Queue empties is less than the Command Queue size. If HQTHCTL.CMDQTH is other than 0, the number of High Priority Command Queue empties is less than the HQTHCTL.CMDQTH threshold. 1: If HQTHCTL.CMDQTH is 0, the number of High Priority Command Queue empties is the Command Queue size. If HQTHCTL.CMDQTH is other than 0, the number of High Priority Command Queue empties is or more than the HQTHCTL.CMDQTH threshold .	R/W*1
4	RSPQFF	High Priority Response Queue Full Flag 0: The number of High Priority Response Queue entries is less than the HQTHCTL .RSPQTH threshold. 1: The number of High Priority Response Queue entries is or more than the HQTHCTL .RSPQTH threshold.	R/W*1
5	TABTF	High Priority Transfer Abort Flag 0: High Priority Transfer Abort does not occur. 1: High Priority Transfer Abort occurs. To clear, write 0 to this bit after 1 is read.	R/W*1
8:6	—	These bits are read as 0. The write value should be 0.	R/W
9	TEF	High Priority Transfer Error Flag 0: High Priority Transfer Error does not occur. 1: High Priority Transfer Error occurs. To clear, write 0 to this bit after 1 is read.	R/W*1
31:10	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE3, P-TYPE3
Note: This register supports I3C master mode and I3C secondary master mode.
Note 1. Clearing (to 0) condition : Writing 0 after the 1 state is read.

TDBEF bit (High Priority Tx Data Buffer Empty Flag)

[Setting condition]

The following 2 conditions are satisfied:

1. The HTSTE.TDBEE bit = 1 (Enables High Priority Tx Data Buffer Empty Interrupt Status Logging).
2. When the number of empties in the High Priority Tx Data Buffer is the HTBTHCTL.TXDBTH[2:0] threshold (see register HTBTHCTL) or more.

[Clearing condition]

- Write 0 to this bit after 1 is read.
- On completion of the last write access to “High Priority Tx Data” by DMAC/DTC.

RDBFF bit (High Priority Rx Data Buffer Full Flag)

[Setting condition]

The following 2 conditions are satisfied:

1. The HTSTE.RDBFE bit = 1 (Enables High Priority Rx Data Buffer Full Interrupt Status Logging).
2. When the number of High Priority Rx Data Buffer entries is >= the HTBTHCTL.RXDBTH[2:0] threshold (see register HTBTHCTL).

[Clearing condition]

- Write 0 to this bit after 1 is read.
- On completion of the last read access to “High Priority Rx Data” by DMAC/DTC.

CMDQEF bit (High Priority Command Queue Empty Flag)

[Setting condition]

The following 2 conditions are satisfied:

1. The HTSTE.CMDQEE bit = 1 (Enables High Priority Command Queue Empty Interrupt Status Logging).
2. If the HQTHCTL.CMDQTH = 0:
   - When High Priority Command Queue is completely empty

   If the HQTHCTL.CMDQTH is other than 0:
   - When the number of High Priority Command Queue empties is the HQTHCTL.CMDQTH threshold (see register HQTHCTL) or more.

[Clearing condition]

- Write 0 to this bit after 1 is read.
- On completion of the last write access to “High Priority Command” by DMAC/DTC.

RSPQFF bit (High Priority Response Queue Full Flag)

[Setting condition]

The following 2 conditions are satisfied:

1. The HTSTE.RSPQFE bit = 1 (Enables High Priority Response Queue Full Interrupt Status Logging).
2. When the number of High Priority Response Queue entries is > the HQTHCTL.RSPQTH threshold (see register HQTHCTL).

[Clearing condition]

- Write 0 to this bit after 1 is read.
- On completion of the last read access to “High Priority Receive Status” by DMAC/DTC.

See the description of the RSPQFF bit for the elements used.

TABTF bit (High Priority Transfer Abort Flag)

[Setting condition]

The following 2 conditions are satisfied:

1. The HTSTE.TABTE bit = 1 (Enables High Priority Transfer Abort Interrupt Status Logging).
2. When any transfer is aborted.

[Clearing condition]

- Write 0 to this bit after 1 is read.

TEF bit (High Priority Transfer Error Flag)

[Setting condition]

The following 2 conditions are satisfied:

1. The HTSTE.TEE bit = 1 (Enables High Priority Transfer Error Interrupt Status Logging).
2. When any transfer error occurs on the I3C Bus. The error type for this error is available in the Response structure corresponding to this transfer/command.

[Clearing condition]

- Write 0 to this bit after 1 is read.

30.2.55 HTSTE : High Priority Transfer Status Enable Register

Base address: I3C = 0x4035_F000
I3C_NS = 0x5035_F000

Offset address: 0x204

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	TEE	—	—	—	TABTE	RSPQFE	CMDQEE	—	RDBFE	TDBEE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	TDBEE	High Priority Tx Data Buffer Empty Enable 0: Disables High Priority Tx Data Buffer Empty Interrupt Status logging. 1: Enables High Priority Tx Data Buffer Empty Interrupt Status logging.	R/W
1	RDBFE	High Priority Rx Data Buffer Full Enable 0: Disables High Priority Rx Data Buffer Full Interrupt Status logging. 1: Enables High Priority Rx Data Buffer Full Interrupt Status logging.	R/W
2	—	This bit is read as 0. The write value should be 0.	R/W
3	CMDQEE	High Priority Command Queue Empty Enable 0: Disables High Priority Command Queue Empty Interrupt Status logging. 1: Enables High Priority Command Queue Empty Interrupt Status logging.	R/W
4	RSPQFE	High Priority Response Queue Full Enable 0: Disables High Priority Response Queue Full Interrupt Status logging. 1: Enables High Priority Response Queue Full Interrupt Status logging.	R/W
5	TABTE	High Priority Transfer Abort Enable 0: Disables High Priority Transfer Abort Interrupt Status logging. 1: Enables High Priority Transfer Abort Interrupt Status logging.	R/W
8:6	—	These bits are read as 0. The write value should be 0.	R/W
9	TEE	High Priority Transfer Error Enable 0: Disables High Priority Transfer Error interrupt Stats logging. 1: Enables High Priority Transfer Error interrupt Stats logging.	R/W
31:10	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE3, P-TYPE3

Note: This register supports I3C master mode and I3C secondary master mode.

TDBEE bit (High Priority Tx Data Buffer Empty Enable)

When TDBEE is 1, the operation of HTST.TDBEF is enabled.

For the setting conditions and clearing conditions of the HTST.TDBEF flag, see the details of HTST.TDBEF.

RDBFE bit (High Priority Rx Data Buffer Full Enable)

When RDBFE is 1, the operation of HTST.RDBFF is enabled.

For the setting conditions and clearing conditions of the HTST.RDBFF flag, see the details of HTST.RDBFF.

CMDQEE bit (High Priority Command Queue Empty Enable)

When CMDQEE is 1, the operation of HTST.CMDQEF is enabled.

For the setting conditions and clearing conditions of the HTST.CMDQEF flag, see the details of HTST.CMDQEF.

RSPQFE bit (High Priority Response Queue Full Enable)

When RSPQFE is 1, the operation of HTST.RSPQFF is enabled.

For the setting conditions and clearing conditions of the HTST.RSPQFF flag, see the details of HTST.RSPQFF.

TABTE bit (High Priority Transfer Abort Enable)

When TABTE is 1, the operation of HTST.TABTF is enabled.

For the setting conditions and clearing conditions of the HTST.TABTF flag, see the details of HTST.TABTF.

TEE bit (High Priority Transfer Error Enable)

When TEE is 1, the operation of HTST.TEF is enabled.

For the setting conditions and clearing conditions of the HTST.TEF flag, see the details of HTST.TEF.

30.2.56 HTIE : High Priority Transfer Interrupt Enable Register

Base address: I3C = 0x4035_F000
I3C_NS = 0x5035_F000

Offset address: 0x208

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	TEIE	—	—	—	TABTIE	RSPQFIE	CMDQEIE	—	RDBFIE	TDBEIE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	TDBEIE	High Priority Tx Data Buffer Empty Interrupt Enable 0: Disables High Priority Tx Data Buffer Empty Interrupt Signal. 1: Enables High Priority Tx Data Buffer Empty Interrupt Signal.	R/W
1	RDBFIE	High Priority Rx Data Buffer Full Interrupt Enable 0: Disables High Priority Rx Data Buffer Full Interrupt Signal. 1: Enables High Priority Rx Data Buffer Full Interrupt Signal.	R/W
2	—	This bit is read as 0. The write value should be 0.	R/W
3	CMDQEIE	High Priority Command Queue Empty Interrupt Enable 0: Disables High Priority Command Queue Empty Interrupt Signal. 1: Enables High Priority Command Queue Empty Interrupt Signal.	R/W

Bit	Symbol	Function	R/W
4	RSPQFIE	High Priority Response Queue Full Interrupt Enable 0: Disables High Priority Response Queue Full Interrupt Signal. 1: Enables High Priority Response Queue Full Interrupt Signal.	R/W
5	TABTIE	High Priority Transfer Abort Interrupt Enable 0: Disables High Priority Transfer Abort interrupt Signal. 1: Enables High Priority Transfer Abort interrupt Signal.	R/W
8:6	—	These bits are read as 0. The write value should be 0.	R/W
9	TEIE	High Priority Transfer Error Interrupt Enable 0: Disables High Priority Transfer Error Interrupt Signal. 1: Enables High Priority Transfer Error Interrupt Signal.	R/W
31:10	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE3, P-TYPE3
Note: This register supports I3C master mode and I3C secondary master mode.

The high priority interrupt signal enable register enables signaling of outstanding high priority interrupts received by I3C.

TDBEIE bit (High Priority Tx Data Buffer Empty Interrupt Enable)

TDBEIE is used to enable or disable the High Priority Tx Data buffer empty interrupt (I3C_HTX) requests when the HTST.TDBEF flag is set to 1.

RDBFIE bit (High Priority Rx Data Buffer Full Interrupt Enable)

RDBFIE is used to enable or disable the High Priority Rx Data buffer full interrupt (I3C_HRX) requests when the HTST.RDBFF flag is set to 1.

CMDQEIE bit (High Priority Command Queue Empty Interrupt Enable)

CMDQEIE is used to enable or disable the High Priority Command Queue empty interrupt (I3C_HCMD) requests when the HTST.CMDQEF flag is set to 1.

RSPQFIE bit (High Priority Response Queue Full Interrupt Enable)

RSPQFIE is used to enable or disable the High Priority Response Queue full interrupt (I3C_HRESP) requests when the HTST.RSPQFF flag is set to 1.

TABTIE bit (High Priority Transfer Abort Interrupt Enable)

TABTIE is used to enable or disable the High Priority Transfer Abort interrupt (I3C_EEI) requests when the HTST.TABTF flag is set to 1.

TEIE bit (High Priority Transfer Error Interrupt Enable)

TEIE is used to enable or disable the High Priority Transfer Error interrupt (I3C_EEI) requests when the HTST.TEF flag is set to 1.

30.2.57 HTSTFC : High Priority Transfer Status Force Register

Base address: I3C = 0x4035_F000
I3C_NS = 0x5035_F000

Offset address: 0x20C

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	TEFC	—	—	—	TABTFC	RSPQFFC	CMDQEFC	—	RDBFFC	TDBEFC
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	TDBEFC	High Priority Tx Data Buffer Empty Force 0: Not Force High Priority Tx Data Buffer Empty Interrupt for software testing. 1: Force High Priority Tx Data Buffer Empty Interrupt for software testing.	W
1	RDBFFC	High Priority Rx Data Buffer Full Force 0: Not Force High Priority Rx Data Buffer Full Interrupt for software testing. 1: Force High Priority Rx Data Buffer Full Interrupt for software testing.	W
2	—	This bit is read as 0.	R
3	CMDQEFC	High Priority Command Queue Empty Force 0: Not Force High Priority Command Queue Empty Interrupt for software testing. 1: Force High Priority Command Queue Empty Interrupt for software testing.	W
4	RSPQFFC	High Priority Response Queue Full Force 0: Not Force High Priority Response Queue Full Interrupt for software testing. 1: Force High Priority Response Queue Full Interrupt for software testing.	W
5	TABTFC	High Priority Transfer Abort Force 0: Not Force High Priority Transfer Abort Interrupt for software testing. 1: Force High Priority Transfer Abort Interrupt for software testing.	W
8:6	—	These bits are read as 0.	R
9	TEFC	High Priority Transfer Error Force 0: Not Force High Priority Transfer Error Interrupt for software testing. 1: Force High Priority Transfer Error Interrupt for software testing.	W
31:10	—	These bits are read as 0.	R

Note: S-TYPE3, P-TYPE3
Note: This register supports I3C master mode and I3C secondary master mode.

30.2.58 BCST : Bus Condition Status Register

Base address: I3C = 0x4035_F000
I3C_NS = 0x5035_F000

Offset address: 0x210

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	BIDLF	BAVLF	BFREF
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	BFREF	Bus Free Detection Flag 0: Have not Detected Bus Free 1: Have Detected Bus Free	R
1	BAVLF	Bus Available Detection Flag*1 0: Have not Detected Bus Available 1: Have Detected Bus Available	R
2	BIDLF	Bus Idle Detection Flag*1 0: Have not Detected Bus Idle 1: Have Detected Bus Idle	R
31:3	—	These bits are read as 0.	R

Note: S-TYPE3, P-TYPE3
Note 1. This bit supports all I3C mode.

BFREF bit (Bus Free Detection Flag)

The Bus Free Condition is a period occurring after a STOP and before a START, and with the following duration:

- For Pure Bus: A duration of at least tCAS (see section 48, Electrical Characteristics)
- For Mixed Bus (at least one Legacy I^2C is present on the I3C Bus): A duration of at least tBUF (see section 48, Electrical Characteristics)

[Setting conditions]

- After a STOP condition is detected, when the number of cycles (I3Cφ) that are set by BFRECDT.FRECYC[8:0] has passed in the state of SCL = SDA = 1.
- After setting BCTL.BUSE to 1, when the number of cycles (I3Cφ) that are set by BFRECDT.FRECYC[8:0] has passed in the state of SCL = SDA = 1.

[Clearing conditions]

- When SCL and SDA are other than high.
- When the BCTL.BUSE bit is set to 0.

BAVLF bit (Bus Available Detection Flag)

The Bus Available Condition is a period during which the Bus Free Condition is sustained continuously for a duration of at least tAVAL (see section 48, Electrical Characteristics). A Slave can only issue a START Request (for an In-Band Interrupt, or for a Master Handoff Request) after a Bus Available Condition.

[Setting conditions]

- After a STOP condition is detected, when the number of cycles (I3Cφ) that are set by BAVLCDT.AVLCYC[8:0] has passed in the state of SCL = SDA = 1.
- After setting BCTL.BUSE to 1, when the number of cycles (I3Cφ) that are set by BAVLCDT.AVLCYC[8:0] has passed in the state of SCL = SDA = 1.

[Clearing conditions]

- When SCL and SDA are other than high.
- When the BCTL.BUSE bit is set to 0.

BIDLF bit (Bus Idle Detection Flag)

The Bus Idle Condition is a period during which the Bus Available Condition is sustained continuously for a duration of at least tIDLE (see section 48, Electrical Characteristics).

[Setting conditions]

- After a STOP condition is detected, when the number of cycles (I3Cφ) that are set by BIDLCDT.IDLCYC[17:0] has passed in the state of SCL = SDA = 1.
- After setting BCTL.BUSE to 1, when the number of cycles (I3Cφ) that are set by BIDLCDT.IDLCYC[17:0] has passed in the state of SCL = SDA = 1.

[Clearing conditions]

- When SCL and SDA are other than high.
- When the BCTL.BUSE bit is set to 0.

30.2.59 SVST : Slave Status Register

Base address: I3C = 0x4035_F000
I3C_NS = 0x5035_F000

Offset address: 0x214

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	SVAF[2:0]		
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	HOAF	—	—	—	—	—	—	—	—	DVIDF	HSMCF	—	—	—	—	GCAF
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	GCAF	General Call Address Detection Flag 0: General call address does not detect. 1: General call address detects.	R/W*1
4:1	—	These bits are read as 0. The write value should be 0.	R/W
5	HSMCF	Hs-mode Master Code Detection Flag 0: Hs-mode Master Code does not detect. 1: Hs-mode Master Code detects.	R/W*1
6	DVIDF	Device-ID Address Detection Flag 0: Device-ID command does not detect. 1: Device-ID command detects. ● This bit set to 1 when the first frame received immediately after a START condition is detected matches a value of (device ID (1111 100) + 0[W]).	R/W*1
14:7	—	These bits are read as 0. The write value should be 0.	R/W
15	HOAF	Host Address Detection Flag 0: Host address does not detect. 1: Host address detects. ● This bit set to 1 when the received slave address matches the host address (0001 000).	R/W*1
18:16	SVAF[2:0]	Slave Address Detection Flag n (n = 0 to 2) 0: Slave n does not detect 1: Slave n detect	R/W*1
31:19	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE3, P-TYPE3
Note: This register supports I2C mode.
Note 1. Clearing (to 0) condition : Writing 0 after the 1 state is read.

GCAF flag (General Call Address Detection Flag)

I2C Normal Wake-Up Mode1 / 2 sets GCAF to 1 when switching from asynchronous operation to synchronous unit.

[Setting conditions]

- This flag is set to 1 at the rising edge of the ninth SCL clock cycle in the first byte when all of the followings are satisfied.
  1. The SVCTL.GCAE bit = 1 (General call address detection is enabled).
  2. When the received slave address matches the general call address (0000 000 + 0 (write)).

[Clearing conditions]

- When 0 is written to the GCAF flag after reading GCAF flag to be 1.
- When a STOP condition is detected.
- When a Repeated START condition is detected.

HSMCF flag (Hs-mode Master Code Detection Flag)

The I2C Normal Wake-Up Mode 1/2 sets 1 to HSMCF when switching from asynchronous operation to synchronous unit.

[Setting conditions]

- This flag is set to 1 at the rising edge of the ninth SCL clock cycle in the first byte when all of the followings are satisfied.
  1. The SVCTL.HSMCE bit = 1 (Hs-mode master code detection is enabled).
  2. When the first byte received immediately after a START condition is detected matches a value of Hs-mode master code (0000 1XXX) + 1 (NACK).

[Clearing conditions]

- When 0 is written to the HSMCF flag after reading HSMCF flag to be 1.
- When a STOP condition is detected.

DVIDF flag (Device-ID Address Detection Flag)

[Setting conditions]

- This flag is set to 1 at the rising edge of the ninth SCL clock cycle in the first byte when all of the followings are satisfied.
  1. The SVCTL.DVIDE bit = 1 (Device-ID address detection is enabled).
  2. When the first byte received immediately after a START condition or Repeated START condition is detected matches a value of Device ID (1111 100) + 0 (write).

[Clearing conditions]

- When 0 is written to the DVIDF flag after reading DVIDF flag to be 1.
- When a STOP condition is detected.
- This flag is set to 0 at the rising edge of the ninth SCL clock cycle in the first byte when the following 1 and 2 or 1 and 3 are satisfied.
  1. The SVCTL.DVIDE bit = 1 (Device-ID address detection is enabled).
  2. When the first byte received immediately after a START condition or Repeated START condition is detected does not match a value of Device ID (1111 100).
  3. When the first byte received immediately after a START condition or Repeated START condition is detected matches a value of (device ID (1111 100) + 0 [W]) and the second byte does not match any of slave addresses 0 to 2.

HOAF flag (Host Address Detection Flag)

I2C Normal Wake-Up Mode1 / 2 sets HOAF to 1 at the time of switching from asynchronous operation to synchronous unit.

[Setting conditions]

- This flag is set to 1 at the rising edge of the ninth SCL clock cycle in the first byte when all of the followings are satisfied.
  1. The SVCTL.HOAE bit = 1 (Host address detection is enabled).
  2. When the received slave address matches the host address (0001 000).

[Clearing conditions]

- When 0 is written to the HOAF flag after reading HOAF flag to be 1.
- When a STOP condition is detected.
- When a Repeated START condition is detected.

SVAF[2:0] flags (Slave Address Detection Flag n (n = 0 to 2))

I2C Normal Wake-Up Mode1 / 2 sets 1 to SVAF[2:0] when switching from asynchronous operation to synchronous unit.

[Setting conditions]

For 7-bit address format: SVDVADn.SADLG bit = 0.

- This flag is set to 1 at the rising edge of the ninth SCL clock cycle in the first byte when all of the followings are satisfied.
  1. The SVCTL.SVAEn bit = 1 (Slave n enabled).
  2. When the received slave address matches the SVDVADn.SVAD[6:0] bits value.

For 10-bit address format: SVDVADn.SADLG bit = 1.

- This flag is set to 1 at the rising edge of the ninth SCL clock cycle in the second byte when all of the followings are satisfied.
  1. The SVCTL.SVAEn bit = 1 (Slave n enabled).
  2. When the received slave address matches a value of 11110 + SVDVADn.SVAD[9:8] bits and the following address matches the SVDVADn.SVAD[7:0] value.

[Clearing conditions]

- When 0 is written to the SVAF[2:0] flag after reading SVAF[2:0] flag to be 1.
- When a STOP condition is detected.

For 7-bit address format: SVDVADn.SADLG bit = 0.

- This flag is set to 0 at the rising edge of the ninth SCL clock cycle in the first byte when all of the followings are satisfied.
  1. The SVCTL.SVAEn bit = 1 (Slave n enabled).
  2. When the received slave address does not match SVDVADn.SVAD[6:0] bits value.

For 10-bit address format: SVDVADn.SADLG bit = 1.

- This flag is set to 0 at the rising edge of the ninth SCL clock cycle in the first byte when all of the followings are satisfied.
  1. The SVCTL.SVAEn bit = 1 (Slave n enabled).
  2. When the received slave address does not match a value of 11110 + SVDVADn.SVAD[9:8] bits.
- This flag is set to 0 at the rising edge of the ninth SCL clock cycle in the second byte when all of the followings are satisfied.
  1. The SVCTL.SVAEn bit = 1 (Slave n enabled).
  2. When the received slave address matches a value of 11110 + SVDVADn.SVAD[9:8] bits and the following address does not match the SVDVADn.SVAD[7:0] value.

30.2.60 WUST : Wake Up Unit Operating Status Register

Base address: I3C = 0x4035_F000
I3C_NS = 0x5035_F000

Offset address: 0x218

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	WUASYNF
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	WUASYNF	Wake-up function asynchronous operation status flag 0: I3C synchronous circuit enable condition. 1: I3C asynchronous circuit enable condition.	R
31:1	—	These bits are read as 0.	R

Note: S-TYPE3, P-TYPE3

WUASYNF flag (Wake-up function asynchronous operation status flag)

This bit shows whether I3C is in the TCLK asynchronous operation (WUCTL.WUFE bit = 1).

[Setting condition]

- All of the followings are satisfied.
  1. The WUCTL.WUFE bit = 1 (Wake-up function is enabled)
  2. When the BCST.BFREF flag = 1 after 0 is written to the WUCTL.WUFSYNE bit

[Clearing condition : I^2C slave]

- The WUCTL.WUFE bit = 0 (Wake-up function is disabled)
- All of the followings are satisfied.
  1. The WUCTL.WUFE bit = 1 (Wake-up function is enabled)
  2. Wake-up event is detected
  3. When 1 is written to the WUCTL.WUFSYNE bit during WUASYNF flag = 1

[Clearing condition : I3C slave]

- The WUCTL.WUFE bit = 0 (Wake-up function is disabled)
- All of the followings are satisfied.
  1. The WUCTL.WUFE bit = 1 (Wake-up function is enabled)
  2. Wake-up event is detected
  3. When 1 is written to the WUCTL.WUFSYNE bit during WUASYNF flag = 1
  4. When a STOP condition is detected.

[Clearing condition : I^2C/I3C slave]

- All of the followings are satisfied.
  1. The WUCTL.WUFE bit = 1 (Wake-up function is enabled)
  2. Wake-Up event is not detected
  3. The WUASYNF flag = 1
  4. The WUCTL.WUFSYNE bit = 1
  5. When a STOP condition is detected.

[Clearing condition : I3C master]

- The WUCTL.WUFE bit = 0 (Wake-up function is disabled)
- All of the followings are satisfied.
  1. The WUCTL.WUFE bit = 1 (Wake-up function is enabled)
  2. Wake-up event is detected.
  3. The WUASYNF flag = 1
  4. The WUCTL.WUFSYNE bit = 1

30.2.61 MRCCPT : MsyncCNT Counter Capture Register

Base address: I3C = 0x4035_F000
I3C_NS = 0x5035_F000

Offset address: 0x21C

Bit position:	31																												0
Bit field:																													
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	n/a	MSyncCNT Counter Capture Used in Async Mode 1, not used in Async Mode0.	R

Note: S-TYPE3, P-TYPE3
Note: This register supports I3C master mode and I3C secondary master mode.

MRCCPT[31:0] Bits

- Async Mode 1 (Asynchronous Advanced Mode)
  When ATCCNTE.ATCE is enabled, it starts counting. It captures as MSyncCNT for each aME (SDA falling edge of START condition), and store it in the capture register.

30.2.62 DATBASm : Device Address Table Basic Register m (m = 0 to 7)

Base address: I3C = 0x4035_F000
I3C_NS = 0x5035_F000

Offset address: 0x224 + 0x08 × m

Bit position:	31	30	29	28	27	26	25	24	23							16
Bit field:	DVTYP	DVNACK[1:0]		—	—	—	—	—	DVDYAD[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6						0
Bit field:	DVIBITS	DVMRRJ	DVSIRRJ	DVIBIPL	—	—	—	—	—	DVSTAD[6:0]						
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
6:0	DVSTAD[6:0]	Device Static Address I3C/I^2C Static Address	R/W
11:7	—	These bits are read as 0. The write value should be 0.	R/W
12	DVIBIPL	Device IBI Payload 0: IBIs from this Device do not carry a Data Payload. 1: IBIs from this Device do carry a Data Payload.	R/W
13	DVSIRRJ	Device In-Band Slave Interrupt Request Reject 0: This Device shall ACK the SIR. 1: This Device shall NACK the SIR and send the auto-disable CCC.	R/W
14	DVMRRJ	Device In-Band Master Request Reject 0: This Device shall ACK Master Requests. 1: This Device shall NACK Master Requests and send the auto-disable command.	R/W
15	DVIBITS	Device IBI Time-stamp 0: The Master shall not time-stamp IBIs from this Device with Master Time-stamps. 1: The Master shall time-stamp IBIs for this Device with Master Time-stamps.	R/W
23:16	DVDYAD[7:0]	Device I3C Dynamic Address Bit 23 is the parity bit, per the I3C specification, computed and updated by the software driver.	R/W

Bit	Symbol	Function	R/W
28:24	—	These bits are read as 0. The write value should be 0.	R/W
30:29	DVNACK[1:0]	Device NACK Retry Count Device-specific retry count	R/W
31	DVTYP	Device Type 0: I3C Device 1: I^2C Device	R/W

Note: S-TYPE3, P-TYPE3
Note: This register supports I3C master mode and I3C secondary master mode.

DVIBIPL bit (Device IBI Payload)

Indicates whether IBIs from this Device have a Data Payload. This field reflects the IBI Payload bit in the Device's Bus Characteristics Register (BCR).

During IBI handling for this Device, the Master shall use this field to determine whether or not to drive reception of the IBI Data Payload. Data continuation is indicated by the T-Bit.

DVSIRRJ bit (Device In-Band Slave Interrupt Request Reject)

Controls whether this Device, when operating in the Master role, will accept vs. reject Slave Interrupt Requests from other Devices.

DVMRRJ bit (Device In-Band Master Request Reject)

Controls whether this Device, when operating in the Master role, will accept vs. reject Master requests from other Devices.

This bit is only valid if I3C declares Non-Current Master Capability.

DVIBITS bit (Device IBI Time-stamp)

Enables or disables IBI time-stamping for a specific Device.

Note: The IBI Status Descriptor for each IBI event indicates whether or not the individual IBI event was actually time-stamped. Set to 0 except for Async mode 0 and Async mode 1 of timing control.

DVNACK[1:0] bits (Device NACK Retry Count)

These bits set the number of retries when a NACK response is received from the slave for the transaction set in the Command Descriptor.

Note: When ENTDAA is executed by Address Assign Command, the setting of this bit is ignored and the transaction ends when NACK is received once.

Note: I3C will retry according to the setting of DVNACK[1:0] bit, even if it receives a NACK for the broadcast address.

Note: If DVNACK[1:0] bits are 0x0, I3C will not retry even for Direct CCCs.

30.2.63 EXDATBAS : Extended Device Address Table Basic Register

Base address: I3C = 0x4035_F000
I3C_NS = 0x5035_F000

Offset address: 0x2A0

Bit position:	31	30	29	28	27	26	25	24	23							16
Bit field:	EDTYP	EDNACK[1:0]		—	—	—	—	—	EDDYAD[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6						0
Bit field:	—	—	—	—	—	—	—	—	—	EDSTAD[6:0]						
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
6:0	EDSTAD[6:0]	Extended Device Static Address I3C/I2C static address	R/W
15:7	—	These bits are read as 0. The write value should be 0.	R/W
23:16	EDDYAD[7:0]	Extended Device I3C Dynamic Address Bit 23 is the parity bit, per the I3C specification, computed and updated by the software driver.	R/W
28:24	—	These bits are read as 0. The write value should be 0.	R/W
30:29	EDNACK[1:0]	Extended Device NACK Retry Count Device-specific retry count	R/W
31	EDTYP	Extended Device Type 0: I3C Device 1: I2C Device	R/W

Note: S-TYPE3, P-TYPE3
Note: This register supports I3C master mode and I3C secondary master mode.

30.2.64 SDATBASn : Slave Device Address Table Basic Register n (n = 0 to 2)

Base address: I3C = 0x4035_F000
I3C_NS = 0x5035_F000

Offset address: 0x2B0 + 0x04 × n

Bit position:	31	30	29	28	27	26	25	24	23	22						16
Bit field:	—	—	—	—	—	—	—	—	—	SDDYAD[6:0]						
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9									0
Bit field:	—	—	—	SDIBIPL	—	SDADLS	SDSTAD[9:0]									
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
9:0	SDSTAD[9:0]	Slave Device Static Address*2 I3C Static Address	R/W
10	SDADLS	Slave Device Address Length Selection*3 0: Slave device address length 7 bits selected. 1: Slave device address length 10 bits selected. (I2C device only)	R/W
11	—	This bit is read as 0. The write value should be 0.	R/W
12	SDIBIPL*1	Slave Device IBI Payload*4 This bit is the mirror bit of the SVDCT.TBCR2. 0: IBIs from this device do not carry a data payload. 1: IBIs from this device carry a data payload.	R/W
15:13	—	These bits are read as 0. The write value should be 0.	R/W
22:16	SDDYAD[6:0]*1	Slave Device I3C Dynamic Address*5	R/W
31:23	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE3, P-TYPE3
Note: SW write to the SDATBAS register of the main master is prohibited.
Note 1. This bit is valid only in SDATBAS0 register.
Note 2. These bits support I2C, I3C secondary master, and I3C slave mode.
Note 3. This bit supports I2C mode.
Note 4. This bit supports I3C secondary master mode and I3C slave mode.
Note 5. These bits support I3C secondary master mode and I3C slave mode.

SDSTAD[9:0] bits (Slave Device Static Address)

When the 7-bit address format is selected (SDADLS bit is 0), the lower 7 bits of SDSTAD[9:0] function as the 7-bit address.

When the 10-bit address format is selected (SDADLS bit is 1), the SDSTAD[9:0] function as the 10-bit address. While the SVCTL.SVAEn bit is 0, the setting of this bit is ignored.

SDIBIPL bit (Slave Device IBI Payload)

Indicates whether IBIs from this Device have a Data Payload. This field reflects the IBI Payload bit in the Device's Bus Characteristics Register (BCR).

During IBI handling for this Device, the Master shall use this field to determine whether or not to drive reception of the IBI Data Payload. Data continuation is indicated by the T-Bit.

SDDYAD[6:0] bits (Slave Device I3C Dynamic Address)

[Update conditions]

- When writing Dynamic Address value.
- When Slave Address value is its own Static Address in receiving SETDASA CCC (Direct), these bits are updated to Dynamic Address value.*1
- When Dynamic Address Assignment procedure that starts by receiving ENTDAA CCC (Broadcast) is established.*1
- When receiving RSTDAA CCC (Broadcast), all bits are cleared to 0. *1
- When Slave Address value is its own Dynamic Address in receiving RSTDAA CCC (Direct), all bits are cleared to 0. *1
- When Slave Address value is its own Dynamic Address in receiving SETNEWDA CCC (Direct), these bits are updated to the Dynamic Address value. *1
- When receiving SETAASA CCC (Broadcast), these bits are updated to the value of SDSTAD[6:0] bits*2.

Note 1. See the MIPI I3C Specification v1.0.
Note 2. See the MIPI I3C Basic Specification v1.0.

30.2.65 MSDCTm : Master Device Characteristic Table Register m (m = 0 to 7)

Base address: I3C = 0x4035_F000
I3C_NS = 0x5035_F000

Offset address: 0x2D0 + 0x04 × m

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	RBCR76[1:0]		RBCR5	RBCR4	RBCR3	RBCR2	RBCR1	RBCR0	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	—	These bits are read as 0. The write value should be 0.	R/W
8	RBCR0	Max Data Speed Limitation*1 0: No Limitation 1: Limitation	R/W
9	RBCR1	IBI Request Capable 0: Not Capable 1: Capable	R/W

Bit	Symbol	Function	R/W
10	RBCR2	IBI Payload 0: No data byte follows the accepted IBI. 1: Mandatory one or more data bytes follow the accepted IBI. Data byte continuation is indicated by T-Bit.	R/W
11	RBCR3	Offline Capable*2 0: Device will always respond to I3C bus commands. 1: Device will not always respond to I3C bus commands.	R/W
12	RBCR4	Bridge Identifier*3 0: Not a Bridge Device 1: A Bridge Device	R/W
13	RBCR5	SDR Only / SDR and HDR Capable 0: SDR only 1: HDR Capable	R/W
15:14	RBCR76[1:0]	Device Role 0 0: I3C Slave 0 1: I3C Master*4 Others: Setting prohibited	R/W
31:16	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE3, P-TYPE3
Note: This register supports I3C master mode and I3C secondary master mode.
Note 1. Master shall use the GETMXDS CCC to interrogate the Slave for specific limitation.
Note 2. Offline Capable Devices retain the Dynamic Address.
Note 3. Bridge Devices are required to comply with this MIPI Specification for I3C.
Note 4. For an I3C Device acting as I3C Main Master, the BCR Device Role bits will contain the value 01.

The DCT table captures the Device characteristics (PID, BCR, DCR) and assigned Dynamic Address of each Device on the I3C Bus that participates in the Dynamic Address Allocation (ENTDAA) procedure.

RBCRn bits (Received Bus Characteristic Register)

Each I3C Device that is connected to the I3C Bus shall have an associated read-only Bus Characteristics Register (BCR). This read-only register describes the I3C compliant Device's role and capabilities for use in Dynamic Address assignment and Common Command Codes.

Note: When RBCR2 is 0 and when ACK response to Slave Interrupt Request from I3C Slave by DATBASm.DVSIRRJ = 0 (m = 0 to 7), STOP Condition is issued after ACK response. When RBCR2 is 1 and when ACK response to Slave Interrupt Request from I3C Slave by DATBASm.DVSIRRJ = 0 (m = 0 to 7), IBI Payload is received after ACK response. STOP Condition is issued after end of IBI Payload.

[Update condition]

- When receiving of Bus Characteristics Register (BCR) from Device in the Dynamic Address Assignment procedure starting by receiving ENTDAA CCC (Broadcast).*1

Note 1. See the MIPI I3C Specification v1.0

30.2.66 SVDCT : Slave Device Characteristic Table Register

Base address: I3C = 0x4035_F000
I3C_NS = 0x5035_F000

Offset address: 0x320

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	0
Bit field:	TBCR76[1:0]		TBCR5	TBCR4	TBCR3	TBCR2	TBCR1	TBCR0	TDCR[7:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	TDCR[7:0]	Transfer Device Characteristic Register 255 available codes for describing the type of sensor, or device. Examples: Accelerometer, gyroscope, composite devices Default value is 0x0: Generic Device	R/W
8	TBCR0	Max Data Speed Limitation*1 0: No Limitation 1: Limitation	R/W
9	TBCR1	IBI Request Capable 0: Not Capable 1: Capable	R/W
10	TBCR2	IBI Payload 0: No data byte follows the accepted IBI. 1: Mandatory one or more data bytes follow the accepted IBI. Data byte continuation is indicated by T-Bit.	R/W
11	TBCR3	Offline Capable*2 0: Device will always respond to I3C bus commands. 1: Device will not always respond to I3C bus commands.	R/W
12	TBCR4	Bridge Identifier*3 0: Not a Bridge Device 1: A Bridge Device	R/W
13	TBCR5	SDR Only / SDR and HDR Capable 0: SDR only 1: HDR capable	R/W
15:14	TBCR76[1:0]	Device Role 0 0: I3C Slave 0 1: I3C Master*4 Others: Setting prohibited	R/W
31:16	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE3, P-TYPE3
Note: This register supports I3C secondary master mode and I3C slave mode.
Note 1. Master shall use the GETMXDS CCC to interrogate the Slave for specific limitation.
Note 2. Offline Capable Devices retain the Dynamic Address.
Note 3. Bridge Devices are required to comply with this MIPI Specification for I3C.
Note 4. For an I3C Device acting as I3C Main Master, the BCR Device Role bits will contain the value 01b.

The DCT table captures the Device characteristics (PID, BCR, DCR) and assigned Dynamic Address of each device on the I3C bus that participates in the Dynamic Address Allocation (ENTDAA) procedure.

TDCR[7:0] bits (Transfer Device Characteristic Register)

Each I3C device that is connected to the I3C bus has an associated Device Characteristics Register (DCR). This register describes the I3C compliant device type such as accelerometer and gyroscope, for use in Dynamic Address assignment and Common Command Codes.

TBCRn bits (Transfer Bus Characteristic Register)

Each I3C device that is connected to the I3C bus has an associated Bus Characteristics Register (BCR). This register describes the role and capabilities of the I3C compliant device for use in Dynamic Address assignment and Common Command Codes.

When I3C Slave issues IBI by Command Descriptor, the condition of TBCRn is described as follows:

[Slave Interrupt Request : No IBI Payload follow the accepted IBI]

- TBCR1 = 1
- TBCR2 = 0

Note: Set DATA_LENGTH[15:0] of Command Descriptor to 0.

[Slave Interrupt Request : IBI Payload follow the accepted IBI]

- TBCR1 = 1
- TBCR2 = 1

Note: Set DATA_LENGTH[15:0] of Command Descriptor to any value.

[Mastership Request]

- TBCR1 = 1
- TBCR76[1:0] = 01b

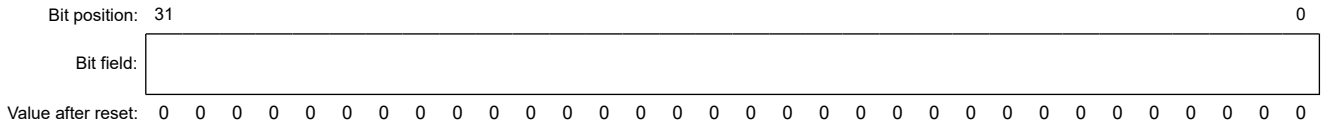
When I3C Slave receives CCC from I3C Master, it performs the following operations according to the setting of TBCRn:

- When TBCR2 = 1, CMRLG.IBIPSZ[7:0] is sent as the 3rd byte data to GETMRL CCC from I3C Master
- When TBCR0 = 0, NACK responses to GETMXDS CCC from I3C Master
- When TBCR0 = 1, ACK responses to GETMXDS CCC from I3C Master and sends data from CMDSPW, CMDSPR, and CMDSPT registers

30.2.67 SDCTPIDL : Slave Device Characteristic Table Provisional ID Low Register

Base address: I3C = 0x4035_F000
I3C_NS = 0x5035_F000

Offset address: 0x324



Bit	Symbol	Function	R/W
31:0	n/a	Transfer Device Provisional ID Low Bits 31 to 16 are read as 0. Bits 15 to 0 are bits [15:0] of device's I3C PID.	R/W

Note: S-TYPE3, P-TYPE3
Note: This register supports I3C secondary master mode and I3C slave mode.

30.2.68 SDCTPIDH : Slave Device Characteristic Table Provisional ID High Register

Base address: I3C = 0x4035_F000
I3C_NS = 0x5035_F000

Offset address: 0x328

Bit position:	31																												0
Bit field:																													
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	n/a	Transfer Device Provisional ID High Bits [47:16] of device's I3C PID.	R/W

Note: S-TYPE3, P-TYPE3
Note: This register supports I3C secondary master mode and I3C slave mode.

30.2.69 SVDVADn : Slave Device Address Register n (n = 0 to 2)

Base address: I3C = 0x4035_F000
I3C_NS = 0x5035_F000

Offset address: 0x330 + 0x04 × n

Bit position:	31	30	29	28	27	26	25									16
Bit field:	SDYADV	SSTADV	—	—	SADLG	—	SVAD[9:0]									
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	—	These bits are read as 0.	R
25:16	SVAD[9:0]	Slave Address*1 A slave address is set. When rewriting SVAD, change to SVAE = 0 and rewrite.	R
26	—	This bit is read as 0.	R
27	SADLG	Slave Address Length*2 0: The 7-bit address format is selected. 1: The 10-bit address format is selected.	R
29:28	—	These bits are read as 0.	R
30	SSTADV	Slave Static Address Valid*1 0: Slave address is disabled. 1: Slave address is enabled.	R
31	SDYADV*4	Slave Dynamic Address Valid*3 0: Dynamic Address is disabled. 1: Dynamic Address is enabled.	R

Note: S-TYPE3, P-TYPE3
Note 1. These bits support I^2C, I3C secondary master, and I3C slave mode.
Note 2. This bit supports I^2C mode.
Note 3. This bit supports I3C secondary master mode and I3C slave mode.
Note 4. This bit is valid only in SVDVAD0 register.

SVAD[9:0] bits (Slave Address)

The SVAD[9:0] bits indicate a valid slave address.

[The SVDVAD0.SDYADV bit = 1]

Note: This condition is only for SVDVAD0.SVAD[9:0].

- The SVAD[9:7] bits = 0
- The SVAD[6:0] bits = the SDATBAS0.SDDYAD[6:0] bits

[The SVDVADn.SSTADV bit = 1 and the SVDVADn.SADLG bit = 0]

- The SVAD[9:7] bits = 0
- The SVAD[6:0] bits = the SDATBASn.SDSTAD[6:0] bits

[The SVDVADn.SSTADV bit = 1 and the SVDVADn.SADLG bit = 1]

- The SVAD[9:0] bits = the SDATBASn .SDSTAD[9:0] bits

SADLG bit (Slave Address Length)

[Setting conditions]

- All of the followings are satisfied:

1. The PRTS.PRTMD bit = 1 (I^2C Protocol mode)
2. The SVCTL.SVAEn bit = 1 (Slave n is enabled)
3. The SDATBASn .SDADLS bit = 1 (The address length is 10 bits)

[Clearing condition]

- [Setting condition] is not satisfied.

SSTADV bit (Slave Static Address Valid)

[Setting conditions]

- All of the followings are satisfied:

1. The SVCTL.SVAEn bit = 1 (Slave n is enabled)
2. The SVDVAD0.SDYADV bit = 0 (Dynamic Address is disabled)

   Note: This condition is only for SVDVAD0.SSTADV.
3. If the SVDVADn.SADLG bit = 0, the SDATBASn .SDSTAD[6:0] bits are not all 0
   If the SVDVADn.SADLG bit = 1, the SDATBASn .SDSTAD[9:0] bits are not all 0

[Clearing condition]

- [Setting condition] is not satisfied.

SDYADV bit (Slave Dynamic Address Valid)

[Setting conditions]

- All of the followings are satisfied:

1. The PRTS.PRTMD bit = 0 (I3C Protocol mode)
2. The SVCTL.SVAEn bit = 1 (Slave n is enabled)
3. The SDATBAS0.SDDYAD[6:0] bits are not all 0

Note: This condition is only for SVDVAD0.SDYADV.

[Clearing condition]

- [Setting condition] is not satisfied.

30.2.70 CSECMD : CCC Slave Events Command Register

Base address: I3C = 0x4035_F000
I3C_NS = 0x5035_F000

Offset address: 0x350

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	MSRQE	SVIRQE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	SVIRQE	Slave Interrupt Requests Enable 0: DISABLED: Slave-initiated Interrupts is Disabled by the Master to control. 1: ENABLED: Slave-initiated Interrupts is Enabled by the Master to control.	R/W
1	MSRQE	Mastership Requests Enable 0: DISABLED: Mastership requests from Secondary Masters is Disabled by the Current Master to control. 1: ENABLED: Mastership requests from Secondary Masters is Enabled by the Current Master to control.	R/W
31:2	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE3, P-TYPE3
Note: This register supports I3C secondary master mode and I3C slave mode.

SVIRQE bit (Slave Interrupt Requests Enable)

This bit allows the Master to control when Slave-initiated Interrupts are allowed on the I3C Bus.

These four Direct (ENEC/DISEC Format 1) or Broadcast (ENEC/DISEC Format 2) CCCs allows the Master to control when Slave- initiated traffic is (Enable) vs. is not (Disable) allowed on the I3C Bus. This control governs a Slave's attempts to request an Interrupt (ENI), or to request Mastership (ENMR).

[Setting conditions]

- When writing 1
- When receiving ENEC CCC (Broadcast) with ENINT bit = 1.*1
- When ENINT bit = 1 with own Slave Address in receiving ENEC CCC (Direct).*1

[Clearing conditions]

- When writing 0.
- When receiving DISEC CCC (Broadcast) with DISINT bit = 1.*1
- When DISINT bit = 1 with own Slave Address in receiving DISEC CCC (Direct).*1

MSRQE bit (Mastership Requests Enable)

This bit allows the Current Master to control when Mastership requests from Secondary Masters are allowed on the I3C Bus.

[Setting conditions]

- When writing 1.
- When receiving ENEC CCC (Broadcast) with ENMR bit = 1.*1
- When ENMR bit = 1 with own Slave Address in receiving ENEC CCC (Direct).*1

[Clearing conditions]

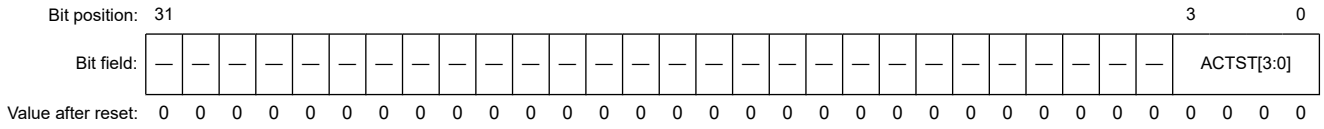
- When writing 0.
- When receiving DISEC CCC (Broadcast) with DISMR bit = 1.*1
- When DISMR bit = 1 with own Slave Address in receiving DISEC CCC (Direct).*1

Note 1. See the MIPI I3C Specification v1.0

30.2.71 CEACTST : CCC Enter Activity State Register

Base address: I3C = 0x4035_F000
I3C_NS = 0x5035_F000

Offset address: 0x354



Bit	Symbol	Function	R/W
3:0	ACTST[3:0]	Activity State 0x1: ENTAS0 (1µs: Latency-free operation) 0x2: ENTAS1 (100 µs) 0x4: ENTAS2 (2 ms) 0x8: ENTAS3 (50 ms: Lowest-activity operation) Others: Setting prohibited	R/W
31:4	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE3, P-TYPE3
Note: This register supports I3C secondary master mode and I3C slave mode.

ACTST[3:0] bits (Activity State)

[Update conditions]

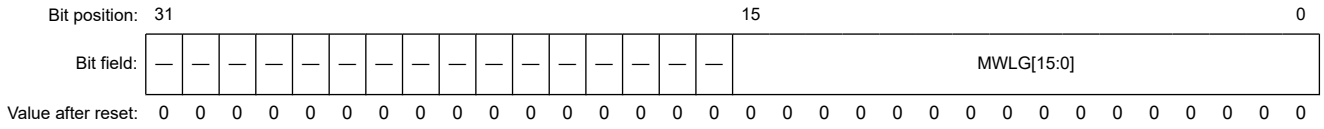
- When writing Activity State value.
- When receiving ENTAS0 CCC (Broadcast), these bits are updated to 0x1.*1
- When receiving ENTAS1 CCC (Broadcast), these bits are updated to 0x2.*1
- When receiving ENTAS2 CCC (Broadcast), these bits are updated to 0x4.*1
- When receiving ENTAS3 CCC (Broadcast), these bits are updated to 0x8.*1
- When Slave Address value is its own Slave Addres in receiving ENTAS0 CCC (Direct), these bits are updated to 0x1.*1
- When Slave Address value is its own Slave Addres in receiving ENTAS1 CCC (Direct), these bits are updated to 0x2.*1
- When Slave Address value is its own Slave Addres in receiving ENTAS2 CCC (Direct), these bits are updated to 0x4.*1
- When Slave Address value is its own Slave Addres in receiving ENTAS3 CCC (Direct), these bits are updated to 0x8.*1

Note 1. See the MIPI I3C Specification v1.0.

30.2.72 CMWLG : CCC Max Write Length Register

Base address: I3C = 0x4035_F000
I3C_NS = 0x5035_F000

Offset address: 0x358



Bit	Symbol	Function	R/W
15:0	MWLG[15:0]	Max Write Length	R/W
31:16	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE3, P-TYPE3
Note: This register supports I3C secondary master mode and I3C slave mode.

MWLG[15:0] bits (Max Write Length)

These bits use for the I3C Master to set or get a maximum data write length in bytes for one Slave Device.

This Max Write Length does not affect data write lengths for Broadcast CCCs. The Set/Get Max Write Length value is transmitted over two bytes, with the most significant byte (MSB) transmitted first. The minimum value that Max Write Length can be set to is 8.

[Update conditions]

- When writing Max Write Length value.
- When receiving SETMWL CCC (Broadcast), these bits are updated to MWL value.*1
- When Slave Address value is its own Slave Address in receiving SETMWL CCC (Direct), these bits are updated to MWL value.*1

Note 1. See the MIPI I3C Specification v1.0

30.2.73 CMRLG : CCC Max Read Length Register

Base address: I3C = 0x4035_F000
I3C_NS = 0x5035_F000

Offset address: 0x35C

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	IBIPSZ[7:0]								MRLG[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	MRLG[15:0]	Max Read Length	R/W
23:16	IBIPSZ[7:0]	IBI Payload Size	R/W
31:24	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE3, P-TYPE3
Note: This register supports I3C secondary master mode and I3C slave mode.

MRLG[15:0] bits (Max Read Length)

These bits use for the I3C Master to set or get a maximum data read length for one Slave Device.

The Set/Get Max Read Length value is transmitted over the first two bytes, with most significant byte (MSB) transmitted first. The minimum value to which Max Read Length can be set is 16.

[Update conditions]

- When writing Max Read Length value.
- When receiving SETMRL CCC (Broadcast), these bits are updated to MRL value.*1
- When Slave Address value is its own Slave Address in receiving SETMRL CCC (Direct), these bits are updated to MRL value.*1

IBIPSZ[7:0] bits (IBI Payload Size)

These bits use for the I3C Master to set or get optionally a maximum IBI payload size.

For devices with BCR bit 2 set to 1, the Max IBI payload size value is added as a third-byte, where a value of 0 indicates an unlimited payload size. If Timing Control is used, then the minimum IBI payload size is either four bytes or five bytes. If Timing Control is not used, then the minimum IBI payload size is 1 (one byte).

This CCC is optional for the Slave, with two exceptions:

1. This CCC is required if both (a) any private Read Request Message (s) and/or any extended Read Request CCC (s) implemented by the Slave support a variable limit on the maximum number of data bytes that the Slave may return per Message, and (b) this limit is greater than 16 bytes.
2. This CCC is required if the Slave both (a) supports an IBI Payload (as indicated with BCR bit 1), and (b) will transmit more than one byte of private payload (not counting Timing Control bytes, when Timing Control used).

[Update conditions]

- When writing Max IBI payload size value.
- When receiving SETMRL CCC (Broadcast), these bits are updated to IBI payload size value.*1
- When Slave Address value is its own Slave Address in receiving SETMRL CCC (Direct), these bits are updated to IBI payload size value.*1

Note 1. See the MIPI I3C Specification v1.0.

30.2.74 CETSTMD : CCC Enter Test Mode Register

Base address: I3C = 0x4035_F000
I3C_NS = 0x5035_F000

Offset address: 0x360

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	TSTMD[7:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	TSTMD[7:0]	Test Mode 0x00: Exit Test Mode This value removes all I3C devices from Test Mode. 0x01: Vendor Test Mode This value indicates that I3C devices shall return a random 32bit value in the provisional ID during the Dynamic Address Assignment procedure. Others: Setting prohibited	R
31:8	—	These bits are read as 0.	R

Note: S-TYPE3, P-TYPE3
Note: This register supports I3C secondary master mode and I3C slave mode.

TSTMD[7:0] bits (Test Mode)

When these bits set to 0x00, all I3C Devices remove from Test Mode.

When these bits set to 0x01, I3C Devices shall return a random 32bit value in the Provisional ID during the Dynamic Address Assignment procedure.

The Broadcast CCC informs all I3C Devices that the Master is entering a specified Test Mode during manufacturing or Device test. The Enter Test Mode command Frame format includes a byte that specifies which Test Mode to enter. Supporting I3C Devices shall enter the indicated Test Mode upon receipt of the Enter Test Mode CCC.

[Update condition]

- When receiving ENTTM CCC (Broadcast), these bits are updated to Test Mode Byte value.*1

Note 1. See the MIPI I3C Specification v1.0.

30.2.75 CGDVST : CCC Get Device Status Register

Base address: I3C = 0x4035_F000
I3C_NS = 0x5035_F000

Offset address: 0x364

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	8	7	6	5	4	3	0
Bit field:	VDRSV[7:0]		ACTMD[1:0]		PRTE	—	PNDINT[3:0]	
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
3:0	PNDINT[3:0]	Pending Interrupt Contains the interrupt number of any pending interrupt, or 0 if no interrupts are pending. This encoding allows for up to 15 numbered interrupts. If more than one interrupt is set, then the highest priority interrupt shall be returned.	R/W
4	—	This bit is read as 0. The write value should be 0.	R/W
5	PRTE	Protocol Error 0: The Slave has not detected a protocol error since the last Status read. 1: The Slave has detected a protocol error since the last Status read.	R/W
7:6	ACTMD[1:0]	Slave Device's current Activity Mode 0 0: Activity Mode 0 0 1: Activity Mode 1 1 0: Activity Mode 2 1 1: Activity Mode 3	R/W
15:8	VDRSV[7:0]	Vendor Reserved Reserved for vendor-specific meaning	R/W
31:16	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE3, P-TYPE3
Note: This register supports I3C secondary master mode and I3C slave mode.

PRTE bit (Protocol Error)

If this bit set to 1, then the Slave detects a protocol error since the last Status read.

The Slave checks for such errors. Note that this value self-clears by the hardware upon every successful completion of a Master read of the Slave's Status.

The Direct CCC is a Get request for one I3C Slave Device to return its current Status, in the two-byte format detailed. Note that byte 0 is the LSB, and byte 1 is the MSB.

[Setting condition]

- When the Slave detected a protocol error.*1

[Clearing condition]

- When transmission by own Slave Address is completed without error after receiving GETSTATUS CCC (Direct).*1

ACTMD[1:0] bits (Slave Device's current Activity Mode)

Contains the two-bit ID of the Slave Device's current Activity Mode (readiness to support data read of sensor or related information).

Note 1. See the MIPI I3C Specification v1.0.

30.2.76 CMDSPW : CCC Max Data Speed W (Write) Register

Base address: I3C = 0x4035_F000
I3C_NS = 0x5035_F000

Offset address: 0x368

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2		0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	MSWDR[2:0]		
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
2:0	MSWDR[2:0]	Maximum Sustained Write Data Rate 0 0 0: fscl Max (default value) 0 0 1: 8 MHz 0 1 0: 6 MHz 0 1 1: 4 MHz 1 0 0: 2 MHz Others: Setting prohibited	R/W
31:3	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE3, P-TYPE3
Note: This register supports I3C secondary master mode and I3C slave mode.

30.2.77 CMDSPR : CCC Max Data Speed R (Read) Register

Base address: I3C = 0x4035_F000
I3C_NS = 0x5035_F000

Offset address: 0x36C

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
2:0	MSRDR[2:0]	Maximum Sustained Read Data Rate 0 0 0: fscl Max (default value) 0 0 1: 8 MHz 0 1 0: 6 MHz 0 1 1: 4 MHz 1 0 0: 2 MHz Others: Setting prohibited	R/W

Bit	Symbol	Function	R/W
5:3	CDTTIM[2:0]	Clock to Data Turnaround Time (TSCO) 0 0 0: 8 ns or less (default value) 0 0 1: 9 ns or less 0 1 0: 10 ns or less 0 1 1: 11 ns or less 1 0 0: 12 ns or less 1 1 1: TSCO is more than 12 ns, and is reported by private agreement. Others Setting prohibited	R/W
31:6	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE3, P-TYPE3
Note: This register supports I3C secondary master mode and I3C slave mode.

30.2.78 CMDSPT : CCC Max Data Speed T (Turnaround) Register

Base address: I3C = 0x4035_F000
I3C_NS = 0x5035_F000

Offset address: 0x370

Bit position:	31								23																				0
Bit field:	MRTE	—	—	—	—	—	—	—	MRTTIM[23:0]																				
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
23:0	MRTTIM[23:0]	Maximum Read Turnaround Time 24-bit field can encode turnaround times from 0.0 seconds to 16 seconds. 0x000000: 0 µs (minimum value) 0x000001: 1 µs (resolution) ⋮ 0xF42400: 16 seconds (maximum value) Others: Setting prohibited	R/W
30:24	—	These bits are read as 0. The write value should be 0.	R/W
31	MRTE	Maximum Read Turnaround Time Enable 0: Disables transmission of the Maximum Read Turnaround Time. (GETMXDS Format 1: Without Turnaround) 1: Enables transmission of the Maximum Read Turnaround Time. (GETMXDS Format 2: With Turnaround)	R/W

Note: S-TYPE3, P-TYPE3
Note: This register supports I3C secondary master mode and I3C slave mode.

30.2.79 CETSM : CCC Exchange Timing Support Information M (Mode) Register

Base address: I3C = 0x4035_F000
I3C_NS = 0x5035_F000

Offset address: 0x374

Bit position:	31	30	29	28	27	26	25	24	23							16	15							8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	INAC[7:0]								FREQ[7:0]								—	—	—	—	—	SPTASYN1	SPTASYN0	SPTSYN
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	SPTSYN	Supports Sync Mode 0: Sync Mode is not supported. 1: Sync Mode is supported.	R/W
1	SPTASYN0	Support Async Mode 0 0: Async Mode 0 is not supported. 1: Async Mode 0 is supported.	R/W
2	SPTASYN1	Support Async Mode 1 0: Async Mode 1 is not supported. 1: Async Mode 1 is supported.	R/W
7:3	—	These bits are read as 0. The write value should be 0.	R/W
15:8	FREQ[7:0]	Frequency Byte This byte represents the Slave's internal oscillator frequency in increments of 0.5 MHz (500 kHz), up to 127.5 MHz. 0x00: 32.0 KHz 0x01: 0.5 MHz 0x02: 1.0 MHz ⋮ 0xFD: 126.5 MHz 0xFE: 127.0 MHz 0xFF: 127.5 MHz	R/W
23:16	INAC[7:0]	Inaccuracy Byte This byte represents the maximum variation of the Slave's internal oscillator in 1/10th percent (0.1%) increments, up to 25.5%. 0x00: 0.0% 0x01: 0.1% 0x02: 0.2% ⋮ 0xFD: 25.3% 0xFE: 25.4% 0xFF: 25.5%	R/W
31:24	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE3, P-TYPE3
Note: This register supports I3C secondary master mode and I3C slave mode.

SPTSYN bit (Supports Sync Mode)

Bit mask indicating which Supports Sync Mode of Timing Control Mode (s) the target Slave supports.

If this bit set (has value 1), then that Slave supports the corresponding Supports Sync Mode of Timing Control Mode.

SPTASYN0 bit (Support Async Mode 0)

Bit mask indicating which Supports Async Mode 0 of Timing Control Mode (s) the target Slave supports.

If this bit set (has value 1), then that Slave supports the corresponding Supports Async Mode 0 of Timing Control Mode.

SPTASYN1 bit (Support Async Mode 1)

Bit mask indicating which Supports Async Mode 1 of Timing Control Mode (s) the target Slave supports.

If this bit set (has value 1), then that Slave supports the corresponding Supports Async Mode 1 of Timing Control Mode.

The Directed CCC provides the framework for the Master to query the Exchange Timing capabilities supported by the I3C Slaves. The Get Exchange Timing Support Information CCC causes the addressed Slave to return four data bytes containing key information on supported Timing Control modes, current state, and internal oscillator/clock frequency and inaccuracy.

30.2.80 CETSS : CCC Exchange Timing Support Information S (State) Register

Base address: I3C = 0x4035_F000
I3C_NS = 0x5035_F000

Offset address: 0x378

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	ICOVF	—	—	—	—	ASYNE[1:0]		SYNE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	SYNE	Sync Mode Enabled 0: Sync Mode Disabled 1: Sync Mode Enabled	R/W
2:1	ASYNE[1:0]	Async Mode Enabled Async Mode 3, 2 are unsupported and set to 0. 0 0: All Mode Disable 0 1: Async Mode 0 Enabled 1 0: Async Mode 1 Enabled Others: Setting prohibited	R/W
6:3	—	These bits are read as 0. The write value should be 0.	R/W
7	ICOVF	Internal Counter Overflow 0: Slave has not experienced a counter overflow since the most recent previous check. 1: Slave experienced a counter overflow since the most recent previous check.	R/W
31:8	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE3, P-TYPE3
Note: This register supports I3C secondary master mode and I3C slave mode.

Bit mask indicating which Timing Control Mode (if any) is currently enabled for the target Slave, and whether any counter overflows have occurred since the most recent previous check. If a Timing Control Mode bit is set (has value 1), then that Slave has currently enabled the corresponding Timing Control Mode. If the Overflow bit is set (has value 1), then that Slave experienced a counter overflow since the most recent previous check.

ASYNE[0] Bit (Async Mode 0 Enabled)

Slave Timing Control Async Mode 0 is enabled.

[Setting condition]

- When writing 1.
- When CETSM.SPTASYN[0] bit = 1 and either of the following 1 or 2 are satisfied.

1. When receiving SETXTIME CCC (Broadcast) with Defining byte value 0xDF.
2. When Slave Address value is its own Slave Address in receiving SETXTIME CCC (Direct) with Defining byte value 0xDF.

[Clearing condition]

- When writing 0.
- When CETSM.SPTASYN[0] bit = 1 and either of the following 1 or 2 are satisfied.

1. When receiving SETXTIME CCC (Broadcast) with Defining byte value 0xEF.

2. When Slave Address value is its own Slave Address in receiving SETXTIME CCC (Direct) with Defining byte value 0xEF.

ASYNE[1] Bit (Async Mode 1 Enabled)

Slave Timing Control Async Mode 1 is enabled.

[Setting condition]

- When writing 1.
- When CETSM.SPTASYN[1] bit = 1 and either of the following 1 or 2 are satisfied.

1. When receiving SETXTIME CCC (Broadcast) with Defining byte value 0xEF.
2. When Slave Address value is its own Slave Address in receiving SETXTIME CCC (Direct) with Defining byte value 0xEF.

[Clearing condition]

- When writing 0.
- When CETSM.SPTASYN[1] bit = 1 and either of the following 1 or 2 are satisfied.

1. When receiving SETXTIME CCC (Broadcast) with Defining byte value 0xDF.
2. When Slave Address value is its own Slave Address in receiving SETXTIME CCC (Direct) with Defining byte value 0xDF.

30.2.81 CGHDRCAP : CCC Get HDR Capability Register

Base address: I3C = 0x4035_F000
I3C_NS = 0x5035_F000

Offset address: 0x37C

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	TSLEN	TSPEN	DDREN
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	DDREN	HDR-DDR Operation Enable 0: HDR-DDR Operation is Disabled. 1: HDR-DDR Operation is Enabled.	R/W
1	TSPEN	HDR-TSP Operation Enable 0: HDR-TSP Operation is Disabled. 1: HDR-TSP Operation is Enabled.	R/W
2	TSLEN	HDR-TSL Operation Enable 0: HDR-TSL Operation is Disabled. 1: HDR-TSL Operation is Enabled.	R/W
31:3	—	These bits are read as 0. The write value should be 0.	R

Note: S-TYPE3, P-TYPE3
Note: This register supports I3C secondary master mode and I3C slave mode.

DDREN bit (HDR-DDR Operation Enable)

This bit is used to enable or disable the HDR-DDR communication when used with I3C Slave.

HDR-DDR communication is permitted only when SVDCT.TBCR5 = 1 and DDREN = 1.

[Setting condition]

- When writing 1.

[Clearing condition]

- When writing 0.

TSPEN bit (HDR-TSP Operation Enable)

This bit is used to enable or disable the HDR-TSP communication when used with I3C Slave.

HDR-TSP communication is permitted only when SVDCT.TBCR5 = 1 and TSPEN = 1.

[Setting condition]

- When writing 1.

[Clearing condition]

- When writing 0.

TSLEN bit (HDR-TSL Operation Enable)

This bit is used to enable or disable the HDR-TSL communication when used with I3C Slave.

HDR-TSL communication is permitted only when SVDCT.TBCR5 = 1 and TSLEN = 1.

[Setting condition]

- When writing 1.

[Clearing condition]

- When writing 0.

Note: Refer to the MIPI I3C Specification v1.0.
The lower 8 bits of this register are used as the response data of GETHDRCAP CCC.

30.2.82 BITCNT : Bit Count Register

Base address: I3C = 0x4035_F000
I3C_NS = 0x5035_F000

Offset address: 0x380

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	BCNT[4:0]				
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
4:0	BCNT[4:0]	Bit Counter Indicates the number of bits remaining to be transferred. For details on the values, see Table 30.7 and Table 30.8.	R
31:5	—	These bits are read as 0.	R

Note: S-TYPE3, P-TYPE3

BCNT[4:0] bits (Bit Counter)

These bits function as a counter that indicates the number of bits remaining to be transferred at the detection of a sampling edge on the I3C_SCL line.

Table 30.7 I²C / Legacy I²C transfer (1 of 2)

BCNT[4:0]	Master		Slave	
	Address phase	Data phase	Address phase	Data phase
0x00	2 to 1 bits	2 to 1 bits	3 to 1 bits	2 to 1 bits
0x01	3 bits	3 bits	4 bits	3 bits

Table 30.7 I²C / Legacy I²C transfer (2 of 2)

BCNT[4:0]	Master		Slave	
	Address phase	Data phase	Address phase	Data phase
0x02	4 bits	4 bits	5 bits	4 bits
0x03	5 bits	5 bits	6 bits	5 bits
0x04	6 bits	6 bits	7 bits	6 bits
0x05	7 bits	7 bits	8 bits	7 bits
0x06	8 bits	8 bits	9 bits	8 bits
0x07	9 bits	9 bits	—	9 bits

Table 30.8 I3C transfer

BCNT[4:0]	SDR*1		HDR-DDR		HDR-TS
	Transmission	Reception	Command/Data	CRC	
0x00	1 bit	2 to 1 bits	19, 1 bits	11, 1 bits	1 Symbol
0x01	2 bits	3 bits	20, 2 bits	12, 2 bits	2 Symbols
0x02	3 bits	4 bits	3 bits	3 bits	3 Symbols
0x03	4 bits	5 bits	4 bits	4 bits	4 Symbols
0x04	5 bits	6 bits	5 bits	5 bits	5 Symbols
0x05	6 bits	7 bits	6 bits	6 bits	6 Symbols
0x06	7 bits	8 bits	7 bits	7 bits	7 Symbols
0x07	8 bits	9 bits	8 bits	8 bits	8 Symbols
0x08	9 bits	—	9 bits	9 bits	9 Symbols
0x09	—	—	10 bits	10 bits	10 Symbols
0x0A	—	—	11 bits	—	11 Symbols
0x0B	—	—	12 bits	—	12 Symbols
0x0C	—	—	13 bits	—	—
0x0D	—	—	14 bits	—	—
0x0E	—	—	15 bits	—	—
0x0F	—	—	16 bits	—	—
0x10	—	—	17 bits	—	—
0x11	—	—	18 bits	—	—

Note 1. The address phase is the same as in Table 30.7.

30.2.83 NQSTLV : Normal Queue Status Level Register

Base address: I3C = 0x4035_F000
I3C_NS = 0x5035_F000

Offset address: 0x394

Bit position:	31	30	29	28	24	23	16	15	8	7	0
Bit field:	—	—	—	IBISCNT[4:0]		IBIQLV[7:0]		RSPQLV[7:0]		CMDQFLV[7:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0	0

Bit	Symbol	Function	R/W
7:0	CMDQFLV[7:0]	Normal Command Queue Free Level*1 Number of free buffer entries currently in the Normal Command Queue. Reset value is the depth of the Normal Command Queue.	R

Bit	Symbol	Function	R/W
15:8	RSPQLV[7:0]	Normal Response Queue Level*1 Number of buffer entries currently in the Normal Response Queue.	R
23:16	IBIQLV[7:0]	Normal IBI Queue Level*1 Number of buffer entries currently in the Normal IBI Queue.	R
28:24	IBISCNT[4:0]	Normal IBI Status Count*2 Number of IBI Status entries currently in the Normal IBI Queue.	R
31:29	—	These bits are read as 0.	R

Note: S-TYPE3, P-TYPE3
Note 1. These bits support all I3C mode.
Note 2. These bits support I3C master mode and I3C secondary master mode.

30.2.84 NDBSTLV0 : Normal Data Buffer Status Level Register 0

Base address: I3C = 0x4035_F000
I3C_NS = 0x5035_F000

Offset address: 0x398

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	RDBLV[7:0]								TDBFLV[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

Bit	Symbol	Function	R/W
7:0	TDBFLV[7:0]	Normal Tx Data Buffer Free Level Indicates the number of free Tx Data Buffer entries in the Tx Data Queue. Reset value is the depth of the Tx Data Queue.	R
15:8	RDBLV[7:0]	Normal Rx Data Buffer Level Indicates the number of Rx Data Buffer entries in the Rx Data Queue.	R
31:16	—	These bits are read as 0.	R

Note: S-TYPE3, P-TYPE3
Note: This register supports all I3C mode.

30.2.85 NRSQSTLV : Normal Receive Status Queue Status Level Register

Base address: I3C = 0x4035_F000
I3C_NS = 0x5035_F000

Offset address: 0x3C0

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	RSQLV[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	RSQLV[7:0]	Normal Receive Status Queue Level	R
31:8	—	These bits are read as 0.	R

Note: S-TYPE3, P-TYPE3
Note: This register supports I3C secondary master mode and I3C slave mode.

30.2.86 HQSTLV : High Priority Queue Status Level Register

Base address: I3C = 0x4035_F000
I3C_NS = 0x5035_F000

Offset address: 0x3C4

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	RSPQLV[7:0]								CMDQLV[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0

Bit	Symbol	Function	R/W
7:0	CMDQLV[7:0]	High Priority Command Queue Level Number of free buffer entries currently in the High Priority Command Queue. Reset value is the depth of the High Priority Command Queue.	R
15:8	RSPQLV[7:0]	High Priority Response Queue Level Number of buffer entries currently in the High Priority Response Queue.	R
31:16	—	These bits are read as 0.	R

Note: S-TYPE3, P-TYPE3
Note: This register supports I3C master mode and I3C secondary master mode.

30.2.87 HDBSTLV : High Priority Data Buffer Status Level Register

Base address: I3C = 0x4035_F000
I3C_NS = 0x5035_F000

Offset address: 0x3C8

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15							8	7							0
Bit field:	RDBLV[7:0]								TDBFLV[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0

Bit	Symbol	Function	R/W
7:0	TDBFLV[7:0]	High Priority Tx Data Buffer Free Level Indicates the number of free High Priority Tx Data Buffer entries in the High Priority Tx Data Queue. Reset value is the depth of the High Priority Tx Data Queue.	R
15:8	RDBLV[7:0]	High Priority Rx Data Buffer Level Indicates the number of High Priority Rx Data Buffer entries in the High Priority Rx Data Queue.	R
31:16	—	These bits are read as 0.	R

Note: S-TYPE3, P-TYPE3
Note: This register supports I3C master mode and I3C secondary master mode.

30.2.88 PRSTDBG : Present State Debug Register

Base address: I3C = 0x4035_F000
I3C_NS = 0x5035_F000

Offset address: 0x3CC

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	SDOLV	SCOLV	SDILV	SCILV
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	1	1	1	1

Bit	Symbol	Function	R/W
0	SCILV	I3C_SCL Line Signal Level This bit is used to check the I3C_SCL Line level, in order to recover from errors and for debugging.	R
1	SDILV	I3C_SDA Line Signal Level This bit is used to check the I3C_SDA Line level, in order to recover from errors and for debugging.	R
2	SCOLV	SCL Output Level 0: I3C has driven the I3C_SCL pin low. 1: I3C has released the I3C_SCL pin.	R
3	SDOLV	SDA Output Level 0: I3C has driven the I3C_SDA pin low. 1: I3C has released the I3C_SDA pin.	R
31:4	—	These bits are read as 0.	R

Note: S-TYPE3, P-TYPE3

SCILV bit (I3C_SCL Line Signal Level)

This bit is used to check the I3C_SCL Line level, in order to recover from errors and for debugging.

SDILV bit (I3C_SDA Line Signal Level)

This bit is used to check the I3C_SDA Line level, in order to recover from errors and for debugging.

SCOLV bit (SCL Output Level)

This bit is used to select the output level of I3C_SCL pin.

SDOLV bit (SDA Output Level)

This bit is used to select the output level of I3C_SDA pin.

30.2.89 MSERRCNT : Master Error Counters Register

Base address: I3C = 0x4035_F000
I3C_NS = 0x5035_F000

Offset address: 0x3D0

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	M2ECNT[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	M2ECNT[7:0]	M2 Error Counter Counts I3C Type M2 errors on the I3C Bus. Cleared upon read out.	R
31:8	—	These bits are read as 0.	R

Note: S-TYPE3, P-TYPE3
Note: This register supports I3C master mode and I3C secondary master mode.

30.2.90 SC1CPT : SC1 Capture Monitor Register

Base address: I3C = 0x4035_F000
I3C_NS = 0x5035_F000

Offset address: 0x3E0

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	SC1C[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	SC1C[15:0]	SC1 Capture	R
31:16	—	These bits are read as 0.	R

Note: S-TYPE3, P-TYPE3
Note: This register supports I3C secondary master mode and I3C slave mode.

SC1C[15:0] bit (SC1 Capture)

- Async Mode 0 (Asynchronous Basic Mode)
  After enabling ATCCNTE.ATCE, SC1C[15:0] Counter counts up from SC1C[15:0] count trigger[*1] to SCL rise edge next to ACK for the IBI, and capture it as SC1C[15:0].
- Async Mode 1 (Asynchronous Advanced Mode)
  After enabling ATCCNTE.ATCE, SC1C[15:0] Counter counts up from SC1C[15:0] count trigger[*1] to the first aME, and capture it as SC1C[15:0].

Note: As the timing control specification, the SC1C[15:0] counter value is included in the IBI frame as IBI data and is sent to I3C Master, therefore it is not necessary for the I3C Slave to read this register. If the I3C Slave needs to read this register, read it after completing the IBI frame.

Note 1. SW or external trigger can be selected by selection bits.

30.2.91 SC2CPT : SC2 Capture Monitor Register

Base address: I3C = 0x4035_F000
I3C_NS = 0x5035_F000

Offset address: 0x3E4

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	SC2C[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	SC2C[15:0]	SC2 Capture	R
31:16	—	These bits are read as 0.	R

Note: S-TYPE3, P-TYPE3
Note: This register supports I3C secondary master mode and I3C slave mode.

SC2C[15:0] bits (SC2 Capture)

- Async Mode 0 (Asynchronous Basic Mode)
  After enabling ATCCNTE.ATCE, SC2C[15:0] Counter counts up from SCL rise edge next to ACK for the IBI transmitted from I3C Slave to SCL rise edge next to Tbit after Mandatory Byte, and capture it as SC2C[15:0].
- Async Mode 1 (Asynchronous Advanced Mode)
  After enabling ATCCNTE.ATCE, SC2C[15:0] Counter counts up from SCL rise edge next to ACK for the IBI transmitted from I3C Slave to SCL rise edge next to Tbit after Mandatory Byte, and capture it as SC2C[15:0].

Note: As the timing control specification, the SC2C[15:0] counter value is included in the IBI frame as IBI data and is sent to I3C Master, therefore it is not necessary for the I3C Slave to read this register. If the I3C Slave needs to read this register, read it after completing the IBI frame.

30.2.92 CECTL : Clock Enable Control Register

Base address: I3C = 0x4035_F000
I3C_NS = 0x5035_F000

Offset address: 0x010

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	CLKE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	CLKE	Clock Enable 0: Clock disable 1: Clock enable	R/W
31:1	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE3, P-TYPE3

CLKE bit (Clock Enable)

- This bit controls enabling/disabling of clock supply of the communication function.

30.3 Operation

30.3.1 Data Structures

30.3.1.1 Command Descriptor

The write-only Command Descriptor structure is 64 bits in length. The Command Descriptor is put to the Command Queue with writes to the Command Queue Port (High Priority or Normal).

Write to the Command Queue Port (High Priority or Normal) in the following order:

1. First write : The least significant DWORD (Command Descriptor Structure Low).
2. Second write : The most significant DWORD (Command Descriptor Structure High).

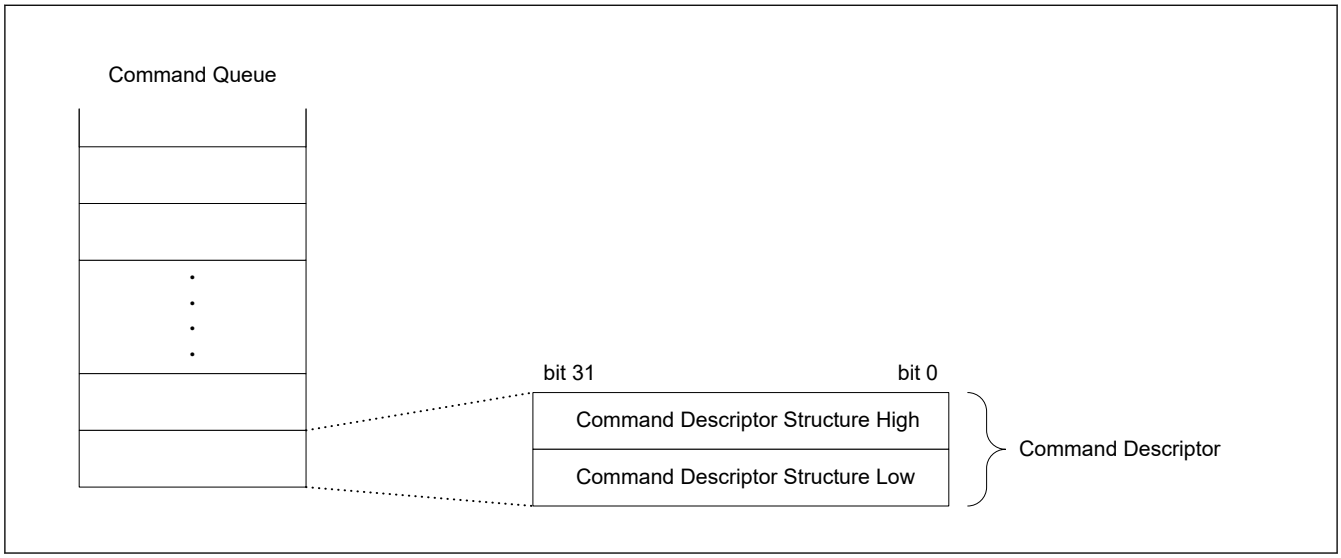

Figure 30.2 Command descriptor data structure

I3C provides a Command Descriptor structure for each command type as follows:

- Address Assign Command
- Immediate Transfer Command
- Regular Transfer Command
- Combo Transfer Command
- Internal Control Command

Details are explained in the following sections.

30.3.1.1.1 Address Assign Command

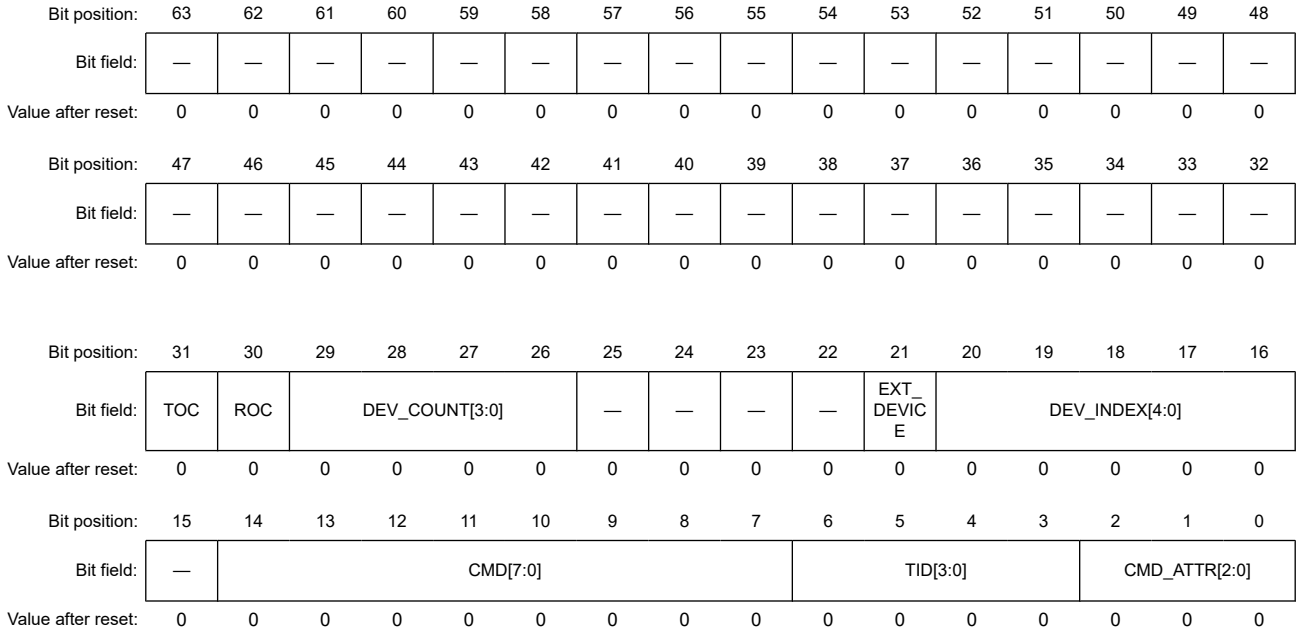
This command is used for address assignment (ENTDAA, SETDASA).

Note: When issuing SETAASA CCC, use the Immediate Transfer command.

The I3C provides an address assign command for the following mode:

- I3C Master mode

Details of the Address Assign command structure are as follows.



Bit position:	63	62	61	60	59	58	57	56	55	54	53	52	51	50	49	48
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	47	46	45	44	43	42	41	40	39	38	37	36	35	34	33	32
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	TOC	ROC	DEV_COUNT[3:0]				—	—	—	—	EXT_DEVICE	DEV_INDEX[4:0]				
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	CMD[7:0]								TID[3:0]				CMD_ATTR[2:0]		
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
2:0	CMD_ATTR[2:0]	Command Attributes 0x0: XFER: Regular Transfer 0x1: IMMED_DATA_XFER: Immediate Data Transfer 0x2: ADDR_ASSGN_CMD: Address Assignment Command 0x3: WWR_COMBO_XFER: Write + Write/Read Combo Transfer 0x7: INTERNAL_CONTROL: Internal Control command Others: Setting prohibited	W
6:3	TID[3:0]	Transaction ID	W
14:7	CMD[7:0]	Transfer Command CCC Value	W
15	—	The write value should be 0.	W
20:16	DEV_INDEX[4:0]	Device Index	W
21	EXT_DEVICE	Extended Device Index 0: Use the DATBASm table indicated by DEV_INDEX[4:0]. 1: Use the EXDATBAS table.	W
25:22	—	The write value should be 0.	W
29:26	DEV_COUNT[3:0]	Device Count	W
30	ROC	Response on Completion 0: NOT_REQUIRED: Response Status is not required. 1: REQUIRED: Response Status is required.	W
31	TOC	Terminate on Completion 0: RESTART: Issue Repeated START (Sr) at end of transfer 1: STOP: Issue STOP (P) at end of transfer	W
63:32	—	The write value should be 0.	W

CMD_ATTR[2:0] bits (Command Attributes)

Command Type, defining the format of the other fields.

TID[3:0] bits (Transaction ID)

Used as an identification tag for this command. This field shall be populated by the software Driver, and the same value shall be reflected in the Response Descriptor.

CMD[7:0] bits (Transfer Command CCC Value)

Specifies CCC code indicating whether Address Assignment uses ENTDAA or SETDASA commands. The field comprises the entire command code (ENTDAA or SETDASA).

DEV_INDEX[4:0] bits (Device Index)

Indicates the DATBASm table index for the Slave device being addressed with the transfer. Static and device addressing related information are stored to this index in the DATBASm.

DEV_COUNT[3:0] bits (Device Count)

Indicates the number of devices that a dynamic address is assigned to.

ROC bit (Response on Completion)

Controls whether Response Status is sent after successful completion of the Transfer command. The successful completion is read from register NRSPQP. Upon unsuccessful transfer the Response Status is sent.

TOC bit (Terminate on Completion)

Controls what bus condition to issue after the Transfer command completes.

For ENTDAA, a STOP condition is issued regardless of the setting value of TOC. It is meaningful for SETDASA transfers.

When sending SETDASA CCC by TOC = 0 (RESTART), the next command must be set to SETDASA CCC with the Address Assign Command.

When the next command is not the same SETDASA CCC flame, it must be set to TOC = 1 (STOP).

30.3.1.1.2 Immediate Transfer Command

This structure directly contains data (max 4 bytes) to be transferred, and as a result is only useful for Transfers/CCCs that write data. This structure shall not be used for Read operations (for example, to Rx data).

When transmitting data of 4 bytes or less, use this Immediate Transfer Command to communicate.

When transmitting data of 5 bytes or more, use the Regular Transfer Command to communicate.

For the Regular Transfer Command, see section 30.3.1.1.3. Regular Transfer Command.

I3C provides an Immediate Transfer Command for the following mode:

- I3C Master Mode

Details of the Immediate Transfer Command Structure of each mode are shown in this section.

Bit position:	63	62	61	60	59	58	57	56	55	54	53	52	51	50	49	48
Bit field:	DATA_BYTE_4[7:0]								DATA_BYTE_3[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit position:	47	46	45	44	43	42	41	40	39	38	37	36	35	34	33	32
Bit field:	DATA_BYTE_2[7:0]								DATA_BYTE_1[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	TOC	ROC	RNW	MODE[2:0]			BYTE_CNT[2:0]			—	EXT_DEVICE	DEV_INDEX[4:0]				
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	CP	CMD[7:0]								TID[3:0]				CMD_ATTR[2:0]		
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
2:0	CMD_ATTR[2:0]	Immediate Data Transfer Command Attribute 0x0: XFER: Regular Transfer 0x1: IMMED_DATA_XFER: Immediate Data Transfer 0x2: ADDR_ASSGN_CMD: Address Assignment Command 0x3: WWR_COMBO_XFER: Write + Write/Read Combo Transfer 0x7: INTERNAL_CONTROL: Internal Control command Others: Setting prohibited	W
6:3	TID[3:0]	Immediate Data Transfer Transaction ID	W
14:7	CMD[7:0]	Immediate Data Transfer CCC / HDR Command Code Value For CCC: 8 bits For HDR: 7 bits	W
15	CP	Immediate Data Transfer Command Present 0: TRANFSER: This structure describes an SDR transfer, so the CMD field is not valid. 1: CCC_HDR: This structure describes a CCC or HDR transfer, so the CMD field is valid.	W
20:16	DEV_INDEX[4:0]	Immediate Data Transfer Device Index	W
21	EXT_DEVICE	Immediate Data Transfer Extended Device Index 0: Use the DATBASm table indicated by DEV_INDEX[4:0]. 1: Use the EXDATBAS table.	W
22	—	The write value should be 0.	W
25:23	BYTE_CNT[2:0]	Immediate Data Transfer Byte Count 0x0: No payload 0x1 to 0x4: N bytes are valid. Others: Setting prohibited	W
28:26	MODE[2:0]	Immediate Data Transfer Mode and Speed Values 0x0: I3C SDR0 / Data rate : STDBR (I3C mode) Legacy I^2C Message 0 / Data rate : STDBR (I^2C mode) 0x1: I3C SDR1 / Data rate : EXTBR (I3C mode) Legacy I^2C Message 0 / Data rate : EXTBR (I2C mode) 0x2: I3C SDR2 / Data rate : STDBR × 2 (I3C mode) Reserved (I^2C mode) 0x3: I3C SDR3 / Data rate : EXTBR × 2 (I3C mode) Reserved (I^2C mode) 0x4: I3C SDR4 / Data rate : EXTBR × 4 (I3C mode) Reserved (I^2C mode) 0x5: I3C HDR-TS / Data rate : STDBR (I3C mode) HDR-Ternary Mode. Selection of HDR-TSP vs. HDR-TSL depends on the value of register BCTL, field BMDS Reserved (I^2C mode) 0x6: I3C HDR-DDR / Data rate : STDBR (I3C mode) Reserved (I^2C mode) Others: Setting prohibited	W
29	RNW	Immediate Data Transfer R/W 0: WRITE: Write transfer 1: READ: Read transfer	W

Bit	Symbol	Function	R/W
30	ROC	Immediate Data Transfer Response on Completion 0: NOT_REQUIRED: Response Status is not required. 1: REQUIRED: Response Status is required.	W
31	TOC	Immediate Data Transfer Terminate on Completion 0: RESTART: Issue Repeated START (Sr) at end of data transfer 1: STOP: Issue STOP (P) at end of data transfer	W
39:32	DATA_BYTE_1[7:0]	Immediate Data Transfer Data Byte 1 Direct argument	W
47:40	DATA_BYTE_2[7:0]	Immediate Data Transfer Data Byte 2 Direct argument	W
55:48	DATA_BYTE_3[7:0]	Immediate Data Transfer Data Byte 3 Direct argument	W
63:56	DATA_BYTE_4[7:0]	Immediate Data Transfer Data Byte 4 Direct argument	W

CMD_ATTR[2:0] bits (Immediate Data Transfer Command Attribute)

Command Type, defining the format of the other fields.

TID[3:0] bits (Immediate Data Transfer Transaction ID)

Used as an identification tag for this command. This field shall be populated by the software Driver, and the same value shall be reflected in the Response Descriptor.

CP bit (Immediate Data Transfer Command Present)

Indicates whether CMD field is valid for CCC or HDR Transfer.

DEV_INDEX[4:0] bits (Immediate Data Transfer Device Index)

Indicates the DATBASm Table index for the Slave Device being addressed with the transfer. Static and Device addressing related information will be stored to this index in the DATBASm.

BYTE_CNT[2:0] bits (Immediate Data Transfer Byte Count)

Number of valid data bytes to use in this Immediate Data Transfer Descriptor.

This field must be set to non-zero value, except for CCCs that does not have payload defined.

This field must be set to even value, when specifying HDR mode (MODE[2:0] = 0x5 or 0x6).

MODE[2:0] bits (Immediate Data Transfer Mode and Speed Values)

Sets the mode and speed for the I3C or I^2C transfer.

Interpretation of this field depends on whether the Device is in I3C Mode vs. I^2C Mode (see the DEVICE field in the DATBASm Table entry indexed by field DEV_INDEX).

RNW bit (Immediate Data Transfer R/W)

Identifies direction of the transfer.

This field shall always be set to 0, because Immediate transfers are valid for Write transactions only.

ROC bit (Immediate Data Transfer Response on Completion)

Controls whether Response Status is required after successful completion of the data transfer command. The successful completion shall be read from NRSPQP register. Upon unsuccessful transfer the Response Status shall always be sent.

TOC bit (Immediate Data Transfer Terminate on Completion)

Controls what Bus condition is issued after completion of the data transfer.

When sending Direct CCC by TOC = 0 (RESTART), next command must be set to same Direct CCC.

When the next command is not the same Direct CCC, must be set to TOC = 1 (STOP).

30.3.1.1.3 Regular Transfer Command

This structure does not contain data to be transferred.

For Master Mode, the data buffer is available through Transfer Data Queue Port (Rx Data Queue Port and Tx Data Queue Port).

When transmitting data of 5 bytes or more, use this Regular Transfer Command to communicate.

When transmitting data of 4 bytes or less, use the Immediate Transfer Command to communicate.

For the Immediate Transfer Command, see section 30.3.1.1.2. Immediate Transfer Command.

For I3C Slave Mode, the IBI Payload buffer is available through IBI Queue Port.

I3C provides a Regular Transfer Command for the following modes:

- I3C Master Mode
- I3C Slave Mode

Details of the regular transfer command structure of each mode are as follows.

(1) I3C Master Mode

Bit position:	63	62	61	60	59	58	57	56	55	54	53	52	51	50	49	48
Bit field:	DATA_LENGTH[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	47	46	45	44	43	42	41	40	39	38	37	36	35	34	33	32
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	TOC	ROC	RNW	MODE[2:0]			—	—	—	—	EXT_DEVICE	DEV_INDEX[4:0]				
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	CP	CMD[7:0]								TID[3:0]				CMD_ATTR[2:0]		
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
2:0	CMD_ATTR[2:0]	Data Transfer Command Attribute Command Type, defining the format of the other fields. Values: 0x0: XFER: Regular Transfer 0x1: IMMED_DATA_XFER: Immediate Data Transfer 0x2: ADDR_ASSGN_CMD: Address Assignment Command 0x3: WWR_COMBO_XFER: Write + Write/Read Combo Transfer 0x7: INTERNAL_CONTROL: Internal Control command Others: Setting prohibited	W
6:3	TID[3:0]	Data Transfer Transaction ID Identification tag for this command	W
14:7	CMD[7:0]	Data Transfer CCC / HDR Command Code Value Specifies the I3C Command code For CCC: 8 bits For HDR: 7 bits	W
15	CP	Data Transfer Command Present 0: TRANFSER: This structure describes an SDR transfer, so the CMD field is not valid. 1: CCC_HDR: This structure describes a CCC or HDR transfer, so the CMD field is valid.	W

Bit	Symbol	Function	R/W
20:16	DEV_INDEX[4:0]	Data Transfer Device Index	W
21	EXT_DEVICE	Data Transfer Extended Device Index 0: Use the DATBASm Table indicated by DEV_INDEX[4:0]. 1: Use the EXDATBAS table.	W
25:22	—	The write value should be 0.	W
28:26	MODE[2:0]	Data Transfer Speed and Mode 0x0: I3C SDR0 / Data rate : STDBR (I3C mode) Legacy I2C Message 0 / Data rate : STDBR (I2C mode) 0x1: I3C SDR1 / Data rate : EXTBR (I3C mode) Legacy I2C Message 0 / Data rate : EXTBR (I2C mode) 0x2: I3C SDR2 / Data rate : STDBR × 2 (I3C mode) Reserved (I2C mode) 0x3: I3C SDR3 / Data rate : EXTBR × 2 (I3C mode) Reserved (I2C mode) 0x4: I3C SDR4 / Data rate : EXTBR × 4 (I3C mode) Reserved (I2C mode) 0x5: I3C HDR-TS / Data rate : STDBR × 4 (I3C mode) HDR-Ternary Mode. Selection of HDR-TSP vs. HDR-TSL depends on the value of register BCTL, field BMDS Reserved (I2C mode) 0x6: I3C HDR-DDR / Data rate : STDBR (I3C mode) Reserved (I2C mode) Others: Setting prohibited	W
29	RNW	Data Transfer R/W 0: WRITE: Write transfer 1: READ: Read transfer	W
30	ROC	Data Transfer Response on Completion 0: NOT_REQUIRED: Response Status is not required. 1: REQUIRED: Response Status is required.	W
31	TOC	Data Transfer Terminate on Completion 0: RESTART: Issue Repeated START (Sr) at end of transfer 1: STOP: Issue STOP (P) at end of transfer	W
47:32	—	The write value should be 0.	W
63:48	DATA_LENGTH [15:0]	Data Transfer Data Length Indicates the number of bytes to be transferred. This field must be set to non-zero value, except for CCCs that does not have payload defined.	W

CMD_ATTR[2:0] bits (Data Transfer Command Attribute)

Command Type, defining the format of the other fields.

TID[3:0] bits (Data Transfer Transaction ID)

Used as an identification tag for this command. This field shall be populated by the software Driver, and the same value shall be reflected in the Response Descriptor.

CP bit (Data Transfer Command Present)

Indicates whether he contents of the CMD field is valid for a CCC or HDR Transfer.

DEV_INDEX[4:0] bits (Data Transfer Device Index)

Indicates the DATBASm Table index for the Slave Device being addressed with the transfer. Static and Device addressing related information will be stored to this index in the DATBASm.

MODE[2:0] bits (Data Transfer Speed and Mode)

Sets the mode and speed for the I3C or I^2C transfer.

Interpretation of this field depends on whether the Device is in I3C Mode vs. I^2C Mode (see the DEVICE field in the DATBASm Table entry indexed by field DEV_INDEX).

RNW bit (Data Transfer R/W)

Identifies direction of the transfer.

ROC bit (Data Transfer Response on Completion)

Controls whether Response Status is required after successful completion of the transfer command. The successful completion shall be read from NRSPQP register. Upon unsuccessful transfer the Response Status shall always be sent.

TOC bit (Data Transfer Terminate on Completion)

Controls what Bus condition will be issued after completion of the transfer.

When sending Direct CCC by TOC = 0 (RESTART), next command must be set to same Direct CCC.

When the next command is not the same Direct CCC, must be set to TOC = 1 (STOP).

DATA_LENGTH[15:0] bits (Data Transfer Data Length)

Number of valid data bytes to use in this Regular Transfer Descriptor.

This field must be set to non-zero value, except for CCCs that does not have payload defined.

This field must be set to even value, when specifying HDR mode (MODE[2:0] = 0x5 or 0x6).

Length setting of GETMXDS command should be fixed to 5.

(2) I3C Slave Mode

Bit position:	63	62	61	60	59	58	57	56	55	54	53	52	51	50	49	48
Bit field:	DATA_LENGTH[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	ROC	RNW	—	—	—	—	—	—	ITS	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	TID[3:0]				CMD_ATTR[2:0]		
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
2:0	CMD_ATTR[2:0]	Data Transfer Command Attribute Command Type, defining the format of the other fields. Values: 0x0: XFER: Regular Transfer 0x1: IMMED_DATA_XFER: Immediate Data Transfer 0x2: ADDR_ASSGN_CMD: Address Assignment Command 0x3: WWR_COMBO_XFER: Write + Write/Read Combo Transfer 0x7: INTERNAL_CONTROL: Internal Control command Others: Setting prohibited	W
6:3	TID[3:0]	Data Transfer Transaction ID Identification tag for this command	W

Bit	Symbol	Function	R/W
21:7	—	The write value should be 0.	W
22	ITS	Include timestamp for Async Mode 0: Do not include timestamp. 1: Include timestamp.	W
28:23	—	The write value should be 0.	W
29	RNW	Data Transfer R/W 0: WRITE: Write transfer (Mastership Request) 1: READ: Read transfer (Slave Interrupt Request)	W
30	ROC	Data Transfer Response on Completion 0: NOT_REQUIRED: Response Status is not required. 1: REQUIRED: Response Status is required.	W
47:31	—	The write value should be 0.	W
63:48	DATA_LENGTH [15:0]	Data Transfer Data Length Indicates the number of bytes to be transferred. This field must be set to non-zero value, except for CCCs that does not have payload defined.	W

CMD_ATTR[2:0] bits (Data Transfer Command Attribute)

Command Type, defining the format of the other fields.

TID[3:0] bits (Data Transfer Transaction ID)

Used as an identification tag for this command. This field shall be populated by the software Driver, and the same value shall be reflected in the Response Descriptor.

RNW bit (Data Transfer R/W)

Identifies direction of the transfer.

ROC bit (Data Transfer Response on Completion)

Controls whether Response Status is required after successful completion of the transfer command. The successful completion shall be read from NRSPQP register. Upon unsuccessful transfer the Response Status shall always be sent.

30.3.1.1.4 Combo Transfer Command

This structure contains a combined Write + Read/Write operation.

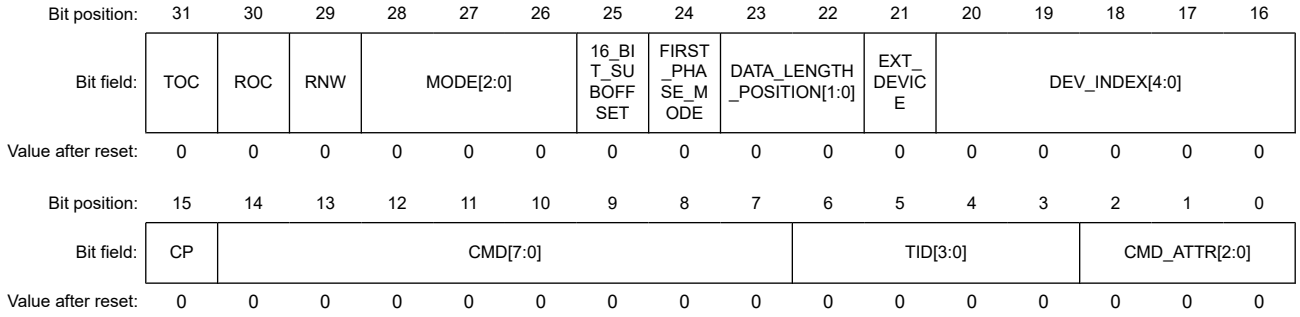
The data buffer is available through Transfer Data Queue Port (Rx Data Queue Port and Tx Data Queue Port).

I3C provides a Combo Transfer Command for the following mode:

- I3C Master mode

Details of the Combo Transfer Command Structure of each mode are as follows.

Bit position:	63	62	61	60	59	58	57	56	55	54	53	52	51	50	49	48
Bit field:	DATA_LENGTH[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit position:	47	46	45	44	43	42	41	40	39	38	37	36	35	34	33	32
Bit field:	OFFSET[15:0]/SUBOFFSET[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0



Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	TOC	ROC	RNW	MODE[2:0]			16_BIT_SUBOFFSET	FIRST_PHASE_MODE	DATA_LENGTH_POSITION[1:0]		EXT_DEVICE	DEV_INDEX[4:0]				
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	CP	CMD[7:0]								TID[3:0]				CMD_ATTR[2:0]		
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
2:0	CMD_ATTR[2:0]	Combo Transfer Command Attribute Command Type, defining the format of the other fields. 0x0: XFER: Regular Transfer 0x1: IMMED_DATA_XFER: Immediate Data Transfer 0x2: ADDR_ASSGN_CMD: Address Assignment Command 0x3: WWR_COMBO_XFER: Write + Write/Read Combo Transfer 0x7: INTERNAL_CONTROL: Internal Control command Others: Setting prohibited	W
6:3	TID[3:0]	Combo Transfer Transaction ID Identification tag for the command	W
14:7	CMD[7:0]	Combo Transfer HDR Command Code Value Specifies the I3C Command code (7 bits).	W
15	CP	Combo Transfer Command Present Indicates whether the CMD field is valid for a HDR Transfer 0: TRANFSER: This structure describes an SDR transfer, so the CMD field is not valid. 1: CCC_HDR: This structure describes a HDR transfer, so the CMD field is valid.	W
20:16	DEV_INDEX[4:0]	Combo Transfer Device Index	W
21	EXT_DEVICE	Combo Transfer Extended Device Index 0: Use the DATBASm table indicated by DEV_INDEX[4:0]. 1: Use the EXDATBAS table.	W
23:22	DATA_LENGTH_POSITION[1:0]	Data Length Field Position 0 0: NO: Do not put length field. 0 1: FIRST: Put length as first field. 1 0: SECOND: Put length as second field. Others: Setting prohibited	W
24	FIRST_PHASE_MODE	Combo Transfer First Phase Mode 0: SDR: First phase is executed in SDR mode. 1: MODE: First phase is executed in the mode indicated by the MODE field.	W
25	16_BIT_SUBOFFSET	Combo Transfer Sub Offset Size 0: 8_BIT_SUBOFFSET: Sub-offset is 8-bits long. Value is encoded in Lower Byte of OFFSET / SUBOFFSET field. 1: 16_BIT_SUBOFFSET: Sub-offset is 16-bits long.	W
28:26	MODE[2:0]	Combo Transfer Speed and Mode Values for I3C Mode 0x0: I3C SDR0 / Data rate : STDBR 0x1: I3C SDR1 : Data rate : EXTBR 0x2: I3C SDR2 / Data rate : STDBR × 2 0x3: I3C SDR3 / Data rate : EXTBR × 2 0x4: I3C SDR4 / Data rate : EXTBR × 4 0x5: I3C HDR-TS / Data rate : STDBR × 4 HDR-Ternary Mode. Selection of HDR-TSP vs. HDR-TSL depends on the value of register BCTL, field BMDS 0x6: I3C HDR-DDR / Data rate : STDBR Others: Setting prohibited	W

Bit	Symbol	Function	R/W
29	RNW	Combo Transfer R/W Identifies direction of the transfer 0: WRITE: Write transfer 1: READ: Read transfer	W
30	ROC	Combo Transfer Response on Completion 0: NOT_REQUIRED: Response Status is not required. 1: REQUIRED: Response Status is required.	W
31	TOC	Combo Transfer Terminate on Completion 0: RESTART: Issue Repeated START (Sr) at end of transfer 1: STOP: Issue STOP (P) at end of transfer	W
47:32	OFFSET[15:0]/ SUBOFFSET[15:0]	Combo Transfer Offset / Sub-Offset Offset of the target operation	W
63:48	DATA_LENGTH [15:0]	Combo Transfer Data Length Number of bytes to be transferred. This field must be set to non-zero value.	W

CMD_ATTR[2:0] bits (Combo Transfer Command Attribute)

Command Type, defining the format of the other fields.

TID[3:0] bits (Combo Transfer Transaction ID)

Used as an identification tag for this command. This field shall be populated by the software Driver, and the same value shall be reflected in the Response Descriptor.

CP bit (Combo Transfer Command Present)

Indicates whether the contents of the CMD field is valid for a HDR Transfer.

DEV_INDEX[4:0] bits (Combo Transfer Device Index)

Indicates the DATBASm table index for the Slave Device being addressed with the transfer. Static and Device addressing related information will be stored to this index in the DATBASm.

DATA_LENGTH_POSITION[1:0] bits (Data Length Field Position)

Indicates whether and where to put Data Length (DATA_LENGTH) in the first phase of the transfer. This field is only applicable if first phase of the transfer is executed in HDR mode.

Whether 8-bit or 16-bit of Data Length field is used is indicated with 16_BIT_SUBOFFSET field. In case of 8-bit value, it is encoded in Lower Byte of DATA_LENGTH field.

FIRST_PHASE_MODE bits (Combo Transfer First Phase Mode)

Indicates whether the first phase of the Combo Transfer is executed in SDR mode, or the mode indicated by the MODE field.

MODE[2:0] bits (Combo Transfer Speed and Mode Values for I3C Mode)

Sets the mode and speed for the I3C or I^2C transfer.

Interpretation of this field depends on whether the Device is in I3C mode or I^2C mode (see the DEVICE field in the DATBASm Table entry indexed by field DEV_INDEX).

RNW bit (Combo Transfer R/W Identifies direction of the transfer)

Identifies direction of the transfer.

ROC bit (Combo Transfer Response on Completion)

Controls whether Response Status is required after successful completion of the data transfer command. The successful completion shall be read from NRSPQP register. Upon unsuccessful transfer the Response Status shall always be sent.

TOC bit (Combo Transfer Terminate on Completion)

Controls what Bus condition is issued after completion of the data transfer.

When sending 2nd flame by TOC = 0 (RESTART) and HDR mode (MODE[2:0] = 0x5 or 0x6), next command must be set to that 1st flame will be the same as HDR mode (MODE[2:0] = 0x5 or 0x6).

When the next command is not the same HDR mode (MODE[2:0] = 0x5 or 0x6), must be set to TOC = 1 (STOP).

DATA_LENGTH[15:0] bit (Combo Transfer Data Length)

Number of valid data bytes to use in this Combo Transfer Descriptor.

This field must be set to non-zero value.

This field must be set to even value, when specifying HDR mode (MODE[2:0] = 0x5 or 0x6).

30.3.1.1.5 Internal Control Command

This structure is used for controlling I3C itself (not for transfer commands).

I3C provides an Internal Control Command for the following mode:

- I3C Master mode

Details of the Internal Control Command Structure are as follows:

Bit position:	63	62	61	60	59	58	57	56	55	54	53	52	51	50	49	48
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	47	46	45	44	43	42	41	40	39	38	37	36	35	34	33	32
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	ON_OFF	MIPI_CMD[3:0]				—	TID[3:0]				CMD_ATTR[2:0]		
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
2:0	CMD_ATTR[2:0]	Command Attribute*2 Command Type, defining the format of the other fields. 0x0: XFER: Regular Transfer 0x1: IMMED_DATA_XFER: Immediate Data Transfer 0x2: ADDR_ASSGN_CMD: Address Assignment Command 0x3: WWR_COMBO_XFER: Write + Write/Read Combo Transfer 0x7: INTERNAL_CONTROL: Internal Control command Others: Setting prohibited	W
6:3	TID[3:0]	Transaction ID Identification tag for the command	W
7	—	The write value should be 0.	W
11:8	MIPI_CMD[3:0]	MIPI Alliance Command 0x00: NoOp, so the ON_OFF field is not valid. 0x02: Include 7E (IBA), so the ON_OFF field is valid. Others: Setting prohibited	W
12	ON_OFF	Bus Instance 7E On / Off*1 Enables or disables automatic transmission of the I3C Broadcast Header after every START condition on this I3C Bus instance. 0: IBA_INCLUDE off 1: IBA_INCLUDE on	W

Bit	Symbol	Function	R/W
63:13	—	The write value should be 0.	W

Note 1. The IBA_INCLUDE on state set by MIPI_CMD [3:0] = 0x2 and ON_OFF = 1 is cleared by setting RSTCTL.INTLRST to 1.
Note 2. The Response descriptor is not stored when the Internal Control Command is executed.

30.3.1.2 Response Descriptor

The Response Descriptor is a read-only structure describing the success or failure of a command, and the amount of data transferred.

The Response Descriptor is read from Response Queue with reads from Response Queue Port.

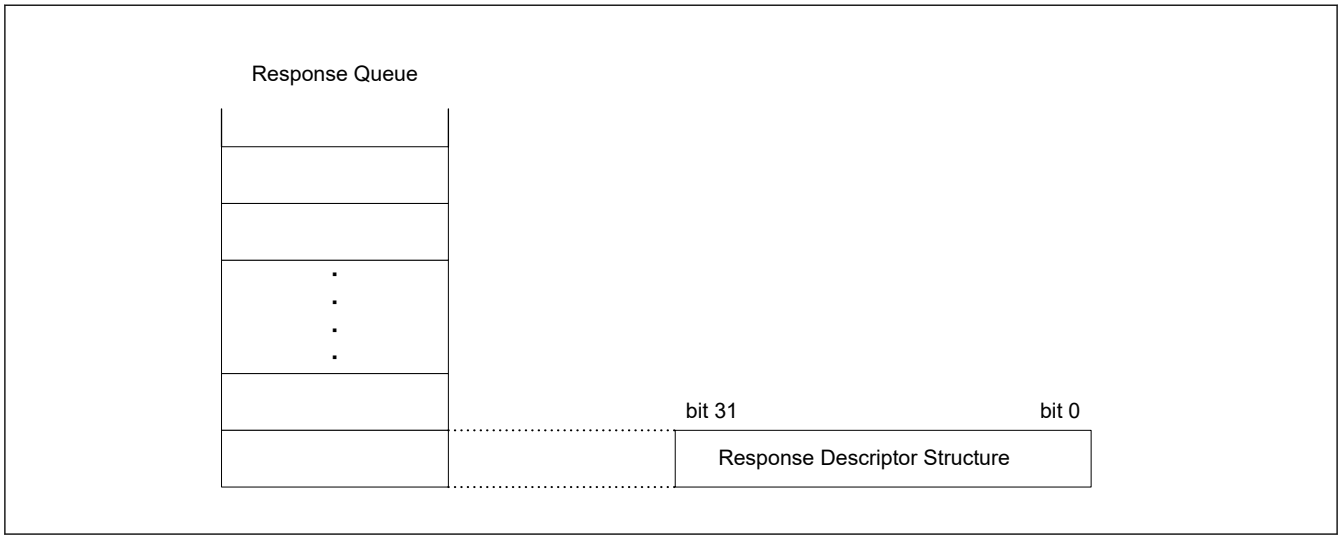


Figure 30.3 Response descriptor data structure

I3C provides a Response Descriptor for the following modes:

- I3C Master mode
- I3C Slave mode

Details of the Response Descriptor structure of each mode are shown in the following sections.

(1) I3C Master Mode

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	ERR_STATUS[3:0]				TID[3:0]				—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	DATA_LENGTH[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	DATA_LENGTH [15:0]	Data Length / Device Count The meaning of this field depends on the context: For Write Transfer: Remaining data length (in bytes) For Read Transfer: Received data length (in bytes) For Address Assignment: Remaining Device count	R
23:16	—	These bits are read as 0.	R

Bit	Symbol	Function	R/W
27:24	TID[3:0]	Command/Response Transaction ID Identification tag for the command. This value shall match one of commands sent on the Bus. 0x0-0x7: Valid Transaction IDs Others: Reserved	R
31:28	ERR_STATUS[3:0]	Response Error Status 0x0: SUCCESS: Transfer successful, no error 0x1: CRC: CRC Error 0x2: PARITY: Parity Error 0x3: FRAME: Frame Error 0x4: ADDR_HEADER: Address Header Error 0x5: NACK: Address NACKed or Dynamic Address Assignment NACKed 0x6: OVL: Receive Overflow or Transfer Underflow Error 0x8: ABORTED: Aborted 0x9: I^2C_WR_DATA_NACK: NACK received for the I^2C Write Data transfer 0xA: NOT_SUPPORTED: Command with specific parameters not supported by I3C implementation (for example, specific Internal Control codes may not be supported) Others: Reserved	R

Note: In I3C Master mode, when an abnormal command with a specific parameter that is not supported is stored in Command Descriptor, it is indicated as NOT_SUPPORTED (0xA) in ERR_STATUS [3:0].

(2) I3C Slave Mode

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	ERR_STATUS[3:0]				TID[3:0]				—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	DATA_LENGTH[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	DATA_LENGTH [15:0]	Data Length Remaining data length (in bytes) for Slave Interrupt Request	R
23:16	—	These bits are read as 0.	R
27:24	TID[3:0]	Command/Response Transaction ID Identification tag for the command. This value matches one of commands sent on the bus. 0x0-0x7: Valid Transaction IDs Others: Reserved	R
31:28	ERR_STATUS[3:0]	Response Error Status 0x0: SUCCESS: Transfer successful, no error. 0x3: FRAME: Frame Error 0x4: ADDR_HEADER: Address Header Error 0x5: NACK: Address NACK'ed or Dynamic Address Assignment NACK'ed 0x6: OVL: Receive Overflow or Transfer Underflow Error 0x8: ABORTED: Aborted 0xA: NOT_SUPPORTED: Command with specific parameters not supported by I3C implementation (for example, specific Internal Control codes may not be supported) Others: Reserved	R

Note: In I3C Slave mode, it is indicated as NOT_SUPPORTED (0xA) in ERR_STATUS[3:0] in the following cases:

- When an abnormal command with a specific parameter that is not supported is stored in the Command Descriptor.
- When the IBI to be transmitted is disabled in the CSECMD register.
- After the normal command for IBI transmission is prepared in the Command Queue, when that IBI is disabled in the CSECMD register by the DISEC CCC frame from the I3C Master.

30.3.1.3 IBI Status Descriptor

The IBI Status Descriptor is a read-only structure describing an IBI event received from a Slave device on the I3C Bus.

The IBI Status Descriptor is read from IBI Queue with reads from IBI Queue Port.

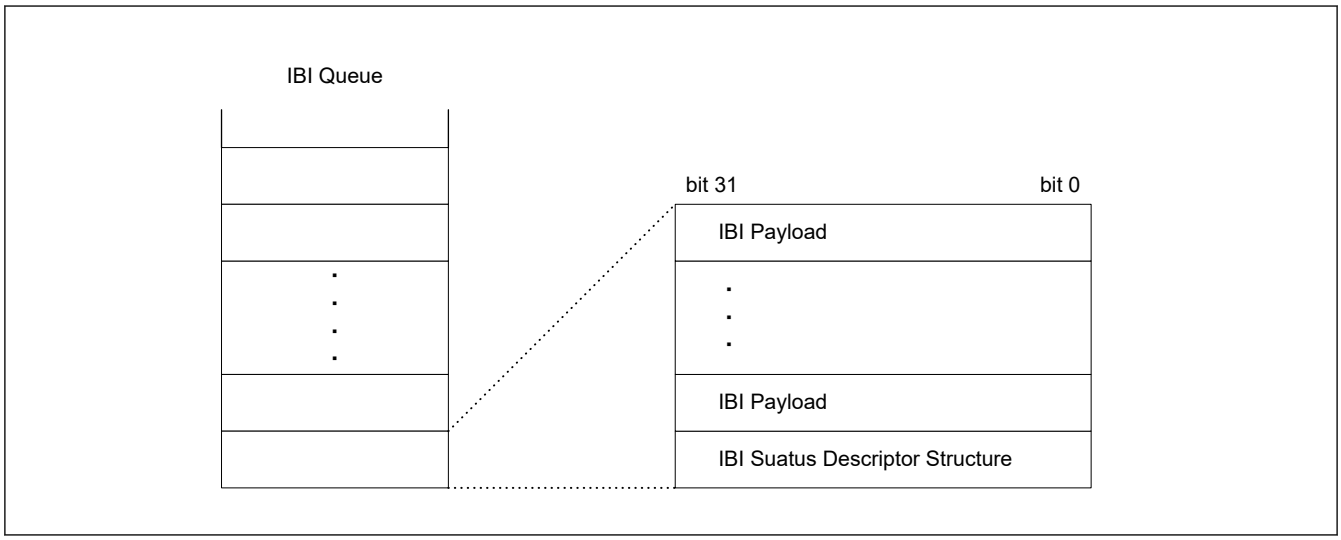

Figure 30.4 IBI status descriptor data structure

I3C provides a IBI Status Descriptor for the following mode:

- I3C Master mode

Details of the IBI Status Descriptor Structure are as follows.

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	IBI_ST	—	—	ERR_STATUS[2:0]			TS	LAST_STATUS	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	IBI_ID[7:0]								DATA_LENGTH[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	DATA_LENGTH[7:0]	IBI Data Length Number of data bytes in IBI Data.	R
15:8	IBI_ID[7:0]	IBI Received ID The meaning of this field depends on the context: For Slave Interrupt or Master Request: Bits 15:9 contain the Slave's Device Address, and bit 8 contains the R/W bit.	R
23:16	—	These bits are read as 0. The write value should be 0.	R
24	LAST_STATUS	Last IBI Status Last IBI status for the IBI transaction.	R

Bit	Symbol	Function	R/W
25	TS	IBI Time-stamp Present Indicates whether a time-stamp is available for the IBI. 0: OFF: IBI is not time-stamped. 1: ON: IBI is time-stamped.	R
28:26	ERR_STATUS[2:0]	IBI Error Status 0x0: SUCCESS 0x3: ERROR: FRAME (Frame Error) 0x4: ERROR: ADDR_HEADER (Address Header Error) 0x5: NACK: Address NACKed 0x7: ERROR: ABORT (Aborted to Master) Others: Reserved	R
30:29	—	These bits are read as 0.	R
31	IBI_ST	IBI Received Status Indicates how the received IBI was handled. 0: The IBI was handled with ACK. 1: NACK: The IBI was handled with NACK, and then Auto-Disabled.	R

LAST_STATUS bits (Last IBI Status)

Even if LAST_STATUS is set to 0, the software driver still evaluates the data payload length by examining the DATA_LENGTH field.

30.3.1.4 Receive Status Descriptor

The Receive Status Descriptor is a read-only structure describing the success or failure of read/write operation from the master, and the amount of data transferred.

The Receive Status Descriptor is read from Receive Status Queue with reads from Receive Status Queue Port.

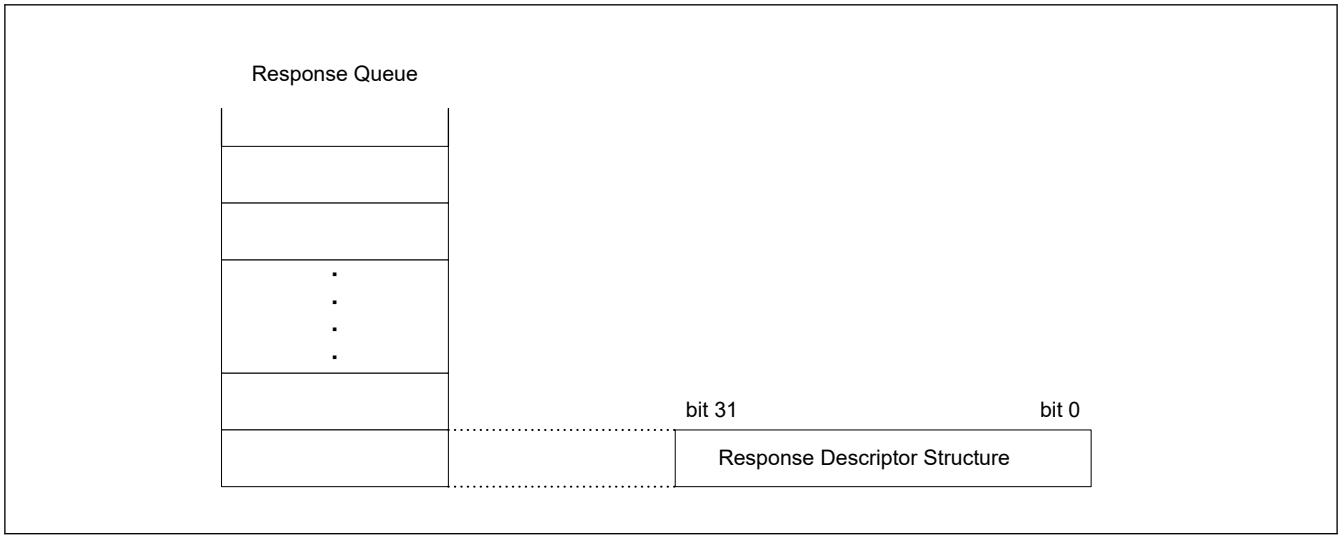

Figure 30.5 Receive status descriptor data structure

I3C provides a Receive Status Descriptor for the following mode:

- I3C Slave mode

Details of the Receive Status Descriptor structure of each mode are as follows.

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	DEV_INDEX[2:0]			TRANSFER_TYPE[1:0]		ERR_STATUS[2:0]			CMD[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	DATA_LENGTH[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	DATA_LENGTH [15:0]	Data Length The meaning of this field depends on the context. For Write Transfer: Received data length (in bytes) For Read Transfer: Transmitted data length (in bytes)	R
23:16	CMD[7:0]	The contents are different depending on the operation mode. Details are as follows: [SDR Private Message Mode] CMD[7]: R/W Type CMD[6:4]: Reserved CMD[3]: I3C_I^{2}C Type CMD[2:0]: Reserved [SDR CCC Mode] CCC code[7:0] [HDR-DDR mode] HDR CMD[7:0] 0x00 – 0x7F: Write Command 0x80 – 0xFF: Read Command [HDR-TSL/TSP mode] HDR CMD[7:0]	R
26:24	ERR_STATUS[2:0]	Error Status 0x0: SUCCESS 0x1: ERROR: CRC (CRC Error) 0x2: ERROR: PARITY (Parity Error) 0x3: ERROR: FRAME (Frame Error) 0x4: ERROR: ADDR_HEADER (Address Header Error) 0x5: ERROR: NACK (Slave NACKed) 0x6: ERROR: OVL (FIFO Overflow/Underflow) 0x7: ERROR: ABORT (Aborted to Master)	R
28:27	TRANSFER_TYPE [1:0]	Transfer Type 0 0: I3C SDR/I^{2}C Message 0 1: I3C CCC 1 0: I3C HDR-DDR 1 1: I3C HDR-TS	R
31:29	DEV_INDEX[2:0]	Device Index Indicates the SVDVADn index for the response with the transfer.	R

30.3.2 Details of Function

30.3.2.1 Operation Mode

The support relationship between the mode select (I3C mode / I^{2}C mode) and operation mode (Master / Slave) on the I3C bus or the I^{2}C bus is shown in Table 30.9.

Table 30.9 Support of operating mode

I3C/I^{2}C Bus	I3C mode		I^{2}C mode	
	Master	Slave	Master	Slave
I3C Bus	✓	✓	—	✓
I^{2}C Bus	—	—	✓	✓

Note: ✓: Supported

—: Un-Supported

30.3.2.1.1 Master Mode Operation

(1) I2C Master Operation

(a) Data Write Transfer (Single Buffer transfer)

In master transmit operation, I3C outputs the SCL clock and transmitted data signals as the master device, and the slave device returns acknowledgments. Figure 30.143 shows an example of usage of master transmission and Figure 30.6 to Figure 30.8 show the timing of operations in master transmission.

The following describes the procedure and operations for master transmission.

1. Initial settings. For details, see section 30.3.3.1. Initial Setting Flow.
2. Read the BCST.BFREF flag to check that the bus is open, and then set the CNDCTL.STCND bit to 1 (START condition issuance request). Upon receiving the request, I3C issues a START condition. At the same time, the BFREF flag bit is automatically set to 0, the BST.STCNDDF flag is automatically set to 1 and the STCND bit is automatically set to 0. At this time, if the START condition is detected and the internal levels for the SDA output state and the levels on the I3C_SDA line have matched while the STCND bit = 1, I3C recognizes that issuing of the START condition as requested by the STCND bit has been successfully completed, and bits CRMS and TRMD in the PRSST register are automatically set to 1, placing I3C in master transmit mode. The NTST.TDBEF0 flag is also automatically set to 1 in response to setting of the TRMD bit to 1.
3. Check that the NTST.TDBEF0 flag = 1, and then write the value for transmission (the slave address and the R/W# bit) to the NTDTBP0 register. Once the data for transmission are written to the NTDTBP0 register, the TDBEF0 flag is automatically set to 0, the data are transferred from the Normal Tx Data Buffer to the Shift Register, and the TDBEF0 flag is again set to 1. After the byte containing the slave address and R/W# bit has been transmitted, the value of the TRMD bit is automatically updated to select master transmit or master receive mode in accord with the value of the transmitted R/W# bit. If the value of the R/W# bit was 0, I3C continues in master transmit mode. Because the BST.NACKDF flag being 1 at this time indicates that no slave device recognized the address or there was an error in communications, write 1 to the CNDCTL.SPCND bit to issue a STOP condition. For data transmission with an address in the 10-bit format, start by writing 1111 0, the 2 higher-order bits of the slave address, and W to the NTDTBP0 register as the first address transmission. Then, as the second address transmission, write the 8 lower-order bits of the slave address to the NTDTBP0 register.
4. After confirming that the NTST.TDBEF0 flag = 1, write the data for transmission to the NTDTBP0 register. I3C automatically holds the I3C_SCL line low until the data for transmission are ready or a STOP condition is issued.
5. After all bytes of data for transmission have been written to the NTDTBP0 register, wait until the value of the BST.TENDF flag returns to 1, and then set the CNDCTL.SPCND bit to 1 (STOP condition issuance request). Upon receiving a STOP condition issuance request, I3C issues the STOP condition.
6. Upon detecting the STOP condition, I3C automatically sets bits CRMS and TRMD in the PRSST register to 00 and enters slave receive mode. Furthermore, it automatically sets the TDBEF0 and TENDF flags to 0, and sets the BST.SPCNDDF flag to 1.
7. After checking that the BST.SPCNDDF flag = 1, set the BST.NACKDF and SPCNDDF flags to 0 for the next transfer operation.

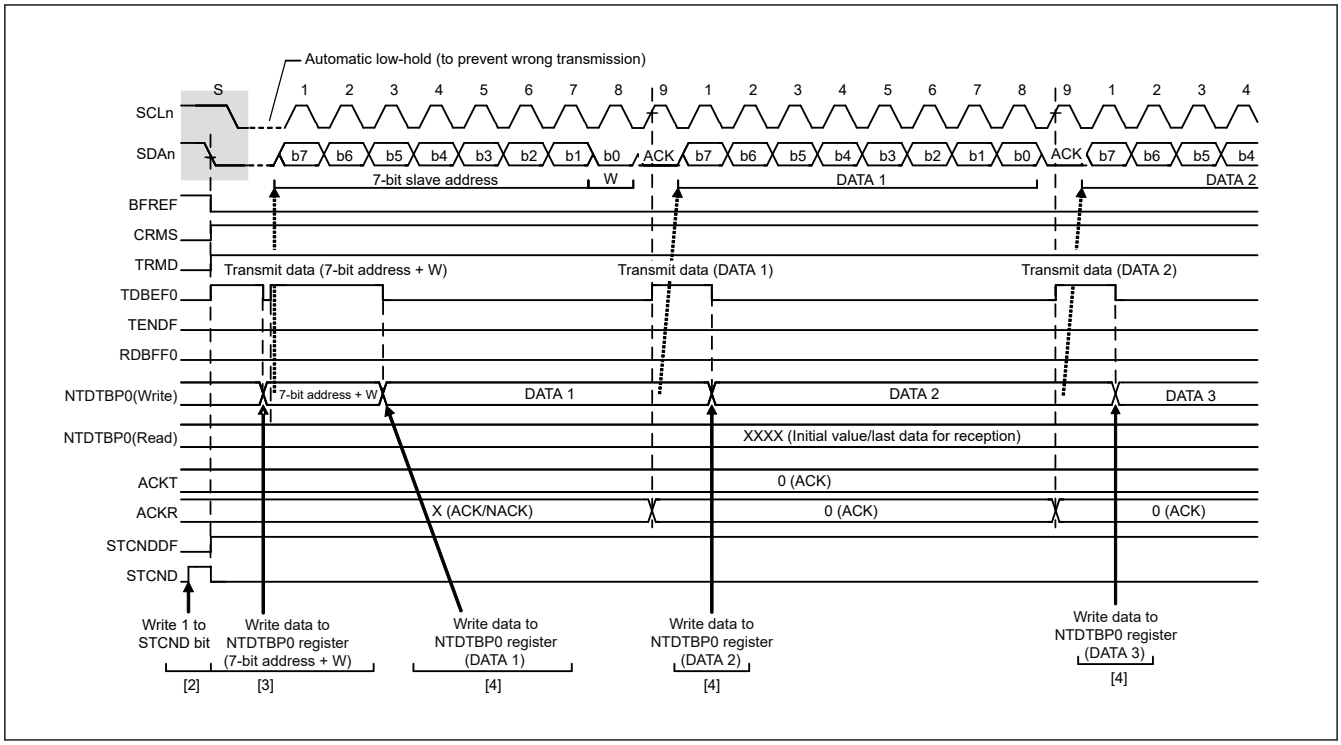

Figure 30.6 Master transmit operation timing (1) (7-bit address format)

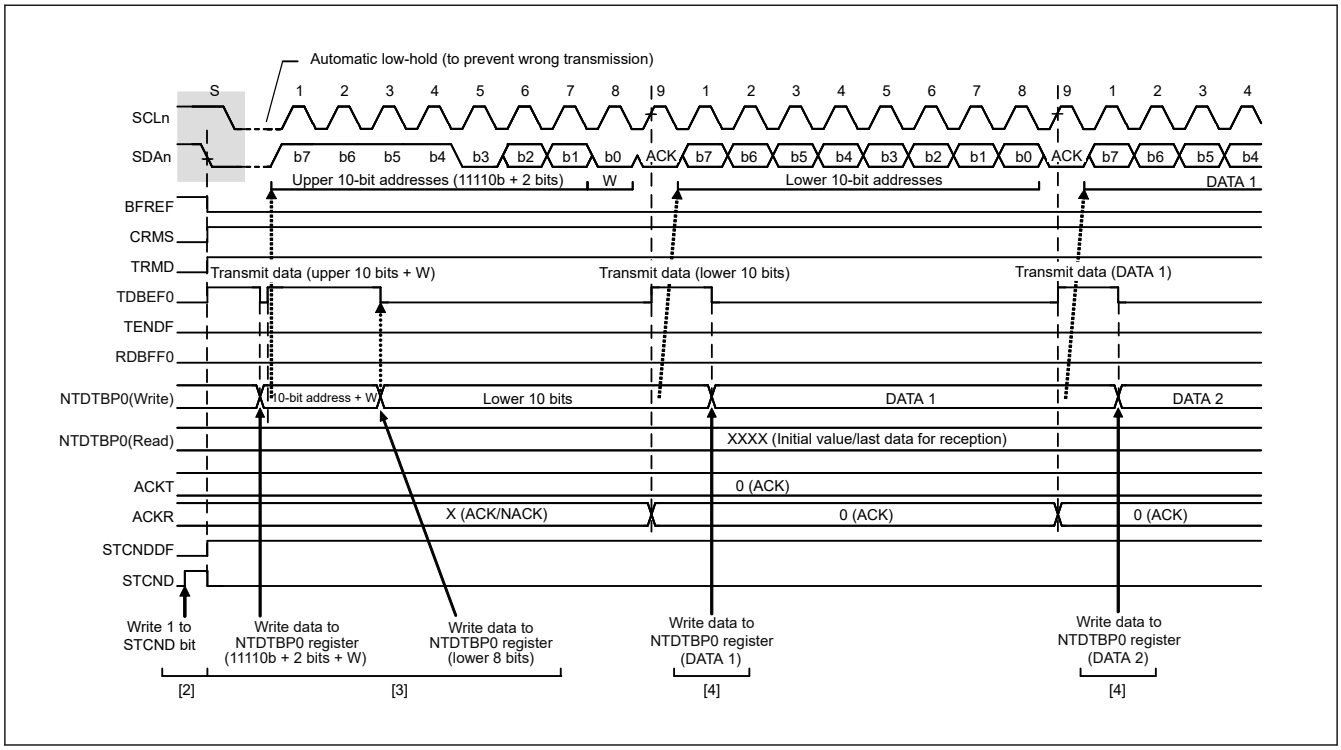

Figure 30.7 Master transmit operation timing (2) (10-bit address format)

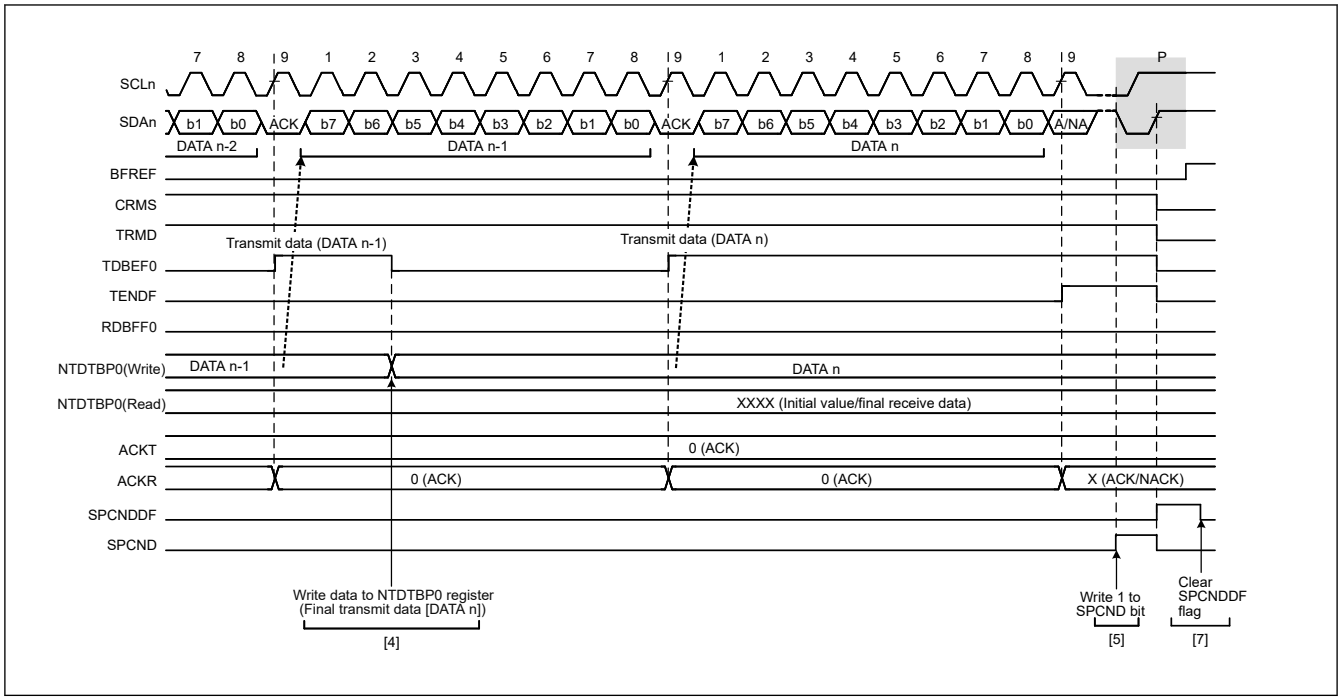

Figure 30.8 Master transmit operation timing (3)

(b) Data Read Transfer (Single Buffer transfer)

In master receive operation, I3C as a master device outputs the SCL clock, receives data from the slave device, and returns acknowledgments. Because I3C must start by sending a slave address to the corresponding slave device, this part of the procedure is performed in master transmit mode, but the subsequent steps are in master receive mode.

Figure 30.144 and Figure 30.145 show examples of usage of master reception (7-bit address format) and Figure 30.9 to Figure 30.11 show the timing of operations in master reception.

The following describes the procedure and operations for master reception.

1. Initial settings. For details, see section 30.3.3.1. Initial Setting Flow.
2. Read the BCST.BFREF flag to check that the bus is open, and then set the CNDCTL.STCND bit to 1 (START condition issuance request). Upon receiving the request, I3C issues a START condition. When I3C detects the START condition, the BFREF flag is automatically set to 0 and the BST.STCNDDF flag is automatically set to 1 and the STCND bit is automatically set to 0. At this time, if the START condition is detected and the levels for the SDA output and the levels on the I3C_SDA line have matched while the STCND bit = 1, I3C recognizes that issuing of the START condition as requested by the STCND bit has been successfully completed, and bits CRMS and TRMD in the PRSST register are automatically set to 1, placing I3C in master transmit mode. The NTST.TDBEF0 flag is also automatically set to 1 in response to setting of the TRMD bit to 1.
3. Check that the NTST.TDBEF0 flag = 1, and then write the value for transmission (the first byte indicates the slave address and value of the R/W# bit) to the NTDTBP0 register. Once the data for transmission are written to the NTDTBP0 register, the TDBEF0 flag is automatically set to 0, the data are transferred from the Normal Tx Data Buffer to the Shift Register, and the TDBEF0 flag is again set to 1. Once the byte containing the slave address and R/W# bit has been transmitted, the value of the PRSST.TRMD bit is automatically updated to select transmit or receive mode in accord with the value of the transmitted R/W# bit. If the value of the R/W# bit was 1, the TRMD bit is set to 0 on the rising edge of the ninth cycle of SCL clock, placing I3C in master receive mode. At this time, the TDBEF0 flag is set to 0. The NTST.RDBFF0 flag is automatically set to 1 when ACK response is received from the slave device. If the slave device is not recognized or a communication failure occurs, the BST.NACKDF flag will be set to 1. At this time, set 1 to the CNDCTL.SPCND bit to issue a STOP condition. For master reception from a device with a 10-bit address, start by using master transmission to issue the 10-bit address, and then issue a Repeated START condition. After that, transmitting 1111 0, the two higher-order bits of the slave address, and the R bit places I3C in master receive mode.
4. Dummy read the NTDTBP0 register after confirming that the NTST.RDBFF0 flag = 1; this makes I3C start output of the SCL clock and start data reception.
5. After 1 byte of data has been received, the NTST.RDBFF0 flag is set to 1 on the rising edge of the eighth or ninth cycle of SCL clock (the clock signal) as selected by the SCSTRCTL.ACKTWE bit. Reading the NTDTBP0 register at

this time will produce the received data, and the RDBFF0 flag is automatically set to 0 at the same time. Furthermore, the value of the acknowledgment field received during the ninth cycle of SCL clock is returned as the value set in the ACKCTL.ACKT bit. Furthermore, if the next byte to be received is the next to last byte, set the SCSTRCTL.RWE bit to 1 (for wait insertion) before reading the NTDTBP0 register (containing the second byte from last). As well as enabling NACK output even in the case of delays in processing to set the ACKCTL.ACKT bit to 1 (NACK) in step 6, due to other interrupts, etc., this fixes the I3C_SCL line to the low level on the falling edge of the ninth clock cycle in reception of the last byte, so the state is such that issuing a STOP condition is possible.

6. When the SCSTRCTL.ACKTWE bit = 0 and the slave device must be notified that it is to end transfer for data reception after transfer of the next (final) byte, set the ACKCTL.ACKT bit to 1 (NACK).
7. After reading the byte before last from the NTDTBP0 register, if the value of the NTST.RDBFF0 flag is confirmed to be 1, write 1 to the CNDCTL.SPCND bit (STOP condition issuance request) and then read the last byte from the NTDTBP0 register. When 1 is written to the CNDCTL.SPCND bit, I3C is released from the wait state and issues the STOP condition after low-level output in the ninth clock cycle is completed or the I3C_SCL line is released from the low-hold state.
8. Upon detecting the STOP condition, I3C automatically sets bits CRMS and TRMD in the PRSST register to 00 and enters slave receive mode. Furthermore, detection of the STOP condition leads to setting of the BST.SPCNDDF flag to 1.
9. After checking that the BST.SPCNDDF flag = 1, set the BST.NACKDF and SPCNDDF flags to 0 for the next transfer operation.

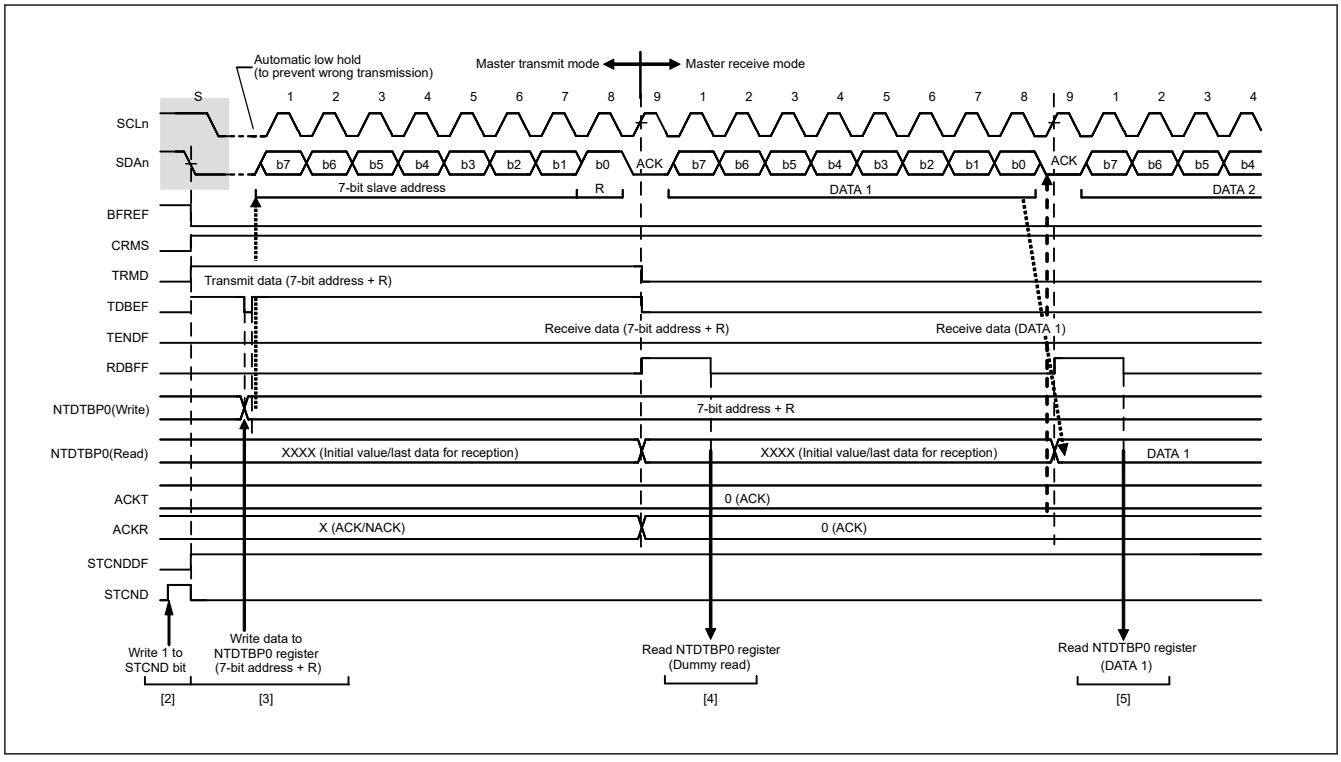

Figure 30.9 Master receive operation timing (1) (7-bit address format, when ACKTWE = 0)

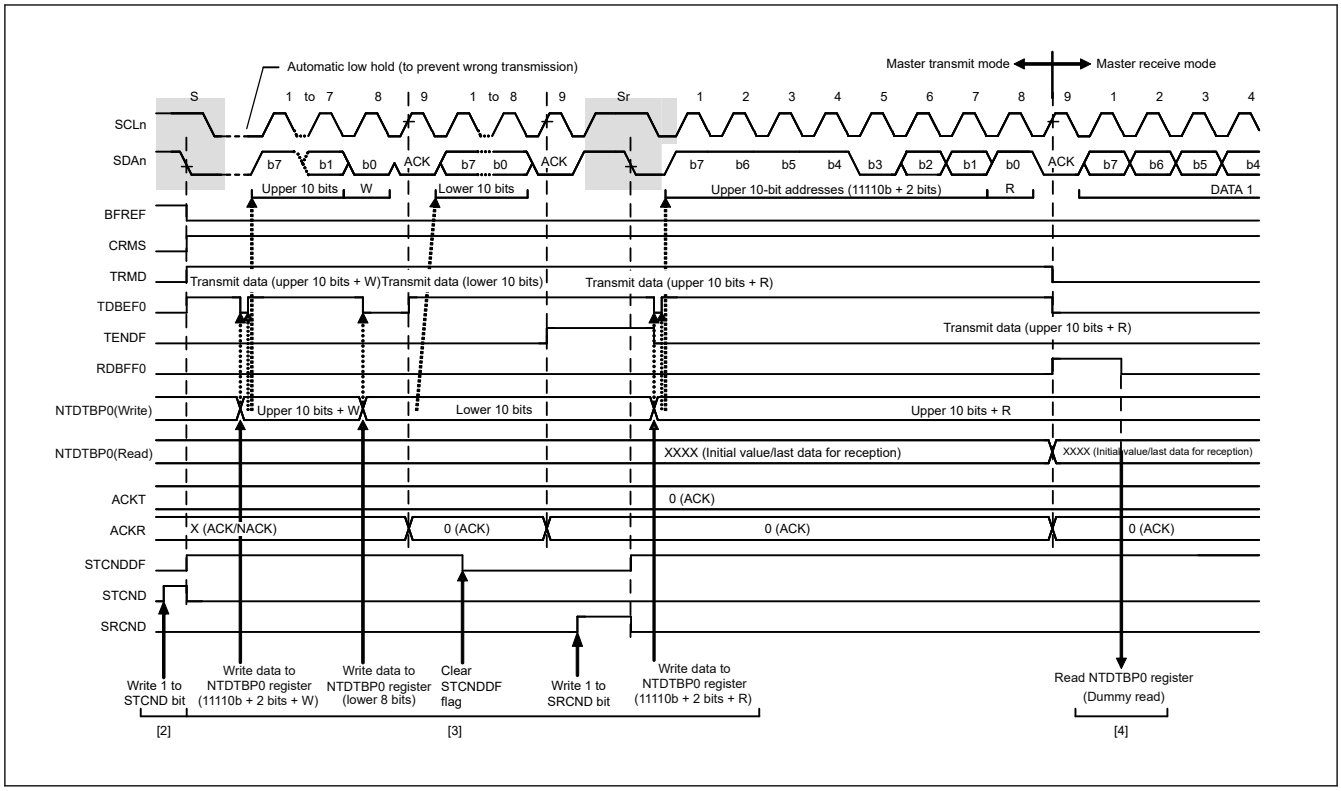

Figure 30.10 Master receive operation timing (2) (10-bit address format, when ACKTWE = 0)

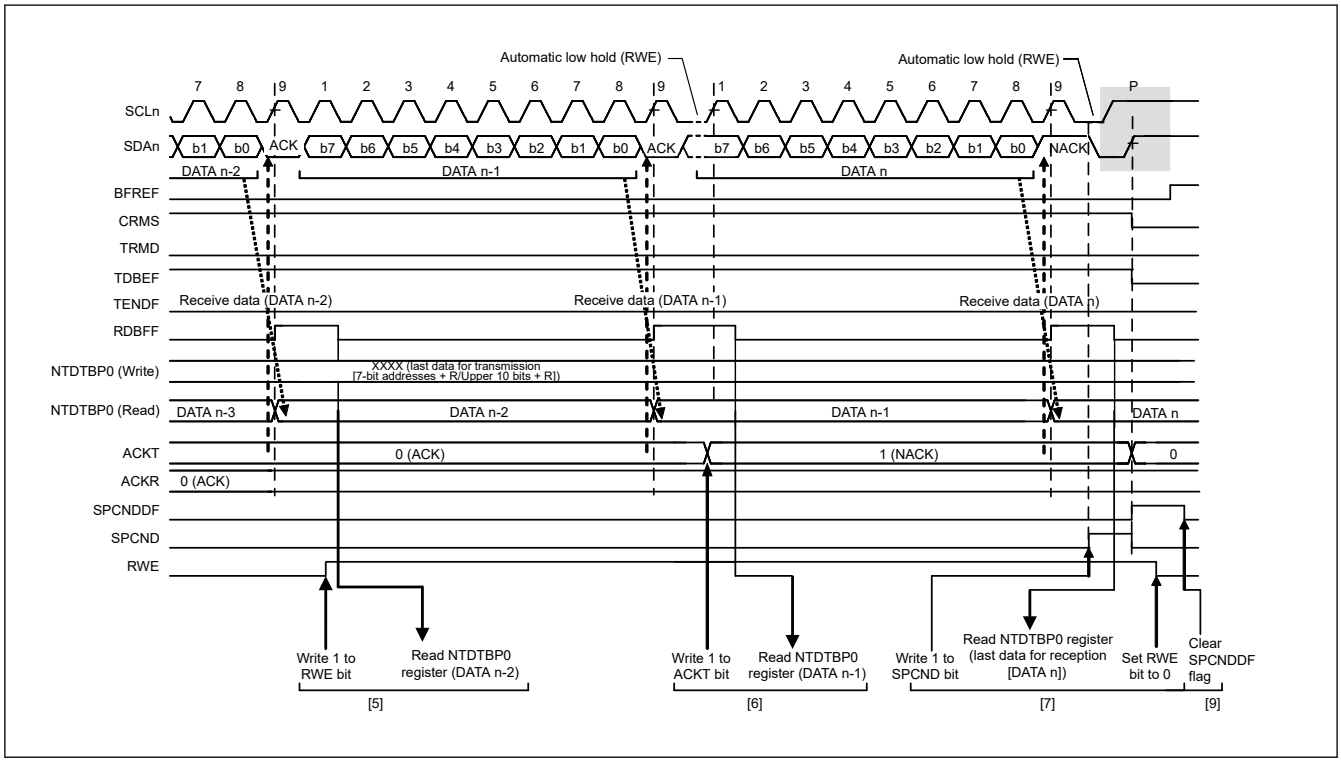

Figure 30.11 Master receive operation timing (3) (when ACKTWE = 0)

(2) I3C Master Operation

(a) Dynamic Address Assign Procedure

After initializing I3C, first execute Dynamic Address Assign Procedure for I3C Slave connected on the I3C Bus. The following describes the procedure.

1. Initial setting (see section 30.3.3.1.2. I3C Initial Setting Flow for details)
2. Execute Dynamic Address Assign with ENTDAA or SETDASA Common Command Code (CCC) for I3C Slave set in DAT (DATBASm register).
   Write Command Descriptor (Address Assign Command) to Command Buffer via the NCMDQP register.
3. When Command Descriptor is written to Command Buffer, Transaction is issued on I3C Bus.
4. When ENTDAA is specified for CMD[7:0] of Address Assign Command:
   Execute Dynamic Address Assign for I3C Slave for the number of DATs specified by DEV_COUNT[3:0] starting with DAT specified by DEV_INDEX[4:0] of Address Assign Command.
   When SETDASA is specified for CMD[7:0] of Address Assign Command:
   Execute Dynamic Address Assign for I3C Slave indicated by DAT specified by DEV_INDEX[4:0] of Address Assign Command.
5. In case of ENTDAA, the Provisional ID, BCR, DCR transmitted from I3C Slave is stored in Receive Data Buffer (BCR is also automatically stored in the MSDCTm register).
   Read the Provisional ID, BCR, and DCR from the Receive Data Buffer via the NTDTBPn register with an interrupt by RDBFF0 = 1.
6. When execution of Dynamic Address Assign is completed, issue STOP condition and store the Response Descriptor into the Response Buffer.
7. Read the Response Descriptor via the NRSPQP register and check the status.
8. Check whether the value of the DATA_LENGTH[15:0] bits of the Response Descriptor matches the value of DEV_COUNT[3:0] of the Address Assign Command.

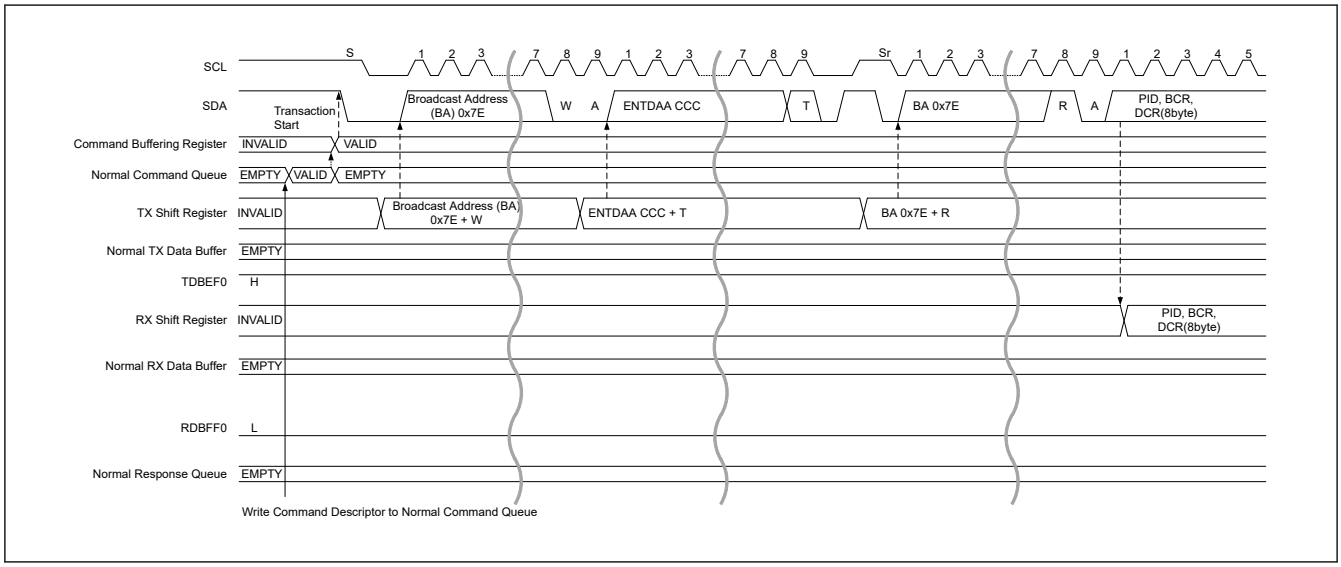

Figure 30.12 Dynamic address assign procedure (ENTDAA CCC) timing (1/3)

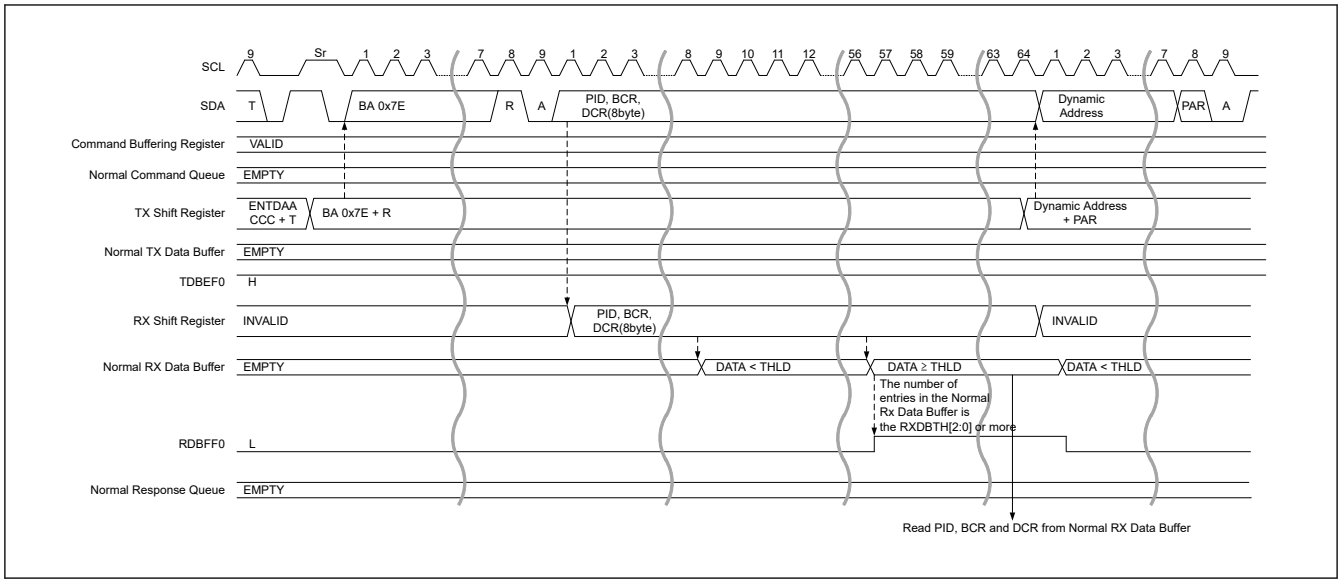

Figure 30.13 Dynamic address assign procedure (ENTDAA CCC) timing (2/3)

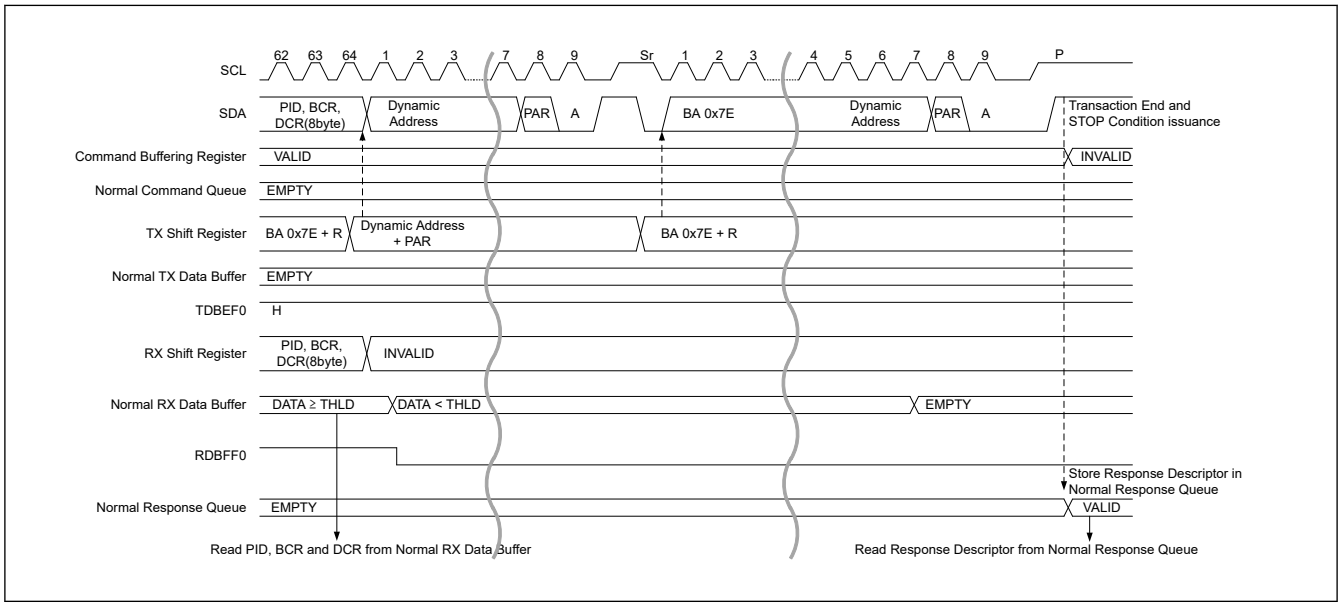

Figure 30.14 Dynamic address assign procedure (ENTDAA CCC) timing (3/3)

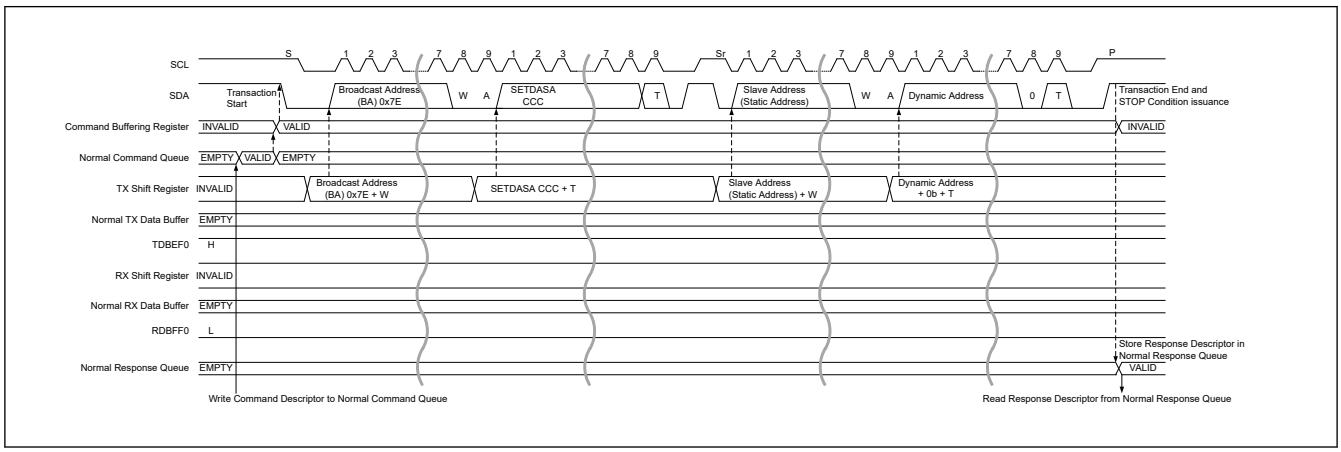

Figure 30.15 Dynamic address assign procedure (SETDASA CCC) timing

(b) SDR Data Write Transfer

1. Write data for transmission to the Tx Data Buffer via the NTDTBPn register.
2. Write a Command Descriptor (Immediate Transfer Command or Regular Transfer Command or Combo Transfer Command) for Data Transfer to the Command Buffer via the NCMDQP register.
3. When Command Descriptor is written to Command Buffer, transaction is issued on I3C Bus.
   When NACK is received with the Address Header, transaction of the same command is automatically issued according to the NACK Retry Count value (DATBASm.DVNACK) of DAT.
4. If data for transmission still remain, write data for transmission by an interrupt with TDBEF0 = 1 to the Tx Data Buffer via the NTDTBPn register.
5. When data transmission for the number of Data Length specified by the DATA_LENGTH[15:0] bits of the Command Descriptor is completed, the Repeated START condition or STOP condition is issued and the Response Descriptor is stored in the Response Buffer.
6. Read the Response Descriptor via the NRSPQP register and check the status.
7. Check that the value of the DATA_LENGTH[15:0] bits of the Response Descriptor is 0.

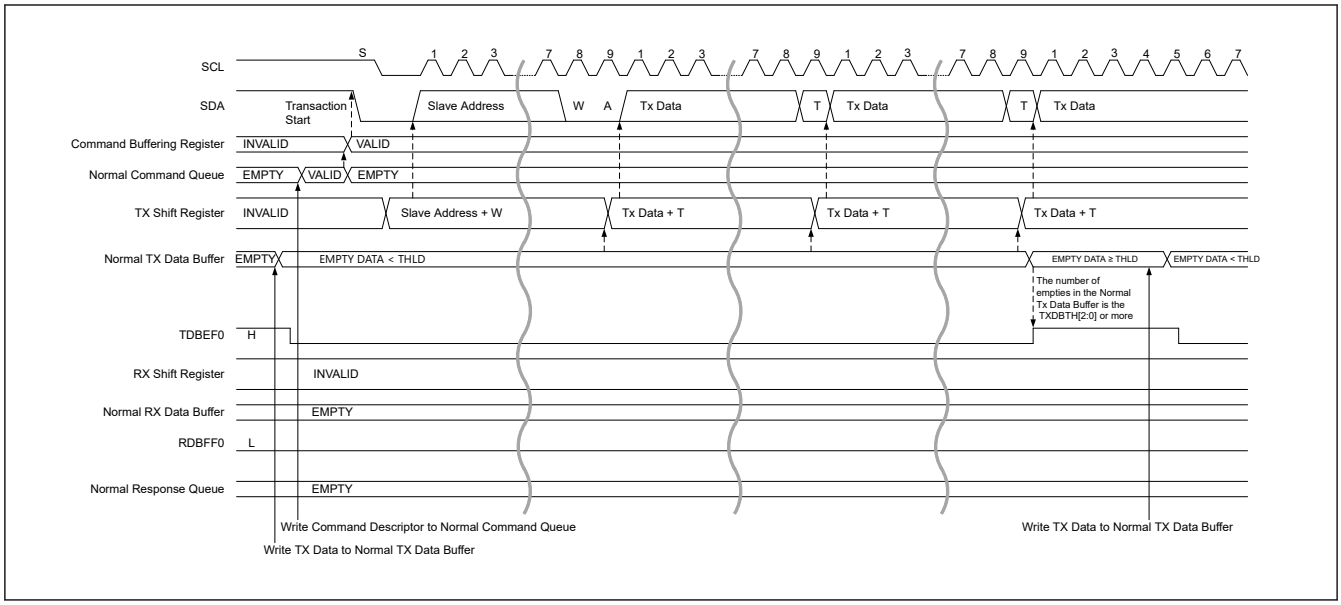

Figure 30.16 SDR data write transfer timing (1/2)

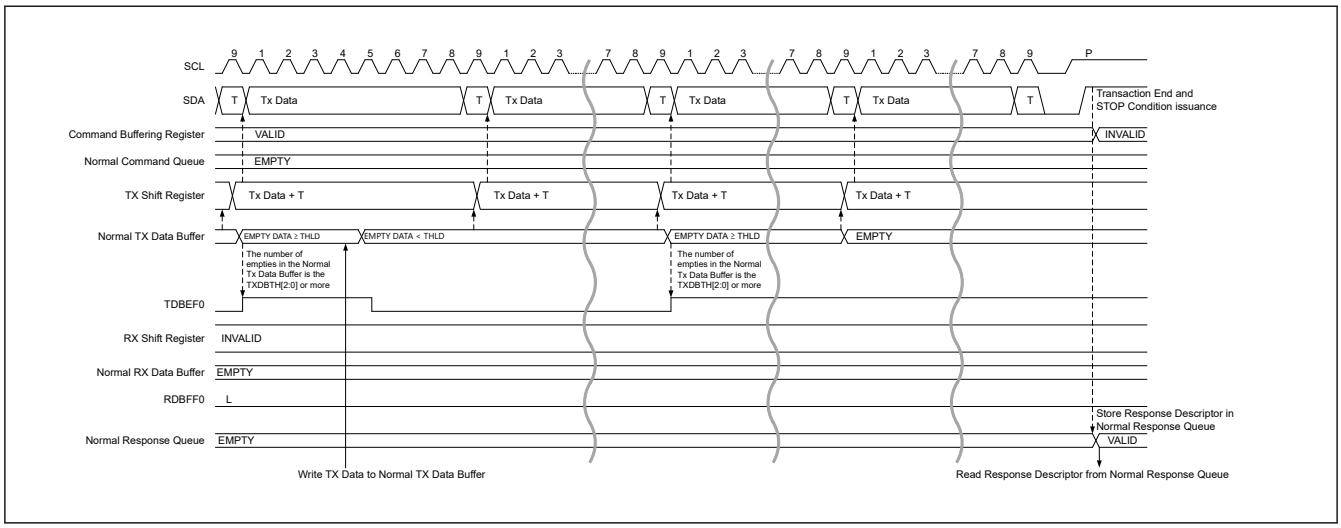

Figure 30.17 SDR data write transfer timing (2/2)

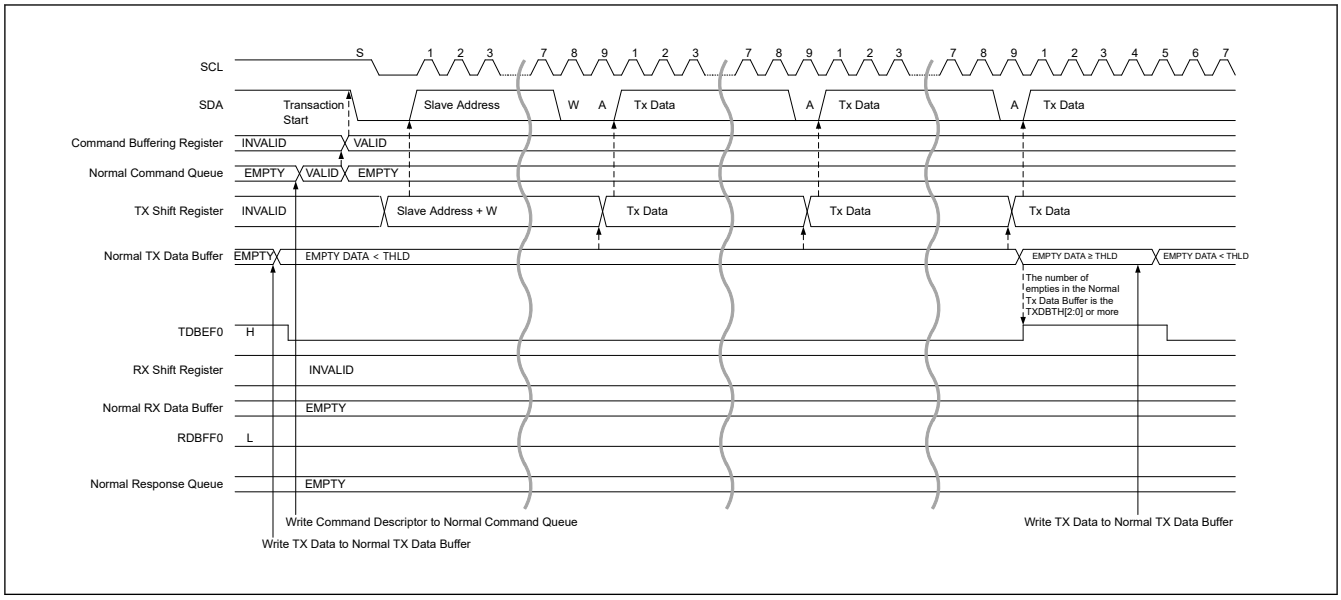

Figure 30.18 Legacy I²C message data write timing (1/2)

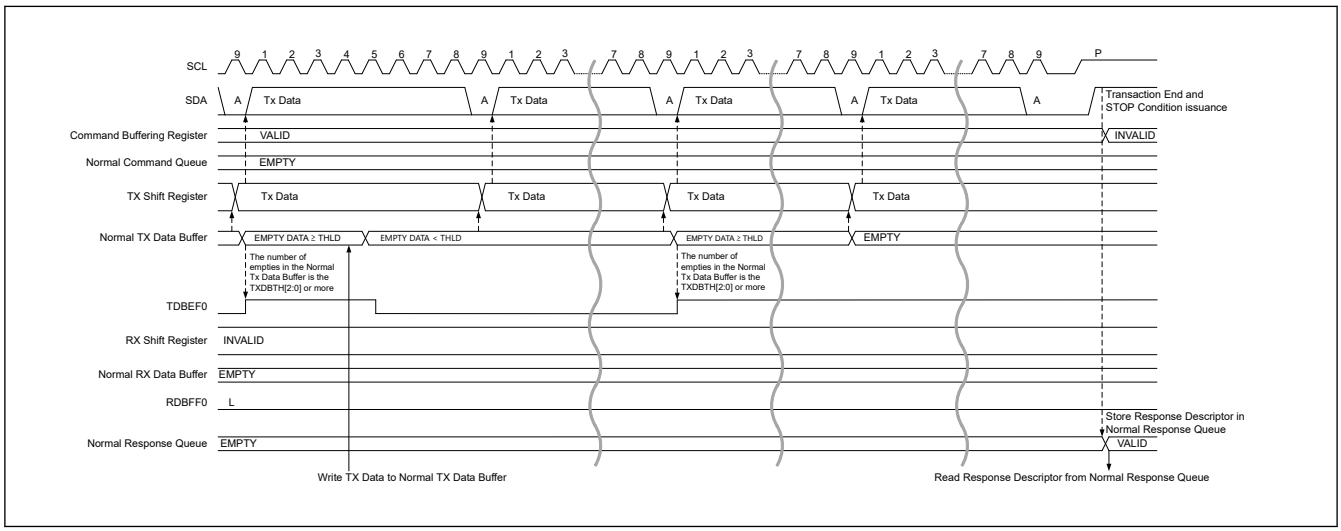

Figure 30.19 Legacy I²C message data write timing (2/2)

(c) SDR Data Read Transfer

1. Write a Command Descriptor (Immediate Transfer Command or Regular Transfer Command or Combo Transfer Command) for Data Transfer to the Command Buffer via the NCMDQP register.
2. When Command Descriptor is written to Command Buffer, transaction is issued on I3C Bus.
   When NACK is received with the Address Header, transaction of the same command is automatically issued according to the NACK Retry Count value (DATBASm.DVNACK) of DAT.
3. Data received from the I3C Slave is stored in the Receive Data Buffer.
4. With the RDBFF0 = 1 interrupt, the received data is read from the Receive Data Buffer via the NTDTBPn register.
5. SDR:
   Detecting Low in T-bit or receiving Data for the number of Data Length specified by the DATA_LENGTH[15:0] bits of Command Descriptor is completed, issue Repeated START condition or STOP condition and store the Response Descriptor into the Response Buffer.
   Legacy I²C Message:
   When data reception for the number of Data Length specified by the DATA_LENGTH[15:0] bits of Command Descriptor is completed, NACK is issued. After that, issue a Repeated START condition or STOP condition and store the Response Descriptor into the Response Buffer.
6. Read the Response Descriptor via the NRSPQP register and check the status.

7. Check whether the value of the DATA_LENGTH[15:0] bits of the Response Descriptor matches the data length setting value of the Command Descriptor.

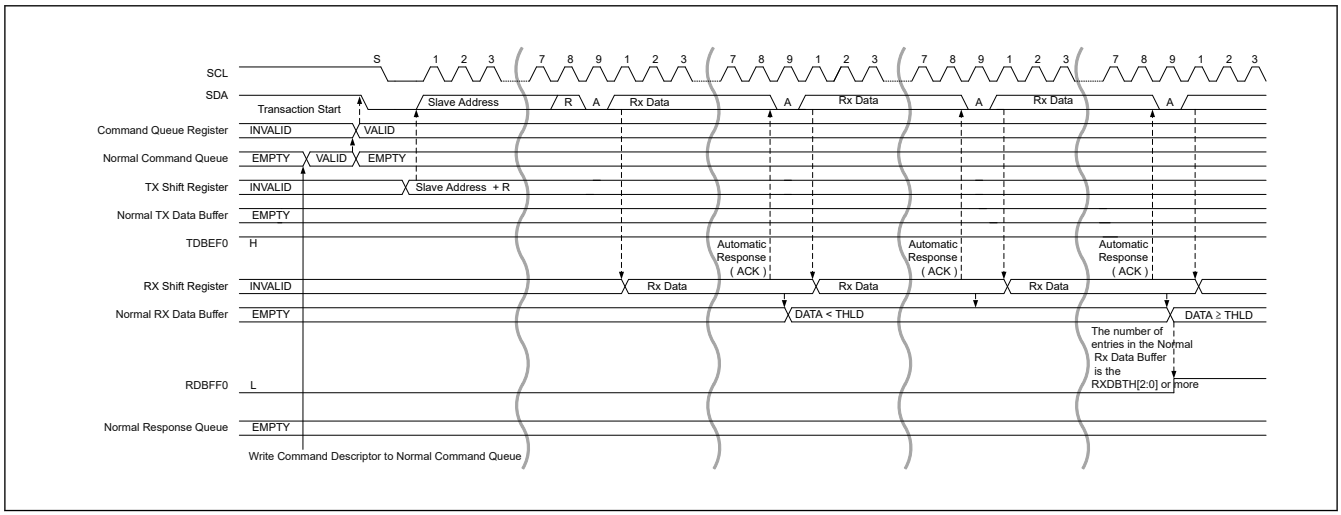

Figure 30.20 SDR data read transfer timing (1/2)

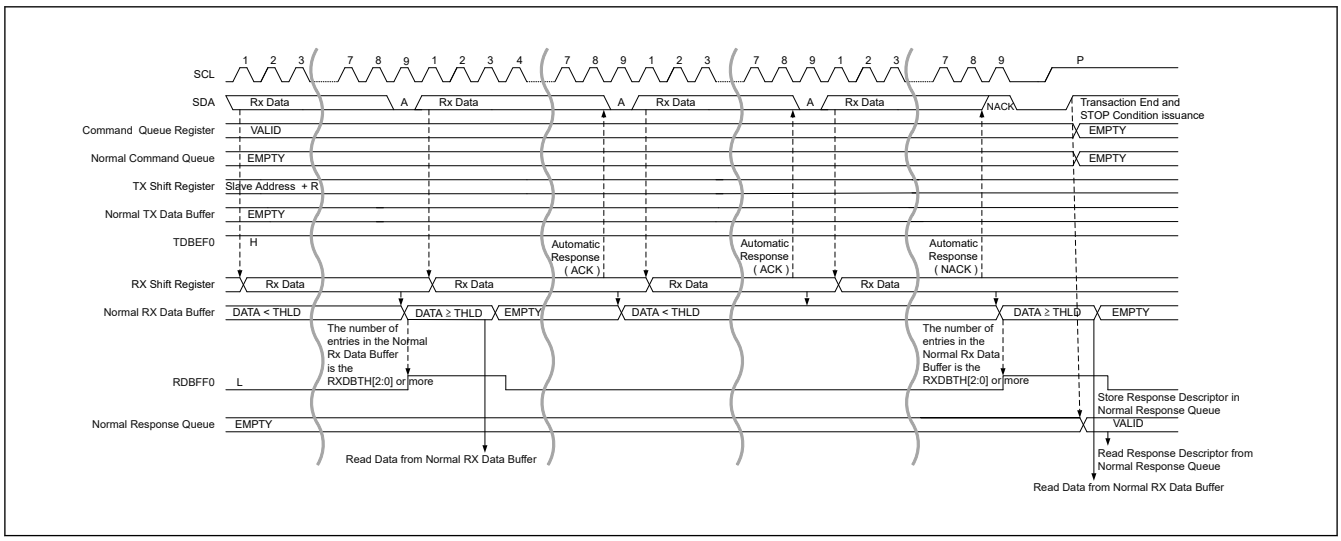

Figure 30.21 SDR data read transfer timing (2/2)

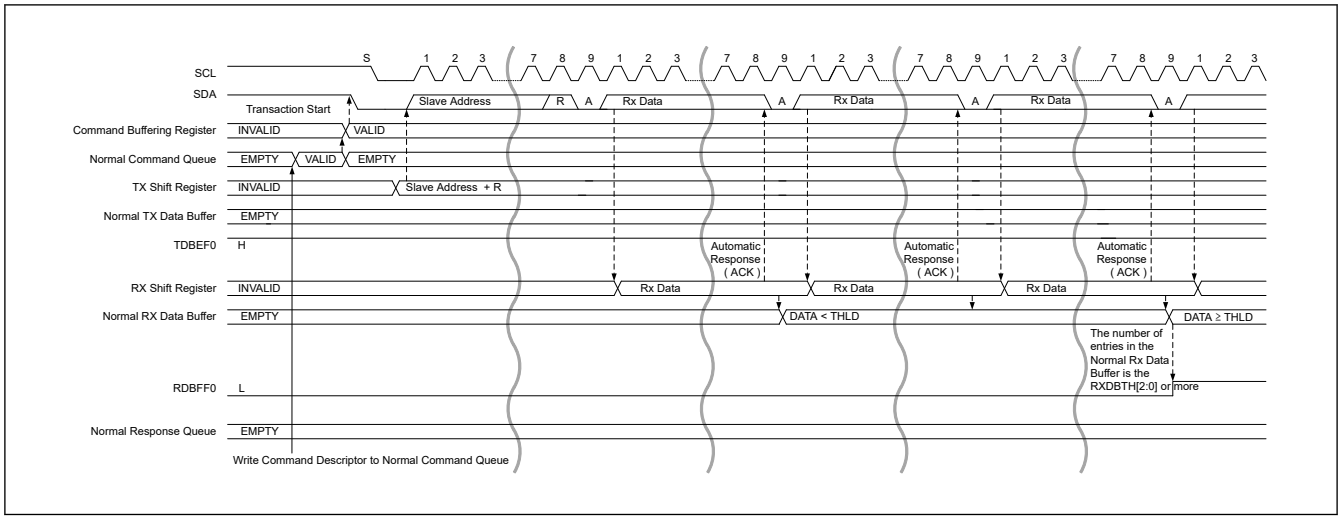

Figure 30.22 Legacy I²C message data read transfer timing (1/2)

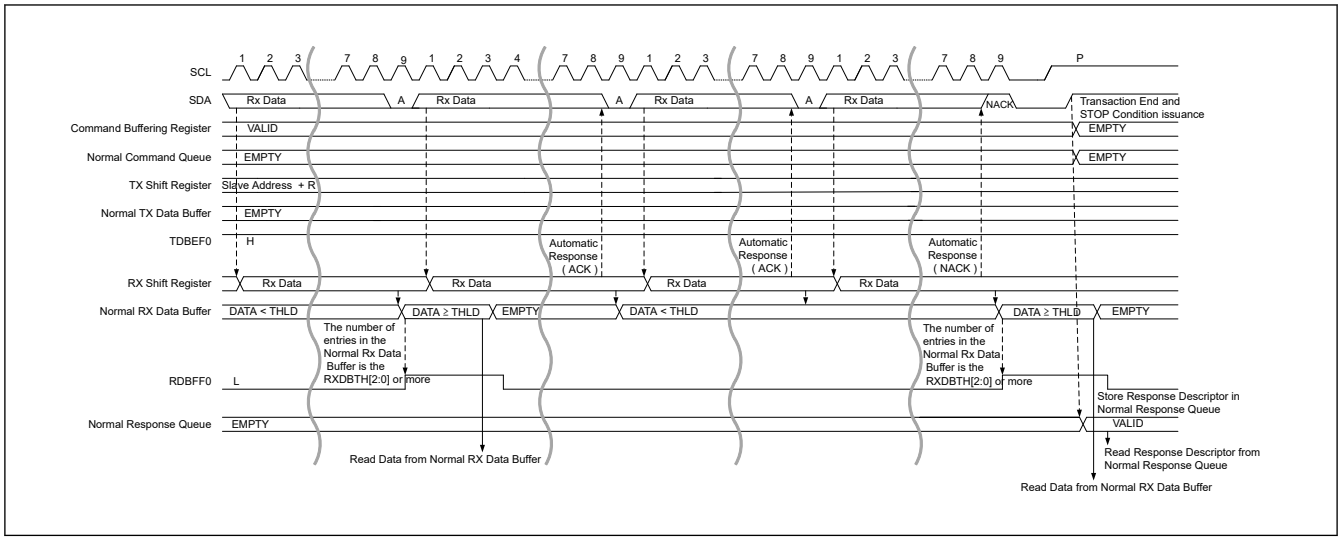

Figure 30.23 Legacy I²C message data read transfer timing (2/2)

(d) HDR Data Write Transfer

1. Write data for transmission to the Tx Data Buffer via the NTDTBPn register.
2. Write a Command Descriptor (Immediate Transfer Command or Regular Transfer Command or Combo Transfer Command) for Data Transfer to the Command Buffer via the NCMDQP register.
3. When Command Descriptor is written to Command Buffer, transaction is issued on I3C Bus.
   When NACK is received with the Address Header, transaction of the same command is automatically issued according to the NACK Retry Count value (DATBASm.DVNACK) of DAT.
4. If data for transmission still remains, write data for transmission by an interrupt with TDBEF0 = 1 to the Tx Data Buffer via the NTDTBPn register.
5. HDR-DDR:
   When the data transmission for the number of Data Length specified by the DATA_LENGTH[15:0] bits of the Command Descriptor is completed, CRC Word is transmitted. After that, issue HDR Restart Pattern or HDR Exit Pattern + STOP condition and store the Response Descriptor into Response Buffer.
   HDR-Ternary:
   When the data transmission for the number of Data Length specified by the DATA_LENGTH[15:0] bits of the Command Descriptor is completed, the HDR Restart Pattern or HDR Exit Pattern + STOP condition is issued and the Response Descriptor is stored in the Response Buffer.
6. Read the Response Descriptor via the NRSPQP register and check the status.
7. Check that the value of the DATA_LENGTH[15:0] bits of the Response Descriptor is 0.

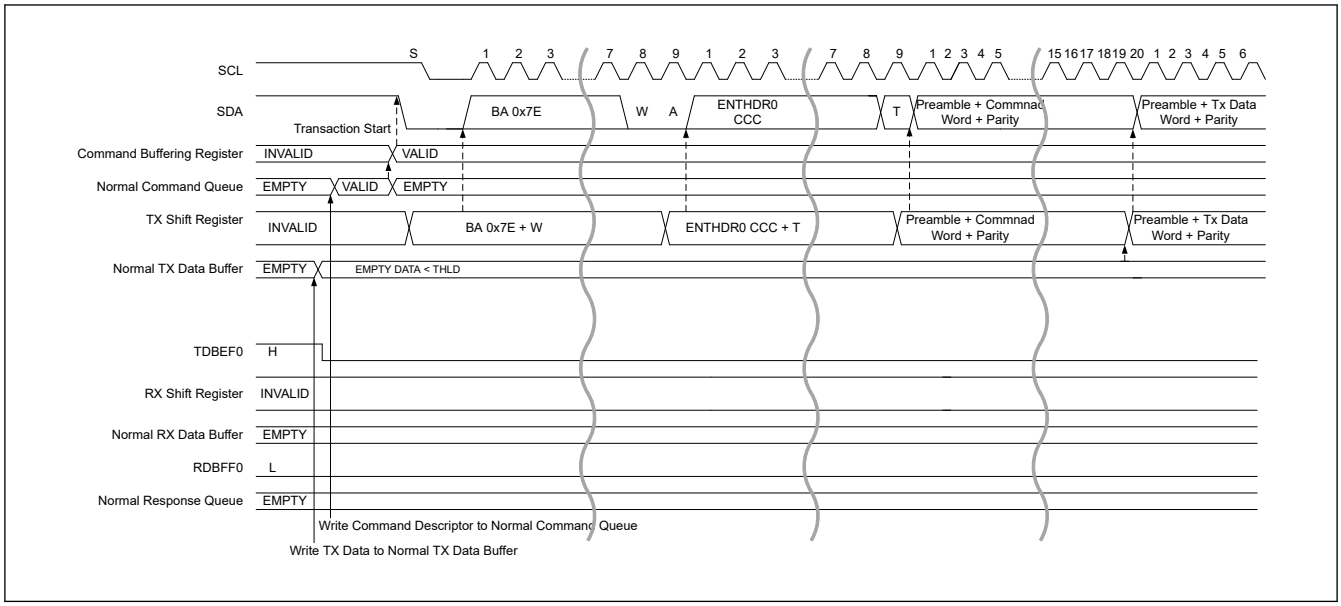

Figure 30.24 HDR data write transfer (HDR-DDR) timing (1/4)

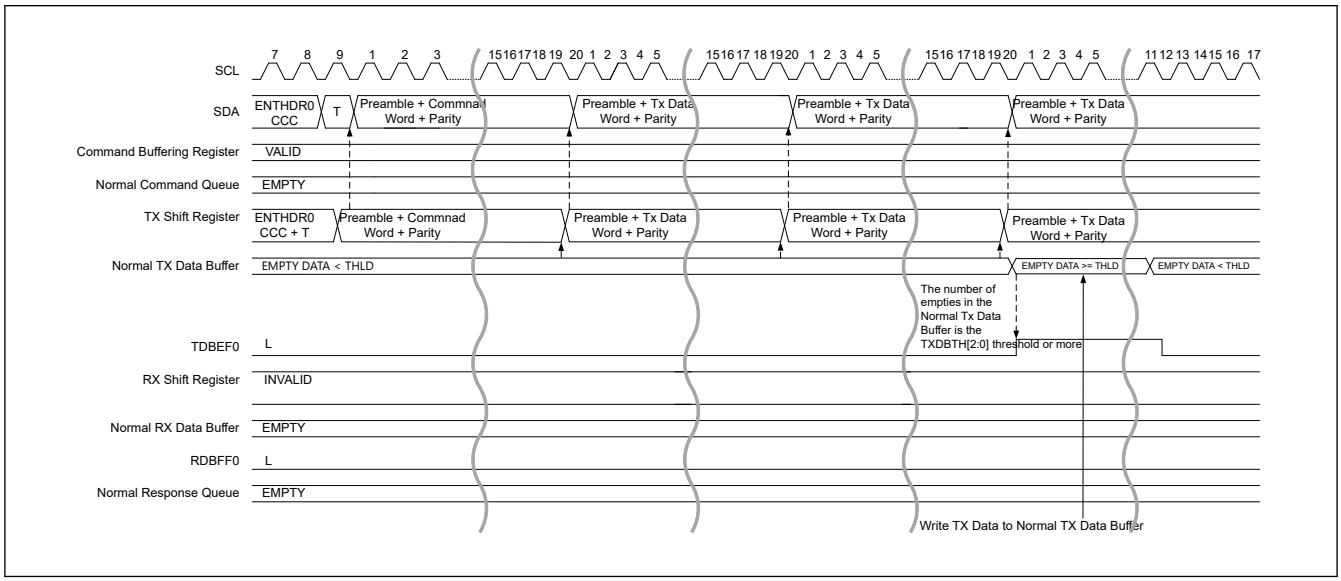

Figure 30.25 HDR data write transfer (HDR-DDR) timing (2/4)

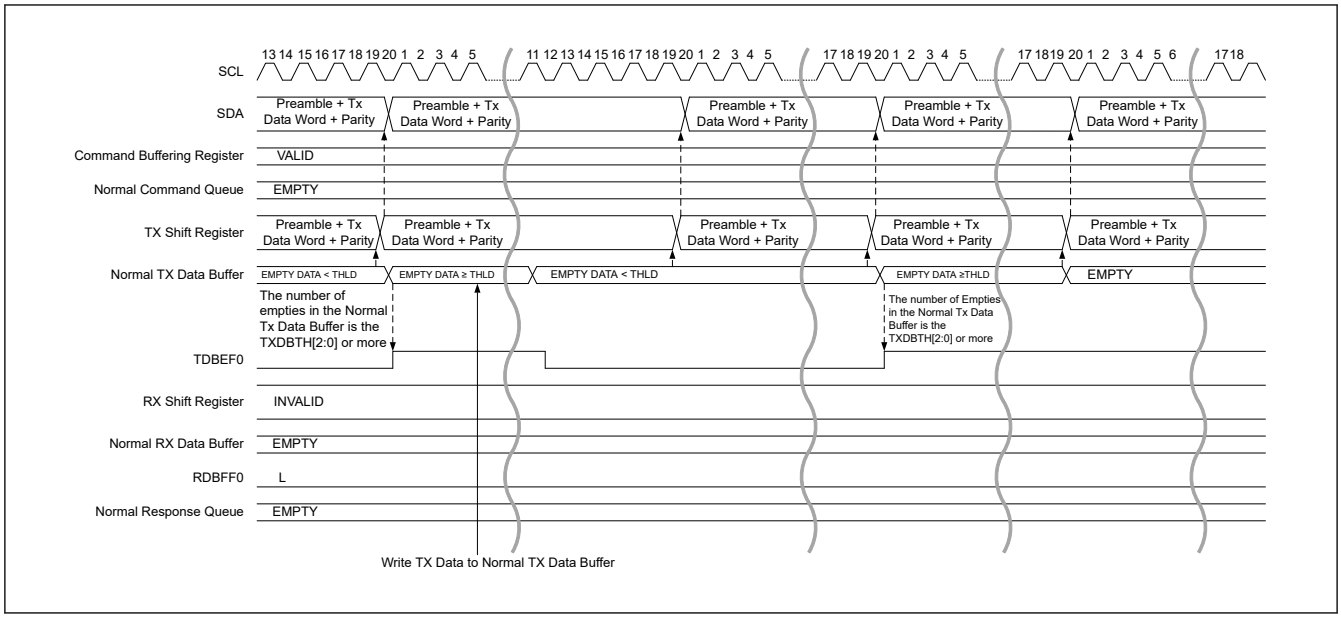

Figure 30.26 HDR data write transfer (HDR-DDR) timing (3/4)

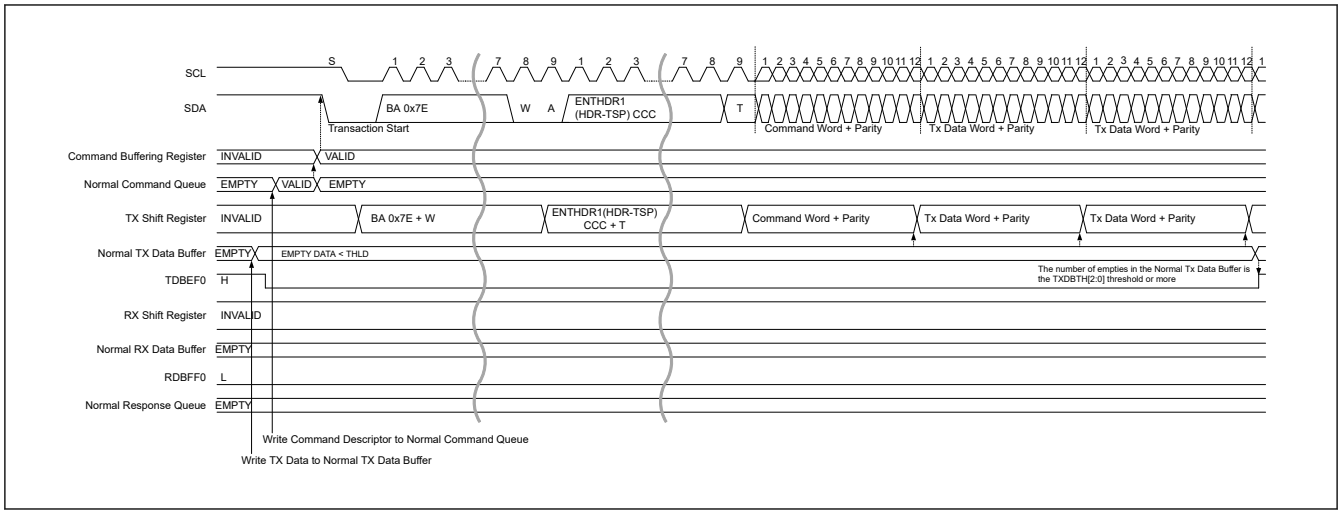

Figure 30.28 HDR data write transfer (HDR-TSP, TSL) timing (1/2)

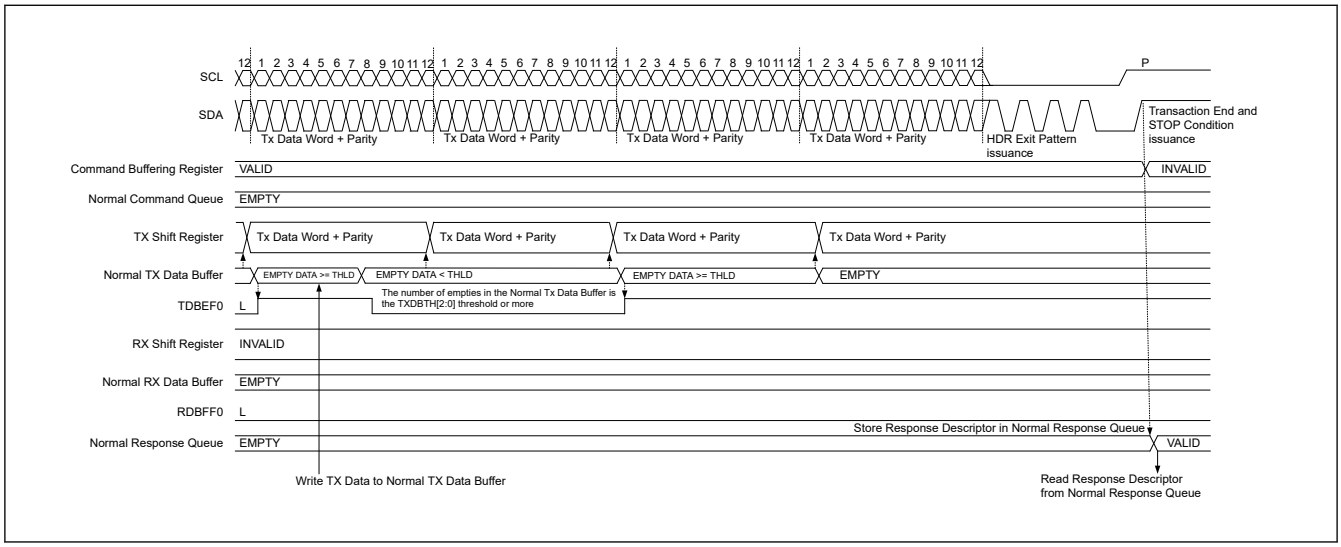

Figure 30.29 HDR data write transfer (HDR-TSP, TSL) timing (2/2)

(e) HDR Data Read Transfer

1. Write a Command Descriptor (Immediate Transfer Command or Regular Transfer Command or Combo Transfer Command) for Data Transfer to the Command Buffer via the NCMDQP register.
2. When Command Descriptor is written to Command Buffer, transaction is issued on I3C Bus.
   When NACK is received with the Address Header, transaction of the same command is automatically issued according to the NACK Retry Count value (DATBASm.DVNACK) of DAT.
3. Data received from the I3C Slave is stored in the Receive Data Buffer.
4. With the RDBFF0 = 1 interrupt, the received data is read from the Receive Data Buffer via the NTDTBPn register.
5. HDR-DDR:
   (a) When CRC Word is received, it issues HDR Restart Pattern or HDR Exit Pattern + STOP condition and stores the Response Descriptor into the Response Buffer.
   (b) When the preamble following the received data for the number of Data Length specified by the DATA_LENGTH[15:0] bits of Command Descriptor indicates Data Word (11), drive (Abort) low to the second bit of the preamble. After that, issue HDR Restart Pattern or HDR Exit Pattern + STOP condition and store the Response Descriptor into the Response Buffer.

   HDR-Ternary:
   When detecting the start of the HDR Restart Pattern or HDR Exit Pattern from I3C Slave, issue HDR Restart Pattern or HDR Exit Pattern + STOP condition and store the Response Descriptor into the Response Buffer.

6. Read the Response Descriptor via the NRSPQP register and check the status.
7. Check whether the value of the DATA_LENGTH[15:0] bits of the Response Descriptor matches the data length setting value of the Command Descriptor.

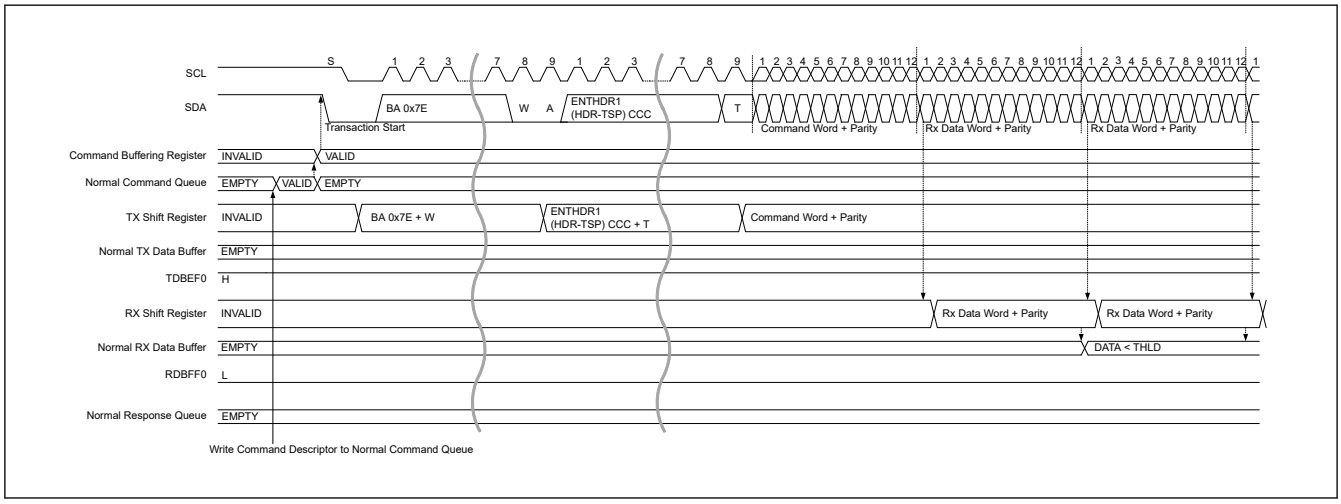

Figure 30.32 HDR data read transfer (HDR-TSP, TSL) timing (1/2)

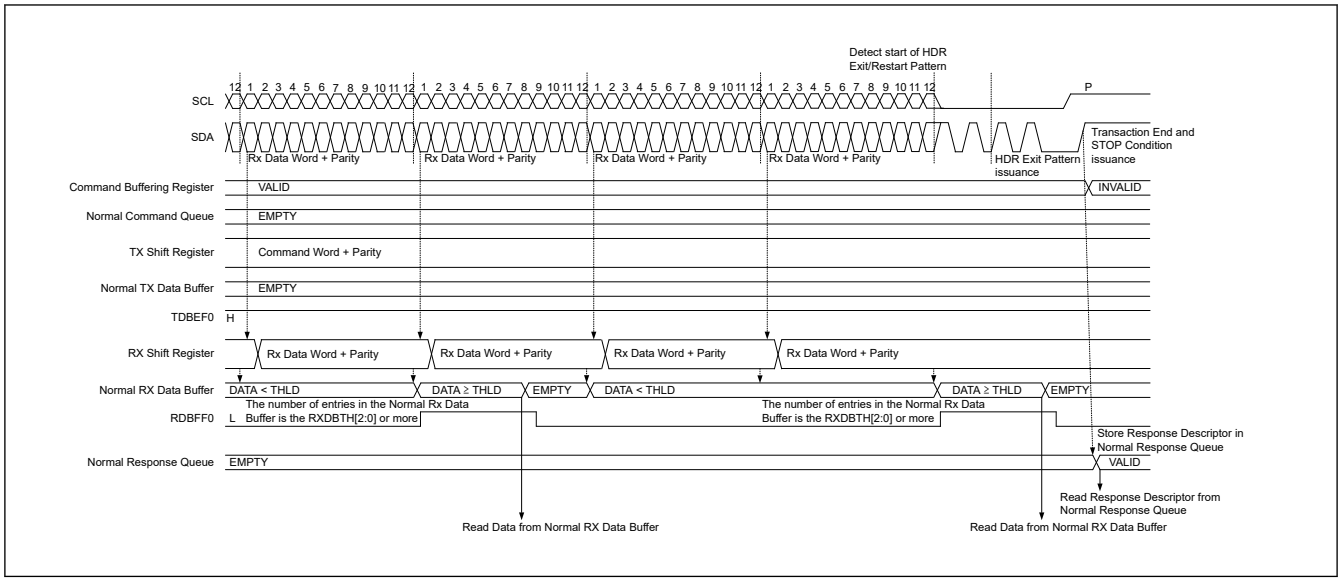

Figure 30.33 HDR data read transfer (HDR-TSP, TSL) timing (2/2)

(f) IBI Transfer

1. Write Command Descriptor to the Command Buffer and issue Transaction on I3C Bus.
   If START Request (SDA Low Drive) is issued from the slave device, I3C drives SCL to Low and completes START condition.
   Thereafter, the SCL is supplied and In-Band Interrupt Request is received.
2. In Slave Address with RnW of the Address Header, if losing Arbitration by issuing In-Band Interrupt from I3C Slave, stop issuing Transaction.
3. According to section 30.3.2.3.8. In-Band Interrupt [I3C mode], detect In-Band Interrupt and process.
4. In the interrupt with IBIQEFF = 1, read the IBI Status Descriptor from the IBI Queue via the NIBIQP register and check the status.
   When detected a Slave Interrupt Request and responded with ACK, Read the IBI Data for the Data Length indicated by the DATA_LENGTH[15:0] bits of the IBI Status Descriptor from the IBI Data Buffer via the NIBIQP register.
5. Restart issuing Transaction of Command of Step1.

An example of the processing procedure after detection of In-Band Interrupt is shown below.

Processing procedure for detecting Mastership Request and transferring master right to Secondary Master

1. If the I3C Secondary Master wins the Arbitration, issue a DEFSLVS CCC and notify Slave information to Secondary Master.
2. Issue a GETACCMST CCC and complete CCC by a STOP condition.

The Mastership processing flow is shown in Figure 30.36

Note:
- After transferring master right to Secondary Master, to get master right again, issue a Mastership Request according to (f) IBI Transfer of (2) I3C Slave Operation.
- After Mastership Request is accepted by the Current Master, to get master right again at receiving the GETACCMST CCC and complete CCC by a STOP condition.

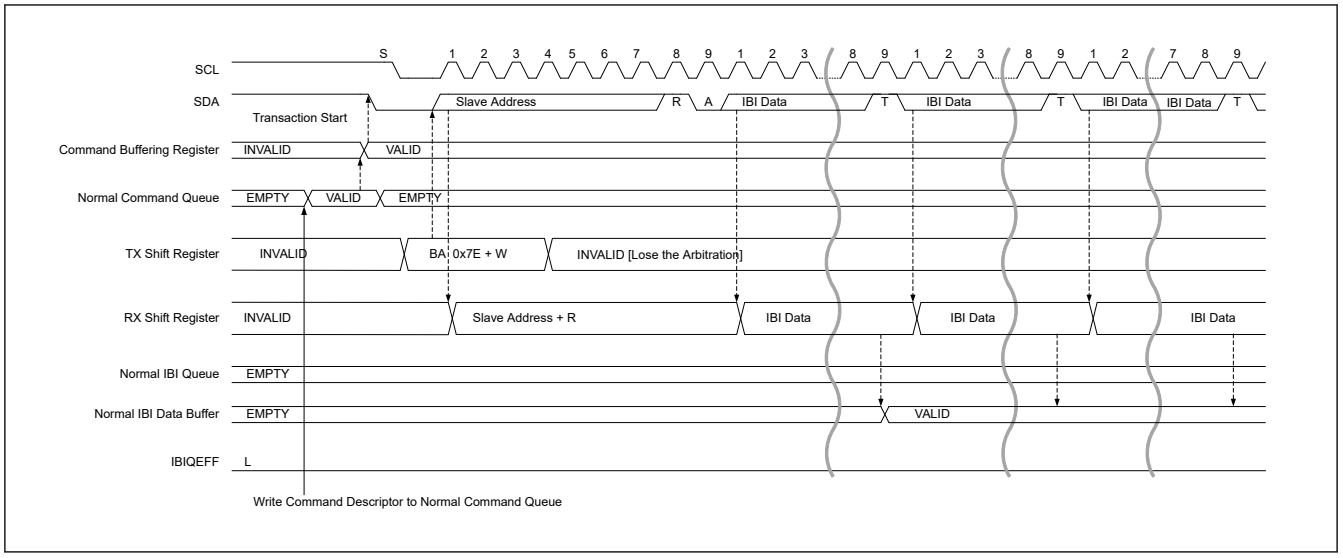

Figure 30.34 I3C master IBI transfer timing (1/2)

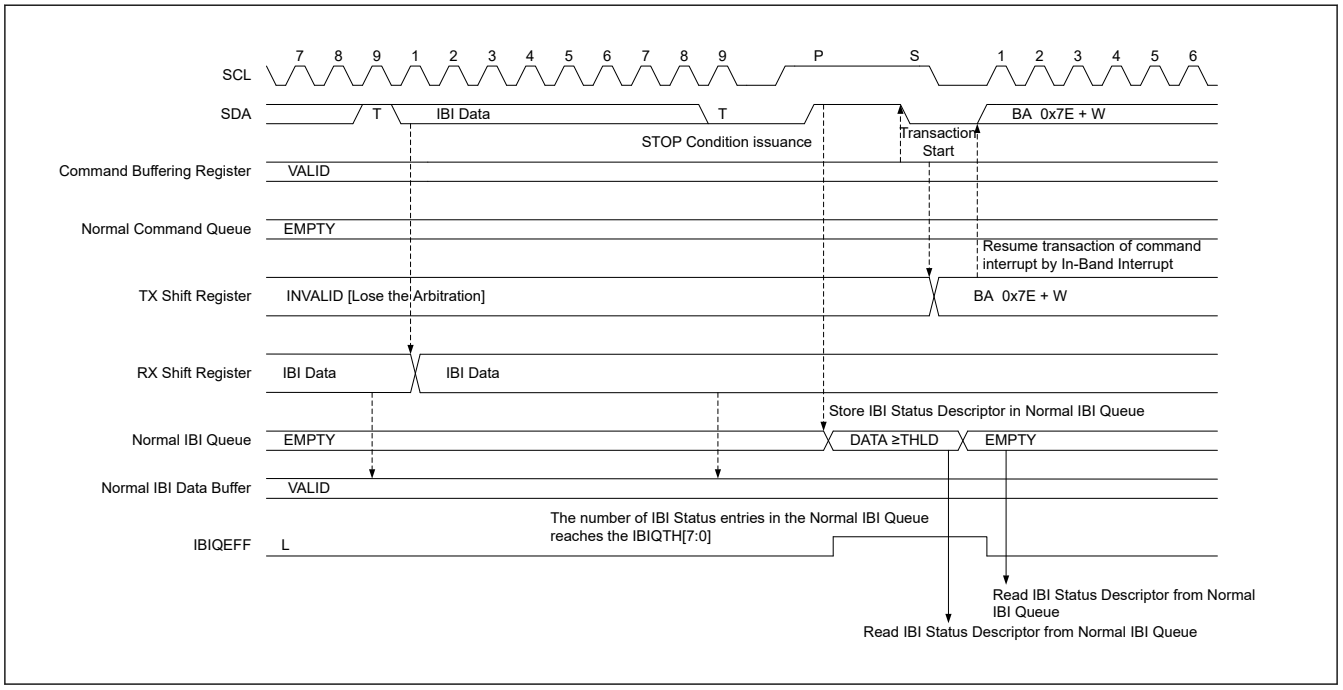

Figure 30.35 I3C master IBI transfer timing (2/2)

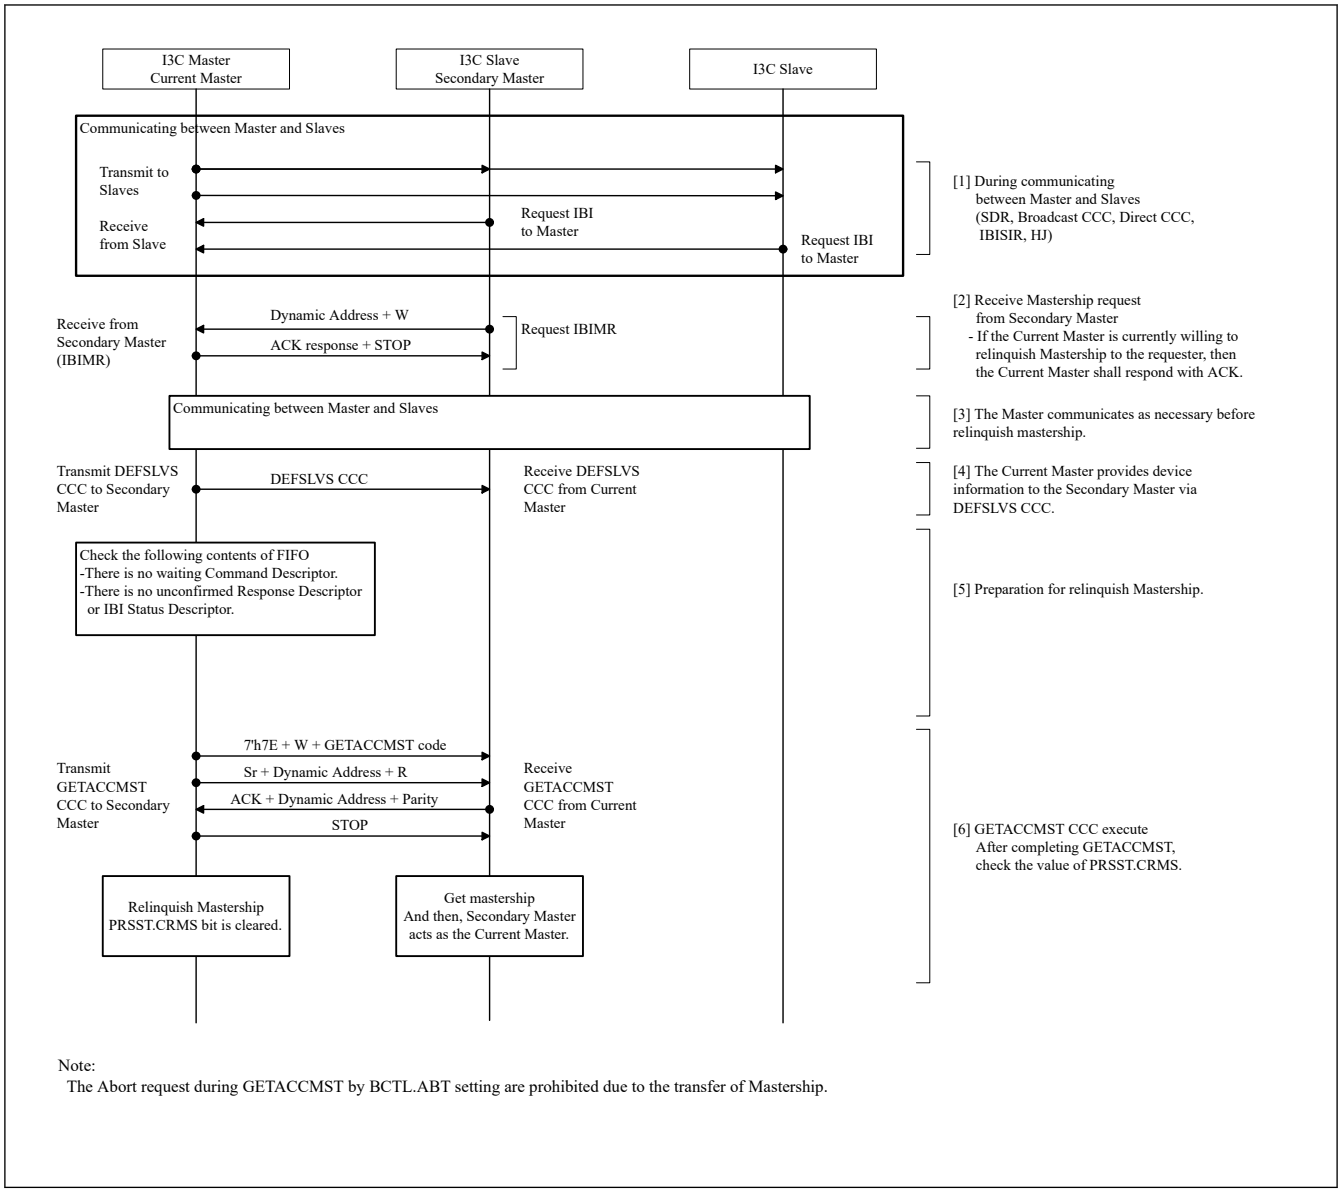

Figure 30.36 I3C Master Mastership processing flow

30.3.2.1.2 Slave Mode Operation

(1) I²C Slave Operation

(a) Data Write Transfer (Single Buffer transfer)

In slave receive operation, the master device outputs the SCL clock and transmit data, and I3C returns acknowledgments as a slave device.

Figure 30.153 shows an example of usage of slave reception and Figure 30.37 and Figure 30.38 show the timing of operations in slave reception.

The following describes the procedure and operations for slave reception.

1. Initial settings. For details, see section 30.3.3.1. Initial Setting Flow. After initial settings, I3C will stay in the standby state until it receives a slave address that it matches.
2. After receiving a matching slave address, I3C sets one of the corresponding bits SVST.HOAF, GCAF, and SVAF[n] (n = 0 to 2) to 1 on the rising edge of the ninth cycle of SCL clock (the clock signal) and outputs the acknowledge bit (ACK) on the ninth cycle of SCL clock. If the value of the R/W# bit that was also received at this time is 0, I3C continues to place itself in slave receive mode and sets the NTST.RDBFF0 flag to 1.

3. After the BST.SPCNDDF flag is confirmed to be 0 and the NTST.RDBFF0 flag to be 1, dummy read the NTDTBP0 register (the dummy value consists of the slave address and R/W# bit when the 7-bit address format is selected, or the lower 8 bits when the 10-bit address format is selected).
4. When the NTDTBP0 register is read, I3C automatically sets the NTST.RDBFF0 flag to 0. If reading of the NTDTBP0 register is delayed and a next byte is received while the RDBFF0 flag is still set to 1, I3C holds the I3C_SCL line low from one SCL cycle before the timing with which RDBFF0 should be set. In this case, reading the NTDTBP0 register releases the I3C_SCL line from being held at the low level. When the BST.SPCNDDF flag = 1 and the NTST.RDBFF0 flag is also 1, read the NTDTBP0 register until all the data is completely received.
5. Upon detecting the STOP condition, I3C automatically clears bits SVST.HOAF, GCAF, and SVAF[n] (n = 0 to 2) to 0.
6. After checking that the BST.SPCNDDF flag = 1, set the BST.SPCNDDF flag to 0 for the next transfer operation.

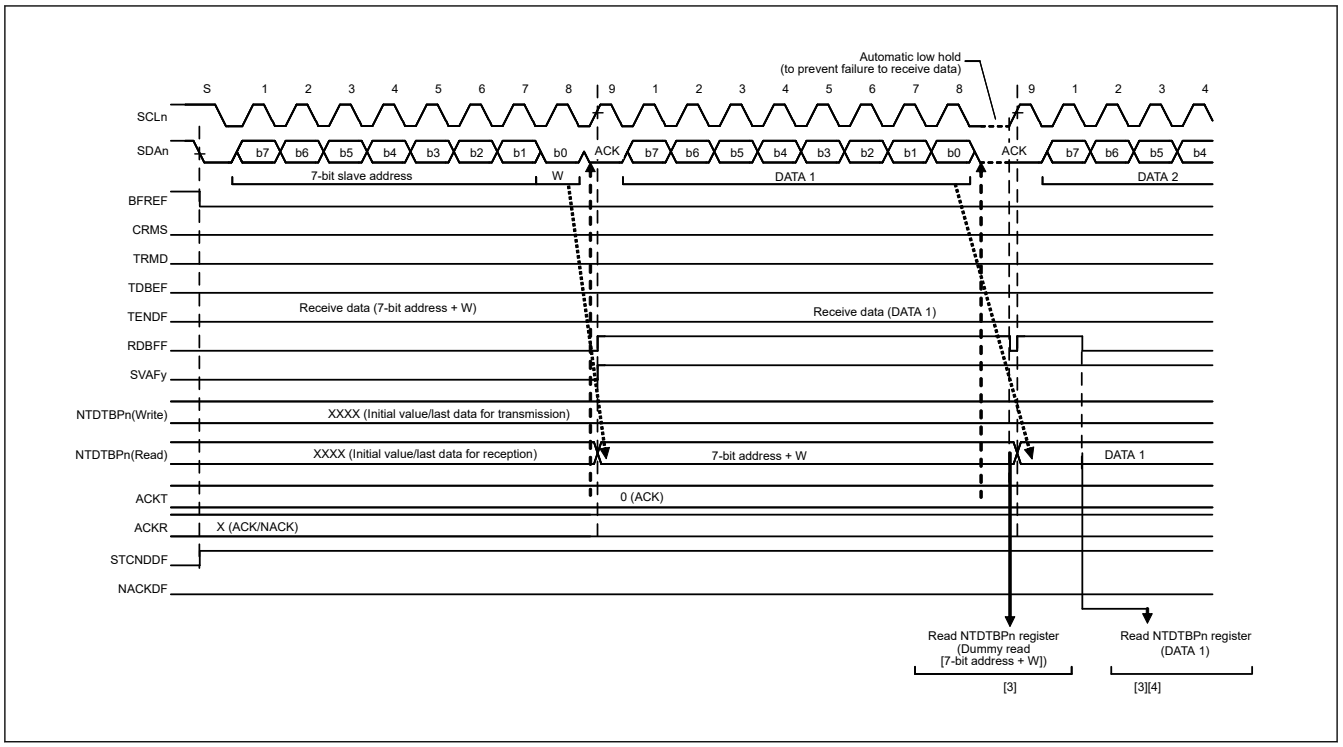

Figure 30.37 Slave receive operation timing (1) (7-bit address format, when ACKTWE = 0)

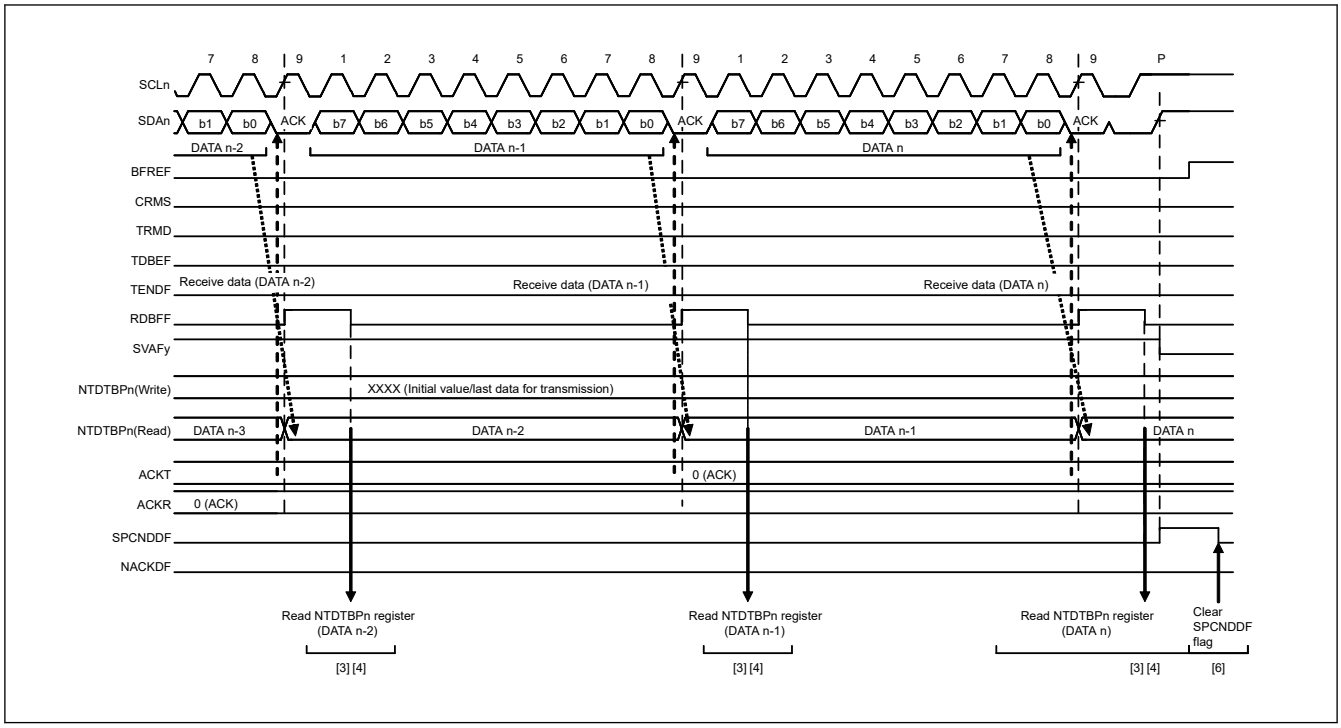

Figure 30.38 Slave receive operation timing (2) (when ACKTWE = 0)

(b) Data Read Transfer (Single Buffer transfer)

In slave transmit operation, the master device outputs the SCL clock, I3C transmits data as a slave device, and the master device returns acknowledgments.

Figure 30.152 shows an example of usage of slave transmission and Figure 30.39 and Figure 30.40 show the timing of operations in slave transmission.

The following describes the procedure and operations for slave transmission.

1. Initial settings. For details, see section 30.3.3.1. Initial Setting Flow.
   After initial settings, I3C will stay in the standby state until it receives a slave address that it matches.
2. After receiving a matching slave address, I3C sets one of the corresponding bits SVST.HOAF, GCAF, and SVAF[n] (n = 0 to 2) to 1 on the rising edge of the ninth cycle of SCL clock (the clock signal) and outputs the acknowledge bit (ACK) on the ninth cycle of SCL clock. If the value of the R/W# bit that was also received at this time is 1, I3C automatically places itself in slave transmit mode by setting both the PRSST.TRMD bit and the NTST.TDBEF0 flag to 1.
3. After the NTST.TDBEF0 flag is confirmed to be 1, write the data for transmission to the NTDTBP0 register.
   At this time, if I3C does not receive acknowledge from the master device (receives an NACK signal) while the BSTE.NACKDE bit = 1, I3C aborts transfer of the next data.
4. Wait until the following (a) or (b) condition.
   (a) The BST.NACKDF flag is set to 1.
   (b) The BST.TENDF flag is set to 1 while the NTST.TDBEF0 flag = 1, after the last byte for transmission is written to the NTDTBP0 register.
5. When the BST.NACKDF flag or the BST.TENDF flag = 1, dummy read the NTDTBP0 register to complete the processing. This releases the I3C_SCL line.
6. Upon detecting the STOP condition, I3C automatically sets bits SVST.HOAF, GCAF, and SVAF[n] (n = 0 to 2), flags NTST.TDBEF0 and BST.TENDF, and the PRSST.TRMD bit to 0, and enters slave receive mode.
7. After checking that the BST.SPCNDDF flag = 1, set the BST.NACKDF and SPCNDDF flags to 0 for the next transfer operation.

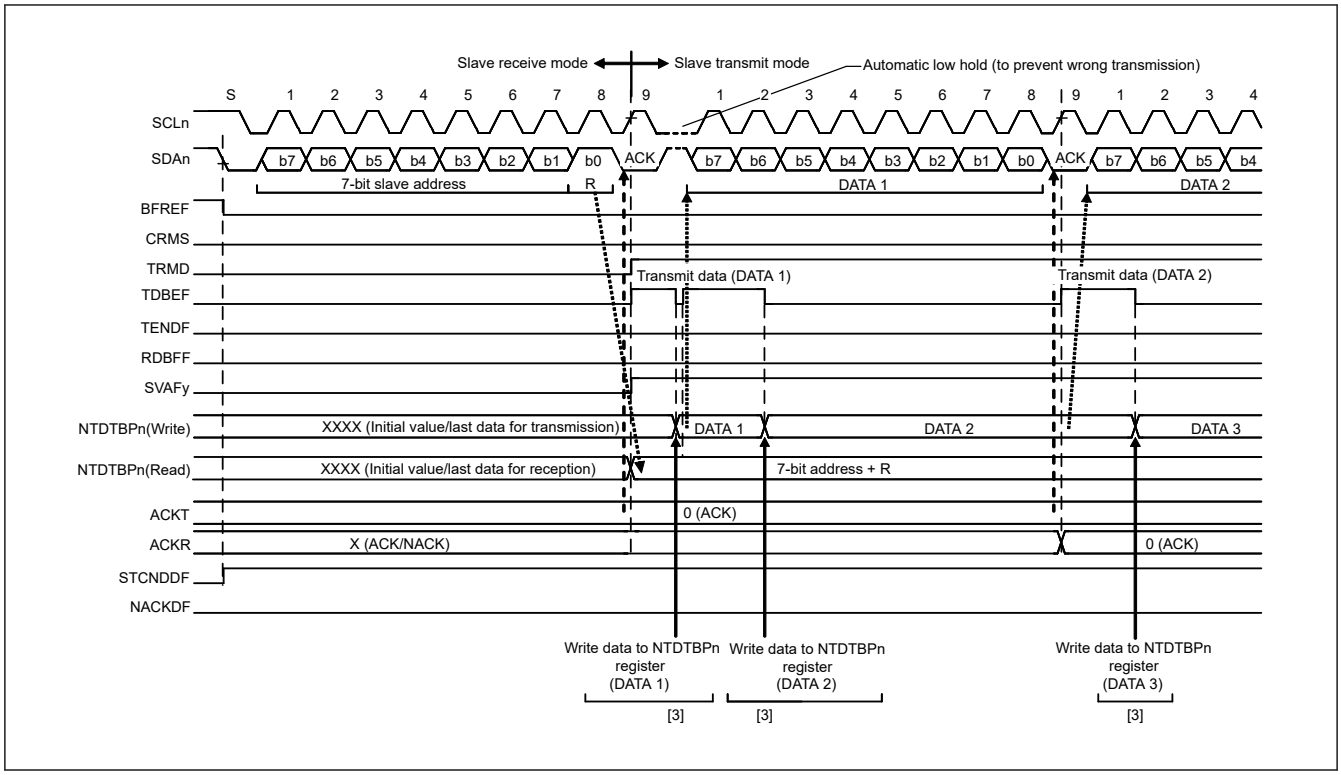

Figure 30.39 Slave transmit operation timing (1) (7-bit address format)

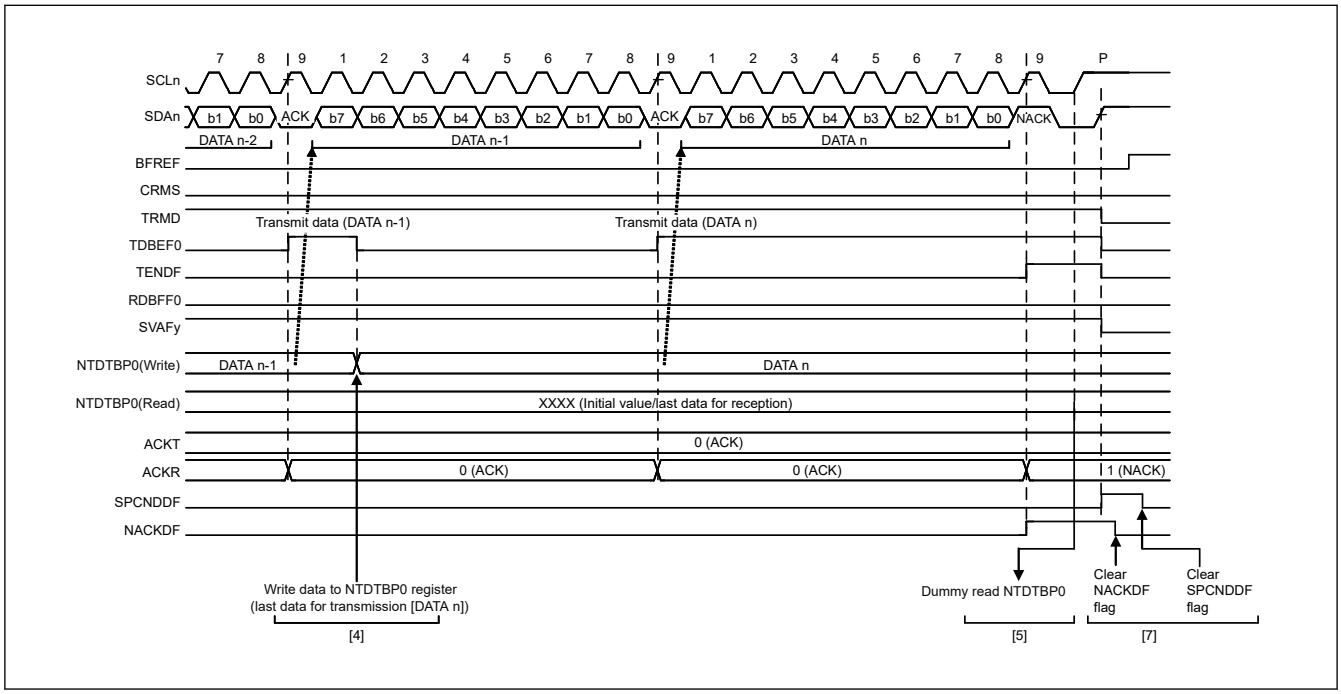

Figure 30.40 Slave transmit operation timing (2)

(2) I3C Slave Operation

(a) Dynamic Address Assign Procedure

After initializing I3C, the I3C master first performs Dynamic Address Assign Procedure.

The operation of R-I3 during the Dynamic Address Assign Procedure by ENTDAA CCC is described below.

1. Initial setting (For details, see section 30.3.3.1.2. I3C Initial Setting Flow)

2. When ENTDAA CCC is received, I3C transmits Provisional ID (SDCTPIDH[31:0], SDCTPIDL[15:0]), BCR (SVDCT.TBCRn), DCR (SVDCT.TDCR[7:0]) until a dynamic address is assigned. (For details, see "In case of Broadcast CCC (ENTDAA)" of (6) CCC detection function [I3C mode].)
3. When ENTDAA CCC is completed and a STOP condition is detected, Receive Status Descriptor is stored in Receive Status Queue.
4. Read Receive Status Descriptor via NRSQP register and check the status.
5. Read the data for the Data Length indicated by the DATA_LENGTH[15:0] bits of the Receive Status Descriptor from the Receive Data Buffer via the NTDTBP0 register.

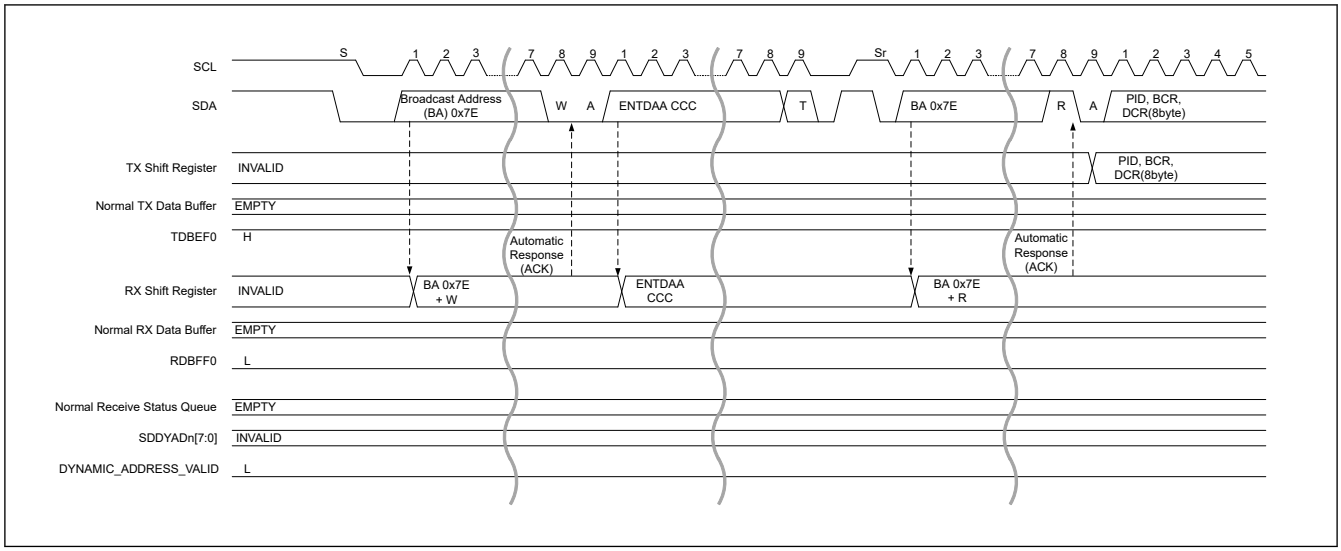

Figure 30.41 Dynamic address assign procedure (ENTDAA CCC) timing (1/3)

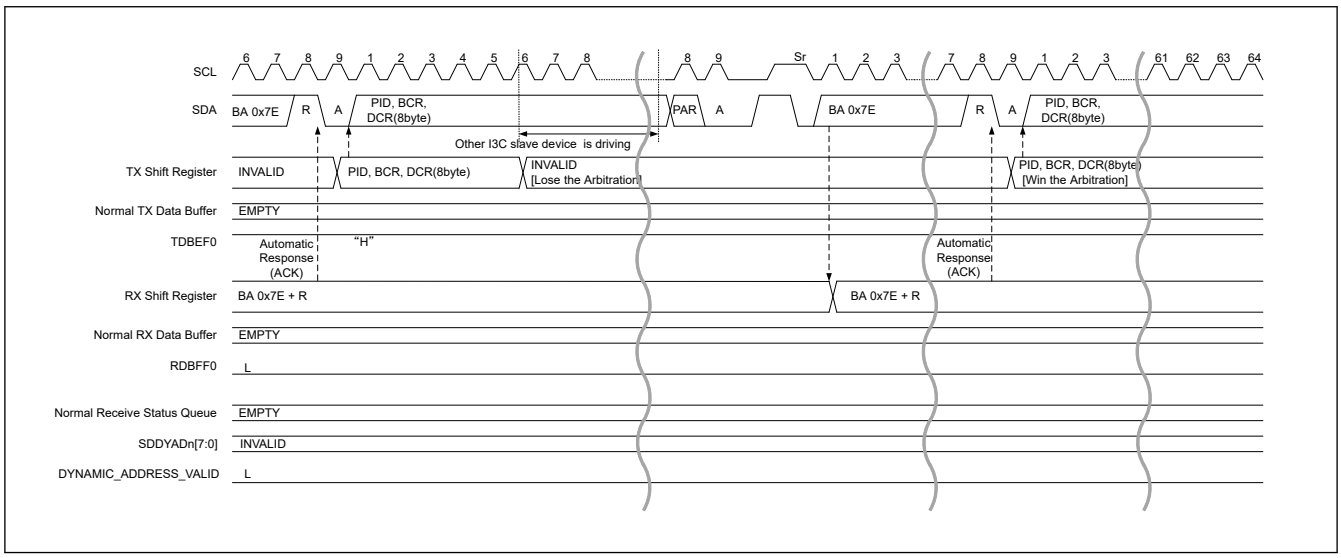

Figure 30.42 Dynamic address assign procedure (ENTDAA CCC) timing (2/3)

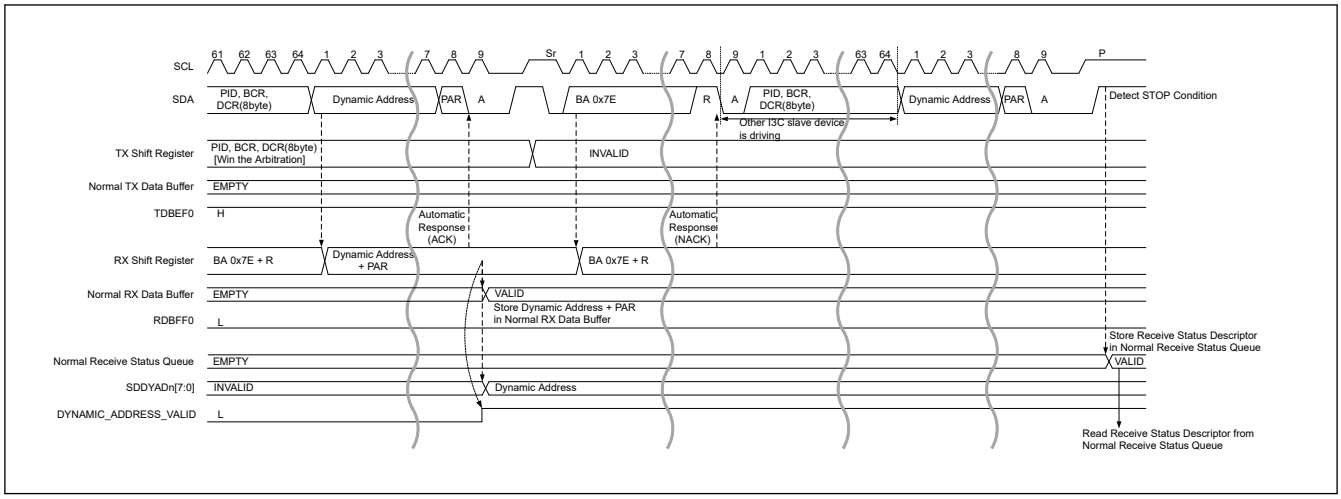

Figure 30.43 Dynamic address assign procedure (ENTDAA CCC) timing (3/3)

When communicating with a Static Address until the Dynamic Address is assigned from the I3C Master, by setting to the DVSTAD[6:0] bit of DAT (SDATBASn register), the SSTADV bit of the SVDVADn register is set to 1 and the Static Address Will be effective.

If the I3C Slave has a Static Address and the I3C Master executes the Dynamic Address Assign Procedure, it is possible to assign a Dynamic Address with SETDASA CCC.

The operation of I3C during SETDASA CCC Dynamic Address Assign Procedure is described below.

1. Initial setting (For details, see section 30.3.3.1.2. I3C Initial Setting Flow)
2. When SETDASA CCC which agrees with its own Static Address is received, the SDDYAD [7:0] bit of DAT (SDATBAS0 register) is renewed and SDYADV bit of SVDVAD0 register is set in 1. (For details, see "In case of Direct Write CCC" of (6) CCC detection function [I3C mode].)
3. When SETDASA CCC is completed and a STOP condition is detected, Receive Status Descriptor is stored in Receive Status Queue.
4. Read Receive Status Descriptor via NRSQP register and check the status.

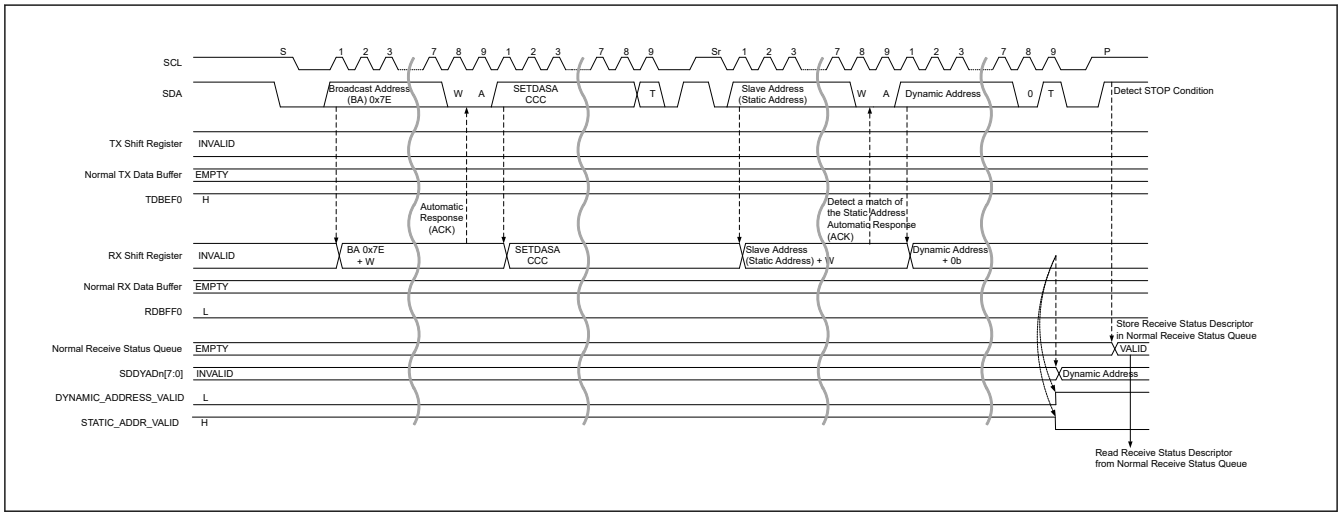

Figure 30.44 Dynamic address assign procedure (SETDASA CCC) timing

(b) SDR Data Write Transfer

1. When Transaction is issued from the I3C Master, it compares the Slave Address of Address Header with its own Slave Address, and if it matches, I3C responds with ACK.
   When a Transaction is received, if the Receive Data Buffer is full, the I3C Slave will respond with NACK in the Address Header.
   In preparation for retrying the I3C Master, read the data from the Receive Data Buffer via the NTDTBPn register, and empty the Receive Data Buffer.

2. Data received from I3C Master is stored in the Receive Data Buffer.
3. With the RDBFF0 = 1 interrupt, the received data is read from the Receive Data Buffer via the NTDTBPn register.
4. When Repeated START condition or STOP condition is detected, the Receive Status Descriptor is stored in the Receive Status Queue.
5. Read Receive Status Descriptor via NRSQP register and check the status.

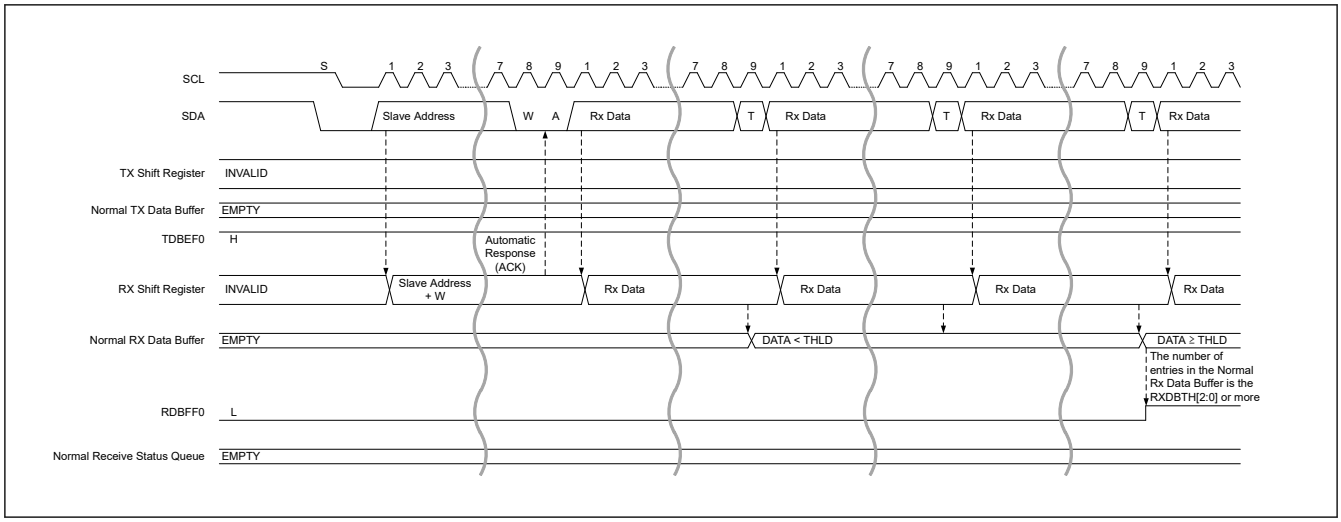

Figure 30.45 SDR data write transfer timing (1/2)

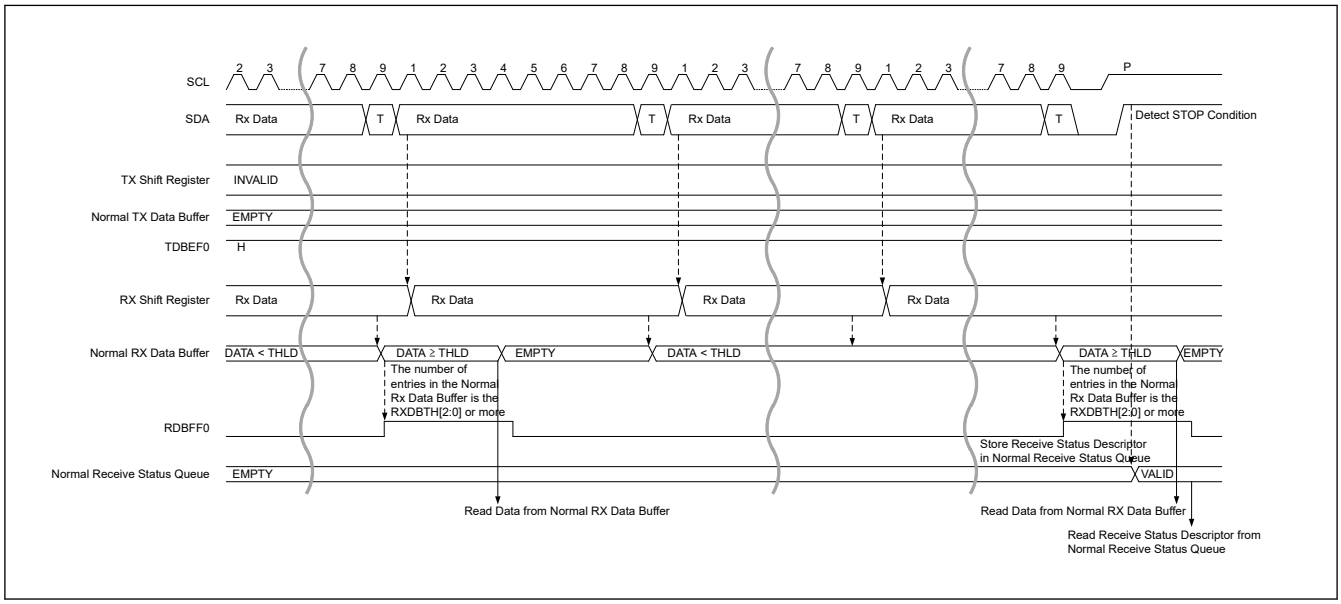

Figure 30.46 SDR data write transfer timing (2/2)

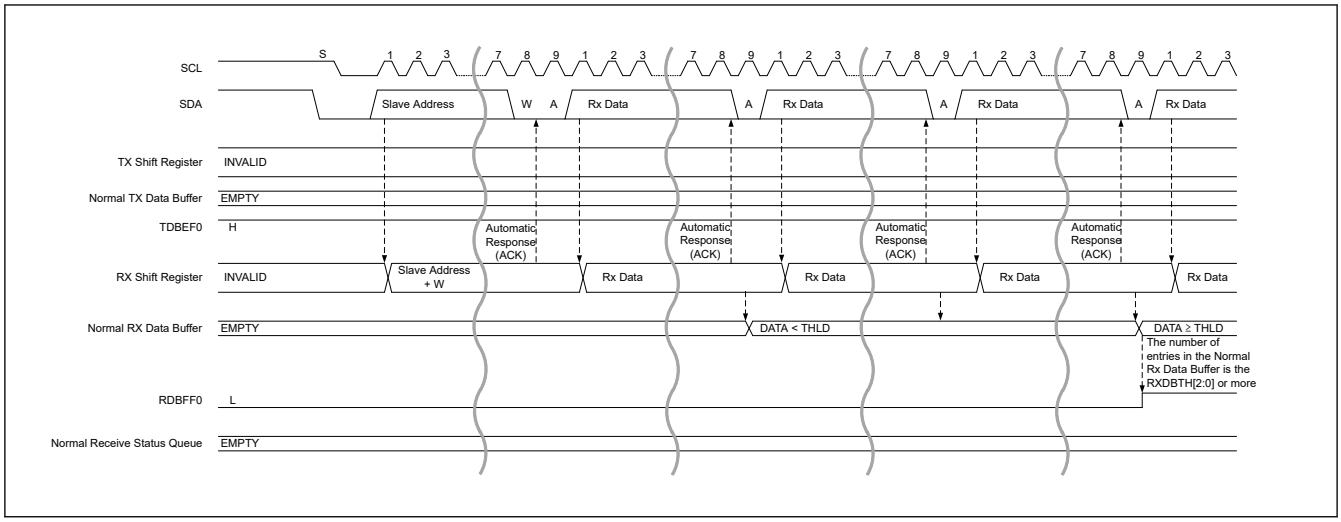

Figure 30.47 Legacy I²C message data write transfer timing (1/2)

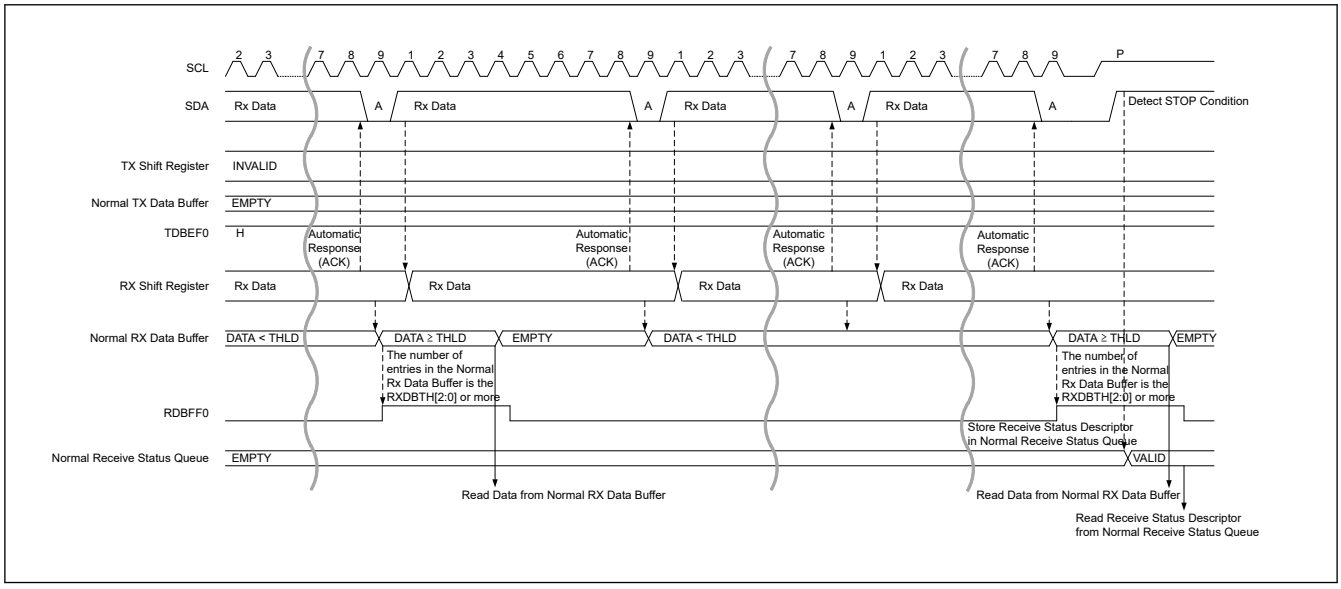

Figure 30.48 Legacy I²C message data write transfer timing (2/2)

(c) SDR Data Read Transfer

1. Write the data requested from the I3C Master to the Tx Data Buffer via the NTDTBPn register.
2. When Transaction is issued from the I3C Master, it compares the Slave Address of Address Header with its own Slave Address, and if it matches, I3C responds with ACK.
   When a Transaction is received, if the Tx Data Buffer is EMPTY, I3C Slave responds with NACK with the Address Header.
   In preparation for retrying the I3C Master, write data to the Tx Data Buffer via the NTDTBPn register.
3. Transmit the data stored in the Tx Data Buffer.
4. If data to be transmitted still remains, write the data to be transmitted with an interrupt by TDBEF0 = 1 to the Tx Data Buffer via the NTDTBPn register.
5. SDR:
   When the transmission of the data stored in the Tx Data Buffer is completed, Low is output to the T-bit following Data, and it is notified to the I3C Master that it is the final data.
   Legacy I²C Message:
   When NACK is detected, data transmission is terminated.
6. When a Repeated START condition or STOP condition is detected, the Receive Status Descriptor is stored in the Receive Status Queue.

7. Read the Receive Status Descriptor via NRSQP and check the status.

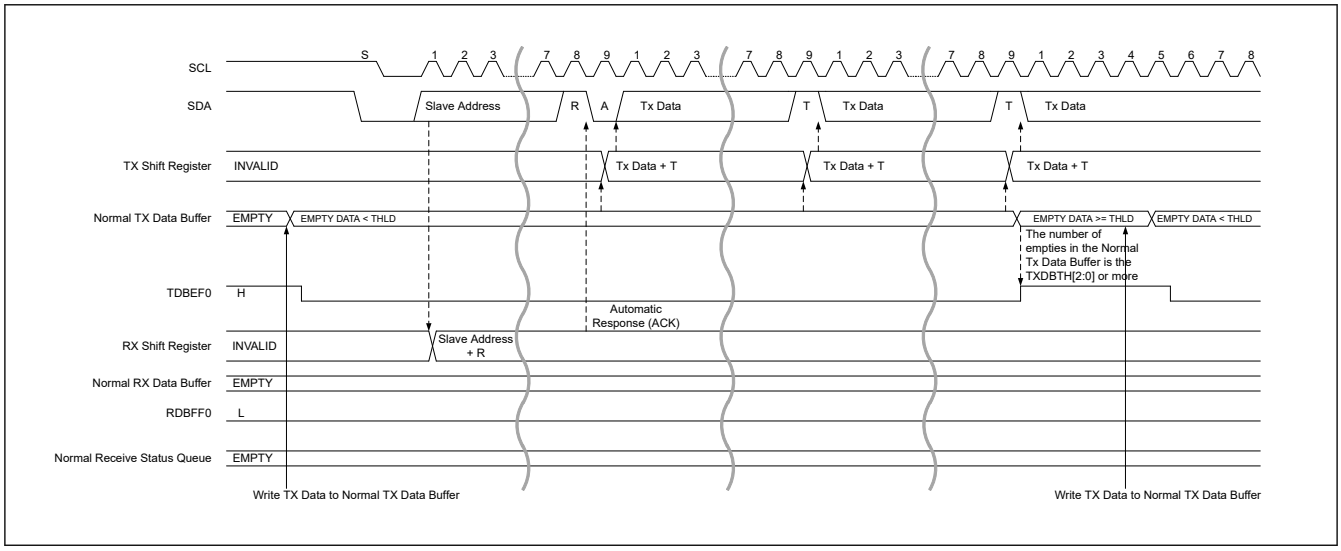

Figure 30.49 SDR data read transfer timing (1/2)

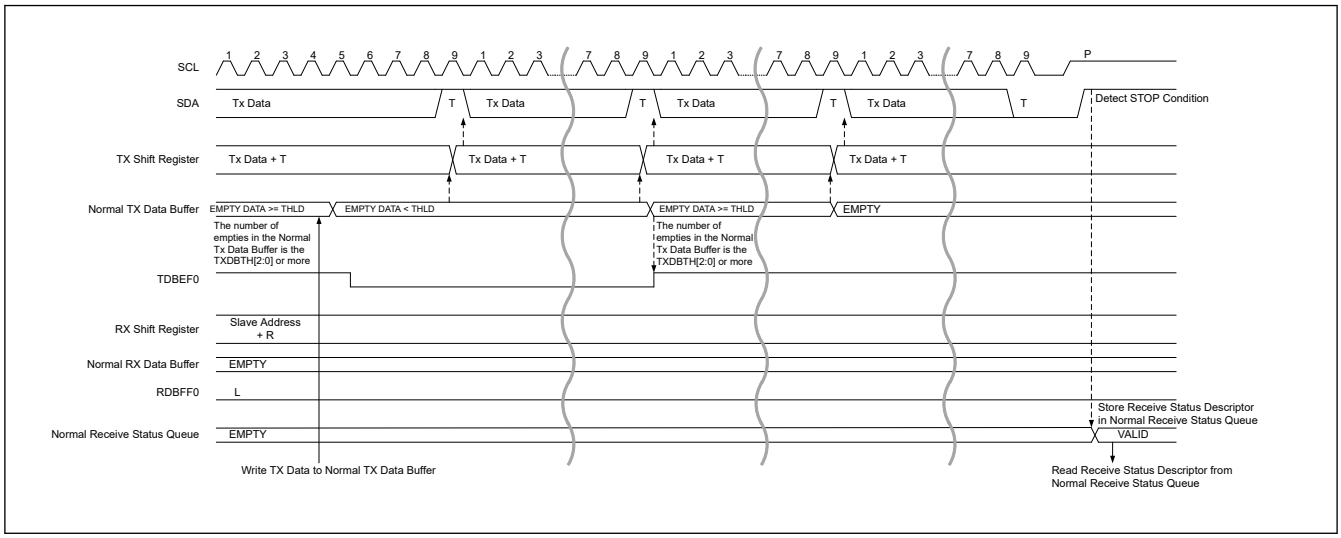

Figure 30.50 SDR data read transfer timing (2/2)

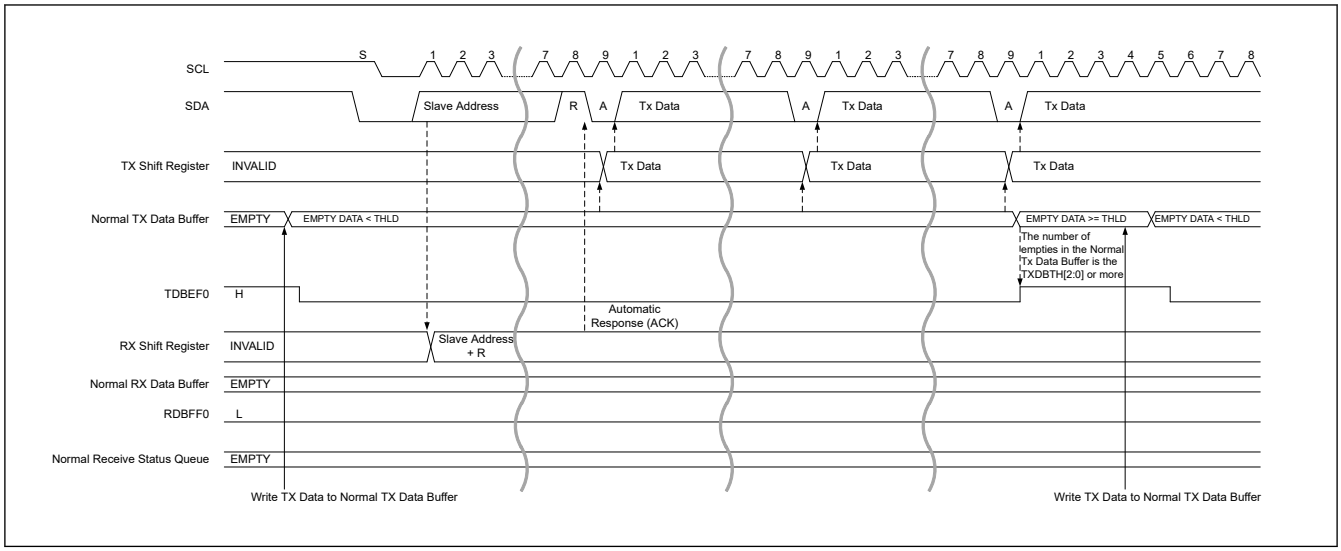

Figure 30.51 Legacy I²C message data read transfer timing (1/2)

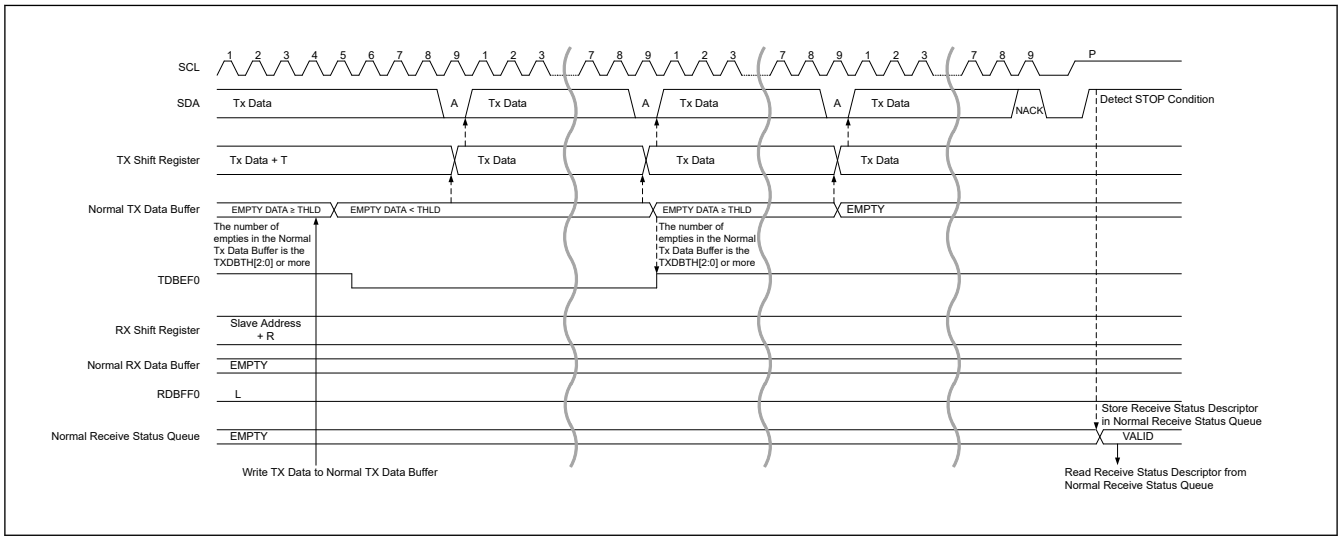

Figure 30.52 Legacy I²C message data read transfer timing (2/2)

(d) HDR Data Write Transfer

1. Upon receipt of ENTHDR * CCC from the I3C Master, it transits to HDR mode (For details, see "In case of Broadcast CCC (ENTHDR *)" of (6) CCC detection function [I3C mode]).
2. Compare the Slave Address of the HDR Command Word issued from the I3C Master with its own Slave Address, and if it matches, receive the following Data Word.
3. Data received from the I3C Master is stored in the Receive Data Buffer.
4. With the RDBFF0 = 1 interrupt, the received data is read from the Receive Data Buffer via the NTDTBPn register.
5. When detecting HDR Restart Pattern or HDR Exit Pattern + STOP condition, it stores the Receive Status Descriptor into the Receive Status Queue.
6. Read the Receive Status Descriptor via NRSQP and check the status.

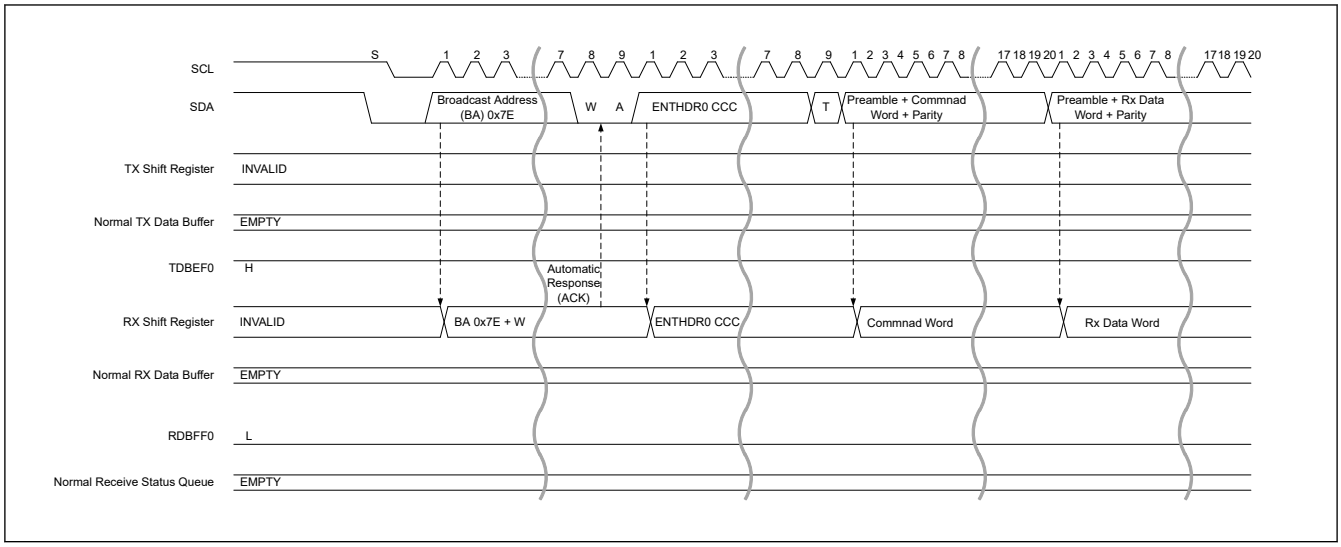

Figure 30.53 HDR data write transfer (HDR-DDR) timing (1/3)

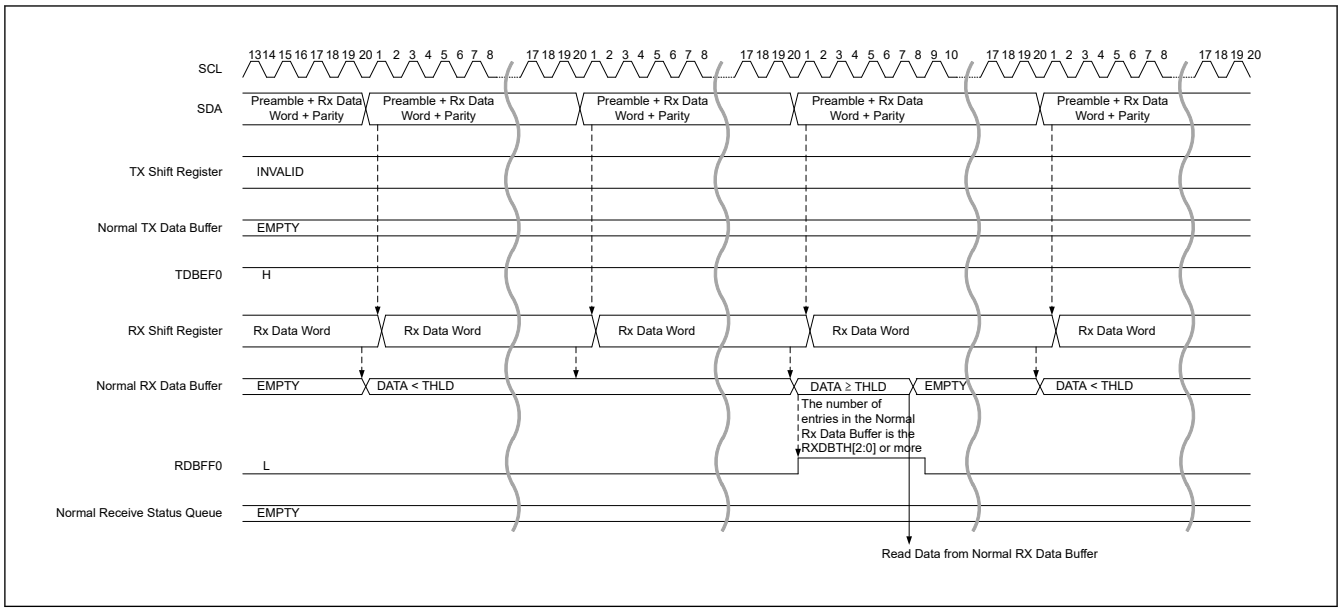

Figure 30.54 HDR data write transfer (HDR-DDR) timing (2/3)

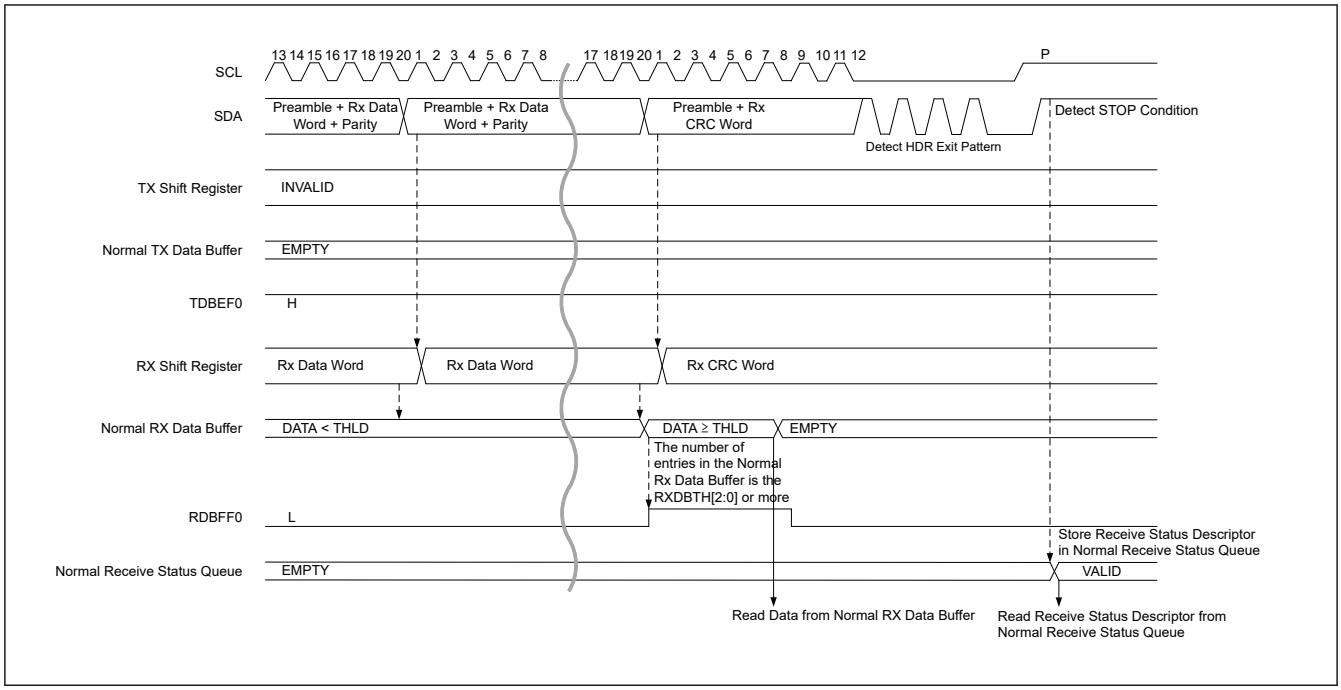

Figure 30.55 HDR data write transfer (HDR-DDR) timing (3/3)

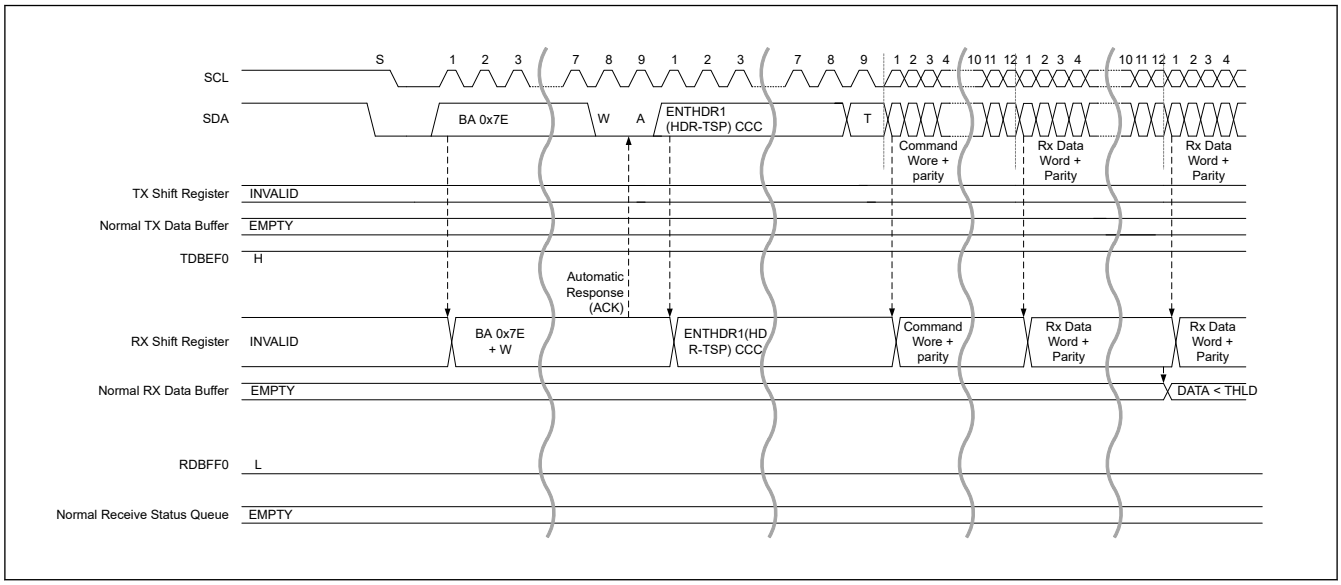

Figure 30.56 HDR data write transfer (HDR-TSP, TSL) timing (1/2)

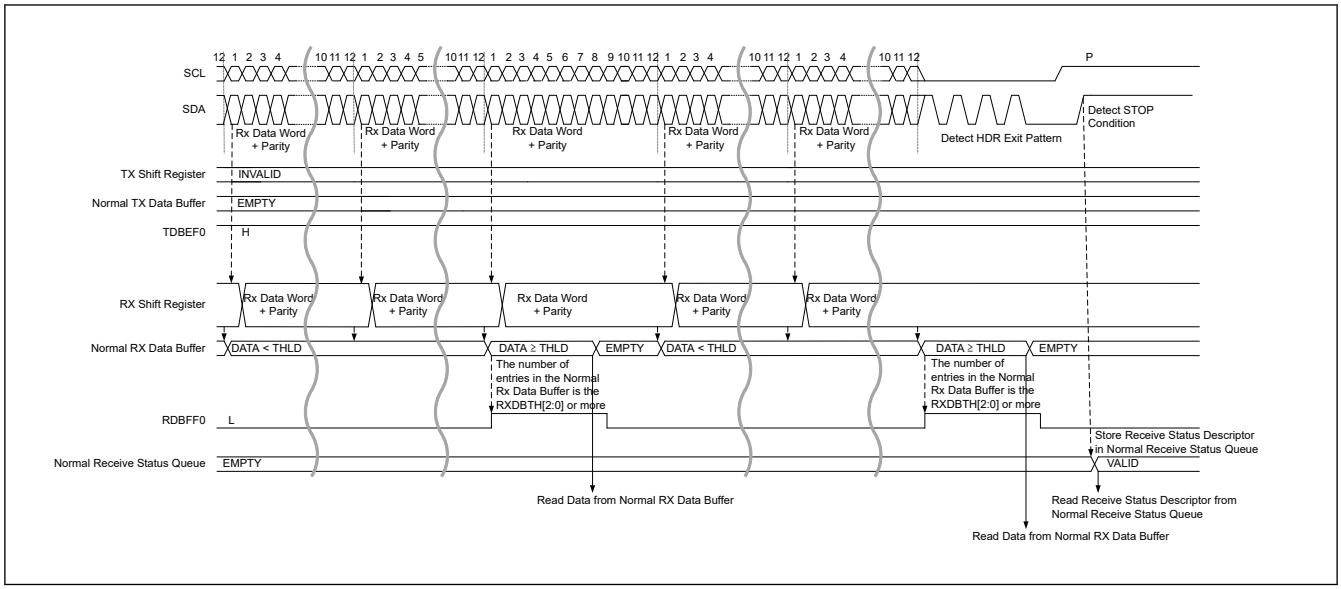

Figure 30.57 HDR data write transfer (HDR-TSP, TSL) timing (2/2)

(e) HDR Data Read Transfer

1. Write the data requested by the I3C Master to the Tx Data Buffer via the NTDTBPn register.
2. Upon receipt of ENTHDR * CCC from the I3C Master, it transits to HDR mode (For details, see "In case of Broadcast CCC (ENTHDR *)" of (6) CCC detection function [I3C mode]).
3. When comparing the Slave Address of the HDR Command Word issued from the I3C Master with its own Slave Address, if it matches, the Data stored in the Tx Data Buffer is transmitted.
   If the Tx Data Buffer is EMPTY when the Slave Address of the HDR Command Word matches its own Slave Address, a NACK response will be sent.
   NACK response :
   - HDR-DDR :
     Send 11 followed by Command Word followed by Preamble.
   - HDR-Ternary :
     Send the beginning of HDR Restart and HDR Exit Pattern (in English translation: "start of the HDR Restart Pattern and HDR Exit Pattern." In MIPI Spec)
4. If data to be transmitted still remains, Write the data to be transmitted with an interrupt by TDBEF0 = 1 to the Tx Data Buffer via the NTDTBPn register.
5. HDR-DDR:
   When the transmission of the data stored in the Tx Data Buffer is completed, the CRC Word is sent continuously to notify the I3C Master that it is the final data.
   HDR-Ternary:
   When the transmission of the data stored in the Tx Data Buffer is completed, the beginning of the HDR Restart or HDR Exit Pattern is sent continuously to notify the I3C Master that it is the final data.
6. When detecting HDR Restart Pattern and HDR Exit Pattern + STOP condition, it stores the Receive Status Descriptor into the Receive Status Queue.
7. Read the Receive Status Descriptor via NRSQP and check the status.

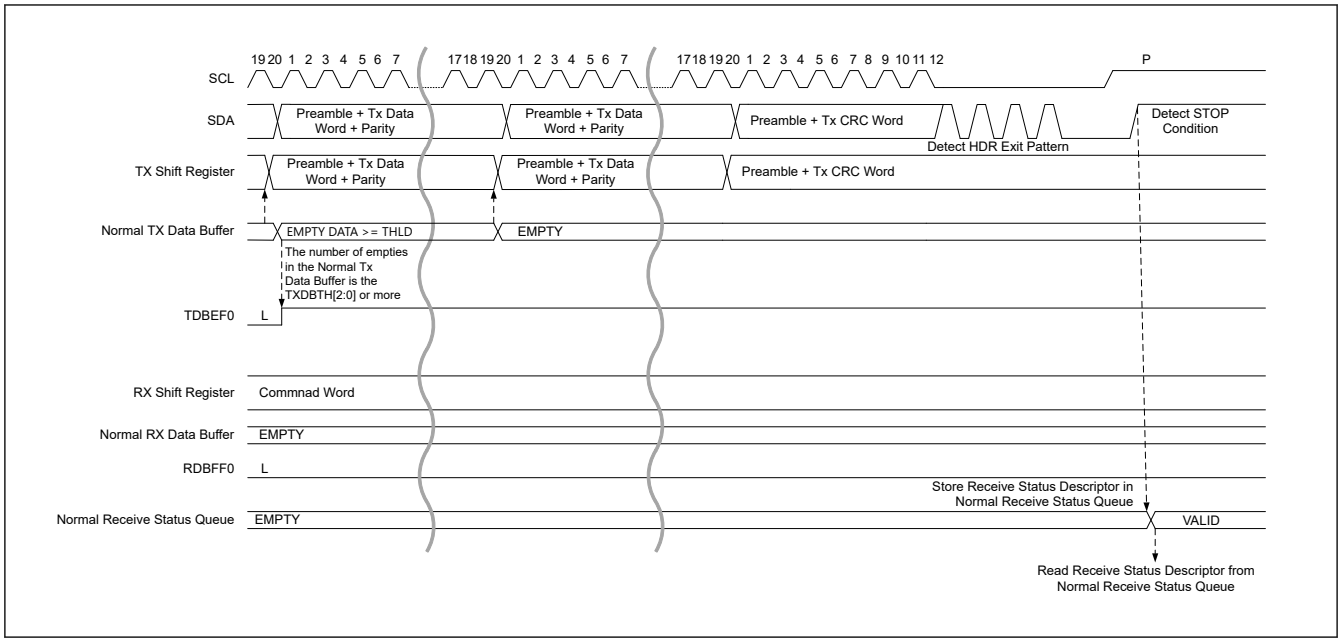

Figure 30.60 HDR data read transfer (HDR-DDR) timing (3/3)

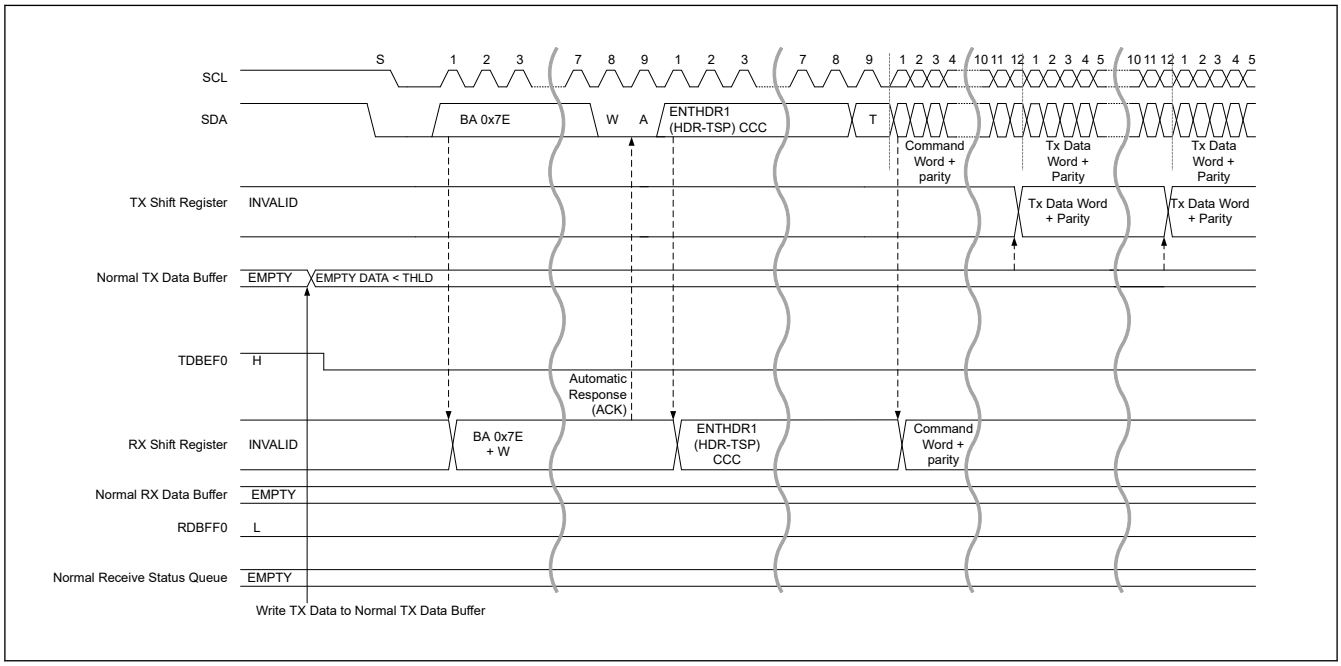

Figure 30.61 HDR data read transfer (HDR-TSP, TSL) timing (1/2)

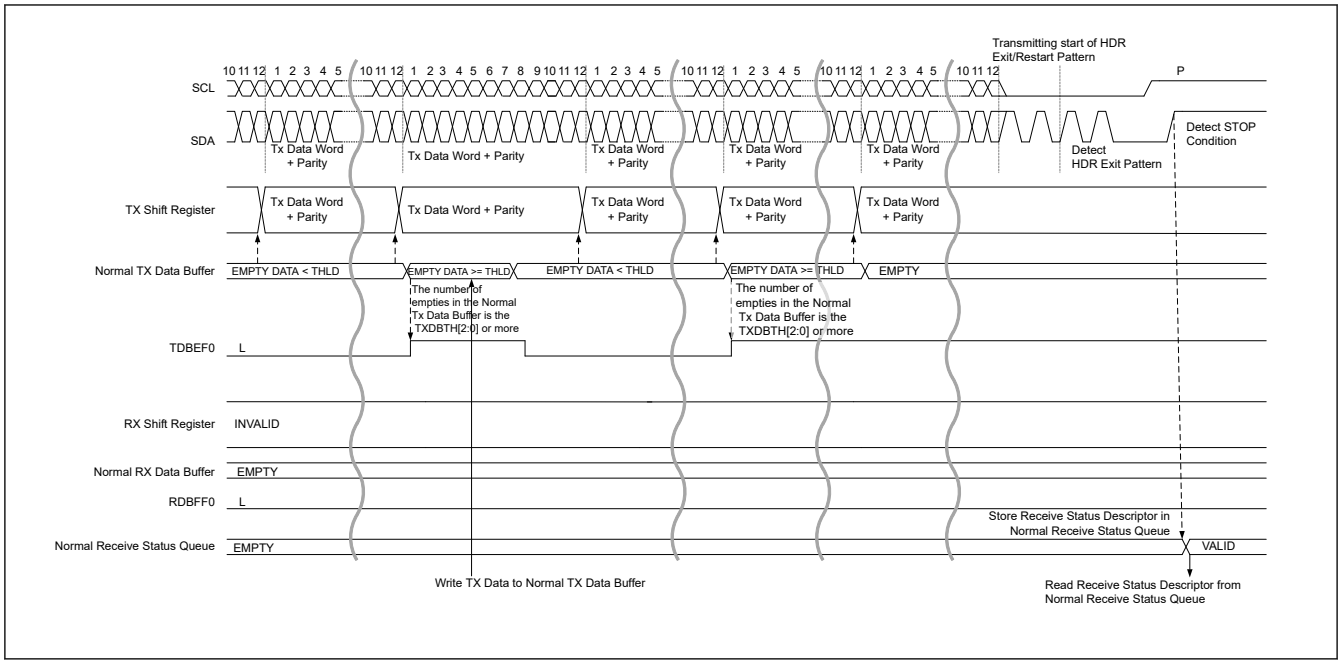

Figure 30.62 HDR data read transfer (HDR-TSP, TSL) timing (2/2)

(f) IBI Transfer

1. When sending Slave Interrupt Request.
   When transmitting IBI Data, write IBI Data to the IBI Data Buffer via the NIBIQP register.
2. Write Command Descriptor (Immediate Transfer Command or Regular Transfer Command) to the Command Buffer for IBI Transfer via the NCMDQP register.
3. When Command Descriptor is written to Command Buffer, IBI Transaction is issued under the following conditions.
   - When START condition is detected in Slave Interrupt Request or Mastership Request. (Does not apply a Repeated START condition)
   - If no START is forthcoming within the following Bus Condition, then this module issue a START Request by pulling the I3C_SDA line Low.
   - (a) Slave Interrupt Request, Mastership Request : Bus Available
4. In Slave Address with RnW of the Address Header, if losing Arbitration by issuing a Transaction from I3C Master, stop issuing Transaction.
   When detecting Repeated START condition or STOP condition, store the Response Descriptor into the Response Buffer.
5. When sending Slave Interrupt Request:
   - When IBI data for transmission still remain, write IBI data with an interrupt by IBIQEFF = 1 to the IBI Data Buffer via the NIBIQP register.
   - When the transmission of IBI Data for the number of Data Length specified by the DATA_LENGTH[15:0] bits of the Command Descriptor is completed, output Low to the T-bit following IBI Data and notify the I3C Master that it is the final IBI Data.
6. When detecting Repeated START condition or STOP condition, store the Response Descriptor into the Response Buffer.
7. Read the Response Descriptor form the Response Buffer with the NRSPQP register and check the status. If NACK is responded, repeat steps 1 to 7.
8. When sending Slave Interrupt Request:
   Check that the value of the DATA_LENGTH[15:0] bit of the Response Descriptor is 0.

The Mastership processing flow is shown in Figure 30.65.

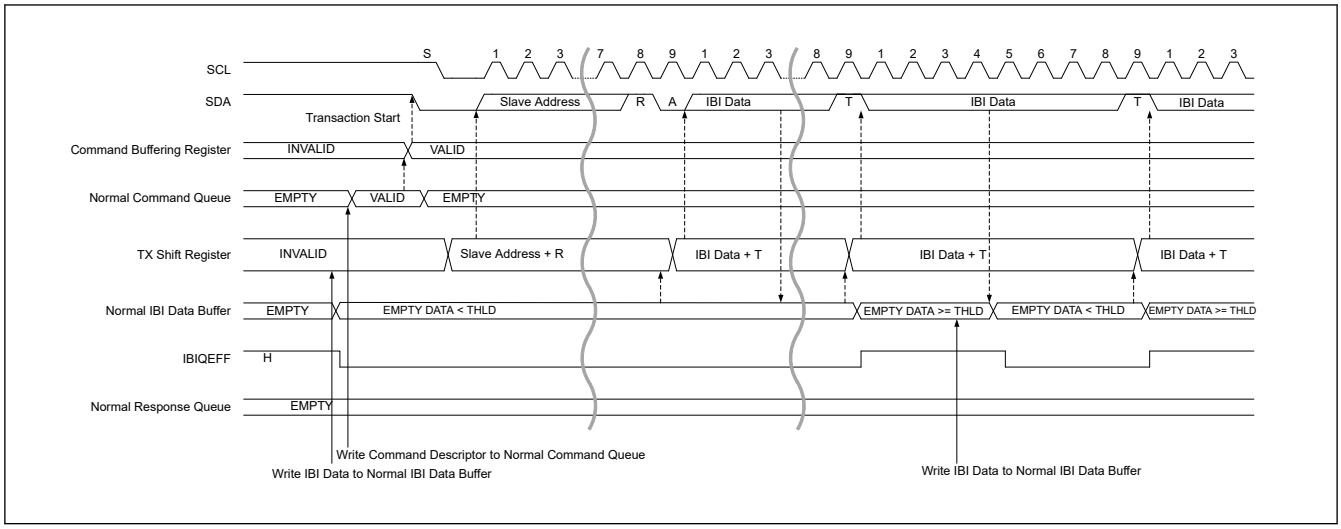

Figure 30.63 I3C slave IBI transfer timing (1/2)

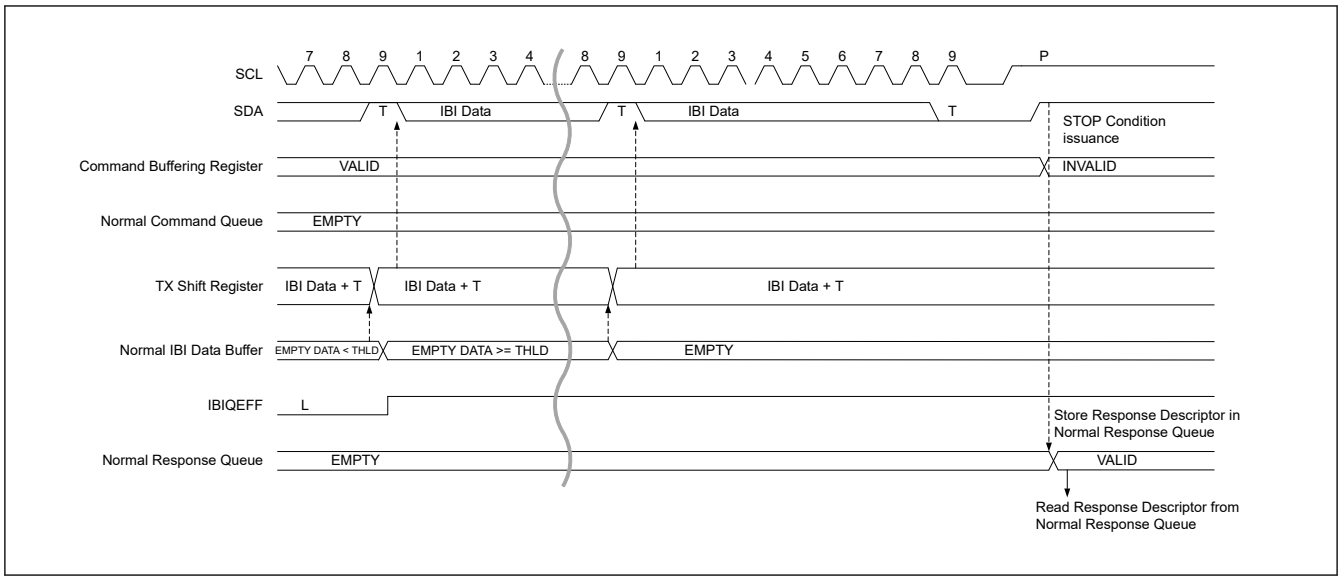

Figure 30.64 I3C slave IBI transfer timing (2/2)

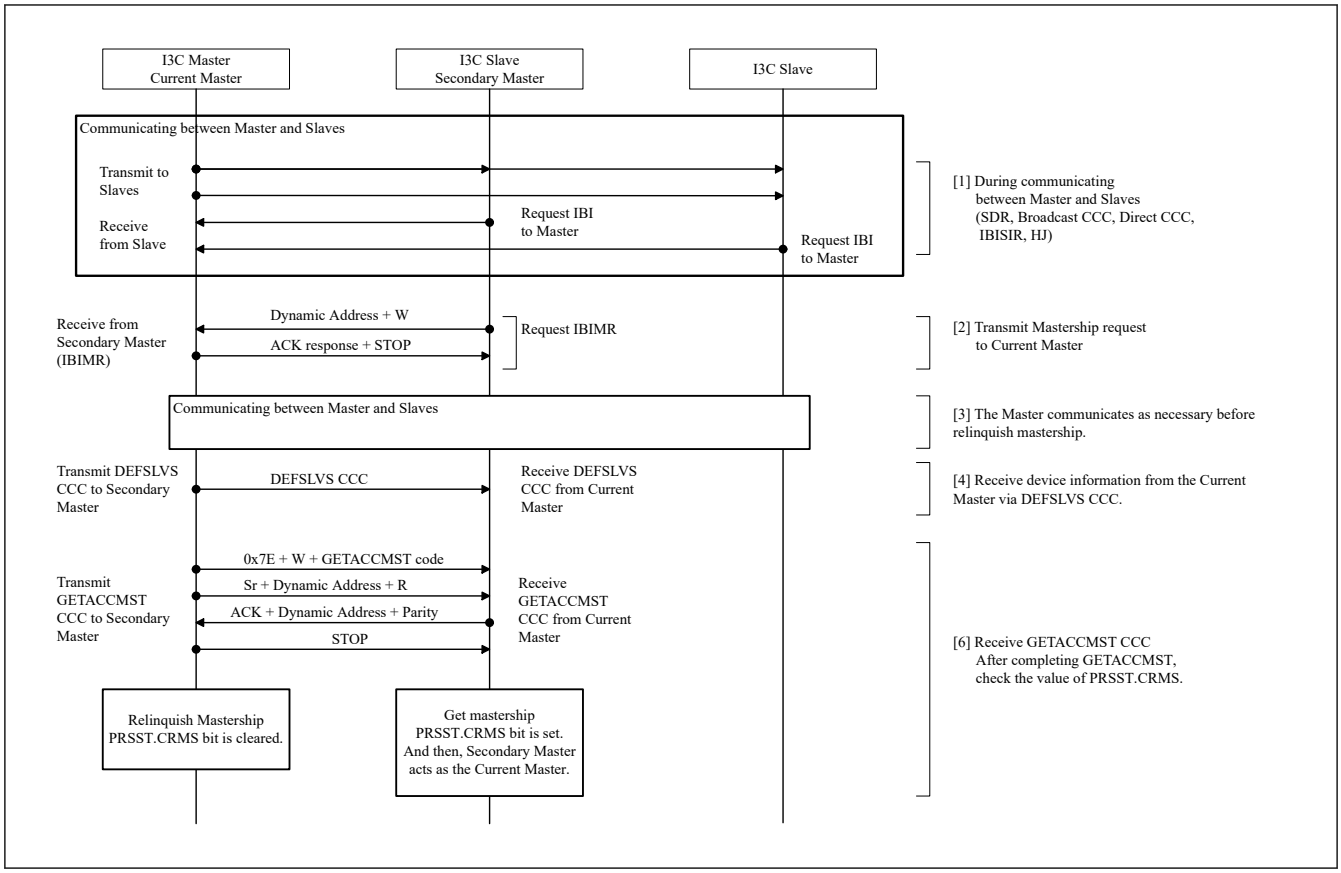

Figure 30.65 I3C Slave Mastership processing flow

30.3.2.2 Data Handler

The relationship between the transfer method and the queue is shown in Table 30.10.

Table 30.10 Transfer method and queue

Protocol	Transfer method	Queue/Buffer	size	Master	Slave	Secondary Master
I2C Mode	Single buffer transfer	Normal Tx Data	1 byte	✓	✓	—
		Normal Rx Data	1 byte	✓	✓	—
I3C Mode	Normal FIFO buffer transfer	Normal Command	4 QUEUEs	✓	✓	✓
		Normal Response	4 QUEUEs	✓	✓	✓
		Normal Tx Data	16 DWORDs	✓	✓	✓
		Normal Rx Data	16 DWORDs	✓	✓	✓
		Normal Receive Status	2 QUEUEs	—	✓	✓
		Normal IBI Status	2 QUEUEs	✓	—	✓
		Normal IBI Data	8 DWORDs	✓	✓	✓
	High Priority FIFO buffer transfer (in Master Mode only)	High Priority Command	2 QUEUEs	✓	—	✓
		High Priority Response	2 QUEUEs	✓	—	✓
		High Priority Tx Data	2 DWORDs	✓	—	✓
		High Priority Rx Data	2 DWORDs	✓	—	✓

30.3.2.2.1 Transfer Method in I²C Mode

(1) Single Buffer transfer

Each process (condition issue, data transfer, ACK / NACK response) is controlled by software.

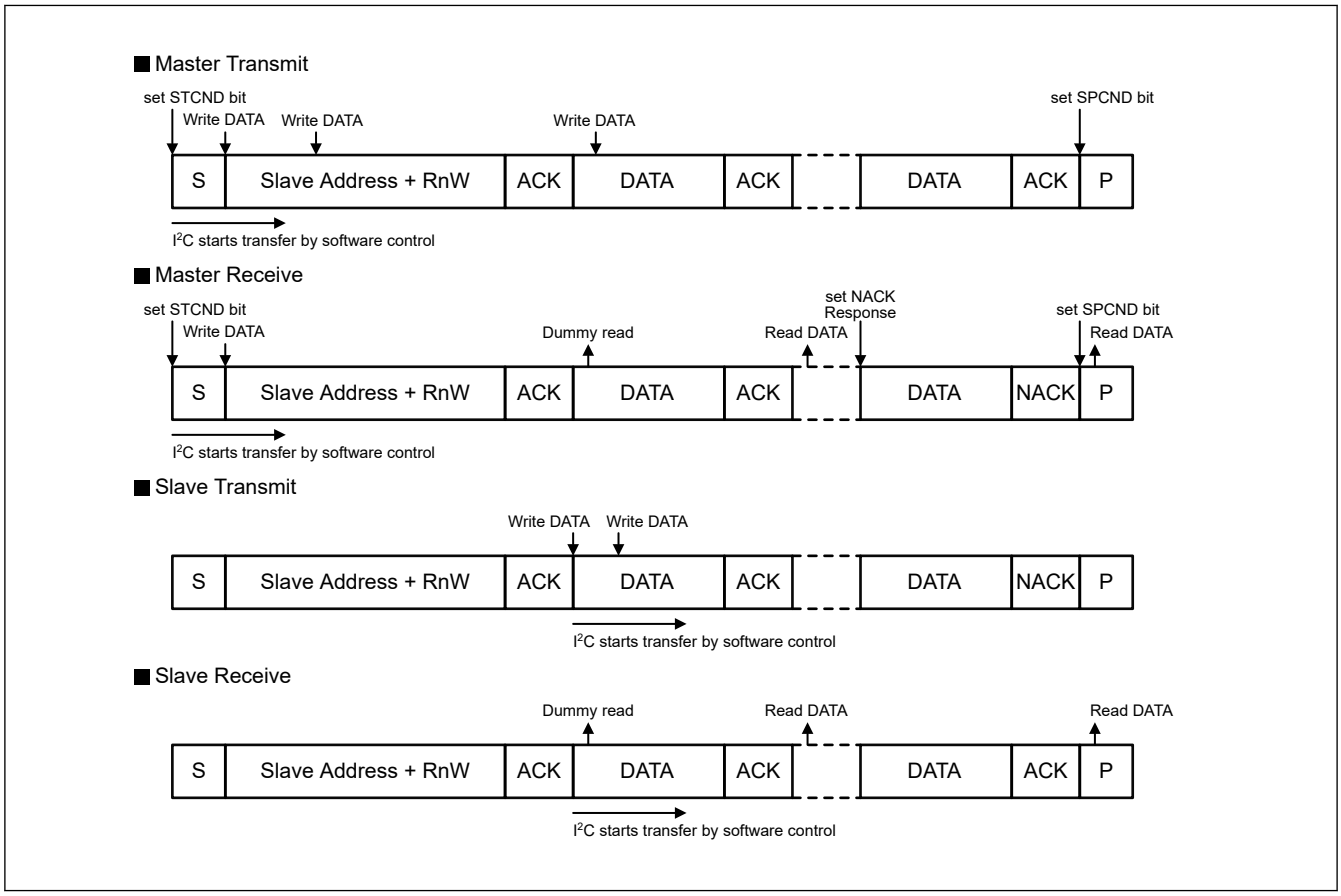

Figure 30.66 Data handler with single buffer transfer

30.3.2.2.2 Transfer Method in I3C Mode

(1) Normal FIFO Buffer Transfer

I3C autonomously starts transfer when data and command are written.

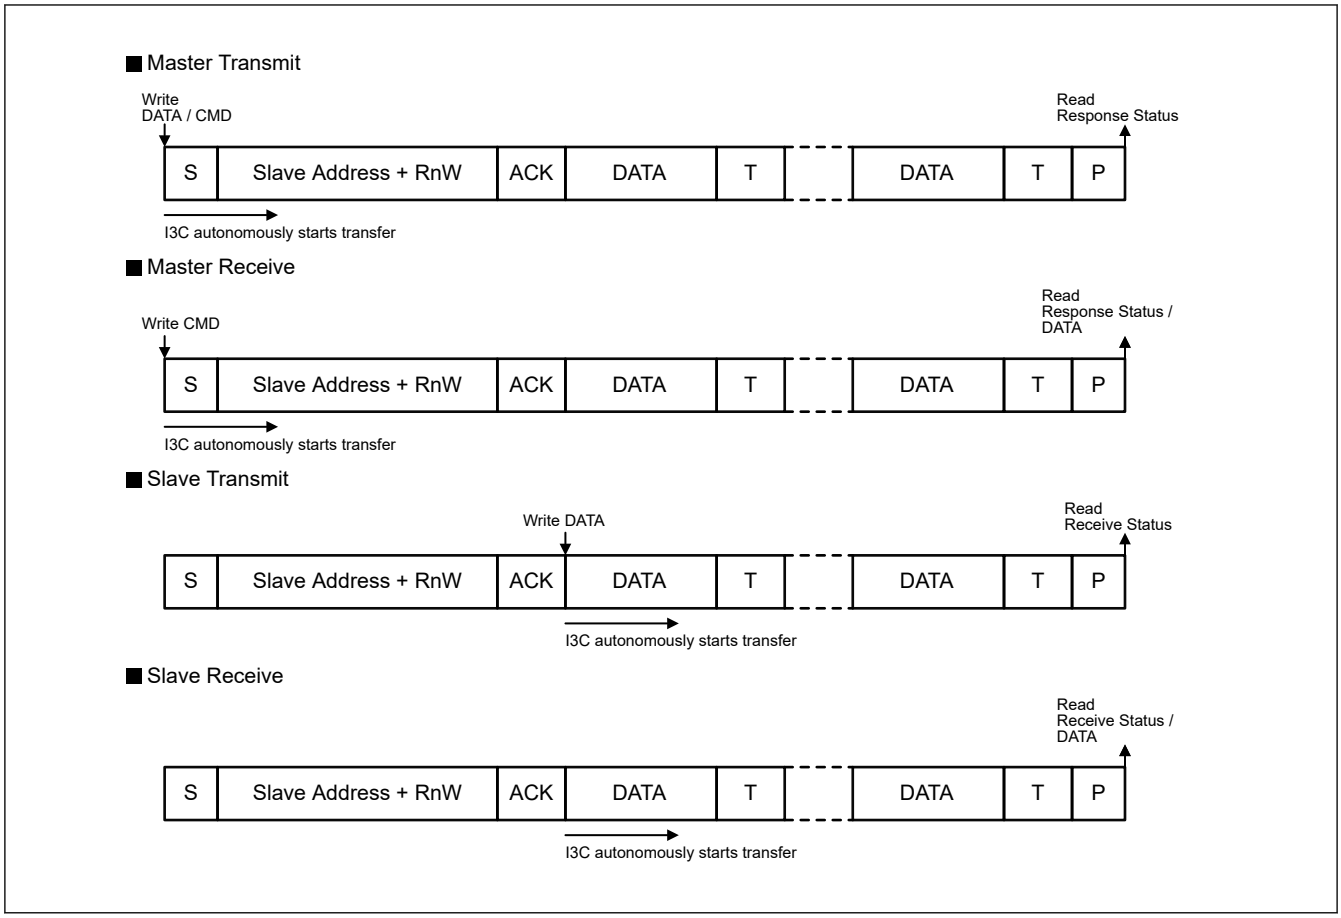

Figure 30.67 Data handler with normal FIFO buffer transfer

(2) High Priority FIFO Buffer Transfer

I3C handles the command of the High Priority FIFO buffer transfer higher priority than the command of the normal FIFO buffer transfer.

If data and commands are written to the High Priority FIFO buffer during normal FIFO buffer transfer, I3C waits for the STOP condition and then processes the command in the High Priority FIFO buffer.

After the command processing in the High Priority FIFO buffer is completed, if the command remains in the normal FIFO buffer, the I3C resumes processing the command in the normal FIFO buffer.

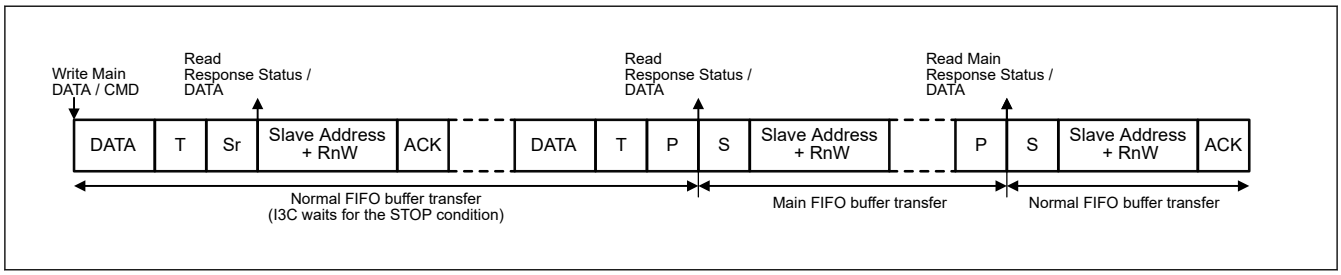

Figure 30.68 Data handler with high priority FIFO buffer transfer

30.3.2.3 I²C/I3C Protocol

30.3.2.3.1 Communication Protocol

(1) I²C Communication Data Format

The I²C bus format consists of 8-bit data and 1-bit acknowledge. The frame following a START condition or Repeated START condition is an address frame used to specify a slave device with which the master device communicates. The specified slave is valid until a new slave is specified or a STOP condition is issued.

Figure 30.69 shows the I²C bus format, and Figure 30.70 shows the I²C bus timing.

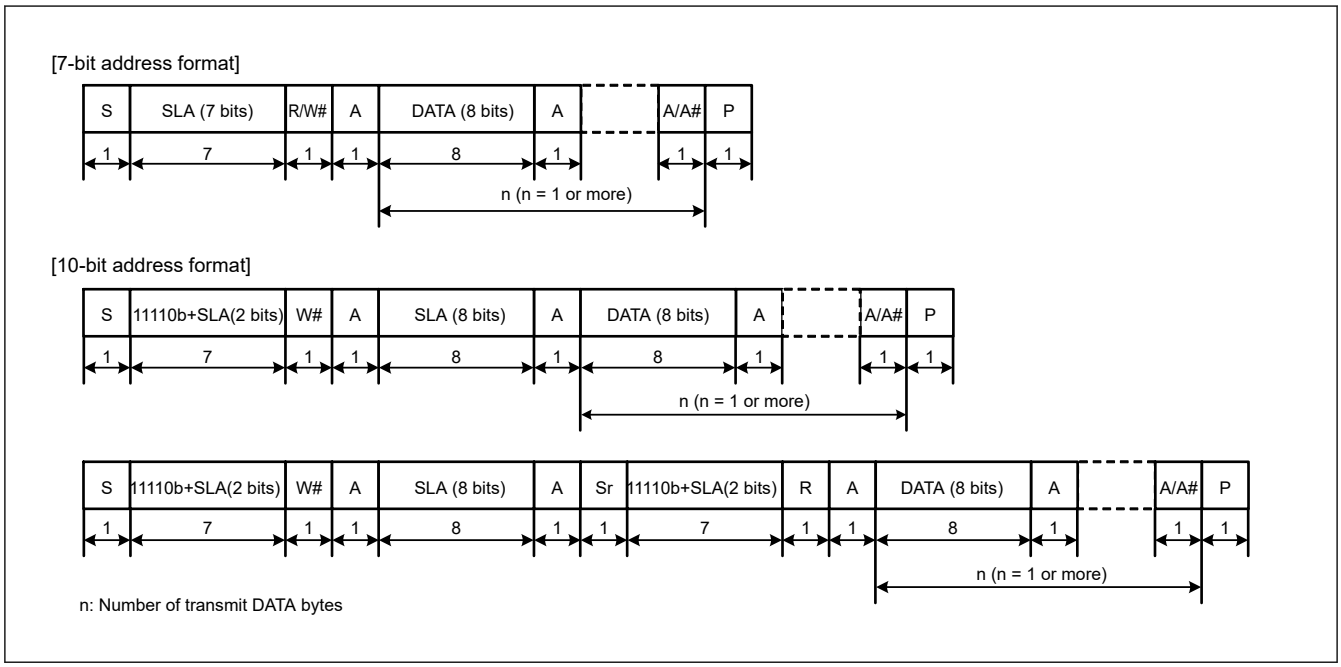

Figure 30.69 I²C bus format

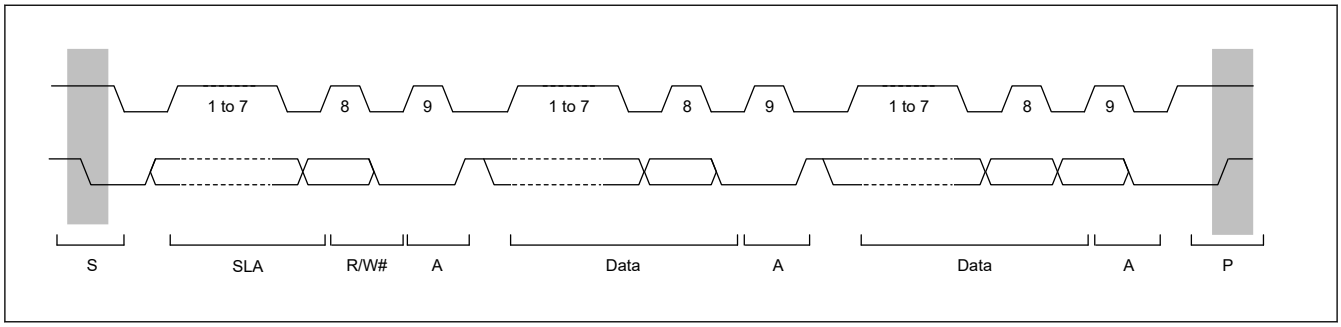

Figure 30.70 I²C bus timing (SLA = 7 bits)

S:	START condition. The master device drives the I3C_SDA line low from high level while the I3C_SCL line is at a high level.
SLA:	Slave address, by which the master device selects a slave device.
R/W#:	Indicates the direction of data transfer: from the slave device to the master device when R/W = 1, or from the master device to the slave device when R/W = 0.
A:	Acknowledge. The receive device drives the I3C_SDA line low. (In master transmit mode, the slave device returns acknowledge. In master receive mode, the master device returns acknowledge.)
A#:	Not Acknowledge. The receive device drives the I3C_SDA line high.
Sr:	Repeated START condition. The master device drives the I3C_SDA line low from the high level after the setup time has elapsed with the I3C_SCL line at the high level.

DATA: Transmitted or received data

P: STOP condition. The master device drives the I3C_SDA line high from low level while the I3C_SCL line is at a high level.

(2) I3C Communication Data Format

Figure 30.71 through Figure 30.77Figure 30.74 illustrate a typical communication for each of the six I3C Protocols. While these diagrams do not exhaustively illustrate all possible I3C communications, they do serve as useful introductions to the signaling and transmission formatting used in each I3C Protocol.

Figure 30.71 illustrates example communication using I3C Single Data Rate (SDR) coding with Broadcast (0x7E). It shows the Master reading a byte of data from the Slave at Address 0x2B in SDR Mode. From the Bus Free Condition, the Master issues a START by driving the I3C_SDA line Low while keeping the I3C_SCL line High. It then issues the Broadcast Address (0x7E) followed by RnW (0 for Write). Then the Master turns on a pull-up resistor and goes to Open Drain.

All Slaves ACK by pulling the I3C_SDA line Low (in the Figure, pink fill means the Slave is in control of the I3C_SDA line at this time). The Master then issues a Repeated START, then the Address of the Slave (0x2B) it wants to read followed by RnW (1 for Read). The Master then turns on a pull-up resistor and goes to Open Drain, allowing the Slave to acknowledge by pulling the I3C_SDA line Low. At this point, the Master continues to toggle the I3C_SCL line and release the I3C_SDA line, allowing the Slave to drive SDA to send one byte of data (0x4A) followed by T. T = 1 informs the Master that there is additional data, whereas T = 0 signals the end. Here there is additional data, so the Slave drives SDA High until SCL goes High, at which time it releases SDA. The Master has the option of holding SDA High with a weak pullup, which signals to the Slave that the Master allows another byte to be transmitted, or to pull SDA Low (while SCL is High – hence a Repeated START), which would signal to the Slave that the Master has terminated the Read and is taking over.

SDR Mode is backwards compatible with Legacy I2C Devices, because the High time of an SCL pulse is always less than 50ns and therefore SCL will always appear to be Low because of the I2C 50ns Spike Filter.

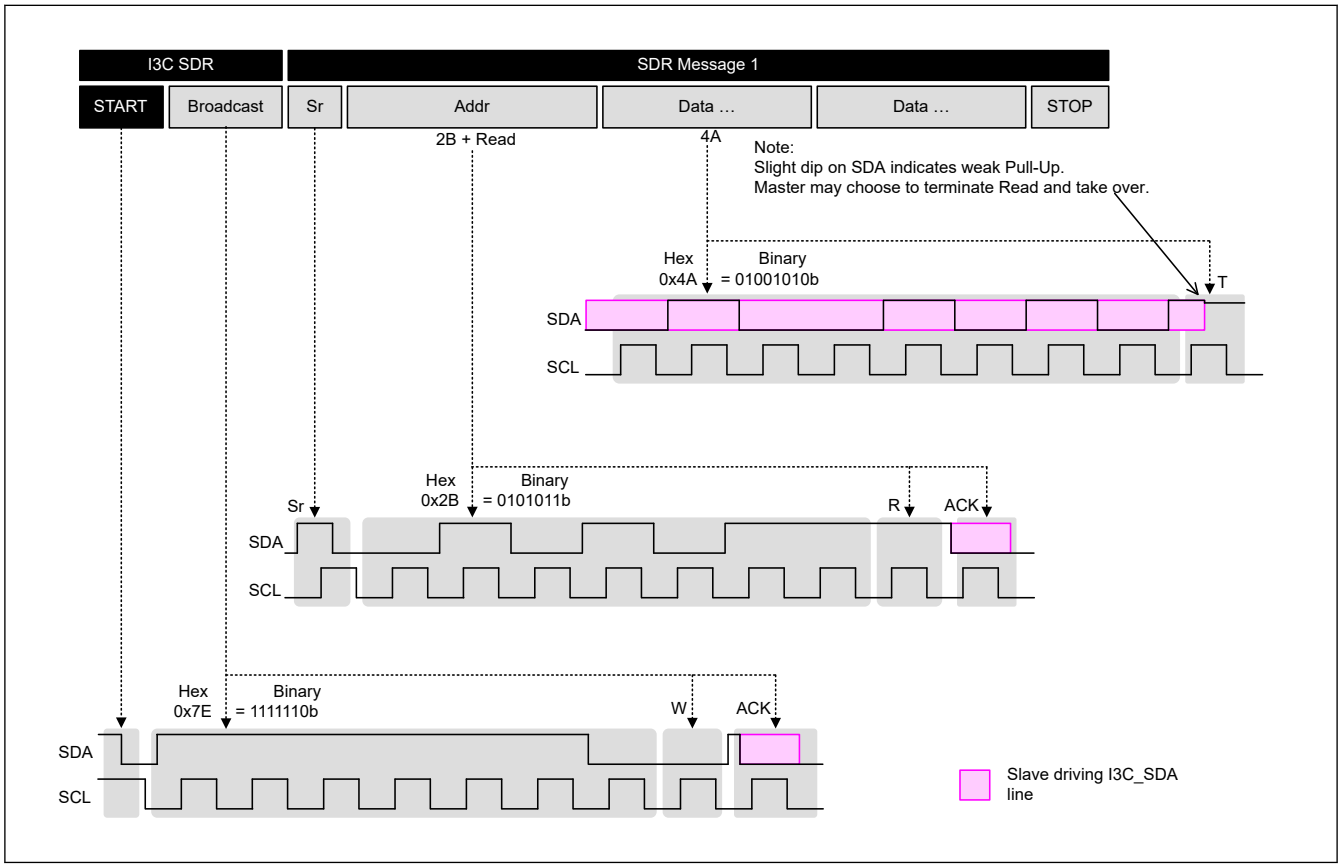

Figure 30.71 Example communication using I3C coding SDR with broadcast (0x7E)

Figure 30.72 illustrates example communication using I3C Single Data Rate (SDR) coding without Broadcast (0x7E). It shows the Master reading a byte of data from the Slave at Address 0x2B in SDR Mode. From the Bus Free Condition, The Master then issues a START, then the Address of the Slave (0x2B) it wants to read followed by RnW (1 for Read).

The Master then turns on a pull-up resistor and goes to Open Drain, allowing the Slave to acknowledge by pulling the I3C_SDA line Low. At this point, the Master continues to toggle the I3C_SCL line and release the I3C_SDA line, allowing the Slave to drive SDA to send one byte of data (0x4A) followed by T. T = 1 informs the Master that there is additional data, whereas T = 0 signals the end. Here there is additional data, so the Slave drives SDA High until SCL goes High, at which time it releases SDA. The Master has the option of holding SDA High with a weak pull-up, which signals to the Slave that the Master allows another byte to be transmitted, or to pull SDA Low (while SCL is High – hence a Repeated START), which would signal to the Slave that the Master has terminated the Read and is taking over.

SDR Mode is backwards compatible with Legacy I2C Devices, because the High time of an SCL pulse is always less than 50ns and therefore SCL will always appear to be Low because of the I2C 50ns Spike Filter.

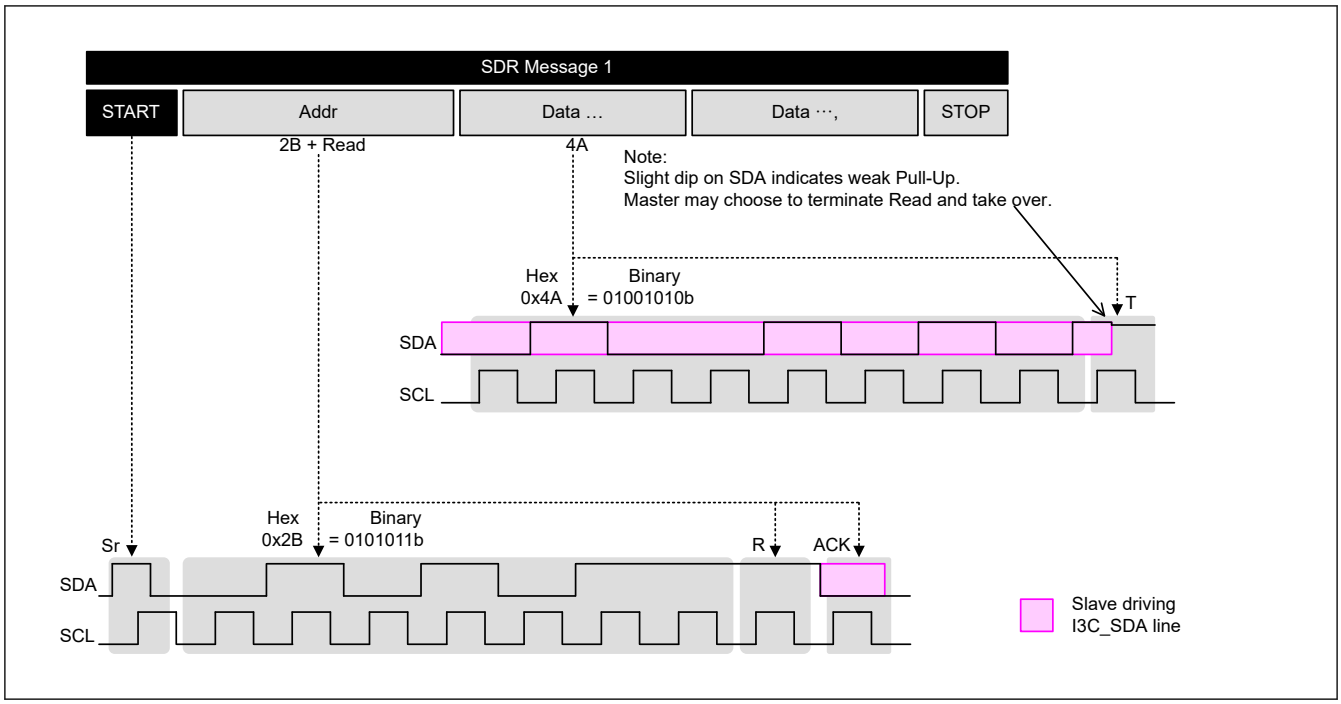

Figure 30.72 Example communication using I3C coding SDR without broadcast (0x7E)

Figure 30.73 shows the Master issuing a CCC Direct Command to a single Slave. This particular command (GETPID) reads the Provisional ID of a Slave.

From the Bus Free Condition, the Master issues a START by driving the I3C_SDA line Low while keeping the I3C_SCL line High. It then issues the Broadcast Address (0x7E) followed by RnW (0 for Write). Then the Master turns on a pull-up resistor and goes to Open Drain. All Slaves ACK by pulling SDA Low (in the Figure, pink fill means the Slaves are in control of SDA at this time). The Master then issues the Direct Common Command Code for GETPID (0x8C) followed by parity bit T (odd parity = 0 for 0x8C) then the 7-bit Dynamic Address of the Slave (chosen arbitrarily here to be 0x2B) followed by a RnW bit (1 for Read). Then the Master turns on a pull-up resistor and goes to Open Drain, allowing the Slave at Address 0x2B to ACK by pulling SDA Low, which tells the Master that the Slave Acknowledges the command and will comply. (Alternatively, the Slave may NACK by not pulling SDA Low, which would inform the Master that the Slave will not comply – in this case, that an error occurred.) Following the ACK the Slave outputs its 48-bit PID one byte at a time, and then the Master issues a Repeated START (this part of the waveform sequence is not shown in the Figure).

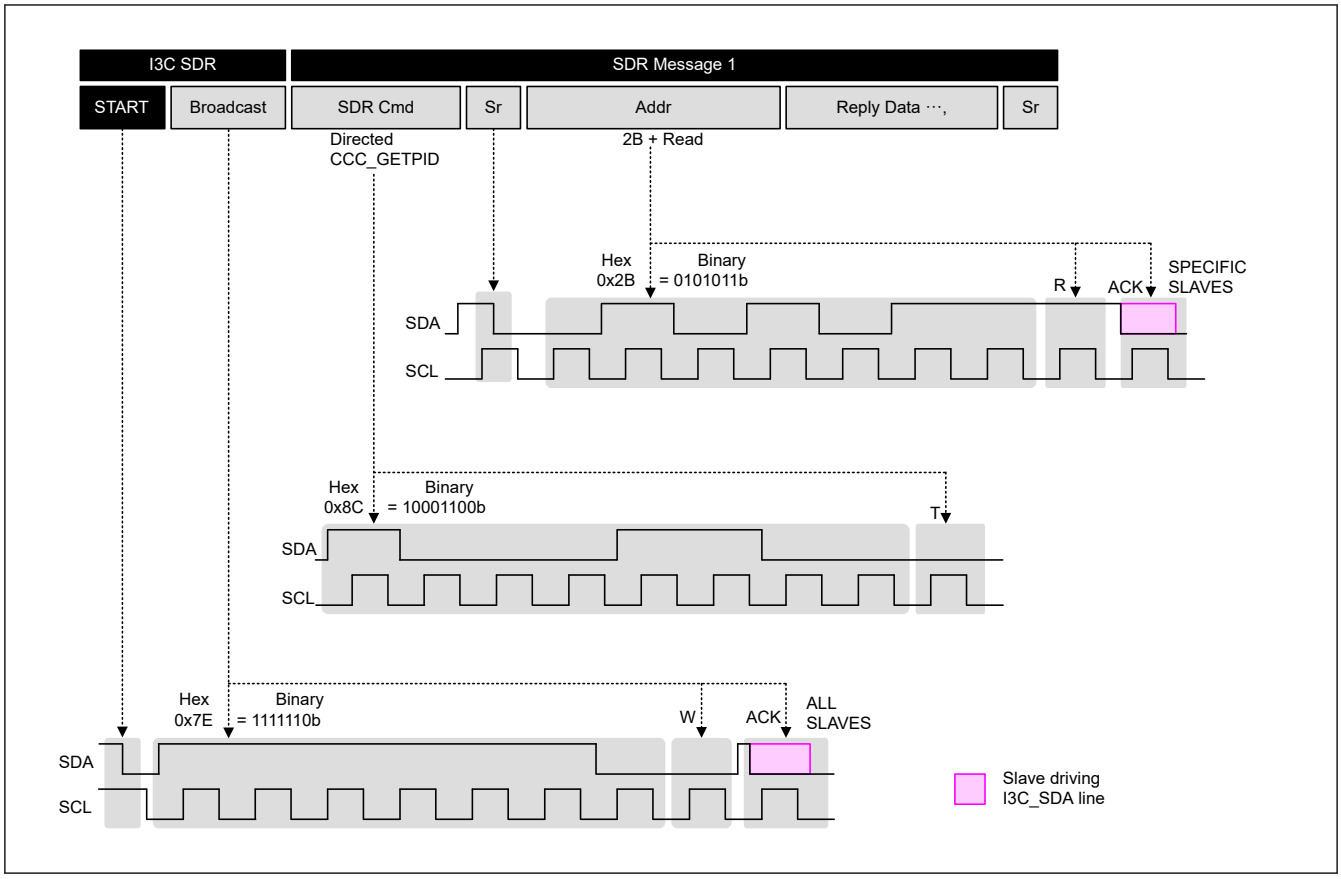

Figure 30.73 Example communication using I3C coding SDR with CCC direct addressing

Figure 30.74 illustrates example SDR communication with a CCC Broadcast command. The command used in this example sets the Maximum Read Length of all Slaves to 43 bytes (0x002B).

From the Bus Free Condition, the Master issues a START by driving the I3C_SDA line Low while keeping the I3C_SCL line High. It then issues the Broadcast Address (0x7E) followed by RnW (0 for Write). Then the Master turns on a pull-up resistor and goes to Open Drain. All Slaves ACK by pulling SDA Low (in the Figure, pink fill means the Slaves are in control of SDA at this time). The Master then issues the Broadcast Common Command Code for SETMRL (0x09) followed by parity bit T (odd parity = 1 for 0x09), and then 2 data bytes (MSB first) to define the maximum number of bytes which can be read from a Slave in a single read operation. Each data byte is followed by a T bit (parity bit – odd parity). After this the Master issues a Repeated START.

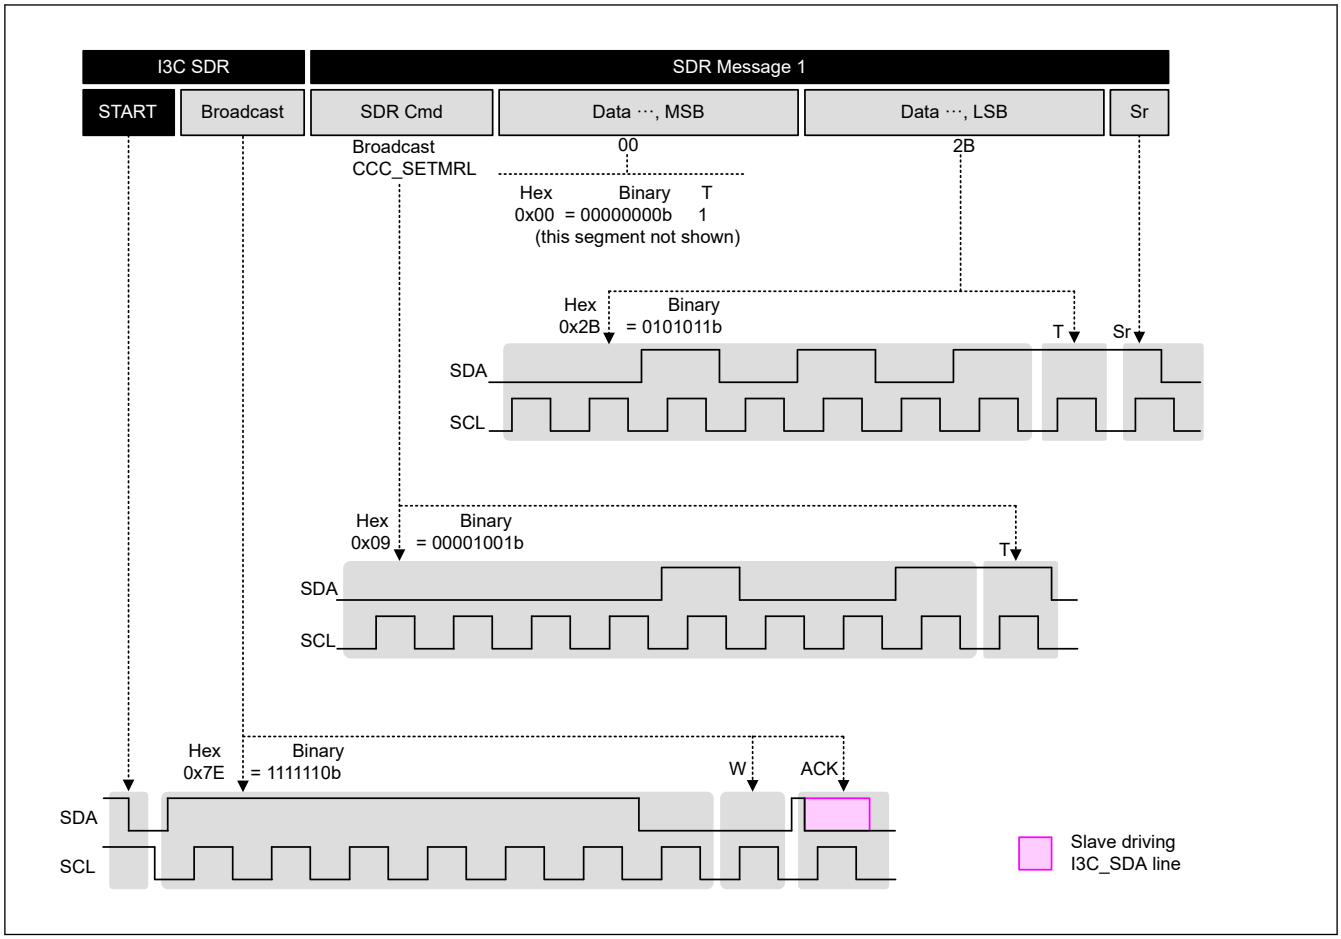

Figure 30.74 Example communication using I3C coding SDR with CCC broadcast

Figure 30.75 illustrates use of the HDR-DDR (Double Data Rate) Mode. It shows how the Master can change the Mode from SDR (Single Data Rate) Mode to HDR-DDR Mode, and a sample of the HDR-DDR data format.

From the Bus Free Condition, the Master issues a START by driving the I3C_SDA line Low while keeping the I3C_SCL line High. The Master then issues the Broadcast Address (0x7E) followed by RnW (0 for Write). Then the Master turns on a pull-up resistor and goes to Open Drain. All Slaves 'ACK' by pulling SDA Low (in the Figure, pink fill means the Slaves are in control of SDA at this time). The Master then issues the Broadcast Common Command Code for ENTHDR0 (0x20), followed by parity bit T (odd parity = 0 for 0x20). At this point, the Bus is in HDR-DDR Mode. In the HDR-DDR protocol, the I3C_SDA line is sampled on every SCL edge (both Low-to-High and High-to-Low transitions of SCL). The HDR-DDR Word consists of a 2-bit Preamble, followed by two bytes of data, followed by two parity bits. The waveform for the 5-bit CRC and following traffic is not shown in the Figure.

HDR-DDR Mode is backwards compatible with Legacy I^2C Devices, because the High time of an SCL pulse is always less than 50ns and as a result SCL will always appear to be Low because of the I^2C 50ns Spike Filter.

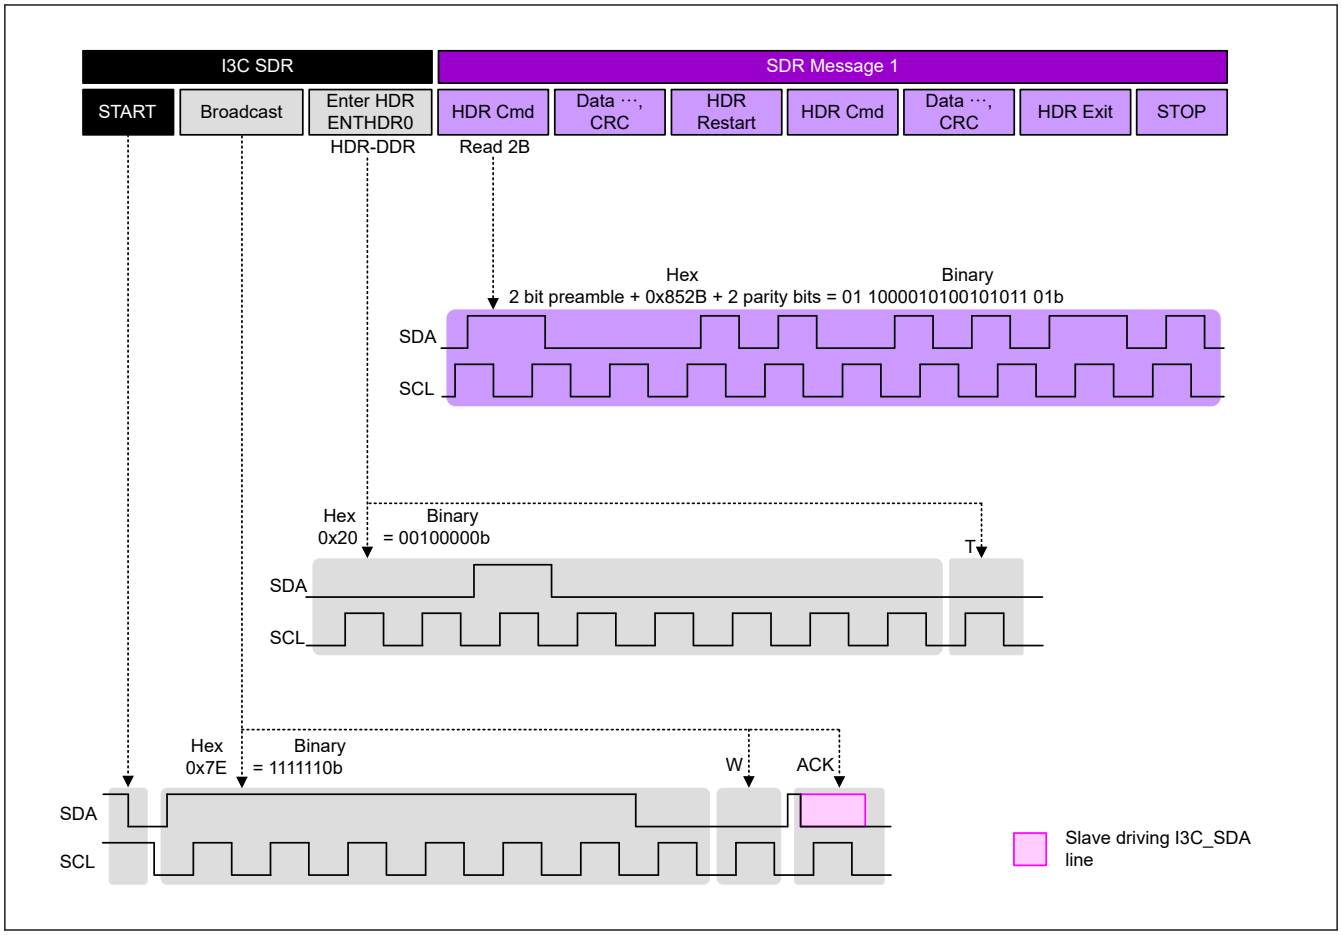

Figure 30.75 Example communication using HDR-DDR protocol

Figure 30.76 illustrates use of the HDR-TSL (Ternary Symbol Legacy) Mode, which is only used if a Legacy I^{2}C Device is present on the Bus. It shows how the Master can change the Mode from SDR (Single Data Rate) Mode to HDR-TSL Mode, and a sample of the HDR-TSL data format.

From the Bus Free Condition, the Master issues a START by driving the I3C_SDA line Low while keeping the I3C_SCL line High. It then issues the Broadcast Address (0x7E) followed by RnW (0 for Write). Then the Master turns on a pull-up resistor and goes to Open Drain. All Slaves ACK by pulling SDA Low (in the Figure, pink fill means the Slaves are in control of SDA at this time). The Master then issues the Broadcast Common Command Code for ENTHDR2 (0x22) followed by parity bit 'T' (odd parity = 1 for 0x22). At this point, the Bus is in HDR-TSL Mode. In this protocol, the I3C_SCL line is more than just the clock. Both SDA transitions and SCL transitions carry data. The ternary conversion can be understood by considering that each octal digit is equivalent to two ternary Symbols. For example, for octal sequence 412255 we have: 4 = 3 + 1, 1 = 0 + 1, 2 = 0 + 2, 2 = 0 + 2, 5 = 3 + 2, 5 = 3 + 2. The clock pulse occurs when SCL transitions, when SDA transitions, or when both lines transition simultaneously.

HDR-TSL Mode is backwards compatible with Legacy I^{2}C Devices, because the High time of an SCL pulse is always less than 50ns, and as a result SCL will always appear to be Low due to the I^{2}C 50ns Spike Filter. Note that in the Figure, the thick blue High-to-Low transitions of SCL are dummy edges added in order to make sure that SCL pulses are always less than 50ns. High-to-Low SCL transitions that occur without a simultaneous SDA transition are always dummy transitions.

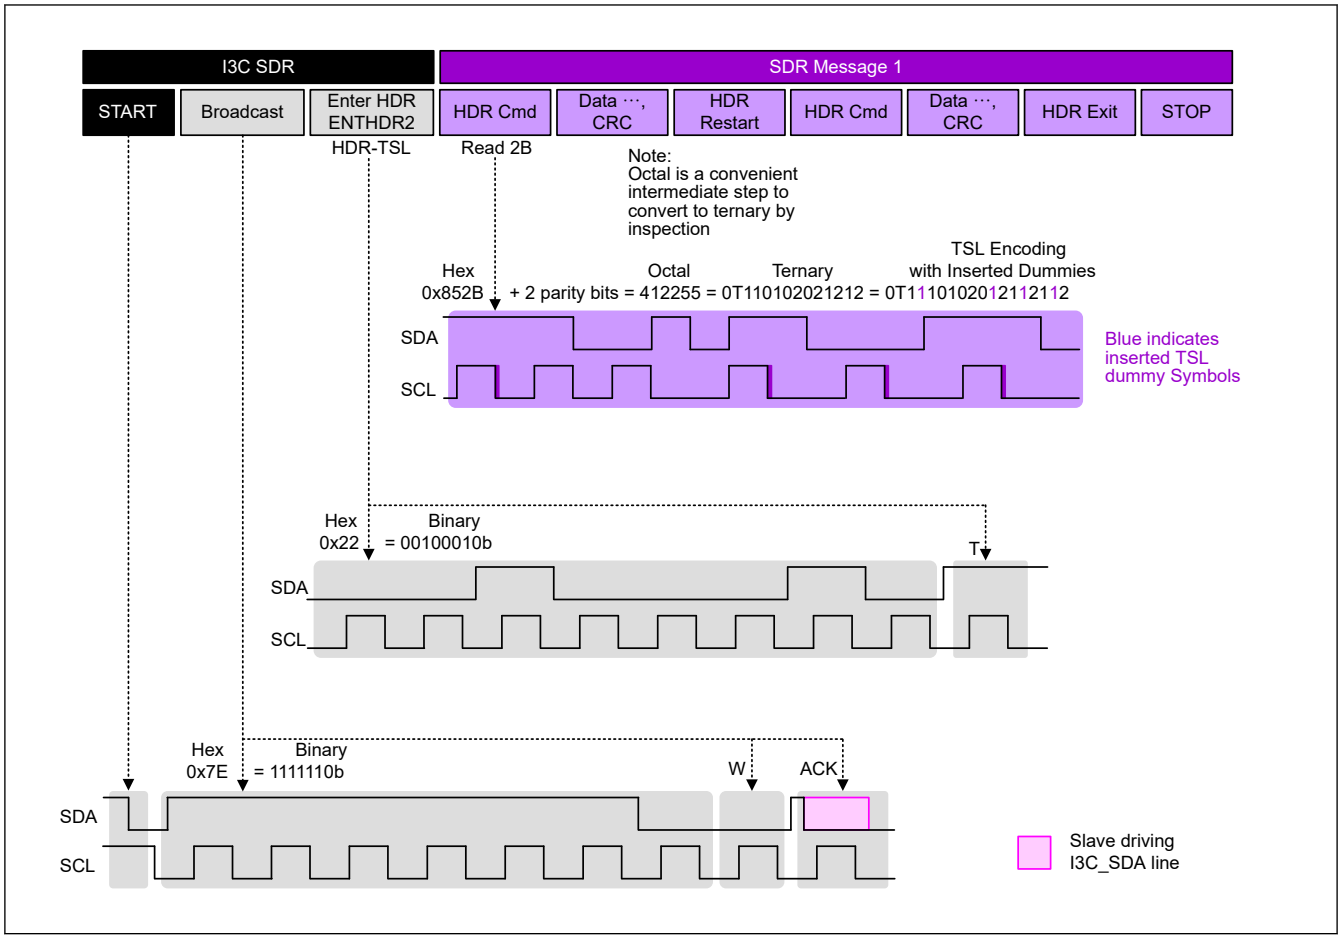

Figure 30.76 Example communication using HDR-TSL protocol

Figure 30.77 illustrates use of HDR-TSP (High Data Rate – Ternary Symbol for Pure Bus) Mode. This protocol is only used when there are no I^2C Devices on the Bus. The Figure shows how the Master can change the Mode from SDR (Single Data Rate) to HDR-TSP Mode, and a sample of the TSL data format.

From the Bus Free Condition, the Master issues a START by driving the I3C_SDA line Low while keeping the I3C_SCL line High. The Master then issues the Broadcast Address (0x7E) followed by RnW (0 for Write). Then the Master turns on a pull-up resistor and goes to Open Drain. All Slaves ACK by pulling SDA Low (in the Figure, pink fill means the Slaves are in control of SDA at this time). The Master then issues the Broadcast Common Command Code for ENTHDR1 (0x21) followed by parity bit 'T' (odd parity = 1 for 0x21). At this point, the Bus is in HDR-TSP Mode. In the HDRTSP protocol, the SCL is more than just the clock. Both SDA transitions and SCL transitions carry data. The ternary conversion can be understood by considering that each octal digit is equivalent to two ternary Symbols. For example, for octal sequence 412255 (4 = 3 + 1, 1 = 0 + 1, 2 = 0 + 2, 2 = 0 + 2, 5 = 3 + 2, 5 = 3 + 2). The clock pulse occurs when SCL transitions, when SDA transitions, or when both lines transition simultaneously.

HDR-TSP Mode supports the highest data-rate and uses the least energy per byte, however it is not backwards compatible with Legacy I^2C Devices since the High duration of an SCL pulse can exceed 50ns.

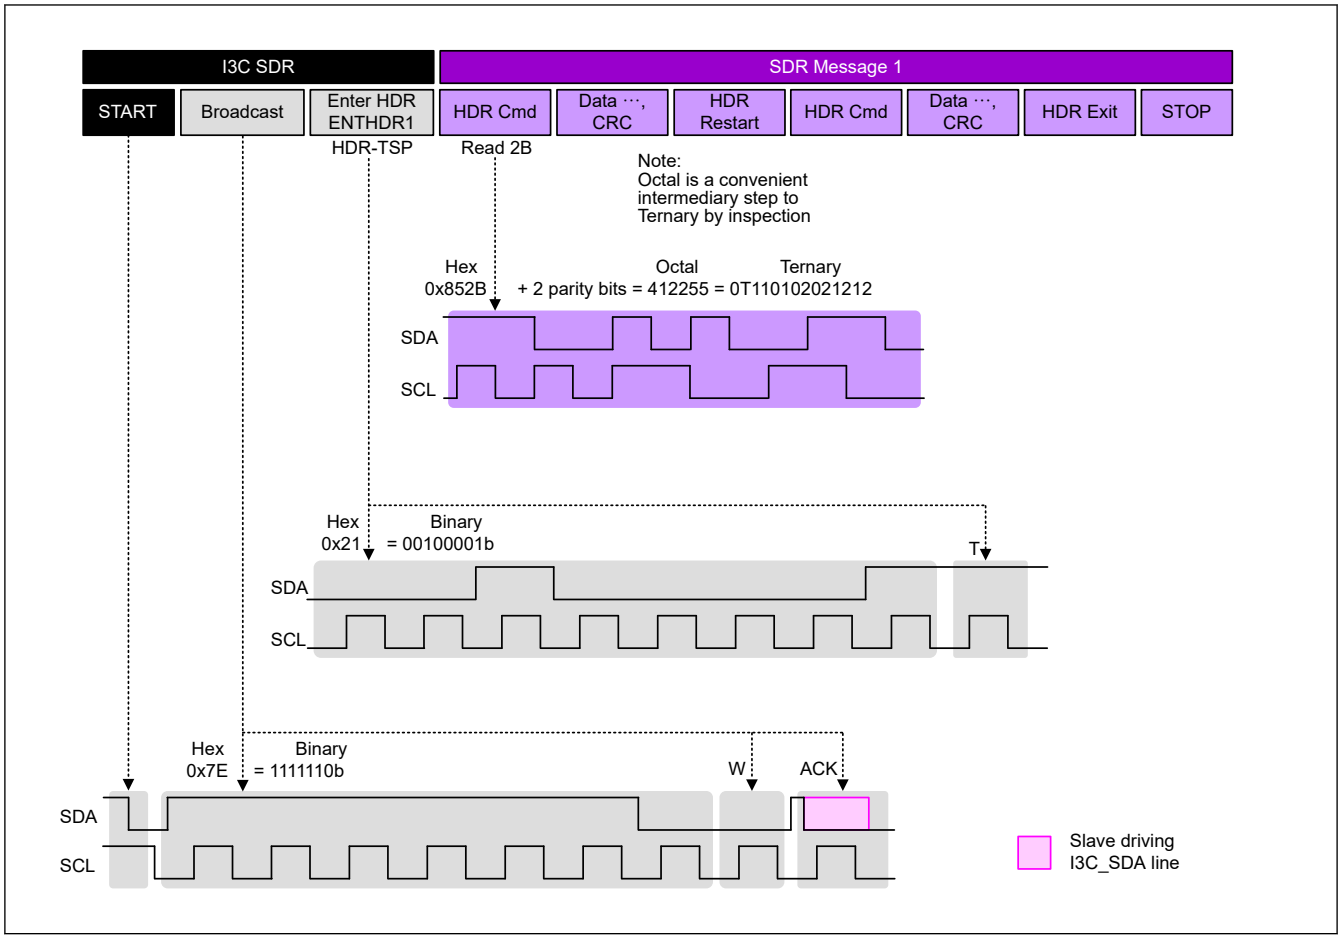

Figure 30.77 Example communication using HDR-TSP protocol

30.3.2.3.2 Bus Conditions

I3C defines three distinct conditions in which the I3C Bus shall be considered inactive: Bus Free, Bus Available, and Bus Idle (see Figure 30.78).

(1) Bus Free Condition

State on the I3C Bus where both the I3C_SCL line and the I3C_SDA line are High for at least the period set by BFRECDT.FRECYC[8:0] bit.

(2) Bus Available Condition [I3C mode]

State on the I3C Bus where both the I3C_SCL line and the I3C_SDA line are High for at least the period set by BAVLCDT.AVLCYC[8:0] bit.

A Slave may only issue a START Request (For example, for an In-Band Interrupt, or for a Master Handoff Request) after a Bus Available Condition.

(3) Bus Idle Condition [I3C mode]

State on the I3C Bus where both the I3C_SCL line and the I3C_SDA line are High for at least the period set by BIDLCDT.IDLCYC[17:0] bit.

A Slave may only issue a START Request after a Bus Idle Condition.

Specifications are as follows. IDLE needs to be the largest.

BFRECDT.FRECYC[8:0] < BAVLCDT.AVLCYC[8:0] < BIDLCDT.IDLCYC[17:0]

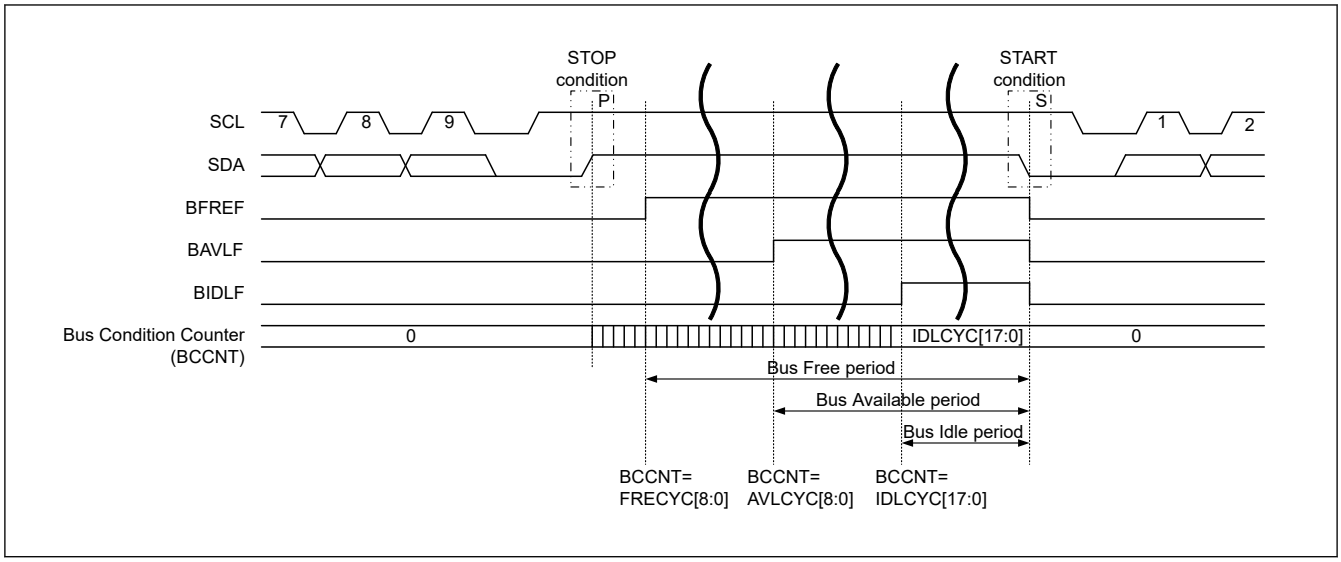

Figure 30.78 Bus conditions

30.3.2.3.3 START Condition / Repeated START Condition / STOP Condition Issuing Function

(1) Issuing a START Condition

I3C issues a START condition when the CNDCTL.STCND bit is set to 1.

Set the STCND bit to 1 (START condition issuance request) when the BCST.BFREF flag is set to 1 (bus free state).

I3C issues a START condition.

When a START condition is issued normally, I3C automatically shifts to the master transmit mode. A START condition is issued in the following sequence.

[START condition issuance]

- Drive the I3C_SDA line low (high level to low level).
- Ensure the time set in STDBR.SBRHO[7:0] and the START condition hold time.
- Drive the I3C_SCL line low (high level to low level).
- Detect low level of the I3C_SCL line and ensure the low-level period of I3C_SCL line set in STDBR.SBRLO[7:0].

(2) Issuing a Repeated START Condition

I3C issues a Repeated START condition when the CNDCTL.SRCND bit is set to 1.

When the SRCND bit is set to 1, a Repeated START condition issuance request is made and I3C issues a Repeated START condition when the BCST.BFREF flag = 0 (bus busy state) and the PRSST.CRMS bit = 1 (master mode).

A Repeated START condition is issued in the following sequence.

[Repeated START condition issuance]

- Release the I3C_SDA line.
- Ensure the low-level period of I3C_SCL line set in STDBR.SBRLO[7:0] or EXTBR.EBRLO[7:0] .
- Release the I3C_SCL line (low level to high level).
- Detect a high level of the I3C_SCL line and ensure the time set in STDBR.SBRLO[7:0] or EXTBR.EBRLO[7:0] and the Repeated START condition setup time.
- Drive the I3C_SDA line low (high level to low level).
- Ensure the time set in STDBR.SBRHO[7:0] or EXTBR.EBRHO[7:0] or EXTBR.EBRHO[7:0] and the Repeated START condition hold time.
- Drive the I3C_SCL line low (high level to low level).

- Detect a low level of the I3C_SCL line and ensure the low-level period of I3C_SCL line set in STDBR.SBRLO[7:0] or EXTBR.EBRLO[7:0] .

Note: When issuing Repeated START conditions request, write the slave address to NTDTBP0 after confirming CNDCTL.SRCND = 0. Data written in the period of CNDCTL.SRCND = 1 is not forwarded because retransmission condition before the occurrence.

To issue a Repeated START condition in Hs-mode, follow the steps below.

1. Wait for PRSTDBG.SCOLV=0.
2. Set EXTBR.EBRHO[7:0] to satisfy the hold time of the Repeated START condition.
3. Set the CNDCTL.SRCND bit to 1.
4. After confirming CNDCTL.SRCND=0, wait for PRSTDBG.SCOLV=0.
5. Set EXTBR.EBRHO [7: 0] according to the High period of the SCL clock in Hs-mode.
6. Write the slave address to NTDTBP0.

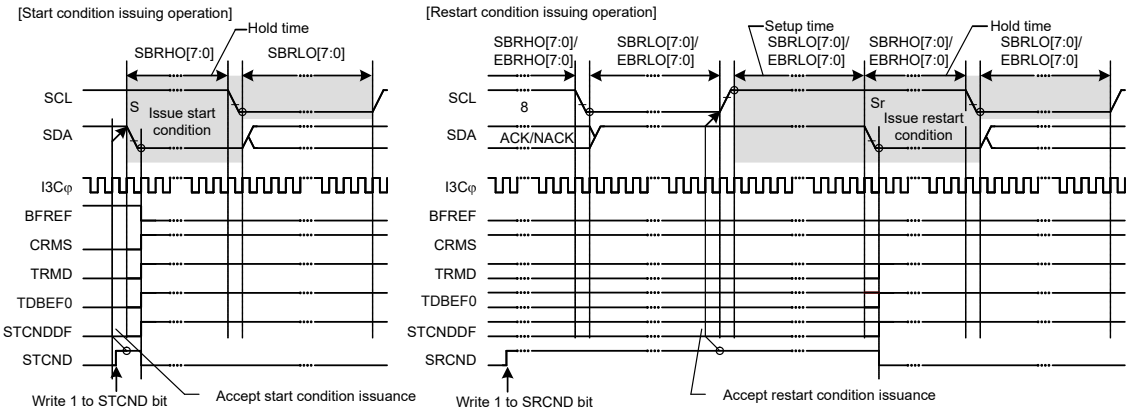

Figure 30.79 START condition / repeated START condition issue timing (STCND and SRCND bits)

Figure 30.80 shows the operation to issue a Repeated START condition after the master transmission.

[Repeated START condition issuance after the master transmission]

- Initial setting. For details, see section 30.3.3.1. Initial Setting Flow.
- Read the BFREF flag in BCST to check that the bus is open, and then set the STCND bit in CNDCTL to 1 (START condition issuance request). Upon receiving the request, I3C issues a START condition. At the same time, the BFREF flag is automatically set to 0 and the STCNDDF flag in BST is automatically set to 1 and the STCND bit is automatically set to 0. At this time, if the START condition is detected and the internal levels for the SDA output state and the levels on the I3C_SDA line have matched while the STCND bit = 1, I3C recognizes that issuing of the START condition as requested by the STCND bit has been successfully completed, and CRMS and TRMD bits in PRSST is automatically set to 1, placing I3C in master transmit mode. The NTST.TDBEF0 flag is also automatically set to 1 in response to setting of the TRMD bit to 1.
- Check that the NTST.TDBEF0 flag = 1, and then write the value for transmission (the slave address and the R/W# bit) to NTDTBP0. Once the data for transmission are written to NTDTBP0, the TDBEF0 flag is automatically set to 0, the data are transferred from NTDTBP0, and the TDBEF0 flag is again set to 1. After the byte containing the slave address and R/W# bit has been transmitted, the value of the TRMD bit is automatically updated to select master transmit or master receive mode in accord with the value of the transmitted R/W# bit. If the value of the R/W# bit was 0, I3C continues in master transmit mode. Since the BST.NACKDF flag being 1 at this time indicates that no slave device recognized the address or there was an error in communications, write 1 to CNDCTL.SPCND bit to issue a STOP condition. For data transmission with an address in the 10-bit format, start by writing 1111 0, the 2 higher-order bits of the slave address, and W to NTDTBP0 as the first address transmission. Then, as the second address transmission, write the 8 lower-order bits of the slave address to NTDTBP0.

- After confirming that the NTST.TDBEF0 flag = 1, write the data for transmission to the NTDTBP0 register. I3C automatically holds the I3C_SCL line low until the data for transmission are ready, a Repeated START condition is issued or a STOP condition is issued.
- After all bytes of data for transmission have been written to the NTDTBP0 register, wait until the value of the BST.TENDF flag returns to 1, and then, after check that the BST.STCNDDF flag = 1, set the BST.STCNDDF flag to 0.
- Set the SRCND bit in CNDCTL to 1 (Repeated START condition issuance request). Upon receiving the request, I3C issues a Repeated START condition.
- After check that the BST.STCNDDF flag = 1, write the value for transmission (the slave address and the R/W# bit) to NTDTBP0.

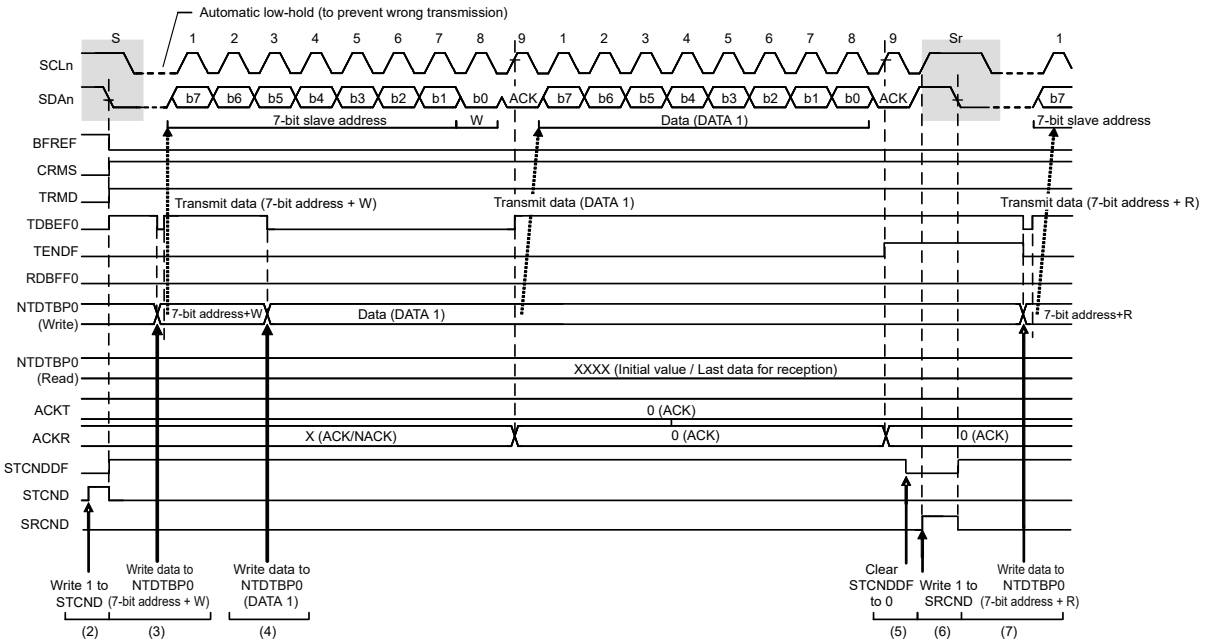

Figure 30.80 Repeated START condition issuance after the master transmission timing

(3) Issuing a STOP Condition

I3C issues a STOP condition when the SPCND bit in CNDCTL is set to 1.

When the SPCND bit is set to 1, a STOP condition issuance request is made and I3C issues a STOP condition when the BCST.BFREF flag = 0 (bus busy state) and the PRSST.MST bit = 1 (master mode).

A STOP condition is issued in the following sequence.

[STOP condition issuance]

- Drive the I3C_SDA line low (high level to low level).
- Ensure the low-level period of I3C_SCL line set in STDBR.SBRLO[7:0] or EXTBR.EBRLO[7:0] .
- Release the I3C_SCL line (low level to high level).
- Detect a high level of the I3C_SCL line and ensure the time set in STDBR.SBRHO[7:0] or EXTBR.EBRHO[7:0] and the STOP condition setup time.
- Release the I3C_SDA line (low level to high level).
- Ensure the time set in BFRECDT.FRECYC[8:0] and the bus free time.
- Set the BFREF flag to 1 (to release the bus mastership).

Note: To issue a STOP condition in Hs-mode, follow the steps below.

1. Wait for PRSTDBG.SCOLV=0.

2. Set EXTBR.EBRHO[7:0] to satisfy the setup time for the STOP condition.
3. Set the CNDCTL.SPCND bit to 1.
4. Wait for CNDCTL.SPCND=0.
5. Set EXTBR.EBRHO [7:0] according to the High period of the SCL clock in Hs-mode.

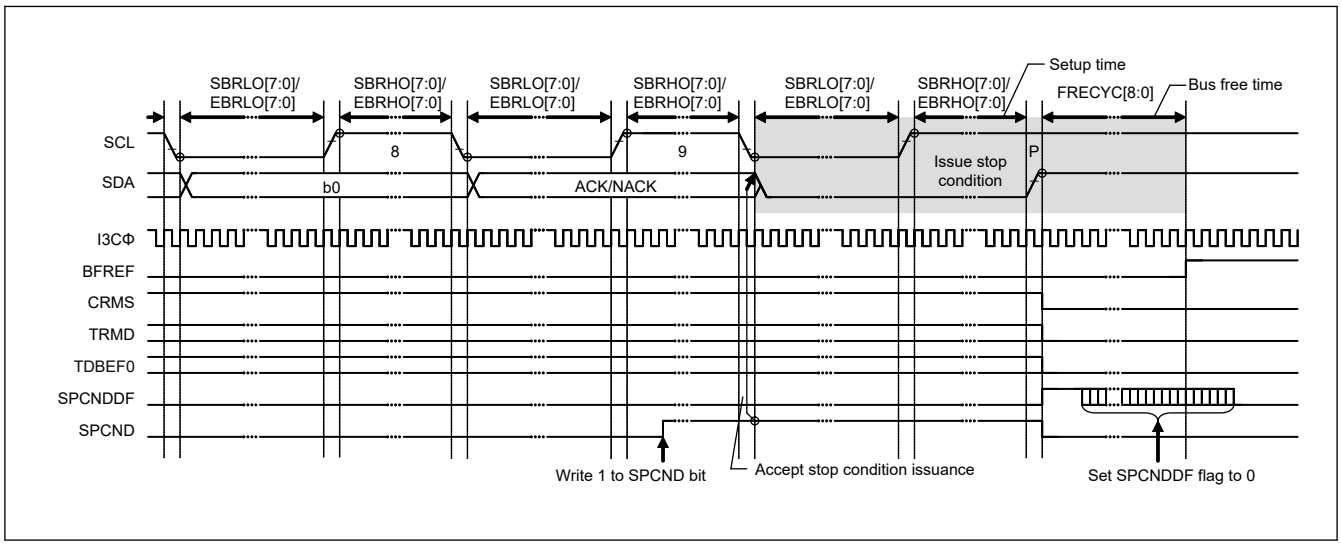

Figure 30.81 STOP condition issue timing (SPCND bit)

30.3.2.3.4 Address Match Detection

I3C can set three unique slave addresses in addition to the general call address and host address, and also can set 7- bit or 10- bit slave addresses.

(1) Slave-Address Match Detection [I2C mode]

I3C can set three unique slave addresses, and has a slave address detection function for each unique slave address.

When the SVCTL.SVAEy bit (y = 0 to 2) is set to 1, the slave addresses set in the SVDVADy register (y = 0 to 2) can be detected.

When I3C detects a match of the set slave address, the corresponding SVST.SVAF[y] flag (y = 0 to 2) is set to 1 at the rising edge of the ninth SCL clock cycle, and the NTST.RDBFF0 flag or the NTST.TDBEF0 flag is set to 1 by the following R/W# bit. This causes a Normal Rx Data buffer full interrupt (I3C_RX) or Normal Tx Data buffer empty interrupt (I3C_TX) to be generated. The SVAF[y] flag is used to identify which slave address has been specified.

Figure 30.82 to Figure 30.84 show the SVAF[y] flag set timing in three cases.

