The register bits of each process can be identified by the number in the register name like GR0_xxxx, GR1_xxxx, GR2_xxxx, GR3_xxxx, and GR_OIR_xxxx, respectively. In the sections except for Register Descriptions, however, the number is omitted like GR_xxxx for convenience sake.

In the VIN synthesizer, graphics data read is not controlled and the blending register GR_VIN_xxxx is present. In this manual, the name is omitted like GR_xxxx for convenience sake. The synthesizer does not have the read control register (GR_FLM).

### (1) Updating Registers

The Vsync signal is used to control the update timing of the registers for graphics display and frame buffer read control, except for some of the registers.

After 1 is set to the bits in the update control register, the contents of the relevant registers are actually modified at the rising edge of the Vsync signal, when the update control register is automatically cleared to 0.

**Table 35.1 Register Update Control**

| Register Name | Bit Name | Initial Value | Description |
|---|---|---|---|
| GR_UPDATE | GR_UPDATE | 0 | Frame Buffer Read Control Register Update<br>0: Registers are not updated.<br>1: Registers are updated. |
| GR_UPDATE | GR_P_VEN | 0 | Graphics Display Register Update<br>0: Registers are not updated.<br>1: Registers are updated at the rising edge of the Vsync. |
| GR_UPDATE | GR_IBUS_VEN | 0 | Frame Buffer Read Register Update*<br>0: Registers are not updated.<br>1: Registers are updated at the rising edge of the Vsync. |

Note: * This bit is not supported for the VIN synthesizer.

### (2) Frame Buffer Burst Transfer Mode

Either 32-byte or 128-byte transfer mode can be selected for accessing the frame buffer in which video data and graphics data are stored.

**Table 35.2 Frame Buffer Burst Transfer Mode**

| Register Name | Bit Name | Initial Value | Description |
|---|---|---|---|
| GR_FLM1 | GR_BST_MD | 0 | Frame Buffer Burst Transfer Mode<br>0: 32-byte transfer<br>1: 128- byte transfer |

### (3) Frame Buffer Control Mode

More than one frame of data is read from the frame buffer.

For graphics data, set the GR_FLM_SEL[1:0] bits to 1, and set the specific display frame number with the GR_FLM_NUM[9:0] bits. For video data, select a mode with the GR_FLM_SEL[1:0] bits depending on the writing process used; the quantity of the frames used for video data is set in the writing process block.

**Table 35.3 Frame Buffer Control Mode**

| Register Name | Bit Name | Initial Value | Description |
|---|---|---|---|
| GR_FLM1 | GR_FLM_SEL[1:0] | 0 | Frame Buffer Address Setting Signal Select<br>0: Control linked to scaling-down process, or frame 0 selected. *1<br>1: Register GR_FLM_NUM selected.<br>2: Control linked to distortion correction, or frame 0 selected. *2<br>3: Control linked to pointer buffer, or setting prohibited. *3 |
| GR_FLM3 | GR_FLM_NUM[9:0] | 0 | Frame Number of Frame Buffer<br>Manually set the frame number when GR_FLM_SEL = 1. |

Notes: 1. For the graphics 0, 1, and OIR processes, frame buffer control links to the scaling-down process. For the graphics 2 and 3 processes, frame 0 is selected.
2. For the graphics 0 and OIR processes, frame buffer control links to distortion correction. For the graphics 1, 2 and 3 processes, frame 0 is selected.
3. For the graphics 0, 1, and OIR processes, frame buffer control links to the pointer buffer. For the graphics 2 and 3 processes, setting is prohibited.

### (4) Frame Buffer Read Control

The following bit enables or disables read access to the frame buffer.

**Table 35.4 Frame Buffer Read Control**

| Register Name | Bit Name | Initial Value | Description |
|---|---|---|---|
| GR_FLM_RD | GR_R_ENB | 0 | Frame Buffer Read Enable<br>0: Disables read access to the frame buffer.<br>1: Enables read access to the frame buffer. |

### (5) Distortion Correction Frame Buffer Control

Two frames (frames 0 and 1) are used for distortion correction, and the frame numbers to be read by the image renderer are set.

The frame numbers to be read (frames 0 and 1) can be switched by setting the GR_IMR_FLM_INV bit.

This bit is enabled only when the GR_FLM_SEL bits are set to 2.

**Table 35.5 Distortion Correction Frame Buffer Control**

| Register Name | Bit Name | Initial Value | Description |
|---|---|---|---|
| GR1_FLM1 | GR1_IMR_FLM_INV | 0 | Sets the frame buffer number for distortion correction.*<br>0:Does not switch the frame numbers to be read.<br>1:Switches the frame numbers to be read. |

Note: * This function is supported for the graphics 0 and OIR processes only.

## (6) Frame Buffer Size

The following bits set the size of the frame buffer to be read.

The numbers of horizontal pixels and of lines in the vertical direction are set with the GR_HW[10:0] and GR_FLM_LNUM[10:0] bits, respectively.

**Table 35.6 Frame Buffer Size**

| Register Name | Bit Name | Initial Value | Description |
|---|---|---|---|
| GR_FLM6 | GR_HW[10:0] | 0 | Sets the width of the horizontal valid period.<br>The width is (GR_HW + 1) pixels.<br>Note: Set to 2 or greater. |
| GR_FLM5 | GR_FLM_LNUM[10:0] | 0 | Sets the number of lines in a frame<br>The number of lines is (GR_FLM_LNUM + 1). |

## (7) Calculating Addresses in Frame Buffer

The data area in the frame buffer is defined using the addresses specified by GR_BASE[31:0], GR_LN_OFF[14:0], and GR_FLM_OFF[22:0] bits and the display frame number.

The GR_LN_OFF[14:0] and GR_FLM_OFF[22:0] bits should be set in units of 32/128 bytes (the lower 5/7 bits should be fixed to 0).

The GR_BASE[31:0] bits should be set in units of 64 bits to set the display data start position (the lower three bits should be fixed).

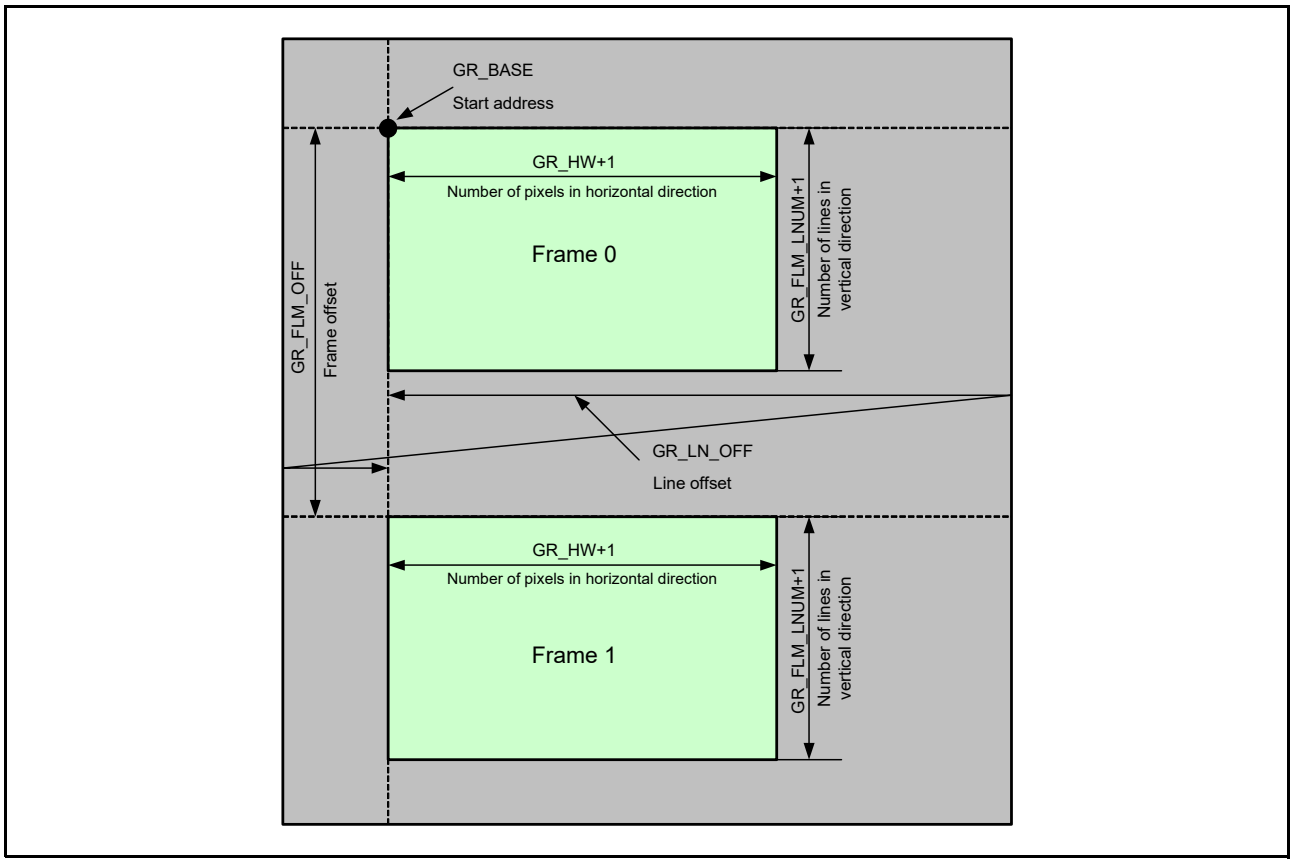

**Figure 35.2 Data Arrangement in Frame Buffer**

**Table 35.7 Calculation of Addresses in Frame Buffer**

| Register Name | Bit Name | Initial Value | Description |
|---|---|---|---|
| GR_FLM2 | GR_BASE[31:0] | 0 | Frame Buffer Base Address<br>Sets the start address of the frame buffer where frame data is to be stored.<br>GR_BASE[4:3] and GR_BASE[6:3] are referred to during 32-byte burst transfer and 128-byte burst transfer, respectively, to skip the start line data.<br>The lower 3 bits should be set to 000. |

| GR_FLM4 | GR_FLM_OFF[22:0] | 0 | Frame Buffer Frame Offset Address (lower)<br>Specifies the frame offset address used for calculating the start address of each frame buffer when more than one buffer is used.<br>Buffer 0: GR_BASE<br>Buffer 1: GR_BASE + GR_FLM_OFF × 1<br>:<br>Buffer n: GR_BASE + GR_FLM_OFF × n<br>For 32-byte transfer, the lower 5 bits should be fixed to 0_0000.<br>For 128-byte transfer, the lower 7 bits should be fixed to 000_0000. |

## (8) Setting Frame Buffer Size Smaller than One Frame

Frame buffer size can be set in one-line units.

When the number of lines set with the GR_FLM_LOOP[10:0] bits is smaller than the value of the GR_FLM_LNUM[10:0] bits, data is again read from the start address of the frame buffer after the number of lines set with the (GR_FLM_LOOP[10:0] + 1) bits have been read.

**Table 35.8 Setting of Frame Buffer Size Smaller than One Frame**

| Register Name | Bit Name | Initial Value | Description |
|---|---|---|---|
| GR_FLM5 | GR_FLM_LOOP[10:0] | 1023 | Number of lines when reading the addresses repeatedly by returning to the start address after reaching the end address.<br>The number of lines is (GR_FLM_LOOP + 1). |

## (9) Line Offset Control for Frame Buffer

The following bit sets the line offset address direction of the frame buffer.

**Table 35.9 Line Offset Address Direction Control for Frame Buffer**

| Register Name | Bit Name | Initial Value | Description |
|---|---|---|---|
| GR_FLM1 | GR_LN_OFF_DIR | 0 | Selects the line offset address direction of the frame buffer.<br>0:Increments the address by the line offset address.<br>1:Decrements the address by the line offset address. |

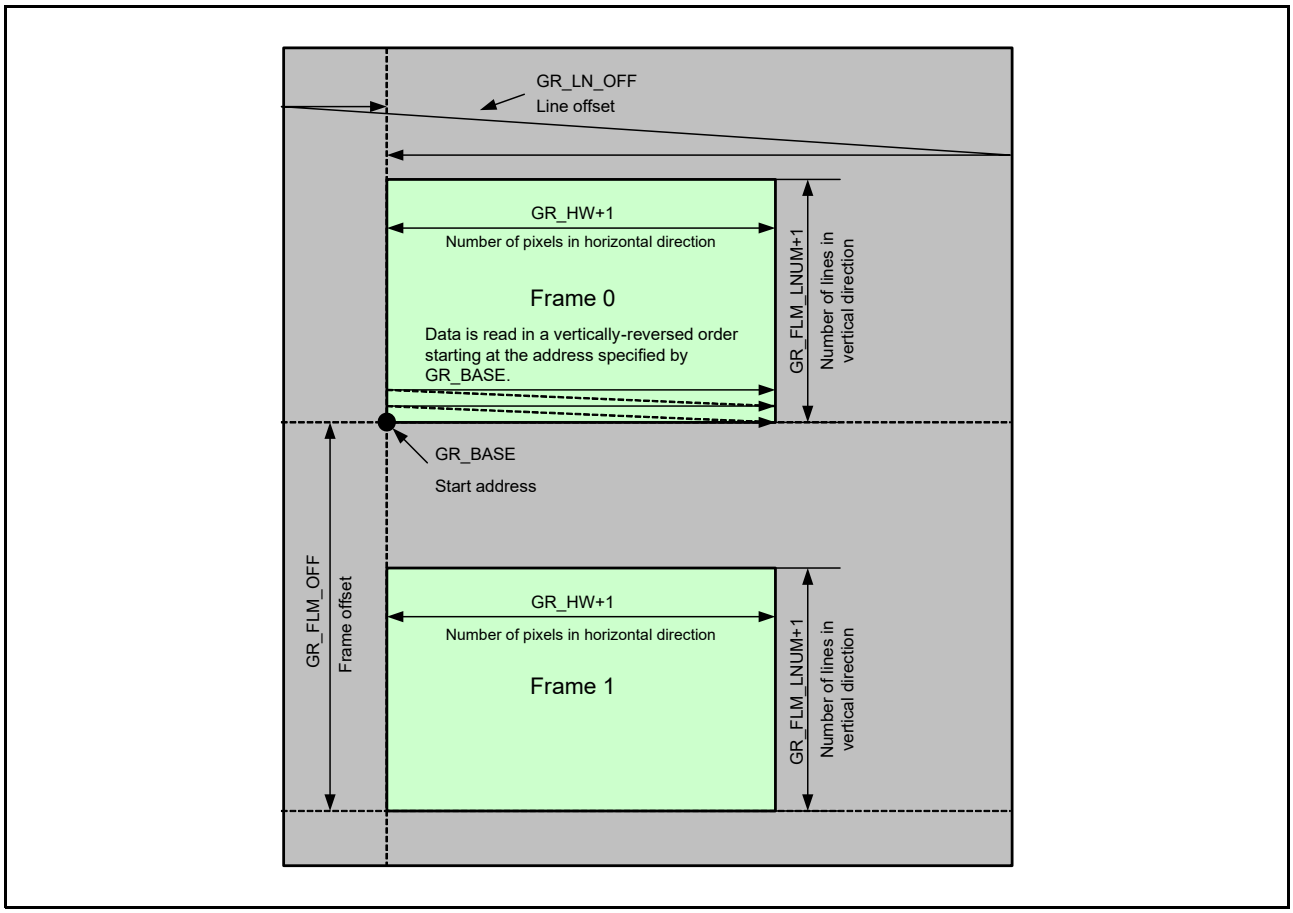

**Figure 35.3 Data Arrangement with Line Offset and Decrement Control**

## (10) Selecting Format of Frame Buffer Read Signal

Signal formats RGB565, RGB888, αRGB1555, αRGB4444, αRGB8888, RGBα5551, RGBα8888, CLUT8, CLUT4 and CLUT1 are supported for the graphics 0, 1, 2, 3, and OIR processes. The YCbCr422 and YCbCr444 formats are also supported for the graphics 0 and 1 processes.

The GR_FORMAT[3:0] bits select a signal format.

**Table 35.10 Format Selection for Frame Buffer Read Signal**

| Register Name | Bit Name | Initial Value | Description |
|---|---|---|---|
| GR_FLM6 | GR_FORMAT[3:0] | 0 | Sets the format of the frame buffer read signal.<br>0: RGB565<br>1: RGB888<br>2: αRGB1555<br>3: αRGB4444<br>4: αRGB8888<br>5: CLUT8<br>6: CLUT4<br>7: CLUT1<br>8: YCbCr422 or setting prohibited *<br>9: YCbCr444 or setting prohibited *<br>10: RGBα5551<br>11: RGBα8888<br>12 to 15: Setting prohibited |

Note: * Setting this value selects YCbCr422 and YCbCr444 for the graphics 0 and 1 processes, and is prohibited for the graphics 2, 3, and OIR processes.

## (11) Endian Control

In the frame buffer, data is handled in 64-bit units, and endian of the data to be read can be controlled by setting the GR_RDSWA[2:0] bits. Bit 0 of these bits indicates whether 8-bit data is swapped. Bit 1 indicates whether 16-bit data is swapped. Bit 2 indicates whether 32-bit data is swapped. In the YCbCr422 format, data can be arranged with the GR_YCC_SWAP[2:0] bits.

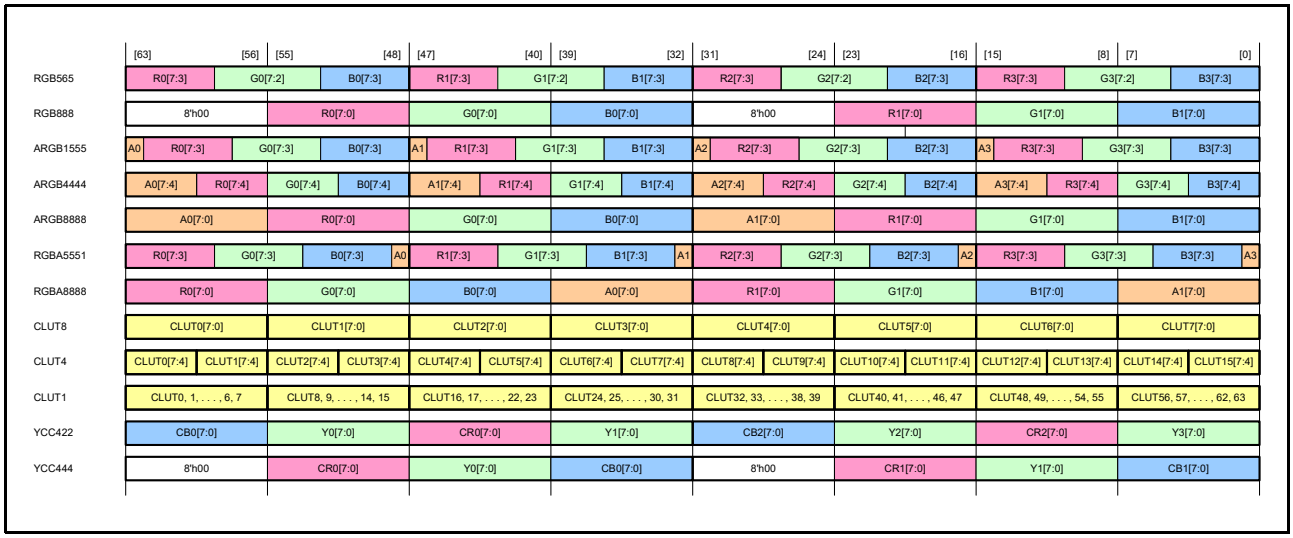

**Figure 35.4 Data Arrangement with Endian Control Disabled (GR_RDSWA = 000)**

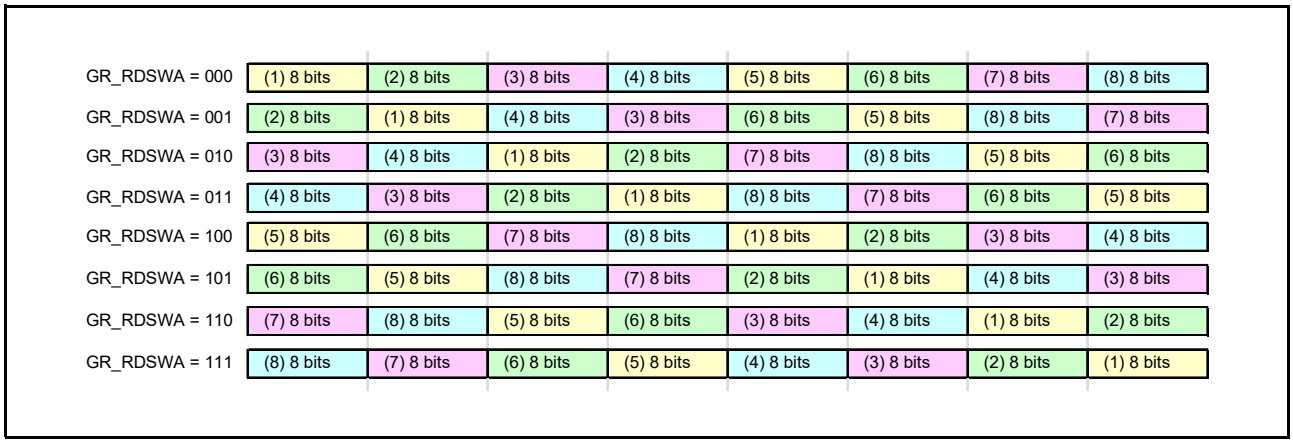

**Figure 35.5 Data Arrangement with Endian Control Enabled**

Note: * These bits are supported for the graphics 0 and 1 processes only.

## (12) Display Start Pixel Setting for Read Data

When a horizontal offset is applied to display the image data in the frame buffer, the display start pixel is set with the GR_BASE[31:0] and GR_STA_POS[5:0] bits. Calculation of the values for the GR_BASE[31:0] and GR_STA_POS[5:0] bits depends on the signal format. The display start pixel can be calculated with the formulas in the table below, where H_OFF is a horizontal offset from the display start pixel.

**Table 35.12 Calculation of Display Start Position for Various Signal Formats**

| Signal Format of Video/Graphics | Number of Bits per Pixel | Calculation Formula *1 |
|---|---|---|
| RGB888<br>αRGB8888,<br>RGBα8888<br>YCbCr422*2<br>YCbCr444*3 | 32 | GR_BASE[31:3] = t (H_OFF ÷ 2)<br>GR_STA_POS[5:0] = mod (H_OFF ÷ 2) |
| RGB565<br>αRGB1555,<br>RGBα5551<br>αRGB4444 | 16 | GR_BASE[31:3] = int (H_OFF ÷ 4)<br>GR_STA_POS[5:0] = mod (H_OFF ÷ 4) |
| CLUT8 | 8 | GR_BASE[31:3] = int (H_OFF ÷ 8)<br>GR_STA_POS[5:0] = mod (H_OFF ÷ 8) |
| CLUT4 | 4 | GR_BASE[31:3] = int (H_OFF ÷ 16)<br>GR_STA_POS[5:0] = mod (H_OFF ÷ 16) |
| CLUT1 | 1 | GR_BASE[31:3] = int (H_OFF ÷ 64)<br>GR_STA_POS[5:0] = mod (H_OFF ÷ 64) |

Notes: 1. The functions int() and mod() output a quotient and a remainder, respectively.
2. The YCbCr422 format is not supported for the graphics 2, 3, and OIR processes.
In the YCbCr422 format, 32 bits are used for two pixels (Cb, Y0, Cr, and Y1 components). Therefore, the start position is controlled in units of 32 bits.
3. The YCbCr444 format is not supported for the graphics 2, 3, and OIR processes.

**Table 35.13 Setting of Display Start Pixel of Read Data**

| Register Name | Bit Name | Initial Value | Description |
|---|---|---|---|
| GR_FLM6 | GR_STA_POS[5:0] | 0 | Sets the amount of data to be skipped through.<br>Specifically data amount equal to the amount indicated by GR_STA_POS is skipped from the start of the line. |
| GR_FLM2 | GR_BASE[31:0] | 0 | Frame Buffer Base Address<br>Sets the start address of the frame buffer where frame data is to be stored.<br>GR_BASE[4:3] and GR_BASE[6:3] are referred to during 32-byte burst transfer and 128-byte burst transfer, respectively, to skip the start line data.<br>The lower 3 bits should be fixed to 000. |

## (13) YCbCr422 to YCbCr444 Conversion

Data format for the graphics 0 and 1 processes are converted from YCbCr422 to YCbCr444.

This function is not supported for the graphics 2, 3, and OIR processes.

**Table 35.14 YCbCr422 to YCbCr444 Conversion**

| Register Name | Bit Name | Initial Value | Description |
|---|---|---|---|
| GR1_FLM6 | GR1_CNV444_MD | 0 | Sets the interpolation mode for YCbCr422 to YCbCr444 conversion. *<br>0: Hold interpolation<br>1: Average interpolation |

Note: * This register is not provided for the graphics 2, 3, and OIR processes, for which the YCbCr422 format is not supported.

## (14) Bit Extension

When the value of the GR_FORMAT[3:0] bits is 0 to 3, the RGB565, RGB888, αRGB1555, and αRGB4444 formats are converted to the αRGB8888 format. When the value of the GR_FORMAT[3:0] bits is 10, the RGBα5551 format is converted to the RGBα8888 format. The RGBα5551 to RGBα8888 format conversion is omitted because it differs from the αRGB5551 to αRGB8888 format conversion only in the position of α.

- RGB565 to αRGB8888 Format Conversion

  After conversion, α[7:0] is fixed to 255.

  After conversion, R[7:0] = R[4:0] × 263 ÷ 32 (round off to an integer), approximation of #R[4:0] × 255 ÷ 31

  After conversion G[7:0] = G[5:0] × 259 ÷ 64 (round off to an integer), approximation of #G[5:0] × 255 ÷ 63

  After conversion, B[7:0] = B[4:0] × 263 ÷ 32 (round off to an integer), approximation of #B[4:0] × 255 ÷ 31

- RGB888 to αRGB8888 Format Conversion

  After conversion, α[7:0] is fixed to 255.

- αRGB1555 to αRGB8888 Format Conversion

  After conversion, α[7:0] is GR_A1 when α input is 1, and GR_A0 when 0.

  After conversion, R[7:0] = R[4:0] × 263 ÷ 32 (round off to an integer), approximation of #R[4:0] × 255 ÷ 31

  After conversion, G[7:0] = G[4:0] × 263 ÷ 32 (round off to an integer), approximation of #G[4:0] × 255 ÷ 31

  After conversion, B[7:0] = B[4:0] × 263 ÷ 32 (round off to an integer), approximation of #B[4:0] × 255 ÷ 31

- αRGB4444 to αRGB8888 Format Conversion

  After conversion, α[7:0] = α[3:0] × 17

  After conversion, R[7:0] = R[3:0] × 17

  After conversion, G[7:0] = G[3:0] × 17

  After conversion, B[7:0] = B[3:0] × 17

## (15) Buffer Underflow Processing

When data read from the frame buffer cannot be completed due to bus-traffic related problems, an underflow interrupt signal is output.

### 35.1.3 Setting Graphics Display Area

The graphics display area is set with the GR_GRC_HS[10:0], GR_GRC_HW[10:0], GR_GRC_VS[10:0], and GR_GRC_VW[10:0] bits based on the rising edges of the Hsync and Vsync signals.

Figure 35.7 shows the graphics display area.

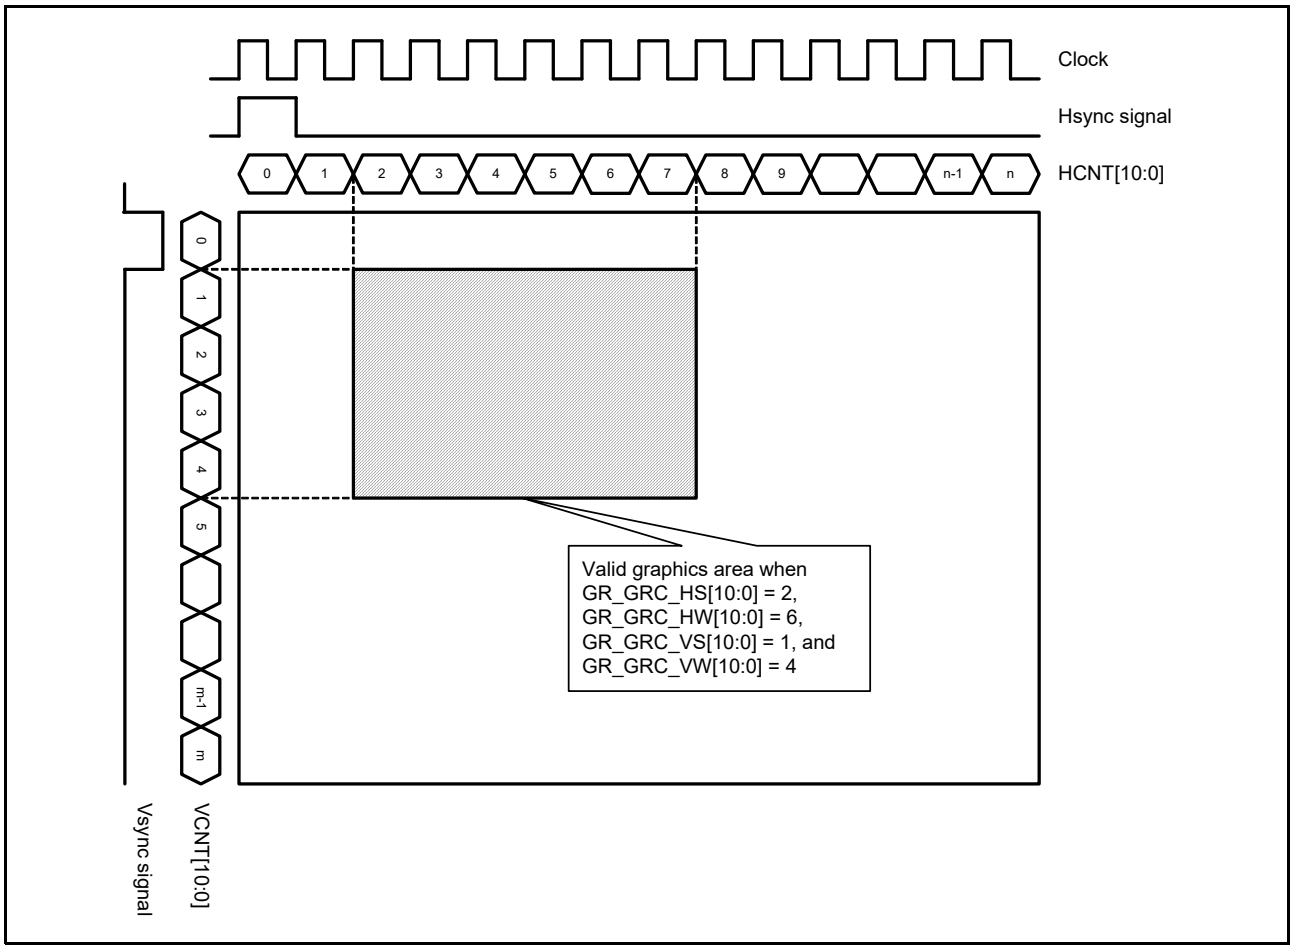

**Figure 35.7 Graphics Display Area**

The frame line of the graphics area can be displayed by setting the GR_GRC_DISP_ON bit to 1.

**Table 35.15 Graphics Image Area Setting**

| Register Name | Bit Name | Initial Value | Description |
|---|---|---|---|
| GR_AB3 | GR_GRC_HS[10:0] | 0 | Sets the horizontal start position of the graphics image area.<br>Note: Set to 16 or greater clocks and the result of GR_GRC_HS + GR_GRC_HW should be smaller than or equal to 2015 clocks. |
| GR_AB3 | GR_GRC_HW[10:0] | 0 | Sets the horizontal width of the graphics image area.<br>Note: For displaying an image with 1- or 2-pixel horizontal width, set GR_HW to 2 and GR_GRC_HW to 1 (1-pixel) or 2 (2-pixel). |
| GR_AB2 | GR_GRC_VS[10:0] | 0 | Sets the vertical start position of the graphics image area.<br>Note: Set to 4 or greater lines and the result of GR_GRC_VS + GR_GRC_VW should be smaller than or equal to 2039 lines. |
| GR_AB2 | GR_GRC_VW[10:0] | 0 | Sets the vertical width of the graphics image area. |

### 35.1.4 Interrupt Generation at Specified Line

An interrupt signal can be generated at the line specified with the GR_LINE[10:0] bits.

**Table 35.16 Interrupt Generation at Specified Line**

| Register Name | Bit Name | Initial Value | Description |
|---|---|---|---|
| GR_CLUT_INT | GR_LINE[10:0] | 0 | Line Interrupt Set *<br>When the number of lines matches the value of the GR_LINE bits, an interrupt signal is output. This function is supported for the graphics 3 and OIR processes only. This function supported for the graphics 3 process is enabled even when the graphics 3 process is not used. This function supported for the graphics OIR process is enabled only when the output image generator is enabled. |

Note: * This function is supported for the graphics 3 and OIR processes only; these bits are not supported for the graphics 0, 1, and 2 processes.

### 35.1.5 Formats of Frame Buffer Read Signals and Corresponding Alpha Blending Types

Setting the GR_FORMAT[3:0] bits selects the format of the signal read from the frame buffer.

Table 35.17 shows the signal formats and the corresponding alpha blending types. The priority of the alpha value is: alpha blending in rectangular area > chroma-key processing > alpha blending in pixel units.

**Table 35.17 Formats of Frame Buffer Read Signal and Corresponding Alpha Blending Types**

| GR_FORMAT[3:0] | Signal Format | Alpha Blending in Rectangular Area | RGB-Index Chroma-Key Processing | CLUT-Index Chroma-Key Processing | Alpha Blending in Pixel Units |

| 11 | RGBα8888 | Supported | Supported | Not supported | Supported |

Notes:
1. When each color component of the RGB signal read from the frame buffer is not 8 bits, it is converted to 8 bits by calculation in RGB-index chroma-key processing. (See section 35.1.2 (14) Bit Extension.)
2. Since α value is 255, the current graphics is always displayed.
3. α value for data read from the frame buffer is specified with one bit. This one-bit signal selects one of the two registers, each of which holds an 8-bit α value.
4. CLUT value for the frame buffer signal is specified with one bit. This one-bit signal selects one of the two registers, each of which holds the α, G, B, and R values (8 bits for each value). The CLUT table is not referenced.
5. YCbCr422 and YCbCr444 are supported for the graphics 0 and 1 processes, but any type of blending and chroma-key processing cannot be used.

### 35.1.6 Display Selection

The GR_DISP_SEL[1:0] bits select the graphics to be displayed from the background color, the lower-layer graphics, the current graphics, and the blended image of the lower-layer graphics and the current graphics. For blending, alpha blending in a rectangular area, multiplication with current alpha at alpha blending in a rectangular area, RGB-index chroma-key processing, CLUT-index chroma-key processing, alpha blending in one-pixel units, or premultiplication at alpha blending in one-pixel units can be selected. Only alpha blending in a rectangular area can be selected in the VIN synthesizer.

Table 35.18 shows the settings for various display types.

**Table 35.18 Settings for Various Display Types**

| GR_DISP_SEL [1:0] | GR_ARC_ON | GR_CK_ON | GR_ARC_MUL | GR_ACALC_MD | Processing for Graphics Area | Processing for the Area outside the Graphics Area |
|---|---|---|---|---|---|---|
| 0 | — | — | — | — | Background color | Background color |
| 1 | — | — | — | — | Lower-layer graphics | Lower-layer graphics |
| 2 | — | — | — | — | Current graphics | Background color |

| 3 | 0 | 0 | — | 1 | Premultiplication at alpha blending in one-pixel units*2 | Lower-layer graphics |

Notes: 1. The alpha blending in a rectangular area is not supported for the graphics 0 process in the scaler and the graphics OIR process. When this processing is selected in the VIN synthesizer, cascaded connection cannot be selected in the scaler.
2. The multiplication with current alpha at alpha blending in a rectangular area and alpha blending function in one-pixel units are supported for the graphics 1, 2, and 3 processes only.
3. The RGB-index or CLUT-index chroma-key processing is not supported for the VIN synthesizer.

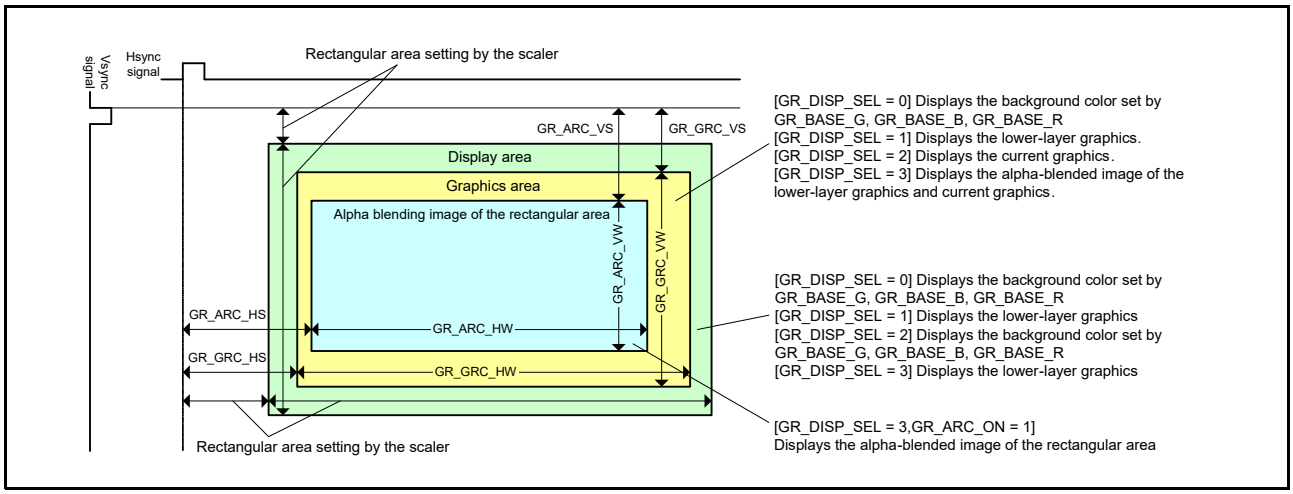

**Figure 35.8 Graphic Display Types**

Figure 35.9 shows the graphics planes displayed when the GR_DISP_SEL bits are set to 3.

For correspondence between the lower-layer graphics and the current graphics, see Figure 35.1.

Notes: 1. The graphics 0 and OIR processes support the chroma-key processing only. When performing chroma-key processing, set the α value for converting the pixels to be subjected to chroma-key processing, and the α value of the pixels not to be subjected to the chroma-key processing to 255 to display the current graphics only. The VIN synthesizer supports display processing with alpha blending in a rectangular area only.
2. This function is supported only for the graphics 1, 2, and 3 processes and the VIN synthesizer. This bit is not provided for the graphics 0 and OIR processes.
3. This function is supported only for the graphics 1, 2, and 3 processes. This bit is not provided for the graphics 0 and OIR processes and the VIN synthesizer.
4. This bit is not provided for the VIN synthesizer.

### 35.1.7 Background Color Display Processing

The color set with the GR_BASE_G[7:0], GR_BASE_B[7:0], and GR_BASE_R[7:0] bits is displayed.

G output = GR_BASE_G

B output = GR_BASE_B

R output = GR_BASE_R

**Table 35.20 Background Color Setting**

| Register Name | Bit Name | Initial Value | Description |
|---|---|---|---|

| GR_BASE | GR_BASE_R[7:0] | 0 | Background color R signal<br>R: 8 bits; unsigned (0 to 255 [LSB]) |

### 35.1.8 Lower-Layer Graphics Display Processing

The lower-layer graphics are displayed as follows:

G output = G input of lower-layer graphics

B output = B input of lower-layer graphics

R output = R input of lower-layer graphics

### 35.1.9 Current Graphics Display Processing

The current graphics are displayed as follows:

G output = G input of current graphics

B output = B input of current graphics

R output = R input of current graphics

### 35.1.10 Display with Alpha Blending in a Rectangular Area

The rectangular area subjected to alpha blending is set with the GR_ARC_HS[10:0], GR_ARC_HW[10:0], GR_ARC_VS[10:0], and GR_ARC_VW[10:0] bits based on the rising edges of the Hsync and Vsync signals. This function is not supported for the graphics 0 and OIR processes.

Figure 35.10 shows the rectangular area setting for alpha blending.

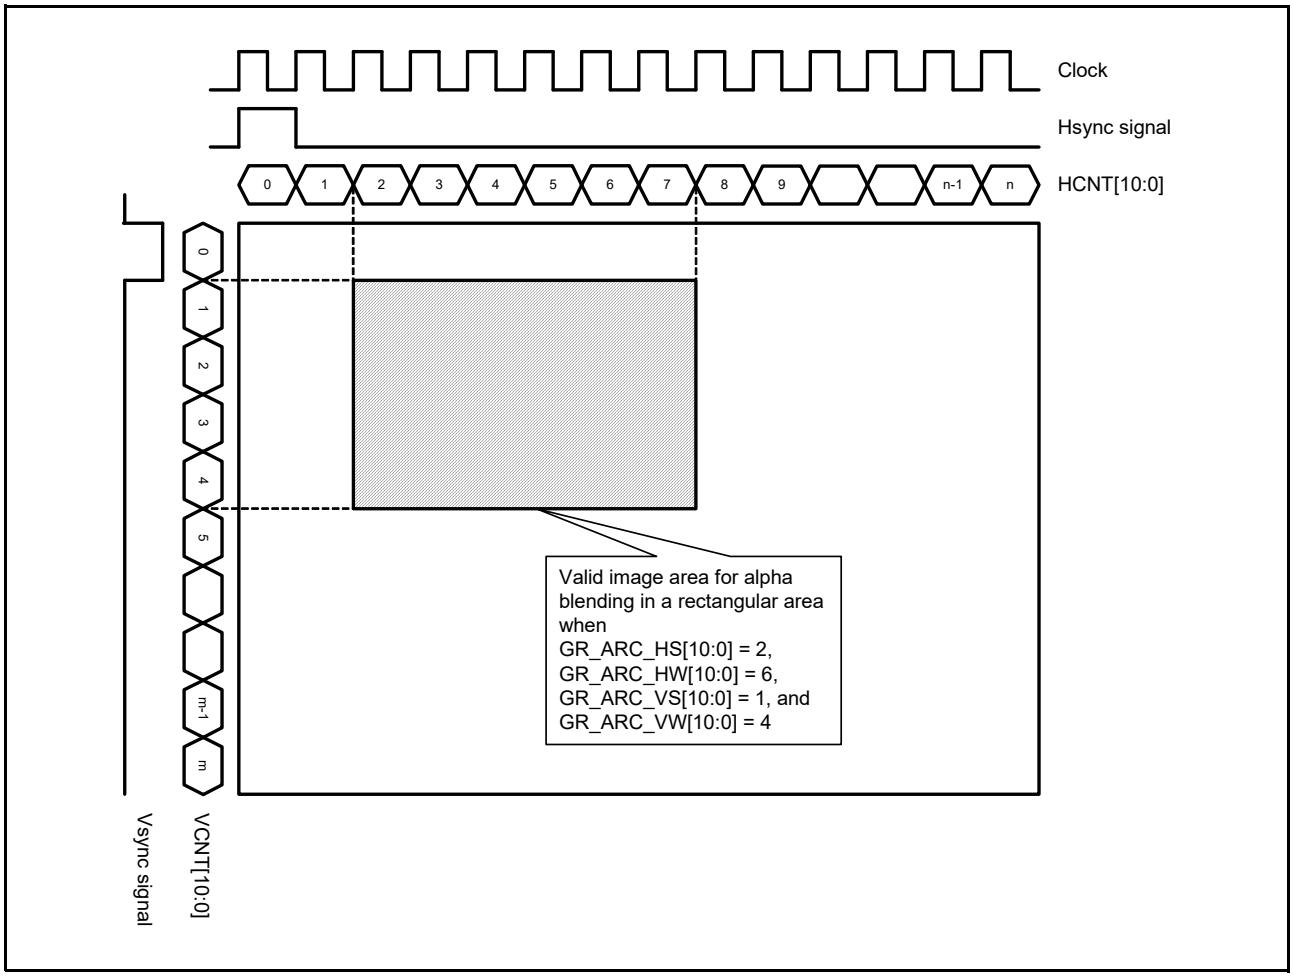

**Figure 35.10 Rectangular Area Setting for Alpha Blending**

The frame line of graphics area can be displayed by setting the GR_ARC_DISP_ON bit to 1.

**Table 35.21 Setting of Rectangular Area for Alpha Blending**

| Register Name | Bit Name | Initial Value | Description |
|---|---|---|---|
| GR_AB5 | GR_ARC_HS[10:0] | 0 | Sets the horizontal start position of the valid image area for alpha blending in a rectangular area. |
| GR_AB5 | GR_ARC_HW[10:0] | 0 | Sets the horizontal width of the valid image area for alpha blending in a rectangular area. |
| GR_AB4 | GR_ARC_VS[10:0] | 0 | Sets the vertical start position of the valid image area for alpha blending in a rectangular area. |
| GR_AB4 | GR_ARC_VW[10:0] | 0 | Sets the vertical width of the valid image area for alpha blending in a rectangular area. |
| GR_AB1 | GR_ARC_DISP_ON | 0 | Turns on/off frame-line display of the valid image area for alpha blending in a rectangular area.<br>0: Frame-line display off<br>1: Frame-line display on |

In alpha blending in a rectangular area, the current graphics are faded in or out by setting the fade-in or fade-out coefficients with the GR_ARC_DEF[7:0], GR_ARC_MODE, GR_ARC_COEF[7:0], and GR_ARC_RATE[7:0] bits.

First, the value of the GR_ARC_DEF[7:0] bits is assigned to the α value.

Then, each time the Vsync signal rises for the number of times set with the GR_ARC_RATE[7:0] bits + 1, the value of the GR_ARC_COEF[7:0] bit is added to or subtracted from the α value.

The values specified with the following expressions are used in the alpha blending calculation described in section 35.1.14, Alpha Blending Calculation.

α value = Fade-in/out coefficient

G value = G input of the current graphics

B value = B input of the current graphics

R value = R input of the current graphics

### 35.1.11 RGB-Index Chroma-Key Processing

The pixels that satisfy all the expressions below are subjected to RGB-index chroma-key processing.

G input of the current graphics = GR_CK_KG

B input of the current graphics = GR_CK_KB

R input of the current graphics = GR_CK_KR

In RGB-index chroma-key processing, the values specified with the following expressions are used in the alpha blending calculation described in section 35.1.14, Alpha Blending Calculation. This function is not supported in the VIN synthesizer.

α value = GR_CK_A

G value = GR_CK_G

B value = GR_CK_B

R value = GR_CK_R

For the pixels that are not subjected to RGB-index chroma-key processing, the values specified with the following expressions are used in the alpha blending calculation described in section 35.1.14, Alpha Blending Calculation.

α value = α input of the current graphics

G value = G input of the current graphics

B value = B input of the current graphics

R value = R input of the current graphics

| GR_AB9 | GR_CK_R[7:0] | 0 | Replaced R Signal after RGB-Index Chroma-Key Processing<br>R: 8 bits; unsigned (0 to 255 [LSB]) |

Note: * To use this function for the graphics 0 and OIR processes, the alpha value should be set to 255.

### 35.1.12 CLUT-Index Chroma-Key Processing

The pixels that satisfy the expression below are subjected to CLUT-index chroma-key processing.

CLUT input of the current graphics = GR_CK_KCLUT

In CLUT-index chroma-key processing, the values specified with the following expressions are used in the alpha blending calculation described in section 35.1.14, Alpha Blending Calculation. This function is not supported in the VIN synthesizer.

α value = GR_CK_A

G value = GR_CK_G

B value = GR_CK_B

R value = GR_CK_R

For the pixels that are not subjected to CLUT-index chroma-key processing, the values specified with the following expressions are used in the alpha blending calculation described in section 35.1.14, Alpha Blending Calculation.

α value = α input of the current graphics

G value = G input of the current graphics

B value = B input of the current graphics

R value = R input of the current graphics

Note: * To use this function for the graphics 0 and OIR processes, the alpha value should be set to 255.

### 35.1.13 Display with Alpha Blending in One-Pixel Units

In the alpha blending in one-pixel units, the values specified with the following expressions are used in the alpha blending calculation described in section 35.1.14, Alpha Blending Calculation. This function is not supported in the graphics 0 and OIR processes and the VIN synthesizer.

α value = α input of the current graphics

G value = G input of the current graphics

B value = B input of the current graphics

R value = R input of the current graphics

### 35.1.14 Alpha Blending Calculation

Alpha blending of two input signals is performed using the α value as described below (rounded up if the result includes a decimal fraction).

[GR_ACALC_MD = 0]

G output = (G value × α value + G input of the lower-layer graphics × (255 − α value)) ÷ 256

B output = (B value × α value + B input of the lower-layer graphics × (255 − α value)) ÷ 256

R output = (R value × α value + R input of the lower-layer graphics × (255 − α value)) ÷ 256

[GR_ACALC_MD = 1 (premultiplication)]

G output = (G value + G input of the lower-layer graphics × (255 − α value)) ÷ 256

B output = (B value + B input of the lower-layer graphics × (255 − α value)) ÷ 256

R output = (R value + R input of the lower-layer graphics × (255 − α value)) ÷ 256

### 35.1.15 CLUT Table

When the signal format is CLUT8 or CLUT4, the format is converted to αRGB8888 based on the CLUT table. When the format is CLUT1, it is converted to αRGB8888 based on the register value.

Figure 35.12 shows data arrangement in the CLUT table.

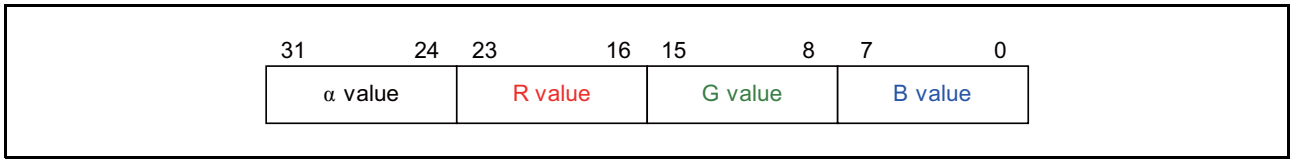

**Figure 35.12 Data Arrangement in CLUT Table**

The CLUT tables are arranged in the following addresses (channel 0). For the arrangement in channel 1, see the register configuration described in section 35.2, Register Descriptions.