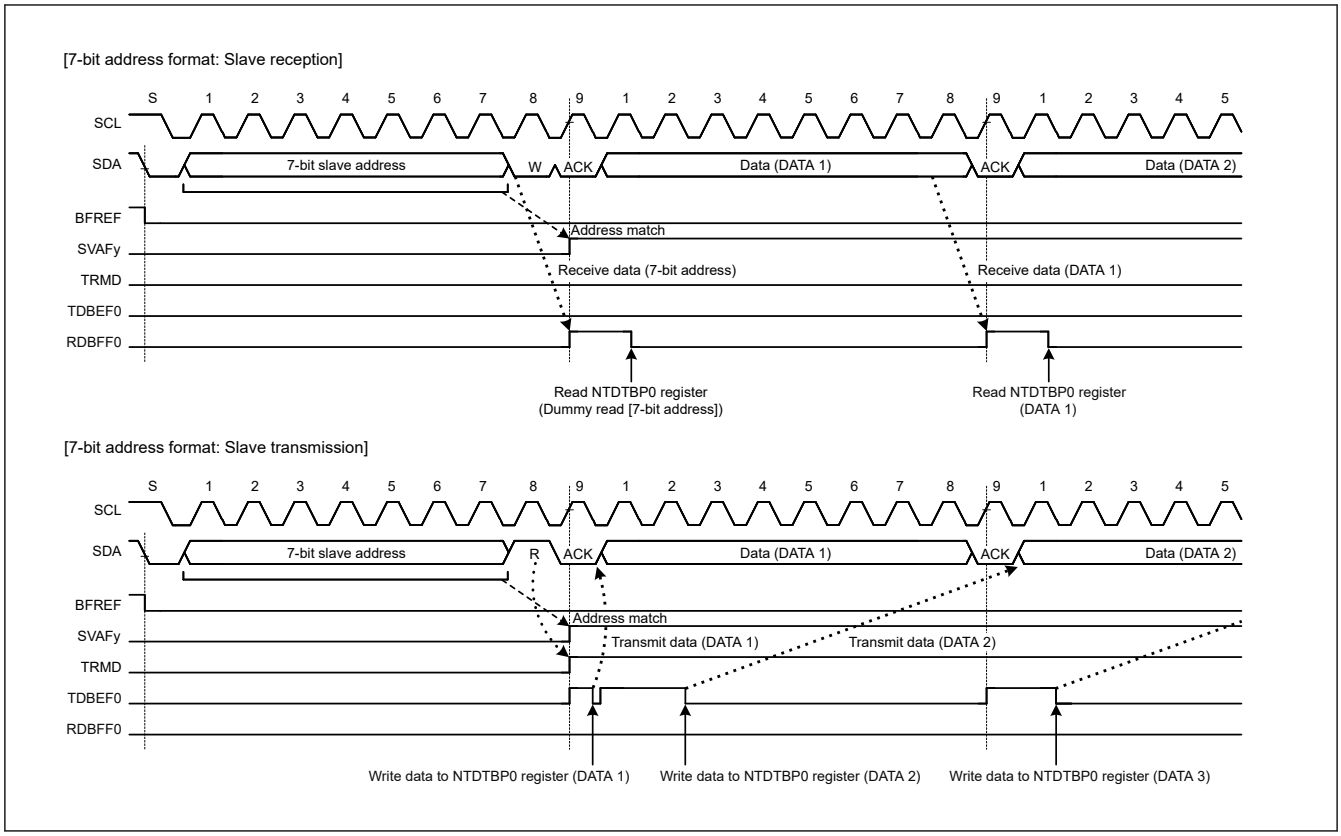

Figure 30.82 SVAFy flag set timing with 7-bit address format selected

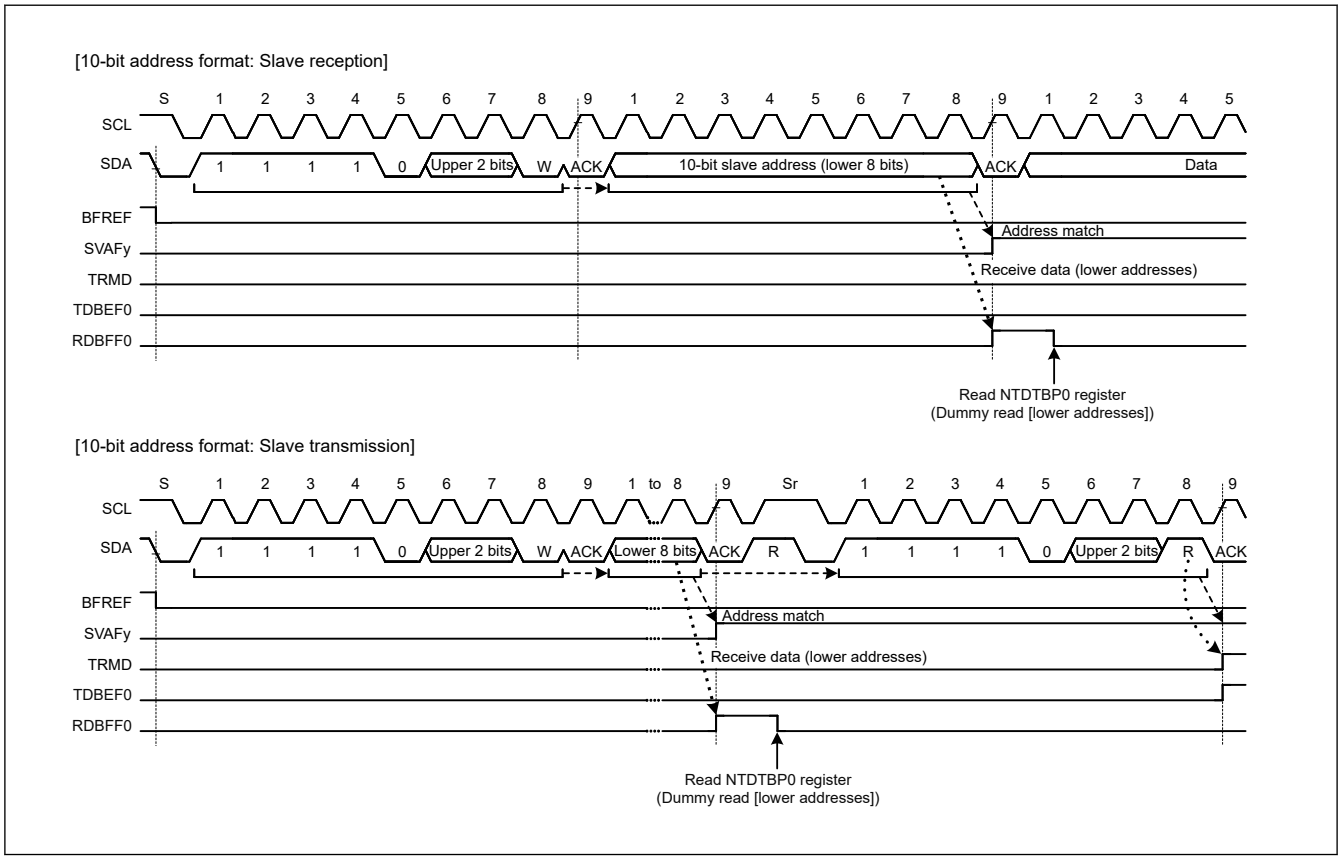

Figure 30.83 SVAFy flag set timing with 10-bit address format selected

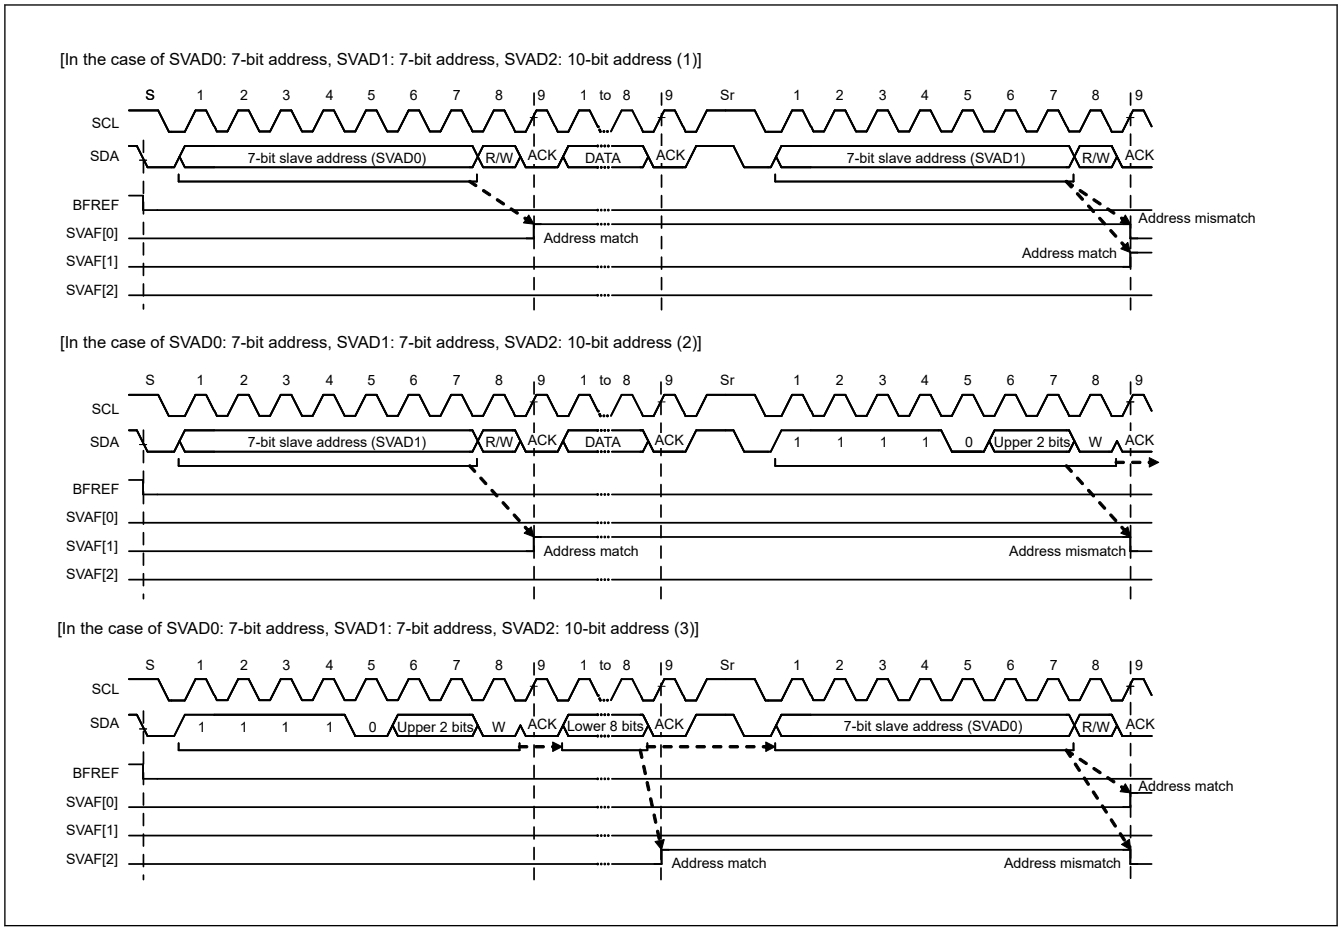

Figure 30.84 SVAFy flag set/clear timing with 7-bit/10-bit address formats mixed

(2) Detection of the General Call Address [I2C mode]

I3C has a facility for detecting the general call address (0000 000 + 0 (write)). This is enabled by setting the SVCTL.GCAE bit to 1.

If the address received after a START or Repeated START condition is issued is 0000 000 + 1 (read) (start byte), I3C recognizes this as the address of a slave device with an all-zero address but not as the general call address.

When I3C detects the general call address, both the SVST.GCAF flag and the NTST.RDBFF0 flag are set to 1 on the rising edge of the ninth cycle of SCL clock. This leads to the generation of a Normal Rx Data buffer full interrupt (I3C_RX). The value of the GCAF flag can be confirmed to recognize that the general call address has been transmitted.

Operation after detection of the general call address is the same as normal slave receive operation.

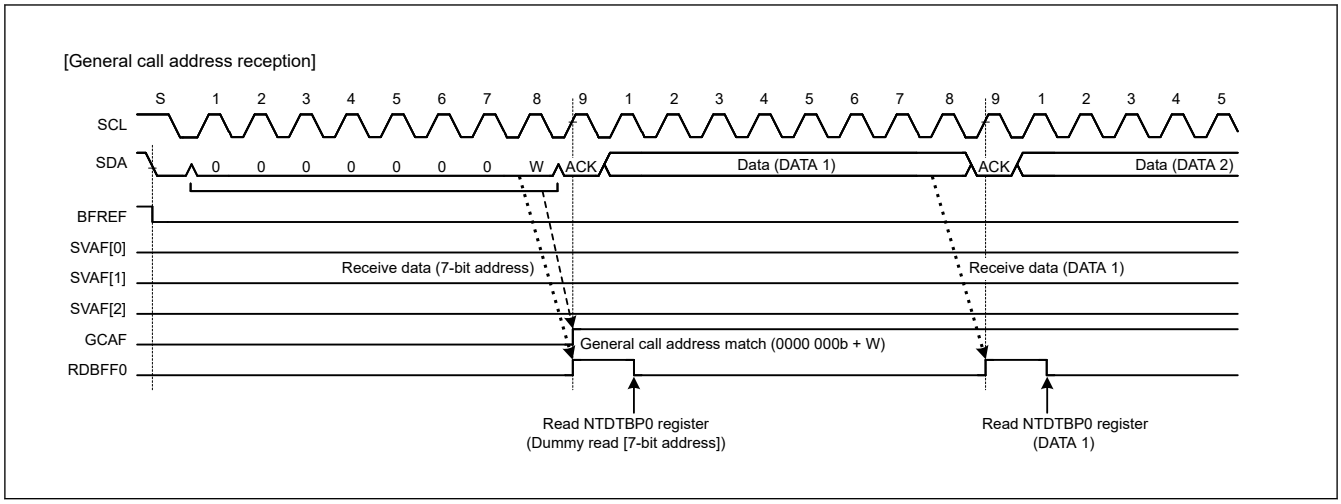

Figure 30.85 Timing of GCAF flag setting during reception of general call address

(3) Device-ID Address Detection [I2C mode]

I3C module has a facility for detecting device-ID addresses conformant with the I2C-bus specification (Rev.03). When I3C receives 1111 100 as the first byte after a START condition or Repeated START condition was issued with the SVCTL.DVIDE bit set to 1, I3C recognizes the address as a device ID, sets the SVST.DVIDF flag to 1 on the rising edge of the ninth SCL clock cycle when the following R/W# bit = 0, and then compares the second and subsequent bytes with its own slave address. If the address matches the value in the slave address register, I3C sets the corresponding SVST.SVAF[y] flag (y = 0 to 2) to 1.

After that, when the first byte received after a START or Repeated START condition is issued matches the device ID address (1111 100) again and the following R/W# bit = 1, I3C does not compare the second and subsequent bytes and sets the NTST.TDBEF0 flag to 1.

In the device-ID address detection function, I3C sets the DVIDF flag to 0 if a match with I3C's own slave address is not obtained or a match with the device ID address is not obtained after a match with I3C's own slave address and the detection of a Repeated START condition. If the first byte after detection of a START or Repeated START condition matches the device ID address (1111 100) and the R/W# bit = 0, I3C sets the DVIDF flag to 1 and compares the second and subsequent bytes with I3C's slave address. If the R/W# bit = 1, the DVIDF flag holds the previous value and I3C does not compare the second and subsequent bytes. Therefore, the reception of a device-ID address can be checked by reading the DVIDF flag after confirming that TDBEF0 flag = 1.

Furthermore, prepare the device-ID fields (3 bytes: 12 bits indicating the manufacturer + 9 bits identifying the part + 3 bits indicating the revision) that must be sent to the host after reception of a continuous device-ID field as normal data for transmission. For details of the information that must be included in device-ID fields, contact NXP Semiconductors.

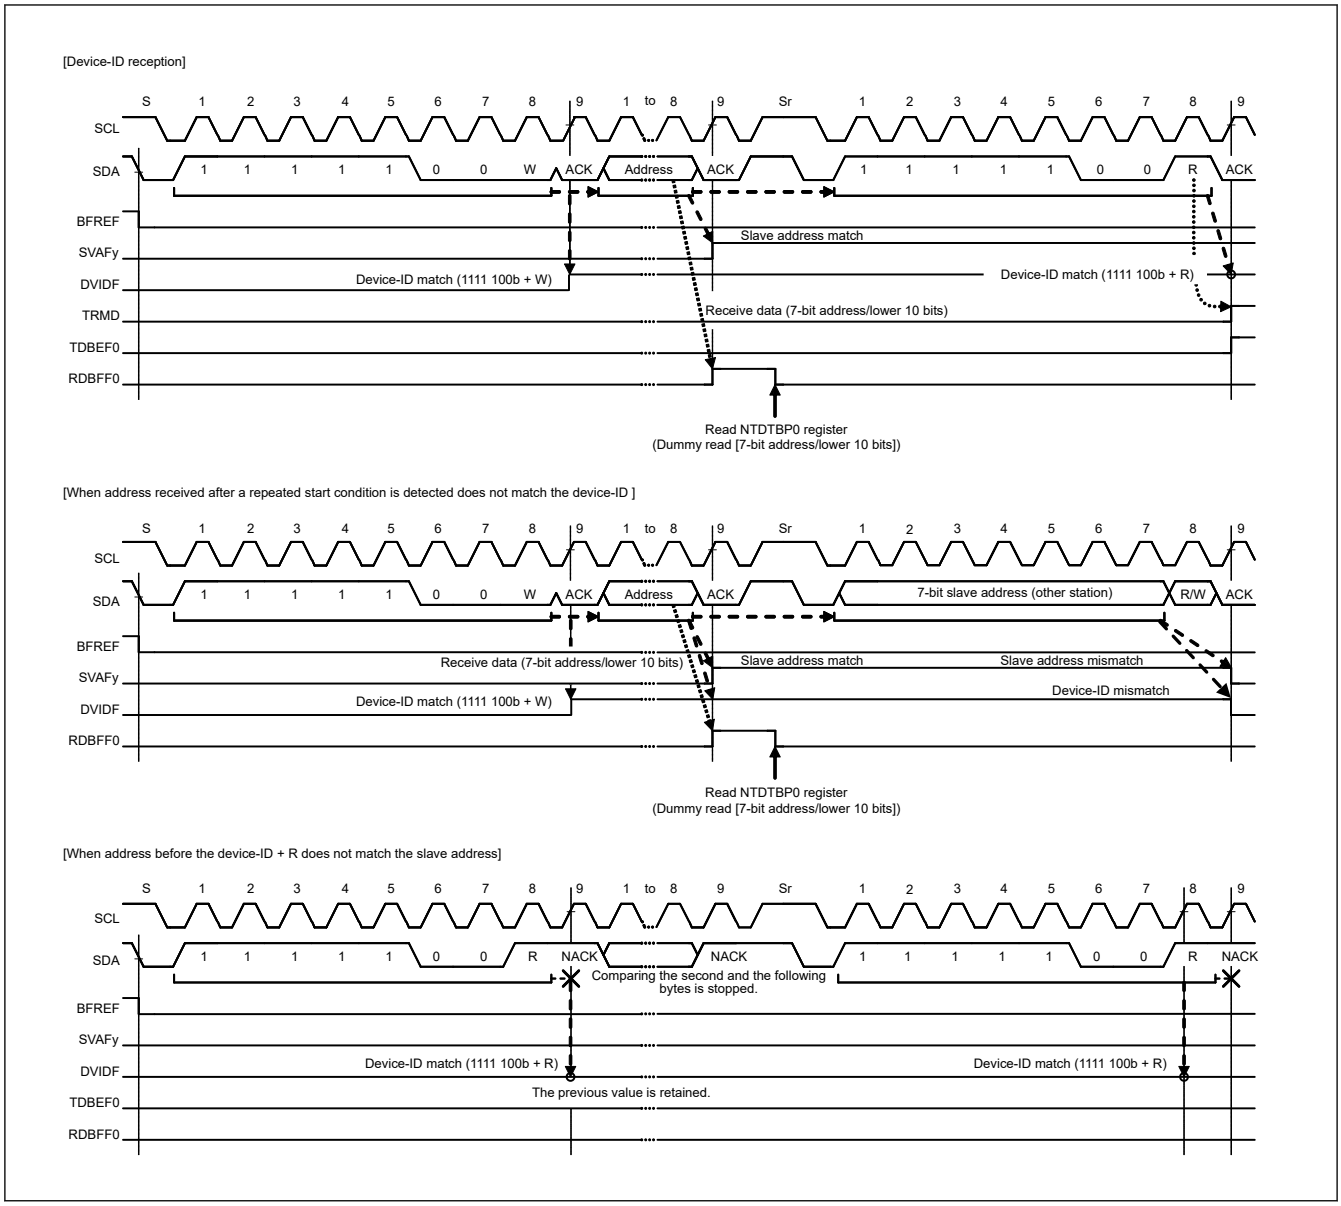

Figure 30.86 SVAFy/DVIDF flag set/clear timing during reception of device-ID

(4) Host Address Detection [I2C mode]

I3C has a function to detect the host address while the SMBus is operating. When the SVCTL.HOAE bit is set to 1 while the BFCTL.SMBS bit = 1, I3C can detect the host address (0001 000) in slave receive mode (bits CRMS and TRMD in the PRSST register = 00).

When I3C detects the host address, the SVST.HOAF flag is set to 1 at the rising edge of the ninth SCL clock cycle, and at the same time, the NTST.RDBFF0 flag is set to 1 when the R/W# bit = 0 (Wr bit). This causes a Normal Rx Data buffer full interrupt (I3C_RX) to be generated. The HOAF flag is used to recognize that the host address was sent from the smart battery or other devices.

If the bit following the host address (0001 000) is an Rd bit (R/W# bit = 1), I3C can also detect the host address. After the host address is detected, I3C operates in the same manner as normal slave operation.

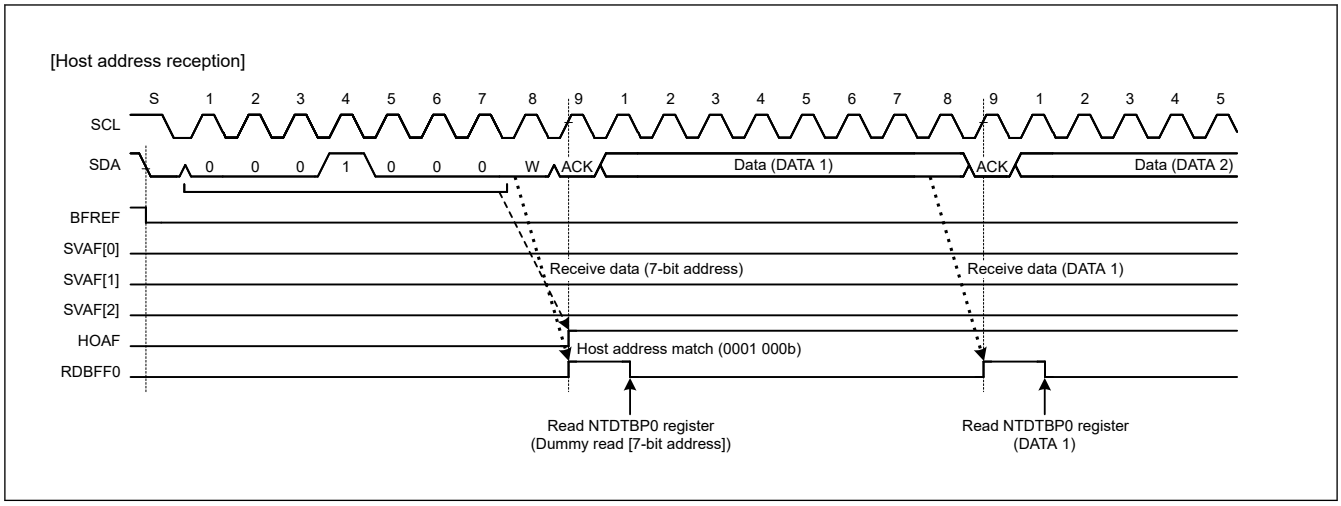

Figure 30.87 HOAF flag set timing during reception of host address

(5) Hs-mode master code Detection [I^2C mode]

IIC has a facility for detecting the Hs-mode master code (0000 1XXXb). When IIC receives the Hs-mode master code (0000 1XXXb) as the first byte after a START condition was issued with the SVCTL.HSMCE bit set to 1, this module recognizes the address as the Hs-mode master code, sets the SVST.HSMCF flag to 1 on the rising edge of the ninth SCL clock cycle. The first byte after Repeated START after NACK response to Hs-mode master code is recognized as a slave address and compared with the slave address set by SVDVADy.SVAD[9:0] (y = 0 to 2). When IIC detects a match of the set slave address, the corresponding SVST.SVAF[y] flag (y = 0 to 2) is set to 1 at the rising edge of the ninth SCL clock cycle, and the NTST.RDBFF0 flag or the NTST.TDBEF0 flag is set to 1 by the following R/W# bit. This causes a Normal Rx Data buffer full interrupt (I3C_RX) or Normal Tx Data buffer empty interrupt (I3C_TX) to be generated. The SVAF[y] flag is used to identify which slave address has been specified. The SVST.HSMCF flag is cleared to 0 when the STOP condition is detected.

Note: If the Hs-mode master code (0000 1XXXb) is received with the SVCTL.HSMCE bit set to 0, other patterns are ignored until the STOP condition is detected.

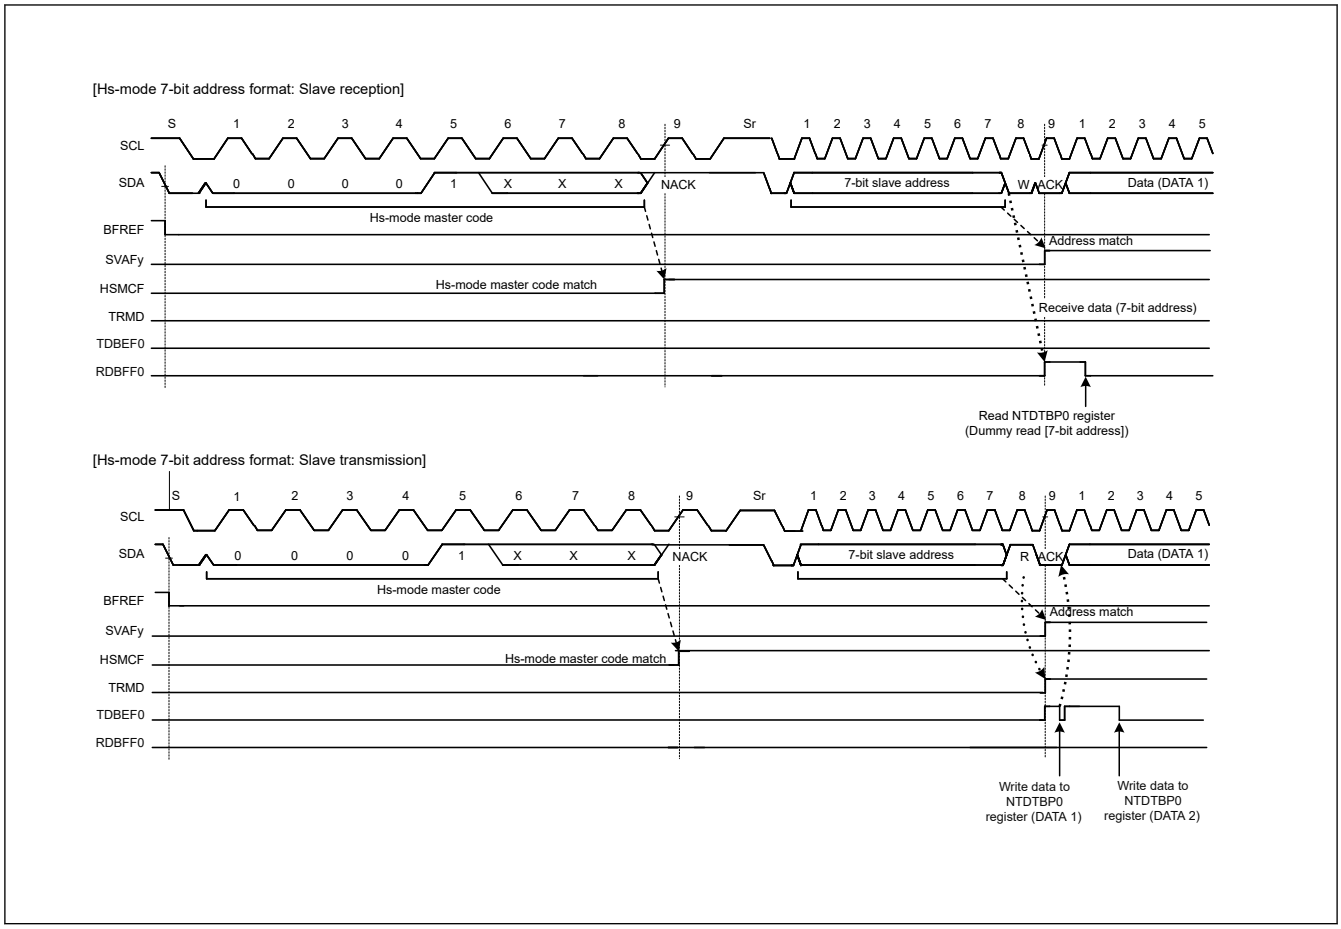

Figure 30.88 SVAFy/HSMCF Flag Set Timing during Reception of Hs-mode master code

(6) CCC detection function [I3C mode]

- In case of Broadcast CCC
  1. It receives Broadcast Address (0x7E) and R/W# = 0 after START condition or Repeated START.
  2. Respond to ACK.
  3. Receive Common Command Code (CCC).
  4. In accordance with the CCC, the following data is stored. (Storage destination: see Table 30.11)
  5. Store the Receive Status Descriptor into the Receive Status Queue.
- In case of Broadcast CCC (ENTDAA)
  1. It receives Broadcast Address (0x7E) and R/W# = 0 after START condition.
  2. Respond to ACK.
  3. Receive ENTDAA.
  4. If receives Broadcast Address (0x7E) and R/W# = 1 after Repeated START.
  5. When the Dynamic Address is not assigned, ACK response is done.
  6. This Provisional ID (SDCTPIDH[31:0], SDCTPIDL[15:0]), BCR (SVDCT.TBCRn) and DCR (SVDCT.TDCR[7:0]) are transmitted.
  7. When winning the arbitration in a transmission of the above Step 6, the dynamic address following that is received. When losing arbitration in a transmission of the above Step 6, processing of Step 6 is repeated from Step 4.
  8. When parity of the Dynamic Address is valid, ACK response is done.
  9. When parity of the Dynamic Address is invalid, NACK replies, and repeat the process from Steps 4 to 7.
  10. SDATBAS0.SDDYAD[7:0] is renewed and the SVDVAD0.SDYADV bit is set to 1.

11. Upon detecting the STOP condition, Store the Receive Status Descriptor into the Receive Status Queue.

- In case of Broadcast CCC (ENTHDR*)
  1. It receives Broadcast Address (0x7E) and R/W# = 0 after START condition or Repeated START.
  2. Respond to ACK.
  3. Receive ENTHDR*.
  4. Transit to HDR mode according to ENTHDR*.
  5. Receives the HDR command word.
  6. Compare the Dynamic Address in the HDR command word with the assigned Dynamic Address, and if they match, transmit / receive according to the Read / Write bit.
     If they do not match, wait for HDR Restart Pattern or HDR Exit Pattern + STOP.
  7. When HDR Restart Pattern or HDR Exit Pattern + STOP is received, Receive Status Descriptor is stored in Receive Status Queue.
     For HDR Restart Pattern, repeat Steps 5 to 6.
- In case of Direct Write CCC
  1. It receives Broadcast Address (0x7E) and R/W# = 0 after START condition or Repeated START.
  2. Respond to ACK.
  3. Receive Common Command Code (CCC).
  4. Receive Dynamic Address and R/W# = 0 after Repeated START.
  5. Compare the received Dynamic Address with the assigned Dynamic Address, and if it matches, I3C responds with ACK.
     If they do not match, it responds with NACK and waits for Repeated START or STOP.
  6. In accordance with the CCC, the following data is stored. (Storage destination: see Table 30.11)
  7. Store the Receive Status Descriptor into the Receive Status Queue.
- In case of Direct Read CCC
  1. It receives Broadcast Address (0x7E) and R/W# = 1 after START condition or Repeated START.
  2. Respond to ACK.
  3. Receive Common Command Code (CCC).
  4. Receive Dynamic Address and R/W# = 1 after Repeated START.
  5. Compare the received Dynamic Address with the assigned Dynamic Address, and if it matches, I3C responds with ACK.
     If they do not match, it responds with NACK and waits for Repeated START or STOP.
  6. Respond from SFR according to CCC. (Responding CCC: see Table 30.11)
  7. Store the Receive Status Descriptor into the Receive Status Queue.

Table 30.11 Common command code operation (1 of 2)

30.3.2.3.5 Arbitration-Lost Detection [I^2C mode]

In addition to the normal arbitration-lost detection function defined by the I^2C-bus specification, the I3C has functions to prevent double-issue of a start condition, to detect arbitration-lost during transmission of NACK, and to detect arbitration-lost in slave transmit mode.

(1) Master Arbitration-Lost Detection (MALE Bit)

The I3C drives the I3C_SDA line low to issue a start condition. However, if the I3C_SDA line has already been driven low by another master device issuing a start condition, this module causes arbitration to be lost, so priority is given to transfer by the other master device. Similarly, if the CNDCTL.STCND bit is set to 1 while the BCST.BFREF flag is 0 (bus busy state), arbitration is lost, so priority is given to transfer by the other master device. No start condition is issued in this case.

When a start condition is issued successfully, if the data for transmission including the address bits (the internal SDA output level) and the level on the I3C_SDA line do not match (the high output as the internal SDA output, that is, the I3C_SDA pin is in the high-impedance state) and the low level is detected on the I3C_SDA line, the I3C loses in arbitration.

I3C detects master arbitration-lost when the following conditions are met while the BSTE.ALE bit = 1 and the BFCTL.MALE bit = 1 (master arbitration-lost detection enabled).

If arbitration of mastership is lost, I3C immediately enters slave receive mode.

If a slave address (including the general call address) matches its own address at this time, I3C continues in slave operation.

[Conditions for master arbitration-lost]

- Non-matching of the internal level for output on SDA and the level on the I3C_SDA line after a START condition was issued by setting the CNDCTL.STCND bit to 1 while the BCST.BFREF flag was set to 1 (erroneous issuing of a START condition)
- Setting of the CNDCTL.STCND bit to 1 (START condition double-issue error) while the BFREF flag is set to 0

  Note: I3C does not issue a START condition.
- When the transmit data excluding acknowledge (internal SDA output level) does not match the level on the I3C_SDA line in master transmit mode (bits CRMS and TRMD in the PRSST register = 11b)

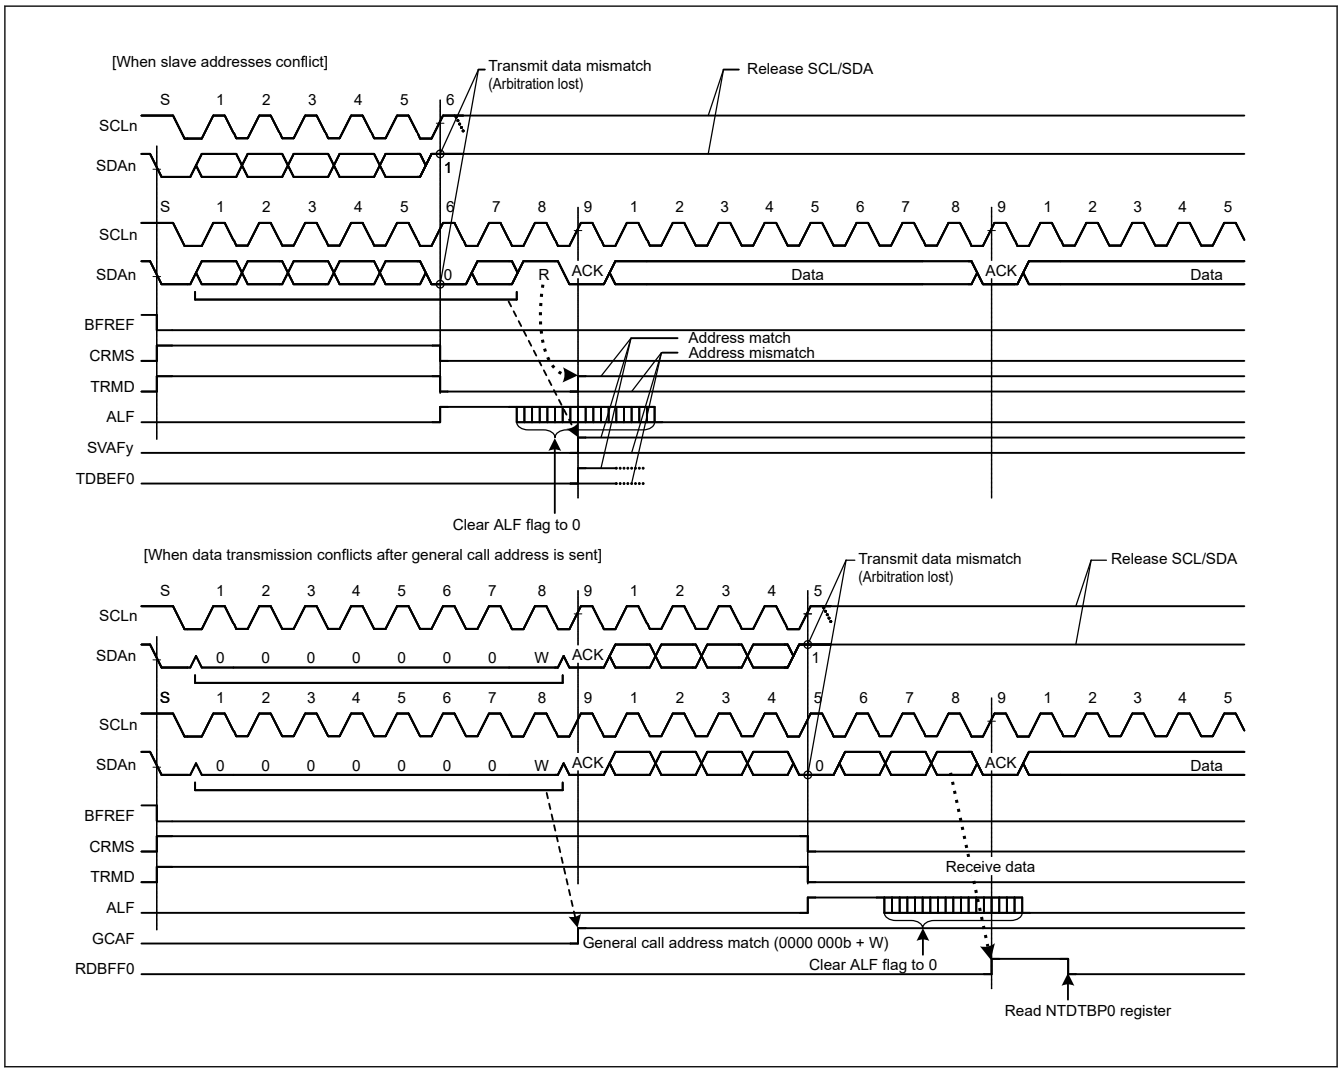

Figure 30.89 Examples of master arbitration-lost detection (MALE = 1)

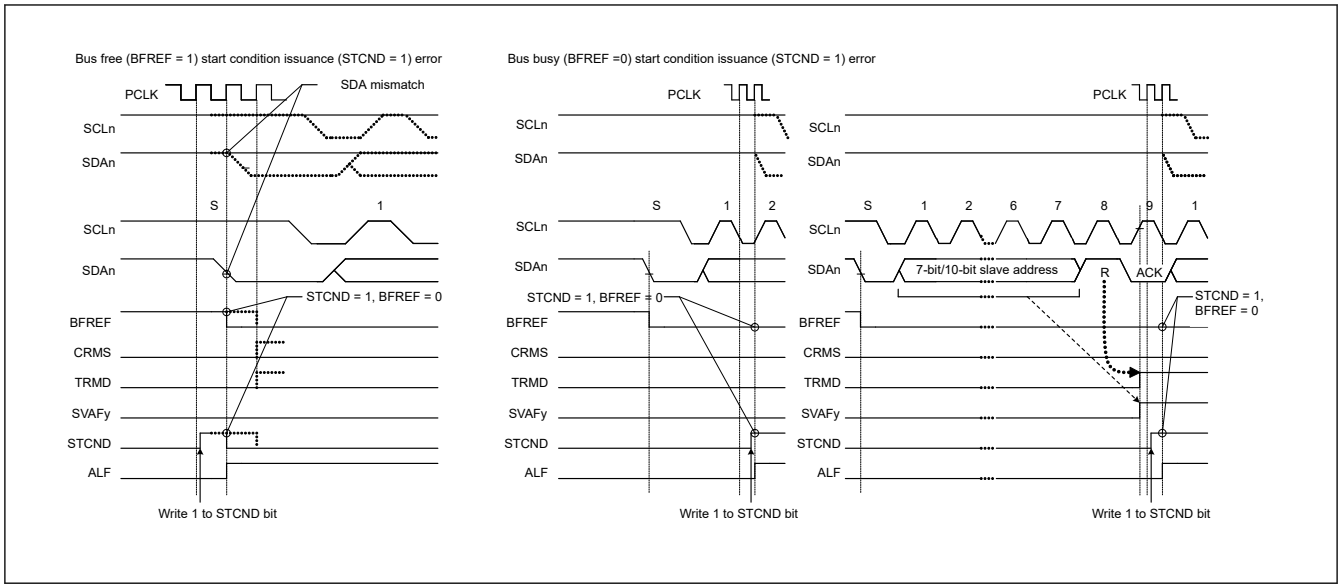

Figure 30.90 Arbitration-lost detection when a START condition is issued (MALE = 1)

(2) Arbitration-Lost Detection during NACK Transmission (NALE Bit)

The I3C has a function to cause arbitration to be lost if the internal SDA output level does not match the level on the I3C_SDA line (the high output as the internal SDA output; i.e. the I3C_SDA pin is in the high-impedance state) and the low level is detected on the I3C_SDA line during transmission of NACK in receive mode. Arbitration is lost due to a conflict of NACK transmission and ACK transmission when two or more master devices receive data from the same slave device simultaneously in a multi-master system. Such conflict occurs when multiple master devices send/receive the same information through a single slave device.

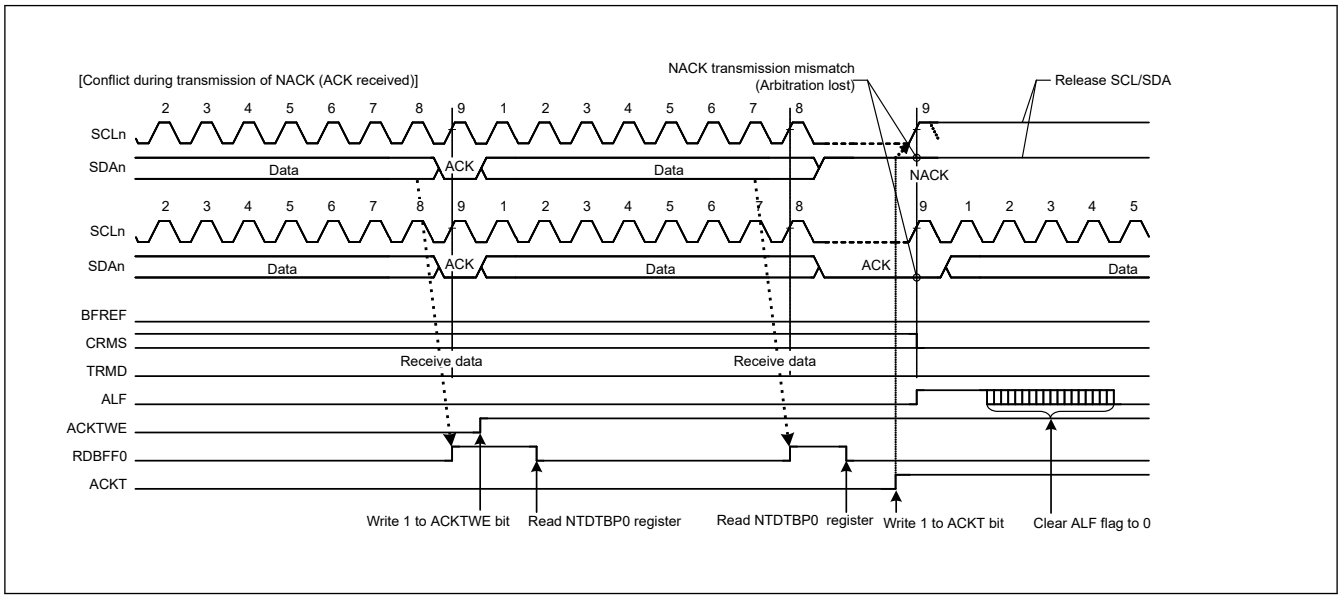

Figure 30.91 Example of arbitration-lost detection during transmission of NACK (NALE = 1)

The following section explains arbitration-lost detection using an example where two master devices (master A and master B) and a single slave device are connected through the bus. In this example, master A receives 2 bytes of data from the slave device, and master B receives 4 bytes of data from the slave device.

If master A and master B access the slave device simultaneously, because the slave address is identical, arbitration is not lost in both master A and master B during access to the slave device. Therefore, both master A and master B recognize that they have obtained the bus mastership and operate as such. In this example,, master A sends NACK when it has received 2 final bytes of data from the slave device. Meanwhile, master B sends ACK because it has not received the necessary 4 bytes of data. At this time, the NACK transmission from master A and the ACK transmission from master B conflict. In general, if

a conflict like this occurs, master A cannot detect ACK transmitted by master B and issues a stop condition. Therefore, the issuance of the stop condition conflicts with the SCL clock output of master B, which disturbs communication.

When this module receives ACK during transmission of NACK, it detects a defeat in conflict with other master devices and causes arbitration to be lost.

If arbitration is lost during transmission of NACK, this module is immediately released from the slave-matched state and enters slave receive mode. This prevents a stop condition from being issued, preventing a communication failure on the bus.

Similarly, in the ARP command processing of SMBus, the function to detect loss of arbitration during transmission of NACK is also available for eliminating the extra clock cycle processing (such as 0xFF transmission processing) necessary if the UDID (Unique Device Identifier) of assign address does not match in the Get UDID (general) processing after the Assign Address command.

The I3C detects arbitration-lost during transmission of NACK when the following condition is met while the BSTE.ALE bit = 1 and the BFCTL.NALE bit = 1 (arbitration-lost detection during NACK transmission enabled).

[Condition for arbitration-lost during NACK transmission]

- When the internal SDA output level does not match the I3C_SDA line (ACK is received) during transmission of NACK (ACKCTL.ACKT bit = 1)

(3) Slave Arbitration-Lost Detection (SALE Bit)

The I3C has a function to cause arbitration to be lost if the data for transmission (the internal SDA output level) and the level on the I3C_SDA line do not match (the high output as the internal SDA output, that is, the I3C_SDA pin is in the high impedance state) and the low level is detected on the I3C_SDA line in slave transmit mode. This arbitration-lost detection function is mainly used when transmitting a UDID (Unique Device Identifier) over an SMBus.

If arbitration is lost during transmission of DATA, this module is immediately released from the slave-matched state and enters slave receive mode. This function can detect conflicts of data during transmission of UDIDs over an SMBus and eliminate subsequent redundant processing (processing for the transmission of 0xFF).

The I3C detects slave arbitration-lost when the following condition is met while the BSTE.ALE bit = 1 and the BFCTL.SALE bit = 1 (slave arbitration-lost detection enabled).

[Condition for slave arbitration-lost]

- When the transmit data excluding acknowledge (internal SDA output level) does not match the level on the I3C_SDA line in slave transmit mode (bits CRMS and TRMD in the PRSST register = 01b).

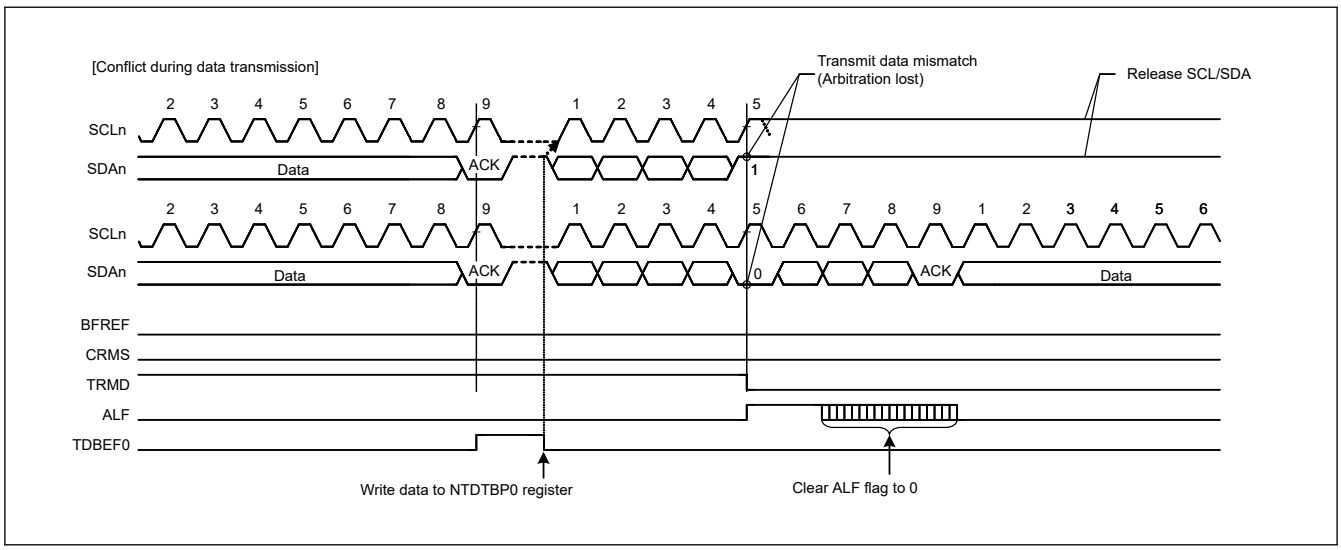

Figure 30.92 Example of slave arbitration-lost detection (SALE = 1)

30.3.2.3.6 Clock Stretching [I²C mode]

(1) Function to Prevent Wrong Transmission of Transmit Data

When data have not been written to the Normal Transfer Data Buffer Port Register 0 (NTDTBP0) with I3C in transmission mode (PRSST.TRMD = 1), the I3C_SCL line is automatically held at the low level over the intervals shown below. This low-hold period is extended until data for transmission have been written, which prevents the unintended transmission of erroneous data.

Master transmit mode

- Low-level interval after a START condition or Repeated START condition is issued
- Low-level interval between the ninth clock cycle of one transfer and the first clock cycle of the next

Slave transmit mode

- Low-level interval between the ninth clock cycle of one transfer and the first clock cycle of the next

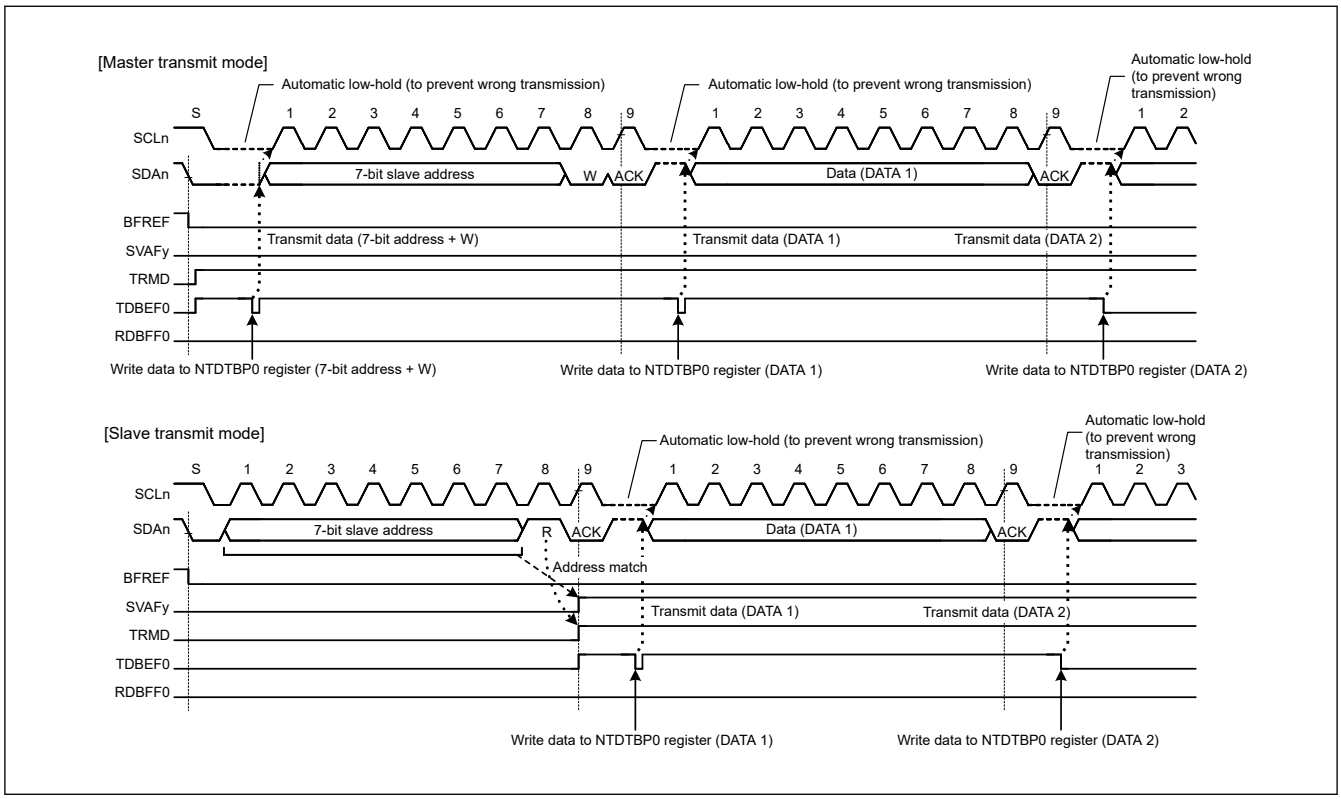

Figure 30.93 Automatic low-hold operation in transmit mode

(2) NACK Reception Transfer Abort Function

I3C has a function to abort transfer operation when NACK is received in transmit mode (PRSST.TRMD = 1). This function is enabled when the BSTE.NACKDE bit is set to 1 (transfer abort enabled). If the next transmit data has already been written (NTST.TDBEF0 = 0) when NACK is received, next data transmission at the falling edge of the ninth SCL clock cycle is automatically aborted. This prevents the I3C_SDA line output level from being held low when the MSB of the next transmit data is 0.

If the transfer operation is aborted by this function (BST.NACKDF = 1), transmit operation and receive operation are discontinued. To restore transmit/receive operation, be sure to set the NACKDF flag to 0. In master transmit mode, restore operation using either of the methods below:

- After issuing a Repeated START condition, set the NACKDF flag to 0
- After issuing a STOP condition, set the NACKDF flag to 0 and then issue a START condition

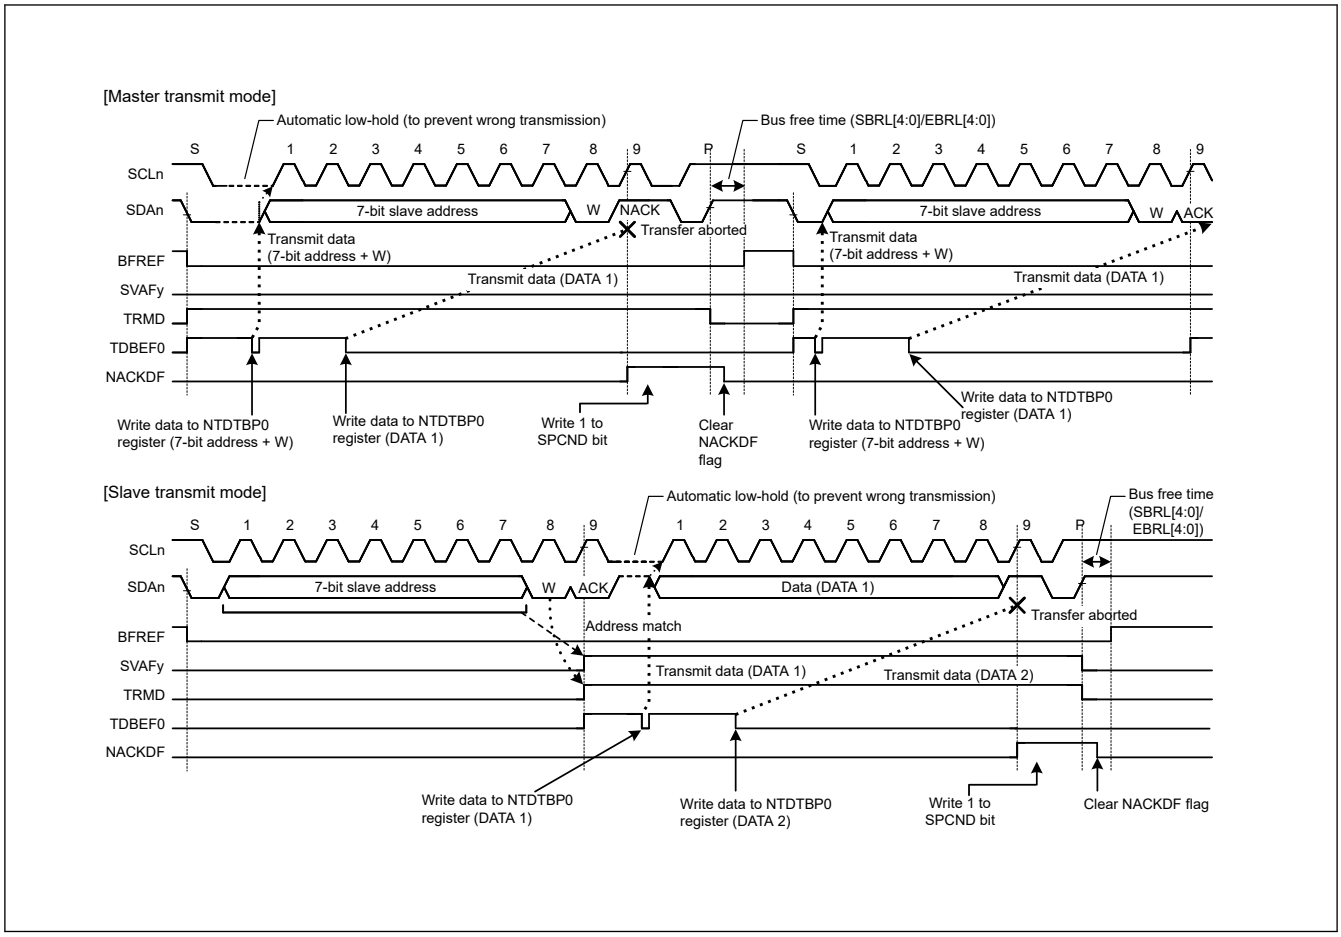

Figure 30.94 Abort of data transfer when NACK is received (NACKE = 1)

(3) Function to Prevent Failure to Receive Data

If response processing is delayed when receive data (NTDTBP0) read is delayed for a period of one transfer frame or more with receive data full (NTST.RDBFF0 = 1) in receive mode (PRSST.TRMD = 0), I3C holds the I3C_SCL line low automatically immediately before the next data is received to prevent failure to receive data.

This function to prevent failure to receive data using the automatic low-hold function is also enabled even if the read processing of the final receive data is delayed and, in the meantime, I3C's own slave address or another slave address is received after a STOP condition is issued.

Sections in which the I3C_SCL line is held low can be selected with a combination of the RWE and ACKTWE bits in SCSTRCTL.

(a) 1-Byte Receive Operation and Automatic Low-Hold Function Using the RWE Bit

When the SCSTRCTL.RWE bit is set to 1, I3C performs 1-byte receive operation using the RWE bit function.

Furthermore, when the SCSTRCTL.ACKTWE bit = 0, I3C automatically sends the ACKCTL.ACKT bit value for the acknowledge bit in the period from the falling edge of the eighth SCL clock cycle to the falling edge of the ninth SCL clock cycle, and automatically holds the I3C_SCL line low at the falling edge of the ninth SCL clock cycle using the RWE bit function. This low-hold is released by reading data from NTDTBP0, which enables bytewise receive operation.

The RWE bit function is enabled for receive frames after a match with I3C's own slave address (including the general call address and host address) is obtained in master receive mode or slave receive mode.

(b) 1-Byte Receive Operation (ACK/NACK Transmission Control) and Automatic Low-Hold Function Using the ACKTWE Bit

When the SCSTRCTL.ACKTWE bit is set to 1, I3C performs 1-byte receive operation using the ACKTWE bit function.

When the ACKTWE bit is set to 1, the NTST.RDBFF0 flag (Normal Rx Data buffer full) is set to 1 at the rising edge of the eighth SCL clock cycle, and the I3C_SCL line is automatically held low at the falling edge of the eighth SCL clock

cycle. This lowhold is released by writing a value to the ACKCTL.ACKT bit, but cannot be released by reading data from NTDTBP0, which enables receive operation by the ACK/NACK transmission control according to the data received in byte units.

The ACKTWE bit function is enabled for receive frames after a match with I3C's own slave address (including the general call address and host address) is obtained in master receive mode or slave receive mode.

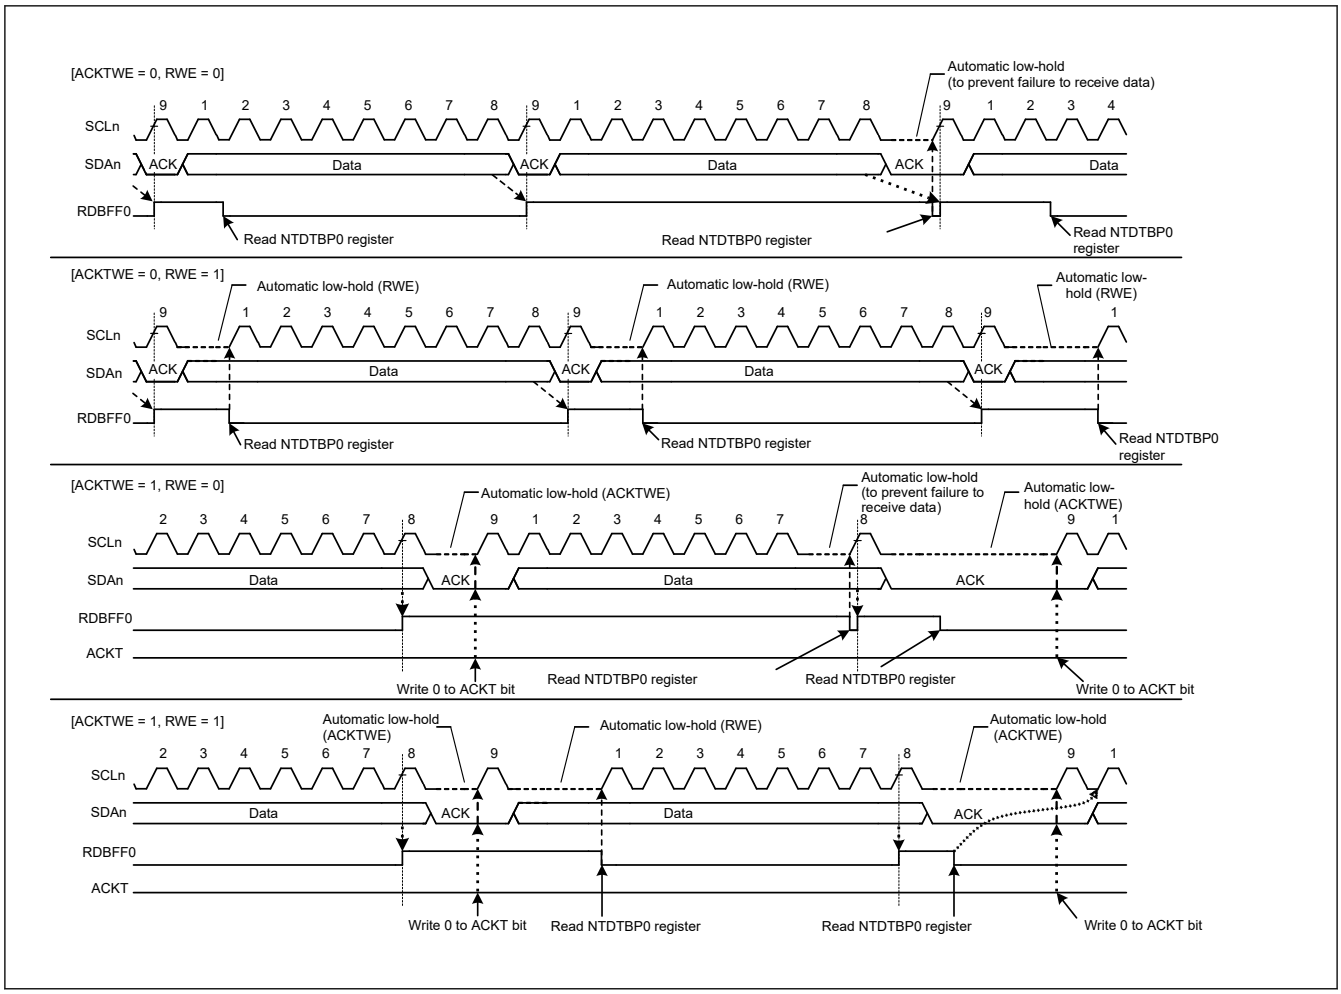

Figure 30.95 Automatic low-hold operation in receive mode (using ACKTWE and RWE bits)

30.3.2.3.7 Clock Stalling [I3C mode]

I3C has the function of stalling the SCL during the SCL Low period.

The SCL stall control is described in the table below.

Table 30.12 I3C clock stalling (1 of 2)

Clock stalling condition	Clock stalling control	Clock stalling period
I3C Transfer, ACK/NACK Phase	SCSTLCTL.ACKPE bit setting	During the count period of SCSTLCTL.STLCYC [15:0] value
	Tx Data Buffer Empty	Until data is written to the Tx Data Buffer
	Rx Data Buffer Full	Until data is read from the Rx Data Buffer
I3C Write Data Transfer, Parity Bit	SCSTLCTL.PARPE bit setting	During the count period of SCSTLCTL.STLCYC [15:0] value
	Tx Data Buffer Empty	Until data is written to the Tx Data Buffer
I3C Read Transfer, Transition Bit	Rx Data Buffer Full	Until data is read from the Rx Data Buffer

Table 30.12 I3C clock stalling (2 of 2)

Clock stalling condition	Clock stalling control	Clock stalling period
Assigned Address Phase	SCSTLCTL.AAPE bit setting	During the count period of SCSTLCTL.STLCYC [15:0] value

The following figure shows the stalling timing of each Condition.

(1) I3C Transfer, ACK/NACK Phase

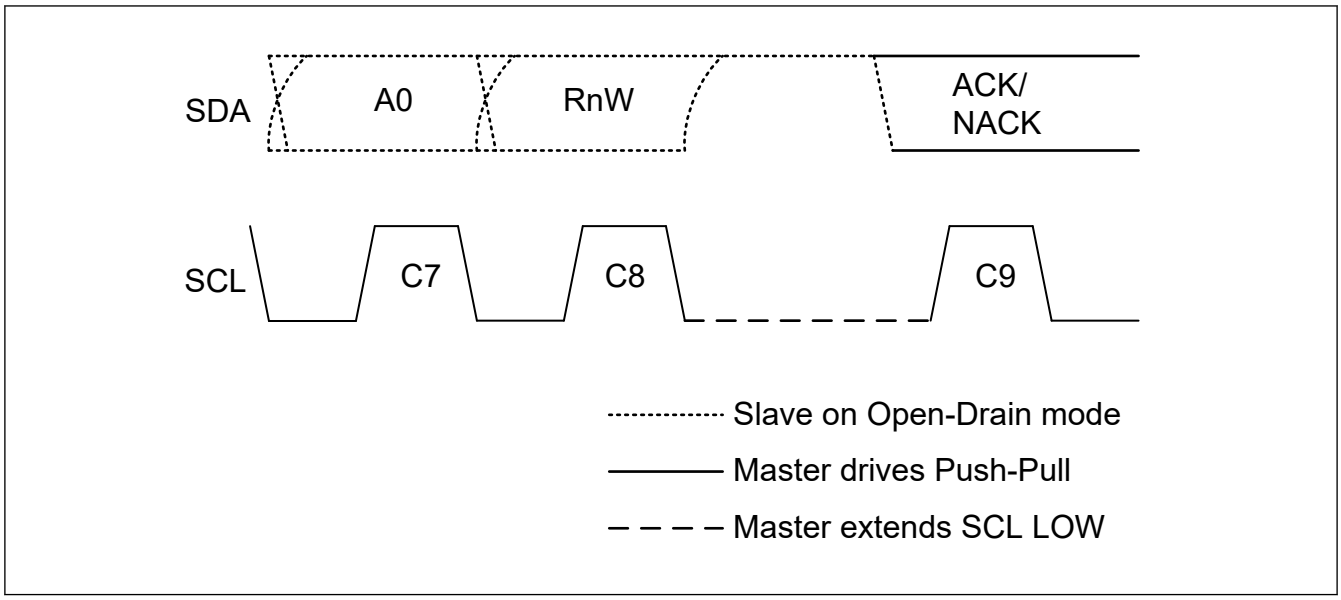

Figure 30.96 Master clock stalling in ACK phase

(2) I3C Write Data Transfer, Parity Bit

(3) I3C Read Transfer, Transition Bit

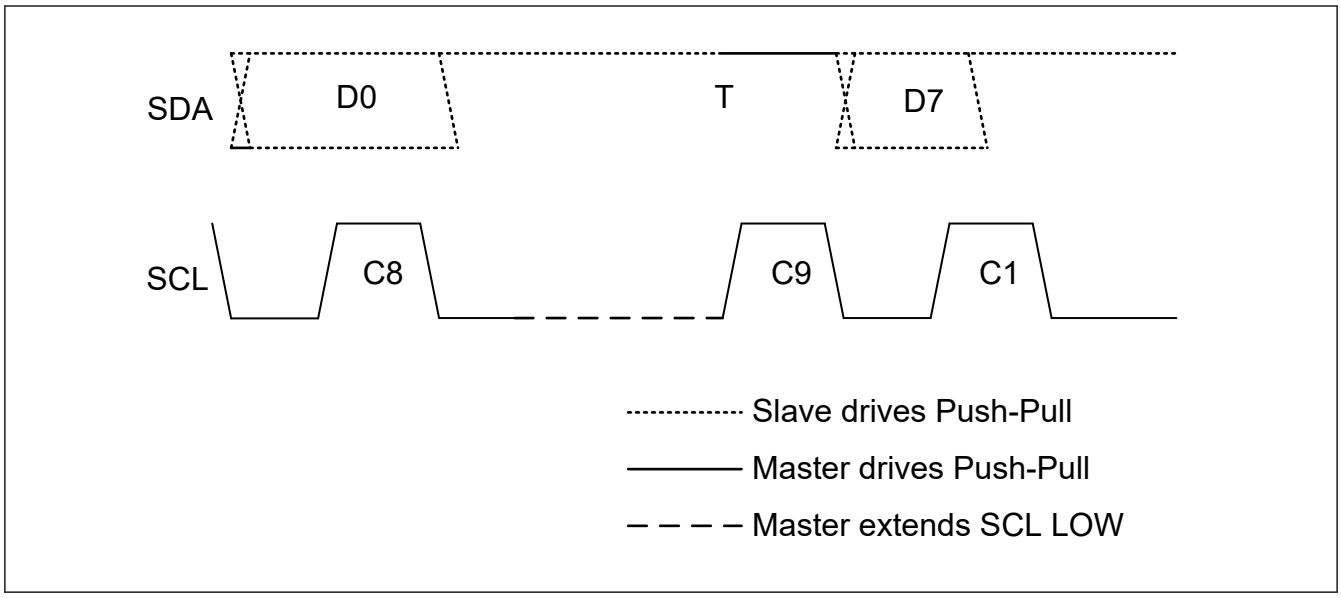

Figure 30.98 Master clock stalling in T-bit before next read data

(4) Dynamic Address Assignment, First Bit of Assigned Address

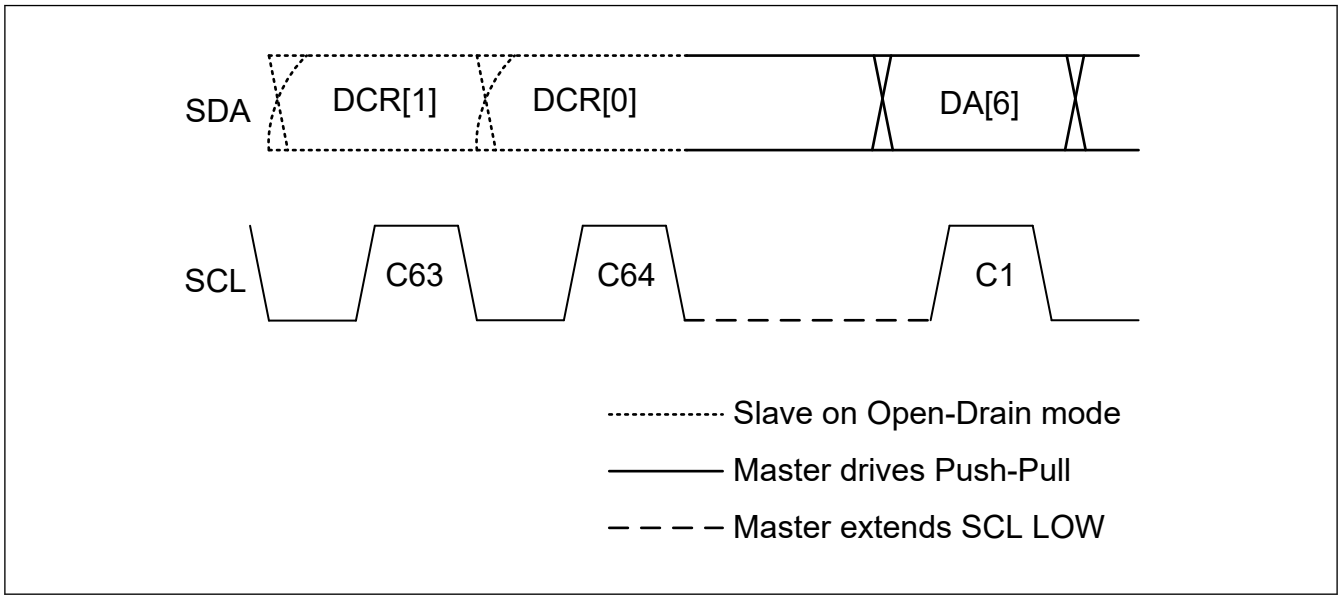

Figure 30.99 Master clock stalling in dynamic address first bit

30.3.2.3.8 In-Band Interrupt [I3C mode]

I3C detects In-Band Interrupt in the arbitrated Address Header following a START condition (but not following a Repeated START). If START Request (SDA Low Drive) is issued from Slave Device, I3C drives SCL low and completes START condition. After that, it supplies SCL and receives In-Band Interrupt Request.

The In-Band Interrupt to be detected is classified into the following three types.

- Slave Interrupt Request
- Mastership Request

The operation when detecting each In-Band Interrupt is described below.

(1) Slave Interrupt Request

1. Detect Slave Address with RnW bit High in Address Header.
2. Compare the detected Slave Address with the DVDYAD[7:0] in each DAT (DATBASm register).
3. When it does not match DAT.DVDYAD[7:0]:
   Responds NACK, then issues the STOP condition.
   When it matches the DAT.DVDYAD[7:0] bits and the DAT.DVSIRRJ bit = 1:
   It operates in the following order:
   (a) Responds NACK.
   (b) Issues Repeated START condition, then automatically issues Direct DISEC CCC to the detected Slave.
   (c) Issues the STOP condition.

   When it matches the DAT.DVDYAD[7:0] bits and the DAT.DVSIRRJ bit = 0:
   Responds ACK.
4. When DAT.DVIBIPL = 0:
   Issues the STOP condition.
   When DAT.DVIBIPL = 1:
   Drives the SCL to receive the IBI Data from the Slave following the ACK response and receives IBI Data.
   It stores the received IBI Data into the IBI Data Queue.
   Each time IBI Data of the size set by the NQTHCTL.IBIDSSZ[7:0] bits is received, the IBI Status Descriptor is stored in the IBI Queue.
5. After detection of Low of T-bit following IBI Data, issues STOP condition.
6. After issues of STOP condition
   NACK response:
   - If IBINCTL.NRSIRCTL = 0, the IBI Status Descriptor is not stored into the IBI Queue.
   - If IBINCTL.NRSIRCTL = 1, the IBI Status Descriptor is stored into the IBI Queue.

   ACK response:
   Stores the IBI Status Descriptor into the IBI Queue.

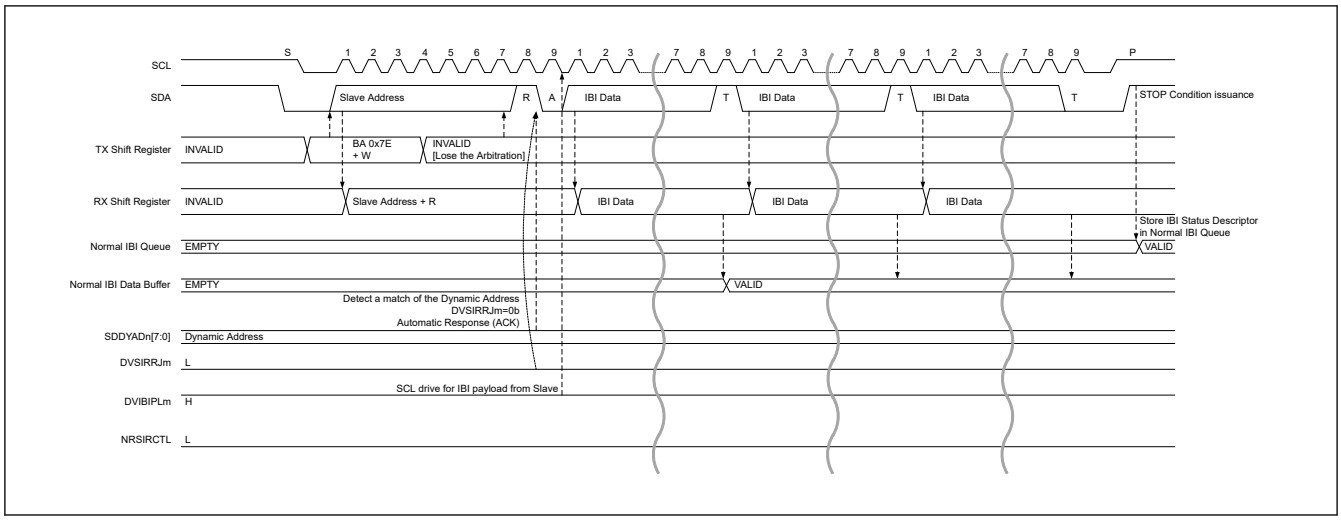

Figure 30.100 Slave interrupt request : ACK and DVIBIPL = 1

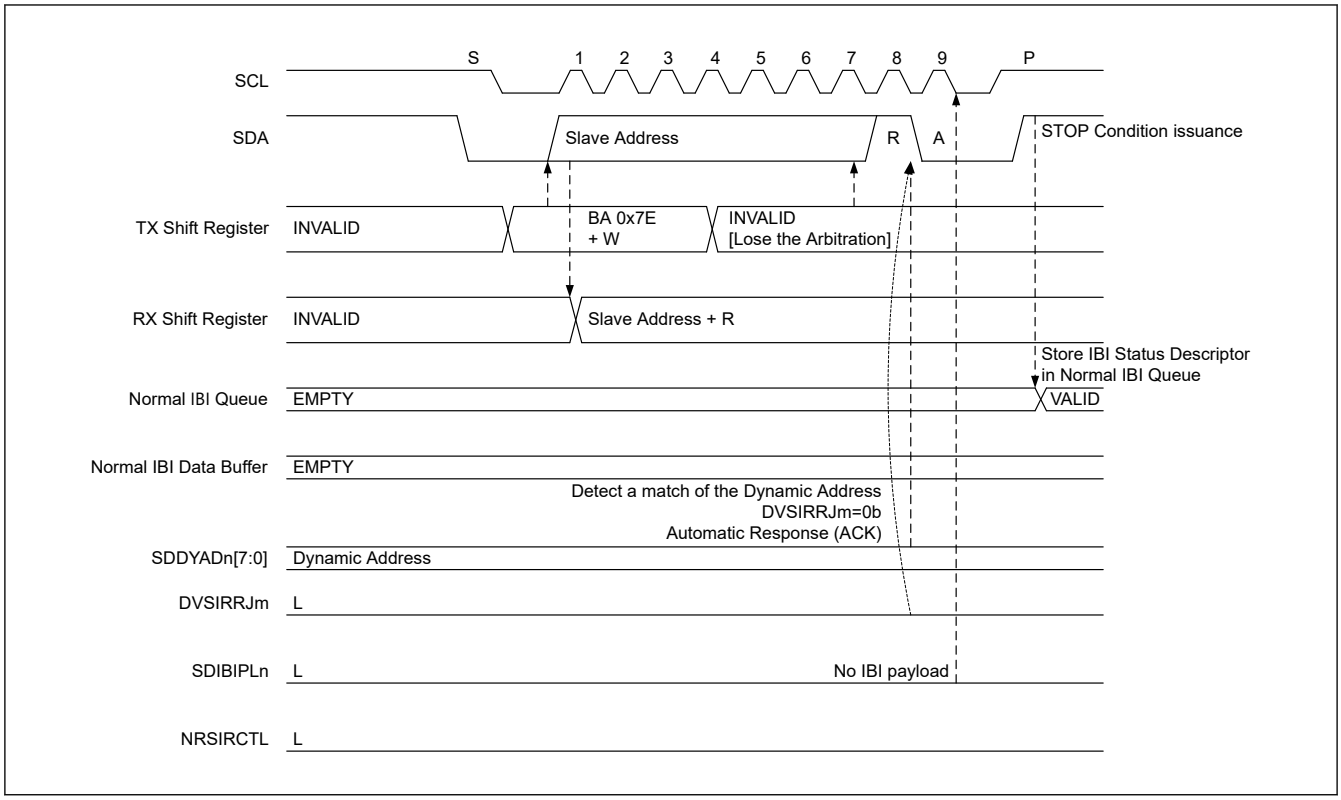

Figure 30.101 Slave interrupt request : ACK and DVIBIPL = 0

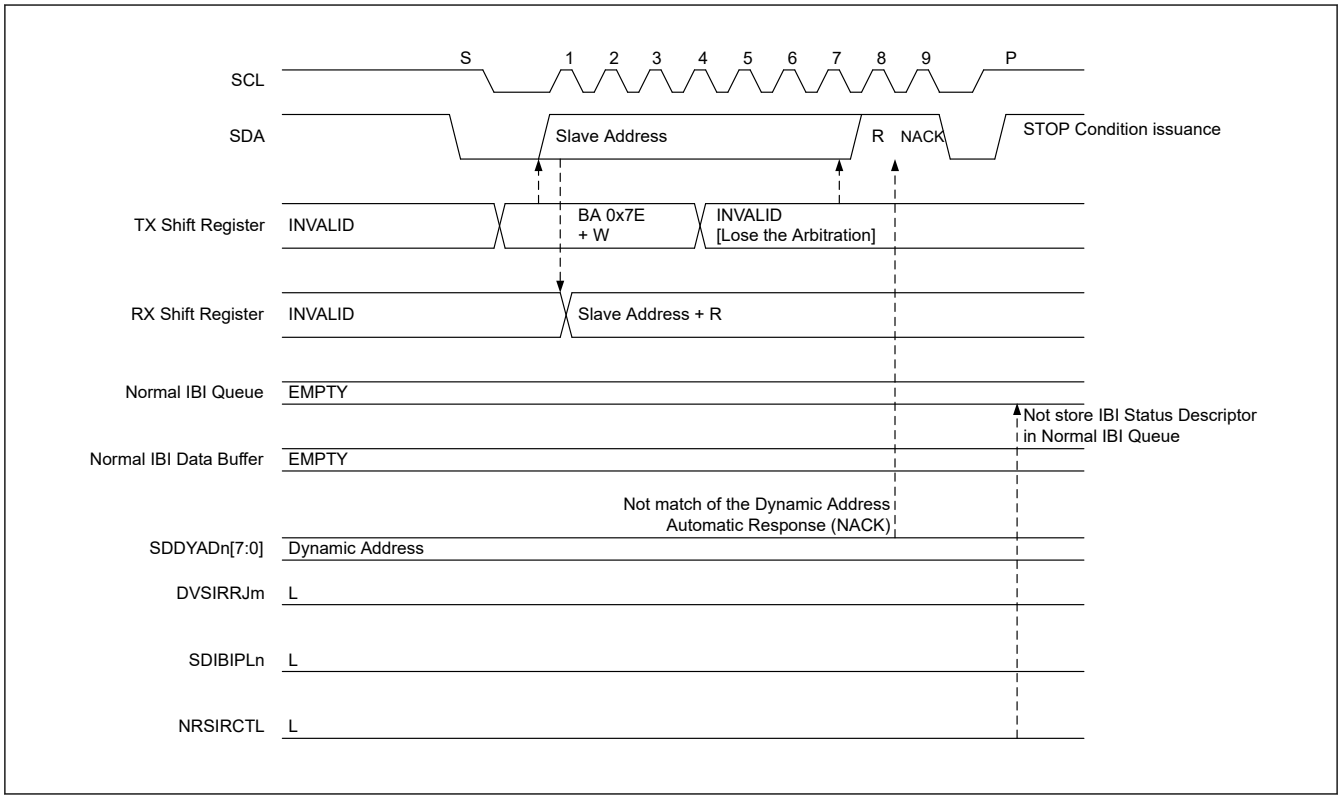

Figure 30.102 Slave interrupt request : NACK (not match the SDDYAD[7:0] of DAT) and NRSIRCTL = 0

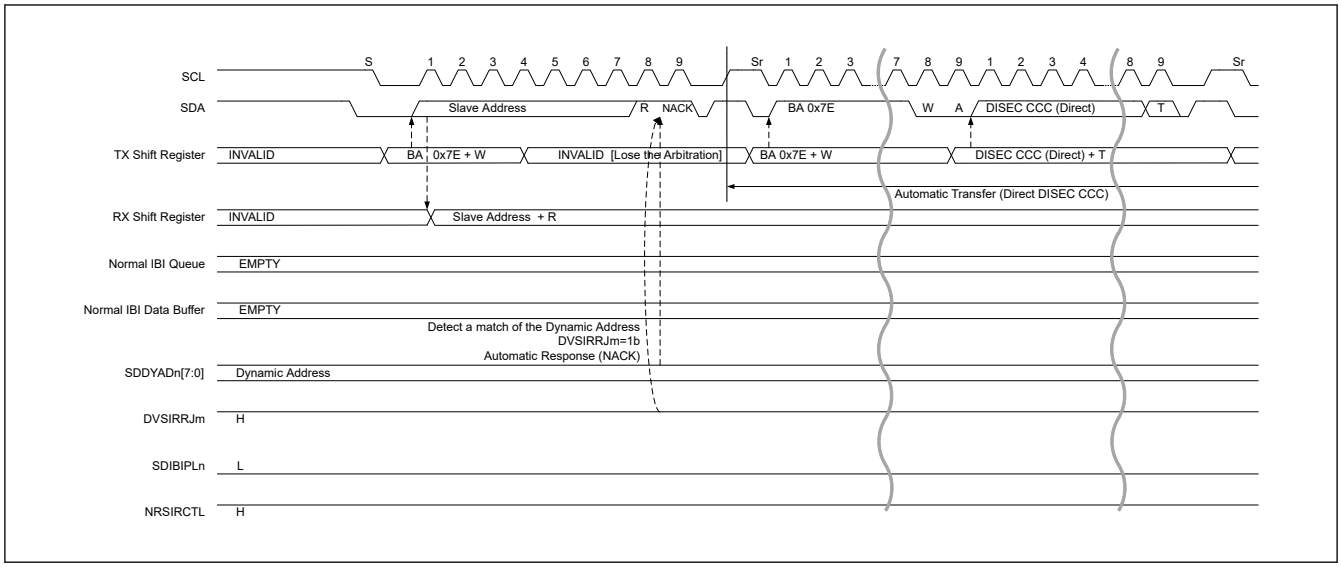

Figure 30.103 Slave interrupt request : NACK (DVSIRRJ = 1) and NRSIRCTL = 1 (1/2)

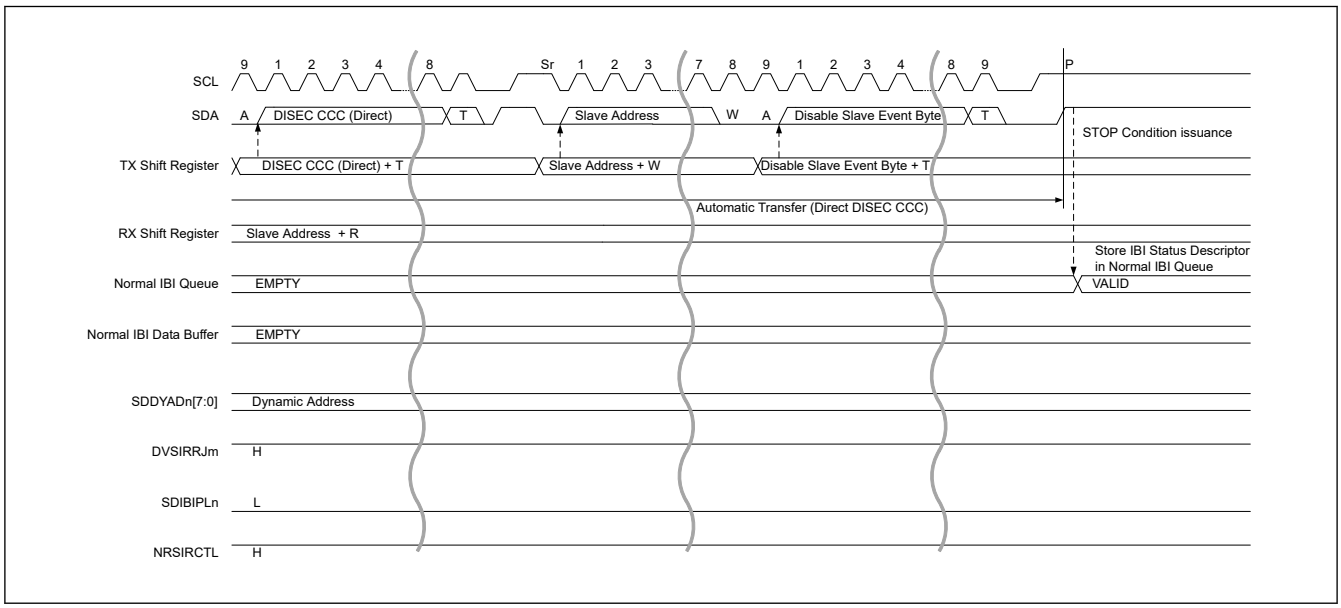

Figure 30.104 Slave interrupt request : NACK (DVSIRRJ = 1) and NRSIRCTL = 1 (2/2)

(2) Mastership Request

1. Detect Slave Address with RnW bit Low in Address Header.
2. Compare the detected Slave Address with the DVDYAD[7:0] in each DAT (DATBAS register).
3. When it does not match DAT.DVDYAD[7:0]:
   Responds NACK, then issues the STOP condition.
   When it matches the DAT.DVDYAD[7:0] bits and Device Role[1:0] in RBCR (MSDCTm) is other than I3C Master (01b):
   Responds NACK, then issues the STOP condition.
   When it matches the DAT.DVDYAD[7:0] bits and Device Role[1:0] in RBCR (MSDCTm) is I3C Master (01b):
   - When DAT.DVMRRJ = 1
     It operates in the following order.
     (a) Responds NACK.
     (b) Issued Repeated START condition and automatically issues Direct DISEC CCC to the detected Slave.
     (c) Issues the STOP condition.

- When DAT.DVMRRJ = 0
  Responds ACK, then issues STOP condition.

4. After issues of STOP condition,
   NACK response:
   - If IBINCTL.NRMRCTL = 0, the IBI Status Descriptor is not stored into the IBI Queue.
   - If IBINCTL.NRMRCTL = 1, the IBI Status Descriptor is stored into the IBI Queue.

   ACK response:
   Stores the IBI Status Descriptor into the IBI Queue.

30.3.2.3.9 Timing Control

Timing Control is a function that enables Master to efficiently read data from Slave by controlling and grasping the timing at which the Slave Device samples the sensor value.

For details, refer to 5.1.8 Timing Control of MIPI I3C Specification v1.0.

In I3C, timing Control supports the following three modes.

- Sync mode
- Async mode 0 (Asynchronous Basic mode)
- Async mode 1 (Asynchronous Advanced mode)

The resources for realizing Timing Control in each mode are described in the following sections.

(1) Sync Mode

1. I3C Master
   - When STCTL.STOE is set to 1, when the master sends an ST message (SETXTIME CCC with ST subcommand), there is a function to issue the synchronous timing event under the START condition of the ST message.
     While measuring the T_ph period with an external timer, the start of T_ph and the Delay Time [DT] of the ST message can be measured by capturing the count value with the synchronous timing event.
     The measured value of Delay Time is sent as a DT message (SETXTIME CCC with DT subcommand) following the ST message.
2. I3C Slave
   - When STCTL.STOE is set to 1, there is a function to issue the synchronous timing event for each START condition. STCTL.STOE is cleared when an ST message is received (SETXTIME CCC using the ST subcommand).
     Check the reception of the ST message with the Receive Status Descriptor, and use an external timer to correct the T_ph period based on the count value captured in the synchronous timing event and the Delay Time obtained from the DT message.
     While measuring the T_ph period with an external timer, the start of T_ph and the Delay Time [DT] of the ST message can be measured by capturing the count value with the synchronous timing event.
     The sampling timing is recalculated by the corrected T_ph.

(2) Async Mode 0 (Asynchronous Basic Mode)

For timing control in Async Mode 0, set the ATCTL register if necessary.

1. I3C Master

I3C has counters of MREFMREF (32-bit) and MC2 (16-bit) for Async mode 0.

- MREF Counter
  When ATCCNTE.ATCE is enabled, it starts counting.
  It captures as MREF on the SCL rise edge next to ACK for the IBI transmitted from the I3C Slave.
- MC2 Counter
  After enabling ATCCNTE.ATCE, it counts up from the SCL rise edge next to ACK for the IBI transmitted from the I3C Slave to the SCL rise edge next to the Tbit after Mandatory Byte, and capture it as MC2.

The MREF and MC2 capture values are stored next to the IBI Status Descriptor when IBI is received from the I3C Slave with the DATBASm.DVIBITS bit set to 1.

The MREF counter implemented in I3C is 32-bit counter.

However, if the 32-bit counter is insufficient due to system requirements, I3C has MREF counter overflow and MREF capture event for expansion. These events are enabled by setting ATCTL.MREFOE to 1.

MREF counter overflow is output when the internal MREF counter overflows.

The MREF counter can be extended by using it as a count event for an external timer. MREF capture event is output at the same timing as the capture timing of the internal MREF counter. By using it as the capture timing of the external timer, it can be used as an MREF counter concatenated with the value stored in the IBI Data buffer.

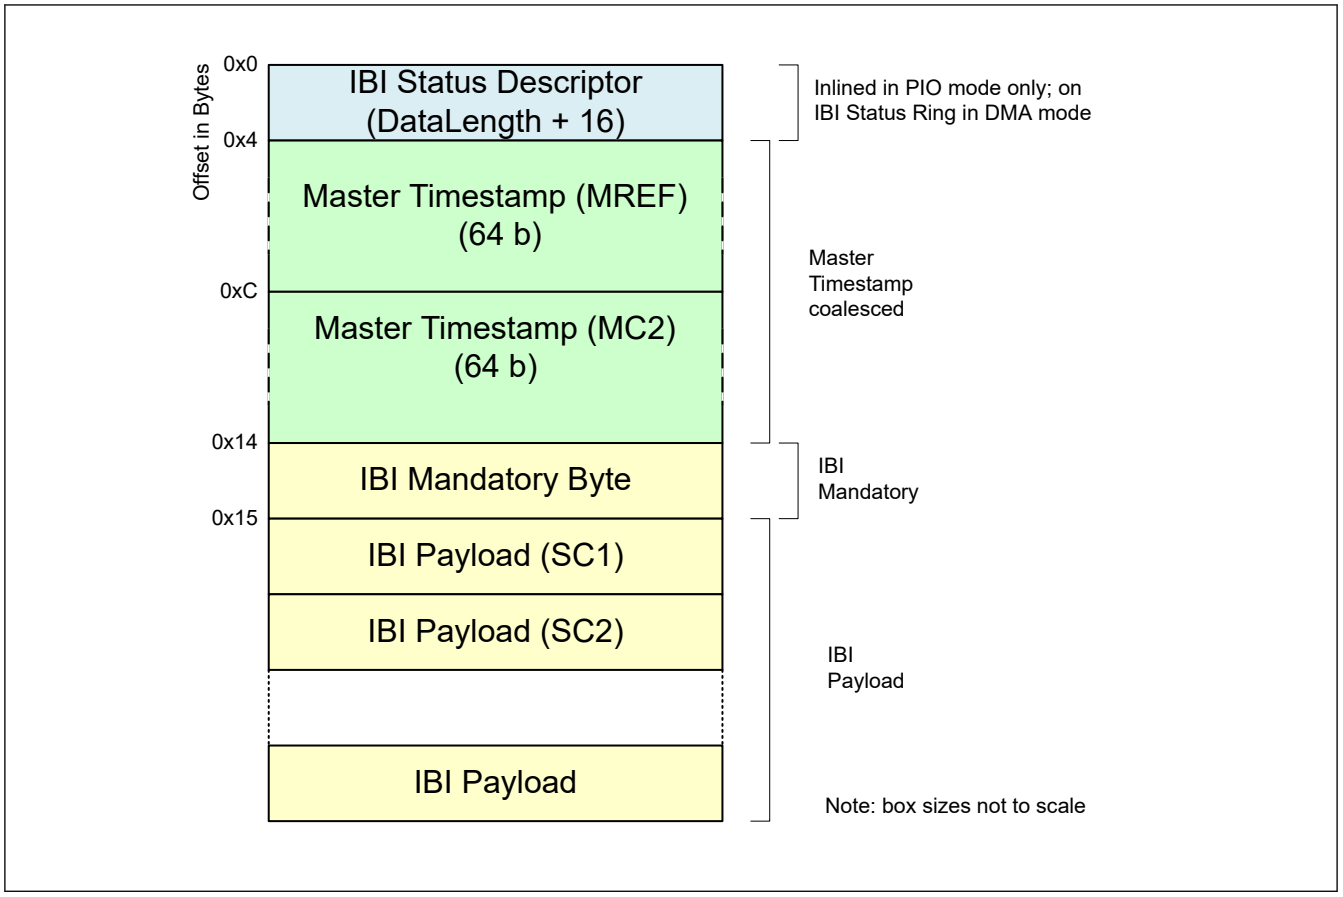

Figure 30.110 Master timestamp counters for IBI event

Note: Please evaluate the Sensor Event time of I3C Slave according to the calculation formula of the MIPI I3C specification v1.0 document.

2. I3C Slave

I3C has counters of SC1 (16-bit) and SC2 (8-bit) for Async mode 0.

- SC1 Counter

After enabling ATCCNTE.ATCE, it counts up from SC1 count trigger*1 to SCL rise edge next to ACK for the IBI, and capture it as SC1.

Note 1. SW or external trigger can be selected by selection bits.

- SC2 Counter
  After enabling ATCCNTE.ATCE, it counts up from SCL rise edge next to ACK for the IBI transmitted from I3C Slave to SCL rise edge next to Tbit after Mandatory Byte, and capture it as SC2.

When the CETSS.ASYNE [0] bit = 1 and the ITS bit in Command Descriptor for issuing IBI is 1, the SC1 and SC2 capture values are transmitted following the IBI Mandatory Byte as shown in the following figure.

If the SC1 and SC2 counters overflow, 0xFFFF and 0xFF are captured and CETSS.ICOVF is set 1.

The DATA_LENGTH[15:0] bits value of the Command Descriptor sets a value obtained by adding the number of data of SC1 and SC2 to the number of transmission data.

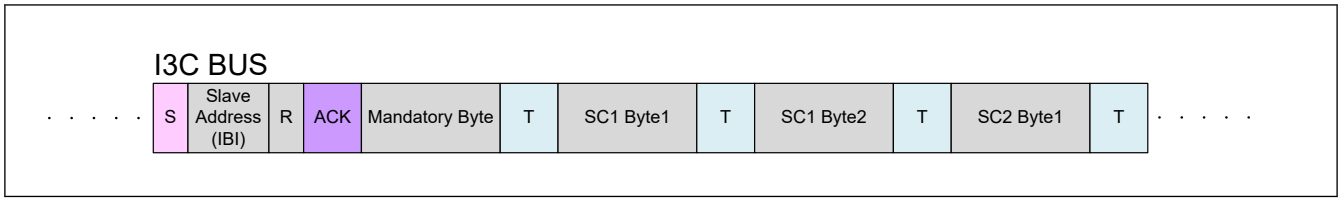

Figure 30.111 Example of asynchronous mode 0 timestamp data transfer

(3) Async Mode 1 (Asynchronous Advanced Mode)

For timing control in Async Mode 1, set the ATCTL register if necessary.

1. I3C Master
   I3C has counters of MREF (32-bit), MSyncCNT (32-bit) and MC2 (16-bit) for Async mode 1.
   - MREF Counter
     When ATCCNTE.ATCE is enabled, it starts counting.
     It captures as MREF at the SCL rise edge next to ACK for the IBI transmitted from the I3C Slave.
   - MSyncCNT Counter
     When ATCCNTE.ATCE is enabled, it starts counting.
     It captures as MSyncCNT for each aME (SDA falling edge of START condition), and store it in the capture register.
   - MC2 Counter
     After enabling ATCCNTE.ATCE, it counts up from SCL rise edge next to ACK for the IBI transmitted from I3C Slave to SCL rise edge next to Tbit after Mandatory Byte, and capture it as MC2.

   The MREF and MC2 capture values are stored next to the IBI Status Descriptor when the IBI is received from the I3C Slave with the DATBASm.DVIBITS bit set to 1 (same as Async mode 0).
   When ATCTL.AMEOE is enabled, an aME Event is issued for each aME. Use that event as a trigger to read the MSyncCNT capture value from the MRCCPT register and hold it in an external memory.
2. I3C Slave
   I3C has counters of SC1 (16-bit), SC2 (8-bit) and aME_TICK (8-bit) for Async mode 1.
   - SC1 Counter
     After enabling ATCCNTE.ATCE, it counts up from SC1 count trigger *1 to the first aME, and capture it as SC1.

     Note 1. SW or external trigger can be selected by selection bits.
   - SC2 Counter
     After enabling ATCCNTE.ATCE, it counts up from SCL rise edge next to ACK for the IBI transmitted from I3C Slave to SCL rise edge next to Tbit after Mandatory Byte, and capture it as SC2.
   - aME_TICK Counter
     After enabling ATCCNTE.ATCE, it counts every aME, and capture it as aME_TICK at the SCL rise edge next to ACK for the IBI.
     The aME_TICK counter is cleared on the first aME after the SC1 count trigger.

When the CETSS.ASYNE[1] bit = 1 and the ITS bit in Command Descriptor for issuing IBI is 1, the SC1, SC2 and aME_TICK capture values are transmitted following the IBI Mandatory Byte as shown in the following figure.

If the SC1 and SC2 counters overflow, 0xFFFF and 0xFF are captured and CETSS.ICOVF is set 1.

The DATA_LENGTH[15:0] bits value of the Command Descriptor sets a value obtained by adding the number of data of SC1, SC2 and aME_TICK to the number of transmission data.

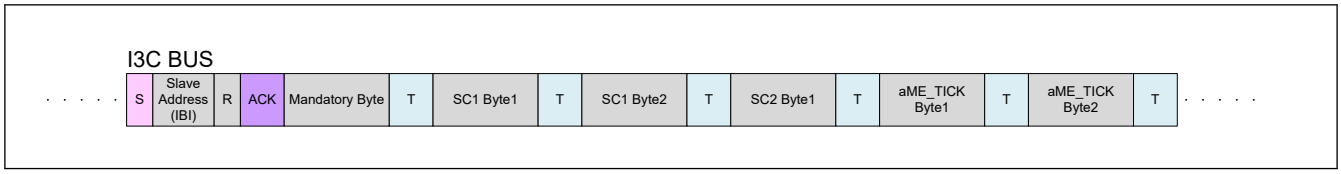

Figure 30.112 Example of asynchronous mode 1 timestamp data transfer

30.3.2.3.10 HDR-DDR CRC5 Algorithm

The CRC5 value is computed on a complete message, including the Command Word and all Data Words.

For a Command Word, the CRC5 is computed based on the value of the 16-bit payload, including:

- The Read vs. Write bit
- The Command Value
- The Slave Address, and
- The lowest-order bit (Write Reserved and Read Parity adjustment).

For Data Words, the CRC5 is computed based on all Data 16-bit values transmitted for that Command.

The CRC5 value is initialized to 0x1F. The CRC5 polynomial is below.

$CRC5 = X^5 + X^2 + X^0$

30.3.2.3.11 Port Control

(1) Extra SCL Clock Cycle Output Function

In master mode, I3C module has a facility for the output of extra SCL clock cycles to release the I3C_SDA line of the slave device from being held at the low level due to the master being out of synchronization with the slave device.

This function is mainly used in master mode to release the I3C_SDA line of the slave device from the state of being fixed to the low level by including extra cycles of SCL output from I3C with single cycles of the SCL clock as the unit in the case of a bus error where I3C cannot issue a Repeated START condition or a STOP condition because the slave device is holding the I3C_SDA line at the low level. Do not use this facility in normal situations. Using it when communications are proceeding correctly will lead to malfunctions.

When the OUTCTL.EXCYC bit is set to 1, an additional clock pulse at the frequency set by the REFCKCTL.IREFCKS[2:0] bits and the STDBR.SBRHO[7:0] and STDBR.SBRLO[7:0] registers is output from the I3C_SCL pin. After output of this clock pulse, the EXCYC bit automatically becomes 0. After confirming that the EXCYC bit is 0, wait for the setup time of the Repeated START condition or STOP condition, and then confirm the detection of the Repeated START condition or STOP condition. If the Repeated START condition or STOP condition is not detected, consecutive additional clock pulses can be output by writing 1 to the EXCYC bit again.

When I3C module is in master mode and the slave device is holding the I3C_SDA line at the low level because synchronization with the slave device has been lost due to the effects of noise, etc., the output of a Repeated START condition or a STOP condition is not possible. The facility for output of an extra cycle of the SCL clock can be used to output extra cycles of SCL one by one to make the slave device release the I3C_SDA line from being held at the low level, thus recovering the bus from an unusable state. Release of the I3C_SDA line by the slave device can be monitored by reading the SDILV bit in PRSTDBG. After the I3C_SDA line has been released by the slave device, the preset of a Repeated START condition or a STOP condition is issued.

Use this function with the BFCTL.MALE bit set to 0 (master arbitration-lost detection is disabled).

[Output conditions for using the EXCYC bit in OUTCTL]

- When the bus is free (BFREF flag in BCST = 1) or in master mode (CRMS bit = 1 in PRSST and BFREF flag = 0 in BCST)
- When the communication device does not hold the I3C_SCL line low

Figure 30.113 shows the operation timing of the extra SCL clock cycle output function (EXCYC bit).

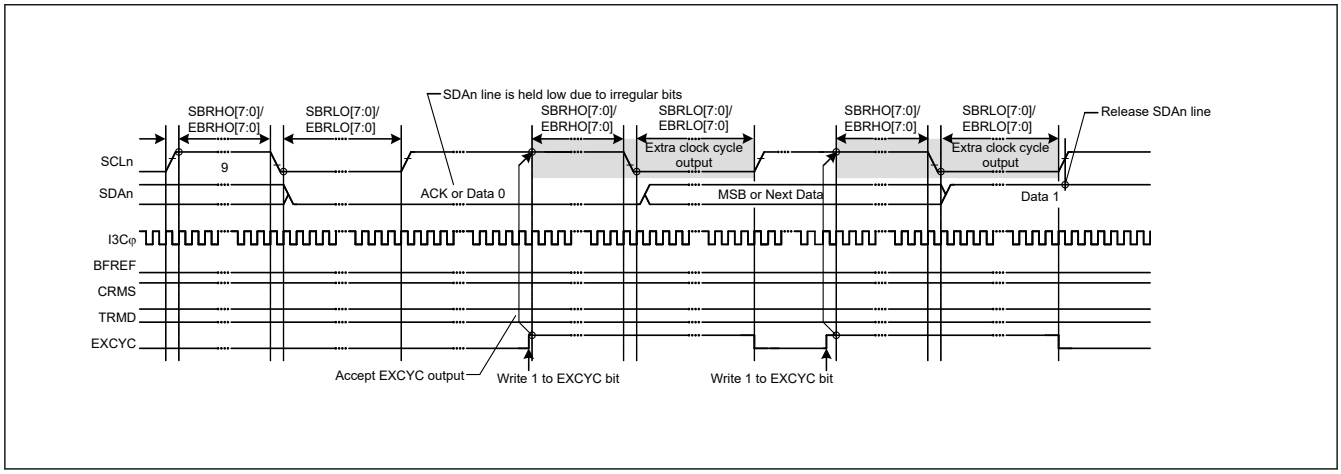

Figure 30.113 Extra SCL clock cycle output function (EXCYC bit)

30.3.2.3.12 SMBus Operation [I²C mode]

I3C is available for data communication conforming to the SMBus (Version 2.0). To perform SMBus communication, set the BFCTL.SMBS bit to 1. To use the transfer rate within a range of 10 kbps to 100 kbps of the SMBus specification, set the REFCKCTL.IREFCKS[2:0] bits, the STDBR.SBRHO[7:0] bits, and the STDBR.SBRLO[7:0] bits. In addition, determine the values of the OUTCTL.SDODCS bit and the OUTCTL.SDOD[2:0] bits to meet the data hold time specification of 300 ns or more. If I3C is used only as an I²C slave device, the transfer rate setting is not necessary, whereas the STDBR.SBRLO[7:0] bits needs to be set to a value longer than the data setup time (250 ns).

For the SMBus device default address (1100 001), use one of the slave device address table basic registers 0 to 2 (SDATBASn .SDSTAD[6:0] bits (y = 0 to 2), and set the corresponding SDATBASn .SDADLS bit (7-bit/10-bit address format select) (y = 0 to 2) to 0 (7-bit address format).

When transmitting the UDID (Unique Device Identifier), set the BFCTL.SALE bit to 1 to enable the slave arbitration lost detection function.

(1) SMBus Timeout Measurement

(a) Measuring timeout of slave device

The following period (timeout interval: $T_{LOW:SEXT}$) must be measured for slave devices in SMBus communication.

- From START condition to STOP condition

To measure timeout for slave devices, measure the period from START condition detection to STOP condition detection with the GPT timer using a START condition detection interrupt (I3C_EEI) and STOP condition detection interrupt (I3C_EEI) of I3C. The measured timeout period must be within the total clock low-level period [slave device] $T_{LOW:SEXT}$: 25 ms (max.) of the SMBus specification.

If the time measured with the GPT exceeds the clock low-level detection timeout $T_{TIMEOUT}$: 25 ms (min.) of the SMBus specification, the slave device must release the bus by writing 1 to the RSTCTL.INTLRST bit to issue an internal reset of I3C. When an internal reset is issued, I3C stops driving the bus for the I3C_SCL pin and I3C_SDA pin and make the I3C_SCL/I3C_SDA pin outputs high-impedance, which releases the bus.

(b) Measuring timeout of master device

The following periods (timeout interval: $T_{LOW:MEXT}$) must be measured for master devices in SMBus communication.

- From START condition to acknowledge bit
- Between acknowledge bits

- From acknowledge bit to STOP condition

To measure timeout for master devices, measure these periods with the GPT timer using a START condition detection interrupt (I3C_EEI), STOP condition detection interrupt (I3C_EEI), and transmit end interrupt (I3C_TEND) or Normal Rx Data buffer full interrupt (I3C_RX) of I3C. The measured timeout period must be within the total clock lowlevel extended period (master device) $T_{LOW:MEXT}$: 10 ms (max.) of the SMBus specification, and the total of all $T_{LOW:MEXT}$ from START condition to STOP condition must be within $T_{LOW:SEXT}$: 25 ms (max.).

For the ACK receive timing (rising edge of the ninth SCL clock cycle), monitor the BST.TENDF flag in master transmit mode (master transmitter) and the NTST.RDBFF0 flag in master receive mode (master receiver). For this reason, perform bytewise transmit operation in master transmit mode, and hold the SCSTRCTL.ACKTWE bit 0 until the byte just before reception of the final byte in master receive mode. While the ACKTWE bit = 0, the RDBFF0 flag is set to 1 at the rising edge of the ninth SCL clock cycle.

If the period measured with the GPT exceeds the total clock low-level extended period (master device) $T_{LOW:MEXT}$: 10 ms (max.) of the SMBus specification or the total of measured periods exceeds the clock low-level detection timeout $T_{TIMEOUT}$: 25 ms (min.) of the SMBus specification, the master device must stop the transaction by issuing a STOP condition. In master transmit mode, immediately stop the transmit operation (writing data to NTDTBP0).

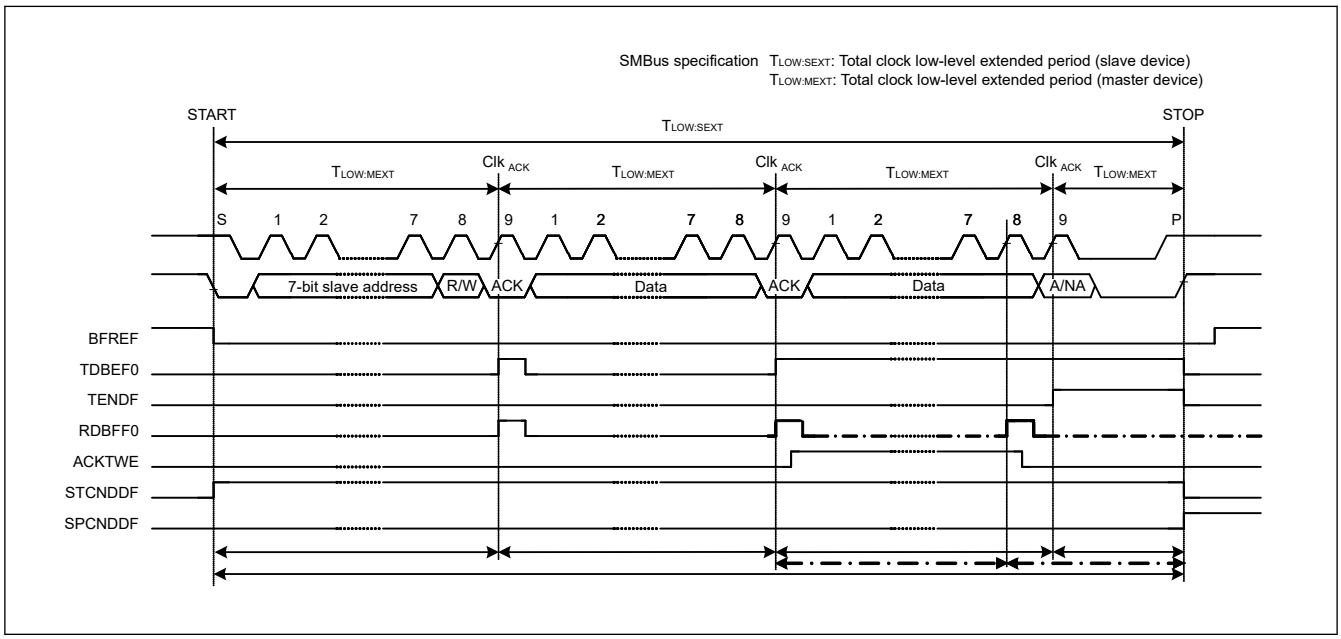

Figure 30.114 SMBus timeout measurement

(2) Packet Error Code (PEC)

This MCU incorporates a CRC calculator. The CRC calculator enables transmission of a packet error code (PEC) or checking the received data of the SMBus in data communication of I3C. For the CRC generating polynomials of the CRC calculator, see section 35, Cyclic Redundancy Check (CRC).

The PEC data in master transmit mode can be generated by writing all transmit data to the CRC data input register (CRCDIR) in the CRC calculator.

The PEC data in master receive mode can be checked by writing all receive data to CRCDIR in the CRC calculator and comparing the obtained value in the CRC data output register (CRCDOR) with the received PEC data.

To send ACK or NACK according to the match or mismatch result when the final byte is received as a result of the PEC code check, set the SCSTRCTL.ACKTWE bit to 1 before the rising edge of the eighth SCL clock cycle during reception of the final byte, and hold the I3C_SCL line low at the falling edge of the eighth clock cycle.

(3) SMBus Host Notification Protocol (Notify ARP Master Command)

In communications over an SMBus, a slave device can temporarily act as a master device to notify the SMBus host (or ARP master) of its own slave address or to request its own slave address from the SMBus host.

For a product of this MCU to operate as an SMBus host (or ARP master), the host address (0001 000) sent from the slave device must be detected as a slave address, so I3C has a function for detecting the host address. To detect the host address as a slave address, set the BFCTL.SMBS bit and the SVCTL.HOAE bit to 1. Operation after the host address has been detected is the same as normal slave operation.

30.3.2.3.13 Common Command Codes (CCC) [I3C mode]

For the common command code (CCC), refer to 5.1.9 Common Command Codes (CCC) in MIPI I3C Specification v1.0. I3C is based on Table 15 I3C Common Command Codes in 5.1.9.3 Common Command Definitions of MIPI I3C Specification v1.0.

The MIPI Reserved area and Vendor Extension area of Command Code are described below.

I3C Master mode :

When sending CCCs in the MIPI Reserved area and Vendor Extension area from the I3C Master, only Broadcast/Direct SET CCCs using the Immediate Transfer Command can be sent.

Sending Direct GET CCC is not supported.

I3C Slave mode :

Only Broadcast/Direct SET CCC can be received for CCC in MIPI Reserved area and Vendor Extension area.

Receiving Direct GET CCC is not supported.

30.3.2.4 Error Detection

30.3.2.4.1 SDR Error Detection and Recovery Methods for I3C Slave Devices [I3C mode]

The seven error types summarized in Table 30.13 are supported for all I3C slave devices. Each error type is further explained below the table.

Table 30.13 SDR slave error types

Error type	Description	Error detection method	Error recovery method
S0	Broadcast address/W (= 0x7E/W) or Dynamic address/RW	Detect any of the following: 0x3E / W 0x5E / W 0x6E / W 0x76 / W 0x7A / W 0x7C / W 0x7F / W 0x7E / R	Enable HDR EXIT Detector and ignore all other patterns
S1	CCC code	Parity check, using T-Bit	Enable HDR EXIT detector and neglect other patterns
S2	Write data	Parity check, using T-Bit	Enable STOP detector and neglect other patterns
S3	Assigned address during Dynamic address arbitration	Parity check, using PAR Bit	Generate NACK (after PAR), then wait for another Repeated START and 7E/R to re-transmit the Provisional ID
S4	0x7E/R after Sr during Dynamic address arbitration	Detect any value other than 0x7E/R after Sr during Dynamic Address Arbitration	Generate NACK (after 0x7E/R), then enable STOP Detector and ignore all other patterns
S5	Transaction after detecting CCC	Detect illegally formatted CCC	Generate NACK (after Slave Address), then enable STOP Detector and ignore all other patterns
S6 (optional)	Monitoring error	Slave detects (through monitoring) that transmitted Data differs from what it intended to transmit (Does not apply during Dynamic address arbitration)	Stop the transmission, then enable STOP Detector and ignore all other patterns

30.3.2.4.2 SDR Error Detection and Recovery Methods for I3C Master Devices [I3C mode]

The two error types summarized in Table 30.14 are supported for all I3C master devices. Each error type is further explained below the table.

Table 30.14 SDR master error types

Error type	Description	Error detection method	Error recovery method
M0	Transaction after sending CCC	Detect illegally formatted CCC	Stop the transmission, then send STOP and retry the transmission.
M1 (optional)	Monitoring error	Master detects (through monitoring) transmitted data different from what it intended to transmit (Does not apply during Dynamic address arbitration)	Stop the transmission, then send STOP and retry the transmission.
M2	No response to Broadcast address (0x7E)	Master detects NACK after Broadcast address (0x7E) transmission	Upon detection of NACK, master transmits HDR exit pattern followed by STOP

30.3.2.4.3 HDR-DDR Error Detection

Four error types are defined for HDR-DDR mode.

Table 30.15 HDR-DDR error types

Error type	Description	Error detection method	Error recovery method
Framing	The Preamble 2-bits before command and data	The Slave detects that the Preamble 2-bits before command and data is not valid values.*1	Master: Issue SCL clocks until 19 SCL clocks (38 bits) have been seen with SDA High. The Master shall then Park SCL Low, and emit an HDR Exit Pattern using SDA. Slave: Wait for HDR EXIT Pattern
Parity checking	Parity error	The Master and the Slave detects mismatched parity.*2	
CRC5 checking	CRC5 error	The Master and the Slave detects mismatched CRC.*3	
NACK receiving	NACK by the Slave on a Read command	The Master detects a NACK by the Slave on a Read command.*4	Issue SCL clocks until 19 SCL clocks (38 bits) have been seen with SDA high. The Master shall then Park SCL low, and emit either an HDR exit pattern or an HDR restart pattern using SDA.
Monitoring	Monitoring error	Both the Master and the Slave should always monitor the data that they each transmit, and they detect the monitored data differs from the data that the Master or Slave intended to send.*5	Both the Master and the Slave can stop the transmission and then Master and Slave should each do the following. Master: Issue SCL clocks until 19 SCL clocks (38 bits) have been seen with SDA High. The Master shall then Park SCL Low, and emit an HDR Exit Pattern using SDA. After the Master sends HDR EXIT, it can retry the transmission. Slave: Wait for HDR Exit Pattern

Note 1. This supports a positional error detection mechanism:
- A Command Word shall always follow the Enter HDR CCC and HDR Restart Pattern, and shall never appear in any other position. It is an error condition for a Command Word to appear in any other position, or to be missing where expected.
- A Data Word shall always follow either a Command Word or another Data Word, and shall never appear in any other position. It is an error condition for a Data Word to appear in any other position, or to be missing where expected.
- A single CRC Word shall always follow the last Data Word for a Command, such that it ends the Message. As a result, a CRC Word shall always be followed by either the HDR Restart Pattern or the HDR Exit Pattern. It is error condition for a CRC Word to appear in any other position, or to be missing where expected.
- The first nibble of a valid CRC shall contain the allowed value 0xC. Any other value in the first nibble should be considered a framing error.

Note 2. Parity encoding (for transmitters) parity checking (for receivers) shall be performed on all Command Words and Data Words. Mismatched parity is an error condition.
Note 3. CRC5 encoding (for transmitters) and CRC5 checking (for receivers) shall be performed on all payload bits for Command Words and Data Words. Mismatched CRC is an Error.
Note 4. NACK by the Slave on a Read command is not a normal behavior (ACK is normal). The Master may choose to treat a NACK on a Read command as a possible framing error. The Master can choose to treat the NACK of a Read command as a possible line error, and therefore use the same approach in order to ensure that the Slave is not driving the Bus.
Note 5. If the Master or Slave performs such monitoring, and if the monitored Data differs from the Data that the Master or Slave intended to send (except for Data transferred during a Dynamic Address Arbitration procedure), then this shall be considered an error.

30.3.2.4.4 HDR-TSP/TSL Error Detection

Two error types are defined for HDR-TSP/TSL Mode.

Table 30.16 HDR-TSP/TSL error types

Error type	Description	Error detection method	Error recovery method
Symbol 2 checking	Continuous error of symbol 2	More than one symbol 2 in a row. (In symbol 2 the I3C_SCL line does not change, and the I3C_SDA line does change.) *1	Master: Wait until the Slave stops transitioning the Bus for 2x the maximum edge-to-edge duration used by that Slave. Then the Master shall force out the HDR Exit Pattern. Slave: Wait for HDR Exit Pattern.
Parity checking	Parity errors	The Slave detects mismatched parity. *2	
Monitoring	Monitoring error	Both the Master and the Slave should always monitor the data that they each transmit, and they detect the monitored data differs from the data that the Master or Slave intended to send.*3	Both the Master and the Slave can stop the transmission and then Master and Slave should each do the following. Master: Wait until the Slave stops transitioning the Bus for 2x the maximum edge-to-edge duration used by that Slave. Then the Master shall force out the HDR Exit Pattern. After the Master sends HDR EXIT, it can retry the transmission. Slave: Wait for HDR EXIT Pattern.

Note 1. Exception: More than one Symbol 2 in a row is allowed for HDR Restart or HDR Exit, but only from a known starting state (SCL Low and SDA High), and only at a Data Word boundary (allowing for one Symbol to set up that state). Thus the Symbol pattern 2,2 is only allowed under the following situations:
- As part of the HDR Exit Pattern, which uses 3 or 4 such Symbol pairs and involves SCL Low
- As part of the HDR Restart pattern, which uses 2 such Symbol pairs and involves SCL Low
- As the result of one normal Symbol ending in 2, and the next Symbol starting with 2

Note 2. An error may be seen by an HDR Slave, or by an HDR Master when a Slave is driving the I3C Bus:
- A Slave that sees an error shall stop tracking Symbols and use HDR Exit and HDR Restart Pattern detection. This means to wait until safe. A Slave shall enable the HDR Exit and HDR Restart Pattern Detector upon entry to any HDR Mode, ensuring that it is always safe.
- A Master that sees an error shall wait until the Slave stops transitioning the Bus for 2x the maximum edge-toedge duration used by that Slave. Then the Master shall force out the HDR Exit Pattern.

Note 3. If the Master or Slave performs such monitoring, and if the monitored Data differs from the Data the Master or Slave intended to send (except for data transferred during the Dynamic Address Arbitration procedure), then this shall be considered an error.

Note: It could be appropriate to wait for the Symbol 2,2, but the Master would still need to see quiescence. If the Master is seeing errors, then the results of even a Symbol 2,2 are questionable.

30.3.2.4.5 Timeout Error Detection

I3C includes a timeout function for detecting when the I3C_SCL line has been stuck longer than the predetermined time. I3C can detect an abnormal bus state by monitoring that the I3C_SCL line is stuck low or high for a predetermined time.

The timeout function monitors the I3C_SCL line state and counts the low-level period or high-level period using the internal counter. The timeout function resets the internal counter each time the I3C_SCL line changes (rising or falling), but continues to count unless the I3C_SCL line changes. If the internal counter overflows due to no I3C_SCL line change, I3C can detect the timeout and report the bus hung state.

This timeout function is enabled when BSTE.TODE = 1. It detects a hung state that the I3C_SCL line is stuck low or high during the following conditions: (When TMOCTL.TOMDS[1:0] = 00b)

- The bus is busy (BCST.BFREF = 0) in master mode (PRSST.CRMS = 1).
- I3C's own slave address is detected (SVST register is not 0x0000) and the bus is busy (BCST.BFREF = 0) in slave mode (PRSST.CRMS = 0).
- The bus is free (BCST.BFREF = 1) while generation of a START condition is requested (CNDCTL.STCND = 1).

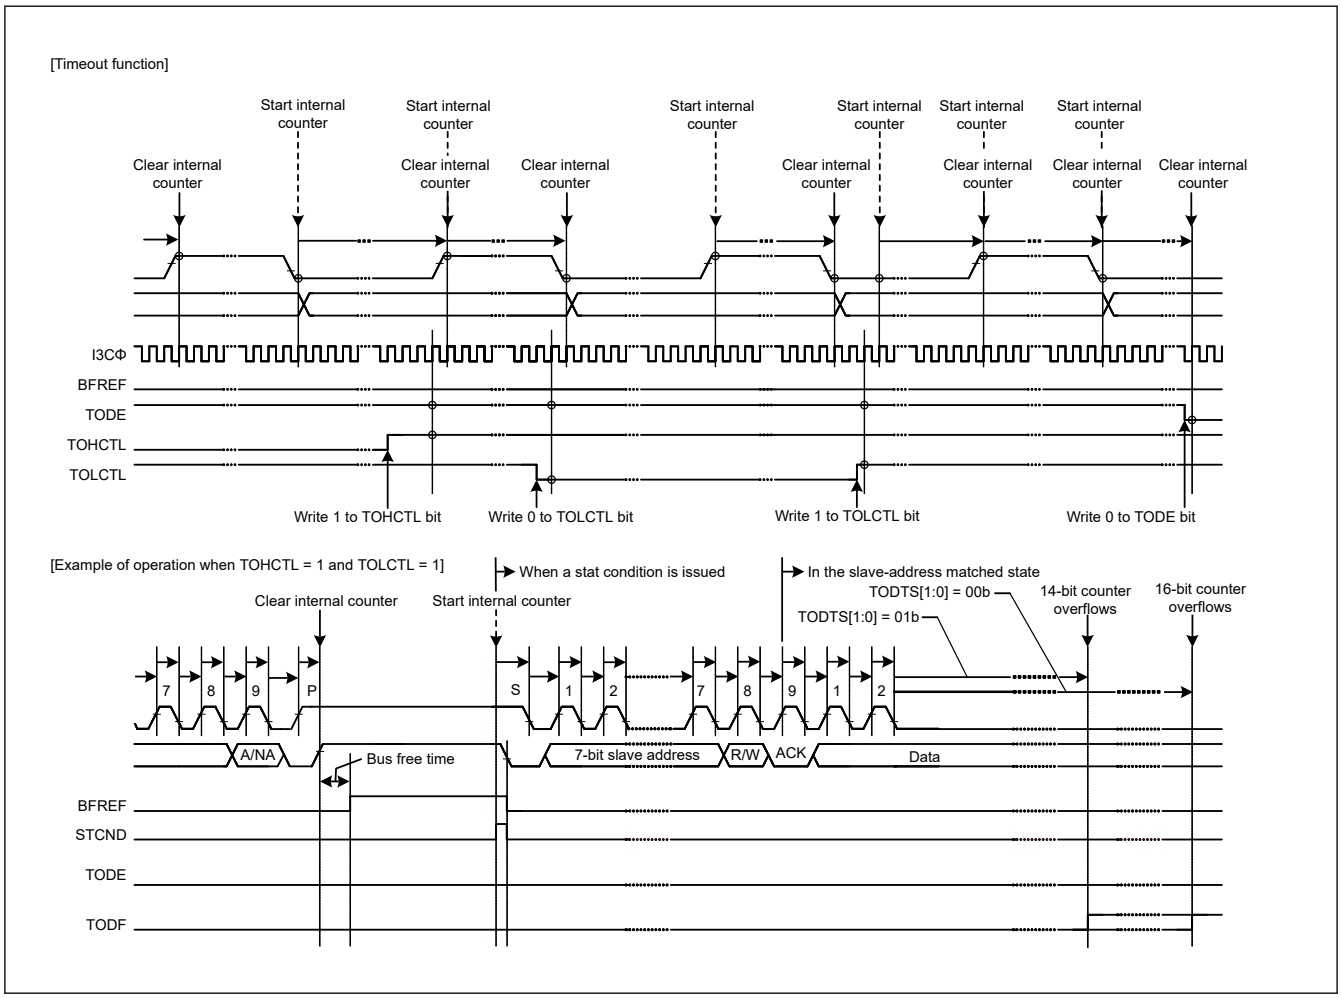

Figure 30.115 Timeout error detection (TODE, TODTS[1:0], TOHCTL, and TOLCTL bits)

30.3.2.4.6 Resume Operation [I3C mode]

I3C enters the Halt state as a result of any type of error occurring in a transfer.

The error type is indicated by the field ERR_STATUS in Response Descriptor or Receive Status Descriptor. After I3C has entered the Halt state, the user must write the value 1 to the RSM bit to resume operation. I3C shall auto-clear the RSM bit once it has initiated the next Command transfer or detected the START condition.

30.3.2.4.7 Abort Operation [I3C mode]

When the BCTL.ABT bit is set to 1, I3C relinquish control of the bus before completing the currently issued transfer. In response to an abort request, I3C issues the STOP condition on the bus after the complete data byte is transferred or received. After I3C has aborted, the user shall clear the BCTL.ABT bit to allow operation on the bus.

Note: For Read transaction, when BCTL.ABT is set to 1, that receive data is stored in Rx data buffer. However, for HDR-TSP / TSL, receive data received after that is not stored.

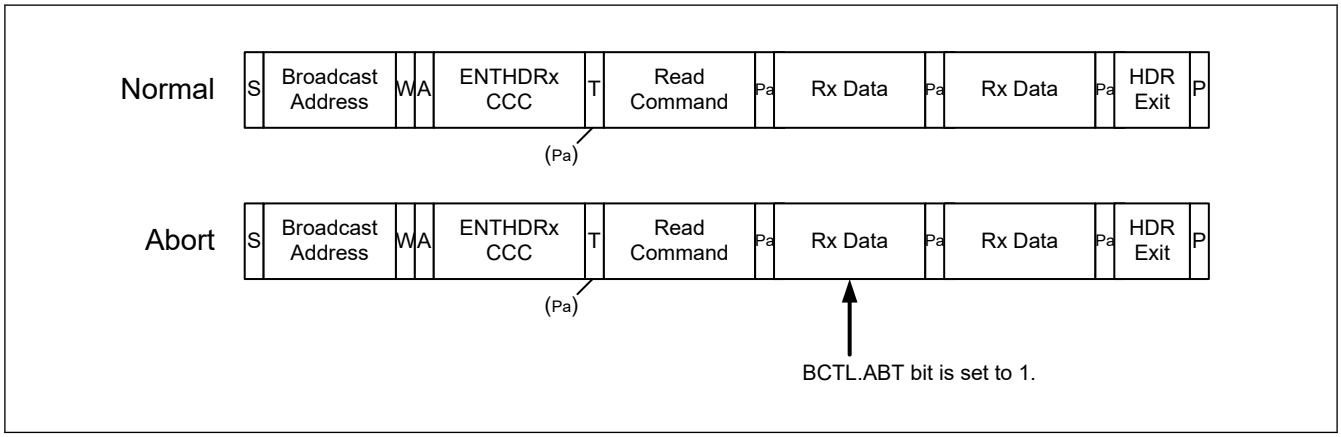

Figure 30.121 Abort operation of HDR-TSP/TSL read transfer

30.3.2.4.8 Error Recovery Operation

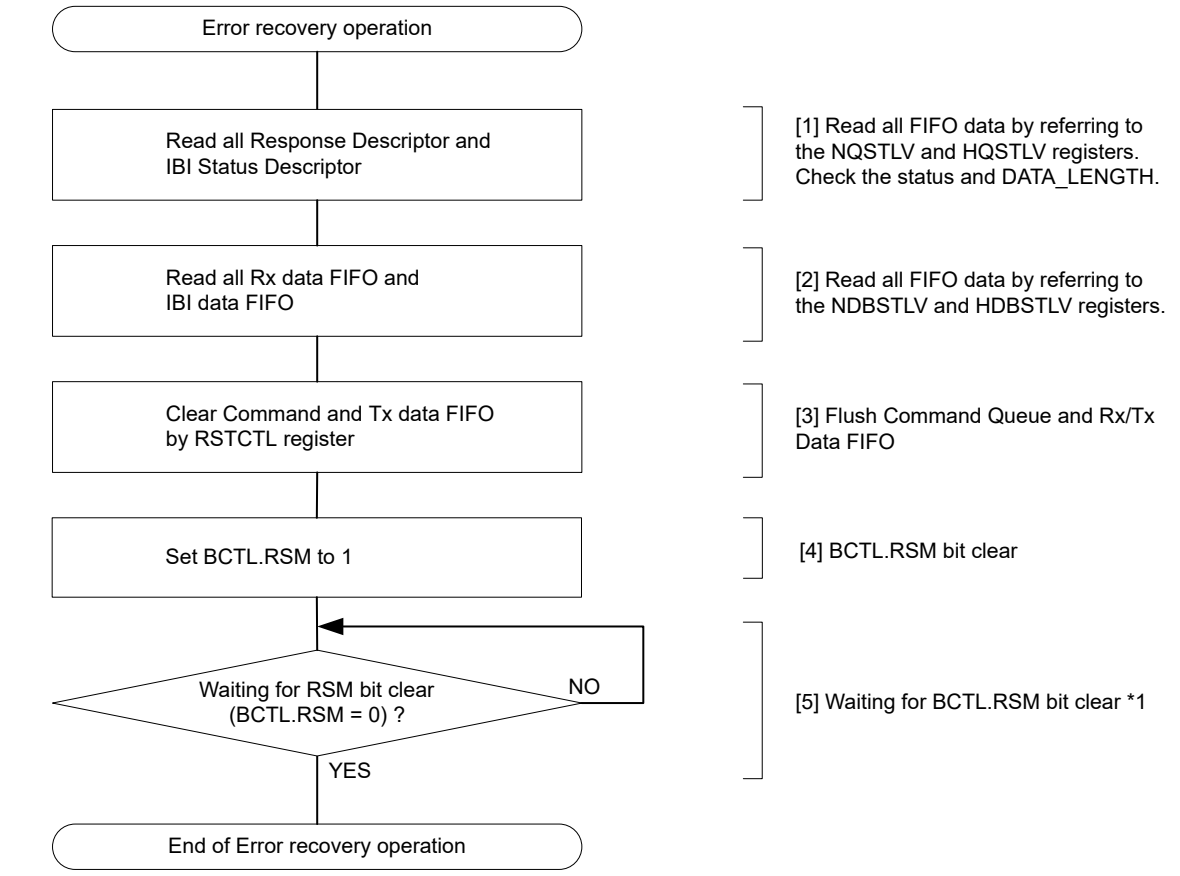
(1) Error Recovery Operation

When an error occurs, the INST.INEF, NTST.TEF, NTST.TABTF, HTST.TEF and HTST.TABTF flags are set to 1 according to the cause of the error, or the interrupts associated with each flag are asserted (when detection and interrupts are enabled.)

There is a possibility of communication error or internal module error.

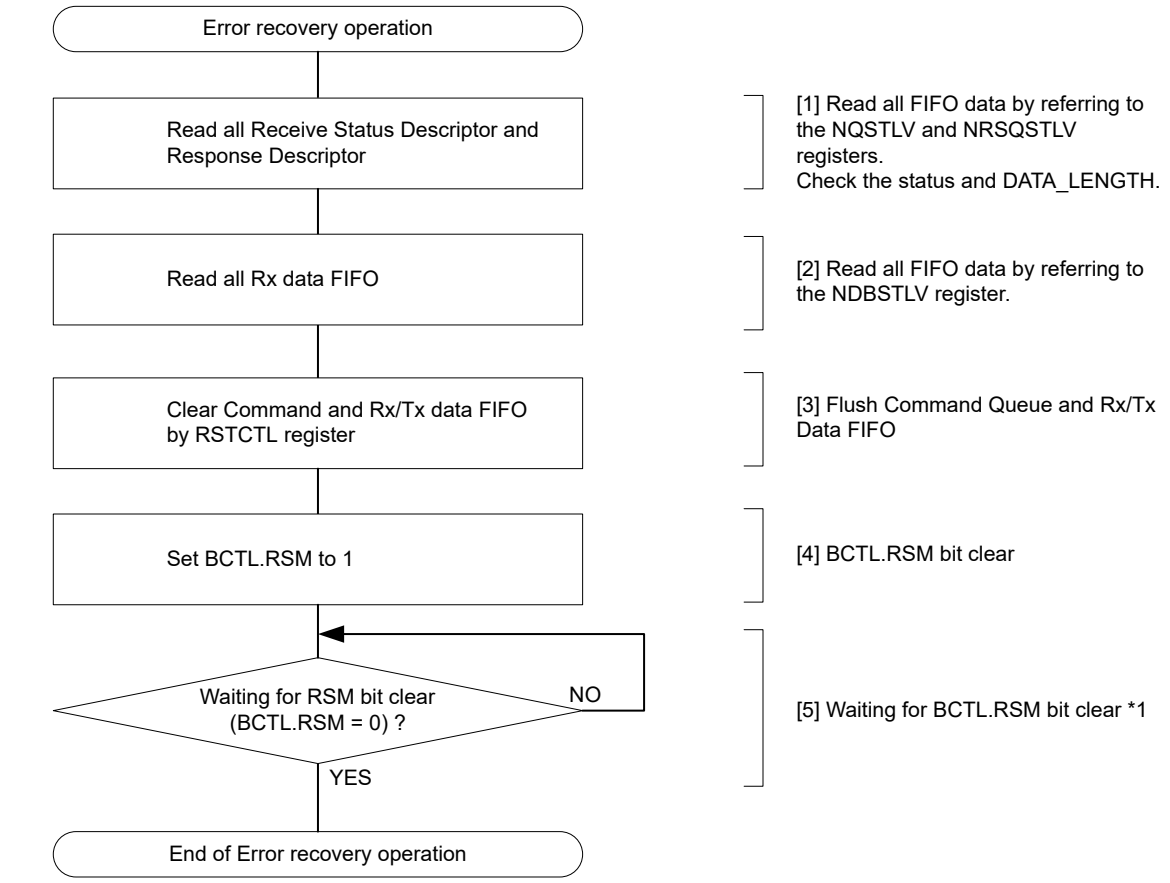
Note: If an error occurs, I3C will be suspended (BCTL.RSM becomes 1). After I3C is suspended, the application must write the value 1 to the BCTL.RSM bit to resume I3C operaion and recover from the suspended state.

Figure 30.122 and Figure 30.123 show the error recovery flow.



Note 1. The Command Descriptor can be written to the Command Queue via writing to the Command Queue Port (NCMDQP or HCMDQP) before the RSM bit is cleared.

Figure 30.122 Example of error recovery operation flowchart for I3C master



Note 1. The Command Descriptor for issuing IBI can be written to the Command Queue via writing to the Command Queue Port (NCMDQP) before the RSM bit is cleared.

Figure 30.123 Example of error recovery operation flowchart for I3C slave

When I3C Slave recovers from an error according to the error recovery flow, after setting BCTL.RSM to 1, BCTL.RSM becomes 0 after detecting a state in which Bus Available period communication is not performed on I3C Bus.

If communication occurs on the I3C bus within the Bus Available period, BCTL.RSM is not set to 0 and error recovery is not completed, NACK response will be made to the communication.

(2) Master Error Detection and Escalation Handling

If the Master does not receive an ACK of a transmitted private message to a slave and steps 1 and 2 described in Chapter 5.1.10.2.4 of MIPI I3C Spec v1.0 fail, the processing flow of step 3 is shown in Figure 30.124 and Figure 30.125.

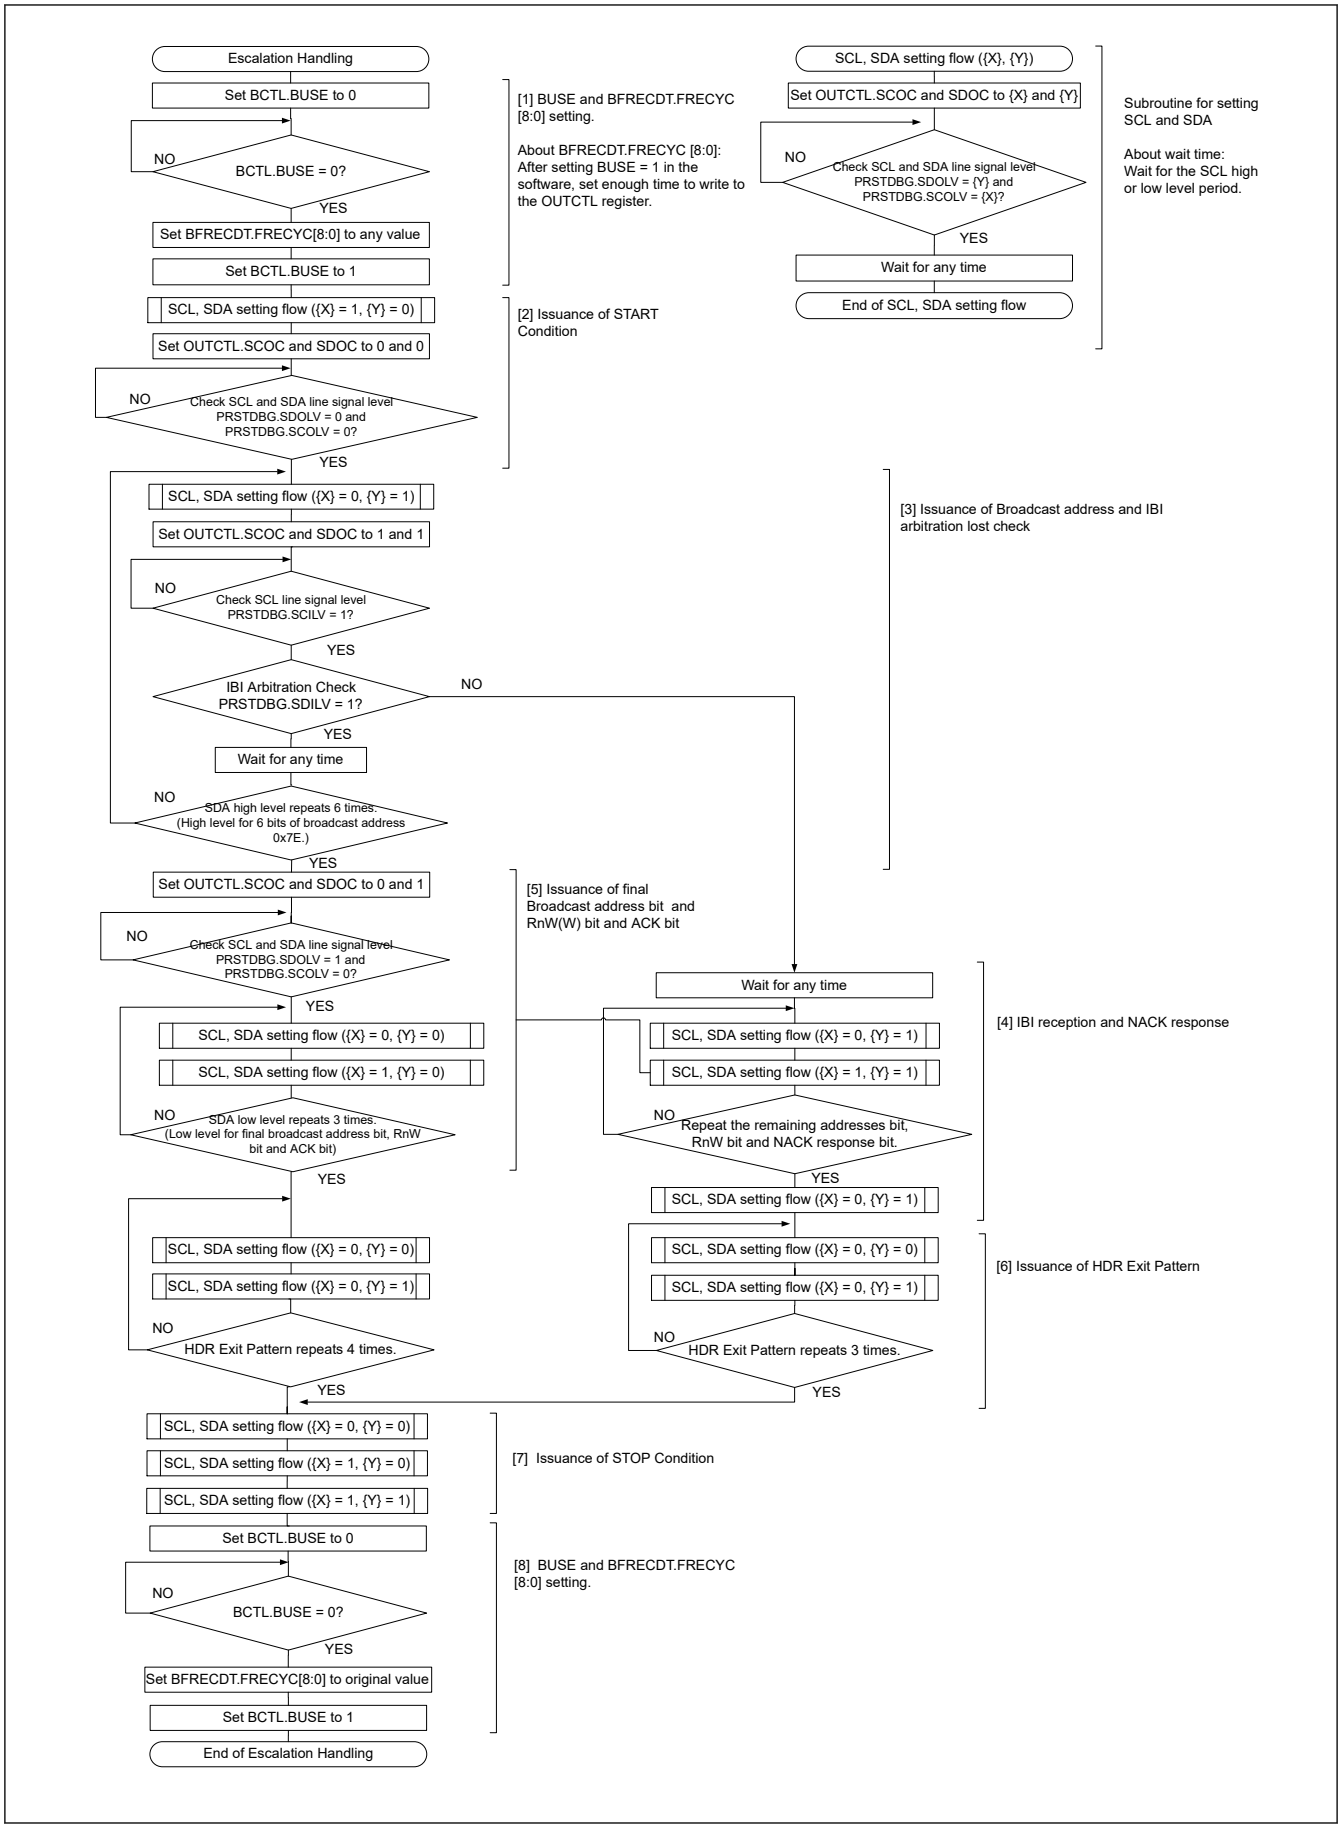


Figure 30.124 Escalation handling flowchart for I3C master

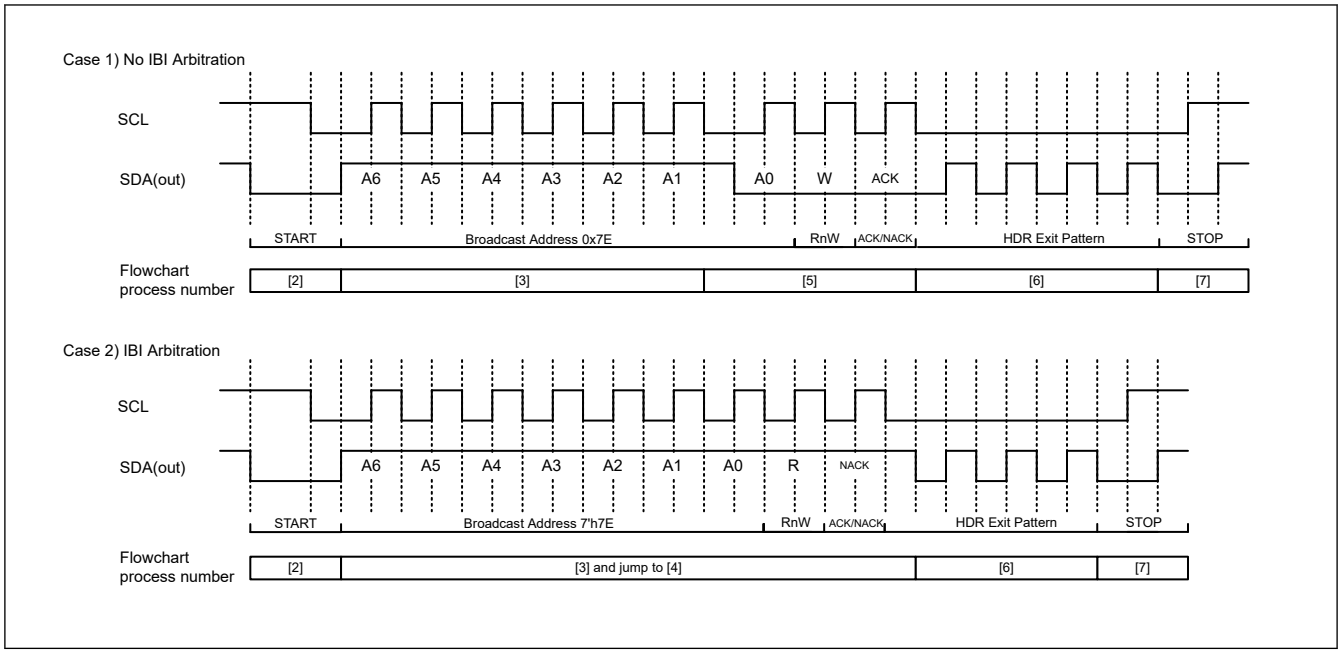

Figure 30.125 I3C escalation handling timing diagram for I3C Master

30.3.2.5 Low Power Function

30.3.2.5.1 Wake Up function [I^2C mode]

I3C is equipped with the Wake-up function that causes the microcomputer to transition from low power consumption mode with system clock (ICLK) is stopped (software standby mode, etc.) to the normal operation. The Wake-up function is used to generate a Wake-up interrupt signal when the received data matches the address set to Wake-up interrupt factor also receives data in a state where the operating clock (PCLK/TCLK) is stopped (PCLK/TCLK asynchronous operation). This wake-up interrupt signal causes the microcomputer to transition to the normal operation. After Wake-up interrupt occurs, switch I3C to PCLK/TCLK synchronous operation, it will be able to continue the communication operation.

The Wake-up function has four wake-up operation modes (normal WU mode 1, normal WU mode 2, command recovery mode, and EEP response mode). The table below describes the behavior in these four wake-up operation modes.

Table 30.17 Wake-up operation mode

	ACK response timing	ACK Type responded before recovery to PCLK/TCLK synchronous operation	SCL state before recovery to PCLK/TCLK synchronous operation
Normal WU mode 1	Before recovery to PCLK/TCLK synchronous operation*1	ACK	Fixed to L
Normal WU mode 2	After recovery to PCLK/TCLK synchronous operation*2	Before recovery: no response (NACK level retained) After recovery: ACK response	Fixed to L
Command recovery mode	Before recovery to PCLK/TCLK synchronous operation*1	ACK	Open
EEP response mode	Before recovery to PCLK/TCLK synchronous operation*1	NACK	Open

Note 1. Switching timing from PCLK/TCLK asynchronous operation to PCLK/TCLK synchronous operation is the fall of the 9th clock of SCL.
Note 2. Switching timing from PCLK/TCLK asynchronous operation to PCLK/TCLK synchronous operation is the fall of the 8th clock of SCL.

The following is able to select as Wake-Up interrupt factor.

- Host address detection (valid when SVCTL.HOAE = 1)
- General call address detection (valid when SVCTL.GCAE = 1)
- Slave address 0*1 detection (valid when SVCTL.SVAE[0] = 1)
- Slave address 1*1 detection (valid when SVCTL.SVAE[1] = 1)

- Slave address 2[*1] detection (valid when SVCTL.SVAE[2] = 1)

Note 1. 7-bit address only can be set. Set SDADLS bit to 0 in SDATBASn .

(1) Normal Wake-Up mode 1

This section describes the behavior, the timing, and a use case of normal WU mode 1.

A wake-up interrupt triggered by the match of the slave address makes the transition to the normal operation in the manner described below. Also, the detailed timing is provided in Figure 30.128.

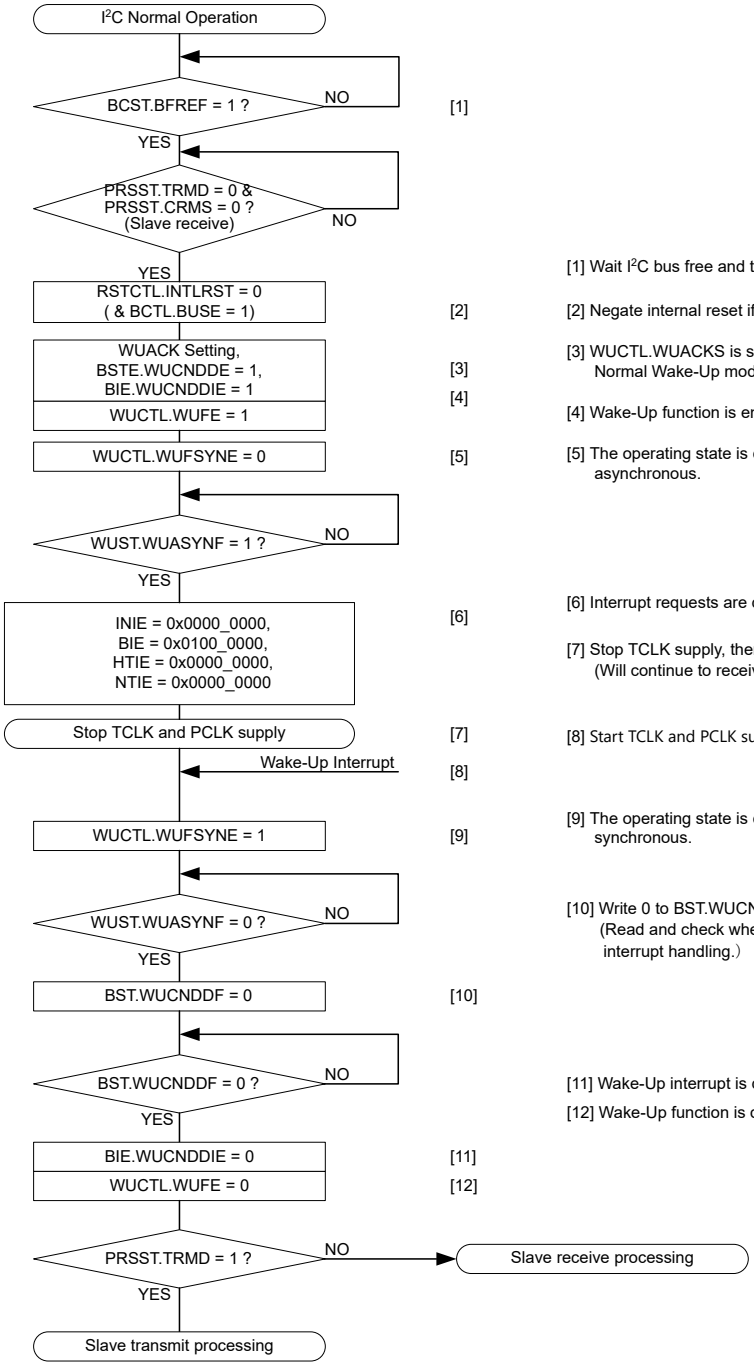
Before wake-up recovery:	ACK is sent in response to the data received with its own slave address.
During wake-up recovery:	ACK response is made at the 9th clock cycle of SCL, and the SCL is held low afterwards.[*1]
After wake-up recovery:	Normal operation continues.

Note 1. Between ninth clock cycle and first clock cycle during Wake-Up recovery, SCSTRCTL.RWE = 1 does not work.

If the slave address does not match, the I3C_SCL line is not held low after the fall of the 9th clock cycle of SCL, and the slave operation continues.

See Figure 30.126 below for a use case.

A wake-up interrupt is not generated at the transition to the normal operation if the transition is triggered by a cause (other recovery causes (IRQ)) other than a wake-up interrupt signal generated by a slave address match. BST.WUCNDDF is not set in this case. Carry out the following processing according to Figure 30.127.



[1] Wait I2C bus free and this module stay in the standby state.

[2] Negate internal reset if assert the internal reset.

[3] WUCTL.WUACKS is set up according to each mode. (Normal Wake-Up mode 1/ Normal Wake-Up mode 2) Wake-Up Interrupt is enabled.

[4] Wake-Up function is enabled.

[5] The operating state is changed from PCLK/TCLK synchronous to PCLK/TCLK asynchronous.

[6] Interrupt requests are disabled except WUI.

[7] Stop TCLK supply, then stop PCLK supply. (Will continue to receive)

[8] Start TCLK and PCLK supply by Wake-Up interrupt (address match).

[9] The operating state is changed from PCLK/TCLK asynchronous to PCLK/TCLK synchronous.

[10] Write 0 to BST.WUCNDDF. (Read and check whether clearing has been completed befor return from interrupt handling.)

[11] Wake-Up interrupt is disabled.

[12] Wake-Up function is disabled.

Figure 30.126 Use case of normal WU mode 1 (wake-up recovery by a wake-up interrupt triggered by the match of the slave address)

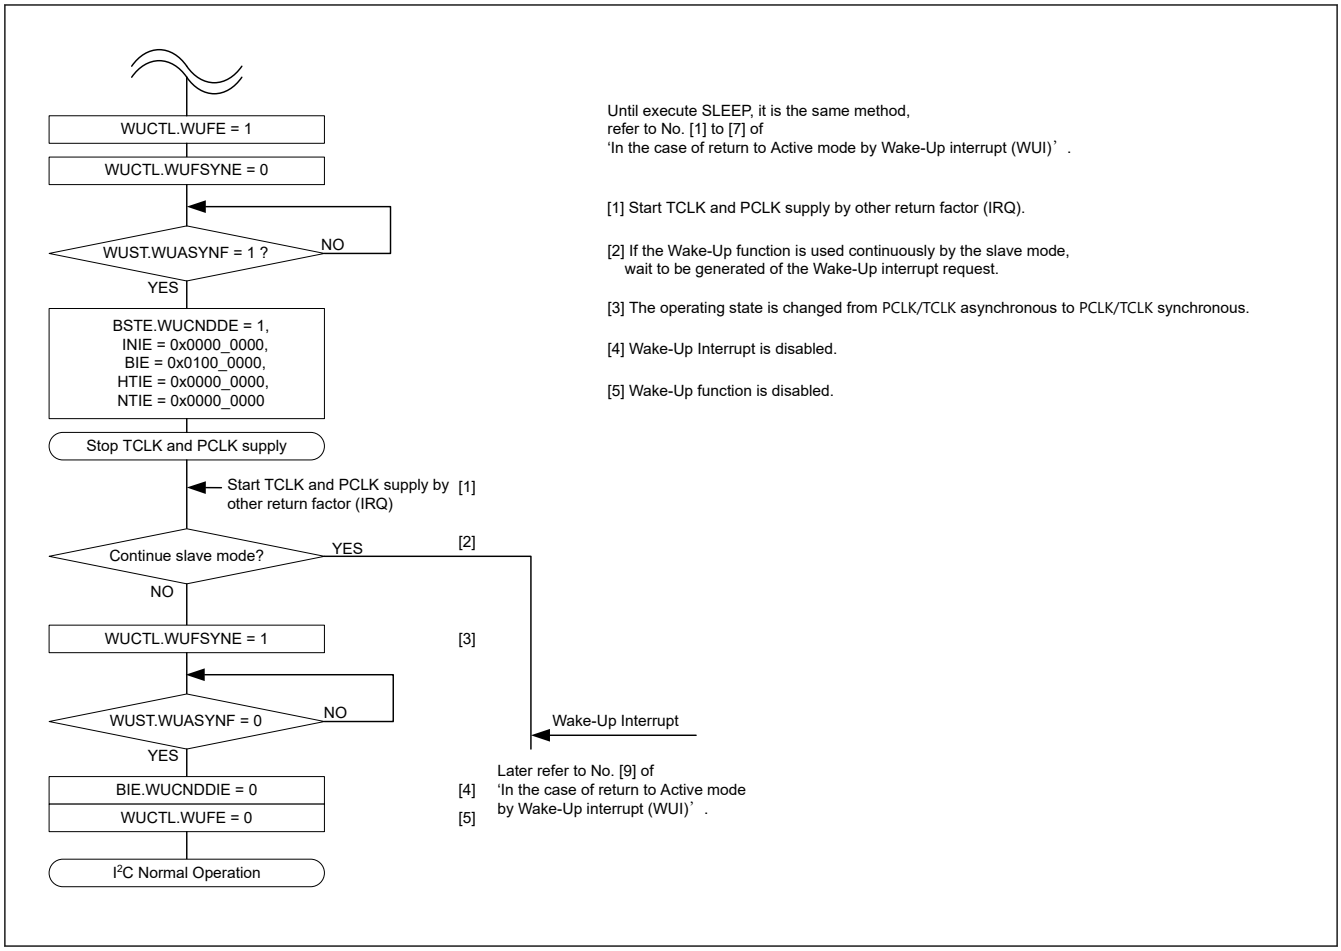


Figure 30.127 Use case of normal WU modes 1 and 2 (wake-up recovery by other recovery causes (IRQ))

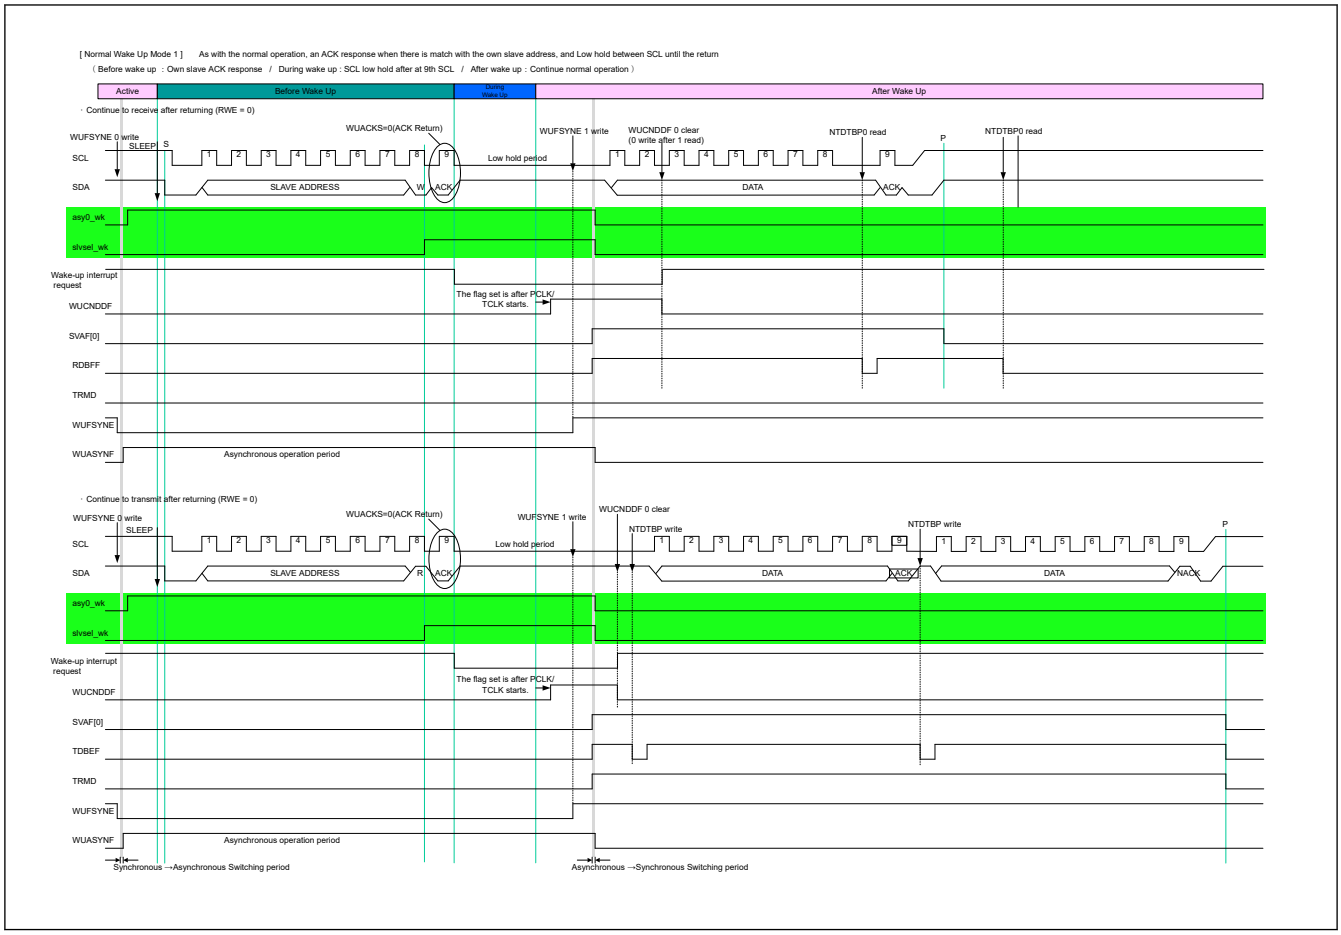

Figure 30.128 Timing of normal wake up mode 1

(2) Normal Wake Up Mode 2

This section describes the behavior, the timing, and a use case of normal WU mode 2.

A wake-up interrupt triggered by the match of the slave address makes the transition to the normal operation in the manner described below.

Also, the detailed timing is provided in Figure 30.130.

Before wake-up recovery:	No response to the data received with its own slave address (until 8th SCL cycle end)
During wake-up recovery:	Holding the I3C_SCL line low during the 8th and 9th clock cycles
After wake-up recovery:	Returning ACK at the 9th clock cycle of SCL, and continuing the normal operation

If the slave address does not match, the I3C_SCL line is not held low after the fall of the 8th SCL v clock cycle. The slave operation continues.

See Figure 30.129 below for a use case.

A wake-up interrupt is not generated at the transition to the normal operation if the transition is triggered by a cause (other recovery causes (IRQ)) other than a wake-up interrupt signal generated by a slave address match. BST.WUCNDDF is not set in this case. Carry out the following processing according to Figure 30.127.

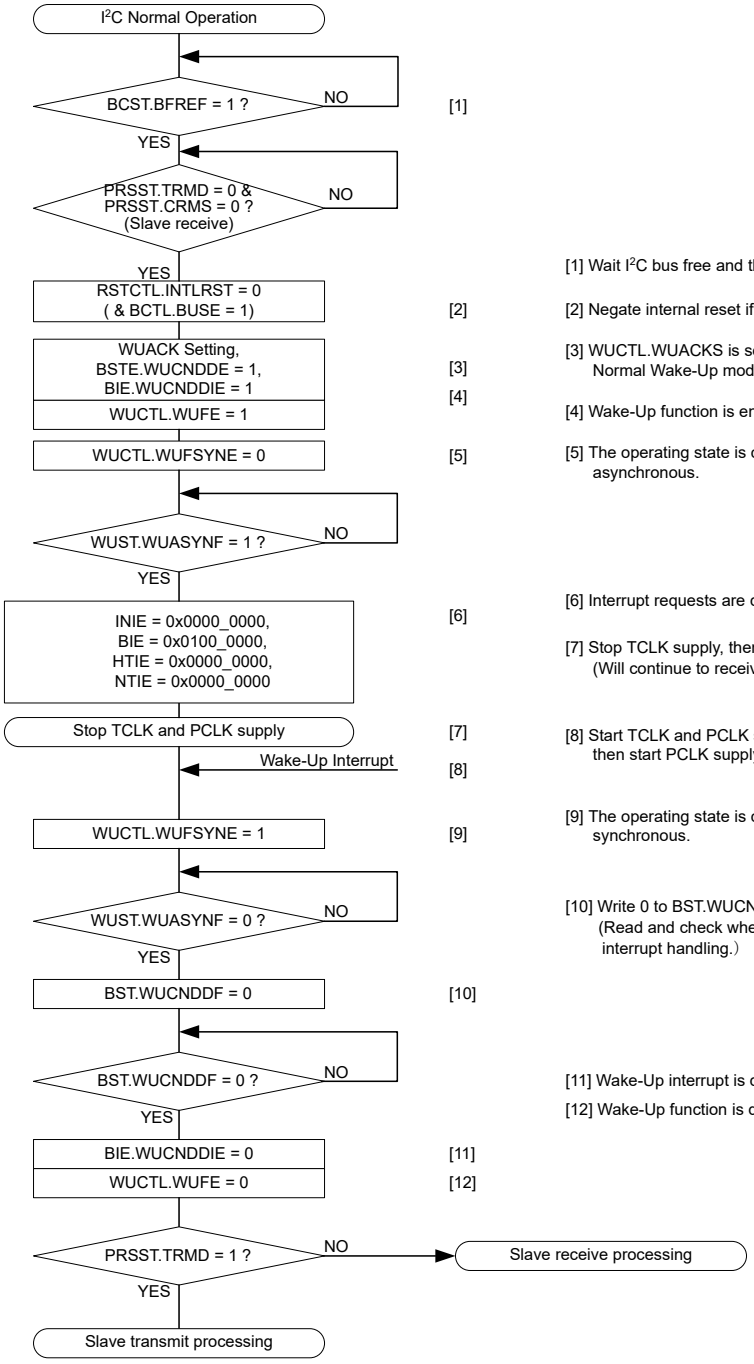

Figure 30.129 Use case of normal WU mode 2 (wake-up recovery by a wake-up interrupt triggered by the match of the slave address)

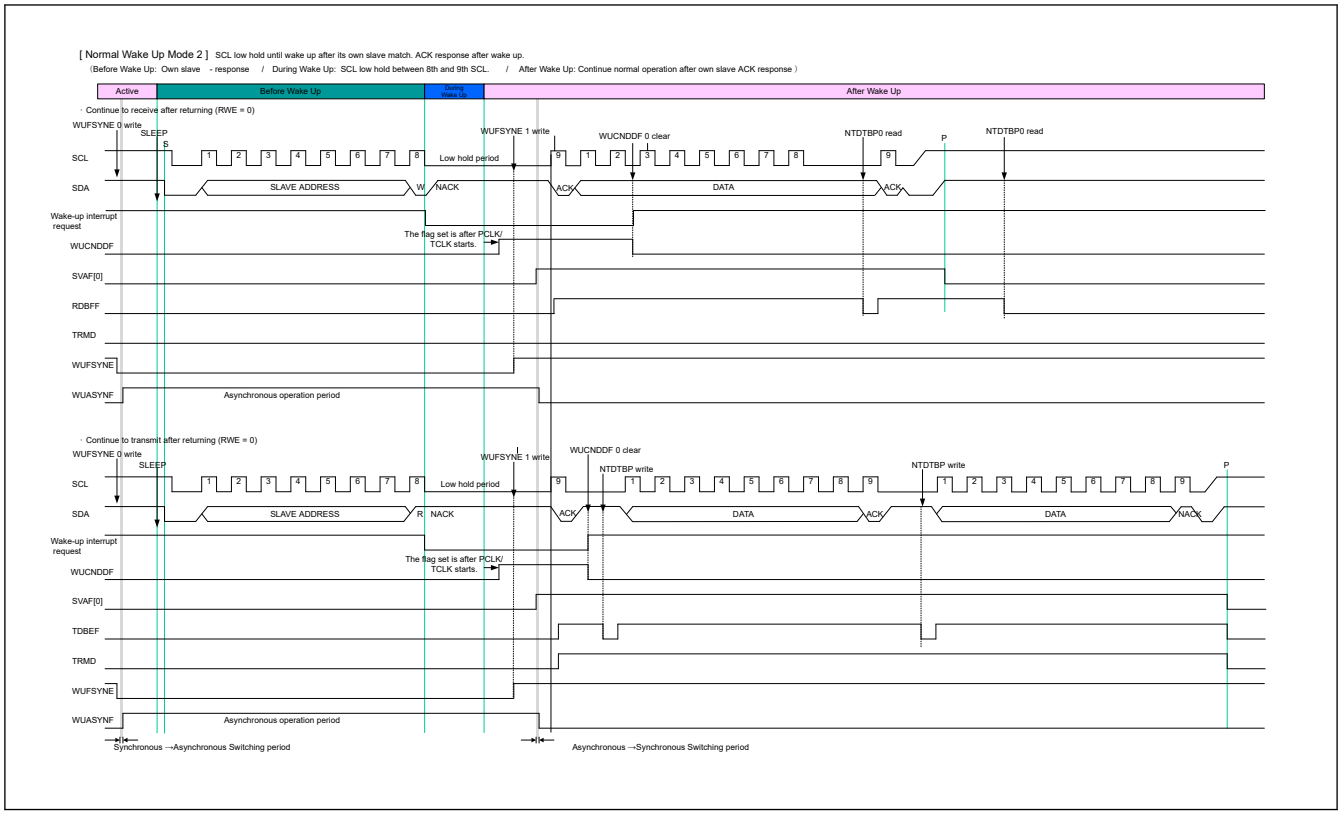

Figure 30.130 Timing of normal wake up mode 2

(3) Command recovery mode/ EEP response mode (Special Wake Up mode)

In the command recovery mode and EEP response mode, the I3C_SCL line is not held low during the wake-up recovery period (after the rise of the 9th clock cycle of SCL), so other I^2C/I3C devices can use the I^2C bus during this period. This section describes the behavior, the timing, and use cases of the command recovery mode and the EEP response mode.

A wake-up interrupt triggered by the match of the slave address makes the transition to the normal operation in the manner described below. Also, the detailed timing is provided in Figure 30.133.

Before wake-up recovery:	In response to the data received with its own slave address, ACK (command recovery mode) or NACK (EEP response mode) is returned.
During wake-up recovery:	The I3C_SCL line is not held low.
After wake-up recovery:	Normal operation continues after I3C initial setting.

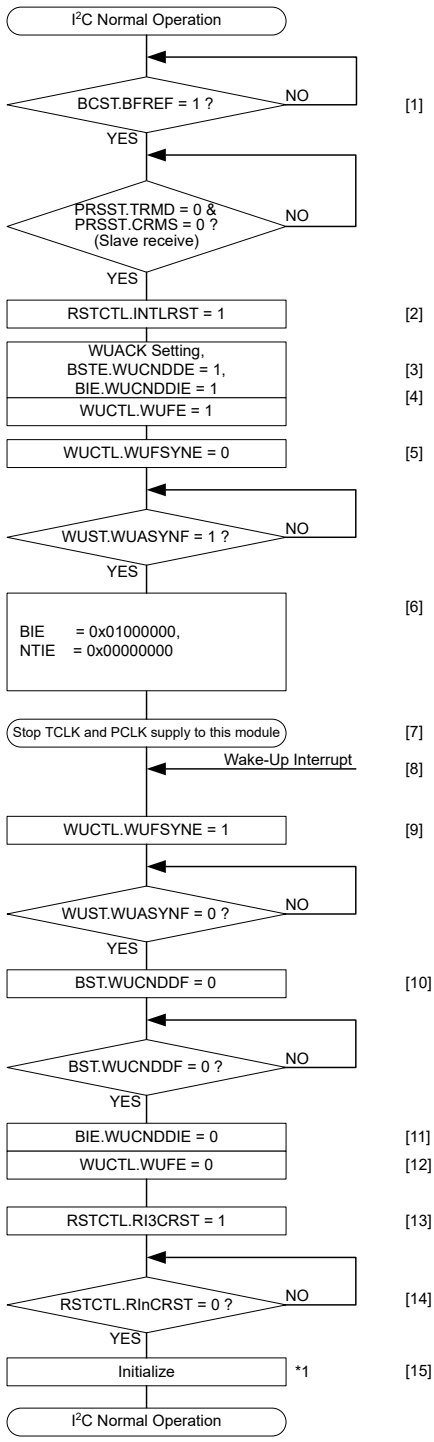
Note: Because the I3C_SCL line is not held low during wake-up recovery, the transmission/reception of the data that follows the slave address is not possible.

Note: The command recovery mode and the EEP response mode are internal reset (RSTCTL.INTLRST = 1) states. Therefore, the match of the slave address does not set the SVST flags (HOAF, GCAF, and SVAF[2:0]).

If the slave address does not match, the slave operation continues.

See Figure 30.132 below for a use case.

A wake-up interrupt is not generated at the transition to the normal operation if the transition is triggered by a cause (other recovery causes (IRQ)) other than a wake-up interrupt signal generated by a slave address match. BST.WUCNDDF is not set in this case. Carry out the following processing according to Figure 30.132.



[1] Wait I²C bus free and this module stay in the standby state.

[2] Assert the internal reset.

[3] WUCTL.WUACKS is set up according to each mode. (Command return mode/ EEP response mode) Wake-Up Interrupt is enabled.

[4] Wake-Up function is enabled.

[5] This module of operating state is changed from PCLK/TCLK synchronous to PCLK/TCLK asynchronous.

[6] Interrupt requests are disabled except WUI.

[7] Stop TCLK supply to this module, then stop PCLK supply to this module. (This module will continue to receive)

[8] Start TCLK and PCLK supply to this module by Wake-Up interrupt (address match), then start PCLK supply to this module.

[9] This module of operating state is changed from PCLK/TCLK asynchronous to PCLK/TCLK synchronous.

[10] Write 0 to BST.WUCNDDF.
(Read and check whether clearing has been completed before return from interrupt handling.)

[11] Wake-Up interrupt is disabled.

[12] Wake-Up function is disabled.

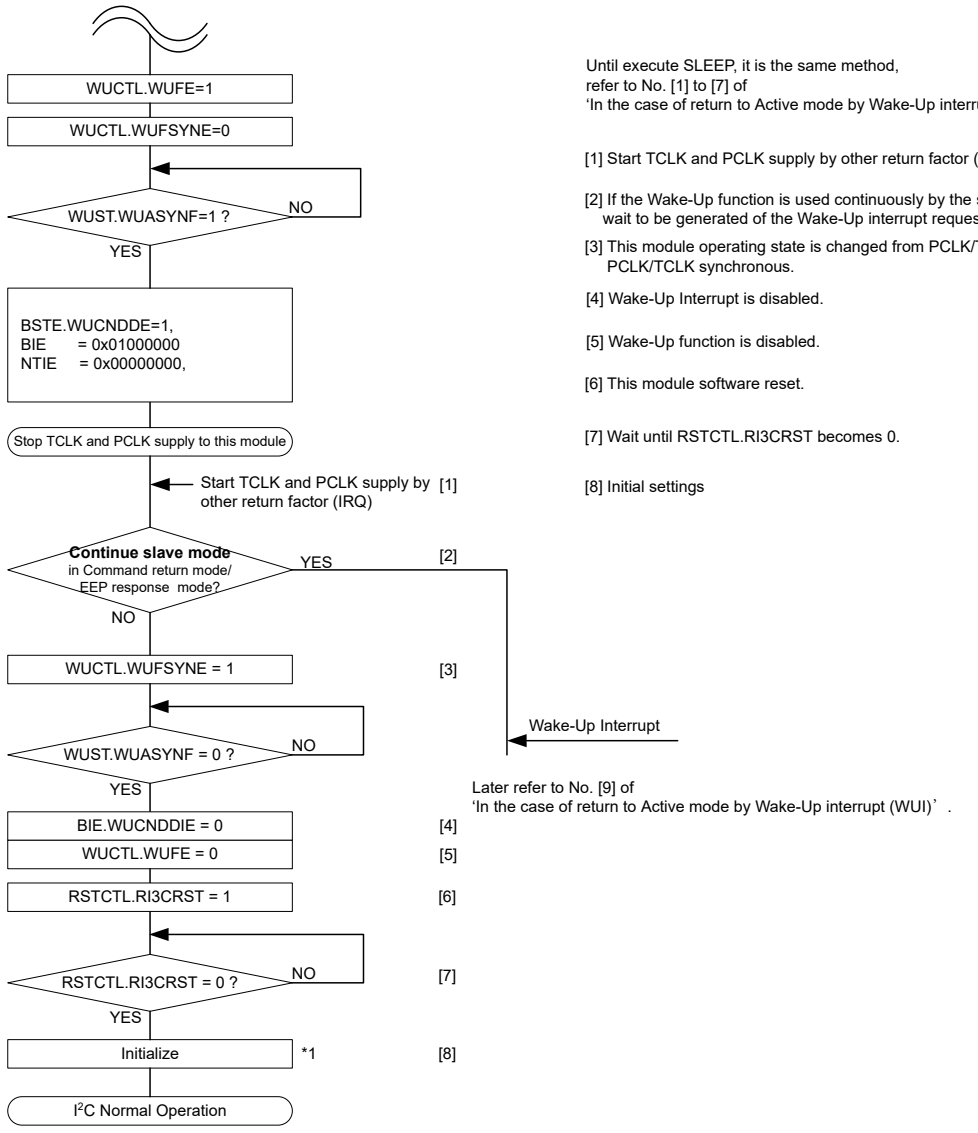
[13] Software reset.

[14] Wait until RSTCTL.RI3CRST becomes 0.

[15] Initial settings

Note 1. See section 30.3.3.1. Initial Setting Flow for details of initialization.

Figure 30.131 Use case of command recover mode and EEP response mode (wake-up recovery by a wake-up interrupt triggered by the match of the slave address)



Note 1. See section 30.3.3.1. Initial Setting Flow for details of initialization.

Figure 30.132 Use case of command recover mode and EEP response mode (wake-up recovery by other recovery causes (IRQ))

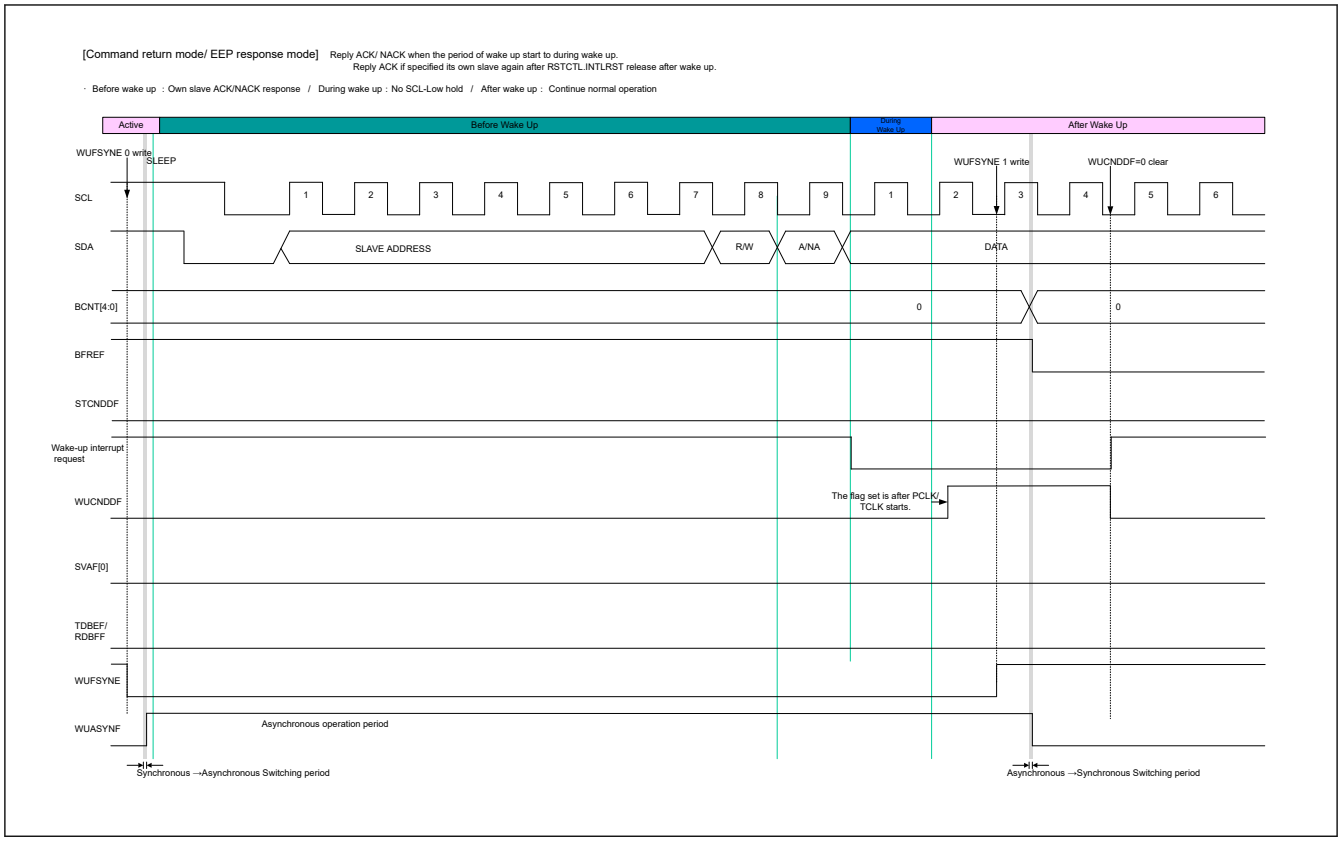


Figure 30.133 Timing of command recovery mode/EEP response mode

(4) Precautions on the use of the Wake-Up function

Precautions on the use of the Wake-up function is shown below.

- Do not change the registers in I3C except the WUCTL.WUFSYNE bit while the WUST.WUASYNF flag = 1 (while PCLK/TCLK asynchronous operation).
- Set WUCTL.WUFE = BSTE.WUCNDDE = BIE.WUCNDDIE = 1 and PRSST.CRMS = PRSST.TRMD = 0 (slave reception mode) before switching PCLK/TCLK asynchronous mode.
- Cannot select the device ID and the 10-bit slave address for wake-up interrupt factor. Set the DVIDE bit in SVCTL and SDADLS bit in SDATBASn (n = 0 to 2) to 0.
- Sets all bits in BIE (TENDIE, NACKDIE, SPCNDDIE, STCNDDIE, ALIE, TODIE) and TDBEIE0 and RDBFIE0 bits in NTIE to 0 (interrupt disabled) before switching the asynchronous operation.
- Do not use the timeout function while the Wake-up function is enabled (WUCTL.WUFE = 1).
- Wake-up interrupt is generated while PCLK/TCLK asynchronous operation (when WUST.WUASYNF = 1). For detecting slave address matching, detection of slave address match in PCLK/TCLK synchronous mode (WUST.WUASYNF = 0) does not generate Wake-up interrupt, and BST.WUCNDDF flag is not set.
- If WUCTL.WUFSYNE bit to 0 write timing and START condition of detecting a conflict, I3C might start the next reception in PCLK/TCLK synchronous operation mode. In this case, WUST.WUASYNF flag becomes 1 (switch to PCLK/TCLK asynchronous mode) when data communication is finished and detected STOP condition and starts the Wake-up event detection.
- If you want to switch from PCLK/TCLK asynchronous operation to PCLK/TCLK synchronous operation without address match detection, it will switch in the STOP condition detection. When the WUCTL.WUFSYNE bit was set to 1 in a bus free state, it is continued PCLK/TCLK asynchronous operation (reception operation: waiting communication frame). WUST.WUASYNF flag becomes to 0 when I3C detect the STOP condition of the next communication frame, and I3C switches to PCLK/TCLK synchronous operation.
- After writing 0 to WUFSYNE bit in WUCTL, do not change I3C operation mode setting register (BFCTL, SCSTRCTL, ACKCTL, INCTL, SVCTL, SDATBASn (n = 0 to 2)) until switched to the PCLK/TCLK asynchronous operation from PCLK/TCLK synchronous operation (while WUST.WUASYNF flag = 1). If register value changes such as by

the interrupt processing in this period, I3C might malfunction without succeeding to the setting to the asynchronous operation.

- During PCLK/TCLK asynchronous operation (WUST.WUASYNF = 1), do not refer to each flag of SVST, BST, NTST, HTST register and BCST.BFREF flag.
- Do not set ACKCTL.ACKT = 1 in order to make an ACK response in the synchronization unit when Wake-up is performed by slave address match in Normal wake-up mode 2.

30.3.2.5.2 Wake Up function

(1) I3C Master Wake-Up

Wake-up interrupt causes of I3C master are shown below.

- SDA low detection (IBI request from I3C slave)

The operation when transitioning to active mode (normal operation) by Wake-Up interrupt of SDA Low detection is shown below.

Before wake-up recovery:	SDA Low Drive is detected and the I3C_WU interrupt is asserted.
During wake-up recovery:	Keep I3C_SCL Line High.
After wake-up recovery:	Drive SCL Low and complete START condition. SCL is supplied on the I3C bus and IBI from I3C slave is received.

If transition to active mode (normal operation) due to other factors, disable the Wake-up function as necessary.

After confirming PRSTDBG.SDILV = 1, set WUCTL.WUFE = 0.

Do not use the timeout function while the Wake-up function is enabled (WUCTL.WUFE = 1).

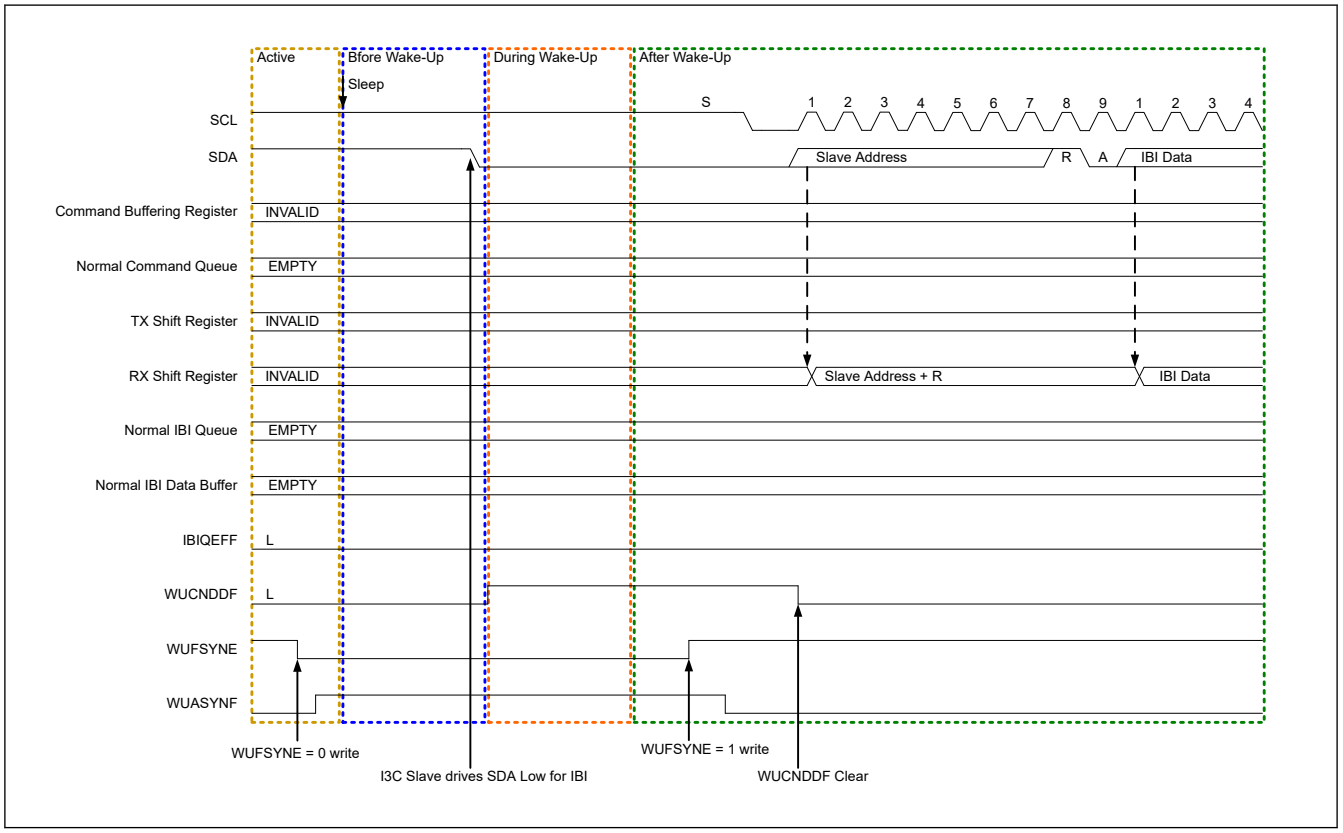

Figure 30.134 I3C master wake-up operation

(2) I3C Slave Wake-Up

Wake-up interrupt causes of I3C slave are shown below.

- Broadcast address (0x7E) and detects its own Slave address match

The operation when the Broadcast address (0x7E) and transition to active mode (normal operation) by Wake-up interrupt by detecting its own Slave address match is shown.

Before wake-up recovery:	1. If I3C detects BA (0x7E/W) following a START (or Repeated START) Condition, then I3C shall generates ACK (after 0x7E/W). 2. If I3C detects its own Dynamic address after a Repeated START condition following Step1, then I3C shall generates NACK (after its own Dynamic address) and then issues a I3C_WU interrupt.
During wake-up recovery:	I3C always generates NACK.
After wake-up recovery:	Normal operation continues.

If transition to active mode (normal operation) due to other factors, disable the Wake-up function as necessary. Do not use the timeout function while the Wake-up function is enabled (WUCTL.WUFE = 1).

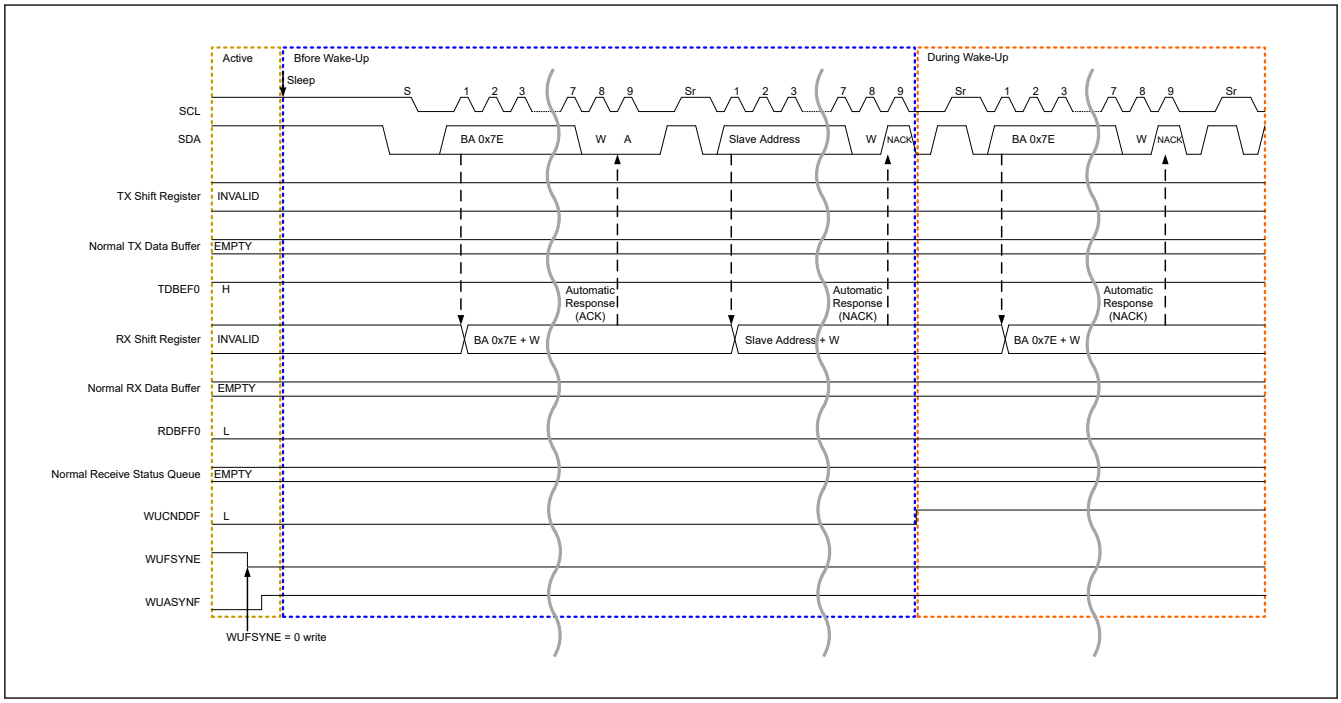

Figure 30.135 I3C slave wake-up operation (1/2)

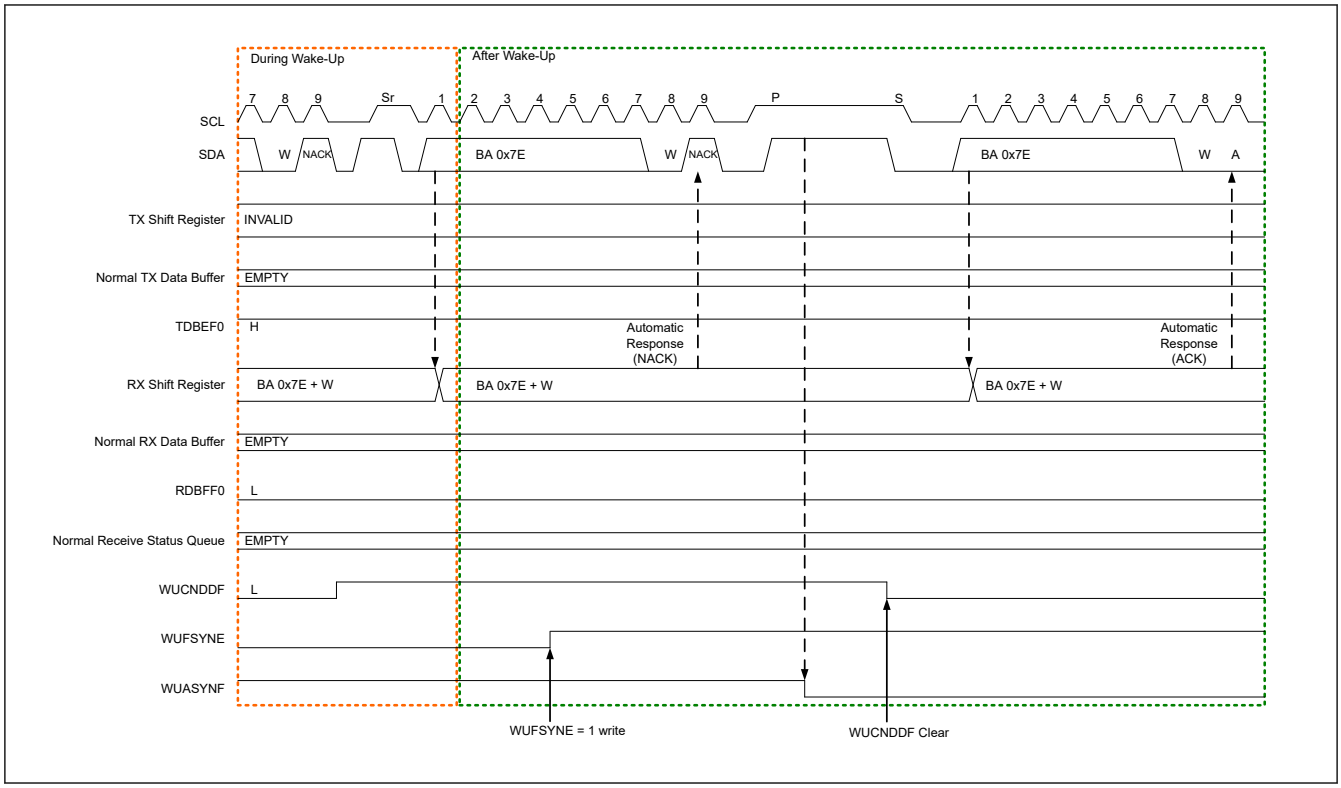

Figure 30.136 I3C slave wake-up operation (2/2)

30.3.2.6 Other

30.3.2.6.1 SCL Synchronization Circuit [I²C mode]

This function is enabled while the PRTS.PRTMD bit is set to 1.

In generation of the SCL clock, I3C starts counting out the value for width at high level specified in STDBR.SBRHO[7:0] when it detects a rising edge on the I3C_SCL line and drives the I3C_SCL line low once counting of the width at high level is complete.

When I3C detects the falling edge of the I3C_SCL line, it starts counting out the width at low level period specified in STDBR.SBRLO[7:0], and then stops driving the I3C_SCL line (releases the line) once counting of the width at low level is complete. The SCL clock is thus generated.

If multiple master devices are connected to the I²C bus, a collision of SCL signals may arise due to contention with another master device. In such cases, the master devices have to synchronize their SCL signals. Since this synchronization of SCL signals must be bit by bit, I3C is equipped with a facility (the SCL synchronization circuit) to obtain bit-by-bit synchronization of the SCL clock signals by monitoring the I3C_SCL line while in master mode.

When I3C has detected a rising edge on the I3C_SCL line and thus started counting out the width at high level specified in STDBR.SBRHO[7:0], and the level on the I3C_SCL line falls because an SCL signal is being generated by another master device, I3C stops counting when it detects the falling edge, drives the level on the I3C_SCL line low, and starts counting out the width at low level specified in STDBR.SBRLO[7:0]. When I3C finishes counting out the width at low level, it stops driving the I3C_SCL line to the low level (releases the line). At this time, if the width at low level of the SCL clock signal from the other master device is longer than the width at low level set in this module, the width at low level of the SCL signal will be extended. Once the width at low level for the other master device has ended, the SCL signal rises because the I3C_SCL line has been released. When I3C finishes outputting the low-level period of the SCL clock, the I3C_SCL line is released and the SCL clock rises. That is, in cases of contention of SCL signals from more than one master, the width at high level of the SCL signal is synchronized with that of the clock having the narrower width, and the width at low level of the SCL signal is synchronized with that of the clock having the broader width. However, such synchronization of the SCL signal is only enabled when the SCSYNE bit in BFCTL is set to 1.

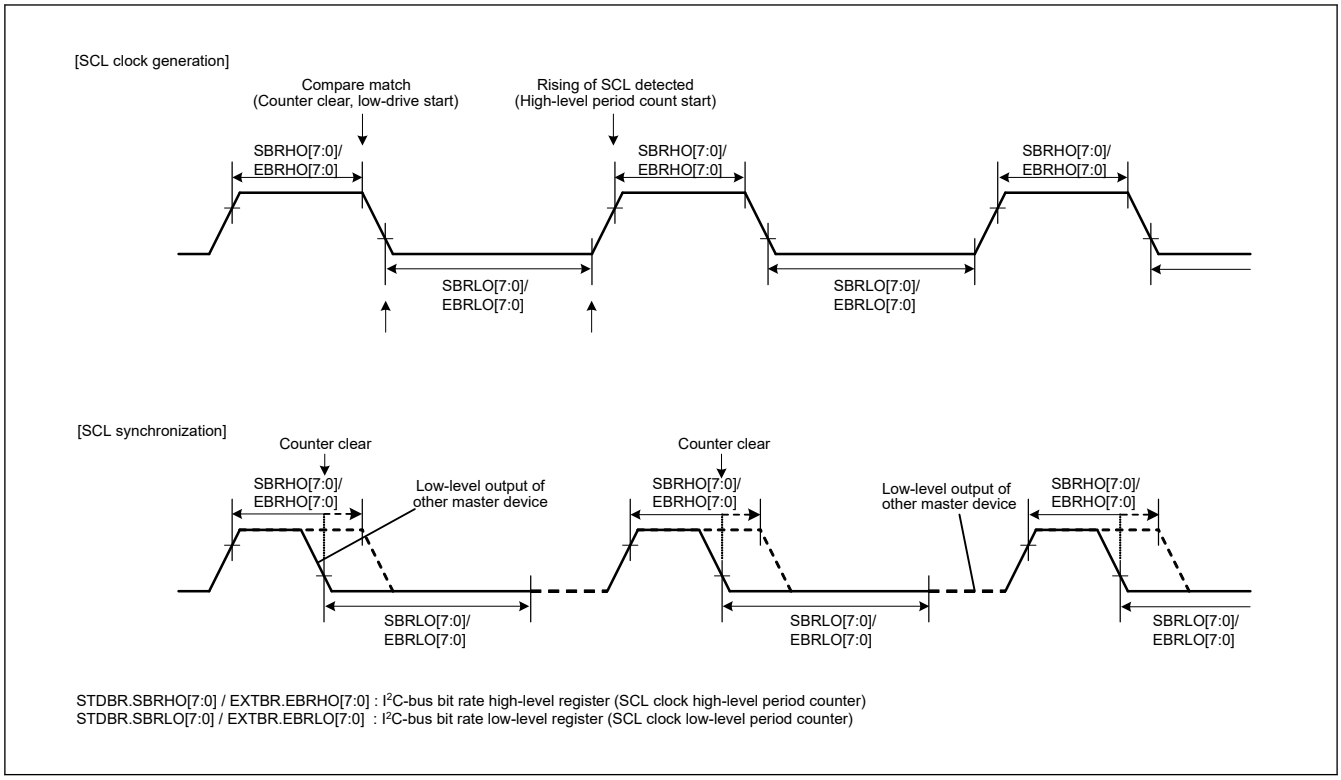

Figure 30.137 Generation and synchronization of the SCL signal

30.3.2.6.2 Facility for Delaying SDA Output [I2C mode]

I3C module incorporates a facility for delaying output on the I3C_SDA line. The delay can be applied to all output (issuing of the START, Repeated START, and STOP conditions, data, and the ACK and NACK signals) on the I3C_SDA line.

With the SDA output delay facility, SDA output is delayed from detection of a falling edge of the SCL signal to ensure that the SDA signal is output within the interval over which the SCL clock is at the low level. Doing this leads to usage with the aim of preventing erroneous operation of communications devices, with the aim of satisfying the 300 ns (minimum) data-hold time requirement of the SMBus specification.

The output delay facility is enabled by setting the SDOD[2:0] bits in OUTCTL to any value other than 000b, and disabled by setting the same bits to 000b.

While the SDA output delay facility is enabled (while the SDOD[2:0] bits in OUTCTL are set to any value other than 000b), the SDODCS bit in OUTCTL selects the clock source for counting by the SDA output delay counter as the internal base clock (I3Cφ) for I3C module or as a clock signal derived by dividing the frequency of the internal base clock by two (I3Cφ/2). The counter counts the number of cycles set in the SDOD[2:0] bits in OUTCTL. After counting of the set number of cycles of delay is completed, I3C module places the required output (START, Repeated START, or STOP condition, data, or an ACK or NACK signal) on the I3C_SDA line.

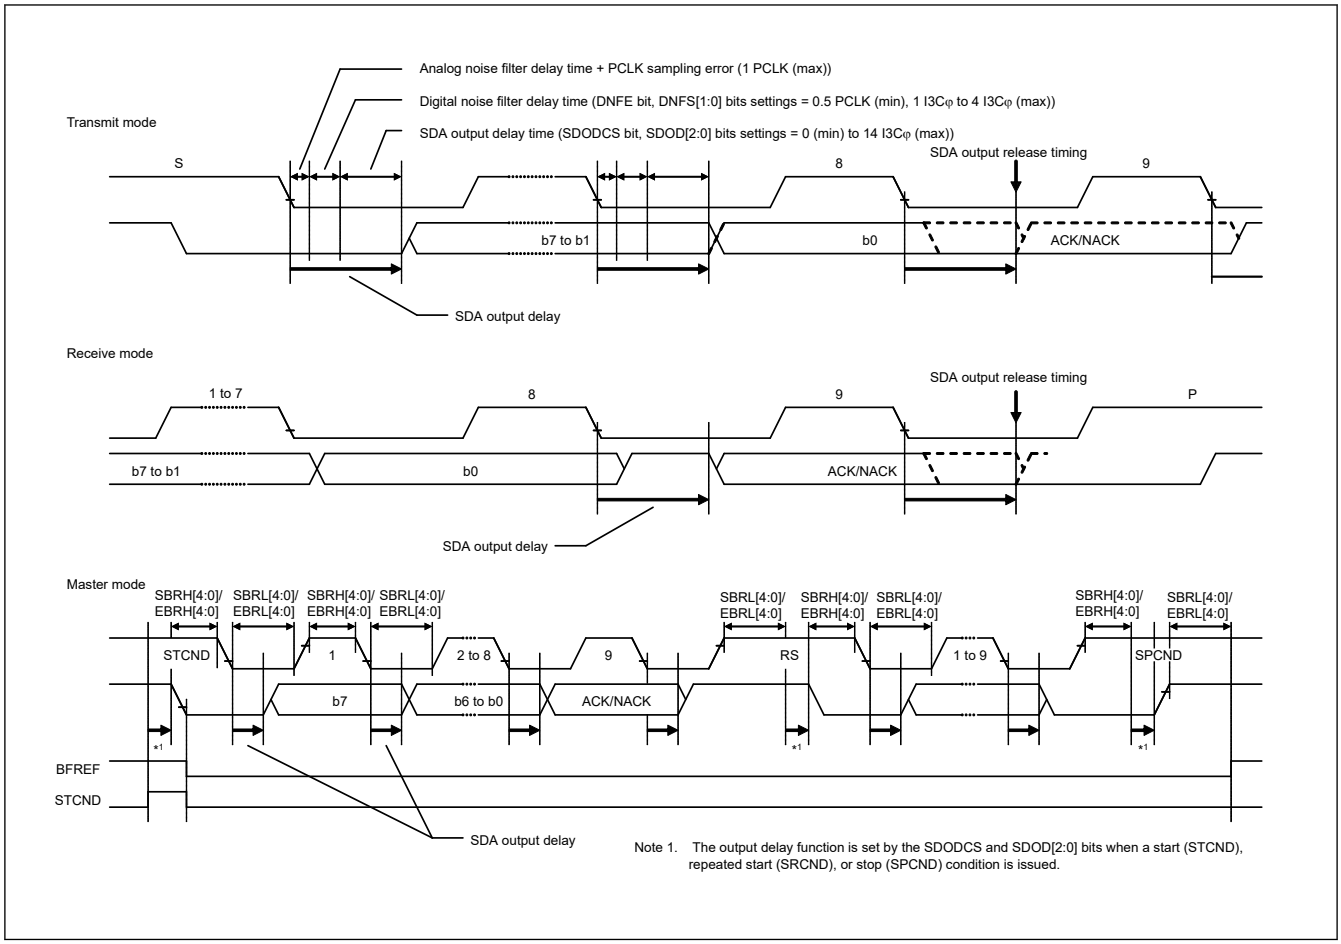

Figure 30.138 SDA output delay facility

30.3.2.6.3 Digital Noise-Filter Circuits [I^2C mode]

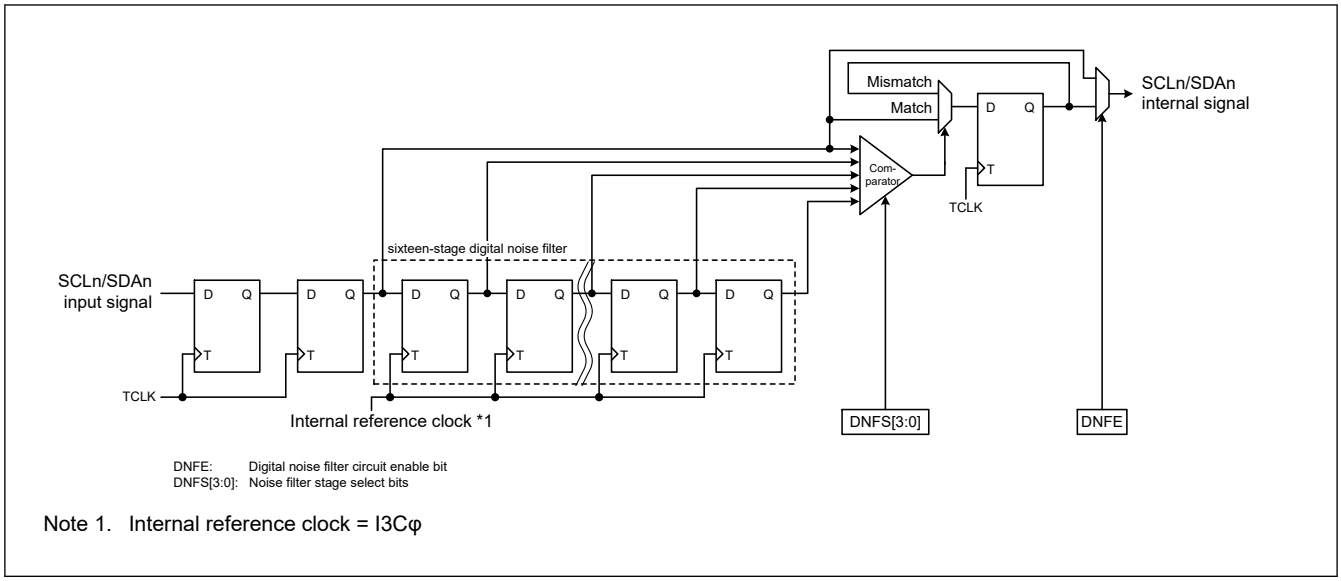
The states of the I3C_SCL and I3C_SDA pins are conveyed to the internal circuitry through digital noise-filter circuits. Figure 30.139 is a block diagram of the digital noise-filter circuit.

The on-chip digital noise-filter circuit of I3C consists of 16 flip-flop circuit stages connected in series and a match detection circuit. When HS mode is selected, only the first four flip-flop circuits stages are enabled.

The number of effective stages in the digital noise filter is selected by the INCTL.DNFS[3:0] bits. The selected number of effective stages determines the noise-filtering capability as a period from one to sixteen I3Cφ cycles.

The input signal to the I3C_SCL pin (or I3C_SDA pin) is sampled on rising edges of the I3Cφ signal. When the input signal level matches the output level of the number of effective flip-flop circuit stages as selected by the INCTL.DNFS[3:0] bits, the signal level is conveyed to the subsequent stage. If the signal levels do not match, the previous value is retained.

If the ratio between the frequency of the internal operating clock (TCLK) and the transfer rate is small (For example, data transfer at 400 kbps with TCLK = 4 MHz), the characteristics of the digital noise filter may lead to the elimination of needed signals as noise.



Note 1. Internal reference clock = I3Cφ

Figure 30.139 Block diagram of digital noise filter circuit

30.3.3 Operation

30.3.3.1 Initial Setting Flow

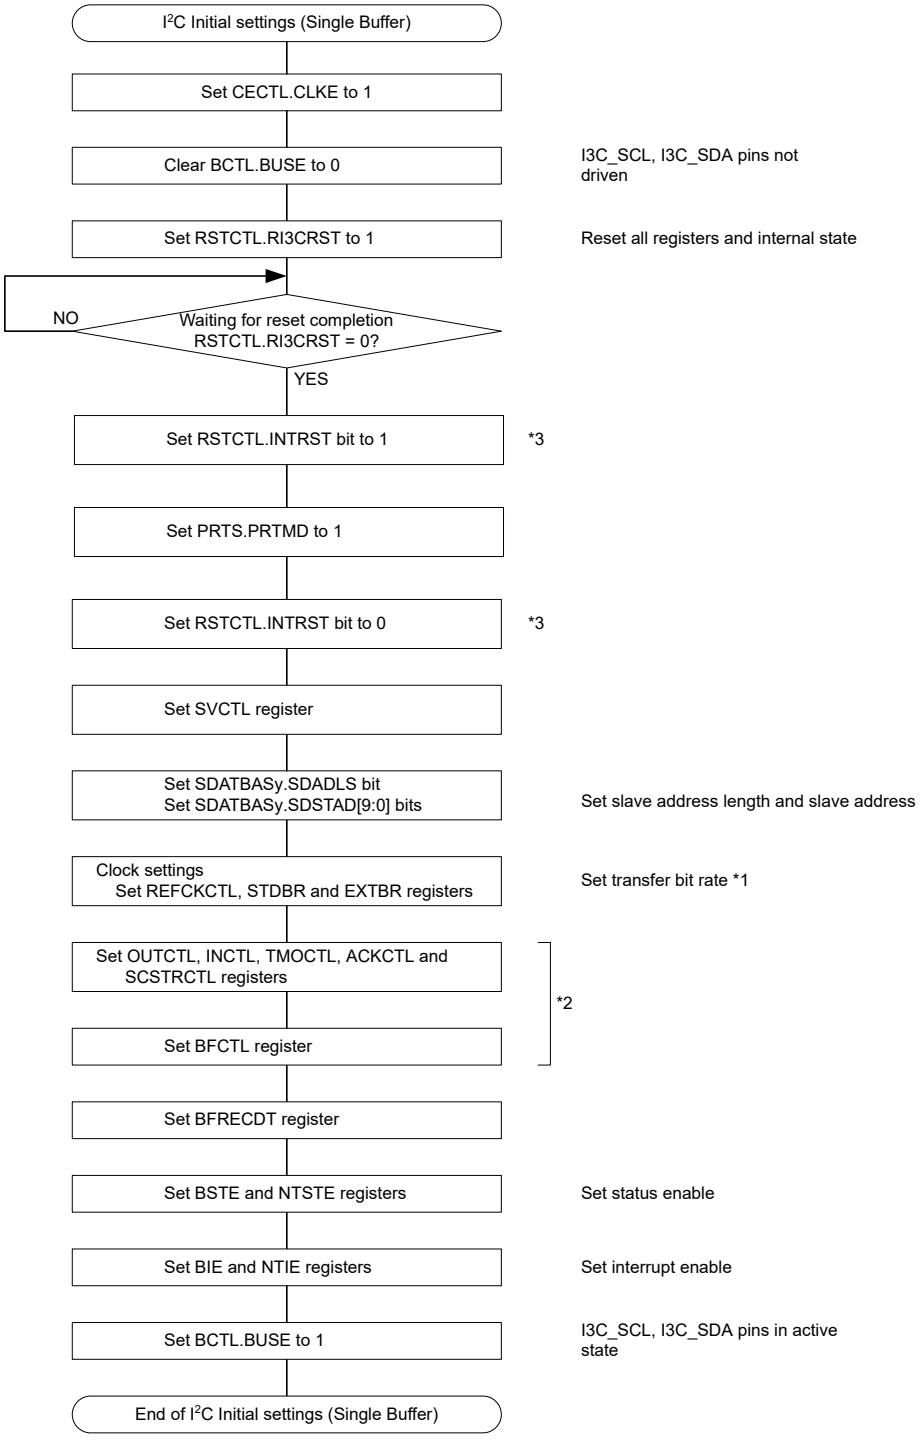
30.3.3.1.1 I2C Initial Setting Flow (Single Buffer Transfer)

Before starting data transmission and reception in I2C protocol mode, initialize I3C module.

First, set the CECTL.CLKE to 1, and set the BCTL.BUSE bit to 0 (I3C_SCL, I3C_SDA pins not driven).

Next, Set the RSTCTL.RI3CRST bit to 1. This initialize the registers and internal state of I3C module. Then, it waits for RI3CRST to become "0". For flags and registers to be initialized by this operation, see section 30.6. Reset Descriptions.

After that, set each registers required for operation. For detail procedure, see Figure 30.140.



Note: y = 0 to 2
Note 1. When the I3C is used only in slave mode, set the STDBR register to a value longer than the data setup time.
Note 2. Set these registers as necessary.
Note 3. This step can be omitted if certain conditions are met. For details, see .

Figure 30.140 Example of I²C initialization flowchart (single buffer transfer)

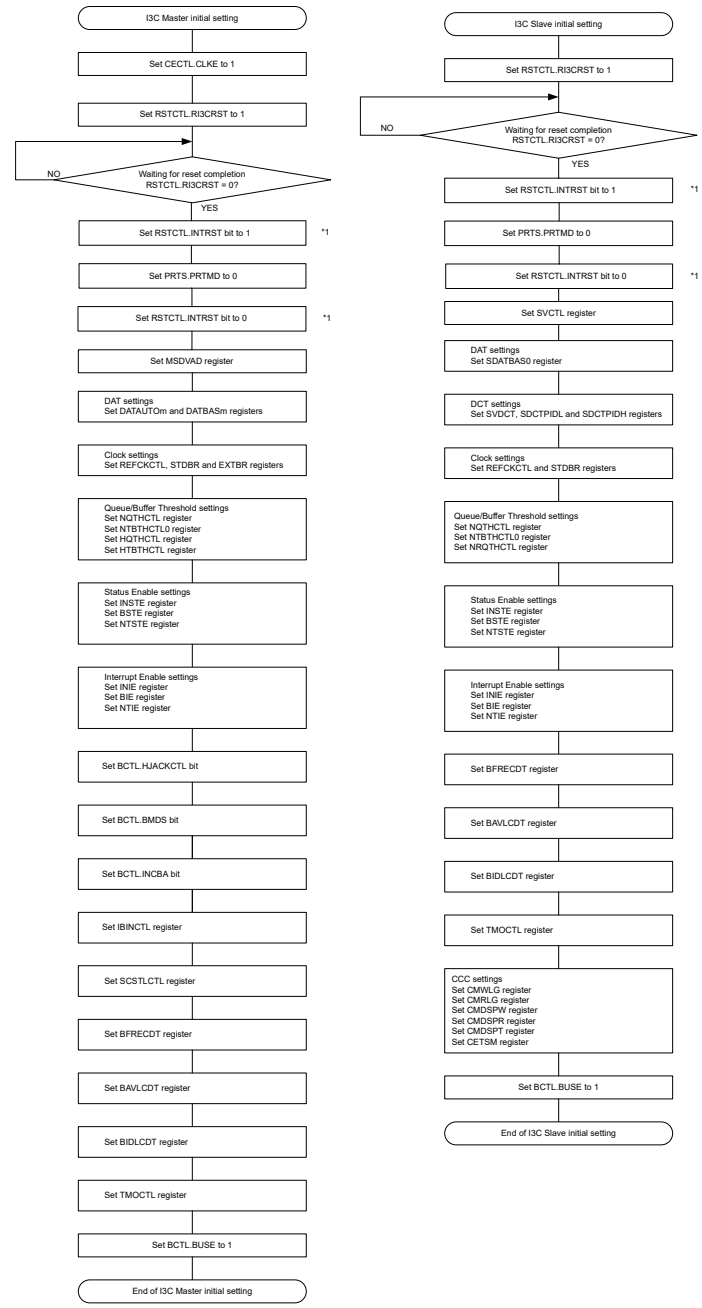
30.3.3.1.2 I3C Initial Setting Flow

Before starting data transmission and reception in I3C protocol mode, initialize I3C module.

First, set the CECTL.CLKE to 1.

Next, Set the RSTCTL.RI3CRST bit to 1. This initialize the registers and internal state of I3C module. Then, it waits for RI3CRST to become 0. For flags and registers to be initialized by this operation, see section 30.6. Reset Descriptions.

After that, set each registers required for operation. For detail procedure on each of the master mode and slave mode, see Figure 30.141.



Note 1. This step can be omitted if certain conditions are met. For details, see .

Figure 30.141 Example of each initialization flowchart for I3C master mode and slave mode

30.3.3.2 I3C Communication Flow

Figure 30.142 illustrates how I3C communication is initiated:

- All I3C communication occurs within a frame. The frame begins with a START, followed by one or more transfers, and a STOP.

- For the HDR modes:
  - First the dedicated Broadcast I3C address (0x7E) is issued to all Slaves on the I3C bus.
  - Then one of the EnterHDR CCCs is issued, indicating that the Master is entering an HDR mode. Each HDR mode has its own EnterHDR CCC.
  - This is followed by one or more HDR transfers.
  - HDR mode is ended by using the HDR exit pattern protocol.

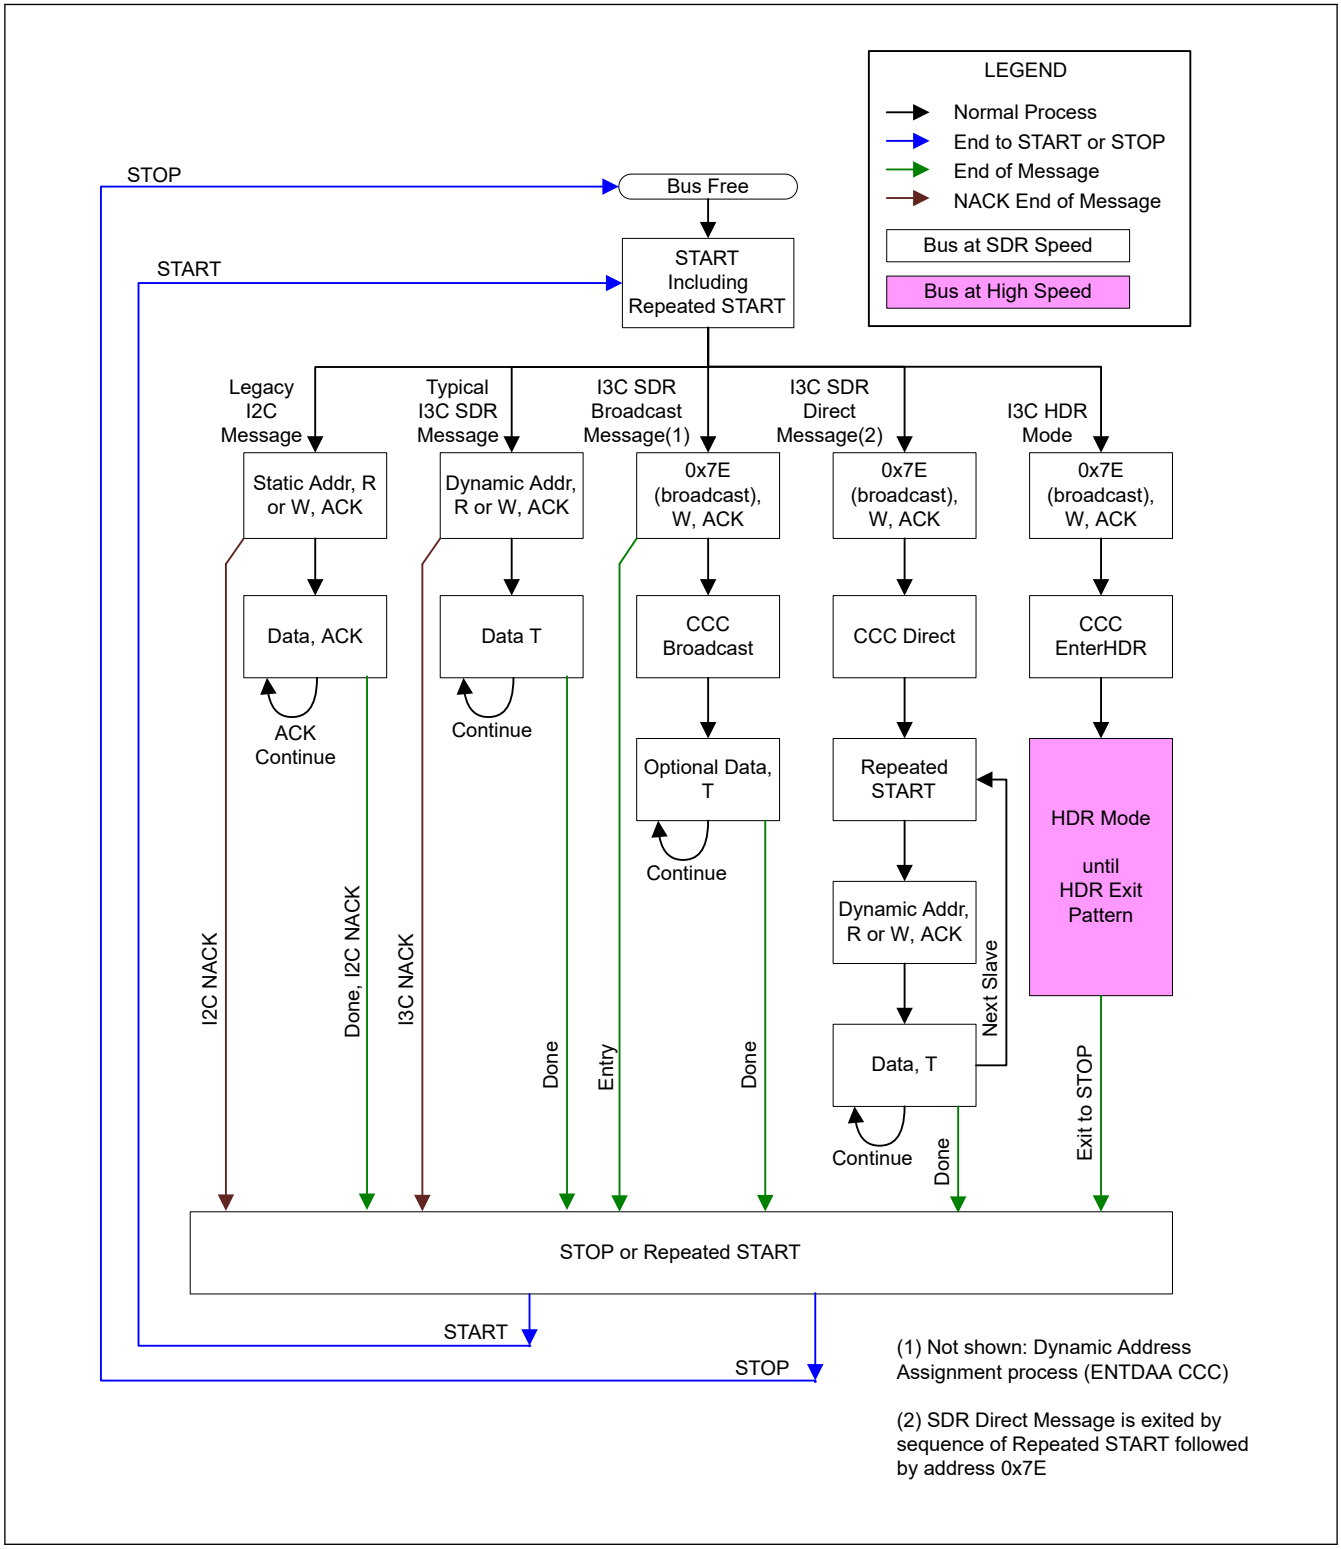


Figure 30.142 I3C communication flow

I3C is based on a frame encapsulation approach. A frame includes a data payload. The transfer protocol for the data payload is either SDR or HDR. Frames are bordered by I^2C-like bus management.

The I3C frame always includes at least the START, the Header, the Data, and the STOP. The Header following a START allows for Bus Arbitration. The Master uses the Header to address Slave device (s). Slave devices (s) may use the Header Arbitration for multiple purposes: for In-Band Interrupt, and for Secondary Master functionality.

Common Command Codes (CCCs) are used to enter the High Data Rate (HDR) modes. It is important to understand that I3C bus activity for the HDR Message does not follow the Legacy I^2C format.

I3C allows only one Master to have control of the I3C bus at a time. Mechanisms for handoff of the Master role from one device to another device are provided.

30.3.3.3 Master Mode Communication Flow

30.3.3.3.1 I²C Master Transmission Flow (Single Buffer Transfer)

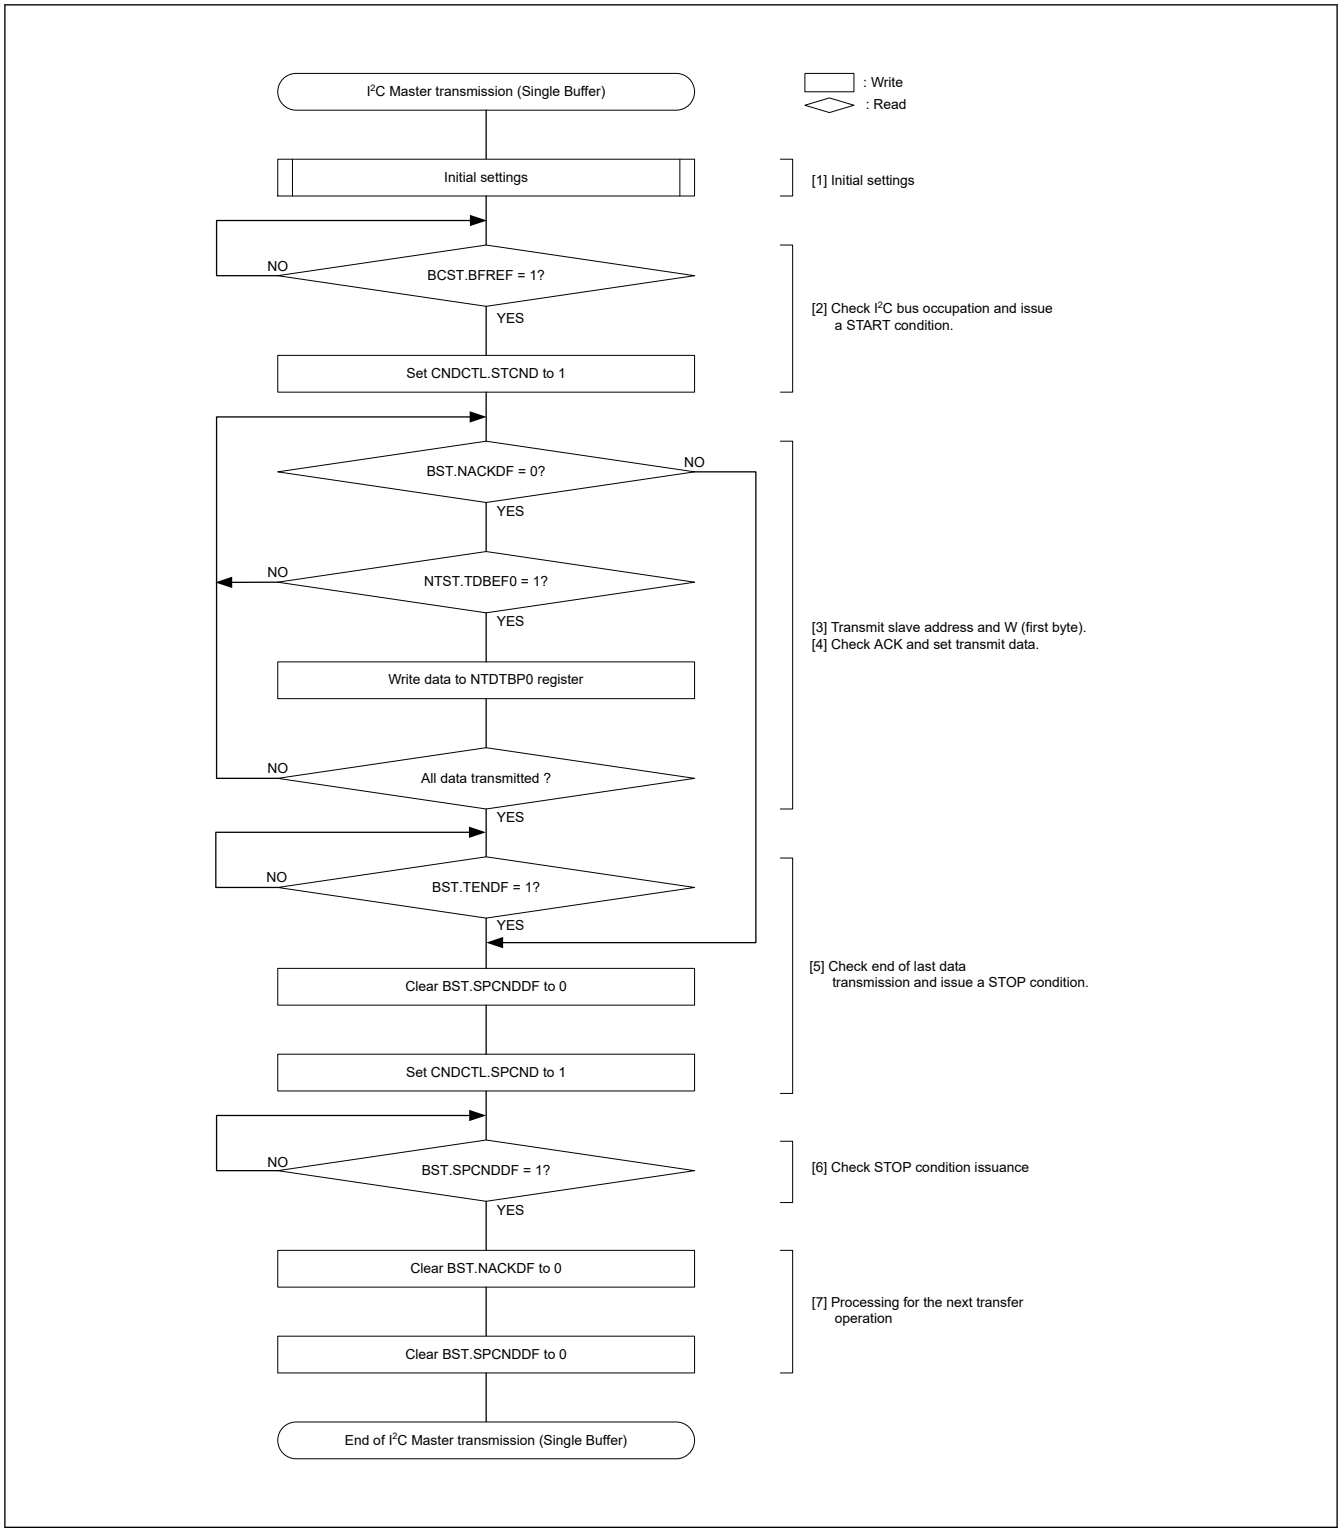

Figure 30.143 Example of I²C master transmission flowchart (single buffer transfer)

30.3.3.3.2 I²C Master Reception Flow (Single Buffer Transfer)

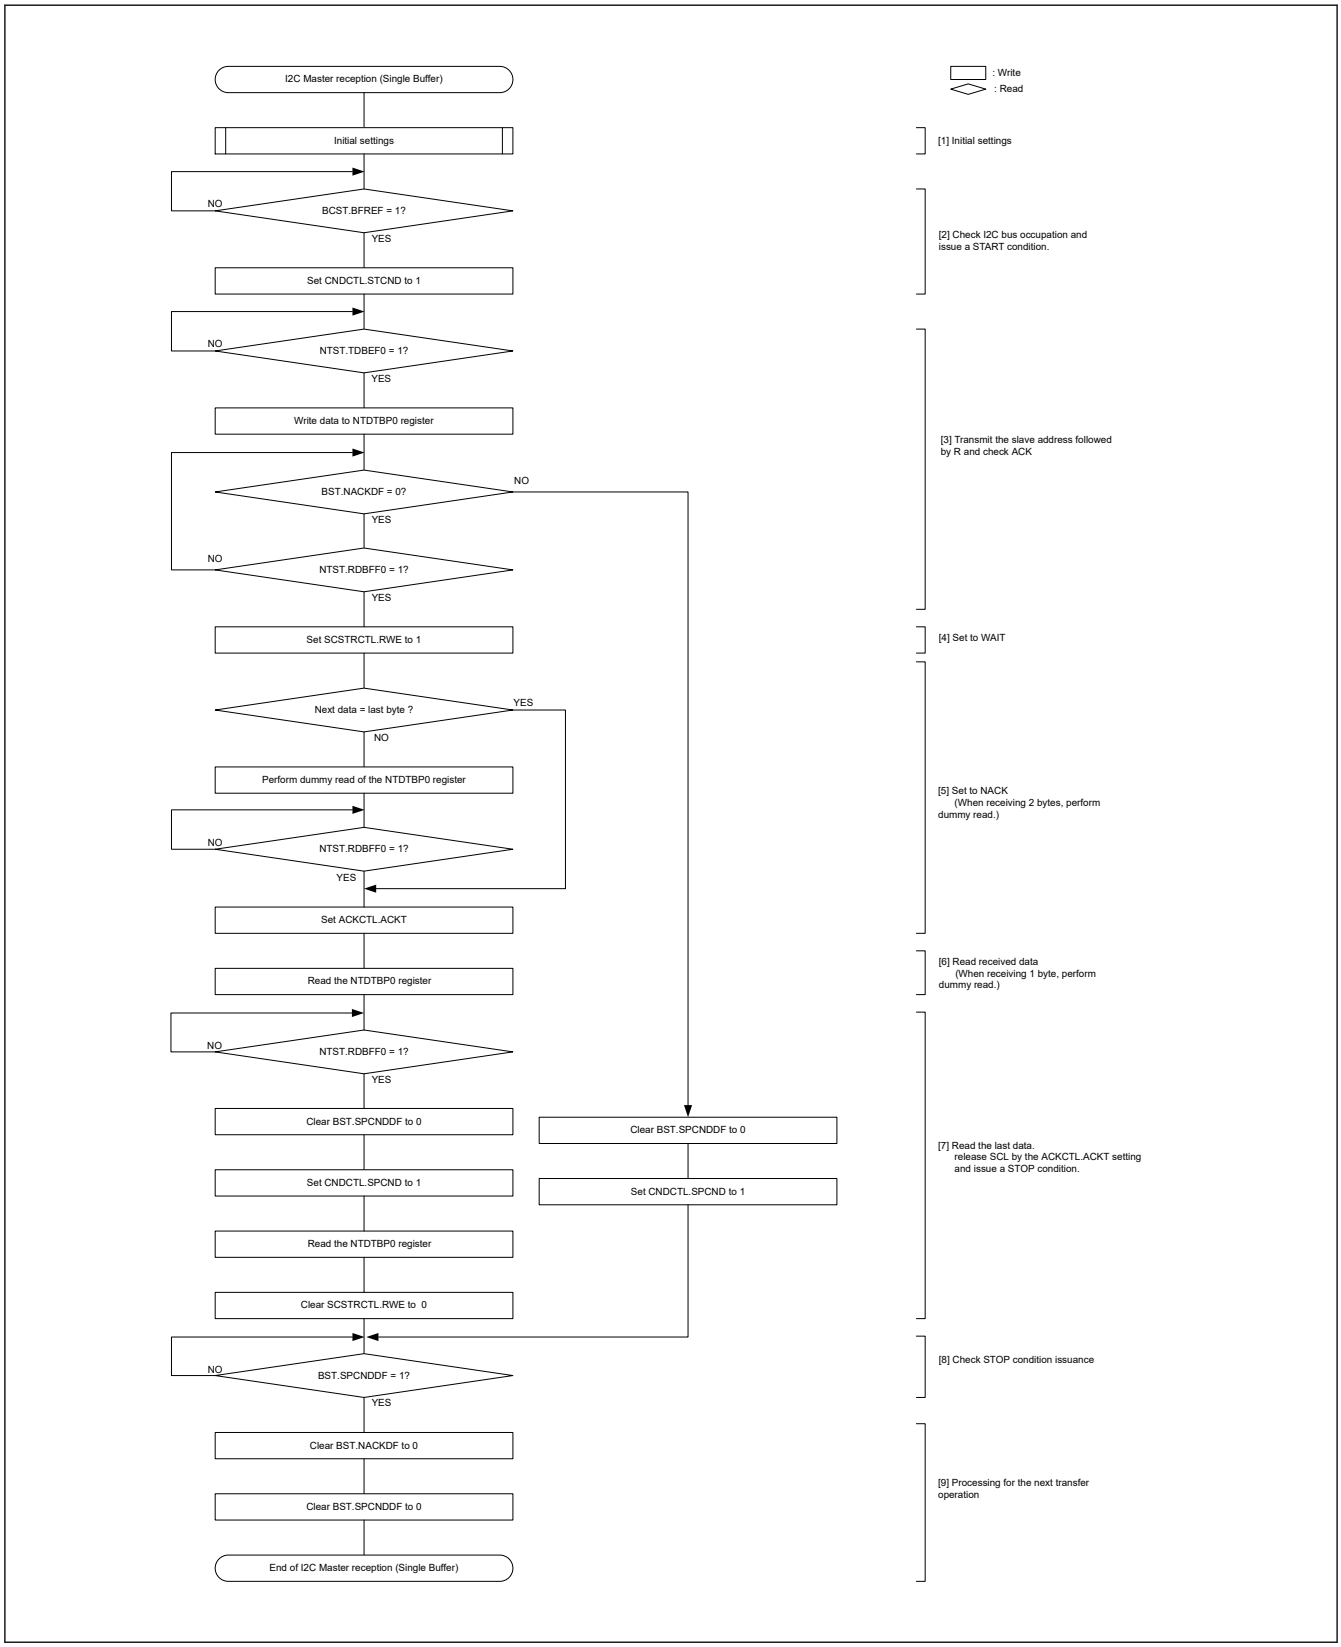

Figure 30.144 Example of I²C master reception flowchart (7-bit address format, 1 or 2 bytes)

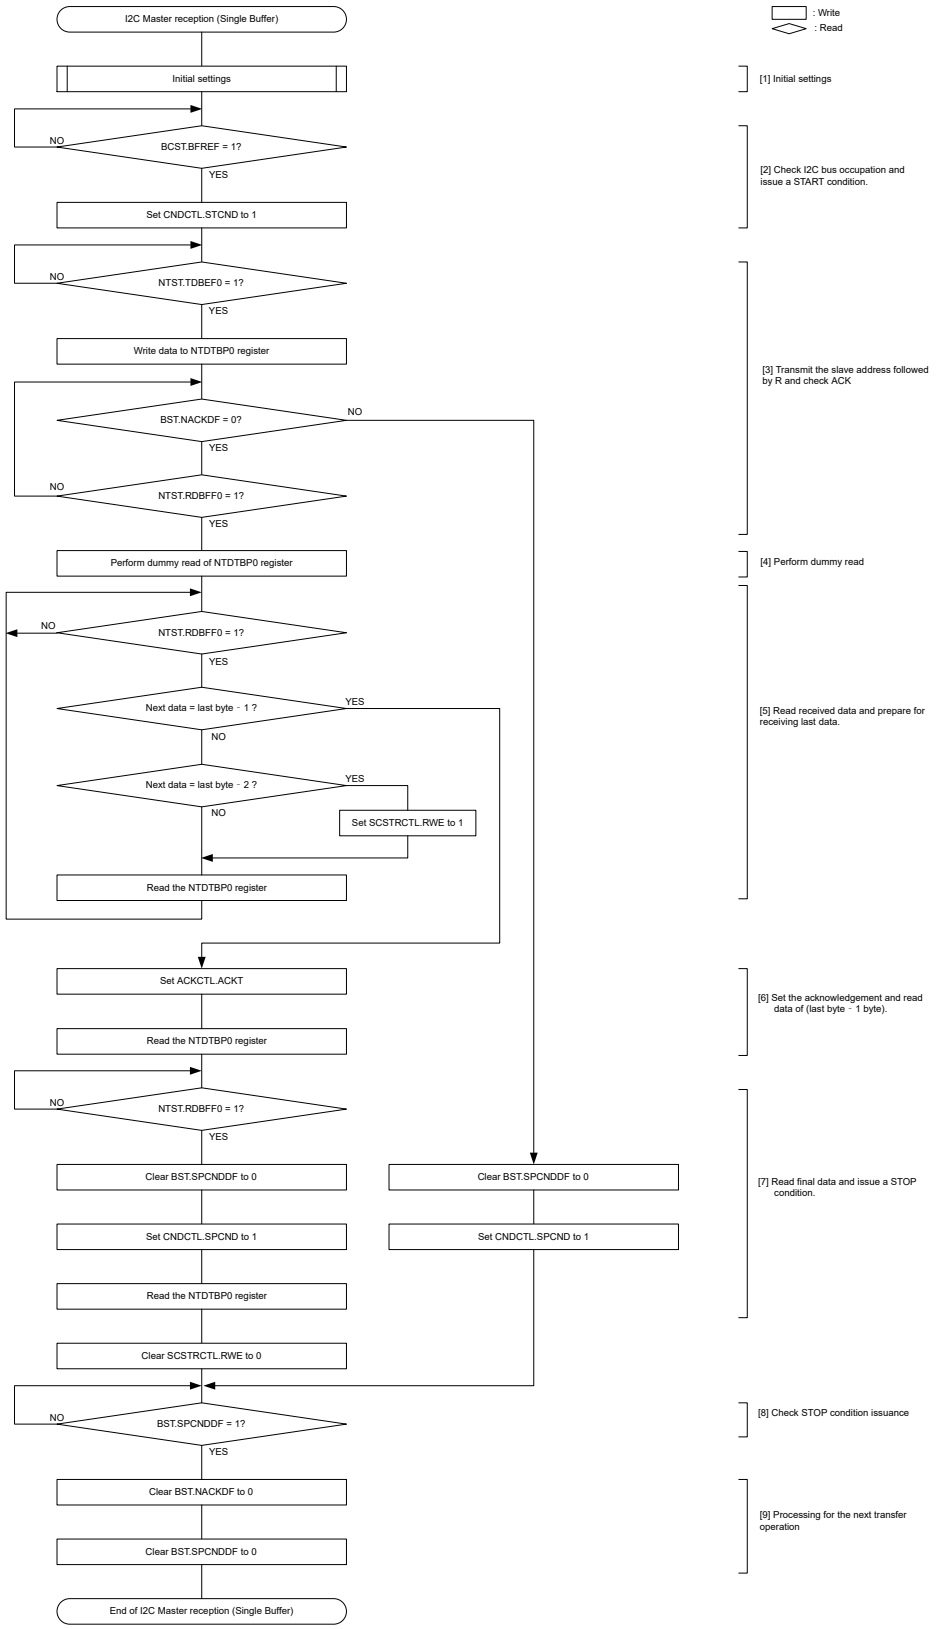

Figure 30.145 Example of I²C master reception flowchart (7-bit address format, 3 bytes or more)

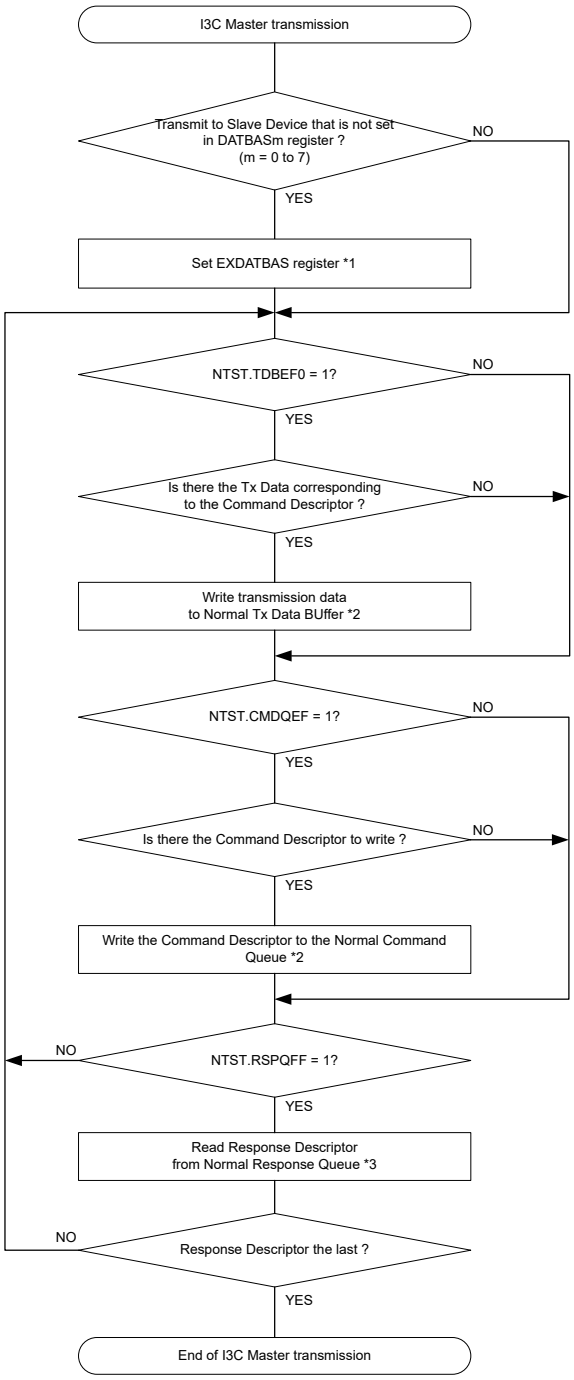
30.3.3.3.3 I3C Master Transmission Flow (Normal FIFO Buffer Transfer)

Master transmission flow in I3C normal FIFO buffer transfer is common to Legacy I^2C and SDR (Private Transfer, Broadcast CCC, Direct CCC), HDR-DDR, and HDR-TSP/TSL.

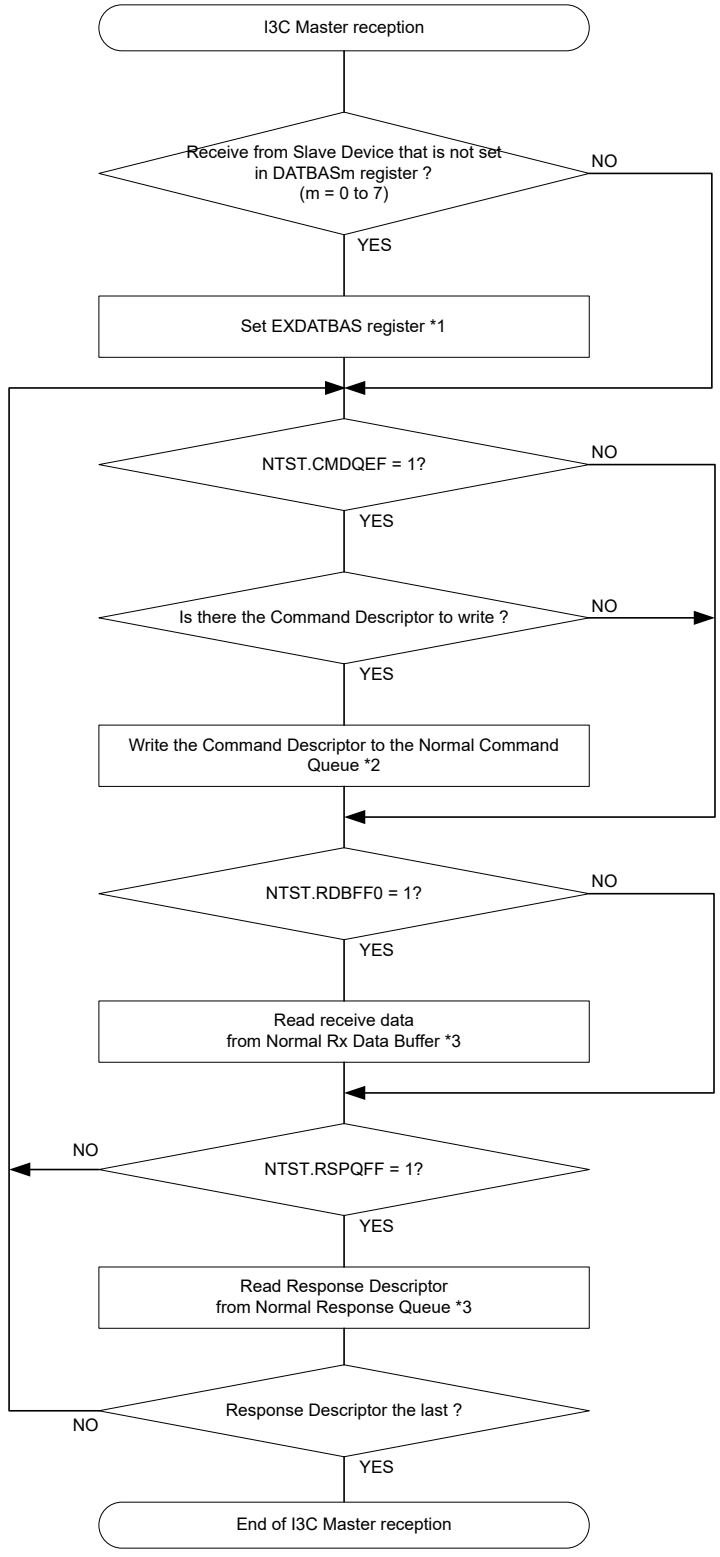


Note 1. Changing the EXDATBAS register is prohibited until all response descriptors of command for the Slave device set in the EXDATBAS register are stored.
Note 2. In the case the register is write by a way other than DMAC/DTC, clear corresponding flags after write access.
Note 3. In the case the register is read by a way other than DMAC/DTC, clear corresponding flags after read access.

Figure 30.146 Example of I3C master transmission flowchart (normal FIFO buffer transfer)

30.3.3.3.4 I3C Master Reception Flow (Normal FIFO Buffer Transfer)

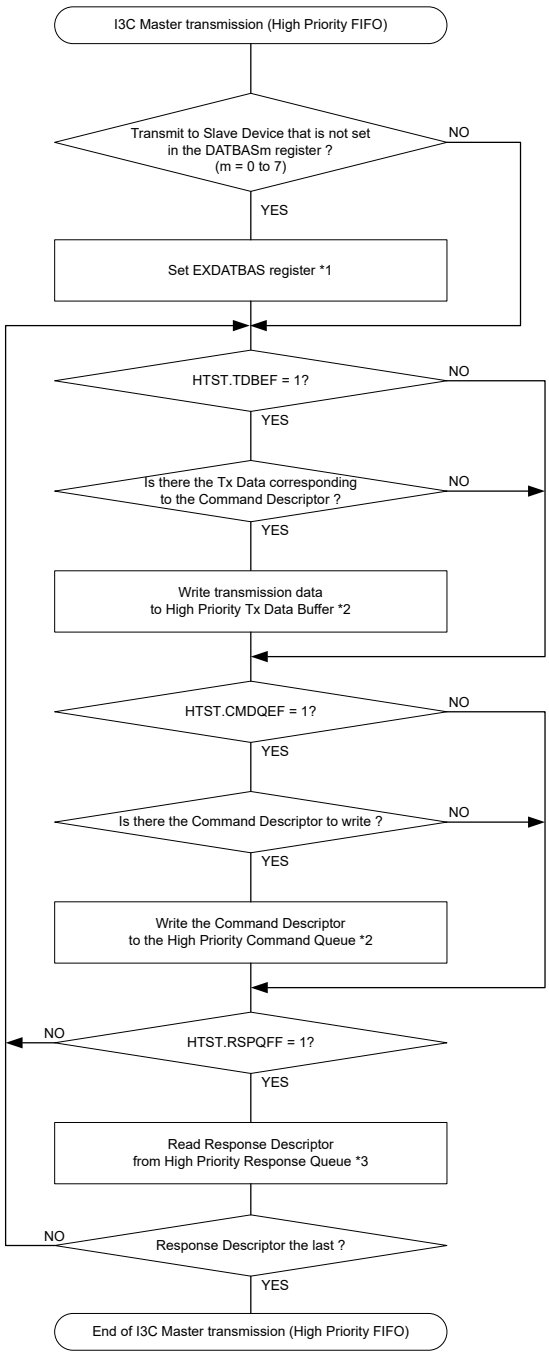
Master reception flow in I3C normal FIFO buffer transfer is common to Legacy I^2C and SDR (Private Transfer, Broadcast CCC, Direct CCC), HDR-DDR, and HDR-TSP/TSL.



Note 1. Changing the EXDATBAS register is prohibited until all response descriptors of command for the Slave device set in the EXDATBAS register are stored.
Note 2. In the case the register is write by a way other than DMAC/DTC, clear corresponding flags after write access.
Note 3. In the case the register is read by a way other than DMAC/DTC, clear corresponding flags after read access.

Figure 30.147 Example of I3C master reception flowchart (normal FIFO buffer transfer)

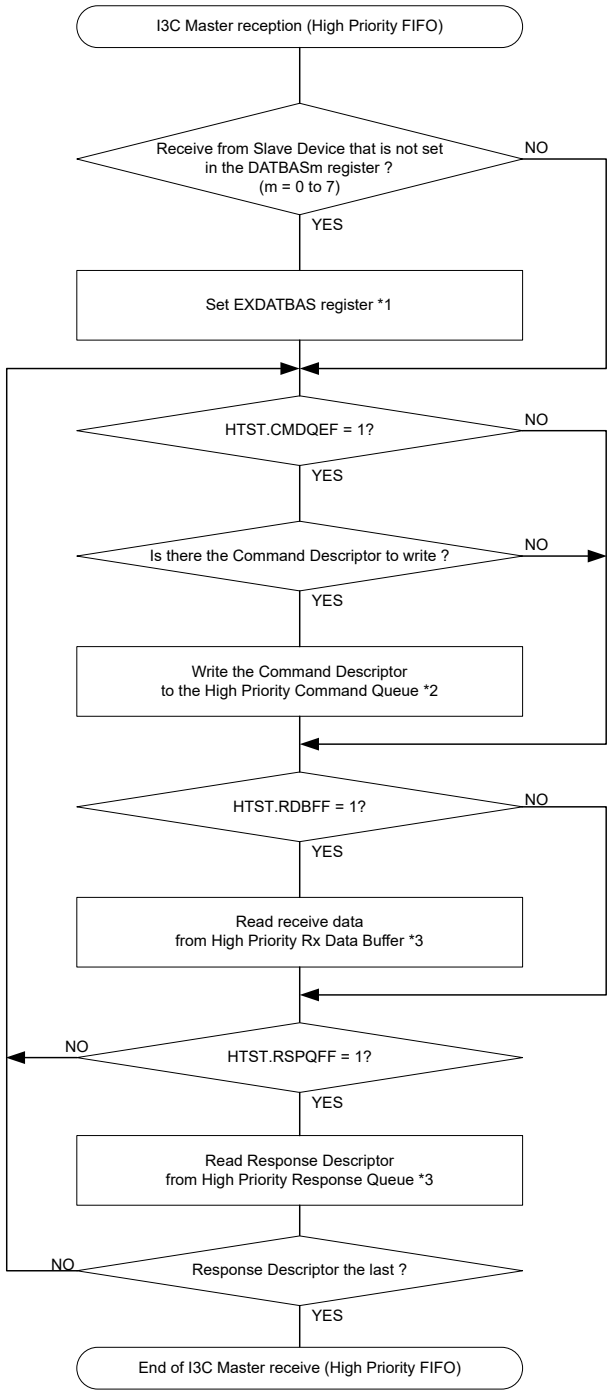
30.3.3.3.5 I3C Master Transmission Flow (High Priority FIFO Buffer Transfer)



Note 1. Changing the EXDATBAS register is prohibited until all response descriptors of command for the Slave device set in the EXDATBAS register are stored.
Note 2. In the case the register is write by a way other than DMAC/DTC, clear corresponding flags after write access.
Note 3. In the case the register is read by a way other than DMAC/DTC, clear corresponding flags after read access.

Figure 30.148 Example of I3C master transmission flowchart (high priority FIFO buffer transfer)

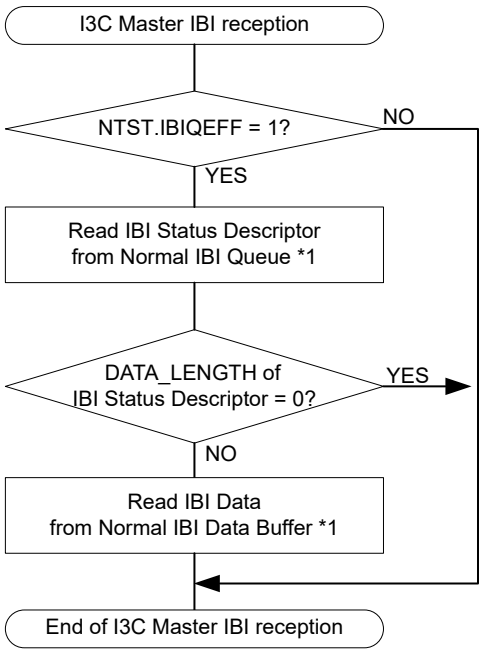
30.3.3.3.6 I3C Master Reception Flow (High Priority FIFO Buffer Transfer)



Note 1. Changing the EXDATBAS register is prohibited until all response descriptors of command for the Slave device set in the EXDATBAS register are stored.
Note 2. In the case the register is write by a way other than DMAC/DTC, clear corresponding flags after write access.
Note 3. In the case the register is read by a way other than DMAC/DTC, clear corresponding flags after read access.

Figure 30.149 Example of I3C master reception flowchart (high priority FIFO buffer transfer)

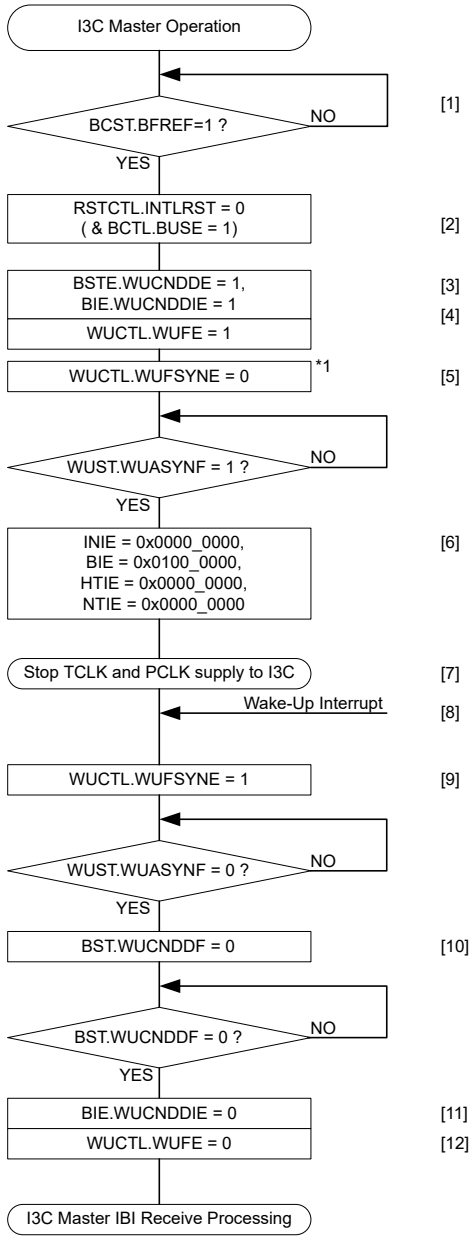
30.3.3.3.7 I3C Master IBI Reception Flow



Note 1. In the case the register is read by a way other than DMAC/DTC, clear corresponding flags after read access.

Figure 30.150 Example of I3C master IBI reception flowchart

30.3.3.3.8 I3C Master Wake-Up Flow



[1] Wait I3C bus free and I3C stay in the standby state.

[2] Negate internal reset if assert the internal reset.

[3] Wake-Up Interrupt is enabled.

[4] Wake-Up function is enabled.

[5] I3C of operating state is changed from PCLK/TCLK synchronous to PCLK/TCLK asynchronous.

[6] Interrupt requests are disabled except WUI.

[7] Stop TCLK supply to I3C, then stop PCLK supply to I3C.
(I3C will continue to receive)

[8] Start TCLK and PCLK supply to I3C by Wake-Up interrupt, then start PCLK supply to I3C.

[9] I3C of operating state is changed from PCLK/TCLK asynchronous to PCLK/TCLK synchronous.

[10] Write 0 to BST.WUCNDDF.
(Read and check whether clearing has been completed befor return from interrupt handling.)

[11] Wake-Up interrupt is disabled.

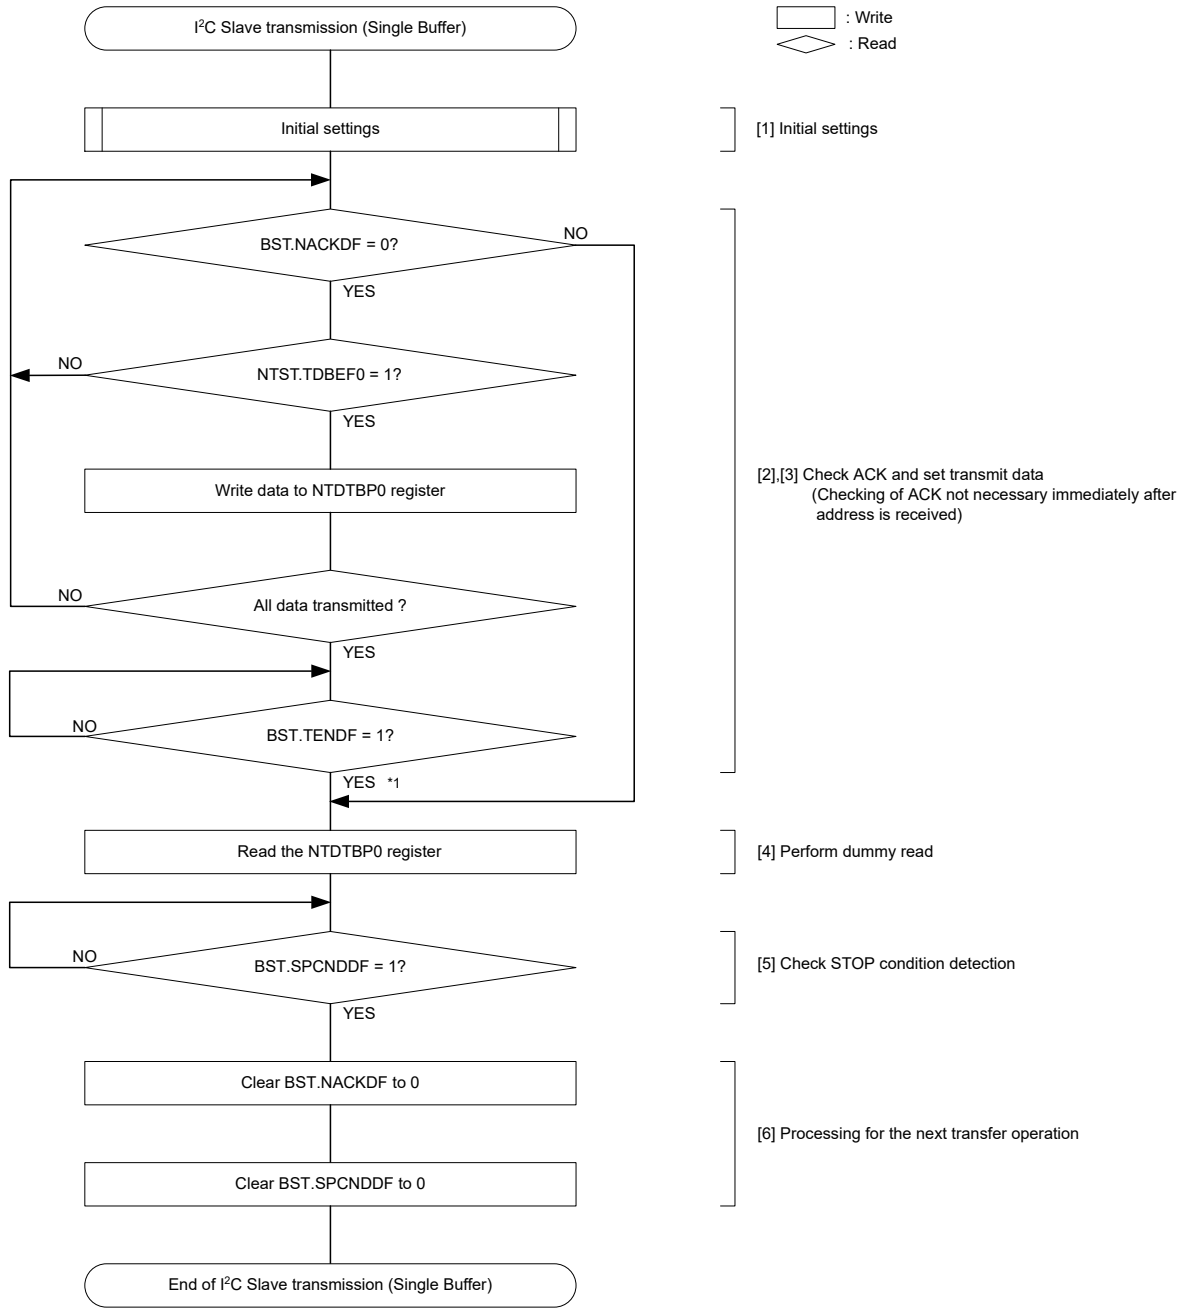
[12] Wake-Up function is disabled.

Note 1. After switching the I3C_SDA pin to the general I/O port (Input) in the I/O port function setting, set WUCTL.WUFSYNE to 1. Then wait until WUST.WUASYNF = 1, and switch the I3C_SDA pin to the peripheral function in the I/O port function setting.

Figure 30.151 Use case of I3C master wake-up

30.3.3.4 Slave Mode Communication Flow

30.3.3.4.1 I²C Slave Transmission Flow (Single Buffer Transfer)



Note 1. Normally, Master responds to the last byte with NACK, so when BST.TENDF=1, BST.NACKDF will also 1. If BST.NACKDF is 0 after BST.TENDF=1, the master may be hang up, so reset I3C with RSTCTL.INTLRST.

Figure 30.152 Example of I²C slave transmission flowchart (single buffer transfer)

30.3.3.4.2 I²C Slave Reception Flow (Single Buffer Transfer)

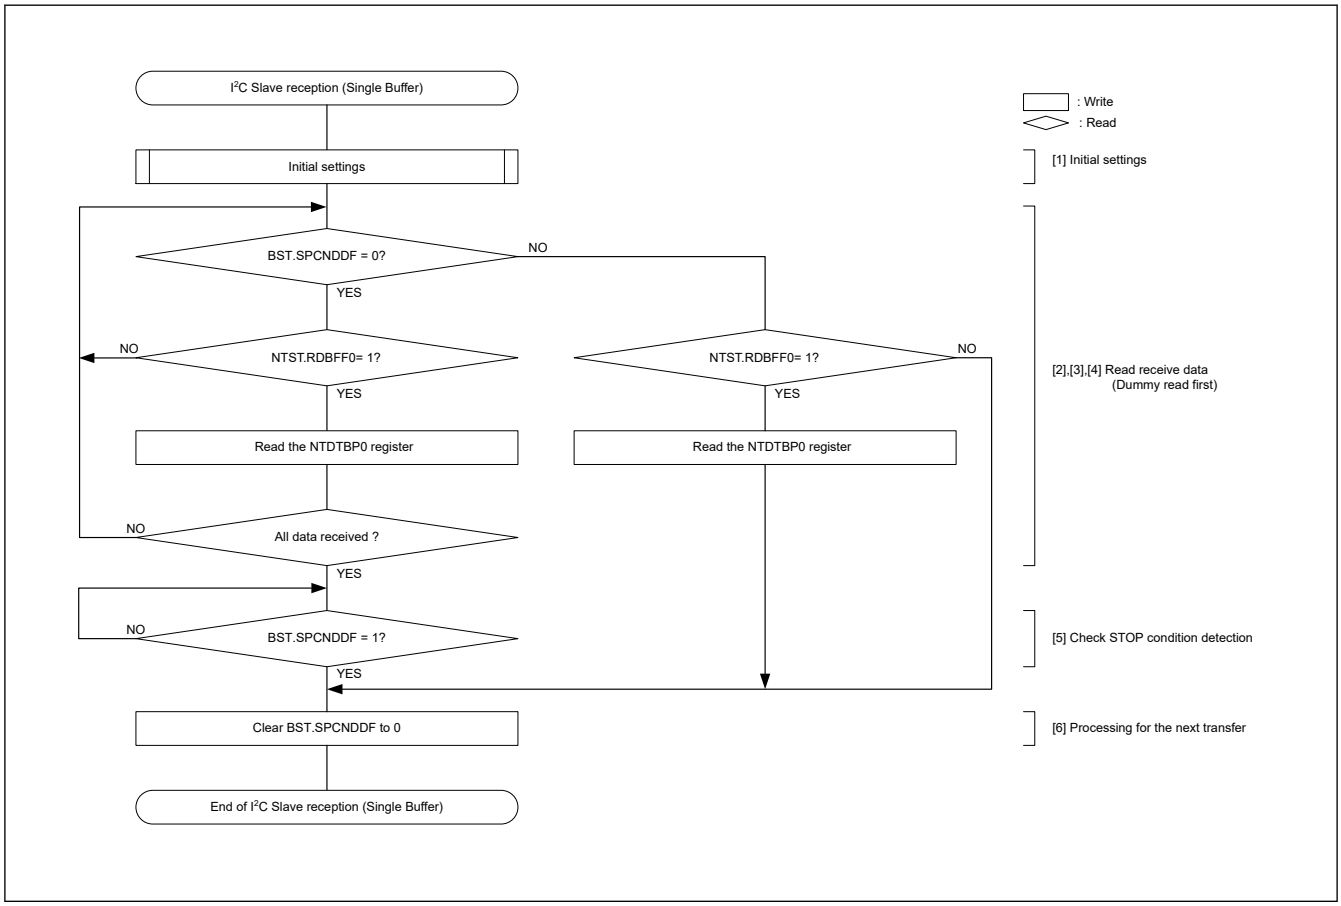


Figure 30.153 Example of I²C slave reception flowchart (single buffer transfer)

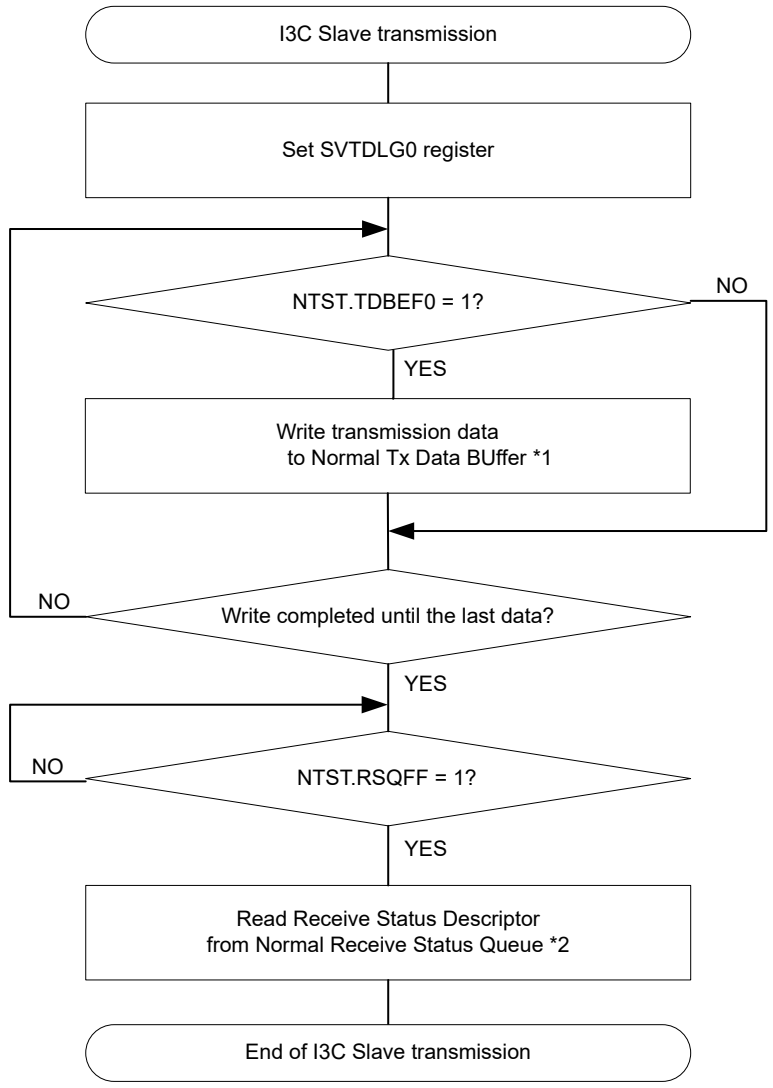
30.3.3.4.3 I3C Slave Transmission Flow (Normal FIFO Buffer Transfer)

Slave Transmission Flow in I3C normal FIFO buffer transfer is common to Legacy I²C, SDR (Private Transfer, Broadcast CCC, Direct CCC), HDR-DDR, and HDR-TSP/TSL.

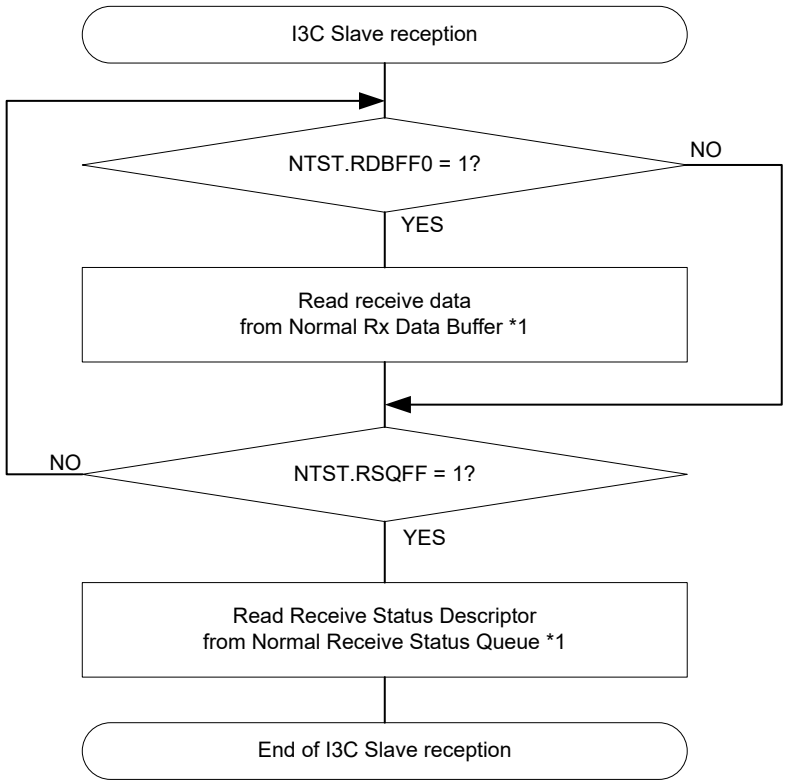


Note 1. In the case the register is write by a way other than DMAC/DTC, clear corresponding flags after write access.
Note 2. In the case the register is read by a way other than DMAC/DTC, clear corresponding flags after read access.

Figure 30.154 Example of I3C slave transmission flowchart (normal FIFO buffer transfer)

30.3.3.4.4 I3C Slave Reception Flow (Normal FIFO Buffer Transfer)

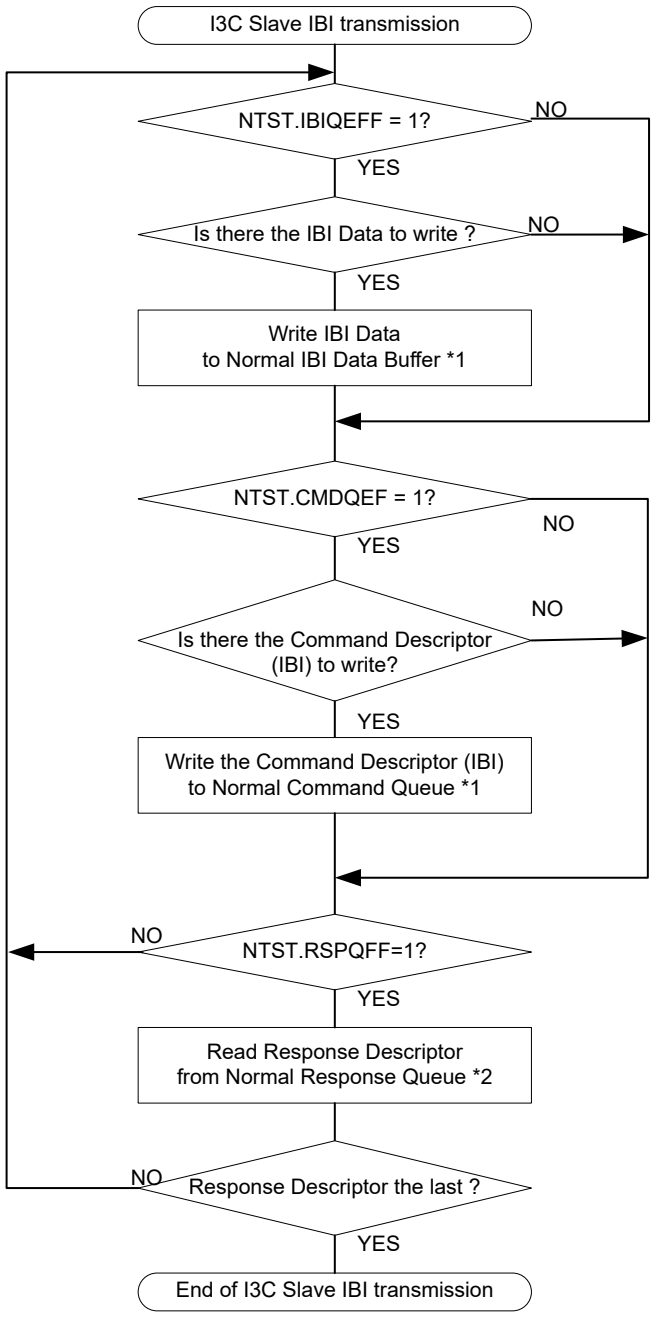
Slave Reception Flow in I3C normal FIFO buffer transfer is common to Legacy I^2C, SDR (Private Transfer, Broadcast CCC, Direct CCC), HDR-DDR, and HDR-TSP/TSL.



Note 1. In the case the register is read by a way other than DMAC/DTC, clear corresponding flags after read access.

Figure 30.155 Example of I3C slave reception flowchart (normal FIFO buffer transfer)

30.3.3.4.5 I3C Slave IBI Transmission Flow



Note 1. In the case the register is write by a way other than DMAC/DTC, clear corresponding flags after write access.
Note 2. In the case the register is read by a way other than DMAC/DTC, clear corresponding flags after read access.

Note: ✓ : Support
— : Not support

Note: I^2C: I^2C Master/Slave (Single Buffer)
I3CM: I3C Master
I3C2M: I3C Secondary Master
I3CS: I3C Slave

Note: There is a delay time between the execution of a write instruction for a peripheral module by the CPU and actual writing to the module. Thus, when an interrupt flag has been cleared, read the relevant flag again to check whether clearing has been completed, and then return from interrupt handling. Returning from interrupt handling without checking that writing to the module has been completed creates a possibility of repeated processing of the same interrupt.

For I2C Protocol mode:

- Since I3C_TX is an edge-detected interrupted, it does not require clearing. Furthermore, the NTST.TDBEF0 flag (a condition for I3C_TX) is automatically set to 0 when data for transmission are written to NTDTBP0 or a STOP condition is detected (SPCNDDF flag = 1 in BST).

- Since I3C_RX is an edge-detected interrupted, it does not require clearing. Furthermore, the NTST.RDBFF0 flag (a condition for I3C_RX) is automatically set to 0 when data are read from NTDTBP0.

For I3C Protocol mode:

For details, refer to the detailed explanation of each flag bit.

- The I3C_CMD, I3C_TX, I3C_HCMD, I3C_HTX and I3C_IBI (I3C Slave) interrupts are cleared under the following conditions.
  On completion of the last write access by DMAC/DTC.
  Write 0 to this bit after 1 state is read by CPU.
- The I3C_RESP, I3C_IBI (I3C Master), I3C_RX, I3C_RCV, I3C_HRESP and I3C_HRX interrupts are cleared under the following conditions.
  On completion of the last read access by DMAC/DTC.
  Write 0 to this bit after 1 state is read by CPU.

30.4.2 Buffer Operation for Buffer Full/Empty Interrupts

If the conditions for generating the each buffer full/empty interrupts are satisfied while the corresponding IR flag is 1, the interrupt request is not output for the ICU but retained internally (the capacity for internal retention is one request per source).

An interrupt request that was being retained within the ICU is output when the value of the IELSRn.IR flag becomes 0. Internally retained interrupt requests are automatically cleared under normal conditions of usage. Internally retained interrupt requests can also be cleared by writing 0 to the interrupt enable bit within the given peripheral module.

30.5 Event Link Output

I3C handles event output for the event link controller (ELC) corresponding to the following sources.

(1) Communication event

When a Communication event (arbitration-lost detection, detection of NACK, detection of timeout, detection of a START condition, or detection of a STOP condition) occurs, the corresponding event signal can be output for another module through the ELC.

(2) Rx Data buffer full

When a receive data register becomes full, the corresponding event signal can be output for another module through the ELC.

(3) Tx Data buffer empty

When a transmit data register becomes empty, the corresponding event signal can be output for another module through the ELC.

(4) Transmit end

On completion of transfer, the corresponding event signal can be output for another module through the ELC.

Other events are also available. For details, see section 17, Event Link Controller (ELC)18.2.3 ELSRn : Event Link Setting Register n.

30.5.1 Interrupt Handling and Event Linking

I3C module produces four kinds of interrupt: communication event (arbitration-lost detection, detection of NACK, detection of timeout, detection of a START condition, or detection of a STOP condition), Rx Data buffer full, Tx Data buffer empty, and transmit end interrupts. Each of these has an enable bit to control enabling and disabling of the interrupt signal. An interrupt request signal is output for the CPU when an interrupt source condition is satisfied while the setting of the corresponding enable bit is enabled.

The corresponding event link output signals are sent to other modules as event signals via the ELC when the interrupt source conditions are satisfied, regardless of the settings of the interrupt enable bits. For details on interrupt sources, see section 30.4.1. Overview.

30.6 Reset Descriptions

30.7 Usage Notes

30.7.1 Settings for the Operating Clock

The following relation is required between the frequencies of the bus clock (PCLK) and transfer clock(TCLK).

$TCLK/2 \leq PCLK \leq TCLK$

30.7.2 Settings for the SCL frequency Clock

As described in Chapter 5.1.2.4 of MIPI I3C Specification V1.0, the SCL frequency setting is required depending on the bus configuration.

In Mixed Bus with both I3C and legacy I2C devices are present on the bus, If the Legacy I2C device has a 50ns Spike Filter, I3C Master can change the frequency by setting the SCL High period to less than 50ns (tDIG_H_MIXED).

30.7.3 Module-stop function

I3C operation can be disabled or enabled using Module Stop Control Register B (MSTPCRB). The I3C module is initially stopped after reset. Releasing the module-stop state enables access to the registers. For details, see section 10, Low Power Modes.

30.7.4 Notes on Rewriting the PRTS.PRTMD Bit

When the PRTS.PRTMD bit is rewritten, the SCL terminal (and SDA terminal) may output low. In this case, the bus line is unintentionally put into a busy state, and communication cannot be started even if the communication start setting is made after that.

Set the RSTCTL.INTRST bit to 1 and issue an internal software reset before rewriting the PRTMD bit. After rewriting, set the RSTCTL.INTRST bit to 0 to release the internal software reset.

However, no countermeasure is necessary if the following conditions are applicable:

- When the PRTS.PRTMD bit is not changed from its initial value of 1 (I^2C protocol mode) to 0 (I3C protocol mode)
- When the clock source selected by SCKSCR.CKSEL[2:0] and I3CCKCR.I3CCKSEL[3:0] are the same.
- In master mode, when the timeout error detection function is enabled under the following conditions and a software reset is set in the I3C error interruption routine to release unintended low output.
  1. Set the BSTE.TODE bit to 1 to enable the timeout error detection function.
  2. Select TMOCTL.TOMDS[1:0] = 00b or 01b as the timeout operation mode and set the TMOCTL.TOLCTL bit = 1 and TMOCTL.TOHCTL bit = 1 to treat the SCL line fixed at low and fixed at high as errors.
  3. In the I3C error interruption routine, set the RSTCTL.RI3CRST bit to 1 to perform an I3C software reset, or set the RSTCTL.INTLRST bit to 1 to perform an internal software reset.
- In slave mode, when the timeout error detection function is enabled under the following conditions and a software and TMOCTL.TOHCTL bit = 1 to treat the SCL line fixed at low and fixed at high as errors.
  1. Set the BSTE.TODE bit to 1 to enable the timeout error detection function.
  2. Select TMOCTL.TOMDS[1:0] = 01b as the timeout operation mode and set TMOCTL.TOLCTL = 1 and TMOCTL.TOHCTL = 1 to treat the SCL line fixed at low and fixed at high as errors.
  3. In the I3C error interruption routine, set the RSTCTL.RI3CRST bit to 1 to perform an I3C software reset, or set the RSTCTL.INTLRST bit to 1 to perform an internal software reset.

31. CAN with Flexible Data-rate (CANFD)

31.1 Overview

The CAN with Flexible Data-rate (CANFD) supports the following functions:

- CAN with Flexible Data-rate.*1

Note 1. This feature is not available in the classical CAN function.

The CANFD module has a flexible message buffer and FIFO structure that meet the requirements of various applications. It also provides test modes to achieve high testability of the module that can be useful for power-on testing.

This specification describes of the CANFD module.

The CANFD mode is only available in certain products that support it.

31.1.1 CANFD Module

Table 31.1 CANFD module specifications (1 of 2)

Parameter		Specifications
Communication		CAN functionality conforms to CANFD ISO 11898-1 (2015)
Protocol engine version		RS-CANFD_PE V3.0
Data transfer rate	CANFD*1 *2	Up to 1 Mbps for arbitration phase and up to 8 Mbps for data phase, individually for CAN channel
	Classical CAN	Up to 1 Mbps
Operation frequency of Peripheral module clock		120 MHz (PCLKA) RAM clock: 240 MHz (PCLKE)
Data Link Layer (DLL) clock		8 MHz to 80MHz The following clocks can be selected. ● CANMCLK : External Oscillator Clock ● CANFDCLK : CANFD Core Clock
Input/Output pins		CRXn/CTXn (n = 0, 1)
CAN channels		2 channels
Selectable ID type		11-bit Standard ID
		11-bit Standard ID + 18-bit Extended ID
Selectable frame type		Data frame (RTR = 0) (CAN and CANFD frames)
		Remote frame (RTR = 1) (only CAN frames)
Variable data byte count for data frames		DLC range: 0 to F
Message buffer		Up to 16 reception message buffers
		4 transmit message buffers per channel
		1 transmission queue per channel Automatic message transfer into transmission queues supported
FIFO number		2 reception FIFO buffers 1 COMMON FIFO individually configurable as: ● Reception FIFO ● Transmission FIFO
Automatic delay interval timer for transmission		The delay timer can be applied to: ● Transmission FIFO

Table 31.1 CANFD module specifications (2 of 2)

Parameter	Specifications
Enhanced reception filtering	Support of 11 bits and 29 bits CAN identifier
	Programmable 29 bits CAN identifier acceptance filter mask for each entry
	Programmable routing capability for each FIFO and reception message buffers (up to 2 routing destinations)
	RTR and IDE masking
	Data Length Code (DLC) filter
	Message buffer payload overload protection
	Payload filter
	Updating Acceptance Filter List (AFL) entry during communication
General software support	Automatic label information added to receive message (for upper software layer support)
Timer	TX and RX Time Stamp function
Power down function	Module start stop function for each CAN node (Channel and Global Sleep mode)
RAM	RAM ECC protected (2 bits error detection, 1-bit error correction)
Module-stop function	Module-stop state can be set for each channels to reduce power consumption.
TrustZone Filter	Security and Privilege attribution can be set for each channels.

Note 1. The CANFD mode is available only for CANFD supported product.
Note 2. The bit rate for communications depends on the board design and external environment. Determine if following sufficient evaluation.

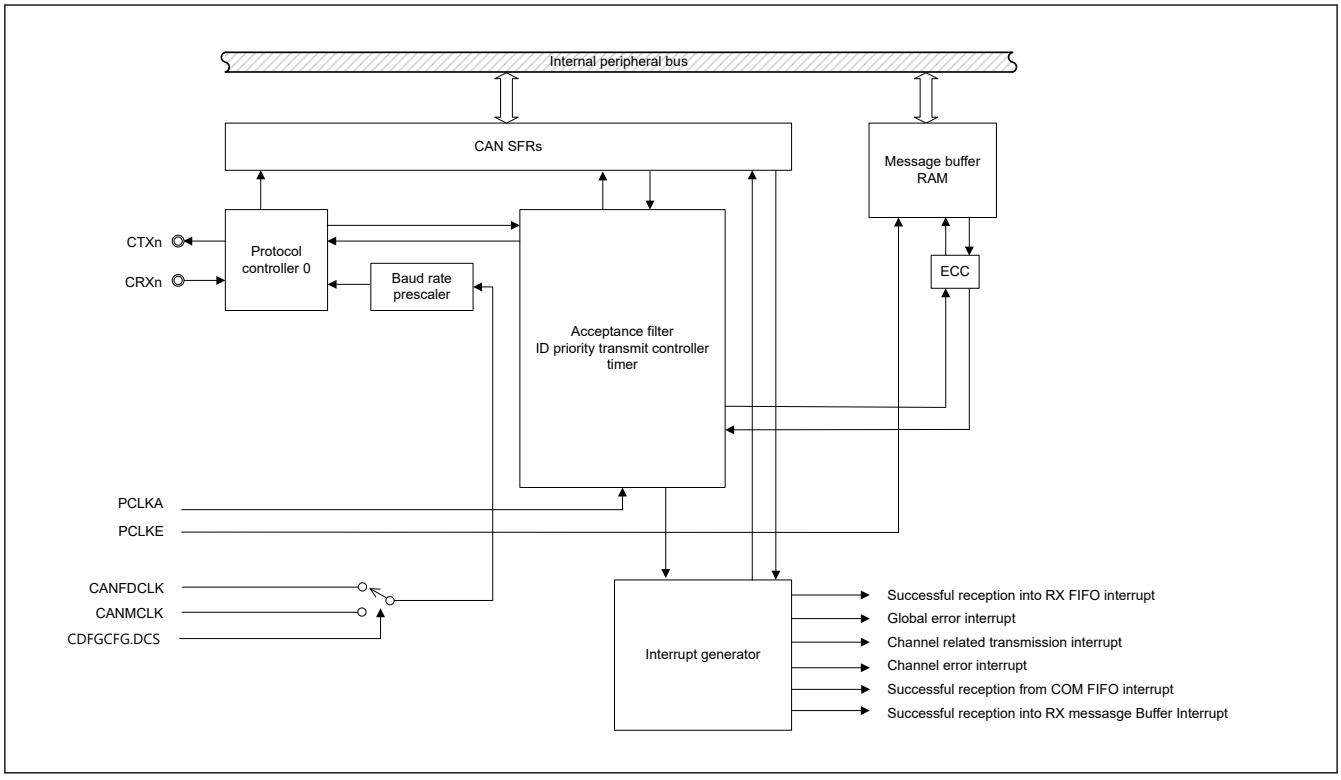

Figure 31.1 Overview of the CANFD module

- CRXn/CTXn:
  Input/Output pins of the CANFD module
- Protocol controller:

Handles CAN protocol processing such as bus arbitration, bit timing at transmission and reception, stuffing, error handling

- Message buffer RAM (MBRAM):
  This RAM is used to store messages after reception or for transmission using a normal message buffer or a FIFO. Each message entry has an individual ID, data length code, data field, message pointer for upper layer application usage and a time stamp.
  This RAM is used to store the message acceptance filtering entries. Each acceptance filter entry has an individual ID, data length code, data field, message pointer for upper layer application usage and message direction pointer.
- Acceptance filter list RAM (AFLRAM):
  Performs filtering of received messages. The entries in the Acceptance filter list RAM are used for the filtering process.
- Two timers:
  - Reception Timestamp function
  - Transmission separation time for FIFO buffers
- Interrupt generator:
  Generates several types of global and channel interrupts
- CAN Special Function Registers (SFRs):
  Registers associated with CAN. See section 31.2. Register Descriptions.

31.1.2 Clock Restriction

For the CAN communication the following restriction for the clocks should be satisfied:

- PCLKE / 2 = PCLKA ≥ CANFDCLK
- PCLKE / 2 = PCLKA ≥ CANMCLK

To avoid missing events the CAN engine clock (CANFDCLK or CANMCLK) frequency must be less than the PCLKA clock frequency.

To avoid loss of CAN message, the PCLKA should be set to a clock with a frequency depend on the CAN communication Baud Rate. The constraint of a baud rate and a PCLKA clock is shown in Table 31.2.

Table 31.2 Clock restriction

	Baud rate	PCLKA
CANFD	1 Mbps Nominal 8 Mbps Data*1	PCLKA ≥ 40 MHz
	500 Kbps Nominall 5 Mbps Data	PCLKA ≥ 32 MHz
Classical CAN	1 Mbps Data	PCLKA ≥ 32 MHz

Note 1. The bit rate for communications depends on the board design and external environment. Determine if following sufficient evaluation.

The frequency of CANFDCLK and CANMCLK depend on the required baud rate. For information how to configure the baud rate, refer to section 31.4.1.3. Baud Rate.

31.2 Register Descriptions

31.2.1 Register Table

The reset value shown for the RAM area, consisting of CFDGAFLIDr, CFDGAFLMr, CFDGAFLP0r, CFDGAFLP1r, CFDRMBCPb, CFDRFMBCPb, CFDCFMBCP0, CFDTMBCPb, CFDTHLACC0, CFDTHLACC1 and CFDRPGACCk is valid after initialization of a hardware reset. See section 31.4.2. CAN Module Configuration after Hardware Reset for details of the initialization process.

If a write access with a size of 8 or 16 bits is performed for the RAM area, then the CANFD module does a read-modify write-access to the RAM location, because the RAM requires a 32-bit access through the ECC module.

For single bit error, the correct data is written back. For multiple bit errors, unknown data is written back.

Do not access the space where the register is not assigned.

The read data from the space where the register is not assigned is unknown.

31.2.2 CFDC0NCFG : Nominal Bitrate Configuration Register

Base address: CANFDn = 0x4038_0000 + 0x2000 × n (n = 0, 1)
CANFDn_NS = 0x5038_0000 + 0x2000 × n (n = 0, 1)

Offset address: 0x0000

Bit position:	31 to 25	24 to 17	16 to 10	9 to 0
Bit field:	NTSEG2[6:0]	NTSEG1[7:0]	NSJW[6:0]	NBRP[9:0]
Value after reset:	0 0 0 0 0 0 0	0 0 0 0 0 0 0 0	0 0 0 0 0 0 0	0 0 0 0 0 0 0 0 0 0

Bit	Symbol	Function	R/W
9:0	NBRP[9:0]	Channel Nominal Baud Rate Prescaler Nominal baud rate prescaler division ratio	R/W
16:10	NSJW[6:0]	Resynchronization Jump Width 0x00: 1 Tq 0x01: 2 Tq ⋮ 0x7E: 127 Tq 0x7F: 128 Tq	R/W
24:17	NTSEG1[7:0]	Timing Segment 1 0x00: Reserved 0x01: 2 Tq 0x02: 3 Tq 0x03: 4 Tq ⋮ 0xFE: 255 Tq 0xFF: 256 Tq	R/W
31:25	NTSEG2[6:0]	Timing Segment 2 0x00: Reserved 0x01: 2 Tq ⋮ 0x7E: 127 Tq 0x7F: 128 Tq	R/W

Note: S-TYPE-3, P-TYPE-3
Note: Tq means time quantum.

This register configures the transmission/reception nominal baud rate parameters of the channels.

NBRP[9:0] bits (Channel Nominal Baud Rate Prescaler)

The NBRP[9:0] bits are used to define the peripheral bus clock periods contained in a time quantum.

Do not write to these bits in CH_OPERATION or CH_SLEEP mode.

Only write to these bits when the CANFD channel is in CH_RESET or CH_HALT mode.

NSJW[6:0] bits (Resynchronization Jump Width)

The NSJW[6:0] bits set the synchronization jump width. A value from 1 to 128 time quanta can be set.

Do not write to these bits in CH_OPERATION or CH_SLEEP mode.

Only write to these bits when the CANFD channel is in CH_RESET or CH_HALT mode.

NTSEG1[7:0] bits (Timing Segment 1)

The NTSEG1[7:0] bits set the segment TSEG1 to compensate for edges on the CAN bus with a positive phase error. These bits contain the propagation segment.

Do not write to these bits in CH_OPERATION or CH_SLEEP mode.

Only write to these bits when the CANFD channel is in CH_RESET or CH_HALT mode.

Additionally, configure a Tq value only between 2 and 256, inclusive. See section 31.4.1.2. CAN Bit Timing for more details.

NTSEG2[6:0] bits (Timing Segment 2)

The NTSEG2[6:0] bits set the segment TSEG2 to compensate for edges on the CAN bus with a negative phase error.

Do not write to these bits in CH_OPERATION or CH_SLEEP mode.

Only write to these bits when the CANFD channel is in CH_RESET or CH_HALT mode.

Additionally, configure a Tq value only between 2 and 128, inclusive.

31.2.3 CFDC0CTR : Control Register

Base address: CANFDn = 0x4038_0000 + 0x2000 × n (n = 0, 1)
CANFDn_NS = 0x5038_0000 + 0x2000 × n (n = 0, 1)

Offset address: 0x0004

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

31	ROM*1	Restricted Operation Mode 0: Restricted operation mode disabled 1: Restricted operation mode enabled	R/W

Note: S-TYPE-3, P-TYPE-3
Note 1. These bits are not available in the classical CAN function.

Channel Control register controls the modes of the related channel. It is used to enable generation of interrupts if errors are detected on the CAN bus connected to this channel. It is also used to configure the channel in test mode.

CHMDC[1:0] bits (Channel Mode Control)

The CHMDC[1:0] bits can be used to configure modes of the CAN channel.

CAN mode transitions are described in more details in section 31.3.3. Channel Modes.

Setting CHMDC[1:0] bits to 11b has no effect. When the CANFD module is in GL_HALT mode, these bits can only be set to 10b or 01b. These bits cannot be set in CH_SLEEP mode.

These bits can change automatically when transitioning to Halt mode by the CFDC0CTR.BOM settings.

If CPU write access to CFDC0CTR.CHMDC occurs at the same time when the CAN channel enters Halt mode (at the start of bus-off when CFDC0CTR.BOM = 01b, or at the end of bus-off when CFDC0CTR.BOM = 10b), then the CPU write access has the highest priority.

The CAN channel changes the value of CFDC0CTR.CHMDC within the Channel Control Registers for the specified cases only if the CFDC0CTR.CHMDC value is 00b (Operation mode).

CSLPR bit (Channel Sleep Request)

When the CSLPR bit is 1, a Sleep mode request is generated for the corresponding CAN channel

When this bit is 0, a request to exit Sleep mode is generated for the related CANFD channel.

Only write to this bit when the related CANFD channel is in CH_RESET or CH_SLEEP mode.

RTBO bit (Return from Bus-Off)

When the protocol controller of the CAN channel enters bus-off state, you can force a recovery from bus-off state by setting the RTBO bit in the Channel Control Register to 1.

The error state changes from bus-off state to integrating with a maximum delay of 1 CAN bit time.

When the RTBO bit is set to 1, the REC and TEC registers are initialized and the Bus-Off Status bit (Channel Bus-off Status, CFDC0STS.BOSTS) is set to 0.

Registers other than the REC and TEC registers are not initialized by this command. Even if CFDC0CTR.BORIE is set, a bus-off recovery interrupt is not generated by this recovery from the bus-off state.

The RTBO bit cannot be set in CH_SLEEP mode. Setting this bit in any state other than bus-off state has no effect and the bit is cleared immediately. The read value is always 0.

Return from the Bus-Off command should be used only when CFDC0CTR.BOM is set to 00b.

Only write to this bit when the related CANFD channel is in CH_OPERATION mode. This bit is automatically cleared when set by software.

BEIE bit (Bus Error Interrupt Enable)

When the BEIE and the CFDC0ERFL.BEF bits are both 1, an error interrupt request is generated.

This bit cannot be set in CH_SLEEP mode. Only write to this bit when the related CANFD channel is in CH_RESET mode.

EWIE bit (Error Warning Interrupt Enable)

When the EWIE and the CFDC0ERFL.EWF bits are both 1, an error interrupt request is generated.

The EWIE bit cannot be set in CH_SLEEP mode. Only write to this bit when the related CANFD channel is in CH_RESET mode.

EPIE bit (Error Passive Interrupt Enable)

An error interrupt request is generated when the EPIE bit and the CFDC0ERFL.EPF are both 1.

The EPIE bit cannot be set in CH_SLEEP mode. Only write to this bit when the related CANFD channel is in CH_RESET mode.

BOEIE bit (Bus-Off Entry Interrupt Enable)

When the BOEIE and the CFDC0ERFL.BOEF bits are both 1, an error interrupt request is generated.

The BOEIE bit cannot be set in CH_SLEEP mode. Only write to this bit when the related CANFD channel is in CH_RESET mode.

BORIE bit (Bus-Off Recovery Interrupt Enable)

When the BORIE and the CFDC0ERFL.BORF bits are both 1, an error interrupt request is generated.

The BORIE bit cannot be set in CH_SLEEP mode. Only write to this bit when the related CANFD channel is in CH_RESET mode.

OLIE bit (Overload Interrupt Enable)

When the OLIE and the CFDC0ERFL.OVLF bits are both 1, an error interrupt request is generated.

Do not write to this bit in CH_SLEEP mode. Only write to this bit when the related CANFD channel is in CH_RESET mode.

BLIE bit (Bus Lock Interrupt Enable)

When the BLIE and the CFDC0ERFL.BLF bits are both 1, an error interrupt request is generated.

Do not write to this bit in CH_SLEEP mode. Only write to this bit when the related CANFD channel is in CH_RESET mode.

ALIE bit (Arbitration Lost Interrupt Enable)

When the ALIE and the CFDC0ERFL.ALF bits are both 1, an error interrupt request is generated.

Do not write to this bit in CH_SLEEP mode. Only write to this bit when the related CANFD channel is in CH_RESET mode.

TAIE bit (Transmission Abort Interrupt Enable)

When the TAIE bit is 1 and a transmission is successfully aborted from a TX MB belonging to the corresponding CAN channel, an interrupt request is generated.

Do not write to this bit in CH_SLEEP mode. Only write to this bit when the related CANFD channel is in CH_RESET mode.

EOCOIE bit (Error Occurrence Counter Overflow Interrupt Enable)

When the EOCOIE bit is 1 and the CFDC0FDSTS.EOCO bit belonging to the corresponding CAN channel is 1, an error interrupt request is generated.

The EOCOIE bit cannot be set in CH_SLEEP mode. Only write to this bit when the related CANFD channel is in CH_RESET mode.

SOCOIE bit (Successful Occurrence Counter Overflow Interrupt Enable)

When the SOCOIE bit is 1 and the CFDC0FDSTS.SOCO bit belonging to the corresponding CAN channel is 1, an error interrupt request is generated.

The SOCOIE bit cannot be set in CH_SLEEP mode. Only write to this bit when the related CANFD channel is in CH_RESET mode.

TDCVFIE bit (Transceiver Delay Compensation Violation Interrupt Enable)

When the TDCVFIE bit is 1 and the CFDC0FDSTS.TDCVF bit belonging to the corresponding CAN channel is 1, an error interrupt request is generated.

The TDCVFIE bit cannot be set in CH_SLEEP mode.

Only write to this bit when the related CANFD channel is in CH_RESET mode. Do not set this bit when in Classical CAN mode.

Note: This bit is not available in the classical CAN function.

BOM[1:0] bits (Channel Bus-Off Mode)

The BOM[1:0]bits control the timing of the recovery from Bus-Off mode of the CANFD Channel.

Do not write to these bits in CH_SLEEP mode. Only write to these bits when the related CANFD channel is in CH_RESET mode.

Only write to these bits when the related CANFD channel is in CH_RESET mode.

ERRD bit (Channel Error Display)

The ERRD bit controls the display mode of the error flag bits [14:8] in the Channel Error Flag Register (CFDC0ERFL).

If the ERRD bit is 0 and more than one error occur at the same time, the error flag bits are set for all the errors that occurred at the same time. No further errors are flagged until CFDC0ERFL[14:8] is cleared.

Do not write to the ERRD bit in CH_SLEEP mode. Only write to this bit when the related CANFD channel is in CH_RESET or CH_HALT mode.

CTME bit (Channel Test Mode Enable)

The CTME bit enables the channel test modes.

Do not write to this bit in CH_SLEEP mode. Only write to this bit when the related CANFD channel is in CH_HALT mode.

CTMS[1:0] bits (Channel Test Mode Select)

The CTMS[1:0] bits are used to select the required test mode.

Do not write to these bits in CH_SLEEP or CH_RESET mode. Only write to these bits when the related CANFD channel is in CH_HALT mode.

These bits are cleared automatically when the related CANFD channel is in CH_RESET mode.

BFT bit (Bit Flip Test)

The BFT bit checks the internal CRC generator logic of the protocol controller.

It inverts the first bit (ID bit) of the CAN message data stream being received, so that the internal generated CRC result will not match the received CRC value of the frame. Refer to the bit stuffing rule, when using this feature, as there is the possibility of receiving a stuff error (due to the inversion) rather than a CRC error.

The internal generated CRC value is always observed in the following registers:

- CFDC0ERFL.CRCREG (Classical CAN frames)
- CFDC0FDCRC.CRCREG (CANFD frames).*1

Note 1. This feature is not available in the classical CAN function.

Some restriction exist when using this bit:

Other CAN node will send a reference message and the receiver node(s) can invert one bit of incoming bit stream.

Note: The transmitter and receiver modes share the same CRC generator, therefore it is not necessary to consider the modes separately when testing.

The Bit Flip test mode is enabled if the BFT (new control signal that inverts the first bit of the bit stream) and CTME bits are both 1 and CFDC0CTR.CTMS is 0x00.

If this function is used by a transmitting node, a bit error or an arbitration lost will occur.

Do not write to the BFT bit in CH_SLEEP mode. Users should not use this function when the Self test mode 1 (Internal Loop back mode). Only write to this bit when the related CANFD channel is in CH_HALT mode.

This bit is cleared automatically when the related CANFD channel is in CH_RESET mode.

ROM bit (Restricted Operation Mode)

When the ROM and CTME bits are both 1, the restricted operation mode is enabled. This mode should only be used in basic test mode (CFDC0CTR.CTMS[1:0] = 00b).

The ROM bit cannot be set in CH_SLEEP mode. Only write to this bit when the related CANFD channel is in CH_HALT mode.

This bit is cleared automatically when the related CANFD channel is in CH_RESET mode. Do not set this bit when in Classical CAN mode.

Note: This bit is not available in the classical CAN function.

31.2.4 CFDC0STS : Status Register

Base address: CANFDn = 0x4038_0000 + 0x2000 × n (n = 0, 1)
CANFDn_NS = 0x5038_0000 + 0x2000 × n (n = 0, 1)

Offset address: 0x0008

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	TEC[7:0]								REC[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	ESIF	COMSTS	RECSTS	TRMSTS	BOSTS	EPSTS	CSLPSTS	CHLTSTS	CRSTSTS
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0	1

Bit	Symbol	Function	R/W
0	CRSTSTS	Channel Reset Status 0: Channel not in Reset mode 1: Channel in Reset mode	R
1	CHLTSTS	Channel Halt Status 0: Channel not in Halt mode 1: Channel in Halt mode	R
2	CSLPSTS	Channel Sleep Status 0: Channel not in Sleep mode 1: Channel in Sleep mode	R
3	EPSTS	Channel Error Passive Status 0: Channel not in error passive state 1: Channel in error passive state	R
4	BOSTS	Channel Bus-Off Status 0: Channel not in bus-off state 1: Channel in bus-off state	R
5	TRMSTS	Channel Transmit Status 0: Channel is not transmitting 1: Channel is transmitting	R
6	RECSTS	Channel Receive Status 0: Channel is not receiving 1: Channel is receiving	R
7	COMSTS	Channel Communication Status 0: Channel is not ready for communication 1: Channel is ready for communication	R
8	ESIF*1	Error State Indication Flag 0: No CANFD message has been received when the ESI flag was set 1: At least one CANFD message was received when the ESI flag was set	R/W
15:9	—	These bits are read as 0. The write value should be 0.	R/W
23:16	REC[7:0]	Reception Error Count These bits increment or decrement the counter value according to error status of the CAN channel during reception.	R
31:24	TEC[7:0]	Transmission Error Count These bits increment or decrement the counter value according to error status of the CAN channel during transmission.	R

Note: S-TYPE-3, P-TYPE-3
Note 1. This bit is not available in the classical CAN function.

Channel Status Register shows the mode, error and transmission or reception status of the related channel together with its reception and transmission error count values.

CRSTSTS bit (Channel Reset Status)

The CRSTSTS bit indicates whether the related CAN channel is in Reset mode.

This bit is set automatically when the related CAN channel enters Channel Reset mode. When the mode is changed from Reset mode to Sleep mode, the CRSTSTS bit remains 1.

This bit is cleared automatically when the related CAN channel exits the Channel Reset mode, except when changing to Sleep mode.

CHLTSTS bit (Channel Halt Status)

The CHLTSTS bit indicates whether the related CAN channel is in Halt mode.

This bit is set automatically when the related CAN module enters Halt mode, and is cleared automatically when the related CAN module exits Halt mode.

CSLPSTS bit (Channel Sleep Status)

The CSLPSTS bit indicates whether the related CAN channel is in Sleep mode.

This bit is set automatically when the related CANFD channel enters Sleep mode, and is cleared automatically when the related CANFD channel exits Sleep mode.

EPSTS bit (Channel Error Passive Status)

The EPSTS bit indicates whether the related CANFD channel has entered the error passive state.

This bit is set automatically when the value of the CAN Transmission or Reception Counter Register exceeds the value of 0x7F.

This bit is cleared automatically when the related CANFD channel exits the error passive state or enters Reset mode.

BOSTS bit (Channel Bus-Off Status)

The BOSTS bit indicates whether the related CANFD channel has entered the error bus-off state.

This bit is set automatically when the value of the related CAN Transmission Error Count Register exceeds 0xFF and the related CANFD channel is in the bus-off state (CAN Transmission Error Count Register > 0xFF).

This bit is cleared automatically when the related CANFD channel exits bus-off state.

TRMSTS bit (Channel Transmit Status)

The TRMSTS bit indicates whether the related CANFD channel is transmitting a message.

This bit is set automatically when the related CANFD channel is operating as a transmitter node or is in the bus-off state.

This bit is cleared automatically when the related CANFD channel is in the bus-idle state or starts operating as a receiver node.

RECSTS bit (Channel Receive Status)

The RECSTS bit indicates whether the related CANFD channel is receiving a message.

This bit is set automatically when the related CANFD channel is operating as a receiver node.

This bit is cleared automatically when the related CANFD channel is in the bus-idle state or starts operating as a transmitter node.

COMSTS bit (Channel Communication Status)

The COMSTS bit indicates whether the related CANFD channel is ready for communication.

This bit is set automatically when the related CANFD channel is ready to perform communication following the detection of 11 consecutive recessive bits after exiting the Reset or Halt mode.

This bit is cleared automatically when the related CANFD channel is in CH_RESET or CD_HALT mode.

Note: This bit is 1 during bus-off state.

ESIF bit (Error State Indication Flag)

The ESIF bit is set when the ESI bit is sampled recessively for a reception CAN message without any error. When in Loopback or Mirror mode, the self-transmitted messages are considered reception messages.

If a set from the CANFD channel occurs simultaneously with a clear by a write access, then the bit is set.

This bit is cleared by writing 0 to it. This bit is cleared automatically when the related CANFD channel is in CH_RESET mode.

Only write to this bit when the related CANFD channel is in CH_HALT or CH_OPERATION mode.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1.

Note: This bit is not available in the classical CAN function.

REC[7:0] bits (Reception Error Count)

The REC[7:0] bits increment or decrement the counter value according to error status of the CANFD channel during reception, and display the value of the REC error counter.

The value in bus-off state is indeterminate.

These bits are cleared automatically when the CANFD module enters GL_RESET or the CANFD channel is in CH_RESET mode.

TEC[7:0] bits (Transmission Error Count)

The TEC[7:0] bits increment or decrement the counter value according to error status of the CANFD channel during transmission, and display the value of the TEC error counter.

Only write to these bits when in test mode and CANFD channel is in CH_HALT mode.

These bits are cleared automatically when CANFD module is in GL_RESET or CANFD channel is in CH_RESET mode.

31.2.5 CFDC0ERFL : Error Flag Register

Base address: CANFDn = 0x4038_0000 + 0x2000 × n (n = 0, 1)
CANFDn_NS = 0x5038_0000 + 0x2000 × n (n = 0, 1)

Offset address: 0x000C

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	CRCREG[14:0]														
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

13	B0ERR	Bit 0 Error 0: Channel bit 0 error not detected 1: Channel bit 0 error detected	R/W
14	ADERR	Acknowledge Delimiter Error 0: Channel acknowledge delimiter error not detected 1: Channel acknowledge delimiter error detected	R/W
15	—	This bit is read as 0. The write value should be 0.	R/W
30:16	CRCREG[14:0]	CRC Register value These bits show the CRC value calculated for the CAN2.0 CAN frame.	R
31	—	This bit is read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

Channel Error Flag register shows the status of various error conditions detectable regardless of the setting of the related CAN Channel Error Interrupt Enable Register. It also shows the status of the various bus errors detectable by the CAN channel. Refer to the CAN specification (ISO 11898-1) to check when each error condition occurs.

For this register, only a single bit can be cleared by software. Do not use the bit clear instruction to clear the bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1.

Example in assembler language to clear the CFDC0ERFL.BEF bit:

mov.b #0x0FE, CFDC0ERFL ;

BEF bit (Bus Error Flag)

The BEF bit indicates a detection of a CAN channel bus error state, flagged by bits [14:8] in this register.

This bit is cleared by writing 0 to it, and can only be set by CANFD module logic. Writing 1 has no effect.

This bit is set automatically when a bus error is detected, and is cleared automatically when the related CANFD channel is in CH_RESET mode.

If a set from the CAN channel occurs simultaneously with a clear by a write access, then the bit is set.

Only write to this bit when the related CANFD channel is in CH_HALT or CH_OPERATION mode.

EWF bit (Error Warning Flag)

The EWF bit indicates whether an error warning condition has been detected for the CAN channel.

This bit is cleared by writing 0 to it, and can only be set by CANFD module logic. Writing 1 has no effect.

This bit is set automatically when either TEC or REC exceeds 0x5F.

The setting of this bit only occurs when the TEC or REC initially exceeds 0x5F. Therefore, if the TEC or REC remains > 0x5F and the EWF bit is cleared by software, it is not set again until both the TEC and REC go below 0x60 and either TEC or REC crosses over again from a value 0x5F to a value > 0x5F.

If a set condition occurs simultaneously with a clear condition, then the bit is set. It is cleared automatically when the related CANFD channel is in CH_RESET mode.

Only write to this bit when the related CANFD channel is in CH_HALT or CH_OPERATION mode.

EPF bit (Error Passive Flag)

The EPF bit indicates a detection of a CAN channel error passive state.

This bit is cleared by writing 0 to it, and can only be set by CANFD module logic. Writing 1 has no effect.

This bit is set automatically when the CAN error state becomes error passive state.

The setting of this bit only occurs when the TEC or REC initially exceeds 0x7F. Therefore, if the TEC or REC remains > 0x7F and the bit is cleared by software, it is not set again until both the TEC and REC go below 0x80 and either TEC or REC crosses over again from a value ≤ 0x7F to a value > 0x7F.

If a set condition occurs simultaneously with a clear condition, then the bit is set. It is cleared automatically when the related CANFD channel is in CH_RESET mode.

Only write to this bit when the related CANFD channel is in CH_HALT or CH_OPERATION mode.

BOEF bit (Bus-Off Entry Flag)

The BOEF bit indicates a detection of a CAN channel bus-off entry state.

This bit is cleared by writing 0 to it, and can only be set by CANFD module logic. Writing 1 has no effect.

This bit is set automatically when the CAN error state enters the bus-off state.

This bit is cleared automatically when the related CANFD channel is in CH_RESET mode. If a set condition occurs simultaneously with a clear condition, then the bit is set.

Only write to this bit when the related CANFD channel is in CH_HALT or CH_OPERATION mode.

BORF bit (Bus-Off Recovery Flag)

The BORF bit indicates a detection of a CAN channel bus-off recovery state.

This bit is cleared by writing 0 to it, and can only be set by CANFD module logic. Writing 1 has no effect.

This bit is set automatically if CAN channel recovers from bus-off state in the following conditions:

- When CFDC0CTR.BOM is 00b and normal recovery (11 consecutive recessive bits x 128 times detected) occurs
- When CFDC0CTR.BOM is 10b and normal recovery (11 consecutive recessive bits x 128 times detected) occurs
- When CFDC0CTR.BOM is 11b and normal recovery (11 consecutive recessive bits x 128 times detected) occurs.

The bit is not set if CAN channel recovers from bus-off state in the following conditions:

- When CAN Reset mode is requested
- When CFDC0CTR.RTBO is set to 1 (the CAN channel returns to error active)
- When CFDC0CTR.BOM is 01b
- When CFDC0CTR.BOM is 11b and a halt request is asserted before the CAN channel reaches the end of the bus-off state.

This bit is cleared automatically when the related CANFD channel is in CH_RESET mode. If a set condition occurs simultaneously with a clear condition, the flag is set.

Only write to this bit when the related CANFD channel is in CH_HALT or CH_OPERATION mode.

OVLF bit (Overload Flag)

The OVLF flag indicates a detection of a CAN channel overload state.

The OVLF bit is cleared by writing 0 to it, and can only be set by CANFD module logic. Writing 1 has no effect.

This bit is set automatically when an overload condition is detected. If a set condition occurs simultaneously with a clear condition, then the bit is set.

This bit is cleared automatically when the related CANFD channel is in CH_RESET mode.

Only write to this bit when the related CANFD channel is in CH_HALT or CH_OPERATION mode.

BLF bit (Bus Lock Flag)

The BLF bit indicates a detection of a CAN channel bus lock condition.

This bit is cleared by writing 0 to it, and can only be set by CANFD module logic. Writing 1 has no effect.

This bit is set automatically when 32 consecutive dominant bits are detected on the CAN bus while the CAN channel is in Operation mode.

If a set condition occurs simultaneously with a clear condition, then the bit is set. It is cleared automatically when the related CANFD channel is in CH_RESET mode.

Only write to this bit when the related CANFD channel is in CH_HALT or CH_OPERATION mode.

It is cleared automatically when the related CANFD channel is in CH_RESET mode.

ALF bit (Arbitration Lost Flag)

The ALF bit indicates a detection of a CAN channel bus arbitration lost condition.

This bit is cleared by writing 0 to it, and can only be set by CANFD module logic. Writing 1 has no effect.

The bit is set automatically when an arbitration lost condition is detected on the CAN bus while the CAN channel is in Operation mode.

If a set condition occurs simultaneously with a clear condition, then the bit is set. It is cleared automatically when the related CANFD channel is in CH_RESET mode.

Only write to this bit when the related CANFD channel is in CH_HALT or CH_OPERATION mode.

SERR bit (Stuff Error)

The SERR bit indicates a detection of a CAN stuff error.

This bit is cleared by writing 0 to it, and can only be set by CANFD module logic. Writing 1 has no effect.

To clear this bit, use the following sequence:

1. Clear the corresponding flag bit.
2. Read if the flag bit is cleared.
3. If yes, continue, else go back to step 1.

This bit is set automatically when a stuff error is detected. If CFDC0CTR.ERRD bit is 1 and if the set and clear conditions occur at the same time for this bit, then this bit is set.

This bit is cleared automatically when the related CANFD channel is in CH_RESET mode. If CFDC0CTR.ERRD bit is 0 and the set and clear conditions occur at the same time for this bit, then it is cleared if a bit at CFDC0ERFL[14:8] is already set. Otherwise, this bit is set if CFDC0ERFL[14:8] is 0000000b.

Only write to this bit when the related CANFD channel is in CH_HALT or CH_OPERATION mode.

FERR bit (Form Error)

The FERR bit indicates a detection of a CAN form error.

This bit is cleared by writing 0 to it, and can only be set by CANFD module logic. Writing 1 has no effect.

To clear this bit, use the following sequence:

1. Clear the corresponding flag bit.
2. Read if the flag bit is cleared.

3. If yes, continue, else go back to step 1.

This bit is set automatically when a form error is detected. If CFDC0CTR.ERRD bit is 1 and if the set and clear conditions occur at the same time for this bit, then this bit is set.

This bit is cleared automatically when the related CANFD channel is in CH_RESET mode. If CFDC0CTR.ERRD bit is 0 and the set and clear conditions occur at the same time for this bit, then it is cleared if a bit at CFDC0ERFL[14:8] is already set. Otherwise, this bit is set if CFDC0ERFL[14:8] is 0000000b.

Only write to this bit when the related CANFD channel is in CH_HALT or CH_OPERATION mode.

AERR bit (Acknowledge Error)

The AERR bit indicates a detection of a CAN acknowledge error.

This bit is cleared by writing 0 to it, and can only be set by CANFD module logic. Writing 1 has no effect.

To clear this bit, use the following sequence:

1. Clear the corresponding flag bit.
2. Read if the flag bit is cleared.
3. If yes, continue, else go back to step 1.

This bit is set automatically when an acknowledge error is detected. If CFDC0CTR.ERRD bit is 1 and if the set and clear conditions occur at the same time for this bit, then this bit is set.

This bit is cleared automatically when the related CANFD channel is in CH_RESET mode. If CFDC0CTR.ERRD bit is 0 and the set and clear conditions occur at the same time for this bit, then it is cleared if a bit at CFDC0ERFL[14:8] is already set. Otherwise, this bit is set if CFDC0ERFL[14:8] is 0000000b.

Only write to this bit when the related CANFD channel is in CH_HALT or CH_OPERATION.

CERR bit (CRC Error)

The CERR bit indicates a detection of a CAN CRC error.

This bit is cleared by writing 0 to it, and can only be set by CANFD module logic. Writing 1 has no effect.

To clear this bit, use the following sequence:

1. Clear the corresponding flag bit.
2. Read if the flag bit is cleared.
3. If yes, continue, else go back to step 1.

This bit is set automatically when a CRC error is detected. If CFDC0CTR.ERRD bit is 1 and if the set and clear conditions occur at the same time for this bit, then this bit is set.

This bit is cleared automatically when the related CANFD channel is in CH_RESET mode. If CFDC0CTR.ERRD bit is 0 and the set and clear conditions occur at the same time for this bit, then it is cleared if a bit at CFDC0ERFL[14:8] is already set. Otherwise, this bit is set if CFDC0ERFL[14:8] is 0000000b.

Only write to this bit when the related CANFD channel is in CH_HALT or CH_OPERATION mode.

B1ERR bit (Bit 1 Error)

The B1ERR bit indicates a detection of a recessive bit error.

This bit is cleared by writing 0 to it, and can only be set by CANFD module logic. Writing 1 has no effect.

To clear this bit, use the following sequence:

1. Clear the corresponding flag bit.
2. Read if the flag bit is cleared.
3. If yes, continue, else go back to step 1.

This bit is set automatically when a recessive bit error (expected recessive bit, sampled as dominant bit) is detected. If CFDC0CTR.ERRD bit is 1 and if the set and clear conditions occur at the same time for this bit, then this bit is set.

This bit is cleared automatically when the related CANFD channel is in CH_RESET mode. If CFDC0CTR.ERRD bit is 0 and the set and clear conditions occur at the same time for this bit, then it is cleared if a bit at CFDC0ERFL[14:8] is already set. Otherwise, this bit is set if CFDC0ERFL[14:8] is 0000000b.

Only write to this bit when the related CANFD channel is in CH_HALT or CH_OPERATION mode.

B0ERR bit (Bit 0 Error)

The B0ERR bit indicates a detection of a dominant bit error.

This bit is cleared by writing 0 to it, and can only be set by CANFD module logic. Writing 1 has no effect.

To clear this bit, use the following sequence:

1. Clear the corresponding flag bit.
2. Read if the flag bit is cleared.
3. If yes, continue, else go back to step 1.

This bit is set automatically when a dominant bit error (expected dominant bit, sampled as recessive bit) is detected. If CFDC0CTR.ERRD bit is 1 and if the set and clear conditions occur at the same time for this bit, then this bit is set.

This bit is cleared automatically when the related CANFD channel is in CH_RESET mode. If CFDC0CTR.ERRD bit is 0 and the set and clear conditions occur at the same time for this bit, then it is cleared if a bit at CFDC0ERFL[14:8] is already set. Otherwise, this bit is set if CFDC0ERFL[14:8] is 0000000b.

Only write to this bit when the related CANFD channel is in CH_HALT or CH_OPERATION mode.

ADERR bit (Acknowledge Delimiter Error)

The ADERR bit indicates a detection of an acknowledge delimiter bit error.

This bit is cleared by writing 0 to it, and can only be set by CANFD module logic. Writing 1 has no effect.

To clear this bit, use the following sequence:

1. Clear the corresponding flag bit.
2. Read if the flag bit is cleared.
3. If yes, continue, else go back to step 1.

This bit is set automatically when a form error is detected during the acknowledge delimiter state of frame transmission. If CFDC0CTR.ERRD bit is 1 and if the set and clear conditions occur at the same time for this bit, then this bit is set.

This bit is cleared automatically when the related CANFD channel is in CH_RESET mode. If CFDC0CTR.ERRD bit is 0 and the set and clear conditions occur at the same time for this bit, then it is cleared if a bit at CFDC0ERFL[14:8] is already set. Otherwise, this bit is set if CFDC0ERFL[14:8] is 0000000b.

Only write to this bit when the related CANFD channel is in CH_HALT or CH_OPERATION mode.

CRCREG[14:0] bits (CRC Register value)

The CRCREG[14:0] bits read the calculated CRC value when CFDC0CTR.CTME bit is 1 for the channel.

If CFDC0CTR.CTME bit is 0, then these bits are always read as 0.

These bits show the CAN2.0 CRC value calculated by the CANFD channel logic when the CTME bit is enabled.

The CFDC0ERFL.CRCREG value is updated in the first bit of the CRC field of the CAN frame (reception and transmission).

These bits are cleared automatically when the related CANFD channel is in CH_RESET mode.

31.2.6 CFDC0DCFG : Data Bitrate Configuration Register

This register is not available in the classical CAN function.

Base address: CANFDn = 0x4038_0000 + 0x2000 × n (n = 0, 1)
CANFDn_NS = 0x5038_0000 + 0x2000 × n (n = 0, 1)

Offset address: 0x0100

Bit position:	31				27				24				19				16				12				8	7						0
Bit field:	—	—	—	—	DSJW[3:0]				—	—	—	—	DTSEG2[3:0]				—	—	—	DTSEG1[4:0]					DBRP[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	DBRP[7:0]	Channel Data Baud Rate Prescaler Data Baud Rate Prescaler division ratio	R/W
12:8	DTSEG1[4:0]	Timing Segment 1 0x00: Reserved 0x01: 2 Tq 0x02: 3 Tq 0x03: 4 Tq ⋮ 0x1E: 31 Tq 0x1F: 32 Tq	R/W
15:13	—	These bits are read as 0. The write value should be 0.	R/W

31:28	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3
Note: Tq means time quantum.

The Data Bitrate Configuration Register configures the transmission/reception data baud rate parameters of the channels.

The channel of Classical CAN mode does not perform configuration of this register.

DBRP[7:0] bits (Channel Data Baud Rate Prescaler)

The DBRP[7:0] bits define the peripheral bus clock periods contained in a time quantum.

Do not write to these bits in CH_OPERATION or CH_SLEEP mode.

Only write to these bits when the related CANFD channel is in CH_RESET or CH_HALT mode.

DTSEG1[4:0] bits (Timing Segment 1)

The DTSEG1[4:0] bits set the segment TSEG1 to compensate for edges on the CAN bus with a positive phase error. A value from 2 to 32 time quanta can be set.

The DTSEG1[4:0] bits are also used to set the propagation segment.

Do not write to these bits in CH_OPERATION or CH_SLEEP mode.

Only write to these bits when the related CANFD channel is in CH_RESET or CH_HALT mode. Do not write any other value to these bits. See section 31.4.1.2. CAN Bit Timing for more details.

DTSEG2[3:0] bits (Timing Segment 2)

The DTSEG2[3:0] bits set the segment TSEG2 to compensate for edges on the CAN bus with a negative phase error. A value from 2 to 16 time quanta can be set.

Do not write to these bits in CH_OPERATION or CH_SLEEP mode.

Only write to these bits when the related CANFD channel is in CH_RESET or CH_HALT mode. Do not write any other value to these bits.

DSJW[3:0] bits (Resynchronization Jump Width)

The DSJW[3:0] bits set the synchronization jump width. A value from 1 to 16 time quanta can be set.

Do not write to these bits in CH_OPERATION or CH_SLEEP mode.

Only write to these bits when the related CANFD channel is in CH_RESET or CH_HALT mode.

31.2.7 CFDC0FDCFG : CANFD Configuration Register

Base address: CANFDn = 0x4038_0000 + 0x2000 × n (n = 0, 1)
CANFDn_NS = 0x5038_0000 + 0x2000 × n (n = 0, 1)

Bit	Symbol	Function	R/W
29	REFE	RX Edge Filter Enable 0: RX edge filter disabled 1: RX edge filter enabled	R/W
30	CLOE*2 *3	Classical CAN Enable 0: Classical CAN mode disabled 1: Classical CAN mode enabled	R/W
31	—	This bit is read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3
Note 1. The value after reset is 0 for products that support the CAN-FD protocol, and 1 for products that support only classical CAN protocol.
Note 2. These bits are not available in the classical CAN function.
Note 3. This bit can only be written for products that support the CAN-FD protocol. For products that support only classical CAN protocol, this bit is reserved and fixed to 1.

The CANFD Configuration Register configures which communication direction (transmitter/receiver) errors are counted.

EOCCFG[2:0] bits (Error Occurrence Counter Configuration)

The EOCCFG[2:0] bits select which type of CAN frame configuration and direction, including protocol errors are counted.

Do not write to these bits in CH_OPERATION or CH_SLEEP mode.

Only write to these bits when the related CANFD channel is in CH_RESET or CH_HALT mode.

TDCOC bit (Transceiver Delay Compensation Offset Configuration)*1

The TDCOC bit selects which offset is used when defining the position of the secondary sample point (SSP) for the CANFD channel. If the bit is set to 0, the position of the SSP is the measured transceiver delay plus the fixed offset. If the bit is 1, the position of the SSP is defined only by the offset.

Do not write to this bit in CH_OPERATION or CH_SLEEP mode.

Only write to this bit when the related CANFD channel is in CH_RESET or CH_HALT mode. Do not set this bit when in Classical CAN mode.

TDCE bit (Transceiver Delay Compensation Enable)*1

The TDCE bit enables the transceiver delay compensation for the CANFD channel.

Do not write to this bit in CH_OPERATION or CH_SLEEP mode.

Only write to this bit when the related CANFD channel is in CH_RESET or CH_HALT mode. Do not set this bit when in Classical CAN mode.

ESIC bit (Error State Indication Configuration)*1

The ESIC bit controls the transmission of either the ESI flag information or the message of ESI flag information (CFDCFFDCSTS.CFESI or CFDTMFDCTRb.TMESI).

Do not write to this bit in CH_OPERATION or CH_SLEEP mode.

Only write to this bit when the related CANFD channel is in CH_RESET or CH_HALT mode. Do not set this bit when in Classical CAN mode.

TDCO[7:0] bits (Transceiver Delay Compensation Offset)*1

The TDCO[7:0] bits set the secondary sample point offset. How this value is used, depends on the CFDC0FDCFG.TDCOC setting.

If CFDC0FDCFG.TDCOC = 0, the transceiver delay compensation result is equal to the Trv_Delay (measured delay) + the value in CFDC0FDCFG.TDCO, rounded down to the nearest integer number of time quanta. Otherwise, the result is equal to the value in CFDC0FDCFG.TDCO. See section 31.4.1.5. Transmitter Delay Compensation for details on how CFDC0FDCFG.TDCO is used.

The actual offset value is interpreted as TDCO + 1. For example, if 4 is set in TDCO, the offset is 5 clock cycles. Clock cycle is 1 cycle of CAN channel DLL clock.

Do not write to the TDCO[7:0] bits in CH_OPERATION or CH_SLEEP mode.

Only write to these bits when the related CANFD channel is in CH_RESET or CH_HALT mode. Do not set this bit when in Classical CAN mode.

FDOE bit (FD-Only Enable)*1

The FDOE bit enables the reception and transmission of CANFD-only frames. If enabled, communication in Classical CAN frame format is disabled. Transmission of Classical CAN frames is not possible because the FDF bit of the message buffer is a don't care (CFDCFFDCSTS.CFFDF/CFDTMFDCTRb.TMFDF).

If messages with Classical CAN frame format are received, the protocol controller treats them as invalid frames and response with error frames. When a Classical CAN frame is configured for transmitting, the FDF bit is sent as recessive, therefore an FD frame is sent. If the data length code (DLC) is configured of greater than 8 bytes, the remaining data bytes are padded with 0xCC.

The FDOE bit cannot be written in CH_OPERATION, CH_HALT or CH_SLEEP mode.

Do not set CFDC0FDCFG.FDOE and CFDC0FDCFG.CLOE simultaneously.

REFE bit (RX Edge Filter Enable)

The REFE bit enables the RX edge filter during the IDLE detection (bus integration). When the bit is enabled, two consecutive dominant time quanta are required to detect a synchronization edge.

The REFE bit cannot be written in CH_OPERATION, CH_HALT and CH_SLEEP mode. Do not set this bit when in Classical CAN mode.

CLOE bit (Classical CAN Enable)*1

The CLOE bit enables the Classical CAN mode. If this bit is 1, the protocol controller can only send classical frames and response with a form or CRC error on FD frames.

Do not set CFDC0FDCFG.CLOE and CFDC0FDCFG.FDOE simultaneously.

CFDC0FDCFG.CLOE	CFDC0FDCFG.FDOE	Channel mode
0	0	CANFD mode
0	1	FD-only mode
1	0	Classical CAN mode
1	1	Reserved

The CANFD mode is available only for CANFD supported product.

Do not write to this bit in CH_OPERATION, CH_HALT or CH_SLEEP mode.

Only write to these bits when the CANFD channel is in CH_RESET mode.

Note 1. These bits are not available in the classical CAN function.

31.2.8 CFDC0FDCTR : CANFD Control Register

Base address: CANFDn = 0x4038_0000 + 0x2000 × n (n = 0, 1)
CANFDn_NS = 0x5038_0000 + 0x2000 × n (n = 0, 1)

Offset address: 0x0108

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	SOCCLR	EOCCLR
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	EOCCLR	Error Occurrence Counter Clear 0: No error occurrence counter clear 1: Clear error occurrence counter	R/W
1	SOCCLR	Successful Occurrence Counter Clear 0: No successful occurrence counter clear 1: Clear successful occurrence counter	R/W
31:2	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

The CANFD Control Register controls the error and successful occurrence counters.

EOCCLR bit (Error Occurrence Counter Clear)

The EOCCLR bit is used to clear the error occurrence counter.

Do not write to this bit in CH_SLEEP or CH_RESET mode. The read value is always 0.

This bit is cleared automatically by the CANFD module logic and when the related CANFD channel is in CH_RESET mode.

SOCCLR bit (Successful Occurrence Counter Clear)

The SOCCLR bit is used to clear the successful occurrence counter.

Do not write to this bit in CH_SLEEP or CH_RESET mode. The read value is always 0.

This bit is cleared automatically by the CANFD module logic and when the related CANFD channel is in CH_RESET mode.

31.2.9 CFDC0FDSTS : CANFD Status Register

Base address: CANFDn = 0x4038_0000 + 0x2000 × n (n = 0, 1)
CANFDn_NS = 0x5038_0000 + 0x2000 × n (n = 0, 1)

Offset address: 0x010C

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	SOC[7:0]								EOC[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

9	SOCO	Successful Occurrence Counter Overflow 0: Successful occurrence counter has not overflowed 1: Successful occurrence counter has overflowed	R/W
14:10	—	These bits are read as 0. The write value should be 0.	R/W
15	TDCVF*1	Transceiver Delay Compensation Violation Flag 0: Transceiver delay compensation violation has not occurred 1: Transceiver delay compensation violation has occurred	R/W
23:16	EOC[7:0]	Error Occurrence Counter These bits show the error occurrence counter value.	R

Bit	Symbol	Function	R/W
31:24	SOC[7:0]	Successful occurrence counter These bits show the successful occurrence counter value.	R

Note: S-TYPE-3, P-TYPE-3
Note 1. These bits are not available in the classical CAN function.

The CANFD Status Register indicates the transceiver compensation delay result and its related FIFO message lost status.

TDCR[7:0] bits (Transceiver Delay Compensation Result)

The TDCR[7:0] bits are set when the transceiver delay has been measured.

The measured delay is a multiple of the CAN channel DLL clock. The result depends on the CFDC0FDCFG.TDCOC configuration and the offset value in CFDC0FDCFG.TDCO. See section 31.4.1.5. Transmitter Delay Compensation for details on how this value is derived.

The TDCR[7:0] bits are updated at the falling edge between FDF and the RES bit when CFDC0FDCFG.TDCOC = 0 and the transceiver delay compensation is enabled (CFDC0FDCFG.TDCE = 1).

These bits are cleared automatically when the related CANFD channel is in CH_RESET mode.

Note: These bits are not available in the classical CAN function.

EOCO bit (Error Occurrence Counter Overflow)

The EOCO bit indicates whether the related CAN channel error occurrence counter has overflowed. This bit is cleared by writing 0 to it. Writing 1 has no effect.

This bit is set automatically when CFDC0FDSTS.EOC is 0xFF and a CAN bus error is detected based on the configuration defined in CFDC0FDCFG.EOCCFG.

If the set from the CAN channel occurs simultaneously with the clear by the write access, then the bit is set.

This bit is cleared automatically when the related CANFD channel is in CH_RESET mode.

Only write to this bit when the related CANFD channel is in CH_HALT or CH_OPERATION mode.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1.

SOCO bit (Successful Occurrence Counter Overflow)

The SOCO bit indicates whether the related CAN channel successful occurrence counter has overflowed. This bit is cleared by writing 0 to it. Writing 1 has no effect.

This bit is set automatically when CFDC0FDSTS.SOC is 0xFF and a successful message reception or successful message transmission occurs.

If the set from the CAN channel occurs simultaneously with the clear by the write access, then the bit is set.

This bit is cleared automatically when the related CANFD channel is in CH_RESET mode.

Write to this bit only when the related CANFD channel is in CH_HALT or CH_OPERATION mode.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1.

TDCVF bit (Transceiver Delay Compensation Violation Flag)

The CANFD module captures internally the transmitted data bit-by-bit. This data is then compared against the received CAN bus level which is delayed by the transceiver loop delay.

The transceiver delay has some variations depending on the physical parameters such as temperature. The result bit CFDC0FDSTS.TDCR is updated by each message. However, temporary maximum delay violation could be missed. Therefore, the TDCVF bit captures this violation.

This bit is cleared by writing 0 to it. Writing 1 has no effect.

This bit is set automatically when the transceiver delay compensation is greater than the maximum delay compensation (6 data bit times - 2 clk_dlc) and the internal bit is overrun.

If the set from the CAN channel occurs simultaneously with the clear by the write access, then the bit is set.

This bit is cleared automatically when the related CANFD channel is in CH_RESET mode.

Only write to this bit when the related CANFD channel is in CH_HALT or CH_OPERATION mode.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1.

Note: This bit is not available in the classical CAN function.

EOC[7:0] bits (Error Occurrence Counter)

The EOC[7:0] bits are used together with the SOC[7:0] bits to support an option for host-controlled fall-back to payload bit rate identical to arbitration bit rate when messages utilizing the reduced payload bit length have significant higher error rates compared to other messages.

This higher error rate can be detected depending on the configuration of the CFDC0FDCFG.EOCCFG bits.

The EOC[7:0] bits are set only by CANFD module logic. These bits are cleared by writing 1 to CFDC0FDCTR.EOCCLR. Writing any other value has no effect.

These bits are updated when an error occurs, according to the configuration of the CFDC0FDCFG.EOCCFG bits. When the counter reaches the value of 0xFF, the update stops.

These bits are cleared automatically when the related CANFD channel is in CH_RESET mode.

SOC[7:0] bits (Successful occurrence counter)

The SOC[7:0] bits are used together with the EOC[7:0] bits to support an option for host-controlled fall-back to payload bit rate identical to arbitration bit rate when messages utilizing the reduced payload bit length have significant higher error rates compared to other messages.

The SOC[7:0] bits are set only by CANFD module logic. Writing any other value has no effect.

These bits are updated when the occurrence of any error-free messages on the bus is detected through reception or transmission. When the counter reaches the value of 0xFF, the update stops.

Note: In Loopback mode, the counter is incremented twice.

These bits are cleared by writing 1 to CFDC0FDCTR.SOCCLR.

These bits are cleared automatically when the related CANFD channel is in CH_RESET mode.

31.2.10 CFDC0FDCRC : CANFD CRC Register

This register is not available in the classical CAN function.

Base address: CANFDn = 0x4038_0000 + 0x2000 × n (n = 0, 1)
CANFDn_NS = 0x5038_0000 + 0x2000 × n (n = 0, 1)

Offset address: 0x0110

Bit position:	31				27				24				20																			0
Bit field:	—	—	—	—	SCNT[3:0]				—	—	—	CRCREG[20:0]																					
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
20:0	CRCREG[20:0]	CRC Register value These bits show the CRC value calculated for the CANFD frame.	R
23:21	—	These bits are read as 0.	R
27:24	SCNT[3:0]	Stuff bit count These bits shows the stuff bit count (mod 8) for the CANFD frame.	R
31:28	—	These bits are read as 0.	R

Note: S-TYPE-3, P-TYPE-3

The CANFD CRC Register holds the CRC value calculated for the CANFD frame.

CRCREG[20:0] bits (CRC Register value)

The CRCREG[20:0] bits contain the CRC value calculated by the CANFD channel logic when the CFDC0CTR.CTME bit is enabled.

The CFDC0FDCRC.CRCREG value is updated in the first bit of the CRC field of the CANFD frame (reception and transmission).

When the CFDC0CTR.CTME bit is 0, the CRCREG[20:0] bits are always read as 0.

When bit 17th of the CRC field is used, CRCREG[20:17] are always read as 0.

These bits are cleared automatically when the related CANFD channel is in CH_RESET mode.

SCNT[3:0] bits (Stuff bit count)

The SCNT[3:0] bits contain the stuff count value of the CANFD frame. These bits indicate the number of inserted stuff bits (modulo 8, Graycoded) for a CANFD frame when the CFDC0CTR.CTME bit is enabled in CFDC0FDCRC.SCNT[3:1]. SCNT[0] is the parity bit.

When the CFDC0CTR.CTME bit is 0, the SCNT[3:0] bits are always read as 0.

The SCNT value is updated in the first bit of CRC field of the CANFD frame (reception and transmission).

These bits are cleared automatically when the related CANFD channel is in CH_RESET mode.

31.2.11 CFDGCFG : Global Configuration Register

Base address: CANFDn = 0x4038_0000 + 0x2000 × n (n = 0, 1)
CANFDn_NS = 0x5038_0000 + 0x2000 × n (n = 0, 1)

Offset address: 0x0014

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	ITRCP[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	TSSS	TSP[3:0]				—	—	CMPOC	DCS	MME	DRE	DCE	TPRI
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	TPRI	Transmission Priority 0: ID priority 1: Message buffer number priority	R/W
1	DCE	DLC Check Enable 0: DLC check disabled 1: DLC check enabled	R/W
2	DRE	DLC Replacement Enable 0: DLC replacement disabled 1: DLC replacement enabled	R/W
3	MME	Mirror Mode Enable 0: Mirror mode disabled 1: Mirror mode enabled	R/W
4	DCS	Data Link Controller Clock Select 0: CANFD core clock (CANFDCLK) 1: External oscillator clock (CANMCLK)	R/W
5	CMPOC*1	CANFD Message Payload Overflow Configuration 0: Message is rejected 1: Message payload is cut to fit to configured message size	R/W

Bit	Symbol	Function	R/W
11:8	TSP[3:0]	Timestamp Prescaler 0x0: Timestamp prescaler = 1 0x1: Timestamp prescaler = 2 0x2: Timestamp prescaler = 4 0x3: Timestamp prescaler = 8 ⋮ 0xD: Timestamp prescaler = 8192 0xE: Timestamp prescaler = 16384 0xF: Timestamp prescaler = 32768	R/W
12	TSSS	Timestamp Source Select 0: Source clock for timestamp counter is peripheral clock 1: Source clock for timestamp counter is bit time clock	R/W
15:13	—	These bits are read as 0. The write value should be 0.	R/W
31:16	ITRCP[15:0]	Interval Timer Reference Clock Prescaler FIFO interval timer prescaler value	R/W

Note: S-TYPE-3, P-TYPE-3
Note 1. This bit is not available in the classical CAN function.

The Global Configuration Register is used to select the transmission priority to be used for all the TX message buffers and the clock source for the CAN protocol engine of CAN channel. The CFDGCFG register is also used to select the source for the timestamp clock and to configure the frequency for the timestamp clock and interval timer reference clock.

TPRI bit (Transmission Priority)

The TPRI bit selects the transmission priority for CAN channel.

Do not write to this bit in GL_SLEEP mode. Only write to this bit when CANFD module is in GL_RESET mode.

Message buffer number priority should not be used together with TX queue transmission.

DCE bit (DLC Check Enable)

The DCE bit enables data length code (DLC) check for CAN channel.

Do not write to this bit in GL_SLEEP mode. Only write to this bit when CANFD module is in GL_RESET mode.

DRE bit (DLC Replacement Enable)

When the DRE bit is 1 and the DCE is 1, the CANFD stores the configured value (CFDGAFLP0r.GAFLDLC) of the DLC in the destination RX message buffer or FIFO buffer if the DLC check passes. Otherwise, the DLC value in the destination RX message buffer or FIFO buffer is unchanged.

Do not write to this bit in GL_SLEEP mode. Only write to this bit when CANFD module is in GL_RESET mode.

MME bit (Mirror Mode Enable)

The MME bit enables the Mirror mode for CAN channel.

Do not write to this bit in GL_SLEEP mode. Only write to this bit when CANFD module is in GL_RESET mode.

DCS bit (Data Link Controller Clock Select)

The DCS bit selects CANFDCLK or CANMCLK as the clock source for CAN communication.

Do not write to this bit in GL_SLEEP or GL_OPERATION mode. Only write to this bit when CANFD module is in GL_RESET mode.

CMPOC bit (CANFD Message Payload Overflow Configuration)

The CMPOC bit controls the message payload acceptance mechanism when the received payload is higher than the message buffer payload size CFDRMNB.RMPLS, CFDRFCCa.RFPLS, and CFDCFCC.CFPLS. The received message payload is always compared with the available message payload size in the message buffer.

Do not write to this bit in GL_SLEEP or GL_OPERATION mode. Only write to this bit when CANFD module is in GL_RESET mode.

When this bit is set and payload overflow occurs, the DLC value is stored in the RX message buffer or FIFO buffer unchanged.

Note: This bit is not available in the classical CAN function.

TSP[3:0] bits (Timestamp Prescaler)

The value configured in the TSP[3:0] bits defines the period of the clock source used for the timestamp counter.

Do not write to this bit in GL_SLEEP mode. Only write to this bit when CANFD module is in GL_RESET mode.

TSSS bit (Timestamp Source Select)

The TSSS bit allows the selection of the clock source for the timestamp counter.

Do not write to this bit in GL_SLEEP mode. Only write to this bit when CANFD module is in GL_RESET mode. Additionally, do not set this bit to 1 when CANFD communication is used.*1

Note: The bit time clock varies depending on the nominal and data rate bit configuration.

Note 1. This feature is not available in the classical CAN function.

ITRCP[15:0] bits (Interval Timer Reference Clock Prescaler)

The ITRCP[15:0] bits allow the definition of a reference clock for the FIFO interval timer source clock.

When these bits are 0x0000, the timer is disabled.

Do not write to this bit in GL_SLEEP mode. Only write to this bit when CANFD module is in GL_RESET mode.

31.2.12 CFDGCTR : Global Control Register

Base address: CANFDn = 0x4038_0000 + 0x2000 × n (n = 0, 1)
CANFDn_NS = 0x5038_0000 + 0x2000 × n (n = 0, 1)

Offset address: 0x0018

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	TSRST
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	CMPOFIE	THLEIE	MEIE	DEIE	—	—	—	—	—	GSLPR	GMDC[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0	1

Bit	Symbol	Function	R/W
1:0	GMDC[1:0]	Global Mode Control 0 0: Global operation mode request 0 1: Global reset mode request 1 0: Global halt mode request 1 1: Keep current value	R/W
2	GSLPR	Global Sleep Request 0: Global sleep request disabled 1: Global sleep request enabled	R/W
7:3	—	These bits are read as 0. The write value should be 0.	R/W
8	DEIE	DLC Check Interrupt Enable 0: DLC check interrupt disabled 1: DLC check interrupt enabled	R/W
9	MEIE	Message Lost Error Interrupt Enable 0: Message lost error interrupt disabled 1: Message lost error interrupt enabled	R/W
10	THLEIE	TX History List Entry Lost Interrupt Enable 0: TX history list entry lost interrupt disabled 1: TX history list entry lost interrupt enabled	R/W

Bit	Symbol	Function	R/W
11	CMPOFIE*1	CANFD Message Payload Overflow Flag Interrupt Enable 0: CANFD message payload overflow flag interrupt disabled 1: CANFD message payload overflow flag interrupt enabled	R/W
15:12	—	These bits are read as 0. The write value should be 0.	R/W
16	TSRST	Timestamp Reset 0: Timestamp not reset 1: Timestamp reset	R/W
31:17	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3
Note 1. This bit is not available in the classical CAN function.

The Global Control Register controls the global mode of the CANFD module and the timestamp function. The register also enables and disables the global error interrupts.

GMDC bits (Global Mode Control)

The GMDC bits can be used to configure the modes for the CANFD module. Additionally, if CFDGCTR.GSLPR bit is 1 when the CANFD module is in Reset mode, the CANFD module enters Global Sleep mode.

Setting the GMDC bits to 11b has no effect. Mode transition is described in detail in section 31.3.2. Global Modes.

Do not write to this bit when the CANFD module is in GL_SLEEP mode.

GSLPR bit (Global Sleep Request)

The GSLPR bit globally selects the sleep request for CANFD module including CAN channels. Channel sleep request is set automatically for channels.

Only write to this bit when the CANFD module is in GL_RESET or GL_SLEEP mode.

DEIE bit (DLC Check Interrupt Enable)

When the DEIE bit is 1, an interrupt is generated if a DLC error is detected in the received frames.

Do not write to this bit when the CANFD module is in GL_SLEEP mode.

MEIE bit (Message Lost Error Interrupt Enable)

When the MEIE bit is 1, an interrupt is generated if a message lost condition occurs.

Do not write to this bit when the CANFD module is in GL_SLEEP mode.

THLEIE bit (TX History List Entry Lost Interrupt Enable)

When the THLEIE bit is 1, an interrupt is generated if a TX history list entry lost condition occurs.

Do not write to this bit when the CANFD module is in GL_SLEEP mode.

CMPOFIE bit (CANFD Message Payload Overflow Flag Interrupt Enable)

When the CMPOFIE bit is 1, an interrupt is generated when a CANFD message payload overflow condition occurs.

Do not write to this bit when the CANFD module is in GL_SLEEP mode.

Note: This bit is not available in the classical CAN function

TSRST bit (Timestamp Reset)

When the TSRST bit is 1, the Global Timestamp Register is reset to 0x0000.

Do not write to this bit when the CANFD module is in GL_SLEEP or GL_RESET mode.

Read value is always 0.

This bit is cleared automatically by the CANFD module logic.

31.2.13 CFDGSTS : Global Status Register

Base address: CANFDn = 0x4038_0000 + 0x2000 × n (n = 0, 1)
CANFDn_NS = 0x5038_0000 + 0x2000 × n (n = 0, 1)

Offset address: 0x001C

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	GRAMINIT	GSLPSTS	GHLTSTS	GRSTSTS
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	1	1	0	1

Bit	Symbol	Function	R/W
0	GRSTSTS	Global Reset Status 0: Not in Reset mode 1: In Reset mode	R
1	GHLTSTS	Global Halt Status 0: Not in Halt mode 1: In Halt mode	R
2	GSLPSTS	Global Sleep Status 0: Not in Sleep mode 1: In Sleep mode	R
3	GRAMINIT	Global RAM Initialization 0: RAM initialization is complete 1: RAM initialization is ongoing	R
31:4	—	These bits are read as 0.	R

Note: S-TYPE-3, P-TYPE-3

The Global Status Register indicates the global status of the CANFD module.

GRSTSTS bit (Global Reset Status)

The GRSTSTS bit indicates the status of Global CANFD module Reset mode.

This bit is set automatically when the CANFD module enters GL_RESET mode. When the mode changes from GL_RESET mode to GL_SLEEP mode, this bit remains set.

This bit is cleared automatically when the CANFD module exits the GL_RESET mode.

GHLTSTS bit (Global Halt Status)

The GHLTSTS bit indicates the status of Global CANFD module Halt mode.

This bit is set automatically when the CANFD module enters GL_HALT mode.

This bit is cleared automatically when the CANFD module exits the GL_HALT mode.

GSLPSTS bit (Global Sleep Status)

The GSLPSTS bit indicates the status of Global CANFD module Sleep mode.

This bit is set automatically when the CANFD module enters GL_SLEEP mode.

This bit is cleared automatically when the CANFD module exits the GL_SLEEP mode.

GRAMINIT bit (Global RAM Initialization)

The GRAMINIT bit indicates the status of Global CANFD module RAM initialization.

This bit is set automatically when the CANFD module enters GL_SLEEP mode after a hardware reset.

This bit is cleared automatically when the CANFD module completed RAM initialization.

This bit is cleared when the test_mode input port is set to 1.

31.2.14 CFDGERFL : Global Error Flag Register

Base address: CANFDn = 0x4038_0000 + 0x2000 × n (n = 0, 1)
CANFDn_NS = 0x5038_0000 + 0x2000 × n (n = 0, 1)

Offset address: 0x0020

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—		EEF0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	CMPOF	THLES	MES	DEF
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	DEF	DLC Error Flag 0: DLC error not detected 1: DLC error detected	R/W
1	MES	Message Lost Error Status 0: Message lost error not detected 1: Message lost error detected	R
2	THLES	TX History List Entry Lost Error Status 0: TX history list entry lost error not detected 1: TX history list entry lost error detected	R
3	CMPOF*1	CANFD Message Payload Overflow Flag 0: CANFD message payload overflow not detected 1: CANFD message payload overflow detected	R/W
15:4	—	These bits are read as 0. The write value should be 0.	R/W
16	EEF0	ECC Error Flag 0: ECC error not detected during TX-SCAN 1: ECC error detected during TX-SCAN	R/W
31:17	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3
Note 1. This bit is not available in the classical CAN function.

The Global Error Flag register indicates the detection of global errors.

DEF bit (DLC Error Flag)

The DEF bit indicates the error status of the DLC.

Do not write to this bit when the CANFD module is in GL_SLEEP or GL_RESET mode. Writing 1 has no effect.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1.

This bit is set automatically when a DLC error is detected in a received frame.

If the set from the CAN channel occurs simultaneously with the clear by the write access, then the bit is set

The bit is cleared by writing 0 to it.

This bit is cleared automatically in GL_RESET mode.

MES bit (Message Lost Error Status)

The MES bit indicates status of the message lost error.

This bit is set automatically when a FIFO message lost error is detected.

This bit is cleared automatically when:

- All FIFO message lost flags are cleared
- The CANFD module is in GL_RESET mode.

THLES bit (TX History List Entry Lost Error Status)

The THLES bit indicates status of the TX history list entry lost error.

This bit is set automatically when a TX history list entry lost error is detected.

This bit is cleared automatically when:

- All TX history list entry lost flags are cleared
- The CANFD module is in GL_RESET mode.

CMPOF bit (CANFD Message Payload Overflow Flag)

The CMPOF bit is set automatically when a CANFD message payload overflow is detected on at least one channel.

Do not write to this bit when the CANFD module is in GL_SLEEP or GL_RESET mode.

This bit is cleared by writing 0 to it. Writing 1 to this bit has no effect.

If the set from the CAN channel occurs simultaneously with the clear by the write access, then the bit is set.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1.

This bit is cleared automatically in GL_RESET mode.

Note: This bit is not available in the classical CAN function

EEF0 bit (ECC Error Flag)

The EEF0 bit specifies whether an ECC error has occurred.

Do not write to this bit when the CANFD module is in GL_SLEEP or GL_RESET mode. Writing 1 to this bit has no effect.

If the set from the CAN channel occurs simultaneously with the clear by the write access, then the bit is set.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1.

The bit is cleared by writing 0 to it. This bit is cleared automatically in GL_RESET mode.

31.2.15 CFDGTINTSTS : Global TX Interrupt Status Register

Base address: CANFDn = 0x4038_0000 + 0x2000 × n (n = 0, 1)
CANFDn_NS = 0x5038_0000 + 0x2000 × n (n = 0, 1)

Offset address: 0x00A4

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	THIF0	CFTIF0	TQIF0	TAI0	TSIF0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	TSIF0	TX Successful Interrupt Flag 0: Channel n TX Successful Interrupt flag not set 1: Channel n TX Successful Interrupt flag set	R
1	TAI0	TX Abort Interrupt Flag 0: Channel n TX Abort Interrupt flag not set 1: Channel n TX Abort Interrupt flag set	R

Bit	Symbol	Function	R/W
2	TQIF0	TX Queue Interrupt Flag 0: Channel n TX Queue Interrupt flag not set 1: Channel n TX Queue Interrupt flag set	R
3	CFTIF0	COM FIFO TX Mode Interrupt Flag 0: Channel n COM FIFO TX Mode Interrupt flag not set 1: Channel n COM FIFO TX Mode Interrupt flag set	R
4	THIF0	TX History List Interrupt 0: Channel n TX History List Interrupt flag not set 1: Channel n TX History List Interrupt flag set	R
31:5	—	These bits are read as 0.	R

Note: S-TYPE-3, P-TYPE-3

The Global TX Interrupt Status register indicates the detection of transmit specific interrupts.

TSIF0 bit (TX Successful Interrupt Flag)

The TSIF0 bit is set to 1 when the TX Successful Interrupt flag of the related channel is set (when the interrupt is enabled). This bit is cleared automatically:

- When the related TX MB Result Status bits are cleared (when the interrupt enable is disabled)
- When in GL_RESET or CH_RESET mode.

TAI0 bit (TX Abort Interrupt Flag)

The TAIF0 bit is set to 1 when the TX Abort Interrupt flag of the related channel is set (when the interrupt is enabled).

This bit is cleared automatically:

- When the related TX MB Result Status bits are cleared (when the interrupt enable is disabled)
- When in GL_RESET or CH_RESET mode.

TQIF0 bit (TX Queue Interrupt Flag)

The TQIF0 bit is set to 1 when the TX Queue Interrupt flag of the related channel is set (when the interrupt is enabled). This bit is cleared automatically:

- When the related TX Queue Interrupt flag is cleared (when the interrupt is enable disabled)
- When in GL_RESET or CH_RESET mode.

CFTIF0 bit (COM FIFO TX Mode Interrupt Flag)

The CFTIF0 bit is set to 1 when the related COM TX FIFO Mode Interrupt flag (CFDCFSTS.CFTXIF) is set (when the interrupt is enabled).

This bit is cleared automatically:

- When the related COM TX FIFO Mode Interrupt flag (CFDCFSTS.CFTXIF) is cleared (when the interrupt enable is disabled)
- When in GL_RESET or CH_RESET mode.

THIF0 bit (TX History List Interrupt)

The THIF0 bit is set to 1 when the related TX History List Interrupt flag (CFDTHLSTS.THLIF) is set (when the interrupt is enabled).

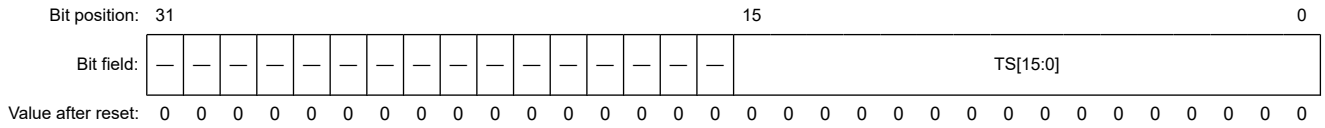
This bit is cleared automatically:

- When the related TX History List Interrupt flag (CFDTHLSTS.THLIF) is cleared (when the interrupt enable is disabled)
- When in GL_RESET or CH_RESET mode.

31.2.16 CFDGTSC : Global Timestamp Counter Register

Base address: CANFDn = 0x4038_0000 + 0x2000 × n (n = 0, 1)
CANFDn_NS = 0x5038_0000 + 0x2000 × n (n = 0, 1)

Offset address: 0x0024



Bit	Symbol	Function	R/W
15:0	TS[15:0]	Timestamp value	R
31:16	—	These bits are read as 0.	R

Note: S-TYPE-3, P-TYPE-3

The Global Timestamp Counter register stores the timestamp based on the selected configuration.

TS[15:0] bits (Timestamp value)

The Timestamp value is stored in the Global Timestamp Counter register based on the configuration of TSSS, TSBTCS and TSP. The accuracy of the timestamp counter cannot be guaranteed when transitioning to halt state.

The Timestamp value is stored in this register based on the configuration of TSSS, TSBTCS and TSP.

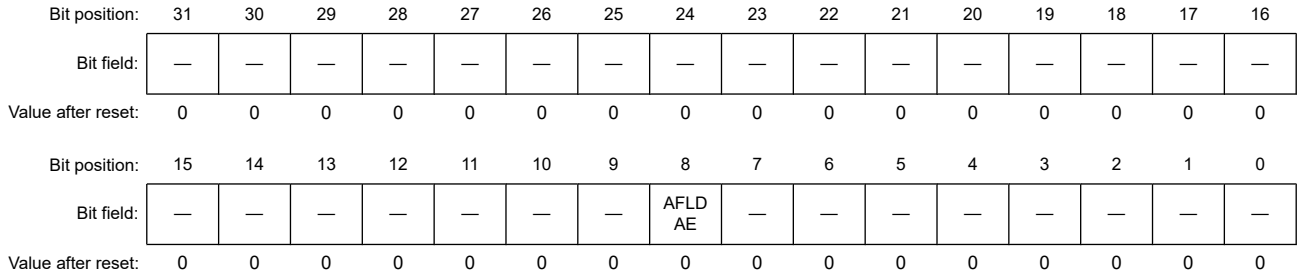
Do not write to bits TS[15:0] when the CANFD module is in GL_RESET or GL_SLEEP mode.

The TS[15:0] bits are cleared automatically in GL_RESET mode.

31.2.17 CFDGAFLECTR : Global Acceptance Filter List Entry Control Register

Base address: CANFDn = 0x4038_0000 + 0x2000 × n (n = 0, 1)
CANFDn_NS = 0x5038_0000 + 0x2000 × n (n = 0, 1)

Offset address: 0x0028



Bit	Symbol	Function	R/W
7:0	—	These bits are read as 0. The write value should be 0.	R/W
8	AFLDAE	Acceptance Filter List Data Access Enable 0: Acceptance Filter List data access disabled 1: Acceptance Filter List data access enabled	R/W
31:9	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

The Global Acceptance Filter List Entry Control Register is used to select the Global Acceptance Filter List page for reading or writing entries into the Global Acceptance Filter List.

AFLDAE bit (Acceptance Filter List Data Access Enable)

The AFLDAE bit prevents write access to the Acceptance Filter List when cleared after configuration of the Acceptance Filter List.

Data can be read from the Acceptance Filter List independent of the status of this bit.

Do not write to this bit when the CANFD module is in GL_SLEEP mode. Set this bit to enable write access for the Acceptance Filter List.

31.2.18 CFDGAFLCFG : Global Acceptance Filter List Configuration Register

Base address: CANFDn = 0x4038_0000 + 0x2000 × n (n = 0, 1)
CANFDn_NS = 0x5038_0000 + 0x2000 × n (n = 0, 1)

Offset address: 0x002C

Bit position:	31											20			16														0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	RNC0[4:0]				—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	—	These bits are read as 0. The write value should be 0.	R/W
20:16	RNC0[4:0]	Rule Number Number of rules dedicated	R/W
31:21	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

The Global Acceptance Filter List Configuration Register is used to define the number of rules for entries in the Acceptance Filter List.

The total number of available entries in the Acceptance Filter List is 16.

RNC0[4:0] bits (Rule Number)

The RNC0[4:0] bits define the number of rules in the Acceptance Filter List.

Only write to these bits when the CANFD module is in GL_RESET mode. These bits can set to 5 bits for 16 rules.

31.2.19 CFDGAFLIDr : Global Acceptance Filter List ID Registers (r = 1 to 16)

Base address: CANFDn = 0x4038_0000 + 0x2000 × n (n = 0, 1)
CANFDn_NS = 0x5038_0000 + 0x2000 × n (n = 0, 1)

Offset address: 0x0120 + 0x0010 × (r - 1)

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	GAFLIDE	GAFLRTR	GAFLLB	GAFLID[28:16]												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	GAFLID[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
28:0	GAFLID[28:0]	Global Acceptance Filter List Entry ID Field ID part of the Global Acceptance Filter List entry	R/W
29	GAFLLB	Global Acceptance Filter List Entry Loopback Configuration 0: Global Acceptance Filter List entry ID for acceptance filtering with attribute RX 1: Global Acceptance Filter List entry ID for acceptance filtering with attribute TX	R/W
30	GAFLRTR	Global Acceptance Filter List Entry RTR Field 0: Data frame 1: Remote frame	R/W

Bit	Symbol	Function	R/W
31	GAFLIDE	Global Acceptance Filter List Entry IDE Field 0: Standard identifier of rule entry ID is valid for acceptance filtering 1: Extended identifier of rule entry ID is valid for acceptance filtering	R/W

Note: S-TYPE-3, P-TYPE-3

The Global Acceptance Filter List ID Registers are used to configure the ID field for the rules of entries in the Global Acceptance Filter List.

GAFLID[28:0] bits (Global Acceptance Filter List Entry ID Field)

The GAFLID[28:0] bits represent the CAN identifier (ID) field of each entry in the Global Acceptance Filter List.

Do not write to these bits when CFDGAFLECTR.AFLDAE bit is 0.

Only write to these bits when the related CANFD channel is in CH_RESET or CH_HALT mode.

GAFLLB bit (Global Acceptance Filter List Entry Loopback Configuration)

The GAFLLB bit selects whether entry in the Global Acceptance Filter List gets the attribute RX or TX.

This attribute determines the validity of the entry in Mirror mode, Loopback test mode, and during standard (non-loopback) reception. See section 31.5.5. Loopback Modes for detailed description of the validity of the Global Acceptance Filter List entry depending on transmitter/receiver case, the type of loopback mode, and RX/TX attribute.

Do not write to this bit when CFDGAFLECTR.AFLDAE bit is 0.

Only write to this bit when the related CANFD channel is in CH_RESET or CH_HALT mode.

GAFLRTR bit (Global Acceptance Filter List Entry RTR Field)

The GAFLRTR bit allows the configuration of the specified frame format (data frame or remote frame) for each entry of the Global Acceptance Filter List. For each rule entry in a CAN channel, the acceptance filter process compares this bit against the RTR bit of the received CAN message.

Do not write to this bit when CFDGAFLECTR.AFLDAE bit is 0.

Only write to this bit when the related CANFD channel is in CH_RESET or CH_HALT mode.

GAFLIDE bit (Global Acceptance Filter List Entry IDE Field)

The GAFLIDE bit allows the configuration of the ID format (standard ID or extended ID) for each entry in the Global Acceptance Filter List. For each rule entry in a CAN channel, the acceptance filter process compares this bit against the IDE bit of the received CAN message.

Do not write to this bit when CFDGAFLECTR.AFLDAE bit is 0.

Only write to this bit when the related CANFD channel is in CH_RESET or CH_HALT mode.

31.2.20 CFDGAFLMr : Global Acceptance Filter List Mask Registers (r = 1 to 16)

Base address: CANFDn = 0x4038_0000 + 0x2000 × n (n = 0, 1)
CANFDn_NS = 0x5038_0000 + 0x2000 × n (n = 0, 1)

Offset address: 0x0124 + 0x0010 × (r - 1)

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	GAFLIDEM	GAFLRTRM	GAFLIFL1	GAFLIDM[28:16]												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	GAFLIDM[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
28:0	GAFLIDM[28:0]	Global Acceptance Filter List ID Mask Field Global Acceptance Filter List Mask field bits for ID field	R/W
29	GAFLIFL1	Global Acceptance Filter List Information Label 1 Global Acceptance Filter List information label bit 1	R/W
30	GAFLRTRM	Global Acceptance Filter List Entry RTR Mask 0: RTR bit is not used for ID matching 1: RTR bit is used for ID matching	R/W
31	GAFLIDEM	Global Acceptance Filter List IDE Mask 0: IDE bit is not used for ID matching 1: IDE bit is used for ID matching	R/W

Note: S-TYPE-3, P-TYPE-3

The Global Acceptance Filter List Mask Registers are used to configure the Mask field of each rule for entries in the Global Acceptance Filter List.

GAFLIDM[28:0] bits (Global Acceptance Filter List ID Mask Field)

GAFLIDM[28:0] bits are the filter mask bits for the related bits in the CAN Identifier field of each Global Acceptance Filter List entry.

0	Corresponding STD-ID/EXT-ID bit is not used for ID matching
1	Corresponding STD-ID/EXT-ID bit is used for ID matching

Do not write to these bits when CFDGAFLECTR.AFLDAE bit is 0.

Only write to these bits when the related CANFD channel is in CH_RESET or CH_HALT mode.

GAFLIFL1 bit (Global Acceptance Filter List Information Label 1)

The GAFLIFL1 bit allows the configuration of a 2-bit information label to be attached to a received message accepted by the associated entry in the Global Acceptance Filter List. This bit is a MSB bit of an information label.

Do not write to this bit when CFDGAFLECTR.AFLDAE bit is 0.

Only write to this bit when the related CANFD channel is in CH_RESET or CH_HALT mode.

This bit is stored in the Information Label Field [1] (CFDRMFDSTSb.RMIFL [1], CFDRFFDSTSb.RFIFL [1], CFDCFFDCSTS.CFIFL [1]) of the storage location of an incoming message.