Graphics 0 CLUT table: H'FCFF6000 to H'FCFF63FF
(For CLUT4, addresses H'FCFF6000 to H'FCFF603F are valid.)

Graphics 1 CLUT table: H'FCFF6400 to H'FCFF67FF
(For CLUT4, addresses H'FCFF6400 to H'FCFF643F are valid.)

Graphics 2 CLUT table: H'FCFF6800 to H'FCFF6BFF
(For CLUT4, addresses H'FCFF6800 to H'FCFF683F are valid.)

Graphics 3 CLUT table: H'FCFF6C00 to H'FCFF6FFF
(For CLUT4, addresses H'FCFF6C00 to H'FCFF6C3F are valid.)

Graphics OIR CLUT table: H'FCFF7000 to H'FCFF73FF
(For CLUT4, addresses H'FCFF7000 to H'FCFF703F are valid.)

Two CLUT tables (CLUT table 0, CLUT table 1) on the different planes are allocated to the same address and one of the

tables is selected with the GR_CLT_SEL bit. This allows rewriting one CLUT table when this module refers to the other CLUT table.
When switching the CLUT after overwriting the CLUT, please execute a dummy read of the CLUT table address. And switch the CLUT table by GR_CLT_SEL after dummy-read.

### 35.1.16 Multiplication Processing with Current Alpha at Alpha Blending in Rectangular Area

In multiplication processing with current alpha at alpha blending in a rectangular area, the values specified with the following expressions are used in the alpha blending calculation described in section 35.1.14, Alpha Blending Calculation.

[GR_ARC_MUL = 0]

α value = Fade-in/out coefficient

G value = G input of the current graphics

B value = B input of the current graphics

R value = R input of the current graphics

[GR_ARC_MUL = 1 (multiplication)]

α value = Fade-in/out coefficient x α input of current graphics

G value = G input of the current graphics

B value = B input of the current graphics

R value = R input of the current graphics

### 35.1.17 Selection of Lower-Layer/Current Graphics in VIN Synthesizer

Graphics 0 and 1 are allocated to the lower-layer/current graphics in the VIN synthesizer, respectively.

**Table 35.26 Selection of Lower-Layer Plane in Scaler**

## 35.2 Register Descriptions

Table 35.27 to Table 35.34 show the register configuration.

- Symbols used in Register Description:

| | |
|---|---|
| Initial value: | Register value after a reset |
| —: | Undefined value |
| R/W: | Readable/writable. The written value can be read. |
| R/WC0: | Readable/writable. Writing 0 initializes the bit. Writing 1 is ignored. |
| R/WC1: | Readable/writable. Writing 1 initializes the bit. Writing 0 is ignored. |
| R: | Read-only. The write value should always be 0. |
| —/W: | Write-only. The read value is undefined. |

## 35.3 Usage Method

### 35.3.1 Mute Image

The initial values of the GR0_DISP_SEL[1:0], GR1_DISP_SEL[1:0], GR2_DISP_SEL[1:0], GR3_DISP_SEL[1:0], GR_VIN_DISP_SEL[1:0], and GR_OIR_DISP_SEL[1:0] bits are all 0. Accordingly, in the initial setting, a background color is displayed both inside and outside the graphics area for the graphics 0, 1, 2, 3, and OIR processes and the VIN synthesizer. Since the default background color is black, the black mute image is displayed in the initial state.

### 35.3.2 Alpha Blending in Rectangular Area

The alpha coefficient and the frame rate can be changed during fade in and fade out by modifying the GR_ARC_MODE, GR_ARC_COEF[7:0] and GR_ARC_RATE[7:0] bits, respectively.

# 36. Video Display Controller 5 (6): Output Image Generator

## 36.1 Output Image Generation Functions

### 36.1.1 Overview of Functions

The output image generator can be used to store the RGB output from the image synthesizer in the frame buffer. In addition to storing the RGB data, it can also read the graphics data and display them. In cooperation with the image renderer for display (channel 0 only), it can also distort the output image according to a display panel.

When the display functions described above (reading and displaying of graphics data and displaying of an image after distortion) are not in use, the signals from the image synthesizer can be output directly to the output control block, bypassing the output image generator.

The output image generator has the same circuit configuration as the scaler. However, note the following differences from the scaler.

(1) The scaling-up/-down function is not available.
(2) The rotation control function is not available.
(3) The pointer buffer function is not available.
(4) The field control function is not available because the inputs are always progressive signals.
(5) The I/O signals are always RGB signals.

The functional block diagram of the output image generator is shown below.

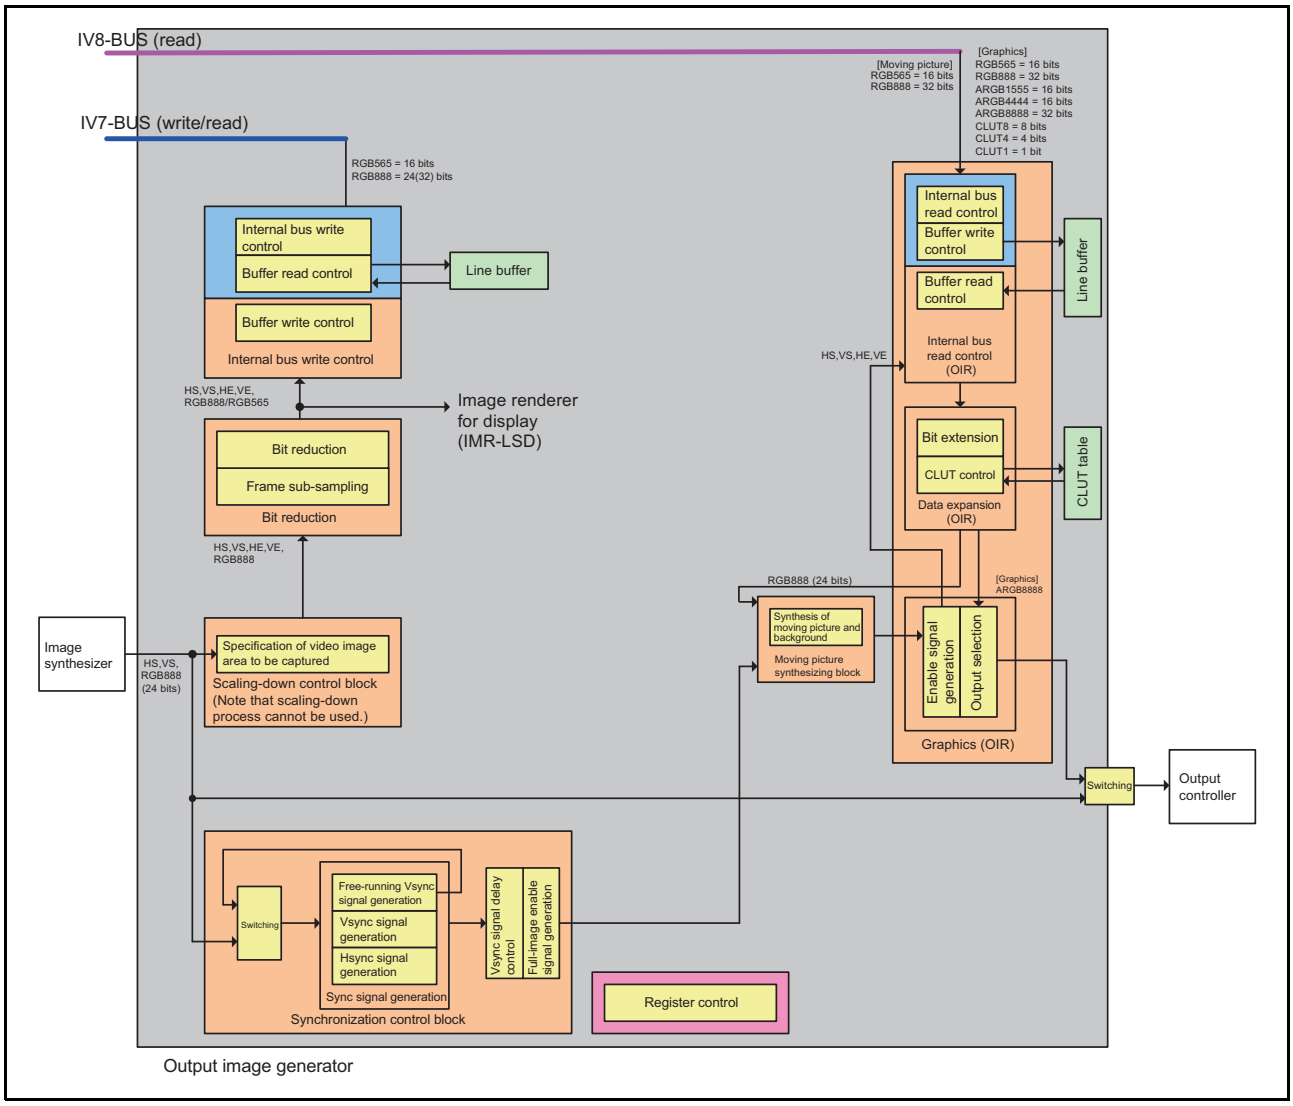

**Figure 36.1 Functional Block Diagram of Output Image Generator**

## 36.1.2 Register Control

### (1) Updating Registers

The Vsync signal is used to control the update timing of all the registers of the output image generator and graphics block (OIR) except some registers of the sync control block.

After 1 is set to the bits in the update control register, the contents of the relevant registers are modified at the rising edge of the Vsync signal. The update control register is automatically cleared to 0 after the modification.

**Table 36.1 Register Update Control**

| Register Name | Bit Name | Initial Value | Description |
|---|---|---|---|
| OIR_SCL0_ UPDATE | OIR_SCL0_ UPDATE | 0 | SYNC Control Register Update<br>0: Registers are not updated.<br>1: Registers are updated. |
| OIR_SCL0_ UPDATE | OIR_SCL0_ VEN_D | 0 | Frame Buffer Read Control Register Update<br>0: Registers are not updated.<br>1: Registers are updated at the rising edge of the Vsync. |
| OIR_SCL0_ UPDATE | OIR_SCL0_ VEN_C | 0 | Frame Buffer Read Control Register Update<br>0: Registers are not updated.<br>1: Registers are updated at the rising edge of the Vsync. |
| OIR_SCL0_ UPDATE | OIR_SCL0_ VEN_B | 0 | Synchronization Control Register Update<br>0: Registers are not updated.<br>1: Registers are updated at the rising edge of the Vsync. |
| OIR_SCL0_ UPDATE | OIR_SCL0_ VEN_A | 0 | Scaling-Down Control Register Update<br>0: Registers are not updated.<br>1: Registers are updated at the rising edge of the Vsync. |
| OIR_SCL1_ UPDATE | OIR_SCL1_ UPDATE_A | 0 | Frame Buffer Write Control Register Update<br>0: Registers are not updated.<br>1: Registers are updated. |
| OIR_SCL1_ UPDATE | OIR_SCL1_ VEN_B | 0 | Frame Buffer Write Control Register Update<br>0: Registers are not updated.<br>1: Registers are updated at the rising edge of the Vsync. |
| OIR_SCL1_ UPDATE | OIR_SCL1_ VEN_A | 0 | Frame Buffer Write Control Register Update<br>0: Registers are not updated.<br>1: Registers are updated at the rising edge of the Vsync. |
| GR_OIR_VEN | GR_OIR_P_ VEN | 0 | Graphics Display Register Update<br>0: Registers are not updated.<br>1: Registers are updated at the rising edge of the Vsync. |
| GR_OIR_VEN | GR_OIR_IBUS_ VEN | 0 | Frame Buffer Read Control Register Update<br>0: Registers are not updated.<br>1: Registers are updated at the rising edge of the Vsync. |

The registers controlled by OIR_SCL0_VEN_A, OIR_SCL_0_VEN_C, OIR_SCL1_VEN_A, and OIR_SCL1_VEN_B are modified at the rising edge of the input Vsync signal.

The registers controlled by OIR_SCL0_VEN_B, OIR_SCL0_VEN_D, GR_OIR_P_VEN, and GR_OIR_IBUS_VEN are modified at the rising edge of the output Vsync signal.

### 36.1.3 Enabling or Disabling Output Image Generator

The output signal from the image synthesizer can be selected.

**Table 36.2 Output Image Generator Enable Control**

| Register Name | Bit Name | Initial Value | Description |
|---|---|---|---|
| OIR_SCL0_FRC3 | OIR_RES_EN | 0 | Enabling or Disabling the Output Image Generator<br>0: The input data from the image synthesizer is directly output.<br>1: Signals from the graphics block (OIR) are output. |

### 36.1.4 Synchronization Control

#### (1) Selecting Vsync Signal

The Vsync signal to be output from the output image generator can be selected.

**Table 36.3 Vsync Signal Selection Control**

| Register Name | Bit Name | Initial Value | Description |
|---|---|---|---|
| OIR_SCL0_FRC3 | OIR_RES_VS_SEL | 1 | Vsync Signal Output Select<br>0: Vsync signal input from the image synthesizer<br>1: Internally generated free-running Vsync signal |

#### (2) Masking Repeated Vsync Signals

Take measures against the repeated Vsync signals by using the Vsync control block in the scaler. Accordingly, repeated Vsync signal masking control must be disabled in the output image generator when it is in use.

**Table 36.4 Repeated Vsync Signal Mask Control**

| Register Name | Bit Name | Initial Value | Description |
|---|---|---|---|
| OIR_SCL0_FRC1 | OIR_RES_VMASK_ON | 1 | Repeated Vsync Signal Masking Control<br>This bit should always be set to 0 when the output image generator is in use.<br>0: Repeated Vsync signal masking control is disabled.<br>1: Repeated Vsync signal masking control is enabled. |

#### (3) Compensating for Missing Vsync Signals

Take measures against the missed Vsync signals by using the Vsync control block in the scaler. Accordingly, compensation of missing Vsync signals must be disabled in the output image generator when it is in use.

**Table 36.5 Missing Vsync Compensation Control**

| Register Name | Bit Name | Initial Value | Description |
|---|---|---|---|
| OIR_SCL0_FRC2 | OIR_RES_VLACK_ON | 1 | Missing Vsync Signal Compensation<br>This bit should always be set to 0 when the output image generator is in use.<br>0: Compensation of missing Vsync signals is disabled.<br>1: Compensation of missing Vsync signals is enabled. |

### (4) Free-Running Period

Free-running Vsync and Hsync periods can be set.

Hsync period [usec] = (RES_FH + 1) ÷ pixel clock frequency [MHz]

Vsync period [usec] = horizontal period [usec] × (RES_FV + 1)

**Table 36.6 Free-Running Period Control**

| Register Name | Bit Name | Initial Value | Description |
|---|---|---|---|
| OIR_SCL0_FRC4 | OIR_RES_FV [10:0] | 524 | Free-Running Vsync Period Setting<br>Free-running Vsync period = (OIR_RES_FV + 1) × horizontal period [usec] |
| OIR_SCL0_FRC4 | OIR_RES_FH [10:0] | 799 | Hsync Period Setting<br>Hsync period [usec] = (OIR_RES_FH +1) ÷ pixel clock frequency [MHz] |

When selecting a Vsync signal input from the image synthesizer, set the OIR_RES_VS_SEL bit to 0. At this time, the internally generated free-running Vsync signal is not output.

In the meantime, the Hsync signal is always generated according to the free-running signal setting and output from the output image generator.

### (5) Vsync Signal Delay Control

Delay of Vsync signal output from the output image generator can be controlled.

The delay is used to adjust the frame buffer read timing.

**Table 36.7 Vsync Output Delay Control**

| Register Name | Bit Name | Initial Value | Description |

## 36.1.5 Setting Angle of View

### (1) Setting Image Area to be Captured

The area to be captured for the input image can be set.

The area is defined by specifying its start position and width based on the input Hsync and Vsync signals.

**Table 36.8 Control of Image Area to be Captured**

| Register Name | Bit Name | Initial Value | Description |
|---|---|---|---|
| OIR_SCL0_DS2 | OIR_RES_VS [10:0] | 18 | Vertical Position Setting for Video Signal Capturing (VSYNC + V backporch lines)<br>Note: The set value should be four or more (lines). OIR_RES_VS + OIR_RES_VW should be equal to or less than 2039 (lines). |
| OIR_SCL0_DS2 | OIR_RES_VW [10:0] | 240 | Vertical Width of Video Signal to be Captured (lines)<br>Note: OIR_RES_VS + OIR_RES_VW should be equal to or less than 2039 (lines). |

| OIR_SCL0_DS3 | OIR_RES_HW [10:0] | 1440 | Horizontal Width of Video Signal to be Captured (video-image clock cycles)<br>Note: OIR_RES_HS + OIR_RES_HW should be equal to or less than 2015 (clock cycles). |

### (2) Generating a Full-Screen Enable Signal

The valid period of the full screen to be output from the output image generator can be set.

The valid period is defined by specifying its start position and width based on the Hsync and Vsync signals output from the output image generator.
The vertical front porch should be set to four or more lines, and the horizontal front porch should be 16 or more clock cycles.

**Table 36.9 Full-Screen Enable Control**

| Register Name | Bit Name | Initial Value | Description |
|---|---|---|---|
| OIR_SCL0_FRC6 | OIR_RES_F_VS [10:0] | 35 | Vertical Enable Signal Start Position for Full Screen. (VSYNC + V backporch lines)<br>Note: The set value should be four or more (lines). OIR_RES_F_VS + OIR_RES_F_VW should be equal to or less than 2039 (lines). |

### (3) Generating an Image Output Enable Signal

The valid period of the image to be output can be set.

The valid period is defined by specifying its start position and width based on the Hsync and Vsync signals output from the output image generator.

**Table 36.10 Image Output Enable Control**

| Register Name | Bit Name | Initial Value | Description |
|---|---|---|---|
| OIR_SCL0_US2 | OIR_RES_P_VS [10:0] | 35 | Vertical Enable Signal Start Position for Output Image. (VSYNC + V backporch lines)<br>Note: The set value should be four or more (lines). OIR_RES_P_VS + OIR_RES_P_VW should be equal to or less than 2039 (lines). |

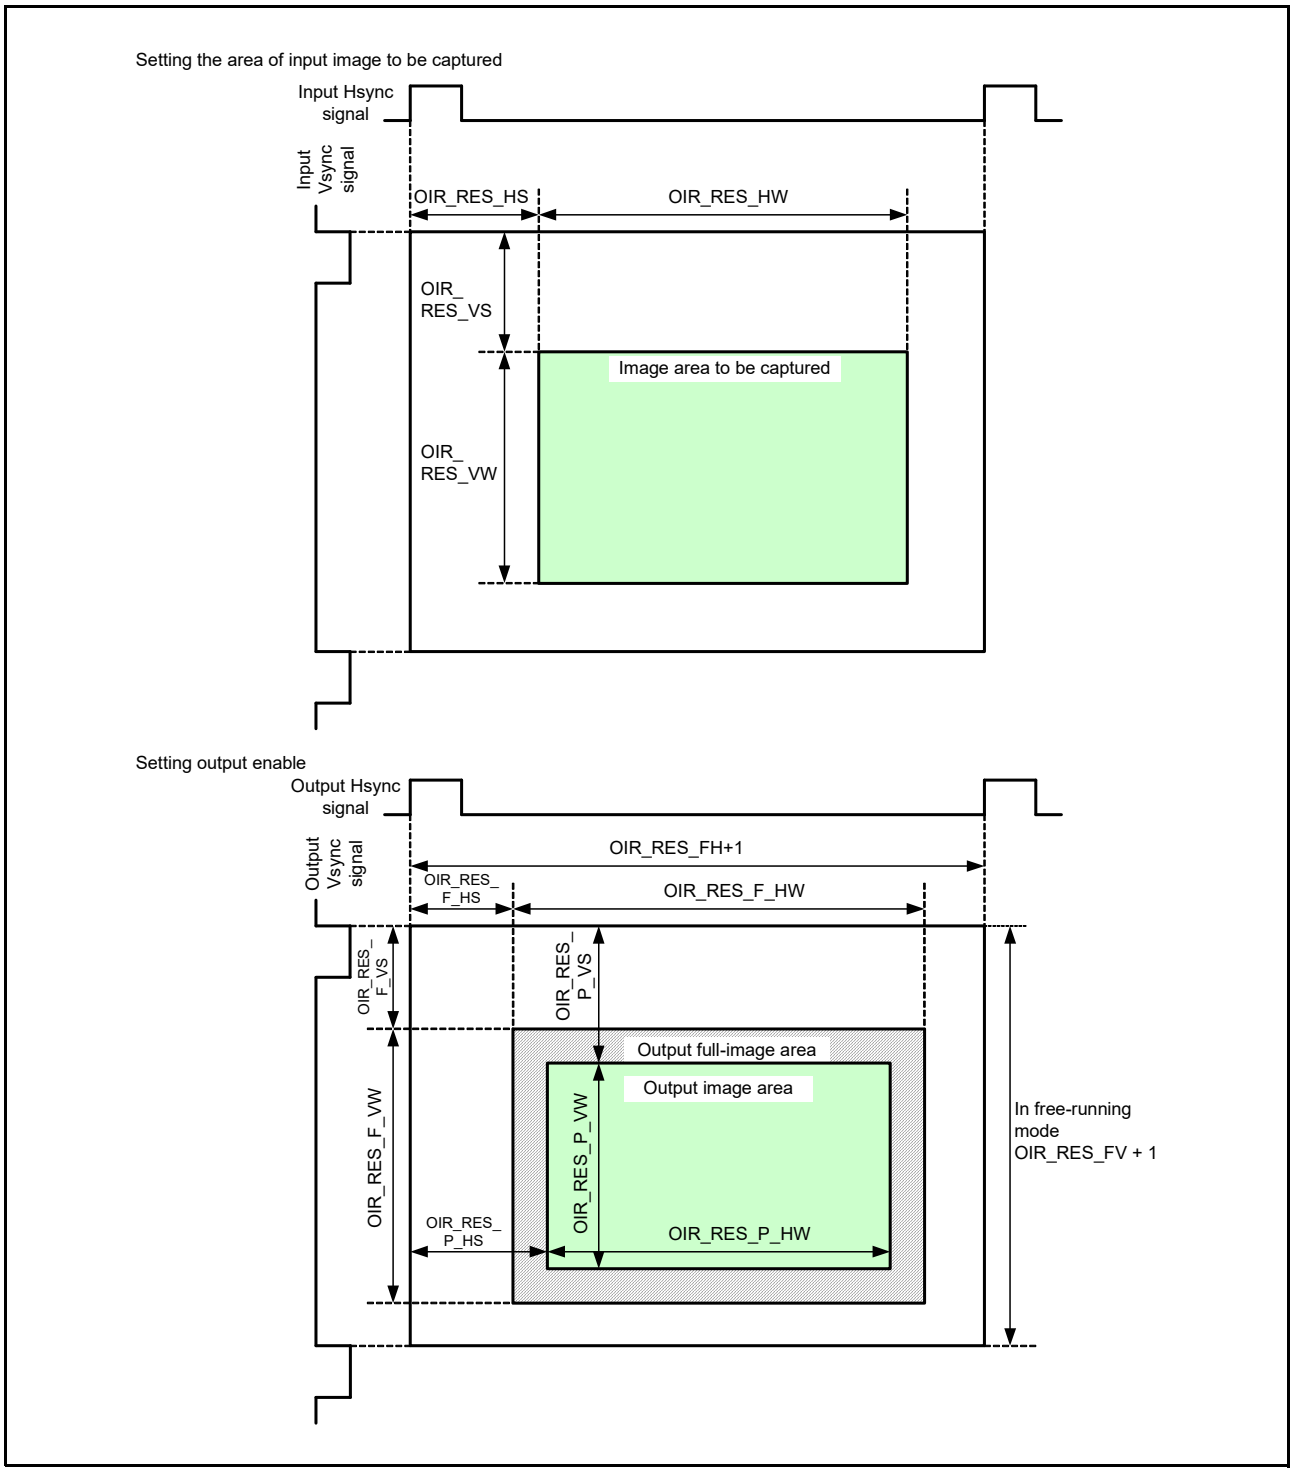

**Figure 36.3 Enable Settings**

### 36.1.6 Scaling Settings

Scaling up and down is not available in the output image generator. Accordingly, scaling up and down control must be off when the output image generator is in use.

**Table 36.11 Scaling-Up/-Down Control**

| Register Name | Bit Name | Initial Value | Description |
|---|---|---|---|
| OIR_SCL0_DS1 | OIR_RES_DS_H_ON | 1 | Horizontal Scale Down On/Off<br>This bit should always be set to 0 when the output image generator is in use.<br>0: Off<br>1: On |

### 36.1.7 Screen Synthesis

During the valid full-screen period, the image area can be overlayed before being output. If the image area to be output is smaller than a full-screen, the background color specified by the OIR_RES_BK_COL_R, OIR_RES_BK_COL_G, and OIR_RES_BK_COL_B bits are displayed to fill the background.

**Table 36.12 Screen Synthesis Control**

## 36.1.8 Selecting Format for Writing Video Image Signals to Frame Buffer

A format can be selected for writing video image signals to the frame buffer.

Although 24-bit RGB signals are input to the output image generator, they are converted into 16-bit RGB565 signals or 32-bit RGB888 signals before being written to the frame buffer.

As bit reduction processing of RGB565, rounding off or 2 × 2 pattern dither can be selected with the OIR_RES_DTH_ON bit. For details on pattern dither, see Figure 37.1.7, Dither Process in section 37, Video Display Controller 5 (7): Output Controller.

RGB888 signals are output to the image renderer for display (this function is only available in channel 0).

For distortion correction for display, refer to section 42, Image Renderer for Display (IMR-LSD).

**Table 36.13 Frame Buffer Writing Mode Setting**

| OIR_RES_BITDEC_ON | OIR_RES_MD[1:0] | Writing Mode |
|---|---|---|
| 0 | 2 | RGB888 (normal, distortion correction) |
| 1 | 1 | RGB565 (normal) |

**Table 36.14 Video Signal Writing Format Selection Control**

| Register Name | Bit Name | Initial Value | Description |
|---|---|---|---|
| OIR_SCL1_WR1 | OIR_RES_MD[1:0] | 0 | Frame Buffer Video-Signal Writing Format<br>0: Setting prohibited<br>1: RGB565 (16 bits)<br>2: RGB888 (24 (32) bits)<br>3: Setting prohibited |

## 36.1.9 Writing to Frame Buffer

### (1) Frame Buffer Transfer Mode

Either 32-byte or 128-byte transfer mode can be selected for accessing the frame buffer in which video image data and graphics data are stored.

**Table 36.15 Frame Buffer Transfer Mode**

| Register Name | Bit Name | Initial Value | Description |
|---|---|---|---|
| OIR_SCL1_<br>WR1 | OIR_RES_<br>BST_MD | 0 | Transfer Burst Length for Frame Buffer Writing<br>0: 32-byte<br>1: 128-byte |

### (2) Frame Buffer Write Control

Frame buffer writing is enabled or disabled.

**Table 36.16 Frame Buffer Writing Control**

| Register Name | Bit Name | Initial Value | Description |
|---|---|---|---|
| OIR_SCL1_<br>WR5 | OIR_RES_<br>WENB | 0 | Frame Buffer Write Enable<br>After making the setting to enable writing, writing starts from the second frame.<br>0: Frame buffer writing is disabled.<br>1: Frame buffer writing is enabled. |

### (3) Frame Buffer Writing Rate Selection

A frame buffer writing rate can be selected from among 1/1, 1/2, 1/4, and 1/8 the vertical frequency of the input signal.

When 1/2, 1/4, or 1/8 is selected, either the top or bottom field can be selected for writing.

The field operating mode should always be progressive because the progressive signals are always input to the output image generator.

**Table 36.17 Frame Buffer Write Control**

| Register Name | Bit Name | Initial Value | Description |
|---|---|---|---|
| OIR_SCL1_WR5 | OIR_RES_FS_RATE[1:0] | 0 | Writing Rate<br>Sets the frame buffer writing rate to the vertical frequency of the input signal.<br>0: 1/1 an input signal (The OIR_RES_FLD_SEL setting is invalid.)<br>1: 1/2 an input signal<br>2: 1/4 an input signal<br>3: 1/8 an input signal |
| OIR_SCL1_WR5 | OIR_RES_INTER | 1 | Field Operating Mode Select<br>This bit should always be set to 0 when the output image generator is in use.<br>0: Progressive<br>1: Interlace |

### (4) Frame Buffer Write Addresses

Frame buffer addresses are specified using the base address, line offset address, frame offset address, data size of a line, and the number of lines in a frame.

The OIR_RES_BASE[31:0], OIR_RES_LN_OFF[14:0], and OIR_RES_FLM_OFF[22:0] bits should be set in 32-byte units (the lower five bits should be fixed to 0).

For 128-byte transfer, bits [6:5] in the address control registers should be fixed to 0 since addresses should be specified in 128-byte units.

For the data size of a line and the number of lines in a frame, the relevant register values set for the scaling-down control block are used.

**Table 36.18 Frame Buffer Write Address Control**

| Register Name | Bit Name | Initial Value | Description |
|---|---|---|---|
| OIR_SCL1_WR2 | OIR_RES_BASE[31:0] | 0 | Frame Buffer Base Address<br>Sets the start address of the frame buffer where frame data is to be stored.<br>For 32-byte transfer: The lower five bits should be fixed to 0_0000.<br>For 128-byte transfer: The lower seven bits should be fixed to 000_0000. |

| OIR_SCL1_WR4 | OIR_RES_FLM_OFF [22:0] | 524288 | Frame Buffer Frame Offset Address<br>Sets the frame offset address for calculating the start address of each frame.<br>Buffer 0: OIR_RES_BASE<br>Buffer 1: OIR_RES_BASE + OIR_RES_FLM_OFF × 1<br>:<br>Buffer n: OIR_RES_BASE + OIR_RES_FLM_OFF × n<br>For 32-byte transfer: The lower five bits should be fixed to 0_0000.<br>For 128-byte transfer: The lower seven bits should be fixed to 000_0000. |

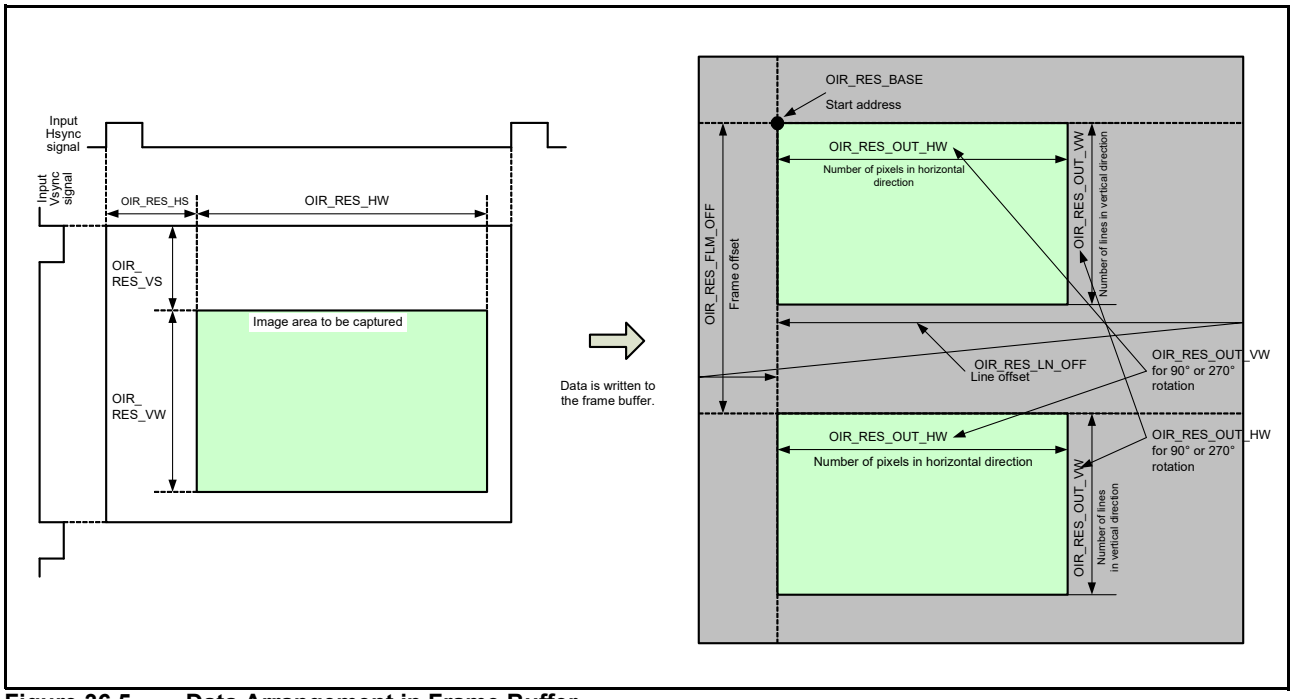

**Figure 36.5 Data Arrangement in Frame Buffer**

## (5) Frame Buffer Management

The output image generator can handle multiple frames as the frame buffer.

Data is written to the buffer in cyclic mode according to the number of frames specified by the OIR_RES_FLM_NUM bits.

**Table 36.19 Frame Buffer Write Control**

| Register Name | Bit Name | Initial Value | Description |
|---|---|---|---|
| OIR_SCL1_WR3 | OIR_RES_FLM_ NUM[9:0] | 1 | Number of Frames of Buffer to be Written to<br>Number of frames defined by OIR_RES_FLM_NUM + 1 are used.<br>For video recording: the number of frames to be stored − 1 |
| OIR_SCL1_WR7 | OIR_RES_FLM_ CNT[9:0] | — | Frame Number Before Frame Being Accessed |

## (6) Buffer Overflow Handling

If writing to the frame buffer cannot be completed due to bus-traffic related problems, an overflow interrupt can be output to the interrupt controller.

**Table 36.20 Buffer Overflow Detection**

| Register Name | Bit Name | Initial Value | Description |
|---|---|---|---|
| OIR_SCL1_WR7 | OIR_RES_ OVERFLOW | — | Line Buffer Overflow Detect<br>1: Line buffer has overflowed.<br>0: Line buffer has not overflowed. |

## (7) Frame Buffer Write End Flag

When writing one frame of data to the frame buffer is completed, a frame buffer write end interrupt can be output to the interrupt controller.

### 36.1.10 Selecting an Input Video Image Signal Processing or Graphics (OIR) Processing

Scale-up processing is not possible in the generator. Accordingly, set the OIR_RES_IBUS_SYNC_SEL bit to 1 to select graphics display.

**Table 36.21 Selection of Output Image Control Block or Graphics (OIR) Processing Block**

| Type of Output Image Generation Display | OIR_RES_ IBUS_ SYNC_SEL | Sync Signals for Frame Buffer Read | Frame Buffer Read Size Setting Bits | Display Enabling Bits |
|---|---|---|---|---|
| Graphics display | 1 | Output from graphics (OIR) processing block | GR_OIR_FLM_LNUM* GR_OIR_HW* | GR_OIR_GRC_VS GR_OIR_GRC_VW GR_OIR_GRC_HS GR_OIR_GRC_HW |

Note: * The value set to the register + 1 is the actual read size.

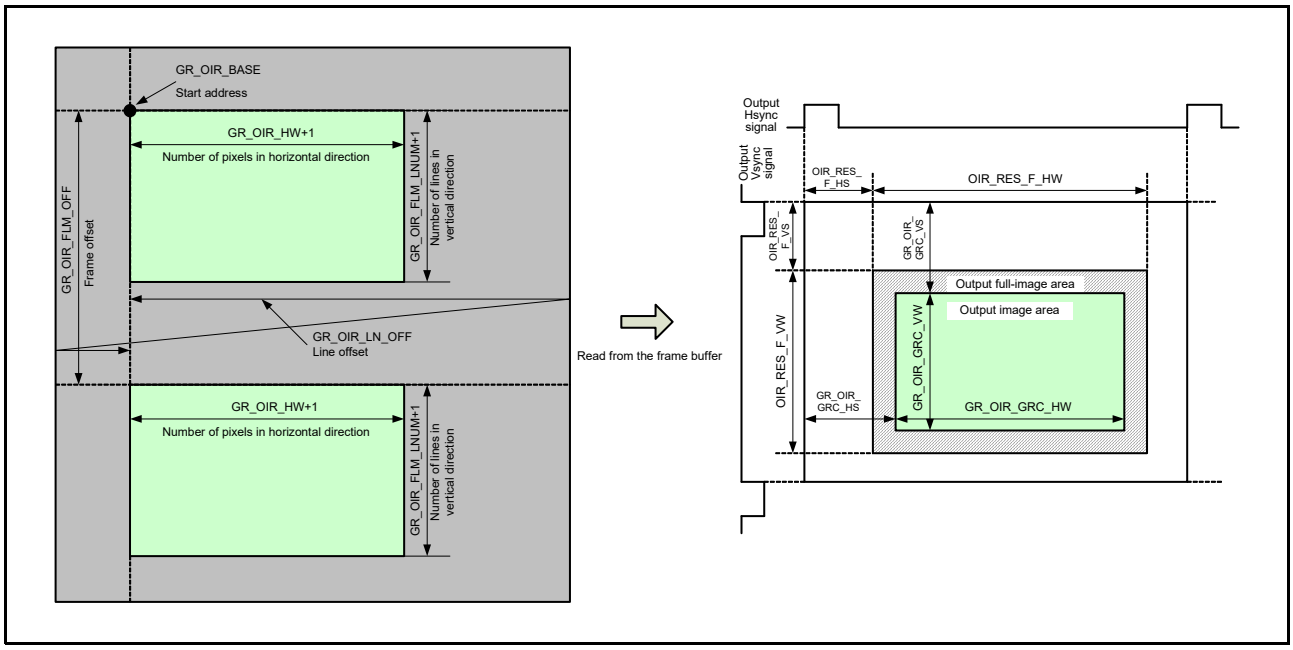

**Figure 36.6 Area Setting for Graphics Display**

**Table 36.22 Output Image Control Block or Graphics (OIR) Processing Block Selection Control**

| Register Name | Bit Name | Initial Value | Description |
|---|---|---|---|
| OIR_ SCL0_US8 | OIR_RES_IBUS_ SYNC_SEL | 0 | Sync Signal Select for Frame Buffer Read Block<br>This bit should always be set to 1 when the output image generator is in use.<br>0: Sync signals from the output image control block<br>1: Sync signals from the graphics processing block |

For details on the graphics processing, refer to the section 35, Video Display Controller 5 (5): Image Synthesizer.

## 36.2 Register Descriptions

Table 36.23 and Table 36.24 show the register configuration.

- Symbols used in Register Description:

  Initial value: Register value after a reset
  —: Undefined value
  R/W: Readable/writable. The written value can be read.
  R/WC0: Readable/writable. Writing 0 initializes the bit. Writing 1 is ignored.
  R/WC1: Readable/writable. Writing 1 initializes the bit. Writing 0 is ignored.
  R: Read-only. The write value should always be 0.
  —/W: Write-only. The read value is undefined.

# 37. Video Display Controller 5 (7): Output Controller

## 37.1 Output Controller

### 37.1.1 Overview of Functions

The output controller subjects RGB signals output from the output image generator to brightness adjustment, contrast adjustment, gamma correction of individual RGB, dither process, and output format conversion. The output controller also generates various timing signals for LCD panel drive.

Output from the LVDS is also possible. For the LVDS output, see section 40, LVDS Output Interface.

Figure 37.1 shows the function block diagram of the output controller.

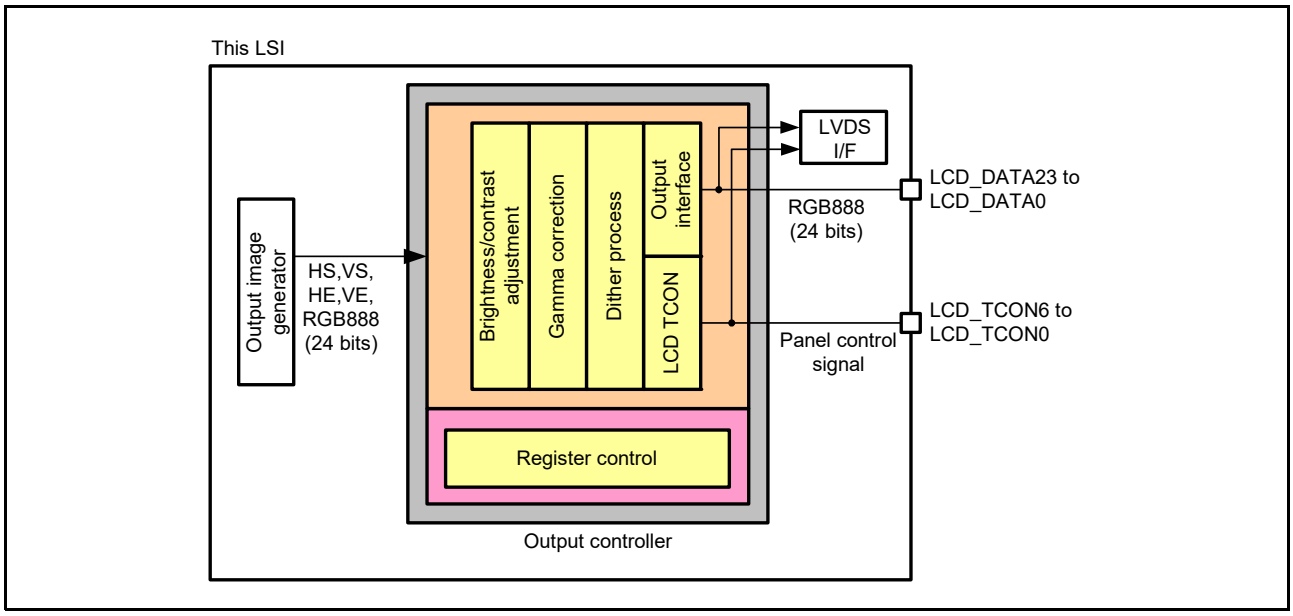

**Figure 37.1 Functional Block Diagram of Output Controller**

### 37.1.2 Register Update Control

The Vsync signal is used to control the update timing of all the registers of the output controller.

After 1 is set to the bits in the update control register, the contents of the relevant registers are actually modified at the rising edge of the Vsync signal, when the update control register is automatically cleared to 0.

**Table 37.1 Register Update Control**

| Register Name | Bit Name | Initial Value | Description |
|---|---|---|---|
| OUT_UPDATE | OUTCNT_VEN | 0 | Brightness/Contrast Control, Dither Process, Output Interface Register Update<br>0: Registers are not updated.<br>1: Registers are updated at the rising edge of the Vsync. |

| TCON_UPDATE | TCON_VEN | 0 | LCD TCON Register Update<br>0: Registers are not updated.<br>1: Registers are updated at the rising edge of the Vsync. |

### 37.1.3 Route Selection

The processing sequence of the brightness/contrast control and gamma correction control can be swapped according to the settings of the register.

**Table 37.2 Route Selection**

| Register Name | Bit Name | Initial Value | Description |
|---|---|---|---|
| OUT_CLK_PHASE | OUTCNT_<br>FRONT_GAM | 0 | Correction Circuit Sequence Control<br>0: Brightness → contrast → gamma correction<br>1: Gamma correction → brightness → contrast |

### 37.1.4 Panel Brightness Adjustment

Brightness (DC) adjustment is individually performed for RGB signals from output image generator.

(BRT_R/G/BOUT after brightness adjustment has many bits to prevent overflow or underflow. The overflow or underflow process is performed at contrast calculation.)

#### (1) Calculation formulas for brightness (DC) adjustment

BRT_GOUT = GIN + PBRT_G − 512

BRT_BOUT = BIN + PBRT_B − 512

BRT_ROUT = RIN + PBRT_R − 512

**Table 37.3 Brightness (DC) Adjustment**

| Register Name | Bit Name | Initial Value | Description |
|---|---|---|---|
| OUT_BRIGHT1 | PBRT_G[9:0] | 512 | Brightness (DC) Adjustment of G Signal<br>Unsigned (0 (-512) to 512 (0) to 1023 (+511) [LSB], 512 [LSB] with offset) |
| OUT_BRIGHT2 | PBRT_B[9:0] | 512 | Brightness (DC) Adjustment of B Signal<br>Unsigned (0 (-512) to 512 (0) to 1023 (+511) [LSB], 512 [LSB] with offset) |
| OUT_BRIGHT2 | PBRT_R[9:0] | 512 | Brightness (DC) Adjustment of R Signal<br>Unsigned (0 (-512) to 512 (0) to 1023 (+511) [LSB], 512 [LSB] with offset) |

### 37.1.5 Contrast Adjustment

Contrast is calculated for RGB signals obtained after brightness calculation.

(If an overflow or underflow occurs, contrast is clipped to the maximum or minimum value.)

#### (1) Calculation formulas for contrast (gain) adjustment

GOUT = BRT_GOUT × CONT_G/128

BOUT = BRT_BOUT × CONT_B/128

ROUT = BRT_ROUT × CONT_R/128

**Table 37.4 Contrast (Gain) Adjustment**

| Register Name | Bit Name | Initial Value | Description |
|---|---|---|---|
| OUT_CONTRAST | CONT_G [7:0] | 128 | Contrast (Gain) Adjustment of G Signal<br>0/128 to 255/128 (approx.2 times) |
| OUT_CONTRAST | CONT_B [7:0] | 128 | Contrast (Gain) Adjustment of B Signal<br>0/128 to 255/128 (approx.2 times) |
| OUT_CONTRAST | CONT_R [7:0] | 128 | Contrast (Gain) Adjustment of R Signal<br>0/128 to 255/128 (approx.2 times) |

### 37.1.6 Gamma Correction

Gamma correction is carried out by dividing an input signal having 256 gradation levels into 32 and controlling the gain of each area. Gain coefficient of each area can be set as 0 to approx. 2.0 [times]

#### (1) Gamma correction formula for each area

$$DOUT = ((DIN - TH_{(n)}) \times GAIN_{(n)} + OFFSET_{(n)})/256$$

DIN: Input signal (8-bit)

DOUT: Output signal (10-bit)

TH(n): Threshold (8-bit)

OFFSET(n): Offset value (19-bit)

GAIN(n): Gain coefficient (11-bit)

#### (2) Offset calculation formulas for each area

$$OFFSET_{(n)} = OFFSET_{(n-1)} + DEF_O_{(n)} \text{ (When n = 0, } OFFSET_{(0)} = 0.)$$

$$DEF_O_{(n)} = (TH_{(n)} - TH_{(n-1)}) \times GAIN_{(n-1)} \text{ (When n = 0, } OFFSET_{(0)} = 0.)$$

OFFSET(n): Offset value of current area (19-bit)

OFFSET(n-1): Offset value of previous area (19-bit)

DEF_O(n): Difference in offset value of Current and previous area (19-bit)

TH(n): Threshold of current area (8-bit)

TH(n-1): Threshold of previous area (8-bit)

GAIN(n-1): Gain coefficient of previous area (11-bit)

### 37.1.7 Dither Process

Dither process is carried out by adjusting brightness/contrast or reducing 10-bit RGB signals output from the gamma correction block to 8-bit, 6-bit, or 5-bit RGB signals. The operation mode of dither process can be selected from truncate mode, round-off mode, 2 × 2 pattern dither mode and random pattern dither mode.

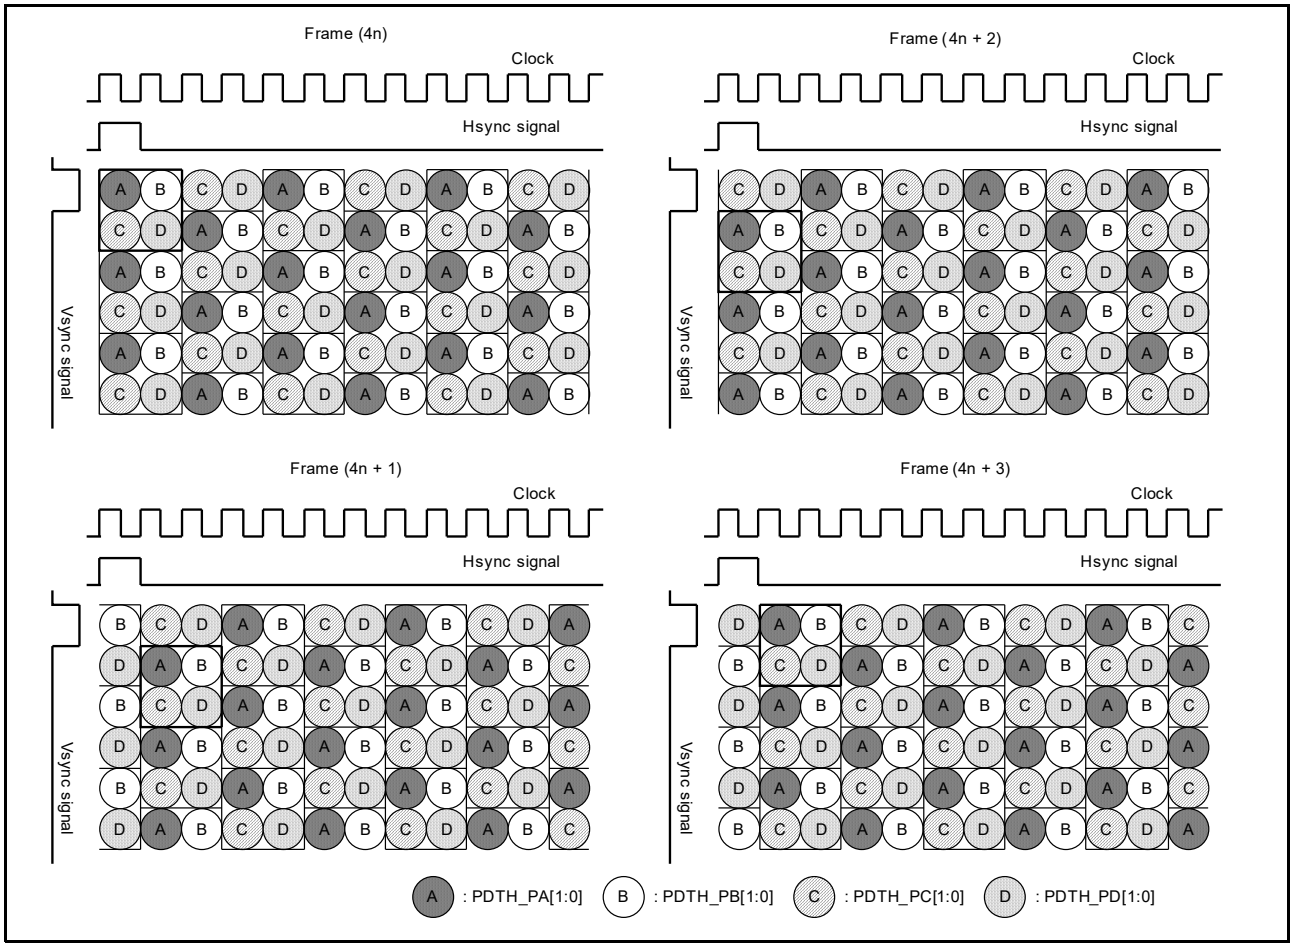

**Figure 37.4 Operation Specification of 2 × 2 Pattern Dither**

The conversion equations are as follows.

[Truncate mode]

(a) 10 bits to 8 bits

Output RGB data[7:0] = Input RGB data[9:0] ÷ 4 (truncate the number below the decimal point)

(b) 10 bits to 6 bits

Output RGB data[7:2] = Input RGB data[9:0] ÷ 16 (truncate the number below the decimal point)

(c) 10 bits to 5 bits

Output RGB data[7:3] = Input RGB data[9:0] ÷ 32 (truncate the number below the decimal point)

[Round-off mode]

(a) 10 bits to 8 bits

Output RGB data[7:0] = Input RGB data[9:0] ÷ 4 (round off to an integer)

(b) 10 bits to 6 bits

Output RGB data[7:2] = Input RGB data[9:0] ÷ 16 (round off to an integer)

(c) 10 bits to 5 bits

Output RGB data[7:3] = Input RGB data[9:0] ÷ 32 (round off to an integer)

[2 × 2 pattern dither mode, random pattern dither mode]

(a) 10 bits to 8 bits

Output RGB data[7:0] = Input RGB data[9:0] ÷ 4 + pattern value at the first decimal place (truncate the number below the decimal point after addition)

(b) 10 bits to 6 bits

Output RGB data[7:2] = Input RGB data[9:0] ÷ 16 + pattern value at the first decimal place (truncate the number below the decimal point after addition)

(c) 10 bits to 5 bits

Output RGB data[7:3] = Input RGB data[9:0] ÷ 32 + pattern value at the first decimal place (truncate the number below the decimal point after addition)

### 37.1.8 Output Format Conversion

In output format conversion, the RGB signal after dither process is converted to LCD output signal having any of the following formats, namely, parallel RGB888, parallel RGB666, parallel RGB565, and serial RGB.

Further, converted data can be allocated to LCD output pins as selected.

### (4) Bit Allocation of LCD Signal for Serial RGB Output

For serial RGB output, RGB signal input shown Table 37.10 is allocated to rgb internal signals and the signals are converted from parallel to serial format and output as LCD signals. R/G/BIN[7:0] are the RGB internal signals after dither process.

The internal signals r[7:0], g[7:0], and b[7:0] are serially output to LCD_DATA7 to LCD_DATA0.

## (5) Parallel to Serial Conversion

As shown in Table 37.11, four types of parallel to serial conversions are possible by controlling clock speed mode and selecting the scan direction ('n' in the table are natural numbers).

**Table 37.11 Specifications of Serial RGB Output**

Figure 37.5 and Figure 37.6 show the timing of parallel to serial conversion in triple speed and quadruple speed modes, respectively.

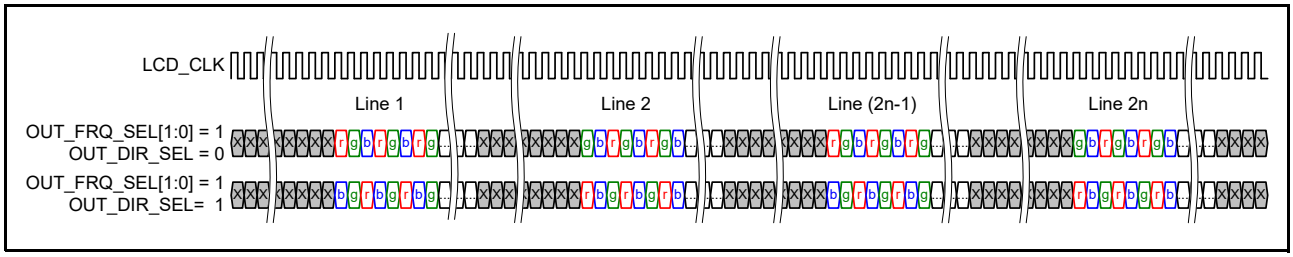

**Figure 37.5 Timing of Parallel to Serial Conversion in Triple Speed Mode**

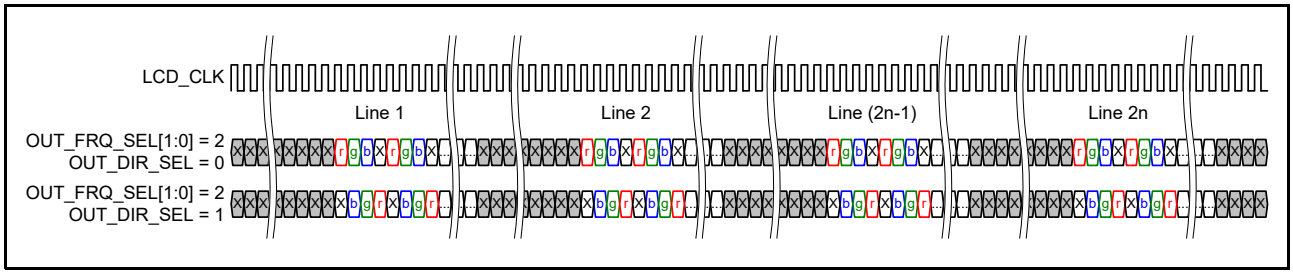

**Figure 37.6 Timing of Parallel to Serial Conversion in Quadruple Speed Mode**

During serial output, the phase timing with the HE signal can be adjusted by OUT_PHASE[0:1].

Figure 37.7 shows the timing of the clock phases of the serial RGB output (triple speed mode).

## 37.1.9 LCD TCON

The LCD TCON generates various timing signals for driving the LCD panel.

Specifically, the timing include two vertical panel driver signals, five horizontal panel driver signals, and one composite signal of the vertical and horizontal panel driver signals. Table 37.13 lists the timing signals that are generated by LCD TCON

**Table 37.13 Signals Generated by LCD TCON**

| Signal Name | Type | Description |
|---|---|---|

### (1) Horizontal Reference Offset Control

The horizontal reference offset control enables generation of a reference signal with a clock delay equivalent to the value of TCON_OFFSET[10:0] from the rising edge of the Hsync signal. If a signal that spans across the Hsync signal needs to be generated, such a signal is generated with reference to the offset reference signal.

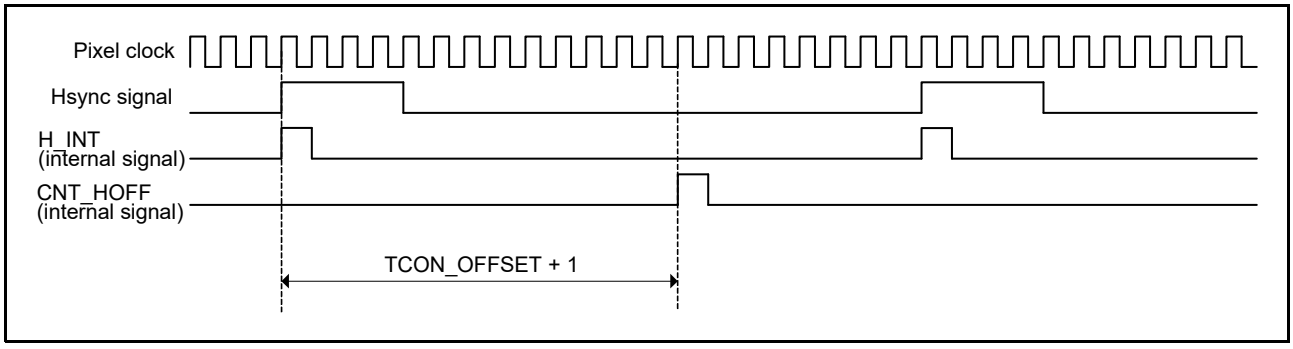

**Figure 37.9 Generation of Offset Horizontal Reference (H_OFF) Signal**

Note: When generating the POLA and POLB signals in reverse mode, the bits TCON_POLA_HS_SEL and TCON_POLB_HS_SEL should be set to 0.

### (2) Horizontal Panel Driver Signal Generation (A)

Horizontal synchronous panel driver signal generation (A) involves generation of a timing signal that changes twice in a horizontal period according to the values of TCON_xxxx_HS[10:0] and TCON_xxxx_HW[10:0] bits, which set the first changing timing and the second changing timing, respectively.

The internal counter performs the following operations.

1. Resets the counter value at the rising edge of the Hsync signal as the reference.
2. Increments the counter value at the rising edge of the panel clock.

A fixed output value of 0 can be obtained by setting 0 in TCON_xxxx_HW[10:0], which set the second changing timing.

### (3) Horizontal Panel Driver Signal Generation (B)

In addition to the normal mode operation described in (2), reverse mode operation, that is, horizontal panel driver signal generation (B) is provided. In reverse mode, operation starts at the rising edge of the Vsync signal as the reference and a signal is generated such that its polarity is inverted every horizontal period in the timing set by the TCON_xxxx_HS[10:0] bits, which set the first changing timing.

In reverse mode, regardless of whether the number of lines in the vertical direction is odd or even, the polarity of the signals generated is inverted every horizontal period. The following three reverse modes are selectable for polarity inversion operation.

**Table 37.16 Horizontal Panel Driver Signal Generation Modes**

### (4) Vertical Panel Driver Signal Generation

The vertical synchronous panel driver signal generation involves the following operations.

1. Initialization at the rising edge of the Vsync signal
2. Generation of a timing signal that changes twice in a vertical period according to the values of the internal counter, and TCON_xxxx_VS[10:0] and TCON_xxxx_VW[10:0] bits, which set the first changing timing and the second changing timing, respectively.

The internal counter increments the counter value in the following two cases.

1. At the rising edge of the Hsync signal
2. At the point reached after a clock delay specified by the value of TCON_HALF[10:0] from the rising edge of the Hsync signal (normally, 1/2fH is set).

## (5) DE Timing Signal Generation

DE timing signal generation involves generation of data enable signal (DE) that indicates the valid period of the video signal by synthesizing the horizontal panel driver (HE) signal and the vertical panel driver (VE) signal (AND).

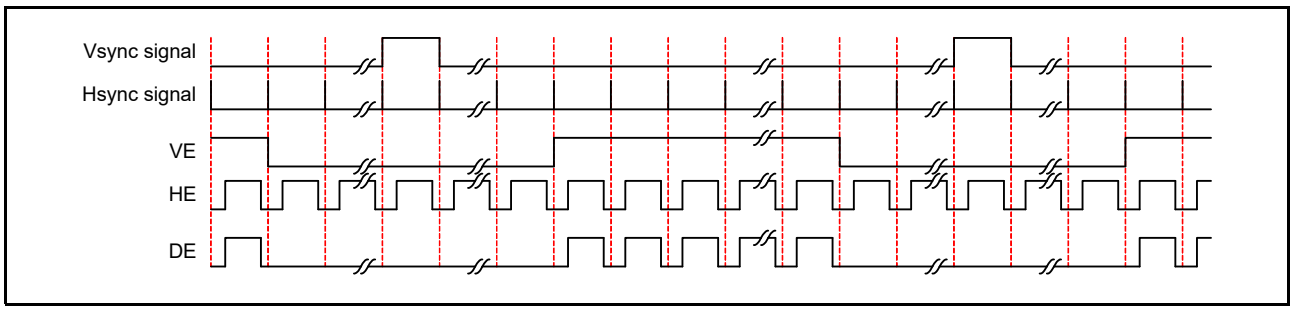

**Figure 37.20 Data Enable Signal Generation**

## (6) Polarity Inversion

Polarity inversion enables inversion of polarity of each signal generated by the signal generating circuit.

## 37.2 Register Descriptions

Table 37.23 to Table 37.28 shows the register configuration.

- Symbols used in Register Description:

  Initial value: Register value after a reset
  —: Undefined value
  R/W: Readable/writable. The written value can be read.
  R/WC0: Readable/writable. Writing 0 initializes the bit. Writing 1 is ignored.
  R/WC1: Readable/writable. Writing 1 initializes the bit. Writing 0 is ignored.
  R: Read-only. The write value should always be 0.
  —/W: Write-only. The read value is undefined.

## 37.3 Usage Methods

### 37.3.1 Gamma Correction Adjustment Method

The characteristics of G, B, R of each panel to be connected should be measured and gamma correction should be made to suit the panel.

Since the gamma correction adjustment depends on to the characteristics of the panel, there are no recommended setting values.

### 37.3.2 Dither Usage Method

Dither is used when pseudo contour is appeared on the display screen.

**Table 37.29 Dither Settings**

| Bit Name | Setting Value |
|---|---|
| PDTH_FORMAT[1:0] | Selects the format.<br>For RGB888: 0<br>For RGB666: 1<br>For RGB565: 2 |
| PDTH_SEL[1:0] | When 2 × 2 pattern dither is to be used: 2 |
| PDTH_PA[1:0] | Normally 3 (initial value) |
| PDTH_PB[1:0] | Normally 0 (initial value) |
| PDTH_PC[1:0] | Normally 2 (initial value) |
| PDTH_PD[1:0] | Normally 1 (initial value) |

### 37.3.3 Output Format Adjustment Method

The setting example of the typical output format is shown in Table 37.30 and Table 37.31.

It is necessary to carry out the setting of synchronization system signals of each output format similarly as the setting of output after scaling.

**Table 37.30 Setting Example of Synchronizing Signal**

| Register Name | Bit Name | VGA | SVGA | Description |

# 38. Video Display Controller 5 (8):System Controller

## 38.1 System Controller

### 38.1.1 Overview of Functions

The system controller provides interrupt control, panel clock control, CLUT table read select signal status flag output functions.

### 38.1.2 Interrupt Control

Twenty three interrupt signals are output from the scaler and image synthesizer. The system controller controls whether to output these interrupt signals.

One is written to the corresponding INT_STA* bit when an interrupt signal is to be accepted. After 1 has been written to the bit, however, its value is still read out as 0 until the interrupt signal is accepted. Once the interrupt signal has been accepted, the INT_STA* bit is read out as 1.

The bit for an accepted interrupt signal is cleared by writing 0 to the INT_STA* bit. If further interrupt signals are to be accepted after the INT_STA* bit has been cleared, 1 is again written to the bit.

**Table 38.1 Interrupt Signals**

| Request Source Name | Bit Name | Function |
|---|---|---|
| S0_VI_VSYNC | INT_STA 0 | Vsync signal input to scaler 0 |
| S0_LO_VSYNC | INT_STA 1 | Vsync signal output from scaler 0 |
| S0_VSYNCERR | INT_STA 2 | Missing Vsync signal for scaler 0 |
| GR3_VLINE | INT_STA 3 | Specified line signal for panel output in graphics 3 |
| S0_VFIELD | INT_STA 4 | Field end signal for recording function in scaler 0 |

## 38.2 Register Descriptions

The following register sets are allocated in the SH register map area.

- Symbols used in Register Descriptions

  Initial value: Register value after a reset
  —: Undefined value
  R/W: Readable/writable. The written value can be read.
  R/WC0: Readable/writable. Writing 0 initializes the bit. Writing 1 is ignored.
  R/WC1: Readable/writable. Writing 1 initializes the bit. Writing 0 is ignored.
  R: Read-only. The write value should always be 0.
  —/W: Write-only. The read value is undefined.

# 40. LVDS Output Interface

This LSI has a module for providing a low voltage differential signaling (LVDS) output interface. This module converts the RGB signals output from video display controller 5 to the LVDS format that has six bits each for R, G, and B signals, and outputs the converted signals. It has a dedicated phase-locked loop (PLL) circuit, which can generate a clock with a desired frequency by dividing or multiplying the input clock frequency.

The clock output from this PLL can be used as the panel clock for video display controller 5 even when LVDS output is not used. This PLL is called LVDS PLL in this section.

## 40.1 Features

- Four pairs of differential output conforming to the TIA/EIA-644 standard (three pairs for data and one pair for the clock)
- When LVDS output is not used, the LVDS pins can be used as CMOS input/output pins.
- LVDS PLL for generating a clock with a desired frequency
- LVDS PLL power-down function

## 40.2 Block Diagram

## 40.5 Operation

This module receives the RGB888 signals output from video display controller 5 and the SYNC signal, converts the video signals to the LVDS format, and outputs them. The precision of the RGB signals is reduced to six bits each. The operating clock is generated in the LVDS PLL.

### 40.5.1 LVDS PLL Settings

The input clock select circuit, frequency dividers 1 to 3, and LVDS PLL circuit are used to generate operating clocks. For input and output of each circuit, allowable frequency ranges are determined; be sure to make appropriate settings to generate input and output frequencies within the ranges.

Before modifying various setting registers, check that the panel clock operation in video display controller 5 is disabled (SYSCNT_PANEL_CLK.PANEL_ICKEN = 0) and the LVDS PLL output is disabled (LPLLSETR.LVDS_CLK_EN = 0).

Figure 40.3 shows a block diagram of the LVDS PLL and its peripheral circuits.

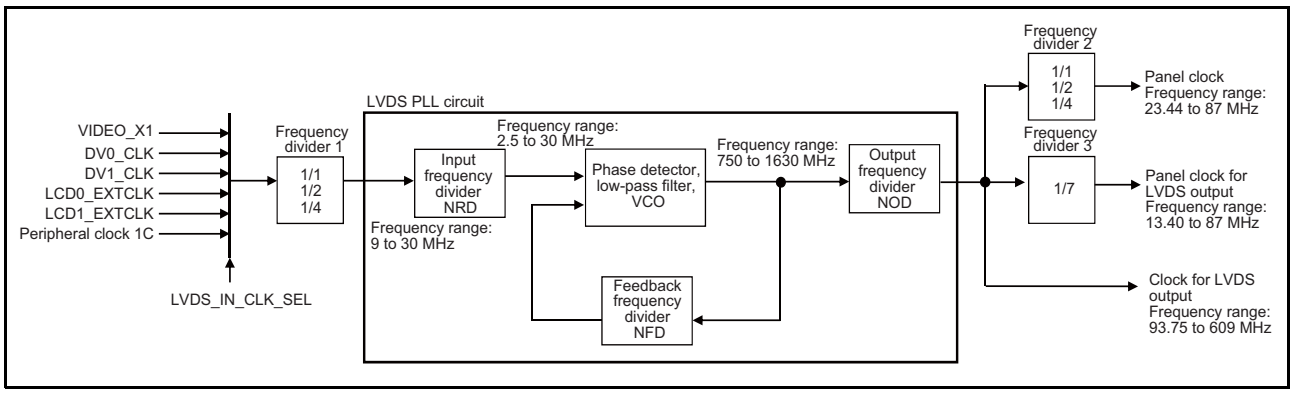

**Figure 40.3 Block Diagram of LVDS PLL and Peripheral Circuits**

#### (1) Clock Input to LVDS PLL

The clock input to the LVDS PLL can be selected from among VIDEO_X1, DV0_CLK, DV1_CLK, LCD0_EXTCLK, LCD1_EXTCLK, and peripheral clock 1C (P1φ) clocks through the LVDS_IN_CLK_SEL bit setting in LVDS_CLKSELR.

The frequency of this input clock should be within the range from 9 to 30 MHz. When the input clock frequency is higher than the upper limit of this range, use frequency divider 1 placed before the LVDS PLL and reduce the frequency so that it is within the allowed range.

### (2) LVDS PLL Frequency Setting

The LVDS PLL has three internal frequency dividers: input frequency divider NRD, feedback frequency divider NFD, and output frequency divider NOD.

The frequency of the clock output from the LVDS PLL is calculated by the following equations. Note that the reference frequency, VCO output frequency, LVDS PLL input frequency, and LVDS PLL output frequency should be within the respective ranges shown below the equations.

FREF = FIN / NRD (Reference frequency)
FVCO = FIN × NFD / NRD (VCO output frequency )
FOUT = FIN × NFD / (NRD × NOD) (LVDS PLL output frequency )

Note:
FREF: Reference frequency. Frequency range = 2.5 MHz to 30 MHz
FVCO: VCO output frequency. Frequency range = 750 MHz to 1630 MHz
FIN: LVDS PLL input frequency. Frequency range = 9 MHz to 30 MHz
FOUT: LVDS PLL output frequency. Frequency range = 609 MHz max.

### (3) LVDS PLL Frequency Setting Timing

Before making settings for each frequency divider in the PLL circuit described in (2), place the PLL in the power-down state (PD = 1) and wait for at least 0.5 µs. After making frequency divider settings, wait for a retention period of at least 0.5 µs and release the power-down state (PD = 0).

Figure 40.4 shows this timing.

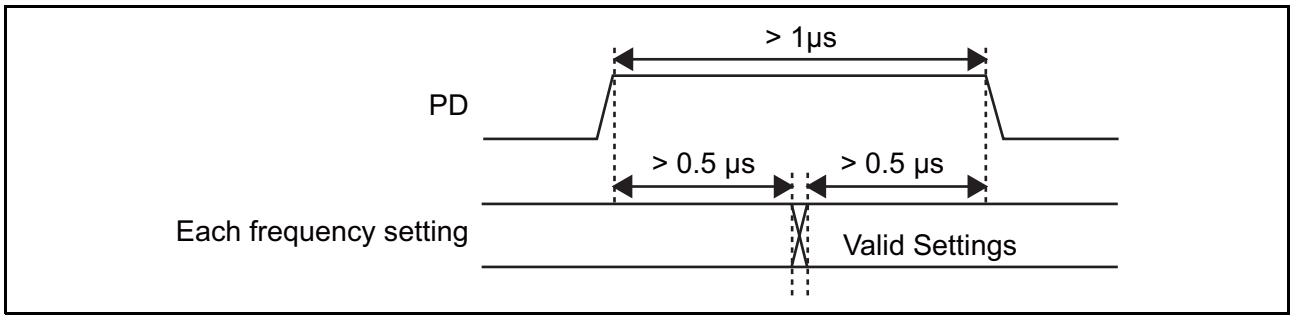

**Figure 40.4 PLL Setting Timing**

### (4) LVDS PLL Output Enable Timing

Output of the clock from the LVDS PLL can be enabled or disabled through the LVDS_CLK_EN bit setting in LCLKSELR.

To allow time for stabilization of oscillation by the PLL, wait for at least 200 us after release from the power-down state before enabling the LVDS PLL output. The LVDS_CLK_EN bit in LCLKSELR should be modified only while the panel clock operation in video display controller 5 is disabled (SYSCNT_PANEL_CLK.PANEL_ICKEN = 0).

### (5) LVDS PLL Output Clock Frequency Setting

When using the clock output from the LVDS PLL as the clock for the LVDS output interface, select the clock from frequency divider 3 (divided by 7) as the panel clock for video display controller 5.

When using the clock output from the LVDS PLL as the clock for digital RGB output, select the clock from frequency divider 2 as the panel clock for video display controller 5. In addition, make appropriate settings so that the clock frequency after frequency division is 87 MHz or lower. This limitation on the frequency is not applied when the clock is used for the LVDS output interface.

The panel clock can be selected through the PANEL_OCKSEL bits in SYSCNT_PANEL_CLK in video display controller 5.

## 40.5.2 LVDS Output Format

This module converts and then outputs the LCD data output from video display controller 5 and the timing signals generated by the LCD TCON.

### (1) LVDS Output Format

#### (a) LCD data

After converted into the LVDS format, LCD data is output from LCD_DATA23 to LCD_DATA18, LCD_DATA15 to LCD_DATA10, and LCD_DATA7 to LCD_DATA2 pins.

#### (b) Timing signals generated by LCD TCON

After converted into the LVDS format, the timing signals are output from the LCD_TCON0, LCD_TCON2, and LCD_TCON3 pins.

Figure 40.5 shows the bit alignment in the LVDS output format.

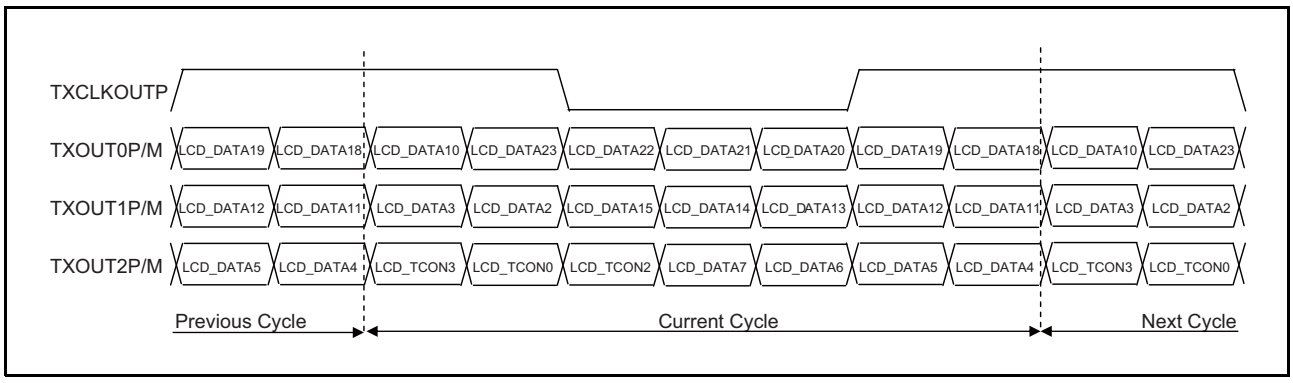

**Figure 40.5 Data Map of LVDS Output Format**

## (2) Setting Example

The following is the setting example of the LVDS output format. The register the setting is applied is register in video display controller 5. For the details of the register, see section 37, Video Display Controller 5 (7): Output Controller.

**Table 40.3 Setting Example of LVDS Output Format**

| Register | Bit | Value | Remark |
|---|---|---|---|
| OUT_SET | OUT_ENDIAN_ON | 0 | Bit endian change is off. |
| | OUT_SWAP_ON | 0 | B/R signal swap is off. |
| | OUT_FORMAT[1:0] | 0 | RGB888 is selected as an output format (the upper six-bit data is output in the LVDS format). |
| TCON_TIM_STVA2 | TCON_TIM_STVA2 | 0 | The VS signal is selected for the LCD_TCON0 pin. |
| TCON_TIM_STVA1 | TCON_STVA_VS[10:0] | Arbitrary | The VS signal timing is set. |
| | TCON_STVA_VW[10:0] | Arbitrary | The VS signal timing is set. |
| TCON_TIM_STH2 | TCON_STH_SEL[2:0] | 2 | The HS signal is selected for the LCD_TCON2 pin. |
| TCON_TIM_STH1 | TCON_STH_HS[10:0] | Arbitrary | The HS signal timing is set. |
| | TCON_STH_VS[10:0] | Arbitrary | The HS signal timing is set. |
| TCON_TIM_STB2 | TCON_STB_SEL[2:0] | 7 | The DE signal is selected for the LCD_TCON3 pin. |
| TCON_TIM_STVB1 | TCON_STVB_VS[10:0] | Arbitrary | The DE signal timing is set. |
| | TCON_STVB_VW[10:0] | Arbitrary | The DE signal timing is set. |
| TCON_TIM_STB1 | TCON_STB_HS[10:0] | Arbitrary | The DE signal timing is set. |
| | TCON_STB_HW[10:0] | Arbitrary | The DE signal timing is set. |

## 40.5.3 Procedures for Register Settings

### (1) Initial Settings after Power-on Reset

The following shows an example of initial settings after a power-on reset.

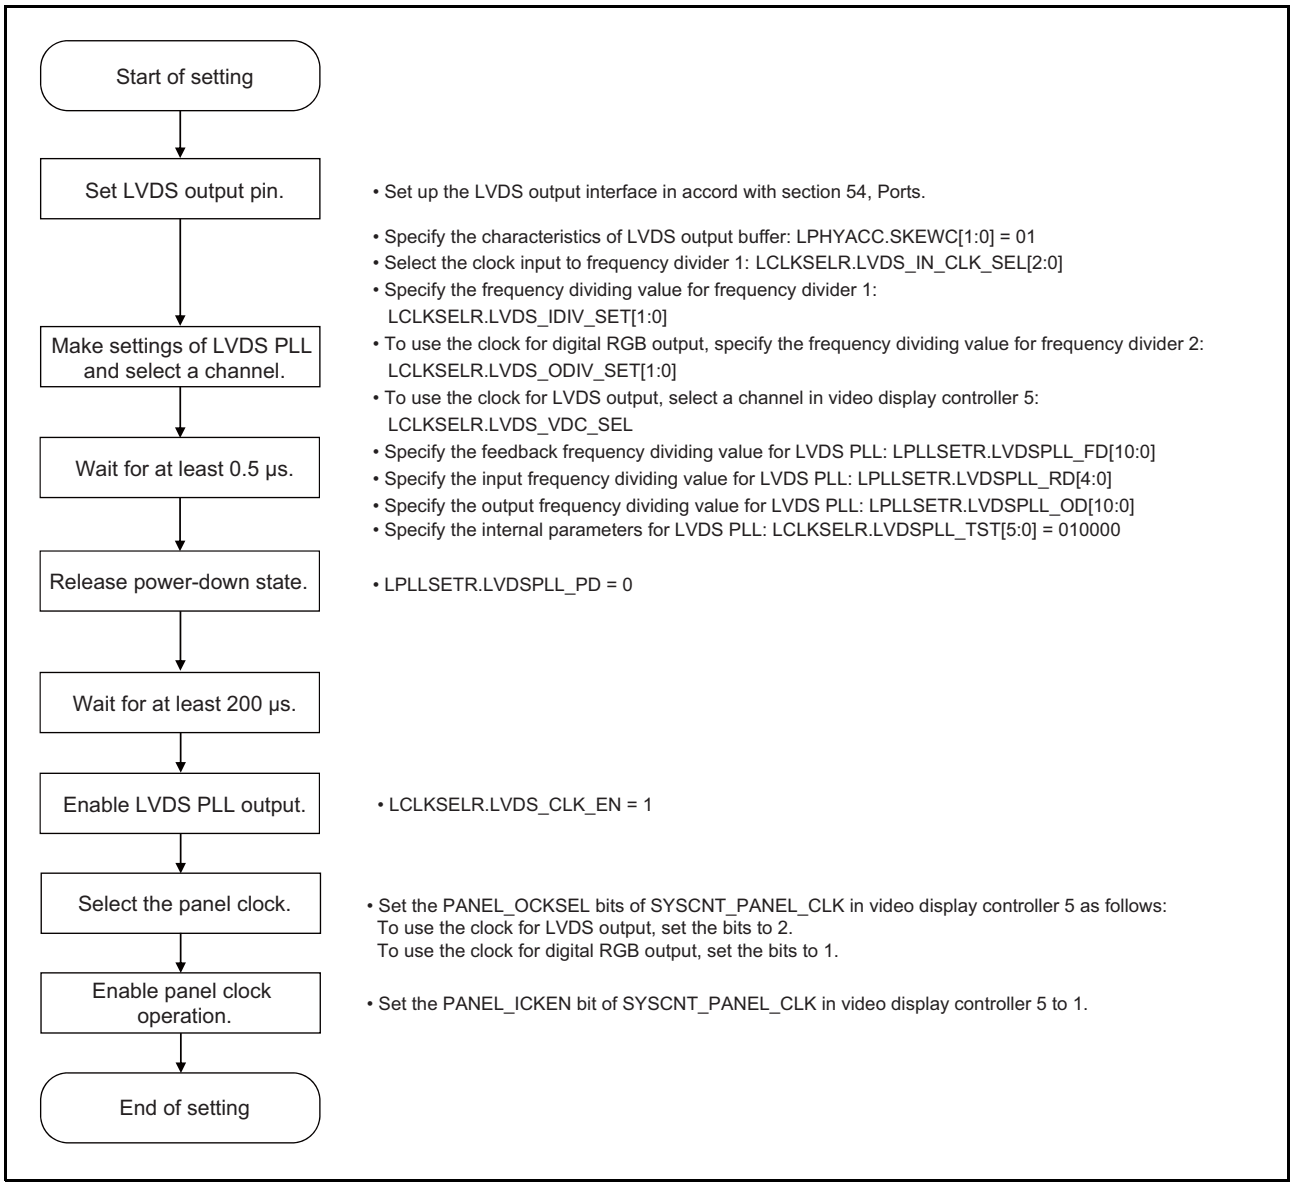

**Figure 40.7 Example of Initial Settings after Power-On Reset**

### (2) Frequency Modification Settings

The following shows an example of modifying frequencies.

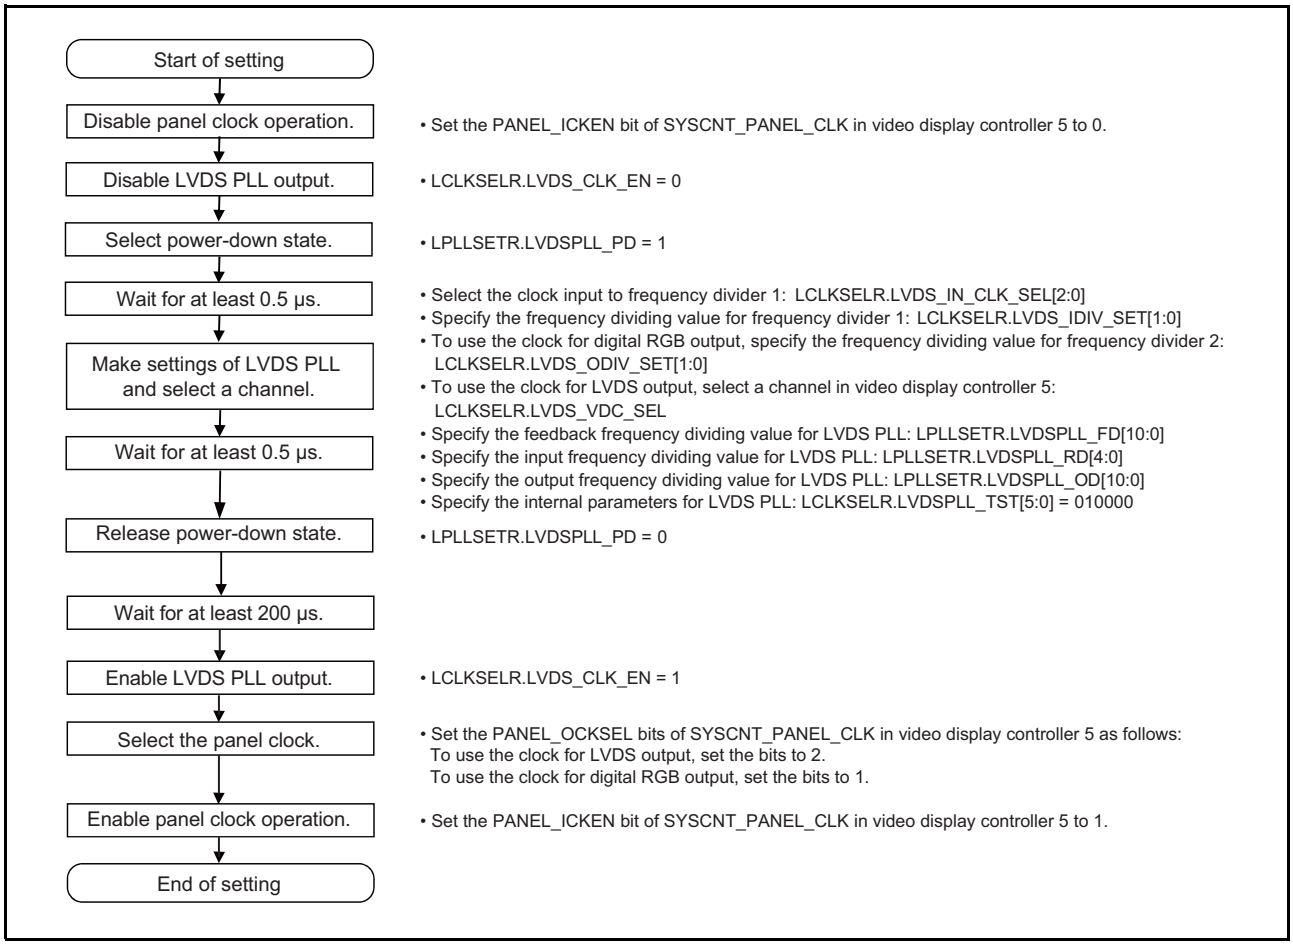

**Figure 40.8 Example of Modifying Frequencies for LVDS Output**

## 40.6 Notes

### 40.6.1 LVDS Output Pin Settings

The LVDS output buffers enter a low power consumption state when pins are set up other than for an LVDS output interface in accord with section 54, Ports. Although the LVDS output buffers return from the low power consumption state after pins are set to operate as an LVDS output interface, this requires up to 0.5 µs. Accordingly, at least 0.5 µs are required before actual LVDS output starts after pins have been set to operate as an LVDS output interface.

# 43. Display Out Comparison Unit

The display out comparison unit (DISCOM) checks whether the data output from the graphics display module* agrees with the expected graphics data. This checking is accomplished by comparing the CRC code of the data output from the graphics display module with the pre-calculated CRC code of the expected graphics data. Since this LSI incorporates two channels of graphics display modules, it also incorporates two channels of the DISCOM units corresponding to them.

Note: * This indicates video display controller 5 in this LSI.

## 43.1 Features

This module has the following features.

- Comparison of Graphics Planes of Graphics Display Module
  One of the graphics planes of the graphics display module can be selected and its CRC code can be compared with the expected CRC code.
- Comparison of Data after α Blending
  The CRC code of the graphics data obtained after α blending in the graphics display module can be compared with the expected CRC code.
- Rectangular Area Specification
  The rectangular area can be specified based on the graphics data output from the graphics display module (graphics plane or graphics data obtained after α blending) and its CRC code can be compared with the expected CRC code.
- Pixel Format
  A pixel format for 32 bits/pixel or 16 bits/pixel can be selected.
  ARGB8888/RGB888 are available for 32 bits/pixel, and only RGB565 is available for 16 bits/pixel.

### 43.3.2 Status Register (DOCMSTR)

DOCMSTR returns the comparison result of the CRC code. The result is reflected in this register when the end of the valid period of the graphics data is detected.

| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

### 43.3.3 Status Clear Register (DOCMCLSTR)

Writing 1 to the CMPCLST bit causes clearing of the CMPST bit in DOCMSTR to 0. However, clearing of the CMPST bit in DOCMSTR after 1 is written to the CMPCLST bit takes a fixed amount of time. Confirm that the CMPST bit in DOCMSTR is actually cleared after writing 1 to the CMPCLST bit.

| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

### 43.3.4 Interrupt Enable Register (DOCMIENR)

DOCMIENR enables interrupt of the corresponding status bits in DOCMSTR.

| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

## 43.4 Operation

### 43.4.1 Overview of Operations

This module is capable of calculating the CRC code of the arbitrary rectangular area of graphics data. By comparing the CRC code with the pre-calculated expected CRC code value, this module can detect whether the display output is obtained as expected.
Main features of this module are as follows.

- Graphics data can be selected from graphics plane 1 to graphics plane 5
- Graphics data after α blending can be selected
- Arbitrary rectangular area of the selected graphics data can be specified
- Pixel format can be selected from ARGB8888 and RGB888 for 32 bits/pixel or RGB565 for 16 bits/pixel
- Interrupt is generated when the compared CRC codes do not match.

### 43.4.2 System Configuration

This module is configured as shown in Figure 43.2.
The CRC code is calculated after receiving the graphics data output from the graphics display module. The calculated CRC code is then compared with the pre-calculated expected CRC code value. The graphics data can be selected from graphics plane 1 to graphics plane 5, and the data after α blending. Note that the graphics planes 1 to 4 correspond respectively to graphics (0) to (3) in the image synthesizer of video display controller 5, and the graphics plane 5 corresponds to graphics (OIR) of the output video image generation block.

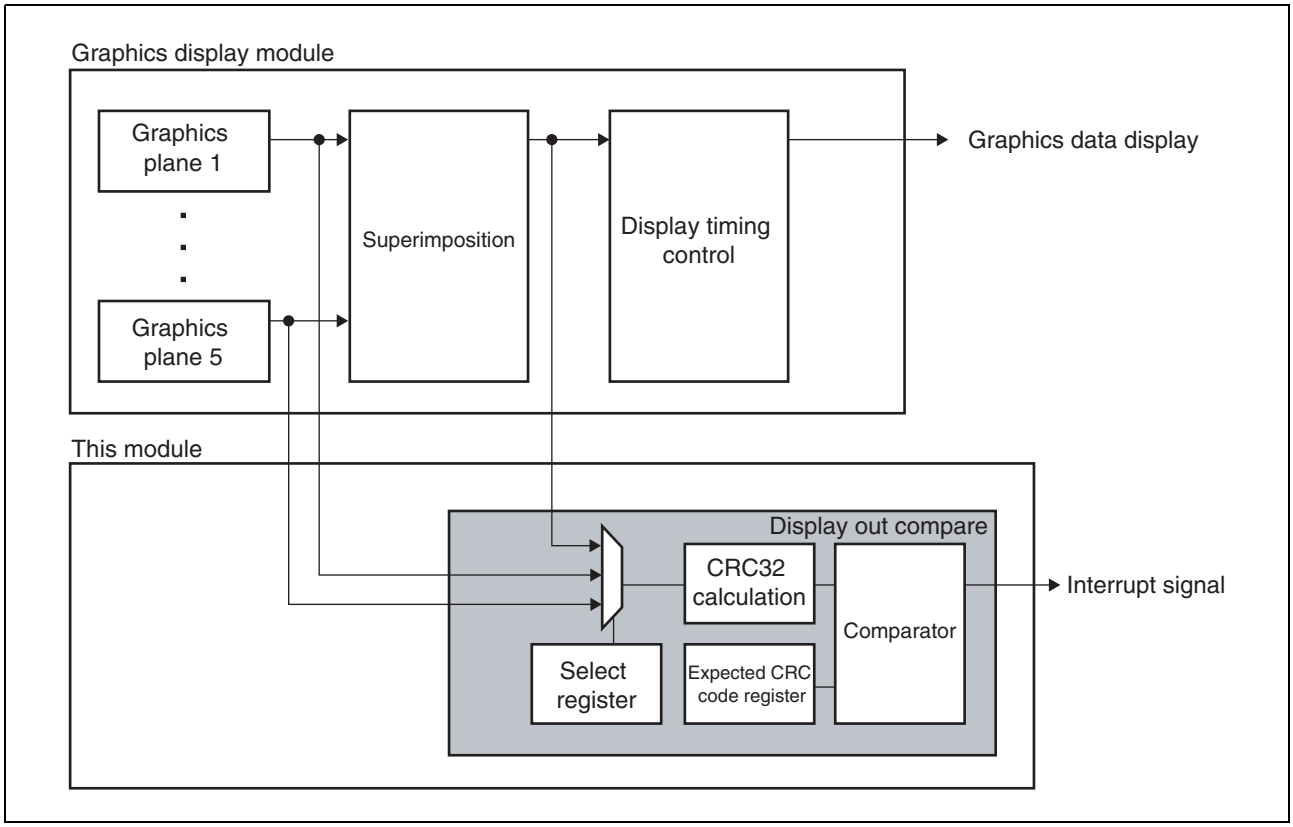

**Figure 43.2 System Configuration**

### 43.4.3 CRC Calculation Method

The display out comparison unit generates a 32-bit CRC code by using the following CRC polynomial (IEEE802.3).

$x^{32}+ x^{26}+ x^{23}+ x^{22}+ x^{16}+ x^{12}+ x^{11}+ x^{10}+ x^{8}+ x^{7}+ x^{5}+ x^{4}+ x^{2}+ x+1$

CRC is sequentially calculated beginning with LSB in pixel units.
In other words, for 32 bits/pixel, it is calculated in units of 32 bits and for 16 bits/pixel, it is calculated in units of 16 bits.
During CRC calculation of data, pixel data is input when the graphics data is output (top left to bottom right).

### 43.4.4 Graphics Data Selection for CRC Code Generation

The graphics data for which the CRC code is calculated can be selected from the graphics plane 1 to graphics plane 5 or the graphics data after α blending by setting the CMPSELP[3:0] bits in DOCMPMR.

### 43.4.5 Pixel Format

#### (1) Pixel Format Specification

DOCMPMR specifies the pixel format. The pixel formats are given in Table 43.3.

**Table 43.3 Pixel Format**

| Bits in DOCMPMR | | CMPBT | CMPDFA[7:0] | CMPDAUF |
|---|---|---|---|---|
| 32 bits/pixel | ARGB8888 | 0 | — | — |
| | RGB888 | | Arbitrary | Arbitrary |
| 16 bits/pixel | RGB565 | 1 | — | — |

#### (2) Data Arrangement for Available Pixel Formats

Data arrangement for each pixel format is given below.

- ARGB8888 (32 bits/pixel)

| b31 – b24 | b23 – b16 | b15 – b8 | b7 – b0 |
|---|---|---|---|
| α 8 bits | Red 8 bits | Green 8 bits | Blue 8 bits |

- RGB888 (32 bits/pixel)

| b31 – b24 | b23 – b16 | b15 – b8 | b7 – b0 |
|---|---|---|---|
| * | Red 8 bits | Green 8 bits | Blue 8 bits |

Note: * When CMPDAUF = 0, α value is the value output from the graphics display module.
When CMPDAUF = 1, α value is the value specified by CMPDFA[7:0].

- RGB565 (16 bits/pixel)

| b15 – b11 | b10 – b5 | b4 – b0 |
|---|---|---|
| Red 5 bits | Green 6 bits | Blue 5 bits |

### 43.4.6 Rectangular Area Settings

Based on the selected graphics data, the start position and size of the rectangular area for which the CRC code is calculated can be set with the registers. Figure 43.3 shows such a rectangular area and Table 43.4 shows the register settings for the area.

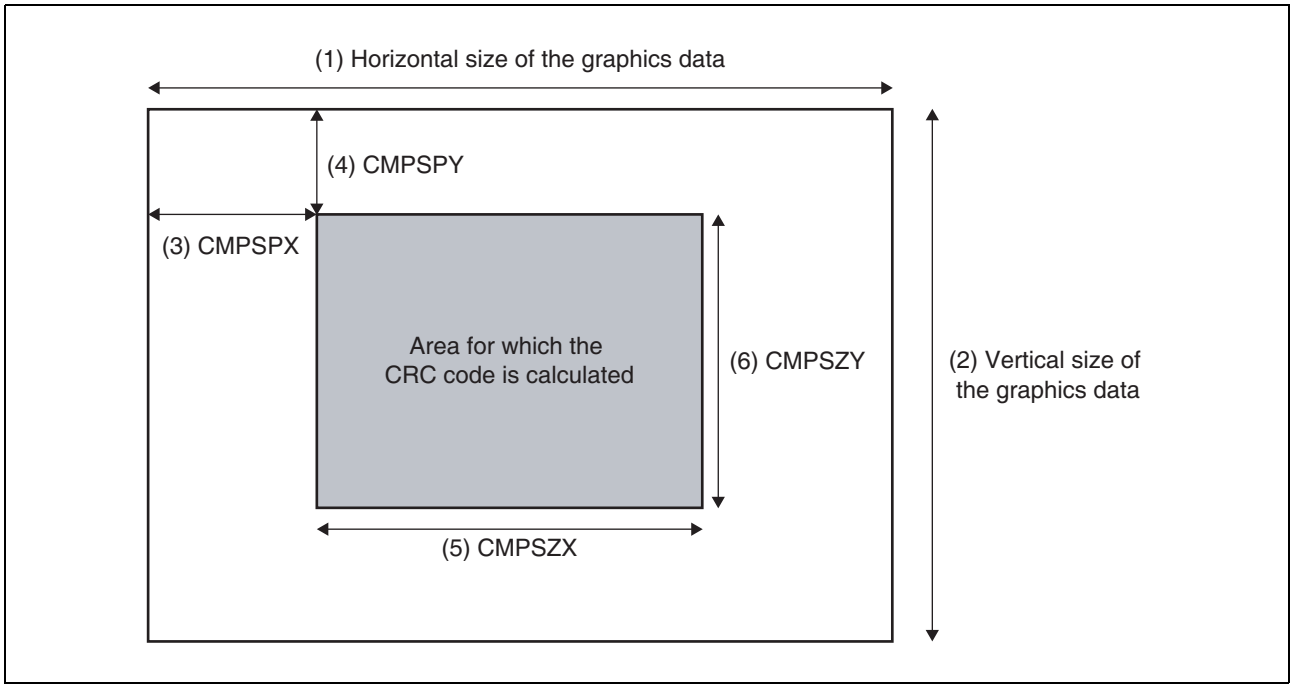

**Figure 43.3 Rectangular Area for which the CRC Code is Calculated**

**Table 43.4 Register Settings for the Rectangular Area for which the CRC Code is Calculated**

| No. | Symbol in the Figure | Register Used for Setting | Description |
|---|---|---|---|
| (1) | Horizontal size of the graphics data | | Horizontal size of the graphics data.<br>Set the size using the graphics display module. |
| (2) | Vertical size of the graphics data | | Vertical size of the graphics data.<br>Set the size using the graphics display module. |
| (3) | CMPSPX (horizontal start position) | DOCMSPXR | Set the horizontal distance from the upper left origin of the graphics data to the rectangular area for which the CRC code is calculated in pixel units. |
| (4) | CMPSPY (vertical start position) | DOCMSPYR | Set the vertical distance from the upper left origin of the graphics data to the rectangular area for which the CRC code is calculated in line units. |
| (5) | CMPSZX (horizontal size) | DOCMSZXR | Set the horizontal size of the rectangular area for which the CRC code is calculated in pixel units.<br>The value should be set as follows:<br>Horizontal size of the graphics data ≥ CMPSPX + CMPSZX. |
| (6) | CMPSZY (vertical size) | DOCMSZYR | Set the vertical size of the rectangular area for which the CRC code is calculated in line units.<br>The value should be set as follows:<br>Vertical size of the graphics data ≥ CMPSPY + CMPSZY. |

### 43.4.7 CRC Calculation Time Period and Comparison Timing

Figure 43.4 shows the CRC calculation time period and timing of comparing the calculated result with the expected value.