GAFLRTRM bit (Global Acceptance Filter List Entry RTR Mask)

The GAFLRTRM bit allows the configuration of the RTR mask bit for each entry in the Global Acceptance Filter List.

Do not write to this bit when CFDGAFLECTR.AFLDAE bit is 0.

Only write to this bit when the related CANFD channel is in CH_RESET or CH_HALT mode.

GAFLIDEM bit (Global Acceptance Filter List IDE Mask)

The GAFLIDEM bit allows the configuration of the IDE mask bit for each entry in the Global Acceptance Filter List.

When the IDE mask bit is 0, the ID comparison depends on the received IDE bit.

If the received IDE bit is 0, the STD-ID comparison takes place.

If the received IDE bit is 1, the EXT-ID comparison takes place.

Do not write to this bit when CFDGAFLECTR.AFLDAE bit is 0.

Only write to this bit when the related CANFD channel is in CH_RESET or CH_HALT mode.

31.2.21 CFDGAFLP0r : Global Acceptance Filter List Pointer 0 Registers (r = 1 to 16)

Base address: CANFDn = 0x4038_0000 + 0x2000 × n (n = 0, 1)
CANFDn_NS = 0x5038_0000 + 0x2000 × n (n = 0, 1)

Offset address: 0x0128 + 0x0010 × (r - 1)

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	GAFLPTR[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	GAFLRMV	—	—	GAFLRMDP[4:0]					GAFLIFL0	—	—	—	GAFLDLC[3:0]			
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
3:0	GAFLDLC[3:0]	Global Acceptance Filter List DLC Field Minimum number of data bytes in a data frame required for acceptance	R/W
6:4	—	These bits are read as 0. The write value should be 0.	R/W
7	GAFLIFL0	Global Acceptance Filter List Information Label 0	R/W
12:8	GAFLRMDP[4:0]	Global Acceptance Filter List RX Message Buffer Direction Pointer RX message buffer number for storage of received messages	R/W
14:13	—	These bits are read as 0. The write value should be 0.	R/W
15	GAFLRMV	Global Acceptance Filter List RX Message Buffer Valid 0: Single message buffer direction pointer is invalid 1: Single message buffer direction pointer is valid	R/W
31:16	GAFLPTR[15:0]	Global Acceptance Filter List Pointer	R/W

Note: S-TYPE-3, P-TYPE-3

The Global Acceptance Filter List Pointer 0 Registers are used to configure the data length code (DLC), software pointer, single message buffer select, and message buffer direction pointer for each rule entry in the Global Acceptance Filter List.

GAFLDLC[3:0] bits (Global Acceptance Filter List DLC Field)

The GAFLDLC[3:0] bits allow the configuration of a minimum data length code (DLC) value for a message to be accepted by the associated entry in the Global Acceptance Filter List (automatic DLC filter function).

DLC filter process is only passed if the DLC value of the message accepted by an entry in the Global Acceptance Filter List is equal to or higher than the DLC value configured for this associated Global Acceptance Filter List entry. Automatic DLC filter function is disabled for the corresponding rule entry when this field is set to 0.

Table 31.3 shows DLC value that can be configured.

Table 31.3 Configuration of DLC value (1 of 2)

Format	DLC[3]	DLC[2]	DLC[1]	DLC[0]	Description
CAN and CANFD	0	0	0	0	DLC of received message = 0 or more (DLC filter check is disabled)
CAN and CANFD	0	0	0	1	DLC of received message = 1 or more
CAN and CANFD	0	0	1	0	DLC of received message = 2 or more
CAN and CANFD	0	0	1	1	DLC of received message = 3 or more
CAN and CANFD	0	1	0	0	DLC of received message = 4 or more
CAN and CANFD	0	1	0	1	DLC of received message = 5 or more

Table 31.3 Configuration of DLC value (2 of 2)

Format	DLC[3]	DLC[2]	DLC[1]	DLC[0]	Description
CAN and CANFD	0	1	1	0	DLC of received message = 6 or more
CAN and CANFD	0	1	1	1	DLC of received message = 7 or more
CAN	1	x	x	x	DLC of received message = 8 or more
CANFD	1	0	0	0	DLC of received message = 8 or more*1
CANFD	1	0	0	1	DLC of received message = 12 or more*1
CANFD	1	0	1	0	DLC of received message = 16 or more*1
CANFD	1	0	1	1	DLC of received message = 20 or more*1
CANFD	1	1	0	0	DLC of received message = 24 or more*1
CANFD	1	1	0	1	DLC of received message = 32 or more*1
CANFD	1	1	1	0	DLC of received message = 48 or more*1
CANFD	1	1	1	1	DLC of received message = 64*1

Note 1. This setting is not available in the classical CAN function.

Do not write to these bits when CFDGAFLECTR.AFLDAE bit is 0.

Only write to these bits when the related CANFD channel is in CH_RESET or CH_HALT mode.

GAFLIFL0 bit (Global Acceptance Filter List Information Label 0)

The GAFLIFL0 bit allows the configuration of a 2-bit information label that can be attached to a received message accepted by the related Global Acceptance Filter List entry. This bit is a LSB bit of an information label.

You cannot write to this bit when CFDGAFLECTR.AFLDAE bit is 0.

Only write to the bit when the related CANFD channel is in CH_RESET or CH_HALT mode.

This bit is stored in Information Label Field[0] (CFDRMFDSTSb.RMIFL[0], CFDRFFDSTSb.RFIFL[0], CFDCFFDCSTS.CFIFL[0]) of the storage location of an incoming message.

GAFLRMDP[4:0] bits (Global Acceptance Filter List RX Message Buffer Direction Pointer)

The GAFLRMDP[4:0] bits allow the configuration of a single reception message buffer as the destination target for a received message that passes the acceptance check of the related Global Acceptance Filter List entry. The value entered is the single destination message buffer number.

Do not write to these bits when CFDGAFLECTR.AFLDAE bit is 0.

Only write to these bits when the related CANFD channel is in CH_RESET or CH_HALT mode.

CFDRMNB.NRXMB[4:0] is the value entered in the RX Message Buffer Number Register to configure the number of RX message buffers. The value to be entered in CFDGAFLP0r.GAFLRMDP[4:0] bits should only be between 0x00 and CFDMNB.NMB[4:0] to 1 less.

If CFDRMNB.NRXMB[4:0] = 0x00, the GAFLRMV bit should be configured as 0.

GAFLRMV bit (Global Acceptance Filter List RX Message Buffer Valid)

The GAFLRMV bit allows the enabling or disabling of a single reception message buffer as the target for a received message that passes the acceptance check of the related Global Acceptance Filter List entry.

Do not write to these bits when CFDGAFLECTR.AFLDAE bit is 0.

Only write to these bits when the related CANFD channel is in CH_RESET or CH_HALT mode.

GAFLPTR[15:0] bits (Global Acceptance Filter List Pointer)

The GAFLPTR[15:0] bits allow the configuration of a 16-bit pointer to be attached to a received message accepted by the related Global Acceptance Filter List entry. The pointer is added during message storage in the Message Buffer area and can be used by the application as a support function. The pointer information can be used for example, to support PDU Identifier allocation for the received message in AUTOSAR systems.

Do not write to these bits when CFDGAFLECTR.AFLDAE bit is 0.

Only write to these bits when the related CANFD channel is in CH_RESET or CH_HALT mode.

31.2.22 CFDGAFLP1r : Global Acceptance Filter List Pointer 1 Registers (r = 1 to 16)

Base address: CANFDn = 0x4038_0000 + 0x2000 × n (n = 0, 1)
CANFDn_NS = 0x5038_0000 + 0x2000 × n (n = 0, 1)

Offset address: 0x012C + 0x0010 × (r - 1)

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	GAFL FDP8	—	—	—	—	—	—	GAFL FDP1	GAFL FDP0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	GAFLFDP0	Global Acceptance Filter List FIFO Direction Pointer FIFO direction pointer bits for received message storage 0: Disable RX FIFO 0 as target for reception 1: Enable RX FIFO 0 as target for reception	R/W
1	GAFLFDP1	Global Acceptance Filter List FIFO Direction Pointer FIFO direction pointer bits for received message storage 0: Disable RX FIFO 1 as target for reception 1: Enable RX FIFO 1 as target for reception	R/W
7:2	—	These bits are read as 0. The write value should be 0.	R/W
8	GAFLFDP8	Global Acceptance Filter List FIFO Direction Pointer FIFO direction pointer bits for received message storage 0: Disable Common FIFO as target for reception 1: Enable Common FIFO as target for reception	R/W
31:9	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

The Global Acceptance Filter List Pointer 1 registers are used to configure the FIFO direction pointer fields in each Rule Entry of the Global Acceptance Filter List.

GAFLFDP8, GAFLFDP1, GAFLFDP0 bits (Global Acceptance Filter List FIFO Direction Pointer)

These bits allow the configuration of FIFO Buffers as the target for a received message passing the acceptance check of the related Global Acceptance Filter List entry. Each bit of the GAFLFDP8, GAFLFDP1, GAFLFDP0 is configuring a dedicated FIFO.

Users cannot write to these bits when CFDGAFLECTR.AFLDAE bit is 0.

For storage in Common FIFO, target for reception can only be those Common FIFO Buffers that are configured as RX FIFO.

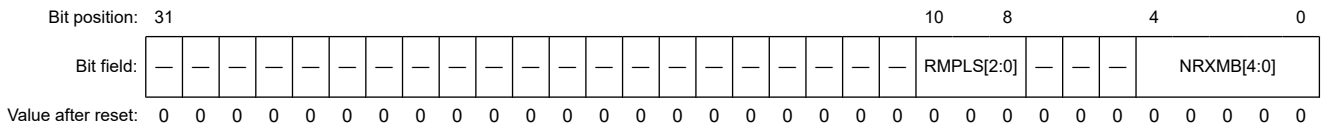
Only write to these bits when the related CANFD channel is in CH_RESET or CH_HALT mode.

Users should only configure up to 2 destination FIFO Buffers or 1 destination FIFO Buffers plus one RX Message Buffer.

31.2.23 CFDRMNB : RX Message Buffer Number Register

Base address: CANFDn = 0x4038_0000 + 0x2000 × n (n = 0, 1)
CANFDn_NS = 0x5038_0000 + 0x2000 × n (n = 0, 1)

Offset address: 0x0030



Bit	Symbol	Function	R/W
4:0	NRXMB[4:0]	Number of RX Message Buffers	R/W
7:5	—	These bits are read as 0. The write value should be 0.	R/W
10:8	RMPLS[2:0]	Reception Message Buffer Payload Data Size 0 0 0: 8 bytes 0 0 1: 12 bytes 0 1 0: 16 bytes 0 1 1: 20 bytes 1 0 0: 24 bytes 1 0 1: 32 bytes 1 1 0: 48 bytes 1 1 1: 64 bytes	R/W
31:11	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

The RX Message Buffer Number register is used to configure the total number of RX message buffers allocated to channels.

NRXMB[4:0] bits (Number of RX Message Buffers)

The NRXMB[4:0] bits are used to configure the number of RX message buffers.

Only write to these bits when the CANFD module is in GL_RESET mode.

Enter only values between 0 and 16 inclusive, with 0x00 indicating that no RX message buffer is allocated.

RMPLS[2:0] bits (Reception Message Buffer Payload Data Size)

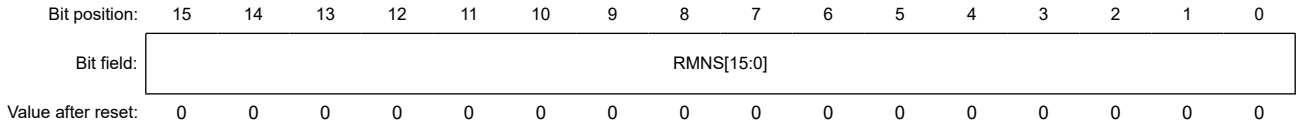
The RMPLS[2:0] bits are used to configure the message buffer payload data size.

Only write to these bits when the CANFD module is in GL_RESET mode.

31.2.24 CFDRMND : RX Message Buffer New Data Register

Base address: CANFDn = 0x4038_0000 + 0x2000 × n (n = 0, 1)
CANFDn_NS = 0x5038_0000 + 0x2000 × n (n = 0, 1)

Offset address: 0x0034



Bit	Symbol	Function	R/W
15:0	RMNS[15:0]	RX Message Buffer New Data Status 0: New data not stored in corresponding RX message buffer 1: New data stored in corresponding RX message buffer	R/W

Note: S-TYPE-3, P-TYPE-3

The RX Message Buffer New Data Status Register specifies the new data storage status of the RX message buffers.

RMNS[15:0] bits (RX Message Buffer New Data Status)

The RMNS[15:0] bits indicate the status of new data for the corresponding RX message buffer. RMNS bit [0] corresponds to RX message buffer [0] and so on.

The bit position of CFDRMND corresponds to the buffer number of RXMB.

Do not write to these bits when the CANFD module is in GL_RESET or GL_SLEEP mode. Writing 1 has no effect.

These bits cannot be cleared when message storage in the corresponding RX message buffer is in progress.
Do not use the bit clear instruction to clear these bits. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1.

These bits are set automatically when storage of new messages are in the corresponding RX message buffer. These bits are cleared by writing 0. These bits are cleared automatically when the CANFD module is in GL_RESET mode.

When CFDRMNB.RMPLS = 000b (maximum 8 bytes payload), the duration of message storage is 6 PCLKA cycles.

When CFDRMNB.RMPLS > 000b, the duration of message storage is 6 PCLKA cycles + 1 for each 4 bytes (maximum of 20 PCLKA cycles for 64 bytes).

Note: This feature is not available in the classical CAN function.

31.2.25 CFDRFCCa : RX FIFO Configuration/Control Registers a (a = 0 to 1)

Base address: CANFDn = 0x4038_0000 + 0x2000 × n (n = 0, 1)
CANFDn_NS = 0x5038_0000 + 0x2000 × n (n = 0, 1)

Offset address: 0x003C + 0x04 × a

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

31:16	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3
Note 1. These bits are not available in the classical CAN function.

The RX FIFO Configuration/Control Registers are used to configure and control the two RX FIFOs.

RFE bit (RX FIFO Enable)

The RFE bit enables the FIFO. When this bit is set to 0, the RX FIFO is cleared to empty.

Only write to this bit when the CANFD module is in GL_HALT or GL_OPERATION mode.

This bit can only be set if the configured FIFO depth is greater than 0x000 (CFDRFCCa.RFDC > 0x000) and less than 0x110.

Set the RFE bit with a separate write access to the CFDRFCCa register, after all the other bits in the CFDRFCCa register are set.

This bit is cleared automatically when the CANFD module is in GL_RESET mode.

RFIE bit (RX FIFO Interrupt Enable)

The RFIE bit enables generation of the FIFO interrupt.

Do not write to this bit when the CANFD module is in GL_SLEEP mode.

RFPLS[2:0] bits (Rx FIFO Payload Data Size Configuration)

The RFPLS[2:0] bits define the message data payload allocation in the RAM.

This is the maximum number of bytes which can be received by this FIFO.

Only write to these bits when the CANFD module is in GL_RESET mode.

Note: These bits are not available in the classical CAN function.

RFDC[2:0] bits (RX FIFO Depth Configuration)

The RFDC[2:0] bits select the depth of the FIFO in terms of the number of messages. If the FIFO depth is configured to 0 messages, the FIFO cannot be used.

Only write to these bits when the CANFD module is in GL_RESET mode.

RFIM bit (RX FIFO Interrupt Mode)

The RFIM bit selects the interrupt generation condition for the FIFO.

Do not write to this bit when the CANFD module is in GL_SLEEP mode.

Only write to this bit when the CANFD module is in GL_RESET mode.

RFIGCV[2:0] bits (RX FIFO Interrupt Generation Counter Value)

The RFIGCV[2:0] bits select the counter value of the FIFO for generation of FIFO interrupts. These values represent fractions of the FIFO depth for which an interrupt is generated.

Do not write to these bits when the CANFD module is in GL_SLEEP mode.

The setting of the RFIGCV[2:0] bits should be synchronized with the RFDC[2:0] bits.

Only write to these bits when the CANFD module is in GL_RESET mode.

31.2.26 CFDRFSTSa : RX FIFO Status Registers a (a = 0 to 1)

Base address: CANFDn = 0x4038_0000 + 0x2000 × n (n = 0, 1)
CANFDn_NS = 0x5038_0000 + 0x2000 × n (n = 0, 1)

Offset address: 0x0044 + 0x04 × a

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	RFMC[5:0]						—	—	—	—	RFIF	RFMLT	RFFLL	RFEMP
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

Bit	Symbol	Function	R/W
0	RFEMP	RX FIFO Empty 0: FIFO not empty 1: FIFO empty	R
1	RFFLL	RX FIFO Full 0: FIFO not full 1: FIFO full	R
2	RFMLT	RX FIFO Message Lost 0: No message lost in FIFO 1: FIFO message lost	R/W
3	RFIF	RX FIFO Interrupt Flag 0: FIFO interrupt condition not satisfied 1: FIFO interrupt condition satisfied	R/W
7:4	—	These bits are read as 0. The write value should be 0.	R/W
13:8	RFMC[5:0]	RX FIFO Message Count Number of messages stored in FIFO	R
31:14	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

The RX FIFO Status Registers show the status of messages stored in the corresponding FIFO buffers.

RFEMP bit (RX FIFO Empty)

The RFEMP bit is set automatically when:

- The RFMC bit is 0
- RX FIFO is disabled by setting the CFDRFCCa.RFE bit to 0
- The CANFD module is in GL_RESET mode.

The RFEMP bit is cleared automatically when the first message is stored in the RX FIFO buffer.

RFFLL bit (RX FIFO Full)

The RFFLL bit is set automatically when the number of CAN messages stored in the FIFO buffer matches the configured FIFO depth.

The RFFLL is cleared automatically when:

- The number of CAN messages stored in the FIFO buffer is less than the configured FIFO depth
- RX FIFO is disabled by setting the CFDRFCCa.RFE bit to 0
- The CANFD module is in GL_RESET mode.

RFMLT bit (RX FIFO Message Lost)

Only write to the RFMLT bit when CANFD module is in GL_HALT or GL_OPERATION mode. Writing 1 has no effect.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1.

This bit is set automatically whenever a message is lost due to attempted storage when the FIFO buffer is already full. If a set from the CAN channel occurs simultaneously with a clear by a write access, then the bit is set.

The bit is cleared:

- By writing 0 to it
- When the CANFD module is in GL_RESET mode.

RFIF bit (RX FIFO Interrupt Flag)

The RFIF bit is set automatically when the configured interrupt condition is satisfied. This bit is not automatically cleared when the RX FIFO buffer is disabled.

Only write to this bit when the CANFD module is in GL_HALT or GL_OPERATION mode. Writing 1 has no effect.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1.

If a set from the CAN channel occurs simultaneously with a clear by a write access, then this bit is set.

The bit is cleared by writing 0 to it. The bit is also cleared when CANFD module is in GL_RESET mode.

RFMC[5:0] bits (RX FIFO Message Count)

The RFMC[5:0] bits indicate the number of CAN messages stored in the RX FIFO buffer that can be read by the CPU.

These bits are cleared automatically when the FIFO is disabled and when the CANFD module is in GL_RESET mode.

31.2.27 CFDRFPCTRa : RX FIFO Pointer Control Registers a (a = 0 to 1)

Base address: CANFDn = 0x4038_0000 + 0x2000 × n (n = 0, 1)
CANFDn_NS = 0x5038_0000 + 0x2000 × n (n = 0, 1)

Offset address: 0x004C + 0x04 × a

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	RFPC[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	RFPC[7:0]	RX FIFO Pointer Control Increments read pointer of the corresponding RX FIFO buffers	W
31:8	—	The write value should be 0.	W

Note: S-TYPE-3, P-TYPE-3

The RX FIFO Pointer Control Registers can be used to increment the read pointer of the corresponding RX FIFO buffers.

RFPC bits (RX FIFO Pointer Control)

When the value 0xFF is written to the RFPC bits, the pointer of the corresponding RX FIFO buffer is moved to the next FIFO entry. Only write 0xFF to these registers when the corresponding RX FIFO buffer is enabled and not empty.

The read value from these bits is always 0x00.

Only write to these bits when the CANFD module is in GL_HALT or GL_OPERATION mode.

Do not write to the RX FIFO Pointer Control registers when DMA is enabled.

31.2.28 CFDCFCC : Common FIFO Configuration/Control Register

Base address: CANFDn = 0x4038_0000 + 0x2000 × n (n = 0, 1)
CANFDn_NS = 0x5038_0000 + 0x2000 × n (n = 0, 1)

Offset address: 0x0054

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	CFITT[7:0]								CFDC[2:0]			—	—	—	CFTML[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

17:16	CFTML[1:0]	Common FIFO TX Message Buffer Link Transmission scan link position of the corresponding channel	R/W
20:18	—	These bits are read as 0. The write value should be 0.	R/W
23:21	CFDC[2:0]	Common FIFO Depth Configuration 0 0 0: FIFO Depth = 0 message 0 0 1: FIFO Depth = 4 messages 0 1 0: FIFO Depth = 8 messages 0 1 1: FIFO Depth = 16 messages 1 0 0: FIFO Depth = 32 messages 1 0 1: FIFO Depth = 48 messages 1 1 0: FIFO Depth = Reserved 1 1 1: FIFO Depth = Reserved	R/W
31:24	CFITT[7:0]	Common FIFO Interval Transmission Time Delay the start of transmission from the FIFO if configured in TX mode, delay is a multiple of basic Interval Timer Clock Source unit	R/W

Note: S-TYPE-3, P-TYPE-3
Note 1. These bits are not available in the classical CAN function.

CFE bit (Common FIFO Enable)

The CFE bit enables the FIFO when set. FIFO is disabled when this bit is cleared.

This bit can also be used, by clearing it, to abort transmission from Common FIFO when configured in TX mode, or to stop reception into the Common FIFO in RX mode.

Only write to this bit when the CANFD module is in GL_HALT or GL_OPERATION mode and the related CANFD channel is not in CH_RESET mode for FIFOs configured as TX FIFO.

This bit can only be set if the configured FIFO depth is greater than 0x000 (CFDCFCC.CFDC > 0x000) and less than 0x110 (0x110 > CFDCFCC.CFDC > 0x000).

Set the CFE bit with a separate write access to the CFDCFCC register, after all the other bits in this register are set.

This bit is cleared automatically when the CANFD module is in GL_RESET mode.

This bit is also cleared automatically when the related channel is in CH_RESET mode if the FIFO is configured in TX mode.

CFRXIE bit (Common FIFO RX Interrupt Enable)

The CFRXIE bit enables generation of FIFO interrupts when the interrupt flag is set after reception of a frame in the corresponding FIFO buffer.

Do not write to this bit when the CANFD module is in GL_SLEEP mode.

CFTXIE bit (Common FIFO TX Interrupt Enable)

The CFTXIE bit enables generation of common FIFO interrupts when the interrupt flag is set after transmission of a frame from the corresponding FIFO buffer.

Do not write to this bit when the CANFD module is in GL_SLEEP mode.

CFPLS[2:0] bits (Common FIFO Payload Data Size Configuration)

The CFPLS[2:0] bits define the message data payload allocation in the RAM. This is the maximum number of bytes which can be received or transmitted by the FIFO buffer.

For details, see section 31.6. FIFO Buffers and Normal Message Buffer Configuration.

Only write to this bit when the CANFD module is in GL_RESET mode.

Note: These bits are not available in the classical CAN function.

CFM bit (Common FIFO Mode)

The CFM bit selects the mode of the FIFO. When a hardware reset is applied, all the Common FIFO buffers are configured in RX FIFO mode.

Do not write to these bits in GL_OPERATION or GL_SLEEP mode.

Only write to these bits when the CANFD module is in GL_RESET mode.

CFITSS bit (Common FIFO Interval Timer Source Select)

The CFITSS bit selects the basic clock source for the Interval Transmission Timer.

Do not write to this bit when the CANFD module is in GL_SLEEP mode. In addition, do not write to this bit when the CFE bit is set to 1.

Do not write 1 to this bit when CANFD communication is used.*1

Note: The bit time clock can vary depending on the nominal and data rate bit configuration.

Note 1. This feature is not available in the classical CAN function.

CFITR bit (Common FIFO Interval Timer Resolution)

The CFITR bit selects the resolution of the reference clock for the Interval Transmission Timer (peripheral clock is the source for the reference clock).

Do not write to this bit when the CANFD module is in GL_SLEEP mode. Also, do not write to this bit when the CFE bit is set to 1.

CFIM bit (Common FIFO Interrupt Mode)

The CFIM bit selects the interrupt generation condition for the FIFO buffer.

Do not write to this bit in GL_SLEEP mode.

Only write to this bit when the CANFD module is in GL_RESET mode.

CFIGCV[2:0] bits (Common FIFO Interrupt Generation Counter Value)

The CFIGCV[2:0] bits select the message counter value for the generation of FIFO interrupts. These values represent fractions of the FIFO depth at which the interrupt is to be generated.

Do not write to these bits when the CANFD module is in GL_SLEEP mode.

The setting of these bits should be synchronized with the CFDC[2:0] bits.

Only write to these bits when the CANFD module is in GL_RESET mode.

CFTML[1:0] bits (Common FIFO TX Message Buffer Link)

The CFTML[1:0] bits select the normal transmit message buffer position where the TX FIFO is linked to, for transmission scanning.

Do not write to these bits in GL_OPERATION or GL_SLEEP mode.

Only write to this bit when the CANFD module is in GL_RESET mode.

CFDC[2:0] bits (Common FIFO Depth Configuration)

The CFDC[2:0] bits select the depth of the common FIFO in terms of the number of messages. If the FIFO depth is configured to 0 message, the FIFO cannot be used.

Only write to these bits when the CANFD module is in GL_RESET mode.

CFITT[7:0] bits (Common FIFO Interval Transmission Time)

The CFITT[7:0] bits select the delay in the start of transmission for all messages transmitted from this FIFO buffer when configured in TX mode. The delay is a multiple of the basic interval timer clock source period (reference clock × 1, reference clock × 10, or bit time clock of the related CAN channel).

Do not write to these bits when the CANFD module is in GL_SLEEP mode.

Do not write to these bits when the CFE bit is set to 1.

When CFDGCFG.ITRCP[15:0] = 0x0000, set the CFITT[7:0] bits to 0x0000.

31.2.29 CFDCFSTS : Common FIFO Status Register

Base address: CANFDn = 0x4038_0000 + 0x2000 × n (n = 0, 1)
CANFDn_NS = 0x5038_0000 + 0x2000 × n (n = 0, 1)

Offset address: 0x0058

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	CFMC[5:0]						—	—	—	CFTXIF	CFRXIF	CFMLT	CFFLL	CFEMP
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

Bit	Symbol	Function	R/W
0	CFEMP	Common FIFO Empty 0: FIFO not empty 1: FIFO empty	R
1	CFFLL	Common FIFO Full 0: FIFO not full 1: FIFO full	R
2	CFMLT	Common FIFO Message Lost 0: Number of message lost in FIFO 1: FIFO message lost	R/W
3	CFRXIF	Common RX FIFO Interrupt Flag 0: FIFO interrupt condition not satisfied after frame reception 1: FIFO interrupt condition satisfied after frame reception	R/W
4	CFTXIF	Common TX FIFO Interrupt Flag 0: FIFO interrupt condition not satisfied after frame transmission 1: FIFO Interrupt condition satisfied after frame transmission	R/W
7:5	—	These bits are read as 0. The write value should be 0.	R/W
13:8	CFMC[5:0]	Common FIFO Message Count Number of messages stored in FIFO	R
31:14	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

CFEMP bit (Common FIFO Empty)

The CFEMP bit is set automatically when:

- The CPU has read all messages from the FIFO configured in RX mode
- All messages have been transmitted from the FIFO configured in TX mode
- The FIFO is disabled by setting the CFE bit to 0
- The CANFD module is in GL_RESET mode

- The related CANFD channel is in CH_RESET when FIFO configured in TX mode.

The CFEMP bit is cleared automatically when:

- The first reception message is stored in the FIFO buffer when configured in RX mode
- The first message to be transmitted is stored in the FIFO buffer when configured in TX mode.

CFFLL bit (Common FIFO Full)

The CFFLL bit is set automatically when the number of CAN messages stored in the FIFO matches the configured FIFO depth.

The CFFLL bit is cleared automatically when:

- The number of CAN messages stored in the FIFO is less than the configured FIFO depth
- The FIFO is disabled by setting the CFE bit to 0
- The CANFD module is in GL_RESET mode
- The related CANFD channel is in CH_RESET mode when FIFO buffer is configured in TX mode.

CFMLT bit (Common FIFO Message Lost)

The CFMLT bit is set automatically whenever a message is lost due to attempted storage of a new message when FIFO is already full in RX mode.

If a set from the CAN channel occurs simultaneously with a clear by a write access, then this bit is set.

Only write to this bit when the CANFD module is in GL_HALT or GL_OPERATION mode and the related CANFD channel is not in CH_RESET mode for FIFO configured as TX FIFO. Writing 1 has no effect.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1.

The CFMLT bit is cleared:

- By writing 0 to it
- When the CANFD module is in GL_RESET mode
- When the related CANFD channel is in CH_RESET mode if the FIFO buffer is configured in TX mode.

CFRXIF bit (Common RX FIFO Interrupt Flag)

The CFRXIF bit is not cleared automatically if the Common FIFO buffer is disabled.

Only write to this bit when the CANFD module is in GL_HALT or GL_OPERATION mode and the related CANFD channel is not in CH_RESET mode for FIFO configured as TX FIFO. Writing 1 has no effect.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1.

This bit is set automatically when the configured interrupt condition is satisfied for Common FIFO buffers when configured in RX mode.

If the set from the CAN channel occurs simultaneously with the clear by the write access, then the bit is set.

The CFRXIF bit is cleared:

- By writing 0 to it
- When the CANFD module is in GL_RESET mode

CFTXIF bit (Common TX FIFO Interrupt Flag)

The CFTXIF bit is not cleared automatically if the Common FIFO buffer is disabled.

Only write to this bit when the CANFD module is in GL_HALT or GL_OPERATION mode and the related CANFD channel is not in CH_RESET mode for FIFO buffer configured as TX FIFO. Writing 1 has no effect.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1.

This bit is set automatically when the configured interrupt condition is satisfied for Common FIFO buffers configured in TX mode.

If the set from the CAN channel occurs simultaneously with the clear by the write access, then the bit is set.

The CFTXIF bit is cleared:

- By writing 0 to it
- When the CANFD module is in GL_RESET mode
- When the related CANFD channel is in CH_RESET mode if the FIFO buffer is configured in TX mode.

CFMC[5:0] bits (Common FIFO Message Count)

The CFMC[5:0] bits indicate the following:

- Number of CAN messages stored by the CPU in the FIFO buffer configured in TX mode pending for transmission
- Number of CAN messages stored in the FIFO buffer configured in RX mode by CANFD module to be read by the CPU

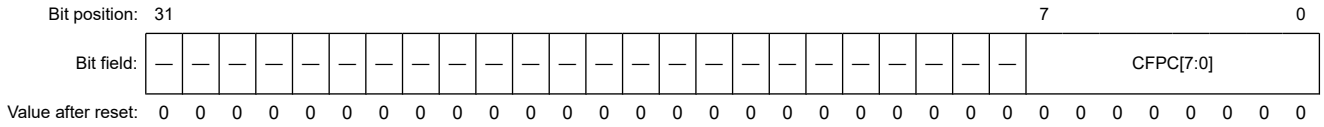
The CFMC[5:0] bits are cleared automatically when:

- The FIFO is disabled
- The CANFD module is in GL_RESET mode
- The related CANFD channel is in CH_RESET mode if the FIFO buffer is configured in TX mode.

31.2.30 CFDCFPCTR : Common FIFO Pointer Control Register

Base address: CANFDn = 0x4038_0000 + 0x2000 × n (n = 0, 1)
CANFDn_NS = 0x5038_0000 + 0x2000 × n (n = 0, 1)

Offset address: 0x005C



Bit	Symbol	Function	R/W
7:0	CFPC[7:0]	Common FIFO Pointer Control Increments read or write pointer of the corresponding Common FIFO buffers depending on the mode configuration.	W
31:8	—	The write value should be 0.	W

Note: S-TYPE-3, P-TYPE-3

The Common FIFO Pointer Control Registers can be used to increment the read or write pointer of the corresponding Common FIFO buffer.

CFPC[7:0] bits (Common FIFO Pointer Control)

When the value 0xFF is written into the CFPC[7:0] bits, the read pointer of the corresponding Common FIFO buffer (when configured in RX mode), or the write pointer of the corresponding Common FIFO buffer (when configured in TX mode) moves to the next FIFO entry.

The read value from these bits is always 0x00.

Only write to these bits when the CANFD module is in GL_HALT or GL_OPERATION mode.

Only write 0xFF to this register when:

- The Common FIFO buffer is enabled and is not empty if configured in RX mode
- The Common FIFO buffer is enabled and is not full if configured in TX mode

Do not write to the Common FIFO Pointer Control registers when DMA is enabled.

31.2.31 CFDFESTS : FIFO Empty Status Register

Base address: CANFDn = 0x4038_0000 + 0x2000 × n (n = 0, 1)
CANFDn_NS = 0x5038_0000 + 0x2000 × n (n = 0, 1)

Offset address: 0x0060

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	CFEMP	—	—	—	—	—	—	RFXEMP[1:0]	
Value after reset:	0	0	0	0	0	0	0	1	0	0	0	0	0	0	1	1

Bit	Symbol	Function	R/W
1:0	RFXEMP[1:0]	RX FIFO Empty Status 0: Corresponding FIFO not empty 1: Corresponding FIFO empty	R
7:2	—	These bits are read as 0.	R
8	CFEMP	Common FIFO Empty Status 0: Corresponding FIFO not empty 1: Corresponding FIFO empty	R
31:9	—	These bits are read as 0.	R

Note: S-TYPE-3, P-TYPE-3

The FIFO Empty Status register shows status of the empty bits of the FIFO buffers.

RFXEMP[1:0] bits (RX FIFO Empty Status)

The RFXEMP[1:0] bits are set when the CANFD module is in GL_RESET mode.

Each bit is set automatically when the corresponding bit is set in the RX FIFO Status Registers.

Each bit is cleared automatically when the corresponding bit is cleared in the RX FIFO Status Registers.

CFEMP bit (Common FIFO Empty Status)

The CFEMP bits are set when the CANFD module is in GL_RESET mode.

Each bit is set automatically when the corresponding bit is set in the Common FIFO Status Registers.

Each bit is cleared automatically when the corresponding bit is cleared in the Common FIFO Status Registers.

31.2.32 CFDFFSTS : FIFO Full Status Register

Base address: CANFDn = 0x4038_0000 + 0x2000 × n (n = 0, 1)
CANFDn_NS = 0x5038_0000 + 0x2000 × n (n = 0, 1)

Offset address: 0x0064

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	CFFLL	—	—	—	—	—	—	RFXFLL[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
1:0	RFXFLL[1:0]	RX FIF0 Full Status 0: Corresponding FIFO not full 1: Corresponding FIFO full	R
7:2	—	These bits are read as 0.	R
8	CFFLL	Common FIF0 Full Status 0: Corresponding FIFO not full 1: Corresponding FIFO full	R
31:9	—	These bits are read as 0.	R

Note: S-TYPE-3, P-TYPE-3

The FIFO Full Status Register shows status of the full bits of the FIFO buffers.

RFXFLL[1:0] bits (RX FIF0 Full Status)

The RFXFLL[1:0] bits are cleared when CANFD module is in GL_RESET mode.

Each bit is set automatically when the corresponding bit is set in the RX FIFO Status Registers.

Each bit is cleared automatically when the corresponding bit is cleared in the RX FIFO Status Registers.

CFFLL bits (Common FIF0 Full Status)

The CFFLL bits are cleared when the CANFD module is in GL_RESET mode.

Each bit is set automatically when the corresponding bit is set in the Common FIFO Status Registers.

Each bit is cleared automatically when the corresponding bit is cleared in the Common FIFO Status Registers.

31.2.33 CFDFMSTS : FIFO Message Lost Status Register

Base address: CANFDn = 0x4038_0000 + 0x2000 × n (n = 0, 1)
CANFDn_NS = 0x5038_0000 + 0x2000 × n (n = 0, 1)

Offset address: 0x0068

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	CFMLT	—	—	—	—	—	—	RFXMLT[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
1:0	RFXMLT[1:0]	RX FIFO Message Lost Status 0: Corresponding FIFO Message Lost flag not set 1: Corresponding FIFO Message Lost flag set	R
7:2	—	These bits are read as 0.	R
8	CFMLT	Common FIFO Message Lost Status 0: Corresponding FIFO Message Lost flag not set 1: Corresponding FIFO Message Lost flag set	R
31:9	—	These bits are read as 0.	R

Note: S-TYPE-3, P-TYPE-3

The FIFO Message Lost Status Register shows status of the Msg Lost bits of the FIFO buffers.

RFXMLT[1:0] bits (RX FIFO Message Lost Status)

The RFXMLT[1:0] bits are cleared when the CANFD module is in GL_RESET mode.

Each bit is set automatically when the corresponding bit is set in the RX FIFO Status Registers.

Each bit is cleared automatically when the corresponding bit is cleared in the RX FIFO Status Registers.

CFMLT bits (Common FIFO Message Lost Status)

The CFMLT bits are cleared when the CANFD module is in GL_RESET mode.

Each bit is set automatically when the corresponding bit is set in the Common FIFO Status Registers.

Each bit is cleared automatically when the corresponding bit is cleared in the Common FIFO Status Registers.

31.2.34 CFDRFISTS : RX FIFO Interrupt Flag Status Register

Base address: CANFDn = 0x4038_0000 + 0x2000 × n (n = 0, 1)
CANFDn_NS = 0x5038_0000 + 0x2000 × n (n = 0, 1)

Offset address: 0x006C

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	RFXIF[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
1:0	RFXIF[1:0]	RX FIFO[x] Interrupt Flag Status 0: Corresponding RX FIFO Interrupt flag not set 1: Corresponding RX FIFO Interrupt flag set	R
31:2	—	These bits are read as 0.	R

Note: S-TYPE-3, P-TYPE-3

The FIFO Interrupt Flag Status Register shows status of the interrupt flag bits of the RX FIFO buffers.

RFXIF[1:0] bits (RX FIFO[x] Interrupt Flag Status)

Each bit is set automatically when the corresponding interrupt flag bit is set in the RX FIFO Status Registers.

The RFXIF[1:0] bits are cleared when the CANFD module is in GL_RESET mode.

Each bit is cleared automatically when the corresponding interrupt flag bit is cleared in the RX FIFO Status Registers.

31.2.35 CFDCDTCT : DMA Transfer Control Register

Base address: CANFDn = 0x4038_0000 + 0x2000 × n (n = 0, 1)
CANFDn_NS = 0x5038_0000 + 0x2000 × n (n = 0, 1)

Offset address: 0x00C8

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	CFDMAE	—	—	—	—	—	—	RFDMAE1	RFDMAE0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	RFDMAE0	DMA Transfer Enable for RXFIFO 0 0: DMA transfer request disabled 1: DMA transfer request enabled	R/W
1	RFDMAE1	DMA Transfer Enable for RXFIFO 1 0: DMA transfer request disabled 1: DMA transfer request enabled	R/W
7:2	—	These bits are read as 0. The write value should be 0.	R/W
8	CFDMAE	DMA Transfer Enable for Common FIFO 0 0: DMA transfer request disabled 1: DMA transfer request enabled	R/W
31:9	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

The DMA Transfer Control Register controls the start and stop of DMA transfer operation.

RFDMAEe (e = 0 to 1) bit (DMA Transfer Enable for RXFIFO e)

The RFDMAEe bit cannot be set in GL_SLEEP or GL_RESET mode.

This bit is cleared when the CANFD module is in GL_RESET mode.

CFDMAE bit (DMA Transfer Enable for Common FIFO)

The CFDMAE bit enables or disables DMA transfer request for common FIFO

The CFDMAE bit cannot be set in GL_SLEEP or GL_RESET mode.

Do not enable a DMA transfer for a Common FIFO that is configured as TX FIFO.

This bit is cleared when the CANFD module is in GL_RESET mode.

31.2.36 CFDCDTSTS : DMA Transfer Status Register

Base address: CANFDn = 0x4038_0000 + 0x2000 × n (n = 0, 1)
CANFDn_NS = 0x5038_0000 + 0x2000 × n (n = 0, 1)

Offset address: 0x00CC

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	CFDMASTS	—	—	—	—	—	—	RFDMASTS1	RFDMASTS0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	RFDMASTS0	DMA Transfer Status for RX FIFO 0 0: DMA transfer stopped 1: DMA transfer on going	R
1	RFDMASTS1	DMA Transfer Status for RX FIFO 1 0: DMA transfer stopped 1: DMA transfer on going	R
7:2	—	These bits are read as 0.	R
8	CFDMASTS	DMA Transfer Status only for Common FIFO 0: DMA transfer stopped 1: DMA transfer on going	R
31:9	—	These bits are read as 0.	R

Note: S-TYPE-3, P-TYPE-3

The DMA Transfer Status Register shows the status of the DMA transfer.

RFDMASTSe (e = 0 to 1) bit (DMA Transfer Status for RX FIFO e)

Each bit is set automatically when the corresponding DMA enable bit is set and the corresponding DMA FIFO is not empty.

Each bit is cleared automatically when the DMA transfer stops either because the DMA is disabled or the DMA FIFO is empty.

When CFDCDTCT.RFDMAEe (see CFDCDTCT.RFDMAEe bit in section 31.2.35. CFDCDTCT : DMA Transfer Control Register) is set to 0 while DMA transfer for the corresponding FIFO is on going, the RFDMASTSe bit becomes 0 when the DMA transfer is complete.

This bit is cleared when the CANFD module is in GL_RESET mode.

CFDMASTS bit (DMA Transfer Status only for Common FIFO)

Each bit is set automatically when the corresponding DMA enable bit is set and the corresponding DMA FIFO is not empty.

Each bit is cleared automatically when the DMA transfer stops either because the DMA is disabled or the DMA FIFO is empty.

When CFDCDTCT.CFDMAE (see CFDCDTCT.CFDMAE bit in section 31.2.35. CFDCDTCT : DMA Transfer Control Register) is set to 0 while DMA transfer for the corresponding FIFO is on going, the CFDMASTS bit becomes 0 when the DMA transfer is complete.

This bit is cleared when the CANFD module is in GL_RESET mode.

31.2.37 CFDTMCi : TX Message Buffer Control Registers i (i = 0 to 3)

Base address: CANFDn = 0x4038_0000 + 0x2000 × n (n = 0, 1)
CANFDn_NS = 0x5038_0000 + 0x2000 × n (n = 0, 1)

Offset address: 0x0070 + 0x01 × i

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	TMOM	TMTAR	TMTR
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	TMTR	TX Message Buffer Transmission Request 0: TX Message buffer transmission not requested 1: TX message buffer transmission requested	R/W
1	TMTAR	TX Message Buffer Transmission Abort Request 0: TX message buffer transmission request abort not requested 1: TX message buffer transmission request abort requested	R/W
2	TMOM	TX Message Buffer One-shot Mode 0: TX message buffer not configured in one-shot mode 1: TX message buffer configured in one-shot mode	R/W
7:3	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

The TX Message Buffer Control Registers configure the TX message buffer functions.

TMTR bit (TX Message Buffer Transmission Request)

When the TMTR bit is set, the CANFD module logic tries to transmit the message stored in the corresponding message buffer.

Only write to this bit when the related CANFD module is in CH_HALT or CH_OPERATION mode.

Do not set this bit if the corresponding TX message buffer is linked to a COM FIFO in TX mode or is a part of TX Queue.

This bit cannot be directly cleared by a CPU write access.

This bit can only be set when the Transmission Result flag bits (CFDTMSTSj.TMTRF) in the CFDTMSTSj register corresponding to the message buffer are cleared to 00b.

The TMTR bit is automatically cleared by the:

- CANFD module logic at the end of a successful transmission
- CANFD module logic at the end of a transmission abort, requested by the corresponding CFDTMCi.TMTAR bit
- CANFD module logic when there is a detection of a CAN bus error or arbitration loss if CFDTMCi.TMOM bit is set for the message buffer
- CANFD module logic when the CANFD module is in GL_RESET mode or the related channel is in CH_RESET mode.

TMTAR bit (TX Message Buffer Transmission Abort Request)

When the TMTAR bit is set, the CANFD module logic tries to abort the transmission of the frame stored in the corresponding message buffer.

In most cases, transmission cannot be aborted if the internal scan for transmission is complete and the message buffer has already been selected for transmission. In this case, frame may be transmitted successfully from the message buffer. The message buffer selection is released by entering CH_HALT mode.

However, message buffer selected for transmission can be aborted by an abort request when the CAN node detects a new message on the bus (RX pin) before it starts transmission from the selected message buffer.

Only write to the TMTAR bit when the related CANFD channel is in CH_HALT or CH_OPERATION mode. This bit can only be set when the related transmit request TMTR bit is set.

The TMTAR bit cannot be cleared by a CPU write access. Clearing of this bit by CANFD has priority over setting by a CPU write access.

The TMTAR bit is automatically cleared by:

- The CANFD module logic at the end of a successful transmission
- The CANFD module logic at the end of a transmission abort
- The CANFD module logic when there is detection of a CAN bus error or arbitration loss
- The CANFD module logic when the CANFD module is in GL_RESET mode or the related channel enters CH_RESET mode.

TMOM bit (TX Message Buffer One-shot Mode)

When the TMOM bit is set, the CANFD module logic tries to transmit the message only once.

If the transmission is successful, the CFDTMSTSj.TMTRF bits are set to 10b or 11b. Otherwise, the transmission is automatically aborted and CFDTMSTSj.TMTRF bits are set to 01b due to a bus error or a bus arbitration lost.

The TMOM bit remains set if the transmission has completed successfully or aborted due to an error or a loss of arbitration.

Only write to this bit when the related CANFD channel is in CH_HALT or CH_OPERATION mode.

Set this bit at the same time as the TMTR bit. Clear this bit with a write access.

If a message has already been requested for transmission, do not write to this bit until the message has been successfully transmitted or transmission has been aborted.

The TMOM bit is automatically cleared by the CANFD module logic when the CANFD module is in GL_RESET mode or the related channel is in CH_RESET mode.

31.2.38 CFDTMSTSj : TX Message Buffer Status Registers j (j = 0 to 3)

Base address: CANFDn = 0x4038_0000 + 0x2000 × n (n = 0, 1)
CANFDn_NS = 0x5038_0000 + 0x2000 × n (n = 0, 1)

Offset address: 0x0074 + 0x01 × j

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	TMTARM	TMTRM	TMTRF[1:0]		TMTSTS
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	TMTSTS	TX Message Buffer Transmission Status 0: No on-going transmission 1: On-going transmission	R
2:1	TMTRF[1:0]	TX Message Buffer Transmission Result Flag 0 0: No result 0 1: Transmission aborted from the TX message buffer 1 0: Transmission successful from the TX message buffer and transmission abort was not requested 1 1: Transmission successful from the TX message buffer and transmission abort was requested	R/W
3	TMTRM	TX Message Buffer Transmission Request Mirrored 0: TX message buffer transmission not requested 1: TX message buffer transmission requested	R
4	TMTARM	TX Message Buffer Transmission Abort Request Mirrored 0: TX message buffer transmission request abort not requested 1: TX message buffer transmission request abort requested	R
7:5	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

The TX Message Buffer Status Registers show status of the transmission and transmission abort for the corresponding message buffers.

TMTSTS bit (TX Message Buffer Transmission Status)

The TMTSTS bit is set automatically at the start of the transmission from the corresponding TX message buffer.

This bit is cleared automatically when:

- Transmission stops
- The CANFD module is in GL_RESET mode
- The related CANFD channel is in CH_RESET mode.

TMTRF[1:0] bits (TX Message Buffer Transmission Result Flag)

The TMTRF[1:0] bits show the result for the corresponding TX message buffer. The status is as follows:

- 00: Transmission in progress or has not been requested
- 01: Transmission has been aborted from the corresponding TX message buffer
- 10: Transmission was successful from the corresponding TX message buffer and the CFDTMCi.TMTAR bit was not set for this TX message buffer
- 11: Transmission was successful from the corresponding TX message buffer, but the CFDTMCi.TMTAR bit was set for this TX message buffer.

Only write to these bits when the related CANFD channel is in CH_HALT or CH_OPERATION mode.

The TMTRF[1:0] bits are cleared automatically when the CANFD module is in GL_RESET mode or the related channel is in CH_RESET mode.

If the set from the CAN channel occurs simultaneously with the clear by the write access, then the bit is set.

TMTRM bit (TX Message Buffer Transmission Request Mirrored)

The TMTRM bit is set when the CFDTMCi.TMTR bit in the corresponding CFDTMCi register is set.

This bit is cleared when the CFDTMCi.TMTR bit in the corresponding CFDTMCi register is cleared.

TMTARM bit (TX Message Buffer Transmission Abort Request Mirrored)

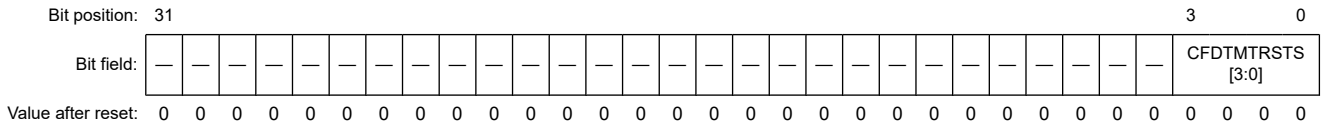
The TMTARM bit is set when the CFDTMCi.TMTAR bit in the corresponding CFDTMCi register is set.

This bit is cleared when the CFDTMCi.TMTAR bit in the corresponding CFDTMCi register is cleared.

31.2.39 CFDTMTRSTS : TX Message Buffer Transmission Request Status Register

Base address: CANFDn = 0x4038_0000 + 0x2000 × n (n = 0, 1)
CANFDn_NS = 0x5038_0000 + 0x2000 × n (n = 0, 1)

Offset address: 0x0078



Bit	Symbol	Function	R/W
3:0	CFDTMTRSTS[3:0]	TX Message Buffer Transmission Request Status 0: Transmission not requested for corresponding TX message buffer 1: Transmission requested for corresponding TX message buffer	R
31:4	—	These bits are read as 0.	R

Note: S-TYPE-3, P-TYPE-3

These bits show the TX Message Buffer Transmission Request Status for the corresponding TX Message Buffer. The bit 0 of a CFDTMTRSTS register corresponds to the TX message buffer 0.

The bit position of CFDTMTRSTS corresponds to the buffer number of TX message buffer.

CFDTMTRSTS[3:0] bits (TX Message Buffer Transmission Request Status)

The CFDTMTRSTS[3:0] bits show status of the CFDTMCi.TMTR bits of the TX Message Buffer Control Registers.

Each bit is set automatically when the corresponding bit is set in the TX Message Buffer Control Registers (CFDTMCi), and only when the message buffer does not belong to a TX Queue.

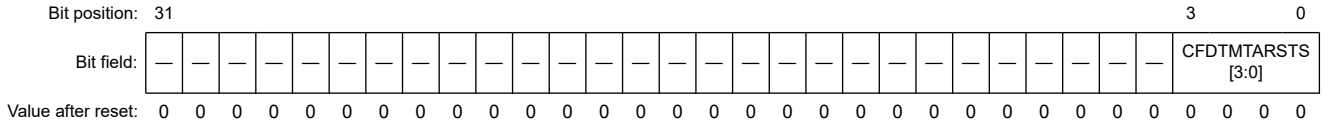
Each bit is cleared automatically when:

- The corresponding bit is cleared in the TX Message Buffer Control Registers
- The CANFD module is in GL_RESET mode
- The related CANFD channel is in CH_RESET mode.

31.2.40 CFDTMTARSTS : TX Message Buffer Transmission Abort Request Status Register

Base address: CANFDn = 0x4038_0000 + 0x2000 × n (n = 0, 1)
CANFDn_NS = 0x5038_0000 + 0x2000 × n (n = 0, 1)

Offset address: 0x007C



Bit	Symbol	Function	R/W
3:0	CFDTMTARSTS[3:0]	TX Message Buffer Transmission Abort Request Status 0: Transmission abort not requested for corresponding TX message buffer 1: Transmission abort requested for corresponding TX message buffer	R
31:4	—	These bits are read as 0.	R

Note: S-TYPE-3, P-TYPE-3

These bits show the TX Message Buffer Transmission Abort Request Status for the corresponding TX Message Buffer. The bit 0 of a CFDTMTARSTS register corresponds to the TX message buffer 0.

The bit position of CFDTMTARSTS corresponds to the buffer number of TX message buffer.

CFDTMTARSTS[3:0] bits (TX Message Buffer Transmission Abort Request Status)

The CFDTMTARSTS[3:0] bits show status of the CFDTMCi.TMTAR bits of the TX Message Buffer Control Registers.

Each bit is set automatically when the corresponding bit is set in the TX Message Buffer Control Registers, and when the message buffer belongs to a TX Queue.

Each bit is cleared automatically when:

- The corresponding bit is cleared in the TX Message Buffer Control Registers
- The CANFD module is in GL_RESET mode
- The related CANFD channel is in CH_RESET mode.

31.2.41 CFDTMTCSTS : TX Message Buffer Transmission Completion Status Register

Base address: CANFDn = 0x4038_0000 + 0x2000 × n (n = 0, 1)
CANFDn_NS = 0x5038_0000 + 0x2000 × n (n = 0, 1)

Offset address: 0x0080

Bit position:	31																										3	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	CFDTMTCSTS[3:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
3:0	CFDTMTCSTS[3:0]	TX Message Buffer Transmission Completion Status 0: Transmission not complete for corresponding TX message buffer 1: Transmission completed for corresponding TX message buffer	R
31:4	—	These bits are read as 0.	R

Note: S-TYPE-3, P-TYPE-3

These bits show the TX Message Buffer Transmission Completion Status for the corresponding TX Message Buffer. The bit 0 of a CFDTMTCSTS register corresponds to the TX message buffer 0.

The bit position of CFDTMTCSTS corresponds to the buffer number of TX message buffer.

CFDTMTCSTS[3:0] bits (TX Message Buffer Transmission Completion Status)

The CFDTMTCSTS[3:0] bits show status of successful completion of the TX Message Buffer Status Registers.

Each bit is set automatically when the corresponding bit is set in the TX Message Buffer Status Registers.

Each bit is cleared automatically when:

- The corresponding bit is cleared in the TX Message Buffer Status Registers
- The CANFD module is in GL_RESET mode
- The related CANFD channel is in CH_RESET mode.

If a CAN channel enters CH_RESET mode, then the bits related to that channel are cleared.

31.2.42 CFDTMTASTS : TX Message Buffer Transmission Abort Status Register

Base address: CANFDn = 0x4038_0000 + 0x2000 × n (n = 0, 1)
CANFDn_NS = 0x5038_0000 + 0x2000 × n (n = 0, 1)

Offset address: 0x0084

Bit position:	31																										3	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	CFDTMTASTS[3:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
3:0	CFDTMTASTS[3:0]	TX Message Buffer Transmission Abort Status 0: Transmission not aborted for corresponding TX message buffer 1: Transmission aborted for corresponding TX message buffer	R
31:4	—	These bits are read as 0.	R

Note: S-TYPE-3, P-TYPE-3

These bits show the TX Message Buffer Transmission abort Status for the corresponding TX Message Buffer. The bit 0 of a CFDTMTASTS register corresponds to the TX message buffer 0.

The bit position of CFDTMTASTS corresponds to the buffer number of TX message buffer.

CFDTMTASTS[3:0] bits (TX Message Buffer Transmission Abort Status)

The CFDTMTASTS[3:0] bits show status of the successful transmission abort of the corresponding TX message buffer.

Each bit is set automatically when the CFDTMSTSj.TMTRF bits are set to 01b in the corresponding TX Message Buffer Status Register.

Each bit is cleared automatically when:

- The CFDTMSTSj.TMTRF bits are cleared in the corresponding TX Message Buffer Status Register
- The CANFD module is in GL_RESET mode
- The related CANFD channel is in CH_RESET mode.

31.2.43 CFDTMIEC : TX Message Buffer Interrupt Enable Configuration Register

Base address: CANFDn = 0x4038_0000 + 0x2000 × n (n = 0, 1)
CANFDn_NS = 0x5038_0000 + 0x2000 × n (n = 0, 1)

Offset address: 0x0088

Bit position:	31																											3	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	TMIEg[3:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
3:0	TMIEg[3:0]	TX Message Buffer Interrupt Enable 0: TX message buffer interrupt disabled for corresponding TX message buffer 1: TX message buffer interrupt enabled for corresponding TX message buffer	R/W
31:4	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

These bits show the TX Message Buffer Interrupt Enable for the corresponding TX Message Buffer.

The bit 0 of a CFDTMIEC register corresponds to the TX message buffer 0.

The bit position of CFDTMIEC corresponds to the buffer number of TX message buffer.

g = [0…3]

TMIEg[3:0] bits (TX Message Buffer Interrupt Enable)

If the TMIEg[3:0] bits are set, an interrupt is generated at the end of a successful transmission from the corresponding message buffer.

See section 31.7. Interrupts and DMA for TX Message Buffer Interrupt specification.

Do not write to the TMIEg[7:0] bits when:

- The CANFD module is in GL_SLEEP mode
- The related CANFD channel is in CH_SLEEP mode
- The corresponding TX message buffer is linked to a Common FIFO with the CFDCFCC.CFTML bits.

31.2.44 CFDTXQCC : TX Queue Configuration/Control Register

Base address: CANFDn = 0x4038_0000 + 0x2000 × n (n = 0, 1)
CANFDn_NS = 0x5038_0000 + 0x2000 × n (n = 0, 1)

Offset address: 0x008C

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	TXQDC[1:0]		TXQIM	—	TXQTXIE	—	—	—	—	TXQE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	TXQE	TX Queue Enable 0: TX Queue disabled 1: TX Queue enabled	R/W
4:1	—	These bits are read as 0. The write value should be 0.	R/W
5	TXQTXIE	TX Queue TX Interrupt Enable 0: TX Queue TX interrupt disabled 1: TX Queue TX interrupt enabled	R/W
6	—	This bit is read as 0. The write value should be 0.	R/W
7	TXQIM	TX Queue Interrupt Mode 0: When the last message is successfully transmitted 1: At every successful transmission	R/W
9:8	TXQDC[1:0]	TX Queue Depth Configuration 0x00: 0 messages 0x01: Reserved 0x10: 3 messages 0x11: 4 messages	R/W
31:10	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

The TX Queue Configuration/Control Registers are used to configure the TX Queue transmission.

TXQ is composed of TXMB0 to TXMB3 (at the maximum) when TXQE is enabled.

TXQE bit (TX Queue Enable)

The TXQE bit cannot be set if the configured TX Queue depth is 0x00 (CFDTXQCC.TXQDC == 0x00).

You cannot write to this bit when the CANFD module is in GL_SLEEP mode.

Do not write to this bit when the related CANFD channel is in CH_RESET or CH_SLEEP mode.

The TXQE bit is cleared automatically when the related CANFD channel is in CH_RESET mode.

TXQTXIE bit (TX Queue TX Interrupt Enable)

When the TXQTXIE bit is set, an interrupt is generated based on the setting of the TXQIM bit.

You cannot write to this bit when the CANFD module is in GL_SLEEP mode.

Do not write to this bit when the related CANFD channel is in CH_SLEEP mode.

TXQIM bit (TX Queue Interrupt Mode)

The TXQIM bit selects the interrupt generation condition for the TX Queue.

You cannot write to this bit when the CANFD module is in GL_SLEEP mode.

Do not write to this bit when the related CANFD channel is in any of the following modes:

- CH_SLEEP
- CH_HALT
- CH_OPERATION.

TXQDC[1:0] bits (TX Queue Depth Configuration)

The TXQDC[1:0] bits select the depth of the transmission queue. The message buffer selection starts from MB[0] up to MB[3] depending on the configured depth.

You cannot write to this bit when the CANFD module is in GL_SLEEP mode.

Do not write to this bit when the related CANFD channel is in any of the following modes:

- CH_SLEEP
- CH_HALT
- CH_OPERATION.

31.2.45 CFDTXQSTS : TX Queue Status Register

Base address: CANFDn = 0x4038_0000 + 0x2000 × n (n = 0, 1)
CANFDn_NS = 0x5038_0000 + 0x2000 × n (n = 0, 1)

Offset address: 0x0090

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	TXQMC[2:0]			—	—	—	—	—	TXQTXIF	TXQFLL	TXQEMP
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

Bit	Symbol	Function	R/W
0	TXQEMP	TX Queue Empty 0: TX Queue not empty 1: TX Queue empty	R
1	TXQFLL	TX Queue Full 0: TX Queue not full 1: TX Queue full	R
2	TXQTXIF	TX Queue TX Interrupt Flag 0: TX Queue interrupt condition not satisfied after a frame TX 1: TX Queue interrupt condition satisfied after a frame TX	R/W
7:3	—	These bits are read as 0. The write value should be 0.	R/W
10:8	TXQMC[2:0]	TX Queue Message Count Number of messages in the TX Queue.	R
31:11	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

The TX Queue Status Registers show the status of the TX Queue of corresponding CAN channel.

TXQEMP bit (TX Queue Empty)

The TXQEMP bit is set automatically when the TX Queue is disabled or no messages are stored in the TX Queue.

This bit is set automatically when:

- The last message is transmitted from the TX Queue
- The related CANFD channel is in CH_RESET mode.

The bit is cleared automatically when the first message to be transmitted is stored in the TX Queue.

TXQFLL bit (TX Queue Full)

The TXQFLL bit is set automatically when the number of CAN messages stored in the TX Queue matches the configured TX Queue depth.

This bit is cleared automatically when:

- The number of CAN messages stored in the TX Queue is less than the configured TX Queue depth
- The related CANFD channel is in CH_RESET mode.

TXQTXIF bit (TX Queue TX Interrupt Flag)

The TXQTXIF bit is not cleared automatically if the TX Queue is disabled.

When stopping the TX Queue, this bit should be cleared, after disabling TXQE and checking an empty state of TX Queue.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1. Writing 1 has no effect.

This bit is set automatically when the configured interrupt condition is satisfied for the TX Queue.

If the set from the CAN channel occurs simultaneously with the clear by the write access, then the bit is set.

You cannot write to this bit when the related CANFD channel is in CH_SLEEP or CH_RESET mode.

The bit is cleared:

- By writing 0 to it
- When the related CANFD channel is in CH_RESET mode.

TXQMC[2:0][13:8] bits (TX Queue Message Count)

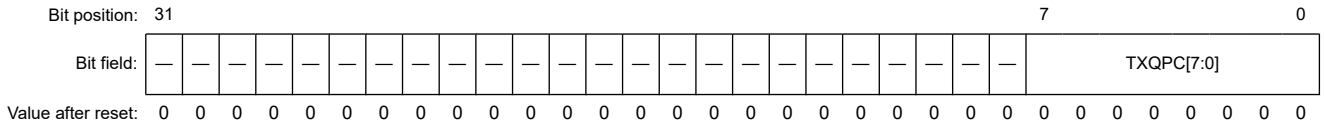
The TXQMC[2:0] bits show the number of CAN messages in the TX Queue.

These bits are cleared automatically when the related CANFD channel is in CH_RESET mode.

31.2.46 CFDTXQPCTR : TX Queue Pointer Control Register

Base address: CANFDn = 0x4038_0000 + 0x2000 × n (n = 0, 1)
CANFDn_NS = 0x5038_0000 + 0x2000 × n (n = 0, 1)

Offset address: 0x0094



Bit	Symbol	Function	R/W
7:0	TXQPC[7:0]	TX Queue Pointer Control Increments the write pointer to the TX Queue buffer in the corresponding channel	W
31:8	—	The write value should be 0.	W

Note: S-TYPE-3, P-TYPE-3

The TX Queue Pointer Control Registers are used to confirm storage of a full message in the corresponding TX Queue buffers.

TXQPC[7:0] bits (TX Queue Pointer Control)

When the value 0xFF is written to the TXQPC[7:0] bits, the write pointer of the corresponding TX Queue buffer is updated and a transmit request is initiated for this message.

The read value from these bits is always 0x00. Do not write to the FIFO control registers when DMA is enabled.

You cannot write to these bits when the related CANFD channel is in CH_SLEEP or CH_RESET mode.

Only write 0xFF to this register when:

- The corresponding TX Queue is enabled and not full

- The Common FIFO is enabled.

31.2.47 CFDTHLCC : TX History List Configuration/Control Register

Base address: CANFDn = 0x4038_0000 + 0x2000 × n (n = 0, 1)
CANFDn_NS = 0x5038_0000 + 0x2000 × n (n = 0, 1)

Offset address: 0x0098

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	THLDTE	THLIM	THLIE	—	—	—	—	—	—	—	THLE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	THLE	TX History List Enable 0: TX History List disabled 1: TX History List enabled	R/W
7:1	—	These bits are read as 0. The write value should be 0.	R/W
8	THLIE	TX History List Interrupt Enable 0: TX History List Interrupt disabled 1: TX History List Interrupt enabled	R/W
9	THLIM	TX History List Interrupt Mode 0: Interrupt generated if TX History List level reaches ¾ of the TX History List depth 1: Interrupt generated for every successfully stored entry	R/W
10	THLDTE	TX History List Dedicated TX Enable 0: TX FIFO + TX Queue 1: Flat TX MB + TX FIFO + TX Queue	R/W
31:11	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

The TX History List Configuration/Control Register configures the TX History List functions.

THLE bit (TX History List Enable)

The THLE bit enables the TX History List buffer when it is set.

You cannot write to this bit when the related CANFD channel is in CH_RESET or CH_SLEEP mode.

This bit is cleared automatically when the related CANFD channel is in CH_RESET mode.

THLIE bit (TX History List Interrupt Enable)

The THLIE bit enables the generation of the TX History List interrupt when it is set.

You cannot write to this bit when the CANFD module is in GL_SLEEP mode.

THLIM bit (TX History List Interrupt Mode)

The THLIM bit selects the interrupt generation condition for the FIFO.

You cannot write to this bit when the CANFD module is in GL_SLEEP mode.

Do not write to this bit when the CANFD module is in GL_HALT or GL_OPERATION mode.

THLDTE bit (TX History List Dedicated TX Enable)

The THLDTE bit selects the condition for storing an entry in the TX History List after successful transmission.

You cannot write to this bit when the CANFD module is in GL_SLEEP mode.

Do not write to this bit when the CANFD module is in GL_HALT or GL_OPERATION mode.

31.2.48 CFDTHLSTS : TX History List Status Register

Base address: CANFDn = 0x4038_0000 + 0x2000 × n (n = 0, 1)
CANFDn_NS = 0x5038_0000 + 0x2000 × n (n = 0, 1)

Offset address: 0x009C

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	THLMC[3:0]				—	—	—	—	THLIF	THLELT	THLFLL	THLEMP
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

Bit	Symbol	Function	R/W
0	THLEMP	TX History List Empty 0: TX History List not empty 1: TX History List empty	R
1	THLFLL	TX History List Full 0: TX History List not full 1: TX History List full	R
2	THLELT	TX History List Entry Lost 0: No entry lost in TX History List 1: TX History List entry Lost	R/W
3	THLIF	TX History List Interrupt Flag 0: TX History List interrupt condition not satisfied 1: TX History List interrupt condition satisfied	R/W
7:4	—	These bits are read as 0. The write value should be 0.	R/W
11:8	THLMC[3:0]	TX History List Message Count Number of messages stored in TX History List	R
31:12	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

The TX History List Status register shows the status of data stored in the TX History List buffer.

THLEMP bit (TX History List Empty)

The THLEMP bit is set automatically when the CPU has read all the entries from the TX History List buffer.

This bit is cleared automatically when the first entry is stored to the TX History List.

This bit is set automatically when:

- TX History List is disabled
- The related CANFD channel is in CH_RESET mode.

THLFLL bit (TX History List Full)

The THLFLL bit is set automatically when the number of entries in the TX History List buffer matches the TX History List depth.

Each TX History List can store up to 8 entries.

This bit is cleared automatically when:

- The number of entries in the TX History List buffer is less than the TX History List depth
- The TX History List is disabled
- The related CANFD channel is in CH_RESET mode.

THLELT bit (TX History List Entry Lost)

The THLELT bit is set when a new entry cannot be stored because the related TX History List buffer is already full.

Only write to this bit when the related CANFD channel is in CH_HALT or CH_OPERATION mode. Writing 1 has no effect.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1.

If the set from the CAN channel occurs simultaneously with the clear by the write access, then the bit is set.

This bit is cleared:

- By writing 0 to it
- When the related CANFD channel is in CH_RESET mode.

THLIF bit (TX History List Interrupt Flag)

The THLIF bit is set when the configured interrupt condition is satisfied.

Only write to this bit when the related CANFD channel is in CH_HALT or CH_OPERATION mode. Writing 1 has no effect.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1.

If the set from the CAN channel occurs simultaneously with the clear by the write access, then the bit is set.

This bit is cleared:

- By writing 0 to it
- When the related CANFD channel is in CH_RESET mode.

The bit is cleared by writing 0 to it.

This bit is automatically cleared in CH_RESET mode.

THLMC[3:0] bits (TX History List Message Count)

The THLMC[3:0] bits show the number of transmitted messages stored in the TX History List.

These bits are cleared automatically when the related CANFD channel is in CH_RESET mode.

31.2.49 CFDTHLACC0 : TX History List Access Register 0

Base address: CANFDn = 0x4038_0000 + 0x2000 × n (n = 0, 1)
CANFDn_NS = 0x5038_0000 + 0x2000 × n (n = 0, 1)

Offset address: 0x0740

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	TMTS[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	BN[1:0]		BT[2:0]		
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
2:0	BT[2:0]	Buffer Type 0 0 1: Flat TX message buffer 0 1 0: TX FIFO message buffer number 1 0 0: TX Queue message buffer number	R
4:3	BN[1:0]	Buffer Number Number of the message buffer	R

Bit	Symbol	Function	R/W
15:5	—	These bits are read as 0.	R
31:16	TMTS[15:0]	Transmit Timestamp Transmit timestamp value for software drivers	R

Note: S-TYPE-3, P-TYPE-3

The TX History List Access Registers 0 provide access to the entry in the TX History List based on the read timestamp value.

BT[2:0] bits (Buffer Type)

The BT[2:0] bits indicate whether data has been stored following a transmission from a FIFO buffer, a TX Queue or a TX message buffer.

BN[1:0] bits (Buffer Number)

The BN[1:0] bits show the message buffer from which transmission was successfully completed. If a message from a Common FIFO is transmitted, then these bits show the message buffer that is linked to the Common FIFO for transmission.

TMTS[15:0] bits (Transmit Timestamp)

The TMTS[15:0] bits indicate the timestamp for use by software drivers.

31.2.50 CFDTHLACC1 : TX History List Access Register 1

Base address: CANFDn = 0x4038_0000 + 0x2000 × n (n = 0, 1)
CANFDn_NS = 0x5038_0000 + 0x2000 × n (n = 0, 1)

Offset address: 0x0744

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	TIFL[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	TID[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	TID[15:0]	Transmit ID These bits indicate that message buffer reference ID, TX FIFO reference ID, or AFL pointer field is stored for software drivers.	R
17:16	TIFL[1:0]	Transmit Information Label These bits indicate that message buffer information label, TX FIFO information label, or AFL information label is stored for software drivers.	R
31:18	—	These bits are read as 0.	R

Note: S-TYPE-3, P-TYPE-3

The TX History List Access Registers 1 provide access to entry in the TX History List based on the read pointer value.

TID[15:0] bits (Transmit ID)

The TID[15:0] bits indicate whether the message buffer reference ID (CFDTMFDCTRb.TMPTR) or the TX FIFO reference ID (CFDCFFDCSTS.CFPTR) is for use by software drivers.

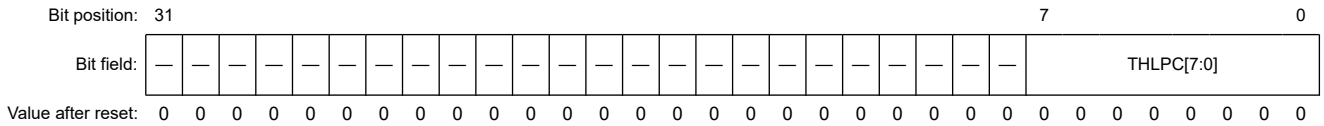
TIFL[1:0] bits (Transmit Information Label)

The TIFL[1:0] bits indicate whether the message buffer information label (CFDTMFDCTRb.TMIFL) or the TX FIFO information label (CFDCFFDCSTS.CFIFL) is for use by software drivers.

31.2.51 CFDTHLPCTR : TX History List Pointer Control Register

Base address: CANFDn = 0x4038_0000 + 0x2000 × n (n = 0, 1)
CANFDn_NS = 0x5038_0000 + 0x2000 × n (n = 0, 1)

Offset address: 0x00A0



Bit	Symbol	Function	R/W
7:0	THLPC[7:0]	TX History List Pointer Control Increments the write pointer to the TX History List in the corresponding channel	W
31:8	—	The write value should be 0.	W

Note: S-TYPE-3, P-TYPE-3

The TX History List Pointer Control Registers are used to increment the read pointer of the TX History List.

THLPC[7:0] bits (TX History List Pointer Control)

When 0xFF is written to the THLPC[7:0] bits, the read pointer of the TX History List is moved to the next TX History List entry address.

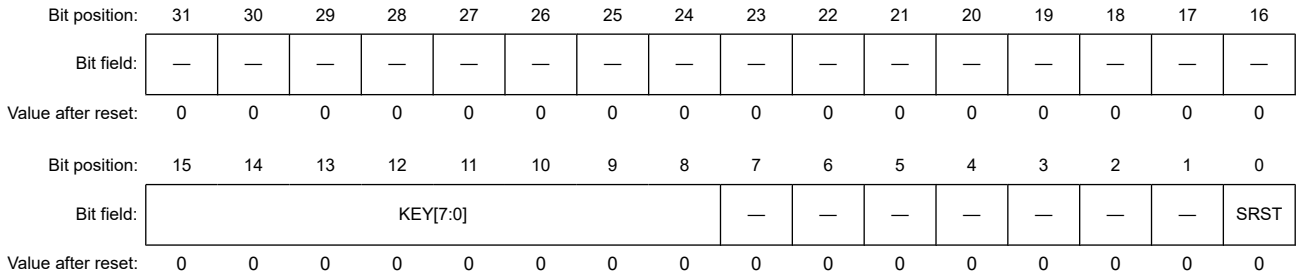
The read value from these bits is always 0x00. Only write to these bits when the related CANFD channel is in CH_HALT or CH_OPERATION mode.

Only write 0xFF to these registers when the corresponding TX History List is enabled and not empty.

31.2.52 CFDGRSTC : Global SW reset Register

Base address: CANFDn = 0x4038_0000 + 0x2000 × n (n = 0, 1)
CANFDn_NS = 0x5038_0000 + 0x2000 × n (n = 0, 1)

Offset address: 0x00D8



Bit	Symbol	Function	R/W
0	SRST	SW Reset 0: Normal state 1: SW reset state	R/W
7:1	—	These bits are read as 0. The write value should be 0.	R/W
15:8	KEY[7:0]	Key Code These bits control the validity of rewriting of a SRST bit.	W
31:16	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

SRST bit (SW Reset)

When the SRST bit is set, the CANFD module is in the same state as hardware reset. When a reset is required, write 1 then write 0 to this bit.

This bit is cleared when the CANFD module is in GL_SLEEP mode.

When this bit is cleared, the RAM initialization sequence does not operate. The configuration of RAM is performed by software.

The RAM is not initialized when software reset is performed during the initialization of RAM. Software must perform the initialization of RAM.

KEY[7:0] bits (Key Code)

When 0xC4 is written in the KEY[15:8] bits, a write to the SRST bit is valid.

The read value from these bits is always 0x00.

CFDGRSTC.SRST bit and the CFDGRSTC.KEY bit should be written simultaneously.

31.2.53 CFDGTSTCFG : Global Test Configuration Register

Base address: CANFDn = 0x4038_0000 + 0x2000 × n (n = 0, 1)
CANFDn_NS = 0x5038_0000 + 0x2000 × n (n = 0, 1)

Offset address: 0x00A8

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	RTMPS[3:0]			
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	—	These bits are read as 0. The write value should be 0.	R/W
19:16	RTMPS[3:0]	RAM Test Mode Page Select Select a RAM test mode page	R/W
31:20	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

The Global Test Configuration Register is used to configure the RAM test mode page.

RTMPS[3:0] bits (RAM Test Mode Page Select)

The RTMPS[3:0] bits select the RAM page mode for CPU read/write access when the CANFD module is configured in RAM test mode.

See section 31.9.2.1. RAM Test Mode for the RAM test mode specification.

Do not write to these bits when the CANFD module is in GL_RESET or GL_SLEEP mode.

Only enter values from 0 to 8 (0x008) for the message buffer RAM.

Only write to these bits when the CANFD module is in GL_HALT mode.

These bits are cleared automatically when the related CANFD channel is in GL_RESET mode.

31.2.54 CFDGTSTCTR : Global Test Control Register

Base address: CANFDn = 0x4038_0000 + 0x2000 × n (n = 0, 1)
CANFDn_NS = 0x5038_0000 + 0x2000 × n (n = 0, 1)

Offset address: 0x00AC

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	RTME	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
1:0	—	These bits are read as 0. The write value should be 0.	R/W
2	RTME	RAM Test Mode Enable 0: RAM test mode disabled 1: RAM test mode enabled	R/W
31:3	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

The Global Test Control register is used to control the global test modes of the CANFD module.

RTME bit (RAM Test Mode Enable)

When the RTME bit is set, the CANFD module is configured in RAM test mode. See section 31.9.2.1. RAM Test Mode for RAM test mode specification.

Only write to this bit when the CANFD module is in GL_HALT mode.

Clear this bit when the CANFD module is in GL_HALT mode.

This bit is cleared automatically when the CANFD module is in GL_RESET mode.

31.2.55 CFDGFDCFG : Global FD Configuration Register

Base address: CANFDn = 0x4038_0000 + 0x2000 × n (n = 0, 1)
CANFDn_NS = 0x5038_0000 + 0x2000 × n (n = 0, 1)

Offset address: 0x00B0

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

7:1	—	These bits are read as 0. The write value should be 0.	R/W

Bit	Symbol	Function	R/W
9:8	TSCCFG[1:0]	Timestamp Capture Configuration 0 0: Timestamp capture at the sample point of SOF (start of frame) 0 1: Timestamp capture at frame valid indication 1 0: Timestamp capture at the sample point of RES bit 1 1: Reserved	R/W
31:10	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

RPED bit (RES Bit Protocol Exception Disable)

The RPED bit configures the protocol exception event handling according to ISO 11898-1.

When this bit is enabled, the protocol exception event detection is disabled, and the protocol controller transmits an error frame when the protocol exception event is detected (RES bit is sampled recessive).

Only write to this bit when the CANFD module is in GL_RESET mode.

TSCCFG[1:0] bits (Timestamp Capture Configuration)

The TSCCFG[1:0] bits configure the different capture points of the timestamp for transmission and reception.

When CFDGFDCFG.TSCCFG[1:0] = 10b, the timestamp capture is performed for CANFD frames at RES bit and for Classical frames at the start of frame.

Only write to these bits when the CANFD module is in GL_RESET mode.

31.2.56 CFDGLOCKK : Global Lock Key Register

Base address: CANFDn = 0x4038_0000 + 0x2000 × n (n = 0, 1)
CANFDn_NS = 0x5038_0000 + 0x2000 × n (n = 0, 1)

Offset address: 0x00B8

Bit position:	31															15															0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	LOCK[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	LOCK[15:0]	Lock Key Key bits for unlocking the protection of test modes	W
31:16	—	The write value should be 0.	W

Note: S-TYPE-3, P-TYPE-3

The Global Lock Key register is a write-only register that is used to unlock the protection for special test bits.

See section 31.9.2. Global Test Modes for Lock key specification.

LOCK[15:0] bits (Lock Key)

The unlock key sequence must be written in the LOCK[15:0] bits to configure the CANFD module in RAM test modes.

The read value from these bits is always 0x0000.

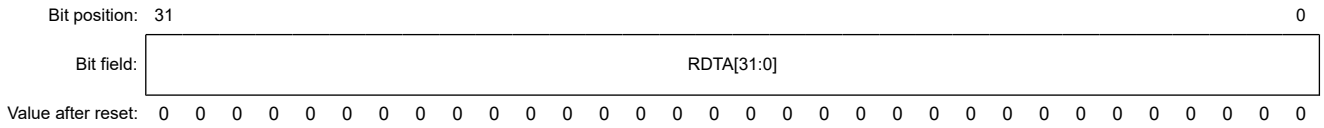
You cannot write to these bits when the CANFD module is in GL_SLEEP or GL_RESET mode.

Do not write to these bits when the CANFD module is in GL_OPERATION mode.

31.2.57 CFDRPGACCk : RAM Test Page Access Registers k (k = 0 to 63)

Base address: CANFDn = 0x4038_0000 + 0x2000 × n (n = 0, 1)
CANFDn_NS = 0x5038_0000 + 0x2000 × n (n = 0, 1)

Offset address: 0x0280 + 0x0004 × k



Bit	Symbol	Function	R/W
31:0	RDTA[31:0]	RAM Data Test Access RAM data bytes	R/W

Note: S-TYPE-3, P-TYPE-3

RDTA[31:0] bits (RAM Data Test Access)

Data can be read from or written into the RDTA[31:0] bits when the CANFD module is configured in RAM test mode.

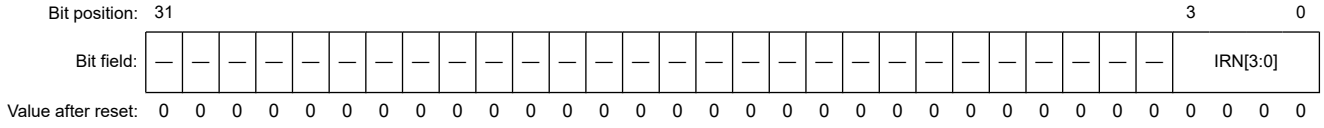
Only write to this bit when the CANFD module is in GL_HALT mode and RAM test mode is enabled.

Software data should be read/written in the RAM Test Page Access registers during RAM test mode.

31.2.58 CFDGAFLIGNENT : Global AFL Ignore Entry Register

Base address: CANFDn = 0x4038_0000 + 0x2000 × n (n = 0, 1)
CANFDn_NS = 0x5038_0000 + 0x2000 × n (n = 0, 1)

Offset address: 0x00C0



Bit	Symbol	Function	R/W
3:0	IRN[3:0]	Ignore Rule Number Define rule number which ignores an AFL entry.	R/W
31:4	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

IRN[3:0] bits (Ignore Rule Number)

The IRN[3:0] bits define the rule number which updates an AFL entry.

Enter only values between 0 and 15 (0x0F) inclusive.

Only write to these bits when the CFDGAFLIGNCTR.IREN bit is 0.

You cannot write to these bits when the CANFD module is in GL_SLEEP mode.

31.2.59 CFDGAFLIGNCTR : Global AFL Ignore Control Register

Base address: CANFDn = 0x4038_0000 + 0x2000 × n (n = 0, 1)
CANFDn_NS = 0x5038_0000 + 0x2000 × n (n = 0, 1)

Offset address: 0x00C4

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	KEY[7:0]								—	—	—	—	—	—	—	IREN
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	IREN	Ignore Rule Enable 0: AFL entry number is not ignored 1: AFL entry number is ignored	R/W
7:1	—	These bits are read as 0. The write value should be 0.	R/W
15:8	KEY[7:0]	Key Code These bits control the validity of rewriting the IREN bit.	W
31:16	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

IREN bit (Ignore Rule Enable)

When the IREN bit is set, the entry number (selected by CFDGAFLIGNENT register) is ignored.

This bit is cleared automatically when the CANFD module is in GL_RESET mode.

KEY[7:0] bits (Key Code)

When 0xC4 is written in the KEY[7:0] bits, a write to the IREN bit is valid.

The read value from these bits is always 0x00.

CFDGAFLIGNCTR.IREN bit and the CFDGAFLIGNCTR.KEY bit should be written simultaneously

31.2.60 CFDRMIEC : RX Message Buffer Interrupt Enable Configuration Register

Base address: CANFDn = 0x4038_0000 + 0x2000 × n (n = 0, 1)
CANFDn_NS = 0x5038_0000 + 0x2000 × n (n = 0, 1)

Offset address: 0x0038

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	RMIE[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	RMIE[15:0]	RX Message Buffer Interrupt Enable 0: RX Message Buffer Interrupt disabled for corresponding RX message buffer 1: RX Message Buffer Interrupt enabled for corresponding RX message buffer	R/W

Note: S-TYPE-3, P-TYPE-3

These bits show the RX Message Buffer Interrupt Enable for the corresponding RX Message Buffer. CFDRMIEC bit 0 corresponds to RX Message Buffer 0 and so on.

The bit position of CFDRMIEC corresponds to the buffer number of RXMB.

RMIE[15:0] bit (RX Message Buffer Interrupt Enable)

If this bit is set, then an interrupt will be generated at the end of a successful reception from the corresponding Message Buffer.

For details, see section 31.7.1. Interrupts.

Users cannot write to this bit when the CANFD module is in GL_SLEEP mode.

31.2.61 Message Buffer Component Structure

31.2.61.1 Start Addresses

The start address for each of the Message Buffer component is calculated using the number of related Message Buffer components.

The start addresses for each register in the Message Buffer component are depicted in Table 31.4.

Table 31.4 Message Buffer Component Register Start Addresses

b = Message buffer component index	MBCP	p	Register	Start Address
[0…15] b = [0…7]	RMBCPb[0]	x	RMID	0x0920 + b × 0x004C
		x	RMPTR	0x0924 + b × 0x004C
		x	RMFDSTSb	0x0928 + b × 0x004C
		[1…15]	RMDFbp	0x092C + b × 0x004C + p × 0x0004
[0…15] b = [8…15]	RMBCPb[0]	x	RMIDb	0x0D20 + (b-8) × 0x004C
		x	RMPTRb	0x0D24 + (b-8) × 0x004C
		x	RMFDSTSb	0x0D28 + (b-8) × 0x004C
		[1…15]	RMDFbp	0x0D2C + (b-8) × 0x004C + p × 0x0004
[0…1]	RFMBCPb[0]	x	RFIDb	0x0520 + b × 0x004C
		x	RFPTRb	0x0524 + b × 0x004C
		x	RFFDSTSb	0x0528 + b × 0x004C
		[1…15]	RFDFbp	0x052C + b × 0x004C + p × 0x0004
[0]	CFMBCPb[0]	x	CFID	0x05B8
		x	CFPTR0	0x05BC
		x	CFFDCSTS0	0x05C0
		[1…15]	CFDFp0	0x05C4 + p × 0x0004
[0…3]	TMBCPb[0]	x	TMIDb	0x0604 + b × 0x004C
		x	TMPTRb	0x0608 + b × 0x004C
		x	TMFDCTRb	0x060C + b × 0x004C
		[1…15]	TMDFbp	0x0610 + b × 0x004C + p × 0x0004

The message buffer configuration consists of four types of Message Buffer components:

- RX Message Buffer Component (CFDRMBCPb[0])
- RX FIFO Access Message Buffer Component (CFDRFMBCPb[0])
- Common FIFO Access Message Buffer Component (CFDCFMBCP0[0])
- TX Message Buffer Component (CFDTMBCPb[0]).

Where b = the Message Buffer component index that has a range that varies based on the type of Message Buffer component.

For a summary of this configuration, see Figure 31.28. For a detailed description of the number of and the different types of message buffers, see section 31.6. FIFO Buffers and Normal Message Buffer Configuration.

As described in section 31.2. Register Descriptions, each Message Buffer component consists of the following registers:

- Identifier (ID)
- Pointer (PTR)
- Data Field (DFp).

Where p = the Data Field register index that has a range that varies based on the type of message buffer component.

Rc is the Message Buffer Component register where c = Message Buffer Component register index that has a range that varies based on the type of Message Buffer component.

A description of the registers, their associated bits and their accessibility are shown below the summary and detailed figures of each component.

In each of the figures, a cell that contains '-' means reserved and has the same behavio as reserved bits for registers in section 31.2.61. Message Buffer Component Structure.

31.2.61.2 CFDRMBCPb[0] : RX Message Buffer Component b (b = 0 to 15)

Base address: CANFDn = 0x4038_0000 + 0x2000 × n (n = 0, 1)
CANFDn_NS = 0x5038_0000 + 0x2000 × n (n = 0, 1)

Offset address: See Table 31.4

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	Rc[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	Rc[15:0]	RX Message Buffer Component c Refer to Table 31.5, Table 31.6 and the descriptions that follow for a detailed description of each register and its related bits, contained within this message buffer component.	R/W

Note: S-TYPE-3, P-TYPE-3

Where the total number of CFDRMBCPb = 16 as shown in Figure 31.28 (c = RX Message Buffer Component Register index = [0…18])

Rc[15:0] bit (RX Message Buffer Component c)

The RX Message Buffer Component is made up of the following registers: CFDRMIDb, CFDRMPTRb, CFDRMFDSTSb, and CFDRMDFbp. Refer to Table 31.6 for details of how to interpret the structure of this buffer component and how to access the respective registers.

Table 31.5 RX Message Buffer Component Summary (1 of 2)

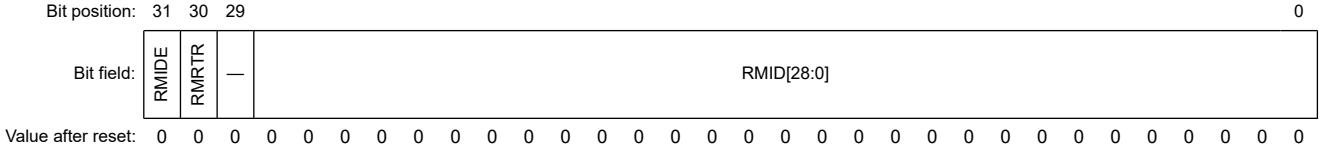
31.2.61.3 CFDRMIDb : RX Message Buffer ID Registers (b = 0 to 15)

Base address: CANFDn = 0x4038_0000 + 0x2000 × n (n = 0, 1)
CANFDn_NS = 0x5038_0000 + 0x2000 × n (n = 0, 1)

Offset address: 0x0920 + 0x004C × b (b = 0 to 7)
0x0D20 + 0x004C × (b - 8) (b = 8 to 15)



Bit	Symbol	Function	R/W
28:0	RMID[28:0]	RX Message Buffer ID Field STD-ID/EXT-ID fields	R
29	—	This bit is read as 0.	R

Bit	Symbol	Function	R/W
30	RMRTR	RX Message Buffer RTR Bit 0: Data frame 1: Remote frame	R
31	RMIDE	RX Message Buffer IDE Bit 0: STD-ID is stored 1: EXT-ID is stored	R

Note: S-TYPE-3, P-TYPE-3

The RX Message Buffer ID Register b (b = 0 to 15) store the ID field, IDE bit, and RTR bit of the received message.

RMID[28:0] bits (RX Message Buffer ID Field)

The RMID[28:0] are the bits of the STD-ID/EXT-ID fields of the message stored in the RX message buffer.

See section 31.2.61.1. Start Addresses for details on how to interpret the structure of this buffer component.

RMRTR bit (RX Message Buffer RTR Bit)

The RMRTR bit shows whether a data frame or a remote frame was stored in the RX message buffer.

Note: There are no remote frames in CANFD format. When a CANFD frame is received, the register reflects the state of the received value (the RRS bit in FD frame format).

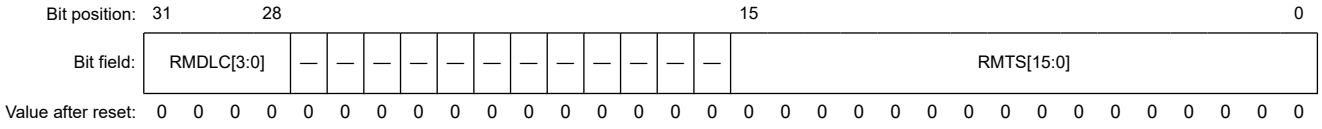
RMIDE bit (RX Message Buffer IDE Bit)

The RMIDE bit shows whether message with Standard Identifier or Extended Identifier was stored in the RX message buffer.

31.2.61.4 CFDRMPTRb : RX Message Buffer Pointer Registers (b = 0 to 15)

Base address: CANFDn = 0x4038_0000 + 0x2000 × n (n = 0, 1)
CANFDn_NS = 0x5038_0000 + 0x2000 × n (n = 0, 1)

Offset address: 0x0924 + 0x004C × b (b = 0 to 7)
0x0D24 + 0x004C × (b - 8) (b = 8 to 15)



Bit	Symbol	Function	R/W
15:0	RMTS[15:0]	RX Message Buffer Timestamp Field Timestamp value stored for the message in the RX message buffer	R
27:16	—	These bits are read as 0.	R
31:28	RMDLC[3:0]	RX Message Buffer DLC Field Number of data bytes received in a CAN frame.	R

Note: S-TYPE-3, P-TYPE-3

The RX Message Buffer Pointer Register b (b = 0 to 15) store the DLC and Timestamp fields for the received message.

RMTS[15:0] bits (RX Message Buffer Timestamp Field)

The RMTS[15:0] bits store the timestamp value taken at the capture point as configured by CFDGFDCFG.TSCCFG of the received message.

RMDLC[3:0] bits (RX Message Buffer DLC Field)

The RMDLC[3:0] bits store the number of data bytes that were received in the RX message buffer.

See Table 5 in ISO 11898-1 (2015) Specification for details in defining the number of data bytes that were received.

Note: The maximum capacity of the buffer belongs to CFDRMNB.RMPLS and this is not available in the classical CAN function.

31.2.61.5 CFDRMFDSTSb : RX Message Buffer CANFD Status Registers (b = 0 to 15)

Base address: CANFDn = 0x4038_0000 + 0x2000 × n (n = 0, 1)
CANFDn_NS = 0x5038_0000 + 0x2000 × n (n = 0, 1)

Offset address: 0x0928 + 0x004C × b (b = 0 to 7)
0x0D28 + 0x004C × (b - 8) (b = 8 to 15)

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	RMPTR[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	RMIFL[1:0]		—	—	—	—	—	RMFDF	RMBRS	RMESI
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	RMESI*1	Error State Indicator bit 0: CANFD frame received from error active node 1: CANFD frame received from error passive node	R
1	RMBRS*1	Bit Rate Switch bit 0: CANFD frame received with no bit rate switch 1: CANFD frame received with bit rate switch	R
2	RMFDF*1	CAN FD Format bit 0: Non CANFD frame received 1: CANFD frame received	R
7:3	—	These bits are read as 0.	R
9:8	RMIFL[1:0]	RX Message Buffer Information Label Field	R
15:10	—	These bits are read as 0.	R
31:16	RMPTR[15:0]	RX Message Buffer Pointer Field	R

Note: S-TYPE-3, P-TYPE-3
Note 1. This bit is not available in the classical CAN function.

The RX Message Buffer CANFD Status Register b (b = 0 to 15) show the status of the FDF, BRS and ESI bits, and pointer of the received CANFD frame.

RMESI bit (Error State Indicator bit)

The RMESI bit has the same value as the ESI bit of the received CANFD frame.

When the received FDF bit is 0, this means a CAN2.0 frame is received and 0 is stored to this bit.

Note: This bit is not available in the classical CAN function.

RMBRS bit (Bit Rate Switch bit)

The RMBRS bit has the same value as the BRS bit of the received CANFD frame.

When the received FDF bit is 0, this means a CAN2.0 frame is received and 0 is stored to this bit.

Note: This bit is not available in the classical CAN function.

RMFDF bit (CAN FD Format bit)

The RMFDF bit has the same value as the FDF bit of the received CANFD frame.

Note: This bit is not available in the classical CAN function.

RMIFL[1:0] bits (RX Message Buffer Information Label Field)

The RMIFL[1:0] bits store the information label value from the related Global Acceptance Filter List entry.

RMPTR[15:0] bits (RX Message Buffer Pointer Field)

The RMPTR[15:0] bits store the pointer value from the related Global Acceptance Filter List entry.

31.2.61.6 CFDRMDFb_p : RX Message Buffer Data Field p Registers (p = 0 to 15, b = 0 to 15)

Base address: CANFDn = 0x4038_0000 + 0x2000 × n (n = 0, 1)
CANFDn_NS = 0x5038_0000 + 0x2000 × n (n = 0, 1)

Offset address: 0x092C + 0x004C × b + 0x0004 × p (b = 0 to 7 , p = 0 to 15)
0x0D2C + 0x004C × (b - 8) + 0x0004 × p (b = 8 to 15 , p = 0 to 15)

Bit position:	31 … 24	23 … 16	15 … 8	7 … 0
Bit field:	RMDB_HH[7:0]	RMDB_HL[7:0]	RMDB_LH[7:0]	RMDB_LL[7:0]
Value after reset:	0 0 0 0 0 0 0 0	0 0 0 0 0 0 0 0	0 0 0 0 0 0 0 0	0 0 0 0 0 0 0 0

Bit	Symbol	Function	R/W
7:0	RMDB_LL[7:0]	RX Message Buffer Data Byte (p × 4)	R
15:8	RMDB_LH[7:0]	RX Message Buffer Data Byte ((p × 4) + 1)	R
23:16	RMDB_HL[7:0]	RX Message Buffer Data Byte ((p × 4) + 2)	R
31:24	RMDB_HH[7:0]*1	RX Message Buffer Data Byte ((p × 4) + 3)	R

Note: S-TYPE-3, P-TYPE-3
Note 1. These bits are not available in the classical CAN function.

The RX Message Buffer Data Field p Register b (p = 0 to 15, b = 0 to 15) store the data bytes (p × 4) to data bytes ((p × 4) + 3) of the received message.

RMDB_LL[7:0] bits (RX Message Buffer Data Byte (p × 4))

The RMDB_LL[7:0] bits store data bytes (p × 4) of the message in the RX message buffer.

Unused data bytes are filled with 0x00.

RMDB_LH[7:0] bits (RX Message Buffer Data Byte ((p × 4) + 1))

The RMDB_LH[7:0] bits store data bytes ((p × 4) + 1) of the message in the RX message buffer.

Unused Data Bytes will be filled with 0x00.

RMDB_HL[7:0] bits (RX Message Buffer Data Byte ((p × 4) + 2))

The RMDB_HL[7:0] bits store data bytes ((p × 4) + 2) of the message in the RX message buffer.

Unused data bytes are filled with 0x00.

RMDB_HH[7:0] bits (RX Message Buffer Data Byte ((p × 4) + 3))

The RMDB_HH[7:0] bits store data bytes ((p × 4) + 3) of the message in the RX message buffer.

Unused data bytes are filled with 0x00.

31.2.61.7 CFDRFMBCPb[0] : RX FIFO Access Message Buffer Component b (b = 0 to 1)

Base address: CANFDn = 0x4038_0000 + 0x2000 × n (n = 0, 1)
CANFDn_NS = 0x5038_0000 + 0x2000 × n (n = 0, 1)

Offset address: see Table 31.4

Bit position:	31 … 0
Bit field:	Rc[31:0]
Value after reset:	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

Bit	Symbol	Function	R/W
31:0	Rc[31:0]	RX FIFO Access Message Buffer Component c See Table 31.7, Table 31.8 and the descriptions that follow for a detailed description of each register and its related bits, contained within this message buffer component.	R

Note: S-TYPE-3, P-TYPE-3

Where the total number of CFDRFMBCPb = 2 as shown in Figure 31.28 (c = RX FIFO Access Message Buffer Component Register index = [0…18])

Rc[31:0] bits (RX FIFO Access Message Buffer Component c)

The RX FIFO Access Message Buffer component comprises of the following registers:

- CFDRFIDb
- CFDRFPTRb
- CFDRFFDSTSb
- CFDRFDFbp

See Table 31.8 for details on how to interpret the structure of this buffer component and how to access the respective registers.

31.2.61.8 CFDRFIDb : RX FIFO Access ID Register b (b = 0 to 1)

Base address: CANFDn = 0x4038_0000 + 0x2000 × n (n = 0, 1)
CANFDn_NS = 0x5038_0000 + 0x2000 × n (n = 0, 1)

Offset address: 0x0520 + 0x004C × b

Bit position:	31	30	29	0
Bit field:	RFIDE	RFRTR	—	RFID[28:0]
Value after reset:	0	0	0	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

Bit	Symbol	Function	R/W
28:0	RFID[28:0]	RX FIFO Buffer ID Field STD-ID/EXT-ID fields	R
29	—	This bit is read as 0.	R
30	RFRTR	RX FIFO Buffer RTR bit 0: Data frame 1: Remote frame	R
31	RFIDE	RX FIFO Buffer IDE bit 0: STD-ID has been received 1: EXT-ID has been received	R

Note: S-TYPE-3, P-TYPE-3

The RX FIFO Access ID Registers b (b = 0 to 1) store the ID field, IDE bit and RTR bit of the message.

RFID[28:0] bits (RX FIFO Buffer ID Field)

The RFID[28:0] bits are the bits of the STD-ID/EXT-ID fields of the message in the FIFO buffer.

For alignment of these bits in standard and extended frame format, see Identifier Bits Alignment.

RFRTR bit (RX FIFO Buffer RTR bit)

The RFRTR bit shows whether a data frame or a remote frame was stored in the FIFO buffer.

Note: There are no remote frames in CANFD format. When a CANFD frame was received, the register reflects the state of the received value (RRS bit in FD frame format).

RFIDE bit (RX FIFO Buffer IDE bit)

The RFIDE bit shows whether message with the Standard Identifier or Extended Identifier was received in the FIFO buffer.

31.2.61.9 CFDRFPTRb : RX FIFO Access Pointer Register b (b = 0 to 1)

Base address: CANFDn = 0x4038_0000 + 0x2000 × n (n = 0, 1)
CANFDn_NS = 0x5038_0000 + 0x2000 × n (n = 0, 1)

Offset address: 0x0524 + 0x004C × b

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	RFDLC[3:0]				—	—	—	—	—	—	—	—	—	—	—	—	RFTS[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	RFTS[15:0]	RX FIFO Timestamp Value Timestamp value of the received CAN frame	R
27:16	—	These bits are read as 0.	R
31:28	RFDLC[3:0]	RX FIFO Buffer DLC Field Number of data bytes received in a CAN frame	R

Note: S-TYPE-3, P-TYPE-3

The FIFO Access Pointer Registers b (b = 0 to 1) store the DLC and Timestamp fields for the received message.

RFTS[15:0] bits (RX FIFO Timestamp Value)

The RFTS[15:0] bits store the timestamp value taken at the capture point as configured by the CFDGFDCFG.TSCCFG bit of the received message.

RFDLC[3:0] bits (RX FIFO Buffer DLC Field)

The RFDLC[3:0] bits store the number of data bytes that were received in the RX FIFO buffer.

See Table 5 in ISO 11898-1 (2015) Specification for details in defining the number of data bytes that were received.

31.2.61.10 CFDRFFDSTSb : RX FIFO Access CANFD Status Register b (b = 0 to 1)

Base address: CANFDn = 0x4038_0000 + 0x2000 × n (n = 0, 1)
CANFDn_NS = 0x5038_0000 + 0x2000 × n (n = 0, 1)

Offset address: 0x0528 + 0x004C × b

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	CFDRFPTR[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	RFIFL[1:0]		—	—	—	—	—	RFFDF	RFBRS	RFESI
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	RFESI*1	Error State Indicator bit 0: CANFD frame received from error active node 1: CANFD frame received from error passive node	R
1	RFBRS*1	Bit Rate Switch bit 0: CANFD frame received with no bit rate switch 1: CANFD frame received with bit rate switch	R
2	RFFDF*1	CAN FD Format bit 0: Non CANFD frame received 1: CANFD frame received	R
7:3	—	These bits are read as 0.	R

Bit	Symbol	Function	R/W
9:8	RFIFL[1:0]	RX FIFO Buffer Information Label Field	R
15:10	—	These bits are read as 0.	R
31:16	CFDRFPTR[15:0]	RX FIFO Buffer Pointer Field	R

Note: S-TYPE-3, P-TYPE-3
Note 1. This bit is not available in the classical CAN function.

The RX FIFO Access CANFD Status Registers b (b = 0 to 1) show the status of the FDF, BRS, and ESI bits, including the pointer of the received CANFD frame.

RFESI bit (Error State Indicator bit)

The RFESI bit has the same value as the ESI bit of the received CANFD frame.

When the received FDF bit is 0, this means a CAN2.0 frame is received and 0 is stored to this bit.

Note: This bit is not available in the classical CAN function.

RFBRS bit (Bit Rate Switch bit)

The RFBRS bit has the same value as the BRS bit of the received CANFD frame.

When the received FDF bit is 0, this means a CAN2.0 frame is received and 0 is stored to this bit.

Note: This bit is not available in the classical CAN function.

RFFDF bit (CAN FD Format bit)

The RFFDF bit has the same value as the FDF bit of the received CANFD frame.

Note: This bit is not available in the classical CAN function.

RFIFL[1:0] bits (RX FIFO Buffer Information Label Field)

The RFIFL[1:0] bits store the information label value from the related Global Acceptance Filter List entry.

CFDRFPTR[15:0] bits (RX FIFO Buffer Pointer Field)

The CFDRFPTR[15:0] bits store the pointer value from the related Global Acceptance Filter List entry.

31.2.61.11 CFDRFDFb_p : RX FIFO Access Data Field p Register b (p = 0 to 15, b = 0 to 1)

Base address: CANFDn = 0x4038_0000 + 0x2000 × n (n = 0, 1)
CANFDn_NS = 0x5038_0000 + 0x2000 × n (n = 0, 1)

Offset address: 0x052C + 0x004 × p + 0x04C × b

Bit position:	31 … 24	23 … 16	15 … 8	7 … 0
Bit field:	RFDB_HH[7:0]	RFDB_HL[7:0]	RFDB_LH[7:0]	RFDB_LL[7:0]
Value after reset:	0 0 0 0 0 0 0 0	0 0 0 0 0 0 0 0	0 0 0 0 0 0 0 0	0 0 0 0 0 0 0 0

Bit	Symbol	Function	R/W
7:0	RFDB_LL[7:0]	RX FIFO Buffer Data Byte (p × 4)	R
15:8	RFDB_LH[7:0]	RX FIFO Buffer Data Byte ((p × 4) + 1)	R
23:16	RFDB_HL[7:0]	RX FIFO Buffer Data Byte ((p × 4) + 2)	R
31:24	RFDB_HH[7:0]	RX FIFO Buffer Data Byte ((p × 4) + 3)	R

Note: S-TYPE-3, P-TYPE-3

The RX FIFO Access Data Field p Registers b (p = 0 to 15, b = 0 to 1) store data bytes ((p × 4) to data byte ((p × 4) + 3) of the received message.

RFDB_LL[7:0] bits (RX FIFO Buffer Data Byte (p × 4))

The RFDB_LL[7:0] bits store data bytes (p × 4) of the message present in the FIFO buffer.

Unused data bytes are filled with 0x00 according to the configured data payload size CFDRFCCa.RFPLS.

RFDB_LH[7:0] bits (RX FIFO Buffer Data Byte ((p × 4) + 1))

The RFDB_LH[7:0] bits store data bytes ((p × 4) + 1)) of the message present in the FIFO buffer.

Unused data bytes are filled with 0x00.

RFDB_HL[7:0] bits (RX FIFO Buffer Data Byte ((p × 4) + 2))

The RFDB_HL[7:0] bits store data bytes ((p × 4) + 2) of the message present in the FIFO buffer.

Unused data bytes are filled with 0x00.

RFDB_HH[7:0] bits (RX FIFO Buffer Data Byte ((p × 4) + 3))

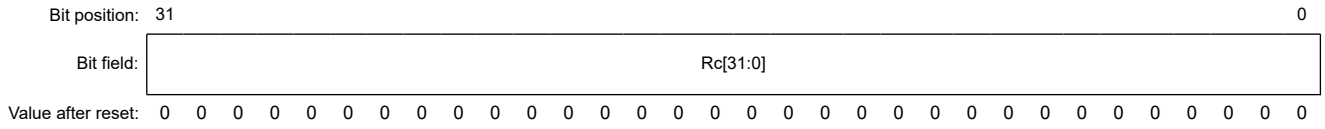
The RFDB_HH[7:0] bits store data bytes ((p × 4) + 3) of the message present in the FIFO buffer.

Unused data bytes are filled with 0x00.

31.2.61.12 CFDCFMBCP0[0] : Common FIFO Access Message Buffer Component

Base address: CANFDn = 0x4038_0000 + 0x2000 × n (n = 0, 1)
CANFDn_NS = 0x5038_0000 + 0x2000 × n (n = 0, 1)

Offset address: See Table 31.4



Bit	Symbol	Function	R/W
31:0	Rc[31:0]	Common FIFO Access Message Buffer Component c Refer to Table 31.9, Table 31.10 and the descriptions that follow for a detailed description of each register and its related bits, contained within this message buffer component.	R

Note: S-TYPE-3, P-TYPE-3

Where the total number of CFDCFMBCP0 = 1 as shown in Figure 31.28 (c = Common FIFO Message Buffer Component Register index = [0…18])

Rc[31:0] bit (Common FIFO Access Message Buffer Component c)

The Common FIFO Access Message Buffer Component is made up of the following registers: CFDCFID, CFDCFPTR, CFFDSTS0, and CFDCFDFp. Refer to Table 31.10 for details of how to interpret the structure of this buffer component and how to access the respective registers.

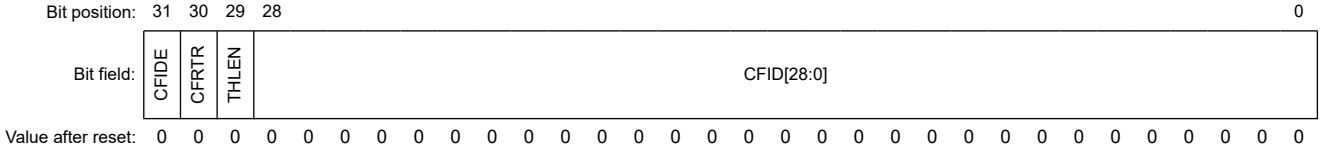
31.2.61.13 CFDCFID : Common FIFO Access ID Register

Base address: CANFDn = 0x4038_0000 + 0x2000 × n (n = 0, 1)
CANFDn_NS = 0x5038_0000 + 0x2000 × n (n = 0, 1)

Offset address: 0x05B8



Bit	Symbol	Function	R/W
28:0	CFID[28:0]	Common FIFO Buffer ID Field STD-ID / EXT-ID fields	R/W

Bit	Symbol	Function	R/W
29	THLEN	THL Entry enable TX FIFO Mode: 0: Entry will not be stored in THL after successful TX. 1: Entry will be stored in THL after successful TX. RX FIFO Mode: Reserved, this bit is read as 0	R/W
30	CFRTR	Common FIFO Buffer RTR Bit 0: Data Frame 1: Remote Frame	R/W
31	CFIDE	Common FIFO Buffer IDE Bit 0: STD-ID will be transmitted or has been received 1: EXT-ID will be transmitted or has been received	R/W

Note: S-TYPE-3, P-TYPE-3

The Common FIFO Access ID registers store the ID field, IDE bit and RTR bit of the message.

In TX mode, users can read data from the FIFO, only for the current entry based on the write pointer value, not for the other entries.

CFID[28:0] bit (Common FIFO Buffer ID Field)

These are the bits of the STD-ID / EXT-ID fields of the message in the FIFO Buffer.

In TX mode, users can write and read from FIFO buffers.

In RX mode, users can only read data from FIFO buffers.

THLEN bit (THL Entry enable)

This bit controls the storage of an entry corresponding to the transmitted message in the TX History list at the end of a successful transmission.

In TX mode, users can write and read from FIFO buffers.

In RX mode, users can only read data from FIFO buffers.

CFRTR bit (Common FIFO Buffer RTR Bit)

This bit selects whether a Data Frame or a Remote Frame will be transmitted from or was received in the FIFO Buffer.

Note: There are no remote frames in CANFD format. In case a CANFD frame was received (RX mode) the register reflects the state of the received value (RRS bit in FD frame format). In case of CANFD transmission (TX mode CFDCFID.CFFDF =1) the bit is always transmitted dominant (Data Frame).

In TX mode, users can write and read from FIFO buffers.

In RX mode, users can only read data from FIFO buffers.

CFIDE bit (Common FIFO Buffer IDE Bit)

This bit selects whether a message with EXT-ID or STD-ID will be transmitted from or was received in the FIFO Buffer.

In TX mode, users can write and read from FIFO buffers.

In RX mode, users can only read data from FIFO buffers.

31.2.61.14 CFDCFPTR : Common FIFO Access Pointer Register

Base address: CANFDn = 0x4038_0000 + 0x2000 × n (n = 0, 1)
CANFDn_NS = 0x5038_0000 + 0x2000 × n (n = 0, 1)

Offset address: 0x05BC

Bit position:	31			28												15														0
Bit field:	CFDLC[3:0]				—	—	—	—	—	—	—	—	—	—	—	—	CFTS[15:0]														
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	CFTS[15:0]	Common FIFO Timestamp Value Timestamp value of the received CAN frame (FIFO in RX mode).	R/W
27:16	—	These bits are read as 0. The write value should be 0.	R/W
31:28	CFDLC[3:0]	Common FIFO Buffer DLC Field Number of data bytes received in a CAN frame, or to be transmitted in a CAN frame.	R/W

Note: S-TYPE-3, P-TYPE-3

The Common FIFO Access Pointer Registers store the DLC and Timestamp fields.

In TX mode, you can read data from the FIFO buffer, only for the current entry based on the write pointer value, and not for the other entries.

CFTS[15:0] bits (Common FIFO Timestamp Value)

The CFTS[15:0] bits store the timestamp value taken at the capture point as configured by the CFDGFDCFG.TSCCFG bit of the received message (if FIFO is configured in RX mode).

In TX mode, you can read and write from FIFO buffers.

In RX mode, you can only read data from FIFO buffers.

CFDLC[3:0] bits (Common FIFO Buffer DLC Field)

The CFDLC[3:0] bits store the number of data bytes that were received in the FIFO buffer or are to be transmitted.

See Table 5 in ISO 11898-1 (2015) Specification for details in defining the number of data bytes.

In TX mode, you can read and write from the FIFO buffers. Do not read data for the other entries in the FIFO when configured in TX mode.

In RX mode, you can only read data from the FIFO buffers.

31.2.61.15 CFDCFFDCSTS : Common FIFO Access CANFD Control/Status Register

Base address: CANFDn = 0x4038_0000 + 0x2000 × n (n = 0, 1)
CANFDn_NS = 0x5038_0000 + 0x2000 × n (n = 0, 1)

Offset address: 0x05C0

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	CFPTR[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	CFIFL[1:0]		—	—	—	—	—	CFFDF	CFBRS	CFESI
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	CFESI*1	Error State Indicator bit 0: CANFD frame received or to transmit by error active node 1: CANFD frame received or to transmit by error passive node	R/W
1	CFBRS*1	Bit Rate Switch bit 0: CANFD frame received or to transmit with no bit rate switch 1: CANFD frame received or to transmit with bit rate switch	R/W
2	CFFDF*1	CAN FD Format bit 0: Non CANFD frame received or to transmit 1: CANFD frame received or to transmit	R/W
7:3	—	These bits are read as 0. The write value should be 0.	R/W
9:8	CFIFL[1:0]	COMMON FIFO Buffer Information Label Field	R/W
15:10	—	These bits are read as 0. The write value should be 0.	R/W

Bit	Symbol	Function	R/W
31:16	CFPTR[15:0]	Common FIFO Buffer Pointer Field	R/W

Note: S-TYPE-3, P-TYPE-3
Note 1. This bit is not available in the classical CAN function.

The Common FIFO Access CANFD Control/Status Registers show the status of the FDF, BRS and ESI bits, including the pointer of the received CANFD frame or the CANFD frame to transmit.

In TX mode, you can read data from the FIFO, only for the current entry based on the write pointer value, and not for the other entries.

CFESI bit (Error State Indicator bit)

In TX mode, you can read and write from FIFO buffers. In this mode, when the CANFD module is not in error passive, the CFESI bit equals the write value. Otherwise, it is a don’t care and the bit is transmitted as 1 on the CAN bus, indicating this is an error passive node.

In RX mode, you can only read data from FIFO buffers.

In RX mode, the CFESI bit is updated with the ESI bit value of the CANFD frame when it has been received, indicating the error state of the transmitting node. In RX mode, 0 is stored to this bit when the received FDF bit is 0, this means a CAN 2.0 frame is received.

Note: This bit is not available in the classical CAN function.

CFBRS bit (Bit Rate Switch bit)

In TX mode, you can read and write from FIFO buffers. In this mode, the CANFD module either transmits a 0 to indicate no bit rate switch in the frame to be transmitted or a 1 to indicate a bit rate switch in the frame to be transmitted.

In RX mode, you can only read data from FIFO buffers.

In RX mode, the CFBRS bit is updated with the BRS bit value of the CANFD frame when it has been received, indicating whether there is a bit rate switch (1) or (0) on the CANFD frame.

In RX mode, 0 is stored to the CFBRS bit when the received FDF bit is 0, this means a CAN 2.0 frame is received.

Note: This bit is not available in the classical CAN function.

CFFDF bit (CAN FD Format bit)

In TX mode, you can read and write from FIFO buffers. In this mode, the CANFD module either transmits a 0 to indicate a CAN 2.0 frame is to be transmitted or a 1 to indicate a CANFD frame is to be transmitted.

In RX mode, you can only read data from FIFO buffers.

In RX mode, the CFFDF bit is updated with the FDF bit value of the CAN frame when it has been received, indicating whether it is a CAN 2.0 frame (0) or a CANFD frame (1).

Note: This bit is not available in the classical CAN function.

CFIFL[1:0] bits (COMMON FIFO Buffer Information Label Field)

If the Common FIFO is configured in TX mode, the value programmed in CFDCFFDCSTS.CFIFL[1:0] is stored together with additional message information, to the TX History List after successful transmission of the message.

The information label value from the related Global Acceptance Filter List entry is stored in these bits (if FIFO is configured in either RX mode).

In TX mode, you can read and write from FIFO buffers.

In RX mode, you can only read data from FIFO buffers.

CFPTR[15:0] bits (Common FIFO Buffer Pointer Field)

If the Common FIFO is configured in TX mode, the value programmed in CFDCFFDCSTS.CFPTR[15:0] is stored together with additional message information, to the TX History List after successful transmission of the message.

The pointer value from the related Global Acceptance Filter List entry is stored in these bits (if FIFO is configured in either RX mode).

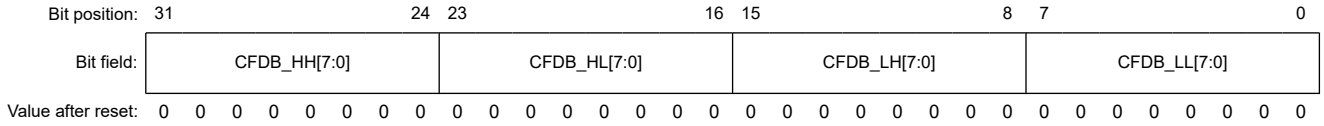
In TX mode, you can read and write from FIFO buffers.

In RX mode, you can only read data from FIFO buffers.

31.2.61.16 CFDCFDFp : Common FIFO Access Data Field p Registers (p = 0 to 15)

Base address: CANFDn = 0x4038_0000 + 0x2000 × n (n = 0, 1)
CANFDn_NS = 0x5038_0000 + 0x2000 × n (n = 0, 1)

Offset address: 0x05C4 + 0x004 × p



Bit	Symbol	Function	R/W
7:0	CFDB_LL[7:0]	Common FIFO Buffer Data Bytes (p × 4)	R/W
15:8	CFDB_LH[7:0]	Common FIFO Buffer Data Bytes ((p × 4) + 1)	R/W
23:16	CFDB_HL[7:0]	Common FIFO Buffer Data Bytes ((p × 4) + 2)	R/W
31:24	CFDB_HH[7:0]	Common FIFO Buffer Data Bytes ((p × 4) + 3)	R/W

Note: S-TYPE-3, P-TYPE-3

The FIFO Access Data Field p Registers (p = 0 to 15) store data bytes (p × 4) to data bytes ((p × 4) + 3) of the message.

In TX mode, you can read data from the FIFO, only for the current entry based on the write pointer value, and not for the other entries.

CFDB_LL[7:0] bits (Common FIFO Buffer Data Bytes (p × 4))

The CFDB_LL[7:0] bits store data bytes (p × 4) of the message present in the FIFO buffer.

In TX mode, you can read and write from the FIFO buffers.

In RX mode, you can only read data from the FIFO buffers.

In RX mode, unused data bytes are filled with 0x00, according to their configured data payload size CFDCFCC.CFPLS.*1

CFDB_LH[7:0] bits (Common FIFO Buffer Data Bytes ((p × 4) + 1))

The CFDB_LH[7:0] bits store data bytes ((p × 4) + 1) of the message present in the FIFO buffer.

In TX mode, you can read and write from the FIFO buffers.

In RX mode, you can only read data from the FIFO buffers.

In RX mode, unused data bytes are filled with 0x00, according to their configured data payload size CFDCFCC.CFPLS.*1

CFDB_HL[7:0] bits (Common FIFO Buffer Data Bytes ((p × 4) + 2))

The CFDB_HL[7:0] bits store data bytes ((p × 4) + 2) of the message present in the FIFO buffer.

In TX mode, you can read and write from the FIFO buffers.

In RX mode, you can only read data from the FIFO buffers.

In RX mode, unused data bytes are filled with 0x00, according to their configured data payload size CFDCFCC.CFPLS.*1

CFDB_HH[7:0] bits (Common FIFO Buffer Data Bytes ((p × 4) + 3))

The CFDB_HH[7:0] bits store data bytes ((p × 4) + 3) of the message present in the FIFO buffer.

In TX mode, you can read and write from the FIFO buffers.

In RX mode, you can only read data from the FIFO buffers.

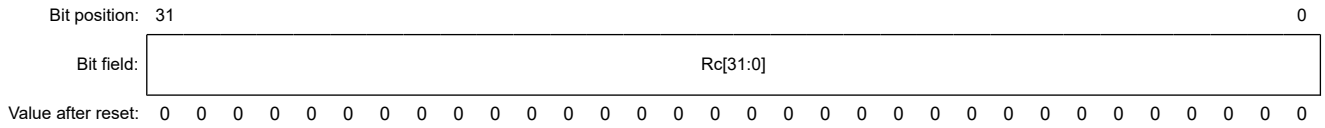
In RX mode, unused data bytes are filled with 0x00, according to their configured data payload size CFDCFCC.CFPLS.*1

Note 1. In RX mode, unused data bytes are filled with 0x00 according to the configured data payload size CFDCFCC.CFPLS, which is a CANFD feature not found in classical CAN.

31.2.61.17 CFDTMBCPb[0] : TX Message Buffer Component b (b = 0 to 3)

Base address: CANFDn = 0x4038_0000 + 0x2000 × n (n = 0, 1)
CANFDn_NS = 0x5038_0000 + 0x2000 × n (n = 0, 1)

Offset address: See Table 31.4



Bit	Symbol	Function	R/W
31:0	Rc[31:0]	TX Message Buffer Component c Refer to Table 31.11, Table 31.12 and the descriptions that follow for a detailed description of each register and its related bits, contained within this message buffer component.	R

Note: S-TYPE-3, P-TYPE-3

Where the total number of CFDTMBCPn = 4 as shown in Figure 31.28 (c = TX Message Buffer Component Register index = [0…18])

Rc[31:0] bit (TX Message Buffer Component c)

TX Message Buffer Component c

The TX Message Buffer Component is made up of the following registers: CFDTMIDb, CFDTMPTRb, CFDTMFDCTRb, and CFDTMDFbp. Refer to Table 31.12 for details of how to interpret the structure of this buffer component and how to access the respective registers.

Table 31.11 TX Message Buffer Component Summary

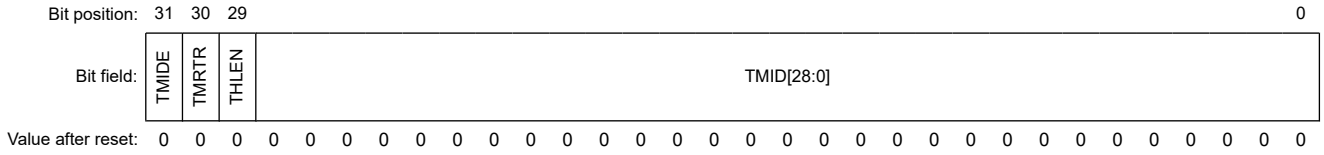
31.2.61.18 CFDTMIDb : TX Message Buffer ID Registers (b = 0 to 3)

Base address: CANFDn = 0x4038_0000 + 0x2000 × n (n = 0, 1)
CANFDn_NS = 0x5038_0000 + 0x2000 × n (n = 0, 1)

Offset address: 0x0604 + 0x004C × b



Bit	Symbol	Function	R/W
28:0	TMID[28:0]	TX Message Buffer ID Field STD-ID/EXT-ID fields	R/W
29	THLEN	Tx History List Entry 0: Entry not stored in THL after successful TX 1: Entry stored in THL after successful TX	R/W
30	TMRTR	TX Message Buffer RTR bit 0: Data frame 1: Remote frame	R/W
31	TMIDE	TX Message Buffer IDE bit 0: STD-ID is transmitted 1: EXT-ID is transmitted	R/W

Note: S-TYPE-3, P-TYPE-3

Each TX Message Buffer ID Register b (b = 0 to 3) are used to store the ID, IDE, RTR fields and history configuration of the message to be transmitted from the associated buffer.

TMID[28:0] bits (TX Message Buffer ID Field)

The TMID[28:0] bits are bits of the STD-ID/EXT-ID fields of the message stored in this TX message buffer.

Do not write to these bits when the related CANFD channel is in CH_SLEEP mode.

THLEN bit (Tx History List Entry)

The THLEN bit controls the storage of an entry corresponding to the transmitted message in the TX History list at the end of a successful transmission.

Do not write to these bits when the related CANFD channel is in CH_SLEEP mode.

TMRTR bit (TX Message Buffer RTR bit)

The TMRTR bit selects whether a data frame or remote frame is to be transmitted from this TX message buffer.

Note: There are no remote frames in CANFD format. For a CANFD transmission (CFDTMFDCTRb.CFFDF = 1), this bit is always transmitted dominant (data frame).

Do not write to these bits when the related CANFD channel is in CH_SLEEP mode.

TMIDE bit (TX Message Buffer IDE bit)

The TMIDE bit selects whether a message with EXT-ID or STD-ID is to be transmitted from this TX message buffer.

Do not write to these bits when the related CANFD channel is in CH_SLEEP mode.

31.2.61.19 CFDTMPTRb : TX Message Buffer Pointer Register (b = 0 to 3)

Base address: CANFDn = 0x4038_0000 + 0x2000 × n (n = 0, 1)
CANFDn_NS = 0x5038_0000 + 0x2000 × n (n = 0, 1)

Offset address: 0x0608 + 0x004C × b

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	TMDLC[3:0]	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
27:0	—	The read values are undefined. The write value should be 0.	R/W
31:28	TMDLC[3:0]	TX Message Buffer DLC Field Number of data bytes to be transmitted in a CAN frame.	R/W

Note: S-TYPE-3, P-TYPE-3

Each TX Message Buffer Pointer Register b (b = 0 to 3) is used to store the DLC fields of the message to transmit from the associated buffer.

TMDLC[3:0] bits (TX Message Buffer DLC Field)

The TMDLC[3:0] bits select the number of data bytes to be transmitted from this TX message buffer when the corresponding TMRTR bit is configured as 0.

See Table 5 in ISO 11898-1 (2015) Specification for details in defining the number of data bytes to be transmitted.

Do not write to these bits when the related CANFD channel is in CH_SLEEP mode.

31.2.61.20 CFDTMFDCTRb : TX Message Buffer CANFD Control Register (b = 0 to 3)

Base address: CANFDn = 0x4038_0000 + 0x2000 × n (n = 0, 1)
CANFDn_NS = 0x5038_0000 + 0x2000 × n (n = 0, 1)

Offset address: 0x060C + 0x004C × b

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	TMPTR[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	TMIFL[1:0]		—	—	—	—	—	TMFDF	TMBRS	TMESI
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	TMESI*1	Error State Indicator bit 0: CANFD frame to transmit by error active node 1: CANFD frame to transmit by error passive node	R/W
1	TMBRS*1	Bit Rate Switch bit 0: CANFD frame to transmit with no bit rate switch 1: CANFD frame to transmit with bit rate switch	R/W
2	TMFDF*1	CAN FD Format bit 0: Non CANFD frame to transmit 1: CANFD frame to transmit	R/W
7:3	—	The read values are undefined. The write value should be 0.	R/W
9:8	TMIFL[1:0]	TX Message Buffer Information Label Field	R/W
15:10	—	The read values are undefined. The write value should be 0.	R/W
31:16	TMPTR[15:0]	TX Message Buffer Pointer Field	R/W

Note: S-TYPE-3, P-TYPE-3
Note 1. This bit is not available in the classical CAN function.

The TX Message Buffer CANFD Control Registers b (b = 0 to 3) show the status of the FDF, BRS and ESI bits, including the pointer fields of the CANFD frame to be transmitted.

TMESI bit (Error State Indicator bit)

If the channel is not in error passive, then the TMESI bit equals the write value, otherwise it is a don’t care and the bit is transmitted as 1 on the CAN bus, indicating this is an error passive node.

Do not write to the TMESI bit when the related CANFD channel is in CH_SLEEP mode.

Note: This bit is not available in the classical CAN function.

TMBRS bit (Bit Rate Switch bit)

Do not write to the TMBRS bit when the related CANFD channel is in CH_SLEEP mode.

Note: This bit is not available in the classical CAN function.

TMFDF bit (CAN FD Format bit)

Do not write to the TMFDF bit when the related CANFD channel is in CH_SLEEP mode.

Note: This bit is not available in the classical CAN function.

TMIFL[1:0] bits (TX Message Buffer Information Label Field)

The TMIFL[1:0] bits store the information label value to be copied, together with additional message information, in the TX History List after successful transmission of the message.

Do not write to these bits when the related CANFD channel is in CH_SLEEP mode.

TMPTR[15:0] bits (TX Message Buffer Pointer Field)

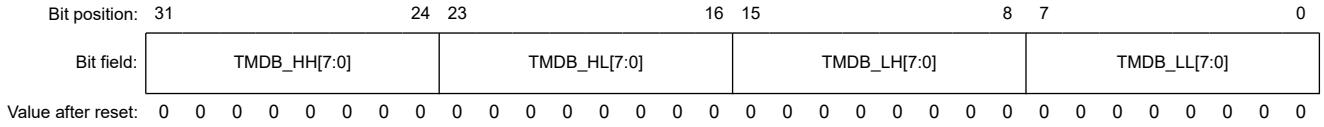
The TMPTR[15:0] bits store the pointer value to be copied, together with additional message information in the TX History List after successful transmission of the message.

Do not write to these bits when the related CANFD channel is in CH_SLEEP mode.

31.2.61.21 CFDTMDFb_p : TX Message Buffer Data Field Register (p= 0 to 15 , b= 0 to 3)

Base address: CANFDn = 0x4038_0000 + 0x2000 × n (n = 0, 1)
CANFDn_NS = 0x5038_0000 + 0x2000 × n (n = 0, 1)

Offset address: 0x0610 + 0x004 × p + 0x004C × b



Bit	Symbol	Function	R/W
7:0	TMDB_LL[7:0]	TX Message Buffer Data Byte (p × 4)	R/W
15:8	TMDB_LH[7:0]	TX Message Buffer Data Byte ((p × 4) + 1)	R/W
23:16	TMDB_HL[7:0]	TX Message Buffer Data Byte ((p × 4) + 2)	R/W
31:24	TMDB_HH[7:0]	TX Message Buffer Data Byte ((p × 4) + 3)	R/W

Note: S-TYPE-3, P-TYPE-3

Each TX Message Buffer Data Field p Register b (p = 0 to 15, b = 0 to 3) is used to store data bytes (p × 4) to data bytes ((p × 4) + 3) of the message to transmit from the associated buffer.

TMDB_LL[7:0] bits (TX Message Buffer Data Byte (p × 4))

TMDB_LL[7:0] bits store data bytes (p × 4) of the message in the TX message buffer.

Do not write to these bits when the related CANFD channel is in CH_SLEEP mode.

TMDB_LH[7:0] bits (TX Message Buffer Data Byte ((p × 4) + 1))

TMDB_LH[7:0] bits store data bytes ((p × 4) + 1) of the message in the TX message buffer.

Do not write to these bits when the related CANFD channel is in CH_SLEEP mode.

TMDB_HL[7:0] bits (TX Message Buffer Data Byte ((p × 4) + 2))

TMDB_HL[7:0] bits store data bytes ((p × 4) + 2) of the message in the TX message buffer.

Do not write to these bits when the related CANFD channel is in CH_SLEEP mode.

TMDB_HH[7:0] bits (TX Message Buffer Data Byte ((p × 4) + 3))

TMDB_HH[7:0] bits store data bytes ((p × 4) + 3) of the message in the TX message buffer.

Do not write to these bits when the related CANFD channel is in CH_SLEEP mode.

31.3 Modes of Operation

31.3.1 Overview

The modes of the CANFD module can be classified into 2 groups:

- Global modes
- Channel modes

31.3.2 Global Modes

These modes are applicable for the complete CANFD module and therefore are called Global modes. The global modes of the CANFD module are:

- Global Sleep
- Global Reset
- Global Halt

- Global Operation.

Figure 31.2 shows the possible transitions between the Global modes.

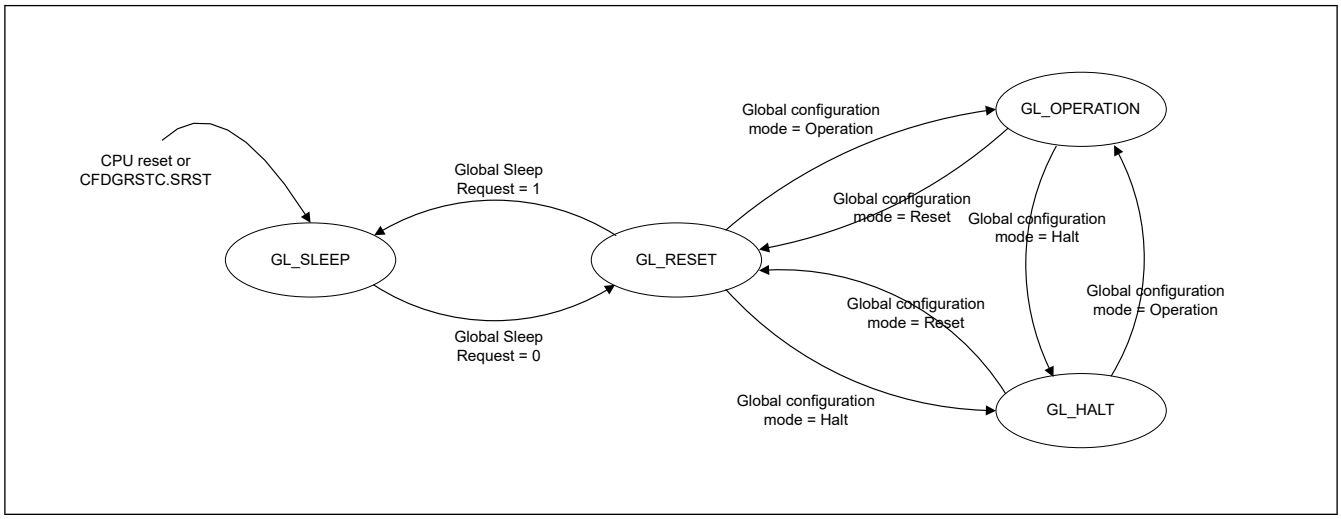


Figure 31.2 Transition between CANFD Global modes

Change in the Global mode can affect the Channel mode. Table 31.13 shows the effect of a Global mode transition on a Channel mode.

Table 31.13 Possible CANFD Channel modes and Global modes

Current Global mode	Target Global mode			
	Sleep	**Reset**	**Halt**	**Operation**
Sleep		Ch-Sleep: Keep Ch-Reset: N/A Ch-Halt: N/A Ch-Oper: N/A		
Reset	Ch-Sleep: Keep Ch-Reset: → Ch-Sleep Ch-Halt: N/A Ch-Oper: N/A		Ch-Sleep: Keep Ch-Reset: Keep Ch-Halt: N/A Ch-Oper: N/A	Ch-Sleep: Keep Ch-Reset: Keep Ch-Halt: N/A Ch-Oper: N/A
Halt		Ch-Sleep: Keep Ch-Reset: Keep Ch-Halt: → Ch-Reset Ch-Oper: N/A		Ch-Sleep:Keep Ch-Reset: Keep Ch-Halt: Keep Ch-Oper: N/A
Operation		Ch-Sleep: Keep Ch-Reset: Keep Ch-Halt: → Ch-Reset Ch-Oper: → Ch-Reset	Ch-Sleep: Keep Ch-Reset: Keep Ch-Halt: Keep Ch-Oper: → Ch-Halt	

31.3.2.1 Global Sleep Mode

After the release of a hardware reset or after setting and clearing a CFDGRSTC.SRST bit, the CANFD module automatically enters Global Sleep mode.

The CANFD module also enters the Global Sleep mode when the Global Sleep Request bit is set while it is in Global Reset mode. This control bit cannot be set in Global Halt mode or Global Operation mode.

Setting the Global Sleep Request bit sets Channel Sleep Request bit and forces the channel into the Channel Sleep mode.

Sleep mode is used for power saving purpose. When CANFD module is in Global Sleep mode, only the clock for CPU write access to the Global Sleep Mode Request bit is active. All other clocks are stopped and all other functions of the CANFD module are suspended.

Read access from all registers is still possible and all register values are preserved.

After setting the Global Sleep Request bit, it is necessary to confirm that the Global Sleep status has been updated, indicating successful transition to Global Sleep mode before the Global Sleep Request bit can be cleared again.

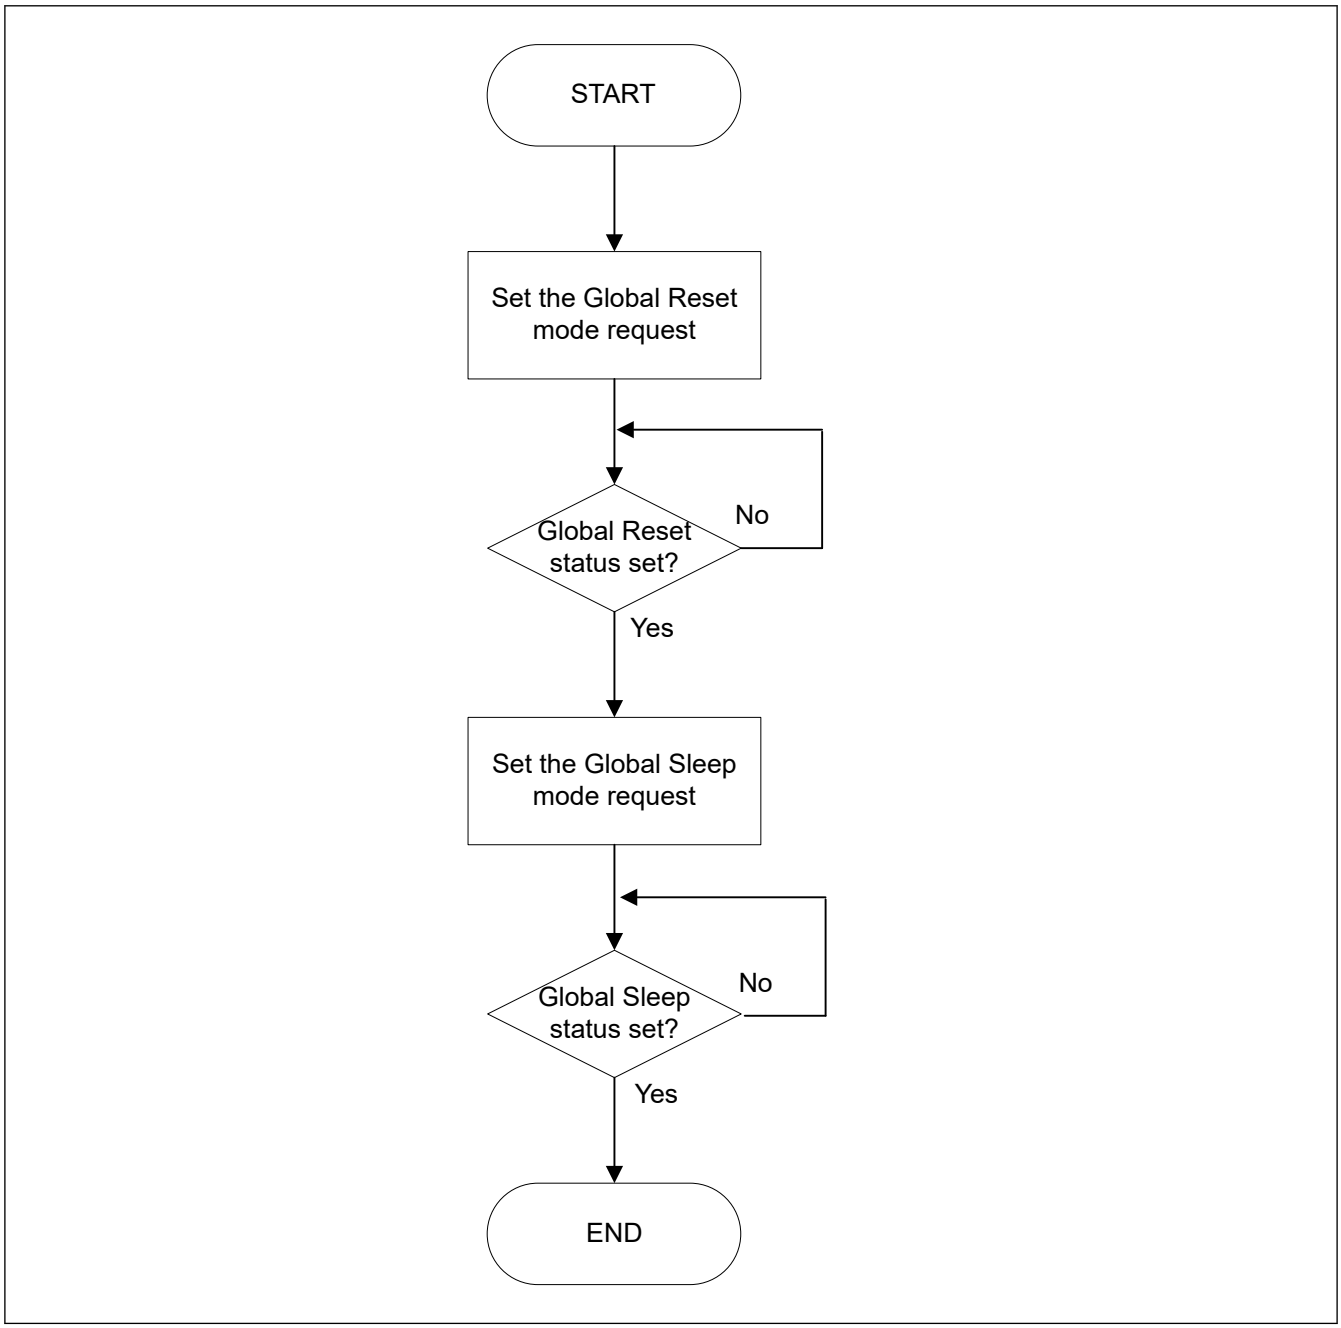

Figure 31.3 Procedure for entering Global Sleep mode

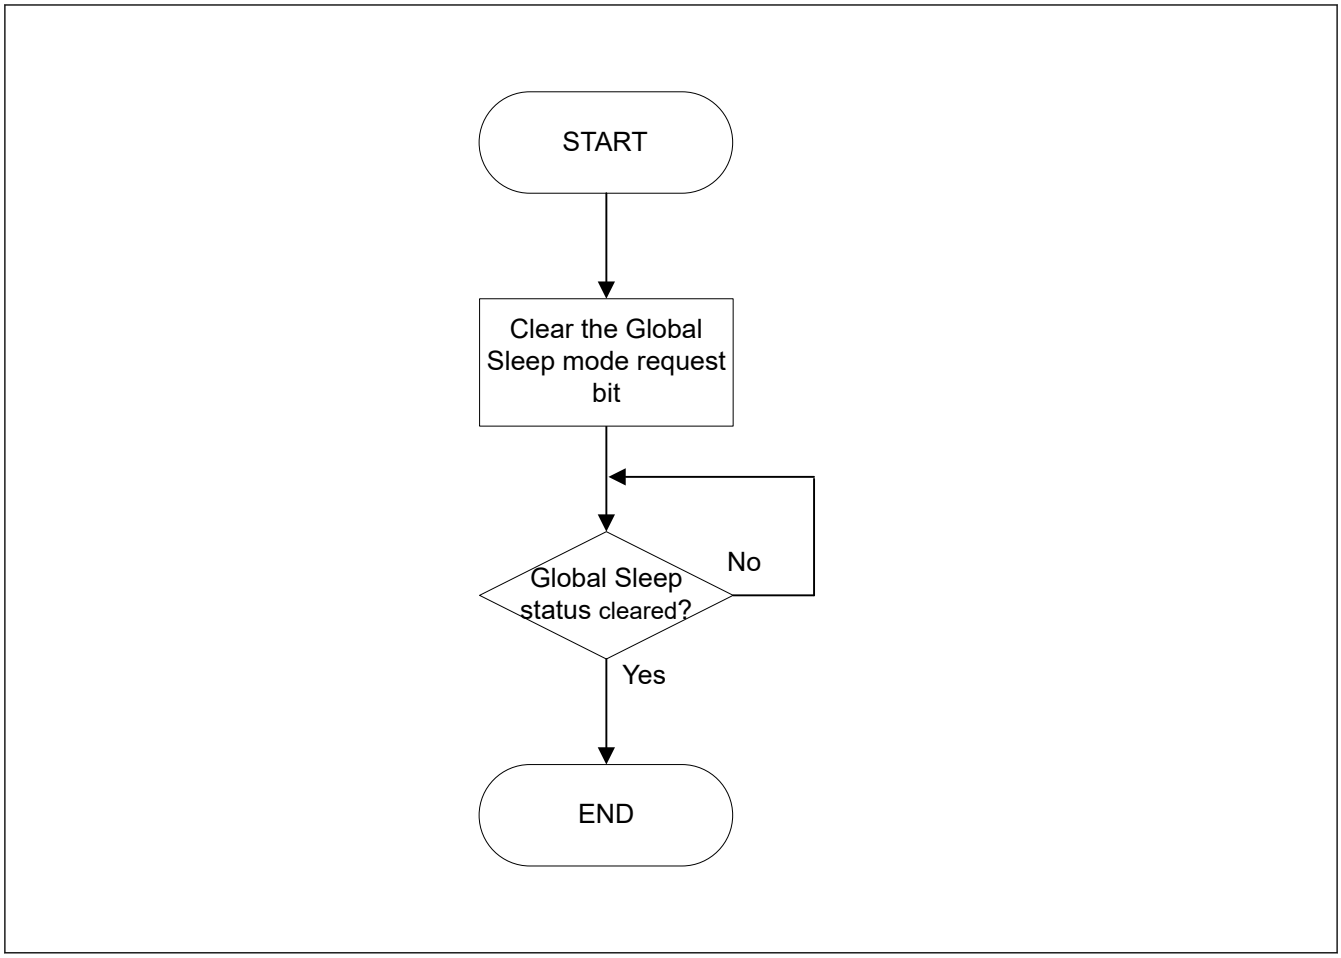

Figure 31.4 Procedure for exiting Global Sleep mode

31.3.2.2 Global Reset Mode

The CANFD module enters this mode in the following ways:

- Global Mode Control bit CFDGCTR.GMDC in the Global Control Register is configured for Global Reset mode while the CANFD module is in Global Halt or Global Operation mode
- Global Sleep Mode Request bit is cleared while CANFD module is in Global Sleep mode.

In Global Reset mode, all CANFD module functions are suspended and all status and flag registers are initialized.

Additionally all FIFOs and TX Queues are disabled and transmission control bits are cleared.

Configuration registers (except the test mode registers) are not initialized in this mode to their MCU reset values and the CANFD module can be configured.

See section 31.3.4. Global Mode and Channel Mode Transition Interactions for a detailed description of the behavior of all registers when transition to Global Reset mode is performed.

Setting the Global mode to Reset by setting the Global Mode Control bits CFDGCTR.GMDC in the Global Control Register to 01b sets Channel Mode Control bits CFDC0CTR.CHMDC in the Channel Control Registers to 01b and forces the channel into the Channel Reset mode.

For channels that are already in Channel Reset mode or Channel Sleep mode, this automatic transition is not performed (CFDC0CTR.CHMDC of related channel already set to 01b).

After setting Global Mode Control bit CFDGCTR.GMDC to Reset mode, it is necessary to confirm that the Reset Mode Status bit CFDGSTS.GRSTSTS in the Global Status Register has been updated, indicating successful transition to Global Reset mode before CFDGCTR.GMDC can be changed again.

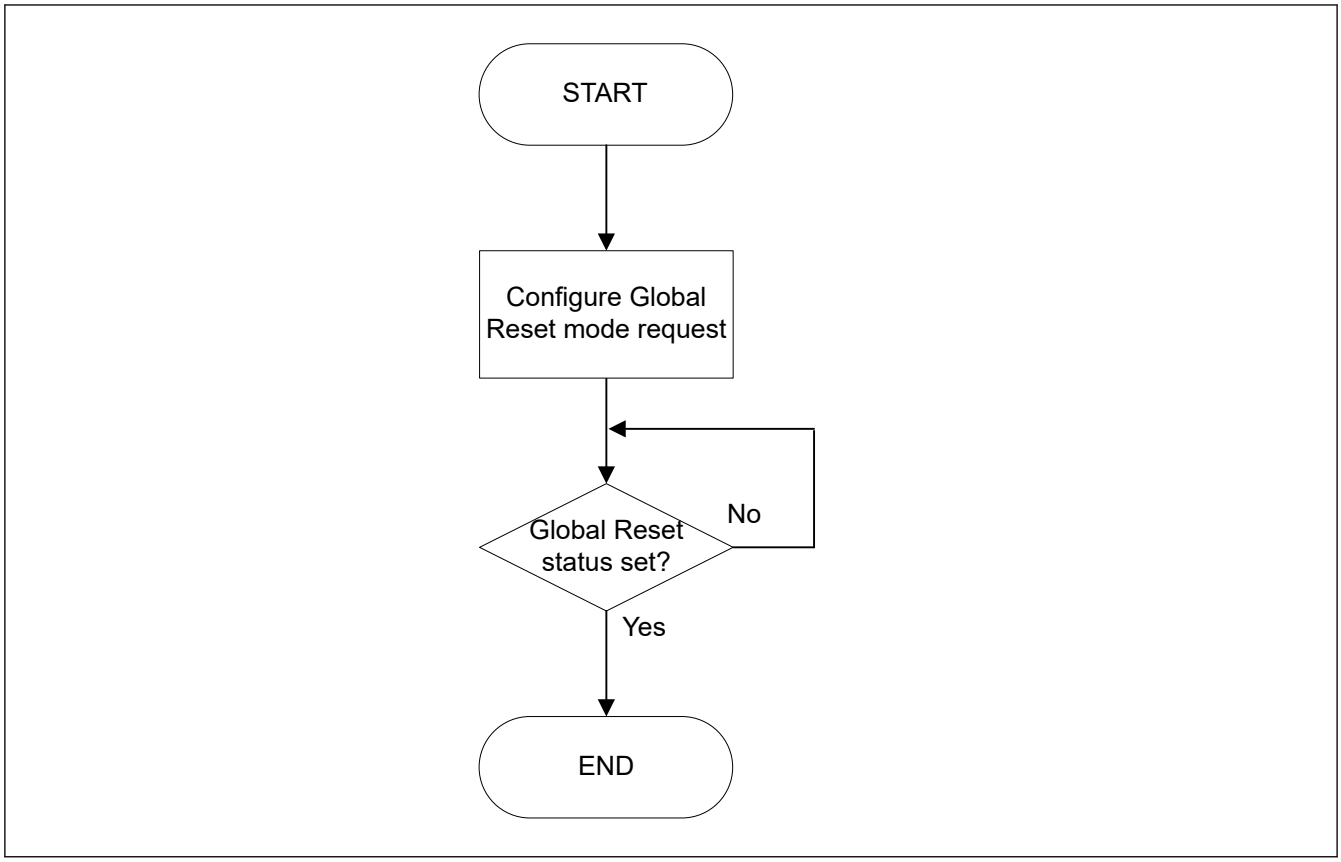

Figure 31.5 Procedure for entering Global Reset mode

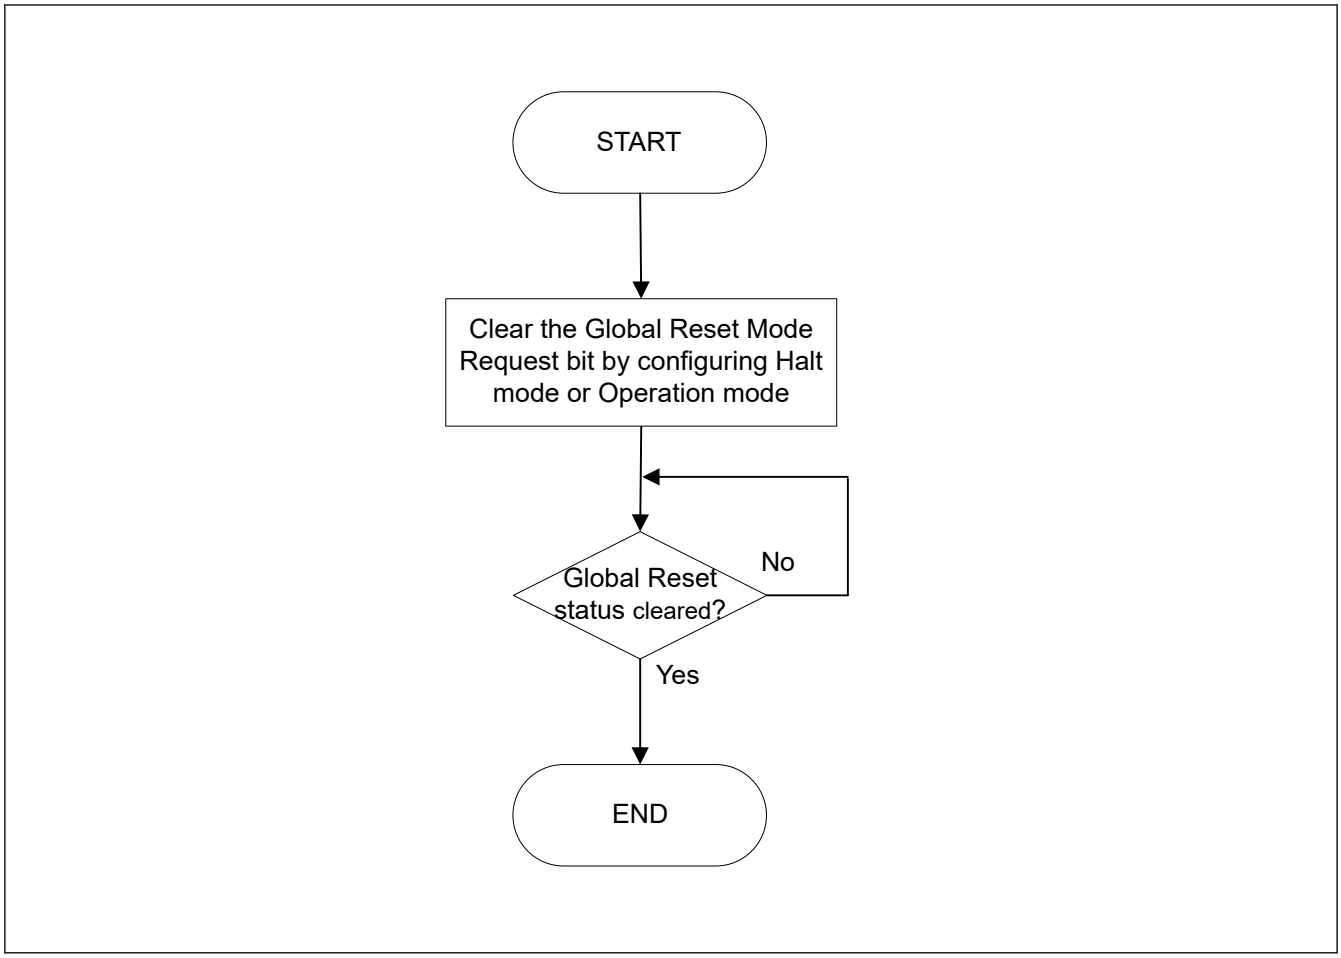

Figure 31.6 Procedure for exiting Global Reset mode

31.3.2.3 Global Halt Mode

The CANFD module enters this mode in the following ways:

- Global Mode Control bit CFDGCTR.GMDC in the Global Control Register is configured for Global Halt mode while the CANFD module is in Global Reset mode:
  - the channel in either Channel Reset or Channel Sleep mode remains in this mode
- Global Mode Control bit CFDGCTR.GMDC in the Global Control Register is configured for Global Halt mode while the CANFD module is in Global Operation mode:
  - the channel in Channel Reset, Channel Halt, or Channel Sleep mode remains in this mode
  - the channel in Channel Operation mode transitions to Channel Halt mode
  - Global Halt Mode Status bit is set when the channel has left Channel Operation mode.

If a transmission or reception is ongoing for a channel, the transition to Channel Halt mode is delayed until completion of the communication.

Similarly, if a channel is in bus-off, the full bus-off recovery sequence may be delayed depending on the channel configuration.

In Global Halt mode, all communications are suspended and CANFD logic does not cause any change to the Status and Flag registers (only when a channel is in the bus-off that its REC and TEC values are cleared). Additionally, the test mode configuration and control registers are not initialized in this mode.

The Global Halt mode should be used to configure global module test modes.

See section 31.3.4. Global Mode and Channel Mode Transition Interactions for a detailed description of the behavior of all registers when transition to Global Halt mode is performed.

Setting the Global mode to Halt by setting the Global Mode Control bit CFDGCTR.GMDC in the Global Control Register to 10b sets Channel Mode Control bits CFDC0CTR.CHMDC in the Channel Control Registers to 10b for the channel that are in Channel Operation mode and forces these channels into the Channel Halt mode.

For the channel that are already in Channel Reset, Channel Halt, or Channel Sleep mode, this automatic transition is not performed.

Therefore, the Global Halt mode request can be used to shut down all CANFD channel communications without loss of messages and disruption on the related CAN bus (no interruption of reception/transmission processes on the channels).

After setting the Global Mode Control bit CFDGCTR.GMDC to Halt mode, it is necessary to confirm that the Halt Mode Status bit CFDGSTS.GHLTSTS in the Global Status Register has been updated to indicate a successful transition to Global Halt mode. Do not specify any other SFR setting until confirming CFDGSTS.GHLTSTS is set.

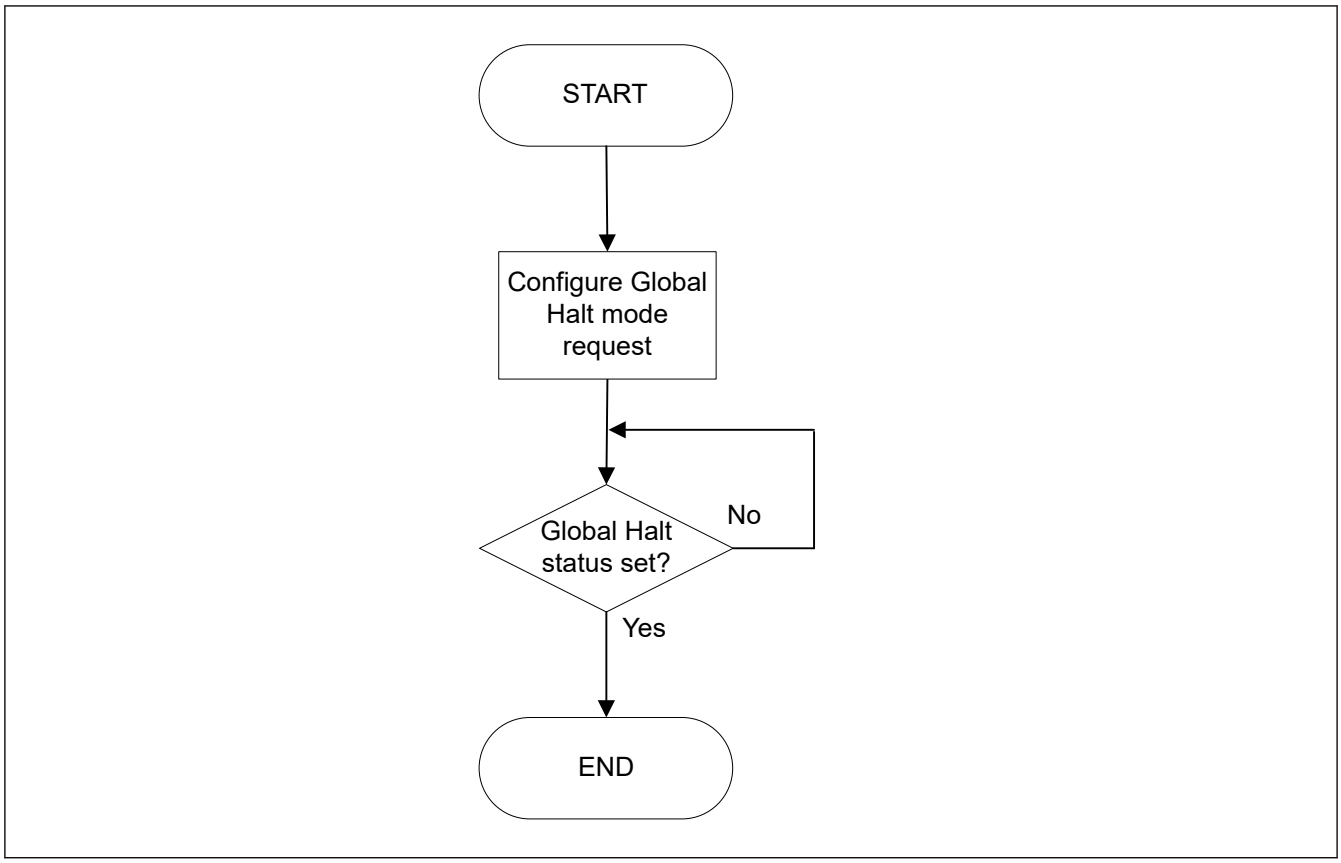

Figure 31.7 Procedure for entering Global Halt mode

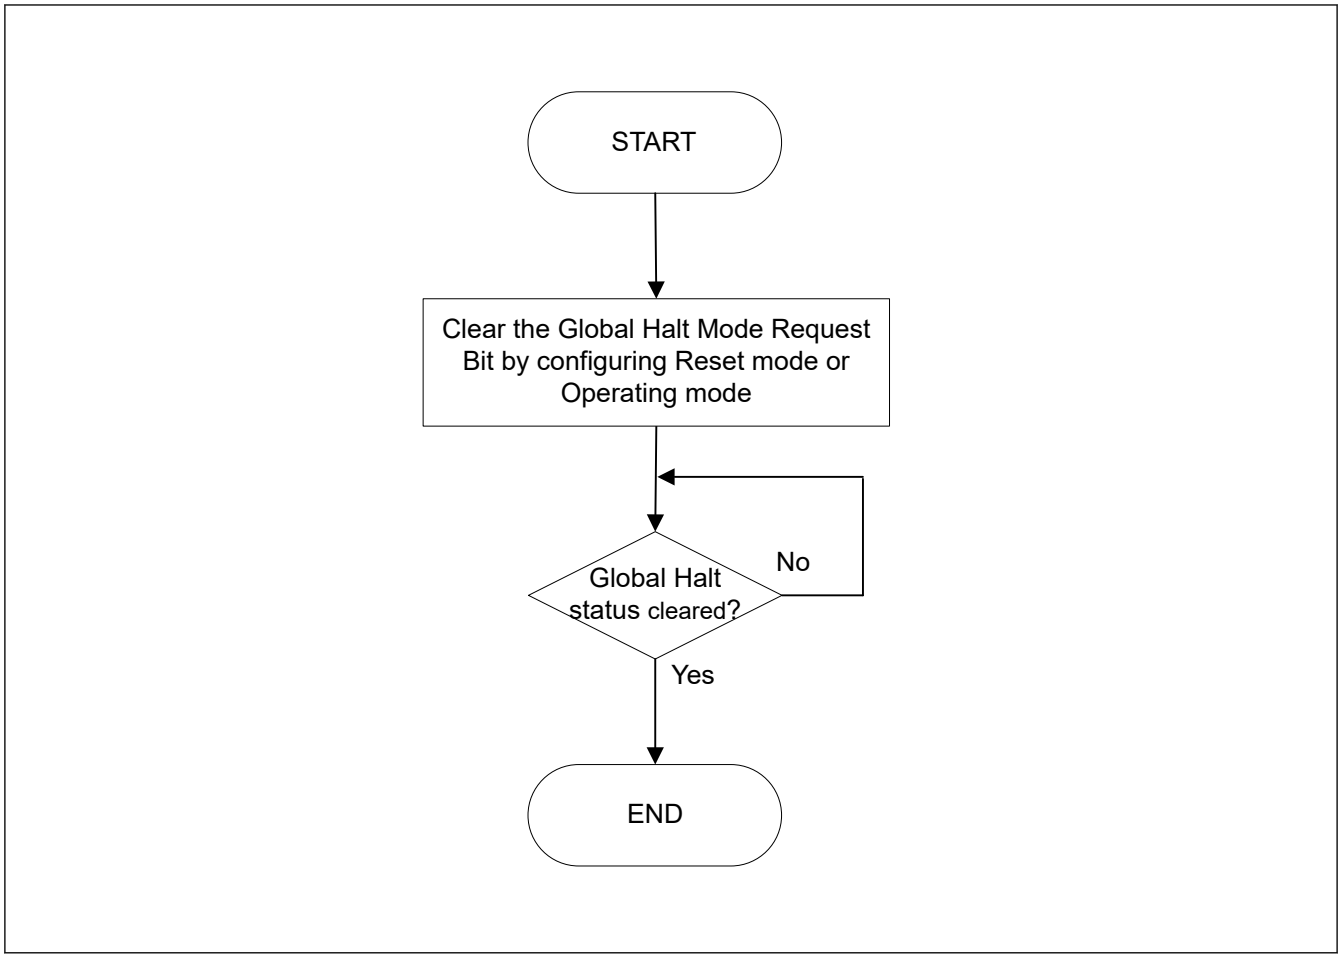

Figure 31.8 Procedure for exiting Global Halt mode

31.3.2.4 Global Operation Mode

The CANFD module enters this mode when the Global Mode Configuration bits are set to Global Operation mode.

The CANFD channel can only be set to Channel Operation mode and start CAN communication when CANFD is in Global Operation mode.

After setting the Global Mode Control bit CFDGCTR.GMDC to Global Operation mode, it is necessary to confirm that the Global Reset Mode Status bit CFDGSTS.GRSTSTS and the Global Halt Mode Status bit CFDGSTS.GHLTSTS in the Global Status Register have been cleared to indicate a successful transition to Global Operation mode before CFDGCTR.GMDC can be modified again.

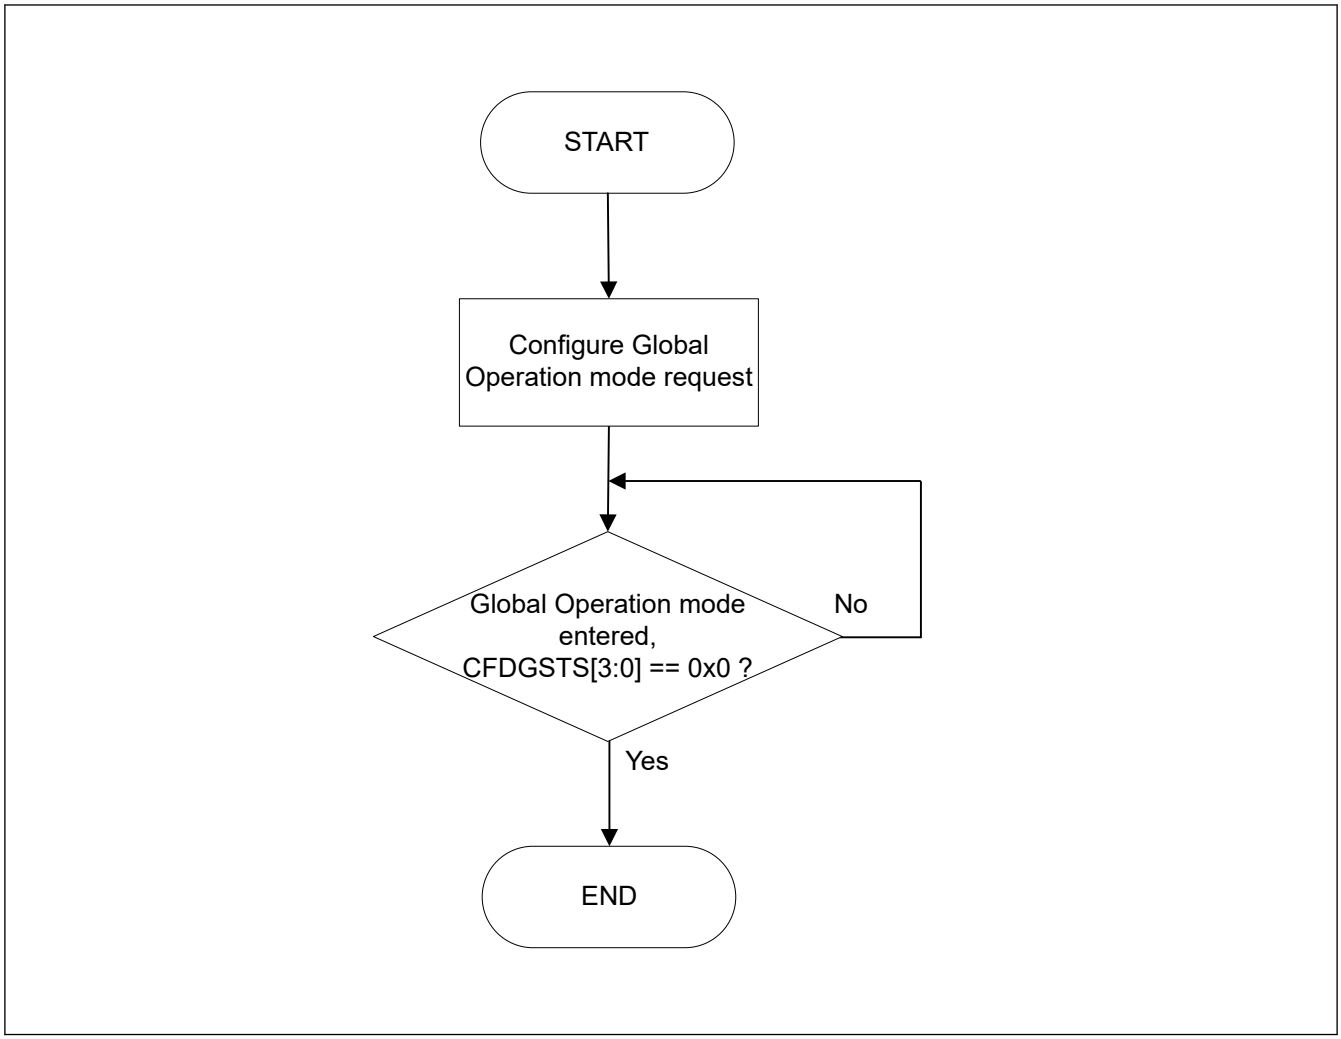

Figure 31.9 Procedure for entering Global Operation mode

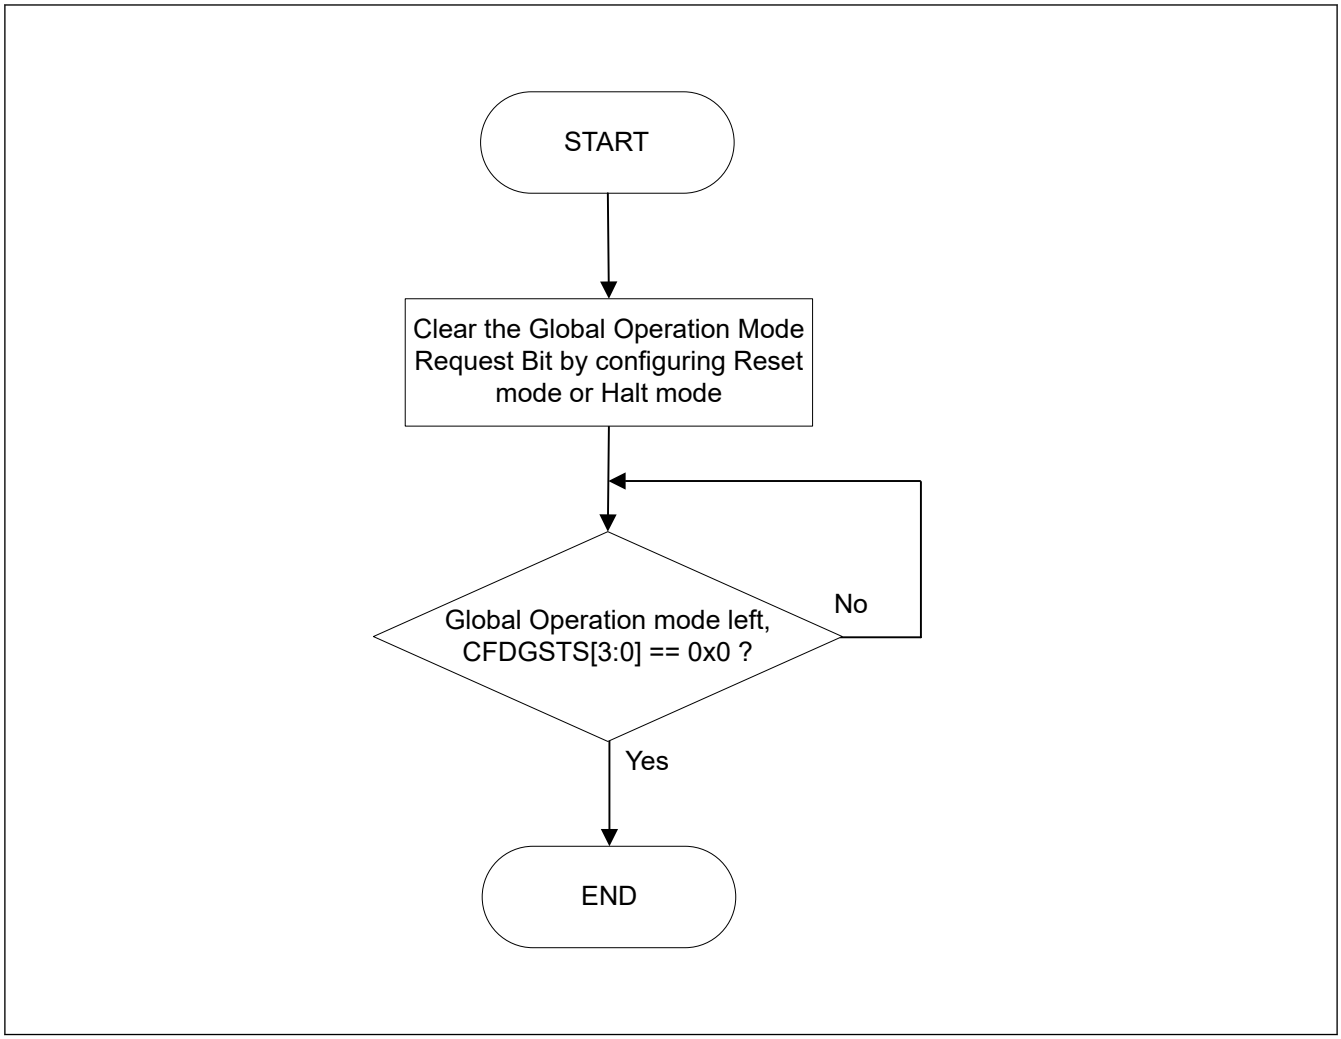

Figure 31.10 Procedure for exiting Global Operation mode

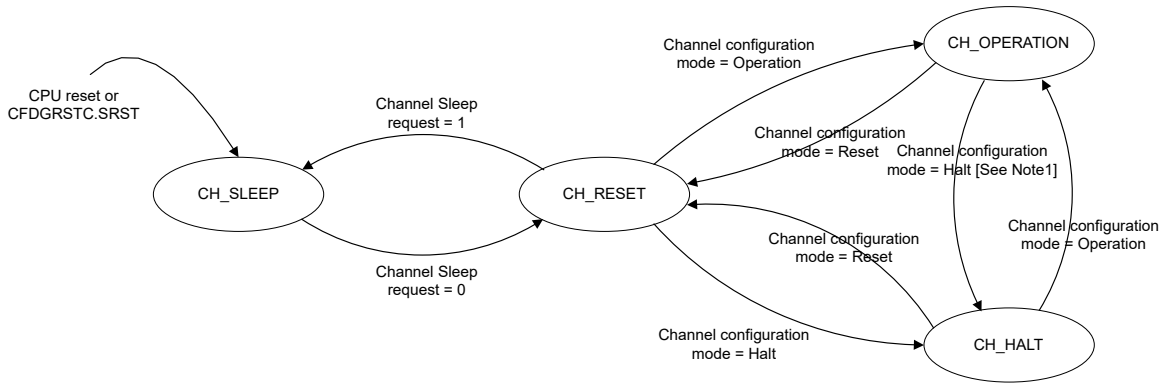
31.3.3 Channel Modes

A CAN channel can be in one of the following four channel modes:

- Reset
- Halt
- Operation
- Sleep.

Figure 31.11 shows the possible transitions between the channel modes.



Note 1. The transition timing depends on BOM setting in the Channel Configuration Register:
- when BOM = 01b, the state transition timing is immediate after entering bus-off state
- when BOM = 10b, the state transition timing is at the end of bus-off state
- when BOM = 11b, the state transition timing is matching with the setting of CHMDC to Halt mode.

Figure 31.11 Transition between CAN channel modes

31.3.3.1 CAN Channel Sleep Mode

After the release of a hardware reset or after setting and clearing the CFDGRSTC.SRST bit, a CAN channel of the CANFD module automatically enters Channel Sleep mode.

A CAN channel also enters Channel Sleep mode when the related Channel Sleep Mode Request bit is set while the CAN channel is in Channel Reset mode. Do not set this control bit in Channel Halt mode or Channel Operation mode.

Entering the CAN Channel Sleep mode instantly stops the clock supplied to the CAN channel unit and therefore reduces power consumption.

After setting the Channel Sleep Mode Request bit, it is necessary to confirm that the Channel Sleep mode status has been updated to indicate a successful transition to Channel Sleep mode before the Channel Sleep Mode Request bit can be cleared again.

During Channel Sleep mode, do not write to channel related registers. Read operation is still possible.

31.3.3.2 CAN Channel Reset Mode

A CANFD CAN channel enters this mode in the following ways:

- Channel Mode Control bit CFDC0CTR.CHMDC in the Channel Control Registers is configured for Channel Reset mode while the related CAN channel is in Channel Halt mode or Channel Operation mode
- Channel Sleep Mode Request bit is cleared while the related CAN channel is in Channel Sleep mode
- Global Mode Control bit CFDGCTR.GMDC is set to Global Reset mode and CAN channel is not in Channel Sleep mode or Channel Reset mode.

In Channel Reset mode, all CAN channel status and flag registers are initialized.

Additionally all channel related transmission control bits are cleared and the channel related TX Queue is disabled.

Configuration registers (except the Channel Test Mode registers) are not initialized in this mode and the CAN channel can be configured for communication.

See section 31.3.4. Global Mode and Channel Mode Transition Interactions for a detailed description of the behavior of all registers when transition to Channel Reset mode is performed.

After setting the Channel Mode Control bit CFDC0CTR.CHMDC to Channel Reset mode, it is necessary to confirm that the Reset Mode Status bit CFDC0STS.CRSTSTS in the related Channel Status Registers has been updated to indicate a successful transition to Channel Reset mode before the related CFDC0CTR.CHMDC bit can be modified again.

See Table 31.14 for the behavior of transitioning to Channel Reset mode while CAN communication is ongoing.

31.3.3.3 CAN Channel Halt Mode

A CANFD CAN channel enters this mode in the following ways:

- Channel Mode Control bit CFDC0CTR.CHMDC in the Channel Control Registers is configured for Channel Halt mode while the related CAN channel is in Channel Reset mode or Channel Operation mode
- Global Mode Control bit CFDGCTR.GMDC is set to Global Halt mode and CAN channel is in Channel Operation mode.

In Channel Halt mode, all channel CAN communication is suspended but all status and flag registers remain unchanged during Channel Halt mode entry (except for the bus-off case where REC and TEC values are cleared for this channel).

In addition, the Channel Test Mode Configuration and Control registers are not initialized in this mode.

The Channel Halt mode should be used to configure channel test modes.

See section 31.3.4. Global Mode and Channel Mode Transition Interactions for a detailed description of the behavior of all registers when transition to Channel Halt mode is performed.

After setting the Channel Mode Control bit CFDC0CTR.CHMDC to Channel Halt mode, it is necessary to confirm that the Halt Mode Status bit CFDC0STS.CHLTSTS in the related Channel Status Register has been updated to indicate a successful transition to Channel Halt mode before the related CFDC0CTR.CHMDC can be modified again.

See Table 31.14 for the transition behavior to Channel Halt mode while CAN communication is ongoing.

Table 31.14 Transition behavior in CAN Reset mode and Halt mode

Mode	State		
	Receiver	**Transmitter**	**Bus-Off**
CAN Channel Reset mode (CFDC0CTR.CHMDC = 01b)	The CAN channel enters Channel Reset mode without waiting for the completion of the ongoing reception.*1	The CAN channel enters Channel Reset mode without waiting for the completion of the ongoing transmission.*1	The CAN channel enters Channel Reset mode without waiting for the completion of the bus-off recovery.
CAN Channel Halt mode (CFDC0CTR.CHMDC = 10b)	CAN channel enters Channel Halt mode at the end of the ongoing reception or error.*2	CAN channel enters Channel Halt mode after completion of the ongoing transmission.	When CFDC0CTR.BOM is set to 00b, a Channel Halt mode request is accepted only after the completion of the full bus-off recovery sequence. When CFDC0CTR.BOM is set to 10b, the CAN channel transits automatically to Channel Halt mode after waiting for the completion of the bus-off recovery. When CFDC0CTR.BOM is set to 01b, the CAN channel transits automatically to Channel Halt mode without waiting for the completion of the bus-off recovery. When CFDC0CTR.BOM is set to 11b, the CAN channel enters Channel Halt mode as soon as Channel Halt mode is requested (without waiting for the completion of the bus-off recovery).

Note 1. If the entry to Channel Reset mode is required only at the end of an ongoing communication, then Channel Halt mode can be requested first to prevent interruption of CAN communication by direct transition to Channel Reset mode. After the CAN channel enters Channel Halt mode, the Channel Reset mode can be requested.

Note 2. If CAN communication is locked at dominant level after an error flag, software can detect this situation by monitoring the channel related BusLock flag and resolve lock condition by setting the CAN channel to Channel Reset mode.

31.3.3.4 CAN Channel Operation Mode

The Channel Operation mode is activated by setting the CFDC0CTR.CHMDC bits to 00b. If 11 consecutive recessive bits are detected after entering the CAN Operation mode, the CFDC0STS.COMSTS bit is set and the CAN channel:

- Enables the functions of the channel communication by allowing the channel to become an active node on the CAN network
- Releases the internal fault confinement logic including receive and transmit error counters

At this point, the CAN channel can start transmission and reception of CAN messages.

Within the CAN Channel Operation mode, the channel may be in four different sub-modes, depending on which type of communication functions are performed (see Figure 31.12):

- Channel idle: The CAN channel is neither receiving nor transmitting
- Channel receives: The channel is receiving a CAN message sent by another CAN node
- Channel transmits: The channel is transmitting a CAN message

  Note: The channel may receive its own message simultaneously when Self-test mode is enabled.
- Channel is in bus-off state: The CAN channel is cut-off from CAN bus communication.

After setting the Channel Mode Control bit CFDC0CTR.CHMDC to Channel Operation mode, it is necessary to confirm that the Channel Reset Mode Status bit CFDC0STS.CRSTSTS and the Channel Halt Mode Status bit CFDC0STS.CHLTSTS in the Channel Status Register have been updated to indicate a successful transition to Channel Operation mode before the related CFDC0CTR.CHMDC bit can be changed again.

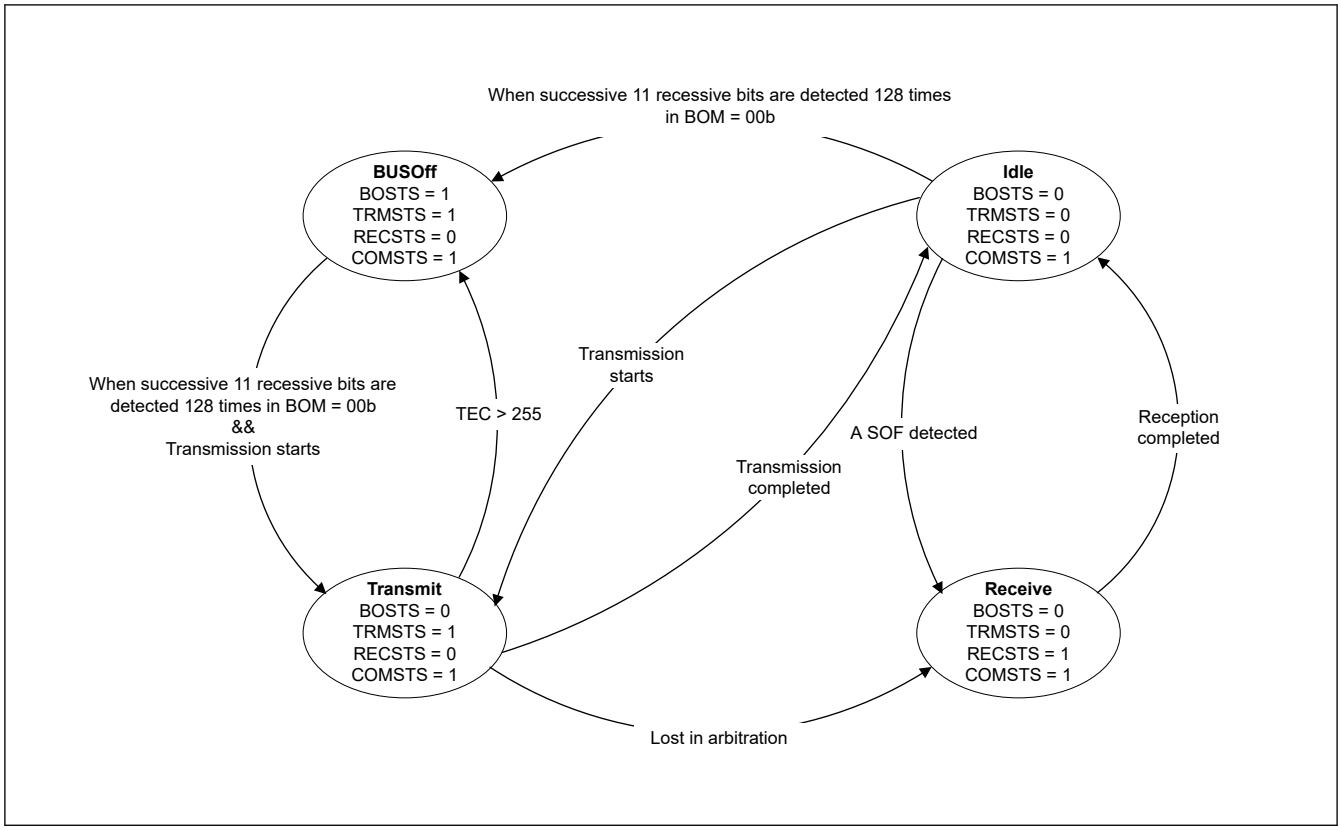


Figure 31.12 Sub-modes of CAN Channel Operation mode (only when BOM = 00b)

31.3.3.5 CAN Channel Bus-Off State

The CAN channel bus-off state is entered according to the fault confinement rules of the CAN specification. The following modes can be configured for returning to the CAN Channel Operation mode from the bus-off state:

- CFDC0CTR.BOM = 00b:
  Bus-Off recovery is compliant to ISO 11898-1, namely the CAN channel re-enters CAN communication (error active state) after 11 consecutive recessive bits are detected 128 times. TEC and REC counters are initialized to 0. The Bus-Off Recovery Flag CFDC0ERFL.BORF is set in this case.
- CFDC0CTR.BOM = 01b:

The CAN channel changes the value of the CFDC0CTR.CHMDC bits within the CAN Channel Control Register to 10b and switches immediately to Channel Halt mode automatically after entering bus-off state. TEC and REC counters are initialized to 0 and the Bus-Off Recovery Flag CFDC0ERFL.BORF is not set in this case.

- CFDC0CTR.BOM = 10b:
  The CAN channel changes the value of the CFDC0CTR.CHMDC bits within the CAN Channel Control Register to 10b as soon as it reaches bus-off state and enters Channel Halt mode automatically after the CAN channel has completed the bus-off recovery sequence (after 11 consecutive recessive bits are detected 128 times). TEC and REC counters are initialized to 0 and the Bus-Off Recovery Flag CFDC0ERFL.BORF is set in this case.
- CFDC0CTR.BOM = 11b:
  Bus-off recovery is initiated but CAN channel can immediately enter Channel Halt mode when still in bus-off state if a request is made to enter Channel Halt mode.
  TEC and REC counters are initialized to 0 and the Bus-Off Recovery Flag CFDC0ERFL.BORF is not set.
  Without setting CFDC0CTR.CHMDC [1:0] = 10b and when 11 recessive bits is detected 128 times continuously, transition conditions become the same as CFDC0CTR.BOM = 00b.

Note: If the recovery from bus-off occurs normally in this mode (after waiting for 128 sequences of 11 consecutive recessive bits), and no halt request has been generated during this period, then the Bus-Off Recovery flag CFDC0ERFL.BORF is set.

When software writes to the CFDC0CTR.CHMDC bit at the same time as the CAN channel enters Halt mode (at the start of bus-off when CFDC0CTR.BOM = 01b, or at the end of bus-off when CFDC0CTR.BOM = 10b), the software request has the highest priority.

Note: In the above case, the automatic setting of the CFDC0CTR.CHMDC bit to Channel Halt mode request is performed when the CFDC0CTR.CHMDC bit value is previously 00b (Channel Operation mode).

Additionally, it is possible to force the CAN channel to recover from the bus-off state by setting CFDC0CTR.RTBO to 1. The error state changes from bus-off state to integrating state with a maximum delay of 1 CAN bit time, and the CAN communication becomes possible again after 11 consecutive recessive bits are detected. The Bus-Off Recovery Flag is not set in this case, and the TEC and REC counters are initialized to 0.

Before setting CFDC0CTR.RTBO to 1, all pending transmissions from the TX message buffers, TX Queues and/or Common FIFO in TX mode should be disabled.

The disable of the pending transmission message buffer, TX Queue or FIFO must be confirmed by the corresponding acknowledge flags.

For the TX message buffer, the acknowledge flags are the Transmission Result Flags (CFDTMSTSj.TMTRF). For the TX Queue, it is the TX Queue Empty flag (CFDTXQSTS.TXQEMP). For the FIFO, it is the FIFO Empty flag (CFDCFSTS.CFEMP).

The CFDC0CTR.RTBO bit should be used for bus-off recovery only when CFDC0CTR.BOM is set to 00b.

Setting this bit in any state other than bus-off has no effect and the bit is cleared immediately.

Table 31.15 shows the settings for the Bus-Off Entry flag CFDC0ERFL.BOEF and the Bus-Off Recovery flag CFDC0ERFL.BORF for the different configurations of CFDC0CTR.BOM.

Table 31.15 Behavior of Bus-off Entry and Recovery flags

BOM	BOEF bit set	BORF bit set
00b	Always (on entry to bus-off)	Always (on exit from bus-off)
00b CFDC0CTR.RTBO set to 1	Always (on entry to bus-off)	Only if normal bus-off recovery occurs before software sets CFDC0CTR.RTBO to 1'
01b	Always (on entry to bus-off)	Never
10b	Always (on entry to bus-off)	Always (on exit from bus-off)
11b	Always (on entry to bus-off)	Only if normal bus-off recovery occurs before software issues a Halt request

For an efficient software procedure, it is not necessary to wait for the bus-off recovery sequence to end.

It is possible to perform a transmission re-initialization during bus-off recovery. To do this, follow the recommended software flow in Figure 31.13.

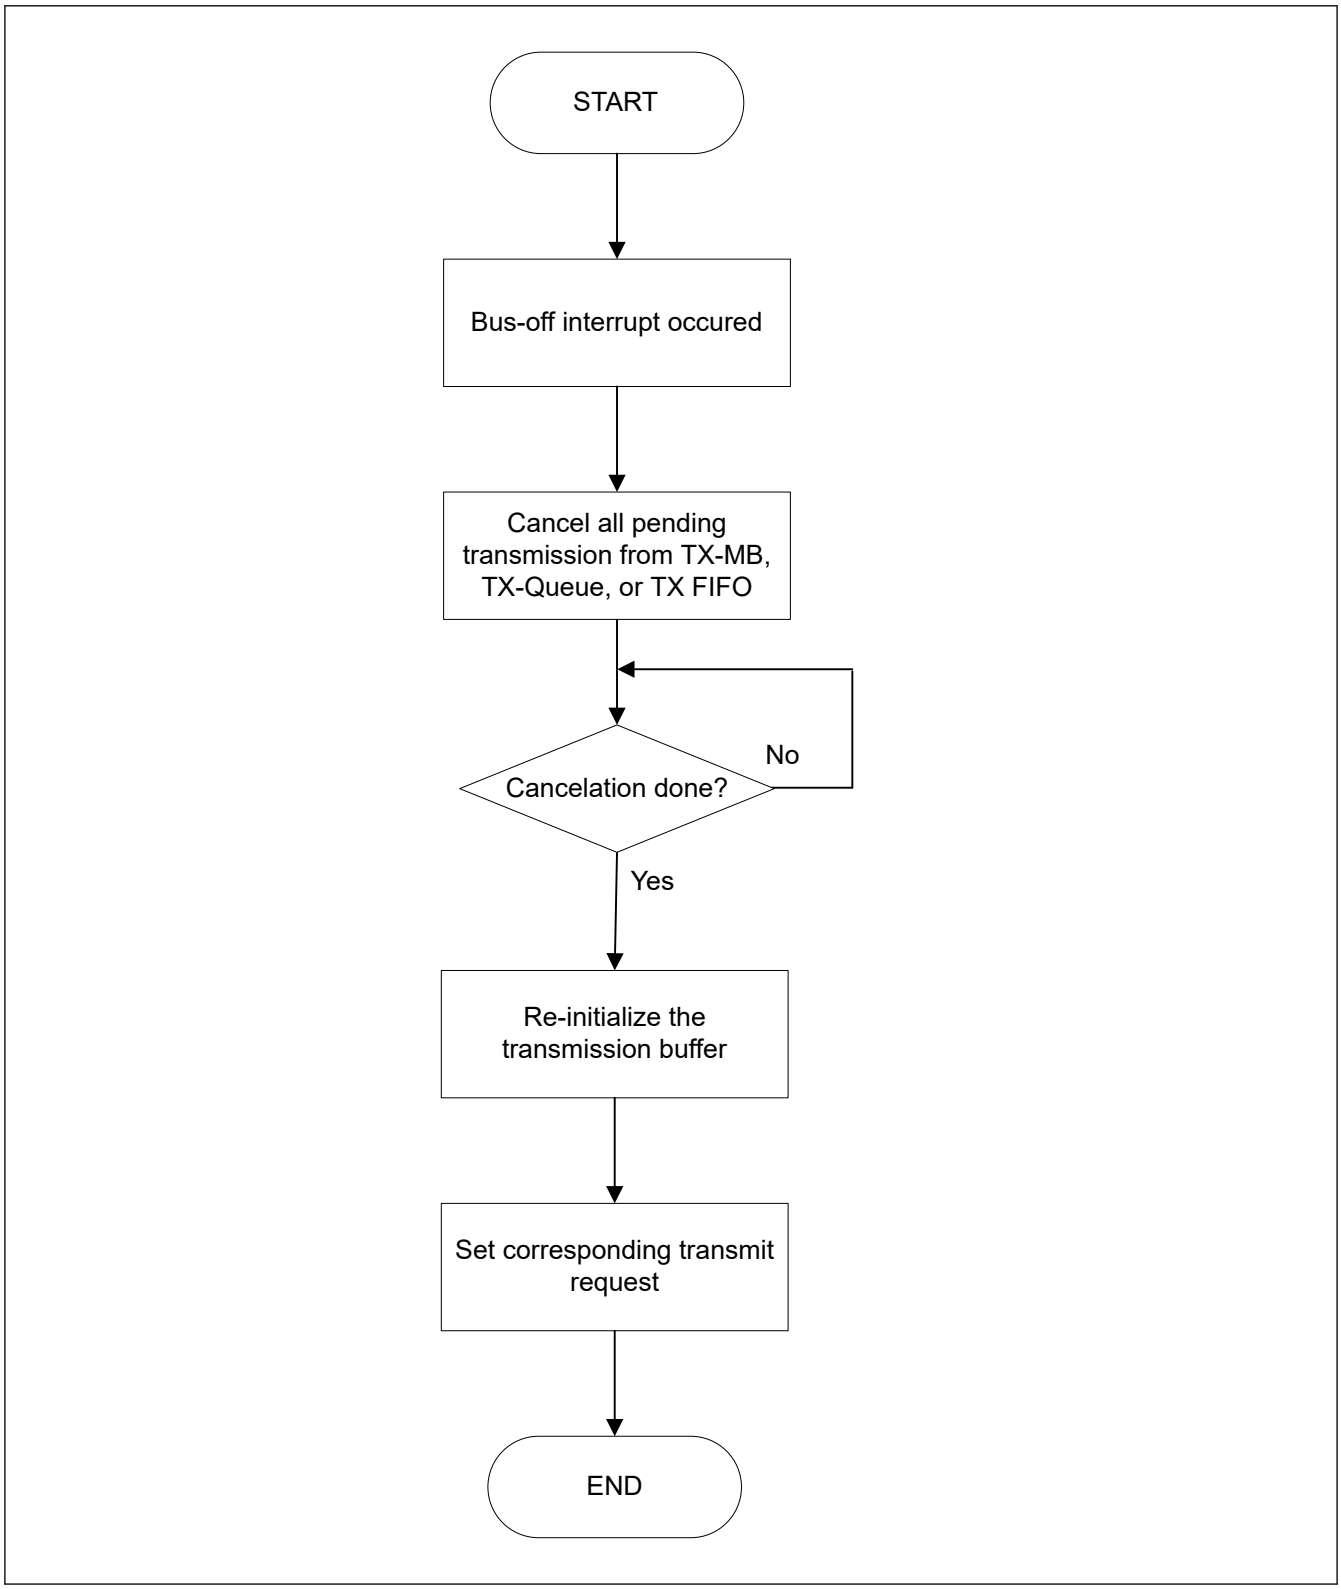

Figure 31.13 Transmission re-initialization during bus-off

31.3.4 Global Mode and Channel Mode Transition Interactions

The interaction between Global mode setting and Channel mode setting is as follows:

- Changing the Channel Mode Control bit CFDC0CTR.CHMDC in the Channel Control Registers does not affect the Global Mode Control bit CFDGCTR.GMDC.
- Changing the Global Mode Control bit CFDGCTR.GMDC affects the channel mode control as described in Table 31.16.

Table 31.16 Interaction between Global and Channel mode transition

Global mode change	Channel mode	Channel mode transition action
Sleep → Reset	Sleep	Channel remains in Sleep mode
Sleep → Halt	— (Global mode change not possible)	
Sleep → Operation	— (Global mode change not possible)	
Reset → Sleep	Sleep	Channel remains in Sleep mode
	Reset	Channel Sleep request bit is set automatically, channel enters Sleep Mode
Reset → Halt	Sleep	Channel remains in Sleep mode
	Reset	Channel remains in Reset mode
Reset → Operation	Sleep	Channel remains in Sleep mode
	Reset	Channel remains in Reset mode
Halt → Sleep	— (Global mode change not possible)	
Halt → Reset	Sleep	Channel remains in Sleep mode
	Reset	Channel remains in Reset mode
	Halt	Channel mode control is set to Reset mode, channel enters Reset mode
Halt → Operation	Sleep	Channel remains in Sleep mode
	Reset	Channel remains in Reset mode
	Halt	Channel remains in Halt mode
Operation → Sleep	— (Global mode change not possible)	
Operation → Reset	Sleep	Channel remains in Sleep mode
	Reset	Channel remains in Reset mode
	Halt	Channel mode control is set to Reset mode, channel enters Reset mode
	Operation	Channel mode control is set to Reset mode, channel enters Reset mode
Operation → Halt	Sleep	Channel remains in Sleep mode
	Reset	Channel remains in Reset mode
	Halt	Channel remains in Halt mode
	Operation	Channel mode control is set to Halt mode, channel enters Halt mode after communication finished

31.3.4.1 Timing of Global Mode Change

The transition time for the Global mode changes are shown in the following table.

Table 31.17 Maximum transition time for the global mode (1 of 2)

From	To	Maximum transition time
GL_SLEEP	GL_RESET	3 peripheral clock cycles*2
GL_RESET	GL_SLEEP	3 peripheral clock cycles
GL_RESET	GL_HALT	10 peripheral clock cycles
GL_RESET	GL_OPERATION	10 peripheral clock cycles

Table 31.17 Maximum transition time for the global mode (2 of 2)

From	To	Maximum transition time
GL_HALT	GL_RESET	2 CAN bit times
GL_HALT	GL_OPERATION	3 peripheral clock cycles
GL_OPERATION	GL_RESET	2 CAN bit times
GL_OPERATION	GL_HALT	3 CAN frames*1 *3

Note 1. The given transition time is the time without any errors on the bus. In case of an error condition, the transition time can lengthen to an uncalculated result. The transition time can also come to a stuck condition for locked RX lines or continued error conditions.
Note 2. Exit GL_SLEEP mode only when CFDGSTS.GRAMINIT is cleared.
Note 3. TQ, CAN frame and CAN bits are related to the individual channels. For the maximum transition time, the channel with the lowest baud rate must be used.

31.3.4.2 Timing of Channel Mode Change

The transition time for the Channel mode changes are shown in the following table.

Table 31.18 Maximum transition time for the channel mode

From	To	max. transition time
CH_SLEEP	CH_RESET	3 peripheral clock cycles
CH_RESET	CH_SLEEP	3 peripheral clock cycles
CH_RESET	CH_HALT	3 CAN bit times
CH_RESET	CH_OPERATION	4 CAN bit times
CH_HALT	CH_RESET	2 CAN bit times
CH_HALT	CH_OPERATION	4 CAN bit times*3
CH_OPERATION	CH_RESET	2 CAN bit times
CH_OPERATION	CH_HALT	2 CAN frames*1 *2

Note 1. The time specified for this transition does not include the case where channel enters bus-off state. For bus-off, the timing depends on the configuration of the CFDC0CTR.BOM[1:0] bits.
Note 2. The given transition time is the time without any errors on the bus. In case of an error condition, the transition time can lengthen to an uncalculated result. The transition time can also come to a stuck condition for locked RX lines or continued error conditions.
Note 3. In general, if the baudrate prescaler value CFDC0NCFG.NBRP is changed in CH_HALT mode, the transition time can deviate. The internal prescaler is a free running down counter that creates the TQ clock, and new BRP value is captured when the counter reaches the value 0.

31.4 Initialization

Before joining CAN communications, configure the following settings:

- Clock setting
- Bit timing setting (nominal and data rate)
- Baud Rate setting (nominal and data rate)
- CANFD setting
- Acceptance Filter setting (configuration of Global Acceptance Filter List)
- Reception, Transmission and GW-FIFO setting
- CAN Operation mode setting

31.4.1 Initialization of CAN Clock, Bit Timing and Baud Rate

31.4.1.1 Bit Timing Conditions

The following lines describe the composition of each segment and the restriction that apply to the segment setting.

1. Each segment setting
   SS = Fixed to 1 TQ

TSEG1 = See to (CFDC0NCFG) and (CFDC0DCFG)*1
TSEG2 = See to (CFDC0NCFG) and (CFDC0DCFG)*1
SJW = See to (CFDC0NCFG) and (CFDC0DCFG)*1
SS + TSEG1 + TSEG2 = 5 to 49 TQs for Data Bit Rate and 8 to 385 for Nominal Bit Rate

2. Restriction on TSEG1, TSEG2 and SJW
TSEG1(N) > TSEG2(N) ≥ SJW(N)
TSEG1(D) ≥ TSEG2(D) ≥ SJW(D)*1
When only classical frames are used, configure the bit fields TSEG1 and TSEG2 of CFDC0DCFG to valid values.

Note 1. This feature is not available in the classical CAN function.

Table 31.19 shows an example of how to set the bit timing to achieve the required Sample Point settings.

Table 31.19 Bit timing examples

1 bit	Set value (TQ)				Sample point*1(%)
	SS	TSEG1	TSEG2	SJW	
5TQ	1	2	2	1	60.00
8TQ	1	4	3	1	62.50
	1	5	2	1	75.00
10TQ	1	6	3	1	70.00
	1	7	2	1	80.00
12TQ	1	8	3	1	75.00
	1	9	2	1	83.33
15TQ	1	10	4	1	73.33
	1	11	3	1	80.00
16TQ	1	10	5	1	68.75
	1	11	4	1	75.00
20TQ	1	12	7	1	65.00
	1	13	6	1	70.00
24TQ	1	15	8	1	66.66
	1	16	7	1	70.83
50TQ	1	39	10	4	80.00

Note 1. Sample point (in case of 75%)

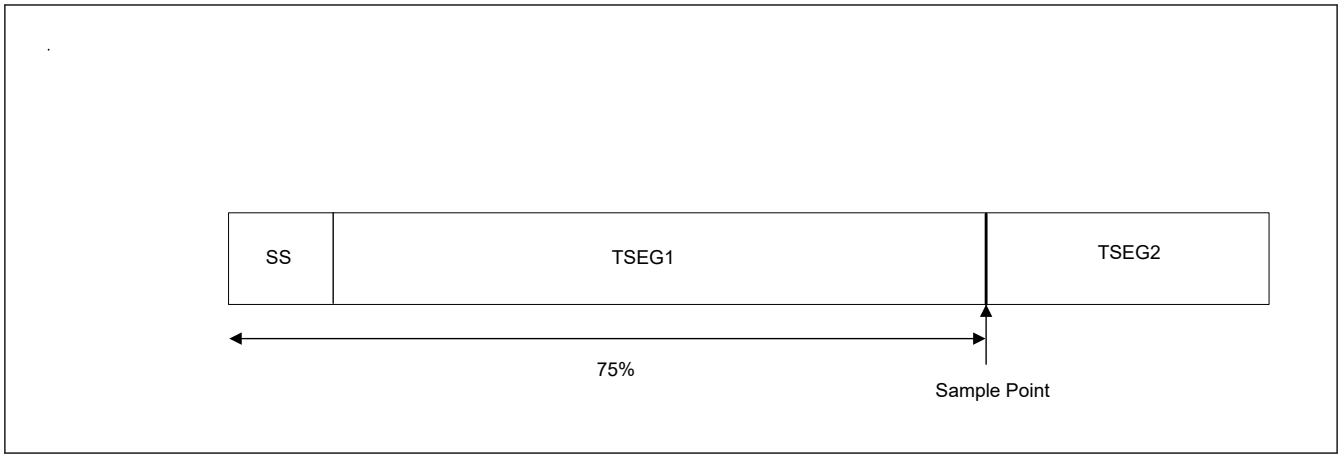

Figure 31.14 Sample point (in case of 75%)

31.4.1.2 CAN Bit Timing

In the CAN protocol, each bit in a communication frame is composed of three segments that can be configured individually for channel using the related CFDC0NCFG and CFDC0DCFG*1 registers.

Note 1. This register is not available in the classical CAN function.

Figure 31.15 shows the segment composition of a bit and the sample point in it.

Of these segments, the Time Segment 1 (TSEG1) and Time Segment 2 (TSEG2) are used to specify the position of the sample point, so that the timing at which each bit on the CAN bus is sampled can be altered by changing the values of these segments.

The minimum resolution for this timing is referred to as Time Quantum (TQ), which is determined by the clock frequency supplied to the CAN channel and the divide-by-N value of the baud rate prescaler (nominal and data rate).

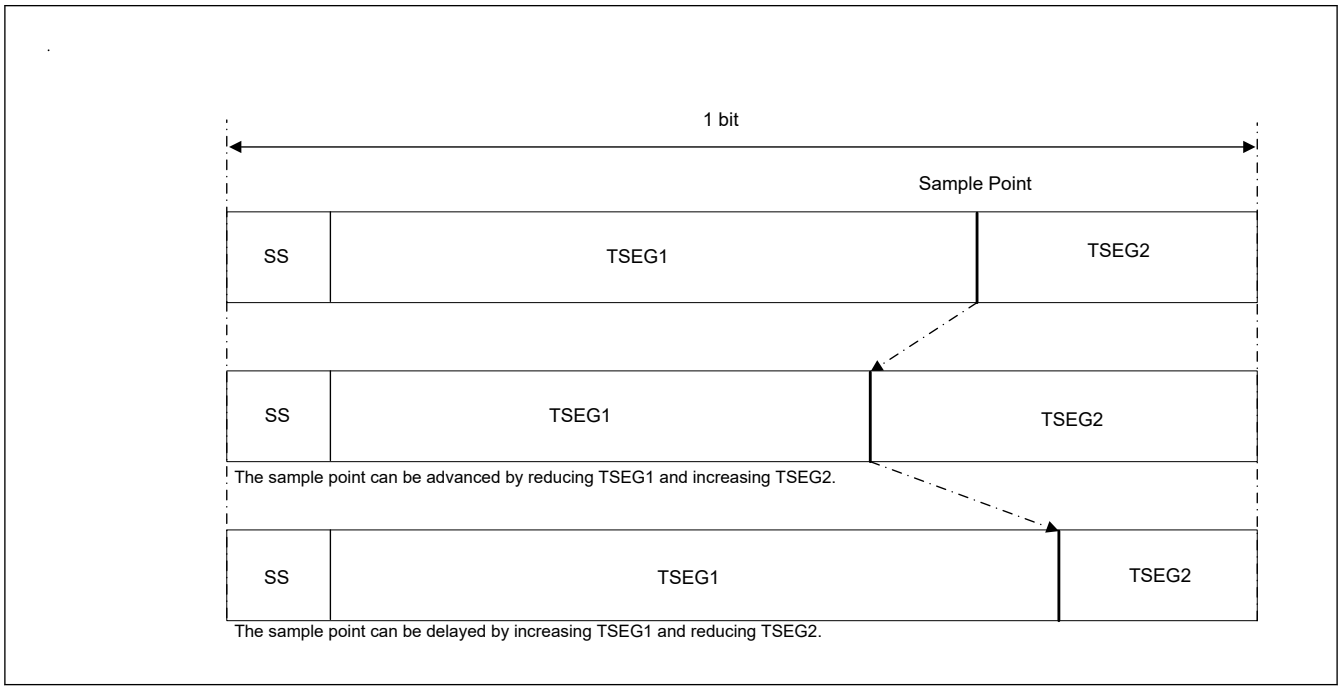

Figure 31.15 Segment composition of a bit and the sample point

1. SS: Synchronization Segment
   This segment is used to synchronize bits by monitoring a recessive-to-dominant edge during the interframe space. This comprises of intermission, suspend transmission, bus idle, during bus idle, and all nodes that can start transmission.
2. TSEG1: Time Segment 1
   This segment absorbs physical delays on the CAN network. A physical delay on the network is two times the total sum of a bus delay, input comparator delay, and output driver delay. It can be lengthened by SJW.
3. TSEG2: Time Segment 2
   This segment is used to correct a phase error by performing resynchronization. It can be shortened by SJW. While sending or receiving a message, communication frames between some nodes may get out of sync due to a drift in the oscillator frequency or a delay in the transmission path. This is referred to as a phase error.
4. SJW: Resynchronization Jump Width
   This is the maximum width by which bits that have become out of sync due to a phase error may be corrected.

Figure 31.15 shows only one symbolic sample point.

31.4.1.3 Baud Rate

Either the CANFD core clock (CANFDCLK) or the external oscillator clock (CANMCLK) can be selected globally as CAN communication clock.

The transfer speed is determined by the DLL clock, the divide-by-N value of the baud rate prescaler, and the number of TQs in one bit.

$$\text{baudrate} = \frac{\text{DLL_Clock}}{(\text{number_of_time_quanta_per_bit}) \times (\text{BRP} + 1)}$$

Figure 31.16 shows a block diagram of the circuit that generates the CAN channel communication clock and Table 31.20 shows a baud rate examples.

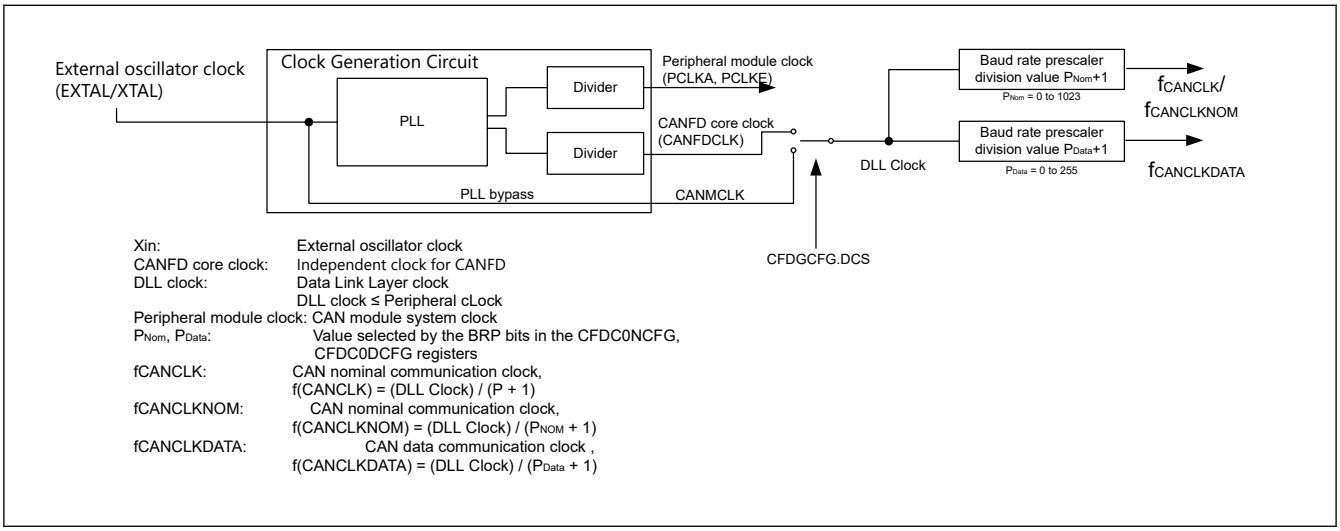

Figure 31.16 Block diagram of the circuit that generates the CAN channel communication clock

Table 31.20 Nominal baud rate calculation formula and example CAN communication configurations

Baud rate calculation formula	(DLL clock) (baud rate prescaler divide-by-N value*1) × (number of TQs in one bit)								
	80 MHz	40 MHz	32 MHz	30 MHz	24 MHz	20 MHz	16 MHz	10 MHz	8 MHz*2
1 Mbps	8TQ (10) 20TQ (4)	8TQ (5) 20TQ (2)	8TQ (4) 16TQ (2)	10TQ (3) 15TQ (2)	8TQ (3) 12TQ (2) 24TQ (1)	10TQ (2) 20TQ (1)	8TQ (2) 16TQ (1)	10TQ (1)	8TQ (1)
500 Kbps	8TQ (20) 20TQ (8)	8TQ (10) 20TQ (4)	8TQ (8) 16TQ (4)	10TQ (6) 15TQ (4) 20TQ (3)	8TQ (6) 12TQ (4) 24TQ (2)	10TQ (4) 20TQ (2)	8TQ (4) 16TQ (2)	10TQ (2) 20TQ (1)	8TQ (2) 16TQ (1)
250 Kbps	8TQ (40) 20TQ (16)	8TQ (20) 20TQ (8)	8TQ (16) 16TQ (8)	10TQ (12) 15TQ (8) 20TQ (6)	8TQ (12) 12TQ (8) 24TQ (4)	10TQ (8) 20TQ (4)	8TQ (8) 16TQ (4)	10TQ (4) 20TQ (2)	8TQ (4) 16TQ (2)
125 Kbps	8TQ (80) 20TQ (32)	8TQ (40) 20TQ (16)	8TQ (32) 16TQ (16)	10TQ (24) 15TQ (16) 20TQ (12)	8TQ (24) 12TQ (16) 24TQ (8)	10TQ (16) 20TQ (8)	8TQ (16) 16TQ (8)	10TQ (8) 20TQ (4)	8TQ (8) 16TQ (4)
83.3 Kbps	8TQ (120) 12TQ (80) 16TQ (60) 24TQ (40)	8TQ (60) 12TQ (40) 16TQ (30) 24TQ (20)	8TQ (48) 12TQ (32) 16TQ (24) 24TQ (16)	8TQ (45) 10TQ (36) 12TQ (30) 15TQ (24) 20TQ (18) 24TQ (15)	8TQ (36) 12TQ (24) 16TQ (18) 24TQ (12)	8TQ (30) 10TQ (24) 12TQ (20) 15TQ (16) 16TQ (15) 20TQ (12) 24TQ (10)	8TQ (24) 12TQ (16) 16TQ (12) 24TQ (8)	8TQ (15) 10TQ (12) 12TQ (10) 15TQ (8) 20TQ (6) 24TQ (5)	8TQ (12)
33.3 Kbps	8TQ (300) 12TQ (200) 16TQ (150) 20TQ (120) 24TQ (100)	8TQ (150) 12TQ (100) 16TQ (75) 20TQ (60) 24TQ (50)	8TQ (120) 10TQ (96) 12TQ (80) 15TQ (64) 16TQ (60) 20TQ (48) 24TQ (40)	10TQ (90) 12TQ (75) 15TQ (60) 20TQ (45)	8TQ (90) 10TQ (72) 12TQ (60) 15TQ (48) 16TQ (45) 20TQ (36) 24TQ (30)	8TQ (75) 10TQ (60) 12TQ (50) 15TQ (40) 20TQ (30) 24TQ (25)	8TQ (60) 10TQ (48) 12TQ (40) 15TQ (32) 16TQ (30) 20TQ (24) 24TQ (20)	10TQ (30) 12TQ (25) 15TQ (20) 20TQ (15)	8TQ (30)

Note: Shown in ( ) are the baud rate prescaler divide-by-N value.
Note 1. Baud rate prescaler divide-by-N value = P + 1 (P = 0 - 1023) P: value selected by the BRP bits in the Channel Configuration Registers.
Note 2. Minimum frequency to achieve maximum nominal baud rate of 1 Mbps.

Table 31.21 Baud rate calculation example for nominal and data bit rate CAN communication configurations

Baud rate calculation formula	(DLL clock) (baud rate prescaler divide-by-N value*1) × (number of TQs in one bit)		
	80 MHz	40 MHz	20 MHz
Nominal 1 Mbps Data 8 Mbps	80TQ (1)	40TQ (1)	20TQ (1)
	10TQ (1)	5TQ (1)	Not possible
Nominal 1 Mbps Data 5 Mbps	80TQ (1)	40TQ (1)	20TQ (1)
	16TQ (1)	8TQ (1)	Not possible
Nominal 500 Kbps Data 2 Mbps	160TQ (1)	80TQ (1)	40TQ (1)
	40TQ (1)	20TQ (1)	10TQ (1)

Note: Shown in ( ) are the baud rate prescaler divide-by-N values and this table is not available in the classical CAN function.
Note 1. Baud rate prescaler divide-by-N value = P + 1 (P = 0 - 1023) P: value selected by the BRP bits in the Channel Configuration Registers.

For optimum clock tolerance in networks using the FD frame format, the length of the time quantum should be the same in nominal bit time and in data bit time. This means CFDC0NCFG.NBRP = CFDC0DCFG.DBRP.

Additionally, if transceiver delay compensation is used, do not program the CFDC0DCFG.DBRP bit to be greater than 1, as 1 means divide by 2.

31.4.1.4 Setting of CAN Clock, Bit Timing and Baud Rate

Figure 31.17 shows the procedure for setting the CAN clock and the baud rate for each channel.

These settings should be performed during Channel Reset mode (Configuration mode) for the CAN channels.

Before going to channel communication state, the baud rate must be configured, otherwise the mode does not switch correctly.

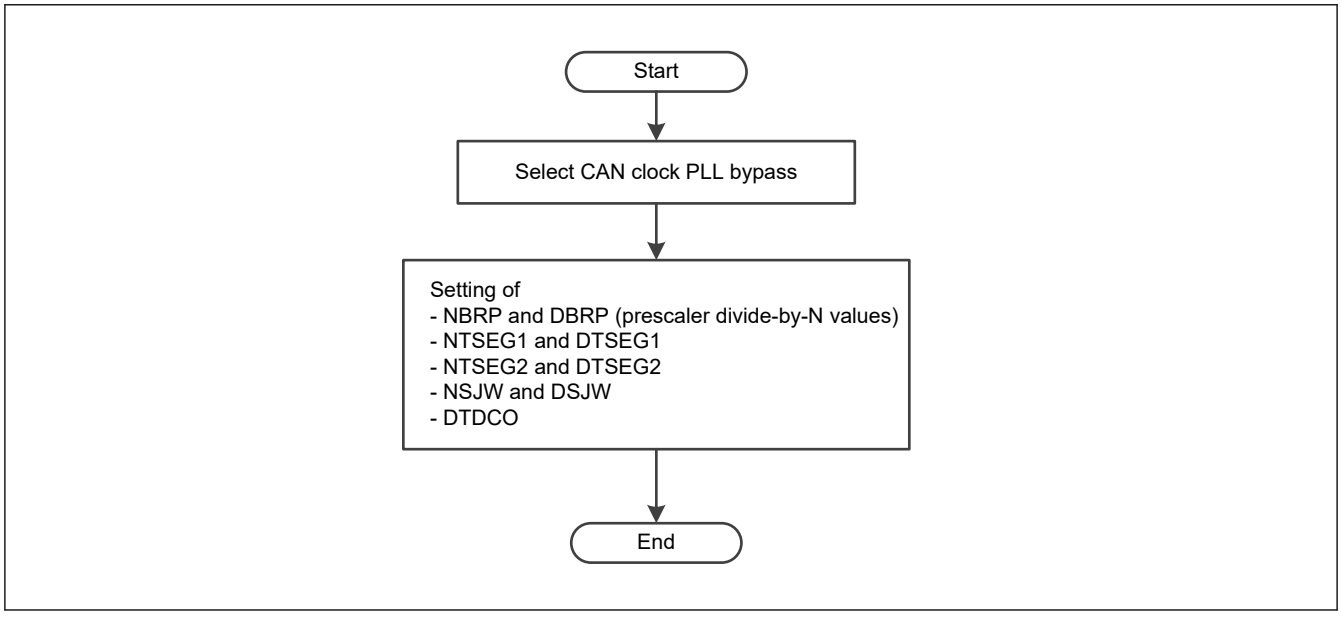

Figure 31.17 Procedure for setting the CAN bit timing and baud rate

31.4.1.5 Transmitter Delay Compensation

This chapter is not valid for classical CAN.

When a high baud rate is used such as 5 to 8 Mbps for the data phase, the transmitter delay can become greater than TSEG1. In this case, the transmitter always detects a bit-error in the data phase of the CANFD frame. The TDC compensates for the inability of the transmitter to receive its own transmitted bit at the sample point of that bit.

There is another symbolic sample point known as the Secondary Sample Point (SSP) that is used only during the data phase of CANFD frames. This is derived from the Transceiver Delay Compensation Result bit (CFDC0FDSTS.TDCR) as shown in Figure 31.18.

The resolution of the configuration, measured and offset values is based on the CAN channel DLL clock.

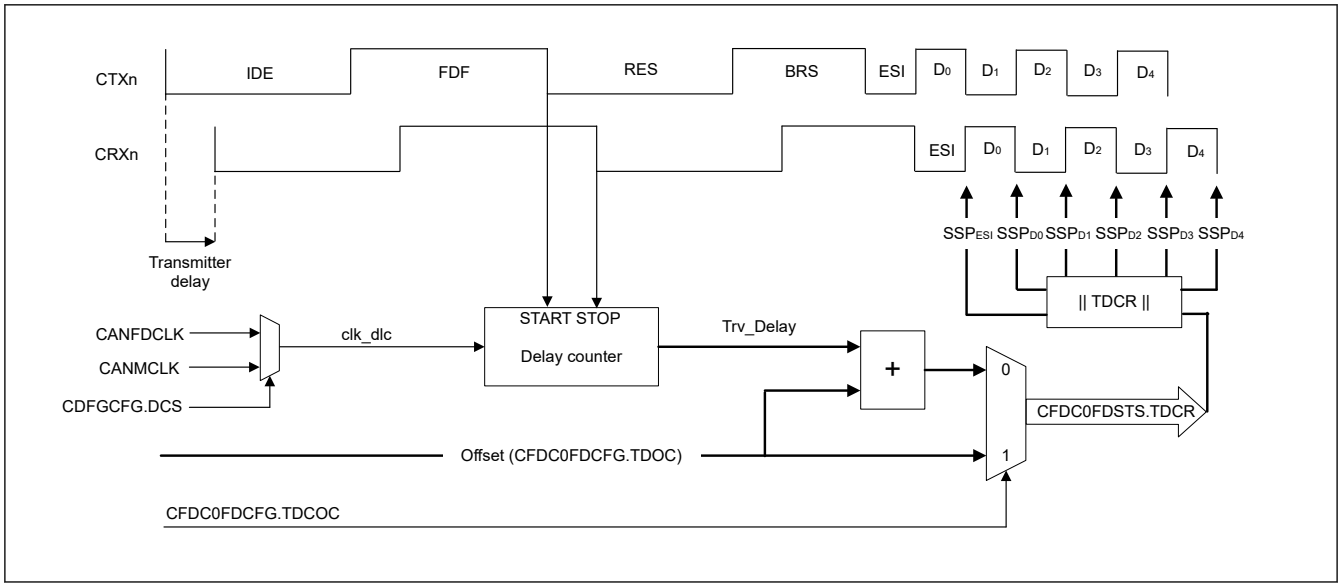

Figure 31.18 Transmitter delay compensation

The measured Trv_Delay is based on the number of clk_dlc clock cycles.The delay is counted up by one for each started clock until the dominant value is seen on CRXn. Figure 31.19 shows the measured result. Trv_Delay counted to maximum 127 with a clk_dlc clock.

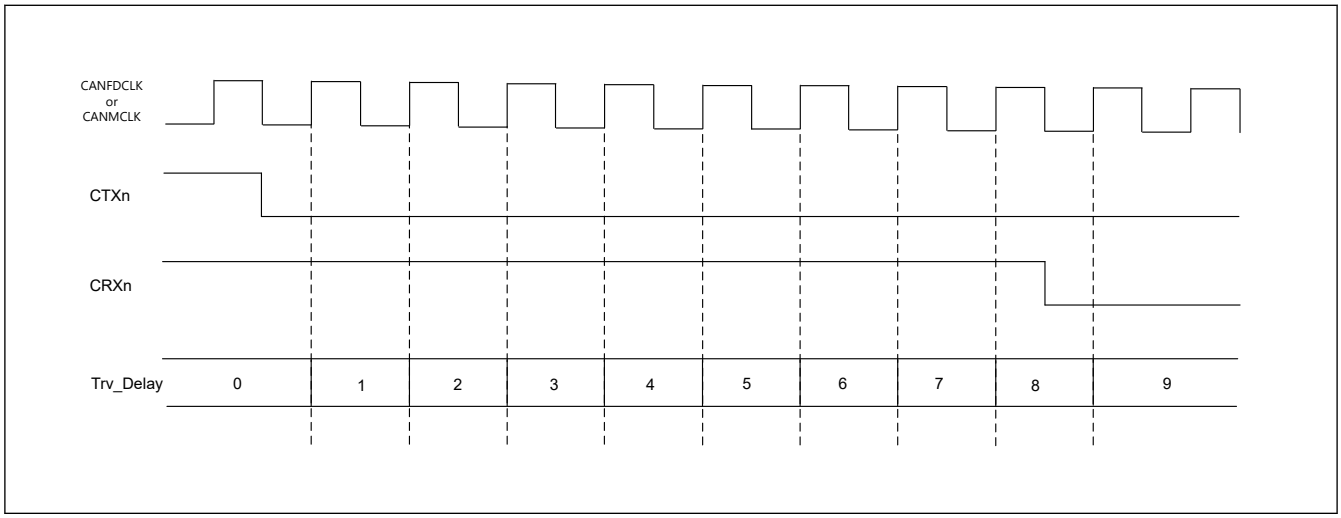

Figure 31.19 Trv_Delay measurement example

The SSP is calculated by taking the result from CFDC0FDSTS.TDCR and rounding the value down to the nearest integer number of data time quanta.

Figure 31.20 shows the positioning of the secondary sample point. When CFDC0FDCFG.TDCOC is equal to 0, the SSP is equal to the Trv_Delay (measured delay) + CFDC0FDCFG.TDCO, rounded down to the nearest integer number of time quanta. Usually, the TDCO value should have the size of (SyncSegmentdata + TSEG1data) to position the SSP to a theoretical location of the sample point.

If the CFDC0FDCFG.TDCOC is equal to 1, the SSP is defined by CFDC0FDCFG.TDCO. If CFDC0DCFG.DBRP is greater than 0, the value is also rounded down to the nearest integer number of time quanta.

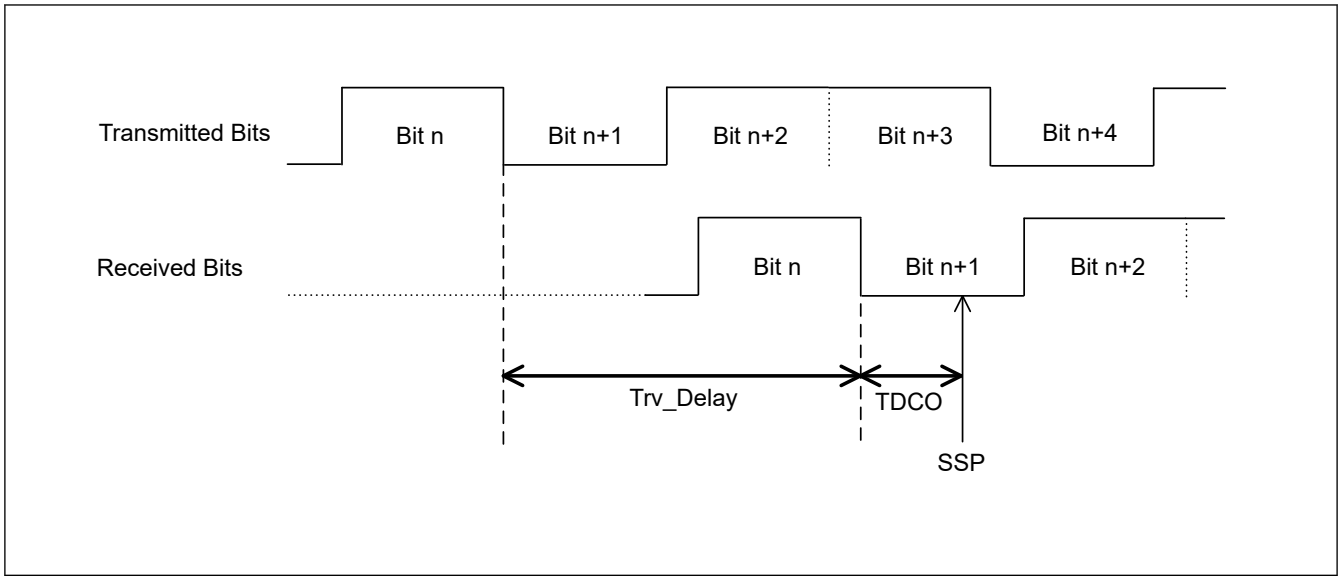

Figure 31.20 Position of the secondary sample point

The maximum delay (Trv_Delay + TDCO) which can be compensated by the CANFD module is (6 data bits - 2clk_dlc).

The ISO 11898-1 allows you to set different values for BRP_data and BRP_nom.

If different values are used for CFDC0NCFG.NBRP and CFDC0DCFG.DBRP, then two CAN nodes may be out of synchronization at the point when the bit rate changes from nominal bit rate to data bit rate after sample point of the BRS bit. This condition is shown in Figure 31.21.

The length of the time quantum should be the same in the nominal bit time and in the data bit time. This means CFDC0NCFG.NBRP = CFDC0DCFG.DBRP.

Different bit rates can be achieved by selecting different configuration values for the Time Segments. The nominal bit rate can be configured from 8 to 385 TQs and the data bit rate from 5 to 49 TQs.

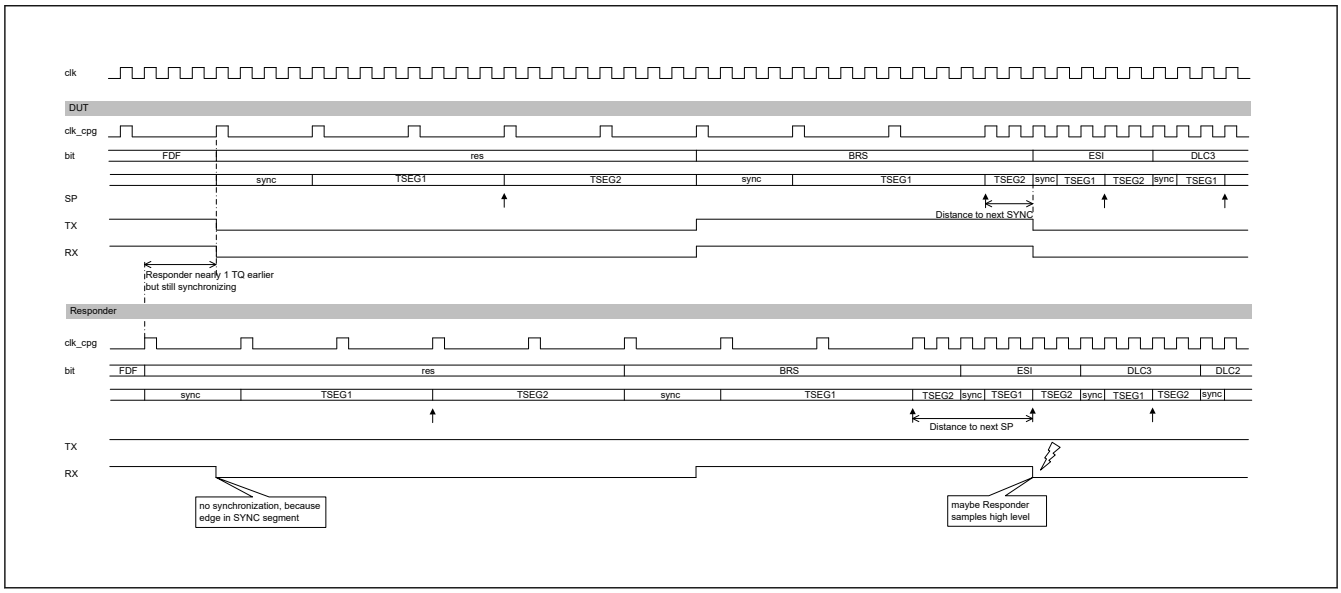

Figure 31.21 Loss of synchronization between two CAN nodes

The transmitter delay compensation measurement result is updated at the falling edge from FDF bit to RES bit when configured accordingly (CFDC0FDCFG.TDCE = 1, CFDC0FDCFG.TDCOC = 0).

Figure 31.22 shows the read flow to get the measured transmitter delay compensation result.

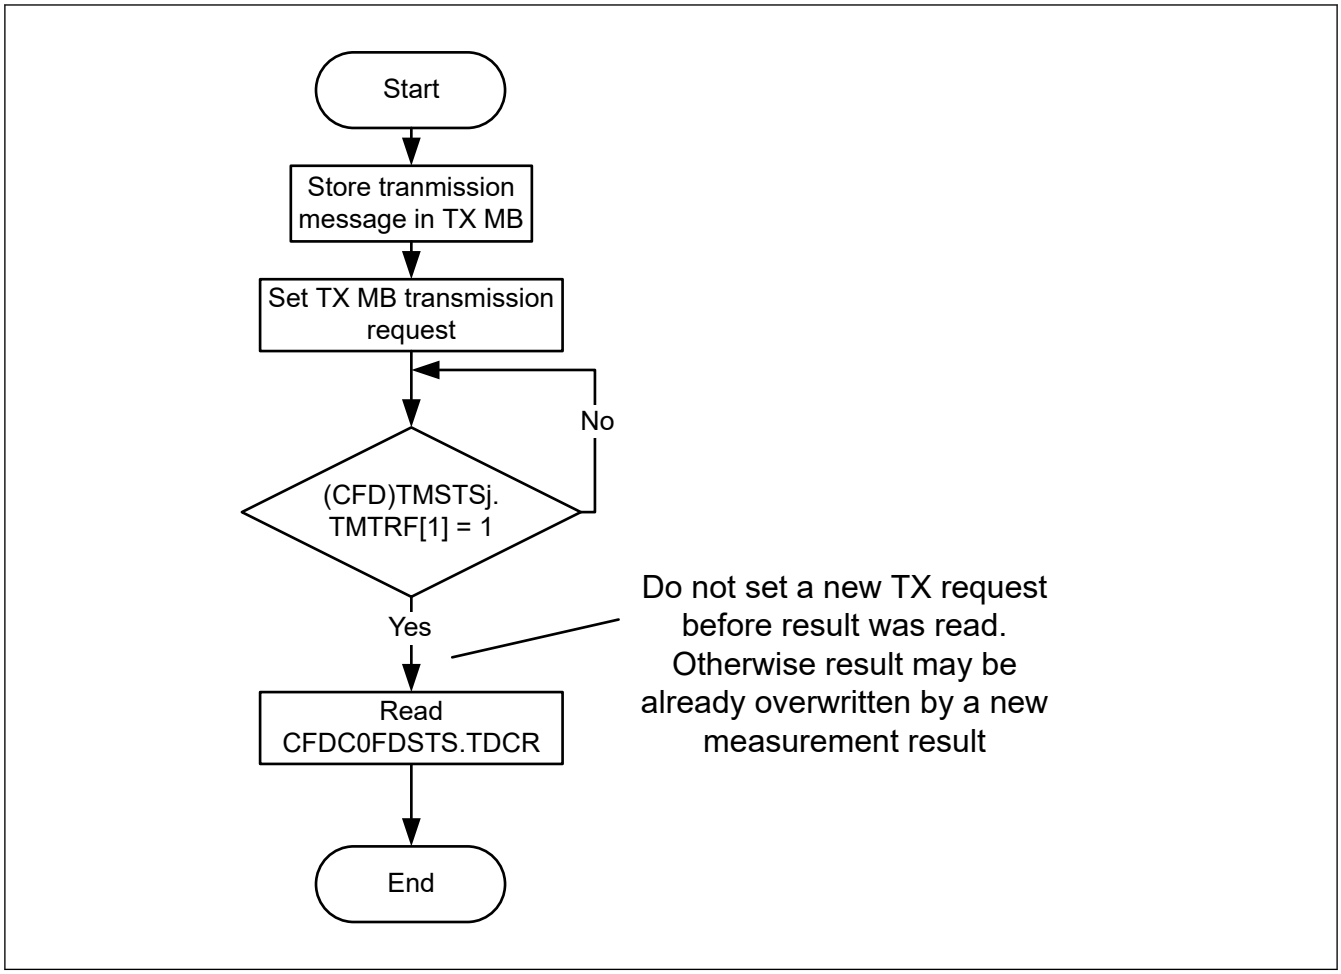

Figure 31.22 TDC result read flow

31.4.2 CAN Module Configuration after Hardware Reset

After a hardware reset (power on reset) or after setting and clearing a CFDGRSTC.SRST bit, the CANFD module enters Global Sleep mode automatically.

To enable configuration of the CANFD module, you must exit Sleep mode by clearing the Global Sleep Request bit CFDGCTR.GSLPR to 0.

After a hardware reset, the module starts RAM initialization, the CFDGSTS.GRAMINIT bit in the Global Status Register is set automatically to indicate that the CANFD logic is initializing the RAM.

After RAM initialization is complete, this bit is cleared automatically.

RAM initialization is necessary to avoid setting of false ECC error flag after HW reset the random data presented in the RAM.

Do not access registers of CANFD in either read or write until RAM initialization is complete and the CFDGSTS.GRAMINIT bit is cleared.

Before going to communication mode, the Global Acceptance Filter List and message FIFO buffers must be configured. In addition, CAN channel must be configured such as CAN bit timing. For this configuration, CAN channel must be released from Channel Sleep mode and must be configured for communication in Channel Reset mode (Configuration mode).

Figure 31.23 shows the configuration procedure. For details about each step, see section 31.5. Acceptance Filtering Function using Global Acceptance Filter List (AFL), section 31.6. FIFO Buffers and Normal Message Buffer Configuration, section 31.7. Interrupts and DMA and section 31.4.1.3. Baud Rate.

The CANFD module does not perform the RAM initialization sequence after executing a software reset by setting CFDGRSTC.SRST.

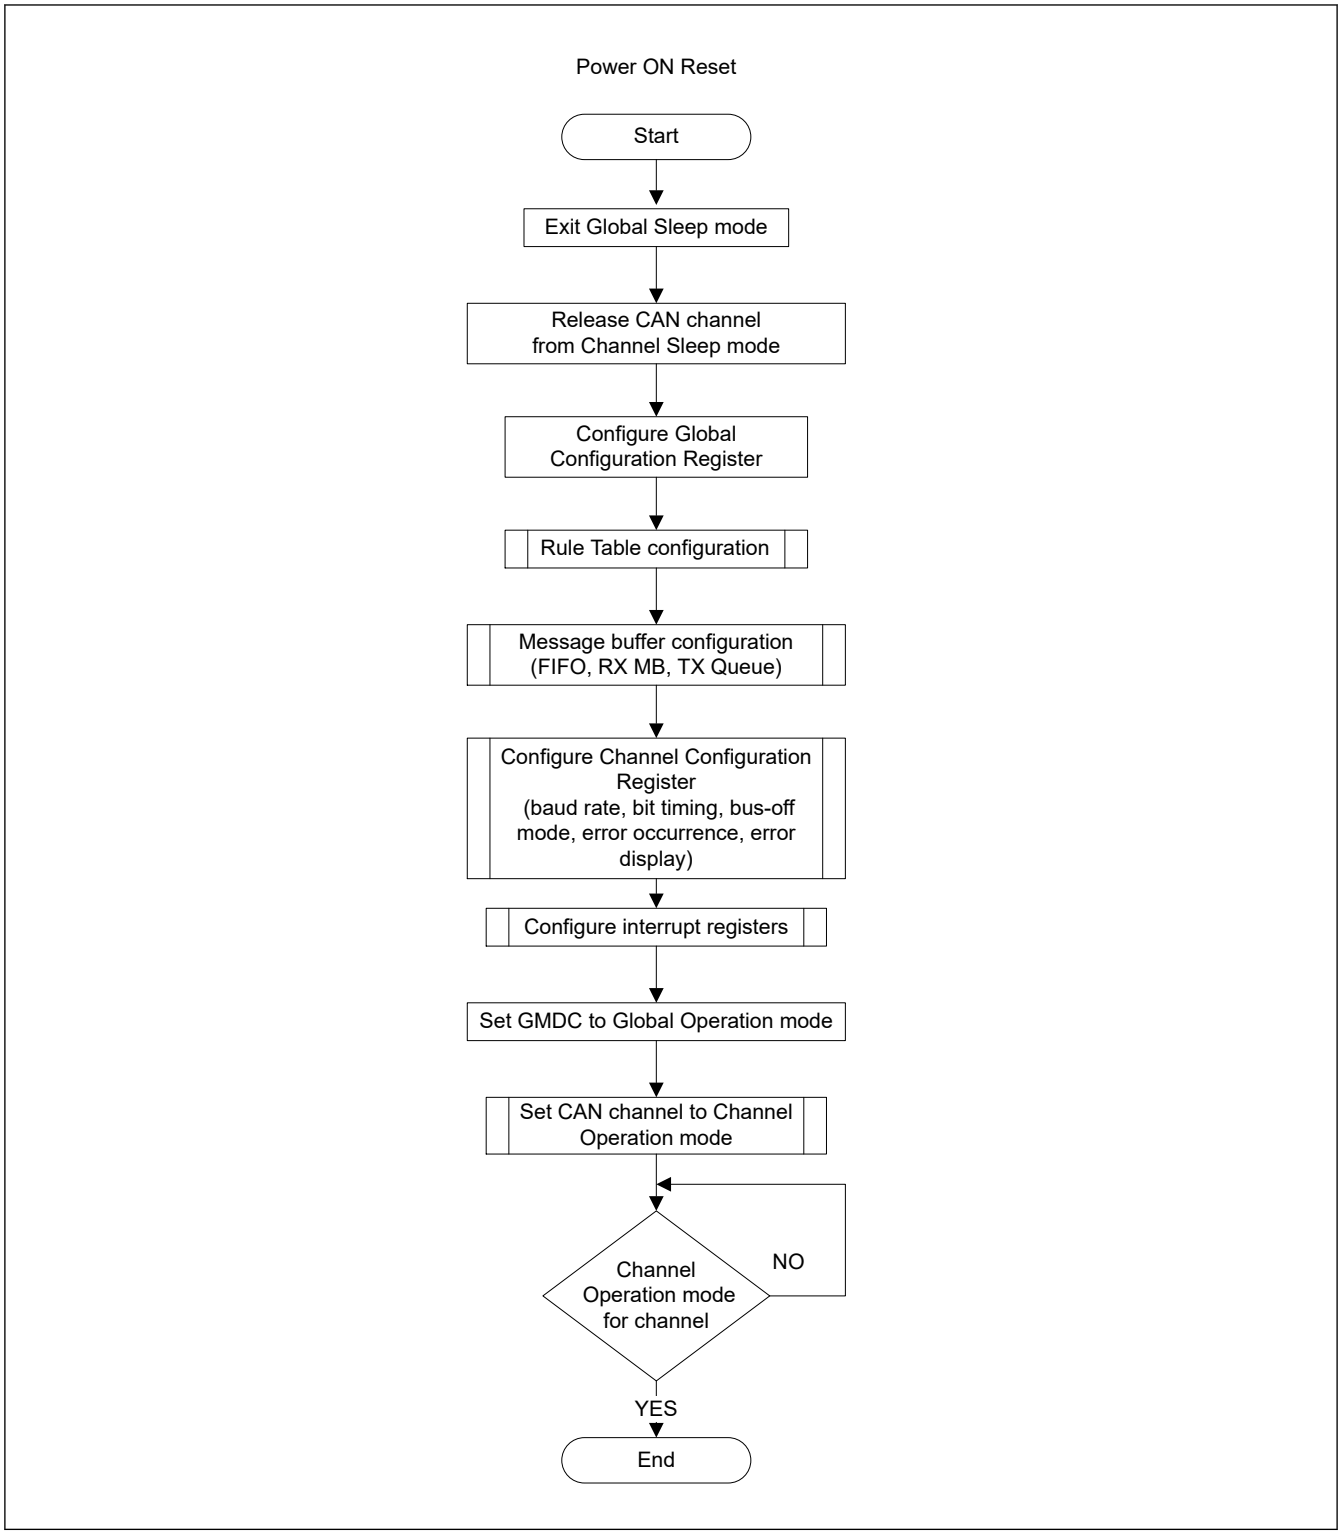

Figure 31.23 Configuration procedure after a hardware reset

31.5 Acceptance Filtering Function using Global Acceptance Filter List (AFL)

31.5.1 Overview

The CANFD module can handle message acceptance filtering with a global Acceptance Filter List (called AFL). Each element of the AFL defines a filter rule for messages received on a specific channel.

The following actions are performed based on the AFL entries:

- Acceptance filtering based on received CAN Identifier and masking
- DLC filtering based on received DLC value
- Message data payload according to the CFDGCFG.CMPOC bit*1
- Storage of accepted messages in the message buffer objects defined in the related AFL entry
- Attaching a 16-bit pointer to the stored messages defined in the related AFL entry, for example to support AUTOSAR applications
- Attaching a 2-bit information label to the stored messages defined in the related AFL entry

Note 1. This feature is not available in the classical CAN function.

The CANFD module allows a maximum of 16 AFL entries.

During acceptance filtering process, each AFL entry in a channel is checked against the received message by the acceptance filter unit. The check starts from the lowest AFL entry number for this channel.

AFL search stops when a match of the received identifier with a configured identifier/mask combination occurs or when the received identifier has been compared against all AFL entries defined for the related channel. If no match occurs, then the received message is rejected. No notification is given to the application in this case.

Additionally, an automatic DLC filtering is performed for each accepted message if DLC check is globally enabled. If the DLC value of the received message is equal to or higher than the configured DLC value in the matching AFL entry, the DLC check is passed.

If DLC replacement (CFDGCFG.DRE bit) is enabled, DLC value configured in the matching AFL entry is greater than 0x0 and DLC check passes, then the configured value of DLC in the matching AFL entry is stored in the destination RXMB or FIFO Buffer.

If the received value of DLC is greater than the configured DLC value in the matching AFL entry, then the additional data bytes received on the CAN Bus are not stored in the destination RXMB or FIFO Buffer. These additional data bytes are stored as 0x00 in the destination RXMB or FIFO Buffer.

If DLC replacement is enabled and DLC value of matching AFL entry is 0x0, then the received value of DLC is stored in the destination RX MB or FIFO Buffer.

If DLC replacement (the CFDGCFG.DRE bit) is disabled and DLC check passes, then the received value of DLC on the CAN bus is stored in the destination RXMB or FIFO buffer.

If the received value of DLC is greater than the configured DLC value in the matching AFL entry, then the additional data bytes received from the CAN bus are also stored in the destination RXMB or FIFO buffer.

If DLC value of the received message is less than the configured DLC value in the matching AFL entry, then DLC check fails. In this case, the received message is rejected and is not stored in any RXMB or FIFO buffer.

Additionally, DLC check failure is flagged by the DLC Error Flag in the Global Error Flag Register. If configured, an error interrupt is also generated. The DLC replacement configuration has no impact if the DLC check fails.

If a message has passed both acceptance filtering and DLC filtering, it is stored in a single reception message buffer and/or in FIFO buffers configured for reception function.

This message storage target information is also defined in the same AFL entry. Do not set a target at the AFL entry which is not configured.

Each accepted received message can be stored into a maximum of 2 different target destinations (single reception message buffer and/or FIFO buffers).

The programming of more than 2 target destinations is not allowed. If more destinations are programmed, then the internal timing might lead to a race condition that prevents the storage of received messages in the message RAM.. Correct configuration of the numbers of target destination is the responsibility of the application.

Additional protection mechanism is made for the case when a received message contains more data payload Bytes than possible to store in the target destination (CFDRMNB.RMPLS, CFDRFCCa.RFPLS or CFDCFCC.CFPLS).

If CFDGCFG.CMPOC = 0, the message is completely rejected and is stored in the target destination. When CFDGCFG.CMPOC = 0 and RX or Common FIFO full including the received message contains more data payload bytes than possible to store in the target destination (CFDRMNB.RMPLS, CFDRFCCa.RFPLS or CFDCFCC.CFPLS), the corresponding CFDFMSTS.RFxMLT or CFDFMSTS.CFxMLT bit is not set to 1, respectively.

When CFDGCFG.CMPOC = 1, the received data bytes greater than CFDRMNB.RMPLS is rejected. When CFDGCFG.CMPOC = 1 and RX or Common FIFO full including the received message contains more data payload bytes than possible to store in the target destination (CFDRMNB.RMPLS, CFDRFCCa.RFPLS or CFDCFCC.CFPLS), the corresponding CFDFMSTS.RFxMLT or CFDFMSTS.CFxMLT bit is set to 1, respectively.

Depending on the CFDGCFG.DRE bit, the original received DLC or the DLC value configured at the AFL entry is stored.

Regardless of the CFDGCFG.CMPOC bit setting, CFDGERFL.CMPOF is set to 1 if a payload overflow condition is detected.

The DLC filtering is performed before the payload overflow function. So for one reception frame, only one flag can be set at the same time with CFDGERFL.DEF or CFDGERFL.CMPOF*1.

Note 1. This bit is not available in the classical CAN function.

31.5.2 Allocation of AFL Entries

The number of AFL entries per channel can be configured using the dedicated field in the related Global Acceptance Filter Configuration Registers (see Figure 31.24).

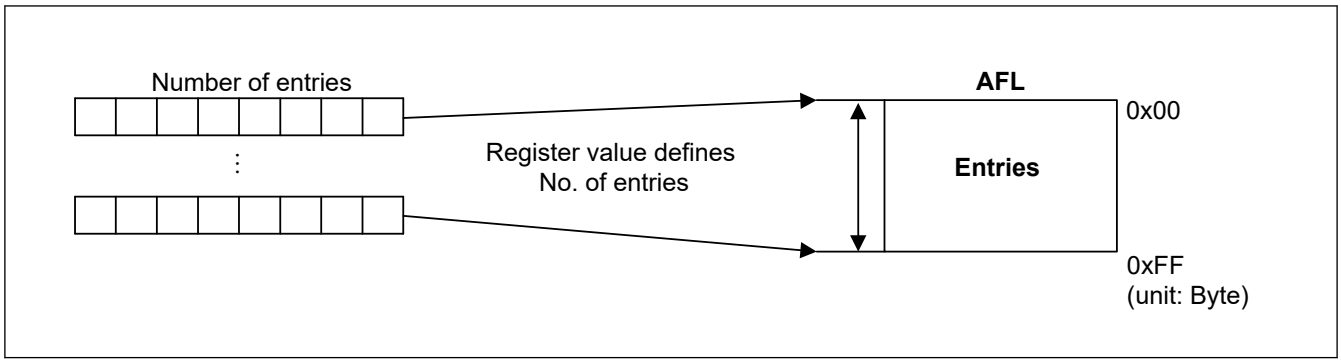

Figure 31.24 Configuration of AFL for each channel

The minimum number of entries for one channel is 0 (no entries defined for the channel) and the maximum number of entries is 16.

All entries are unique for a channel and overlapping or sharing of entries is not supported. Correct configuration of the AFL is the responsibility of the application.

The CANFD module does not flag errors related to the configuration of the AFL.

31.5.3 AFL Entry Description

Each AFL entry consists of 16 bytes. The fields in all entries are identical.

Each entry contains the following information for acceptance filtering and DLC filtering:

- Identifier (11 bits for Standard Frame format, 29 bits for Extended Frame format):
  Acceptance filter unit checks the identifier field of the received message against the identifier field of each AFL entry (full 29 bits masking of identifier bits is possible, see information that follows).
- IDE bit:
  Acceptance filter unit checks the IDE bit of the received message against this bit and selects the relevant part of the identifier field for acceptance filtering (masking of IDE bit is possible, see the information that follows).
- RTR bit:
  Acceptance filter unit only accepts data frames (RTR = 0) or remote frames (RTR = 1) according to the setting of this bit (masking of RTR bit is possible, see the information that follows).
- Loopback Configuration bit:
  This bit can enable or disable the AFL entry depending on the Loopback Configuration or Mirror mode condition.
- Mask for Identifier bits (29 bits):

Each bit in the identifier mask can mask the corresponding identifier bit in the AFL entry during acceptance filtering, see Figure 31.25.

- Mask for IDE bit:
  If this Mask bit masks the IDE bit of the AFL entry in both Standard Identifier and Extended Identifier format, messages can be accepted by this AFL entry. The identifier of the received message is compared against the Standard Identifier part of the AFL entry for Standard Identifier format messages and against the Extended Identifier part of the AFL entry for Extended Identifier format messages.

- Mask for RTR bit:
  If this Mask bit masks the RTR bit of the AFL entry in both frame formats, data frame and remote frame formats are accepted by this AFL entry.

- Pointer information (16 bits):
  This 16-bit pointer is attached to a received message accepted by the related AFL entry. The pointer is added during message storage in the message buffer area and can be used by application as support function. The pointer information can be used for example to support PDU identifier allocation for the received message in AUTOSAR systems.

- Information label (2 bits):
  This 2-bit label is attached to a received message accepted by the related AFL entry. The label is added during message storage in the message buffer area and can be used by application as support function.

- DLC value for automatic DLC filtering:
  If the DLC value of the received message is equal or higher than the configured DLC value, the DLC check is passed.

If the DLC value in this AFL entry is configured to 0, DLC filtering is effectively disabled for this entry (all accepted messages pass DLC filtering).

Each AFL entry contains the following information for the handling of received messages:

- Message buffer number of one single reception message buffer as target for received message storage
- Single reception message buffer enable bit to configure the single reception message buffer number to be valid or invalid, as target for received message storage
- FIFO direction pointer - each bit of the FIFO direction pointer configures a dedicated FIFO as possible target for a received message

There is no hardware protection against such storage of message. Therefore, the FIFO direction pointer must be configured carefully.

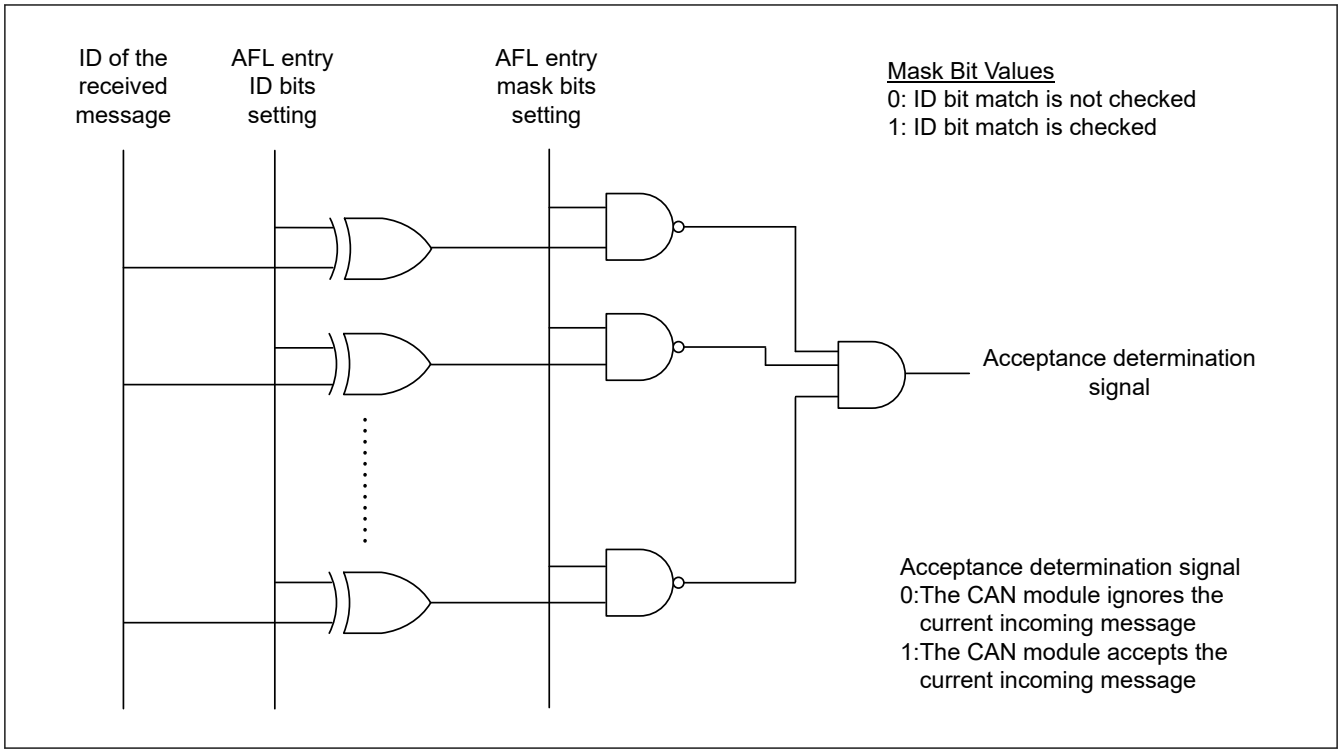

Figure 31.25 Acceptance function

31.5.4 Entering Entries in the AFL

Application software can enter one full entry into the AFL using the following registers:

- Global AFL ID Entry Register: Part 1 of the AFL entry
- Global AFL Mask Entry Register: Part 2 of the AFL entry
- Global AFL Pointer 0 Entry Register: Part 3 of the AFL entry
- Global AFL Pointer 1 Entry Register: Part 4 of the AFL entry.

16 sets of these registers form a group of AFL entries. The AFL should only be configured in CH_RESET or CH_HALT mode.

Follow the configuration shown in Figure 31.26 to program the AFL.

After entering all entries in Configuration mode, locking of the AFL access should be performed to protect unwanted write access to the AFL.

Write protection is active during all Global modes (GL_RESET, GL_HALT, and GL_OPERATION) if the lock bit is set.

Read access to AFL is still possible during all Global modes even when AFL data access is disabled (consistency check of AFL contents is possible during run time).

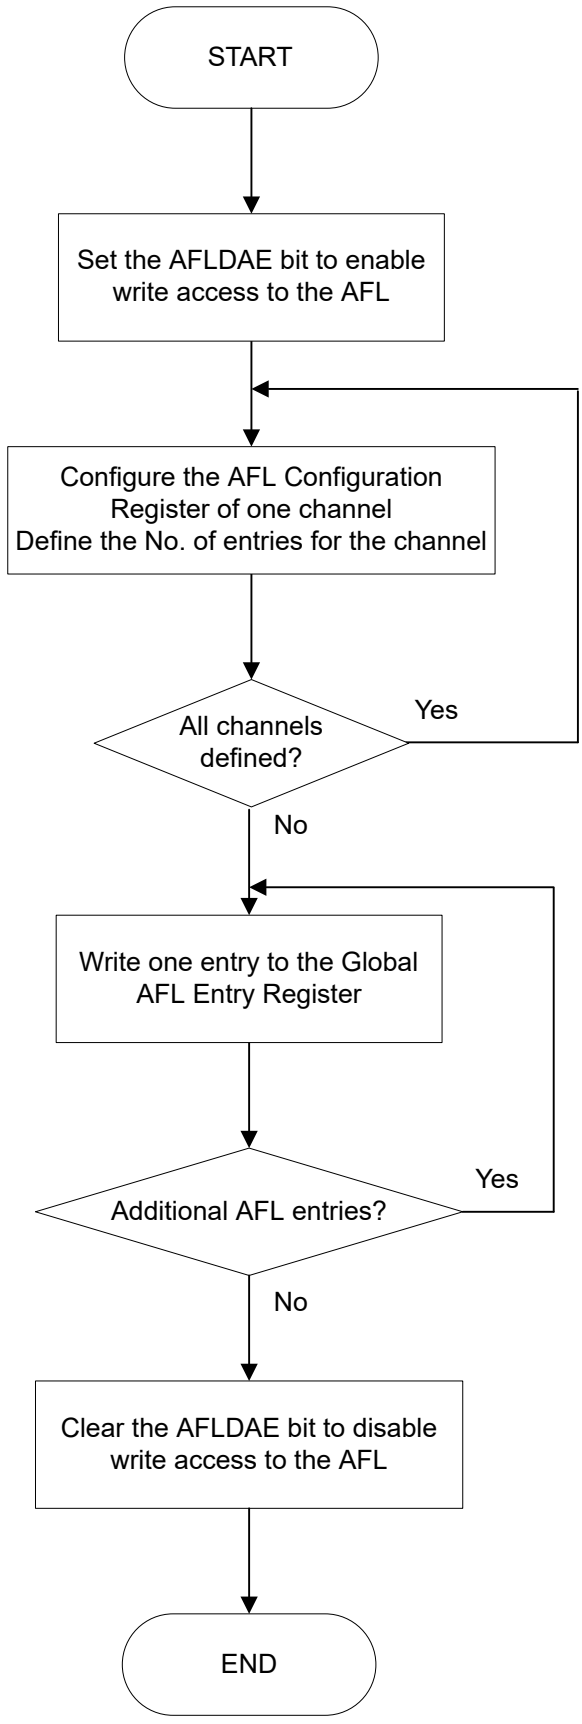

Figure 31.26 AFL configuration flow

31.5.5 Loopback Modes

If the Loopback Configuration bit is set, the AFL entry is only valid in Loopback test mode (Self-test mode 0 or Self-test mode 1) or in mirror mode when receiving messages that were transmitted by the respective CAN channel itself.

The AFL entry is not valid for received messages in loopback mode transmitted by other CAN nodes on the bus. The expression valid or invalid for the related entry means that this AFL entry is or is not compared against the received message ID respectively.

If the Loopback Configuration bit is 0, the AFL entry is only valid for:

- Received messages transmitted by other CAN nodes on the bus in normal (non-loopback mode) and mirror modes
- Received messages transmitted by other CAN nodes or the CAN channel itself in Loopback test mode.

The mirror mode can be enabled with the CFDGCFG.MME bit in the Global Configuration Register. If CFDGCFG.MME bit is set, then a successfully transmitted message can be stored back in an RX message buffer or FIFO buffer if a matching entry is configured in the AFL for that channel.

The Loopback Configuration bit in the matching AFL entry must be set to store this frame.

If Mirror mode and Loopback test mode are configured at the same time, the Loopback test mode behavior applies.

Table 31.22 shows the behavior of the acceptance filter unit depending on the setting of the related input signals.

Table 31.22 Behavior of acceptance filter based on the loopback configuration setting in AFL entry

Mirror Mode Enable (MME Configuration bit)	Loopback in test mode (Self-test mode 0 or Self-test mode 1)	Channel mode	Loopback Configuration bit in AFL entry	AFL entry
0	0	Receiver	0	Valid
			1	Invalid
		Transmitter	0	Invalid
			1	Invalid
	1	Receiver	0	Valid
			1	Invalid
		Transmitter	0	Valid
			1	Valid
1	0	Receiver	0	Valid
			1	Invalid
		Transmitter	0	Invalid
			1	Valid
	1	Receiver	0	Valid
			1	Invalid
		Transmitter	0	Valid
			1	Valid

Note: The expression valid or invalid for the related entry means that this AFL entry is or is not compared against the received message ID, respectively.

31.5.6 IDE Masking

When the GAFLIDEM bit is 0 in an AFL entry, the IDE bit configured in the AFL entry is not used for ID matching. In this case, the use of ID[10:0] or ID[28:0] matching is based on the received IDE bit.

Consider the following example:

- The ID and Mask fields of an AFL entry x is configured as follows:
  - CFDGAFLID [x] = 0xC0553A20 → IDE = 1, RTR = 1, LLB = 0, ID[10:0] = 0x220 / ID[28:0] = 0x00553A20
  - CFDGAFLMr = 0x0000FFFF → IDEM = 0. RTRM = 0, IDM[10:0] = 0x7FF / IDM[28:0] = 0x0000FFFF

- The comparison result for the four different received IDs with AFL entry x is described as follows:
  - If a frame with IDE = 0 and ID = 0x220 is received, this is considered as a match
  - If a frame with IDE = 0 and ID = 0x320 is received, this is not a match
  - If a frame with IDE = 1 and ID = 0x1FFF3A20 is received, this is considered as a match
  - If a frame with IDE = 1 and ID = 0x08803220 is received, this is not a match.

31.5.7 Updating AFL Entry during Communication

You can update the AFL entry without disabling all CAN communications. Choose the entry number to be updated by setting the AFL entry number, and ignore the enable bit.

This entry number is ignored from the AFL matching while the entry is being updated.

Figure 31.27 shows the update flow for an AFL entry.

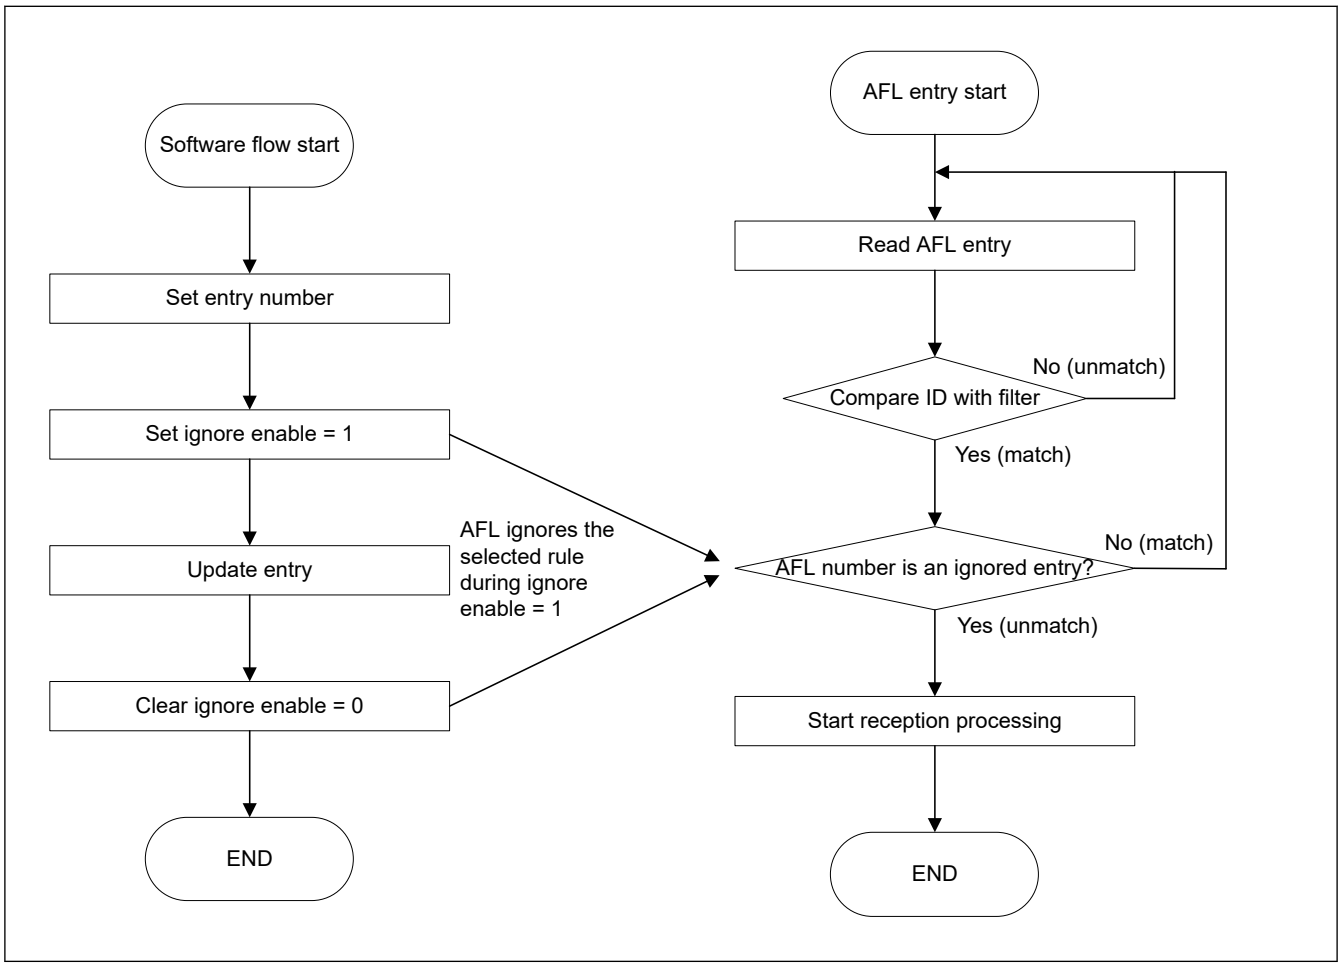

Figure 31.27 Update flow for an AFL entry

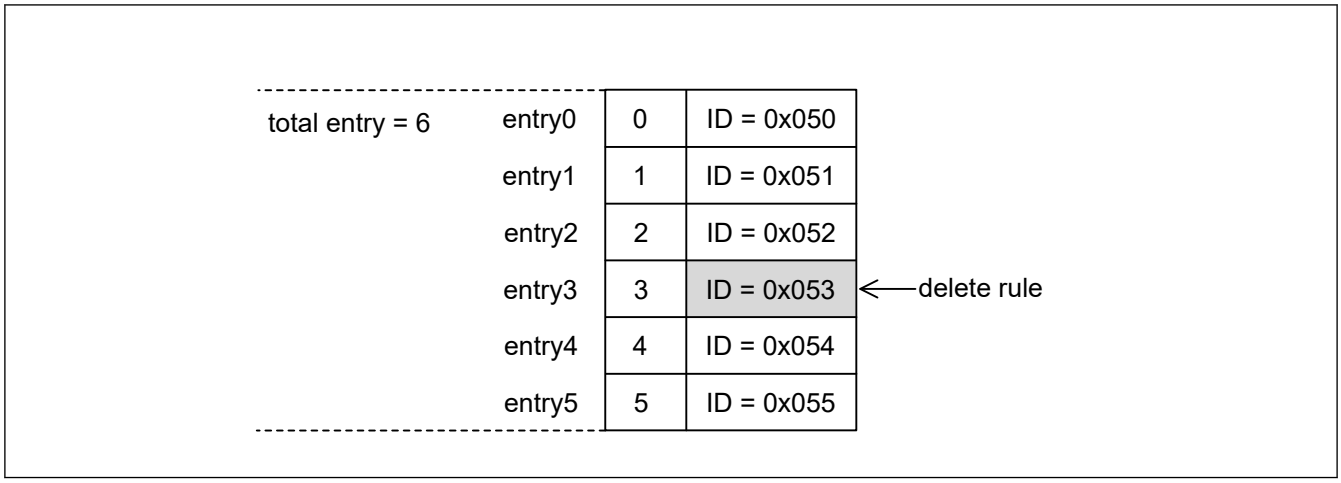
The method to update an AFL entry is as follows:

1. Set the entry number to CFDGAFLIGNENT register.
2. Set the value 0xC401 (key code and enable bit) to CFDGAFLIGNCTR register.
3. CFDGAFLECTR.AFLDAE is set to 1.
4. Set the new rule to CFDGAFLIDr, CFDGAFLMr, CFDGAFLP0r, CFDGAFLP1r registers.
5. CFDGAFLECTR.AFLDAE is cleared to 0.
6. Set the value 0xC400 (key code and clear enable bit) to CFDGAFLIGNCTR register.

Note: This entry number is ignored during the periods from (2) to (5).

(1) Example 1: Deleting an entry

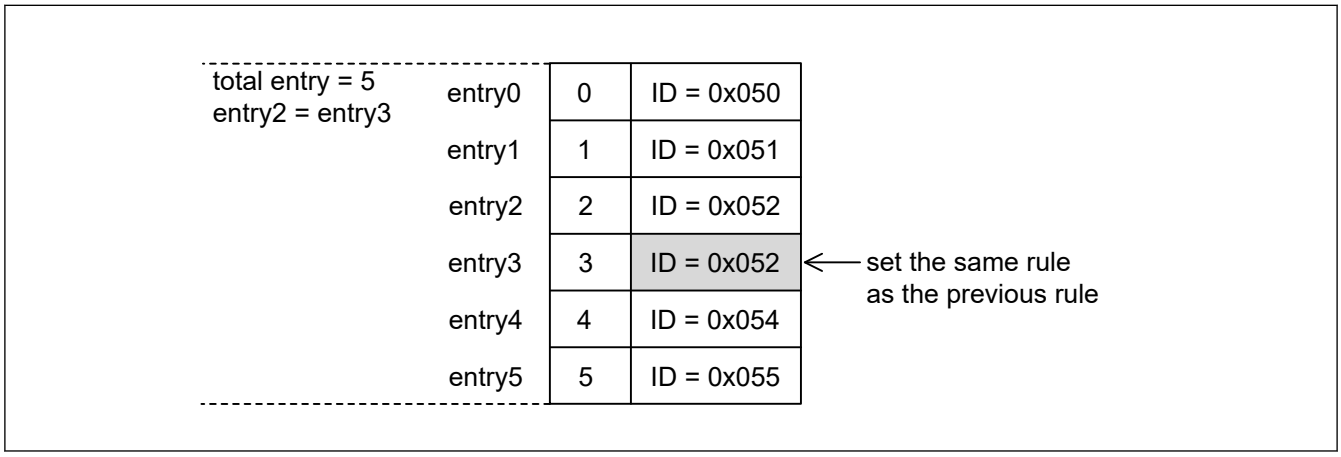
Deleting entry3 when the total number of entries is 6 channel.



How to delete an entry

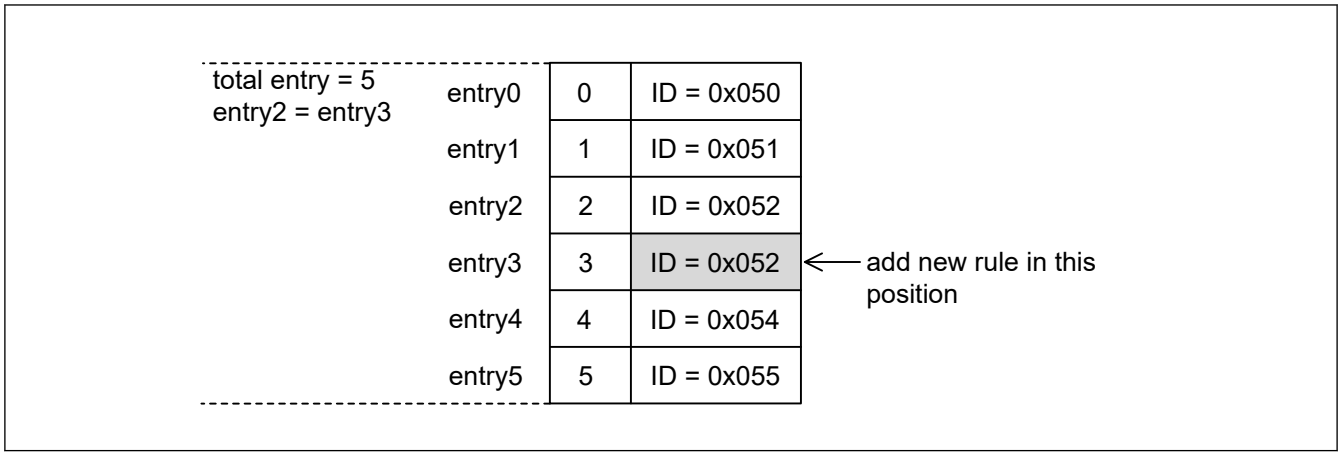
1. Set 0x00000003 to CFDGAFLIGNENT register.
2. Set 0x0000C401 to CFDGAFLIGNCTR register.
3. Set 0x00000100 to CFDGAFLECTR register.
4. Set the same rule as the previous rule by accessing CFDGAFLIDr, CFDGAFLMr, CFDGAFLP0r, CFDGAFLP1r (r = 3, this is entry3).
5. Set 0x00000000 to CFDGAFLECTR register.
6. Set 0x0000C400 to CFDGAFLIGNCTR register.

Entry3 is now deleted.



(2) Example 2: Adding an entry

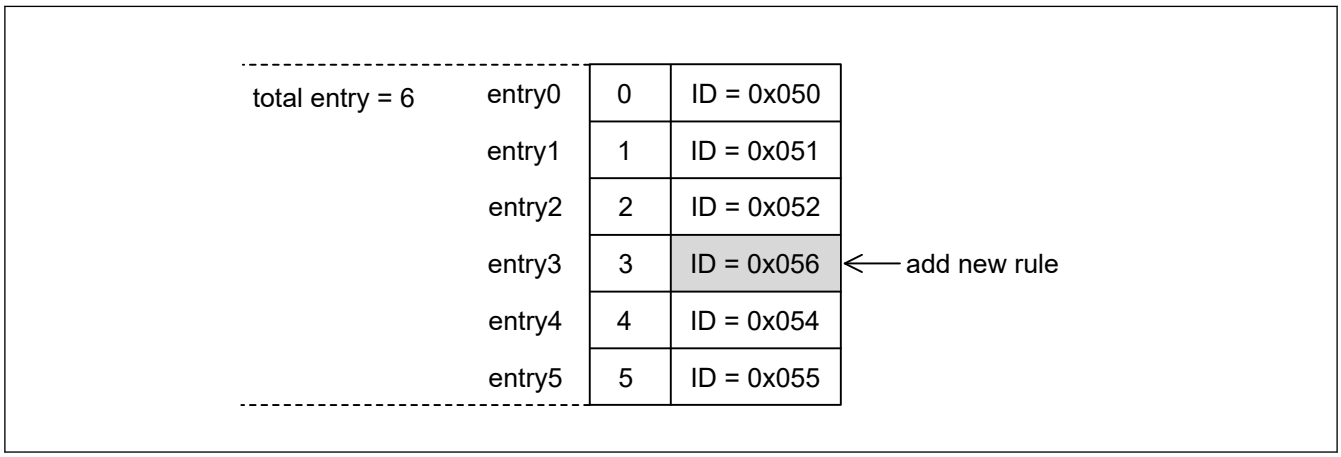
Adding a new entry to entry3 when the total number of entries is 6.



How to add an entry

1. Set 0x00000003 to CFDGAFLIGNENT register.
2. Set 0x0000C401 to CFDGAFLIGNCTR register.
3. Set 0x00000100 to CFDGAFLECTR register.
4. Set the new rule by accessing CFDGAFLIDr, CFDGAFLMr, CFDGAFLP0r, CFDGAFLP1r (r = 3, this is entry3).
5. Set 0x00000000 to CFDGAFLECTR register.
6. Set 0x0000C400 to CFDGAFLIGNCTR register.

The new entry is now added.



The AFL filter can be used to set CFDGAFLCFG, and addition/deletion of an entry is possible. Therefore, it is necessary to set the maximum number to be used to CFDGAFLCFG.

31.6 FIFO Buffers and Normal Message Buffer Configuration

This section describes the process for configuring the number of RX message buffers, the FIFO buffers, and the flat TX message buffers in the CANFD module. The message buffers are mapped as shown in Figure 31.28.

The RX message buffers can be accessed with the RX Message Buffer Registers.

The RX FIFO buffers and the common FIFO buffers configured in RX mode or TX mode can only be accessed with the FIFO Access Registers.

If the common FIFO is configured in TX mode, you can only write data into the FIFO buffer using the FIFO Access registers.

If the common FIFO is configured in RX mode, you can only read data from the FIFO Access Registers.

The TX message buffers can be accessed with the TX Message Buffer Registers.

If unused message buffer locations are read, the message buffer locations are read as unknown values.

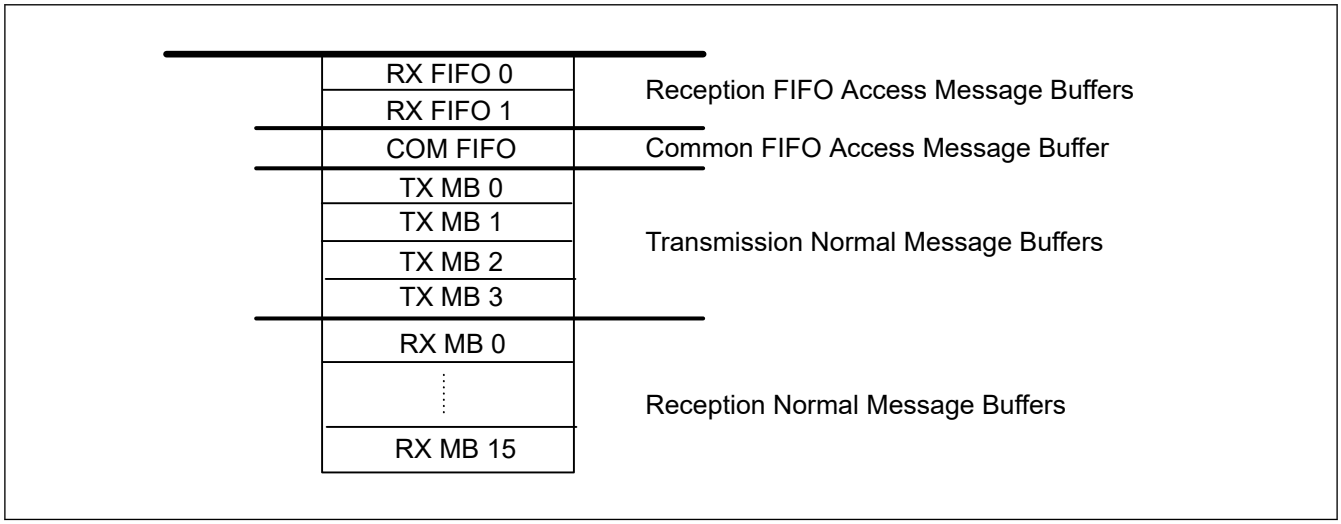


Figure 31.28 Message buffer configuration

31.6.1 Normal RX Message Buffers

In CANFD module, the frames received can be stored in normal RX message buffers based on the configuration of the AFL entries.

Additionally, the number of normal RX message buffers required in the system can be chosen up to a fixed maximum limit.

31.6.1.1 Normal RX Message Buffer Configuration

In CANFD module, the number of normal RX message buffers can be configured by writing to the RX Message Buffer Number Register.

The limiting values for the configuration of number of message buffers are:

- Minimum value = 0x00 (no normal RX MB)
- Maximum value = 0x10

Do not use values outside these limits.

The AFL entries for routing the received messages to normal RX message buffers must be configured to match the requirements of the system.

The AFL entries must also be configured properly, and an AFL entry for normal RX message buffers should not exceed the number of message buffers configured in the RX Message Buffer Number Register.

Note: There is no internal check procedure provided in CANFD module against wrong configuration of the AFL.

The data field size of the RX message buffer can be configured with the CFDRMNB.RMPLS bit. The default size is 8 bytes and the maximum data payload size is 64 bytes.

When the receiving frame exceeds the data field size, then the acceptance depends on the configuration of CFDGCFG.CMPOC (message rejecting or data payload cut).

Note: RMPLS and CMPOC bit is not available in the classical CAN function, so, these feature is not valid for classical CAN.

31.6.2 FIFO Buffers

The CANFD module provides a fixed number of FIFO buffers to support storage of frames for reception and transmission functions .

The number of reception-only FIFO buffers is fixed to 2. However, common FIFO buffer channel can be configured to store messages for transmission or reception function.

These FIFO buffers can be enabled or disabled, and the following parameters can be configured to match the system requirements:

- Size
- Interrupt structure
- Message lost mechanism
- Message overwrite mechanism of the FIFO buffers
- Location of the TX FIFO.

When the receiving frame exceeds the data field size, the acceptance depends on the configuration of the CFDGCFG.CMPOC bit (message rejecting or data payload cut).

31.6.2.1 FIFO Buffers Configuration

In CANFD module, the FIFO buffers can be configured to match the system requirements.

The total number of FIFO buffers = 2 RX FIFO buffers + 1 common FIFO buffer = 3 FIFO buffers.

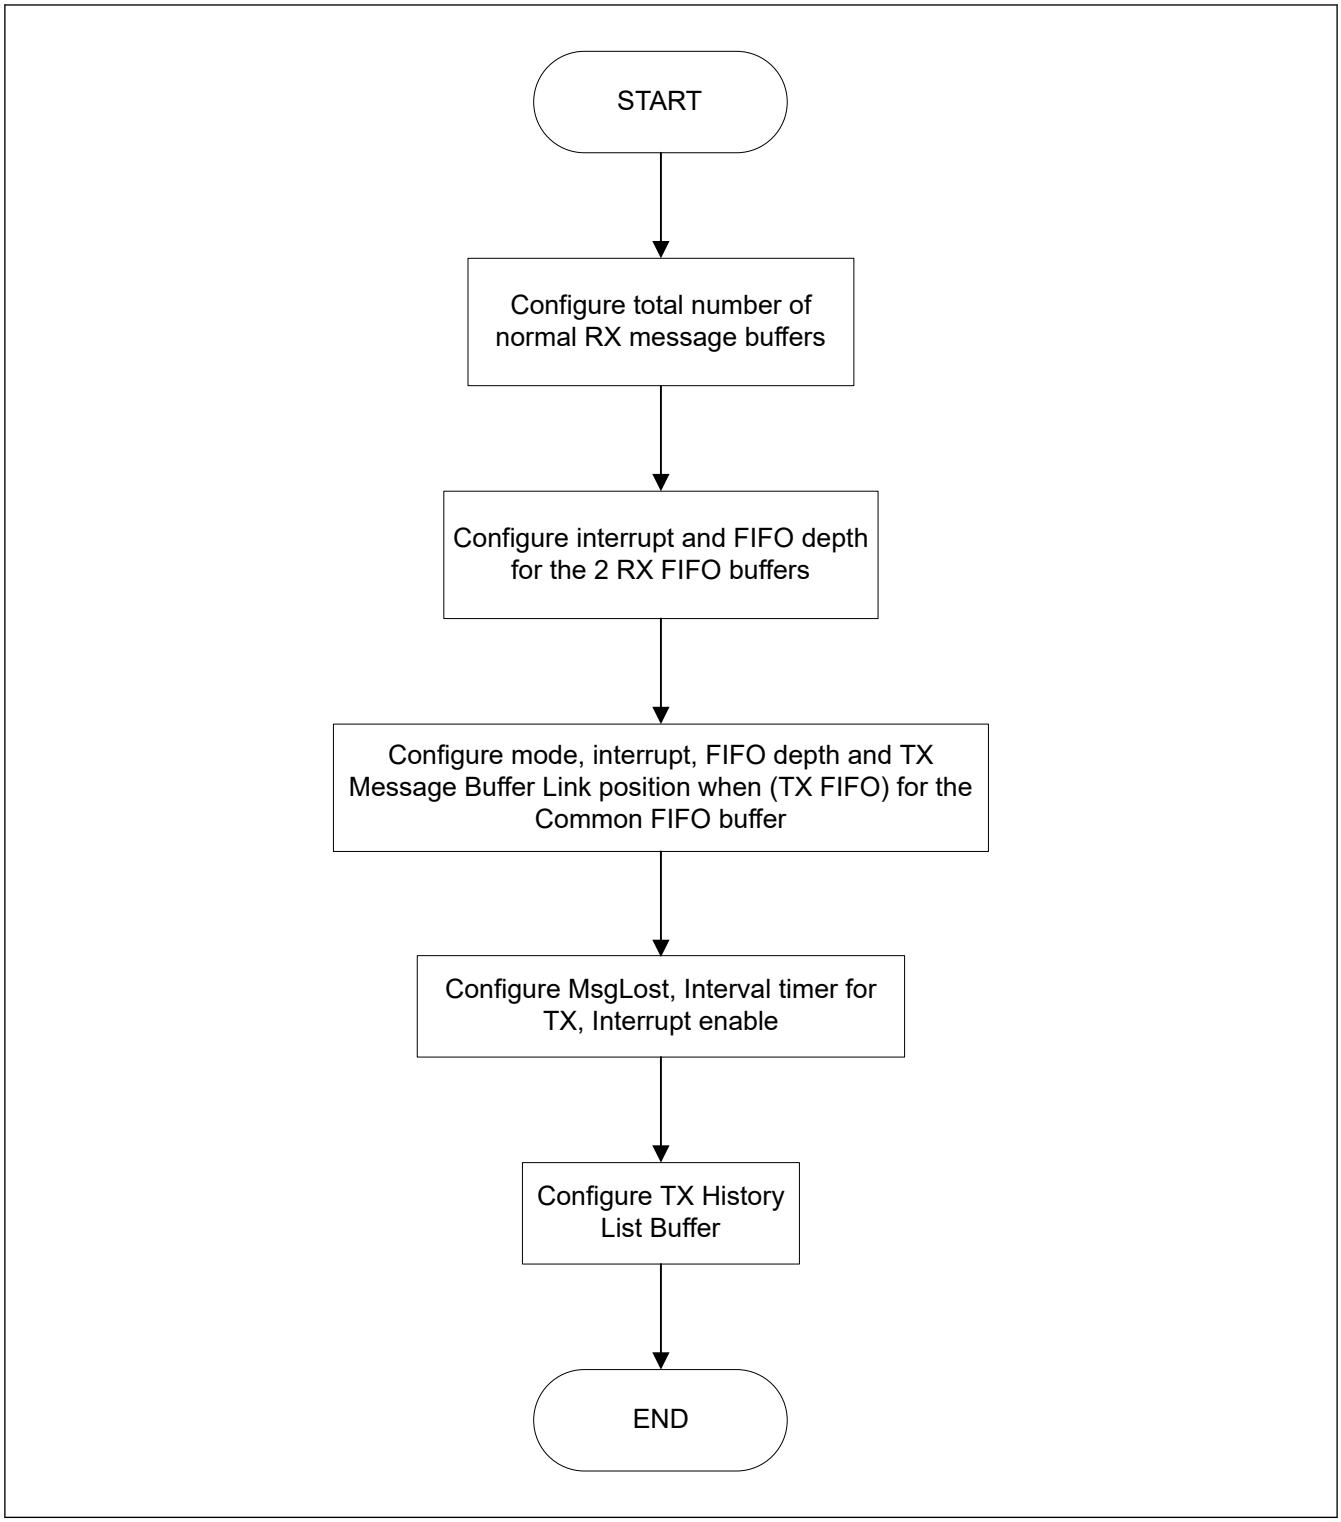

Figure 31.29 FIFO buffer configuration flow in CANFD module

As shown in Figure 31.29, the various FIFO buffers can be configured by writing to the RX FIFO Configuration/Control Registers and the Common FIFO Configuration/Control Registers.

For the 2 RX FIFO buffers, the following parameters can be configured:

- Interrupts
- FIFO depth
- FIFO payload data size.

For the common FIFO buffer, the following parameters can be configured:

- Mode
- Interrupts FIFO depth
- FIFO payload data size
- FIFO TX link position.

(1) FIFO mode configuration of Common FIFO buffer

The mode of the common FIFO buffer can be configured by writing to the CFDCFCC.CFM[1:0] bits in the Common FIFO Configuration/Control Register. The possible modes of configuration for Common FIFO buffer are:

- 0b RX mode (default mode after hardware reset)
- 1b TX mode

Messages can only be read from the RX FIFO buffers and the Common FIFO buffer configured in RX mode. Messages are stored by the CAN module in these FIFO buffers based on the AFL entries.

Messages can be read and written into the Common FIFO buffer configured in TX mode. These messages are transmitted on the appropriate CAN channel.

The pointers can only be incremented when a new message is stored in the FIFO buffer and decremented when a message is transmitted on the corresponding CAN channel by the CANFD module.

After a hardware reset, the Common FIFO buffer is configured in RX mode by default. Only enable the FIFO buffers after configuring the Common FIFO buffer in the required modes.

(2) FIFO TX message buffer link configuration

When the common FIFO is configured as TX FIFO, the FIFO buffer must be linked to a normal TX message buffer to participate in the transmission scan.

Do not write data into a TX message buffer that is linked to a Common FIFO buffer. Also, the TX message buffer linked to a Common FIFO buffer should not be a part of the TX Queue.

The TX message buffer link of each Common FIFO buffer can be configured by writing to the CFDCFCC.CFTML[1:0] bits in the Common FIFO Configuration/Control Registers. Available options for TX message buffer link configuration are:

- 0x00: TX Message Buffer 0
- 0x01: TX Message Buffer 1
- 0x10: TX Message Buffer 2
- 0x11: TX Message Buffer 3

(3) FIFO depth configuration

The depth of each FIFO buffer can be configured by writing to the CFDRFCCa.RFDC[2:0] bits and CFDCFCC.CFDC[2:0] bits in the RX FIFO Configuration/Control Registers and the Common FIFO Configuration/Control Registers. The 6 available options for depth configuration are:

- 0x000: 0 Message (FIFO buffer cannot be enabled)
- 0x001: 4 Messages
- 0x010: 8 Messages
- 0x011: 16 Messages
- 0x100: 32 Messages
- 0x101: 48 Messages

The RAM allocation for RX message buffers along with FIFO buffers is limited to 16 messages with 64 data bytes (76 bytes including ID and PTR). Configuration of the RX message buffers, along with FIFO buffers, that exceeds this maximum limit should not be done.

CANFD module logic does not check the validity of the configuration.

Note: If the FIFO depth of a common FIFO is 4 messages or more (CFDCFCC.CFDC[2:0] > 000b), then the Common FIFO TX message buffer link is valid when the FIFO is disabled or enabled.

If FIFO depth is 0 messages, then the Common FIFO TX message buffer link is not valid when the FIFO is disabled or enabled.

(4) FIFO payload size configuration

The data size of each FIFO buffer can be configured by writing to the CFDRFCCa.RFPLS[2:0] bits and CFDCFCC.CFPLS[2:0] bits in the RX FIFO Configuration/Control Registers and the Common FIFO Configuration/Control Registers. The eight available options for depth configuration are:

- 000b: 8 bytes
- 001b: 12 bytes
- 010b: 16 bytes
- 011b: 20 bytes
- 100b: 24 bytes
- 101b: 32 bytes
- 110b: 48 bytes
- 111b: 64 bytes

The RAM allocation for RX message buffers along with FIFO buffers is limited to 16 messages with 64 data bytes (76 bytes including ID and PTR). Configuration of the RX message buffers, along with FIFO buffers, that exceeds this maximum limit should not be done.

CANFD module logic does not check the validity of the configuration.

Note: This feature is not available in the classical CAN function.

(5) FIFO interrupt configuration

The Interrupt generation conditions for the FIFO buffers can be configured by writing to the CFDRFCCa.RFIM and CFDCFCC.CFIM bit in the RX FIFO Configuration/Control Registers and the Common FIFO Configuration/Control Registers. The two available options are:

- 0:
  - RX FIFO mode: Interrupt generated when the Common FIFO counter reaches CFDRFCCa.RFIGCV/ CFDCFCC.CFIGCV value
  - TX FIFO mode: Interrupt generated when the Common FIFO transmits the last message successfully
- 1:
  - RX FIFO mode: Interrupt generated at the end of storage of every received message
  - TX FIFO mode: Interrupt generated for every successfully transmitted message

If the Interrupt Mode bit is 0 for a RX FIFO, then interrupt is generated based on the configuration of the CFDRFCCa.RFIGCV[2:0] bits.

Similarly, if the Interrupt Mode bit is 0 for a Common FIFO configured in RX mode, then interrupt is generated based on the configuration of CFDCFCC.CFIGCV[2:0] bits.

The eight available options for configuring the FIFO counter value for generation of an interrupt are:

- 000b: Interrupt generated when FIFO is 1/8th Full
- 001b: Interrupt generated when FIFO is 1/4th Full
- 010b: Interrupt generated when FIFO is 3/8th Full
- 011b: Interrupt generated when FIFO is 1/2 Full
- 100b: Interrupt generated when FIFO is 5/8th Full
- 101b: Interrupt generated when FIFO is 3/4th Full

- 110b: Interrupt generated when FIFO is 7/8th Full
- 111b: Interrupt generated when FIFO is Full.

In this case, an interrupt is generated when the message count matches the configured value.

However, there are some limitations on the configuration of the CFDRFCCa.RFIGCV[2:0] and CFDCFCC.CFIGCV[2:0] bits depending on the FDC[2:0] bits (FIFO Depth Configuration), see Table 31.23.

Table 31.23 FIFO interrupt generation counter and FIFO depth configuration

RFDC[2:0] (CFDC[2:0])	RFIGCV[2:0] (CFIGCV[2:0])							
	111b	110b	101b	100b	011b	010b	001b	000b
000b	Don't care (FIFO cannot be enabled)							
001b	Allowed	Not allowed	Allowed	Not allowed	Allowed	Not allowed	Allowed	Not allowed
010b	Allowed							
011b	Allowed							
100b	Allowed							
101b	Allowed							
110b	Allowed							
111b	Allowed							

31.6.2.2 FIFO Buffers Control

The FIFO interrupt must be enabled by setting any one of the following bits in the RX FIFO Configuration/Control Registers:

- CFDRFCCa.RFIE

In addition, the FIFO interrupt must be enabled by setting any one of the following bits in the Common FIFO Configuration/Control Register:

- CFDCFCC.CFRXIE
- CFDCFCC.CFTXIE

After configuration is complete, each FIFO can be enabled by setting the CFDRFCCa.RFE and CFDCFCC.CFE bits in the RX FIFO Configuration/Control Registers and the Common FIFO Configuration/Control Register to allow transmission and reception of messages.

31.7 Interrupts and DMA

31.7.1 Interrupts

The CANFD module generates several interrupts. The interrupt output, which is connected to the Interrupt Controller Unit (ICU), can be controlled by the corresponding interrupt enable bit.

The status flag is set independent from this enable bit.

The channel transmission interrupt has an additional status flag register. The status bits are set when the corresponding interrupt enables are set.

The status flag register supports the identification of the interrupt source for the channel transmission, as this interrupt is driven by several trigger sources.

The interrupts in the CANFD module can be classified into two groups, global interrupts and channel interrupts:

- Global interrupts:
  The CANFD module can generate 3 global interrupts:
  - Global interrupt for successful reception into the 2 RX FIFO buffers
  - Global error interrupt.
  - Global Interrupt for successful reception into the 16 RX message buffers

- Channel interrupts:
  Channel of the CANFD module can generate 3 channel interrupts:
  1. Channel transmission
     - Transmission completion from channel
     - Transmission abort from channel
     - Transmission from TX Queue for a channel
     - Channel THL interrupt
     - Successful transmission from a Common FIFO in TX mode for a channel.
  2. Channel error interrupt
  3. Successful reception in a Common FIFO in RX mode for a channel.

The interrupts are cleared when the corresponding flag bits are cleared or the Interrupt enable bits are cleared.

Table 31.24 gives an overview of interrupt sources for the different interrupt outputs. The interrupt outputs are active-high.

Table 31.24 Interrupt source overview

Parameter	Interrupt	Name	Interrupt source	Interrupt clearing
Global Interrupts	Successful reception into at least one RX FIFO	CAN_RXF	Interrupt flag of corresponding RX FIFO for which interrupt is enabled	Clear the interrupt flag of corresponding RX FIFO buffer for which interrupt is enabled
	Global Error	CAN_GLERR	Any of the following: • DLC Error flag • Message Lost Status bit • TX History Entry Lost Status bit • CANFD Message Payload overflow flag	Clear all of : • DLC Error flag • Message Lost flags in all of the FIFO Status Registers • TX History List Entry Lost flag • CANFD Message Payload overflow flag
	Successful reception into at least one RXMB	CANn_RXMB (n = 0, 1)	Interrupt flag of corresponding RXMB for which interrupt is enabled	Clear the interrupt flag of corresponding RXMB buffer for which interrupt is enabled
Channel Transmission Interrupts	Channel successful transmission	CANn_TX (n = 0, 1)	Any channel related TXMB Successful flag when interrupt is enabled*1	Clear all channel related TXMB Result status bits for which the interrupt is enabled
	Channel Abort		Any channel related TXMB Abort flag when interrupt is enabled*1	Clear all channel related TXMB Result Status bits for which the interrupt is enabled globally
	Channel transmission from TX Queue		Related channel TX Queue Interrupt flag	Clear related channel TX Queue Interrupt flag
	Channel THL Interrupt		Channel THL Interrupt status flag	Clear the relevant THL Interrupt status flag
	Channel COM FIFO TX Interrupt		Interrupt Flag for Common FIFOs in TX mode belonging to the related channel	Clear the interrupt flags of Common FIFOs in TX mode belonging to the related channel
Channel Error Interrupt	Channel Error	CANn_CHERR (n = 0, 1)	Any channel related error flag in the Channel Error Flag Register for which interrupt is enabled in the Channel Error Interrupt Enable Register	Clear all channel related error flags in the Channel Error Flag Register for which interrupt is enabled in the Channel Error Interrupt Enable Register
Channel COM RX FIFO Interrupt	Channel COM FIFO RX Interrupt	CANn_COMFRX (n = 0, 1)	Interrupt flag for Common FIFOs in RX mode belonging to the related channel	Clear the interrupt flags of Common FIFOs in RX mode belonging to the related channel

Note 1. These interrupts are only set for TX Message Buffers that do not belong to anenabled TX Queue andare not pointing to a common FIFO.
Separate interrupts are provided for common FIFO buffers and TX Queue.

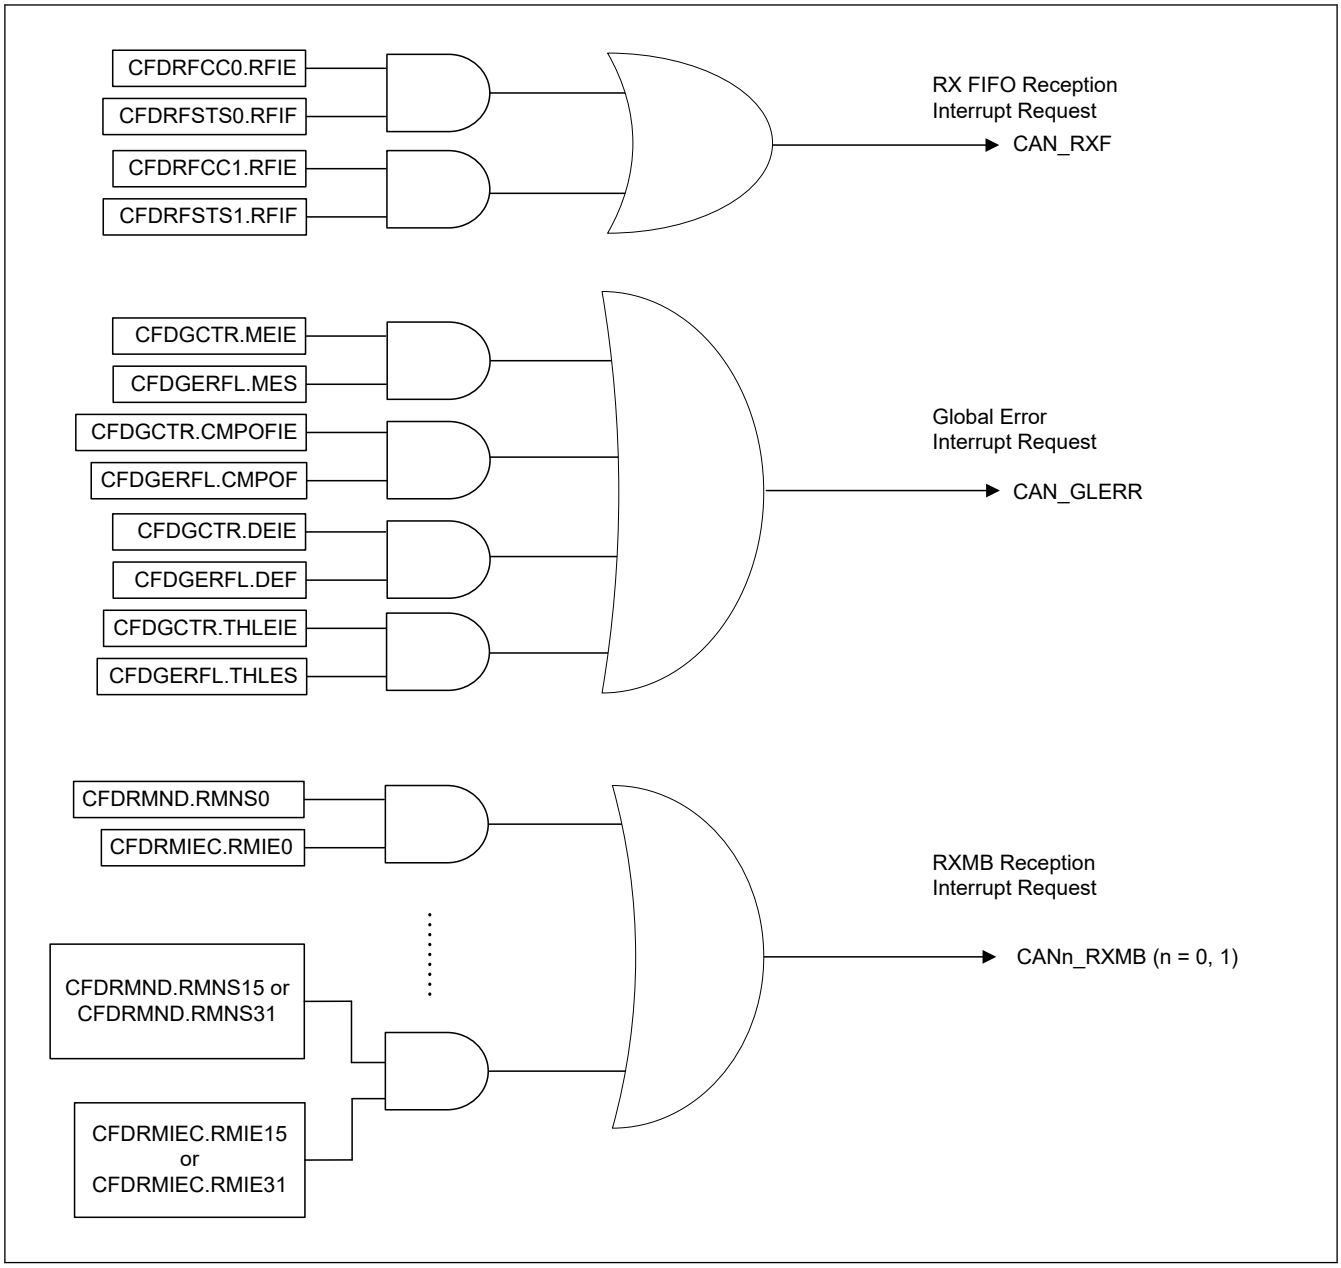

Figure 31.30 Global interrupt block diagram

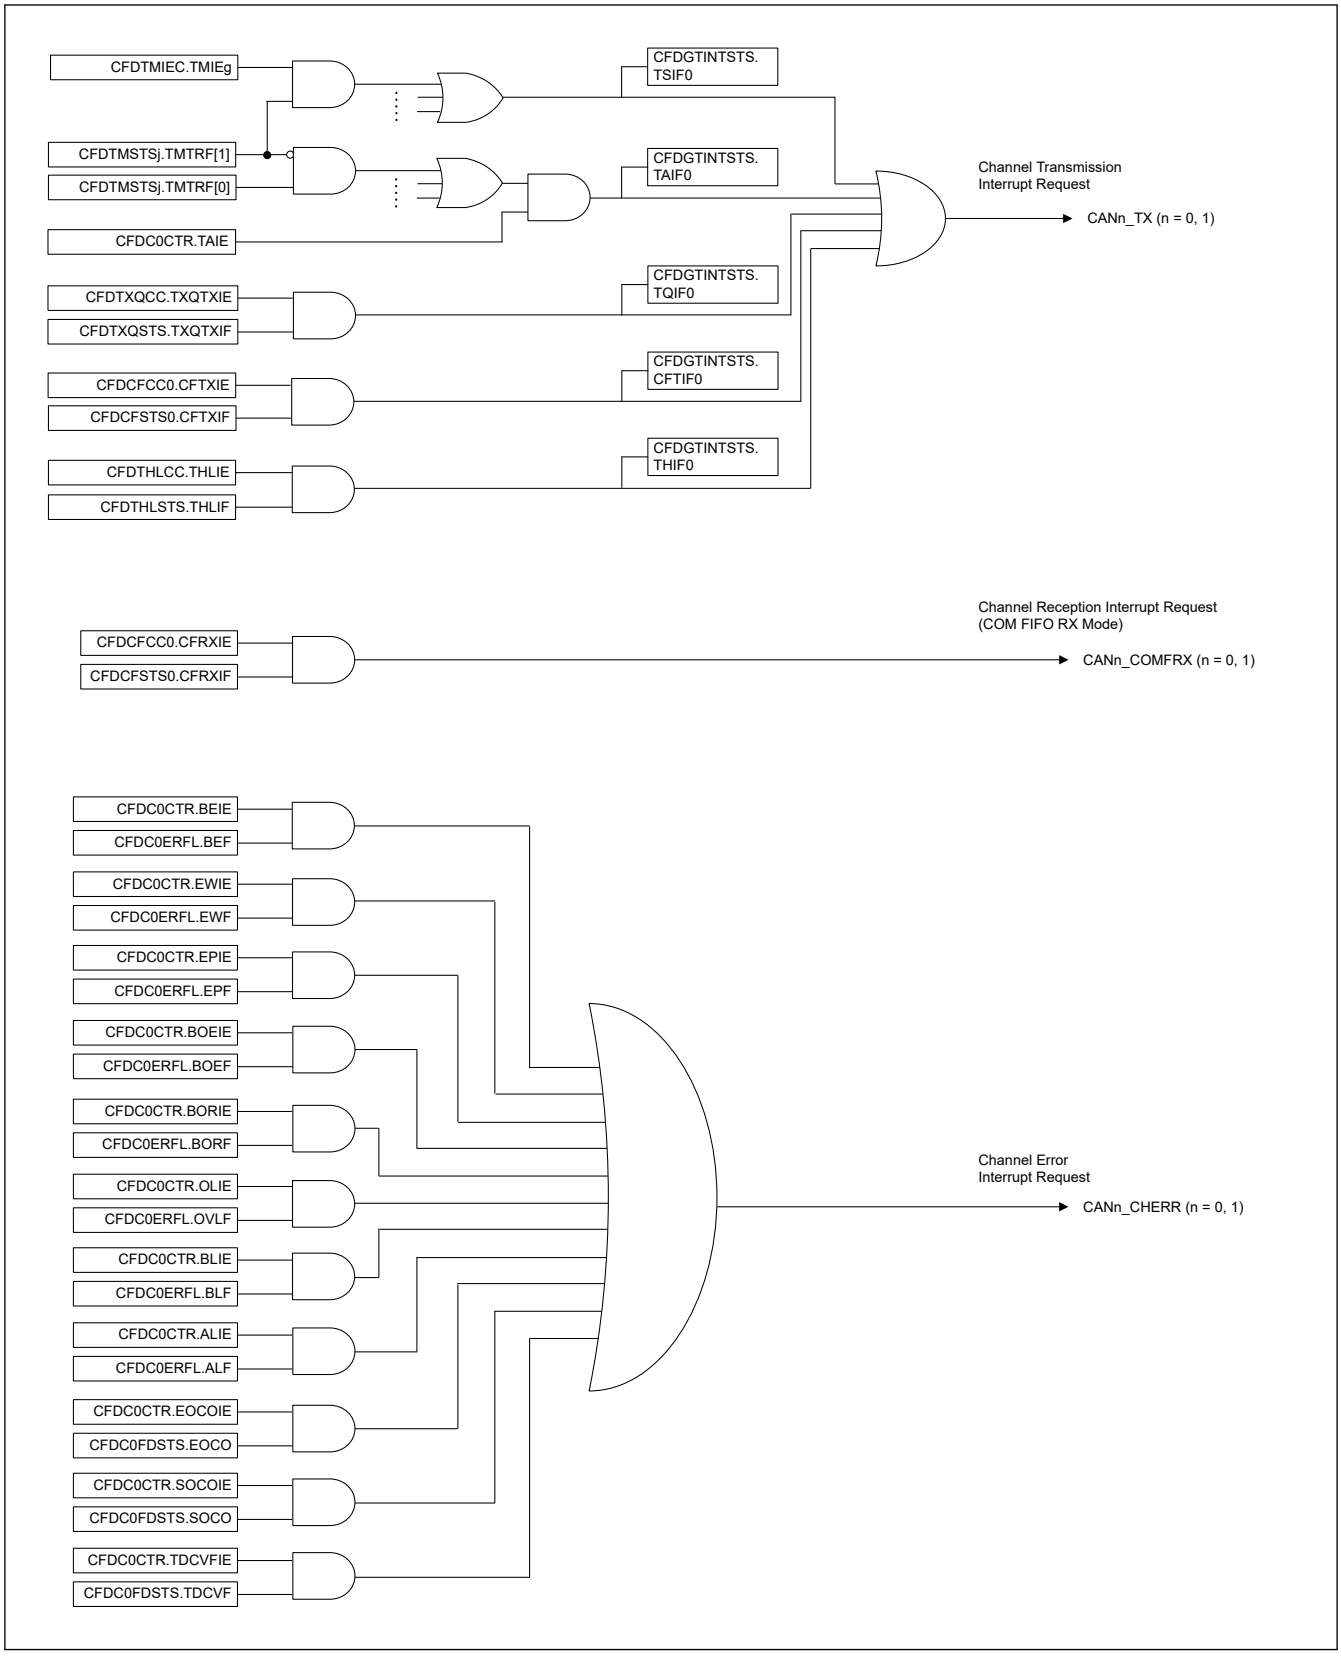

Figure 31.31 Channel interrupt block diagram

31.7.2 DMA Transfer

The CANFD module has message buffers that can be associated with a DMA channel:

- Reception DMA

– 2 RX FIFO message buffers
– Common FIFO Message Buffer

Figure 31.32 shows the potential DMA channels.

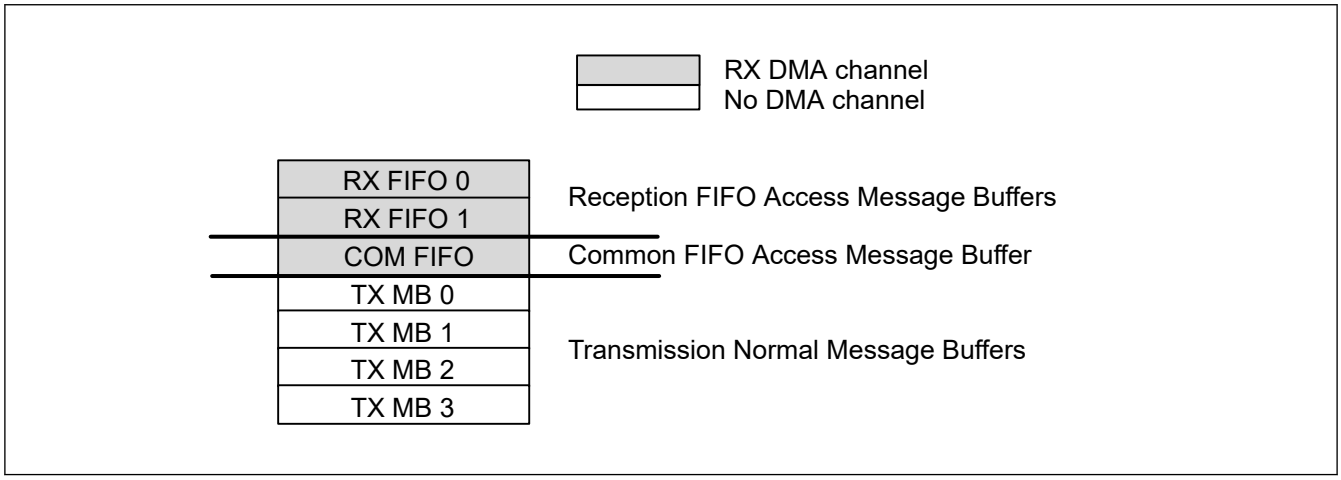

Figure 31.32 Message buffer connectable to a DMA channel

A DMA channel transfer request is generated for each FIFO entry to the DMAC when the related CFDCDTCT.RFDMAE or CFDCDTCT.CFDMAE is set to 1 and the belonging FIFO is not empty.

Reception FIFO Interrupt should be disabled for this particular FIFO (CFDRFCCa.RFIE or CFDCFCC.CFRXIE)

Use the regular start address for the DMA access window address. See Figure 31.33.

Table 31.25 DMA channel access window address

b = Message buffer component index	Message Buffer Component	Register	P	Regular Start Address
b = [0…1]	RFMBCPb[0]	CFDRFIDb	x	0x0520 + b × 0x004C
		CFDRFPTRb	x	0x0524 + b × 0x004C
		CFDRFFDSTSb	x	0x0528 + b × 0x004C
		CFDRFDFbp	[0…15]	0x052C + p × 0x0004 + b × 0x004C
—	CFMBCP0[0]	CFDCFID	x	0x05B8
		CFDCFPTR	x	0x05BC
		CFDCFFDCSTS	x	0x05C0
		CFDCFDFp	[0…15]	0x05C4 + p × 0x0004

DMA FIFO pointer decrement is done automatically by reading the last configured data payload byte (CFDRFCCa.RFPLS or CFDCFCC.CFPLS).

Note: The DMA must read the exact length of the configured data payload size (CFDRFCCa.RFPLS or CFDCFCC.CFPLS).

Note: This feature is not available for classical CAN function because CFDRFCCa.RFPLS and CFDCFCC.CFPLS are not in classical CAN.

Do not write to the FIFO control registers when DMA is enabled. The DMA enable of the particular DMA FIFO (CFDCDTCT.RFDMAE or CFDCDTCT.CFDMAE) can be set at any time. Figure 31.33 shows a configuration flow for an initial setup.

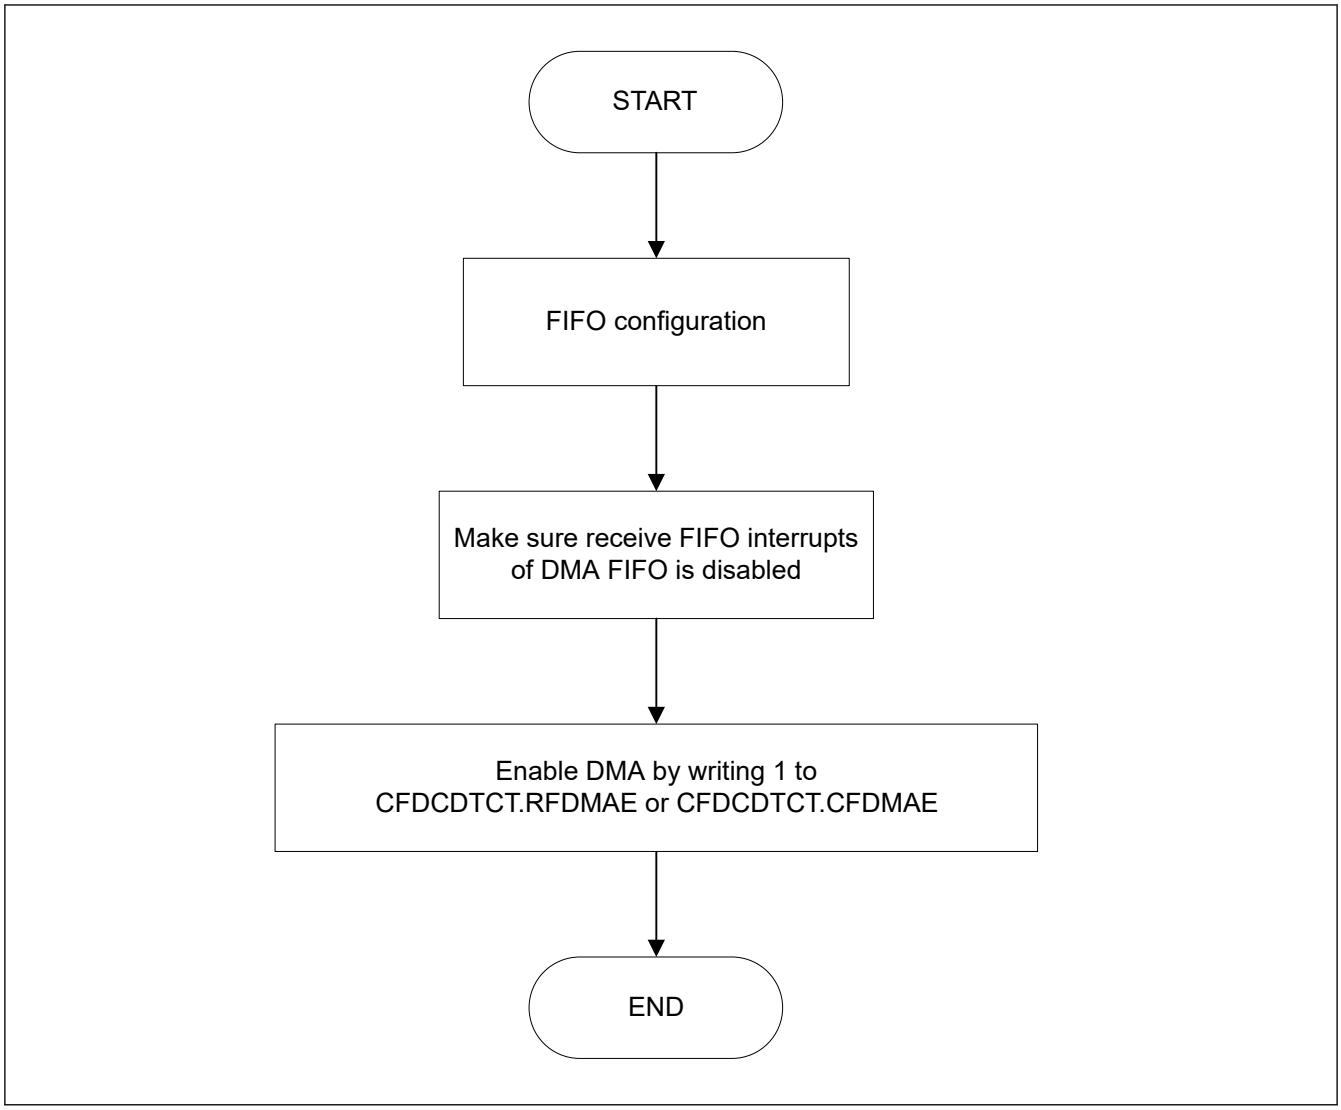

Figure 31.33 DMA enable flow

To disable a DMA transfer request, you must disable the particular DMA enable bit (CFDCDTCT.RFDMAE or CFDCDTCT.CFDMAE). If the disable is made during an ongoing transfer, then the transfer must be completed first before further action can be taken. The transfer status can be identified by the CFDCDTSTS.RFDMASTS or CFDCDTSTS.CFDMASTS bit. See Figure 31.34 for the DMA disable flow. When the DMA is disabled, consideration should be made for the remaining or new incoming messages to this particular reception FIFO.

When the FIFO is not disabled, reception to the FIFO continues.

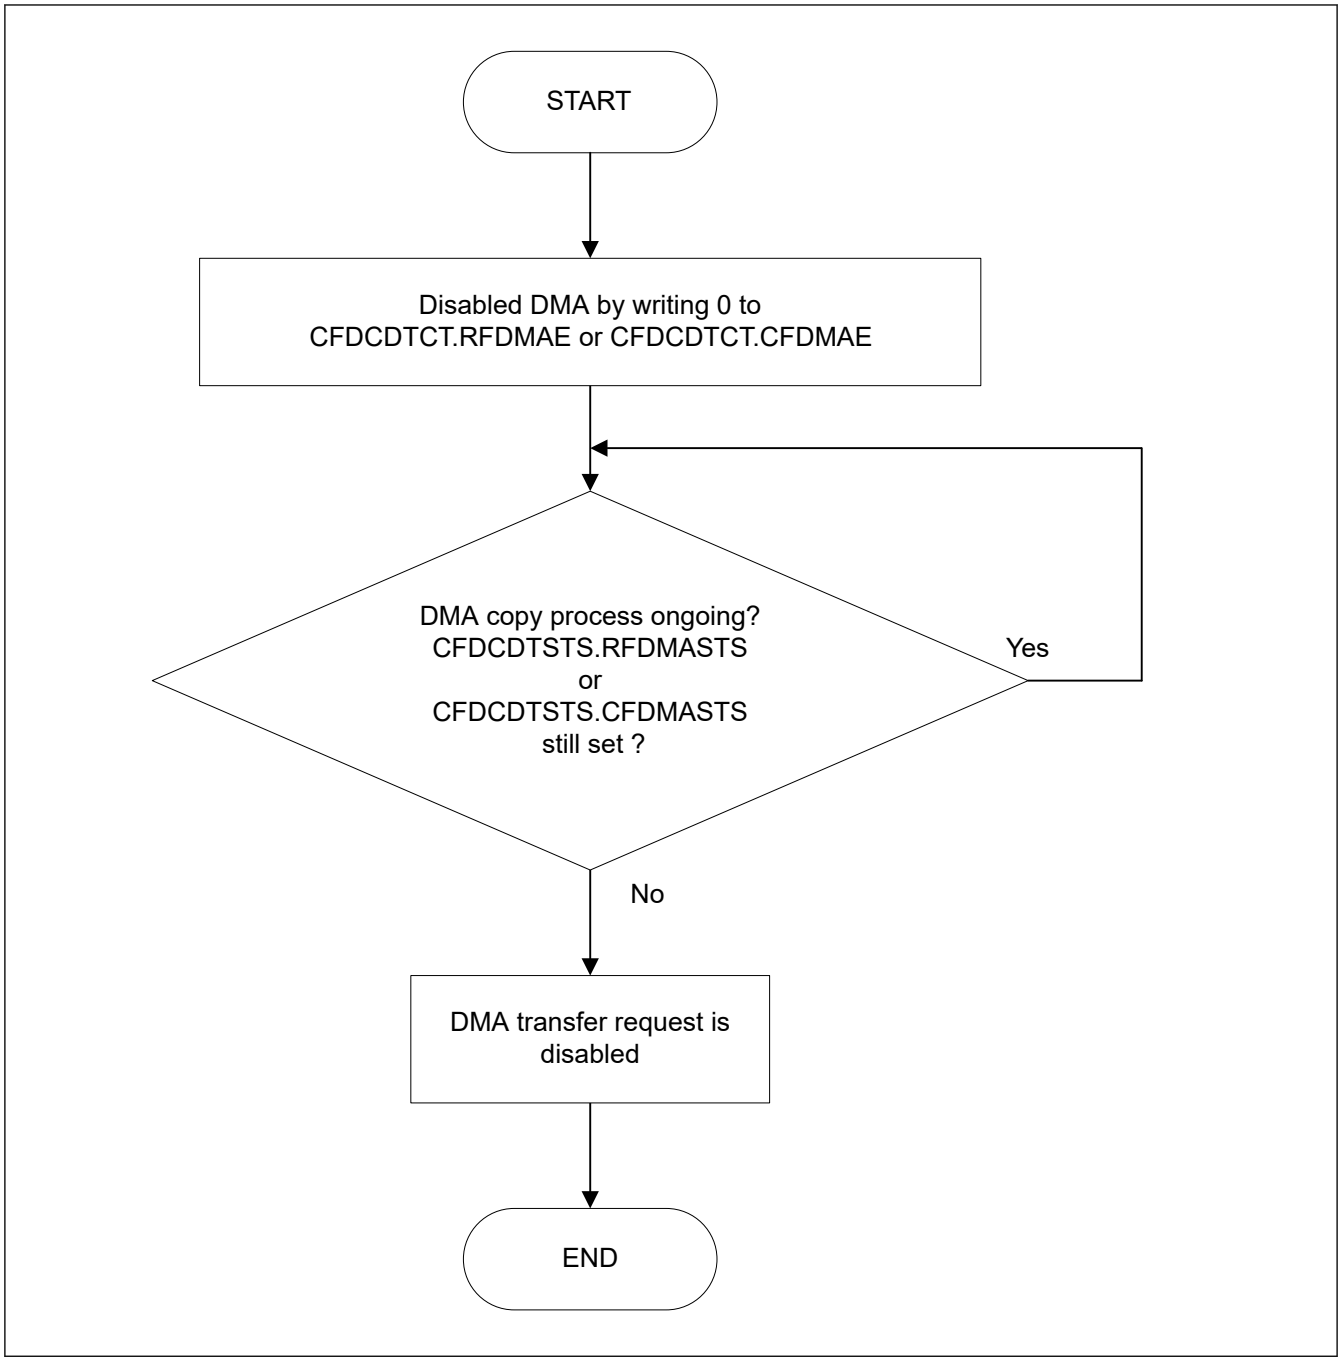

Figure 31.34 DMA disable flow

31.8 Reception and Transmission

31.8.1 Reception

In the CANFD module, CAN messages received on any of the channels are stored in RX message buffers, RX FIFO buffers, or Common FIFO buffers configured in RX mode depending on the Acceptance Filter List entries.

- Up to 16 RX message buffers can be configured
- 2 RX FIFO buffers available
- 1 Common FIFO Buffer can be configured in RX mode

31.8.1.1 Message Storage in RX Message Buffers

When a message is successfully received and stored in a RX message buffer, the corresponding New Data flag is set in the RX Message Buffer New Data Register.

The CAN message can be read from the corresponding RX message buffer.

If a new message is stored into a RX message buffer before the previous message in this message buffer can be read, then the original message is overwritten. There is no mechanism for preventing a new message from overwriting the current message in the RX message buffer. If such a loss of messages is not acceptable, then RX FIFO should be used for storing related messages.

Note: Users should do the same processing as the existing software flow also when using interrupt. (see Figure 31.36)

Note: Unused data bytes are filled with 0x00 depending on the DLC value.

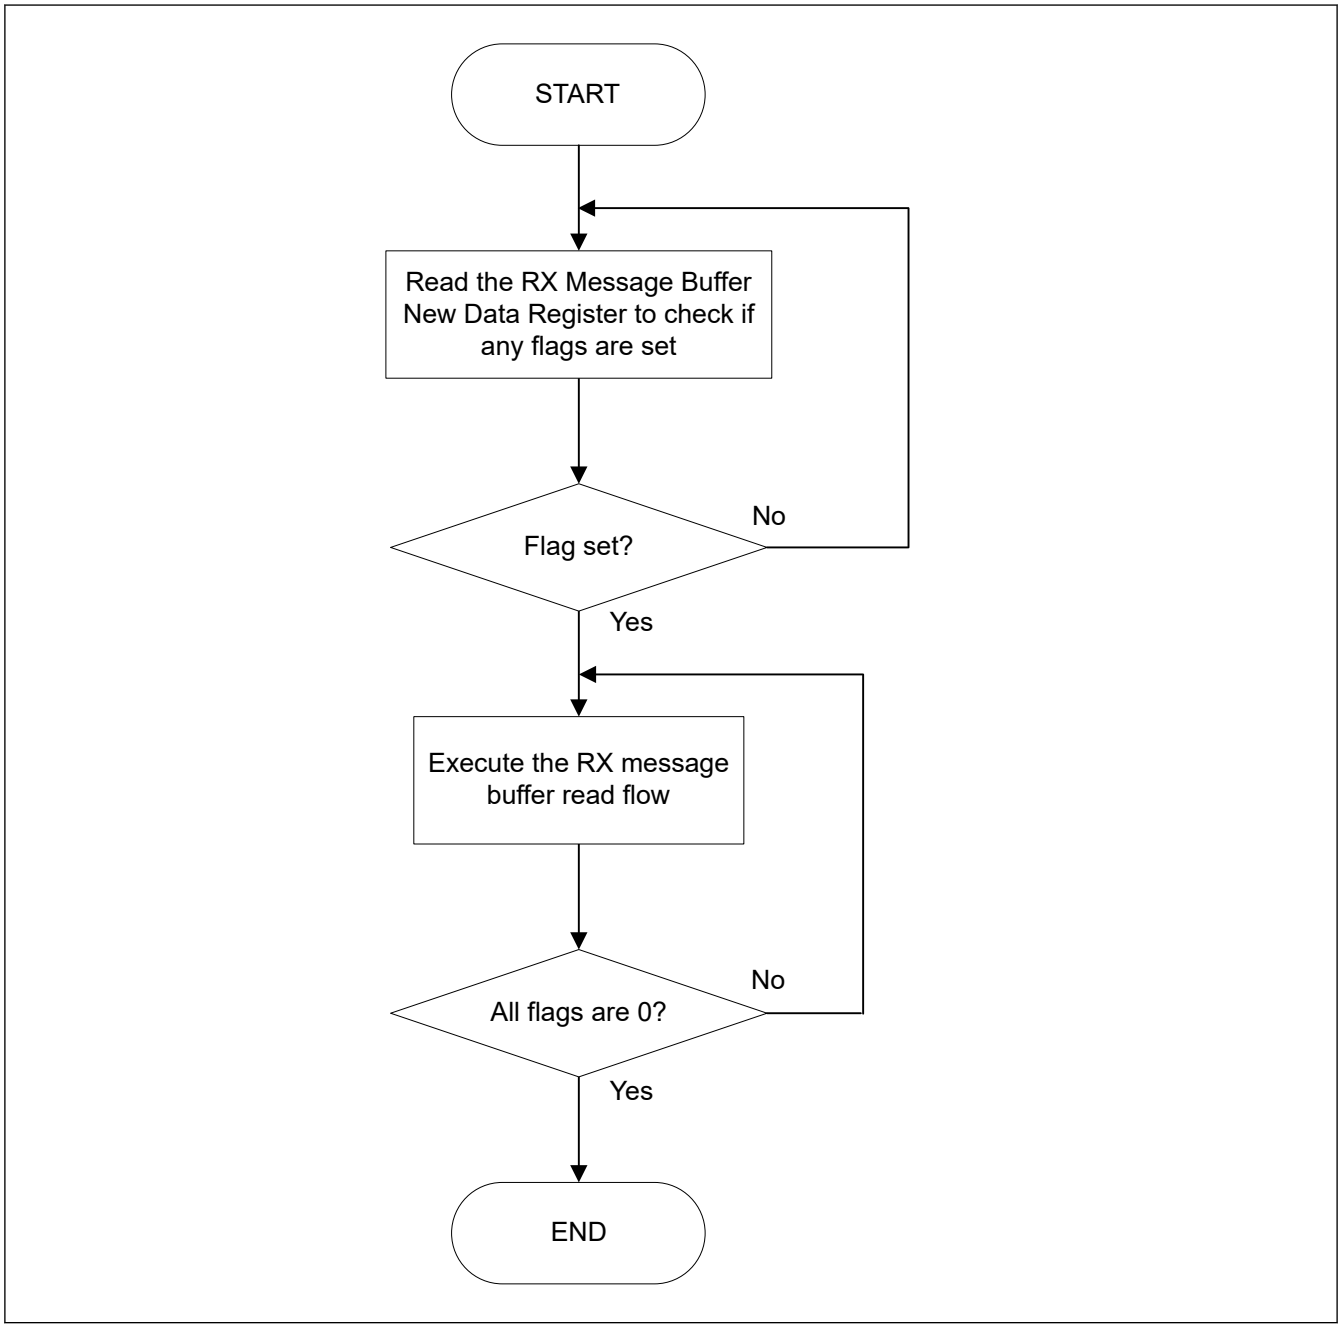

Figure 31.35 Access flow of RX message buffer (Polling)

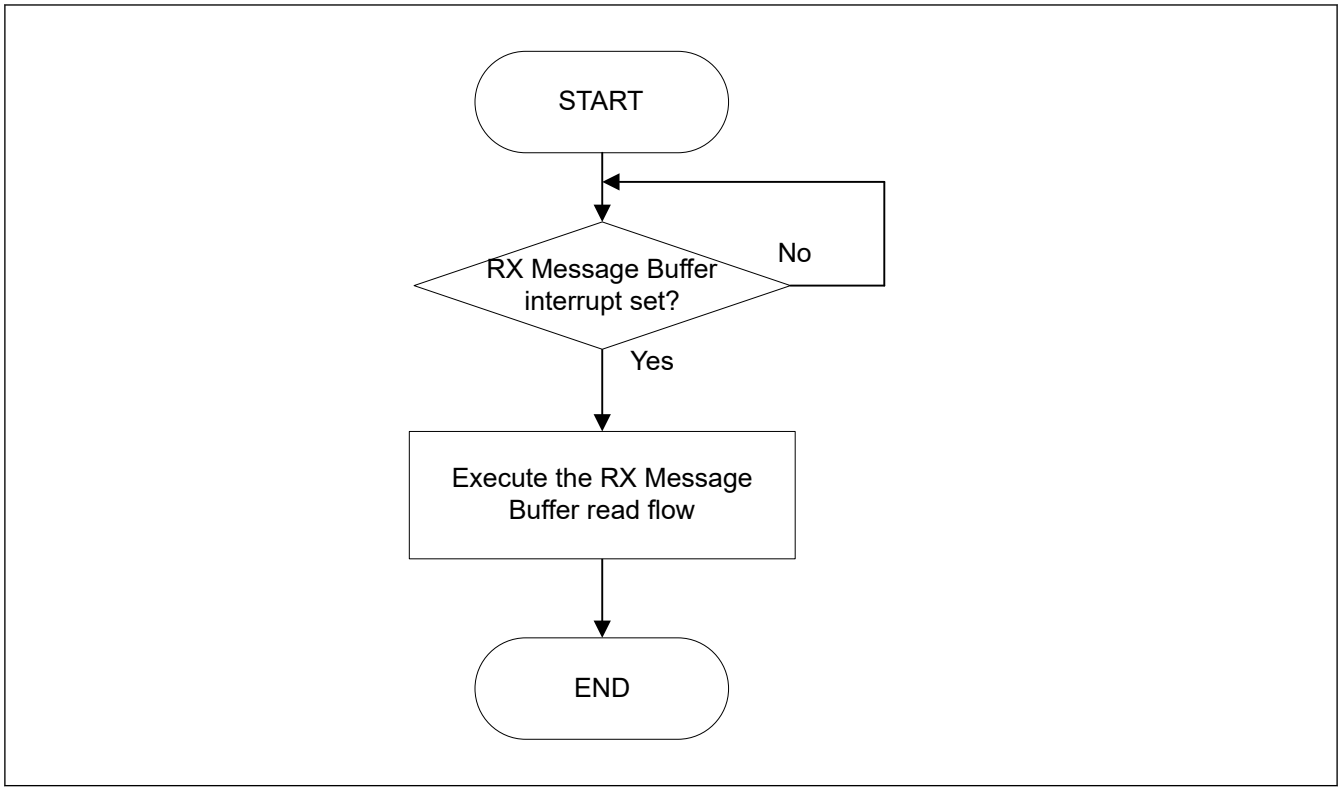

Figure 31.36 RX Message Buffer Message Access Flow (interrupt)

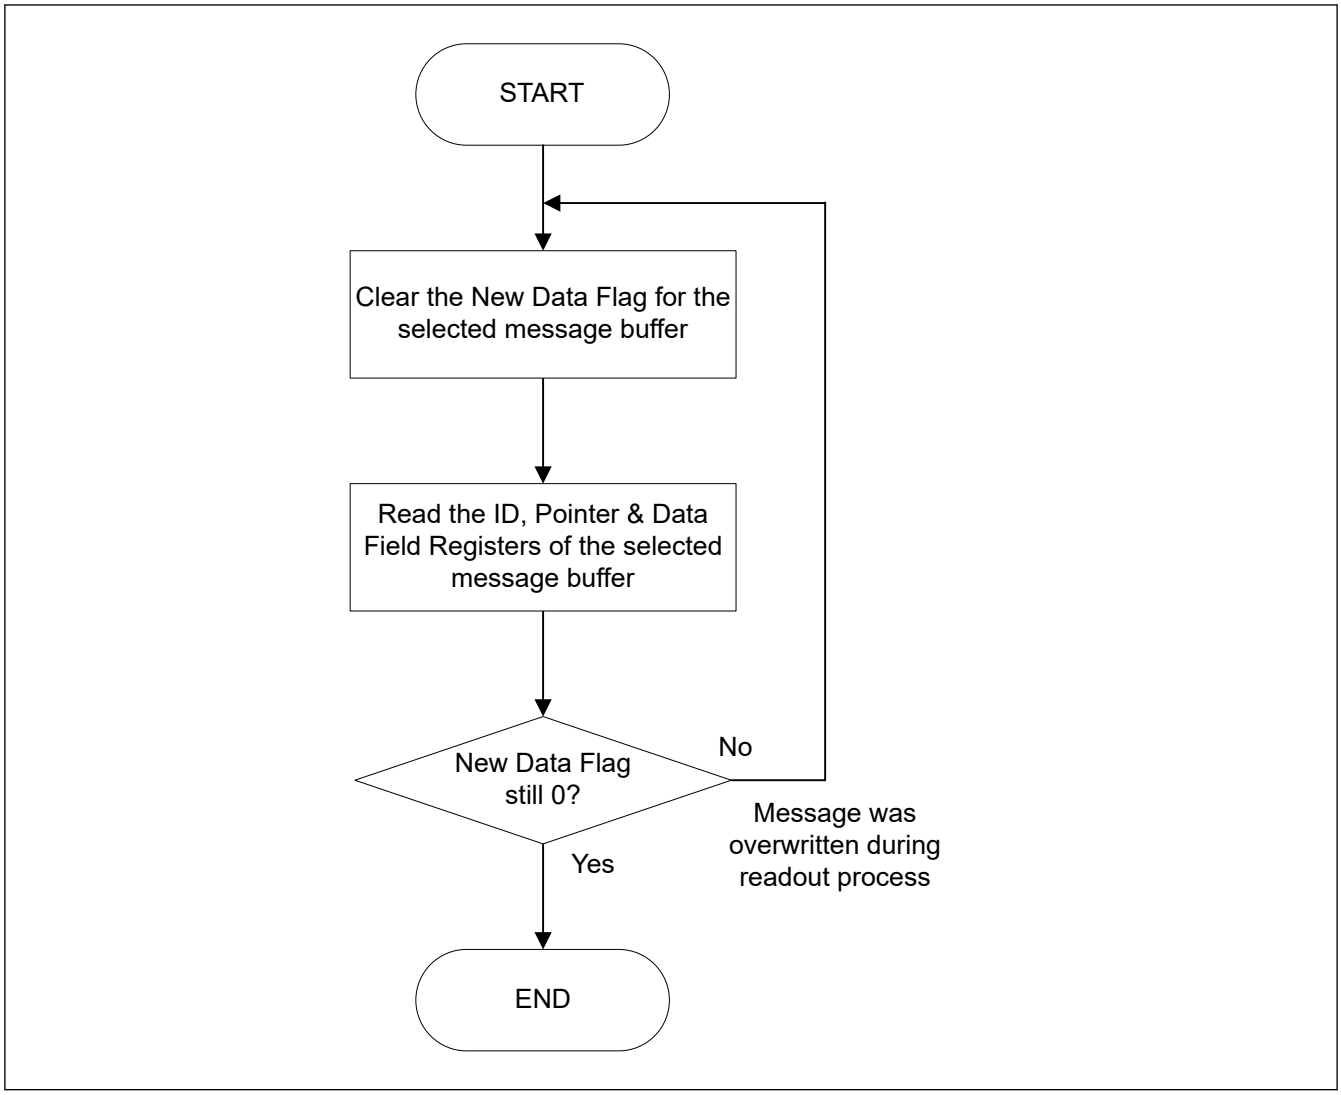

Figure 31.37 Read flow of RX message buffer

31.8.1.2 Message Storage in FIFO Buffers

The AFL entries for routing the received messages to RX FIFO buffers or Common FIFO buffer configured in RX mode should be configured based on system requirements.

The CFDGAFLP1r.GAFLFDP[8,1:0] field in the matching AFL entry selects the FIFO buffers to which the related reception message is stored.

When the received message is stored in one or more RX FIFO buffers or Common FIFO buffer configured in RX mode, the message counter value is incremented in the corresponding RX FIFO Status Registers or Common FIFO Status Register.

Depending on the configuration of the FIFO buffers, an interrupt might also be generated.

The message can be read from the corresponding FIFO Access registers.

Note: Because many messages can be stored in the FIFO buffers, reading more than one message may be required to read the latest message stored in a FIFO buffer.

If the message count value matches the FIFO depth, the FIFO Full flag is set.

When the value 0xFF is written to the corresponding FIFO Pointer Control Register, the message count is decremented by 1.

Only write 0xFF to the FIFO Pointer Control register after reading the complete message from the FIFO Access registers of the corresponding FIFO.

When all the messages stored in the FIFO are read, the FIFO Empty flag is set.

If a new message is stored into the FIFO when the FIFO message count matches the FIFO depth (FIFO full condition), the FIFO Message Lost flag is set and the new message is lost (no overwrite of already stored messages takes place).

An appropriate value can be configured as warning level to generate an interrupt before the FIFO full condition occurs to avoid loss of a message due to an overrun condition.

Note: The message lost can be set only in RX mode by CAN, and the flag is not set when the CPU is overloading the FIFO buffers.

The RX FIFO buffers and the Common FIFO buffers configured in RX mode can be disabled at any time by clearing the CFDRFCCa.RFE or CFDCFCC.CFE bit in the RX FIFO Configuration/Control Registers and the Common FIFO Configuration/Control Registers.

When the CFDRFCCa.RFE or CFDCFCC.CFE bit is cleared, the message read and write pointers of the FIFO are cleared and are no longer active. Therefore, all messages in the FIFO buffers are lost and no further messages can be stored into the FIFO.

When the RX FIFO buffers or Common FIFO buffer configured in RX mode is assigned as a DMA channel, software should not access the FIFO Access Register of this FIFO buffer or write 0xFF to the FIFO Pointer Control Register (CFDCFPCTR.CFPC or CFDRFPCTRa.RFPC). This can lead to unintended FIFO message decrement. The DMA channel controls the FIFO decrement automatically.

Note: If the interrupt flag is set for a FIFO buffer and then the FIFO is disabled, the interrupt flag is not cleared automatically. The interrupt flag should be cleared before disabling the FIFO.

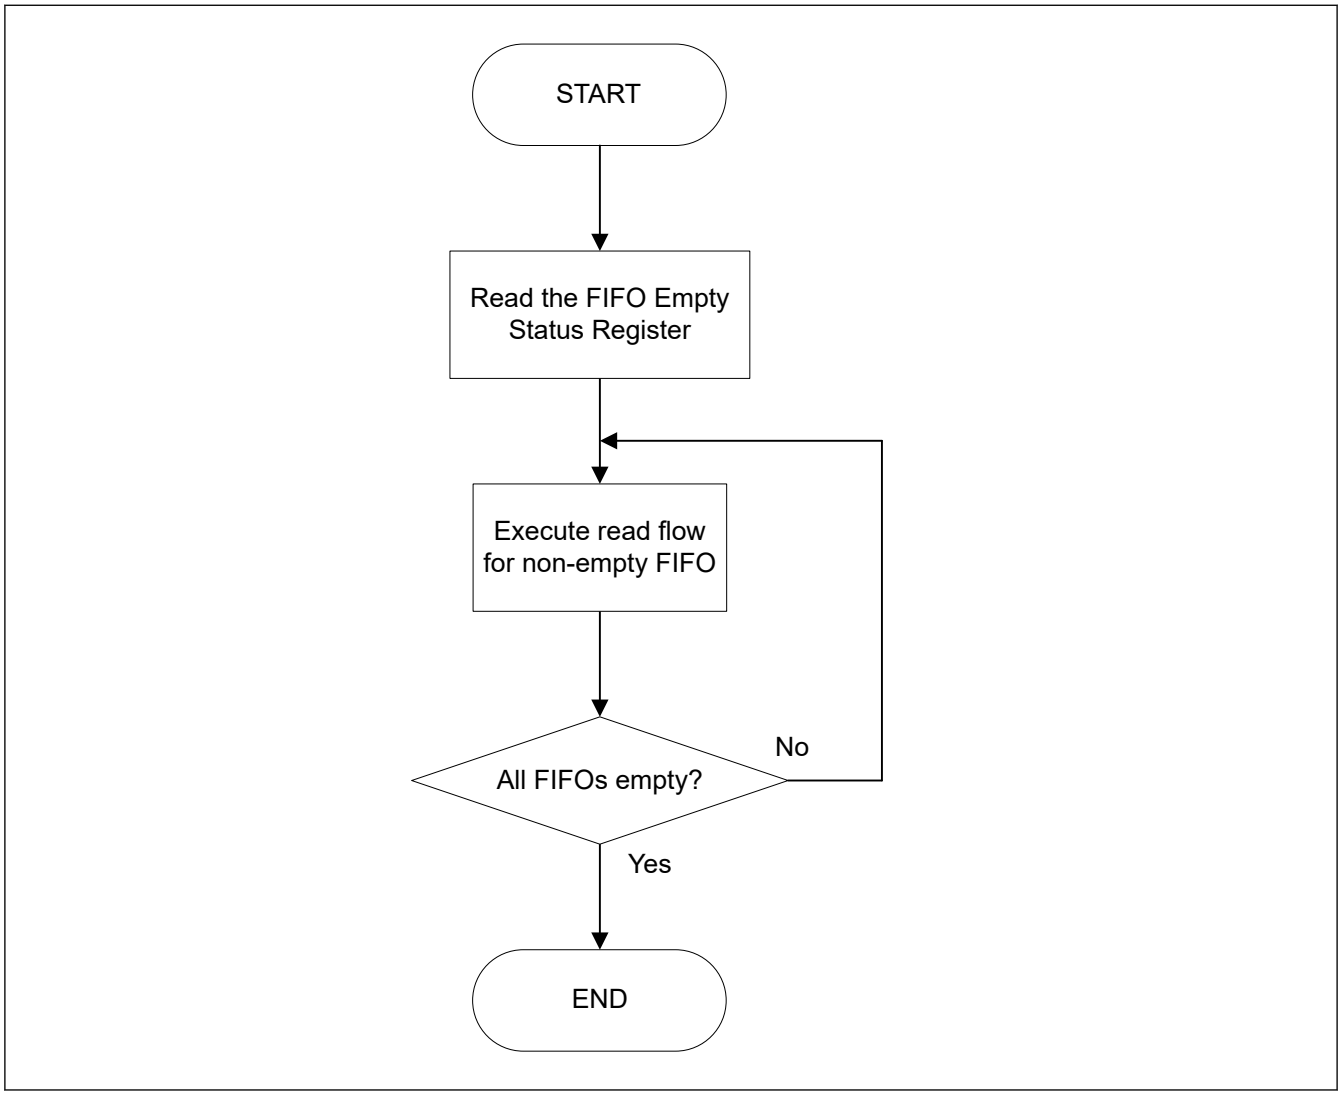

Figure 31.38 Access flow of FIFO buffer message (example for polling case)

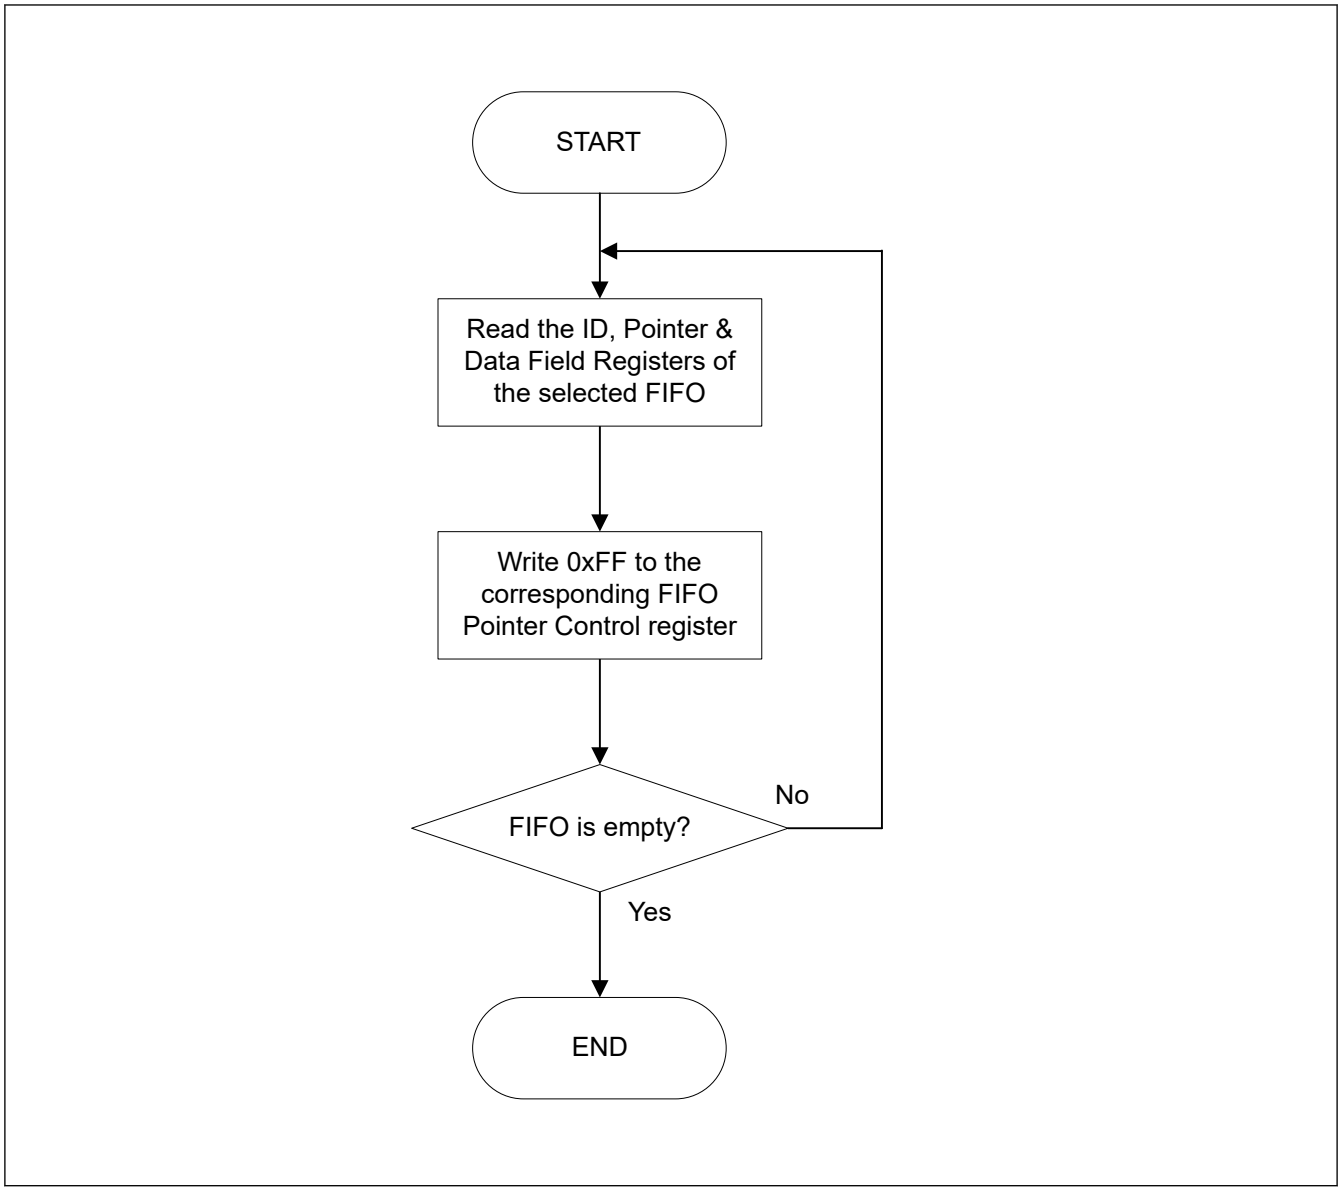

Figure 31.39 Read flow of RX FIFO buffer message (example for polling case)

Note: When the next frame is received before clearing the completion interrupt flag of reception, the completion interrupt of reception is not set again.

Even when an interruption flag is cleared after the completion processing of reception, the already received interrupt flag is not set.

It is necessary to perform the completion processing of reception even before the next completion of frame reception, and to clear an interruption flag.

When processing does not meet the condition, after checking that receiving data is empty, interrupt flag is cleared and it checks that receiving data is empty again.

31.8.1.3 Timestamp

The timestamp counter is a free-running counter that can be used to check reception time of an incoming message or transmission time of successful transmitted messages. The Timestamp counter value is captured based on the CFDGFDCFG.TSCCFG[1:0] configuration (at the sample point of start of frame, point in time when the frame is valid, or for CANFD frames also at the sample point of the RES bit). For reception, it is stored together with the message ID and data into the target RX message buffer or RX FIFO.

For transmit message, the timestamp counter value is stored as part of the TX History List entry.

The counter can be clocked with the peripheral clock or with the CAN channel bit timing clock. The counter source clock can be configured with the CFDGCFG.TSSS bit of the Global Configuration Register. If this bit is 0, the peripheral clock is used. If the bit is 1, the selected CAN channel bit time clock is used.

The channel selection is performed with the CFDGCFG.TSBTCS bit of the Global Configuration Register.

Care must be taken when using selected CAN channel bit time clock as the clock source. When entering Channel Halt mode or Channel Reset node, for this channel, the timestamp counter is stopped. For other CAN channels, the timestamp counter value is not updated.

If peripheral clock is selected as the timestamp counter clock source, Channel modes do not affect the timestamp counter function.

The source clock for the timestamp counter can be divided by a factor defined by the CFDGCFG.TSP bits (timestamp prescaler) in the Global Configuration Register.

The timestamp counter can be reset to 0x0000 with the CFDGCTR.TSRST bit (timestamp reset).

31.8.2 Transmission

There are several possible transmission configurations:

- Normal transmission
- FIFO transmission
- TX Queue transmission
  A fixed number of transmission message buffers (4 TX message buffers) are dedicated. These message buffers are only used for transmission and cannot be configured for reception.
  Additionally transmission from TX Queue or Common FIFO in TX mode can be configured in the following way (see Figure 31.40):
  – TX Queue: Up to four transmission message buffers can be grouped to form a TX Queue with a common access window.
    Upper transmission message buffers are used to form the TXQ.
    TXQ has an access window.
    • TXQ is transmission Message Buffer 0.
- Common FIFO (TX mode): Common FIFO in TX mode is linked to a dedicated channel.
  Channel has a fixed number of one Common FIFO assigned to it. Within the channel, a Common FIFO configured in TX mode, can be freely linked (assigned) between 0 and 3 transmission message buffers (only one FIFO to one transmission message buffer).
  The Common FIFO buffer then replaces the transmission message buffer linked to it.
  Transmission Control and Status registers of these transmission message buffers should not be used.

See Figure 31.28 for information about Common FIFO buffer assignment to related channel.

Note: Common FIFO buffer should not be linked to TX message buffers that are already part of a TX Queue.

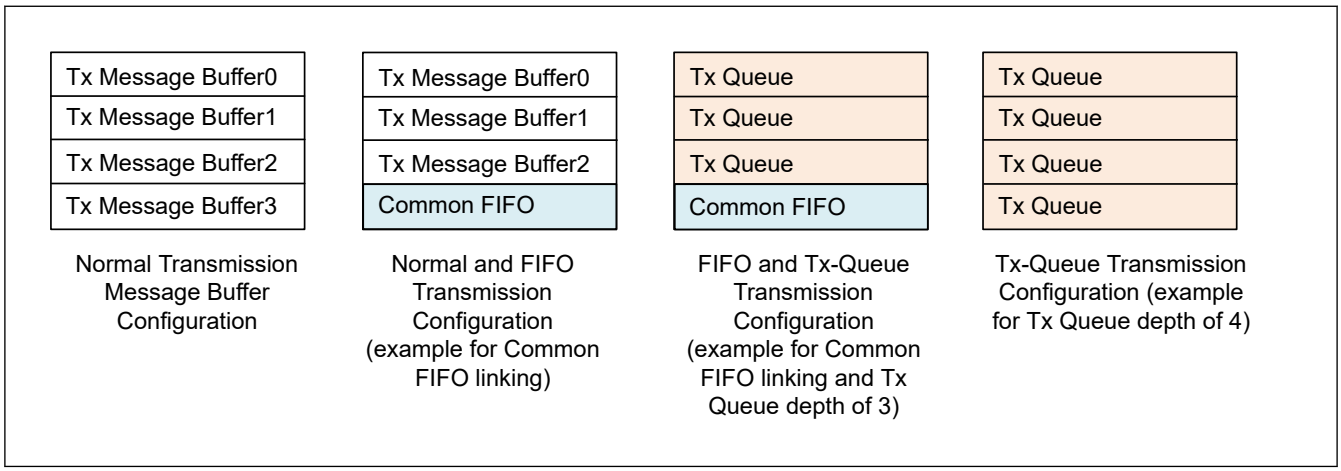

Figure 31.40 Configuration of channel transmission message buffer

31.8.2.1 Transmission Priority

If two or more transmission message buffers of a channel are configured for transmission, then the transmission priority in the CANFD module can be selected from the following two modes:

- CAN ID priority
- Message buffer number priority.

The transmission priority mode is common for all message buffers. It can be configured with the CFDGCFG.TPRI bit in the Global Configuration Register.

For message buffer number priority transmission, the smallest message buffer number with transmission request has the highest priority for transmission. This also includes the TX message buffers linked to the Common FIFO buffer configured in TX mode.

However, message buffer number priority should not be used if TX Queue is enabled.

For CAN ID priority transmission, ID priority complies with the CAN bus arbitration rule (as specified in ISO 11898-1 specification). All TX message buffers can enter the ID priority comparison for message buffers configured for transmission. This also includes the TX message buffers linked to the Common FIFO buffer configured in TX mode and includes the TX Queue message buffers.

If the ID of two or more message buffers is the same, then the smaller message buffer number has higher priority for transmission.

Note: For Common FIFO buffer configured in TX mode, only the message currently being pointed to by the FIFO read pointer can be included in the transmission arbitration.

If the message is being transmitted from the FIFO, then the next pending message within the same FIFO is considered in the transmission arbitration.

In contrast to this, all transmission message buffers of a TX Queue participate in internal transmission arbitration.

Figure 31.41 shows the transmission configuration flow.

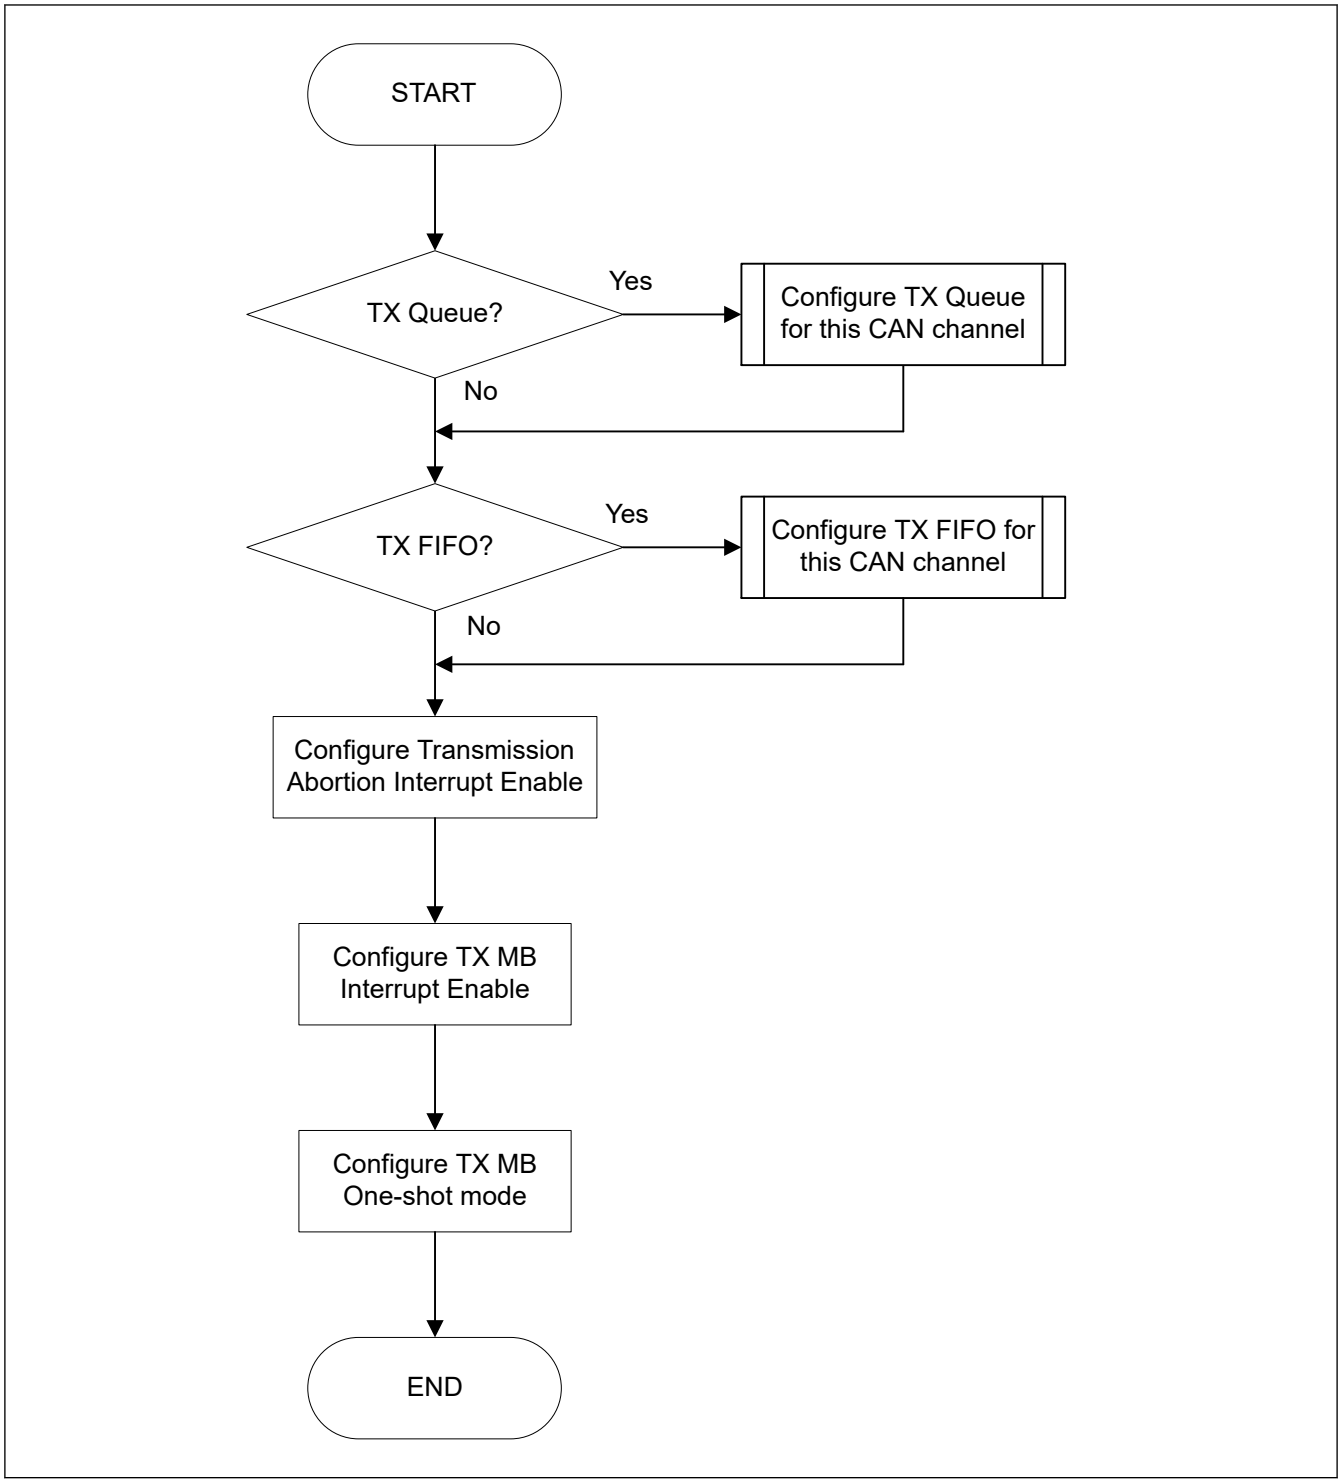

Figure 31.41 Flow for transmission configuration

31.8.2.2 Normal Transmission

Each transmission message buffer has two modes of message transmission:

1. Regular transmission mode
   If the message buffer is placed in regular transmission mode, the data frame or remote frame set in that message buffer can be transmitted.
   Completion of regular transmission can be checked through the related TX Message Buffer Transmission Result flag bits (CFDTMSTSj.TMTRF) in the TX Message Buffer Status Registers. These bits are set to 10b or 11b when the regular transmission is successful.

When arbitration is lost or an error occurs, message transmission is further attempted if no transmission abort request is set for this transmission message buffer.
New internal transmission arbitration for this channel is performed for all message buffers with transmission request.

2. One-shot transmission mode

When the CFDTMCi.TMOM bit of the TX Message Buffer Control Registers is set for a transmission message buffer, the message buffer is placed in One-shot transmission mode and attempts to transmit a message only once.

Completion of One shot transmission can be checked through the related TX Message Buffer Transmission Result Flag bits (CFDTMSTSj.TMTRF) in the TX Message Buffer Status Registers. The CFDTMSTSj.TMTRF bits are set to 10b or 11b when One-shot transmission is successful.

The CFDTMSTSj.TMTRF bits are set to 01b when arbitration is lost or an error occurs during transmission of the related message buffer.

Additional message transmission is not attempted in this case.

The regular transmission request procedure after a configuration is shown in Figure 31.42.

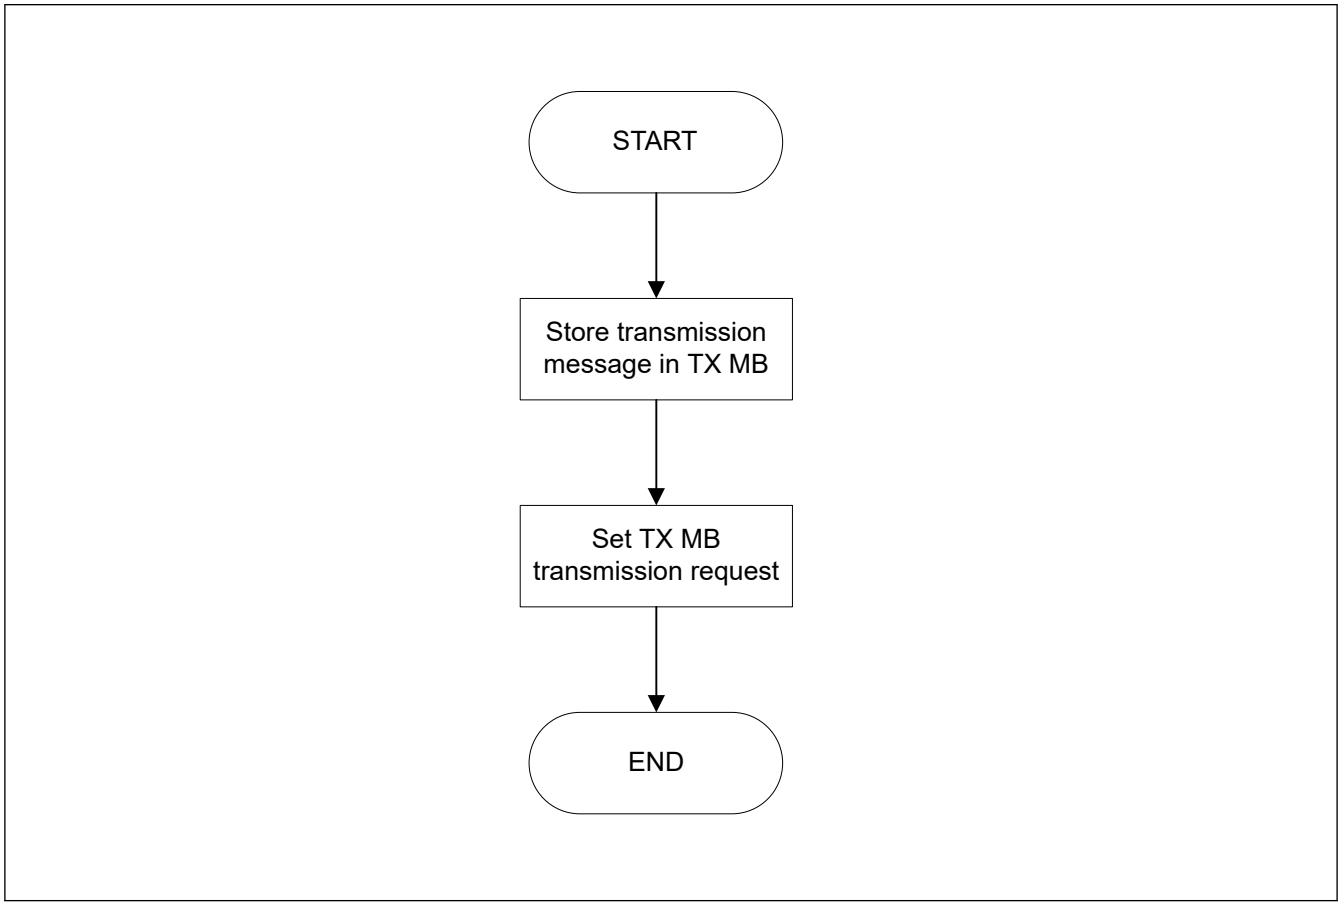

Figure 31.42 Transmission request procedure using normal TX Message Buffer mode

(1) Setting for TX Message Buffer Control Register

Table 31.26 shows configuration of a normal CAN transmission mode.