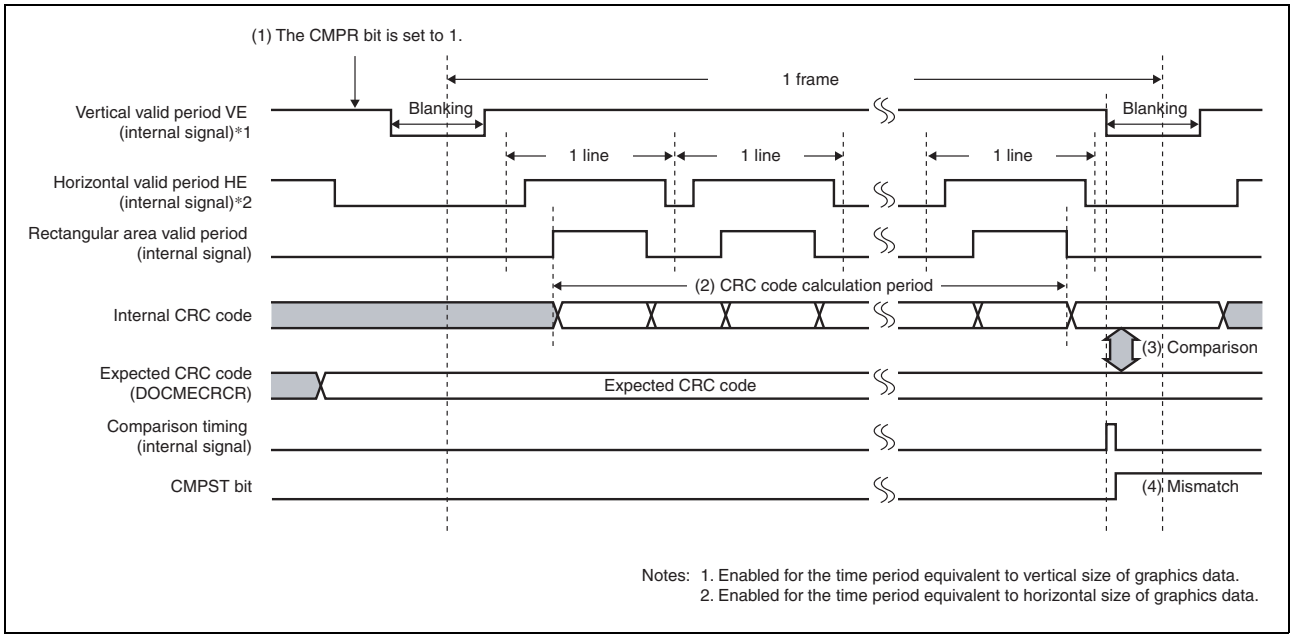

**Figure 43.4 CRC Calculation Time Period and Timing of Comparing the Calculated Result with the Expected Value**

[Operation]

(1) The operation starts at the next frame after the CMPR bit in DOCMCR is set to 1. For the register update timing, see section 43.4.8, Register Update Timing.

(2) CRC code is calculated in the set rectangular area.

(3) The CRC code calculation result is compared with the expected CRC code value (DOCMECRCR) at the end of the valid period of the graphics data.

(4) If the compared CRC codes do not match, the CMPST bit in DOCMSTR is set.

## 43.4.8 Register Update Timing

### (1) Timing when Register Values are Loaded Inside

All the register bits except the CMPR bit in DOCMCR are loaded inside immediately after the registers are written to. Thus, if the register is updated with the CMPRU bit in DOCMCR as 1, an unexpected result is likely to be obtained in the CRC code calculation. The registers that affect the CRC code calculation (i.e., registers other than DOCMCLSTR and DOCMIENR) should be updated after confirming that the CMPRU bit in DOCMCR is 0.
The CMPR bit in DOCMCR is loaded inside upon detection of the start of the valid period of the graphics data. Thus, even if the register is rewritten to in the middle of a frame, the CRC code calculation of the frame does not get affected.

### (2) Timing when Internal State is Reflected in Registers

The internal state is reflected in DOCMSTR and DOCMCCRCR at the end of the valid period of the graphics data. The internal state of the CMPR bit is reflected in the CMPRU bit in DOCMCR at the start of the valid period of the graphics data.
Figure 43.5 shows the register update timing.

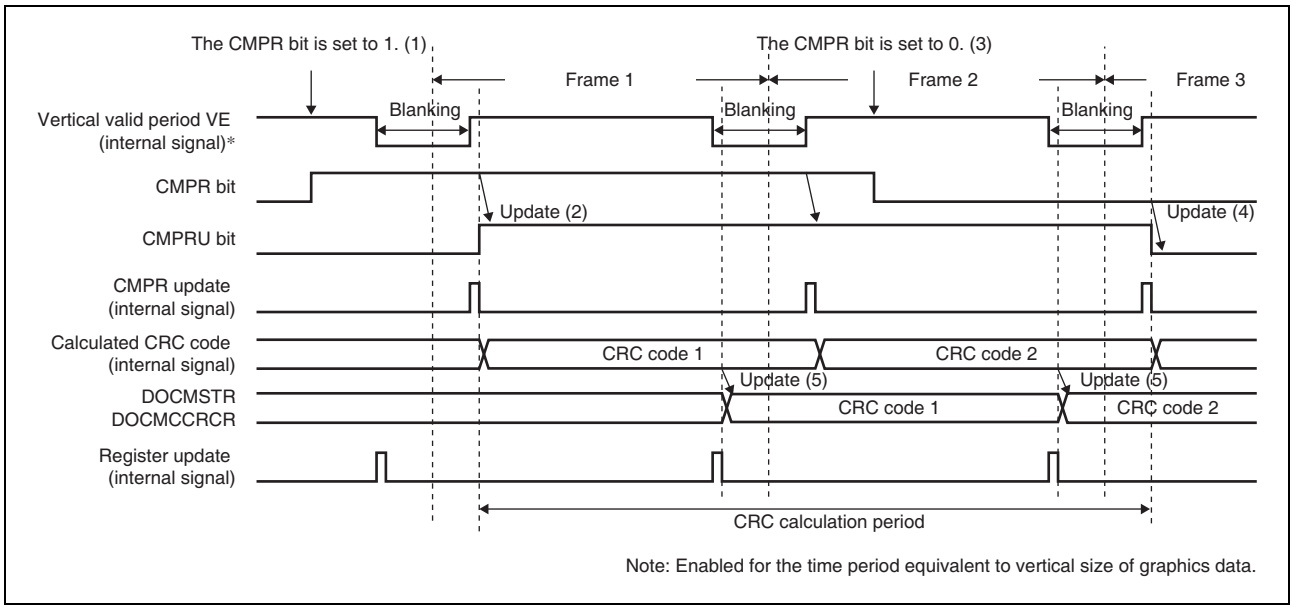

**Figure 43.5 Register Update Timing**

[Operation]

(1) The CMPR bit is set to 1. This bit is not immediately loaded inside.
(2) CRC calculation is carried out after the CMPR bit value is loaded inside upon detection of the start of the valid period of the graphics data.
(3) To suspend the CRC comparison, the CMPR bit is set to 0. Similarly to (1), this bit is not immediately loaded inside.
(4) The CRC calculation is suspended after the CMPR bit value is loaded inside upon detection of the start of the valid period of the graphics data.
(5) The internal state is reflected in the register at the end of the valid period of the graphics data.

### 43.4.9 Operation Flow

#### (1) Procedure for Starting Display Out Comparison

Figure 43.6 shows a sample procedure for starting the display out comparison.

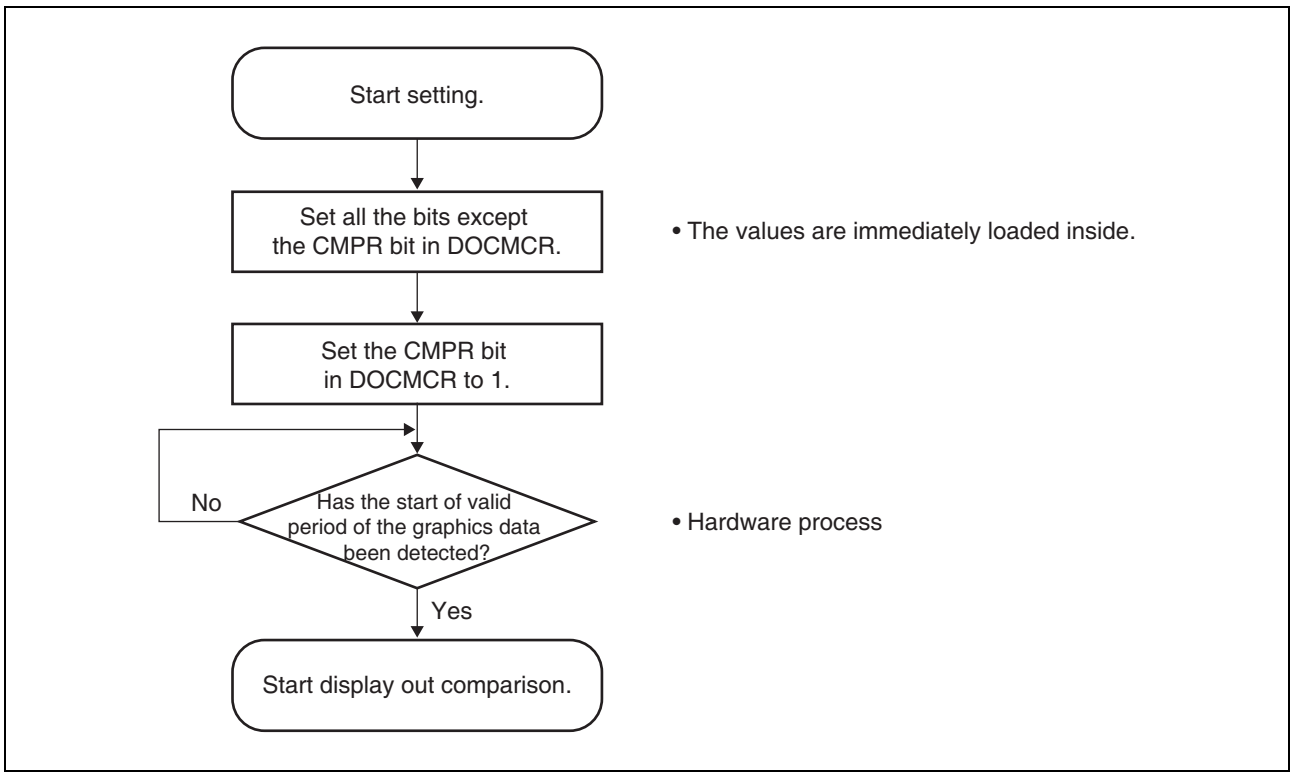

**Figure 43.6 Sample Procedure for Starting the Display Out Comparison**

### (2) Procedure for Changing Register Setting

Figure 43.7 shows a sample procedure for changing the register setting during display out comparison.

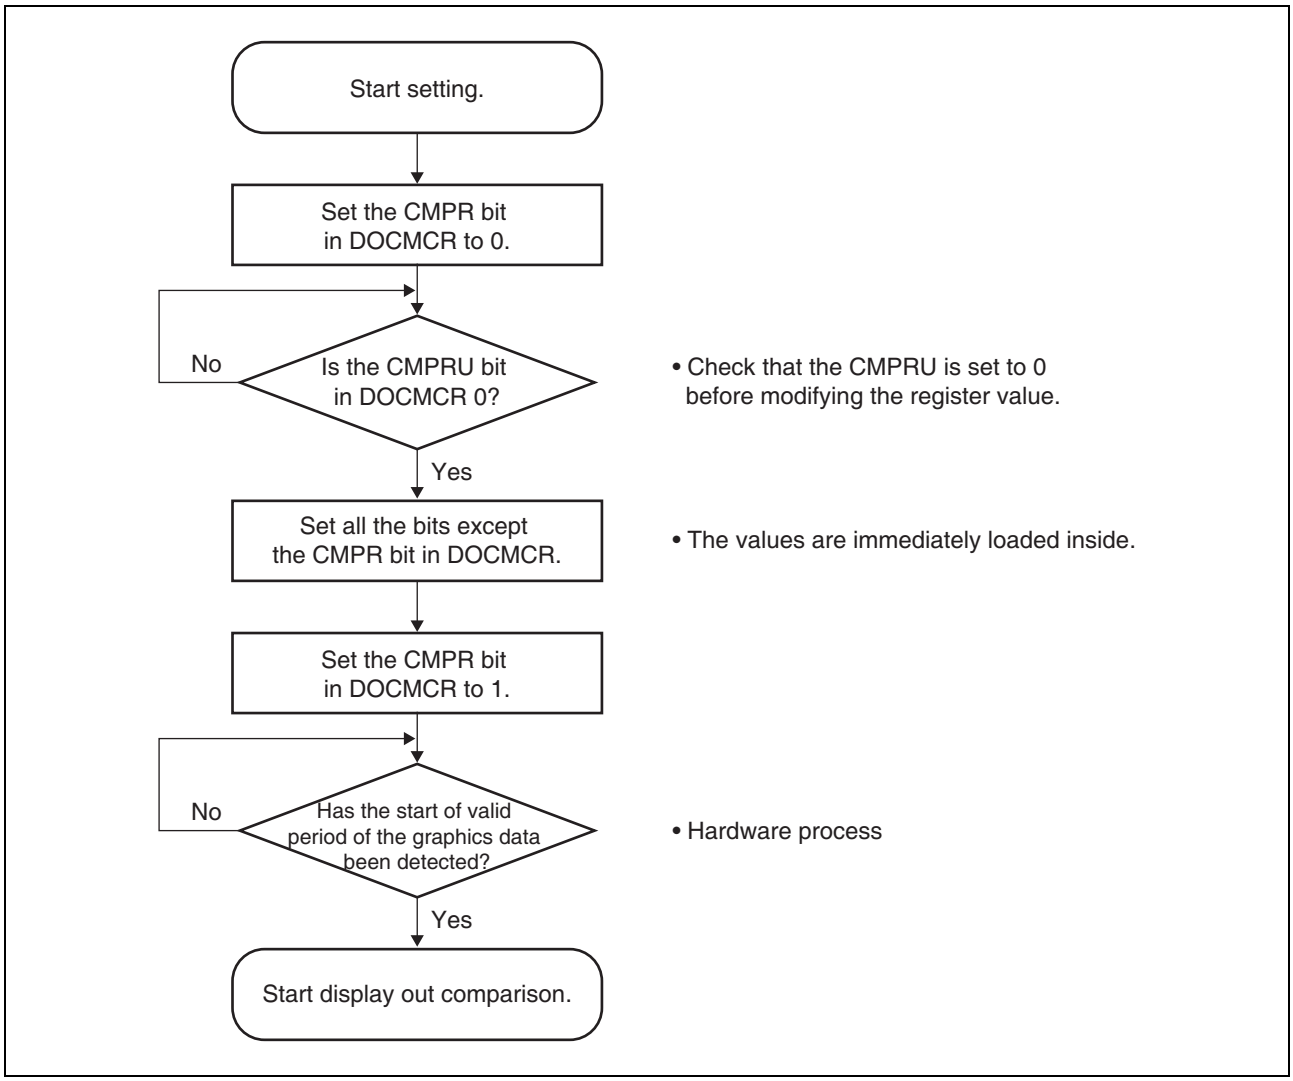

**Figure 43.7 Sample Procedure for Changing the Register Setting during Display Out Comparison**

## 43.5 Interrupt

The display out comparison mismatch detection interrupt is provided as an interrupt source.
The interrupt request is generated when the CMPIEN bit in DOCMIENR and the CMPST bit in DOCMSTR are both set to 1.

## 43.6 Usage Note

### 43.6.1 Expected CRC Value

When graphics plane 1 to graphics plane 5 are selected, the expected CRC code value (DOCMECRCR) should be calculated from the graphics data to be used by using the software. When the graphics data after α blending is selected, the graphics data after α blending should be selected at the time of debugging and the calculated CRC code value read from DOCMCCRCR should be used as the expected CRC code value. This is because there is a possibility of mismatching of the result of superimposition of the graphics data by the software and the result of superimposition by the graphics display module due to an error in calculation when the graphics data after α blending is selected.

### 43.6.2 Expansion Control Functionality

When scaling settings are applied for expansion processing by video display controller 5, this module becomes incapable of generating CRC codes. Stop this module while expansion processing is being applied.

# 44. Renesas Graphics Processor for OpenVG™

## 44.1 Specification

This processor supports OpenVG™1.1, an open source 2D vector graphics API. Dedicated hardware and a programmable shader are used to accelerate OpenVG™ Stage 2 to Stage 8 processing.
Please refer to the Khronos Group Web site for the specifications of OpenVG™1.1.

# 45. JPEG Codec Unit

The JPEG codec unit (JCU) incorporates a JPEG codec conforming to the JPEG baseline compression and decompression standard to provide high-speed compression of image data and high-speed decoding of JPEG data.

## 45.1 Features

The JPEG codec unit has the following features:

- Conforms to the JPEG baseline standard within the range described in this document.
  This module does not support the following basic features:
  Scanning with two elements
  Non-interleave scanning with multiple elements
- Operational precision: Conforming to JPEG Part 2, ISO-IEC10918-2
- Image input/output system: Block interleave method
- Pixel format:
  Compression: YCbCr422 (H = 2:1:1, V = 1:1:1)
  Decompression: YCbCr444 (H = 1:1:1, V = 1:1:1), YCbCr422 (H = 2:1:1, V = 1:1:1), YCbCr411 (H = 4:1:1, V = 1:1:1), YCbCr420 (H = 2:1:1, V = 2:1:1)
  Output pixel format to the buffer: YCbCr422, ARGB8888, RGB565
- Four quantization tables provided
- Four Huffman tables provided (two tables for AC coefficients and two tables for DC coefficients)
- Markers supported: SOI (start of image), SOF0 (start of frame type 0), SOS (start of scan), DQT (define quantization tables), DHT (define Huffman tables), DRI (define restart interval), RSTm (restart marks), and EOI (end of image)
- Image data rate: Max. 133.34 Mbytes/s (at 66.67-MHz operation)
- The buffer size can be reduced by using the mode in which data transfer is temporarily stopped each time the specified number of lines or the specified amount of data is transferred during image data or coded data input/output.
- Processing unit: 8-byte address boundary units can be set
- Image sizes that can be processed: Sizes divisible by the minimum coded unit (MCU): 8 lines by 8 pixels in YCbCr444; 8 lines by 16 pixels in YCbCr422; 8 lines by 32 pixels in YCbCr411; 16 lines by 16 pixels in YCbCr420

Note: • Compression and decompression processing of images in unsupported pixel formats or unsupported image sizes should be avoided.

## 45.2.2 JPEG Code Command Register (JCCMD)

JCCMD sets commands. Bits of this register need not be cleared to 0 after setting a command.
Multiple commands must not be set simultaneously.

### 45.2.3 JPEG Code Quantization Table Number Register (JCQTN)

JCQTN sets the quantization table number before compression process is started.

- To use quantization table No. 0 (JCQTBL0) as the first color component, set QT1 to B'00
- To use quantization table No. 1 (JCQTBL1) as the first color component, set QT1 to B'01
- To use quantization table No. 2 (JCQTBL2) as the first color component, set QT1 to B'10
- To use quantization table No. 3 (JCQTBL3) as the first color component, set QT1 to B'11

| Bit: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|
| | — | — | QT3[1:0] | | QT2[1:0] | | QT1[1:0] | |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W(compress): | R | R | R/W | R/W | R/W | R/W | R/W | R/W |
| R/W(decompress): | R | R | R | R | R | R | R | R |

| Bit | Bit Name | Initial Value | R/W | | Description |
|---|---|---|---|---|---|
| | | | Compression | De-compression | |
| 7, 6 | — | All 0 | R | | Reserved<br>These bits are always read as 0. The write value should always be 0. |
| 5, 4 | QT3[1:0] | 00 | R/W | R | Quantization table number for the third color component |
| 3, 2 | QT2[1:0] | 00 | R/W | R | Quantization table number for the second color component |
| 1, 0 | QT1[1:0] | 00 | R/W | R | Quantization table number for the first color component |

### 45.2.4 JPEG Code Huffman Table Number Register (JCHTN)

JCHTN sets the Huffman table number (AC/DC) before compression process is started.

- To use DC/AC Huffman table No. 0 (JCHTBD0 and JCHTBA0) as the first color component, set bits HTA1 and HTD1 to B'0
- To use DC/AC Huffman table No. 1 (JCHTBD1 and JCHTBA1) as the first color component, set bits HTA1 and HTD1 to B'1

| Bit: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|
| | — | — | HTA3 | HTD3 | HTA2 | HTD2 | HTA1 | HTD1 |

| Bit | Bit Name | Initial Value | R/W | | Description |
|---|---|---|---|---|---|
| | | | Compression | De-compression | |
| 7, 6 | — | All 0 | R | | Reserved<br>These bits are always read as 0. The write value should always be 0. |
| 5 | HTA3 | 0 | R/W | R | Huffman table number (AC) for the third color component |
| 4 | HTD3 | 0 | R/W | R | Huffman table number (DC) for the third color component |
| 3 | HTA2 | 0 | R/W | R | Huffman table number (AC) for the second color component |
| 2 | HTD2 | 0 | R/W | R | Huffman table number (DC) for the second color component |
| 1 | HTA1 | 0 | R/W | R | Huffman table number (AC) for the first color component |
| 0 | HTD1 | 0 | R/W | R | Huffman table number (DC) for the first color component |

### 45.2.5 JPEG Code DRI Upper Register (JCDRIU)

JCDRIU sets the upper bytes of the minimum coded units (MCUs) preceding an RST marker.

| Bit: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|
| | DRIU[7:0] | | | | | | | |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W(compress): | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |
| R/W(decompress): | Undefined | Undefined | Undefined | Undefined | Undefined | Undefined | Undefined | Undefined |

| Bit | Bit Name | Initial Value | R/W | | Description |
|---|---|---|---|---|---|
| | | | Compression | De-compression | |
| 7 to 0 | DRIU[7:0] | H'00 | R/W | Invalid | Upper Bytes of MCUs Preceding RST Marker<br>When both upper and lower bytes are set to H'00, neither a DRI nor an RST marker is placed. |

## 45.2.6 JPEG Code DRI Lower Register (JCDRID)

JCDRID sets the lower bytes of MCUs preceding an RST marker.

| Bit: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|
| | DRID[7:0] | | | | | | | |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W(compress): | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |
| R/W(decompress): | Undefined | Undefined | Undefined | Undefined | Undefined | Undefined | Undefined | Undefined |

| Bit | Bit Name | Initial Value | R/W | | Description |
|---|---|---|---|---|---|
| | | | Compression | De-compression | |
| 7 to 0 | DRID[7:0] | H'00 | R/W | Invalid | Lower Bytes of MCUs Preceding RST Marker<br>When both upper and lower bytes are set to H'00, neither a DRI nor an RST marker is placed. |

## 45.2.7 JPEG Code Vertical Size Upper Register (JCVSZU)

JCVSZU sets the upper bytes of the vertical image size.

| Bit: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|
| | VSZU[7:0] | | | | | | | |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W(compress): | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |
| R/W(decompress): | R | R | R | R | R | R | R | R |

| Bit | Bit Name | Initial Value | R/W | | Description |
|---|---|---|---|---|---|
| | | | Compression | De-compression | |
| 7 to 0 | VSZU[7:0] | H'00 | R/W | R | Upper Bytes of Vertical Image Size<br>In decompression process, a downloaded value from the JPEG coded data is set. |

## 45.2.8 JPEG Code Vertical Size Lower Register (JCVSZD)

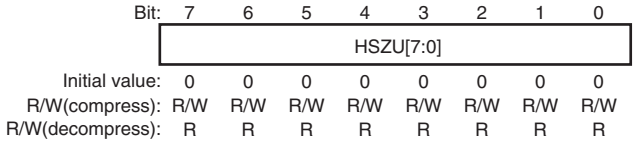
JCVSZD sets the lower bytes of the vertical image size.

| Bit: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|
| | VSZD[7:0] | | | | | | | |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W(compress): | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |
| R/W(decompress): | R | R | R | R | R | R | R | R |

| Bit | Bit Name | Initial Value | R/W | | Description |
|---|---|---|---|---|---|
| | | | Compression | De-compression | |
| 7 to 0 | VSZD[7:0] | H'00 | R/W | R | Lower Bytes of Vertical Image Size<br>In decompression process, a downloaded value from the JPEG coded data is set. |

## 45.2.9 JPEG Code Horizontal Size Upper Register (JCHSZU)

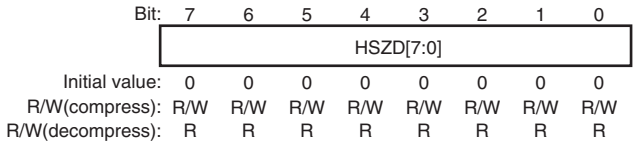
JCHSZU sets the upper bytes of the horizontal image size.



| Bit | Bit Name | Initial Value | R/W | | Description |
|---|---|---|---|---|---|
| | | | Compression | De-compression | |
| 7 to 0 | HSZU[7:0] | H'00 | R/W | R | Upper Bytes of Horizontal Image Size<br>In decompression process, a downloaded value from the JPEG coded data is set. |

## 45.2.10 JPEG Coded Horizontal Size Lower Register (JCHSZD)

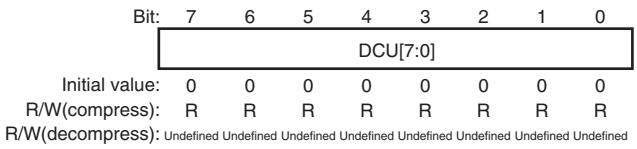
JCHSZD sets the lower bytes of the horizontal image size.



| Bit | Bit Name | Initial Value | R/W | | Description |
|---|---|---|---|---|---|
| | | | Compression | De-compression | |
| 7 to 0 | HSZD[7:0] | H'00 | R/W | R | Lower Bytes of Horizontal Image Size<br>In decompression process, a downloaded value from the JPEG coded data is set. |

## 45.2.11 JPEG Code Data Count Upper Register (JCDTCU)

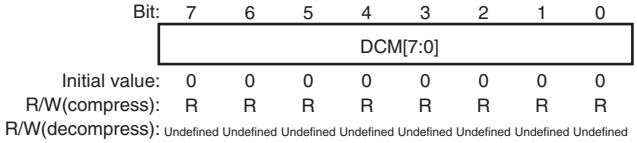
The upper bytes for the counted amount of data to be compressed are set to JCDTCU. The values of this register are reset before compression starts.



| Bit | Bit Name | Initial Value | R/W | | Description |
|---|---|---|---|---|---|
| | | | Compression | De-compression | |
| 7 to 0 | DCU[7:0] | H'00 | R | Invalid | Upper bytes of the counted amount of data to be compressed |

## 45.2.12 JPEG Code Data Count Middle Register (JCDTCM)

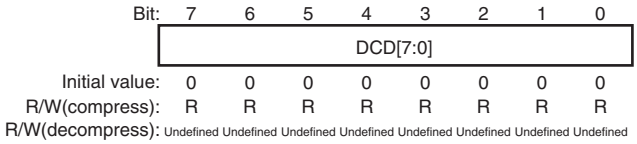
The middle bytes for the counted amount of data to be compressed are set to JCDTCM. The values of this register are reset before compression starts.



| Bit | Bit Name | Initial Value | R/W | | Description |
|---|---|---|---|---|---|
| | | | Compression | De-compression | |
| 7 to 0 | DCM[7:0] | H'00 | R | Invalid | Middle bytes of the counted amount of data to be compressed |

## 45.2.13 JPEG Code Data Count Lower Register (JCDTCD)

The lower bytes for the counted amount of data to be compressed are set to JCDTCD. The values of this register are reset before compression starts.



| Bit | Bit Name | Initial Value | R/W | | Description |
|---|---|---|---|---|---|
| | | | Compression | De-compression | |
| 7 to 0 | DCD[7:0] | H'00 | R | Invalid | Lower bytes of the counted amount of data to be compressed |

## 45.2.14 JPEG Interrupt Enable Register 0 (JINTE0)

JINTE0 enables interrupts.

When any of bits INT7 to INT5 is set to B'1, the INS5 bit in JINTS0 indicates B'1 as the error status upon occurrence of the compression data error, and the ERR bit in JCDERR indicates the particular error code.

| Bit: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|
| | INT7 | INT6 | INT5 | — | INT3 | — | — | — |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W(compress): | Undefined | Undefined | Undefined | R | Undefined | R | R | R |
| R/W(decompress): | R/W | R/W | R/W | R | R/W | R | R | R |

| Bit | Bit Name | Initial Value | R/W | | Description |
|---|---|---|---|---|---|
| | | | Compression | De-compression | |
| 7 | INT7 | 0 | Invalid | R/W | This bit enables an interrupt to be generated when the number of data in the restart interval of the Huffman-coding segment is not correct in decompression.<br>When this bit is not set to enable interrupt generation, an error code is not returned. |
| 6 | INT6 | 0 | Invalid | R/W | This bit enables an interrupt to be generated when the total number of data in the Huffman-coding segment is not correct in decompression.<br>When this bit is not set to enable interrupt generation, an error code is not returned. |
| 5 | INT5 | 0 | Invalid | R/W | This bit enables an interrupt to be generated when the final number of MCU data in the Huffman-coding segment is not correct in decompression.<br>When this bit is not set to enable interrupt generation, an error code is not returned. |
| 4 | — | 0 | | R | Reserved<br>This bit is always read as 0. The write value should always be 0. |
| 3 | INT3 | 0 | Invalid | R/W | This bit enables an interrupt to be generated when it has been determined that the image size and the subsampling setting of the compressed data can be read through analyzing the data. |
| 2 to 0 | — | All 0 | | R | Reserved<br>These bits are always read as 0. The write value should always be 0. |

## 45.2.15 JPEG Interrupt Status Register 0 (JINTS0)

JINTS0 identifies the interrupt sources.
The interrupt sources of this register should be cleared by clearing the corresponding interrupt status bits to 0 and setting the relevant bit in JCCMD appropriately.

| Bit: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|
| | — | INS6 | INS5 | — | INS3 | — | — | — |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W(compress): | R | R/W* | Undefined | R | Undefined | R | R | R |
| R/W(decompress): | R | R/W* | R/W* | R | R/W* | R | R | R |

Note: * Clear this bit by writing 0 to it.
Do not write 1 to this bit.

| Bit | Bit Name | Initial Value | R/W: Compression | R/W: De-compression | Description |
|---|---|---|---|---|---|
| 7 | — | 0 | R | | Reserved<br>This bit is always read as 0. The write value should always be 0. |
| 6 | INS6 | 0 | R/W* | | This bit is set to 1 when the JCU completes compression process normally. |
| 5 | INS5 | 0 | Invalid | R/W* | This bit is set to 1 when a compressed data error occurs. |
| 4 | — | 0 | R | | Reserved<br>This bit is always read as 0. The write value should always be 0. |
| 3 | INS3 | 0 | Invalid | R/W* | This bit is set to 1 when the image size and pixel format can be read. When an interrupt occurs, this module stops processing and the state is indicated by the JCRST register. To make the JCU resume processing, set the JPEG core process stop clear command bit (JRST) in JCCMD. |
| 2 to 0 | — | All 0 | R | | Reserved<br>These bits are always read as 0. The write value should always be 0. |

Note: * Clear this bit by writing 0 to it. Do not write 1 to this bit.

## 45.2.16 JPEG Code Decode Error Register (JCDERR)

JCDERR indicates the error code to identify the type of the error which has occurred in the compressed data analysis for decompression. The values of this register are reset before the JCU starts decompression.

| Bit: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|
| | — | — | — | — | ERR[3:0] | | | |
| Initial value: | 0 | 0 | 0 | 0 | 1 | 0 | 1 | 0 |
| R/W(compress): | R | R | R | R | Undefined | Undefined | Undefined | Undefined |
| R/W(decompress): | R | R | R | R | R/W | R/W | R/W | R/W |

| Bit | Bit Name | Initial Value | R/W: Compression | R/W: De-compression | Description |
|---|---|---|---|---|---|
| 7 to 4 | — | All 0 | R | | Reserved<br>These bits are always read as 0. |
| 3 to 0 | ERR[3:0] | 1010 | Invalid | R/W | Error Code<br>(See Table 45.3 and Table 45.4) |

## 45.2.17 JPEG Code Reset Register (JCRST)

JCRST indicates a processing-stopped state caused by requests to read the image size and pixel format (enabled by the INT3 bit in JINTE0). To resume processing, set the JPEG core process stop clear command bit (JRST) in JCCMD.

| Bit: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|
| | — | — | — | — | — | — | — | RST |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W(compress): | R | R | R | R | R | R | R | Undefined |
| R/W(decompress): | R | R | R | R | R | R | R | R |

| Bit | Bit Name | Initial Value | R/W | | Description |
|---|---|---|---|---|---|
| | | | Compression | De-compression | |
| 7 to 1 | — | All 0 | R | | Reserved<br>These bits are always read as 0. |
| 0 | RST | 0 | Invalid | R/W | Operating State<br>0: State other than below<br>1: Suspended state caused by interrupt sources of JINTE0 |

## 45.2.18 JPEG Interface Compression Control Register (JIFECNT)

JIFECNT controls the compression process.

| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

## 45.2.19 JPEG Interface Compression Source Address Register (JIFESA)

JIFESA sets the source address of the input image data. This register should be set in 8-byte units.

| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

| 2 to 0 | ESA[2:0] | 0000 | R | | The lower three bits should be set to 0. |

## 45.2.20 JPEG Interface Compression Line Offset Register (JIFESOFST)

JIFESOFST sets the line offset of the input image data (refer to section 45.3.4, Storing Image Data). This register should be set in 8-byte units.

| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

## 45.2.22 JPEG Interface Compression Source Line Count Register (JIFESLC)

JIFESLC sets the number of input image data lines when the count mode for stopping the input of image data lines is on (the DINLC bit in JIFECNT is set to 1). This register should be set in 8-line units.

| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

## 45.2.23 JPEG Interface Compression Destination Count Register (JIFEDDC)

JIFEDDC sets the amount of output coded data when the count mode for stopping the output of coded data is on (the JOUTC bit in JIFECNT is set to 1). This register should be set in 8-byte units.

| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

## 45.2.26 JPEG Interface Decompression Line Offset Register (JIFDDOFST)

JIFDDOFST sets the line offset of the output image data to be transferred to the external buffer (refer to section 45.3.4, Storing Image Data). This register should be set in 8-byte units.

| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

## 45.2.27 JPEG Interface Decompression Destination Address Register (JIFDDA)

JIFDDA sets the destination address of the output image data. This register should be set in 8-byte units.

| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

## 45.2.28 JPEG Interface Decompression Source Data Count Register (JIFDSDC)

JIFDSDC sets the amount of input coded data when the count mode for stopping the input of coded data is on (the JINC bit in JIFDCNT is set to 1). This register should be set in 8-byte units.

| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

## 45.2.29 JPEG Interface Decompression Destination Line Count Register (JIFDDLC)

JIFDDLC sets the number of lines of output image data when the count mode for stopping the output of image data lines is on (the DOUTLC bit in JIFECNT is set to 1). This register is used to set the number of lines of output image data in MCU units.

| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

## 45.3 Operation

### 45.3.1 Compression

#### (1) Overview of Processing

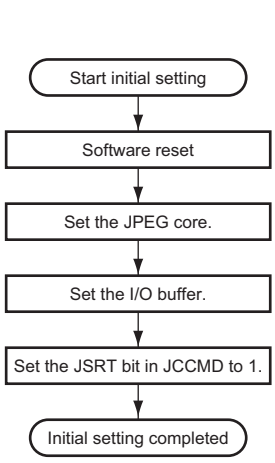
The compression process flows are described below.

1. The JPEG core is activated.
   A marker is output. (After a marker is output, image data can be input.)
   Approximately 30,000 cycles (necessary for making SOI to SOS markers)
2. Image data is transferred in MCUs from the external buffer to the JCU.
   If the count mode for stopping the input of image data lines is on, reading is stopped each time the number of lines set in JIFESLC is read. Reading is resumed by setting the DINRCMD bit in JIFECNT to 1.
   When the DINRINI bit in JIFECNT is zero, the addresses for reading on resumption are continued from the addresses in the previous round of transfer.
   When the DINRINI bit is one, the address set in JIFESA is used on resumption.
   Reading is also stopped when one frame of image data is completely transferred.
   If the count mode for stopping the input of image data lines is off, reading is continued until one frame of image data is completely transferred.
3. Image data is input to the JPEG core.
   The input data is processed in MCUs at any time in the JPEG core.
4. Coded data is transferred from the JCU to the external buffer.
   When the count mode for stopping the output of coded data is on, writing is stopped each time the amount of coded data set in JIFEDDC is written. Writing is resumed by setting the JOUTRCMD bit in JIFECNT to 1.
   When the JOUTRINI bit in JIFECNT is zero, the addresses for writing on resumption are continued from the addresses in the previous round of transfer.
   When the JOUTRINI bit is one, the address set in JIFEDA is used on resumption.
   Writing is also stopped when one frame of coded data is completely transferred.
   If the count mode for stopping the output of coded data is off, writing is continued until one frame of coded data is completely transferred.
5. Compression is completed after one frame of data is processed completely.

## (2) Flowchart (Compression)

### (a) Initial Settings

After completing the JPEG core settings and input/output buffer settings and transferring image data to the external buffer, activate this module by setting the JSRT bit in JCCMD to 1. After the JCU has been activated, the JPEG markers (SOI to SOS) are generated and output. It takes approximately 30,000 cycles to generate the markers.



Software reset
Reset this module in advance by setting the SRST21 bit in SWRSTCR2 of the power-down modes.

**Figure 45.2 Compression Initial Setting Flow**

### (b) Compression Process

The compression process flows are described below.

- When JPEG compression process has been completed, the INS6 bit in JINTS0 is set to 1. However, the JCU continues processing since the coded data remains to be transferred. The CBTF bit in JINTS1 is set to 1 when the last coded data is transferred. The interrupt source is cleared by writing 0 to the INS6 bit. However, the interrupt request asserted by this interrupt source cannot be cleared by writing 0 to the INS6 bit. Set an interrupt request clear command (by setting the JEND bit in JCCMD to 1) to clear the interrupt request.
- When the JCU has completed compression and all coded data has been transferred, the CBTF flag in JINTS1 is set to 1. When the CBTEN bit in JINTE1 is 1 here, an interrupt is generated. The interrupt source is cleared by writing 0 to the CBTF flag.
- If the count mode for stopping image data lines is on, when the specified number of image data lines set in JIFESLC has been read, the DINLF flag in JINTS1 is set to 1, and reading is stopped. When the DINLEN bit in JINTE1 is 1 here, an interrupt is generated. An interrupt source is cleared by writing 0 to the DINLEN bit. Setting the DINRCMD bit in JIFECNT to 1 resumes reading.
  When the DINRINI bit in JIFECNT is zero, the addresses for reading on resumption are continued from the addresses in the previous round of transfer.
  When the DINRINI bit is one, the address set in JIFESA is used on resumption.
- If the count mode for stopping the output of coded data is on, when the specified amount of coded data set in JIFEDDC has been written, the JOUTF flag in JINTS1 is set to 1, and writing is stopped. When the JOUTEN bit in JINTE1 is 1 here, an interrupt is generated. An interrupt source is cleared by writing 0 to the JOUTF bit. Setting the JOUTRCMD bit in JIFECNT to 1 resumes writing.

When the JOUTRINI bit in JIFECNT is zero, the addresses for writing on resumption are continued from the addresses in the previous round of transfer.
When the JOUTRINI bit is one, the address set in JIFEDA is used on resumption.

## (3) JPEG Coded Data Format

Figure 45.4 shows the data output stream in compression. The amount of coded data from SOI to EOI is indicated by JCDTCU, JCDTCM, and JCDTCD. When both JCDRIU and JCDRID are set to H'0000 0000, the following markers are not output.

- DRI marker
- RST marker (in compressed image data)

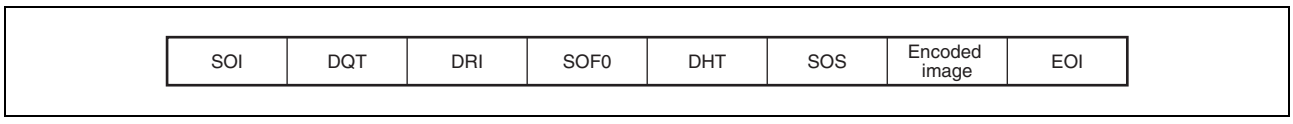

**Figure 45.4 JPEG Coded Data Format**

DQT: Not output for unused table.
DHT: Output in order DC0, AC0, DC1, and AC1. Not output for unused table.
SOF0: Component identifiers are C1 = first color component, C2 = second color component, and C3 = third color component.
SOS: Scan component selectors are CS1 = first color component, CS2 = second color component, and CS3 = third color component.

**Header Volume (Reference):**

- SOI: 2 bytes (FFD8)
- DQT: 134 bytes when two quantization tables are used, 199 bytes when three quantization tables are used (±65 bytes/table increase or decrease)
- DRI: 6 bytes
- SOF0: 19 bytes (4:2:2)
- DHT: 420 bytes (two tables are used)
- SOS: 14 bytes (4:2:2)
- EOI: 2 bytes (FFD9)

## (4) Table Setting

### (a) Quantization Table Specification

The order of addresses shown in 8 × 8 blocks corresponds to that of the register addresses. Do not access this table while the JCU is in processing.

### (b) Huffman Table Specification

Examples of the Huffman table specification given in the ITU-T T81 Annex K.3.3 recommended by JPEG are shown below. In compression, the following settings must be specified for all the codes so that Huffman codes can be generated for all the group numbers.

- DC Huffman table: The number of codes for each code length is 12.
  The group numbers in order of frequency of occurrence are 12.
- AC Huffman table: The number of codes for each code length is 162.
  The zero run length/the group numbers in order of frequency of occurrence are 162.

Do not access the following tables while the JCU is in processing. In particular, read access is prohibited.

### (5) Input Pixel Format

Image data in the YCbCr422 format can be input to this module. Allocation of data in the YCbCr422 format can be changed by the DINSWAP bits in JIFECNT as shown below.

- When the DINSWAP bits = 000

### (6) Output Coded Data

In the case of compression, coded data are output. This module handles the output of coded data in 16-bit units. For this reason, if the coded data have an odd code length (are fractional), the final code for output will be H'D9FF.
The JOUTSWAP bits in JIFECNT can be used to alter the arrangement of coded data in the output.

## 45.3.2 Decompression

### (1) Overview of Processing

The decompression process flows are described below.

1. The JPEG core is activated.
2. Coded data is transferred from the external buffer to the JCU.
   If the count mode for stopping the input of coded data is on, reading is stopped each time the amount of coded data set in JIFDSLC is read. Reading is resumed by setting the JINRCMD bit in JIFDCNT to 1. When the JINRINI bit in JIFDCNT is zero, the addresses for reading on resumption are continued from the addresses in the previous round of transfer.
   When the JINRINI bit is one, the address set in JIFDSA is used on resumption. Reading is stopped when the end of the coded data is detected.
   If the count mode for stopping the input of coded data is off, reading is continued until the end of code is detected. With this module, more coded data may be read than the coded data size since coded data reading is continued until the end of code is detected.
3. Coded data is input to the JPEG core.
   The input data is processed in MCUs at any time in the JPEG core.
4. Image data is transferred in MCUs from the JCU to the external buffer.
   When the count mode for stopping the output of image data lines is on, writing is stopped each time the number of image data lines set in JIFDDLC is written. Writing is resumed by setting the DOUTRCMD bit in JIFECNT to 1. When the DOUTRINI bit in JIFDCNT is zero, the addresses for writing on resumption are continued from the addresses in the previous round of transfer.
   When the DOUTRINI bit is one, the address set in JIFDDA is used on resumption. Writing is stopped when one frame of image data is completely transferred.
   If the count mode for stopping the output of image data lines is off, writing is continued until one frame of image data is completely transferred.
5. Decompression is completed after one frame of data is processed completely.

### (a) Initial Settings

- When the INT3 bit in JINTE0 is set to 0:
  After completing the JPEG core settings and input/output buffer settings and transferring coded data to the external buffer, activate this module by setting the JSRT bit in JCCMD to 1.
- When the INT3 bit in JINTE0 is set to 1:
  After completing the JPEG core settings and input buffer settings and transferring coded data to the external buffer, activate this module by setting the JSRT bit in JCCMD to 1.
  When the image size and pixel format become readable after the coded data has been decompressed, the INS3 bit in JINTS0 is set. At this time, decompression is temporarily stopped.
  After the image size and pixel format have been read, set the output buffer.
  Setting the JRST bit in JCCMD to 1 after interrupt handling resumes decompression.

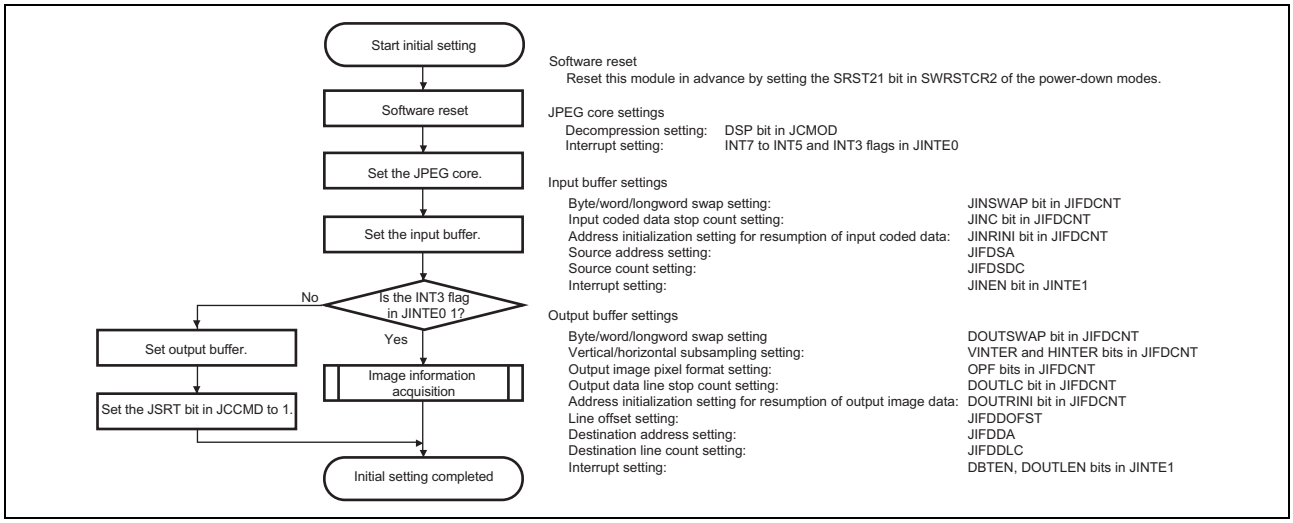

**Figure 45.5 Decompression Initial Setting Flow**

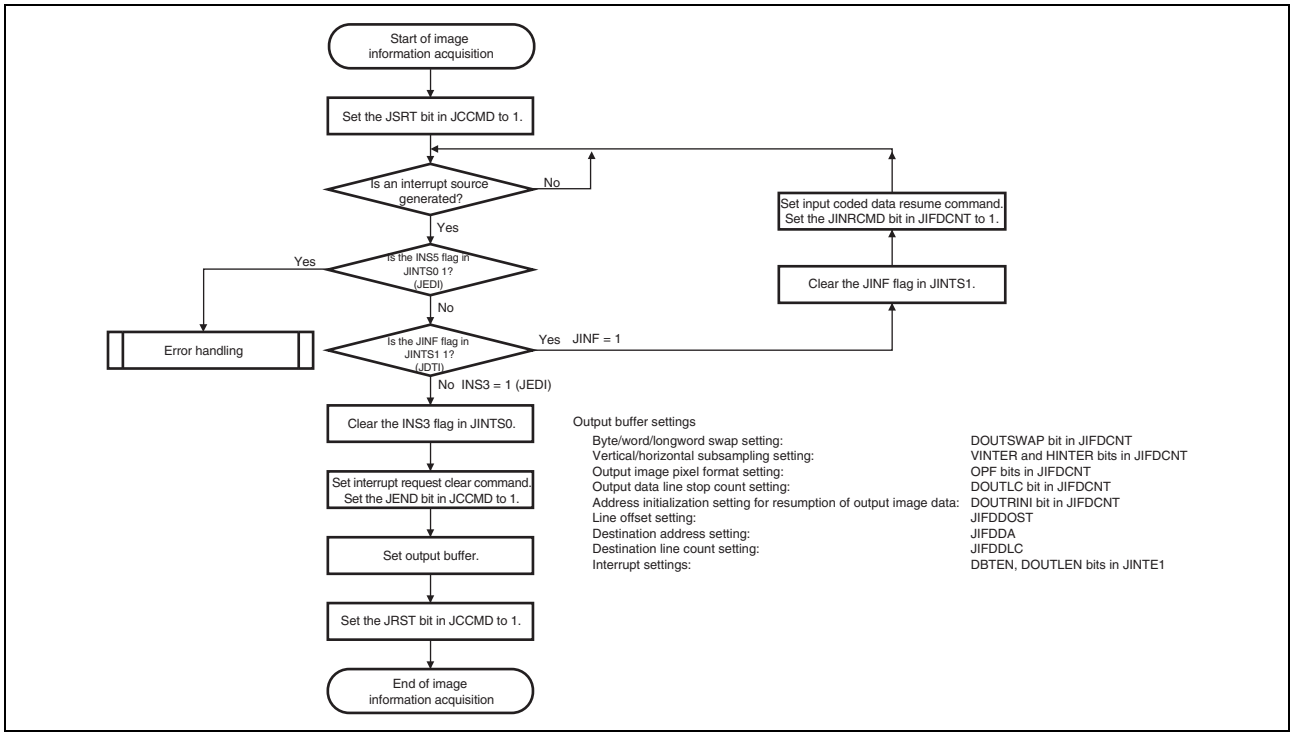

**Figure 45.6 Image Information Acquisition Flow**

### (b) Decompression Process

The decompression process flows are described below.

- When JPEG decompression process has been completed, the INS6 bit in JINTS0 is set to 1. However, the JCU continues processing since the image data remains to be transferred. The DBTF bit in JINTS1 is set to 1 when the last image data is transferred. The interrupt source is cleared by writing 0 to the INS6 bit. However, the interrupt request asserted by this interrupt source cannot be cleared by writing 0 to the INS6 bit. Set an interrupt request clear command (by setting the JEND bit in JCCMD to 1) to clear the interrupt request.
- When the JCU has completed decompression process and all image data has been transferred, the DBTF flag in JINTS1 is set to 1. When the DBTEN bit in JINTE1 is 1 here, an interrupt is generated. The interrupt source is cleared by writing 0 to the DBTF flag.
- If the count mode for stopping input coded data is on, when the specified amount of coded data set in JIFDSDC have been read, the JINF flag in JINTS1 is set to 1, and reading is stopped. When the JINEN bit in JINTE1 is 1 here, an interrupt is generated. An interrupt source is cleared by writing 0 to the JINF bit. Setting the JINRCMD bit in JIFDCNT to 1 resumes reading.
  When the JINRINI bit in JIFDCNT is zero, the addresses for reading on resumption are continued from the addresses in the previous round of transfer.
  When the JINRINI bit is one, the address set in JIFDSA is used on resumption.
- If the count mode for stopping the output image data is on, when the specified number of image data lines set in JIFDDLC have been written, the DOUTLF flag in JINT1 is set to 1, and writing is stopped. When the DOUTLEN bit in JINTE1 is 1 here, an interrupt is generated. An interrupt source is cleared by writing 0 to the DOUTLF bit. Setting the DOUTRCMD bit in JIFDCNT to 1 resumes writing.
  When the DOUTRINI bit in JIFDCNT is zero, the addresses for writing on resumption are continued from the addresses in the previous round of transfer.
  When the DOUTRINI bit is one, the address set in JIFDDA is used on resumption.

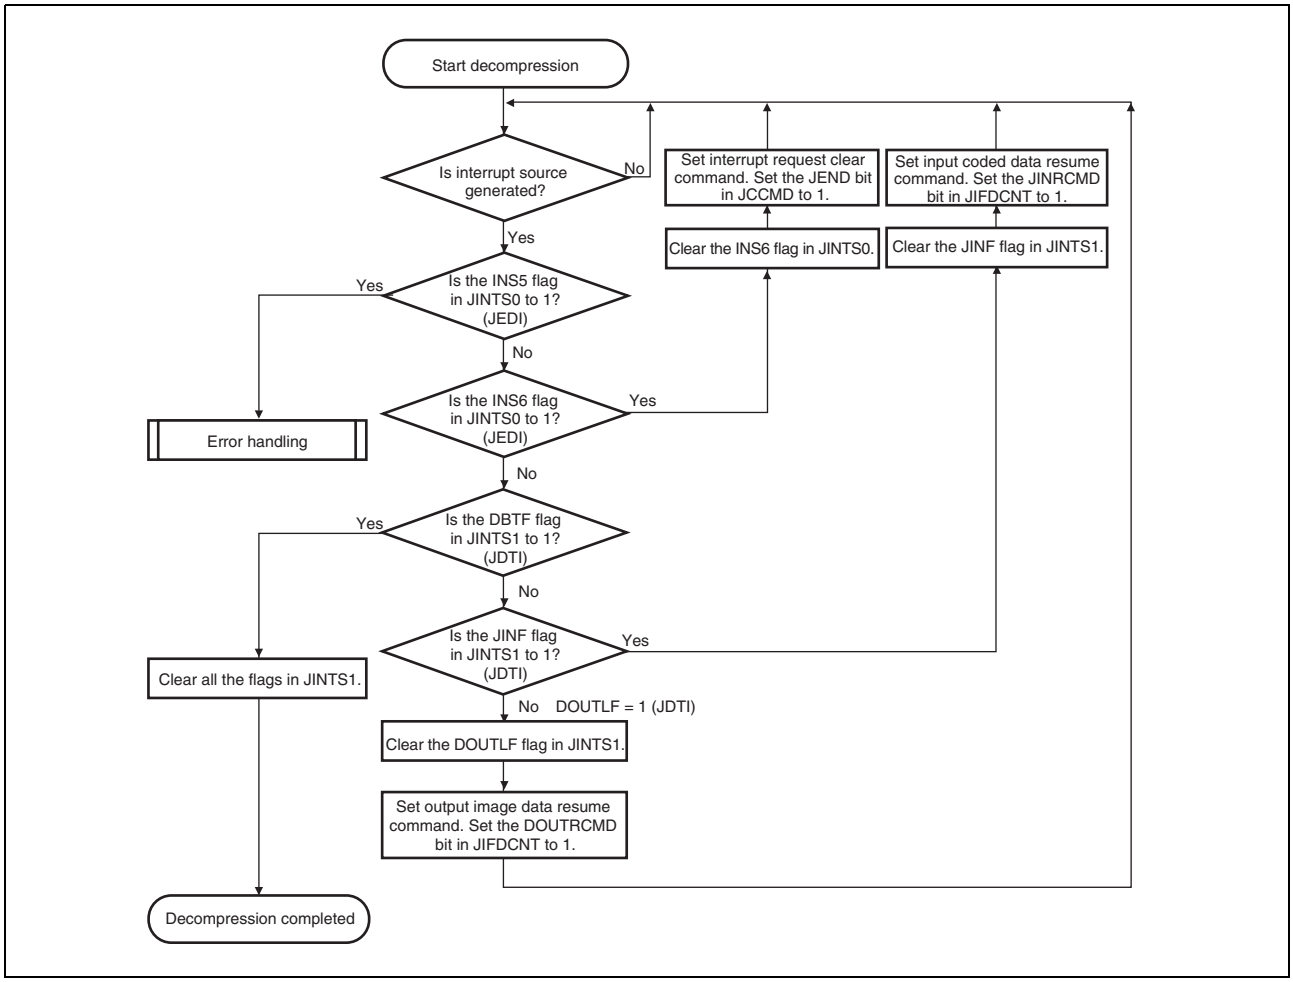

**Figure 45.7 Decompression Process Flow**

### (c) Error Handling

If the INS5 bit in JINTS0 is 1, it indicates that there is an error in the input JPEG coded data and that the decompression process by this module has been ended. Read the ERR bits in JCDERR to determine the cause of the error. The interrupt signal asserted due to the interrupt source indicated by the INS5 bit cannot be negated by clearing the interrupt status through 0-writing. To clear the interrupt request, set the interrupt request clear command (by setting the JEND bit in JCCMD to 1).
If decompression or compression is to proceed after error handling is completed, start by making the initial settings.

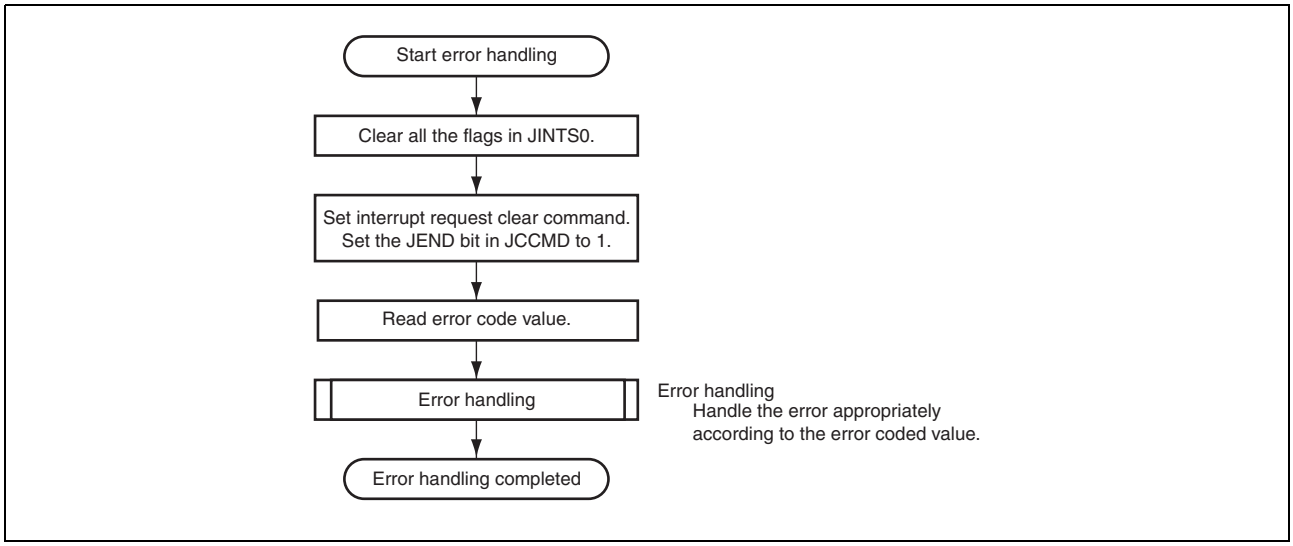

**Figure 45.8 Error Handling Flow**

## (2) Input JPEG Coded Data

Markers to be processed in decompression are SOI, SOF0, SOS, DQT, DHT, DRI, RSTm, and EOI. Other markers except for the error markers shown below are ignored even if they are read.
The JINSWAP bits in JIFDCNT can be used to alter the arrangement for the input of coded data.

## (3) JPEG Decompression Errors

### (a) Error Marker

If a marker error is found while analyzing compressed data for decompression, the code to identify the error type (shown in Table 45.3) is set to ERR bits in JCDERR. When an error is detected, the JCU generates an interrupt signal and terminates decoding. The stored code value will be set to B'1010 (default value) at the start of processing of the next frame or after a bus reset.

**Table 45.3 Decompression Error Codes**

| Code | Description |
|---|---|
| B'0000 | Normal |
| B'0001 | SOI not detected: SOI not detected until EOI detected |
| B'0010 | SOF1 to SOFF detected |
| B'0011 | Unprovided pixel format detected |
| B'0100 | SOF accuracy error: Other than 8 detected |
| B'0101 | DQT accuracy error: Other than 0 detected |
| B'0110 | Component error 1: The number of SOF0 header components detected is other than 1, 3, or 4 |
| B'0111 | Component error 2: The number of components differs between SOF0 header and SOS |
| B'1000 | SOF0, DQT, and DHT not detected when SOS detected |
| B'1001 | SOS not detected: SOS not detected until EOI detected |
| B'1010 | EOI not detected (default) |
| B'1011 | Restart interval data number error detected |
| B'1100 | Image size error detected |
| B'1101 | Last MCU data number error detected |
| B'1110 | Block data number error detected |

### (b) Huffman Coded Segment Error

During the compressed data analysis in decompression operation, if there is an increase or decrease in the decoded data count due to an error resulting from bit reversal or missing data in the Huffman-coded segment, determine the error type, and set the error code in the ERR bit in JCDERR. Table 45.4 lists the segment error codes. The error code is set, interrupt signal is issued, and the process is ended only if the bits INT7 to INT5 in JINTE0 corresponding to the detected error is set to 1. The set code value will turn to the default value (B'1010) at the start of processing of the next frame or after a bus reset.

However, in this error detection, if an error in the Huffman-coded segment does not result in an alteration in the decoded data count, the error will go undetected.

[Example]

The number of data in a Huffman coded segment with pixel format setting YCbCr422, DRI = 2, X = 80 pixels, and Y = 8 pixels

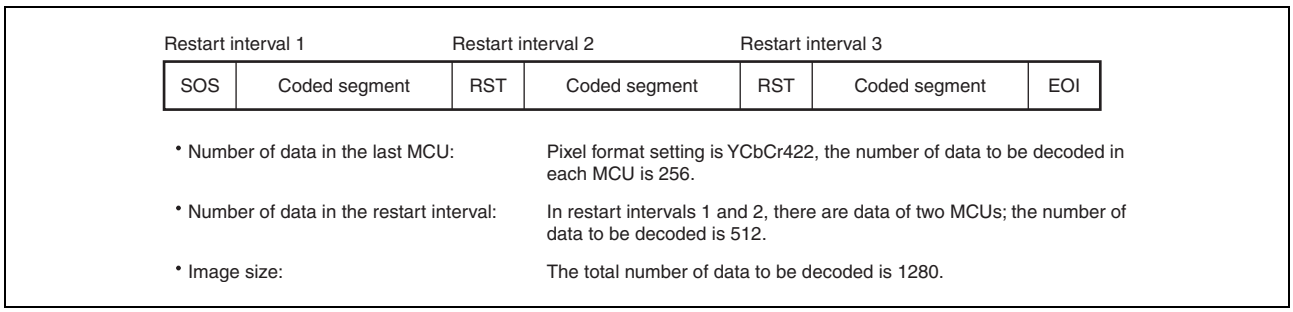

**Figure 45.9 Huffman Coded Segment**

**Table 45.4 Segment Error Codes**

| Code | Description |
|---|---|
| B'0000 | Normal |
| B'1011 | Restart interval data number error:<br>The number of data in each interval is compared with the number of data specified by the DRI marker. If an interval has more or less data that is specified by the DRI marker, the decompression error code (1011) is set. The last interval which is shorter than the restart interval is not compared.<br>If the DRI marker segment is not placed or the specified number is 00, an error is not detected even if the RSTm marker is placed. Also an m which indicates the order of RSTm marker modulo 8 (m = 0 to 7) is exempt from the error detection analysis.<br>When the INT7 bit in JINTE0 is set to 0, this error is not detected. |
| B'1100 | Image size error:<br>The data number of an image which is calculated from the number of lines specified by the frame parameter and the number of samples per line is compared with the total number of data from SOS to EOI (in pixel units). If the numbers of data do not match, the decompression error code (1100) is set. When the INT6 bit in JINTE0 is set to 0, this error is not detected. The data number of an image is shown in MCU units. Thus the number of lines and the number of samples per line for calculation need to be shown in MCU units. |
| B'1101 | Last MCU data number error:<br>Whether the number of data in the MCUs at the EOI detection is shown in MCU units is checked and fractions are detected. If error (1100) occurs simultaneously, error (1100) has priority. When the INT5 bit in JINTE0 is set to 0, this error is not detected. |
| B'1110 | Block data number error:<br>Whether a block is an 8 × 8 array is checked; the check is performed for fractions. When bits INT7 to INT5 in JINTE0 are all set to 0, this error is not detected. |

## 45.3.3 Output Pixel Format in Decompression

This module is capable of decompressing JPEG encoded data created in the YCbCr444, YCbCr422, YCbCr411 and YCbCr420 formats. The pixel format of the output image will be YCbCr422, ARGB8888, or RGB565. The flow of conversion of decompressed data to the given output pixel format is shown below.

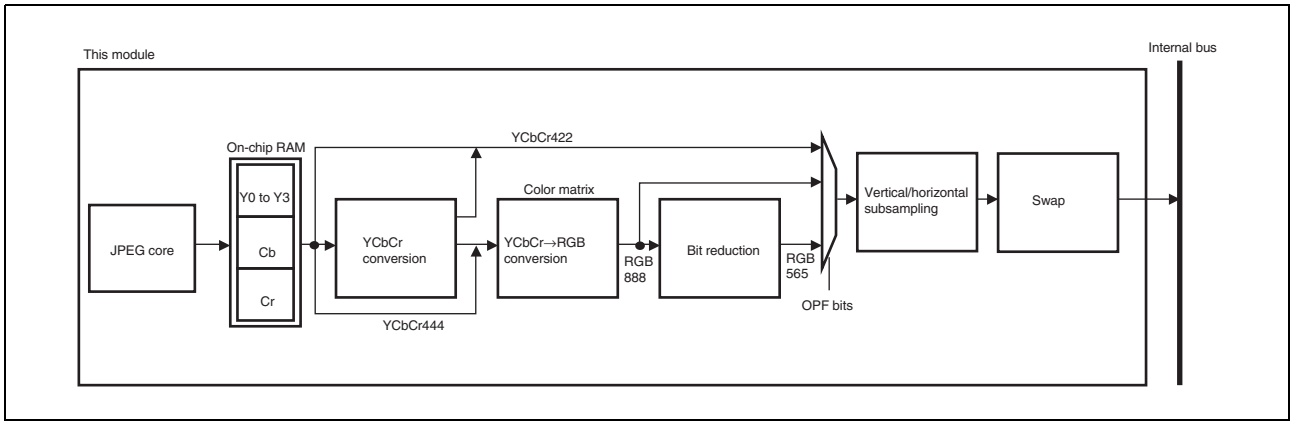

**Figure 45.10 Block Diagram of Output Pixel Format Conversion in Decompression**

### (1) On-chip RAM

Data decoded by the JPEG core are stored in MCUs on RAM in this module.

### (2) YCbCr Conversion

When data are to be output in the ARGB8888 or RGB565 format, data in the YCbCr422, YCbCr411 or YCbCr420 format are first converted to the YCbCr444 format.

When data are to be output in the YCbCr422 format, data in the YCbCr444, YCbCr411 or YCbCr420 format are converted to the YCbCr422 format.

Conversion is performed using simple interpolation.

### (3) YCbCr → RGB Conversion

Data in the YCbCr444 format are converted to the RGB888 format. The following formulae are used.
R = 1.000Y + 1.402Cr
G = 1.000Y - 0.344Cb - 0.714Cr
B = 1.000Y + 1.772Cb

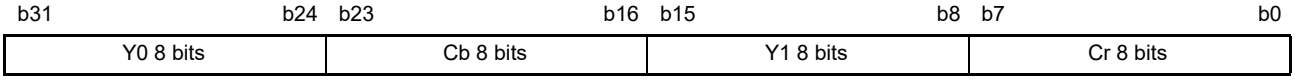
### (4) Bit Reduction

RGB888 data is reduced to RGB565 data. The lower three bits of red and blue, and lower two bits of green are removed.

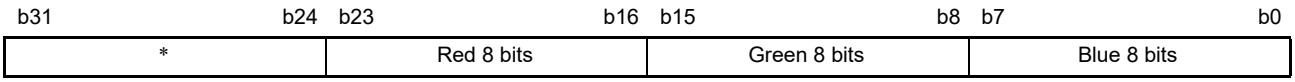
### (5) Output Pixel Format Selection

The pixel format to be output is selected by the OPF bit in JIFDCNT.
Allocation of data (while the DOUTSWAP bits in JIFDCNT = 000) in the pixel format is shown below.

- YCbCr422 (32 bits/pixel)

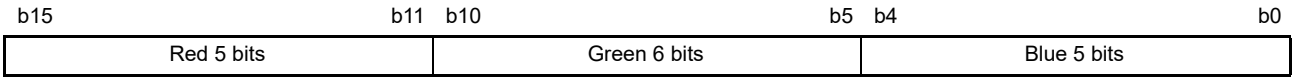


- ARGB8888 (32 bits/pixel)



Note: * This value is determined by the ALPHA[7:0] bits in JIFDADT.

- RGB565 (16 bits/pixel)



### (6) Vertical/Horizontal Subsampling

The output data can be horizontally and vertically subsampled according to the VINTER and HINTER bit setting in JIFDCNT.
Figure 45.11 to Figure 45.13 show line subsampling modes.
For the output formats ARGB8888 and RGB565, one cell represents one pixel in the figures.
For the output format YCbCr422, one cell represents one set of Y0Cb0Y1Cr0 in the figures.
As subsampling is carried out by minimum coded units (MCU), the numbers of the horizontal and vertical block units will vary according to the decompressed pixel format.
Table 45.5 and Table 45.6 show the values of n and m in the figures.
Horizontal:

**Table 45.5 Number of Horizontal Blocks**

| Compression Format | Output Format | n |
|---|---|---|
| YCbCr444 | YCbCr422 | 1/2 |
| YCbCr444 | ARGB8888, RGB565 | 1 |
| YCbCr422 | YCbCr422 | 1 |
| YCbCr422 | ARGB8888, RGB565 | 2 |
| YCbCr411 | YCbCr422 | 2 |
| YCbCr411 | ARGB8888, RGB565 | 4 |
| YCbCr420 | YCbCr422 | 1 |
| YCbCr420 | ARGB8888, RGB565 | 2 |

Vertical:

**Table 45.6 Number of Vertical Blocks**

| Compression Format | Output Format | m |
|---|---|---|
| YCbCr444 | YCbCr422 | 1 |

### (7) Swap

Allocation of data can be changed by the DOUTSWAP bits in JIFECNT.

### 45.3.4 Storing Image Data

Figure 45.14 shows the buffer area for storing the image data.

## 45.4 Interrupts

Two types of interrupt requests, namely compression/decompression process interrupt request (JEDI) and data transfer interrupt request (JDTI), are available in this module. The two types of interrupt requests are each related to multiple sources. The interrupt request cancellation methods differ depending on the source of the interrupt request.

### 45.4.1 Compression/Decompression Process Interrupt Request (JEDI)

The flags in JINTS0 indicate compression/decompression-related sources. The interrupt requests asserted by these interrupt sources cannot be negated by clearing the corresponding interrupt status bits to 0. Issue an interrupt request clear command (by setting the JEND bit in JCCMD to 1) to clear the interrupt request. When a flag in JINTS0 is set to 1, a compression/decompression process interrupt request is sent to the interrupt controller.

#### (1) Compression

- JPEG compression process end
  When the INS6 bit in JINTS0 is 1, the JPEG compression process has been successfully completed. After all of the coded data is transferred, the JCU completes compression.

#### (2) Decompression

- JPEG decompression process end
  When the INS6 bit in JINTS0 is 1, the JPEG decompression process has been successfully completed. After all of the image data is transferred, JCU completes decompression.
- JPEG decompression error occurrence
  When the INS5 bit in JINTS0 is 1, the input JPEG coded data has an error and the JCU has stopped the decompression process. Read the error code (ERR bits in JCDERR) and identify the error source. This interrupt occurs when any of the INT7 to INT5 bits in JINTE0 is 1.
- Request for reading the image size and pixel format
  When the INS3 bit in JINTS0 is 1, JPEG coded data has been input and information regarding the image size and pixel format can be read. Since the JPEG decompression process is suspended, resume the JPEG decompression process by setting the process stop clear command after accessing the necessary registers. This interrupt occurs when the INT3 bit in JINTE0 is 1.

### 45.4.2 Data Transfer Interrupt Request (JDTI)

The flags in JINTS1 are the interrupt sources for transferring the image data and coded data. The interrupt requests asserted by these interrupt sources can be negated by clearing the corresponding interrupt status bits to 0.

#### (1) Compression

- Interrupt request generated after the specified number of input image data lines has been read
  When the DINLF bit in JINTS1 is 1, the number of image data lines specified by JIFESLC has been transferred; transfer the rest of the image data to the external buffer and resume transferring the data from the external buffer. A data transfer interrupt request is sent when the DINLEN bit in JINTE1 is 1.
- Interrupt request generated after the specified amount of output coded data have been written to
  When the JOUTF bit in JINTS1 is 1, the amount of coded data specified by JIFEDDC has been transferred. Secure a space for the next coded data in the external buffer, and resume transfer process. The data transfer interrupt request is sent when the JOUTEN bit in JINTE1 is 1.
- Interrupt request generated after all processes are completed
  When the CBTF bit in JINTS1 is 1, the JCU has completed compression and transferred all of the coded data. The data transfer interrupt request is sent when the CBTEN bit in JINTE1 is set to 1.

### (2) Decompression

- Interrupt request generated after the specified number of output image data lines has been written to
  When the DOUTLF bit in the JINTS1 is 1, the number of image data lines specified by JIFDDLC has been transferred. Secure a space for the next coded data in the external buffer, and resume transfer process. A data transfer interrupt request is sent when the DOUTLEN bit in JINTE1 is 1.
- Interrupt request generated after the specified amount of input coded data has been read
  The JINF bit in JINTS1 becomes 1 when the amount of coded data specified by JIFDSDC has been transferred. Secure the next coded data in the external buffer, and resume transfer process. A data transfer interrupt is also sent at this time if the JINEN bit in JINTE1 is 1.
- Interrupt request generated after all processes are completed
  The DBTF bit in JINTS1 becomes 1 when the JCU has completed decompression and transferred all of the coded data. A data transfer interrupt request is also sent at this time if the DBTEN bit in JINTE1 is set to 1.

## 45.5 Bus Reset Processing

Issuing the bus reset command (setting the BRST bit in JCCMD to 1) causes a bus reset.
When the JCU is in operation, the bus reset command should not be issued. Registers below are initialized by a bus reset.

- JPEG code data count upper register (JCDTCU)
- JPEG code data count middle register (JCDTCM)
- JPEG code data count lower register (JCDTCD)
- JPEG interrupt status register 0 (JINTS0)
- JPEG code decode error register (JCDERR)
- JPEG code reset register (JCRST)

# 46. Capture Engine Unit

The capture engine unit (CEU) is a capture module that fetches image data externally input and transfers it to the memory. The CEU is connected to the system bus via bus bridge modules.

## 46.1 Features of CEU

Lists the features of CEU as follows.

### (1) Image data fetch

- Captures an image output from an external module and writes YCbCr data to the memory with it separated into Y data and CbCr data.
- Fetches image data other than YCbCr data, e.g. JPEG data, RGB565, from an externally connected module, such as a camera, and sequentially writes the image data to the memory.
- Fetches an interlace source image in both-field units or one-field units and writes it to the memory. In both-field capture, an image can be stored in the memory as a frame image.

### (2) Filter processing

- Performs scale-down and removal of high-frequency components (only in the horizontal direction) for an image using internal filters. Note that the scaled-down image must not exceed VGA. The filter processing can be applied to only YCbCr input data.

### (3) Format conversion

- Converts image data input in the YCbCr422 format into the YCbCr420 format and writes it to the memory. Note that the conversion algorithm is simple skipping in which the chrominance component (CbCr) of the even-numbered lines is skipped.

## 46.2 Functional Overview of CEU

The functional overview of the CEU is shown in Table 46.1, and the main functions and their details are shown in Table 46.1.

In both-field capture, an image can be stored in the memory as a frame image. |
| Filter processing | Performs scale-down and removal of high-frequency components (only in the horizontal direction) for an image using internal filters.<br>Note that the scaled-down image must not exceed VGA. The filter processing can be applied to only YCbCr input data. |
| Format conversion | Converts image data input in the YCbCr422 format into the YCbCr420 format and writes it to the memory.<br>Note that the conversion algorithm is simple skipping in which the chrominance component (CbCr) of the even-numbered lines is skipped. |

## 46.3 Pin Configuration of CEU

The pin configuration of the CEU is shown in Table 46.3.

**Table 46.3 Pin Configuration of CEU**

| Pin Name | Function | I/O | Description |
|---|---|---|---|
| VIO_D15 to VIO_D0* | CEU data bus | Input | Camera image data input to the CEU |
| VIO_CLK | CEU clock | Input | Camera clock input to the CEU |
| VIO_VD | CEU vertical sync | Input | Camera vertical sync signal input to the CEU |
| VIO_HD | CEU horizontal sync | Input | Camera horizontal sync signal input to the CEU |
| VIO_FLD | Field signal | Input | Field identification signal to the CEU |

Note: * When the distinction according to the bus width for the data bus is not needed, VIO_D is used in this manual. Otherwise, VIO_D15 to VIO_D0 are used.

## 46.4 Register Descriptions of CEU

The register configuration of the CEU is shown in Table 46.4.

Most CEU registers have a 2-plane configuration (plane A and plane B). The CEU switches the planes when using these 2-plane registers. A mirror address, which is an address that can always access the register on the unused plane, is provided for each 2-plane register. Figure 46.2 shows the timing to switch the register planes. The CEU switches the register planes at the same time a VD interrupt is asserted.

In the following register descriptions, "during operation" indicates the period that begins when the CEU is activated by the CE bit in the capture start register (CAPSR) and ends when a capture end interrupt (CPE) of the capture event flag clear register (CETCR) occurs. In the read-only bits in each register, the write value should always be 0. If a value other than 0 is written to any of these bits, correct operation cannot be guaranteed.

Clear the CE bit to 0 when writing 1 to this bit. Processing of the capture software reset is indicated by this bit being set to 1. When this bit is 1, do not start capturing since reset processing is in progress. When restarting capture operations, after referring to the CPTON bit in CSTSR to ensure that the CEU is halted (in the idle state), wait until this bit is cleared to 0. The timing of restarting capture operations is shown in Figure 46.6.<br>When a software reset is generated by this bit, a capture end interrupt (CPE bit in CETCR) may be output immediately after the software reset. However, such kind of interrupt should be ignored. Also, even if the capture end interrupt is not output, the interrupt source (CPE bit) must be cleared before capturing of the next frame.<br>0: Normal state<br>1: Software reset of capturing |

| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| 0 | CE | 0 | R/W | • Single-capture<br>This bit reserves capturing of the next frame. When 1 is written to this bit, the capture of one frame starts from the next VD input, and stops when the one-frame capture end interrupt (CPE bit in CETCR) is asserted (Figure 46.7). To perform capture again, write 1 to this bit. After the VD or HD polarity is changed, do not write 1 to this bit until the next VD interrupt is asserted.<br>As this bit indicates the capture reserve state, this bit is read as 1 after it is set to 1 and until VD is input. When VD is input, this bit returns to 0 and so is read as 0.<br>The capture end is determined by the one-frame capture end interrupt (CPE bit). This is similar in data fetch mode.<br>Registers should be set before the VD interrupt of the frame where capture starts next. The new register settings take effect at the next VD input. When registers are modified during capturing, the register settings take effect from the capture operations of the next VD input. If a setting register to which writing during capturing is prohibited is modified during capturing, an interrupt source (IGRW bit in CETCR) is generated. For details on the interrupt source, see the description on CETCR.<br>• Continuous capture<br>When this bit is set to 1 while the CTNCP bit in CAPCR is set to 1, continuous capture starts from the next frame (Figure 46.8). Note that this bit is not cleared to 0 but remains as 1. To stop capturing, clear this bit to 0; capturing stops after the current frame is completed.<br>Continuous capture operations are possible in only image capture mode. The start address of the memory to which the captured data is written to must be set for each frame.<br>0: Stops capturing<br>1: Starts capturing |

When both the VD (vertical sync signal) and HD (horizontal sync signal) polarities are high-active, one frame is defined as a period from a VD rising edge to the next VD rising edge, and one line as a period from an HD rising edge to the next HD rising edge. Figure 46.3 shows the timing of one frame (when both the VD and HD polarities are high-active).

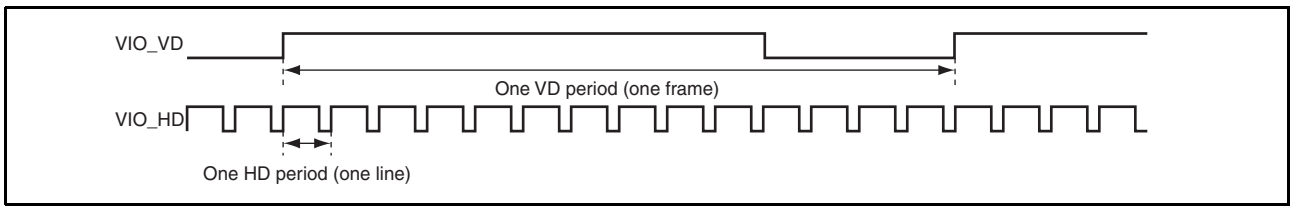

**Figure 46.3 Frame Timing**

When both the VD and HD polarities are high-active, similar to one frame, one field is defined as follows:

- Period from a VD rising edge to the next VD rising edge
- One line is a period from an HD rising edge to the next HD rising edge

The field identification signal FLD should be fixed for at least 1-HD period from a VD input. Figure 46.4 shows the timing of one field (when both the VD and HD polarities are high-active).

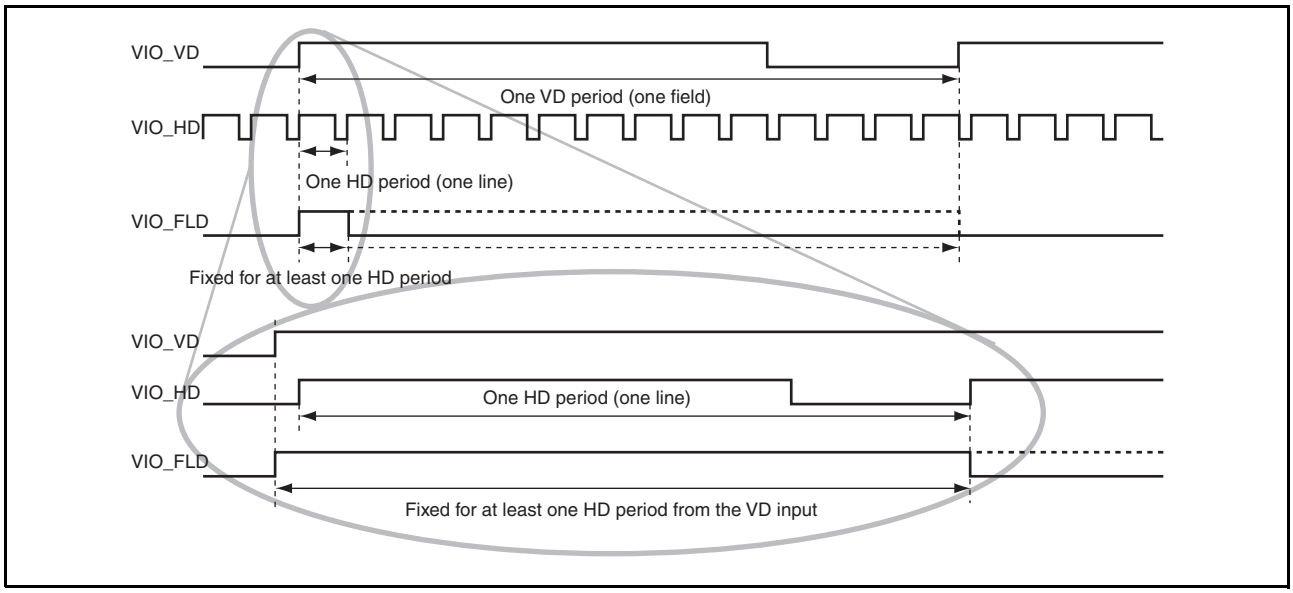

**Figure 46.4 One Field Timing**

In data enable fetch*, one frame is defined as a period from a VD rising edge to the VD falling edge. With the HD as an enable signal (positive polarity), data of a cycle in which the HD is asserted is fetched while the VD is high. Figure 46.5 shows the timing of one frame for data enable fetch.

Note: * Data enable fetch mode cannot be set in this product.

## 46.4.2 Capture Control Register (CAPCR)

CAPCR sets continuous-frame capture and the frame drop intervals.

Do not modify this register during operation. If this register is modified during operation, correct operation cannot be guaranteed. In addition, the IGRW bit (interrupt source) in CETCR is set to B'1.

### 46.4.3 Capture Interface Control Register (CAMCR)

CAMCR sets the capture interface.

The following items are set by CAMCR.

- Selection between image capture operation or data fetch operation
- Polarities of the vertical and horizontal sync signals
- Input order of image data components (Y, Cb, and Cr) (only for image capture mode)
- Selection of digital image input pins (8 bits or 16 bits)
- Polarity of the field identification signal

CAMCR must be set according to the module connected. In data fetch mode, set the DTARY bits to B'0. Do not modify this register during operation. If this register is modified during operation, correct operation cannot be guaranteed. In addition, the IGRW bit (interrupt source) in CETCR is set to B'1.

Note: After changing the setting of this register, do not start capture until at least 10 external input clock cycles have elapsed.

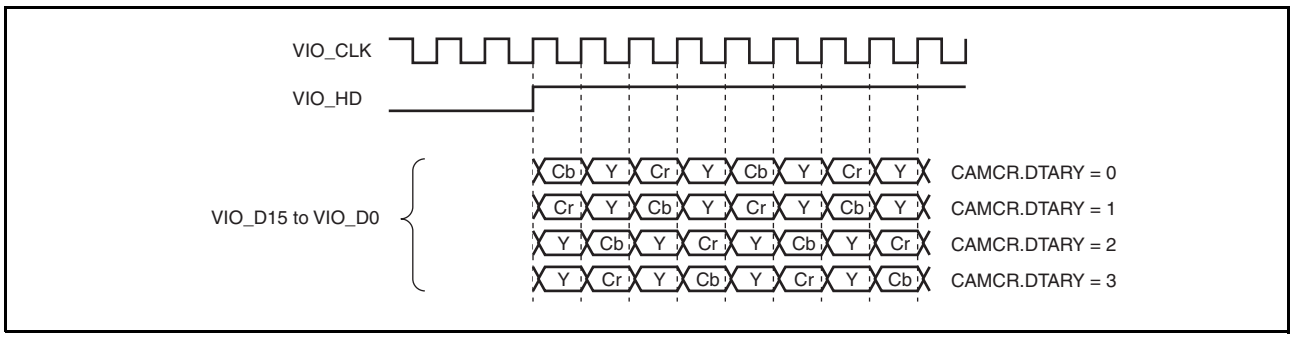

**Figure 46.11 Input Order of Image Data**

The JPG bit in CAMCR selects whether digital image data is fetched or data such as JPEG is fetched. In addition, when data such as JPEG is fetched, select whether the specified amount of data is continuously fetched in synchronization with the sync signal or data is fetched while the horizontal sync signal is enabled*.

Note: * Data enable fetch mode cannot be set in this product.

In data enable fetch mode, one frame is defined as a period from the rising edge to the falling edge of the vertical sync signal (VD) for data fetching. The horizontal sync signal (HD) is enabled only when the VD is high and treated as an enable signal. Data input in the cycle in which the HD is asserted (high) is fetched and output to the memory continuously.

This module starts fetching data at the rising edge of the VD and stops fetching data at the falling edge of the VD in data enable fetch mode. Thus, if the VD remains high and does not go low, end processing does not start. In addition, if the VD remains high and the HD also remains asserted, data continues to be fetched.

Figure 46.12 and Figure 46.13 show the interface timing in data enable fetch mode.

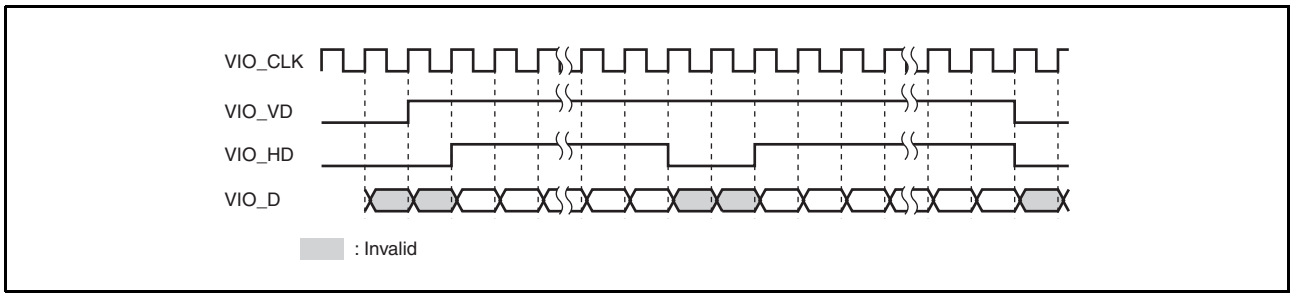

**Figure 46.12 Data Enable Fetch Timing (HD Asserted (High) While VD is High)**

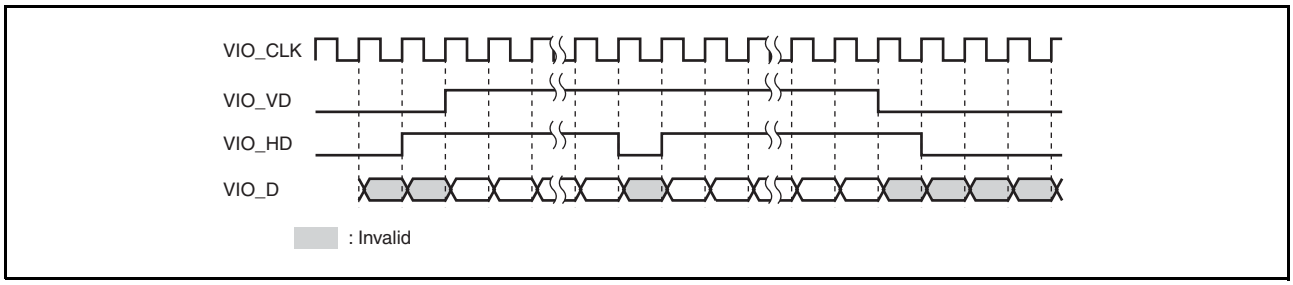

**Figure 46.13 Data Enable Fetch Timing (HD Asserted (High) When VD is Not High)**

In data enable fetch mode, this module generates a VD interrupt in response to detection of the active level of VD. In image capture mode and data synchronous fetch mode, this module generates a VD interrupt in response to the first detection of the active level of HD following detection of the active level of VD. Note that, when VD and HD are asserted and detected at the same time, this module generates a VD interrupt at that time.
Figure 46.14 to Figure 46.16 show the relationships between the VIO_VD signal and the VD interrupt, the VIO_VD and VIO_HD signals and the VD interrupt, and the VIO_HD signal and the HD interrupt.

### 46.4.4 Capture Interface Cycle Register (CMCYR)

CMCYR is used to detect an illegal VD and an illegal HD. For HD, the number of cycles from a rising edge of HD to the next rising edge is set (falling edges when low-active is selected for HD). For VD, the number of HD inputs from a rising edge of VD to the next rising edge is set (falling edges when low-active is selected for VD).

Do not modify this register during operation. If this register is modified during operation, correct operation cannot be guaranteed. In addition, the IGRW bit (interrupt source) in CETCR is set to B'1.

Set 0 in all bits of this register, during data enable fetch mode.

Note: After changing the setting of this register, do not start capture until at least 10 external input clock cycles have elapsed.

### 46.4.5 Capture Interface Offset Register (CAMOR)

CAMOR sets the location to start capturing when capturing images.

Since the number of HD (horizontal sync signal) inputs from a VD (vertical sync signal) input to the start of a valid image period, and the number of clock cycles from an HD input to the start of a valid image period differ among external modules, these must be set in CAMOR. By setting a value greater than the valid image area, part of the image can be clipped for capture. When fetching data, the setting of this register becomes the number of cycles (HD count) up to the start of a valid data period.

This register is not used, during data enable fetch mode.

### 46.4.7 Capture Interface Input Format Register (CAIFR)

CAIFR sets the input mode (progressive or interlace) for capturing images, the images to be captured (frame, both-field, or one-field), the image from which capturing starts (top field or bottom field), etc. CAIFR is not used in data fetch mode.

Do not modify this register during operation. If this register is modified during operation, correct operation cannot be guaranteed. In addition, the IGRW bit (interrupt source) in CETCR is set to B'1.

The items set by CAIFR are listed in Table 46.7.

In frame image capture and one-field image capture, a one-frame capture end interrupt occurs when capture for 1 VD finishes. In both-field image capture, a one-field capture end interrupt occurs when capture for 1 VD finishes and a one-frame capture end interrupt occurs when capture for 2 VD finishes. At this time, a one-field capture end interrupt occurs simultaneously with a one-frame capture end interrupt. Figure 46.24 shows the timing of a one-frame capture end interrupt and one-field capture end interrupt in both-field image capture.

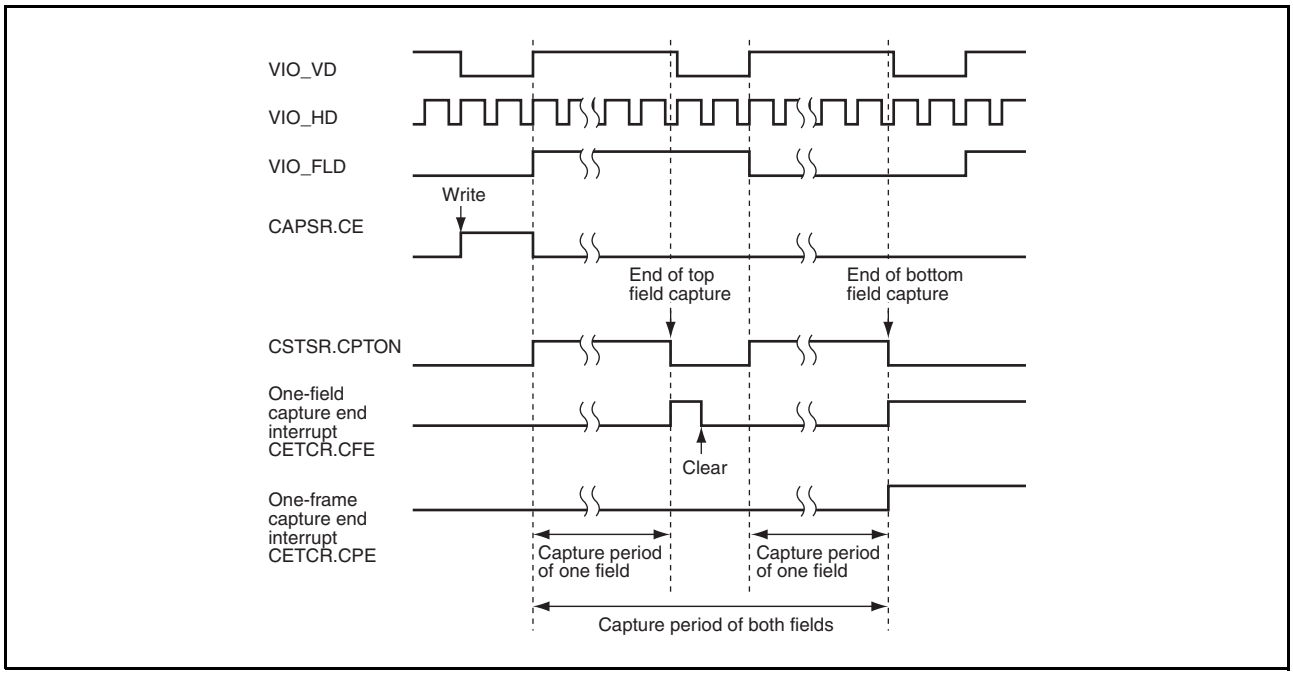

**Figure 46.23 One-Frame Capture End Interrupt and One-Field Capture End Interrupt in Both-Field Image Capture**

A captured frame image or captured one-field image is stored in the memory from the addresses set in CDAYR and CDACR (Figure 46.24). Captured both-field images are stored in different memory areas depending on whether it is a top-field or bottom-field image. A top-field image is stored in the memory from the addresses set in CDAYR and CDACR whereas a bottom-field image is stored in the memory from the addresses set in CDBYR and CDBCR (Figure 46.25).

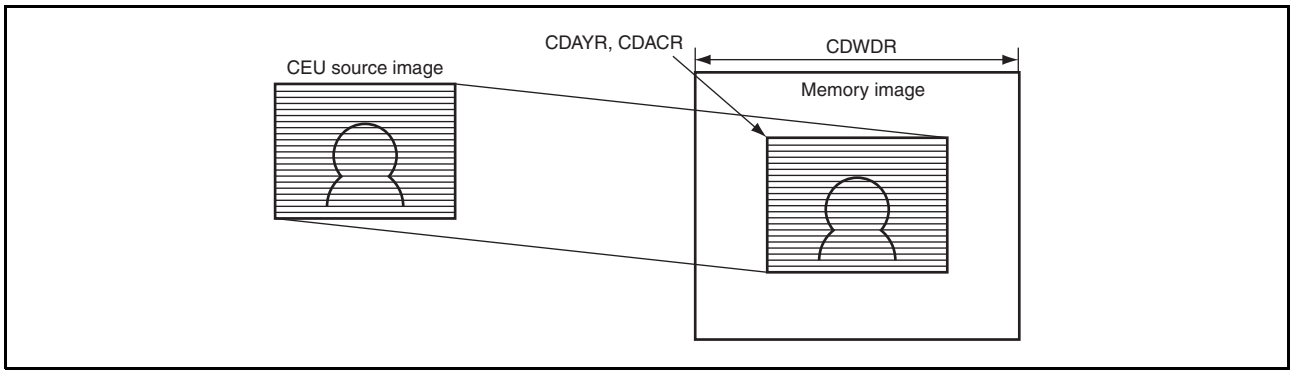

**Figure 46.24 Image of Storing Captured Frame Image or Captured One-Field Image in Memory**

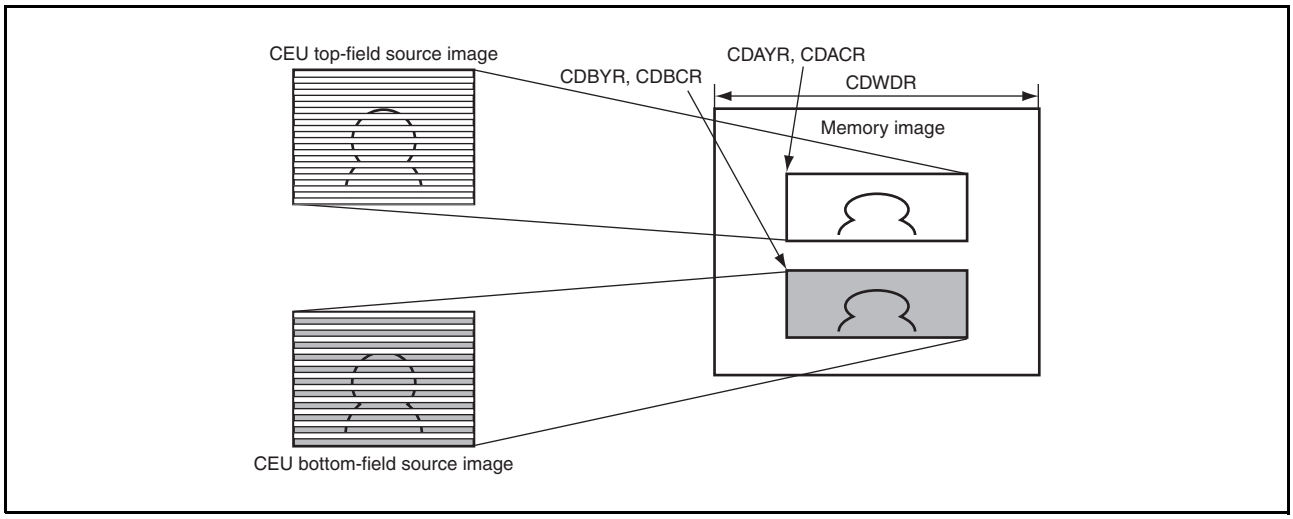

**Figure 46.25 Image of Storing Captured Both-Field Images in Memory**

If the FCI bits are set to B'00 for continuous capture in interlace input mode, images are continuously captured for 2 VD with the first captured field as the reference in both-field image capture (Figure 46.26). In one-field image capture, only the first captured field is continuously captured for 1 VD (Figure 46.27).