Table 31.26 Configuration of CAN transmission mode (1 of 2)

Transmission request CFDTMCi.TMTR	Transmission abort request CFDTMCi.TMTAR	One-shot enable CFDTMCi.TMOM	Communication activity
0	0	0	Message buffer disabled
0	0	1	Message buffer disabled

Table 31.26 Configuration of CAN transmission mode (2 of 2)

Transmission request CFDTMCi.TMTR	Transmission abort request CFDTMCi.TMTAR	One-shot enable CFDTMCi.TMOM	Communication activity
1	0	0	Configured as a transmission message buffer for a data frame or a remote frame
1	0	1	Configured as a one-shot transmission message buffer for a data frame or a remote frame
1	1	0	Transmission abort requested
1	1	1	One-shot transmission abort requested

The configuration bits can be configured in the TX Message Buffer Control Registers.

Figure 31.43 shows timings for successful transmission for two message buffers.

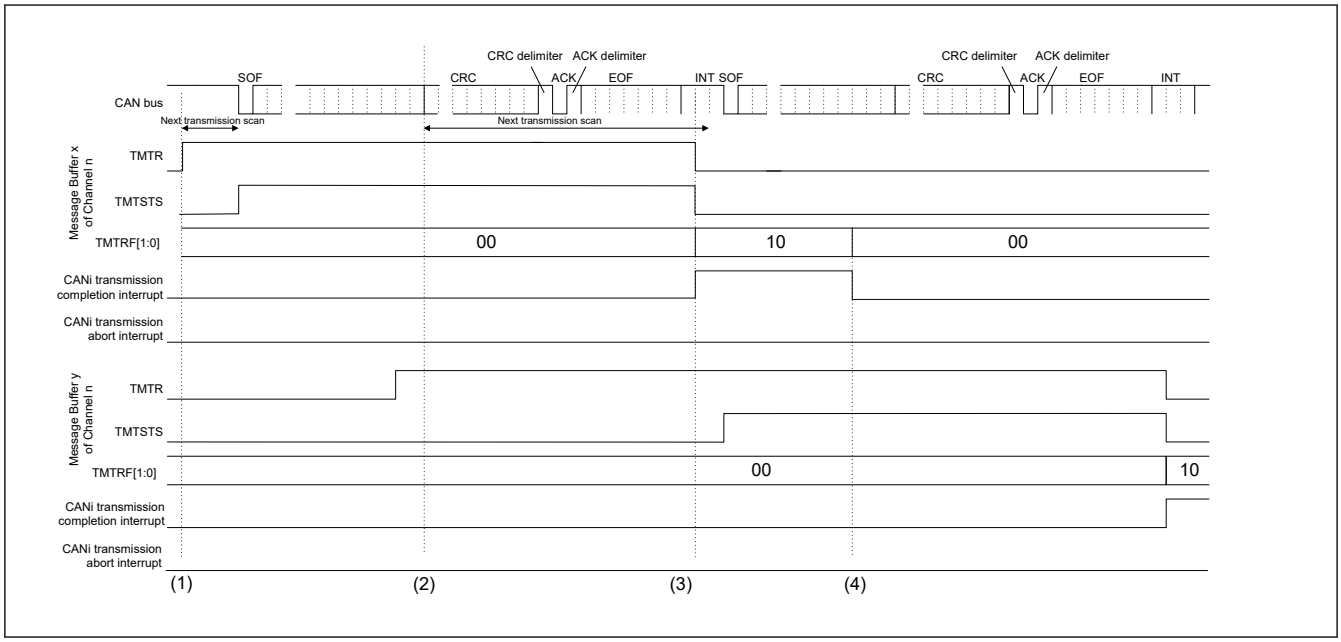

Figure 31.43 Timing of request and flag bits for successful transmission

1. If the CFDTMCi.TMTR bit in the TX Message Buffer Control Registers is set in the bus idle state, the message buffer scanning procedure determines the highest priority message buffer for transmission.
   When the transmission message buffer is determined, the CFDTMSTSj.TMTSTS bit in the related TX Message Buffer Status Registers is set (transmitting/transmitter), and CAN channel starts the transmission *1.
2. At the first bit of CRC, the transmission scanning procedure starts for the next possible transmission when pending transmission requests exist.
3. If the message has been successfully transmitted, the CFDTMSTSj.TMTRF[1:0] bits in the corresponding TX Message Buffer Status Registers are set to 10b and CFDTMSTSj.TMTSTS and the CFDTMCi.TMTR bits are cleared.
   When the TMIE bit in the TX Message Buffer Interrupt Enable Configuration Registers is set (interrupt enabled), the CAN successful transmission interrupt request is generated.
   To clear the related interrupt line, clear the CFDTMSTSj.TMTRF flag bits.
4. Before starting the next transmission, clear the CFDTMSTSj.TMTRF bits. Load the next message in the transmission message buffer and set the CFDTMCi.TMTR bit again.
   CFDTMCi.TMTR bit cannot be set again before CFDTMSTSj.TMTRF[1:0] bits are cleared.

Note 1. If arbitration is lost after the CAN channel starts the transmission, the CFDTMSTSj.TMTSTS bit is cleared.

The transmission scanning procedure is performed again to search for the highest priority transmission message buffer from the beginning of the first CRC bit.

If an error occurs either during transmission or following the loss of arbitration, then during the error frame, the transmission scanning procedure is performed again to search for the highest priority transmission message buffer.

Note: The setting point of CFDTMSTSj.TMTSTS is not always fixed at the start of the SOF. It may be delayed up to the start of the standard ID due to the synchronization logic implemented for the PLL bypass.

Figure 31.44 shows timings for transmission abort for two message buffers.

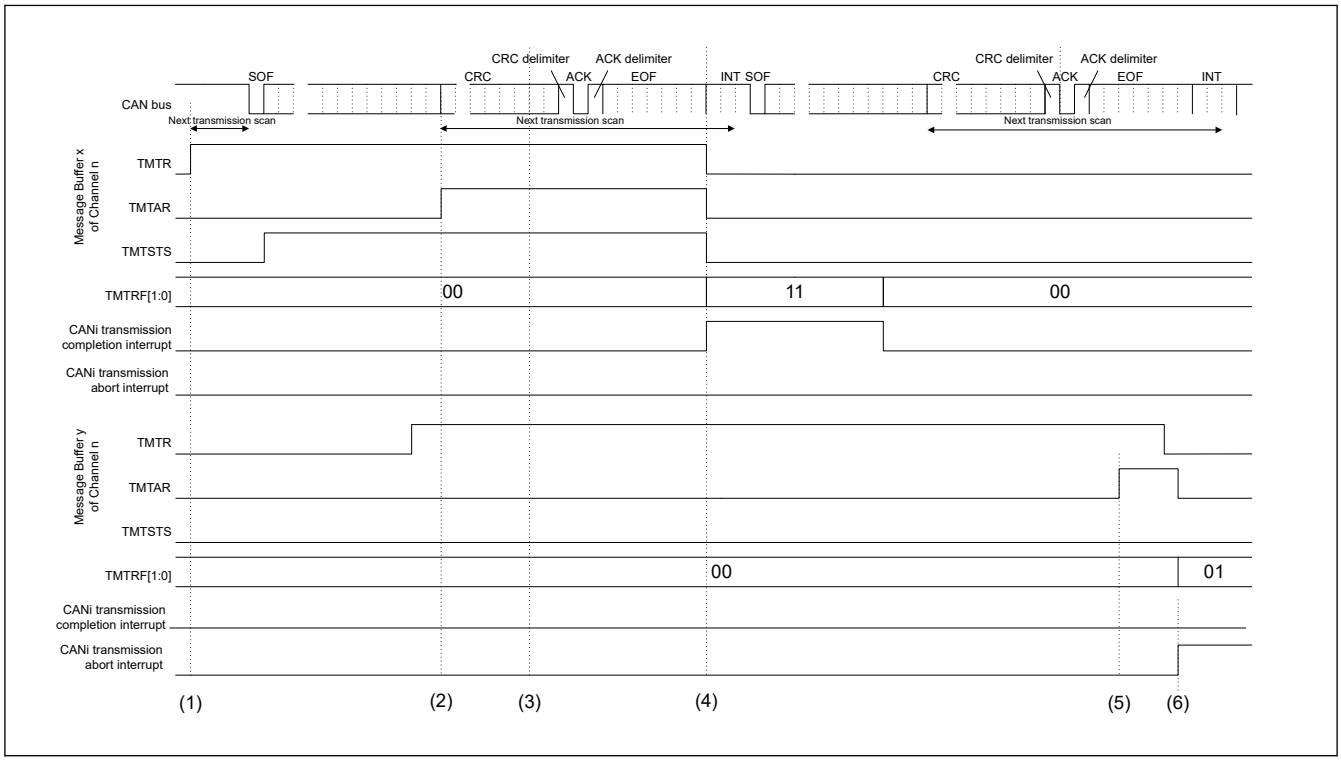

Figure 31.44 Timing of request and flag bits for transmission abort

1. If the CFDTMCi.TMTR bit in the TX Message Buffer Control Registers is set in the bus idle state, the message buffer scanning procedure determines the highest priority message buffer for transmission.
   When the transmission message buffer is determined, the CFDTMSTSj.TMTSTS bit in the TX Message Buffer Status Registers is set (transmitting/transmitter), and CAN channel starts the transmission*1.
2. If the CFDTMCi.TMTAR bit is set when the related message buffer is already selected for transmission or currently transmitting, the message is not aborted, if no error occurs or arbitration is lost.
3. At the first CRC bit, the transmission scanning procedure starts for the next transmission. In this example, timing chart message buffer y is not selected as the next transmission message buffer.
4. If the message has been successfully transmitted, the CFDTMSTSj.TMTRF[1:0] bits in the corresponding TX Message Buffer Status Registers are set to 11b and the CFDTMSTSj.TMTSTS and CFDTMCi.TMTR bits are cleared.
   When the TMIE bit in the TX Message Buffer Interrupt Enable Configuration Registers is set (interrupt enabled), the CAN successful transmission interrupt request is generated.
   To clear the related interrupt line, clear the CFDTMSTSj.TMTRF[1:0] bits.
5. Another CAN node is transmitting on the CAN bus (CFDTMSTSj.TMTSTS is not set). If the CFDTMCi.TMTAR bit is set when the related channel is under transmission scan, the transmission request cannot be cleared.
6. After internal processing time, the transmission is aborted and the CFDTMSTSj.TMTRF[1:0] bits are set to 01b.
   If the message buffer is not transmitting or selected as the next transmission message buffer or under transmit scan, then the abort is immediately accepted and the corresponding CFDTMSTSj.TMTRF[1:0] bits in the TX Message Buffer Status Registers are set to 01b.
   In addition, CFDTMCi.TMTR, and CFDTMCi.TMTAR bits are cleared automatically.
   When the transmission abort interrupt enable TAIE bit of the related Channel Control Register is set then an interrupt is generated for successful transmission abort.
   To clear the related interrupt line the CFDTMSTSj.TMTRF[1:0] bits have to be cleared.

Note 1. If arbitration is lost after the CAN channel starts the transmission, the CFDTMSTSj.TMTSTS bit is cleared.

The transmission scanning procedure is performed again to search for the highest priority transmission message buffer from the beginning of the first CRC bit.

If an error occurs, either during transmission, or following the loss of arbitration, then during the error frame, the transmission scanning procedure is performed again to search for the highest priority transmission message buffer.

31.8.2.3 TX FIFO Transmission

One common FIFO buffer is assigned to CANFD module. The FIFO buffer can be linked to any normal TX message buffer position for this channel with the CFDCFCC.CFTML bits in the Common FIFO Configuration/Control Register if configured in TX mode.

When the transmission scan starts and the FIFO buffer corresponding to this TX message buffer is enabled, the relevant message in the FIFO buffer participates in the transmission scan.

Configuration of a TX message buffer linked to a FIFO buffer configured in TX mode should not be done.

(1) TX FIFO Operation

CAN messages can be written into the TX FIFO by writing to the corresponding FIFO Access registers.

When the value 0xFF is written into the corresponding FIFO Pointer Control Register, the message count of the related FIFO is incremented by 1.

Only write to the FIFO Pointer Control register after writing the complete message to the corresponding FIFO Access registers. If the message count matches the FIFO depth, the FIFO Full flag is set.

The oldest message in the TX FIFO is included in the scan for transmission by the corresponding CANFD module channel logic.

When a message is successfully transmitted from the TX FIFO, the message count value is decremented by 1. When all the messages from the FIFO are transmitted, the FIFO Empty flag is set.

The interrupt generation conditions for the TX FIFO buffer can be configured by configuring the CFDCFCC.CFIM bit in the corresponding Common FIFO Configuration/Control Register.

If CFDCFCC.CFIM bit is 0, then interrupt is generated when the last message is successfully transmitted from the TX FIFO buffer.

If CFDCFCC.CFIM bit is 1, then interrupt is generated for every successfully transmitted message from the TX FIFO buffer.

The Common FIFO can set interrupt when CAN frame transmission is complete.

The Common FIFO buffer configured in TX Mode can be disabled by clearing the CFDCFCC.CFE bit in the Common FIFO Configuration/Control Register. If this bit is cleared to 0, the FIFO Empty flag is set as follows:

- Immediately if the message from the TX FIFO is neither scheduled for the next transmission nor in transmission
- Following the transmission completion, the detection of an error on the CAN bus, loss of arbitration or transition to Channel or Global Halt mode if the transmission from the TX FIFO is already scheduled for transmission or already in transmission.

Note: The Common FIFO buffer is considered as disabled after clearing the CFDCFCC.CFE bit only when the Empty flag is set for the corresponding Common FIFO buffer.

Other possible messages pending from the TX FIFO are lost and their transmission must be requested again. Before CFDCFCC.CFE is set again, ensure that CFDCFSTS.CFEMP bit is set and that there are no pending abort from the TX FIFO.

When the CFDCFCC.CFE bit is cleared, the message read and write pointers of the FIFO are cleared and are no longer active. Therefore, all messages in the FIFO buffers are lost and no further message can be stored into the FIFO.

The FIFO transmission request procedure after configuration is shown in Figure 31.45.

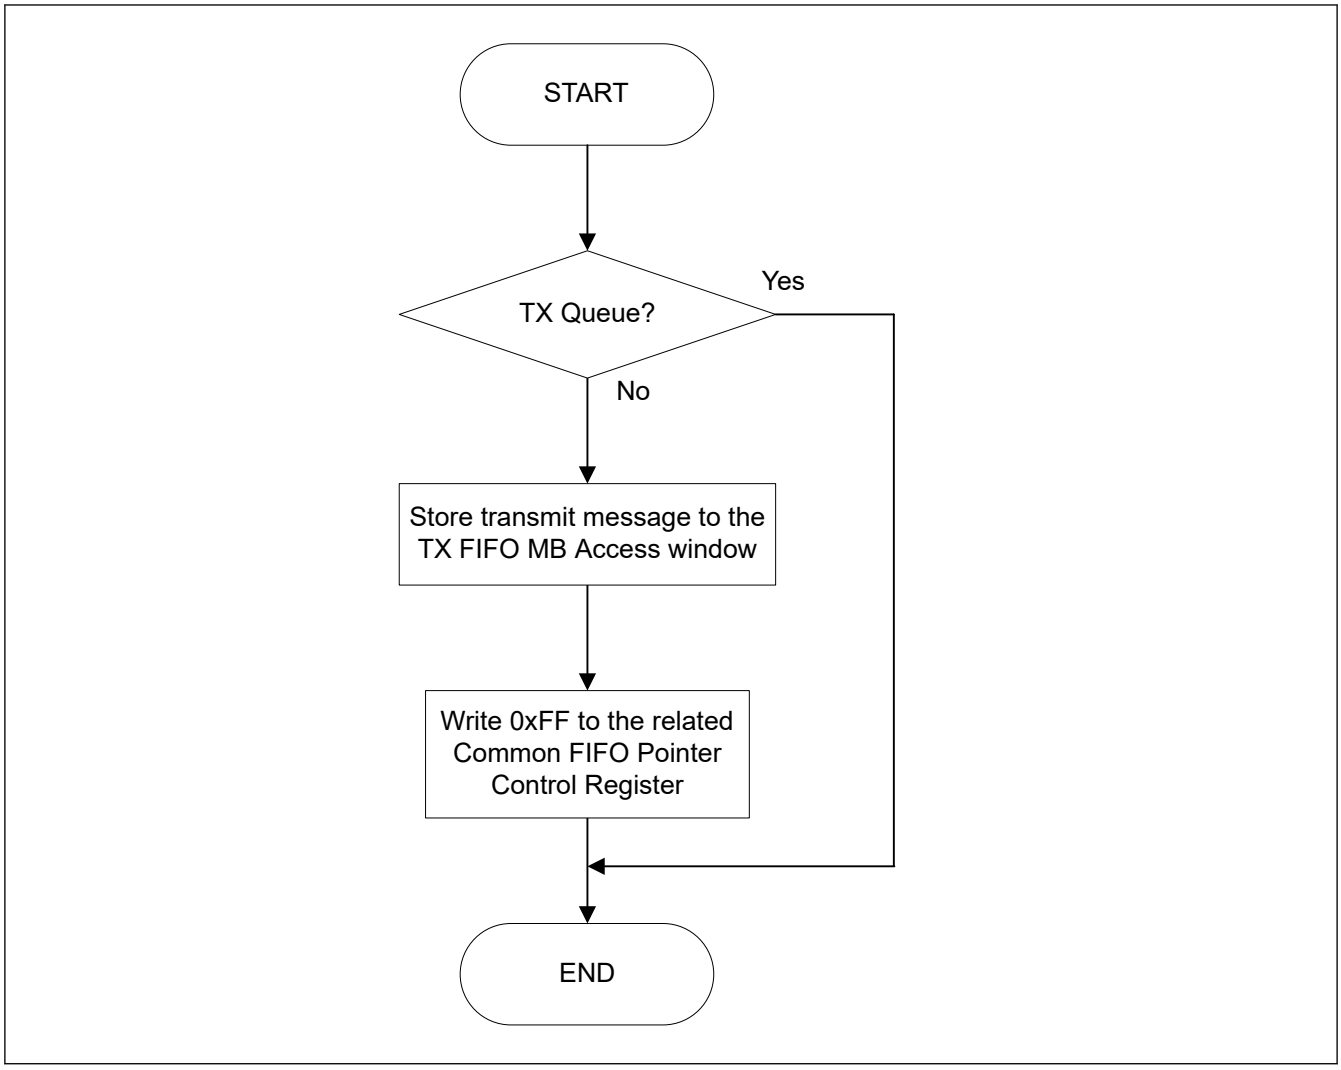

Figure 31.45 Request procedure for TX FIFO transmission

(2) Interval Timer for FIFO Transmission

For each Common FIFO in TX mode, it is possible to specify a delay between two consecutive messages that are configured for transmission from the same FIFO buffer. This delay is called interval time. This interval time starts after the first message has been successfully transmitted from the FIFO buffer after the CFDCFCC.CFE bit is set.

When the Common FIFO in TX mode is enabled, the first message is transmitted without considering this interval time.

The interval timer stops counting when:

- FIFO is disabled by clearing the CFDCFCC.CFE bit.
- CAN channel is in CH_RESET mode.

The interval time is specified by the CFDCFCC.CFITT value from 0 to 255 timer units in the Common FIFO Configuration/Control Register.

The timer unit can be defined based on two different source clocks for the interval timer. To disable the interval timer for FIFO transmission, select a value of 0.

The timer source can be selected with the configuration bit CFITSS in the Common FIFO Configuration/Control Register.

If CAN channel bit time clock is configured as the clock source, and the CAN channel enters CH_HALT, CH_RESET, or CH_SLEEP mode, the interval timer is stopped for that channel.

If peripheral clock is selected as the interval timer clock source, the interval timer is stopped only when the CAN channel is in CH_RESET or CH_SLEEP mode.

The reference clock can be used to configure the interval time in fixed time units. It is based on the peripheral clock. The reference clock prescaler value CFDGCFG.ITRCP in the Global Configuration Register defines the relation between the peripheral clock frequency/period and the reference clock period.

See Table 31.27 for CFDGCFG.ITRCP configuration values to achieve different reference clock periods based on the peripheral clock frequency and period.

Table 31.27 Configuration example for the reference clock of the FIFO interval timer

Reference clock/Peripheral clock	1 µs	100 µs	500 µs
16 MHz/62.5 ns	16	1600	8000
20 MHz/50 ns	20	2000	10000
32 MHz/31.25 ns	32	3200	16000
50 MHz/20 ns	50	5000	25000

The reference clock resolution can be specified by the interval timer reference clock resolution value CFDCFCC.CFITR in the Common FIFO Configuration/Control Register.

The interval time is based on the reference clock period multiplied by the configured value (x1 or x10). The reference clock based interval timer can be used to satisfy the requirements of the ISO 15765-2 Separation Time. The whole range for the separation time from 100 µs to 127 ms can be covered.

The specified interval time starts after successful transmission event (after EOF7 state of the CAN protocol).

When the interval time has elapsed, the next transmission request is raised by the related TX FIFO. Therefore, the interval time defines the minimum time between two messages transmitted from one FIFO.

The next message is sent at earliest after this interval time. Figure 31.46 shows an example timing of the internal processing.

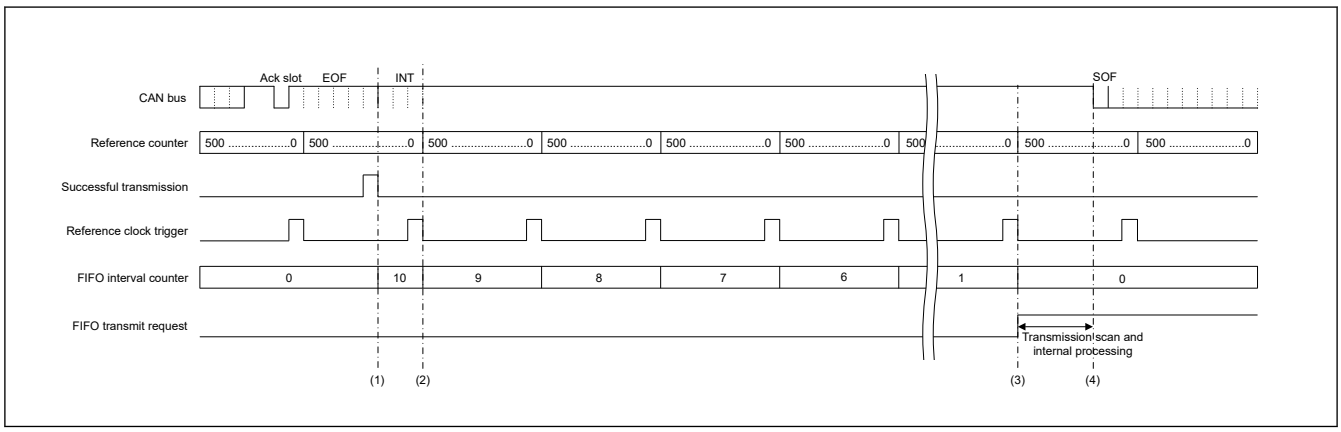

Figure 31.46 Example for interval processing time

The configuration for the timing in Figure 31.46 is as follows:

- Peripheral clock frequency = 50 MHz
- Interval timer reference clock (CFDGCFG.ITRCP) = 500 times
- Reference clock from the settings in Figure 31.46 = 10 µs
- Common FIFO interval timer source selection (CFDCFCC.CFITSS) = 0
- Common FIFO interval timer resolution (CFDCFCC.CFITR) = 0
- Common FIFO interval transmission time (CFDCFCC.CFITT) = 10 times
- Theoretical message separation interval = 100 µs

1. Internal FIFO interval timer is restarted with the occurrence of successful transmission result. This restart is not synchronized to the reference clock trigger. Therefore, the first interval is counting less or equal to 1 reference clock interval.
2. With the next reference clock trigger the FIFO interval timer is decremented.

3. When the FIFO interval timer reached the value 0, the FIFO transmit request is set.
4. When the FIFO is selected for transmission, the transmission starts. Due to internal processing, this usually takes less than 3 CAN bit time, between the internal FIFO transmit request set in step 3. and the actual transmission.

In the worst case when multiple events such as a reception scan, an internal message routing, a transmit scan on all channels occur, it can take up to 120 peripheral clock cycles.

As shown in Figure 31.46, it is not guaranteed that the minimum interval is always equal to the configured value. If a minimum time must never be breached, configure CFDCFCC.CFITT to the required minimum value plus 1.

If additional TX message buffers or TX FIFO are configured for transmission of the same channel, the real delay between two messages transmitted from a TX FIFO can be much longer than specified by the interval time. This is due to higher priority message transmission from these TX message buffers or TX FIFO.

Figure 31.47 shows a block diagram of the FIFO interval time generation circuit.

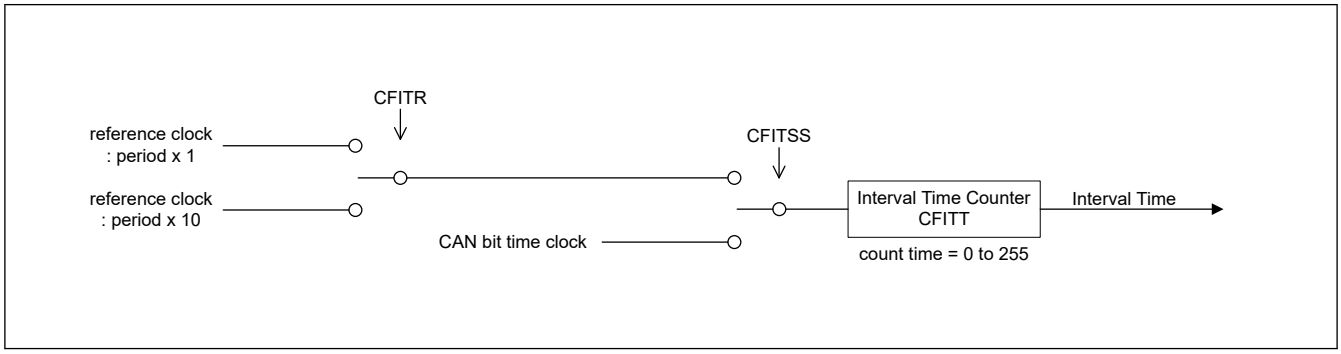

Figure 31.47 Block diagram of FIFO interval timer

31.8.2.4 TX Queue

Each enabled TX Queue for a specific channel consists of 3 to 4 TX message buffers, which are accessed through one access window.

- The first TX Queue can be configured with a depth of three up to four buffers and uses TX Message Buffer No. 0 as access window (referred to as TXQ)

All the TXQ messages enter the priority comparison for the transmission, which should be only ID Priority (CFDGCFG.TPRI = 0).

The registers for TXQ are:

- CFDTXQCC
- CFDTXQSTS
- CFDTXQPCTR

See related access registers TX Message Buffer ID Registers (TMID[m]), TX Message Buffer Pointer Registers (TMPTR[m]), TX Message Buffer Data Field 0 Registers, and TX Message Buffer Data Field 1 Registers (TMDF[0:1][m]) when access window TXQ0 is used.

The depth of each TXQ buffer can be configured by writing to the CFDTXQCC.TXQDC[1:0] bits of the TX Queue Configuration/Control Register. TXQ can be set from TXMB0 to TXMB3 as a queue buffer at the maximum.

The 4 available options for the depth configuration of TXQ buffer are:

- 0x00: TX Queue disabled
- 0x01: reserved
- 0x10: 3 Messages
- 0x11: 4 Messages

Do not access all the TX message buffers forming the TX Queue directly (except TX Message Buffer No. 0, which act as TX Queue access window).

When a system writes in TXQ, it writes in send data, after checking the state of TXQ.

Do not access or configure the related TX Message Buffer Control Registers.

The messages stored to the TX Queue access window are internally stored to a free buffer of the TX Queue.

When the buffer is full, no further access should be done to the queue, until it is no longer full. If access is a software write when the buffer of TXQ is full, send data is overwritten.

The TX Queue can be disabled by clearing the TXQE bit in the TX Queue Configuration/Control Register. If this bit is cleared, the TX Queue Empty flag is set as follows:

- Immediately if the message from the TX Queue is neither scheduled for the next transmission nor in transmission
- Following the transmission completion, the detection of an error on the CAN bus, loss of arbitration or transition to Channel or Global Halt mode if the transmission from the TX Queue is already scheduled for transmission or already in transmission.

Note: The TX Queue is disabled only when the Empty flag is set after clearing the TXQE bit for the corresponding TX Queue.

Other possible messages pending from the TX Queue are lost and their transmission must be requested again.

Before TXQE is set again, ensure that the CFDTXQSTS.TXQEMP bit is set and that there is no pending abort from the TX Queue.

When the TXQE bit is cleared, all messages in the TX Queue buffers are lost and no further message should be stored in the TX Queue.

When a message has been stored to the TX Queue, write 0xFF in the TX Queue Pointer Control Register. This sets the transmit request automatically and changes the internal message buffer pointer to the next free message buffer location of the TX Queue.

Note: If two messages with the same ID are stored in the TX Queue, the order of transmission of these messages can be different from the order in which they were stored in the TX Queue.

To avoid this condition, it is important to confirm that the previous message with the same ID was successfully transmitted before a new message with the same ID is stored in the TX Queue.

For the TX Queue, a dedicated interrupt can be enabled by setting the TXQIE bit of the TX Queue Configuration/Control Register.

The interrupt mode can be configured with the CFDTXQCC.TXQIM bit of the same register either to generate an interrupt for every transmitted message or for the last transmitted message.

The TX Queue transmission request procedure after configuration is shown in Figure 31.48.

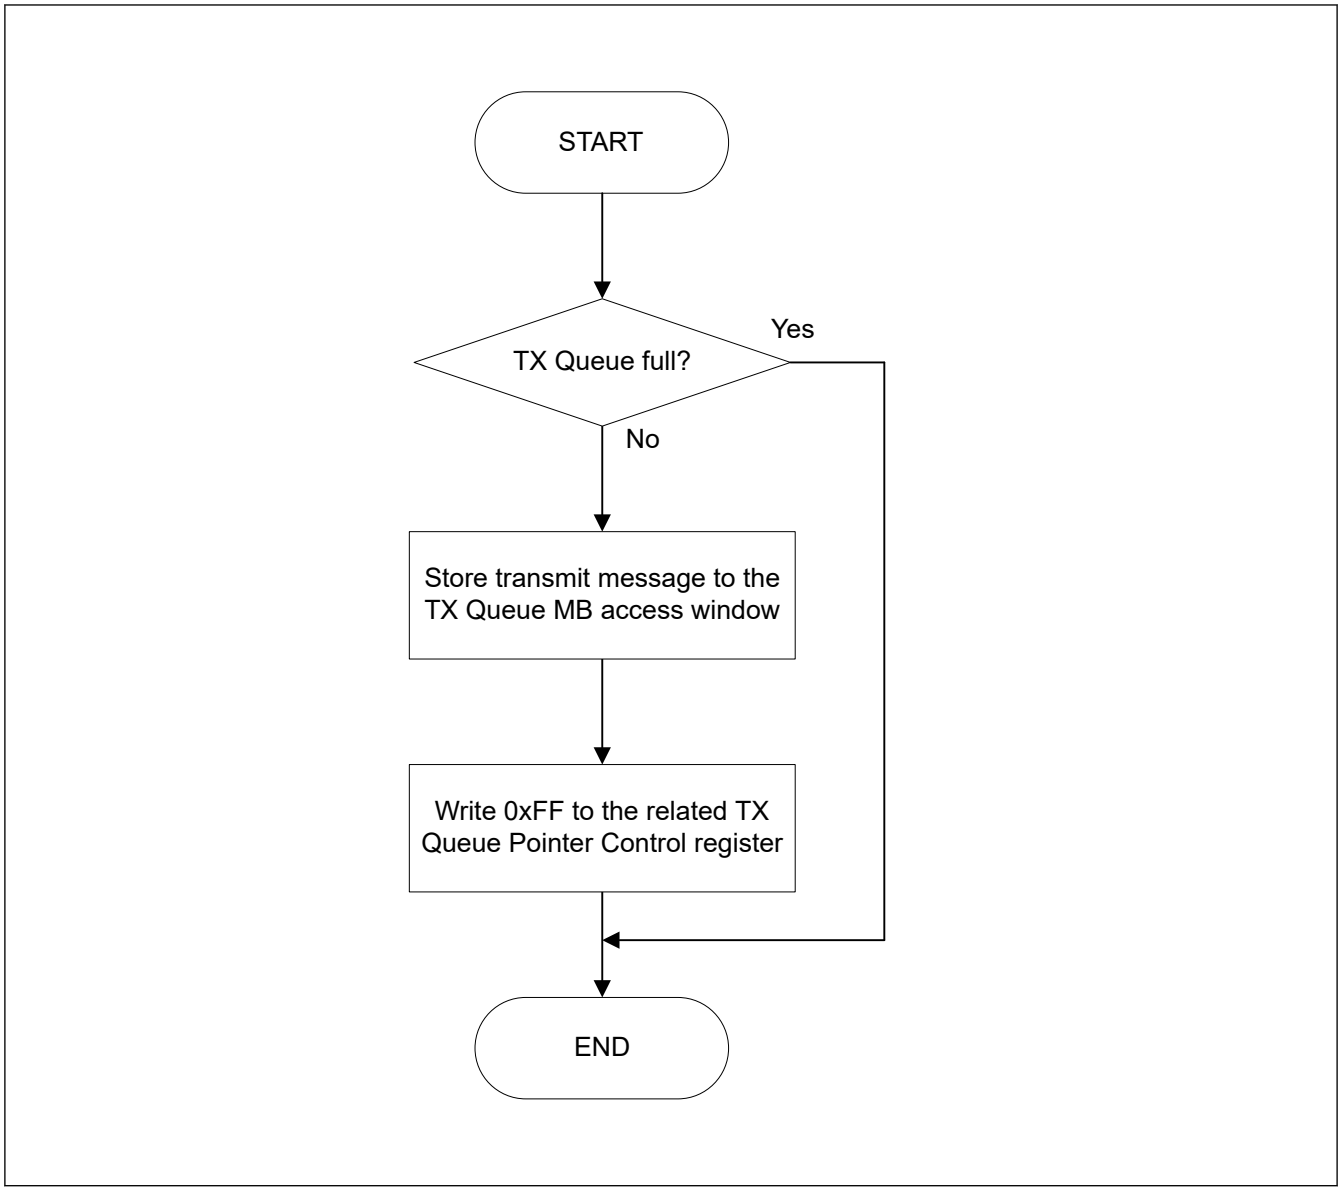

Figure 31.48 TX Queue transmission request

31.8.2.5 TX History List

The TX History List function records the information of the successfully transmitted message in the TX History List Buffers. Two TX History List buffers are provided and THL buffer can store up to 8 TX History List entries.

The CFDTHLCC.THLDTE bit of the TX History List Configuration/Control Register can be used to configure if only message information from TX FIFO or TX Queue is stored, or if all transmit message information from TX Queue, TX FIFO, or normal TX message buffers is stored in the TX History List.

Each transmit message can be individually configured for acceptance to the TX History List with the CFDCFID.THLEN bit in the Message Buffer Pointer Register.

The message information is stored to the TX History List Buffer of a CAN channel after the message is successfully transmitted.

Storing to the list is not synchronized with the status of CFDTMSTSj.TMTRF[1:0] bits in the TX Message Buffer Status Register.

Due to internal processing, the storage to the list can happen with a delay after the successful transmission indication.

Storing the TX History List data can be recognized by the condition that the THLIF is set to 1 when the THLIE bit is configured to 1 or when the TX History List counter CFDTHLSTS.THLMC[5:0] is increased.

In worst case when multi events like reception scan, internal message routing on happen.

- Maximum delay time from setting the CFDTMSTSj.TMTRF to store the TX History List data is 70 peripheral bus clock cycles.

The History list records the following information of a transmitted message:

- Buffer type:
  - 001: TX Message Buffer
  - 010: TX FIFO
  - 100: TX Queue
- Buffer number:
  TX message buffer, TX Queue message buffer or TX message buffer link for the Common FIFO buffer from which transmission occurred. The number depends on the buffer type. See Table 31.28.
- Transmission ID:
  Transmission pointer stored in the transmission message
- Transmit timestamp:
  Message timestamp captured at capture point as configured by CFDGFDCFG.TSCCFG.
- Transmission information label:
  Transmission information label stored in the transmission message.

Table 31.28 TX History List Buffer number entry

Buffer Number	BT[2:0] Buffer Type		
	001b TX Message Buffer	101b TX FIFO	100b TX Queue
00b	Message Buffer 0	Number shown corresponds to the common FIFO. TX Message Buffer Link CFTML of the related Common FIFO configuration	Number shown corresponds to the Message Buffer belonging to the TX Queue which the frame was transmitted
01b	Message Buffer 1		
10b	Message Buffer 2		
11b	Message Buffer 3		

The Transmission ID entry is used to identify which message of a TX FIFO or TX Queue has been successfully transmitted because the TX FIFO or TX Queue number alone is not sufficient.

Therefore, a unique number can be attached to each transmission message stored in a TX FIFO or TX Queue. This unique identification number should be written to the CFDCFFDCSTS.CFPTR[15:0] part of the Common FIFO Access Pointer Register for a TX FIFO or to the CFDTMFDCTRb.TMPTR[15:0] part of the TX Message Buffer Pointer Register of the TX Queue access window message buffer.

When the message is successfully transmitted, this identification number is stored together with the other message related information to the TX History List and can be read using the Transmission ID (TID) of the TX History List Access Register.

Also, for normal TX message buffers, the CFDTMFDCTRb.TMPTR[15:0] part of the TX Message Buffer Pointer Register is stored in the Transmission History List and the information label is the same.

Figure 31.49 shows a transmission preparation flow when TX History List is used.

Read access to the TX History List Access Register is done for every single entry.

After reading one entry, 0xFF must be written to the corresponding TX History List Pointer Control Register to be able to access the next entry until TX History List is empty.

Figure 31.50 shows an example flow for processing the TX History List information.

The TX History Lists have dedicated interrupts, which can be configured with the CFDTHLCC.THLIM bit of the corresponding TX History List Configuration/Control Register and enabled with the CFDTHLCC.THLIE bit of the same

registers, either to generate an interrupt when the History List reached a filling level of 75% or for every new TX History List entry.

An entry lost indication is flagged by the CFDTHLSTS.THLELT bit in the TX History List Status Register. The status of this bit is also shown by the THLES bit in the Global Error Flag Register.

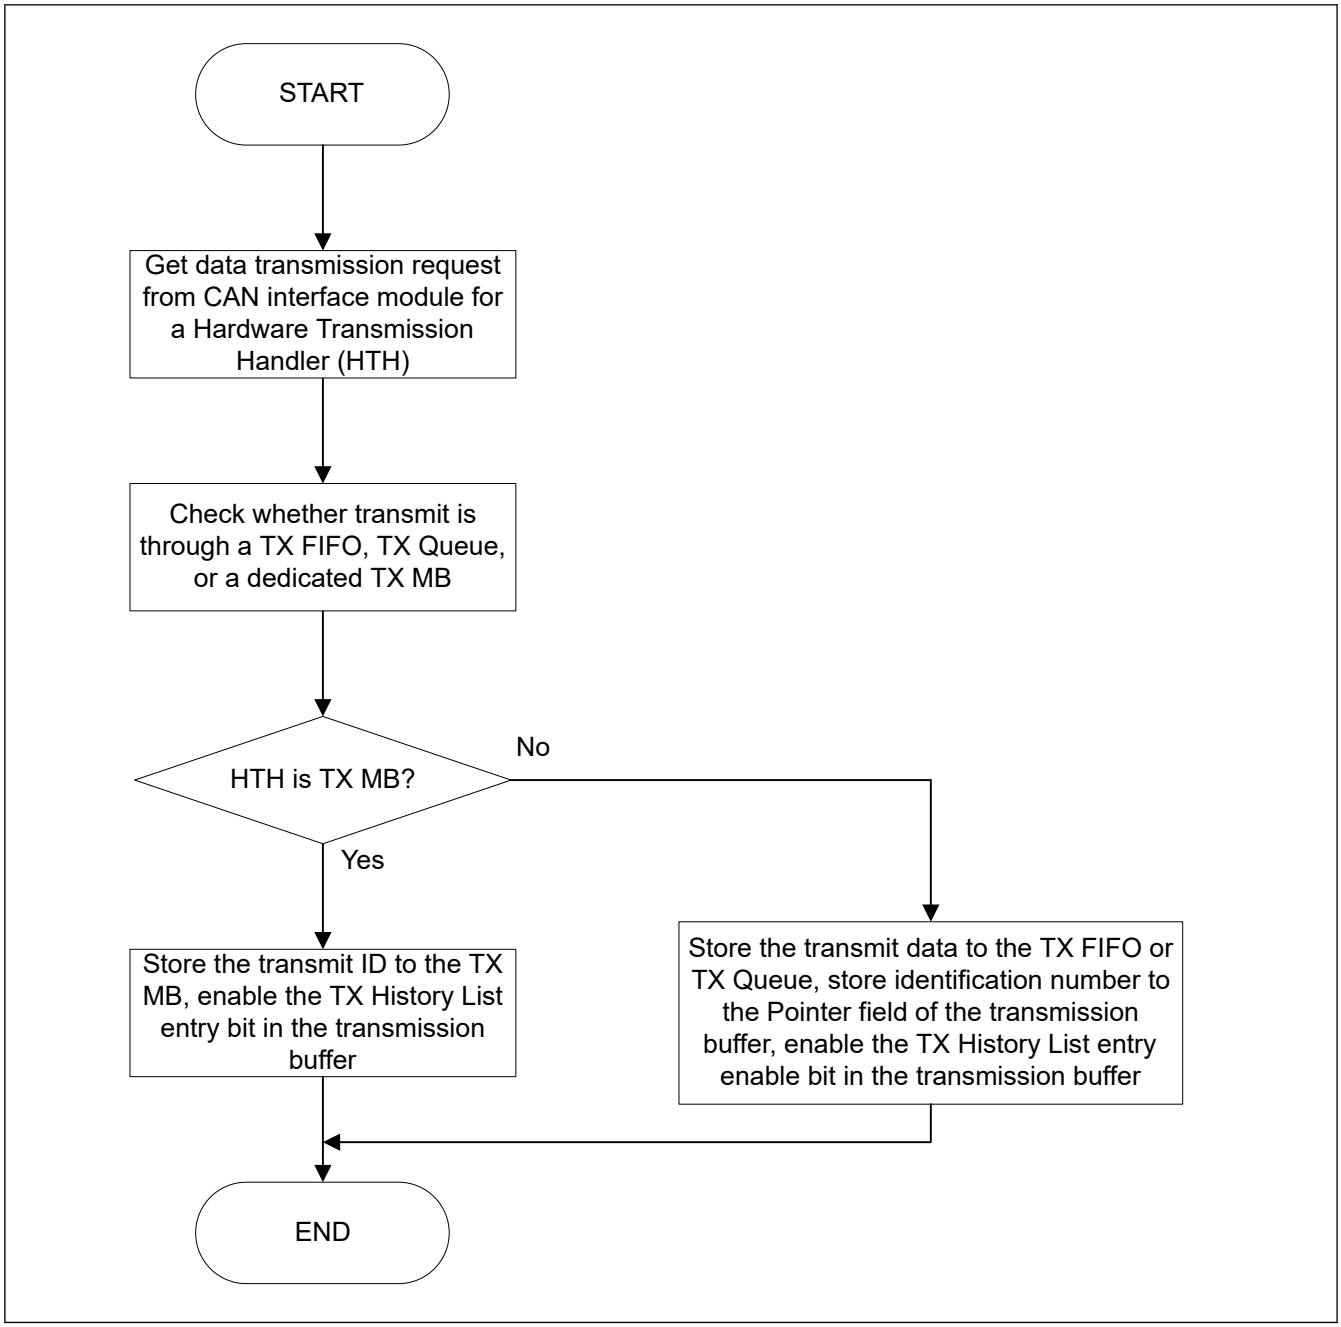

Figure 31.49 TX History List preparation flow

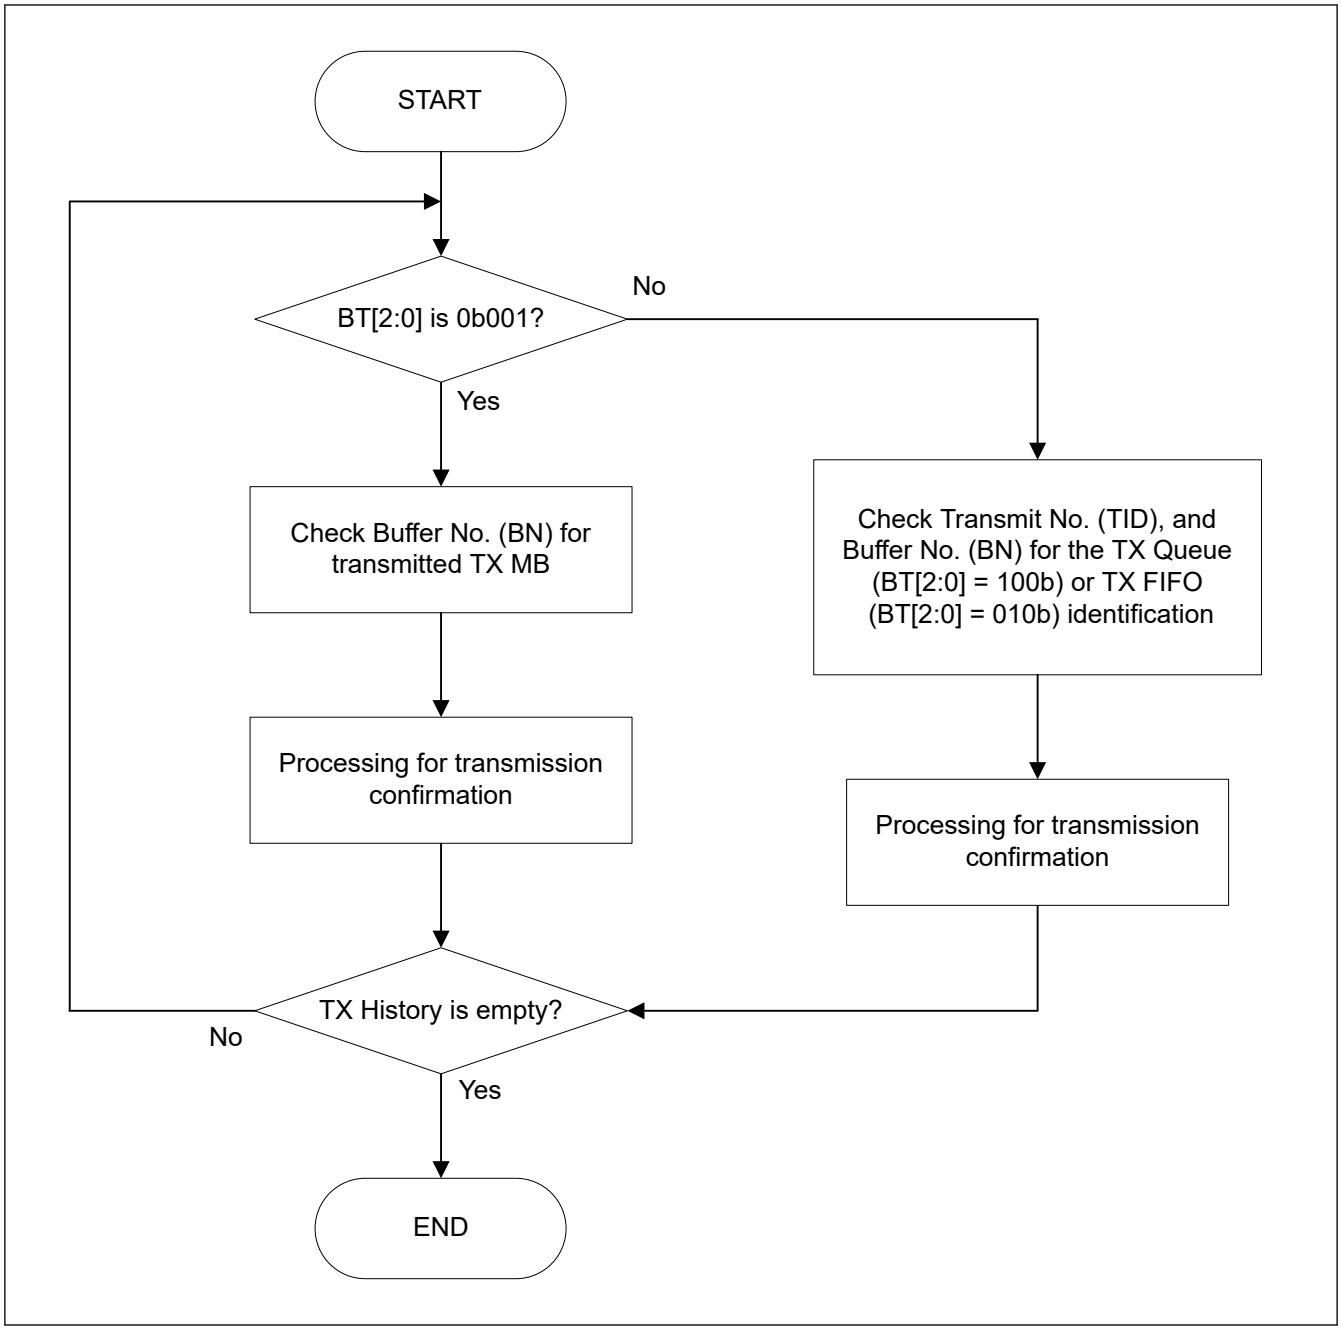

Figure 31.50 TX History List processing flow

31.8.2.6 TX Data Padding

This chapter is not valid for classical CAN.

If the data length code (DLC) of the transmitting message has a higher number of data bytes than the buffer size, the data bytes beyond the restricted range are replaced by bytes with the value of 0xCC.

This can happen for Common FIFO configured as (TX mode) when the transmit message DLC is higher than the CFDCFCC.CFPLS.

This can also happen in FD only mode, if a Classical frame is configured with a DLC bigger than 8.

31.9 Test Mode

The CANFD module can be configured into test modes to allow testing of certain features. These features are provided only for special purposes and care must be taken when configuring the CANFD module in test modes.

Note: All test modes are mutually exclusive unless it is explicitly stated that some functions can be enabled across other test modes.

Do not enable any combination of the various test modes specified in this section.

The test modes can be broadly split into 2 groups:

- Channel specific test modes
- Global test modes.

31.9.1 Channel Specific Test Modes

CAN channel can be configured into the following test modes:

- Basic test mode
- Listen-only mode
- Self-test mode 0 (External loop back mode)
- Self-test mode 1 (Internal loop back mode)
- Restricted operation mode.

31.9.1.1 Basic Test Mode

The basic test mode should be used when there is requirement for a particular test setting to be enabled other than when in Listen-only and Self-test modes.

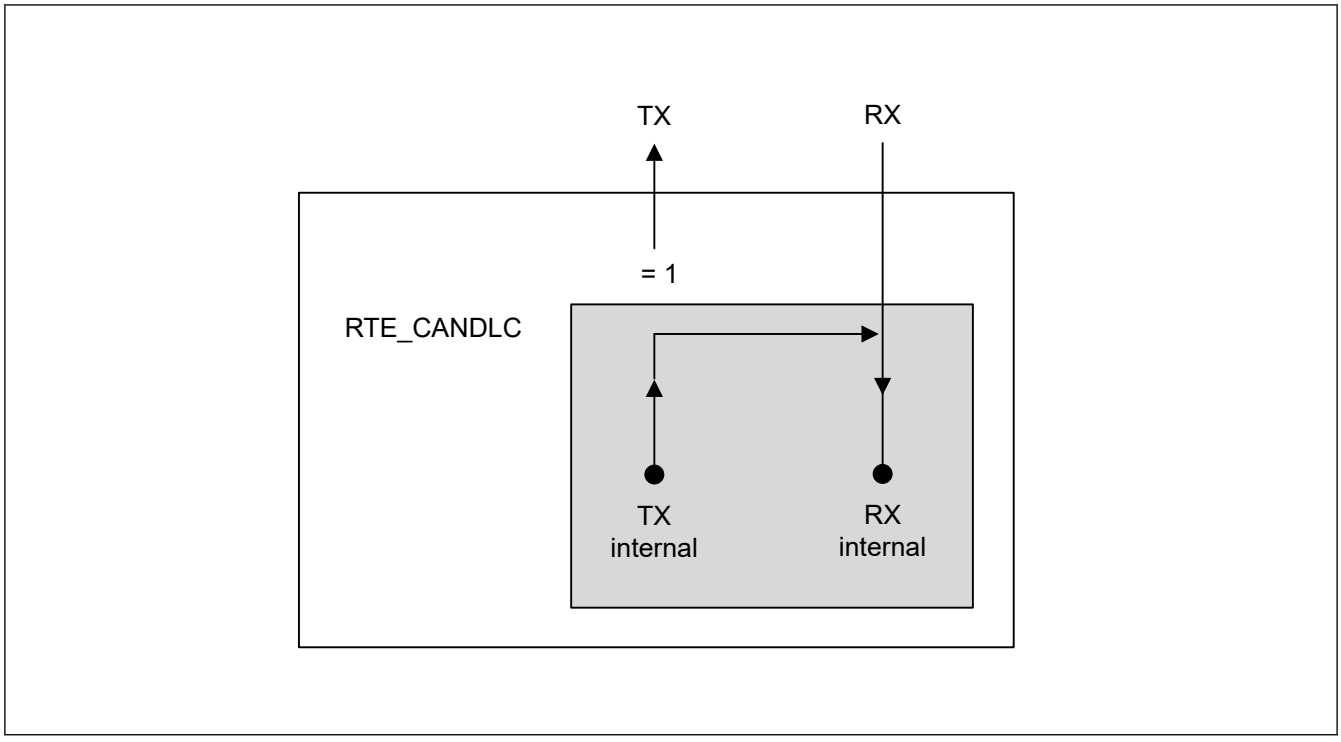
31.9.1.2 Listen-only Mode

The ISO 11898-1 recommends an optional bus-monitoring mode. In this mode, the CAN channel is able to receive valid data frames and valid remote frames. However, it sends only recessive bits on the CAN bus and is not allowed to transmit.

If the CAN engine is required to send a dominant bit (ACK bit, overload flag, active error flag), the bit is routed internally so that the CAN engine monitors this as dominant. The external TX pin remains in recessive state.

This mode can be used for baud rate detection. In this mode, an error interrupt is generated if a bus error occurs and the interrupt is enabled.

In this mode, it is not permitted to request transmission from any normal TX message buffer or TX FIFO.

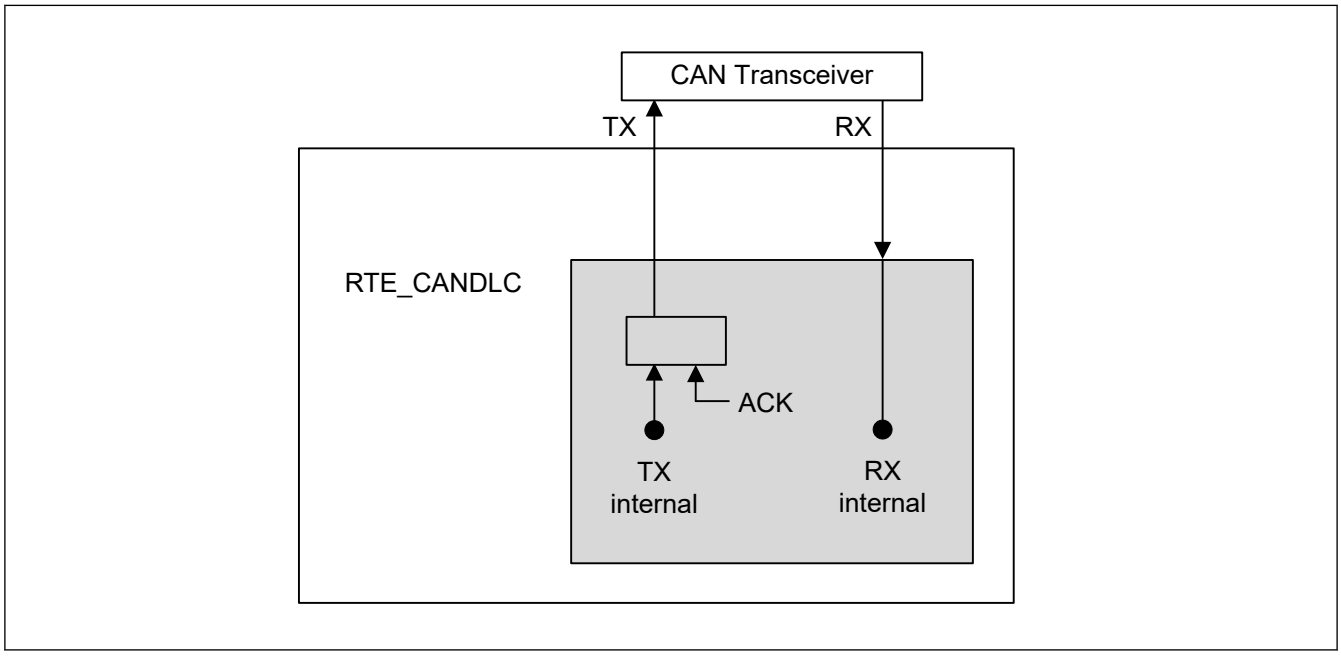


31.9.1.3 Self-test Mode 0 (External loopback mode)

In Self-test mode 0, the CAN engine treats its own transmitted messages as received messages through the CAN transceiver and stores them into its receive message buffers.

To be independent from external stimulation, the engine generates its own Acknowledge bit.

This test can be used for CAN transceiver tests and the RX/TX pins should be connected to the transceiver.

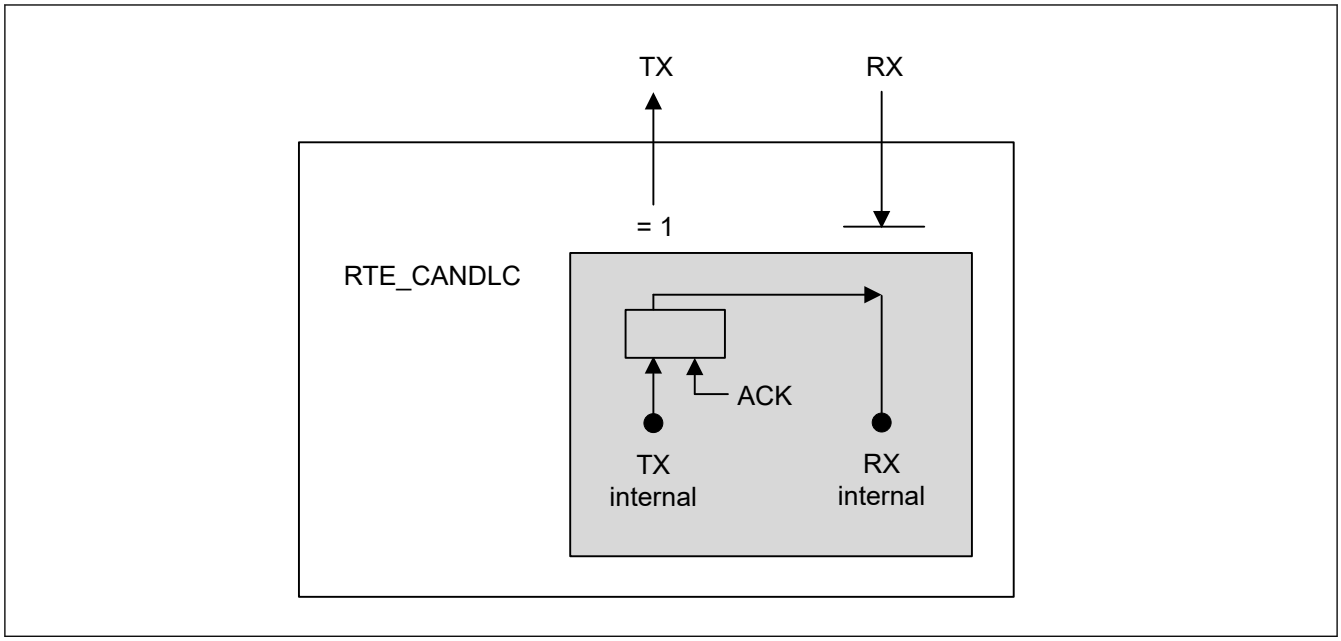


31.9.1.4 Self-test Mode 1 (Internal loopback mode)

In Self-test mode 1, the CAN engine treats its own transmitted messages as received messages and stores them into the receive buffer. This mode is provided for self-test functions. To be independent from external stimulation, the CAN engine generates its own Acknowledge bit. In this mode the CAN engine performs an internal feedback from TX internal to RX internal. The actual value of the external RX input is disregarded by the CAN engine.

The external TX pin outputs only recessive bits. The RX/TX pins do not need to be connected to the CAN bus or any external device.

Note: The channel pins are also disconnected from the internal CAN bus communication line.



31.9.1.5 Restricted Operation Mode

This chapter is not valid for classical CAN.

In Restricted operation mode, the CAN node is able to receive valid data and remote frames generating the Acknowledge bit.

Active error or overload frames cannot be transmitted, instead it waits for the occurrence of bus idle condition to resynchronize itself to the CAN communication after an error or overload condition occurs.

Additionally, the Receive and Transmit Error Counter (REC and TEC) are frozen independently from the occurrence of errors. The mode is specified in ISO 11898-1 and the setting of transmit request is permitted.

31.9.2 Global Test Modes

The CANFD module can be configured into the following test modes:

- RAM test mode
- Bit Flip Test

The test modes in the following table are protected by a special software procedure to enable the mode. This software procedure enables write access to the test mode by a specific unlock key as shown in the table.

Test mode	Unlock key 1	Unlock key 2
RAM test mode	0x7575	0x8A8A

If the software sequence of the two consecutive unlock key write accesses (half-word or word access) is interrupted by any other write access to the register or if incorrect data is written to the Global Unlock Key Register, the corresponding test mode cannot be set and the sequence must be restarted.

After the two unlock key write accesses, the next write access should be to set the corresponding test mode enable bit. If this is not followed, the unlock mechanism reset and the test mode enable bit cannot be set and the unlock sequence must be restarted.

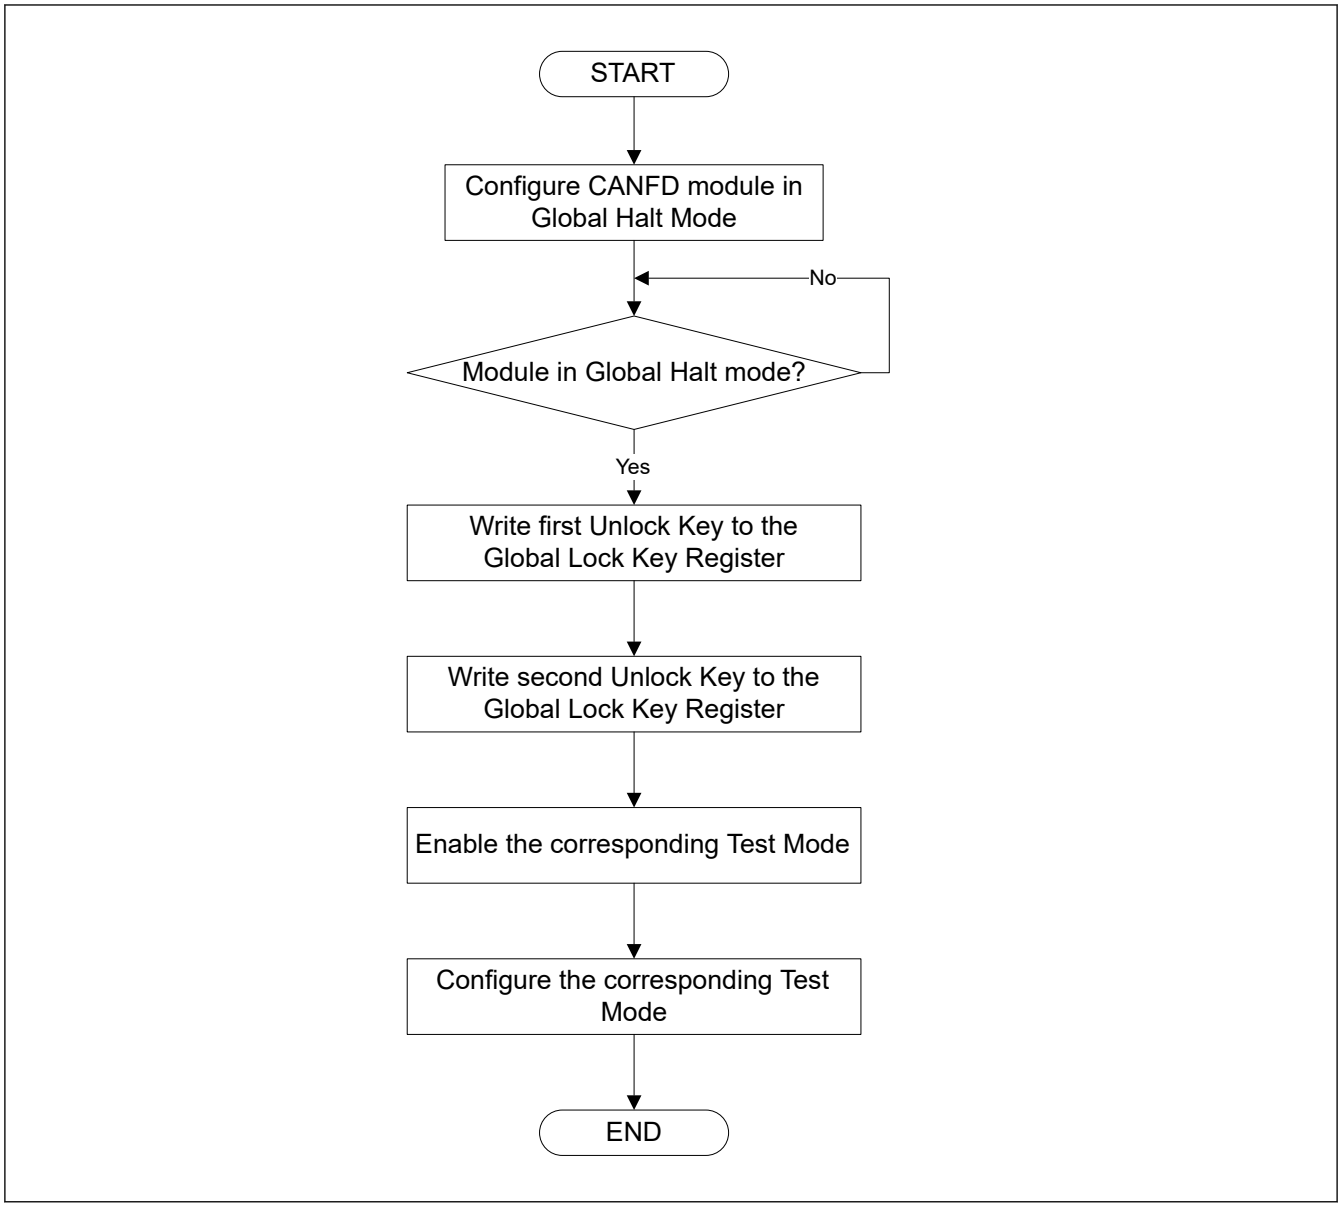


Figure 31.51 Unlock software protection routine

31.9.2.1 RAM Test Mode

The CANFD module can be configured in RAM test mode by setting the CFDGTSTCTR.RTME bit in the Global Test Control Register when the corresponding lock key is previously written. This is a special test mode, in which, the complete RAM area can be accessed.

Note: The actual RAM size is bigger than the RAM area initialized after a hardware reset. Therefore, ECC error flag (of the ECC macro) may be set if CPU reads data from this uninitialized RAM area while CANFD module is in RAM test mode.

In this mode, the RAM area is split into number of pages (pn) of 256 bytes, each which can be accessed with the CFDRPGACCk register.

The page should be selected for read/write access by writing to the CFDGTSTCFG.RTMPS[3:0] bits in the Global Test Control Register. Data can then be read from or written in to the RAM Test Page Access Registers.

Figure 31.52 shows the structure of the pages in the RAM when performing a RAM test mode.

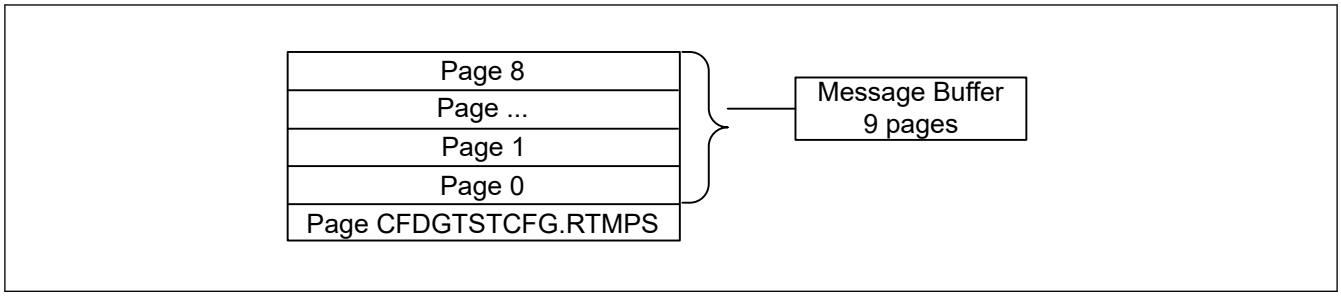

Figure 31.52 RAM page structure

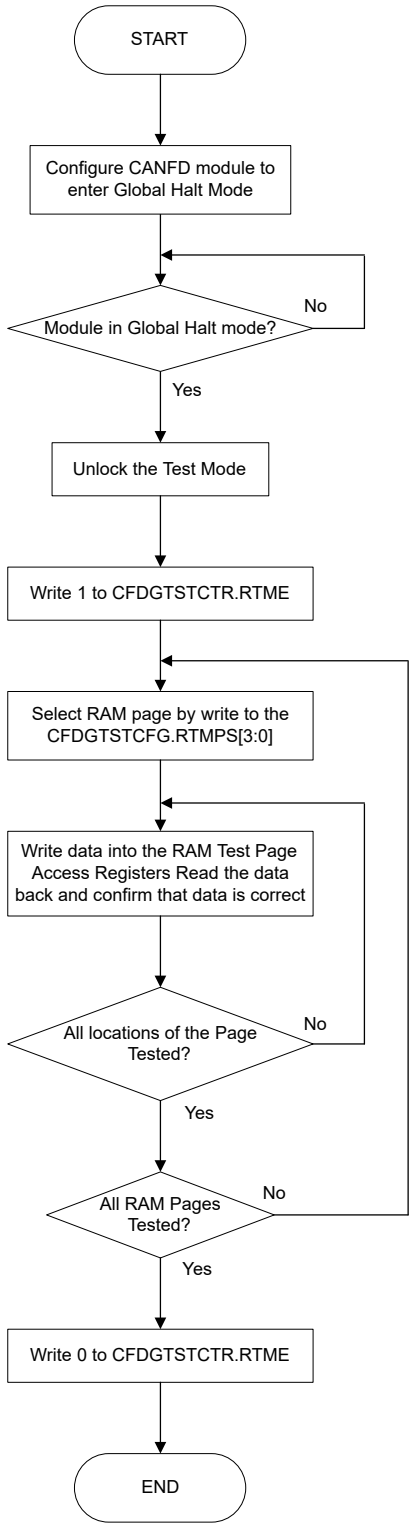
The total available RAM size is 2072 bytes for the Message Buffer RAM.

The pn and CFDGTSTCFG.RTMPS[3:0] values for the MB RAMs are calculated in the following way:

pn = ceil (total RAM size in bytes / number of bytes per page)

- MB RAM:
  pn = ceil (2072 / 256) = 9 pages
  CFDGTSTCFG.RTMPS[3:0] = 0 to 8 inclusive
  (User should not access more than 24 Bytes in the last page)

Figure 31.53 shows the software flow for RAM test mode.



Note 1. Change into the following status before changing to RAMTEST.
- Cancel of a request for transmission.
- Disable of all the FIFO and TXQ.
- Clear of the receiving flag for a receiving buffer.

Figure 31.53 Software flow for RAM test mode

To exit this test mode, the CFDGTSTCTR.RTME bit must be cleared. The CFDGTSTCTR.RTME bit is cleared by writing 0 to it.

The CFDGTSTCTR.RTME bit is cleared automatically when the CANFD module enters Global Reset mode from the test mode.

31.9.2.2 Bit Flip Test

Bit Flip Test can invert the bit (the 1st bit of ID) of the beginning of the bit stream to receive.

If this function is used by a transmitting node, a bit error or an arbitration lost will occur.

If this function is used by a receiving node, a CRC error or a stuff error will occur.

Users should refer to the bit stuffing rule when using this feature, as there is the possibility of receiving a stuff error (due to the inversion) rather than a CRC error.

The following sequence should be used to perform CRC Error testing. In the sequence below CANFD module is the receiver.

1. Set the CFDC0CTR.BFT bit to 1’b1, in order to invert the first bit of the incoming bit stream from sending node
2. Wait for the CANn_CHERR (n = 0, 1) output signal to set to 1’b1
3. Read either the CFDC0ERFL.CRCREG or the CFDC0FDCRC.CRCREG (depending on the received frame type: Classical or FD). The value should be different from the received CRC value of the reference message from sending node.
4. Check that CFDC0ERFL.CERR is 1’b1

As the CRC generator logic is shared for RX and TX there is no need to create a separate TX CRC Error test.

31.10 RAM Area Configuration

The RAM area used in CANFD (refers to as MRAM) can be split into the following groups as shown in Figure 31.54.

- AFL Rule Table area
- PFL Rule Table area
- Message Buffer*1 area (RX MB + FIFO Buffer)
- OTB area
- THL area
- TX MB area.

Physically, the RAM is the Message Buffer RAM*2 (RX MB, RX FIFO, Common FIFO*3 TX MB, THL, OTB, AFL Rule Table, PFL Rule Table).

Note 1. Refers to as MB
Note 2. Refers to as MRAM
Note 3. Refers to as CFIFO

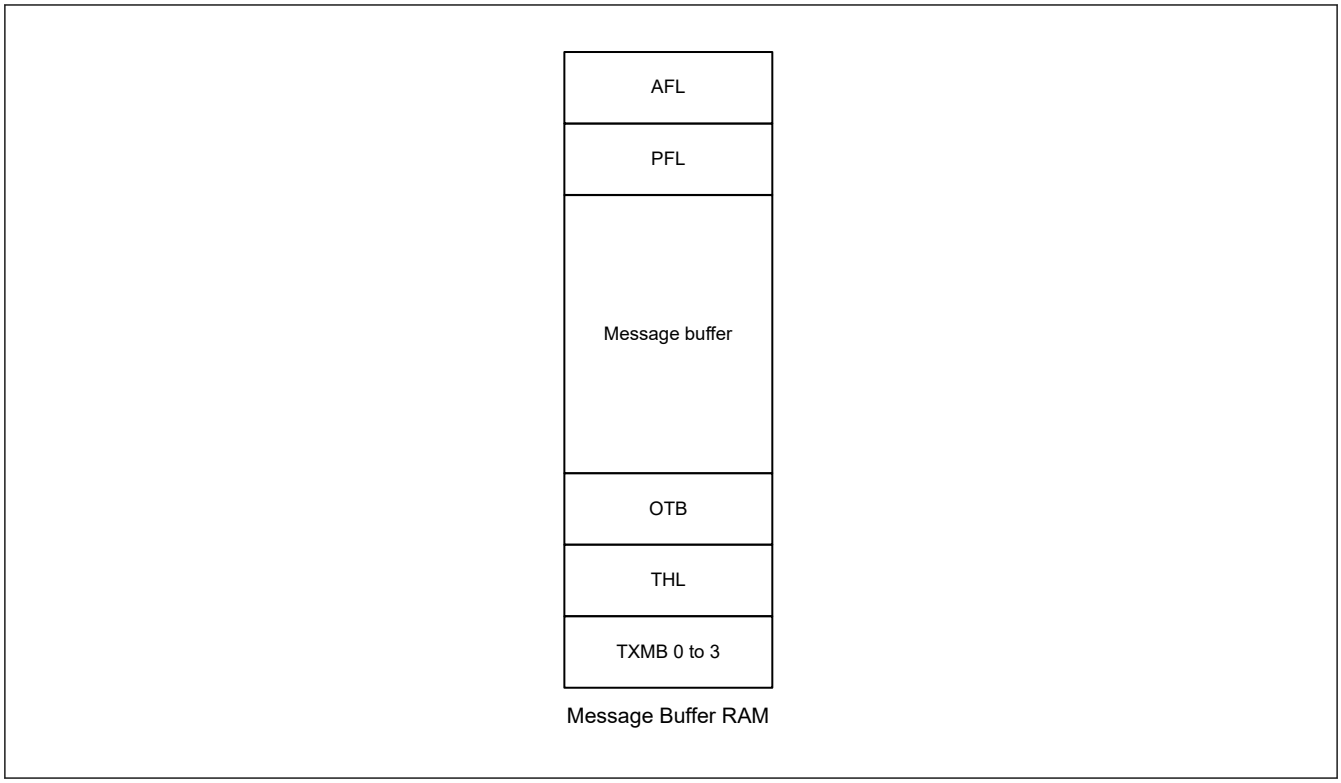


Figure 31.54 RAM area grouping

The MRAM area starts with the TX MB area at address 0x0000. The TX MB area is followed immediately by the THL area which is then followed immediately by the OTB area. The size of the TX MB, THL, and OTB areas is fixed. The OTB area is followed by the Message Buffer area. The Message Buffer area size depends on the configuration of the flat RXMBs, RXFIFOs, and CFIFO. When all are configured, the RX MB area is followed by the RX FIFO area which is followed by the CFIFO area.

The configured MRAM area can then be calculated as follows:

MRAM_cfg = RXMB_MRAM_cfg + RXFIFO_MRAM_cfg + CFIFO_MRAM_cfg + TXMB_MRAM_cfg + THL_MRAM_cfg + OTB_MRAM_cfg + AFL_MRAM_cfg + PFL_MRAM_cfg

RXMB_MRAM_cfg = (12 bytes + CFDRMNB.RMPLS) × CFDRMNB.NRXMB

RXFIFO_MRAM_cfg = SUM ((12 bytes + CFDRFCCa.RFPLS) × CFDRFCCa.RFDC)

CFIFO_MRAM_cfg = (12 bytes + CFDCFCC.CFPLS) × CFDCFCC.CFDC

TXMB_MRAM_cfg = 304 bytes

THL_MRAM_cfg = 64 bytes

OTB_MRAM_cfg = 160 bytes

PFL_MRAM_cfg = 72 bytes

AFL_MRAM_cfg = 256 bytes

“a” means RX FIFO index = [0...no_of_RFIFOs - 1]

no_of_RFIFOs : Number of configured RX FIFOs

Note: For CFDRFCCa.RFDC, CFDCFCC.CFDC, CFDRMNB.RMPLS, CFDRMNB.NRXMB, CFDRFCCa.RFPLS, and CFDCFCC.CFPLS the related number of bytes must be used.

Table 31.29 shows the calculation of the different RAM areas used for the AFL entries, OTB buffers, TX/RX message buffers, RX/Common FIFOs, and PFL entries.

Table 31.29 MRAM area calculation

RAM name	RAM property	RAM area calculation method	RAM values
AFL	Average rule entries	—	16
	Number of bytes in a rule entry	Fixed	16
	Number of bytes in AFL area	Average rule entries × Number of bytes in a rule entry	256
PFL	Average rule entries	—	2
	Number of bytes in a rule entry	Fixed	36
	Number of bytes in PFL area	Average rule entries × Number of bytes in a rule entry	72
TX MB	Number of TX MBs	Fixed	4
	Number of bytes required for each TX MB	Fixed	76
	Number of bytes in TX MB area	Number of TX MBs × Number of bytes required for each TX MB	304
THL	Number of entries in one THL buffer	Fixed	8
	Number of bytes required for each THL entry	Fixed	8
	Number of bytes in THL area	Number of entries in one THL buffer × Number of bytes required for each THL entry	64
OTB	Average number of buffers	—	2
	Number of bytes for OTB entry	Fixed	80
	Number of bytes in OTB area	Average number of buffers × Number of bytes for OTB entry	160
Message Buffer	Number of RX MBs	Fixed	32
	Number of RX FIFOs	Fixed	2
	Number of Common FIFO	Fixed	1
	Average number of messages for RX MB and FIFO buffers	—	16
	Number of bytes for each stored message	Fixed	—
	Average size of a Message Buffer in bytes	—	76
	Number of bytes in Message Pool area	Average number of messages for RX MB and FIFO buffers × Average size of a Message Buffer in bytes	1216
	Number of bytes message RAM	Number of bytes in Message Pool area + Number of bytes in OTB area + Number of bytes in THL area + Number of bytes in TX MB area + Number of bytes in PFL area + Number of bytes in AFL area	2072

31.10.1 Examples

Figure 31.55 shows one possible configuration.

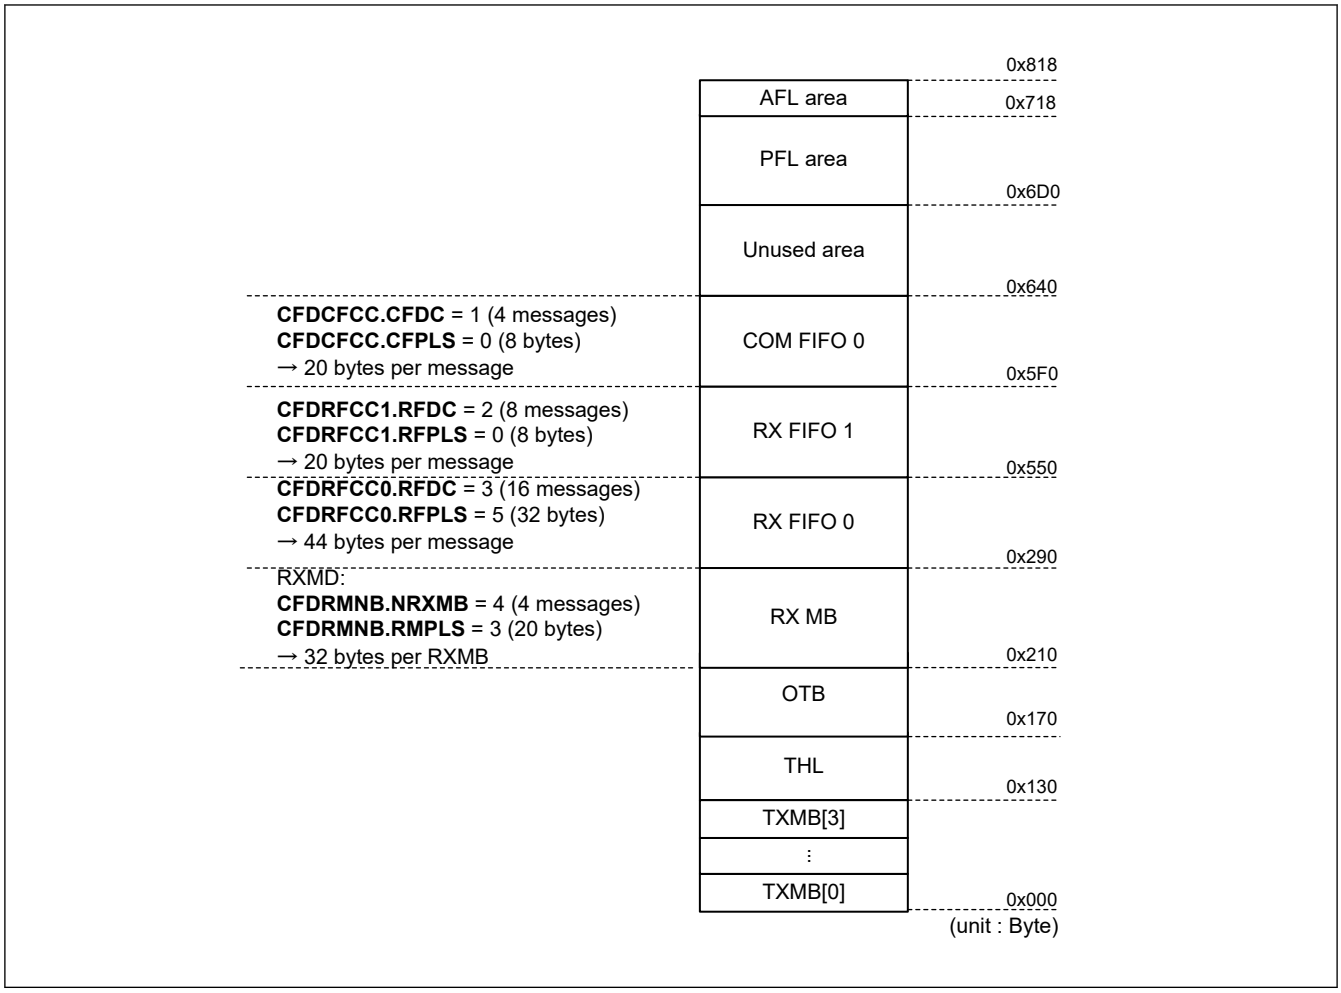

Figure 31.55 RX MB + FIFO buffers RAM area configuration examples

31.10.2 OTB Area

The OTB area starts immediately after the area allocated for THL buffers. The OTB is a special purpose buffer used by the CANFD. This section of RAM area can be accessed only by the CPU in RAM Test mode. Buffer requires 80 bytes and the average number of buffers is 2. Therefore, the total number of bytes allocated for the OTB is 2 × 80 bytes.

31.10.3 RAM Initialization Cycle

The number of RAM initialization cycles and the RAM number of pages are shown in Table 31.30.

Table 31.30 RAM initialization cycle

MRAM area size	RAM initialization cycles [PCLKA cycle]	RAM Test RTMPS range
2072	520	0x0 to 0x8

31.11 Usage notes

31.11.1 Module-stop function

CANFD operation can be disabled or enabled using Module Stop Control Register C (MSTPCRC). The CANFD module is initially stopped after reset. Releasing the module-stop state enables access to the registers. For details, see section 10, Low Power Modes.

32. CANFD ECC (CNECC)

32.1 Overview

MBRAM have ECC function of 2-bit ECC error detection and 1-bit ECC error detection and correction*1. The ECC module adds 7 bits ECC data to 32 bits RAM data.

Note 1. The ECC module cannot detect 3 or more bits error. In this case, the ECC module detects 1-bit or 2-bit error, does not detect errors, or corrects the erroneous bit to erroneous data by setting. When all RAM data are fixed to 0 or 1, it is detected as 2-bit ECC error.

32.2 Register Descriptions

32.2.1 EC710CTL : ECC Control Register

Base address: ECCMBn = 0x4036_F200 + 0x0100 × n (n = 0, 1)
ECCMBn_NS = 0x5036_F200 + 0x0100 × n (n = 0, 1)

Offset address: 0x00

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	ECDEDF0	ECSEDF0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0

Bit	Symbol	Function	R/W
0	ECEMF	ECC Error Message Flag 0: There is no bit error in present RAM output data 1: There is bit error in present RAM output data	R
1	ECER1F	ECC Error Detection and Correction Flag 0: After clearing this bit, 1-bit error correction has not occurred 1: 1-bit error has occurred	R
2	ECER2F	2-bit ECC Error Detection Flag 0: After clearing this bit, 2-bit error has not occurred 1: 2-bit error has occurred	R
3	EC1EDIC	ECC 1-bit Error Detection Interrupt Control 0: Disable 1-bit error detection interrupt request 1: Enable 1-bit error detection interrupt request	R/W
4	EC2EDIC	ECC 2-bit Error Detection Interrupt Control 0: Disable 2-bit error detection interrupt request 1: Enable 2-bit error detection interrupt request	R/W
5	EC1ECP	ECC 1-bit Error Correction Permission 0: At 1-bit error detection, the error correction is executed 1: At 1-bit error detection, the error correction is not executed	R/W
6	ECERVF	ECC Error Judgment Enable Flag 0: Error judgment disable 1: Error judgment enable	R/W
8:7	—	These bits are read as 0. The write value should be 0.	R/W
9	ECER1C	Accumulating ECC Error Detection and Correction Flag Clear 0: No effect 1: Clear accumulating ECC error detection and correction flag	R/W
10	ECER2C	2-bit ECC Error Detection Flag Clear 0: No effect 1: Clear 2-bit ECC error detection flag	R/W

Bit	Symbol	Function	R/W
11	ECOVFF	ECC Overflow Detection Flag 0: No effect 1: ECC overflow detection flag	R
13:12	—	These bits are read as 0. The write value should be 0.	R/W
15:14	EMCA[1:0]	Access Control to ECC Mode Select bit These bits enable or disable write access to ECERVF bit.	R/W
16	ECSEDF0	ECC Single bit Error Address Detection Flag 0: There is no bit error in EC710EAD0 after reset or clearing ECER1F bit 1: Address captured in EC710EAD0 shows that 1-bit error occurred and captured	R
17	ECDEDF0	ECC Dual Bit Error Address Detection Flag 0: There is no bit error in EC710EAD0 after reset or clearing ECER2F bit 1: Address captured in EC710EAD0 shows that 2-bit error occurred and captured	R
31:18	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

ECEMF bit (ECC Error Message Flag)

The ECEMF bit shows that there is error in present read data bus. This bit is updated by every RAM output data.

When RAM output data is undefined and the ECERVF bit is set to 1, the value of this bit is undefined.

[Setting condition]

There is bit error in present RAM output data under the condition that error judgement is enabled.

[Clearing condition]

- Under the condition that there is no 1-bit error in input data to decode circuit
- When ECC error judgement is disabled (ECERVF = 0).

ECER1F bit (ECC Error Detection and Correction Flag)

The ECER1F bit shows that the bit errors are detected in the one part of RAM read data [38:0] at RAM read access when the error judgment is enabled.

When the 1-bit error interrupt output is enabled, error interrupt is generated by setting this flag.

This bit is read-only, so writing 1 or 0 has no effect.

At clearing, write 1 to the ECER1C bit.

When 1-bit error is detected again under the condition that this bit is set, the interrupt is not generated.

[Setting condition]

When the error judgment is enabled and there is 1-bit error to RAM output data (when not setting ECER1C = 1).

[Clearing condition]

- Writing ECER1C = 1
- When ECC error judgement is disabled (ECERVF = 0).

ECER2F bit (2-bit ECC Error Detection Flag)

The ECER2F bit shows that the bit errors are detected in the two parts of RAM read data [38:0] at RAM read access when the error judgment is enabled.

When the 2-bit error interrupt output is enabled, error interrupt is generated by setting this flag.

This bit is read-only, so writing 1 or 0 has no effect.

At clearing, write 1 to the ECER2C bit.

When 2-bit error is detected again under the condition that this bit is set, the interrupt is not generated.

[Setting condition]

When the error judgment is enabled and there is 2-bit error to RAM output data (when not setting ECER2C = 1).

[Clearing condition]

- Writing ECER2C = 1
- When ECC error judgement is disabled (ECERVF = 0).

EC1EDIC bit (ECC 1-bit Error Detection Interrupt Control)

The EC1EDIC controls the interrupt output at detecting 1-bit error. By setting 1 to this bit, the 1-bit error interrupt is outputted when 1-bit error detected.

EC2EDIC bit (ECC 2-bit Error Detection Interrupt Control)

The EC2EDIC controls the interrupt output at detecting 2-bit error. By setting 1 to this bit, the 2-bit error interrupt is outputted when 2-bit error detected.

EC1ECP bit (ECC 1-bit Error Correction Permission)

The EC1ECP sets enable or disable to correct the 1-bit error when ECC error detection and correction is valid. By setting 1 to this bit, the non-corrected data is outputted if 1-bit error is detected.

ECERVF bit (ECC Error Judgment Enable Flag)

Setting the ECERVF bit to 1 enables the judgment of error. The correction of output data and the interrupt output depend on setting of the EC1ECP bit, EC2EDIC bit, and EC1EDIC bit.

The write access to this bit is valid when the write value of the EMCA[1:0] is 01b. So only the 16 bits or 32 bits operation command is valid in the case of the write access to this bit.

ECER1C bit (Accumulating ECC Error Detection and Correction Flag Clear)

The ECER1C bit clears the status flag of the ECER1F bit.

The read value is always 0. By writing 0, the internal condition is not changed. When the competition between writing 1 to this bit and setting the ECER1F bit, the former has priority.

The ECER1F bit is cleared by writing 1 to this bit while the ECER1F bit is set. Additionally, the Overflow Detection flag (ECOVFF), ECC Dual Bit Error flag (ECDEDF0) and ECC Single Bit Error flag (ECSEDF0) are also cleared.

ECER2C bit (2-bit ECC Error Detection Flag Clear)

The ECER2C bit clears the status flag of the ECER2F bit.

The read value is always 0. By writing 0, the internal condition is not changed. When the competition between writing 1 to this bit and setting the ECER2F bit, the former has priority.

The ECER2F bit is cleared by writing 1 to this bit while the ECER2F bit is set. Additionally, the Overflow Detection flag (ECOVFF), ECC Dual Bit Error flag (ECDEDF0), and ECC Single Bit Error flag (ECSEDF0) are also cleared.

ECOVFF bit (ECC Overflow Detection Flag)

The ECOVFF bit is set and the overflow interruption is outputted by detecting the new error address under the condition that error address is already captured in the EC710EAD0 register. The overflow interrupt is outputted again when this bit is set and new error is detected.

This bit is read-only, so writing 1 or 0 has no effect.

To clear this bit, write 1 to the ECER2C bit and the ECER1C bit.

[Setting condition]

When new error address is captured under the condition that error address is already captured in the EC710EAD0 register (when not setting ECER2C = 1 or ECER1C = 1).

[Clearing condition]

- Writing ECER2C = 1 or ECER1C = 1
- When ECC error judgement is disabled (ECERVF = 0).

EMCA[1:0] bit (Access Control to ECC Mode Select bit)

The EMCA[1:0] bits are the write trigger reserved bits to the ECERVF bit. The read value is always 0. When the value of these bits is 01b, it is possible to have write access to the ECERVF bit. If these bits are not 01b, write access to the ECERVF bit is ignored and the value is not written.

ECSEDF0 bit (ECC Single bit Error Address Detection Flag)

The ECSEDF0 bit shows that the error is captured in the error address register when error detection is valid. This bit is set by 1-bit error detection.

When 1-bit error is detected after the 2-bit error address is already captured in the EC710EAD0 register, this bit is not updated but the EC710EAD0 register is updated.

This bit is read-only, so writing 1 or 0 has no effect. To clear these bits, write 1 to the ECER1C bit.

[Setting condition]

When there is 1-bit error to RAM output data and error address is captured in EC710EAD0 under the condition that the error judgment is permitted (when not setting ECER1C = 1).

[Clearing condition]

- Writing ECER1C = 1
- When ECC error judgement is disabled (ECERVF = 0).

ECDEDF0 bit (ECC Dual Bit Error Address Detection Flag)

The ECDEDF0 bit shows that the error is captured in the error address register when error detection is valid. This bit is set by 2-bit error detection.

When 2-bit error is detected after the 1-bit error address is already captured in the EC710EAD0 register, this bit is not updated and the EC710EAD0 register is updated.

This bit is read-only, so writing 1 or 0 has no effect. To clear these bits, write 1 to the ECER2C bit.

[Setting condition]

When there is 2-bit error to RAM output data and error address is captured in EC710EAD0 under the condition that the error judgment is permitted (when not setting ECER2C = 1).

[Clearing condition]

- Writing ECER2C = 1
- When ECC error judgement is disabled (ECERVF = 0).

32.2.2 EC710TMC : ECC Test Mode Control Register

Base address: ECCMBn = 0x4036_F200 + 0x0100 × n (n = 0, 1)
ECCMBn_NS = 0x5036_F200 + 0x0100 × n (n = 0, 1)

Offset address: 0x04

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	ETMA[1:0]		—	—	—	—	—	—	ECTMCE	—	—	—	—	—	ECDCS	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	—	This bit is read as 0. The write value should be 0.	R/W
1	ECDCS	ECC Decode Input Select 0: Input lower 32 bits of RAM output data to data area of decode circuit 1: Input ECEDB31-0 in EC710TED register to data area of decode circuit	R/W
6:2	—	These bits are read as 0. The write value should be 0.	R/W
7	ECTMCE	ECC Test Mode Control Enable 0: The access to test mode register and bit is disabled 1: The access to test mode register and bit is enabled	R/W
13:8	—	These bits are read as 0. The write value should be 0.	R/W
15:14	ETMA[1:0]	ECC Test Mode Bit Access Control These bits enable or disable write access to ECTMCE bit.	R/W

Note: S-TYPE-3, P-TYPE-3

ECDCS bit (ECC Decode Input Select)

The ECDCS bit selects either the lower 32 bits data value from RAM or value from the internal test register (EDEDB[31:0] in EC710TED) as input signal to decoder.

The write access to this bit is valid under the condition of ECTMCE = 1 (it is possible to set them at the same time.)

This bit is cleared by setting ECTMCE = 0.

ECTMCE bit (ECC Test Mode Control Enable)

The ECTMCE bit selects the access enable or disable to test register and test control bit.

The write access to this bit is valid under the condition that the value of the ETMA[1:0] bits is 10b.

ETMA[1:0] bits (ECC Test Mode Bit Access Control)

The ETMA[1:0] bits are the write trigger reserved bits to the ECTMCE bit. The read value is always 0. When the value of these bits is 10b, it is possible to have write access to the ECTMCE bit. If these bits are not 10b, the write access to the ECTMCE bit is ignored and the value is not written.

32.2.3 EC710TED : ECC Test Substitute Data Register

Base address: ECCMBn = 0x4036_F200 + 0x0100 × n (n = 0, 1)
ECCMBn_NS = 0x5036_F200 + 0x0100 × n (n = 0, 1)

Offset address: 0x0C

Bit position:	31																												0
Bit field:	ECEDB[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	ECEDB[31:0]	ECC Test Substitute Data Substitute data in ECC test mode.	R/W

Note: S-TYPE-3, P-TYPE-3

This register is for the 32 bits data for ECC decode. It is possible to read and write using 32 bits operation command when ECTMCE = 1. When ECTMCE = 0, all bits are always 0.

ECEDB[31:0] bits (ECC Test Substitute Data)

When ECDCS in EC710TMC register is 1, the value of this register is bits [31:0] of the input data to the decode circuit.

32.2.4 EC710EAD0 : ECC Error Address Register

Base address: ECCMBn = 0x4036_F200 + 0x0100 × n (n = 0, 1)
ECCMBn_NS = 0x5036_F200 + 0x0100 × n (n = 0, 1)

Offset address: 0x10

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	ECEAD[9:0]									
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
9:0	ECEAD[9:0]	ECC Error Address	R

Bit	Symbol	Function	R/W
31:10	—	These bits are read as 0.	R

Note: S-TYPE-3, P-TYPE-3

This is a read-only register to hold the ECC error address.

ECEAD[9:0] bits (ECC Error Address)

When ECC error is detected for permitting ECC error judgment, RAM address is captured by the detected signal as a trigger and is hold as the error occurring address. The error address is not captured when the error occurred again to the one held by the same factor.

If 2-bit error occurred under the condition that 1-bit error address is already captured, the 2-bit error address is over-written and the ECDEDF0 bit is set to 1.

If 1-bit error occurred under the condition that 2-bit error address is already captured, the 1-bit error address is not overwritten and the ECSEDF0 bit is not set to 1.

32.3 Operation

32.3.1 ECC Function Setting

Figure 32.1 shows a procedure for ECC function setting.

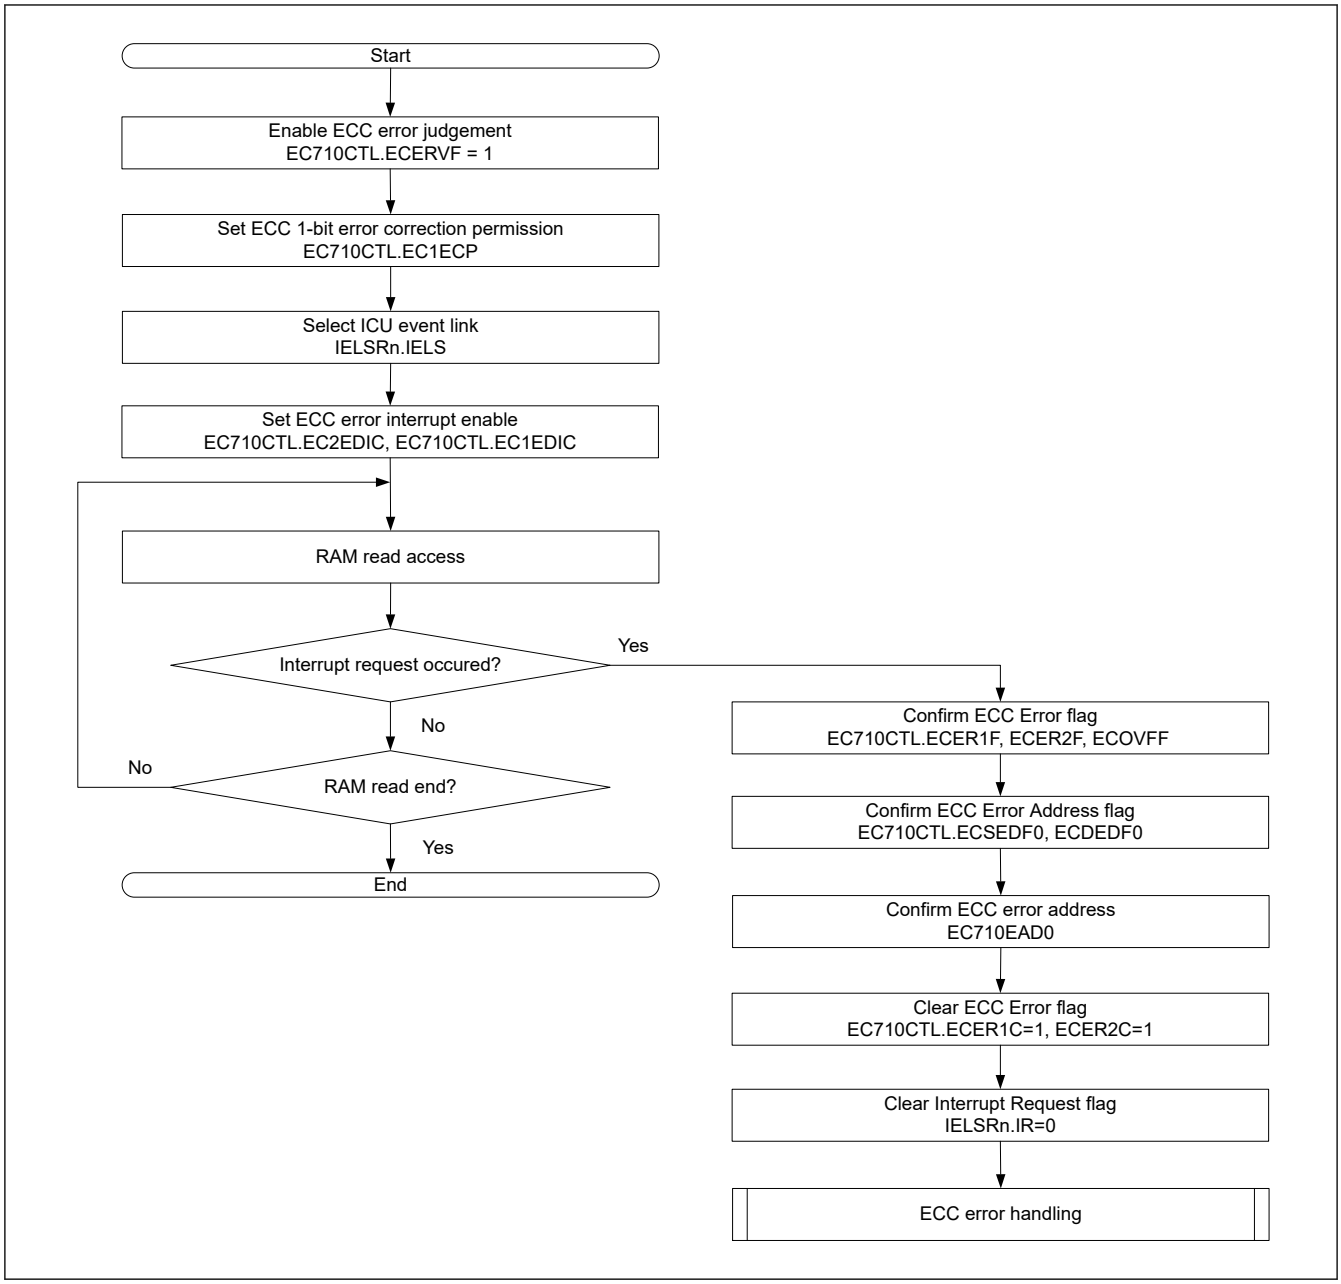

Figure 32.1 Setting procedure for ECC function

32.3.2 ECC Decoder Testing

ECC interrupts can be intentionally generated by ECC test mode. Figure 32.2 shows a procedure for ECC decoder testing.

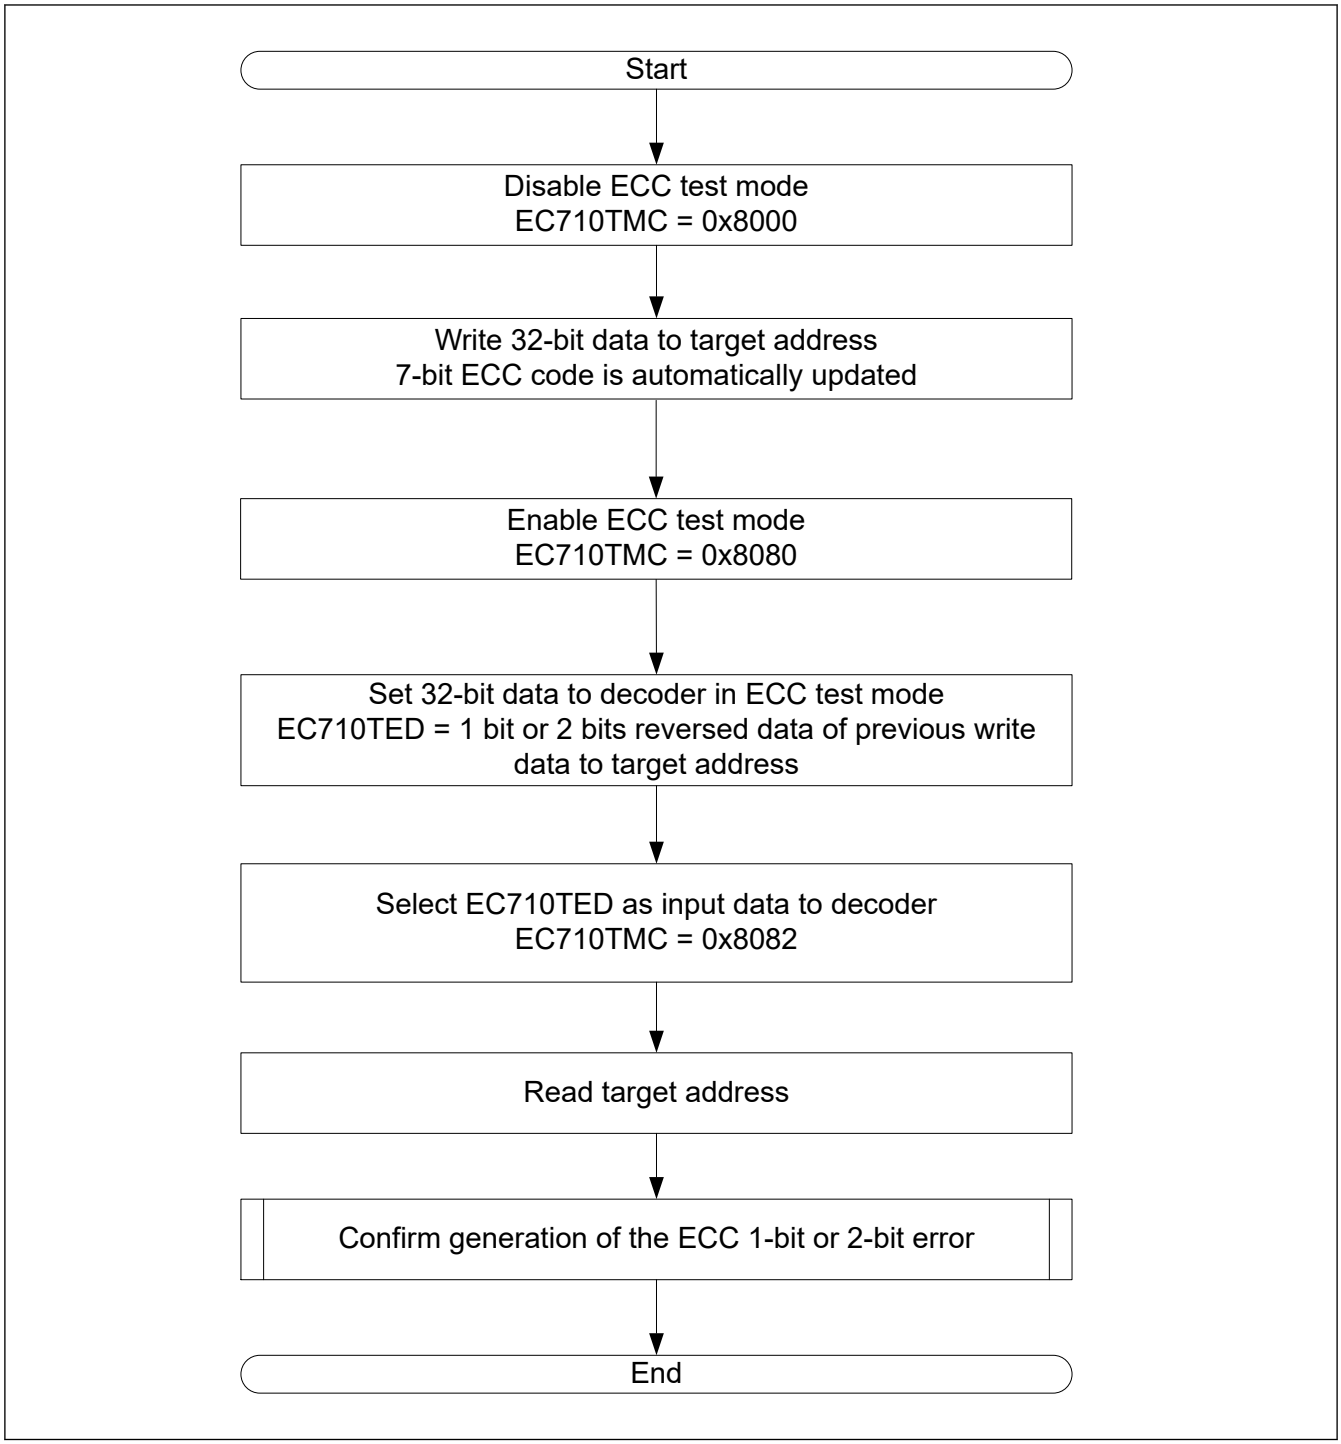

Figure 32.2 Testing procedure for ECC decoder

32.4 Interrupts

The ECC module issues three interrupt requests:

- CANn_MRAM_ERI (n = 0, 1)

Interrupt sources of each interrupt request include:

- 1-bit ECC error
- 2-bit ECC error
- ECC error overflow.

33. Serial Peripheral Interface (SPI)

This is the SPI_B version of the SPI peripheral module.

SPI_B is referred to as SPI in this chapter.

33.1 Overview

The Serial Peripheral Interface (SPI) has 2 channels. The SPI provides high-speed full-duplex synchronous serial communications with multiple processors and peripheral devices. Table 33.1 lists the SPI specifications, Figure 33.1 shows a block diagram of SPI, Figure 33.2 shows a clock source selector block diagram and Table 33.2 lists the I/O pins.

In this section, PCLK refers to PCLKA.

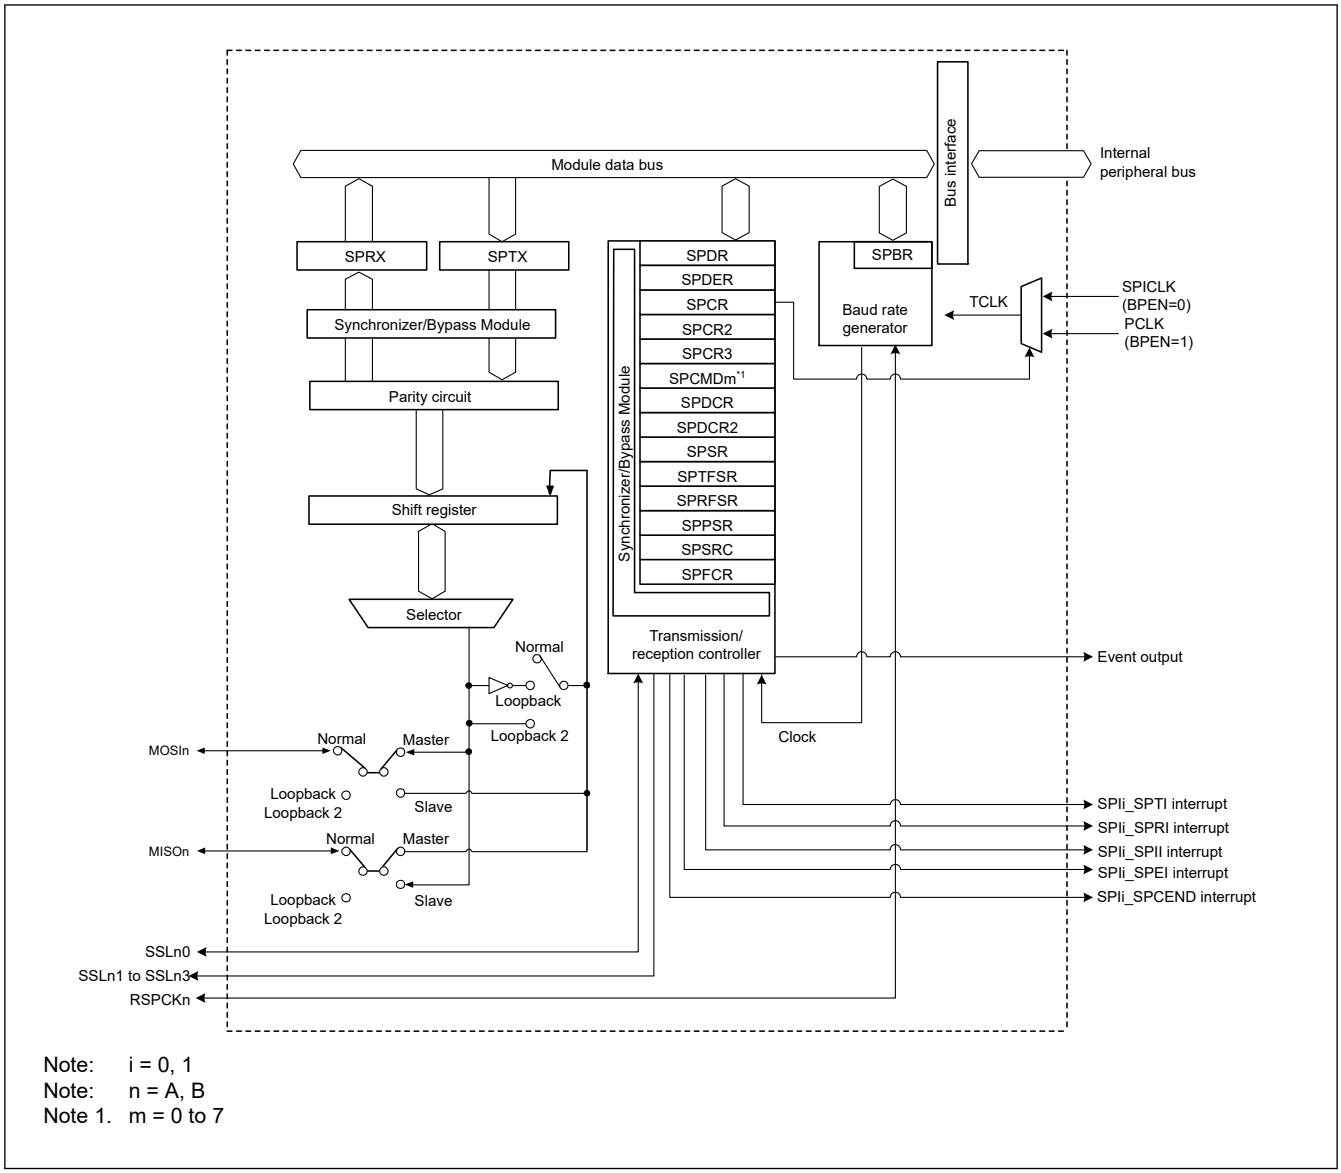
Table 33.1 SPI specifications (1 of 2)

Parameter	Specifications
Number of channels	Two channels
SPI transfer functions	• Use of MOSI (master out/slave in), MISO (master in/slave out), SSL (slave select), and RSPCK (SPI clock) signals allows serial communications through SPI operation (4-wire method) or clock synchronous operation (3-wire method) • Transmit-only operation available • Receive-only operation is available • Communication mode selectable to full-duplex, transmit-only or receive-only • RSPCK polarity switching • RSPCK phase switching
Data format	• MSB-first or LSB-first selectable • Transfer bit length selectable from 4 to 32 bits • 32 bit × 4 stages FIFO is available as transmit buffer or receive buffer • Byte swap operating function • Transmit/receive data can be inverted.
Operation clock (TCLK)	Synchronized clock (PCLK) or independent clock (SPICLK) can be selected.
Bit rate	• In master mode, the on-chip baud rate generator generates RSPCK by frequency-dividing TCLK (the division ratio ranges from divided by 2 to divided by 4096) • In slave mode, the minimum TCLK clock divided by 2 can be input as RSPCK (TCLK divided by 2 is the maximum RSPCK frequency) Width at high level: 1 TCLK cycle; width at low level: 1 TCLK cycle
Buffer configuration	• Double buffer configuration for the transmit and receive buffers
Error detection	• Mode fault error detection • Underrun error detection • Overrun error detection*1 • Parity error detection • Receive data ready detection
SSL control function	[motorola SPI mode/TI SSP mode common] • Four SSL pins (SSLni: SSLn0 to SSLn3) (n = A, B) for each channel • In single-master mode, SSLn0 to SSLn3 pins are output • In multi-master mode, SSLn0 pin for input, and SSLn1 to SSLn3 pins either for output or unused • In slave mode, SSLn0 pin for input and SSLn1 to SSLn3 pins unused • Controllable wait for next-access SSL output assertion (next-access delay) Range: 1 to 8 RSPCK cycles (set in RSPCK-cycle units) • Function for changing SSL polarity • Delay between frames in burst transfer is settable [only Motorola mode] • Controllable delay from RSPCK stop to SSL output negation (SSL negation delay) Range: 1 to 8 RSPCK cycles (set in RSPCK-cycle units) • Controllable delay from SSL output assertion to RSPCK operation (RSPCK delay) Range: 1 to 8 RSPCK cycles (set in RSPCK-cycle units) [only TI SSP mode] • Controllable delay from RSPCK stop to SSL output negation (SSL negation delay) Range: 0 to 8 RSPCK cycles (set in RSPCK-cycle units) • Controllable delay from OE output assertion to RSPCK operation (RSPCK delay) Range: 1 to 8 RSPCK cycles (set in RSPCK-cycle units)
Communication protocol	• Motorola SPI • TI SSP(Synchronous Serial Protocol)

Table 33.1 SPI specifications (2 of 2)

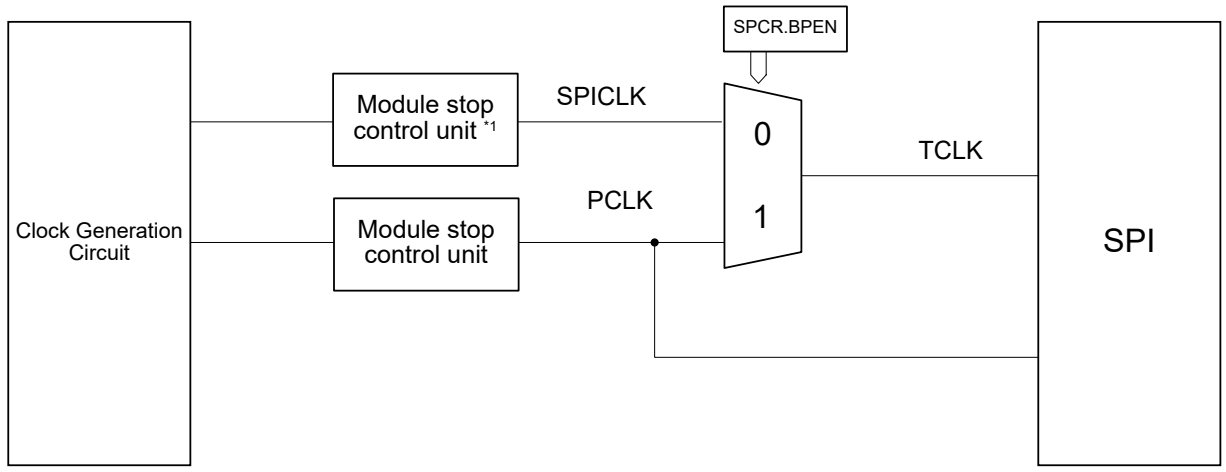
Parameter	Specifications
Synchronization bypass function	Synchronization circuit can be bypassed only when the same clock is input to bus clock (PCLK) and operation clock (TCLK).
Control in master transfer	● Transfers of up to eight commands each can be executed sequentially in looped execution ● For each command, the following can be set: SSL signal value, bit rate, RSPCK polarity and phase, transfer data length, MSB- or LSB-first, burst, RSPCK delay, SSL negation delay, and next-access delay ● Transfers can be initiated by writing to the transmit buffer ● MOSI signal value specifiable in SSL negation ● RSPCK auto-stop function
Interrupt sources	Interrupt sources: ● Receive buffer full / Receive data ready interrupt ● Transmit buffer empty interrupt ● SPI error interrupt (mode fault error, under run error, over run error, parity error, receive data ready) ● SPI idle interrupt (SPI idle) ● Communication end interrupt
Event link function	The following events can be output to the Event Link Controller (ELC): ● Receive buffer full / receive data ready signal ● Transmit buffer empty signal ● Mode fault, underrun, overrun, parity error, or receive data ready signal ● SPI idle signal ● Communication end signal
Other functions	● Switching between CMOS output and open-drain output ● SPI initialization function ● Loopback mode ● SPE bit status polling function
Module-stop function	Module-stop state can be set for each channels to reduce power consumption.
TrustZone Filter	Security and Privilege attribution can be set for each channels.

Note 1. In master reception and when the RSPCK auto-stop function is enabled, an overrun error does not occur because the transfer clock is stopped on overrun error detection.



Note: i = 0, 1
Note: n = A, B
Note 1. m = 0 to 7

Figure 33.1 SPI block diagram



Note 1. If the module-stop state of any SPI channel is canceled, SPICLK is supplied.

Figure 33.2 Clock source selector block diagram

The SPI automatically switches the I/O direction of the SSLn0 pin. SSLn0 is set as an output when the SPI is a single master, and as an input when the SPI is a multi-master or a slave. The RSPCKn, MOSIn, and MISOn pins are automatically set as inputs or outputs based on the master or slave setting and the level input on the SSLn0 pin. For details, see section 33.3.2. Controlling the SPI Pins.

Table 33.2 SPI I/O pins

Channel	Pin name	I/O	Description
SPI0	RSPCKA	I/O	Clock input/output pin
	SSLA0	I/O	Slave selection input/output
	SSLA1 to SSLA3	Output	Slave selection output
	MOSIA	I/O	Master transmit data input/output
	MISOA	I/O	Slave transmit data input/output
SPI1	RSPCKB	I/O	Clock input/output pin
	SSLB0	I/O	Slave selection input/output
	SSLB1 to SSLB3	Output	Slave selection output
	MOSIB	I/O	Master transmit data input/output
	MISOB	I/O	Slave transmit data input/output

Note: Pin names are indicated as “...A” or “...An” for SPI0, and “...B” or “...Bn” for SPI1 (n = 0, 1, 2, or 3).

33.2 Register Descriptions

33.2.1 SPDR : SPI Data Register

Base address: SPIn_B = 0x4035_C000 + 0x0100 × n (n = 0, 1)
SPIn_B_NS = 0x5035_C000 + 0x0100 × n (n = 0, 1)

Offset address: 0x00

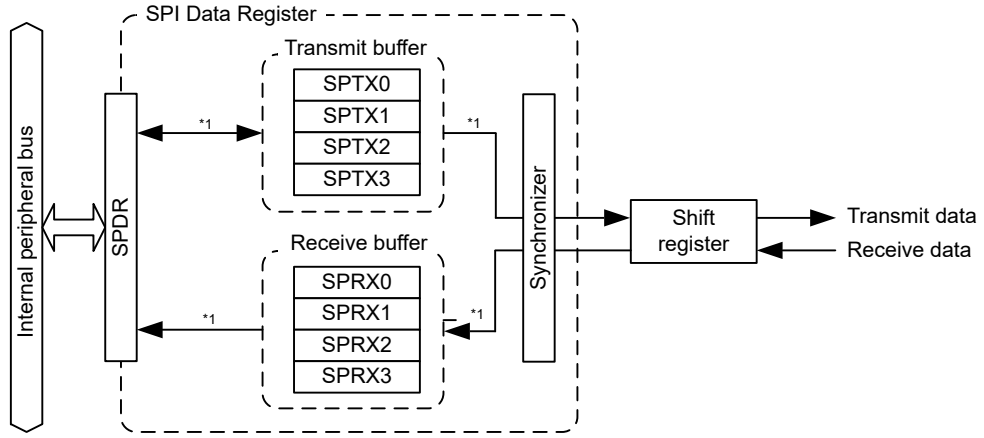
Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	SPD[31:16]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	SPD[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	SPD[31:0]	These bits are the interface with the buffers that hold data for transmission and reception by the SPI.	R/W

Note: S-TYPE-3, P-TYPE-3

SPDR is the interface with the buffers that hold data for transmission and reception by the SPI. When accessing this register in words, access SPDR. The transmit buffer (SPTX) and receive buffer (SPRX) are independent but both are mapped to SPDR. Figure 33.3 shows the configuration of the SPDR register.



Note 1. The destination buffer and stage for access is automatically switched by hardware.

Figure 33.3 Structure of SPDR

32 bits × 4 stage transmit FIFO and 32 bits × 4 stage receive FIFO are provided. These 8 stage FIFO are mapped to one address in the SPDR. Transmit buffers (SPTXn, n = 0 to 3) can be written by writing data to SPDR to transmit written data.

Upon completion of receiving data, receive buffers store received data. When an overrun error occurs, data in the receive buffer is not updated.

(1) Bus Interface

The SPI data register has 32 bits × 4 stage transmit FIFO and 32 bits × 4 stage receive FIFO (32 bytes in total). These 32 bytes are mapped to the 4-byte space of SPDR. Write transmit data from the LSB. Received data is stored from the LSB.

SPDR register write operation and read operation are described below.

1. Write

A transmit buffer write pointer is provided for transmit buffers. When data is written to SPDR, the pointer automatically switches to the next buffer. The following illustrates the structure of the transmit buffer bus interface (write).

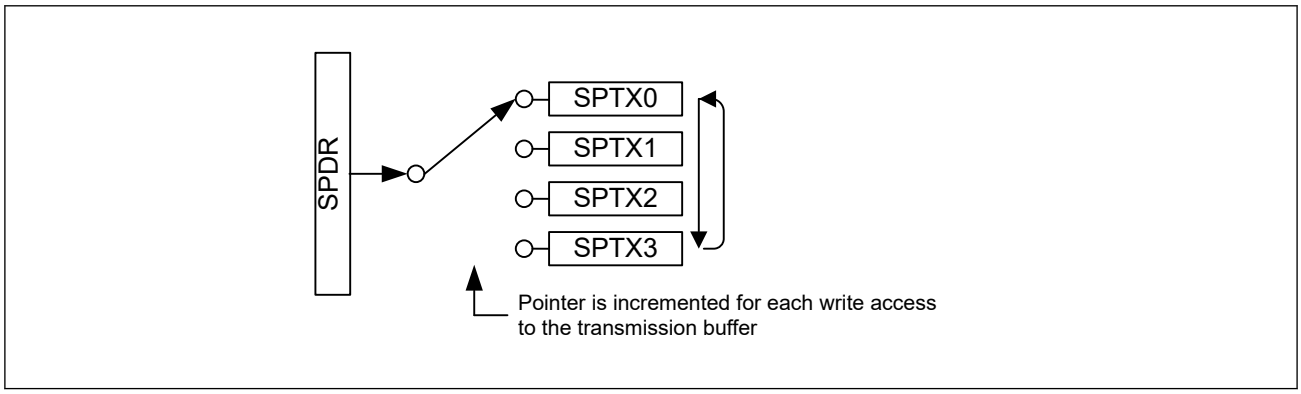


Figure 33.4 Structure of SPDR (Write)

The transmit buffer (SPTX0 to SPTX3) switching order:
SPTX0→SPTX1→SPTX2→SPTX3→SPTX0→SPTX1→…
When writing transmit data to transmit buffers (SPTXn), write transmit data of frames +1 specified by the Transmission FIFO threshold setting bits of SPI data control register 2 (SPDCR2.TTRG[1:0]) while an SPI transmit buffer empty interrupt is present (SPSR.SPTEF flag = 1). Writing to the transmit buffer (SPTXn, n = 0 to 3) in the state where there is no empty stage in the transmit FIFO does not update the buffer value.

2. Read

Values can be read from receive buffers (SPRXn, n = 0 to 3) or transmit buffers (SPTXn, n = 0 to 3) by reading the SPDR register. Reading a receive buffer or reading a transmit buffer can be selected by the SPI receive data or transmit data select bit (SPDCR.SPRDTD) in the SPI data control register.
The SPDR register is read according to the independent receive buffer read pointer and the transmit buffer read pointer. The following illustrates the structure of the receive buffer and transmit buffer bus interface (read).

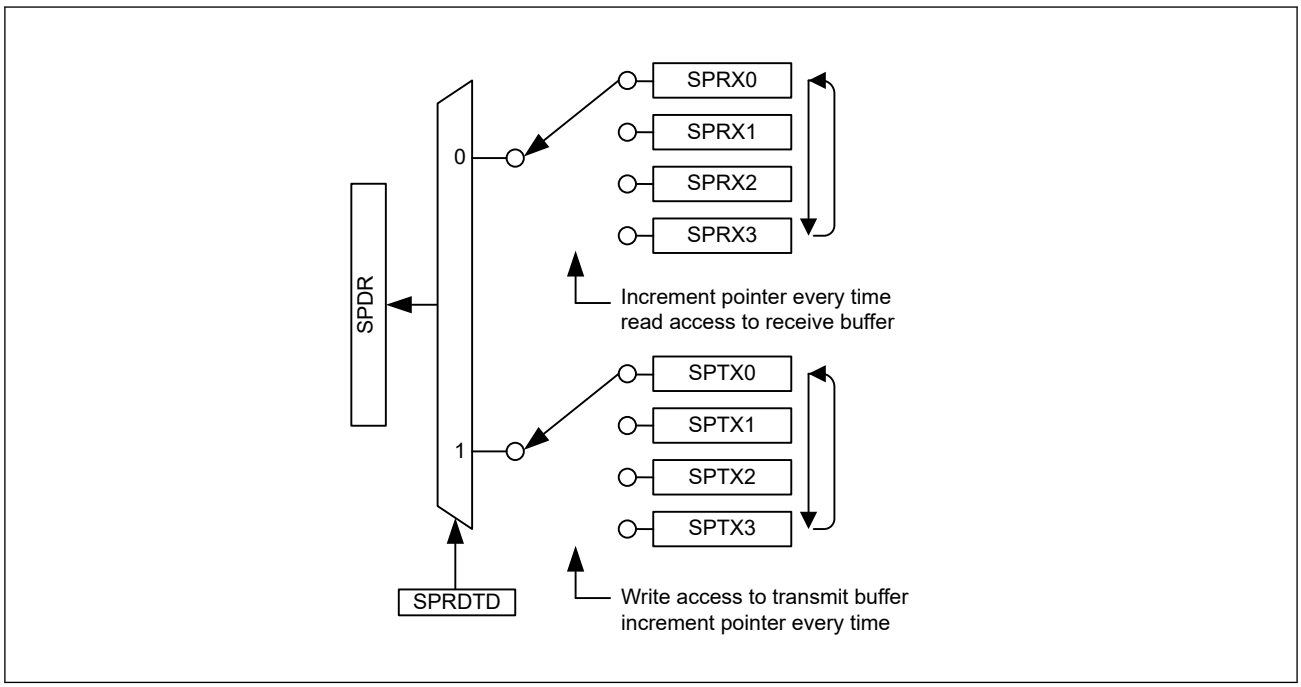

Figure 33.5 Structure of SPDR (Read)

When a receive buffer is read, the receive buffer read pointer automatically switches to the next buffer. The receive buffer read pointer switches in the same order as the transmit buffer write pointer.
The transmit buffer read pointer is updated during the SPDR write access, but it is not updated during the transmit buffer read access. When a transmit buffer is read, the value written to SPDR last can be read.

33.2.2 SPDECR : SPI Delay Control Register

Base address: SPIn_B = 0x4035_C000 + 0x0100 × n (n = 0, 1)
SPIn_B_NS = 0x5035_C000 + 0x0100 × n (n = 0, 1)

Offset address: 0x04

31:19	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

SCKDL[2:0] bit (RSPCK Delay)

[In the Motorola-SPI case]

The RSPCK delay bits (SCKDL) are used to set the period (RSPCK delay) from SSL signal assertion start until RSPCK oscillates while the SCKDEN bit in the SPI command register (SPCMD) is 1. If SCKDL is modified while the MSTR bit and the SPE bit in the SPI control register (SPCR) are 1, subsequent operation is not guaranteed.

To use the SPI in slave mode, set SCKDL[2:0] bits to 000b.

[In the TI-SSP case]

The RSPCK delay bits (SCKDL) are used to set the period (RSPCK delay) from SSL signal assertion start until RSPCK oscillates while the SCKDEN bit in the SPI command register (SPCMD) is 1. Also that is used to set the period until the SSL signal is negated. If SCKDL is modified while the MSTR bit and the SPE bit in the SPI control register (SPCR) are 1, subsequent operation is not guaranteed.

To use the SPI in slave mode, set SCKDL[2:0] bits to 000b.

SLNDL[2:0] bit (SSL Negation Delay)

[In the Motorola-SPI case]

The SSL negation delay bits (SLNDL) are used to set the period (SSL negation delay) after the SPI in master mode sends the final RSPCK edge during serial transfer until it negates the SSL signal while the SLNDEN bit in the SPI command register (SPCMD) is 1. If SLNDL is modified while the MSTR bit and the SPE bit in the SPI control register (SPCR) are 1, subsequent operation is not guaranteed.

To use the SPI in slave mode except TI-SSP, set SLNDL[2:0] bits to 000b.

[In the TI-SSP case]

The SSL negation delay bits (SLNDL) are used to set the period (OE negation delay) after the SPI in master mode sends the final RSPCK edge during serial transfer until it negates the OE signal while the SLNDEN bit in the SPI command register (SPCMD) is 1. Also, that is used to set the period from when the SPI in slave mode detects the last RSPCK edge of serial transfer to when the OE signal is negated. If SLNDL is modified while the SPE bit in the SPI control register (SPCR) are 1, subsequent operation is not guaranteed.

SPNDL[2:0] bit (SPI Next-Access Delay)

The SPI next-access delay register (SPDECR.SPNDL) is used to set the SSL signal inactive period (next-access delay) after completion of serial transfer while the SPNDEN bit in the SPI command register (SPCMD) is 1. If SPNDL is modified while the MSTR bit and the SPE bit in the SPI control register (SPCR) are 1, subsequent operation is not guaranteed.

These bits are used to set the next-access delay value when the SPNDEN bit in SPCMD is 1. To use the SPI in slave mode, set SPNDL[2:0] bits to 000b.

33.2.3 SPCR : SPI Control Register

Base address: SPIn_B = 0x4035_C000 + 0x0100 × n (n = 0, 1)
SPIn_B_NS = 0x5035_C000 + 0x0100 × n (n = 0, 1)

Offset address: 0x08

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	BPEN	MSTR	TXMD[1:0]		—	—	SPFRF	SPMS	—	—	CENDIE	SPTIE	SPDRES	SPIIE	SPRIE	SPEIE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit field:	—	MODFEN	BFDS	SCKASE	PTE	—	SPOE	SPPE	—	—	—	—	—	—	—	SPE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	SPE	SPI Function Enable 0: SPI function is disabled. 1: SPI function is enabled.	R/W
7:1	—	These bits are read as 0. The write value should be 0.	R/W
8	SPPE	Parity Enable 0: A parity bit is not added to transmit data. Received-data parity check is not performed. 1: A parity bit is added to transmit data. Received-data parity check is performed.	R/W
9	SPOE	Parity Mode 0: Even parity is used for transmission and reception. 1: Odd parity is used for transmission and reception.	R/W
10	—	This bit is read as 0. The write value should be 0.	R/W
11	PTE	Parity Self-Diagnosis Enable 0: Parity circuit self-diagnosis function is disabled. 1: Parity circuit self-diagnosis function is enabled.	R/W
12	SCKASE	RSPCK Auto-Stop Function Enable 0: RSPCK auto-stop function is disabled. 1: RSPCK auto-stop function is enabled.	R/W
13	BFDS	Between Burst Transfer Frames Delay Select 0: Delay (RSPCK delay, SSL negation delay and next-access delay) between frames is inserted in burst transfer 1: Delay between frames is not inserted in burst transfer.	R/W
14	MODFEN	Mode Fault Error Detection Enable 0: Mode fault error detection is disabled. 1: Mode fault error detection is enabled.	R/W
15	—	This bit is read as 0. The write value should be 0.	R/W
16	SPEIE	SPI Error Interrupt Enable 0: SPI error interrupt request is disabled. 1: SPI error interrupt request is enabled.	R/W
17	SPRIE	SPI Receive Buffer Full Interrupt Enable 0: SPI receive buffer full interrupt request is disabled. 1: SPI receive buffer full interrupt request is enabled.	R/W
18	SPIIE	SPI Idle Interrupt Enable 0: Idle interrupt request is disabled. 1: Idle interrupt request is enabled.	R/W
19	SPDRES	SPI receive data ready error select Select the interrupt request to be generated when the reception data ready is detected 0: Receive data full interrupt 1: Error interrupt	R/W
20	SPTIE	SPI Transmit Buffer Empty Interrupt Enable 0: SPI transmit buffer empty interrupt request is disabled. 1: SPI transmit buffer empty interrupt request is enabled.	R/W
21	CENDIE	SPI Communication End Interrupt Enable 0: Communication end interrupt request is disabled. 1: Communication end interrupt request is enabled.	R/W
23:22	—	These bits are read as 0. The write value should be 0.	R/W
24	SPMS	SPI Mode Select 0: SPI operation (4-wire) 1: Clock synchronous operation (3-wire)	R/W
25	SPFRF	SPI Frame Format Select 0: Motorola-SPI 1: TI-SSP Note: When SPMS = 1 (clock synchronous operation (3-wire)), this bit setting is invalid.	R/W

Bit	Symbol	Function	R/W
27:26	—	These bits are read as 0. The write value should be 0.	R/W
29:28	TXMD[1:0]	Communication Mode Select 0 0: Transmit-Receive 0 1: Transmit only Others: Receive only	R/W
30	MSTR	SPI Master/Slave Mode Select 0: Slave mode 1: Master mode	R/W
31	BPEN	Synchronization Circuit Bypass Enable 0: Non-Bypass 1: Bypass	R/W

Note: S-TYPE-3, P-TYPE-3

The SPI control register (SPCR) is used to set operating mode of the SPI. If the set BPEN, MSTR, TXMD[1:0], SPFRF, SPMS, MODFEN, BFDS, SCKASE, PTE, SPOE, SPPE bit value is modified while the SPE bit = 1, subsequent operation is not guaranteed.

SPE bit (SPI Function Enable)

This bit is used to enable or disable SPI functions. Setting this bit to 1 enables SPI functions. When the MODF flag in the SPI status register (SPSR) is 1, the SPE bit is cleared to 0 and the SPE bit cannot be set to 1 until the MODF flag is cleared to 0. (See section 33.3.10. Error Detection) Setting the SPE bit to 0 disables SPI functions and initializes a part of module functions. (See section 33.3.11. Initializing the SPI)

SPPE bit (Parity Enable)

This bit is used to enable or disable the parity function.

SPOE bit (Parity Mode)

This bit is used to specify even parity or odd parity.

In even parity mode, the parity bit is determined so that the sum of 1 (parity bit + transmit characters or receive characters) becomes an even number. In the same way, in odd parity mode, a parity bit is determined so that the sum of 1 (parity bit + transmit characters or receive characters) becomes an odd number. The SPOE bit is valid only when the SPPE bit in SPCR is set to 1.

PTE bit (Parity Self-Diagnosis Enable)

This bit is used to enable or disable self-diagnosis of the parity circuit to confirm that the parity function is normal.

SCKASE bit (RSPCK Auto-Stop Function Enable)

This bit is used to enable or disable the RSPCK auto-stop function. When this function is enabled, the RSPCK clock stops immediately before an overrun error occurs during data reception in master mode. For details, see section 33.3.10.1. Overrun errors.

BFDS bit (Between Burst Transfer Frames Delay Select)

This bit controls whether insert the delay time between the burst transfer frames.

Valid in the master mode (SPCR.MSTR = 1) for frames with the SPCMDn.SSLKP bit set to 1.

This bit should be set to 0 in slave mode. The usage of SSL delay control between transfer frames is shown as below. For details, see section 33.3.12.1. Master mode operation.

1. Non-burst transmits
2. Burst transmit with delay between frames
   2-1. From the 1st frame to the last previous frame
   2-2. The last frame
3. Burst transmit with no delay between frames
   3-1. From the 1st frame to the last previous frame

3-2. The last frame

Table 33.3 Usage of SSL delay control between transfer frames (Master mode)

	SPCMDn. SSLKP bit	SPCR.BFDS bit	SSL delay control register*1 (RSPCK clock delay, SSL negation delay, next access delay)
1	0	0	Any given value. You can control each delay value according to setting for RSPCK clock delay, SSL negation delay and next access delay
2-1	1	0	
2-1	0	0	
3-1	1	1	Any given value. But delay is inserted only below. ● RSPCK clock delay of the 1st frame ● SSL negation delay and next access delay of the last frame
3-2	0	1	

Note 1. Whether the setting value of following bits are valid or not depends on the setting value of the SPCMD.SPNDEN bit. (See section 33.2.6. SPCMDm : SPI Command Register (m = 0 to 7).)
The SPDECR.SCKDL[2:0] bits: RSPCK delay
The SPDECR.SLNDL[2:0] bits: SSL negate delay
The SPDECR.SPNDL[2:0] bits: Next access delay

< Setting / operation example > (Motorola SPI, BFDS = 1 Case)

SPCMD0.SSLKP = 1 → Burst transfer / no interframe delay between 0 and 1 (SSL keep active)

SPCMD1.SSLKP = 1 → Burst transfer / no interframe delay between 1 and 2 (SSL keep active)

SPCMD2.SSLKP = 1 → Burst transfer / no interframe delay between 2 and 3 (SSL keep active))

SPCMD3.SSLKP = 1 → Burst transfer / no interframe delay between 3 and 4 (SSL keep active)

SPCMD4.SSLKP = 0 → do not Burst Transfer, and inactive SSL. (BFDS setting is invalid because it does not Burst Transfer.)

SPCMD5.SSLKP = 1 → Burst transfer / no interframe delay between 5 and 6 (SSL keep active)

SPCMD6.SSLKP = 1 → Burst transfer / no interframe delay between 6 and 7 (SSL keep active)

SPCMD7.SSLKP = 0 → do not Burst Transfer, and inactive SSL. (BFDS setting is invalid because it does not Burst Transfer.)

MODFEN bit (Mode Fault Error Detection Enable)

This bit is used to enable or disable detection of a mode fault error. (See section 33.3.10. Error Detection.) The SPI determines SSL0 pin input or output direction according to the combination of the MODFEN and MSTR bits. (See section 33.3.2. Controlling the SPI Pins.)

SPEIE bit (SPI Error Interrupt Enable)

This bit is used to enable or disable an SPI error interrupt request when the SPI detects a mode fault error or an underrun error and sets the MODF flag in the SPI status register (SPSR) to 1, when the SPI detects an overrun error and sets the OVRF flag in SPSR to 1, or when the SPI detects a parity error and sets the PERF flag in SPSR to 1. (See section 33.3.10. Error Detection)

SPRIE bit (SPI Receive Buffer Full Interrupt Enable)

This bit is used to enable or disable a receive buffer full interrupt request of the SPI.

SPIIE bit (SPI Idle Interrupt Enable)

This bit is used to enable or disable an idle interrupt request of the SPI after the SPI detects the idle state and sets the IDLNF flag in the SPI status register (SPSR) to 0.

SPDRES bit (SPI receive data ready error select)

When a receive data ready is detected (SPSR.SPDRF = 1), select whether to use SPIi_SPRI (i = 0, 1) interrupt request or SPIi_SPEI (i = 0, 1) interrupt request.

SPTIE bit (SPI Transmit Buffer Empty Interrupt Enable)

This bit is used to enable or disable a transmit buffer empty interrupt request of the SPI.

A transmit buffer empty interrupt request at the beginning of transmission is generated by setting the SPE bit to 1 simultaneously when or after the SPTIE bit is set to 1. Note that a transmit buffer empty interrupt is generated while the SPTIE bit is 1 even though SPI functions are disabled (SPE bit = 0).

CENDIE bit (SPI Communication End Interrupt Enable)

This bit controls generation of a communication end interrupt request.

SPMS bit (SPI Mode Select)

This bit is used to select SPI operation (4-wire) or clock synchronous operation (3-wire).

For clock synchronous operation, the SSL pin is not used but three pins RSPCK, MOSI, and MISO are used for communication. When SPMS = 1 (clock synchronous operation (3-wire)), the setting of the SPFRF bit is invalid.

To perform clock synchronous operation in master mode (SPCR.MSTR = 1), set the CPHA bit in the SPI command register (SPCMD) to 0 or 1. To perform clock synchronous operation in slave mode (SPCR.MSTR = 0), set the CPHA bit to 1. If this bit is set to 0 for clock synchronous operation in slave mode (SPCR.MSTR = 0), subsequent operation is not guaranteed.

The communication status according to the settings of the MSTR bit, TXMD[1:0] bits, SPFRF bit, and SPMS bit of the SPI control register (SPCR) as follows.

Table 33.4 SPI Communication Status

SPCR.MSTR	SPCR.TXMD[1]	SPCR.TXMD[0]	SPCR.SPFRF	SPCR.SPMS	Communication Status	Communication Status No
1	0	0	0	0	Transmit-Receive Master / Motorola SPI / SPI operation (4-wire)	1-(1)
1	0	0	1	0	Transmit-Receive Master / TI-SSP / SPI operation (4-wire)	1-(2)
1	0	0	—	1	Transmit-Receive Master /Clock synchronous operation (3-wire)	1-(3)
1	0	1	0	0	Transmit only Master / Motorola SPI / SPI operation (4-wire)	1-(4)
1	0	1	1	0	Transmit only Master / TI-SSP / SPI operation (4-wire)	1-(5)
1	0	1	—	1	Transmit only Master /Clock synchronous operation (3-wire)	1-(6)
1	1	—	0	0	Receive only Master / Motorola SPI / SPI operation (4-wire)	1-(7)
1	1	—	1	0	Receive only Master / TI-SSP / SPI operation (4-wire)	1-(8)
1	1	—	—	1	Receive only Master /Clock synchronous operation (3-wire)	1-(9)
0	0	0	0	0	Transmit-Receive Slave / Motorola SPI / SPI operation (4-wire) (default)	0-(1)
0	0	0	1	0	Transmit-Receive Slave / TI-SSP / SPI operation (4-wire)	0-(2)
0	0	0	—	1	Transmit-Receive Slave /Clock synchronous operation (3-wire)	0-(3)
0	0	1	0	0	Transmit only Slave / Motorola SPI / SPI operation (4-wire)	0-(4)
0	0	1	1	0	Transmit only Slave / TI-SSP / SPI operation (4-wire)	0-(5)
0	0	1	—	1	Transmit only Slave /Clock synchronous operation (3-wire)	0-(6)
0	1	—	0	0	Receive only Slave / Motorola SPI / SPI operation (4-wire)	0-(7)
0	1	—	1	0	Receive only Slave / TI-SSP / SPI operation (4-wire)	0-(8)
0	1	—	—	1	Receive only Slave /Clock synchronous operation (3-wire)	0-(9)

SPFRF bit (SPI Frame Format Select)

This bit selects the communication protocol.

The format of the SPI terminal (RSPCK, SSL0 to 7) can be set according to the set communication protocol.

When SPMS = 1 (clock synchronous operation (3-wire)), this bit is invalid because SSL is not used.

TXMD[1:0] bit (Communication Mode Select)

This bit is used to select the transmit-receive, transmit-only, and receive-only serial communication.

When TXMD[1:0] is set to 01 for communication, transmit-only is performed without reception.

When TXMD[1] is set to 1 for communication, receive-only is performed without transmission.

When TXMD[1:0] is set to 01 for communication, a receive buffer full interrupt request cannot be used.

When TXMD[1] is set to 1 for communication, a transmit buffer empty interrupt request cannot be used.

(See section 33.3.6. Communication Operating Mode.)

MSTR bit (SPI Master/Slave Mode Select)

This bit is used to select master mode or slave mode of the SPI. The SPI determines input/output directions of pins RSPCK, MOSI, MISO, and SSL1 to SSL3 according to the MSTR bit setting.

BPEN bit (Synchronization Circuit Bypass Enable)

This bit selects whether to enable or disable the synchronization bypass function. Set this bit to 1 when the bus clock (PCLK) is also used as operation clock (TCLK), see Figure 33.2.

33.2.4 SPCR2 : SPI Control Register 2

Base address: SPIn_B = 0x4035_C000 + 0x0100 × n (n = 0, 1)
SPIn_B_NS = 0x5035_C000 + 0x0100 × n (n = 0, 1)

Offset address: 0x0C

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	MOIFE	MOIFV	—	—	SPLP2	SPLP
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit field:	SPDRC[7:0]								RMSTTG	RMEDTG	—	RMFM[4:0]				
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
4:0	RMFM[4:0]	Frame processing count setting in Master Receive only The number of received frames can be adjusted in master receive only. 0x00: This function is not used*1 0x01: Automatically stop communication after processing 1 received frame ⋮ 0x1F: Automatically stop communication after processing 31 received frames	R/W
5	—	This bit is read as 0. The write value should be 0.	R/W
6	RMEDTG	End Trigger in Master Receive only 1: Receive End (Writable only when Master Receive only) Reading value is always 0	W
7	RMSTTG	Start Trigger in Master Receive only 1: Receive Start (Writable only when Master Receive only) Reading value is always 0	W
15:8	SPDRC[7:0]	SPI received data ready detect adjustment 0x00: Disable receive data ready detection function 0x01: Performs reception data ready judgment after 1 TCLK ⋮ 0xFF: Performs reception data ready judgment after 255 TCLK	R/W
16	SPLP	SPI Loopback 0: Normal mode 1: Loopback mode (inverted transmit data = receive data)	R/W
17	SPLP2	SPI Loopback 2 0: Normal mode 1: Loopback mode (transmit data = receive data)	R/W

Bit	Symbol	Function	R/W
19:18	—	These bits are read as 0. The write value should be 0.	R/W
20	MOIFV	MOSI Idle Fixed Value 0: The fixed value of MOSI idle = 0. 1: The fixed value of MOSI idle = 1.	R/W
21	MOIFE	MOSI Idle Fixed Value Enable 0: The MOSI output value is the last data of previous transfer. 1: The MOSI output value is the set MOIFV bit value.	R/W
31:22	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3
Note 1. See SW flow in the section 33.3.12.1. Master mode operation.

RMFM[4:0] bit (Frame processing count setting in Master Receive only)

The number of received frames can be adjusted when operating in master receive only. Valid only when the master mode (SPCR.MSTR = 1) and the communication operation mode select bits (SPCR.TXMD [1:0]) are 10b.

Only the start bit in master mode reception automatically stops communication after starts frame processing according to the value set in this bit after reception starts.

If the RMFM [4:0] bits are rewritten while the SPE bit of the SPI control register (SPCR) is 1, subsequent operations are not guaranteed.

RMEDTG bit (End Trigger in Master Receive only)

This bit is used to end reception when master receive only. Valid only when the master mode (SPCR.MSTR = 1) and the communication mode select bits (SPCR.TXMD [1:0]) are 10b.

RMSTTG bit (Start Trigger in Master Receive only)

This bit is used to start reception when master receive only. Valid only when the master mode (SPCR.MSTR = 1) and the communication mode select bits (SPCR.TXMD [1:0]) are 10b.

Writing 1 to this bit during reception is not accepted. Write again after reception is completed.

SPDRC[7:0] bit (SPI received data ready detect adjustment)

The receive data ready detection function can be disabled or, if used, the period until detection can be set from 1 to 255 TCLK.

The value set in the SPDRC [7:0] bits is used to 1 set the SPDRF flag. For details, see the description of SPDRF in section 33.2.9. SPSR : SPI Status Register.

If the set value is changed while the SPE bit is 1, subsequent operations are not guaranteed.

SPLP bit (SPI Loopback)

When the SPLP bit is set to 1, the SPI shuts down the route between the MISO pin and the shift register (when the MSTR bit in the SPI control register is 1) or shuts down the route between the MOSI pin and the shift register, inverts the input route value in the shift register, and then connects the route to the output route (when the MSTR bit in the SPI control register is 0) (loopback mode).

SPLP2 bit (SPI Loopback 2)

When the SPLP2 bit is set to 1, the SPI shuts down the route between the MISO pin and the shift register (when the MSTR bit in the SPI control register is 1) or shuts down the route between MOSI pin and the shift register and then connects the route to the output route without inverting the input route value in the shift register (when the MSTR bit in the SPI control register is 0) (loopback mode). If this bit is set to 1 together with the SPLP bit, setting this bit takes precedence.

MOIFV bit (MOSI Idle Fixed Value)

This bit is used to select the MOSI pin output value during the SSL negation period (including SSL retention period in burst transfer) when the MOIFE bit is 1 in master mode.

If this bit is modified with the SPE bit in the SPI control register (SPCR) set to 1, subsequent operation is not guaranteed.

MOIFE bit (MOSI Idle Fixed Value Enable)

This bit is used for the SPI in master mode to fix the MOSI output value during the SSL negation period (including SSL retention period in burst transfer). When MOIFE bit = 0, the SPI outputs the last data of the previous serial transfer to MOSI during the SSL negation period. When MOIFE bit = 1, the SPI outputs the fixed MOIFV bit value to MOSI.

If this bit is modified with the SPE bit in the SPI control register (SPCR) set to 1, subsequent operation is not guaranteed.

33.2.5 SPCR3 : SPI Control Register 3

Base address: SPIn_B = 0x4035_C000 + 0x0100 × n (n = 0, 1)
SPIn_B_NS = 0x5035_C000 + 0x0100 × n (n = 0, 1)

Offset address: 0x10

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	SPSLN[2:0]			—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

3	SSL3P	SSL3 Signal Polarity [In the Motorola-SPI case] 0: The SSL3 signal is active low. 1: The SSL3 signal is active high. [In the TI-SSP case] 0: The SSL3 signal is active high. 1: The SSL3 signal is active low.	R/W
7:4	—	These bits are read as 0. The write value should be 0.	R/W
15:8	SPBR[7:0]	SPI Bit Rate	R/W
23:16	—	These bits are read as 0. The write value should be 0.	R/W

Bit	Symbol	Function	R/W
26:24	SPSLN[2:0]	SPI Sequence Length 0 0 0: Sequence Length is 1 (Referenced SPCMDn, n = 0→0→…) 0 0 1: Sequence Length is 2 (Referenced SPCMDn, n = 0→1→0→…) 0 1 0: Sequence Length is 3 (Referenced SPCMDn, n = 0→1→2→0→…) 0 1 1: Sequence Length is 4 (Referenced SPCMDn, n = 0→1→2→3→0→…) 1 0 0: Sequence Length is 5 (Referenced SPCMDn, n = 0→1→2→3→4→0→…) 1 0 1: Sequence Length is 6 (Referenced SPCMDn, n = 0→1→2→3→4→5→0→…) 1 1 0: Sequence Length is 7 (Referenced SPCMDn, n = 0→1→2→3→4→5→6→0→…) 1 1 1: Sequence Length is 8 (Referenced SPCMDn, n = 0→1→2→3→4→5→6→7→0→…)	R/W
31:27	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

SSLiP bits (SSL Signal Polarity Bits)

These bits are used to specify the polarity of SSL signals. The set SSLiP bit (i = 0 to 3) values indicate the active polarity of SSLi signals.

If any of these SSLiP bits is modified with the SPE bit in the SPI control register (SPCR) set to 1, subsequent operation is not guaranteed.

Note: SSL0 is different from SSL1-SSL3. When slave or multi-master, it functions as an input.

For details, see section 33.3.3.2. Single-master/single-slave with the MCU as a slave, and section 33.3.3.5. Multi-master/multi-slave with the MCU as a master.

SPBR[7:0] bit (SPI Bit Rate)

The SPI bit rate bits (SPBR) is used to set the bit rate in master mode. If SPBR is modified while the MSTR bit in the SPI control register (SPCR) is 1, subsequent operation is not guaranteed.

When the SPI is used in slave mode, the bit rate depends on the input clock bit rate regardless of the SPCMD.BRDV setting. (Specify a bit rate that meets electrical characteristics.)

The bit rate is determined by a combination of the set SPBR value and the set BRDV[1:0] bits value in the SPI command register (SPCMD0 to SPCMD7).

The bit rate is calculated by the following expression, where n is the set SPBR value (0 to 255) and N is the set BRDV[1:0] bits value (0 to 3).

$$\text{Bit rate} = \frac{f(\text{TCLK})}{2 \times (n+1) \times 2^N}$$

The following table shows an example of correspondence between bit rates and set values of SPBR and BRDV[1:0].

Table 33.5 Corresponding Between Bit Rates and Set Values (Example)

SPBR Value (n)	BRDV Value (N)	Division Ratio	Bit Rate				
			TCLK = 32 MHz	TCLK = 36 MHz	TCLK = 40 MHz	TCLK = 50 MHz	TCLK = 120MHz
0	0	2	16.0 Mbps	18.0 Mbps	20.0 Mbps	25.0 Mbps	60.0Mbps
1	0	4	8.00 Mbps	9.00 Mbps	10.0 Mbps	12.5 Mbps	30.0Mbps
2	0	6	5.33 Mbps	6.00 Mbps	6.67 Mbps	8.33 Mbps	20.0Mbps
3	0	8	4.00 Mbps	4.50 Mbps	5.00 Mbps	6.25 Mbps	15.0Mbps
4	0	10	3.20 Mbps	3.60 Mbps	4.00 Mbps	5.00 Mbps	12.0Mbps
5	0	12	2.67 Mbps	3.00 Mbps	3.33 Mbps	4.16 Mbps	10.0Mbps
5	1	24	1.33 Mbps	1.50 Mbps	1.67 Mbps	2.08 Mbps	5.0Mbps
5	2	48	677 kbps	750 kbps	833 kbps	1.04 Mbps	2.5Mbps
5	3	96	333 kbps	375 kbps	417 kbps	521 kbps	1.25Mbps
255	3	4096	7.81 kbps	8.80 kbps	9.78 kbps	12.2 kbps	29.3kbps

SPSLN[2:0] bit (SPI Sequence Length)

These bits are used to set the sequence length for the SPI in master mode to perform sequence operation. According to the sequence length specified by SPSLN[2:0] bits, the SPI in master mode changes SPI command registers 0 to 7 (SPCMD0 to SPCMD7) to be referenced and the reference sequence. For details, see section 33.3.13.1. Master mode operation.

The SPI in slave mode always references SPCMD0.

33.2.6 SPCMDm : SPI Command Register (m = 0 to 7)

Base address: SPIn_B = 0x4035_C000 + 0x0100 × n (n = 0, 1)
SPIn_B_NS = 0x5035_C000 + 0x0100 × n (n = 0, 1)

Offset address: 0x14 + 0x04 × m

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	SSLA[2:0]			—	—	—	SPB[4:0]				
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1	1

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	SCKDEN	SLNDEN	SPNDEN	LSBF	—	—	—	—	SSLKP	—	—	—	BRDV[1:0]		CPOL	CPHA
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	CPHA	RSPCK Phase 0: Data is sampled at an odd edge and changes at an even edge. 1: Data changes at an odd edge and is sampled at an even edge.	R/W
1	CPOL	RSPCK Polarity 0: RSPCK in idle state is 0. 1: RSPCK in idle state is 1.	R/W
3:2	BRDV[1:0]	Bit Rate Division 0 0: Base bit rate 0 1: Base bit rate divided by 2 1 0: Base bit rate divided by 4 1 1: Base bit rate divided by 8	R/W
6:4	—	These bits are read as 0. The write value should be 0.	R/W
7	SSLKP	SSL Signal Level Hold 0: All SSL signals are negated at the end of transfer. 1: SSL signal level is held after the transfer ends until the next access starts.	R/W
11:8	—	These bits are read as 0. The write value should be 0.	R/W
12	LSBF	SPI LSB First 0: MSB first 1: LSB first	R/W
13	SPNDEN	SPI Next-Access Delay Enable 0: Next-access delay is 1RSPCK + 5TCLK 1: Next-access delay is the set value of the SPI next-access delay (SPDECR.SPNDL).	R/W
14	SLNDEN	SSL Negation Delay Setting Enable 0: [Master] SSL negation delay is 1RSPCK. [Slave in the TI-SSP] SSL negation delay is 1TCLK 1: SSL negation delay is the set value of the slave select negation delay (SPDECR.SLNDL).	R/W

Bit	Symbol	Function	R/W
15	SCKDEN	RSPCK Delay Setting Enable [In the Motorola-SPI case] 0: RSPCK delay is 1 RSPCK. 1: RSPCK delay is the set value of the RSPCK delay (SPDECR.SCKDL). [In the TI-SSP case] 0: RSPCK delay is 0 RSPCK. 1: RSPCK delay is the set value of the RSPCK delay (SPDECR.SCKDL).	R/W
20:16	SPB[4:0]	SPI Data Length 0x00 to 0x02: Setting prohibited 0x03: 4 bits 0x04: 5 bits 0x05: 6 bits ⋮ 0x1E: 31 bits 0x1F: 32 bits	R/W
23:21	—	These bits are read as 0. The write value should be 0.	R/W
26:24	SSLA[2:0]	SSL Signal Assertion 0 0 0: SSL0 0 0 1: SSL1 0 1 0: SSL2 0 1 1: SSL3 Others: Setting prohibited	R/W
31:27	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

The SPI has eight SPI command registers (SPCMD0 to SPCMD7) that are used to set the transfer format of the SPI in master mode. Furthermore, some bits in SPCMD0 are used to set the transfer format of the SPI in slave mode. The SPI in master mode sequentially references SPCMD0 to SPCMD7 according to the setting of the SPSLN[2:0] bits in the SPI Control register 3 (SPCR3), and then performs serial transfer specified in the referenced SPCMD.

SPI set the SPCMD register before setting data to be transmitted by referencing the SPCMD when the transmit buffer is empty (while the next-transfer data has not been set).

The SPCMD referenced by the SPI in master mode is indicated by SPCP[2:0] in the SPI status register (SPSR). If SPCMD0 is modified while the SPI in slave mode is enabled (SPCR.SPE = 1), subsequent operation is not guaranteed.

CPHA bit (RSPCK Phase)

This bit is used to set the RSPCK phase of the SPI in master mode or slave mode. To perform data communication between SPI modules, the same RSPCK phase must be set for both modules.

When SPCR.SPMS = 0 and SPCR.SPFRF = 1 (in TI SSP mode), setting CPHA = 0 is invalid.

CPOL bit (RSPCK Polarity)

This bit is used to set the RSPCK polarity of the SPI in master mode or slave mode. To perform data communication between SPI modules, the same RSPCK polarity must be set for both modules.

BRDV[1:0] bit (Bit Rate Division)

This register is used to determine the bit rate with a combination of the set values of the BRDV[1:0] bits and the SPI bit rate register (SPCR3.SPBR). The set SPBR value determines the base bit rate. The set BRDV[1:0] bits value is used to select undivided, 2-divided, 4-divided, or 8-divided base bit rate. SPCMD0 to SPCMD7 enable setting of different BRDV[1:0] values. This makes it possible to perform serial transfer with a different bit rate for each command.

SSLKP bit (SSL Signal Level Hold)

This bit is used to set whether to hold or negate the SSL signal level of the current command during a period from the SSL negation timing for the current command to the SSL assertion timing for the next command when the SPI in master mode performs serial transfer. Setting this bit to 1 enables burst transfer in SPI operation master mode. For details, see section 33.3.12.1. Master mode operation.

To use the SPI in slave mode, set SSLKP bit to 0.

LSBF bit (SPI LSB First)

This bit is used to set the data format of the SPI in master mode or slave mode to MSB first or LSB first.

SPNDEN bit (SPI Next-Access Delay Enable)

This bit is used to set the period (next-access delay) after the SPI in master mode inactivates the SSL signal at the end of serial transfer until it enables SSL signal assertion of the next access. When SPNDEN bit = 0, the SPI sets the next-access delay to 1 RSPCK + 5TCLK. When SPNDEN bit = 1, the SPI inserts the next-access delay in accordance with the SPI next-access delay register (SPDECR.SPNDL) setting.

To use the SPI in slave mode, set SPNDEN bit to 0.

SLNDEN bit (SSL Negation Delay Setting Enable)

[In the Motorola-SPI case]

This bit is used to set the period (SSL negation delay) after the SPI in master mode stops RSPCK oscillation until it inactivates the SSL signal. When SLNDEN bit = 0, the SPI sets the SSL negation delay to 1 RSPCK. When SLNDEN bit = 1, the SPI negates the SSL signal with the RSPCK delay in accordance with the slave select negation delay register (SPDECR.SLNDL) setting.

To use the SPI in slave mode, set SLNDEN bit to 0.

[In the TI-SSP case]

This bit is used to set the period from when the master mode SPI stops RSPCK oscillation to when the OE signal is inactivated, or when the slave mode SPI detects the last edge of RSPCK and then negates the OE signal. When the SLNDEN bit is 0, the SSL negate delay is 1 RSPCK in master mode and 1 TCLK in slave mode. When SLNDEN bit = 1, the SPI negates the SSL signal with the RSPCK delay in accordance with the slave select negation delay register (SPDECR.SLNDL) setting.

When using SPI in slave mode except TI SSP setting, set the SLNDEN bit to 0.

SCKDEN bit (RSPCK Delay Setting Enable)

[In the Motorola-SPI case]

This bit is used to set the period (RSPCK delay) after the SPI in master mode activates the SSL signal until it oscillates RSPCK. When SCKDEN bit = 0, the SPI sets the RSPCK delay to 1 RSPCK. When SCKDEN bit = 1, the SPI starts RSPCK oscillation with the RSPCK delay in accordance with the RSPCK delay register (SPDECR.SCKDL) setting.

To use the SPI in slave mode, set SCKDEN bit to 0.

[In the TI-SSP case]

This bit is used to set the period from the start of assertion of the SSL signal to the RSPCK oscillation (RSPCK delay) and the period of the SSL signal to negation by the SPI in master mode. When SCKDEN bit = 0, the SPI does not sets the RSPCK delay. When SCKDEN bit = 1, the SPI starts RSPCK oscillation with the RSPCK delay in accordance with the RSPCK delay register (SPDECR.SPCKDL) setting.

To use the SPI in slave mode, set SCKDEN bit to 0.

SPB[4:0] bit (SPI Data Length)

These bits are used to set the transfer data length of the SPI in master mode or slave mode.

SSLA[2:0] bit (SSL Signal Assertion)

These bits are used to control SSL signal assertion for the SPI in master mode to perform serial transfer. The set SSLA[2:0] bits value controls assertion of the SSL3 to SSL0 signals. The signal polarity when the SSL signal is asserted depends on the set value of the SPI slave select polarity register (SPCR3.SSLiP). When SSLA[2:0] bits are set to 000b in multi-master mode, serial transfer is performed with all SSL signals negated (because SSL0 is input).

To use the SPI in slave mode, set SSLA[2:0] bits to 000b.

33.2.7 SPDCR : SPI Data Control Register

Base address: SPIn_B = 0x4035_C000 + 0x0100 × n (n = 0, 1)
SPIn_B_NS = 0x5035_C000 + 0x0100 × n (n = 0, 1)

Offset address: 0x40

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Bit	Symbol	Function	R/W
0	BYSW	Byte Swap Operating Mode Select 0: Byte Swap OFF 1: Byte Swap ON	R/W
2:1	—	These bits are read as 0. The write value should be 0.	R/W
3	SPRDTD	SPI Receive Data or Transmit Data Select 0: The SPDR reads the receive buffer. 1: The SPDR reads the transmit buffer	R/W
4	SINV	Serial data invert bit 0: Not invert serial data 1: Invert serial data.	R/W
7:5	—	These bits are read as 0. The write value should be 0.	R/W
9:8	SPFC[1:0]	Frame Count 0 0: 1 frame 0 1: 2 frames 1 0: 3 frames 1 1: 4 frames	R/W
31:10	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

The SPI data control register (SPDCR) controls the data format.

If the value set in this register is changed while the SPE bit is 1, subsequent operations are not guaranteed.

BYSW bit (Byte Swap Operating Mode Select)

It is a setting bit, that is to swap a transmit/receive data in byte units. A data after byte swap is different by a data length (setting of SPCMD.SPB[4:0]).

When byte swap, A data length (setting of SPB[4:0]) must be set to 32bit or 16bit. Other case of data length (i.e. 4 to 15, 17 to 31-bit length), byte swap is not guaranteed. For the arrangement of data before and after swapping data lengths of 32 bits and 16 bits, see section 33.3.4.3. Byte Swap Transmission and section 33.3.4.4. Byte Swap Reception.

When the parity function set to valid, the behavior is not guaranteed.

SPRDTD bit (SPI Receive Data or Transmit Data Select)

This bit is used to select receive buffer or transmit buffer from which the SPI data register (SPDR) value is read.

When the transmit buffer is read, the value that was written to SPDR immediately before is read.

SINV bit (Serial data invert bit)

This bit is used to invert transmit data and receive data.

When the SINV bit is set to 1, transmit buffer (SPTX) data is inverted to invert transmit data and receive data, and then the inverted data is stored in the receive buffer (SPRX). The parity bit is the value corresponding to the inverted transmission/reception data.

SPFC[1:0] bit (Frame Count)

Used for the condition to set the CENDF flag in slave receive only mode.

For details on the CENDF flag setting conditions, see section 33.2.9. SPSR : SPI Status Register.

Note that this bit is invalid except in the slave receive only mode.

33.2.8 SPDCR2 : SPI Data Control Register 2

Base address: SPIn_B = 0x4035_C000 + 0x0100 × n (n = 0, 1)
SPIn_B_NS = 0x5035_C000 + 0x0100 × n (n = 0, 1)

Offset address: 0x44

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	TTRG[1:0]		—	—	—	—	—	—	RTRG[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
1:0	RTRG[1:0]	Receive FIFO threshold setting 0 0: threshold 0 0 1: threshold 1 1 0: threshold 2 1 1: threshold 3	R/W
7:2	—	These bits are read as 0. The write value should be 0.	R/W
9:8	TTRG[1:0]	Transmission FIFO threshold setting 0 0: threshold 0 0 1: threshold 1 1 0: threshold 2 1 1: threshold 3	R/W
31:10	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

SPI data control register 2 (SPDCR2) controls the FIFO threshold. If the value set in this register is changed while the SPE bit is 1, subsequent operations are not guaranteed.

RTRG[1:0] bit (Receive FIFO threshold setting)

Set the receive FIFO threshold.

When the number of data stored in the receive FIFO > the number of frames set by RTRG[1:0], the receive buffer full flag is set.

TTRG[1:0] bit (Transmission FIFO threshold setting)

Set the transmit FIFO threshold.

When the number of empty stages in the transmit FIFO > the number of frames set in TTRG[1:0], the transmit buffer empty flag is set.

33.2.9 SPSR : SPI Status Register

Base address: SPIn_B = 0x4035_C000 + 0x0100 × n (n = 0, 1)
SPIn_B_NS = 0x5035_C000 + 0x0100 × n (n = 0, 1)

Offset address: 0x50

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	SPRF	CENDF	SPTEF	UDRF	PERF	MODF	IDLNF	OVRF	SPDRF	—	—	—	—	—	—	—
Value after reset:	0	0	1	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	SPECM[2:0]			—	SPCP[2:0]			—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	—	These bits are read as 0. The write value should be 0.	R
10:8	SPCP[2:0]	SPI Command Pointer 0 0 0: SPCMD0 0 0 1: SPCMD1 0 1 0: SPCMD2 0 1 1: SPCMD3 1 0 0: SPCMD4 1 0 1: SPCMD5 1 1 0: SPCMD6 1 1 1: SPCMD7	R
11	—	This bit is read as 0. The write value should be 0.	R
14:12	SPECM[2:0]	SPI Error Command 0 0 0: SPCMD0 0 0 1: SPCMD1 0 1 0: SPCMD2 0 1 1: SPCMD3 1 0 0: SPCMD4 1 0 1: SPCMD5 1 1 0: SPCMD6 1 1 1: SPCMD7	R
22:15	—	These bits are read as 0. The write value should be 0.	R
23	SPDRF	SPI Receive Data Ready Flag 0: Receive data ready not detected 1: Receive data ready detected	R
24	OVRF	Overrun Error Flag 0: No overrun error is present. 1: An overrun error is present.	R
25	IDLNF	SPI Idle Flag 0: The SPI is in the idle state. 1: The SPI is in the transfer state.	R
26	MODF	Mode Fault Error Flag 0: Neither mode fault error nor underrun error is present. 1: A mode fault error or underrun error is present.	R
27	PERF	Parity Error Flag 0: No parity error is present. 1: A parity error is present.	R
28	UDRF	Underrun Error Flag 0: When MODF=0, neither mode fault error nor underrun error is present. When MODF=1, a mode fault error is present. 1: When MODF=0, neither mode fault error nor underrun error is present. When MODF=1, an underrun error is present.	R

Bit	Symbol	Function	R/W
29	SPTEF	SPI Transmit Buffer Empty Flag 0: The number of empty stages in the transmit FIFO ≤ the value set in SPDCR2.TTRG 1: The number of empty stages in the transmit FIFO > the value set in SPDCR2.TTRG	R
30	CENDF	Communication End Flag 0: The SPI is not communicating or communicating. 1: The SPI communication completed.	R
31	SPRF	SPI Receive Buffer Full Flag 0: The number of data stored in the receive FIFO ≤ number of frames set by the SPDCR2.RTRG bit. 1: The number of data stored in the receive FIFO > number of frames set by the SPDCR2.RTRG bit.	R

Note: S-TYPE-3, P-TYPE-3

The SPI status register (SPSR) stores flags that indicate SPI's operating status.

SPCP[2:0] bit (SPI Command Pointer)

These bits indicate SPI command registers 0 to 7 (SPCMD0 to SPCMD7) indicated by the current pointer in the SPI sequence control. For details about the SPI sequence control, see section 33.3.13.1. Master mode operation.

SPECM[2:0] bit (SPI Error Command)

These bits indicate SPI command registers 0 to 7 (SPCMD0 to SPCMD7) indicated by the command pointer (SPCP[2:0] bits) when an error was detected in the SPI sequence control. The SPI updates the SPECM[2:0] bits value only when an error is detected. When no error is present (OVRF, MODF, and PERF flags in SPSR are 0), the SPECM[2:0] bits value has no meaning. For the SPI's error detection function, see section 33.3.10. Error Detection. For the SPI's sequence control, see section 33.3.13.1. Master mode operation.

SPDRF bit (SPI Receive Data Ready Flag)

During communication (SPCR.SPE = 1), a certain period of time has elapsed while the number of data stored in the reception FIFO ≤ the reception FIFO threshold.

This bit is set to 0 when the reception operation is not performed (SPCR.TXMD[1:0] = 01b).

[Setting condition]

All the following two conditions are met.

- SPCR2.SPDRC[7:0] ≠ 0x00.
- After the receive FIFO has been written, when the number of data stored in the receive FIFO ≤ the receive FIFO threshold and the value set by SPDRC[7:0] has elapsed

[Clearing condition]

- When 1 is written to the SPSRC.SPDRFC bit.

OVRF bit (Overrun Error Flag)

This flag indicates whether an overrun error is present. When the RSPCK clock auto-stop function is enabled (SPCR.SCKASE = 1) in master mode (SPCR.MSTR = 1), no overrun error occurs and, therefore, this flag is not set to 1. For details, see section 33.3.10.1. Overrun errors.

[Setting condition]

When serial transfer is completed in one of the following two conditions with data stored in the receive FIFO for the number of FIFO stages.

- SPCR.TXMD[1:0] = 00b. (transmit-receive mode)
- SPCR.TXMD[1:0] = 10b. (receive only)

[Clearing condition]

- When 1 is written to the SPSRC.OVRFC bit.

IDLNF bit (SPI Idle Flag)

This flag indicates transfer status of the SPI.

[Setting condition]

[Transmit-Receive, Transmit-only Master mode]

- None of the clearing conditions (Transmit-Receive / Transmit-only in Master mode) below is met.

[Receive-only Master mode]

- When 1 is written to RMSTTG of SPCR2.

[Slave mode]

- The SPE bit in SPCR is 1 (SPI function enabled).

[Clearing conditions]

Communication status: 1-(1) to (6) * For details of communication status, see Table 33.4.

[Transmit-Receive, Transmit-only Master mode]

Any of the following two conditions is met.

- The SPE bit in SPCR is 0 (SPI initialization).
- All the following three conditions are met.
  - The next transfer data is not set in the transmission buffer (SPTXn, n = 0 to 3)
  - The SPCP bits in SPSR are 000b (at the beginning of sequence control).
  - The operation completed by the next access delay (the master main state machine has transitioned to the idle state)

[Receive-only Master mode]

Communication status: 1-(7) to (9)

Any of the following two conditions is met.

- The SPE bit in SPCR is 0 (SPI initialization).
- Any of the following 3 conditions is met.
  When RMFM[4:0] = 0x00, after writing 1 to RMEDTG, the operation completed by the next access delay (the master main state machine has transitioned to the idle state)
  When RMFM[4:0] ≠ 0x00, after writing 1 to RMEDTG, the operation completed by the next access delay (the master main state machine has transitioned to the idle state)
  When RMFM[4:0] ≠ 0x00, the operation completed by the next access delay after processing is completed for the number of received frames set in RMFM[4:0] (the master main state machine has transitioned to the idle state)

[Slave mode]

Communication status: 0-(1) to (9)

- The SPE bit in SPCR is 0 (SPI initialization).

MODF bit (Mode Fault Error Flag)

This flag indicates whether a mode fault error or an underrun error is present. The UDRF flag allows you to see which error (mode fault error or underrun error) has occurred.

[Setting condition]

[Multi-master mode]

- The SSL0 pin input level becomes active level while the SPCR.MSTR bit = 1 (master mode) and the SPCR.MODFEN bit = 1 (mode fault error detection enabled), and then the SPI has detected a mode fault error.

[Slave, Motorola-SPI mode]

Any of the following two conditions is met.

- The SSL0 pin is negated before the RSPCK cycles necessary for data transfer end while the SPCR.MSTR bit = 0 (slave mode), SPCR.SPFRF bit = 0 (Motorola-SPI) and the SPCR.MODFEN bit = 1 (mode fault error detection enabled), and then the SPI has detected a mode fault error.
- Serial transfer is started before transmit data output becomes ready while the SPCR.SPE bit = 1 (SPI function enabled), and then the SPI has detected an underrun error.

[Slave, TI-SSP mode]

Any of the following two conditions is met.

- The SSL0 pin is asserted before the RSPCK cycles necessary for data transfer end while the SPCR.MSTR bit = 0 (slave mode), SPCR.SPFRF bit = 1 (TI-SSP) and the SPCR.MODFEN bit = 1 (mode fault error detection enabled), and then the SPI has detected a mode fault error.
- Serial transfer is started before transmit data output becomes ready while the SPCR.SPE bit = 1 (SPI function enabled), and then the SPI has detected an underrun error.

The SSL0 signal active level depends on the SPCR3.SSLiP bits (SSL signal polarity bits).

[Clearing condition]

- When 1 is written to the SPSRC.MODFC bit.

PERF bit (Parity Error Flag)

This flag indicates whether a parity error is present.

[Setting condition]

When the serial transfer ends and a parity error is detected with the SPPE bit of SPCR set to 1 under any of the following 2 conditions.

- SPCR.TXMD[1:0] = 00b. (transmit-receive master mode or transmit-receive slave mode)
- SPCR.TXMD[1:0] = 10b. (receive-only master mode or receive-only slave mode)

[Clearing condition]

- When 1 is written to the SPSRC.PERFC bit.

UDRF bit (Underrun Error Flag)

This flag indicates that a mode fault error or an underrun error is present.

[Setting condition]

- Serial transfer is started before transmit data output becomes ready while the SPCR.MSTR bit = 0 and the SPCR.TXMD[1:0] bit = 00b or 01b (transmit-receive slave mode or transmit-only slave mode) and the SPCR.SPE bit = 1 (SPI function enabled), and then the SPI has detected an underrun error.

[Clearing condition]

- When 1 is written to the SPSRC.UDRFC bit.

SPTEF bit (SPI Transmit Buffer Empty Flag)

This flag indicates the transmit buffer (SPTX) status in the SPI data register (SPDR).

[Setting condition]

Any of the following 3 conditions is met.

- The SPE bit is set to 0 (SPI initialization).
- When the number of empty transmission FIFO stages > the value set in SPDCR2.TTRG[1:0].
- When 1 is written to SPFCR.SPFRST.

[Clearing condition]

Any of the following two conditions is met.

- At the time of final access when transmission data is written to SPDR (SPTXn, n = 0 to 3) in one processing routine using DTC / DMAC.
- When 1 is written to the SPSRC.SPTEFC bit.

Writing a value to the SPDR register is enabled only while the SPTEF flag = 1. If a value is written to the SPDR register while the SPTEF flag = 0, transmit buffer data is not updated.

CENDF bit (Communication End Flag)

This flag indicates communication end status of SPI. It turns 1 at communication end and turns 0 at starting next communication.

[Setting condition]

[Transmit-Receive / Transmit-only Master mode]

Communication status: 1-(1) to (6) * For details of communication status, see Table 33.4.

The following 3 conditions are met.

- The next transfer data is not set in the transmission buffer (SPTXn, n = 0 to 3)
- The SPSR.SPCP[2:0] are 000b. (It means the head of the sequential control.)
- The operation completed by the next access delay (the master main state machine has transitioned to the idle state)

[Receive-only Master mode]

Communication status: 1-(7) to (9)

Any of the following 3 conditions is met.

- When RMFM[4:0] = 0x00, after writing 1 to RMEDTG, the operation completed by the next access delay (the master main state machine has transitioned to the idle state)
- When RMFM[4:0] ≠ 0x00, after writing 1 to RMEDTG, the operation completed by the next access delay (the master main state machine has transitioned to the idle state)
- When RMFM[4:0] ≠ 0x00, the operation completed by the next access delay after processing is completed for the number of received frames set in RMFM[4:0] (the master main state machine has transitioned to the idle state)

[Transmit-receive / transmit-only slave, Motorola-SPI mode at SPI serial communication (4-wire: the SPCR.SPMS bit is 0)]

Communication status: 0-(1), (4)

The following 3 conditions are met.

- The next transfer data is not set in the transmission buffer
- The transmission shift register is empty. (It means SPI does not do serial transfer.)
- SSL0 was negated.

[Transmit-receive / transmit-only slave, TI-SSP mode at SPI serial communication (4-wire: the SPCR.SPMS bit is 0)]

Communication status: 0-(2), (5)

The following 3 conditions are met.

- The next transfer data is not set in the transmission buffer
- The transmission shift register is empty. (It means SPI does not do serial transfer.)
- When the SSL0 negate delay is completed.

[Transmit-receive / transmit only slave mode at clock synchronous (3-wire: the SPCR.SPMS bit is 1)]

Communication status: 0-(3), (6)

The following 3 conditions are met.

- The next transfer data is not set in the transmission buffer
- The transmission shift register is empty. (It means SPI does not do serial transfer.)
- The last even edge of RSPCK of the frame was detected. (When the SPCMD.CPHA bit is 1.)

[Receive only slave, Motorola-SPI mode at SPI serial communication (4-wire: the SPCR.SPMS bit is 0)]

Communication status: 0-(7)

The following condition is met.

- SSL0 input was negated after getting frames for SPDCR.SPFC set value in the receive buffer.

[Receive only slave, TI-SSP mode at SPI serial communication (4-wire: the SPCR.SPMS bit is 0)]

Communication status: 0-(8)

The following condition is met.

- SSL0 negate delay is completed after getting frames for SPDCR.SPFC set value in the receive buffer.

[Receive only slave mode at clock synchronous (3-wire: the SPCR.SPMS bit is 1)]

Communication status: 0-(9)

The following condition is met.

- The last even edge of RSPCK of the Last frame received for SPFC sets value. (When the SPCMD.CPHA bit is 1.)

[Clearing condition]

[Transmit-Receive / Transmit-only Master mode]

Communication status: 1-(1) to (6)

Any of the following 2 conditions is met.

- The next transmit data was written to the transmit buffer (SPTX).
- When 1 is written to the SPSRC.CENDFC bit.

[Receive -only Master mode]

Communication status: 1-(7) to (9)

Any of the following 2 conditions is met.

- When 1 is written to the SPCR2.RMSTTG bit with SPE = 1.
- When 1 is written to the SPSRC.CENDFC bit.

[Transmit-receive / transmit only slave mode]

Communication status: 0-(1) to (6)

Satisfy one of following.

- The next transmit data was written to the transmit buffer (SPTX).
- When 1 is written to the SPSRC.CENDFC bit.

[Receive only slave mode at SPI serial communication (4-wire: the SPCR.SPMS bit is 0)]

Communication status: 0-(7) to (8)

Satisfy one of following.

- SSL0 assertion of next data was detected.
- When 1 is written to the SPSRC.CENDFC bit.

[Receive only slave mode at clock synchronous (3-wire: the SPCR.SPMS bit is 1)]

Communication status: 0-(9)

Satisfy one of following.

- The first edge of RSPCK of the next data was detected.
- When 1 is written to the SPSRC.CENDFC bit.

SPRF bit (SPI Receive Buffer Full Flag)

This flag indicates the receive buffer (SPRX) status in the SPI data register (SPDR).

[Setting condition]

When the number of data stored in the receive FIFO > the number of frames set in the SPDCR2.RTRG[1:0] bits in Transmit-Receive, receive-only mode. However, the SPRF flag does not change from 0 to 1 while the OVRF flag = 1. (See section 33.3.10. Error Detection.)

[Clearing condition]

Any of the following 3 conditions is met.

- At the last access when read data is read from SPDR (SPRXn, n = 0 to 3) in one processing routine using DTC / DMAC
- When 1 is written to the SPSRC.SPRFC bit
- When 1 is written to the SPFCR.SPFRST bit

33.2.10 SPTFSR : SPI Transfer FIFO Status Register

Base address: SPIn_B = 0x4035_C000 + 0x0100 × n (n = 0, 1)
SPIn_B_NS = 0x5035_C000 + 0x0100 × n (n = 0, 1)

Offset address: 0x58

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	TFDN[2:0]		
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
2:0	TFDN[2:0]	Transmit FIFO data empty stage number 0 0 0: Number of empty stages 0 ⋮ 1 0 0: Number of empty stages 4	R
31:3	—	These bits are read as 0. The write value should be 0.	R

TFDN[2:0] bit (Transmit FIFO data empty stage number)

Displays the number of empty transmission FIFO stages. By clearing the SPCR.SPE bit, TFDN[2:0] will be the initial value after reset (= all empty).

33.2.11 SPRFSR : SPI Receive FIFO Status Register

Base address: SPIn_B = 0x4035_C000 + 0x0100 × n (n = 0, 1)
SPIn_B_NS = 0x5035_C000 + 0x0100 × n (n = 0, 1)

Offset address: 0x5C

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	RFDN[2:0]		
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0	0

Bit	Symbol	Function	R/W
2:0	RFDN[2:0]	Receive FIFO data store stage number 0 0 0: Number of store stages 0 ⋮ 1 0 0: Number of store stages 4	R
31:3	—	These bits are read as 0. The write value should be 0.	R

Note: S-TYPE-3, P-TYPE-3

RFDN[2:0] bit (Receive FIFO data store stage number)

Displays the number of stores receive FIFO stages. RFDN [2:0] is cleared by clearing the SPCR.SPE bit.

33.2.12 SPPSR : SPI Polling Register

Base address: SPIn_B = 0x4035_C000 + 0x0100 × n (n = 0, 1)
SPIn_B_NS = 0x5035_C000 + 0x0100 × n (n = 0, 1)

Offset address: 0x60

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	SPEPS
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	SPEPS	SPI Polling Status 0: SPCR.SPE is 0 1: SPCR.SPE is 1	R
31:1	—	These bits are read as 0. The write value should be 0.	R

SPEPS bit (SPI Polling Status)

This bit indicates status of SPCR.SPE bit after synchronization from bus clock (PCLK) to operation clock (TCLK).

33.2.13 SPSRC : SPI Status Clear Register

Base address: SPIn_B = 0x4035_C000 + 0x0100 × n (n = 0, 1)
SPIn_B_NS = 0x5035_C000 + 0x0100 × n (n = 0, 1)

Offset address: 0x68

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	SPRFC	CENDFC	SPTEFC	UDRFC	PERFC	MODFC	—	OVRFC	SPDRFC	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
22:0	—	The write value should be 0.	W
23	SPDRFC	SPI Receive Data Ready Flag Clear By writing 1, the SPI Receive Data Ready Flag can be cleared. Reading value is always 0.	W

Bit	Symbol	Function	R/W
24	OVRFC	Overrun Error Flag Clear By writing 1, the Overrun Error Flag can be cleared. Reading value is always 0.	W
25	—	The write value should be 0.	W
26	MODFC	Mode Fault Error Flag Clear By writing 1, the Mode Fault Error Flag can be cleared. Reading value is always 0.	W*1
27	PERFC	Parity Error Flag Clear By writing 1, the Parity Error Flag can be cleared. Reading value is always 0.	W
28	UDRFC	Underrun Error Flag Clear By writing 1, the Underrun Error Flag can be cleared. Reading value is always 0.	W*2
29	SPTEFC	SPI Transmit Buffer Empty Flag Clear By writing 1, the SPI Transmit Buffer Empty Flag can be cleared. Reading value is always 0.	W
30	CENDFC	Communication End Flag Clear By writing 1, the Communication End Flag can be cleared. Reading value is always 0.	W
31	SPRFC	SPI Receive Buffer Full Flag Clear By writing 1, the SPI Receive Buffer Full Flag can be cleared. Reading value is always 0.	W

Note: S-TYPE-3, P-TYPE-3
Note 1. Before setting MODFC and UDRFC, make sure that SPSR.MODF and UDRF are set to 1.
Note 2. When clearing the UDRF flag, clear the MODF flag at the same time (MODFC = 1).

The SPI status clear register (SPSRC) is a register that clears the status flag (SPSR) that indicates the operating status of SPI.

33.2.14 SPFCR : SPI FIFO Clear Register

Base address: SPIn_B = 0x4035_C000 + 0x0100 × n (n = 0, 1)
SPIn_B_NS = 0x5035_C000 + 0x0100 × n (n = 0, 1)

Offset address: 0x6C

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	SPFRST
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	SPFRST	SPI FIFO clear By writing 1, the pointer in the FIFO and the stored data are initialized. Reading value is always 0.	W
31:1	—	The write value should be 0.	W

Note: S-TYPE-3, P-TYPE-3

The FIFO clear register (SPFCR) is used to clear the FIFO.

If SPFCR is rewritten while the SPE bit of the SPI control register (SPCR) is 1, subsequent operations are not guaranteed.

SPFRST bit (SPI FIFO clear)

Initializing the pointer and stored data in the transmit / receive FIFO by writing 1

33.3 Operation

In this section, the serial transfer period refers to the period from the beginning of driving valid data to the fetching of the final valid data.

33.3.1 Overview of SPI Operation

The SPI is capable of synchronous serial transfers in the following modes:

- Slave mode (SPI operation)
- Single-master mode (SPI operation)
- Multi-master mode (SPI operation)
- Slave mode (clock synchronous operation)
- Master mode (clock synchronous operation)

The SPI mode can be selected by using the MSTR, MODFEN, SPMS, and SPFRF bits in SPCR. Table 33.6 lists the relationship between SPI modes and SPCR settings, and a description of each mode.

Table 33.6 Relationship between SPCR settings and SPI modes (1 of 2)

Mode	Slave (SPI operation)	Single-master (SPI operation)	Multi-master (SPI operation)	Slave (clock synchronous operation)	Master (clock synchronous operation)
MSTR bit setting	0	1	1	0	1
MODFEN bit setting	0 or 1	0	1	0	0
SPMS bit setting	0	0	0	1	1
SPFRF bit setting	valid	valid	valid	Invalid	Invalid
RSPCKn pins	Input	Output	Output/Hi-Z	Input	Output
MOSIn pin	Input	Output	Output/Hi-Z	Input	Output
MISOn pin	Output/Hi-Z	Input	Input	Output	Input
SSLn0 pins	Input	Output	Input	Hi-Z*1	Hi-Z*1
SSLn1 to SSLn3 pins	Hi-Z*1	Output	Output/Hi-Z	Hi-Z*1	Hi-Z*1
SSL polarity change function	Supported	Supported	Supported	—	—
Max transfer rate	TCLK/2	TCLK/2	TCLK/2	TCLK/2	TCLK/2
Clock source	RSPCK input	On-chip baud rate generator	On-chip baud rate generator	RSPCK input	On-chip baud rate generator
Clock polarity	Two				
Clock phase	Two*6	Two*6	Two*6	One (CPHA = 1)	Two
Transfer data length	4 to 32 bits				
Burst transfer	Possible (CPHA = 1)	Possible (CPHA = 0, 1)	Possible (CPHA = 0, 1)	—	—
RSPCK delay control	Not supported	Supported	Supported	Not supported	Supported
SSL negation delay control	Not supported*7	Supported	Supported	Not supported	Supported
Next-access delay control	Not supported	Supported	Supported	Not supported	Supported
Transfer trigger	SSL input active or RSPCK oscillation	Write to transmit buffer on generation of transmit buffer empty interrupt request (SPTEF = 1)	Write to transmit buffer on generation of transmit buffer empty interrupt request (SPTEF = 1)	RSPCK oscillation	Write to transmit buffer on generation of transmit buffer empty interrupt request (SPTEF = 1)
Sequence control	Not supported	Supported	Supported	Not supported	Supported
Transmit buffer empty detection	Supported*5				
Receive buffer full detection	Supported*2				
Overrun error detection	Supported*2	Supported*2 *4	Supported*2 *4	Supported*2	Supported*2

Table 33.6 Relationship between SPCR settings and SPI modes (2 of 2)

Mode	Slave (SPI operation)	Single-master (SPI operation)	Multi-master (SPI operation)	Slave (clock synchronous operation)	Master (clock synchronous operation)
Parity error detection	Supported*3 *2				
Mode fault error detection	Supported (MODFEN = 1)	Not supported	Supported	Not supported	Not supported
Underrun error detection	Supported*5	Not supported	Not supported	Supported*5	Not supported

Note 1. This function is not supported in this mode.
Note 2. When SPI is transmit-master mode or transmit-slave mode (see Table 33.4), detection of receive buffer full, overrun error, and parity error are not performed.
Note 3. When the SPCR.SPPE bit is 0, parity error detection is not performed.
Note 4. When the SPCR.SCKASE bit is 1, overrun error detection does not proceed.
Note 5. When SPI is receive only slave mode, none of transmit buffer empty and underrun error is detected.
Note 6. CPHA = 0 is invalid in TI SSP mode. (If it is set, the operation is the same as when CPHA = 1.)
Note 7. Supported only in TI SSP mode.

33.3.2 Controlling the SPI Pins

Based on the settings of the MSTR, MODFEN, and SPMS bits in SPCR and the PmnPFS.NCODR bit for I/O Ports, the SPI can switch pin states. Table 33.7 lists the relationship between pin states and bit settings. Setting the PmnPFS.NCODR bit for an I/O port to 0 selects the CMOS output. Setting it to 1 selects the open-drain output. The I/O port settings must follow this relationship.

Table 33.7 Relationship between pin states and bit settings (1 of 2)

Mode	Pin	Pin state*2	
		PmnPFS.NCODR bit for I/O ports = 0	PmnPFS.NCODR bit for I/O ports = 1
Single-master mode (SPI operation) (MSTR = 1, MODFEN = 0, SPMS = 0)	RSPCKn	CMOS output	Open-drain output
	SSLn0 to SSLn3	CMOS output	Open-drain output
	MOSIn	CMOS output	Open-drain output
	MISOn	Input	Input
Multi-master mode (SPI operation) (MSTR = 1, MODFEN = 1, SPMS = 0)	RSPCKn*3	CMOS output/Hi-Z	Open-drain output/Hi-Z
	SSLn0	Input	Input
	SSLn1 to SSLn3*3	CMOS output/Hi-Z	Open-drain output/Hi-Z
	MOSIn*3	CMOS output/Hi-Z	Open-drain output/Hi-Z
	MISOn	Input	Input
Slave mode (SPI operation) (MSTR = 0, SPMS = 0)	RSPCKn	Input	Input
	SSLn0	Input	Input
	SSLn1 to SSLn3*5	Hi-Z*1	Hi-Z*1
	MOSIn	Input	Input
	MISOn*4	CMOS output/Hi-Z	Open-drain output/Hi-Z
Master mode (clock synchronous operation) (MSTR = 1, MODFEN = 0, SPMS = 1)	RSPCKn	CMOS output	Open-drain output
	SSLn0 to SSLn3*5	Hi-Z*1	Hi-Z*1
	MOSIn	CMOS output	Open-drain output
	MISOn	Input	Input

Table 33.7 Relationship between pin states and bit settings (2 of 2)

Mode	Pin	Pin state*2	
		PmnPFS.NCODR bit for I/O ports = 0	PmnPFS.NCODR bit for I/O ports = 1
Slave mode (clock synchronous operation) (MSTR = 0, SPMS = 1)	RSPCKn	Input	Input
	SSLn0 to SSLn3*5	Hi-Z*1	Hi-Z*1
	MOSIn	Input	Input
	MISOn	CMOS output	Open-drain output

Note 1. This function is not supported in this mode.
Note 2. SPI settings are not reflected in multiplexed pins for which the SPI function is not selected.
Note 3. Motorola-SPI: When SSLn0 is at the active level, the pin state is Hi-Z. Whether or not the input signal is at the active level determines the setting of the SPCR3.SSL0P bit.
TI-SSP: From when SSL0 is at the active level until communication is completed, the pin state is Hi-Z under the condition SPCR.SPE = 1.
Note 4. Motorola-SPI: When SSLn0 is at the non-active level or the SPCR.SPE bit is 0, the pin state is Hi-Z. Whether or not the input signal is at the active level determines the setting of the SPCR3.SSL0P bit.
TI-SSP: When SSL0 is except the communication period or when the SPE bit of SPCR is 0 (assertion after SPE = 1 and communication is completed), the pin status changes to Hi-Z.
Note 5. These pins are available for use as I/O port pins.

The SPI in single-master mode (SPI operation) or multi-master mode (SPI operation) determines the MOSI signal values during the SSL negation period (including the SSL retention period during a burst transfer) based on the MOIFE and MOIFV bit settings in SPCR2, as listed in Table 33.8.

Table 33.8 MOSI signal value determination during SSL negation

MOIFE bit	MOIFV bit	MOSIn signal value during SSL negation
0	0, 1	Final data from previous transfer
1	0	Low
1	1	High

33.3.3 SPI System Configuration Examples

This configuration example describes that 0 level of SSL0n signals is active level.

When connecting and using in a multi-slave or multi-master mode, the transfer format of the connected device should be unified to either Motorola-SPI or TI-SSP.

33.3.3.1 Single-master/single-slave with the MCU as a master

Figure 33.6 shows a single-master/single-slave SPI system configuration example where the MCU is used as a master. In the single-master/single-slave configuration, the SSLni outputs of the MCU (master) are not used. The SSL input of the SPI slave is fixed to the low level, and the SPI slave is maintained in the selected state.*1

Note 1. In the transfer format configured when the SPCMDm.CPHA bit is 0, the SSL signal for some slave devices cannot be fixed to an active level. In this case, always connect the SSLni output of the MCU to the SSL input of the slave device.

The MCU (master) drives the RSPCKn and MOSIn signals. The SPI slave drives the MISO signal.

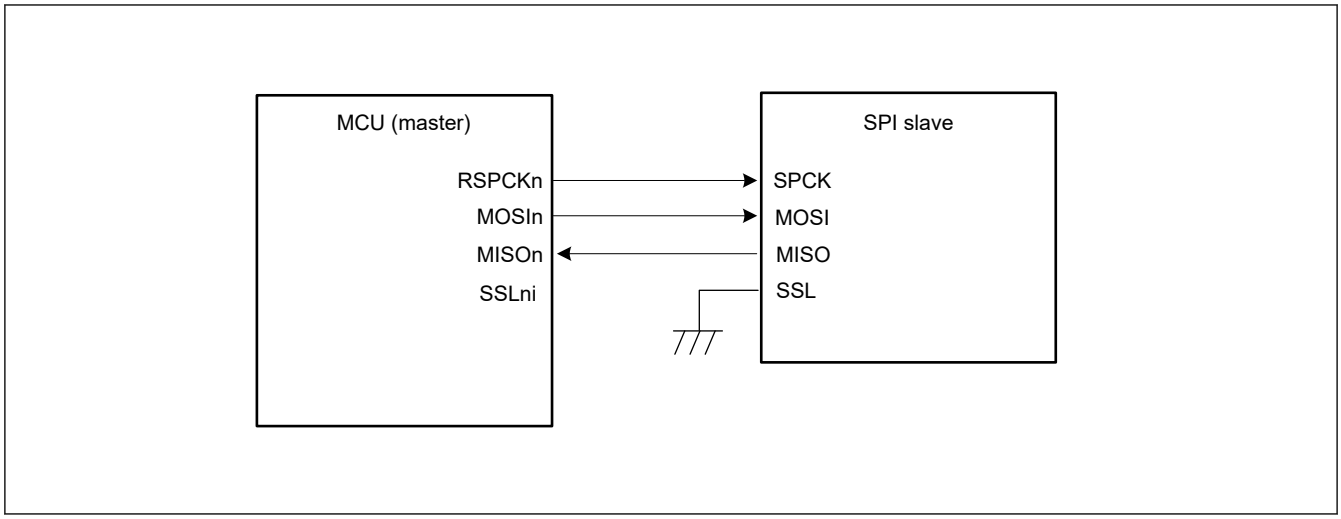

Figure 33.6 Single-master/single-slave configuration example with the MCU as a master

33.3.3.2 Single-master/single-slave with the MCU as a slave

Figure 33.7 shows a single-master/single-slave SPI system configuration example where the MCU is used as a slave. When the MCU operates as a slave, the SSLn0 pin is used as SSL input. The SPI master drives the RSPCK and MOSI signals. The MCU (slave) drives the MISOn signal.*1

Note 1. When SSLn0 is at a non-active level, the pin state is Hi-Z.

In the single-slave configuration when the SPCMDm.CPHA bit is set to 1, the SPCR.SPFRF bit is set to 0, and SPCR.SPMS is set to 0, the SSLn0 input of the MCU (slave) is fixed to the low level and the MCU (slave) is maintained in the selected state. This enables serial transfer execution (Figure 33.8). However, the communication end interrupt does not output when SSL0 input is fixed as Figure 33.8.

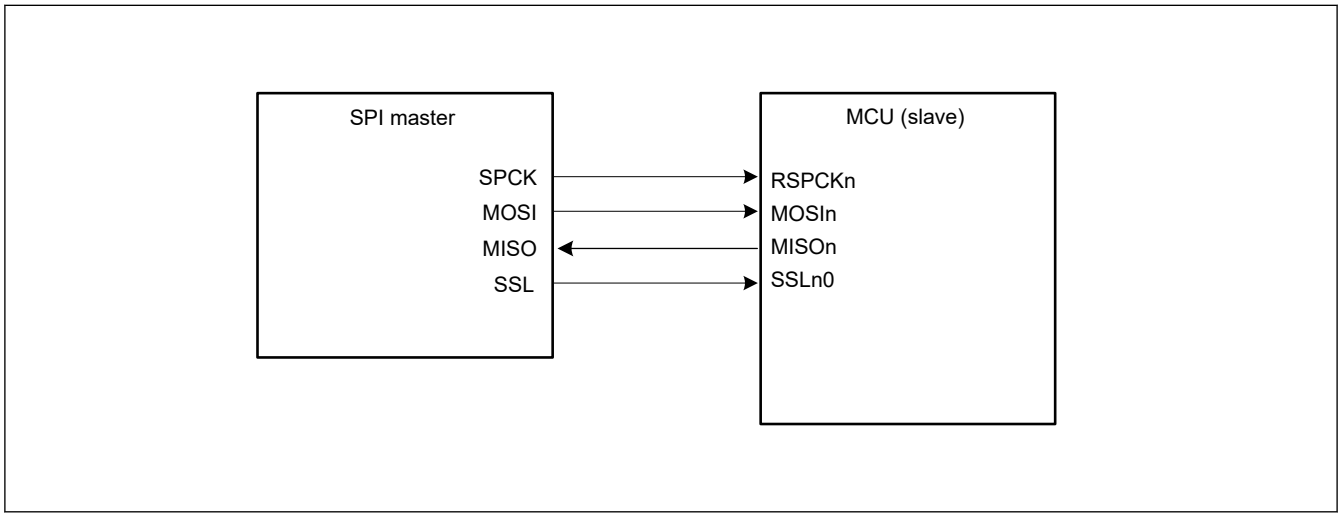

Figure 33.7 Single-master/single-slave configuration example with the MCU as a slave and CPHA = 0

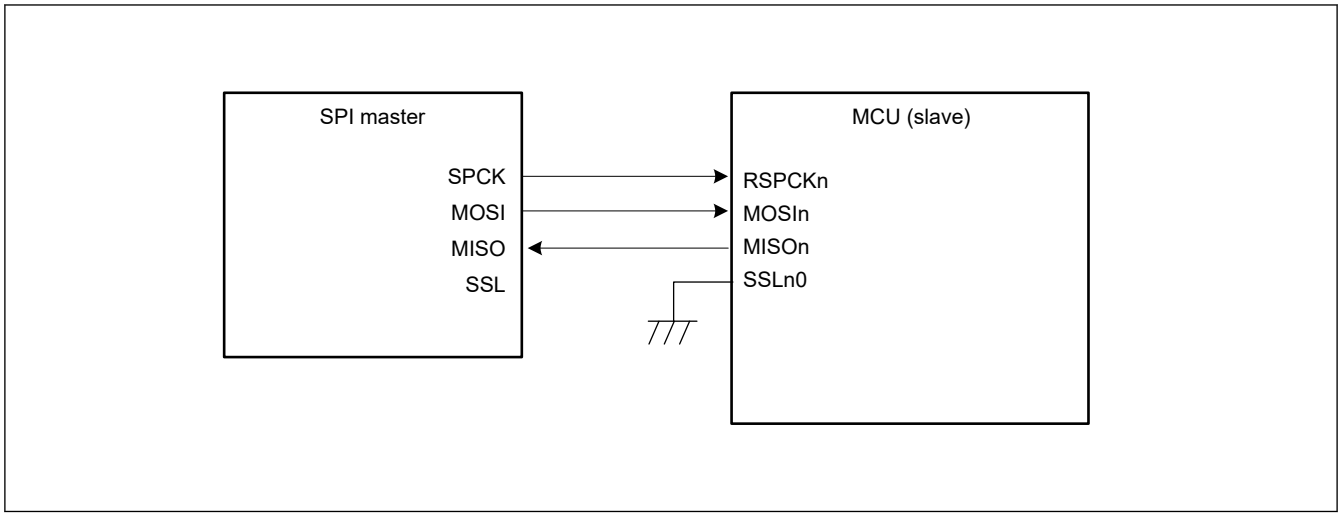

Figure 33.8 Single-master/single-slave configuration example with the MCU as a slave and CPHA = 1

33.3.3.3 Single-master/multi-slave with the MCU as a master

Figure 33.9 shows a single-master/multi-slave SPI system configuration example where the MCU is used as a master. In this example, the SPI system includes the MCU (master) and four slaves (SPI slave 0 to SPI slave 3).

The RSPCKn and MOSIn outputs of the MCU (master) are connected to the RSPCK and MOSI inputs of SPI slaves 0 to 3. The MISO outputs of SPI slaves 0 to 3 are all connected to the MISOn input of the MCU (master). The SSLn0 to SSLn3 outputs of the MCU (master) are connected to the SSL inputs of SPI slaves 0 to 3, respectively.

The MCU (master) drives the RSPCKn, MOSIn, and SSLn0 to SSLn3 signals. Out of the SPI slaves 0 to 3, the slave that receives low-level input into the SSL input drives the MISO signal.

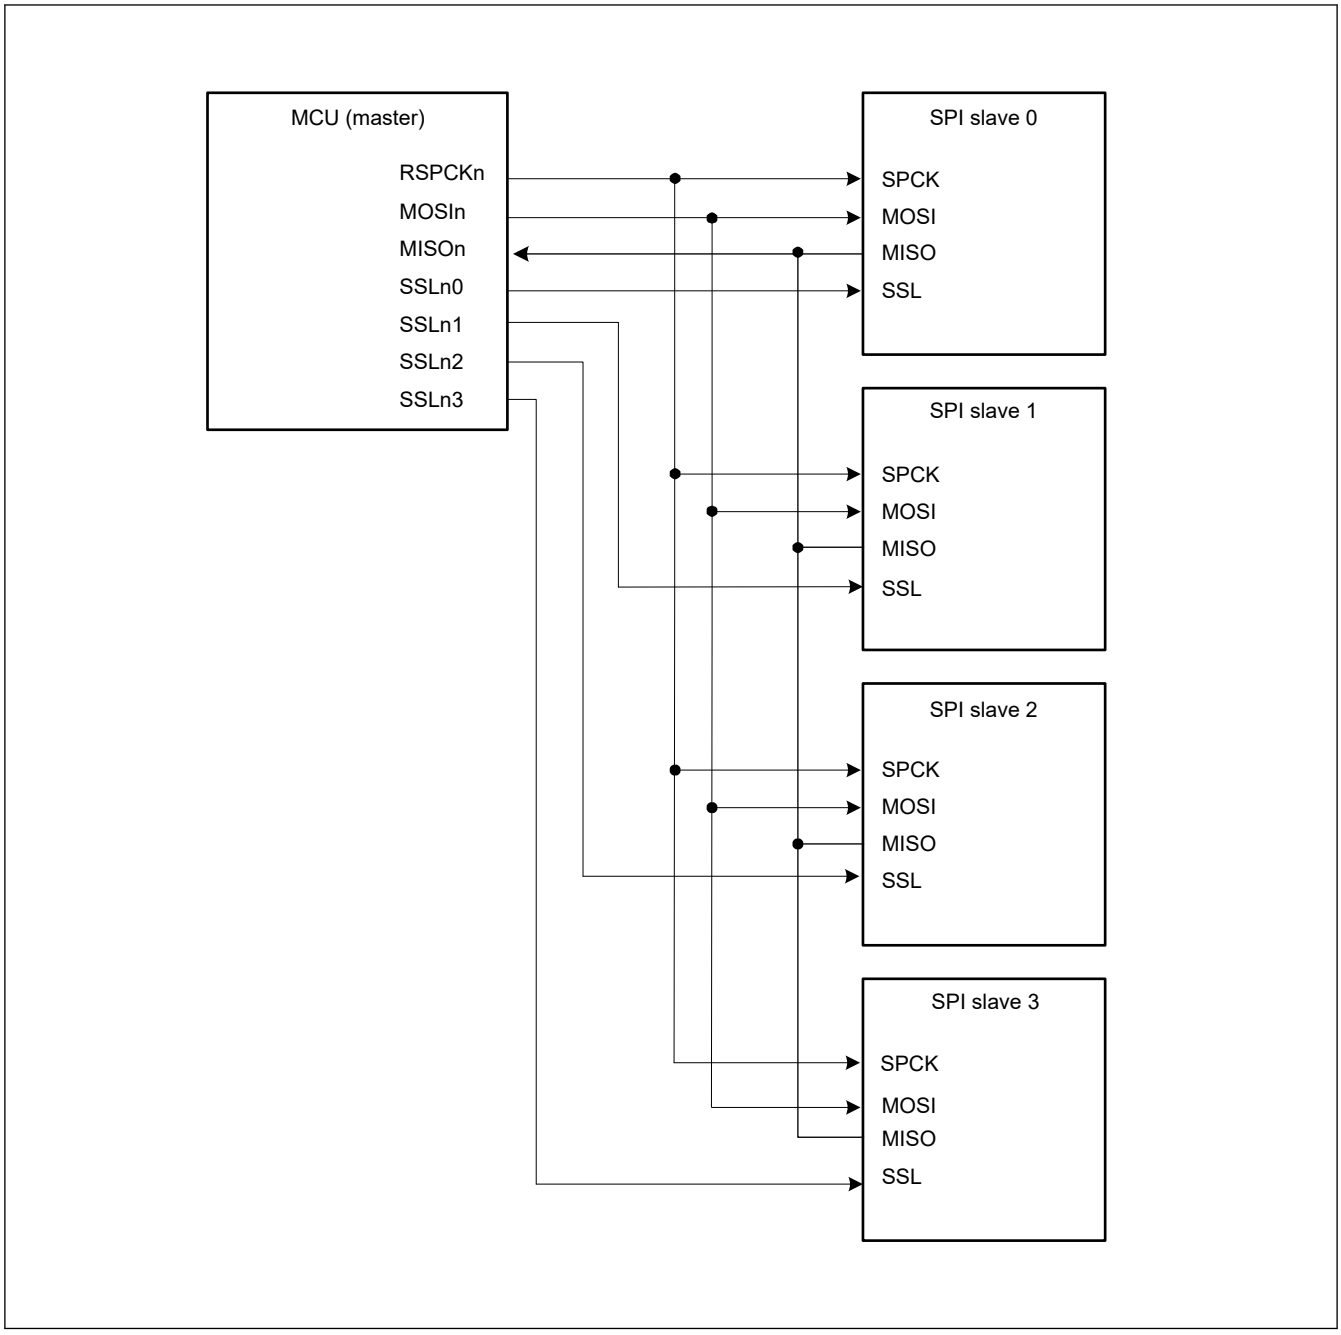

Figure 33.9 Single-master/multi-slave configuration example with the MCU as a master

33.3.3.4 Single-master/multi-slave with the MCU as a slave

Figure 33.10 shows a single-master/multi-slave SPI system configuration example where the MCU is used as a slave. In this example, the SPI system includes an SPI master and two MCUs (slaves X and Y).

The SPCK and MOSI outputs of the SPI master are connected to the RSPCKn and MOSIn inputs of the MCUs (slaves X and Y). The MISOn outputs of the MCUs (slaves X and Y) are all connected to the MISO input of the SPI master. The SSLX and SSLY outputs of the SPI master are connected to the SSLn0 inputs of the MCUs (slaves X and Y, respectively).

The SPI master drives the SPCK, MOSI, SSLX, and SSLY signals. Of the MCUs (slaves X and Y), the slave that receives low-level input into the SSLn0 input drives the MISOn signal.

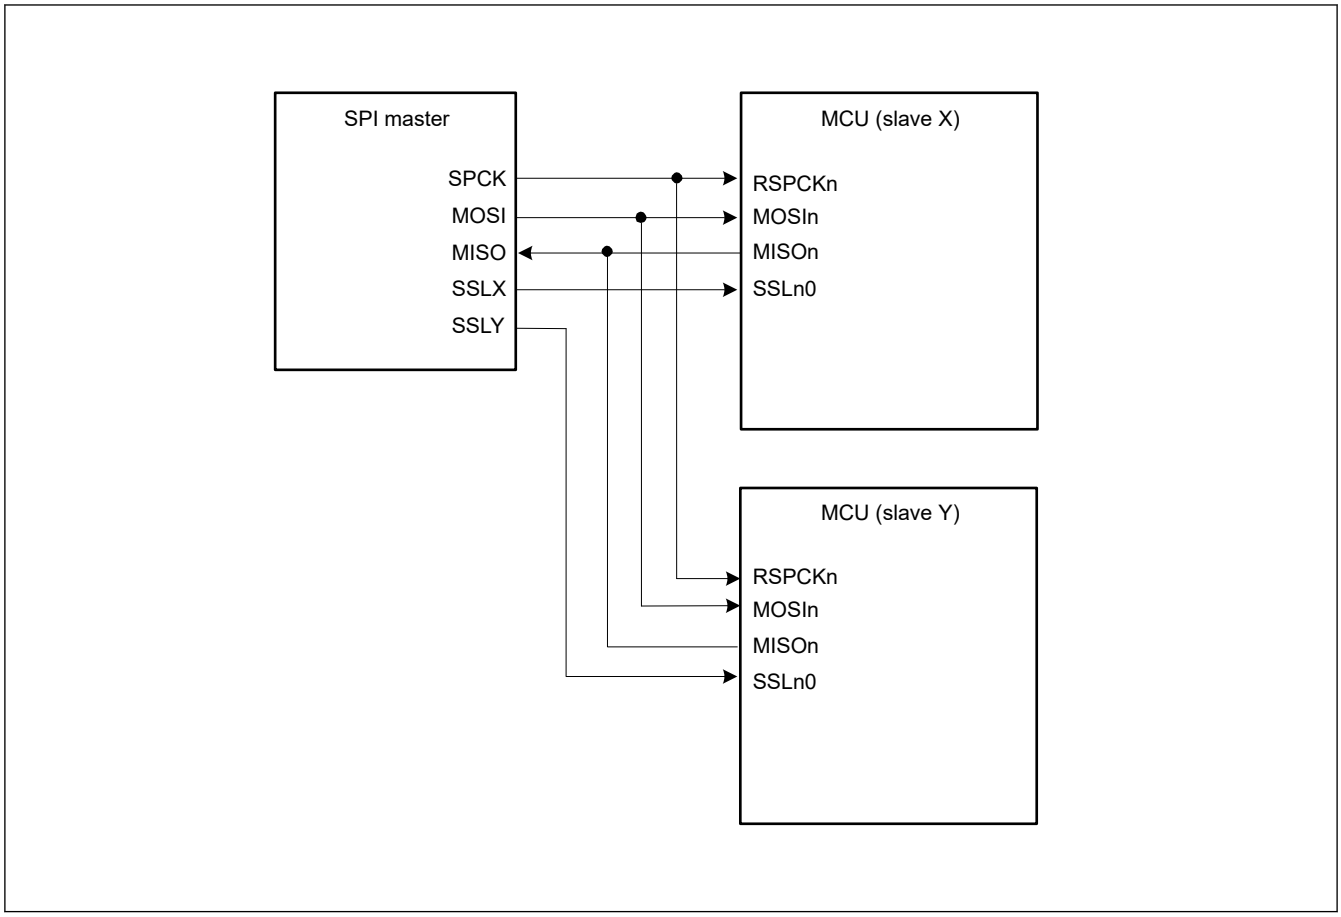

Figure 33.10 Single-master/multi-slave configuration example with the MCU as a slave

33.3.3.5 Multi-master/multi-slave with the MCU as a master

Figure 33.11 shows a multi-master/multi-slave SPI system configuration example where the MCU is used as a master. In this example, the SPI system includes two MCUs (masters X and Y) and two SPI slaves (SPI slaves 1 and 2).

The RSPCKn and MOSIn outputs of the MCUs (masters X and Y) are connected to the RSPCK and MOSI inputs of SPI slaves 1 and 2. The MISO outputs of SPI slaves 1 and 2 are connected to the MISOn inputs of the MCUs (masters X and Y). Any generic port Y output from the MCU (master X) is connected to the SSLn0 input of the MCU (master Y). Any generic port X output of the MCU (master Y) is connected to the SSLn0 input of the MCU (master X). The SSLn1 and SSLn2 outputs of the MCUs (masters X and Y) are connected to the SSL inputs of the SPI slaves 1 and 2. In this configuration example, because the system can be comprised solely of SSLn0 input, and SSLn1 and SSLn2 outputs for slave connections, the SSLn3 output of the MCU is not required.

The MCU drives the RSPCKn, MOSIn, SSLn1, and SSLn2 signals when the SSLn0 input level is high. When the SSLn0 input level is low, the MCU detects a mode fault error, sets RSPCKn, MOSIn, SSLn1, and SSLn2 to Hi-Z, and releases the SPI bus directly to the other master. Of the SPI slaves 1 and 2, the slave that receives low-level input into the SSL input drives the MISO signal.

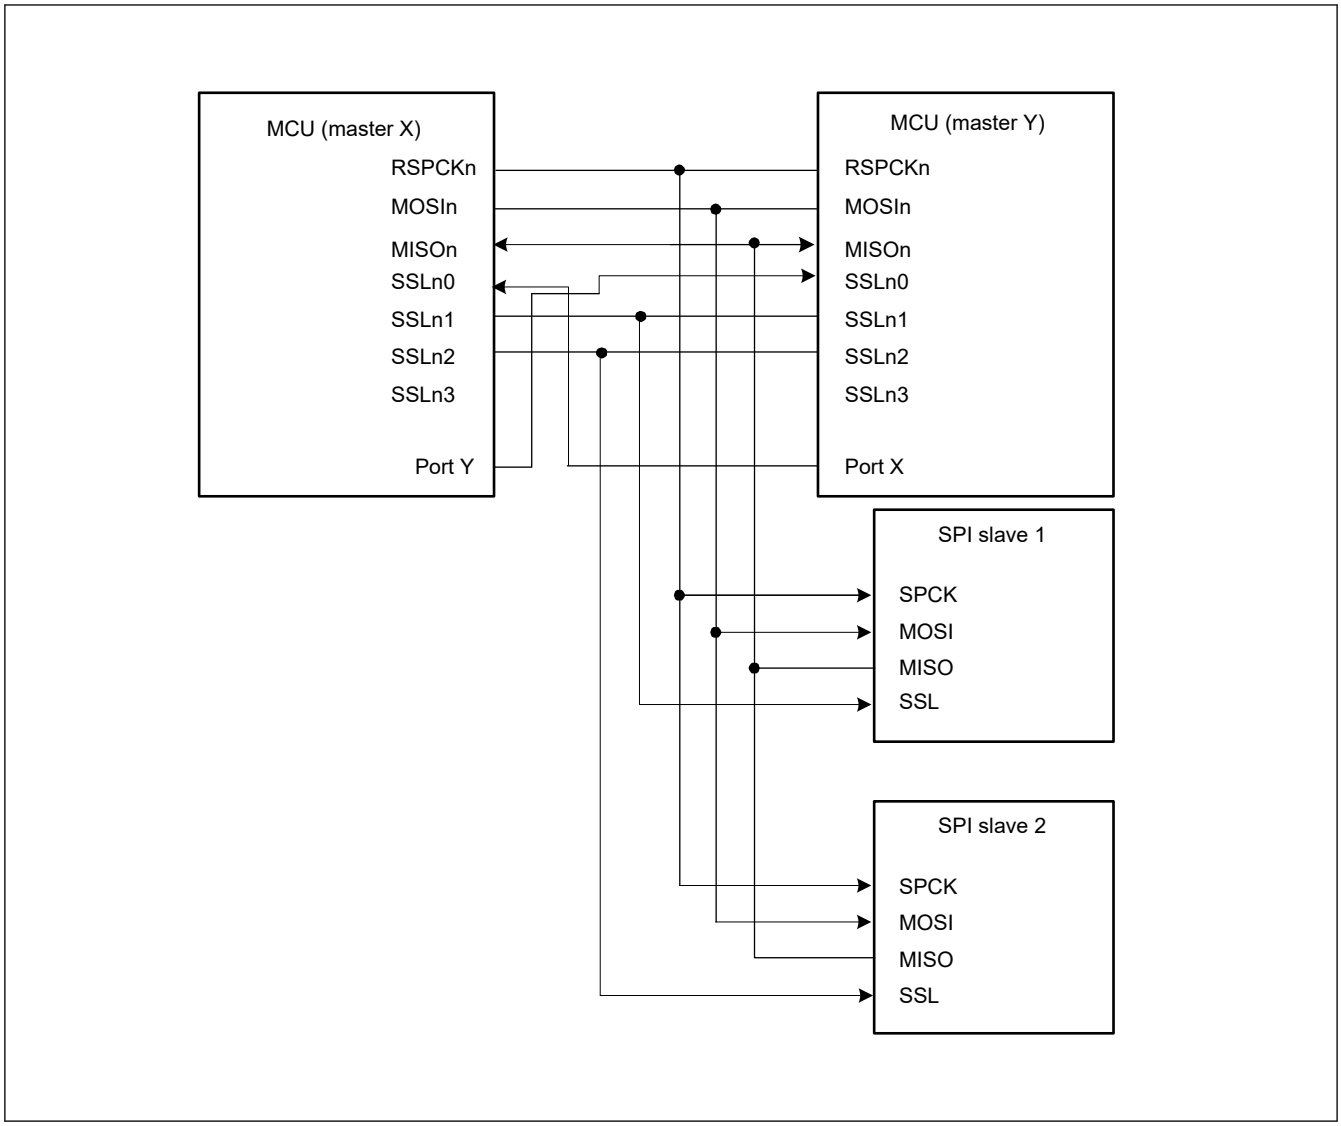

Figure 33.11 Multi-master/multi-slave configuration example with the MCU as a master

When setting TI SSP, enter the following levels for port X and port Y.

- Start of communication: the value of SPCR3.SSL0P of the other master.
- End of communication: the inverted value of SPCR3.SSL0P of the other master.

33.3.3.6 Master and slave in clock synchronous mode with the MCU configured as a master

Figure 33.12 shows a master and slave in clock synchronous mode configuration example where the MCU is used as a master. In this configuration, SSLni of the MCU (master) are not used.

The MCU (master) drives the RSPCKn and MOSIn signals. The SPI slave drives the MISO signal.

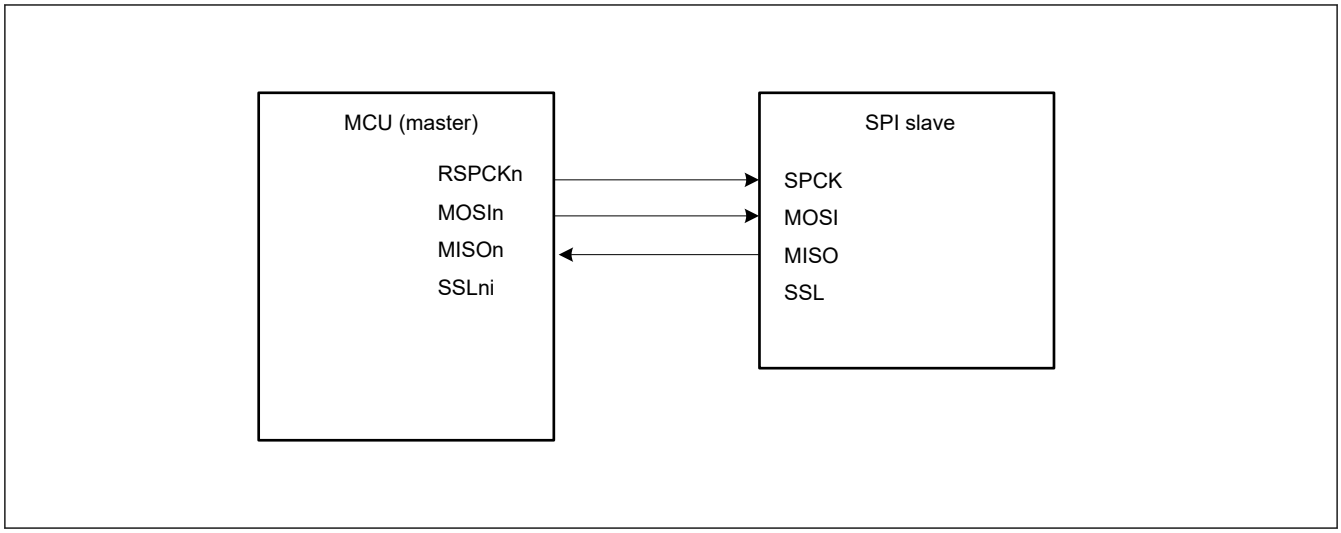

Figure 33.12 Clock synchronous master/slave configuration example with the MCU as a master

33.3.3.7 Master and slave in clock synchronous mode with the MCU as a slave

Figure 33.13 shows a master and slave in clock synchronous mode configuration example where the MCU is used as a slave. When the MCU operates as a slave (clock synchronous operation), the MCU (slave) drives the MISOn signal and the SPI master drives the SPCK and MOSI signals. In addition, SSLn0 to SSLn3 of the MCU (slave) are not used.

The MCU (slave) can only execute serial transfers in the single-slave configuration when the SPCMDm.CPHA bit is set to 1.

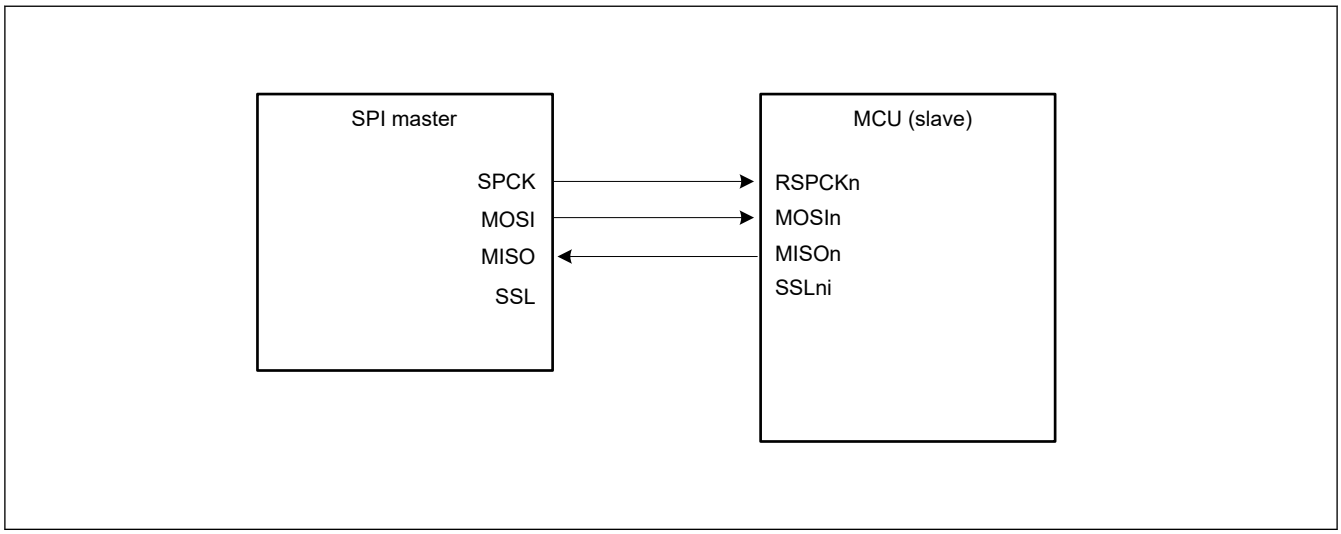

Figure 33.13 Clock synchronous master/slave configuration example with the MCU as a slave and CPHA = 1

33.3.4 Data Formats

The data format of the SPI depends on the settings in SPI Command Register m (SPCMDm) and the parity enable bit in SPI Control Register (SPCR.SPPE). Regardless of whether the MSB or LSB is first, the SPI treats the range from the LSB bit in the SPI Data Register (SPDR) to the bit associated with the selected data length, as transfer data.

This section shows the format of one frame of data before or after transfer.

Data format with parity disabled

When parity is disabled, transmission or reception of data proceeds with the length in bits selected in the SPI data length setting in SPI Command Register m (SPCMDm.SPB[4:0]).

Data format with parity enabled

When parity is enabled, transmission or reception of data proceeds with the length in bits selected in the SPI data length setting in SPI Command Register m (SPCMDm.SPB[4:0]). In this case, however, the last bit is a parity bit.

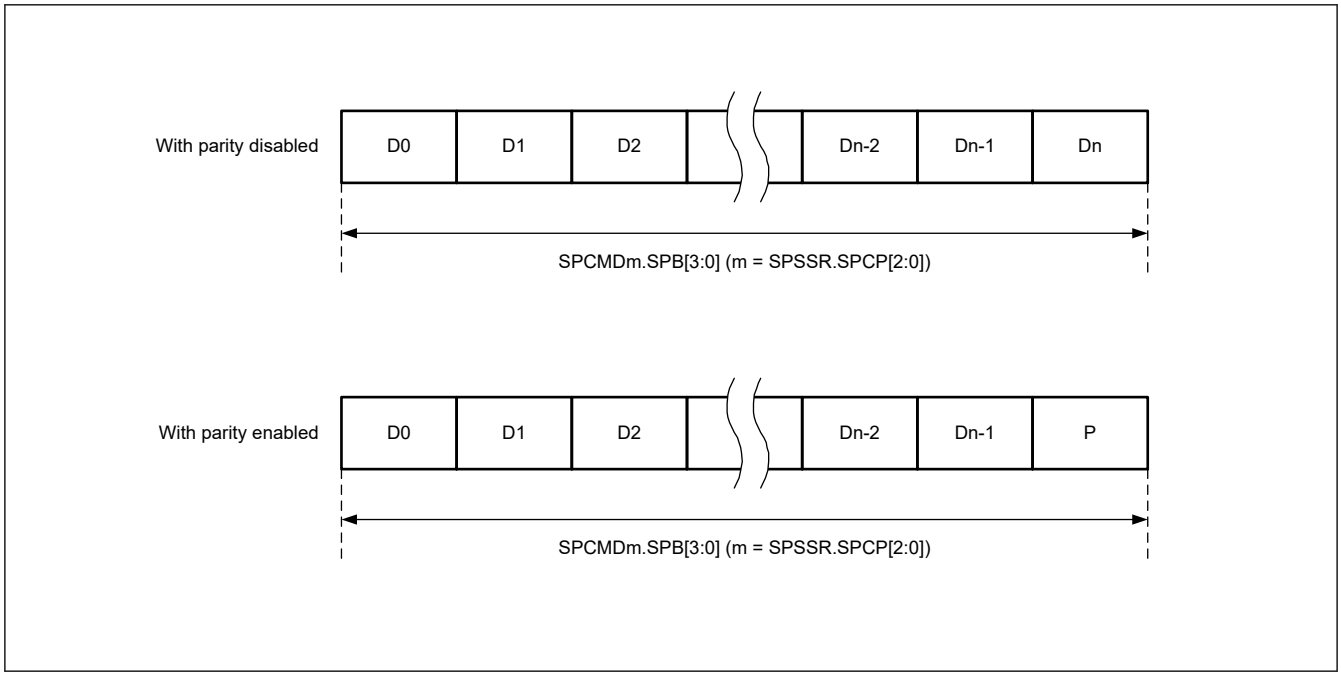

Figure 33.14 Data format with parity disabled and enabled

33.3.4.1 Operation when parity is disabled (SPCR.SPPE = 0)

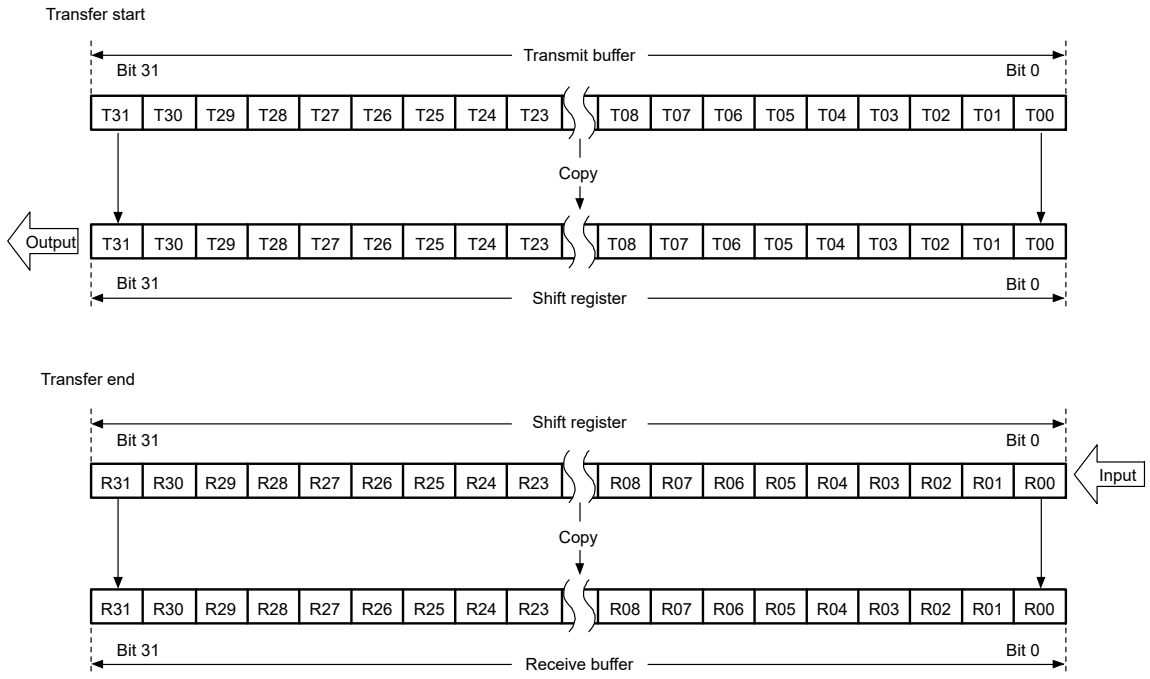
When parity is disabled, data for transmission is copied to the shift register with no pre-processing. This section describes the connection between the SPI Data Register (SPDR) and the shift register in terms of the combination of MSB- or LSB-first order and data length.

(1) MSB-first transfer with 32-bit data

Figure 33.15 shows the operation of the SPI Data Register (SPDR) and the shift register in a transfer with parity disabled, a SPI data length of 32 bits, and MSB-first selected.

In transmission, bits T31 to T00 from the current stage of the transmit buffer are copied to the shift register. Data for transmission is shifted out from the shift register from T31 to T30, and continuing to T00.

In reception, received data is shifted in bit-by-bit through bit[0] of the shift register. When the R31 to R00 bits are collected after input of the required number of RSPCK cycles, the value in the shift register is copied to the receive buffer.



Note: Output = MOSI (master)/MISO (slave), input = MISO (master)/MOSI (slave)

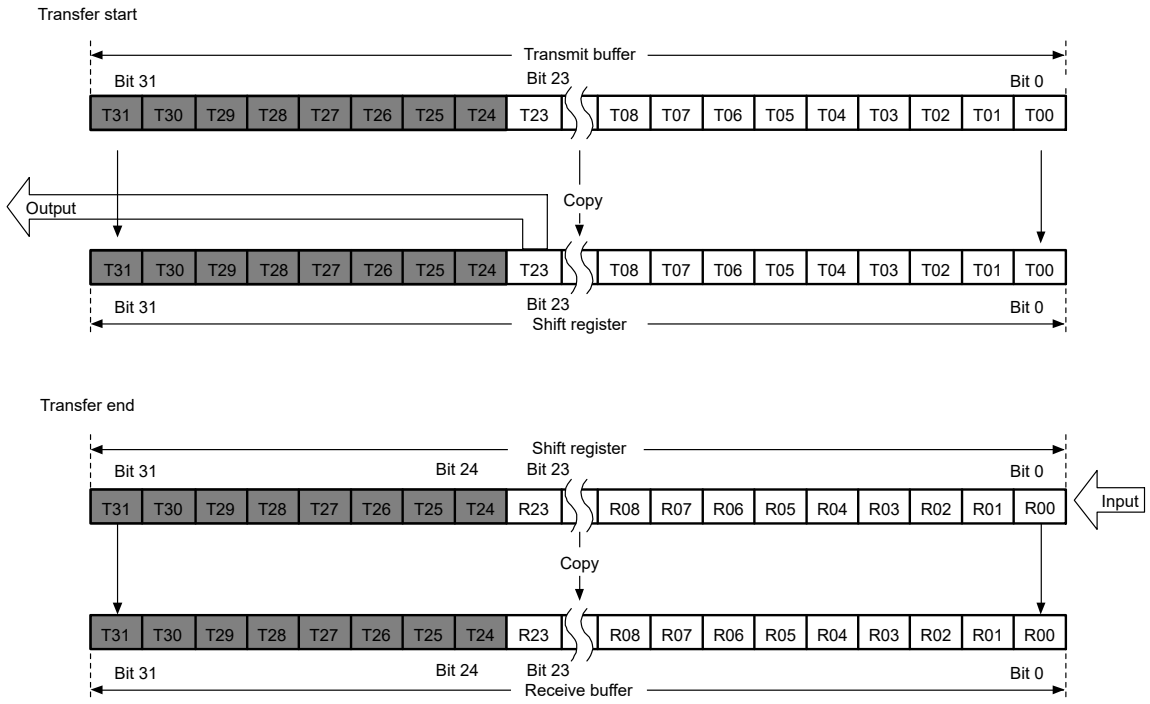
Figure 33.15 MSB-first transfer with 32-bit data and parity disabled

(2) MSB-first transfer with 24-bit data

Figure 33.16 shows the operation of the SPI Data Register (SPDR) and the shift register in a transfer with parity disabled, an SPI data length of 24 bits for an example that is not 32 bits, and MSB-first selected.

In transmission, the lower 24 bits (T23 to T00) from the current stage of the transmit buffer are copied to the shift register. Data for transmission is shifted out from the shift register from T23 to T22, and continuing to T00.

In reception, received data is shifted in bit-by-bit through bit[0] of the shift register. When the R23 to R00 bits are collected after input of the required number of RSPCK cycles, the value in the shift register is copied to the receive buffer.



Note: Output = MOSI (master)/MISO (slave), input = MISO (master)/MOSI (slave)

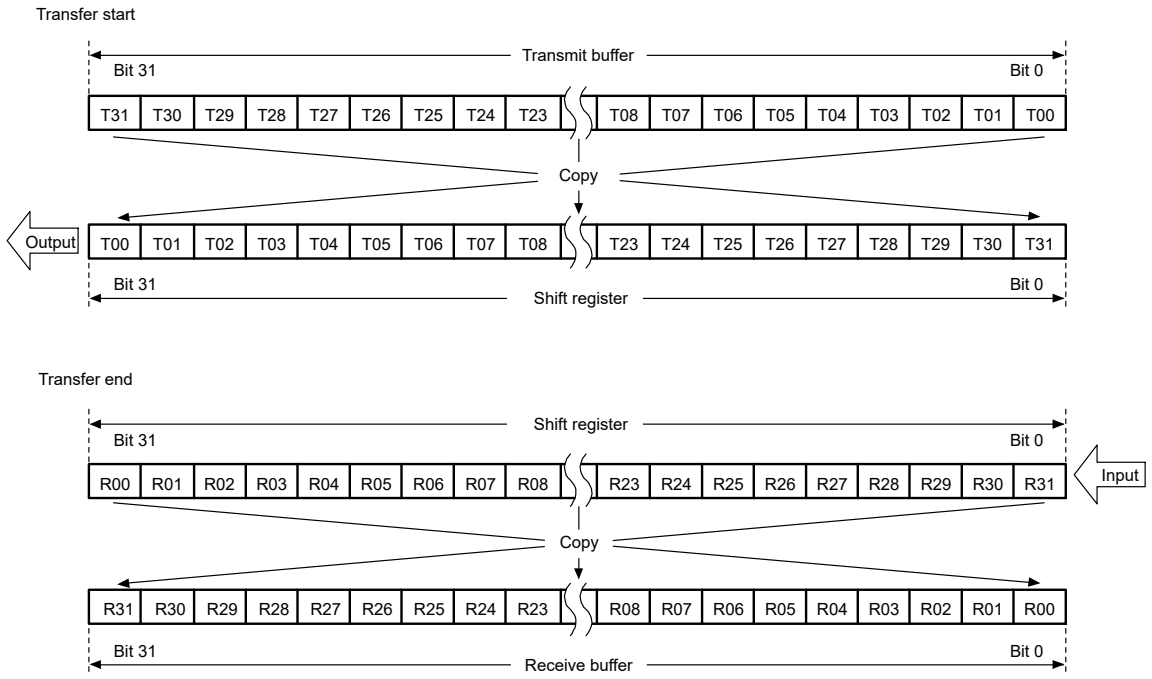
Figure 33.16 MSB-first transfer with 24-bit data and parity disabled

(3) LSB-first transfer with 32-bit data

Figure 33.17 shows the operation of the SPI Data Register (SPDR) and the shift register in a transfer with parity disabled, an SPI data length of 32 bits, and LSB-first selected.

In transmission, bits T31 to T00 from the current stage of the transmit buffer are reordered bit-by-bit to obtain the order T00 to T31 for copying to the shift register. Data for transmission is shifted out from the shift register in order from T00 to T01, and continuing to T31.

In reception, received data is shifted in bit-by-bit through bit[0] of the shift register. When the R00 to R31 bits are collected after input of the required number of RSPCK cycles, the value in the shift register is copied to the receive buffer.



Note: Output = MOSI (master)/MISO (slave), input = MISO (master)/MOSI (slave)

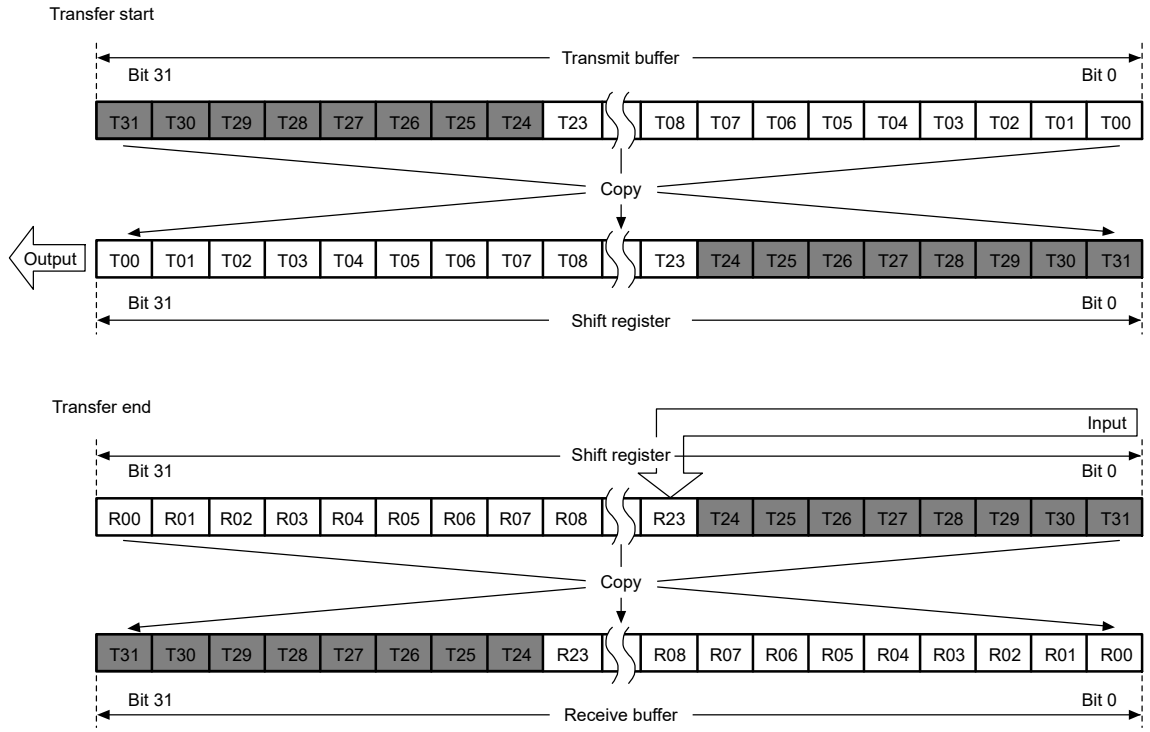
Figure 33.17 LSB-first transfer with 32-bit data and parity disabled

(4) LSB-first transfer with 24-bit data

Figure 33.18 shows the operation of the SPI Data Register (SPDR) and the shift register in transfers with parity disabled, an SPI data length of 24 bits for an example that is not 32, and LSB-first selected.

In transmission, the lower 24 bits (T23 to T00) from the current stage of the transmit buffer are reordered bit-by-bit to obtain the order T00 to T23 for copying to the shift register. Data for transmission is shifted out from the shift register from T00 to T01, and continuing to T23.

In reception, received data is shifted in bit-by-bit through bit[8] of the shift register. When the R00 to R23 bits are collected after input of the required number of RSPCK cycles, the value in the shift register is copied to the receive buffer.



Note: Output = MOSI (master)/MISO (slave), input = MISO (master)/MOSI (slave)

Figure 33.18 LSB-first transfer with 24-bit data and parity disabled

33.3.4.2 Operation when parity is enabled (SPCR.SPPE = 1)

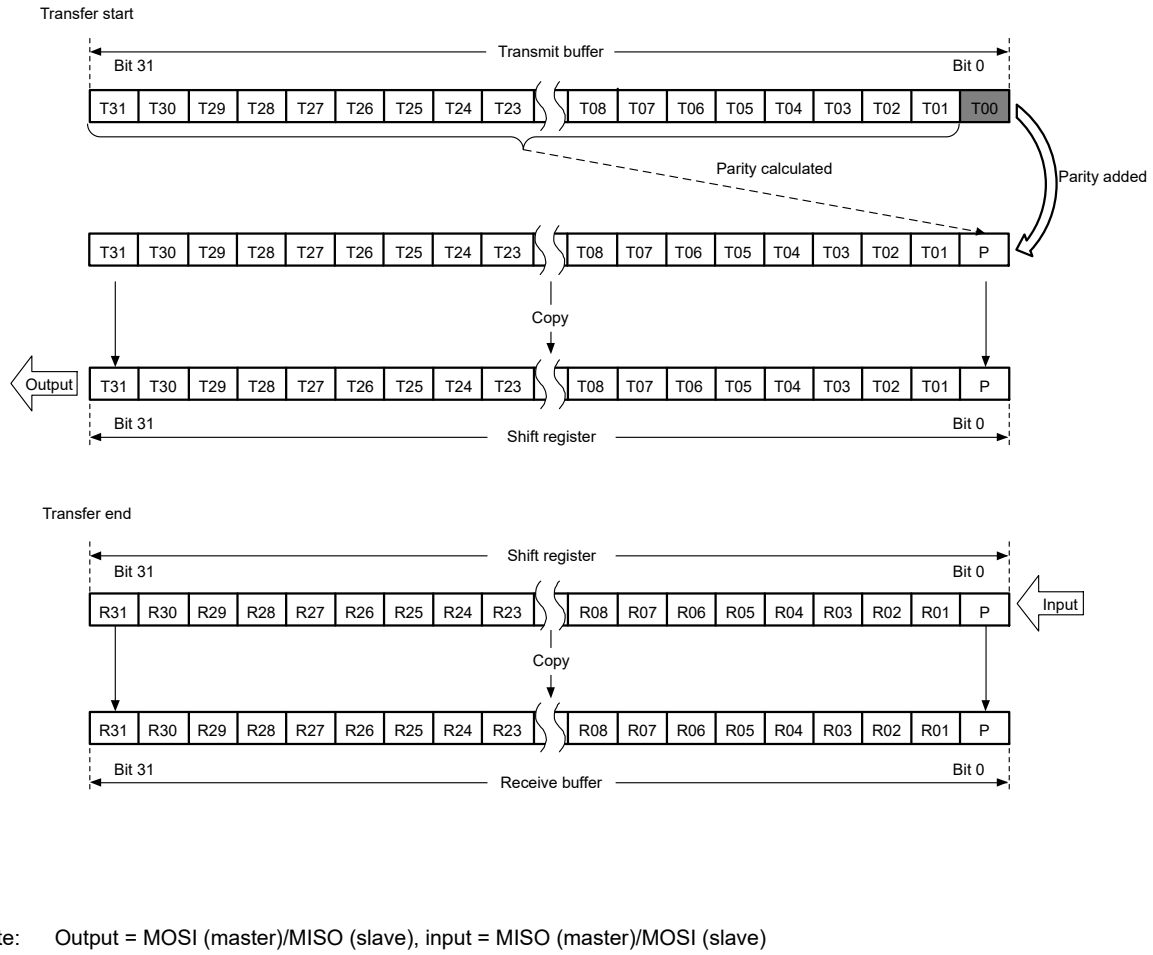
When parity is enabled, the lowest-order bit of the data for transmission becomes a parity bit. Hardware calculates the value of the parity bit.

(1) MSB-first transfer with 32-bit data

Figure 33.19 shows the operation of the SPI Data Register (SPDR) and the shift register in a transfer with parity enabled, an SPI data length of 32 bits, and MSB-first selected.

In transmission, the value of the parity bit (P) is calculated from bits T31 to T01. This replaces the final bit, T00, and the whole value is copied to the shift register. Data is transmitted in the order T31, T30, …, T01, and P.

In reception, received data is shifted in bit-by-bit through bit[0] of the shift register. When the R31 to P bits are collected after input of the required number of RSPCK cycles, the value in the shift register is copied to the receive buffer. On copying of data to the shift register, the data from R31 to P is checked for parity.



Note: Output = MOSI (master)/MISO (slave), input = MISO (master)/MOSI (slave)

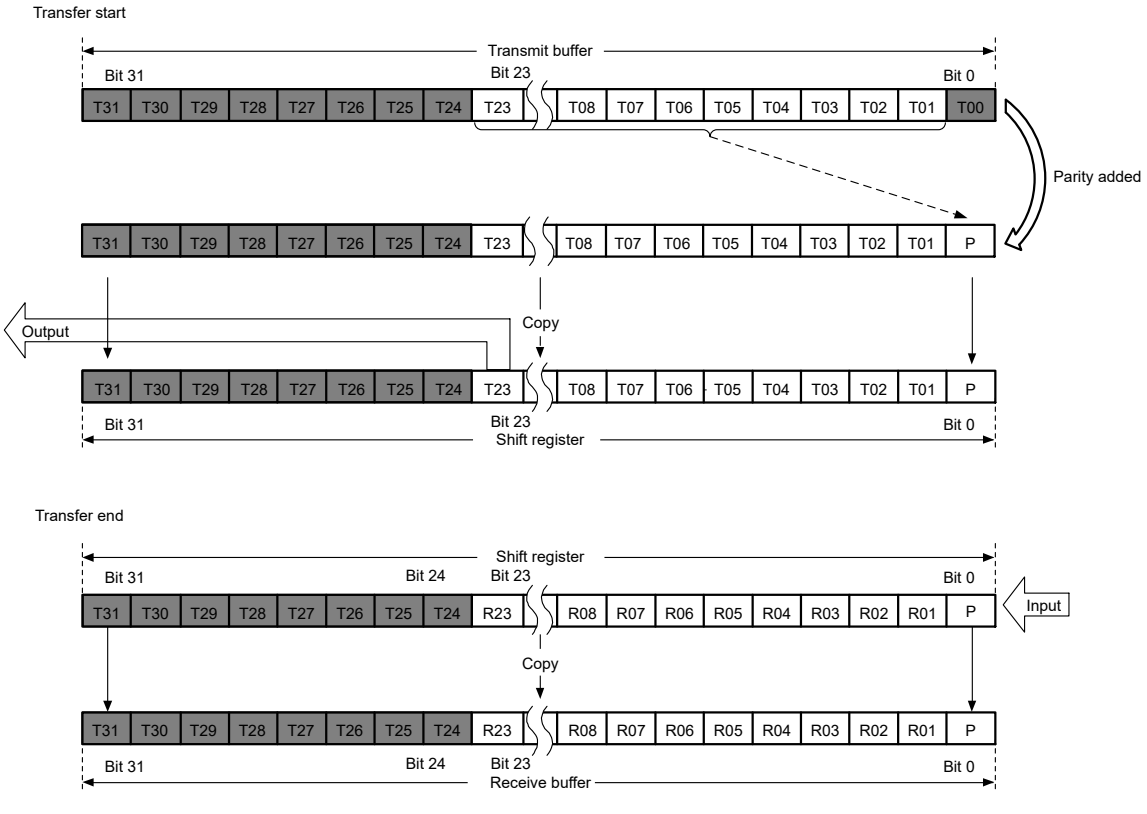
Figure 33.19 MSB-first transfer with 32-bit data and parity enabled

(2) MSB-first transfer with 24-bit data

Figure 33.20 shows the operation of the SPI Data Register (SPDR) and the shift register in a transfer with parity enabled, a SPI data length of 24 bits, and MSB-first selected.

In transmission, the value of the parity bit (P) is calculated from bits T23 to T01. This replaces the final bit, T00, and the whole value is copied to the shift register. Data is transmitted in the order T23, T22, …, T01, and P.

In reception, received data is shifted in bit-by-bit through bit[0] of the shift register. When the R23 to P bits are collected after input of the required number of RSPCK cycles, the value in the shift register is copied to the receive buffer. On copying of data to the shift register, the data from R23 to P is checked for parity.



Note: Output = MOSI (master)/MISO (slave), input = MISO (master)/MOSI (slave)

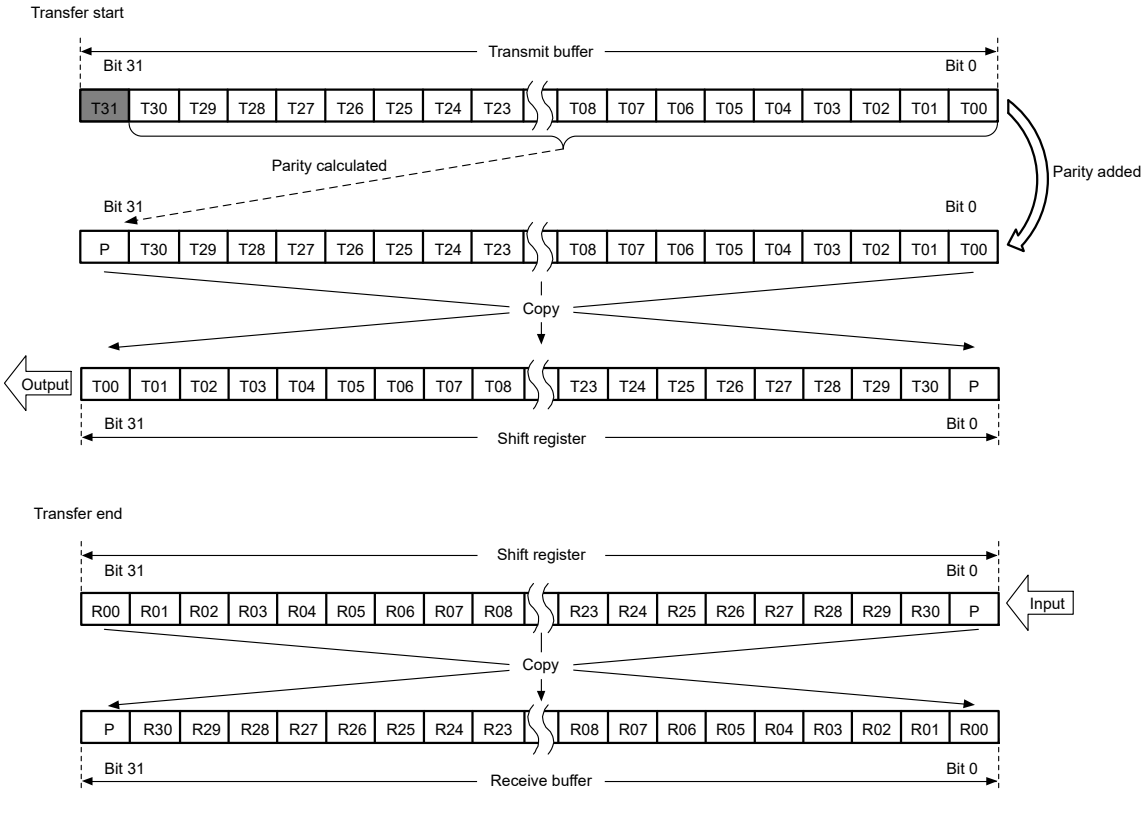
Figure 33.20 MSB-first transfer with 24-bit data and parity enabled

(3) LSB-first transfer with 32-bit data

Figure 33.21 shows the operation of the SPI Data Register (SPDR) and the shift register in a transfer with parity enabled, an SPI data length of 32 bits, and LSB-first selected.

In transmission, the value of the parity bit (P) is calculated from bits T30 to T00. This replaces the final bit, T31, and the whole value is copied to the shift register. Data is transmitted in the order T00, T01, …, T30, and P.

In reception, received data is shifted in bit-by-bit through bit[0] of the shift register. When the R00 to P bits are collected after input of the required number of RSPCK cycles, the value in the shift register is copied to the receive buffer. On copying of data to the shift register, the data from R00 to P is checked for parity.



Note: Output = MOSI (master)/MISO (slave), input = MISO (master)/MOSI (slave)

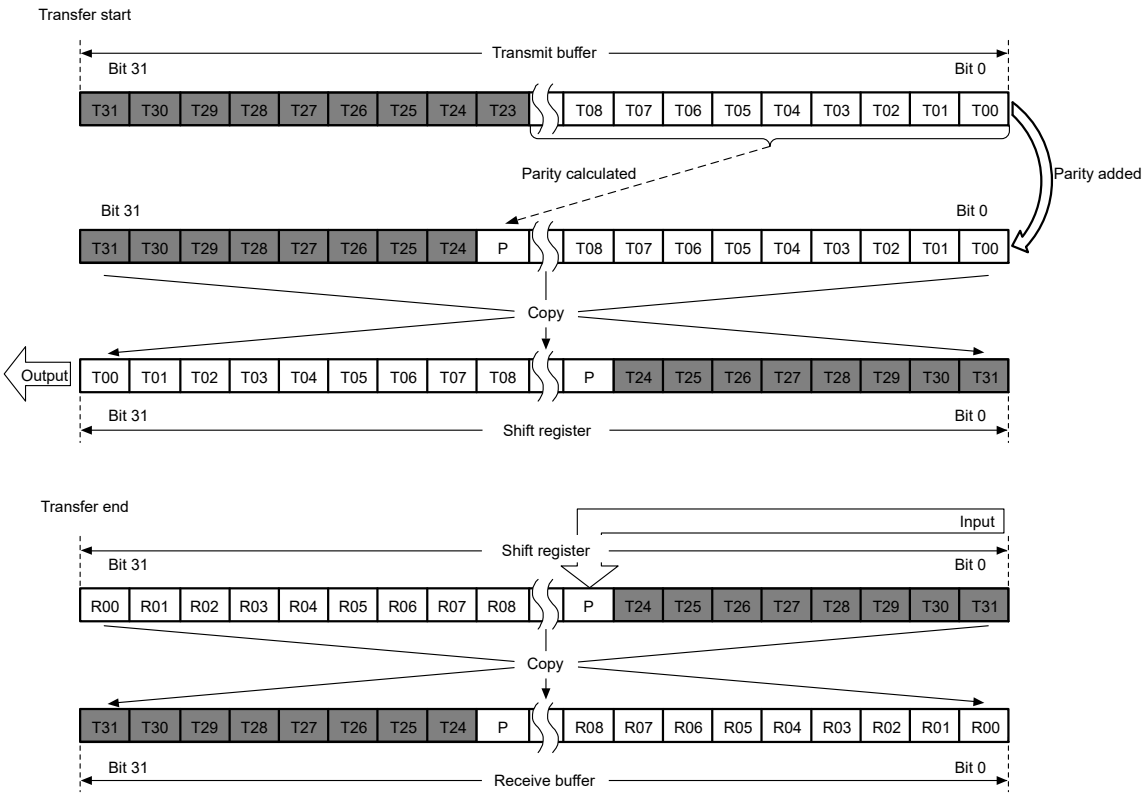
Figure 33.21 LSB-first transfer with 32-bit data and parity enabled

(4) LSB-first transfer with 24-bit data

Figure 33.22 shows the operation of the SPI Data Register (SPDR) and the shift register in a transfer with parity enabled, a SPI data length of 24 bits, and LSB-first selected.

In transmission, the value of the parity bit (P) is calculated from bits T22 to T00. This replaces the final bit, T23, and the whole value is copied to the shift register. Data is transmitted in the order T00, T01, …, T22, and P.

In reception, received data is shifted in bit-by-bit through bit[8] of the shift register. When the R00 to P bits are collected after input of the required number of RSPCK cycles, the value in the shift register is copied to the receive buffer. On copying of data to the shift register, the data from R00 to P is checked for parity.



Note: Output = MOSI (master)/MISO (slave), input = MISO (master)/MOSI (slave)

Figure 33.22 LSB-first transfer with 24-bit data and parity enabled

33.3.4.3 Byte Swap Transmission

When byte swapping is enabled, the data in the transmission buffer, swapped in 8-bit units, is copied to the shift register. Figure 33.23 shows the relationship between the SPDR (transmit buffer) and the shift register when transferring data with a 32-bit data length, using a combination of MSB / LSB first and with / without byte swap.

(1) MSB-first transfer. (When the byte swap is disabled.)

Data (Byte3 [T31 to T24] to Byte0 [T07 to T00]) in the transmit buffer are copied to the shift register.

Bit values in the shift register are shifted and transmitted in the order of T31 → T30 → … → T00 as transmit data.

(2) MSB-first transfer. (When the byte swap is enabled.)

Byte values of the transmit buffer (Byte3 [T31 to T24] to Byte0 [T07 to T00]) are reversed in byte units and are copied to the shift register in the order of Byte0 [T07 to T00] to Byte3 [T31 to T24].

Bit values in the shift register are shifted and transmitted in the order of T07 → T06 → … → T00 → T15 → T14 → … → T08 → T23 → T22 → … → T16 → T31 → T30 → … → T24 as transmit data.

(3) LSB-first transfer. (When the byte swap is disabled.)

Bit values of the transmit buffer (Byte3 [T31 to T24] to Byte0 [T07 to T00]) are reversed in bit units and are copied to the shift register in the order of Byte0 [T00 to T07] to Byte3 [T24 to T31].

Bit values in the shift register are shifted and transmitted in the order of T00 → T01 → … → T31 as transmit data.

(4) LSB-first transfer. (When the byte swap is enabled.)

Bit values of each byte of the transmit buffer (Byte3 [T31 to T24] to Byte0 [T07 to T00]) are reversed in bit units and are copied to the shift register in the order of Byte3 [T24 to T31] to Byte0 [T00 to T07].

Bit values in the shift register are shifted and transmitted in the order of T24 → T25 → … → T31 → T16 → T17 → … → T23 → T08 → T09 → … → T15 → T00 → T01 → … → T07 as transmit data.

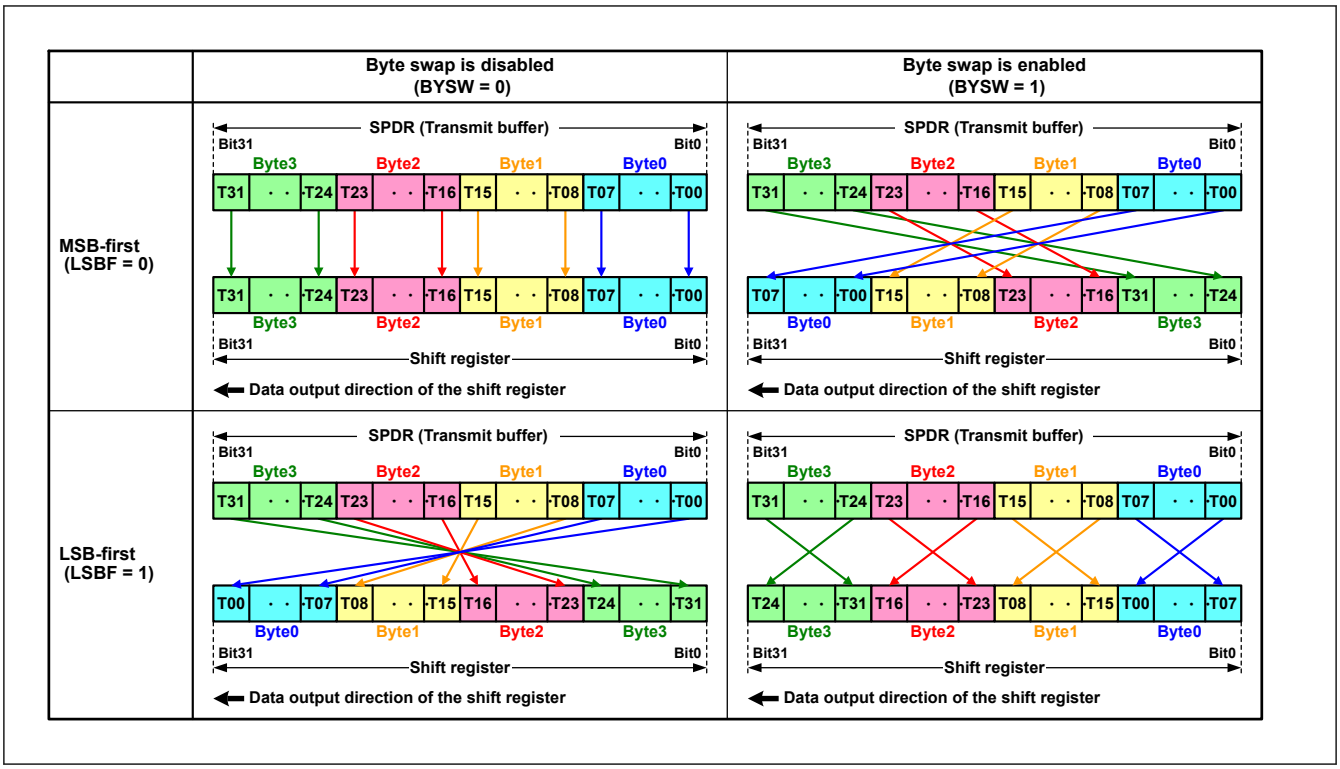


Figure 33.23 Byte swap with MSB/LSB transfer (32bit)

Figure 33.24 shows the relationship between the SPDR (transmit buffer) and the shift register when transferring data with a 16-bit data length, using a combination of MSB / LSB first and with / without byte swap.

1. MSB-first transfer. (When the byte swap is disabled.)
   Data (Byte1 [T15 to T08] to Byte0 [T07 to T00]) in the transmit buffer are copied to the shift register in the order of Byte1 [T15 to T08] to Byte0 [T07 to T00], Byte1 [T15 to T08] to Byte0 [T07 to T00]. Bit values in the shift register are shifted and transmitted in the order of T15 → T14 → … T00 as transmit data.
2. MSB-first transfer. (When the byte swap is enabled.)
   Byte values of the transmit buffer (Byte1 [T15 to T08] to Byte0 [T07 to T00]) are reversed in byte units and are copied to the shift register in the order of Byte0 [T07to T00] to Byte1 [T15 to T08], Byte0 [T07 to T00] to Byte1 [T15 to T08]. Bit values in the shift register are shifted and transmitted in the order of T07 → T06 → … T00 → T15 → T14 → … T08 as transmit data.
3. LSB-first transfer. (When the byte swap is disabled.)
   Bit values of the transmit buffer (Byte1 [T15 to T08] to Byte0 [T07 to T00]) are reversed in bit units and are copied to the shift register in the order of Byte0 [T00 to T07] to Byte1 [T08 to T15], Byte0 [T00 to T07] to Byte1 [T08 to T15]. Bit values in the shift register are shifted and transmitted in the order of T00 → T01 → … T15 as transmit data.
4. LSB-first transfer. (When the byte swap is enabled.)
   Bit values of each byte of the transmit buffer (Byte1 [T15 to T08] to Byte0 [T07 to T00]) are reversed in bit units and are copied to the shift register in the order of Byte1 [T08 to T15] to Byte0 [T00 to T07], Byte1 [T08 to T15] to Byte0 [T00 to T07]. Bit values in the shift register are shifted and transmitted in the order of T08 → T09 → … T15 → T00 → T01 → … T07 as transmit data.

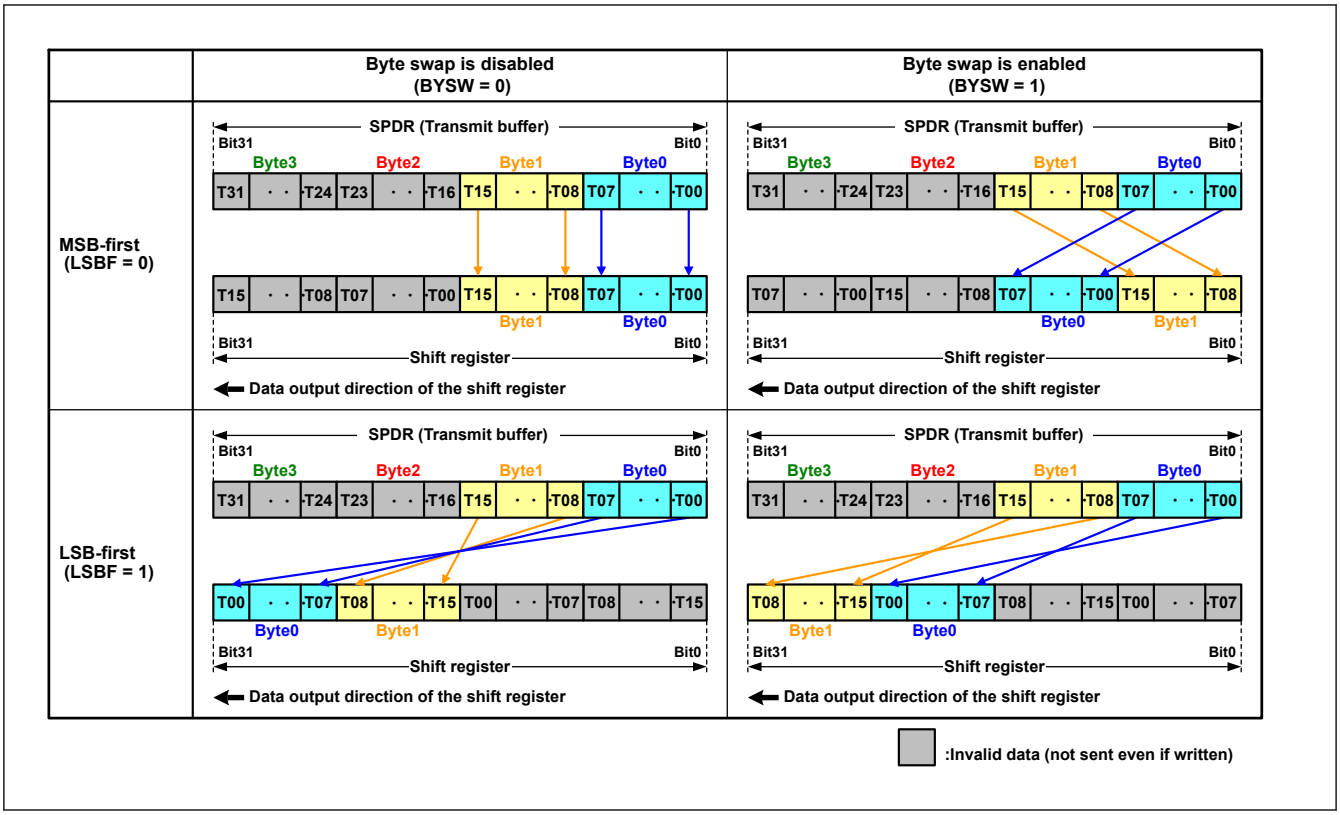

Figure 33.24 Byte swap with MSB/LSB transfer (16bit)

Note:
1. When using the byte swap, set 16 bits or 32 bits to the data length (SPCMDm.SPB[4:0] setting). If setting the other length, the behavior is not guaranteed.
2. When the byte swap is valid, set the parity function as invalid (SPCR.SPPE bit = 0). If setting the parity function as valid (SPPE bit = 1), the behavior is not guaranteed.
3. Set SPDCR.BYSW bit, when SPCR.SPE bit is 0. If rewriting BYSW bit, when SPE bit is 1, the behavior after it is not guaranteed.

33.3.4.4 Byte Swap Reception

When byte swap is enabled, the data in the shift register, swapped in 8-bit units, is copied to the receive buffer. Figure 33.25 shows the relationship between the shift register and SPDR (reception buffer) when transferring data with a 32-bit data length, using a combination of MSB / LSB first and with / without byte swap.

(1) MSB-first transfer (When the byte swap is disabled)

The first received data (R31) is stored in bit 0 of the shift register, and received data is shifted in the order of R31 → R30 → … → R00.

When necessary RSPCK cycles are input and data is stored from Byte3 [R31 to R24] to Byte0 [R07 to R00], the shift register value is copied to the receive buffer.

(2) MSB-first transfer (When the byte swap is enabled)

The first received data (R07) is stored in bit 0 of the shift register, and received data is shifted in the order of R07 → R06 → … → R00 → R15 → R14 → … → R08 → R23 → R22 → … → R16 → R31 → R30 → … → R24.

When necessary RSPCK cycles are input and data is stored from Byte0 [R07 to R00] to Byte3 [R31 to R24], byte values in the shift register are reversed in byte units and are copied to the receive buffer in the order of Byte3 [R31 to R24] to Byte0 [R07 to R00].

(3) LSB-first transfer (When the byte swap is disabled)

The first received data (R00) is stored in bit 0 of the shift register, and received data is shifted in the order of R00 → R01 → … → R31.

When necessary RSPCK cycles are input and data is stored from Byte0 [R00 to R07] to Byte3 [R24 to R31], bit values in the shift register are reversed in bit units and are copied to the receive buffer in the order of Byte3 [R31 to R24] to Byte0 [R07 to R00].

(4) LSB-first transfer (When the byte swap is enabled)

The first received data (R24) is stored in bit 0 of the shift register, and received data is shifted in the order of R24 → R25 → … → R31 → R16 → R17 → … → R23 → R08 → R09 → … → R15 → R00 → R01 → … → R07.

When necessary RSPCK cycles are input and data is stored from Byte3 [R24 to R31] to Byte0 [R00 to R07], bit values of each byte in the shift register are reversed in bit units and are copied to the receive buffer in the order of Byte3 [R31 to R24] to Byte0 [R07 to R00].

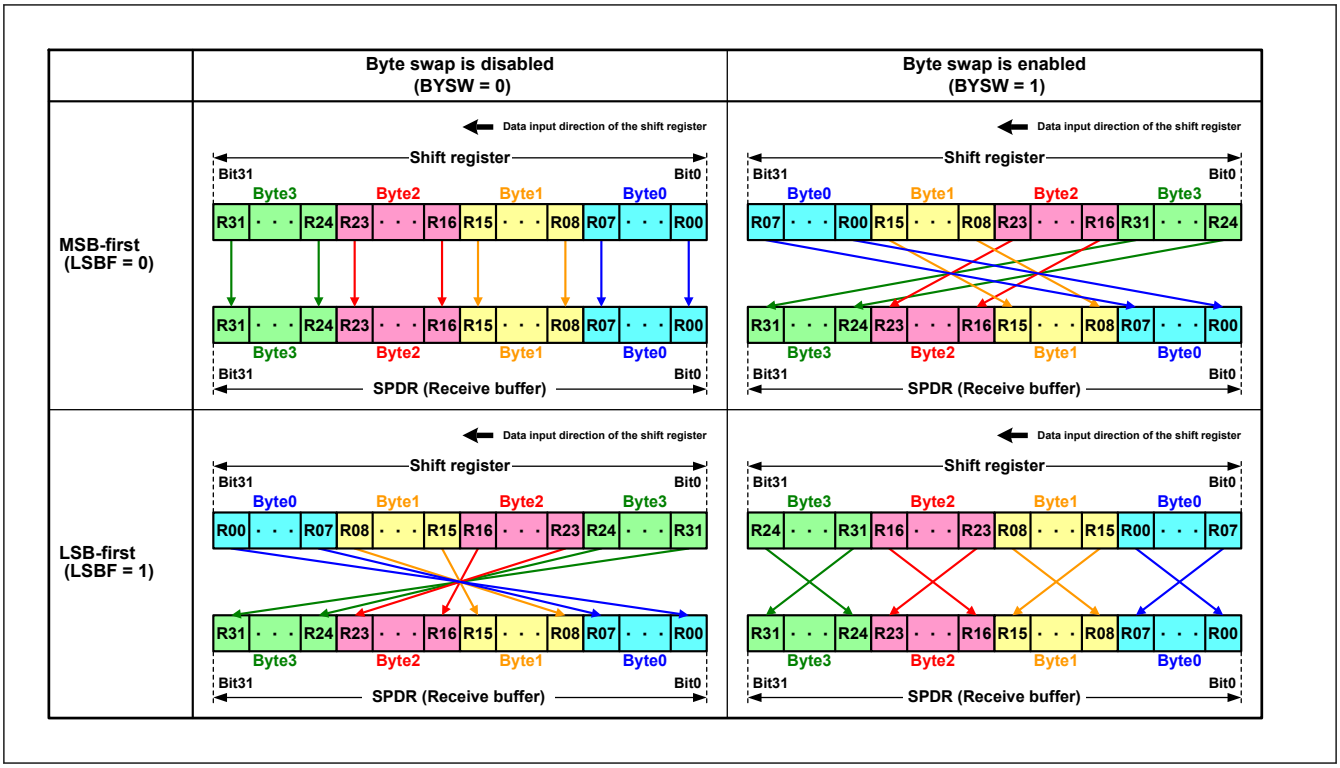

Figure 33.25 Byte swap with MSB/LSB transfer (32-bit)

Figure 33.26 shows the relationship between the shift register and SPDR (reception buffer) when transferring data with a 16-bit data length, using a combination of MSB / LSB first and with / without byte swap.

1. MSB-first transfer (when the byte swap is disabled)
   The first received data (R15) is stored in bit 0 of the shift register, and received data is shifted in the order of R15 → R14 → … R00. When necessary RSPCK cycles are input and data is stored from Byte3 [R31 to R24] to Byte0 [R07 to R00], the shift register value is copied to the receive buffer.
2. MSB-first transfer (when the byte swap is enabled)
   The first received data (R07) is stored in bit 0 of the shift register, and received data is shifted in the order of R07 → R06 → … R00 → R15 → R14 → … R08. When necessary RSPCK cycles are input and data is stored from Byte0 [R07 to R00] to Byte1 [R15 to R08], byte values in the shift register are reversed in byte units and are copied to the receive buffer in the order of Byte3 [R31 to R24] to Byte0 [R07 to R00].
3. LSB-first transfer (when the byte swap is disabled)
   The first received data (R00) is stored in bit 15 of the shift register, and received data is shifted in the order of R00 → R01 → … R07 → R08 → R09 → … R15. When necessary RSPCK cycles are input and data is stored from Byte0 [R00 to R07] to Byte1 [R08 to R15], bit values in the shift register are reversed in bit units and are copied to the receive buffer in the order of Byte3 [R31 to R24] to Byte0 [R07-R00].
4. LSB-first transfer (when the byte swap is enabled)
   The first received data (R08) is stored in bit 15 of the shift register, and received data is shifted in the order of R08 → R09 → … R15 → R00 → R01 → … R07. When necessary RSPCK cycles are input and data is stored from Byte1 [R08

to R15] to Byte0 [R00 to R07], bit values of each byte in the shift register are reversed in bit units and are copied to the receive buffer in the order of Byte3 [R31 to R24] to Byte0 [R07 to R00].

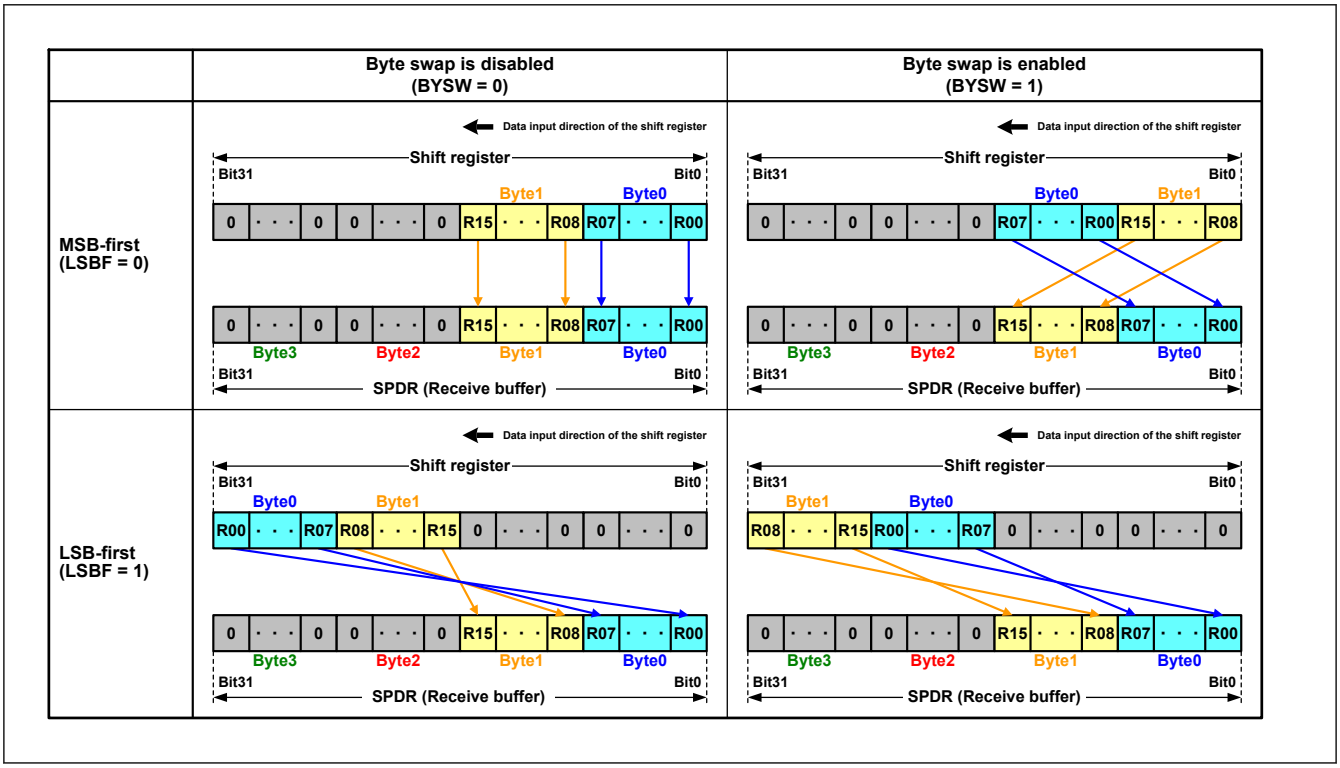

Figure 33.26 Byte swap with MSB/LSB transfer(16-bit)

Note: 1. When using the byte swap, set 16 bits or 32 bits to the data length (SPCMDm.SPB[4:0] setting). If setting the other length, the behavior is not guaranteed.
2. When the byte swap is valid, set the parity function as invalid (SPCR.SPPE bit = 0). If setting the parity function as valid (SPPE bit = 1), the behavior is not guaranteed.
3. Set SPDCR.BYSW bit, when SPCR.SPE bit is 0. If rewriting BYSW bit, when SPE bit is 1, the behavior after it is not guaranteed.

33.3.5 Transfer Formats

33.3.5.1 When CPHA = 0

Figure 33.27 shows an example transfer format for the serial transfer of 8-bit data when the SPCMDm.CPHA bit is 0. Do not perform clock synchronous operation (SPCR.SPMS = 1) when the SPI operates in slave mode (SPCR.MSTR = 0) and the CPHA bit is 0. In Figure 33.27, RSPCKn (CPOL = 0) indicates the RSPCKn signal waveform when the SPCMDm.CPOL bit is 0, and RSPCKn (CPOL = 1) indicates the RSPCKn signal waveform when the CPOL bit is 1. The sampling timing represents the timing at which the SPI fetches serial transfer data into the shift register. The I/O directions of the signals depend on the SPI settings. For details, see section 33.3.2. Controlling the SPI Pins.

When the SPCMDm.CPHA bit is 0, the driving of valid data to the MOSIn and MISOn signals begins at an SSLni signal assertion. The first RSPCKn signal change that occurs after the SSLni signal assertion becomes the first transfer data fetch. After this, data is sampled every 1 RSPCKn cycle. The change timing for MOSIn and MISOn signals is 1/2 RSPCK cycles after the transfer data fetch timing. The CPOL bit setting does not affect the RSPCKn signal operation timing as it only affects the signal polarity.

t1 denotes the RSPCK delay, the period from an SSLni signal assertion to RSPCKn oscillation. t2 denotes the SSL negation delay, the period from the termination of RSPCKn oscillation to an SSLni signal negation. t3 denotes the next-access delay, the period in which SSLni signal assertion is suppressed for the next transfer after the end of serial transfer. t1, t2, and t3 are controlled by a master device running on the SPI system. For a description of t1, t2, and t3 when the SPI is in master mode, see section 33.3.12.1. Master mode operation.

[In the Motorola-SPI case]

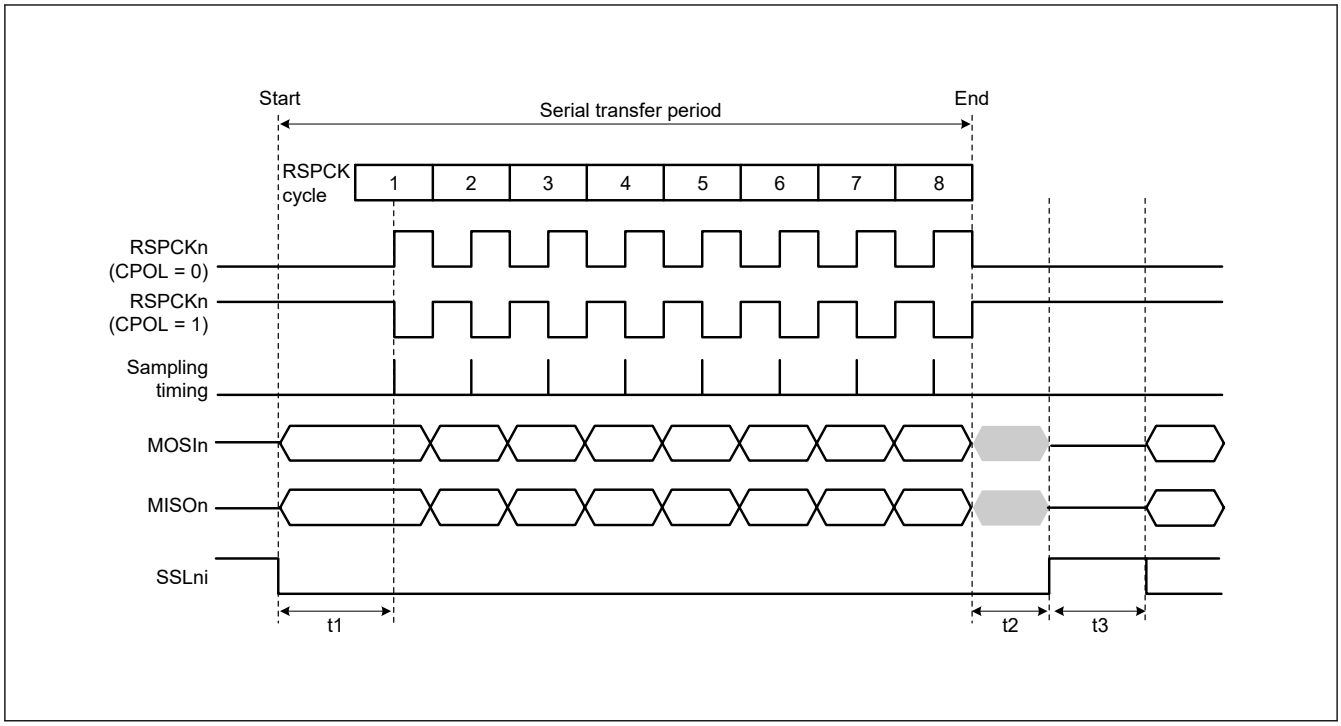

Figure 33.27 SPI transfer format when CPHA = 0, SPFRF = 0

[In TI-SSP case]

Not supported in CPHA = 0

33.3.5.2 When CPHA = 1

Figure 33.28 shows an example transfer format for the serial transfer of 8-bit data when the SPCMDm.CPHA bit is 1. However, when the SPCR.SPMS bit is 1, the SSLni signals are not used, and only the three signals RSPCKn, MOSIn, and MISOn handle communications. In Figure 33.28, RSPCKn (CPOL = 0) indicates the RSPCKn signal waveform when the SPCMDm.CPOL bit is 0 and RSPCKn (CPOL = 1) indicates the RSPCKn signal waveform when the CPOL bit is 1. The sampling timing represents the timing at which the SPI fetches serial transfer data into the shift register. The I/O directions of the signals depend on the SPI mode (master or slave mode). For details, see section 33.3.2. Controlling the SPI Pins.

When the SPCMDm.CPHA bit is 1, the driving of invalid data to the MISOn signal begins at an SSLni signal assertion. The output of valid data to the MOSIn and MISOn signals begins at the first RSPCKn signal change that occurs after the SSLni signal assertion. After this, data is updated every 1 RSPCK cycle. The transfer data fetch timing is 1/2 RSPCK cycles after the data update timing. The SPCMDm.CPOL bit setting does not affect the RSPCKn signal operation timing. It only affects the signal polarity.

t1, t2, and t3 are the same as those when CPHA = 0. For a description of t1, t2, and t3 when the SPI of the MCU is in master mode, see section 33.3.12.1. Master mode operation.

[In the Motorola-SPI case]

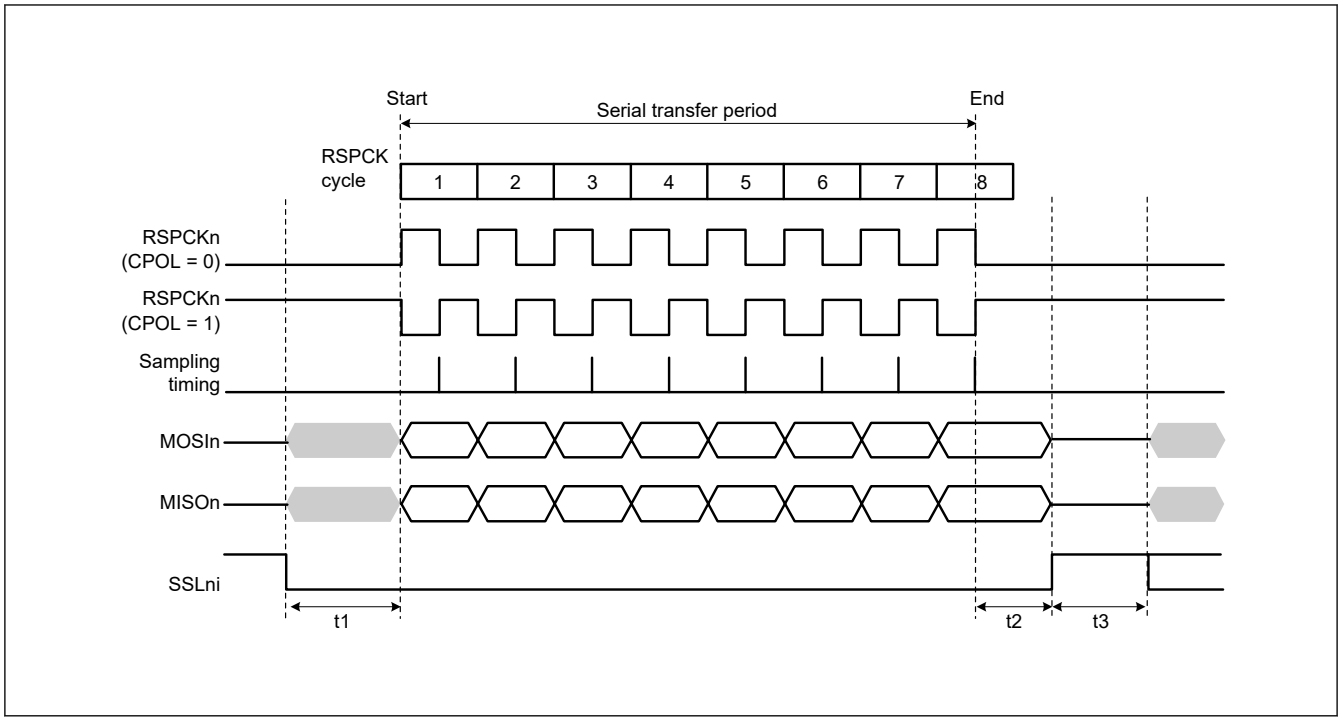

Figure 33.28 SPI transfer format when CPHA = 1, SPFRF = 0

[In the TI-SSP case]

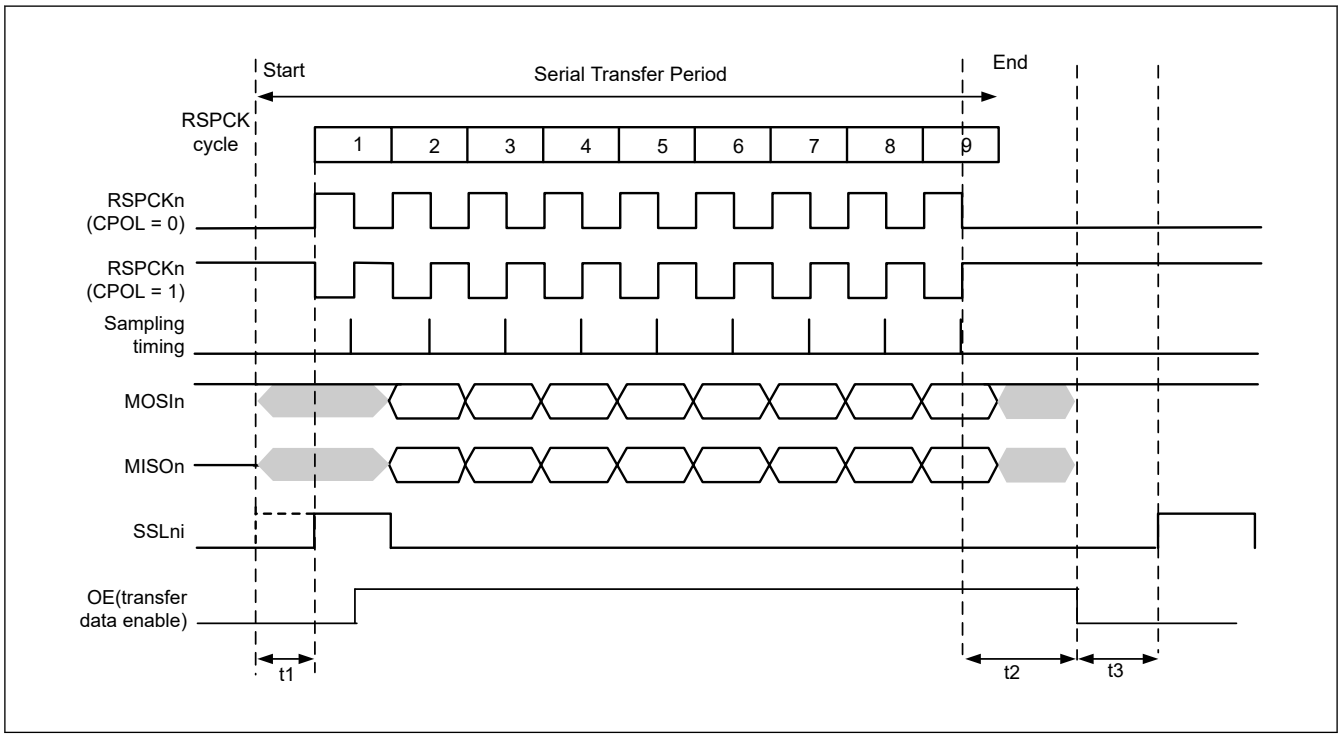

Figure 33.29 SPI transfer format when CPHA = 1, SPFRF = 1

33.3.6 Communication Operating Mode

Transmit-Receive serial communication, transmit-only operation, and Receive-only operation are selected by setting the Communication Mode Select bits (TXMD [1:0]) of the SPI control register (SPCR).

SPDR access described in Figure 33.30, Figure 33.31, Figure 33.32 shows an access to the SPI data register (SPDR). W shows a write cycle.

33.3.6.1 Transmit-Receive Serial Communication (TXMD[1:0] = 00b)

Figure 33.30 shows an example of operation when the communication mode select bit (TXMD[1:0]) in the SPI control register (SPCR) is set to 00b. In the example, the SPI performs an 8-bit serial transfer when the SPDCR2.TTRG is 0, the SPDCR2.RTRG is FIFO stage - 1, the SPCMDm.CPHA bit is 1, and the SPCMDm.CPOL bit is 0. The numbers given for RSPCKn in the waveform represent the number of RSPCK cycles, such as the number of transferred bits.

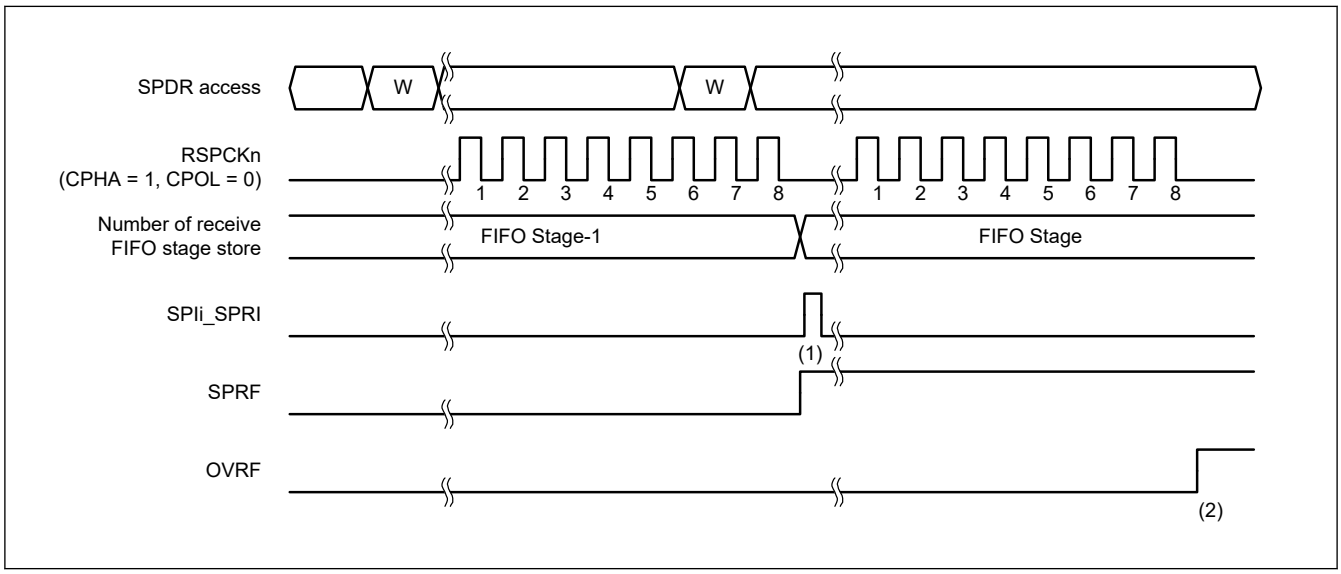

Figure 33.30 Operation example when SPCR.TXMD[1:0] = 00b

The operation of the flags at timings (1) and (2) in Figure 33.30 is as follows:

1. When serial transfer ends while the number of SPDR receive buffer store matches the number of frames set in SPDCR2.RTRG, the SPI generates a receive buffer full interrupt request (SPIi_SPRI), the SPI sets the SPSR.SPRF flag to 1, and copies the received data in the shift register to the receive buffer.
2. When serial transfer ends with data for the number of FIFO stages stored in the SPDR receive buffer, the SPI sets the SPSR.OVRF flag to 1, and discards the received data in the shift register. For details about the operation of the SPSR.OVRF flag, see section 33.3.10.1. Overrun errors.

In Transmit-Receive serial communication (TXMD[1:0] = 00b), transmit data is transmitted and receive data is received. Therefore, the SPRF flag and the OVRF flag are set to 1 at timings (1) and (2) respectively.

33.3.6.2 Transmit-Only Serial Communications (TXMD[1:0] = 01b)

Figure 33.31 shows an example of operation when the communication mode select bit (TXMD[1:0]) in the SPI control register (SPCR) is set to 01b. In this example, the SPI performs an 8-bit serial transfer when the SPDCR2.TTRG is 0, the SPDCR2.RTRG is 0, the SPCMDm.CPHA bit is 1, and the SPCMDm.CPOL bit is 0. The numbers given for RSPCKn in the waveform represent the number of RSPCK cycles, such as the number of transferred bits.

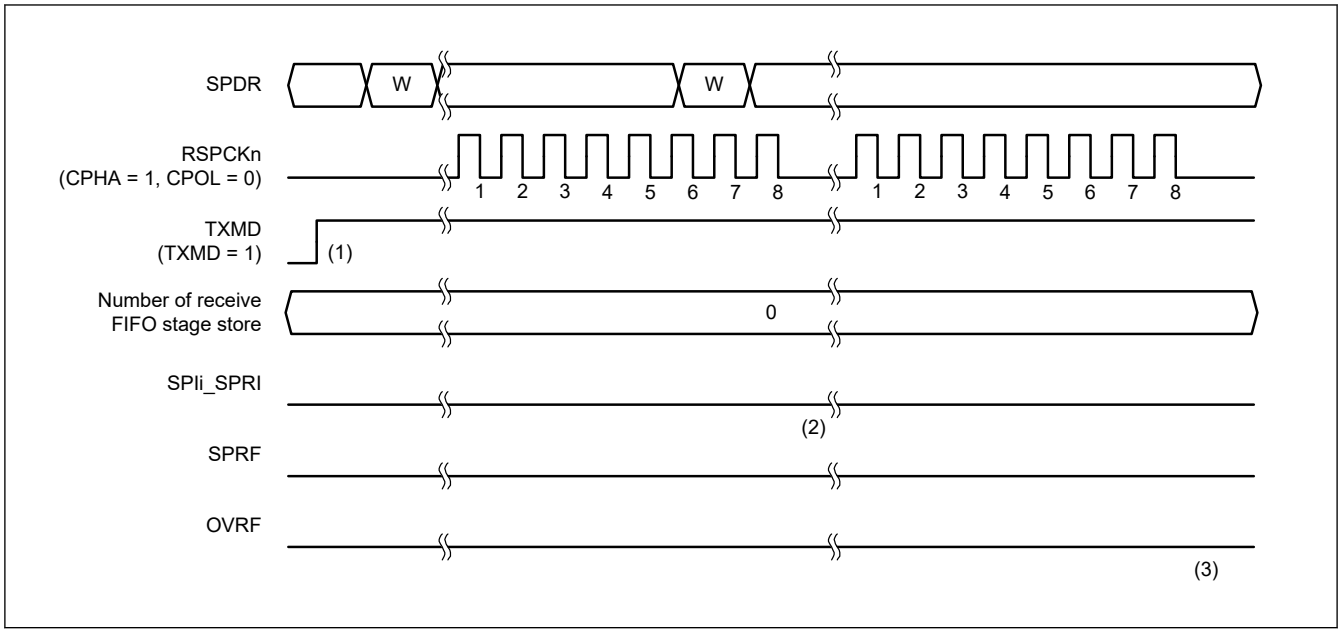

Figure 33.31 Operation example when SPCR.TXMD[1:0] = 01b

The operation of the flags at timings (1) to (3) in Figure 33.31 is as follows:

1. Make sure there is no data left in the receive buffer (the SPSR.SPRF flag is 0) and the SPSR.OVRF flag is 0 before entering transmit-only mode (SPCR.TXMD[1:0] = 01b).
2. When a serial transfer ends without receiving data in the receiving FIFO of SPDR, if the transmit-only mode is selected (SPCR.TXMD[1:0] = 01b), the SPSR.SPRF flag retains the value of 0, and the SPI does not copy the data in the shift register to the receive buffer.
3. Because the receive buffer of SPDR does not hold data that was received in the previous serial transfer, even when a serial transfer ends, the SPSR.OVRF flag retains the value of 0, and the data in the shift register is not copied to the receive buffer.

In transmit-only mode (SPCR.TXMD[1:0] = 01b), the SPI transmits data but does not receive data. Therefore, the SPSR.SPRF and SPSR.OVRF flags remain 0 at timings (1) to (3).

33.3.6.3 Receive-Only Serial Communication (TXMD[1:0] = 10b)

Figure 33.32 shows an example of operation when the communication mode select bit (TXMD[1]) in the SPI control register (SPCR) is set to 1. In this example, the SPI performs an 8-bit serial transfer when the SPDCR2.TTRG is FIFO stage - 1, the SPDCR2.RTRG is 0, the SPCMDm.CPHA bit is 1, and the SPCMDm.CPOL bit is 0. The numbers given for RSPCKn in the waveform represent the number of RSPCK cycles, such as the number of transferred bits.

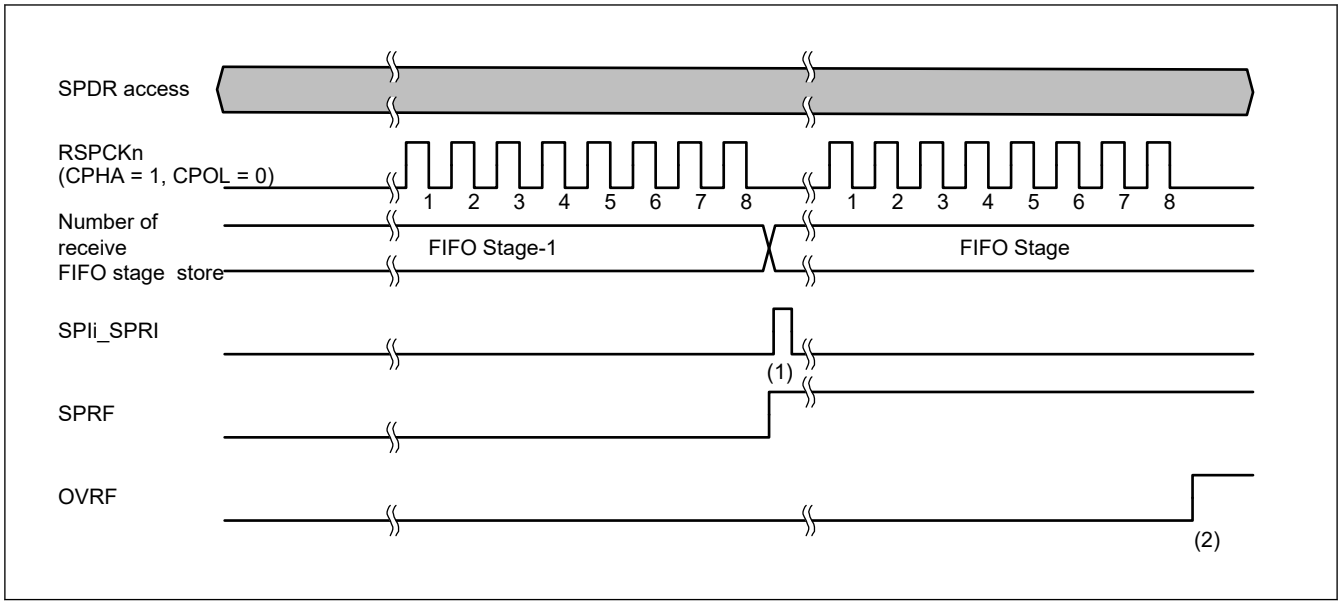

Figure 33.32 Example of Operation when SPCR.TXMD[1:0] = 10b

The following describes operation of flags at timings (1) and (2) in the figure above.

1. When serial transfer ends while the number of SPDR receive buffer store matches the number of frames set in SPDCR2.RTRG, the SPI generates a receive buffer full interrupt request (SPIi_SPRI), the SPI sets the SPSR.SPRF flag to 1, and copies the received data in the shift register to the receive buffer
2. When serial transfer ends with data for the number of FIFO stages stored in the SPDR receive buffer, the SPI sets the SPSR.OVRF flag to 1 and discards the received data in the shift register.

33.3.7 Transmit Buffer Empty and Receive Buffer Full Interrupts

Figure 33.33 show examples of operation of the transmit buffer empty interrupt (SPIi_SPTI (i = 0, 1)) and the receive buffer full interrupt (SPIi_SPRI). The SPDR register accesses shown in these figures indicate the conditions of access to the register, where W denotes a write cycle and R a read cycle. In Figure 33.33, the SPI performs an 8-bit serial transfer when SPCR.TXMD[1:0] bits are 00b, the SPDCR2.TTRG bit is 0, the SPDCR2.RTRG bit is 0, the SPCMDm.CPHA bit is 0, and the SPCMDm.CPOL bit is 0. The numbers given for RSPCKn in the waveform represent the number of RSPCK cycles, such as the number of transferred bits.

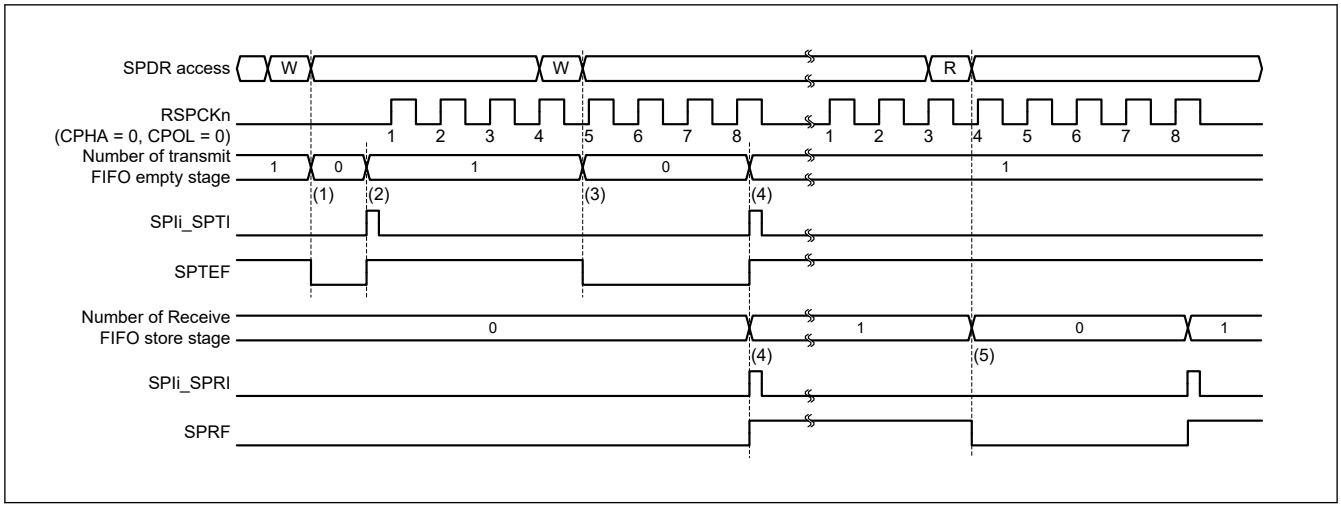

Figure 33.33 Operation example of the SPIi_SPTI and SPIi_SPRI interrupts when CPHA = 0 and CPOL = 0 in master mode

The operation of the SPI at timings (1) to (5) in Figure 33.33 is as follows:

1. When transmit data is written to SPDR with the transmit buffer of SPDR is before the next transfer data is set, the SPI writes data to the transmit buffer. When transmit data is written to SPDR in one processing routine using DTC / DMAC, the SPSR.SPTEF flag is cleared to 0 at the last access.
2. If the shift register is empty, the SPI copies the data in the transmit buffer to the shift register. At this time, if transmit FIFO empty stage number > TTRG value, then the SPI generates a transmit buffer empty interrupt request (SPIi_SPTI), and sets the SPSR.SPTEF flag to 1. How a serial transfer is started depends on the SPI mode. For details, see section 33.3. Operation, and section 33.3.13. Clock Synchronous Operation.
3. When transmit data is written to SPDR either by the transmit buffer empty interrupt routine, or by the processing of the transmit buffer empty using the SPTEF flag, the SPI writes data to the transmit buffer. When the transmit data is written to SPDR in one processing routine using DTC / DMAC, the SPTEF flag is cleared to 0 at the last access. Because the data being transferred serially is stored in the shift register, the SPI does not copy the data in the transmit buffer to the shift register.
4. When the serial transfer ends with the receive buffer of SPDR > FIFO stage number, the SPI copies the receive data in the shift register to the receive buffer, generates a receive buffer full interrupt request (SPIi_SPRI), and sets the SPRF flag to 1. Because the shift register becomes empty on completion of the serial transfer, if the next transfer data is set in the transmit FIFO before the serial transfer ended, the SPI sets the SPTEF flag to 1 and copies data in the transmit buffer to the shift register. Even when received data is not copied from the shift register to the receive buffer in an overrun error status, on completion of the serial transfer, the SPI determines that the shift register is empty, so data transfer from the transmit buffer to the shift register is enabled.
5. When SPDR is read either by the receive buffer full interrupt routine or processing of the receive buffer full interrupt using the SPRF flag, the receive data can be read. If the received data is read from SPDR in one processing routine using DTC / DMAC, the SPRF flag is cleared to 0 at the last access.

When transmit data is written to the SPDR register while no empty stages in the transmit FIFO, the SPI does not update data in the transmit buffer. When writing to SPDR, always use either a transmit buffer empty interrupt request or check the empty or processing of the transmit buffer empty interrupt using the SPTEF flag. To use a transmit buffer empty interrupt, set the SPTIE bit in SPCR to 1. If the SPI function is disabled (the SPCR.SPE bit is 0), set the SPTIE bit to 0.

When serial transfer ends while data is stored in the receive FIFO for the number of FIFO stages, the SPI does not copy data from the shift register to the receive buffer, and it detects an overrun error (see section 33.3.10. Error Detection). To prevent a receive data overrun error, read the received data using a receive buffer full interrupt request before the next serial transfer ends. To use an SPI receive buffer full interrupt, set the SPCR.SPRIE bit to 1.

Transmission and reception interrupts or the associated IELSRn.IR flags (where n is the interrupt vector number) in the ICU can be used to confirm the states of the transmit and receive buffers.

Similarly, the SPTEF and SPRF flags can be used to confirm the states of the transmit and receive buffers. See section 12, Interrupt Controller Unit (ICU) for the interrupt vector numbers.

33.3.8 Idle Interrupt

When the SPCP[2:0] of the SPI status register (SPSR) becomes 000b (start of sequence control), the IDLNF flag in the SPI status register (SPSR) is set to 1 and an idle interrupt request is made during master mode operation. An interrupt request is also made by clearing the SPCR.SPE bit to 0.

[In the Motorola-SPI case]

Figure 33.34 shows an example of idle interrupt operation during normal operation.

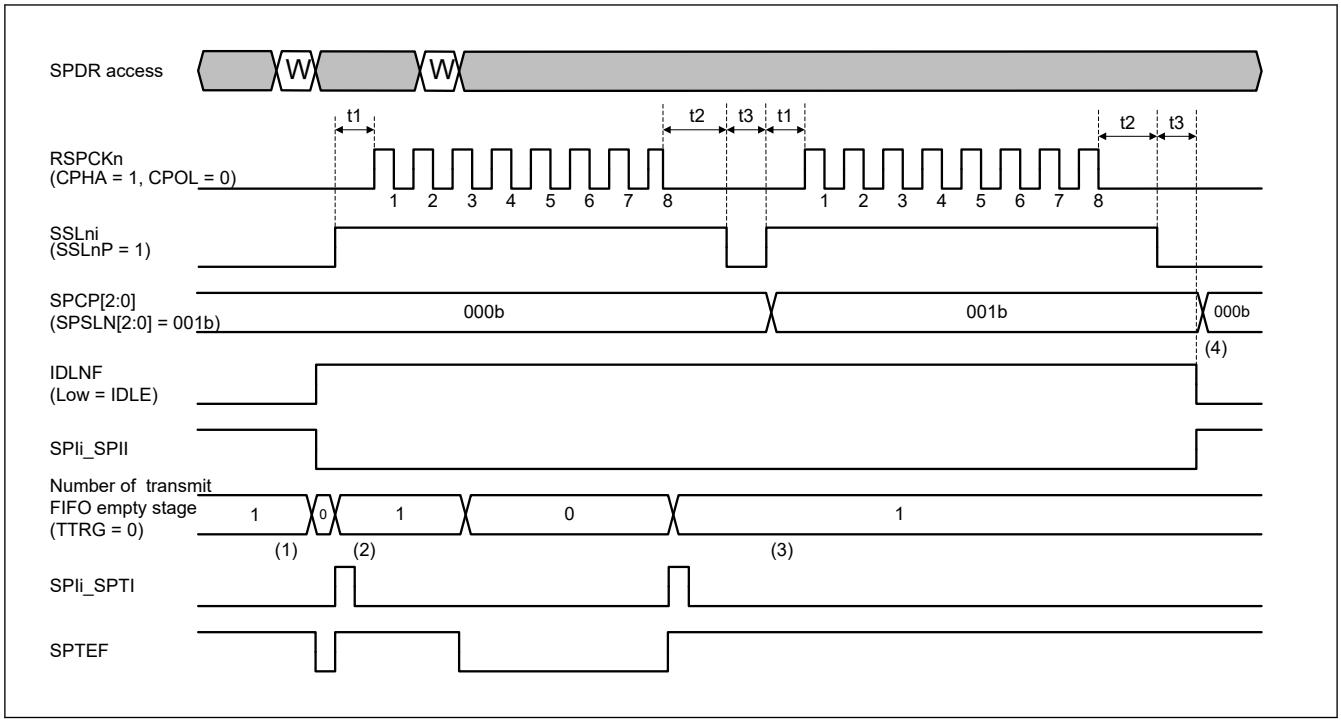

Figure 33.34 Example of Idle Interrupt Operation (Master mode / Motorola-SPI)

1. At the start of transmission, if the next transfer data is not set in the transmission buffer, the IDLNF flag is 0 (IDLE). Writing transmit data sets the IDLNF flag to 1 (BUSY). When the SPIIE bit in the SPI control register (SPCR) is set to 1 before transmit data is written, interrupt processing is required before transmission start. For this reason, set the SPIIE bit to 0 before starting transmission.
2. After transmission has started, the IDLNF flag remains 1 (BUSY) regardless of the transmit buffer state.
3. The SPCP[2:0] bits change the command to the next command at the end of t3 cycle. When the next command is not 000b, the IDLNF flag remains unchanged even when the next transmit data has not been written.
4. The IDLNF flag is cleared to 0 (IDLE) at the end of t3 cycle because the next command is 000b and the next transmit data is not present. When the SPIIE bit is 1 currently, an SPIi_SPII (i = 0, 1) interrupt is output.

[In the TI-SSP case]

Figure 33.35 shows an example of idle interrupt operation during normal operation.

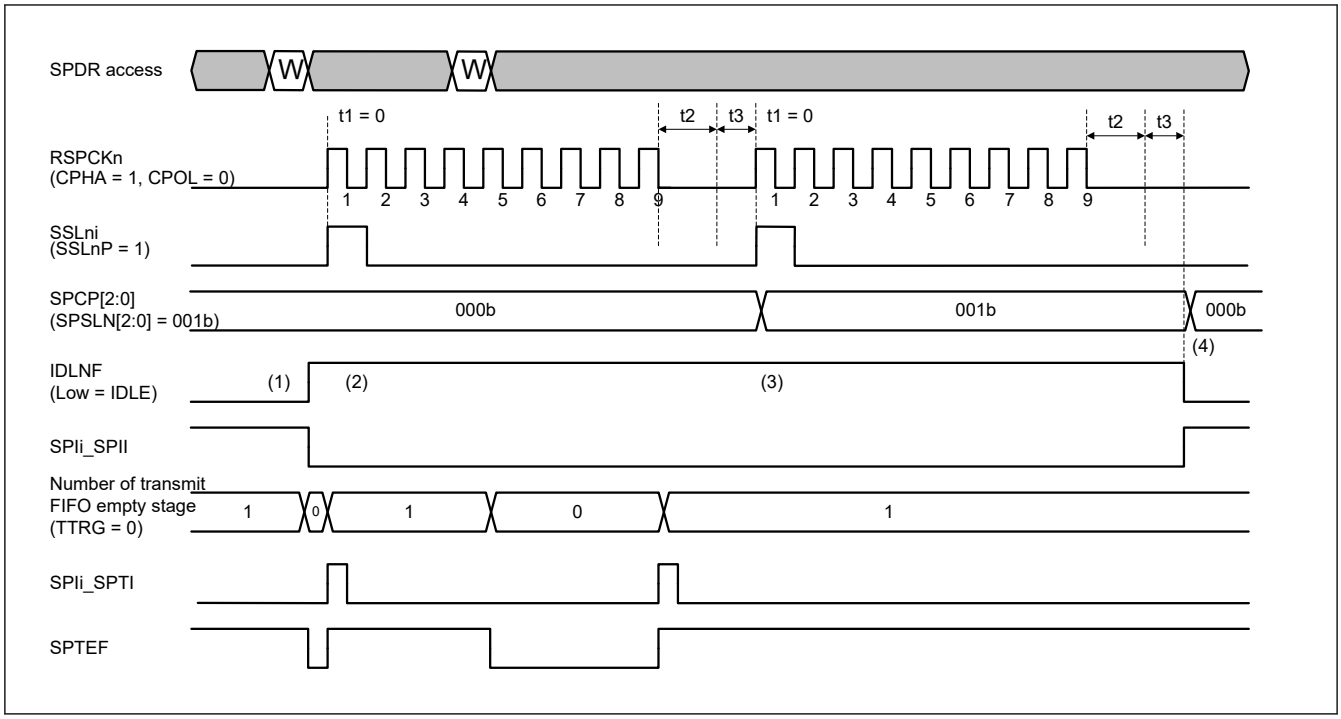

Figure 33.35 Example of Idle Interrupt Operation (Master mode / TI-SSP)

1. At the start of transmission, if the next transfer data is not set in the transmission buffer, the IDLNF flag is 0 (IDLE). Writing transmit data makes sets the IDLNF flag to 1 (BUSY). When the SPIIE bit in the SPI control register (SPCR) is set to 1 before transmit data is written, interrupt processing is required before transmission start. For this reason, set the SPIIE bit to 0 before starting transmission.
2. After transmission has started, the IDLNF flag remains 1 (BUSY) regardless of the transmit buffer state.
3. The SPCP[2:0] bits change the command to the next command at the end of t3 cycle. When the next command is not 000b, the IDLNF flag remains unchanged even when the next transmit data has not been written.
4. The IDLNF flag is cleared to 0 (IDLE) at the end of t3 cycle because the next command is 000b and the next transmit data is not present. When the SPIIE bit is 1 currently, an SPIi_SPII interrupt is output.

33.3.9 Communication End Interrupt

33.3.9.1 Transmit-Receive/Transmit in Master Mode

See the description of the CENDF bit in section 33.2.9. SPSR : SPI Status Register for the setting / clearing conditions of the communication completion flag during Transmit-Receive/Transmit-only in Master Mode.

[In the Motorola-SPI case]

Figure 33.36 shows an example of communication end interrupt operation during transmit-receive/transmit master mode.

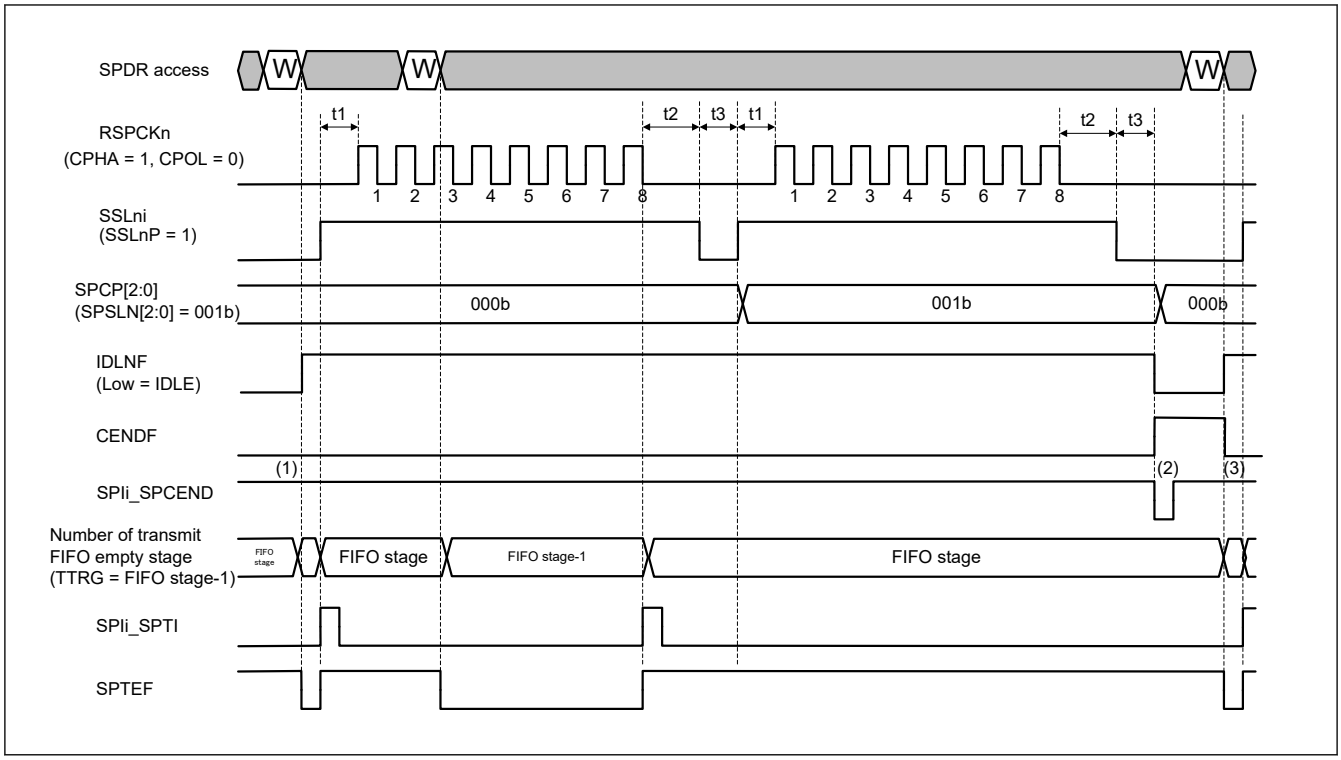

Figure 33.36 Example of Communication End Interrupt Operation (Transmit-Receive/Transmit Master mode/Motorola-SPI)

1. The CENDF flag is 0 and the level of SPIi_SPCEND (i = 0, 1) is 1 before communication start, and these have kept during communication.
2. The CENDF flag will be 1 (Communication End) at the end of t3 cycle because the next command is 000b and there is no next transmit data, and then the SPIi_SPCEND interrupt output when the CENDIE bit is 1.
3. The CENDF flag is cleared when the next transmission data is written to the transmit buffer (SPTX). Or when 1 is written to the SPSRC.CENDFC bit, then the CENDF flag is 0.

[In the TI-SSP case]

Figure 33.37 shows an example of communication end interrupt operation during transmit-receive/transmit-only master mode.

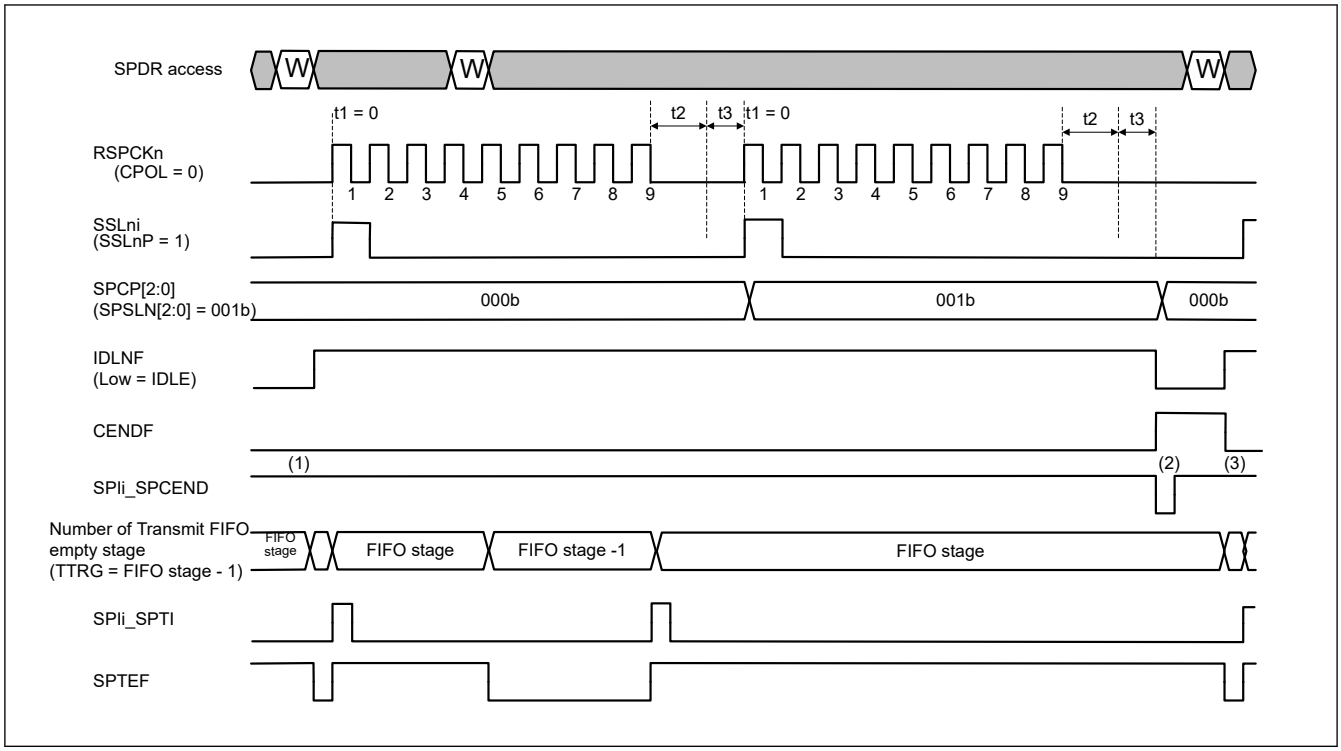

Figure 33.37 Example of Communication End Interrupt Operation (Transmit-Receive/Transmit-only Master mode/TI-SSP)

1. The CENDF flag is 0 and the level of SPIi_SPCEND is 1 before communication start, and these have kept during communication.
2. The CENDF flag will be 1 (Communication End) at the end of t3 cycle because the next command is 000b and there is no next transmit data, and then the SPIi_SPCEND interrupt outputs with PCLK 1 cycle width if the CENDIE bit is 1.
3. The CENDF flag is cleared when the next transmission data is written to the transmit buffer (SPTX). Or when 1 is written to the SPSRC.CENDFC bit, then the CENDF flag is 0.

In slave mode operation, the output timing of the communication end interrupt is deferent due to the value of the SPCR.SPMS bit (SPI mode select bit), and the clear timing of the communication end interrupt is deferent due to the communication mode (transmit-receive or transmit-only or receive-only).

33.3.9.2 Receive-only in Master Mode

See the description of the CENDF bit in section 33.2.9. SPSR : SPI Status Register for the setting / clearing conditions of the communication completion flag during Receive-only in Master Mode.

Figure 33.38 shows an example of communication end interrupt operation during receive-only master mode at RMFM[4:0] = 0.

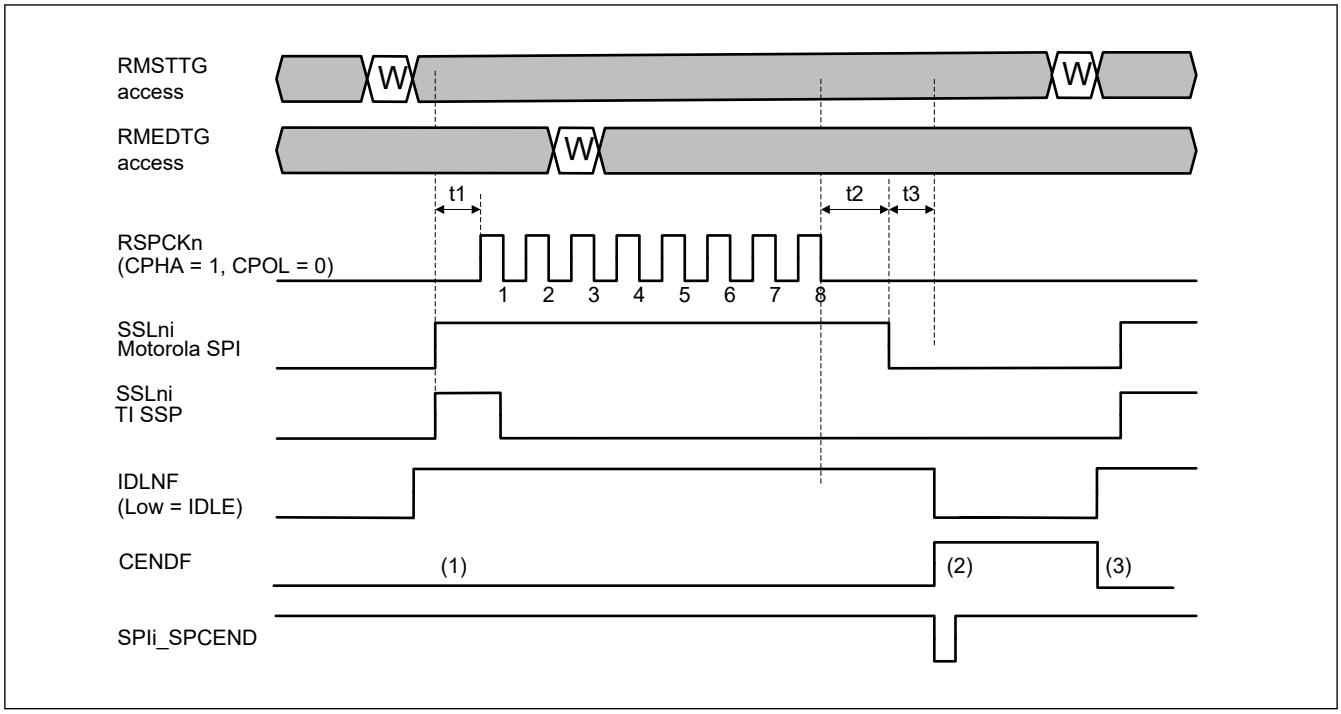

Figure 33.38 Example of Communication End Interrupt Operation (Receive-only Master mode / Motorola-SPI) at RMFM [4:0] = 0

1. The CENDF flag is 0 and the level of SPIi_SPCEND is 1 before communication start. These have kept during communication.
2. The CENDF flag will be 1 (Communication End) at the end of t3 cycle by writing 1 to RMEDTG during the communication frame. Then the SPIi_SPCEND interrupt outputs with PCLK 1 cycle width if the CENDIE bit is 1.
3. The CENDF flag is cleared when writing 1 to RMSTTG. Also when 1 is written to the SPSRC.CENDFC bit, then the CENDF flag is 0.

Figure 33.39 shows an example of communication end interrupt operation during receive-only master mode at RMFM[4:0] ≠ 0.

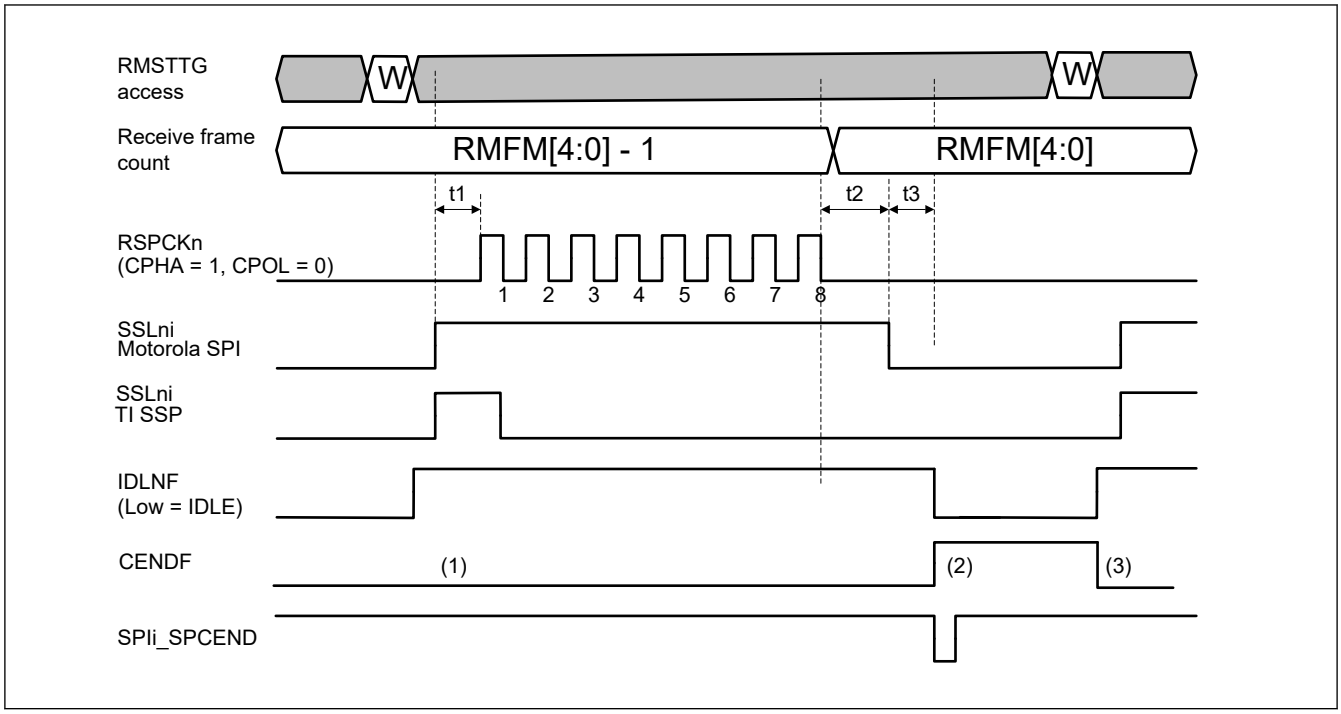

Figure 33.39 Example of Communication End Interrupt Operation (Receive-only Master mode / Motorola-SPI) at RMFM [4:0] ≠ 0

1. The CENDF flag is 0 and the level of SPIi_SPCEND is 1 before communication start. These have kept during communication.
2. The CENDF flag will be 1 (Communication End) at the end of t3 cycle after receiving the number of frames set by RMFM[4:0]. Then the SPIi_SPCEND interrupt outputs with PCLK 1 cycle width if the CENDIE bit is 1.
3. The CENDF flag is cleared when writing 1 to RMSTTG. Also when 1 is written to the SPSRC.CENDFC bit, then the CENDF flag is 0.

33.3.9.3 Transmit-Receive/Transmit in Slave Mode on SPI Operation (4-wire)

See the description of the CENDF bit in section 33.2.9. SPSR : SPI Status Register for the setting / clearing conditions of the communication completion flag during Transmit-Receive/Transmit-only in Slave Mode (4-wire).

[In the Motorola-SPI case]

Figure 33.40 shows an example of communication end interrupt operation during transmit-receive/transmit slave mode on SPI operation.

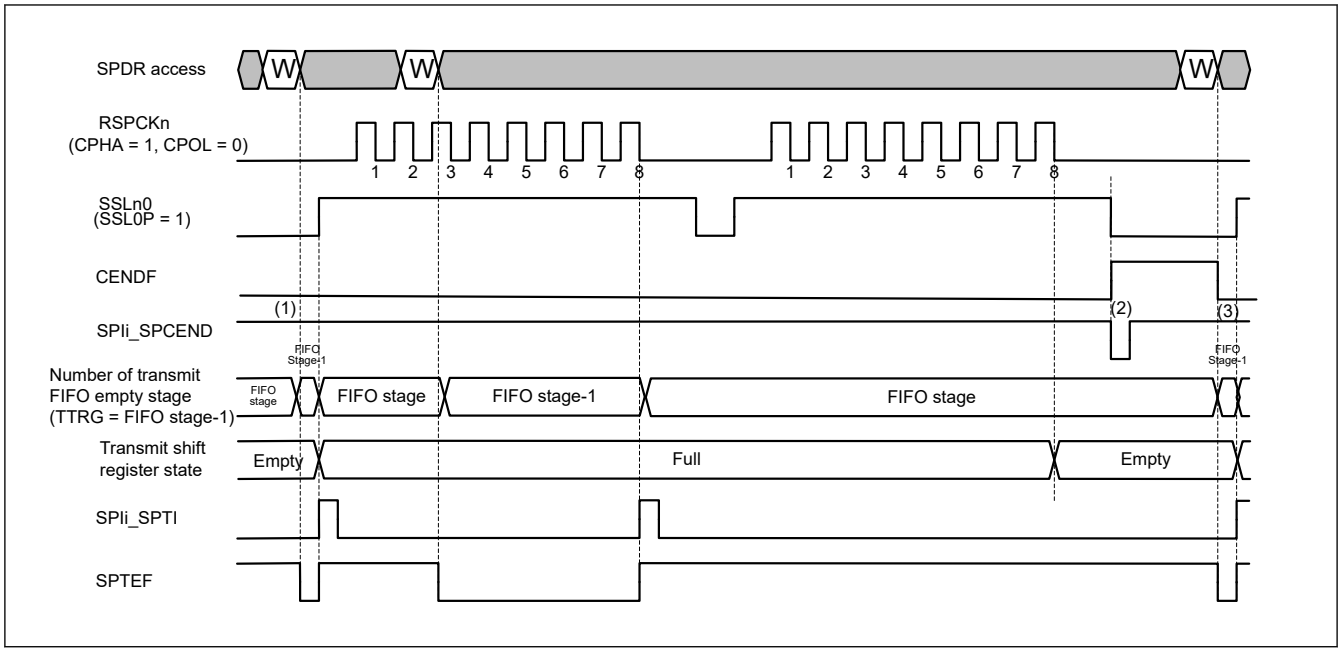

Figure 33.40 Example of Communication End Interrupt Operation (Transmit-Receive/Transmit Slave mode on SPI Operation/Motorola-SPI)

1. The CENDF flag is 0 and the level of SPIi_SPCEND is 1 before communication start, and these have kept during communication.
2. The CENDF flag will be 1 (Communication End) at the timing of SSLn0 negate when the next transfer data is not set in the transmit FIFO and the transmit shift register is empty. Then the SPIi_SPCEND interrupt outputs with PCLK 1 cycle width if the CENDIE bit is 1.
3. The CENDF flag is cleared when the next transmission data is written to the transmit buffer (SPTX). Or when 1 is written to the SPSRC.CENDFC bit, then the CENDF flag is 0.

[In the TI-SSP case]

Figure 33.41 shows an example of communication end interrupt operation during transmit-receive/transmit-only slave mode on SPI operation.

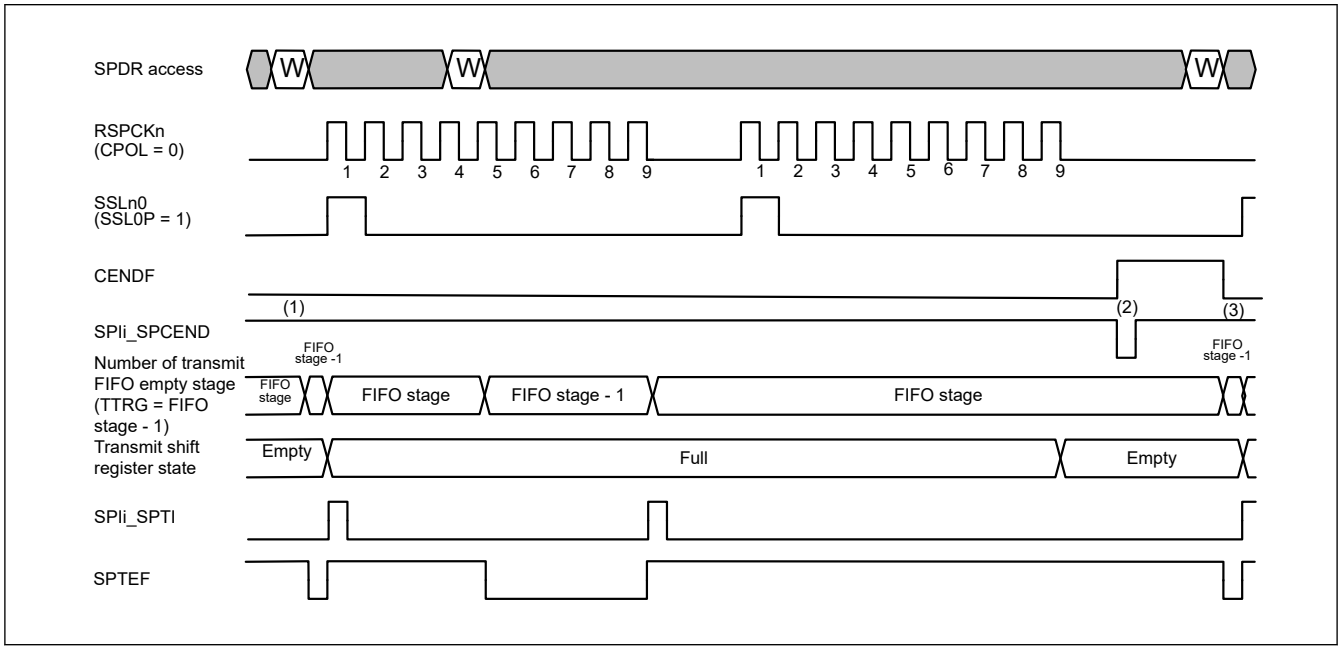

Figure 33.41 Example of Communication End Interrupt Operation (Transmit-Receive/Transmit-only Slave mode on SPI Operation / TI-SSP)

1. The CENDF flag is 0 and the level of SPIi_SPCEND is 1 before communication start, and these have kept during communication.
2. The CENDF flag will be 1 (Communication End) at the RSPCKn last data bit sampling when the next transfer data is not set in the transmit FIFO and the transmit shift register is empty. Then the SPIi_SPCEND interrupt outputs with PCLK 1 cycle width if the CENDIE bit is 1.
3. The CENDF flag is cleared when the next transmission data is written to the transmit buffer (SPTX). Or when 1 is written to the SPSRC.CENDFC bit, then the CENDF flag is 0.

33.3.9.4 Receive Only in Slave Mode on SPI Operation (4-wire)

See the description of the CENDF bit in section 33.2.9. SPSR : SPI Status Register for the setting / clearing conditions of the communication completion flag during Receive-only in Slave Mode (4-wire).

[In the Motorola-SPI case]

Figure 33.42 shows an example of communication end interrupt operation during receive only slave mode on SPI operation (4-wire).

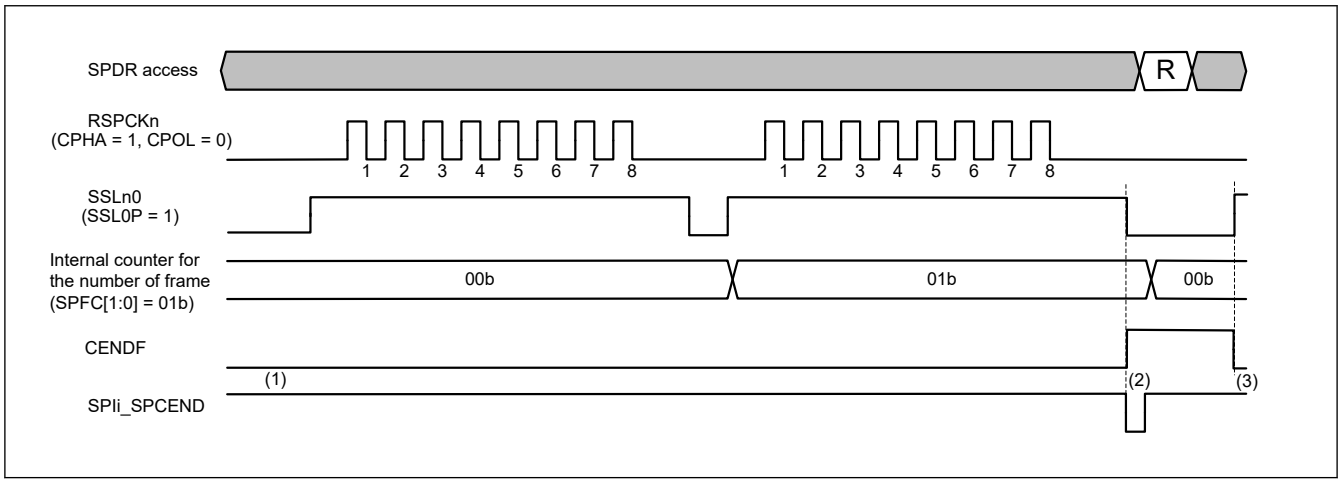

Figure 33.42 Example of Communication End Interrupt Operation (Receive only Slave mode on SPI Operation / Motorola-SPI)

1. The CENDF flag is 0 and the level of SPIi_SPCEND is 1 before communication start, and these have kept during communication.
2. After the frames for SPFC set value in the SPI data control register (SPDCR) are stored in the receive buffer, the CENDF flag becomes 1 (communication completed) at the timing of SSLn0 negation. Then the SPIi_SPCEND interrupt outputs with PCLK 1 cycle width if the CENDIE bit is 1.
3. The CENDF flag is cleared at the SSLn0 assert when the next transmission start. Or when 1 is written to the SPSRC.CENDFC bit, then the CENDF flag is 0.

[In the TI-SSP case]

Figure 33.43 shows an example of communication end interrupt operation during receive only slave mode on SPI operation (4-wire).

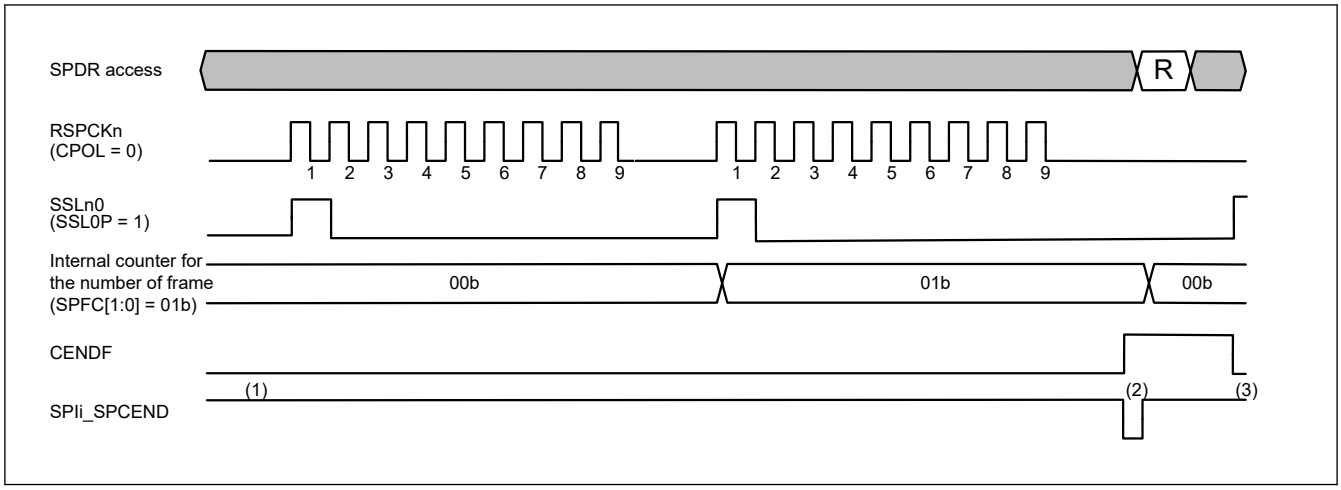

Figure 33.43 Example of Communication End Interrupt Operation (Receive-only Slave mode on SPI Operation / TI-SSP)

1. The CENDF flag is 0 and the level of SPIi_SPCEND is 1 before communication start, and these have kept during communication.
2. The CENDF flag will be 1 (Communication End) at the RSPCK last data bit sampling when the last frame transmission ends. Then the SPIi_SPCEND interrupt outputs with PCLK 1 cycle width if the CENDIE bit is 1.
3. The CENDF flag is cleared at the SSLn0 assert when the next transmission start. Or when 1 is written to the SPSRC.CENDFC bit, then the CENDF flag is 0.

33.3.9.5 Transmit-Receive/Transmit in Slave Mode on Clock Synchronous Operation (3-wire)

See the description of the CENDF bit in section 33.2.9. SPSR : SPI Status Register for the setting / clearing conditions of the communication completion flag during Transmit-Receive/Transmit-only in Slave Mode on Clock Synchronous (3-wire).

Figure 33.44 shows an example of communication end interrupt operation during transmit-receive/transmit slave mode on clock synchronous operation (3-wire).

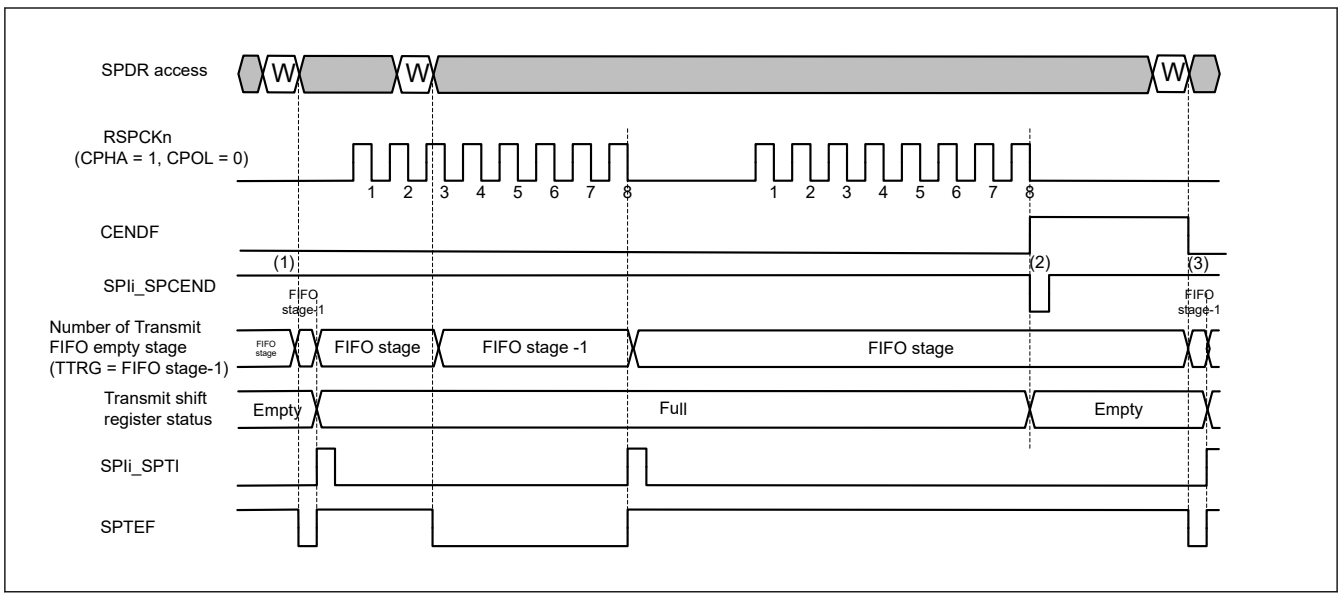

Figure 33.44 Example of Communication End Interrupt Operation (Transmit-Receive/Transmit Slave mode on Clock Synchronous Operation)

1. The CENDF flag is 0 and the level of SPIi_SPCEND is 1 before communication start, and these have kept during communication.

2. When the next transfer data is not set in the transmit FIFO and the transmit shift register is empty, then the SPIi_SPCEND interrupt outputs with PCLK 1 cycle width if the CENDIE bit is 1.
3. The CENDF flag is cleared when the next transmission data is written to the transmit buffer (SPTX). Or when 1 is written to the SPSRC.CENDFC bit, then the CENDF flag is 0.

33.3.9.6 Receive Only in Slave Mode on Clock Synchronous Operation (3-wire)

See the description of the CENDF bit in section 33.2.9. SPSR : SPI Status Register for the setting / clearing conditions of the communication completion flag during Receive -only in Slave Mode on Clock Synchronous (3-wire).

Figure 33.45 shows an example of communication end interrupt operation during receive only slave mode on clock synchronous operation.

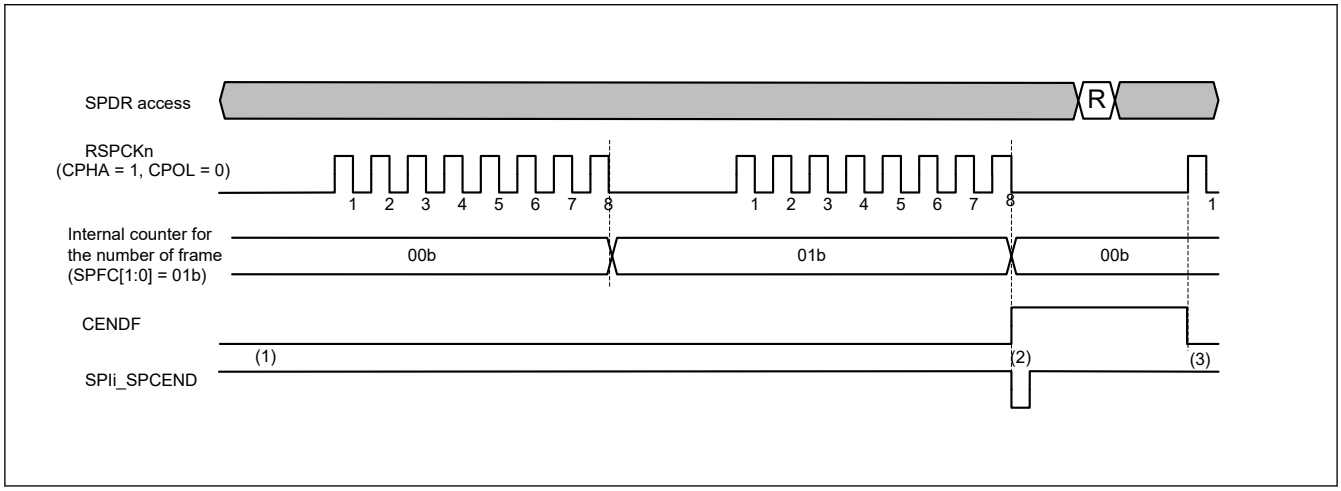

Figure 33.45 Example of Communication End Interrupt Operation (Receive-only Slave mode on Clock Synchronous Operation)

1. The CENDF flag is 0 and the level of SPIi_SPCEND is 1 before communication start, and these have kept during communication.
2. The CENDF flag is set to 1 (communication completed) at the timing of the last data bit sampling of RSPCKn in the last frame communication when the last frame of the SPI data control register (SPDCR) SPFC set value is received. Then the SPIi_SPCEND interrupt outputs with PCLK 1 cycle width if the CENDIE bit is 1.
3. The CENDF flag is cleared at the first edge of RSPCKn for the next transmission. Or when 1 is written to the SPSRC.CENDFC bit, then the CENDF flag is 0.

33.3.9.7 Common Operation

In this chapter, the operation common to each mode / area option communication in section 33.3.9.1. Transmit-Receive/ Transmit in Master Mode to section 33.3.9.6. Receive Only in Slave Mode on Clock Synchronous Operation (3-wire) is explained. When the enable of SPI communication end interrupt (CENDIE) is 0, at the time of communication completion, a flag of communication end (CENDF) is set and an event of communication end is output, but no interrupt is output. However, if the enable of communication end interrupt (CENDIE) is set to 1 before clearing the flag of communication end (CENDF) while the enable of SPI function (SPE) is 1, the communication end interrupt (SPIi_SPCEND) is output.

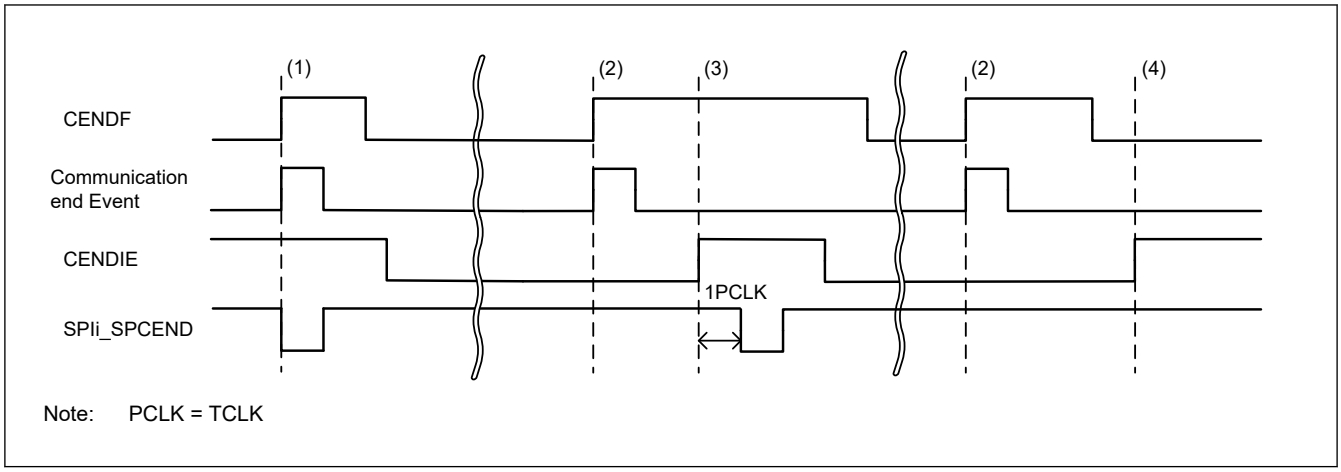

Figure 33.46 Example of Communication End Interrupt Operation (Enable control)

1. When the enable of SPI communication end interrupt (CENDIE) is 1, at the time of communication completion, the following three are the same timing.
   - A flag of communication end (CENDF)
   - An event of communication end
   - The communication end interrupt (SPIi_SPCEND)
2. When the enable of SPI communication end interrupt (CENDIE) is 0, at the time of communication completion, the following two are the same timing, but no interrupt.
   - A flag of communication end (CENDF)
   - An event of communication end
3. After (2), if the enable of communication end interrupt (CENDIE) is set when the enable of SPI function (SPE) and the flag of communication end (CENDF) are 1, the communication end interrupt (SPIi_SPCEND) is output after 1 TCLK.
4. After (2), even if the enable of communication end interrupt (CENDIE) is set when the enable of SPI function (SPE) or the flag of communication end (CENDF) is 0, the communication end interrupt (SPIi_SPCEND) is not output.

33.3.10 Error Detection

In normal SPI serial transfers, data written to the transmit buffer of SPDR is transmitted, and received data can be read from the receive buffer of SPDR. If access is made to SPDR, an abnormal transfer might occur, depending on the status of the transmit or receive buffer or the status of the SPI at the beginning or end of serial transfer.

If an abnormal transfer occurs, the SPI detects the event as an underrun error, overrun error, parity error, or mode fault error. Table 33.9 lists the relationship between non-normal transfer operations and the SPI error detection function.

Table 33.9 Relationship between non-normal transfer operations and SPI error detection (1 of 2)

Operation	Occurrence condition	SPI operation	Error detection
1	SPDR is written while no empty stages in the transmit FIFO.	• The contents of the transmit buffer are kept • Write data is missing	None
2	SPDR is read while no data stored in receive FIFO.	The contents of the receive buffer and previously received data are output.	None
3	Serial transfer is started in slave mode when the SPI is not able to transmit data.	• Serial transfer is suspended • Transmit or receive data is missing • Driving of the MISOn output signal is stopped • SPI function is disabled	Underrun error
4	Serial transfer ends when data is stored in the receive FIFO for the number of FIFO stages.	• Keeps the contents of the receive FIFO • Missing receive data	Overrun error

Table 33.9 Relationship between non-normal transfer operations and SPI error detection (2 of 2)

Operation	Occurrence condition	SPI operation	Error detection
5	An incorrect parity bit is received during full-duplex synchronous serial communication with the parity function enabled in following mode: • Transmit-receive master mode • Receive-only master mode • Transmit-receive slave mode • Receive-only slave mode	The parity error flag is asserted	Parity error
6	The SSLn0 input signal is asserted when the serial transfer is idle in multi-master mode.	• Driving of the RSPCKn, MOSIn, SSLn1 to SSLn3 output signals is stopped • SPI function is disabled	Mode fault error
7	The SSLn0 input signal is asserted during serial transfer in multi-master mode.	• Serial transfer is suspended • Transmit or receive data is missing • Driving of the RSPCKn, MOSIn, SSLn1 to SSLn3 output signals is stopped • SPI function is disabled	Mode fault error
8	[In the Motorola-SPI case] The SSLn0 input signal is negated during serial transfer in slave mode.	• Serial transfer is suspended • Transmit or receive data is missing • Driving of the MISOn output signal is stopped • SPI function is disabled	Mode fault error
9	[In the TI-SSP case] The SSLn0 input signal is asserted during serial transfer in slave mode.	• Serial transfer is suspended • Transmit or receive data is missing • Driving of the MISOn output signal is stopped • SPI function is disabled	Mode fault error
10	After data is stored in the receive FIFO with SPDRES = 1, the number of stored data is less than the threshold value and no receive data is written for the set value of SPDRC [7:0]	Assert the receive data ready flag	Receive data ready

In operation 1 described in Table 33.9, the SPI does not detect an error. To prevent data omission during writes to SPDR, the writes to SPDR must be executed using a transmit buffer empty interrupt request (when the SPSR.SPTEF flag is 1).

Similarly, the SPI does not detect an error in operation 2. To prevent extraneous data from being read, SPDR read must be executed with an SPI receive buffer full interrupt request (when the SPSR.SPRF flag is 1).

For information on the other errors, see the following sections:

- Underrun error, indicated in operation 3, see section 33.3.10.4. Underrun errors
- Overrun error, indicated in operation 4, see section 33.3.10.1. Overrun errors
- Parity error, indicated in operation 5, see section 33.3.10.2. Parity errors
- Mode fault error, indicated in operations 6 to 9, see section 33.3.10.3. Mode fault errors
- For the transmit and receive interrupts, see section 33.3.7. Transmit Buffer Empty and Receive Buffer Full Interrupts.
- For the reception data ready in operations 10, see section 33.3.10.5. Received data ready.

33.3.10.1 Overrun errors

If a serial transfer ends when the receive buffer of SPDR is full, the SPI detects an overrun error and sets the SPSR.OVRF flag to 1. When the OVRF flag is 1, the SPI does not copy data from the shift register to the receive buffer, so the data prior to the error occurrence is retained in the receive buffer. To set the OVRF flag to 0, issue a system reset or 1 is written to the SPSRC.OVRFC bit.

Figure 33.47 shows an example of operation of the OVRF and SPRF flags. The SPSRC and SPDR accesses shown in Figure 33.47 indicate the condition of accesses to the SPSRC and SPDR register, where W denotes a write cycle, and R a read cycle. In this example, the SPI performs an 8-bit serial transfer when SPCMDm.CPHA bit is 1 and the SPCMDm.CPOL bit is 0. The numbers given for RSPCKn in the waveform represent the number of RSPCK cycles, such as the number of transferred bits.

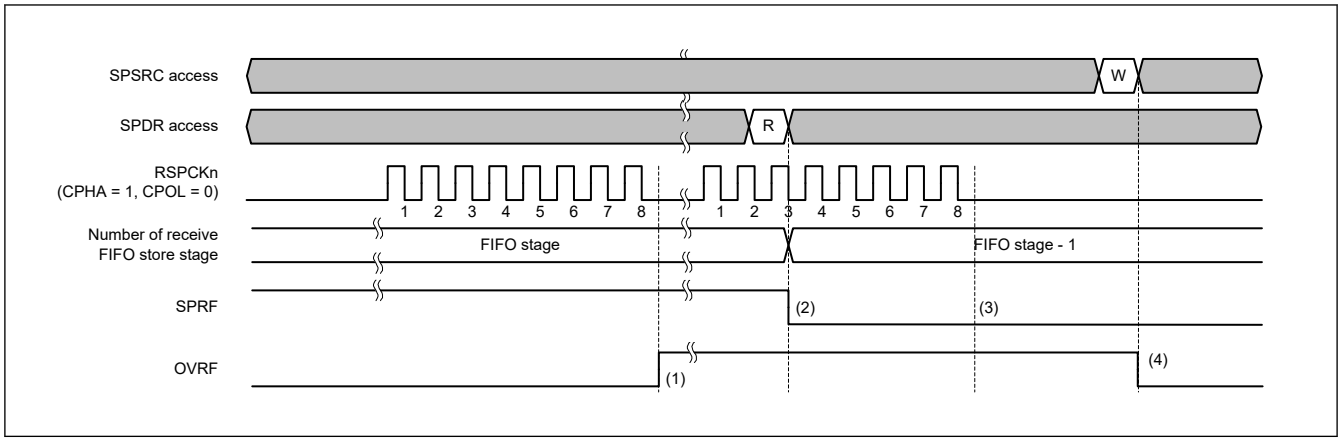

Figure 33.47 Operation example of the OVRF and SPRF flags

The operation of the flags at timings (1) to (4) in Figure 33.47 is as follows:

1. When serial transfer ends while data is stored for the number of FIFO stages, the SPI detects an overrun error and sets the OVRF flag to 1. The SPI does not copy shift register data to the receive buffer. The SPI does not detect a parity error even when SPPE = 1. In master mode, the SPI copies the value of pointer to the SPI command register (SPCMDm) to the SPECM[2:0] bits in the SPI status register (SPSR).
2. When SPDR is read, the SPI outputs the data in the receive buffer. At this time, the SPRF flag is cleared to 0 at the last access when the received data is read from SPDR in one processing routine using DTC / DMAC.
3. If the serial transfer ends with the OVRF flag set to 1 (overrun error occurred), the SPI does not copy data in the shift register to the receive buffer (the SPRF flag does not set to 1). A receive buffer full interrupt is not generated. Even when the SPPE bit is 1, parity errors are not detected. In an overrun error state when the SPI does not copy the received data from the shift register to the receive buffer, on termination of the serial transfer, the SPI determines that the shift register is empty. This enables data transfer from the transmit buffer to the shift register.
4. When 1 is written to the SPSRC.OVRFC bit, the SPSR.OVRF flag is cleared.

The occurrence of an overrun can be checked either by reading SPSR or by using an SPI error interrupt and reading SPSR. When executing a serial transfer, you must ensure that overrun errors are detected early, for example by reading SPSR immediately after SPDR is read.

If an overrun error occurs and the OVRF flag sets to 1, normal reception operations cannot be performed until the OVRF flag is set to 0.

When the RSPCK auto-stop function is enabled (SPCR.SCKASE = 1) in master mode, an overrun error does not occur. Figure 33.48 and Figure 33.49 show the clock stop waveform when a serial transfer continues while the receive buffer is full in master mode.

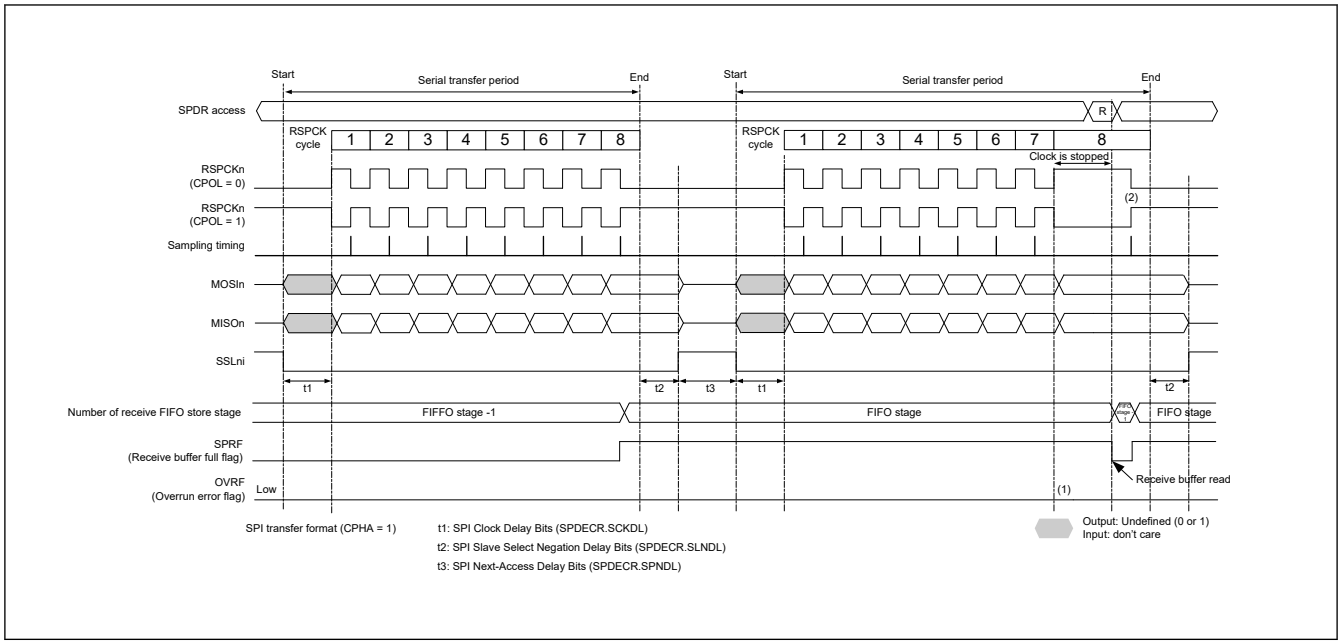

Figure 33.48 Clock stop waveform when serial transfer continues with data is stored for the number of FIFO stages in master mode (CPHA = 1)

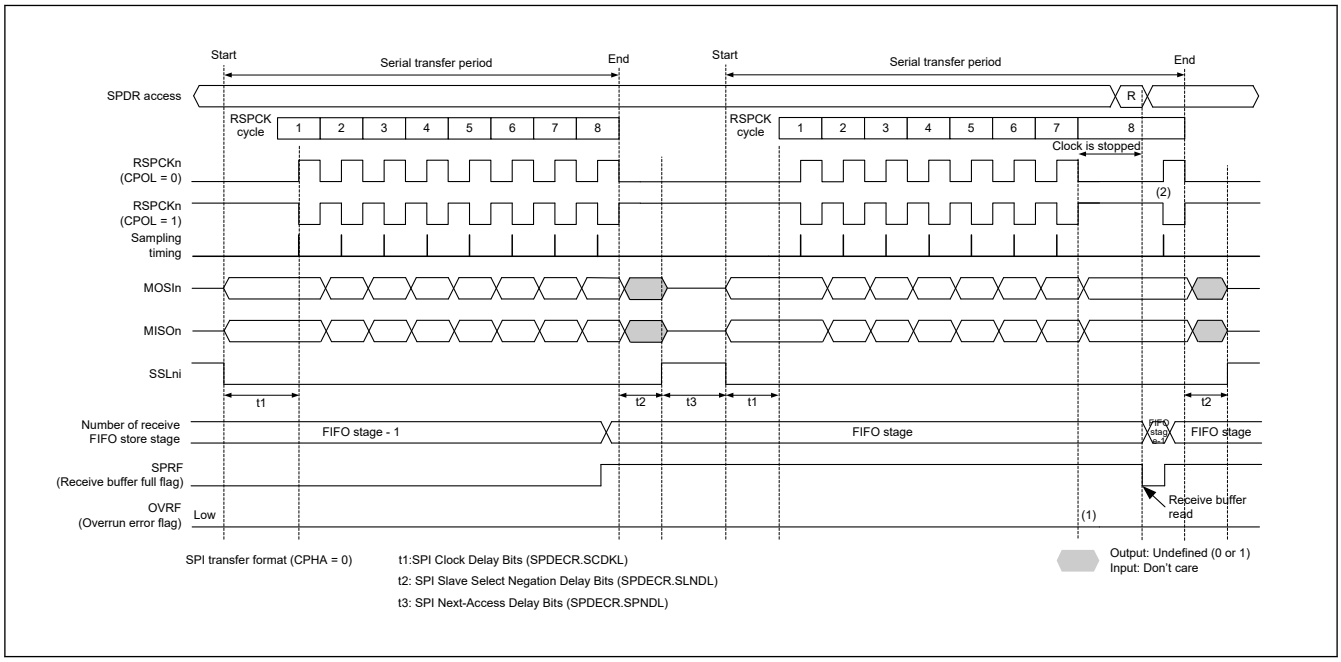

Figure 33.49 Clock stop waveform when serial transfer continues with data is stored for the number of FIFO stages in master mode (CPHA = 0)

The operation of the flags at timings (1) and (2) in Figure 33.48 and Figure 33.49 is as follows:

1. While data is stored in the receive FIFO for the number of FIFO stages, the RSPCK clock is deactivated and no overrun error occurs.
2. If SPDR is read while the clock is stopped, data in the receive buffer can be read. The RSPCK clock restarts.

Overrun error does not occur when RSPCK automatic stop function is enabled for transfer with no delay of between frames during burst transfer in master mode. Figure 33.50 and Figure 33.51 show the clock stop waveform, when there is no delay between frames at burst transfer and the serial transfer continues in the data is stored in the receive FIFO for the number of FIFO stages.

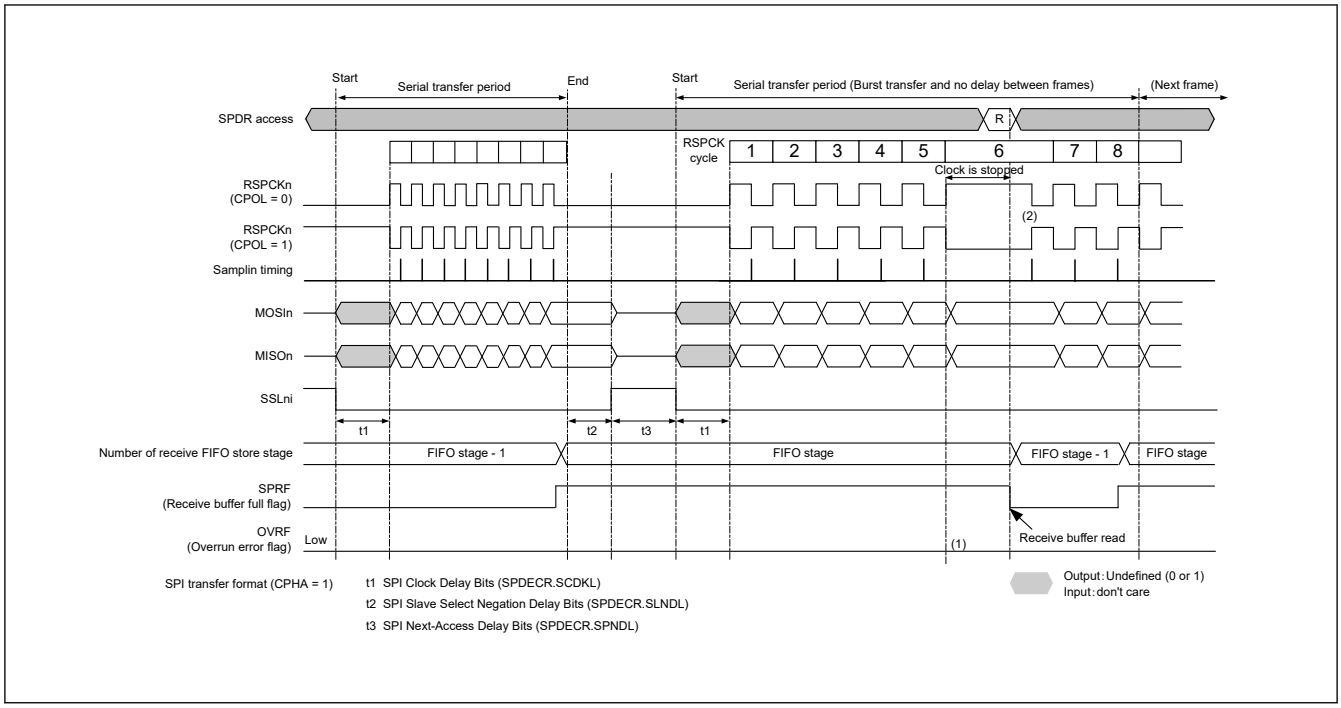

Figure 33.50 Clock Stop Waveform when Serial Transfer Continues in the Receive Buffer Full with data is stored for the number of FIFO stages (at burst transfer and no delay between frames CPHA = 1)

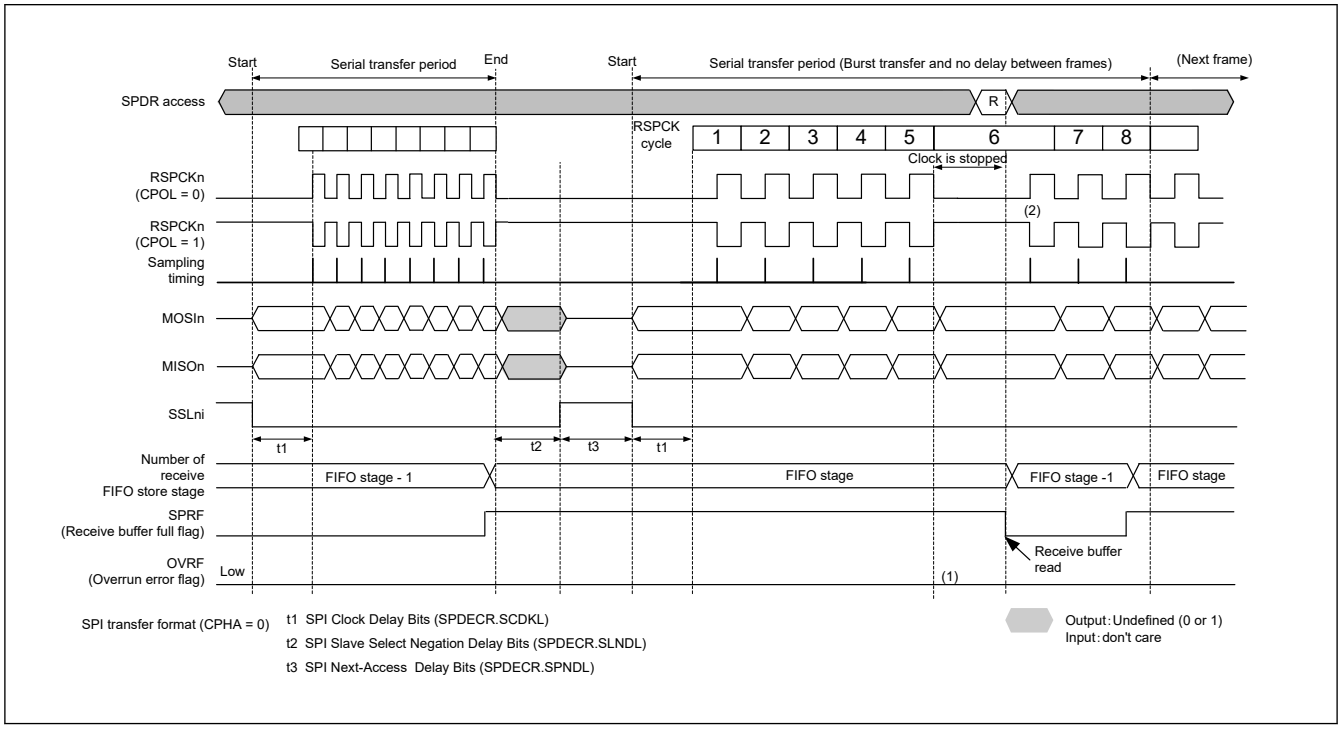

Figure 33.51 Clock Stop Waveform when Serial Transfer Continues with data is stored for the number of FIFO stages in Master Mode (at burst transfer and no delay between frames CPHA = 0)

The following describes operation of flags at timings (1) and (2) in the figure above.

1. While the data is stored for the number of FIFO stages, the RSPCK clock is deactivated and no overrun error occurs.
2. Receive buffer data can be read by reading SPDR during clock stop. After the receive buffer data has been read the RSPCK clock restarts.

33.3.10.2 Parity errors

After transfer in transmit-receive or receive-only master mode, transmit-receive slave mode or receive only slave mode while the SPPE bit in the SPI control register (SPCR) is 1, the SPI checks occurrence of a parity error. When the SPI detects a parity error in received data, the PERF flag in the SPI status register (SPSR) is set to 1. While the OVRF flag is 1, the SPI does not copy shift register data to the receive buffer. Therefore, parity error in received data is not detected. To clear the PERF flag in SPSR to 0, issue a system reset or 1 is written to the SPSRC.PERFC bit.

Figure 33.52 shows an example of operation of the OVRF and PERF flags. The SPSR access shown in Figure 33.52 indicates the condition of access to the register, where W denotes a write cycle, and R a read cycle. In this example, full-duplex serial communication is performed while the SPCR.SPPE bit is 1. The SPI performs an 8-bit serial transfer when SPCMDm.CPHA bit is 1 and the SPCMDm.CPOL bit is 0. The numbers given for RSPCKn in the waveform represent the number of RSPCK cycles, such as the number of transferred bits.

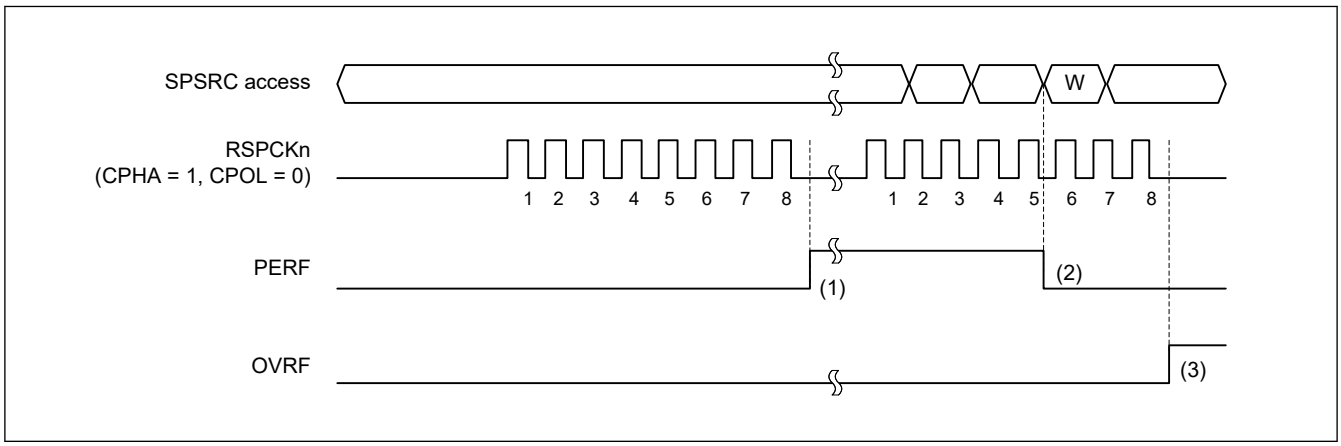

Figure 33.52 Operation example of the OVRF and PERF flags

The operation of the flags at timings (1) to (3) in Figure 33.52 is as follows:

1. When the SPI does not detect an overrun error and terminates the serial transfer, the SPI copies shift register data to the receive buffer. When the SPI checks the received data and detects a parity error at this time, the PERF flag is set to 1. In master mode, the SPI copies the value of pointer to the SPI command register (SPCMDm) to the SPECM[2:0] bits in the SPI Data control register 2 (SPDCR2).
2. When 1 is written to the SPSRC.PERFC bit, then clear the PERF flag.
3. When the SPI detects an overrun error and serial transfer is terminated, the data in the shift register is not copied to the receive buffer. The SPI does not perform parity error detection at this time.

Parity errors can be checked for by either reading the SPSR register or using an SPI error interrupt and reading the SPSR register. When executing a serial transfer, such checks are required to ensure early detection of parity errors. When the SPI is used in master mode, the pointer value to the SPCMDm register at the occurrence of the error can be checked by reading the SPDCR2.SPECM[2:0] bits.

33.3.10.3 Mode fault errors

The SPI operates in multi-master mode when the SPCR.MSTR bit is 1, the SPCR.SPMS bit is 0, and the SPCR.MODFEN bit is 1.

If the active level is input for the SSLn0 input signal of the SPI in multi-master mode, the SPI detects a mode fault error regardless of the status of the serial transfer, and sets the SPSR.MODF flag to 1.

On detecting the mode fault error, the SPI copies the value of the pointer to SPCMD to the SPECM[2:0] bits.

The active level of the SSLn0 signal is determined by the SPCR3.SSL0P bit.

When the MSTR bit is 0, the SPI operates in slave mode.

When the SPCR.MODFEN bit = 1 and the SPMS bit = 0 in slave mode, if the SSLn0 input signal is negated during the serial transfer period (from valid data drive start to final valid data latch), the SPI detects a mode fault error, while any of the following 2 conditions is met.

[In the Motorola-SPI case]

When the SSLn0 input signal is negated while serial data transfer.

[In the TI-SSP case]

When the SSLn0 input signal is asserted while serial data transfer. However, during burst transfer, no error is detected even if the SSLn0 input signal is asserted during the last bit of frame.

When the SPI detects a mode fault error, it stops driving output signals and clears the SPE bit in the SPCR register. When the SPE bit is cleared, the SPI function is disabled (as described in section 33.3.12. SPI Operation). In a multi-master configuration, the mastership can be released by stopping driving output signals and disabling the SPI function by using a mode fault error.

Whether a mode fault error is present can be checked by reading SPSR or by reading an SPI error interrupt and SPSR. To detect a mode fault error without using an SPI error interrupt, poll SPSR. When the SPI is used in master mode, the pointer value to SPCMD when an error is present can be checked by reading the SPECM[2:0] bits in SPSR.

While the MODF flag = 1, the SPI ignores writing 1 to the SPE bit. To enable the SPI function after a mode fault error is detected, clear the MODF flag to 0 without fail.

33.3.10.4 Underrun errors

While the SPI is operating in slave mode (SPCR.MSTR bit = 0) and the communication mode select bit (TXMD[1:0]) in the SPI control register (SPCR) is set to 00b or 01b, if serial transfer is started before transmit data output is ready with the SPCR.SPE bit set to 1 (SPI function enabled), the SPI detects an underrun error and sets the SPSR.MODF and SPSR.UDRF flags to 1.

On detecting an underrun error, the SPI stops the driving of output signals and clears the SPCR.SPE bit to 0 (see section 33.3.11. Initializing the SPI).

The occurrence of underrun errors can be checked either by reading SPSR or by using an SPI error interrupt and reading SPSR. Detecting underrun errors without using the SPI error interrupt requires polling of SPSR.

When the MODF flag is 1, writing 1 to the SPE bit is ignored by the SPI. To enable the SPI function after the detection of an underrun error, the MODF flag must be set to 0.

33.3.10.5 Received data ready

When SPCR.TXMD[1:0] = 00b, 01b, or 11b, and SPCR2.SPDRC[7:0] ≠ 0x00, after receiving data in the receive FIFO during communication (SPE = 1), SPSR.SPDRF flag is set to 1 when the received data is not stored even after the number of received FIFOs is equal to or less than ≤ the threshold value and the value set in SPDRC[7:0] has elapsed.

When the receive data ready is detected, the interrupt and event link output can be selected as SPIi_SPRI or SPIi_SPEI with the SPCR.SPDRES bit.

Figure 33.53 shows an example of reception data ready detection operation.

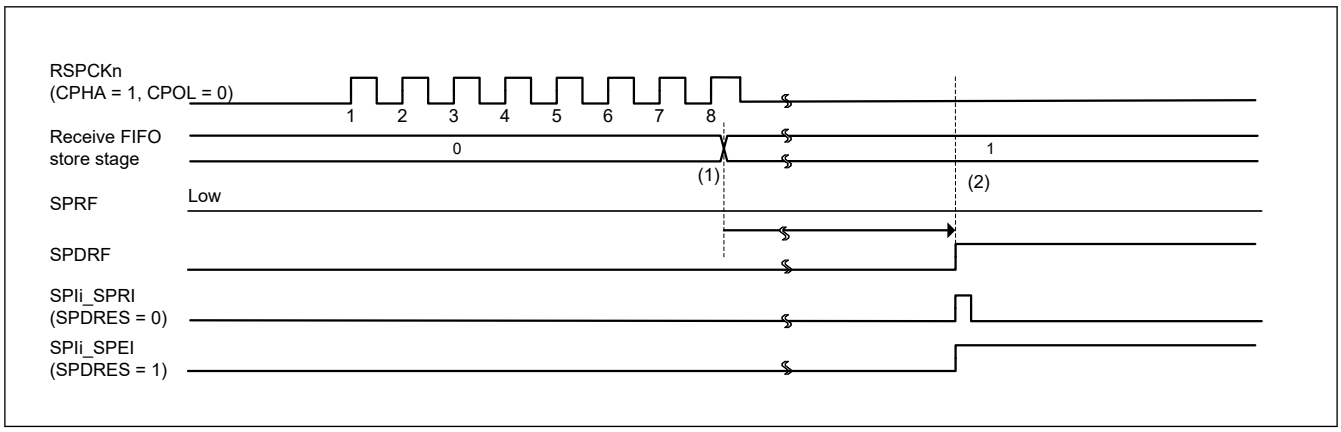

Figure 33.53 Received data ready

The following describes the operation at the timings indicated by (1) and (2) in the figure.

(1) Store the received data in the receive FIFO. SPRF is 0, because receive FIFO store stage ≤ number of frames set by SPDCR2.RTRG[1:0] .

(2) Set SPDRF and assert SPIi_SPRI or SPIi_SPEI because there is no writing to the receive FIFO for the amount of SPDRFC [7:0] set from above (1).

33.3.11 Initializing the SPI

If 0 is written to the SPCR.SPE bit or if the SPI sets the SPE bit to 0 because it detected a mode fault error or an underrun error, the SPI disables the SPI function and initializes some of the module functions. When a system reset is generated, the SPI initializes all of the module functions. This section describes initialization by clearing of the SPCR.SPE bit and by a system reset.

33.3.11.1 Initialization by clearing of the SPCR.SPE bit

When the SPCR.SPE bit is set to 0, the SPI initializes by:

- Suspending any serial transfer that is being executed
- Stopping the driving of output signals (Hi-Z) in slave mode
- Initializing the internal state of the SPI
- Initializing the transmit buffer of the SPI (the SPSR.SPTEF flag sets to 1)

Initialization by clearing of the SPE bit does not initialize the control bits of the SPI. For this reason, the SPI can be started in the same transfer mode in use prior to initialization when the SPE bit is set to 1 again.

The SPSR.CENDF, SPSR.SPRF, SPSR.OVRF, SPSR.MODF, SPSR.PERF, and SPSR.UDRF flags are not initialized, and the value of the SPDCR2.SPECM[2:0] and SPDCR2.SPCP[2:0] bits are not initialized. Therefore, even after the SPI is initialized, data from the receive buffer can be read to check the communication completion status and the error status during an SPI transfer.

The transmit buffer is initialized to an empty state (the SPSR.SPTEF flag sets to 1). Therefore, if the SPCR.SPTIE bit is set to 1 after SPI initialization, a transmit buffer empty interrupt is generated. To disable any transmit buffer empty interrupts when the SPI is initialized, write 0 to the SPTIE bit simultaneously while writing 0 to the SPE bit.

33.3.11.2 Initialization by system reset

A system reset completely initializes the SPI by initializing all SPI control bits, status bits, and data registers, in addition to the requirements described in section 33.3.11.1. Initialization by clearing of the SPCR.SPE bit.

33.3.12 SPI Operation

33.3.12.1 Master mode operation

The only difference between single- and multi-master mode operation is the use of mode fault error detection (see section 33.3.10. Error Detection). In single-master mode, the SPI does not detect mode fault errors whereas in multi-master mode, it does. This section explains operations that are common to both modes.

(1) Starting a serial transfer

When data is written to the SPI data register (SPDR) while the next transfer data is not set in the transmit FIFO, the SPI updates the transmit buffer (SPTXn, n = 0 to 3) data in SPDR. When the shift register is empty, the SPI copies data from the transmit buffer to the shift register and starts serial transfer. On copying transmit data to the shift register, the SPI changes the status of the shift register to full. On termination of the serial transfer, it changes the status of the shift register to empty. The status of the shift register cannot be referenced.

The polarity of the SSLni output pins depends on the SPCR3.SSLnP (n = 0 to 3) bits settings. For details on the SPI transfer format, see section 33.3.5. Transfer Formats.

(2) Terminating a serial transfer

[Except Receive-only in Master Mode]

After the SPI detects the RSPCKn edge corresponding to the final sampling timing regardless of the CPHA bit value in the SPI command register (SPCMD), the SPI terminates serial transfer. When the number of data stored in the receive FIFO is less than the number of FIFO stages, data is copied from the shift register to the receive buffer in the SPI data register (SPDR) after serial transfer.

The final sampling timing varies depending on the bit length of transfer data. In master mode, the SPI data length depends on the SPCMDm.SPB[4:0] bit settings. The polarity of the SSLni output pin depends on the SPCR3.SSLnP (n = 0 to 3) bits settings. For details on the SPI transfer format, see section 33.3.5. Transfer Formats.

[Receive-only in Master Mode]

When any of the following 2 conditions is met, then SPI terminating the serial transfer.

- After the SPI detects the RSPCKn edge corresponding to the final sampling timing regardless of the CPHA bit value in the SPI command register (SPCMD), the SPI terminates serial transfer.
- When writing SPCR2.RMEDTG = 1 during the serial transfer period, SPI terminating the serial transfer.

When the number of data stored in the receive FIFO is less than the number of FIFO stages, data is copied from the shift register to the receive buffer in the SPI data register (SPDR) after serial transfer.

The final sampling timing varies depending on the transfer data bit length. The data length of the SPI in master mode depends on the set value of the SPB[4:0] bits in the SPI command register (SPCMD). The SSLni output signal polarity depends on the set SPI SSLi signal polarity bit (SPCR3.SSLiP) (i = 0 to 3) value. For details about the SPI transfer format, see section 33.3.5. Transfer Formats.

(3) Sequence control

The transfer format in master mode is determined as follows.

The transfer format used in master mode is determined by the SPCR3, SPCMDm, and SPDECR registers.

The SPCR3.SPSLN[2:0] bits determine the sequence configuration for serial transfers that are executed by the SPI in master mode. The following items are set in the SPCMDm register:

- SSLni pin output signal value
- MSB- or LSB-first
- Data length
- Some of the bit rate settings
- RSPCKn polarity and phase
- Whether SPDECR.SCKDL is to be referenced
- Whether SPDECR.SLNDL is to be referenced
- Whether SPDECR.SPNDL is to be referenced

SPCR3.SPBR holds some of the bit rate settings, including SPDECR.SCKDL (SPI clock delay), SPDECR.SLNDL (SSL negation delay), and SPDECR.SPNDL (next-access delay).

Based on the sequence length assigned in SPCR3.SPSLN, the SPI makes up a sequence comprised of a part or all of the SPCMDm register. The SPI contains a pointer to the SPCMDm register that makes up the sequence. The value of this pointer can be checked by reading the SPDCR2.SPCP[2:0] bits. When the SPCR.SPE bit is set to 1 and the SPI function is enabled, the SPI loads the pointer to the commands in SPCMD0, and incorporates the SPCMD0 settings into the transfer format at the beginning of serial transfer. The SPI increments the pointer each time the next-access delay period for a data transfer ends. On completion of the serial transfer that corresponds to the final command in the sequence, the SPI sets the pointer to SPCMD0, and in this way the sequence is executed repeatedly.

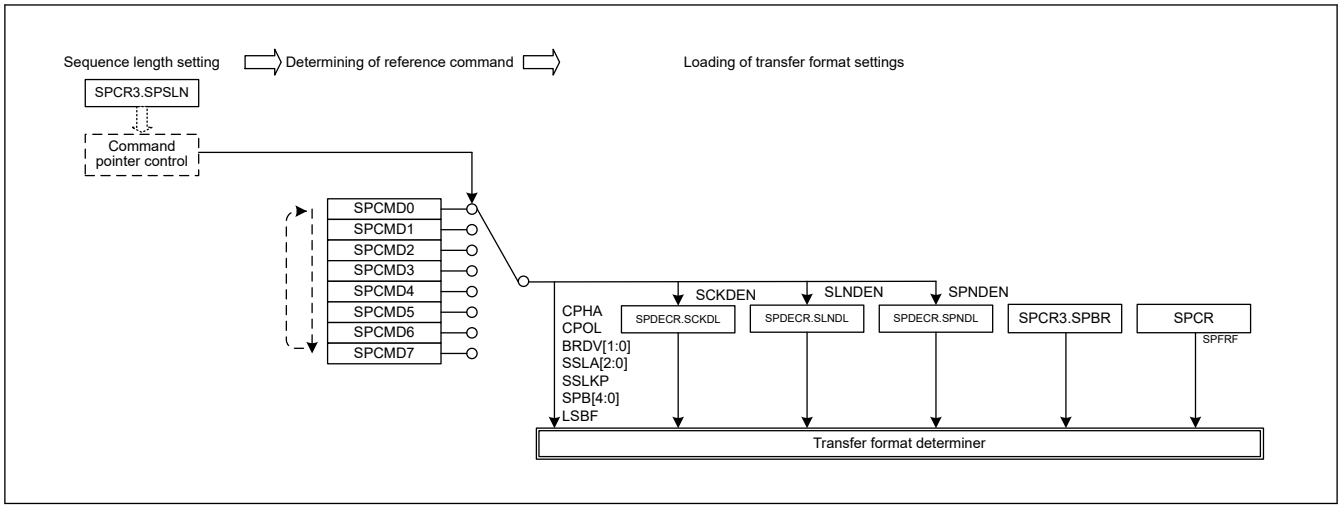

Figure 33.54 Procedure for determining the form of a serial transfer in master mode

In this section, a frame is the combination of the data in SPDR and the settings in SPCMDm.

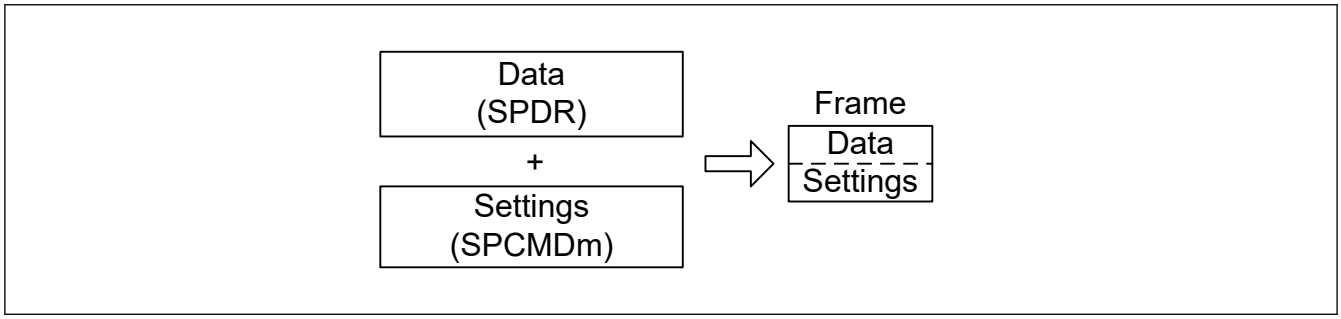

Figure 33.55 Conceptual diagram of frames

Figure 33.56 shows the correspondence between the commands and the transmit and receive buffers in the sequence of operations specified by the settings.

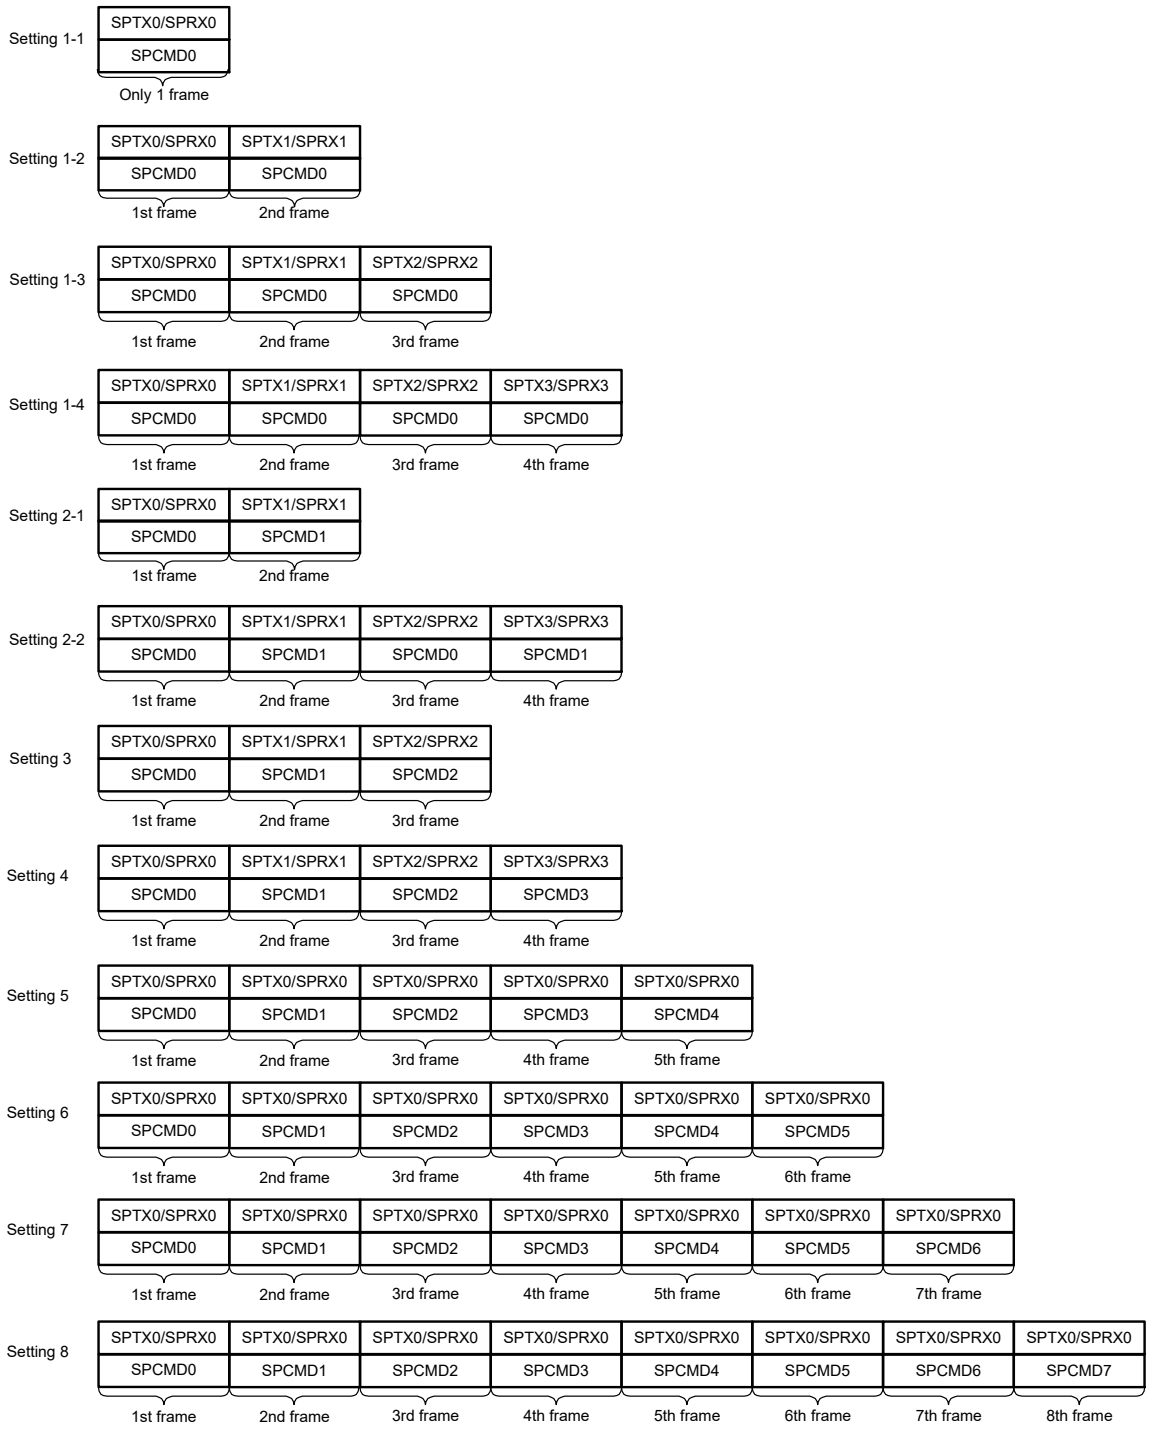

Figure 33.56 Correspondence between SPI Command Register and transmit and receive buffers in sequence operations

(4) Burst transfers

This section describes burst transfer during transmit-receive/transmit-only operation.

[In the Motorola-SPI case]

If the SPCMDm.SSLKP bit that the SPI references during the current serial transfer is 1, the SPI maintains the SSLni signal level during the serial transfer until the beginning of the SSLni signal assertion for the next serial transfer. If the SSLni signal level for the next serial transfer is the same as the SSLni signal level for the current serial transfer, the SPI can execute continuous serial transfers while keeping the SSLni signal assertion status (burst transfer).

- When Between Burst Transfer Frames Delay Select bit (BFDS) of SPI control register (SPCR) is 0.

Figure 33.57 shows an example of an SSLni signal operation for a burst transfer that is implemented using the SPCMD0 and SPCMD1 register settings. This section describes SPI operations (1) to (8) shown in Figure 33.57.

Note: The polarity of the SSLni output signal depends on the SPCR3.SSLnP (n = 0 to 3) bits settings.

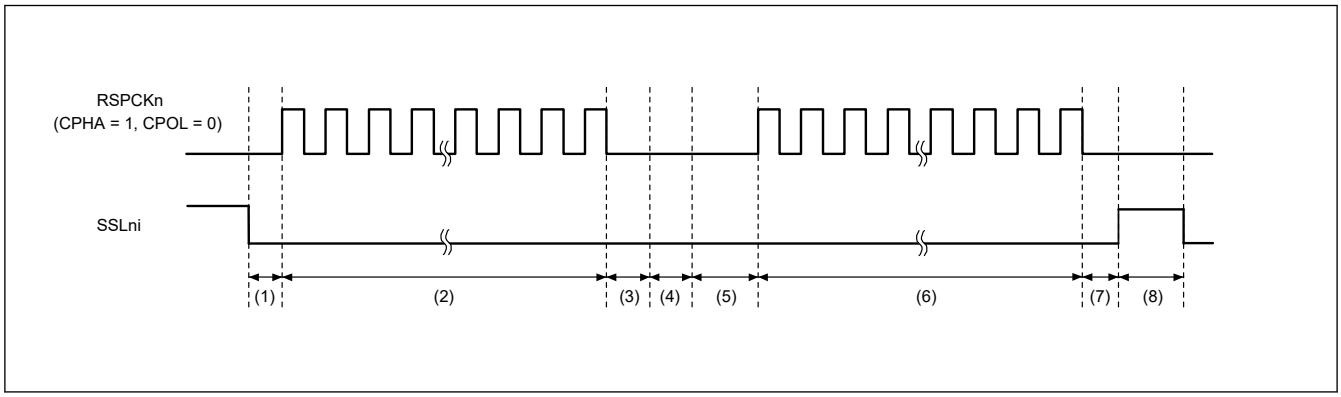

Figure 33.57 Example of burst transfer operation using the SSLKP bit (BFDS = 0, SPFRF = 0)

The SPI operation at times (1) to (8) in the figure is as follows:

1. Based on the SPCMD0 settings, the SPI asserts the SSLni signal and inserts RSPCK delays.
2. The SPI executes serial transfers in accordance with the SPCMD0 settings.
3. The SPI inserts an SSL negation delay.
4. Because the SPCMD0.SSLKP bit is 1, the SPI keeps the SSLni signal value specified in SPCMD0. This period additionally continues for 5 TCLK cycles (at minimum) that is the same as the next-access delay time of SPCMD0. If the shift register is empty after the passage of the minimum period, this period is sustained until the transmit data is stored in the shift register for the next transfer.
5. Based on the SPCMD1 settings, the SPI asserts the SSLni signal and inserts RSPCK delays.
6. The SPI executes serial transfers in accordance with the SPCMD1 settings.
7. Insert SSL negate delay.
8. Because the SPCMD1.SSLKP bit is 0, the SPI negates the SSLni signal. In addition, a next-access delay is inserted in accordance with SPCMD1.

If the SSLni signal output settings in the SPCMDm register where 1 is assigned to the SSLKP bit are different from the SSLni signal output settings in the SPCMDm register to be used in the next transfer, the SPI switches the SSLni signal status to SSLni signal assertion as shown in (5) in Figure 33.57. This corresponds to the command for the next transfer.

Note: If such an SSLni signal switching occurs, the slaves that drive the MISOn signal compete, and collision of signal levels might occur.

The SPI in master mode references the SSLni signal operation within the module when the SSLKP bit is not used. When the SPCMDm.CPHA bit is 0, the SPI can accurately start serial transfers by using the SSLni signal assertion for the next transfer that is detected internally.

- When Between Burst Transfer Frames Delay Select bit (BFDS) of SPI control register (SPCR) is 1.

Figure 33.58 shows an example of SSLni signal operation when burst transfer is achieved by using the settings of SPCMD0 and SPCMD1. The following describes SPI operations of (1) to (6) shown in Figure 33.58. The SSLni output signal polarity depends on the set SPCR3.SSLnP (n = 0 to 3) value.

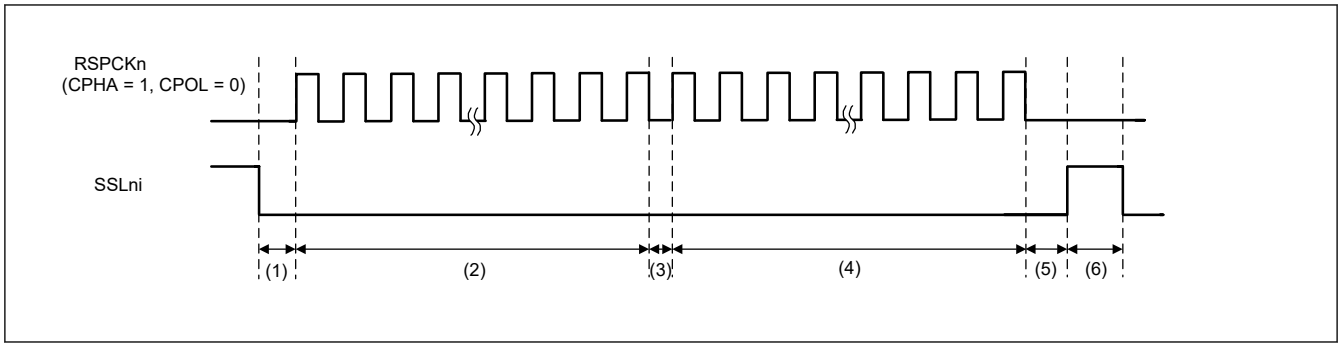

Figure 33.58 Example of Burst Transfer Operation Using SSLKP Bit (BFDS = 1, SPFRF = 0)

1. Assert the SSLni signal and insert an RSPCK delay according to SPCMD0. The RSPCK delay is inserted only the first frame of burst transmission.
2. Perform serial transfer according to SPCMD0. Wait last clock until the next transmit data is stored in the shift register, if the shift register is empty during RSPCK negate period between frames.
3. The value of SSLni signal according to SPCMD0 was hold, because the SPCMD0.SSLKP bit is 1. RSPCK negate period between frames is 0.5RSPCK, if the shift register is not empty.
4. Perform serial transfer according to SPCMD1.
5. Insert SSLni negate delay for the last frame.
6. The SSLni signal is negated because the SSLKP bit in SPCMD1 is 0. Furthermore, the next-access delay is inserted according to SPCMD1.

[In the TI-SSP case]

SPI asserts the SSLni signal for one cycle at the start of serial transfer.

Serial transfer can be executed continuously by asserting the SSLni signal for one cycle at the start of the next serial transfer (burst transfer).

- When the SSLni signal level holding bit (SSLKP) of the SPI command register (SPCMD) is 1 and the burst transfer frame delay selection bit (BFDS) of the SPI control register (SPCR) is 1, SPCMD0 to SPCMD1 are shown in Figure 33.59. The following shows an example of SSLni signal operation and serial data MISOn/MOSIn when burst transfer is realized using the settings. The SSLni output signal polarity depends on the set SPI SSLi signal polarity bit (SPCR3.SSLiP) (i = 0 to 3) value.

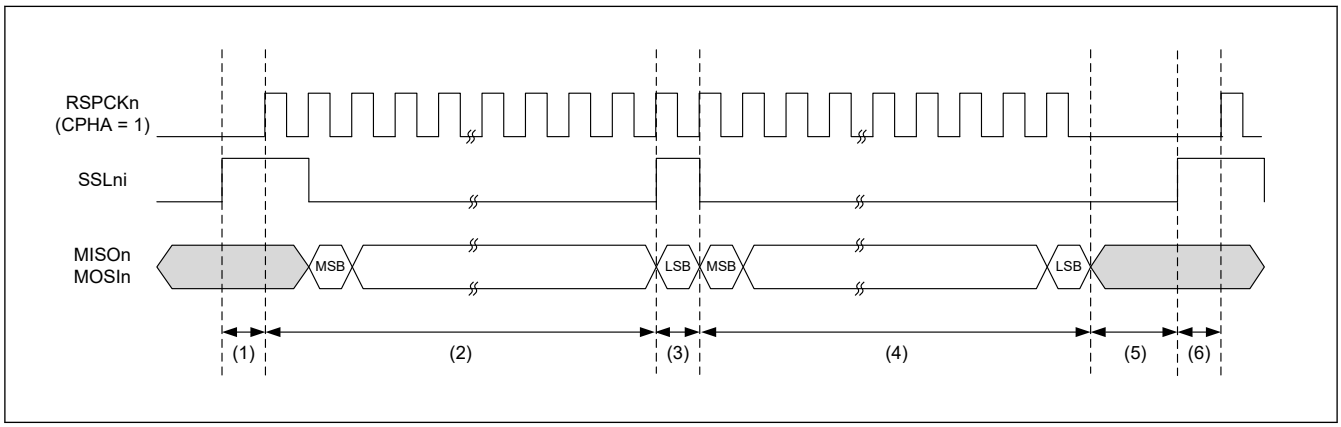

Figure 33.59 Example of Burst Transfer Operation (SPFRF = 1)

1. Assert the SSLni signal and insert an RSPCK delay according to SPCMD0.
   The RSPCK delay is inserted only the first frame of burst transmission.
2. Perform serial transfer according to SPCMD0.
3. Final data transfer and SSLni assertion are performed simultaneously. If the shift register is empty during the RSPCK negation period between frames, wait for the output of the last clock until the transmission data for the next transfer is stored in the shift register.

4. Perform serial transfer according to SPCMD1.
5. Insert OE negate delay for the last frame.
6. Insert the next access delay according to SPCMD1.

If the SSLni signal output setting in SPCMD with the SSLKP bit set to 1 differs from the SSLni signal output setting in SPCMD to be used for the next transfer, the SPI changes the SSLni signal state when the SSLni signal corresponding to the next-transfer command is asserted ((5)). Note that, if an SSLni signal change like this takes place, slaves that drive the MISOn signal may conflict with each other, which may cause collision of signal level.

This section describes burst transfer during receive-only operation.

[In the Motorola-SPI case]

When the SSLKP bit in the SPI command register (SPCMD), which the SPI references in the current serial transfer, is 1, the SPI retains the SSLni signal level during serial transfer until the SSLni signal assertion of the next serial transfer starts. When the SSLni signal level in the next serial transfer is the same as the SSLni signal level in the current serial transfer, the SPI can continuously perform serial transfer while holding the SSLni signal assertion status (burst transfer).

- When Between Burst Transfer Frames Delay Select bit (BFDS) of SPI control register (SPCR) is 0.

Figure 33.60 shows an example of SSLni signal operation when burst transfer is achieved by using the settings of SPCMD0 and SPCMD1. The following describes SPI operations of (1) to (8) shown in Figure 33.60. The SSLni output signal polarity depends on the set SPI SSLni signal polarity bit (SPCR3.SSLiP) (i = 0 to 3) value.

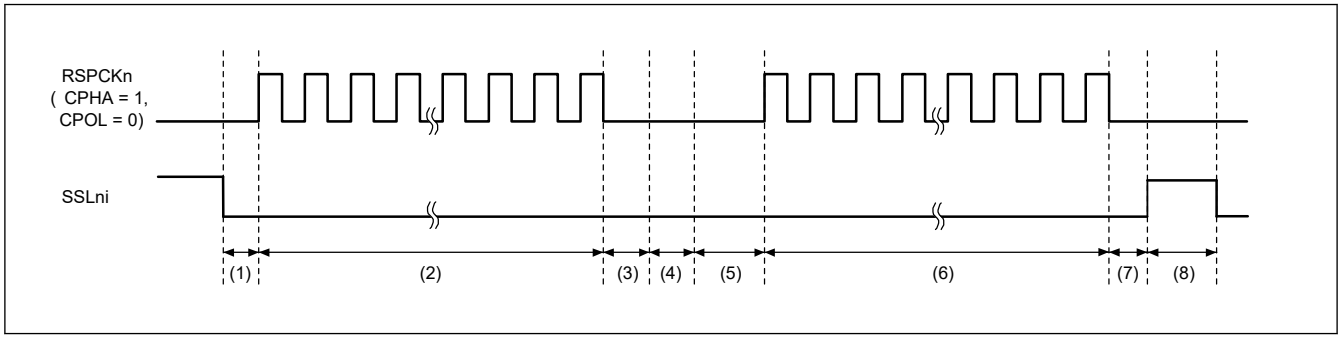

Figure 33.60 Example of Burst Transfer Operation Using SSLKP Bit (BFDS = 0, SPFRF = 0)

1. Assert the SSLni signal and insert an RSPCK delay according to SPCMD0.
2. Perform serial transfer according to SPCMD0.
3. Insert an SSLni negation delay.
4. The SSLni signal value in SPCMD0 is retained because the SSLKP bit in SPCMD0 is 1. This period additionally continues for 5 TCLK cycles (at minimum) that is the same as the next-access delay time of SPCMD0.
5. Assert the SSLni signal and insert an RSPCK delay according to SPCMD1.
6. Perform serial transfer according to SPCMD1.
7. Insert SSLni negate delay.
8. The SSLni signal is negated because the SSLKP bit in SPCMD1 is 0. Furthermore, the next-access delay is inserted according to SPCMD1.

If the SSLni signal output setting and the SSLni signal output setting between SPCMDs used for burst transfer are different, SPI switches the SSLni signal state when the SSLni signal corresponding to the next transfer command is asserted (5). Note that, if an SSLni signal change like this takes place, slaves that drive the MISOn signal may conflict with each other, which may cause collision of signal level.

The SPI in master mode references the SSLni signal operation in the module when SSLKP is not used.

Even when the CPHA bit in SPCMD is 0, the SPI can accurately start serial transfer by using the next transfer SSLni signal assertion detected internally. For this reason, burst transfer in master mode is enabled regardless of the set CPHA bit value. (See section 33.3.11. Initializing the SPI.)

- When Between Burst Transfer Frames Delay Select bit (BFDS) of SPI control register (SPCR) is 1.

Figure 33.61 shows an example of SSLni signal operation when burst transfer is achieved by using the settings of SPCMD0 and SPCMD1. The following describes SPI operations of (1) to (6) shown in Figure 33.61. The SSLni output signal polarity depends on the set SPI SSLi signal polarity bit (SPCR3.SSLiP) (i = 0 to 3) value.

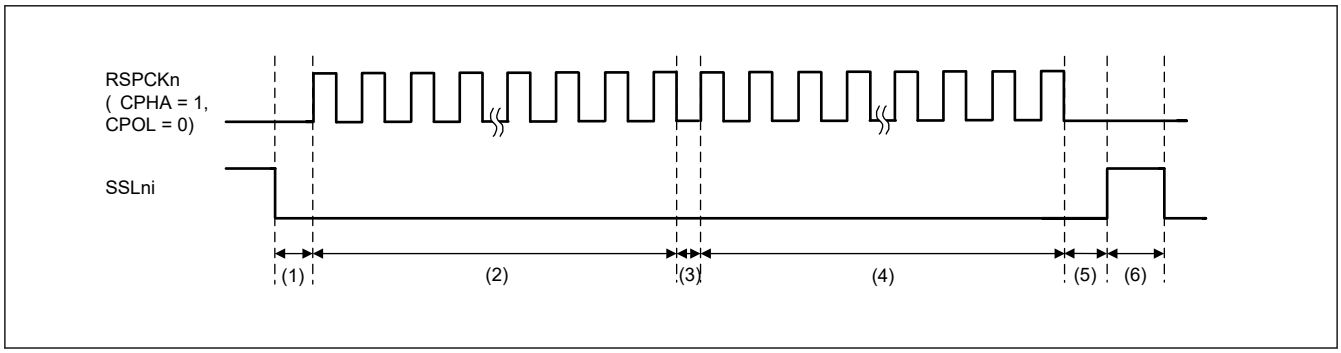

Figure 33.61 Example of Burst Transfer Operation Using SSLKP Bit (BFDS = 1, SPFRF = 0)

1. Assert the SSLni signal and insert an RSPCK delay according to SPCMD0.
   The RSPCK delay is inserted only the first frame of burst transmission.
2. Perform serial transfer according to SPCMD0.
3. Since it is not the last frame, the SSLni signal value at SPCMD0 is retained. RSPCKn negation between frames is 0.5 RSPCKn for the next frame.
4. Perform serial transfer according to SPCMD1.
5. Insert SSLni negate delay for the last frame.
6. The SSLni signal is negated. Furthermore, the next-access delay is inserted according to SPCMD1.

Note: Last frame: Frame set by RMFM[4:0] bits when SPCR2.RMFM[4:0] ≠ 0x00
Or, a frame in which SPCR2.RMEDTG = 1 has been accepted.

[In the TI-SSP case]

SPI asserts the SSLni signal for one cycle at the start of serial transfer.

Serial transfer can be executed continuously by asserting the SSLni signal for one cycle at the start of the next serial transfer (burst transfer).

- When the SSLni signal level holding bit (SSLKP) of the SPI command register (SPCMD) is 1 and the burst transfer frame delay selection bit (BFDS) of the SPI control register (SPCR) is 1, SPCMD0 to SPCMD1 are shown in Figure 33.62. The following shows an example of SSLni signal operation and serial data MISOn / MOSIn when burst transfer is realized using the settings. The SSLni output signal polarity depends on the set SPI SSLi signal polarity bit (SPCR3.SSLiP) (i = 0 to 3) value.

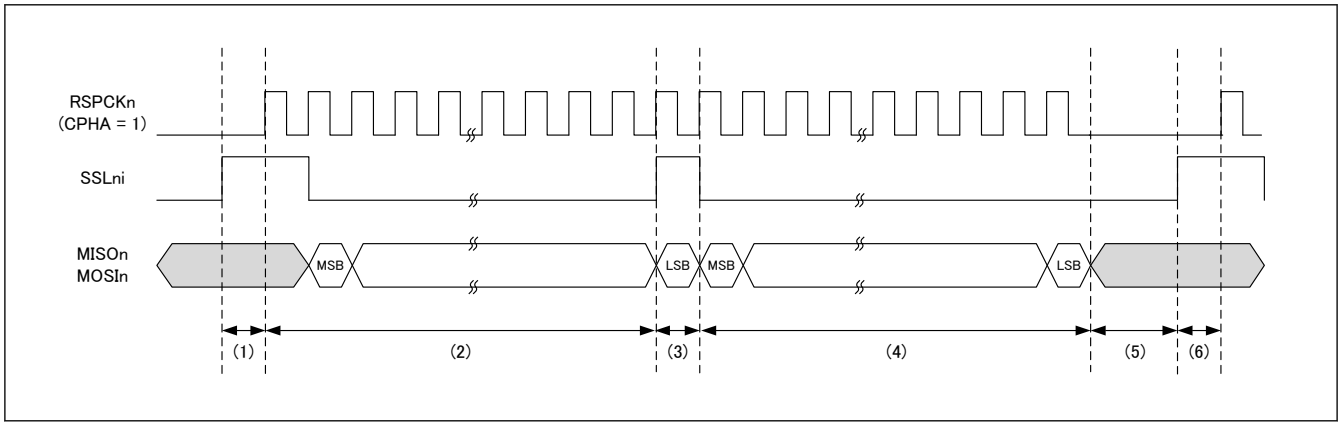

Figure 33.62 Example of Burst Transfer Operation (SPFRF = 1)

1. Assert the SSLni signal and insert an RSPCK delay according to SPCMD0.
   The RSPCK delay is inserted only the first frame of burst transmission.

2. Perform serial transfer according to SPCMD0.
3. Final data transfer and SSLni assertion are performed simultaneously.
4. Perform serial transfer according to SPCMD1.
5. Insert OE negate delay for the last frame.
6. Insert the next access delay according to SPCMD1.

Note: Last frame: Frame set by RMFM[4:0] bits when SPCR2.RMFM[4:0] ≠ 0x00
Or, a frame in which SPCR2.RMEDTG = 1 has been accepted.

If the SSLni signal output setting between the SPCMDs used for burst transfer differs from the SSLni signal output setting, SPI switches the SSLni signal state when the SSLni signal corresponding to the next transfer command is asserted (5). Note that, if an SSLni signal change like this takes place, slaves that drive the MISOn signal may conflict with each other, which may cause collision of signal level.

(5) RSPCK delay (t1)

The RSPCK delay value of the SPI in master mode depends on the SPCMDm.SCKDEN bit setting and the SPDECR.SCKDL[2:0] bits setting. The SPI determines the SPCMDm register to be referenced during a serial transfer by pointer control, and determines an RSPCK delay using the SPCMDm.SCKDEN bit and SPDECR.SCKDL[2:0] bits, as listed in Table 33.10. For a definition of RSPCK delay, see section 33.3.5. Transfer Formats.

RSPCK delay insert to only the first frame of burst transmission, when transmit without “Between Burst Transfer Frames Delay”. (The SPCMD.SSLKP bit is 1 and the SPCR.BFDS bit is 1.)

Table 33.10 Relationship between the SPCMDm.SCKDEN bit, SPDECR.SCKDL[2:0] bits, and RSPCK delay

SPCMDm.SCKDEN bit	SPDECR.SCKDL[2:0] bits	RSPCK delay	
		Motorola-SPI	TI-SSP
0	000b to 111b	1 RSPCK	0 RSPCK
1	000b	1 RSPCK	1 RSPCK
	001b	2 RSPCK	2 RSPCK
	010b	3 RSPCK	3 RSPCK
	011b	4 RSPCK	4 RSPCK
	100b	5 RSPCK	5 RSPCK
	101b	6 RSPCK	6 RSPCK
	110b	7 RSPCK	7 RSPCK
	111b	8 RSPCK	8 RSPCK

(6) SSL negation delay (t2)

The SSL negation delay value of the SPI in master mode depends on the SPCMDm.SLNDEN bit setting and the SPDECR.SLNDL[2:0] bits setting. The SPI determines the SPCMDm register to be referenced by pointer control during a serial transfer, and determines an SSL negation delay using the SPCMDm.SLNDEN bit and SPDECR.SLNDL[2:0] bits, as listed in Table 33.11. For a definition of SSL negation delay, see section 33.3.5. Transfer Formats.

An SSL negation delay is inserted to only the last frame of the burst transmission, that is, transmit without between burst transfer frames delay. (SPCMD.SSLKP bit is 1 and SPCR.BFDS bit is 1).

Table 33.11 Relationship between the SPCMDm.SLNDEN bit, SPDECR.SLNDL[2:0] bits, and SSL negation delay (1 of 2)

SPCMDm.SLNDEN bit	SPDECR.SLNDL[2:0] bits	SSL negation delay
0	000b to 111b	1 RSPCK

Table 33.11 Relationship between the SPCMDm.SLNDEN bit, SPDECR.SLNDL[2:0] bits, and SSL negation delay (2 of 2)

SPCMDm.SLNDEN bit	SPDECR.SLNDL[2:0] bits	SSL negation delay
1	000b	1 RSPCK
	001b	2 RSPCK
	010b	3 RSPCK
	011b	4 RSPCK
	100b	5 RSPCK
	101b	6 RSPCK
	110b	7 RSPCK
	111b	8 RSPCK

(7) Next-access delay (t3)

The next-access delay value of the SPI in master mode depends on the SPCMDm.SPNDEN bit setting and the SPDECR.SPNDL[2:0] bits setting. The SPI determines the SPCMDm register to be referenced during serial transfer by pointer control, and then determines a next-access delay during serial transfer using the SPCMDm.SPNDEN bit and SPDECR.SPNDL[2:0] bits, as listed in Table 33.12. For a definition of next-access delay, see section 33.3.5. Transfer Formats.

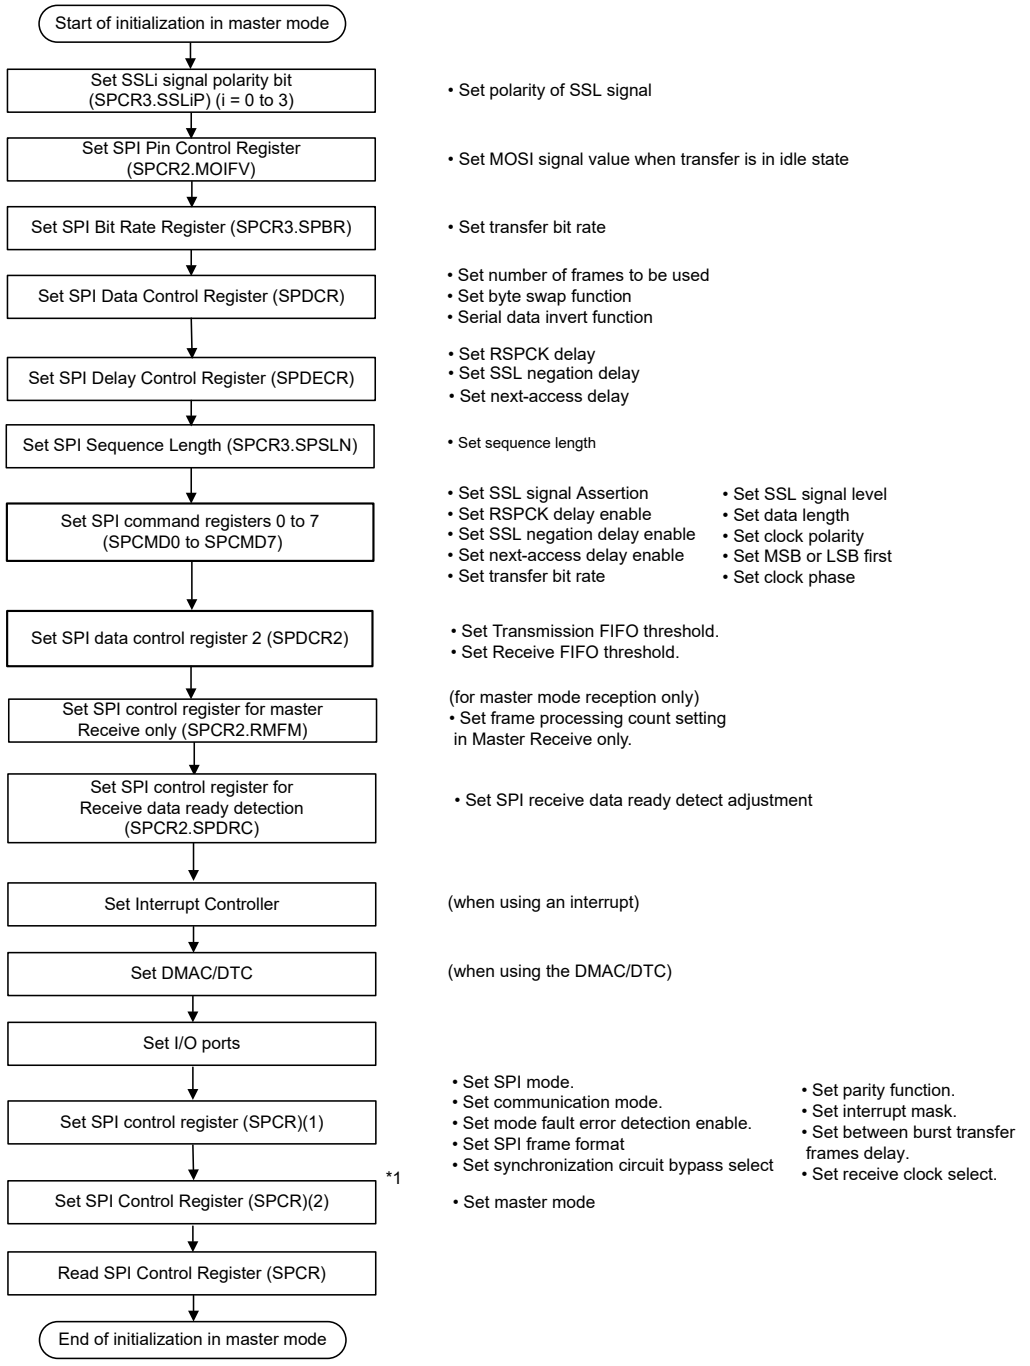
A next-Access delay is inserted to only the last frame of the burst transmission, that is, transmit without between burst transfer frames delay. (SPCMD.SSLKP bit is 1 and SPCR.BFDS bit is 1).

Table 33.12 Relationship between the SPCMDm.SPNDEN bit, SPDECR.SPNDL[2:0] bits, and next-access delay

SPCMDm.SPNDEN bit	SPDECR.SPNDL[2:0] bits	Next-access delay
0	000b to 111b	1 RSPCK + 5 TCLK
1	000b	1 RSPCK + 5 TCLK
	001b	2 RSPCK + 5 TCLK
	010b	3 RSPCK + 5 TCLK
	011b	4 RSPCK + 5 TCLK
	100b	5 RSPCK + 5 TCLK
	101b	6 RSPCK + 5 TCLK
	110b	7 RSPCK + 5 TCLK
	111b	8 RSPCK + 5 TCLK

(8) Initialization flow

Figure 33.63 shows an example of SPI initialization flow when the SPI is in master mode. For information on how to set up the Interrupt Controller Unit (ICU), DMAC or DTC, and I/O ports, see the descriptions given in the individual blocks.



Note 1. Regarding the setting of the SPI control register (SPCR), leave an interval of 1TCLK between setting (1) (initial setting other than MSTR bit) and setting (2) (MSTR setting).

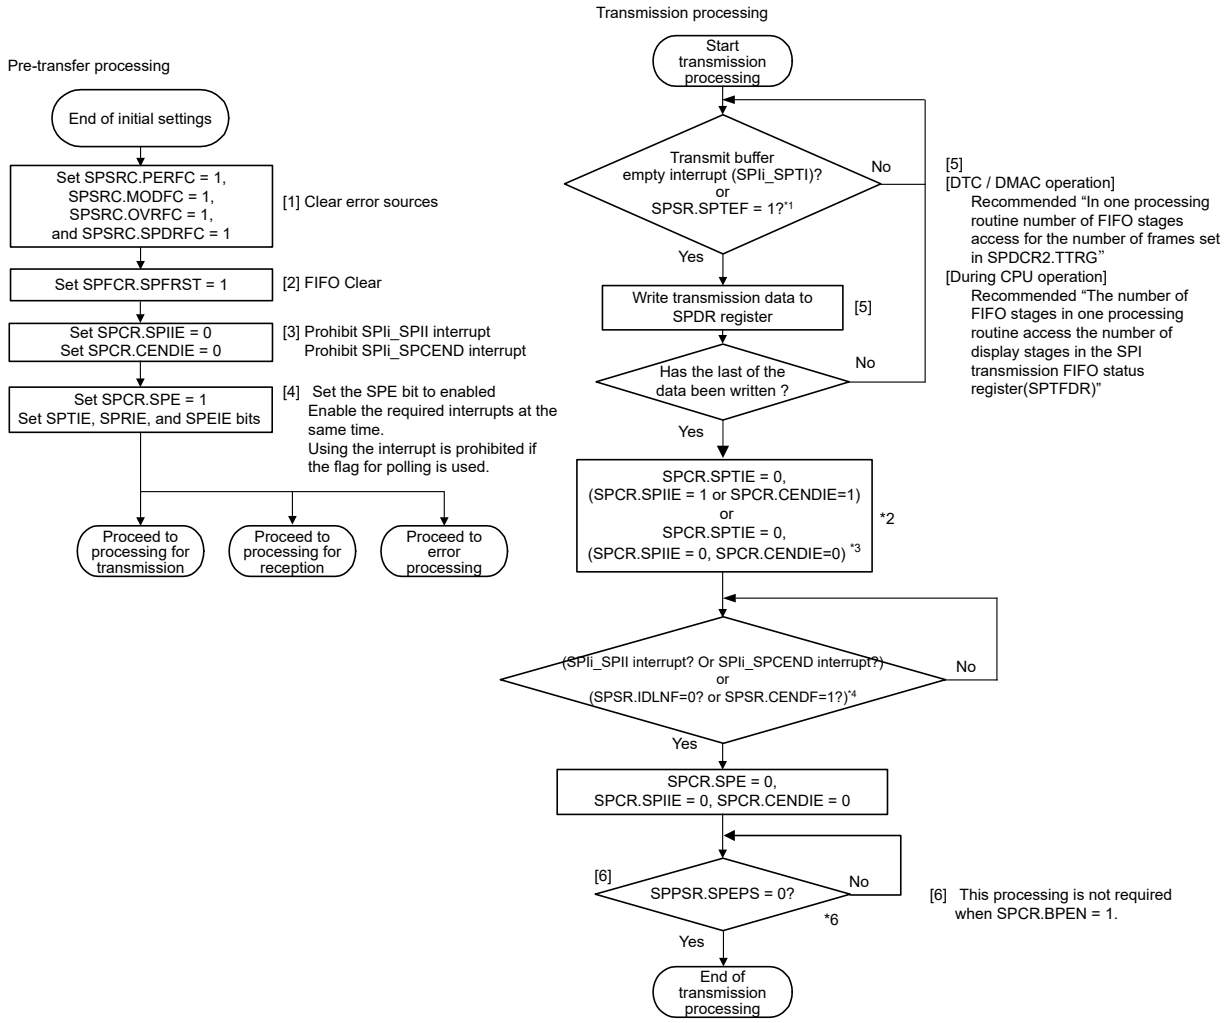
Figure 33.63 Example of initialization flow in master mode for SPI operation

(9) Software processing flow

Figure 33.64 to Figure 33.67 show examples of the software processing flow.

Transmit processing flow

When transmitting data, with the SPIi_SPII or SPIi_SPCEND interrupt enabled, the CPU is notified of the completion of data transmission after the last data write for transmission.

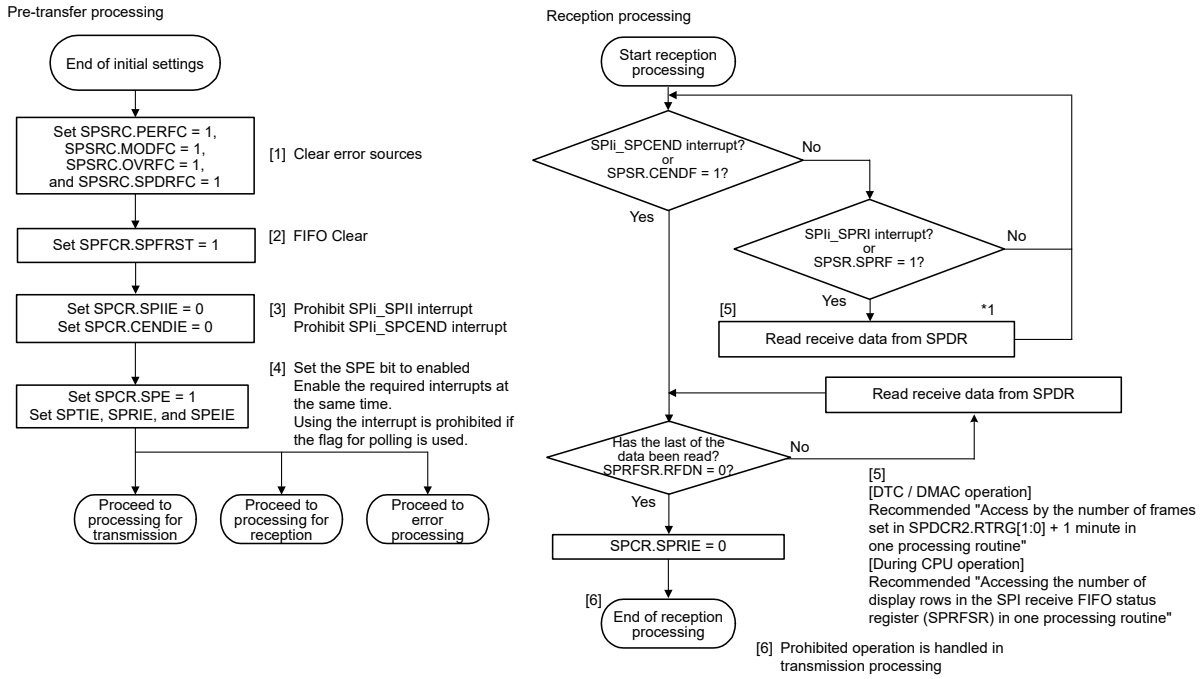


Note 1. Proceed to process of writing data for transmission after reading SPSR.SPTEF flag is 1, if the user uses the flag for polling.
Note 2. The user can know the communication end by SPIi_SPII interrupt (IDLNF flag) or SPIi_SPCEND interrupt (CENDF flag). Use either SPIi_SPII interrupt (IDLNF flag) or SPIi_SPCEND interrupt (CENDF flag).
Note 3. Set SPIi_SPII interrupt prohibited (SPCR.SPIIE = 0) and SPIi_SPCEND interrupt prohibited (SPCR.CENDIE = 0), if the user uses the flag for polling.
Note 4. Wait more than 1 PCLK, after writing data for transmission to SPDR, and before starting polling of SPSR.IDLNF or SPSR.CENDF, if the user uses the flag for polling.
Note 5. During CPU operation, Write 1 to SPI transmit buffer empty flag clear bit (SPSRC.SPTEFC) after one processing routine.
Note 6. When setting to 0 in slave mode and SPCR.BPEN = 0, check that SPPSR.SPEPS has become 0. (Not required when BPEN = 1.)

Figure 33.64 Transmission flow in master mode

Receive processing flow

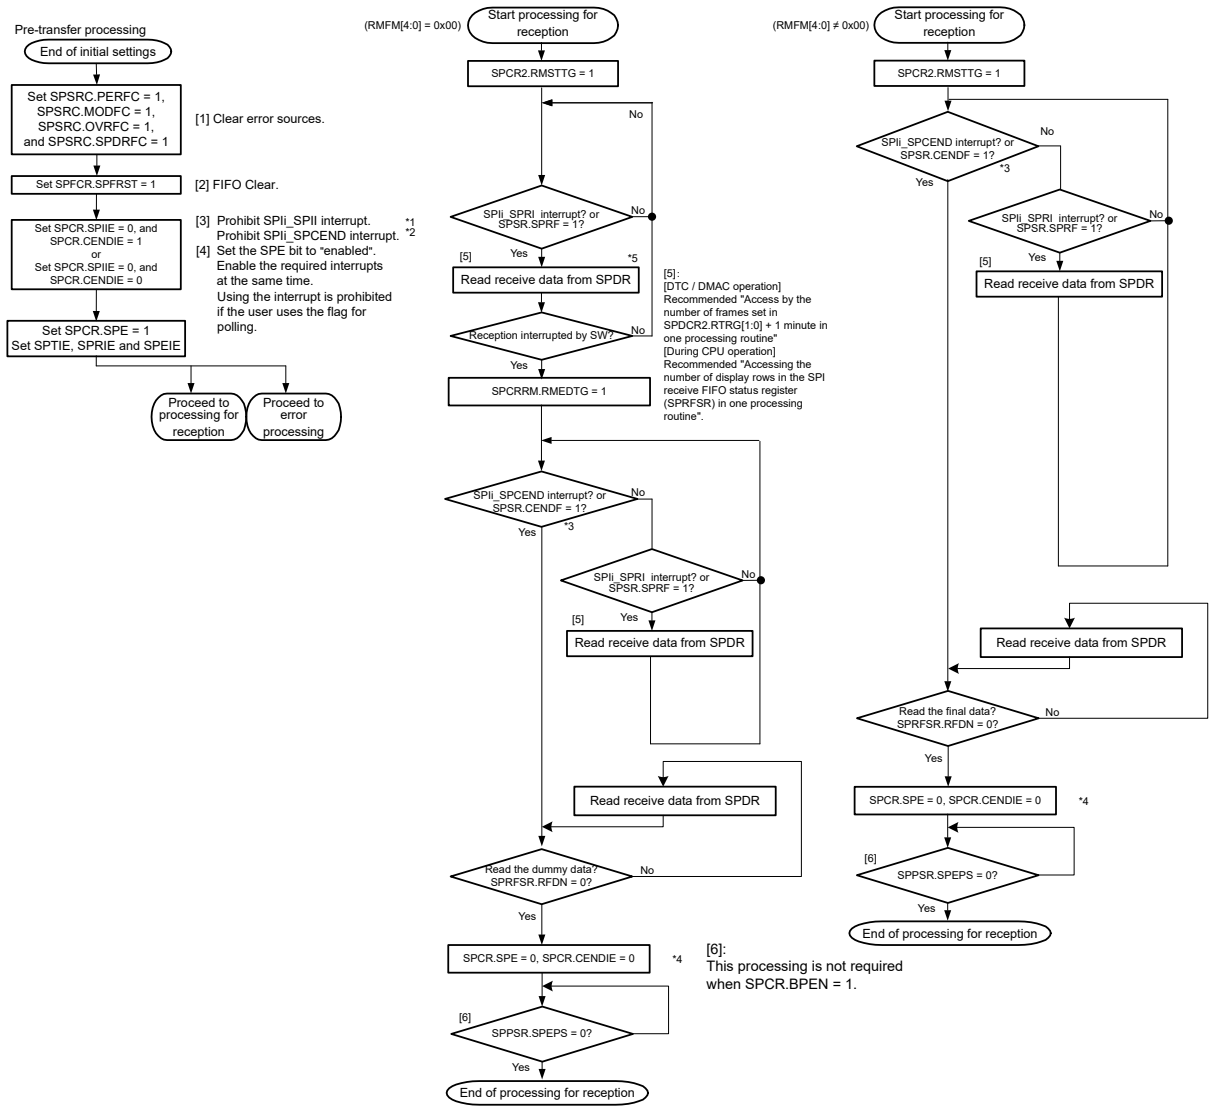
The SPI has receive only operation in slave mode.



Note 1. During CPU operation, write 1 to the SPSRC.SPRFC bit (SPI receive buffer full flag clear bit) after one processing routine.

Figure 33.65 Reception flow in master mode

Receive only processing flow in master mode



Note 1. The end of communication can be determined by the SPIi_SPCEND interrupt (CENDF flag). Use the SPIi_SPCEND interrupt (CENDF flag).
Note 2. Disable SPIi_SPCEND interrupt (SPCR.CENDIE = 0) during flag polling.
Note 3. A communication completion interrupt at reception only operation (Master) occurs at a predetermined timing under any of the following conditions.
- Frame number processing set by RMFM completed (RMFM[4:0] ≠ 0x00)
- RMEDTG = 1, when processing of the number of frames set by RMFM is not completed (including RMFM[4:0] = 0x00)

Note 4. Internal trigger is also cleared.
Note 5. During CPU operation, write 1 to the SPI receive buffer full flag clear bit (SPSRC.SPRFC) after one processing routine.

Figure 33.66 Software Processing Flowchart in Master Mode (Reception-only)

Error processing flow

The SPI detects the following errors:

- Mode fault error
- Underrun error
- Overrun error
- Parity error

When a mode fault error is generated, the SPCR.SPE bit is automatically cleared, stopping operations for transmission and reception. For errors from other sources, the SPCR.SPE bit is not cleared and operations for transmission and reception continue. Therefore, Renesas recommends clearing the SPCR.SPE bit to stop operations for errors other than mode fault errors. Not doing so leads to updating of the SPDCR2.SPECM[2:0] bits.

When an error is detected using an interrupt, clear the ICU.IELSRn.IR flag in the error processing routine. If this is not done, the ICU.IELSRn.IR flag might continue to indicate the SPIi_SPTI or SPIi_SPRI interrupt request. If the SPIi_SPRI interrupt request is indicated, read the receive buffer and initialize the sequencer in the SPI.

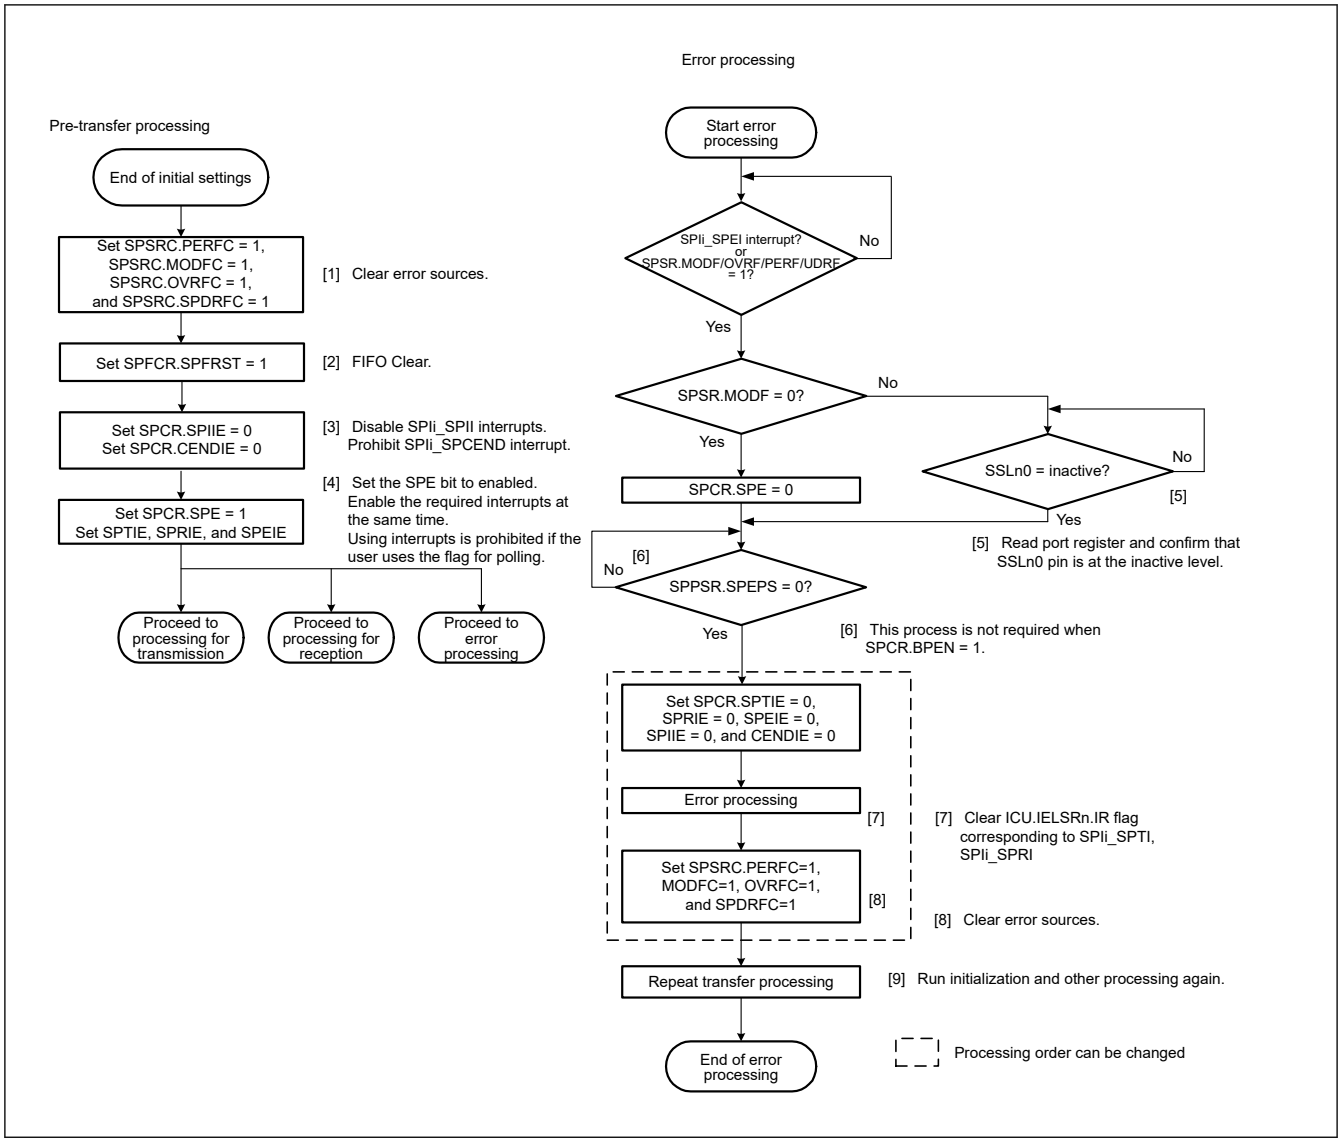


Figure 33.67 Error processing flow in master mode

33.3.12.2 Slave mode operation

(1) Starting a serial transfer

When the SPCMD0.CPHA bit is 0, if the SPI detects an SSLn0 input signal assertion, it must drive valid data to the MISOn output signal. For this reason, when the CPHA bit is 0, the assertion of the SSLn0 input signal triggers the start of a serial transfer.

When the CPHA bit is 1, if the SPI detects the first RSPCKn edge in an SSLn0 signal asserted condition, it must drive valid data to the MISOn output signal. For this reason, when the CPHA bit is 1, the first RSPCKn edge in an SSLn0 signal asserted condition triggers the start of a serial transfer.

Regardless of the CPHA bit setting, the SPI drives the MISOn output signal on SSLn0 signal assertion. The data that is output by the SPI is either valid or invalid, depending on the CPHA bit setting.

For details on the SPI transfer format, see section 33.3.5. Transfer Formats. The polarity of the SSLn0 input signal depends on the SPCR3.SSL0P setting.

(2) Terminating a serial transfer

Regardless of the SPCMD0.CPHA bit setting, the SPI terminates the serial transfer after detecting an RSPCKn edge corresponding to the final sampling timing. When the number of data stored in the receive FIFO is less than the number of FIFO stages, on termination of serial transfer, the SPI copies received data from the shift register to the receive buffer of the SPDR register. On termination of a serial transfer, the SPI changes the status of the shift register to empty, regardless of the receive buffer state. A mode fault error occurs if the SPI detects an SSLn0 input signal negation from the beginning of serial transfer to the end of serial transfer (see section 33.3.10. Error Detection).

The final sampling timing changes depending on the bit length of transfer data. In slave mode, the SPI data length is determined by the SPCMD0.SPB[4:0] bits setting. The polarity of the SSLn0 input signal is determined by the SPCR3.SSL0P bit setting. For details on the SPI transfer format, see section 33.3.5. Transfer Formats.

(3) Notes on single-slave operations

[In the Motorola-SPI case]

If the SPCMD0.CPHA bit is 0, the SPI starts serial transfers when it detects the assertion edge for an SSLn0 input signal. In the configuration shown in Figure 33.8, if the SPI is used in single-slave mode, the SSLn0 signal is fixed at an active state. Therefore, when the CPHA bit is set to 0, the SPI cannot correctly start a serial transfer. For the SPI to correctly execute transmit and receive operations in slave mode when the SSLn0 input signal is fixed at an active state, the CPHA bit must be set to 1. Do not fix the SSLn0 input signal if there is a requirement for setting the CPHA bit to 0.

[In the TI-SSP case]

When SPI is used as a single slave in the configuration shown in the Figure 33.8, the SSLn0 input signal is always fixed to the inactive state, so the SPI cannot start the serial transfer.

When using a single slave, use the configuration shown in the example in Figure 33.7.

(4) Burst transfer

[In the Motorola-SPI case]

If the SPCMD0.CPHA bit is 1, continuous serial transfer (burst transfer) can be executed while retaining the assertion state for the SSLn0 input signal. When the CPHA bit is 1, the serial transfer period is the period from the first RSPCKn edge to the sampling timing for the reception of the final bit in an SSLn0 signal active state. Even when the SSLn0 input signal remains at the active level, the SPI can accommodate burst transfers, because it can detect the start of an access.

When the CPHA bit is 0, the second and subsequent serial transfers during burst transfer cannot be executed correctly.

[In the TI-SSP case]

In serial transfer, data transfer starts after the SSLn0 input signal is asserted for RSPCK 1 cycle. Since frame transfer starts from the SSLn0 input signal, SSLn0 must be asserted between frames.

(5) Initialization flow

Figure 33.68 shows an example of initialization flow for SPI operation when the SPI is in slave mode. For a description of how to set up the ICU, DMAC or DTC, and I/O ports, see the descriptions given in the individual blocks.

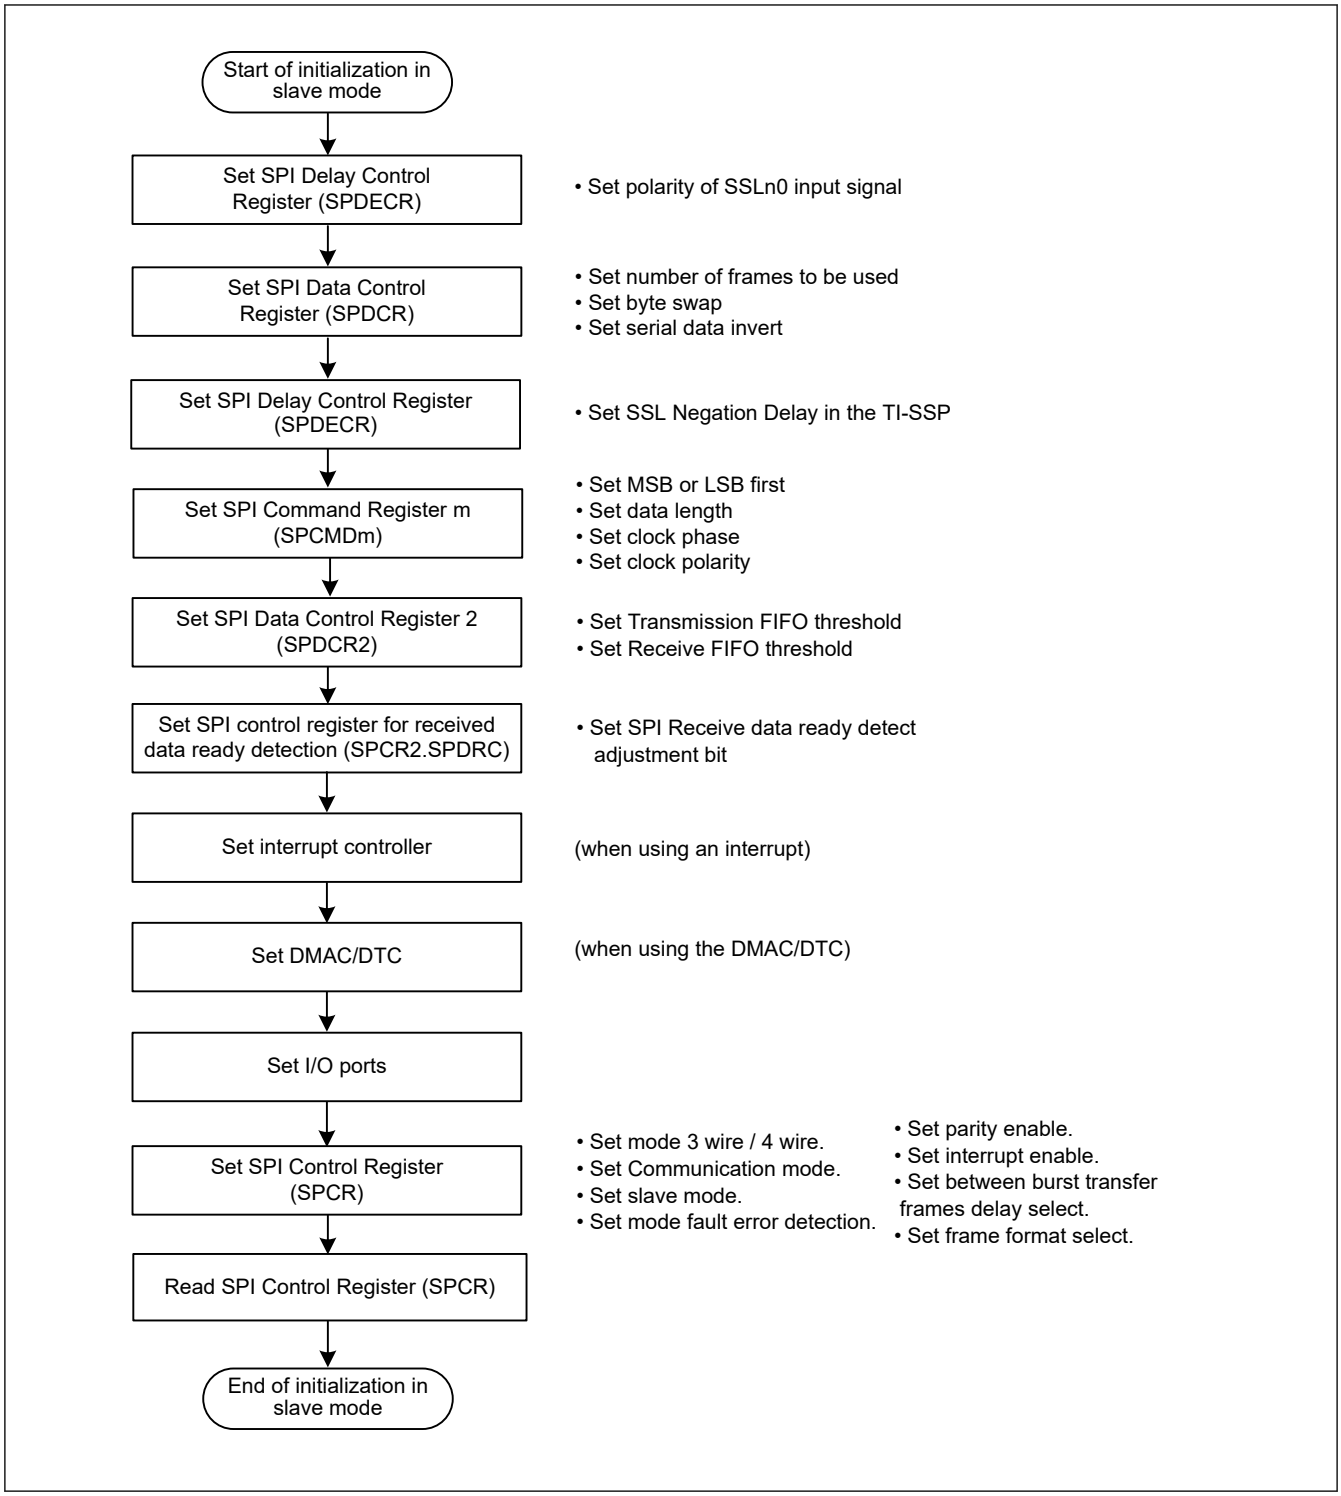

Figure 33.68 Example initialization flow in slave mode for SPI operation

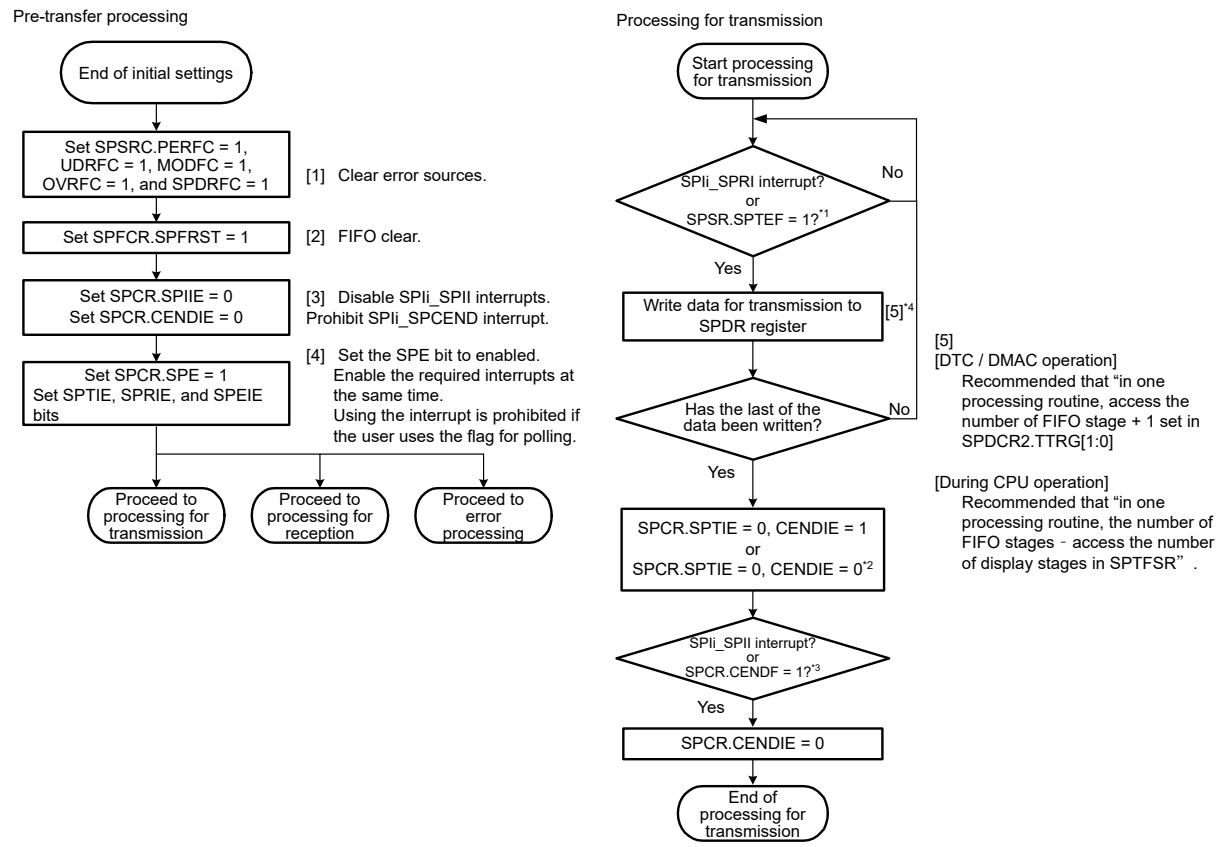
(6) Software processing flow

Figure 33.69 to Figure 33.72 show examples of the flow of software processing.

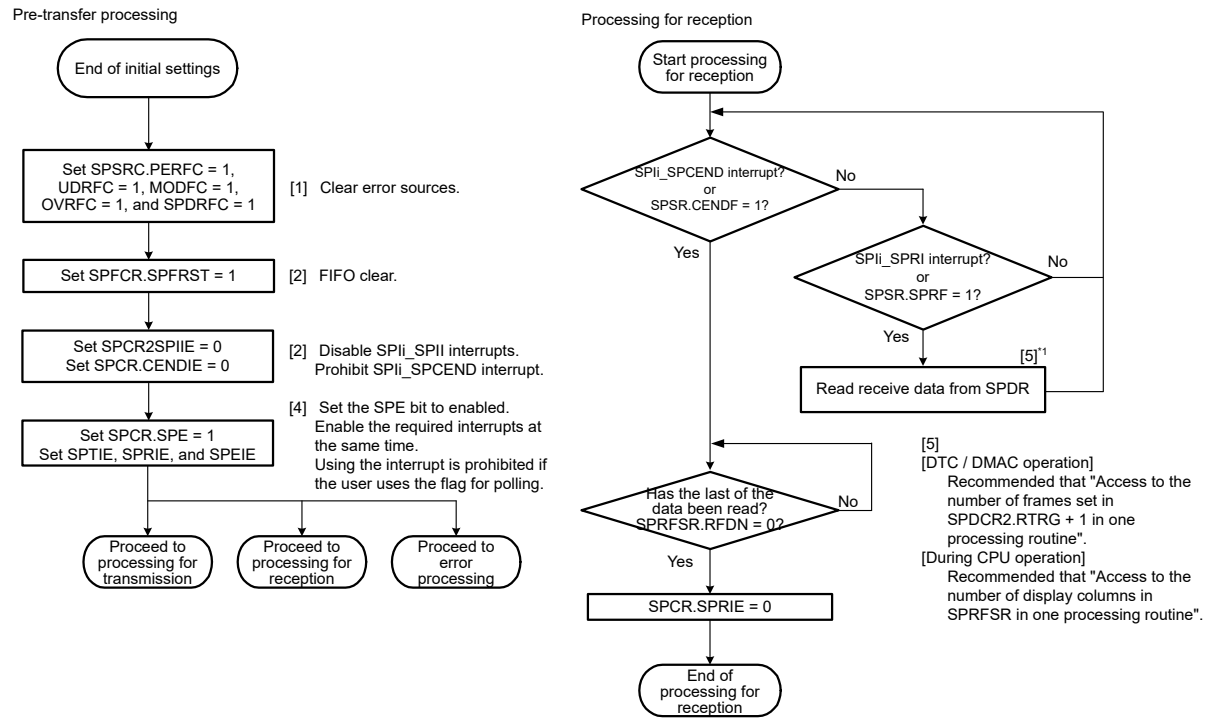
Transmit processing flow



Note 1. Before writing data for transmission to SPDR register, check the transmit buffer empty interrupt by reading SPSR.SPTEF flag, if the flag for polling is used.
Note 2. Set SPIi_SPCEND interrupt prohibited (SPCR.CENDIE = 0), if the user uses the flag for polling.
Note 3. Wait more than 1 PCLK, after writing data for transmission to SPDR, and before starting polling of SPSR.IDLNF or SPSR.CENDF, if the user uses the flag for polling.
Note 4. During CPU operation, write 1 to SPI transmit buffer empty flag clear bit (SPSRC.SPTEFC) after one processing routine.

Figure 33.69 Transmission flow in slave mode

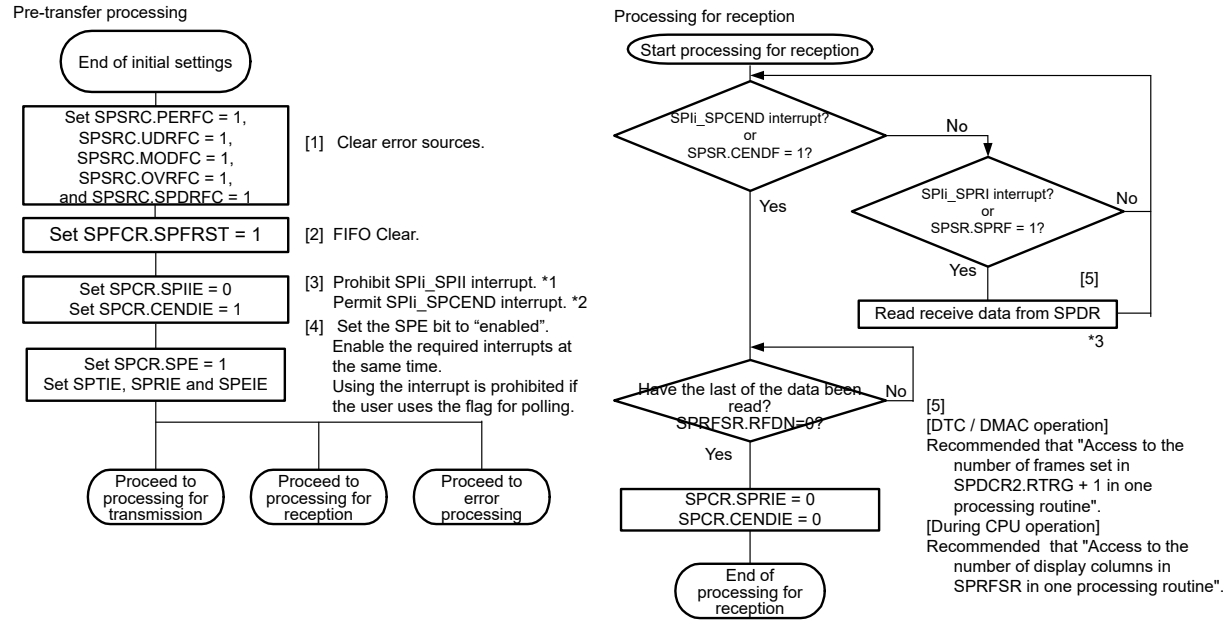
Receive processing flow



Note 1. During CPU operation, write 1 to the SPI receive buffer full flag clear bit (SPSRC.SPTEFC) after one processing routine.

Figure 33.70 Reception flow in slave mode

Master Reception-only processing flow



Note 1. The end of communication can be determined by the SPIi_SPCEND interrupt (CENDF flag). Use the SPIi_SPCEND interrupt (CENDF flag).
Note 2. Disable the SPIi_SPCEND interrupt (SPCR.CENDIE = 0) during flag polling.
Note 3. During CPU operation, write 1 to the SPI receive buffer full flag clear bit (SPSRC.SPTEFC) after one processing routine.

Figure 33.71 Software Processing Flowchart in Master Mode (Reception-only)

Error processing flow

In slave mode operation, even when a mode fault error is generated, the SPSR.MODF flag can be cleared regardless of the state of the SSLn0 pin.

When an error is detected by using an interrupt, clear the ICU.IELSRn.IR flag in the error processing routine. If this is not done, the ICU.IELSRn.IR flag might continue to indicate the SPIi_SPTI or SPIi_SPRI interrupt request. If the SPIi_SPRI interrupt request is indicated, read the receive buffer and initialize the sequencer in the SPI.

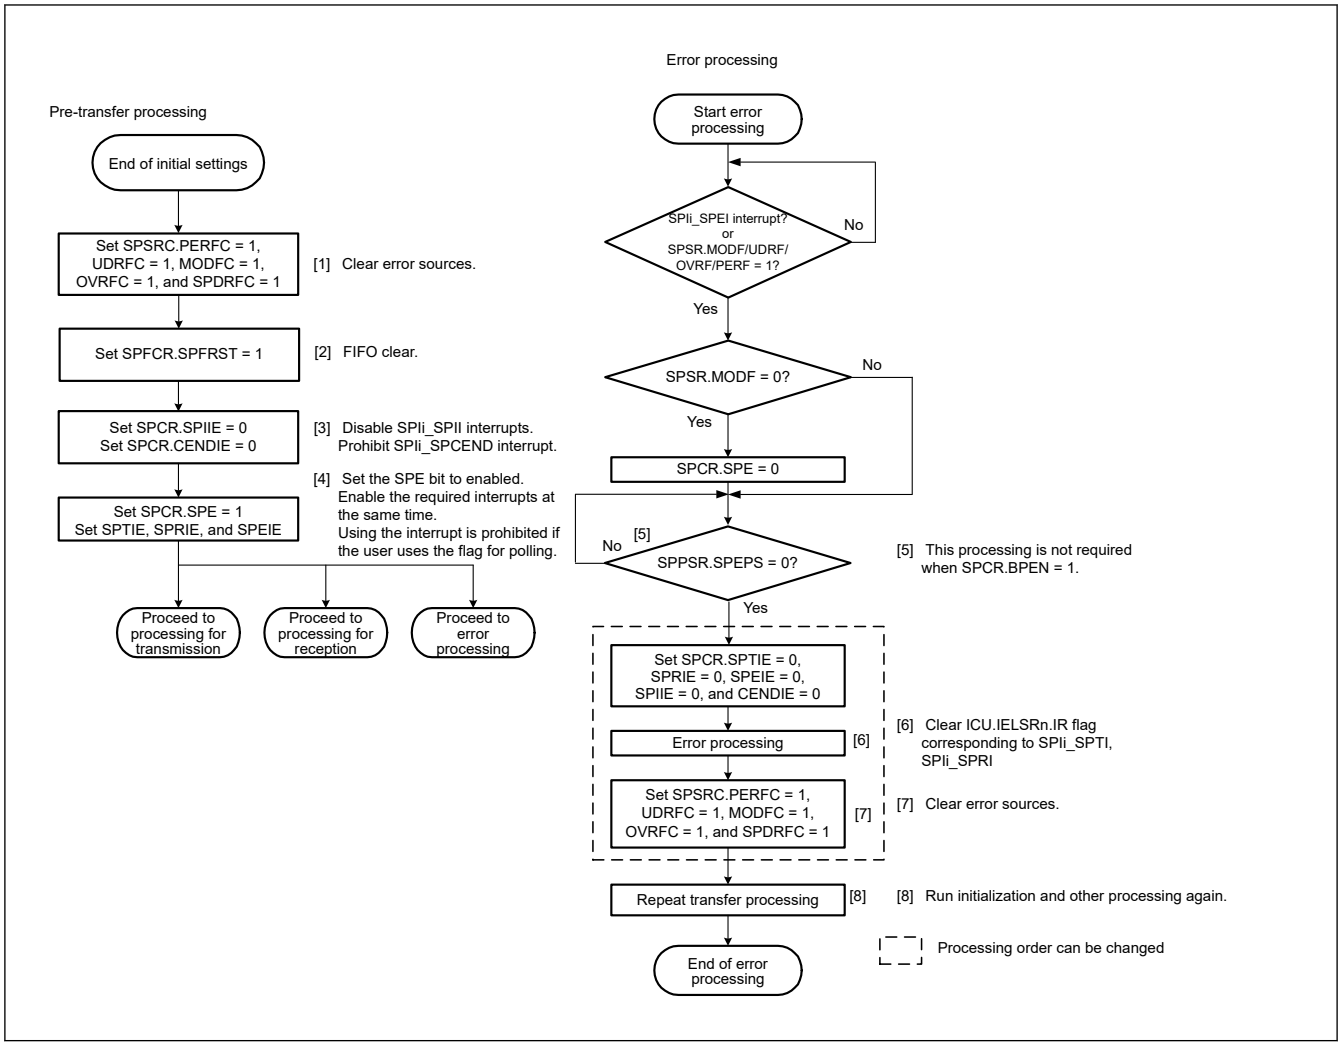


Figure 33.72 Error processing flow for slave mode

33.3.13 Clock Synchronous Operation

Setting the SPCR.SPMS bit to 1 selects clock synchronous operation of the SPI. In clock synchronous operation, the SSLni pin is not used, and the RSPCKn, MOSIn, and MISOn pins handle communications. All SSLni pins are available as I/O port pins.

Although clock synchronous operation does not require the use of the SSLni pin, operation of the module is the same as in SPI operation. In both master mode and slave mode operations, communications can be performed with the same flow as in SPI operation. However, mode fault errors are not detected, because the SSLni pin is not used.

Additionally, do not perform operation if clock synchronous operation is enabled when the SPCMDm.CPHA bit is set to 0 in slave mode (SPCR.MSTR = 0).

33.3.13.1 Master mode operation

(1) Starting serial transfer

When data is written to the SPI data register (SPDR) while the next transfer data is not set in the transmit FIFO, the SPI updates the transmit buffer (SPTXn, n = 0 to 3) data in SPDR.While the shift register is empty, the SPI copies transmit buffer data to the shift register to start serial transfer. After the SPI copies transmit data to the shift register, it changes the shift register status to full. Upon completion of serial transfer, the SPI changes the shift register status to empty. The shift register status cannot be monitored.

For details about the SPI transfer format, see section 33.3.5. Transfer Formats. In clock synchronous operation, however, the SSLn0 output signal is not used for communication.

(2) Terminating serial transfer

The SPI terminates the serial transfer after transmitting an RSPCKn edge corresponding to the sampling timing. If the number of data stored in the receive FIFO < the number of FIFO stages, on termination of serial transfer, the SPI copies data from the shift register to the receive buffer of the SPI Data Register (SPDR).

The final sampling timing varies depending on the bit length of transfer data. In master mode, the SPI data length depends on the SPCMDm.SPB[4:0] bits setting. Transfer in clock synchronous operation is conducted without the SSLn0 output signal. For details on the SPI transfer format, see section 33.3.5. Transfer Formats.

(3) Sequence control

The transfer format used in master mode is determined by the SPCR3, SPCMDm, and SPDECR registers. Although the SSLni signals are not output in clock synchronous operation, these settings are valid.

The SPCR3.SPSLN[2:0] bits determine the sequence configuration for serial transfers that are executed by the SPI in master mode. The following parameters are specified in the SPCMDm register:

- SSLni output signal value
- MSB or LSB first
- Data length
- Some of the bit rate settings
- RSPCKn polarity and phase
- Whether SPDECR.SCKDL is to be referenced
- Whether SPDECR.SLNDL is to be referenced
- Whether SPDECR.SPNDL is to be referenced

SPCR3.SPBR holds some of the bit rate settings such as SPDECR.SCKDL, an SPI clock delay value, SPDECR.SLNDL, an SSL negation delay, and SPDECR.SPNDL, a next-access delay value.

Based on the sequence length that is assigned to SPCR3, the SPI makes up a sequence comprised of a part or all of SPCMDm register. The SPI contains a pointer to the SPCMDm register that makes up the sequence. The value of this pointer can be checked by reading the SPDCR2.SPCP[2:0] bits. When the SPCR.SPE bit is set to 1 and the SPI function is enabled, the SPI loads the pointer to the commands in SPCMD0 register, and incorporates the SPCMD0 register setting into the transfer format at the beginning of serial transfer. The SPI increments the pointer each time the next-access delay period for a data transfer ends. On completion of the serial transfer that corresponds to the final command comprising the sequence, the SPI sets the pointer to the SPCMD0 register, and in this manner the sequence is executed repeatedly.

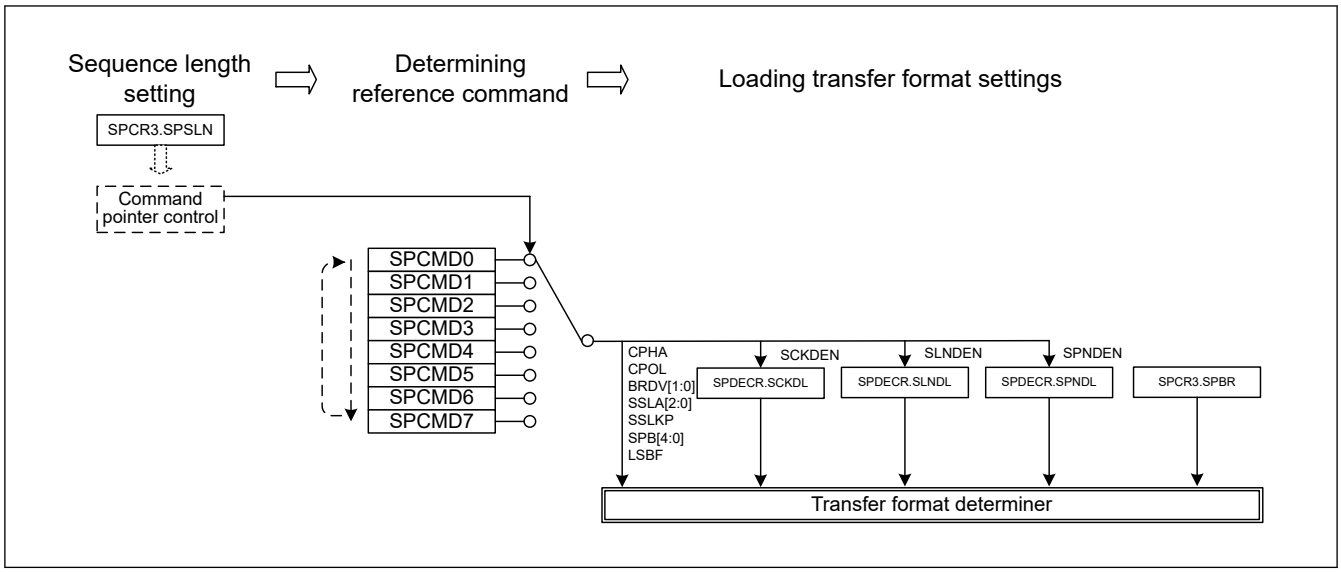

Figure 33.73 Procedure for determining the form of serial transmission in master mode

In this section, a frame is the combination of the data (SPDR) and the settings (SPCMDm).

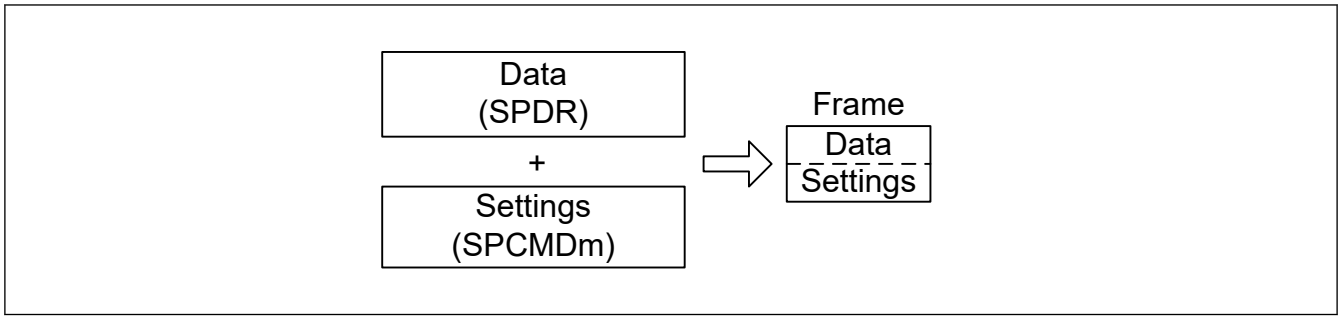

Figure 33.74 Conceptual diagram of frames

Figure 33.75 shows the relationship between the command and the transmit and receive buffers in the sequence of operations specified by the settings.

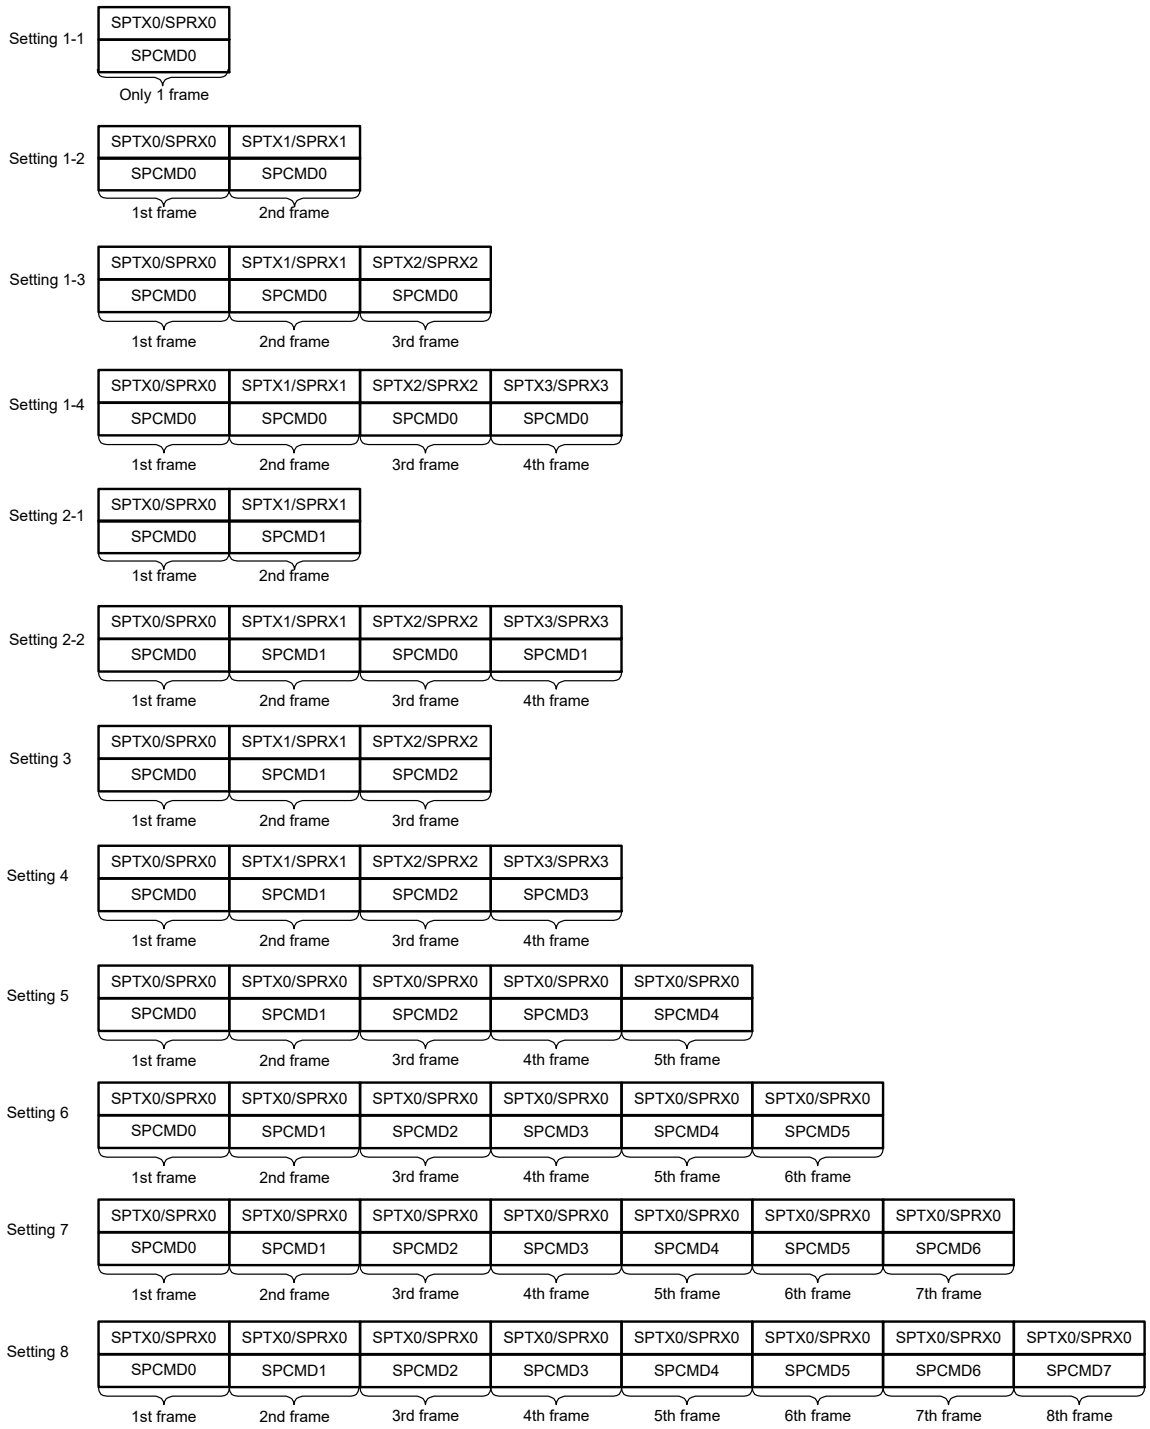

Figure 33.75 Correspondence between SPI Command Register and transmit and receive buffers in sequence operations

(4) Initialization flow

Figure 33.76 shows an example of initialization flow for clock synchronous operation when the SPI is used in master mode. For information on how to set up the ICU, DMAC or DTC, and I/O ports, see the descriptions given in the individual blocks.

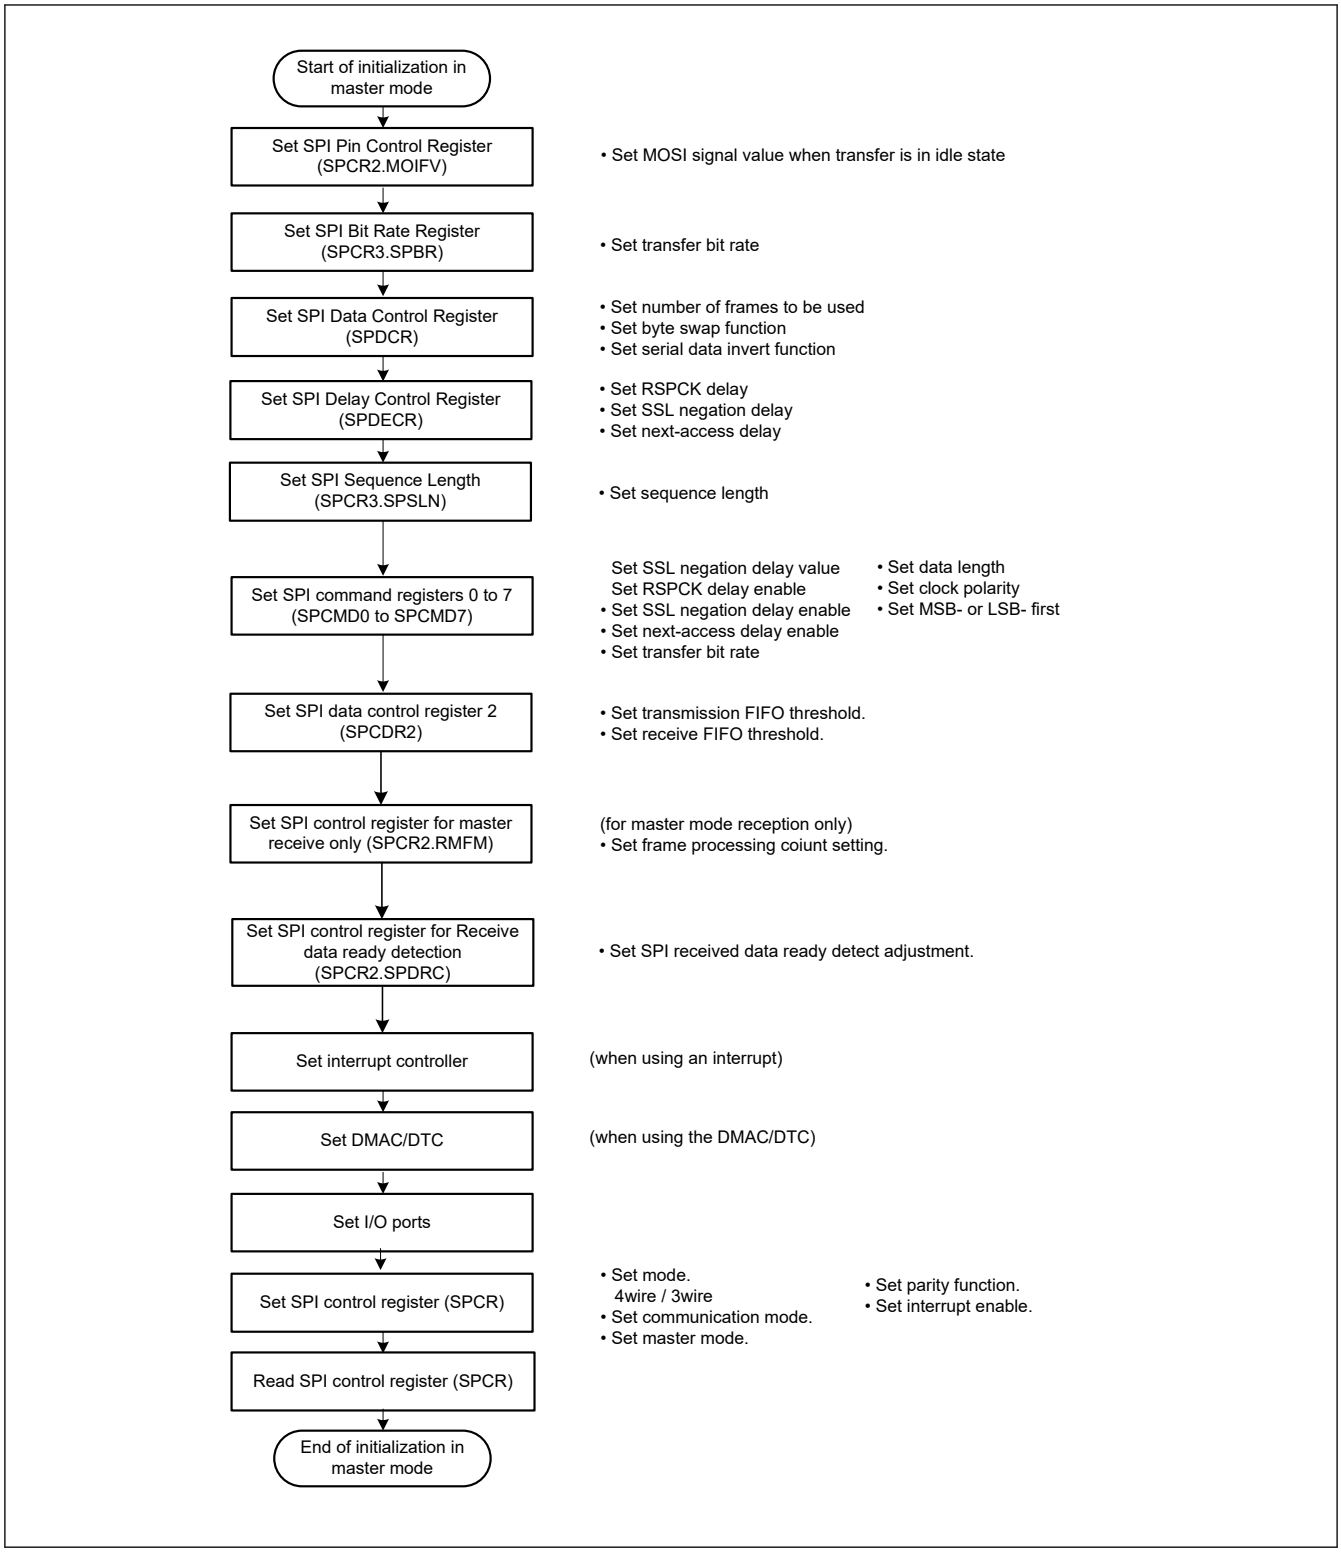

Figure 33.76 Example of initialization flow in master mode for clock synchronous operation

(5) Software processing flow

Software processing during clock synchronous master operation is the same as that for SPI master operation. For details, see (9) Software processing flow in section 33.3.12.1. Master mode operation. Mode fault errors do not occur in clock synchronous operation.

33.3.13.2 Slave mode operation

(1) Starting serial transfer

When the SPCR.SPMS bit is 1, the first RSPCKn edge triggers the start of a serial transfer in the SPI, and the SPI drives the MISOn output signal. The SSLn0 input signal is not used in clock synchronous operation. For details on the SPI transfer format, see section 33.3.5. Transfer Formats.

(2) Terminating serial transfer

The SPI terminates the serial transfer after detecting an RSPCKn edge corresponding to the final sampling timing. When the number of data stored in the receive FIFO < the number of FIFO stages, on termination of serial transfer, the SPI copies received data from the shift register to the receive buffer of the SPDR register. On termination of a serial transfer, the SPI changes the status of the shift register to empty regardless of the receive buffer.

The final sampling timing changes depending on the bit length of transfer data. In slave mode, the SPI data length depends on the SPCMD0.SPB[4:0] bits setting. For details on the SPI transfer format, see section 33.3.5. Transfer Formats.

(3) Initialization flow

Figure 33.77 shows an example of initialization flow for clock synchronous operation when the SPI is used in slave mode. For a description of how to set up the ICU, DMAC or DTC, and I/O ports, see the descriptions given in the individual blocks.

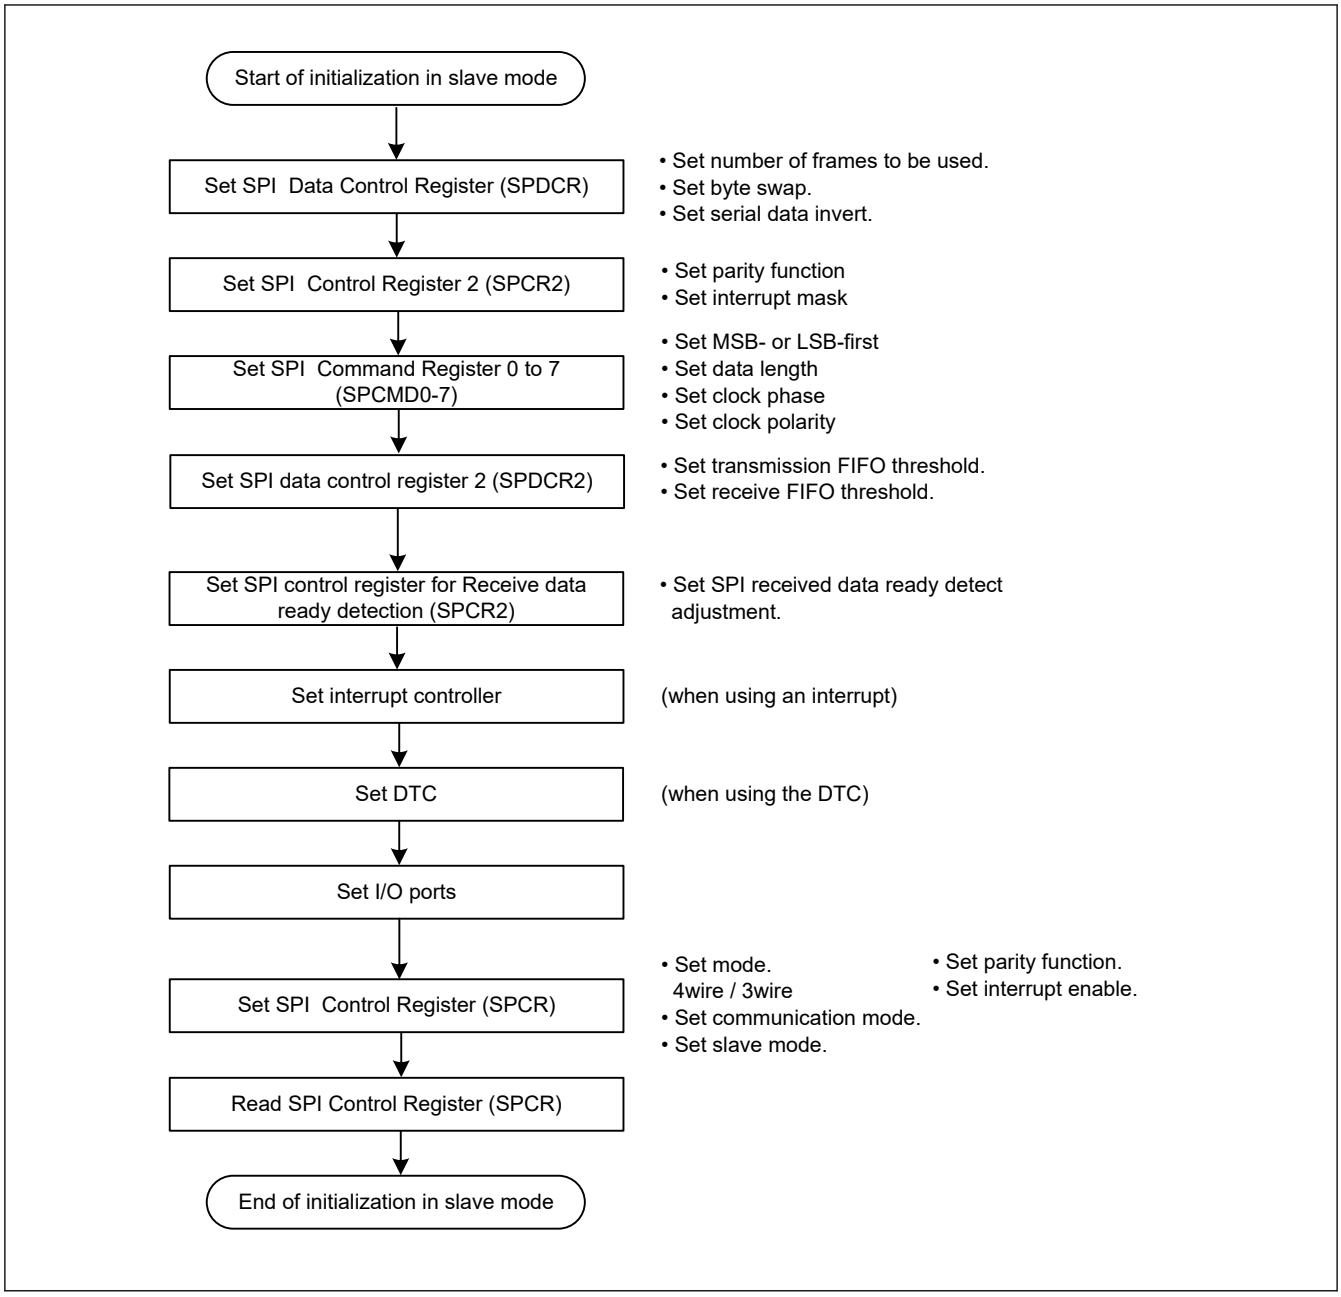

Figure 33.77 Example of initialization flow in slave mode for clock synchronous operation

(4) Software processing flow

Software processing during clock synchronous slave operation is the same as that for SPI slave operation. For details, see (6) Software processing flow. Mode fault errors do not occur in clock synchronous mode.

33.3.14 Loopback Mode

When 1 is written to the SPCR2.SPLP2 bit or SPCR2.SPLP bit, the SPI shuts off the path between the MISOn pin and the shift register if the SPCR.MSTR bit is 1, or between the MOSIn pin and the shift register if the SPCR.MSTR bit is 0, and connects the input and output paths of the shift register, establishing a loopback mode. The SPI does not shut off the path between the MOSIn pin and the shift register if the SPCR.MSTR bit is 1, or between the MISOn pin and the shift register if the SPCR.MSTR bit is 0. This is called loopback mode. When a serial transfer is executed in loopback mode, the transmit data for the SPI or the reversed transmit data becomes the received data for the SPI.

Table 33.13 lists the relationship between the SPLP2 and SPLP bits and the received data. Figure 33.78 shows the configuration of the shift register I/O paths when the SPI in master mode is set to loopback mode (SPCR2.SPLP2 = 0, SPCR2.SPLP = 1).

Table 33.13 SPLP2 and SPLP bit settings and received data

SPCR2.SPLP2 bit	SPCR2.SPLP bit	Received data
0	0	Input data from the MOSIn pin or MISOn pin
0	1	Inverted transmit data
1	0	Transmit data
1	1	Transmit data

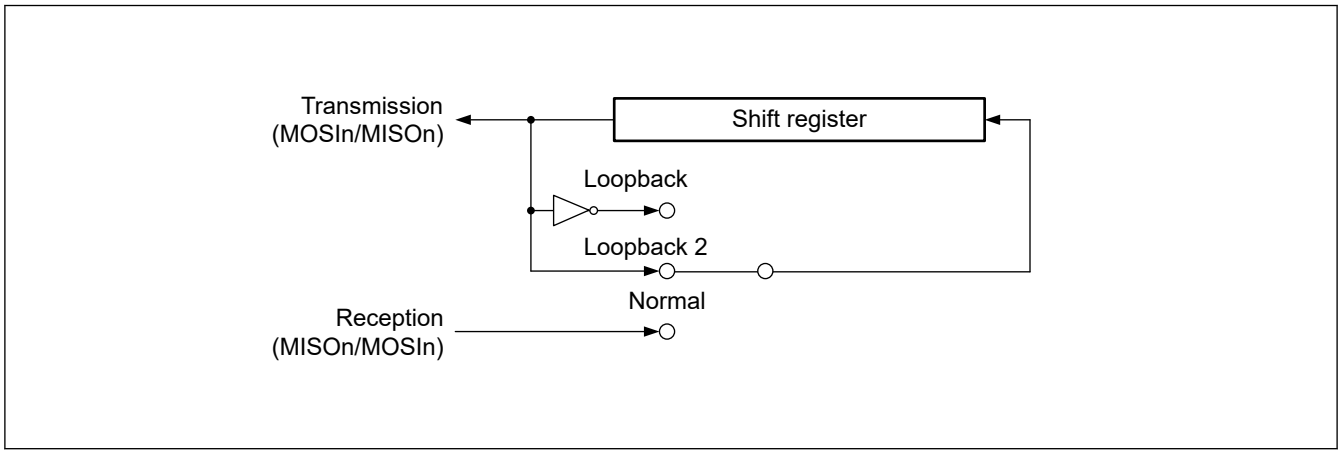

Figure 33.78 Configuration of shift register I/O paths in loopback mode for master mode

33.3.15 Self-Diagnosis of Parity Bit Function

The parity circuit consists of a parity bit adding unit used for transmit data and an error detecting unit used for received data. To detect defects in the parity bit adding unit and error detecting unit, the parity circuit performs self-diagnosis as shown in Figure 33.79.

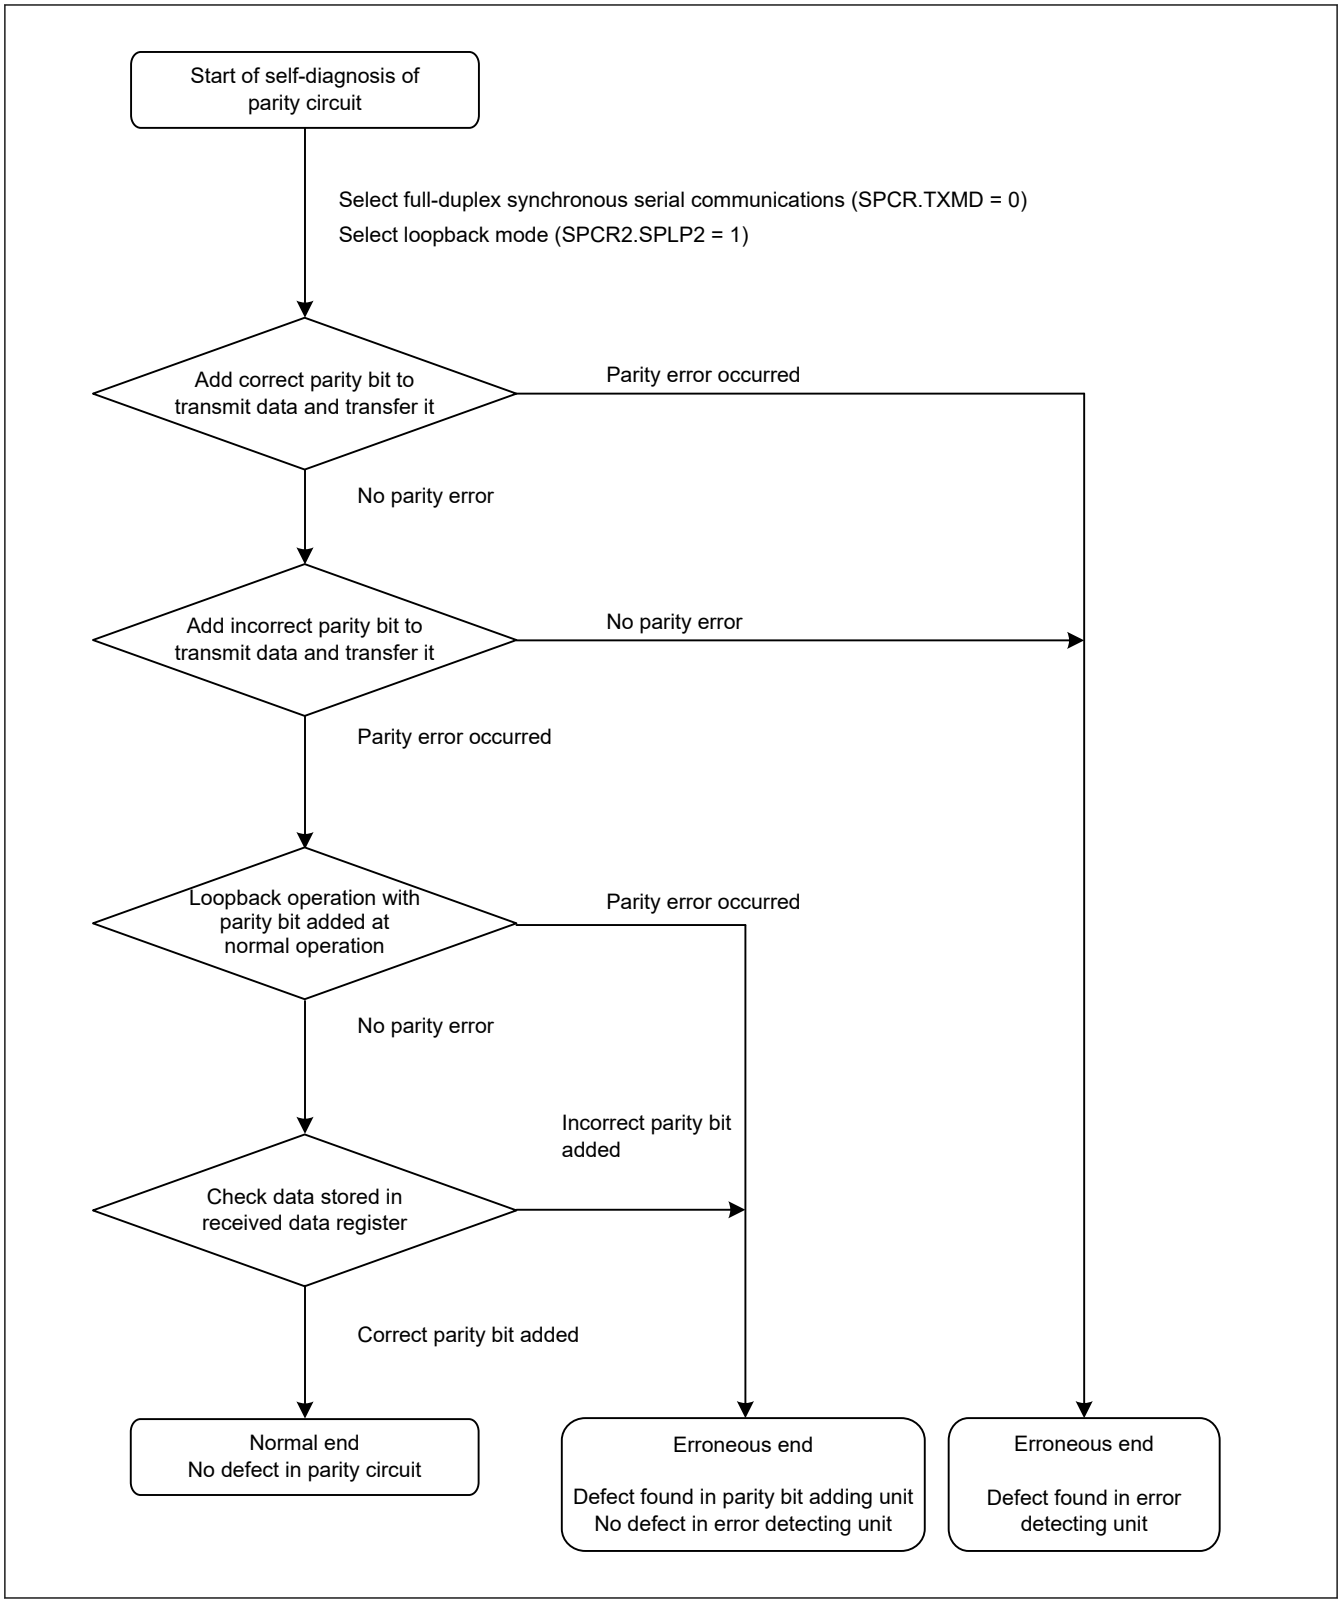

Figure 33.79 Self-diagnosis flow for parity circuit

33.3.16 Interrupt Sources

The SPI has the following interrupt sources:

- Receive buffer full
- Transmit buffer empty

- SPI error (mode-fault, underrun, overrun, or parity error)
- SPI idle
- Communication-end

The DMAC or DTC can be activated by the receive buffer full or transmit buffer empty interrupt to perform data transfer.

Because the vector address for the SPIi_SPEI (SPI error interrupt) is allocated to interrupt requests on mode-fault, underrun, overrun, and parity errors, the actual interrupt source must be determined from the flags. Interrupt sources for the SPI are listed in Table 33.14. An interrupt is generated on satisfaction of one of the interrupt conditions in Table 33.14. Clear the receive buffer full and transmit buffer empty sources through a data transfer.

When using the DMAC or DTC to perform data transmission and reception, you must first set up the DMAC or DTC to be in a transfer-enabled status before setting the SPI. For information on setting up the DMAC or DTC, see section 15, DMA Controller (DMAC) and section 16, Data Transfer Controller (DTC).

If the conditions for generating a transmit buffer empty or receive buffer full interrupt occur while the ICU.IELSRn.IR flag is 1, the interrupt is not output as a request for the ICU but is retained internally (the capacity for retention is one request per source). A retained interrupt request is output when the ICU.IELSRn.IR flag becomes 0. A retained interrupt request is automatically discarded when it is output as an actual interrupt request. The interrupt enable bit (the SPCR.SPTIE or SPCR.SPRIE bit) for an internally retained interrupt request can also be set to 0.

Table 33.14 SPI interrupt sources

Interrupt source	Symbol	Interrupt condition	DTC/DMAC activation
Receive buffer full	SPIi_SPRI	The receive buffer becomes full (SPSR.SPRF flag is 1) while the SPCR.SPRIE bit is 1 or The receive data become ready (SPSR.SPDRF flag is 1) while the SPCR.SPDRES bit is 0	Possible
Transmit buffer empty	SPIi_SPTI	The transmit buffer becomes empty (SPSR.SPTEF flag is 1) while the SPCR.SPTIE bit is 1	Possible
SPI error (mode-fault, underrun, overrun, or parity error)	SPIi_SPEI	The SPSR.MODF, OVRF, or PERF flag sets to 1, or the SPSR.SPDRES and SPDRF flag set to 1 while the SPCR.SPEIE bit is 1	Impossible
SPI idle	SPIi_SPII	The SPSR.IDLNF flag sets to 0 while the SPCR.SPIIE bit is 1	Impossible
Communication-end	SPIi_SPCEND	CENDIE = 1 and CENDF = 1	Impossible

33.4 Event Link Controller Event Output

The Event Link Controller (ELC) can produce the following event output signals:

- Receive buffer full event output
- Transmit buffer empty event output
- Mode-fault, underrun, overrun, or parity error event output
- SPI idle event output
- Transmission-completed event output

The event link output signal is output regardless of the interrupt enable bit setting.

33.4.1 Receive Buffer Full Event Output

When the number of data stored in the receive FIFO > the threshold value, or when the number of data stored in the receive FIFO ≤ the threshold value and SPDRES = 0 has elapsed after writing to the receive FIFO, and the SPDRC [7:0] has elapsed outputs an event.

33.4.2 Transmit Buffer Empty Event Output

An event is output when the number of empty transmission FIFO stage > the threshold or when the SPCR.SPE bit changes from 0 to 1.

33.4.3 Mode-Fault, Underrun, Overrun, Parity Error, or received data ready Event Output

This event signal is output when mode-fault, underrun, overrun, or parity error is detected. See section 33.5.4. Constraints on Mode-Fault, Underrun, Overrun, Parity Error, or Receive Data Ready Event Output if using this event signal.

(1) Mode-fault

Table 33.15 lists the conditions for occurrence of a mode-fault event.

Table 33.15 Conditions for mode-fault occurrence

SPI mode	SPCR.MODFEN bit	SSLn0 pin	Remarks
SPI operation (SPMS = 0) Slave (SPCR.MSTR = 0) Motorola-SPI (SPCR.SPFRF = 0)	1	Not active	Event is output only when the SSLn0 pin is deactivated during transmission
SPI operation (SPMS = 0) Slave (SPCR.MSTR = 0) TI-SSP (SPCR.SPFRF = 1)	1	active	Event is output only when the SSLn0 pin is activated during transmission

(2) Underrun

This event signal is output in response to an underrun when a serial transfer starts while the transmission data is not ready, and the value of the SPCR.MSTR bit is 0 and the SPCR.SPE bit is 1. Under these conditions, the MODF and UDRF flags are set to 1.

(3) Overrun

This event signal is output in response to an overrun when a serial transfer completes while the receive buffer contains unread data and the value of the SPCR.TXMD[1:0] bits are 00b or 10b. Under these conditions, the OVRF flag is set to 1.

(4) Parity error

This event signal is output in response to a parity error detected on completion of a serial transfer while the value of the SPPE bit in SPCR is 1.

(5) Receive Data Ready

When TXMD[1:0] of SPCR = 00b or 10b and SPDRES = 1 as the receive data ready event output condition, the number of data stored in the receive FIFO is received after writing the receive FIFO. An event will be output when the set value of SPDRC[7:0] has elapsed while the number is less than the FIFO threshold.

33.4.4 SPI Idle Event Output

(1) In master mode

In Transmit-Receive / Transmit-only master mode, an event is output when the IDLNF flag in SPSR changes from 1 to 0.

The IDLNF flag changes from 1 to 0 only when either of the conditions 1) and 2) below is met.

1. The SPE bit in SPCR is cleared to 0 (SPI initialized) during transmission.
2. All of the following three conditions are met.
   - The transmit buffer (SPTXn, n = 0 to 3) is empty (next transfer data has not been set).
   - The SPCP [2:0] bits in SPSR are 000b (at the start of sequence control).
   - Operation completed by the next access delay (when the master main state machine transitions to the idle state).

In receive only master mode

Any of the following 2 conditions is met.

1. SPE bit of SPCR is 0 (SPI initialization)
2. When any of the following is met
   - When RMFM [4:0] = 0x00, after writing 1 to RMEDTG, operation completed by the next access delay (when the master main state machine transitions to the idle state).

- When RMFM [4:0] ≠ 0x00, after writing 1 to RMEDTG, operation completed by the next access delay (when the master main state machine transitions to the idle state).
- When RMFM [4:0] ≠ 0x00, the SPI internal sequencer transitions to the idle state after operation completed by the next access delay (when the master main state machine transitions to the idle state).

(2) In slave mode

In slave mode, an event is output when the SPCR.SPE bit is set to 0 (SPI is initialized).

33.4.5 Communication End Event Output

In master mode, an event is output when the IDLNF flag (SPI idle flag) changes from 1 to 0. In slave mode, an event occurs with conditions shown in Table 33.16 and Table 33.17

Table 33.16 Communication End Event Generating Conditions (transmit-receive/transmit slave mode)

	Transmit Buffer Status	Shift Register Status	Others
SPI operation (SPMS = 0, SPFRF = 0)	Empty	Empty	SSLn0 input is negated
SPI operation (SPMS = 0, SPFRF = 1)	Empty	Empty	SSL negation delay completed
Clock synchronous operation (SPMS = 1)	Empty	Empty	The last even edge of RSPCK of last data was detected (CPHA = 1)

Table 33.17 Communication End Event Generating Conditions (receive only slave mode)

	Others
SPI operation (SPMS = 0, SPFRF = 0)	After storing the frames corresponding to the SPFC setting value in the receive buffer, negate SSLn0 input.
SPI operation (SPMS = 0, SPFRF = 1)	After storing the frames corresponding to the SPFC setting value in the receive buffer, SSL negation delay completed
Clock synchronous operation (SPMS = 1)	RSPCK last even edge detection when receiving the last frame for the SPFC set value (CPHA = 1)

Regardless of master mode or slave mode, no event is output when 0 is written to the SPCR.SPE bit during transmission or when the SPCR.SPE bit is cleared due to a mode fault error or an underrun error.

A communication end event is output at the following timing. The communication end event output timing in master operation is omitted because it is output at the same timing as an idle event.

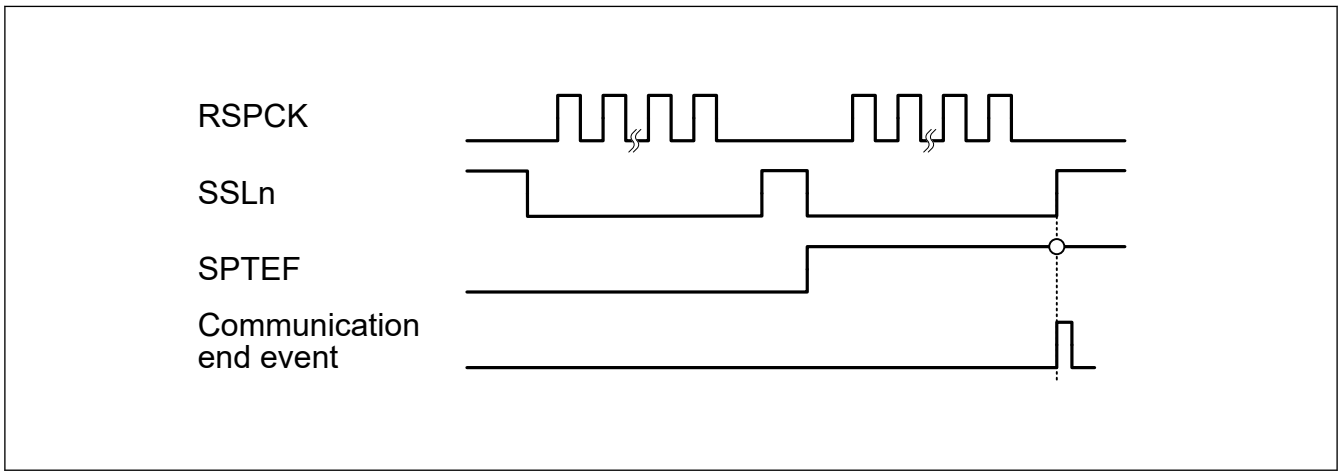

Figure 33.80 Communication End Event Output Timing (Transmit slave mode, Motorola SPI operation)

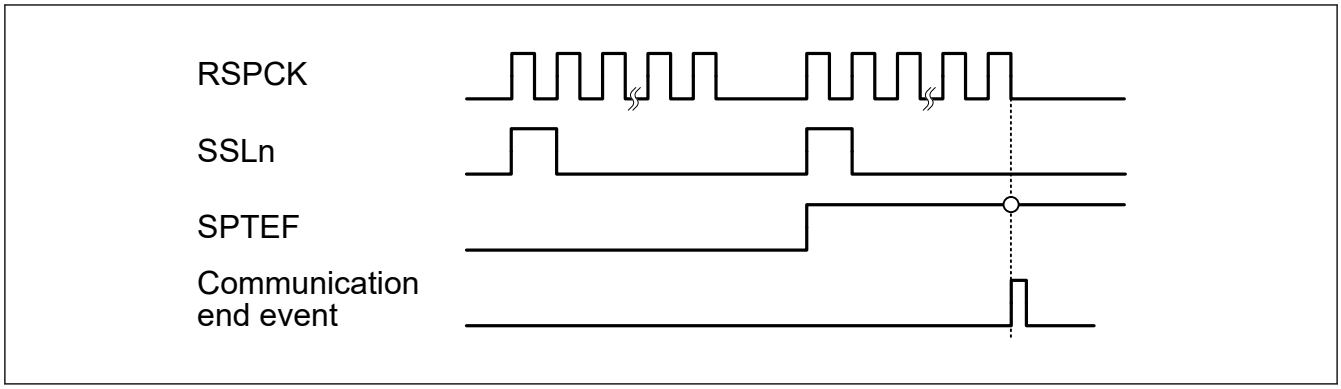

Figure 33.81 Communication End Event Output Timing (Transmit slave mode, TI-SSP Operation)

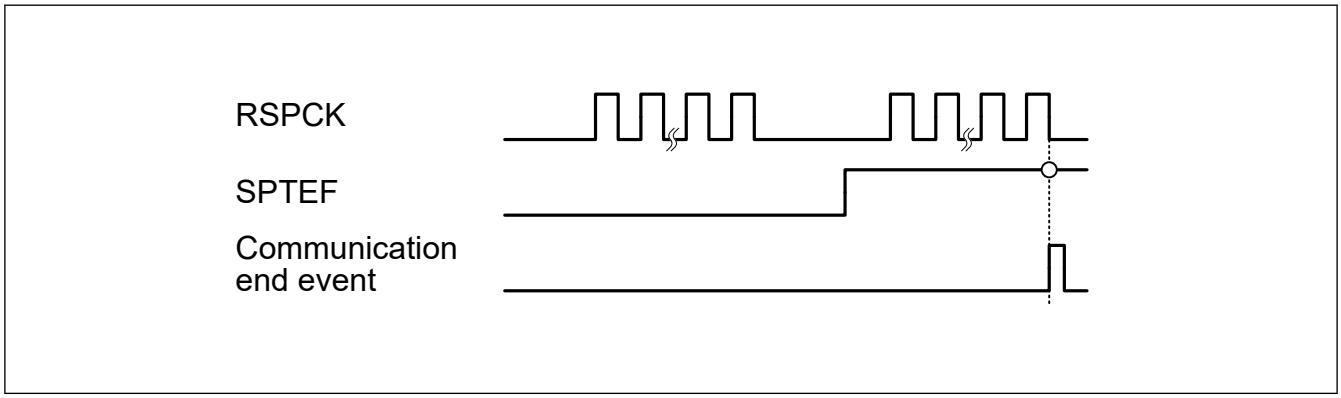

Figure 33.82 Communication End Event Output Timing (Transmit slave mode, Clock Synchronous Operation)

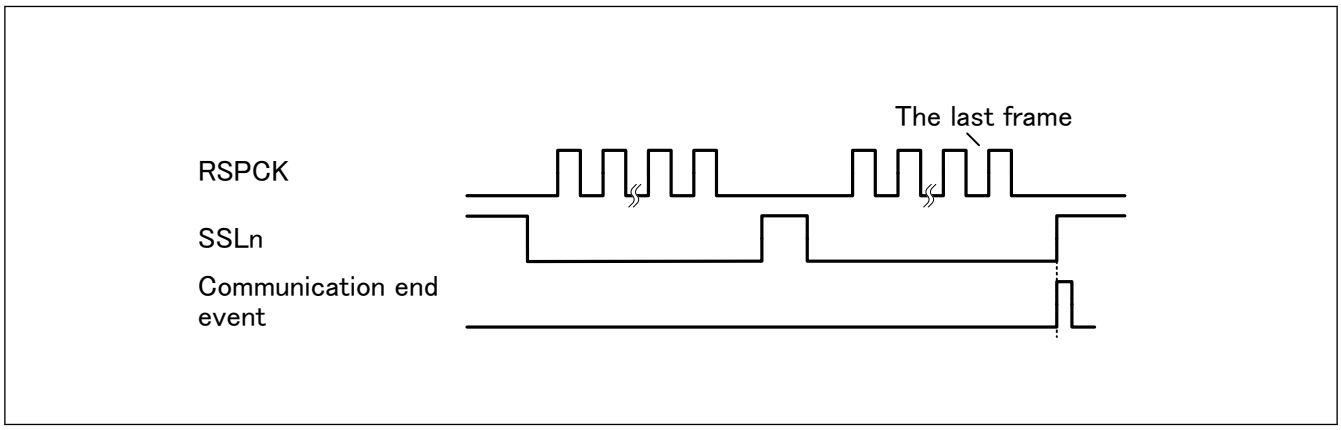

Figure 33.83 Communication End Event Output Timing (Receive only slave mode, Motorola SPI operation)

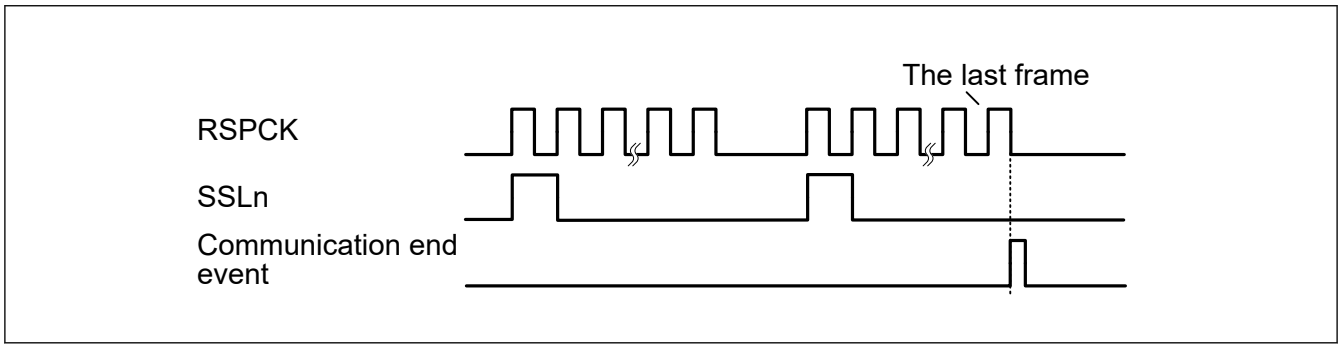

Figure 33.84 Communication End Event Output Timing (Receive only slave mode, TI-SSP Operation)

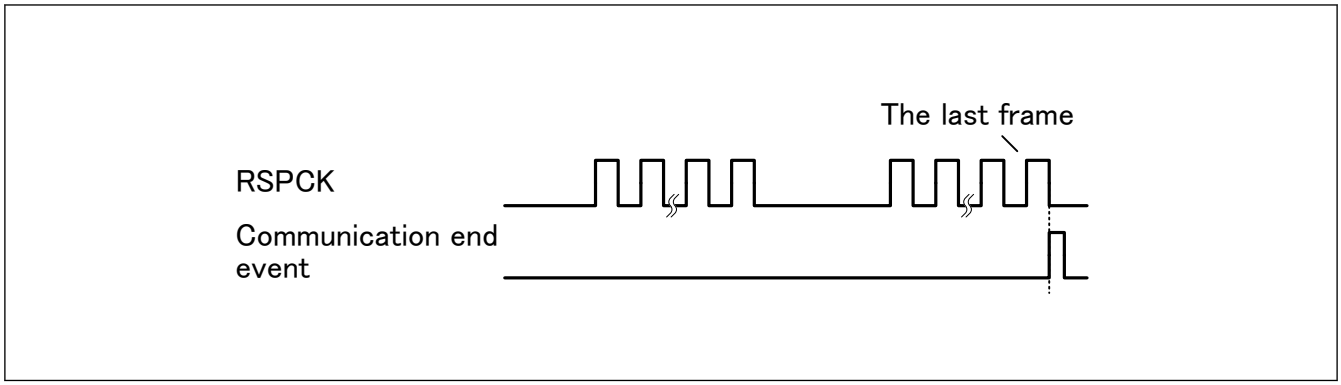

Figure 33.85 Communication End Event Output Timing (Receive only slave mode, Clock Synchronous Operation)

33.4.6 Synchronization bypass function

SPI has an internal clock (PCLK) and an operation clock (TCLK), and each has its own operation circuit. Therefore, a synchronization circuit is inserted between the signals between different clocks, and a signal delay between different clocks requires a synchronization delay time.

However, the synchronization circuit can be bypassed by the BPEN = 1 of the SPI control register (SPCR) only when the same clock is input as the internal bus clock and the operation clock. In this case, the synchronization delay time is excluded, and responsiveness is improved.

In addition, SPI has a synchronization circuit between the communication clock (RSPCK) and the operation clock (TCLK), but this synchronization circuit cannot be bypassed.

33.5 Usage Notes

33.5.1 Settings for the Module-Stop State

The Module Stop Control Register B (MSTPCRB) can enable or disable the SPI operation. The SPI is initially stopped after reset. Releasing the module-stop state enables access to the registers. For details on the Module Stop Control Register B, see section 10, Low Power Modes.

33.5.2 Constraint on Low-Power Functions

When using the module-stop function and entering a low-power mode other than CPU Sleep mode or CPU Deep Sleep mode, set the SPCR.SPE bit to 0 before completing communication.

33.5.3 Constraints on Starting Transfer

If the ICU.IELSRn.IR flag is 1 when transfer starts, the interrupt request is internally retained, which can lead to unanticipated behavior of the ICU.IELSRn.IR flag.

To prevent this, use the following procedure to clear interrupt requests before enabling operations (by setting the SPCR.SPE bit to 1):

1. Confirm that transfer stopped (the SPCR.SPE bit is 0).
2. Set the associated interrupt enable bit (SPCR.SPTIE bit or SPCR.SPRIE bit) to 0.
3. Read the associated interrupt enable bit (SPCR.SPTIE bit or SPCR.SPRIE bit) and confirm that its value is 0.
4. Set the ICU.IELSRn.IR flag to 0.

33.5.4 Constraints on Mode-Fault, Underrun, Overrun, Parity Error, or Receive Data Ready Event Output

Using the mode-fault, underrun, overrun, parity error, or receive data ready event is prohibited if the SPI is in multi-master mode (when the SPCR.SPMS bit is 0, the SPCR.MSTR bit is 1, and the SPCR.MODFEN bit is 1).

33.5.5 Constraints on the SPSR.SPRF and SPSR.SPTEF Flags

If the polling flags, SPRF and SPTEF, are used, using the interrupts is prohibited, and you must set the SPCR.SPRIE and SPCR.SPTIE bits to 0. Either the interrupts or the flags can be used, but not both.

34. SD/MMC Host Interface (SDHI)

34.1 Overview

The Secure Digital Host Interface (SDHI) and MultiMediaCard (MMC) Interface provide the functionality required to connect a variety of external memory cards with the MCU. The SDHI supports both 1- and 4-bit buses for connecting different memory cards that support SD, SDHC, and SDXC formats. When developing host devices that are compliant with the SD Specifications, you must comply with the SD Host/Ancillary Product License Agreement (SD HALA).

The MMC interface supports 1-bit, 4-bit, and 8-bit MMC buses that provide eMMC 4.51 (JEDEC Standard JESD 84- B451) device access. This interface also provides backward compatibility and supports for high-speed SDR transfer modes.

Table 34.1 lists the SD/MMC Host Interface specifications and Figure 34.1 shows a block diagram.

Table 34.1 SD/MMC Host Interface specifications

Interface	Parameter	Specifications
SD	SD bus interface	• Compatible with SD memory card and SDIO card • Transfer bus mode selectable from 4-bit wide bus mode or 1-bit default bus mode • Compatible with SD, SDHC, and SDXC formats
	Transfer modes	Default Speed mode, High Speed mode, SDR12 or SDR25
SD and MMC shared	SDHI clock frequency	The SDHI clock is generated by dividing PCLKB by 2^n (n = 0 to 9)
	Error check functions	CRC7 (command/response), CRC16 (transfer data)
	Interrupt sources	Card access interrupt (SDHI_MMCn_ACCS), SDIO access interrupt (SDHI_MMCn_SDIO), Card detection interrupt (SDHI_MMCn_CARD) (n = 0, 1)
	DMA transfer sources	DMAC and DTC triggerable by the DMA transfer requests (SDHI_MMCn_ODMSDBREQ (n = 0, 1)) interrupt SD buffer is read and write accessible using the DMAC
	Other functions	• Card detect function • Write protect support
MMC	MMC bus interface	Transfer bus mode selectable from 1-bit, 4-bit, or 8-bit
	Transfer modes	Backward compatible mode or high-speed SDR mode selectable
	Other functions	e.MMC device access supported
Module-stop function	Module-stop state can be set for each channel to reduce power consumption.	
TrustZone Filter	Security and Privilege attribution can be set for each channel.	

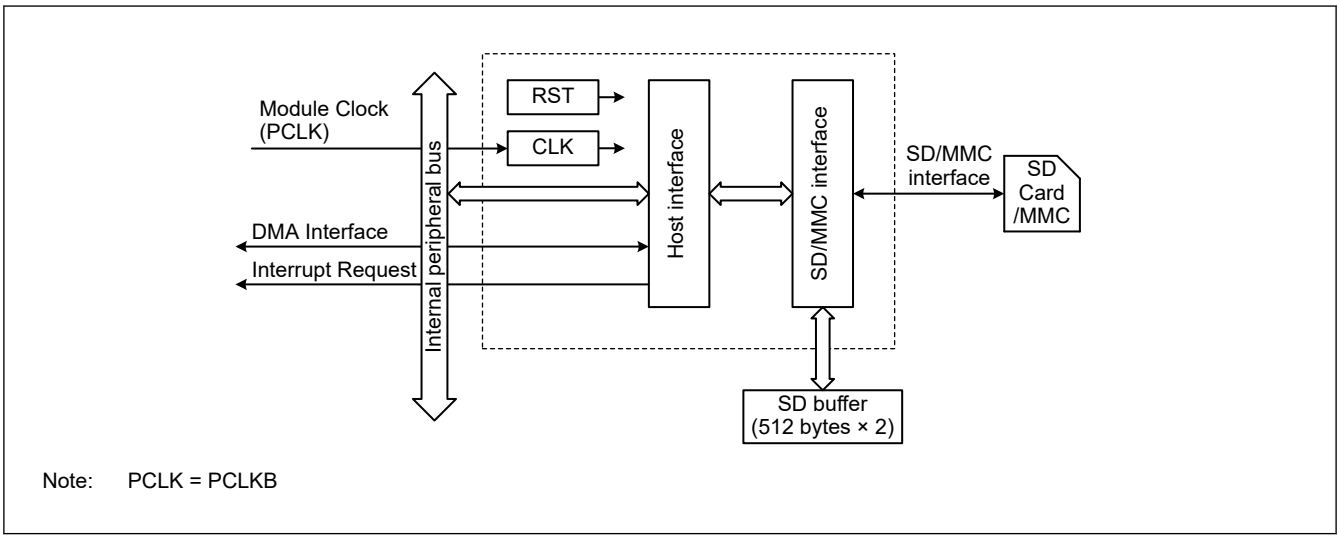

Figure 34.1 SD/MMC Host Interface block diagram

Table 34.2 SDHI I/O pins (n = 0, 1)

Channel	Pin name	I/O	Description
Ch n	SDnCLK	Output	SDHI clock
	SDnCMD	I/O	Command output, response input
	SDnDAT0	I/O	Data 0 (DAT0)
	SDnDAT1	I/O	Data 1 (DAT1), SDIO interrupt
	SDnDAT2	I/O	Data 2 (DAT2), SDIO Read wait
	SDnDAT3	I/O	Data 3 (DAT3), SD Card detect
	SDnDAT4	I/O	MMC Data 4 (DAT4)
	SDnDAT5	I/O	MMC Data 5 (DAT5)
	SDnDAT6	I/O	MMC Data 6 (DAT6)
	SDnDAT7	I/O	MMC Data 7 (DAT7)
	SDnCD	Input	SD card detection
	SDnWP	Input	SD card write protection

34.2 Register Descriptions

34.2.1 SD_CMD : Command Type Register

Base address: SDHIn = 0x4025_2000 + 0x0400 × n (n = 0, 1)
SDHIn_NS = 0x5025_2000 + 0x0400 × n (n = 0, 1)

Offset address: 0x000

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	CMD12AT[1:0]		TRSTP	CMDRW	CMDTP	RSPTP[2:0]			ACMD[1:0]		CMDIDX[5:0]					
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
5:0	CMDIDX[5:0]	Command Index Field Value Select These bits configure the command index field value. The examples shown include the bit values for the ACMD[1:0] bits. 0x06: CMD6 0x12: CMD18 0x4D: ACMD13	R/W
7:6	ACMD[1:0]	Command Type Select 0 0: CMD 0 1: ACMD Others: Setting prohibited	R/W
10:8	RSPTP[2:0]	Response Type Select*1 0 0 0: Normal mode Depending on the command, the response type and transfer method are selected in the ACMD[1:0] and CMDIDX[5:0] bits. At this time, the values for bits 15 to 11 in this register are invalid. 0 1 1: Extended mode and no response 1 0 0: Extended mode and R1, R5, R6, or R7 response 1 0 1: Extended mode and R1b response 1 1 0: Extended mode and R2 response 1 1 1: Extended mode and R3 or R4 response Others: Setting prohibited	R/W

Bit	Symbol	Function	R/W
11	CMDTP	Data Transfer Select*2 0: Do not include data transfer (bc, bcr, or ac) in command 1: Include data transfer (adtc) in command	R/W
12	CMDRW	Data Transfer Direction Select*3 0: Write (SD/MMC Host Interface → SD card/MMC) 1: Read (SD/MMC Host Interface ← SD card/MMC)	R/W
13	TRSTP	Block Transfer Select*3 0: Single block transfer 1: Multiple blocks transfer	R/W
15:14	CMD12AT[1:0]	CMD12 Automatic Issue Select*4 0 0: Automatically issue CMD12 during multiblock transfer 0 1: Do not automatically issue CMD12 during multiblock transfer Others: Setting prohibited	R/W
31:16	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3
Note 1. Some commands cannot be used in normal mode.
Note 2. The CMDTP bit is only valid when the RSPTP[2:0] bits are 011b, 100b, 101b, 110b, or 111b.
Note 3. Bits CMDRW and TRSTP are only valid when the RSPTP[2:0] bits are 011b, 100b, 101b, 110b, or 111b, and the CMDTP bit is 1.
Note 4. The CMD12AT[1:0] bits are only valid when the RSPTP[2:0] bits are 011b, 100b, 101b, 110b, or 111b, and the TRSTP bit is 1.

The command type and response type are set in the SD_CMD register. The command type and transfer mode must be set when the RSPTP[2:0] bits are 011b, 100b, 101b, 110b, or 111b. The sequence starts when a value is written to this register. See Table 34.8 and Table 34.9 for setting examples. Do not write to the SD_CMD register when the SD_INFO2.CBSY flag is 1.

34.2.2 SD_ARG : SD Command Argument Register

Base address: SDHIn = 0x4025_2000 + 0x0400 × n (n = 0, 1)
SDHIn_NS = 0x5025_2000 + 0x0400 × n (n = 0, 1)

Offset address: 0x008

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:																
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:																
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	—	These bits specify command format[39:8] (argument).	R/W

Note: S-TYPE-3, P-TYPE-3

The SD_ARG register is used for setting the argument field value. Set the SD_ARG register before setting the SD_CMD register. The argument field value of the automatically issued CMD12 is 0x0000_0000 regardless of the SD_ARG register value.

34.2.3 SD_ARG1 : SD Command Argument Register 1

Base address: SDHIn = 0x4025_2000 + 0x0400 × n (n = 0, 1)
SDHIn_NS = 0x5025_2000 + 0x0400 × n (n = 0, 1)

Offset address: 0x00C

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:																
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	—	These bits specify command format[39:24] (argument).	R/W
31:16	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

The SD_ARG1 register is used for setting the argument field value. Set the SD_ARG1 register before setting the SD_CMD register. The argument field value of the automatically issued CMD12 is 0x0000_0000 regardless of the SD_ARG1 register value.

34.2.4 SD_STOP : Data Stop Register

Base address: SDHIn = 0x4025_2000 + 0x0400 × n (n = 0, 1)
SDHIn_NS = 0x5025_2000 + 0x0400 × n (n = 0, 1)

Offset address: 0x010

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	SEC	—	—	—	—	—	—	—	STP
Value after reset:	0	0	0	0	0	0	0	0*1	0	0	0	0	0	0	0	0*1

Bit	Symbol	Function	R/W
0	STP	Transfer Stop Data transfer stops when this bit is set to 1.	R/W
7:1	—	These bits are read as 0. The write value should be 0.	R/W
8	SEC	Block Count Register Value Select*2 0: Disable SD_SECCNT register value 1: Enable SD_SECCNT register value	R/W
31:9	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3
Note 1. The value is initialized by a reset and also on reset triggered by the SOFT_RST.SDRST flag.
Note 2. Do not rewrite this bit when the SD_INFO2.CBSY flag is 1.

The SD_STOP register stops data transfer. During a multiblock transfer sequence, the SD_SECCNT register value (number of blocks to be transferred) can be set to valid or invalid by setting the SD_STOP register.

STP bit (Transfer Stop)

When the STP bit is set to 1 during multiple block transfer, CMD12 is issued to halt the transfer through the SDHI. However, if a command sequence is halted because of a communications error or timeout, CMD12 is not issued. Although continued buffer access is possible even after STP is set to 1, the buffer access error bit (ILR or ILW) in SD_INFO2 is set accordingly.

When STP is set to 1 during transfer for single block write, the access end flag sets when SD_BUF becomes empty, and CMD12 is not issued. If SD_BUF does contain data, the access end flag sets on completion of reception of the busy state without CMD12 being issued.

When STP is set to 1 during transfer for single block read, the access end flag sets immediately after the STP bit is set, and CMD12 is not issued.

When STP is set to 1 during reception of the busy state after an R1b response, the access end flag sets on completion of reception of the busy state without CMD12 being issued.

When STP is set to 1 after a command sequence is completed, CMD12 is not issued and the access end flag does not set.

Set STP to 1 after the response end flag sets.

Set STP to 0 after the access end flag sets.

SEC bit (Block Count Register Value Select)

When SD_CMD is set in the following section to start the command sequence while the SEC bit is set to 1, CMD12 is automatically issued to stop multiblock transfer with the number of blocks set in SD_SECCNT.

CMD18 or CMD25 in normal mode (SD_CMD[10:8] = 000b)

SD_CMD[15:13] = 001b in extended mode (CMD12 is automatically issued, multiple block transfer)

When the command sequence is halted because of a communications error or timeout, CMD12 is not automatically issued.

34.2.5 SD_SECCNT : Block Count Register

Base address: SDHIn = 0x4025_2000 + 0x0400 × n (n = 0, 1)
SDHIn_NS = 0x5025_2000 + 0x0400 × n (n = 0, 1)

Offset address: 0x014

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:																
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:																
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	—	These bits set the number of blocks to be transferred.	R/W

Note: S-TYPE-3, P-TYPE-3

When performing a multiblock transfer, SD_SECCNT is a read/write register used to set the number of blocks to be transferred. For example, when the register value is 0x0000_0001, 1 block is transferred. When the register value is 0x0000_FFFF, 65,535 blocks are transferred and when the register value is 0xFFFF_FFFF, 4,294,967,295 blocks are transferred. Do not set this register to 0x0000_0000. Do not rewrite the SD_SECCNT register when the SD_INFO2.CBSY flag is 1.

34.2.6 SD_RSPi : SD Card Response Register i (i = 10, 32, 54)

Base address: SDHIn = 0x4025_2000 + 0x0400 × n (n = 0, 1)
SDHIn_NS = 0x5025_2000 + 0x0400 × n (n = 0, 1)

Offset address: 0x018 (SD_RSP10)
0x020 (SD_RSP32)
0x028 (SD_RSP54)

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:																
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:																
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	—	These bits store the response from the SD card/MMC.	R

Note: S-TYPE-3, P-TYPE-3

34.2.7 SD_RSPj : SD Card Response Register j (j = 1, 3, 5)

Base address: SDHIn = 0x4025_2000 + 0x0400 × n (n = 0, 1)
SDHIn_NS = 0x5025_2000 + 0x0400 × n (n = 0, 1)

Offset address: 0x01C (SD_RSP1)
0x024 (SD_RSP3)
0x02C (SD_RSP5)

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:																
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	—	These bits store the response from the SD card/MMC.	R
31:16	—	These bits are read as 0.	R

Note: S-TYPE-3, P-TYPE-3

34.2.8 SD_RSP76 : SD Card Response Register 76

Base address: SDHIn = 0x4025_2000 + 0x0400 × n (n = 0, 1)
SDHIn_NS = 0x5025_2000 + 0x0400 × n (n = 0, 1)

Offset address: 0x030

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	SD_RSP76[23:16]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	SD_RSP76[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
23:0	SD_RSP76[23:0]	These bits store the response from the SD card/MMC.	R
31:24	—	These bits are read as 0.	R

Note: S-TYPE-3, P-TYPE-3

34.2.9 SD_RSP7 : SD Card Response Register 7

Base address: SDHIn = 0x4025_2000 + 0x0400 × n (n = 0, 1)
SDHIn_NS = 0x5025_2000 + 0x0400 × n (n = 0, 1)

Offset address: 0x034

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	SD_RSP7[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	SD_RSP7[7:0]	These bits store the response from the SD card/MMC.	R
31:8	—	These bits are read as 0.	R

Note: S-TYPE-3, P-TYPE-3

SD_RSP10, SD_RSP32, SD_RSP54, SD_RSP1, SD_RSP3, SD_RSP5, SD_RSP76, and SD_RSP7 are read-only registers that store the response from the SD card/MMC. Depending on the type of response from the SD card/MMC, the SD/MMC Host Interface divides and stores the response among the four registers.

Table 34.3 lists the correspondence between the response type and its storage destination.

Table 34.3 Correspondence between response type and storage destination (1 of 2)

Response type	SD_RSP10 register	SD_RSP32 register	SD_RSP54 register	SD_RSP1 register	SD_RSP3 register	SD_RSP5 register	SD_RSP76 register	SD_RSP7 register
R1	[39:8]	—	[39:8]*1	—	—	—	—	—
R1b	[39:8]	—	[39:8]*1	—	—	—	—	—
R2	[39:8]	[71:40]	[103:72]	—	—	—	[127:104]	—
R3	[39:8]	—	—	—	—	—	—	—
R4	[39:8]	—	—	—	—	—	—	—

Table 34.3 Correspondence between response type and storage destination (2 of 2)

Response type	SD_RSP10 register	SD_RSP32 register	SD_RSP54 register	SD_RSP1 register	SD_RSP3 register	SD_RSP5 register	SD_RSP76 register	SD_RSP7 register
R5	[39:8]	—	—	—	—	—	—	—
R6	[39:8]	—	—	—	—	—	—	—
R7	[39:8]	—	—	—	—	—	—	—

Note 1. The responses for CMD18 and CMD25 are stored in registers SD_RSP10 and SD_RSP54. Therefore, even if the SD_RSP10 register is overwritten with the response for the automatically issued CMD12, the response for CMD18 or CMD25 can be confirmed by reading the SD_RSP54 register.

34.2.10 SD_INFO1 : SD Card Interrupt Flag Register 1

Base address: SDHIn = 0x4025_2000 + 0x0400 × n (n = 0, 1)
SDHIn_NS = 0x5025_2000 + 0x0400 × n (n = 0, 1)

Offset address: 0x038

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	SDD3MON	SDD3IN	SDD3RM	SDWPMON	—	SDCDMON	SDCDIN	SDCDRM	ACEND	—	RSPEND
Value after reset:	0	0	0	0	0	x	0	0	x	0	x	0	0	0*1	0	0*1

Bit	Symbol	Function	R/W
0	RSPEND	Response End Detection Flag 0: Response end not detected 1: Response end detected	R/(W)*2
1	—	This bit is read as 0. The write value should be 0.	R/W
2	ACEND	Access End Detection Flag 0: Access end not detected 1: Access end detected	R/(W)*2
3	SDCDRM	SDnCD Removal Flag 0: SD card/MMC removal not detected by the SDnCD pin 1: SD card/MMC removal detected by the SDnCD pin	R/(W)*2
4	SDCDIN	SDnCD Insertion Flag 0: SD card/MMC insertion not detected by the SDnCD pin 1: SD card/MMC insertion detected by the SDnCD pin	R/(W)*2
5	SDCDMON	SDnCD Pin Monitor Flag 0: SDnCD pin level is high*3 1: SDnCD pin level is low*3	R
6	—	This bit is read as 0. The write value should be 0.	R/W
7	SDWPMON	SDnWP Pin Monitor Flag 0: SDnWP pin level is high 1: SDnWP pin level is low	R
8	SDD3RM	SDnDAT3 Removal Flag 0: SD card/MMC removal not detected by the SDnDAT3 pin 1: SD card/MMC removal detected by the SDnDAT3 pin	R/(W)*2
9	SDD3IN	SDnDAT3 Insertion Flag 0: SD card/MMC insertion not detected by the SDnDAT3 pin 1: SD card/MMC insertion detected by the SDnDAT3 pin	R/(W)*2
10	SDD3MON	SDnDAT3 Pin Monitor Flag 0: SDnDAT3 pin level is low 1: SDnDAT3 pin level is high	R

Bit	Symbol	Function	R/W
31:11	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3
Note 1. The value is initialized by a reset and also on reset triggered by the SOFT_RST.SDRST flag.
Note 2. The flag does not change even if set to 1. Writing 0 changes the flag value to 0.
Note 3. The flag changes when the pin level continues for the period set in the SD_OPTION.CTOP[3:0] bits or longer.

The SD_INFO1 register indicates the detection of a response end or access end for a command sequence. The SD_INFO1 register also indicates the detection SD card/MMC insertion/removal and the write protection status.

During a multiblock transfer sequence, if CMD12 or CMD52 (SDIO abort) is issued, the ACEND flag sets to 1, but the RSPEND flag remains set to 0.

If the command sequence is stopped because of a communication error or timeout, the ACEND flag or RSPEND flag sets to 1.

After a reset is canceled, the SDD3MON bit, SDD3IN flag, and SDD3RM flag values are changed in accordance with the status of the SDnDAT3 (n = 0, 1) pin, and their values are changed when data is being transferred in wide bus mode. These 3 bits are used only for SD card. Set flags to be cleared to 0. Set flags that are not being cleared to 1.

RSPEND flag (Response End Detection Flag)

The RSPEND flag indicates that a response end was detected.

[Setting conditions]

- When reception of the response is completed
- When transmission of a command without response is completed
- When reception of the busy state after R1b response is completed
- When reception of the response to CMD52 that was issued by setting the C52PUB bit to 1 is completed for transfer of multiple block read
- When reception of the response to CMD52 that was issued by setting the C52PUB bit to 1 is completed for transfer of multiple block write
- This bit is set when a command sequence is halted because of a communications error or timeout.

[Clearing conditions]

- When 0 is written to RSPEND
- When a command without data is issued.

Note: When a command is issued in absence of data transfer, the RSPEND flag becomes 1 after the command sequence ends.

ACEND flag (Access End Detection Flag)

The ACEND flag indicates that an access end was detected.

[Setting conditions]

- When read access to the buffer is completed for transfer of single block read
- When read access to the buffer for the last block of data is completed for transfer of multiple block read
- When read access to the buffer and reception of the response to CMD12 are completed for transfer of multiple block read with automatic issuing of CMD12
- When reception of the busy state after reception of the CRC status is completed for transfer of single block write
- When reception of the busy state after reception of the CRC status of the last block of data is completed for transfer of multiple block write
- When reception of the response busy state for CMD12 is completed for transfer of multiple block write with automatic issuing of CMD12
- When reception of the response to CMD12 that was issued by setting the STP bit to1 is completed for transfer of multiple block read

- When reception of the response busy state for CMD12 that was issued by setting the STP bit to1 is completed for transfer of multiple block write
- When reception of the response to CMD52 that was issued by setting the IOABT bit to 1 is completed for transfer of multiple block read
- When reception of the response to CMD52 that was issued by setting the IOABT bit to1 is completed for transfer of multiple block write
- This bit is set when a command sequence is halted because of a communications error or timeout.

[Clearing conditions]

- When 0 is written to ACEND
- When the access end bit is set to 1.

Note: The ACEND flag becomes 1 after the command sequence ends.

SDCDRM flag (SDnCD Removal Flag)

The SDCDRM flag indicates that SDnCD was removed.

[Setting condition]

- After a change in SDnCD from 0 to 1, Mcycle elapsed with SDnCD held at 1.

[Clearing conditions]

- When 0 is written to SDCDRM.

Note: Mcycle is set in bits [3:0] in SD_OPTION.

SDCDIN flag (SDnCD Insertion Flag)

The SDCDIN flag indicates that SDnCD was inserted.

[Setting condition]

- After a change in SDnCD from 1 to 0, Mcycle elapsed with SDnCD held at 0.

[Clearing conditions]

- When 0 is written to SDCDIN.

Note: Mcycle is set in bits [3:0] in SD_OPTION.

SDD3RM flag (SDnDAT3 Removal Flag)

The SDD3RM flag indicates that SDnDAT3 was removed.

[Setting condition]

- After a change in SDnDAT3 from 1 to 0, two cycles of PCLKB elapsed with SDnDAT3 held at 0.

[Clearing condition]

- When 0 is written to SDD3RM.

SDD3IN flag (SDnDAT3 Insertion Flag)

The SDD3IN flag indicates that SDnDAT3 was inserted.

[Setting condition]

- After a change in SDnDAT3 from 0 to 1, two cycles of PCLKB elapsed with SDnDAT3 held at 1.

[Clearing condition]

- When 0 is written to SDD3IN.

34.2.11 SD_INFO2 : SD Card Interrupt Flag Register 2

Base address: SDHIn = 0x4025_2000 + 0x0400 × n (n = 0, 1)
SDHIn_NS = 0x5025_2000 + 0x0400 × n (n = 0, 1)

Offset address: 0x03C

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	ILA	CBSY	SD_CLK_CTRLEN	—	—	—	BWE	BRE	SDD0MON	RSPTO	ILR	ILW	DTO	ENDE	CRCE	CMDE
Value after reset:	0*1	0*1	1*1	0	x	0	0*1	0*1	x	0*1	0*1	0*1	0*1	0*1	0*1	0*1

Bit	Symbol	Function	R/W
0	CMDE	Command Error Detection Flag 0: Command error not detected 1: Command error detected	R/W*2
1	CRCE	CRC Error Detection Flag 0: CRC error not detected 1: CRC error detected	R/W*2
2	ENDE	End Bit Error Detection Flag 0: End bit error not detected 1: End bit error detected	R/W*2
3	DTO	Data Timeout Detection Flag 0: Data timeout not detected 1: Data timeout detected	R/W*2
4	ILW	SD_BUF0 Illegal Write Access Detection Flag 0: Illegal write access to the SD_BUF0 register not detected 1: Illegal write access to the SD_BUF0 register detected	R/W*2
5	ILR	SD_BUF0 Illegal Read Access Detection Flag 0: Illegal read access to the SD_BUF0 register not detected 1: Illegal read access to the SD_BUF0 register detected	R/W*2
6	RSPTO	Response Timeout Detection Flag 0: Response timeout not detected 1: Response timeout detected	R/W*2
7	SDD0MON	SDnDAT0 Pin Status Flag 0: SDnDAT0 pin is low 1: SDnDAT0 pin is high	R
8	BRE	SD_BUF0 Read Enable Flag 0: Disable read access to the SD_BUF0 register 1: Enable read access to the SD_BUF0 register	R/W*2
9	BWE	SD_BUF0 Write Enable Flag 0: Disable write access to the SD_BUF0 register 1: Enable write access to the SD_BUF0 register	R/W*2
10	—	This bit is read as 0. The write value should be 0.	R/W
11	—	The read value is undefined. The write value should be 1.	R/W
12	—	This bit is read as 0. The write value should be 0.	R/W
13	SD_CLK_CTRLEN	SD_CLK_CTRL Write Enable Flag 0: SD/MMC bus (CMD and DAT lines) is busy, so write access to the SD_CLK_CTRL.CLKEN and CLKSEL[7:0] bits is disabled 1: SD/MMC bus (CMD and DAT lines) is not busy, so write access to the SD_CLK_CTRL.CLKEN and CLKSEL[7:0] bits is enabled	R

Bit	Symbol	Function	R/W
14	CBSY	Command Sequence Status Flag 0: Command sequence complete 1: Command sequence in progress (busy)	R
15	ILA	Illegal Access Error Detection Flag 0: Illegal access error not detected 1: Illegal access error detected	R/W*2
31:16	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3
Note 1. The value is initialized by a reset and also on reset triggered by the SOFT_RST.SDRST flag.
Note 2. The flag does not change even if set to 1. Writing 0 changes the flag value to 0.

The SD_INFO2 register indicates the status of the SD buffer and the status of the SD card/MMC. Set flags to be cleared to 0. Set flags that are not being cleared to 1.

CMDE flag (Command Error Detection Flag)

The CMDE flag indicates that a command error was detected. The command sequence stops when a command error occurs. When the SDIO_MODE.C52PUB bit is set to 1 and CMD52 is automatically issued, if a communication error or response timeout occurs, the command sequence is not completed. Perform the error processing shown in section 34.3.12. IO_RW_EXTENDED Command (SD: CMD53/Multiple Block Read) or section 34.3.13. IO_RW_EXTENDED Command (SD: CMD53/Multiple Block Write), and complete the command sequence.

[Setting conditions]

- The command index of the transmitted command differs from the command index of the received response.
- The command index of a command issued within a command sequence differs from the command index of the received response.

[Clearing condition]

- When 0 is written to CMDE.

CRCE flag (CRC Error Detection Flag)

The CRCE flag indicates that a CRC error was detected. The command sequence stops when a CRC error occurs. When the SDIO_MODE.C52PUB bit is set to 1 and CMD52 is automatically issued, if a communication error or response timeout occurs, the command sequence is not completed. Perform the error processing shown in section 34.3.12. IO_RW_EXTENDED Command (SD: CMD53/Multiple Block Read) or section 34.3.13. IO_RW_EXTENDED Command (SD: CMD53/Multiple Block Write), and complete the command sequence.

[Setting conditions]

- When an error occurs in the CRC status.
- When a CRC error occurs in the read data.
- When a CRC error occurs in the response.
- A CRC error in the response to a command issued within a command sequence.

[Clearing condition]

- When 0 is written to CRCE.

ENDE flag (End Bit Error Detection Flag)

The ENDE flag indicates that an end bit error was detected. The command sequence is stopped when an end bit error occurs. When the SDIO_MODE.C52PUB bit is set to 1 and CMD52 is automatically issued, if a communication error or response timeout occurs, the command sequence is not completed. Perform the error processing shown in section 34.3.12. IO_RW_EXTENDED Command (SD: CMD53/Multiple Block Read) or section 34.3.13. IO_RW_EXTENDED Command (SD: CMD53/Multiple Block Write), and complete the command sequence.

[Setting conditions]

- When an error occurs in the response length (and the end bit is not detected).
- When an error occurs in the read data length (and the end bit is not detected among the valid bits).

- When an error occurs in the CRC status length (and the end bit is not detected).
- An error in the length of a response to a command issued within a command sequence, for example when the end bit is not detected.

[Clearing condition]

- When 0 is written to ENDE.

DTO flag (Data Timeout Detection Flag)

The DTO flag indicates that a data timeout was detected. The command sequence stops when a data timeout occurs.

[Setting conditions]

- After R1b response, the busy state (SDnDAT0 = 0) continues for longer than Ncycle.
- After CRC status, the busy state (SDnDAT0 = 0) continues for longer than Ncycle.
- After write data, the CRC status is not received though Ncycle has elapsed.
- After read command, read data is not received though a time longer than Ncycle has elapsed.
- After CMD12 is issued within a command sequence, the busy state (SDnDAT0 = 0) for longer than Ncycle continues.
- After the reception of read data, read data for the next block are not received though a time longer than Ncycle has elapsed.
- After release of the read wait state, read data for the next block are not received though a time longer than Ncycle has elapsed.

Note: Ncycle is set in bits [7:4] in SD_OPTION.

[Clearing condition]

- When 0 is written to DTO.

ILW flag (SD_BUF0 Illegal Write Access Detection Flag)

The ILW flag indicates that an SD_BUF0 illegal write access was detected.

[Setting conditions]

- When data is written to SD_BUF0 while it is not in the data read/write command state.
- When data is written to SD_BUF0 while SD_BUF is full.
- When data is written to SD_BUF0 while an error occurs in the CRC status or CRC status length.
- When data is written to SD_BUF0 while a busy state after the CRC status continues for longer than Ncycle.

Note: Ncycle is set in bits [7:4] in SD_OPTION.

[Clearing condition]

- When 0 is written to ILW.

ILR flag (SD_BUF0 Illegal Read Access Detection Flag)

The ILR flag indicates that an SD_BUF0 illegal read access was detected.

[Setting conditions]

- When SD_BUF is empty while SD_BUF0 is read.
- When data with a CRC error or END error is read from SD_BUF0.

[Clearing condition]

- When 0 is written to ILR.

RSPTO flag (Response Timeout Detection Flag)

The RSPTO flag indicates that a response timeout was detected. The command sequence is stopped when a response timeout occurs. When the SDIOMD.C52PUB bit is set to 1 and CMD52 is automatically issued, if a communication error

or response timeout occurs, the command sequence is not completed. Perform the error processing shown in section 34.3.12. IO_RW_EXTENDED Command (SD: CMD53/Multiple Block Read) or section 34.3.13. IO_RW_EXTENDED Command (SD: CMD53/Multiple Block Write), and complete the command sequence.

[Setting condition]

- When a response is not received though a time longer than 640 cycles of SD/MMC clock has elapsed (including a response to a command issued within a command sequence).

[Clearing condition]

- When 0 is written to RSPTO.

SDD0MON flag (SDnDAT0 Pin Status Flag)

The SDD0MON flag indicates the status of the SDnDAT0 pin. If the data timeout (DTO) is set but the response timeout (RSPTO) is not set after the Erase command is issued, the end of the Erase sequence (SDD0MON = 1) is confirmed by polling DAT0.

If a communication error or timeout occurs during a write sequence, the DAT0 bit might retain the value 0.

While the SD/MMC clock is stopped, the DAT0 bit retains the value before the clock is stopped.

BRE flag (SD_BUF0 Read Enable Flag)

The BRE flag indicates that SD_BUF0 is enabled for reading.

[Setting conditions]

- When data set in SD_SIZE is stored in SD_BUF0 at single block transfer.
- When data set in SD_SIZE is stored in either bank 1 or bank 2 of SD_BUF0 at multiple block transfer.

[Clearing conditions]

- When 0 is written to BRE
- Reading of a block of data from SD_BUF0 by DMA transfer

When data is read from SD_BUF0 by the CPU, clear BRE then read the amount of data specified in SD_SIZE.

Even if a CRC error or an END error occurs while block data is read, data is stored in SD_BUF0 and BRE is set.

BWE flag (SD_BUF0 Write Enable Flag)

The BWE flag indicates that SD_BUF0 is enabled for writing.

[Setting conditions]

- When SD_BUF0 is empty at single block transfer.
- When either bank 1 or bank 2 of SD_BUF0 is empty at multiple block transfer.

[Clearing conditions]

- When 0 is written to BWE.
- Writing of a block of data to SD_BUF0 by DMA transfer.

When data is written to SD_BUF0 by the CPU, clear BWE and then write the amount of data specified in SD_SIZE.

SD_CLK_CTRLEN flag (SD_CLK_CTRL Write Enable Flag)

When a command sequence is started by writing to SD_CMD, the CBSY bit is set to 1 and, at the same time, the SD_CLK_CTRLEN bit is set to 0. The SD_CLK_CTRLEN bit is set to 1 after 8 cycles of SDCLK have elapsed after the CBSY bit clears to 0 on completion of the command sequence.

ILA flag (Illegal Access Error Detection Flag)

The ILA flag indicates that an illegal access error was detected.

[Setting conditions]

- Writing of data to SD_CMD within a command sequence (CBSY = 1).

- When SD_CMD[11] = 1 (command with data transfer) and SD_CMD[7:0] = 0000 1100b (CMD12) are set in SD_CMD.

[Clearing condition]

- When 0 is written to ILA.

34.2.12 SD_INFO1_MASK : SD INFO1 Interrupt Mask Register

Base address: SDHIn = 0x4025_2000 + 0x0400 × n (n = 0, 1)
SDHIn_NS = 0x5025_2000 + 0x0400 × n (n = 0, 1)

Offset address: 0x040

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	SDD3INM	SDD3RMM	—	—	—	SDCDINM	SDCDRMM	ACENDM	—	RSPENDM
Value after reset:	0	0	0	0	0	0	1	1	0	0	0	1	1	1	0	1

Bit	Symbol	Function	R/W
0	RSPENDM	Response End Interrupt Request Mask 0: Do not mask response end interrupt request 1: Mask response end interrupt request	R/W
1	—	This bit is read as 0. The write value should be 0.	R/W
2	ACENDM	Access End Interrupt Request Mask 0: Do not mask access end interrupt request 1: Mask access end interrupt request	R/W
3	SDCDRMM	SDnCD Removal Interrupt Request Mask 0: Do not mask SD card/MMC removal interrupt request by the SDnCD pin 1: Mask SD card/MMC removal interrupt request by the SDnCD pin	R/W
4	SDCDINM	SDnCD Insertion Interrupt Request Mask 0: Do not mask SD card/MMC insertion interrupt request by the SDnCD pin 1: Mask SD card/MMC insertion interrupt request by the SDnCD pin	R/W
7:5	—	These bits are read as 0. The write value should be 0.	R/W
8	SDD3RMM	SDnDAT3 Removal Interrupt Request Mask 0: Do not mask SD card/MMC removal interrupt request by the SDnDAT3 pin 1: Mask SD card/MMC removal interrupt request by the SDnDAT3 pin	R/W
9	SDD3INM	SDnDAT3 Insertion Interrupt Request Mask 0: Do not mask SD card/MMC insertion interrupt request by the SDnDAT3 pin 1: Mask SD card/MMC insertion interrupt request by the SDnDAT3 pin	R/W
31:10	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

The SD_INFO1_MASK register enables or disables interrupt requests from the status flags in the SD_INFO1 register. See Table 34.5, for details on the relationship between the status flags and the requested interrupt source.

34.2.13 SD_INFO2_MASK : SD INFO2 Interrupt Mask Register

Base address: SDHIn = 0x4025_2000 + 0x0400 × n (n = 0, 1)
SDHIn_NS = 0x5025_2000 + 0x0400 × n (n = 0, 1)

Offset address: 0x044

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	ILAM	—	—	—	—	—	BWEM	BREM	—	RSPTOM	ILRM	ILWM	DTOM	ENDEM	CRCEM	CMDEM
Value after reset:	1	0	0	0	1	0	1	1	0	1	1	1	1	1	1	1

Bit	Symbol	Function	R/W
0	CMDEM	Command Error Interrupt Request Mask 0: Do not mask command error interrupt request 1: Mask command error interrupt request	R/W
1	CRCEM	CRC Error Interrupt Request Mask 0: Do not mask CRC error interrupt request 1: Mask CRC error interrupt request	R/W
2	ENDEM	End Bit Error Interrupt Request Mask 0: Do not mask end bit detection error interrupt request 1: Mask end bit detection error interrupt request	R/W
3	DTOM	Data Timeout Interrupt Request Mask 0: Do not mask data timeout interrupt request 1: Mask data timeout interrupt request	R/W
4	ILWM	SD_BUF0 Register Illegal Write Interrupt Request Mask 0: Do not mask illegal write detection interrupt request for the SD_BUF0 register 1: Mask illegal write detection interrupt request for the SD_BUF0 register	R/W
5	ILRM	SD_BUF0 Register Illegal Read Interrupt Request Mask 0: Do not mask illegal read detection interrupt request for the SD_BUF0 register 1: Mask illegal read detection interrupt request for the SD_BUF0 register	R/W
6	RSPTOM	Response Timeout Interrupt Request Mask 0: Do not mask response timeout interrupt request 1: Mask response timeout interrupt request	R/W
7	—	This bit is read as 0. The write value should be 0.	R/W
8	BREM*1	BRE Interrupt Request Mask 0: Do not mask read enable interrupt request for the SD buffer 1: Mask read enable interrupt request for the SD buffer	R/W
9	BWEM*1	BWE Interrupt Request Mask 0: Do not mask write enable interrupt request for the SD_BUF0 register 1: Mask write enable interrupt request for the SD_BUF0 register	R/W
10	—	This bit is read as 0. The write value should be 0.	R/W
11	—	This bit is read as 1.The write value should be 1.	R/W
14:12	—	These bits are read as 0. The write value should be 0.	R/W
15	ILAM	Illegal Access Error Interrupt Request Mask 0: Do not mask illegal access error interrupt request 1: Mask illegal access error interrupt request	R/W
31:16	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3
Note 1. When the SD_INFO2_MASK.BWEM bit is 0 or the SD_INFO2_MASK.BREM bit is 0, set the SD_DMAEN.DMAEN bit to 0. When the SD_DMAEN.DMAEN bit is 1, set the SD_INFO2_MASK.BWEM bit to 1 and the SD_INFO2_MASK.BREM bit to 1.

The SD_INFO2_MASK register enables or disables interrupt requests from the status flags in the SD_INFO2 register. See Table 34.5 for details on the relationship between the status flags and the requested interrupt source.

34.2.14 SD_CLK_CTRL : SD Clock Control Register

Base address: SDHIn = 0x4025_2000 + 0x0400 × n (n = 0, 1)
SDHIn_NS = 0x5025_2000 + 0x0400 × n (n = 0, 1)

Offset address: 0x048

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	CLKCTRLEN	CLKEN	CLKSEL[7:0]							
Value after reset:	0	0	0	0	0	0	0	0*1	0	0	1	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	CLKSEL[7:0]	SDHI Clock Frequency Select*2 0xFF PCLKB 0x00: PCLKB/2 0x01: PCLKB/4 0x02: PCLKB/8 0x04: PCLKB/16 0x08: PCLKB/32 0x10: PCLKB/64 0x20: PCLKB/128 0x40: PCLKB/256 0x80: PCLKB/512 Others: Setting prohibited	R/W
8	CLKEN	SD/MMC Clock Output Control*2 0: Disable SD/MMC clock output (fix SDnCLK signal low) 1: Enable SD/MMC clock output	R/W
9	CLKCTRLEN	SD/MMC Clock Output Automatic Control Select 0: Disable automatic control of SD/MMC clock output 1: Enable automatic control of SD/MMC clock output	R/W
31:10	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3
Note 1. The value is initialized by a reset and also on reset triggered by the SOFT_RST.SDRST flag.
Note 2. Bits CLKSEL[7:0] and CLKEN cannot be write accessed when the SD_INFO2.SD_CLK_CTRLEN flag is 0.

The SD_CLK_CTRL register controls the SD/MMC clock frequency settings and output. Set the CLKEN bit to 1 before writing to the SD_CMD register to start a command sequence. Do not write to the SD_CLK_CTRL register when the SD_INFO2.SD_CLK_CTRLEN flag is 0.

CLKCTRLEN bit (SD/MMC Clock Output Automatic Control Select)

The CLKCTRLEN bit enables or disables the automatic control function for SD/MMC clock output, which causes the SD/MMC clock to output only within a command sequence.

The timing with which SD/MMC clock output starts and stops is as follows:

- SD/MMC clock output starts after writing to SD_CMD
- SD/MMC clock output stops when 8 cycles of SD/MMC clock have elapsed after the end of the command sequence.

In addition, SD/MMC clock is fixed to 0 while SCLKEN of SD_CLK_CTRL is 0, regardless of the value of this bit.

34.2.15 SD_SIZE : Transfer Data Length Register

Base address: SDHIn = 0x4025_2000 + 0x0400 × n (n = 0, 1)
SDHIn_NS = 0x5025_2000 + 0x0400 × n (n = 0, 1)

Offset address: 0x04C

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	LEN[9:0]									
Value after reset:	0	0	0	0	0	0	1	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
9:0	LEN[9:0]	Transfer Data Size Setting These bits specify the transfer data size.*1	R/W
31:10	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3
Note 1. Do not rewrite these bits when the SD_INFO2.CBSY flag is 1.

The SD_SIZE register sets the transfer data size.

LEN[9:0] bits (Transfer Data Size Setting)

When using single block transfer, the transfer data size can be set in the LEN[9:0] bits from 1 byte to 512 bytes. When CMD12 is automatically issued during a multiblock transfer sequence (CMD18 and CMD25), the transfer data size can only be set to 512 bytes. When CMD12 is not automatically issued during a multiblock transfer sequence, the transfer data size can be set to 32, 64, 128, 256, or 512 bytes. However, a 32, 64, 128, or 256 bytes multiblock read transfer can only be performed during an SDIO multiblock transfer (CMD53). Do not set these bits to 0 when using a command that includes data transfer.

34.2.16 SD_OPTION : SD Card Access Control Option Register

Base address: SDHIn = 0x4025_2000 + 0x0400 × n (n = 0, 1)
SDHIn_NS = 0x5025_2000 + 0x0400 × n (n = 0, 1)

Offset address: 0x050

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	WIDTH	—	WIDTH8	—	—	—	—	TOUTMASK	TOP[3:0]				CTOP[3:0]			
Value after reset:	0*1	1	0*1	0	0	0	0	0*1	1*1	1*1	1*1	0*1	1*1	1*1	1*1	0*1

Bit	Symbol	Function	R/W
3:0	CTOP[3:0]	Card Detection Time Counter*2 0x0: PCLKB × 2^{10} 0x1: PCLKB × 2^{11} 0x2: PCLKB × 2^{12} 0x3: PCLKB × 2^{13} 0x4: PCLKB × 2^{14} 0x5: PCLKB × 2^{15} 0x6: PCLKB × 2^{16} 0x7: PCLKB × 2^{17} 0x8: PCLKB × 2^{18} 0x9: PCLKB × 2^{19} 0xA: PCLKB × 2^{20} 0xB: PCLKB × 2^{21} 0xC: PCLKB × 2^{22} 0xD: PCLKB × 2^{23} 0xE: PCLKB × 2^{24} 0xF: Setting prohibited	R/W
7:4	TOP[3:0]	Timeout Counter*2 0x0: SDHI clock × 2^{13} 0x1: SDHI clock × 2^{14} 0x2: SDHI clock × 2^{15} 0x3: SDHI clock × 2^{16} 0x4: SDHI clock × 2^{17} 0x5: SDHI clock × 2^{18} 0x6: SDHI clock × 2^{19} 0x7: SDHI clock × 2^{20} 0x8: SDHI clock × 2^{21} 0x9: SDHI clock × 2^{22} 0xA: SDHI clock × 2^{23} 0xB: SDHI clock × 2^{24} 0xC: SDHI clock × 2^{25} 0xD: SDHI clock × 2^{26} 0xE: SDHI clock × 2^{27} 0xF: Setting prohibited	R/W
8	TOUTMASK	Timeout Mask 0: Activate timeout 1: Inactivate timeout (do not set RSPTO and DTO bits of SD_INFO2 or CRCBSYTO, CRCTO, RDTO, BSYTO1, BSYTO0, RSPTO1 and RSPTO0 bits of SD_ERR_STS2) When timeout occurs because of an inactivated timeout, execute a software reset to terminate the command sequence.	R/W
12:9	—	These bits are read as 0. The write value should be 0.	R/W
13	WIDTH8	Bus Width*2 See bit 15 WIDTH bit.	R/W
14	—	This bit is read as 1. The write value should be 1.	R/W
15	WIDTH	Bus Width*2 **WIDTH / WIDTH8 / Bus Width** 0 / 1 / 8-bit width 0 / 0 / 4-bit width 1 / 0 / 1-bit width 1 / 1 / 1-bit width For 1-byte write transfers, set 4-bit or 1-bit width. Do not set 8-bit width.	R/W
31:16	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3
Note 1. The value is initialized by a reset and also on reset triggered by the SOFT_RST.SDRST flag.

Note 2. Do not rewrite these bits when the SD_INFO2.CBSY flag is 1.

The SD bus width and timeout counter are set in the SD_OPTION register.

34.2.17 SD_ERR_STS1 : SD Error Status Register 1

Base address: SDHIn = 0x4025_2000 + 0x0400 × n (n = 0, 1)
SDHIn_NS = 0x5025_2000 + 0x0400 × n (n = 0, 1)

Offset address: 0x058

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	CRCTK[2:0]			CRCTKE	RDCRCE	RSPCRCE1	RSPCRCE0	—	—	CRCLENE	RDLENE	RSPLENE1	RSPLENE0	CMDE1	CMDE0
Value after reset:	0	0*1	1*1	0*1	0*1	0*1	0*1	0*1	0	0	0*1	0*1	0*1	0*1	0*1	0*1

Bit	Symbol	Function	R/W
0	CMDE0	Command Error Flag 0 0: No error exists in command index field value of a command*2 response 1: Error exists in command index field value of a command*2 response	R
1	CMDE1	Command Error Flag 1 0: No error exists in command index field value of a command*3 response 1: Error exists in command index field value of a command*3 response (with SD_CMD.CMDIDX[5:0] setting, an error that occurs with CMD12 issue is indicated in the CMDE0 flag)	R
2	RSPLENE0	Response Length Error Flag 0 0: No error exists in command*2 response length 1: Error exists in command*2 response length	R
3	RSPLENE1	Response Length Error Flag 1 0: No error exists in command*3 response length 1: Error exists in command*3 response length (with SD_CMD.CMDIDX[5:0] setting, an error that occurs with CMD12 issue is indicated in the RSPLENE0 flag)	R
4	RDLENE	Read Data Length Error Flag 0: No read data length error occurred 1: Read data length error occurred	R
5	CRCLENE	CRC Status Token Length Error Flag 0: No CRC status token length error occurred 1: CRC status token length error occurred	R
7:6	—	These bits are read as 0.	R
8	RSPCRCE0	Response CRC Error Flag 0 0: No CRC error detected in command*2 response 1: CRC error detected in command*2 response	R
9	RSPCRCE1	Response CRC Error Flag 1 0: No CRC error detected in command*3 response (with SD_CMD.CMDIDX[5:0] setting, an error that occurs with CMD12 issue is indicated in the RSPCRCE0 flag) 1: CRC error detected in command*3 response	R
10	RDCRCE	Read Data CRC Error Flag 0: No CRC error detected in read data 1: CRC error detected in read data	R
11	CRCTKE	CRC Status Token Error Flag 0: No error detected in CRC status token 1: Error detected in CRC status token	R

Bit	Symbol	Function	R/W
14:12	CRCTK[2:0]	CRC Status Token These bits store the CRC status token value (normal value is 010b).	R
31:15	—	These bits are read as 0.	R

Note: S-TYPE-3, P-TYPE-3
Note 1. The value is initialized by a reset and also on reset triggered by the SOFT_RST.SDRST flag.
Note 2. CMD other than CMD12 when automatic issuing is enabled for multiple block transfer by the setting in SD_CMD, CMD12 when the STP bit in SD_STOP is set to 1, or CMD52 when the C52PUB or IOABT bit in SDIO_MODE is set to 1.
Note 3. CMD12 when automatic issuing is enabled for multiple block transfer by the setting in SD_CMD, CMD12 when the STP bit in SD_STOP is set to 1, or CMD52 when the C52PUB or IOABT bit in SDIO_MODE is set to 1.

The SD_ERR_STS1 register indicates the CRC status token, CRC error, end bit error, and command error.

34.2.18 SD_ERR_STS2 : SD Error Status Register 2

Base address: SDHIn = 0x4025_2000 + 0x0400 × n (n = 0, 1)
SDHIn_NS = 0x5025_2000 + 0x0400 × n (n = 0, 1)

Offset address: 0x05C

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	CRCBSYTO	CRCTO	RDTO	BSYTO1	BSYTO0	RSPTO1	RSPTO0
Value after reset:	0	0	0	0	0	0	0	0	0	0*1	0*1	0*1	0*1	0*1	0*1	0*1

Bit	Symbol	Function	R/W
0	RSPTO0	Response Timeout Flag 0 0: After command*2 was issued, response was received in less than 640 cycles of the SD/MMC clock 1: After command*2 was issued, response was not received in 640 or more cycles of the SD/MMC clock	R
1	RSPTO1	Response Timeout Flag 1 0: After command*3 was issued, response was received in less than 640 cycles of the SD/MMC clock 1: After command*3 was issued, response was not received after 640 or more cycles of the SD/MMC clock (with SD_CMD.CMDIDX[5:0] setting, an error that occurs with CMD12 issue is indicated in the RSPTO0 flag)	R
2	BSYTO0	Busy Timeout Flag 0 0: After R1b response was received, SD/MMC was released from the busy state during the specified period*4 1: After R1b response was received, SD/MMC was in the busy state after the specified period*4 elapsed	R
3	BSYTO1	Busy Timeout Flag 1 0: After CMD12 was automatically issued, SD/MMC was released from the busy state during the specified period*4 1: After CMD12 was automatically issued, SD/MMC was in the busy state after the specified period*4 elapsed (with SD_CMD.CMDIDX[5:0] setting, an error that occurs with CMD12 issue is indicated in the BSYTO0 flag)	R
4	RDTO	Read Data Timeout Flag When a read command is issued, this flag sets to 1 when read data is not received after the specified period*4 elapses. When read data is received, this flag sets to 1 when the next block of read data is not received after the specified period*4 elapses. When the SD/MMC exits the read wait state, this flag sets to 1 when the next block of read data is not received after the specified period*4 elapses.	R

Bit	Symbol	Function	R/W
5	CRCTO	CRC Status Token Timeout Flag 0: After CRC data was written to the SD card/MMC, a CRC status token was received during the specified period*4 1: After CRC data was written to the SD card/MMC, a CRC status token was not received after the specified period*4 elapsed	R
6	CRCBSYTO	CRC Status Token Busy Timeout Flag 0: After a CRC status token was received, the SD/MMC was released from the busy state during the specified period*4 1: After a CRC status token was received, the SD/MMC was in the busy state after the specified period*4 elapsed	R
31:7	—	These bits are read as 0.	R

Note: S-TYPE-3, P-TYPE-3
Note 1. The value is initialized by a reset and also on reset triggered by the SOFT_RST.SDRST flag.
Note 2. CMD other than CMD12 when automatic issuing is enabled for multiple block transfer by the setting in SD_CMD, CMD12 when the STP bit in SD_STOP is set to 1, or CMD52 when the C52PUB or IOABT bit in SDIO_MODE is set to 1.
Note 3. CMD12 when automatic issuing is enabled for multiple block transfer by the setting in SD_CMD, CMD12 when the STP bit in SD_STOP is set to 1, or CMD52 when the C52PUB or IOABT bit in SDIO_MODE is set to 1.
Note 4. Set the SD_OPTION.TOP[3:0] bits to select the number of *n* cycles.

The SD_ERR_STS2 register indicates the timeout status.

34.2.19 SD_BUF0 : SD Buffer Register

Base address: SDHIn = 0x4025_2000 + 0x0400 × n (n = 0, 1)
SDHIn_NS = 0x5025_2000 + 0x0400 × n (n = 0, 1)

Offset address: 0x060

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:																
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:																
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x

Bit	Symbol	Function	R/W
31:0	n/a	When writing to the SD card, the write data is written to this register. When reading from the SD card, the read data is read from this register.	R/W

This register is internally connected to two 512-byte buffers.

If both buffers are not empty when executing multiple block read, the SD card/MMC clock is stopped to suspend receiving data. When one of the buffers is empty, the SD card/MMC clock is supplied to resume receiving data.

34.2.20 SDIO_MODE : SDIO Mode Control Register

Base address: SDHIn = 0x4025_2000 + 0x0400 × n (n = 0, 1)
SDHIn_NS = 0x5025_2000 + 0x0400 × n (n = 0, 1)

Offset address: 0x068

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	C52PUB	IOABT	—	—	—	—	—	RWREQ	—	INTEN
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	INTEN	SDIO Interrupt Acceptance Enable*1 0: Disable SDIO interrupt acceptance 1: Enable SDIO interrupt acceptance	R/W
1	—	This bit is read as 0. The write value should be 0.	R/W
2	RWREQ	Read Wait Request 0: Allow SD/MMC to exit read wait state 1: Request for SD/MMC to enter read wait state	R/W
7:3	—	These bits are read as 0. The write value should be 0.	R/W
8	IOABT	SDIO Abort If this bit is set to 1 during multiblock transfer triggered by CMD53, CMD52 is immediately issued, and the command sequence is aborted.	R/W
9	C52PUB	SDIO None Abort If this bit is set to 1 during multiblock transfer triggered by CMD53, CMD52 is issued after the transfer process is complete, and the command sequence is completed.	R/W
31:10	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3
Note 1. Do not rewrite this bit when the SD_INFO2.CBSY flag is 1.

The SDIO_MODE register controls reception of the SDIO interrupt, CMD52 issuance during multiblock transfer, and read wait request. Do not set bits C52PUB and IOABT to 1 at the same time.

RWREQ bit (Read Wait Request)

When RWREQ is set to 1 in the CMD53 (multiple block) read sequence, the block transfer enters the read wait state between blocks.

[Read wait state releasing]

- The read wait state is released, when RWREQ is cleared to 0 in the read wait state.
- When IOABT is set to 1 in the read wait state, RWREQ is automatically cleared to 0 after CMD52 is issued, and then the read wait state is released.
- When C52PUB and RWREQ are set to 1 simultaneously in the CMD53 (multiple block) read sequence, the read wait state is not automatically released. Therefore, after the CMD52 response is received, clear RWREQ. You must set RWREQ and C52PUB simultaneously.

When RWREQ is set to 1 while the last block in the CMD53 (multiple block) read sequence is transferred, the read wait state is not entered and RWREQ is automatically cleared to 0 by setting access end. Set RWREQ to 1 after the response end flag sets.

IOABT bit (SDIO Abort)

When the IOABT bit is set to 1 in a CMD53 (multiple block) sequence, the CMD53 sequence is halted and CMD52 is issued. However, if a command sequence is halted because of a communication error or timeout, CMD52 is not issued.

Although continued buffer access is possible even after IOABT is set to 1, the buffer access error bit (ILR or ILW) in SD_INFO2 is set accordingly. Set SD_ARG before setting IOABT to 1.

When IOABT is set to 1 during transfer for a single block write, the access end flag sets when SD_BUF0 becomes empty, and CMD52 is not issued. If SD_BUF0 contains data, the access end flag sets on completion of reception of the busy state without CMD52 being issued.

When IOABT is set to 1 during transfer for single block read, the access end flag sets immediately after IOABT is set, and CMD52 is not issued.

When IOABT is set to 1 during reception of the busy state after an R1b response, the access end flag sets on completion of reception of the busy state without CMD52 being issued.

When IOABT is set to 1 after a command sequence is completed, CMD52 is not issued and the access end flag does not set.

Set IOABT to 1 after the response end flag sets.

Set IOABT to 0 after the access end flag sets.

C52PUB bit (SDIO None Abort)

When the C52PUB bit is set to 1 in the CMD53 (multiple block) write sequence, CMD52 is automatically issued between blocks if SD_BUF0 becomes empty. C52PUB is automatically cleared to 0 after reception of the response to CMD52 is completed. Additionally, if C52PUB is set to 1 while the last block is being transferred, CMD52 is not issued. In this case, C52PUB is automatically cleared to 0 after the access end flag sets to 1.

When C52PUB and RWREQ are set to 1 in the CMD53 (multiple block) read sequence, the block transfer enters the read wait state between blocks and CMD52 is automatically issued. C52PUB is automatically cleared to 0 after reception of the response to CMD52 is completed. Additionally, if C52PUB is set to 1 while the last block is being transferred, CMD52 is not issued. In this case, C52PUB is automatically cleared to 0 after the access end flag sets to 1.

If C52PUB is set to 1 in the CMD53 (multiple block) read sequence, you must set RWREQ to 1 in addition to C52PUB.

Set SD_ARG before setting C52PUB to 1.

Set C52PUB to 1 after the response end flag sets.

34.2.21 SDIO_INFO1 : SDIO Interrupt Flag Register

Base address: SDHIn = 0x4025_2000 + 0x0400 × n (n = 0, 1)
SDHIn_NS = 0x5025_2000 + 0x0400 × n (n = 0, 1)

Offset address: 0x06C

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	EXWT	EXPUB52	—	—	—	—	—	—	—	—	—	—	—	—	—	IOIRQ
Value after reset:	0*1	0*1	0	0	0	0	0	0	0	0	0	0	0	x	x	0*1

Bit	Symbol	Function	R/W
0	IOIRQ	SDIO Interrupt Status Flag 0: No SDIO interrupt detected 1: SDIO interrupt detected	R/(W)*2
2:1	—	The read values are undefined. The write value should be 1.	R/W
13:3	—	These bits are read as 0. The write value should be 0.	R/W
14	EXPUB52	EXPUB52 Status Flag Indicates the status of the EXPUB52.	R/(W)*2
15	EXWT	EXWT Status Flag Indicates the status of the EXWT.	R/(W)*2

Bit	Symbol	Function	R/W
31:16	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3
Note 1. The value is initialized by a reset and also on reset triggered by the SOFT_RST.SDRST flag.
Note 2. Only 0 can be written to clear the bit.

The SDIO_INFO1 register indicates the status of the SDIO card access. Set flags to be cleared to 0. Set flags that are not being cleared to 1.

IOIRQ flag (SDIO Interrupt Status Flag)

The IOIRQ flag indicates that an SDIO interrupt occurred.

[Setting condition]

- When SDIO interrupt from an SDIO card is received while INTEN in SDIO_MODE is set to 1.

[Clearing condition]

- When 0 is written to IOIRQ.*1

Note 1. Before clearing this bit, access the SDIO card to negate the SDIO interrupt signal from the SDIO card. If the interrupt signal is not negated, this bit can be set again.

EXPUB52 flag (EXPUB52 Status Flag)

The EXPUB52 flag indicates the EXPUB52 status.

[Setting conditions]

- While the last block in the CMD53 (multiple block) sequence is transferred, C52PUB in SDIO_MODE is set to 1.
- While C52PUB is set to 1 in the CMD53 (multiple block) write sequence, the last block is transferred.

[Clearing condition]

- When 0 is written to EXPUB52.

EXWT flag (EXWT Status Flag)

The EXWT flag indicates the EXWT status.

[Setting condition]

- While the last block in the CMD53 (multiple block) read sequence is transferred, RWREQ in SDIO_MODE is set to 1.

[Clearing condition]

- When 0 is written to EXWT.

34.2.22 SDIO_INFO1_MASK : SDIO INFO1 Interrupt Mask Register

Base address: SDHIn = 0x4025_2000 + 0x0400 × n (n = 0, 1)
SDHIn_NS = 0x5025_2000 + 0x0400 × n (n = 0, 1)

Offset address: 0x070

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	EXWTM	EXPUB52M	—	—	—	—	—	—	—	—	—	—	—	—	—	IOIRQM
Value after reset:	1	1	0	0	0	0	0	0	0	0	0	0	0	1	1	1

Bit	Symbol	Function	R/W
0	IOIRQM	IOIRQ Interrupt Mask Control 0: Do not mask IOIRQ interrupts 1: Mask IOIRQ interrupts	R/W
2:1	—	These bits are read as 1.The write value should be 1.	R/W
13:3	—	These bits are read as 0. The write value should be 0.	R/W
14	EXPUB52M	EXPUB52 Interrupt Request Mask Control 0: Do not mask EXPUB52 interrupt requests 1: Mask EXPUB52 interrupt requests	R/W
15	EXWTM	EXWT Interrupt Request Mask Control 0: Do not mask EXWT interrupt requests 1: Mask EXWT interrupt requests	R/W
31:16	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

The SDIO_INFO1_MASK register enables or disables interrupt requests from the status flags in the SDIO_INFO1 register. See Table 34.5 for details on the relationship between the status flags and the requested interrupt source.

34.2.23 SD_DMAEN : DMA Mode Enable Register

Base address: SDHIn = 0x4025_2000 + 0x0400 × n (n = 0, 1)
SDHIn_NS = 0x5025_2000 + 0x0400 × n (n = 0, 1)

Offset address: 0x1B0

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	DMAEN	—
Value after reset:	0	0	0	1	0	0	0	0	0	0	0	1	0	0	0	0

Bit	Symbol	Function	R/W
0	—	This bit is read as 0. The write value should be 0.	R/W
1	DMAEN	DMA Transfer Enable*1 *2 0: Disable use of DMA transfer to access SD_BUF0 register 1: Enable use of DMA transfer to access SD_BUF0 register	R/W
3:2	—	These bits are read as 0. The write value should be 0.	R/W
4	—	This bit is read as 1. The write value should be 1.	R/W
11:5	—	These bits are read as 0. The write value should be 0.	R/W
12	—	This bit is read as 1. The write value should be 1.	R/W
31:13	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3
Note 1. Do not rewrite this bit when the SD_INFO2.CBSY bit is 1.
Note 2. When the SD_INFO2_MASK.BWEM bit is 0 or the SD_INFO2_MASK.BREM bit is 0, set the SD_DMAEN.DMAEN bit to 0. When the SD_DMAEN.DMAEN bit is 1, set the SD_INFO2_MASK.BWEM bit to 1 and the SD_INFO2_MASK.BREM bit to 1.

The SD_DMAEN register enables or disables DMA transfers.

DMAEN bit (DMA Transfer Enable)

When using DMA transfer to access the SD buffer, set the DMAEN bit to 1 before setting the SD_CMD register.

34.2.24 SOFT_RST : Software Reset Register

Base address: SDHIn = 0x4025_2000 + 0x0400 × n (n = 0, 1)
SDHIn_NS = 0x5025_2000 + 0x0400 × n (n = 0, 1)

Offset address: 0x1C0

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	SDRST
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1	1

Bit	Symbol	Function	R/W
0	SDRST	Software Reset Control 0: Reset SD/MMC Host Interface software 1: Cancel reset of SD/MMC Host Interface software	R/W
2:1	—	These bits are read as 1. The write value should be 1.	R/W
31:3	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

Table 34.4 lists the bits and flags initialized by SD/MMC Host Interface software reset.

Table 34.4 Bits and flags initialized by SD/MMC Host Interface software reset

Register	Bit/flag
SD_STOP	SEC, STP
SD_INFO1	RSPEND, ACEND
SD_INFO2	CMDE, CRCE, ENDE, DTO, ILW, ILR, RSPTO, BRE, BWE, SD_CLK_CTRLEN, CBSY, ILA
SD_CLK_CTRL	CLKEN
SD_OPTION	CTOP[3:0], TOP[3:0], TOUTMASK, WIDTH8, WIDTH
SD_ERR_STS1	CMDE0, CMDE1, RSPLENE0, RSPLENE1, RDLENE, CRCLENE, RSPCRCE0, RSPCRCE1, RDCRCE, CRCTKE, CRCTK[2:0]
SD_ERR_STS2	RSPTO0, RSPTO1, BSYTO0, BSYTO1, RDTO, CRCTO, CRCBSYTO
SDIO_INFO1	IOIRQ, EXPUB52, EXWT
SDIF_MODE	NOCHKCR

34.2.25 SDIF_MODE : SD Interface Mode Setting Register

Base address: SDHIn = 0x4025_2000 + 0x0400 × n (n = 0, 1)
SDHIn_NS = 0x5025_2000 + 0x0400 × n (n = 0, 1)

Offset address: 0x1CC

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	NOCHKCR	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0*1	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	—	These bits are read as 0. The write value should be 0.	R/W
8	NOCHKCR	CRC Check Mask CRC check mask bit for MMC test commands. Set when CRC16 or CRC status value check is not executed. 0: Enable CRC check 1: Disable CRC Check (ignore CRC16 valued when reading and ignore CRC status value when writing)	R/W
31:9	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3
Note 1. The value is initialized by a reset and also on reset triggered by the SOFT_RST.SDRST flag.

NOCHKCR bit (CRC Check Mask)

The NOCHKCR bit is used for MMC test commands. This bit is set when CRC16 or CRC status value check is not executed.

34.2.26 EXT_SWAP : Swap Control Register

Base address: SDHIn = 0x4025_2000 + 0x0400 × n (n = 0, 1)
SDHIn_NS = 0x5025_2000 + 0x0400 × n (n = 0, 1)

Offset address: 0x1E0

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	BRSWP	BWSWP	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
5:0	—	These bits are read as 0. The write value should be 0.	R/W
6	BWSWP	SD_BUF0 Swap Write*1 0: Normal write operation 1: Swap the byte endian order before writing to SD_BUF0 register	R/W
7	BRSWP	SD_BUF0 Swap Read*1 0: Normal read operation 1: Swap the byte endian order before reading SD_BUF0 register	R/W
31:8	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3
Note 1. Do not rewrite this bit when the SD_INFO2.CBSY flag is 1.

The EXT_SWAP register selects whether or not the byte endian order is swapped when accessing the SD_BUF0 register. See section 34.3.1. SD/MMC Interface for details on the differences in accessing the SD_BUF0 register based on the EXT_SWAP register value.

34.3 Operation

34.3.1 SD/MMC Interface

When data is read from the SD card/MMC, the process is as follows:

1. The SD/MMC Host Interface receives data from the SD card/MMC through the SDnDAT signal (see Figure 34.2 and Figure 34.3).
2. The received data is stored in SD_BUF of the MMC Host Interface (see Figure 34.4).

3. The data stored in SD_BUF is read from SD_BUF0 (see Figure 34.5).

When data is written to the SD card/MMC, the specified procedure is reversed.

When accessing SD_BUF0, pay attention to the transfer order in SDnDAT and the store order in SD_BUF. If required, you can change the byte endian of the data read from or written to SD_BUF0 using the SDSWAP register. See Figure 34.6.

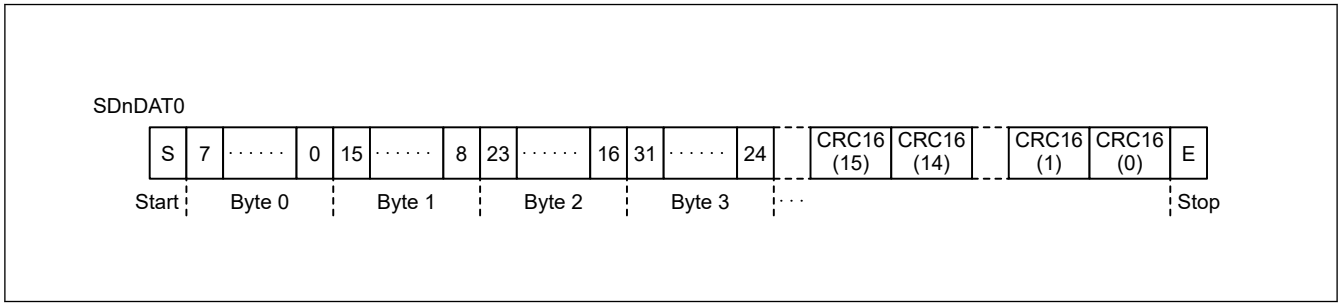

Figure 34.2 SDnDAT in 1-bit width mode

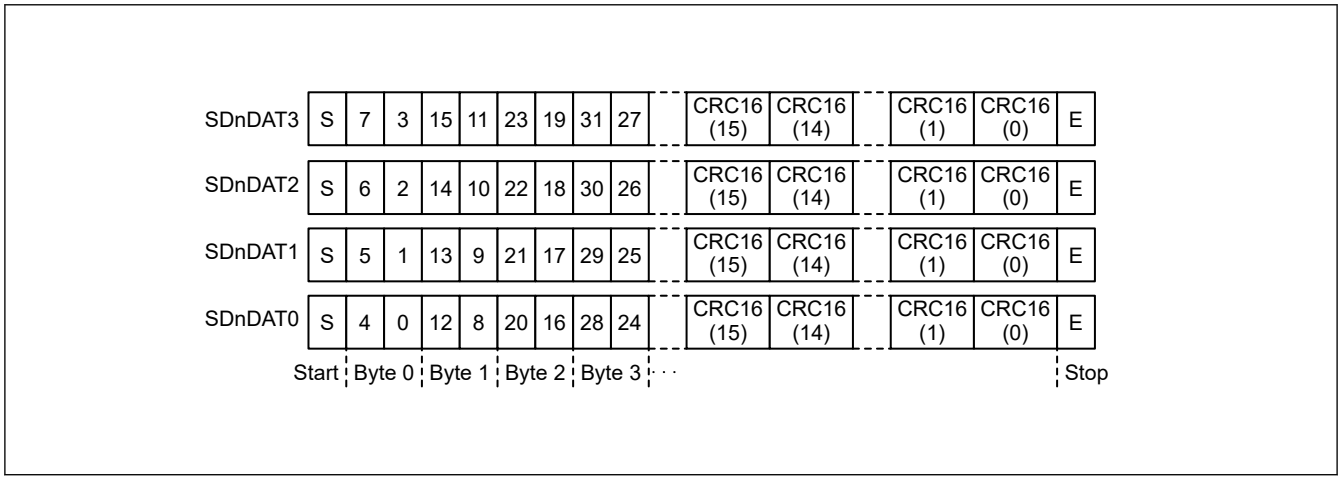

Figure 34.3 SDnDAT in 4-bit width mode

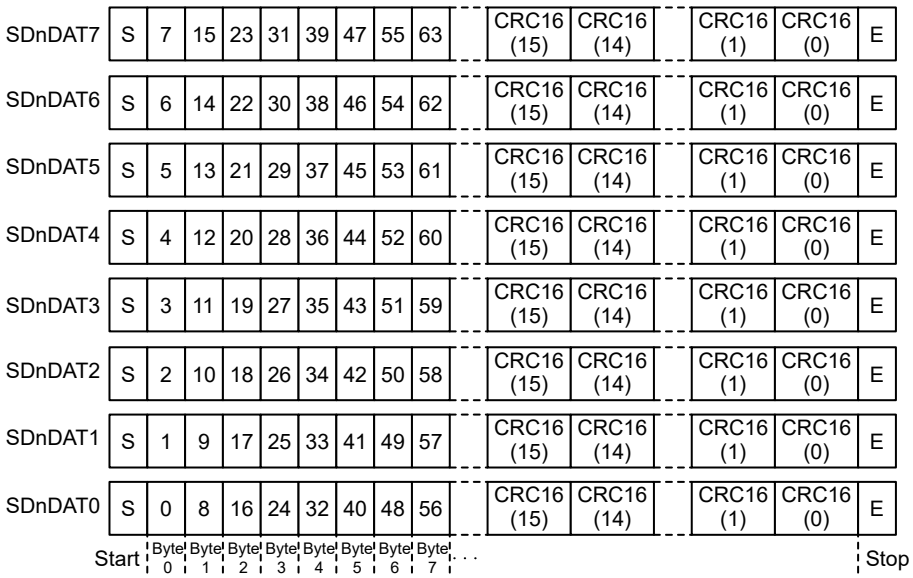

Figure 34.4 SDnDAT in 8-bit width mode

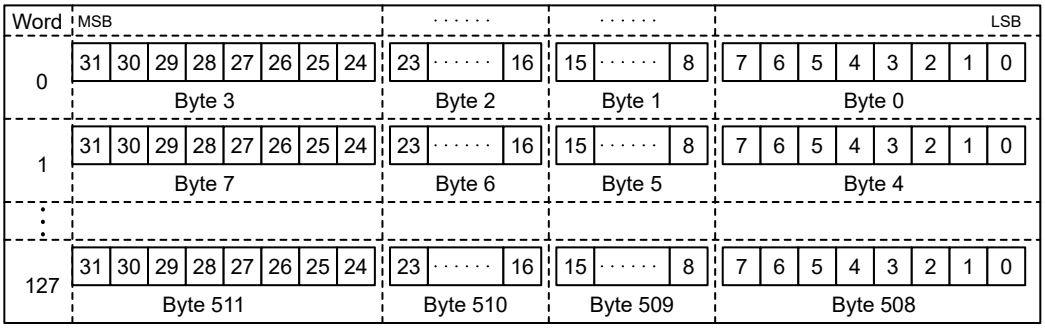

Figure 34.5 SD_BUF store data

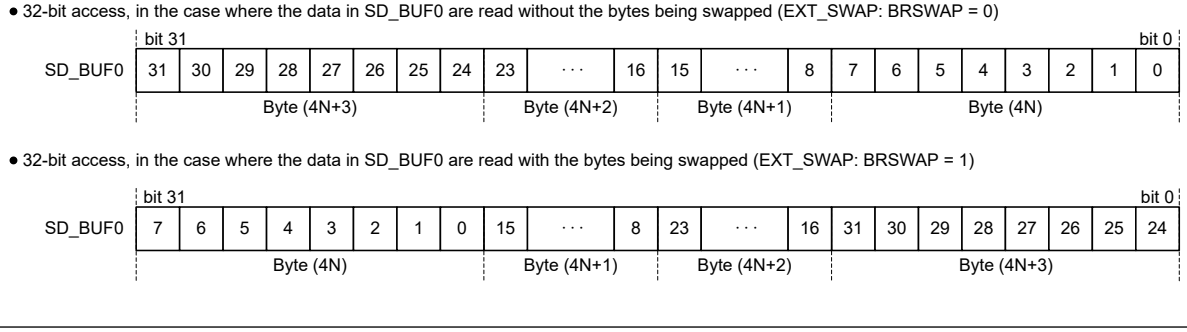

Figure 34.6 Read from SD_BUF0

34.3.2 Card Detect/Write Protect

34.3.2.1 Card detect

The SD/MMC Host Interface has two types of card detect functions.

(1) Card detect with SDnCD (n = 0, 1)

Figure 34.7 shows the timing for card detect using SDnCD. SDnCD is connected to the card socket and pulled up on the host device. The resistance of the pull-up resistor is determined by the specification of the SD/MMC host device.

(2) Card insertion

SDnCD is pulled down when a card is inserted. At this point, if SDnCD is pulled down for the Mcycle period (set in SD_OPTION), SDCDIN in SD_INFO1 is set to 1. It is cleared by writing 0.

(3) Card removal

SDnCD is pulled up when a card is removed. At this point, if SDnCD is pulled up for the Mcycle period (set in SD_OPTION), SDCDRM in SD_INFO1 is set to 1. It is cleared by writing 0.

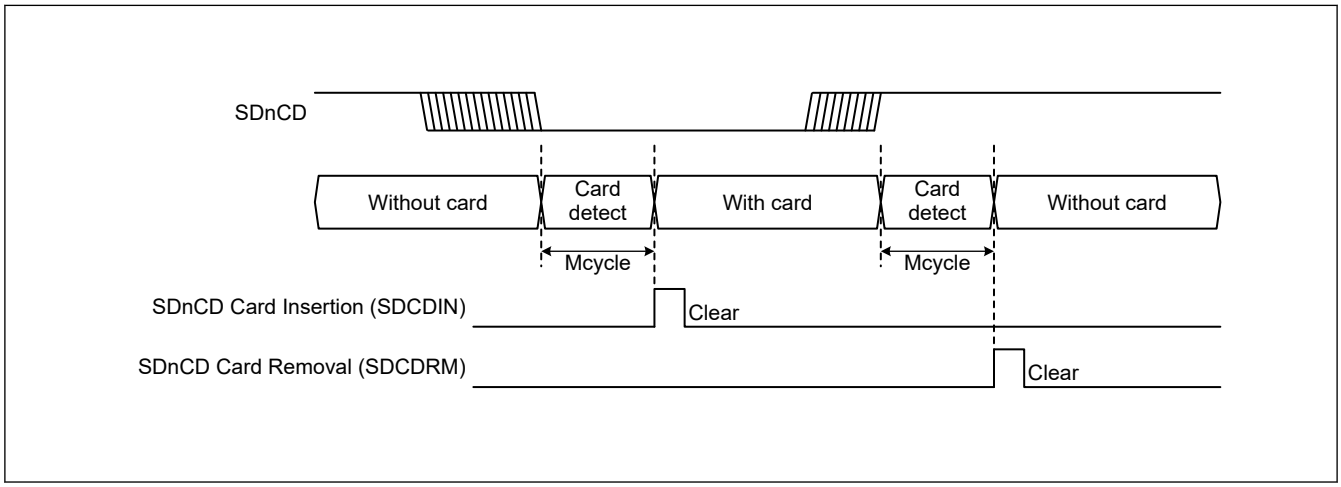

Figure 34.7 Example of card detect with SDnCD

(4) SD card detect with SDnDAT3 (n = 0, 1)

Figure 34.8 shows the timing when the SD card is detected with SDnDAT3. In addition, SDnDAT3 is pulled down by the host device, and the resistance value for pulling down is determined by the specification of the SD host device.

(5) Card insertion

When an SD card is inserted, SDnDAT3 is pulled up and SDD3IN in SD_INFO1 is set to 1. It is cleared by writing 0.

(6) Card removal

When an SD card is removed, SDnDAT3 is pulled down and SDD3RM in SD_INFO1 is set to 1. It is cleared by writing 0.

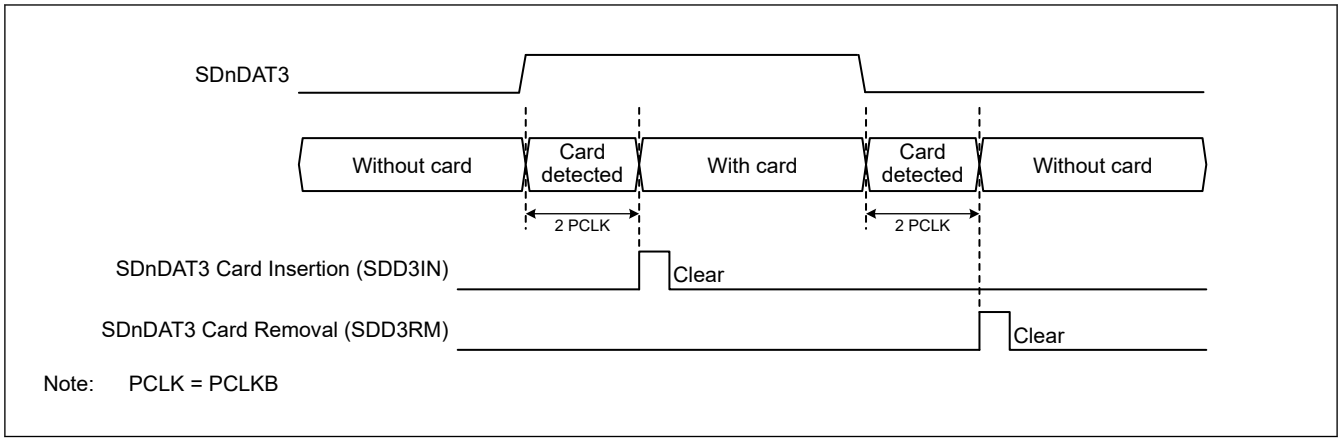

Figure 34.8 SD card detect with SDnDAT3

34.3.2.2 Write protect

The SD/MMC Host Interface has two types of write protect functions.

(1) Write protect with SDnWP (n = 0, 1)

SDnWP is connected to the card socket and pulled up or pulled down by the card insertion. The selection of pulling up or pulling down and the resistance value is determined by the specification of the SD host device. When the SDnWP state is reflected to SDWPMON in SD_INFO1, the write protect state is set after the SD card is inserted.

(2) Write protect with command

The internal write protection of the card and the lock/unlock operation of the card are realized by the command.

34.3.3 Interrupt Request and DMA Transfer Request

34.3.3.1 Interrupts

Table 34.5 lists the SDHI interrupt sources. The SDHI requests an interrupt when:

- The status flags in registers SD_INFO1, SD_INFO2, and SDIO_INFO1 set to 1.
- The associated bits in the SD_INFO1_MASK, SD_INFO2_MASK, and SDIO_INFO1_MASK registers are 0.

When clearing the status flags in registers SD_INFO1, SD_INFO2, and SDIO_INFO1, write 0 to the status flags to be cleared and write 1 to the status flags that are not being cleared.

Table 34.5 Interrupt sources

Interrupt sources	Status flag register		Interrupt mask register		Interrupt name
	Register symbol	Bit symbol	Register symbol	Bit symbol	Channel n (n = 0, 1)
Card Access Interrupt (CACI)	SD_INFO1	ACEND	SD_INFO1_MASK	ACENDM	SDHI_MMCn_ACCS
		RSPEND		RSPENDM	
	SD_INFO2	ILA	SD_INFO2_MASK	ILAM	
		BWE		BWEM	
		BRE		BREM	
		RSPTO		RSPTOM	
		ILR		ILRM	
		ILW		ILWM	
		DTO		DTOM	
		ENDE		ENDEM	
		CRCE		CRCEM	
		CMDE		CMDEM	
SDIO Access Interrupt (SDACI)	SDIO_INFO1	EXWT	SDIO_INFO1_MASK	EXWTM	SDHI_MMCn_SDIO
		EXPUB52		EXPUB52M	
		IOIRQ		IOIRQM	
Card Detect Interrupt (CDETI)	SD_INFO1	SDD3IN	SD_INFO1_MASK	SDD3INM	SDHI_MMCn_CARD
		SDD3RM		SDD3RMM	
		SDCDIN		SDCDINM	
		SDCDRM		SDCDRMM	

34.3.3.2 DMA transfer requests (SDHI_MMCn_ODMSDBREQ, n = 0, 1)

The SD/MMC Host Interface has two types of DMA transfer requests.

(1) SD_BUF write DMA transfer request

- When the BWE bit in SD_INFO2 is set to 1 while the DMAEN bit in SD_DMAEN is set to 1, the SD_BUF write DMA transfer request is asserted.
- The SD_BUF write DMA transfer request is negated when the last data in one block (based on the transfer data size set in SD_SIZE) is transferred. The SD_BUF write DMA transfer request is also negated by clearing the SDRST bit in SOFT_RST to 0 or setting the STP bit in SD_STOP to 1. However, if a communications error or timeout occurs at the DMA transfer, the SD_BUF write DMA transfer request is not negated.
- The BWE bit in SD_INFO2 is cleared after transfer of the last data in one block following a request for writing to SD_BUF by DMA transfer.
- The number of DMA transfers must be n × one block. (n = integer, one block = the transfer data size set in SD_SIZE)
- When the IOABT bit in SDIO_MODE is set to 1, the SD_BUF write DMA transfer request is negated.
- The DMA transfer request is also negated by clearing the DMAEN bit to 0. However, the DMA transfer request is asserted again when the DMAEN bit is set to 1 before writing to SD_CMD.
- Because the BWE bit in SD_INFO2 is not cleared in response to setting the STP/IOABT bit, or to a communications error or timeout, clear the bit to 0 before issuing the next command. The next request to write to SD_BUF by DMA transfer is not issued while the BWE bit is set.

(2) SD_BUF read DMA transfer request

- When the BRE bit in SD_INFO2 is set to 1 while the DMAEN bit in the SD_DMAEN register is set to 1, the SD_BUF read DMA transfer request is asserted.

- The SD_BUF read DMA transfer request is negated when the last data in one block (based on the transfer data size set in SD_SIZE) is transferred. The SD_BUF read DMA transfer request is also negated by clearing the SDRST bit in SOFT_RST to 0 or setting the STP bit in SD_STOP to 1. However, if a communications error or timeout occurs at the DMA transfer, the SD_BUF read DMA transfer request is not negated.
- The BRE bit in SD_INFO2 is cleared after transfer of the last data in one block following a request to write to SD_BUF by DMA transfer.
- The number of DMA transfers must be n × one block. (n = integer, one block = the transfer data size set in SD_SIZE)
- When the IOABT bit in SDIO_MODE is set to 1, the SD_BUF read DMA transfer request is negated.
- The DMA transfer request is also negated by clearing the DMAEN bit to 0. However, the DMA transfer request is asserted again when the DMAEN bit is set to 1 before writing to SD_CMD.
- Because the BRE bit in SD_INFO2 is not cleared in response to setting the STP/IOABT bit or in response to a communications error or timeout, clear the bit to 0 before issuing the next command. The next request to write to SD_BUF by DMA transfer is not issued while the BRE bit is set.

34.3.4 Communication Errors and Timeouts

When a communication error or timeout error occurs, depending on the type of error, the associated status flag in the SD_INFO2 register sets to 1. Also, depending on the source of the error, the associated flag in the SD_ERR_STS1 or SD_ERR_STS2 register sets to 1.

The status flags in registers SD_ERR_STS1 and SD_ERR_STS2 clear to 0 by writing to the SD_CMD register, or by setting the SOFT_RST.SDRST bit to 0.

Table 34.6 Communication errors

Communication error	Interrupt flag register		Error status register		This occurs when…
	Register symbol	Bit symbol	Register symbol	Bit symbol	
End bit error	SD_INFO2	ENDE	SD_ERR_STS1	CRCLENE	The CRC status token length is in error
				RDLENE	The read data length is in error
				RSPLENE1	The response length is in error*1
				RSPLENE0	The response length is in error*2
CRC error		CRCE		CRCTKE	The CRC status token is in error
				RDCRCE	There is a CRC error in the read data
				RSPCRCE1	There is a CRC error in the response*1
				RSPCRCE0	There is a CRC error in the response*2
Command error		CMDE		CMDE1	The command index field value for the transmitted command and received response do not match*1
				CMDE0	The command index field value for the transmitted command and received response do not match*2

Note 1. CMD12 when automatic issuing is enabled for multiple block transfer by the setting in SD_CMD, CMD12 when the STP bit in SD_STOP is set to 1, or CMD52 when the C52PUB or IOABT bit in SDIO_MODE is set to 1.
Note 2. CMD other than CMD12 when automatic issuing is enabled for multiple block transfer by the setting in SD_CMD, CMD12 when the STP bit in SD_STOP is set to 1, or CMD52 when the C52PUB or IOABT bit in SDIO_MODE is set to 1.

Table 34.7 Timeouts

Timeout	Interrupt flag register		Error status register		This occurs when…
	Register symbol	Bit symbol	Register symbol	Bit symbol	
Response timeout	SD_INFO2	RSPTO	SD_ERR_STS2	RSPTO1	A response is not received even after a minimum of 640 SDHI clock cycles elapse*1
				RSPTO0	A response is not received even after a minimum of 640 SDHI clock cycles elapse*2
Data timeout (excluding response timeout)		DTO		CRCBSYTO	After the CRC status token is received, the SDHI is busy for at least the period set*3
				CRCTO	After the write data is transmitted, the CRC status token is not received even after at least the period set*3 elapses
				RDTO	After the read command is issued, the read data is not received even after at least the period set*3 elapses
					After the read data is received, the next block read data is not received even after at least the period set*3 elapses
					After the SDHI exits the read wait state, the next block read data is not received even after at least the period set*3 elapses
				BSYTO1	After CMD12 is issued during the command sequence, the SDHI is busy for at least the period set*3
				BSYTO0	After the R1b response is received, the SDHI is busy for at least the period set*3 (a command other than CMD12 is issued during the command sequence)

Note 1. CMD12 when automatic issuing is enabled for multiple block transfer by the setting in SD_CMD, CMD12 when the STP bit in SD_STOP is set to 1, or CMD52 when the C52PUB or IOABT bit in SDIO_MODE is set to 1.
Note 2. CMD other than CMD12 when automatic issuing is enabled for multiple block transfer by the setting in SD_CMD, CMD12 when the STP bit in SD_STOP bit is set to 1, or CMD52 when the C52PUB or IOABT bit in SDIO_MODE is set to 1.
Note 3. The period is set in the SD_OPTION.TOP[3:0] bits.

34.3.5 Command without Data Transfer (SD/MMC)

The following legend is used for description of register read/write.

W (register name, value): Write to register

R (register name): Read from register

Figure 34.9 and Figure 34.10 show example flows.

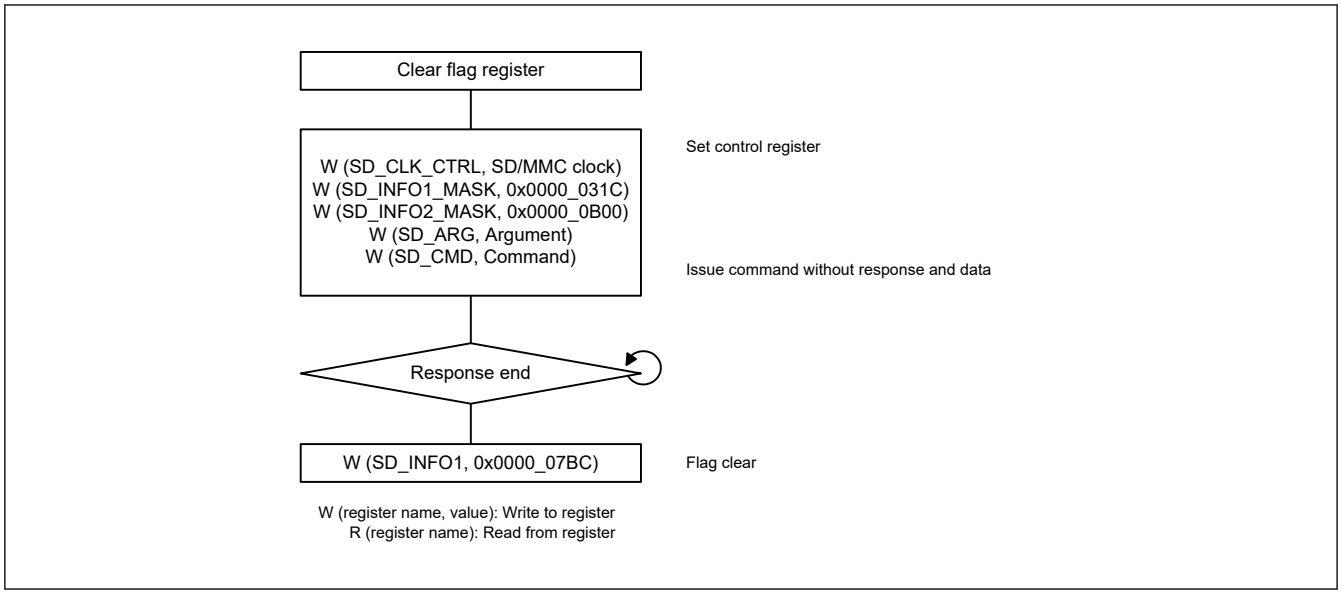

Figure 34.9 Example flow of command without response or data

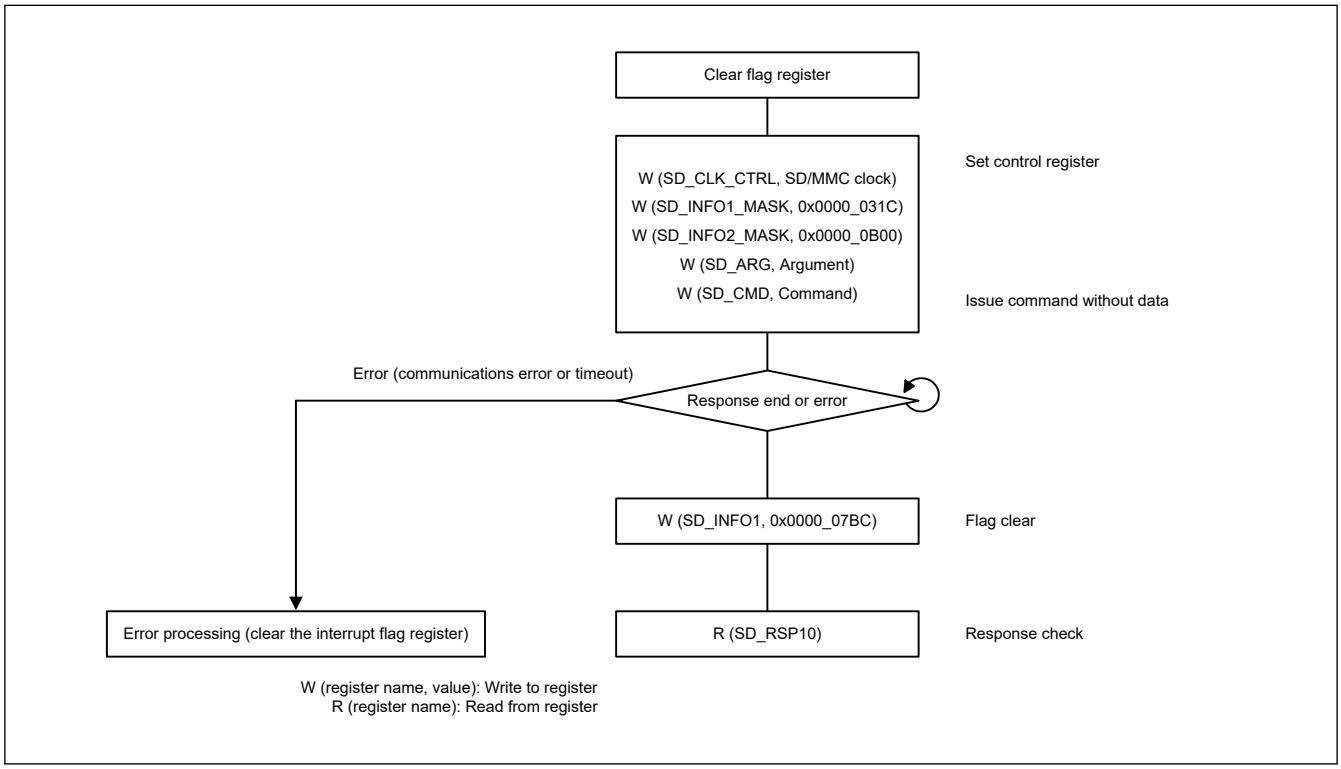

Figure 34.10 Example flow of command without data

34.3.5.1 Operation for command without data transfer

The operation is described in the following section.

(1) Command without response and data

a. Flag register clear
First, clear the bits in the flag register. (SD_INFO1 and SD_INFO2)

b. Control register set
Set the SD/MMC clock and interrupt masking. (SD_CLK_CTRL, SD_INFO1_MASK, and SD_INFO2_MASK)

c. Command issue
Set CMD argument in SD_ARG and write to SD_CMD.

Accordingly, CMD is issued, and the operation is started.

d. Flag clear
When transmission of a command is completed, RSPEND (response end) in SD_INFO1 is set to 1 to generate an interrupt. Clear RSPEND to 0.

(2) Command without data

a. Flag register clear
First, clear the bits in the flag register. (SD_INFO1 and SD_INFO2)

b. Control register set
Set the SD/MMC clock and interrupt masking. (SD_CLK_CTRL, SD_INFO1_MASK, and SD_INFO2_MASK)

c. Command issue
Set CMD argument in SD_ARG and write to the SD_CMD.
Accordingly, CMD is issued, and the operation is started.

d. Flag clear
When a response is received, RSPEND (response end) in SD_INFO1 is set to 1 to generate an interrupt. Clear RSPEND to 0.

e. Read a response from SD_RSP10. Additionally, perform error processing (clear the interrupt flag register) if a communication error or timeout occurs.

34.3.6 Single Block Read (SD/MMC)

Figure 34.11 shows an example flow of a single block read operation.

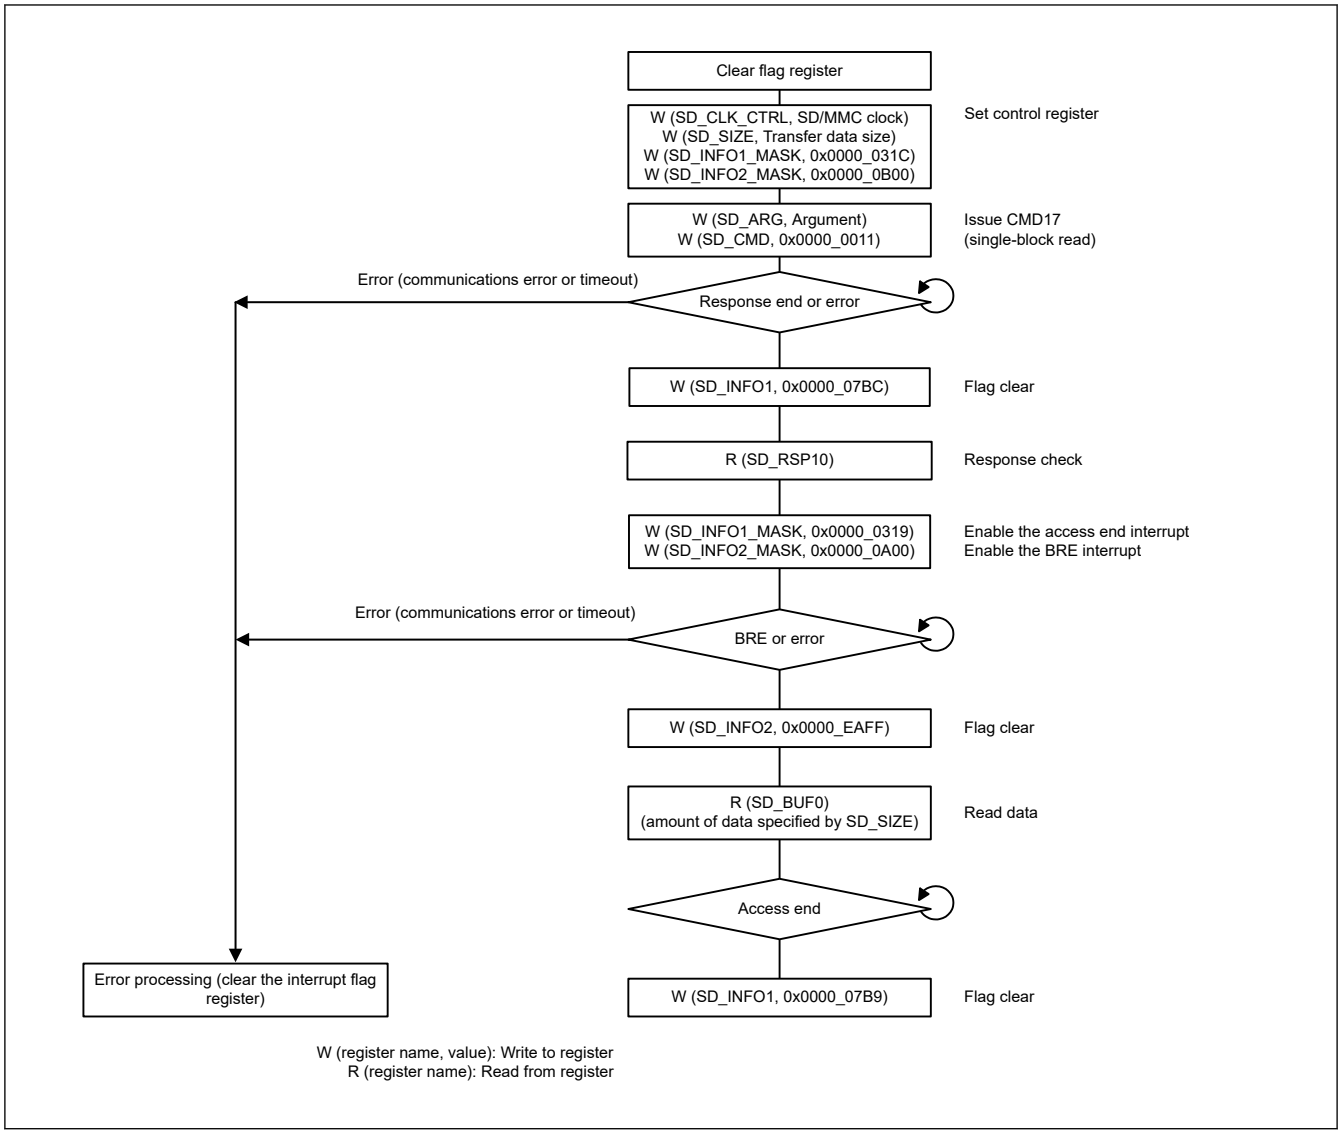

Figure 34.11 Example flow of single block read operation

34.3.6.1 Single block read operation

The operation of the single block read is described as follows:

a. Flag register clear
First, clear the bits in the flag register (SD_INFO1 and SD_INFO2).

b. Control register set
Set the SD/MMC clock, transfer data size, interrupt mask (SD_CLK_CTRL, SD_SIZE, SD_INFO1_MASK, and SD_INFO2_MASK).

c. Command issue (CMD17)
Set CMD17 argument in SD_ARG and write 0x0000_0011 to SD_CMD. CMD17 is issued and the single block read operation is started.

d. Response check
On receiving the response, RSPEND (response end) in SD_INFO1 is set to 1 to generate an interrupt. Clear RSPEND to 0 and read the response from SD_RSP10. If the result of response decoding is an error, the command sequence can be halted by setting the STP bit in SD_STP or the IOABT bit in SDIO_MODE to 1. In addition, this causes CMD12 and CMD52 to not be issued. If the ACEND bit (access end) in SD_INFO1 is set, halting the command sequence also leads to the generation of an interrupt.

e. Data receive from SD card/MMC and data read

Write 0x0000_0319 to SD_INFO1_MASK to enable the access end interrupt. In addition, write 0x0000_0A00 to SD_INFO2_MASK to enable the BRE interrupt. When the data received from the SD card/MMC is completed, the BRE bit in SD_INFO2 is set to 1 to generate an interrupt. Clear the BRE bit to 0 and read the amount of data specified in SD_SIZE from SD_BUF0.
A communication error or timeout might be generated if data is being received while reading of SD_BUF0 is in progress.

f. Operation complete
When the data read from SD_BUF0 is completed, ACEND (access end) in SD_INFO1 is set to 1 to generate an interrupt. Clear ACEND to 0 to end the single block read operation.
Additionally, perform error processing (clear the interrupt flag register) if a communication error or timeout occurs.

34.3.7 Single Block Write (SD/MMC)

Figure 34.12 shows an example flow of a single block write operation.

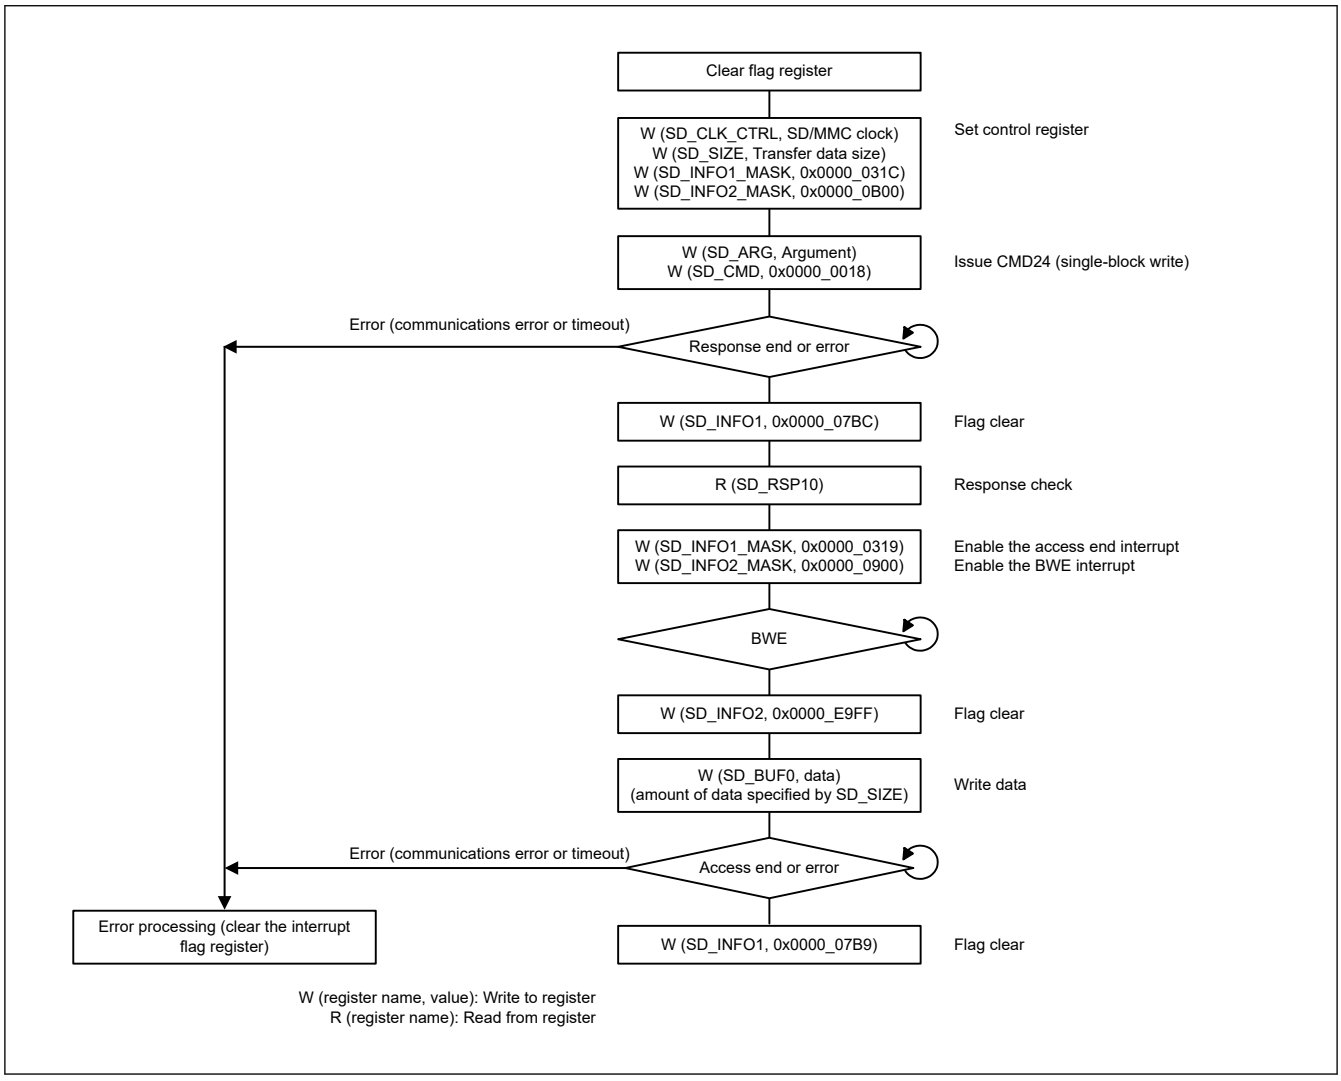

Figure 34.12 Example of single block write operation

34.3.7.1 Single block write operation

The operation of the single block write is described as follows:

a. Flag register clear
First, clear the bits in the flag register (SD_INFO1 and SD_INFO2).

b. Control register set

Set the SD/MMC clock, transfer data size, interrupt mask (SD_CLK_CTRL, SD_SIZE, SD_INFO1_MASK, and SD_INFO2_MASK).

c. Command issue (CMD24)
Set CMD24 argument in SD_ARG and write 0x0000_0018 to SD_CMD. CMD24 is issued and the single block write operation is started.

d. Response check
On receiving the response, RSPEND (response end) in SD_INFO1 is set to 1 to generate an interrupt. Clear RSPEND to 0 and read the response from SD_RSP10. If the result of response decoding is an error, the command sequence can be halted by setting the STP bit in SD_STP or the IOABT bit in SDIO_MODE to 1. In addition, this causes CMD12 and CMD52 to not be issued. If the ACEND bit (access end) in SD_INFO is set, halting the command sequence also leads to the generation of an interrupt.

e. Data write and data transmit to SD card/MMC
Write 0x0000_0319 to SD_INFO1_MASK to enable the access end interrupt. In addition, write 0x0000_0900 to SD_INFO2_MASK to enable the BWE interrupt. When SD_BUF0 is ready for the data to be written, the BWE bit in SD_INFO2 is set to 1 to generate an interrupt. Clear the BWE bit to 0 and write the amount of data specified in SD_SIZE to SD_BUF0. When the data write to SD_BUF0 is completed, data is transmitted to the SD card. Then, the CRC status and busy state are received from the SD card/MMC.
However, a communications error or timeout might be generated if data is being transmitted after writing to SD_BUF0.

f. Operation complete
When the CRC status and busy state are received from the SD card/MMC, ACEND (access end) in SD_INFO1 is set to 1 to generate an interrupt. Clear the ACEND bit to 0 to end the single block write operation.
In addition, perform error processing (clear the interrupt flag register) if a communication error or timeout occurs.

34.3.8 Multiple Block Read (SD/MMC)

Figure 34.13 shows an example flow of a multiple block read operation.

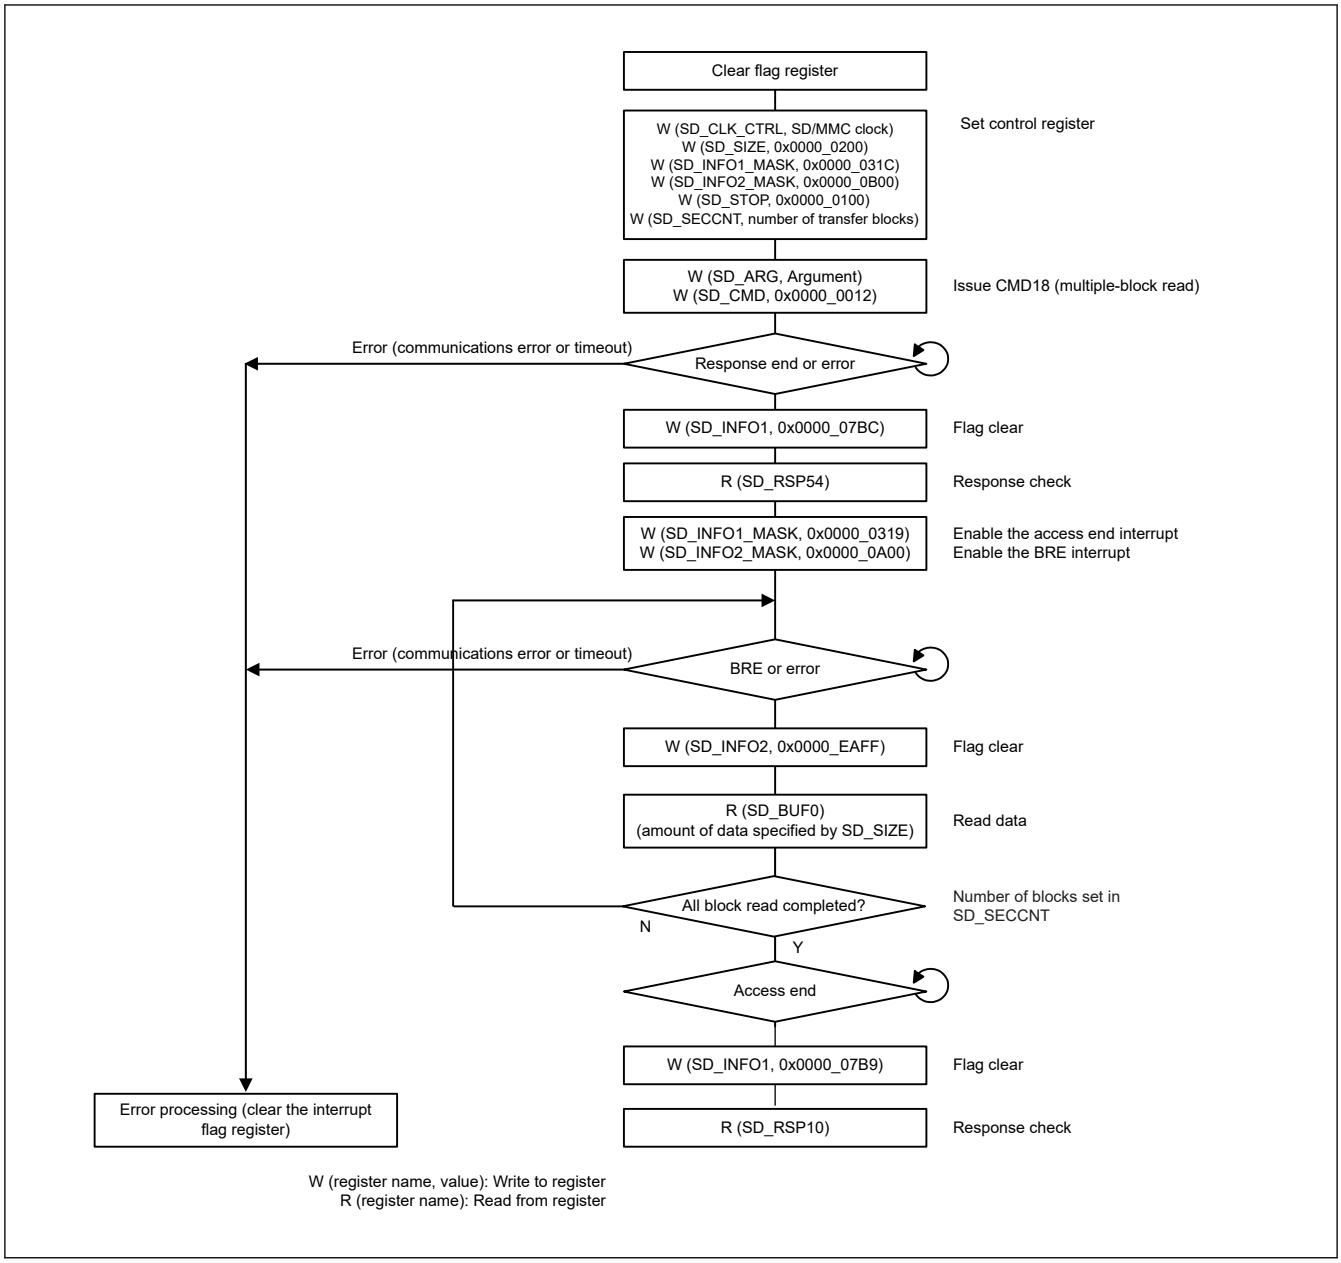

Figure 34.13 Example of multiple block read operation

34.3.8.1 Multiple block read operation

The operation of the multiple block read is described as follows:

a. Flag register clear
First, clear the bits in the flag register (SD_INFO1 and SD_INFO2).

b. Control register set
Set the SD/MMC clock, transfer data size, interrupt mask (SD_CLK_CTRL, SD_SIZE, SD_INFO1_MASK, and SD_INFO2_MASK).
Set SEC in SD_STOP to 1, and set the number of transfer blocks in SD_SECCNT.

c. Command issue (CMD18)
Set CMD18 argument in SD_ARG and write 0x0000_0012 to SD_CMD. CMD18 is issued and the multiple block read operation is started.

d. Response check
On receiving the response, RSPEND (response end) in SD_INFO1 is set to 1 to generate an interrupt. Clear RSPEND to 0 and read the response from SD_RSP54. If the result of response decoding is an error, the command sequence can be

halted by setting the STP bit in SD_STP to 1. Setting the STP bit to 1 also causes CMD12 to be issued and the response received. If the command sequence is halted because the access end interrupt is enabled, an interrupt is generated when the ACEND bit (access end) bit in SD_INFO1 sets to 1 on completion of response reception. Clear the ACEND bit to 0 and read the response.

e. Data receive from SD card/MMC and data read
Write 0x0000_0319 to SD_INFO1_MASK to enable the access end interrupt. In addition, write 0x0000_0A00 to SD_INFO2_MASK to enable the BRE interrupt. When one-block data received from the SD card/MMC is completed, the BRE bit in SD_INFO2 is set to 1 to generate an interrupt. Clear the BRE bit to 0 and read the amount of data specified in SD_SIZE from SD_BUF0. Doing this repeats transfer of the number of blocks set in SD_SECCNT. However, a communication error or timeout might be generated if data is being received while reading of SD_BUF0 is in progress. CMD12 is automatically issued to stop multiblock transfer with the number of blocks that is set to SD_SECCNT and the response is received. At this point, CMD12 argument is automatically set to 0x0000_0000.

f. Operation complete
When all-block data read and the CMD12 response received are completed, ACEND (access end) in SD_INFO1 is set to 1 to generate an interrupt. Clear ACEND to 0 to read the response. This is the end of multiple block read operation. In addition, perform error processing (clear the interrupt flag register) if a communication error or timeout occurs.

34.3.9 Multiple Block Write (SD/MMC Using Internal Timer)

Figure 34.14 shows an example flow of a multiple block write using internal timer.

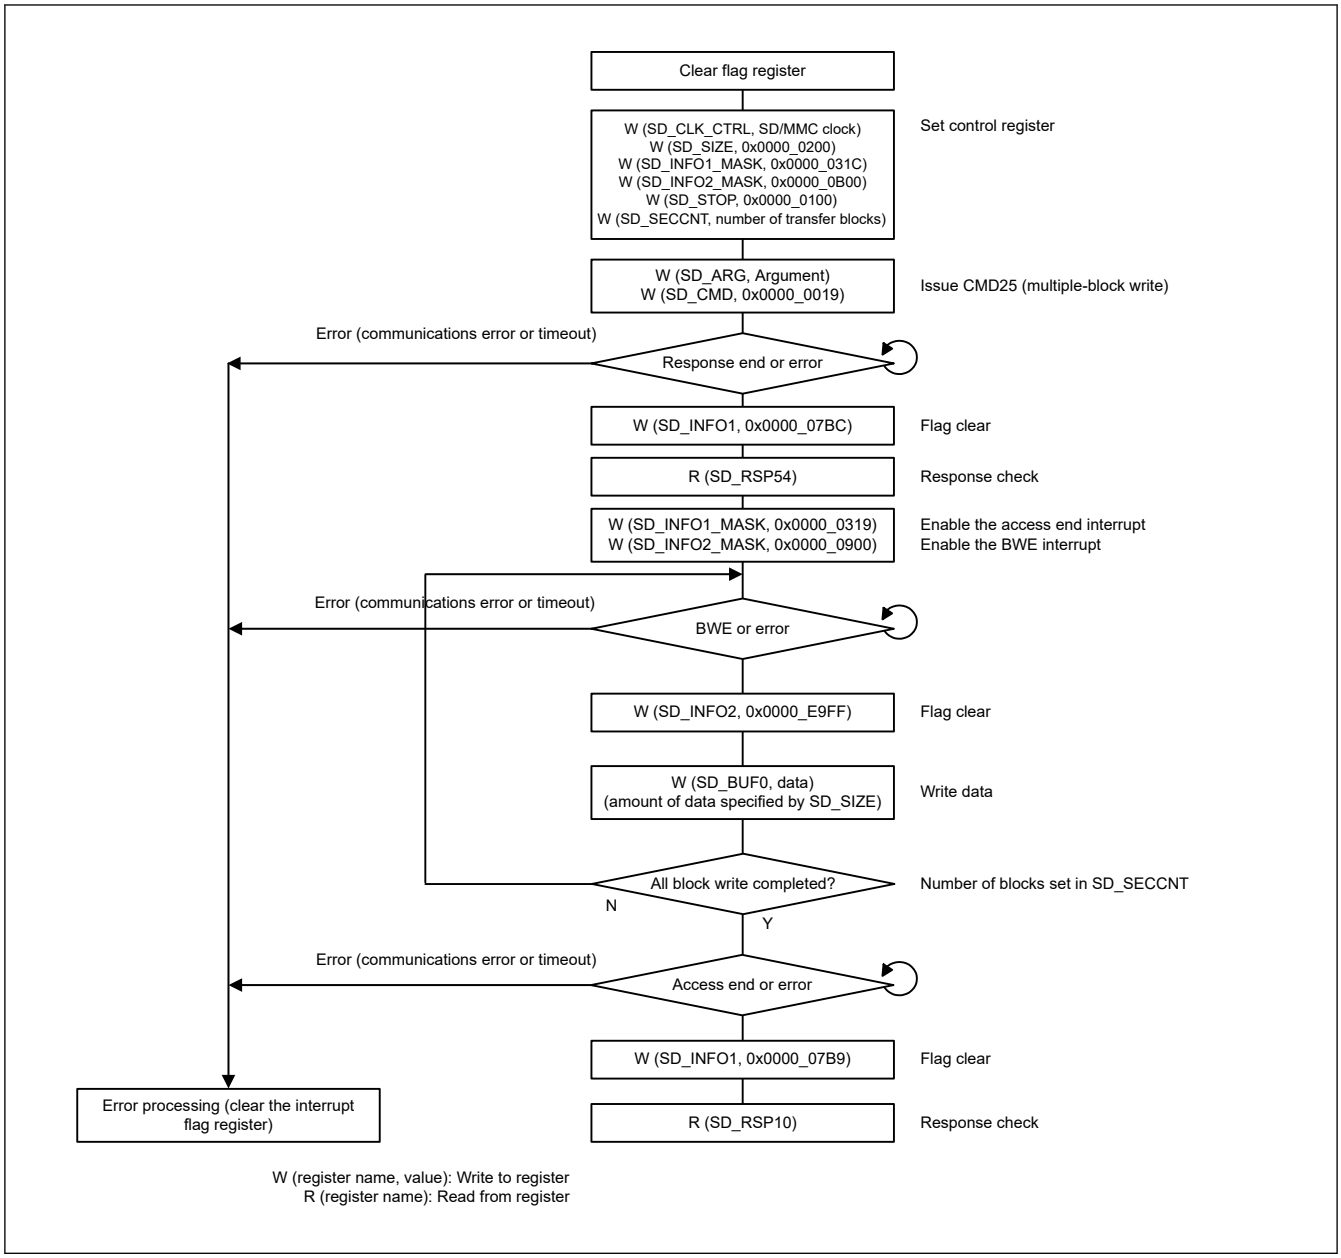

Figure 34.14 Example of multiple block write operation using internal timer

34.3.9.1 Multiple block write operation using internal timer

The operation of the multiple block write is described as follows:

a. Flag register clear
First, clear the bits in the flag register (SD_INFO1 and SD_INFO2).

b. Control register set
Set the SD/MMC clock, transfer data size, interrupt mask (SD_CLK_CTRL, SD_SIZE, SD_INFO1_MASK, and SD_INFO2_MASK).
Set the SEC bit in SD_STOP to 1, and set the number of transfer blocks in SD_SECCNT.

c. Command issue (CMD25)
Set CMD25 argument in SD_ARG and write 0x0000_0019 to SD_CMD. CMD25 is issued and the multiple block write operation is started.

d. Response check
On receiving the response, the RSPEND bit (response end) in SD_INFO1 is set to 1 to generate an interrupt.

Clear the RSPEND bit to 0 and read the response from SD_RSP54. If the result of response decoding is an error, the command sequence can be halted by setting the STP bit in SD_STP to 1. Setting the STP bit to 1 also causes CMD12 to be issued and the response received. If the command sequence is halted because the access end interrupt is enabled, an interrupt is generated by when the ACEND bit (access end) bit in SD_INFO1 sets to 1 on completion of response reception. Clear the ACEND bit to 0 and read the response.

e. Data write and data transmit to SD card/MMC
Write 0x0000_0319 to SD_INFO1_MASK to enable the access end interrupt. In addition, write 0x0000_0900 to SD_INFO2_MASK to enable the BWE interrupt. When SD_BUF0 is ready for the data to be written, the BWE bit in the SD_INFO2 resister is set to 1 to generate an interrupt. Clear the BWE bit to 0 and write the amount of data specified in SD_SIZE to SD_BUF0. When the data write to SD_BUF0 is completed, data is transmitted to the SD card/MMC. The CRC status and busy state are received from the SD card/MMC. This repeats transfer of the number of blocks set in SD_SECCNT. However, a communication error or timeout might be generated if data is being received while writing to SD_BUF0 is in progress. CMD12 is automatically issued to stop multiblock transfer with the number of blocks which is set to SD_SECCNT and the response is received. At this point, CMD12 argument is automatically set to 0x0000_0000.

f. Operation complete
When all-block data transmit and the CRC status receive are completed, the ACEND bit (access end) in SD_INFO1 is set to 1 to generate an interrupt. Clear the ACEND bit to 0 to read the response. This is the end of multiple block write operation. Additionally, perform error processing (clear the interrupt flag register) if a communications error or timeout occurs.

34.3.10 Multiple Block Write (MMC using external timer)

Figure 34.15 shows an example flow of a multiple block write using an external timer.

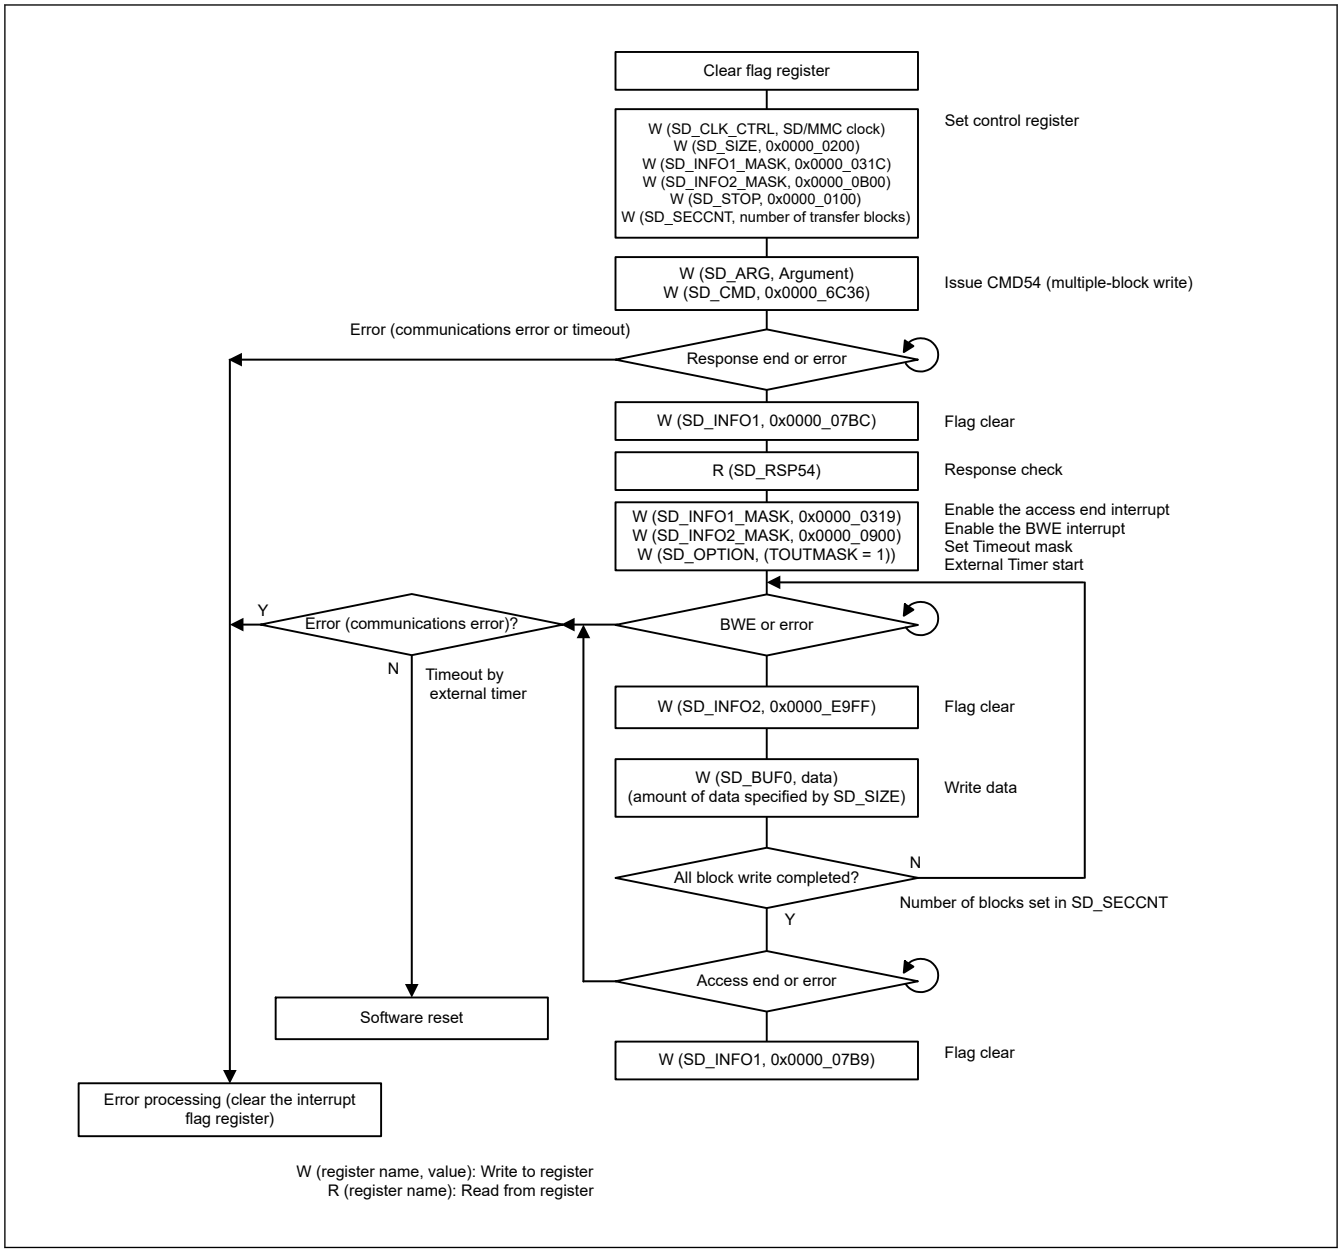

Figure 34.15 Example of multiple block write operation using external timer

34.3.10.1 Multiple block write operation using external timer

The operation of the multiple block write is described as follows:

a. Flag register clear
First, clear the bits in the flag register (SD_INFO1 and SD_INFO2).

b. Control register set
Set the MMC clock, transfer data size, interrupt mask (SD_CLK_CTRL, SD_SIZE, SD_INFO1_MASK, and SD_INFO2_MASK).
Set the SEC bit in SD_STOP to 1, and set the number of transfer blocks in SD_SECCNT.

c. Command issue (CMD54)
Set CMD54 Argument in SD_ARG and write 0x0000_6C36 to SD_CMD. CMD54 is issued and the multiple block write operation is started.

d. Response check
On receiving the response, the RSPEND bit (response end) in SD_INFO1 is set to 1 to generate an interrupt. Clear the RSPEND bit to 0 and read the response from SD_RSP54. If the result of response decoding is an error, the command sequence can be halted by setting the STP bit in SD_STP to 1. Setting the STP bit to 1 also causes CMD12 to be issued

and the response received. If the command sequence is halted because the access end interrupt is enabled, an interrupt is generated by when the ACEND bit (access end) bit in SD_INFO1 sets to 1 on completion of response reception. Clear the ACEND bit to 0 and read the response.

e. Data write and data transmit to MMC
Write 0x0000_0319 to SD_INFO1_MASK to enable the access end interrupt, write 0x0000_0900 to SD_INFO2_MASK to enable the BWE interrupt and set 1 to TOUTMASK of SD_OPTION to inactivate timeout. In addition, start external timer. When SD_BUF0 is ready for the data to be written, the BWE bit in the SD_INFO2 resister is set to 1 to generate an interrupt. Clear the BWE bit to 0 and write the amount of data specified in SD_SIZE to SD_BUF0. When the data write to SD_BUF0 is completed, data is transmitted to the MMC. The CRC status and busy state are received from the MMC. Doing this repeats transfer of the number of blocks set in SD_SECCNT. However, a communication error or timeout might be generated if data is being received while writing to SD_BUF0 is in progress.

f. Operation complete
When all-block data transmit and the CRC status receive are completed, the ACEND bit (access end) in SD_INFO1 is set to 1 to generate an interrupt. Clear the ACEND bit to 0 to read the response. This is the end of multiple block write operation. Additionally, perform error processing (clear the interrupt flag register) if a communications error or timeout occurs when receiving response. Execute software reset if a timeout by external timer occurs when transmitting data.

34.3.11 IO_RW_DIRECT Command (SD: CMD52)

Figure 34.16 shows an example flow of an IO_DIRECT command (CMD52) operation.

34.4 Usage Notes

34.4.1 SD_BUF Illegal Write Access (SD/MMC)

When writing data to SD_BUF0 after the single block write or multi block write command is issued, the data of the size specified in SD_SIZE must be written.

If the data exceeds the size specified in SD_SIZE is written, the ERR4 bit in SD_INFO2 is set to 1. In addition, the data written to SD_BUF0 might not be transmitted and the SD_CLK_CTRLEN bit in SD_INFO2 is held at the value of 0. If this occurs, clearing the SDRST bit in SOFT_RST to 0 and then restoring its value to 1 clears the SD_CLK_CTRLEN bit to 1.

However, this does not apply to the single byte or three bytes when the SD_SIZE setting is odd, or to the fraction of bytes when the SD_SIZE setting is even (the 2 bytes that are not in a 4-byte unit), because the portion of dummy data writing is regarded as excess data and ignored.

34.4.2 Block Number Constraint for Multiple Block Read (SD)

When performing a multiple block read of one or two blocks, depending on the timing with which the SD card response register is read, the response value might not be read properly. To prevent this, do one of the following:

1. When receiving one or two blocks of data, use single block reading.
2. Read the response to CMD18 from SD_RSP54.

34.4.2.1 Mechanism of incorrect reading

Figure 34.25 shows the processing flows of the SDHI (hardware) operation and software operation when a multiple block read is performed on two blocks. As shown in the incorrect operation in Figure 34.25, when an interrupt is generated on reception of the CMD18 response and the timing with which the SD card response register (SD_RSP10) is read by the interrupt is delayed, the data during the CMD12 response reception or the CMD12 response might be read. This problem does not occur for multiple block reads of three or more blocks, because CMD12 is not issued until the block of data is read. The problem also does not occur for multiple block writes, because the CMD25 response is read before the block of data is sent.

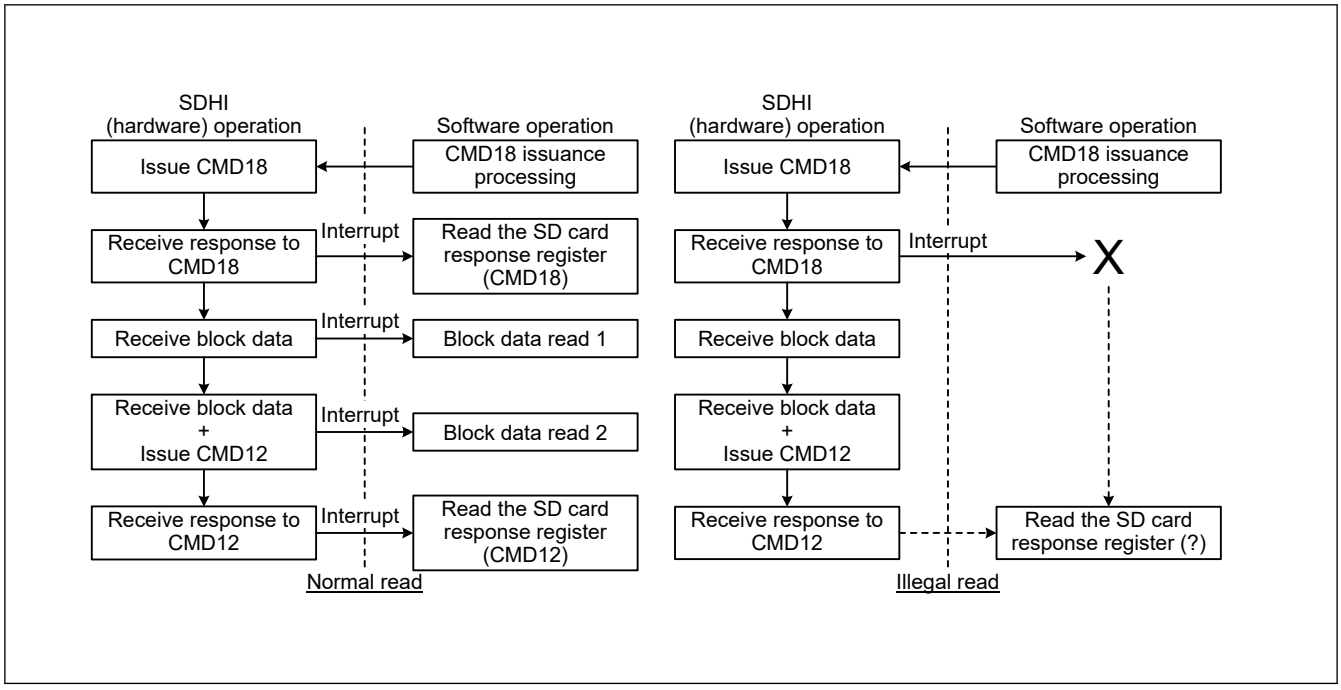

Figure 34.25 Multiple block read operation flow chart (two blocks)

34.4.3 Automatic Control of SD/MMC Clock Output (SD/MMC)

In the SD Card/MMC standard, 74 cycles of SD/MMC clock must be output before initialization of the card. For this reason, use automatic control of SD/MMC clock output after 74 cycles of SD/MMC clock are output. In addition, if

automatic control of SD/MMC clock output was in use, SD/MMC clock output is stopped on completion of the sequence for a communications error or timeout. When state transitions within the SD card/MMC are necessary after completion of the sequence, release automatic control of SD/MMC clock output and restart supply of the SD/MMC clock to the SD card/MMC.

34.4.4 Control of the C52PUB Setting for Multiple Block Write (SD)

If the C52PUB bit in SDIO_MODE is set to 1 during a sequence of multiple block write because of CMD53, CMD52 is not issued until SD_BUF becomes empty. For this reason, set the C52PUB bit after suspending writing to SD_BUF by using one of the following procedures, as appropriate:

(a) When DMA transfer is not in use

1. Before setting the C52PUB bit, suspend writing to SD_BUF by making the setting in SD_INFO2 to disable BWE interrupts.
2. Set the C52PUB bit in SDIO_MODE to 1 (so that CMD52 is issued when SD_BUF becomes empty).
3. After the RSPEND interrupt processing in SD_INFO1 because the issuing of CMD52 is completed, restart writing to SD_BUF by making the setting in SD_INFO2 to enable BWE interrupts.

(b) When DMA transfer is in use

1. Every time DMA transfer of the value set in SD_SIZE × n blocks (where n = 1, 2,…) proceeds, suspend writing to SD_BUF by DMA transfer before the C52PUB bit is set.
2. Set the C52PUB bit in SDIO_MODE to 1 (so that CMD52 is issued when SD_BUF becomes empty).
3. After the RSPEND interrupt processing in SD_INFO1 because the issuing of CMD52 is completed, restart writing to SD_BUF by DMA transfer.

34.4.5 Notes on SD_CLK_CTRL Register Settings (SD/MMC)

When the SD_CLK_CTRLEN bit in SD_INFO2 is 0, SD_CLK_CTRL cannot be written to. Before writing to SD_CLK_CTRL, you must check that the SD_CLK_CTRLEN bit in SD_INFO2 is 1.

34.4.6 Specification Limitations

1. The Suspend/Resume operation of the SDIO is not supported.
2. The SPI bus is not supported. (SD/MMC)
3. The shared bus and 8-bit SD bus of the embedded SDIO are not supported.
4. Stream transfer of MMC is not supported.
5. High Priority Interrupt (HPI) of MMC is not supported.
6. Boot Operation/Alternative Boot Operation of MMC is not supported.
7. Open-ended multiple block transfer of MMC is not supported.

34.4.7 STP Bit Setting during Multiple Block Read (SD/MMC)

During execution of multiple block read with automatic CMD12 execution by setting the SEC bit in SD_STOP to 1, even if the STP bit in SD_STOP is set to 1 to forcibly stop the execution, the command sequence might not stop depending on the timing of setting the STP bit.

To avoid this, when setting the STP bit in SD_STOP to 1 during multiple block transfer, clear the SEC bit in SD_STOP to 0 at the same time. (Even when the SD_CLK_CTRLEN bit in SD_INFO2 is 0, change the SEC bit from 1 to 0.)

When the command sequence does not stop because the SEC bit was not cleared to 0, the command sequence can be stopped by clearing the SDRST bit in SOFT_RST to 0.

When forcibly terminating the CMD53 multiple block transfer through the IOABT bit in SDIO_MODE, you must leave the SEC bit in SD_STOP as 1.

34.4.8 Register Setting Notes

1. All registers in section 34.2. Register Descriptions are accessed in 32-bit access-only.
2. When setting registers, set them after the I/O Port Register setting.

34.4.9 Module-stop function

SDHI operation can be disabled or enabled using Module Stop Control Register C (MSTPCRC). The SDHI module is initially stopped after reset. Releasing the module-stop state enables access to the registers. For details, see section 10, Low Power Modes.

35. Cyclic Redundancy Check (CRC)

35.1 Overview

The Cyclic Redundancy Check (CRC) calculator generates CRC codes to detect errors in the data. The bit order of CRC calculation results can be switched for LSB-first or MSB-first communication. Additionally, various CRC-generation polynomials are available. The snoop function allows monitoring reads from and writes to specific addresses. This function is useful in applications that require CRC code to be generated automatically in certain events, such as monitoring writes to the serial transmit buffer and reads from the serial receive buffer.

Table 35.1 lists the CRC calculator specifications and Figure 35.1 shows a block diagram.

Table 35.1 CRC calculator specifications

Item	Description	
Data size	8-bit	32-bit
Data for CRC calculation*1	CRC code generated for data in 8n-bit units (where n is a natural number)	CRC code generated for data in 32n-bit units (where n is a natural number)
CRC processor unit	Operation executed on 8 bits in parallel	Operation executed on 32 bits in parallel
CRC generating polynomial	One of three generating polynomials that is selectable: [8-bit CRC] • $X^8 + X^2 + X + 1$ (CRC-8) [16-bit CRC] • $X^{16} + X^{15} + X^2 + 1$ (CRC-16) • $X^{16} + X^{12} + X^5 + 1$ (CRC-CCITT)	One of two generating polynomials that is selectable: [32-bit CRC] • $X^{32} + X^{26} + X^{23} + X^{22} + X^{16} + X^{12} + X^{11} + X^{10} + X^8 + X^7 + X^5 + X^4 + X^2 + X + 1$ (CRC-32) • $X^{32} + X^{28} + X^{27} + X^{26} + X^{25} + X^{23} + X^{22} + X^{20} + X^{19} + X^{18} + X^{14} + X^{13} + X^{11} + X^{10} + X^9 + X^8 + X^6 + 1$ (CRC-32C)
CRC calculation switching	The bit order of CRC calculation results can be switched for LSB-first or MSB-first communication	
Module-stop function	Module-stop state can be set to reduce power consumption	
CRC snoop	Monitor reads from and writes to a certain register address	
TrustZone Filter	Security and Privilege attribution can be set	

Note 1. This function cannot divide data used in CRC calculations. Write data in 8-bit or 32-bit units.

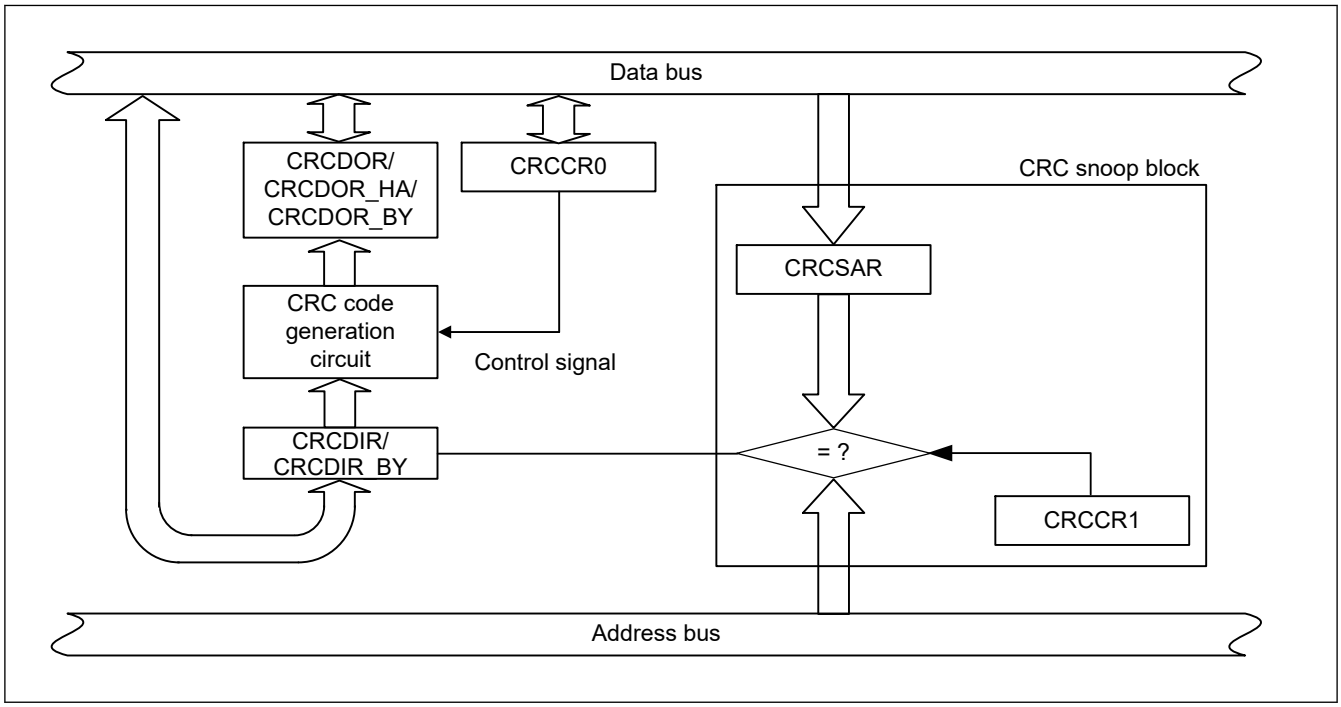

Figure 35.1 CRC calculator block diagram

35.2 Register Descriptions

35.2.1 CRCCR0 : CRC Control Register 0

Base address: CRC = 0x4031_0000
CRC_NS = 0x5031_0000

Offset address: 0x00

Bit position:	7	6	5	4	3	2	1	0
Bit field:	DORCLR	LMS	—	—	—	GPS[2:0]		
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
2:0	GPS[2:0]	CRC Generating Polynomial Switching 0 0 1: 8-bit CRC-8 ($X^8 + X^2 + X + 1$) 0 1 0: 16-bit CRC-16 ($X^{16} + X^{15} + X^2 + 1$) 0 1 1: 16-bit CRC-CCITT ($X^{16} + X^{12} + X^5 + 1$) 1 0 0: 32-bit CRC-32 ($X^{32} + X^{26} + X^{23} + X^{22} + X^{16} + X^{12} + X^{11} + X^{10} + X^8 + X^7 + X^5 + X^4 + X^2 + X + 1$) 1 0 1: 32-bit CRC-32C ($X^{32} + X^{28} + X^{27} + X^{26} + X^{25} + X^{23} + X^{22} + X^{20} + X^{19} + X^{18} + X^{14} + X^{13} + X^{11} + X^{10} + X^9 + X^8 + X^6 + 1$) Others: No calculation is executed	R/W
5:3	—	These bits are read as 0. The write value should be 0.	R/W
6	LMS	CRC Calculation Switching 0: Generate CRC code for LSB-first communication 1: Generate CRC code for MSB-first communication	R/W
7	DORCLR	CRCDOR/CRCDOR_HA/CRCDOR_BY Register Clear 0: No effect 1: Clear the CRCDOR/CRCDOR_HA/CRCDOR_BY register	W

Note: S-TYPE3, P-TYPE3

GPS[2:0] bits (CRC Generating Polynomial Switching)

The GPS[2:0] bits select the CRC generating polynomial.

LMS bit (CRC Calculation Switching)

The LMS bit selects the bit order of generated CRC code. Transmit the lower byte of the CRC code first for LSB-first communication and the upper byte first for MSB-first communication. For details on transmitting and receiving CRC code, see section 35.3. Operation.

DORCLR bit (CRCDOR/CRCDOR_HA/CRCDOR_BY Register Clear)

Write 1 to the DORCLR bit to set the CRCDOR/CRCDOR_HA/CRCDOR_BY register to 0x00000000. This bit is read as 0. Only 1 can be written to it.

35.2.2 CRCCR1 : CRC Control Register 1

Base address: CRC = 0x4031_0000
CRC_NS = 0x5031_0000

Offset address: 0x01

Bit position:	7	6	5	4	3	2	1	0
Bit field:	CRCSEN	CRCSWR	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
5:0	—	These bits are read as 0. The write value should be 0.	R/W
6	CRCSWR	Snoop-On-Write/Read Switch 0: Snoop-on-read 1: Snoop-on-write	R/W
7	CRCSEN	Snoop Enable 0: Disabled 1: Enabled	R/W

Note: S-TYPE3, P-TYPE3

CRCSWR bit (Snoop-On-Write/Read Switch)

The CRCSWR bit selects the direction of access in the CRC snoop function.

When this bit is set to 0 (initial value), the CRC snoop operation to read a specific register is enabled. Similarly, when this bit is set to 1, the CRC snoop operation to write a specific register is enabled.

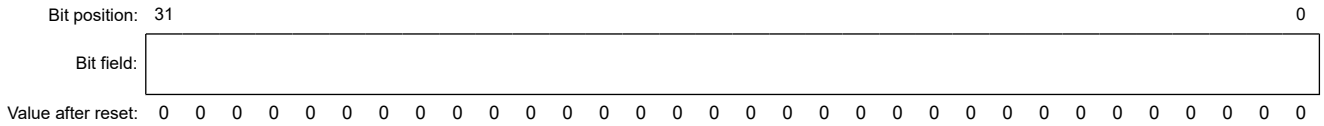
CRCSEN bit (Snoop Enable)

When the CRCSEN bit is set to 1, the CRC snoop operation is enabled. When this bit is set to 0, the CRC snoop operation is disabled.

35.2.3 CRCDIR/CRCDIR_BY : CRC Data Input Register

Base address: CRC = 0x4031_0000
CRC_NS = 0x5031_0000

Offset address: 0x04



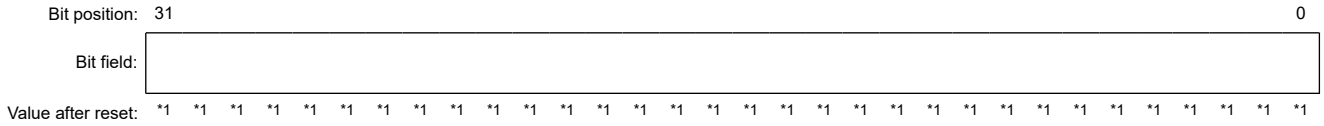
Bit	Symbol	Function	R/W
31:0	n/a	CRC input data The CRCDIR register is a 32-bit read/write register to write data for CRC-32 or CRC-32C calculation. The CRCDIR_BY (CRCDIR[31:24]) is an 8-bit read/write register to write data for CRC-8, CRC-16, or CRC-CCITT calculation.	R/W

Note: S-TYPE3, P-TYPE3

35.2.4 CRCDOR/CRCDOR_HA/CRCDOR_BY : CRC Data Output Register

Base address: CRC = 0x4031_0000
CRC_NS = 0x5031_0000

Offset address: 0x08



Bit	Symbol	Function	R/W
31:0	n/a	CRC output data The CRCDOR register is a 32-bit read/write register for CRC-32 or CRC-32C calculation. The CRCDOR_HA (CRCDOR[31:16]) register is a 16-bit read/write register for CRC-16 or CRC-CCITT calculation. The CRCDOR_BY (CRCDOR[31:24]) register is an 8-bit read/write register for CRC-8 calculation. Rewrite the CRCDOR/CRCDOR_HA/CRCDOR_BY register to perform the calculations using a value other than the initial value. Data written to the CRCDIR/CRCDIR_BY register is CRC calculated and the result is stored in the CRCDOR/CRCDOR_HA/CRCDOR_BY register. If the CRC code is calculated following the transferred data and the result is 0x00000000, there is no CRC error.	R/W

Note: S-TYPE3, P-TYPE3
Note 1. If FSBL is executed in reset, then value after reset is 1, if FSBL is skipped in reset, then values after reset is 0.

35.2.5 CRCSAR : Snoop Address Register

Base address: CRC = 0x4031_0000
CRC_NS = 0x5031_0000

Offset address: 0x0C

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	CRCSA[13:0]													
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
13:0	CRCSA[13:0]	Register Snoop Address These bits store the TDR or RDR address in the SCI module to snoop	R/W
15:14	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE3, P-TYPE3

CRCSA[13:0] bits (Register Snoop Address)

The CRCSA[13:0] bits specify the lower address 14 bits of the register monitored by the CRC snoop operation.

Only the following addresses can be used for the CRCSA[13:0] bits:

[secure region address]

- 0x4035_8004: SCI0.TDR, 0x4035_8000: SCI0.RDR
- 0x4035_8104: SCI1.TDR, 0x4035_8100: SCI1.RDR
- 0x4035_8204: SCI2.TDR, 0x4035_8200: SCI2.RDR
- 0x4035_8304: SCI3.TDR, 0x4035_8300: SCI3.RDR
- 0x4035_8404: SCI4.TDR, 0x4035_8400: SCI4.RDR
- 0x4035_8904: SCI9.TDR, 0x4035_8900: SCI9.RDR

[non-secure region address]

- 0x5035_8004: SCI0.TDR, 0x5035_8000: SCI0.RDR
- 0x5035_8104: SCI1.TDR, 0x5035_8100: SCI1.RDR
- 0x5035_8204: SCI2.TDR, 0x5035_8200: SCI2.RDR
- 0x5035_8304: SCI3.TDR, 0x5035_8300: SCI3.RDR
- 0x5035_8404: SCI4.TDR, 0x5035_8400: SCI4.RDR
- 0x5035_8904: SCI9.TDR, 0x5035_8900: SCI9.RDR

35.3 Operation

35.3.1 Basic Operation

The CRC calculator generates CRC codes for use in LSB-first or MSB-first transfer.

The following examples show CRC code generation for input data (0xF0) using the 16-bit CRC-CCITT generating polynomial ($X^{16} + X^{12} + X^5 + 1$). In these examples, the value of the CRC Data Output Register (CRCDOR_HA) is cleared before CRC calculation.

When an 8-bit CRC (with the polynomial $X^8 + X^2 + X + 1$) is in use, the valid bits of the CRC code are obtained in CRCDOR_BY. When a 32-bit CRC is in use, the valid bits of the CRC code are obtained in CRCDOR.

Figure 35.2 and Figure 35.3 show the LSB-first and MSB-first data transmission examples respectively. Figure 35.4 and Figure 35.5 show the LSB-first and MSB-first data reception examples.

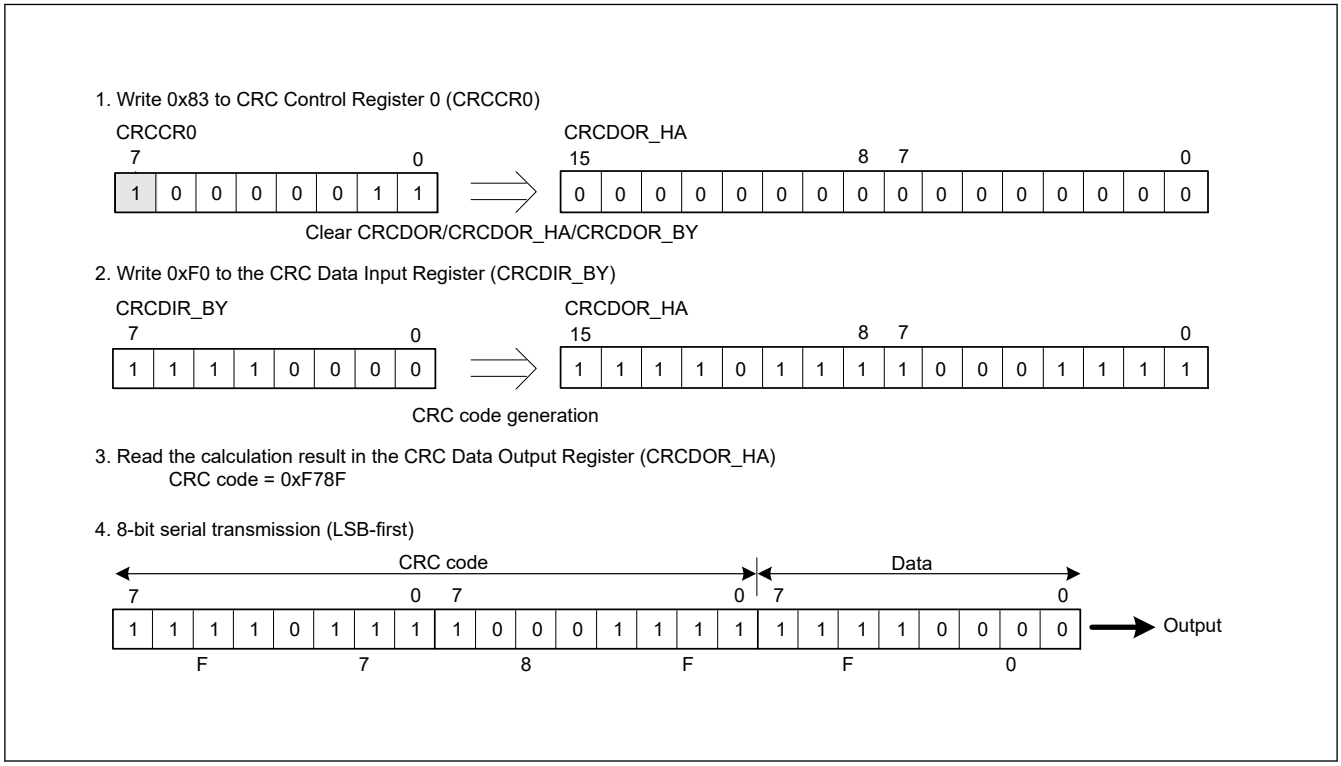


Figure 35.2 LSB-first data transmission

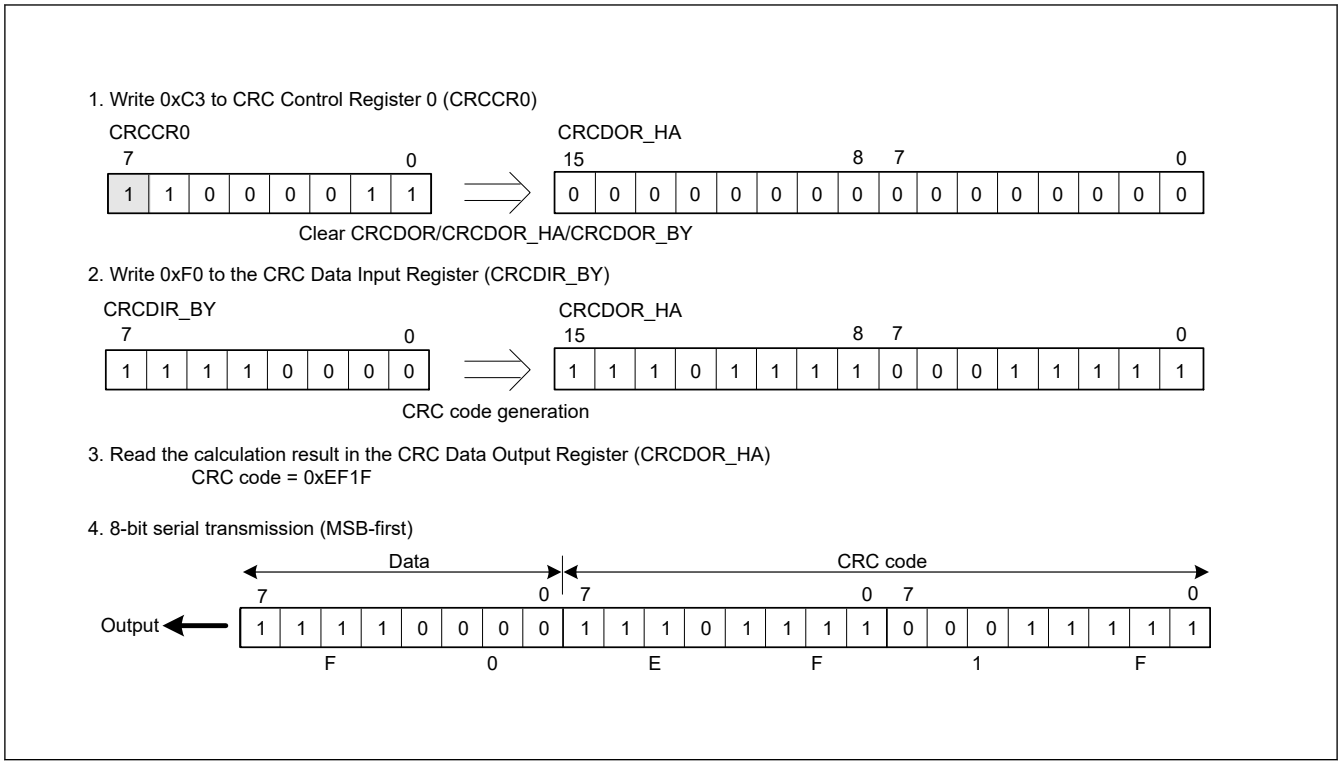

Figure 35.3 MSB-first data transmission

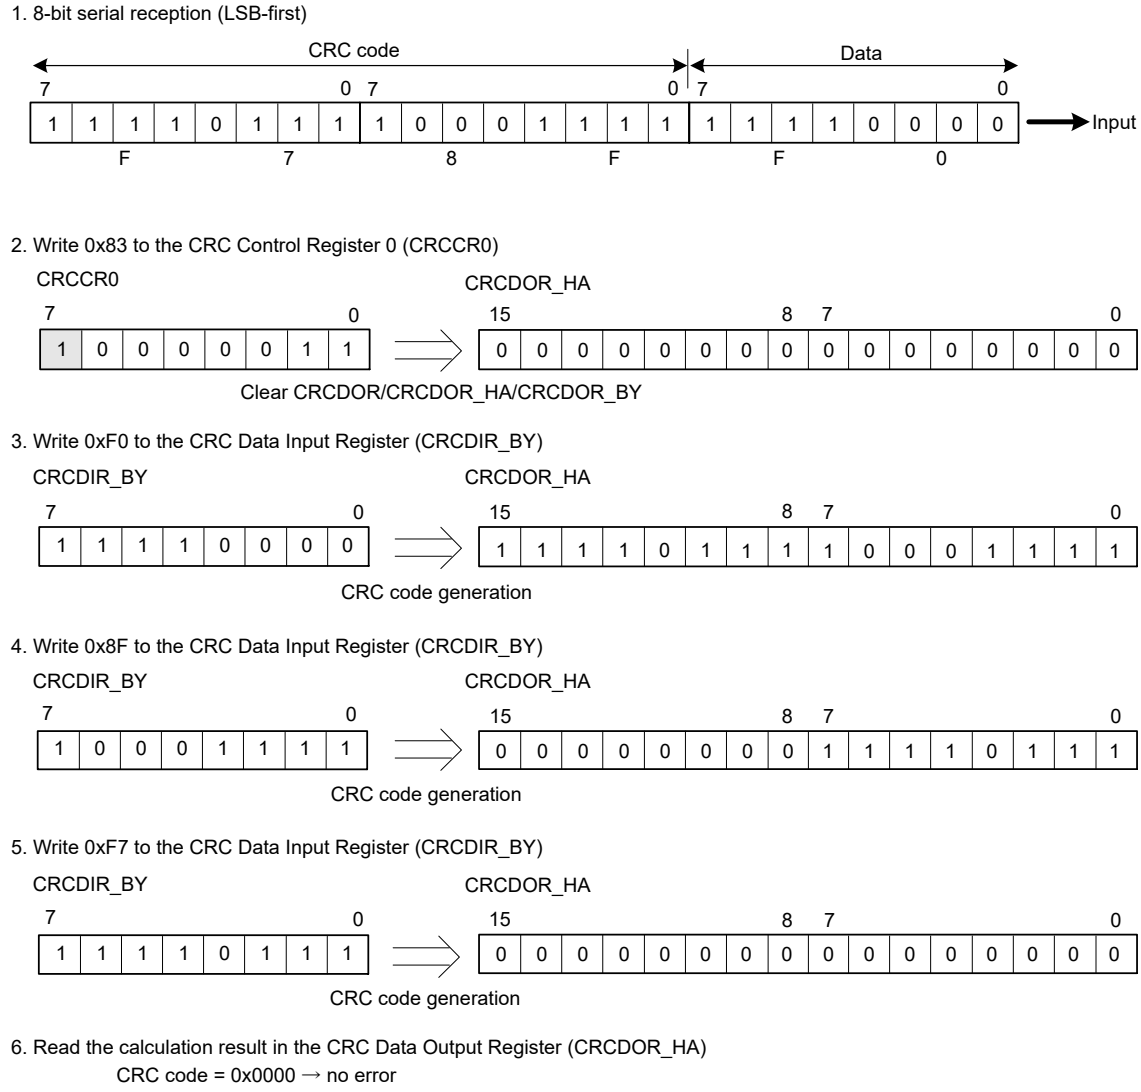

Figure 35.4 LSB-first data reception

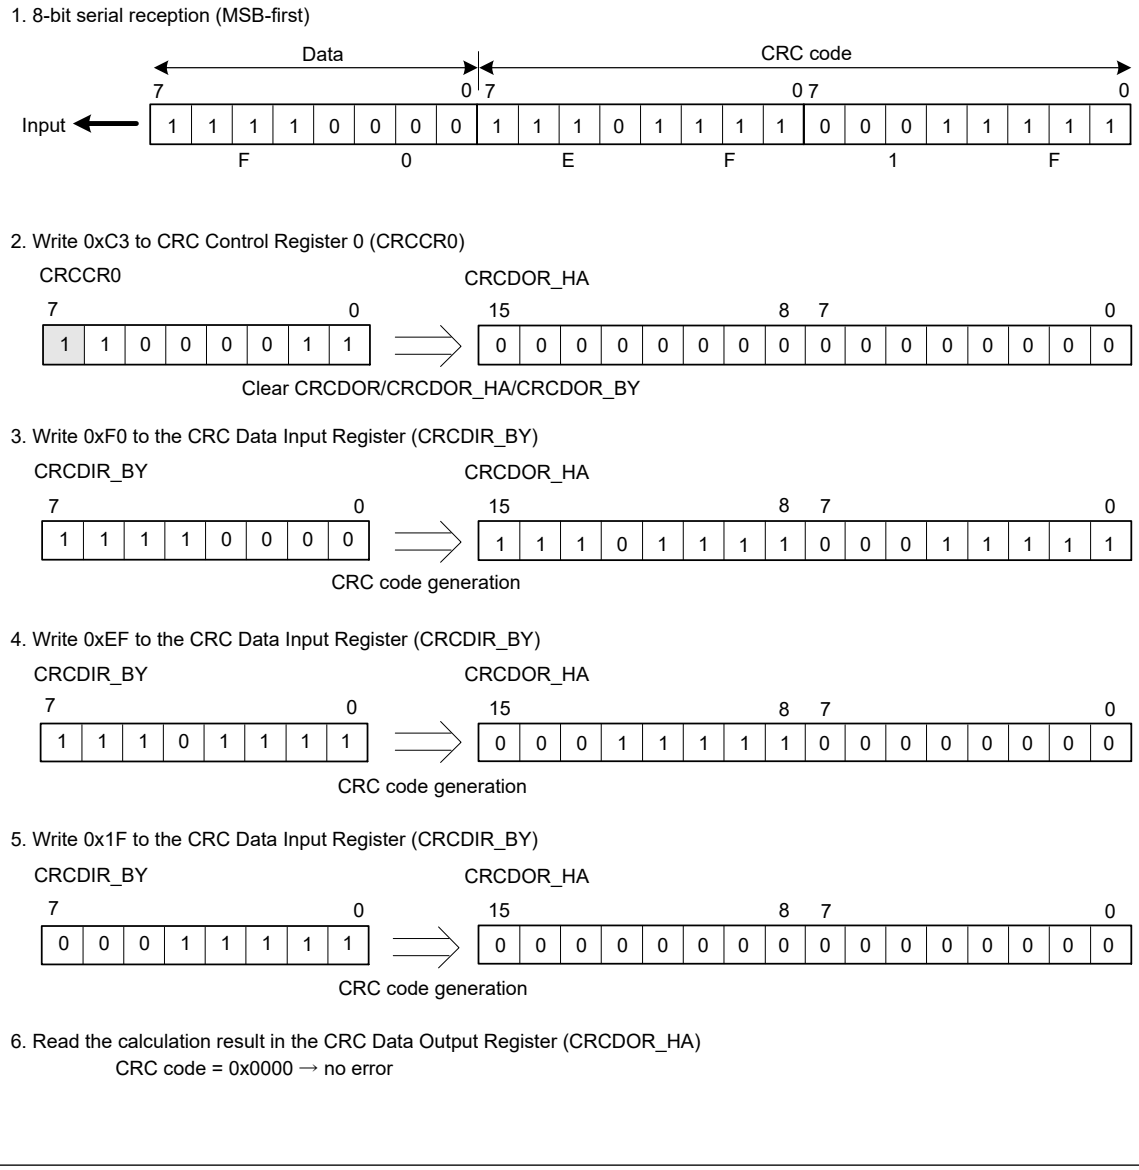

Figure 35.5 MSB-first data reception

35.3.2 CRC Snoop Function

The CRC snoop function monitors reads from and writes to a specific register and performs CRC calculation on the monitored data automatically. Because the CRC snoop function recognizes writes to and reads from a specific register address as a trigger to automatically perform CRC calculation, there is no need to write data to the CRCDIR register. All I/O register specified in the section 35.2.5. CRCSAR : Snoop Address Register are subject to the CRC snoop. The CRC snoop is useful in monitoring writes to the SCIn.TDR (n = 0 to 4, 9) register, and reads from the SCIn.RDR (n = 0 to 4, 9) register.

To use this function, write the lower address 14 bits of a specific register to bits CRCSA13 to CRCSA0 in the CRCSAR register, and set CRCSEN bit in the CRCCR1 register to 1. Then, set the CRCSWR bit in the CRCCR1 register to 1 to enable snooping on writes to the target register, or set the CRCSWR bit in the CRCCR1 register to 0 to enable snooping on reads from the target register. It is possible that access to a target I/O register may be executed before the CRCSWR bit write completed. In this case, the data is not stored in the CRCDIR register. To avoid this issue, before accessing I/O register, read back the CRCSWR bit that was written to confirm that the write completed.

When both the CRCSEN and CRCSWR bits are set to 1, and data is written to a target register in a bus master module such as the CPU, DMAC, and DTC, the CRC calculator stores the data in the CRCDIR register and performs CRC calculation. Similarly, when the CRCSEN bit is set to 1, CRCSWR bit to 0, and data is read from a target register in a bus master

module such as the CPU, DMAC, and DTC, the CRC calculator stores the data in the CRCDIR register and performs CRC calculations.

When the CRC code is generated by using CRC-8, CRC-16, and CRC-CCITT generating polynomial, the target register is accessed in 1 byte (8 bits). RDR_BY and TDR_LL should be used to access RDR and TDR. Similarly, when the CRC code is generated by using CRC-32 and CRC-32C generating polynomial, the target register is accessed in words (32 bits). Note that for RDR and TDR, CRC codes are generated that contain data other than RDAT and TDAT.

When CRC is marked as secure by PSARC.PSARC1 bit, the CRC snoop function is available for secure access to the specified I/O registers. When CRC is marked as non-secure by PSARC.PSARC1 bit, the CRC snoop function is available for non-secure access to the specified I/O registers.

35.4 Usage Notes

35.4.1 Settings for the Module-Stop State

The Module Stop Control Register C (MSTPCRC) can enable or disable CRC calculator operation. The CRC calculator is initially stopped after a reset. Releasing the module-stop state enables access to the registers. For details, see section 10, Low Power Modes.

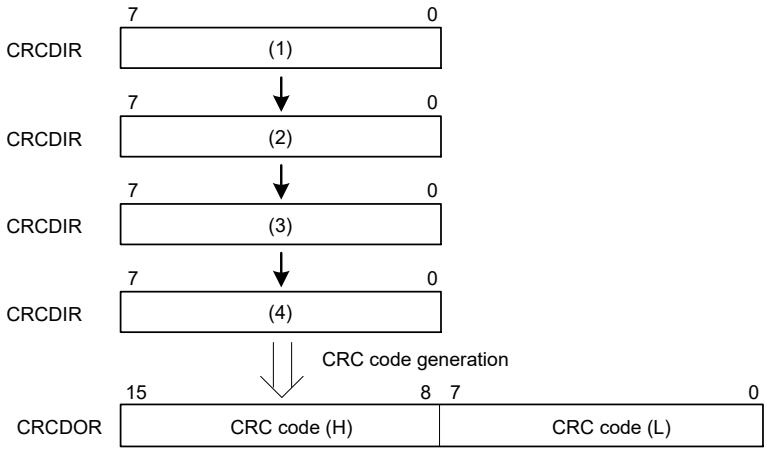
35.4.2 Note on Transmission

The transmission sequence for the CRC code differs based on whether the transmission is LSB-first or MSB-first. Figure 35.6 shows an LSB-first and MSB-first data transmission.

When transmitting 32-bit data (for operation executed on 8 bits in parallel)

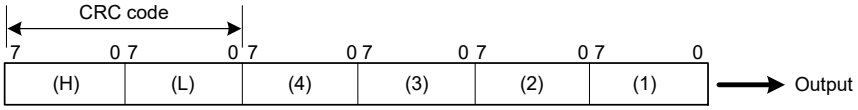
1. CRC code

After specifying the method for generation calculation, write data to CRCDIR in order of (1), (2), (3), and (4).



2. Transmit data

(i) When transmission is LSB-first



(ii) When transmission is MSB-first

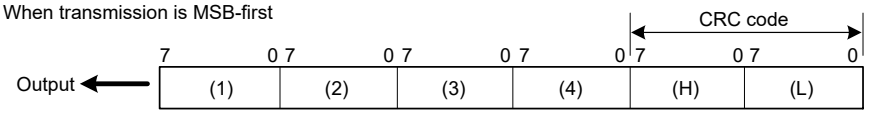


Figure 35.6 LSB-first and MSB-first data transmission

36. Boundary Scan

36.1 Overview

The boundary scan function provides a serial I/O interface based on the JTAG (Joint Test Action Group), IEEE Std.1149.1, and IEEE Standard Test Access Port and Boundary Scan Architecture. Table 36.1 lists the boundary scan specifications, Figure 36.1 shows a block diagram, and Table 36.2 lists the I/O pins.

Table 36.1 Boundary scan specifications

Parameter	Specifications
Execution condition	Boundary scan must be executed when the RES pin is driven low.
Test modes	• BYPASS mode • EXTEST mode • SAMPLE/PRELOAD mode • CLAMP mode • HIGHZ mode • IDCODE mode

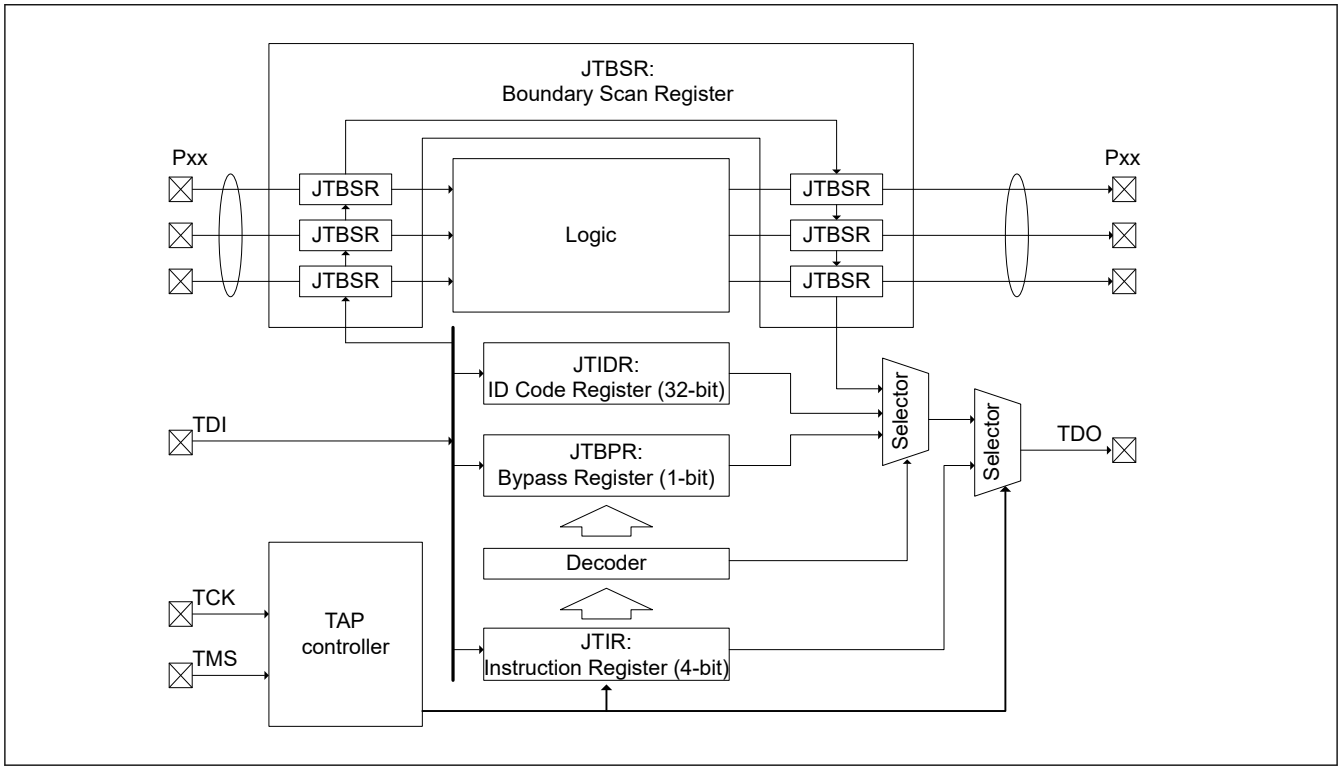

Figure 36.1 Boundary scan function block diagram

Table 36.2 Boundary scan I/O pins

Pin name	I/O	Description
TCK	Input	Test clock input pin Clock signal for boundary scan. The input clock duty cycle is 50% when the boundary scan function is used.
TMS	Input	Test mode select pin
TDI	Input	Test data input pin
TDO	Output	Test data output pin

Note: This device does not support the TRST pin for the JTAG interface.

36.2 Register Descriptions

Table 36.3 lists the boundary scan registers.

Table 36.3 Boundary scan registers

Register name	Symbol	Value after reset
Instruction Register	JTIR	0xE
ID Code Register	JTIDR	0x0841_9447
Bypass Register	JTBPR	Undefined
Boundary Scan Register	JTBSR	Undefined

Usage notes for the boundary scan registers:

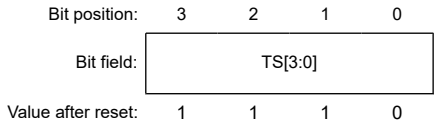
- Instructions can be input to the Instruction Register (JTIR) through the TDI pin by serial transfer.
- The Bypass Register (JTBPR), which is a 1-bit register, is connected between the TDI and TDO pins in BYPASS mode.
- The Boundary Scan Register (JTBSR), which is configured according to the BSDL description, is connected between the TDI and TDO pins when test data is being shifted in.

Table 36.4 shows the availability of serial transfer for the registers.

Table 36.4 Serial transfer for registers

Register name	Serial input	Serial output
Instruction Register (JTIR)	Available	Available
ID Code Register (JTIDR)	Available	Available
Bypass Register (JTBPR)	Available	Available
Boundary Scan Register (JTBSR)	Available	Available

36.2.1 JTIR : Instruction Register

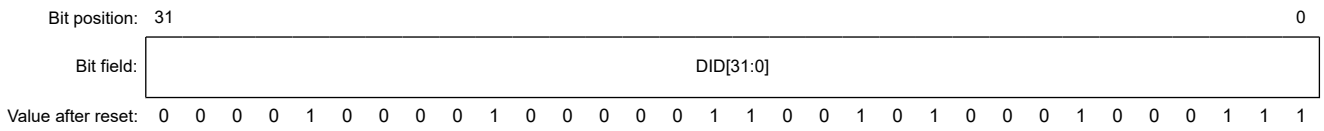


Bit	Symbol	Function	R/W
3:0	TS[3:0]	Test Bit Set The command configuration for these bits	—

TS[3:0]	Instruction
0x0	EXTEST
0x1	SAMPLE/PRELOAD
0x3	IDCODE (Renesas code)
0x5	CLAMP
0x6	HIGHZ
0xF	BYPASS
Others	Reserved

JTAG instructions can be transferred to the JTIR register by serial input from the TDI pin. The JTIR register is initialized when a power-on reset occurs, or when the TAP controller is in the Test-Logic-Reset state.

36.2.2 JTIDR : ID Code Register



Bit	Symbol	Function	R/W
31:0	DID[31:0]	Device ID These bits store the fixed value that indicates the device IDCODE (0x0841_9447).	—

The JTIDR register data is output from the TDO pin when the IDCODE instruction is executed. After a reset release, the DID[31:0] of JTIDR changes into the Arm® debug code. See the *Arm® CoreSight™ SoC-400 Technical Reference Manual* (ARM DDI 0480F).

36.2.3 JTBPR : Bypass Register

The JTBPR register is a 1-bit register and is connected between the TDI and TDO pins when the JTIR register is set to BYPASS mode. The JTBPR register cannot be read from or written to by the CPU.

36.2.4 JTBSR : Boundary Scan Register

The JTBSR register is a shift register for controlling the external input and output pins of this device, and is distributed across the pads. To apply the JTBSR register in boundary-scan testing, issue the EXTEST, SAMPLE/PRELOAD, CLAMP and HIGHZ instructions. The BSDL file describes the associations between the JTBSR register bits and the pins of this device. The value after reset is undefined.

36.3 Operation

During a reset, the JTAG ports, TCK, TMS, TDI and TDO are assigned as default pin functions. The TCK, TMS and TDI pins are pulled up by the pull-up resistors. Boundary scan testing can be executed after the setup time elapses when POR is negated and RES is driven low.

36.3.1 TAP Controller

Figure 36.2 shows the state transition diagram of the TAP controller. All transitions are controlled by the TMS signal.

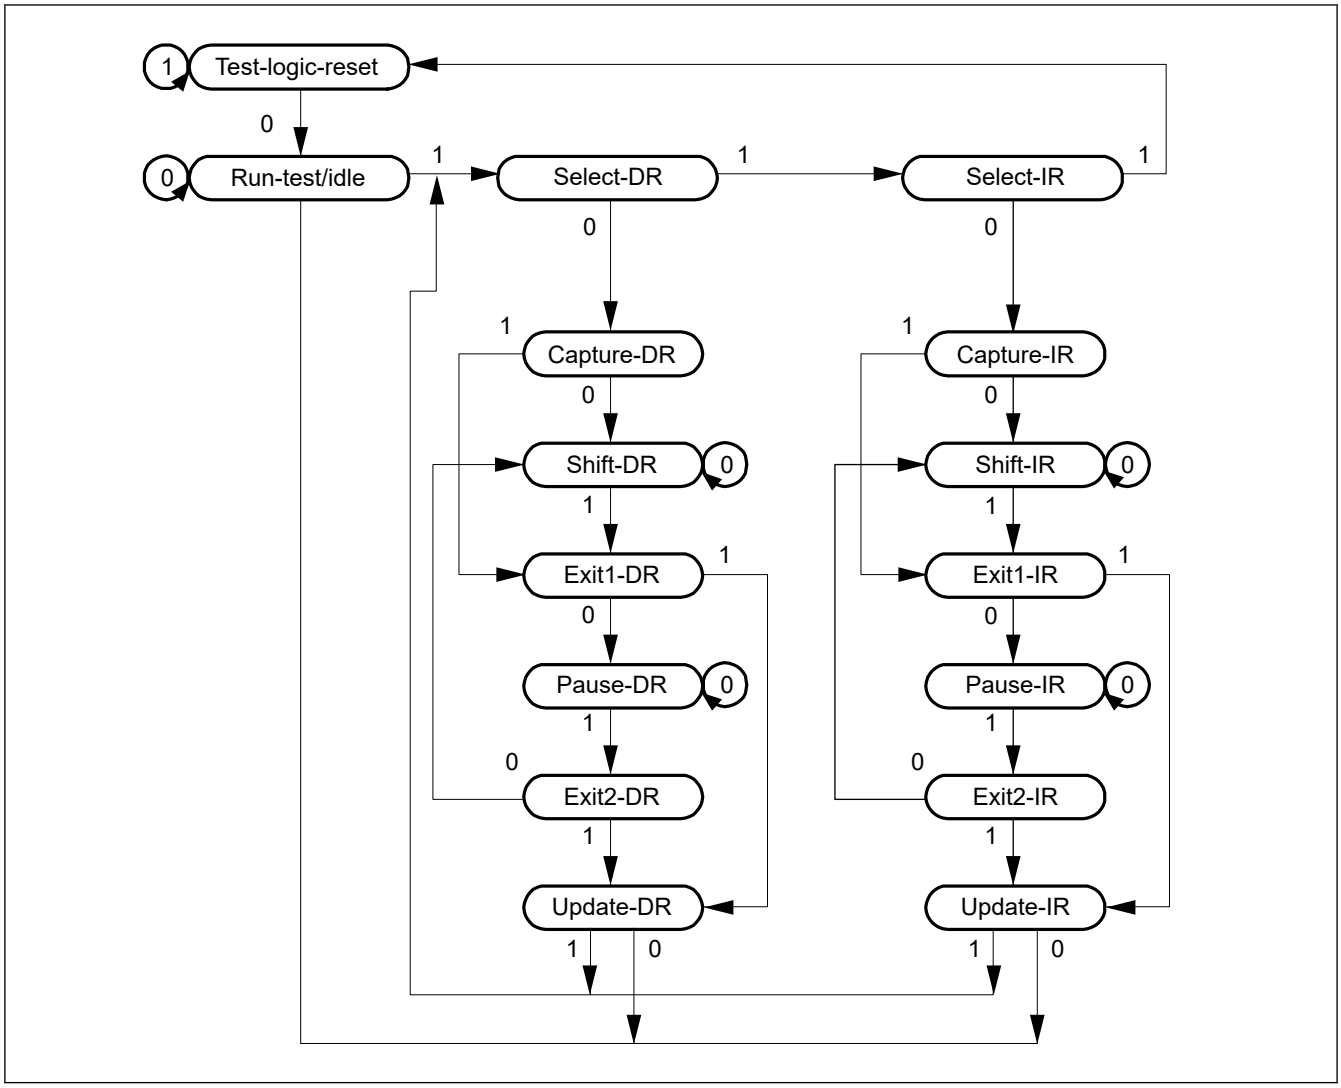


Figure 36.2 State transition diagram of TAP controller

36.3.2 Commands

(1) BYPASS

The BYPASS instruction drives the Bypass Register (JTBPR). This instruction shortens the shift path, facilitating the transfer of serial data to other LSIs on a printed circuit board at higher speeds. While this instruction is being executed, the test circuit has no effect on the system circuits.

The JTBPR register is connected between the TDI and TDO pins. Bypass operation is initiated from the Shift-DR operation. The TDO is low in the first clock cycle in the Shift-DR state. In the subsequent clock cycles, values input to the TDI pin are output from the TDO pin.

(2) EXTEST

The EXTEST instruction is used to test external circuits when this device is installed on the printed circuit board. If this instruction is executed, output pins are used to output test data (specified in the SAMPLE/PRELOAD instruction) from the Boundary Scan Register (JTBSR) to the other devices, and input pins are used to input the test result.

(3) SAMPLE/PRELOAD

The SAMPLE/PRELOAD instruction is used to input data from the internal circuits of this device to the JTBSR register, output data from the scan path, and reload the data to the scan path. While this instruction is executed, input signals are directly input to this device and output signals are also directly output to the external circuits. This device system circuit is not affected by this instruction.

In SAMPLE operation, the JTBSR register latches a snapshot of the data transferred from the input pins to the internal circuit or data transferred from the internal circuit to the output pins. The latched data is read from the scan path. The JTBSR register latches the data snapshot on the rising edge of the TCK pin in the Capture-DR state. The data snapshot is only transferred from the internal circuit to the output pins during a reset.

In PRELOAD operation, the initial value is written from the scan path to the parallel output latch of the JTBSR register prior to the EXTEST instruction execution. If EXTEST is executed without executing this PRELOAD operation, undefined values are output from the beginning to the end (transfer to the output latch) of the EXTEST sequence. (In the EXTEST instruction, output parallel latches are always output to the output pins.)

(4) IDCODE

When the IDCODE instruction is selected, the ID Code Register (JTIDR) value is output to the TDO pin in the Shift-DR state of the TAP controller. In this case, the JTIDR register value is output LSB-first. During this instruction execution, the test circuit does not affect the system circuit.

(5) CLAMP

When the CLAMP instruction is selected, output pins output the JTBSR register value that was specified in the SAMPLE/PRELOAD instruction in advance. While the CLAMP instruction is selected, the status of the JTBSR register is maintained regardless of the TAP controller state.

The JTBPR register is connected between the TDI and TDO pins, leading to the same operation as when the BYPASS instruction is selected.

(6) HIGHZ

When the HIGHZ instruction is selected, all output pins enter high-impedance state. While the HIGHZ instruction is selected, the JTBSR register is maintained regardless of the state of the TAP controller.

The JTBPR register is connected between the TDI and TDO pins, leading to the same operation as when the BYPASS instruction is selected.

36.4 Usage Notes

The boundary scan function is subject to the following constraints:

- The boundary scan must be executed when the RES pin is driven low
- Serial data input/output is in LSB order, as shown in Figure 36.3

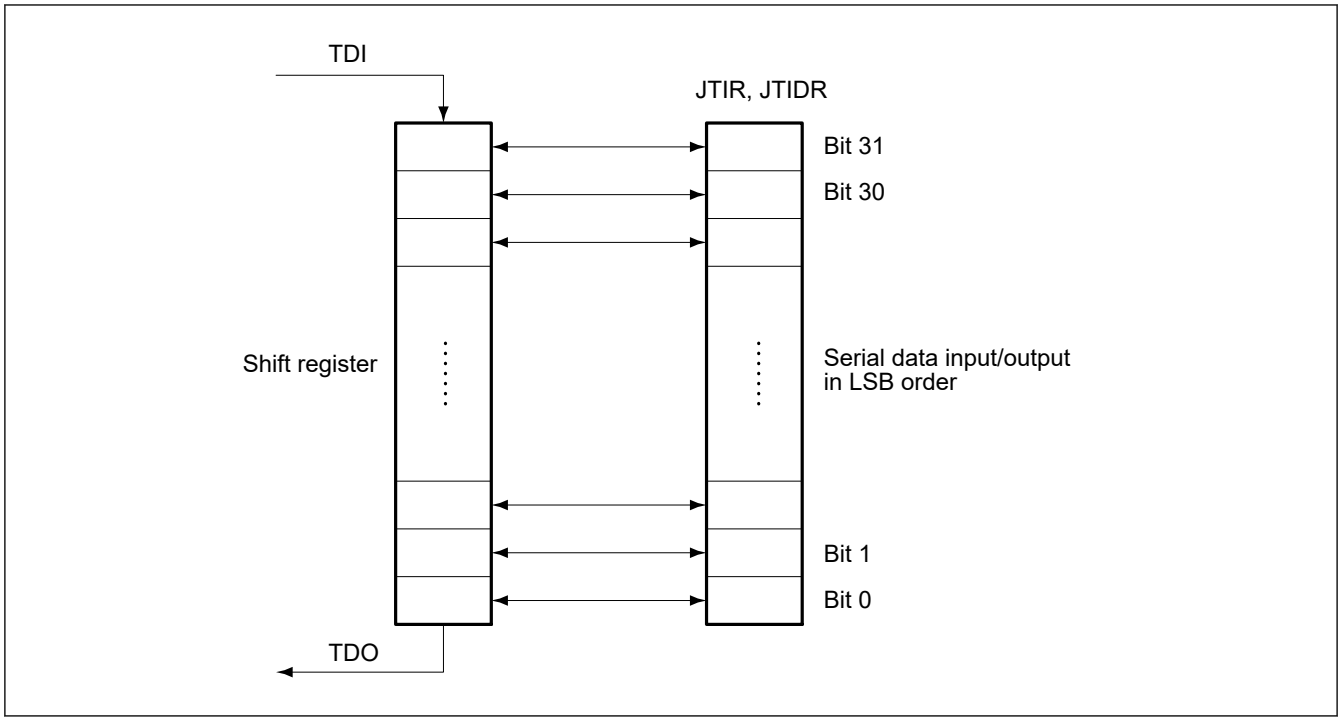

Figure 36.3 Serial data input/output

The following pins cannot be boundary-scanned:

- Power supply pins (VCC, VCC2, VCC_DCDC, VCL, VSS, VSS_DCDC, AVCC0, AVSS0, VCC_USB, VSS_USB)
- Analog reference pins (VREFH0, VREFL0, VREFH, VREFL)
- Clock pins (EXTAL, XTAL, XCIN, and XCOUT)
- Reset pin (RES)
- USBFS pin (USB_DP, USB_DM)
- The boundary-scan pins (TCK, TMS, TDI, and TDO).
- The switching regulator pin (VLO)

37. Security Features

37.1 Features

- Armv8-M TrustZone Technology
  - Implementation Defined Attribution Unit (IDAU) is implemented
  - Security Attribution Unit (SAU) is implemented
    - 8 regions
  - Master Security Attribution Unit (MSAU) is implemented (IDAU for master other than CPU)
  - Code flash
    - Up to 2 regions (secure/non-secure) in linear mode
    - Up to 4 regions (2 secure regions/2 non-secure regions) in dual mode
  - Data flash
    - Up to 2 regions (secure/non-secure)
  - SRAM
    - Up to 2 regions (secure/non-secure) per SRAM
  - Standby SRAM
    - Up to 2 regions (secure/non-secure)
  - Peripheral
    - Security attributes can be set individually for each unit/channel
  - CSC[*1]
    - CSC region is defined as non-secure
  - SDRAM[*1]
    - SDRAM region is defined as non-secure
- Privileged control
  - Access permissions for memory except Standby SRAM are controlled by MPU managed by the privileged code
  - Privilege attributes of Standby SRAM are controlled by the registers of each controller
  - Individual privileged or unprivileged attribution for each peripheral.
- Device lifecycle management
- Three debug levels
  - AL2: Non-secure and secure debug functions are enabled and accessible from the debugger
  - AL1: Only non-secure debug functions is enabled, and the debugger can access only defined non-secure debug accessible regions
  - AL0: No debug functions are available.
- Key injection
- Secure factory programming
  - Supports image programming in ciphertext format in an untrusted factory
- Secure boot
  - Verify the integrity and authenticity of image to be programmed
  - Verify the integrity and authenticity of the executable image by the immutable (ROM) First Stage Bootloader (FSBL) prior to executing the image.
- Cryptographic accelerator
  - See section 38, Renesas Secure IP (RSIP-E51A).

- Secure pin multiplexing
  - All I/O port pins can be configured individually as secure or non-secure
  - Peripheral pin function is valid when the security attribute of peripheral and I/O port match. See section 18, I/O Ports.

Note 1. There is no TrustZone filter in the external RAM and external device area. Therefore, even though these regions are marked as secure in the SAU settings, the non-secure masters except the CPU can access them.

37.2 Arm Security Features

37.2.1 Arm TrustZone Technology

Arm TrustZone technology divides the system and the application into secure and non-secure domains. A secure application can issue both secure and non-secure transactions, but a non-secure application can only issue non-secure transactions. Secure transactions can only access secure memory and resources, and non-secure transactions can only access non-secure memory and resources. Secure transactions can be issued only using secure region addresses and non-secure transactions can be issued only using non-secure region addresses. Figure 37.1shows the security attributes of transactions that can be issued by each master.

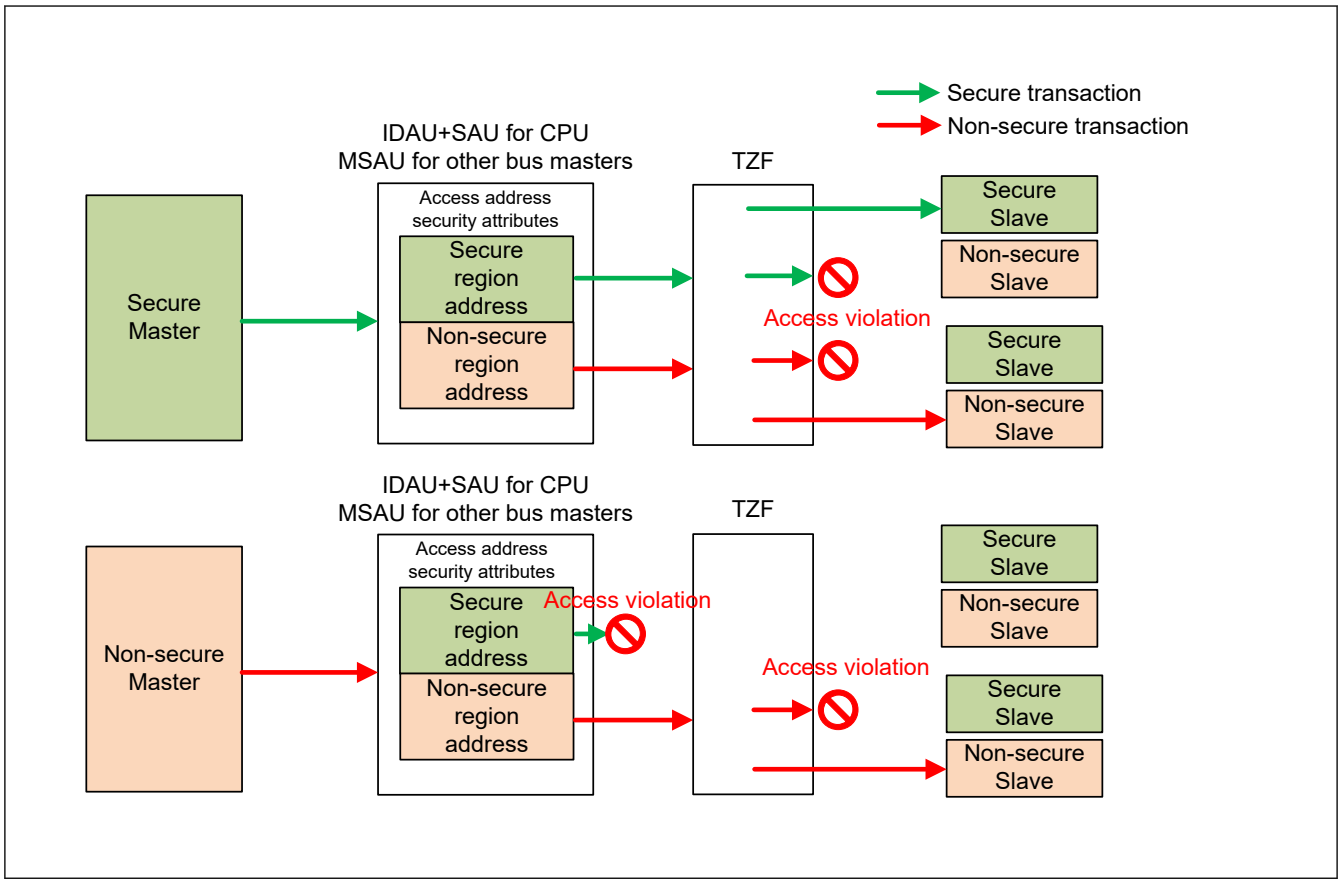

Figure 37.1 Transactions that can be issued by each master

For more details, see the *Arm® v8-M Architecture Reference Manual and Arm® Platform Security Architecture Trusted Base System Architecture for Arm®v8-M 1.0*.

37.2.2 Privileged Control

Systems and applications are divided into privileged and unprivileged domains. The CPU can limit or exclude access to some resources by executing code in privileged or unprivileged mode. Privileged mode can access both privileged and unprivileged domains, but unprivileged mode can access only the unprivileged domain.

For more details, see the *Arm® v8-M Architecture Reference Manual and Arm® Platform Security Architecture Trusted Base System Architecture for Arm®v8-M 1.0*.

37.2.3 Security Attribution

The TrustZone for Armv8.1-M implementation consists of the Security Attribution Unit (SAU) and Implementation Defined Attribution Unit (IDAU). The 4GB memory space is partitioned into Secure (S) and Non-secure (NS) memory regions. The Secure memory space is further divided into two types, Non-secure Callable (NSC) and Secure.

Note:
- S = Secure addresses are used for memory and peripherals that are only accessible by secure software or secure masters.
- NSC = A special type of secure location. This type of memory is the only type in which an Armv8.1-M processor permits to hold a Secure Gateway (SG) instruction that enables software to transition from Non-secure to Secure state.
- NS = Non-secure addresses are used for memory and peripherals accessible by all software running on the device.

37.2.3.1 Implementation Defined Attribution Unit (IDAU)

The IDAU defines the code, SRAM and peripheral region into the secure alias region and the non-secure alias region by the address bit [28]. The secure code region and secure SRAM region are assigned the NSC security attributes. The security map defined by IDAU is fixed in hardware and cannot be changed by software.

37.2.3.2 Master Security Attribution Unit (MSAU)

MSAU is IDAU that defines system-specific security address map for masters other than CPU. The MSAU defines secure and non-secure alias regions but does not define the Non-secure Callable (NSC) and region number. Masters other than the CPU can issue a security transaction using the secure alias address defined by MSAU. However, non-secure masters are prohibited from issuing secure transactions using an address in the secure alias region. Figure 37.2 shows the defined security map of IDAU and MSAU. The security map defined by MSAU is fixed in hardware and cannot be changed by software.

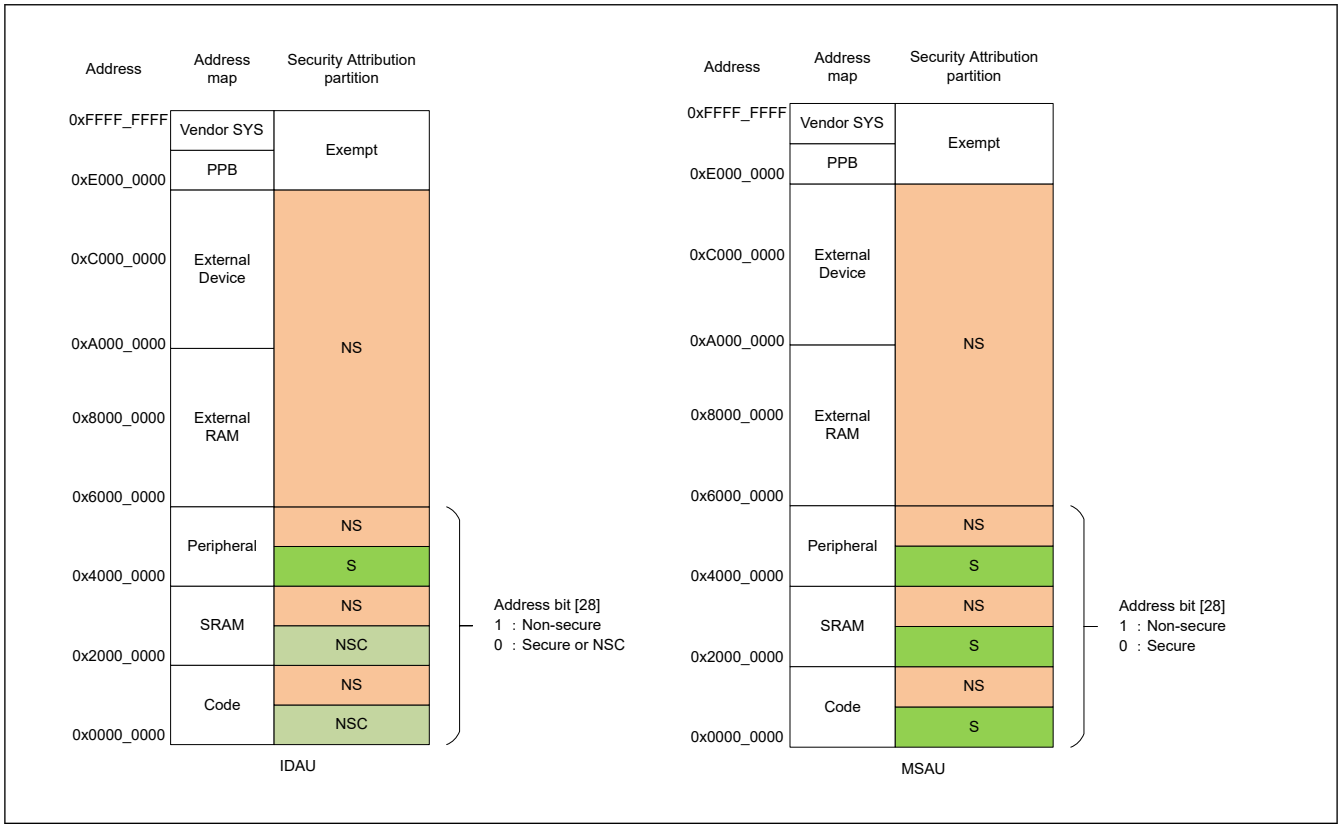

Figure 37.2 IDAU and MSAU defined security map

37.2.3.3 Secure Attribution Unit (SAU)

The SAU is a programmable unit that determines the security of an address. The SAU is programmable in the Secure state and has a programmers' model similar to the MPU. If an address maps to regions defined by both IDAU and SAU, the region of the highest security level is selected. Secure master can issue secure and non-secure transactions using the address of each security alias region. Non-secure master cannot issue secure transactions using the address of the secure alias region. Figure 37.3 shows the final determination of the address map security level.