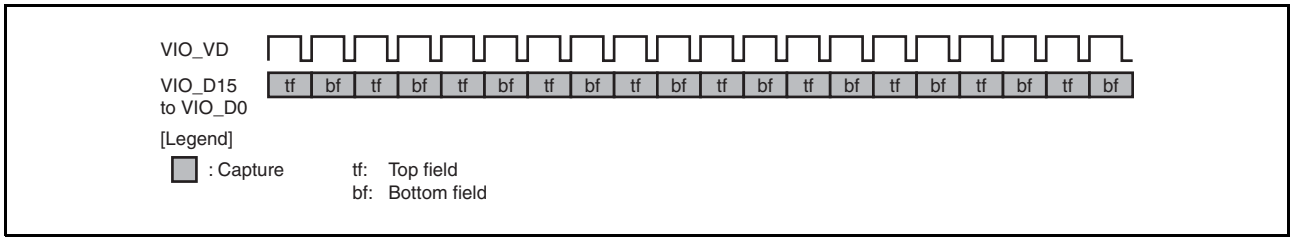

**Figure 46.26 Continuous Both-Field Capture in Interlace Mode (Image Immediately after Activation is Top Field (FCI Bits = B'00))**

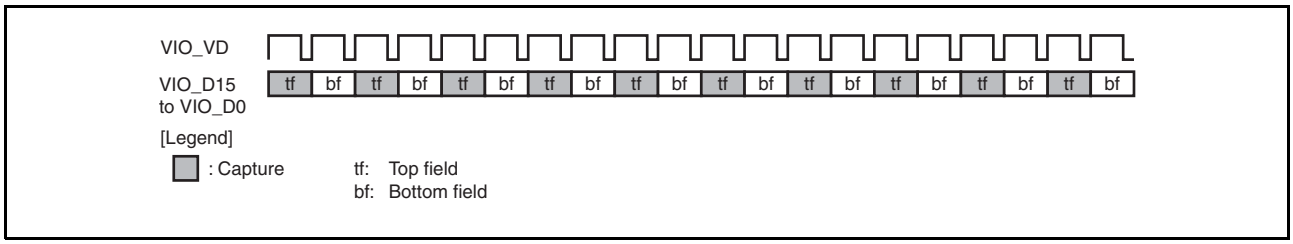

**Figure 46.27 Continuous One-Field Capture in Interlace Mode (Image Immediately after Activation is Top Field (FCI Bits = B'00))**

### (1) Storage of Interlace Input as Frame Image

The CEU can store an interlace source image in the memory as a frame image. To store an interlace source image as a frame image, make the following register settings:

Input mode: Interlace (IFS bit = B'1)
Capture image: Both-field (CIM bit = B'0)
Image to start capture: Any setting other than the prohibited setting (FCI bits = as desired)

Figure 46.28 shows a memory image of capturing both fields of an interlace input and storing it as a frame image in the memory. Set the start addresses of the memory destination for the captured top-field image in CDAYR and CDACR, and the start addresses of the memory destination for the captured bottom-field image in CDBYR and CDBCR. When storing an interlace image as a frame image in the memory, set the horizontal image size of the memory area in CDWDR with the top-field image and bottom-field image placed next to each other as shown in Figure 46.28. In addition, set the number of captured lines of the field image in the VWDTH bits in CAPWR.

A memory image of folding the horizontal image size of the memory area in Figure 46.28 at CDWDR/2 is shown in Figure 46.29. Setting the registers to form the image in Figure 46.28 enables an interlace image to be stored as a frame image in the memory as shown in Figure 46.29.

## 46.4.9 CEU Register Forcible Control Register (CRCMPR)

CRCMPR forcibly controls switching of the planes of registers with a 2-plane configuration. Setting this register enables direct control of register plane switching.

Do not modify this register during operation. If this register is modified during operation, correct operation cannot be guaranteed. In addition, the IGRW bit (interrupt source) in CETCR is set to B'1.

## 46.4.10 Capture Filter Control Register (CFLCR)

CFLCR sets the scale-down factor for the filter to scale images down.

The CEU has an image scale-down filter which can be used to scale down the captured images before storing them in the memory. Set CFLCR to 0 when not performing scale-down (same size output). If a value other than 0 is set in CFLCR, scale-down is performed. In data fetch mode, set CFLCR to 0.

When handling an interlace source image as a frame image, set CFLCR to 0 not to use the filter.

An image scale-down filter is installed in the CEU, and the captured images can be scaled down and stored in the memory.

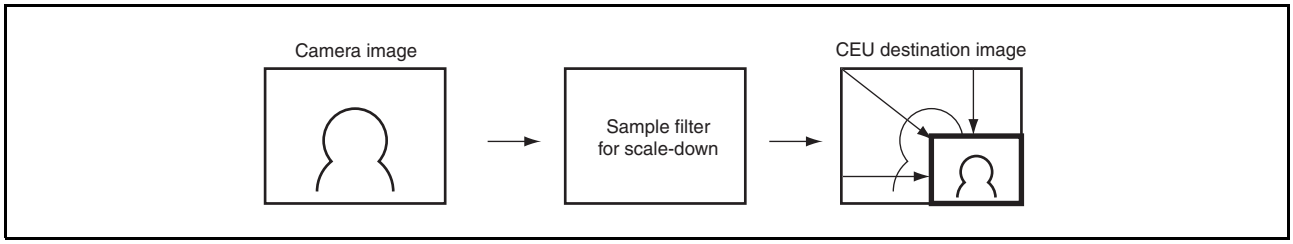

**Figure 46.32 Scale-Down of Captured Image**

The formulas for obtaining the MANT (VMANT or HMANT) and FRAC (VFRAC or HFRAC) values from the input pixel count and output pixel count of the filter are shown below. Set the MANT and FRAC bits in order to obtain the desired output pixel count from the number of pixels input to the CEU.

First, calculate preliminary MANT and FRAC values. The parameters needed for calculation are defined as follows:

$$\alpha = MANT \times 4096 + FRAC \quad \text{. . . Formula 1}$$

$$SCL \text{ (scaling factor)} = \frac{4096}{\alpha} \quad \text{. . . Formula 2}$$

Assuming an operator $\lfloor x \rfloor$ which discards fractions of an integer $x$, the MANT and FRAC values can be temporarily set as follows, according to formula 1 and formula 2.

$$MANT = \left\lfloor \frac{1}{SCL} \right\rfloor, \quad FRAC = \left\lfloor 512 \times \left( \frac{1}{SCL} - MANT \right) \right\rfloor \times 8$$

Here, the scaled-down filter output size ($SIZE_D$) can be calculated using the input image size $S_{in}$ (8-bit interface: half of the CAPWR setting, 16-bit interface: CAPWR setting) in the following formula.

$$SIZE_D = \left\lfloor 1 + \left( \left\lfloor \frac{1}{2} + \frac{S_{in} - 1}{MANT_{pre}} \right\rfloor - 1 \right) \times \frac{MANT_{pre} \times 4096}{\alpha} \right\rfloor \quad \text{. . . Formula 3}$$

$$\begin{bmatrix} MANT_{pre} = 1 \longrightarrow (0 \le MANT < 2) \\ MANT_{pre} = 2 \longrightarrow (2 \le MANT < 4) \\ MANT_{pre} = 4 \longrightarrow (4 \le MANT < 8) \\ MANT_{pre} = 8 \longrightarrow (8 \le MANT\ ) \end{bmatrix}$$

The number of output pixels can be obtained by substituting the temporarily calculated MANT, FRAC, and input image size into these formulas. If the calculated number of output pixels is smaller than the number of output pixels used to obtain the preliminary MANT and FRAC values, recalculate with a smaller FRAC (α) value, and set the MANT and FRAC values in this register so that a pixel value greater than the desired number of output pixels can be obtained.

Example: Scale down 640 pixels to 480 pixels

SCL = 480/640 = 3/4, and the preliminary settings of MANT = 1, $MANT_{pre}$ = 1, and FRAC = H'550 are made. Substituting these in the following formula results in an output pixel count of 479.

$$SIZE_D = \left\lfloor 1 + \left( \left\lfloor \frac{1}{2} + \frac{S_{in} - 1}{MANT_{pre}} \right\rfloor - 1 \right) \times \frac{MANT_{pre} \times 4096}{\alpha} \right\rfloor \quad \text{. . . Formula 3}$$

Since this output pixel count is smaller than the desired output pixel count of 480, the formula is recalculated with a FRAC value of H'548, a value eight less than the previous time. The obtained result of output pixel count = 480 is equal to the desired output pixel count of 480, so this register is set as MANT = 1 and FRAC = H'548.

**Table 46.8 Setting Examples for Each Scale-Down Filter Factor**

Note: This scale-down filter uses a VGA-size line memory for scale-down. Therefore, when an image larger than the VGA size is input for scale-down, settings must be made so that the output image size is equal to or larger than the SubQCIF size and equal to or smaller than the VGA size. When an image is not scaled down (same size output), this restriction does not apply.

## 46.4.11 Capture Filter Size Clip Register (CFSZR)

CFSZR sets the clipping size for fine adjustment of the image size output from the filter, and must be set in combination with CFLCR. When clipping the output size of the filter, set the clipping size as a number of pixels, and the setting unit should be four pixels. CFSZR must be set even when scale-down is not performed (same size output).

In data synchronous fetch mode, set CFSZR according to the setting of CAPWR.

The scale-down filter in the CEU may output an odd number of pixels or lines depending on the settings. To adjust the output size of the filter, the CEU clips the destination image by using the number of pixels specified in CFSZR, as shown in Figure 46.33. The clipping size must be specified vertically and horizontally in 4-pixel units.

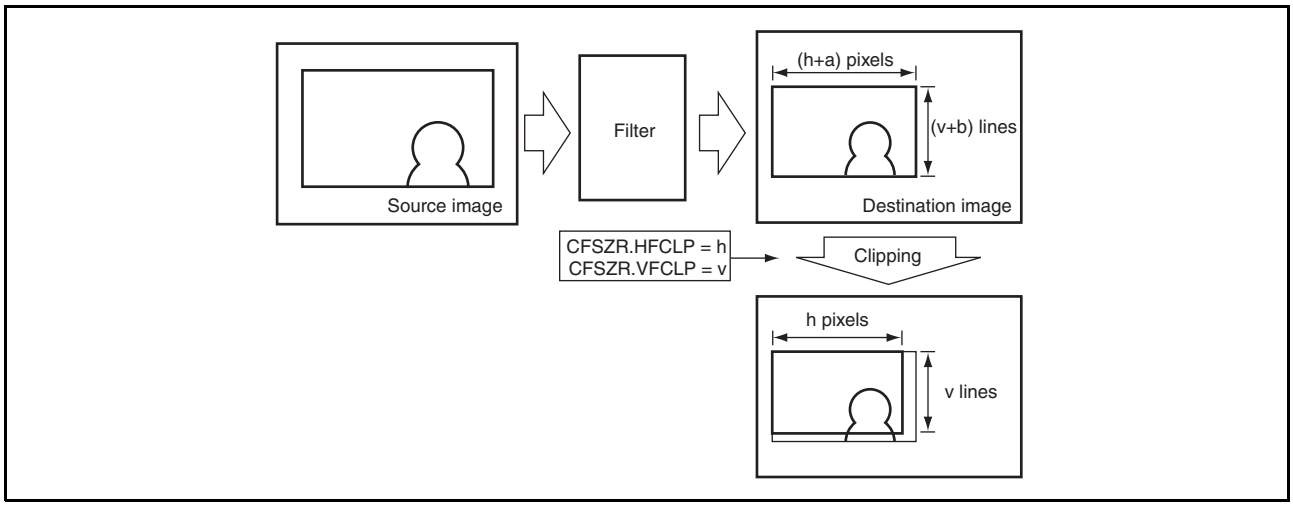

**Figure 46.33 Clipping of Image Output from Filter**

The pixels to be clipped are counted from the top-left corner of a display. The pixels located to the right of the specified number of pixels or below the specified number of lines are discarded by the clipping function. If the number of pixels specified in CFSZR is larger than that output from the filter, correct operation cannot be guaranteed. To avoid this, the clipping size specified in CFSZR must be equal to or smaller than the number of pixels output from the filter.

Note: In data synchronous fetch mode, the following settings are required. Data cannot be fetched correctly unless the following settings are made.
8-bit interface: VFCLP = CAPWR.VWDTH
HFCLP = CAPWR.HWDTH/2
16-bit interface: VFCLP = CAPWR.VWDTH
HFCLP = CAPWR.HWDTH

### 46.4.12 Capture Destination Width Register (CDWDR)

CDWDR sets the horizontal image size in the memory area where the captured image is to be output in 4-byte units (4-pixel units).

In data synchronous fetch mode, set CDWDR according to the setting of CAPWR.

This register is not used, during data enable fetch mode.

Therefore, the horizontal image size in the memory area where the captured image is to be stored must be set in these bits.<br>The maximum value to be set is 8188 bytes (8188 pixels).<br>In data synchronous fetch mode, set as follows:<br>8-bit interface: CHDW = CAPWR.HWDTH<br>16-bit interface: CHDW = CAPWR.HWDTH × 2<br>Note: * 8-byte units when writing to other than the on-chip RAM |

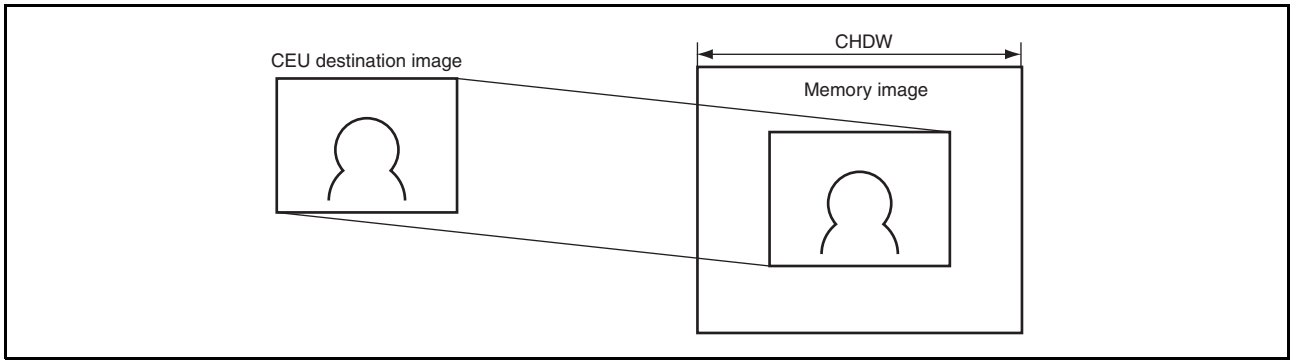

**Figure 46.34 Captured Image and Memory Area Image**

### 46.4.13 Capture Data Address Y Register (CDAYR)

CDAYR specifies the address where the luminance (Y) component of the captured data is to be stored in frame image capture or one-field image capture, the address where the luminance (Y) component of the captured top field is to be stored in both-field image capture, and the address where the fetched data is to be stored in data fetch. The CEU separates the captured image data into the luminance component data (Y) and the chrominance component data (C), and stores them in the memory via the bus. In frame image capture or one-field image capture, set the start address of the memory area where the Y (luminance) component of the captured data is to be stored by CDAYR. In both-field image capture, set the start address of the memory area where the Y (luminance) component of the captured top-field image is to be stored by CDAYR. In data fetch, set the start address of the memory area where data is to be stored by CDAYR.

Because the address must be specified in 32 bits, the address set by CDAYR must be in longword units. As the setting is in 4-pixel units for image capture and 4-byte units for data fetch, the lower two bits are always fixed to 0.

Set the address of the starting point of the memory area where the fetched data is to be stored in this register, as shown in Figure 46.35.

- Frame image capture: Set the address of the starting point of the memory area where the Y component of the captured image is to be stored.
- One-field image capture: Set the address of the starting point of the memory area where the Y component of the captured image is to be stored.
- Both-field image capture: Set the address of the starting point of the memory area where the Y component of the captured top-field image is to be stored.
- Data fetch: Set the address of the starting point of the memory area where the fetched data is to be stored. In data fetch mode, the data is simply stuffed in order from the start address so the end address becomes as follows:

**End address = CDAYR + number of fetched bytes**

- Data enable fetch bundle write: Set the address in 32-byte units.

## 46.4.14 Capture Data Address C Register (CDACR)

CDACR specifies the address where the chrominance (C) component of the captured data is to be stored in frame image capture or one-field image capture, and the address where the chrominance (C) component of the captured top field is to be stored in both-field image capture. The CEU separates the captured image data into the luminance component data (Y) and the chrominance component data (C), and stores them in the memory via the bus. In frame image capture or one-field image capture, set the start address of the memory area where the C (chrominance) component of the captured data is to be stored by CDACR. In both-field image capture, set the start address of the memory area where the C (chrominance) component of the captured top-field image is to be stored by CDACR. CDACR is not used in data fetch.

Because the address must be specified in 32 bits, the address set by CDACR must be in longword units. As the setting is in 4-pixel units, the lower two bits are always fixed to 0.

Set the address of the starting point of the memory area where the C component of the captured image is to be stored in this register, as shown in Figure 46.36. The C component has an output data format like that in Figure 46.37, and is saved in the memory in this format.

- Frame image capture: Set the address of the starting point of the memory area where the C component of the captured image is to be stored.
- One-field image capture: Set the address of the starting point of the memory area where the C component of the captured image is to be stored.
- Both-field image capture: Set the address of the starting point of the memory area where the C component of the captured top-field image is to be stored.

### 46.4.15 Capture Data Bottom-Field Address Y Register (CDBYR)

CDBYR specifies the address where the luminance (Y) component of the captured bottom-field data is to be stored in both-field image capture. The CEU separates the captured image data into the luminance component data (Y) and the chrominance component data (C), and stores them in the memory via the bus. Set the start address of the memory area where the Y (luminance) component of the captured bottom-field image is to be stored by CDBYR. CDBYR is not used in frame image capture, one-field image capture, or data fetch.

Because the address must be specified in 32 bits, the address set by CDBYR must be in longword units. As the setting is in 4-pixel units, the lower two bits are always fixed to 0.

### 46.4.16 Capture Data Bottom-Field Address C Register (CDBCR)

CDBCR specifies the address where the chrominance (C) component of the captured bottom-field data is to be stored in both-field image capture. The CEU separates the captured image data into the luminance component data (Y) and the chrominance component data (C), and stores them in the memory via the bus. Set the start address of the memory area where the C (chrominance) component of the captured bottom-field image is to be stored by CDBCR. CDBCR is not used in frame image capture, one-field image capture, or data fetch.

Because the address must be specified in 32 bits, the address set by CDBCR must be in longword units. As the setting is in 4-pixel units, the lower two bits are always fixed to 0.

Set the address of the starting point of the memory area where the C component of the captured bottom-field image is to be stored in this register, as shown in Figure 46.39. The C component has an output data format like that in Figure 46.40, and is saved in the memory in this format.

## 46.4.17 Capture Bundle Destination Size Register (CBDSR)

CBDSR sets the size of output to memory in a bundle write. The number of output lines should be specified for image capture or data synchronous fetch. The number of bytes should be specified for data enable fetch.

### (a) Image capture and data synchronous fetch

Set the number of lines of captured data to be written to the memory by a bundle write as a multiple of eight. This register is valid only when the CBE bit in CDOCR is 1. When the CBE bit in CDOCR is 1 and this register cleared to H'0, this module operates with the number of lines of captured data to be written to the memory as eight. The maximum number of lines that can be set is 1,920 (H'780). Only bits CBVS[11:3] are valid.

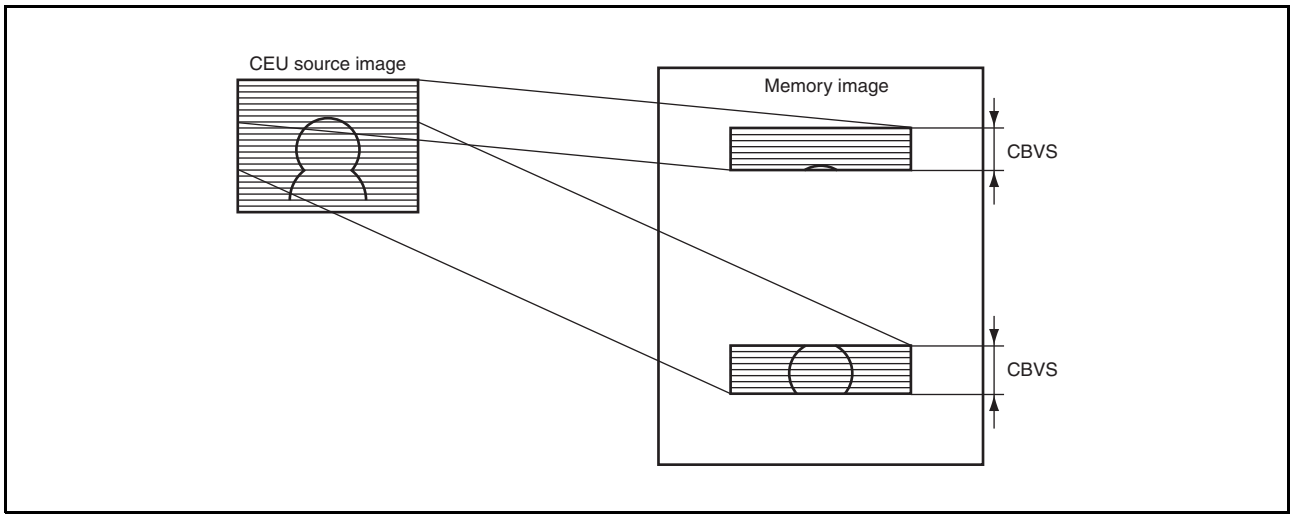

**Figure 46.41 Image of Storing Captured Image in Memory by Bundle Write**

### (b) Data enable fetch

Set the number of bytes of captured data to be written to the memory by a bundle write as a multiple of 32. This register is valid only when the CBE bit in CDOCR is 1. The minimum settable size is 512 bytes. When a number smaller than 512 bytes is specified, operation is not guaranteed.

## 46.4.18 Capture Low-Pass Filter Control Register (CLFCR)

CLFCR specifies whether or not to operate the low-pass filter. In data fetch mode, clear the LPF bit to B'0.

The characteristic of the low-pass filter installed in the CEU causes the phase location of the image processed by the low-pass filter to be shifted right by one pixel compared to the raw image.

## 46.4.19 Firewall Operation Control Register (CFWCR)

CFWCR specifies the upper limit of the write addresses in data enable fetch. When the VD input from an external module dose not go low and end notification is not given, this register can prevent writing to memory from being out of control.

This register is enabled only in data enable fetch.

For data output from the CEU, the COLS, COWS, and COBS bits control swapping in 32-bit, 16-bit, and 8-bit units, respectively. Set these bits when data is misaligned because of a difference in endian. The data swapping bits are shown below. These bits can be set similarly in data fetch mode.

Data can be swapped in 8-bit, 16-bit, 32-bit units, or in 32 bits, 16 bits and 8 bits, as shown in Figure 46.45. To enable data swapping, set the corresponding control bit to B'1.

## 46.4.22 Capture Event Flag Clear Register (CETCR)

CETCR notifies the CPU of the source of an interrupt that is generated in the CEU. The flags of CETCR can be used as interrupt signals. When the corresponding interrupt is enabled, an interrupt is generated. To clear the interrupt, clear the bit corresponding to the interrupt source to 0. After several cycles have passed after modifying the bit, the interrupt is cleared.

To clear the bit corresponding to the interrupt source to be cleared to 0 and retain that state, write 1 to that bit. For example, to clear only the CPE bit to 0, write H'FFFF FFFE to CETCR.

In CETCR, only bits to which 0 is written are cleared. Bits to which 1 is written retain their current values. To clear an interrupt source, write 0 only to the bit corresponding to the interrupt source to be cleared, and 1 to the other bits.

Note: Since the CETCR value becomes undefined in the following cases, clear all bits in CETCR to 0.

- VD and HD bits immediately after power-on reset or the deep-standby mode is entered
- All bits after the software standby or module standby mode is entered
- VD and HD bits after the polarities of the capture interface sync signals are changed

## 46.4.23 Capture Status Register (CSTSR)

CSTSR indicates the internal status of the CEU. CSTSR differs from CETCR in that no interrupt is generated for the events indicated in CSTSR.

The CEU operating/halt state can be confirmed using CSTSR. To confirm the halt state of the CEU, make sure that the status bit (bit 0) indicating that the CEU is operating is cleared to 0 for sure.

## 46.4.25 Capture Data Address Y Register 2 (CDAYR2)

CDAYR2 specifies the address for the luminance (Y) component used in a bundle write and the address for data storage in a bundle write in data fetch. CDAYR2 is used only in a bundle write.

CDAYR2 specifies the address where the Y component of the captured data is to be stored in frame image capture or one-field image capture, the address where the Y component of the captured top field is to be stored in both-field image capture, and the address where data is to be stored in data fetch. The CEU separates the captured image data into the luminance component data (Y) and the chrominance component data (C), and stores them in the memory via the bus. In frame image capture or one-field image capture, set the start address of the memory area where the Y component of the captured data is to be stored by CDAYR2. In both-field image capture, set the start address of the memory area where the Y component of the captured top-field image is to be stored by CDAYR2. In data fetch, set the start address of the memory area to be used for data storage.

The address specified by this register must be in 32-bit units. As the setting is in 4-pixel units, the lower two bits are always fixed to 0.

### 46.4.26 Capture Data Address C Register 2 (CDACR2)

CDACR2 specifies the address for the chrominance (C) component used in a bundle write. CDACR2 is used only in a bundle write.

CDACR2 specifies the address where the C component of the captured data is to be stored in frame image capture or one-field image capture, and the address where the C component of the captured top field is to be stored in both-field image capture. The CEU separates the captured image data into the luminance component data (Y) and the chrominance component data (C), and stores them in the memory via the bus. In frame image capture or one-field image capture, set the start address of the memory area where the C component of the captured data is to be stored by CDACR2. In both-field image capture, set the start address of the memory area where the C component of the captured top-field image is to be stored by CDACR2. CDACR2 is not used in data fetch.

The address specified by this register must be in 32-bit units. As the setting is in 4-pixel units, the lower two bits are always fixed to 0.

## 46.4.27 Capture Data Bottom-Field Address Y Register 2 (CDBYR2)

CDBYR2 specifies the address for the luminance (Y) component of the bottom field used in a bundle write. CDBYR2 is used only in a bundle write.

CDBYR2 specifies the address where the Y component of the captured bottom-field data is to be stored in both-field image capture. The CEU separates the captured image data into the luminance component data (Y) and the chrominance component data (C), and stores them in the memory via the bus. Set the start address of the memory area where the Y component of the bottom-field image captured in both-field image capture is to be stored by CDBYR2. CDBYR2 is not used in frame image capture, one-field image capture, or data fetch.

The address specified by this register must be in 32-bit units. As the setting is in 4-pixel units, the lower two bits are always fixed to 0.

In this register, set the address of the starting point of the memory area where the Y component of the captured bottom-field image is to be stored in a bundle write, as shown in Figure 46.54.

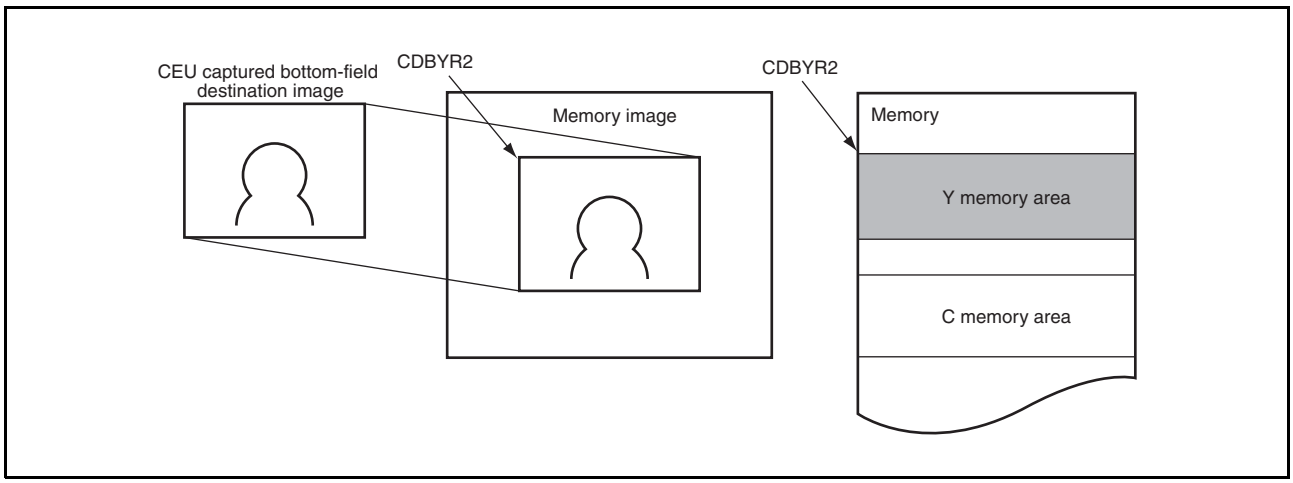

**Figure 46.54 Relationship between Captured Bottom-Field Image and Y Component Memory Area**

## 46.4.28 Capture Data Bottom-Field Address C Register 2 (CDBCR2)

CDBCR2 specifies the address for the chrominance (C) component of the bottom field used in a bundle write. CDBCR2 is used only in a bundle write.

CDBCR2 specifies the address where the C component of the captured bottom-field data is to be stored in both-field image capture. The CEU separates the captured image data into the luminance component data (Y) and the chrominance component data (C), and stores them in the memory via the bus. Set the start address of the memory area where the C component of the bottom-field image captured in both-field image capture is to be stored by CDBCR2. CDBCR2 is not used in frame image capture, one-field image capture, or data fetch.

The address specified by this register must be in 32-bit units. As the setting is in 4-pixel units, the lower two bits are always fixed to 0.

## 46.5 Usage Notes for CEU

### 46.5.1 Conditions for Connection to an External Module

#### (1) Clock Frequency

The external input clock should have a frequency at most the same as the CEU operating clock frequency (Bφ), with jitter on both sides included.

CEU operating clock frequency (Bφ) ≥ External input clock frequency

#### (2) Blanking Period

The period from the last valid pixel in each line to the next horizontal sync signal HD must be at least 20 cycles.

#### (3) Fixed Period of Field Identification Signal

The field identification signal FLD should be fixed for at least 1-HD period since a VD input

### 46.5.2 Restrictions on Input/Output Functions

Table 46.11 lists the restrictions regarding the CEU input/output functions.

**Table 46.11 Restrictions on CEU Input/Output Functions**

| Item | Restrictions |
|---|---|
| External module interface | The operating clock of the external module (VIO_CLK) should always have a frequency at most the same as that of the CEU operating clock (Bφ), with jitter on both sides included. |
| | Selecting the interface, or modifying the frequency of the external module operating clock or HD/VD polarity must be done when capture operations are halted for sure. |
| | The capture horizontal size in image capture must be specified as follows:<br>8-bit interface: 8-cycle units*1<br>16-bit interface: 4-cycle units*2<br>Note 1. 16-cycle units when writing to other than the on-chip RAM<br>Note 2. 8-cycle units when writing to other than the on-chip RAM |
| | The capture horizontal size in data fetch must be specified as follows:<br>8-bit interface: 4-cycle units*1<br>16-bit interface: 2-cycle units*2<br>Note 1. 8-cycle units when writing to other than the on-chip RAM<br>Note 2. 4-cycle units when writing to other than the on-chip RAM |
| | The capture vertical size must be specified in 4-line units. |
| | The maximum number of cycles in the horizontal sync signal period should be 16,375 cycles of external input clock for 8-bit digital image input pins, or 16,379 cycles of external input clock for 16-bit digital image input pins. |
| | The maximum number of lines (HD count) in the vertical sync signal should be 16,382 lines. |
| | The minimum number of captured pixels should be sub-QCIF (128 × 96). |
| | The maximum number of captured pixels should be 5 megapixels (2,560 × 1,920). |
| | Captured size in data enable fetch<br>Maximum: 6 Mbytes (2,048 × 1,536 × 2)<br>Minimum: 16 bytes |

### 46.5.3 Cooperation with Video Display Controller 5

Since the input data are written to the memory separately as Y data and CbCr data in image capture mode, the captured data cannot be displayed in the video display controller 5.

### 46.5.4 Software Reset

For transitions to the software reset state by the CPKIL bit in the CAPSR register, see section 55.3.6, Software Reset. However, where the procedure refers to the SRST bit, read this as the CPKIL bit in the CAPSR register.

# 47. Pixel Format Converter

The pixel format converter has a color matrix that is used to adjust offsets and nine-axis gain for image data in the YCbCr or RGB format. This enables brightness adjustment, gain adjustment, and YCbCr and RGB mutual conversion. This LSI incorporates two channels of pixel format converters.

## 47.1 Features

- Input pixel data
  [RGB] RGB888 and RGB565
  [YCbCr] YCbCr422
- Output pixel data
  [RGB] ARGB888 and RGB565
  [YCbCr] YCbCr422
- Input buffer: 32-byte FIFO buffer configuration
- Output buffer: 32-byte FIFO buffer configuration
- Interrupt sources: Three
  Input FIFO empty, output FIFO full, and PFV error (input FIFO overflow and output FIFO underflow)
- The input FIFO empty and output FIFO full interrupts can activate the direct memory access controller (DMAC) to transfer data.
- When this module is not used, it can be stopped to reduce power consumption by stopping the clock supply to this module.

Figure 47.1 shows a block diagram of this module.

## 47.2.4 PFV Input Buffer Register (PFVID)

PFVID is 32-byte buffer memory that stores pixel data to be converted. The buffer memory has a FIFO structure (FIFO buffer). If an attempt is made to write data to the input buffer while it does not have empty space, the input FIFO overflow interrupt flag is set to 1; the written data is ignored in this case.

## 47.2.5 PFV Output Buffer Register (PFVOD)

PFVOD is 32-byte buffer memory that stores the converted pixel data. The buffer memory has a FIFO structure (FIFO buffer). If an attempt is made to read data from the output buffer while it does not have valid data, the output FIFO underflow interrupt flag is set to 1; the read data is undefined in this case.

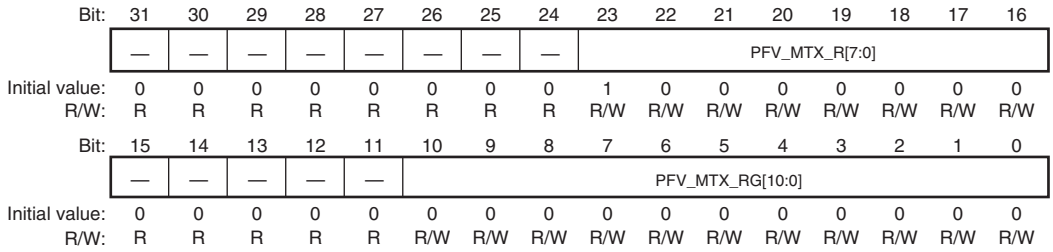
## 47.2.14 PFV Matrix CRR Adjustment Register 0 (PFV_MTX_CRR_ADJ0)

This register specifies offset and gain adjustment for output Cr/R data.



| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| 31 to 24 | — | All 0 | R | Reserved<br>These bits are always read as 0. The write value should always be 0. |

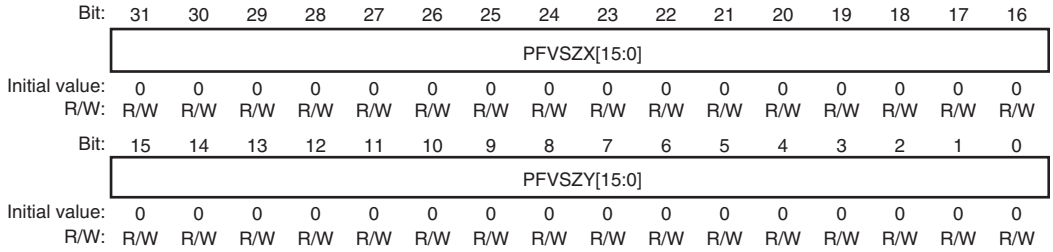
## 47.2.16 PFV Image Size Setting Register (PFVSZR)

This register specifies the horizontal and vertical sizes of an image.

Be sure to set up this register when the output pixel format is RGB565 and 2 × 2 pattern dither is used for bit reduction.



| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| 31 to 16 | PFVSZX[15:0] | H'0000 | R/W | Horizontal Size<br>These bits specify the horizontal size. |
| 15 to 0 | PFVSZY[15:0] | H'0000 | R/W | Vertical Size<br>These bits specify the vertical size. |

## 47.3 Operation

### 47.3.1 Overview

This module uses a color matrix for offset and nine-axis gain adjustment to apply brightness adjustment, gain adjustment, and YCbCr and RGB mutual conversion for image data in the YCbCr or RGB format.

### 47.3.2 Input/Output Data Format

This module allows selection of input and output data formats from RGB888 (ARGB8888 for output), RGB565, and YCbCr422. When the input and output FIFOs are accessed in 32 bits, data allocation can be modified through the DINSWAP32 and DOUTSWAP32 bit settings in PFVCR as shown below.

#### (1) RGB888 (ARGB8888) 32 bits/pixel

[DINSWAP32 and DOUTSWAP32 = 00 is specified]

| b31 b24 | b23 b16 | b15 b8 | b7 b0 |
|---|---|---|---|
| Alpha* 8 bits | Red 8 bits | Green 8 bits | Blue 8 bits |

[DINSWAP32 and DOUTSWAP32 = 01 is specified]

| b31 b24 | b23 b16 | b15 b8 | b7 b0 |
|---|---|---|---|
| Red 8 bits | Alpha* 8 bits | Blue 8 bits | Green 8 bits |

[DINSWAP32 and DOUTSWAP32 = 10 is specified]

| b31 b24 | b23 b16 | b15 b8 | b7 b0 |
|---|---|---|---|
| Green 8 bits | Blue 8 bits | Alpha* 8 bits | Red 8 bits |

[DINSWAP32 and DOUTSWAP32 = 11 is specified]

| b31 b24 | b23 b16 | b15 b8 | b7 b0 |
|---|---|---|---|
| Blue 8 bits | Green 8 bits | Red 8 bits | Alpha* 8 bits |

Note: * Alpha is used only for output and it is the value specified in the ALPHA bits in PFVACR.

#### (2) RGB565 16 bits/pixel

[DINSWAP32 and DOUTSWAP32 = 00 is specified]

| b31 b24 | b23 b16 | b15 b8 | b7 b0 |
|---|---|---|---|
| RGB565 0 pixels | | RGB565 1 pixel | |

[DINSWAP32 and DOUTSWAP32 = 01 is prohibited]

[DINSWAP32 and DOUTSWAP32 = 10 is specified]

| b31 b24 | b23 b16 | b15 b8 | b7 b0 |
|---|---|---|---|
| RGB565 1 pixel | | RGB565 0 pixels | |

[DINSWAP32 and DOUTSWAP32 = 11 is prohibited]

### (3) YCbCr422 32bits/pixel

[DINSWAP32 and DOUTSWAP32 = 00 is specified]

| b31 b24 | b23 b16 | b15 b8 | b7 b0 |
|---|---|---|---|
| Cb 8 bits | Y0 8 bits | Cr 8 bits | Y1 8 bits |

[DINSWAP32 and DOUTSWAP32 = 01 is specified]

| b31 b24 | b23 b16 | b15 b8 | b7 b0 |
|---|---|---|---|
| Y0 8 bits | Cb 8 bits | Y1 8 bits | Cr 8 bits |

[DINSWAP32 and DOUTSWAP32 = 10 is specified]

| b31 b24 | b23 b16 | b15 b8 | b7 b0 |
|---|---|---|---|
| Cr 8 bits | Y1 8 bits | Cb 8 bits | Y0 8 bits |

[DINSWAP32 and DOUTSWAP32 = 11 is specified]

| b31 b24 | b23 b16 | b15 b8 | b7 b0 |
|---|---|---|---|
| Y1 8 bits | Cr 8 bits | Y0 8 bits | Cb 8 bits |

## 47.3.3 Color Matrix

By using a color matrix, input data offsets and nine-axis gain can be adjusted. This enables brightness adjustment, gain adjustment, and YCbCr and GBR mutual conversion.

### (1) GBR to GBR Conversion

YGIN_A = YGIN + PFV_MTX_YG – 128
CBBIN_A = CBBIN + PFV_MTX_B – 128
CRRIN_A = CRRIN + PFV_MTX_R – 128
YGOUT = (PFV_MTX_GG × YGIN_A + PFV_MTX_GB × CBBIN_A + PFV_MTX_GR × CRRIN_A) ÷ 256
CBBOUT = (PFV_MTX_BG × YGIN_A + PFV_MTX_BB × CBBIN_A + PFV_MTX_BR × CRRIN_A) ÷ 256
CRROUT = (PFV_MTX_RG × YGIN_A + PFV_MTX_RB × CBBIN_A + PFV_MTX_RR × CRRIN_A) ÷ 256

### (2) GBR to YCbCr Conversion

YGIN_A = YGIN + PFV_MTX_YG – 128
CBBIN_A = CBBIN + PFV_MTX_B – 128
CRRIN_A = CRRIN + PFV_MTX_R – 128
YGOUT = (PFV_MTX_GG × YGIN_A + PFV_MTX_GB × CBBIN_A + PFV_MTX_GR × CRRIN_A) ÷ 256
CBBOUT = (PFV_MTX_BG × YGIN_A + PFV_MTX_BB × CBBIN_A + PFV_MTX_BR × CRRIN_A) ÷ 256 + 128
CRROUT = (PFV_MTX_RG × YGIN_A + PFV_MTX_RB × CBBIN_A + PFV_MTX_RR × CRRIN_A) ÷ 256 + 128

**Table 47.2 Matrix Coefficient (Typical Value) for SMPTE 293M**

| | YGIN | | CBBIN | | CRRIN | |

### (3) YCbCr to GBR Conversion

YGIN_A = YGIN + PFV_MTX_YG – 128
CBBIN_A = CBBIN – 128
CRRIN_A = CRRIN – 128
YGOUT = (PFV_MTX_GG × YGIN_A + PFV_MTX_GB × CBBIN_A + PFV_MTX_GR × CRRIN_A) ÷ 256
CBBOUT = (PFV_MTX_BG × YGIN_A + PFV_MTX_BB × CBBIN_A + PFV_MTX_BR × CRRIN_A) ÷ 256
CRROUT = (PFV_MTX_RG × YGIN_A + PFV_MTX_RB × CBBIN_A + PFV_MTX_RR × CRRIN_A) ÷ 256

**Table 47.3 Matrix Coefficient (Typical Value) for SMPTE 293M**

| | YGIN | | CBBIN | | CRRIN | |

| YGOUT | 1.000 | PFV_MTX_GG= 256 | –0.344 | PFV_MTX_GB= 1960 | –0.714 | PFV_MTX_GR= 1865 |
| CBBOUT | 1.000 | PFV_MTX_BG= 256 | 1.772 | PFV_MTX_BB= 454 | 0.000 | PFV_MTX_BR= 0 |
| CRROUT | 1.000 | PFV_MTX_RG= 256 | 0.000 | PFV_MTX_RB= 0 | 1.402 | PFV_MTX_RR= 359 |

### (4) YCbCr to YCbCr Conversion

YGIN_A = YGIN + PFV_MTX_YG – 128
CBBIN_A = CBBIN – 128
CRRIN_A = CRRIN – 128
YGOUT = (PFV_MTX_GG × YGIN_A + PFV_MTX_GB × CBBIN_A + PFV_MTX_GR × CRRIN_A) ÷ 256
CBBOUT = (PFV_MTX_BG × YGIN_A + PFV_MTX_BB × CBBIN_A + PFV_MTX_BR × CRRIN_A) ÷ 256 + 128
CRROUT = (PFV_MTX_RG × YGIN_A + PFV_MTX_RB × CBBIN_A + PFV_MTX_RR × CRRIN_A) ÷ 256 + 128

### 47.3.4 Bit Reduction

For RGB565 output, the number of RGB data bits is reduced from eight bits to six or five bits. The operation mode can be selected from round-off mode and 2 × 2 pattern dither mode through the DTH_ON bit in PFVCR. When selecting 2 × 2 pattern dither mode, be sure to set up the PFVSZX and PFVSZY bits in PFVSZR.
From the values set in the PFVSZX and PFVSZY bits in PFVSZR, this module generates horizontal and vertical sync signals.
The following shows the specifications of 2 × 2 pattern dither operation.

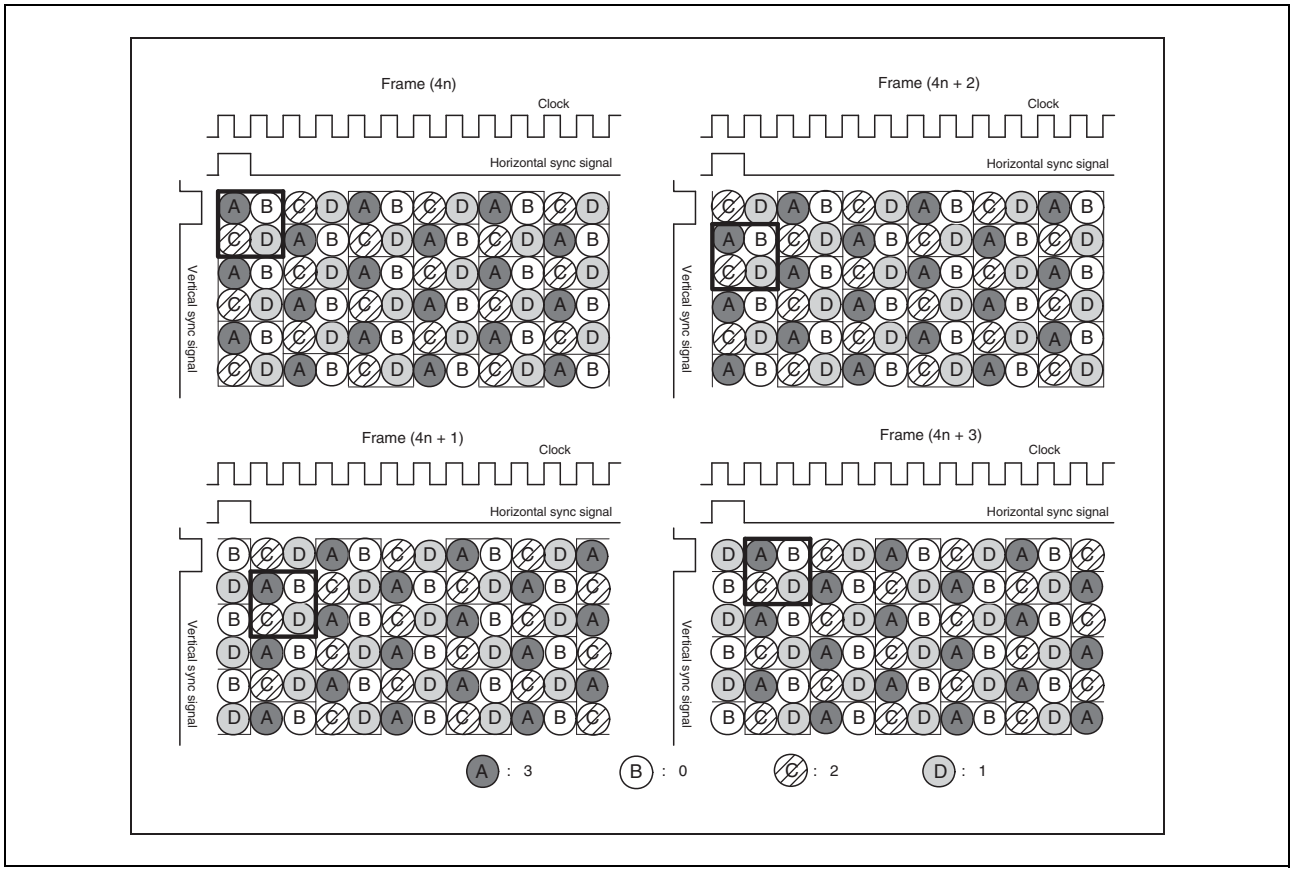

**Figure 47.2 Specifications of 2 × 2 Pattern Dither Operation**

The conversion equations are as follows.

- Round-off mode

1. 8 bits to 6 bits
   Output RGB data[7:2] = Input RGB data[7:0] ÷ 4 (round off to an integer)
2. 8 bits to 5 bits
   Output RGB data[7:3] = Input RGB data[7:0] ÷ 8 (round off to an integer)

- 2 × 2 pattern dither

1. 8 bits to 6 bits
   Output RGB data[7:2] = Input RGB data[7:0] ÷ 4 + pattern value at the first decimal place (truncate the number below the decimal point after addition)
2. 8 bits to 5 bits
   Output RGB data[7:3] = Input RGB data[7:0] ÷ 32 + pattern value at the first decimal place (truncate the number below the decimal point after addition)

## 47.4 Interrupt Requests

This module has three interrupt requests: input FIFO empty, output FIFO full, and PFV error. Table 47.4 summarizes the interrupt requests.

**Table 47.4 List of Interrupt Requests**

| Interrupt Request | Abbreviation | Interrupt Request Condition | DMAC Activation |
|---|---|---|---|
| Input FIFO empty | IFEI | (PFVISR.IFEMP = 1) & (PFVICR.IFEN = 1) | Possible |
| Output FIFO full | OFFI | (PFVISR.OFFUL = 1) & (PFVICR.OFEN = 1) | Possible |
| PFV error | PFVEI | ((PFVISR.IFOVF=1) \| (PFVISR.OFUDF=1)) & (PFVICR.PFVEEN=1) | Not possible |

When an interrupt condition shown in Table 47.4 becomes 1, this module sends an interrupt request. The input FIFO empty and output FIFO full interrupt requests can activate the direct memory access controller when the direct memory access controller is set to allow this. In this case, the interrupts from this module are not sent to the CPU.

# 48. SCUX

The SCUX consists of sampling converters, digital volume units, and a mixer. It is connected to the SSIF module to have an interface with external modules.

## 48.1 Features

### (1) [SRC] Sampling Rate Conversion

- Asynchronous or synchronous sampling rate conversion is possible*1
- Sampling rate (synchronous mode)*2
  Input [KHz]: 8, 11.025, 12, 16, 22.05, 24, 32, 44.1, 48, 64, 88.2, or 96 is selectable
  Output [KHz]: 8, 16, 24, 32, 44.1, 48, or 96 is selectable
- Sampling rate (asynchronous mode)*2
  Input/output [KHz]: 1 to 96
- Supported bit sizes are 16 bits and 24 bits
- Sound quality: −132 dB or less*3
- 1, 2, 4, 6, or 8 channels are supported*4
- DMA transfer with on-chip memory or external memory and direct transfer with the SSIF module are possible

Note 1. The synchronous mode can be selected only when the SCUX is connected to the FFD and FFU modules. For details, refer to section 48.4.5.
Note 2. The selectable sampling rates depend on the number of used channels and rate ratio. For details, refer to section 48.3.22 and section 48.4.7.
Note 3. The data format is a 24-bit value.
Note 4. The number of selectable channels depends on the sampling rate and route. For details, refer to section 48.4.7.