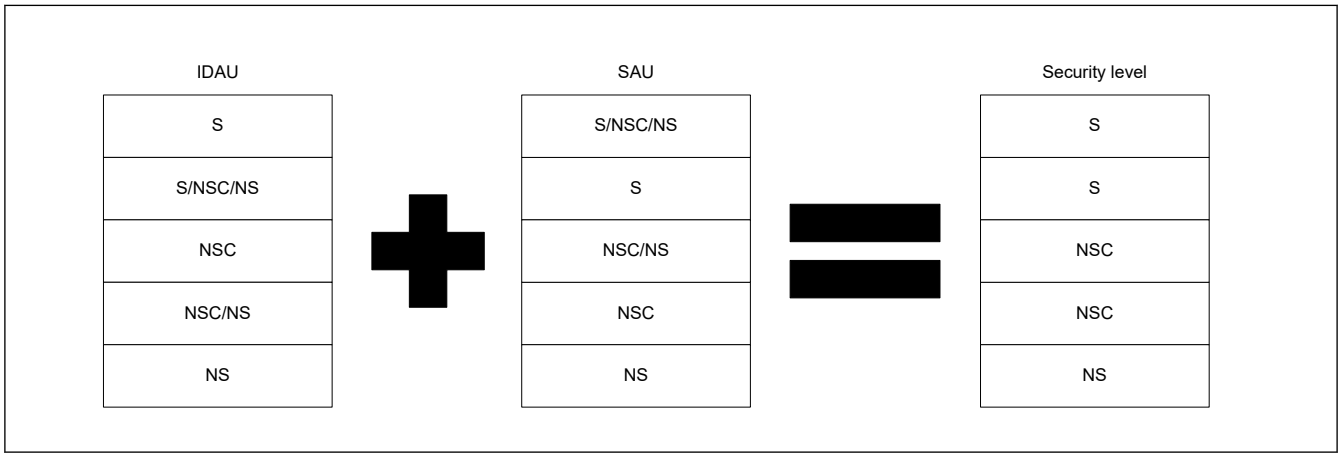

Figure 37.3 Final determination of address map security level

When using TrustZone to perform secure and non-secure region separation, SAU MUST be set according to the following.

The regions set as NS attribute in IDAU MUST be set to NS in the SAU as well. The regions set to NS attribute in IDAU are:

0x1000_0000 to 0x1FFF_FFFF (SAU Region 1 in Figure 37.4)

0x3000_0000 to 0x3FFF_FFFF (SAU Region 3 in Figure 37.4)

0x5000_0000 to 0xDFFF_FFFF (SAU Region 3 in Figure 37.4)

At least one NSC region MUST be created within any region defined as NSC by the IDAU. The regions set to NSC attribute by the IDAU are:

0x0000_0000 to 0x0FFF_FFFF (SAU Region 0 in Figure 37.4)

0x2000_0000 to 0x2FFF_FFFF (SAU Region 2 in Figure 37.4)

If you do not wish to define any isolation by means of using TrustZone, do not change SAU_CTRL.ALLNS = 0 and SAU_CTRL.ENABLE = 0 (initial value).

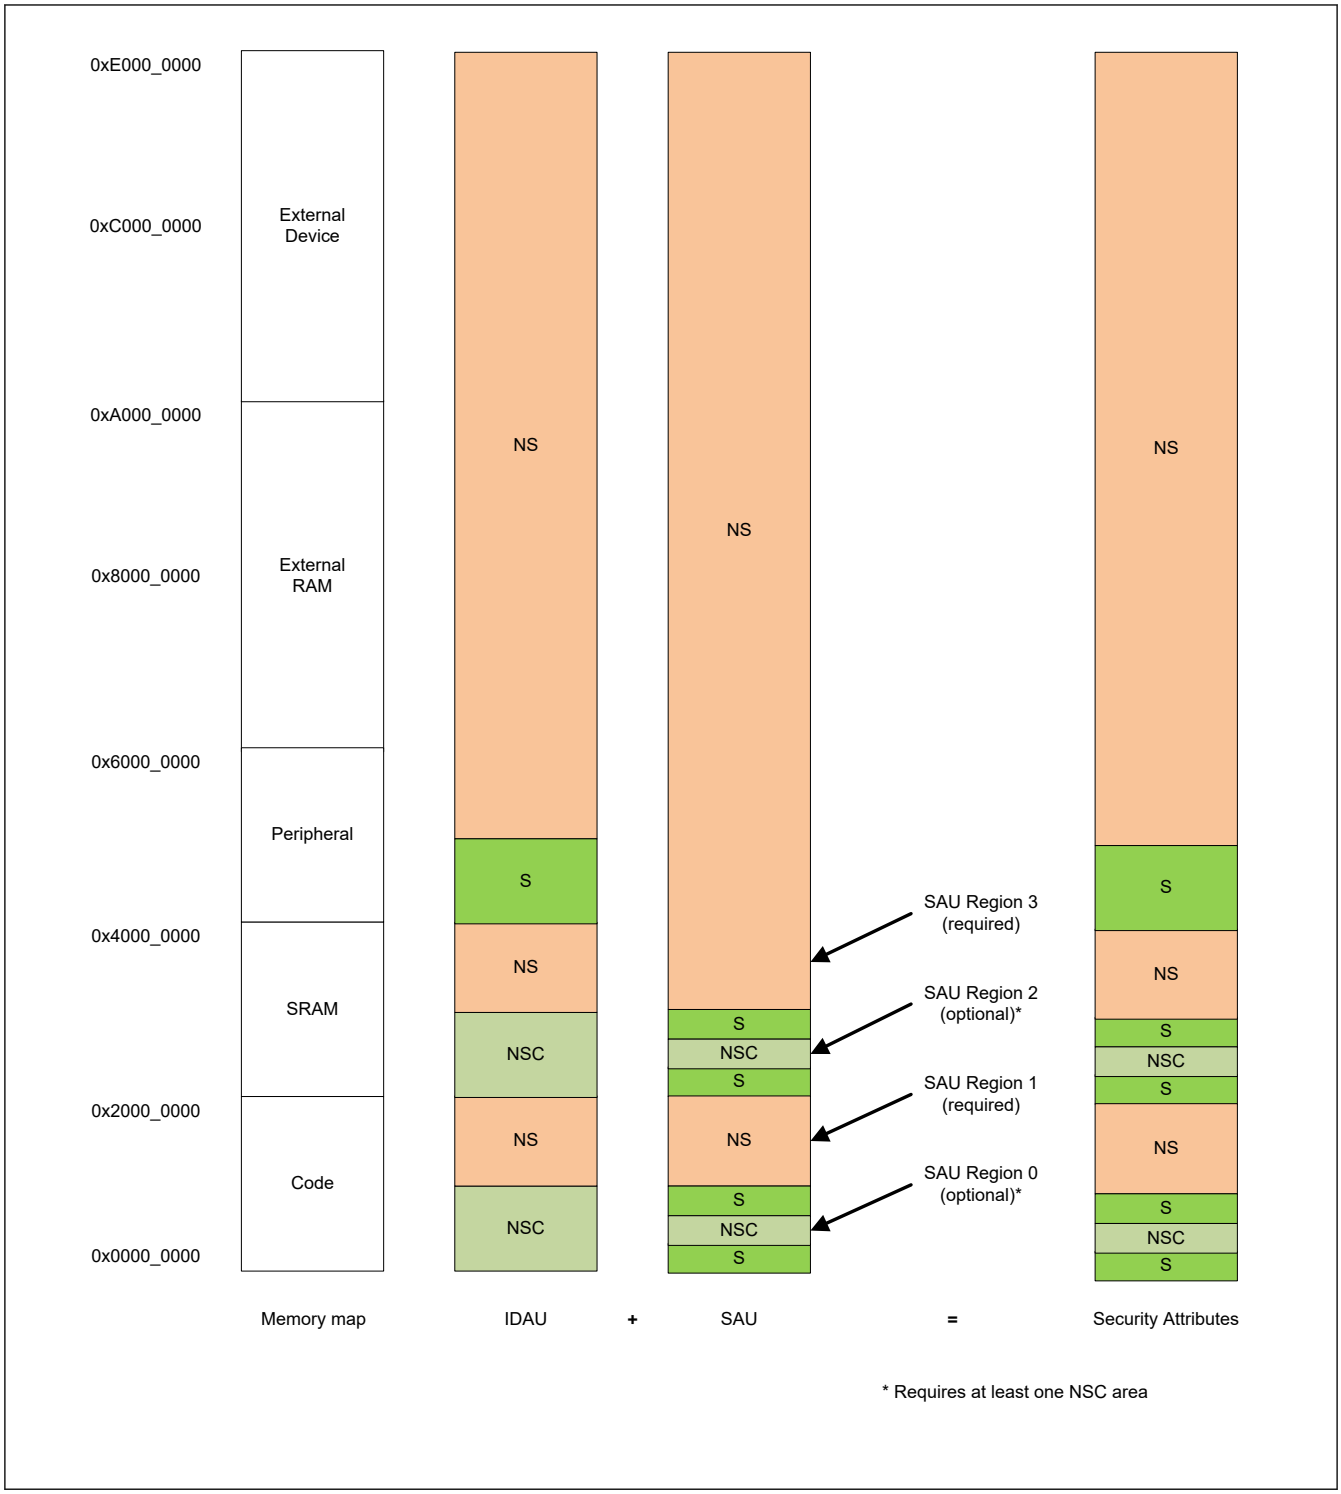

Figure 37.4 SAU settings and resulting security attributes

37.2.3.4 Region Number

The SAU and IDAU also define region numbers for each of the memory regions and security attributes. This region number is used by software to determine if a contiguous range of memory shares common security attributes. Figure 37.5 shows the defined region number of IDAU.

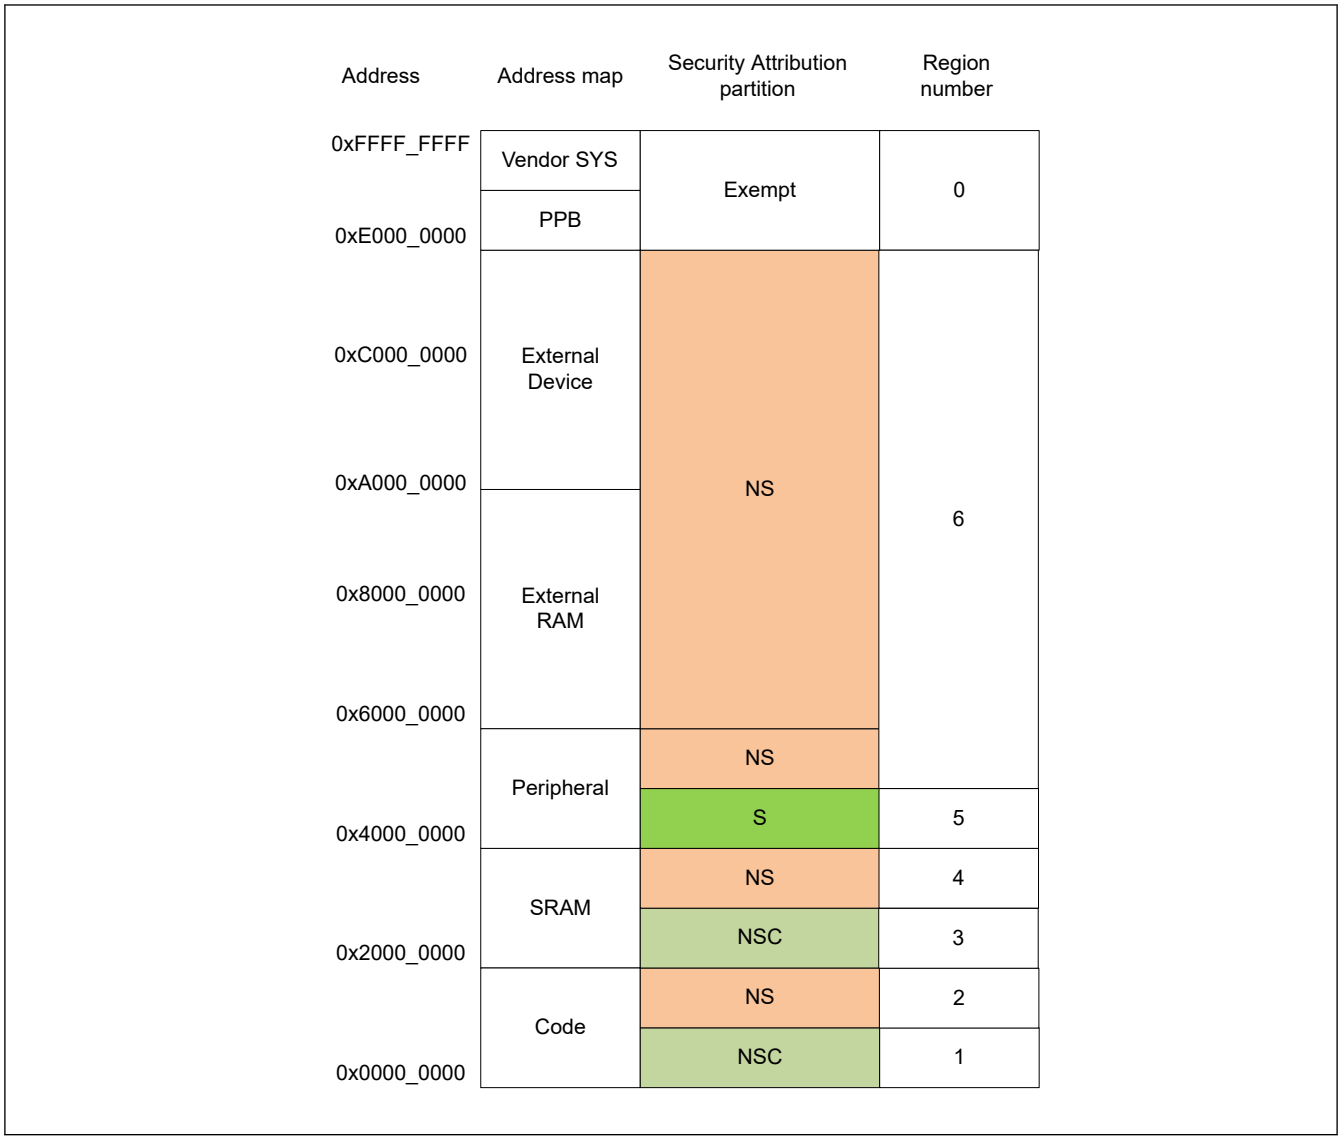

Figure 37.5 IDAU defined region numbers

37.2.3.5 Memory Security Attribution of TrustZone filter

The memories are divided into S and NS regions. The memory security attribution of code flash and data flash is stored into nonvolatile memory by a boot firmware command when the device lifecycle is in the OEM state and the authentication level is AL2. These memory security attributions are applied before application execution. They cannot be updated by the application but are readable using dedicated registers. The memory security attributions of SRAM and standby SRAM are set by a dedicated security attribution register writable only by secure access.

The code flash can be divided in up to two regions in linear mode and four regions in dual mode. The partitioning is the same between bank0 and bank1 in the dual mode. The data flash can be divided in up to two regions. The SRAM and standby SRAM can be divided in up to two regions. Figure 37.6 shows the memory mapping. Table 37.1 shows size of the memory region and Table 37.2 shows access permission of the memory region.

It is prohibited to place Secure or Non-secure Callable regions in a block swappable area in linear mode because the secure application would be placed in the non-secure region after block swapping.

Bank swapping by the Non-secure user may change the code in the Secure or Non-secure callable areas. The following is recommended to prevent this.

- Set BANKSEL_SEL.BANKSWP[2:0] = 000b to disable the bank swapping for Non-secure users.
- Make the code in Secure or Non-secure callable areas for both banks the same when allow Non-secure user to swap banks.

See section 37.7. Field Updating in Dual Mode.

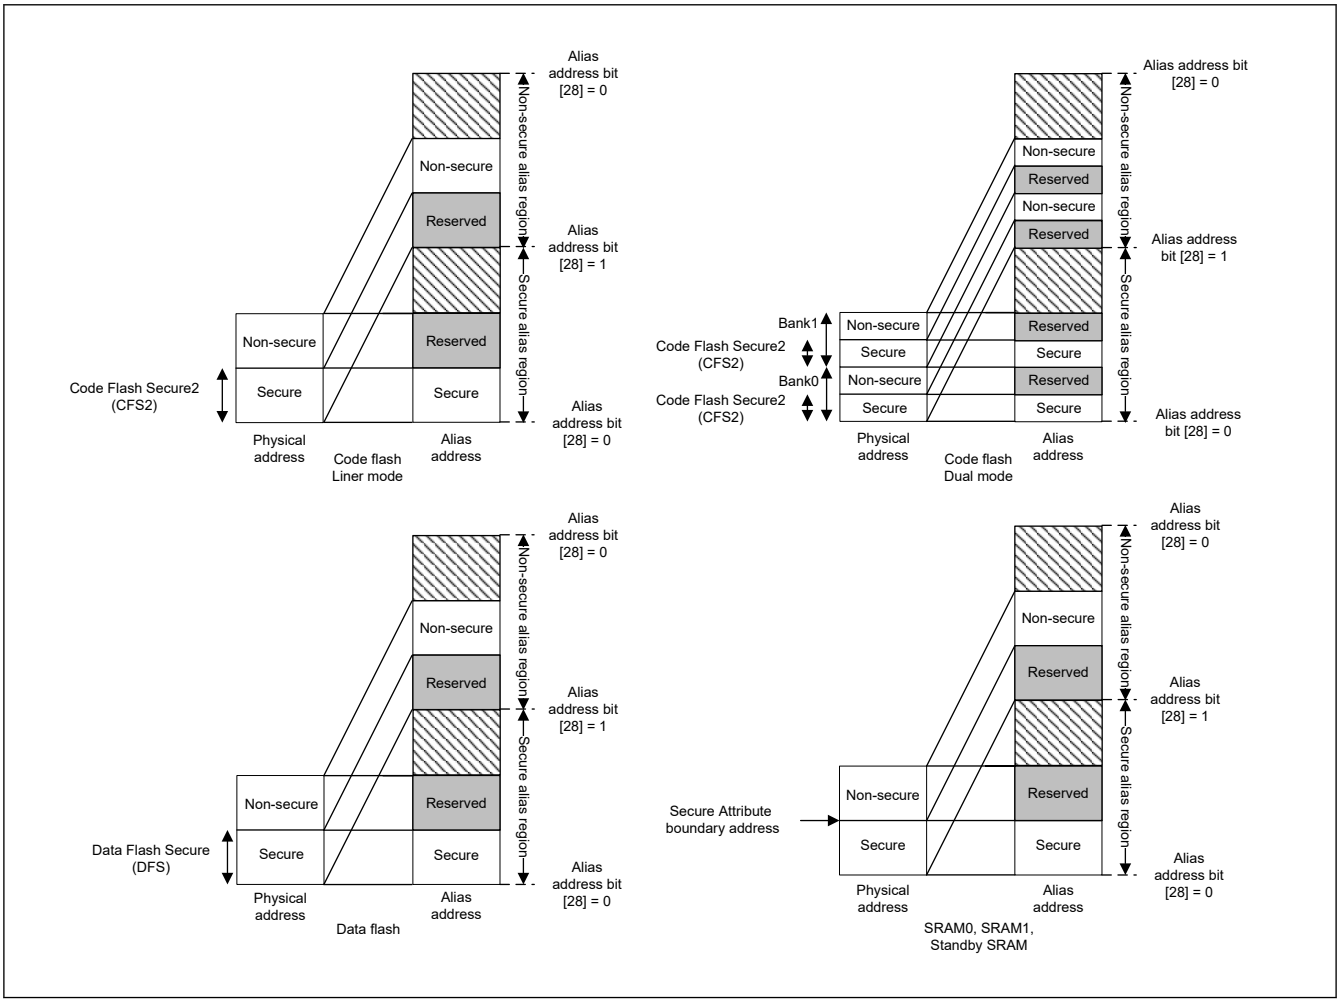

Figure 37.6 Memory mapping

Table 37.1 Size of memory region

Memory region		Start address	Size
Linear mode	Code flash secure	0x0200_0000	CFS2 size (32 KB)
	Code flash non-secure	0x1200_0000 + CFS2 size (32 KB)	Code flash size - CFS2 size (32 KB)
Dual mode	Code flash bank0 secure	0x0200_0000	CFS2 size (32 KB)
	Code flash bank0 non-secure	0x1200_0000 + CFS2 size (32 KB)	Code flash size/2 - CFS2 size (32 KB)
	Code flash bank1 secure	0x0220_0000	CFS2 size (32 KB)
	Code flash bank1 non-secure	0x1220_0000 + CFS2 size (32 KB)	Code flash size/2 - CFS2 size (32 KB)
Data flash secure		0x2700_0000	DFS size (1 KB)
Data flash non-secure		0x3700_0000 + DFS size (1 KB)	Data flash size - DFS size (1 KB)
SRAM0 secure		0x2200_0000	BA (8 KB)
SRAM0 non-secure		0x3200_0000 + BA (8 KB)	SRAM0 size - BA (8 KB)
SRAM1 secure		0x2206_0000	BA (8 KB)
SRAM1 non-secure		0x3206_0000 + BA (8 KB)	SRAM1 size - BA (8 KB)
Standby SRAM secure		0x2600_0000	BA (128 bytes)
Standby SRAM non-secure		0x3600_0000 + BA (128 bytes)	Standby SRAM size - BA (128 bytes)

Note: The number in parentheses indicates the smallest unit that can be set by the user.
Note: BA is the setting value of the security attribution boundary address register for each memory region.

Table 37.2 Access permission of the memory region

Memory region	Secure transaction	Non-secure transaction
Each memory region configured as S or NSC	Allowed	Write ignored/Read ignored TrustZone access error is generated
Each memory region configured as NS	Write ignored/Read ignored TrustZone access error is generated	Allowed

37.2.3.6 Peripheral Security Attribution of TrustZone filter

Each peripheral can be configured as secure or non-secure and privileged or unprivileged.

Peripherals are divided into two types.

Type1 peripherals has one security and privilege attribution. Access to all registers is controlled by one security and privilege attribution. Type1 peripheral security and privilege attribution is set to the PSARx (x = B to E) and the PPARx (x = B to E) register by the secure and privileged application.

Type2 peripheral has the security attribution for each register or for each bit and access to each register or bit field is controlled according to these security attributions. Type2 peripheral security attribution is set to the Security Attribution register in each module by the secure application. For details on the Security Attribution register, see each section.

Table 37.3 shows the classification of peripheral type.

Table 37.3 Classification of peripheral type

Type1	Type2
SCI, SPI, ETHERC, EDMAC, USBFS, IIC, I3C,RSIP-E51A, CANFD, DOC, SDHI, CRC, CAC, ACMPHS, TSN, ADC12, DAC12, POEG, AGT, GPT, ULPT, IWDT, and WDT	System control (Resets, PVD, Clock Generation Circuit, Low Power Modes, Flash memory controller, Flash cache, SRAM controller, CPU cache, DMAC, DTC, ICU, MPU, BUS, Security setting, ELC, and I/O ports

Table 37.4 shows the access permission of type1 peripherals. The access permission of type2 peripherals is different by peripherals. Each register description of type2 peripherals includes the note of S-TYPE and P-TYPE indicating the specification of the access permission. For details on S-TYPE and P-TYPE, see section Appendix 4, Note for Register R/W.

Table 37.4 Access permission of type1 peripherals

	Secure and Privileged access	Secure and Unprivileged access	Non-secure and Privileged access	Non-secure and Unprivileged access
Peripheral configured as Secure and Privileged	Allowed	Write ignored/Read ignored TrustZone Access error is generated	Write ignored/Read ignored TrustZone Access error is generated	Write ignored/Read ignored TrustZone Access error is generated
Peripheral configured as Secure and Unprivileged	Allowed	Allowed	Write ignored/Read ignored TrustZone Access error is generated	Write ignored/Read ignored TrustZone Access error is generated
Peripheral configured as Non-secure and Privileged	Write ignored/Read ignored TrustZone Access error is generated	Write ignored/Read ignored TrustZone Access error is generated	Allowed	Write ignored/Read ignored TrustZone Access error is generated
Peripheral configured as Non-secure and Unprivileged	Write ignored/Read ignored TrustZone Access error is generated	Write ignored/Read ignored TrustZone Access error is generated	Allowed	Allowed

37.2.4 TrustZone Access Error

Table 37.5 shows the behavior when TrustZone access error occurs. The behavior varies depending on the master or the slave area to be accessed.

Table 37.5 Behavior of TrustZone access error

DAP	CPU	DMAC/DTC	EDMAC
• Only error response is returned*1	• IDAU/SAU detects SecureFault exception • TrustZone filter detects BusFault exception • Can issue a reset*2	• Stop transfer • Issue NMI or reset*2 • Generate interrupt (DMA0_TRANSERR)	• Issue NMI or reset*2 • Generate interrupt (ETHER_EINT0)*3

Note: This behavior is not applicable for bufferable write access. For more information on when a bufferable write access error is detected, see section 13.7.2. Operations When a Bus Error Occurs.
Note 1. When a TrustZone access error occurs by a debugger access, exception, NMI, or reset does not occur. Only the error response is returned.
Note 2. The operation after error detection is selected by the BUSOAD.SRERROAD bit.
Note 3. Address Error flag in EESR.ADE bit is set. The interrupt occurs when it is enabled in EESIPR.ADEIP bit.

37.3 Device Lifecycle Management

Device Lifecycle Management (DLM) identifies the current development/production/deployment phase of the device and controls the capabilities of the debug function, the serial programming interface, and Renesas test mode. Figure 37.7 shows the available device lifecycle states and Table 37.6 shows the lifecycle state definitions and capabilities in each state.

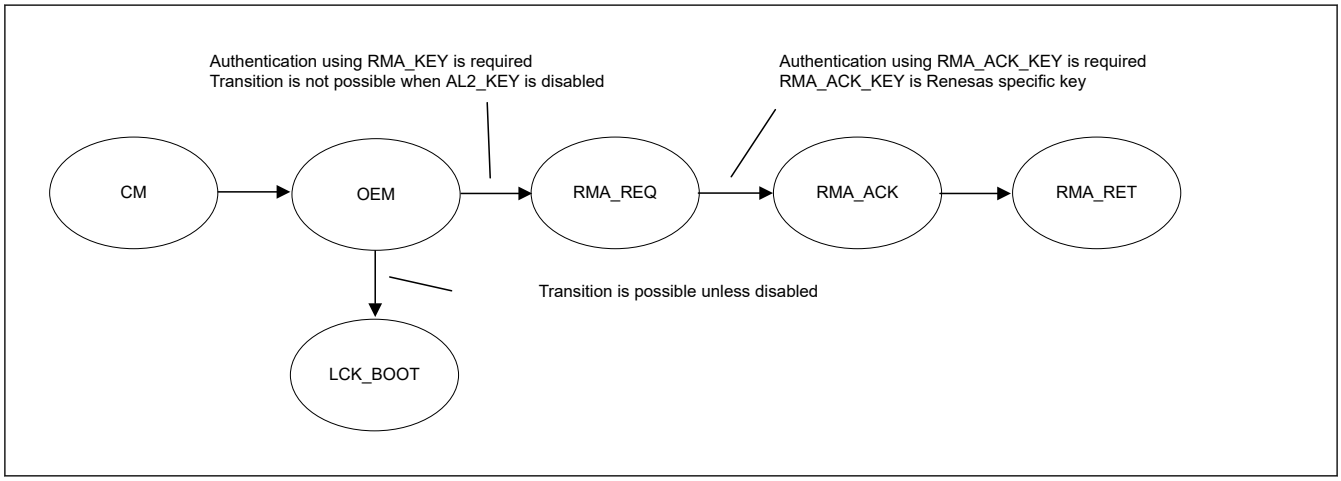

Figure 37.7 Device lifecycle states

Table 37.6 Lifecycle state definition and capabilities in each state (1 of 2)

Lifecycle	Definition	Protection level	Debug function	Serial programming	Renesas test mode
CM	“Chip Manufacturing”	PL2	Available in the secure and non-secure debug	Available Cannot access code/data flash area	Not available
OEM	“Original Equipment Manufacturer” The device is owned by the customer.	PL2 or PL1 or PL0	Depend on the authentication level		Not available
LCK_BOOT	“LoCKed BOOT interface” The debug interface and the serial programming interface are permanently disabled.	PL0	Not available	Not available	Not available
RMA_REQ	“Return Material Authorization REQuest” Request for RMA. The customer must send the device to Renesas in this state.	PL0	Not available	Available Cannot access code/data flash area	Not available
RMA_ACK	“Return Material Authorization ACKnowledged” Failure analysis in Renesas	PL2	Available in the secure and non-secure debug	Available Cannot access code/data flash area	Available

Table 37.6 Lifecycle state definition and capabilities in each state (2 of 2)

Lifecycle	Definition	Protection level	Debug function	Serial programming	Renesas test mode
RMA_RET	“Return Material Authorization RETurn” The device is back to the customer. The device does not boot.	PL0	Not available	Not available	Not available

Note: The customer receives the device in either CM or OEM state (Protection level: PL2).

37.3.1 Changing the Lifecycle State

Use the boot firmware commands to change the device lifecycle state. These commands are available via the boot firmware's UART and USB interfaces, plus SWD/JTAG. See the boot firmware application note for details of the command. The lifecycle state cannot be updated by an application, but the current lifecycle state can be read through the dedicated registers.

As shown in Figure 37.7, each transition is one-way and the state cannot be regressed.

Transition from OEM to RMA_REQ requires key authentication using the RMA_KEY which must have been previously injected by the customer. The key length of the RMA_KEY is 128 bits. Inject the RMA_KEY as shown in section 37.4. Secure Key Injection. RMA_KEY can be injected in AL2.

The key authentication uses a challenge and response authentication or authentication using the MCU's unique ID. The response (challenge and response authentication) or the authentication code (using the MCU's unique ID) can be calculated as follows:

Response = AES-128 CMAC (RMA_KEY, 128-bit challenge)

Authentication code = AES-128 CMAC (RMA_KEY, 128-bit MCU unique ID)

The contents of the flash memory except permanently locked blocks or registers are erased when transitioning to RMA_REQ. The contents of the permanently locked blocks or registers can be read by Renesas at failure analysis. A flash block can permanently locked by setting the PBPS/PBPS_SEC and BPS_SEL registers to permanently disable programming and erasure of the block. The SAS register can be permanently locked by the FSPR bit, permanently disabling programming and erasure of the register. Transition to RMA_REQ is not possible if the AL2_KEY is disabled. The MCU does not respond after changing the device lifecycle state to RMA_REQ. To continue to use boot firmware commands, you must enter boot mode again after a reset. See the boot firmware application note for details.

Transition from OEM to LCK_BOOT is possible unless that transition has been explicitly disabled. Use the parameter setting command in AL2 or AL1 to prohibit the transition to LCK_BOOT. The LCK_BOOT transition prohibition is a permanent setting and cannot be undone. The debug interface and serial programming interface are permanently disabled in LCK_BOOT.

Note: For proper DLM state management, it is required to issue an initial DLM state transition command to OEM in case of receiving in CM state.

37.3.2 Protection and Authentication Level

The protection level (PL) and the authentication level (AL) determine the availability of the debug function and the serial programming interface. PL and AL are fixed except in the OEM state. For PL and for AL, three levels can be set for each in the OEM state. AL indicates a temporary authentication status and is initialized to PL after an MCU power-on reset. Both PL and AL can be changed only by the boot firmware and cannot be changed by the application. Figure 37.8 shows the available Protection Level and Authentication Level states and transitions. Table 37.7 shows the availability of the debug function and the serial programming interface in each level.

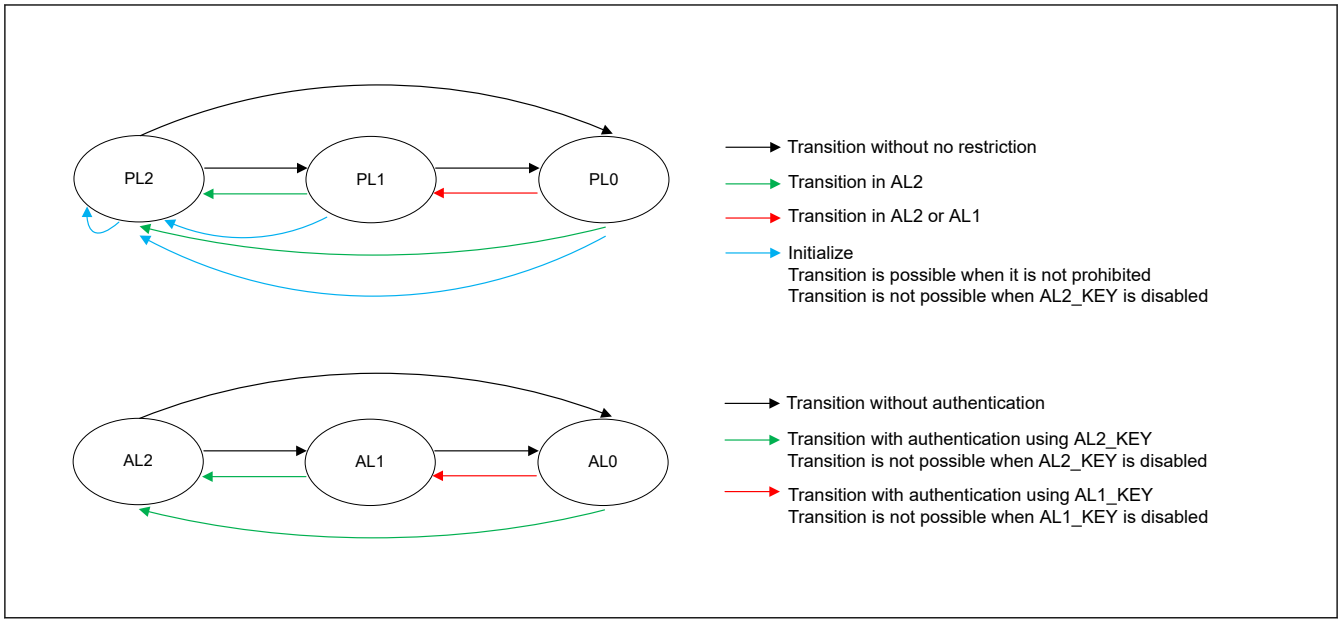

Figure 37.8 PL and AL states and transitions

Table 37.7 Availability of the debug function and the serial programming interface in each authentication level

AL	Debug function	Serial programming interface
AL2	Non-secure and Secure debug functions are enabled and accessible from the debugger	All functions are available
AL1	Only non-secure debug function is enabled, and debugger can access only defined non-secure debug accessible regions	Available but cannot program, erase, or read secure code or data flash area
AL0	No debug functions are available	Available but cannot access code or data flash area

Use the boot firmware commands to change PL and AL. See the boot firmware application note for details of the command.

Changing to a lower PL can be done with no restriction. Changing to a higher PL requires that the MCU be at that AL or higher. For example, when the current AL is AL1, changing to PL1 is possible but changing to PL2 is impossible. PL can be reset by the Initialize command unless the command itself is disabled. The Initialize command will set the PL to PL2 and the content in the flash memory will be erased. If there are any permanently locked blocks or registers, the Initialize command does not execute. In other words, when all the bits of the PBPS and PBPS_SEC registers are 1 and the FSPR bit is 1, the Initialize command is executable. The Initialize command can be disabled permanently in all AL states by the parameter setting command to prevent users from erasing the contents of flash memory. The Initialize command is disabled also when AL2_KEY is disabled. The MCU does not respond after executing the Initialize command. To continue to use the boot firmware commands, enter boot mode again after a reset. See the boot firmware application note for details.

Changing to a lower AL can be done without authentication. Changing to a higher AL requires key authentication using AL2_KEY or AL1_KEY, as appropriate. These keys are 128-bit keys. Injection of AL2_KEY or AL1_KEY is performed as shown in section 37.4. Secure Key Injection. AL2_KEY can be injected in AL2, AL1_KEY can be injected in AL2 or AL1. The key authentication uses a challenge and response authentication. The response can be calculated as follows:

Response = AES-128 CMAC (KEY, 128 bits challenge)

AL2_KEY can be disabled permanently in AL2 by parameter setting command. AL1_KEY can be disabled permanently in AL2 or AL1 by parameter setting command.

37.3.3 Serial Programming

Whether a serial programmer can be connected and the range of flash memory that can be accessed depends on the device lifecycle state and AL as shown in Table 37.6 and Table 37.7. In addition, the accepted serial programming commands differ depending on the device lifecycle state and AL. See the boot firmware application note for details of the commands.

37.3.4 Device Lifecycle State and PL Change Example

The following section describes a typical device lifecycle state and PL change example.

- Secure developer
  - Change the device lifecycle state from CM to OEM using the boot firmware command
  - Set the memory security attribution of the code flash and data flash using the boot firmware command
  - Program and debug the secure application. Debug is possible if the lifecycle is CM, but it is not possible to set the memory security attribution in CM state. If the memory security attribution is not set, all area of the code flash and data flash is secure. Inject application AES, RSA, ECC, HMAC keys listed in Table 37.8 (if required)
  - If the AL2_KEY and RMA_KEY are required, inject them using the boot firmware commands.
  - Prepare the MCU for the Non-secure developer
    - If the Non-secure Developer will not be permitted to use the Initialize command, disable it using the boot firmware command.
    - If the AL2_KEY will not be used and the Non-secure Developer will not be permitted to use the Initialize function, disable the AL2_KEY using the boot firmware command.
    - Change the PL from PL2 to PL1 using the boot firmware command
- Non-secure developer
  - Program and debug the non-secure application. Inject application AES, RSA, ECC, HMAC keys listed in Table 37.8 (if required)
  - If the AL1_KEY is required, inject it using the boot firmware command.
  - Prepare the MCU for end-product deployment
    - Disable the Initialize command using the boot firmware command (if required)
    - If the AL1_KEY will not be used, disable the AL1_KEY using the boot firmware command.
    - Change the PL from PL1 to PL0 using the boot firmware command

37.3.5 Failure Analysis

If the customer requests failure analysis by Renesas, it is necessary to send the device after changing the device lifecycle state to RMA_REQ. If the device lifecycle state is not RMA_REQ, Renesas cannot perform the failure analysis. After failure analysis, Renesas changes the lifecycle to RMA_RET and returns the device to the customer.

Note: RMA_KEY is required to change the device lifecycle state to RMA_REQ or the MCU's Unique ID must be used as part of an authentication code. See section 37.3.1. Changing the Lifecycle State for details.

37.4 Secure Key Injection

To inject a user key into the MCU, perform the following steps.

Renesas provides the Security Key Management Tool, available on the Renesas web site, to assist with key injection preparation.

1. Create a 256-bit installation key.
   This key is called the User Factory Programming Key (UFPK) and is used to wrap a user key
2. Get the wrapped version (W-UFPK) of the UFPK through the Renesas Key Wrapping Service.
3. Wrap the user key using the UFPK.
4. Send the W-UFPK and the wrapped user key to the MCU using a boot firmware interface.
   The user key is unwrapped, wrapped with the MCU's hardware unique key, and stored in nonvolatile memory. DLM keys are stored in upmapped flash. Application keys are stored at the address specified with the key injection command.

Figure 37.9 shows an example of key injection and Table 37.8 shows the keys that can be injected.

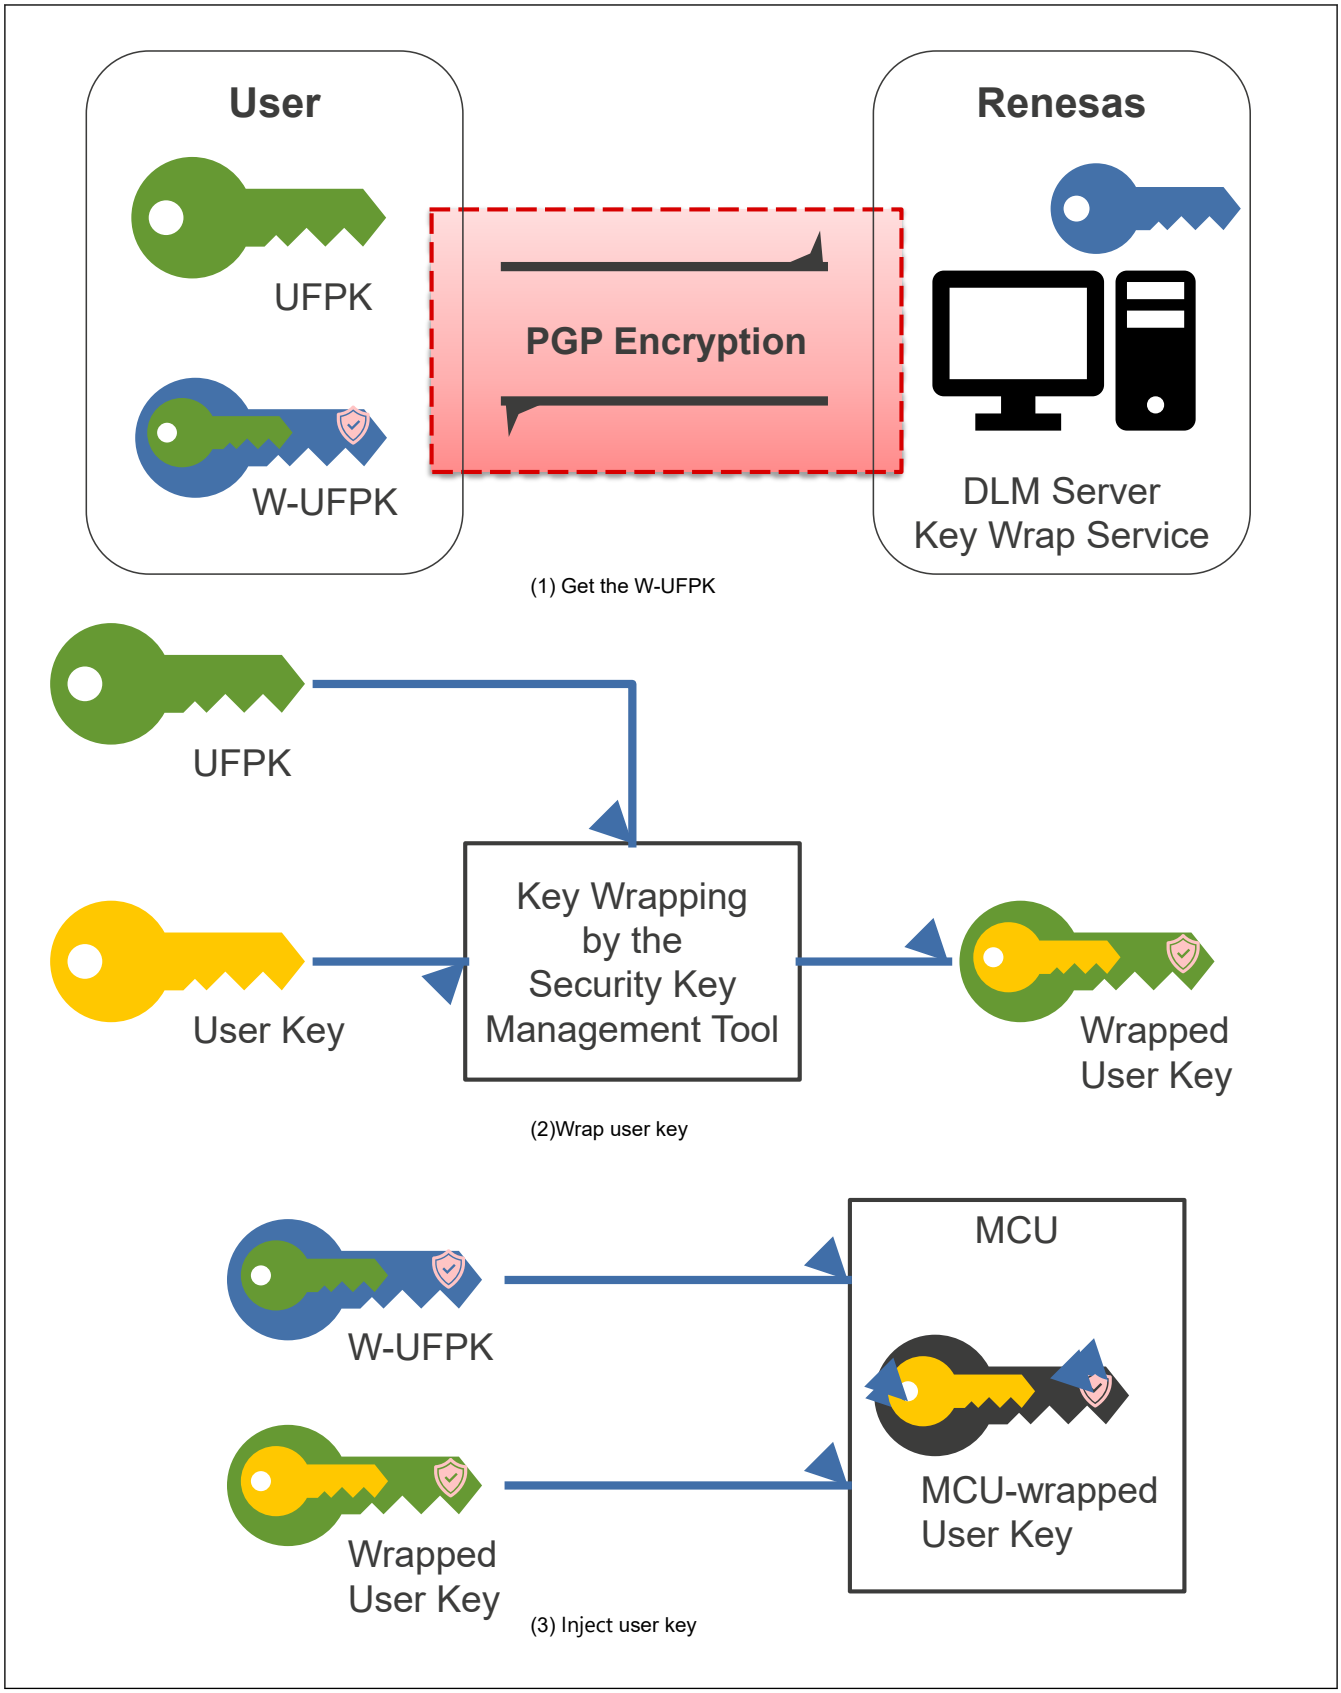

Figure 37.9 Key injection

Table 37.8 Keys that can be injected

DLM transition	AL transition	AES	RSA	ECC	HMAC	EdDSA	Secure boot	Other
RMA_KEY	AL2_KEY, AL1_KEY	AES-128, AES-192, AES-256, AES-XTS-128, AES-XTS-256	RSA-1024, RSA-2048, RSA-3072, RSA-4096 (Public and Private) RSA-2048 Public Key for TLS	secp192r1, secp224r1, secp256r1, secp384r1, secp521r1, Brainpool P256r1, Brainpool P384r1, Brainpool P521r1, Koblitz secp256k1 (Public and Private)	HMAC-SHA224, HMAC-SHA256, HMAC-SHA384, HMAC-SHA512, HMAC-SHA512/224, HMAC-SHA512/256	Ed25519 (Public and Private)	OEM_ROOT_PK	Key-Update Key

37.5 Secure Factory Programming

In addition to secure key injection support for injecting user keys (DLM, debug authentication, application, and secure boot keys), the MCU supports the programming of a firmware image in ciphertext format to prevent assets from being leaked during production programming. This enables secure factory programming in a non-secure environment. Secure factory programming is supported by boot firmware. The maximum capacity that can be programmed with the secure factory programming is almost 16 MB. See the security key management tool user's manual or the boot firmware application note for details of the capacity limitation. Figure 37.10 shows an example of secure factory programming of an encrypted firmware image. The customer wraps the Image Encryption Key with the UFPK and encrypts the image with the Image Encryption Key using AES128-CCM. When the customer sends the W-UFPK, the wrapped Image Encryption Key, and encrypted image to the MCU through the serial programming interface, the MCU decrypts and programs the firmware image.

To further support secure factory programming in a non-secure environment, the DLM state, Protection Level, and Authentication Keys can all be set via a single boot firmware command. Points to note about this boot firmware command include:

- Encrypted firmware programming can be performed only when the MCU is in the OEM state.
- This command will change the Protection Level of the MCU. The initial PL must be PL2. The final PL must be PL0.
- If the DLM state will remain in the OEM state, AL2 key must be injected. Do not inject AL1 key.
- The MCU can be transitioned to the LCK_BOOT state. In this case, AL keys cannot be injected.
- AL2 key must be wrapped with the same UFPK as the Image Encryption Key.
- This command will erase all code and data flash area except option-setting memory before programming encrypted firmware image. If there are any permanently locked blocks, this command can not be executed.
- Prohibit to execute this command if the current register setting or write value to the registers related to startup area selection and startup bank selection are other than the following.
  - SAS.BTFLG = 1b
  - BANKSEL.BANKSWP[2:0] = 111b
  - BANKSEL_SEC.BANKSWP[2:0] = 111b
- All option-setting memory values must be included in the encrypted firmware image, including those not changed from their default values. However, if the following areas are write-protected, the write data in these areas should not be included in the image. If included, this command will terminate with an error.
  - SAS register
  - Lockable Area 0 to 2 in the data flash option setting memory

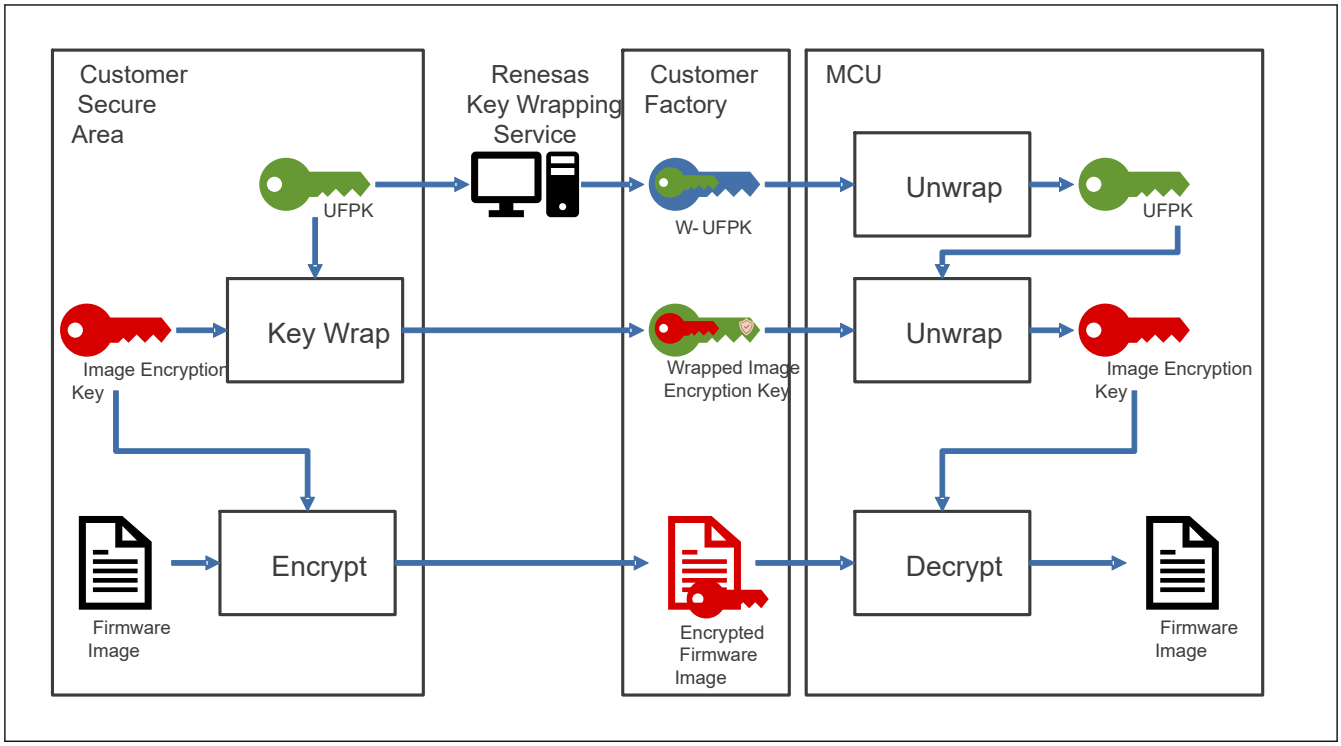

Figure 37.10 Secure factory encrypted image programming

37.6 Secure Boot

Secure boot verifies the integrity and authenticity of an OEM boot loader (called OEM_BL) starting at the beginning of application executable memory.

The OEM_BL is verified when it is initially programmed and prior to execution.

OEM_BL is verified when it is programmed using the boot firmware. Two certificates are used for validation. One is the key certificate, which is used to certify the OEM_BL verification key (called the OEM_BL_PK, the public part of the OEM_BL verification key pair). The key certificate is signed by the secret part of OEM_BL verification root key pair (called OEM_ROOT_SK). The public part of OEM_BL verification root key pair (called OEM_ROOT_PK) is registered with the MCU as the root of trust key using secure key injection as described in section 37.4. Secure Key Injection.
The OEM_ROOT_SK and OEM_ROOT_PK are a 256-bit ECC (secp256r1 curve) key pair. The SHA2-256 hash of the OEM_ROOT_PK is stored during the secure key injection process.

The other certificate for validation during programming is the code certificate, which is used to certify the OEM_BL.
The code certificate is signed by the secret part of OEM_BL verification key pair (called OEM_BL_SK). After successful validation of the OEM_BL, the HMAC value of OEM_BL and the code certificate (called OEM_BL_digest) is generated and programmed to flash. HMAC SHA2-256 is used to generate the HMAC value. A derived key from the HUK is used as the HMAC key, so the HMAC value is unique in each MCU.

In single-chip mode, the immutable first stage boot loader (called FSBL) in ROM is executed after reset when the FSBL is enabled in the FSBLCTRL0 register. When secure boot is selected in FSBLCTRL1 register, the FSBL generates the HMAC value of the OEM_BL and the code certificate, and compares it to the expected HMAC value. When the HMAC value is the same, the FSBL jumps to the OEM_BL. When CRC boot is selected in the FSBLCTRL1 register, the FSBL calculates the CRC of the OEM_BL and compares it to the expected CRC value, which is located in the code certificate. If the CRC values match, the FSBL jumps to the OEM_BL.

The Code certificate must be programmed into flash, and its location in flash must be programmed into the SACC0 register or SACC1 register. The SACC0 register specifies the start address of the code certificate when BANKSWP[2:0] = 111b in dual mode or when BTFLG = 1 in linear mode. The SACC1 register specifies the start address of the code certificate when BANKSWP[2:0] = 000b in dual mode or when BTFLG = 0 in linear mode.

When measurement reporting is enabled in the FSBLCTRL1 register, the FSBL stores the measurement report to the SRAM address specified by the SAMR register.

FSBL execution can be skipped after a software reset or deep software standby reset, as configured by the FSBLCTRL0 register.

If the generated HMAC or CRC value is different from the expected value, the high level is output to the port set by the FSBLCTRL2 register and the MCU goes to CPU Sleep mode.

Programming the hash of OEM_ROOT_PK and FSBL related registers can be permanently locked. It is strongly recommended to lock these items during production programming.

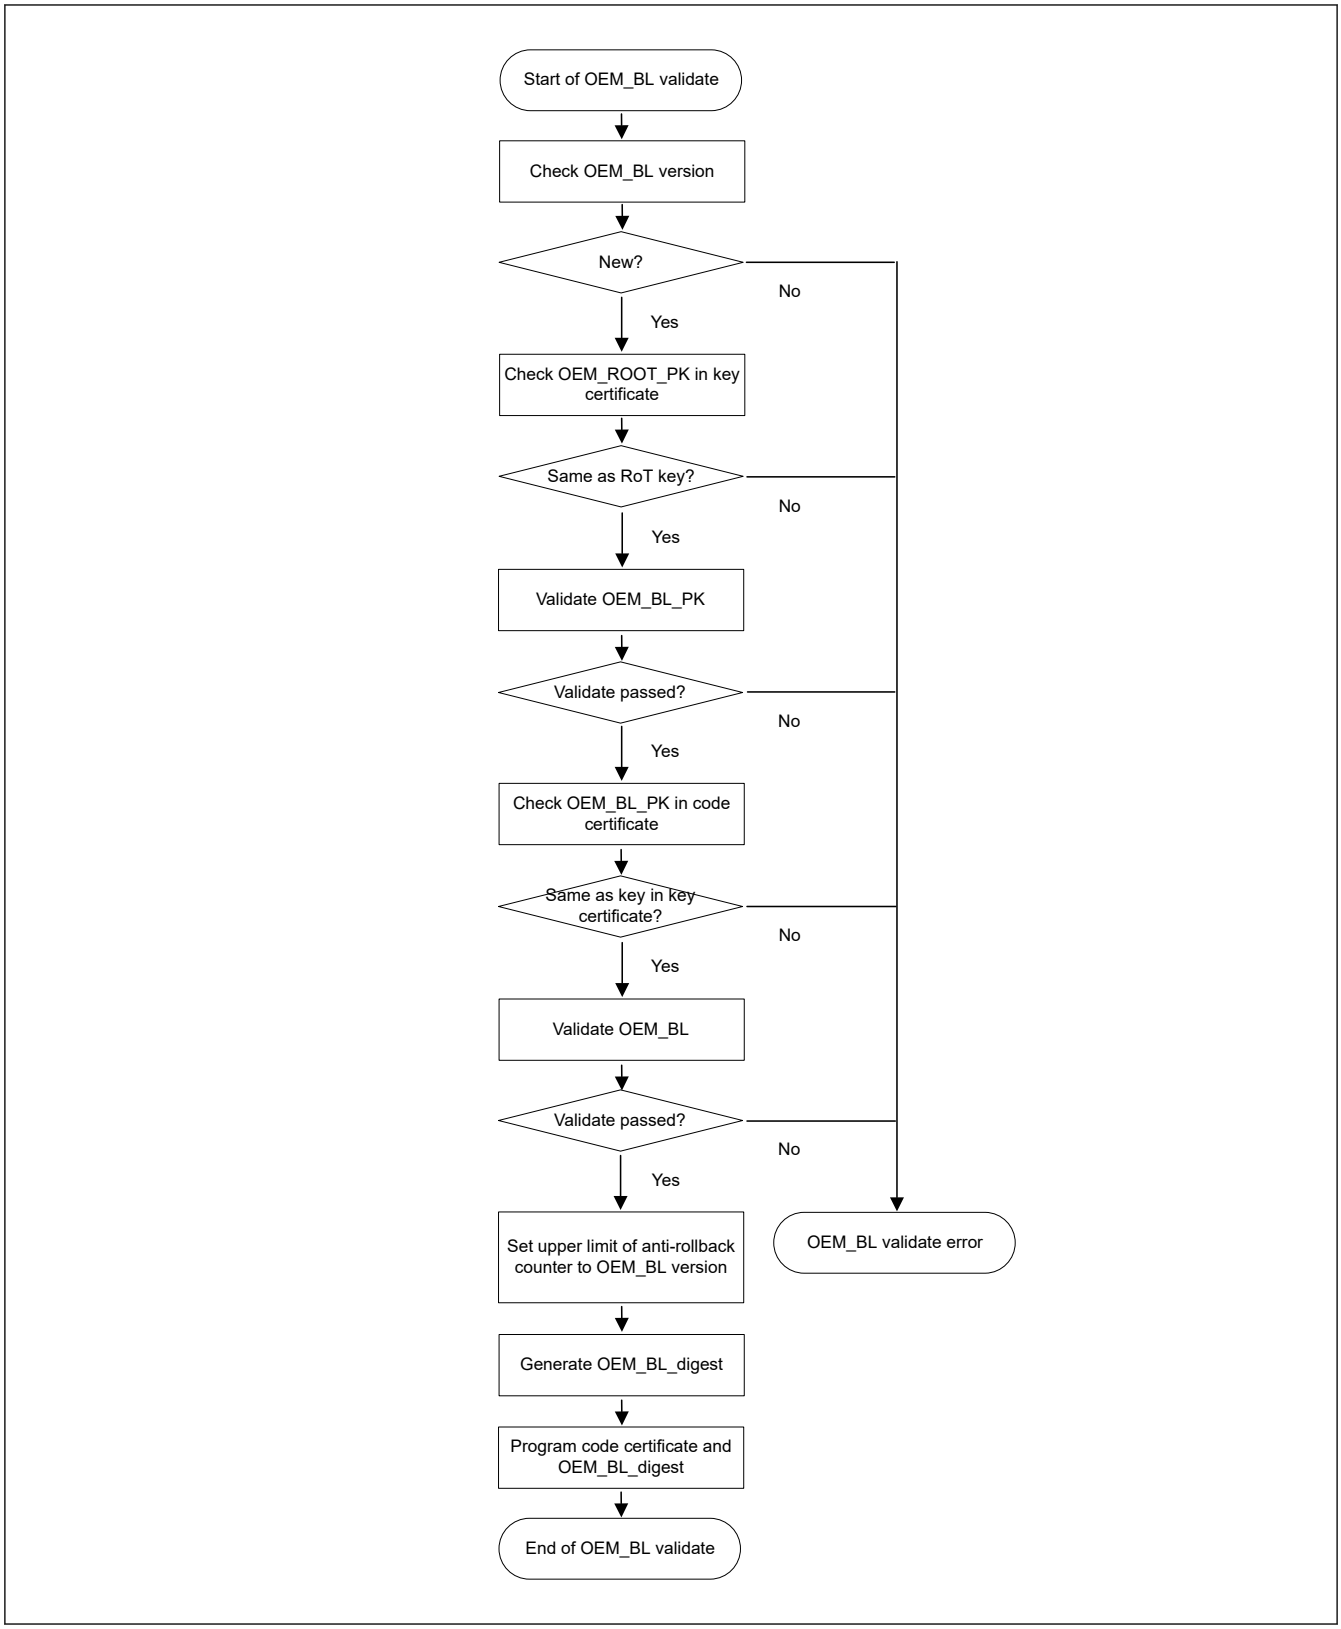

Figure 37.11 OEM_BL validation flow in serial programming mode

Header	Magic	4	Set to 0x636F6463
	Manifest version	4	Set to 0x00010000
	Flags	4	Set to 0x00000000
	Load Addr	4	Set to 0x02000000
	Dest Addr	4	Set to 0x02000000
	Image size	4	Size in bytes of OEM_BL set in multiples of 16, minimum size is 64 bytes
	Image version	4	Version number of OEM_BL. Can be specified from 1 to 64
	Build number	4	Set to 0x00000000
TLV length		4	Length in bytes of TLV field
TLV ECCPUBKEY	Type & Length	4	Set to 0x01088010
	Value	64	ECC P-256 OEM_BL_PK
TLV EXPECTED_CRC	Type & Length	4	Set to 0x40000001
	Value	4	CRC32 of OEM_BL

Table 37.10 Detail of code certificate (2 of 2)

Field		Size [byte]	Description
TLV SIGNER_ID	Type & Length	4	Set to 0x10144008
	Value	32	SHA2-256 hash value of OEM_BL_PK
TLV EXPECTED_SIG	Type & Length	4	Set to 0x25088410
	Value	64	Signature of [Code Certificate | OEM_BL], signed by the OEM_BL_SK When generating the signature, enter the code certificate and OEM_BL in the hash function in this order.

Table 37.11 Detail of OEM_BL_digest

Field		Size [byte]	Description
TLV EXPECTED_MAC	Type & Length	4	Fixed value 0x30184008
	Value	32	Unique OEM_BL_digest in each MCU

Note: OEM_BL_digest should be programmed in the area contiguous with the code certificate.

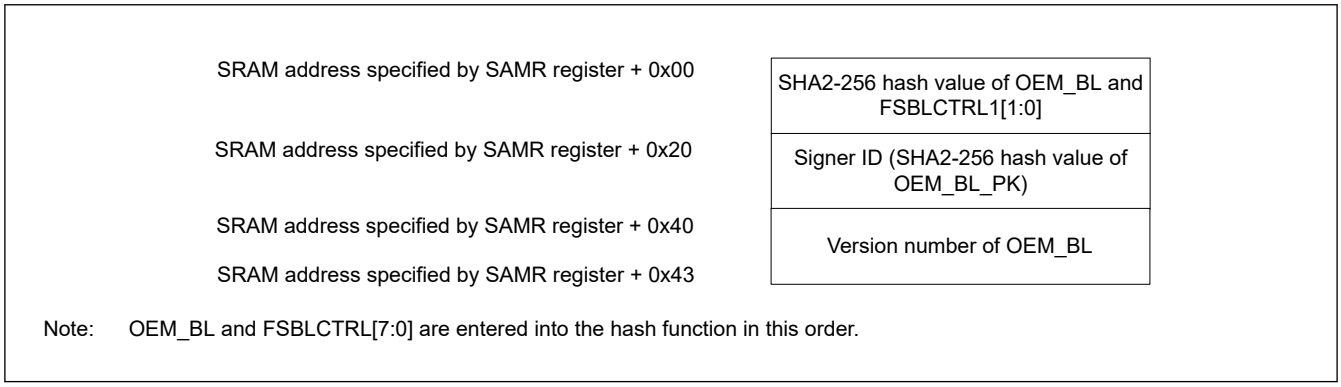

Figure 37.14 Format and location of the measurement report

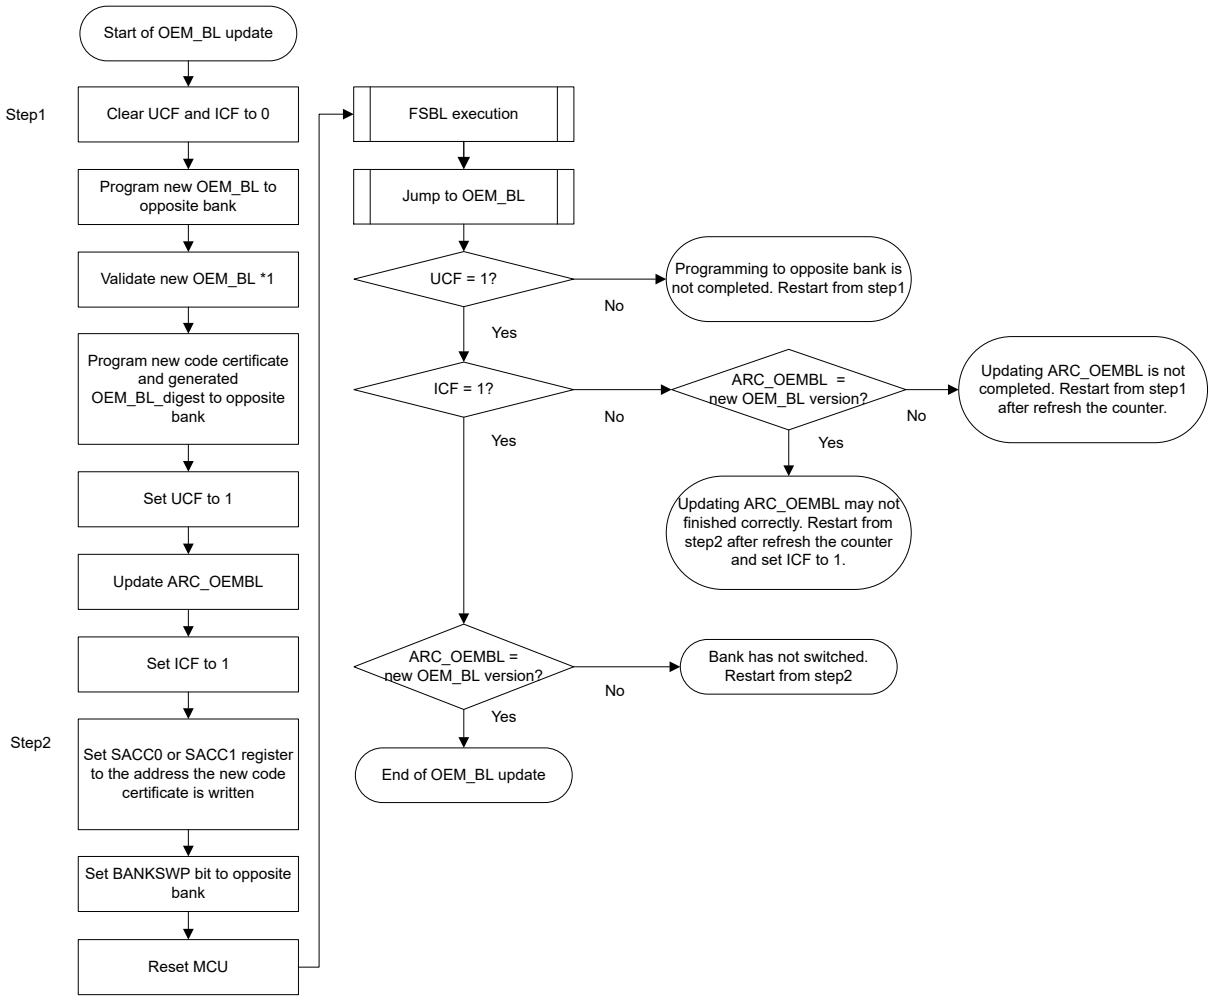
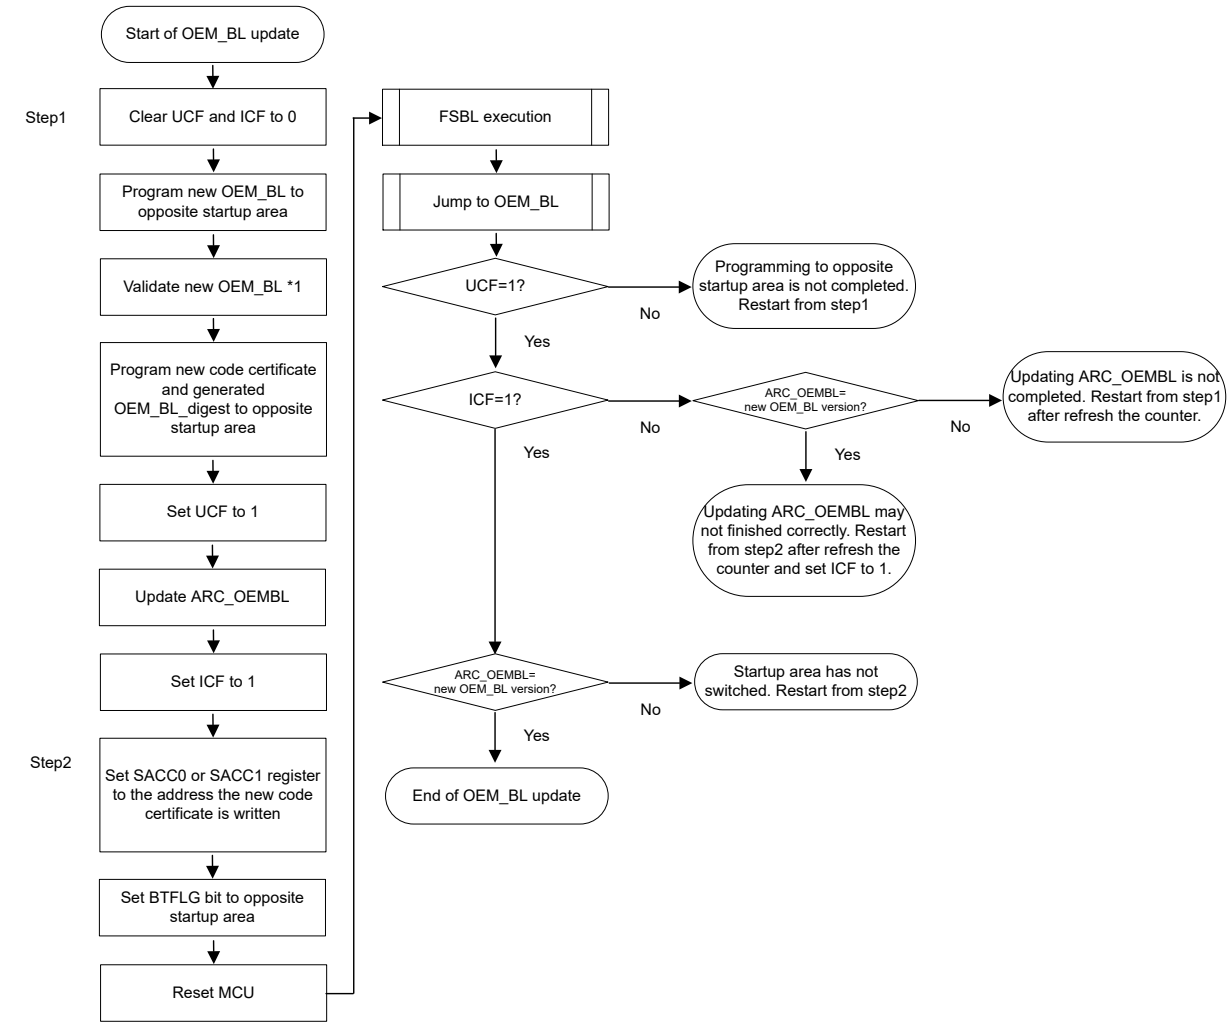
OEM_BL can be updated by application code. In this case, the application code must validate the updated bootloader, generate the OEM_BL_digest, and store it immediately after the new code certificate, as per the flow described by Figure 37.11.Figure 37.15 and Figure 37.16 show the OEM_BL update flow in dual mode or linear mode. When using linear mode, if the total size of OEM_BL, code certificate, and OEM_BL_digest is larger than the startup area size of 8 KB, you cannot use this update flow. It is recommended to use dual mode.

The implementation of the OEM_BL is user defined and application specific. However, it is recommended to implement status flags such as Update Complete Flag (UCF) and Increment Complete Flag (ICF) in the user lockable area of the data flash option-setting memory as a countermeasure against update errors due to unexpected power failure. If an update error occurs, it can be recovered as shown in the following figures. If an update error occurs, the current OEM_BL is executed after FSBL execution. Note that the update error determination program is required for both the current OEM_BL and the new OEM_BL.



Note 1. Validate new OEM_BL the same way as Figure 37.11.

Figure 37.15 OEM_BL update flow in dual mode



Note 1. Validate new OEM_BL the same way as Figure 37.11.

Figure 37.16 OEM_BL update flow in linear mode

37.7 Field Updating in Dual Mode

Be careful when performing in-field firmware update to keep the contents of secure (S or NSC) or Non-secure (NS) regions after bank swapping in the dual mode. Figure 37.17 and Figure 37.18 show the performing in-field update of information flow of secure or non-secure regions in the dual mode.

Figure 37.17 and Figure 37.18 show updating the Secure and the Non-secure regions respectively when operating in dual bank mode. Initially, BANK0 contains Version 1 of the firmware, and BANK1 is blank. As shown in Figure 37.17, to update the S or NSC firmware to Version 2, first copy the Version 1 NS firmware in BANK0 to BANK1, update the S or NSC to Version 2, and then execute the bank swap.

As shown in Figure 37.18, to update the NS firmware to Version 2, first copy the Version 1 S and NSC firmware from BANK0 to BANK1. Note that this process must be done by a secure service. After that, non-secure users should update the NS firmware to Version 2 and execute the bank swap.

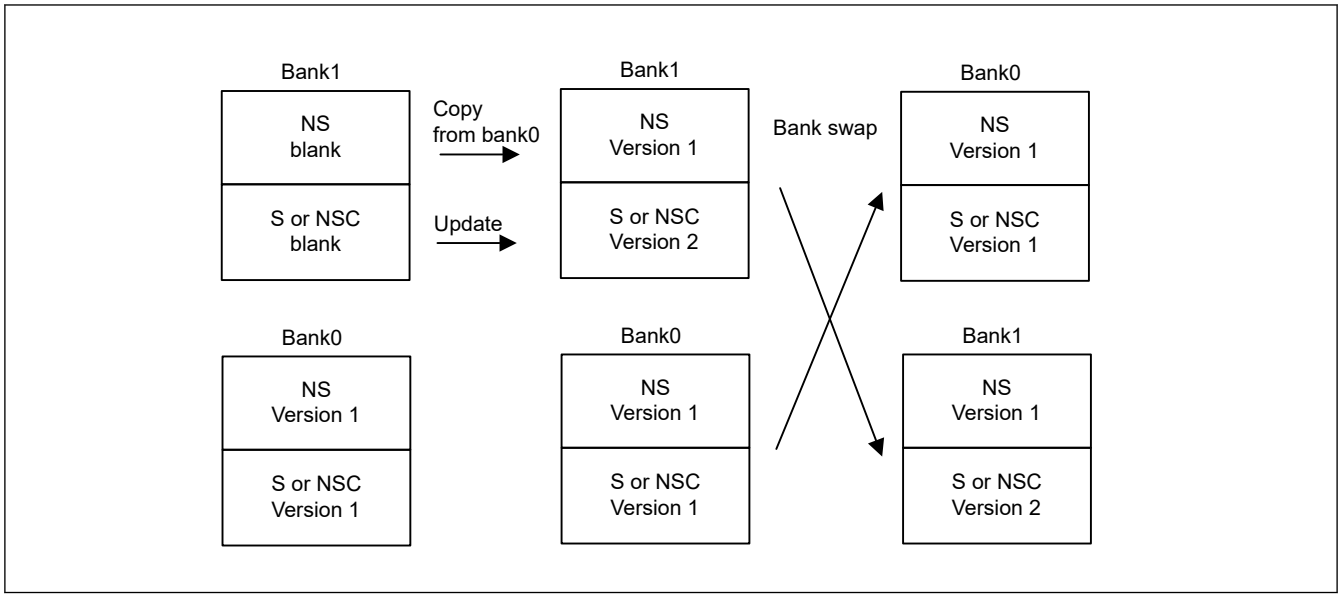


Figure 37.17 Field updating flow of secure or non-secure callable regions

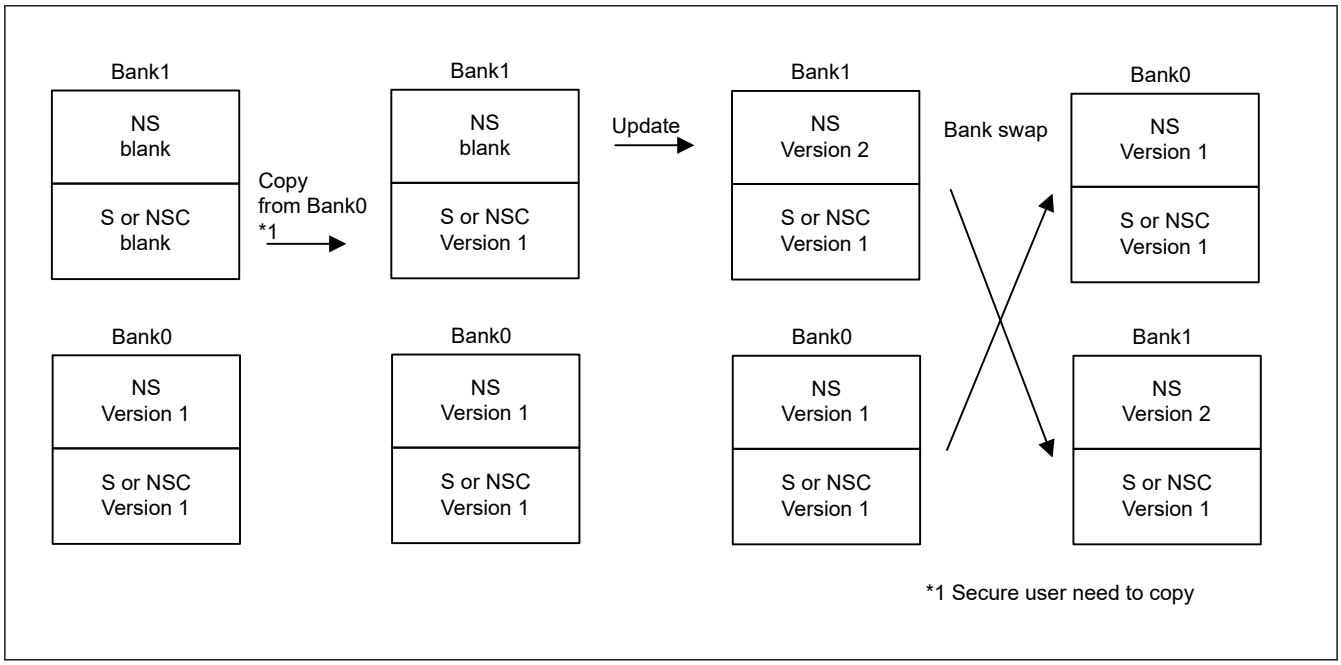

Figure 37.18 Field updating flow of non-secure region

37.8 Register Description

37.8.1 PSARB : Peripheral Security Attribution Register B

Base address: PSCU = 0x4020_4000
PSCU_NS = 0x5020_4000

Offset address: 0x04

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	PSARB31	PSARB30	PSARB29	PSARB28	PSARB27	—	—	—	—	PSARB22	—	—	PSARB19	PSARB18	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	PSARB15	—	—	—	PSARB11	—	PSARB9	PSARB8	—	—	—	PSARB4	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
3:0	—	These bits are read as 0. The write value should be 0.	R/W
4	PSARB4	I3C Bus Interface Security Attribution Target module: I3C and the MSTPCRB.MSTPB4 bit 0: Secure 1: Non-secure	R/W
7:5	—	These bits are read as 0. The write value should be 0.	R/W
8	PSARB8	I2C Bus Interface 1 Security Attribution Target module: IIC1 and the MSTPCRB.MSTPB8 bit 0: Secure 1: Non-secure	R/W
9	PSARB9	I2C Bus Interface 0 Security Attribution Target module: IIC0 and the MSTPCRB.MSTPB9 bit 0: Secure 1: Non-secure	R/W
10	—	This bit is read as 0. The write value should be 0.	R/W
11	PSARB11	Universal Serial Bus 2.0 FS Interface 0 Security Attribution Target module: USBFS0 and the MSTPCRB.MSTPB11 bit 0: Secure 1: Non-secure	R/W
14:12	—	These bits are read as 0. The write value should be 0.	R/W
15	PSARB15	ETHERC/EDMAC Controller Security Attribution Target module: ETHERC/EDMAC, the MSTPCRB.MSTPB15 bit, and the PFENET.PHYMODE0 bit 0: Secure 1: Non-secure	R/W
17:16	—	These bits are read as 0. The write value should be 0.	R/W
18	PSARB18	Serial Peripheral Interface 1 Security Attribution Target module: RSPI1 and the MSTPCRB.MSTPB18 bit 0: Secure 1: Non-secure	R/W
19	PSARB19	Serial Peripheral Interface 0 Security Attribution Target module: RSPI0 and the MSTPCRB.MSTPB19 bit 0: Secure 1: Non-secure	R/W
21:20	—	These bits are read as 0. The write value should be 0.	R/W

Bit	Symbol	Function	R/W
22	PSARB22	Serial Communication Interface 9 Security Attribution Target module: SCI9 and the MSTPCRB.MSTPB22 bit 0: Secure 1: Non-secure	R/W
26:23	—	These bits are read as 0. The write value should be 0.	R/W
27	PSARB27	Serial Communication Interface 4 Security Attribution Target module: SCI4 and the MSTPCRB.MSTPB27 bit 0: Secure 1: Non-secure	R/W
28	PSARB28	Serial Communication Interface 3 Security Attribution Target module: SCI3 and the MSTPCRB.MSTPB28 bit 0: Secure 1: Non-secure	R/W
29	PSARB29	Serial Communication Interface 2 Security Attribution Target module: SCI2 and the MSTPCRB.MSTPB29 bit 0: Secure 1: Non-secure	R/W
30	PSARB30	Serial Communication Interface 1 Security Attribution Target module: SCI1 and the MSTPCRB.MSTPB30 bit 0: Secure 1: Non-secure	R/W
31	PSARB31	Serial Communication Interface 0 Security Attribution Target module: SCI0 and the MSTPCRB.MSTPB31 bit 0: Secure 1: Non-secure	R/W

Note: S-TYPE-1, P-TYPE-1.

The PSARB register specifies the security attribution for each module and the corresponding bit in Module Stop Control Register.

37.8.2 PSARC : Peripheral Security Attribution Register C

Base address: PSCU = 0x4020_4000
PSCU_NS = 0x5020_4000

Offset address: 0x08

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	PSARC31	—	—	—	PSARC27	PSARC26	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	PSARC13	PSARC12	PSARC11	—	—	—	—	—	—	—	—	—	PSARC1	PSARC0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	PSARC0	Clock Frequency Accuracy Measurement Circuit Security Attribution register specifies the security attribution for each module and the corresponding bit in Module Stop Control Register. Target module: CAC and the MSTPCRC.MSTPC0 bit 0: Secure 1: Non-secure	R/W
1	PSARC1	Cyclic Redundancy Check Calculator Security Attribution Target module: CRC and the MSTPCRC.MSTPC1 bit 0: Secure 1: Non-secure	R/W
10:2	—	These bits are read as 0. The write value should be 0.	R/W

Bit	Symbol	Function	R/W
11	PSARC11	Secure Digital Host IF 1 Security Attribution Target module: SDHI1 and the MSTPCRC.MSTPC11 bit 0: Secure 1: Non-secure	R/W
12	PSARC12	Secure Digital Host IF 0 Security Attribution Target module: SDHI0 and the MSTPCRC.MSTPC12 bit 0: Secure 1: Non-secure	R/W
13	PSARC13	Data Operation Circuit Security Attribution Target module: DOC and the MSTPCRC.MSTPC13 bit 0: Secure 1: Non-secure	R/W
25:14	—	These bits are read as 0. The write value should be 0.	R/W
26	PSARC26	Controller Area Network with Flexible Data-Rate 1 Security Attribution Target module: CANFD1 and the MSTPCRC.MSTPC26 bit 0: Secure 1: Non-secure	R/W
27	PSARC27	Controller Area Network with Flexible Data-Rate 0 Security Attribution Target module: CANFD0 and the MSTPCRC.MSTPC27 bit 0: Secure 1: Non-secure	R/W
30:28	—	These bits are read as 0. The write value should be 0.	R/W
31	PSARC31	RSIP-E51A Security Attribution Target module:RSIP-E51A and the MSTPCRC.MSTPC31 bit 0: Secure 1: Non-secure	R/W

Note: S-TYPE-1, P-TYPE-1.

The PSARC register specifies the security attribution for each module and the corresponding bit in Module Stop Control Register.

37.8.3 PSARD : Peripheral Security Attribution Register D

Base address: PSCU = 0x4020_4000
PSCU_NS = 0x5020_4000

Offset address: 0x0C

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	PSARD28	PSARD27	—	—	—	—	PSARD22	—	PSARD20	—	—	—	PSARD16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	PSARD15	PSARD14	PSARD13	PSARD12	PSARD11	—	—	—	—	—	PSARD5	PSARD4	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
3:0	—	These bits are read as 0. The write value should be 0.	R/W
4	PSARD4	Low Power Asynchronous General Purpose Timer 1 Security Attribution Target module: AGT1 and the MSTPCRD.MSTPD4 bit 0: Secure 1: Non-secure	R/W
5	PSARD5	Low Power Asynchronous General Purpose Timer 0 Security Attribution Target module: AGT0 and the MSTPCRD.MSTPD5 bit 0: Secure 1: Non-secure	R/W

Bit	Symbol	Function	R/W
10:6	—	These bits are read as 0. The write value should be 0.	R/W
11	PSARD11	Port Output Enable for GPT Group 3 Security Attribution Target module: POEG Group D and the MSTPCRD.MSTPD11 bit 0: Secure 1: Non-secure	R/W
12	PSARD12	Port Output Enable for GPT Group 2 Security Attribution Target module: POEG Group C and the MSTPCRD.MSTPD12 bit 0: Secure 1: Non-secure	R/W
13	PSARD13	Port Output Enable for GPT Group 1 Security Attribution Target module: POEG Group B and the MSTPCRD.MSTPD13 bit 0: Secure 1: Non-secure	R/W
14	PSARD14	Port Output Enable for GPT Group 0 Security Attribution Target module: POEG Group A and the MSTPCRD.MSTPD14 bit 0: Secure 1: Non-secure	R/W
15	PSARD15	12-Bit A/D 1 Converter Security Attribution Target module: ADC12_1 and the MSTPCRD.MSTPD15 bit 0: Secure 1: Non-secure	R/W
16	PSARD16	12-Bit A/D 0 Converter Security Attribution Target module: ADC12_0 and the MSTPCRD.MSTPD16 bit 0: Secure 1: Non-secure	R/W
19:17	—	These bits are read as 0. The write value should be 0.	R/W
20	PSARD20	12-Bit D/A Converter Security Attribution Target module: DAC12 and the MSTPCRD.MSTPD20 bit 0: Secure 1: Non-secure	R/W
21	—	This bit is read as 0. The write value should be 0.	R/W
22	PSARD22	Temperature Sensor Security Attribution Target module: TSN and the MSTPCRD.MSTPD22 bit 0: Secure 1: Non-secure	R/W
26:23	—	These bits are read as 0. The write value should be 0.	R/W
27	PSARD27	High Speed Analog Comparator 1 Security Attribution Target module: ACMPHS1 and the MSTPCRD.MSTPD27 bit 0: Secure 1: Non-secure	R/W
28	PSARD28	High Speed Analog Comparator 0 Security Attribution Target module: ACMPHS0 and the MSTPCRD.MSTPD28 bit 0: Secure 1: Non-secure	R/W
31:29	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-1, P-TYPE-1.

The PSARD register specifies the security attribution for each module and the corresponding bit in Module Stop Control Register.

37.8.4 PSARE : Peripheral Security Attribution Register E

Base address: PSCU = 0x4020_4000
PSCU_NS = 0x5020_4000

Offset address: 0x10

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	PSARE31	PSARE30	PSARE29	PSARE28	PSARE27	PSARE26	PSARE25	PSARE24	PSARE23	PSARE22	PSARE21	PSARE20	PSARE19	PSARE18	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	PSARE9	PSARE8	—	—	—	—	PSARE3	PSARE2	PSARE1	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	—	This bit is read as 0. The write value should be 0.	R/W
1	PSARE1	WDT Security Attribution Target module: WDT 0: Secure 1: Non-secure	R/W
2	PSARE2	IWDT Security Attribution Target module: IWDT 0: Secure 1: Non-secure	R/W
3	PSARE3	Real Time Clock Security Attribution Target module: RTC 0: Secure 1: Non-secure	R/W
7:4	—	These bits are read as 0. The write value should be 0.	R/W
8	PSARE8	ULPT1 Security Attribution Target module: ULPT1 and the MSTPCRE.MSTPE8 bit 0: Secure 1: Non-secure	R/W
9	PSARE9	ULPT0 Security Attribution Target module: ULPT0 and the MSTPCRE.MSTPE9 bit 0: Secure 1: Non-secure	R/W
17:10	—	These bits are read as 0. The write value should be 0.	R/W
18	PSARE18	General PWM Timer Channel 13 Security Attribution Target module: GPT13 and the MSTPCRE.MSTPE18 bit 0: Secure 1: Non-secure	R/W
19	PSARE19	General PWM Timer Channel 12 Security Attribution Target module: GPT12 and the MSTPCRE.MSTPE19 bit 0: Secure 1: Non-secure	R/W
20	PSARE20	General PWM Timer Channel 11 Security Attribution Target module: GPT11 and the MSTPCRE.MSTPE20 bit 0: Secure 1: Non-secure	R/W
21	PSARE21	General PWM Timer Channel 10 Security Attribution Target module: GPT10 and the MSTPCRE.MSTPE21 bit 0: Secure 1: Non-secure	R/W

Bit	Symbol	Function	R/W
22	PSARE22	General PWM Timer Channel 9 Security Attribution Target module: GPT9 and the MSTPCRE.MSTPE22 bit 0: Secure 1: Non-secure	R/W
23	PSARE23	General PWM Timer Channel 8 Security Attribution Target module: GPT8 and the MSTPCRE.MSTPE23 bit 0: Secure 1: Non-secure	R/W
24	PSARE24	General PWM Timer Channel 7 Security Attribution Target module: GPT7 and the MSTPCRE.MSTPE24 bit 0: Secure 1: Non-secure	R/W
25	PSARE25	General PWM Timer Channel 6 Security Attribution Target module: GPT6 and the MSTPCRE.MSTPE25 bit 0: Secure 1: Non-secure	R/W
26	PSARE26	General PWM Timer Channel 5 Security Attribution Target module: GPT5 and the MSTPCRE.MSTPE26 bit 0: Secure 1: Non-secure	R/W
27	PSARE27	General PWM Timer Channel 4 Security Attribution Target module: GPT4 and the MSTPCRE.MSTPE27 bit 0: Secure 1: Non-secure	R/W
28	PSARE28	General PWM Timer Channel 3 Security Attribution Target module: GPT3 and the MSTPCRE.MSTPE28 bit 0: Secure 1: Non-secure	R/W
29	PSARE29	General PWM Timer Channel 2 Security Attribution Target module: GPT2 and the MSTPCRE.MSTPE29 bit 0: Secure 1: Non-secure	R/W
30	PSARE30	General PWM Timer Channel 1 Security Attribution Target module: GPT1 and the MSTPCRE.MSTPE30 bit 0: Secure 1: Non-secure	R/W
31	PSARE31	General PWM Timer Channel 0 Security Attribution Target module: GPT0, GPT_OPS and the MSTPCRE.MSTPE31 bit 0: Secure 1: Non-secure	R/W

Note: S-TYPE-1, P-TYPE-1.

The PSARE register specifies the security attribution for each module and the corresponding bit in Module Stop Control Register.

37.8.5 MSSAR : Module Stop Security Attribution Register

Base address: PSCU = 0x4020_4000
PSCU_NS = 0x5020_4000

Offset address: 0x14

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	MSSAR31	—	—	—	—	—	—	—	—	MSSAR22	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	MSSAR15	—	—	—	—	—	—	—	—	—	—	—	—	—	MSSAR1	MSSAR0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	MSSAR0	SRAM0 Clock Stop Security Attribution Target module: the MSTPCRA.MSTPA0 bit 0: Secure 1: Non-secure	R/W
1	MSSAR1	SRAM1 Clock Stop Security Attribution Target module: the MSTPCRA.MSTPA1 bit 0: Secure 1: Non-secure	R/W
14:2	—	These bits are read as 0. The write value should be 0.	R/W
15	MSSAR15	Standby RAM Clock Stop Security Attribution Target module: the MSTPCRA.MSTPA15 bit 0: Secure 1: Non-secure	R/W
21:16	—	These bits are read as 0. The write value should be 0.	R/W
22	MSSAR22	DMAC/DTC Clock Stop Security Attribution Target module: the MSTPCRA.MSTPA22 bit 0: Secure 1: Non-secure	R/W
30:23	—	These bits are read as 0. The write value should be 0.	R/W
31	MSSAR31	ELC Clock Stop Security Attribution Target module: the MSTPCRC.MSTPC14 bit 0: Secure 1: Non-secure	R/W

Note: S-TYPE-1, P-TYPE-1.

The MSSAR register specifies the security attribution for the corresponding bit in Module Stop Control Register.

37.8.6 PPARB : Peripheral Privilege Attribution Register B

Base address: PSCU = 0x4020_4000
PSCU_NS = 0x5020_4000

Offset address: 0x1C

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	PPARB31	PPARB30	PPARB29	PPARB28	PPARB27	—	—	—	—	PPARB22	—	—	PPARB19	PPARB18	—	—
Value after reset:	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	PPARB15	—	—	—	PPARB11	—	PPARB9	PPARB8	—	—	—	PPARB4	—	—	—	—
Value after reset:	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

Bit	Symbol	Function	R/W
3:0	—	These bits are read as 1. The write value should be 1.	R/W
4	PPARB4	I3C Bus Interface Privilege Attribution Target module: I3C and the MSTPCRB.MSTPB4 bit 0: Privileged 1: UnPrivileged	R/W
7:5	—	These bits are read as 1. The write value should be 1.	R/W
8	PPARB8	I2C Bus Interface 1 Privilege Attribution Target module: IIC1 and the MSTPCRB.MSTPB8 bit 0: Privileged 1: UnPrivileged	R/W
9	PPARB9	I2C Bus Interface 0 Privilege Attribution Target module: IIC0 and the MSTPCRB.MSTPB9 bit 0: Privileged 1: UnPrivileged	R/W
10	—	This bit is read as 1. The write value should be 1.	R/W
11	PPARB11	Universal Serial Bus 2.0 FS Interface 0 Privilege Attribution Target module: USBFS0 and the MSTPCRB.MSTPB11 bit 0: Privileged 1: UnPrivileged	R/W
14:12	—	These bits are read as 1. The write value should be 1.	R/W
15	PPARB15	ETHERC/EDMAC Controller Privilege Attribution Target module: ETHERC/EDMAC, the MSTPCRB.MSTPB15 bit, and the PFENET.PHYMODE0 bit 0: Privileged 1: UnPrivileged	R/W
17:16	—	These bits are read as 1. The write value should be 1.	R/W
18	PPARB18	Serial Peripheral Interface 1 Privilege Attribution Target module: RSPI1 and the MSTPCRB.MSTPB18 bit 0: Privileged 1: UnPrivileged	R/W
19	PPARB19	Serial Peripheral Interface 0 Privilege Attribution Target module: RSPI0 and the MSTPCRB.MSTPB19 bit 0: Privileged 1: UnPrivileged	R/W
21:20	—	These bits are read as 1. The write value should be 1.	R/W
22	PPARB22	Serial Communication Interface 9 Privilege Attribution Target module: SCI9 and the MSTPCRB.MSTPB22 bit 0: Privileged 1: UnPrivileged	R/W
26:23	—	These bits are read as 1. The write value should be 1.	R/W

Bit	Symbol	Function	R/W
27	PPARB27	Serial Communication Interface 4 Privilege Attribution Target module: SCI4 and the MSTPCRB.MSTPB27 bit 0: Privileged 1: UnPrivileged	R/W
28	PPARB28	Serial Communication Interface 3 Privilege Attribution Target module: SCI3 and the MSTPCRB.MSTPB28 bit 0: Privileged 1: UnPrivileged	R/W
29	PPARB29	Serial Communication Interface 2 Privilege Attribution Target module: SCI2 and the MSTPCRB.MSTPB29 bit 0: Privileged 1: UnPrivileged	R/W
30	PPARB30	Serial Communication Interface 1 Privilege Attribution Target module: SCI1 and the MSTPCRB.MSTPB30 bit 0: Privileged 1: UnPrivileged	R/W
31	PPARB31	Serial Communication Interface 0 Privilege Attribution Target module: SCI0 and the MSTPCRB.MSTPB31 bit 0: Privileged 1: UnPrivileged	R/W

Note: S-TYPE-2, P-TYPE-1.

The PPARB register specifies the privilege attribution for each module and the corresponding bit in Module Stop Control Register.

37.8.7 PPARC : Peripheral Privilege Attribution Register C

Base address: PSCU = 0x4020_4000
PSCU_NS = 0x5020_4000

Offset address: 0x20

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	PPARC31	—	—	—	PPARC27	PPARC26	—	—	—	—	—	—	—	—	—	—
Value after reset:	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

9	PPARE9	ULPT0 Privilege Attribution Target module: ULPT0 and the MSTPCRE.MSTPE9 bit 0: Privileged 1: UnPrivileged	R/W
17:10	—	These bits are read as 1. The write value should be 1.	R/W
18	PPARE18	General PWM Timer Channel 13 Privilege Attribution Target module: : GPT13 and the MSTPCRE.MSTPE18 bit 0: Privileged 1: UnPrivileged	R/W
19	PPARE19	General PWM Timer Channel 12 Privilege Attribution Target module: : GPT12 and the MSTPCRE.MSTPE19 bit 0: Privileged 1: UnPrivileged	R/W
20	PPARE20	General PWM Timer Channel 11 Privilege Attribution Target module: : GPT11 and the MSTPCRE.MSTPE20 bit 0: Privileged 1: UnPrivileged	R/W
21	PPARE21	General PWM Timer Channel 10 Privilege Attribution Target module: : GPT10 and the MSTPCRE.MSTPE21 bit 0: Privileged 1: UnPrivileged	R/W

Bit	Symbol	Function	R/W
22	PPARE22	General PWM Timer Channel 9 Privilege Attribution Target module: : GPT9 and the MSTPCRE.MSTPE22 bit 0: Privileged 1: UnPrivileged	R/W
23	PPARE23	General PWM Timer Channel 8 Privilege Attribution Target module: : GPT8 and the MSTPCRE.MSTPE23 bit 0: Privileged 1: UnPrivileged	R/W
24	PPARE24	General PWM Timer Channel 7 Privilege Attribution Target module: : GPT7 and the MSTPCRE.MSTPE24 bit 0: Privileged 1: UnPrivileged	R/W
25	PPARE25	General PWM Timer Channel 6 Privilege Attribution Target module: : GPT6 and the MSTPCRE.MSTPE25 bit 0: Privileged 1: UnPrivileged	R/W
26	PPARE26	General PWM Timer Channel 5 Privilege Attribution Target module: : GPT5 and the MSTPCRE.MSTPE26 bit 0: Privileged 1: UnPrivileged	R/W
27	PPARE27	General PWM Timer Channel 4 Privilege Attribution Target module: : GPT4 and the MSTPCRE.MSTPE27 bit 0: Privileged 1: UnPrivileged	R/W
28	PPARE28	General PWM Timer Channel 3 Privilege Attribution Target module: : GPT3 and the MSTPCRE.MSTPE28 bit 0: Privileged 1: UnPrivileged	R/W
29	PPARE29	General PWM Timer Channel 2 Privilege Attribution Target module: : GPT2 and the MSTPCRE.MSTPE29 bit 0: Privileged 1: UnPrivileged	R/W
30	PPARE30	General PWM Timer Channel 1 Privilege Attribution Target module: : GPT1 and the MSTPCRE.MSTPE30 bit 0: Privileged 1: UnPrivileged	R/W
31	PPARE31	General PWM Timer Channel 0 Privilege Attribution Target module: : GPT0 and the MSTPCRE.MSTPE31 bit 0: Privileged 1: UnPrivileged	R/W

Note: S-TYPE-2, P-TYPE-1.

The PPARE register specifies the privilege attribution for each module and the corresponding bit in Module Stop Control Register.

37.8.10 MSPAR : Module Stop Privilege Attribution Register

Base address: PSCU = 0x4020_4000
PSCU_NS = 0x5020_4000

Offset address: 0x2C

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	MSPAR31	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

Bit	Symbol	Function	R/W
30:0	—	These bits are read as 1. The write value should be 1.	R/W
31	MSPAR31	ELC Clock Stop Privilege Attribution Target module: the MSTPCRC.MSTPC14 bit 0: Privileged 1: UnPrivileged	R/W

Note: S-TYPE-2, P-TYPE-1.

The MSPAR register specifies the privilege attribution for the corresponding bit in the Module Stop Control Register.

37.8.11 CFSAMONA : Code Flash Security Attribution Monitor Register A

Base address: PSCU = 0x4020_4000
PSCU_NS = 0x5020_4000

Offset address: 0x30

Bit position:	31								23								15														0
Bit field:	—	—	—	—	—	—	—	—	CFS2[8:0]								—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	*1	*1	*1	*1	*1	*1	*1	*1	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Note 1. The value in a blank product is 0x1FF. It is set to the value written by your application.

Bit	Symbol	Function	R/W
14:0	—	These bits are read as 0.	R
23:15	CFS2[8:0]	Code Flash Secure Area Indicate the area of secure region for code flash.	R
31:24	—	These bits are read as 0.	R

Note: S-TYPE-5, P-TYPE-5.

37.8.12 DFSAMON : Data Flash Security Attribution Monitor Register

Base address: PSCU = 0x4020_4000
PSCU_NS = 0x5020_4000

Offset address: 0x34

Bit position:	31																15						10								0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	DFS[5:0]						—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	*1	*1	*1	*1	*1	*1	0	0	0	0	0	0	0	0	0

Note 1. The value in a blank product is 0x3F. It is set to the value written by your application.

Bit	Symbol	Function	R/W
9:0	—	These bits are read as 0.	R
15:10	DFS[5:0]	Data Flash Secure Area Indicate the area of secure region for data flash.	R
31:16	—	These bits are read as 0.	R

Note: S-TYPE-5, P-TYPE-5.

37.8.13 DLMMON : Device Lifecycle Management State Monitor Register

Base address: PSCU = 0x4020_4000
PSCU_NS = 0x5020_4000

Offset address: 0x38

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	DLMMON[3:0]			
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	*1	*1	*1	*1

Note 1. The value in a blank product is 0001b. These bits depend on DLM status.

Bit	Symbol	Function	R/W
3:0	DLMMON[3:0]	Device Lifecycle Management State Monitor Indicate DLM status value. 0x0: Reserved 0x1: CM 0x2: Reserved 0x3: Reserved 0x4: OEM 0x5: Reserved 0x6: LCK_BOOT 0x7: RMA_REQ 0x8: RMA_ACK 0x9: RMA_RET Others: Reserved	R
31:4	—	These bits are read as 0.	R

Note: S-TYPE-5, P-TYPE-5.

37.8.14 MSAOAD : Master Security Attribution Operation After Detection Register

Base address: BUS = 0x4000_3000

Offset address: 0x1010

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	KEY[7:0]								—	—	—	—	—	—	—	OAD
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	OAD	Operation after detection 0: NMI 1: Reset	R/W
7:1	—	These bits are read as 0. The write value should be 0.	R/W

Bit	Symbol	Function	R/W
15:8	KEY[7:0]	Key Code These bits enable or disable writing of the OAD bit.	W

Note: S-TYPE-6, P-TYPE-2.

OAD bit (Operation after detection)

The OAD bit specifies operation when the access violation is detected. When OAD = 0, error response is returned and NMI is generated. When OAD = 1, reset request is generated. When writing to the OAD bit, write 0xA5 simultaneously to the KEY[7:0] bits using halfword access.

KEY[7:0] bits (Key Code)

The KEY[7:0] bits enable or disable writing to the OAD bit. When writing to the OAD bit, write 0xA5 simultaneously to the KEY[7:0] bits. If this value is not written to the KEY[7:0] bits, the OAD bit is not updated.

37.8.15 MSAPT : Master Security Attribution Protect Register

Base address: BUS = 0x4000_3000

Offset address: 0x1014

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	KEY[7:0]								—	—	—	—	—	—	—	PROTECT
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	PROTECT	Protection of register 0: MSAOAD register writing is possible. 1: MSAOAD register writing is protected. Read is possible.	R/W
7:1	—	These bits are read as 0. The write value should be 0.	R/W
15:8	KEY[7:0]	Key Code These bits enable or disable writing of the PROTECT bit.	W

Note: S-TYPE-6, P-TYPE-2.

PROTECT bit (Protection of register)

The PROTECT bit enables or disables writes to the associated registers to be protected.

MSAPT.PROTECT controls the MSAOAD register.

When the PROTECT bit is set simultaneously, write 0xA5 to the KEY[7:0] bits using half word access.

KEY[7:0] bits (Key Code)

The KEY[7:0] bits enable or disable writing to the PROTECT bit. When writing to the PROTECT bit, write 0xA5 simultaneously to the KEY[7:0] bits. If this value is not written to the KEY[7:0] bits, the PROTECT bit is not updated.

37.9 Usage Note

37.9.1 Security or Privilege Bit Write Timing

When writing a security or privilege attribution bit, confirm that the write is complete by reading the security or privilege register until it matches the value written. The protection is not effective until the write to the security or privilege register is complete.

38. Renesas Secure IP (RSIP-E51A)

38.1 Overview

This security engine consists of an isolated subsystem comprising an access management circuit, storage area, encryption/decryption circuit, and random number generation circuit. In combination with the RSIP library, the security engine can prevent eavesdropping (to maintain confidentiality), falsification of information (to ensure integrity), and impersonation (to verify authenticity).

Because key information required for encryption and decryption is stored only in the security engine and all accesses from the outside can be blocked, the security engine enables building a more robust security system.

Table 38.1 lists the security engine specifications. Figure 38.1 shows the security engine block diagram.

Table 38.1 Security engine specifications (1 of 2)

Parameter	Specifications
Access control	Access management circuit ● In case of irregular access to the security engine due to a tampered program or CPU runaway, this circuit blocks all subsequent accesses and stops data output from the security engine
Symmetric cryptography	AES: Compliant with NIST FIPS PUB 197 ● Key length: 128, 192, or 256 bits ● Data block size: 128 bits ● AES supports following block cipher mode ECB, CBC, CTR: Compliant with NIST SP 800-38A CCM: Compliant with NIST SP 800-38C GCM: Compliant with NIST SP 800-38D XTS: Compliant with IEEE 1619-2007 ● AES supports following authentication algorithm CMAC: Compliant with NIST SP 800-38B GMAC: Compliant with NIST SP 800-38D ● AES does not support the KEY size of 192-bit in CCM, GCM, XTS, CMAC and GMAC.
Random number generation	128-bit true random number generation circuit
Asymmetric cryptography	RSA ● Maximum number of operable bits: 4224 bits ● Supported key sizes: 1024-bit, 2048-bit, 3072-bit, and 4096-bit ● Signature generation, signature verification, public-key encryption, private-key decryption ECC ● Maximum number of operable bits: 576 bits ● Support for curve – NIST P-192, P-224, P-256, P-384 and P-521 – Brainpool P256r1, P384r1, and P512r1 – Ed25519 – secp256k1 ● Signature generation, signature verification, key generation
Message digest computation	HASH ● Block size: 512-bit(SHA-224, SHA-256) 1024-bit(SHA-512/224, SHA-512/256, SHA-384, SHA-512) ● Key size: 512-bit or less ● HASH supports following secure hash algorithms SHA-224, SHA-256, SHA-512/224, SHA-512/256, SHA-384 and SHA-512: Compliant with FIPS PUB 180-4 ● HASH supports following message authentication algorithm HMAC: Compliant with FIPS PUB 198

Table 38.1 Security engine specifications (2 of 2)

Parameter	Specifications
Hardware Unique Key	● A read-only, 256-bit Hardware Unique Key (HUK) is exclusively accessible by the security engine access management circuit through a dedicated bus. ● Key derivation functions (KDFs) combine the Hardware Unique Key with the key generation information. The derived keys implement the key wrapping for user key secure storage. ● The HUK uniqueness prevents the illicit cloning and copying of keys to another MCU of the MCU group. ● The HUK itself is stored in wrapped (encrypted, non-plain) format in an isolated memory area. Therefore, it is protected from illicit access and copy.
Application Key Management	● Wrapped keys are only valid within the security engine.
Unique ID	● A read-only, 128-bit ID unique to an MCU (Unique ID) is accessible from the access management circuit. ● Key derivation functions (KDFs) combine the Unique ID with the key generation information. Such derived keys are used to unwrap the HUK within the security engine boundary.
OEM boot loader version	● The security engine outputs OEM boot loader version (OEM BL Ver.). ● Flash sequencer supports Anti-Rollback Counter Protection using the OEM boot loader version, which is protected by the security engine.
Tamper Resistance	Countermeasures available for side-channel attacks, including SPA/DPA and timing attacks.
Module-stop function	Module-stop state can be set to reduce power consumption
TrustZone Filter	Security and Privilege attribution can be set

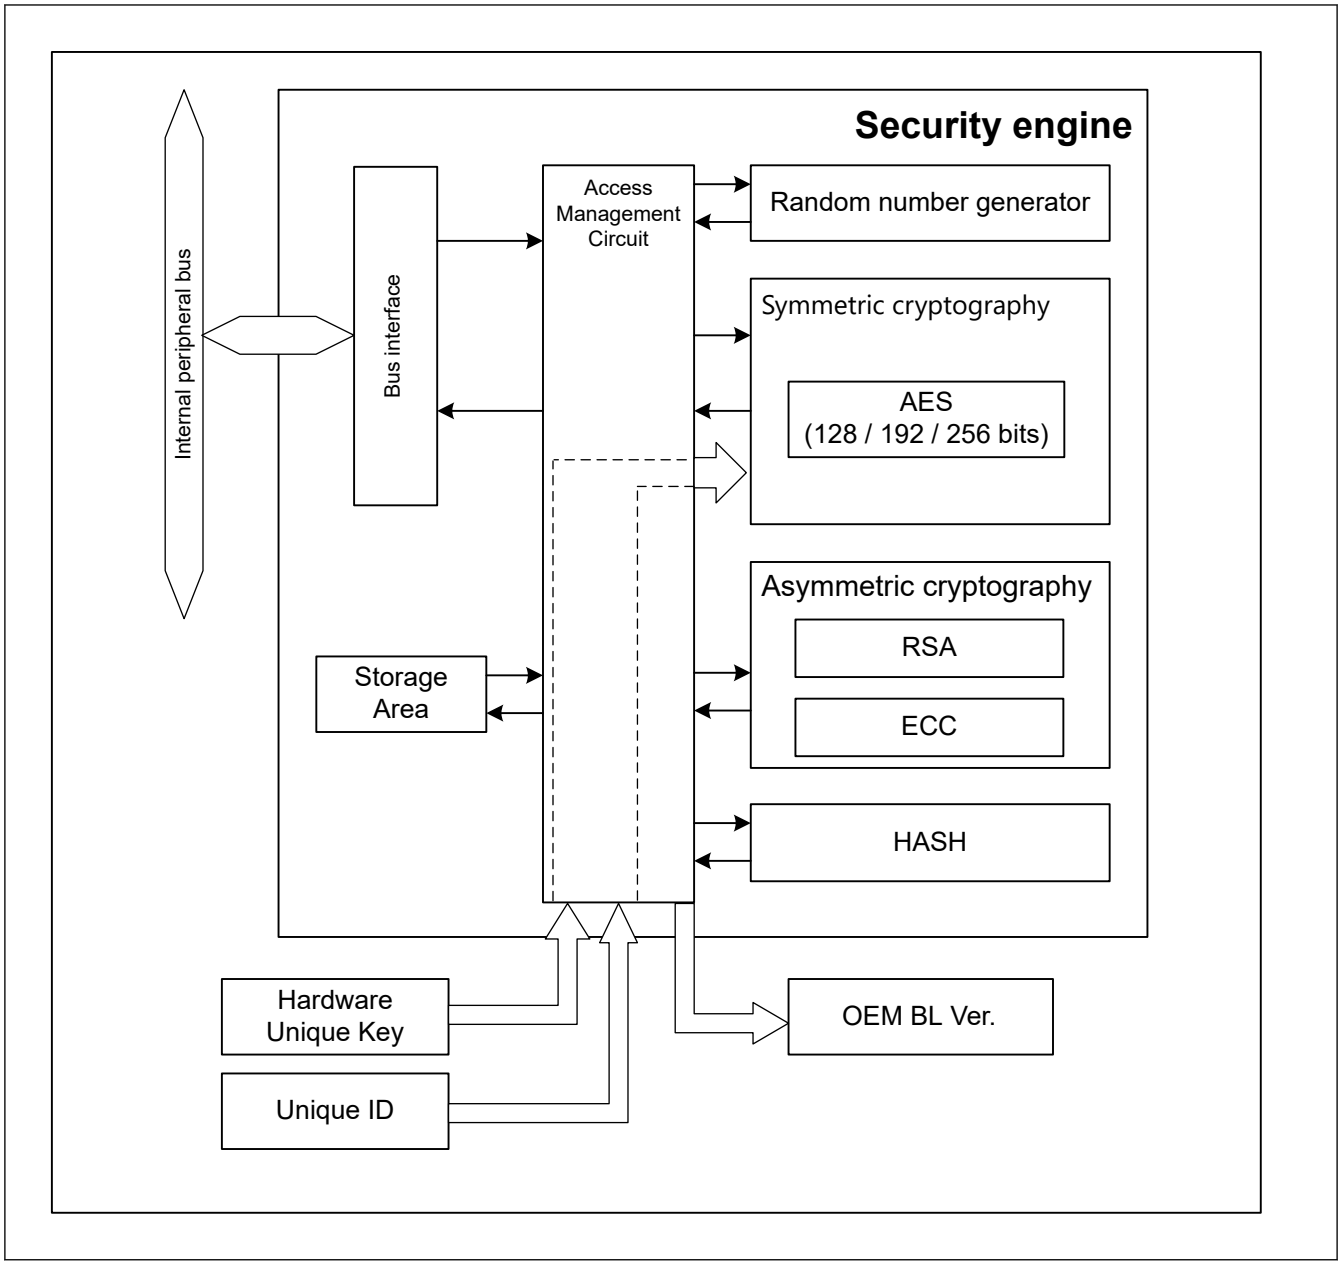

Figure 38.1 Security engine block diagram

38.2 Operation

38.2.1 Symmetric cryptography

Figure 38.2 shows conceptual block diagram of the symmetric cryptography installed in the security engine.

The symmetric cryptography uses the input key information and converts the plaintext data to ciphertext or ciphertext data to plaintext through the hardware.

The encryption/decryption process can be completed without exposing the key data and the process's intermediate data outside of the security engine. This process is performed by the encryption/decryption circuit and storage area of the security engine internally.

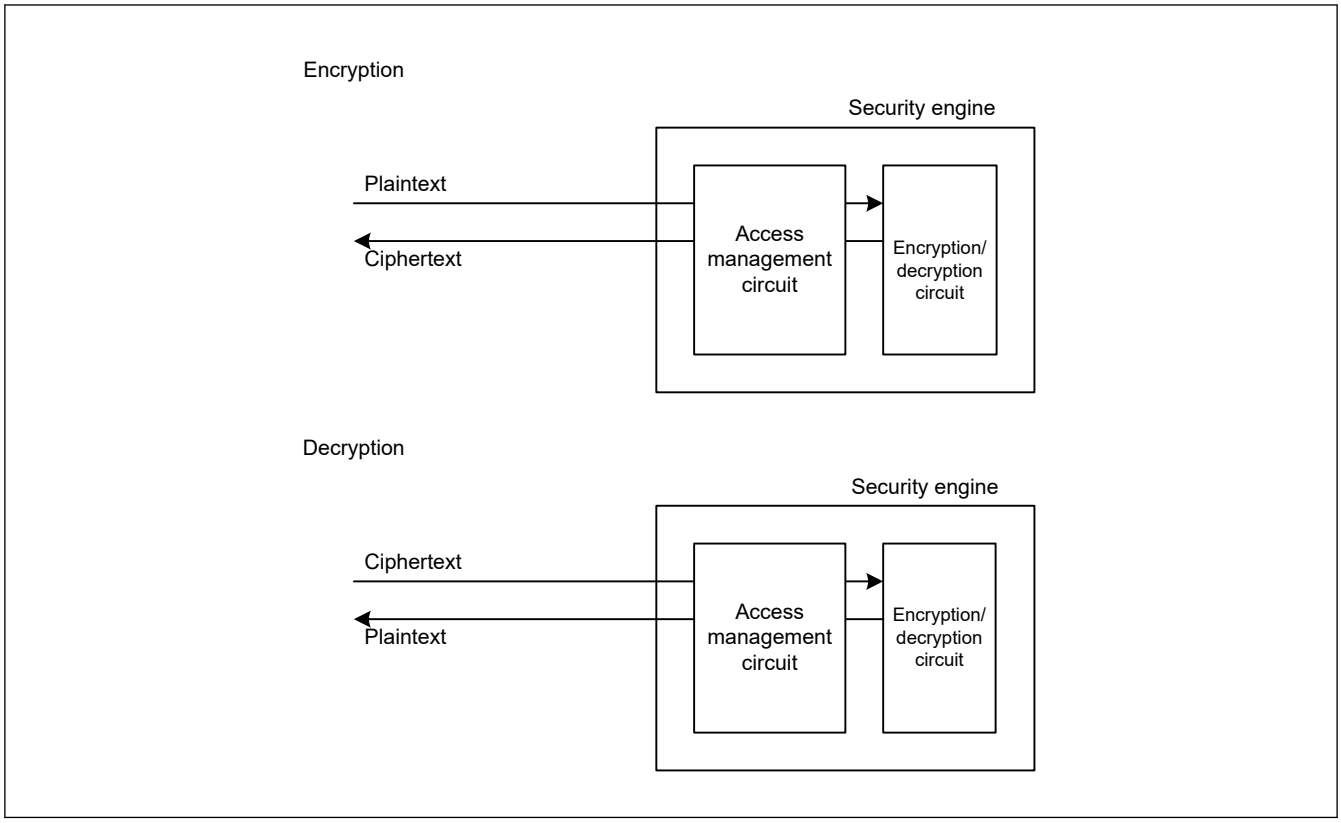

Figure 38.2 Conceptual diagram of the symmetric cryptography

38.2.2 Asymmetric Cryptography

Figure 38.3 shows conceptual block diagram of the asymmetric cryptography installed in the security engine.

The asymmetric cryptography uses the input key information and converts the plaintext data to ciphertext or ciphertext data to plaintext or generates/verifies the signature.

The encryption/decryption or signature generation/verification process can be completed without exposing the key data and the process's intermediate data outside of the security engine. This process is performed by the cryptographic circuit and storage area of the security engine internally.

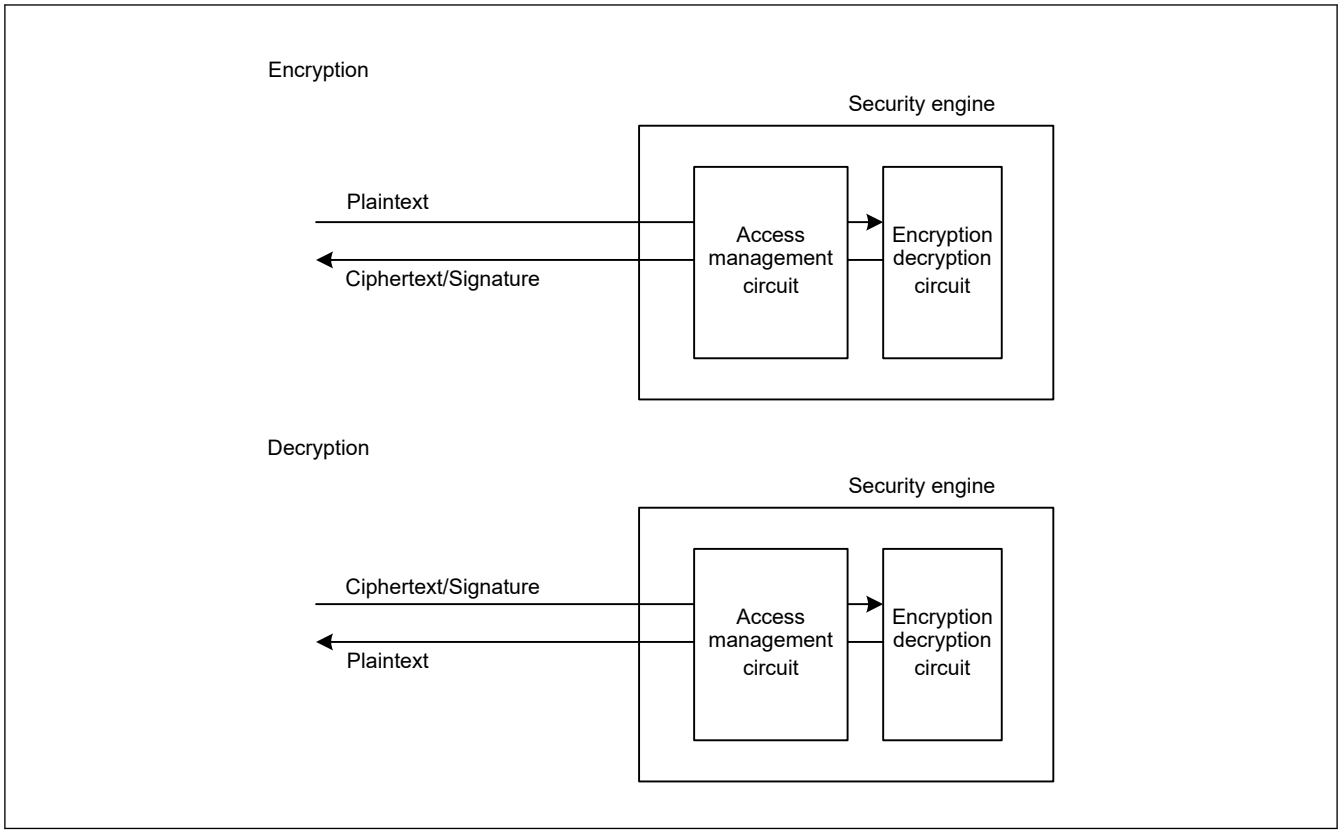

Figure 38.3 Conceptual diagram of the asymmetric cryptography

38.2.3 Hash generator

Figure 38.4 shows conceptual block diagram of the hash generator installed in the security engine.

The hash generator generates uses the input key information (if required for the hash calculation) and generates the message digest or tag.

The calculation process can be completed without exposing any key data and the process's intermediate data outside of the security engine. This process is performed by the hash circuit and storage area of the security engine internally.

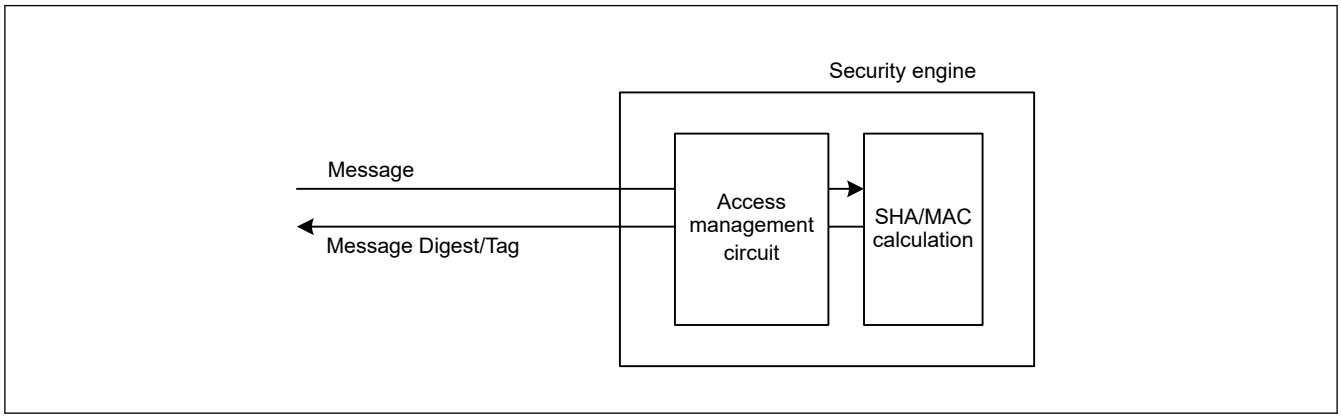

Figure 38.4 Conceptual diagram of the hash generator

38.2.4 Encryption and Decryption

Follow the procedure below to encrypt and decrypt the data:

1. Input the key information to the security engine.
2. Input the target data to the security engine. Plaintext data is converted to ciphertext and ciphertext data to plaintext.
3. Read the converted data.

The encryption/decryption circuit has input and output buffers, and can perform encryption/decryption in parallel with data input/output. Figure 38.5 shows the encryption engine timing.

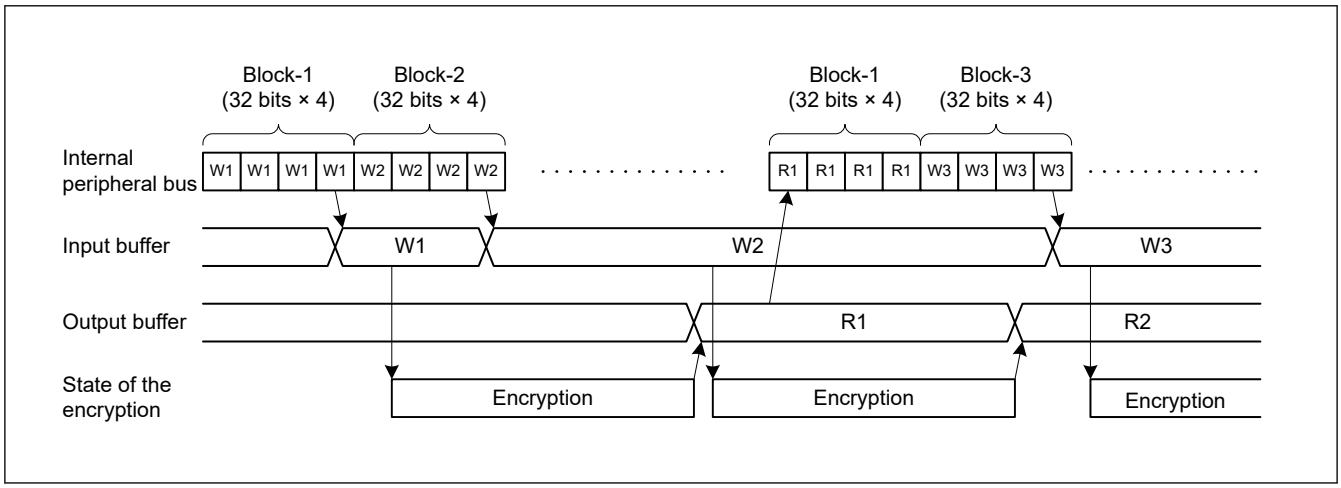

Figure 38.5 Encryption and decryption timing (AES)

38.3 Usage Notes

38.3.1 Software Standby Mode

When Software Standby mode is entered while the security engine is in process, proper processing cannot be resumed after cancelling Software Standby mode. Software Standby mode should therefore be entered while the security engine is not running.

38.3.2 Module-Stop Function Setting

The security engine operation can be disabled or enabled using Module Stop Control Register C (MSTPCRC). The security engine module is initially stopped after reset. Releasing the module-stop state enables access to the registers.

38.3.3 SPA/DPA Protections

SPA/DPA protections can optionally be enabled for encryption/decryption processing.

38.3.4 Restrictions on Open process

While open process of security engine's API (R_RSIP_Open) is running, the following restrictions is applied.

- Available CPU frequency is up to 240MHz
- Do not change frequency of CPUCLK, ICLK and PCLKn (n = A to E)
- Do not change MSTPCRn registers (n = A to E)
- Do not transition to CPU Sleep mode, CPU Deep Sleep mode, Software Standby mode and Deep Software Standby mode 1/2/3."

39. 12-Bit A/D Converter (ADC12)

39.1 Overview

The MCU includes 12-bit successive approximation A/D converter (ADC12) units. In unit 0, up to 12 analog input channels are selectable. In unit 1, up to 13 analog input channels, temperature sensor output, internal reference voltage can be selected for conversion in respective units.

The A/D conversion accuracy is selectable from 12-bit, 10-bit, 8-bit conversion, making it possible to optimize the trade-off between speed and resolution in generating a digital value.

The ADC12 supports the following operating modes:

- Single scan mode to convert analog inputs of selected channels in ascending order of channel number
- Continuous scan mode to convert analog inputs of selected channels continuously in ascending order of channel number
- Group scan mode to divide analog inputs of channels into two groups (group A and B) and convert the analog inputs of selected channels for each group in ascending order of channel number.

In group scan mode, select two groups (group A and B). You can individually select the scan start conditions for each group (group A, B) and start scanning of each group at different times. In addition, when group A priority control operation is set, the ADC12 accepts group A scan start during group B A/D conversion, suspending group B conversion. This allows you to assign higher priority to A/D conversion start for group A.

In double trigger mode, the analog input of a selected channel is converted in single scan mode or group scan mode (group A), and data converted by the first and second A/D conversion start triggers are stored in different registers, providing duplexing of A/D converted data.

Self-diagnosis is performed once at the beginning of each scan, and one of the three reference voltage values generated in ADC12 is A/D converted.

The temperature sensor output and the internal reference voltage is selectable at the same time as the analog input of the channel. First A/D conversion is performed for the analog input of the channel, next the temperature sensor output and then for the internal reference voltage.

The ADC12 also provides a compare function (window A and window B). The compare function specifies the upper reference value for window A and lower reference value for window B, and outputs an interrupt when the A/D converted value of the selected channel meets the comparison conditions.

The A/D data storage buffer is a ring buffer consisting of 16 buffers to sequentially store A/D converted data.

Table 39.1 lists the ADC12 specifications and Table 39.2 lists the functions. Figure 39.1 shows a block diagram of ADC12 and Table 39.3 lists the I/O pins.

Table 39.1 ADC12 specifications (1 of 3)

Parameter	Specifications
Number of units	Two units
Input channels	Up to 25 channels (AN000 to AN002, AN004 to AN008, AN016 to AN019, AN100 to AN102, AN104 to AN106, AN116 to AN122)
Analog function	Temperature sensor output, internal reference voltage
Conversion method	Successive approximation method
Resolution	12-bit, 10-bit, 8-bit
Conversion time	0.4 µs/channel (when 12-bit A/D conversion clock PCLKC (ADCLK) is operating at 60 MHz)
A/D conversion clock	Peripheral module clock PCLKA and A/D conversion clock PCLKC (ADCLK) can be set with the following division ratios: PCLKA to PCLKC (ADCLK) frequency ratio = 1:1, 2:1, 4:1, 8:1, 1:2, 1:4

Table 39.1 ADC12 specifications (2 of 3)

Parameter	Specifications
Data registers[*1]	• 25 registers for analog input • One register for A/D-converted data duplication in double trigger mode • Two registers for A/D-converted data duplication during extended operation in double trigger mode • One register for temperature sensor output • One register for internal reference voltage • One register for self-diagnosis • A/D conversion results are stored in A/D data registers • 12-bit, 10-bit, 8-bit accuracy for A/D conversion results • A/D-converted value addition mode, in which the sum of all A/D-converted results is stored in the A/D data registers as a value with the conversion accuracy bit count + extended bits • Double-trigger mode (selectable in single scan and group scan modes): – The first unit of A/D-converted analog input data on one selected channel is stored in the data register for the channel, and the second unit is stored in the duplication register. • Extended operation in double trigger mode (available for specific triggers): – A/D-converted analog input data on one selected channel is stored in the duplication register provided for the associated trigger.
Operating modes[*2]	• Single scan mode: – A/D conversion is performed only once on the analog inputs of arbitrarily selected channels, on the temperature sensor output, on the internal reference voltage. • Continuous scan mode: A/D conversion is performed repeatedly on the analog inputs of the selected channels on the temperature sensor output, and on the internal reference voltage. • Group scan mode: – Analog inputs of selected channels, the temperature sensor output, and the internal reference voltage are divided into groups A and B. Then A/D conversion of the analog inputs selected on a group basis is performed once. – The scan start conditions can be independently selected for group A, B, allowing A/D conversion of group A, B to be started independently. • Group scan mode (when group priority operation is selected): – If a priority group trigger is input during scanning of a lower-priority group, the scanning of the lower-priority group is stopped and then scanning of the priority group is started. The order of priority is group A > group B. – It is possible to select whether to restart scanning (rescan) of the lower-priority group upon completion of the priority group scan. It is also possible to specify rescanning to be started from the first channel of the selected channels or from the channel for which A/D conversion has not been completed.
Conditions for A/D conversion start	• Software trigger • Synchronous triggers from the Event Link Controller (ELC) and GPT • Asynchronous triggering by the external trigger pins, ADTRG0 (unit 0) and ADTRG1 (unit 1)
Functions	• Dedicated sample-and-hold function with optional constant sampling and 3 channels in unit 0 • Variable sampling state count • Self-diagnosis of A/D converter • Selectable A/D-converted value addition mode or average mode • Analog input disconnection detection function (discharge and precharge functions) • Double-trigger mode (duplication of A/D conversion data) • Automatic clear function for A/D data registers • Digital comparison of values in the comparison register and data register, and comparison between values in the data registers • Ring buffer

Table 39.1 ADC12 specifications (3 of 3)

Parameter	Specifications
Interrupt sources	• In single scan mode (double trigger deselected), an A/D scan end interrupt request (ADC12i_ADI (i = 0, 1)) and ELC event signal (ADC12i_ADI (i = 0, 1)) can be generated on completion of single scan. – A compare interrupt request (ADC12i_CMPAI (i = 0, 1)/ADC12i_CMPBI (i = 0, 1)) can be generated in response to a match with a digital comparison condition. – A window compare ELC event signal (ADC12i_WCMPM (i = 0, 1)) can be generated in response to a match with a digital comparison condition. – A window compare ELC event signal (ADC12i_WCMPUM (i = 0, 1)) can be generated in response to a mismatch with a digital comparison condition. • In single scan mode (double trigger selected), an A/D scan end interrupt request (ADC12i_ADI (i = 0, 1)) and ELC event signal (ADC12i_ADI (i = 0, 1)) is generated on completion of two scans. • In continuous scan mode, an A/D scan end interrupt request (ADC12i_ADI (i = 0, 1)) and ELC event signal (ADC12i_ADI (i = 0, 1)) is generated on completion of all the selected channel scans. • In group scan mode (double trigger deselected), an A/D scan end interrupt request (ADC12i_ADI (i = 0,1)) and ELC event signal (ADC12i_ADI (i = 0, 1)) is generated on completion of group A scan, and an A/D scan end interrupt request for group B (ADC12i_GBADI (i = 0, 1)) can be generated on completion of group B scan. • In group scan mode (double trigger selected), an A/D scan end interrupt request (ADC12i_ADI (i = 0, 1)) and ELC event signal (ADC12i_ADI (i = 0, 1)) is generated on completion of two group A scans, and an A/D scan end interrupt request for group B (ADC12i_GBADI (i = 0, 1)) can be generated on completion of group B scan. • ADC12i_ADI (i = 0, 1), ADC12i_GBADI (i = 0, 1), ADC12i_WCMPM (i = 0, 1), and ADC12i_WCMPUM (i = 0, 1) can activate the Data Transfer Controller (DTC).
ELC interface	• An event is generated upon completion of group A scan in group-scan mode. • An event is generated upon completion of group B scan in group-scan mode. • An event is generated when all scans complete. • Scan can be started by a trigger from the ELC. • An event is generated according to conditions of the compare function window in single-scan mode.
Reference voltage	• Unit 0: VREFH0 is the analog reference voltage. VREFL0 is the analog reference ground. • Unit 1: VREFH is the analog reference voltage. VREFL is the analog reference ground.
Analog channel input SA judgement function	Input channels of analog can be valid only when the security attribution of ADC12n (n = 0, 1) match the security attribution of PORT (PmSAR). When the security attribution of ADC12n (n = 0, 1) does not match the PORT security attribution, the conversion result of ADC input channel will be unexpected. Internal reference voltage, Temperature sensor output have no Security Attribution judgement function.
Module-stop function	Module-stop state can be set to for each units reduce power consumption.*3
TrustZone Filter	Security and Privilege attribution can be set for each unit

Note 1. Changing the A/D conversion accuracy also changes the A/D conversion time. For details, see section 39.3.6. Analog Input Sampling and Scan Conversion Time.
Note 2. When selecting the temperature sensor output, the internal reference voltage, do not use continuous scan mode or group scan mode.
Note 3. For details, see section 10, Low Power Modes.

Table 39.2 ADC12 functions (1 of 2)

Parameter			Function
Analog input channel			AN000 to AN002, AN004 to AN008, AN016 to AN019 (unit 0), AN100 to AN102, AN104 to AN106, AN116 to AN122 (unit 1) Internal reference voltage Temperature sensor output
Conditions for A/D conversion starts	Software	Software trigger	Enabled
	Asynchronous trigger (external trigger)	Trigger input pin	ADTRGn (n = 0, 1)
	Synchronous trigger (trigger from ELC)	ELC trigger	ELC_AD00 (unit 0) and ELC_AD10 (unit 1), ELC_AD01 (unit 0) and ELC_AD11 (unit 1)
		GPT trigger	GTCIADAm, GTCIADBm (unit 0) (m = 0 to 3) GTCIADAn, GTCIADBn (unit 1) (n = 4 to 7)

Table 39.2 ADC12 functions (2 of 2)

Parameter	Function
Channel-dedicated sample-and-hold function Target channel	AN000 to AN002 (unit 0)
Interrupt	ADC12i_ADI (i = 0, 1) ADC12i_GBADI (i = 0, 1) ADC12i_CMPAI (i = 0, 1) ADC12i_CMPBI (i = 0, 1)
Output to ELC	ADC12i_ADI (i = 0, 1) ADC12i_WCMPM (i = 0, 1) ADC12i_WCMPUM (i = 0, 1)
Module-stop function settings*1 *2	MSTPCRD.MSTPD16 bit (unit 0) MSTPCRD.MSTPD15 bit (unit 1)

Note 1. For details, see section 10, Low Power Modes.
Note 2. Wait 1 µs or longer to start A/D conversion after release from the module-stop state.

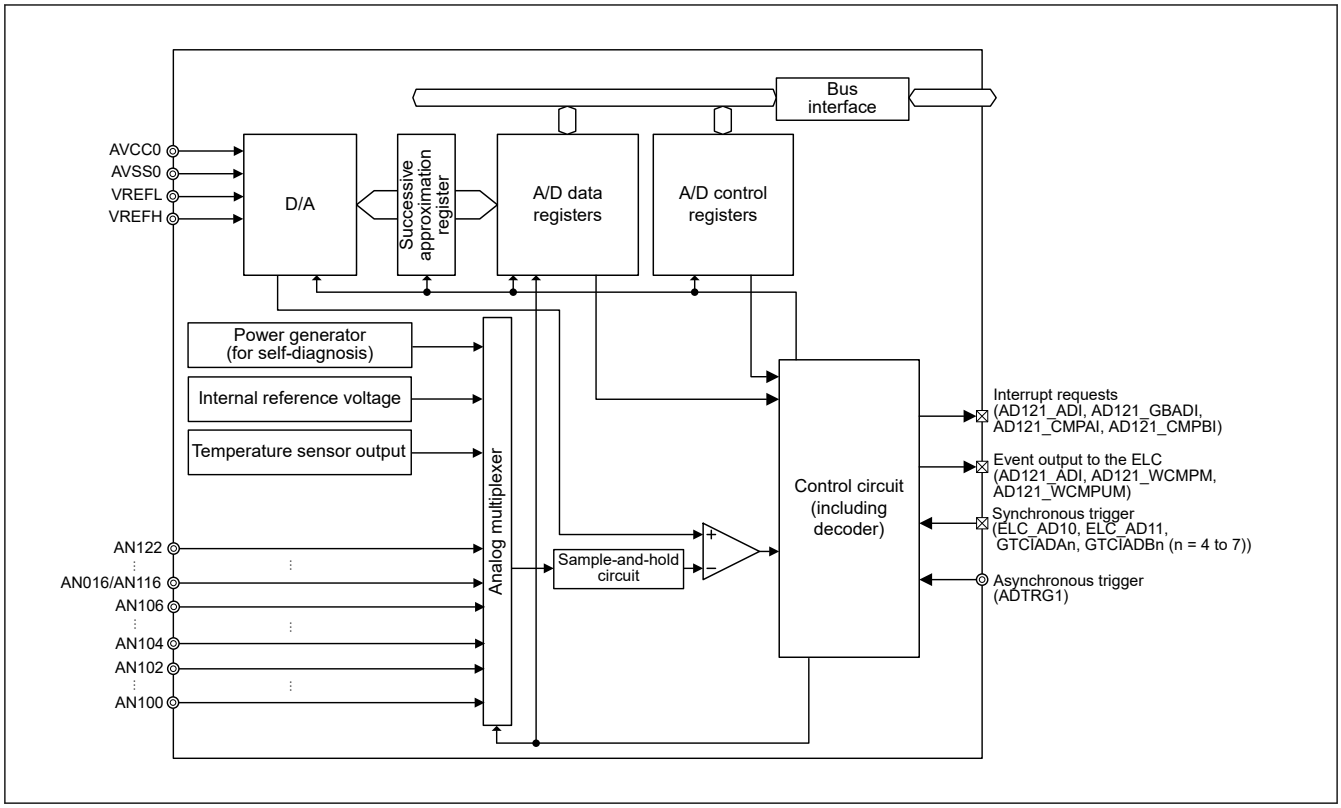

Figure 39.2 ADC12 block diagram (unit 1)

Table 39.3 lists the ADC12 I/O pins.

Table 39.3 ADC12 I/O pins (unit 0)

Pin name	I/O	Function
AVCC0	Input	Analog block power supply pin (Connect to VCC when ADC12/DAC12 is not used.)
AVSS0	Input	Analog block power supply ground pin (Connect to VSS when ADC12/DAC12 is not used.)
VREFH0	Input	Analog reference voltage supply pin
VREFL0	Input	Analog reference ground pin
AN000 to AN002, AN004 to AN008, AN016 to AN019	Input	Analog input pins 0 to 2, 4 to 8, 16 to 19
ADTRG0	Input	External trigger input pin for starting A/D conversion

Table 39.4 ADC12 I/O pins (unit 1)

Pin name	I/O	Function
AVCC0	Input	Analog block power supply pin (Connect to VCC when ADC12/DAC12 is not used.)
AVSS0	Input	Analog block power supply ground pin (Connect to VSS when ADC12/DAC12 is not used.)
VREFH	Input	Analog reference voltage supply pin
VREFL	Input	Analog reference ground pin
AN100 to AN102, AN104 to AN106, AN116 to AN122	Input	Analog input pins 0 to 2, 4 to 6, 16 to 22
ADTRG1	Input	External trigger input pin for starting A/D conversion

39.2 Register Descriptions

39.2.1 ADDRn : A/D Data Registers n

Base address: ADC12m = 0x4033_2000 + 0x0200 × m (m = 0, 1)
ADC12m_NS = 0x5033_2000 + 0x0200 × m (m = 0, 1)

Offset address: 0x020 + 0x2 × n (n = 0 to 2, 4 to 8, 16 to 19, m = 0)
0x020 + 0x2 × n (n = 0 to 2, 4 to 6, 16 to 22, m = 1)

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	ADDR [15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	ADDR [15:0]	Converted Value 15 to 0 Functions vary depending on the selected mode and accuracy. See Table 39.5 and Table 39.6.	R

Note: S-TYPE-3, P-TYPE-3

ADDRn registers are 16-bit read-only registers to store A/D conversion results.

The following conditions determine the formats for data in the A/D data registers:

- Setting of the A/D Data Register Format Select bit (ADCER.ADRFMT) (flush-left or flush-right)
- The setting in the A/D Conversion Accuracy Select bits (ADCER.ADPRC[1:0]) (12-bit, 10-bit, 8-bit is selectable.)
- Setting of the Addition/Average Count Select bits (ADADC.ADC[2:0]) (1, 2, 3, 4, or 16 times)
- Setting of the Average Mode Enable bit (ADADC.AVEE) (addition or average).

This section describes the data formats for these conditions in different modes.

(1) When A/D-converted value addition/average mode is not selected

Table 39.5 shows the example of bit assignment for 12-bit accuracy.

Table 39.5 Example of bit assignment for 12-bit accuracy

Accuracy	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Right-justified data with 12-bit accuracy	These bits are read as 0.				Converted Value 11 to 0: 12-bit A/D-converted value											
Left-justified data with 12-bit accuracy	Converted Value 11 to 0: 12-bit A/D-converted value												These bits are read as 0.			

(2) When A/D-converted value average mode is selected

A/D-converted value average mode can be selected when 2 or 4 times is specified in the A/D-converted value addition mode. When A/D converted value average mode is selected, these registers indicate the mean of A/D-converted values on a specific channel. The value is stored in the A/D data register based on the setting of the A/D Data Register Format Select bit in the same way as for normal A/D conversion.

(3) When A/D-converted value addition mode is selected

For 12-bit, 10-bit, 8-bit accuracy, 1, 2, 3, or 4 times can be selected in the A/D-converted value addition mode. A/D conversion results are stored in the A/D data register as a 2-bit-extended value of the specified conversion accuracy.

For 12-bit accuracy, 16 times can also be selected in the A/D-converted value addition mode. In A/D-converted value addition mode, these registers indicate the value that is obtained by adding A/D-converted values on a specific channel. A/D conversion results are stored in the A/D data register as a 4-bit-extended value of the specified conversion accuracy.

When A/D-converted value addition mode is selected, the value is stored in the A/D data register based on the settings of the A/D Data Register Format Select bits.

Table 39.6 shows example of the bit assignment for 12-bit accuracy.

Table 39.6 Example of bit assignment for 12-bit accuracy when A/D-converted value addition mode is selected

Accuracy		b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Right-justified data with 12-bit accuracy	When 16 conversion times is specified	Added Value 15 to 0: 16-bit sum of A/D conversion results															
	When 1, 2, 3, or 4 conversion times is specified	These bits are read as 0.		Added Value 13 to 0: 14-bit sum of A/D conversion results													
Left-justified data with 12-bit accuracy	When 1, 2, 3, or 4 conversion times is specified	Added Value 15 to 0: 16-bit sum of A/D conversion results															
	When 16 conversion times is specified	Added Value 13 to 0: 14-bit sum of A/D conversion results														These bits are read as 0.	

39.2.2 ADDBLDR : A/D Data Duplexing Register

Base address: ADC12m = 0x4033_2000 + 0x0200 × m (m = 0, 1)
ADC12m_NS = 0x5033_2000 + 0x0200 × m (m = 0, 1)

Offset address: 0x018

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	ADDBLDR [15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	ADDBLDR [15:0]	Converted Value 15 to 0 Functions vary depending on the selected mode and accuracy. See Table 39.7 and Table 39.8.	R

Note: S-TYPE-3, P-TYPE-3

ADDBLDR register is a 16-bit read-only register to store A/D conversion results in response to a second trigger in double-trigger mode.

The following conditions determine the formats for data in the A/D data registers:

- Setting of the A/D Data Register Format Select bit (ADCER.ADRFMT) (flush-left or flush-right)
- The setting in the A/D Conversion Accuracy Select bits (ADCER.ADPRC[1:0]) (12-bit, 10-bit, 8-bit is selectable.)
- Setting of the Addition/Average Count Select bits (ADADC.ADC[2:0]) (1, 2, 3, 4, or 16 times)
- Setting of the Average Mode Enable bit (ADADC.AVEE) (addition or average).

This section describes the data formats for these conditions in different modes.

(1) When A/D-converted value addition/average mode is not selected

Table 39.7 shows the example of bit assignment for 12-bit accuracy.

Table 39.7 Example of bit assignment for 12-bit accuracy

Accuracy	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Right-justified data with 12-bit accuracy	These bits are read as 0.				Converted Value 11 to 0: 12-bit A/D-converted value											
Left-justified data with 12-bit accuracy	Converted Value 11 to 0: 12-bit A/D-converted value												These bits are read as 0.			

(2) When A/D-converted value average mode is selected

A/D-converted value average mode can be selected when 2 or 4 times is specified in the A/D-converted value addition mode. When A/D converted value average mode is selected, this register indicates the mean of A/D-converted values on a specific channel. The value is stored in the A/D data register based on the setting of the A/D Data Register Format Select bit in the same way as for normal A/D conversion.

(3) When A/D-converted value addition mode is selected

For 12-bit, 10-bit, 8-bit accuracy, 1, 2, 3, or 4 times can be selected in the A/D-converted value addition mode. A/D conversion results are stored in the A/D data register as a 2-bit-extended value of the specified conversion accuracy.

For 12-bit accuracy, 16 times can also be selected in the A/D-converted value addition mode. In A/D-converted value addition mode, this register indicates the value that is obtained by adding A/D-converted values on a specific channel. A/D conversion results are stored in the A/D data register as a 4-bit-extended value of the specified conversion accuracy.

When A/D-converted value addition mode is selected, the value is stored in the A/D data register based on the settings of the A/D Data Register Format Select bits.

Table 39.8 shows example of the bit assignment for 12-bit accuracy.

Table 39.8 Example of bit assignment for 12-bit accuracy when A/D-converted value addition mode is selected

Accuracy		b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Right-justified data with 12-bit accuracy	When 16 conversion times is specified	Added Value 15 to 0: 16-bit sum of A/D conversion results															
	When 1, 2, 3, or 4 conversion times is specified	These bits are read as 0.		Added Value 13 to 0: 14-bit sum of A/D conversion results													
Left-justified data with 12-bit accuracy	When 1, 2, 3, or 4 conversion times is specified	Added Value 15 to 0: 16-bit sum of A/D conversion results															
	When 16 conversion times is specified	Added Value 13 to 0: 14-bit sum of A/D conversion results														These bits are read as 0.	

39.2.3 ADDBLDRn : A/D Data Duplexing Register n (n = A, B)

Base address: ADC12m = 0x4033_2000 + 0x0200 × m (m = 0, 1)
ADC12m_NS = 0x5033_2000 + 0x0200 × m (m = 0, 1)

Offset address: 0x084 (n = A)
0x086 (n = B)

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	ADDBLDR [15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	ADDBLDR [15:0]	Converted Value 15 to 0 Functions vary depending on the selected mode and accuracy. See Table 39.9 and Table 39.10.	R

Note: S-TYPE-3, P-TYPE-3

ADDBLDRn registers are 16-bit read-only registers to store A/D conversion results in response to respective triggers during extended operation in double-trigger mode.

The following conditions determine the formats for data in the A/D data registers:

- Setting of the A/D Data Register Format Select bit (ADCER.ADRFMT) (flush-left or flush-right)
- The setting in the A/D Conversion Accuracy Select bits (ADCER.ADPRC[1:0]) (12-bit, 10-bit, 8-bit is selectable.)

- Setting of the Addition/Average Count Select bits (ADADC.ADC[2:0]) (1, 2, 3, 4, or 16 times)
- Setting of the Average Mode Enable bit (ADADC.AVEE) (addition or average).

This section describes the data formats for these conditions in different modes.

(1) When A/D-converted value addition/average mode is not selected

Table 39.9 shows the example of bit assignment for 12-bit accuracy.

Table 39.9 Example of bit assignment for 12-bit accuracy

Accuracy	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Right-justified data with 12-bit accuracy	These bits are read as 0.				Converted Value 11 to 0: 12-bit A/D-converted value											
Left-justified data with 12-bit accuracy	Converted Value 11 to 0: 12-bit A/D-converted value												These bits are read as 0.			

(2) When A/D-converted value average mode is selected

A/D-converted value average mode can be selected when 2 or 4 times is specified in the A/D-converted value addition mode. When A/D converted value average mode is selected, these registers indicate the mean of A/D-converted values on a specific channel. The value is stored in the A/D data register based on the setting of the A/D Data Register Format Select bit in the same way as for normal A/D conversion.

(3) When A/D-converted value addition mode is selected

For 12-bit, 10-bit, 8-bit accuracy, 1, 2, 3, or 4 times can be selected in the A/D-converted value addition mode. A/D conversion results are stored in the A/D data register as a 2-bit-extended value of the specified conversion accuracy.

For 12-bit accuracy, 16 times can also be selected in the A/D-converted value addition mode. In A/D-converted value addition mode, these registers indicate the value that is obtained by adding A/D-converted values on a specific channel. A/D conversion results are stored in the A/D data register as a 4-bit-extended value of the specified conversion accuracy.

When A/D-converted value addition mode is selected, the value is stored in the A/D data register based on the settings of the A/D Data Register Format Select bits.

Table 39.10 shows example of the bit assignment for 12-bit accuracy.

Table 39.10 Example of bit assignment for 12-bit accuracy when A/D-converted value addition mode is selected

Accuracy		b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Right-justified data with 12-bit accuracy	When 16 conversion times is specified	Added Value 15 to 0: 16-bit sum of A/D conversion results															
	When 1, 2, 3, or 4 conversion times is specified	These bits are read as 0.		Added Value 13 to 0: 14-bit sum of A/D conversion results													
Left-justified data with 12-bit accuracy	When 1, 2, 3, or 4 conversion times is specified	Added Value 15 to 0: 16-bit sum of A/D conversion results															
	When 16 conversion times is specified	Added Value 13 to 0: 14-bit sum of A/D conversion results														These bits are read as 0.	

39.2.4 ADTSDR : A/D Temperature Sensor Data Register

Base address: ADC12m = 0x4033_2000 + 0x0200 × m (m = 0, 1)
ADC12m_NS = 0x5033_2000 + 0x0200 × m (m = 0, 1)

Offset address: 0x01A

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	ADTSDR [15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	ADTSDR [15:0]	Converted Value 15 to 0 Functions vary depending on the selected mode and accuracy. See Table 39.11 and Table 39.12.	R

Note: S-TYPE-3, P-TYPE-3

ADTSDR register is a 16-bit read-only register to store A/D conversion result of the temperature sensor output.

The following conditions determine the formats for data in the A/D data registers:

- Setting of the A/D Data Register Format Select bit (ADCER.ADRFMT) (flush-left or flush-right)
- The setting in the A/D Conversion Accuracy Select bits (ADCER.ADPRC[1:0]) (12-bit, 10-bit, 8-bit is selectable.)
- Setting of the Addition/Average Count Select bits (ADADC.ADC[2:0]) (1, 2, 3, 4, or 16 times)
- Setting of the Average Mode Enable bit (ADADC.AVEE) (addition or average).

This section describes the data formats for these conditions in different modes.

(1) When A/D-converted value addition/average mode is not selected

Table 39.11 shows the example of bit assignment for 12-bit accuracy.

Table 39.11 Example of bit assignment for 12-bit accuracy

Accuracy	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Right-justified data with 12-bit accuracy	These bits are read as 0.				Converted Value 11 to 0: 12-bit A/D-converted value											
Left-justified data with 12-bit accuracy	Converted Value 11 to 0: 12-bit A/D-converted value												These bits are read as 0.			

(2) When A/D-converted value average mode is selected

A/D-converted value average mode can be selected when 2 or 4 times is specified in the A/D-converted value addition mode. When A/D converted value average mode is selected, this register indicates the mean of A/D-converted values on a specific channel. The value is stored in the A/D data register based on the setting of the A/D Data Register Format Select bit in the same way as for normal A/D conversion.

(3) When A/D-converted value addition mode is selected

For 12-bit, 10-bit, 8-bit accuracy, 1, 2, 3, or 4 times can be selected in the A/D-converted value addition mode. A/D conversion results are stored in the A/D data register as a 2-bit-extended value of the specified conversion accuracy.

For 12-bit accuracy, 16 times can also be selected in the A/D-converted value addition mode. In A/D-converted value addition mode, this register indicates the value that is obtained by adding A/D-converted values on a specific channel. A/D conversion results are stored in the A/D data register as a 4-bit-extended value of the specified conversion accuracy.

When A/D-converted value addition mode is selected, the value is stored in the A/D data register based on the settings of the A/D Data Register Format Select bits.

Table 39.12 shows example of the bit assignment for 12-bit accuracy.

Table 39.12 Example of bit assignment for 12-bit accuracy when A/D-converted value addition mode is selected

Accuracy		b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Right-justified data with 12-bit accuracy	When 16 conversion times is specified	Added Value 15 to 0: 16-bit sum of A/D conversion results															
	When 1, 2, 3, or 4 conversion times is specified	These bits are read as 0.	Added Value 13 to 0: 14-bit sum of A/D conversion results														
Left-justified data with 12-bit accuracy	When 1, 2, 3, or 4 conversion times is specified	Added Value 15 to 0: 16-bit sum of A/D conversion results															
	When 16 conversion times is specified	Added Value 13 to 0: 14-bit sum of A/D conversion results														These bits are read as 0.	

39.2.5 ADOCDR : A/D Internal Reference Voltage Data Register

Base address: ADC12m = 0x4033_2000 + 0x0200 × m (m = 0, 1)
ADC12m_NS = 0x5033_2000 + 0x0200 × m (m = 0, 1)

Offset address: 0x01C

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	ADOCDR [15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	ADOCDR [15:0]	Converted Value 15 to 0 Functions vary depending on the selected mode and accuracy. See Table 39.13 and Table 39.14.	R

Note: S-TYPE-3, P-TYPE-3

ADOCDR register is a 16-bit read-only register to store A/D conversion result of the internal reference voltage.

The following conditions determine the formats for data in the A/D data registers:

- Setting of the A/D Data Register Format Select bit (ADCER.ADRFMT) (flush-left or flush-right)
- The setting in the A/D Conversion Accuracy Select bits (ADCER.ADPRC[1:0]) (12-bit, 10-bit, 8-bit is selectable.)
- Setting of the Addition/Average Count Select bits (ADADC.ADC[2:0]) (1, 2, 3, 4, or 16 times)
- Setting of the Average Mode Enable bit (ADADC.AVEE) (addition or average).

This section describes the data formats for these conditions in different modes.

(1) When A/D-converted value addition/average mode is not selected

Table 39.13 shows the example of bit assignment for 12-bit accuracy.

Table 39.13 Example of bit assignment for 12-bit accuracy

Accuracy	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Right-justified data with 12-bit accuracy	These bits are read as 0.				Converted Value 11 to 0: 12-bit A/D-converted value											
Left-justified data with 12-bit accuracy	Converted Value 11 to 0: 12-bit A/D-converted value												These bits are read as 0.			

(2) When A/D-converted value average mode is selected

A/D-converted value average mode can be selected when 2 or 4 times is specified in the A/D-converted value addition mode. When A/D converted value average mode is selected, this register indicates the mean of A/D-converted values on a

specific channel. The value is stored in the A/D data register based on the setting of the A/D Data Register Format Select bit in the same way as for normal A/D conversion.

(3) When A/D-converted value addition mode is selected

For 12-bit, 10-bit, 8-bit accuracy, 1, 2, 3, or 4 times can be selected in the A/D-converted value addition mode. A/D conversion results are stored in the A/D data register as a 2-bit-extended value of the specified conversion accuracy.

For 12-bit accuracy, 16 times can also be selected in the A/D-converted value addition mode. In A/D-converted value addition mode, this register indicates the value that is obtained by adding A/D-converted values on a specific channel. A/D conversion results are stored in the A/D data register as a 4-bit-extended value of the specified conversion accuracy.

When A/D-converted value addition mode is selected, the value is stored in the A/D data register based on the settings of the A/D Data Register Format Select bits.

Table 39.14 shows example of the bit assignment for 12-bit accuracy.

Table 39.14 Example of bit assignment for 12-bit accuracy when A/D-converted value addition mode is selected

Accuracy		b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Right-justified data with 12-bit accuracy	When 16 conversion times is specified	Added Value 15 to 0: 16-bit sum of A/D conversion results															
	When 1, 2, 3, or 4 conversion times is specified	These bits are read as 0.		Added Value 13 to 0: 14-bit sum of A/D conversion results													
Left-justified data with 12-bit accuracy	When 1, 2, 3, or 4 conversion times is specified	Added Value 15 to 0: 16-bit sum of A/D conversion results															
	When 16 conversion times is specified	Added Value 13 to 0: 14-bit sum of A/D conversion results														These bits are read as 0.	

39.2.6 ADRD : A/D Self-Diagnosis Data Register

Base address: ADC12m = 0x4033_2000 + 0x0200 × m (m = 0, 1)
ADC12m_NS = 0x5033_2000 + 0x0200 × m (m = 0, 1)

Offset address: 0x01E

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	DIAGST[1:0]		—	—	AD[11:0]											
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
11:0	AD[11:0]	Converted Value 11 to 0 12-bit A/D-converted value	R
13:12	—	These bits are read as 0.	R
15:14	DIAGST[1:0]	Self-Diagnosis Status For details on self-diagnosis, see section 39.2.15. ADCER : A/D Control Extended Register. 0 0: Self-diagnosis not executed after power-on. 0 1: Self-diagnosis was executed using the 0 V voltage. 1 0: Self-diagnosis was executed using the reference voltage*1 × 1/2. 1 1: Self-diagnosis was executed using the reference voltage *1.	R

Note: S-TYPE-3, P-TYPE-3
Note: The example of the bit assignment for the right-justified data with 12-bit accuracy is indicated.
Note 1. The reference voltage refers to VREFH0 for unit 0 and to VREFH for unit 1.

ADRD is a 16-bit read-only register that holds the A/D conversion results based on the self-diagnosis of the ADC12. In addition to the AD[11:0] bits indicating the A/D-converted value, it includes the Self-Diagnosis Status bit (DIAGST[1:0]).

The settings of the A/D data register format and the A/D conversion accuracy determines the formats for data in this register.

The A/D-converted value addition and average modes cannot be applied to the A/D self-diagnosis function. For details on self-diagnosis, see section 39.2.15. ADCER : A/D Control Extended Register.

This section describes the data formats for each condition. The register diagram and the register bit table shown in this section indicate example of the bit assignment for the left and right-justified data with 12-bit accuracy.

Table 39.15 Bit assignment for each right-justified accuracy

Accuracy	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Right-justified data with 12-bit accuracy	DIAGST[1:0]		—		AD[11:0]											

Table 39.16 Bit assignment for each left-justified accuracy

Accuracy	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Left-justified data with 12-bit accuracy	AD[11:0]												—		DIAGST[1:0]	

39.2.7 ADCSR : A/D Control Register

Base address: ADC12m = 0x4033_2000 + 0x0200 × m (m = 0, 1)
ADC12m_NS = 0x5033_2000 + 0x0200 × m (m = 0, 1)

Offset address: 0x000

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	ADST	ADCS[1:0]		—	—	—	TRGE	EXTRG	DBLE	GBADIE	—	DBLANS[4:0]				
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
4:0	DBLANS[4:0]	Double Trigger Channel Select These bits select one analog input channel for double-trigger operation. The setting is only valid in double-trigger mode.	R/W
5	—	This bit is read as 0. The write value should be 0.	R/W
6	GBADIE	Group B Scan End Interrupt and ELC Event Enable Group B scan only works in group scan mode. 0: Disable ADC12i_GBADI (i = 0, 1) interrupt generation on group B scan completion. 1: Enable ADC12i_GBADI (i = 0, 1) interrupt generation on group B scan completion.	R/W
7	DBLE	Double Trigger Mode Select 0: Deselect double-trigger mode. 1: Select double-trigger mode.	R/W
8	EXTRG	Trigger Select*1 0: Start A/D conversion by the synchronous trigger (GPT, ELC). 1: Start A/D conversion by the asynchronous trigger (ADTRGn*2).	R/W
9	TRGE	Trigger Start Enable 0: Disable A/D conversion to be started by the synchronous or asynchronous trigger 1: Enable A/D conversion to be started by the synchronous or asynchronous trigger	R/W
12:10	—	These bits are read as 0. The write value should be 0.	R/W
14:13	ADCS[1:0]	Scan Mode Select 0 0: Single scan mode 0 1: Group scan mode 1 0: Continuous scan mode 1 1: Setting prohibited	R/W

Bit	Symbol	Function	R/W
15	ADST	A/D Conversion Start 0: Stop A/D conversion process. 1: Start A/D conversion process.	R/W

Note: S-TYPE-3, P-TYPE-3
Note 1. To start A/D conversion using an external pin (asynchronous trigger):
After a high-level signal is input to the external pin (ADTRGn), write 1 to both the TRGE and EXTRG bits in the ADCSR register and drive the ADTRGn pin low. With these settings, the scan conversion process starts on detection of the falling edge of ADTRGn. The pulse width of the low-level input must be at least PCLKA 1.5 clock cycles.
Note 2. n = 0 (unit 0), 1 (unit 1)

The ADCSR register sets double-trigger mode and A/D conversion start trigger, enables or disables scan end interrupt, selects the scan mode, and starts or stops A/D conversion.

DBLANS[4:0] bits (Double Trigger Channel Select)

The DBLANS[4:0] bits select one channel for A/D conversion data duplication in double-trigger mode. This can be selected by setting the binary value of the channel number to be duplicated. The A/D conversion results of the analog input of the channel selected in the DBLANS[4:0] bits are stored in A/D Data Register y when conversion is started by the first trigger, and stored in the A/D Data Duplexing Register when conversion is started by the second trigger.

In double-trigger mode, the channels selected in the ADANSA0 and ADANSA1 registers, are invalid, and the channel selected in the DBLANS[4:0] bits is A/D converted instead.

When double-trigger mode is used in group scan mode, double-trigger control is only applied to group A and not to group B.

Also, in double trigger mode, the analog inputs of multiple channels, temperature sensor outputs, or internal reference voltage cannot be selected for group A, but can be selected for groups B.

Only set the DBLANS[4:0] bits when the ADST bit is 0. Do not set the DBLANS[4:0] bits at the same time that you write 1 to the ADST bit.

To enter A/D-converted value addition/average mode when in double-trigger mode, set the same channel in the ADADS0 and ADADS1 registers as the channel selected in the DBLANS[4:0] bits.

A/D-converted data from the self-diagnosis function temperature sensor output and internal reference voltage cannot be used in double-trigger mode.

GBADIE bit (Group B Scan End Interrupt and ELC Event Enable)

The GBADIE bit enables or disables group B scan end interrupt (ADC12i_GBADI (i = 0, 1)) in group scan mode.

DBLE bit (Double Trigger Mode Select)

The DBLE bit selects or deselects double-trigger mode. Double-trigger mode can only be operated by the synchronous trigger (GPT, ELC) selected in the ADSTRGR.TRSA[5:0] bits.

Double-trigger operation is as follows:

1. The ADC12i_ADI (i = 0, 1) interrupt is not output on completion of the first conversion but on completion of the second conversion.
2. The A/D conversion results from the duplication channel (selected in DBLANS[4:0]) started by the first trigger are stored in A/D Data Register y and those started by the second trigger are stored in the A/D Data Duplexing Register.

When the DBLE bit is set (double-trigger mode is selected), the channels specified in the ADANSA0 and ADANSA1 registers are invalid. Double-trigger mode is deselected by setting DBLE to 0. Setting DBLE to 1 again enables the same double-trigger operation described in 1. and 2. for first time scanning with the first trigger.

Do not select double-trigger mode in continuous scan mode. When using double trigger mode in group scan mode, A/D conversion of the temperature sensor output and internal reference voltage should not be selected for group A. Software triggering cannot be used in double-trigger mode. Always set the ADST bit to 0 before setting the DBLE bit. Do not set the DBLE bit at that same time as writing 1 to the ADST bit.

EXTRG bit (Trigger Select)

The EXTRG bit selects the synchronous or asynchronous trigger as the trigger for starting A/D conversion.

In group scan mode, the setting of this bit takes effect on the trigger selected for group A. For group B, A/D conversion is started by the selected synchronous trigger regardless of this bit setting.

TRGE bit (Trigger Start Enable)

The TRGE bit enables or disables A/D conversion by the synchronous and asynchronous triggers. In group scan mode, set this bit to 1.

ADCS[1:0] bits (Scan Mode Select)

The ADCS[1:0] bits select the scan mode.

In single scan mode, A/D conversion is performed for the analog inputs of the channels selected in the ADANSA0 and ADANSA1 registers, in ascending order of channel number. When 1 cycle of A/D conversion completes for all the selected channels, the scan conversion stops.

In continuous scan mode, when the ADCSR.ADST bit is 1, A/D conversion is performed for the analog inputs of the channels selected with the ADANSA0 and ADANSA1 registers , in ascending order of channel number. When 1 cycle of A/D conversion completes for all the selected channels, A/D conversion repeats from the first channel. If the ADCSR.ADST bit is set to 0 during continuous scan, A/D conversion stops even if scanning is in progress.

In group scan mode:

- Group A scanning is started by the synchronous trigger (GPT, ELC) selected in the TRSA[5:0] bits in the ADSTRGR register. A/D conversion is performed on group A analog inputs of the channels selected in the ADANSA0 and ADANSA1 registers, in ascending order of channel number. When 1 cycle of A/D conversion completes for all the selected channels, A/D conversion stops.
- Group B scanning is started by the synchronous trigger (GPT, ELC) selected in the ADSTRGR.TRSB[5:0] bits. A/D conversion is performed on group B analog inputs of the channels selected in the ADANSB0 and ADANSB1 registers, in ascending order of channel number. When 1 cycle of A/D conversion completes for all the selected channels, A/D conversion stops.

If the conversion processes in group A and group B occur at the same time, those conversions cannot be controlled separately. In this case, set group A Priority Control Setting bit (ADGSPCR.PGS) in the A/D Group Scan Priority Control Register (ADGSPCR) to 1 to assign a priority to group A conversion.

In group scan mode, select different channels and triggers for group A and group B.

Only set the ADCS[1:0] bits when the ADST bit is 0. Do not set the ADCS[1:0] bits at the same time that you write 1 to the ADST bit.

Table 39.17 Selectable targets for A/D conversion depending on scan and double-trigger mode settings

Scan mode setting	Double-trigger mode setting	Targets for A/D conversion				
		Self-diagnosis	Analog input (group A)	Analog input (group B)	Temperature sensor output	Internal reference voltage
Single scan	DBLE = 0	✓	✓	—	✓	✓
	DBLE = 1	—	✓ (1 ch only)	—	—	—
Continuous scan	DBLE = 0	✓	✓	—	✓	✓
	DBLE = 1	—	—	—	—	—
Group scan	DBLE = 0	✓	✓	✓	✓	✓
	DBLE = 1	—	✓ (1 ch only)	✓	✓	✓

Note: ✓: Selectable, —: Not selectable

ADST bit (A/D Conversion Start)

The ADST bit starts or stops the A/D conversion process. Before the ADST bit is set to 1, set the A/D conversion clock, the conversion mode, and the conversion target analog input.

[Setting conditions]

- 1 is written.

- The synchronous trigger (GPT, ELC) selected in the ADSTRGR.TRSA[5:0] bits is detected when ADCSR.EXTRG is 0 and ADCSR.TRGE is 1.
- The synchronous trigger (GPT, ELC) selected in the ADSTRGR.TRSB[5:0] bits is detected when ADCSR.TRGE is set to 1 in group scan mode.
- The asynchronous trigger is detected when the ADCSR.TRGE and ADCSR.EXTRG bits are set to 1 and the ADSTRGR.TRSA[5:0] bits are set to 0x00.
- When group priority operation mode is enabled (ADCSR.ADCS[1:0] = 01b and ADGSPCR.PGS = 1), the ADGSPCR.GBRP bit is set to 1, and each time A/D conversion on the group with the lowest priority is started.

[Clearing conditions]

- 0 is written.
- The A/D conversion of all the selected channels, the temperature sensor output the internal reference voltage completes in single scan mode.
- Group A scan completes in group scan mode.
- Group B scan completes in group scan mode.
- When group priority operation mode is enabled (ADCSR.ADCS[1:0] = 01b and ADGSPCR.PGS = 1), the ADGSPCR.GBRSCN bit is set to 1, and A/D conversion on the group with the lowest priority started by trigger completes.

Note: When group priority operation mode is enabled (ADCSR.ADCS[1:0] = 01b and ADGSPCR.PGS = 1), do not set the ADST bit to 1.
Note: When group priority operation mode is enabled (ADCSR.ADCS[1:0] = 01b and ADGSPCR.PGS = 1), do not set the ADST bit to 0. When forcing A/D conversion to terminate, follow the procedure for clearing the ADST bit.

39.2.8 ADANSA0 : A/D Channel Select Register A0

Base address: ADC12m = 0x4033_2000 + 0x0200 × m (m = 0, 1)
ADC12m_NS = 0x5033_2000 + 0x0200 × m (m = 0, 1)

Offset address: 0x004

Bit	Symbol	Function	R/W
15:0	ANSA15 to ANSA00*1	A/D Conversion Channels Select Bit 15 (ANSA15) is associated with ANm15 and bit 0 (ANSA00) is associated with ANm00. 0: Do not select associated input channel. 1: Select associated input channel.	R/W

Note: S-TYPE-3, P-TYPE-3
Note: Bits associated with non-existent pins are reserved. This bit is read as 0. The write value should be 0.
Note 1. 00 to 02, 04 to 08 (unit 0), 00 to 02, 04 to 06 (unit 1) is available.

ADANSA0 register selects analog input channels for A/D conversion. In group scan mode, this register selects group A channels.

Only set the ADANSA0 register when the ADCSR.ADST bit is 0.

ANSAn bits (A/D Conversion Channels Select)

The ADANSA0 register selects any combination of analog input channels for A/D conversion. The channels and the number of channels can be arbitrarily set.

In double trigger mode, the channels selected in the ADANSA0 register are invalid, and the channel selected in the ADCSR.DBLANS[4:0] bits is selected in group A instead.

When group scan mode is selected, do not select the channels specified in A/D Channel Select Register B0 (ADANSB0) and A/D Channel Select Register B1 (ADANSB1).

ADANSB0 selects analog input channels for A/D conversion in group B when group scan mode is selected. The ADANSB0 register is not used in any scan mode other than group scan mode.

Only set the ADANSB0 register when the ADCSR.ADST bit is 0.

ANSBn bits (A/D Conversion Channels Select)

The ADANSB0 register selects any combination of analog input channels in group B for A/D conversion when group scan mode is selected. The ADANSB0 register is used for group scan mode only and not for any other modes.

Do not select channels specified in group A as selected in the ADANSA0 and ADANSA1 registers or the ADCSR.DBLANS[4:0] bits in double-trigger mode.

Security attribution function between ADC12n (n = 0, 1) and PORT (PmSAR). Detail conversion result please see section 39.3.12. Security Attribution between ADCn (n = 0, 1) and PORT (PmSAR (m = 0 to 9, A, B)).

39.2.11 ADANSB1 : A/D Channel Select Register B1

Base address: ADC12m = 0x4033_2000 + 0x0200 × m (m = 0, 1)
ADC12m_NS = 0x5033_2000 + 0x0200 × m (m = 0, 1)

Offset address: 0x016

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	ANSB31 to ANSB16*1	A/D Conversion Channels Select Bit 15 (ANSB31) is associated with ANm31 and bit 0 (ANSB16) is associated with ANm16. 0: Do not select associated input channel. 1: Select associated input channel.	R/W

Note: S-TYPE-3, P-TYPE-3
Note: Bits associated with non-existent pins are reserved. This bit is read as 0. The write value should be 0.
Note 1. 16 to 19 (unit 0), 16 to 22 (unit 1) is available.

ADANSB1 selects analog input channels for A/D conversion in group B when group scan mode is selected. The ADANSB1 register is not used in any scan mode other than group scan mode.

Only set the ADANSB1 register when the ADCSR.ADST bit is 0.

ANSBn bits (A/D Conversion Channels Select)

The ADANSB1 register selects any combination of analog input channels in group B for A/D conversion when group scan mode is selected. The ADANSB1 register is used for group scan mode only and not for any other modes.

Do not select channels specified in group A as selected in the ADANSA0 and ADANSA1 registers or the ADCSR.DBLANS[4:0] bits in double-trigger mode.

Security attribution function between ADC12n (n = 0, 1) and PORT (PmSAR). Detail conversion result please see section 39.3.12. Security Attribution between ADCn (n = 0, 1) and PORT (PmSAR (m = 0 to 9, A, B)).

39.2.12 ADADS0 : A/D-Converted Value Addition/Average Channel Select Register 0

Base address: ADC12m = 0x4033_2000 + 0x0200 × m (m = 0, 1)
ADC12m_NS = 0x5033_2000 + 0x0200 × m (m = 0, 1)

Offset address: 0x008

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	ADS15	ADS14	ADS13	ADS12	ADS11	ADS10	ADS09	ADS08	ADS07	ADS06	ADS05	ADS04	ADS03	ADS02	ADS01	ADS00
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	ADS15 to ADS00*1	A/D-Converted Value Addition/Average Channel Select Bit 15 (ADS15) is associated with ANm15 and bit 0 (ADS00) is associated with ANm00. 0: Do not select associated input channel. 1: Select associated input channel.	R/W

Note: S-TYPE-3, P-TYPE-3
Note: Bits associated with non-existent pins are reserved. This bit is read as 0. The write value should be 0.
Note 1. 00 to 02, 04 to 08 (unit 0), 00 to 02, 04 to 06 (unit 1) is available.

ADSn bits (A/D-Converted Value Addition/Average Channel Select)

The ADSn bits determine which A/D-converted channels are subject to A/D-converted value addition/averaging. When an ADSn bit associated with a channel selected for A/D conversion is set to 1, A/D conversion of the analog input of the respective channel is performed successively 1, 2, 3, 4, or 16 times, as specified in the ADC[2:0] bits in the ADADC register.

When the ADADC.AVEE bit is 0, the value obtained by addition is stored in the A/D data register. When the ADADC.AVEE bit is 1, the mean value of the results obtained by addition is stored in the A/D data register.

The ADSn bits apply only to channels that are selected for A/D conversion in:

- The ANSAn bits in the ADANSA0 register or the DBLANS[4:0] bits in the ADCSR register
- The ANSBn bits in the ADANSB0 register

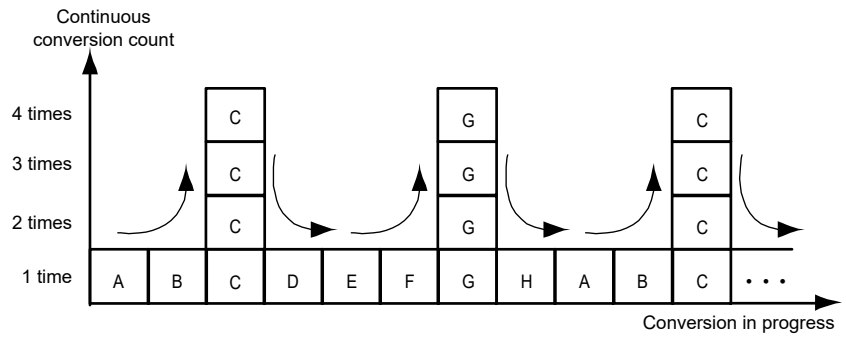
For channels on which the A/D conversion is performed and for which addition/average mode is not selected, a normal 1-time conversion is executed, and the conversion result is stored in the A/D data register.

Only set ADADS0 register bits when the ADCSR.ADST bit is 0.

Figure 39.3 shows a scanning operation sequence in which the ADADS0 register bits (channel c and g) are set to 1. In this figure:

- Addition mode is selected (ADADC.AVEE = 0)
- The number of conversions is set to 4 (ADADC.ADC[1:0] = 11b)
- The analog input channels (a to h) are selected by ADANSA0 register in continuous scan mode (ADCSR.ADCS[1:0] = 10b).

The conversion process begins with analog input A (channel a). The analog input C (channel c) conversion is performed successively 4 times and the added value is returned to A/D Data Register c (ADDRc). Next, the analog input D (channel d) conversion process is started. The analog input G (channel g) is performed successively 4 times and the added value is returned to A/D Data Register g (ADDRg). After conversion of analog input H (channel h), the conversion operation repeats in the same sequence starting with analog input A (channel a).



Note: A to H are analog inputs (channel a to h)

Figure 39.3 Scan conversion sequence with ADADC.ADC[2:0] = 011b, set 1 for analog inputs C and G by ADADS0/1

39.2.13 ADADS1 : A/D-Converted Value Addition/Average Channel Select Register 1

Base address: ADC12m = 0x4033_2000 + 0x0200 × m (m = 0, 1)
ADC12m_NS = 0x5033_2000 + 0x0200 × m (m = 0, 1)

Offset address: 0x00A

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	ADS31	ADS30	ADS29	ADS28	ADS27	ADS26	ADS25	ADS24	ADS23	ADS22	ADS21	ADS20	ADS19	ADS18	ADS17	ADS16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	ADS31 to ADS16*1	A/D-Converted Value Addition/Average Channel Select Bit 15 (ADS31) is associated with ANm31 and bit 0 (ADS16) is associated with ANm16. 0: Do not select associated input channel. 1: Select associated input channel.	R/W

Note: S-TYPE-3, P-TYPE-3
Note: Bits associated with non-existent pins are reserved. This bit is read as 0. The write value should be 0.
Note 1. 16 to 19 (unit 0), 16 to 22 (unit 1) is available.

ADSn bits (A/D-Converted Value Addition/Average Channel Select)

The ADSn bits determine which A/D-converted channels are subject to A/D-converted value addition/averaging. When an ADSn bit associated with a channel selected for A/D conversion is set to 1, A/D conversion of the analog input of the respective channel is performed successively 1, 2, 3, 4, or 16 times, as specified in the ADC[2:0] bits in the ADADC register.

When the ADADC.AVEE bit is 0, the value obtained by addition is stored in the A/D data register. When the ADADC.AVEE bit is 1, the mean value of the results obtained by addition is stored in the A/D data register.

The ADSn bits apply only to channels that are selected for A/D conversion in:

- The ANSAn bits in the ADANSA1 register or the DBLANS[4:0] bits in the ADCSR register
- The ANSBn bits in the ADANSB1 register.

For channels on which the A/D conversion is performed and for which addition/average mode is not selected, a normal 1-time conversion is executed, and the conversion result is stored in the A/D data register.

Only set ADADS1 register when the ADCSR.ADST bit is 0.

39.2.14 ADADC : A/D-Converted Value Addition/Average Count Select Register

Base address: ADC12m = 0x4033_2000 + 0x0200 × m (m = 0, 1)
ADC12m_NS = 0x5033_2000 + 0x0200 × m (m = 0, 1)

Offset address: 0x00C

Bit position:	7	6	5	4	3	2	1	0
Bit field:	AVEE	—	—	—	—	ADC[2:0]		
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
2:0	ADC[2:0]	Addition/Average Count Select 0 0 0: 1-time conversion (no addition, same as normal conversion) 0 0 1: 2-time conversion (1 addition) 0 1 0: 3-time conversion (2 additions) 0 1 1: 4-time conversion (3 additions) 1 0 1: 16-time conversion (15 additions) Others: Setting prohibited	R/W
6:3	—	These bits are read as 0. The write value should be 0.	R/W
7	AVEE	Average Mode Select 0: Enable addition mode 1: Enable average mode	R/W

Note: S-TYPE-3, P-TYPE-3

ADADC sets the addition or average mode and addition count for A/D conversion. Table 39.18 lists the settable combinations of ADADC register.

Table 39.18 Settable combinations of ADADC register

Mode select	Resolution	Conversion time				
		1-time	2-time	3-time	4-time	16-time
Addition mode (AVEE = 0)	8-bit	✓	✓	✓	✓	—
	10-bit	✓	✓	✓	✓	—
	12-bit	✓	✓	✓	✓	✓
Average mode (AVEE = 1)	8, 10, 12 bits	—	✓	—	✓	—

Note: ✓: Selectable, —: Not selectable

ADC[2:0] bits (Addition/Average Count Select)

The ADC[2:0] bits set the addition count in all channels for which A/D conversion and addition/average mode are selected, including the channel selected in double trigger mode with the ADCSR.DBLANS[4:0] bits. The count also applies to A/D conversion of the temperature sensor output and the internal reference voltage.
When self-diagnosis is executed (ADCER.DIAGM = 1), do not set the ADC[2:0] bits to any value other than 000b.

AVEE bit (Average Mode Select)

The AVEE bit selects addition or average mode in all channels for which A/D conversion and addition/average mode are selected, including the channels selected in double-trigger mode in the ADCSR.DBLANS[4:0] bits, temperature sensor output, internal reference voltage.

39.2.15 ADCER : A/D Control Extended Register

Base address: ADC12m = 0x4033_2000 + 0x0200 × m (m = 0, 1)
ADC12m_NS = 0x5033_2000 + 0x0200 × m (m = 0, 1)

Offset address: 0x00E

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	ADRFMT	—	—	—	DIAGM	DIAGLD	DIAGVAL[1:0]		—	—	ACE	—	—	ADPRC[1:0]		—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	—	This bit is read as 0. The write value should be 0.	R/W
2:1	ADPRC[1:0]	A/D Conversion Accuracy Specify 0 0: 12-bit accuracy 0 1: 10-bit accuracy 1 0: 8-bit accuracy 1 1: Setting prohibited	R/W
4:3	—	These bits are read as 0. The write value should be 0.	R/W
5	ACE	A/D Data Register Automatic Clearing Enable 0: Disable automatic clearing 1: Enable automatic clearing	R/W
7:6	—	These bits are read as 0. The write value should be 0.	R/W
9:8	DIAGVAL[1:0]	Self-Diagnosis Conversion Voltage Select 0 0: Setting prohibited when self-diagnosis is enabled 0 1: 0 volts 1 0: Reference voltage*1 × 1/2 1 1: Reference voltage*1	R/W
10	DIAGLD	Self-Diagnosis Mode Select 0: Select rotation mode for self-diagnosis voltage 1: Select mixed mode for self-diagnosis voltage	R/W
11	DIAGM	Self-Diagnosis Enable 0: Disable ADC12 self-diagnosis 1: Enable ADC12 self-diagnosis	R/W
14:12	—	These bits are read as 0. The write value should be 0.	R/W
15	ADRFMT	A/D Data Register Format Select 0: Select right-justified for the A/D data register format 1: Select left-justified for the A/D data register format	R/W

Note: S-TYPE-3, P-TYPE-3
Note 1. The reference voltage refers to VREFH0 for unit 0 and to VREFH for unit 1.

ADPRC[1:0] bit (A/D Conversion Accuracy Specify)

The ADPRC[1:0] bits set the A/D conversion accuracy. Changing the A/D conversion accuracy also changes the bit width of valid data stored in the result register and the A/D conversion time. For details, see section 39.3.6. Analog Input Sampling and Scan Conversion Time. Only set the ADPRC[1:0] bits while the ADCSR.ADST bit is 0.

ACE bit (A/D Data Register Automatic Clearing Enable)

The ACE bit enables or disables automatic clearing (all 0) of the ADDRy, ADRD, ADDBLDR, ADDBLDRA, ADDBLDRB, ADTSDR or ADOCDR register after any of these registers is read by the CPU or DTC. Automatic clearing of the A/D data registers enables detection of failures that are not updated in the A/D data registers. For details, see section 39.3.7. Usage Example of A/D Data Register Automatic Clearing Function.

DIAGVAL[1:0] bits (Self-Diagnosis Conversion Voltage Select)

The DIAGVAL[1:0] bits select the voltage value used in self-diagnosis fixed voltage mode. For details, see the DIAGLD bit description.

Do not execute self-diagnosis by setting the DIAGLD bit to 1 when the DIAGVAL[1:0] bits are set to 00b.

DIAGLD bit (Self-Diagnosis Mode Select)

The DIAGLD bit selects whether the three voltage values are rotated, or the fixed voltage is used in self-diagnosis.

Setting the DIAGLD bit to 0 selects conversion of the voltages in rotation mode, where 0 V, the reference voltage × 1/2, and the reference voltage are converted, in that order. After reset and when self-diagnosis voltage rotation mode is selected, self-diagnosis is executed from 0 V. The self-diagnosis voltage value does not return to 0 V when scan conversion completes. When scan conversion is restarted, rotation starts at the voltage value following the previous value.

Setting the DIAGLD bit to 1 selects fixed voltage, in which the fixed voltage specified in the ADCER.DIAGVAL[1:0] bits is converted. If fixed mode is switched to rotation mode, rotation starts at the fixed voltage value.

Only set the DIAGLD bit when the ADCSR.ADST bit is 0.

DIAGM bit (Self-Diagnosis Enable)

The DIAGM bit enables or disables self-diagnosis.

Self-diagnosis is used to detect a failure of the ADC12. In self-diagnosis mode, one of the three voltage values (0 V, the reference voltage × 1/2, or the reference voltage) is converted. When conversion completes, information on the converted voltage and the conversion result is stored into the A/D Self-Diagnosis Data Register (ADRD). The ADRD register can be read to determine whether the conversion result falls within the normal or abnormal range.

Self-diagnosis is executed once at the beginning of each scan, and one of the three voltages is converted. In double trigger mode (ADCSR.DBLE = 1), self-diagnosis (DIAGM = 0) is deselected. When self-diagnosis is selected in group scan mode, self-diagnosis is executed separately for group A and group B.

Only set the DIAGM bit when the ADCSR.ADST bit is 0.

ADRFMT bit (A/D Data Register Format Select)

The ADRFMT bit specifies flush-right or flush-left for data to be stored in the ADDRy, ADDBLDR, ADDBLDRA, ADDBLDRB, ADTSDR, ADOCDR, ADCMPDR0/1, ADWINLLB, ADWINULB, or ADRD register.

Only set the ADRFMT bit when the ADCSR.ADST bit is 0.

39.2.16 ADSTRGR : A/D Conversion Start Trigger Select Register

Base address: ADC12m = 0x4033_2000 + 0x0200 × m (m = 0, 1)
ADC12m_NS = 0x5033_2000 + 0x0200 × m (m = 0, 1)

Offset address: 0x010

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	TRSA[5:0]						—	—	TRSB[5:0]					
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
5:0	TRSB[5:0]	A/D Conversion Start Trigger Select for Group B Select the A/D conversion start trigger for group B in group scan mode.	R/W
7:6	—	These bits are read as 0. The write value should be 0.	R/W
13:8	TRSA[5:0]	A/D Conversion Start Trigger Select Select the A/D conversion start trigger in single scan mode and continuous scan mode. In group scan mode, the A/D conversion start trigger for group A is selected.	R/W
15:14	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

TRSB[5:0] bits (A/D Conversion Start Trigger Select for Group B)

The TRSB[5:0] bits select the trigger to start scanning of the analog input selected in group B. The TRSB[5:0] bits must only be set in group scan mode and are not used in any other scan mode. For the scan conversion start trigger for group B, setting a software trigger or an asynchronous trigger is prohibited. In group scan mode, set the TRSB[5:0] bits to a value other than 0x00 and set the ADCSR.TRGE bit to 1.

When group A is given priority in group scan mode, setting the ADGSPCR.GBRP bit to 1 allows group B to continuously operate in single scan mode. When setting the ADGSPCR.GBRP bit to 1, set the TRSB[5:0] bits to 0x3F. The issuance period for a conversion trigger must be more than or equal to the actual scan conversion time (t_{SCAN}). If the issuance period is less than t_{SCAN}, A/D conversion by the trigger might have no effect.

When the GPT module is selected as an A/D conversion start trigger, a delay for synchronization processing occurs. For details, see section 39.3.6. Analog Input Sampling and Scan Conversion Time.

Table 39.19 lists the A/D conversion startup sources selected in the TRSB[5:0] bits.

Table 39.19 Selection of A/D conversion start sources in the TRSB[5:0] bits

Source	Remarks	TRSB[5]	TRSB[4]	TRSB[3]	TRSB[2]	TRSB[1]	TRSB[0]

GTCIADA2 (unit 0) and GTCIADA6 (unit 1), GTCIADB2 (unit 0) and GTCIADB6 (unit 1)	GPT	0	1	1	0	1	1
GTCIADA3 (unit 0) and GTCIADA7 (unit 1), GTCIADB3 (unit 0) and GTCIADB7 (unit 1)	GPT	0	1	1	1	0	0

TRSA[5:0] bits (A/D Conversion Start Trigger Select)

The TRSA[5:0] bits select the trigger to start A/D conversion in single scan mode and continuous scan mode, or the trigger to start scanning of group A analog inputs in group scan mode. When scanning is executed in group scan mode or double trigger mode, software trigger or asynchronous trigger is prohibited.

- When using a synchronous trigger (GPT, ELC), set the TRGE bit in the ADCSR register to 1 and set the EXTRG bit in the ADCSR register to 0.
- When using the asynchronous trigger (ADTRGn (n = 0, 1), set the TRGE bit in the ADCSR register to 1 and set the EXTRG bit in the ADCSR register to 1.
- Software trigger (ADCSR.ADST) is enabled regardless of the settings of the ADCSR.TRGE bit, the ADCSR.EXTRG bit, or the TRSA[5:0] bits.

The issuance period for a conversion trigger must be more than or equal to the actual scan conversion time (tSCAN). If the issuance period is less than tSCAN, A/D conversion by a trigger might have no effect.

When the GPT module is selected as an A/D conversion start trigger, a delay for synchronization processing occurs. For details, see section 39.3.6. Analog Input Sampling and Scan Conversion Time.

Table 39.20 lists the A/D conversion start sources selected in the TRSA[5:0] bits.

7:2	—	These bits are read as 0. The write value should be 0.	R/W
8	TSSA	Temperature Sensor Output A/D Conversion Select 0: Disable A/D conversion of temperature sensor output 1: Enable A/D conversion of temperature sensor output	R/W
9	OCSA	Internal Reference Voltage A/D Conversion Select 0: Disable A/D conversion of internal reference voltage 1: Enable A/D conversion of internal reference voltage	R/W
10	TSSB	Temperature Sensor Output A/D Conversion Select for Group B 0: Disable A/D conversion of temperature sensor output 1: Enable A/D conversion of temperature sensor output	R/W
11	OCSB	Internal Reference Voltage A/D Conversion Select for Group B 0: Disable A/D conversion of internal reference voltage 1: Enable A/D conversion of internal reference voltage	R/W
15:12	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

TSSAD bit (Temperature Sensor Output A/D-Converted Value Addition/Average Mode Select)

When the TSSAD bit is set to 1, A/D conversion of the temperature sensor output is selected and performed successively the number of times specified in the ADC[2:0] bits in ADADC. When the ADADC.AVEE bit is 0, the value obtained by addition (integration) is returned to the A/D Temperature Sensor Data Register (ADTSDR). When the ADADC.AVEE bit is 1, the mean value is returned to ADTSDR.

Only set the TSSAD bit while the ADCSR.ADST bit is 0.

OCSAD bit (Internal Reference Voltage A/D-Converted Value Addition/Average Mode Select)

When the OCSAD bit is set to 1, A/D conversion of the internal reference voltage is selected and performed successively the number of times specified in the ADC[2:0] bits in ADADC. When the ADADC.AVEE bit is 0, the value obtained by addition (integration) is returned to the A/D Internal Reference Voltage Data Register (ADOCDR). When the ADADC.AVEE bit is 1, the mean value is returned to ADOCDR.

Only set the OCSAD bit while the ADCSR.ADST bit is 0.

TSSA bit (Temperature Sensor Output A/D Conversion Select)

The TSSA bit selects A/D conversion of the temperature sensor output for group A in single scan mode, continuous scan mode, or group scan mode. When A/D conversion of the temperature sensor output is selected and performed, set the ADCSR.DBLE bit to 0.

Only set the TSSA bit while the ADCSR.ADST bit is 0.

OCSA bit (Internal Reference Voltage A/D Conversion Select)

The OCSA bit selects A/D conversion of the internal reference voltage for group A in single scan mode, continuous scan mode, or group scan mode. When A/D conversion of the internal reference voltage is selected and performed, set the ADCSR.DBLE bit to 0.

Only set the OCSA bit while the ADCSR.ADST bit is 0. In addition, wait for 400 ns or more after the OCSA bit is set to 1 before starting A/D conversion.

TSSB bit (Temperature Sensor Output A/D Conversion Select for Group B)

The TSSB bit selects A/D conversion of the temperature sensor output for group B in group scan mode. Only set the TSSB bit while the ADCSR.ADST bit is 0. Do not set the TSSB bit to 1 while the TSSA bit is 1.

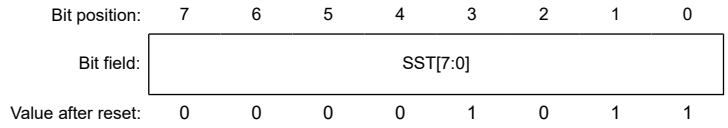
OCSB bit (Internal Reference Voltage A/D Conversion Select for Group B)

The OCSB bit selects A/D conversion of the internal reference voltage for group B in group scan mode. Only set the OCSB bit while the ADCSR.ADST bit is 0. Do not set the OCSB bit to 1 while the OCSA bit is 1. Moreover, start the A/D conversion after waiting for 400 ns or more after the OCSB bit is set to 1.

39.2.18 ADSSTRn/ADSSTRL/ADSSTRT/ADSSTRO: A/D Sampling State Register (n = 0 to 2, 4 to 8)

Base address: ADC12m = 0x4033_2000 + 0x0200 × m (m = 0, 1)
ADC12m_NS = 0x5033_2000 + 0x0200 × m (m = 0, 1)

Offset address: 0x0E0 + 0x1 × n (n = 0 to 2, 4 to 8, m = 0)
0x0E0 + 0x1 × n (n = 0 to 2, 4 to 6, m = 1)
0x0DD (ADSSTRL)
0x0DE (ADSSTRT)
0x0DF (ADSSTRO)



Bit	Symbol	Function	R/W
7:0	SST[7:0]	Sampling Time Setting These bits set the sampling time in the range from 5 to 255 states.	R/W

Note: S-TYPE-3, P-TYPE-3

The ADSSTRn register sets the sampling time for analog input.

The sampling time can be adjusted if the impedance of the analog input signal source is too high to secure sufficient sampling time, or if the ADCLK clock is slow. The set value indicates the time for one ADCLK cycle, and the required sampling time is specified by the voltage conditions. For details, see section 48.5. ADC12 Characteristics.

The lower limit of the sampling time setting depends on the frequency ratio:

- If the frequency ratio of PCLKA to PCLKC (ADCLK) = 1:1, 2:1, 4:1, or 8:1 the sampling time must be set to a value of more than 5 states
- If the frequency ratio of PCLKA to PCLKC (ADCLK) = 1:2 or 1:4, the sampling time must be set to a value of more than 6 states.

Table 39.21 shows the relationship between the A/D Sampling State Register and the associated channels. For details, see section 39.3.6. Analog Input Sampling and Scan Conversion Time.

Only set the SST[7:0] bits when the ADCSR.ADST bit is 0.

Table 39.21 Relationship between A/D sampling state register and associated channels

Bit name	Associated channels
ADSSTRn.SST[7:0] bits (n = 0 to 8 (unit 0), 0 to 6 (unit 1)00 to 02, 04 to 08 (unit 0), 00 to 02, 04 to 06 (unit 1))*1	AN000 to AN002, AN004 to AN008, AN100 to AN102, AN104 to AN106
ADSSTRL.SST[7:0] bits	AN016 to AN019, AN116 to AN122
ADSSTRT.SST[7:0] bits	Temperature sensor output
ADSSTRO.SST[7:0] bits	Internal reference voltage

Note 1. When the self-diagnosis function is selected, the sampling time set in the ADSSTR0.SST[7:0] bits is applied.

39.2.19 ADSHCR : A/D Sample and Hold Circuit Control Register

Base address: ADC12m = 0x4033_2000 + 0x0200 × m (m = 0)
ADC12m_NS = 0x5033_2000 + 0x0200 × m (m = 0)

Offset address: 0x066

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	SHANS[2:0]			SSTSH[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	1	1	0	0	0

Bit	Symbol	Function	R/W
7:0	SSTSH[7:0]	Channel-Dedicated Sample-and-Hold Circuit Sampling Time Setting Sampling time (4 to 255 states).	R/W
10:8	SHANS[2:0]	Channel-Dedicated Sample-and-Hold Circuit Bypass Select Select whether to use or bypass channel-dedicated sample-and-hold circuits for AN000 to AN002 (unit 0). 0: Bypass the circuits 1: Use the circuits	R/W
15:11	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

SSTSH[7:0] bits (Channel-Dedicated Sample-and-Hold Circuit Sampling Time Setting)

The SSTSH[7:0] bits set the sampling time for the channel-dedicated sample-and-hold circuits. If one state is 1 ADCLK (A/D conversion clock) cycle and the ADCLK clock is 60 MHz, one state is 16.7 ns. The initial value is 24 states. The sampling time can be adjusted if the impedance of the analog input signal source is too high to secure sufficient sampling time, or if the ADCLK clock is slow.

Only set the SSTSH[7:0] bits while the ADCSR.ADST bit is 0. The sampling time must be set to a value that is 4 states or more and 255 or less.

SHANS[2:0] bits (Channel-Dedicated Sample-and-Hold Circuit Bypass Select)

The SHANS[2:0] bits select whether to use or bypass the channel-dedicated sample-and-hold circuits for AN000 to AN002 (unit 0). In unit 0, the SHANS[0] bit is associated with AN000, the SHANS[1] bit with AN001, and the SHANS[2] bit with AN002.

If any channel from among AN000 to AN002 (unit 0) is selected for group B while operation is in group scan mode under group A priority control, use this setting to bypass the dedicated sample-and-hold circuit of the channel.

Only set the SHANS[2:0] bits while the ADCSR.ADST bit is 0 and the ADSHMSR.SHMD bit is 0.

39.2.20 ADSHMSR : A/D Sample and Hold Operation Mode Selection Register

Base address: ADC12m = 0x4033_2000 + 0x0200 × m (m = 0)
ADC12m_NS = 0x5033_2000 + 0x0200 × m (m = 0)

Offset address: 0x07C

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	SHMD
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	SHMD	Sampling Operation Selection 0: Sampling Operation Selection 1: Enable continuous sampling function	R/W
7:1	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

SHMD bit (Sampling Operation Selection)

Setting SHMD to 1 enables the constant sampling function of the channel-dedicated sample-and-hold selected in the ADSHCR.SHANS[2:0] bits. Only set the SHMD bit while the ADCSR.ADST bit is 0.

When the sampling function is enabled, the sample-and-hold circuit operates sampling while the ADC12 is not operating, and it operates holding while the ADC12 is operating.

Note: The ADCSR.ADST bit must become 1 after a time of 400 ns or more elapses after the SHMD bit is set to 1 (when the permissible signal source impedance is 1 kΩ). The sampling period of the sample-and-hold circuit must be 400 ns or more (when the permissible signal source impedance is 1 kΩ).

39.2.21 ADDISCR : A/D Disconnection Detection Control Register

Base address: ADC12m = 0x4033_2000 + 0x0200 × m (m = 0, 1)
ADC12m_NS = 0x5033_2000 + 0x0200 × m (m = 0, 1)

Offset address: 0x07A

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	PCHG	ADNDIS[3:0]			
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
3:0	ADNDIS[3:0]	Disconnection Detection Assist Setting 0x0: The disconnection detection assist function is disabled 0x1: Setting prohibited Others: The number of states for the discharge or precharge period.	R/W
4	PCHG	Precharge/discharge select 0: Discharge 1: Precharge	R/W
7:5	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

The ADDISCR register selects either precharge or discharge, and the period of precharge or discharge for the A/D disconnection detection assist function. Only set the ADDISCR register when the ADCSR.ADST bit is 0. When the temperature sensor output or internal reference voltage is converted, the A/D converter executes discharge automatically.

Disable the disconnection detection assist function if any of the following functions are used:

- The temperature sensor

- The internal reference voltage
- A/D self-diagnosis

ADNDIS[3:0] bits (Disconnection Detection Assist Setting)

The ADNDIS[3:0] bits specify the period of precharge or discharge. When ADNDIS[3:0] = 0000b, the disconnection detection assist function is disabled. Setting the ADNDIS[3:0] bits to 0001b is prohibited. Except when ADNDIS[3:0] = 0000b or 0001b, the specified value indicates the number of states for the period of precharge or discharge. When the ADNDIS[3:0] bits are set to any values other than 0000b or 0001b, the disconnection detection assistance function is enabled.The ADNDIS[4:0] should be set while the ADCSR.ADST bit is 0. When the ADNDIS[3:0] bits are set to any values other than 0000b, and the disconnection detection assistance is enabled, the disconnection detection assistance for the channel-dedicated sample-and-hold circuit used for analog inputs are also enabled. When the temperature sensor output or internal reference voltage is converted or self-diagnosis is used, the disconnection detection assistance cannot be used. In that case, the ADNDIS[3:0] bits should be set to 0000b.

PCHG bit (Precharge/discharge select)

The PCHG bit selects either precharge or discharge.

39.2.22 ADGSPCR : A/D Group Scan Priority Control Register

Base address: ADC12m = 0x4033_2000 + 0x0200 × m (m = 0, 1)
ADC12m_NS = 0x5033_2000 + 0x0200 × m (m = 0, 1)

Offset address: 0x080

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	GBRP	LGRRS	—	—	—	—	—	—	—	—	—	—	—	—	GBRSCN	PGS
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	PGS	Group Priority Operation Setting*1 0: Operate without group priority control. 1: Operate with group priority control.	R/W
1	GBRSCN	Lower-Priority Group Restart Setting (enabled only when PGS = 1 and reserved when PGS = 0.) 0: Disable rescanning of the group that was stopped in group priority operation 1: Enable rescanning of the group that was stopped in group priority operation.	R/W
13:2	—	These bits are read as 0. The write value should be 0.	R/W
14	LGRRS	Restart Channel Select Enabled only when PGS = 1 and GBRSCN = 1. 0: Start rescanning from the first channel for scanning 1: Start rescanning from the channel for which A/D conversion is not completed.	R/W
15	GBRP	Single Scan Continuous Start*2 (enabled only when PGS = 1 and reserved when PGS = 0.) 0: Single scan is not continuously activated. 1: Single scan for the group with the lower-priority is continuously activated.	R/W

Note: S-TYPE-3, P-TYPE-3
Note 1. The ADCSR.ADCS[1:0] bits must be set to 01b (group scan mode) before setting PGS to 1. Operation is not guaranteed if these bits are set to any other value.
Note 2. When the GBRP bit is set to 1, single scan is performed continuously for the group with the lower-priority regardless of the setting in the GBRSCN bit.

PGS bit (Group Priority Operation Setting)

The PGS bit controls group priority operation in group scan mode. Set the PGS bit to 1 to enable group priority operation.

The ADCSR.ADCS[1:0] bits must be set to 01b (group scan mode) before setting the PGS bit to 1. Operation is not guaranteed if the bits are set to any other value.

When the PGS bit is set to 0, a clear operation must be performed by software as described in section 39.6.3. Constraints on Stopping A/D Conversion. When the PGS bit is set to 1, use the settings described in section 39.3.4.3. Group Priority Operation.

GBRSCN bit (Lower-Priority Group Restart Setting)

The GBRSCN bit controls the restarting of scan operation in group priority operation.

When the GBRSCN bit is set to 1, if the scan operation of a lower-priority group is stopped by a trigger input of a priority group, the lower-priority group scanning is restarted on completion of the priority group scanning. If a trigger of a lower-priority group is input during scanning of the priority group, the lower-priority group scanning is started on completion of the priority group scanning.

When the GBRSCN bit is set to 0, triggers input during scanning are ignored. Set the GBRSCN bit while the ADCSR.ADST bit is 0.

LGRRS bit (Restart Channel Select)

This bit sets the channel from which rescanning is to be started in group priority operation. The setting of the LGRRS bit is valid when the PGS and GBRSCN bits are 1.

If the LGRRS bit is 0, scanning of a lower-priority group that was stopped in group priority operation is restarted from the first channel after scanning of the priority group completes.

If the LGRRS bit is 1, scanning of a lower-priority group that was stopped in group priority operation is restarted (upon completion of scanning of the priority group) from the channel for which A/D conversion is not complete. If A/D conversion of the addition setting channel was not completed the specified number of times when scanning stopped, A/D conversion of the addition setting channel is performed again the specified number of times when scanning restarts.

Set the LGRRS bit while the ADCSR.ADST bit is 0.

GBRP bit (Single Scan Continuous Start)

The GBRP bit is set when a single scan operation is to be performed continuously on the group with the lower-priority.

Setting the GBRP bit to 1 starts a single scan of the group with the lower-priority. On completion of the scan, another single scan of the group with the lower-priority is started automatically. If scanning has been stopped during group priority operation, single scan of the group with the lower-priority is automatically restarted on completion of the A/D conversion of the priority group.

Before setting the GBRP bit to 1, disable input of a trigger for the lower-priority group. If the GBRP bit is set to 1, rescanning is performed only on the group with the lower-priority even if the GBRSCN bit is set to 0.

39.2.23 ADCMPCR : A/D Compare Function Control Register

Base address: ADC12m = 0x4033_2000 + 0x0200 × m (m = 0, 1)
ADC12m_NS = 0x5033_2000 + 0x0200 × m (m = 0, 1)

Offset address: 0x090

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	CMPAIE	WCMPE	CMPBIE	—	CMPAE	—	CMPBE	—	—	—	—	—	—	—	CMPAB[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
1:0	CMPAB[1:0]	Window A/B Composite Conditions Setting These bits are valid when both window A and window B are enabled (CMPAE = 1 and CMPBE = 1). 0 0: Output ADC12i_WCMPM (i = 0, 1) when window A OR window B comparison conditions are met. Otherwise, output ADC12i_WCMPUM (i = 0, 1). 0 1: Output ADC12i_WCMPM (i = 0, 1) when window A EXOR window B comparison conditions are met. Otherwise, output ADC12i_WCMPUM (i = 0, 1). 1 0: Output ADC12i_WCMPM (i = 0, 1) when window A AND window B comparison conditions are met. Otherwise, output ADC12i_WCMPUM (i = 0, 1). 1 1: Setting prohibited.	R/W

Bit	Symbol	Function	R/W
8:2	—	These bits are read as 0. The write value should be 0.	R/W
9	CMPBE	Compare Window B Operation Enable 0: Disable compare window B operation. Disable ADC12i_WCMPM (i = 0, 1) and ADC12i_WCMPUM (i = 0, 1) outputs. 1: Enable compare window B operation.	R/W
10	—	This bit is read as 0. The write value should be 0.	R/W
11	CMPAE	Compare Window A Operation Enable 0: Disable compare window A operation. Disable ADC12i_WCMPM (i = 0, 1) and ADC12i_WCMPUM (i = 0, 1) outputs. 1: Enable compare window A operation.	R/W
12	—	This bit is read as 0. The write value should be 0.	R/W
13	CMPBIE	Compare B Interrupt Enable 0: Disable ADC12i_CMPBI (i = 0, 1) interrupt when comparison conditions (window B) are met. 1: Enable ADC12i_CMPBI (i = 0, 1) interrupt when comparison conditions (window B) are met.	R/W
14	WCMPE	Window Function Setting 0: Disable window function Window A and window B operate as a comparator to compare the single value on the lower side with the A/D conversion result. 1: Enable window function Window A and window B operate as a comparator to compare the two values on the upper and lower sides with the A/D conversion result.	R/W
15	CMPAIE	Compare A Interrupt Enable 0: Disable ADC12i_CMPAI (i = 0, 1) interrupt when comparison conditions (window A) are met. 1: Enable ADC12i_CMPAI (i = 0, 1) interrupt when comparison conditions (window A) are met.	R/W

Note: S-TYPE-3, P-TYPE-3

CMPAB[1:0] bits (Window A/B Composite Conditions Setting)

The CMPAB[1:0] bits are valid when both window A and window B are enabled (CMPAE = 1 and CMPBE = 1) in single scan mode. These bits specify the compare function match/mismatch event output conditions and monitoring conditions of ADWINMON.MONCOMB. Only set the CMPAB[1:0] bits while the ADCSR.ADST bit is 0.

CMPBE bit (Compare Window B Operation Enable)

The CMPBE bit enables or disables the compare window B operation. Set the CMPBE bit while the ADCSR.ADST bit is 0.

Set this bit to 0 before setting the following registers:

- A/D Channel Select Registers A0, A1, B0, B1 (ADANSA0, ADANSA1, ADANSB0, ADANSB1)
- OCSB, TSSB, OCSA, or TSSA bits in the A/D Conversion Extended Input Control Register (ADEXICR)
- CMPCHB[5:0] bits in the Window B Channel Select Register (ADCMPBNSR)

CMPAE bit (Compare Window A Operation Enable)

The CMPAE bit enables or disables the compare window A operation. Set the CMPAE bit while the ADCSR.ADST bit is 0.

Set this bit to 0 before setting the following registers:

- A/D Channel Select Registers A0, A1, B0, B1 (ADANSA0, ADANSA1, ADANSB0, ADANSB1)
- OCSB, TSSB, OCSA, or TSSA bits in the A/D Conversion Extended Input Control Register (ADEXICR)
- Window A Channel Select Registers 0 and 1 (ADCMPANSR0 and ADCMPANSR1)
- Window A Extended Input Select Register (ADCMPANSER)

CMPBIE bit (Compare B Interrupt Enable)

The CMPBIE bit enables or disables the ADC12i_CMPBI (i = 0, 1) interrupt output when the comparison conditions (window B) are met.

WCMPE bit (Window Function Setting)

The WCMPE bit enables or disables the window function. Set the WCMPE bit while the ADCSR.ADST bit is 0.

CMPAIE bit (Compare A Interrupt Enable)

The CMPAIE bit enables or disables the ADC12i_CMPAI (i = 0, 1) interrupt output when the comparison conditions (window A) are met.

39.2.24 ADCMPANSR0 : A/D Compare Function Window A Channel Select Register 0

Base address: ADC12m = 0x4033_2000 + 0x0200 × m (m = 0, 1)
ADC12m_NS = 0x5033_2000 + 0x0200 × m (m = 0, 1)

Offset address: 0x094

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	CMPCHA15	CMPCHA14	CMPCHA13	CMPCHA12	CMPCHA11	CMPCHA10	CMPCHA09	CMPCHA08	CMPCHA07	CMPCHA06	CMPCHA05	CMPCHA04	CMPCHA03	CMPCHA02	CMPCHA01	CMPCHA00
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	CMPCHA15 to CMPCHA00*1	Compare Window A Channel Select Bit 15 (CMPCHA15) is associated with ANm15 and bit 0 (CMPCHA00) is associated with ANm00. 0: Disable compare function for associated input channel 1: Enable compare function for associated input channel	R/W

Note: S-TYPE-3, P-TYPE-3
Note: Bits associated with non-existent pins are reserved. This bit is read as 0. The write value should be 0.
Note 1. 00 to 02, 04 to 08 (unit 0), 00 to 02, 04 to 06 (unit 1) is available.

CMPCHAn bits (Compare Window A Channel Select)

The compare function is enabled by writing 1 to the CMPCHAn bits with the same number as the A/D conversion channel selected in the ADANSA0.ANSAn bits and the ADANSB0.ANSBn bits.

Set the CMPCHAn bits while the ADCSR.ADST bit is 0.

39.2.25 ADCMPANSR1 : A/D Compare Function Window A Channel Select Register 1

Base address: ADC12m = 0x4033_2000 + 0x0200 × m (m = 0, 1)
ADC12m_NS = 0x5033_2000 + 0x0200 × m (m = 0, 1)

Offset address: 0x096

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	CMPCHA31	CMPCHA30	CMPCHA29	CMPCHA28	CMPCHA27	CMPCHA26	CMPCHA25	CMPCHA24	CMPCHA23	CMPCHA22	CMPCHA21	CMPCHA20	CMPCHA19	CMPCHA18	CMPCHA17	CMPCHA16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	CMPCHA31 to CMPCHA16*1	Compare Window A Channel Select Bit 15 (CMPCHA31) is associated with ANm31 and bit 0 (CMPCHA16) is associated with ANm16. 0: Disable compare function for associated input channel 1: Enable compare function for associated input channel	R/W

Note: S-TYPE-3, P-TYPE-3
Note: Bits associated with non-existent pins are reserved. This bit is read as 0. The write value should be 0.
Note 1. 16 to 19 (unit 0), 16 to 22 (unit 1) is available.

CMPCHAn bits (Compare Window A Channel Select)

The compare function is enabled by writing 1 to the CMPCHAn bits with the same number as the A/D conversion channel selected in the ADANSA1.ANSA bits and the ADANSB1.ANSB bits.

Set the CMPCHAn bits while the ADCSR.ADST bit is 0.

39.2.26 ADCMPANSER : A/D Compare Function Window A Extended Input Select Register

Base address: ADC12m = 0x4033_2000 + 0x0200 × m (m = 0, 1)
ADC12m_NS = 0x5033_2000 + 0x0200 × m (m = 0, 1)

Offset address: 0x092

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	CMPOCA	CMPTSA
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	CMPTSA	Temperature Sensor Output Compare Select 0: Exclude the temperature sensor output from the compare Window A target range. 1: Include the temperature sensor output in the compare Window A target range.	R/W
1	CMPOCA	Internal Reference Voltage Compare Select 0: Exclude the internal reference voltage from the compare Window A target range. 1: Include the internal reference voltage in the compare Window A target range.	R/W
7:2	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

CMPTSA bit (Temperature Sensor Output Compare Select)

The compare Window A function is enabled by setting the CMPTSA bit to 1 while the ADEXICR.TSSA bit or the ADEXICR.TSSB bit is 1. Set the CMPTSA bit while the ADCSR.ADST bit is 0.

CMPOCA bit (Internal Reference Voltage Compare Select)

The compare window A function is enabled by setting the CMPOCA bit to 1 when the ADEXICR.OCSA and ADEXICR.OCSB bit is 1. Set the CMPOCA bit when the ADCSR.ADST bit is 0.

39.2.27 ADCMPLR0 : A/D Compare Function Window A Comparison Condition Setting Register 0

Base address: ADC12m = 0x4033_2000 + 0x0200 × m (m = 0, 1)
ADC12m_NS = 0x5033_2000 + 0x0200 × m (m = 0, 1)

CMPLCHAn bits (Compare Window A Comparison Condition Select)

The CMPLCHAn bits specify the comparison conditions for channels to which Window A comparison conditions are applied. These bits can be set for each analog input to be compared. When the comparison result of each analog input meets the set condition, the ADCMPSR0.CMPSTCHAn flag sets to 1 and a compare interrupt (ADC12i_CMPAI (i = 0, 1)) is generated.

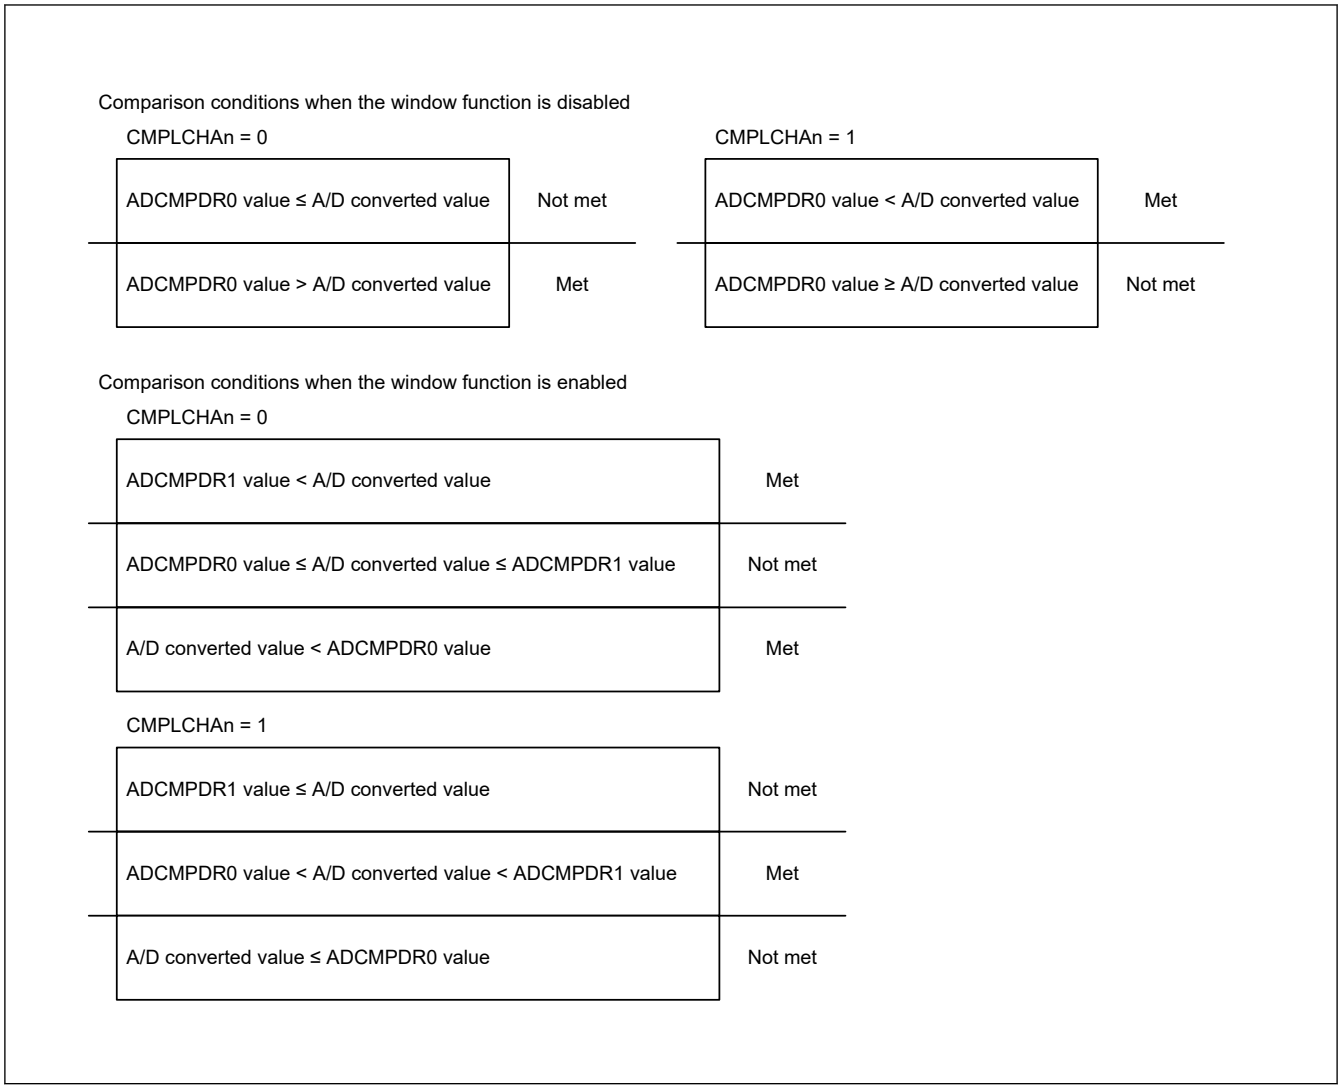

Figure 39.4 Explanation of comparison conditions for compare function Window A

Note: S-TYPE-3, P-TYPE-3

CMPLTSA bit (Compare Window A Temperature Sensor Output Comparison Condition Select)

The CMPLTSA bit specifies comparison conditions when the temperature sensor output is the target for the Window A comparison condition. When the temperature sensor output comparison result meets the set condition, the ADCMPSER.CMPSTTSA flag sets to 1 and a compare interrupt (ADC12i_CMPAI (i = 0, 1)) is generated.

CMPLOCA bit (Compare Window A Internal Reference Voltage Comparison Condition Select)

The CMPLOCA bit specifies comparison conditions when the internal reference voltage is the target for the Window A comparison condition. When the internal reference voltage comparison result meets the set condition, the ADCMPSER.CMPSTOCA flag sets to 1 and a compare interrupt (ADC12i_CMPAI (i = 0, 1)) is generated.

39.2.30 ADCMPDRn : A/D Compare Function Window A Lower-Side/Upper-Side Level Setting Register (n = 0, 1)

Base address: ADC12m = 0x4033_2000 + 0x0200 × m (m = 0, 1)
ADC12m_NS = 0x5033_2000 + 0x0200 × m (m = 0, 1)

Offset address: 0x09C + (0x2 × n)

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:																
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Note: S-TYPE-3, P-TYPE-3

The ADCMPDRy (y = 0, 1) register specifies the reference data when the compare window A function is used. ADCMPDR0 sets the lower reference for window A, and ADCMPDR1 sets the upper reference for window A.

ADCMPDRy are read/write registers.

ADCMPDRy are writable even during A/D conversion. The reference data can be dynamically changed by rewriting register values during A/D conversion*1.

Set these registers so that the upper reference is not less than the lower reference (ADCMPDR1 ≥ ADCMPDR0). ADCMPDR1 are not used when the window function is disabled.

Note 1. The lower and the upper references are changed when each register is written. For example, when the upper reference value is changed and the lower reference value is being changed, the MCU compares the upper reference (after rewrite), and the lower reference (before rewrite) with the A/D conversion result. See Figure 39.5. If the comparison during the rewriting of these two references is erroneous, then rewrite these reference values when both ADCSR.ADST and the target Compare Window Operation Enable bit (ADCMPCR.CMPAE or ADCMPCR.CMPBE) are 0.

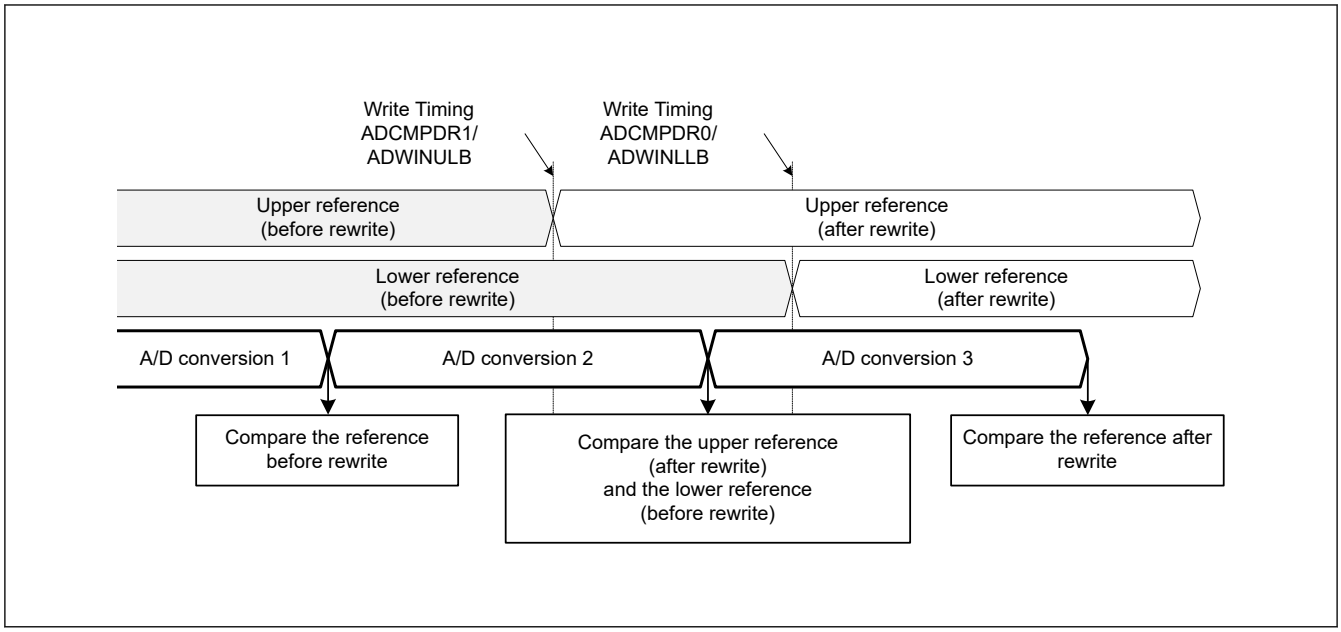

Figure 39.5 Comparison between upper and lower references before and after a rewrite

The ADCMPDRy registers use different formats depending on the following conditions:

- The value of A/D Data Register Format Select bit (flush-right or flush-left)
- The value of the A/D Conversion Accuracy Select bit (12-bit, 10-bit, 8-bit)
- The value of A/D-Converted Value Addition/Average Channel Select bits (A/D-converted value addition mode selected or not selected).

The data formats for each condition are shown as follows:

1. When A/D-converted value addition mode is not selected
   - Flush-right data with 12-bit accuracy — Lower 12 bits ([11:0]) are valid
   - Flush-right data with 10-bit accuracy — Lower 10 bits ([9:0]) are valid
   - Flush-right data with 8-bit accuracy — Lower 8 bits ([7:0]) are valid
   - Flush-left data with 12-bit accuracy — Upper 12 bits ([15:4]) are valid
   - Flush-left data with 10-bit accuracy — Upper 10 bits ([15:6]) are valid
   - Flush-left data with 8-bit accuracy — Upper 8 bits ([15:8]) are valid
2. When A/D-converted value addition mode is selected
   - Flush-right data with 12-bit accuracy — Lower 14 bits ([13:0]) are valid
   - Flush-right data with 10-bit accuracy — Lower 12 bits ([11:0]) are valid
   - Flush-right data with 8-bit accuracy — Lower 10 bits ([9:0]) are valid
   - Flush-left data with 12-bit accuracy — Upper 14 bits ([15:2]) are valid
   - Flush-left data with 10-bit accuracy — Upper 12 bits ([15:4]) are valid
   - Flush-left data with 8-bit accuracy — Upper 10 bits ([15:6]) are valid

39.2.31 ADWINnLB : A/D Compare Function Window B Lower-Side/Upper-Side Level Setting Register (n = L, U)

Base address: ADC12m = 0x4033_2000 + 0x0200 × m (m = 0, 1)
ADC12m_NS = 0x5033_2000 + 0x0200 × m (m = 0, 1)

Offset address: 0x0A8 (n = L)
0x0AA (n = U)

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:																
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Note: S-TYPE-3, P-TYPE-3

The ADWINULB and ADWINLLB registers specify the reference data when the compare window B function is used. ADWINLLB sets the lower reference for window B, and ADWINULB sets the upper reference for window B.

ADWINnLB are read/write registers.

ADWINnLB are writable even during A/D conversion. The reference data can be dynamically changed by rewriting register values during A/D conversion*1.

Set these registers so that the upper reference is not less than the lower reference (ADWINULB ≥ ADWINLLB). ADWINULB are not used when the window function is disabled.

Note 1. The lower and the upper references are changed when each register is written. For example, when the upper reference value is changed and the lower reference value is being changed, the MCU compares the upper reference (after rewrite), and the lower reference (before rewrite) with the A/D conversion result. See Figure 39.6. If the comparison during the rewriting of these two references is erroneous, then rewrite these reference values when both ADCSR.ADST and the target Compare Window Operation Enable bit (ADCMPCR.CMPAE or ADCMPCR.CMPBE) are 0.

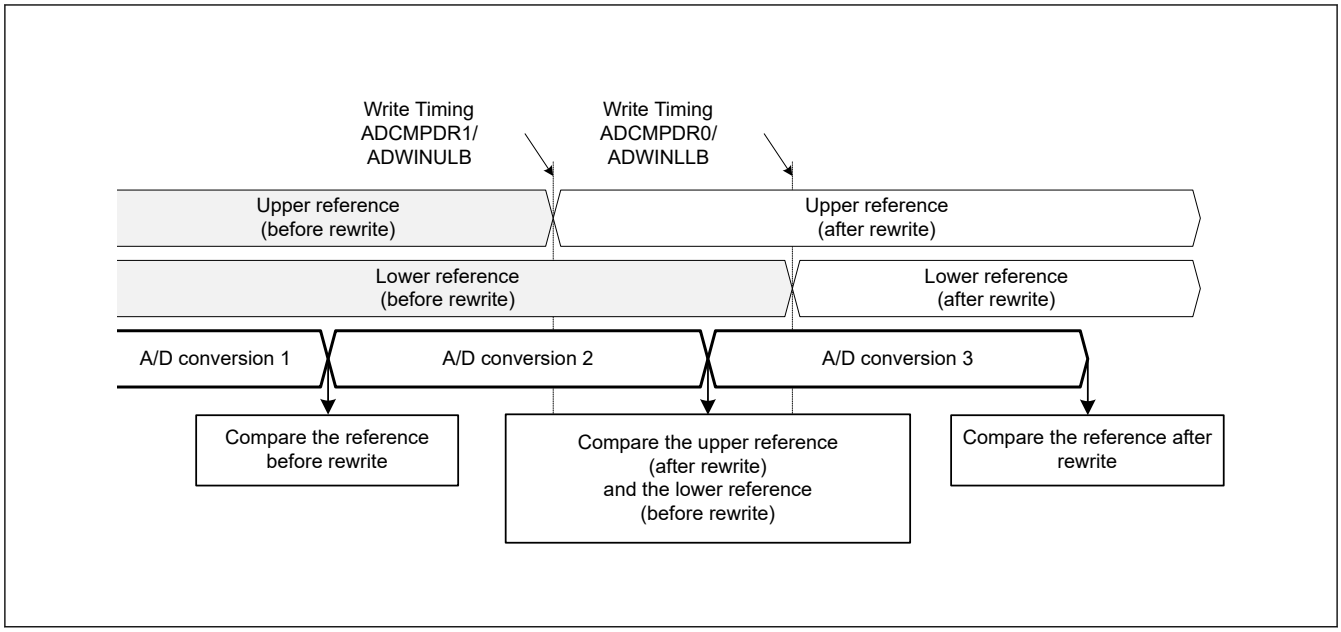

Figure 39.6 Comparison between upper and lower references before and after a rewrite

The ADWINnLB registers use different formats depending on the following conditions:

- The value of A/D Data Register Format Select bit (flush-right or flush-left)
- The value of the A/D Conversion Accuracy Select bit (12-bit, 10-bit, 8-bit)
- The value of A/D-Converted Value Addition/Average Channel Select bits (A/D-converted value addition mode selected or not selected).

The data formats for each condition are shown as follows:

1. When A/D-converted value addition mode is not selected
   - Flush-right data with 12-bit accuracy — Lower 12 bits ([11:0]) are valid
   - Flush-right data with 10-bit accuracy — Lower 10 bits ([9:0]) are valid
   - Flush-right data with 8-bit accuracy — Lower 8 bits ([7:0]) are valid
   - Flush-left data with 12-bit accuracy — Upper 12 bits ([15:4]) are valid
   - Flush-left data with 10-bit accuracy — Upper 10 bits ([15:6]) are valid
   - Flush-left data with 8-bit accuracy — Upper 8 bits ([15:8]) are valid
2. When A/D-converted value addition mode is selected
   - Flush-right data with 12-bit accuracy — Lower 14 bits ([13:0]) are valid
   - Flush-right data with 10-bit accuracy — Lower 12 bits ([11:0]) are valid
   - Flush-right data with 8-bit accuracy — Lower 10 bits ([9:0]) are valid
   - Flush-left data with 12-bit accuracy — Upper 14 bits ([15:2]) are valid
   - Flush-left data with 10-bit accuracy — Upper 12 bits ([15:4]) are valid
   - Flush-left data with 8-bit accuracy — Upper 10 bits ([15:6]) are valid

39.2.32 ADCMPSR0 : A/D Compare Function Window A Channel Status Register 0

Base address: ADC12m = 0x4033_2000 + 0x0200 × m (m = 0, 1)
ADC12m_NS = 0x5033_2000 + 0x0200 × m (m = 0, 1)

Offset address: 0x0A0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	CMPSTCHA15	CMPSTCHA14	CMPSTCHA13	CMPSTCHA12	CMPSTCHA11	CMPSTCHA10	CMPSTCHA09	CMPSTCHA08	CMPSTCHA07	CMPSTCHA06	CMPSTCHA05	CMPSTCHA04	CMPSTCHA03	CMPSTCHA02	CMPSTCHA01	CMPSTCHA00
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	CMPSTCHA15 to CMPSTCHA00*1	Compare Window A Flag When Window A operation is enabled (ADCMPCR.CMPAE = 1b), these bits indicate the comparison result of channels to which Window A comparison conditions are applied. Bit 15 (CMPSTCHA15) is associated with ANm15 and bit 0 (CMPSTCHA00) is associated with ANm00. 0: Comparison conditions are not met. 1: Comparison conditions are met.	R/W

Note: S-TYPE-3, P-TYPE-3
Note: Bits associated with non-existent pins are reserved. This bit is read as 0. The write value should be 0.
Note 1. 00 to 02, 04 to 08 (unit 0), 00 to 02, 04 to 06 (unit 1) is available.

CMPSTCHAn flags (Compare Window A Flag)

The CMPSTCHAn flags indicate the comparison results for channels to which Window A comparison conditions are applied. When a comparison condition set in ADCMPLR0.CMPLCHA is met at the end of A/D conversion, the associated CMPSTCHAn flag sets to 1. When the ADCMPCR.CMPAIE bit is 1, a compare interrupt request (ADC12i_CMPAI (i = 0, 1)) is generated when this flag sets to 1.

Writing 1 to the CMPSTCHAn flags is invalid.

[Setting condition]

- The condition set in ADCMPLR0.CMPLCHA is met when ADCMPCR.CMPAE = 1.

[Clearing condition]

- Writing 0 after reading 1.

39.2.33 ADCMPSR1 : A/D Compare Function Window A Channel Status Register1

Base address: ADC12m = 0x4033_2000 + 0x0200 × m (m = 0, 1)
ADC12m_NS = 0x5033_2000 + 0x0200 × m (m = 0, 1)

Note: S-TYPE-3, P-TYPE-3
Note: Bits associated with non-existent pins are reserved. This bit is read as 0. The write value should be 0.
Note 1. 16 to 19 (unit 0), 16 to 22 (unit 1) is available.

CMPSTCHAn flags (Compare Window A Flag)

The CMPSTCHAn flags indicate the comparison results for channels to which Window A comparison conditions are applied. When the comparison condition set in ADCMPLR1.CMPLCHA is met at the end of A/D conversion, the associated CMPSTCHAn flag sets to 1. When the ADCMPCR.CMPAIE bit is 1, a compare interrupt request (ADC12i_CMPAI (i = 0, 1)) is generated when this flag sets to 1.

Writing 1 to the CMPSTCHAn flags is invalid.

[Setting condition]

- The condition set in ADCMPLR1.CMPLCHA is met when ADCMPCR.CMPAE = 1.

[Clearing condition]

- Writing 0 after reading 1.

39.2.34 ADCMPSER : A/D Compare Function Window A Extended Input Channel Status Register

Base address: ADC12m = 0x4033_2000 + 0x0200 × m (m = 0, 1)
ADC12m_NS = 0x5033_2000 + 0x0200 × m (m = 0, 1)

Offset address: 0x0A4

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	CMPSTOCA	CMPSTTSA
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	CMPSTTSA	Compare Window A Temperature Sensor Output Compare Flag When Window A operation is enabled (ADCMPCR.CMPAE = 1), this bit indicates the temperature sensor output comparison result. 0: Comparison conditions are not met. 1: Comparison conditions are met.	R/W

Bit	Symbol	Function	R/W
1	CMPSTOCA	Compare Window A Internal Reference Voltage Compare Flag When Window A operation is enabled (ADCMPCR.CMPAE = 1), this bit indicates the internal reference voltage comparison result. 0: Comparison conditions are not met. 1: Comparison conditions are met.	R/W
7:2	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

The ADCMPSER register stores compare results of compare function window A.

CMPSTTSA flag (Compare Window A Temperature Sensor Output Compare Flag)

The CMPSTTSA flag indicates the temperature sensor output comparison result. When the comparison condition set in ADCMPLER.CMPLTSA is met at the end of A/D conversion, this flag sets to 1. When the ADCMPCR.CMPAIE bit is 1, a compare interrupt request (ADC12i_CMPAI (i = 0, 1)) is generated when this flag sets to 1.

Writing 1 to the CMPSTTSA flag is invalid.

[Setting condition]

- The condition set in ADCMPLER.CMPLTSA is met when ADCMPCR.CMPAE = 1.

[Clearing condition]

- Writing 0 after reading 1.

CMPSTOCA flag (Compare Window A Internal Reference Voltage Compare Flag)

The CMPSTOCA flag indicates the internal reference voltage comparison result. When the comparison condition set in ADCMPLER.CMPLOCA is met at the end of A/D conversion, this flag sets to 1. When the ADCMPCR.CMPAIE bit is 1, a compare interrupt request (ADC12i_CMPAI (i = 0, 1)) is generated when this flag sets to 1.

Writing 1 to the CMPSTOCA flag is invalid.

[Setting condition]

- The condition set in ADCMPLER.CMPLOCA is met when ADCMPCR.CMPAE = 1.

[Clearing condition]

- Writing 0 after reading 1.

</table>

Note: S-TYPE-3, P-TYPE-3

CMPCHB[5:0] bits (Compare Window B Channel Select)

The CMPCHB[5:0] bits specify the channels to be compared with the compare Window B conditions from AN000 to AN002, AN004 to AN008, AN016 to AN019, AN100 to AN102, AN104 to AN106, AN116 to AN122, the temperature sensor and the internal reference voltage The compare Window B function is enabled by specifying the hexadecimal number of the A/D conversion channel selected in the ADANSA0, ADANSA1, ADANSB0, ADANSB1 registers.

Set the CMPCHB[5:0] bits while the ADCSR.ADST bit is 0.

CMPLB bit (Compare Window B Comparison Condition Setting)

The CMPLB bit specifies the comparison conditions for channels for Window B. When the comparison result of an analog input meets the set condition, the associated ADCMPBSR.CMPSTB flag sets to 1 and a compare interrupt request (ADC12i_CMPBI (i = 0, 1)) is generated.

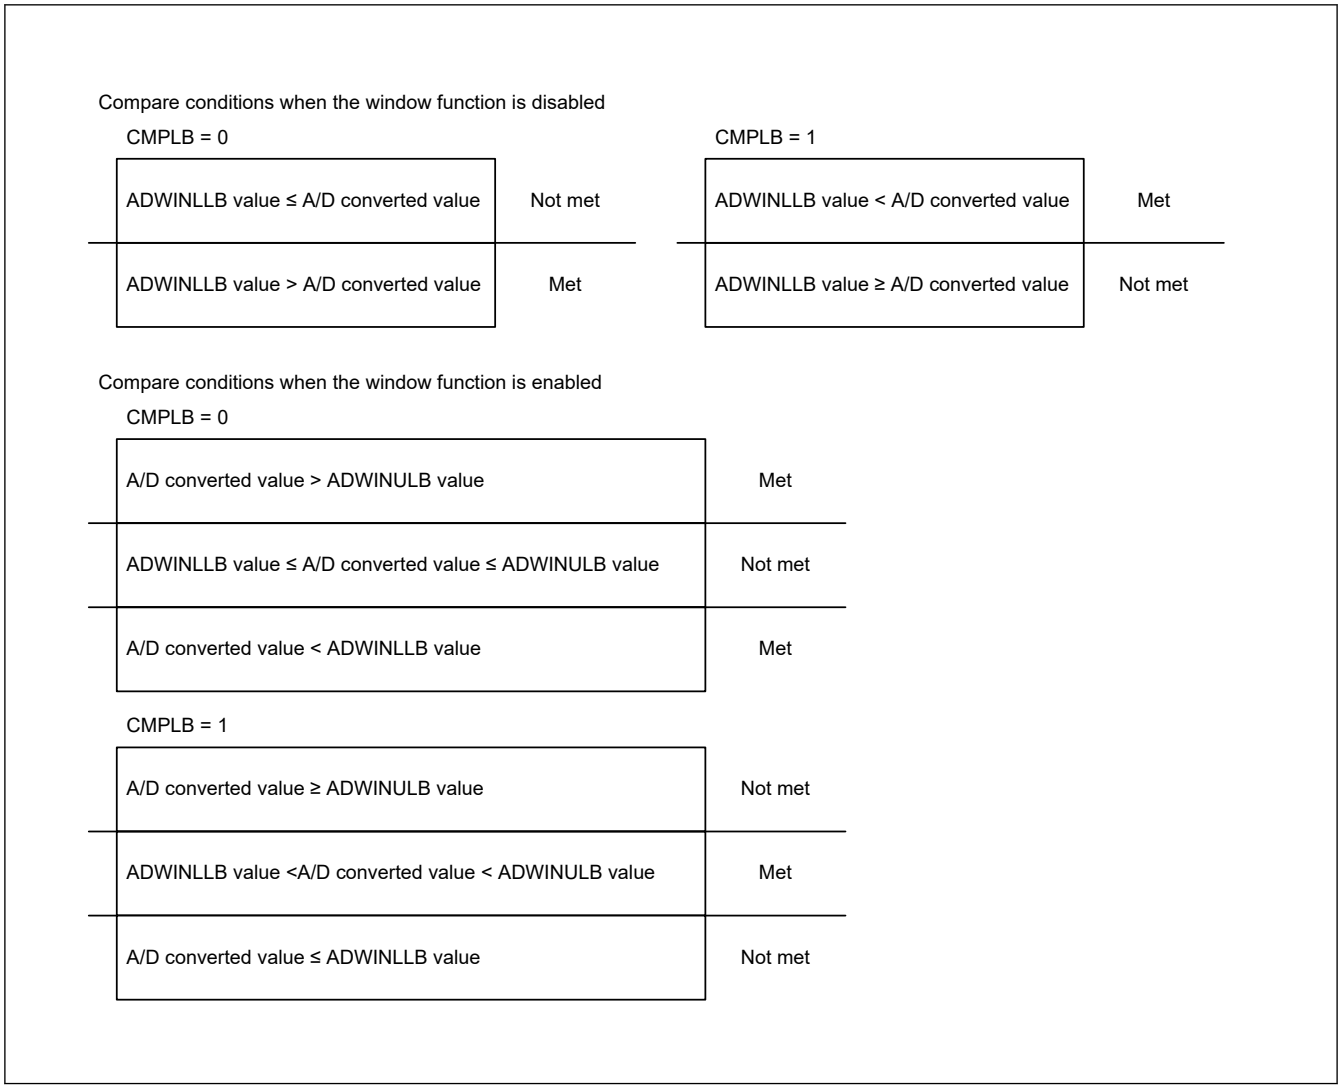

Figure 39.7 Explanation of compare conditions for compare function Window B

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	CMPSTB
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	CMPSTB	Compare Window B Flag When Window B operation is enabled (ADCMPCR.CMPBE = 1), this bit indicates the comparison result of channels to which Window B comparison conditions are applied, temperature sensor output, internal reference voltage. 0: Comparison conditions are not met. 1: Comparison conditions are met.	R/W
7:1	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

CMPSTB flag (Compare Window B Flag)

The CMPSTB flag indicates the comparison result of channels to which Window B comparison conditions are applied, the temperature sensor output, internal reference voltage. When the comparison condition set in ADCMPBNSR.CMPLB is met at the end of A/D conversion, this flag sets to 1. When the ADCMPCR.CMPBIE bit is 1, a compare interrupt request (ADC12i_CMPBI (i = 0, 1)) is generated when this flag sets to 1.

Writing 1 to the CMPSTB flag is invalid.

[Setting condition]

- The condition set in ADCMPBNSR.CMPLB is met when ADCMPCR.CMPBE = 1.

[Clearing condition]

- Writing 0 after reading 1.

39.2.37 ADWINMON : A/D Compare Function Window A/B Status Monitor Register

Base address: ADC12m = 0x4033_2000 + 0x0200 × m (m = 0, 1)
ADC12m_NS = 0x5033_2000 + 0x0200 × m (m = 0, 1)

Offset address: 0x08C

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	MONCMPB	MONCMPA	—	—	—	MONCOMB
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	MONCOMB	Combination Result Monitor This bit indicates the combination result. This bit is valid when both Window A and Window B operations are enabled. 0: Window A/B composite conditions are not met. 1: Window A/B composite conditions are met.	R
3:1	—	These bits are read as 0.	R
4	MONCMPA	Comparison Result Monitor A 0: Window A comparison conditions are not met. 1: Window A comparison conditions are met.	R
5	MONCMPB	Comparison Result Monitor B 0: Window B comparison conditions are not met. 1: Window B comparison conditions are met.	R
7:6	—	These bits are read as 0.	R

Note: S-TYPE-3, P-TYPE-3

MONCOMB bit (Combination Result Monitor)

The read-only MONCOMB bit indicates the combined result of comparison condition results A and B based on the combination condition set in the ADCMPCR.CMPAB[1:0] bits.

[Setting condition]

- The combined result meets the combination condition set in the ADCMPCR.CMPAB[1:0] bits when ADCMPCR.CMPAE = 1 and ADCMPCR.CMPBE = 1.

[Clearing conditions]

- The combined result does not meet the combination condition set in the ADCMPCR.CMPAB[1:0] bits.
- ADCMPCR.CMPAE = 0 or ADCMPCR.CMPBE = 0.

MONCMPA bit (Comparison Result Monitor A)

The read-only MONCMPA bit is read as 1 when the A/D-converted value of the Window A target channel meets the condition set in ADCMPLR0/ADCMPLR1 and ADCMPLER. Otherwise, it is read as 0.

[Setting condition]

- The A/D-converted value meets the condition set in the ADCMPLR0/ADCMPLR1 and ADCMPLER registers when ADCMPCR.CMPAE = 1.

[Clearing conditions]

- The A/D-converted value does not meet the condition set in the ADCMPLR0/ADCMPLR1 and ADCMPLER registers when ADCMPCR.CMPAE = 1.
- ADCMPCR.CMPAE = 0 (automatically cleared when the ADCMPCR.CMPAE value changes from 1 to 0).

MONCMPB bit (Comparison Result Monitor B)

The read-only MONCMPB bit is read as 1 when the A/D-converted value of the Window B target channel meets the condition set in the ADCMPBNSR.CMPLB bit. Otherwise, it is read as 0.

[Setting condition]

- The A/D-converted value meets the condition set in ADCMPBNSR.CMPLB when ADCMPCR.CMPBE = 1.

[Clearing conditions]

- The A/D-converted value does not meet the condition set in ADCMPBNSR.CMPLB when ADCMPCR.CMPBE = 1.
- ADCMPCR.CMPBE = 0 (automatically cleared when the ADCMPCR.CMPBE value changes from 1 to 0).

39.2.38 ADBUFEN : A/D Data Buffer Enable Register

Base address: ADC12m = 0x4033_2000 + 0x0200 × m (m = 0, 1)
ADC12m_NS = 0x5033_2000 + 0x0200 × m (m = 0, 1)

Offset address: 0x0D0

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	BUFEN
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	BUFEN	Data Buffer Enable 0: The data buffer is not used. 1: The data buffer is used.	R/W
7:1	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

The ADBUFEN register sets whether to enable the data buffer.

BUFEN bit (Data Buffer Enable)

This bit enables the use of the data buffer.

When BUFEN = 1b, A/D conversion result (addition result) other than self-diagnosis result is stored in ADBUFn.

Disable the data storage operation (BUFEN = 0b) before reading ADBUFPTR.

Do not use the data buffer for data duplexing, or group scan.

39.2.39 ADBUFPTR : A/D Data Buffer Pointer Register

Base address: ADC12m = 0x4033_2000 + 0x0200 × m (m = 0, 1)
ADC12m_NS = 0x5033_2000 + 0x0200 × m (m = 0, 1)

Offset address: 0x0D2

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	PTROVF	BUFPTR[3:0]			
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
3:0	BUFPTR[3:0]	Data Buffer Pointer These bits indicate the number of data buffer to which the next A/D converted data is transferred.	R/W
4	PTROVF	Pointer Overflow Flag 0: The data buffer pointer has not overflowed. 1: The data buffer pointer has overflowed.	R/W
7:5	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

ADBUFPTR is a register that indicates the data buffer pointer and overflow status.

BUFPTR[3:0] bit (Data Buffer Pointer)

These bits indicate the number of data buffer to which the next A/D converted data is transferred.

When data has been transferred to data buffer 15, the pointer value becomes 0000b and the PTROVF bit is set to 1.

When the next data has been transferred, the data in data buffer 0 is overwritten.

Writing 0x00 to this register clears the value of these bits. Writing a value other than 0x00 is disabled.

PTROVF bit (Pointer Overflow Flag)

This bit indicates whether the data buffer pointer has overflowed. This bit is set to 1 when the pointer value becomes 0000b (overflow).

Writing 0x00 to this register clears this bit value. Writing a value other than 0x00 is disabled.

39.2.40 ADBUFn : A/D Data Buffer Registers n (n = 0 to 15)

Base address: ADC12m = 0x4033_2000 + 0x0200 × m (m = 0, 1)
ADC12m_NS = 0x5033_2000 + 0x0200 × m (m = 0, 1)

Offset address: 0x0B0 + 0x2 × n (n = 0 to 15)

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	ADBUF[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	ADBUF[15:0]	Converted Value 15 to 0 Functions vary depending on the selected mode and accuracy. See Table 39.22 and Table 39.23.	R

Note: S-TYPE-3, P-TYPE-3

ADBUFn registers are 16-bit read-only registers that sequentially store all A/D conversion results. The automatic clear function is not applied to these registers.

ADBUFn settings are the same as the A/D data register format settings.

The following conditions determine the formats for data in the ADBUFn registers:

- Setting of the Register Format Select bit (ADCER.ADRFMT) (flush-left or flush-right)
- Setting of the Addition/Average Count Select bits (ADADC.ADC[2:0]) (1, 2, 3, 4, or 16 times)
- Setting of the Average Mode Enable bit (ADADC.AVEE) (addition or average).

This section describes the data formats for these conditions in different modes.

(1) When A/D-converted value addition/average mode is not selected

Table 39.22 shows the bit assignment for each accuracy.

Table 39.22 Bit assignment for each accuracy

Accuracy	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Right-justified data with 12-bit accuracy	These bits are read as 0.				Converted Value 11 to 0: 12-bit A/D-converted value											
Left-justified data with 12-bit accuracy	Converted Value 11 to 0: 12-bit A/D-converted value												These bits are read as 0.			

(2) When A/D-converted value average mode is selected

A/D-converted value average mode can be selected when 2 or 4 times is specified in the A/D-converted value addition mode. When A/D converted value average mode is selected, This register indicatesThese registers indicate the mean of A/D-converted values on a specific channel. The value is stored in the A/D data register based on the setting of the A/D Data Register Format Select bit in the same way as for normal A/D conversion.

(3) When A/D-converted value addition mode is selected

For 12-bit, 10-bit, 8-bit accuracy, 1, 2, 3, or 4 times can be selected in the A/D-converted value addition mode. A/D conversion results are stored in the A/D data register as a 2-bit-extended value of the specified conversion accuracy.

For 12-bit accuracy, 16 times can also be selected in the A/D-converted value addition mode. In A/D-converted value addition mode, this register indicatesthese registers indicate the value that is obtained by adding A/D-converted values on a specific channel. A/D conversion results are stored in the A/D data register as a 4-bit-extended value of the specified conversion accuracy.

When A/D-converted value addition mode is selected, the value is stored in the A/D data register based on the settings of the A/D Data Register Format Select bits.

Table 39.23 shows the bit assignment for each accuracy.

Table 39.23 Bit assignment for each accuracy when A/D-converted value addition mode is selected

Accuracy		b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Right-justified data with 12-bit accuracy	When 16 conversion times is specified	Added Value 15 to 0: 16-bit sum of A/D conversion results															
	When 1, 2, 3, or 4 conversion times is specified	These bits are read as 0.	Added Value 13 to 0: 14-bit sum of A/D conversion results														
Left-justified data with 12-bit accuracy	When 1, 2, 3, or 4 conversion times is specified	Added Value 15 to 0: 16-bit sum of A/D conversion results															
	When 16 conversion times is specified	Added Value 13 to 0: 14-bit sum of A/D conversion results														These bits are read as 0.	

39.3 Operation

39.3.1 Scanning Operation

In scanning, A/D conversion is performed sequentially on the analog inputs of the specified channels.

Scan conversion is performed in any of the three operating modes:

- Single scan mode
- Continuous scan mode
- Group scan mode

In single scan mode, one or more specified channels are scanned once. In continuous scan mode, one or more specified channels are scanned repeatedly until software sets the ADCSR.ADST bit to 0. In group scan mode, the selected channels in group A, B are scanned once after scan starts in response to the respective synchronous trigger.

In single scan mode and continuous scan mode, A/D conversion is performed for the ANn channels selected in the ADANSA0 and ADANSA1 registers, starting from the channel with the smallest number n. In group scan mode, A/D conversion is performed for the ANn channels in group A selected in the ADANSA0 and ADANSA1 registers, and for the ANn channels in group B selected in the ADANSB0 and ADANSB1 registers, starting from the channel with the smallest number n.

When self-diagnosis is selected, it is executed once at the beginning of each scan and one of the three reference voltages is converted.

The temperature sensor output and internal reference voltage can be selected at the same time as the analog input of the channels, and A/D conversion is performed on the analog input of channels, temperature sensor output, and internal reference voltage, in that order.

Double trigger mode can be used with single scan mode or group scan mode. With double trigger mode enabled (ADCSR.DBLE = 1), A/D conversion data of a channel selected in the ADCSR.DBLANS[4:0] bits is duplicated only if the conversion is started by the synchronous trigger (GPT, ELC) selected in the ADSTRGR.TRSA[5:0] bits. In group scan mode, only group A can use double trigger mode.

In the extended operation of double trigger mode, the A/D conversion operation is generated from the synchronous trigger combination selected in the ADSTRGR.TRSA[5:0] bits. In addition to normal double trigger mode operation, A/D conversion data with odd number trigger (ELC_AD00 (unit 0), ELC_AD10 (unit 1), GTCIADAn (Unit0) and GTCIADAm (Unit1) (n = 0 to 3, m = 4 to 7)) is stored in A/D Data Duplexing Register A (ADDBLDRA), and A/D conversion data with even number trigger (ELC_AD01 (unit 0), ELC_AD11 (unit1), GTCIADBn (Unit0) and GTCIADBm (Unit1) (n = 0 to 3, m = 4 to 7)) is stored in A/D Data Duplexing Register B (ADDBLDRB). In the extended operation of double trigger mode, when one of the trigger combinations occurs at the same time, the data duplexing register settings for the specified triggers do not work, and A/D conversion data is stored in A/D Data Duplexing Register B (ADDBLDRB).

The ADC12 ignores a synchronous trigger that occurs during the A/D conversion started by another synchronous trigger.

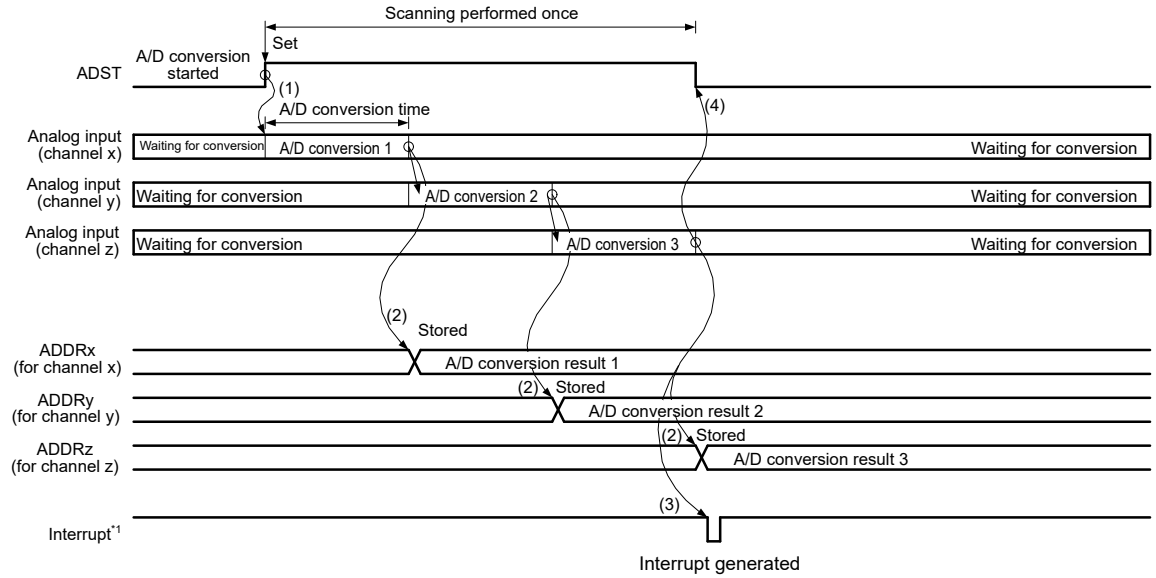
When any of the channels AN000 to AN002 (unit 0) are set as a channel-dedicated sample-and-hold circuit in the SHANS[2:0] bits in ADSHCR, the target analog input specified is sampled and held before the first A/D conversion of each scan.

39.3.2 Single Scan Mode

39.3.2.1 Basic Operation (Without Channel-Dedicated Sample-and-Hold Circuits)

In basic operation of single scan mode, A/D conversion is performed once on the analog input of the specified channels as follows:

1. When the ADCSR.ADST bit is set to 1 (A/D conversion start) by a software trigger, a synchronous trigger input (GPT, ELC), or an asynchronous trigger input, A/D conversion is performed for the ANn channels selected in the ADANSA0 and ADANSA1 registers, starting from the channel with the smallest number n.
2. Each time A/D conversion of a single channel is completed, the A/D conversion result is stored in the associated A/D data register (ADDRy).
3. When A/D conversion of all the selected channels is completed, an ADC12i_ADI (i = 0, 1) interrupt request is generated.
4. The ADST bit remains 1 (A/D conversion start) during A/D conversion and is automatically set to 0 when A/D conversion of all the selected channels is completed. The ADC12 then enters a wait state.



Note: x, y, and z (x < y < z) are the selected channel numbers by ADANSA0/1.
Note 1. ADC12i_ADI (i = 0, 1)

Figure 39.8 Example basic operation in single scan mode when the analog inputs (channel x to z) are selected

39.3.2.2 Basic Operation (With Channel-Dedicated Sample-and-Hold Circuits and Continuous Sampling Disabled)

When the channel-dedicated sample-and-hold circuit is used, sample-and-hold operation is first performed, and then A/D conversion is performed on the analog input of all the specified channels once. The channels whose dedicated sample-and-hold circuit is to be used can be selected in the SHANS[2:0] bits in ADSHCR.

The operation is as follows:

1. Analog input sampling of all channels whose dedicated sample-and-hold circuit is to be used starts when the ADCSR.ADST bit is set to 1 (A/D conversion start) by a software trigger, synchronous trigger input (GPT, ELC), or asynchronous trigger input.
2. After the sample-and-hold operation, A/D conversion is performed on the ANn channels selected in the ADANSA0 and ADANSA1 registers, starting from the channel with the smallest number n.
3. Each time A/D conversion of a single channel completes, the A/D conversion result is stored in the associated A/D data register (ADDRy).
4. When A/D conversion of all the selected channels completes, an ADC12i_ADI (i = 0) interrupt request is generated (no register setting).
5. The ADST bit remains 1 (A/D conversion start) during A/D conversion, and is automatically cleared to 0 when A/D conversion of all the selected channels completes. Then, the ADC12 enters a wait state.

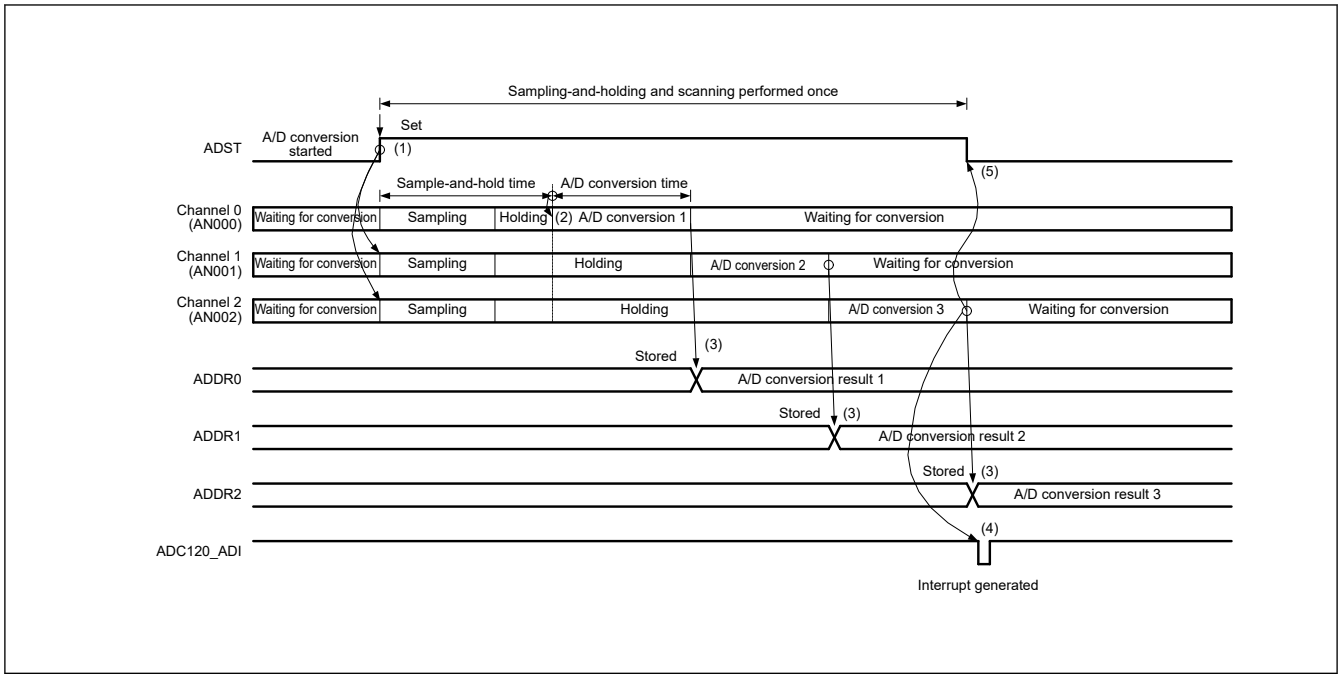


Figure 39.9 Example operation in single scan mode when the channel-dedicated sample-and-hold circuits are used and AN000 to AN002 are selected

39.3.2.3 Basic Operation (With Channel-Dedicated Sample-and-Hold Circuits and Continuous Sampling Enabled)

When a channel-dedicated sample-and-hold circuit is used while continuous sampling is enabled, sample-and-hold operations are performed first, followed by A/D conversion on the analog inputs on all selected channels, once. The ADSHCR.SHANS[2:0] bits specify the channels for which the channel-dedicated sample-and-hold circuits are to be used.

The operation is as follows:

1. When the ADSHMSR.SHMD bit is set to 1, the sample-and-hold circuits selected in the ADSHCR.SHANS[2:0] bits start continuous sampling.
2. Analog input holding starts for all the channels for which the channel-dedicated sample-and-hold circuits are to be used when the ADCSR.ADST bit is set to 1 (A/D conversion start) by a software trigger, input of a synchronous trigger signal (GPT, ELC), or input of an asynchronous trigger.
3. After the stabilization time of the sample-and-hold circuits elapses, A/D conversion is performed on the ANn channels selected in the ADANSA0 and ADANSA1 registers, starting from the channel with the smallest number n.
4. Each time A/D conversion of a single channel completes, the A/D conversion result is stored in the associated A/D data register (ADDRy), and the sample-and-hold circuit restarts continuous sampling.
5. When A/D conversion of all the selected channels completes, an ADC12i_ADI (i = 0) interrupt request is generated (no register setting).
6. The ADCSR.ADST bit remains 1 (A/D conversion start) during A/D conversion, and is automatically cleared to 0 when A/D conversion of all the selected channels completes. Then, the ADC12 enters a wait state. If this is followed by single scanning, set the continuous sampling time for the sample-and-hold circuits to at least 400 ns (when the permissible signal source impedance is 1 kΩ).
7. When the ADSHMSR.SHMD bit is set to 0, the sample-and-hold circuits stop.

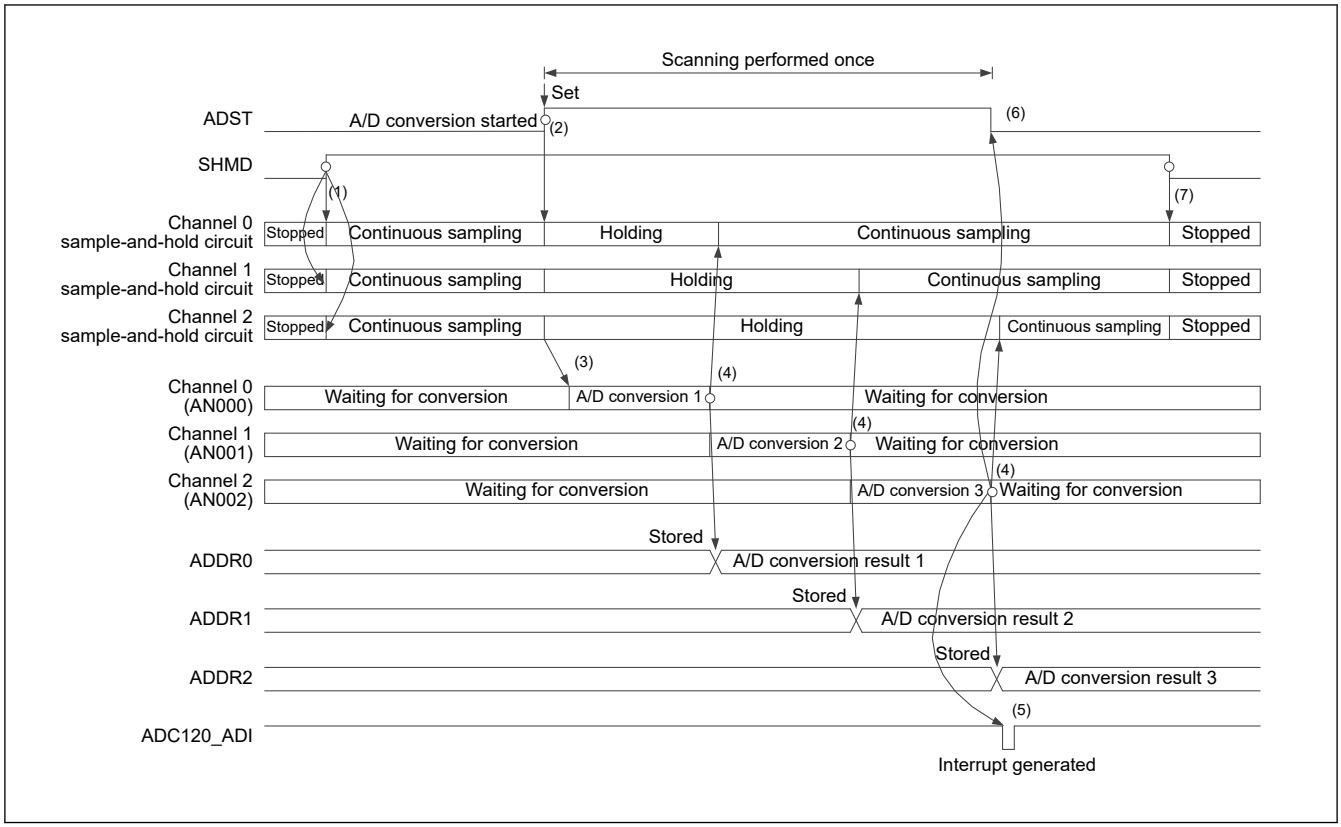

Figure 39.10 Example operation in single scan mode when channel-dedicated sample-and-hold circuits are used, AN000 to AN002 are selected, and continuous sampling is enabled

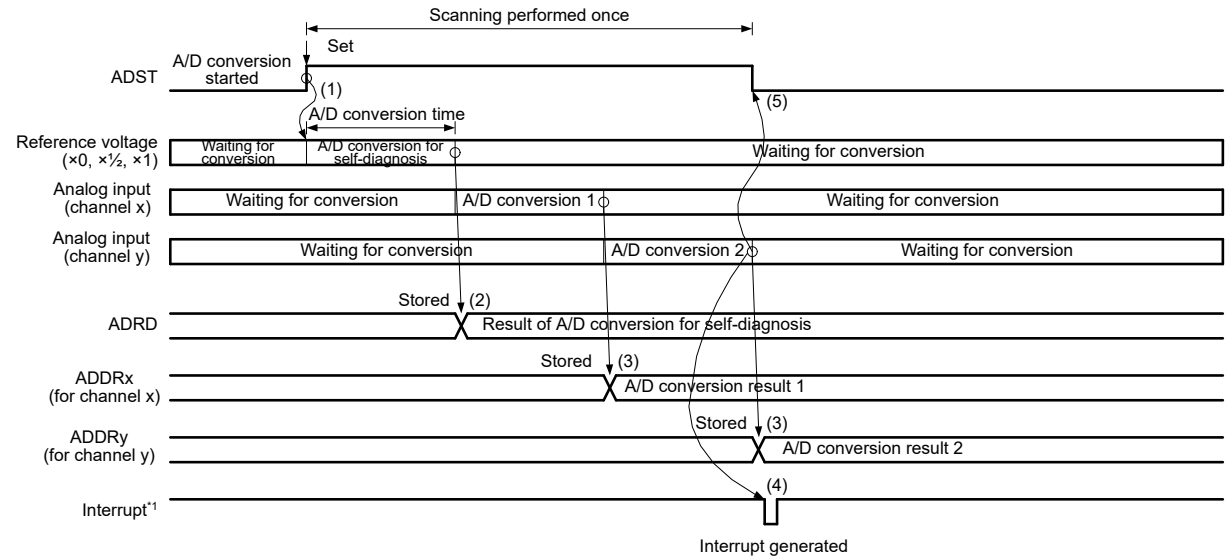
39.3.2.4 Channel Selection and Self-Diagnosis (Without Channel-Dedicated Sample-and-Hold Circuits)

When channels and self-diagnosis are selected, A/D conversion is first performed for the reference voltage VREFH0, VREFH (×0, ×1/2, or ×1), then A/D conversion is performed once on the analog input of the selected channels as follows:

1. A/D conversion for self-diagnosis is first started when the ADCSR.ADST bit is set to 1 (A/D conversion start) by a software trigger input, a synchronous trigger input (GPT, ELC), or an asynchronous trigger input.
2. When A/D conversion for self-diagnosis is completed, the A/D conversion result is stored in the A/D Self-Diagnosis Data Register (ADRD). A/D conversion is then performed for the ANn channels selected in the ADANSA0 and ADANSA1 registers, starting from the channel with the smallest number n.
3. Each time A/D conversion of a single channel is completed, the A/D conversion result is stored in the associated A/D data register (ADDRy).
4. When A/D conversion of all the selected channels is completed, an ADC12i_ADI (i = 0, 1) interrupt request is generated.
5. The ADCSR.ADST bit remains 1 (A/D conversion start) during A/D conversion and is automatically set to 0 when A/D conversion of all the selected channels is completed. The ADC12 then enters a wait state.



Note: x and y (x < y) are the selected channel numbers by ADANSA0/1.
Note 1. ADC12i_ADI (i = 0, 1)

Figure 39.11 Example basic operation in single scan mode when the analog inputs (channel x and y) are selected with self-diagnosis

39.3.2.5 Channel Selection and Self-Diagnosis (With Channel-Dedicated Sample-and-Hold Circuits and Continuous Sampling Disabled)

When channels and self-diagnosis are selected and a channel-dedicated sample-and-hold circuit is used while continuous sampling is disabled, the sample-and-hold operation is performed first, and then A/D conversion is performed once for the reference voltage VREFH0 (unit 0) (×0, ×1/2, or ×1) supplied to the ADC12. After that, A/D conversion is performed only once on the analog input of the selected channels.

The operation is as follows:

1. Analog input sampling starts for all channels whose dedicated sample-and-hold circuit is to be used when the ADCSR.ADST bit is set to 1 (A/D conversion start) by a software trigger, synchronous trigger input (GPT, ELC), or asynchronous trigger input.
2. After the sample-and-hold operation, A/D conversion for self-diagnosis starts.
3. When A/D conversion for self-diagnosis completes, the A/D conversion result is stored in the A/D Self-Diagnosis Data Register (ADRD). A/D conversion is then performed for the ANn channels selected in the ADANSA0 and ADANSA1 registers, starting from the channel with the smallest number n.
4. Each time A/D conversion of a single channel completes, the A/D conversion result is stored in the associated A/D Data Register y (ADDRy).
5. When A/D conversion of all the selected channels completes, an ADC12i_ADI (i = 0) interrupt request is generated (no register setting).
6. The ADST bit remains 1 (A/D conversion start) during A/D conversion, and is automatically cleared to 0 when A/D conversion of all the selected channels completes. Then, the ADC12 enters a wait state.

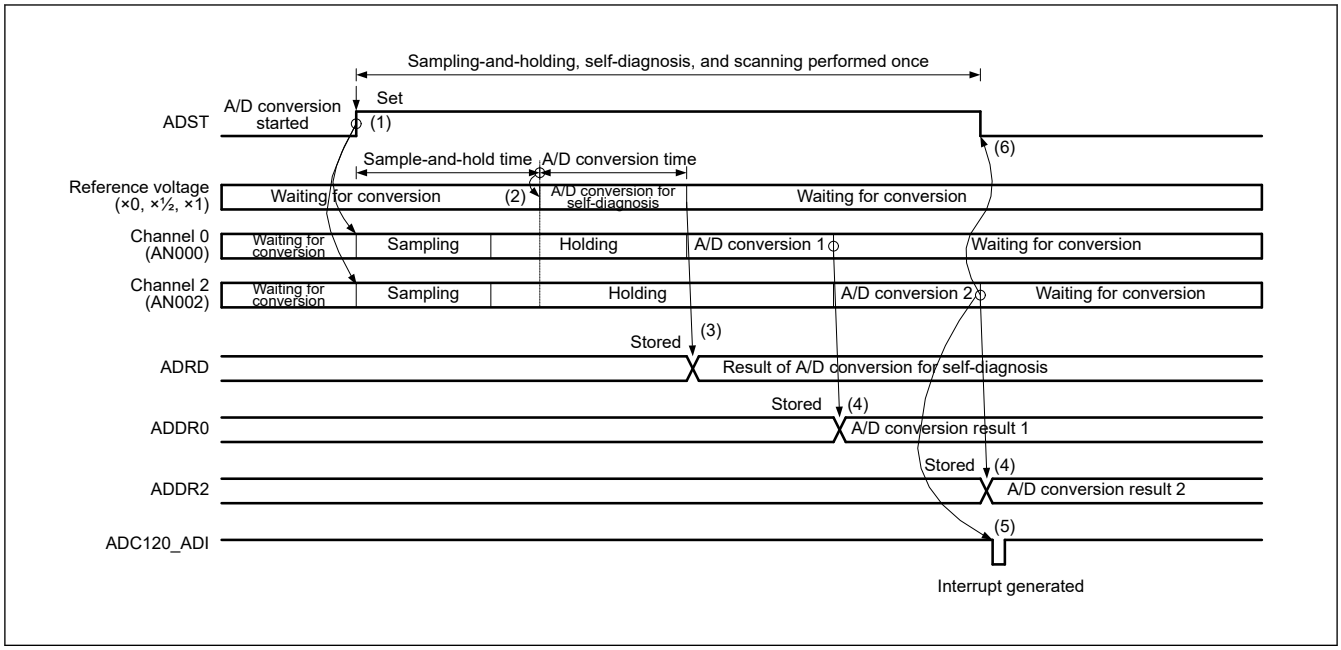


Figure 39.12 Example operation in single scan mode when channel-dedicated sample-and-hold circuits are used, AN000 and AN002 are selected with self-diagnosis, and continuous sampling is disabled

39.3.2.6 Channel Selection and Self-Diagnosis (With Channel-Dedicated Sample-and-Hold Circuits and Continuous Sampling Enabled)

When channels and self-diagnosis are selected and a channel-dedicated sample-and-hold circuit is used while continuous sampling is enabled, sample-and-hold operations are performed first, followed by A/D conversion of the reference voltage VREFH0 (unit 0) supplied to the ADC12. After that, A/D conversion is performed only once on the analog input of the selected channels.

The operation is as follows:

1. When the ADSHMSR.SHMD bit is set to 1, the sample-and-hold circuits selected in the ADSHCR.SHANS[2:0] bits start continuous sampling.
2. Analog input holding starts for all the channels for which the channel-dedicated sample-and-hold circuits are to be used when the ADCSR.ADST bit is set to 1 (A/D conversion start) by a software trigger, input of a synchronous trigger signal (GPT, ELC), or input of an asynchronous trigger. Set the ADCSR.ADST bit to 1 after at least 400 ns (when the permissible signal source impedance is 1 kΩ) elapse after the ADSHMSR.SHMD bit is set to 1.
3. After the stabilization time of the sample-and-hold circuits elapse, A/D conversion for self-diagnosis starts.
4. When A/D conversion for self-diagnosis completes, the A/D conversion result is stored in the A/D Self-Diagnosis Data Register (ADRD). A/D conversion is then performed for the ANn channels selected in the ADANSA0 and ADANSA1 registers, starting from the channel with the smallest number n.
5. Each time A/D conversion of a single channel completes, the A/D conversion result is stored in the associated A/D Data Register y (ADDRy), and the sample-and-hold circuit restarts continuous sampling.
6. When A/D conversion of all the selected channels completes, an ADC12i_ADI (i = 0) interrupt request is generated (no register setting).
7. The ADCSR.ADST bit remains 1 (A/D conversion start) during A/D conversion, and is automatically cleared to 0 when A/D conversion of all the selected channels completes. Then, the ADC12 enters a wait state. If this is followed by single scanning, set the continuous sampling time for the sample-and-hold circuits to at least 400 ns (when the permissible signal source impedance is 1 kΩ).
8. When the ADSHMSR.SHMD bit is set to 0, the sample-and-hold circuits stop.

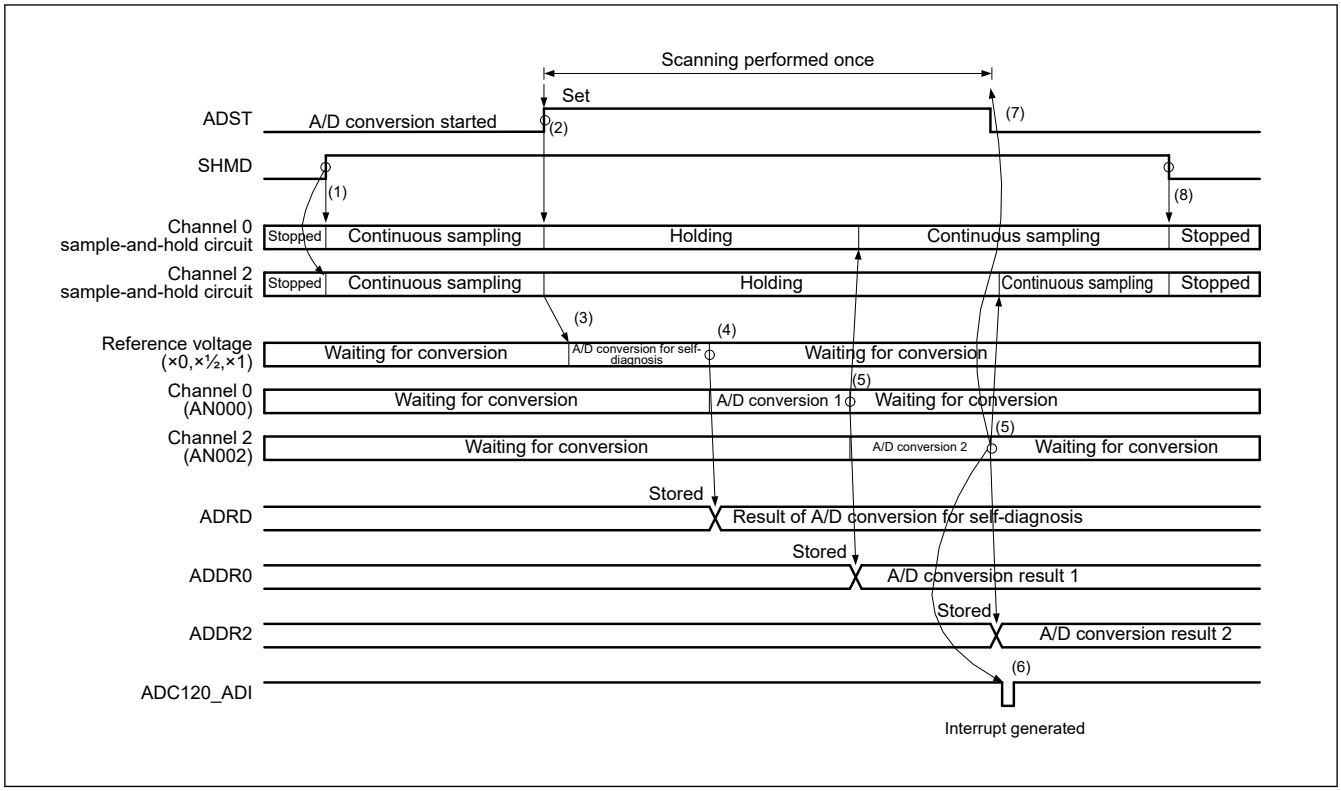

Figure 39.13 Example operation in single scan mode when channel-dedicated sample-and-hold circuits are used, AN000 to AN002 are selected with self-diagnosis, and continuous sampling is enabled

39.3.2.7 A/D Conversion of Temperature Sensor Output or Internal Reference Voltage

When the channels and temperature sensor output or internal reference voltage are selected at the same time, A/D conversion is performed first on the analog input of the selected channels, and once on the temperature sensor output or internal reference voltage. When both temperature sensor output and internal reference voltage are selected, A/D conversion of the temperature sensor output and internal reference voltage is performed, in that order. With the channels deselected, selecting only the temperature sensor output or internal reference voltage is also possible.

The operation is as follows:

1. When a software trigger, synchronous trigger (GPT, ELC), or asynchronous trigger sets the ADCSR.ADST bit to 1 (A/D conversion start), A/D conversion is performed for the ANn channels selected in the ADANSA0 and ADANSA1 registers, starting from the channel with the smallest number n.
2. On completion of A/D conversion on the channels, the result is stored in the associated A/D Data Register y (ADDRy), and then A/D conversion of the temperature sensor output starts.
3. On completion of A/D conversion of the temperature sensor output, the result is stored in the associated A/D Temperature Sensor Data Register (ADTSDR), and then A/D conversion of the internal reference voltage starts.
4. On completion of A/D conversion of the internal reference voltage, the result is stored in the associated A/D Internal Reference Voltage Data Register (ADOCDR), and an ADC12i_ADI (i = 0, 1) interrupt request is generated (no register setting).
5. The ADCSR.ADST bit remains 1 (A/D conversion start) during A/D conversion, and is automatically cleared to 0 on completion of A/D conversion. Then, the ADC12 enters a wait state.

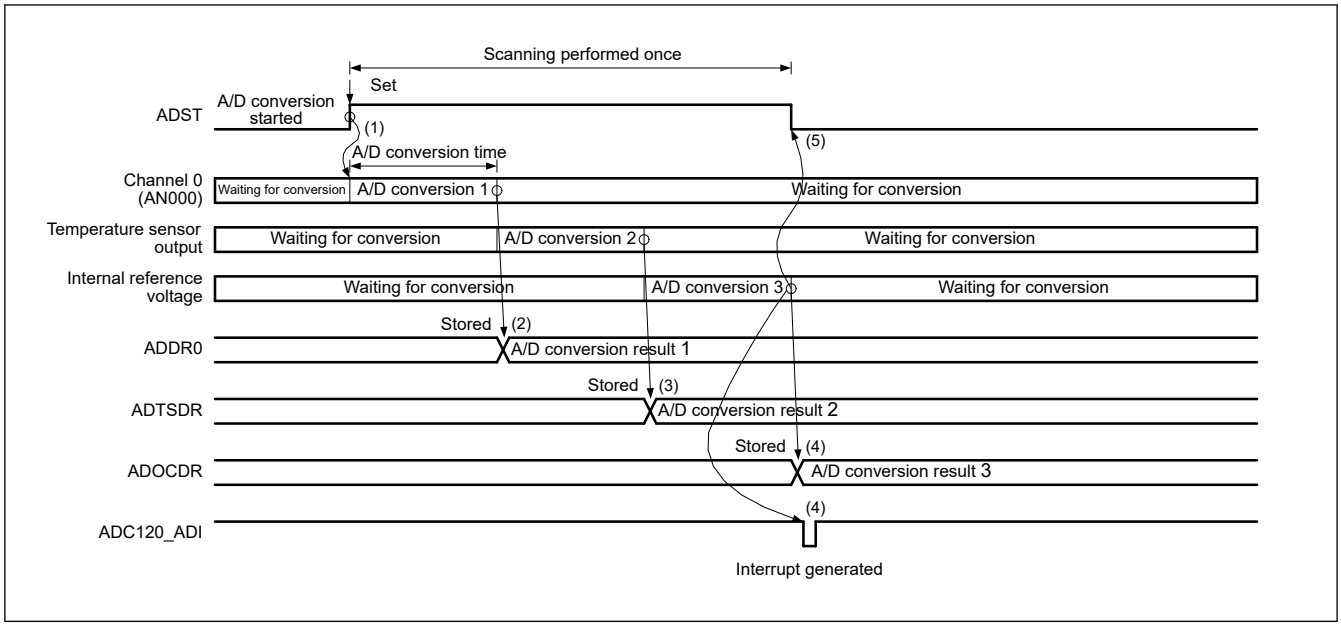

Figure 39.14 Example basic operation in single scan mode when AN000 and temperature sensor output or internal reference voltage are selected

39.3.2.8 A/D Conversion in Double-Trigger Mode

When double trigger mode is selected in single scan mode, two rounds of single scan operation started by a synchronous trigger (GPT, ELC) are performed in sequence.

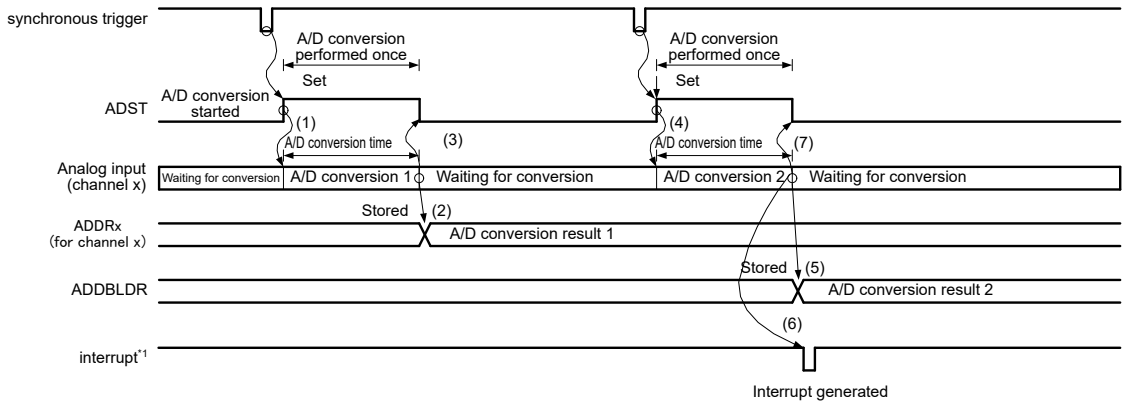
Deselect self-diagnosis and set the temperature sensor output A/D conversion select bit (ADEXICR.TSSA and ADEXICR.TSSB) and the internal reference voltage A/D conversion select bit (ADEXICR.OCSA and ADEXICR.OCSB) to 0.

Duplication of A/D conversion data is enabled by setting the channel numbers to be duplicated in the ADCSR.DBLANS[4:0] bits and setting the ADCSR.DBLE bit to 1. When the ADCSR.DBLE bit is set to 1, channel selection using the ADANSA0 and ADANSA1 registers is invalid.

In double trigger mode, select a synchronous trigger (GPT, ELC) with the ADSTRGR.TRSA[5:0] bits. Additionally, set the ADCSR.EXTRG bit to 0 and the ADCSR.TRGE bit to 1. Do not use a software trigger.

The operation is as follows:

1. When the ADCSR.ADST bit is set to 1 (A/D conversion start) by a synchronous trigger input (GPT, ELC), A/D conversion starts on the single channel selected in the ADCSR.DBLANS[4:0] bits.
2. Each time A/D conversion of a single channel is completed, the A/D conversion result is stored in the associated A/D Data Register y (ADDRy).
3. The ADCSR.ADST bit is automatically set to 0 and the ADC12 enters a wait state. An ADC12i_ADI (i = 0, 1) interrupt request is not generated.
4. When the ADCSR.ADST bit is set to 1 (A/D conversion start) by the second trigger input, A/D conversion starts on the single channel selected in the ADCSR.DBLANS[4:0] bits.
5. When A/D conversion is completed, the result is stored in the A/D Data Duplexing Register (ADDBLDR), which is exclusively used in double-trigger mode.
6. An ADC12i_ADI (i = 0, 1) interrupt request is generated.
7. The ADCSR.ADST bit remains 1 (A/D conversion start) during A/D conversion and is automatically set to 0 when A/D conversion is completed. Then the ADC12 enters a wait state.



Note: x is the selected channel number by ADCSR.DBLANS[4:0].
Note 1. ADC12i_ADI (i = 0, 1)

Figure 39.15 Example operation in single scan mode when double-trigger mode is selected and the analog input (channel x) is duplicated

39.3.2.9 Extended Operations when Double-Trigger Mode is Selected

When double trigger mode is selected in single scan mode, and a synchronous trigger (ELC_AD00 (unit 0) and ELC_AD10 (unit 1)/ELC_AD01 (unit 0) and ELC_AD11 (unit 1), GTCIADA0 (unit 0) and GTCIADA4 (unit 1) / GTCIADB0 (Unit0) and GTCIADB4 (unit 1), GTCIADA1 (unit 0) and GTCIADA5 (unit 1) / GTCIADB1 (Unit0) and GTCIADB5 (unit 1), GTCIADA2 (unit 0) and GTCIADA6 (unit 1) / GTCIADB2 (Unit0) and GTCIADB6 (unit 1) or GTCIADA3 (unit 0) and GTCIADA7 (unit 1) / GTCIADB3 (Unit0) and GTCIADB7 (unit 1)) is selected as the trigger for the start of A/D conversion, two rounds of single scan operation are performed.

Deselect self-diagnosis and set the temperature sensor output A/D conversion select bit (ADEXICR.TSSA and ADEXICR.TSSB), and the internal reference voltage A/D conversion select bit (ADEXICR.OCSA and ADEXICR.OCSB) to 0.

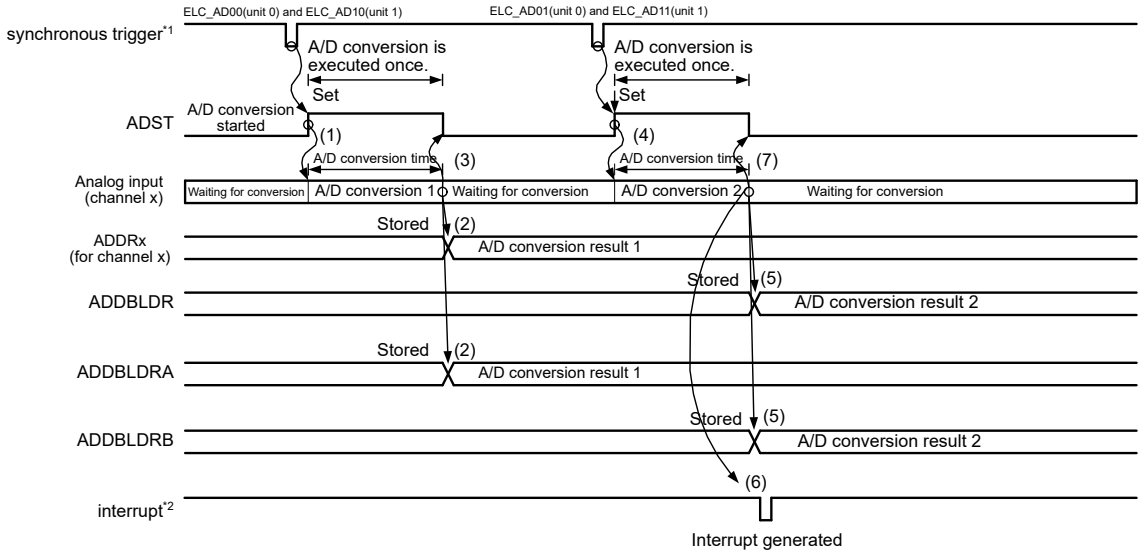
Duplication of A/D conversion data is enabled by setting the channel number to be duplicated to the ADCSR.DBLANS[4:0] bits and setting the ADCSR.DBLE bit to 1. When the ADCSR.DBLE bit is set to 1, channel selection using the ADANSA0 and ADANSA1 registers is invalid.

In extended double trigger mode, select a synchronous trigger combination by setting the ADSTRGR.TRSA[5:0] bits to 0x0B, set the ADCSR.EXTRG bit to 0, and set the ADCSR.TRGE bit to 1. Do not use a software trigger.

The operation is as follows:

1. When the ADCSR.ADST bit is set to 1 (A/D conversion start) by a synchronous trigger input, A/D conversion starts on the single channel selected in the ADCSR.DBLANS[4:0] bits.
2. When A/D conversion completes, the A/D conversion result is stored in the associated A/D Data Register (ADDRy) and in A/D Data Duplexing Register A (ADDBLDRA) or A/D Data Duplexing Register B (ADDBLDRB) when the ELC_ADi0 or ELC_ADi1 trigger is input respectively (i = 0, 1).
3. The ADCSR.ADST bit is automatically set to 0 and the ADC12 enters a wait state. An ADC12i_ADI (i = 0, 1) interrupt request is not generated.
4. When the ADCSR.ADST bit is set to 1 (A/D conversion start) by the second trigger (ELC_AD00 (unit 0) and ELC_AD10 (unit 1)/ELC_AD01 (unit 0) and ELC_AD11 (unit 1)), A/ D conversion starts on the single channel selected in the ADCSR.DBLANS[4:0] bits.
5. When A/D conversion completes, the A/D conversion result is stored in the A/D Data Duplexing Register (ADDBLDR) and in A/D Data Duplexing Register A (ADDBLDRA) or A/D Data Duplexing Register B (ADDBLDRB) when the ELC_ADi0 or ELC_ADi1 trigger is input respectively (i = 0, 1).
6. An ADC12i_ADI (i = 0, 1) interrupt request is generated.

7. The ADCSR.ADST bit remains 1 (A/D conversion start) during A/D conversion and is automatically set to 0 when A/D conversion completes. The ADC12 then enters a wait state.



Note: x is the selected channel number by ADANSA0/1.
Note 1. ELC_AD00 (unit 0) and ELC_AD10 (unit 1)/ELC_AD01 (unit 0) and ELC_AD11 (unit 1)
Note 2. ADC12i_ADI (i = 0, 1)

Figure 39.16 Example extended operation in double trigger mode with duplication selected for the analog input (channel x) and ELC_AD00 (unit 0) and ELC_AD10 (unit 1)/ELC_AD01 (unit 0) and ELC_AD11 (unit 1)

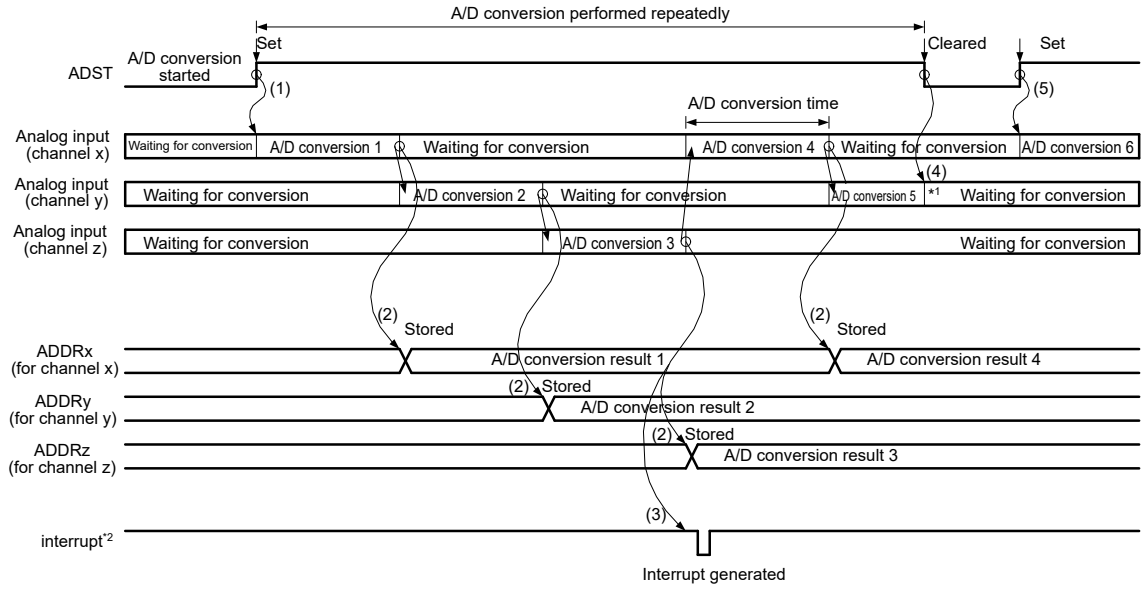
39.3.3 Continuous Scan Mode

39.3.3.1 Basic Operation (Without Channel-Dedicated Sample-and-Hold Circuits)

In continuous scan mode, A/D conversion is performed repeatedly on the analog input of the specified channels.

The operation is as follows:

1. When the ADCSR.ADST bit is set to 1 (A/D conversion start) by a software trigger, a synchronous trigger input (GPT, ELC), or an asynchronous trigger input, A/D conversion is performed for ANn channels selected in the ADANSA0 and ADANSA1 registers, starting from the channel with the smallest number n.
2. Each time A/D conversion of a single channel is completed, the A/D conversion result is stored in the associated A/D Data Register (ADDRy).
3. When A/D conversion of all the selected channels is completed, an ADC12i_ADI (i = 0, 1) interrupt request is generated. The ADC12 sequentially starts A/D conversion for the ANn channels selected in the ADANSA0 and ADANSA1 registers, starting from the channel with the smallest number n.
4. The ADCSR.ADST bit is not automatically cleared, and steps 2. and 3. are repeated as long as ADCSR.ADST remains 1 (A/ D conversion start). When the ADCSR.ADST bit is set to 0 (A/D conversion stop), A/D conversion stops and the ADC12 enters a wait state.
5. When the ADCSR.ADST bit is later set to 1 (A/D conversion start), A/D conversion starts again for the ANn channels selected in the ADANSA0 and ADANSA1 registers, starting from the channel with the smallest number n.



Note: x, y, and z (x < y < z) are the selected channel numbers by ADANSA0/1.
Note 1. Data for A/D conversion 5 is ignored.
Note 2. ADC12i_ADI (i = 0, 1)

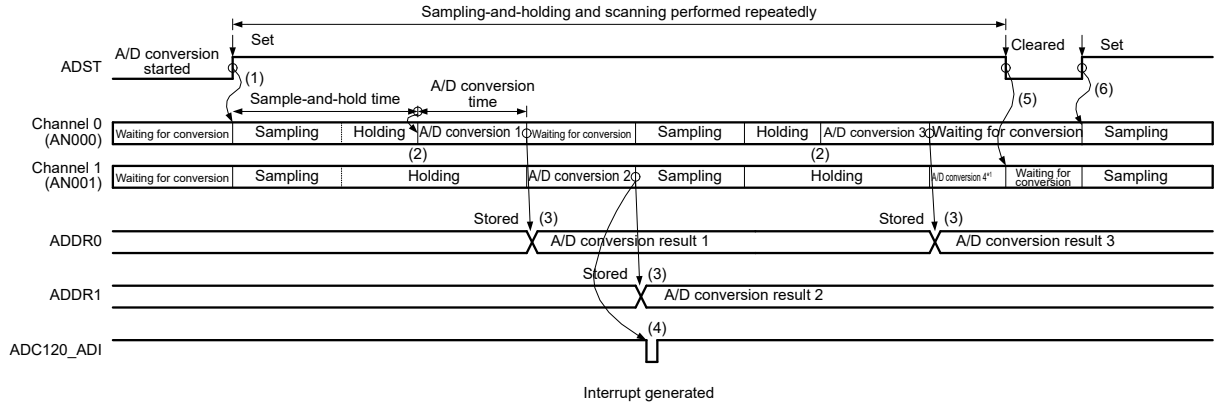
Figure 39.17 Example basic operation in continuous scan mode when the analog inputs (channel x to z) are selected

39.3.3.2 Basic Operation (With Channel-Dedicated Sample-and-Hold Circuits and Continuous Sampling Disabled)

When the channel-dedicated sample-and-hold circuit is used with the continuous sampling disabled, sample-and-hold operation is performed first, and then A/D conversion is repeated on the analog input of all the specified channels. The channels whose dedicated sample-and-hold circuit is to be used can be selected in the SHANS[2:0] bits in ADSHCR.

The operation is as follows:

1. Analog input sampling starts for all channels whose dedicated sample-and-hold circuit is to be used when the ADCSR.ADST bit is set to 1 (A/D conversion start) by a software trigger, synchronous trigger input (GPT, ELC), or asynchronous trigger input.
2. After the sample-and-hold operation, A/D conversion is performed for the ANn channels selected in the ADANSA0 and ADANSA1 registers, starting from the channel with the smallest number n.
3. Each time A/D conversion of a single channel completes, the A/D conversion result is stored in the associated A/D Data Register y (ADDRy).
4. When A/D conversion of all the selected channels completes, an ADC12i_ADI (i = 0) interrupt request is generated (no register setting). At the same time, analog input sampling starts for all channels whose dedicated sample-and-hold circuit is to be used.
5. The ADST bit is not automatically cleared, and steps 2 to 4 are repeated as long as the bit remains 1. When the ADST bit is set to 0 (A/D conversion stop), A/D conversion stops and the ADC12 enters a wait state.
6. When the ADST bit is then set to 1 (A/D conversion start), analog input sampling starts again for all the channels whose dedicated sample-and-hold circuit is to be used.



Note 1. Data for A/D conversion 4 is ignored.

Figure 39.18 Example operation in continuous scan mode when channel-dedicated sample-and-hold circuits are used and AN000 and AN001 are selected

39.3.3.3 Basic Operation (With Channel-Dedicated Sample-and-Hold Circuits and Continuous Sampling Enabled)

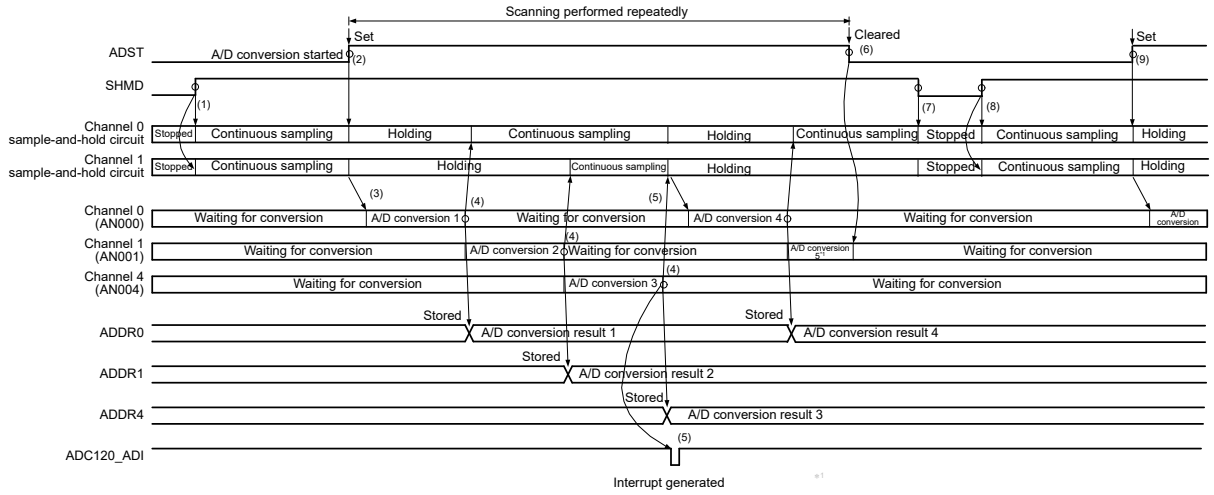
When a channel-dedicated sample-and-hold circuit is used while continuous sampling is enabled, sample-and-hold operations are performed first, after which the analog inputs on all the selected channels are A/D-converted as described in this section. The channels for which the channel-dedicated sample-and-hold circuits are to be used can be selected in the ADSHCR.SHANS[2:0] bits.

The operation is as follows:

1. When the ADSHMSR.SHMD bit is set to 1, the sample-and-hold circuits selected in the ADSHCR.SHANS[2:0] bits start continuous sampling.
2. Analog input holding starts for all channels for which the channel-dedicated sample-and-hold circuits are to be used when the ADCSR.ADST bit is set to 1 (A/D conversion start) by a software trigger, input of a synchronous trigger signal (GPT, ELC), or input of an asynchronous trigger. Set the ADCSR.ADST bit to 1 after at least 400 ns (when the permissible signal source impedance is 1 kΩ) elapse after the ADSHMSR.SHMD bit is set to 1.
3. After the stabilization time of the sample-and-hold circuits elapses, A/D conversion is performed for the ANn channels selected in the ADANSA0 and ADANSA1 registers, starting from the channel with the smallest number n.
4. Each time A/D conversion of a single channel completes, the A/D conversion result is stored in the associated A/D Data Register y (ADDRy), and the sample-and-hold circuit restarts continuous sampling.
5. When A/D conversion of all the selected channels completes, an ADC12i_ADI (i = 0) interrupt request is generated (no register setting). Also, analog input holding starts for all channels for which the channel-dedicated sample-and-hold circuits are to be used.
6. The ADCSR.ADST bit is not automatically cleared, and steps 3 to 5 are repeated as long as the bit remains 1. When the ADCSR.ADST bit is set to 0 (A/D conversion stop), A/D conversion stops and the ADC12 enters a wait state.
7. When the ADSHMSR.SHMD bit is set to 0, the sample-and-hold circuits stop.
8. When the ADSHMSR.SHMD bit is then set to 1, the sample-and-hold circuits selected in the ADSHCR.SHANS[2:0] bits start continuous sampling.
9. When the ADCSR.ADST bit is then set to 1 (A/D conversion start), analog input holding starts for all channels for which the channel-dedicated sample-and-hold circuits are to be used.

Note: If continuous scanning is performed when only those channels with the sample-and-hold circuits are selected, time for continuous sampling cannot be secured in the second and subsequent continuous scans. When continuous sampling by the channel-dedicated sample-and-hold circuits is enabled for continuous scanning, select one or more channels among AN004 to AN008 and AN016 to AN019, temperature sensor output and internal reference voltage for unit 0, and AN100 to AN102, AN104 to AN106 and AN116 to AN122, temperature sensor output and internal

reference voltage for unit 1, and set the continuous sampling time for the sample-and-hold circuits to at least 400 ns (when the permissible signal source impedance is 1 kΩ).



Note 1. Data for A/D conversion 5 is ignored.

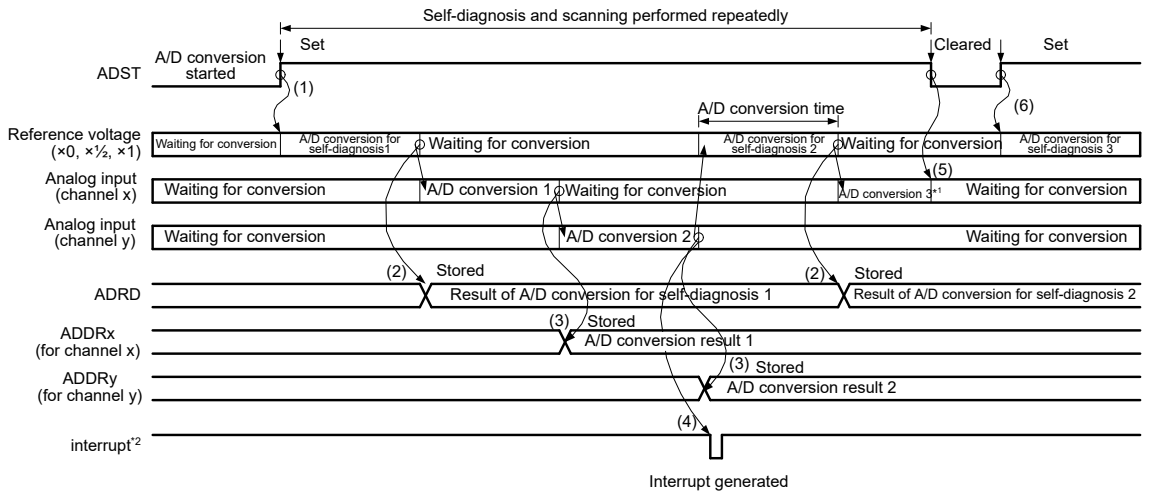
Figure 39.19 Example operation in continuous scan mode when channel-dedicated sample-and-hold circuits are used, AN000, AN001, and AN004 are selected, and continuous sampling is enabled

39.3.3.4 Channel Selection and Self-Diagnosis (Without Channel-Dedicated Sample-and-Hold Circuits)

When channels and self-diagnosis are selected at the same time, A/D conversion is first performed for the reference voltage VREFH0, VREFH (×0, ×1/2, or ×1) supplied to the ADC12, and A/D conversion is performed on the analog input of the selected channels. This sequence is repeated as described in the section that follows.

The operation is as follows:

1. A/D conversion for self-diagnosis is first started when the ADCSR.ADST bit is set to 1 (A/D conversion start) by a software trigger input, a synchronous trigger input (GPT, ELC), or an asynchronous trigger input.
2. When A/D conversion for self-diagnosis is completed, the A/D conversion result is stored in the A/D Self-Diagnosis Data Register (ADRD). A/D conversion is then performed for the ANn channels selected in the ADANSA0 and ADANSA1 registers, starting from the channel with the smallest number n.
3. Each time A/D conversion of a single channel is completed, the A/D conversion result is stored in the corresponding A/D Data Register (ADDRy).
4. When A/D conversion of all the selected channels is completed, an ADC12i_ADI (i = 0, 1) interrupt request is generated. At the same time, the ADC12 starts A/D conversion for self-diagnosis and then on the ANn channels selected in the ADANSA0 and ADANSA1 registers, starting from the channel with the smallest number n.
5. The ADCSR.ADST bit is not automatically cleared, and steps 2. to 4. are repeated as long as the ADCSR.ADST bit remains 1. When the ADST bit is set to 0 (A/D conversion stop), A/D conversion stops and the ADC12 enters a wait state.
6. When the ADST bit is later set to 1 (A/D conversion start), the A/D conversion for self-diagnosis is started again.



Note: x and y (x < y) are the selected channel numbers by ADANSA0/1.
Note 1. Data for A/D conversion 3 is ignored.
Note 2. ADC12i_ADI (i = 0, 1)

Figure 39.20 Example basic operation in continuous scan mode when the analog inputs (channel x and y) are selected with self-diagnosis

39.3.3.5 Channel Selection and Self-Diagnosis (With Channel-Dedicated Sample-and-Hold Circuits and Continuous Sampling Disabled)

When the channels and self-diagnosis are selected and a channel-dedicated sample-and-hold circuit is used while continuous sampling is disabled, sample-and- hold operation is performed first, and then A/D conversion is performed for the reference voltage VREFH0 (unit 0) (×0, ×1/2, or ×1) supplied to the ADC12, and then A/D conversion is performed on the analog input of the selected channels, and this sequence is repeated.

The operation is as follows:

1. Analog input sampling starts for all channels whose dedicated sample-and-hold circuit is to be used when the ADCSR.ADST bit is set to 1 (A/D conversion start) by a software trigger, synchronous trigger input (GPT, ELC), or asynchronous trigger input.
2. After the sample-and-hold operation, A/D conversion for self-diagnosis starts.
3. When A/D conversion for self-diagnosis completes, the A/D conversion result is stored in the A/D Self-Diagnosis Data Register (ADRD). A/D conversion is then performed for the ANn channels selected in the ADANSA0 and ADANSA1 registers, starting from the channel with the smallest number n.
4. Each time A/D conversion of a single channel completes, the A/D conversion result is stored in the associated A/D data register (ADDRy).
5. When A/D conversion of all the selected channels completes, an ADC12i_ADI (i = 0) interrupt request is generated (no register setting). At the same time, analog input sampling starts for all channels whose dedicated sample-and-hold circuit is to be used.
6. The ADST bit is not automatically cleared, and steps 2 to 5 are repeated as long as the bit remains 1. When the ADST bit is set to 0 (A/D conversion stop), A/D conversion stops and the ADC12 enters a wait state.
7. When the ADST bit is then set to 1 (A/D conversion start), analog input sampling starts again for all the channels whose dedicated sample-and-hold circuits are to be used.

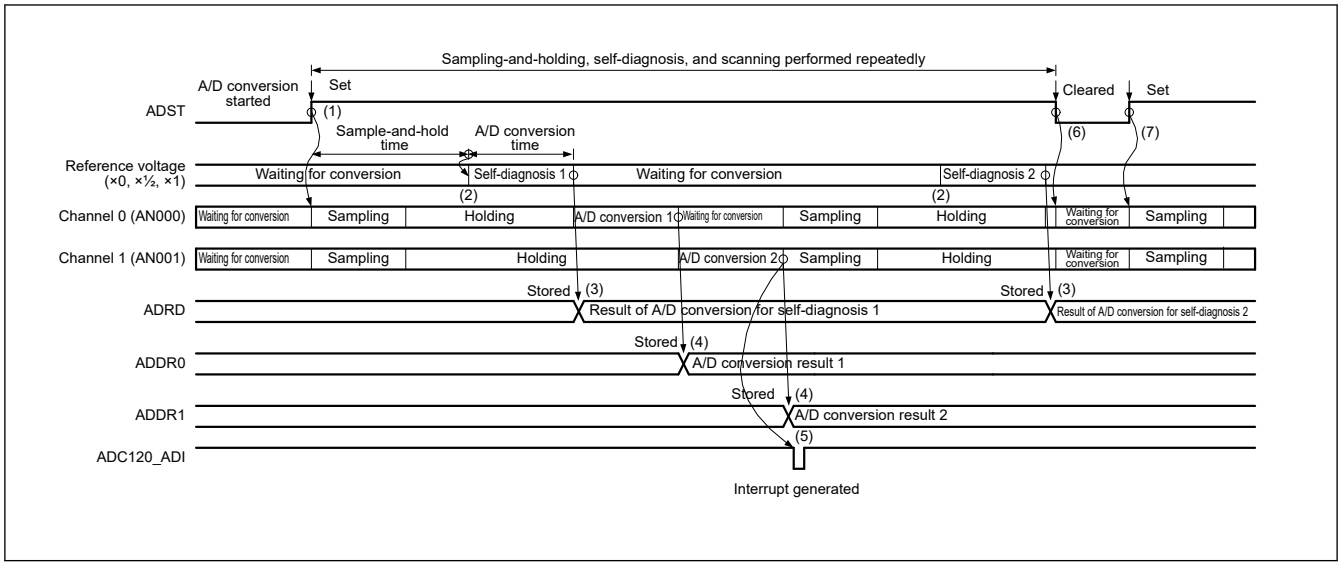


Figure 39.21 Example operation in continuous scan mode when channel-dedicated sample-and-hold circuits are used and AN000 and AN001 are selected with self-diagnosis

39.3.3.6 Channel Selection and Self-Diagnosis (With Channel-Dedicated Sample-and-Hold Circuits and Continuous Sampling Enabled)

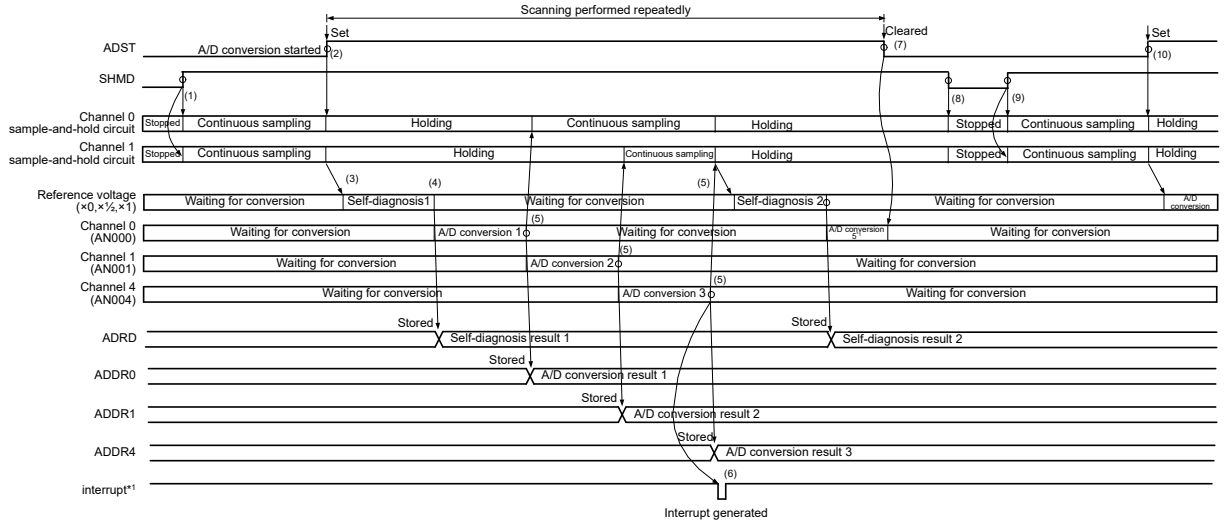
When channels and self-diagnosis are selected and a channel-dedicated sample-and-hold circuit is used while continuous sampling is enabled, the sample-and-hold operation is performed first, and followed by A/D conversion of the reference voltage VREFH0 (unit 0) (×0, ×1/2, or ×1) supplied to the ADC12. After that, A/D conversion is performed on the analog input of the selected channels, and this sequence is repeated.

The operation is as follows:

1. When the ADSHMSR.SHMD bit is set to 1, the sample-and-hold circuits selected in the ADSHCR.SHANS[2:0] bits start continuous sampling.
2. Analog input holding starts for all channels for which the channel-dedicated sample-and-hold circuits are to be used when the ADCSR.ADST bit is set to 1 (A/D conversion start) by a software trigger, input of a synchronous trigger signal (GPT, ELC), or input of an asynchronous trigger. Set the ADCSR.ADST bit to 1 after at least 400 ns (when the permissible signal source impedance is 1 kΩ) elapse after the ADSHMSR.SHMD bit is set to 1.
3. After the stabilization time of the sample-and-hold circuits elapses, A/D conversion for self-diagnosis starts.
4. When A/D conversion for self-diagnosis completes, the A/D conversion result is stored in the A/D Self-Diagnosis Data Register (ADRD). A/D conversion is then performed for the ANn channels selected in the ADANSA0 and ADANSA1 registers, starting from the channel with the smallest number n.
5. Each time A/D conversion of a single channel completes, the A/D conversion result is stored in the associated A/D Data Register y (ADDRy), and the sample-and-hold circuit restarts continuous sampling.
6. When A/D conversion of all the selected channels completes, an ADC12i_ADI (i = 0) interrupt request is generated (no register setting). Also, analog input holding starts for all channels for which the channel-dedicated sample-and-hold circuits are to be used.
7. The ADCSR.ADST bit is not automatically cleared, and steps 3 to 6 are repeated as long as the bit remains 1. When the ADCSR.ADST bit is set to 0 (A/D conversion stop), A/D conversion stops and the ADC12 enters a wait state.
8. When the ADSHMSR.SHMD bit is set to 0, the sample-and-hold circuits stop.
9. When the ADSHMSR.SHMD bit is then set to 1, the sample-and-hold circuits selected in the ADSHCR.SHANS[2:0] bits start continuous sampling.
10. When the ADCSR.ADST bit is then set to 1 (A/D conversion start), analog input holding starts for all channels for which the channel-dedicated sample-and-hold circuits are to be used.

Note: If continuous scanning is performed when only those channels with the sample-and-hold circuits are selected, time for continuous sampling cannot be secured in the second and subsequent continuous scans. When continuous sampling by the channel-dedicated sample-and-hold circuits is enabled for continuous scanning, select one or more

channels among AN004 to AN008 and AN016 to AN019, temperature sensor output and internal reference voltage for unit 0, and AN100 to AN102, AN104 to AN106 and AN116 to AN122, temperature sensor output and internal reference voltage for unit 1, and set the continuous sampling time for the sample-and-hold circuits to at least 400 ns (when the permissible signal source impedance is 1 kΩ).



Note: Data for A/D conversion 5 is ignored.
Note 1. ADC12i_ADI (i = 0)

Figure 39.22 Example operation in continuous scan mode when channel-dedicated sample-and-hold circuits are used, AN000, AN001, and AN004 are selected with self-diagnosis, and continuous sampling is enabled

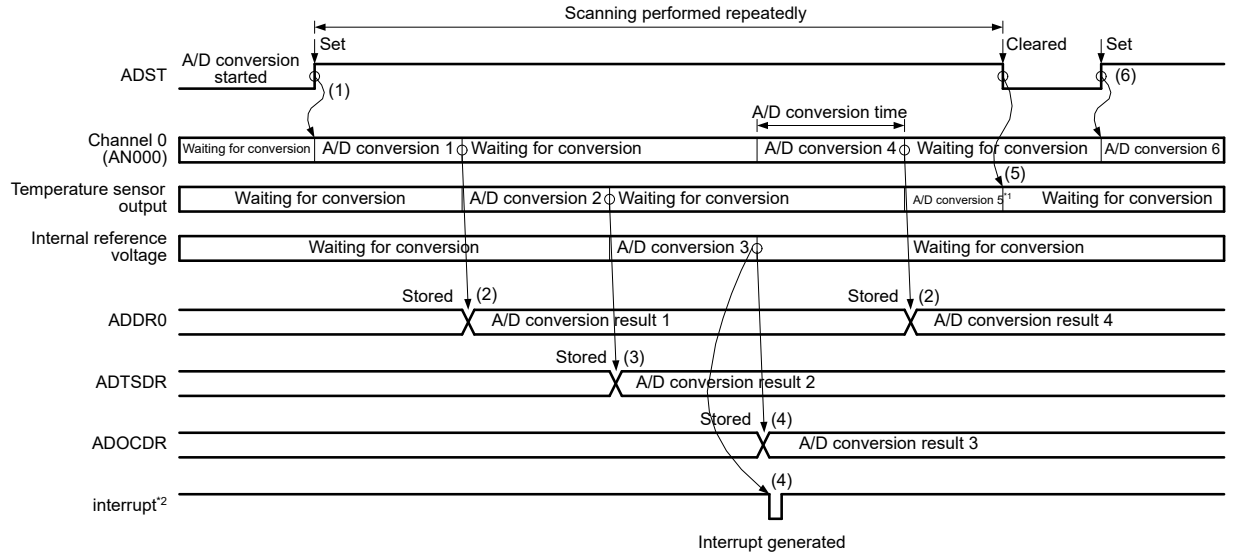
39.3.3.7 A/D Conversion of Temperature Sensor Output or Internal Reference Voltage

When the channels and temperature sensor output or internal reference voltage are selected at the same time, A/D conversion is first performed on the analog input of the selected channels, and then the A/D conversion of the temperature sensor output or internal reference voltage is repeated. When both the temperature sensor output and internal reference voltage are selected, A/D conversion of the temperature sensor output and internal reference voltage is performed, in that order.

With the channels deselected, selecting only the temperature sensor output or internal reference voltage is also possible.

The operation is as follows:

1. When a software trigger, synchronous trigger (GPT, ELC), or asynchronous trigger sets the ADCSR.ADST bit to 1 (A/D conversion start), A/D conversion is performed for the ANn channels selected in the ADANSA0 and ADANSA1 registers, starting from the channel with the smallest number n.
2. On completion of A/D conversion on the channels, the result is stored in the associated A/D Data Register y (ADDRy), and then A/D conversion of temperature sensor output starts.
3. On completion of A/D conversion of the temperature sensor output, the result is stored in the associated A/D Temperature Sensor Data Register (ADTSDR), and then A/D conversion of the internal reference voltage starts.
4. On completion of A/D conversion of the internal reference voltage, the result is stored in the associated A/D Internal Reference Voltage Data Register (ADOCDR), and an ADC12i_ADI (i = 0, 1) interrupt request is generated. In addition, the ADC12 continuously starts A/D conversion for the ANn channels selected in the ADANSA0 and ADANSA1 registers, starting from the channel with the lowest number n.
5. The ADCSR.ADST bit is not cleared automatically, and steps 2 to 4 are repeated as long as this bit remains set to 1. When the ADCSR.ADST bit is set to 0 (A/D conversion stop), A/D conversion stops and the ADC12 enters a wait state.
6. When the ADCSR.ADST bit is then set to 1 (A/D conversion start), A/D conversion starts again for the ANn channels selected in the ADANSA0 and ADANSA1 registers, starting from the channel with the lowest number n.



Note 1. Data for A/D conversion 5 is ignored.
Note 2. ADC12i_ADI (i = 0, 1)

Figure 39.23 Example basic operation in continuous scan mode when AN000 and temperature sensor output or internal reference voltage are selected

39.3.4 Group Scan Mode

39.3.4.1 Basic Operation

In group scan mode, A/D conversion is performed once on the analog input of all the specified channels in group A and B after scanning is started by a synchronous trigger (GPT, ELC). The scan operation of each group is similar to the scan operation in single scan mode.

The synchronous triggers can be selected in the ADSTRGR.TRSA[5:0] bits for group A and in the ADSTRGR.TRSB[5:0] bits for group B. Use different triggers for group A and B to prevent simultaneous A/D conversion of the two groups. Do not use a software trigger.

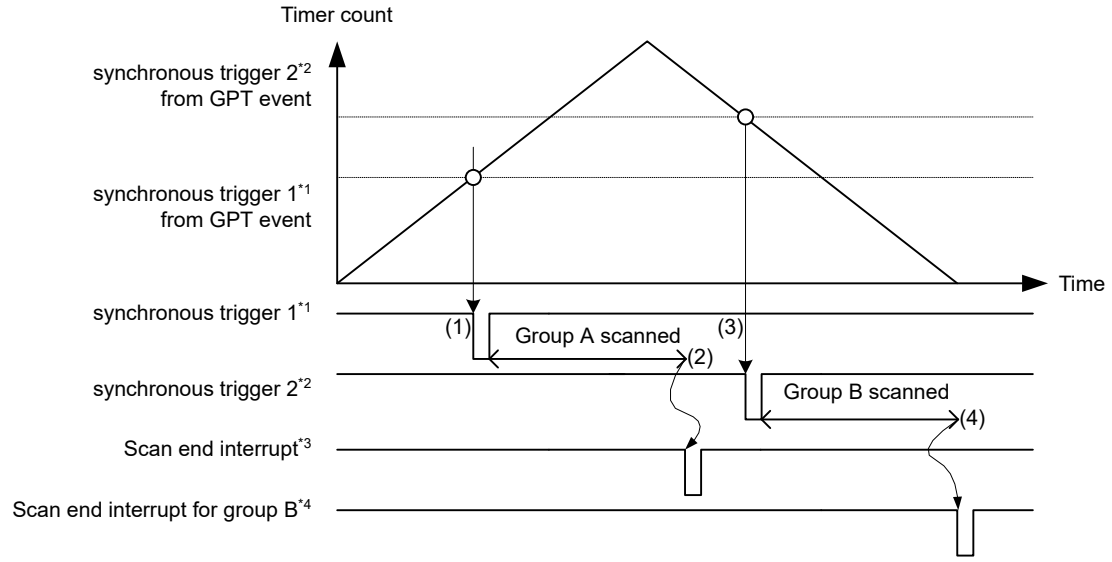
The group A channels to be A/D-converted are selected using the ADANSA0 and ADANSA1 registers and the ADEXICR.TSSA and OCSA bits. The group B channels to be A/D-converted are selected using the ADANSB0 and ADANSB1 registers and the ADEXICR.TSSB and OCSB bits. Group A and B cannot use the same channels.

When self-diagnosis is selected in group scan mode, self-diagnosis is separately executed for Group A and B.

The following sequence describes operation in group scan mode using a synchronous trigger from the ELC. In this example, the ELC_AD00 (unit 0) and ELC_AD10 (unit 1) trigger from the ELC is used to start conversion of group A and the ELC_AD01 (unit 0) and ELC_AD11 (unit 1) trigger from the ELC is used to start conversion of group B. In addition, ELC_AD00 (unit 0) and ELC_AD10 (unit 1) and ELC_AD01 (unit 0) and ELC_AD11 (unit 1) are selected for the GPT event in the associated ELC.ELSRn registers.

The operation is as follows:

1. Scanning of group A is started by ELC_AD00 (unit 0) and ELC_AD10 (unit 1).
2. When group A scanning completes, an ADC12i_ADI (i = 0, 1) interrupt is generated (no register setting).
3. Scanning of group B is started by ELC_AD01 (unit 0) and ELC_AD11 (unit 1).
4. When group B scanning completes, an ADC12i_GBADI (i = 0, 1) interrupt is generated if the ADCSR.GBADIE bit is 1 (ADC12i_GBADI (i = 0, 1) interrupt when scanning completion is enabled).



Note 1. ELC_AD00 (unit 0) and ELC_AD10 (unit 1)
Note 2. ELC_AD01 (unit 0) and ELC_AD11 (unit 1)
Note 3. ADC12i_ADI (i = 0, 1)
Note 4. ADC12i_GBADI (i = 0, 1)

Figure 39.24 Example basic operation in group scan mode when synchronous triggers from the ELC are used

39.3.4.2 A/D Conversion in Double-Trigger Mode

When double trigger mode is selected in group scan mode, two rounds of single scan operation started by a synchronous trigger (GPT, ELC) are performed as a sequence for group A. For group B, single scan operation started by a synchronous trigger (GPT, ELC) is performed once.

In group scan mode, the synchronous trigger can be selected in the ADSTRGR.TRSA[5:0] bits for group A and in the ADSTRGR.TRSB[5:0] bits for group B. Use different triggers for group A, B to prevent simultaneous A/D conversion of the two groups. Do not use a software trigger or an asynchronous trigger.

When an ELC_AD00 (unit 0) and ELC_AD10 (unit 1)/ELC_AD01 (unit 0) and ELC_AD11 (unit 1) is selected as group A synchronous triggers by setting the ADSTRGR.TRSA[5:0] bits to 0x0B, operation proceeds in extended double trigger mode.

The group A channel to be A/D-converted is selected using the DBLANS[4:0] bits in the ADCSR register, while the group B channels to be A/D-converted are selected using the ADANSB0 and ADANSB1 registers. Group A, B cannot use the same channels.

When double-trigger mode is selected in group scan mode, set the A/D conversion select bits for both the temperature sensor output (ADEXICR.TSSA) and the internal reference voltage (ADEXICR.OCSA) to 0 (deselected).

Self-diagnosis cannot be selected when double trigger mode is selected in group scan mode.

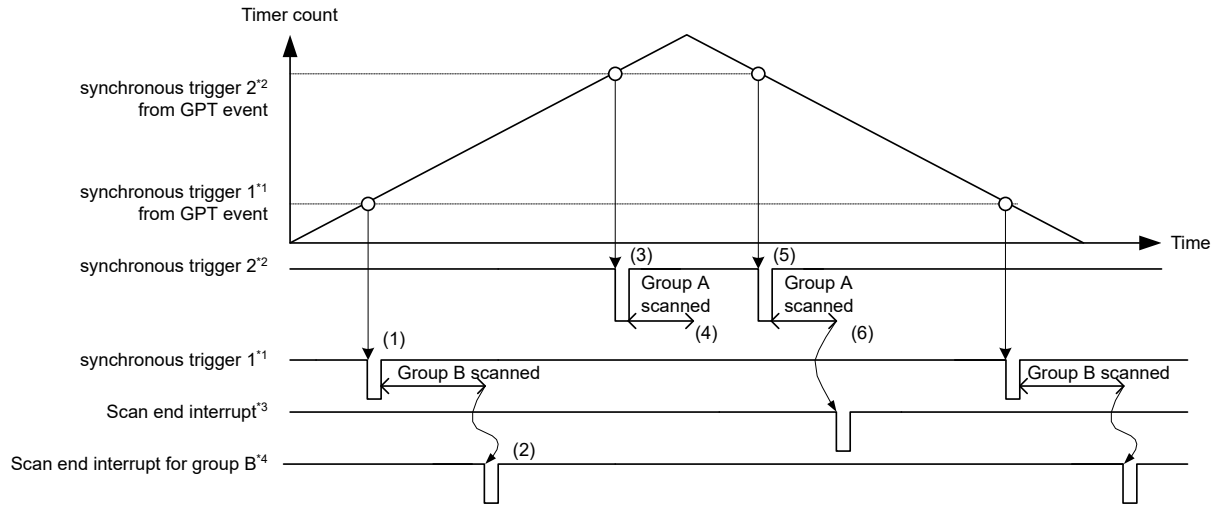
Duplication of A/D conversion data is enabled by setting the channel numbers to be duplicated in the ADCSR.DBLANS[4:0] bits and setting the ADCSR.DBLE bit to 1.

The following sequence describes operation in group scan mode with double trigger mode selected and using a synchronous trigger from the ELC. In this example, the ELC_AD00 (unit 0) and ELC_AD10 (unit 1) trigger is used to start conversion of group A and the ELC_AD01 (unit 0) and ELC_AD11 (unit 1) trigger is used to start conversion of group B. In addition, ELC_AD00 (unit 0) and ELC_AD10 (unit 1) and ELC_AD01 (unit 0) and ELC_AD11 (unit 1) are selected for the GPT event in the associated ELC.ELSRn registers.

The operation is as follows:

1. Scanning of group B is started by the ELC_AD00 (unit 0) and ELC_AD10 (unit 1) trigger from the ELC.

2. When group B scanning completes, an ADC12i_GBADI (i = 0, 1) interrupt is generated if the GBADIE bit in ADCSR is 1 (ADC12i_GBADI (i = 0, 1) interrupt when scanning completion is enabled).
3. The first scan of group A is started by the first ELC_AD01 (unit 0) and ELC_AD11 (unit 1) trigger.
4. When the first scan of group A completes, the conversion result is stored in the associated A/D Data Register y (ADDRy). An ADC12i_ADI (i = 0, 1) interrupt request is not generated.
5. The second scan of group A is started by the second ELC_AD01 (unit 0) and ELC_AD11 (unit 1) trigger.
6. When the second scan of group A completes, the conversion result is stored in ADDBLDR. An ADC12i_ADI (i = 0, 1) interrupt is generated.



Note 1. ELC_AD00 (unit 0) and ELC_AD10 (unit 1)
Note 2. ELC_AD01 (unit 0) and ELC_AD11 (unit 1)
Note 3. ADC12i_ADI (i = 0, 1)
Note 4. ADC12i_GBADI (i = 0, 1)

Figure 39.25 Example basic operation in group scan mode with double-trigger mode when synchronous triggers from the ELC are used

39.3.4.3 Group Priority Operation

Group priority operation is performed by setting the ADGSPCR.PGS bit to 1 in group-scan mode. The priority of groups is group A > group B.

When setting the PGS bit in the ADGSPCR register to 1, follow the procedure described in Figure 39.26. If the procedure is not followed, A/D conversion operation and stored data are not guaranteed.

As the basic operation in group-scan mode, a trigger input generated during A/D conversion of group A, B is ignored, and the A/D conversion operation of each group is similar to the operation in single-scan mode.

In group priority operation, if a trigger for a priority group is input during scanning of a lower-priority group, A/D conversion for the lower-priority group is stopped and A/D conversion for the priority group is performed.

If the setting of the ADGSPCR.GBRSCN bit is 0, the lower-priority group enters a wait state when A/D conversion for the priority group completes. A trigger input of the lower-priority group generated during A/D conversion is ignored.

If the setting of the ADGSPCR.GBRSCN bit is 1, A/D conversion for the lower-priority group automatically restarts upon completion of A/D conversion for the priority group. A trigger input of the lower-priority group generated during A/D conversion on the priority group takes effect, and A/D conversion for the lower-priority group is automatically performed upon completion of A/D conversion on the priority group.

If the ADGSPCR.GBRSCN bit is 1 and the ADGSPCR.LGRRS bit is 0, A/D conversion for the lower-priority group is restarted from the first channel. If the setting of the ADGSPCR.LGRRS bit is 1, A/D conversion for the lower-priority group is restarted from the channel for which the conversion stopped. However, if the self-diagnosis function is used, the A/D conversion is restarted from the channel for which the conversion stopped after self-diagnosis completed.

Table 39.24 summarizes operations in response to the input of a trigger during A/D conversion with the settings of the ADGSPCR.GBRSCN bit.

If the setting of the ADGSPCR.GBRP bit is 1, A/D conversion operation for the lowest-priority group is to continuously perform single scans.

For the trigger settings in group-scan mode, select a synchronous trigger for group A by using the ADSTRGR.TRSA[5:0] bits, a synchronous trigger for group B by using the ADSTRGR.TRSB[5:0] bits. Each trigger must be different from each other. Set the ADSTRGR.TRSB[5:0] bits to 0x3F when setting the ADGSPCR.GBRP bit to 1.

The channels to be scanned must be selected in the registers shown in section 39.3.4. Group Scan Mode.

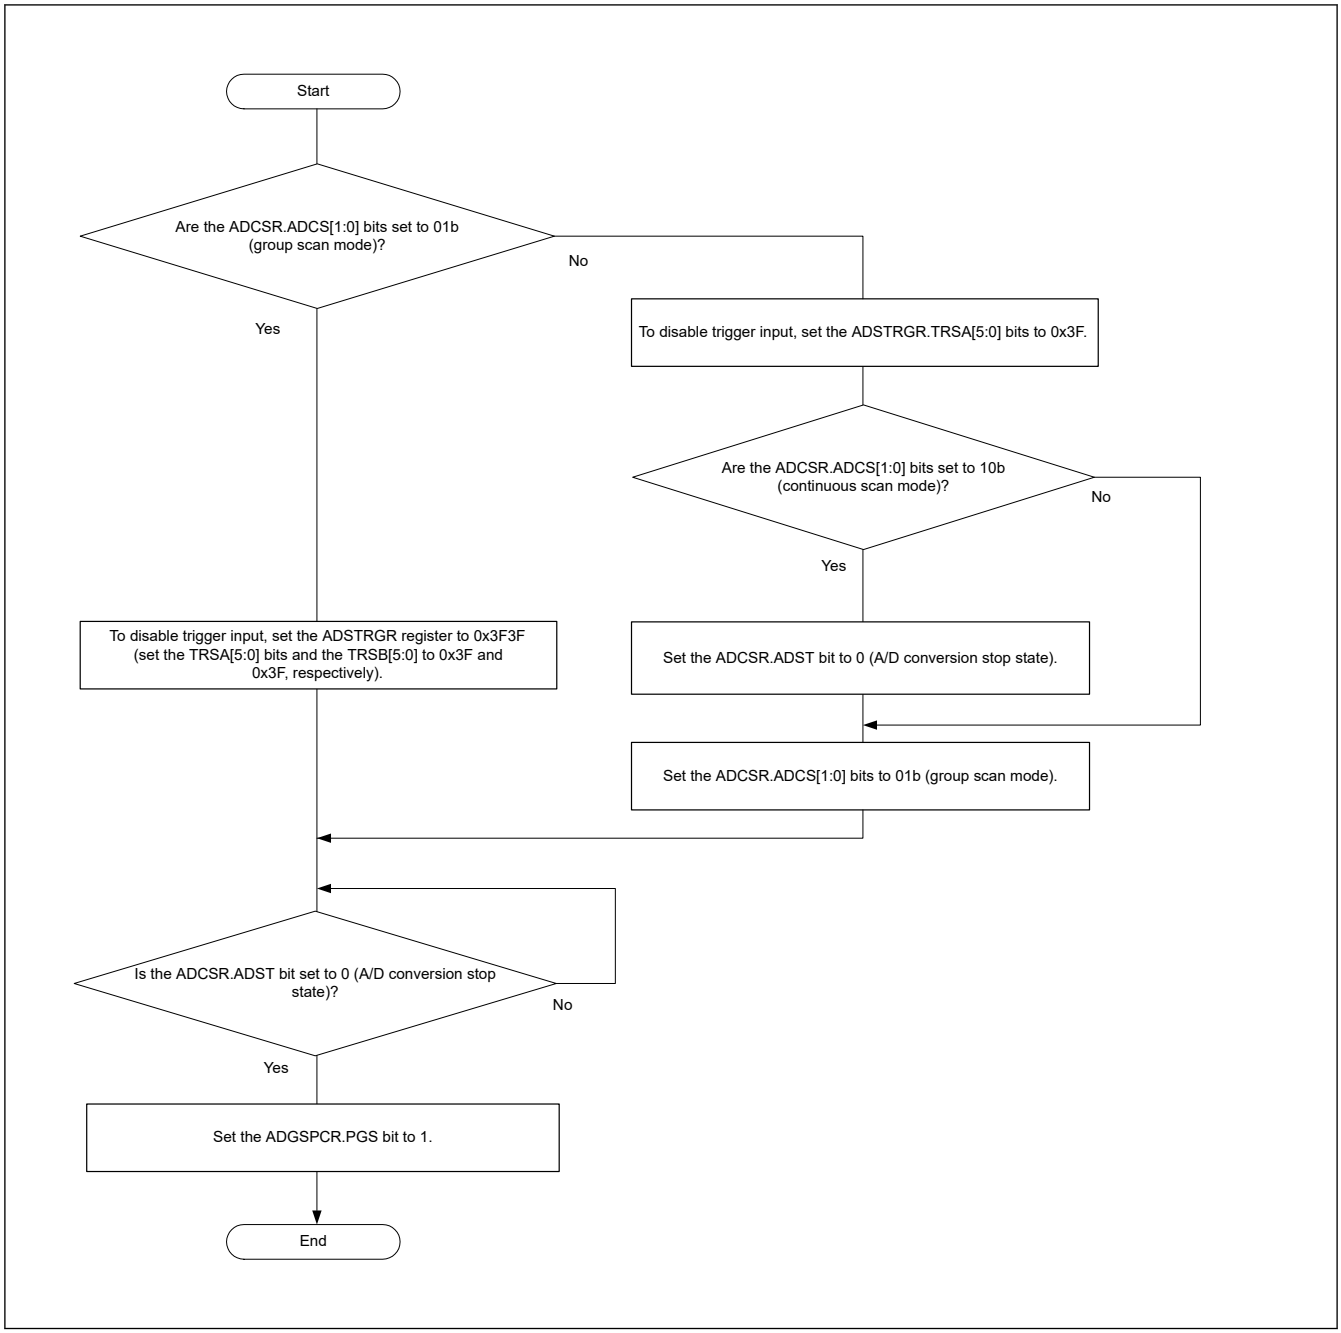


Figure 39.26 Flowchart for ADGSPCR.PGS bit setting

Table 39.24 Control of A/D conversion operations according to ADGSPCR.GBRSCN bit setting

A/D conversion operation	Trigger input	ADGSPCR.GBRSCN = 0	ADGSPCR.GBRSCN = 1
When A/D conversion for group A is in progress	Input of trigger for group A	Trigger input is ineffective.	Trigger input is ineffective.
	Input of trigger for group B	Trigger input is ineffective.	A/D conversion for group B is performed after A/D conversion for group A completes.
When A/D conversion for group B is in progress	Input of trigger for group A	A/D conversion for group B is discontinued and A/D conversion for group A starts.	• A/D conversion for group B is discontinued and A/D conversion for group A starts. • A/D conversion for group B starts after A/D conversion for group A completes.
	Input of trigger for group B	Trigger input is ineffective.	Trigger input is ineffective.

To use group priority operation mode, select the operation mode to be implemented and set the registers according to the following table.

Table 39.25 Group priority operation setting and operation mode for two groups (ADGSPCR.PGS = 1)

ADGSPCR			Operation category
GBRSCN	LGRRS	GBRP	
0	x	0	Group priority operation for two groups (groups A and B) • When a trigger of group A is input, A/D conversion for group B is terminated (and will not be restarted).
1	0	0	Group priority operation for two groups (groups A and B) • After A/D conversion for group B stopped, when A/D conversion for group A completes, A/D conversion for the group B channels selected in the ADANSB0 and ADANSB1 registers restarts according to the conversion order of smaller channel number.
1	1	0	Group priority operation for two groups (groups A and B) • After A/D conversion for group B stopped, when A/D conversion for group A completes, A/D conversion for the group B channels selected in the ADANSB0/1 register restarts according to the conversion order of smaller channel number, beginning from the channel for which A/D conversion stopped.*1
x	0	1	Group priority operation for two groups (groups A and B) • Single scanning for group B is continuously performed without a start trigger input. After A/D conversion for group B stopped, when A/D conversion for group A completes, single scanning for the channels selected in the ADANSB0/1 register restarts according to the conversion order of smaller channel number.
1	1	1	Group priority operation for two groups (groups A and B) • Single scanning for group B is continuously performed without a start trigger input. After A/D conversion for group B stopped, when A/D conversion for group A completes, single scanning for the channels selected in the ADANSB0/1 register restarts according to the conversion order of smaller channel number, beginning from the channel for which A/D conversion stopped.*1

Note: x: Don't care.
Note 1. When the self-diagnosis function is enabled (ADCER.DIAGM = 1), A/D conversion for the channel that has been stopped is started after self-diagnosis is performed.

(1) Group priority operation for two groups (when ADGSPCR.PGS = 1)

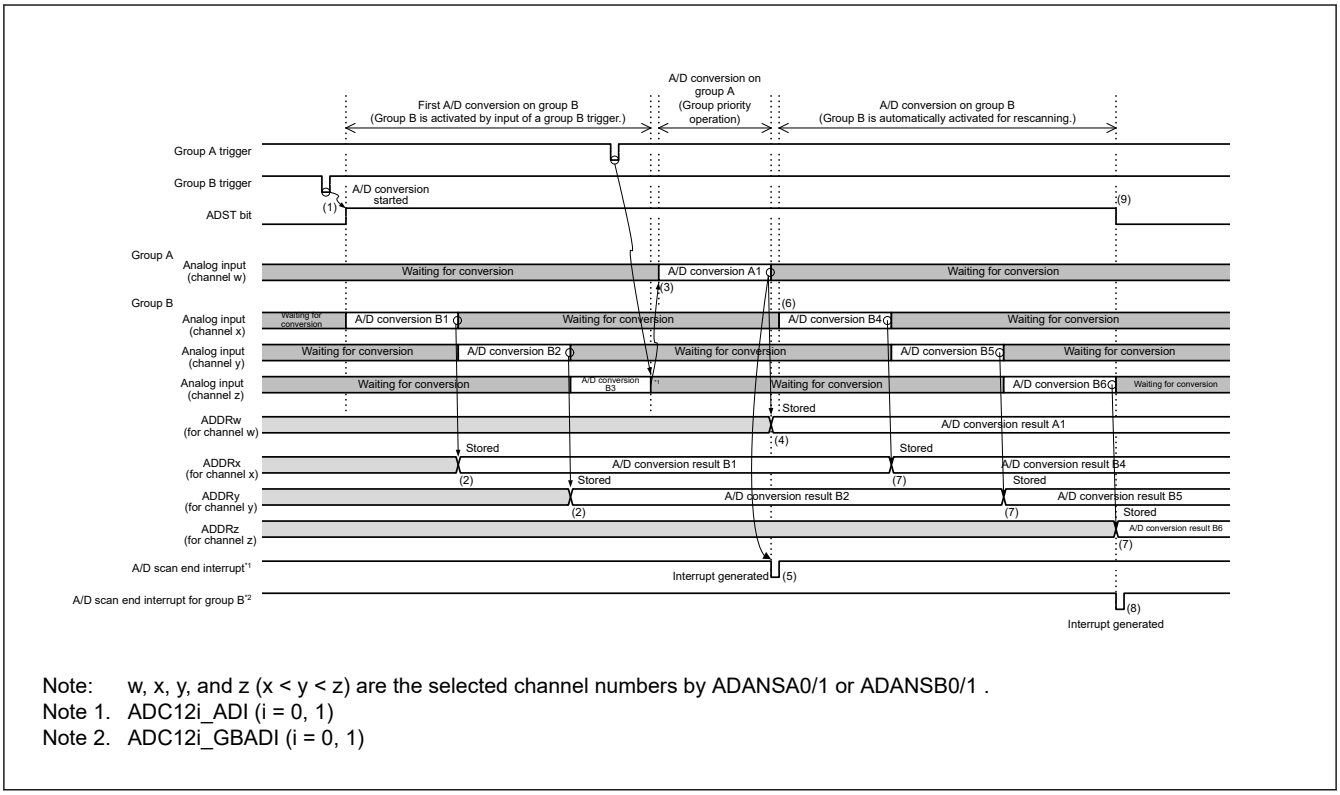
Operation examples 1-1 to 1-3 show group priority operations in group-scan mode (when ADGSPCR.GBRSCN = 1, ADGSPCR.GBRP = 0, and ADGSPCR.LGRRS = 0).

Operation example 1-1: "Group A trigger input during group B scan" when rescanning is enabled

1. When input of a trigger for group B sets the ADCSR.ADST bit to 1 (starting A/D conversion), A/D conversion for the analog input channels selected in the ADANSB0 and ADANSB1 registers starts according to the conversion order from the channel with the smallest number n.
2. On completion of A/D conversion for each channel in group B, the result is stored in the corresponding A/D Data Register y (ADDRy).
3. When a trigger for group A is input during A/D conversion for group B, A/D conversion for group B stops while the ADCSR.ADST bit remains 1. Then A/D conversion for the group A analog input channels selected in the ADANSA0

and ADANSA1 registers starts according to the conversion order from the channel with the smallest number n. If A/D conversion stops before it is completed, the conversion result is not stored in the A/D Data Register y (ADDRy).

4. On completion of A/D conversion on the channels, the result is stored in the corresponding A/D Data Register y (ADDRy).
5. An ADC120_ADI interrupt request is generated.
6. If the setting of the ADGSPCR.GBRSCN bit is 1 (enabling rescanning of the group that was stopped in group priority operation), A/D conversion for the group B analog input channels selected in the ADANSB0 and ADANSB1 registers restarts according to the conversion order from the channel with the smallest number n while the ADCSR.ADST remains 1.
7. On completion of A/D conversion on the channels, the result is stored in the corresponding A/D Data Register y (ADDRy).
8. If the setting of the ADCSR.GBADIE bit is 1 (enabling interrupt generation on completion of group B scan), a group B scan end interrupt request is generated.
9. When A/D conversion for all the channels completes, the ADCSR.ADST bit is automatically cleared and the A/D converter enters a wait state.



Note: w, x, y, and z (x < y < z) are the selected channel numbers by ADANSA0/1 or ADANSB0/1 .
Note 1. ADC12i_ADI (i = 0, 1)
Note 2. ADC12i_GBADI (i = 0, 1)

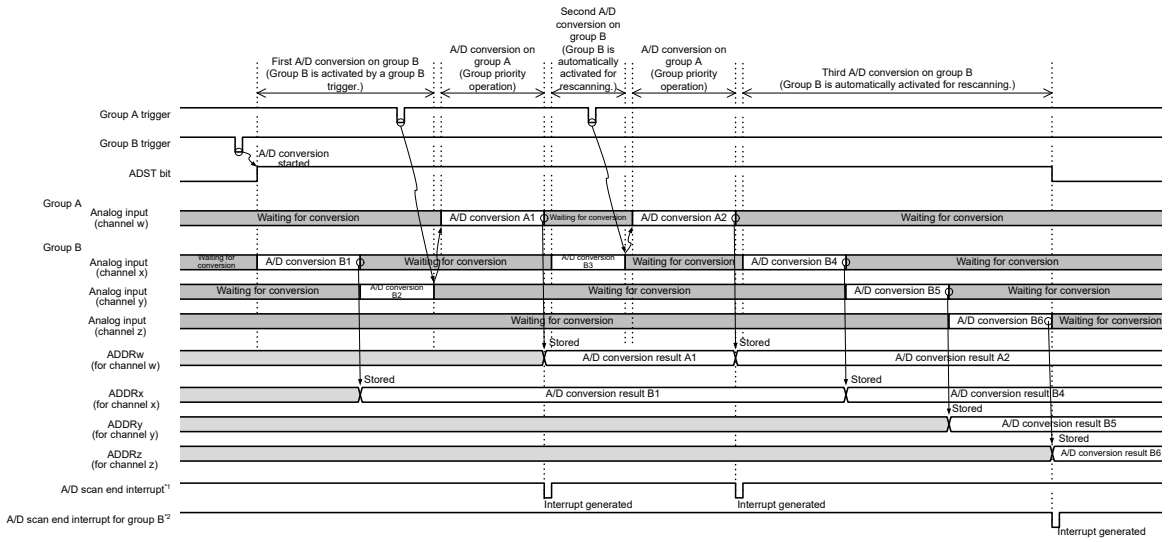
Figure 39.27 Example of group priority operation 1-1: Group A trigger input during group B scanning when rescanning is enabled (when ADGSPCR.GBRSCN = 1, ADGSPCR.GBRP = 0, and ADGSPCR.LGRRS = 0)

Operation example 1-2: “Group A trigger input during rescanning of group B” when rescanning is enabled

Figure 39.28 shows the operation when a group A trigger is input during rescanning operation for group B.

Even during rescanning operation, when a trigger for group A is input, A/D conversion on group B stops and A/D conversion for group A starts. A/D conversion for group B starts after A/D conversion for group A completes.

Operations for setting the ADCSR.ADST bit, storing the A/D conversion result in the corresponding A/D Data Register y (ADDRy), and generating interrupt requests are the same as those in operation example 1-1.



Note: w, x, y, and z (x < y < z) are the selected channel numbers by ADANSA0/1 or ADANSB0/1.
Note 1. ADC12i_ADI (i = 0, 1)
Note 2. ADC12i_GBADI (i = 0, 1)

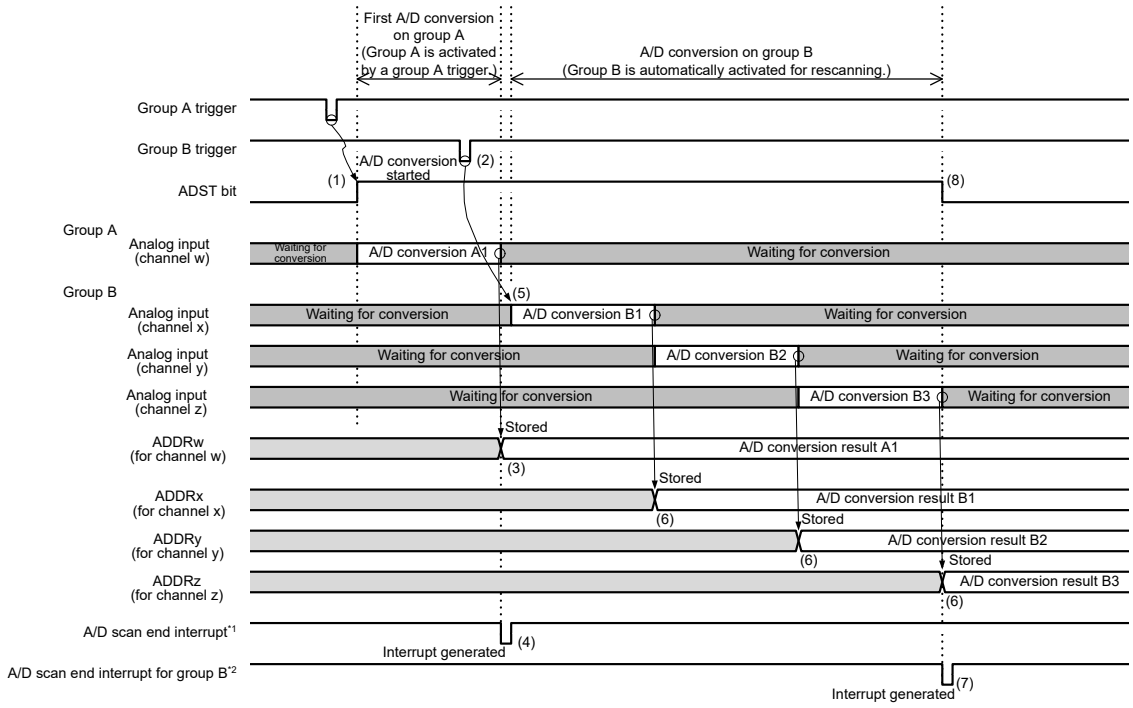
Figure 39.28 Example of group priority operation 1-2: Group A trigger input during rescanning of group B when rescanning is enabled (when ADGSPCR.GBRSCN = 1, ADGSPCR.GBRP = 0, and ADGSPCR.LGRRS = 0)

Operation example 1-3: “Group B trigger input during group A scan” when rescanning is enabled

The following describes the operation when the setting of the ADGSPCR.GBRSCN bit is 1 (enabling rescanning of the group that was stopped in group priority operation) and a trigger for group B is input during scanning operation for group A.

If the setting of the ADGSPCR.GBRSCN bit is 0, any trigger for group B that is input during scanning operation for group A is invalid.

1. When input of a trigger for group A sets the ADCSR.ADST bit to 1 (starting A/D conversion), A/D conversion for the group A analog input channels selected in the ADANSA0 and ADANSA1 registers starts according to the conversion order from the channel with the smallest number n.
2. When a trigger for group B is input during A/D conversion for group A, group B is ready for A/D conversion.
3. On completion of A/D conversion for each channel in group A, the result is stored in the corresponding A/D Data Register y (ADDRy).
4. An ADC120_ADI interrupt request is generated.
5. When A/D conversion for group A completes, while the ADCSR.ADST bit remains 1, A/D conversion for the group B analog input channels selected in the ADANSB0 and ADANSB1 registers starts according to the conversion order from the channel with the smallest number n.
   As with the case of operation example 1-1, if a trigger for group A is input during A/D conversion for group B, A/D conversion for group A starts. Then A/D conversion for group B starts upon completion of A/D conversion for group A.
6. On completion of A/D conversion of a single channel, the result is stored in the corresponding A/D Data Register y (ADDRy).
7. Upon completion of A/D conversion for group B, a group B scan end interrupt request is generated if the setting of the ADCSR.GBADIE bit is 1 (enabling interrupt generation on completion of group B scan).
8. When A/D conversion for all the channels completes, the ADCSR.ADST bit is automatically cleared and the A/D converter enters a wait state.



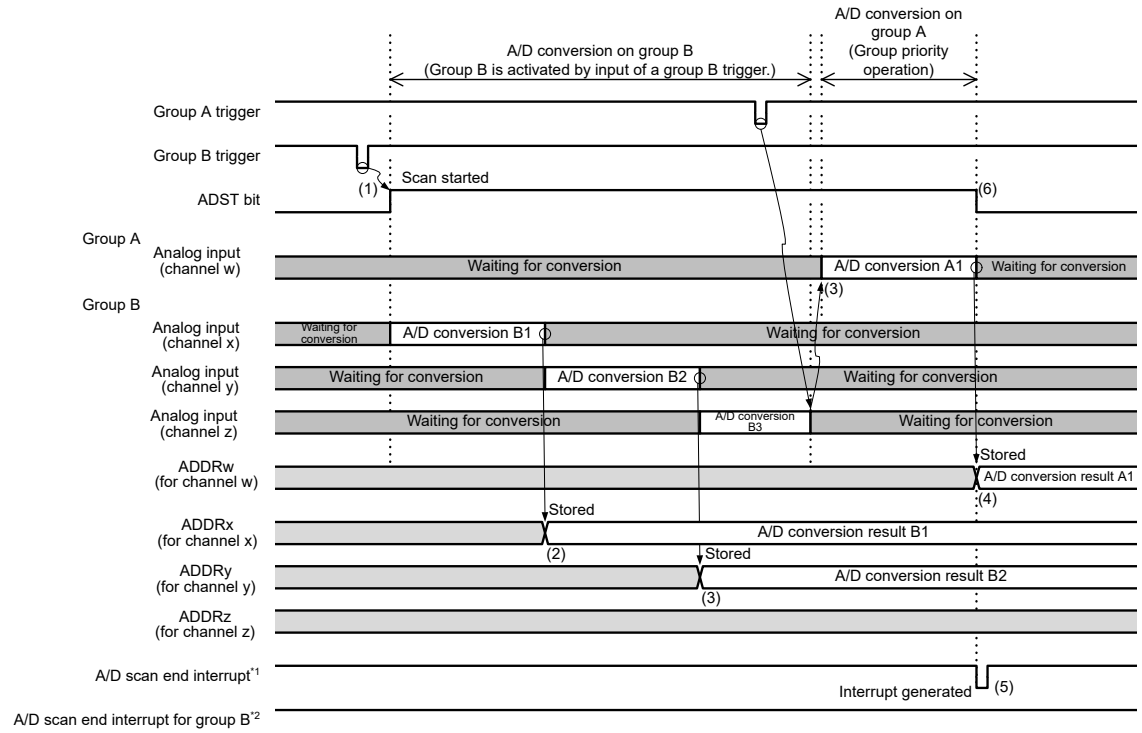
Note: w, x, y, and z (x < y < z) are the selected channel numbers by ADANSA0/1 or ADANSB0/1.
Note 1. ADC12i_ADI (i = 0, 1)
Note 2. ADC12i_GBADI (i = 0, 1)

Figure 39.29 Example of group priority operation 1-3: Group B trigger input during group A scan when rescanning is enabled (when ADGSPCR.GBRSCN = 1, ADGSPCR.GBRP = 0, and ADGSPCR.LGRRS = 0)

Operation example 1-4 shows the group priority operation in group-scan mode (when ADGSPCR.GBRSCN = 0, ADGSPCR.GBRP = 0, and ADGSPCR.LGRRS = 0).

Operation example 1-4: “Group A trigger input during group B scan” when rescanning is disabled

1. When input of a trigger for group B sets the ADCSR.ADST bit to 1 (starting A/D conversion), A/D conversion for the analog input channels selected in the ADANSB0 and ADANSB1 registers starts according to the conversion order from the channel with the smallest number n.
2. On completion of A/D conversion for each channel in group B, the result is stored in the corresponding A/D Data Register y (ADDRy).
3. When a trigger for group A is input during A/D conversion for group B, A/D conversion for group B stops while the ADCSR.ADST bit remains 1, and then A/D conversion for the group A analog input channels selected in the ADANSA0 and ADANSA1 registers starts according to the conversion order from the channel with the smallest number n. If A/D conversion stops before it is completed, the conversion result is not stored in the A/D Data Register y (ADDRy).
4. On completion of A/D conversion of a single channel, the result is stored in the corresponding A/D Data Register y (ADDRy).
5. On completion of A/D conversion for group A, an ADC120_ADI interrupt request is generated.
6. When A/D conversion for group A completes, the ADCSR.ADST bit is automatically cleared and the A/D converter enters a wait state. A/D conversion for group B is not performed until a trigger for group B is input the next time.



Note: w, x, y, and z (x < y < z) are the selected channel numbers by ADANSA0/1 or ADANSB0/1.
Note 1. ADC12i_ADI (i = 0, 1)
Note 2. ADC12i_GBADI (i = 0, 1)

Figure 39.30 Group priority operation example 1-4: "Group A trigger is input during group B scan" when rescanning is disabled (when ADGSPCR.GBRSCN = 0, ADGSPCR.GBRP = 0, and ADGSPCR.LGRRS = 0)

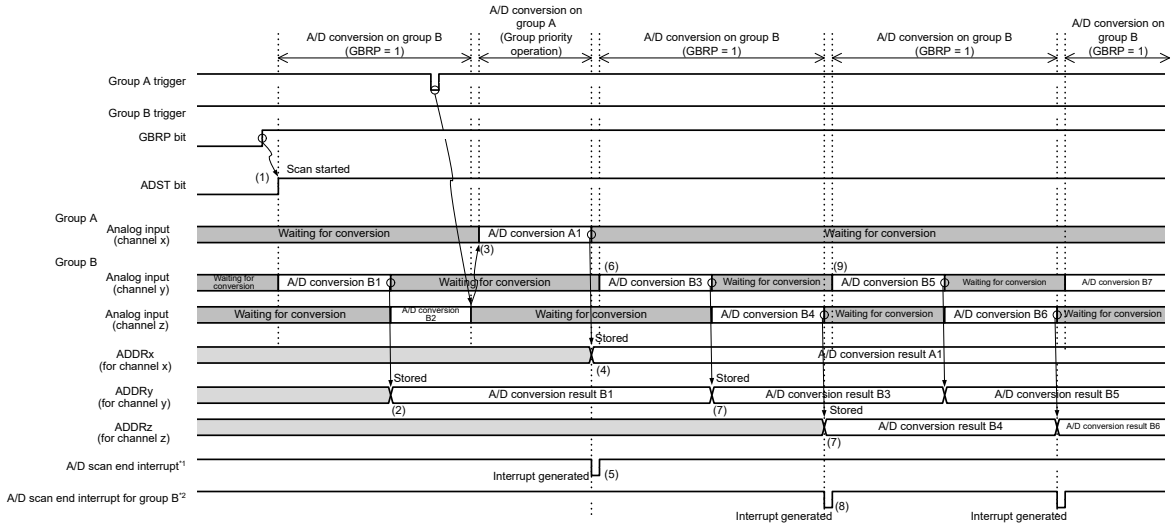
Operation example 1-5 shows the group priority operation in group-scan mode (when ADGSPCR.GBRP = 1, and ADGSPCR.LGRRS = 0).

Operation example 1-5: Continuously activating single-scan operation for group B

1. When ADGSPCR.GBRP = 1 is set, the ADCSR.ADST bit is set to 1 (starting A/D conversion) and A/D conversion for the analog input channels selected in the ADANSB0 and ADANSB1 registers starts according to the conversion order from the channel with the smallest number n.
2. On completion of A/D conversion for each channel in group B, the result is stored in the corresponding A/D Data Register y (ADDRy).
3. When a trigger for group A is input during A/D conversion for group B, A/D conversion for group B stops while the ADCSR.ADST bit remains 1, and then A/D conversion for group A analog input channels selected in the ADANSA0 and ADANSA1 registers starts according to the conversion order from the channel with the smallest number n. If A/D conversion stops before it is completed, the conversion result is not stored in the A/D Data Register y (ADDRy).
4. On completion of A/D conversion of a single channel, the result is stored in the corresponding A/D Data Register y (ADDRy).
5. On completion of A/D conversion for group A, an ADC120_ADI interrupt request is generated.
6. If ADGSPCR.GBRP = 1 is set (performing single scan continuously), A/D conversion for the group B analog input channels selected in the ADANSB0 and ADANSB1 registers restarts according to the conversion order from the channel with the smallest number n while the ADCSR.ADST remains 1 (starting A/D conversion).
7. On completion of A/D conversion of a single channel, the result is stored in the corresponding A/D Data Register y (ADDRy).

8. If the setting of the ADCSR.GBADIE bit is 1 (enabling interrupt generation on completion of group B scan), a group B scan end interrupt request is generated.
9. If ADGSPCR.GBRP = 1 is set (performing single scan continuously), A/D conversion for the group B analog input channels selected in the ADANSB0 and ADANSB1 registers restarts according to the conversion order from the channel with the smallest number n while the ADCSR.ADST remains 1 (starting A/D conversion).

Steps 6 to 9 are repeated as long as the ADGSPCR.GBRP bit remains 1. Do not clear the ADCSR.ADST bit as long as the ADGSPCR.GBRP bit is 1. To forcibly stop A/D conversion while ADGSPCR.GBRP = 1, follow the procedure shown in Figure 39.43.



Note: x, y, and z (y < z) are the selected channel numbers by ADANSA0/1 or ADANSB0/1.
Note 1. ADC12i_ADI (i = 0, 1)
Note 2. ADC12i_GBADI (i = 0, 1)

Figure 39.31 Group priority operation example 1-5: Continuously activating single scan for group B (when ADGSPCR.GBRP = 1, ADGSPCR.LGRRS = 0)

Note: To continuously activate single-scan operation for group B, disable group B trigger input.

39.3.5 Compare Function for Windows A and B

39.3.5.1 Compare Function Windows A and B

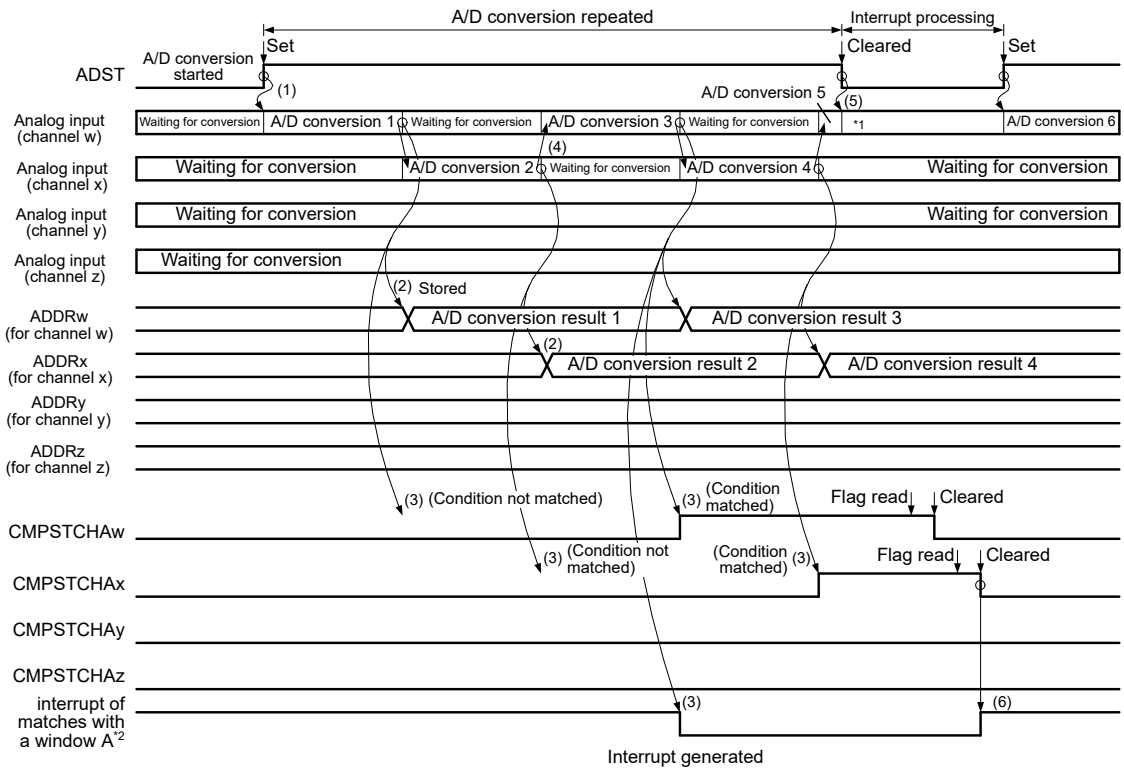
The compare function compares a reference value with the A/D conversion result. The reference value can be set for Window A and Window B independently. When the compare function is in use, the self-diagnosis function and double trigger mode cannot be used. The main differences between Window A and Window B are their different interrupt output signals and the constraint on Window B of only one selectable channel.

This section provides an example operation that combines continuous scan mode and the compare function.

The operation is as follows:

1. When the ADCSR.ADST bit is set to 1 (A/D conversion start) by software, a synchronous trigger (GPT, ELC) or an asynchronous trigger, A/D conversion starts in the order of the selected channels , temperature sensor, and internal reference voltage.
2. On completion of A/D conversion, the A/D conversion result is stored in the associated A/D Data Register y (ADDRy, ADTSDR, or ADOCDR). When ADCMPCR.CMPAE = 1, if bits in the ADCMPANSRy register or the ADCMPANSER register are set for Window A, the A/D conversion result is compared with the set ADCMPDR0/1 register value. When ADCMPCR.CMPBE = 1, if bits in the ADCMPBNSR register are set for Window B, the A/D conversion result is compared with the ADWINULB/ADWINLLB register setting.

3. As a result of the comparison, when Window A meets the condition set in ADCMPLR0/1 or ADCMPLER, the Compare Window A Flag (ADCMPSR0.CMPSTCHAn, ADCMPSR1.CMPSTCHAn, ADCMPSER.CMPSTTSA or ADCMPSER.CMPSTOCA) sets 1. At this time, if the ADCMPCR.CMPAIE bit is 1, an ADC12i_CMPAI (i = 0, 1) interrupt request is generated. In the same way, when Window B meets the condition set in ADCMPBNSR.CMPLB, the Compare Window B Flag (ADCMPBSR.CMPSTB) sets to 1. At this time, if the ADCMPCR.CMPBIE bit is 1, an ADC12i_CMPBI (i = 0, 1) interrupt request is generated.
4. On completion of all selected A/D conversions and comparisons, scan restarts.
5. After the ADC12i_CMPAI (i = 0, 1) and ADC12i_CMPBI (i = 0, 1) interrupts are accepted, the ADCSR.ADST bit is set to 0 (A/D conversion stop) and processing is performed for channels for which the compare flag is set to 1.
6. When all compare flags of Window A are cleared, the ADC12i_CMPAI (i = 0, 1) interrupt request is canceled. In the same way, when all compare flags of Window B are cleared, the ADC12i_CMPBI (i = 0, 1) interrupt request is reset. To perform comparison again, restart the A/D conversion.



Note: w, x, y, and z (w < x < y < z) are the selected channel numbers by ADANSA0/1.
Note 1. Data on conversion is ignored.
Note 2. ADC12i_CMPAI (i = 0, 1)

Figure 39.32 Example of compare function operation, when the analog inputs (channel w to z) are compared

39.3.5.2 Event Output of Compare Function

The event output of the compare function specifies the upper-side reference value and the lower-side reference value for window A and window B, respectively. The output compares the A/D converted value of the selected channel with the upper and lower side reference value and outputs events (ADC12i_WCMPM (i = 0, 1)/ADC12i_WCMPUM (i = 0, 1)) based on event conditions (A OR B, A AND B, A XOR B) and comparison result of window A and window B.

If more than one channel is selected for window A, and even when one channel in window A meets the comparison condition, the comparison result of window A is met. When using this function, perform A/D conversion in single scan mode.

Any channels from analog input, internal reference voltage and temperature sensor output are selectable for window A.

One channel from analog input, internal reference voltage and temperature sensor output is selectable for window B.

The following sequence is an example of how to set up and use the event output of the compare function:

1. Confirm that the value in the ADCSR.ADCS bits is 00b (single scan mode).
2. Select the channel for window A in the ADCMPANSR0/1 and ADCMPANSER registers. Set the window comparison conditions in the ADCMPLR0/1 and ADCMPLER registers. Set the upper-side and lower-side reference values in the ADCMPDR0/1 registers.
3. Select the channel and comparison conditions for Window B in the ADCMPBNSR register, and set the upper and lower reference values in the ADWINULB and ADWINLLB registers.
4. Set the composite conditions for window A/B, window A/B operation enable, and interrupt output enable in the ADCMPCR register.

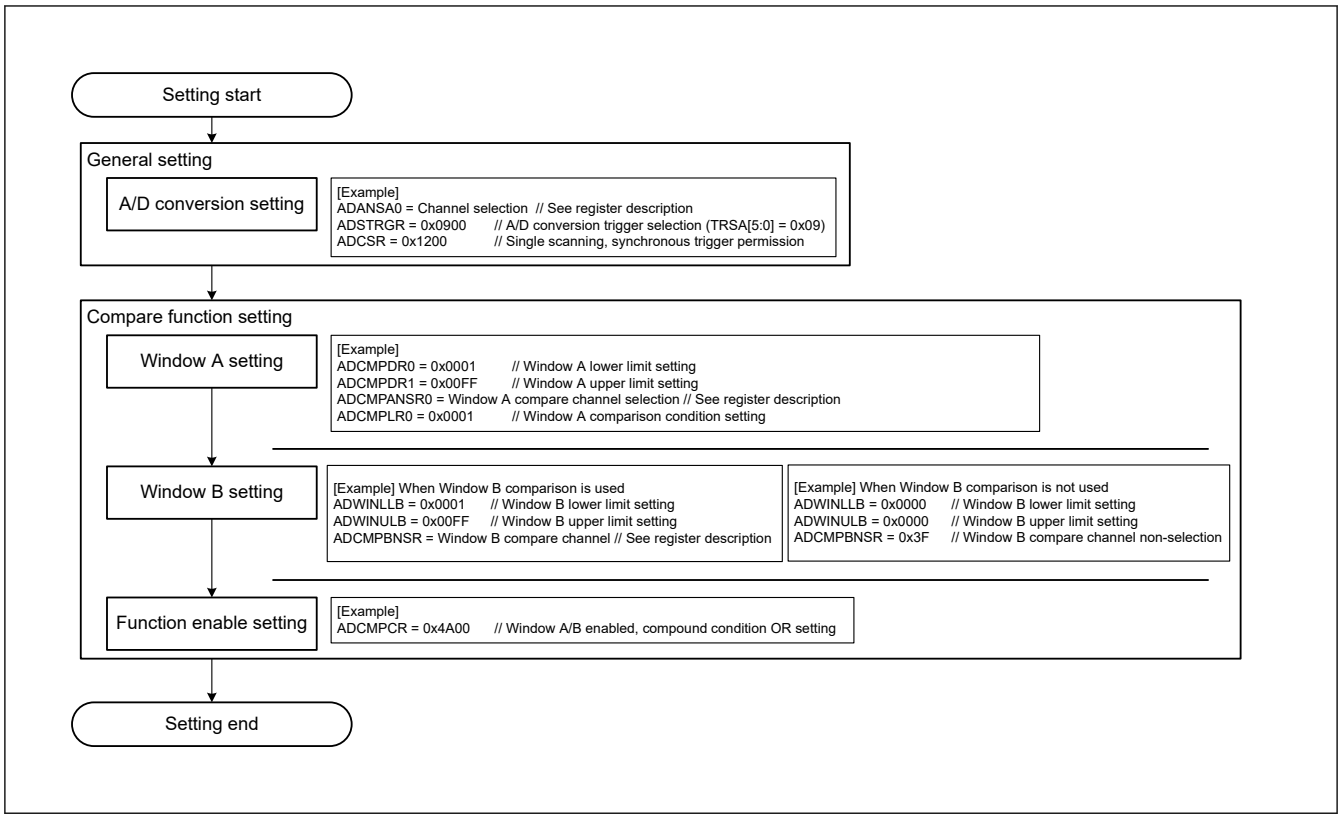


Figure 39.33 Setting example when using the event output of the compare function

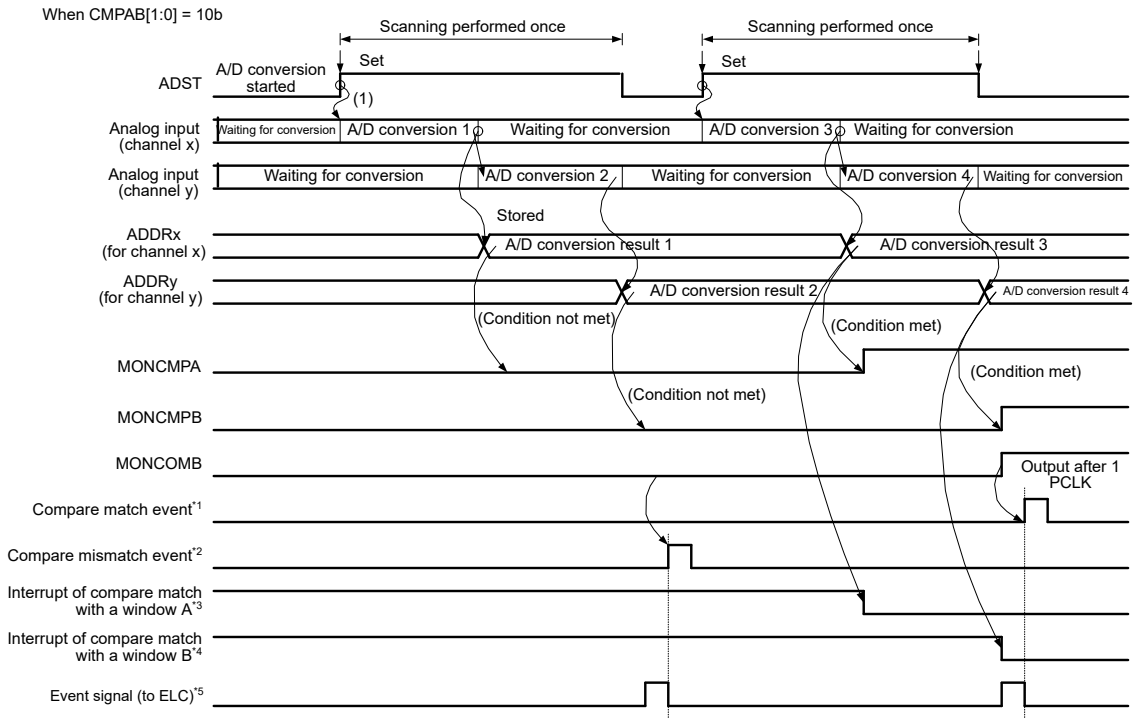
For event output usage when using only window A for the compare function, note the following:

- Enable both Window A and Window B (ADCMPCR.CMPAE = 1, ADCMPCR.CMPBE = 1)
- Set the compound condition of Window A and Window B to “OR condition” (ADCMPCR.CMPAB[1:0] = 00b)
- Set the compared channel of Window B to “No selection” (ADCMPBNSR.CMPCHB[5:0] = 0x3F)
- Set the compare condition of Window B to “0 < results < 0 always means mismatch”. (ADCMPCR.WCMPE = 1, ADWINLLB[15:0] = ADWINULB[15:0] = 0x0000, and ADCMPBNSR.CMPLB = 1)

Figure 39.34 shows the event output operation example of compare function.

A scan end event (ADC12i_ADI (i = 0, 1)) is output with the same timing as single scan completion. A match or mismatch event (ADC12i_WCMPM (i = 0, 1)/ADC12i_WCMPUM (i = 0, 1)) is output with 1 PCLKA cycle delay depending on the ADCMPCR.CMPAB[1:0] settings.

Note: The match and mismatch events are exclusive, so both events are never output simultaneously.



Note: x, and y (x < y) are the selected channel numbers by ADANSA0/1.
Note 1. ADC12i_WCMPM (i = 0, 1)
Note 2. ADC12i_WCMPUM (i = 0, 1)
Note 3. ADC12i_CMPAI (i = 0, 1)
Note 4. ADC12i_CMPBI (i = 0, 1)
Note 5. ADC12i_ADI (i = 0, 1)

Figure 39.34 Example operation of the compare function event output, when the analog inputs (channel x and y) are compared

Note: Event output of compare function outputs match/mismatch from the comparison results of Window A and Window B, based on the ADCMPCR.CMPAB[1:0] settings.

Note: The comparison result of Window A is the logical addition of the comparison results of the comparison target channels of Window A. The comparison results of Window A and Window B are updated by each A/D conversion, and are kept even when single scan ends. Set ADCMPCR.CMPAE and ADCMPCR.CMPBE to 0 to clear the comparison results to 0.

39.3.5.3 Restrictions on Compare Function

The following constraints apply for the compare function:

- The compare function cannot be used together with the self-diagnosis function or double-trigger mode. The compare function is not available for ADRD, ADDBLDR, ADDBLDRA, and ADDBLDRB.
- Specify single scan mode when using match/mismatch event outputs.
- When the temperature sensor output, internal reference voltage is selected for Window A, Window B operations are prohibited.
- When the temperature sensor output, internal reference voltage is selected for Window B, Window A operations are prohibited.
- Setting the same channel for Window A and Window B is prohibited.
- Specify single scan mode when using the buffer function. It is prohibited to use double trigger mode together.
- Set the reference voltage values so that the upper-side reference voltage value is equal to or larger than the lower-side reference voltage value.

39.3.6 Analog Input Sampling and Scan Conversion Time

Scan conversion can be activated either by a software trigger, a synchronous trigger (GPT, ELC), or an asynchronous trigger (ADTRGn (n = 0, 1)). After the start-of-scanning-delay time (t_D) has elapsed, processing by the channel-dedicated sample-and-hold circuits, processing for disconnection detection assistance, and processing of conversion for self-diagnosis all proceed, followed by processing for A/D conversion.

Figure 39.35 shows the scan conversion timing, in which scan conversion is activated by a software trigger or a synchronous trigger (GPT, ELC). Figure 39.36 shows the scan conversion timing, in which scan conversion is activated by an asynchronous trigger (ADTRGn (n = 0, 1)). The scan conversion time (t_{SCAN}) includes the start-of-scanning-delay time (t_D), channel-dedicated sample-and-hold circuit processing time (tSPLSH)*1, disconnection detection assistance processing time (t_{DIS})*2, self-diagnosis A/D conversion processing time (t_{DIAG} and t_{DSD})*3, A/D conversion processing time (t_{CONV} and t_{DSD}), channel-dedicated sample-and-hold circuit end time (tSHED)*4 and end-of-scanning-delay time (t_{ED}).

The A/D conversion processing time (t_{CONV}) consists of input sampling time (t_{SPL}) and time for conversion by successive approximation (t_{SAM}). The sampling time (t_{SPL}) is used to charge sample-and-hold circuits in the A/D converter. If there is not sufficient sampling time due to the high impedance of an analog input signal source, or if the A/ D conversion clock (ADCLK) is slow, sampling time can be adjusted using the ADSSTRn register.

The time for conversion by successive approximation (t_{SAM}) is the following:

- 13 ADCLK states with 12-bit accuracy selected.
- 11 ADCLK states with 10-bit accuracy selected.
- 9 ADCLK states with 8-bit accuracy selected.

Table 39.26 shows the time for conversion by successive approximation (t_{SAM}).

The scan conversion time (t_{SCAN}) in single scan mode for which the number of selected channels is n can be determined as follows:

$$t_{SCAN} = t_D + t_{SPLSH} + (t_{DIS} \times n) + t_{DIAG} + t_{ED} + (t_{CONV} \times n) + t_{ED}$$ *5

The scan conversion time for the first cycle in continuous scan mode is t_{SCAN} for single scan minus t_{ED} . The scan conversion time for the second and subsequent cycles in continuous scan mode is fixed in the following:

$$t_{SPLSH} + (t_{DIS} \times n) + t_{DIAG} + t_{DSD} + t_{SHED} + (t_{CONV} \times n) + t_{SHED}$$ *5

Note 1. When no channel-dedicated sample-and-hold circuits are used, tSPLSH = 0.
Note 2. When disconnection detection assistance is not selected, t_{DIS} = 0.
Note 3. When the self-diagnosis function is not used, t_{DIAG} = 0, t_{DSD} = 0.
Note 4. When no channel-dedicated sample-and-hold circuits are used, t_{SHED} = 0, assuming continuous scan mode is active. In single scan mode and group scan mode, t_{SHED} is included in the end-of-scanning-delay (t_{ED}).
Note 5. When input sampling times (t_{SPL}) of all selected channels are the same, this element equals t_{CONV} × n. If each channel has a different sampling time, this element equals that of t_{SPL} and t_{SAM} set to each selected channel.

Table 39.26 shows the times for conversion during scanning.

Table 39.26 Conversion times during scanning (in numbers of cycles of ADCLK and PCLKA)

Item			Symbol		Type/Conditions			Unit
					Synchronous trigger*4	Asynchronous trigger	Software trigger	
Scan start processing time*1 *2	A/D conversion on group A under group A priority control.	Group B is to be stopped (Group A is activated after group B is stopped by of an A/D conversion source from group A).	t_D		3 PCLKA + 6 ADCLK 5 PCLKA + 3 ADCLK*5	—	—	Cycles
		Group B is not to be stopped (activation by an A/D conversion source from group A).			2 PCLKA + 4 ADCLK	—	—	
	A/D conversion when self-diagnosis is enabled.	A/D conversion for self-diagnosis is to be started.			2 PCLKA + 6 ADCLK	4 PCLKA + 6 ADCLK	6 ADCLK	
	All other				2 PCLKA + 4 ADCLK	2 PCLKA + 4 ADCLK	4 ADCLK	
Channel-dedicated sample-and-hold processing time*1	Sampling time		t_{SPLSH}	t_{SH}	Without continuous sampling: setting in ADSHCR.SSTSH[7:0] (initial value = 0x18 × ADCLK) With continuous sampling: 0			
	Wait time between sampling and A/D Conversion			t_W	12 ADCLK			
Disconnection detection assistance processing time			t_{DIS}		Setting in ADNDIS[3:0] (initial value = 0x0) × ADCLK			
Self-diagnosis conversion processing time*1	Sampling time		t_{DIAG}	t_{SPL}	Setting in ADSSTR00 (initial value = 0x0B) × ADCLK*3	—	—	
	Time for conversion by successive approximation	12-bit conversion accuracy		t_{SAM}	15 ADCLK	—	—	
		10-bit conversion accuracy			13 ADCLK	—	—	
		8-bit conversion accuracy			11 ADCLK	—	—	
	Wait time between self-diagnosis conversion end and analog channel sampling start.			t_{DED}	2 ADCLK			
	Wait time between last channel conversion end and self-diagnosis sampling start in continuous scan mode.		t_{DSD}		2 ADCLK			
A/D conversion processing time*1	Sampling time		t_{CONV}	t_{SPL}	Setting in ADSSTRn (n = 0 to 2, 4 to 8 (unit 0), 0 to 2, 4 to 6 (unit 1), L, T, O, V) (initial value = 0x0B) × ADCLK + 0.5 ADCLK			
	Time for conversion by successive approximation	12-bit conversion accuracy		t_{SAM}	13 ADCLK			
		10-bit conversion accuracy			11 ADCLK			
		8-bit conversion accuracy			9 ADCLK			
Channel-dedicated sample-and-hold end processing time			t_{SHED}		2 ADCLK			
Scan end processing time*1			t_{ED}		1 PCLKA + 3 ADCLK 2 PCLKA + 3 ADCLK*5			

Note 1. See Figure 39.35 and Figure 39.36 for an illustration of times t_D, t_{SPLSH}, t_{DIAG}, t_{CONV}, and t_{ED}.
Note 2. This is the maximum time required from software writing or trigger input to A/D conversion start.
Note 3. The sampling time setting must satisfy the electrical characteristics.
Note 4. This does not include the time consumed in the path from timer output to trigger input.
Note 5. If ADCLK is faster than PCLKA (PCLKA to ADCLK frequency ratio = 1:2 or 1:4), the scan end processing time changes.

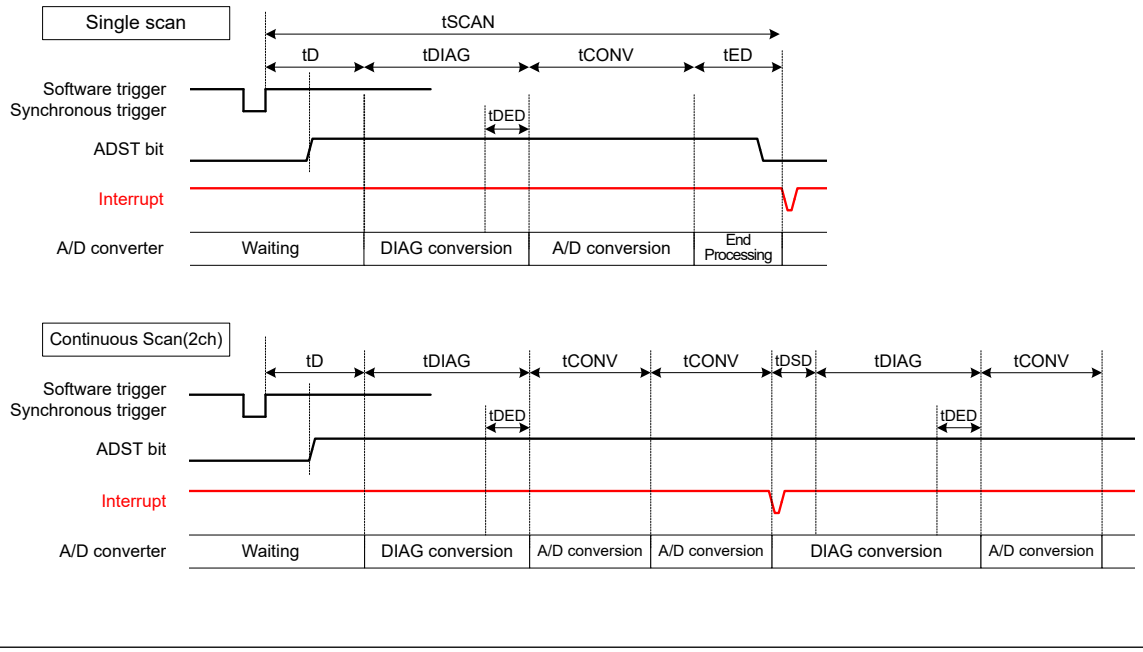


Figure 39.35 Scan conversion timing when activated by software or a synchronous trigger input (GPT, ELC)

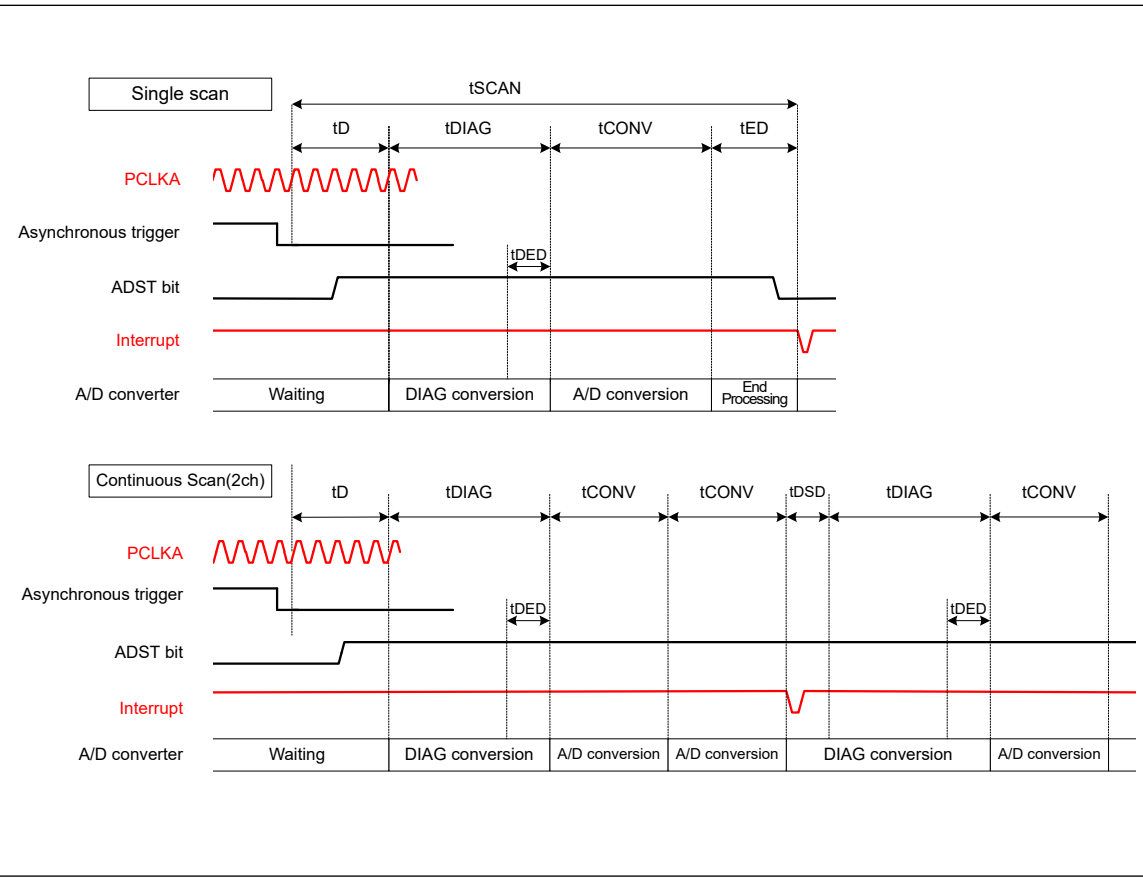

Figure 39.36 Scan conversion timing when activated by an asynchronous trigger input (ADTRGn (n = 0, 1))

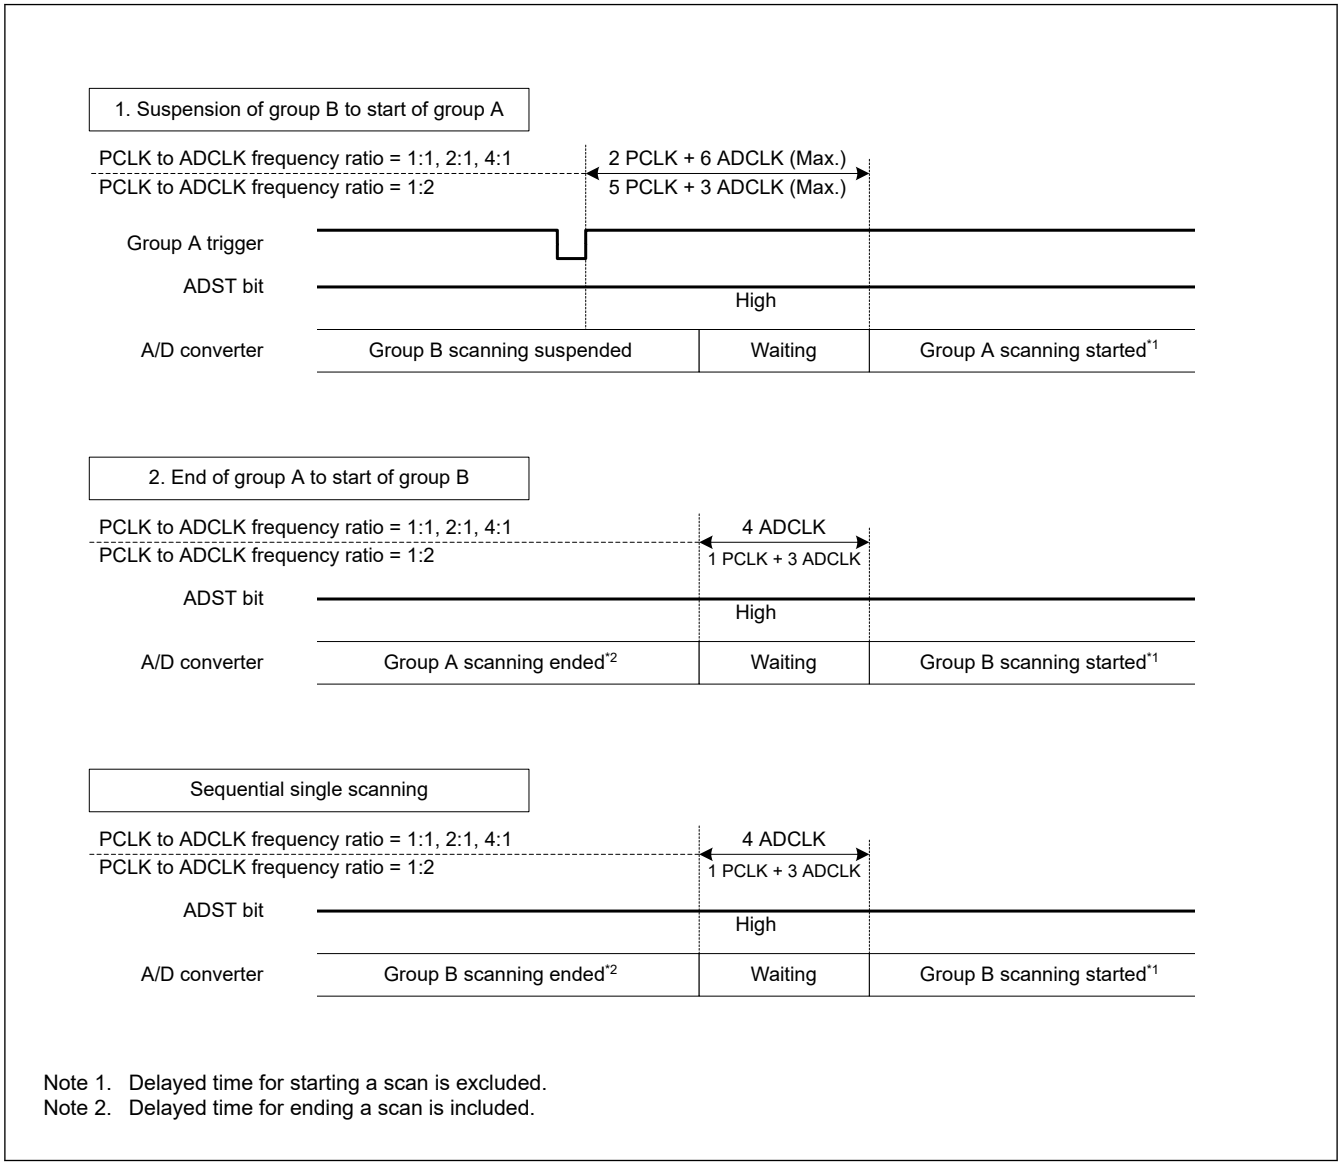
39.3.6.1 Timing of Suspension and Starting of Scanning in Operation under Group Priority Control

The timings for suspension and starting of scanning in operation under group priority control that must considered are listed below.

1. The timing for suspending a scan of a group with a lower-priority and the timing for starting a scan of a group with a higher-priority.
2. The time at which scanning by the group with a lower-priority is resumed on completion of scanning by the higher-priority group when the trigger for scanning by the lower-priority group is accepted during scanning by the higher-priority group.
3. The timing for performing sequential single scans by a lower-priority group.

Figure 1.37 shows the timing diagram of each of the above cases.



Note 1. Delayed time for starting a scan is excluded.
Note 2. Delayed time for ending a scan is included.

Figure 39.37 Timing diagram of suspension and starting of scanning in operation under group priority control

39.3.7 Usage Example of A/D Data Register Automatic Clearing Function

Setting the ADCER.ACE bit to 1 automatically clears the A/D data registers (ADDRy, ADRD, ADDBLDR, ADDBLDRA, ADDBLDRB, ADTSDR, ADOCDR) to 0x0000 when the A/D data registers are read by the CPU or DTC or DMAC.

This function enables detection of update failures of the A/D data registers (ADDRy, ADRD, ADDBLDR, ADDBLDRA, ADDBLDRB, ADTSDR, ADOCDR). This section describes examples in which the function to automatically clear the ADDRy register is enabled and disabled.

- If the ADCER.ACE bit is 0 (automatic clearing is disabled) and for some reason, if the A/D conversion result (0x0222) is not written to the ADDRy register, the ADDRy value retains the old data (0x0111). In addition, if this ADDRy value is read into a general-purpose register using an A/D scan end interrupt, the old data (0x0111) can be saved in the general-purpose register. When checking whether there is an update failure, it is necessary to frequently save the old data in SRAM or in a general-purpose register.
- If the ADCER.ACE bit is 1 (automatic clearing is enabled), when ADDRy = 0x0111 is read by the CPU or DTC or DMAC, ADDRy is automatically set to 0x0000. Next, if the A/D conversion result of 0x0222 cannot be transferred to ADDRy for some reason, the cleared data (0x0000) remains as the ADDRy value. If this ADDRy value is read into a general-purpose register using an A/D scan end interrupt, 0x0000 is saved in the general-purpose register. Occurrence of an ADDRy update failure can be determined by checking that the read data value is 0x0000.

39.3.8 A/D-Converted Value Addition/Average Mode

A/D-converted value addition/average mode can be used when A/D conversion of the analog input of the selected channels, the temperature sensor output and the internal reference voltage is selected.

In A/D-converted value addition mode, the same channel is A/D-converted 1, 2, 3, 4, or 16 consecutive times, and the sum of the converted values is stored in the data register. The conversion count of the addition function can be set to 16 only when 12-bit accuracy is selected. In A/D-converted value average mode, the same channel is A/D-converted 2 or 4 consecutive times, and the mean of the converted values is stored in the data register. The use of the average of these results can improve the accuracy of A/D conversion, depending on the types of noise components that are present. This function, however, cannot always guarantee an improvement in A/D conversion accuracy.

The A/D-converted value addition/average function can be used when A/D conversion of the analog inputs of the selected channels or A/D conversion of the temperature sensor output or A/D conversion of the internal reference voltage is selected. The A/D-converted value addition/average function can also be used for channels for which the double-trigger function is selected.

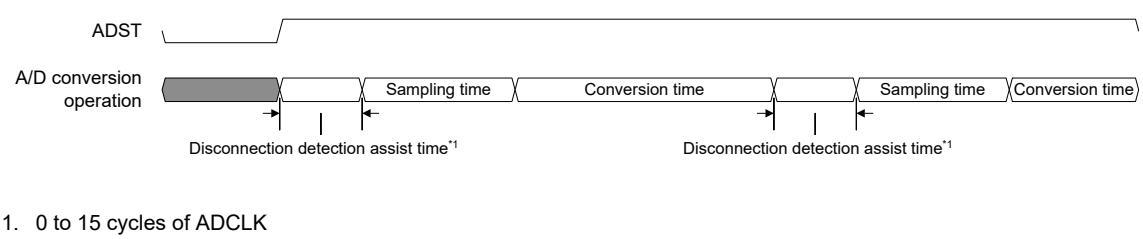
The addition function for self-diagnosis is not provided.

39.3.9 Disconnection Detection Assist Function

The ADC12 incorporates a function to fix the charge for sampling capacitance to the specified state (VREFH0 or VREFL0 for unit 0, VREFH or VREFL for unit 1) before the start of A/D conversion. This function enables disconnection detection in wiring of analog inputs.

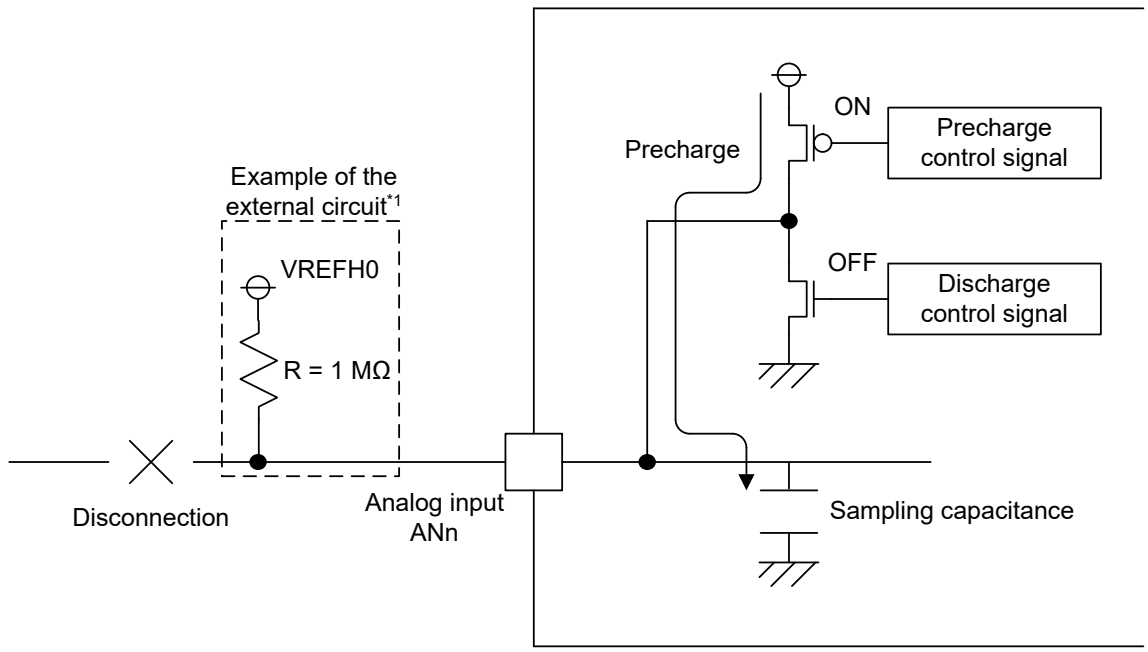
When using the disconnection detection assist function for the channel-dedicated sample-and-hold circuit, set the ADSHMSR.SHMD bit to 0 (select disable continuous sampling function).

Figure 39.38 shows the A/D conversion operation when the disconnection detection assist function is used. Figure 39.39 shows an example of disconnection detection when precharge is selected. Figure 39.40 shows an example of disconnection detection when discharge is selected.



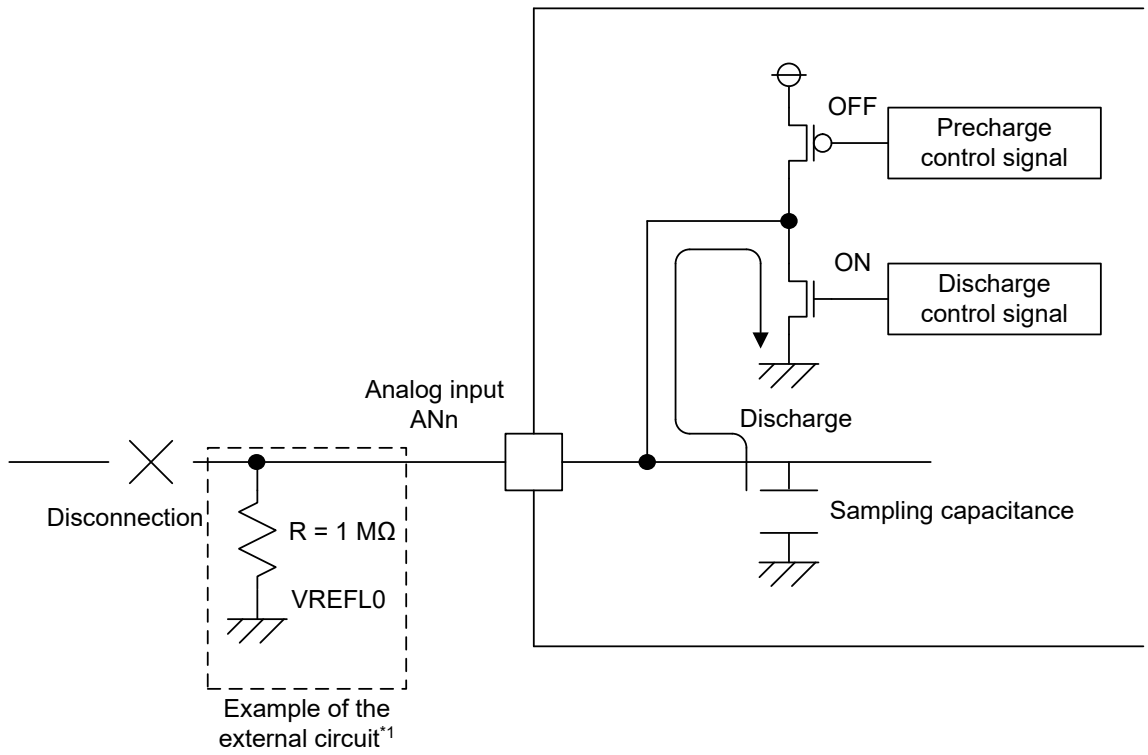
Note 1. 0 to 15 cycles of ADCLK

Figure 39.38 Operation of A/D conversion when disconnection detection assist function is used



Note 1. The converted result should be used after it is fully evaluated because the result data when disconnection occurs varies depending on the external circuit.

Figure 39.39 Example of disconnection detection when precharge is selected



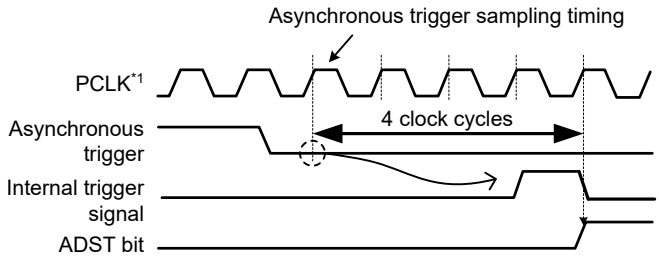
Note 1. The converted result should be used after it is fully evaluated because the result data when disconnection occurs varies depending on the external circuit.

Figure 39.40 Example of disconnection detection when discharge is selected

39.3.10 Starting A/D Conversion with an Asynchronous Trigger

A/D conversion can be started by the input of an asynchronous trigger. To start A/D conversion by an asynchronous trigger, set the pin function in the PmnPFS register, set the A/D Conversion Start Trigger Select bits (ADSTRGR.TRSA[5:0]) to 0x00, then input a high-level signal to the asynchronous trigger (ADTRGn (n = 0, 1) pin). Finally, set both the ADCSR.TRGE and ADCSR.EXTRG bits to 1. Figure 39.41 shows timing of the asynchronous trigger input.

An asynchronous trigger cannot be selected in the A/D conversion start trigger for group B used in group scan mode. For details on setting the pin function, see section 18, I/O Ports.



Note 1. PCLKA

Figure 39.41 Asynchronous trigger input timing

39.3.11 Starting A/D Conversion with a Synchronous Trigger from a Peripheral Module

A/D conversion can be started by a synchronous trigger (GPT, ELC). To do this, set the ADCSR.TRGE bit to 1 and the ADCSR.EXTRG bit to 0, and select the relevant sources in the ADSTRGR.TRSA[5:0] bits and ADSTRGR.TRSB[5:0] bits.

39.3.12 Security Attribution between ADCn (n = 0, 1) and PORT (PmSAR (m = 0 to 9, A, B))

Only when the security attribution of ADC12n (n = 0, 1) match the security attribution of PORT (PmSAR), the correspond analog input channel can be set for ADC conversion. Otherwise the conversion result is unexpected.

Table 39.27 shows the condition of ADC for each Security Attribution setting.

Table 39.27 Analog input pin conditions by security settings

Security Attribution setting		ADC input channel select	
ADC12n (n = 0, 1) security setting PSARD	PORT security setting PmSAR	ADANSA0/ADANSA1 ADANSB0/ADANSB1	Setting Combination result
0 (Secure)	0 (Secure)	1 (channel correspond bit)	Input Valid
1 (Non-secure)	1 (Non-secure)	1 (channel correspond bit)	Input Valid
1 (Non-secure)	0 (Secure)	1 (channel correspond bit)	Input invalid and the conversion result is unexpected
0 (Secure)	1 (Non-secure)	1 (channel correspond bit)	Input invalid and the conversion result is unexpected

39.3.13 Using Data Buffers

A ring buffer function consisting of 16 A/D data buffers is available. This function sequentially stores A/D conversion results other than self-diagnosis result (including addition/average results) in data buffers (ADBUFn, n = 0 to 15).

Each conversion result is stored at the timing when the A/D conversion result is stored in the data register, and most recent 16 conversion result data are retained.

The figure-below shows the schematic of data buffers, pointer, and overflow flag operations. When the BUFEN bit is set to 1, the A/D conversion result is transferred at each end of A/D conversion. The pointer indicates the number of data buffer to which the next transferred data is to be written. When data is written to up to buffer 15, the pointer is reset to 0000b and the overflow flag is set to 1. Subsequently transferred data overwrites the previously written data.

The overflow flag is reset to the initial value by writing 0x00 to the ADBUFPTR register.

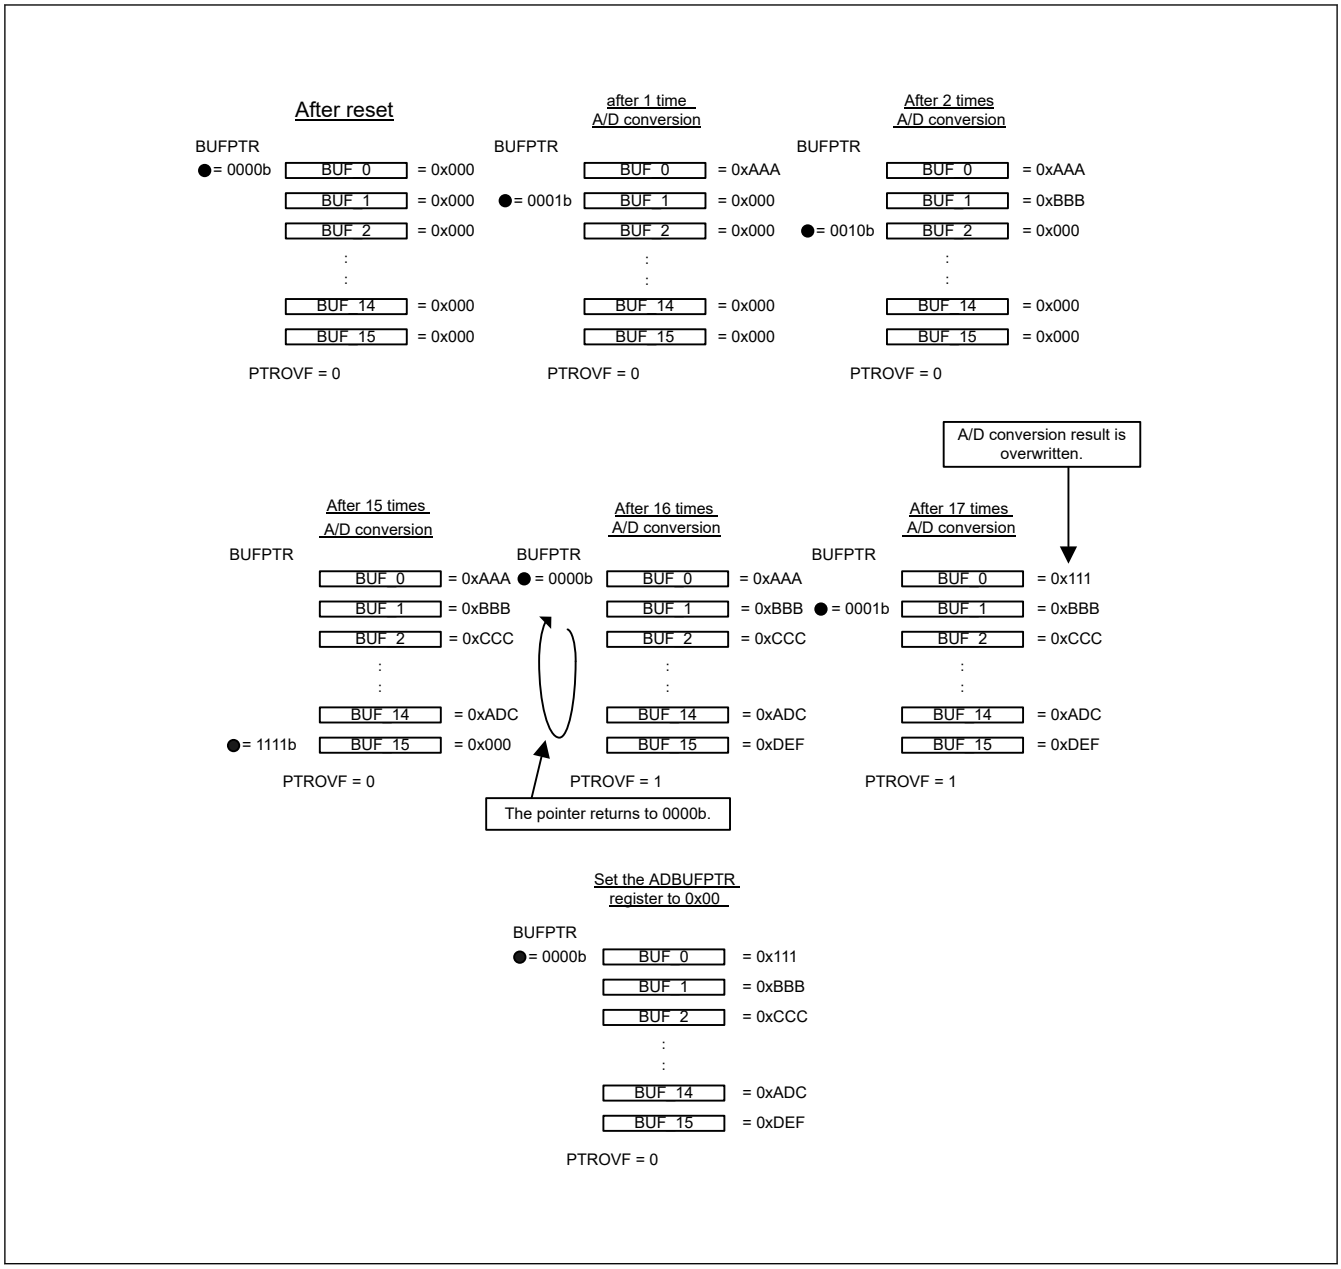


Figure 39.42 Data Buffers, Pointer, and Overflow Flag Operations

39.4 Interrupt Sources and DTC, DMAC Transfer Requests

39.4.1 Interrupt Requests

The ADC12 can send scan end interrupt requests ADC12i_ADI (i = 0, 1) and ADC12i_GBADI (i = 0, 1) to the CPU. The ADC12 also generates the ADC12i_CMPAI (i = 0, 1)/ADC12i_CMPBI (i = 0, 1) interrupt for the CPU in response to matches with a condition for comparison.

An ADC12i_ADI (i = 0, 1) interrupt is always generated. An ADC12i_GBADI (i = 0, 1) interrupt can be generated by setting the ADCSR.GBADIE bit to 1. Similarly, ADC12i_CMPAI (i = 0, 1) and ADC12i_CMPBI (i = 0, 1) interrupts can be generated by setting the ADCMPCR.CMPAIE and ADCMPCR.CMPBIE bit to 1.

In addition, the DTC or DMAC can be started when an ADC12i_ADI (i = 0, 1) or an ADC12i_GBADI (i = 0, 1) interrupt is generated. Using an ADC12i_ADI (i = 0, 1) or ADC12i_GBADI (i = 0, 1) interrupt to activate the DTC or DMAC to read the converted data enables continuous conversion without a burden on software.

Table 39.28 describes the interrupt sources and ELC events available for the ADC12.

Table 39.28 The interrupt source and ELC event of ADC12 (1 of 2)

Operation			Interrupt request or ELC event	Interrupt request	DTC or DMAC activation	ELC event request	Function
Scan mode	Double trigger mode	Compare function Window A/B					
Single scan mode	Deselected	Deselected	ADC12i_ADI (i = 0, 1)	✓	✓	✓	ADC12i_ADI (i = 0, 1) generated at the end of single scan
		Selected	ADC12i_ADI (i = 0, 1)	✓	✓	✓	ADC12i_ADI (i = 0, 1) generated at the end of single scan
			ADC12i_CMPAI (i = 0, 1)	✓	—	—	ADC12i_CMPAI (i = 0, 1) generated on a match comparison condition of Window A
			ADC12i_CMPBI (i = 0, 1)	✓	—	—	ADC12i_CMPBI (i = 0, 1) generated on a match comparison condition of Window B
			ADC12i_WCMPM (i = 0, 1)	—	✓	✓	ADC12i_WCMPM (i = 0, 1) generated on a match condition of the Window A/B compare function
			ADC12i_WCMPUM (i = 0, 1)	—	✓	✓	ADC12i_WCMPUM (i = 0, 1) generated on a mismatch condition of the Window A/B compare function
	Selected	Deselected	ADC12i_ADI (i = 0, 1)	✓	✓	✓	ADC12i_ADI (i = 0, 1) generated at the end of scans in the even numbered times
Continuous scan mode	Deselected	Deselected	ADC12i_ADI (i = 0, 1)	✓	✓	✓	ADC12i_ADI (i = 0, 1) generated at the end of scan of all selected channels
		Selected	ADC12i_CMPAI (i = 0, 1)	✓	—	—	ADC12i_CMPAI (i = 0, 1) generated on a match comparison condition of Window A
			ADC12i_CMPBI (i = 0, 1)	✓	—	—	ADC12i_CMPBI (i = 0, 1) generated on a match comparison condition of Window B

Table 39.28 The interrupt source and ELC event of ADC12 (2 of 2)

Operation			Interrupt request or ELC event	Interrupt request	DTC or DMAC activation	ELC event request	Function
Scan mode	Double trigger mode	Compare function Window A/B					
Group scan mode	Deselected	Deselected	ADC12i_ADI (i = 0, 1)	✓	✓	✓	ADC12i_ADI (i = 0, 1) generated at the end of group A scan
			ADC12i_GBADI (i = 0, 1)	✓	✓	—	ADC12i_GBADI (i = 0, 1) dedicated to group B generated at the end of group B scan
		Selected	ADC12i_ADI (i = 0, 1)	✓	✓	✓	ADC12i_ADI (i = 0, 1) generated at the end of group A scan
			ADC12i_GBADI (i = 0, 1)	✓	✓	—	ADC12i_GBADI (i = 0, 1) dedicated to group B generated at the end of group B scan
			ADC12i_CMPAI (i = 0, 1)	✓	—	—	ADC12i_CMPAI (i = 0, 1) generated on a match comparison condition of Window A
			ADC12i_CMPBI (i = 0, 1)	✓	—	—	ADC12i_CMPBI (i = 0, 1) generated on a match comparison condition of Window B
	Selected	Deselected	ADC12i_ADI (i = 0, 1)	✓	✓	✓	ADC12i_ADI (i = 0, 1) generated at the end of group A scans in the even-numbered times
			ADC12i_GBADI (i = 0, 1)	✓	✓	—	ADC12i_GBADI (i = 0, 1) dedicated to group B generated at the end of group B scan

Note: ✓ available
—: unavailable

For details on DTC settings, see section 16, Data Transfer Controller (DTC).

39.5 Event Link Function

39.5.1 Event Output to the ELC

The ELC uses the ADC12i_ADI (i = 0, 1) interrupt request signal as an event signal ADC12i_ADI (i = 0, 1), enabling link operation for the preset module. The ADC12i_GBADI (i = 0, 1) interrupt and ADC12i_CMPAI (i = 0, 1)/ADC12i_CMPBI (i = 0, 1) interrupts cannot be used as an event signal. For details, see Table 39.28.

An event signal can be output regardless of the settings of the corresponding interrupt request enable bits. For the scan end event (ADC12i_ADI (i = 0, 1)), a high-level pulse for one PCLKA cycle is output at the same output timing as the interrupt output (ADC12i_ADI (i = 0, 1)) shown in Table 39.28. For a compare function match (ADC12i_WCMPM (i = 0, 1)) and mismatch event (ADC12i_WCMPUM (i = 0, 1)) to the ELC, a high-level pulse for one PCLKA cycle is output at the timing delayed by one cycle (PCLKA) from the interrupt output (ADC12i_ADI (i = 0, 1)) shown in Table 39.28.

To use compare function match (ADC12i_WCMPM (i = 0, 1)) or mismatch event (ADC12i_WCMPUM (i = 0, 1)) to the ELC, specify single-scan mode.

39.5.2 ADC12 Operation through an Event from the ELC

The ADC12 can start A/D conversion by the preset event specified in the ELSRn settings for the ELC as follows:

- Select the ELC_AD00 (unit 0) signal in the ELC.ELSR8 register
- Select the ELC_AD01 (unit 0) signal in the ELC.ELSR9 register

- Select the ELC_AD10 (unit 1) signal in the ELC.ELSR10 register
- Select the ELC_AD11 (unit 1) signal in the ELC.ELSR11 register.

If an ELC event occurs during A/D conversion, the event is disabled.

39.6 Usage Notes

39.6.1 Constraints on Setting the Registers

Set each register while the ADCSR.ADST bit is 0.

39.6.2 Constraints on Reading the Data Registers

The following registers must be read in halfword units:

- A/D Data Registers
- A/D Data Duplexing Register
- A/D Data Duplexing Register A
- A/D Data Duplexing Register B
- A/D Temperature Sensor Data Register
- A/D Internal Reference Voltage Register
- A/D Self-Diagnosis Data Register
- A/D Data Buffer Registers n (N = 0 to 15)

If a register is read twice in byte units, that is, the upper byte and lower byte are read separately, the A/D-converted value read initially might disagree with the A/D-converted value read subsequently. To prevent this, never read the data registers in byte units.

39.6.3 Constraints on Stopping A/D Conversion

(1) A/D Conversion Stop Procedure

To stop A/D conversion when an asynchronous trigger or a synchronous trigger is selected as the condition for starting A/D conversion, follow the procedure shown in Figure 39.43.

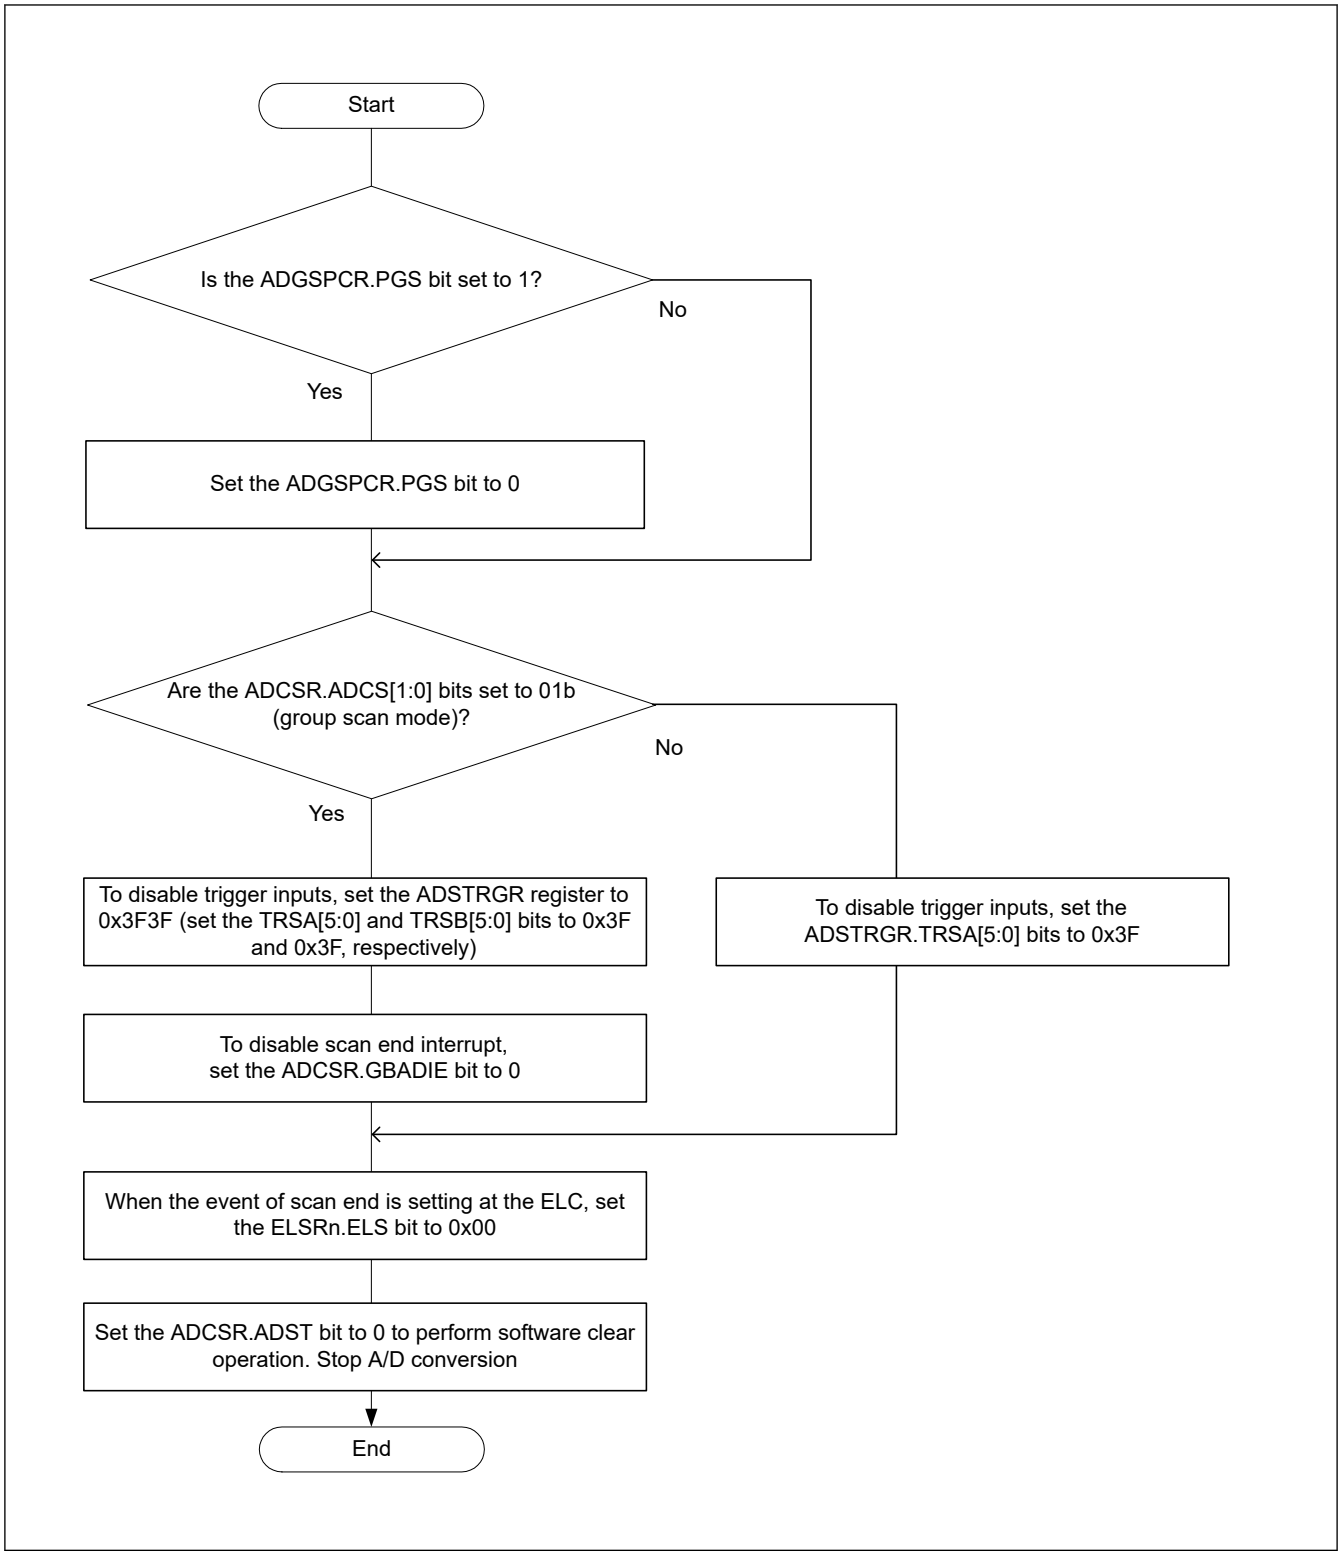

Figure 39.43 Procedures for clearing the ADCSR.ADST bit by software

To specify the following settings after performing the clear operation by software, provide a wait period for at least two ADCLK cycles.

- Enabling scan end interrupts
- Enabling scan end events for the event link controller
- Starting A/D conversion by software
- Enabling trigger input

(2) Notes on Modes and Status Bits

If necessary, individually initialize or set again the voltage status for self-diagnosis, the judgment of the even number or odd number specified for double-trigger mode, and the monitor flags of the compare function.

- To set again the voltage status for self-diagnosis, set the ADCER.DIAGLD bit to 1 and then set a desired value in the ADCER.DIAGVAL[1:0] bits.
- If the setting of the ADCSR.DBLE bit is changed from 0 to 1, the double-trigger mode operation starts from the first scanning.
- To initialize the monitor flags of the compare function (MONCMPA, MONCMPB, and MONCOMB), set the ADCMPCR.CMPAE and ADCMPCR.CMPBE bits to 0.
- To initialize the data storage buffer pointer, set the ADBUFPTR register to 0x00.
- To initialize the continuous sampling function (ADSHMSR.SHMD = 1), set ADSHMSR.SHMD to 0. To use the continuous sampling function again after initialization, set ADSHMSR.SHMD to 1 after waiting for 1 cycle of ADCLK or longer.

39.6.4 A/D Conversion Restart and Termination Timing

A maximum of 6 ADCLK cycles is required for the idle analog unit of the ADC12 to restart on setting the ADCSR.ADST bit to 1. A maximum of 2 ADCLK cycles is required for the operating analog unit of the ADC12 to terminate on setting the ADCSR.ADST bit to 0. A maximum of 1 PCLKA + 1 ADCLK cycles is required for the operating analog unit of the ADC12 to terminate on setting the ADCSR.ADST bit to 0 when PCLKA to ADCLK frequency ratio is 1:2 or 1:4.

39.6.5 Constraints on Scan End Interrupt Handling

When scanning the same analog input twice using any trigger, the first A/D-converted data is overwritten with the second A/D-converted data. This occurs when the CPU does not complete the reading of the A/D-converted data by the time the A/D conversion of the first analog input for the second scan ends after the first scan end interrupt is generated.

39.6.6 Settings for the Module-Stop Function

The Module Stop Control Register can enable or disable ADC12 operation. The ADC12 is initially stopped after a reset. The registers become accessible on release from the module-stop state. After release from the module-stop state, wait for at least 1 µs before starting A/D conversion. For details, see section 10, Low Power Modes.

39.6.7 Notes on Entering the Low-Power States

Before entering the module-stop state or Software Standby mode, be sure to stop A/D conversion. Set the ADCSR.ADST bit to 0 and secure certain period until the analog unit of the ADC12 stops. Follow the procedure shown in Figure 39.43 to clear the ADCSR.ADST bit with software. Then, wait for 2 clock cycles of ADCLK before entering the module-stop state or Software Standby mode.

39.6.8 Notes on Canceling Software Standby Mode

After software standby mode is canceled, wait at least 1 µs after the stabilization time for the oscillator elapses and before starting A/D conversion. For details, see section 10, Low Power Modes

39.6.9 Error in Absolute Accuracy When Disconnection Detection Assistance Is in Use

Using disconnection detection assistance leads to an error in absolute accuracy of the ADC12. This error arises because an erroneous voltage is input to the analog input pins due to the resistive voltage division between the pull-up or pull-down resistor (Rp) and the resistance of the signal source (Rs). This error in absolute accuracy is calculated from the following formula:

$$\text{Maximum error in absolute accuracy (LSB)} = \left(2^{\text{Resolution}} - 1\right) \times \text{Rs} / \left(\text{Rs} + \text{Rp}\right)$$

Only use disconnection detection assistance after thorough evaluation.

39.6.10 Constraints on Operating Modes and Status Bits

Initialize or set again individually, if necessary, the voltage values in self-diagnosis, the value of the first scan or second scan in double trigger mode, the data buffer pointer, and status monitor in the compare function.

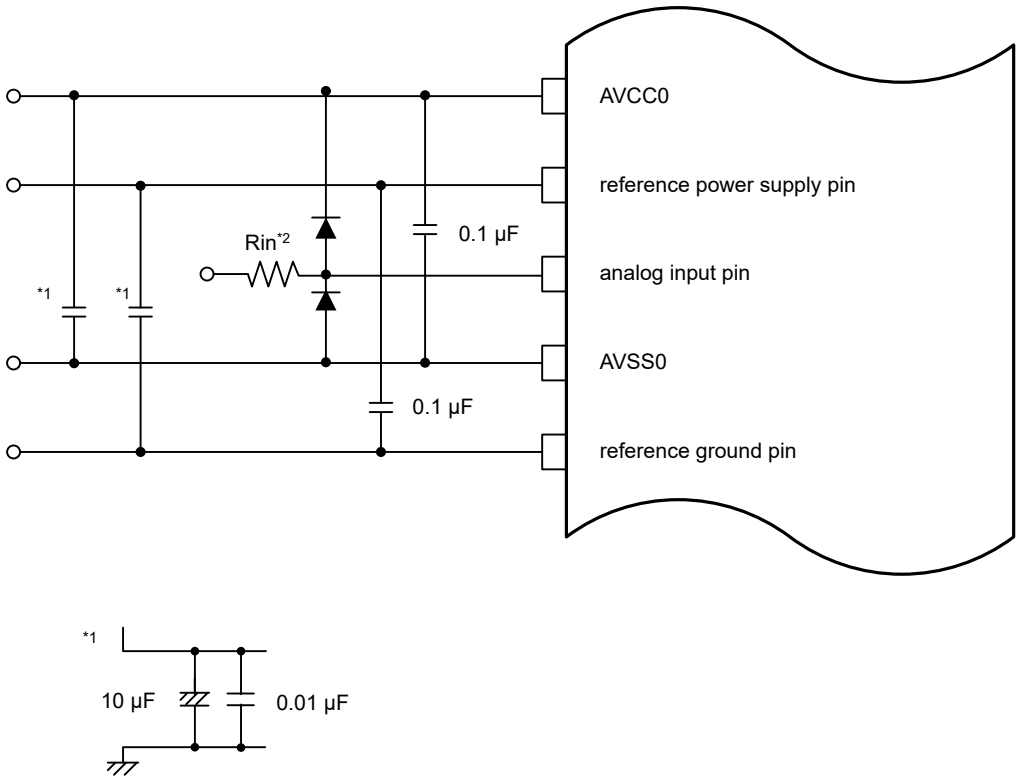
- Select the voltage values in self-diagnosis (ADCER.DIAGVAL[1:0]) after setting ADCER.DIAGLD to 1.
- Double-trigger mode operates as the first scan after setting ADCSR.DBLE from 0 to 1.
- The status monitor bits (MONCMPA, MONCMPB, MONCOMB) in the compare function are initialized after setting ADCMPCR.CMPAE and ADCMPCR.CMPBE to 0.

39.6.11 Notes on Board Design

The board should be designed so that digital circuits and analog circuits are separated from each other as far as possible. In addition, digital circuit signal lines and analog circuit signal lines should not intersect or be placed near each other. If these rules are not followed, noise can occur on analog signals and A/D conversion accuracy is affected. The analog input pins, reference power supply pin (VREFH0, VREFH), reference ground pin (VREFL0, VREFL), and analog power supply (AVCC0) should be separated from digital circuits using the analog ground (AVSS0). The analog ground (AVSS0) should be connected to a stable digital ground (VSS) on the board (single-point ground plane connection).

39.6.12 Constraints on Noise Prevention

To prevent the analog input pins from being destroyed by abnormal voltage such as excessive surge, insert a capacitor between AVCC0 and AVSS0 and between VREFH0 and VREFL0 and between VREFH and VREFL. Additionally, connect a protection circuit to protect the analog input pins as shown in Figure 39.44.



Note 1. The values shown here are reference values.
Note 2. Rin: Signal source impedance

Figure 39.44 Example protection circuit for analog inputs

39.6.13 Port Settings When Using the ADC12 Input

When using the high-precision channels, do not use PORT0 as digital output ports. Renesas recommends that you do not use the digital output that is also used as the AD analog input if normal-precision channel is used. If the digital output that is also used as the AD analog input is used for output signals, perform A/D conversion several times, eliminate the maximum and minimum values, and obtain the average of the other results.

39.6.14 Relationship between ADC12 Units 0 and 1 and the ACMPHS

For the A/D conversion targets in Table 39.29, unit 0 and 1 cannot perform A/D conversion at the same time.

Table 39.29 A/D conversion targets that are mutually exclusive with each other

A/D conversion target	
Unit 0	**Unit 1**
Temperature sensor	
Internal reference voltage	
AN016	AN116
AN017	AN117
AN018	AN118
AN019	AN119

The A/D conversion targets in Table 39.30 should not be selected as ACMPHS input during A/D conversion, because these pins are multiplexed with the ADC12 and ACMPHS.

Table 39.30 A/D conversion targets that are mutually exclusive with ACMPHS

A/D conversion target		
Unit 0	**Unit 1**	**ACMPHS**
AN000	-	ACMPHS0.IVCMP2
AN002	-	ACMPHS0.IVCMP3
AN005	-	ACMPHS0.IVCMP0
AN007/DA0	-	ACMPHS0.IVREF3
AN016	AN116	ACMPHS1.IVCMP0
Internal reference voltage	-	ACMPHS0.IVREF2
-	AN100	ACMPHS1.IVCMP2
-	AN101	ACMPHS1.IVREF0
-	AN102	ACMPHS1.IVCMP3
-	AN104	ACMPHS1.IVREF1
-	AN105/DA1	ACMPHS1.IVCMP1
-	Internal reference voltage	ACMPHS1.IVREF2

39.6.15 Calculation for Sampling Time

The sampling time can be easily estimated by the following figure and formula. This is the time to reach the voltage within 1/4 LSB.

$$t_{SPL} = (R_{EXT} + R_{AD}) \times (C_{EXT} + C_{AD}) \times \ln (C_{AD} / (C_{EXT} + C_{AD}) \times 2^{N+2})$$

R_{EXT} shows external signal source impedance
C_{EXT} shows external capacitance (pin capacitance*1 + PCB parasitic capacitance)
N = 12, 10 or 8 (conversion resolution)
C_{AD} = 5 pF (internal capacitance)
R_{AD} = 1.0 kΩ (internal resistance, case of high-speed channels)
R_{AD} = 2.0 kΩ (internal resistance, case of normal-speed channels)

Note 1. Typical value of analog input pin is 5 pF

For example, if R_{EXT} is 1 kΩ, C_{EXT} is 10 pF and N is 12 bits, t_{SPL} of high-speed channel is 258 ns.

This formula simplifies the general use case. This formula is not guaranteed and should be used only for estimation.

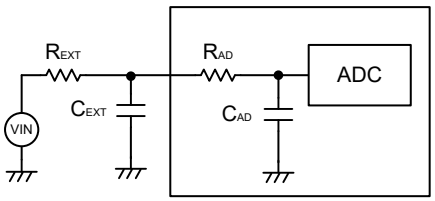


Figure 39.45 Sample and hold circuit simplified diagram

39.6.16 Notes on simultaneous operation with other modules

The following combinations may degrade the ADC accuracy depending on the specific timing of operation.

1. AN000 without channel-dedicated sample-and-hold and AN104 mutually.
2. AN007 and AN105 mutually.
3. Normal-precision channel of unit 0 and 1 mutually when these pins are adjacent or one pin apart.
4. AN000 to AN002 using channel-dedicated sample-and-hold when ADC unit 1, DAC12 or ACMPHS is operated.
5. High-precision channels of ADC unit1 when AN000 to AN002 using channel-dedicated sample-and-hold are operated.
6. AN019 when DAC12 or ACMPHS is operated.
7. AN119 to AN122 when DAC12 is operated in DCDC mode.
8. All channels of ADC unit 1 when ACMPHS is operated.
9. All channels of ADC unit 1 when DAC12 is operated.

To mitigate deterioration, it is recommended to take following measures.

- Performing A/D conversion with average mode.
- For even better results, performing A/D conversion several times, eliminate the maximum and minimum values, and obtain the average of the other results. (For the condition No.4, only performing average mode may not be effective depending on the noise. Eliminating the maximum and minimum is recommended.)
- For the condition No.9, using DA AD synchronous conversion set by DAADSCR.DAADST and DAADUSR.AMADSEL1 bits of DAC12.

Depending on the environment, ADC accuracy may be deteriorated even under conditions not listed here.

40. 12-Bit D/A Converter (DAC12)

40.1 Overview

The MCU provides a 12-bit D/A Converter (DAC12) with an output amplifier. Table 40.1 lists the DAC12 specifications, Figure 40.1 shows a block diagram, and Table 40.2 lists the I/O pins.

Table 40.1 DAC12 specifications

Parameter	Specifications
Resolution	12 bits
Output channels	2 channels
Interference reduction between analog modules	Methods provided to minimize interference between D/A and A/D conversion: • D/A converted data update timing is controlled by the synchronous D/A conversion enable input signal from the ADC12 (unit 1) • Degradation of A/D conversion accuracy caused by interference is reduced by controlling the DAC12 inrush current generation timing with the enable signal.
Module-stop function	Module-stop state can be set to reduce power consumption
Event link function (input)	The DA0 and DA1 conversion can be started on input of an event signal
D/A output amplifier control function	Controls whether the output amplifier (for both amplifier-through and amplifier-bias controls) is used
Destination of D/A output control function	Controls whether the output to the external pin or to the internal modules (ACMPHS) is used
TrustZone Filter	Security and Privilege attribution can be set

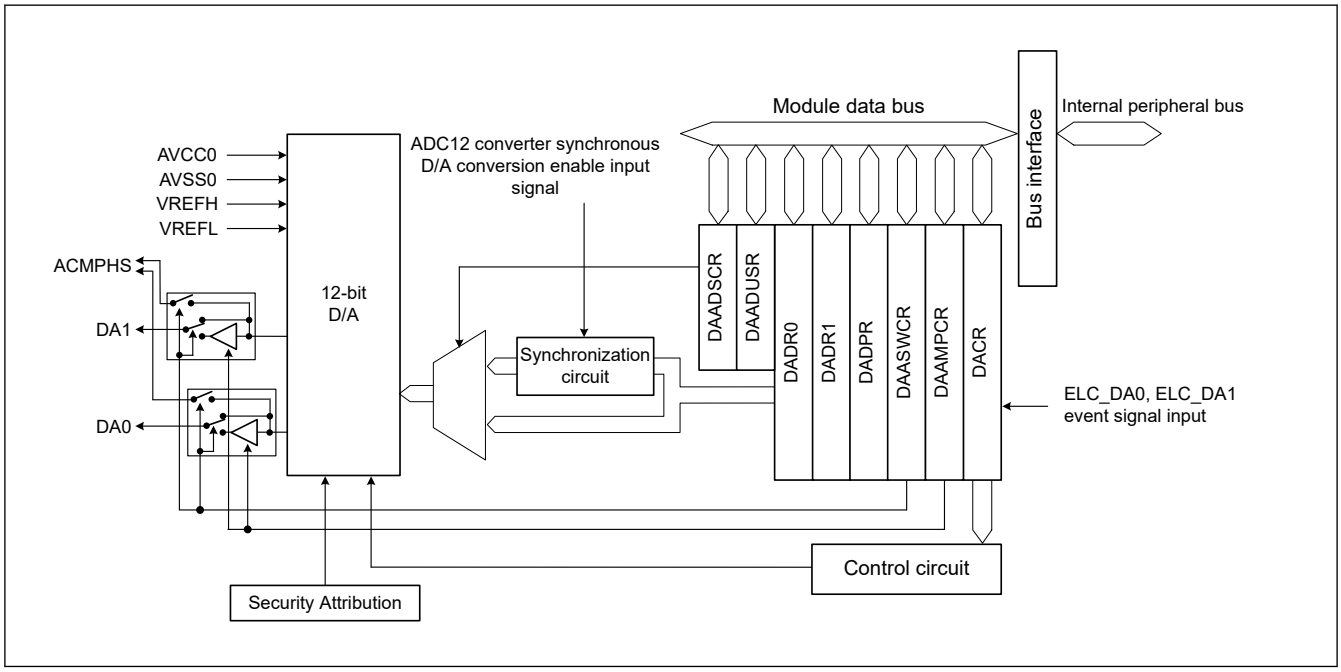

Figure 40.1 DAC12 block diagram

Table 40.2 lists the pin configuration of the DAC12.

Table 40.2 DAC12 I/O pins (1 of 2)

Pin name	I/O	Function
AVCC0	Input	• Analog power and analog reference top voltage supply pin for TSN, ADC12, and DAC12. • Connect to VCC when these modules are not used.
AVSS0	Input	• Analog ground and analog reference ground supply pin for TSN, ADC12, and DAC12. • Connect to VSS when these modules are not used.
VREFH	Input	Analog reference top voltage supply pin for the ADC12 (unit 1) and the DAC12

Table 40.2 DAC12 I/O pins (2 of 2)

Pin name	I/O	Function
VREFL	Input	Analog reference ground pin for the ADC12 (unit 1) and the DAC12
DA0	Output	Channel 0 output pin for the analog signals processed by the DAC12
DA1	Output	Channel 1 output pin for the analog signals processed by the DAC12

40.2 Register Descriptions

40.2.1 DADRn : D/A Data Register n (n = 0, 1)

Base address: DAC12 = 0x4033_3000
DAC12_NS = 0x5033_3000

Offset address: 0x00 + 0x02 × n

Bit position:	15															0
Bit field:																
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Note: S-TYPE-3, P-TYPE-3

DADRn register is 16-bit read/write registers that store data for D/A conversion. When an analog output is enabled, the values in DADRn are converted and output to the analog output pins.

12-bit data can be formatted as left- or right-justified in the DADPR.DPSEL bit setting. In right-justified format (DADPR.DPSEL = 0), the lower 12 bits, [11:0], are valid. In left-justified format (DADPR.DPSEL = 1), the upper 12 bits, [15:4], are valid.

40.2.2 DACR : D/A Control Register

Base address: DAC12 = 0x4033_3000
DAC12_NS = 0x5033_3000

Offset address: 0x04

Bit position:	7	6	5	4	3	2	1	0
Bit field:	DAOE1	DAOE0	DAE	—	—	—	—	—
Value after reset:	0	0	0	1	1	1	1	1

Bit	Symbol	Function	R/W
4:0	—	These bits are read as 1. The write value should be 1.	R/W
5	DAE*1	D/A Enable 0: Control D/A conversion of channels 0 and 1 individually 1: Control D/A conversion of channels 0 and 1 collectively	R/W
6	DAOE0	D/A Output Enable 0 0: Disable D/A conversion and analog output of channel 0 (DA0) 1: Enable D/A conversion and analog output of channel 0 (DA0)	R/W
7	DAOE1	D/A Output Enable 1 0: Disable D/A conversion and analog output of channel 1 (DA1) 1: Enable D/A conversion and analog output of channel 1 (DA1)	R/W

Note: S-TYPE-3, P-TYPE-3
Note 1. This bit controls D/A conversion and analog output in combination with the DAOEi bit (i = 0, 1), which controls the output of the conversion results. For details, see Table 40.3.

Table 40.3 D/A conversion controls

DAE	DAOE1	DAOE0	Description
0	0	0	Disable D/A conversion and analog output pins (DA0, DA1)*1
		1	• Enable D/A conversion of channel 0 and disable D/A conversion of channel 1 • Enable analog output of channel 0 (DA0) and disable analog output of channel 1 (DA1)*1
	1	0	• Disable D/A conversion of channel 0 and enable D/A conversion of channel 1 • Disable analog output of channel 0 (DA0)*1 and enable analog output of channel 1 (DA1)
		1	• Enable D/A conversion of channels 0 and 1 • Enable analog output of channels 0 and 1 (DA0, DA1)
1	x	x	• Enable D/A conversion of channels 0 and 1 • Collective enable analog output of channels 0 and 1 (DA0, DA1)

Note: x: Don't care
Note 1. When analog output is disabled, the analog output signal is placed in the Hi-Z state.

Only set this register while the ADC12 is halted when the DAADSCR.DAADST bit is 1 (interference reduction between D/A and A/D conversion is enabled). Only set DACR while the ADCSR.ADST bit is 0 and after selecting the software trigger, for the ADC12 trigger to securely stop the ADC12. This MCU only supports ADC12 (unit 1).

DAE bit (D/A Enable)

The DAE bit controls D/A conversion, amplifier operation, and analog output in combination with the DAOEi bit (i = 0, 1), the DAAMPCR.DAAMPi bit (i = 0, 1) and the DAASWCR.DAASWi bit (i = 0, 1). See Table 40.4.

When interference reduction between D/A and A/D conversions is enabled (DAADSCR.DAADST = 1), set the ADCSR.ADST bit of the ADC12 (unit 1) to 0. Then, select the software trigger for the ADC12 (unit 1) trigger to securely stop the ADC12 (unit 1).

DAOEi bit (D/A Output Enable i)

The DAOEi bit (i = 0, 1) controls D/A conversion, amplifier operation, and analog output in combination with the DAE bit, DAAMPCR.DAAMPi bit (i = 0, 1) and the DAASWCR.DAASWi bit (i = 0, 1). See Table 40.4.

When both the DAOEi bit (i = 0, 1) and DAE bit are 0, D/A conversion of channel i (i = 0, 1) is not processed, and no conversion result is output.

When interference reduction between D/A and A/D conversions is enabled (DAADSCR.DAADST = 1), set the DAOEi bit while the ADCSR.ADST bit of the ADC12 (unit 1) is set to 0. Then, select the software trigger for the ADC12 (unit 1) trigger to securely stop the ADC12 (unit 1).

The event link function can be used to set the DAOEi bit to 1. The DAOE0 bit is set to 1 when the event specified in the ELSR12 register of the ELC (ELC_DA0 event) occurs, and output of the D/A conversion results starts. The DAOE1 bit is set to 1 when the event specified in the ELSR13 register of the ELC (ELC_DA1 event) occurs, and output of the D/A conversion results starts.

Table 40.4 D/A conversion and analog output control

DACR		DAAMPCR	DAASWCR	Channel i operation	Amplifier operation of channel i	Analog external output of channel i*1	Analog internal output of channel i*2
DAE	DAOEi	DAAMPi	DAASWi				
0	0	x	x	Stop	Stop	Hi-Z	Hi-Z
0	1	0	0	Run	Stop	Amplifier-through	Hi-Z
0	1	0	1	Run	Stop	Hi-Z	Amplifier-through
0	1	1	0	Run	Run	Amplifier output	Hi-Z
0	1	1	1	Run	Run	Hi-Z	Hi-Z
1	x	0	0	Run	Stop	Amplifier-through	Hi-Z
1	x	0	1	Run	Stop	Hi-Z	Amplifier-through
1	x	1	0	Run	Run	Amplifier output	Hi-Z
1	x	1	1	Run	Run	Hi-Z	Hi-Z

Note: x : Don't care
Note 1. output to pin
Note 2. output to ACMPHS

40.2.3 DADPR : DADRn Format Select Register

Base address: DAC12 = 0x4033_3000
DAC12_NS = 0x5033_3000

Offset address: 0x05

Bit position:	7	6	5	4	3	2	1	0
Bit field:	DPSEL	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
6:0	—	These bits are read as 0. The write value should be 0.	R/W
7	DPSEL	DADRn Format Select 0: Right-justified format 1: Left-justified format	R/W

Note: S-TYPE-3, P-TYPE-3

40.2.4 DAADSCR : D/A A/D Synchronous Start Control Register

Base address: DAC12 = 0x4033_3000
DAC12_NS = 0x5033_3000

Offset address: 0x06

Bit position:	7	6	5	4	3	2	1	0
Bit field:	DAADST	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
6:0	—	These bits are read as 0. The write value should be 0.	R/W
7	DAADST	D/A A/D Synchronous Conversion 0: Do not synchronize DAC12 with ADC12 (unit 1) operation (disable interference reduction between D/A and A/D conversion). 1: Synchronize DAC12 with ADC12 (unit 1) operation (enable interference reduction between D/A and A/D conversion).	R/W

Note: S-TYPE-3, P-TYPE-3

To minimize interference between D/A and A/D conversion, the DAADSCR register enables synchronization of the start timing of D/A conversion with the ADC12 synchronous D/A conversion enable input signal.

Only set this register while the ADC12 (unit 1) is halted, that is, while the ADCSR.ADST bit is 0 after selecting the software trigger as the ADC12 (unit 1) trigger.

Select unit 1 as the target ADC12 unit before setting the DAADST bit to 1. Set DAADUSR.AMADSEL1 bit to 1 to select unit 1. This MCU only supports ADC12 unit 1.

DAADST bit (D/A A/D Synchronous Conversion)

Setting the DAADST bit to 0 allows the DADRn register value to be converted into analog data at any time. Setting the DAADST bit to 1 allows synchronization of D/A conversion with the synchronous D/A conversion enable input signal from the ADC12 (unit 1). With this bit set, D/A conversion does not start until the ADC12 (unit 1) completes A/D conversion, even when the DADRn register is changed.

Set this bit while the ADCSR.ADST bit is set to 0. Then, select the software trigger for the ADC12 (unit 1) trigger to securely stop the ADC12 (unit 1). Set the DAADUSR.AMADSEL1 bit to 1 before setting the DAADST bit to 1.

The event link function cannot be used when the DAADST bit is set to 1. Stop the event link function by setting the ELSR12 and ELSR13 registers of the ELC. The setting of the DAADST bit is shared by channels 0 and 1 of the DAC12.

40.2.5 DAAMPCR : D/A Output Amplifier Control Register

Base address: DAC12 = 0x4033_3000
DAC12_NS = 0x5033_3000

Offset address: 0x08

Bit position:	7	6	5	4	3	2	1	0
Bit field:	DAAMP1	DAAMP0	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
5:0	—	These bits are read as 0. The write value should be 0.	R/W
6	DAAMP0	Amplifier Control 0 0: Do not use channel 0 output amplifier 1: Use channel 0 output amplifier	R/W
7	DAAMP1	Amplifier Control 1 0: Do not use channel 1 output amplifier 1: Use channel 1 output amplifier	R/W

Note: S-TYPE-3, P-TYPE-3

The DAAMPCR register selects D/A output with or without using the amplifier.

DAAMP0 bit (Amplifier Control 0)

When the DAAMP0 bit is 0, analog values are output for D/A output of channel 0 without using the amplifier. When the DAAMP0 bit is 1, analog values are output for D/A output of channel 0 through the amplifier.

When both the DACR.DAE and DACR.DAOE0 bits are 0, the amplifier is not used regardless of the setting of the DAAMP0 bit. See Table 40.4 for details.

DAAMP1 bit (Amplifier Control 1)

When the DAAMP1 bit is 0, analog values are output for D/A output of channel 1 without using the amplifier. When the DAAMP1 bit is 1, analog values are output for D/A output of channel 1 through the amplifier.

When both the DACR.DAE and DACR.DAOE1 bits are 0, the amplifier is not used regardless of the setting of the DAAMP1 bit. See Table 40.4 for details.

40.2.6 DAASWCR : D/A Amplifier Stabilization Wait Control Register

Base address: DAC12 = 0x4033_3000
DAC12_NS = 0x5033_3000

Offset address: 0x1C

Bit position:	7	6	5	4	3	2	1	0
Bit field:	DAASW1	DAASW0	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
5:0	—	These bits are read as 0. The write value should be 0.	R/W
6	DAASW0	D/A Amplifier Stabilization Wait 0 and D/A internal output control 0: For output to external pin: Amplifier stabilization wait off (output) for channel 0 For output to internal module: Disable output for channel 0 1: For output to external pin: Amplifier stabilization wait on (high-Z) for channel 0 For output to internal module: Enable output for channel 0	R/W

Bit	Symbol	Function	R/W
7	DAASW1	D/A Amplifier Stabilization Wait 1 and D/A internal output control 0: For output to external pin: Amplifier stabilization wait off (output) for channel 1 For output to internal module: Disable output for channel 1 1: For output to external pin: Amplifier stabilization wait on (high-Z) for channel 1 For output to internal module: Enable output for channel 1	R/W

Note: S-TYPE-3, P-TYPE-3

The DAASWCR register controls D/A output with the output amplifier or D/A output for internal modules. This register is used in the initialization procedure to wait for stabilization of the D/A output amplifier. Each bit in DAASWCR should be set to 1 when both the DACR.DAE bit and the DACR.DAOEi (i = 0, 1) bit are 0. See section 40.7.5. Initialization Procedure with the Output Amplifier.

DAASW0 bit (D/A Amplifier Stabilization Wait 0)

Set the DAASW0 bit to 1 in the initialization procedure to wait for the stabilization of the D/A channel 0 output amplifier. When DAASW0 is set to 1, D/A conversion operates, but the conversion result of D/A is not output from channel 0 to the DA0 pin. When the DAASW0 bit is 0, the stabilization wait time stops, and the D/A conversion result of channel 0 is output through the output amplifier to the DA0 pin. When the amplifier is not used (DAAMPCR.DAAMP0 bit is 0) and DAASW0 is set to 1, D/A conversion result of channel 0 is output to the internal modules.

DAASW1 bit (D/A Amplifier Stabilization Wait 1)

Set the DAASW1 bit to 1 in the initialization procedure to wait for the stabilization of the D/A channel 1 output amplifier. When DAASW1 is set to 1, D/A conversion operates, but the conversion result of D/A is not output from channel 1 to the DA1 pin. When the DAASW1 bit is 0, the stabilization wait time stops, and the D/A conversion result of channel 1 is output through the output amplifier to the DA1 pin. When the amplifier is not used (DAAMPCR.DAAMP1 bit is 0) and DAASW1 is set to 1, D/A conversion result of channel 1 is output to the internal modules.

40.2.7 DAADUSR : D/A A/D Synchronous Unit Select Register

Base address: DAC12 = 0x4033_3000
DAC12_NS = 0x5033_3000

Offset address: 0x10C0

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	AMADSEL1	—
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	—	This bit is read as 0. The write value should be 0.	R/W
1	AMADSEL1	A/D Unit 1 Select 0: Do not select unit 1 1: Select unit 1	R/W
7:2	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

The DAADUSR register selects the target ADC12 unit for D/A and A/D synchronous conversions. Set the AMADSEL1 bit to 1 to select unit 1 as the target synchronous unit for the MCU. When setting the DAADSCR.DAADST bit to 1 for synchronous conversions, select the target unit in this register in advance.

Only set the DAADUSR register while the ADCSR.ADST bit of the ADC12 is set to 0 and the DAADSCR.DAADST bit is set to 0.

40.3 Operation

The DAC12 includes D/A conversion circuits for two channels, each of which can operate independently. When the DAOEn bit (n = 0, 1) in DACR is set to 1, DAC12 is enabled and the conversion result is output.

This following example shows D/A conversion on channel 0. Figure 40.2 shows the timing of this operation.

To process D/A conversion on channel 0:

1. Set the data for D/A conversion in the DADR0 register and the data format in the DADPR.DPSEL bit.
2. Set the DACR.DAOE0 bit to 1 to start D/A conversion. The conversion result is output from the analog output pin DA0 after the conversion time t_{DCONV} elapses. The conversion result continues to be output until DADR0 is written to again or the DAOE0 bit is set to 0. The output value (reference) is expressed by the following formula:

$$\frac{\text{Setting in DADR0}}{4096} \times \text{VREFH}$$

3. To start conversion again, write another value to DADR0. The conversion result is output after the conversion time t_{DCONV} elapses.
   When the DAADSCR.DAADST bit is 1 (interference reduction between D/A and A/D conversion is enabled), a maximum of one A/D conversion time is required for D/A conversion to start. When ADCLK is faster than the peripheral clock, a longer time might be required.
4. To disable analog output, set the DAOE0 bit to 0.

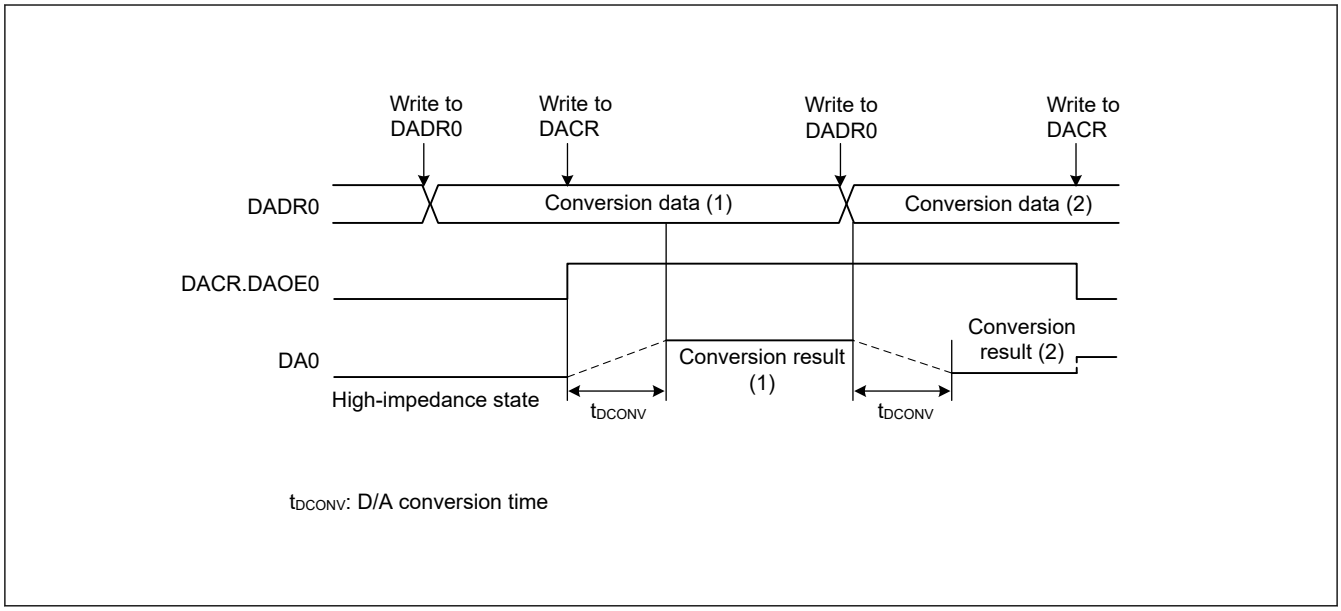

Figure 40.2 Example of DAC12 operation

40.3.1 Reducing Interference between D/A and A/D Conversion

When D/A conversion starts, the DAC12 generates inrush current. Because the DAC12 and ADC12 (unit 1) share the same analog power supply, the generated inrush current can interfere with ADC12 (unit 1) operation.

While the DAADSCR.DAADST bit is 1, D/A conversion does not start immediately on updating the DADRm register. Instead:

- If the DADRm register data is modified while the ADC12 is halted, D/A conversion starts in 1 PCLKA cycle.
- If the DADRm register data is modified while the ADC12 is performing a 12-bit A/D conversion, D/A conversion starts on A/D conversion completion. Therefore, it takes up to one A/D conversion time period for the DADRm register data update to be reflected as the D/A conversion circuit output. Until the D/A conversion completes, the DADRm register value does not correspond to the analog output value.

When the DAADSCR.DAADST bit is 1, it is not possible to check through software whether the DADRm register value was D/A-converted.

The following sequence provides an example of channel 0 D/A conversion, in which the DAC12 is synchronized with the ADC12 (unit 1). Figure 40.3 shows the timing of this operation.

To perform D/A conversion on channel 0 in synchronization with the ADC12 (unit 1):

1. Confirm that the ADC12 (unit 1) is halted and set the DAADUSR.AMADSEL1 bit to 1.

2. Confirm that the ADC12 (unit 1) is halted and set the DAADSCR.DAADST bit to 1.
3. Confirm that the ADC12 (unit 1) is halted and set the DACR.DAOE0 bit to 1.
4. Set the DADR0 register. If ADCLK is faster than the peripheral clock, D/A conversion might be delayed for longer than one A/D conversion time.
   - If the ADC12 (unit 1) is halted (ADCSR.ADST = 0) when the DADR0 register is modified, D/A conversion starts in 1 PCLKA cycle.
   - If the 12-bit A/D conversion is in progress (ADCSR.ADST = 1) when the DADR0 register is modified, D/A conversion starts on A/D conversion completion. If the DADR0 register is modified twice during A/D conversion, the first update might not be converted.

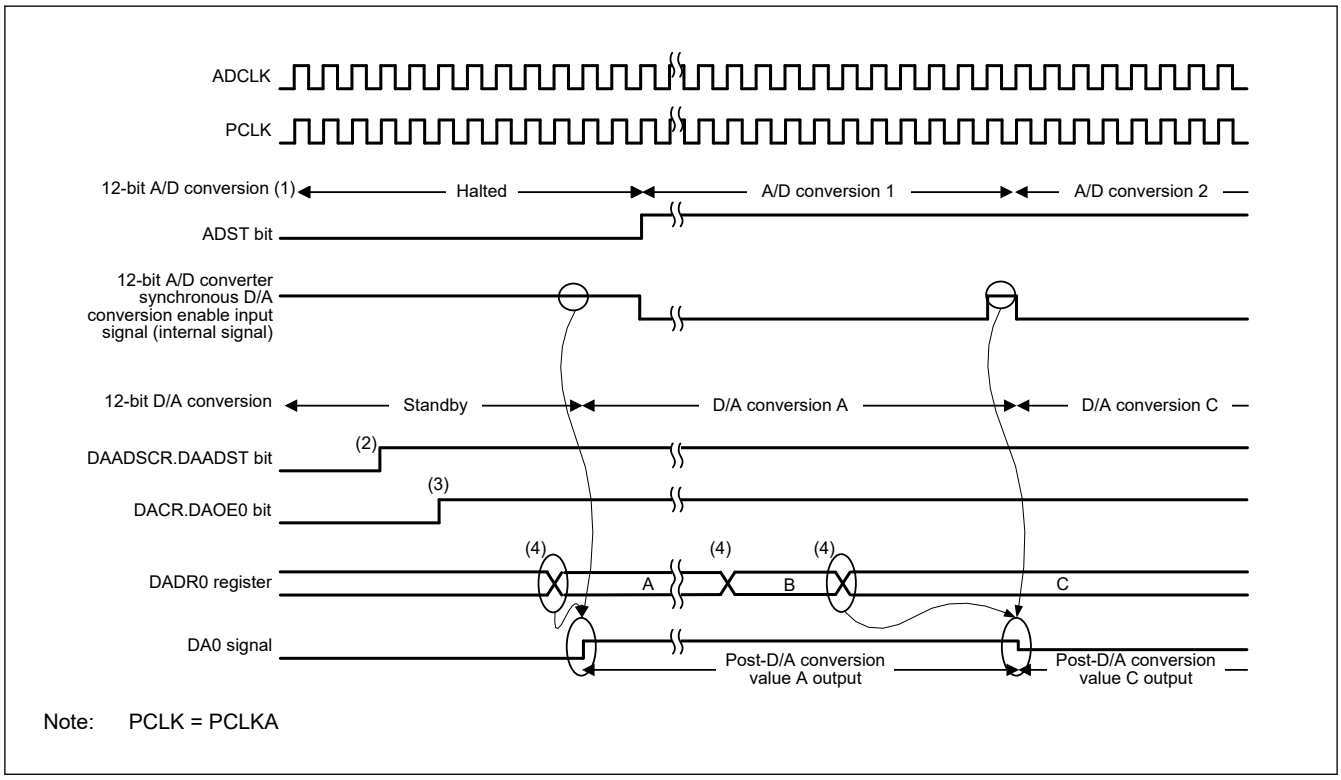

Figure 40.3 Example conversion when DAC12 is synchronized with ADC12 (unit 1)

When ADCLK is faster than PCLKA, the DAC12 might not be able to capture the synchronous D/A conversion enable input signal from the ADC12 (unit 1) during the 1 ADCLK cycle that is output between A/D conversion 1 and A/D conversion 2, as shown in Figure 40.4. In this case, post-D/A conversion value A is continuously output as the DA0 signal.

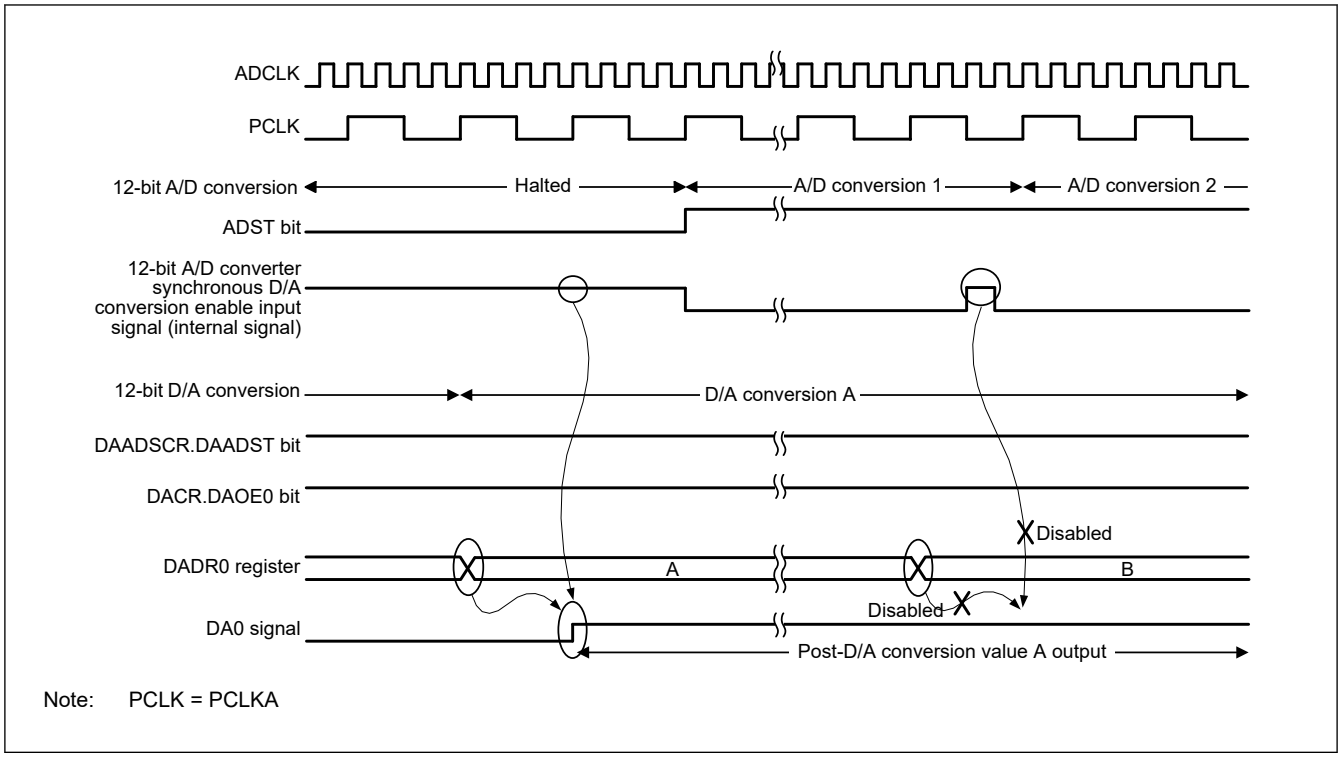

Figure 40.4 Example when the DAC12 cannot capture the synchronous D/A conversion enable input signal from the ADC12 (unit 1)

40.4 Event Link Operation Setting Procedure

This section describes the procedures used in event link operation.

40.4.1 DA0 Event Link Operation Setting Procedure

To set up DA0 event link operation:

1. Set the DADPR.DPSEL bit and the data for D/A conversion in the DADR0 register.
2. Set the ELC_DA0 event signal to be linked to each peripheral module in the ELSR12 register.
3. Set the ELCR.ELCON bit to 1. This enables event link operation for all modules with the event link function selected.
4. Set the event output source module to activate the event link. After the event is output from the module, the DACR.DAOE0 bit becomes 1, and D/A conversion starts on channel 0.
5. Set the ELSR12 register to 0x0000 to stop event link operation of DAC12 channel 0. All event link operation is stopped when the ELCR.ELCON bit is set to 0.

40.4.2 DA1 Event Link Operation Setting Procedure

To set up DA1 event link operation:

1. Set the DADPR.DPSEL bit and set the data for D/A conversion in the DADR1 register.
2. Set the ELC_DA1 event signal to be linked to each peripheral module in the ELSR13 register.
3. Set the ELCR.ELCON bit to 1. This enables the event link operation for all modules with the event link function selected.
4. Set the event output source module to activate the event link. After the event is output from the module, the DACR.DAOE1 bit is becomes 1, and D/A conversion starts on channel 1.
5. Set the ELSR13 register to 0x0000 to stop event link operation on DAC12 channel 1. All event link operation is stopped when the ELCR.ELCON bit is set to 0.

40.5 Analog Output Control by Security Attribution

Analog output to DA0/DA1 pin is controlled by the security attribution of Port and DAC12 as shown in Table 40.5.

Analog output to ACMPHS is not controlled by the security attribution.

Table 40.5 Analog output control by security attribution

Security Attribution			Analog Output	
DAC12 (PSARD)	P014 (PmSAR (m = 0~9, A, B))	P015 (PmSAR (m = 0~9, A, B))	P014 pin output	P015 pin output
0 (secure)	1 (non-secure)	1 (non-secure)	enable	enable
0 (secure)	1 (non-secure)	0 (secure)	enable	enable
0 (secure)	0 (secure)	1 (non-secure)	enable	enable
0 (secure)	0 (secure)	0 (secure)	enable	enable
1 (non-secure)	1 (non-secure)	1 (non-secure)	enable	enable
1 (non-secure)	1 (non-secure)	0 (secure)	enable	disable
1 (non-secure)	0 (secure)	1 (non-secure)	disable	enable
1 (non-secure)	0 (secure)	0 (secure)	disable	disable

40.6 Usage Notes on Event Link Operation

- When the event link function is used, do not use the amplifier output function.
- When the event link function is used, set the DACR.DAE bit to 0.
- When the event specified for the ELC_DA0 event signal is generated while a write to the DACR.DAOE0 bit is performed, the write cycle is stopped, and the generated event takes precedence in setting the bit to 1.
- When the event specified for the ELC_DA1 event signal is generated while a write to the DACR.DAOE1 bit is performed, the write cycle is stopped, and the generated event takes precedence in setting the bit to 1.
- Use of the event link function is prohibited when the DAADSCR.DAADST bit is set to 1 to reduce interference between D/A and A/D conversions.

40.7 Usage Notes

40.7.1 Settings for the Module-Stop Function

DAC12 operation can be disabled or enabled using the Module Stop Control Register. The DAC12 is initially stopped after reset. Releasing the module-stop state enables access to the registers. For details, see section 10, Low Power Modes.

40.7.2 DAC12 Operation in the Module-Stop State

When the MCU enters the module-stop state with D/A conversion enabled, the D/A outputs are retained, and the analog power supply current is the same as during D/A conversion. If the analog power supply current must be reduced in the module-stop state, disable D/A conversion by setting the DACR.DAOE1, DAOE0, and DAE bits to 0.

40.7.3 DAC12 Operation in Software Standby Mode

When the MCU enters Software Standby mode with D/A conversion enabled, the D/A outputs are retained, and the analog power supply current is the same as during D/A conversion. If the analog power supply current must be reduced in Software Standby mode, disable D/A conversion by setting the DACR.DAOE1, DAOE0, and DAE bits to 0.

40.7.4 Constraint on Entering Deep Software Standby Mode

When the MCU enters Deep Software Standby mode with D/A conversion enabled, the outputs of the DAC12 are placed in a high impedance state.

40.7.5 Initialization Procedure with the Output Amplifier

Use the following initialization procedures with the output amplifier. The example shows the case for channel 0.

To initialize the DAC12 with the output amplifier:

1. Write 0x0000 to the DADR0 register.
2. Set the DAASWCR.DAASW0 bit to 1.
3. Set the DAAMPCR.DAAMP0 bit to 1.
4. Set the DACR.DAE bit or the DACR.DAOE0 bit to 1 to start operation of the amplifier.
5. Clear the DAASWCR.DAASW0 bit to 0 after waiting for the duration of D/A conversion time t_{DCONV}.
6. Write the value to be converted in the DADR0 register.

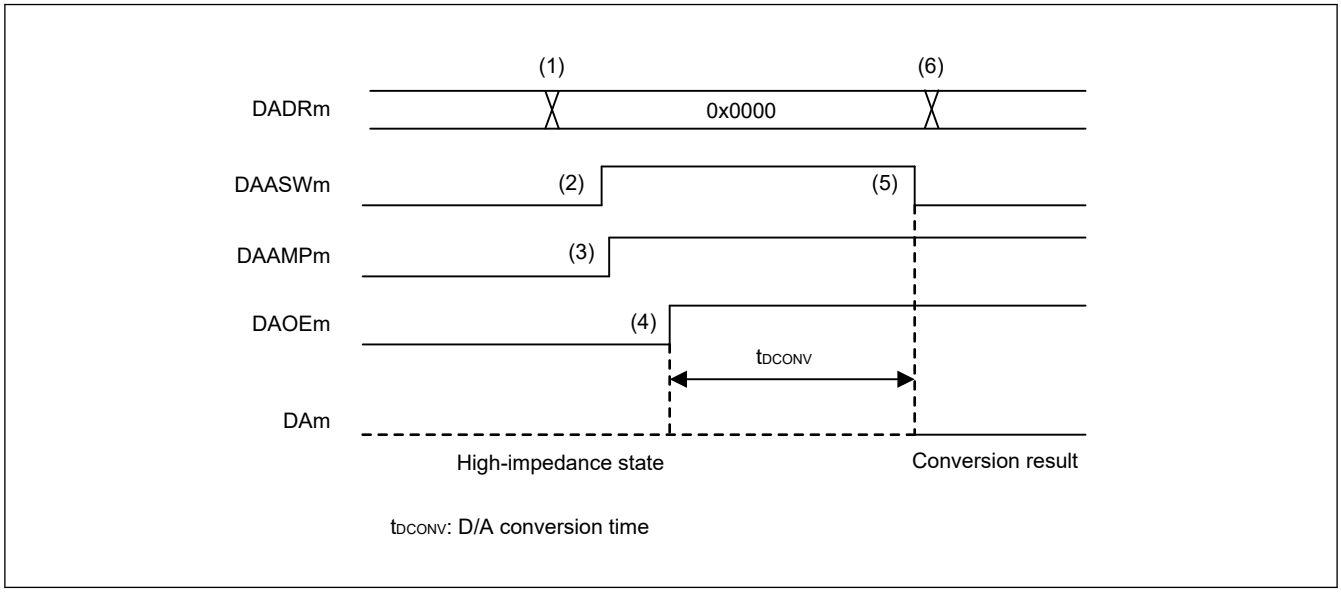

Figure 40.5 Example of the initial flow with the output amplifier in DAC12

While the amplifier is running, clearing the DACR.DAE and DACR.DAOE0 bits to 0 allows the amplifier to stop operation. To use the amplifier again, repeat steps 1 to 6.

40.7.6 Initialization Procedure of the Output to internal modules

Use the following initialization procedures for the output to internal modules.

The example shows the case for channel 0.

1. Set the DAASWCR.DAASW0 bit to 1.
2. Set the DACR.DAE bit or the DACR.DAOE0 bit to 1.
3. Write the value to be converted in the DADR0 register.

When you stop output of the DAC12, set DAASWCR.DAASWi to 0 after setting DACR.DAE to 0 or DACR.DAOEi to 0.

40.7.7 Constraint on Usage When Interference Reduction between D/A and A/D Conversion Is Enabled

When the DAADSCR.DAADST bit is 1, enabling interference reduction between D/A and A/D conversion, do not place the ADC12 in the module-stop state. Doing so can halt D/A conversion in addition to A/D conversion.

41. Temperature Sensor (TSN)

41.1 Overview

The on-chip Temperature Sensor (TSN) determines and monitors the die temperature for reliable operation of the device. The sensor outputs a voltage directly proportional to the die temperature, and the relationship between the die temperature and the output voltage is fairly linear. The output voltage is provided to the ADC12 for conversion and can be further used by the end application.

Table 41.1 lists the TSN specifications, and Figure 41.1 shows a block diagram.

Table 41.1 TSN specifications

Item	Description
Temperature sensor voltage output	Temperature sensor outputs a voltage to the 12-bit A/D converter
Module-stop function	Module-stop state can be set to reduce power consumption
Temperature sensor calibration data	Reference data measured for each chip at factory shipment is stored in a register
TrustZone Filter	Security and Privilege attribution can be set

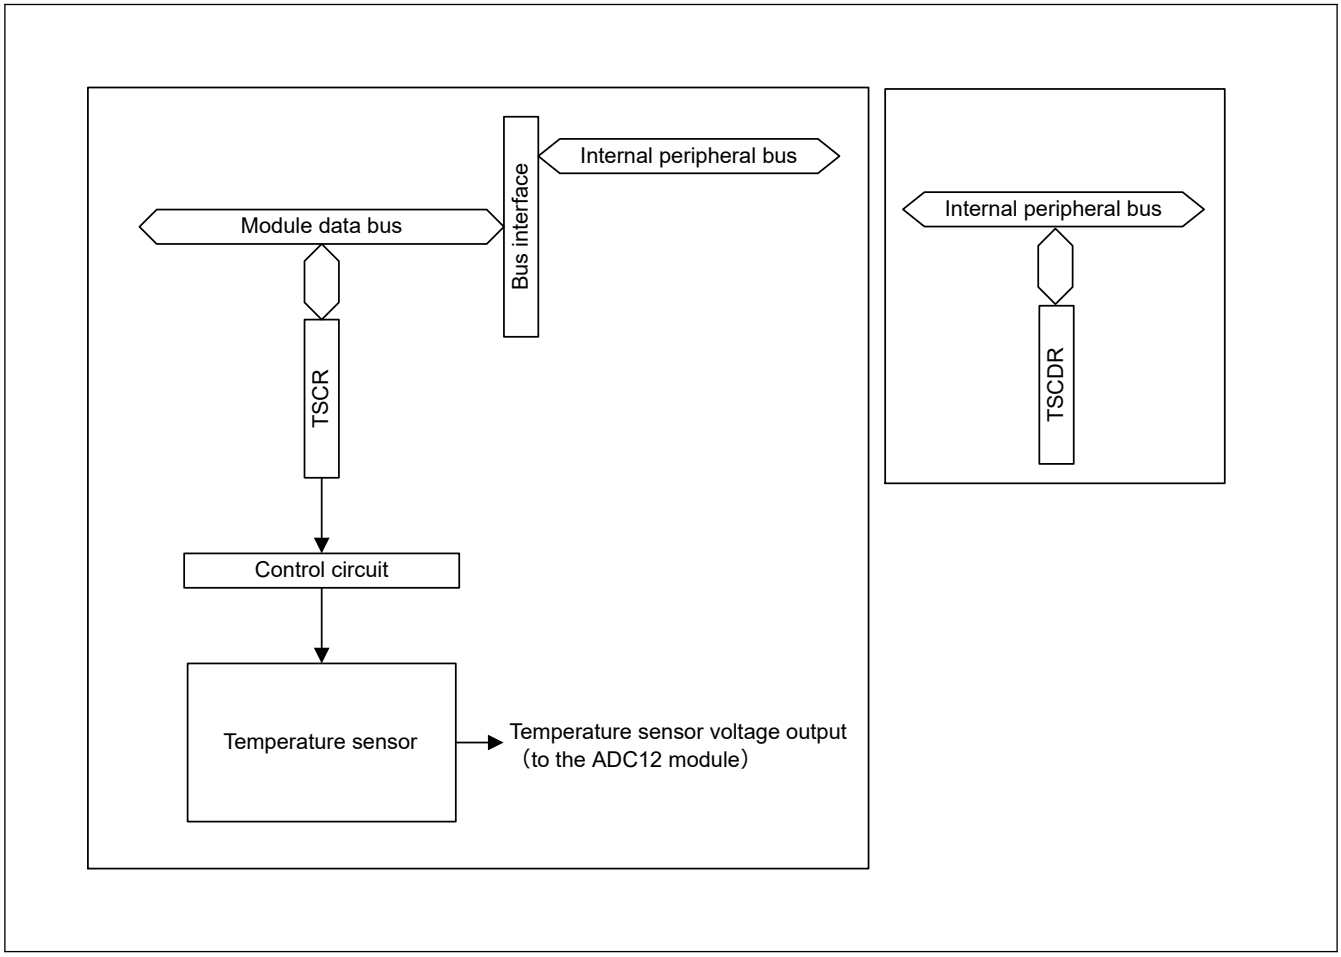

Figure 41.1 TSN block diagram

41.2 Register Descriptions

41.2.1 TSCR : Temperature Sensor Control Register

Base address: TSN = 0x4023_5000
TSN_NS = 0x5023_5000

Offset address: 0x00

Bit position:	7	6	5	4	3	2	1	0
Bit field:	TSEN	—	—	TSOE	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
3:0	—	These bits are read as 0. The write value should be 0.	R/W
4	TSOE	Temperature Sensor Output Enable 0: Disable output from the temperature sensor to the ADC12 1: Enable output from the temperature sensor to the ADC12	R/W
6:5	—	These bits are read as 0. The write value should be 0.	R/W
7	TSEN	Temperature Sensor Enable 0: Stop the temperature sensor 1: Start the temperature sensor.	R/W

Note: S-TYPE3, P-TYPE3

The TSCR is a register which controls the temperature sensor. The timing constraints shown in Figure 41.3 apply to the settings of the TSCR register.

TSOE bit (Temperature Sensor Output Enable)

The TSOE bit enables or disables the temperature sensor output to ADC12.

TSEN bit (Temperature Sensor Enable)

The TSEN bit starts or stops the temperature sensor.

41.2.2 TSCDR : Temperature Sensor Calibration Data Register

Base address: TSD = 0x4011_B000
TSD_NS = 0x5011_B000

Offset Address: 0x017C

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	TSCDR[15:0]															
Value after reset:	Chip-specific value															

Bit	Symbol	Function	R/W
15:0	TSCDR[15:0]	Temperature Sensor Calibration Data Chip-specific value	R
31:16	—	These bits are read as 0.	R

Note: S-TYPE5, P-TYPE5

The TSCDR register stores temperature sensor calibration data measured for each chip at factory shipment.

Temperature sensor calibration data is the output voltage of the temperature sensor under the conditions Tj = 125°C and AVCC0 = VREFH0 = 3.3 V converted to a digital value by the 12-bit A/D converter.

The TSCDR register is a read-only 32-bit register. Read from this register in 32-bit units.

Temperature sensor calibration data is stored in the lower 12 bits of the TSCDR register.

41.3 Using the Temperature Sensor

The temperature sensor outputs a voltage that varies with the temperature. This voltage is converted to a digital value by the 12-bit A/D converter. To obtain the die temperature, convert this value into the temperature.

41.3.1 Preparation for Using the Temperature Sensor

The ambient temperature (T) is proportional to the temperature sensor voltage output (Vs), so ambient temperature is calculated with the following formula:

T = (Vs - V1) / slope + T1

- T: Ambient temperature of MCU as calculation result (°C)
- Vs: Voltage output by the temperature sensor on temperature measurement (V)
- T1: Temperature experimentally measured at one point (°C)
- V1: Voltage output by the temperature sensor on measurement of T1 (V)
- T2: Temperature experimentally measured at a second point (°C)
- V2: Voltage output by the temperature sensor on measurement of T2 (V)
- Slope: Temperature gradient of the temperature sensor (V / °C), slope = (V2 - V1) / (T2 -T1)

Characteristics vary between sensors, so Renesas recommends measuring two different sample temperatures as follows:

1. Use the 12-bit A/D converter to measure the voltage V1 output by the temperature sensor at temperature T1.
2. Again use the 12-bit A/D converter to measure the voltage V2 output by the temperature sensor at a different temperature T2.
3. Obtain the temperature gradient (slope = (V2 - V1) / (T2 - T1)) from these results.
4. Subsequently, obtain temperatures by substituting the slope into the formula for the temperature characteristic (T = (Vs -V1) / slope + T1).

In order to make the temperature Ta and Tj as close as possible, perform the measurement with the power consumption of the MCU as low as possible.

If you are using the temperature gradient given in section 48, Electrical Characteristics, use the A/D converter to measure the voltage V1 output by the temperature sensor at temperature T1, then calculate the temperature characteristic using the following formula:

T = (Vs - V1) / slope + T1

Note: This method produces less accurate temperatures than measurement at two points.

In this MCU, the TSCDR register stores the temperature value (CAL125) of the temperature sensor measured under the condition Ta = Tj = 125°C and AVCC0 = VREFH0 = 3.3 V. If you use this value as the sample measurement result at the first point, you can omit the preparation before using the temperature sensor.

V1 is calculated from CAL125:

V1 = 3.3 × CAL125 / 4096 [V] (In case of 12 bit accuracy)

Using this value, the measured temperature can be calculated according to the following formula:

T = (Vs - V1) / slope + 125 [°C]

- T: Ambient temperature of MCU as calculation result (°C)
- Vs: Voltage output by the temperature sensor when the temperature is measured (V)
- V1: Voltage output by the temperature sensor when Ta = Tj = 125°C and AVCC0 = VREFH0 = 3.3 V (V)

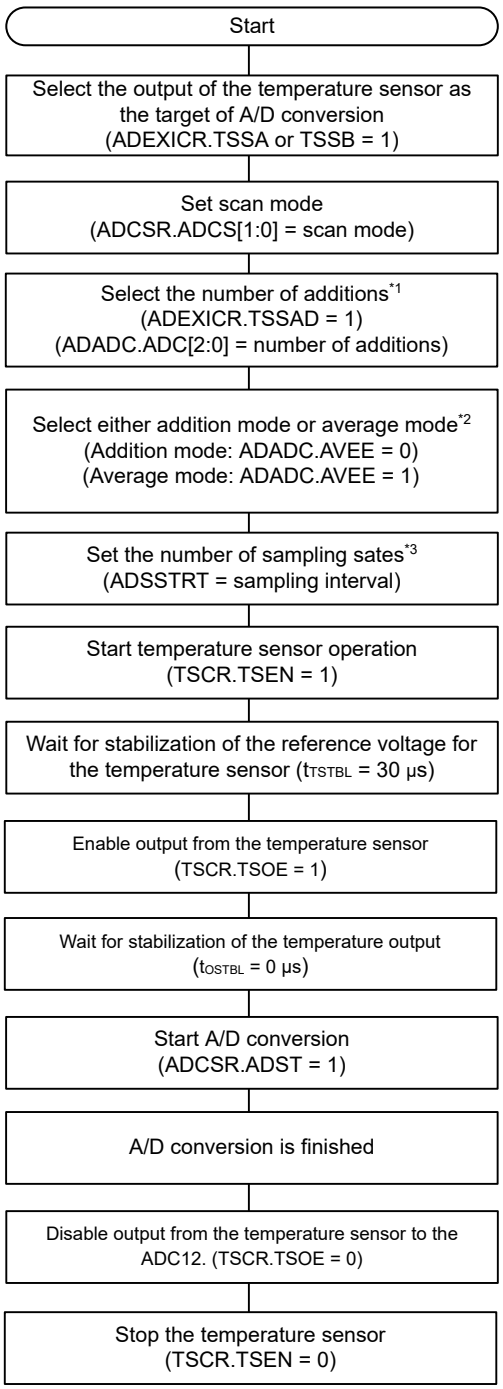
- Slope: Temperature gradient of the temperature sensor*1 / 1000 (V/°C)

Note 1. See section 48, Electrical Characteristics

41.3.2 Procedures for Using the Temperature Sensor

Figure 41.2 shows the procedure for using the TSN.

For details, see section 39, 12-Bit A/D Converter (ADC12).



Note 1. This setting is not required if addition/average mode is not set.
Note 2. The ADADC.ADC[2:0] setting is limited to some values in additions/average mode. For details on the available ADADC.ADC[2:0] settings in additions/average mode, see section 39, 12-Bit A/D Converter (ADC12).
Note 3. Set the sampling time to more than the value described in section 48, Electrical Characteristics.

Figure 41.2 Procedure example for using the TSN

Figure 41.3 shows the timing from the start of temperature sensor operation until the completion of A/D conversion when the ADC12 is in single scan mode (the conversion target is the temperature sensor output only). The times shown in the figure are described in Table 41.2

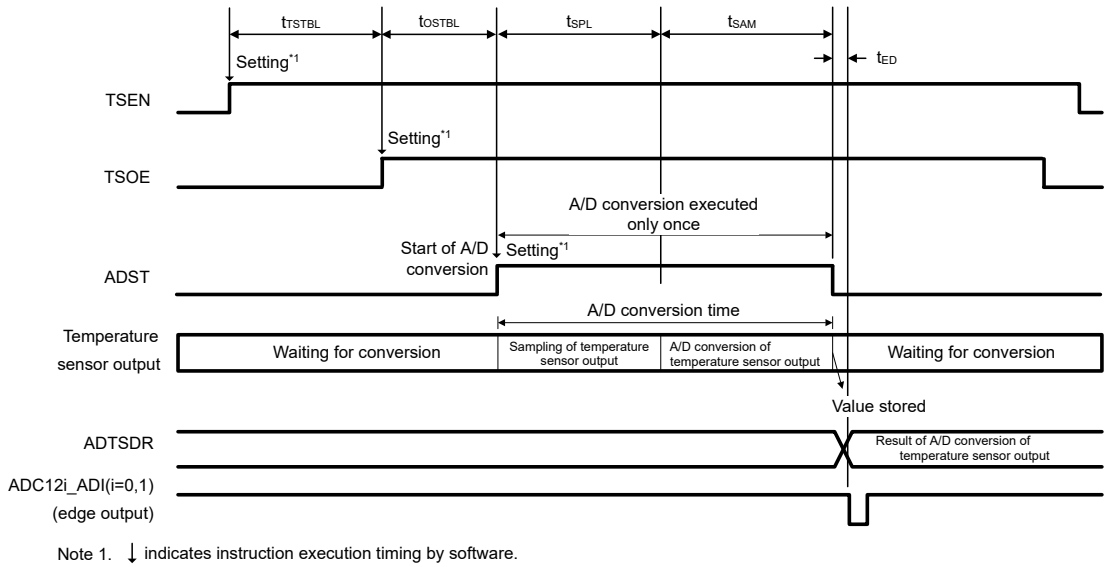


Figure 41.3 Timing from start of temperature sensor operation until completion of A/D conversion

Table 41.2 Time until completion of A/D conversion after start of temperature sensor operation

Parameter	Symbol	Time
Wait time for temperature sensor reference voltage stabilization	t_{TSTBL}	30 µs (min)
Wait time for temperature sensor output stabilization	t_{OSTBL}	0 µs (min)
A/D converter input sampling time	t_{SPL}	ADSSTRn setting × ADCLK period
A/D conversion time	t_{SAM}	See the table in section 39.3.6. Analog Input Sampling and Scan Conversion Time.
Scan conversion end delay	t_{ED}	

41.4 Usage Notes

41.4.1 Settings for the Module-Stop Function

TSN operation can be disabled or enabled using the associated bit in Module Stop Control Register D (MSTPCRD). The TSN is initially stopped after reset. Releasing the module-stop state enables access to the registers. For details, see section 10, Low Power Modes.

41.4.2 Settings for the Software Standby Mode

Before entering Software Standby Mode, set TSCR.TSOE bit to 0 after stopping A/D conversion, then set TSCR.TSEN bit to 0 to stop the TSN.

42. High-Speed Analog Comparator (ACMPHS)

42.1 Overview

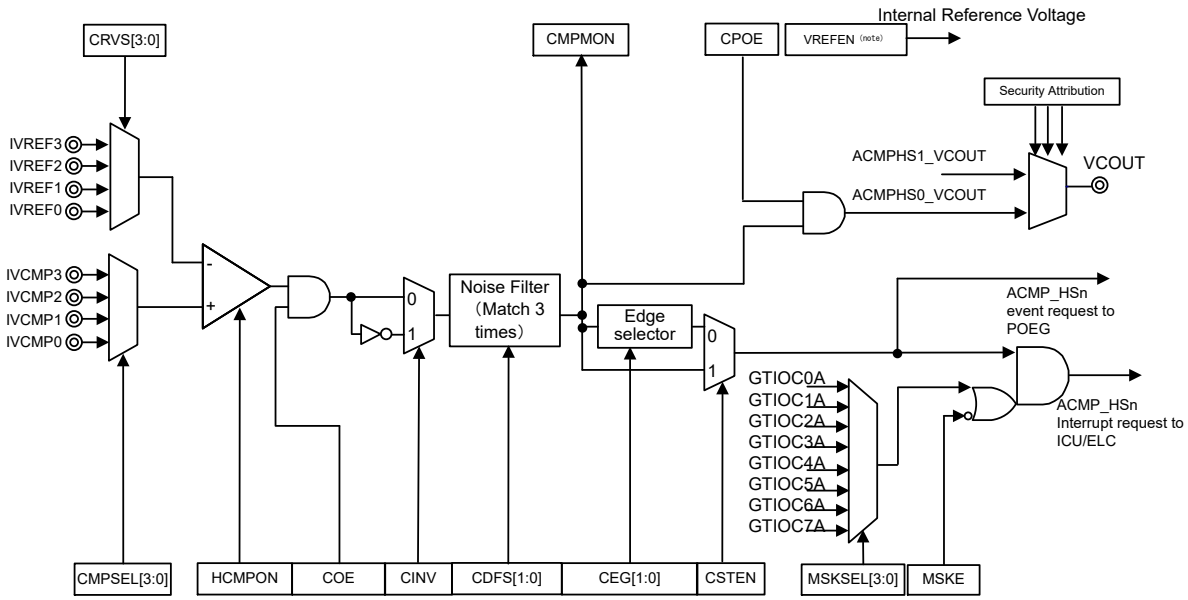
The High-Speed Analog Comparator (ACMPHS) can be used to compare an analog input voltage with a reference voltage and to provide a digital output based on the result of conversion. Both the analog input voltage and the reference voltage can be provided to the ACMPHS from internal sources (D/A converter output or internal reference voltage) and an external source. Such flexibility is useful in applications that require go/no-go comparisons to be performed between analog signals without necessarily requiring A/D conversion.

Table 42.1 lists the ACMPHS specifications, Figure 42.1 shows a block diagram, and Table 42.2 shows the input source configurations.

Table 42.1 ACMPHS specifications

Parameter	Specifications
Number of channels	2 channels: ACMPHSn (n = 0, 1)
Analog input voltage	• Output from internal D/A converter • Input from an external source (compatible with internal A/D converter input pin (one selectable))
Reference voltage	• Internal reference voltage (Vref) • Output from internal D/A converter • Input from an external source (compatible with internal A/D converter input pin (one selectable))
ACMPHS output	• Comparison result output to terminal PIN • Generation of ELC event output • Monitor output from register • Generation of interrupt request output
Interrupt request signal	• Interrupt request generated on valid edge detection from comparison result (when CMPCTL.CSTEN = 0*1) • Selectable to rising edge, falling edge, or both edges (when CMPCTL.CSTEN = 0*1) • Rising edge only (when CMPCTL.CSTEN = 1*1)
Digital filter function	• Selectable to one of three sampling frequencies • Not using the filter function is selectable
Module-stop function	Module-stop state can be set for each groups to reduce power consumption.
TrustZone Filter	Security and Privilege attribution can be set for each group

Note 1. Interrupt request signal selection restriction detail refers to section 42.5. ACMPHS Interrupts and section 42.6. ACMPHS Output to the Event Link Controller (ELC).



n = 0～1

CMPSEL[3:0] : bits in ACMPHSn.CMPSEL0 register
CRVS[3:0] : bits in ACMPHSn.CMPSEL1 register
CPOE, VREFEN : bits in ACMPHSn.CPIOC register
CMPMON : bits in ACMPHSn.CMPMON register
HCMPON, COE, CINV, CDFS[1:0], CEG[1:0], CSTEN : bits in ACMPHSn.CMPCTL register
MSKSEL[3:0] : bits in ACMPHSn.CMPSKCTL register
MSKE : bits in ACMPHSn.CMPINTCTL register

Note : VREFEN exists only in ACMPHS0.

Figure 42.1 ACMPHS block diagram

Table 42.2 Input source configuration of the ACMPHS

Comparator	Reference voltage input source				Analog voltage input source				Output pin
	IVREF3	IVREF2	IVREF1	IVREF0	IVCMP3	IVCMP2	IVCMP1	IVCMP0	
ACMPHS0	DA0*3	Vref*1	AN104	AN101	AN002	AN000	DA1*4	AN005	VCOUT*2
ACMPHS1	DA0*3	Vref*1	AN104	AN101	AN102	AN100	DA1*4	AN016/ AN116	

Note 1. Internal voltage reference.
Note 2. ACMPHS0 to ACMPHS1 compare outputs are bundled with the VCOUT pin.
Note 3. When D/A converter 0 output is not used, the signal can be used as AN007 analog input.
Note 4. When D/A converter 1 output is not used, the signal can be used as AN105 analog input.

42.2 Register Descriptions

42.2.1 CMPCTL : Comparator Control Register

Base address: ACMPHSn = 0x4023_6000 + 0x0100 × n (n = 0, 1)
ACMPHSn_NS = 0x5023_6000 + 0x0100 × n (n = 0, 1)

Offset address: 0x000

Bit position:	7	6	5	4	3	2	1	0
Bit field:	HCMPON	CDFS[1:0]		CEG[1:0]		CSTEN	COE	CINV
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	CINV	Comparator Output Polarity Selection*1 *2 0: Do not invert comparator output 1: Invert comparator output	R/W
1	COE	Comparator Output Enable 0: Disable comparator output (output signal is low level) 1: Enable comparator output	R/W
2	CSTEN	Interrupt Select*3 0: Output through the edge selector 1: Output directly	R/W
4:3	CEG[1:0]	Selection of Valid Edge (Edge Selector) 0 0: Do not detect edge 0 1: Detect rising edge 1 0: Detect falling edge 1 1: Detect both edges	R/W
6:5	CDFS[1:0]	Noise Filter Selection *1 *2 *3 *4 0 0: Do not use noise filter 0 1: Use noise filter sampling frequency of PCLKB/2^3 1 0: Use noise filter sampling frequency of PCLKB/2^4 1 1: Use noise filter sampling frequency of PCLKB/2^5	R/W
7	HCMPON	Comparator Operation Control*5 0: Stop operation (comparator outputs a low-level signal) 1: Enable operation (enables input to the comparator pins)	R/W

Note: S-TYPE-3, P-TYPE-3
Note 1. Disable the ACMPHS output (COE= 0) before changing the CDFS[1:0] and CINV bits.
Note 2. If the CDFS[1:0] and CINV bits are changed, an ACMPHS interrupt request and an ELC event might be generated. Before changing these bits, set the ELSRn register to 0 (the ACMPHS output is not linked). After changing these bits, clear the IR flag in the IELSRn register to 0 to clear the interrupt status.
Note 3. Set the CSTEN bit to 1 and the CDFS[1:0] bits to 00b if the ACMPHS interrupt causes release of Software Standby mode. CSTEN is supported only by the ACMPHS0. ACMPHS1.CMPCTL.CSTEN must be set to 0.
Note 4. If the CDFS[1:0] bits are changed from 00b (noise filter not used) to a value other than 00b (noise filter used), perform sampling four times and update the filter output, and then use the ACMPHS interrupt request or the ELC event.
Note 5. A stabilization wait time is required to permit ACMPHS operation after enabling it (HCMPON = 1). The operation stabilization wait time for ACMPHS modules 0 to 1 is 300 ns.

Note: Set this register before setting registers in the POEG when using comparator output as a POEG source.

The CMPCTL register controls the ACMPHS operation, enables or disables the ACMPHS output, selects the noise filter, selects the valid edge of the interrupt signal, and selects the interrupt.

42.2.2 CMPSEL0 : Comparator Input Select Register

Base address: ACMPHSn = 0x4023_6000 + 0x0100 × n (n = 0, 1)
ACMPHSn_NS = 0x5023_6000 + 0x0100 × n (n = 0, 1)

Offset address: 0x004

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	CMPSEL[3:0]			
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
3:0	CMPSEL[3:0]	Comparator Input Selection*1 *2 *3 0x00: Do not input 0x01: Select IVCMP0 0x02: Select IVCMP1 0x04: Select IVCMP2 0x08: Select IVCMP3 Others: Setting prohibited	R/W

Bit	Symbol	Function	R/W
7:4	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3
Note 1. Use the following procedure to change the CMPSEL[3:0] bits. Writing a value other than 0x00 while the value of the CMPSEL0 register is not 0x00 is invalid. Writing 1 to two or more bits is also invalid. In both cases, the previous value is retained.
To change the CMPSEL[3:0] bits:
1. Set the CMPCTL.COE bit to 0.
2. Set the CMPSEL0 register to 0x00.
3. Set a new value in the CMPSEL[3:0] bits, with 1 set in only one of the bits.
4. Wait for the input switching stabilization wait time (200 ns).
5. Set the CMPCTL.COE bit to 1.
6. Clear the IR flag in the IELSRn register to clear the interrupt status.

Note 2. For details, see Table 42.2.
Note 3. If ACMPHSn level detection signal is used as a POEG source, write access to these bits after the setting of any register in the POEG may generate a POEG source.

42.2.3 CMPSEL1 : Comparator Reference Voltage Select Register

Base address: ACMPHSn = 0x4023_6000 + 0x0100 × n (n = 0, 1)
ACMPHSn_NS = 0x5023_6000 + 0x0100 × n (n = 0, 1)

Offset address: 0x008

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	CRVS[3:0]			
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
3:0	CRVS[3:0]	Reference Voltage Selection*1*2*3*4 0x00: Do not input 0x01: Select IVREF0 0x02: Select IVREF1 0x04: Select IVREF2 0x08: Select IVREF3 Others: Setting prohibited	R/W
7:4	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3
Note 1. Use the following procedure to change the CRVS[3:0] bits. Writing a value other than 0x00 while the value of the CMPSEL1 register is not 0x00 is invalid. Writing 1 to two or more bits is also invalid. In both cases, the previous value is retained.
To change the CRVS[3:0] bits:
1. Set the CMPCTL.COE bit to 0.
2. Set the CMPSEL1 register to 0x00.
3. Set a new value to the CRVS[3:0] bits, with 1 set in only one of the bits.
4. Wait for the input switching stabilization wait time (200 ns)
5. Set the CMPCTL.COE bit to 1.
6. Clear the IR flag in the IELSRn register to clear the interrupt status.

Note 2. For details, see Table 42.2.
Note 3. When the on-chip D/A converter output voltage is used, set the D/A converter to generate comparator C reference voltage before enabling comparator operation (CMPCTL.HCMPON bit = 1). For details on setting the D/A converter, see section 40, 12-Bit D/A Converter (DAC12).
Note 4. If ACMPHSn level detection signal is used as a POEG source, write access to these bits after the setting of any register in the POEG may generate a POEG source.

42.2.4 CMPMON : Comparator Output Monitor Register

Base address: ACMPHSn = 0x4023_6000 + 0x0100 × n (n = 0, 1)
ACMPHSn_NS = 0x5023_6000 + 0x0100 × n (n = 0, 1)

Offset address: 0x00C

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	COMPMON
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	COMPMON	Comparator Output Monitor*1 0: Comparator output is low 1: Comparator output is high	R
7:1	—	These bits are read as 0. The write value should be 0.	R

Note: S-TYPE-3, P-TYPE-3
Note 1. When ACMPHS operation is enabled (CMPCTL.HCMPON = 1 and CMPCTL.COE = 1) but the noise filter is not in use (CDFS[1:0] = 00b), design the software so that the COMPMON bit is read twice and the values are only used after the two consecutive values match.

42.2.5 CPIOC : Comparator Output Control Register

Base address: ACMPHSn = 0x4023_6000 + 0x0100 × n (n = 0, 1)
ACMPHSn_NS = 0x5023_6000 + 0x0100 × n (n = 0, 1)

Offset address: 0x010

Bit position:	7	6	5	4	3	2	1	0
Bit field:	VREFEN	—	—	—	—	—	—	CPOE
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	CPOE	External Pin Output Enable Comparison result by the comparator is output to an external pin. 0: Output to the comparator external pin is disabled (the output signal is fixed to low) 1: Output to the comparator external pin is enabled	R/W
6:1	—	These bits are read as 0. The write value should be 0.	R/W
7	VREFEN	Internal Vref Enable*1 0: Disable internal Vref 1: Enable internal Vref	R/W

Note: S-TYPE-3, P-TYPE-3
Note 1. For ACMPHS modules 0 to 1, VREFEN exists only in ACMPHS0.CPIOC. When using the internal Vref in ACMPHS0 to ACMPHS1, set the VREFEN bit in ACMPHS0.CPIOC to 1. Bit [7] in ACMPHS1.CPIOC should be 0 regardless of whether or not the internal Vref is used.

42.2.6 CPINTCTL : Comparator Interrupt Control Register

Base address: ACMPHSn = 0x4023_6000 + 0x0100 × n (n = 0, 1)
ACMPHSn_NS = 0x5023_6000 + 0x0100 × n (n = 0, 1)

Offset address: 0x040

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	MSKE
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	MSKE	Comparator Interrupt Periodic Mask Enable 0: Disable interrupt masking (Default) 1: Enable interrupt masking by GPT output signal selected by CPMSKCTL.MSKSEL [2:0]	R/W
7:1	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

This register controls the interrupt to ICU/ELC, while the event to POEG (Port Output Enable) is not controlled by this register.

42.2.7 CPMSKCTL : Comparator Interrupt Mask Control Register

Base address: ACMPHSn = 0x4023_6000 + 0x0100 × n (n = 0, 1)
ACMPHSn_NS = 0x5023_6000 + 0x0100 × n (n = 0, 1)

Offset address: 0x044

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	MSKSEL[2:0]		
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
2:0	MSKSEL[2:0]	Comparator Interrupt Periodic Mask Selection 0 0 0: Enable interrupt masking by GTIOC0A output signal 0 0 1: Enable interrupt masking by GTIOC1A output signal 0 1 0: Enable interrupt masking by GTIOC2A output signal 0 1 1: Enable interrupt masking by GTIOC3A output signal 1 0 0: Enable interrupt masking by GTIOC4A output signal 1 0 1: Enable interrupt masking by GTIOC5A output signal 1 1 0: Enable interrupt masking by GTIOC6A output signal 1 1 1: Enable interrupt masking by GTIOC7A output signal	R/W
7:3	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

This register controls the interrupt to ICU/ELC, while the event to POEG (Port Output Enable) is not controlled by this register.

42.3 Operation

The ACMPHS compares a reference voltage to an analog input voltage. Operation is not guaranteed when the values of registers are changed during ACMPHS operation. Table 42.3 shows the procedures for setting the registers associated with ACMPHS.

Table 42.3 Procedure for setting registers associated with ACMPHSn (n = 0, 1) (1 of 2)

Step	Register	Bit	Setting
1	Associated MSTPCRD register	MSTPD28 to MSTPD27	0: Input clock supply.
2	Associated pin function control register (PFS)	ASEL	1: Select the function of pins IVREF and IVCMP.
3	ACMPHSn.CPIOC	VREFEN	1: When using the internal Vref.
4	Associated D/A convertor		When using the D/A convertor, select in the register.
5	CMPSEL0, CMPSEL1	CMPSEL[3:0] CRVS[3:0]	Select the ACMPHSn input, with 1 set in only one of the bits.
6	CMPCTL	CDFS[1:0], CEG[1:0], and CINV	Set up ACMPHSn control.
		HCMPON	1: Enable ACMPHSn operation.
7	CMPSKCTL	MSKCTL[2:0]	Select the interrupt mask source signal (from GPT)

Table 42.3 Procedure for setting registers associated with ACMPHSn (n = 0, 1) (2 of 2)

Step	Register	Bit	Setting
8	CPINT	MSKE	1: Enable interrupt mask function if need
9	Waiting for the ACMPHS stabilization time (minimum 300 ns).		
10	CMPCTL	COE	1: Enable ACMPHSn output.
11	CPIOC	CPOE	Set the VCOUT output
	Associated pin function control register (PFS)	PSEL, PMR	Select the VCOUT port function.
12	IELSRn	IR, IELS[8:0]	When using an interrupt, select the interrupt status flag and the ICU event link.*1
13	ELSRn	ELS[8:0]	When using an ELC, select the event link*2.
14	Operation started		
15	CMPCTL	COE	0: When changing IVREF or IVCMP, to disable ACMPHSn output.
16	CMPSEL1	CRVS[3:0]	Change the CMPSEL1 bits as follows: 1. Set bits CMPSEL1 to 0000 0000b. 2. Set a new value to the CMPSEL1 bits, with 1 set in only one of the bits.
	CMPSEL0	CMPSEL[3:0]	Change the CMPSEL0 bits as follows: 1. Set bits CMPSEL0 to 0000 0000b. 2. Set a new value to the CMPSEL0 bits, with 1 set in only one of the bits.
17	Waiting for the ACMPHS switching stabilization time (minimum 200 ns).		
18	CMPCTL	COE	1: Enable ACMPHSn output.
19	Operation restarted		

Note 1. After ACMPHSn is set, an unnecessary interrupt might occur until operation becomes stable, so initialize the interrupt flag.
Note 2. After ACMPHSn is set, an unnecessary interrupt might occur until operation becomes stable, so initialize the event link select.

Figure 42.2 and Figure 42.3 show an example of ACMPHS operation. The VCOUT output becomes 1 when the analog input voltage is higher than the ACMPHS reference input voltage, and the VCOUT output becomes 0 when the analog input voltage is lower than the reference voltage. When the ACMPHS output changes, an interrupt request and an ELC event are output.

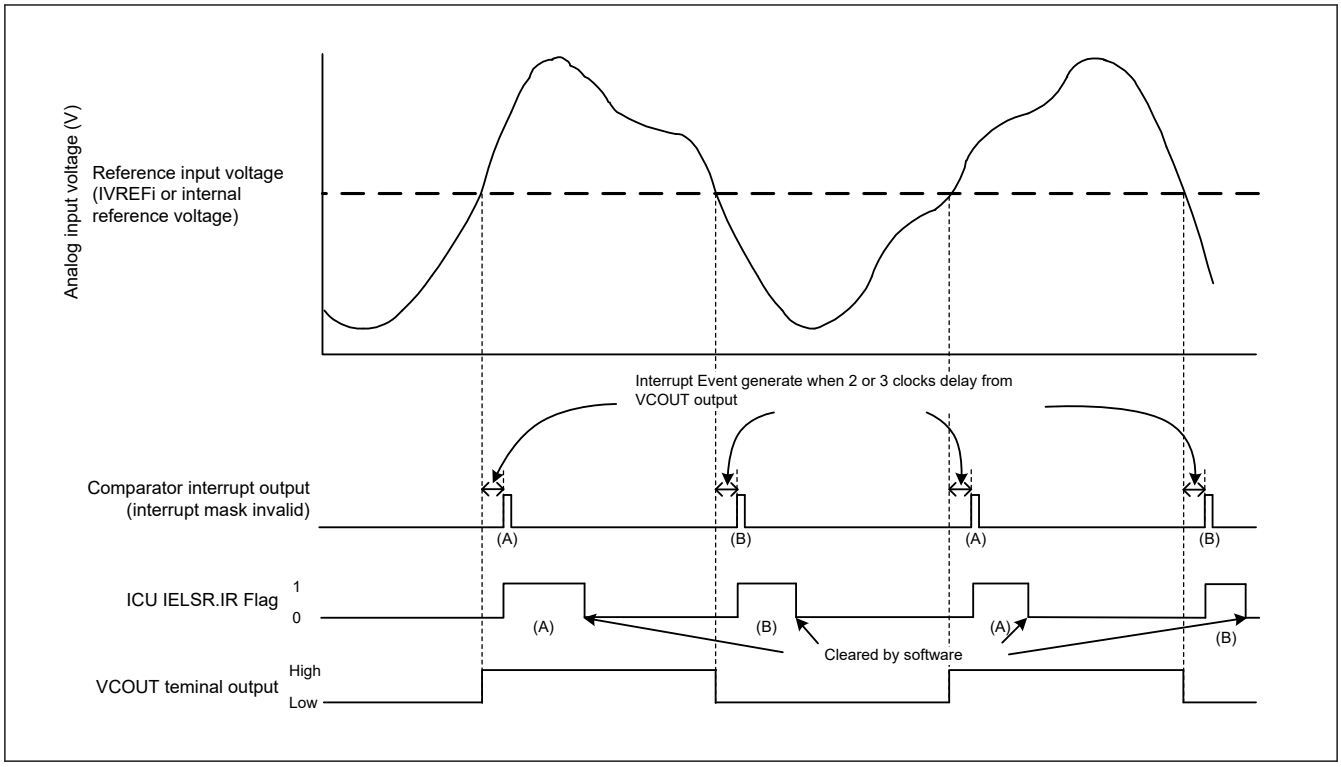


Figure 42.2 ACMPHS operation example (interrupt mask function invalid)

Figure 42.2 applies when CPOE = 1 (pin output enabled), CDFS[1:0] = 00b (filter not used), and CEG[1:0] = 11b (both-edge detection selected). When CINV = 0, CEG[1:0] = 01b (rising-edge detection selected for non-inversion output signal from the ACMPHS), the IELSR.IR flag changes as shown by (A) only. When CINV = 0, CEG[1:0] = 10b (falling-edge detection selected for non-inversion output signal from the ACMPHS), the IR flag changes as shown by (B) only. When CPOE = 1, VCOUT directly outputs.

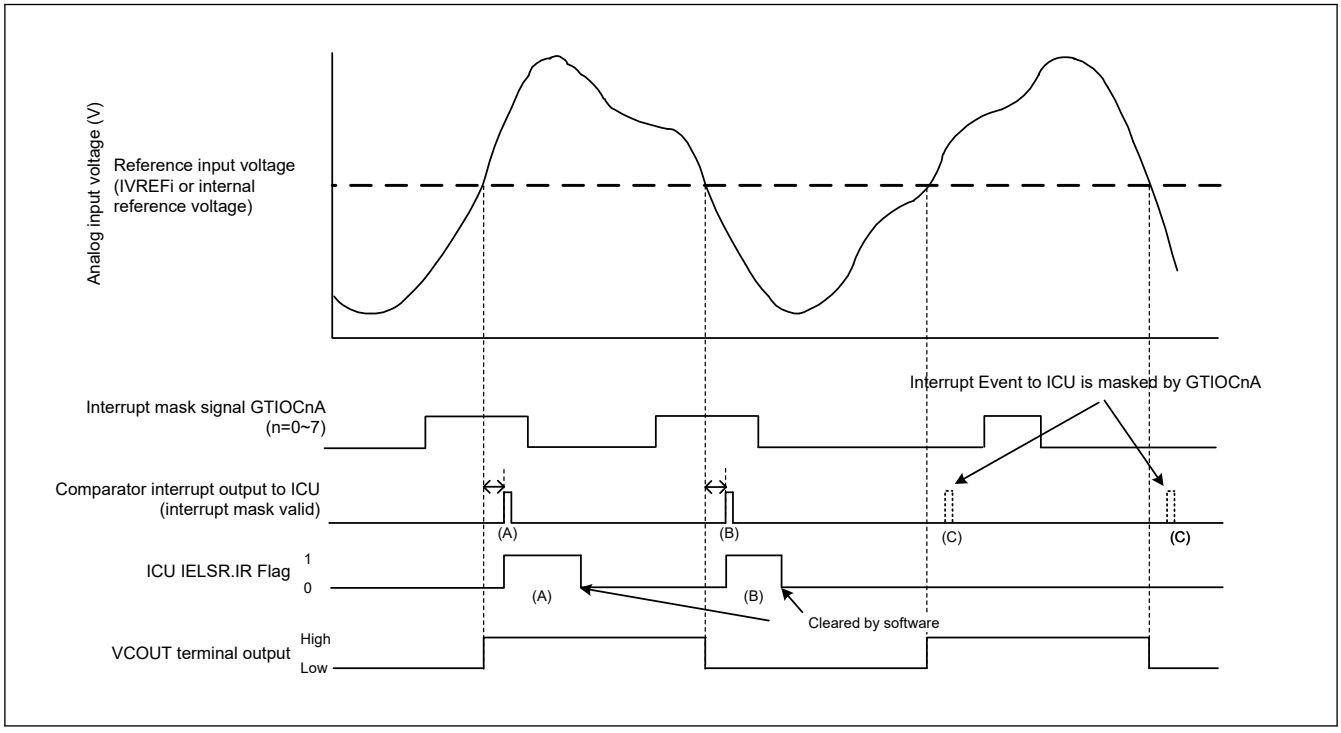

Figure 42.3 ACMPHS operation example (interrupt mask function valid)

Figure 42.3 applies when CPOE = 1 (pin output enabled), CDFS[1:0] = 00b (filter not used), CEG[1:0] = 11b (both-edge detection selected). When CINV = 0, CEG[1:0] = 01b (rising-edge detection selected for non-inversion output signal from

the ACMPHS), the IELSR.IR flag changes as shown by (A) only. When CINV = 0, CEG[1:0] = 10b (falling-edge detection selected for non-inversion output signal from the ACMPHS), the IR flag changes as shown by (B) only.

When MSKE = 1 and MSKSEL[2:0] = 000b, the interrupt signal output to ICU is masked by GTIOC0A when GTIOC0A = low level as shown by (C), while it passes through when GTIOC0A = high level.

When CPOE = 1, VCOUT directly outputs, regardless of the MSKE setting.

42.4 Noise Filter

The ACMPHS contains a noise filter. The sampling clock can be selected in the CMPCTL.CDFS[1:0] bits. The comparator output signal is sampled every sampling clock, and if the same value is sampled three times, the noise filter output at the next sampling clock cycle is used as the ACMPHS output.

Figure 42.4 shows the configuration of the noise filter and edge detector, and Figure 42.5 shows an example of noise filter and interrupt operation.

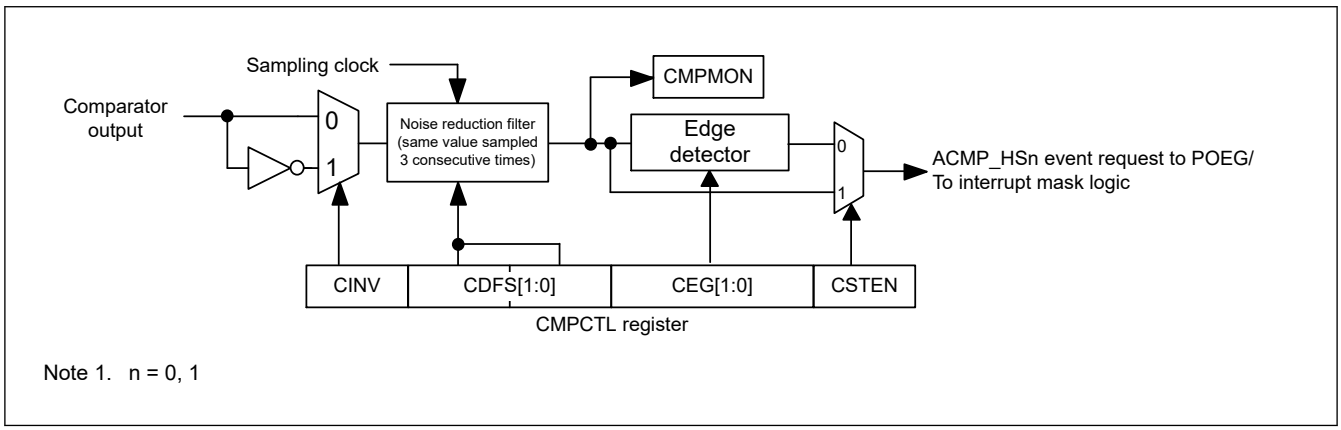

Figure 42.4 Noise filter and edge detection configuration

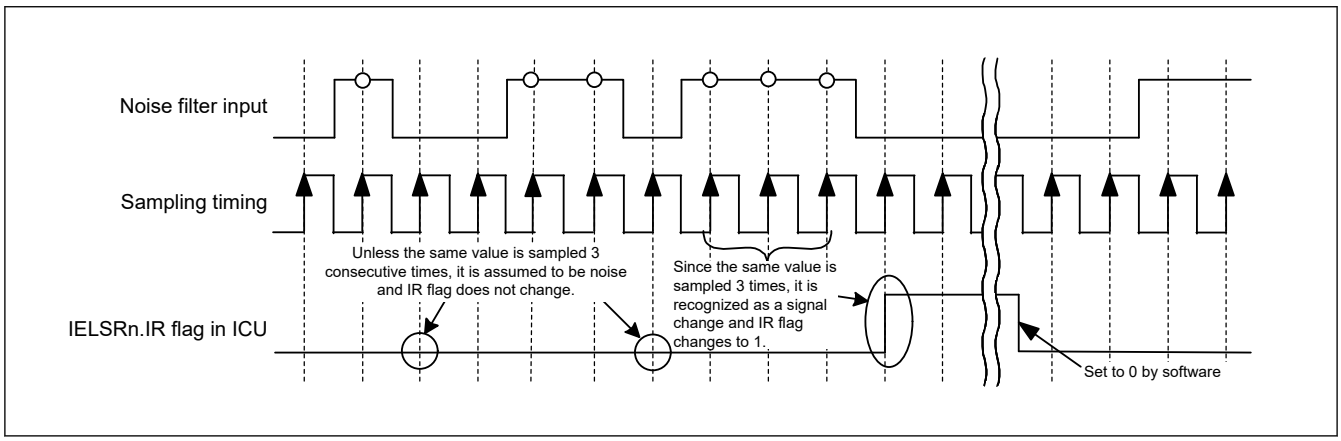

Figure 42.5 Noise filter and interrupt operation example

The operation example in Figure 42.5 applies when the CMPCTL.CDFS[1:0] bits are 01b, 10b, or 11b (noise filter used).

42.5 ACMPHS Interrupts

The ACMPHS generates two interrupt requests from sources ACMPHSn (n = 0, 1). To use an ACMPHS interrupt, select it in the IELSR register in the Interrupt Controller Unit (ICU). Select the interrupt request in the CMPCTL.CSTEN bit either through the edge selector, or not.

Interrupt event to ICU/ELC can be masked by GPT output (GTIOCnA (n = 0 to 7)), it's controlled by CPINTCTL.MSKE bit and CPMSKCTL.MSKSEL[2:0] bits. Detail refer to Figure 42.3.

Event to POEG can't be masked by GPT output (GTIOCnA (n = 0 to 7)), it's not controlled by CPINTCTL.MSKE bit and CPMSKCTL.MSKSEL[2:0] bits.

When using the ACMPHS interrupt through the edge selector, set at least one of the CMPCTL.CEG[1:0] bits to 1 (to a value other than 00b for no edge selection). Set the CMPCTL.CSTEN bit to 0 (output through the edge selector) in Normal mode, CPU Sleep mode, and CPU Deep Sleep mode.

To use the ACMPHS interrupt in Software Standby mode, set the CMPCTL.CSTEN bit to 1 (direct output), set the CMPCTL.CDFS[1:0] bit to 00b (digital noise filter not used), and set CMPCTL.CINV as follows:

- When detecting compare result 0 to 1, set CMPCTL.CINV to 0 (comparator output not inverted)
- When detecting compare result 1 to 0, set CMPCTL.CINV to 1 (comparator output inverted).

An ACMPHS0 interrupt request can be used to release Software Standby mode. ACMPHS1 cannot be used.

ACMPHS0/ACMPHS1 both can not be used in Deep Software Standby mode.

For details on the register settings related to ACMPHS interrupt requests, see section 42.2.1. CMPCTL : Comparator Control Register, section 42.2.6. CPINTCTL : Comparator Interrupt Control Register and section 42.2.7. CPMSKCTL : Comparator Interrupt Mask Control Register.

42.6 ACMPHS Output to the Event Link Controller (ELC)

The ELC uses the ACMPHS interrupt request signal as an ELC event signal, enabling link operation for the preset module. To use the ACMPHS ELC event, select them in the ELSR register in the ELC. When using the ELC event request, set the CMPCTL.CSTEN bit to 0 (output through the edge selector). Also set at least one of the CMPCTL.CEG[1:0] bits to 1 (to a value other than 00b for no edge selection).

Interrupt event to ELC can be masked by GPT output (GTIOCnA (n = 0 to 7)), it's controlled by CPINTCTL.MSKE bit and CPMSKCTL.MSKSEL[2:0] bits.

42.7 ACMPHS Pin Output

The comparison result from the ACMPHS can be output to external pins. Use the CMPCTL.CINV and CPIOC.CPOE bits to set the output polarity (non-inverted or inverted output) and enable or disable output. To output the ACMPHS comparison result to the VCOUT output pin, set the associated port mn pin function control register (PmnPFS) in the I/O register.

Only when the security attribution of Port and ACMPHS match, the ACMPHS comparison result is output to the VCOUT pin as shown in the Table 42.4.

Table 42.4 The output condition of VCOUT pin by the security setting

PORT Security Attribution (PmSAR (m = 0 to 9, A, B))	ACMPHS0 Security Attribution PSARD	ACMPHS1 Security Attribution PSARD	VCOUT pin output
0 (secure)	0 (secure)	0 (secure)	both ACMPHS0/1 output enable
1 (non-secure)	0 (secure)	0 (secure)	both ACMPHS0/1 output disable
0 (secure)	0 (secure)	1 (non-secure)	ACMPHS0_VCOUT output enable ACMPHS1_VCOUT output disable
1 (non-secure)	0 (secure)	1 (non-secure)	ACMPHS0_VCOUT output disable ACMPHS1_VCOUT output enable
0 (secure)	1 (non-secure)	0 (secure)	ACMPHS0_VCOUT output disable ACMPHS1_VCOUT output enable
1 (non-secure)	1 (non-secure)	0 (secure)	ACMPHS0_VCOUT output enable ACMPHS1_VCOUT output disable
0 (secure)	1 (non-secure)	1 (non-secure)	both ACMPHS0/1 output disable
1 (non-secure)	1 (non-secure)	1 (non-secure)	both ACMPHS0/1 output enable

42.8 Usage Notes

42.8.1 Settings for the Module-Stop Function

ACMPHS operation can be disabled or enabled using the Module Stop Control Register. The ACMPHS is initially stopped after reset. Releasing the module-stop state enables access to the registers. For details, see section 10, Low Power Modes.

42.8.2 Settings for the DAC12

ACMPHS is connected to the internal module output of the D/A converter. For details, see section 40, 12-Bit D/A Converter (DAC12).

42.8.3 Relationship with the ADC12

Constraints apply on the simultaneous use of ACMPHS analog input and ADC12 analog input. For details, see section 39.6.14. Relationship between ADC12 Units 0 and 1 and the ACMPHS.

42.8.4 ACMPHS Operation in Module-Stop State

When the module-stop state is entered while ACMPHS is operating, analog circuits in the ACMPHS are not stopped and the analog power supply current is the same as that when ACMPHS is being used. If the analog power supply current needs to be reduced in the module-stop state, set the CMPCTL.HCMPON bit to 0 to stop the ACMPHS.

42.8.5 ACMPHS Operation in Software Standby Mode

When Software Standby mode is entered while ACMPHS is operating, analog circuits in the ACMPHS are not stopped and the analog power supply current is the same as that when ACMPHS is being used. If the analog power supply current needs to be reduced in Software Standby mode, set the CMPCTL.HCMPON bit to 0 to stop the ACMPHS.

42.8.6 Setting the D/A Converter for Generating Reference Voltage

Set the D/A converter to generate reference voltage and wait for the D/A converter output settling time before enabling the comparator. Similarly, before making any changes to the settings of the D/A converter, stop the comparator temporarily. After the changes are made, wait for the D/A converter output settling time before enabling the comparator.

43. Data Operation Circuit (DOC)

This is the DOC_B version of the DOC peripheral module.

DOC_B is referred to as DOC in this chapter.

43.1 Overview

The data operation circuit (DOC) is used to compare, add, and subtract 16 or 32-bit data. An interrupt can be generated when the following conditions apply.

- When the 16 or 32-bit compared values match the detection condition
- When the result of 16 or 32-bit data addition overflows
- When the result of 16 or 32-bit data subtraction underflows

Table 43.1 lists the data operation circuit specifications and Figure 43.1 shows a block diagram of the data operation circuit.

Table 43.1 DOC specifications

Item	Description
Data operation function	• 16 or 32-bit data comparison, comparison to detect data above or below thresholds, and window comparison • 16 or 32-bit data addition, and subtraction
Module-stop function	The module-stop state can be set to reduce power consumption.
Interrupts	• The compared values match the detection condition • The result of data addition is greater than 0xFFFF (DOCR.DOBW = 0) or 0xFFFF_FFFF (DOCR.DOBW = 1) • The result of data subtraction is less than 0x0000 (DOCR.DOBW = 0) or 0x0000_0000 (DOCR.DOBW = 1)
Event link function (output)	• The result of data comparison is consistent with detection condition • The result of data addition is greater than 0xFFFF (DOCR.DOBW = 0) or 0xFFFF_FFFF (DOCR.DOBW = 1) • The result of data subtraction is less than 0x0000 (DOCR.DOBW = 0) or 0x0000_0000 (DOCR.DOBW = 1)
TrustZone Filter	Security and Privilege attribution can be set

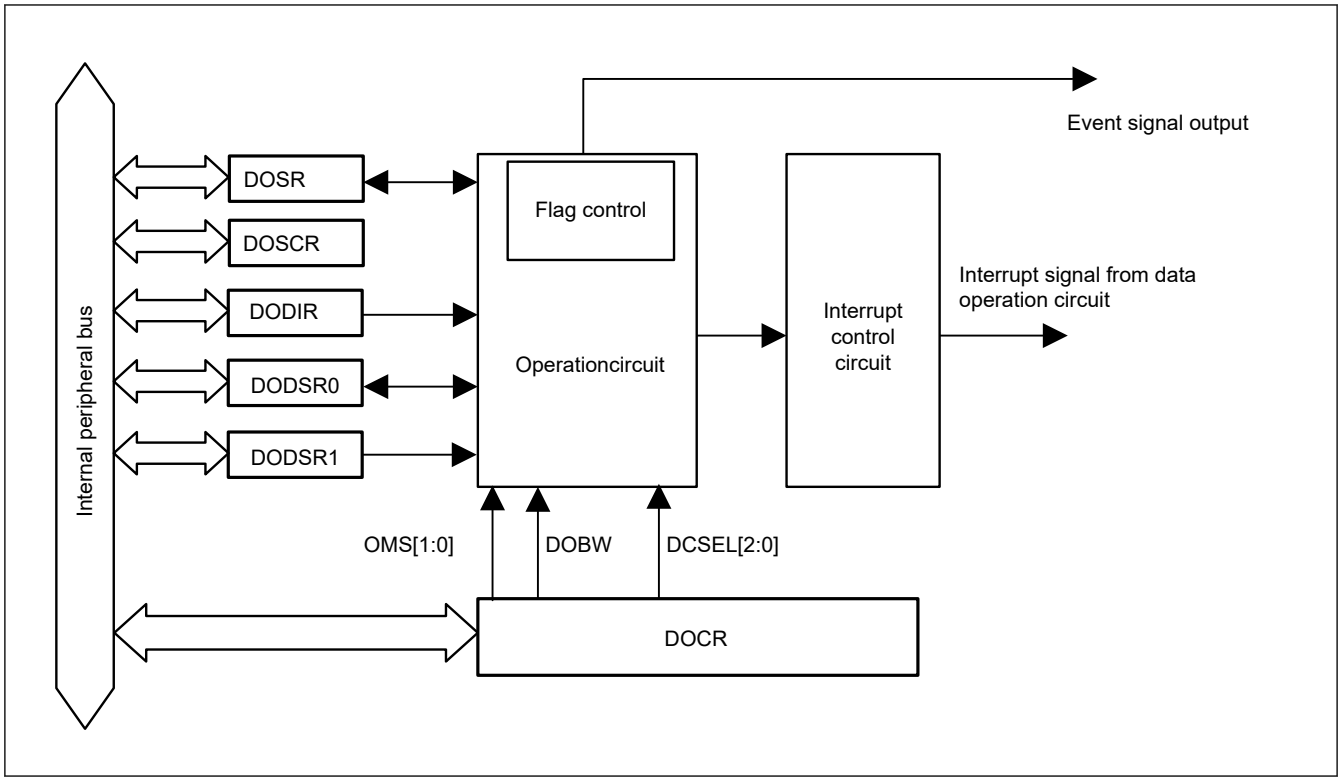

Figure 43.1 DOC block diagram

43.2 DOC Register Descriptions

43.2.1 DOCR : DOC Control Register

Base address: DOC_B = 0x4031_1000
DOC_B_NS = 0x5031_1000

Offset address: 0x00

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	DCSEL[2:0]			DOBW	—	OMS[1:0]	
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
1:0	OMS[1:0]	Operating Mode Select 0 0: Data comparison mode 0 1: Data addition mode 1 0: Data subtraction mode 1 1: Setting prohibited	R/W
2	—	This bit is read as 0. The write value should be 0.	R/W
3	DOBW	Data Operation Bit Width Select 0: 16-bit 1: 32-bit	R/W
6:4	DCSEL[2:0]*1	Detection Condition Select 0 0 0: Mismatch (DODSR0 ≠ DODIR) 0 0 1: Match (DODSR0 = DODIR) 0 1 0: Lower (DODSR0 > DODIR) 0 1 1: Upper (DODSR0 < DODIR) 1 0 0: Inside window (DODSR0 < DODIR < DODSR1) 1 0 1: Outside window (DODIR < DODSR0, DODSR1 < DODIR) Others: Setting prohibited	R/W

Bit	Symbol	Function	R/W
7	—	This bit is read as 0. The write value should be 0.	R/W

Note: S-TYPE3, P-TYPE3
Note 1. Valid only when data comparison mode is selected.

The DOCR is a register which can set the operation mode of data operation circuit and interrupt enable/disable.

OMS[1:0] bits (Operating Mode Select)

These bits select the operating mode of the data operation circuit.

DOBW bit (Data Operation Bit Width Select)

This bit selects the bit width of data operation.

DCSEL[2:0] bits (Detection Condition Select)

These bits are valid only when data comparison mode is selected.

These bits select the condition for detection in data comparison mode.

43.2.2 DOSR : DOC Flag Status Register

Base address: DOC_B = 0x4031_1000
DOC_B_NS = 0x5031_1000

Offset address: 0x04

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	DOPCF
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	DOPCF	Data Operation Circuit Flag Indicates the result of an operation.	R
7:1	—	These bits are read as 0.	R

Note: S-TYPE3, P-TYPE3

The DOSR register indicates the status of the data operation.

DOPCF flag (Data Operation Circuit Flag)

[Setting conditions]

- DOCR.OMS[1:0] bits = 00b (Data comparison mode): The compared value matches the detection condition selected by DOCR.DCSEL[2:0] bits
- DOCR.OMS[1:0] bits = 01b (Data addition mode): The result of data addition is greater than 0xFFFF (DOCR.DOBW = 0) or 0xFFFF_FFFF (DOCR.DOBW = 1)
- DOCR.OMS[1:0] bits = 10b (Data subtraction mode): The result of data subtraction is less than 0x0000 (DOCR.DOBW = 0) or 0x0000_0000 (DOCR.DOBW = 1)

[Clearing condition]

- Writing 1 to the DOSCR.DOPCFCL bit

43.2.3 DOSCR : DOC Flag Status Clear Register

Base address: DOC_B = 0x4031_1000
DOC_B_NS = 0x5031_1000

Offset address: 0x08

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	DOPCFCL
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	DOPCFCL	DOPCF Clear 0: Maintains the DOPCF flag state. 1: Clears the DOPCF flag.	W
7:1	—	The write value should be 0.	W

Note: S-TYPE3, P-TYPE3

The DOSCR is a register which can clear the status of data operation. This register is read as 0x00.

DOPCFCL bit (DOPCF Clear)

Setting this bit to 1 clears the DOPCF flag.

43.2.4 DODIR : DOC Data Input Register

Base address: DOC_B = 0x4031_1000
DOC_B_NS = 0x5031_1000

Offset address: 0x0C

Bit position:	31	0
Bit field:		
Value after reset:	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0	

Bit	Symbol	Function	R/W
31:0	n/a	It stores data used in the operations. Access the DODIR with the bit width of data operation selected by the DOCR.DOBW bit.	R/W

Note: S-TYPE3, P-TYPE3

43.2.5 DODSR0 : DOC Data Setting Register 0

Base address: DOC_B = 0x4031_1000
DOC_B_NS = 0x5031_1000

Offset address: 0x10

Bit position:	31	0
Bit field:		
Value after reset:	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0	

Bit	Symbol	Function	R/W
31:0	n/a	Access the DODSR0 with the bit width of data operation selected by the DOCR.DOBW bit. This register stores data for use as a reference in data comparison mode. When selecting window comparison (DOCR.DCSEL[2:0] = 100b, 101b), set a value less than DODSR1 (DODSR1 > DODSR0). This register also stores the results of operations in data addition and data subtraction modes.	R/W

Note: S-TYPE3, P-TYPE3

43.2.6 DODSR1 : DOC Data Setting Register 1

Base address: DOC_B = 0x4031_1000
DOC_B_NS = 0x5031_1000

Offset address: 0x14

Bit position:	31																												0
Bit field:																													
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	n/a	Access the DODSR1 with the bit width of data operation selected by the DOCR.DOBW bit. This register stores data for use as a reference in data comparison mode. When selecting window comparison (DOCR.DCSEL[2:0] = 100b, 101b), set a value greater than DODSR0 (DODSR1 > DODSR0). This register is only used for window comparisons.	R/W

Note: S-TYPE3, P-TYPE3

43.3 Operation

43.3.1 Data Comparison Mode

Figure 43.2 to Figure 43.7 shows an example of the steps involved in data comparison mode operation by the data operation circuit.

The following is an example of operation when the bit width of data operation is 32-bit.

1. Writing 00b to the DOCR.OMS[1:0] bits selects data comparison mode, and setting the DOCR.DCSEL[2:0] to selects detection condition.
2. The 32-bit reference data is set in DODSR0 and DODSR1.*1
3. 32-bit data for comparison is written to DODIR.
4. If a value written to DODIR match the detection condition set by DOCR.DCSEL[2:0], the DOCR.DOPCF flag is set to 1 and an ELC event and a data operation circuit interrupt are generated.

Note: The comparison operation is executed only by writing to the DODIR

Note 1. The DODSR1 register setting is required only when window comparison is selected. Set a value greater than DODSR0 (DODSR1 > DODSR0).

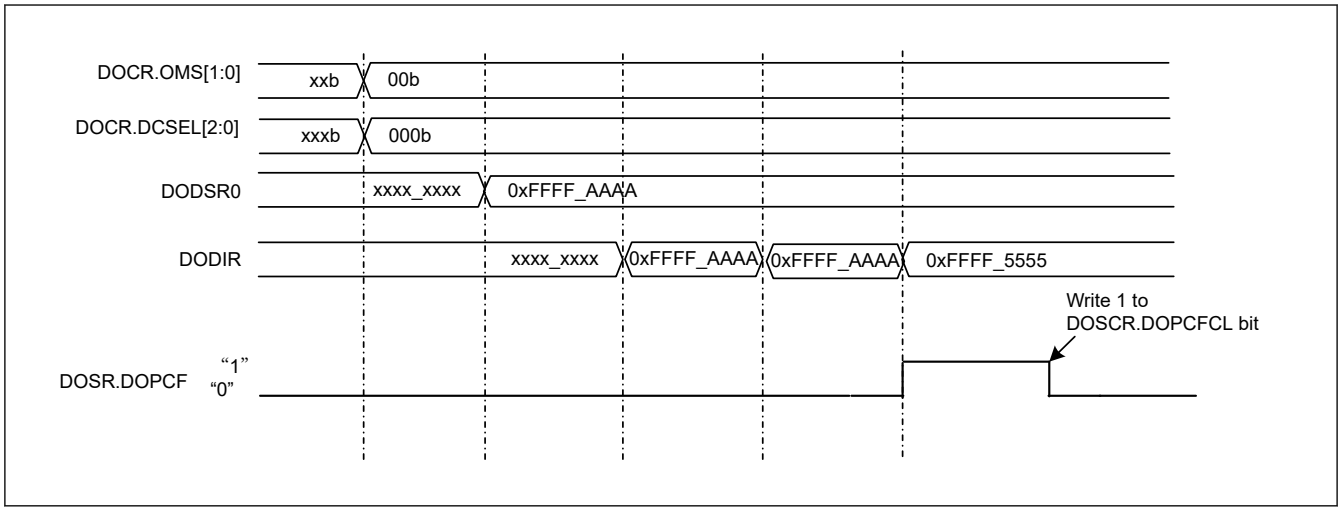

Figure 43.2 Example of Operation in Data Comparison Mode (Detection condition: Mismatch)

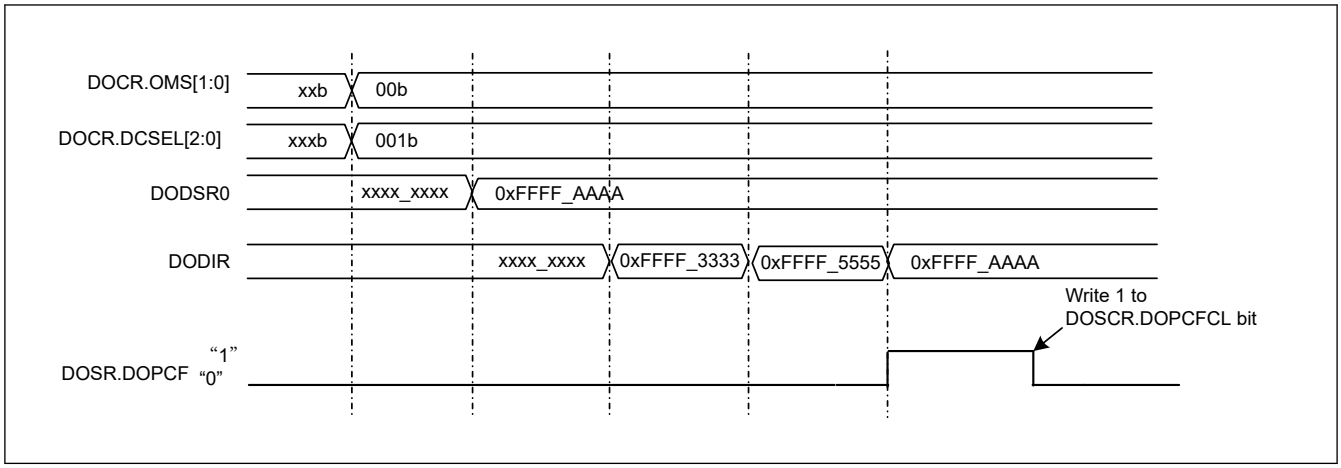

Figure 43.3 Example of Operation in Data Comparison Mode (Detection condition: Match)

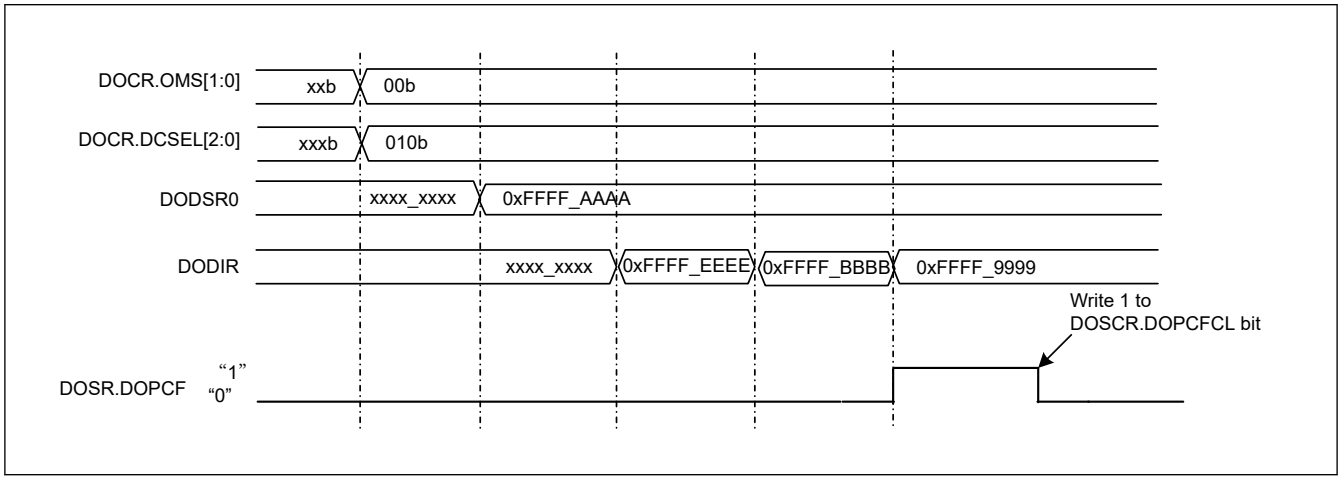

Figure 43.4 Example of Operation in Data Comparison Mode (Detection condition: Lower)

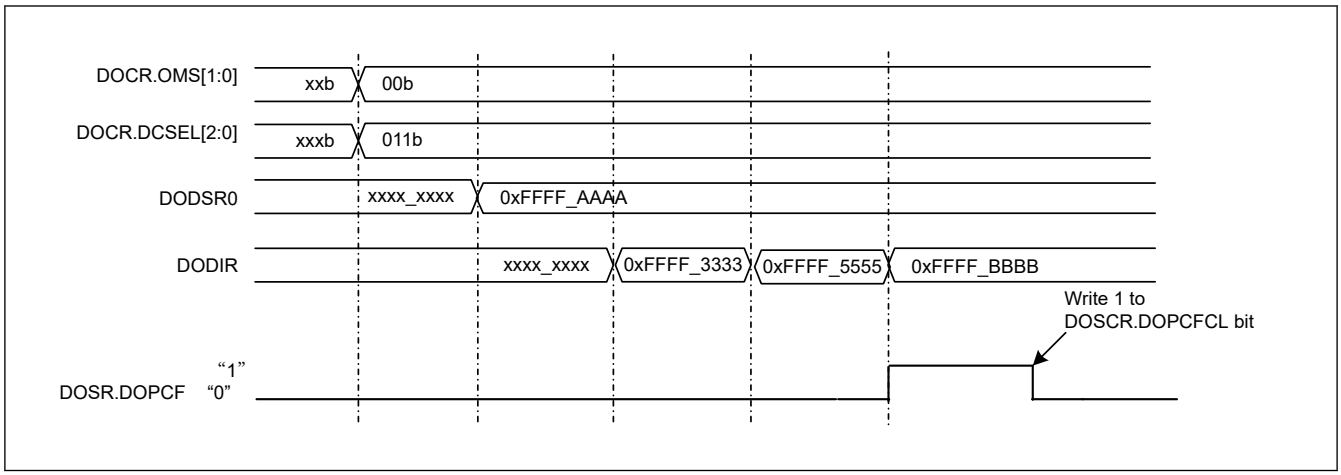

Figure 43.5 Example of Operation in Data Comparison Mode (Detection condition: Upper)

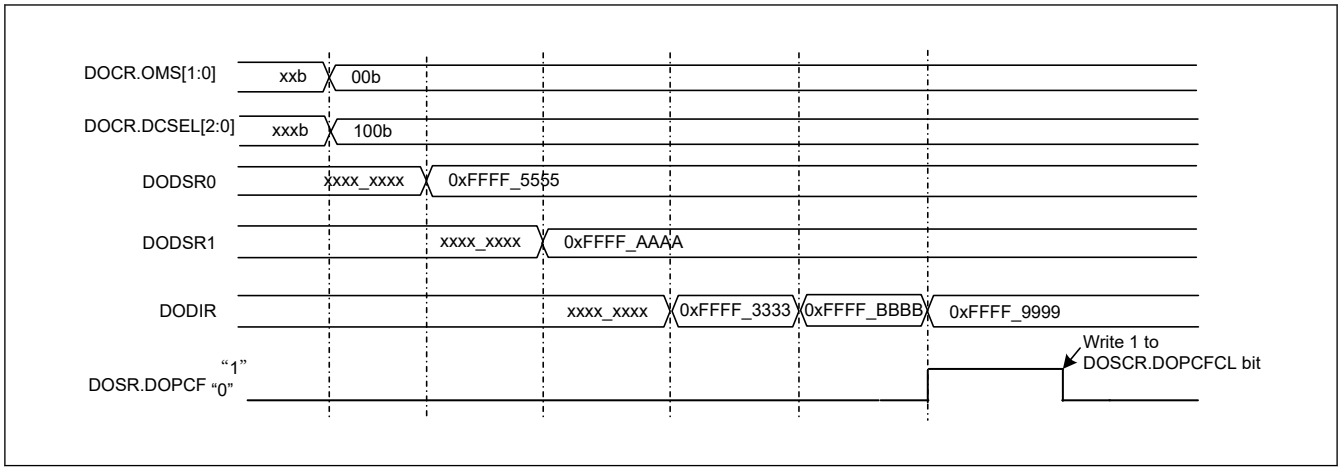

Figure 43.6 Example of Operation in Data Comparison Mode (Detection condition: Inside window)

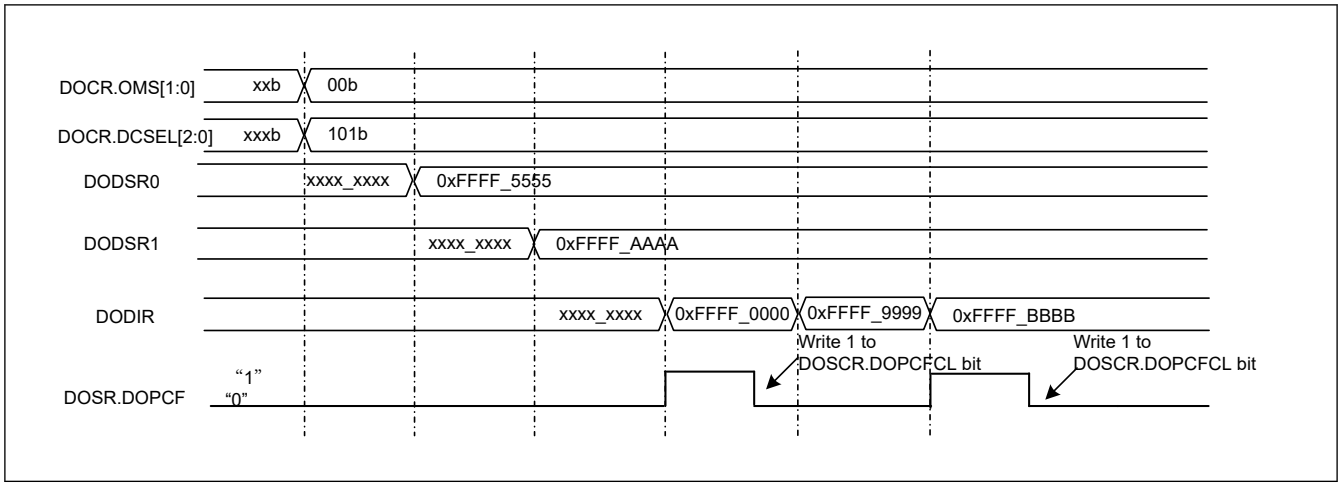

Figure 43.7 Example of Operation in Data Comparison Mode (Detection condition: Outside window)

43.3.2 Data Addition Mode

Figure 43.8 shows an example of the steps involved in data addition mode [*1] operation by the data operation circuit.

The following is an example of operation when the bit width of data operation is 32-bit.

1. Writing 01b to the DOCR.OMS[1:0] bits selects data addition mode.
2. 32-bit data is set in the DODSR0 register as the initial value.
3. 32-bit data to be added is written to DODIR. The result of the operation is stored in DODSR0.
4. Writing of 32-bit data continues until all data for addition have been written to DODIR.
5. If the result of an operation is greater than 0xFFFF_FFFF, the DOSR.DOPCF flag is set to 1 and an ELC event and a data operation circuit interrupt are generated.

Note 1. Addition is executed only by writing to the DODIR.

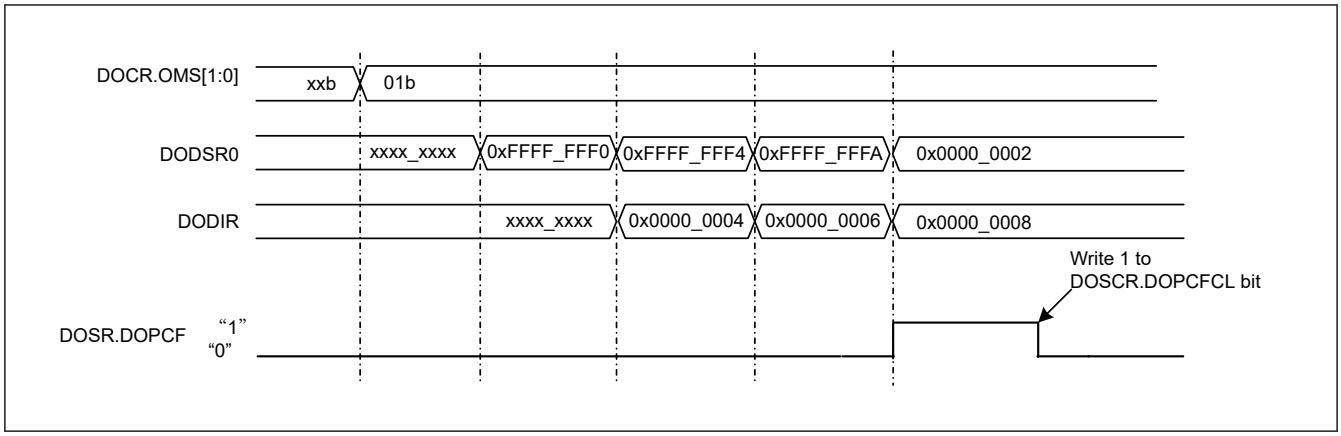

Figure 43.8 Example of Operation in Data Addition Mode

43.3.3 Data Subtraction Mode

Figure 43.9 shows an example of the steps involved in data subtraction mode *1 operation by the data operation circuit.

The following is an example of operation when the bit width of data operation is 32-bit.

1. Writing 10b to the DOCR.OMS[1:0] bits selects data subtraction mode.
2. 32-bit data is set in the DODSR0 register as the initial value.
3. 32-bit data to be subtracted is written to DODIR. The result of the operation is stored in DODSR0.
4. Writing of 32-bit data continues until all data for subtraction have been written to DODIR.
5. If the result of an operation is less than 0x0000_0000, the DOSR.DOPCF flag is set to 1 and an ELC event and a data operation circuit interrupt are generated.

Note 1. Subtraction is executed only by writing to the DODIR.

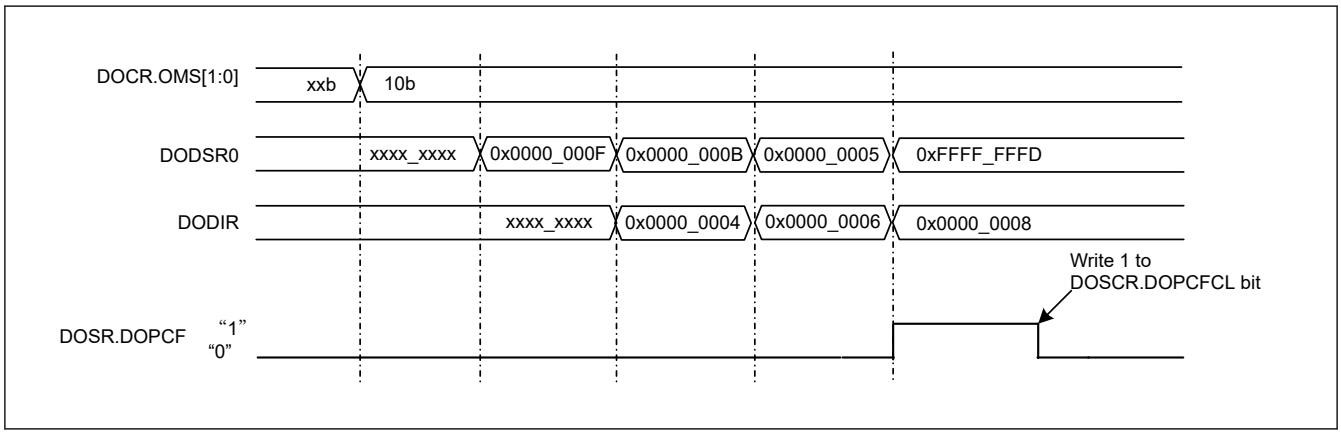

Figure 43.9 Example of Operation in Data Subtraction Mode

43.4 Interrupt Source

The data operation circuit generates the data operation circuit interrupt (DOC_DOPCI) as an interrupt request. When an interrupt source is generated, the data operation circuit flag corresponding to the interrupt is set to 1, and then interrupt request signal is generated. Table 43.2 describes the interrupt request.

Table 43.2 Interrupt request from DOC

Interrupt request	Status flag	Interrupt source
DOC interrupt	DOPCF	• The compared values match the detection condition. • The result of data addition is greater than 0xFFFF (DOCR.DOBW = 0) or 0xFFFF_FFFF (DOCR.DOBW = 1). • The result of data subtraction is less than 0x0000 (DOCR.DOBW = 0) or 0x0000_0000 (DOCR.DOBW = 1).

43.5 Event Link Output

The DOC outputs event signals for the event link controller (ELC) under the following conditions, and these can be used to initiate operations by other modules selected in advance.

- The compared values match the detection condition
- The data addition result is greater than 0xFFFF (DOCR.DOBW = 0) or 0xFFFF_FFFF (DOCR.DOBW = 1)
- The data subtraction result is less than 0x0000 (DOCR.DOBW = 0) or 0x0000_0000 (DOCR.DOBW = 1)

43.6 Interrupt Handling and Event Linking

The DOC has a bit to enable or disable interrupts. An interrupt request signal is output for the CPU when an interrupt source is generated while the corresponding enable bit is enabled.

In contrast, an event link output signal is sent to other modules as an event signal via the ELC when an interrupt source is generated, regardless of the setting of the corresponding interrupt enable bit.

43.7 Usage Notes

43.7.1 Settings for the Module-Stop State

The module Stop Control Register C (MSTPCRC) can enable or disable DOC operation. The DOC is initially stopped after reset. Releasing the module-stop state enables access to the registers. For details, see section 10, Low Power Modes.

44. SRAM

44.1 Overview

The MCU provides an on-chip, high-density SRAM module with either parity-bit checking or Error Correction Code (ECC). SRAM0 is ECC. SRAM1 is Parity check.

Table 44.1 lists the SRAM specifications.

Table 44.1 SRAM specifications

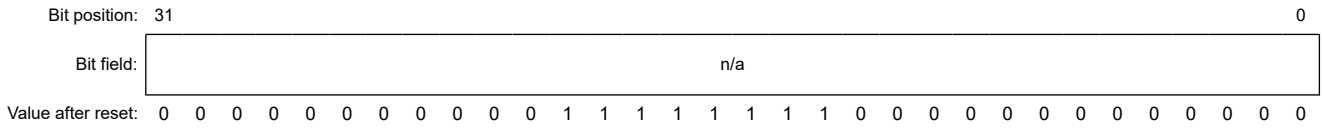
Parameter	SRAM0	SRAM1
SRAM capacity	384 KB	512 KB
SRAM address	0x2200_0000 to 0x2205_FFFF (Secure alias), 0x3200_0000 to 0x3205_FFFF (Non-secure alias)	0x2206_0000 to 0x220D_FFFF (Secure alias), 0x3206_0000 to 0x320D_FFFF (Non-secure alias)
Access	Wait states are inserted into the read cycle by default. If the ICLK frequency is higher than 120 MHz, a wait state is required. If the ICLK frequency is 120 MHz or less, a wait state is not required.	
Data retention function	Not available in Deep Software Standby mode	
Module-stop function	Module-stop state can be set to reduce power consumption	
Error checking	SEC-DED (Single-Error Correction and Double-Error Detection Code)	Even-parity (Data: 8 bits, Parity: 1 bit)
Security	TrustZone Filter is integrated for memory access and SFR access. Access to the memory space is controlled by setting the memory Security Attribution (SA). And access to I/O space (SFR) space is controlled by setting the register SA. See section 44.3.6. TrustZone Filter function.	

44.2 Register Descriptions

44.2.1 SRAMSABARn : SRAM Security Attribute Boundary Address Register (n = 0, 1)

Base address: CPSCU = 0x4000_8000
CPSCU_NS = 0x5000_8000

Offset address: 0x400 + 0x04 × n



Bit	Symbol	Function	R/W
31:0	n/a	Boundary address between Secure and Non-secure. (Start address of Non-secure region)	R/W

Note: S-TYPE-1, P-TYPE-1
Note: This register is write-protected by PRCR_S.PRC4 register.

SRAMSABARn specifies the boundary address between the Secure and Non-secure regions of each SRAM. Write the absolute address to the SRAMSABARn. When writing to SRAMSABARn, writing from b31 to b21 is ignored and the value written from b12 to b0 should be 0.

The region lower than the boundary address is marked as Secure, and higher than or equal to the boundary address is marked as Non-secure.

The boundary address is as follow.

0x2200_0000 + SRAMSABARn (Secure alias)

0x3200_0000 + SRAMSABARn (Non-secure alias)

For SRAMSABAR0

When the boundary address is 0x00000000, whole SRAM0 is marked as Non-secure.

When the boundary address is 0x00060000 or large, whole SRAM0 is marked as Secure.

For SRAMSABAR1

When the boundary address is 0x00060000 or less, whole SRAM1 is marked as Non-secure.

When the boundary address is 0x000E0000 or large, whole SRAM1 is marked as Secure.

44.2.2 SRAMSAR : SRAM Security Attribution Register

Base address: CPSCU = 0x4000_8000
CPSCU_NS = 0x5000_8000

Offset address: 0x10

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	SRAMWTSA	STBRAMSA	—	—	—	—	—	SRAMSA1	SRAMSA0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	SRAMSA0	SRAM0 Register Security Attribution 0: Secure 1: Non-secure	R/W
1	SRAMSA1	SRAM1 Register Security Attribution 0: Secure 1: Non-secure	R/W
6:2	—	These bits are read as 0. The write value should be 0.	R/W
7	STBRAMSA	Standby SRAM Register Security Attribution 0: Secure 1: Non-secure	R/W
8	SRAMWTSA	SRAMWTSC Security Attribution 0: Secure 1: Non-secure	R/W
31:9	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-1, P-TYPE-1
Note: Only Secure access can write to this register. Both Secure access and Non-secure read access are allowed but Non-secure write access is not allowed and TrustZone access error is not generated.
Note: This register is write-protected by PRCR_S.PRC4 register.

SRAMSA0 bit (SRAM0 Register Security Attribution)

The SRAMSA0 bit specifies security attributes of SRAMCR0, SRAMECCRGN0, SRAMESCLR.CLR00, and SRAMESCLR.CLR01.

SRAMSA1 bit (SRAM1 Register Security Attribution)

The SRAMSA1 bit specifies security attributes of SRAMCR1 and SRAMESCLR.CLR1.

STBRAMSA bit (Standby SRAM Register Security Attribution)

The STBRAMSA bit specifies security attributes of STBRAMCR and SRAMESCLR.CLRS.

SRAMWTSA bit (SRAMWTSC Security Attribution)

The SRAMWTSA bit specifies security attributes of SRAMWTSC.

44.2.3 SRAMPRCR_S : SRAM Protection Control Register for Secure

Base address: SRAM = 0x4000_2000

Offset address: 0x00

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	KW[7:0]								—	—	—	—	—	—	—	PR
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	PR	Register Write Control 0: Writing to registers are disabled 1: Writing to registers are enabled	R/W
7:1	—	These bits are read as 0. The write value should be 0.	R/W
15:8	KW[7:0]	Write Key Code Key code protection to the PR bit	R/W

Note: S-TYPE-6, P-TYPE-2

Note: It is necessary to write by half word access.
Byte write access is prohibited. When byte write access is executed, operation is not guaranteed.

PR bit (Register Write Control)

The PR bit controls the write mode of the SRAMWTSC, SRAMCR0, SRAMCR1, SRAMECCRGN0, and STBRAMCR registers that are marked as Secure by SRAMSAR register. When this bit is set to 1, writing to the SRAMWTSC, SRAMCR0, SRAMCR1, SRAMECCRGN0, and STBRAMCR marked as Secure is enabled.

While writing to this register it is necessary to write 0xA5 to the KW[7:0] bits simultaneously.

KW[7:0] bits (Write Key Code)

The KW[7:0] bits enable or disable writing to the PR bit. When you write to the PR bit, write 0xA5 to the KW[7:0] bits simultaneously. When a value other than 0xA5 is written to KW[7:0], the PR bit is not updated. The KW[7:0] bits are always read as 0x00.

44.2.4 SRAMPRCR_NS : SRAM Protection Control Register for Non-secure

Base address: SRAM_NS = 0x5000_2000

Offset address: 0x04

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	KW[7:0]								—	—	—	—	—	—	—	PR
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	PR	Register Write Control 0: Writing to registers are disabled 1: Writing to registers are enabled	R/W
7:1	—	These bits are read as 0. The write value should be 0.	R/W
15:8	KW[7:0]	Write Key Code Key code protection to the PR bit	R/W

Note: S-TYPE-7, P-TYPE-2

Note: It is necessary to write by half word access.
Byte write access is prohibited. When byte write access is executed, operation is not guaranteed.

PR bit (Register Write Control)

The PR bit controls the write mode of the SRAMWTSC, SRAMCR0, SRAMCR1, SRAMECCRGN0, and STBRAMCR registers that are marked as Non-secure by SRAMSAR register. When this bit is set to 1, writing to the SRAMWTSC, SRAMCR0, SRAMCR1, SRAMECCRGN0, and STBRAMCR marked as Non-secure is enabled.

While writing to this register it is necessary to write 0xA5 to the KW[7:0] bits simultaneously.

KW[7:0] bits (Write Key Code)

The KW[7:0] bits enable or disable writing to the PR bit. When you write to the PR bit, write 0xA5 to the KW[7:0] bits simultaneously. When a value other than 0xA5 is written to KW[7:0], the PR bit is not updated. The KW[7:0] bits are always read as 0x00.

44.2.5 SRAMWTSC : SRAM Wait State Control Register

Base address: SRAM = 0x4000_2000
SRAM_NS = 0x5000_2000

Offset address: 0x08

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	WTEN
Value after reset:	0	0	0	0	0	0	0	1

Bit	Symbol	Function	R/W
0	WTEN	SRAM Wait Enable 0: No wait 1: Add wait state in read access cycle to SRAMs	R/W
7:1	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3 (SRAMSAR.SRAMWTSA), P-TYPE-2

This register can be written only when the PR bit in the SRAMPRCR_S or SRAMPRCR_NS register is 1.

WTEN bit (SRAM Wait Enable)

The WTEN bit sets the wait cycle insertion to the access cycle of SRAM. When 1 is set to the WTEN bit, 1 wait cycle is inserted to the read access cycle of SRAM. Also when the WTEN bit is 1, the access to the same region*1 and the same mat*2 is continuous and 1 wait cycle is inserted to the second access cycle. When the access frequency is more than 120 MHz, it is necessary to set 1 wait cycle to the WTEN bit.

Note 1. The region of SRAM is divided into 128 KB units.
Note 2. The mat is divided into 0x0 to 0x7 and 0x8 to 0xF in the lower 4 bits of the address.

For example, the same region and the same mat is 6 areas of SRAM0, and 8 areas of SRAM1 in the figure below. If 1 area is accessed continuously, 1 wait cycle is inserted. If ECC function is enabled or bypass is enabled, ECC region is accessed, and so if access to the same mat continues, 1 wait cycle is inserted.

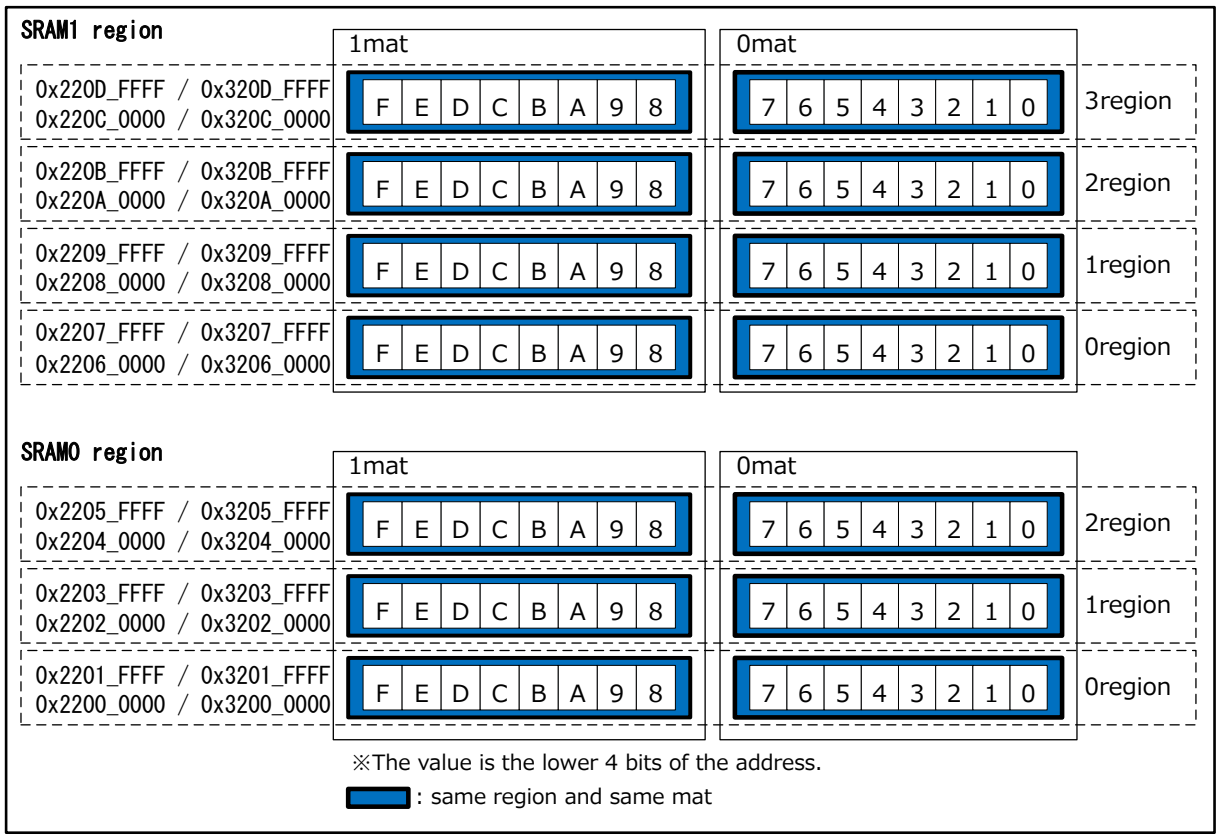


Figure 44.1 Mat configuration of each SRAM

44.2.6 SRAMCR0 : SRAM Control Register 0

Base address: SRAM = 0x4000_2000
SRAM_NS = 0x5000_2000

Offset address: 0x10

Bit position:	7	6	5	4	3	2	1	0
Bit field:	TSTBYP	—	—	E1STSEN	ECCMOD[1:0]		—	OAD
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	OAD	Operation after Detection for ECC Error Detection 0: Non-maskable interrupt 1: Reset.	R/W
1	—	This bit is read as 0. The write value should be 0.	R/W
3:2	ECCMOD[1:0]	ECC Operating Mode Select 0 0: Disable ECC function 0 1: Setting prohibited 1 0: Enable ECC function without error checking 1 1: Enable ECC function with error checking	R/W
4	E1STSEN	ECC 1-Bit Error Information Update Enable 0: Disable updating of 1-bit ECC error information 1: Enable updating of 1-bit ECC error information	R/W
6:5	—	These bits are read as 0. The write value should be 0.	R/W

Bit	Symbol	Function	R/W
7	TSTBYP	ECC Bypass Select 0: Disable ECC bypass 1: Enable ECC bypass	R/W

Note: S-TYPE-3 (SRAMSAR.SRAMSA0), P-TYPE-2

This register can be written only when the PR bit in the SRAMPRCR_S or SRAMPRCR_NS register is 1.

Do not write to this register while access to SRAM is in progress. See section 44.4.2. Note of write to SRAMCR0, SRAMCR1 and SRAMECCRGN0 registers for writing to this register.

OAD bit (Operation after Detection for ECC Error Detection)

The OAD bit selects a reset or non-maskable interrupt when a ECC error is detected.

ECCMOD[1:0] bits (ECC Operating Mode Select)

The ECCMOD[1:0] bits set the access mode to the ECC area.

E1STSEN bit (ECC 1-Bit Error Information Update Enable)

The E1STSEN bit enables or disables updating of the ECC 1-bit error status bit in the SRAMESR in response to a 1-bit error. This bit also functions as an interrupt or a reset mask.

TSTBYP bit (ECC Bypass Select)

The TSTBYP bit enables direct access to ECC code by bypassing the ECC function. The ECC Bypass function is used along with setting the ECCMOD[1:0] bits in the same register as 00b. The ECC must be accessed the same address. The ECC code is assigned to the lower 8 bits. When writing the ECC code, the bits above the ECC bits are ignored. When reading the ECC code, the bits above the ECC bits are undefined.

For details of ECC test, see section 44.3.4. ECC Decoder Testing.

44.2.7 SRAMCR1 : SRAM Control Register 1

Base address: SRAM = 0x4000_2000
SRAM_NS = 0x5000_2000

Offset address: 0x14

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	OAD
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	OAD	Operation after Detection for Parity Error Detection 0: Non-maskable interrupt 1: Reset.	R/W
7:1	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3 (SRAMSAR.SRAMSA1), P-TYPE-2

This register can be written only when the PR bit in the SRAMPRCR_S or SRAMPRCR_NS register is 1.

Do not write to this register while access to SRAM is in progress. See section 44.4.2. Note of write to SRAMCR0, SRAMCR1 and SRAMECCRGN0 registers for writing to this register.

OAD bit (Operation after Detection for Parity Error Detection)

The OAD bit selects a reset or non-maskable interrupt when a parity error is detected.

44.2.8 SRAMECCRGN0 : SRAM0 ECC Region Control Register

Base address: SRAM = 0x4000_2000
SRAM_NS = 0x5000_2000

Offset address: 0x30

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	ECCRGN[1:0]	
Value after reset:	1	1	1	1	1	1	1	1

Bit	Symbol	Function	R/W
1:0	ECCRGN[1:0]	ECC Region Control ECC region selection 0 0: No ECC Region 0 1: 0x2200_0000 – 0x2201_FFFF / 0x3200_0000 – 0x3201_FFFF (128 KB) 1 0: 0x2200_0000 – 0x2203_FFFF / 0x3200_0000 – 0x3203_FFFF (256 KB) 1 1: 0x2200_0000 – 0x2205_FFFF / 0x3200_0000 – 0x3205_FFFF (384 KB) The ECC area selected by this register can be controlled by SRAMCR0.	R/W
7:2	—	These bits are read as 1. The write value should be 1.	R/W

Note: S-TYPE-3 (SRAMSAR.SRAMSA0), P-TYPE-2

This register can be written only when the PR bit in the SRAMPRCR_S or SRAMPRCR_NS register is 1.

Do not write to this register while access to SRAM is in progress. See section 44.4.2. Note of write to SRAMCR0, SRAMCR1 and SRAMECCRGN0 registers for writing to this register.

ECCRGN[1:0] bits (ECC Region Control)

The ECCRGN[1:0] bits select ECC area in SRAM0.

44.2.9 SRAMESR : SRAM Error Status Register

Base address: SRAM = 0x4000_2000
SRAM_NS = 0x5000_2000

Offset address: 0x40

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	ERRS	—	—	—	—	—	—	—	—	—	—	—	ERR1	ERR01	ERR00
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	ERR00	SRAM0 1-bit ECC Error Status 0: 1-bit ECC error has not occurred. 1: 1-bit ECC error has occurred.	R
1	ERR01	SRAM0 2-bit ECC Error Status 0: 2-bit ECC error has not occurred. 1: 2-bit ECC error has occurred.	R
2	ERR1	SRAM1 Parity Error Status 0: Parity error has not occurred. 1: Parity error has occurred.	R
13:3	—	These bits are read as 0.	R
14	ERRS	Standby SRAM Parity Error status 0: Parity error has not occurred. 1: Parity error has occurred.	R
15	—	This bit is read as 0.	R

Note: S-TYPE-5, P-TYPE-2

This register is cleared by the corresponding bit in the SRAMESCLR register or resets other than Bus Error Reset and Memory Error Reset. If error and clear occur at the same time, clear has priority. Also updating register stops during accessing from debugger.

ERR00 bit (SRAM0 1-bit ECC Error Status)

The ERR00 bit shows whether there is a 1-bit ECC error in SRAM0.

When ECC operations are enabled, error correction is selected and updating of the 1-bit error information is enabled. The ERR00 bit is set to 1 if there is a 1-bit error.

When the ERR00 bit is set to 1, a reset or non-maskable interrupt request is generated according to the SRAMCR0.OAD.

ERR01 bit (SRAM0 2-bit ECC Error Status)

The ERR01 bit shows whether there is a 2-bit ECC error in SRAM0.

When ECC operations are enabled, error correction is selected. The ERR01 bit is set to 1 if there is a 2-bit error.

When the ERR01 bit is set to 1, a reset or non-maskable interrupt request is generated according to the SRAMCR0.OAD.

ERR1 bit (SRAM1 Parity Error Status)

The ERR1 bit shows whether there is a parity error or not in the SRAM1.

The ERR1 bit is set if a parity error is detected.

When the ERR1 bit is set to 1, a reset or non-maskable interrupt request is generated according to the SRAMCR1.OAD.

ERRS bit (Standby SRAM Parity Error status)

The ERRS bit shows whether there is a parity error or not in the Standby SRAM.

The ERRS bit is set to 1 if there is an error.

When the ERRS bit is set to 1, a reset or non-maskable interrupt request is generated according to the STBRAMCR.OAD.

44.2.10 SRAMESCLR : SRAM Error Status Clear Register

Base address: SRAM = 0x4000_2000
SRAM_NS = 0x5000_2000

Offset address: 0x48

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	CLRS	—	—	—	—	—	—	—	—	—	—	—	CLR1	CLR01	CLR00
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	CLR00	SRAM0 1-bit ECC Error Status Clear Writing to the CLR00 clears SRAMESR.ERR00. 1: Clear 1-bit ECC error. Read value is always 0.	R/W*1
1	CLR01	SRAM0 2-bit ECC Error Status Clear Writing to the CLR01 clears SRAMESR.ERR01. 1: Clear 2-bit ECC error. Read value is always 0.	R/W*1
2	CLR1	SRAM1 Parity Error Status Clear Writing to the CLR1 clears SRAMESR.ERR1. 1: Clear Parity error. Read value is always 0.	R/W*1
13:3	—	These bits are read as 0. The write value should be 0.	R/W
14	CLRS	Standby SRAM Parity Error Status Clear Writing to the CLRS clears SRAMESR. ERRS. 1: Clear Parity error. Read value is always 0.	R/W*1

Bit	Symbol	Function	R/W
15	—	This bit is read as 0. The write value should be 0.	R/W

Note: S-TYPE-4 (SRAMSAR.SRAMSAn,STBRAMSA), P-TYPE-2
Note 1. For each bit, only 1 can be written to clear the error status.

CLR00 bit (SRAM0 1-bit ECC Error Status Clear)

The CLR00 bit can clear the SRAM0 1-bit ECC error status bit in the SRAMESR. If error and clear occur at the same time, clear has priority.

The SRAMESR.ERR00 bit can be cleared when writing 1 to CLR00.

CLR01 bit (SRAM0 2-bit ECC Error Status Clear)

The CLR01 bit can clear the SRAM0 2-bit ECC error status bit in the SRAMESR. If error and clear occur at the same time, clear has priority.

The SRAMESR.ERR01 bit can be cleared when writing 1 to CLR01.

CLR1 bit (SRAM1 Parity Error Status Clear)

The CLR1 bit can clear the SRAM1 parity error status bit in the SRAMESR. If error and clear occur at the same time, clear has priority.

The SRAMESR.ERR1 bit can be cleared when writing 1 to CLR1.

CLRS bits (Standby SRAM Parity Error Status Clear)

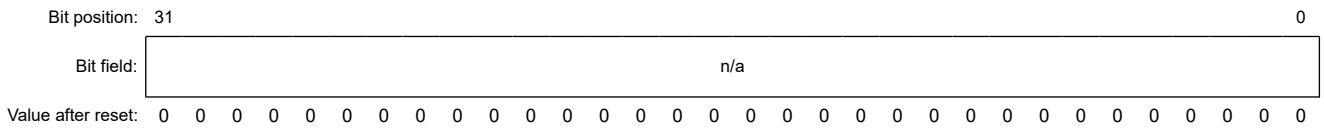
The CLRS bits can clear the Standby SRAM Parity error bit in the SRAMESR. If error and clear occur at the same time, clear has priority.

The SRAMESR.ERRS bit can be cleared when writing 1 to CLRS.

44.2.11 SRAMEARn : SRAM Error Address Register (n = 0 to 2)

Base address: SRAM = 0x4000_2000
SRAM_NS = 0x5000_2000

Offset address: 0x50 + 0x04 × n



Bit	Symbol	Function	R/W
31:0	n/a	When an SRAM error occurs, it stores an error address.	R

Note: S-TYPE-5, P-TYPE-2

This register is cleared by the corresponding bit in the SRAMESCLR register or resets other than Bus Error Reset and Memory Error Reset. If error and clear occur at the same time, clear has priority. Also updating register stops during accessing from debugger.

The error address is as follow.

0x2200_0000 + SRAMEARn (Secure alias)

0x3200_0000 + SRAMEARn (Non-secure alias)

For SRAMEAR0

This register stores the error address where 1-bit ECC error is detected. These bits hold the error address that occurred first. These bits are cleared by clearing 1-bit ECC error from SRAMESCLR.

For SRAMEAR1

This register stores the error address where 2-bit ECC error is detected. These bits hold the error address that occurred first. These bits are cleared by clearing 2-bit ECC error from SRAMESCLR.

For SRAMEAR2

This register stores the error address where parity error is detected. These bits hold the error address that occurred first. These bits are cleared by clearing parity error from SRAMESCLR.

44.3 Operation

44.3.1 Module Stop Function

Power consumption can be reduced by setting module stop control register A (MSTPCRA) to stop supply of the clock signal to SRAM.

SRAMn (n = 0 ,1) is controlled by MSTPAn (n = 0, 1) bit in MSTPCRA register and, in the case of 1, SRAMn becomes the clock stop state.

The SRAM is thus placed in the module-stop state by stopping supply of the clock signals. The SRAM operates after a reset.

SRAM is not accessible if it is in the module-stop state. A transition to the module-stop state should not be made while access to SRAM is in progress.

Access to the SRAM in the module-stop state is prohibited. If access is attempted, correct operation is not guaranteed.

For details on the MSTPCRA register, see section 10, Low Power Modes.

44.3.2 Correction of ECC errors

Enabling and disabling of ECC error correction can be selected through the setting by ECCMOD[1:0] bits of SRAMCR0 register. In the initial state, ECC error correction is disabled. The ECC check type is SEC-DED (Single-Error Correction and Double-Error Detection Code).

When ECC function is enabled, 8-bit check bits are appended to 64-bit data for writing. For reading, 72-bit (data: 64 bits, check bits: 8 bits) data is read out from the SRAM (ECC area) .

When ECC function and error checking are enabled, error correction is done if a 1-bit error occurs and the ERR00 bit in the SRAMESR register is set to 1 if the E1STSEN bit in the SRAMCR0 register is 1. If a 2-bit error occurs, error detection is done and the ERR01 bit in the SRAMESR register is set to 1, though error correction is not performed.

When ECC function is enabled and the error checking is disable, error correction is done if a 1-bit error occurs but ERR00 bit in the SRAMESR register is not updated although E1STSEN bit in the SRAMCR0 register is 1. If a 2-bit error occurs, this error is detected but the ERR01 bit in the SRAMESR register is not updated, and error correction is not performed.

When ECC function is disable, neither error correction nor error detection is done although 1-bit or 2-bit error occur.

So ERR00 and ERR01 bits are not updated.

When updating all the data after the occurrence of an error, the only support of 64 bit data writing.

Since the SRAM data is undefined after power on and release from Deep Software Standby mode, accessing the SRAM when ECC function is enabled and error checking is selected causes an ECC error to occur. Therefore, before using ECC function, initial writing with 64-bit data size, or initial writing with ECC function is enabled and the error checking is disabled, to the area to be used in the SRAM should be done.

When a read access is executed in a row after a write access, read access may be executed with priority. Therefore, during initialization, please do not perform the read access in a row after the write access.

44.3.3 ECC Error Interrupt Function

When ECC function is enabled, error checking is possible in the SRAM0. In the case of a 2-bit error, the ERR01 bit in the SRAMESR register set to 1. In the case of a 1-bit error, the ERR00 bit in the SRAMESR register set to 1 when SRAMCR0.E1STSEN bit is 1.

When the ECC 1-bit error is to be masked, it is necessary to set the SRAMCR0.E1STSEN bit to 0 to disable updating of the ERR00 bit to 1. An ECC error will not be generated while ECC function is disabled or when ECC function is enabled but error checking is not selected using the SRAMCR0.ECCMOD[1:0] bits.

ECC error may result in non-maskable interrupt or reset. When the OAD bit in the SRAMCR0 register is 1, ECC error is outputted to the Reset function. When it is 0, ECC Error interrupt is outputted to the ICU as a non-maskable interrupt.

ECC Error interrupt occurs when one flag in the SRAMESR register is set. ECC Error interrupt continues to occur until the SRAMESR register flag is cleared.

44.3.4 ECC Decoder Testing

ECC decoder testing should be done in the following order.

1. Executes the DMB instruction.
2. Write 0xA501 to the SRAMPRCR_S or SRAMPRCR_NS and enable writes to the SRAM-related registers.
3. Write 0x08 to the SRAMCR0 and enable the ECC function without error checking and disable the ECC bypass.
4. Executes the DMB instruction.
5. Write 8-bytes data to the target address. The 8-bits ECC code is automatically updated.
6. Executes the DMB instruction.
7. Write 0x80 to the SRAMCR0 and enable the ECC bypass.
8. Executes the DMB instruction.
9. Read target address to get 8-bits-ECC code.
10. To generate 1-bit/2-bit ECC error, reverse 1-bit/2-bit of the data read in the previous process and write the data back to the target address.
11. Executes the DMB instruction.
12. Write 0x1C to the SRAMCR0, disable the ECC bypass and enable the updating of 1-bit ECC error information and enable the ECC function with error checking.
13. Executes the DMB instruction.
14. Read the target address.
15. Executes the DMB instruction.
16. Confirm the generation of the ECC error by the SRAMESR.

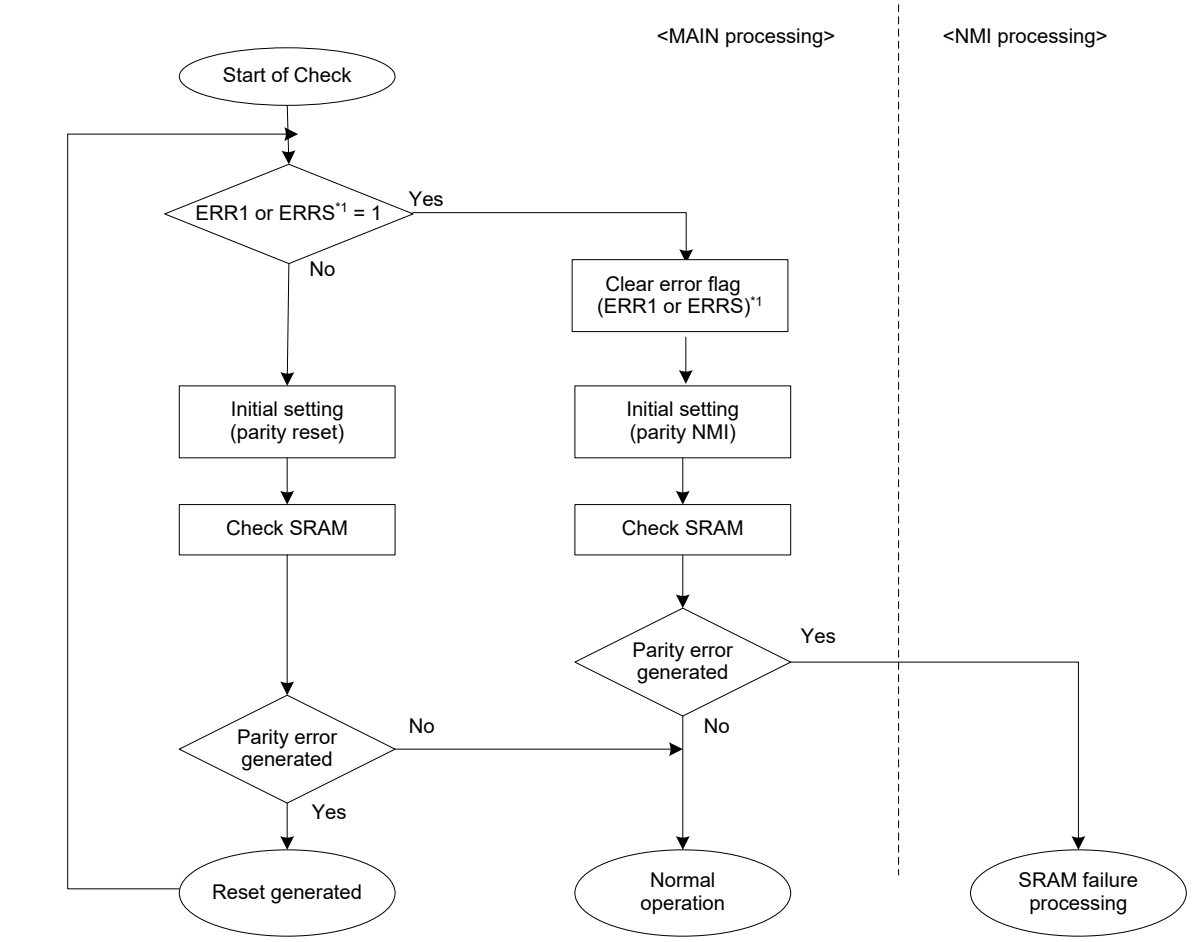
44.3.5 Parity Calculation Function

The IEC60730 standard requires the checking of SRAM data. When data is written, a parity bit is added to every 8-bit data in the SRAM, and when data is read, the parity is checked. When a parity error occurs, a parity-error notification is generated. This function can also be used to trigger a reset.

The parity-error notification can be specified as a non-maskable interrupt or a reset in the OAD bit of the SRAMCR1 register. When the OAD bit is set to 1, a parity error is output to the reset function. When the OAD bit is set to 0, a parity error is output to the ICU as a non-maskable interrupt.

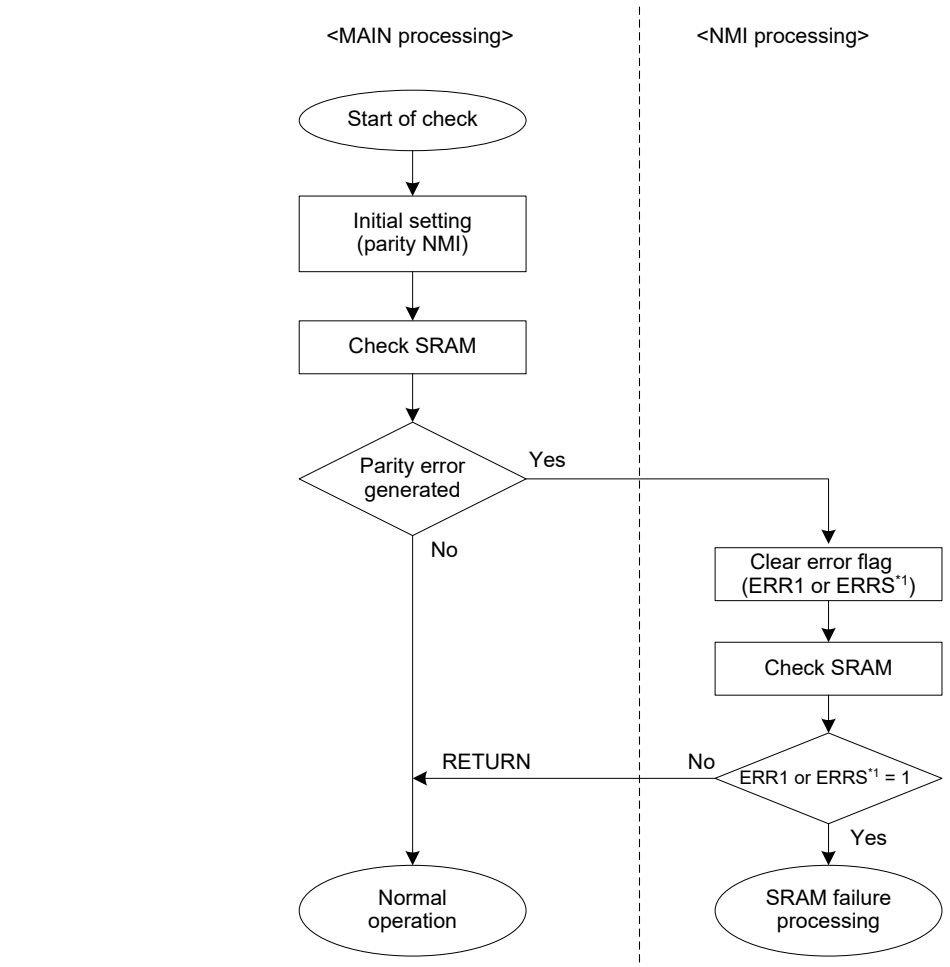
Parity Error often occurs due to noise. It is possible to confirm whether the parity error is caused by noise or destruction of data by following the parity operation flowchart. Figure 44.2 and Figure 44.3 shows flowcharts of SRAM parity check operation..

When a read access is executed in a row after a write access, read access is executed with priority. Therefore, during initialization, do not perform the read access in a row after the write access.



Note 1. ERR1 or ERRS: SRAM error status (SRAMESR.ERR1, ERRS bit)

Figure 44.2 Flow of SRAM parity check when SRAM parity reset is enabled



Note 1. ERR1 or ERRS: SRAM error status (SRAMESR.ERR1, ERRS bit)

Figure 44.3 Flow of SRAM parity check when SRAM parity interrupt is enabled

44.3.6 TrustZone Filter function

44.3.6.1 TrustZone Filter for SRAM Registers

SRAM registers can be protected with a Security Attribution (SA) from Non-secure or Secure transaction. When SA indicates that SRAM registers are Secure status, Non-secure transaction cannot access them because TrustZone Filter detects an error and protects the access. When SA indicates that SRAM registers are Non-secure status, Secure transaction cannot access them because Trust Zone Filter detects an error and protects the access. SA for SRAM registers is just one to be used commonly among SRAM registers.

In the case of a failed access due to TrustZone error, error response is generated.

Table 44.2 Register protection (1 of 2)

SA	Transaction	Write access	Read access
Secure	Secure	Permitted	Permitted
	Non-secure	Protected (TrustZone Filter error)	Protected (TrustZone Filter error)

Table 44.2 Register protection (2 of 2)

SA	Transaction	Write access	Read access
Non-secure	Secure	Protected (TrustZone Filter error)	Protected (TrustZone Filter error)
	Non-secure	Permitted	Permitted

44.3.6.2 TrustZone Filter for SRAM Memory Regions

SRAM0, SRAM1 regions can be divided into Secure and Non-secure independently. The access permissions for these regions are as below.

Table 44.3 Memory protection

SA	Transaction	Write access	Read access
Secure	Secure	Permitted	Permit
	Non-secure	Protected (TrustZone Filter error)	Protected (TrustZone Filter error)
Non-secure	Secure	Protected (TrustZone Filter error)	Protected (TrustZone Filter error)
	Non-secure	Permitted	Permitted

TrustZone filter error for SRAM memory generates an error notification.

44.3.7 Interrupt Source

The SRAM interrupt source includes an ECC error, Parity error and TrustZone filter error. ECC error and Parity error can choose non-maskable interrupt or reset by SRAMCR0.OAD or SRAMCR1.OAD bit. The SRAM interrupt occurs when one error status in the SRAMESR register is set to 1, the SRAM interrupt continues to occur until the SRAMESR register flag is cleared. When Common memory error occur (NMISR.CMST=1 or RSTSR1.CMSR=1), please read SRAMESR and check SRAM interrupt source. When the access from debugger, the error is detected and corrected, but no error flag is set, reset and non-maskable interrupt are maskable. For details on the debug mode, see section 2, CPU.

Table 44.4 SRAM Interrupt Source

Name	Interrupt Source	DTC Activation	DMAC Activation
ECCERR	ECC error (SRAMs with ECC)	Not possible	Not possible
PARITYERR	Parity error (SRAMs with parity)	Not possible	Not possible
TZFLT	TrustZone filter error	Not possible	Not possible

44.3.8 Wait state

When ICLK frequencies is higher than 120 MHz, do not set 0x00 in wait enable bit for the SRAMWTSC register, in order to insert a wait cycle. When the wait is not inserted, the operation is not guaranteed.

Depending on the operating frequency of ICLK, the WAIT setting for SRAM access has the following conditions.

[ICLK frequency]:

- 240 MHz ≥ ICLK > 120 MHz = 1 wait
- 120 MHz ≥ ICLK = No-wait

44.4 Usage Note

44.4.1 Instruction fetch from SRAM area

When using SRAM to operate a program, initialize the SRAM area so that the CPU can correctly prefetch data. A parity or ECC error might occur if the CPU prefetches from an area that is not initialized. Initialize the additional 12-byte area from the end address of the program with the 8-byte boundary. Renesas recommends using the NOP instruction for data initialization.

44.4.2 Note of write to SRAMCR0, SRAMCR1 and SRAMECCRGN0 registers

This chapter provides examples of how to configure SRAMCR0, SRAMCR1 and SRAMECCRGN0.

All of the followings have to be satisfied:

1. CPU does not execute program stored in SRAM
2. All bus masters other than CPU does not access SRAM
3. SRAMCR0, SRAMCR1 and SRAMECCRGN0 are Device-nGnRnE set by MPU
4. SRAMCR0, SRAMCR1 and SRAMECCRGN0 have to be configured with the following procedure:
   1. DMB instruction
   2. Write to SRAMCR0, SRAMCR1 and SRAMECCRGN0 registers
   3. DMB instruction

44.4.3 Notes on Using Error Checking of SRAM

Data in SRAM are undefined when the power is turned on. Therefore, parity check errors or ECC errors occur if the data are read before initialization. The SRAM are read in 8-byte (64-bit) units. Initialize them on 8-byte boundaries.

45. Standby SRAM

45.1 Overview

An on-chip SRAM is provided to retain data in Deep Software Standby mode. Table 45.1 lists the Standby SRAM specifications.

Table 45.1 Standby SRAM specifications

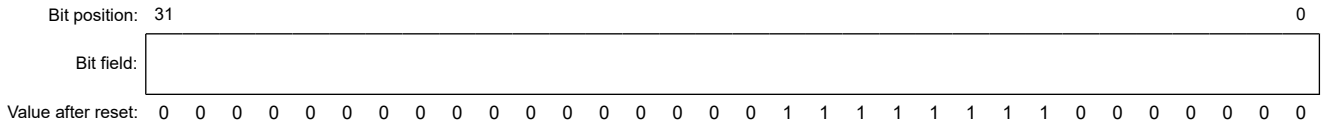
Item	Description
SRAM capacity	1 KB
SRAM address	0x2600_0000 to 0x2600_03FF (Secure alias), 0x3600_0000 to 0x3600_03FF (Non-secure alias)
Access	Wait states are inserted into the access cycle by default. If the ICLK frequency is higher than 120 MHz, a wait state is required. If the ICLK frequency is 120 MHz or less, a wait state is not required.
Data retention function	Data can be retained in Deep Software Standby mode 1. In Deep Software Standby mode 2 and 3, data cannot be retained. See section 45.3.1. Data Retention for details.
parity	Even parity (data: 8 bits, parity: 1 bit)
Module-stop function	Module-stop state can be set to reduce power consumption. See section 45.3.2. Module-stop Function for details.
Security	Permits the read and write operations to Standby RAM following TrustZone Filter function. See section 45.3.4. TrustZone Filter function for details.

45.2 Register Descriptions

45.2.1 STBRAMSABAR : Standby SRAM Security Attribute Boundary Address Register

Base address: CPSCU = 0x4000_8000
CPSCU_NS = 0x5000_8000

Offset address: 0x420



Bit	Symbol	Function	R/W
31:0	n/a	Boundary address between Secure and Non-secure.	R/W

Note: S-TYPE-1, P-TYPE-1
Note: This register is write-protected by PRCR_S.PRC4 register.

STBRAMSABAR specifies the boundary address between the Secure and Non-secure regions of Standby SRAM. Write the absolute address to the STBRAMSABAR. When writing to STBRAMSABAR, writing from b31 to b15 is ignored and the value written from b6 to b0 should be 0.

The region lower than the boundary address is marked as Secure, and higher than or equal to the boundary address is marked as Non-secure. Therefore, when the boundary address is 0x00000000, whole Standby SRAM is marked as Non-secure, and when the boundary address is 0x00000400 or large, whole Standby SRAM is marked as Secure.

The boundary address is as follow.

- 0x2600_0000 + STBRAMSABAR (Secure alias)
- 0x3600_0000 + STBRAMSABAR (Non-secure alias)

45.2.2 STBRAMPABAR_NS : Standby SRAM Privilege Attribute Boundary Address Register for Non-secure

Base address: CPSCU_NS = 0x5000_8000

Offset address: 0x490

Bit position:	31																												0
Bit field:	n/a																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	n/a	Boundary address between Privileged and Unprivileged.	R/W

Note: S-TYPE-7, P-TYPE-2
Note: This register is write-protected by PRCR_NS.PRC4 register.

STBRAMPABAR_NS specifies the boundary address between the Privileged and Unprivileged regions of Standby SRAM Non-secure regions set by STBRAMSABAR. Write the absolute address to the STBRAMPABAR_NS. When writing to STBRAMPABAR_NS, writing from b31 to b15 is ignored and the value written from b6 to b0 should be 0.

The region lower than the boundary address is marked as Privileged, and higher than or equal to the boundary address is marked as Unprivileged. Therefore, when the boundary address is 0x00000000, or less than or equal to start address of Standby SRAM Non-secure regions set by STBRAMSABAR, whole Standby SRAM is marked as Unprivileged, and when the boundary address is 0x00000400 or large, or higher than or equal to end address of Standby SRAM Non-secure regions set by STBRAMSABAR, whole Standby SRAM is marked as Privileged.

The boundary address is as follow.

- 0x3600_0000 + STBRAMPABAR_NS (Non-secure alias)

45.2.3 STBRAMPABAR_S : Standby SRAM Privilege Attribute Boundary Address Register for Secure

Base address: CPSCU = 0x4000_8000

Offset address: 0x494

Bit position:	31																												0
Bit field:	n/a																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	n/a	Boundary address between Privileged and Unprivileged.	R/W

Note: S-TYPE-6, P-TYPE-2
Note: This register is write-protected by PRCR_S.PRC4 register.

STBRAMPABAR_S specifies the boundary address between the Privileged and Unprivileged regions of Standby SRAM Secure regions set by STBRAMSABAR. Write the absolute address to the STBRAMPABAR_S. When writing to STBRAMPABAR_S, writing from b31 to b15 is ignored and the value written from b6 to b0 should be 0.

The region lower than the boundary address is marked as Privileged, and higher than or equal to the boundary address is marked as Unprivileged. Therefore, when the boundary address is 0x00000000, or less than or equal to start address of Standby SRAM Secure regions set by STBRAMSABAR, whole Standby SRAM is marked as Unprivileged, and when the boundary address is 0x00000400 or large, or higher than or equal to end address of Standby SRAM Secure regions set by STBRAMSABAR, whole Standby SRAM is marked as Privileged.

The boundary address is as follow.

- 0x2600_0000 + STBRAMPABAR_S (Secure alias)

45.2.4 STBRAMCR : Standby SRAM Control Register

Base address: SRAM = 0x4000_2000
SRAM_NS = 0x5000_2000

Offset address: 0x110

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	OAD
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	OAD	Operation after detection 0: Non-maskable interrupt. 1: Reset.	R/W
7:1	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3 (SRAMSAR.STBRAMSA), P-TYPE-2

This register can be written only when the PR bit in the SRAMPRCR_S or SRAMPRCR_NS register is 1.

Do not write to this register while access to Standby SRAM is in progress.

OAD bit (Operation after detection)

This bit is specified to generate either reset or non-maskable interrupt when parity error is detected.

45.2.5 STBRAMEAR : Standby SRAM Error Address Register

Base address: SRAM = 0x4000_2000
SRAM_NS = 0x5000_2000

Offset address: 0x150

Bit position:	31	0
Bit field:	n/a	
Value after reset:	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0	

Bit	Symbol	Function	R/W
31:0	n/a	When an SRAM error occurs, it stores an error address.	R

Note: S-TYPE-5, P-TYPE-2

This register is cleared by the corresponding bit in SRAMESCLR register, or resets other than Bus Error Reset and Memory Error Reset. If error and clear occur at the same time, clear has priority. Also during accessing from debugger it is to stop updating register.

The error address is as follow.

- 0x2600_0000 + STBRAMEAR (Secure alias)
- 0x3600_0000 + STBRAMEAR (Non-secure alias)

This register stores the error address where parity error is detected. These bits hold the error address that occurred first. These bits are cleared by clearing parity error from SRAMESCLR.

45.3 Operation

45.3.1 Data Retention

The power supply to the Standby SRAM in Deep Software Standby mode is enabled by the DPSBYCR.SRKEEP bit. If the DPSBYCR.SRKEEP bit are set to 1b, data in the Standby SRAM is retained in Deep Software Standby mode 1. For details on the DPSBYCR.SRKEEP bit, see section 10, Low Power Modes.

45.3.2 Module-stop Function

Power consumption can be reduced by setting module stop control register A (MSTPCRA) to stop supply of the clock signal to SRAM.

If the Standby SRAM bit in MSTPCRA is set to 1, supply of the clock signal to the Standby SRAM is stopped.

The Standby SRAM is thus placed in the module-stop state by stopping supply of the clock signals. The Standby SRAM operates after a reset.

The Standby SRAM is not accessible if it is in the module-stop state. A transition to the module-stop state should not be made while access to the standby SRAM is in progress.

Access to the Standby SRAM in the module-stop state is prohibited. If access is attempted, correct operation is not guaranteed.

For details on the MSTPCRA register, see section 10, Low Power Modes.

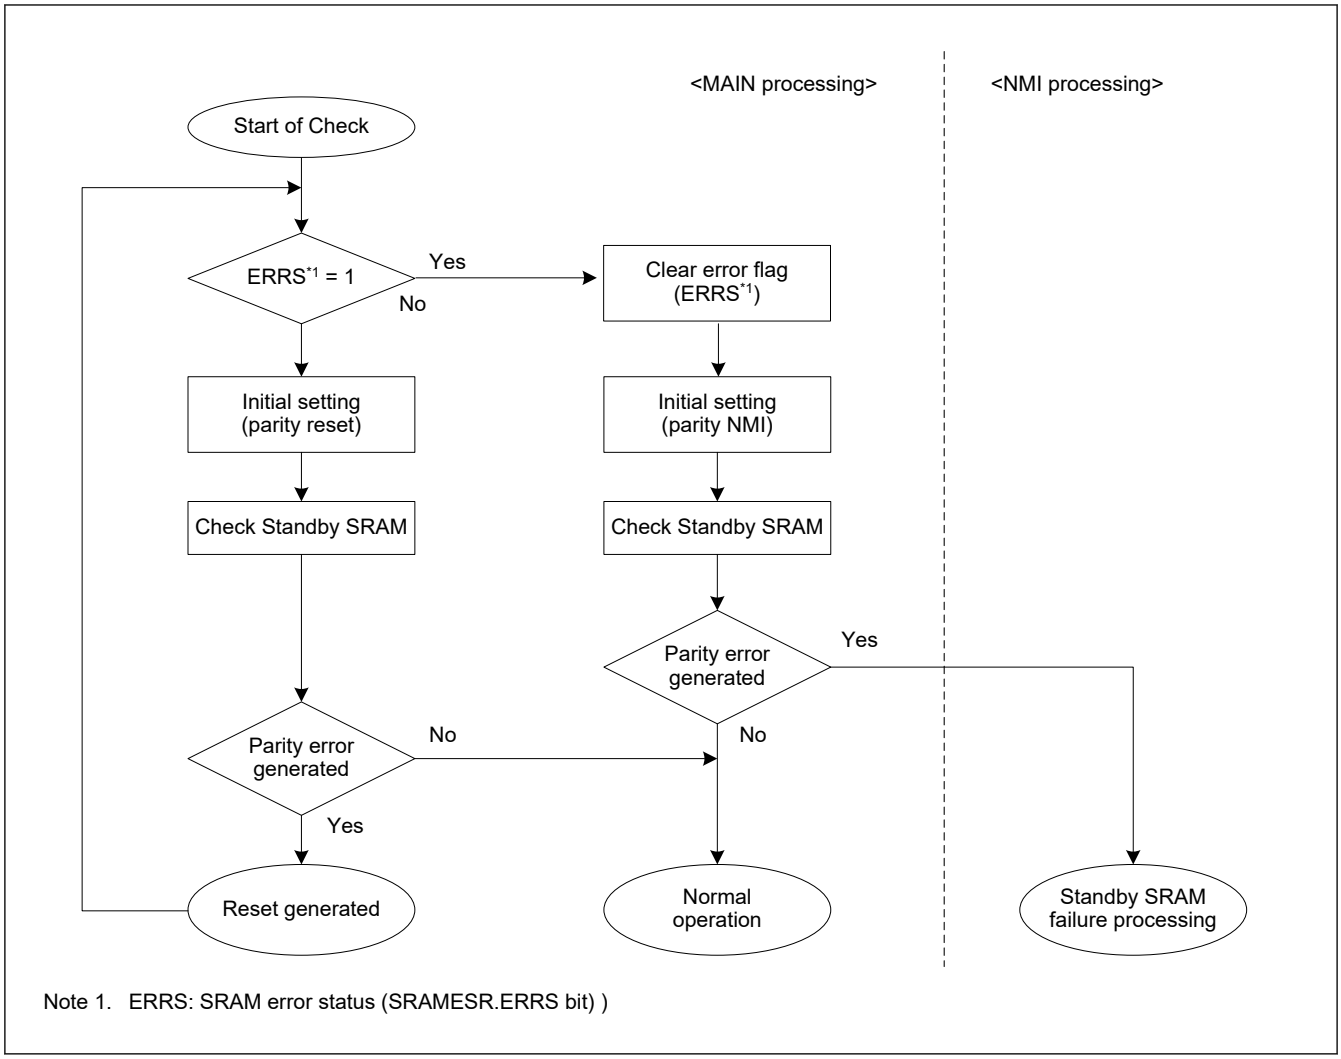
45.3.3 Parity Calculation Function

The IEC60730 standard requires the checking of STBRAMCR data. When data is written, a parity bit is added to every 8-bit data in the Standby SRAM which has 32-bit data width, and when data is read, the parity is checked. When a parity error occurs, a parity error notification is generated. This function can also be used to trigger a reset.

The parity-error notification can be specified as a non-maskable interrupt or a reset in the OAD bit of the STBRAMCR register. When the OAD bit is set to 1, a parity error is output to the reset function. When the OAD bit is set to 0, a parity error is output to the ICU as a non-maskable interrupt.

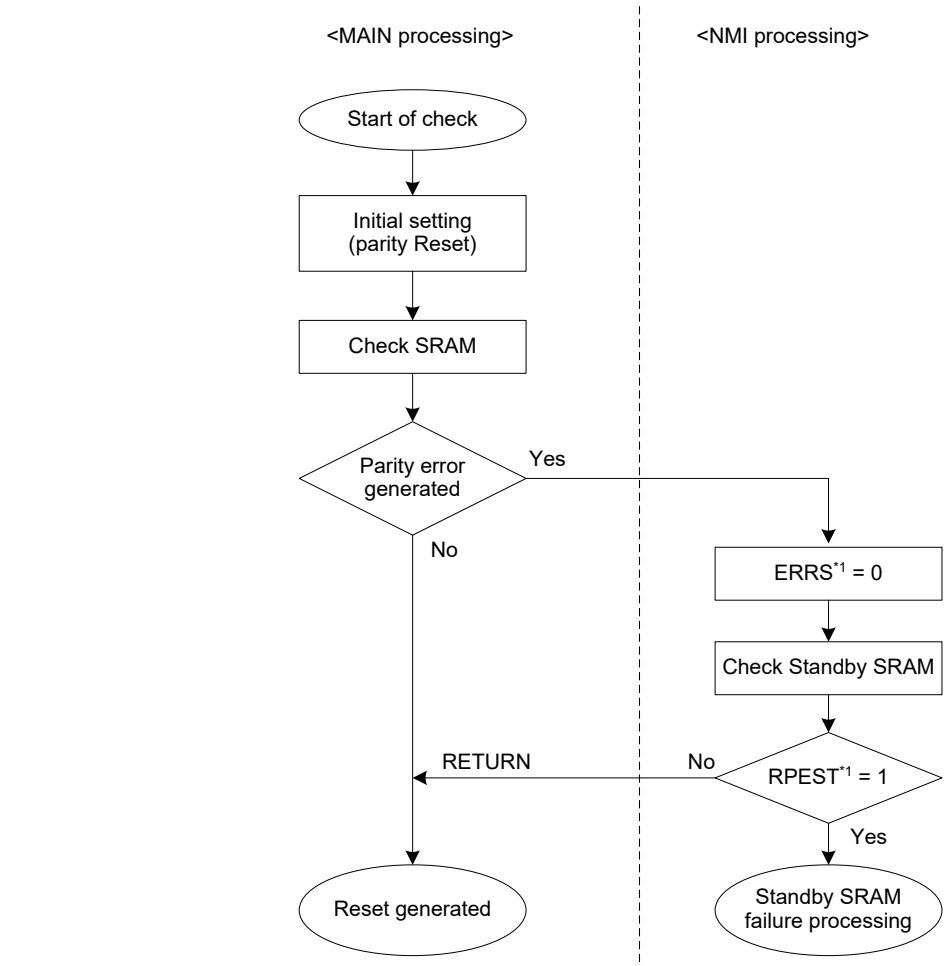
Parity errors often occur because of noise. To confirm whether the cause of the parity error is noise or corruption, follow the parity check flows shown in Figure 45.1 and Figure 45.2.

When a read access is executed in a row after a write access, read access is executed with priority. Therefore, during initialization, do not perform the read access in a row after the write access.



Note 1. ERRS: SRAM error status (SRAMESR.ERRS bit))

Figure 45.1 Flow of Standby SRAM parity check when SRAM parity reset is enabled



Note 1. ERRS: SRAM error status (SRAMESR.ERRS bit)

Figure 45.2 Flow of Standby SRAM parity check when SRAM parity interrupt is enabled

45.3.4 TrustZone Filter function

45.3.4.1 TrustZone Filter for Standby SRAM registers

Standby SRAM registers can be protected with a Security Attribution (SA) from Non-secure or Secure transaction. When SA indicates that Standby SRAM registers are Secure status, Non-secure transaction can not access them because TrustZone Filter detects finds an error and protects the access. When SA indicates that SRAM registers are Non-secure status, Secure transaction can not access them because Trust Zone Filter detects finds an error and protects the access. SA for Standby SRAM registers is just one to be used commonly among Standby SRAM registers.

In the case of a failed access due to TrustZone error, error response is generated.

Table 45.2 Standby SRAM register protection

SA	Transaction	Write access	Read access
Secure	Secure	Permitted	Permitted
	Non-secure	Protected (TrustZone Filter error)	Protected (TrustZone Filter error)
Non-secure	Secure	Protected (TrustZone Filter error)	Protected (TrustZone Filter error)
	Non-secure	Permitted	Permitted

45.3.4.2 TrustZone Filter for Standby SRAM memory regions

Standby SRAM regions can be divided into Secure and Non-secure. The access permissions for these regions are as below.

Table 45.3 Standby SRAM memory protection by Security Attribution

SA	Transaction	Write access	Read access
Secure	Secure	Permitted	Permitted
	Non-secure	Protected (TrustZone Filter error)	Protected (TrustZone Filter error)
Non-secure	Secure	Protected (TrustZone Filter error)	Protected (TrustZone Filter error)
	Non-secure	Permitted	Permitted

Standby SRAM regions can be divided into Privileged and Unprivileged. The access permissions for these regions are as below.

Table 45.4 Standby SRAM memory protection by Privilege Attribution

PA	Transaction	Write access	Read access
Privileged	Privileged	Permitted	Permitted
	Unprivileged	Protected (TrustZone Filter error)	Protected (TrustZone Filter error)
Unprivileged	Privileged	Permitted	Permitted
	Unprivileged	Permitted	Permitted

TrustZone Filter error for Standby SRAM memory generates an error notification.

For details, see section 37, Security Features .

45.3.5 Interrupt Source

The Standby SRAM interrupt source includes a Parity error and TrustZone filter error.

Parity error can choose non-maskable interrupt or reset by STBRAMCR.OAD bit.

The Standby SRAM interrupt occurs when the SRAMESR.ERRS is set to 1. the Standby SRAM interrupt continues to occur until the SRAMESR.ERRS is cleared.

When Common memory error occur(NMISR.CMST=1 or RSTSR1.CMSR=1), please read SRAMESR and check SRAM interrupt source. When the access from debugger, no error flag is set, reset and non-maskable interrupt are maskable.

For more detail on the debug mode, see section 2, CPU.

Table 45.5 Standby SRAM Interrupt Source

Name	Interrupt Source	DTC Activation	DMAC Activation
PARITYERR	Parity error	Not possible	Not possible
TZFLT	TrustZone filter error	Not possible	Not possible

45.3.6 Wait state

When ICLK frequencies is higher than 120 MHz, do not set 0x00 in wait enable bit for the SRAMWTSC register, in order to insert a wait cycle. When the wait is not inserted, the operation is not guaranteed.

Depending on the operating frequency of ICLK, the WAIT setting for Standby SRAM access has the following conditions.

[ICLK frequency]:

- 240 MHz ≥ ICLK > 120 MHz = 1 wait
- 120 MHz ≥ ICLK = No-wait

45.4 Usage Notes

45.4.1 Instruction Fetch from the Standby SRAM Area

When using Standby SRAM to operate a program, initialize the Standby SRAM area so that the CPU can correctly prefetch data. A parity error might occur if the CPU prefetches from an area that is not initialized. Initialize the additional 12-byte area from the end address of the program with the 4-byte boundary. Renesas recommends using the NOP instruction for data initialization.

45.4.2 Notes on Self-Diagnosis of the Standby SRAM

A write buffer is mounted for the Standby Standby SRAM. When the same address is read after a write operation, data in the write buffer, rather than in the memory cell of the Standby SRAM may be read. When the Standby SRAM is self-diagnosed, confirm that the data have been written by following the procedure below so that data will not be read from the write buffer.

1. Write data to the address targeted for diagnosis.
2. Write data to an address which is at least 4 addresses away from the that in step1.
3. Read the data from the address in step1.

46. Flash Memory

This MCU incorporates code flash memory, data flash memory, and option-setting memory. The code flash memory stores instructions and operands, and the data flash memory stores data. For option-setting memory, see section 6, Option-Setting Memory.

46.1 Overview

Table 46.1 lists the specifications of the flash memory, and Figure 46.1 is block diagrams of the flash memory related modules.

The I/O pins used in boot mode, see Table 46.37.

The FCU (flash control unit) controls programming and erasure of the flash memory. The FACI (flash application command interface) controls the FCU according to the specified FACI commands.

Regarding the configuration of the code flash memory, see Figure 46.2 to Figure 46.3, and for the configuration of the data flash memory, see Figure 46.4.

Table 46.1 Specifications of flash memory (1 of 2)

Item	Code flash memory	Data flash memory
Memory capacity	User area: 2 Mbytes max	Data area: 12 Kbytes
Value after erasure	0xFF	Undefined
Programming/erasing method	• Programming and erasing the code flash memory and data flash memory, and programming the option-setting memory are handled by the FACI commands specified in the FACI command issuing area (Secure: 0x4010_0000, Non-secure: 0x5010_0000) (self-programming). • Programming/erasure through transfer by a serial-programmer via a serial interface (serial programming)	
Protection	Protects against erroneous rewriting of the flash memory	
Dual bank function	The dual-bank structure makes a safe update possible in cases where programming is suspended. • Linear mode: the code flash memory is used as one area. • Dual mode: the code flash memory is divided into two areas.	Not available
Block swap function	The block swap structure makes a safe update for a part of Non-secure application possible in case where programming is suspended.	Not available
Background operations (BGOs)	• The code flash memory can be read while the code flash memory is being programmed or erased. • The data flash memory can be read while the code flash memory is being programmed or erased. • The code flash memory can be read while the data flash memory is being programmed or erased.	
Units of programming and erasure	• Units of programming for the user area: 128 bytes • Units of erasure for the user area: Block units	• Unit of programming for the data area:4/8/16 bytes • Unit of erasure for the data area:64/128/256 bytes
Other functions	Interrupts can be accepted during self-programming. In the initial settings of this MCU, an expansion area of the option-setting memory can be set.	
On-board programming (four types)	Programming/erasure in boot mode (for the SCI interface) • The asynchronous serial interface (SCI9) is used. • The transfer rate is adjusted automatically. Programming/erasure in boot mode (for the USB interface) • USBFS is used. • Dedicated hardware is not required, so direct connection to a PC is possible. Programming/erasure in On-chip debug mode • JTAG or SWD interface is used Programming and erasure by self-programming • This allows code flash memory programming/erasure without resetting the system.	

Table 46.1 Specifications of flash memory (2 of 2)

Item	Code flash memory	Data flash memory
Unique ID	A 16-byte ID code provided for each MCU	
FACI command	Program : 128 bytes Block erase: 1 block (8 KB or 32 KB) P/E suspend P/E resume Forced Stop Status Clear Configuration set (16 bytes)	Program: 4/8/16 bytes Block Erase: 1 block (64 bytes) Multi Block Erase: 64/128/256 bytes P/E suspend P/E resume Forced Stop Blank Check: 4 bytes to data flash memory capacity Status Clear Configuration set (4/16 Bytes) Increment Counter: 1bit Refresh Counter Read Counter: 8 Bytes
Security function	Protects against illicit tampering with or reading out of data in flash memory Startup area select setting protection ● BTFLG and FSUACR registers are protected by the FSPR bit. Permanent block protect setting protection ● Code flash memory is permanently protected from programming/erasure operation by the permanent block protect function. Flash memory protection for TrustZone ● Protection for flash memory area (P/E) ● Protection for flash memory area (read) ● Protection for register ● Protection during FACI command operation. ● Code flash P/E mode entry protection ● Data flash configuration area protection ● Anti-rollback Counter	
Safety function	Software protection ● FACI command protection by FENTRYR register. ● Flash memory is protected by FWEPROR register ● The user area is protected by the block protect setting Error protection ● Error is detected when unintended commands or prohibited settings occur. The FACI command is not accepted after an error detection. Boot area protection ● The start-up area select function allows customer to safely update the boot firmware. The size of the start-up area is 8 KB.	
Interrupt request	● FRDYI (flash sequencer ready (processing end)) : Enabled by FRDYIE bit. ● FIFERR (flash sequencer error) : Enabled by CFAEIE/CMDLKIE/DFAEIE bits	
Address conversion	Start-up area select function is supported in linear mode Dual mode and Linear mode ● Bank swap function is supported in dual mode ● Block swap function is supported in linear mode	

Figure 46.1 shows how modules related to flash memory can be configured. The flash sequencer is configured with the FCU and FACI. The FCU executes basic control for rewriting of the flash memory. The FACI receives FACI commands using peripheral bus, and controls FCU operations accordingly.

In response to a reset, the FACI transfers data from the flash memory to the option byte storage registers.

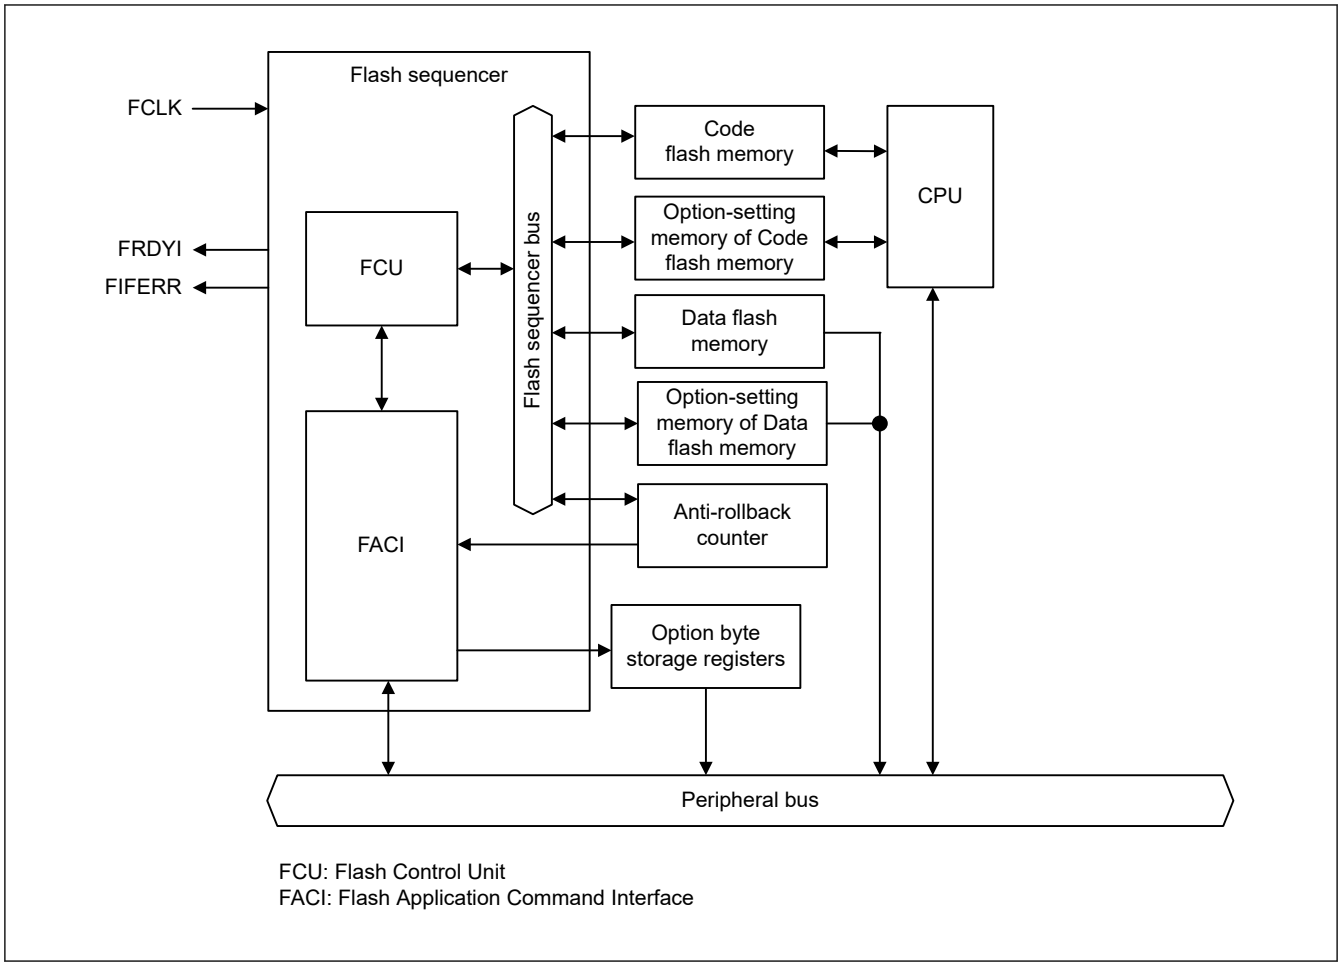


Figure 46.1 Block diagram of flash memory-related modules

46.2 Structure of Memory

Figure 46.2 shows the memory map of code flash memory in linear mode. Figure 46.3 shows the memory map of code flash memory in dual mode. This MCU can use the code flash memory as 2 bank areas by using the dual bank function. This dual-bank structure allows a safe update of a program while a user program is running.

The user area of the code flash memory in this MCU is divided into 8 KB and 32 KB blocks, which serve as the units of erasure.

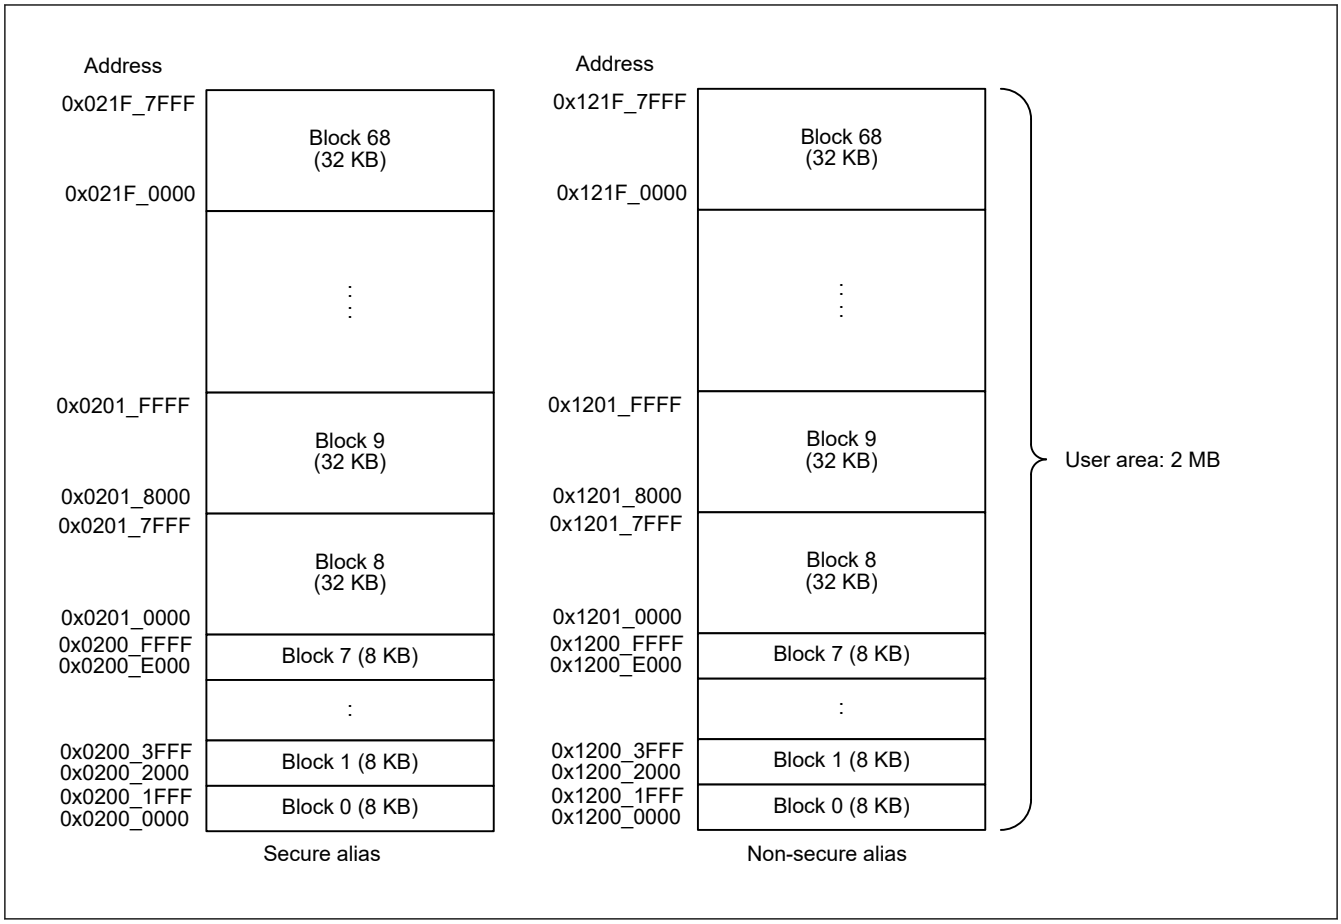

Figure 46.2 Map of the Code Flash Memory in Linear Mode

Table 46.2 Read and programming/erasure address by product for the code flash memory in Linear Mode

Product	Address	Number of blocks
2 MB product	Secure alias : 0x0200_0000 to 0x021F_7FFF Non-secure alias : 0x1200_0000 to 0x121F_7FFF	0 to 68
1 MB product	Secure alias : 0x0200_0000 to 0x020F_FFFF Non-secure alias : 0x1200_0000 to 0x120F_FFFF	0 to 37

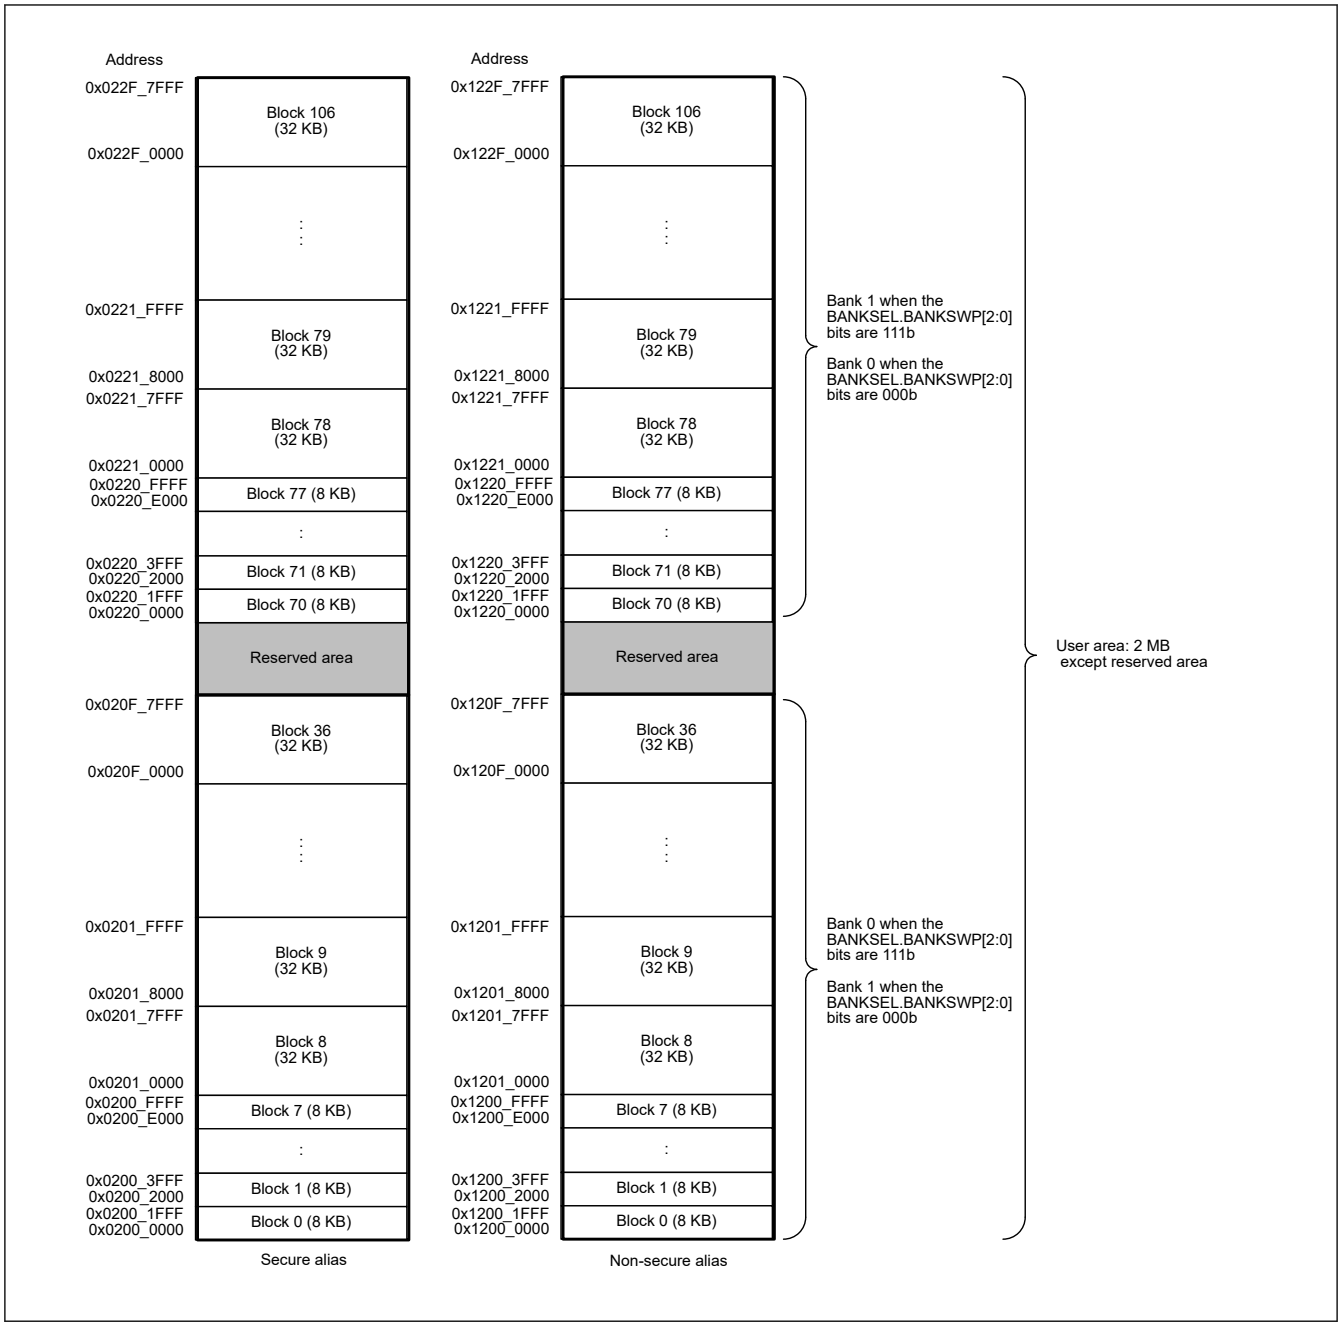

Figure 46.3 Map of the Code Flash Memory in Dual Mode

Table 46.3 Read and programming/erasure address by product for the code flash memory in Dual Mode

Product	Address	Number of blocks
2 MB product, lower side bank	Secure alias : 0x0200_0000 to 0x020F_7FFF Non-secure alias : 0x1200_0000 to 0x120F_7FFF	0 to 36
2 MB product, upper side bank	Secure alias : 0x0220_0000 to 0x022F_7FFF Non-secure alias : 0x1220_0000 to 0x122F_7FFF	70 to 106
1 MB product, lower side bank	Secure alias : 0x0200_0000 to 0x0207_FFFF Non-secure alias : 0x1200_0000 to 0x1207_FFFF	0 to 21
1 MB product, upper side bank	Secure alias : 0x0220_0000 to 0x0227_FFFF Non-secure alias : 0x1220_0000 to 0x1227_FFFF	70 to 91

The data area of the data flash memory in this MCU is divided into 64 byte blocks, with each being a unit for erasure. Figure 46.4 shows the mapping of the data flash memory.

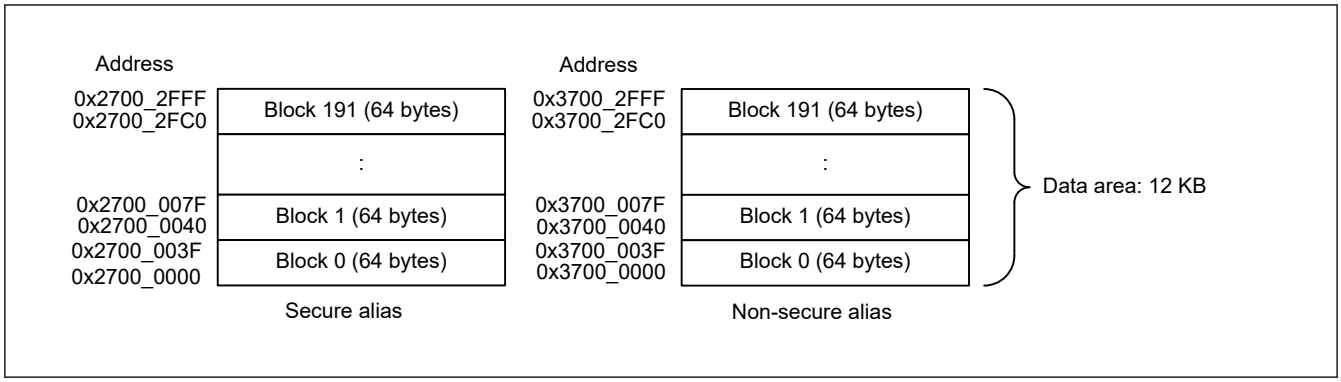

Figure 46.4 Map of the Data Flash Memory

46.3 Address Space

Using the hardware interface with flash memory requires access to all registers of the hardware, which is for issuing FACI commands. Table 46.4 provides information about the hardware interface.

Table 46.4 Information on the hardware interface area

Area	Address	Capacity
Area containing various registers of the hardware	See section 46.4. Register Descriptions.	See section 46.4. Register Descriptions.
FACI command-issuing area	Secure alias : 0x4010_0000 Non-secure alias : 0x5010_0000	4 bytes

For the address information of the flash memory, see Figure 46.2.

46.4 Register Descriptions

46.4.1 FCACHEE : Flash Cache Enable Register

Base address: FCACHE = 0x4001_C100
FCACHE_NS = 0x5001_C100

Offset address: 0x000

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	FCACHEEN
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	FCACHEEN	Flash Cache Enable 0: FCACHE is disabled 1: FCACHE is enabled	R/W
15:1	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-2
Note: Associated SA: FSAR register. See section 46.4.4. FSAR : Flash Security Attribution Register.

FCACHEEN bit (Flash Cache Enable)

FCACHEE.FCACHEEN bit enable and disables the function of Flash Cache of FCACHE1, FCACHE2 and FLPF.

FCACHEE.FCACHEEN bit dose not influence for FCACHEIV.FCACHEIV.

When FCACHE is enabled, it works for accesses marked as cacheable.

It is prohibited to disable FCACHE after enabling.

46.4.2 FCACHEIV : Flash Cache Invalidate Register

Base address: FCACHE = 0x4001_C100
FCACHE_NS = 0x5001_C100

Offset address: 0x004

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	FCACHEIV
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	FCACHEIV	Flash Cache Invalidate 0: Read: Do not invalidate. Write: The setting is ignored. 1: Invalidate FCACHE is invalidated.	R/W
15:1	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-5, P-TYPE-2

This register is not controlled by any security attribute register.

FCACHEIV bit (Flash Cache Invalidate)

When 1 is written to FCACHEIV.FCACHEIV bit, the Flash cache data of FCACHE1, FCACHE2 and FLPF is invalidated.

Invalidate FCACHE with keeping FCACHE enabled after programming or erasing the code flash or the option setting memory.

46.4.3 FLWT : Flash Wait Cycle Register

Base address: FCACHE = 0x4001_C100
FCACHE_NS = 0x5001_C100

Offset address: 0x01C

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	FLWT[2:0]		
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
2:0	FLWT[2:0]	Flash Wait Cycle 0 0 0: 0 wait (ICLK ≤ 48 MHz) 0 0 1: 1 wait (48 MHz < ICLK ≤ 96 MHz) 0 1 0: 2 wait (96 MHz < ICLK ≤144 MHz) 0 1 1: 3 wait (144 MHz <ICLK ≤ 192 MHz) 1 0 0: 4 wait (192 MHz < ICLK ≤ 240 MHz) Others: Setting prohibited	R/W
7:3	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-2
Note: Associated SA: FSAR register. See section 46.4.4. FSAR : Flash Security Attribution Register.

FLWT[2:0] bits (Flash Wait Cycle)

The Flash Wait Cycle Register (FLWT) sets the access wait count for the flash memory.

For faster clock frequencies, set FLWT.FLWT before changing the clock frequency. For slower clock frequencies, set FLWT.FLWT after changing the clock frequency.

For information on the frequency setting, see section 8, Clock Generation Circuit.

46.4.4 FSAR : Flash Security Attribution Register

Base address: FCACHE = 0x4001_C100
FCACHE_NS = 0x5001_C100

Offset address: 0x040

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	FACICMRSA	FACICMISA	FCKMHZSA	—	—	—	—	—	—	FCACHESA	FLWTSA
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	FLWTSA	FLWT Security Attribution Target register : FLWT 0: Secure 1: Non-secure	R/W
1	FCACHESA	FCHACHEEN Security Attribution Target register : FCHACHEEN 0: Secure 1: Non-secure	R/W
7:2	—	These bits are read as 0. The write value should be 0.	R/W
8	FCKMHZSA	FCKMHZ Security Attribution Target register : FCKMHZ 0: Secure 1: Non-secure	R/W
9	FACICMISA	FACI command Issuing Security Attribution Target area : Flash access area 0: Secure 1: Non-secure	R/W
10	FACICMRSA	FACI command Registers Security Attribution Target registers : FASTAT, FAEINT, FRDYIE, FSADDR, FEADDR, FBPROT1, FSTATR, FENTRYR, FSUINITR, FCMDR, FBCCNT, FBCSTAT, FPSADDR, FSUASMON, FCPSR, FPCKAR, FWEPROR 0: Secure 1: Non-secure	R/W
15:11	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-1, P-TYPE-1
Note: Set the PRCR.PRC4 bit to 1 (write enabled) before rewriting this register.

FLWTSA bit (FLWT Security Attribution)

This bit sets the security attribute of FLWT.

FCACHESA bit (FCHACHEEN Security Attribution)

This bit sets the security attribute of FCHACHEEN.

FCKMHZSA bit (FCKMHZ Security Attribution)

This bit sets the security attribute of Flash access area.

FACICMISA bit (FACI command Issuing Security Attribution)

This bit sets the security attribute of Flash access area.

FACICMRSA bit (FACI command Registers Security Attribution)

This bit sets the security attribute of FACI command security registers.

46.4.5 UIDRn : Unique ID Registers n (n = 0 to 3)

Address: 0x0300_8190 + n × 4 (Secure)
0x1300_8190 + n × 4 (Non-secure)

Bit position:	31	0
Bit field:	UID	
Value after reset:	Unique value for each chip	

Bit	Symbol	Function	R/W
31:0	UID	Unique ID	R

Note: S-TYPE-5, P-TYPE-5

The UIDRn is a read-only register that stores a 16-byte ID code (unique ID) for identifying the individual MCU. The UIDRn register should be read in 32-bit units. When reading by the signature request command of the serial programming interface, the data is read in order from the data with the large address. That is, the data in 0x0300_819F is read first, and in 0x0300_8190 is read last.

46.4.6 PNRn : Part Numbering Register n (n = 0 to 3)

Address: 0x0300_80F0 + n × 4 (Secure)
0x1300_80F0 + n × 4 (Non-secure)

Bit position:	31	0
Bit field:	PNR	
Value after reset:	Unique value for each chip	

Bit	Symbol	Function	R/W
31:0	PNR	Part Number	R

Note: S-TYPE-5, P-TYPE-5

The PNRn is a read-only register that stores a 16-byte part numbering. The PNRn register should be read in 32-bit units. Each byte corresponds to the ASCII code representation of the product part number as detailed in Table 1.12. The first character ("R", 0x52 in ASCII code) of the part number is stored in the byte with the smallest address (0x0300_80F0). When reading by the signature request command of the serial programming interface, the data is read in order from the data with the small address. That is, the data in 0x0300_80F0 is read first, and in 0x0300_80FF is read last.

46.4.7 MCUVER : MCU Version Register

Address: 0x0300_81B0 (Secure)
0x1300_81B0 (Non-secure)

Bit position:	7	6	5	4	3	2	1	0
Bit field:	MCUVE							
Value after reset:	Value depend on the chip							

Bit	Symbol	Function	R/W
7:0	MCUVE	MCU Version	R

Note: S-TYPE-5, P-TYPE-5

The MCUVER is a read-only register that stores a MCU version. The MCUVER register should be read in 8-bit units.

46.4.8 FWEPROR : Flash P/E Protect Register

Base address: SYSC = 0x4001_E000
SYSC_NS = 0x5001_E000

Offset address: 0xA54

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	FLWE[1:0]	
Value after reset:	0	0	0	0	0	0	1	0

Bit	Symbol	Function	R/W
1:0	FLWE[1:0]	Flash Programming and Erasure 0 0: Prohibits Program, Block Erase, Multi Block Erase, Blank Check, and Configuration set command processing. 0 1: Permits Program, Block Erase, Multi Block Erase, Blank Check, and Configuration set command processing. 1 0: Prohibits Program, Block Erase, Multi Block Erase, Blank Check, and Configuration set command processing. 1 1: Prohibits Program, Block Erase, Multi Block Erase, Blank Check, and Configuration set command processing.	R/W
7:2	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-2

It is possible that Program, Block Erase, Multi Block Erase, Blank Check, and Configuration set command processing are prohibited by software.

The FWEPROR register is initialized by a reset from the following:

- All reset source
- Transition to Deep Software Standby mode
- Transition to Software Standby mode.

FLWE[1:0] bits (Flash Programming and Erasure)

The FLWE[1:0] bits are used to set the flash P/E protection. The value after reset is 10b.

If these bits are set to other than 01b that does not allow programming and erasure of the flash memory, the following commands cannot be executed. Issuing any of the following commands leads to setting of the FLWEERR bit in the FSTATR register to 1.

Program / Block Erase / Multi Block Erase / Blank Check / Configuration set command

46.4.9 FASTAT : Flash Access Status Register

Base address: FACI = 0x4011_E000
FACI_NS = 0x5011_E000

Offset address: 0x10

Bit position:	7	6	5	4	3	2	1	0
Bit field:	CFAE	—	—	CMDLK	DFAE	—	—	—
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
2:0	—	These bits are read as 0. The write value should be 0.	R/W
3	DFAE	Data Flash Memory Access Violation Flag 0: No data flash memory access violation has occurred 1: A data flash memory access violation has occurred.	R/W*1

Bit	Symbol	Function	R/W
4	CMDLK	Command Lock Flag 0: The flash sequencer is not in the command-locked state 1: The flash sequencer is in the command-locked state.	R
6:5	—	These bits are read as 0. The write value should be 0.	R/W
7	CFAE	Code Flash Memory Access Violation Flag 0: No code flash memory access violation has occurred 1: A code flash memory access violation has occurred.	R/W*1

Note: S-TYPE-3, P-TYPE-2
Note: Associated SA: FSAR register. See section 46.4.4. FSAR : Flash Security Attribution Register
Note 1. Only 0 can be written to clear the flag after 1 is read.

The FASTAT register indicates whether a code flash or data flash memory access violation has occurred. If any of the CFAE, CMDLK, and DFAE bits is set to 1, the flash sequencer enters the command-locked state (see section 46.11.2. Error Protection). To release it from the command-locked state, issue a status clear command or Forced Stop command to the flash sequencer.

DFAE bit (Data Flash Memory Access Violation Flag)

The DFAE bit indicates whether a data flash memory access violation occurred. When this bit is set to 1, the ILGLERR bit in the FSTATR register is set to 1, placing the flash sequencer in the command-locked state.

[Setting conditions]

FACI commands issued in the data flash P/E mode are as follows:

- The setting of the FSADDR or FEADDR register is the reserved portion of the data area
- The Configuration set command is issued while the setting of the FSADDR register is out of 0x2703_0050 to 0x2703_03FF.
- FACI command is issued to data flash memory with the wrong security attribution.

[Clearing conditions]

- When this bit is written as 0 after it is set to 1
- When the flash sequencer starts to process the Status Clear or Forced Stop command.

CMDLK bit (Command Lock Flag)

The CMDLK bit indicates that the flash sequencer is in the command-locked state.

[Setting conditions]

- The flash sequencer detects an error and enters the command-locked state.

[Clearing conditions]

- When the flash sequencer starts to process the Status Clear or Forced Stop command.

CFAE bit (Code Flash Memory Access Violation Flag)

The CFAE bit indicates whether a code flash memory access violation has occurred. When this bit is set to 1, the ILGLERR bit in the FSTATR register is set to 1, placing the flash sequencer in the command-locked state.

[Setting conditions]

FACI commands issued in the code flash P/E mode are as follows:

- The setting of the FSADDR register is the reserved portion of the user area
- The Configuration set command is issued while the setting of the FSADDR register is from 0x0200_A100 to 0x0200_A2F0 in self-programming mode
- FACI command is issued to code flash memory with the wrong security attribution.

[Clearing conditions]

- When this bit is written as 0 after it is set to 1

- When the flash sequencer starts to process the Status Clear or Forced Stop command.

46.4.10 FAEINT : Flash Access Error Interrupt Enable Register

Base address: FACI = 0x4011_E000
FACI_NS = 0x5011_E000

Offset address: 0x14

Bit position:	7	6	5	4	3	2	1	0
Bit field:	CFAEIE	—	—	CMDLKIE	DFAEIE	—	—	—
Value after reset:	1	0	0	1	1	0	0	0

Bit	Symbol	Function	R/W
2:0	—	These bits are read as 0. The write value should be 0.	R/W
3	DFAEIE	Data Flash Memory Access Violation Interrupt Enable 0: Generation of an FIFERR interrupt request is disabled when FASTAT.DFAE is set to 1 1: Generation of an FIFERR interrupt request is enabled when FASTAT.DFAE is set to 1.	R/W
4	CMDLKIE	Command Lock Interrupt Enable 0: Generation of an FIFERR interrupt request is disabled when FASTAT.CMDLK is set to 1 1: Generation of an FIFERR interrupt request is enabled when FASTAT.CMDLK is set to 1.	R/W
6:5	—	These bits are read as 0. The write value should be 0.	R/W
7	CFAEIE	Code Flash Memory Access Violation Interrupt Enable 0: Generation of an FIFERR interrupt request is disabled when FASTAT.CFAE is set to 1 1: Generation of an FIFERR interrupt request is enabled when FASTAT.CFAE is set to 1.	R/W

Note: S-TYPE-3, P-TYPE-2
Note: Associated SA: FSAR register. See section 46.4.4. FSAR : Flash Security Attribution Register.

The FAEINT register enables or disables generation of a flash access error (FIFERR) interrupt request.

DFAEIE bit (Data Flash Memory Access Violation Interrupt Enable)

The DFAEIE bit enables or disables generation of an FIFERR interrupt request when a data flash memory access violation occurs, setting the DFAE bit in the FASTAT register to 1.

CMDLKIE bit (Command Lock Interrupt Enable)

The CMDLKIE bit enables or disables generation of an FIFERR interrupt request when the flash sequencer enters the command-locked state, setting the CMDLK bit in the FASTAT register to 1.

CFAEIE bit (Code Flash Memory Access Violation Interrupt Enable)

The CFAEIE bit enables or disables generation of an FIFERR interrupt request when a code flash memory access violation occur, setting the CFAE bit in the FASTAT register to 1.

46.4.11 FRDYIE : Flash Ready Interrupt Enable Register

Base address: FACI = 0x4011_E000
FACI_NS = 0x5011_E000

Offset address: 0x18

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	FRDYIE
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	FRDYIE	Flash Ready Interrupt Enable 0: Generation of an FRDY interrupt request is disabled 1: Generation of an FRDY interrupt request is enabled.	R/W
7:1	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-2
Note: Associated SA: FSAR register. See section 46.4.4. FSAR : Flash Security Attribution Register

The FRDYIE register enables or disables generation of a flash ready (FRDY) interrupt request.

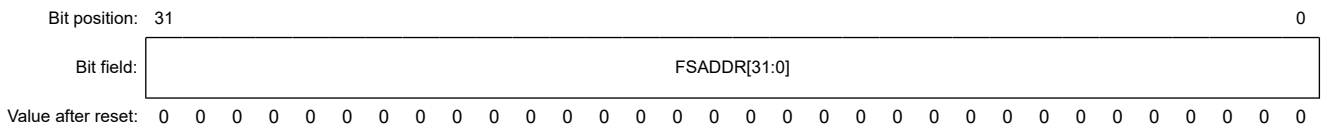
FRDYIE bit (Flash Ready Interrupt Enable)

The FRDYIE bit enables or disables generation of an FRDY interrupt request when the FRDY bit in the FSTATR register is changed from 0 to 1 on completion of processing by the flash sequencer of the Program, Block Erase, Multi Block Erase, Blank Check, and Configuration set command.

46.4.12 FSADDR : FACI Command Start Address Register

Base address: FACI = 0x4011_E000
FACI_NS = 0x5011_E000

Offset address: 0x30



Bit	Symbol	Function	R/W
31:0	FSADDR[31:0]	Start Address for FACI Command Processing	R/W*1

Note: S-TYPE-3, P-TYPE-2
Note: Associated SA: FSAR register. See section 46.4.4. FSAR : Flash Security Attribution Register
Note 1. These bits can be written when the FRDY bit in the FSTATR register is 1. Writing to these bits are ignored when the FRDY bit is 0. Note that b0 and b1 are read-only.

Table 46.5 FACI command address boundary

Command	Address Boundary
Program (code flash memory)	128 byte
Program (data flash memory)	4, 8, 16 byte
Block Erase (code flash memory)	8 KB or 32 KB
Block Erase (data flash memory)	64 byte
Multi Block Erase (data flash memory)	64 byte
Blank Check (data flash memory)	4 byte
For code flash configuration set	16 byte
For data flash configuration set	4, 16 byte

The FSADDR register specifies the address where the target area for command processing starts when the FACI command for Program, Block Erase, Multi Block Erase, Blank Check, or Configuration set is issued.

The FSADDR value is initialized when the SUINIT bit in the FSUINITR register is set to 1. It is also initialized by a reset.

FSADDR[31:0] bits (Start Address for FACI Command Processing)

The FSADDR[31:0] bits specify the start address for FACI command processing. Bits [31:29] and [27:24] are ignored in FACI command processing for the code flash memory. Bits [31:29] and [27:13] are ignored in FACI command processing for the data flash memory. Bit [28] is used the security alias for flash sequencer command. When bit [28] is "0", flash sequencer can update secure region with secure access. When bit [28] is "1", flash sequencer can update non-security region with secure and non-secure access. Bits associated with the address bits of lower order than the address boundary listed in Table 46.5 are also ignored.

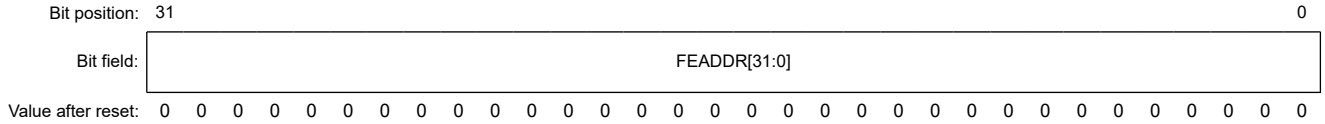
For information on the addresses of the code flash memory and the data flash memory, see section 46.2. Structure of Memory.

For information on the addresses of the configuration setting, see section 46.9.3.15. Configuration Set Command.

46.4.13 FEADDR : FACI Command End Address Register

Base address: FACI = 0x4011_E000
FACI_NS = 0x5011_E000

Offset address: 0x34



Bit	Symbol	Function	R/W
31:0	FEADDR[31:0]	End Address for FACI Command Processing	R/W*1

Note: S-TYPE-3, P-TYPE-2
Note: Associated SA: FSAR register. See section 46.4.4. FSAR : Flash Security Attribution Register
Note 1. These bits can be written when the FRDY bit in the FSTATR register is 1. Writing to these bits are ignored when the FRDY bit is 0. Note that bit [0] and bit [1] are read-only.

The FEADDR register specifies the end address of the target area for Multi Block Erase and Blank Check command processing. When incremental mode is selected as the addressing mode for Blank Checking (when FBCCNT.BCDIR = 0), the address specified in the FSADDR register should be equal to or smaller than the address in the FEADDR register. Conversely, the address in the FSADDR register should be equal to or larger than the address in the FEADDR register when decremental mode is selected as the addressing mode for Blank Check (i.e. when FBCCNT.BCDIR = 1). If the BCDIR, FSADDR, and FEADDR bit settings are inconsistent with the specified rules, the flash sequencer enters the command-locked state (see section 46.11.2. Error Protection).

The FEADDR value is initialized when the SUINIT bit in the FSUINITR register is set to 1. It is also initialized by a reset.

FEADDR[31:0] bits (End Address for FACI Command Processing)

The FEADDR[31:0] bits specify the end address for Multi Block Erase and Blank Check command processing. In command processing, bits 31 to 17 and any bits that do not reach the address boundaries listed in the section 46.4.12. FSADDR : FACI Command Start Address Register are ignored.

For information on the addresses of the flash memory, see section 46.2. Structure of Memory.

46.4.14 FMEPROT : Flash P/E Mode Entry Protection Register

Base address: FACI = 0x4011_E000

Offset address: 0x44

Bit	Symbol	Function	R/W
0	CEPROT	Code Flash P/E Mode Entry Protection 0: FENTRYC bit is not protected 1: FENTRYC bit is protected.	R/W*1 *2 *4
1	—	The read value is undefined. The write value should be 0.	R/W
7:2	—	These bits are read as 0. The write value should be 0.	R/W
15:8	KEY[7:0]	Key Code	W*3

Note: S-TYPE-6, P-TYPE-2
Note 1. Writing to this bit is only possible when the FRDY bit in the FSTATR register is 1. Writing to this bit while the FRDY bit = 0 is ignored.

Note 2. Writing to this bit is only possible when 16 bits are written and the value written to the KEY bits is 0xD9.
Note 3. Written values are not retained by these bits (always read as 0x00).
Note 4. Only Secure access can write to this register. Both Secure access and Non-secure read access are allowed. Non-secure write access is denied, but TrustZone access error is not generated.

CEPROT bit (Code Flash P/E Mode Entry Protection)

The CEPROT bit specifies the protection setting of the FRNTRYC bit in the FENTRYR register.

[Setting condition]

- 1 being written to the CEPROT bit while writing to FMEPROT is enabled.

[Clearing condition]

- 0 being written to the CEPROT bit while writing to FMEPROT is enabled.

46.4.15 FCNTSELR : Flash Counter Select Register

Base address: FACI = 0x4011_E000

Offset address: 0x048

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	CNTSEL[2:0]		
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
2:0	CNTSEL[2:0]	Counter Select 0 0 0: Anti-rollback counter is not selected 0 0 1: ARC_SEC is selected. Counter size is 64 bits. 0 1 0: ARC_OEMBL is selected. Counter size is 64 bits. 0 1 1: Anti-rollback counter is not selected. 1 x x: ARC_NSEC is selected. Counter configuration is 64 or 256 bits. See ,Table 46.6 Table 46.7 and Table 46.8 in details counter select condition. Others: Setting prohibited	R/W
7:3	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-6, P-TYPE-2
Note: If the security attribution is configured as Secure:
- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:
- Secure and Non-secure access are allowed.

CNTSEL[2:0] bits (Counter Select)

FCNTSELR specifies 3 types of anti-rollback counter (ARC_SEC, ARC_NSEC, or ARC_OEMBL) in "Increment Counter", "Refresh Counter", or "Read Counter" command.

FCNTSELR value is initialized when SUINIT bit in FSUINITR is set to "1"

Note: This bit can be written when the FRDY bit in the FSTATR register is 1. Writing to this bit is ignored when the FRDY bit is 0.

Before using the ARC_NSEC counter, it is necessary to set whether the counter is to be used with 4line x 64 bits or 1line x 256 bits using the Data Flash configuration set command. The bits to be set are CNF_ARCNS0 and CNF_ARCNS1. If the CNF_ARCNS1 bit is set to 1, the ARC_NSEC counter cannot be used. Once the counter type is decided, it cannot be changed.

Table 46.6 Select condition of ARC_NSEC (64 bits) in Increment/Refresh/Read Counter Command

FCNTSELR[2:0]	Target Counter	Counter Configuration
100	ARC_NSEC[63:0]	Counter number is 4. Counter size is 64bit.
101	ARC_NSEC[127:64]	
110	ARC_NSEC[191:128]	
111	ARC_NSEC[255:192]	

Table 46.7 Select condition of ARC_NSEC (256 bits) in Increment/Refresh Counter Command

FCNTSELR[2:0]	Target Counter	Counter Configuration
100	ARC_NSEC[255:0]	Counter number is 1. Counter size is 256bit.
101		
110		
111		

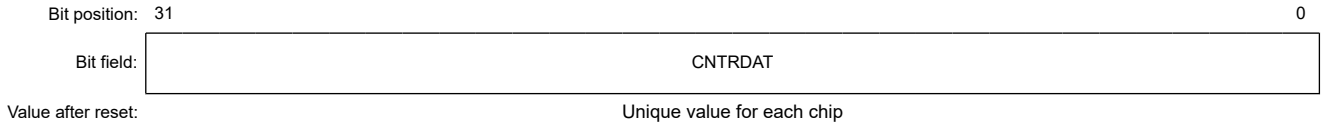
Table 46.8 Select condition of ARC_NSEC (256 bits) in Read Counter Command

FCNTSELR[2:0]	Target Counter	Counter Configuration
100	ARC_NSEC[63:0]	Counter number is 1. Counter size is 256bit.
101	ARC_NSEC[127:64]	
110	ARC_NSEC[191:128]	
111	ARC_NSEC[255:192]	

46.4.16 FCNTDATARn : Flash Counter Data Register n (n = 0, 1)

Base address: FACI = 0x4011_E000

Offset address: 0x04C + 0x004 × n (n = 0 ,1)



Bit	Symbol	Function	R/W
31:0	CNTRDAT	Counter Read Data Reading data of 32 bits (LSB side of counter values) is output to FCNTDATAR0. Reading data of 32 bits (MSB side of counter values) is output to FCNTDATAR1. .	R

Note: S-TYPE-6, P-TYPE-2

FCNTDATAR0 and FCNTDATAR1 indicate anti-rollback counter values (64 bits) that read by "Read Counter" command.

CNTRDAT bit (Counter Read Data)

[Setting condition]

- FACI has accepted "Read Counter" command.

[Clearing condition]

- FACI has accepted flash sequencer command except for "Read Counter" command.
- Flash sequencer enters "Command Lock" state

46.4.17 FBPROT0 : Flash Block Protection Register

Base address: FACI = 0x4011_E000
FACI_NS = 0x5011_E000

Offset address: 0x78

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	KEY[7:0]								—	—	—	—	—	—	—	BPCN0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	BPCN0	Block Protection for Non-secure Cancel 0: Block protection is enabled 1: Block protection is disabled.	R/W*1 *2
7:1	—	These bits are read as 0. The write value should be 0.	R/W
15:8	KEY[7:0]	Key Code	W*3

Note: S-TYPE-3, P-TYPE-2
Note: Associated SA: FSAR register. See section 46.4.4. FSAR : Flash Security Attribution Register
Note 1. This bit can be written when the FRDY bit in the FSTATR register is 1. Writing to this bit is ignored when the FRDY bit is 0.
Note 2. Writing to this bit is only possible when 16 bits are written and the value written to the KEY[7:0] bits is 0x78.
Note 3. Written values are not retained by these bits (always read as 0x00).

The FBPROT0 register is used to disable the block protect function for Non-secure. When the block protect setting is locked by the permanent block setting, it cannot be disabled by this register.

The FBPROT0 value is initialized when the SUINIT bit in the FSUINITR is set to 1, because the FENTRYR value is initialized to 0x0000. It is also initialized by a reset.

BPCN0 bit (Block Protection for Non-secure Cancel)

The BPCN0 bit disables the block protect setting for Non-secure function.

[Setting condition]

- When the write-enabling conditions are satisfied and the FENTRYR is not 0x0000, write 1 to this bit.

[Clearing conditions]

- 8 bits being written to FBPROT0 while the FRDY bit is 1.
- A value other than 0x78 specified in the KEY bits and 16 bits are written to FBPROT0 while the FRDY bit is 1.
- 0 being written to the BPCN0 bit while writing to FBPROT0 is enabled.
- The FENTRYR register value is 0x0000.

46.4.18 FBPROT1 : Flash Block Protection for Secure Register

Base address: FACI = 0x4011_E000

Offset address: 0x7C

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	KEY[7:0]								—	—	—	—	—	—	—	BPCN1
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	BPCN1	Block Protection for Secure Cancel 0: Block protection is enabled 1: Block protection is disabled.	R/W*1 *2
7:1	—	These bits are read as 0. The write value should be 0.	R/W

Bit	Symbol	Function	R/W
15:8	KEY[7:0]	Key Code	W*3

Note: S-TYPE-6, P-TYPE-2
Note: Associated SA: FSAR register. See section 46.4.4. FSAR : Flash Security Attribution Register
Note 1. Writing to this bit is only possible when the FRDY bit in the FSTATR register is 1. Writing to this bit while FRDY bit = 0 is ignored.
Note 2. Writing to this bit is only possible when 16 bits are written and the value written to the KEY[7:0] bits is 0xB1.
Note 3. Written values are not retained by these bits (always read as 0x00).

The FBPROT1 register is used to disable the block protect function for Secure developer. When the block protect setting is locked by the permanent block setting, it cannot be disabled by this register.

The FBPROT1 value is initialized when the SUINIT bit in the FSUINITR is set to 1, because the FENTRYR value is initialized to 0x0000. It is also initialized by a reset.

BPCN1 bit (Block Protection for Secure Cancel)

The BPCN1 bit disables the block protect setting for Secure function.

[Setting condition]

- When the write-enabling conditions are satisfied and the FENTRYR is not 0x0000, write 1 to BPCN1.

[Clearing conditions]

- 8 bits being written to FBPROT1 while the FRDY bit is 1.
- A value other than 0xB1 specified in the KEY bits and 16 bits are written to FBPROT1 while the FRDY bit is 1.
- 0 being written to the BPCN1 bit while writing to FBPROT1 is enabled.
- The FENTRYR register value is 0x0000.

46.4.19 FSTATR : Flash Status Register

Base address: FACI = 0x4011_E000
FACI_NS = 0x5011_E000

Offset address: 0x80

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	ILGCOMERR	FESETERR	SECERR	OTERR	TZFERR	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	FRDY	ILGLERR	ERSERR	PRGERR	SUSRDY	DBFULL	ERSSPD	PRGSPD	—	FLWEERR	—	—	—	—	—	—
Value after reset:	1	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
5:0	—	These bits are read as 0.	R
6	FLWEERR	Flash Write/Erase Protect Error Flag 0: An error has not occurred 1: An error has occurred.	R
7	—	This bit is read as 0.	R
8	PRGSPD	Programming Suspend Status Flag 0: The flash sequencer is not in the programming suspension processing state or programming suspended state 1: The flash sequencer is in the programming suspension processing state or programming suspended state.	R
9	ERSSPD	Erasure Suspend Status Flag 0: The flash sequencer is not in the erasure suspension processing state or the erasure suspended state 1: The flash sequencer is in the erasure suspension processing state or the erasure suspended state.	R

Bit	Symbol	Function	R/W
10	DBFULL	Data Buffer Full Flag 0: The data buffer is empty 1: The data buffer is full.	R
11	SUSRDY	Suspend Ready Flag 0: The flash sequencer cannot receive P/E suspend commands 1: The flash sequencer can receive P/E suspend commands.	R
12	PRGERR	Programming Error Flag 0: Programming has completed successfully 1: An error has occurred during programming.	R
13	ERSERR	Erasure Error Flag 0: Erasure has completed successfully 1: An error has occurred during erasure.	R
14	ILGLERR	Illegal Command Error Flag 0: The flash sequencer has not detected an illegal FACI command or illegal flash memory access 1: The flash sequencer has detected an illegal FACI command or illegal flash memory access.	R
15	FRDY	Flash Ready Flag 0: Program, Block Erase, Multi Block Erase, P/E suspend, P/E resume, Forced Stop, Blank Check, Configuration set, Increment counter, Refresh counter, or Read counter command processing is in progress. 1: None of the above is in progress.	R
18:16	—	These bits are read as 0.	R
19	TZFERR	TrustZone Filter Error 0: A TrustZone filter error has not been detected. 1: A TrustZone filter error has been detected.	R
20	OTERR	Other Error 0: An error has not been detected. 1: An error has been detected.	R
21	SECERR	Security Error 0: A write protection error against MSUASMON.FSPR bit has not been detected. 1: A write protection error against MSUASMON.FSPR bit has been detected.	R
22	FESETERR	FENTRY Setting Error 0: A setting error in the FENTRYR register has not been detected. 1: A setting error in the FENTRYR register has been detected.	R
23	ILGCOMERR	Illegal Command Error 0: An illegal FACI command error has not been detected. 1: An illegal FACI command error has been detected.	R
31:24	—	These bits are read as 0.	R

Note: S-TYPE-3, P-TYPE-2
Note: Associated SA: FSAR register. See section 46.4.4. FSAR : Flash Security Attribution Register

The FSTATR register indicates the state of the flash sequencer.

FLWEERR flag (Flash Write/Erase Protect Error Flag)

The FLWEERR flag indicates a violation of the flash memory overwrite protection setting in the FWEPROR register. When this flag is 1, the flash sequencer is in the command-locked state.

[Setting condition]

- An error has occurred.

[Clearing condition]

- The flash sequencer starts processing the Forced Stop command.

PRGSPD flag (Programming Suspend Status Flag)

The PRGSPD flag indicates that the flash sequencer is in the programming suspension processing state or programming suspended state.

[Setting condition]

- The flash sequencer starts processing in response to the programming suspend command.

[Clearing conditions]

- Reception of the P/E resume command by the flash sequencer (after write access to the FACI command-issuing area is complete)
- The flash sequencer starts processing the Forced Stop command.

ERSSPD flag (Erasure Suspend Status Flag)

The ERSSPD flag indicates that the flash sequencer is in the erasure suspension processing state or erasure suspended state.

[Setting condition]

- The flash sequencer starts processing in response to an erasure suspend command.

[Clearing condition]

- Reception of the P/E resume command by the flash sequencer (after write access to the FACI command-issuing area is complete)
- The flash sequencer starts processing of the Forced Stop command.

DBFULL flag (Data Buffer Full Flag)

The DBFULL flag indicates the state of the data buffer when the program command is issued. The flash sequencer incorporates a buffer for write data (data buffer). When data for writing to the flash memory are written to the FACI command-issuing area while the data buffer is full, the flash sequencer inserts a wait cycle in the peripheral bus.

[Setting condition]

- The data buffer becomes full while program commands are issued.

[Clearing condition]

- The data buffer becomes empty.

SUSRDY flag (Suspend Ready Flag)

The SUSRDY flag indicates whether the flash sequencer can receive a P/E suspend command.

[Setting condition]

- After starting programming/erasure processing, the flash sequencer enters a state in which P/E suspend commands can be received.

[Clearing conditions]

- Reception of the P/E suspend command or Forced Stop command by the flash sequencer (after write access to the FACI command-issuing area is complete)
- During programming or erasure, the flash sequencer enters the command-locked state
- Programming or erasure has completed.

PRGERR flag (Programming Error Flag)

The PRGERR flag indicates the result of programming of the flash memory. When this flag is 1, the flash sequencer is in the command-locked state.

[Setting condition]

- An error has occurred during programming.

[Clearing condition]

- The flash sequencer starts processing of the Status Clear or Forced Stop command.

ERSERR flag (Erasure Error Flag)

The ERSERR flag indicates the result of erasure of the flash memory. When this flag is 1, the flash sequencer is in the command-locked state.

[Setting condition]

- An error has occurred during erasure.

[Clearing condition]

- The flash sequencer starts processing of the Status Clear or Forced Stop command.

ILGLERR flag (Illegal Command Error Flag)

The ILGLERR flag indicates that the flash sequencer has detected an illegal FACI command or flash memory access. If this flag is 1, the flash sequencer is in the command-locked state.

[Setting conditions]

- See section 46.11.2. Error Protection.

[Clearing condition]

- The flash sequencer starts processing of the Status Clear or Forced Stop command.

FRDY flag (Flash Ready Flag)

The FRDY flag indicates the command processing state of the flash sequencer.

[Setting conditions]

- The flash sequencer completes command processing
- The flash sequencer receives a P/E suspend command and suspends programming of the flash memory
- The flash sequencer received the Forced Stop command and ended command processing.

Note: In the case of program command processing, the FRDY flag might be set to 1 even if the flash sequencer does not complete command processing. For details, see section 46.9.3.7. Program Command.

[Clearing conditions]

- The flash sequencer received an FACI command
- For Program and Configuration setting, the first write access to the FACI command-issuing area
- For other commands, the last write access to the FACI command-issuing area.

TZFERR flag (TrustZone Filter Error)

This flag indicates the TrustZone protection error in the FACI command.
See Table 46.30. When this bit is "1", flash sequencer enters "Command Lock" state.

[Setting conditions]

- An error has been detected.

[Clearing conditions]

- Status Clear or Forced Stop command processing is completed.

OTERR flag (Other Error)

This flag indicates that an FACI command has been issued when the condition of accepting commands is not satisfied.
See Table 46.30. When this flag is 1, the flash sequencer is in the command-lock state.

[Setting condition]

- An error has occurred.

[Clearing condition]

- The status clear or forced stop command processing is complete.

SECERR flag (Security Error)

This flag indicates that write protection by the MSUASMON.FSPR bit is violated.
See Table 46.30. When this flag is 1, the flash sequencer is in the command-lock state.

[Setting condition]

- An error has occurred.

[Clearing condition]

- The status clear or forced stop command processing is complete.

FESETERR flag (FENTRY Setting Error)

This flag indicates that a value of 0xAA81 is written in the FENTRYR register or the value in the FENTRYR register differs when P/E is suspended and resumed.
See Table 46.30. When this flag is 1, the flash sequencer is in the command-lock state.

[Setting condition]

- An error has occurred.

[Clearing condition]

- The status clear or forced stop command processing is complete.

ILGCOMERR flag (Illegal Command Error)

This flag indicates that the flash sequencer has detected an illegal FACI command.
See Table 46.30. When this flag is 1, the flash sequencer is in the command-lock state.

[Setting condition]

- An error has occurred.

[Clearing condition]

- The status clear or forced stop command processing is complete.

46.4.20 FENTRYR : Flash P/E Mode Entry Register

Base address: FACI = 0x4011_E000
FACI_NS = 0x5011_E000

Offset address: 0x84

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	KEY[7:0]								FENTRYD	—	—	—	—	—	—	FENTRYC
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	FENTRYC	Code Flash P/E Mode Entry 0: Code flash is in read mode 1: Code flash is in P/E mode.	R/W*1*2
6:1	—	These bits are read as 0. The write value should be 0.	R/W
7	FENTRYD	Data Flash P/E Mode Entry 0: Data flash is in read mode 1: Data flash is in P/E mode.	R/W*1*2
15:8	KEY[7:0]	Key Code	W*3

Note: S-TYPE-3, P-TYPE-2
Note: Associated SA: FSAR register. See section 46.4.4. FSAR : Flash Security Attribution Register
Note 1. These bits can be written when the FRDY bit in the FSTATR register is 1. Writing to these bits are ignored when the FRDY bit is 0.
Note 2. Writing to these bits is only possible when 16 bits are written and the value written to the KEY[7:0] bits is 0xAA.
Note 3. Written values are not retained by these bits (always read 0x00).

FENTRYR is used to specify code flash P/E mode or data flash P/E mode. To specify the code flash P/E mode or data flash P/E mode so that the flash sequencer can receive FACI commands, set either the FENTRYD or FENTRYC bit to 1 to place the flash sequencer in P/E mode.

FENTRYR is initialized when the SUINIT bit in FSUINITR is set to 1. It is also initialized by a reset.

Note: Writing a value of 0XAA81 to this register causes the ILGLERR bit in the FSTATR register to be set to 1, resulting in the flash sequencer being placed in the command-locked state.

FENTRYC bit (Code Flash P/E Mode Entry)

The FENTRYC bit specifies P/E mode for the code flash memory.

[Setting condition]

- Write 1 to the FENTRYC bit while writing to FENTRYR is enabled and FENTRYR is 0x0000.

[Clearing conditions]

- Write 8 bits to FENTRYR while the FRDY bit is 1
- A value other than 0xAA is specified in the KEY[7:0] bits and 16 bits are written to FENTRYR while the FRDY bit is 1
- Write 0 to the FENTRYC bit while writing to FENTRYR is enabled
- Write to FENTRYR while writing is enabled and its value is other than 0x0000
- The protection of FMEPROT register is enabled.

FENTRYD bit (Data Flash P/E Mode Entry)

The FENTRYD bit specifies P/E mode for the data flash memory.

[Setting condition]

- Write 1 to the FENTRYD bit while writing to FENTRYR is enabled and FENTRYR is 0x0000.

[Clearing conditions]

- Write 8 bits to FENTRYR while the FRDY bit is 1
- Writing of 16 bits to FENTRYR with a value other than 0xAA specified for the KEY[7:0] bits while the FRDY bit is 1
- Write 0 to the FENTRYD bit while writing to FENTRYR is enabled
- Write to FENTRYR while writing is enabled and its value is other than 0x0000.

KEY[7:0] bits (Key Code)

The KEY[7:0] bits control writing permission to the FENTRYD or FENTRYC bits.

46.4.21 FSUINITR : Flash Sequencer Setup Initialization Register

Base address: FACI = 0x4011_E000
FACI_NS = 0x5011_E000

Offset address: 0x8C

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	KEY[7:0]								—	—	—	—	—	—	—	SUINIT
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	SUINIT	Set-Up Initialization 0: The FSADDR, FEADDR, FBPROT0, FBPROT1, FENTRYR, FBCCNT, FCPSR, and FCNTSELR flash sequencer setup registers keep their current values 1: The FSADDR, FEADDR, FBPROT0, FBRPOT1, FENTRYR, FBCCNT, FCPSR, and FCNTSELR flash sequencer setup registers are initialized.	R/W*1*2
7:1	—	These bits are read as 0. The write value should be 0.	R/W

Bit	Symbol	Function	R/W
15:8	KEY[7:0]	Key Code	W*3

Note: S-TYPE-3, P-TYPE-2
Note: Associated SA: FSAR register. See section 46.4.4. FSAR : Flash Security Attribution Register
Note 1. This bit can be written when the FRDY bit in the FSTATR register is 1. Writing to this bit is ignored when the FRDY bit is 0.
Note 2. Writing to these bits is only possible when 16 bits are written and the value written to the KEY[7:0] bits is 0x2D.
Note 3. Written values are not retained by these bits (always read 0x00).

FSUINITR is used for initialization of the flash sequencer setup.

SUINIT bit (Set-Up Initialization)

The SUINIT bit initializes the following flash sequencer setup registers:

- FSADDR
- FEADDR
- FBPROT0
- FBPROT1
- FENTRYR
- FBCCNT
- FCPSR
- FCNTSELR

KEY[7:0] bits (Key Code)

The KEY[7:0] bits control writing permission to the SUINIT bit.

46.4.22 FCMDR : FACI Command Register

Base address: FACI = 0x4011_E000
FACI_NS = 0x5011_E000

Offset address: 0xA0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	CMDR[7:0]								PCMDR[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	PCMDR[7:0]	Pre-command Flag The command just before the latest command is stored.	R
15:8	CMDR[7:0]	Command Flag The latest command is stored.	R

Note: S-TYPE-3, P-TYPE-2
Note: Associated SA: FSAR register. See section 46.4.4. FSAR : Flash Security Attribution Register

FCMDR records the two most recent commands accepted by the flash sequencer.

PCMDR[7:0] bits (Pre-command Flag)

The PCMDR[7:0] bits indicate the command received immediately before the latest command received by the flash sequencer.

CMDR[7:0] bits (Command Flag)

The CMDR[7:0] bits indicate the latest command received by the flash sequencer.

Table 46.9 States of FCMDR after receiving commands

Command	CMDR	PCMDR
Program	0xE8	Previous command
Block erase	0xD0	0x20
Multi block erase	0xD0	0x21
P/E suspend	0xB0	Previous command
P/E resume	0xD0	Previous command
Status Clear	0x50	Previous command
Forced Stop	0xB3	Previous command
Blank Check	0xD0	0x71
Configuration set	0x40	Previous command
Increment Counter	0xD0	0x35
Refresh Counter	0xD0	0x37
Read Counter	0xD0	0x39

46.4.23 FBCCNT : Blank Check Control Register

Base address: FACI = 0x4011_E000
FACI_NS = 0x5011_E000

Offset address: 0xD0

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	BCDIR
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	BCDIR	Blank Check Direction 0: Blank checking is executed from the lower addresses to the higher addresses (incremental mode) 1: Blank checking is executed from the higher addresses to the lower addresses (decremental mode).	R/W
7:1	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-2
Note: Associated SA: FSAR register. See section 46.4.4. FSAR : Flash Security Attribution Register

FBCCNT specifies the addressing mode in processing the Blank Check command. FBCCNT is initialized when the SUINIT bit in FSUINITR is set to 1. It is also initialized by a reset.

BCDIR bit (Blank Check Direction)

The BCDIR bit specifies the addressing mode for Blank Check.

46.4.24 FBCSTAT : Blank Check Status Register

Base address: FACI = 0x4011_E000
FACI_NS = 0x5011_E000

Offset address: 0xD4

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	BCST
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	BCST	Blank Check Status Flag 0: The target area is in the non-programmed state, that is, the area has been erased but has not yet been reprogrammed 1: The target area has been programmed with 0s or 1s.	R
7:1	—	These bits are read as 0.	R

Note: S-TYPE-3, P-TYPE-2
Note: Associated SA: FSAR register. See section 46.4.4. FSAR : Flash Security Attribution Register

FBCSTAT stores the results of checking in response to the Blank Check command.

BCST flag (Blank Check Status Flag)

The BCST flag indicates the results of checking in response to the Blank Check command.

46.4.25 FPSADDR : Data Flash Programming Start Address Register

Base address: FACI = 0x4011_E000
FACI_NS = 0x5011_E000

Offset address: 0xD8

Bit position:	31															16															0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	PSADR[16:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
16:0	PSADR[16:0]	Programmed Area Start Address The address of the first programmed area	R
31:17	—	These bits are read as 0. The write value should be 0.	R

Note: S-TYPE-3, P-TYPE-2
Note: Associated SA: FSAR register. See section 46.4.4. FSAR : Flash Security Attribution Register

FPSADDR indicates the address of the first programmed area found in processing of the Blank Check command.

PSADR[16:0] bits (Programmed Area Start Address)

The PSADR[16:0] bits indicate the address of the first programmed area found in processing of the Blank Check command. The address is an offset from the address where the data flash memory starts. The setting of these bits is only valid if the BCST bit in the FBCSTAT register is 1 and while the FRDY bit in the FSTATR register is 1. When the BCST bit in the FBCSTAT register is 0, the PSADR[16:0] bits hold the address produced by the previous check.

46.4.26 FSUASMON : Flash Startup Area Select Monitor Register

Base address: FACI = 0x4011_E000
FACI_NS = 0x5011_E000

Offset address: 0xDC

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	BTFLG	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0/1	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	FSPR	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0/1	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
14:0	—	These bits are read as 0. The write value should be 0.	R
15	FSPR	Protection Programming Flag to set Boot Flag and Startup Area Control 0: Protected state 1: Non-protected state.	R
30:16	—	These bits are read as 0. The write value should be 0.	R
31	BTFLG	Flag of Startup Area Select for Boot Swap 0: The startup area is the alternate block (block 1) 1: The startup area is the default block (block 0).	R

Note: S-TYPE-3, P-TYPE-2
Note: Associated SA: FSAR register. See section 46.4.4. FSAR : Flash Security Attribution Register.

FSPR bit (Protection Programming Flag to set Boot Flag and Startup Area Control)

The FSPR bit indicates the protection state against the configuration set command for the BTFLG bit, and FSUACR Register.

In response to a reset or configuration set command, the FACI transfers data from flash memory to this register.

BTFLG bit (Flag of Startup Area Select for Boot Swap)

The BTFLG bit indicates whether the address of the startup area is exchanged for the boot swap function or not.

In response to a reset or configuration set command, the FACI transfers data from flash memory to this register.

46.4.27 FCPSR : Flash Sequencer Processing Switching Register

Base address: FACI = 0x4011_E000
FACI_NS = 0x5011_E000

Offset address: 0xE0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	ESUSPMD
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	ESUSPMD	Erasure Suspend Mode 0: Suspension priority mode 1: Erasure priority mode.	R/W
15:1	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-2
Note: Associated SA: FSAR register. See section 46.4.4. FSAR : Flash Security Attribution Register

FCPSR selects the erasure suspension mode. FCPSR is initialized when the SUINIT bit in FSUINITR is set to 1. It is also initialized by a reset.

ESUSPMD bit (Erasure Suspend Mode)

The ESUSPMD bit selects the erasure suspension mode when a P/E suspend command is issued while the flash sequencer is executing erasure processing (see section 46.9.3.10. P/E Suspend Command). This bit should be set before issuing Block Erase or Multi Block Erase command.

46.4.28 FPCKAR : Flash Sequencer Processing Clock Notification Register

Base address: FACI = 0x4011_E000
FACI_NS = 0x5011_E000

Offset address: 0xE4

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	KEY[7:0]								PCKA[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	1	1	1	1	0	0

Bit	Symbol	Function	R/W
7:0	PCKA[7:0]	Flash Sequencer Operating Clock Notification These bits are used to set the operating frequency of the flash sequencer while processing FACI commands.	R/W*1*2
15:8	KEY[7:0]	Key Code	W*3

Note: S-TYPE-3, P-TYPE-2
Note: Associated SA: FSAR register. See section 46.4.4. FSAR : Flash Security Attribution Register
Note 1. This bit can be written when the FRDY bit in the FSTATR register is 1. Writing to this bit is ignored when the FRDY bit is 0.
Note 2. Writing to these bits is only possible when 16 bits are written and the value written to the KEY[7:0] bits is 0x1E.
Note 3. Written values are not retained by these bits (always read 0x00).

FPCKAR specifies the operating frequency of the flash sequencer while processing FACI commands. The highest operating frequency for the given product is set as the initial value.

PCKA[7:0] bits (Flash Sequencer Operating Clock Notification)

The PCKA[7:0] bits specify the operating frequency of the flash sequencer while processing FACI commands. Set the desired frequency for these bits before issuing an FACI command. Specifically, convert the frequency in MHz to a binary number and set it for these bits.

Example:

Frequency is 35.9 MHz (PCKA = 0x24)

Round up the first decimal place of 35.9 MHz to a whole number (= 36) and convert it into a binary number.

If the value set in these bits is smaller than the actual operating frequency of the flash sequencer, the flash memory programming/erasure characteristics cannot be guaranteed. If the value set in these bits is greater than the actual operating frequency of the flash sequencer, the flash memory programming/erasure characteristics can be guaranteed but the FACI command processing time such as the time programming/erasure takes will increase. The minimum FACI command processing time is obtained when the operating frequency of the flash sequencer is the same as the PCKA value.

KEY[7:0] bits (Key Code)

The KEY[7:0] bits control writing permission to the PCKA bit.

46.4.29 FSUACR : Flash Startup Area Control Register

Base address: FACI = 0x4011_E000

Offset address: 0xE8

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	KEY[7:0]								—	—	—	—	—	—	SAS[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
1:0	SAS[1:0]	Startup Area Select 0 0: Startup area is selected by BTFLG bit 0 1: Startup area is selected by BTFLG bit 1 0: Startup area is temporarily switched to the default area (block 0) 1 1: Startup area is temporarily switched to the alternate area (block 1).	R/W*1 *3
7:2	—	These bits are read as 0. The write value should be 0.	R/W
15:8	KEY[7:0]	Key Code	W*2

Note: S-TYPE-6, P-TYPE-2
Note 1. Following described the write condition of these bits (these conditions are required at the same time).
1. Access size to this register is 16 bits
2. The value of KEY[7:0] is 0x66
3. The FSPR bit is 1.

Note 2. Written values are not retained by these bits (always read 0x00).
Note 3. Only Secure access can write to this register. Both Secure access and Non-secure read access are allowed. Non-secure write access is denied, but TrustZone access error is not generated.

FSUACR sets the startup area for the boot swap function. Do not use this register in dual mode (the DUALSEL.BANKMD[2:0] bits are 000b). In dual mode, starting up proceeds from startup area 0.

SAS[1:0] bits (Startup Area Select)

The SAS[1:0] bits select the startup area. Three methods are available for changing the startup area.

KEY[7:0] bits (Key Code)

The KEY[7:0] bits control writing permission to the SAS [1:0] bits.

46.4.30 FCKMHZ : Data Flash Access Frequency Register

Base address: FLAD = 0x4011_C000
FLAD_NS = 0x5011_C000

Offset address: 0x40

Bit	Symbol	Function	R/W
7:0	FCKMHZ[7:0]	Data Flash Access Frequency Register These bits optimize the speed of reading the data flash memory.	R/W

Note: S-TYPE-3, P-TYPE-2
Note: If the security attribution is configured as Secure:
- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:
- Secure and Non-secure access are allowed.

This register optimizes the speed of reading the data flash memory.

Set the frequency of the peripheral module clock (FCLK) of internal peripheral bus which is the clock for access to the data flash memory, in MHz units. For example, 35.9 MHz should be rounded up and set the frequency to 36. Number of cycles required for access to the data flash memory are inserted according to the frequency. When changing the frequency of the FCLK, follow the procedure below to modify the value of the data flash access frequency register (FCKMHZ) in either of the following ways according to whether operation is at a lower frequency before or after the change.

- When changing the speed from low to high: Modify FCKMHZ. After confirming the change by reading FCKMHZ, change the frequency.
- When changing the speed from high to low: Change the frequency. After the frequency is changed, modify FCKMHZ.

46.5 Flash Cache

46.5.1 Feature of flash cache

The FCACHE (Flash Cache) speeds up read access from bus master to the flash memory. The FCACHE includes:

- FCACHE1, for CPU instruction fetches
- FCACHE2, for CPU operand access and access from DMAC/DTC
- FLPF, for the prefetch access in CPU instruction fetches

Table 46.10 Flash Cache 1 (FCACHE1) overview

Item	Description
Cache Target Region	Secure alias : 0x0200_0000 - 0x021F_7FFF Non-secure alias : 0x1200_0000 - 0x121F_7FFF
Target Bus Master	CPU instruction Fetch
Capacity	256 bytes
Associativity	8WAY set associative
	128 bits/entry (128 bit aligned data), 2 entries/way
Access Cycle	Cache Hit : 0 wait Cache Miss : wait number of Flash Wait Cycle Register

Table 46.11 Flash Cache 2 (FCACHE2) overview

Item	Description
Cache Target Region	Secure alias : 0x0200_0000 - 0x021F_7FFF Non-secure alias : 0x1200_0000 - 0x121F_7FFF
Target Bus Master	CPU Operand Access and Access from DMAC/DTC
Capacity	16 bytes
Associativity	Full Associative
	128 bits/entry (128 bit aligned data), 1 entry
Access Cycle	Cache Hit : 0 wait Cache Miss : wait number of Flash Wait Cycle Register

Table 46.12 Prefetch Buffer (FLPF) overview

Item	Description
Cache Target Region	Secure alias : 0x0200_0000 - 0x021F_7FFF Non-secure alias : 0x1200_0000 - 0x121F_7FFF
Capacity	32 bytes
Associativity	Full Associative
	128 bits/entry (128 bit aligned data), 2 entries
Request Address	Next address of previous CPU Instruction
Access Cycle	Cache Hit : 0 wait Cache Miss : wait number of Flash Wait Cycle Register

46.6 Operating Modes Associated with Flash Memory

Figure 46.6 is a diagram of the mode transitions associated with the flash memory. For the procedures for setting the modes, see section 6, Option-Setting Memory.

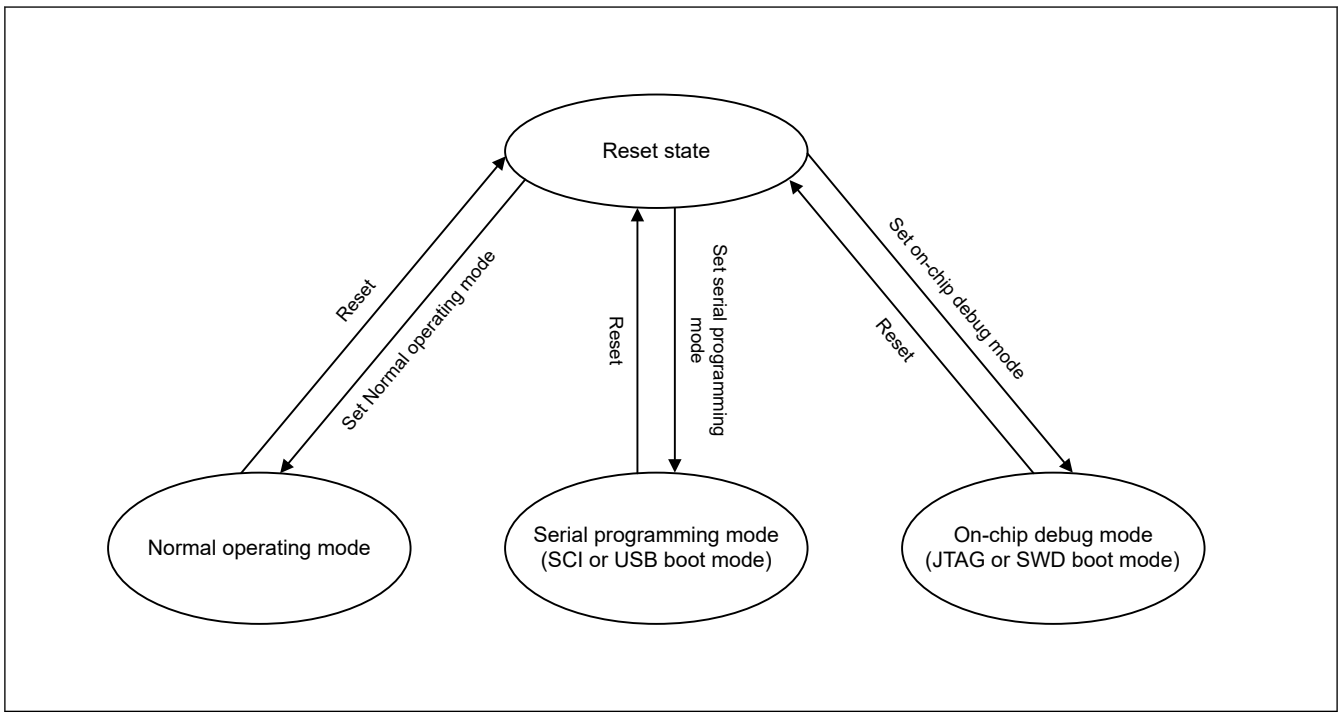

Figure 46.6 Mode Transitions Associated with Flash Memory

The flash memory area where programming and erasure are permitted and the boot program after a reset are different according to each mode. The differences between modes are listed in Table 46.13.

Table 46.13 Differences between Modes

Parameter	Normal operating mode	Serial programming mode (SCI or USB boot mode)	On-chip debug mode (JTAG or SWD boot mode)
Programmable and erasable areas	• Code flash memory • Data flash memory • Option setting memory (programming only)	• Code flash memory • Data flash memory • Option-setting memory (programming only)	• Code flash memory • Data flash memory • Option setting memory (programming only)
Erasure in block units	Possible	Possible	Possible
Boot program at a reset	User area program	Embedded program for serial programming	Depends on debug command

46.7 Overview of Functions

By using a dedicated flash-memory programmer to program the flash memory through a serial interface (serial programming) or JTAG/SWD interface (on-chip debug mode), the device can be rewritten regardless of whether this is before or after it is mounted on the target system.

Furthermore, security functions to prohibit rewriting or reading of the user program written to the flash memory are incorporated, and this can prevent falsification and illicit reading of the programs by third parties.

Programming by the user program (self-programming) is available to suit applications where the application on the target system may require updating after manufacturing or shipment. Protection features for the safe rewriting of the flash memory are also incorporated. Furthermore, interrupt processing during self-programming is supported, so programming can proceed at the same time as processing for external communications, etc., and this is the case in various situations. Table 46.14 lists the overview of the methods of programming and the corresponding operating modes.

Table 46.14 Programming methods

Programming method	Functional overview	Operating mode
Serial programming	A dedicated flash-memory programmer through the SCI or USBFS interface enables on-board programming of the flash memory after the device is mounted on the target system.	Serial programming mode
	A dedicated flash-memory programmer through the SCI or USBFS interface and a dedicated programming adapter board allow off-board programming of the flash memory, for example, programming of the device before it is mounted on the target system.	
Self-programming	A user program written to memory in advance of serial programming execution can also program the flash memory. The background operation capability makes it possible to fetch instructions or otherwise read data from the code flash memory while the data flash memory is programmed. As a result, a program resident in the code flash memory is able to program the data flash memory. For background operations that are not possible, instructions in the code flash memory cannot be fetched and data cannot be accessed while the code flash memory is being programmed by self-programming. In such cases, a program for programming from the internal SRAM or external memory must be transferred in advance and executed.	Normal operating mode
JTAG or SWD programming	A dedicated flash-memory programmer or an on-chip debugger through JTAG or SWD enables on-board programming of the flash memory after the device is mounted on the target system. A dedicated flash-memory programmer or an on-chip debugger through JTAG or SWD and a dedicated programming adapter board allow off-board programming of the flash memory, for example, programming of the device before it is mounted on the target system.	On-chip debug mode

Table 46.15 lists the functions of the flash memory. Serial programmer commands realize each function of serial programming, while reading of the flash memory by an FACI command or the user program realizes each function of self-programming.

Table 46.15 Basic Functions

Function	Functional overview	Availability	
		Serial programming	Self-programming
Blank check	Checks a specified block to ensure that writing to it has not already proceeded. Results of reading from data flash memory to which nothing is written after erasure are not guaranteed, so use blank checking to confirm that writing to memory has not proceeded after erasure.	Not supported	Supported (data flash programming only)
Block erasure	Erases the memory contents in the specified block	Supported	Supported
Programming	Writes to the specified address	Supported	Supported
CRC	Calculates the CRC in the specified range of the flash memory and transfers it to the flash programmer	Supported	Not supported
Read	Reads data programmed in the flash memory	Supported	Not supported (read by user program is possible)
Start-up program protection functions	Configures the start-up program protection functions	Supported	Supported
Option function selection	Selects the option function, and modifies the initial setting of this MCU	Supported	Supported
Dual bank function	Switches different modes (linear or dual)	Supported	Supported
Block swap function	Setting block swap functions	Supported	Supported
Block protection	Setting block protection	Supported	Supported
Device lifecycle transition	Transitions the device lifecycle	Supported	Not supported
Memory security attribution	Setting the memory security attribution	Supported	Not supported
Key	Injects key	Supported	Supported (except the key related to device lifecycle transition)
All erasure	Erase the flash memory to the state after shipment	Supported	Not supported

The flash memory supports various security functions.

Table 46.16 lists the security functions supported by the flash memory.

Table 46.16 Lists of Security Functions

Function	Description
Security flag for Start-up area select	Start-up area selection can be protected by setting of security flag (FSPR).
Permanently block protection	Programming or erasure of each block of code flash memory can be protected permanently.
Protection for TrustZone	Programming or erasure area, readable area, register access, and FACI command operation are protected by ARM TrustZone security.
Data flash configuration area protection	When target area of configuration set command includes protection area by lock bit, flash sequencer detects an error and enters command lock state.
Anti-rollback Counter	Anti-rollback counter used only by Secure applications for firmware updates.
Programming or erasure mode protection	Only Secure developer can enter the programming or erasure mode for code flash.

46.8 Operating Modes of the Flash Sequencer

The flash sequencer has three operating modes as shown in Figure 46.7. Transitions between modes are initiated by changing the value of the FENTRYR register.

When the value of the FENTRYR register is 0x0000, the flash sequencer is in read mode. In this mode, it does not receive FACI commands. The code flash memory and data flash memory are both readable.

When the value of the FENTRYR register is 0x0001, the flash sequencer is in code flash P/E mode where the code flash memory can be programmed or erased by FACI commands. In this mode, the data flash memory is readable. In addition, the code flash memory is not readable if background operation (BGO) is disabled. If BGO is enabled, the code flash memory

that is not selected by FSADDR register is readable when the FRDY bit in the FSTATR register is 0. As for the condition for enabling BGO, see section 46.15.2. Background Operation.

When the value of the FENTRYR register is 0x0080, the flash sequencer is in data flash P/E mode where the data flash memory can be programmed or erased by FACI commands. In this mode, the data flash memory is not readable. However, the code flash memory is readable.

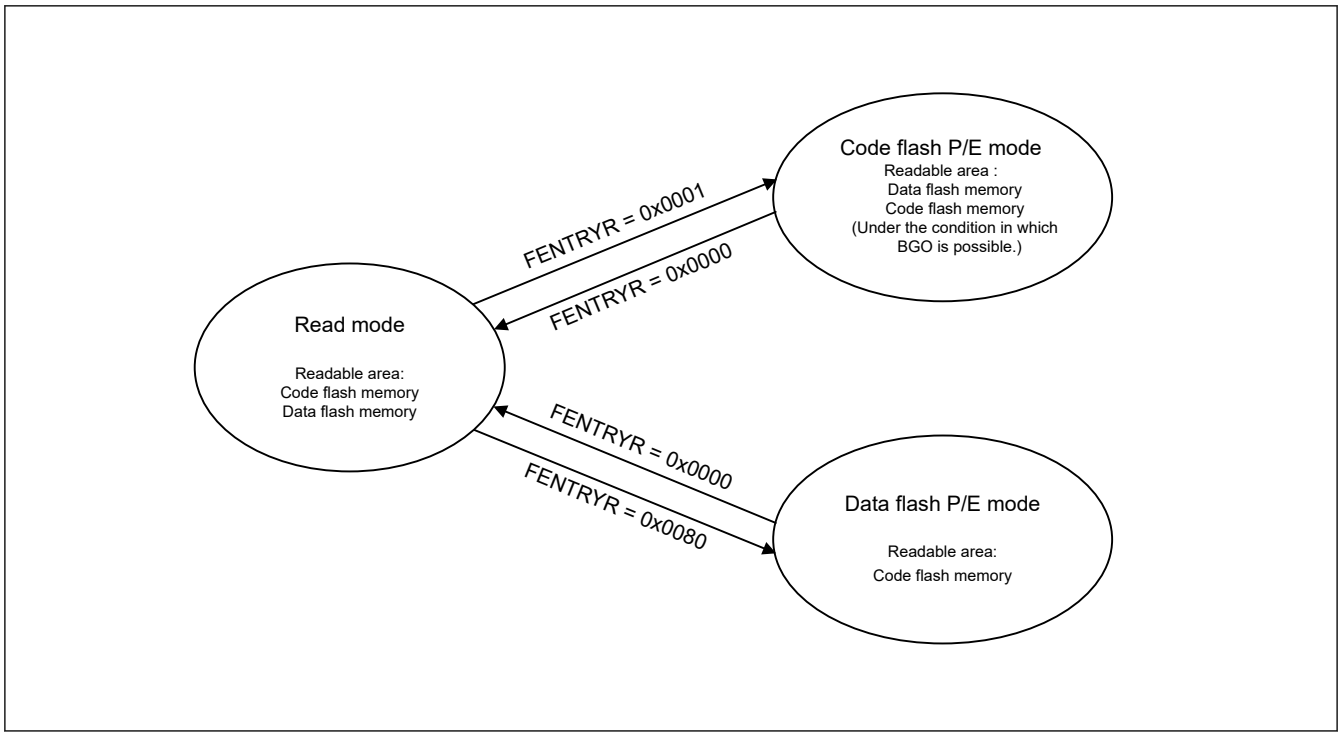

Figure 46.7 Modes of the flash sequencer

46.9 FACI Commands

46.9.1 List of FACI Commands

The FACI controls the FCU according to the specified FACI commands.

This section describes information about the FACI commands and Table 46.17 lists the FACI commands.

Table 46.17 FACI commands (1 of 2)

FACI command	Function
Program	Programs the user area and data area. Units of programming are 128 bytes for the user area and 4, 8, or 16 bytes for the data area.
Block erase	Erases user area and data area. The erase unit is 8 KB or 32 KB for user area, and 64 bytes for data flash.
Multi block erase	Erases data area. The erase unit is 64, 128, 256 bytes for data flash.
P/E suspend	Suspends programming or erasure processing.
P/E resume	Resumes suspended programming or erasure processing.
Status clear	Initializes the ILGLERR, ERSERR, PRGERR, ILGCOMERR, FESETERR, SECERR, and OTERR bits in the FSTATR register and the CMDLK, CFAE, OTERR and TZFERR bits in the FASTAT register, and the flash sequencer released from command-locked state.

Table 46.17 FACI commands (2 of 2)

FACI command	Function
Forced stop	Forcibly stops processing of FACI commands and initializes the FSTATR and FASTAT registers.
Blank check	Checks if data areas are blank. Units of Blank Check: 4 bytes to data flash memory capacity (specified in 4-byte units).
Configuration set	Sets the option-setting memory. Units of setting: • 16 bytes (Code flash memory) • 4/16 bytes (Data flash memory)
Increment Counter (Secure access only)	Increments Anti-rollback counter value . The target of counter is selected by FCNTSELR register. Update data unit is 1bit.
Refresh Counter recovery flow (Secure access only)	This is used to anti-rollback counter recovery flow. The target of counter is selected by FCNTSELR register. This command can refresh anti-rollback counter area without increasing counter value.
Read Counter (Secure access only)	Read Anti-rollback counter value. The target of counter is selected by FCNTSELR register. Reading data is output to FCNTDATAR0 and FCNTDATAR1 registers. Read unit is 64bit.

The FACI commands are issued by writing to the FACI command-issuing area (see Table 46.4). When write access as shown in Table 46.18 proceeds in the specified state, the flash sequencer executes the processing associated with the given command (see section 46.9.2. Relationship between the Flash Sequencer State and FACI Commands).

Table 46.18 FACI command formats (1 of 2)

FACI commands	Number of write access	Write data to the FACI command-issuing area			
		1st access	2nd access	3rd to (N+2)th access	(N+3)th access
Program (user area) N = 64	67	0xE8	0x40 (=N)	WD1 to WD64	0xD0
Program (data area) 4-byte programming: N = 2 8-byte programming: N = 4 16-byte programming: N = 8	N+3	0xE8	0x02 (=N) 0x04 (=N) 0x08 (=N)	WD1 to WDN	0xD0
Block Erase (user area 8K/32K Bytes)	2	0x20	0xD0	—	—
Block Erase (data area 64 bytes)	2	0x20	0xD0	—	—
Multi block erase (data area 64/128/256 bytes)	2	0x21	0xD0	—	—
P/E suspend	1	0xB0	—	—	—
P/E resume	1	0xD0	—	—	—
Status Clear	1	0x50	—	—	—
Forced Stop	1	0xB3	—	—	—
Blank Check	2	0x71	0xD0	—	—
Configuration set (Code flash memory) N = 8	11	0x40	0x08 (=N)	WD1 to WD8	0xD0
Configuration set (Data flash memory) N = 2 (4 Bytes) N = 8 (16 Bytes)	N+3	0x40	0x02 (=N) 0x08 (=N)	WD1 to WDn	0xD0
Increment Counter	2	0x35	0xD0	—	—

Table 46.18 FACI command formats (2 of 2)

FACI commands	Number of write access	Write data to the FACI command-issuing area			
		1st access	2nd access	3rd to (N+2)th access	(N+3)th access
Refresh Counter	2	0x37	0xD0	—	—
Read Counter	2	0x39	0xD0	—	—

Note: WDN (N = 1, 2, …): Nth 16-bit data to be programmed.

The flash sequencer clears the FSTATR.FRDY bit to 0 at the start of a command processing other than the Status Clear command, and sets this bit to 1 on completion.

If the FRDYIE.FRDYIE bit setting is 1, a flash ready (FRDY) interrupt is generated when the FSTATR.FRDY bit is set to 1.

46.9.2 Relationship between the Flash Sequencer State and FACI Commands

The FACI commands are accepted according to the mode/state of the flash sequencer. FACI commands should be issued after transitioning of the flash sequencer to the code flash P/E mode or data flash P/E mode and after checking the state of the flash sequencer.

Use the FSTATR and FASTAT registers to check the state of the flash sequencer. In addition, the occurrence of errors in general can be checked by reading the CMDLK bit in the FASTAT register. The value of the CMDLK bit is the logical OR of the following bits in the FSTATR register:

- ILGLERR
- ILGCOMERR
- FESETERR
- SECERR
- OTERR
- TZFERR
- ERSERR
- PRGERR
- FLWEERR.

Table 46.19 lists the available FACI commands in each operating mode.

Table 46.19 Operating mode and available FACI commands

Operating mode	FENTRYR	Available FACI commands
Read mode	0x0000	None
Code flash P/E mode	0x0001	Program Block erase P/E suspend P/E resume Status Clear Forced Stop Configuration set
Data flash P/E mode	0x0080	Program Block erase Multi block erase P/E suspend P/E resume Status Clear Forced Stop Blank Check Configuration set Increment Counter Refresh Counter Read Counter

Table 46.20 shows the state of the flash sequencer and acceptable FACI commands. An appropriate mode is assumed to have been set before the commands are executed.

Table 46.20 Acceptable FACI commands and state of the flash sequencer

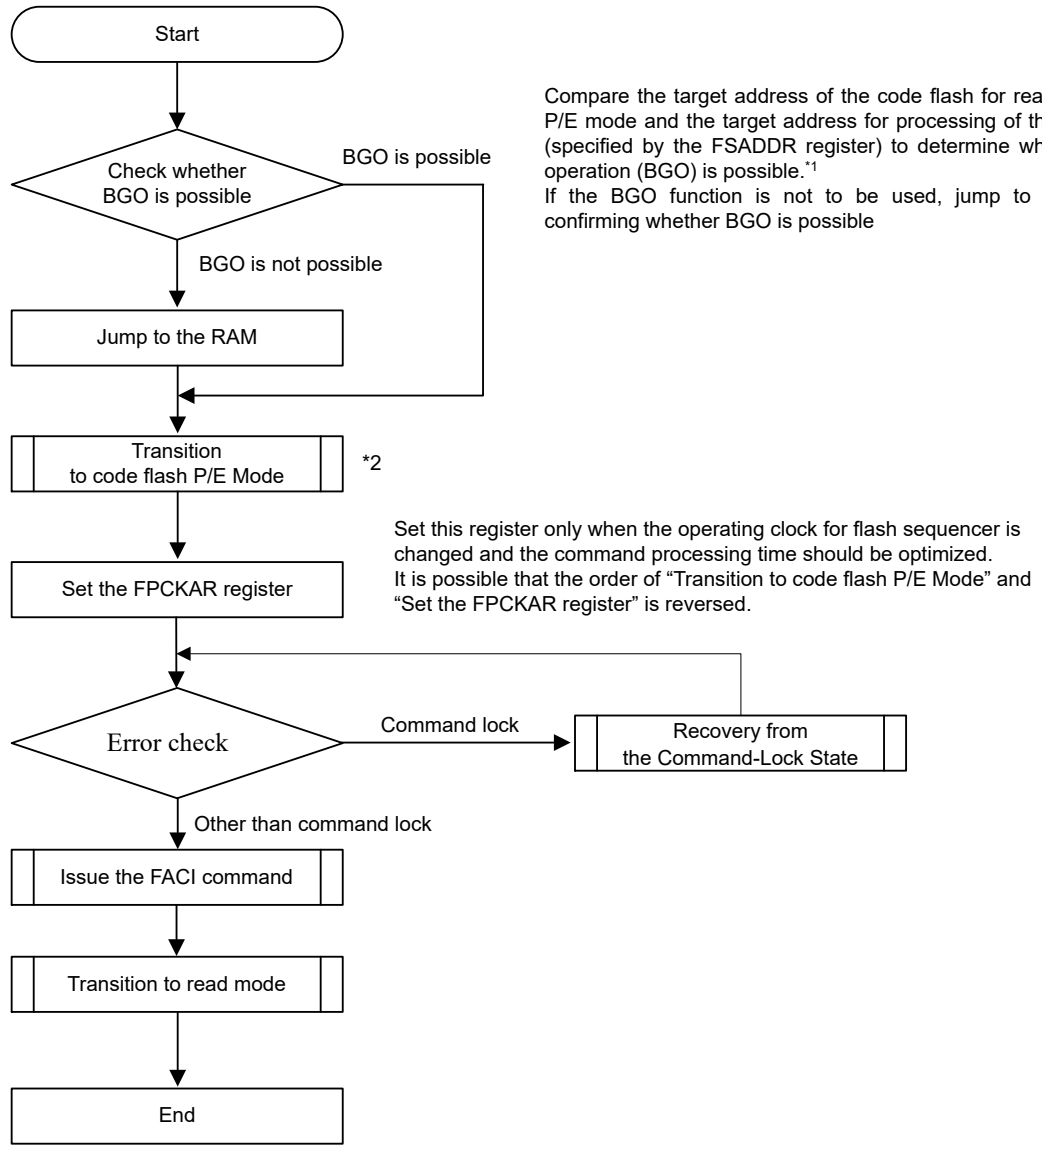
	Program, block erase or multi block erase command processing	Configuration set, configuration clear, increment counter, refresh counter or read counter command processing	Program, block erase or multi block erase command suspension processing	Blank check command processing	Programming suspended	Erasure suspended	Programming while erasure is suspended	Command-locked state (FRDY = 1)	Command-locked state (FRDY = 0)	Processing of forced stop command	Other state
FRDY bit	0	0	0	0	1	1	0	1	0	0	1
SUSRDY bit	1	0	0	0	0	0	0	0	0	0	0
ERSSPD bit	0	0	0/1	0/1	0	1	1	0/1	0/1	0	0
PRGSPD bit	0	0	0/1	0/1	1	0	0	0/1	0/1	0	0
CMDLK bit	0	0	0	0	0	0	0	1	1	0	0
Program	X	X*3	X	X	X	O*2	X	X	X	X	O
Block erase or multi block erase	X	X*3	X	X	X	X	X	X	X	X	O
P/E suspend	O	X*3	X	X	X	X	X	—	X	X	—
P/E resume	X	X*3	X	X	O	O	X	X	X	X	X
Status clear	X	X*3	X	X	O	O	X	O	X	X	O
Forced stop	O	O*3	O	O	O	O	O	O	O	O	O
Blank check	X	X*3	X	X	O*1	O*1	X	X	X	X	O*1
Configuration set	X	X*3	X	X	X	X	X	X	X	X	O
Increment Counter	X	X*3	X	X	X	X	X	X	X	X	O*1
Refresh Counter	X	X*3	X	X	X	X	X	X	X	X	O*1
Read Counter	X	X*3	X	X	X	X	X	X	X	X	O*1

Note: O: Acceptable
X: Not acceptable (places the sequencer in the command-locked state)
—: Ignored
Note 1. Only acceptable in data flash P/E mode.
Note 2. Acceptable when programming area is other than erase suspending block.
Note 3. When configuration set is processing and when FSTATR.DBFULL bit is 1, do not issue this command.

46.9.3 Usage of FACI Commands

46.9.3.1 Overview of Command Usage in Code Flash P/E Mode

Figure 46.8 show an overview of FACI command usage in code flash P/E mode. For the available commands in code flash P/E mode, see Table 46.19.

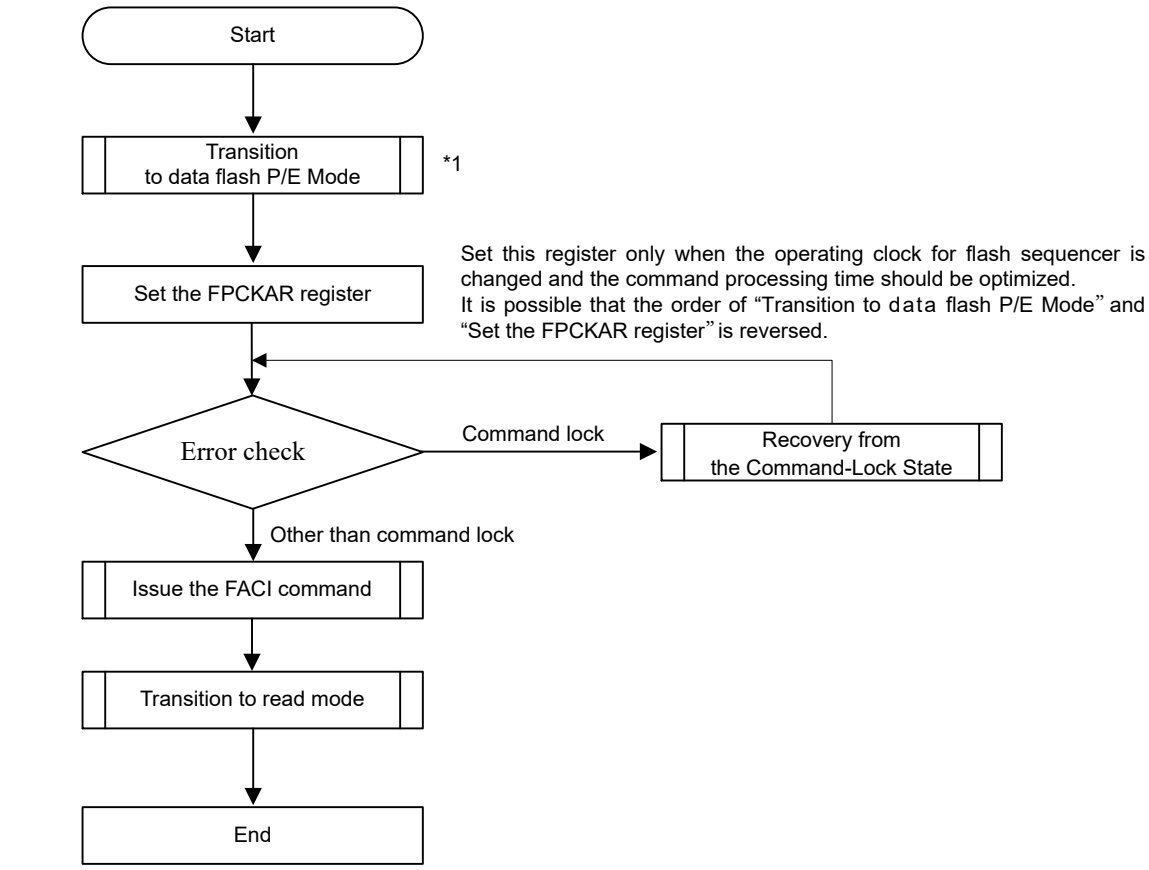


Note 1. See section 46.15.2. Background Operation
Note 2. For the condition in which BGO is possible, see section 46.9.3.3. Transition to Code Flash P/E Mode

Figure 46.8 Overview of command usage in code flash P/E mode

46.9.3.2 Overview of Command Usage in Data Flash P/E Mode

Figure 46.9 shows an overview of FACI command usage in data flash P/E and Table 46.19 lists the available commands in data flash P/E mode.



Note 1. See section 46.9.3.4. Transition to Data Flash P/E Mode

Figure 46.9 Overview of command usage in data flash P/E mode

46.9.3.3 Transition to Code Flash P/E Mode

To issue FACI commands for the code flash memory, a transition to code flash P/E mode is required by setting the FENTRYC bit in the FENTRYR register to 1.

Figure 46.10 shows the procedure to transition to code flash P/E mode.

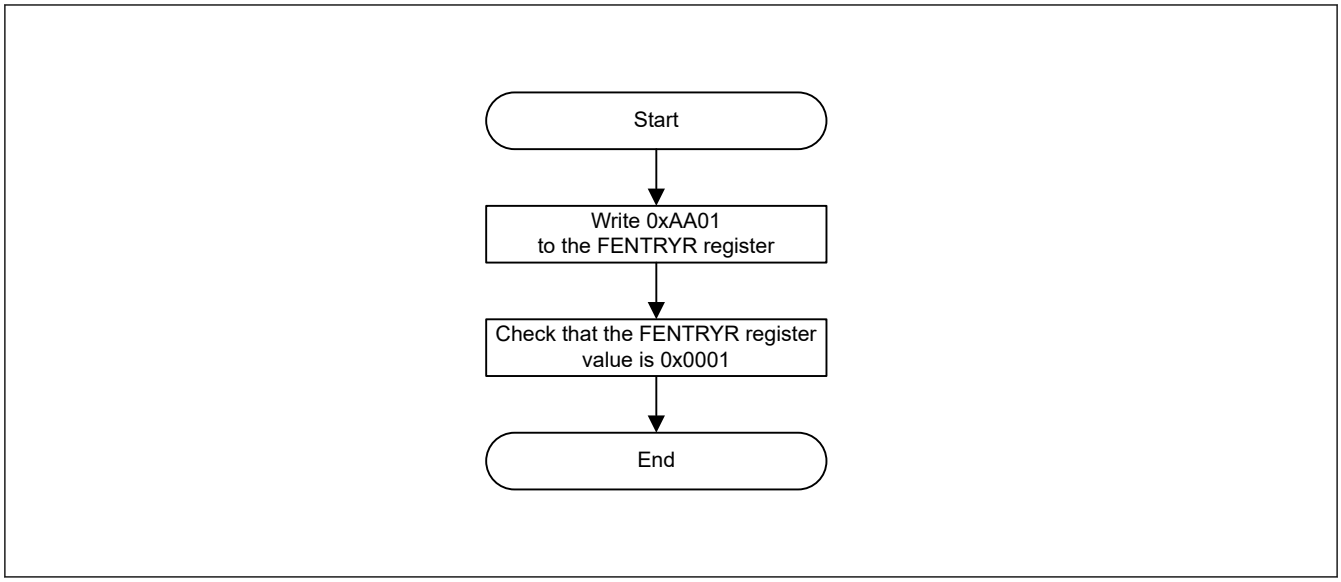


Figure 46.10 Procedure to transition to code flash P/E mode

46.9.3.4 Transition to Data Flash P/E Mode

To issue FACI commands for the data flash memory, a transition to data flash P/E mode is required by setting the FENTRYD bit in the FENTRYR register to 1.

Figure 46.11 shows the procedure to transition to data flash P/E mode.

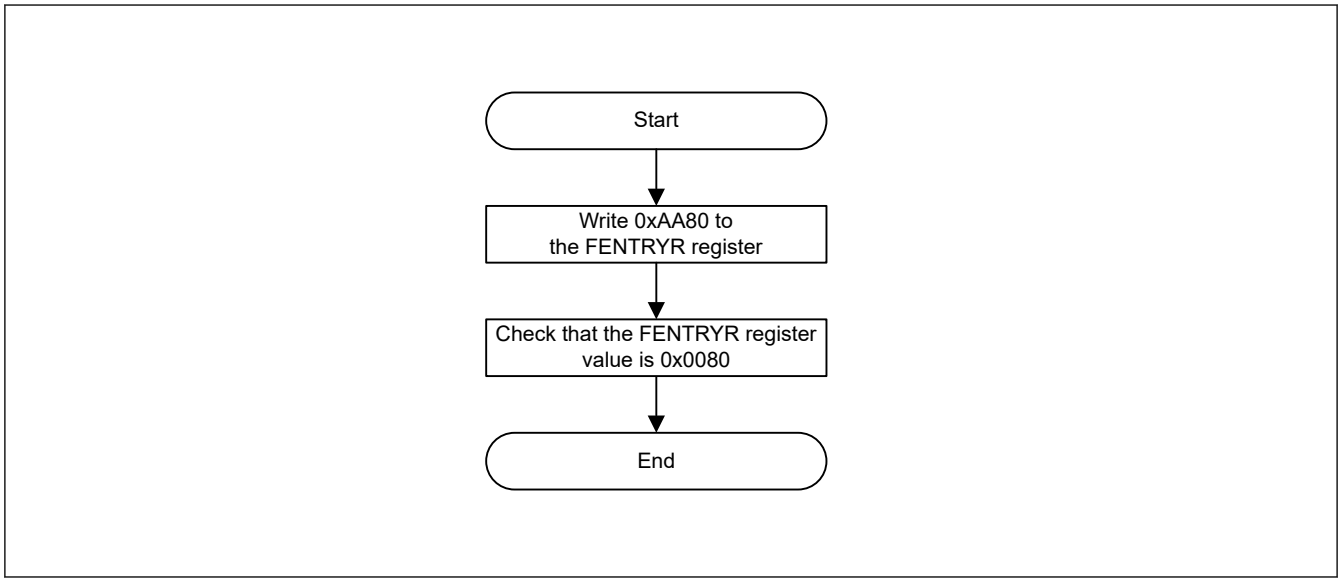

Figure 46.11 Procedure to transition to data flash P/E mode

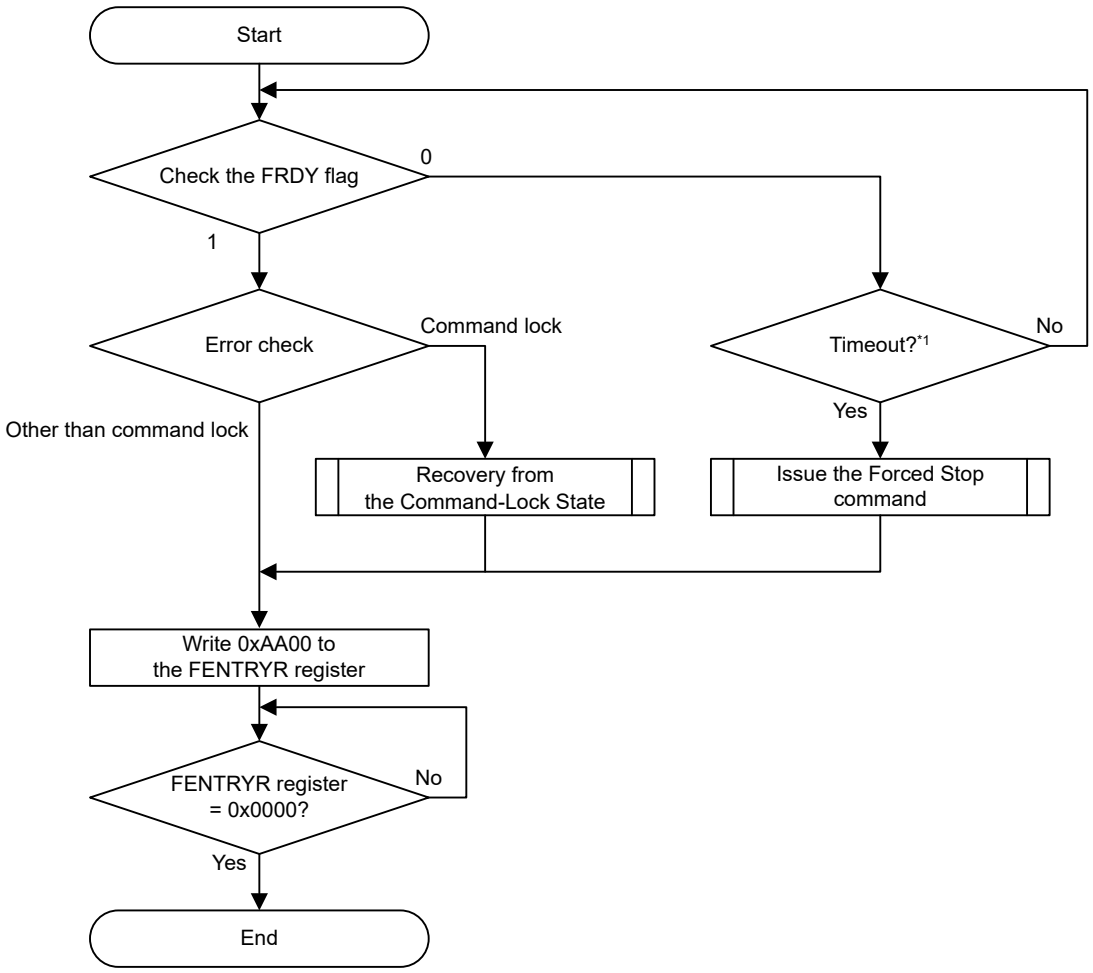
46.9.3.5 Transition to Read Mode

To read the flash memory, a transition to read mode is required by setting the FENTRYR register to 0x0000. The transition to read mode should be made after the flash sequencer completes the processing and while operation is not in the command-locked state.

Figure 46.12 shows the procedure to transition to read mode.



Note 1. Judgment of the timeout is based on 1.1 times the maximum time for processing of the FACI command that is in progress (see section 48, Electrical Characteristics)

Figure 46.12 Procedure to transition to read mode

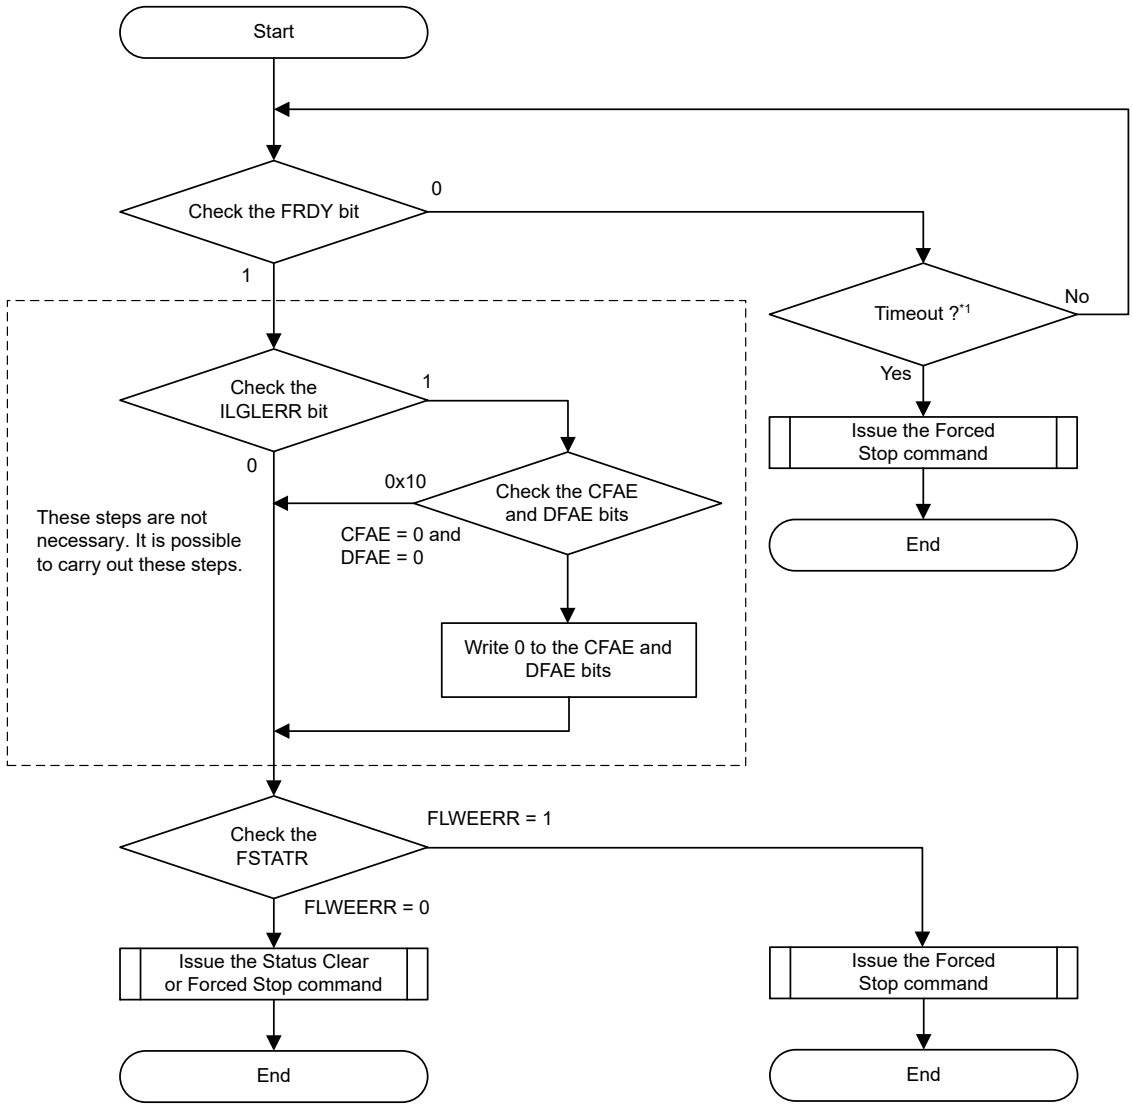
46.9.3.6 Recovery from the Command-Locked State

When the flash sequencer enters the command-locked state, FACI commands cannot be accepted. To release the sequencer from the command-locked state, use the status clear command, forced stop command, or FASTAT register.

When the command-locked state is detected by checking for an error before issuing the P/E suspend command, the FRDY bit in the FSTATR register might be 0 even though command processing has not completed. If processing is not complete by the maximum programming/erasure time specified in the electrical characteristics, this is a timeout and the flash sequencer must be stopped with the forced stop command.