### (2) [DVU] Digital Volume and Mute Functions

- Digital volume, volume ramp, and zero cross mute are provided as functions to adjust the volume
- The digital volume is set as a 24-bit fixed-point value within the range from a multiple of 0 to 8 (mute, −120 to 18 dB)
- Volume ramp can be used to perform soft mute, fade in, fade out, and volume change as desired
- The ramp time of volume ramp can be changed and set within the sampling range of $2^0$ to $2^{23}$
- Zero cross mute turns the sound mute at the zero cross point of audio data
- Direct transfer with the SSIF module and transfer with the mixer are possible

### (3) [MIX] Mixer

- Data of two to four source systems can be mixed (added together) into one system
- The ratio to add the sources can be set
- The ratio can be changed dynamically
- Volume ramp enables mixing to be performed (ramp time is variable)
- Only direct transfer with the SSIF module is possible

Figure 48.1 shows a block diagram of the SCUX.

If the request size equals the FIFO size, the request size must be a multiple of the number of channels so that the operation is correct. For example, the request size and FIFO size are 256, the number of channels can be set to 1, 2, 4, or 8. If the number of channels is not set to any of the numbers, FIFO overflow may occur.<br>2. These bits are only settable for FFD0_0 and FFD0_1. Setting these bits in the registers for FFD0_2 and FFD0_3 is prohibited. |

## 48.3.8 FFD0_n FIFO Download Pass Register (FFDPR_FFD0_n) (n = 0, 1, 2, 3)

FFDPR_FFD0_n is a 32-bit readable/writable register that sets the input/output route of audio data.

## 48.3.11 FFD0_n FIFO Download Event Clear Register (DEVCR_FFD0_n) (n = 0, 1, 2, 3)

DEVCR_FFD0_n is a 32-bit readable/writable register that clears SCUFDIn interrupt requests. When an interrupt event is generated, the relevant bit in this register is automatically set to 1 and 1 is retained until 0 is written to that bit.

| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

## 48.3.17 FFU0_n FIFO Upload Event Clear Register (UEVCR_FFU0_n) (n = 0, 1, 2, 3)

UEVCR_FFU0_n is a 32-bit readable/writable register that clears SCUFUIn interrupt requests. When an interrupt event is generated, the relevant bit in this register is automatically set to 1 and 1 is retained until 0 is written to that bit.

| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

Note 1. Readable/writable. When 0 is written, the bit is initialized. Writing 1 to the bit is ignored. Write 0 only to each bit corresponding to the interrupt source to be cleared; write 1 to other bits.

### 48.3.18 2SRC0_m Initialization Register p (SRCIRp_2SRC0_m) (m = 0, 1; p = 0, 1)

SRCIRp_2SRC0_m is a 32-bit readable/writable register that initializes the SRC internal circuit.

### 48.3.22 2SRC0_m IFS Value Setting Register p (IFSVRp_2SRC0_m) (m = 0, 1; p = 0, 1)

IFSVRp_2SRC0_m is a 32-bit readable/writable register that sets the INTIFS value.

| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| 31 to 28 | — | All 0 | R | Reserved<br>These bits are always read as 0. The write value should always be 0. |
| 27 to 0 | INTIFS | All 0 | R/W | Initial Value of FSI<br>These bits set initial value of FSI. Set the input sampling rate and output sampling rate within the restricted range determined by the number of channels.<br>Example:<br>Fin = 32 kHz<br>Fout = 44.1 kHz<br>FSI = $2^{22}$ * 32000/44100 = 3043485 = 0x02E709D |

When using the SRC in asynchronous mode, INTIFS is given as the initial value of FSI, which is the sampling conversion function. Therefore, after setting the INTIFSEN bit in IFSCRp_2SRC0_m to 1, set the INTIFS bits to the desired value. The SRC automatically detects the input sampling frequency and output sampling frequency. Based on this, the FSI value is calculated so that the following equation is satisfied.

$$\frac{Fin}{Fout} \approx \frac{FSI}{FSO}$$

[Legend]
Fin: Input sampling frequency
Fout: Output sampling frequency
FSI: Input sampling rate
FSO: Output sampling rate (fixed value: $2^{22}$ = 0x0400000)

When using the SRC in synchronous mode, the value set in INTIFS is used as the FSI value from beginning to end. The value set in INITFS is shown in Table 48.3 to Table 48.8.

**Table 48.3 INITFS Setting (Delay Mode: Normal, Number of Channels: 1 or 2)**

### 48.3.24 2SRC0_m Minimum FS Setting Register p (MNFSRp_2SRC0_m) (m = 0, 1; p = 0, 1)

MNFSRp_2SRC0_m is a 32-bit readable/writable register that sets the minimum value of FS.

| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

| 27 to 0 | MINFS | All 0 | R/W | Minimum Value of FS Ratio<br>These bits set the FS ratio to start fading out the output data to mute under the situation that the input timing stops during SRC processing. This setting value should be less than the value of IFSVRp_2SRC0_m register.<br>Example:<br>Fin = 32 kHz<br>Fout = 44.1 kHz<br>FSI = $2^{22}$ * 32000/44100 = 3043485 = 0x02E709D<br>MINFS = FSI * 98% = 2982615 = 0x02D82D7<br>Set the ratio which is out of the range of the jitter.<br>(The recommended value is from 90 to 98 percent.) |

### 48.3.25 2SRC0_m Buffer Size Setting Register p (BFSSRp_2SRC0_m) (m = 0, 1; p = 0, 1)

BFSSRp_2SRC0_m is a 32-bit readable/writable register that sets the buffer size. This register setting is valid only when SRCCRp_2SRC0_m.BUFMD = 1.

| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

After the INIT bit of SRCIRp_2SRC0_m register is set to 0, 0 data is stored into the SRC until the number of input data reaches to the setting value of these bits. The data input before the INIT bit is set to 0 is discarded. After the number of input data reaches to the setting value, input data is stored into the SRC. |

## 48.3.28 2SRC0_m Event Mask Register p (SEVMRp_2SRC0_m) (m = 0, 1; p = 0, 1)

SEVMRp_2SRC0_m is a 32-bit readable/writable register that enables or disables SCUAIm interrupt requests. The name of the interrupt source corresponding to the interrupt request from SEVMRp_2SRC0_0 is SCUAI0 and that corresponding to the interrupt request from SEVMRp_2SRC0_1 is SCUAI1.

## 48.3.29 2SRC0_m Event Clear Register p (SEVCRp_2SRC0_m) (m = 0, 1; p = 0, 1)

SEVCRp_2SRC0_m is a 32-bit readable/writable register that clears SCUAIm interrupt requests. When an interrupt event is generated, the relevant bit in this register is automatically set to 1 and 1 is retained until 0 is written to that bit.

| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

### 48.3.65 DMA Transfer Register for FFD0_n (DMATDn_CIM) (n = 0, 1, 2, 3)

DMATDn_CIM is a 32-bit register that stores the data to be transmitted to FFD0_n. The data written to DMATDn_CIM is automatically stored in FFD0_n. When the number of idle data bytes in FFD0_n becomes equal to or greater than the value set in DRQSR_FFD0_n.SIZE, a data transfer request is issued. When the DMA controller is used (DMACR_CIM.DMAMDFFDn = 1), a transfer request for the number of counts set in DRQSR_FFD0_n.SIZE is sent to the DMA controller. When the interrupt controller is used (DEVMR_FFD0_n.DEVMRQ = 1), data is written in this register for the number of counts set in DRQSR_FFD0_n.SIZE.

In the SCUX internal block, audio data is handled in the 24-bit big endian format. When this register is accessed in 32-bit units, the lower eight bits are not used and only the upper 24 bits are used, as shown in Figure 48.2. When the SCUX is used in 16-bit mode, the valid data needs to be located at the MSB of audio data. Therefore, when this register is accessed in 16-bit units, the written data is located in the upper 16 bits of audio data and the lower eight bits are fixed to 0 in the CIM block. When the SCUX is used in 16-bit mode and this register is accessed in 32-bit units, since bits [15:8] of the data to be written is passed to the FFD block without change, 0 should be written to bits [15:8].

### 48.3.66 DMA Transfer Register for FFU0_n (DMATUn_CIM) (n = 0, 1, 2, 3)

DMATUn_CIM is a 32-bit register that stores the data received from FFU0_n. When data is read from DMATUn_CIM, the next data is automatically transferred from FFU0_n. When the number of data bytes in FFU0_n becomes equal to or greater than the value set in URQSR_FFU0_n.SIZE, a data transfer request is issued. When the DMA controller is used (DMACR_CIM.DMAMDFFUn = 1), a transfer request for the number of counts set in URQSR_FFU0_n.SIZE is sent to the DMA controller. When the interrupt controller is used (UEVMR_FFU0_n.UEVMRQ = 1), data is read from this register for the number of counts set in URQSR_FFU0_n.SIZE.

When this register is accessed in 32-bit units, audio data is located in the upper 24 bits and the lower eight bits are always read as 0, as shown in Figure 48.3. When this register is accessed in 16-bit units, the upper 16 bits of audio data are read as valid data. When the SCUX is used in 16-bit mode and this register is accessed in 32-bit units, the lower eight bits are always read as 0 and bits [15:8] of the read data are read as a value dependent on the internal operation result in the SRC.

## 48.3.67 SSI Route Select Register (SSIRSEL_CIM)

SSIRSEL_CIM is a 32-bit readable/writable register that selects the SSIF channel to be connected to each SRC during direct transfer with the SSIF module. This register setting has no meaning when a route between the FFD or FFU module is selected. The IPSLR_IPC0_n and OPSLR_OPC0_n registers are used to select connection between the SSIF or FFD/FFU module. The DVUBR_DVU0_n register is used to specify whether the DVU is used or not.

## 48.4 Operation

### 48.4.1 Initial Setting Procedure

Figure 48.6 to Figure 48.8 show the initial setting procedure of the SCUX. For details on register setting, refer to section 48.3, Register Descriptions.

### 48.4.2 Transfer Start Procedure and Stop Procedure

Figure 48.9 to Figure 48.11 show the transfer start procedure and stop procedure of the SCUX. For details on register setting, refer to section 48.3, Register Descriptions.

Note: * After it has been used once, the FFD/FFU module can be reused without applying a software reset. If this is required, the number of writing and reading operations to and from the FFD and FFU modules should be an integer multiple of the number of FIFO stages used the first time.

### 48.4.3 Data Rearrangement for Each Channel

Data can be rearranged independently for each channel in the SCUX. Data rearrangement can be performed immediately before input to the SRC and immediately after output from the MIX. Table 48.9 to Table 48.11 show definition of data places. Data rearrangement immediately before the SRC is performed as described in section 48.3.72, SRCn Route Select Register (SRCRSELn_CIM) (n = 0, 1, 2, 3). Data rearrangement immediately after the MIX is performed as described in section 48.3.73, MIX Route Select Register (MIXRSEL_CIM).

### 48.4.4 Pin Connection Specifications of SSIF

SSIF0 to SSIF3 and SSIF3 to SSIF5 can be operated in synchronization with the same SSISCK and SSIWS signals. The AUDIO_CLK input to the SSIF can be selected between external pins AUDIO_CLK and MLB_CLK. These settings are made as described in section 48.3.70, SSI Pin Mode Register (SSIPMD_CIM). Figure 48.12 shows the pin connection specifications of each SSIF module.

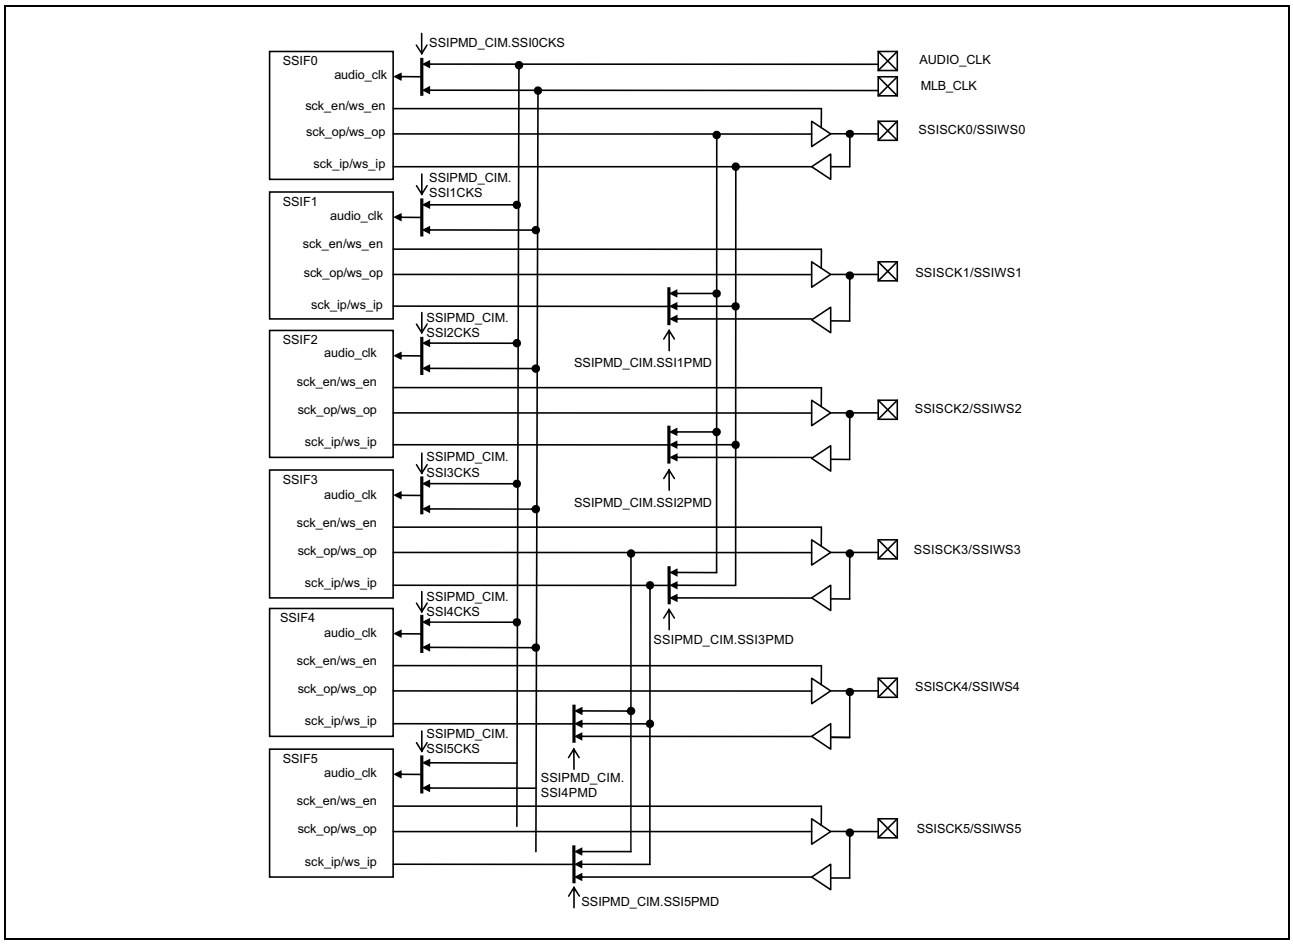

**Figure 48.12 Pin Connection Specifications of SSIF**

### 48.4.5 Data Transfer Route

Table 48.12 to Table 48.14 list the data transfer routes that can be selected by the SCUX.
Table 48.15 to Table 48.17 show the necessary register settings for selecting each transfer route.
The 2SRC0_m bypass register p and DVU0_n bypass register should be set appropriately to bypass the SRC and DVU, respectively.

## 48.4.6 Input Timing Signal and Output Timing Signal

The input timing signal and output timing signal need to be set when using the SRC or MIX. Table 48.18 to Table 48.20 show the input/output timing setting necessary for each transfer route in Table 48.12 to Table 48.14. When direct connection between the SRC and SSIF is selected, the WS signal of the relevant SSIF is automatically selected regardless of the setting of the FFD0_n/FFU0_n timing select register. When direct connection between the MIX and SSIF is selected, set the prescribed value in the FFU0_n timing select register. When connection between the FFD and SRC or connection between the SRC and FFU is selected, a desired value can be set in the FFD0_n/FFU0_n timing select register and timing signals corresponding to the setting are used.

Note 2. When connection to an SRCm for a given route is not being selected by the SOSELn bits of register SSIRSEL_CIM, SSInTX may be set to 1 (m = 0 to 3; n = 0 to 5).

### 48.4.7 2SRC (SRC) Block

The 2SRC block consists of two SRCs (Sampling Rate Converters) which implement the sampling rate conversion function. Each SRC has two modes allowing either synchronous or asynchronous sampling rate conversion to be performed.

- Asynchronous or synchronous sampling rate conversion is possible*1
- Sampling rate (synchronous mode)*2
  Input [KHz]: 8, 11.025, 12, 16, 22.05, 24, 32, 44.1, 48, 64, 88.2, or 96 is selectable
  Output [KHz]: 8, 16, 24, 32, 44.1, 48, or 96 is selectable
- Sampling rate (asynchronous mode)*2
  Input/output [KHz]: 1 to 96
- The supported number of bits is 16 bits and 24 bits
- Sound quality: −132 dB or less*3
- Supports 1, 2, 4, 6, or 8 channels*4
- DMA transfer with on-chip memory or external memory and direct transfer with the SSIF module are possible

Note 1. The synchronous mode can be selected only when the SCUX is connected to the FFD and FFU modules.
Note 2. The selectable sampling rates depend on the number of used channels and rate ratio.
Note 3. The data format is a 24-bit value.
Note 4. The number of selectable channels depends on the sampling rate and route.

Figure 48.13 shows a block diagram of the 2SRC (SRC) block. Input audio data indicates the data before executing the SRC function and output audio data indicates the data after executing the SRC function.
In synchronous SRC mode, the 2SRC (SRC) block outputs the input request signal to the FFD block and outputs the output request signal to the FFU block. In asynchronous SRC mode, the 2SRC (SRC) block receives the input timing signal and output timing signal from an external module and automatically detects the input sampling rate and output sampling rate from these timing signals.
Each SRC in the 2SRC (SRC) block can simultaneously process audio data for a maximum of eight channels. However, the maximum sampling rate that can be handled depends on the number of channels used. When SRC2 or SRC3 is used by the route from the FFD or the route to the FFU, the maximum number of processable channels is two. The number of channels is set by SADIRp_2SRC0_m.CHNUM. When not in bypass mode (SRCBRp_2SRC0_m.BYPASS = 0), unused channels always output 0 after initialization (SRCIRp_2SRC0_m.INIT = 1) unless the CHNUM setting is changed. In bypass mode, the input audio data is output one cycle later in all channels regardless of the CHNUM setting.
The bit width of output audio data can be set to 16 bits or 24 bits by SADIRp_2SRC0_m.OTBL. For input audio data, audio data with the same bit width as the OTBL bit setting in Table 48.21 should be input.

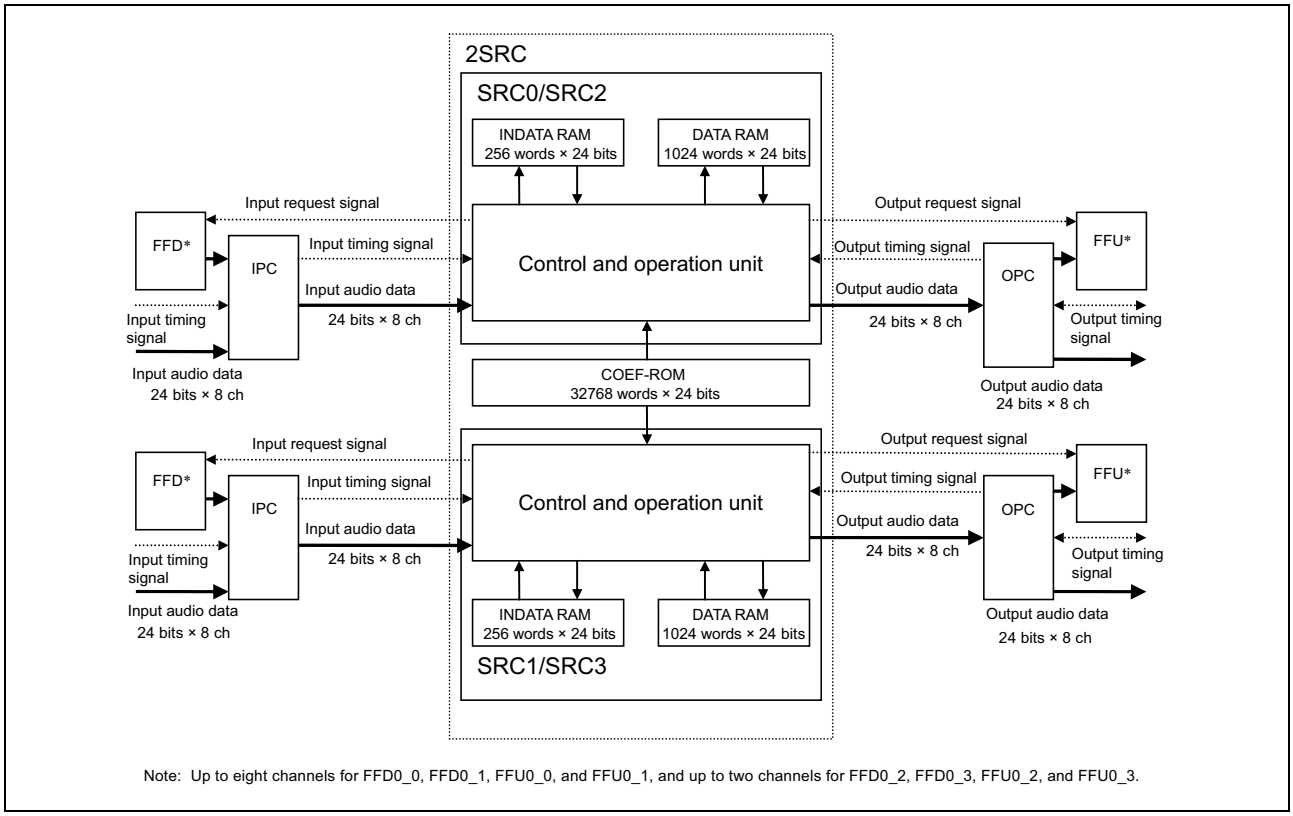

**Figure 48.13 Block Diagram of 2SRC Block**

## 48.4.8 DVU Block

The DVU block is used to control volume and mute. This block can simultaneously process data for a maximum of eight channels.

- Digital volume, volume ramp, and zero cross mute are provided as functions to adjust the volume
- The digital volume is set as a 24-bit fixed-point value within the range from a multiple of 0 to 8 (mute, −120 to 18 dB)
- Volume ramp can be used to perform soft mute, fade in, fade out, and volume change as desired
- The ramp time of volume ramp can be changed and set within the sampling range of $2^0$ to $2^{23}$
- Zero cross mute turns the sound mute at the zero cross point of audio data
- Direct transfer with the SSIF module and transfer with the mixer are possible

The number of channels is set by VADIR_DVU0_n.CHNUM. For unused channels, the input data that is input to the corresponding channels is output one cycle later. In bypass mode, the input data is output one cycle later in all channels regardless of the CHNUM setting.
Figure 48.14 shows the processing image of the DVU block.

Figure 48.15 shows the image of digital volume operation.

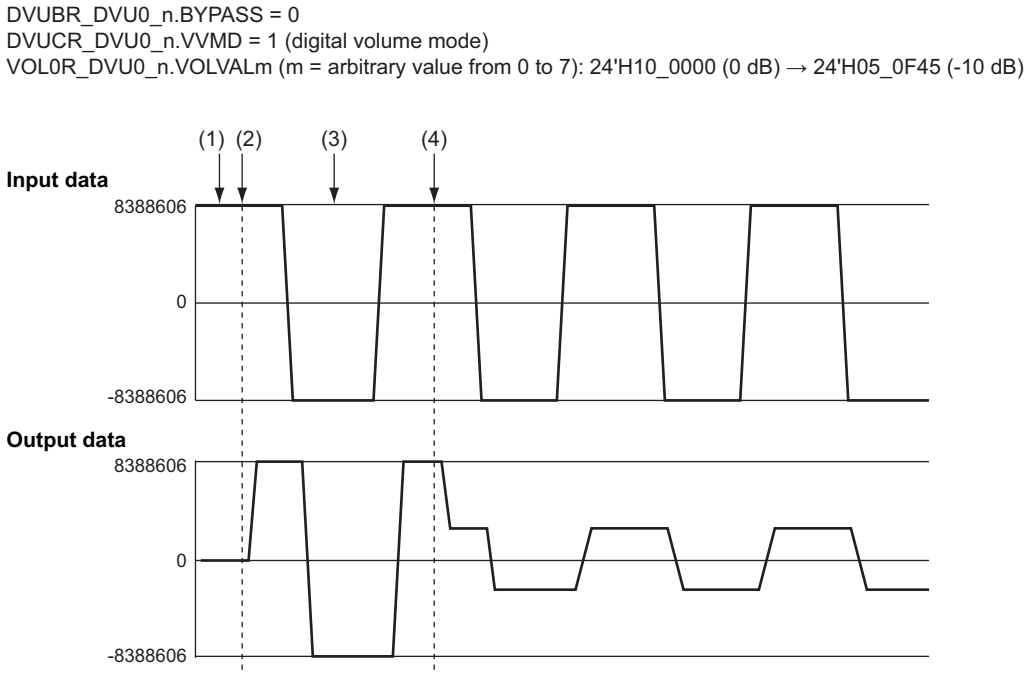

**Figure 48.15 Digital Volume Operation**

### Operation

(1) In the initialized state (DVUIR_DVU0_n.INIT = 1), set the VVMD bit in DVUCR_DVU0_n to 1 (digital volume mode) and the VOLVALm bit in VOL0R_DVU0_n to 24'H10_0000 (0 dB). Until the initialized state is cleared, the DVU does not start operation and its output data is 0.

(2) When the initialized state is cleared (DVUIR_DVU0_n.INIT = 0), the DVU starts operation. Since the VOLVALm bit is set to 0 dB, the output data is the same size as the input data.

(3) Set the DVUEN bit in DVUER_DVU0_n to 0 and the VOLVAL0 bit in VOL0R_DVU0_n to 24'H05_0F45 (-10 dB).

(4) The setting to the VOLVAL0 bit in (3) is enabled by setting the DVUEN bit in DVUER_DVU0_n to 1. The output data is the value obtained by attenuating the input data by -10 dB.

Figure 48.16 shows the image of volume ramp operation.

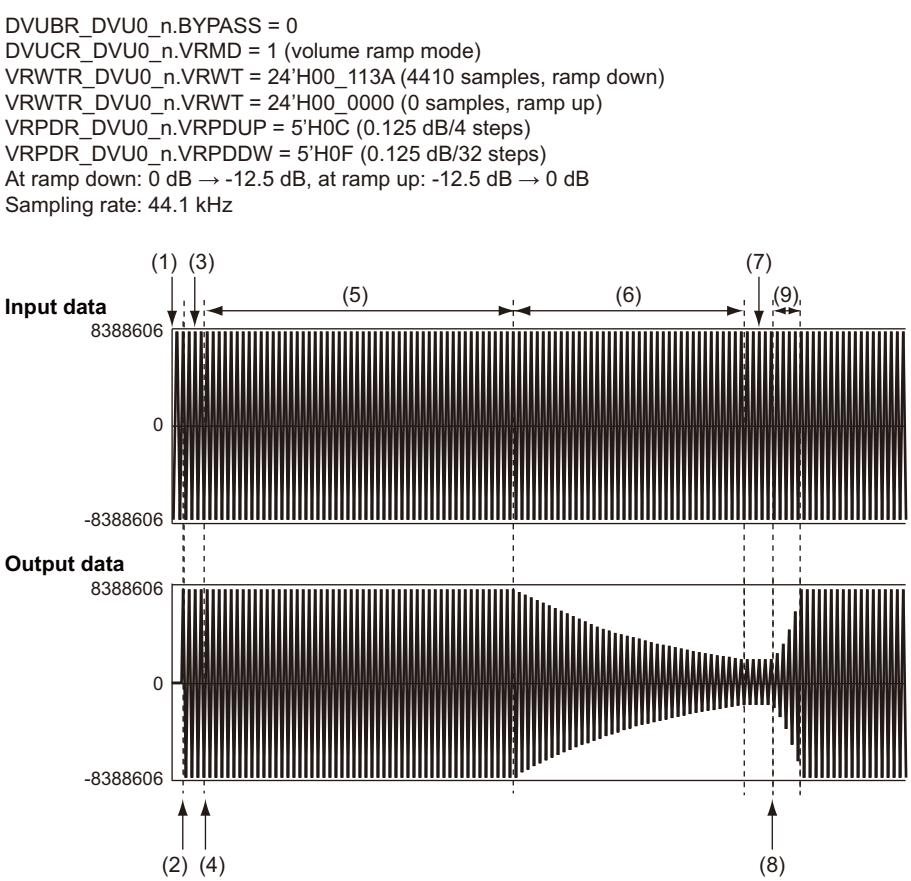

**Figure 48.16 Volume Ramp Operation**

### Operation

(1) In the initialized state (DVUIR_DVU0_n.INIT = 1), set the VRMD bit in DVUCR_DVU0_n to 1 (volume ramp mode) and the VRENm (m: arbitrary value from 0 to 7) bit in VRCTR_DVU0_n to 1. Until the initialized state is cleared, the DVU does not start operation and its output data is 0.

(2) When the initialized state is cleared (DVUIR_DVU0_n.INIT = 0), the DVU starts operation.

Note: Changes to the settings of the VRDB bit of the VRDBR_DVU0_n register made in the INIT state rapidly become applicable on release from the INIT state (independently of the setting of VRWTR_DVU0_n and VRPDR_DVU0_n).

(3) Set the DVUEN bit in DVUER_DVU0_n to 0, the VRPDDW bit in VRPDR_DVU0_n to 5'H0F (0.125 dB/32 steps), the VRDB bit in VRDBR_DVU0_n to 10'H064 (-12.5 dB), and the VRWT bit in VRWTR_DVU0_n to 24'H00_113A (4410 samples).

(4) The setting in (3) is enabled by setting the DVUEN bit in DVUER_DVU0_n to 1.

(5) The VDU waits to start the volume ramp operation for 4410/44100 = 0.1 second because the sampling rate is set to 44.1 kHz with VRWTR_DVU0_n.VRWT = 24'H00_113A (4410 samples).

(6) The VDU starts volume ramp operation after the wait time in (5).
The output data is the value obtained by attenuating the input data by -12.5 dB after 12.5 × 32/0.125 = 3200 steps because the VRPDDW bit in VRPDR_DVU0_n is set to 5'H0F (0.125 dB/32 steps) according to 0d B to -12.5 dB ramp down.

(7) Set the DVUEN bit in DVUER_DVU0_n to 0, the VRPDUP bit in VRPDR_DVU0_n to 5'H0C (0.125 dB/4 steps), the VRDB bit in VRDBR_DVU0_n to 10'H000 (0 dB), and the VRWT bit in VRWTR_DVU0_n to 24'H00_0000 (0 sample).

(8) The setting in (7) is enabled by setting the DVUEN bit in DVUER_DVU0_n to 1.

(9) The VDU starts volume ramp operation without delay because the VRWT bit in VRWTR_DVU0_n is set to 24'H00_0000 (0 sample).
The output data is the same size as the input data after 12.5 × 4/0.125 = 400 steps because the VRPDUP bit in VRPDR_DVU0_n is set to 5'H0C (0.125 dB/4 steps) according to -12.5 dB to 0 dB ramp up.

Table 48.25 shows the latency of the DVU block.

**Table 48.25 DVU Block Latency**

| Item | Bypass | DVU Operation |
|---|---|---|
| Output delay | 1 | 2 |

## 48.4.9 MIX Block

The MIX block is used to mix (add together) the input audio data from a maximum of four systems into one system. Each system can simultaneously process data for a maximum of eight channels.

- Data of two to four source systems can be mixed (added together) into one system
- The ratio to add the sources can be set
- The ratio can be changed dynamically
- Volume ramp enables mixing to be performed (ramp time is variable)
- Only direct transfer with the SSIF module is possible

The number of channels is set by MADIR_MIX0_0.CHNUM. When not in bypass mode (MIXBR_MIX0_0.BYPASS = 0), unused channels always output 0 after initialization (MIXIR_MIX0_0.INIT = 1) unless the CHNUM setting is changed. In bypass mode, the input data is output one cycle later in all channels regardless of the CHNUM setting.
Figure 48.17 shows a block diagram of the MIX block.

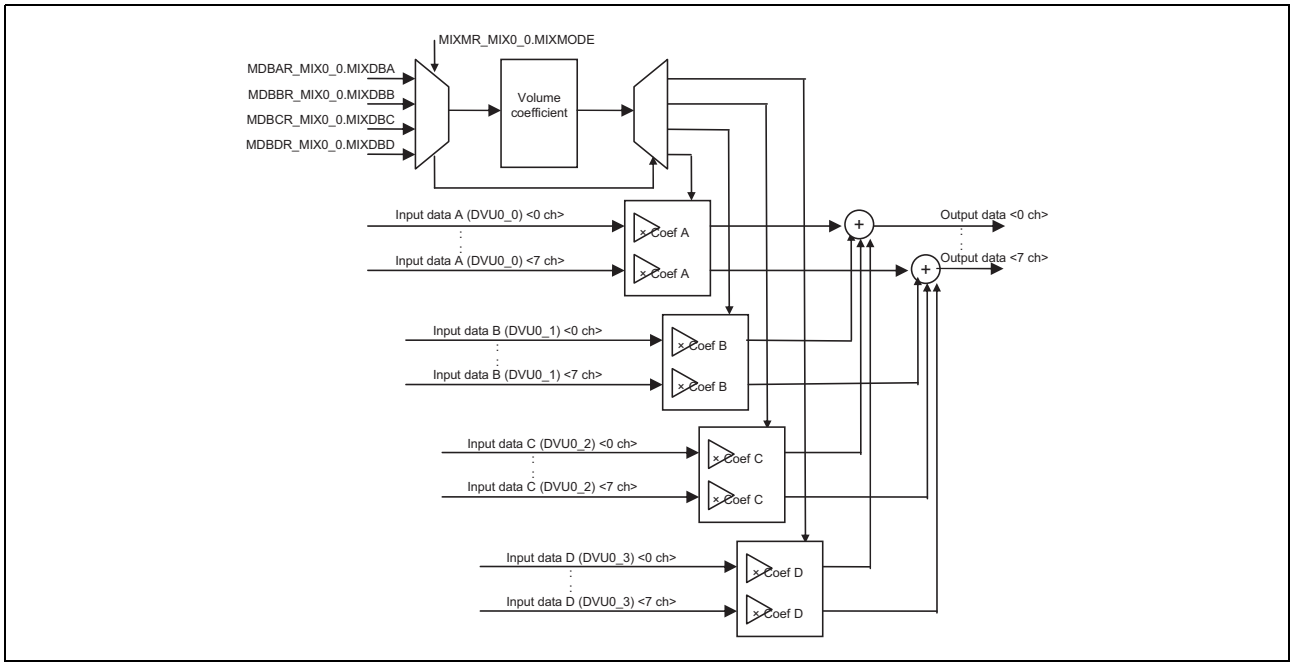

**Figure 48.17 Block Diagram of MIX Block**

Table 48.26 shows the functions of the MIX block.

**Table 48.26 MIX Block Functions**

| Item | Performance |
|---|---|
| Volume step mixer | Mix the data of four systems into one system.<br>The volume of each system can be adjusted by step change. |
| Volume ramp mixer | Mix the data of four systems into one system.<br>The volume of each system can be adjusted by ramp. |

Figure 48.18 shows the image of volume step operation for 1-system data. This figure explains about the operation when the volume is changed from 0 dB to –∞ dB. The volume can change the target dB for one step each. In the case of the volume step mixer, the volume of four systems can be adjusted at each step change (one sample).
Figure 48.19 shows the image of volume ramp operation for 1-system data. This figure explains about the operation when the volume is changed from 0 dB to –∞ dB. The volume can be changed by 0.125-dB/step each and it takes 1024 samples to reach –∞ dB in the maximum case for each system. In the case of the volume ramp mixer, the volume of four

systems can be adjusted at each ramp. In addition, the volume ramp mixer has a mechanism to reduce the noise. If the direction of volume is different among the four systems, it operates from the volume-down systems and after that operates on the volume-up systems automatically. In the case of the same direction, it changes the volume at the same timing.

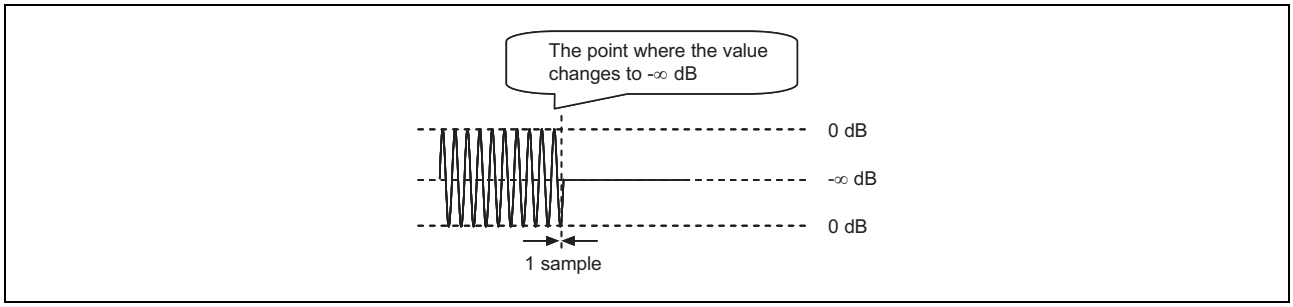

**Figure 48.18 Volume Step Operation**

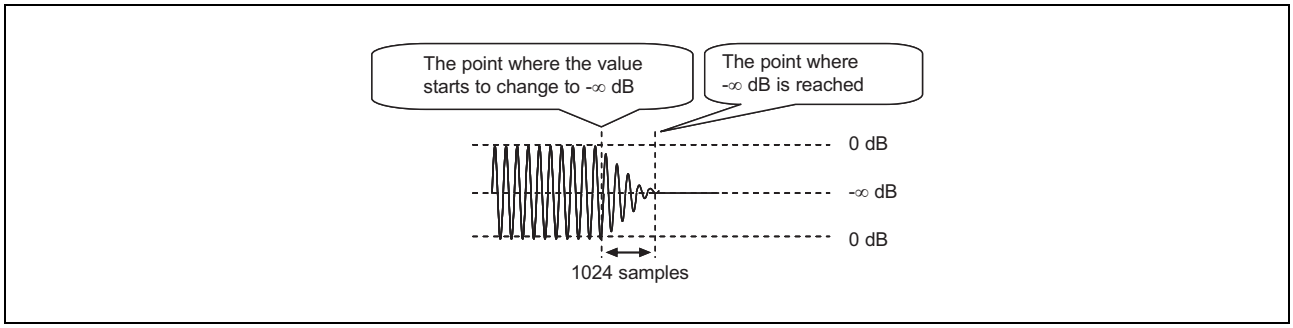

**Figure 48.19 Volume Ramp Operation**

Figure 48.20 shows the image of volume ramp operation for 4-system data.

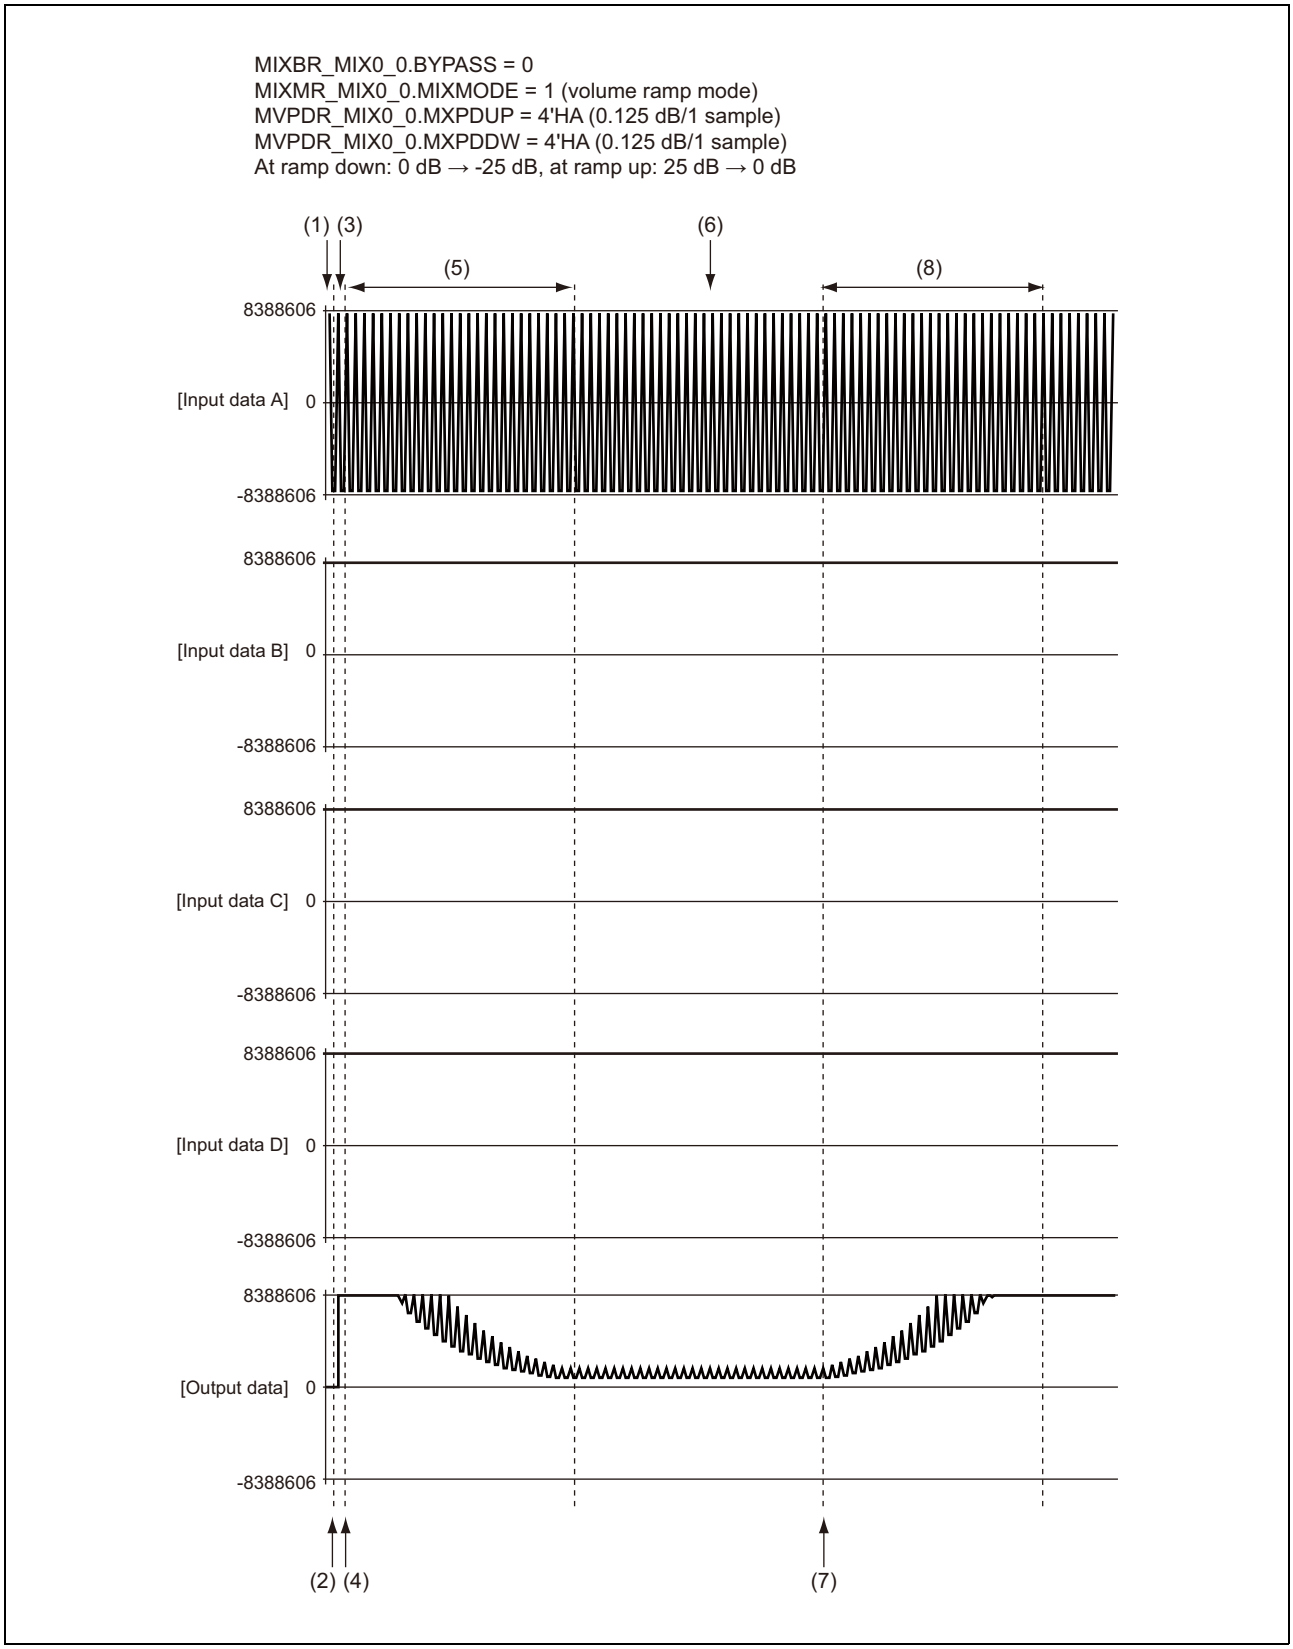

**Figure 48.20 Volume Ramp Operation for 4-System Data**

**Operation**

(1) In the initialized state (MIXIR_MIX0_0.INIT = 1), set the MIXMODE bit in MIXMR_MIX0_0 to 1 (volume ramp mode) and the MXPDDW bit in MVPDR_MIX0_0 to 4'HA (0.125 dB/1 sample).
Until the initialized state is cleared, the MIX does not start operation and its output data is 0.

(2) When the initialized state is cleared (MIXIR_MIX0_0.INIT = 0), the MIX starts operation.

Note: Changes to the settings of the MIXDBA bits of the MDBAR_MIX0_0 register, MIXDBB bits of the MDBBR_MIX0_0 register, MIXDBC bits of the MDBCR_MIX0_0 register and MIXDBD bits of the MDBDR_MIX0_0 register made in the INIT state rapidly become applicable on release from the INIT state (independently of the setting of MVPDR_MIX0_0).

(3) Set as follows:
MDBER_MIX0_0.MIXDBEN = 0
MDBAR_MIX0_0.MIXDBA = 10'H0C8 (-25 dB)
MDBBR_MIX0_0.MIXDBB = 10'H0C8 (-25 dB)
MDBCR_MIX0_0.MIXDBC = 10'H0C8 (-25 dB)
MDBDR_MIX0_0.MIXDBD = 10'H0C8 (-25 dB)

(4) The setting in (3) is enabled by setting the MIXDBEN bit in MDBER_MIX0_0 to 1.

(5) The output data is the value obtained by attenuating and mixing the input data of each system by -25 dB after 25/0.125 = 200 steps because the MXPDDW bit in MVPDR_MIX0_0 is set to 4'HA (0.125 dB/1 sample) according to 0 dB to -25 dB ramp down for each system.

(6) Set as follows:
MDBER_MIX0_0.MIXDBEN = 0
MDBAR_MIX0_0.MIXDBA = 10'H000 (0 dB)
MDBBR_MIX0_0.MIXDBB = 10'H000 (0 dB)
MDBCR_MIX0_0.MIXDBC = 10'H000 (0 dB)
MDBDR_MIX0_0.MIXDBD = 10'H000 (0 dB)

(7) The setting in (6) is enabled by setting the MIXDBEN bit in MDBER_MIX0_0 to 1.

(8) The output data is the value obtained by boosting and mixing the input data of each system by 25 dB after 25/0.125 = 200 steps because the MXPDUP bit in MVPDR_MIX0_0 is set to 4'HA (0.125 dB/1 sample) according to -25 dB to 0 dB ramp up for each system.

Table 48.27 shows the latency of the MIX block.

| Output delay | 1 | 2 |

## 48.5 Usage Note

### 48.5.1 Software Reset

When initializing the internal circuits of this module by clearing the SWRST bit in the SWRSR_CIM register or setting the INIT bit in the IPCIR_IPC0_n, OPCIR_OPC0_n, FFDIR_FFD0_n, FFUIR_FFU0_n, SRCIRp_2SRC0_m, SRCIRR_2SRC0_m, DVUIR_DVU0_n, or MIXIR_MIX0_0 register, be sure to follow the procedures specified in section 48.4.1, Initial Setting Procedure or section 48.4.2, Transfer Start Procedure and Stop Procedure.

# 49. Sound Generator

This LSI has four channels of on-chip sound generator.