The FLWEERR bit in the FSTATR register does not change from 1 to 0 with the status clear command. When these bits are set to 1, use the forced stop command to release from the command-locked state. Bits other than FRDY and FLWEERR in FSTATR register that indicate the command-locked state can be changed from 1 to 0 with the status clear or forced stop command.

Figure 46.13 shows the recovery flow from the command-locked state.



Note 1. Judgment of the timeout is based on 1.1 times the maximum time for processing of the FACI command that is in progress (see section 48, Electrical Characteristics)

Figure 46.13 Recovery flow from the command-locked state

46.9.3.7 Program Command

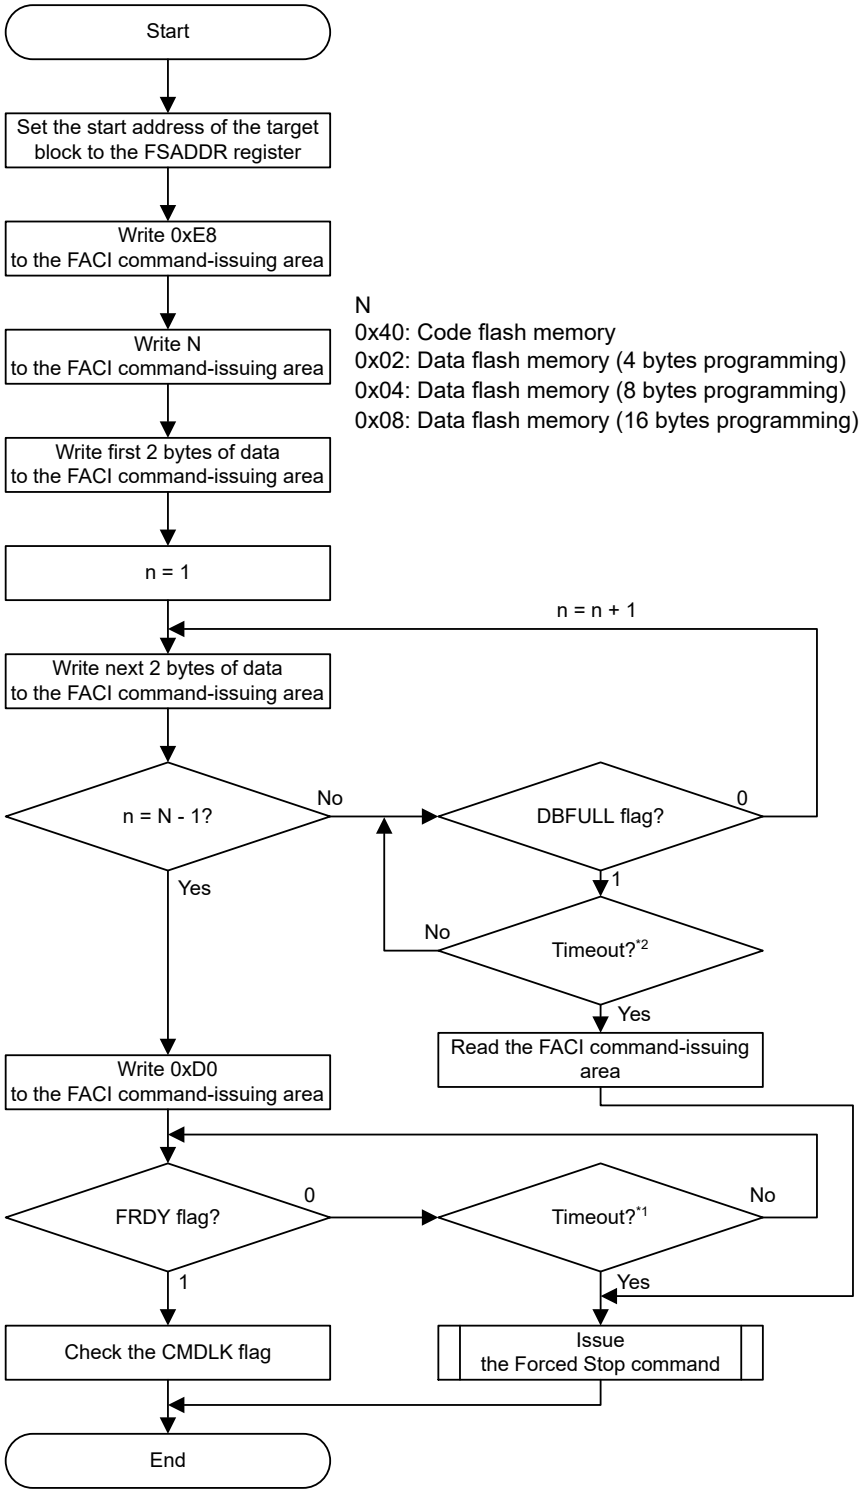
Program commands are used to write to the user and data areas. Before issuing the FACI program command, set the first address of the target block in the FSADDR register.

Program processing is started by writing the last 16 bits of program data (WD64 for code flash and WD2, WD4, and WD8 for data flash in Table 46.18) to the FACI command-issuing area before 0xD0, the final value of the FACI command, is written. Therefore, if it takes time from writing the last 16 bits of program data to writing the final FACI command value 0xD0 (for example, due to interrupt processing), the FSTATR.FRDY bit is set to 1 when program processing is completed even if 0xD0 has not been written. In this case, the program processing has been completed, but the FACI command reception has not been completed. If a subsequent FACI command is issued in this state, an illegal command error will occur. To avoid illegal command errors, disable interrupts with processing that issues FACI commands while program commands are issued (from writing 0xE8 to writing 0xD0).

If the target area for program command processing includes an area that is not for writing, write 0xFFFF to the corresponding area. If a program command is issued while the FACI internal data buffer is full, a wait period may occur on

the peripheral bus, which may affect the communication performance of other peripheral modules. To avoid the occurrence of a waiting period, set the DBFULL bit in the FSTATR register to 0 when issuing a FACI command. Writing to the data area will not cause the data buffer to become full.

Figure 46.14 shows the usage of the program command.



Note 1. Judgment of the timeout is based on 1.1 times the maximum time of programming. See section 48, Electrical Characteristics about those time

Note 2. 1.4 µs (f_{FCLK} ≥ 20 MHz)

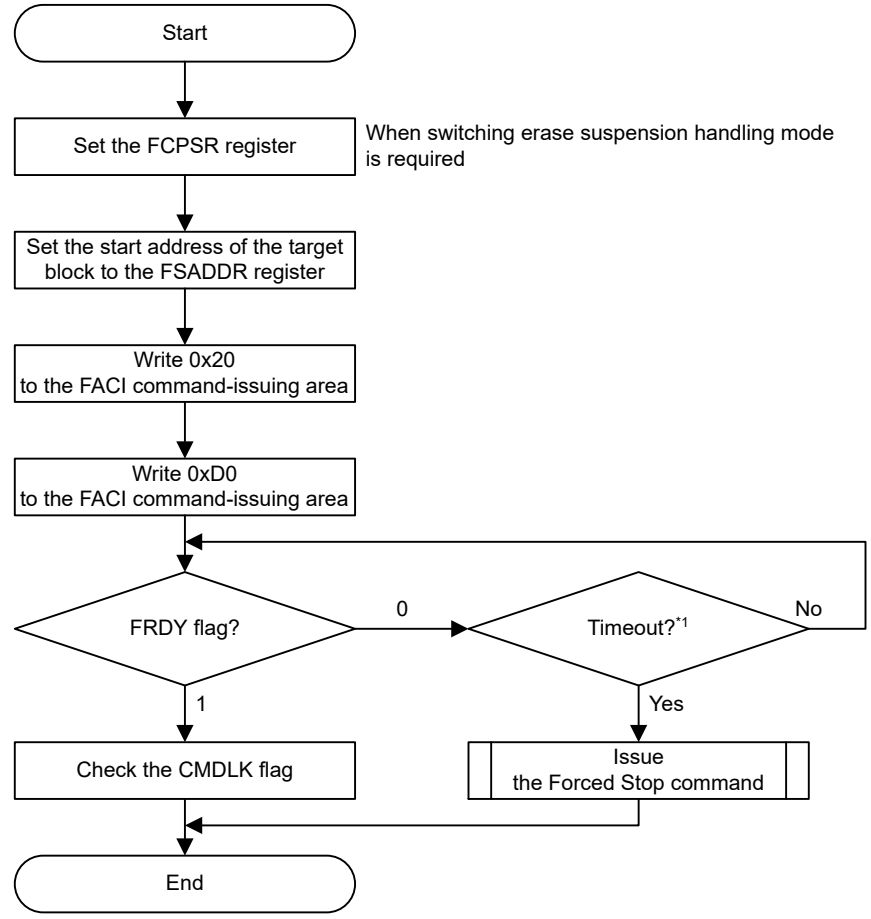
Figure 46.14 Usage flow of the program command

46.9.3.8 Block Erase Command

The block erase command is used for erasing user area or data area. The erase unit is one block. Before issuing a block erase command, set the first address of the target block to FSADDR register. Writing 0xD0 at the second write access of the FACI command triggers the FACI to start the block erase command processing. Completion of command processing can be confirmed with the FRDY bit of FSTATR register.

Set the FCPSR registers before issuing the block erase command. Additionally, FCPSR must be set when the erasure-suspended mode is to be switched.

Figure 46.15 shows the usage of the block erase command.



Note 1. Judgment of the timeout is based on 1.1 times the maximum time of erasure. See section 48, Electrical Characteristics.

Figure 46.15 Usage flow of the block erase command

46.9.3.9 Multi Block Erase Command

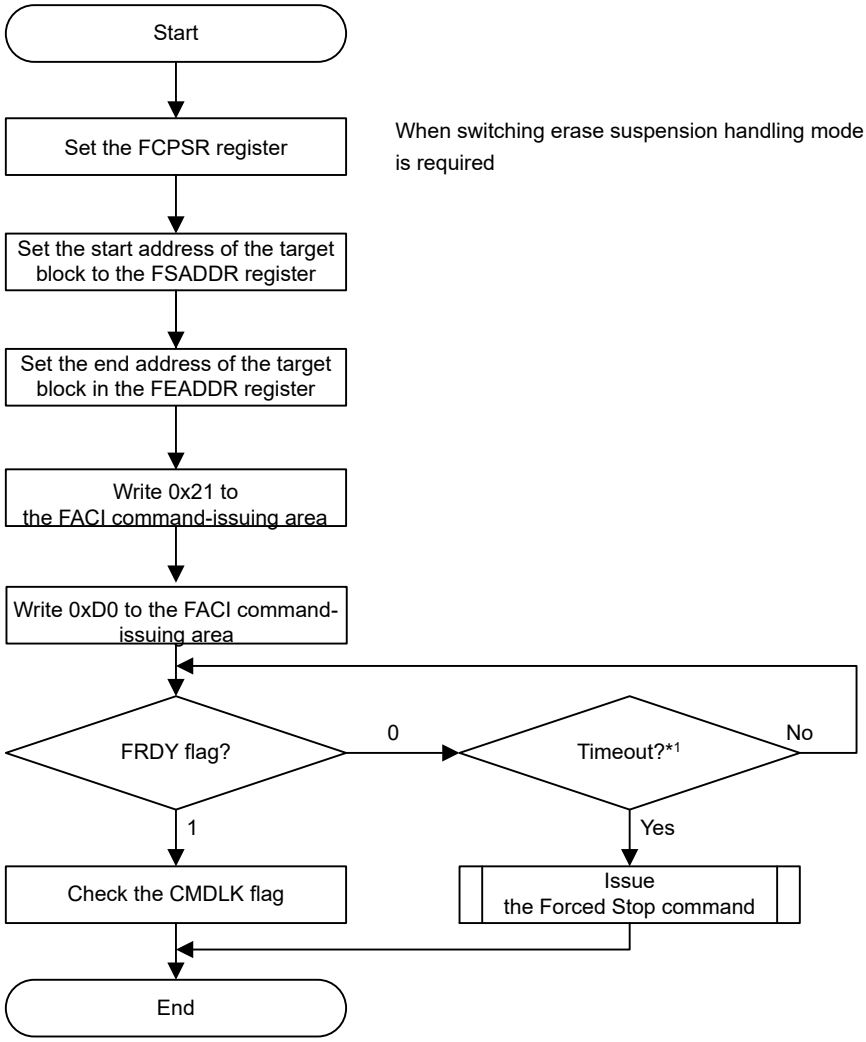
The multi block erase command is used for erasing data area. The erase unit is 64, 128, or 256 bytes. Before issuing the multi block erase command, set the start address to FSADDR register and the end address to FEADDR register. Writing 0xD0 at the second write access of the FACI command triggers FACI to start the multi block erase command processing. Completion of command processing can be confirmed with the FRDY bit of FSTATR register.

Set the FCPSR registers before issuing the multi block erase command. Additionally, FCPSR must be set when the erasure-suspended mode is to be switched.

The erase size is specified by both the FSADDR and FEADDR settings. Table 46.21 describes how to set the FSADDR and FEADDR.

Table 46.21 Settings for the erase size

Erase size	FSADDR	FEADDR
64 bytes	FSA0 to FSA5 = 0 (64 byte-boundary)	FSADDR + 0x3C
128 bytes	FSA0 to FSA6 = 0 (128 byte-boundary)	FSADDR + 0x7C
256 bytes	FSA0 to FSA7 = 0 (256 byte-boundary)	FSADDR + 0xFC



Note 1. Judgment of the timeout is based on 1.1 times the maximum time of erasure. See section 48, Electrical Characteristics.

Figure 46.16 Usage flow of the multi block command

46.9.3.10 P/E Suspend Command

The P/E suspend command is used to suspend programming/erasure. Before issuing a P/E suspend command, check that the CMDLK bit in the FASTAT register is 0, and that the execution of programming/erasure is performed normally. To confirm that the P/E suspend command can be received, check that the SUSRDY bit in the FSTATR register is 1. After issuing a P/E suspend command, read the CMDLK bit to confirm that no error occurs.

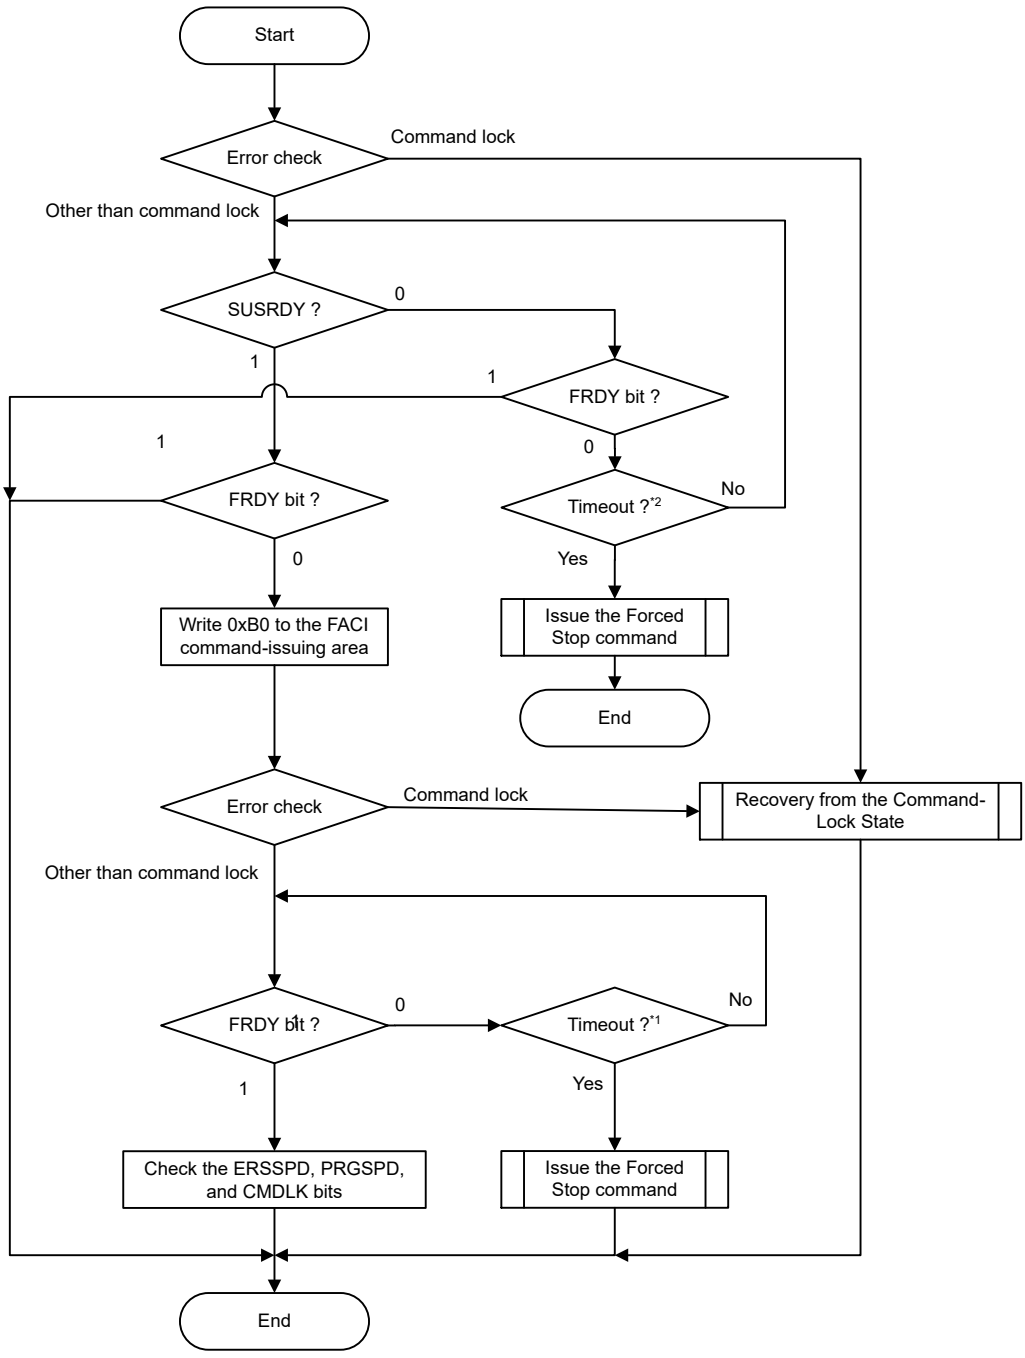
If an error occurs during programming/erasure, the CMDLK bit is set to 1. When programming/erasure processing has finished from the time when the SUSRDY bit is 1 to when the P/E suspend command is received, no error occurs and the

suspended state is not entered (the FRDY bit in the FSTATR register is 1 and the ERSSPD and PRGSPD bits in FSTATR are 0).

When a P/E suspend command is received and the programming/erasure suspend processing finishes normally, the flash sequencer enters the suspended state, the FRDY bit is set to 1, and the ERSSPD or PRGSPD bit is 1. After issuing a P/E suspend command, check that the ERSSPD or PRGSPD bit is 1 and the suspended state is entered, then proceed with the subsequent flow. If a P/E resume command is issued in the subsequent flow even when the suspended state is not entered, an illegal command error occurs and the flash sequencer shifts to the command-locked state (see section 46.11.2. Error Protection).

If the erasure suspended state is entered, programming to blocks other than an erasure target block can be performed. Additionally, the programming and erasure suspended states can shift to read mode by clearing the FENTRYR register.

Figure 46.17 shows the usage of the P/E suspend command.



Note 1. Judgment of the timeout is based on 1.1 times the maximum time of suspend delay during erasure for both code flash and data flash.
See section 48, Electrical Characteristics.
Note 2. 4.4µs (f_{FCLK} >= 20MHz)

Figure 46.17 Usage flow of the P/E suspend command

(1) Suspension during Programming

When issuing a P/E suspend command during flash memory programming, the flash sequencer suspends programming processing. Figure 46.18 shows the suspend programming operation. When receiving programming-related command, the flash sequencer clears the FRDY bit in the FSTATR register to 0 to start programming. If the flash sequencer enters the

state in which the P/E suspend command can be received after programming starts, it sets the SUSRDY bit in the FSTATR register to 1.

When a P/E suspend command is issued, the flash sequencer receives the command and clears the SUSRDY bit to 0. If the flash sequencer receives a P/E suspend command while a programming pulse is applied, the flash sequencer continues with the pulse. After the specified pulse application time, the flash sequencer finishes pulse application, starts the programming suspend processing, and sets the PRGSPD bit in the FSTATR register to 1.

When a suspended processing finishes, the flash sequencer sets the FRDY bit to 1 to enter the programming suspended state. When receiving a P/E resume command in the programming suspended state, the flash sequencer clears the FRDY and PRGSPD bits to 0 and resumes programming.

Figure 46.18 shows the timing for suspension during programming.

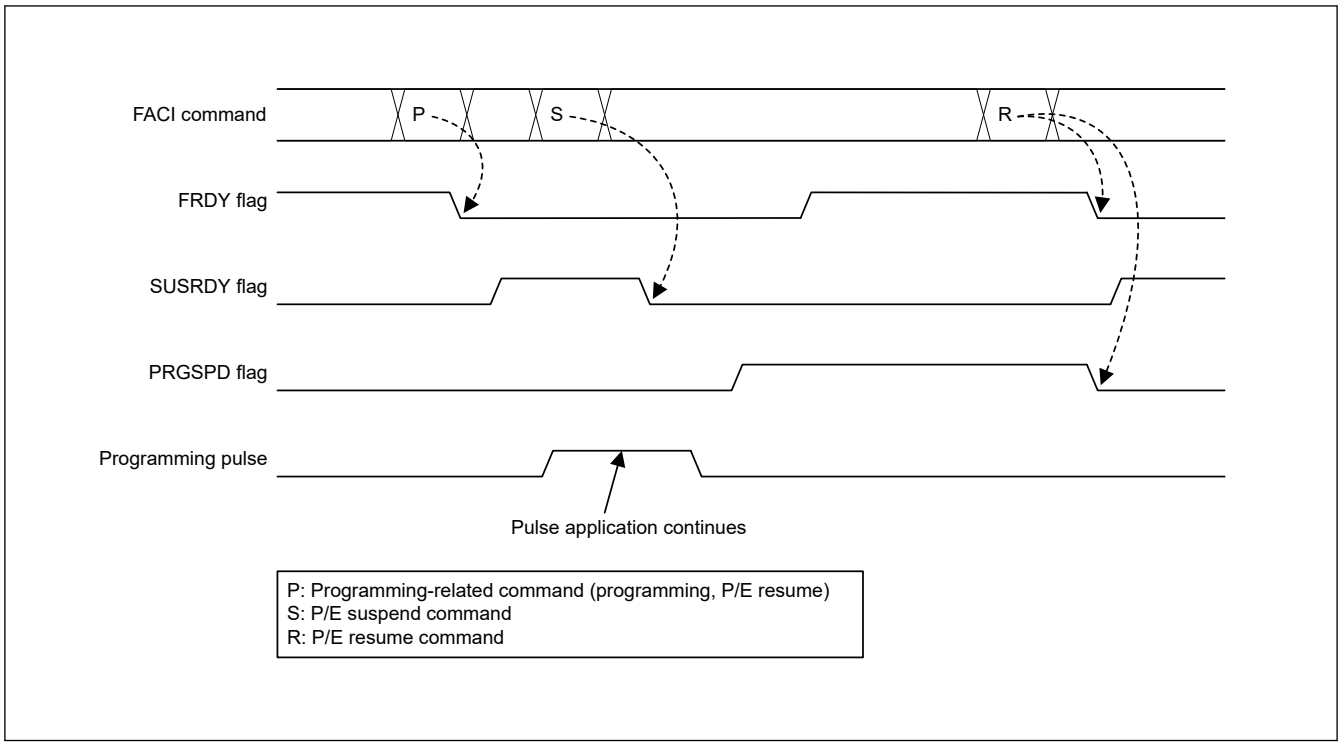


Figure 46.18 Suspension during programming

(2) Suspension during Erasure (Suspension Priority Mode)

The flash sequencer has a suspension priority mode for the suspension of erasure. Figure 46.19 shows the suspend operation of erasure when the erasure suspend mode is set to the suspension priority mode (the ESUSPMD bit in the FCPSR register is 0).

When receiving an erasure-related command, the flash sequencer clears the FRDY bit in the FSTATR register to 0 to start erasure. If the flash sequencer enters the state in which the P/E suspend command can be received after erasure starts, it sets the SUSRDY bit in the FSTATR register to 1.

When a P/E suspend command is issued, the flash sequencer receives the command and clears the SUSRDY bit to 0.

When receiving a suspend command during erasure, the flash sequencer starts the suspend processing and sets the ERSSPD bit in the FSTATR register to 1 even when it is applying an erasure pulse. When the suspended processing finishes, the flash sequencer sets the FRDY bit to 1 to enter the erasure suspended state. When receiving a P/E resume command in the erasure suspended state, the flash sequencer clears the FRDY and ERSSPD bits to 0 and resumes erasure. Operations of the FRDY, SUSRDY, and ERSSPD bits at the suspension and resumption of erasure are the same, regardless of the erasure suspend mode.

The setting of the erasure suspend mode affects the control method of erasure pulses. In suspension priority mode, when receiving a P/E suspend command while erasure pulse A that has not been previously suspended is being applied, the flash sequencer suspends the application of erasure pulse A and enters the erasure suspended state. When receiving a P/E suspend command while reapplying erasure pulse A after erasure is resumed with a P/E resume command, the flash sequencer

continues to apply erasure pulse A. After the specified pulse application time, the flash sequencer finishes erasure pulse application and enters the erasure suspended state.

When the flash sequencer receives a P/E resume command next and erasure pulse B is being applied, the flash sequencer receives a P/E suspend command again, and the application of erasure pulse B is then suspended. In suspension priority mode, delays due to suspension can be minimized because the application of an erasure pulse is suspended once per pulse, and priority is given to the suspend processing.

If the interval of suspension after resume is longer than t_{REST1} (Resume time: priority on suspension, resume after the 1st suspend for the same pulse), suspend delay will be always t_{SESD1} (Suspend delay: priority on suspension, the 1st suspend for the same pulse).

If the interval of suspension after resume is shorter than t_{REST1}, suspend delay becomes either t_{SESD1} or t_{SESD2} (Suspend delay: priority on suspension, the 2nd suspend for the same pulse).

(The value of t_{REST1} / t_{SESD1} / t_{SESD2}, see section 48, Electrical Characteristics.)

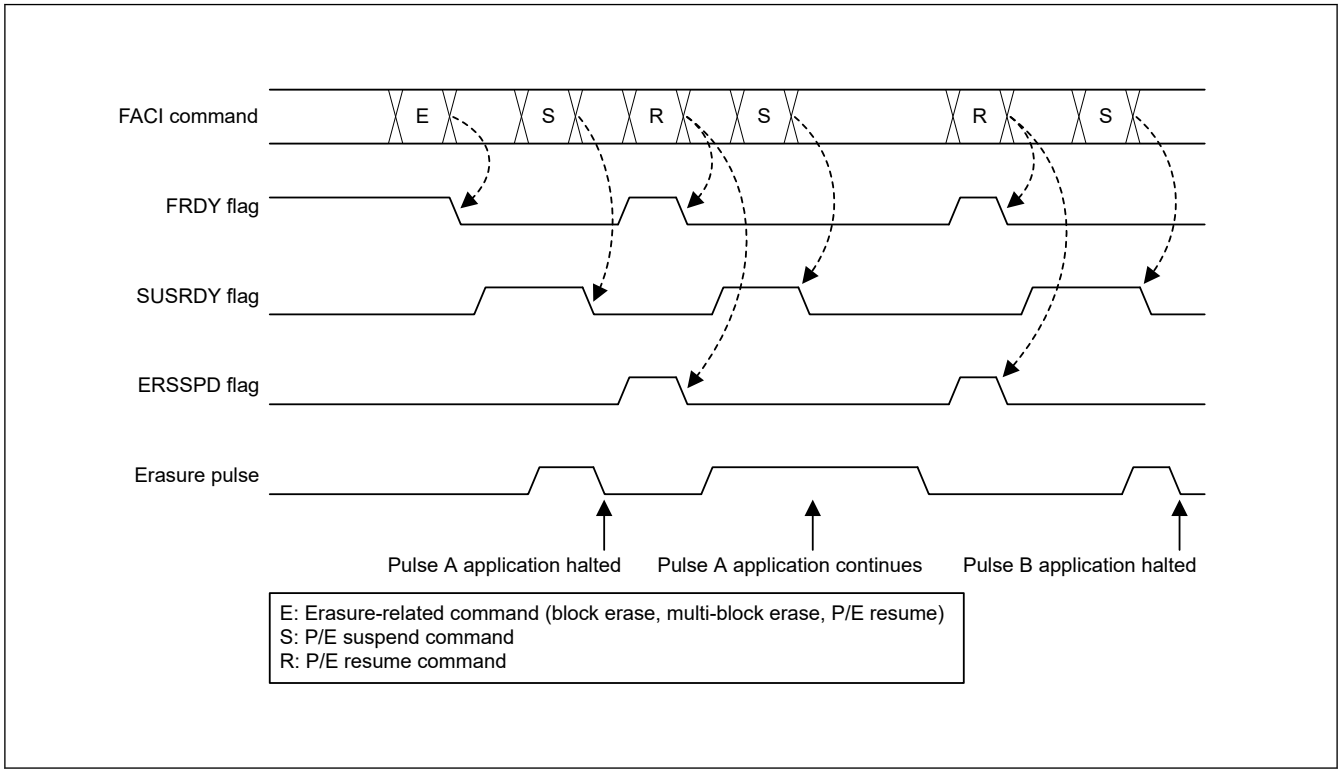

Figure 46.19 Suspension during erasure (suspension priority mode)

(3) Suspension during Erasure (Erasure Priority Mode)

The flash sequencer has an erasure priority mode for the suspension of erasure. Figure 46.20 shows the suspend operation of erasure when the erasure suspend mode is set to the erasure priority mode (the ESUSPMD bit in the FCPSR register is 1). The control method of erasure pulses in erasure priority mode is the same as that of programming pulses for the programming suspend processing.

If the flash sequencer receives a P/E suspend command while an erasure pulse is applied, the flash sequencer continues to apply the pulse. In this mode, the required time for the erasure processing can be reduced compared to the suspension priority mode because the re-application of erasure pulses does not occur when a P/E resume command is issued.

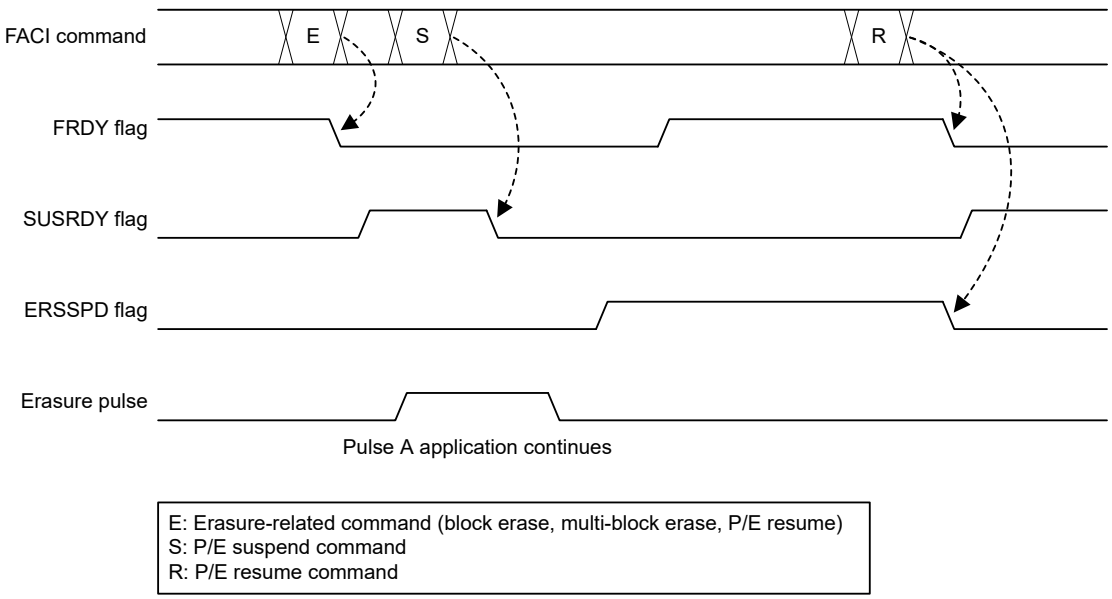

Figure 46.20 Suspension during erasure (erasure priority mode)

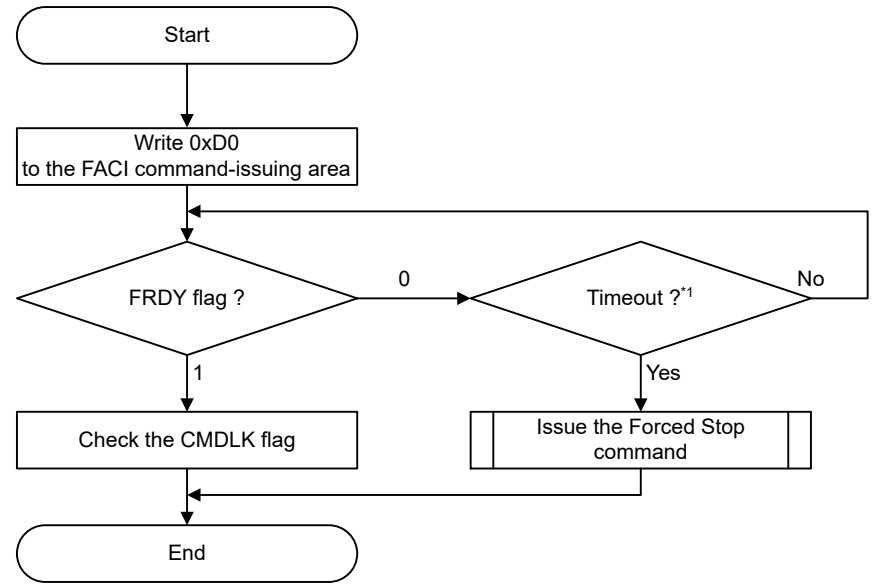
46.9.3.11 P/E Resume Command

The P/E resume command is used to resume suspended programming or erasure. If the FENTRYR setting has been modified during suspension, issue a P/E resume command only after resetting FENTRYR to the previous value that was held before the P/E suspend command was issued. Figure 46.21 shows usage of the P/E resume command.



Note 1. Judgment of the timeout is based on 1.1 times the maximum time for halted processing of the FACI command. See section 48, Electrical Characteristics.

Figure 46.21 Usage flow of the P/E resume command

46.9.3.12 Status Clear Command

The status clear command is used to clear the command-locked state (see section 46.9.3.6. Recovery from the Command-Locked State).

You can use the status clear command to clear the following bits in the FSTATR register in the command-locked state:

- ILGLERR
- ILGCOMERR
- FESETERR
- SECERR
- OTERR
- ERSERR
- PRGERR
- TZFERR

Figure 46.22 shows usage of the status clear command.

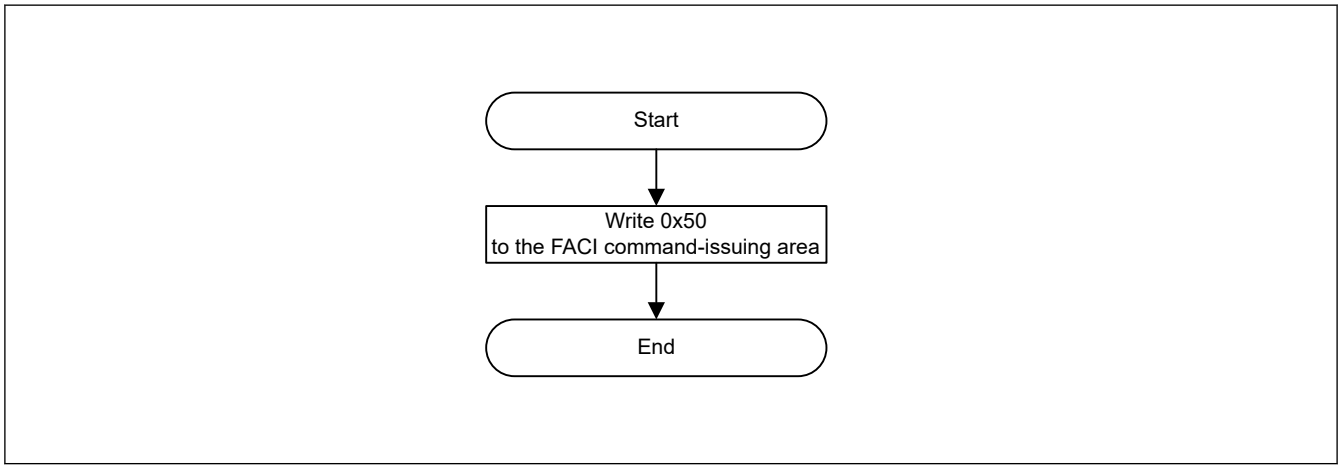


Figure 46.22 Usage flow of the status clear command

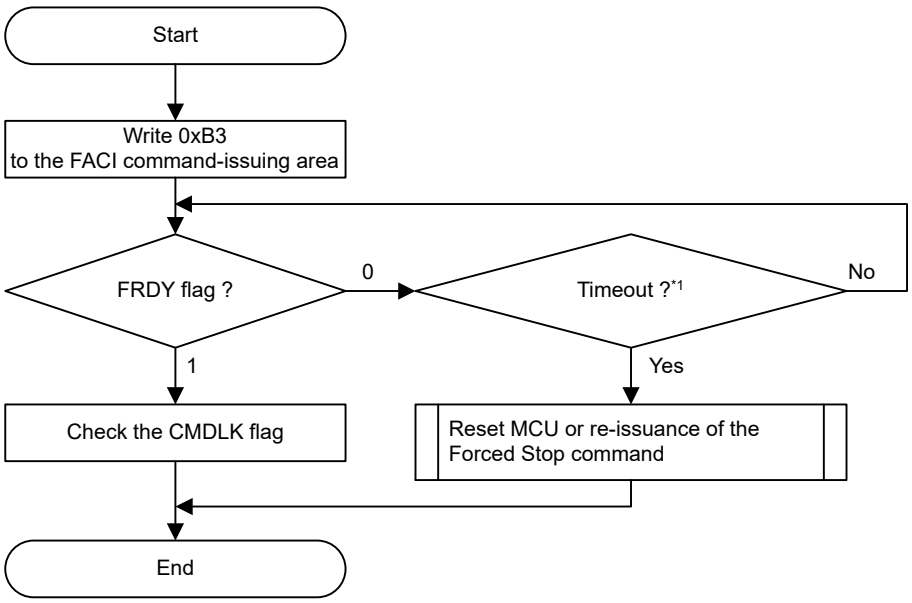
46.9.3.13 Forced Stop Command

The forced stop command is used to forcibly end command processing by the flash sequencer. Although this command halts command processing more quickly than the P/E suspension command, values from the programming or erasure that are in progress are not guaranteed. Additionally, resumption of processing is not possible. Processing of programming or erasure that is halted by the forced stop command is also defined as one programming round.

Executing the forced stop command also initializes part of the FACI, the whole FCU, the FSTATR and FASTAT registers. This command can be used in the procedure for recovery from the command-locked state and for processing in response to a timeout of the flash sequencer (see section 46.9.3.6. Recovery from the Command-Locked State).

Figure 46.23 shows usage of the forced stop command.



Note 1. Judgment of the timeout is based on 1.1 times the maximum time of the Forced Stop command latency. See section 48, Electrical Characteristics.

Figure 46.23 Usage flow of the forced stop command

(1) Notes on Using the Forced Stop Command during Command Issue

When using the forced stop command at the timeout occurrence by DBFULL bit of the program command, writing in the FACI command-issuing area is sometimes processed as writing in data of the program command. See Table 46.4 in section 46.3. Address Space for information on the FACI command-issuing area to force a command lock. Then issue a forced stop command with return method from the command lock status (see Figure 46.14). Locking commands is possible in any case where the unit for reading the FACI command issuing area is 8, 16, or 32 bits.

46.9.3.14 Blank Check Command

The blank check command is used to confirm that an area is in the non-programmed state. Values read from the data flash memory that have been erased but not yet programmed again that is in the non-programmed state, are undefined.

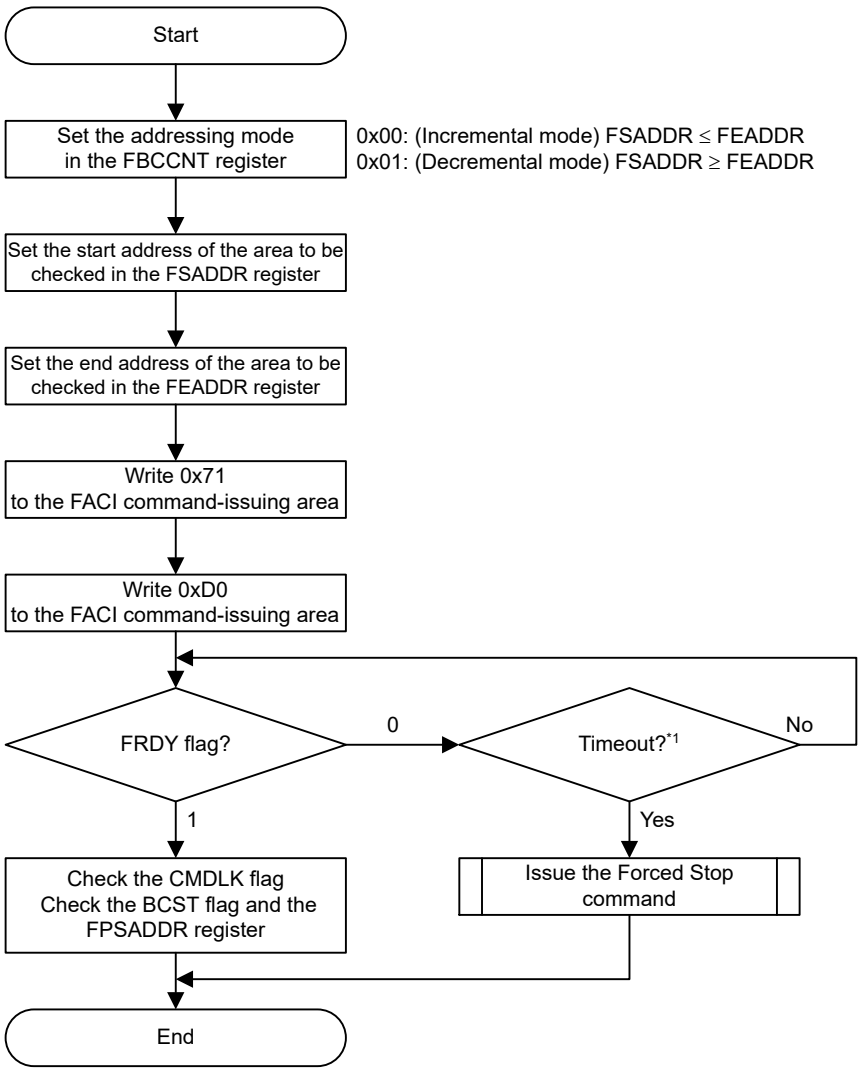
Before issuing the Blank Check command, set addressing mode, start address, and end address of the target area for Blank Check to the FBCCNT, FSADDR, and FEADDR registers. When Blank Check addressing mode is set to decremental mode (i.e. FBCCNT.BCDIR = 1), address specified in FSADDR should be equal to or larger than address in FEADDR.

On the other hand, the address in FSADDR should be equal to or smaller than address in FEADDR when Blank Check addressing mode is set to incremental mode (i.e. FBCCNT.BCDIR = 0).

If the settings of the BCDIR bit, FSADDR, and FEADDR are inconsistent, the flash sequencer enters the command-locked state. The size of the target area for Blank Check is in the range from 4 bytes to the data flash memory capacity and is set in units of 4 bytes.

Write 0x71 and 0xD0 to the FACI command-issuing area to start Blank Check. Completion of processing can be confirmed by the FRDY bit of the FSTATR register. At the end of processing, the result of Blank Check is stored in the BCST bit in the FBCSTAT register. If non-programmed data exists within the target area for Blank Check, flash sequencer stops Blank Check command operation. In this case, address of non-programmed data is indicated to FPSADDR register.

Figure 46.24 shows usage of the blank check command.



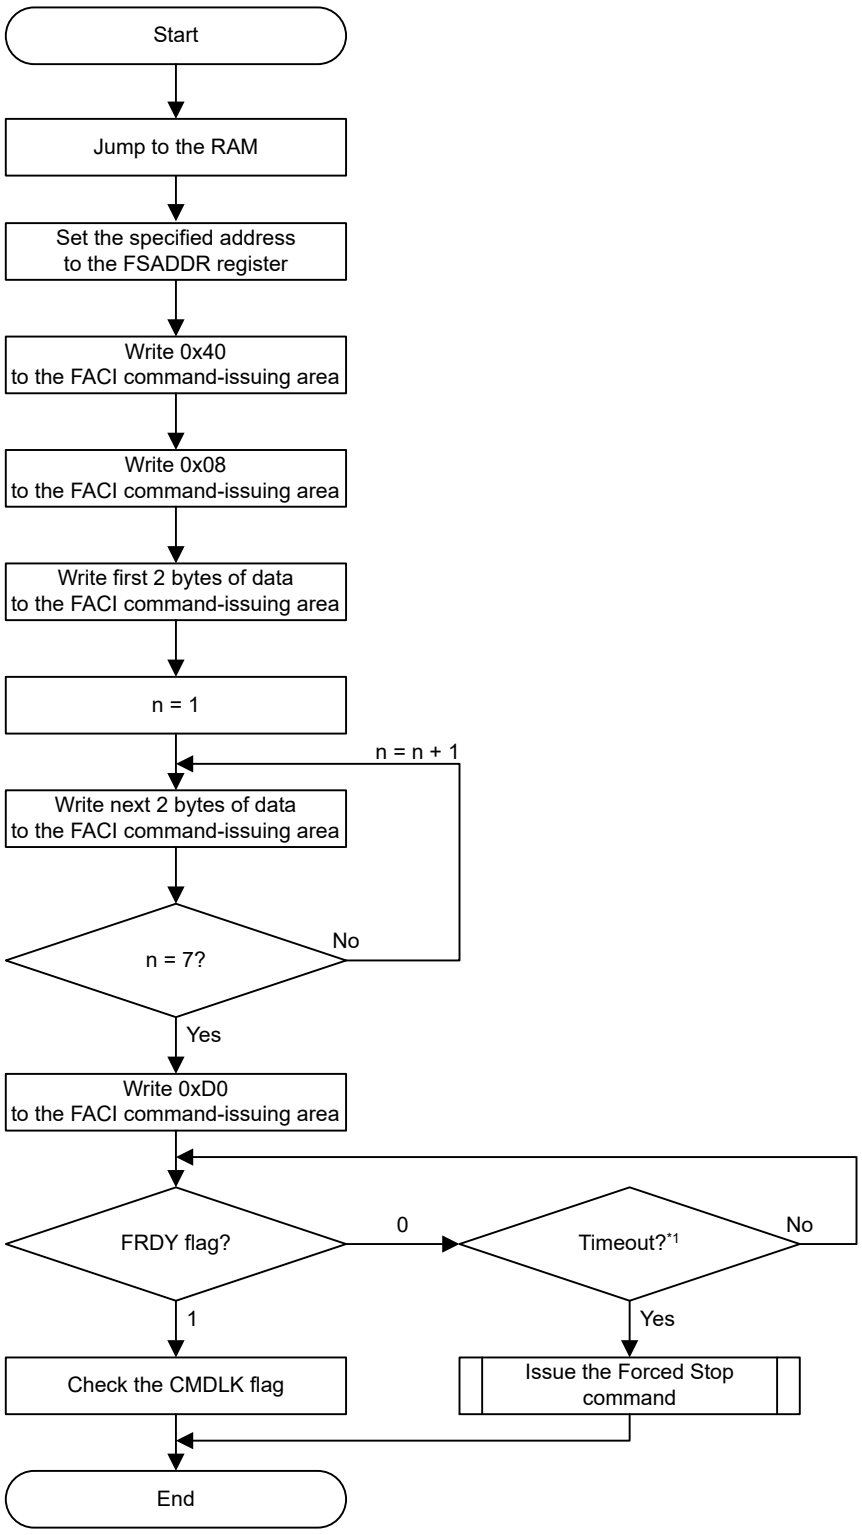
Note 1. Judgment of the timeout is based on 1.1 times the maximum time of Blank Checking for the whole target range. See section 48, Electrical Characteristics.

Figure 46.24 Usage flow of the blank check command

46.9.3.15 Configuration Set Command

The Configuration set command is used to set option-setting memory. Before issuing the Configuration set command, set the specified address (shown in Table 46.22) in the FSADDR register. Writing 0xD0 to the FACI command-issuing area in the final access for issuing the FACI command starts FACI processing of the Configuration set command.

Figure 46.25 shows usage of the configuration set command.



Note 1. Judgment of the timeout is based on 1.1 times the maximum time of programing in option-setting memory. See section 48, Electrical Characteristics.

Figure 46.25 Usage flow of the configuration set command

The correspondence between the possible target data for configuration setting and the address value set in the FSADDR register is shown in Table 46.22. For details, see section 46.4.12. FSADDR : FACI Command Start Address Register.

Table 46.22 Address Used by Configuration Set Command for Secure alias (Code flash memory)

Address	FSADDR Register Value	Setting Data	Operation of additional writing		Timing when the Setting is Enabled
			SAS.FSPR bit is 1	SAS.FSPR bit is 0	
0x0300_A100	0x0300_A100	Option Function Select Register 0 (OFS0)	Writable	Writable	At a reset
0x0300_A104		Option Function Select Register 2 (OFS2)			
0x0300_A110	0x0300_A110	Dual Mode Select Register (DUALSEL)	Writable	Writable	At a reset
0x0300_A134	0x0300_A130	Start-up Area Setting Register (SAS)	Writable	Not writable*1	When a reset or command is executed
0x1300_A180	0x1300_A180	Option Function Select Register 1 (OFS1)	Writable	Writable	At a reset
0x1300_A190	0x1300_A190	Bank Select Register (BANKSEL)	Writable	Writable	At a reset
0x1300_A1C0	0x1300_A1C0	Block Protect Setting Register (BPS)	Writable*2	Writable*2	When a reset or command is executed
0x1300_A1E0	0x1300_A1E0	Permanent Block Protect Setting Register (PBPS)	Writable*3 (from 1 to 0 only)	Writable*3 (from 1 to 0 only)	When a reset or command is executed
0x0300_A200	0x0300_A200	Option Function Select Register 1 Secure (OFS1_SEC)	Writable	Writable	At a reset
0x0300_A210	0x0300_A210	Bank Select Register Secure (BANKSEL_SEC)	Writable	Writable	At a reset
0x0300_A240	0x0300_A240	Block Protect Setting Register Secure (BPS_SEC)	Writable*4	Writable*4	When a reset or command is executed
0x0300_A260	0x0300_A260	Permanent Block Protect Setting Register Secure (PBPS_SEC)	Writable*5 (from 1 to 0 only)	Writable*5 (from 1 to 0 only)	When a reset or command is executed
0x0300_A280	0x0300_A280	Option Function Select Register 1 Select (OFS1_SEL)*6	Writable	Writable	At a reset
0x0300_A290	0x0300_A290	Bank Select Register Select (BANKSEL_SEL)	Writable	Writable	At a reset
0x0300_A2C0	0x0300_A2C0	Block Protect Setting Register Select (BPS_SEL)	Writable*6	Writable*6	At a reset

Note 1. The SAS.FSPR bit cannot be restored to 1 by using the Configuration set command once it is set to 0. Therefore, setting the start-up area select flags again becomes impossible. (when the Configuration set command is issued to the address of 0x0100A134, the command is locked.) Exercise extra caution when handling the SAS.FSPRbit.
Note 2. Once PBPS[n] bit is set to 0, the BPS[n] bit cannot be restored to 1 by using the Configuration set command.
Note 3. Once these bits are set to 0, the bits cannot be restored to 1 by using the Configuration set command. The PBPS[n] bit cannot be set to 0 by using the Configuration set command when the BPS[n] bit is 1.
Note 4. Once PBPS_SEC[n] bit is set to 0, the BPS_SEC[n] bit cannot be restored to 1 by using the Configuration set command.
Note 5. Once these bits are set to 0, the bits cannot be restored to 1 by using the Configuration set command. The PBPS_SEC[n] bit cannot be set to 0 by using the Configuration set command when the BPS_SEC[n] bit is 1.
Note 6. When the Permanent Block Protect bit is enabled, Block protect setting register cannot be written.

Table 46.23 Address Used by Configuration Set Command for Secure alias (Data flash memory) (1 of 2)

Address	FSADDR	Setting Data	Operation of additional writing		Timing when the Setting is Enabled
	Register Value		Lock bit is 1	Lock bit is 0	
0x2703_0080~ 0x2703_017C	0x2703_0080~ 0x2703_017C	Lockable Configuration Data Area 0 (LK_CD_A0)	Writable*1	Not Writable*1	At a reset
0x2703_0180~ 0x2703_027C	0x2703_0180~ 0x2703_027C	Lockable Configuration Data Area 1 (LK_CD_A1)	Writable*1	Not Writable*1	At a reset
0x2703_0280~ 0x2703_037C	0x2703_0280~ 0x2703_037C	Lockable Configuration Data Area 2 (LK_CD_A2)	Writable*1	Not Writable*1	At a reset

Table 46.23 Address Used by Configuration Set Command for Secure alias (Data flash memory) (2 of 2)

Address	FSADDR	Setting Data	Operation of additional writing		Timing when the Setting is Enabled
	Register Value		Lock bit is 1	Lock bit is 0	
0x2703_0380~ 0x2703_0384	0x2703_0380~ 0x2703_0384	Configuration Data Lock Bit Area 0 (CD0_LK)	Writable	Writable	When a reset or command is executed
0x2703_0388~ 0x2703_038C	0x2703_0388~ 0x2703_038C	Configuration Data Lock Bit Area 1 (CD1_LK)	Writable (from 1 to 0 only)	Writable (from 1 to 0 only)	When a reset or command is executed
0x2703_0390	0x2703_0390	Configuration Data Lock Bit Area 2 (CD2_LK)	Writable (from 1 to 0 only)	Writable (from 1 to 0 only)	When a reset or command is executed
0x2703_03C0	0x2703_03C0	Anti-Rollback Counter Lock Setting (ARCLS)	Writable (from 1 to 0 only)	Writable (from 1 to 0 only)	When a reset or command is executed
0x2703_03C2		Anti-Rollback Counter Configuration Setting for ARC_NSEC (ARCCS)	Writable*2	Writable*2	When a reset or command is executed

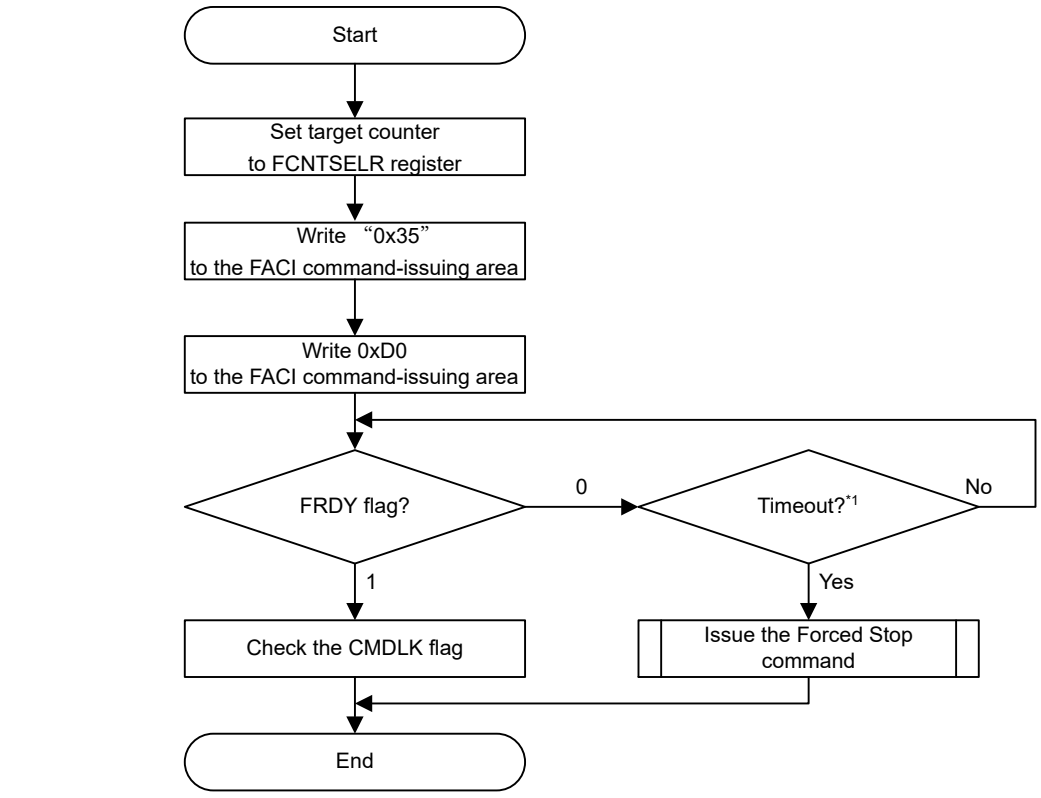
Note 1. For details of relation of write-protection area and lock bit, see section 46.12.4. Data Flash Configuration Area Protection.
Note 2. The ARC_NSEC counter selection bit cannot be changed after set to 00b or 01b. When using the ARC_NSEC counter, this counter can be selected either of 4 lines of 64 bits (00b setting) or 1 line of 256 bits (01b setting).

46.9.3.16 Increment Counter Command

The Increment Counter command is used to security function, safety function. "Increment Counter" command is used for updating 3 types of anti-rollback counter (ARC_SEC, ARC_NSEC, and ARC_OEMBL). The counter update is executed increment processing and cannot be decrement processing.

Writing "0xD0" at 2nd write access of flash sequencer command triggers FACI to start “Increment Counter” command processing. Completion of command processing can be confirmed by FRDY bit of FSTATR register.

If "Command Lock" status occurs during command execution, refresh the counter with "Refresh Counter" command after "Command Lock" state is released.



Note 1. 50msec(FCLK>=20MHz)

Figure 46.26 Usage of the Increment Counter Command

Anti-rollback counter value is not increased the following conditions by “Increment Counter” command.

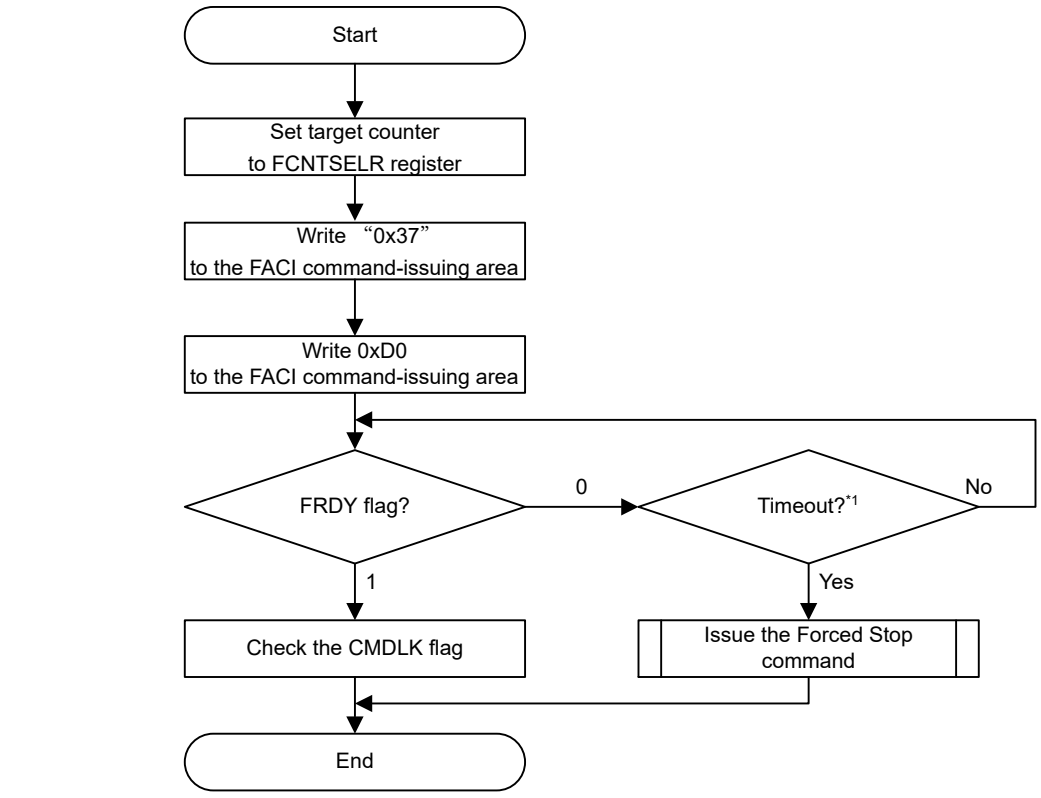
- Target counter is protected by ARCSEC_LK, ARCNSEC_LK0~3, or ARCOEMBL_LK.
- The previous command is not "Read Counter" command against ARC_OEMBL when target counter is ARC_OEMBL.
- The anti-rollback counter for OEM_BL cannot be incremented more than OEM_BL version number specified in the image version of the header of the code certificate. After updated the OEM_BL, the anti-rollback counter for OEM_BL cannot be incremented. For details, see section 37, Security Features .
- Target counter value is maximum. (Error does not occur)
- Target counter is ARC_NSEC when CNF_ARCNSEC0~1 is invalid setting.

46.9.3.17 Refresh Counter Command

The Refresh Counter command is used to security function, safety function. "Refresh Counter" command is used for update of anti-rollback counter when power failure is occurred while “Increment Counter” command processing. Counter value is not changed by "Refresh Counter" command.

Writing "0xD0" at 2nd write access of flash sequencer command triggers FACI to start “Increment Counter” command processing. Completion of command processing can be confirmed by FRDY bit of FSTATR register.

If "Command Lock" status occurs during command execution, refresh the counter with "Refresh Counter" command after "Command Lock" state is released.



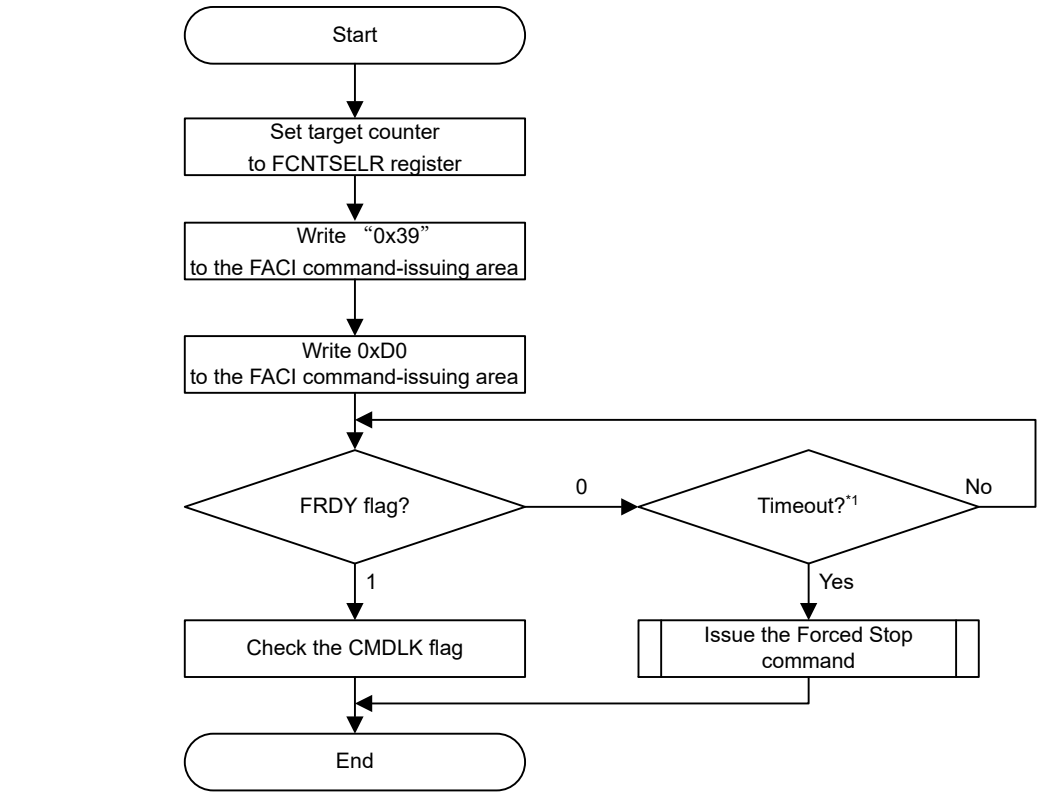
Note 1. 50 msec (FCLK ≥ 20 MHz)

Figure 46.27 Usage of the Refresh Counter Command

46.9.3.18 Read Counter Command

The Read Counter command is used to security function, safety function. "Read Counter" command is used for reading 3 types of anti-rollback counter (ARC_SEC, ARC_NSEC, and ARC_OEMBL). Flash sequencer automatically judges valid area of anti-rollback counter, reads 64 bits data, and stores to FCNTDATAR0 and FCNTDATAR1 registers.

Writing "0xD0" at 2nd write access of flash sequencer command triggers FACI to start “Read Counter” command processing. Completion of command processing can be confirmed by FRDY bit of FSTATR register.



Note 1. 50 msec (FCLK ≥ 20 MHz)

Figure 46.28 Usage of the Read Counter Command

46.10 Suspend Operation

Reading from the flash memory is not possible during programming or erasure if the conditions for background operation given in Table 46.39 are not satisfied. When a P/E suspend command is issued to suspend the programming or erasure of the flash memory, reading from the flash memory is enabled. Regarding P/E suspend commands, there are one suspend command mode for programming and two suspend command modes for erasure (suspension priority mode and erasure priority mode). To resume suspended programming or erasure, the P/E resume command is available. For details on the suspend operation, see Figure 46.17.

46.11 Protection Function

46.11.1 Software Protection

Software protection disables programming and erasure of the code flash memory through the settings of control registers and block protect setting in the user area. If an attempt is made to issue an FACI command against software protection, the flash sequencer enters the command-locked state.

46.11.1.1 Protection through FWEPROR

Unless the FWEPROR.FLWE[1:0] bits are set to 01b, programming cannot proceed in any mode.

46.11.1.2 Protection by FENTRYR

When the FENTRYR register is set to 0x0000, the flash sequencer enters read mode. In read mode, FACI commands cannot be accepted. If an attempt is made to issue an FACI command in read mode, the flash sequencer enters the command-locked state.

46.11.1.3 Protection by Block Protect Setting

Each block in user area has the block protect setting (BPS or BPS_SEC). When the FBPROT0 or FBPROT1 register is 0x0000 and the block protect bit is 0, issuing the Program or Block Erase command to user area of the code flash causes the command-locked state. To program or erase the block whose block protect bit is 0, set the FBPROT0 or FBPROT1 register to 0x0001.

The block protect setting can be locked by the permanent block protect setting (PBPS or PBPS_SEC). When the permanent block protect setting and the block protect setting are 0, issuing a Program or Block erase command to user area of the code flash causes the flash sequencer to enter the command-locked state regardless of the FBPROT0 and FBPROT1 register settings.

Valid block protect setting (BPS or BPS_SEC) depends on the Block Protect Select bit (BPS_SEL).

See section 46.12.2. Permanent Block Protect Setting for details of the block protect setting and permanent block protect setting. See section 46.4.17. FBPROT0 : Flash Block Protection Register and section 46.4.18. FBPROT1 : Flash Block Protection for Secure Register for more information.

For details of block protect setting (BPS or BPS_SEC) and block protect select (BPS_SEL), see section 6, Option-Setting Memory.

The protected area by the block protect setting is always determined by the address of the FSADDR register setting regardless of the address swapping function setting (the startup area select, the block swap in linear mode, and the startup bank select in dual mode). Table 46.24 to Table 46.29 show the relation of user area and the block protect setting in each function setting.

(1) In case of the linear mode

- BPS[0] to BPS[n] or BPS_SEC[0] to BPS_SEC[n] are assigned to the block of user area (for example, address is 0x00_0000 to the last block address).
- BPS[0]/BPS_SEC[0] and BPS[1]/BPS_SEC[1] are assigned to the block of user area depending on the startup area select setting (SAS.BTFLG bit). (See section 46.11.3. Start-Up Program Protection).
- The second half of FLI user area is assigned to block protect setting depending on the block swap select setting (BANKSEL.BLCKSWP[6:0] bits). See section 46.11.5. Block Swap Function.

Table 46.24 shows the block protect setting when the startup area select is disabled (not swapping).

Table 46.25 and later show example of the block protect setting when the address conversion function is used.

Table 46.24 Example of Block Protect setting when SAS.BTFLG is 1

FSADDR[23:0]	Block size	Block protect setting	User area block number	Notes
The last block address	32 KB	BPS[n] or BPS_SEC[n]	Block n	—
⋮	⋮	⋮	⋮	—
0x01_8000 to 0x01_FFFF	32 KB	BPS[9] or BPS_SEC[9]	Block 9	—
0x01_0000 to 0x01_7FFF	32 KB	BPS[8] or BPS_SEC[8]	Block 8	—
0x00_E000 to 0x00_FFFF	8 KB	BPS[7] or BPS_SEC[7]	Block 7	—
0x00_C000 to 0x00_DFFF	8 KB	BPS[6] or BPS_SEC[6]	Block 6	—
⋮	⋮	⋮	⋮	—
0x00_2000 to 0x00_3FFF	8 KB	BPS[1] or BPS_SEC[1]	Block 1	Not swap block 0 and block 1 in this startup area select setting
0x00_0000 to 0x00_1FFF	8 KB	BPS[0] or BPS_SEC[0]	Block 0	Not swap block 0 and block 1 in this startup area select setting

Table 46.25 Example of Block Protect setting when SAS.BTFLG is 0

FSADDR[23:0]	Block size	Block protect setting	User area block number	Notes
The last block address	32 KB	BPS[n] or BPS_SEC[n]	Block n	—
⋮	⋮	⋮	⋮	—
0x01_8000 to 0x01_FFFF	32 KB	BPS[9] or BPS_SEC[9]	Block 9	—
0x01_0000 to 0x01_7FFF	32 KB	BPS[8] or BPS_SEC[8]	Block 8	—
0x00_E000 to 0x00_FFFF	8 KB	BPS[7] or BPS_SEC[7]	Block 7	—
0x00_C000 to 0x00_DFFF	8 KB	BPS[6] or BPS_SEC[6]	Block 6	—

⋮	⋮	⋮	⋮	—
0x00_2000 to 0x00_3FFF	8 KB	BPS[1] or BPS_SEC[1]	Block 1	—
0x00_0000 to 0x00_1FFF	8 KB	BPS[0] or BPS_SEC[0]	Block 0	—

(2) In case of the dual mode (DUALSEL.BANKMD[2:0] = 000b)

- BPS[0] to BPS[n] or BPS_SEC[0] to BPS_SEC[n] are assigned the block of bank 0 user area (for example, address is 0x00000000 to the last block address in the lower side bank).
- BPS[70] to BPS[70 + n] or BPS_SEC[70] to BPS_SEC[70 + n] are assigned to the block of bank 1 user area (for example, address is 0x00200000 to the last block address in the upper side bank).

Bank0 is upper side bank (BANKSEL.BANKSWP[2:0] = 000b)

- BPS[0] to BPS[n] or BPS_SEC[0] to BPS_SEC[n] are assigned to the block of bank1 user area (e.g. Address is 0x00_0000 to The last block address in lower side bank).
- BPS[70] to BPS[70+n] or BPS_SEC[70] to BPS_SEC[70+n] are assigned to the block of bank0 user area (e.g. Address is 0x20_0000 to The last block address in upper side bank).

Table 46.28 and Table 46.29 show example of the block protect setting in the dual mode. See section 46.11.4. Dual Bank Function for details of dual bank function (DUALSEL.BANKMD[2:0] and BANKSEL.BANKSWP[2:0] bits).

Table 46.28 Example of Block Protect setting when BANKSEL.BANKSWP[2:0] is 111b (1 of 2)

FSADDR[23:0]	Block size	Block protect setting	User area block number	Notes
The last block address in upper side bank	32 KB	BPS[70 + n] or BPS_SEC[70 + n]	Block 70 + n	Not swap bank 0 and bank 1 in this startup bank switch setting
⋮	⋮	⋮	⋮

0x00_2000 to 0x00_3FFF	8 KB	BPS[1] or BPS_SEC[1]	Block 71	
0x00_0000 to 0x00_1FFF	8 KB	BPS[0] or BPS_SEC[0]	Block 70	

46.11.2 Error Protection

Error protection detects the issuing of illegal FACI commands, illegal access, and flash sequencer malfunction. FACI command acceptance is disabled (command-locked state) in response to the detection of these errors. The flash memory cannot be programmed or erased while the flash sequencer is in the command-locked state. For release from the command-locked state, issue the Status Clear or Forced Stop command. The Status Clear command can only be used while the FRDY bit in the FSTATR register is 1. The Forced Stop command can be used regardless of the value of the FRDY bit. While the CMDLKIE bit in the FAEINT register is 1, a flash access error (FIFERR) interrupt is generated if the flash sequencer enters the command-locked state (the CMDLK bit in the FASTAT register is set to 1).

If the flash sequencer enters the command-locked state in response to a command other than the P/E suspend command during programming or erasure processing, the flash sequencer continues the processing for programming or erasure. In this

state, the P/E suspend command cannot be used to suspend the processing for programming or erasure. If a command is issued in the command-locked state, the ILGLERR bit becomes 1 and the other bits retain the values set from previous error detection.

Table 46.30 shows the error protection types and status bit values after error detections.

Table 46.30 Error protection type (1 of 3)

Error type	Description	ILGCOMERR	FESETERR	SECERR	OTERR	TZFERR	ILGLERR	ERSERR	PRGERR	FLWEERR	CFAE	DFAE
FENTRYR setting error	The value set in FENTRYR is not 0x0000, 0x0001, or 0x0080	0	1	0	0	0	1	0	0	0	0	0
	The FENTRYR setting at suspension is different from that at resumption	0	1	0	0	0	1	0	0	0	0	0
Illegal command error	An undefined size is specified in the first cycle of the command. (not byte-write)	1	0	0	0	0	1	0	0	0	0	0
	An undefined code is written in the first access of the FACI command	1	0	0	0	0	1	0	0	0	0	0
	The value specified in the last access of the multiple-access FACI command is not 0xD0	1	0	0	0	0	1	0	0	0	0	0
	The value (N) specified in the second write access of the FACI command in the program or configuration set command is wrong	1	0	0	0	0	1	0	0	0	0	0
	Blank Check command is issued with inconsistent BCDIR, FSADDR, and FEADDR settings (see section 46.4.13. FEADDR : FACI Command End Address Register)	1	0	0	0	0	1	0	0	0	0	0/1 *1
	A multi block erase command is issued with inconsistent FSADDR and FEADDR settings. ● FSADDR > FEADDR ● FEADDR is set to reserved area.	1	0	0	0	0	1	0	0	0	0	0/1 *1
	Increment Counter, Refresh Counter, or Read Counter command is issued with inconsistent FCNTSELR[2:0] setting. (Include CNF_ARCNS0,1 setting is the mismatch.)	1	0	0	0	0	1	0	0	0	0	0
	An FACI command not acceptable in each mode is issued (see Table 46.19)	1	0	0	0	0	1	0	0	0	0	0
	An FACI command is issued when command acceptance conditions are not satisfied (see Table 46.20)	0/1	0/1	0/1	0/1	0	1	0/1	0/1	0/1	0/1	0/1
	A program, block erase or multi block erase command is issued against the area protected by the block protect setting (see section 46.11.1.3. Protection by Block Protect Setting)	1	0	0	0	0	1	0	0	0	0	0

Table 46.30 Error protection type (2 of 3)

Error type	Description	ILGCOMERR	FESETERR	SECERR	OTERR	TZFERR	ILGLERR	ERSERR	PRGERR	FLWEERR	CFAE	DFAE
Illegal command error	Configuration set command is issued against Data flash configuration area protected by lock bit setting	1	0	0	0	0	1	0	0	0	0	0
	Increment Counter or Refresh Counter command is issued against anti-rollback area protected by lock bit setting	1	0	0	0	0	1	0	0	0	0	0
	A program command is issued against the erase area in erase suspend	1	0	0	0	0	1	0	0	0	0	0
	Increment counter command against ARC_OEMBL is issued when the RSIP-E51A register setting is same or smaller than ARC_OEMBL value. (see section 46.12.5. Anti-Rollback Counter)	1	0	0	0	0	1	0	0	0	0	0
	Increment counter command against ARC_OEMBL is issued when previous command is not read counter command against ARC_OEMBL.	1	0	0	0	0	1	0	0	0	0	0
	A command is issued against flash sequencer command illegal status (see Table 46.17).	0/1	0/1	0/1	0/1	0	1	0/1	0/1	0/1	0/1	0/1
Erasure error	An error occurs during erasure	0	0	0	0	0	0	1	0	0	0	0
Programming error	An error occurs during programming	0	0	0	0	0	0	0	1	0	0	0
Code flash memory access violation	An FACI command is issued to the reserved portion of the user area in code flash P/E mode	0	0	0	0	0	1	0	0	0	1	0
	Configuration set command is issued to the reserved configuration area in code flash P/E mode.	0/1	0	0	0	0	1	0	0	0	1	0
	Program, block erase, or configuration set command is issued to TrustZone protection area in code flash P/E mode.	0/1	0	0	0	1	1	0	0	0	1	0
Data flash memory access violation	A program or block erase command is issued to the reserved data area in data flash P/E mode	0	0	0	0	0	1	0	0	0	0	1
	A multi block erase command is issued to the reserved data area in data flash P/E mode. (FSADDR is set to reserved data area).	1	0	0	0	0	1	0	0	0	0	1
	Blank Check command is issued to reserved data area in data flash P/E mode. (FSADDR is set to reserved data area).	1	0	0	0	0	1	0	0	0	0	1
	Configuration set command has been issued to reserved configuration area in data flash P/E mode.	0/1	0	0	0	0	1	0	0	0	0	1
	A program, block erase, multi block erase, blank check, configuration set, increment counter, refresh counter, or read counter command is issued to TrustZone protection area in data flash P/E mode.	0	0	0	0	0	1	0	0	0	0	1

Table 46.30 Error protection type (3 of 3)

Error type	Description	ILGCOMERR	FESETERR	SECERR	OTERR	TZFERR	ILGLERR	ERSERR	PRGERR	FLWEERR	CFAE	DFAE
Security error	Configuration set command for the SAS.BTFLG bit setting is issued when the SAS.FSPR bit is 0 (see section 46.9.3.15. Configuration Set Command)	0	0	1	0	0	1	0	0	0	0	0
Others	An FACI command-issuing area is accessed in read mode	0	0	0	1	0	1	0	0	0	0	0
	An FACI command-issuing area is read in code flash P/E mode or data flash P/E mode	0	0	0	1	0	1	0	0	0	0	0
Flash write erase protection error	A flash memory write protection error is detected by the FWEPROR register setting*2 during command processing by the flash sequencer	0	0	0	0	0	0	0/1	0/1	1	0	0

Note 1. DFAE value depends on the FSADDR setting.
Note 2. For details on the FWEPROR register, see section 46.4.8. FWEPROR : Flash P/E Protect Register.

46.11.3 Start-Up Program Protection

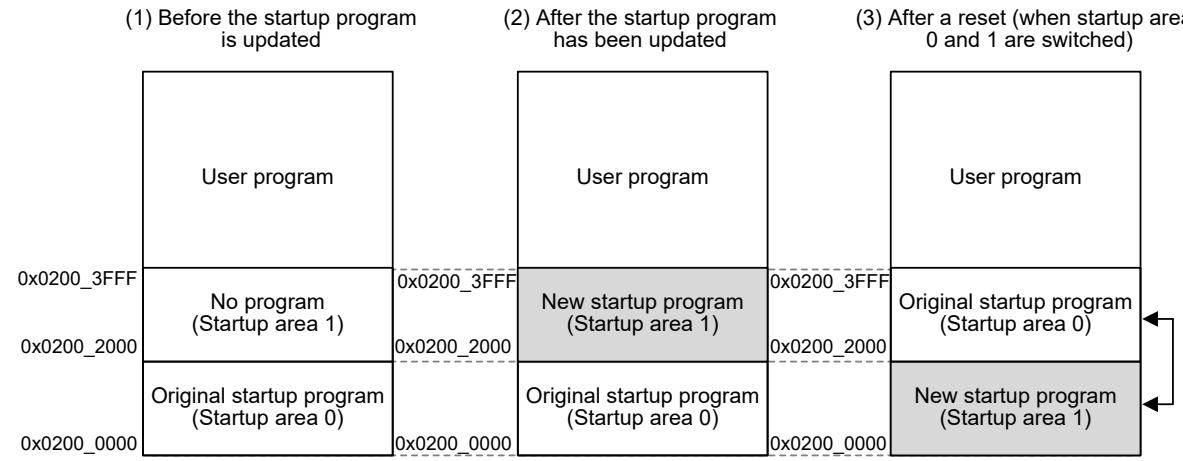
Protection of the startup program is for protection of the program to be started after a reset (the startup program). This function provides a way to safely update the startup program when rewriting is suspended during a reset.

The startup area is 8 Kbytes in size and is assigned to the user area in the code flash memory. This function uses the values of the SAS.BTFLG bit and the FSUACR.SAS[1:0] bits to change the area where the startup program is stored in block units (see Figure 46.29 to Figure 46.32).

In protection of the startup program, the state of the selection of the startup area can be fixed by the FSPR bit. However, the SAS.FSPR bit never be restored to 1 once the flag is set to 0. Exercise extra caution when handling the SAS.FSPR bit.

In addition, this protection cannot be used when dual mode is selected by the bank mode switching function (when the BANKMD[2:0] bits are 000b).

For details of SAS.FSPR bit and DUALSEL.BANKMD[2:0] bits, see section 6, Option-Setting Memory.



Note: The addresses are used for reading, programming, and erasure. Startup area 0 is erased when Block Erase command is issued for the address 0x0200_0000 with allocation shown under 3.

1. Before the startup program is updated
   When the SAS.BTFLG bit is 1 and the FSUACR.SAS[1:0] bits are 0xb, the address range from 0x0100_2000 to 0x0200_3FFF is selected as startup area 1 and the address range from 0x0200_0000 to 0x0200_1FFF is selected as startup area 0.
2. After the startup program has been updated
   A new startup program can be written to startup area 1. At this time, startup area 0 will still contain the previous startup program, so rewriting by starting up from startup area 0 remains possible if rewriting to the startup area 1 fails.
3. After a reset (when startup areas 0 and 1 are switched)
   When rewriting startup area 1 is successfully completed, switch the assignment of startup areas 0 and 1 by rewriting the startup area selection bit (the SAS.BTFLG bit) with Configuration set command. Afterwards, the program is started up from startup area 1 after a reset.

Figure 46.29 Concept of Protection of the Startup Program for Secure alias

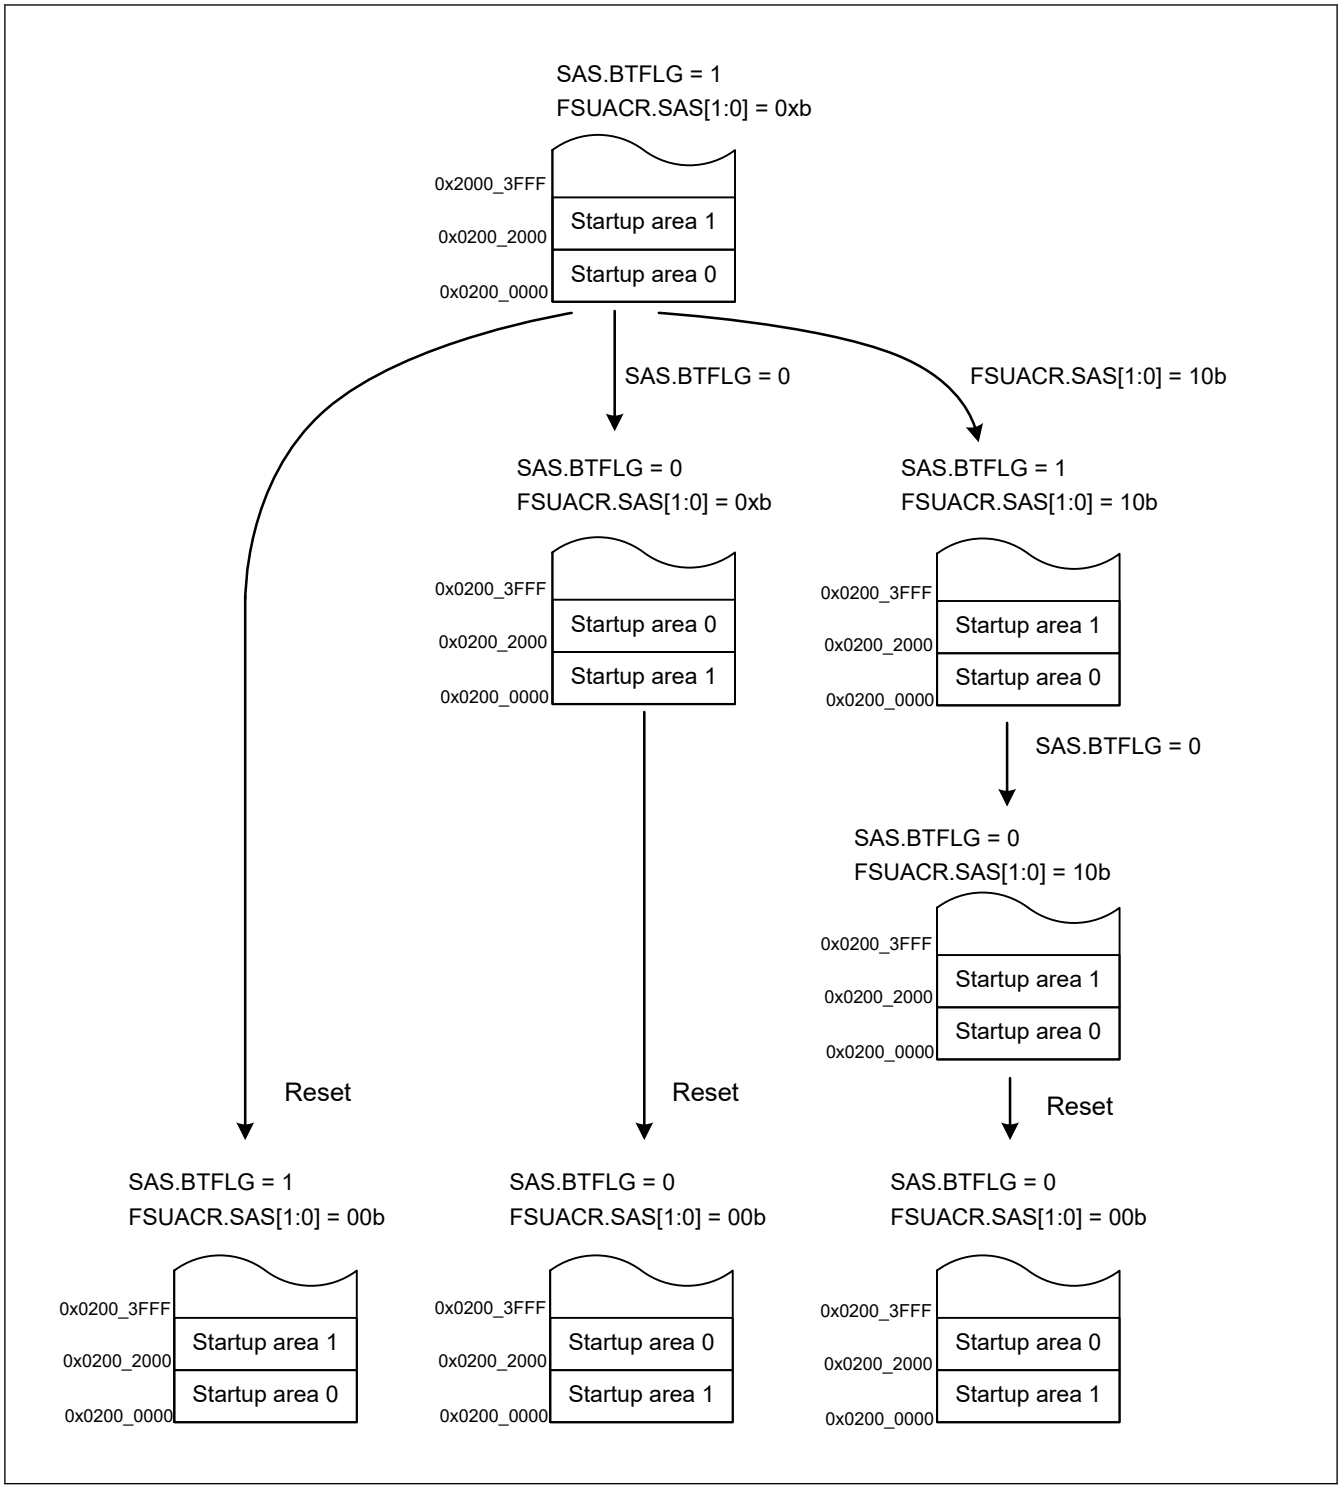


Figure 46.30 Example 1 of Transitions for Startup Program Protection Settings for Secure alias

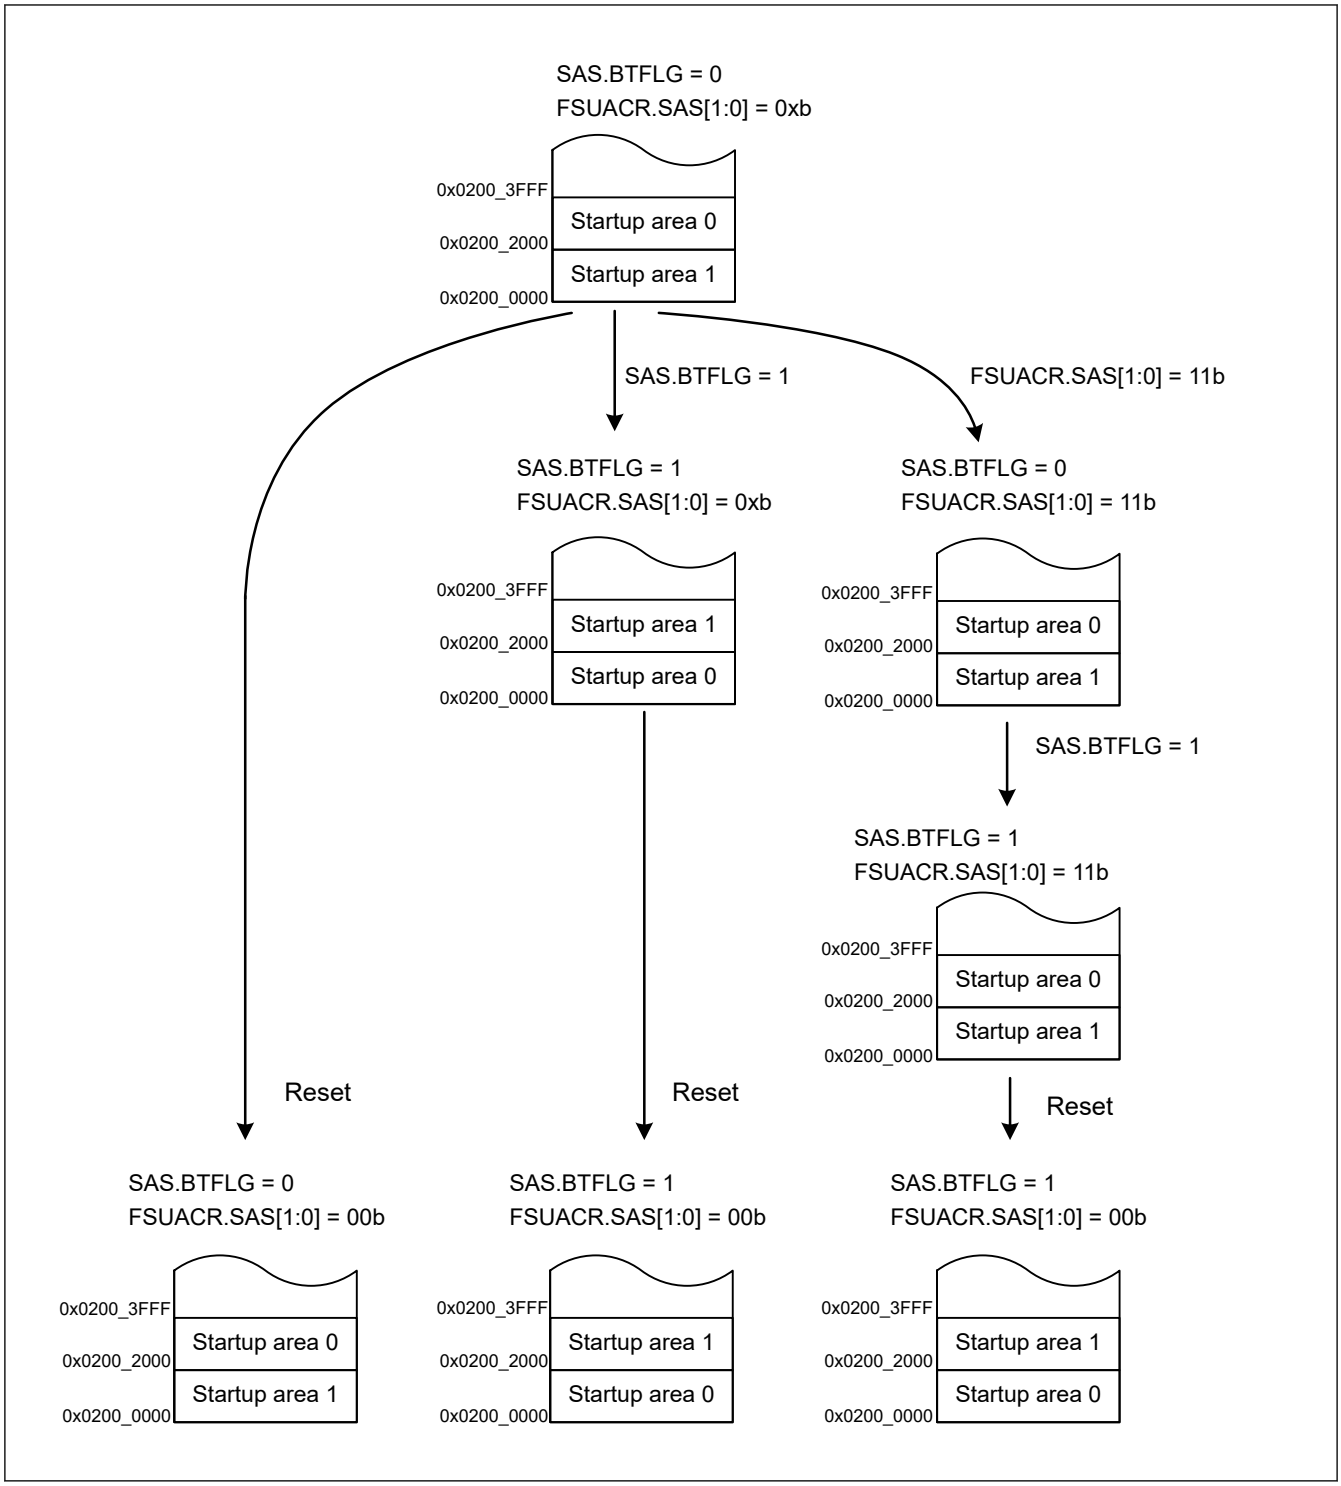

Figure 46.31 Example 2 of Transitions for Startup Program Protection Settings for Secure alias

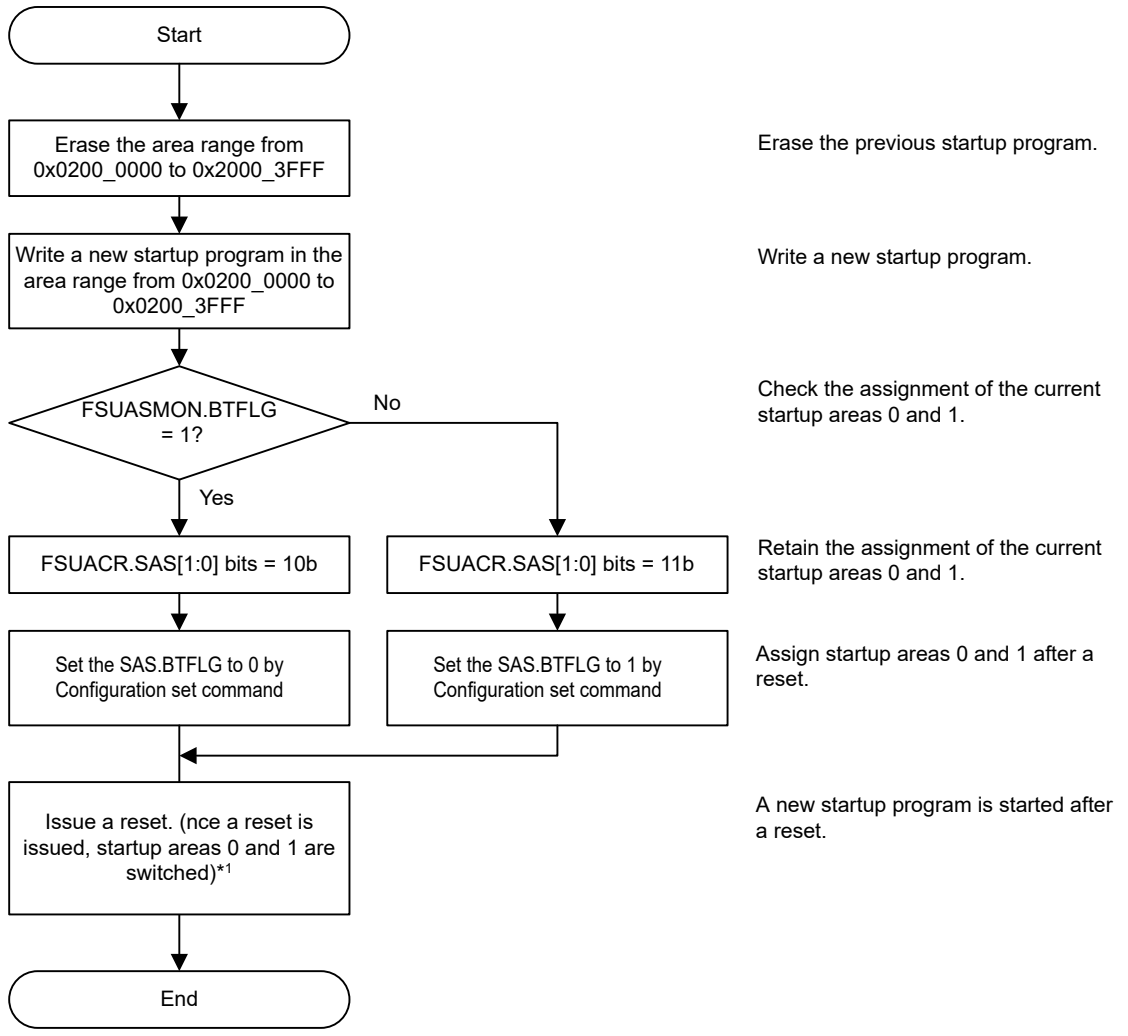

Note 1. For details, see Figure 46.30 and Figure 46.31.

Figure 46.32 Concept of Protection of the Startup Program for Secure alias

46.11.4 Dual Bank Function

This protection uses the functions of bank mode switching and startup bank selection to update a program while a user program is running and to provide a safe method of updating in cases where programming is suspended during a reset.

46.11.4.1 Switching Bank Modes

The bank mode switching function selects either linear mode in which the user area in the code flash memory is used as one area, or dual mode in which the user area is divided into two bank areas. Figure 46.33 shows an example of flow of switching bank modes. A reset after setting the DUALSEL.BANKMD[2:0] bits in the option setting memory determines the mode of the bank mode switching function. Selecting dual mode enables the startup bank selection function.

When dual mode is selected by bank mode switching function (the DUALSEL.BANKMD[2:0] bits are 000b), start-up program protection function cannot be used.

For details of DUALSEL.BANKMD[2:0] bits, see section 6, Option-Setting Memory.

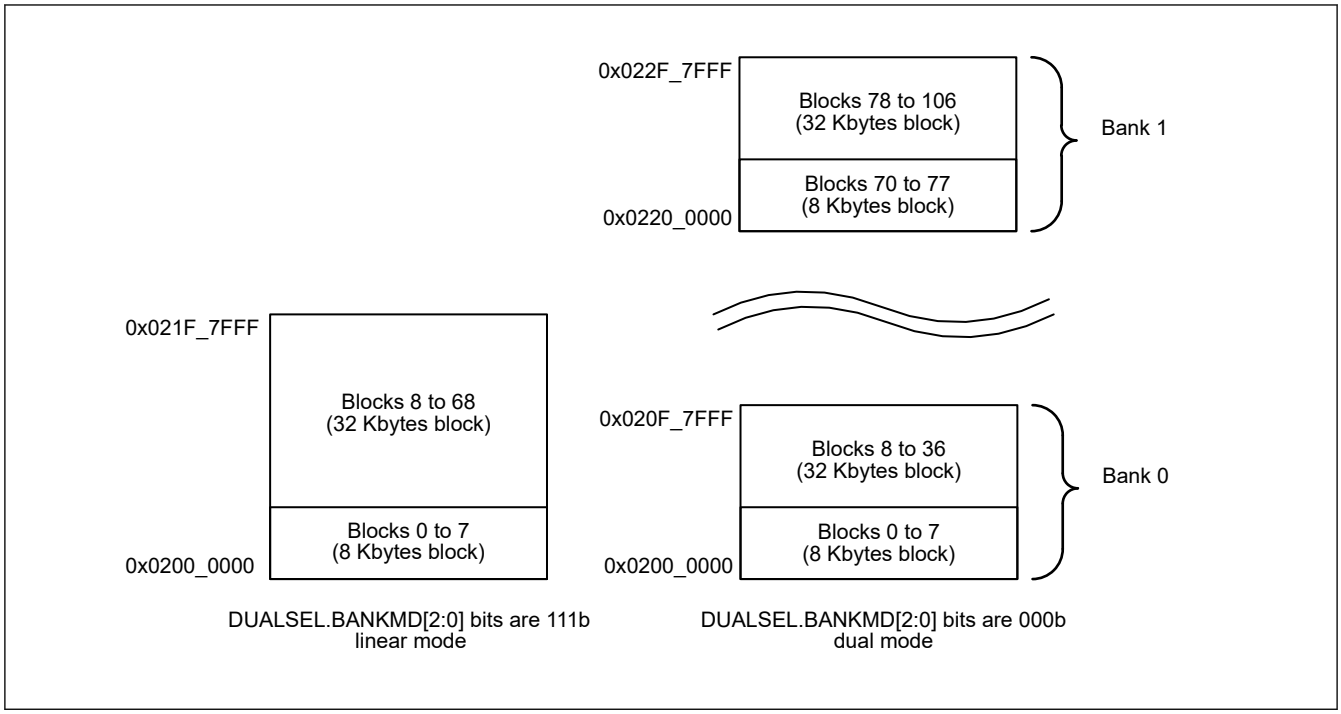

Figure 46.33 Example of Flow of Switching Bank Modes for Secure alias (For Products with 2 Mbytes of Code Flash Memory)

46.11.4.2 Selecting the Startup Bank

Startup bank selection provides a way to safely update the program by selecting a bank area to be started in dual mode (when the DUALSEL.BANKMD[2:0] bits are 000b) when programming is suspended during a reset. Figure 46.34 is a schematic view of startup bank selection and Table 46.31 shows an example of the flow of startup bank selection. A reset after setting the value of the BANKSEL.BANKSWP[2:0] bits in the option-setting memory changes the addresses of banks 0 and 1 and booting up a program proceeds from the updated area. When the address is switched by using startup bank selection, the programming/erasure target for the FACI commands is also switched. This function is invalid in linear mode.

For details of DUALSEL.BANKMD[2:0] bits and BANKSEL.BANKSWP[2:0] bits, see section 6, Option-Setting Memory.

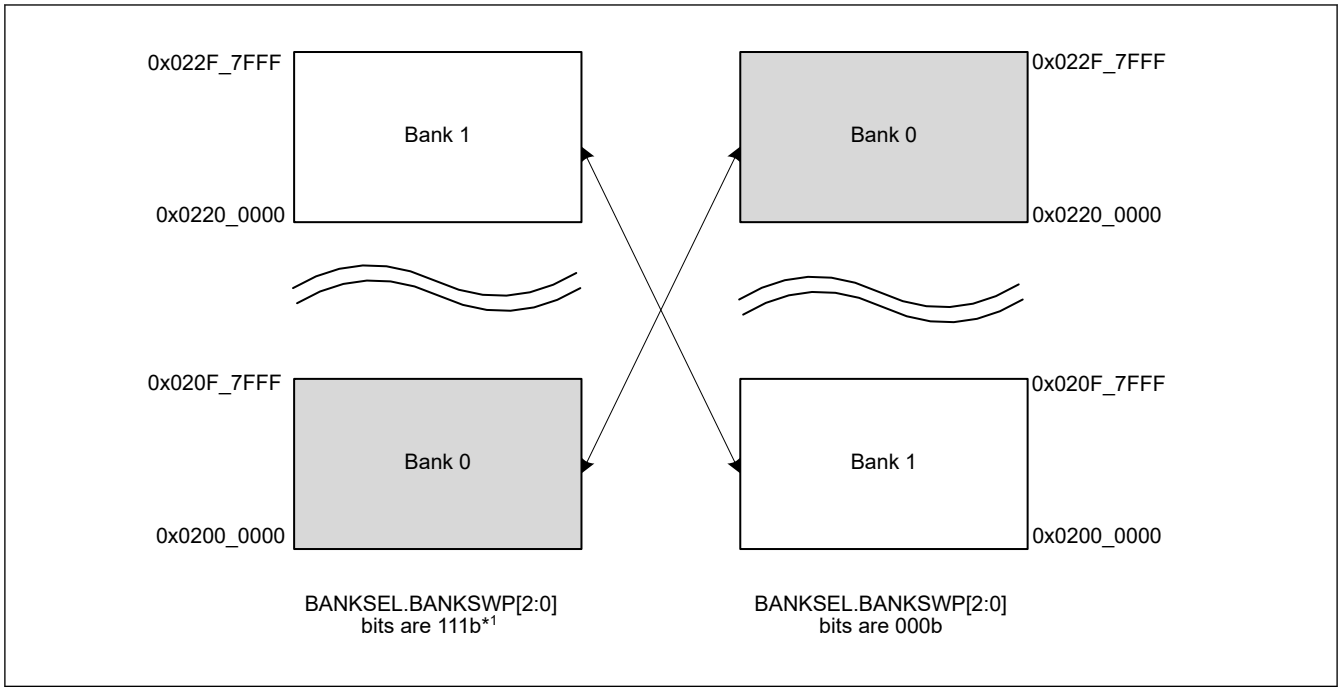

Figure 46.34 Example of Startup Bank Selection for Secure alias (For Products with 2 MB of Code Flash Memory)

Table 46.31 Example of Startup Bank Selection Flow for Secure alias (For Products with 2 MB of Code Flash Memory)

No.	Step Name	Description
1	Erase block	Erase blocks to be programed in the address range from 0x0220_0000 to 0x022F_7FFF
2	Program a new software	Program a new software in the address range from 0x0220_0000 to 0x022F_7FFF
3	Read the value	Read the value of the BANKSEL.BANKSWP [2:0] bits.
4	Write an inverted value	Write an inverted value in the BANKSEL.BANKSWP[2:0] bits*1.
5	Issue a reset	Issue a reset (A reset switches the banks.)

Note 1. Set the inverse of the read value of the BANKSEL.BANKSWP[2:0] bits (000b or 111b).

46.11.5 Block Swap Function

This protection uses the functions of block swap selection to update a program while a user program is running and to provide a safe method of updating in cases where programming is suspended during a reset.

46.11.5.1 Selecting the Block Swap

Block swap selection provides a way to safely update the program when programming is suspended during a reset. Figure 46.35 is a schematic view of block swap selection and Figure 46.36 shows an example of the flow of block swap selection. A reset after setting the value of the BANKSEL.BLCKSWP bit in the option-setting memory changes the addresses of block A and B. When the address is switched, the Programming/erasure target for the FACI commands is also switched.

In addition, this protection cannot be used when dual mode is selected by the bank mode switching function (when the DUALSEL.BANKMD[2:0] bits are 000b).

For details of DUALSEL.BANKMD[2:0] bits and BANKSEL.BLCKSWP bit, see section 6, Option-Setting Memory.

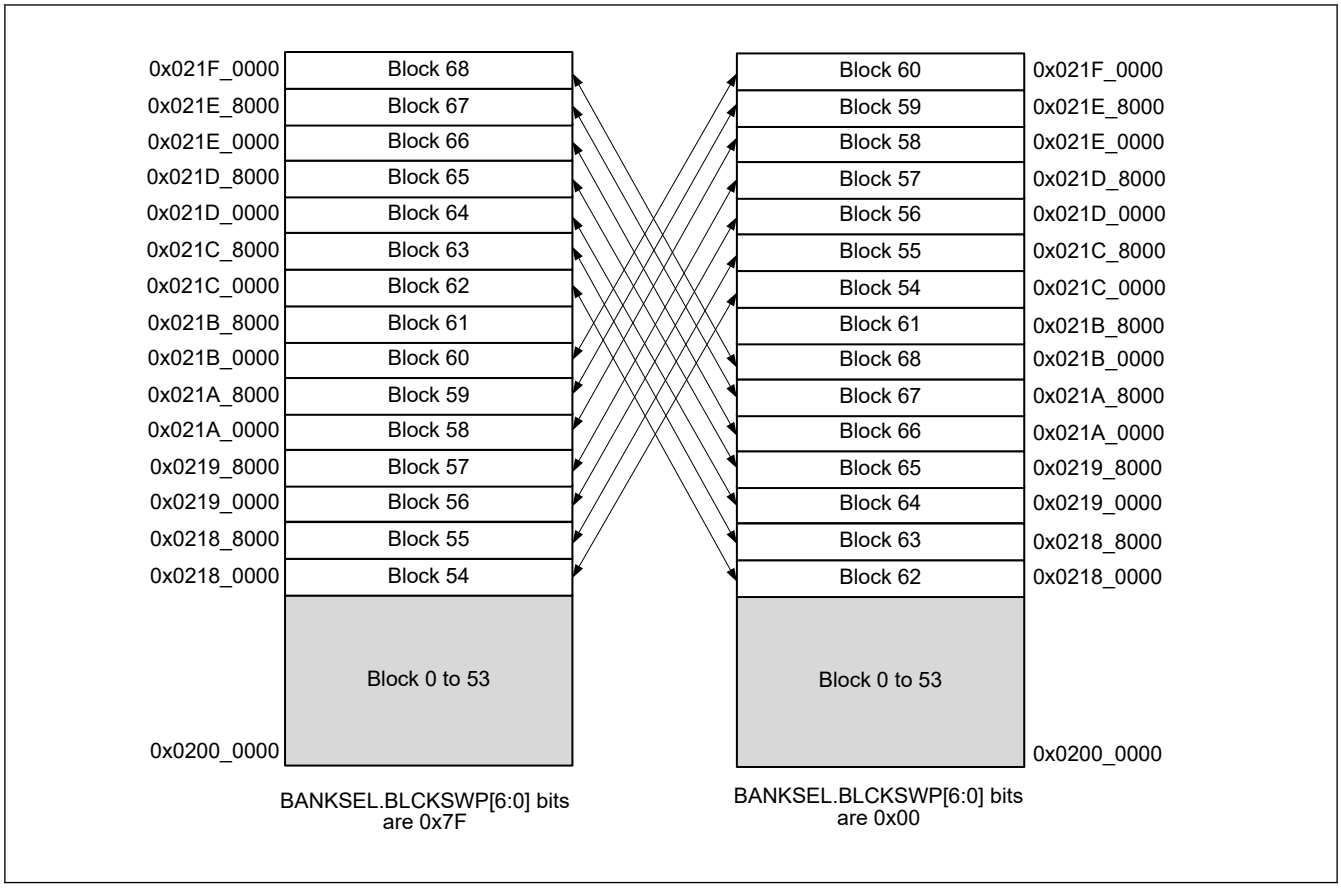

Figure 46.35 Example of Block Swap Selection for Secure alias (For Products with 2 Mbytes of Code Flash Memory)

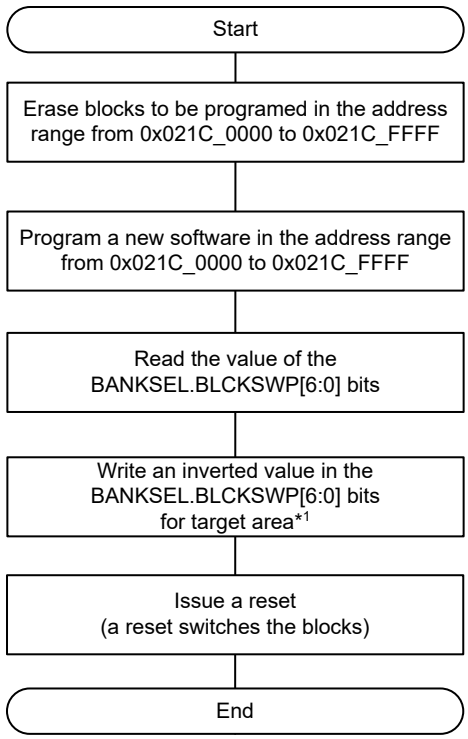

Note 1. See Table 6.2 for the correspondence between the target region and the BANKSEL.BLCKSWP[6:0] bits.

Figure 46.36 Example of Block Swap Selection Flow for Secure alias (For Products with 2 Mbytes of Code Flash Memory)

46.12 Security Function

The flash sequencer supports the following security functions:

- Security flag for startup area
- Permanent block protect setting
- Flash memory protection for TrustZone
- Code Flash P/E mode Entry Protection
- Data flash configuration area protection
- Anti-rollback Counter

46.12.1 Security Flag for Startup Area Select

The security flag (SAS.FSPR) for the startup area is located in the option-setting memory.

When the SAS.FSPR bit is 0, issuing the configuration set command to change the SAS.BTFLG bit causes the flash sequencer to be in the command-locked state. Also, when the SAS.FSPR bit is 0, it is invalid to write to the Startup Area Select bits SAS[1:0] in the FSUACR register. The SAS.FSPR bit enables protection.

46.12.2 Permanent Block Protect Setting

The permanent block protect setting is the clear protection for the block protection setting. User area cannot be permanently updated by the FACI command when the permanent block protect setting is enabled. See section 46.11.1.3. Protection by Block Protect Setting for more details.

The block protect setting and the permanent block protect setting have the write/clear protection against the configuration set command. The flash sequencer does not detect an error when the configuration set command is issued to the write/clear protected settings.

Figure 46.37 and Table 46.32 show the write/clear protection against the block protect setting (BPS[n]) and the permanent protect setting (PBPS[n]). Figure 46.38 and Table 46.33 show the write/clear protection against the block protect setting for Secure (BPS_SEC[n]) and permanent protect setting for Secure (PBPS_SEC[n]).

Effective permanent block protect setting (PBPS or PBPS_SEC) depends on block protect select (BPS_SEL). For details of permanent block protect setting (PBPS or PBPS_SEC) and block protect select (BPS_SEL), see section 6, Option-Setting Memory.

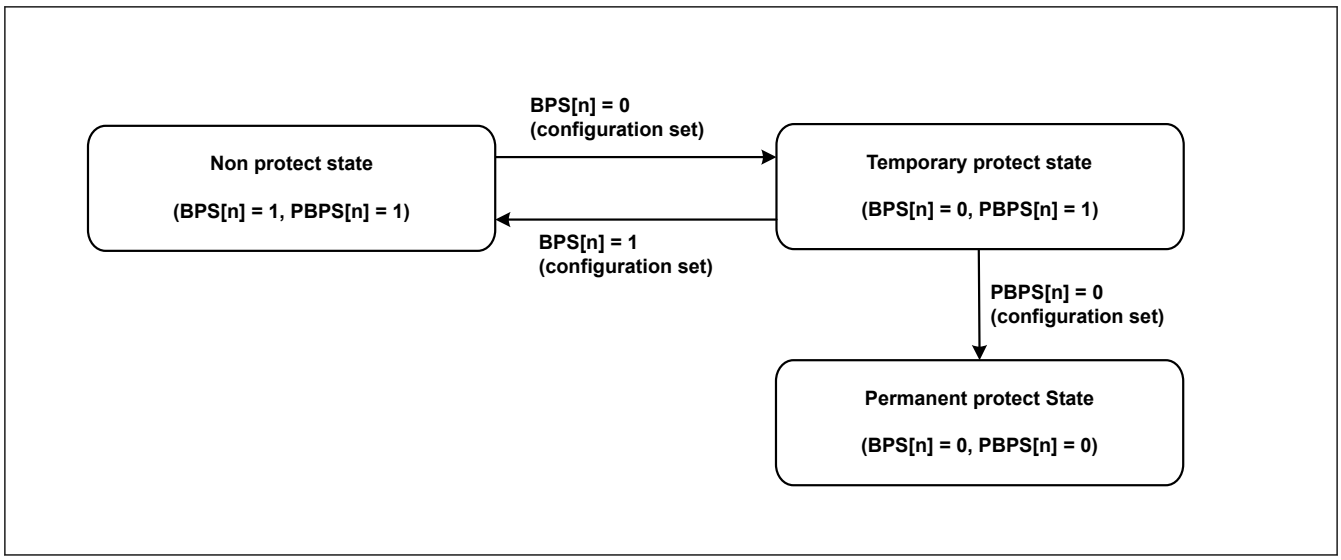

Figure 46.37 Status transition of flash sequencer by BPS[n] and PBPS[n]

Table 46.32 Write/clear protection of BPS[n] , PBPS[n] and BPS_SEL[n]

Current state		Updatable state by configuration set command				
BPS[n]	PBPS[n]	BPS[n] = 1	BPS[n] = 0	PBPS[n] = 1	PBPS[n] = 0	BPS_SEL[n] = 1
1	1	✓	✓	✓	X	✓
1	0	—	—	—	—	—
0	1	✓	✓	✓	✓	✓
0	0	X	✓	X	✓	X

Note:
- ✓ indicates updatable by configuration set command.
- X indicates not updatable by configuration set command (error does not occur).
- — indicates not reaching to this state.

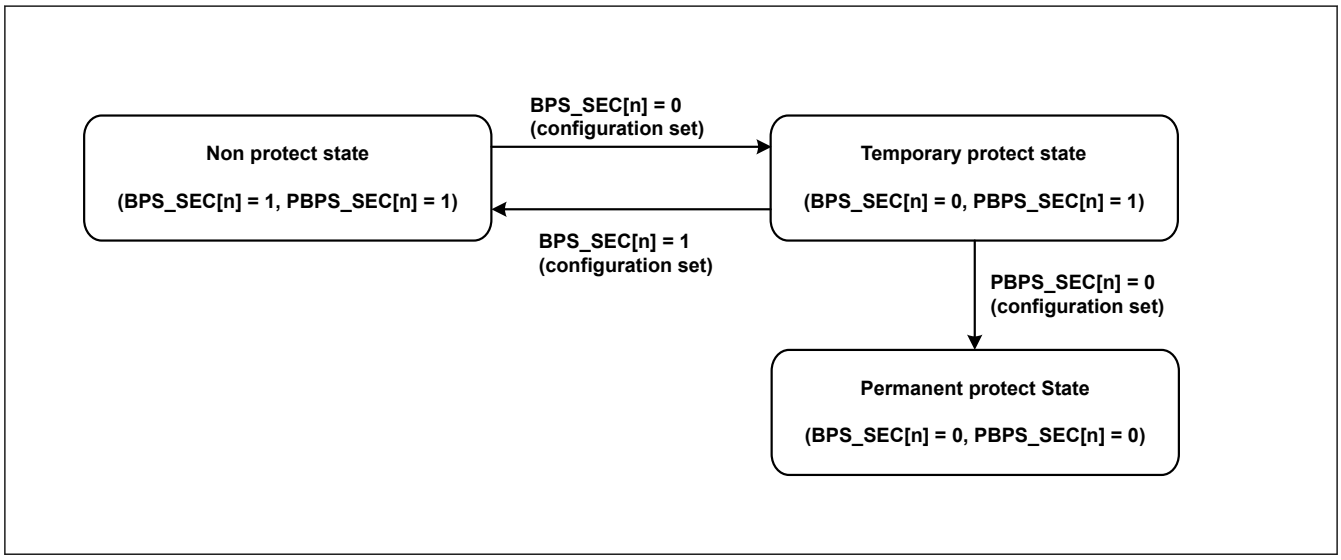

Figure 46.38 Status transition of flash sequencer by BPS_SEC[n] and PBPS_SEC[n]

Table 46.33 Write/clear protection of BPS_SEC[n], PBPS_SEC[n] and BPS_SEL[n]

Current state		Updatable state by configuration set command				
BPS_SEC[n]	PBPS_SEC[n]	BPS_SEC[n] = 1	BPS_SEC[n] = 0	PBPS_SEC[n] = 1	PBPS_SEC[n] = 0	BPS_SEL[n] = 0
1	1	✓	✓	✓	X	✓
1	0	—	—	—	—	—
0	1	✓	✓	✓	✓	✓
0	0	X	✓	X	✓	X

Note:
- ✓ indicates updatable by configuration set command.
- X indicates not updatable by configuration set command (error does not occur).
- — indicates not reaching to this state.

46.12.3 Flash Memory Protection for TrustZone

Information in this section focuses on the flash sequencer operation.

The flash memory provides the following types of protect function against Non-secure access:

- Protection for flash memory area (P/E)
- Protection for flash memory area (read)
- Protection for registers
- Code flash P/E mode entry protection

46.12.3.1 Protection for Flash Memory Area (P/E)

This function protects the Secure region of the code flash and data flash from FACI commands of Non-secure access. The condition of protection depends on the FACI command, the access attribution, and the memory boundary setting.

For details of Secure region, see section 37, Security Features .

See Table 46.34 for information on protection of the flash memory area (P/E).

Table 46.34 Protection for the flash memory area (P/E) (1 of 2)

FACI command	Target area			Issuing FACI command by Non-secure access	Issuing FACI command by Secure access
Program Block Erase	Code flash memory	User area (Non-secure area)	Secure alias*1	X	X
			Non-secure alias*2	✓	✓
		User area (Secure area)	Secure alias*1	X	✓
			Non-secure alias*2	X	X
	Data flash memory	Data area (Non-secure area)	Secure*1 alias	X	X
			Non-secure alias*2	✓	✓
		Data area (Secure area)	Secure alias*1	X	✓
			Non-secure alias*2	X	X
Multi Block Erase Blank Check	Data flash memory	Data area (Non-secure area)	Secure alias*3	X	X
			Non-secure alias*4	✓	✓
		Data area (Secure area)	Secure alias*3	X	✓
			Non-secure alias*4	X	X

Table 46.34 Protection for the flash memory area (P/E) (2 of 2)

FACI command	Target area			Issuing FACI command by Non-secure access	Issuing FACI command by Secure access
Configuration set	Code flash memory	Configuration area (Non-secure area)	Secure alias*1	X	X
			Non-secure alias*2	✓	✓
		Configuration area (Secure area)	Secure alias*1	X	✓
			Non-secure alias*2	X	X
	Data flash memory	Configuration area (Secure area only)	Secure alias*1	X	✓
			Non-secure alias*2	X	X
Increment Counter Refresh Counter Read Counter	Data flash memory	Anti-rollback counter area (Secure area only)	-	X	✓

Note:
- ✓ indicates FACI command operation is not prohibited.
- X indicates FACI command operation is prohibited. Error occurs when the area is selected, and the FACI command is executed.

Note 1. The Secure alias is judged when the address of FSADDR[28] is 0.
Note 2. The Non-secure alias is judged when the address of FSADDR[28] is 1.
Note 3. The Secure alias is judged when the address of FSADDR[28] and FEADDR[28] are 0.
Note 4. The Non-secure alias is judged when the address of FSADDR[28] and FEADDR[28] are 1.

When the target area of FACI command is the user area of code flash, the flash sequencer compares the FSADDR register setting with the memory boundary setting of the code flash and determines whether the target area is in the Secure region.

In linear mode, the memory boundary can be set to 0x0200_0000 to 0x021F_0000 in 32 KB unit.

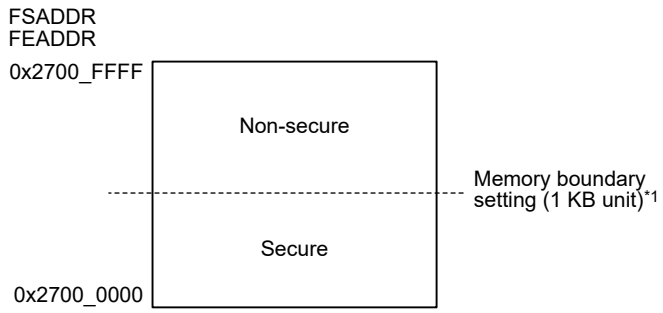
In dual mode, the memory boundary can be set to 0x0200_0000 to 0x0220_0000 in 32 KB unit. When the memory boundary is set to 0x0220_0000 or greater in the dual mode, the entire user area is defined as the Secure region.

Figure 46.39 shows details of the Secure and Non-secure attribute of user area in the code flash.

Note 1. Comparing FSADDR with memory boundary setting of user area and judges whether the target area is in Secure area.

Figure 46.39 Secure and Non-secure region in user area for Secure alias

When the target area of the issuing FACI command is the data area of data flash, the flash sequencer compares the FSADDR/FEADDR register setting with the memory boundary setting of the data flash and determines whether the target area is in Secure region. The memory boundary can be set to 0x0270_0000 to 0x0270_FC00 in 1 KB unit. Figure 46.40 shows details of the Secure and Non-secure attribute of data area in the data flash.



Note 1. Comparing FSADDR/FEADDR with memory boundary setting of data area and judges whether the target area is in Secure area.

Figure 46.40 Secure and Non-secure region in data area for Secure alias

See Figure 46.41 in the details of Secure and Non-secure region of option-setting memory. The flash sequencer judges that target area is Secure region from the FSADDR register setting.

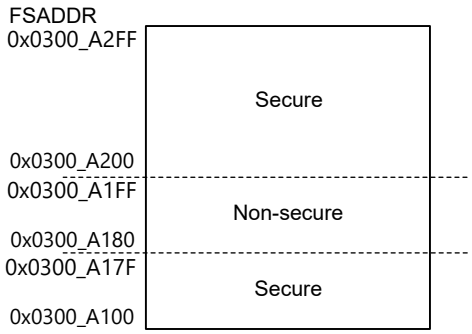


Figure 46.41 Secure and Non-secure region in option-setting memory for Secure alias

46.12.3.2 Protection for Flash Memory Area (Read)

This function protects the Secure region of code flash and data flash from Non-secure bus access.

For details of Secure region, see section 37, Security Features .

46.12.3.3 Protection for Register

The flash sequencer registers have write-access protection against Non-secure access. Table 46.35 shows details of the protected registers of the flash sequencer.

Table 46.35 Protected registers of the flash sequencer for TrustZone

Protection target register	Security attribute setting	Notes
FCKMHZ register	SA register setting (FSAR.FCKMHZSA)	For details of section 46.4.4. FSAR : Flash Security Attribution Register
Flash Access area	SA register setting (FSAR.FACICMISA)	For details of section 46.4.4. FSAR : Flash Security Attribution Register
FACI registers*1 and FWEPROR registers	SA register setting (FSAR.FACICMRSA)	For details of section 46.4.4. FSAR : Flash Security Attribution Register
FCTRCNTR, FCTRLSR FCTRADDR, and FCTRSTATR registers	SA register setting (FSAR.FACITRSA)	For details of section 46.4.4. FSAR : Flash Security Attribution Register
FMEPROT, FCNTSELR, FCNTDATAR0 to 1, FBPROT1 and FSUACR registers	Always Secure	—

Note 1. The target FACI registers are FASTAT, FAEINT, FRDYIE, FSADDR, FEADDR, FBPROT0, FSTATR, FENTRYR, FSUINITR, FCMDR, FBCCNT, FBCSTAT, FPSADDR, FSUASMON, FCPSR, and FPCKAR.

46.12.3.4 Code Flash P/E Mode Entry Protection

The flash sequencer has protection function of code flash P/E by the FMEPROT register for the Secure developer. Secure function can prevent disturbance of reading code flash memory by this protection function. See section 46.4.14. FMEPROT : Flash P/E Mode Entry Protection Register.

For applications that do not require Non-secure region programming/erasure other than from Secure function, it is recommended to always disable Non-secure function of code flash programming/erasure by enabling the protection function of FMEPROT register.

For details, see Figure 46.42 of the code flash P/E sequence example by Non-secure function.

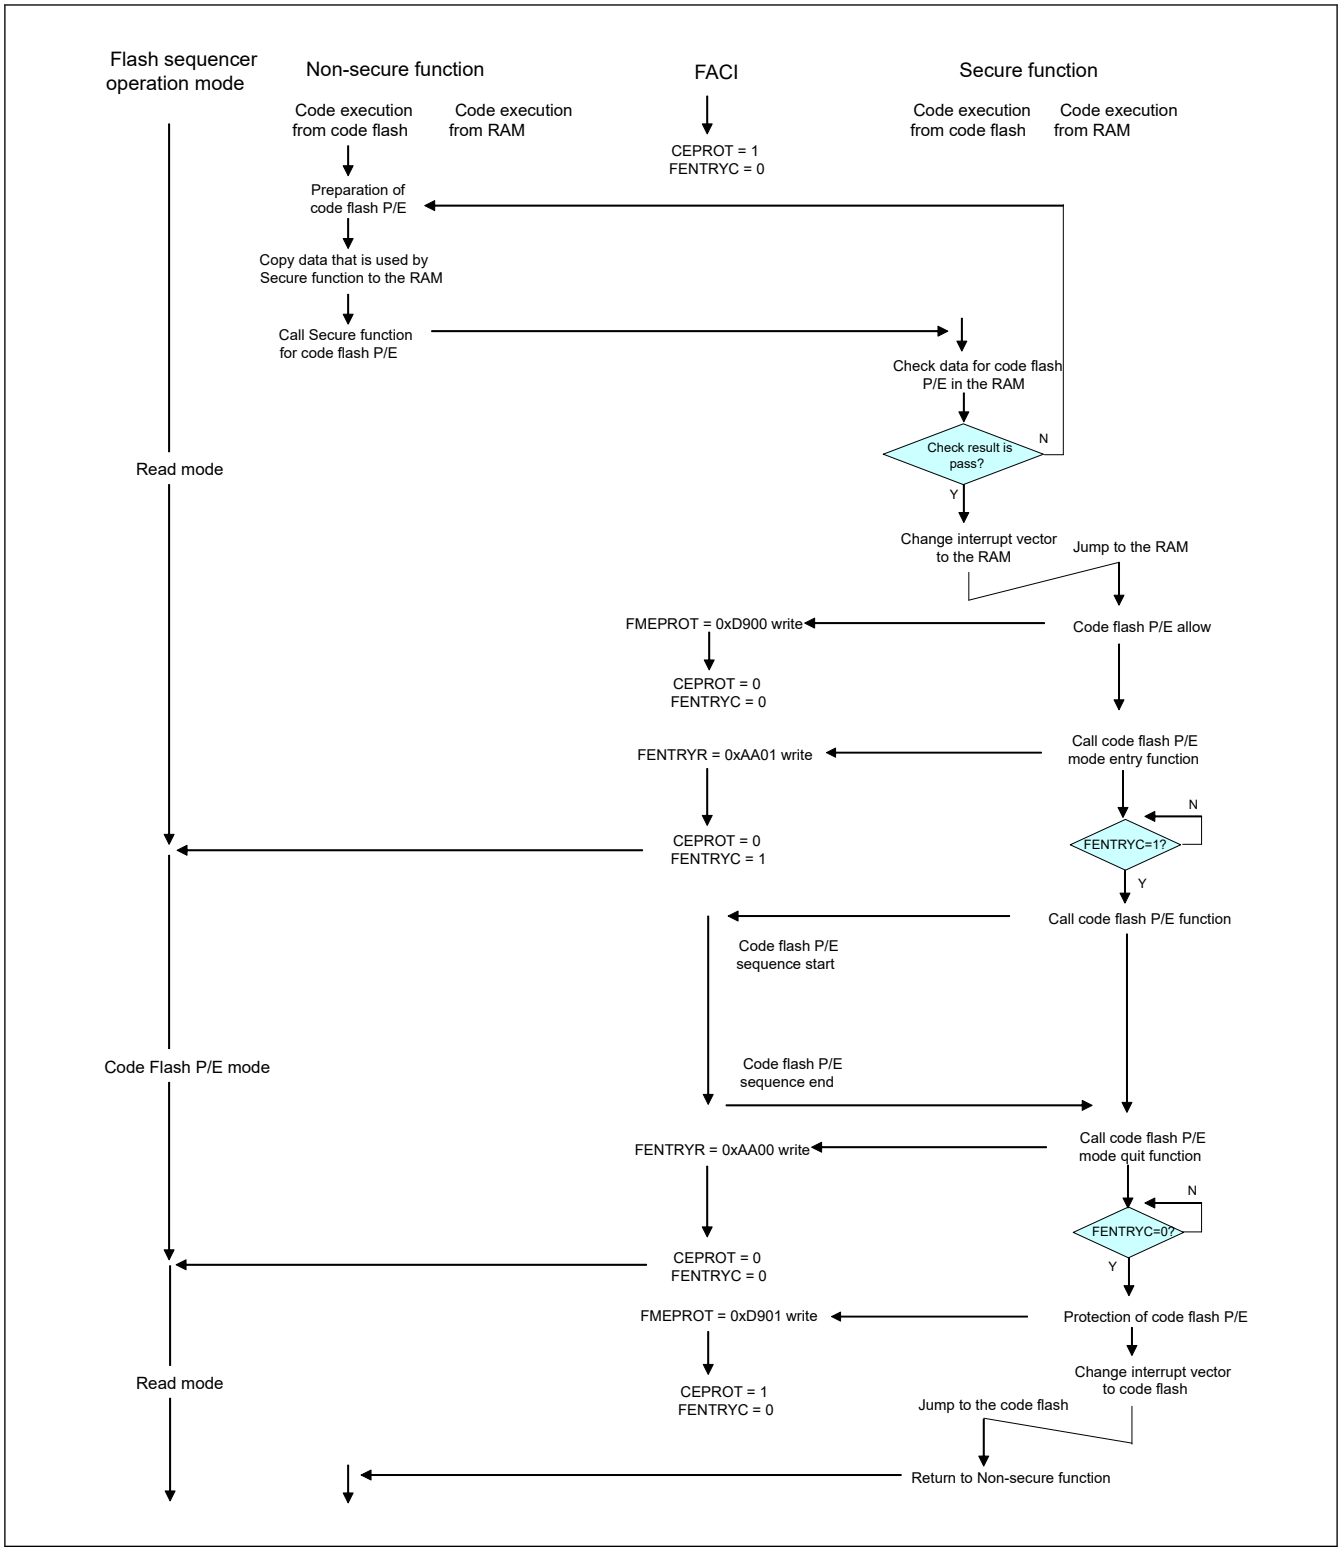

Figure 46.42 Code Flash P/E Sequence Example by Non-secure function (Using Secure function for code flash P/E)

46.12.4 Data Flash Configuration Area Protection

Data flash configuration area has 3 types of lockable area (LK_CD_A0, LK_CD_A1, and LK_CD_A2) by lock bit. When target area of “Configuration set” command includes protection area by lock bit, flash sequencer detects an error and enters "Command Lock" state.

LK_CD_A0 and LK_CD_A1 are protected 4 bytes data by 1 lock bit.

LK_CD_A2 are protected 16 bytes data by 1 lock bit, and 32 bytes (0x2703_0360 to 0x2703_037F) in LK_CD_A2 have writing protection that cannot update except for serial programing mode. For details, see section 46.12.3.1. Protection for Flash Memory Area (P/E). See Table 46.36 in detail of protection condition of lockable area in data flash configuration area.

Table 46.36 Protection Condition of Lockable area in Data Flash Configuration Area for Secure alias

Lockable Area		Protection Size	Lock Bit	Remarks
Area Name	address			
LK_CD_A0	0x2703_0080 to 0x2703_0083	4 bytes	CD0_LK0	In the case of the 16-byte Configuration set command, data cannot be updated if any of the lock bits corresponding to the update address is 0.
	0x2703_0084 to 0x2703_0087	4 bytes	CD0_LK1	
	:	:	:	
	0x2703_0170 to 0x2703_0173	4 bytes	CD0_LK60	
	0x2703_0174 to 0x2703_0177	4 bytes	CD0_LK61	
	0x2703_0178 to 0x2703_017B	4 bytes	CD0_LK62	
	0x2703_017C to 0x2703_017F	4 bytes	CD0_LK63	
LK_CD_A1	0x2703_0180 to 0x2703_0183	4 bytes	CD1_LK0	
	0x2703_0184 to 0x2703_0187	4 bytes	CD1_LK1	
	:	:	:	
	0x2703_0270 to 0x2703_0273	4 bytes	CD1_LK60	
	0x2703_0274 to 0x2703_0277	4 bytes	CD1_LK61	
	0x2703_0278 to 0x2703_027B	4 bytes	CD1_LK62

46.12.5 Anti-Rollback Counter

See section 6.2.21. ARCLS : Anti-Rollback Counter Lock Setting to section 6.2.25. ARC_OEMBLn : Anti-Rollback Counter for OEMBL (n = 0, 1) for Anti-rollback counter related Option flash memory.

Anti-rollback counter cannot be decremented and is used in the firmware update. Only Secure applications are available. Anti-rollback counter shifts one bit to the left with the increment counter command from the initial value of 0. The least

significant bit (bit 0) is set to 1. When anti-rollback counter is maximum value, flash sequencer does not change counter by Increment Counter command (does not occur error).

There are three commands that control the counters. For details, see section 46.9.3.16. Increment Counter Command, section 46.9.3.17. Refresh Counter Command, and section 46.9.3.18. Read Counter Command.

Figure 46.43 shows anti-rollback counter increment image when increment counter command is issued.

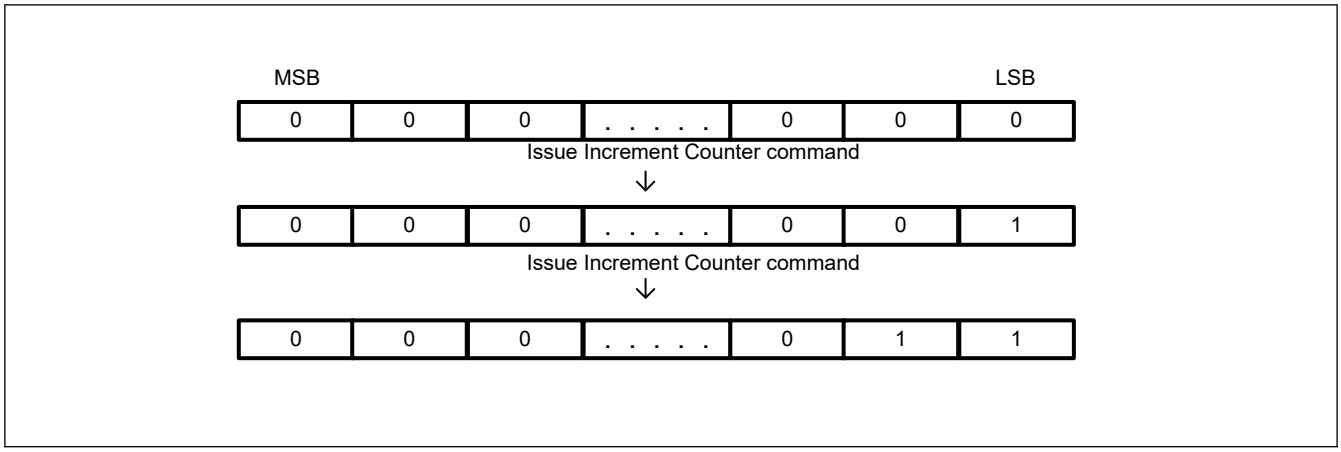

Figure 46.43 Increment image of anti-rollback counter

Anti-rollback counter has 3 types of counters (ARC_SEC, ARC_NSEC, and ARC_OEMBL) and lock bit (ARCSEC_LK, ARCNSEC_LK0 to 3, ARCOEMBL_LK) for protection each counter.

ARC_NSEC can be configured as 1 × 256 or 4 × 64 bits by configuration area setting (CNF_ARCNS0 and CNF_ARCNS0) and cannot be updated in invalid setting.

ARC_OEMBL is used in conjunction with the Secure Boot security feature when updating the OEM boot loader. For details, see section 37.6. Secure Boot. ARC_OEMBL is protected by RSIP-E51A. It can only be incremented when version of the OEMBL update (validated using the RSIP OEMBL integrity check procedure) is higher than the current value stored in FCNTDATAR0 and FCNTDATAR1 registers by the read counter command. For details on RSIP-E51A see section 38, Renesas Secure IP (RSIP-E51A).

46.12.5.1 Anti-Rollback Counter Recovery Flow

Figure 46.44, Figure 46.45 and Figure 46.46-4 shows the recovery flow in the case of OEM_BL anti-rollback counter. The recovery flow for rest anti-rollback counter should be considered necessary processing to depend on customer's application by Secure software developer. As an example, the flow in dual mode is shown. In linear mode, the same operation can be performed using start-up area select, but application size that be managed by anti-rollback counter should be limited to 8 KB.

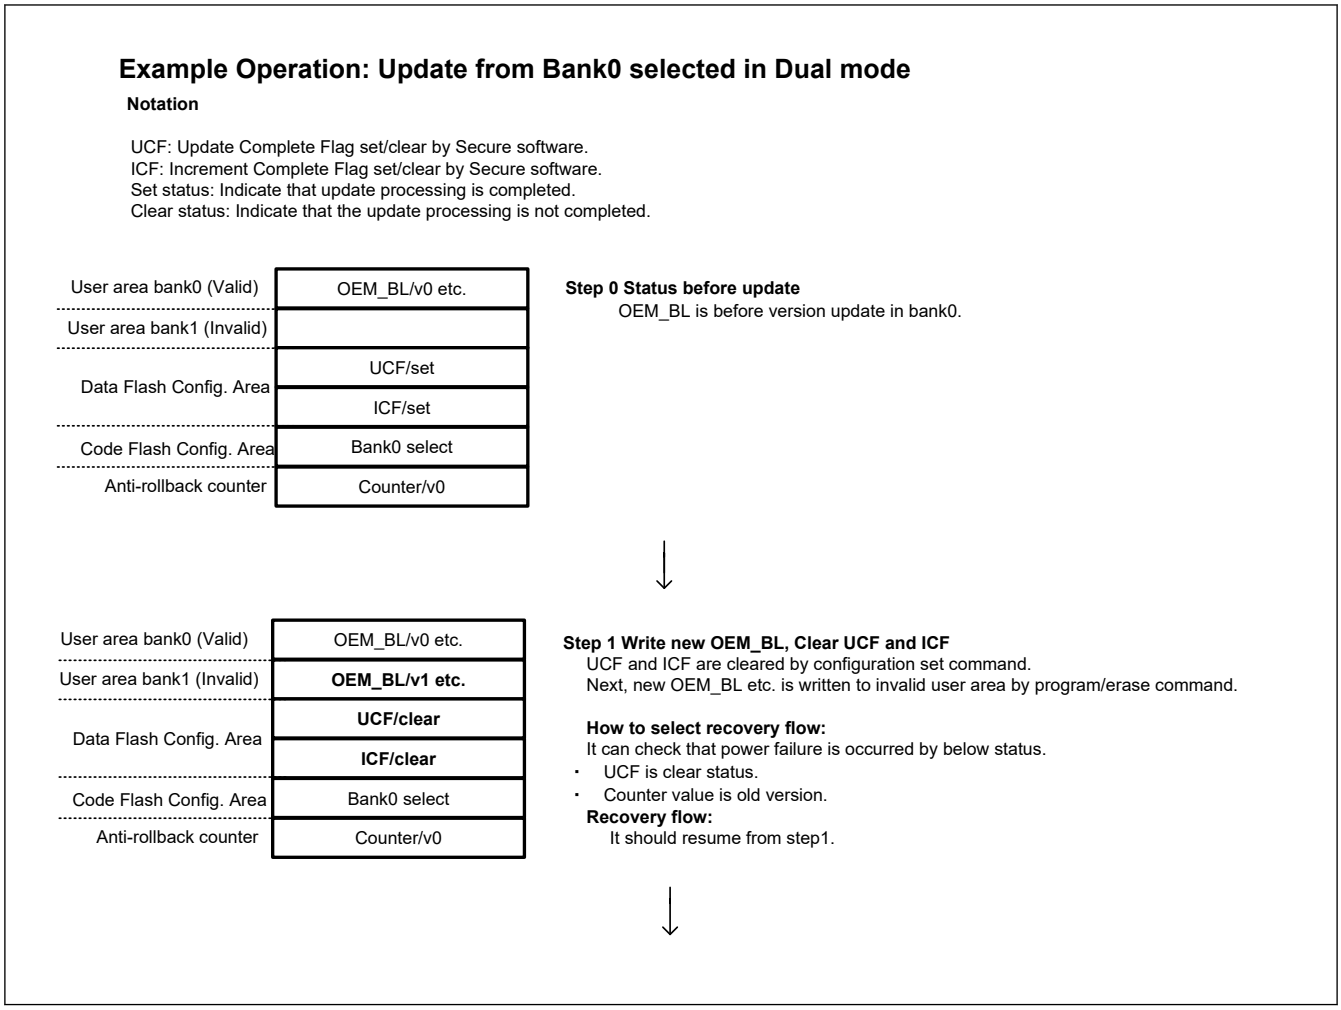

Figure 46.44 Recovery flow of OEM_BL update in Dual mode at power failure (1/3)

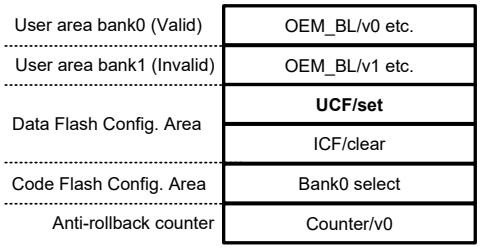
Example Operation: Update from Bank0 selected in Dual mode

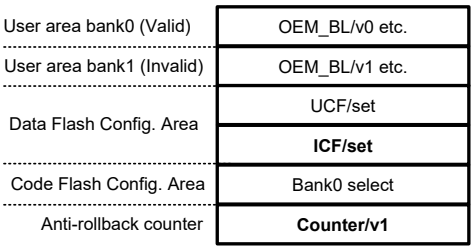
Notation

UCF: Update Complete Flag set/clear by Secure software.
ICF: Increment Complete Flag set/clear by Secure software.
Set status: Indicate that update processing is completed.
Clear status: Indicate that the update processing is not completed.



Step 2 Set UCF
UCF is set by configuration set command.

How to select recovery flow:
Same as step1.
Recovery flow:
Same as step1.



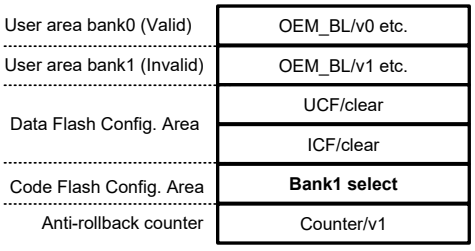
Step 3 Update counter version, Set ICF
OEM_BL version counter is update by increment counter command. Next, ICF is set by configuration set command.

How to select recovery flow(a):
It can check that power failure is occurred by below status.
- UCF is set status.
- ICF is clear status.
- Counter value is old version.

Recovery flow(a):
It should issue refresh counter command. Next, after clearing UCF, it should resume from step1.

How to select recovery flow(b):
It can check that power failure is occurred by below status.
- UCF is set status.
- ICF is clear status.
- Counter value is new version.

Recovery flow(b):
It should issue refresh counter command and set ICF. Next, it should resume from step4.



Step 4 Update bank selection
BANKSWP[2:0] bits are changed to bank1 selection by configuration set command.

How to select recovery flow:
It can check that power failure is occurred by below status.
- UCF is set status.
- ICF is set status.
- Counter value is new version.
- BANKSWP[2:0] bits are bank0 selection.

Recovery flow:
It should resume from step4.

Figure 46.45 Recovery flow of OEM_BL update in Dual mode at power failure (2/3)

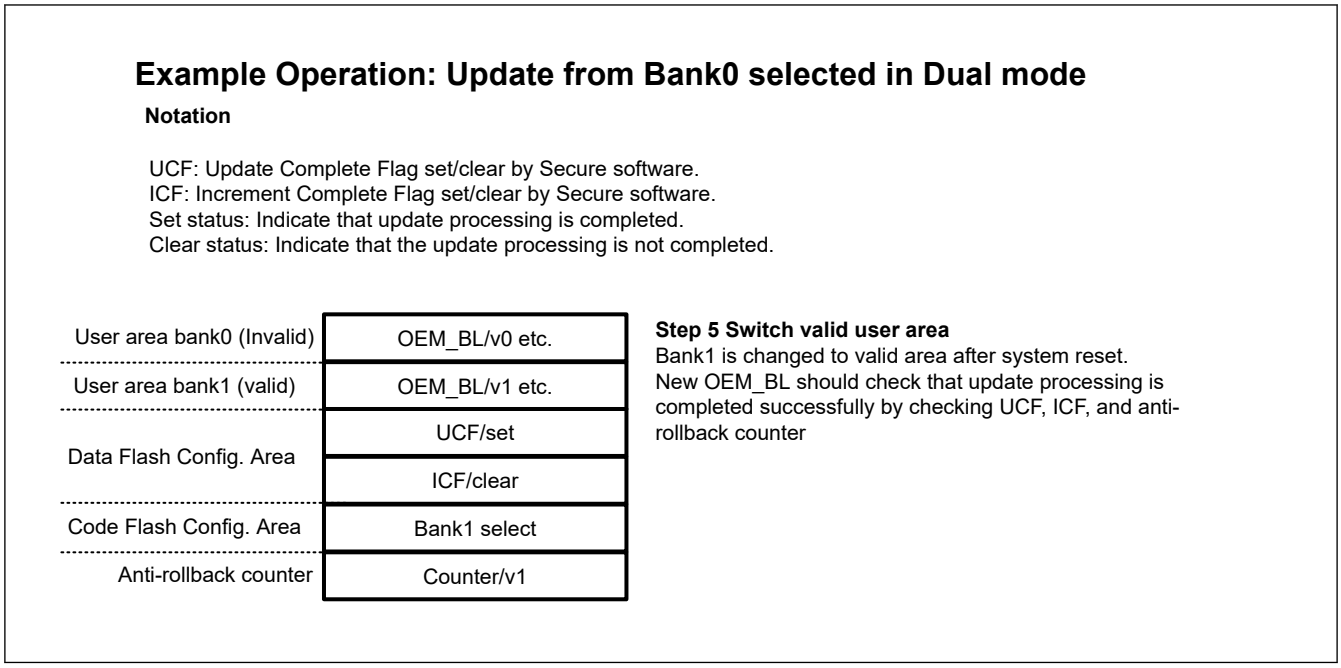


Figure 46.46 Recovery flow of OEM_BL update in Dual mode at power failure (3/3)

46.13 Boot Mode

There are two serial programming modes; the boot mode (for the SCI interface) with SCI9 and the boot mode (for the USB interface) with USBFS. Table 46.37 lists the I/O pins used in boot mode. Table 46.38 lists the available communication interface used in the boot mode.

Table 46.37 I/O Pins Used in Boot Mode

Pin Name	I/O	Mode to be Used	Use
MD	Input	Boot mode (for the SCI interface) Boot mode (for the USB interface) Boot mode (for the JTAG interface) Boot mode (for the SWD interface)	Selection of operating mode
P208/RXD9	Input	Boot mode (for the SCI interface)	For host communication (to receive data through SCI)
P209/TXD9	Output		For host communication (to transmit data through SCI)
USB_DP, USB_DM	I/O	Boot mode (for the USB interface)	Data input/output of USB
USB_VBUS	Input		Detection of connection and disconnection of USB cables
P211/TCK	Input	Boot mode (for the JTAG interface)	Clock pin of JTAG
P210/TMS	Input		Mode Select pin of JTAG
P208/TDI	Input		Data In pin of JTAG
P209TDO	Output		Data Out pin of JTAG
P211/SWCLK	Input	Boot mode (for the SWD interface)	Clock pin of SWD
P210/SWDIO	I/O		Data In-Out pin of SWD

Table 46.38 Available Communication Interface Used in Boot Mode (1 of 2)

Main clock oscillator or external clock is connected	Yes	No	No
Sub clock oscillator is connected*1	Yes or No	Yes	No
Available interface	JTAG, SWD, SCI or USB	JTAG, SWD, SCI or USB	JTAG, SWD or SCI

Table 46.38 Available Communication Interface Used in Boot Mode (2 of 2)

Tool connection time*2	Up to 1 second	Up to 2 seconds	Up to 3 seconds

Note 1. The drive capability of the sub clock oscillator is set to standard by SOMCR.SODRV bit. Note that if you use the crystal corresponding the low drive capability on your board, the crystal may not oscillate in the boot mode.
Note 2. See the boot firmware manual for the detail connection time.

46.13.1 Boot Mode (for the SCI Interface)

In boot mode (for the SCI interface), the host sends control commands and data for programming, and the flash memory is programmed or erased accordingly. An on-chip SCI handles transfer between the host and this MCU in asynchronous mode. Tools for transmission of control commands and the data for programming must be prepared in the host.

When this MCU is activated in boot mode (for the SCI interface), the program on the dedicated area the MCU is executed. The boot program automatically adjusts the bit rate of the SCI and controls programming/erasure by receiving control commands from the host.

Figure 46.47 shows the system configuration for operations in boot mode (for the SCI interface).

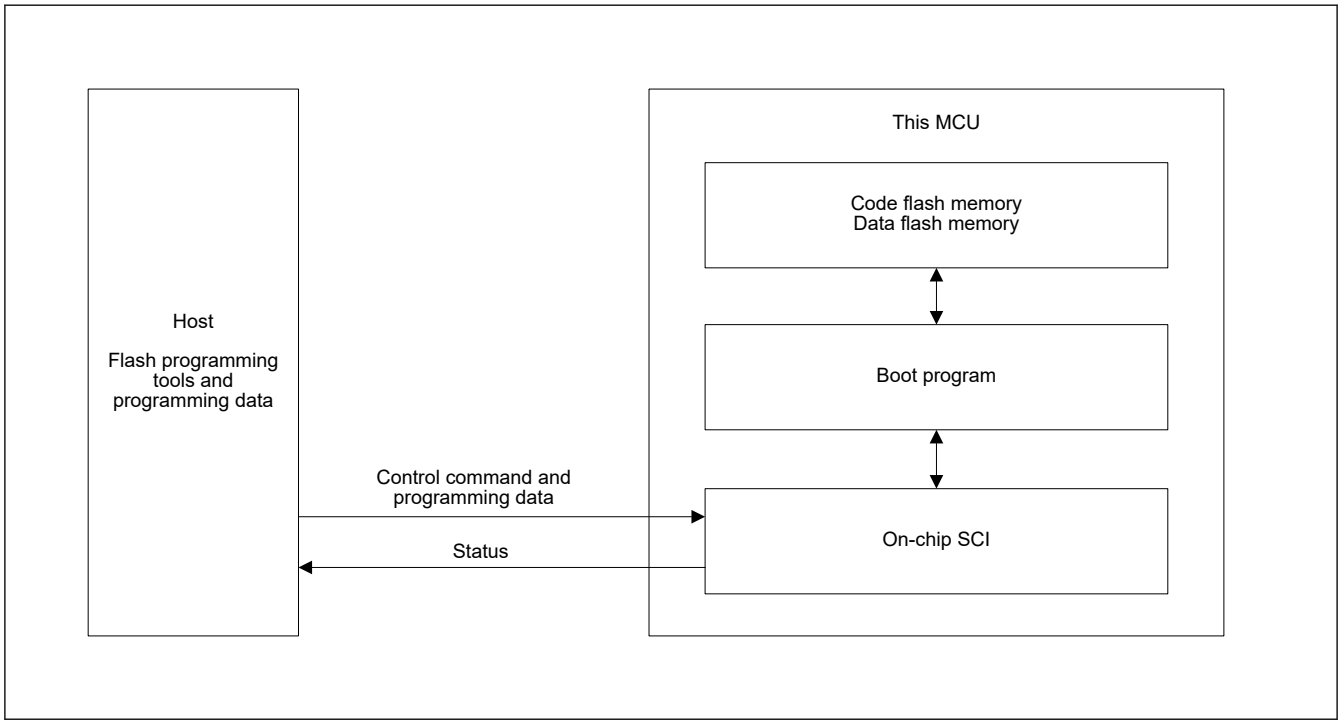

Figure 46.47 System Configuration for Operations in Boot Mode (for the SCI Interface)

46.13.2 Boot Mode (for the USB Interface)

In boot mode (with the USB interface), the flash memory can be programmed or erased by sending control commands and program data from the host. An on-chip USB is used for communications between the host and this MCU. The host requires tools for sending control commands and data for programming. Figure 46.48 shows the configuration of a system for use in boot mode (for the USB interface). The USB cable must be connected on reset release.

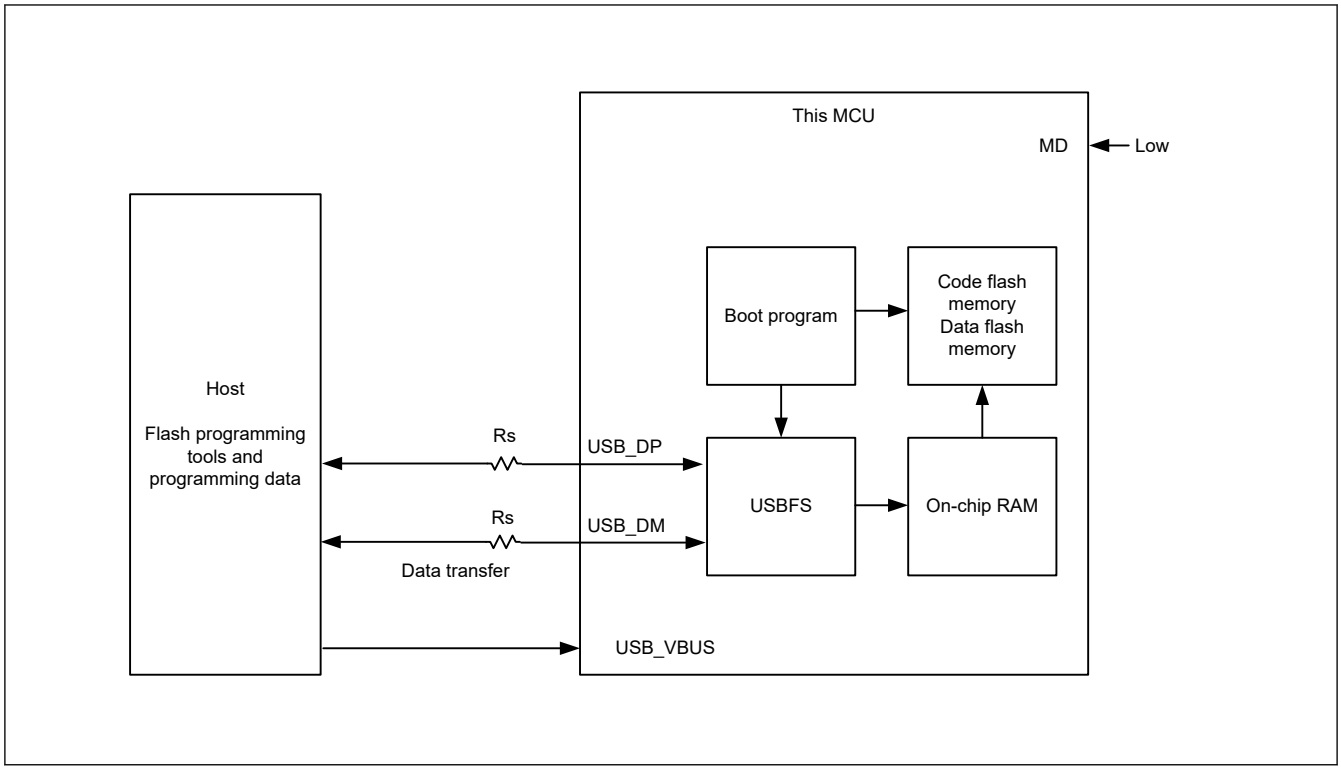

Figure 46.48 System Configuration in Boot Mode (for the USB Interface)

46.14 Using the Serial Programmer for Rewriting

A serial programmer can be used to rewrite flash memory in boot mode.

(1) Serial Programming

This MCU is mounted on the system board at the time of serial programming. Providing a connector to the board enables rewriting of this MCU by the serial programmer to proceed.

46.14.1 Environments for Serial Programming

The recommended environments for rewriting the flash memory of the MCU with data are described below.

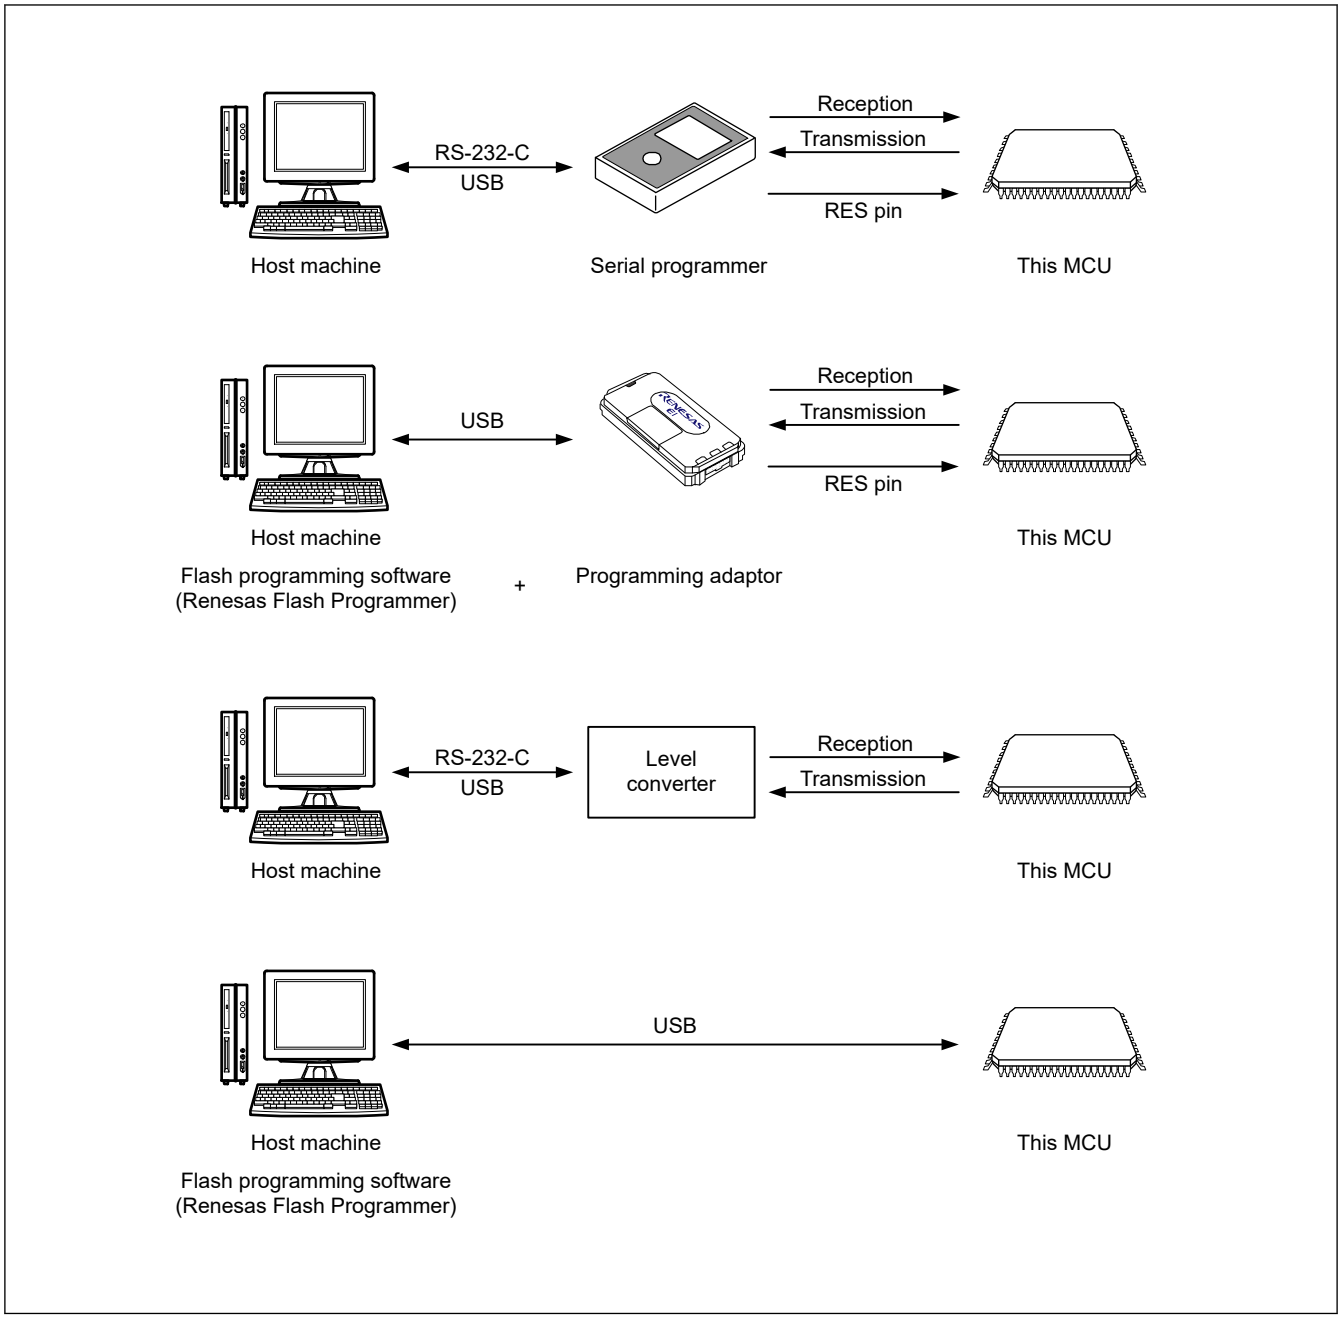

Figure 46.49 Environments for Rewriting the Flash Memory

46.15 Programming through Self-Programming

46.15.1 Overview

This MCU supports programming of the flash memory by the user program itself. The FACI commands can be used with user programs for writing to the flash memory. This allows upgrading of user programs and rewriting of constant data fields.

The program for rewriting must be transferred to the internal RAM or external memory in advance when the BGO is not available or when rewriting the option-setting memory.

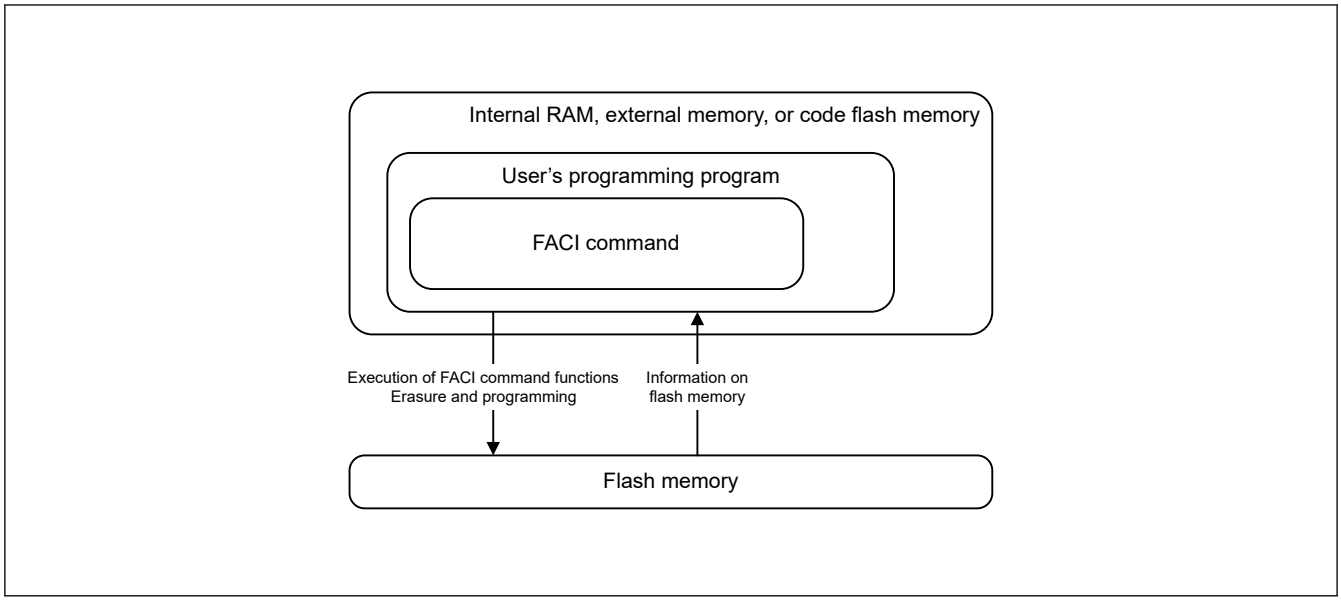

Figure 46.50 Schematic View of Self-Programming

For comprehensive information on the self-programming, see section 46.9. FACI Commands.

46.15.2 Background Operation

The background operation (BGO) can be used to execute the flash rewrite routine on the code flash memory when the data flash memory or other area of code flash memory is rewritten.

Background operations can be used when the combination of the flash memory for rewriting and the flash memory for reading is any of those listed below.

Table 46.39 Conditions under which Background Operation is Usable (1 of 2)

		Range for rewriting	Range for reading
Common to linear and dual modes		Code flash memory	Data flash memory
		Data flash memory	Code flash memory
Liner mode	Products with 2 Mbytes of code flash memory	First half (1 Mbytes) of the code flash memory addresses Secure alias: 0x0200_0000 to 0x020F_FFFF Non-secure alias: 0x1200_0000 to 0x120F_FFFF	Second half (1 Mbytes) of the code flash memory addresses Secure alias: 0x0210_0000 to 0x021F_7FFF Non-secure alias: 0x1210_0000 to 0x121F_7FFF
		Second half (1 Mbytes) of the code flash memory addresses Secure alias: 0x0210_0000 to 0x021F_7FFF Non-secure alias: 0x1210_0000 to 0x121F_7FFF	First half (1 Mbytes) of the code flash memory addresses Secure alias: 0x0200_0000 to 0x020F_FFFF Non-secure alias: 0x1200_0000 to 0x120F_FFFF
	Products with 1 Mbytes of code flash memory	First half (0.5 Mbytes) of the code flash memory addresses Secure alias: 0x0200_0000 to 0x0207_FFFF Non-secure alias: 0x1200_0000 to 0x1207_FFFF	Second half (0.5 Mbytes) of the code flash memory addresses Secure alias: 0x0208_0000 to 0x020F_FFFF Non-secure alias: 0x1208_0000 to 0x120F_FFFF
		Second half (0.5 Mbytes) of the code flash memory addresses Secure alias: 0x0208_0000 to 0x020F_FFFF Non-secure alias: 0x1208_0000 to 0x120F_FFFF	First half (0.5 Mbytes) of the code flash memory addresses Secure alias: 0x0200_0000 to 0x0207_FFFF Non-secure alias: 0x1200_0000 to 0x1207_FFFF

Table 46.39 Conditions under which Background Operation is Usable (2 of 2)

		Range for rewriting	Range for reading
Dual mode	When the BANKSEL_SEC.BANKSWP [2:0] or BANKSEL.BANKSWP[2:0] bits are 111b	Bank 1 area of the code flash memory	Bank 0 area of the code flash memory
	When the BANKSEL_SEC.BANKSWP [2:0] or BANKSEL.BANKSWP[2:0] bits are 000b	Bank 0 area of the code flash memory	Bank 1 area of the code flash memory

46.16 Reading Flash Memory

46.16.1 Reading Code Flash Memory

Special settings are not required to read code flash memory after release from the reset state. Data can simply be read out through access to addresses in the code flash memory.

When reading code flash memory that has been erased but not yet been programming again (i.e. that is in the non-programmed state), all bits are read as 1.

46.16.2 Reading Data Flash Memory

Special settings are not required to read data flash memory after release from the reset state. Data can simply be read out through access to addresses in the data flash memory.

Values read from data flash memory that has been erased but not yet been programming again (i.e. that is in the non-programmed state) are undefined. Use blank checking when you need to confirm that an area is in the non-programmed state.

46.17 Usage Notes

(1) Reading Area Where Programming/Erasure was Interrupted and Area Targeted for Suspension

The data stored in the area where programming or erasure has been suspended or the area where programming or erasure has been suspended by using the suspend command are undefined. To avoid faulty operation caused by reading undefined data, take care not to fetch instructions or read data from areas where programming or erasure was suspended and where programming or erasure was suspended by using the suspend command.

(2) Suspension During Programming/Erasure

When processing of programming/erasure is stopped by issuing the P/E suspend command, the programming/erasure processing can be resumed by issuing the P/E resume command. If the flash sequencer enters the command-locked state for any reason and issues the forced stop command after the suspended processing is normally completed and the ERSSPD flag or PRGSPD flag is set to 1, the suspended processing cannot be resumed. In addition, the values in the area where the processing was suspended are not guaranteed. Erase that area

(3) Prohibition of Additional Programming

Programming a given area of the code flash memory or data flash memory twice is not possible. To program the code flash memory or data flash memory where has been programmed, erase the target area. Programming can be added to the option-setting memory.

(4) Resets During Programming/Erasure, or Blank Checking

In the case of a reset due to the signal on the RES pin during programming/erasure, or blank checking of the flash memory, wait for at least t_{RESW} (see section 48, Electrical Characteristics) of the reset input period once the operating voltage is within the range stipulated in the electrical characteristics, then release the device from the reset state.

(5) Allocation of Vectors for Interrupts and Other Exceptions During Programming/Erasure

Generation of an interrupt or other exception during programming/erasure may lead to fetching of the vector from the code flash memory. Under conditions where BGO cannot be used, set the address of the vector to an address that is not in the code flash memory. Alternatively, make sure that no handling of interrupts or exceptions proceeds during programming/erasure.

(6) Items Prohibited During Programming/Erasure, or Blank Checking

High voltage is applied to the flash memory during programming/erasure, or blank checking. To prevent damage to the flash memory, do not perform the following operations.

- Have the operating voltage from the power supply go beyond the permitted range.
- Change the FWEPROR.FLWE[1:0]bits.
- Change the OPCCR.OPCM[2:0] bits.
- Change the SCKDIVCR.FCK[2:0]bits.
- Change the SCKSCR.CKSEL[2:0]bits.
- Transition to the software standby mode, or Deep Software Standby mode.

(7) Programming/Erasure in Low-Speed Modes

Do not programming/erasure the flash memory when low-speed mode is selected with the operating power control register (OPCCR).

(8) Setting dual bank mode and programming in Boot Mode

The initial mode of the MCU shipped from Renesas is linear mode. In customer's factory when programming dual bank mode and customer's applications on MCU set in linear mode, it is recommended that only area1 in Figure 46.51 is programmed in boot mode and area2 is kept blank. After reset, MCU starts in dual mode and the application is in bank0. Use self-programming when programming area2 for updating in the field. See section 37.7. Field Updating in Dual Mode for details

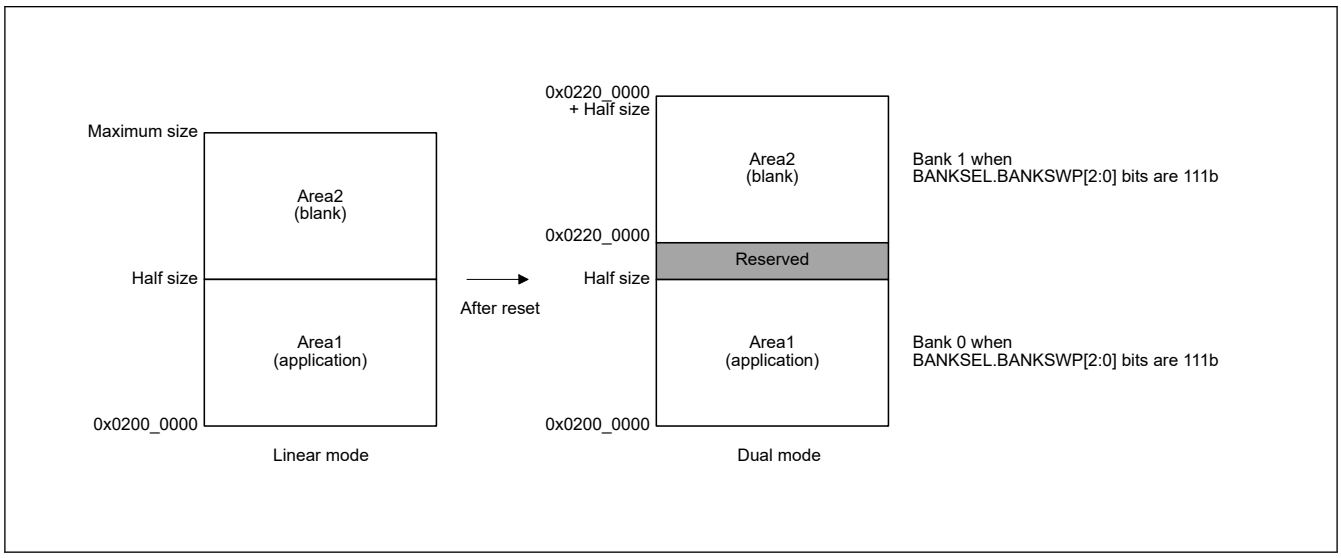

Figure 46.51 Programming the application for the dual mode in the linear mode

(9) Emulator Connection

Renesas provides the emulator which supports both debugging using SWD or JTAG communication and serial programming using SCI communication.

Table 46.40 shows the pinout of 10 pin or 20 pin socket pinouts when using this emulator. The pinout of SWD and JTAG is ARM standard, and MD, TXD, RXD pins are added for the serial programming using SCI communication.

Table 46.40 Pin assign for emulator (1 of 2)

Pin No.	SWD	JTAG	Serial Programming using SCI
1	VCC	VCC	VCC
2	P210/SWDIO	P210/TMS	NC
4	P211/SWCLK	P211/TCK	P201/MD

Table 46.40 Pin assign for emulator (2 of 2)

Pin No.	SWD	JTAG	Serial Programming using SCI
6	P209/SWO	P209/TDO	P209/TXD9
8	P208	P208/TDI	P208/RXD9
9	GNDdetect	GNDdetect	GNDdetect
10	nRESET	nRESET	nRESET

47. Internal Voltage Regulator

47.1 Overview

The MCU supports two power supply providing for core voltage (VDD):

- Switching regulator (DCDC)
- External power supply from external power device (External VDD)

Table 47.1 shows the specifications of Internal voltage regulator.

DCDC or External VDD is selected with the OFS setting.

- When OFS2.DCDCEN is 1, DCDC is selected (DCDC mode)
- When OFS2.DCDCEN is 0, External VDD is selected (External VDD mode)

Table 47.1 Power supply selection

OFS setting (OFS2.DCDCEN)	Power mode
1	DCDC mode
0	External VDD mode

47.2 Operation

47.2.1 DCDC mode

Table 47.2 lists the DCDC mode pin settings, and Figure 47.1 shows the DCDC mode settings.

In DCDC mode, VDD is supplied from VCL through VLO output and an external inductor and capacitor.

Table 47.2 DCDC mode pin settings

Pins	Setting descriptions
All VCC and VCC2 pins	• Connect each pin to the system power supply. • Connect each pin to VSS through a 0.1 µF multilayer ceramic capacitor. Place the capacitor close to the pin.
VCC_DCDC pins	• Connect the pin to the system power supply. • Connect the pin to VSS_DCDC through a 22 µF and 0.1-µF multilayer ceramic capacitor in parallel. Place the capacitor close to the pin.
VCL pins	• Connect each pin to VSS through a 0.22 µF multilayer ceramic capacitor. Place the capacitor close to the pin. • Connect each pin to an external inductor and capacitor. Place the inductor and capacitor close to the pin.(see Figure 47.1.)
All VLO pins	Connect each pin to an external inductor and capacitor. Place the 2.2-µH inductor and 47 µF capacitor close to the pin. This capacitor must be grounded to VSS_DCDC

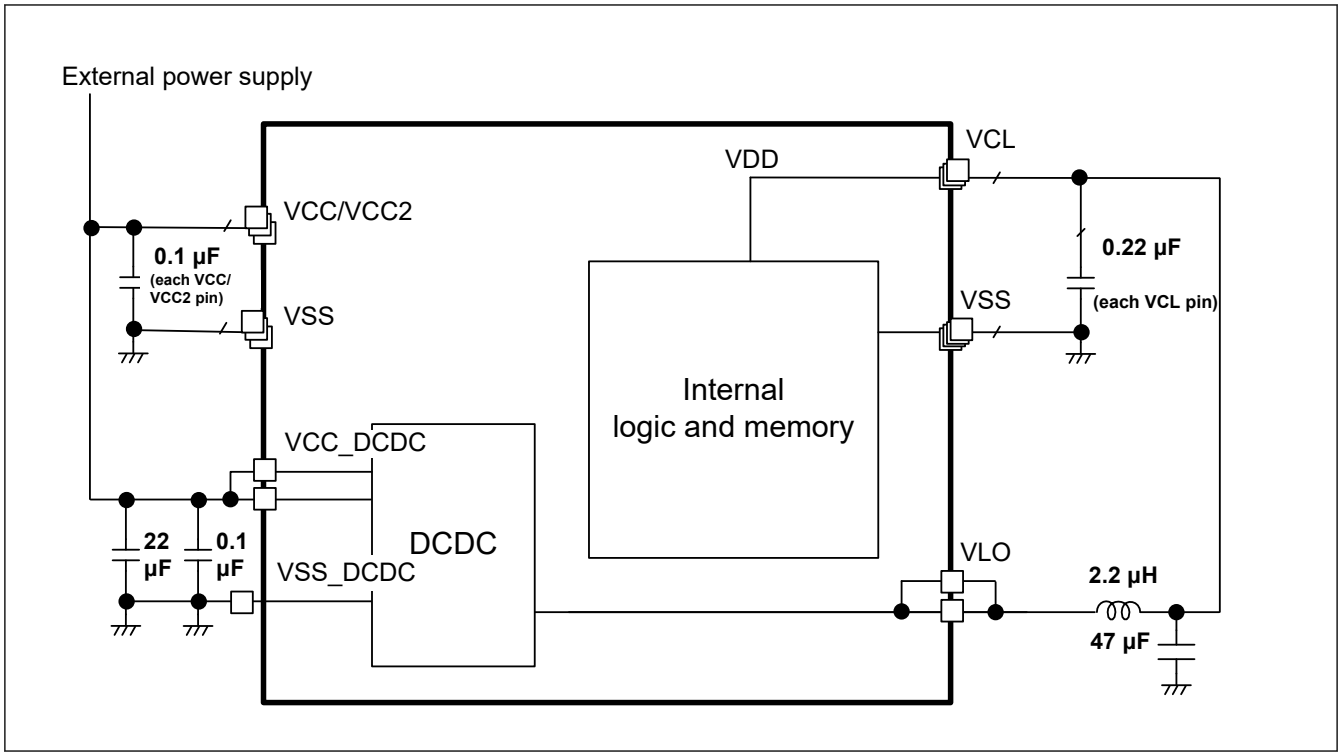

Figure 47.1 DCDC mode setting

47.2.2 External VDD mode

Table 47.3 lists the external VDD mode pin settings, and Figure 47.2 shows the external VDD mode settings.

VDD is supplied from VCL pins.

Note: Low-speed mode, Software Standby mode, and Deep Software Standby mode 1, 2, 3 are not supported in this mode.

Table 47.3 Setting Descriptions for external VDD mode

Pins	Setting descriptions
All VCC and VCC2 pins	• Connect each pin to the system power supply device for VCC. • Connect each pin to VSS through a 0.1 µF multilayer ceramic capacitor. Place the capacitor close to the pin.
VCC_DCDC pins	• Connect the pin to VSS_DCDC through 0.1 µF multilayer ceramic capacitor. Place the capacitor close to the pin.
VCL pins	• Connect each pin to the system power supply device for VDD. • Connect each pin to VSS through a 0.22 µF multilayer ceramic capacitor. Place the capacitor close to the pin.
All VLO pins	Keep pin open

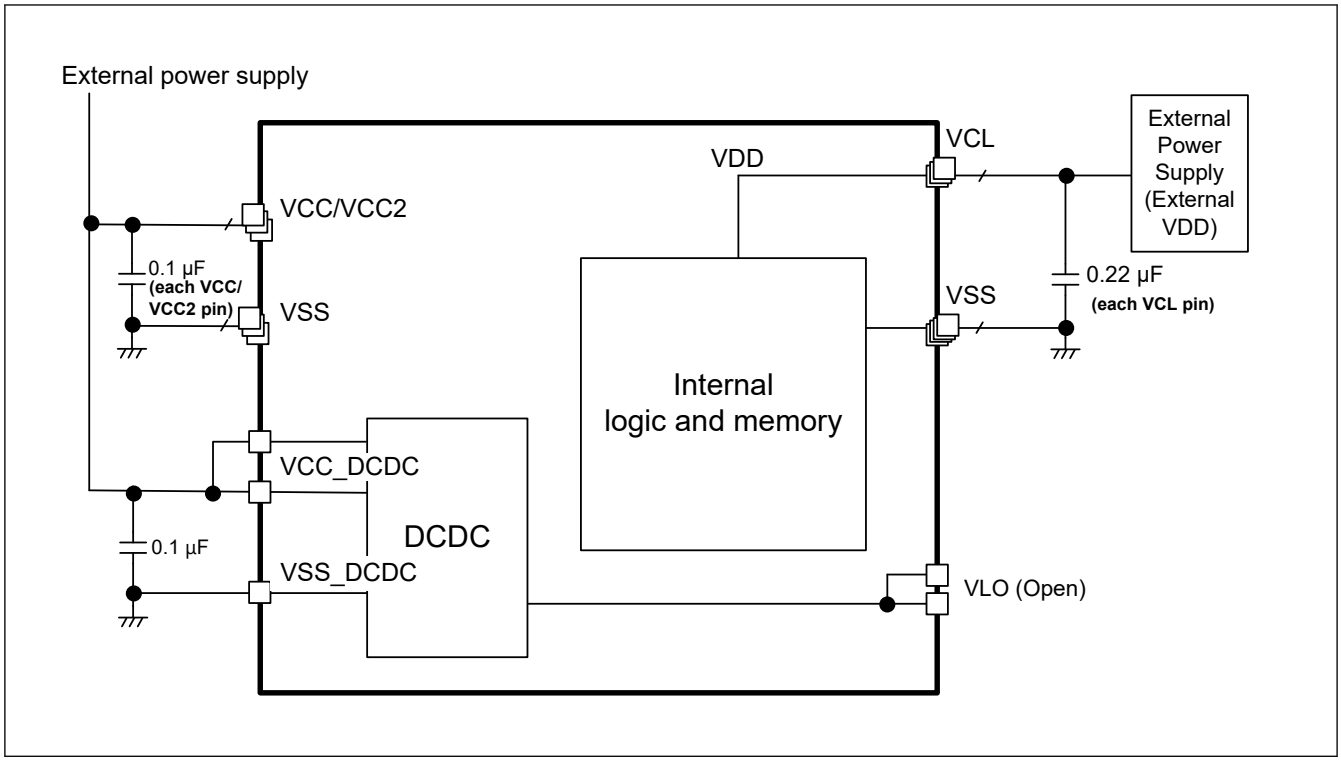

Figure 47.2 External VDD mode setting

In order to startup the device properly, use either of following procedure.

- VCL voltage must be raised 500 µs after VCC voltage is raised to minimum VCC voltage.
- Raise VCC voltage with RES pin is low, and release RES pin after 200 µs when VCL voltage is raised.

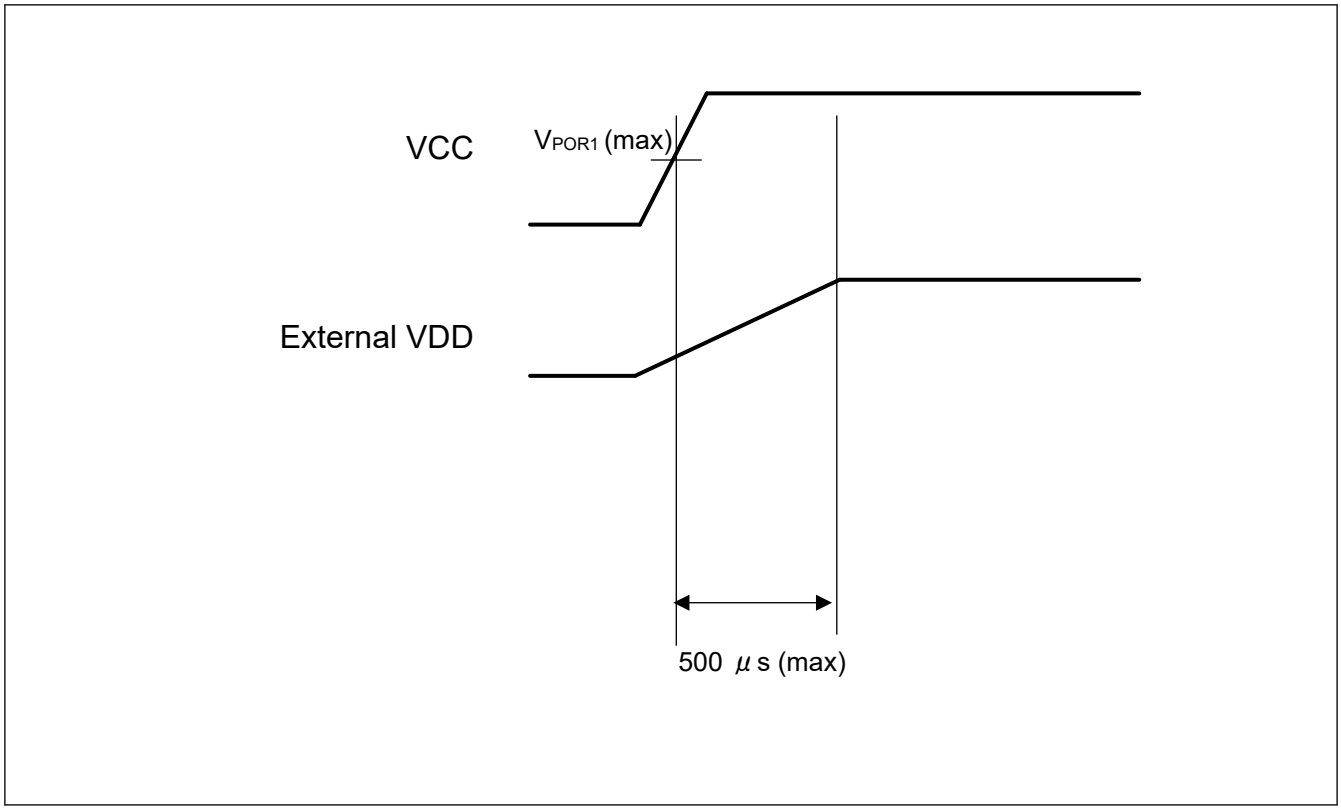

Figure 47.3 Power-up sequence of external VDD mode without using RES pin

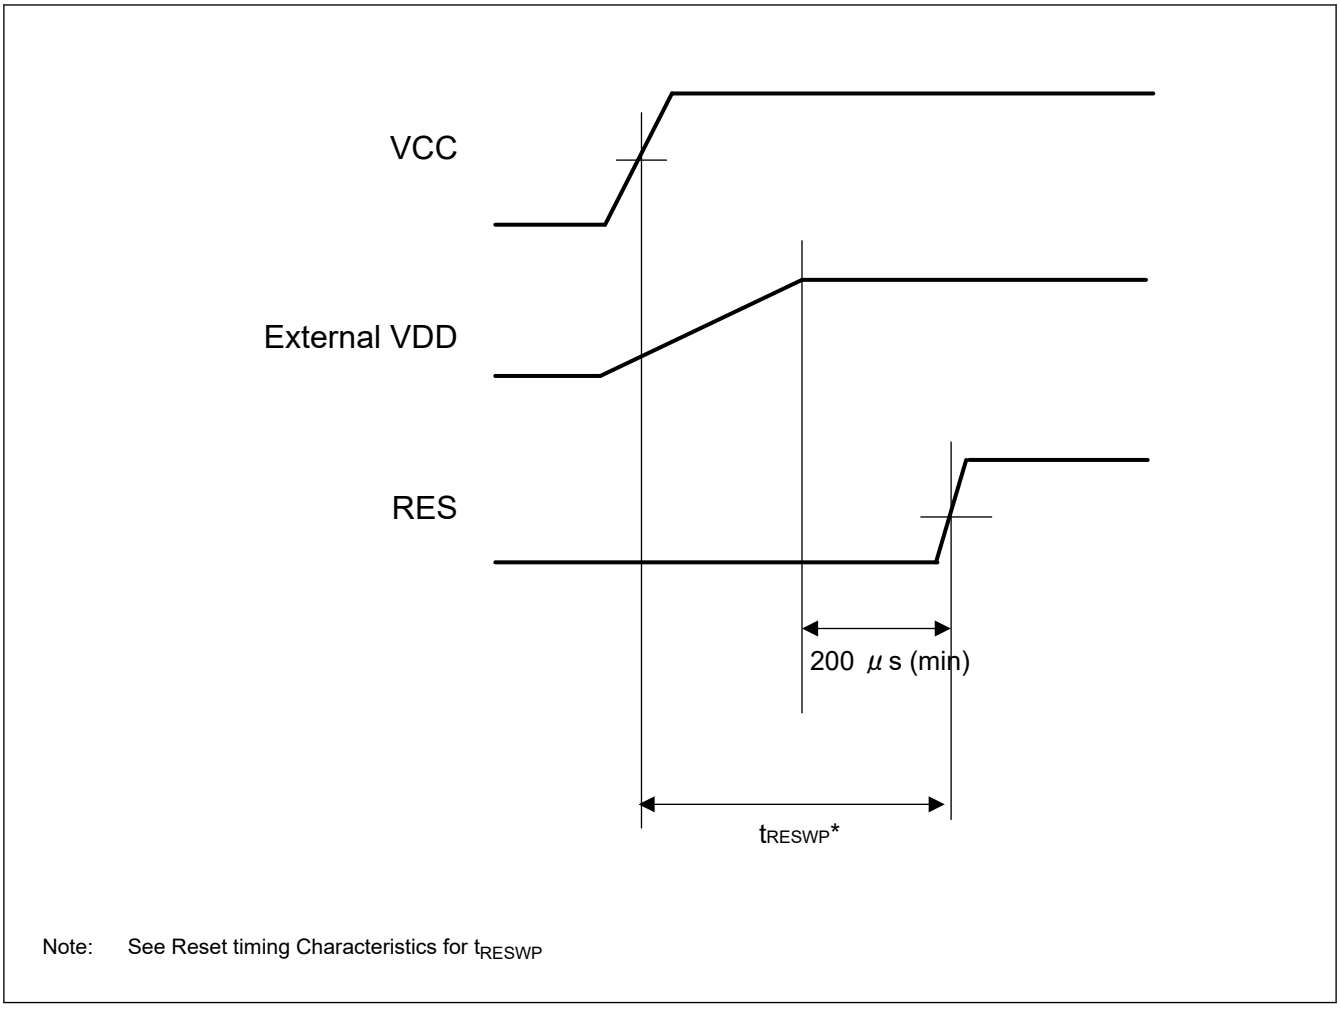

Figure 47.4 Power-up sequence of external VDD mode with using RES pin

47.3 Usage Notes

In DCDC mode, to minimize power loss and maximize efficiency, Renesas recommends using a 2.2-µH inductor with a DC resistance of 100 mΩ or less. Short VCC and VCC_DCDC.

In external VDD mode, the voltage of VDD should always be below the voltage of VCC including the power-on and power-off sequence. Refer to the chapter of electrical characteristics for more information.

48. Electrical Characteristics

Unless otherwise specified, minimum and maximum values are guaranteed by either design simulation, characterization results or test in production.

Supported peripheral functions and pins differ from one product name to another.

Unless otherwise specified, the electrical characteristics of the MCU are defined under the following conditions:

- VCC = VCC_DCDC = VCC_USB = 1.68 to 3.6 V
- VCC2 = 1.65 to 3.6 V
- AVCC0 = 1.65 to 3.6 V
- VREFH0 = 2.7 V to AVCC0
- VREFH = 1.65 V to AVCC0
- VSS = VSS_DCDC = AVSS0 = VREFL0 /VREFL = VSS_USB = 0 V
- VCC voltage is lower than 2.7 V : LVOCR.LVO0E = 1, otherwise LVOCR.LVO0E = 0
- VCC2 voltage is lower than 2.7 V : LVOCR.LVO1E = 1, otherwise LVOCR.LVO1E = 0
- $T_j = T_{opj}$
- When not specified otherwise, typical values are measured at room temperature of 25 °C and VCC = VCC_DCDC = VCC_USB = AVCC0 = VREFH0 = VREFH = 3.3V

Figure 48.1 shows the timing conditions.

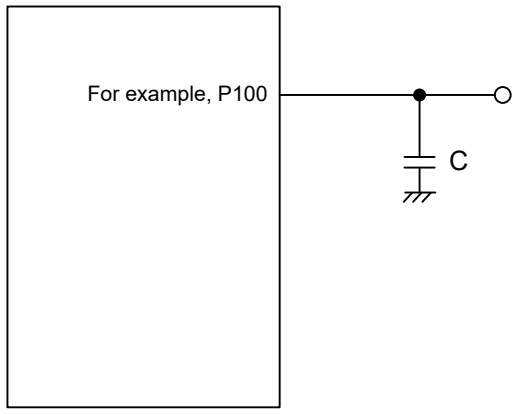

Figure 48.1 Input or output timing measurement conditions

The recommended measurement conditions for the timing specification of each peripheral provided are for the best peripheral operation. Make sure to adjust the driving abilities of each pin to meet your conditions.

48.1 Absolute Maximum Ratings

Table 48.1 Absolute maximum ratings (1 of 2)

Parameter	Symbol	Value	Unit
Power supply voltage	VCC, VCC2, VCC_DCDC, VCC_USB*2	–0.3 to +4.0	V
External power supply voltage	VCL	–0.3 to +1.6	V
Input voltage (except for 5 V-tolerant ports*1)	V_{in}	–0.3 to VCC + 0.3 or –0.3 to VCC2 + 0.3	V

Table 48.1 Absolute maximum ratings (2 of 2)

Parameter	Symbol	Value	Unit
Input voltage (5 V-tolerant ports*1)	V_{in}	–0.3 to + VCC + 4.0 (max. 5.8)	V
Reference power supply voltage	VREFH/VREFH0	–0.3 to AVCC0 + 0.3	V
Analog power supply voltage	AVCC0	–0.3 to +4.0	V
Analog input voltage	V_{AN}	–0.3 to AVCC0 + 0.3	V
Operating junction temperature*3 *4	T_{opj}	–40 to +125	°C
Storage temperature	T_{stg}	–55 to +125	°C

Note 1. Ports P205, P206, P402 to P404, P406 to P415, P511, P512, P709 to P715 and PB01 are 5 V tolerant.
Note 2. Connect VCC_DCDC and VCC_USB to VCC.
Note 3. See section 48.2.1. Tj/Ta Definition.
Note 4. Contact a Renesas Electronics sales office for information on derating operation when Tj = +105°C to +125°C. Derating is the systematic reduction of load for improved reliability.

Caution: Permanent damage to the MCU might result if absolute maximum ratings are exceeded.

Table 48.2 Recommended operating conditions

Parameter	Symbol		Min	Typ	Max	Unit
Power supply voltages	VCC, VCC_DCDC	Other than the following	1.68	—	3.60	V
		When ETHERC/IIC Fast-mode+ is used	2.70	—	3.60	V
		When USB/SDRAM is used	3.00	—	3.60	V
	VCC2		1.65	—	3.60	V
	VCL	When external VDD is used*2	1.20	—	1.25	V
		When DCDC is used (High-speed mode)	—	1.21	—	V
		When DCDC is used (Low-speed mode or Software Standby mode)	—	1.18	—	V
	VSS, VSS_DCDC		—	0	—	V
USB power supply voltages	VCC_USB		—	VCC	—	V
	VSS_USB		—	0	—	V
Analog power supply voltages	AVCC0*1	When ADC is not used	1.65	—	3.60	V
		When ADC is used	2.70	—	3.60	V
	AVSS0		—	0	—	V

Note 1. When the A/D converter, the D/A converter and the High-Speed Analog Comparator are not in use, do not leave the AVCC0, VREFH/VREFH0, AVSS0, and VREFL/VREFL0 pins open. Connect the AVCC0 and VREFH/VREFH0 pins to VCC, and the AVSS0 and VREFL/VREFL0 pins to VSS, respectively.
Note 2. VCL voltage must never be higher than VCC voltage.

48.2 DC Characteristics

48.2.1 Tj/Ta Definition

Table 48.3 DC characteristics

Parameter	Symbol	Typ	Max	Unit	Test conditions
Permissible operating junction temperature	T_j	—	125	°C	High-speed mode Low-speed mode

Note: Make sure that $T_j = T_a + \theta_{ja} \times$ total power consumption (W), where total power consumption = $(VCC - V_{OH}) \times \Sigma I_{OH} + V_{OL} \times \Sigma I_{OL} + (I_{CC}max + I_{CC_DCDC}max) \times VCC$.
Note: Minimum Ambient Temperature(Ta) is -40℃

48.2.2 I/O V_{IH}, V_{IL}

Table 48.4 I/O V_{IH}, V_{IL} except for Schmitt trigger input pins

Parameter		VCC/VCC2/ AVCC0	Symbol	Min	Typ	Max	Unit
Peripheral function pins	EXTAL (external clock input), WAIT, SPI*1 (except RSPCK)	1.68 V or above	V_{IH}	VCC × 0.8	—	—	V
			V_{IL}	—	—	VCC × 0.2	
	SPI*2 (except RSPCKB_A)	1.65 V or above	V_{IH}	VCC2 × 0.8	—	—	
			V_{IL}	—	—	VCC2 × 0.2	
	SD*3	2.70 V or above	V_{IH}	VCC × 0.625	—	VCC + 0.3	
			V_{IL}	VSS − 0.3	—	VCC × 0.25	
		1.70 V ~ 1.95 V	V_{IH}	1.27	—	2	
			V_{IL}	VSS − 0.3	—	0.58	
	SD*4	2.70 V or above	V_{IH}	VCC2 × 0.625	—	VCC2 + 0.3	
			V_{IL}	VSS − 0.3	—	VCC2 × 0.25	
		1.70 V ~ 1.95 V	V_{IH}	1.27	—	2	
			V_{IL}	VSS − 0.3	—	0.58	
	MMC*5	2.70 V or above	V_{IH}	VCC × 0.625	—	VCC + 0.3

Table 48.5 I/O V_{IH}, V_{IL} of Schmitt trigger input pins

Parameter		VCC/VCC2/ AVCC0	Symbol	Min	Typ	Max	Unit
Peripheral function pins	IIC (except for SMBus)	1.68 V or above	V_{IH}	VCC × 0.7	—	VCC + 3.6 (max 5.8)	V
			V_{IL}	—	—	VCC × 0.3	
			ΔV_T	VCC × 0.05	—	—	
	I3C	1.68 V or above	V_{IH}	VCC × 0.7	—	VCC + 0.3	
			V_{IL}	—	—	VCC × 0.3	
			ΔV_T	VCC × 0.1	—	—	
	5 V-tolerant ports*1*5	1.68 V or above	V_{IH}	VCC × 0.8	—	VCC + 3.6 (max 5.8)	
			V_{IL}	—	—	VCC × 0.2	
			ΔV_T	VCC × 0.05	—	—	
	Other VCC input pins*2	1.68 V or above	V_{IH}	VCC × 0.8	—	—	
			V_{IL}	—	—	VCC × 0.2	
			ΔV_T	VCC × 0.05	—	—	
	Other VCC2 input pins*2	1.65 V or above	V_{IH}	VCC2 × 0.8	—	—	
			V_{IL}	—	—	VCC2 × 0.2	
			ΔV_T	VCC2 × 0.05	—	—	
	Other AVCC0 input pins*2	1.65 V or above	V_{IH}	AVCC0 × 0.8	—	—	
			V_{IL}	—	—	AVCC0 × 0.2	
			ΔV_T	AVCC0 × 0.05	—	—	
Ports	5 V-tolerant port*3*5	1.68 V or above	V_{IH}	VCC × 0.8	—	VCC + 3.6 (max 5.8)	V
			V_{IL}	—	—	VCC × 0.2	
	Other VCC input pins*4	1.68 V or above	V_{IH}	VCC × 0.8	—	—	
			V_{IL}	—	—	VCC × 0.2	
	Other VCC2 input pins*4	1.65 V or above	V_{IH}	VCC2 × 0.8	—	—	
			V_{IL}	—	—	VCC2 × 0.2	
	Other AVCC0 input pins*4	1.65 V or above	V_{IH}	AVCC0 × 0.8	—	—	
			V_{IL}	—	—	AVCC0 × 0.2	

Note 1. RES and peripheral function pins associated with P205, P206, P402 to P404, P406 to P415, P511, P512, P709 to P715, PB01 (total 26 pins).
Note 2. All input pins except for the peripheral function pins already described in the table. There is an item for each power supply voltage for each port. Refer to the IO chapter for the power supply of the port.
Note 3. P205, P206, P402 to P404, P406 to P415, P511, P512, P709 to P715, PB01 (total 25 pins).
Note 4. All input pins except for the ports already described in the table. There is an item for each power supply voltage for each port. Refer to the IO chapter for the power supply of the port.
Note 5. When VCC is less than 1.68 V, the input voltage of 5 V-tolerant ports should be less than 3.6 V, otherwise breakdown may occur because 5 V-tolerant ports are electrically controlled so as not to violate the break down voltage.

48.2.3 I/O I_{OH}, I_{OL}

Table 48.6 I/O I_{OH}, I_{OL} (1 of 2)

Parameter			VCC/ VCC2/ AVCC0	Symbol	Min	Typ	Max	Unit
Permissible output current (average value per pin)	Ports P000 to P011, P014, P015, P201	—	—	I_{OH}	—	—	−2.0	mA
				I_{OL}	—	—	2.0	mA
	Ports P205, P206, P402 to P404, P406 to P415, P511, P512, P709 to P715, PA09, PB01 (total 26 pins)	Low drive*1	—	I_{OH}	—	—	−2.0	mA
				I_{OL}	—	—	2.0	mA
		Middle drive*2	—	I_{OH}	—	—	−4.0	mA
				I_{OL}	—	—	4.0	mA
		High drive*3	—	I_{OH}	—	—	−20	mA
				I_{OL}	—	—	20.0	mA
	Ports P100 to P103, P304 to P308, P800 to P804, P808 to P810, PA09 (total 18 pins)	Low drive*1	—	I_{OH}	—	—	−2.0	mA
				I_{OL}	—	—	2.0	mA
		Middle drive*2	—	I_{OH}	—	—	−4.0	mA
				I_{OL}	—	—	4.0	mA
		High drive*3	—	I_{OH}	—	—	−16	mA
				I_{OL}	—	—	16.0	mA
		High-speed high drive*4	—	I_{OH}	—	—	−20	mA
				I_{OL}	—	—	20.0	mA
	Port PA09	Low drive*1	—	I_{OH}	—	—	−2.0	mA
				I_{OL}	—	—	2.0	mA
		Middle drive*2	—	I_{OH}	—	—	−4.0	mA
				I_{OL}	—	—	4.0	mA
		High drive*3	—	I_{OH}	—	—	−20	mA
				I_{OL}	—	—	20.0	mA
		High-speed high drive*4	—	I_{OH}	—	—	−20	mA
				I_{OL}	—	—	20.0	mA
	Other output pins*5	Low drive*1	—	I_{OH}	—	—	−2.0	mA
				I_{OL}	—	—	2.0	mA
		Middle drive*2	—	I_{OH}	—	—	−4.0	mA
				I_{OL}	—	—	4.0	mA
		High drive*3	—	I_{OH}	—	—	−16	mA
				I_{OL}	—	—	16.0	mA

Table 48.6 I/O I_{OH}, I_{OL} (2 of 2)

Parameter			VCC/ VCC2/ AVCC0	Symbol	Min	Typ	Max	Unit
Permissible output current (max value per pin)	Ports P000 to P011, P014, P015, P201	—	—	I_{OH}	—	—	−4.0	mA
				I_{OL}	—	—	4.0	mA
	Ports P205, P206, P402 to P404, P406 to P415, P511, P512, P709 to P715, PA09, PB01 (total 26 pins)	Low drive*1	—	I_{OH}	—	—	−4.0	mA
				I_{OL}	—	—	4.0	mA
		Middle drive*2	—	I_{OH}	—	—	−8.0	mA

				I_{OL}	—	—	40.0	mA
	Ports P100 to P103, P304 to P308, P800 to P804, P808 to P810, PA09 (total 18 pins)	Low drive*1	—	I_{OH}	—	—	−4.0	mA
				I_{OL}	—	—	4.0	mA
		Middle drive*2	—	I_{OH}	—	—	−8.0	mA
				I_{OL}	—	—	8.0	mA
		High drive*3	—	I_{OH}	—	—	−32	mA
				I_{OL}	—	—	32.0	mA
		High-speed high drive*4	—	I_{OH}	—	—	−40	mA
				I_{OL}	—	—	40.0	mA
	Other output pins*5	Low drive*1	—	I_{OH}	—	—	−4.0	mA
				I_{OL}	—	—	4.0	mA
		Middle drive*2	—	I_{OH}	—	—	−8.0	mA
				I_{OL}	—	—	8.0	mA
		High drive*3	—	I_{OH}	—	—	−32	mA
				I_{OL}	—	—	32.0	mA
Permissible output current (max value of total of all pins)	Maximum of all output pins	VCC I/O	1.68 V or above	$\Sigma I_{OH\ (max)}$	—	—	−80	mA
		VCC2 I/O	1.65 V or above		—	—	−80	
		AVCC0 I/O	1.65 V or above		—	—	−33	
		VCC and VCC2 I/O	1.65 V or above	$\Sigma I_{OL\ (max)}$	—	—	80	mA
		AVCC0 I/O	1.65 V or above		—	—	33	

Note 1. This is the value when low driving ability is selected in the Port Drive Capability bit in the PmnPFS register. The selected driving ability except for 400 and P401 is retained in Deep Software Standby mode.
Note 2. This is the value when middle driving ability is selected in the Port Drive Capability bit in the PmnPFS register. The selected driving ability except for 400 and P401 is retained in Deep Software Standby mode.
Note 3. This is the value when high driving ability is selected in the Port Drive Capability bit in the PmnPFS register. The selected driving ability except for 400 and P401 is retained in Deep Software Standby mode.
Note 4. This is the value when high-speed high driving ability is selected in the Port Drive Capability in the PmnPFS register. The selected driving ability is retained in Deep Software Standby mode.
Note 5. Except for P200, which is an input port.

Caution: To protect the reliability of the MCU, the output current values should not exceed the values in this table. The average output current indicates the average value of current measured during 100 µs.

48.2.4 I/O V_{OH}, V_{OL}, and Other Characteristics

Table 48.7 I/O V_{OH}, V_{OL}, and other characteristics (1 of 3)

Parameter		VCC/VCC2/ AVCC0	Symbol	Min	Typ	Max	Unit	Test conditions
Output voltage	IIC	2.70 V or above	V_{OL}	—	—	0.4	V	I_{OL} = 3.0 mA
			V_{OL}	—	—	0.6		I_{OL} = 6.0 mA
		1.68 V or above	V_{OL}	—	—	VCC × 0.2		I_{OL} = 3.0 mA
			V_{OL}	—	—	0.6		I_{OL} = 6.0 mA
	IIC*1	2.70 V or above	V_{OL}	—	—	0.4		I_{OL} = 15.0 mA (ICFER.FMPE = 1)

Table 48.7 I/O V_{OH}, V_{OL}, and other characteristics (3 of 3)

Parameter		VCC/VCC2/ AVCC0	Symbol	Min	Typ	Max	Unit	Test conditions
Pull-up current serving as the SCL current source	I3C*3	3.0 V to 3.6 V	I_{cs}	3	—	12	mA	VCC = 3.0 to 3.6 V V_{in} = 0.3 × VCC to 0.7 × VCC
		1.68 V to 1.95 V						VCC = 1.68 to 1.95 V V_{in} = 0.3 × VCC to 0.7 × VCC
Input capacitance	Ports P014, P015	—	C_{in}	—	—	16	pF	Vbias = 0 V Vamp = 20 mV f = 1 MHz Ta = 25°C
	Ports P814/ USB_DP, P815/ USB_DM	—		—	—	12		
	Ports P400, P401, P409, P410, P511, P512	—		—	—	10		
	Other input pins	—		—	—	8		

Note 1. SCL0_A, SDA0_A, SCL1_A, SDA1_A (total 4 pins).
Note 2. This is the value when high driving ability is selected in the Port Drive Capability bit in the PmnPFS register. The selected driving ability is retained in Deep Software Standby mode.
Note 3. I3C_SCL0 (1 pin). This is the value when IIC high speed mode is selected.

48.2.5 Operating and Standby Current

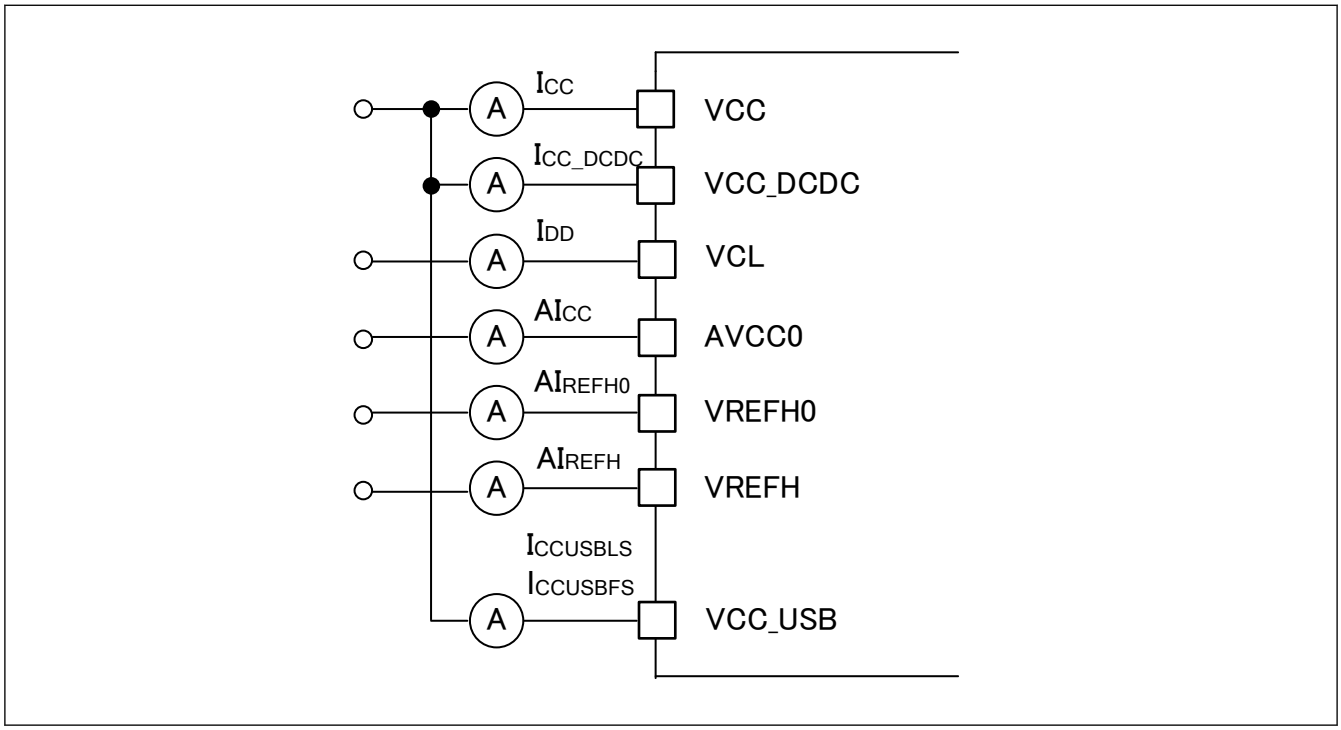

Figure 48.2 Consumption current measurement diagram

Table 48.8 Current of high-speed mode, maximum condition (MVE and peripheral operation) (DCDC mode)

Parameter			Symbol	Typ	Max		Unit	Test conditions
					105℃	125℃		
Supply current *1*2	—		I_{CC}	2.8	7.05	7.19	mA	
	CPUCLK = 480 MHz	VCC_DCDC ≧ 2.5 V	I_{CC_DCDC}*5	159	289	—	mA	VCC_DCDC = 3.3 V CPUCLK = 480 MHz, ICLK = 240 MHz, PCLKA = 120 MHz, PCLKB = 60 MHz, PCLKC = 60 MHz, PCLKD = 120 MHz, PCLKE = 240 MHz, FCLK = 60 MHz, BCLK = 120 MHz
			I_{DD}*3	374	595	—		
		VCC_DCDC < 2.5 V	I_{CC_DCDC}*5	292	320	—		VCC_DCDC = 1.8 V
			I_{DD}	374	400*4	—		
	CPUCLK = 400 MHz	VCC_DCDC ≧ 2.5 V	I_{CC_DCDC}*5	133	255	295	mA	VCC_DCDC = 3.3 V CPUCLK = 400 MHz, ICLK = 200 MHz, PCLKA = 100 MHz, PCLKB = 50 MHz, PCLKC = 50 MHz, PCLKD = 100 MHz, PCLKE = 100 MHz, FCLK = 50 MHz, BCLK = 100 MHz
			I_{DD}*3	312	526	607		
		VCC_DCDC < 2.5 V	I_{CC_DCDC}*5	244	320	320		VCC_DCDC = 1.8 V
			I_{DD}	312	400*4	400*4		
	CPUCLK = 360 MHz	VCC_DCDC ≧ 2.5 V	I_{CC_DCDC}*5	122	243	283	mA	VCC_DCDC = 3.3 V CPUCLK = 360 MHz, ICLK = 120 MHz, PCLKA = 120 MHz, PCLKB = 60 MHz, PCLKC = 60 MHz, PCLKD = 120 MHz, PCLKE = 120 MHz, FCLK = 60 MHz, BCLK = 120 MHz
			I_{DD}*3	287	501	583		
		VCC_DCDC < 2.5 V	I_{CC_DCDC}*5	224	320	320		VCC_DCDC = 1.8 V
			I_{DD}	287	400*4	400*4		
	CPUCLK = 240 MHz	VCC_DCDC ≧ 2.5 V	I_{CC_DCDC}*5	95	210	249	mA	VCC_DCDC = 3.3 V CPUCLK = 240 MHz, ICLK = 240 MHz, PCLKA = 120 MHz, PCLKB = 60 MHz, PCLKC = 60 MHz, PCLKD = 120 MHz, PCLKE = 120 MHz, FCLK = 60 MHz, BCLK = 120 MHz
			I_{DD}*3	224	432	514		
		VCC_DCDC < 2.5 V	I_{CC_DCDC}*5	175	320	320		VCC_DCDC = 1.8 V
			I_{DD}	224	400*4	400*4		

Note 1. Supply current values are with all output pins unloaded and all input pull-up MOSs in the off state.
Note 2. Measured with clocks supplied to the peripheral functions and peripherals being operated. This does not include the BGO operation.
Note 3. I_{DD} depends on f (CPUCLK and ICLK) as follows.
I_{DD} Max. (105℃) = 0.68× f CPUCLK + 0.41 × fICLK + 175 (unit : mA, fCPUCLK and fICLK are MHz)
I_{DD} Max. (125℃) = 0.68 × f CPUCLK + 0.41 × fICLK + 253 (unit : mA, fCPUCLK and fICLK are MHz)
Note 4. Do not actual consumption current during operation exceed the current value described here in VCC_DCDC < 2.5V.
Note 5. Typical DCDC efficiency is applied.

Table 48.9 Current of high-speed mode, maximum condition (MVE and peripheral operation) (External VDD mode)

Parameter	CPUCLK Frequency	Symbol	Typ	Max		Unit	Test conditions
				105℃	125℃		
Supply current*1 *2	—	I_{CC}	2.8	7.05	7.19	mA	
	CPUCLK = 480 MHz	I_{DD}*3	374	595	—	mA	CPUCLK = 480 MHz, ICLK = 240 MHz, PCLKA = 120 MHz, PCLKB = 60 MHz, PCLKC = 60 MHz, PCLKD = 120 MHz, PCLKE = 240 MHz, FCLK = 60 MHz, BCLK = 120 MHz
	CPUCLK = 400 MHz	I_{DD}*3	312	526	607	mA	CPUCLK = 400 MHz, ICLK = 200 MHz, PCLKA = 100 MHz, PCLKB = 50 MHz, PCLKC = 50 MHz, PCLKD = 100 MHz, PCLKE = 100 MHz, FCLK = 50 MHz, BCLK = 100 MHz
	CPUCLK = 360 MHz	I_{DD}*3	287	501	583	mA	CPUCLK = 360 MHz, ICLK = 120 MHz, PCLKA = 120 MHz, PCLKB = 60 MHz, PCLKC = 60 MHz, PCLKD = 120 MHz, PCLKE = 120 MHz, FCLK = 60 MHz, BCLK = 120 MHz
	CPUCLK = 240 MHz	I_{DD}*3	224	432	514	mA	CPUCLK = 240 MHz, ICLK = 240 MHz, PCLKA = 120 MHz, PCLKB = 60 MHz, PCLKC = 60 MHz, PCLKD = 120 MHz, PCLKE = 120 MHz, FCLK = 60 MHz, BCLK = 120 MHz

Note 1. Supply current values are with all output pins unloaded and all input pull-up MOSs in the off state.
Note 2. Measured with clocks supplied to the peripheral functions and peripherals being operated. This does not include the BGO operation.
Note 3. I_{DD} depends on f (CPUCLK and ICLK) as follows.
I_{DD} Max. (105℃) = 0.68 × f CPUCLK + 0.41 × fICLK + 175 (unit : mA, fCPUCLK and fICLK are MHz)
I_{DD} Max. (125℃) = 0.68 × f CPUCLK + 0.41 × fICLK + 253 (unit : mA, fCPUCLK and fICLK are MHz)

Table 48.10 Current of high-speed mode, maximum data processing (MVE operation), peripheral clock ON (DCDC mode)

Parameter		Symbol	Typ	Max		Unit	Test conditions
				105℃	125℃

	CPUCLK = 360 MHz	I_{DD}*3	261	445	528		
	CPUCLK = 240 MHz	I_{DD}*3	194	373	457		

Note 1. Supply current values are with all output pins unloaded and all input pull-up MOSs in the off state.
Note 2. Supply of the clock signal to peripherals is stopped in this state. This does not include the BGO operation.
Note 3. I_{DD} depends on f (CPUCLK and ICLK) as follows.
I_{DD} Max. (105℃) = 0.68 × f CPUCLK + 0.17 × fICLK + 175 (unit : mA, fCPUCLK and fICLK are MHz)
I_{DD} Max. (125℃) = 0.68 × f CPUCLK + 0.17 × fICLK + 253 (unit : mA, fCPUCLK and fICLK are MHz)
Note 4. Same frequency condition is applied as in the maximum condition.

Table 48.14 Current of high-speed mode, CPU Sleep mode (DCDC mode and External VDD mode)

Parameter		Symbol	Typ	Max		Unit	Test conditions
				105℃	125℃		
Supply current*1*3*4	CPUCLK = 240 MHz	I_{DD}*2	29	216	310	mA	—

Note 1. Supply current values are with all output pins unloaded and all input pull-up MOSs in the off state.
Note 2. I_{DD} depends on f (CPUCLK and ICLK) as follows.
I_{DD} Typ. (25℃) = 0.063 × fCPUCLK + 0.13 × fICLK + 17.6 (unit : mA, fCPUCLK and fICLK are MHz)
I_{DD} Max. (105℃) = 0.063 × fCPUCLK + 0.13 × fICLK + 175 (unit : mA, fCPUCLK and fICLK are MHz)
I_{DD} Max. (125℃) = 0.063 × fCPUCLK + 0.13 × fICLK + 253 (unit : mA, fCPUCLK and fICLK are MHz)
Note 3. Supply of the clock signal to peripherals is stopped in this state. This does not include the BGO operation.
Note 4. ICLK, FCLK, BCLK, PCLKA, PCLKB, PCLKC, PCLKD and PCLKE are set to divided by 64.

Table 48.15 Current of high-speed mode, CPU Deep Sleep mode (DCDC mode and External VDD mode)

Parameter		Symbol	Typ	Max		Unit	Test conditions
				105℃	125℃		
Supply current*1*3*4	CPUCLK = 240 MHz	I_{DD}*2	12	85	112	mA	—

Note 1. Supply current values are with all output pins unloaded and all input pull-up MOSs in the off state.
Note 2. I_{DD} depends on f (ICLK) as follows.
I_{DD} Typ. (25℃) = 0.13 × fICLK + 5 (unit : mA, fCPUCLK and fICLK are MHz)
I_{DD} Max. (105℃) = 0.13 × fICLK + 69 (unit : mA, fCPUCLK and fICLK are MHz)
I_{DD} Max. (125℃) = 0.13 × fICLK + 97 (unit : mA, fCPUCLK and fICLK are MHz)
Note 3. Supply of the clock signal to peripherals is stopped in this state. This does not include the BGO operation.
Note 4. ICLK, FCLK, BCLK, PCLKA, PCLKB, PCLKC, PCLKD and PCLKE are set to divided by 64.

Table 48.16 Increase during BGO operation (DCDC mode and External VDD mode)

Parameter		Symbol	Typ	Max		Unit	Test conditions
				105℃	125℃		
Supply current*1	Data flash P/E	I_{CC}	6	—	—	mA	—
	Code flash P/E		8	—	—		

Note 1. Supply current values are with all output pins unloaded and all input pull-up MOSs in the off state.

Table 48.17 Current of Low-speed mode (DCDC mode)

Parameter	Symbol	Typ	Max		Unit	Test conditions
			105℃	125℃		
Supply current*1*2*3	I_{DD}	14.5	—	—	mA	CPUCLK = ICLK = 1MHz

Note 1. Supply current values are with all output pins unloaded and all input pull-up MOSs in the off state.
Note 2. Supply of the clock signal to peripherals is stopped in this state. This does not include the BGO operation.
Note 3. FCLK, BCLK, PCLKA, PCLKB, PCLKC, PCLKD and PCLKE are set to divided by 64 (15.6 kHz).

Table 48.18 Standby current (DCDC mode)

Parameter				Symbol	Typ	Max 125℃	Unit	Test conditions
Supply current*1	Software Standby mode*2			I_{CC}	0.02	0.94	mA	—
	Data of SRAM and TCM is retained			I_{CC_DCDC}	0.88	28.29		VCC_DCDC = 3.3 V PDRAMSCR0.RKEEPn = 1 (n = 0 to 6) PDRAMSCR1.RKEEP0 = 1
	Data of SRAM and TCM is not retained			I_{CC_DCDC}	0.83	26.64		VCC_DCDC = 3.3 V PDRAMSCR0.RKEEPn = 0 (n = 0 to 6) PDRAMSCR1.RKEEP0 = 0
	Deep Software Standby mode 1			I_{CC}	5.21	148	µA	—
				I_{CC_DCDC}	0.57	5.50		
		Increase when the function is activated	Data of Standby SRAM is retained	I_{CC}	0.12	2.60		—
			PVD0, PVD1,PVD2		See Table 48.20			—
			When the LOCO is in use		3.10	—		—
			Crystal oscillator		See Table 48.21			—
			IWDT and ULPT(all units) are operating		0.07	—		—
	Deep Software Standby mode 2			I_{CC}	1.68	43.99		—
				I_{CC_DCDC}	0.57	5.50		
		Increase when the function is activated	PVD0, PVD1,PVD2	I_{CC}	See Table 48.20			—
			Crystal oscillator		See Table 48.21			—
	Deep Software Standby mode 3			I_{CC}	0.99	42.90		—
				I_{CC_DCDC}	0.57	5.50		
		Increase when the function is activated	Crystal oscillator	I_{CC}	See Table 48.21			—

Note 1. Supply current values are with all output pins unloaded and all input pull-up MOSs in the off state.
Note 2. When an external clock is used, EXTAL pin is pull-up or pull-down. In case clock is toggled, software standby mode current consumption is increased by 130µA at 48MHz under typical conditions.

Table 48.19 Coremark and normal mode current (DCDC and External power supply mode)

Parameter			Symbol	Typ	Max	Unit	Test conditions
Supply current*1*2	Coremark	Cache on	I_{DD}	318	—	µA/MHz	CPUCLK = 480 MHz ICLK = 240 MHz PCLKA = 7.5 MHz PCLKB = 7.5 MHz PCLKC = 7.5 MHz PCLKD = 7.5 MHz PCLKE = 7.5 MHz FCLK = 7.5 MHz BCLK = 7.5 MHz
		Cache off, executing from ITCM		281	—		
		Cache off, executing from SRAM		178	—		
		Cache off, executing from flash		169	—		
	Normal mode	All peripheral disabled, Cache on, while (1) code		223	—		
		All peripheral disabled, Cache off, while (1) code executing from flash		138	—		
	Coremark	Cache off, executing from flash		165	—	µA/MHz	CPUCLK = 360 MHz ICLK = 120 MHz PCLKA = 30 MHz PCLKB = 30 MHz PCLKC = 30 MHz PCLKD = 30 MHz PCLKE = 30 MHz FCLK = 30 MHz BCLK = 30 MHz
	Normal mode	All peripheral disabled, Cache off, while (1) code executing from flash		137	—		

Note 1. Supply current values are with all output pins unloaded and all input pull-up MOSs in the off state.
Note 2. Supply of the clock signal to peripherals is stopped in this state. This does not include the BGO operation.

Table 48.20 Increase when the PVD0, PVD1, or PVD2 is enabled in Deep Software Standby mode 1 and 2.

Parameter		Symbol	Typ	Max 125℃	Unit	Test conditions
Supply current	Common circuit when enabling PVDn (n = 0 to 2) in Deep Software Standby mode 1	I_{CC}	4.51	—	µA	—
	Common circuit when enabling PVDn (n = 0 to 2) in Deep Software Standby mode 2		4.97	—		—
	PVD0 enabled with OFS1(_SEC).PVDLPSEL = 1		2.16	—		—
	PVD1 enabled		2.16	—		—
	PVD2 enabled		2.16	—		—

Table 48.21 Increase when the sub-clock oscillator is enabled in Deep Software Standby mode 1, 2 and 3.

Parameter			Symbol	Typ	Max 125℃	Unit	Test conditions
Supply current	When a crystal oscillator is in use	Low Power mode 3	I_{CC}	0.22	—	µA	—
		Low Power mode 2		0.27	—		—
		Low Power mode 1		0.34	—		—
		Standard mode		0.67	—		—

Table 48.22 Inrush current

Parameter				Symbol	Typ	Max 125℃	Unit	Test conditions
Supply current	Inrush current on returning from deep software standby mode	Inrush current of VCC_DCDC*1	DPSBYCR.DCSSMODE = 0	I_{RUSH}	—	630	mA	—
			DPSBYCR.DCSSMODE = 1		—	1020		—

Note 1. Reference value

Table 48.23 Operating current (Analog)

Parameter				Symbol	Typ	Max 125 ℃	Unit	Test conditions
Supply current*1	Oscillator	Main clock oscillator		I_{CC}	0.48	—	mA	MOMCR.MODRV0[2:0] = 000b
					0.58	—	mA	MOMCR.MODRV0[2:0] = 011b
					0.90	—	mA	MOMCR.MODRV0[2:0] = 101b
	Analog power supply current	During 12-bit A/D conversion		AI_{CC}	0.8	1.1	mA	—
		During 12-bit A/D conversion with S/H amp			2.3	3.3	mA	—
		ACMPHS(1unit)			100	150	μA	—
		Temperature sensor			0.1	0.2	mA	—
		During D/A conversion(per unit)	Without AMP output		0.1	0.2	mA	—
			With AMP output		0.8	1.6	mA	—
		Waiting for A/D, D/A conversion (all units)			0.9	1.6	mA	—
		ADC12, DAC12 in standby modes (all units)*2			2	8	μA	—

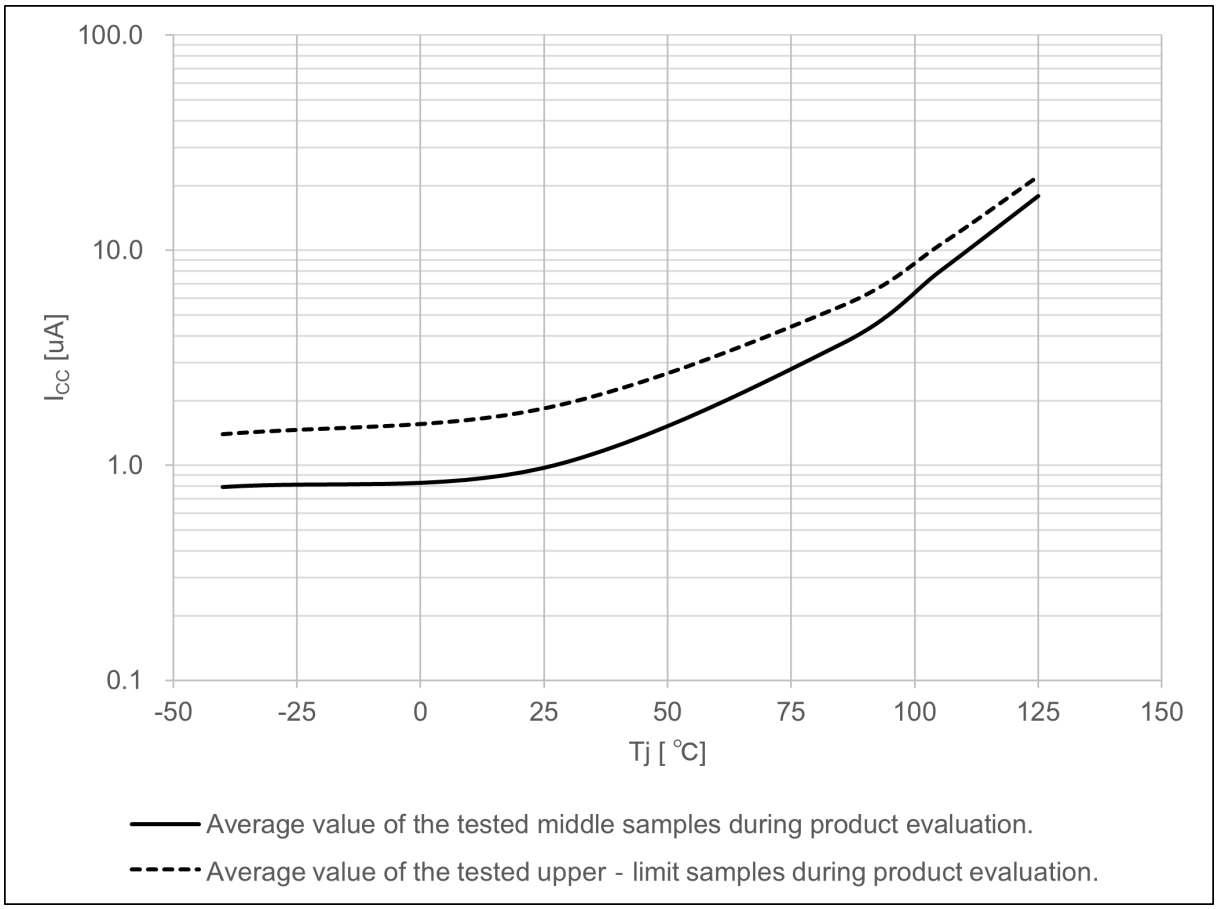

Figure 48.7 Temperature dependency in Deep Software Standby mode 3 (reference data)

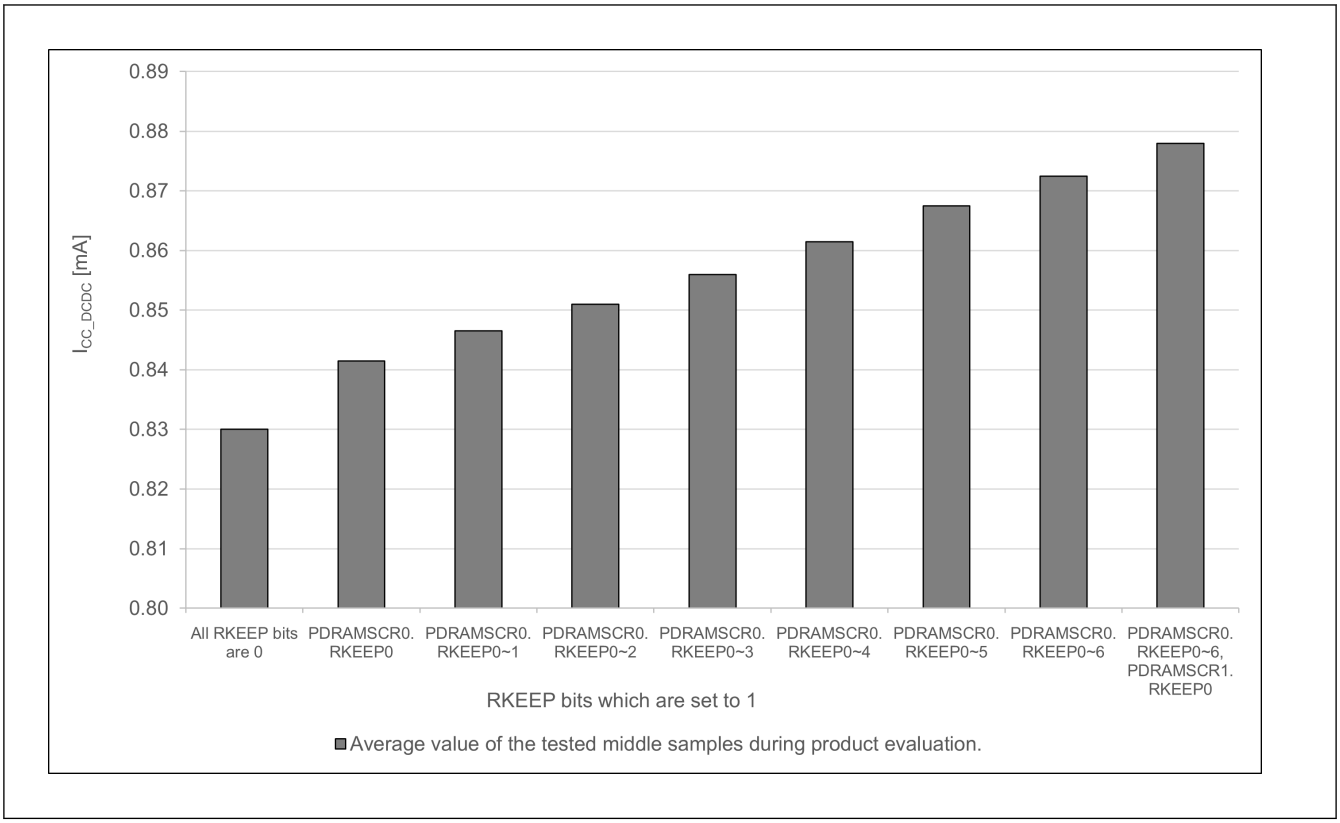

Figure 48.8 Software Standby current per SRAM state (reference data)

The more practical I_{CC_DCDC} value can be obtained with the following formula.

$I_{CC_DCDC} = I_{DD} \times (VCL \div VCC) \div efficiency$

Where: VCL and VCC are the voltage of VCL pin and VCC pin respectively, and efficiency is shown in the following figures.

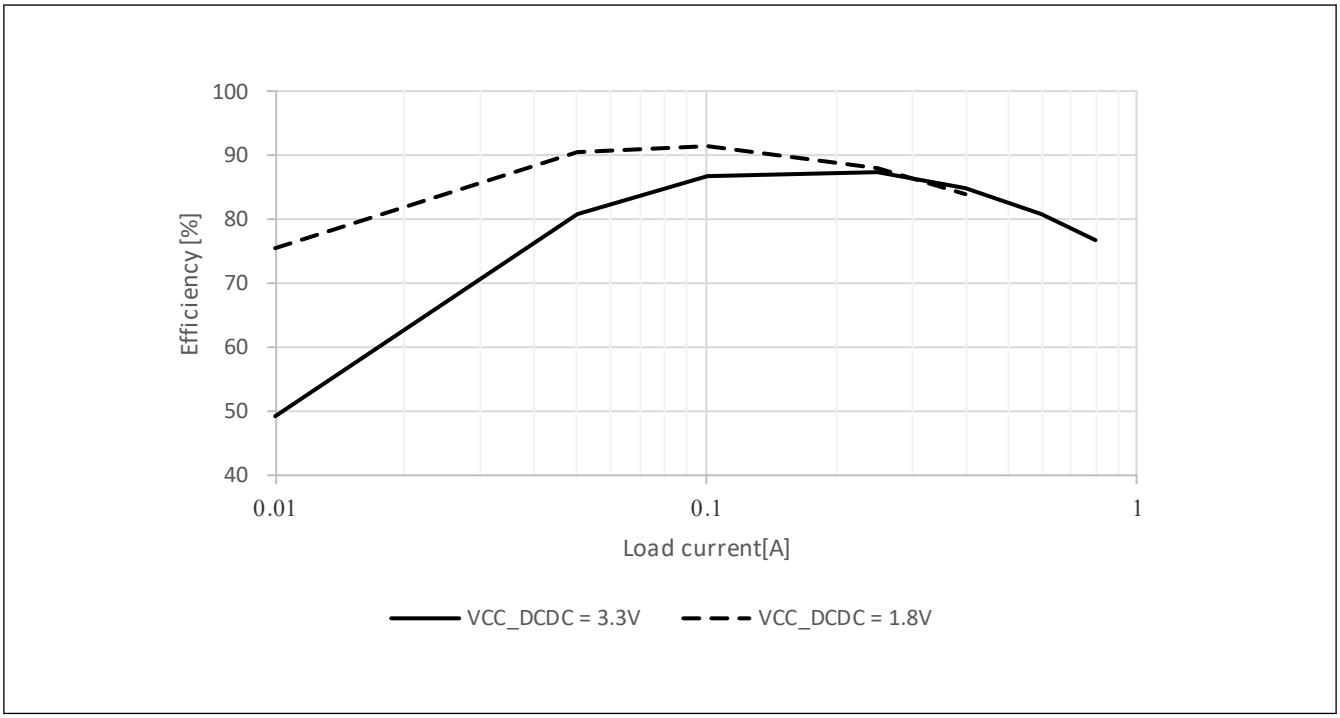

Figure 48.9 Typical DCDC efficiency (%) vs load current (A) in High-speed mode , Tj = 25℃

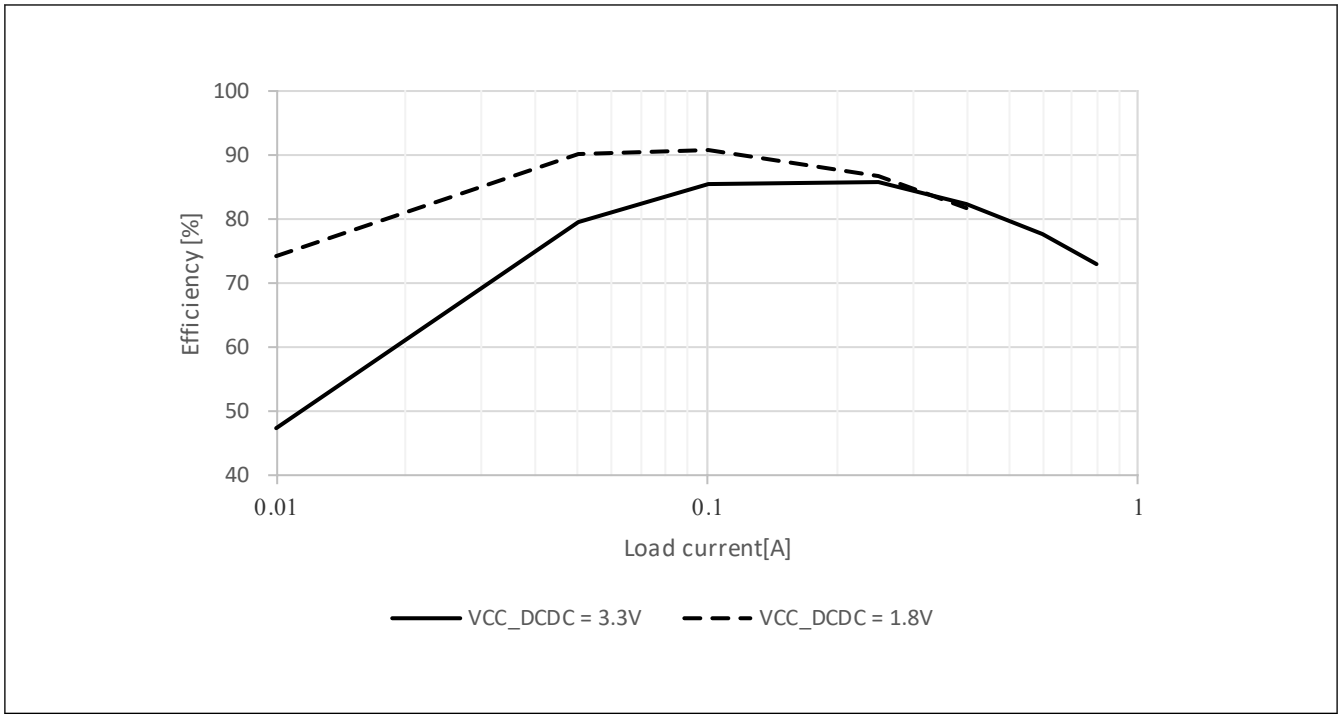

Figure 48.10 Typical DCDC efficiency (%) vs load current (A) in High-speed mode , Tj = 125℃

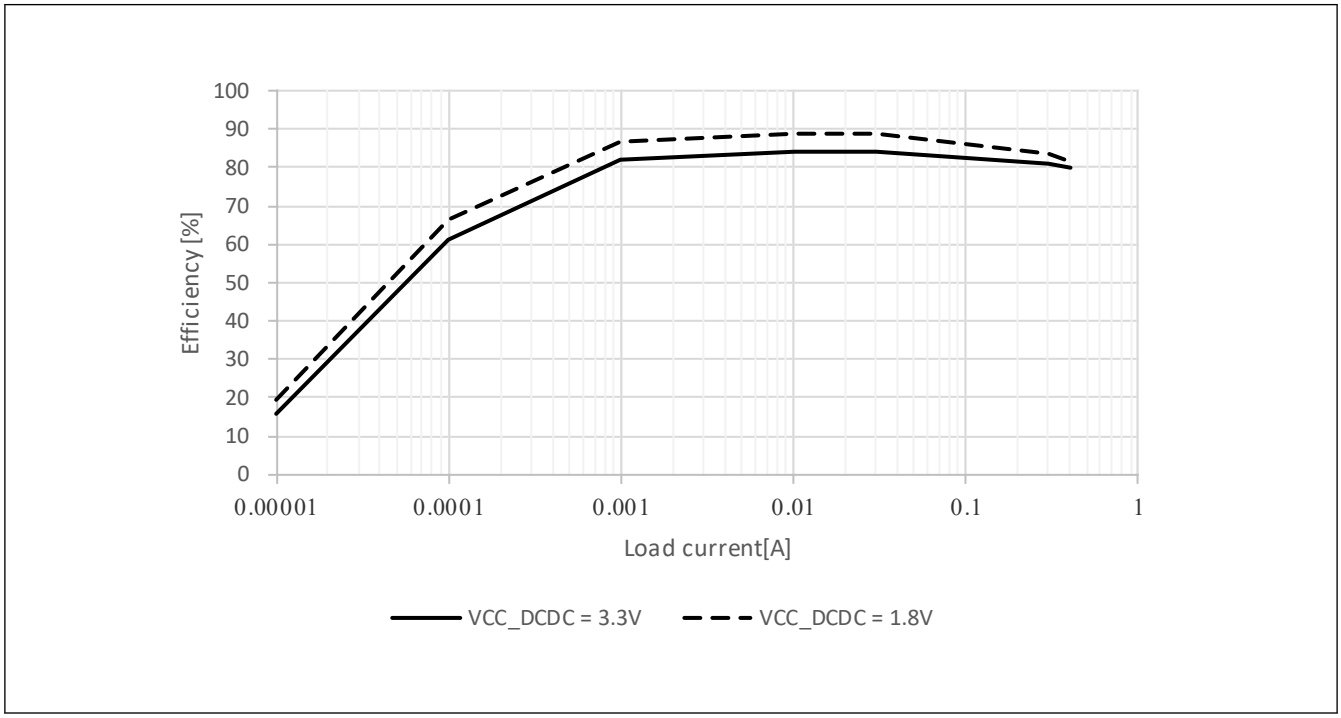

Figure 48.11 Typical DCDC efficiency (%) vs load current (A) in Low-speed mode and Software Standby mode, Tj = 25℃

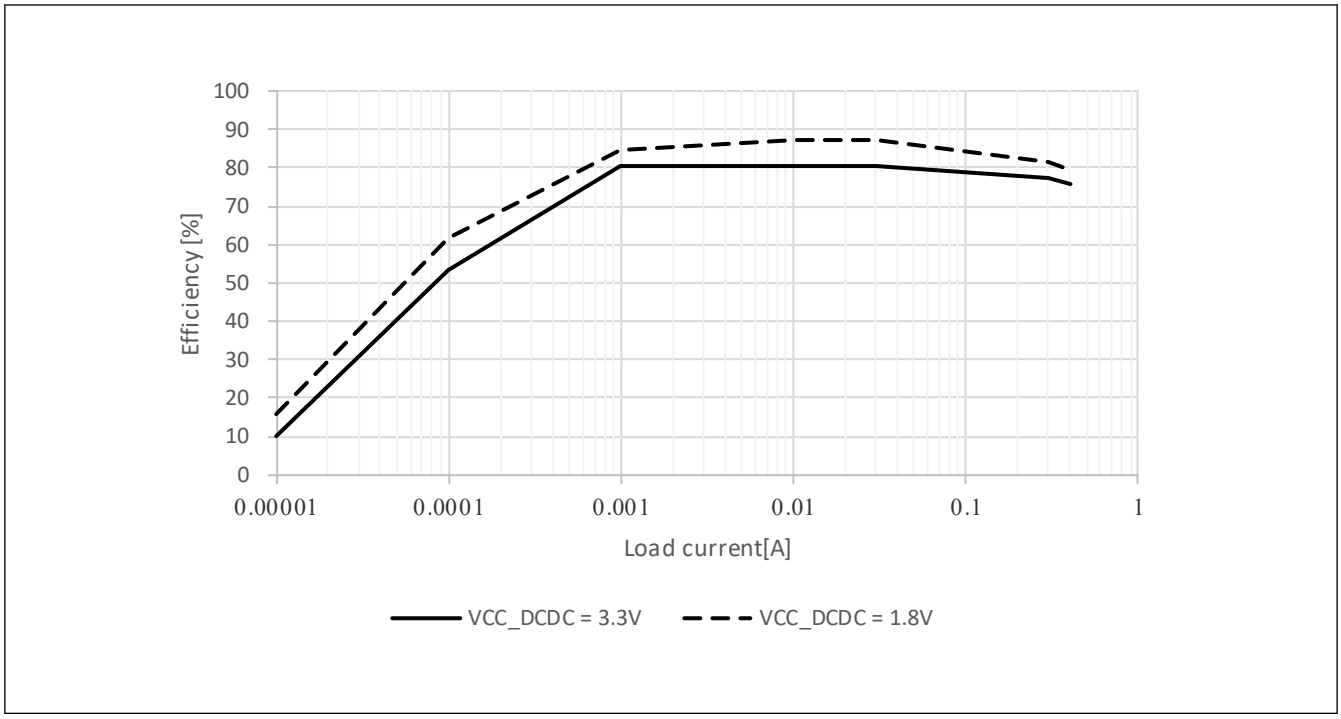

Figure 48.12 Typical DCDC efficiency (%) vs load current (A) in Low-speed mode and Software Standby mode, Tj = 125℃

Note: DCDC efficiency is obtained based on the VCC_DCDC current.

48.2.6 VCC Rise and Fall Gradient and Ripple Frequency

Table 48.24 VCC rise and fall gradient characteristics at power on/off

Parameter	Symbol	Min	Typ	Max	Unit	Test conditions
VCC rising gradient at power on*1	SrVCC	0.0084	—	20	ms/V	—
VCC falling gradient at power off*1	SfVCC1	0.0084	—	—	ms/V	—

Note 1. In case the VCC voltage crosses V_{POR1}.

Table 48.25 VCC ripple frequency and gradient characteristics during operation

The ripple voltage must meet the allowable ripple frequency $f_{r(VCC)}$ within the range between the VCC upper limit (3.6 V) and lower limit (1.68 V). When the VCC change exceeds VCC ±10%, the allowable voltage change rising and falling gradient dt/dVCC must be met.

Parameter	Symbol	Min	Typ	Max	Unit	Test conditions
Allowable ripple frequency	$f_{r\ (VCC)}$	—	—	10.0	kHz	Figure 48.13 $V_{r\ (VCC)} \leq VCC \times 0.2$
		—	—	1.0	MHz	Figure 48.13 $V_{r\ (VCC)} \leq VCC \times 0.08$
		—	—	10.0	MHz	Figure 48.13 $V_{r\ (VCC)} \leq VCC \times 0.06$
Allowable voltage change rising and falling gradient	dt/dVCC*1	1.0	—	—	ms/V	When VCC change exceeds VCC ±10%

Note 1. In case the VCC voltage does not cross V_{POR1}.

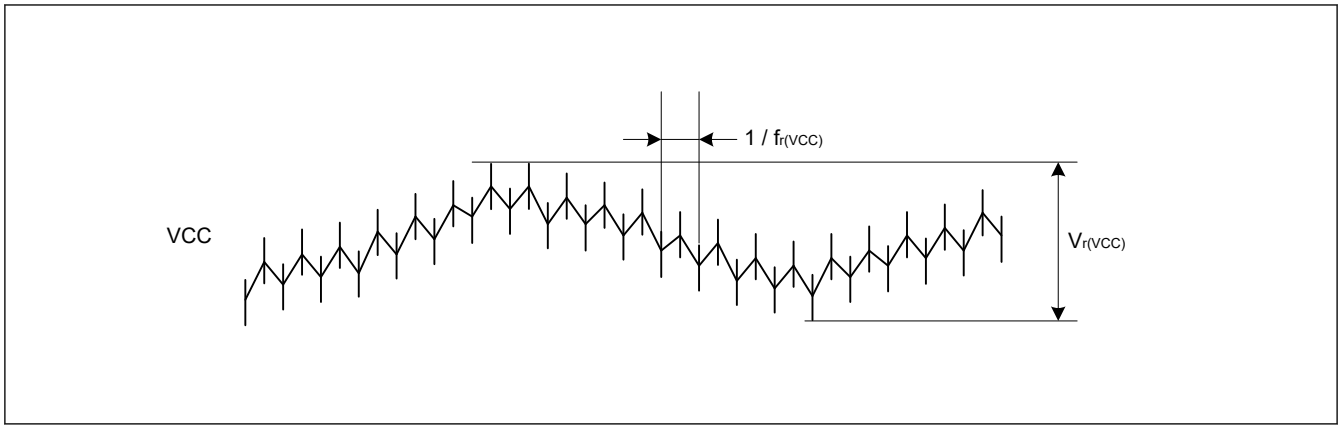

Figure 48.13 Ripple waveform

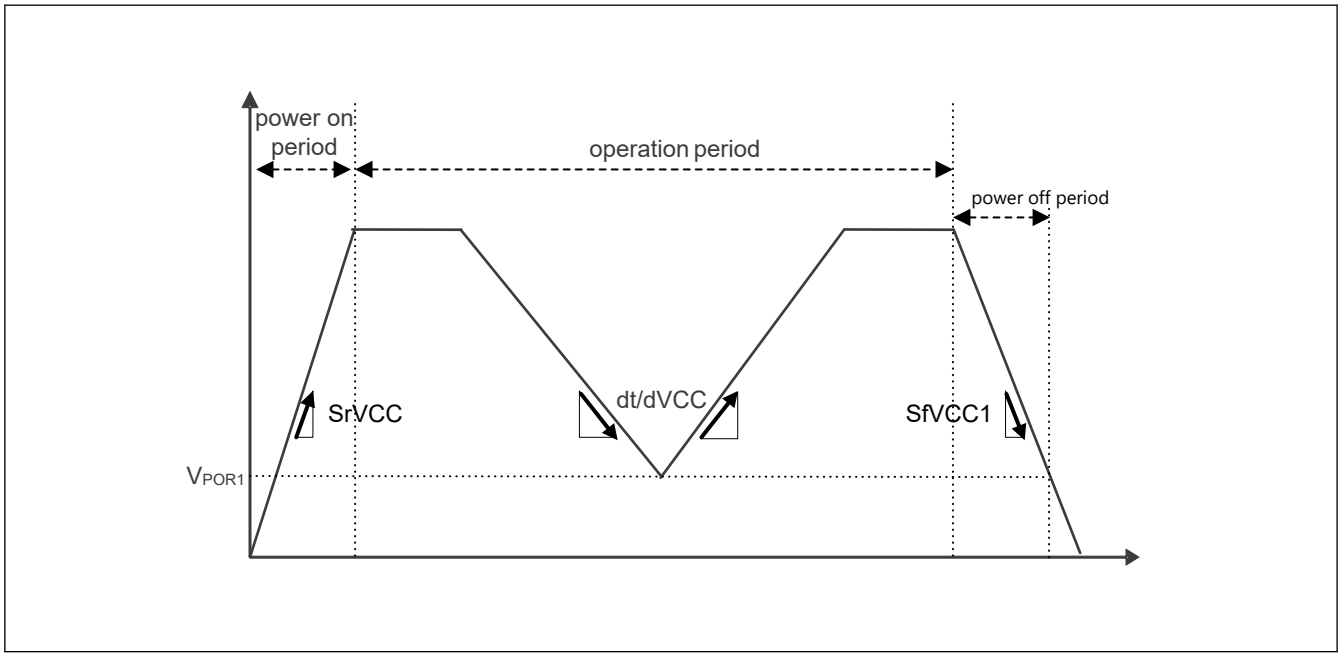

Figure 48.14 VCC rising and falling waveform

48.2.7 Thermal Characteristics

Maximum value of junction temperature (Tj) must not exceed the value of section 48.2.1. Tj/Ta Definition.

Tj is calculated by either of the following equations.

- Tj = Ta + θja × Total power consumption
- Tj = Tt + Ψjt × Total power consumption
  - Tj : Junction Temperature (°C)
  - Ta : Ambient Temperature (°C)
  - Tt : Top Center Case Temperature (°C)
  - θja : Thermal Resistance of “Junction”-to-“Ambient” (°C/W)
  - Ψjt : Thermal Resistance of “Junction”-to-“Top Center Case” (°C/W)
- Total power consumption = Voltage × (Leakage current + Dynamic current)
- Leakage current of IO = Σ (I_{OL} × V_{OL}) /Voltage + Σ (|I_{OH}| × |VCC – V_{OH}|) /Voltage
- Dynamic current of IO = Σ IO (C_{in} + C_{load}) × IO switching frequency × Voltage
  - C_{in}: Input capacitance

– C_{load}: Output capacitance

Regarding θja and Ψjt, see Table 48.26.

Table 48.26 Thermal Resistance

Parameter	Package	Symbol	Value*1	Unit	Test conditions
Thermal Resistance	100-pin LQFP (PLQP0100KP-A)	θja	32.9	°C/W	JESD 51-2 and 51-7 compliant
	144-pin LQFP (PLQP0144KA-B)		31.7		
	176-pin LQFP (PLQP0176KJ-A)		32.0		
	224-pin BGA (PLBG0224GD-A)		21.5		JESD 51-2 and 51-9 compliant
	100-pin LQFP (PLQP0100KP-A)	Ψjt	0.42	°C/W	JESD 51-2 and 51-7 compliant
	144-pin LQFP (PLQP0144KA-B)		0.40		
	176-pin LQFP (PLQP0176KJ-A)		0.42		
	224-pin BGA (PLBG0224GD-A)		0.24		JESD 51-2 and 51-9 compliant

Note 1. The values are reference values when the 4-layer board is used. Thermal resistance depends on the number of layers or size of the board. For details, see the JEDEC standards.

48.2.7.1 Calculation guide of maximum current

Table 48.27 Power consumption of each unit (1 of 2)

Dynamic current/ Leakage current	MCU Domain	Category	Item	Symbol	Frequency [MHz]	Current [uA/MHz]	Current*1 [mA]	Condition
Leakage current	Analog	Regulator and Leak*1	Tj = 95°C	I_{CC}	—	—	0.54	—
			Tj = 105°C		—	—	0.64

Note 1. Regulator and Leak are Internal voltage regulator's current and MCU's leakage current.
It is selected according to the temperature of Tj.
Note 2. To determine the current consumption per channel or unit, divide Current [mA] by the number of channels, groups or units.

Table 48.28 Outline of operation for each unit (1 of 2)

Peripheral	Outline of operation
GPT	Operating modes is set to saw-wave PWM mode.
POEG	Only clear module stop bit.
AGT	AGT is operating with PCLKB.
ULPT	ULPT is operating with LOCO.

Table 48.28 Outline of operation for each unit (2 of 2)

Peripheral	Outline of operation
WDT	WDT is operating with PCLKB.
IWDT	IWDT is operating with IWDTCLK.
ETHERC	Operation modes is set to full-duplex mode. ETHERC is operating using Reduced Media Independent Interface (RMII).
USBFS	Transfer types is set to bulk transfer. USBFS is operating using Full-speed transfer (12 Mbps).
SCI	SCI is transmitting data in clock synchronous mode.
IIC	Communication format is set to I2C-bus format. IIC is transmitting data in master mode.
I3C	Communication format is set to I3C SDR format. I3C is transmitting data in master mode (12.5MHz).
CANFD	CANFD is transmitting and receiving data in self-test mode 1.
SPI	SPI mode is set to SPI operation (4-wire method). SPI master/slave mode is set to master mode. SPI is transmitting 32-bit width data.
SDHI	Transfer bus mode is set to 8-bit wide bus mode. SDHI is issuing CMD24 (single-block write).
ADC	Resolution is set to 12-bit accuracy. Data registers is set to A/D-converted value addition mode. ADC12 is converting the analog input in continuous scan mode.
DAC12	DAC12 is outputting the conversion result while updating the value of data register.
TSN	TSN is operating.
ACMPHS	ACMPHS is operating.
ELC	Only clear module stop bit.
RSIP-E51A	RSIP is doing self-test operation.
CRC	CRC is generating CRC code using 32-bit CRC32-C polynomial.
DOC	DOC is operating in data comparison mode.
CAC	Measurement target clocks is set to PCLKB. Measurement reference clocks is set to PCLKB. CAC is measuring the clock frequency accuracy.
DMAC	Bit length of transfer data is set to 32 bits. Transfer mode is set to block transfer mode. DMAC is transferring data from SRAM0 to SRAM0.
DTC	Bit length of transfer data is set to 32 bits. Transfer mode is set to block transfer mode. DTC is transferring data from SRAM0 to SRAM0.

48.2.7.2 Example of Tj calculation

Assumption :

- Package 224-pin BGA : θja = 21.5 °C/W
- Ta = 80 °C
- $I_{CC} + I_{CC_DCDC}$ = 240 mA
- VCC = 3.5 V (VCC = VCC2 = AVCC0 = VCC_USB)
- I_{OH} = 1 mA, V_{OH} = VCC – 0.5 V, 12 Outputs
- I_{OL} = 20 mA, V_{OL} = 1.0 V, 8 Outputs
- I_{OL} = 1 mA, V_{OL} = 0.5 V, 12 Outputs
- C_{in} = 8 pF, 32 pins, Input frequency = 10 MHz
- C_{load} = 30 pF, 32 pins, Output frequency = 10 MHz

Static current of IO = Σ (VOL × IOL) / Voltage + Σ ((VCC - VOH) × IOH) / Voltage

= (20 mA × 1 V) × 8 / 3.5 V + (1 mA × 0.5 V) × 12 / 3.5 V + ((VCC - (VCC - 0.5 V)) × 1 mA) × 12 / 3.5 V

= 45.7 mA + 1.71 mA + 1.71 mA

= 49.1 mA

Dynamic current of IO = Σ IO (Cin + Cload) × IO switching frequency × Voltage

= ((8 pF × 32) × 10 MHz + (30 pF × 32) × 10 MHz) × 3.5 V

= 42.6 mA

Total power consumption = Voltage × (Static current + Dynamic current)

= (240 mA × 3.5 V) + (49.1 mA + 42.6 mA) × 3.5 V

= 1161 mW (1.161 W)

Tj = Ta + θja × Total power consumption

= 80 °C + 21.5 °C/W × 1.161W

= 105.0 °C

48.3 AC Characteristics

48.3.1 Frequency

Table 48.29 Operation frequency value in high-speed mode

Parameter			Symbol	Min	Typ	Max	Unit
Operation frequency	CPU clock (CPUCLK)*2	DCDC, BGA package, Tj ≤ 105℃*4	f	—	—	480	MHz
		DCDC, BGA package, Tj ≤ 125℃*4		—	—	400	
		External VDD, BGA package, Tj ≤ 105℃		—	—	480	
		External VDD, BGA package, Tj ≤ 125℃		—	—	400	
		DCDC, 176-pin and 144-pin LQFP package, Tj ≤ 125℃*4		—	—	400	
		External VDD, 176-pin and 144-pin LQFP package, Tj ≤ 125℃		—	—	400	
		DCDC, 100-pin LQFP package, Tj ≤ 105℃*4		—	—	360	
		DCDC, 100-pin LQFP package, Tj ≤ 125℃*4		—	—	240	
		External VDD, 100-pin LQFP package, Tj ≤ 105℃		—	—	360	
		External VDD, 100-pin LQFP package, Tj ≤ 125℃		—	—	240	
	System clock (ICLK)*2			—	—	240	
	Peripheral module clock (PCLKA)*2			—	—	120	
	Peripheral module clock (PCLKB)*2			—	—	60	
	Peripheral module clock (PCLKC)*2			—*3	—	60	
	Peripheral module clock (PCLKD)*2			—	—	120	
	Peripheral module clock (PCLKE)*2			—	—	240	
	Flash interface clock (FCLK)*2			—*1	—	60	
	External bus clock (BCLK)*2	VCC ≥ 2.7 V		—	—	120	
		VCC ≥ 1.68 V		—	—	60	
	EBCLK pin output	VCC ≥ 2.7 V		—	—	60	
		VCC ≥ 1.68 V		—	—	30	
	SDCLK pin output	VCC ≥ 3.0 V		—	—	120	
	SCI clock (SCICLK)			—	—	120	
	SPI clock (SPICLK)			—	—	120	
	CANFD core clock (CANFDCLK)			—	—	80	
	USB clock (USBCLK)			—	—	48	
	I3C clock (I3CCLK)			—	—	200	

Note 1. FCLK must run at a frequency of at least 4 MHz when programming or erasing the flash memory.
Note 2. See section 8, Clock Generation Circuit for the relationship between the CPUCLK, ICLK, PCLKA, PCLKB, PCLKC, PCLKD, PCLKE, FCLK, and BCLK frequencies.
Note 3. When the ADC12 is used, the PCLKC frequency must be at least 1 MHz.

Note 4. When DCDC is used with VCC_DCDC < 2.5V, I_{DD} current must be less than the value specified in operating current. Please see Table 48.8.

Table 48.30 Operation frequency value in low-speed mode

Parameter			Symbol	Min	Typ	Max	Unit
Operation frequency	CPU clock (CPUCLK)*2		f	—	—	1	MHz
	System clock (ICLK)*2			—	—	1	
	Peripheral module clock (PCLKA)*2			—	—	1	
	Peripheral module clock (PCLKB)*2			—	—	1	
	Peripheral module clock (PCLKC)*2			—*3	—	1	
	Peripheral module clock (PCLKD)*2			—	—	1	
	Peripheral module clock (PCLKE)*2			—	—	1	
	Flash interface clock (FCLK) *2			—*1	—	1	
	External bus clock (BCLK)*2			—	—	1	
	EBCLK pin output			—	—	1	
	SDCLK pin output	VCC ≥ 3.0 V		—	—	1	
	SCI clock (SCICLK)			—	—	1	
	SPI clock (SPICLK)			—	—	1	
	CANFD core clock (CANFDCLK)			—	—	1	
	USB clock (USBCLK)			—	—	1	
	I3C clock (I3CCLK)			—	—	1	

Note 1. Programming or erasing the flash memory is disabled in low-speed mode.
Note 2. See section 8, Clock Generation Circuit for the relationship between the CPUCLK, ICLK, PCLKA, PCLKB, PCLKC, PCLKD, PCLKE, FCLK, and BCLK frequencies.
Note 3. When the ADC12 is used, the PCLKC frequency must be at least 1 MHz.

48.3.2 Clock Timing

Table 48.31 Clock timing except for sub-clock oscillator (1 of 2)

Parameter		Symbol	Min	Typ	Max	Unit	Test conditions
EBCLK pin output cycle time	VCC = 2.70 V or above	t_{Bcyc}	16.6	—	—	ns	Figure 48.15

		f_{HOCO48}	47.880	48.000	48.120		
HOCO clock oscillation stabilization wait time*2		t_{HOCOWT}	—	—	64.7	µs	—
HOCO stop width time		$t_{HOCOSTP}$	1	—	—	µs	Figure 48.21
HOCO period jitter		Jitter	-3	—	3	%	—
FLL stabilization wait time		t_{FLLWT}	—	—	1.8	ms	—
PLL1/PLL2 VCO frequency		f_{VCO}	640	—	1440.0	MHz	—
PLL1/PLL2 Output frequency for output clock P		t_{PLL}	40	—	480	MHz	—
PLL1/PLL2 Output frequency for output clock Q, R		t_{PLL}	71	—	480	MHz	—
PLL1/PLL2 clock oscillation stabilization wait time		t_{PLLWT}	—	—	40	µs	Figure 48.19
PLL1/PLL2 period jitter		—	—	—	±70	ps	—
PLL1/PLL2 long term jitter		—	—	—	±300	ps	Term: 1 µs, 10 µs

Note 1. When setting up the main clock oscillator, ask the oscillator manufacturer for an oscillation evaluation, and use the results as the recommended oscillation stabilization time. Set the MOSCWTCR register to a value equal to or greater than the recommended value.
After changing the setting in the MOSCCR.MOSTP bit to start main clock operation, read the OSCSF.MOSCSF flag to confirm that it is 1, and then start using the main clock oscillator.

Note 2. This is the time from release from reset state until the HOCO oscillation frequency (f_{HOCO}) reaches the range for guaranteed operation.

Table 48.32 Clock timing for the sub-clock oscillator

Parameter	Symbol	Min	Typ	Max	Unit	Test conditions
Sub-clock frequency	f_{SUB}	—	32.768	—	kHz	—
Sub-clock oscillation stabilization wait time	$t_{SUBOSCWT}$	—	—	—*1	s	Figure 48.20

Note 1. When setting up the sub-clock oscillator, ask the oscillator manufacturer for an oscillation evaluation and use the results as the recommended oscillation stabilization time.
After changing the setting in the SOSCCR.SOSTP bit to start sub-clock operation, only start using the sub-clock oscillator after the sub-clock oscillation stabilization time elapses with an adequate margin. A value that is two times the value shown is recommended.

			Fast		—	0.33	0.50	ms	
		DPSWCR.WSTS = 0x9A	Standard		—	1.60	2.00	ms	
			Fast		—	1.20	1.50	ms	
	Deep Software Standby mode 3		Standard		—	2.10	3.50	ms	
			Fast		—	1.70	2.90	ms	
Wait time after cancellation of Deep Software Standby mode			—	t_{DSBYWT}	47.7	—	64.6	µs	

Note 1. When the frequency of the crystal is 48 MHz (Main Clock Oscillator Wait Control Register (MOSCWTCR) is set to 0x05) and the greatest value of the internal clock division setting is 1.
Note 2. When the frequency of PLL1P is 480 MHz (Main Clock Oscillator Wait Control Register (MOSCWTCR) is set to 0x05) and the greatest value of the internal clock division setting is 8.
Note 3. When the frequency of the external clock is 48 MHz (Main Clock Oscillator Wait Control Register (MOSCWTCR) is set to 0x00) and the greatest value of the internal clock division setting is 1.
Note 4. When the frequency of PLL1P is 480 MHz (Main Clock Oscillator Wait Control Register (MOSCWTCR) is set to 0x00) and the greatest value of the internal clock division setting is 8.
Note 5. The Sub-clock oscillator frequency is 32.768 kHz and the greatest value of the internal clock division setting is 1.
Note 6. The HOCO frequency is 20 MHz and the greatest value of the internal clock division setting is 1.
Note 7. The PLL frequency is 480 MHz and the greatest value of the internal clock division setting is 8.
Note 8. The MOCO frequency is 8 MHz and the greatest value of the internal clock division setting is 1.
Note 9. For details, see SSCR1.SS1FR, DPSBYCR.DCSSMODE bits in the section 10, Low Power Modes.
Note 10. The recovery time can be calculated with the equation of t_{Common} + max(t_{OSCSTB}, t_{PG1}, t_{PGCK}) + max(t_{PG2}, t_{LPW}). And they can be determined with the following values and equations. For n, the greatest value is selected from among the internal clock(CPUCLK, ICLK, PCLKm, FCLK, BCLK and EBCLK) division settings (m = A to E).
t_{OSCSTB} in the table below means the time when each oscillator is active. When multiple oscillators are active, t_{OSCSTB} is determined by the longest t_{OSCSTB} among the active oscillators.
Note 11. The ICLK frequency is 240 MHz. This recovery time corresponds to t_{PG2}.

Table 48.35 Each element of recovery time

Wakeup time	Oscillation keep	Fast return function	Typ						Max						Unit
			t_{Common}	t_{OSCSTB} *1	t_{PG1}	t_{PGCK}	t_{PG2}	t_{LPW}	t_{Common}	t_{OSCSTB} *1	t_{PG1}	t_{PGCK}	t_{PG2}	t_{LPW}

48.3.5 NMI and IRQ Noise Filter

Table 48.36 NMI and IRQ noise filter

Parameter	Symbol	Min	Typ	Max	Unit	Test conditions	
NMI pulse width	t_{NMIW}	200	—	—	ns	NMI digital filter disabled	$t_{Pcyc} \times 2 \leq 200$ ns
		$t_{Pcyc} \times 2$*1	—	—			$t_{Pcyc} \times 2 > 200$ ns
		200	—	—		NMI digital filter enabled	$t_{NMICK} \times 3 \leq 200$ ns
		$t_{NMICK} \times 3.5$*2	—	—			$t_{NMICK} \times 3 > 200$ ns
IRQ pulse width	t_{IRQW}	200	—	—	ns	IRQ digital filter disabled	$t_{Pcyc} \times 2 \leq 200$ ns
		$t_{Pcyc} \times 2$*1	—	—			$t_{Pcyc} \times 2 > 200$ ns
		200	—	—		IRQ digital filter enabled	$t_{IRQCK} \times 3 \leq 200$ ns
		$t_{IRQCK} \times 3.5$*3	—	—			$t_{IRQCK} \times 3 > 200$ ns

Note: 200 ns minimum in Software Standby mode.
Note: If the system clock source is switched, add 4 clock cycles of the switched source.
Note 1. t_{Pcyc} indicates the PCLKB cycle.
Note 2. t_{NMICK} indicates the cycle of the NMI digital filter sampling clock.
Note 3. t_{IRQCK} indicates the cycle of the IRQi digital filter sampling clock.

48.3.6 Bus Timing

Table 48.37 Bus timing (1 of 2)

Condition 1: When using the CS area controller (CSC).
VCC = VCC_DCDC = VCC_USB = 1.68 V to 3.6 V, VCC2 = 1.65 V to 3.6 V
BCLK = 8 to 120 MHz, EBCLK = 8 to 60 MHz (When VCC = VCC_USB = 2.70 to 3.6 V)
BCLK = 8 to 60 MHz, EBCLK = 8 to 30 MHz (When VCC = VCC_USB = 1.68 to 3.6 V)
Output load conditions: VOH = VCC × 0.5, VOL = VCC × 0.5, C = 30 pF
EBCLK: High drive output is selected in the port drive capability bit in the PmnPFS register.
Others: Middle drive output is selected in the port drive capability bit in the PmnPFS register.

Condition 2: When using the SDRAM area controller (SDRAMC).
BCLK = SDCLK = 8 to 120 MHz
VCC = VCC2 = VCC_DCDC = VCC_USB = 3.0 to 3.6 V
Output load conditions: VOH = VCC × 0.5, VOL = VCC × 0.5, C = 15 pF
SDCLK: High-speed high drive output is selected in the port drive capability bit in the PmnPFS register.
Others: High drive output is selected in the port drive capability bit in the PmnPFS register.

Condition 3: When using the SDRAM area controller (SDRAMC) and CS area controller (CSC) simultaneously.
BCLK = SDCLK = 8 to 60 MHz
VCC = VCC2 = VCC_DCDC = VCC_USB = 3.0 to 3.6 V
Output load conditions: VOH = VCC × 0.5, VOL = VCC × 0.5, C = 15 pF
EBCLK/SDCLK: High drive output is selected in the port drive capability bit in the PmnPFS register.
Others: Middle drive output is selected in the port drive capability bit in the PmnPFS register.

Parameter		Symbol	Min	Max	Unit	Test conditions
Address delay	2.70V or above	t_{AD}	1.0	12.5	ns	Figure 48.28 to Figure 48.34

48.3.7 I/O Ports, POEG, GPT, AGT, ULPT and ADC12 Trigger Timing

Table 48.38 I/O ports, POEG, GPT, AGT, ULPT and ADC12 trigger timing (1 of 3)

GPT Conditions:
Middle drive output is selected in the Port Drive Capability bit in the PmnPFS register.
If GPT pins are specified across the VCC I/O and VCC2 I/O, characteristics below is guaranteed only when VCC = VCC2.
AGT Conditions:
Middle drive output is selected in the Port Drive Capability bit in the PmnPFS register.

Parameter		Symbol	Min	Max	Unit	Test conditions
I/O ports	Input data pulse width	t_{PRW}	5.5	—	t_{Icyc}	Figure 48.42
	EXCIN input frequency	t_{EXCIN}	—	36	kHz	
POEG	POEG input trigger pulse width	t_{POEW}	3	—	t_{Pcyc}	Figure 48.43

Table 48.38 I/O ports, POEG, GPT, AGT, ULPT and ADC12 trigger timing (2 of 3)

GPT Conditions:
Middle drive output is selected in the Port Drive Capability bit in the PmnPFS register.
If GPT pins are specified across the VCC I/O and VCC2 I/O, characteristics below is guaranteed only when VCC = VCC2.
AGT Conditions:
Middle drive output is selected in the Port Drive Capability bit in the PmnPFS register.

Parameter			Symbol	Min	Max	Unit	Test conditions
GPT	Input capture pulse width (Cycle)	Single edge	t_{GTICW}*1	1.5	—	t_{PDcyc}	Figure 48.44
		Dual edge		2.5	—		
	Input capture pulse width (Time)	2.70V or above	t_{GTICW}*1	12.5	—	ns	
		1.68V or above (VCC) 1.65V or above (VCC2)		25.0	—		
	GTIOCxY output skew (x = 0 to 7, Y = A or B)	2.70V or above	t_{GTISK}	—	4	ns	Figure 48.45
		1.68V or above (VCC) 1.65V or above (VCC2)		—	5		
	GTIOCxY output skew (x = 8 to 13, Y = A or B)	2.70V or above		—	4		
		1.68V or above (VCC) 1.65V or above (VCC2)		—	5		
	GTIOCxY output skew (x = 0 to 13, Y = A or B)	2.70V or above		—	6		
		1.68V or above (VCC) 1.65V or above (VCC2)		—	7		
	OPS output skew GTOUUP, GTOULO, GTOVUP, GTOVLO, GTOWUP, GTOWLO	2.70V or above	t_{GTOSK}	—	5	ns	Figure 48.46
		1.68V or above (VCC) 1.65V or above (VCC2)		—	6		
AGT	AGTIO, AGTEE input cycle	2.70V or above	t_{ACYC}*2	100	—	ns	Figure 48.47
		1.68V or above (VCC) 1.65V or above (VCC2)		100	—

		1.68V or above (VCC) 1.65V or above (VCC2)		40	—		
	AGTIO, AGTO, AGTOA, AGTOB output cycle	2.70V or above	t_{ACYC2}	62.5	—	ns	
		1.68V or above (VCC) 1.65V or above (VCC2)		62.5	—		

Table 48.38 I/O ports, POEG, GPT, AGT, ULPT and ADC12 trigger timing (3 of 3)

GPT Conditions:
Middle drive output is selected in the Port Drive Capability bit in the PmnPFS register.
If GPT pins are specified across the VCC I/O and VCC2 I/O, characteristics below is guaranteed only when VCC = VCC2.
AGT Conditions:
Middle drive output is selected in the Port Drive Capability bit in the PmnPFS register.

Parameter			Symbol	Min	Max	Unit	Test conditions
ULPT	ULPTEE, ULPTEVI input cycle	2.70V or above	t_{ULCYC}*3	32	-	μs	Figure 48.48
		1.68V or above (VCC) 1.65V or above (VCC2)		32	-		
	ULPTEE, ULPTVI input high width, low width	2.70V or above	t_{ULCKWH}, t_{ULCKWL}	12	-	μs	
		1.68V or above (VCC) 1.65V or above (VCC2)		12	-		
	ULPTO, ULPTOA, ULPTOB output cycle	2.70V or above	t_{ULCYC2}	64	-	μs	
		1.68V or above (VCC) 1.65V or above (VCC2)		64	-		
ADC12	ADC12 trigger input pulse width	2.70V or above	t_{TRGW}	1.5	—	t_{Pcyc}	Figure 48.49
		1.68V or above (VCC) 1.65V or above (VCC2)		3.0	—		

Note: t_{Icyc}: ICLK cycle, t_{Pcyc}: PCLKB cycle, t_{PDcyc}: PCLKD cycle, $t_{ULPTLCLK}$: ULPTLCLK cycle..
Note 1. For Cycle and Time, the longer time characteristics is applied.
Note 2. Constraints on input cycle:
When not switching the source clock: $t_{Pcyc} \times 2 < t_{ACYC}$ should be satisfied.
When switching the source clock: $t_{Pcyc} \times 6 < t_{ACYC}$ should be satisfied.
Note 3. Constraints on input cycle:
ULPTEVI : $t_{Pcyc} \times 2 < t_{ULCYC}$ should be satisfied.
ULPTEE: $t_{ULPTLCLK} \times 2 < t_{ULCYC}$ should be satisfied.

Table 48.41 SCI timing (Simple SPI) (3 of 3)

Conditions: High drive output is selected in the Port Drive Capability bit in the PmnPFS register.
If SCI pins are specified across the VCC I/O and VCC2 I/O, characteristics below is guaranteed only when VCC = VCC2.

Parameter	High Speed/ Default	VCC/VCC2	Symbol	Min	Max	Unit	Note
Slave access time	—	2.70 V or above	t_{SA}	—	3 × t_{Tcyc} + 25	ns	Figure 48.54, Figure 48.55
		1.68 V or above (VCC) 1.65 V or above (VCC2)		—	3 × t_{Tcyc} + 32		
Slave output release time	—	2.70 V or above	t_{REL}	—	3 × t_{Tcyc} + 25	ns	
		1.68 V or above (VCC) 1.65 V or above (VCC2)		—	3 × t_{Tcyc} + 32		

Note: t_{Tcyc}: TCLK cycle.
Note 1. Must use pins that have a letter appended to their name, for instance _A, _B, _C, to indicate group membership. SCI0, SCI1, SCI2, SCI3 and SCI9 are instance _A, SCI4 is instance _B.
Note 2. All pins of group membership can be used.
Note 3. 1 µs at the longest

Table 48.42 SCI timing (Clock synchronous mode) (1 of 4)

Conditions: High drive output is selected in the Port Drive Capability bit in the PmnPFS register.
If SCI pins are specified across the VCC I/O and VCC2 I/O, characteristics below is guaranteed only when VCC = VCC2.

Parameter		High Speed/ Default	VCC/VCC2	Symbol	Min	Max	Unit	Note
SCK clock cycle output	Master	—	2.70 V or above	t_{Scyc}	2.0	—	t_{Tcyc}

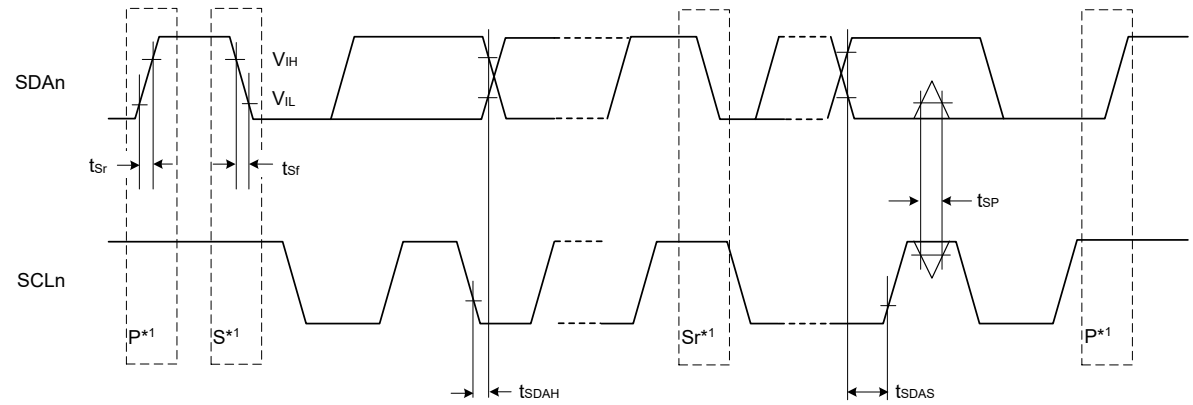
Table 48.43 SCI timing (Simple IIC mode)

Conditions: Middle drive output is selected in the Port Drive Capability bit in the PmnPFS register.
VCC: 1.68V or above, VCC2: 1.65V or above
If SCI pins are specified across the VCC I/O and VCC2 I/O, characteristics below is guaranteed only when VCC = VCC2.

Parameter		Symbol	Min	Max	Unit	Note
Simple IIC (Standard mode)	SCL, SDA input rise time	t_{Sr}	—	1000	ns	
	SCL, SDA input fall time	t_{Sf}	—	300	ns	
	SCL, SDA input spike pulse removal time	t_{SP}	0	4 × t_{Tcyc}	ns	
	Data input setup time	t_{SDAS}	250	—	ns	
	Data input hold time	t_{SDAH}	0	—	ns	
	SCL, SDA capacitive load	C_b *1	—	400	pF	
Simple IIC (Fast mode)	SCL, SDA input rise time	t_{Sr}	—	300	ns	
	SCL, SDA input fall time	t_{Sf}	—	300	ns	
	SCL, SDA input spike pulse removal time	t_{SP}	0	4 × t_{Tcyc}	ns	
	Data input setup time	t_{SDAS}	100	—	ns	
	Data input hold time	t_{SDAH}	0	—	ns	
	SCL, SDA capacitive load	C_b *1	—	400	pF	

Note: t_{Tcyc}: TCLK cycle.
Note 1. C_b indicates the total capacity of the bus line.



Test conditions:
V_{IH} = VCC × 0.7 or VCC2 × 0.7
V_{IL} = VCC × 0.3 or VCC2 × 0.3
V_{OL} = 0.6 V, I_{OL} = 6 mA

Note: n = 0 to 4, 9
Note 1. S, P, and Sr indicate the following conditions:
S: Start condition
P: Stop condition
Sr: Restart condition

48.3.11 IIC Timing

Table 48.45 IIC timing (1) (1 of 2)

(1) Conditions: Middle drive output is selected when VCC is 2.70 V or above, High drive output is selected when VCC is 1.68 to 1.95 V in the port drive capability bit in the PmnPFS register for the following pins: SDA0_B, SCL0_B, SDA1_B, SCL1_B
(2) The following pins do not require setting: SCL0_A, SDA0_A. SCL1_A, SDA1_A
(3) Use pins that have a letter appended to their names, for instance "_A" or "_B", to indicate group membership.
For the IIC interface, the AC portion of the electrical characteristics is measured for each group.

Parameter		Symbol	VCC	Min	Max	Unit	Test conditions
IIC (Standard mode, SMBus) ICFER.FMPE = 0 when VCC is 2.70 V or above, ICFER.FMPE = 1 when VCC is 1.68 to 1.95 V	SCL input cycle time	t_{SCL}	2.70 V or above	6 (12) × t_{IICcyc} + 1300	—	ns	Figure 48.65
			1.68 to 1.95 V				
	SCL input high pulse width	t_{SCLH}	2.70 V or above	3 (6) × t_{IICcyc} + 300	—	ns	
			1.68 to 1.95 V				
	SCL input low pulse width	t_{SCLL}	2.70 V or above	3 (6) × t_{IICcyc} + 300	—	ns	
			1.68 to 1.95 V				
	SCL, SDA rise time	t_{Sr}	2.70 V or above	—	1000	ns	
			1.68 to 1.95 V

			1.68 to 1.95 V				
	SDA input bus free time when wakeup function is disabled	t_{BUF}	2.70 V or above	3 (6) × t_{IICcyc} + 300	—	ns	
			1.68 to 1.95 V				
	SDA input bus free time when wakeup function is enabled	t_{BUF}	2.70 V or above	3 (6) × t_{IICcyc} + 4 × t_{Pcyc} + 300	—	ns	
			1.68 to 1.95 V				
	START condition input hold time when wakeup function is disabled	t_{STAH}	2.70 V or above	t_{IICcyc} + 300	—	ns	
			1.68 to 1.95 V				
	START condition input hold time when wakeup function is enabled	t_{STAH}	2.70 V or above	1 (5) × t_{IICcyc} + t_{Pcyc} + 300	—	ns	
			1.68 to 1.95 V				
	Repeated START condition input setup time	t_{STAS}	2.70 V or above	1000	—	ns	
			1.68 to 1.95 V				
	STOP condition input setup time	t_{STOS}	2.70 V or above	1000	—	ns	
			1.68 to 1.95 V				
	Data input setup time	t_{SDAS}	2.70 V or above	t_{IICcyc} + 50	—	ns	
			1.68 to 1.95 V				
	Data input hold time	t_{SDAH}	2.70 V or above	0	—	ns	
			1.68 to 1.95 V				
	SCL, SDA capacitive load	C_b	2.70 V or above	—	400	pF	
			1.68 to 1.95 V				

Table 48.45 IIC timing (1) (2 of 2)

(1) Conditions: Middle drive output is selected when VCC is 2.70 V or above, High drive output is selected when VCC is 1.68 to 1.95 V in the port drive capability bit in the PmnPFS register for the following pins: SDA0_B, SCL0_B, SDA1_B, SCL1_B
(2) The following pins do not require setting: SCL0_A, SDA0_A. SCL1_A, SDA1_A
(3) Use pins that have a letter appended to their names, for instance "_A" or "_B", to indicate group membership.
For the IIC interface, the AC portion of the electrical characteristics is measured for each group.

Parameter		Symbol	VCC	Min	Max	Unit	Test conditions
IIC (Fast mode) ICFER.FMPE = 0 when VCC is 2.70 V or above, ICFER.FMPE = 1 when VCC is 1.68 to 1.95 V	SCL input cycle time	t_{SCL}	2.70 V or above	6 (12) × t_{IICcyc} + 600	—	ns	Figure 48.65
			1.68 to 1.95 V				
	SCL input high pulse width	t_{SCLH}	2.70 V or above	3 (6) × t_{IICcyc} + 300	—	ns	
			1.68 to 1.95 V				
	SCL input low pulse width	t_{SCLL}	2.70 V or above	3 (6) × t_{IICcyc} + 300	—	ns	
			1.68 to 1.95 V				
	SCL, SDA rise time	t_{Sr}	2.70 V or above	20	300	ns	
			1.68 to 1.95 V				
	SCL, SDA fall time	t_{Sf}	2.70 V or above	20 × (external pullup voltage/5.5 V)*1	300	ns	
			1.68 to 1.95 V				
	SCL, SDA input spike pulse removal time	t_{SP}	2.70 V or above	0	1 (4) × t_{IICcyc}	ns	
			1.68 to 1.95 V				
	SDA input bus free time when wakeup function is disabled	t_{BUF}	2.70 V or above	3 (6) × t_{IICcyc} + 300	—	ns	
			1.68 to 1.95 V				
	SDA input bus free time when wakeup function is enabled	t_{BUF}	2.70 V or above	3 (6) × t_{IICcyc} + 4 × t_{Pcyc} + 300	—	ns	
			1.68 to 1.95 V				
	START condition input hold time when wakeup function is disabled	t_{STAH}	2.70 V or above	t_{IICcyc} + 300	—	ns	
			1.68 to 1.95 V				
	START condition input hold time when wakeup function is enabled	t_{STAH}	2.70 V or above	1 (5) × t_{IICcyc} + t_{Pcyc} + 300	—	ns	
			1.68 to 1.95 V				
	Repeated START condition input setup time	t_{STAS}	2.70 V or above	300	—	ns	
			1.68 to 1.95 V				
	STOP condition input setup time	t_{STOS}	2.70 V or above	300	—	ns	
			1.68 to 1.95 V				
	Data input setup time	t_{SDAS}	2.70 V or above	t_{IICcyc} + 50	—	ns	
			1.68 to 1.95 V				
	Data input hold time	t_{SDAH}	2.70 V or above	0	—	ns	
			1.68 to 1.95 V				
	SCL, SDA capacitive load	C_b	2.70 V or above	—	400	pF	
			1.68 to 1.95 V				

Note: t_{IICcyc}: IIC internal reference clock (IICφ) cycle, t_{Pcyc}: PCLKB cycle.
Note: Values in parentheses apply when ICMR3.NF[1:0] is set to 11b while the digital filter is enabled with ICFER.NFE set to 1.
Note: Must use pins that have a letter appended to their name, for instance "_A", "_B", to indicate group membership. For the IIC interface, the AC portion of the electrical characteristics is measured for each group.
Note 1. Only supported for SCL0_A, SDA0_A, SCL1_A, and SDA1_A.

Table 48.46 IIC timing (2)

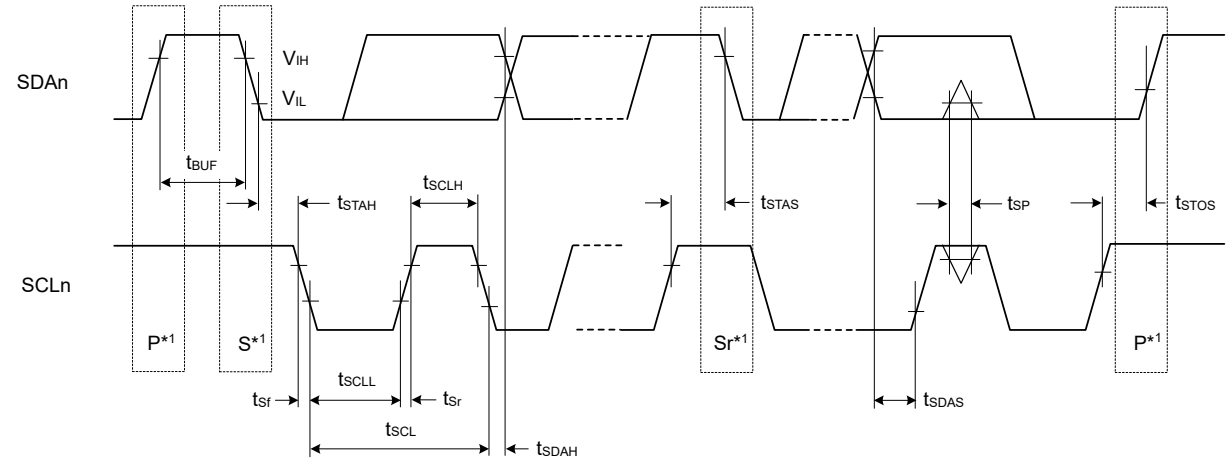
Setting of the SCL0_A, SDA0_A, SCL1_A, SDA1_A pins are not required with the port drive capability bit in the PmnPFS register.

Parameter		Symbol	VCC	Min	Max	Unit	Test conditions
IIC (Fast-mode+) ICFER.FMPE = 1	SCL input cycle time	t_{SCL}	2.70 V or above	6 (12) × t_{IICcyc} + 240	—	ns	Figure 48.65
	SCL input high pulse width	t_{SCLH}	2.70 V or above	3 (6) × t_{IICcyc} + 120	—	ns	
	SCL input low pulse width	t_{SCLL}	2.70 V or above	3 (6) × t_{IICcyc} + 120	—	ns	
	SCL, SDA rise time	t_{Sr}	2.70 V or above	—	120	ns	
	SCL, SDA fall time	t_{Sf}	2.70 V or above	20 × (external pullup voltage/ 5.5V)	120	ns	
	SCL, SDA input spike pulse removal time	t_{SP}	2.70 V or above	0	1 (4) × t_{IICcyc}	ns	
	SDA input bus free time when wakeup function is disabled	t_{BUF}	2.70 V or above	3 (6) × t_{IICcyc} + 120	—	ns	
	SDA input bus free time when wakeup function is enabled	t_{BUF}	2.70 V or above	3 (6) × t_{IICcyc} + 4 × t_{Pcyc} + 120	—	ns	
	Start condition input hold time when wakeup function is disabled	t_{STAH}	2.70 V or above	t_{IICcyc} + 120	—	ns	
	START condition input hold time when wakeup function is enabled	t_{STAH}	2.70 V or above	1 (5) × t_{IICcyc} + t_{Pcyc} + 120	—	ns	
	Restart condition input setup time	t_{STAS}	2.70 V or above	120	—	ns	
	Stop condition input setup time	t_{STOS}	2.70 V or above	120	—	ns	
	Data input setup time	t_{SDAS}	2.70 V or above	t_{IICcyc} + 30	—	ns	
	Data input hold time	t_{SDAH}	2.70 V or above	0	—	ns	
	SCL, SDA capacitive load	C_b*1	2.70 V or above	—	550	pF	

Note: t_{IICcyc}: IIC internal reference clock (IICφ) cycle, tPcyc: PCLKB cycle.

Note: Values in parentheses apply when ICMR3.NF[1:0] is set to 11b while the digital filter is enabled with ICFER.NFE set to 1.

Note 1. Cb indicates the total capacity of the bus line.



Note 1. S, P, and Sr indicate the following conditions:
S: Start condition
P: Stop condition
Sr: Restart condition

Figure 48.65 I^2C bus interface input/output timing

48.3.12 I3C Timing

Table 48.47 IIC timing(1)-1

Setting of the I3C_SCL0, I3C_SDA0 pins are not required with the Port Drive Capability bit in the PmnPFS register.

Parameter		Symbol	VCC	Min	Max	Unit
IIC (Standard mode, SMBus) BFCTL.FMPE = 0	SCL input cycle time	t_{SCL}	2.70 V or above, 1.68 to 1.95 V	10 (18) × t_{I3Ccyc} + 1300	—	ns
	SCL input high pulse width	t_{SCLH}	2.70 V or above, 1.68 to 1.95 V	5 (9) × t_{I3Ccyc} + 300	—	ns
	SCL input low pulse width	t_{SCLL}	2.70 V or above, 1.68 to 1.95 V	5 (9) × t_{I3Ccyc} + 300	—	ns
	SCL, SDA rise time	t_{Sr}	2.70 V or above, 1.68 to 1.95 V	—	1000	ns
	SCL, SDA fall time	t_{Sf}	2.70 V or above, 1.68 to 1.95 V	—	300	ns
	SCL, SDA input spike pulse removal time	t_{SP}	2.70 V or above, 1.68 to 1.95 V	0	1 (4) × t_{I3Ccyc}	ns
	SDA input bus free time when wakeup function is disabled	t_{BUF}	2.70 V or above, 1.68 to 1.95 V	5(9) × t_{I3Ccyc} + 300	—	ns
	SDA input bus free time when wakeup function is enabled	t_{BUF}	2.70 V or above, 1.68 to 1.95 V	5(9) × t_{I3Ccyc} + 4 × t_{Tcyc} + 300	—	ns
	START condition input hold time when wakeup function is disabled	t_{STAH}	2.70 V or above, 1.68 to 1.95 V	t_{I3Ccyc} + 300	—	ns
	START condition input hold time when wakeup function is enabled	t_{STAH}	2.70 V or above, 1.68 to 1.95 V	1(5) × t_{I3Ccyc} + t_{Tcyc} + 300	—	ns
	Repeated START condition input setup time	t_{STAS}	2.70 V or above, 1.68 to 1.95 V	1000	—	ns
	STOP condition input setup time	t_{STOS}	2.70 V or above, 1.68 to 1.95 V	1000	—	ns
	Data input setup time	t_{SDAS}	2.70 V or above, 1.68 to 1.95 V	t_{I3Ccyc} + 50	—	ns
	Data input hold time	t_{SDAH}	2.70 V or above, 1.68 to 1.95 V	0	—	ns
	SCL, SDA capacitive load	C_b*1	2.70 V or above, 1.68 to 1.95 V	—	400	pF

Note: t_{I3Ccyc}: I3C internal reference clock (I3Cφ) cycle, t_{Tcyc}: TCLK cycle.

Note: Values in parentheses apply when INCTL.DNFS[3:0] is set to 0011b while the digital filter is enabled with INCTL.DNFE set to 1.

Note 1. C_b indicates the total capacity of the bus line.

Table 48.48 IIC timing(1)-2

Setting of the I3C_SCL0, I3C_SDA0 pins are not required with the Port Drive Capability bit in the PmnPFS register.

Parameter		Symbol	VCC	Min	Max	Unit
IIC (Fast-mode)	SCL input cycle time	t_{SCL}	2.70 V or above, 1.68 to 1.95 V	10 (18) × t_{I3Ccyc} + 600	—	ns
	SCL input high pulse width	t_{SCLH}	2.70 V or above, 1.68 to 1.95 V	5 (9) × t_{I3Ccyc} + 300	—	ns
	SCL input low pulse width	t_{SCLL}	2.70 V or above, 1.68 to 1.95 V	5 (9) × t_{I3Ccyc} + 300	—	ns
	SCL, SDA rise time	t_{Sr}	2.70 V or above, 1.68 to 1.95 V	20	300	ns
	SCL, SDA fall time	t_{Sf}	2.70 V or above, 1.68 to 1.95 V	20 × (external pull-up voltage/3.6 V)	300	ns
	SCL, SDA input spike pulse removal time	t_{SP}	2.70 V or above, 1.68 to 1.95 V	0	1 (4) × t_{I3Ccyc}	ns
	SDA input bus free time when wakeup function is disabled	t_{BUF}	2.70 V or above, 1.68 to 1.95 V	5 (9) × t_{I3Ccyc} + 300	—	ns
	SDA input bus free time when wakeup function is enabled		2.70 V or above, 1.68 to 1.95 V	5(9) × t_{I3Ccyc} + 4 × t_{Tcyc} + 300	—	ns
	START condition input hold time when wakeup function is disabled	t_{STAH}	2.70 V or above, 1.68 to 1.95 V	t_{I3Ccyc} + 300	—	ns
	START condition input hold time when wakeup function is enabled		2.70 V or above, 1.68 to 1.95 V	1(5) × t_{I3Ccyc} + t_{Tcyc} + 300	—	ns
	Repeated START condition input setup time	t_{STAS}	2.70 V or above, 1.68 to 1.95 V	300	—	ns
	STOP condition input setup time	t_{STOS}	2.70 V or above, 1.68 to 1.95 V	300	—	ns
	Data input setup time	t_{SDAS}	2.70 V or above, 1.68 to 1.95 V	t_{I3Ccyc} + 50	—	ns
	Data input hold time	t_{SDAH}	2.70 V or above, 1.68 to 1.95 V	0	—	ns
	SCL, SDA capacitive load	C_b*1	2.70 V or above, 1.68 to 1.95 V	—	400	pF

Note: t_{I3Ccyc}: I3C internal reference clock (I3Cφ) cycle, t_{Tcyc}: TCLK cycle.

Note: Values in parentheses apply when INCTL.DNFS[3:0] is set to 0011b while the digital filter is enabled with INCTL.DNFE set to 1.

Note 1. C_b indicates the total capacity of the bus line.

Table 48.49 IIC timing(1)-3

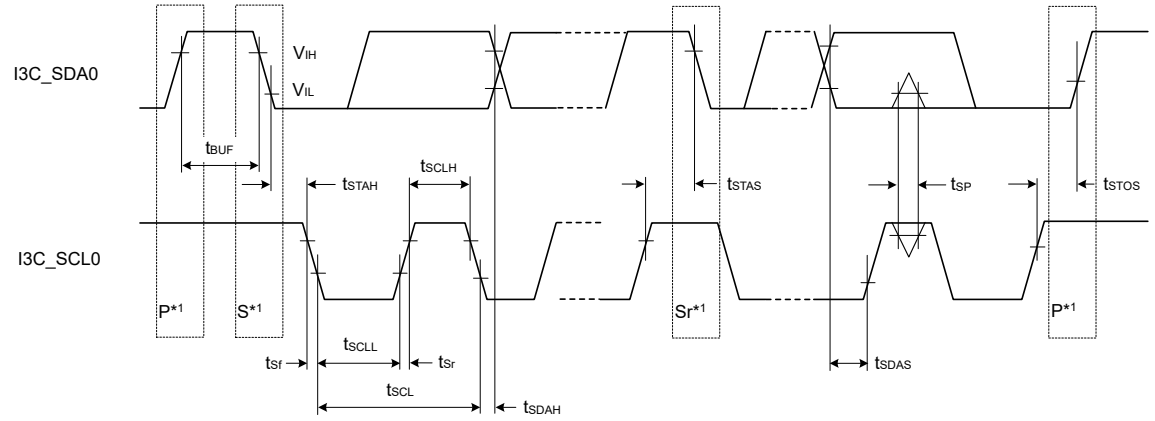
Setting of the I3C_SCL0, I3C_SDA0 pins are not required with the Port Drive Capability bit in the PmnPFS register.

Parameter		Symbol	VCC	Min	Max	Unit
IIC (Fast-mode +) BFCTL.FMPE = 1	SCL input cycle time	t_{SCL}	2.70 V or above	10 (18) × t_{I3Ccyc} + 240	—	ns
	SCL input high pulse width	t_{SCLH}	2.70 V or above	5 (9) × t_{I3Ccyc} + 120	—	ns
	SCL input low pulse width	t_{SCLL}	2.70 V or above	5 (9) × t_{I3Ccyc} + 120	—	ns
	SCL, SDA rise time	t_{Sr}	2.70 V or above	—	120	ns
	SCL, SDA fall time	t_{Sf}	2.70 V or above	20 × (external pull-up voltage/3.3V)	120	ns
	SCL, SDA input spike pulse removal time	t_{SP}	2.70 V or above	0	1 (4) × t_{I3Ccyc}	ns
	SDA input bus free time when wakeup function is disabled	t_{BUF}	2.70 V or above	5 (9) × t_{I3Ccyc} + 120	—	ns
	SDA input bus free time when wakeup function is enabled			5(9) × t_{I3Ccyc} + 4 × t_{Tcyc} + 120		ns
	START condition input hold time when wakeup function is disabled	t_{STAH}	2.70 V or above	t_{I3Ccyc} + 120	—	ns
	START condition input hold time when wakeup function is enabled			1(5) × t_{I3Ccyc} + t_{Tcyc} + 120		ns
	Restart condition input setup time	t_{STAS}	2.70 V or above	120	—	ns
	Stop condition input setup time	t_{STOS}	2.70 V or above	120	—	ns
	Data input setup time	t_{SDAS}	2.70 V or above	t_{I3Ccyc} + 30	—	ns
	Data input hold time	t_{SDAH}	2.70 V or above	0	—	ns
	SCL, SDA capacitive load	C_b*1	2.70 V or above	—	550	pF

Note: t_{I3Ccyc}: I3C internal reference clock (I3Cφ) cycle. t_{Tcyc}: TCLK cycle.

Note: Values in parentheses apply when INCTL.DNFS[3:0] is set to 0011b while the digital filter is enabled with INCTL.DNFE set to 1.

Note 1. C_b indicates the total capacity of the bus line.



Test conditions:
V_{IH} = VCC × 0.7, V_{IL} = VCC × 0.3
V_{OL} = 0.6 V, I_{OL} = 6 mA (BFCTL.FMPE = 0)
V_{OL} = 0.4 V, I_{OL} = 15 mA (BFCTL.FMPE = 1)

Note 1. S, P, and Sr indicate the following conditions:
S: Start condition
P: Stop condition
Sr: Restart condition

Figure 48.66 I^2C bus interface input/output timing

Table 48.50 IIC timing(2)

Setting of the I3C_SCL0, I3C_SDA0 pins are not required with the Port Drive Capability bit in the PmnPFS register.

Parameter			Symbol	VCC	Min	Max	Unit
IIC (Hs-mode) BFCTL.HSME = 1	SCL input cycle time		t_{SCL}	3.00 V or above	47 (49) × t_{I3Ccyc}	—	ns
				1.68 to 1.95 V	48 (50) × t_{I3Ccyc}	—	
	SCL input high pulse width	Cb = 400 pF	t_{SCLH}	3.00 V or above	36 (37) × t_{I3Ccyc}	—	ns
				1.68 to 1.95 V	31 (32) × t_{I3Ccyc}	—	
		Cb = 100 pF		3.00 V or above	18 (19) × t_{I3Ccyc}	—	
				1.68 to 1.95 V	19 (20) × t_{I3Ccyc}	—

				1.68 to 1.95 V	0	70	
	SCL, SDA capacitive load		C_b*1	3.00 V or above	—	400	pF
				1.68 to 1.95 V	—	400	

Note: t_{I3Ccyc}: I3C internal reference clock (I3Cφ) cycle.
Note: Values in parentheses apply when INCTL.DNFS[3:0] is set to 0011b while the digital filter is enabled with INCTL.DNFE set to 1.
Note 1. C_b indicates the total capacity of the bus line.

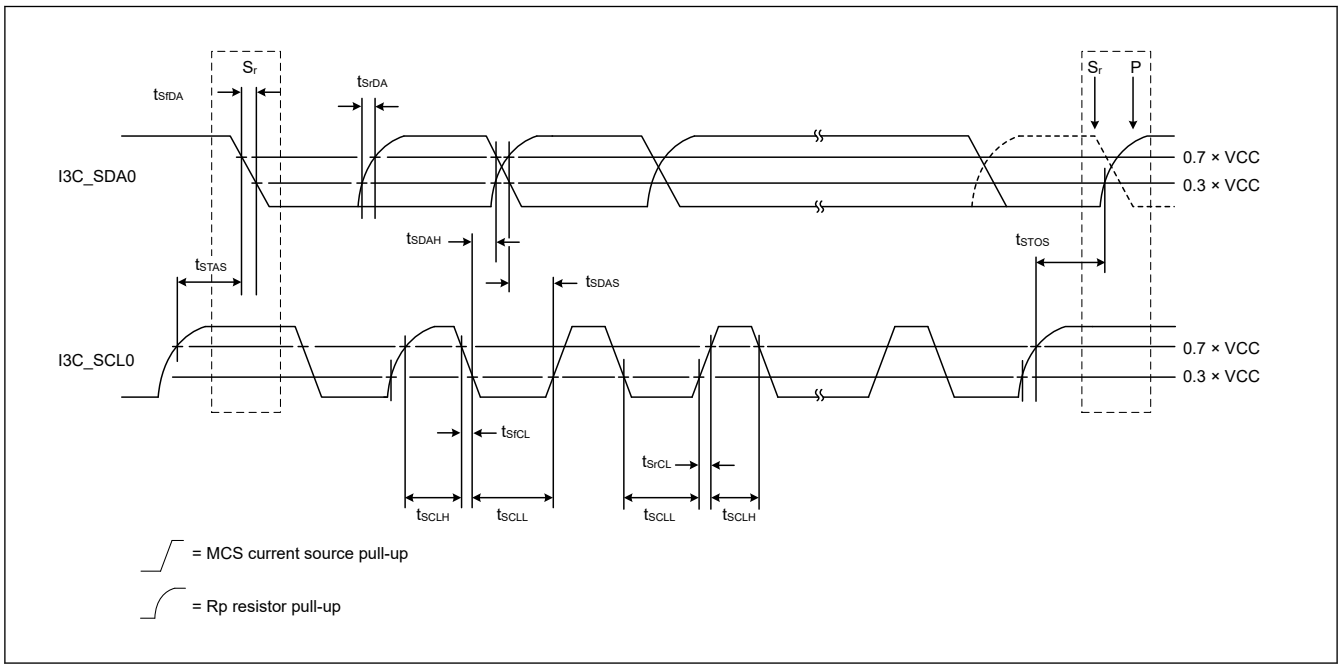

Figure 48.67 I²C bus interface input/output timing (Hs-mode)

Table 48.51 I3C timing (Open Drain Timing Parameters)

Setting of the I3C_SCL0, I3C_SDA0 pins are not required with the Port Drive Capability bit in the PmnPFS register.

Parameter		Symbol	VCC	Min	Max	Unit	Test conditions
I3C Open Drain Timing Parameters	SCL Clock Low Period	t_{LOW_OD} *1 *2	3.00 V or above	200	—	ns	Figure 48.70
			1.68 to 1.95 V	200	—		
		$t_{DIG_OD_L}$	3.00 V or above	t_{LOW_ODmin} + t_{fDA_ODmin}	—	ns	Figure 48.70
			1.68 to 1.95 V	t_{LOW_ODmin} + t_{fDA_ODmin}	—		
	SCL Clock High Period	t_{HIGH} *3 *4	3.00 V or above	—	41	ns	Figure 48.68
			1.68 to 1.95 V	—	41		
		t_{DIG_H}	3.00 V or above	—	t_{HIGH} + t_{CF}	ns	Figure 48.68
			1.68 to 1.95 V	—	t_{HIGH} + t_{CF}		
	SDA Signal Fall Time	t_{fDA_OD}	3.00 V or above	t_{CF}	12	ns	Figure 48.70
			1.68 to 1.95 V	t_{CF}	12		
	SDA Data Setup Time Open Drain Mode	t_{SU_OD} *1	3.00 V or above	12	—	ns	Figure 48.69
			1.68 to 1.95 V	18	—		
	Clock After START (S) Condition	t_{CAS} *5 *6	3.00 V or above	38.4 nano	For ENAS0: 1 µ	seconds	Figure 48.70
					For ENAS1: 100 µ		
					For ENAS2: 2 milli		
					For ENAS3: 50 milli		
			1.68 to 1.95 V	38.4 nano	For ENAS0: 1 µ		
					For ENAS1: 100 µ		
					For ENAS2: 2 milli		
					For ENAS3: 50 milli		
	Clock Before STOP (P) Condition	t_{CBP}	3.00 V or above	t_{CASmin} / 2	—	seconds	Figure 48.71
			1.68 to 1.95 V	t_{CASmin} / 2	—		
	Current Master to Secondary Master Overlap time during handoff	$t_{MMOverlap}$	3.00 V or above	$t_{DIG_OD_Lmin}$	—	ns	Figure 48.77
			1.68 to 1.95 V	$t_{DIG_OD_Lmin}$	—		
	Bus Available Condition	t_{AVAL} *7	3.00 V or above	1	—	µs	—
			1.68 to 1.95 V	1	—		
	Bus Idle Condition	t_{IDLE}	3.00 V or above	1	—	ms	—
			1.68 to 1.95 V	1	—		
	Time Internal Where New Master Not Driving SDA Low	t_{MMLock}	3.00 V or above	$t_{AVALmin}$	—	µs	Figure 48.77
			1.68 to 1.95 V	$t_{AVALmin}$			

Note 1. This is approximately equal to t_{LOWmin} + t_{DS_ODmin} + t_{rDA_ODtyp} + t_{SU_Odmin}.

Note 2. The Master may use a shorter Low period if it knows that this is safe, i.e., that SDA is already above VIH

Note 3. Based on t_{SPIKE}, rise and fall times, and interconnect

Note 4. This maximum High period may be exceeded when the signals can be safely seen by Legacy I^2C Devices, and/or in consideration of the interconnect (e.g., a short Bus).
As a product specification, if this Max value cannot be guaranteed, change this Max value and specify that it cannot be used in the Mixed Bus.

Note 5. On a Legacy Bus where I^2C Devices need to see Start
Note 6. Slaves that do not support the optional ENTASx CCCs shall use the t_{CAS} Max value shown for ENTAS3
Note 7. On a Mixed Bus with Fm Legacy I^2C Devices, t_{AVAL} is 300 ns shorter than the Fm Bus Free Condition time (t_{BUF})

Table 48.52 I3C timing (Push-Pull Timing Parameters for SDR and HDR-DDR Modes)

Setting of the I3C_SCL0, I3C_SDA0 pins are not required with the Port Drive Capability bit in the PmnPFS register.

Parameter			Symbol	VCC	Min	Max	Unit	Test conditions
I3C Push-Pull Timing Parameters for SDR and HDR-DDR Modes	SCL Clock Frequency		f_{SCL} *1	3.00 V or above	0.01	12.5	MHz	—
				1.68 to 1.95 V	0.01	12.5		
	SCL Clock Low Period		t_{LOW}	3.00 V or above	27	—	ns	Figure 48.68
				1.68 to 1.95 V	32	—		
			t_{DIG_L} *2 *4	3.00 V or above	35	—	ns	Figure 48.68
				1.68 to 1.95 V	40	—		
	SCL Clock High Period for Mixed Bus		t_{HIGH_MIXED}	3.00 V or above	24	—	ns	Figure 48.68
				1.68 to 1.95 V	27	—		
			$t_{DIG_H_MIXED}$ *2 *3	3.00 V or above	32	45	ns	Figure 48.68
				1.68 to 1.95 V	35	45		
	SCL Clock High Period		t_{HIGH}	3.00 V or above	24	—	ns	Figure 48.68
				1.68 to 1.95 V	27	—		
			t_{DIG_H} *2	3.00 V or above	32	—	ns	Figure 48.68
				1.68 to 1.95 V	35	—		
	Clock in to Data Out for Slave		t_{SCO}	3.00 V or above	—	12	ns	Figure 48.73
				1.68 to 1.95 V	—	12		
	SCL Clock Rise Time		t_{CR}	3.00 V or above	—	150 × 1 / f_{SCL} (capped at 60)	ns	Figure 48.68
				1.68 to 1.95 V	—	150 × 1 / f_{SCL} (capped at 60)		
	SCL Clock Fall Time		t_{CF}	3.00 V or above	—	150 × 1 / f_{SCL} (capped at 60)	ns	Figure 48.68
				1.68 to 1.95 V	—	150 × 1 / f_{SCL} (capped at 60)		
	SDA Signal Data Hold in Push-Pull Mode	Master	t_{HD_PP} *4*5	3.00 V or above	t_{CR} + 3 and t_{CF} + 3	—	—	Figure 48.72
				1.68 to 1.95 V	t_{CR} + 3 and t_{CF} + 3	—		
		Slave	t_{HD_PP} *5	3.00 V or above	0	—	—	Figure 48.72
				1.68 to 1.95 V	0	—		
	SDA Signal Data Setup in Push-Pull Mode		t_{SU_PP}	3.00 V or above	12	N/A	ns	Figure 48.74
				1.68 to 1.95 V	18	N/A		
	Clock After Repeated START (Sr)		t_{CASr}	3.00 V or above	t_{CASmin}	N/A	ns	Figure 48.76
				1.68 to 1.95 V	t_{CASmin}	N/A		
	Clock Before Repeated START (Sr)		t_{CBSr}	3.00 V or above	t_{CASmin} / 2	N/A	ns	Figure 48.76
				1.68 to 1.95 V	t_{CASmin} / 2	N/A		
	Capacitive Load per Bus Line (SDA/SCL)		C_b	3.00 V or above	—	50	pF	—
				1.68 to 1.95 V	—	50		

Note 1. $f_{SCL} = 1 / (t_{DIG_L} + t_{DIG_H})$
Note 2. t_{DIG_L} and t_{DIG_H} are the clock Low and High periods as seen at the receiver end of the I3C Bus using V_{IL} and V_{IH}.
Note 3. When communicating with an I3C Device on a mixed Bus, the $t_{DIG_H_MIXED}$ period must be constrained in order to make sure that I^2C Devices do not interpret I3C signaling as valid I^2C signaling.
Note 4. As both edges are used, the hold time needs to be satisfied for the respective edges; i.e., t_{CF} + 3 for falling edge clocks, and t_{CR} + 3 for rising edge clocks.
Note 5. In SDR Mode the Hold time parameter is referred to as t_{HD_SDR}, and in DDR Mode it is referred to as t_{HD_DDR}.

Table 48.53 I3C timing (Push-Pull Timing Parameters for HDR-TSP and HDR-TSL Modes)

Setting of the I3C_SCL0, I3C_SDA0 pins are not required with the Port Drive Capability bit in the PmnPFS register.

Parameter		Symbol	VCC	Min	Max	Unit	Test conditions
I3C Push-Pull Timing Parameters for HDR-TSP and HDR-TSL Modes	Edge-to-Edge Period	t_{EDGE} *1 *2	3.00 V or above	t_{DIG_H}	—	ns	Figure 48.68
			1.68 to 1.95 V	t_{DIG_H}	—		
	Allowed Difference Between Signals for 'Simultaneous' Change	t_{SKEW}	3.00 V or above	—	10	ns	
			1.68 to 1.95 V	—	10		
	Stable Condition Between Symbols	t_{EYE}	3.00 V or above	12	—	ns	
			1.68 to 1.95 V	12	—		
	Time Between Successive Symbols	t_{SYMBOL}	3.00 V or above	$t_{EDGE\ Min}$	—	ns	
			1.68 to 1.95 V	$t_{EDGE\ Min}$	—		
	Symbol Clock	t_{CLOCK}	3.00 V or above	1 / f_{SCL} (Max)	—	—	
			1.68 to 1.95 V	1 / f_{SCL} (Max)	—		

Note 1. Edges occur at the rate of 1 / (t_{EDGE} × 2)
Note 2. In a Mixed Bus, HDR-TSL shall respect the maximum $t_{DIG_H_MIXED}$ shown in Figure 48.71.

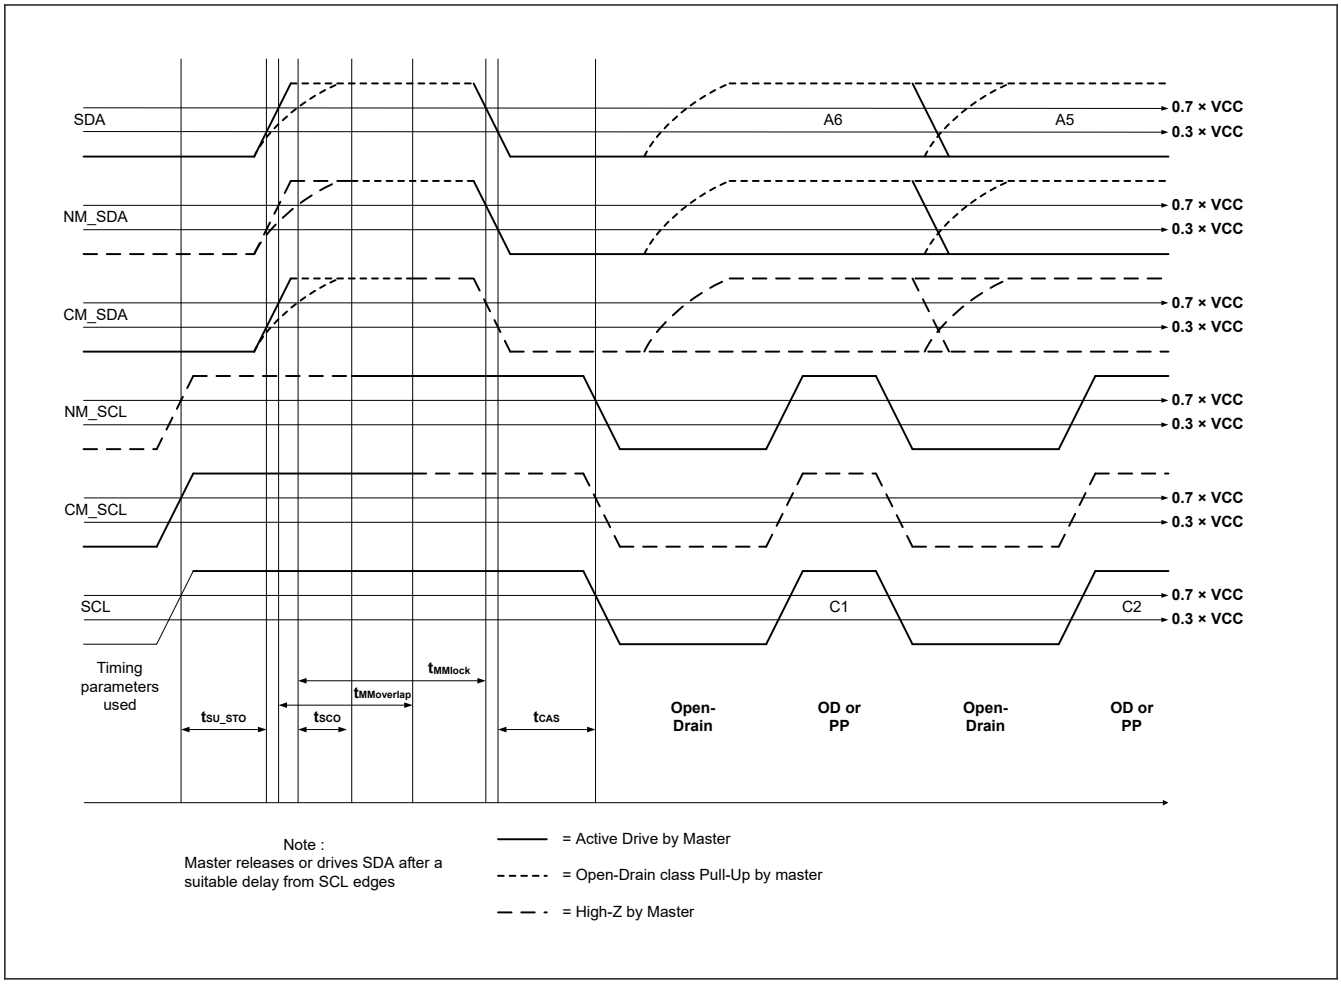

Figure 48.77 Master to Master Bus Handoff

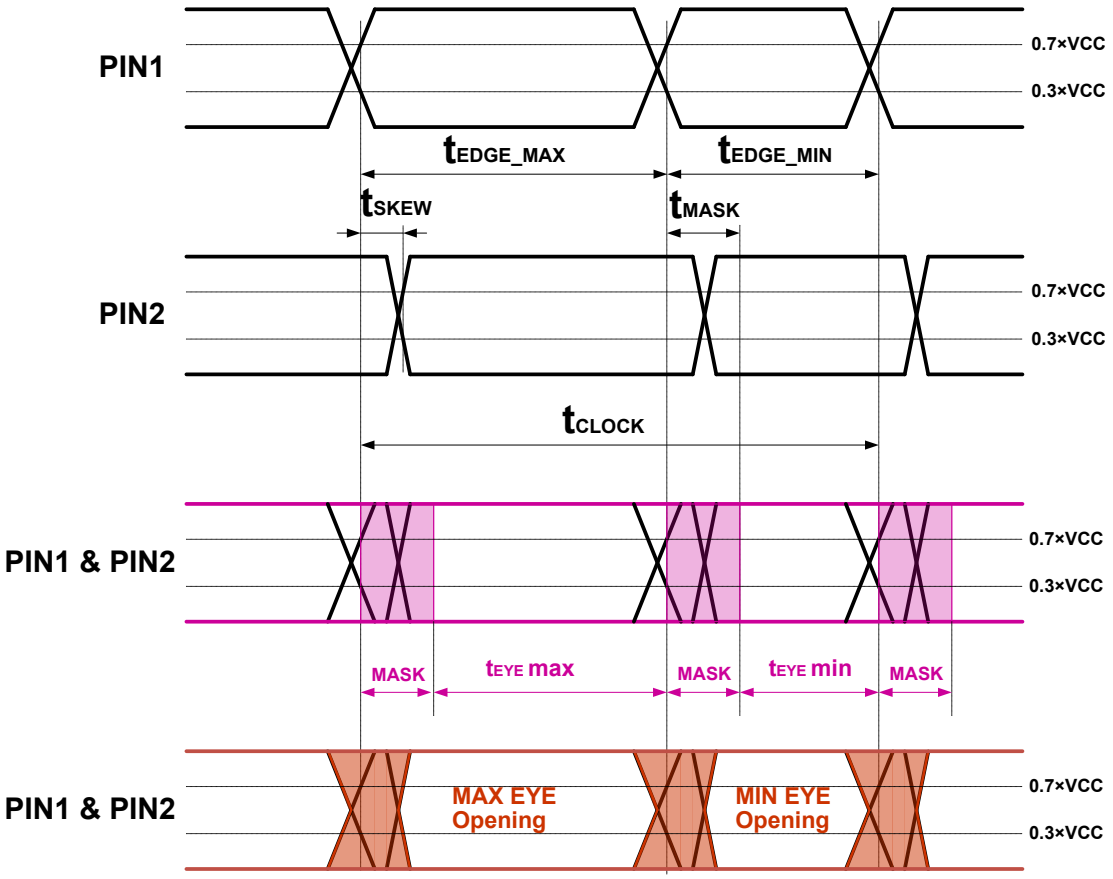

Design Conditions

1. The The differences of load magnitude and drive strength between the SDA and SCL lines result in different slopes, as shown
2. MASK period ≧ MAX t_{SKEW} + MAX rise/fall time between 0.3 × V_{DD} and 0.7 × V_{DD}, respectively, decreased by the time crossing the hysteresis window.

Simplifying Assumptions

1. t_{SKEW} is the same for both edges
2. Base CLOCK (e.g. 12.5MHz) is asymmetrical
3. Falling edges are equal rising edges
4. The MASK is shown as starting, from the last possible moment, whereas in reality it could be shifted left (towards the start point) delayed by the hysteresis window

Figure 48.78 Ternary Protocol Timing

48.3.13 SD/MMC Host Interface Timing

Table 48.54 SD/MMC Host Interface signal timing

Conditions: High drive output is selected in the Port Drive Capability bit in the PmnPFS register.
High-speed high drive output is selected in specific condition, please see note 1.
Clock duty ratio is 50%.

Parameter	Symbol	VCC/VCC2	Min	Max	Unit	Test conditions
SDnCLK clock cycle	t_{SDCYC}	2.70V or above	20	—	ns	Figure 48.79
		1.70 to1.95V*1	20	—		
		1.70 to1.95V	40	—		
SDnCLK clock high pulse width	t_{SDWH}	2.70V or above	6.5	—	ns	
		1.70 to1.95V*1	6.5	—		
		1.70 to1.95V	13.0	—		
SDnCLK clock low pulse width	t_{SDWL}	2.70V or above	6.5	—	ns	
		1.70 to1.95V*1	6.5	—		
		1.70 to1.95V	13.0	—		
SDnCLK clock rise time	t_{SDLH}	2.70V or above	—	3.0	ns	
		1.70 to1.95V*1	—	4.0		
		1.70 to1.95V	—	8.0		
SDnCLK clock fall time	t_{SDHL}	2.70V or above	—	3.0	ns	
		1.70 to1.95V*1	—	4.0		
		1.70 to1.95V	—	8.0		
SDnCMD/SDnDATm output data delay	t_{SDODLY}	2.70V or above	–7.0	4.0	ns	
		1.70 to1.95V*1	–7.0	7.0		
		1.70 to1.95V	–15.0	15.0		
SDnCMD/SDnDATm input data setup	t_{SDIS}	2.70V or above	4.5	—	ns	
		1.70 to1.95V*1	4.5	—		
		1.70 to1.95V	20.0	—		
SDnCMD/SDnDATm input data hold	t_{SDIH}	2.70V or above	1.5	—	ns	
		1.70 to1.95V	1.5	—		

Note: Must use pins that have a letter appended to their name, for instance “_A”, “_B”, to indicate group membership. For the SD/MMC Host interface, the AC portion of the electrical characteristics is measured for each group.
Note: If SD1DAT4_A~SD1DAT7_A are used, characteristics above is guaranteed only when VCC = VCC2.
Note 1. Only supported for Ch0 group B ("SD0*_B") and Ch1 group A ("SD1*_A")
High-speed high drive output is selected in the port drive capability bit in the PmnPFS register for the following pins:
SD0CLK_B, SD1CLK_A

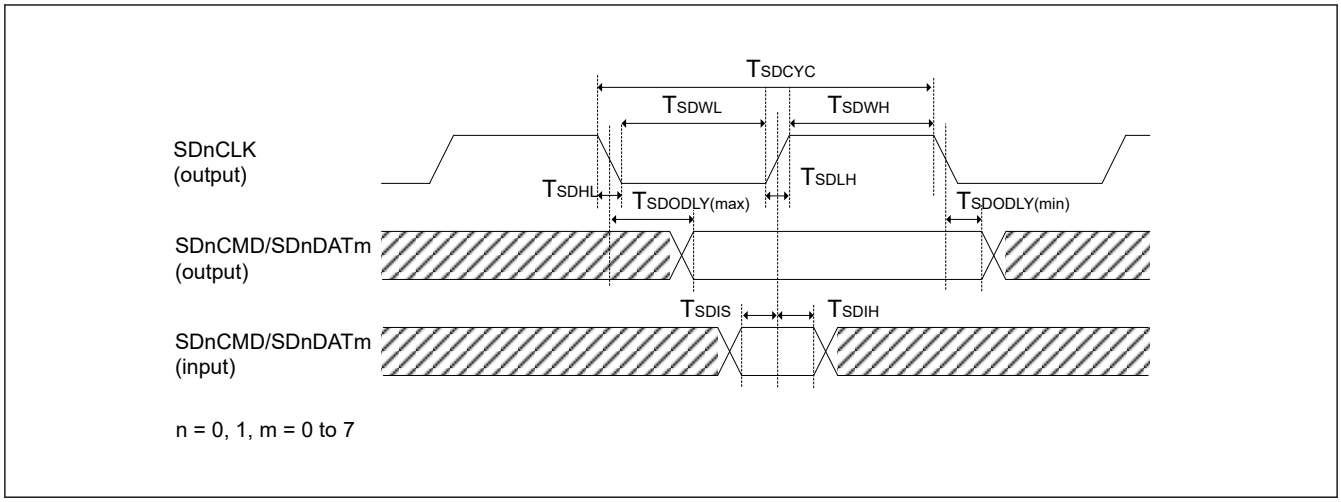

Figure 48.79 SD/MMC Host Interface signal timing

48.3.14 ETHERC Timing

Table 48.55 ETHERC timing

Conditions: ETHERC (RMII): Middle drive output is selected in the Port Drive Capability bit in the PmnPFS register for the following pins: ET0_MDC, ET0_MDIO.
For other pins, high drive output is selected in the Port Drive Capability bit in the PmnPFS register.
ETHERC (MII): Middle drive output is selected in the Port Drive Capability bit in the PmnPFS register.

Parameter		Symbol	VCC	Min	Max	Unit	Test conditions
ETHERC (RMII)	REF50CK0 cycle time	T_{ck}	2.70V or above	20	—	ns	Figure 48.80 to Figure 48.83
	REF50CK0 frequency, typical 50 MHz	—		—	50 + 100 ppm	MHz	
	REF50CK0 duty	—		35	65	%	
	REF50CK0 rise/fall time	$T_{ckr/ckf}$		0.5	3.5	ns

			—	±2.0	±7.5		LQFP package AVCC0 = VREFH0 = 2.7 to 3.6V
			—	±2.0	±7.5		BGA package AVCC0 = 2.7 to 3.6V VREFH0 = 2.7V to AVCC0
	DNL differential nonlinearity error		—	±0.5	±4.5	LSB	—
	INL integral nonlinearity error		—	±1.0	±5.5	LSB	—

Note: These specification values apply when only one A/D is operating and D/A and ACMPHS are not operating and there is no access to the external bus during A/D conversion.
If other A/D, D/A, or ACMPHS is operating or bus access occurs during A/D conversion, values might not fall within the indicated ranges.
The use of ports 0 as digital outputs is not allowed when the 12-Bit A/D converter is used.
The characteristics apply when AVCC0, AVSS0, VREFH0, VREFH, VREFL0, VREFL, and 12-bit A/D converter input voltage is stable.

Note 1. The conversion time includes the sampling and comparison times. The number of sampling states is indicated for the test conditions.

Note 2. Values in parentheses indicate the sampling time.

Table 48.60 A/D conversion characteristics for unit 1 (DCDC mode) (1 of 2)

Note: These specification values apply when only one A/D is operating and D/A and ACMPHS are not operating and there is no access to the external bus during A/D conversion.
If other A/D, D/A, or ACMPHS is operating or bus access occurs during A/D conversion, values might not fall within the indicated ranges.
The use of ports 0 as digital outputs is not allowed when the 12-Bit A/D converter is used.
The characteristics apply when AVCC0, AVSS0, VREFH0, VREFH, VREFL0, VREFL, and 12-bit A/D converter input voltage are stable.

Note 1. The conversion time includes the sampling and comparison times. The number of sampling states is indicated for the test conditions.

Note 2. Values in parentheses indicate the sampling time.

Table 48.61 A/D conversion characteristics for unit 0 (External VDD mode) (1 of 2)

Table 48.63 A/D internal reference voltage characteristics

Parameter	Min	Typ	Max	Unit	Test conditions
A/D internal reference voltage	1.13	1.18	1.28	V	—
Sampling time	4.15	—	—	µs	—

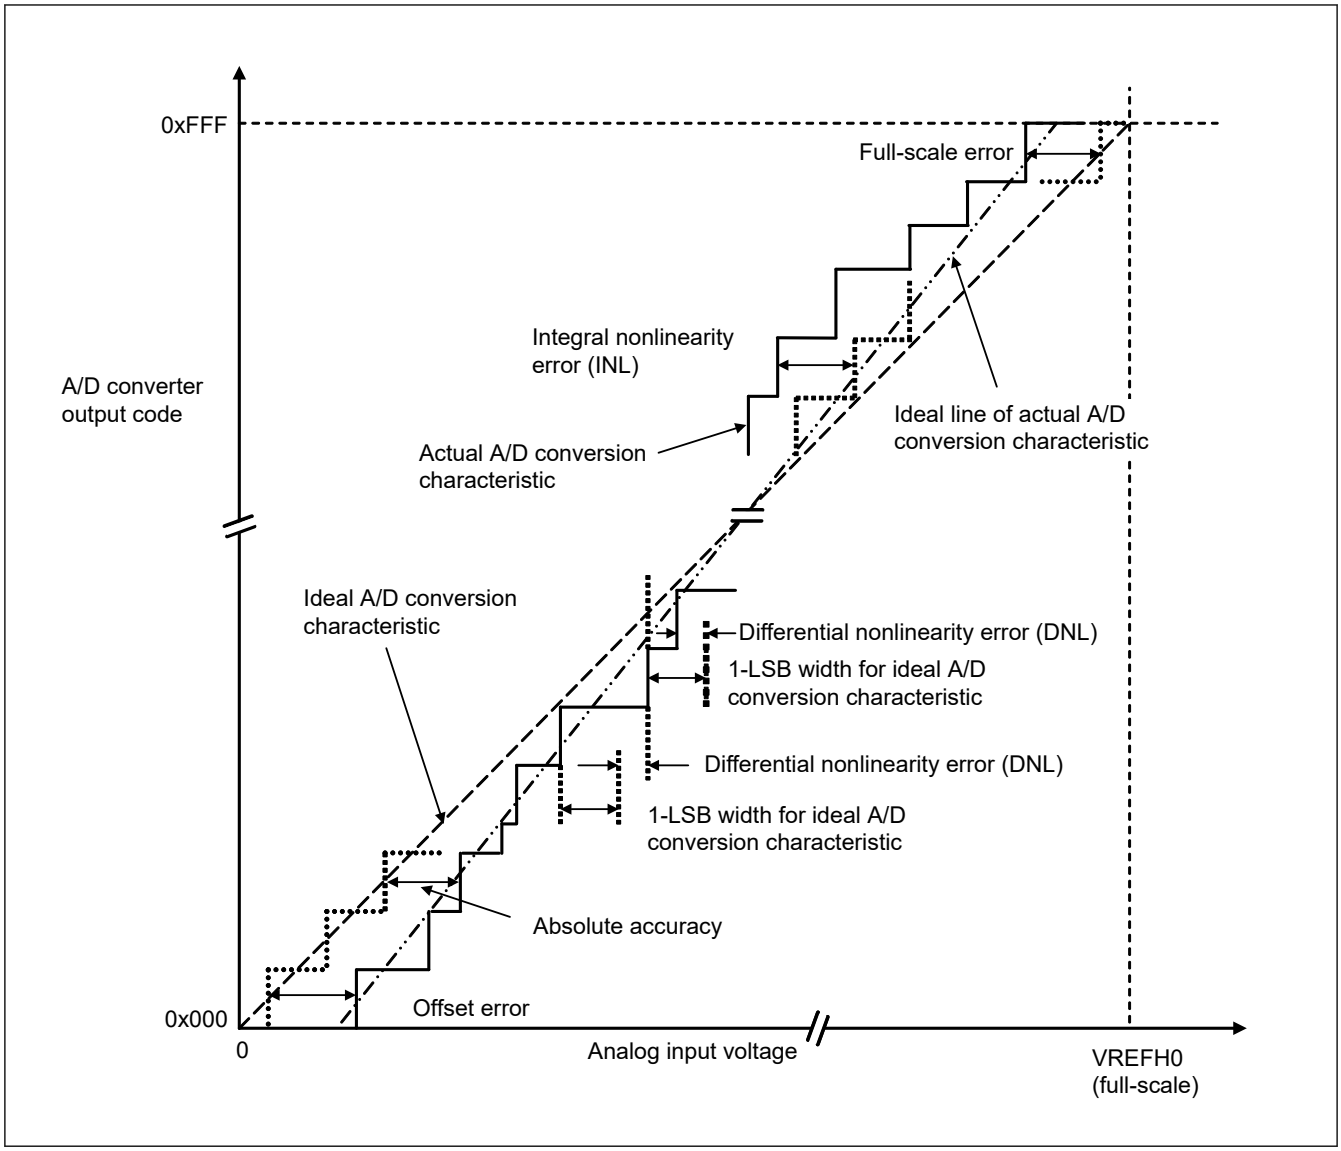

Figure 48.95 Illustration of ADC12 characteristic terms

Absolute accuracy

Absolute accuracy is the difference between output code based on the theoretical A/D conversion characteristics, and the actual A/D conversion result. When measuring absolute accuracy, the voltage at the midpoint of the width of the analog input voltage (1-LSB width), which can meet the expectation of outputting an equal code based on the theoretical A/D conversion characteristics, is used as an analog input voltage. For example, if 12-bit resolution is used and the reference voltage VREFH0 = 3.072 V, then the 1-LSB width becomes 0.75 mV, and 0 mV, 0.75 mV, and 1.5 mV are used as the analog input voltages. If the analog input voltage is 6 mV, an absolute accuracy of ±5 LSB means that the actual A/D conversion result is in the range of 0x003 to 0x00D, though an output code of 0x008 can be expected from the theoretical A/D conversion characteristics.

Integral nonlinearity error (INL)

Integral nonlinearity error is the maximum deviation between the ideal line when the measured offset and full-scale errors are zeroed, and the actual output code.

Differential nonlinearity error (DNL)

Differential nonlinearity error is the difference between the 1-LSB width based on the ideal A/D conversion characteristics and the width of the actual output code.

Offset error

Offset error is the difference between the transition point of the ideal first output code and the actual first output code.

Full-scale error

Full-scale error is the difference between the transition point of the ideal last output code and the actual last output code.

Table 48.64 A/D input voltage range for each input channel

			20*2 *3	—	—	20*2 *3	—	—		Tj = +105°C
			30*2 *3	—	—	30*2 *3	—	—		Tj = +85°C

Note 1. This is the minimum number of times to guarantee all the characteristics after reprogramming. The guaranteed range is from 1 to the minimum value.
Note 2. This indicates the minimum value of the characteristic when reprogramming is performed within the specified range.
Note 3. This result is obtained from reliability testing.

Note 4. The reprogram/erase cycle is the number of erasures for each block. When the reprogram/erase cycle is n times (n = 10,000), erasing can be performed n times for each block. For example, when 128-byte programming is performed 64 times for different addresses in 8-KB blocks, and then the entire block is erased, the reprogram/erase cycle is counted as one. However, programming the same address several times as one erasure is not enabled. Overwriting is prohibited.
Note 5. Time for resumption includes time for reapplying the erasing pulse (up to one full pulse) that was cut off at the time of suspension.
Note 6. The reference value at VCC = 3.3V and room temperature.

Second erasing resume time during erasure in suspend priority modeFirst erasing resume time during erasure in suspend priority mode		t_{DREST2}	—	—	126	—	—	70	µs	
Erasing resume time during erasure in erasure priority mode		t_{DREET}	—	—	126	—	—	70	µs	
Forced stop command		t_{FD}	—	—	32	—	—	20	µs	
Data hold time*3		t_{DRP}	10*3 *4	—	—	10*3 *4	—	—	Year	Tj = +125°C
			20*3 *4	—	—	20*3 *4	—	—		Tj = +105°C
			30*3 *4	—	—	30*3 *4	—	—		Tj = +85°C

Note 1. The reprogram/erase cycle is the number of erasures for each block. When the reprogram/erase cycle is n times (n = 125,000), erasing can be performed n times for each block. For example, when 4-byte programming is performed 16 times for different addresses in 64-byte blocks, and then the entire block is erased, the reprogram/erase cycle is counted as one. However, programming the same address several times as one erasure is not enabled. Overwriting is prohibited.
Note 2. This is the minimum number of times to guarantee all the characteristics after reprogramming. The guaranteed range is from 1 to the minimum value.
Note 3. This indicates the minimum value of the characteristic when reprogramming is performed within the specified range.
Note 4. This result is obtained from reliability testing.
Note 5. Time for resumption includes time for reapplying the erasing pulse (up to one full pulse) that was cut off at the time of suspension.
Note 6. The reference value at VCC = 3.3 V and room temperature.

48.11.3 Option Setting Memory (Code flash memory) Characteristics

Table 48.72 Option setting memory (Code flash memory) characteristics

Conditions: Program: FCLK = 4 to 60 MHz
Read: FCLK ≤ 60 MHz

Parameter	Symbol	FCLK = 4 MHz			20 MHz ≤ FCLK ≤ 60 MHz			Unit	Test conditions
		Min	Typ*4	Max	Min	Typ*4	Max		
Programming time N_{OPC} ≤ 200 times	t_{OP}	—	83	309	—	45	162	ms	
Programming time N_{OPC} > 200 times	t_{OP}	—	100	371	—	55	195	ms	
Reprogramming cycle	N_{OPC}	20000*1	—	—	20000*1	—	—	Times	
Data hold time*2	t_{DRP}	10*2 *3	—	—	10*2 *3	—	—	Years	Tj = +125°C
		20*2 *3	—	—	20*2 *3	—	—		Tj = +105°C
		30*2 *3	—	—	30*2 *3	—	—		Tj = +85°C

Note 1. This is the minimum number of times to guarantee all the characteristics after reprogramming. The guaranteed range is from 1 to the minimum value.
Note 2. This indicates the minimum value of the characteristic when reprogramming is performed within the specified range.
Note 3. This result is obtained from reliability testing.
Note 4. The reference value at VCC = 3.3 V and room temperature.

48.11.4 Option Setting Memory (Data flash memory) Characteristics

Table 48.73 Option Setting Memory (Data flash memory) characteristics

Conditions: Program: FCLK = 4 to 60 MHz
Read: FCLK ≤ 60 MHz

Parameter	Symbol	FCLK = 4 MHz			20 MHz ≤ FCLK ≤ 60 MHz			Unit	Test conditions
		Min	Typ*4	Max	Min	Typ*4	Max		
Command time for configuration set (4 / 16 Byte)	t_{DCCT}	—	68	515	—	35	255	ms	
Update Cycles in Configuration area	N_{cupc}	125000 *1	—	—	125000 *1	—	—	Times	
Data hold time*2	t_{DRP}	10*2 *3	—	—	10*2 *3	—	—	Years	Tj = +125°C
		20*2 *3	—	—	20*2 *3	—	—		Tj = +105°C
		30*2 *3	—	—	30*2 *3	—	—		Tj = +85°C

Note 1. This is the minimum number of times to guarantee all the characteristics after reprogramming. The guaranteed range is from 1 to the minimum value.
Note 2. This indicates the minimum value of the characteristic when reprogramming is performed within the specified range.
Note 3. This result is obtained from reliability testing.
Note 4. The reference value at VCC = 3.3 V and room temperature.

48.11.5 Anti-rollback counter Characteristics

Table 48.74 Anti-rollback counter characteristics (1 of 2)

Conditions: Program: FCLK = 4 to 60 MHz
Read: FCLK ≤ 60 MHz

Parameter	Symbol	FCLK = 4 MHz			20 MHz ≤ FCLK ≤ 60 MHz			Unit	Test conditions
		Min	Typ*4	Max	Min	Typ*4	Max		
Command time for increment counter and refresh counter	t_{IRCT}	—	11.9	81	—	6.3	42	ms	
Command time for read counter	t_{RCT}	—	—	25	—	—	5	µs	

Table 48.74 Anti-rollback counter characteristics (2 of 2)

Conditions: Program: FCLK = 4 to 60 MHz
Read: FCLK ≤ 60 MHz

Parameter	Symbol	FCLK = 4 MHz			20 MHz ≤ FCLK ≤ 60 MHz			Unit	Test conditions
		Min	Typ*4	Max	Min	Typ*4	Max		
Update Cycles (total of increment and refreshing)	N_{cupc}	125000 *1	—	—	125000 *1	—	—	Times	
Data hold time*2	t_{DRP}	10*2 *3	—	—	10*2 *3	—	—	Years	Tj = +125°C
		20*2 *3	—	—	20*2 *3	—	—		Tj = +105°C
		30*2 *3	—	—	30*2 *3	—	—		Tj = +85°C

Note 1. This is the minimum number of times to guarantee all the characteristics after reprogramming. The guaranteed range is from 1 to the minimum value.
Note 2. This indicates the minimum value of the characteristic when reprogramming is performed within the specified range.
Note 3. This result is obtained from reliability testing.
Note 4. The reference value at VCC = 3.3 V and room temperature.

48.12 Boundary Scan

			OPE=0	OPE=1	DSTBY1	DSTBY2/ DSTBY3	IOKEEP = 0	IOKEEP = 1*1
Others	—	Hi-Z	Keep-O		Keep		Hi-Z	Keep

Note: Hi-Z: High-impedance
Keep-O: Output pins retain their previous values. Input pins go to high-impedance.
Keep-I: Pin states are retained same as during periods in Normal mode.
Keep: Pin states are retained same as during periods in Software Standby mode.
Note 1. Retains the I/O port state until the DPSBYCR.IOKEEP bit is cleared to 0.
Note 2. Input is enabled if the pin is specified as the Software Standby canceling source while it is used as an external interrupt pin.
Note 3. Input is enabled if the pin is specified as the Deep Software Standby canceling source.
Note 4. Input is enabled while the pin is used as an input pin.
Note 5. Depending on the operation before the transition to Software Standby Mode, either High-level or Low-level is output. See section 13.9.1. BC0 pin when in Software Standby Mode (SSTBY) and SBYCR.OPE=1.

Appendix 2. Package Dimensions

Information on the latest version of the package dimensions or mountings is displayed in “Packages” on the Renesas Electronics Corporation website.

Appendix 3. I/O Registers

This appendix describes I/O register address and access cycles by function.

3.1 Peripheral Base Addresses

This section provides the base addresses for peripherals described in this manual. Table A3.1 shows the name, description, and the base address of each peripheral.

Table A3.1 Peripheral base address (1 of 3)

Description	Name of Secure registers	Base address of Secure registers in Secure alias region	Name of Non-secure registers	Base address of Non-secure registers in Non-secure alias region
Renesas Memory Protection Unit	RMPU	0x4000_0000	RMPU_NS	0x5000_0000
SRAM Control	SRAM	0x4000_2000	SRAM_NS	0x5000_2000
BUS Control	BUS	0x4000_3000	BUS_NS	0x5000_3000

Note: Name = Peripheral name
Description = Peripheral functionality
Base address = Lowest reserved address or address used by the peripheral

3.2 Access Cycles

This section provides access cycle information for the I/O registers described in this manual.

- Registers are grouped by associated module.
- The number of access cycles indicates the number of cycles based on the specified reference clock.
- In the internal I/O area, reserved addresses that are not allocated to registers must not be accessed, otherwise operations cannot be guaranteed.
- The number of I/O access cycles depends on bus cycles of the internal peripheral bus, divided clock synchronization cycles, and wait cycles of each module. Divided clock synchronization cycles differ depending on the frequency ratio between ICLK and PCLK.
- When the frequency of ICLK is equal to that of PCLK, the number of divided clock synchronization cycles is always constant.

- When the frequency of ICLK is greater than that of PCLK, at least 1 PCLK cycle is added to the number of divided clock synchronization cycles.
- The number of write access cycles indicates the number of cycles obtained by non-bufferable write access.

Note: This applies to the number of cycles when access from the CPU does not conflict with the instruction fetching to the external memory or bus access from other bus masters such as DTC or DMAC.

Table A3.2 Access cycles (1 of 3)

Peripheral base address symbol	Address*1		Number of access cycles				Cycle Unit	Related function
			ICLK = PCLK		ICLK > PCLK*2			
	From	To	Read	Write	Read	Write		
RMPU, SRAM, BUS, ICU_COMMON, CPSCU, DMAC0n, DMA0, DTC0, ICU, CPU_CTRL	0x4000_0000	0x4001_CFFF	3	2	3	2	ICLK	Renesas Memory Protection Unit, SRAM Control, BUS Control, Common Interrupt Controller, CPU System Security Control Unit, Direct memory access controller 0 n, DMAC Module Activation 0, Data Transfer Controller 0, Interrupt Controller, CPU Control Registers

RSIP-E51A	—	—	1 to 3	2	1 to 3	1 to 2	PCLKA	Renesas Security IP

Table A3.2 Access cycles (3 of 3)

Peripheral base address symbol	Address*1		Number of access cycles				Cycle Unit	Related function
			ICLK = FCLK		ICLK > FCLK*2			
	From	To	Read	Write	Read	Write		
FLAD, FACI	0x4011_C040	0x4011_EFFF	4	3	4	3	FCLK	Data Flash, Flash Application Command Interface

Note 1. This table only shows secure address. Access cycle of the non-secure address is the same as its secure address.
Note 2. If the number of PCLK or FCLK cycles is non-integer (for example 1.5), the minimum value is without the decimal point, and the maximum value is rounded up to the decimal point. For example, 1.5 to 2. 5 is 1 to 3.

Appendix 4. Note for Register R/W

- A secure bus master issues a "secure access" using an address marked as secure by IDAU/SAU or MSAU.
- A secure bus master issues a "non-secure access" using an address marked as non-secure by IDAU/SAU or MSAU.
- A non-secure bus master issues a "non-secure access" using an address marked as non-secure by IDAU/SAU or MSAU.

Table A4.1 Type of Register Notes (S-TYPE)

TYPE	UM Description
S-TYPE-1	Only Secure access can write to this register. Read access is always allowed. Non-secure write access is ignored, but TrustZone access error is not generated.
S-TYPE-2	Read access is always allowed If the security attribution is configured as Secure, ● Secure write access is allowed. ● Non-secure write access is ignored, but TrustZone access error is not generated.
	If the security attribution is configured as Non-secure, ● Secure write access is ignored, but TrustZone access error is not generated. ● Non-secure access is allowed.
S-TYPE-3	If the security attribution is configured as Secure, ● Secure access is allowed. ● Non-secure write access is ignored and Non-secure read access is read as 0, TrustZone access error is generated
	If the security attribution is configured as Non-secure, ● Secure write access is ignored and Secure read access is read as 0, TrustZone access error is generated. ● Non-secure access is allowed
S-TYPE-4	If the security attribution is configured as Secure, ● Secure access is allowed ● Non-secure write access is ignored and Non-secure read access is read as 0, but TrustZone access error is not generated.
	If the security attribution is configured as Non-secure, ● Secure write access is ignored and Secure read access is read as 0, but TrustZone access error is not generated. ● Non-secure access is allowed.
S-TYPE-5	Access is always allowed.
S-TYPE-6	Secure access is allowed. Non-secure write access is ignored, and Non-secure read access is read as 0, TrustZone access error is generated.
S-TYPE-7	Secure write access is ignored, and Secure read access is read as 0, TrustZone access error is generated. Non-secure access is allowed.

Note: A non-secure bus master does NOT issue any access using an address marked as secure by IDAU/SAU or MSAU.

Table A4.2 Type of Register Notes (P-TYPE)

TYPE	UM Description
P-TYPE-1	Privileged write access is allowed. Read access is always allowed. Unprivileged write access is ignored, but TrustZone access error is not generated.
P-TYPE-2	Privileged access is allowed. Unprivileged write access is ignored, and Unprivileged read access is read as 0, TrustZone access error is generated.
P-TYPE-3	If the privilege attribution is configured as Privileged, ● Privileged access is allowed. ● Unprivileged write access is ignored and Unprivileged read access is read as 0, TrustZone access error is generated.
	If the privilege attribution is configured as Unprivilege, ● Privileged access and Unprivileged access are allowed.
P-TYPE-4	If the privilege attribution is configured as Privileged, ● Privileged access is allowed. ● Unprivileged write access is ignored and Unprivileged read access is read as 0, TrustZone access error is not generated.
	If the privilege attribution is configured as Unprivilege, ● Privileged access and Unprivileged access are allowed.
P-TYPE-5	Access is always allowed.

Appendix 5. Peripheral Variant

Table A5.1 shows the correspondence between the module name used in this manual and the Peripheral Variant.

Table A5.1 Module name vs Peripheral Variant

Module name	Peripheral variant
SCI	SCI_B
SPI	SPI_B
DOC	DOC_B

Revision History

Revision 1.10 — January 23, 2024

First edition, issued

Revision 1.20 — November 22, 2024

Features:
- Updated Security and Encryption.

1. Overview:
- Updated Table 1.13 Function Comparison.

2. CPU:
- Updated Table 2.9 CPU peripherals.

4. Address Space:
- Updated Note 1 in Figure 4.1 Memory map example of 2 MB flash product.

5. Resets:
- Updated Table 5.3 Module-related registers initialized by each reset source.

6. Option-Setting Memory:
- Updated 6.2.5 OFS1, OFS1_SEC : Option Function Select Register 1 for Non-secure and Secure.
- Updated 6.2.10 PBPS, PBPS_SEC : Permanent Block Protect Setting Register.
- Updated 6.2.20 CFGD2LOCK : Configuration Data 2 Lock Bit.
- Deleted 6.5 References.

8. Clock Generation Circuit:
- Updated Table 8.1 Clock generation circuit specifications for the clock sources.
- Updated 8.2.1 CGFSAR : Clock Generation Function Security Attribute Register.
- Updated 8.2.6 PLLCCR : PLL Clock Control Register.
- Updated 8.2.9 PLL2CCR : PLL2 Clock Control Register.
- Updated 8.2.13 MOSCCR : Main Clock Oscillator Control Register.
- Updated 8.2.16 HOCOCR : High-Speed On-Chip Oscillator Control Register.
- Added 8.2.17 HOCOCR2 : High-Speed On-Chip Oscillator Control Register2.
- Updated 8.2.20 FLLCR2 : FLL Control Register2.
- Updated 8.2.46 TRCKCR : Trace Clock Control Register.
- Added Note 1 to the following sections:
  - 8.10.1 CPU Clock (CPUCLK)
  - 8.10.2 System Clock (ICLK)
  - 8.10.4 Peripheral Module Clock (PCLKA, PCLKB, PCLKC, PCLKD, PCLKE)
  - 8.10.5 FlashIF Clock (FCLK)
  - 8.10.6 External Bus Clock (BCLK, EBCLK)
  - 8.10.7 SDRAM Clock (SDCLK)
  - 8.10.9 SCI Clock (SCICLK)
  - 8.10.10 SPI Clock (SPICLK)
  - 8.10.11 CANFD Core clock (CANFDCLK)
  - 8.10.12 USB Clock (USBCLK)
  - 8.10.13 I3C Clock (I3CCLK)
  - 8.10.20 External Pin Output Clock (CLKOUT)
- Updated Table 8.14 Example of the HOCO initial setting procedure after reset release / after Deep Software Standby cancellation (OFS1(_SEC).HOCOEN = 1, without FLL).
- Updated Table 8.15 Example of the HOCO setting procedure with FLL function after reset release / after Deep Software Standby cancellation (OFS1(_SEC).HOCOEN = 1).

10. Low Power Modes:
- Updated 10.2.3 RSCSAR : RAM Standby Control Security Attribution Register.
- Updated 10.2.11 PDRAMSCR0 : SRAM Power Domain Standby Control Register 0.

11. Register Write Protection:
- Updated Table 11.1 Association between the bits in the PRCR register and registers to be protected.

12. Interrupt Controller Unit:
- Updated Table 12.4 Event table.

13. Buses:
- Updated Figure 13.1 System bus connection.
- Updated Table 13.2 System bus access path.
- Updated 13.3.8 CSnMOD : CSn Mode Register (n = 0 to 7).
- Updated 13.3.10 CSnWCR2 : CSn Wait Control Register 2 (n = 0 to 7).
- Updated 13.7.2 Operations When a Bus Error Occurs.
- Updated Table 13.47 Conditions leading to illegal address access errors.

Revision 1.20 — November 22, 2024

15. DMA Controller:
- Updated 15.2.2 DMACCHPAR : DMA channel Privilege Attribution Register.
- Updated Figure 15.19 Example of use case: from unaligned ring buffer to single ring buffer.
- Updated 15.3.13 Channel Security.

16. Data Transfer Controller:
- Updated 16.8.1 Interrupt Request of Transfer End.

19. Port Output Enable for GPT:
- Updated 19.3.1.1 Digital Filter.
- Updated 19.5 External Trigger Output to the GPT.

20. General PWM Timer:
- Updated the base address in the following sections:
  - 20.2.22 GTADTRk : A/D Conversion Start Request Timing Register k (k = A, B)
  - 20.2.23 GTADTBRk : A/D Conversion Start Request Timing Buffer Register k (k = A, B)
  - 20.2.24 GTADTDBRk : A/D Conversion Start Request Timing Double-Buffer Register k (k = A, B)
- Updated 20.2.28 GTICLF : General PWM Timer Inter Channel Logical Operation Function Setting Register.

21. Low Power Asynchronous General Purpose Timer:
- Updated Figure 21.9 Operation example 2 in event counter mode.

22. Ultra-Low-Power Timer:
- Updated 22.4.7 Standby mode.
- Updated 22.5.9 Restrictions on Event Counting during Deep Software Standby Mode 1.

23. Watchdog Timer:
- Updated 23.3.3 Refresh Operation.

24. Independent Watchdog Timer:
- Updated Figure 24.6 IWDT refresh operation waveforms (IWDTCR.CKS[3:0] = 0000b, IWDTCR.TOPS[1:0] = 11b).
- Updated Figure 24.8 Processing for reading IWDT counter value when IWDTCR.CKS[3:0] = 0000b and IWDTCR.TOPS[1:0] = 11b.
- Updated Figure 24.9 Processing for reading IWDT counter value when IWDTCR.CKS[3:0] = 0010b and IWDTCR.TOPS[1:0] = 11b.

26. Ethernet DMA Controller:
- Updated 26.5.1 Settings for the Module-Stop Function.

27. USB 2.0 Full-Speed Module:
- Updated 27.2.31 PIPESEL : Pipe Window Select Register.
- Updated 27.2.34 PIPEPERI : Pipe Cycle Control Register.
- Updated 27.3.3.1 BRDY interrupt.
- Updated 27.3.5 FIFO Buffer.

28. Serial Communications Interface:
- Updated 28.2.11 FCR : FIFO Control Register.
- Updated 28.3.6 Address Match (Receive Data Match Detection) Function.
- Updated 28.3.8 Serial Data Transmission in Asynchronous Mode.
- Updated 28.3.9 Serial Data Reception in Asynchronous Mode.
- Updated 28.5.3 Initialization of the SCI in Manchester Mode.
- Updated Table 28.44 SCI interrupt sources with FIFO selected.

29. I^2C Bus Interface:
- Updated Precautions on the use of the wakeup function in 29.8 Wakeup Function.

30. I3C Bus Interface:
- Updated 30.2.64 SDATBASn : Slave Device Address Table Basic Register n (n = 0 to 2).

31. CAN-FD:
- Updated 31.2.56 CFDGLOCKK : Global Lock Key Register.
- Updated 31.6.2.1 FIFO Buffers Configuration.
- Updated 31.9.2.1 RAM Test Mode.
- Added 31.10 RAM Area Configuration, 31.10.1 Examples, 31.10.2 OTB Area, 31.10.3 RAM Initialization Cycle.
- Updated Table 31.30 RAM initialization cycle.

33. Serial Peripheral Interface:
- Updated 33.2.10 SPTFSR : SPI Transfer FIFO Status Register.

37. Security Features:
- Updated 37.2.3.5 Memory Security Attribution of TrustZone filter.
- Updated 37.5 Secure Factory Programming.

39. 12-Bit A/D Converter:
- Updated 39.3.6 Analog Input Sampling and Scan Conversion Time.
- Updated 39.6.13 Port Settings When Using the ADC12 Input.

Revision 1.20 — November 22, 2024

46. Flash Memory:
- Updated the base address in the following sections:
  - 46.4.5 UIDRn : Unique ID Registers n (n = 0 to 3)
  - 46.4.6 PNRn : Part Numbering Register n (n = 0 to 3)
  - 46.4.7 MCUVER : MCU Version Register
- Updated 46.5.1 Feature of flash cache.
- Updated Table 46.17 FACI commands.
- Updated Table 46.23 Address Used by Configuration Set Command for Secure alias (Data flash memory).
- Updated Figure 46.36 Example of Block Swap Selection Flow for Secure alias (For Products with 2 Mbytes of Code Flash Memory).
- Updated Table 46.36 Protection Condition of Lockable area in Data Flash Configuration Area for Secure alias.
- Updated 46.12.5 Anti-Rollback Counter.

48. Electrical Characteristics:
- Updated Table 48.8 Current of high-speed mode, maximum condition (MVE and peripheral operation) (DCDC mode).
- Updated Table 48.9 Current of high-speed mode, maximum condition (MVE and peripheral operation) (External VDD mode).
- Updated Table 48.27 Power consumption of each unit.
- Updated Table 48.56 CANFD interface timing.

Appendix 5. Peripheral Variant:
- Added Appendix 5. Peripheral Variant.

Revision 1.30 — December 19, 2025

1. Overview:
- Updated Figure 1.2 Part numbering scheme.
- Updated Table 1.13 Function Comparison.
- Updated Table 1.15 Pin list.

2. CPU:
- Updated Table 2.5 Initial vector table base address.

6. Option-Setting Memory:
- Updated 6.2.5 OFS1, OFS1_SEC : Option Function Select Register 1 for Non-secure and Secure.
- Updated 6.2.6 OFS1_SEL : Option Function Select Register 1 for Security Attribution.
- Updated 6.2.16 SAMR : Start Address of Measurement Report.
- Added 6.4.4 Notes on FSBL execution.

8. Clock Generation Circuit:
- Updated 8.2.31 LOCOUTCR : LOCO User Trimming Control Register.
- Updated 8.2.32 MOCOUTCR : MOCO User Trimming Control Register.
- Updated 8.2.34 MOSCSCR : Main Clock Oscillator Standby Control Register.
- Updated 8.2.35 HOCOSCR : High-Speed On-Chip Oscillator Standby Control Register.
- Updated 8.2.36 USBCKDIVCR : USB Clock Division Control Register.
- Updated 8.2.37 CANFDCKDIVCR : CANFD Core Clock Division Control Register.
- Updated 8.2.38 I3CCKDIVCR : I3C clock Division control register.
- Updated 8.2.39 USBCKCR : USB Clock Control Register.
- Updated 8.2.40 CANFDCKCR : CANFD Core Clock Control Register.
- Updated 8.2.41 I3CCKCR : I3C clock control register.
- Updated 8.2.42 SCICKDIVCR : SCI clock Division control register.
- Updated 8.2.43 SPICKDIVCR : SPI clock Division control register.
- Updated 8.2.44 SCICKCR : SCI clock control register.
- Updated 8.2.45 SPICKCR : SPI clock control register.
- Updated 8.10.1 CPU Clock (CPUCLK).
- Updated 8.10.2 System Clock (ICLK)
- Updated 8.10.4 Peripheral Module Clock (PCLKA, PCLKB, PCLKC, PCLKD, PCLKE).
- Updated 8.10.5 FlashIF Clock (FCLK).
- Updated 8.10.6 External Bus Clock (BCLK, EBCLK).
- Updated 8.10.7 SDRAM Clock (SDCLK).
- Updated 8.10.9 SCI Clock (SCICLK).
- Updated 8.10.10 SPI Clock (SPICLK).
- Updated 8.10.11 CANFD Core clock (CANFDCLK).
- Updated 8.10.12 USB Clock (USBCLK).
- Updated 8.10.13 I3C Clock (I3CCLK).
- Added 8.12.6 Notes on MOSCSCR.MOSCSOKP.

Revision 1.30 — December 19, 2025

10. Low Power Modes:
- Updated Table 10.2 Operating state of processor low power mode.
- Updated Table 10.3 Operating state of each low power mode.
- Updated Figure 10.1 Mode Transitions.
- Updated 10.2.5 MSTPCRB : Module Stop Control Register B.
- Updated 10.2.6 MSTPCRC : Module Stop Control Register C.
- Updated 10.2.9 SBYCR : Standby Control Register.
- Updated Figure 10.8 Additional flow for the canceling software standby mode.
- Added 10.7.11 Interruption During Transition to Low Power Modes.

13. Buses:
- Updated Table 13.9 Bus priorities with fixed-priority arbitration (ARBS = 0).
- Updated Table 13.10 Bus priorities with round-robin arbitration (ARBS = 1).
- Updated 13.3.31 BUSnERRCLR : BUS Error Clear Register (n = 1 to 5, 10).
- Updated Table 13.38 SDRAM connection example (512-Mb × 2, with 16-bit bus).
- Updated Table 13.40 SDRAM connection example (128-Mb × 2, with 16-bit bus).
- Updated Table 13.41 SDRAM connection example with 512-Mb × 2 and 8-bit bus.

18. I/O Ports:
- Updated Table 18.6 Register settings for input/output pin function (PORT1).
- Updated Table 18.7 Register settings for input/output pin function (PORT2).
- Updated Table 18.8 Register settings for input/output pin function (PORT3).
- Updated Table 18.9 Register settings for input/output pin function (PORT4).
- Updated Table 18.11 Register settings for input/output pin function (PORT6).
- Updated Table 18.12 Register settings for input/output pin function (PORT7).
- Updated Table 18.13 Register settings for input/output pin function (PORT8).
- Updated Table 18.14 Register settings for input/output pin function (PORT9)
- Updated Table 18.15 Register settings for input/output pin function (PORTA).
- Updated Table 18.16 Register settings for input/output pin function (PORTB).

20. General PWM Timer:
- Updated 20.2.12 GTCR : General PWM Timer Control Register.
- Updated 20.4.1 Interrupt Sources.
- Updated Figure 20.71 Example of A/D Conversion Start Request Timing Operation.

21. Low Power Asynchronous General Purpose Timer:
- Updated Table 21.1 AGT specifications.
- Updated Table 21.9 Usable settings in Software Standby mode (AGT0).
- Updated Table 21.10 Usable settings in Software Standby mode (AGT1).

22. Ultra-Low-Power Timer (ULPT):
- Updated Table 22.1 ULPT specifications.

23. Watchdog Timer:
- Updated Figure 23.1 WDT block diagram.

24. Independent Watchdog Timer:
- Updated Figure 24.1 IWDT block diagram.
- Updated 24.2.2 IWDTCR : IWDT Control Register.
- Updated Figure 24.2 RPSS[1:0] and RPES[1:0] bits settings and refresh-permitted and refresh-prohibited periods.

26. Ethernet DMA Controller:
- Updated 26.2.17 RPADIR : Receive Data Padding Insert Register.

27. USB 2.0 Full-Speed Module:
- Updated 27.2.31 PIPESEL : Pipe Window Select Register.

29. I^2C Bus Interface:
- Updated 29.3.6 Slave Receive Operation.

30. I3C Bus Interface:
- Updated 30.2.1 PRTS : Protocol Selection Register.
- Updated Figure 30.140 Example of I2C initialization flowchart (single buffer transfer).
- Updated Figure 30.141 Example of each initialization flowchart for I3C master mode and slave mode.
- Added 30.7.4 Notes on Rewriting PRTS.PRTMD Bit.

31. CAN-FD:
- Updated Table 31.1 CANFD module specifications.
- Updated Table 31.2 Clock restriction.

33. Serial Peripheral Interface:
- Updated 33.3.12.1 Master mode operation.
- Updated Figure 33.69 Transmission flow in slave mode.

Revision 1.30 — December 19, 2025

35. Cyclic Redundancy Check:
- Updated 35.2.4 CRCDOR/CRCDOR_HA/CRCDOR_BY : CRC Data Output Register.

37. Security Features:
- Updated 37.2.3.6 Peripheral Security Attribution of TrustZone filter.
- Updated Table 37.4 Access permission of type1 peripherals.
- Updated Table 37.6 Lifecycle state definition and capabilities in each state.
- Updated 37.3.1 Changing the Lifecycle State.
- Updated 37.5 Secure Factory Programming.
- Updated Figure 37.14 Format and location of the measurement report.

39. 12-Bit A/D Converter:
- Updated Table 39.4 ADC12 I/O pins (unit 1).
- Updated 39.3.3.6 Channel Selection and Self-Diagnosis (With Channel-Dedicated Sample-and- Hold Circuits and Continuous Sampling Enabled).
- Updated Table 39.26 Conversion times during scanning (in numbers of cycles of ADCLK and PCLKA).

40. 12-Bit D/A Converter:
- Updated Table 40.2 DAC12 I/O pins.
- Updated 40.2.2 DACR : D/A Control Register.

46. Flash Memory:
- Updated Table 46.11 Flash Cache 2 (FCACHE2) overview.
- Updated Figure 46.27 Usage of the Refresh Counter Command.

48. Electrical Characteristics:
- Updated Table 48.6 I/O I_{OH}, I_{OL}.
- Updated Table 48.54 SD/MMC Host Interface signal timing.
- Added Table 48.64 A/D input voltage range for each input channel.

Appendix 4. Note for Register R/W:
- Updated Table A4.1 Type of Register Notes(S-TYPE).
- Updated Table A4.2 Type of Register Notes(P-TYPE).

Appendix 5. Peripheral Variant:
- Updated Table A5.1 Module name vs Peripheral Variant.