## 49.1 Features

- Capable of adjusting sound volume using 8-bit PWM output
- Selection of operating clocks
  Four types of operating clocks (P0φ/2, P0φ/4, P0φ/8, and P0φ/16) can be selected.
- Frequency settings in the 25-Hz to 20-kHz range with precision of 1% or less
- Output stop procedures can be selected
- Automatic attenuator function can be selected
- Interrupt source: one type
  Attenuation end interrupt can be requested
- Module stop mode can be set

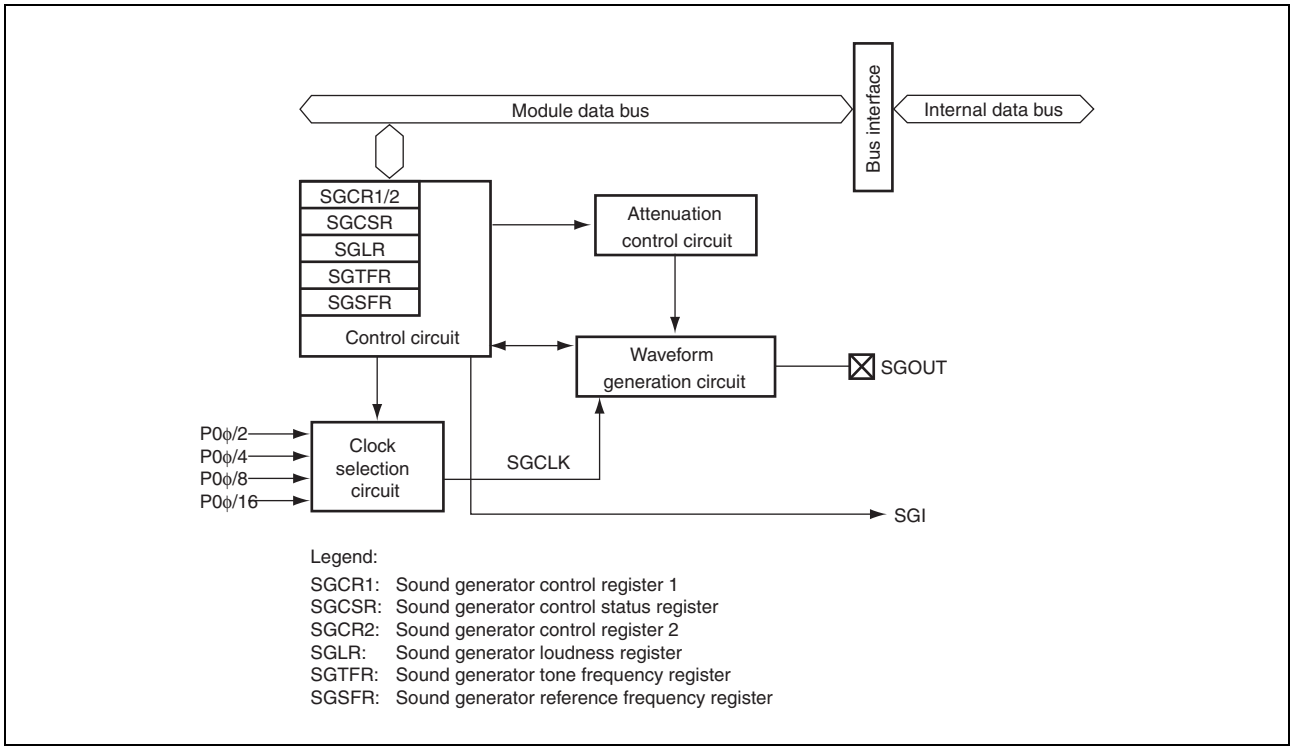

**Figure 49.1 Block Diagram**

## 49.2 Input/Output Pins

Table 49.1 shows the pin configuration.

**Table 49.1 Pin Configuration**

| Name | Abbr. | I/O | Function |

| 5 to 0 | — | All 0 | R | Reserved<br>These bits are always read as 0. The write value should always be 0. |

Note: * Only 0 can be written to clear the flag.

### 49.3.3 Sound Generator Control Register 2 (SGCR2)

SGCR2 is used for the termination of this module.

| Bit: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|
| Bit name: | SGEND | TCHG | — | — | — | — | — | — |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| 5 to 0 | — | All 0 | R | Reserved<br>These bits are always read as 0. The write value should always be 0. |

### 49.3.4 Sound Generator Loudness Register (SGLR)

SGLR sets the SGOUT duty.

| Bit: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|
| Bit name: | LD[7] | LD[6] | LD[5] | LD[4] | LD[3] | LD[2] | LD[1] | LD[0] |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |

| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| 7 to 0 | LD[7:0] | H'00 | R/W | Loudness Data<br>These bits store the duty data for pulse output. |

### 49.3.5 Sound Generator Tone Frequency Register (SGTFR)

SGTFR sets the tone frequency.

| Bit: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|
| Bit name: | — | TONE[6] | TONE[5] | TONE[4] | TONE[3] | TONE[2] | TONE[1] | TONE[0] |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R | R/(W)* | R/(W)* | R/(W)* | R/(W)* | R/(W)* | R/(W)* | R/(W)* |

Note: * These bits can be written to only when TCHG = 1.

| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| 7 | — | 0 | R | Reserved<br>This bit is always read as 0. The write value should always be 0. |
| 6 to 0 | TONE[6:0] | H'00 | R/(W)* | Tone Frequency Setting<br>These bits set the tone frequency based on the reference frequency specified by the SFS bits. Setting H'00 is prohibited. |

Note: * These bits can be written to only when TCHG = 1.

### 49.3.6 Sound Generator Reference Frequency Register (SGSFR)

SGSFR sets the reference frequency.

| Bit: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|
| Bit name: | SFS[7] | SFS[6] | SFS[5] | SFS[4] | SFS[3] | SFS[2] | SFS[1] | SFS[0] |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R/(W)* | R/(W)* | R/(W)* | R/(W)* | R/(W)* | R/(W)* | R/(W)* | R/(W)* |

Note: * These bits can be written to only when TCHG = 1.

| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| 7 to 0 | SFS[7:0] | H'00 | R/(W)* | Reference Frequency Setting<br>These bits set the reference frequency based on the operating clock (SGCLK) specified by the SGCK bits in SGCR1. Setting H'00 is prohibited. |

Note: * These bits can be written to only when TCHG = 1.

## 49.4 Operation

### 49.4.1 Base Operation

#### (1) Initial Settings

Make sure that this module has stopped before setting registers.
The operation stop procedure, operating clock, and attenuator function on/off settings are specified by the STPM, SGCK, and DPF bits in SGCR1, respectively. When the attenuator function is on, the attenuation cycle is selected. The interrupt request is set by the SGIE bit in SGCSR.

#### (2) Activation

The operation of this module is enabled by setting the SGST bit in SGCR1 to 1 and clearing the SGEND bit in SGCR2 to 0. Set the TCHG bit in SGCR2 to 1 to cancel the write protect for SGSFR and SGTFR. Use bits SFS7 to SFS0 in SGSFR to select the reference frequency and bits TONE6 to TONE0 in SGTFR to select the tone frequency. SGLR specifies the output pulse duty. This module starts operation after writing to SGCR2, SGLR, SGTFR, and SGSFR is completed.

#### (3) Stopping

The operation stop procedure of this module is specified by the STPM bit in SGCR1.
When the attenuator function is off and STPM is 0, the operation is stopped by the SGST bit regardless of the SGEND bit setting. When the attenuator function is off and STPM is 1, the operation is stopped by clearing the SGST bit to 0 and setting the SGEND bit to 1.
When the attenuator function is on and STPM is 0, clearing the SGST bit to 0 stops operation even though the automatic attenuation does not end and the SGDEF bit is not set to 1. When the attenuator function is on and STPM is 1, clearing the SGST bit to 0 does not stop operation until the automatic attenuation ends and the SGDEF bit is set to 1.
The conditions for stopping this module are listed in Table 49.3 and examples of stopping operation are shown in Figure 49.2.

**Table 49.3 Stop Conditions**

| Attenuator Function Off | | | | | Attenuator Function On | | | | |
|---|---|---|---|---|---|---|---|---|---|
| **STPM** | **SGST** | **SGEND** | **SGDEF** | **Operation** | **STPM** | **SGST** | **SGEND** | **SGDEF** | **Operation** |

### 49.4.2 Tone Frequency Setting

This module provides tone frequency output in the range of 25 Hz to 20 kHz, with precision of 1% or less.
The tone frequency is calculated by:

Reference frequency (Hz) = SGCLK (Hz)/SFS
Tone frequency (Hz) = Reference frequency (Hz)/(2 × TONE)
= SGCLK (Hz)/(2 × SFS × TONE)

Setting values of the TONE bits in SGTFR and SFS bits in SGFSR are calculated by:

SFS = SGCLK (Hz)/reference frequency (Hz) (0 < SFS ≤ 255)
TONE = Reference frequency (Hz)/(2 × TONE frequency (Hz)) (0 < TONE ≤ 127)

An example of relationship between the tone frequency and output error is shown in Table 49.4.

**Table 49.4 Relationship between Tone Frequency and Output Error**

| Tone Frequency | SFS[7:0] | TONE[6:0] | Error (%) |
|---|---|---|---|
| 220.00 | B1 | 6B | 0.008 |
| 329.63 | 9E | 50 | 0.007 |
| 440.00 | 4D | 7B | 0.02 |
| 659.26 | 4F | 50 | 0.007 |
| 880.00 | 40 | 4A | 0.03 |
| 1318.50 | 28 | 4F | 0.005 |
| 1760.00 | 20 | 4A | 0.03 |
| 2637.00 | 14 | 4F | 0.005 |
| 3520.00 | 10 | 4A | 0.03 |
| 5274.00 | A | 4F | 0.005 |
| 7040.00 | 8 | 4A | 0.03 |

Note: • SGCLK = P0φ [MHz]/4 = 33.33 [MHz]/4 = 8.3 [MHz]

Since changing P0φ frequency affects the tone frequency, care should be taken when changing it.

### 49.4.3 Auto Attenuator Function

When the auto attenuator function is on, the loudness data (LD) determines the initial duty cycle for SGOUT.
The SGOUT duty cycle is attenuated by a factor of 1/32 using the attenuation cycle set by the DPF bits in SGCR1.
The attenuation characteristics are calculated by the equation:

$LD_n = int (LD0 \times (1 - 1/32)^n)$
LD: SGOUT duty cycle (The initial data is SGLR.)
n: Attenuation cycle number

Figure 49.4 is a graph of attenuation characteristics.

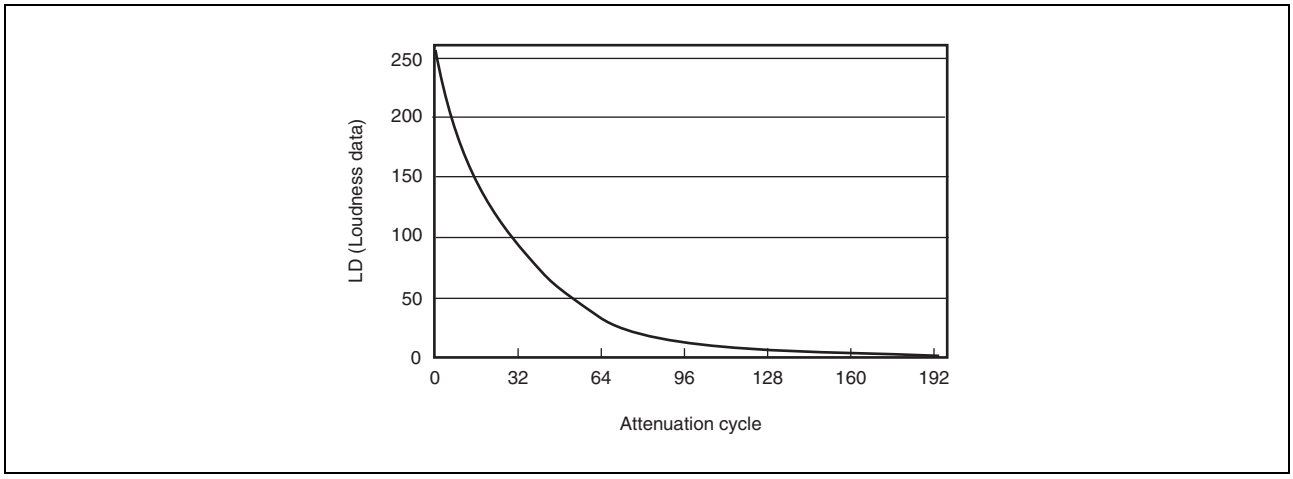

**Figure 49.4 Attenuation Characteristics**

### 49.4.4 Output Waveform

As shown in Figure 49.5, the output waveform of this module is obtained by synthesis of the on-chip 8-bit PWM pulse output and the tone frequency output. The duty cycle for the on-chip 8-bit PWM pulse output is set by SGLR.

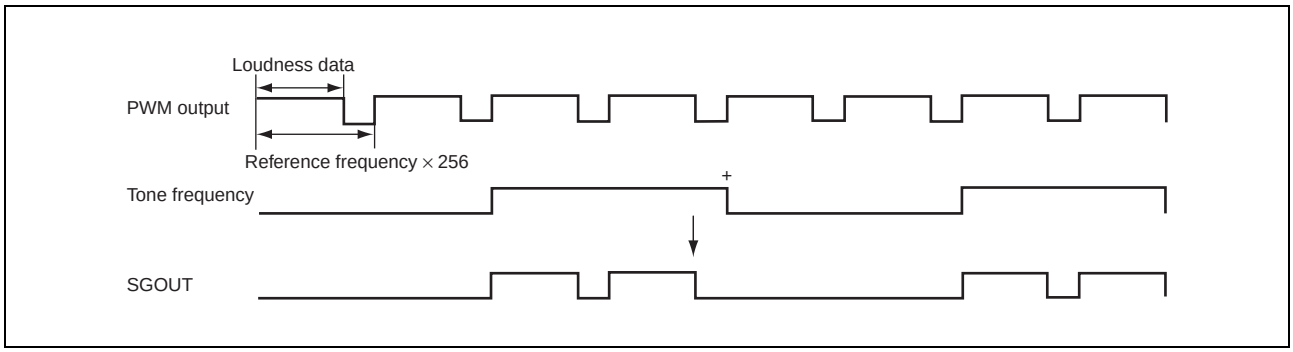

**Figure 49.5 Output Waveforms**

## 49.5 Interrupt Source

When the attenuator function is on and an automatic attenuation operation is completed (duty cycle for the on-chip PWM pulse output is 0), the SGDEF bit in SGCSR is set. An interrupt request is issued if the SGIE bit in SGCSR is set to 1. When STPM = 0, the SGDEF bit is set only when the first attenuation operation is completed. If the SGDEF bit is cleared during automatic attenuation, the SGDEF bit is set when the next attenuation operation is completed.

**Table 49.5 Interrupt Source**

| Name | Interrupt Source | Interrupt Flag |
|---|---|---|
| SGDEI | Attenuation end | SGDEF |

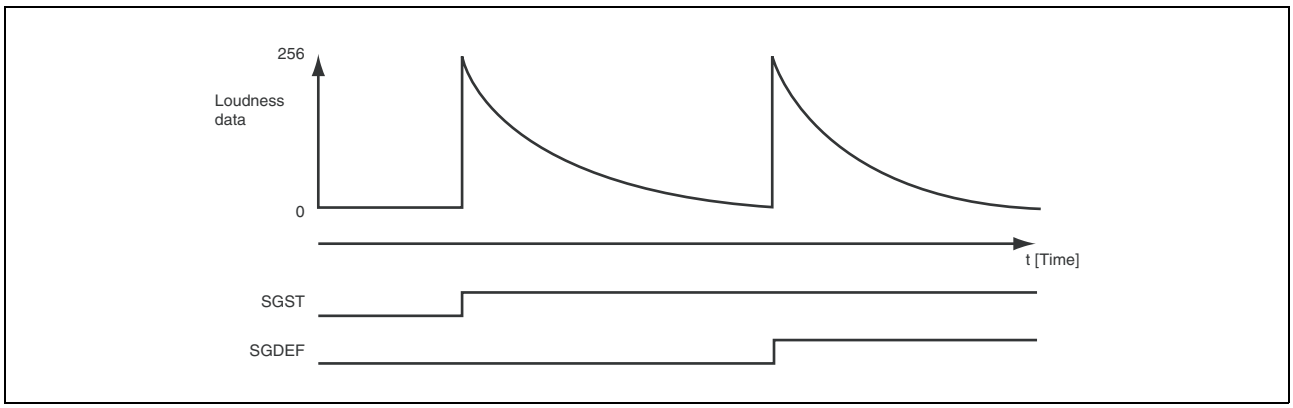

**Figure 49.6 Attenuation End Flag Setting Timing**

## 49.6 Usage Note

### 49.6.1 Module Stop Mode Settings

The module stop control register enables or disables the operation of this module. With the initial setting, the operation of this module is stopped. Register access is enabled by canceling module stop mode. For details, see section 55, Power-Down Modes.

# 50. SD Host Interface

Note: • SD Host/Ancillary Product License Agreement (SD HALA) is required to develop SD host-related products.

## 50.1 Overview

### 50.1.1 Features

- SD memory/IO card interface (1-bit/4-bit SD bus)
- SD memory card: SD, SDHC, SDXC
- Transfer mode: Default mode, High-Speed mode
- SD clock (SD_CLK) frequency = $1/2^n$ P1φ (Peripheral clock 1) frequency (n = 1 to 9)
- Error check function: CRC7 (for command/response), CRC16 (for data)
- Three interrupt requests
- DMA transfer request: SD_BUF read/write
- Card detect function
- Write protect support

### 50.1.2 Block Diagram

Figure 50.1 shows a block diagram of the SD host interface.

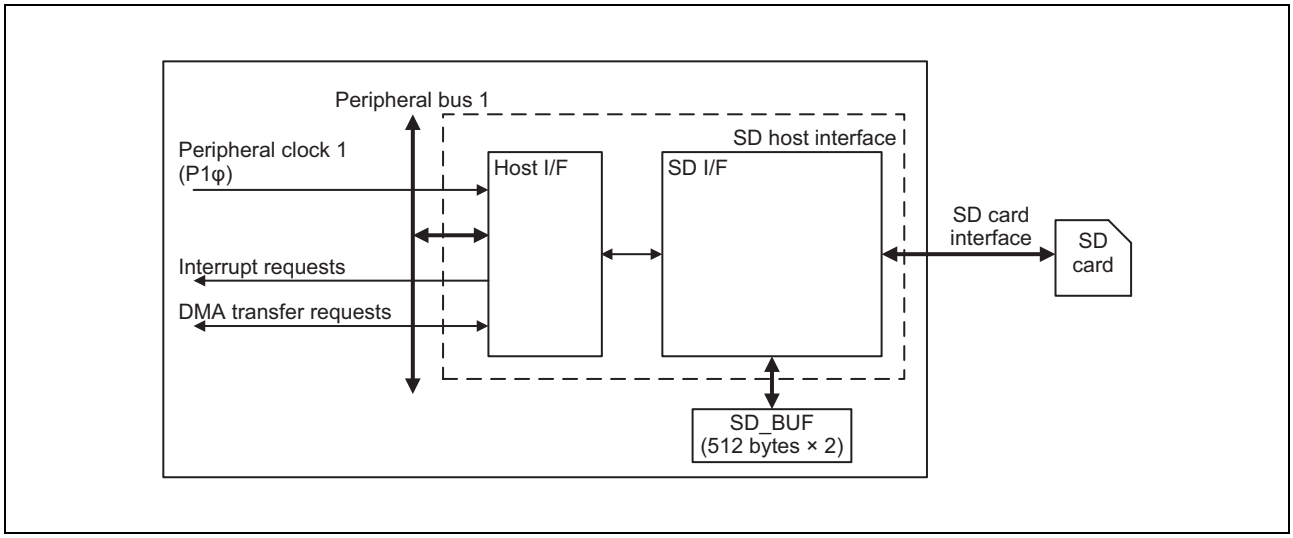

**Figure 50.1 Block Diagram of SD Host Interface**

### 50.1.3 Input/Output Pins

Table 50.1 lists the input and output pins used by the SD host interface.

**Table 50.1 Pin Configuration**

| Pin Name | Signal Name | I/O | Function |
|---|---|---|---|
| SD_CLK[1:0]*1 | SDCLK | Output | SD clock |
| SD_CMD[1:0]*1 | SDCMD | I/O | Command/response |
| SD_D0[1:0]*1 | SDDAT0 | I/O | Data[bit 0] |
| SD_D1[1:0]*1 | SDDAT1 | I/O | Data[bit 1]/SDIO interrupt |
| SD_D2[1:0]*1 | SDDAT2 | I/O | Data[bit 2]/Read wait |
| SD_D3[1:0]*1 | SDDAT3 | I/O | Data[bit 3] |
| SD_CD[1:0]*1 | ISDCD | Input | Card detect*2 |
| SD_WP[1:0]*1 | ISDWP | Input | Write protect*2 |

Note 1. [1:0] indicates the SD Host Interface channel number.
Note 2. When a pin is not in use, fix the corresponding signal to 1.

## 50.2 Register Descriptions

Table 50.2 summaries the registers of the SD host interface.

### 50.2.1 Command Type Register (SD_CMD)

The command type register (SD_CMD) selects the command type and response type. The command sequence is started by writing to SD_CMD. For details on the SD_CMD setting, refer to section 50.4.10, Example of SD_CMD Register Setting.
Do not write to SD_CMD while the SCLKDIVEN bit in SD_INFO2 is set to 0.

| 0 | CF40 | 0 | R/W | |

Note: • SD_CMD cannot be written to when the CBSY bit in SD_INFO2 is 1.

### 50.2.2 SD Command Argument Registers (SD_ARG)

The SD command argument registers (SD_ARG) set the command argument of SD card. Set the command argument before writing to SD_CMD.

- SD_ARG0

| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| 15 to 0 | CF23 to CF8 | All 0 | R/W | Set command format[23:8] (argument) |

- SD_ARG1

| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| 15 to 0 | CF39 to CF24 | All 0 | R/W | Set command format[39:24] (argument) |

### 50.2.3 Data STOP Register (SD_STOP)

The data stop register (SD_STOP) is used to enable or disable block counting at multiple block transfer, and to control the issuing of CMD12 within command sequences.

| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| 15 to 9 | — | All 0 | R | Fixed 0 |
| 8 | SEC | 0*1 | R/W | Block Count Enable*2<br>0: Disables SD_SECCNT setting value.<br>1: Enables SD_SECCNT setting value.<br>Set SEC to 1 at multiple block transfer.<br>When SD_CMD is set as follows to start the command sequence while SEC is set to 1, CMD12 is automatically issued.<br><br>1. CMD18 or CMD25 in normal mode (SD_CMD[10:8] = 000)<br>2. SD_CMD[15:13] = 001 in extended mode (CMD12 is automatically issued, multiple block transfer)<br>When the command sequence is halted because of a communications error or timeout, CMD12 is not automatically issued. |
| 7 to 1 | — | All 0 | R | Fixed 0 |
| 0 | STP | 0*1 | R/W | Stop*3<br>• When STP is set to 1 during multiple block transfer, CMD12 is issued to halt the transfer through the SD host interface.<br><br>However, if a command sequence is halted because of a communications error or timeout, CMD12 is not issued. Although continued buffer access is possible even after STP has been set to 1, the buffer access error bit (ERR5 or ERR4) in SD_INFO2 will be set accordingly.<br>• When STP has been set to 1 during transfer for single block write, the access end flag is set when SD_BUF becomes empty, and CMD12 is not issued. If SD_BUF does contain data, the access end flag is set on completion of reception of the busy state without CMD12 having been issued.<br>• When STP has been set to 1 during transfer for single block read, the access end flag is set immediately after setting of the STP bit and CMD12 is not issued.<br>• When STP is set to 1 during reception of the busy state after an R1b response, the access end flag is set on completion of reception of the busy state without CMD12 having been issued.<br>• When STP is set to 1 after a command sequence has been completed, CMD12 is not issued and the access end flag is not set. |

Note 1. The initial value is applied at a reset and when the SDRST bit in SOFT_RST is 0.
Note 2. Do not change the value of this bit when the SCLKDIVEN bit in SD_INFO2 is set to 0.
Note 3. Do not change the value of this bit from 1 to 0 when the SCLKDIVEN bit in SD_INFO2 is set to 0.

### 50.2.4 Block Count Register (SD_SECCNT)

The block count register (SD_SECCNT) specifies the number of transfer blocks at multiple block transfer.

| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| 15 to 0 | CNT15 to CNT0 | All 0 | R/W | Number of Transfer Blocks*1<br>When 0x0001 is set, the number of transfer blocks is 1.<br>:<br>When 0xFFFF is set, the number of transfer blocks is 65535.<br>However, when 0x0000 is set, the number of transfer blocks is 65536. |

Note 1. Do not change the value of this bit when the SCLKDIVEN bit in SD_INFO2 is set to 0.

### 50.2.5 SD Card Response Registers (SD_RSP)

The SD card response registers (SD_RSP) store the response from the SD card.

- SD_RSP00

| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| 15 to 0 | R23 to R8 | All 0 | R | Store the response from the SD card |

- SD_RSP01

| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| 15 to 0 | R39 to R24 | All 0 | R | Store the response from the SD card |

- SD_RSP02

| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| 15 to 0 | R55 to R40 | All 0 | R | Store the response from the SD card |

- SD_RSP03

| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| 15 to 0 | R71 to R56 | All 0 | R | Store the response from the SD card |

- SD_RSP04

| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| 15 to 0 | R87 to R72 | All 0 | R | Store the response from the SD card |

- SD_RSP05

| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| 15 to 0 | R103 to R88 | All 0 | R | Store the response from the SD card |

- SD_RSP06

| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| 15 to 0 | R119 to R104 | All 0 | R | Store the response from the SD card |

- SD_RSP07

| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| 15 to 8 | — | All 0 | R | Fixed 0 |
| 7 to 0 | R127 to R120 | All 0 | R | Store the response from the SD card |

Table 50.3 lists the response types and corresponding SD_RSP registers.

**Table 50.3 Response Types and Corresponding SD_RSP Registers**

| Response Types | SD_RSP Registers |
|---|---|
| R1, R1b[39:8] | SD_RSP01 and SD_RSP00 |
| R2[127:8] | SD_RSP07 to SD_RSP00 |
| R3[39:8] | SD_RSP01 and SD_RSP00 |
| R4[39:8] | SD_RSP01 and SD_RSP00 |
| R5[39:8] | SD_RSP01 and SD_RSP00 |
| R6[39:8] | SD_RSP01 and SD_RSP00 |
| R7[39:8] | SD_RSP01 and SD_RSP00 |

### 50.2.6 SD Card Interrupt Flag Register 1 (SD_INFO1)

The SD card interrupt flag register 1 (SD_INFO1) indicates the response end and access end in the command sequence. This register also indicates the card detect/write protect state.
For CMD12 and CMD52 (SDIO abort) at multiple block transfer, INFO0 is not set but only INFO2 is set.
Even if the command sequence is halted because of a communications error or timeout, INFO0 or INFO2 is set.
INFO10, INFO9, and INFO8 change depending on the SD_D3 state after a reset is released and continue to change in 4-bit transfer mode.
To clear a flag, write 0 to the bit to be cleared and 1 to the other bits.

| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| 15 to 11 | — | All 0 | R | Fixed 0 |
| 10 | INFO10 | Unknown | R | Indicates the SD_D3 state.<br>1: SD_D3 is set to 1.<br>0: SD_D3 is set to 0. |
| 9 | INFO9 | 0 | R/W*1 | SD_D3 set<br>[Setting condition]<br>After change in SD_D3 from 0 to 1, two cycles of P1φ has elapsed with SD_D3 held 1.<br>[Clearing condition]<br>When 0 is written to INFO9 |

| 4 | INFO4 | 0 | R/W*1 | SD_CD Card Insertion<br>[Setting condition]<br>After change in SD_CD from 1 to 0, Ncycle has elapsed with SD_CD held 0.<br>[Clearing condition]<br>When 0 is written to INFO4<br>Ncycle is set by bits 3 to 0 in SD_OPTION. |
| 3 | INFO3 | 0 | R/W*1 | SD_CD Card Removal<br>[Setting condition]<br>After change in SD_CD from 0 to 1, Ncycle has elapsed with SD_CD held 1.<br>[Clearing condition]<br>When 0 is written to INFO3<br>Ncycle is set by bits 3 to 0 in SD_OPTION. |

| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| 2 | INFO2 | 0*2 | R/W*1 | Access End<br>[Setting conditions]<br>• When read access to the buffer is completed in the case of transfer for single block read<br>• When read access to the buffer for the last block of data is completed in the case of transfer for multiple block read<br>• When read access to the buffer and reception of the response to CMD12 are completed in the case of transfer for multiple block read with automatic issuing of CMD12<br>• When reception of the busy state after reception of the CRC status is completed in the case of transfer for single block write<br>• When reception of the busy state after reception of the CRC status of the last block of data is completed in the case of transfer for multiple block write<br>• When reception of the response busy state for CMD12 is completed in the case of transfer for multiple block write with automatic issuing of CMD12<br>• When reception of the response to CMD12 that was issued by setting the STP bit to1 is completed in the case of transfer for multiple block read<br>• When reception of the response busy state for CMD12 that was issued by setting the STP bit to1 is completed in the case of transfer for multiple block write<br>• When reception of the response to CMD52 that was issued by setting the IOABT bit to1 is completed in the case of transfer for multiple block read<br>• When reception of the response to CMD52 that was issued by setting the IOABT bit to1 is completed in the case of transfer for multiple block write<br>In addition to the above conditions, this bit is set when a command sequence is halted because of a communications error or timeout.<br>[Clearing condition]<br>When 0 is written to INFO2 |
| 1 | — | 0 | R | Fixed 0 |
| 0 | INFO0 | 0*2 | R/W*1 | Response End<br>[Setting conditions]<br>• When reception of the response is completed<br>• When transmission of a command without response is completed<br>• When reception of the busy state after R1b response is completed<br>• When reception of the response to CMD52 that was issued by setting the C52PUB bit to1 is completed in the case of transfer for multiple block read<br>• When reception of the response to CMD52 that was issued by setting the C52PUB bit to1 is completed in the case of transfer for multiple block write<br>In addition to the above conditions, this bit is set when a command sequence is halted because of a communications error or timeout.<br>[Clearing condition]<br>When 0 is written to INFO0 |

Note 1. It is effective only if 0 is written.
Note 2. The initial value is applied at a reset and when the SDRST bit in SOFT_RST is 0.

### 50.2.7 SD Card Interrupt Flag Register 2 (SD_INFO2)

The SD card interrupt flag register 2 (SD_INFO2) indicates the access status of the SD buffer (SD_BUF) and SD card. To clear a flag, write 0 to the bit to be cleared and 1 to the other bits.

| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| 15 | ILA | 0*2 | R/W*1 | Illegal Access Error<br>[Setting conditions]<br>• When data is written to SD_CMD within a command sequence<br>• When SD_CMD[10:8] = 3'b011 (no response) and SD_CMD[11] = 1'b1 (command with data transfer) are set in SD_CMD<br>• When SD_CMD[11] = 1'b1 (command with data transfer) and SD_CMD[7:0] = 8'b00001100 (CMD12) are set in SD_CMD<br>[Clearing condition]<br>When 0 is written to ILA |
| 14 | CBSY | 0*2 | R | Command Type Register Busy<br>1: The command sequence is being executed.<br>0: The command sequence is ended. |

| 3 | ERR3 | 0*2 | R/W*1 | Data Timeout (except response timeout)<br>[Setting conditions]<br>• After R1b response, the busy state (SD_D0 = 0) continues for longer than Ncycle.<br>• After CRC status, the busy state (SD_D0 = 0) continues for longer than Ncycle.<br>• After write data, the CRC status is not received though Ncycle has elapsed.<br>• After read command, read data is not received though a longer time than Ncycle has elapsed.<br>• After CMD12 has been issued within a command sequence, the busy state (SD_D0 = 0) for longer than Ncycle continues.<br>• After the reception of read data, read data for the next block are not received though a longer time than Ncycle has elapsed.<br>• After release of the read wait state, read data for the next block are not received though a longer time than Ncycle has elapsed.<br>[Clearing condition]<br>• When 0 is written to ERR3<br>Ncycle is set by bits 7 to 4 in SD_OPTION.<br>The command sequence is halted by the data timeout. |

| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| 2 | ERR2 | 0*2 | R/W*1 | END Error<br>[Setting conditions]<br>• When an error occurs in the response length (and the end bit has not been detected)<br>• When an error occurs in the read data length (and the end bit has not been detected among the valid bits)<br>• When an error occurs in the CRC status length (and the end bit has not been detected)<br>[Clearing condition]<br>When 0 is written to ERR2<br>The command sequence is halted by the End error.*4 |

| 0 | ERR0 | 0*2 | R/W*1 | CMD Error<br>[Setting condition]<br>When the command index of the transmitted command differed from the command index of the received response<br>[Clearing condition]<br>When 0 is written to ERR0<br>The command sequence is halted by the CMD error.*4 |

Note 1. It is effective only if 0 is written.
Note 2. The initial value is applied at a reset and when the SDRST bit in SOFT_RST is 0.
Note 3. The single byte or three bytes from the fraction of a full 32-bit unit are regarded as excess data due to an odd value for the number of bytes setting in SD_SIZE, or the two bytes from the fraction of a full 32-bit unit are regarded as excess data due if the value for the number of bytes setting in SD_SIZE is even but is not on a four-byte boundary.
Note 4. After the C52PUB bit in SDIO_MODE has been set to 1, if a communications error or timeout for response occurs in response to the CMD52 that is issued, since the command sequence has not been completed, complete the sequence with error processing as in usage examples in Figure 50.17 under section 50.4.7, IO_RW_EXTENDED Command (CMD53/Multiple Block Read) or in Figure 50.20 under section 50.4.8, IO_RW_EXTENDED Command (CMD53/Multiple Block Write).

### 50.2.8 SD_INFO1 Interrupt Mask Register (SD_INFO1_MASK)

The SD_INFO1 interrupt mask register (SD_INFO1_MASK) enables or disables the SD_INFO1 interrupt. When 0 is set in SD_INFO1_MASK while the corresponding flag in SD_INFO1 is set, an interrupt occurs.

| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| 15 to 10 | — | All 0 | R | Fixed 0 |
| 9 | IMASK9 | 1 | R/W | INFO9 interrupt masked |
| 8 | IMASK8 | 1 | R/W | INFO8 interrupt masked |
| 7 to 5 | — | All 0 | R | Fixed 0 |
| 4 | IMASK4 | 1 | R/W | INFO4 interrupt masked |
| 3 | IMASK3 | 1 | R/W | INFO3 interrupt masked |
| 2 | IMASK2 | 1 | R/W | INFO2 interrupt masked |
| 1 | — | 0 | R | Fixed 0 |
| 0 | IMASK0 | 1 | R/W | INFO0 interrupt masked |

### 50.2.9 SD_INFO2 Interrupt Mask Register (SD_INFO2_MASK)

The SD_INFO2 interrupt mask register (SD_INFO2_MASK) enables or disables the SD_INFO2 interrupt. When 0 is set in SD_INFO2_MASK while the corresponding flag in SD_INFO2 is set, an interrupt occurs.

| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| 15 | IMASK | 1 | R/W | ILA interrupt masked |
| 14 to 12 | — | All 0 | R | Fixed 0 |
| 11 | — | 1 | R/W | Reserved. The write value should always be 1. |
| 10 | — | 0 | R | Fixed 0 |
| 9 | BMASK1 | 1 | R/W | BWE interrupt masked |
| 8 | BMASK0 | 1 | R/W | BRE interrupt masked |
| 7 | — | 0 | R | Fixed 0 |
| 6 | EMASK6 | 1 | R/W | ERR6 interrupt masked |
| 5 | EMASK5 | 1 | R/W | ERR5 interrupt masked |
| 4 | EMASK4 | 1 | R/W | ERR4 interrupt masked |
| 3 | EMASK3 | 1 | R/W | ERR3 interrupt masked |
| 2 | EMASK2 | 1 | R/W | ERR2 interrupt masked |
| 1 | EMASK1 | 1 | R/W | ERR1 interrupt masked |
| 0 | EMASK0 | 1 | R/W | ERR0 interrupt masked |

### 50.2.10 SD Clock Control Register (SD_CLK_CTRL)

The SD clock control register (SD_CLK_CTRL) controls the SD clock (SD_CLK) output and sets the frequency. Set SCLKEN to 1 before writing to SD_CMD to issue a command.
Do not write to SD_CLK_CTRL while the SCLKDIVEN bit in SD_INFO2 is set to 0.

| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| 15 to 10 | — | All 0 | R | Fixed 0 |
| 9 | SDCLKOFFEN | 0 | R/W | SD Clock (SD_CLK) Output Automatic Control Enable<br>0: Automatic control for SD clock (SD_CLK) output is disabled.<br>1: Automatic control for SD clock (SD_CLK) output is enabled.<br>This function of automatic control for SD clock (SD_CLK) output causes SD_CLK output only within a command sequence.<br>The timing with which SD_CLK output starts and stops is as follows.<br>SD_CLK output starts after writing to SD_CMD.<br>SD_CLK output stops when 8 cycles of SD_CLK have elapsed after the end of the command sequence.<br>In addition, automatic control for SD clock (SD_CLK) output is enabled when SCLKEN in SD_CLK_CTRL is 1. |
| 8 | SCLKEN | 0*1 | R/W*2 | SD Clock (SD_CLK) Output Control Enable<br>0: SD clock (SD_CLK) output is disabled. The SD_CLK signal is fixed 0.<br>1: SD clock (SD_CLK) output is enabled. |

| 6 | DIV6 | 0 | R/W*2 | |
| 5 | DIV5 | 1 | R/W*2 | |
| 4 | DIV4 | 0 | R/W*2 | |
| 3 | DIV3 | 0 | R/W*2 | |
| 2 | DIV2 | 0 | R/W*2 | |
| 1 | DIV1 | 0 | R/W*2 | |
| 0 | DIV0 | 0 | R/W*2 | |

Note 1. This initial value is applied at a reset and when the SDRST bit in SOFT_RST is 0.
Note 2. Writing is impossible when the CBSY bit in SD_INFO2 is 1.

### 50.2.11 Transfer Data Length Register (SD_SIZE)

The transfer data length register (SD_SIZE) specifies the transfer data size.

| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| 15 to 12 | — | All 0 | R | Fixed 0 |
| 11, 10 | — | All 0 | R | Reserved |
| 9 to 0 | LEN9 to LEN0 | 1000000000 | R/W | Transfer Data Size*1<br>These bits specify a size between 1 and 512 bytes for the transfer of single blocks.<br>In cases of multiple block transfer with automatic issuing of CMD12 (CMD18 and CMD25), the only specifiable transfer data size is 512 bytes.<br>Furthermore, in cases of multiple block transfer without automatic issuing of CMD12, as well as 512 bytes, 32, 64, 128, and 256 bytes are specifiable. However, in the reading of 32, 64, 128, and 256 bytes for the transfer of multiple blocks, this is restricted to cases of multiple block transfer by CMD53. Additionally, if a command accompanies data transfer, do not set these bits to 0. |

Note 1. Do not change the values of these bits when the SCLKDIVEN bit in SD_INFO2 is 0.

### 50.2.12 SD Card Access Control Option Register (SD_OPTION)

The SD card access control option register (SD_OPTION) sets the bus width and timeout counter.

| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| 15 | WIDTH | 0*1 | R/W | Bus Width*2<br>0: 4-bit width<br>1: 1-bit width |
| 14 | — | 1 | R | Fixed 1 |

| 6 | TOP26 | 1*1 | R/W | |
| 5 | TOP25 | 1*1 | R/W | |
| 4 | TOP24 | 0*1 | R/W | |
| 3 | CTOP24 | 1*1 | R/W | Card Detect Time Counter<br>1111: Setting prohibited<br>1110: P1φ × $2^{24}$<br>1101: P1φ × $2^{23}$<br>:<br>0001: P1φ × $2^{11}$<br>0000: P1φ × $2^{10}$ |
| 2 | CTOP23 | 1*1 | R/W | |
| 1 | CTOP22 | 1*1 | R/W | |
| 0 | CTOP21 | 0*1 | R/W | |

Note 1. The initial value is applied at a reset and when the SDRST bit in SOFT_RST is 0.
Note 2. Do not change the values of these bits when the SCLKDIVEN bit in SD_INFO2 is 0.

## 50.2.13 SD Error Status Register 1 (SD_ERR_STS1)

The SD error status register 1 (SD_ERR_STS1) indicates the CRC status, CRC error, End error, and CMD error.

| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| 15 | — | 0 | R | Fixed 0 |
| 14 | E14 | 0*1 | R | These bits store the CRC status. (normal: 010) |
| 13 | E13 | 1*1 | R | |
| 12 | E12 | 0*1 | R | |
| 11 | E11 | 0*1 | R | Set to 1 when an error occurs in the CRC status |
| 10 | E10 | 0*1 | R | Set to 1 when a CRC error occurs in the read data |
| 9 | E9 | 0*1 | R | Set to 1 when a CRC error occurs in the response to a command*2 issued within a command sequence. In cases where CMD12 is issued by setting a command index in SD_CMD, this is indicated in E8. |
| 8 | E8 | 0*1 | R | Set to 1 when a CRC error occurs in a response (other than a response to a command*2 issued within a command sequence) |
| 7, 6 | — | All 0 | R | Fixed 0 |
| 5 | E5 | 0*1 | R | Set to 1 when an error occurs in the CRC status length (and the end bit has not been detected) |
| 4 | E4 | 0*1 | R | Set to 1 when an error occurs in the read data length (and the end bit has not been detected among the valid bits) |
| 3 | E3 | 0*1 | R | Set to 1 when an error occurs in the response length to a command*2 issued within a command sequence. In cases where CMD12 is issued by setting a command index in SD_CMD, this is indicated in E2. |
| 2 | E2 | 0*1 | R | Set to 1 when an error occurs in the response length (other than a response to a command*2 issued within a command sequence) |
| 1 | E1 | 0*1 | R | Set to 1 when an error occurs in the command index of the response to a command*2 issued within a command sequence. In cases where CMD12 is issued by setting a command index in SD_CMD, this is Indicated in E0. |
| 0 | E0 | 0*1 | R | Set to 1 when an error occurs in the command index of a response (other than a response to a command*2 issued within a command sequence). |

Note 1. The initial value is applied at a reset and when the SDRST bit in SOFT_RST is 0.
Note 2. "Command issued within a command sequence" refers to CMD12 when automatic issuing is enabled for multiple block transfer by the setting in SD_CMD, CMD12 when the STP bit in SD_STOP is set to 1, or CMD52 when the C52PUB or IOABT bit in SDIO_MODE is set to 1.

### 50.2.14 SD Error Status Register 2 (SD_ERR_STS2)

The SD error status register 2 (SD_ERR_STS2) indicates the timeout state. Ncycle is set by bits 7 to 4 in SD_OPTION.

| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| 15 to 7 | — | All 0 | R | Fixed 0 |
| 6 | E6 | 0*1 | R | Set to 1 when the busy state continues for longer than Ncycle after the CRC status |
| 5 | E5 | 0*1 | R | Set to 1 when the CRC status is not received though a longer time than Ncycle has elapsed after data writing |
| 4 | E4 | 0*1 | R | Set to 1 when read data is not received though a longer time than Ncycle has elapsed after read command.<br>Set to 1 when read data for the next block are not received though a longer time than Ncycle has elapsed after the reception of read data.<br>Set to 1 when read data for the next block are not received though a longer time than Ncycle has elapsed after release of the read wait state. |
| 3 | E3 | 0*1 | R | Set to 1 when the busy state for longer than Ncycle continues after CMD12 has been issued within a command sequence. In cases where CMD12 is issued by setting a command index in SD_CMD, this is indicated in E2. |
| 2 | E2 | 0*1 | R | Set to 1 when the busy state for longer than Ncycle continues after R1b response |
| 1 | E1 | 0*1 | R | Set to 1 when the response to a command*2 issued within a command sequence is not received though a longer time than 640 cycles of SD_CLK has elapsed. In cases where CMD12 is issued by setting a command index in SD_CMD, this is indicated in E0. |
| 0 | E0 | 0*1 | R | Set to 1 when the response (other than a response to a command*2 issued within a command sequence) is not received though a longer time than 640 cycles of SD_CLK has elapsed. |

Note 1. The initial value is applied at a reset and when the SDRST bit in SOFT_RST is 0.
Note 2. "Command issued within a command sequence" refers to CMD12 when automatic issuing is enabled for multiple block transfer by the setting in SD_CMD, CMD12 when the STP bit in SD_STOP is set to 1, or CMD52 when the C52PUB or IOABT bit in SDIO_MODE is set to 1.

### 50.2.15 SD Buffer Read/Write Register (SD_BUF0)

| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| 31 to 0 | BUF31 to BUF0 | Unknown | R/W | When writing to the SD card, the write data is written to this register.<br>When reading from the SD card, the read data is read from this register.<br>This register is internally connected to two 512-byte (128-word) buffers. |

## 50.2.16 SDIO Mode Control Register (SDIO_MODE)

The SDIO mode control register (SDIO_MODE) controls the CMD52 issuance and the read wait state at multiple block transfer, and the reception of SDIO interrupt. C52PUB and IOABT should not be set to 1 simultaneously.

| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|

C52PUB is automatically cleared to 0 after reception of the response to CMD52 is completed. Additionally, if C52PUB is set to 1 while the last block is being transferred, CMD52 is not issued. In this case, C52PUB is automatically cleared to 0 after the access end flag has been set to 1.<br>• When C52PUB and RWREQ are set to 1 in the CMD53 (multiple block) read sequence, the block transfer enters the read wait state between the current one-block and next-block and CMD52 is automatically issued. C52PUB is automatically cleared to 0 after reception of the response to CMD52 is completed. Additionally, if C52PUB is set to 1 while the last block is being transferred, CMD52 is not issued. In this case, C52PUB is automatically cleared to 0 after the access end flag has been set to 1.<br>• If C52PUB is set to 1 in the CMD53 (multiple block) read sequence, be sure to set RWREQ to 1 as well as C52PUB.<br>• Set SD_ARG before setting C52PUB to 1. |

Note 1. Do not change the value of this bit when the SCLKDIVEN bit in SD_INFO2 is set to 0.
Note 2. Do not change the values of these bits from 1 to 0 when the SCLKDIVEN bit in SD_INFO2 is set to 0.
Note 3. Clear this bit after reception of the response to CMD52 is completed.

### 50.2.17 SDIO Interrupt Flag Register (SDIO_INFO1)

The SDIO interrupt flag register (SDIO_INFO1) indicates the status regarding to the SDIO card access. To clear a flag, write 0 to the bit to be cleared and 1 to the other bits.

| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| 15 | EXWT | 0*2 | R/W*1 | [Setting condition]<br>While the last block in the CMD53 (multiple block) read sequence is transferred, RWREQ in SDIO_MODE is set to 1.<br>[Clearing condition]<br>When 0 is written to EXWT |

Note 1. It is effective only if 0 is written.
Note 2. The initial value is applied at a reset and when the SDRST bit in SOFT_RST is 0.
Note 3. Before clearing this bit, access the SDIO card to negate the SDIO interrupt signal from the SDIO card (after CMD25 has been issued and the response received). If the interrupt signal is not negated, this bit may be set again.

### 50.2.18 SDIO_INFO1 Interrupt Mask Register (SDIO_INFO1_MASK)

The SDIO_INFO1 interrupt mask register (SDIO_INFO1_MASK) enables or disables the SD_INFO1 interrupt. When 0 is set in SDIO_INFO1_MASK while the corresponding flag in SD_INFO1 is set, an interrupt occurs.

| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| 15 | MEXWT | 1 | R/W | EXWT interrupt masked |
| 14 | MEXPUB52 | 1 | R/W | EXPUB52 interrupt masked |
| 13 to 3 | — | All 0 | R | Fixed 0 |
| 2, 1 | — | All 1 | R/W | Reserved<br>The write value should always be 1. |
| 0 | IOMSK | 1 | R/W | IOIRQ interrupt masked |

### 50.2.19 DMA Mode Enable Register (CC_EXT_MODE)

The DMA mode enable register (CC_EXT_MODE) enables the DMA transfer.

| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| 15 to 13 | — | All 0 | R | Fixed 0 |
| 12 | — | 1 | R | Reserved |

| 0 | — | 0 | R | Reserved |

Note 1. Do not change the values of these bits when the SCLKDIVEN bit in SD_INFO2 is set to 0.

### 50.2.20 Software Reset Register (SOFT_RST)

The software reset register (SOFT_RST) sets a software reset. Make sure to release the reset before using the SD host interface.

| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| 15 to 3 | — | All 0 | R | Fixed 0 |
| 2 | — | 1 | R | Reserved |
| 1 | — | 1 | R | Reserved |
| 0 | SDRST | 0 | R/W | Software Reset of SD I/F Unit<br>0: Reset<br>1: Reset released |

### 50.2.21 Version Register (VERSION)

The version register (VERSION) indicates the version of the SD host interface.

| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| 15 to 12 | — | 1000 | R | Reserved |
| 11 to 8 | UR3 to UR0 | 4'h2 | R | Version of Renesas IP |
| 7 to 0 | IP7 to IP0 | 8'h0B | R | Version of adopted IP |

## 50.2.22 Swap Control Register (EXT_SWAP)

The swap control register (EXT_SWAP) can replace data when SD_BUF0 is accessed.

| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| 15 | — | 0 | R/W | Reserved<br>The write value should always be 0. |
| 14, 13 | — | All 0 | R | Reserved |

Moreover, if a communications error or timeout occurs during the 64-byte unit DMA transfer, this bit should be set to 0 and re-setting again before using DMA transfer. If a software reset occurs during the 64-byte unit DMA transfer, this bit should be set to 0 and re-setting again before using DMA transfer. |

| 6 | SDBWSWAP | 0 | R/W | SD_BUF0 Swap Write*1<br>When writing to SD_BUF0, data to be written can be replaced and then stored in SD_BUF0.*2<br>0: The current data is written without replacement.<br>1: Data replacement for writing proceeds in bytes. |
| 5 | — | 0 | R | Fixed 0 |
| 4, 3 | — | All 0 | R/W | Reserved<br>The write value should always be 0. |
| 2 | — | 0 | R | Fixed 0 |
| 1 | — | 0 | R/W | Reserved<br>The write value should always be 0. |
| 0 | — | 0 | R | Fixed 0 |

Note 1. Do not change the values of these bits when the SCLKDIVEN bit in SD_INFO2 is set to 0.
Note 2. Details on SD_BUF0 access with data replacement or non-replacement are indicated in (1) SD Data Format in section 50.3.1, SD I/F.

## 50.3 Operation

### 50.3.1 SD I/F

#### (1) SD Data Format

When data is read from the SD card, the procedure is as follows.

1. The SD host interface receives data from the SD card via the SD_D signal. (SD_D signal: see Figure 50.2 and Figure 50.3.)
2. The receive data is stored in SD_BUF of the SD host interface. (SD_BUF store data: see Figure 50.4)
3. The data stored in SD_BUF is read by SD_BUF0. (Reading from SD_BUF0: see Figure 50.5)

When data is written to the SD card, the above procedure will be reversed.
When accessing SD_BUF0, caution should be taken for the transfer order in SD_D and the store order in SD_BUF. In addition, data stored in SD_BUF0 can be replaced in bytes with the EXT_SWAP. (See Figure 50.5)

## 50.3.2 Card Detect/Write Protect

### (1) Card Detect

The SD host interface has two types of card detect functions as described in the following.

- Card detect with SD_CD
  Figure 50.6 shows the timing chart of card detect using SD_CD. SD_CD is connected to the card socket and pulled up on the host device. The resistance of the pull-up resistor is decided by the specification of the SD host device.

[Card insertion]
SD_CD is pulled down when a card is inserted. At this time, if SD_CD has been pulled down for the Ncycle period (set in SD_OPTION), INFO4 in SD_INFO1 is set to 1. (It is cleared to by writing 0.)
[Card removal]
SD_CD is pulled up when a card is removed. At this time, if SD_CD has been pulled up for the Ncycle period (set in SD_OPTION), INFO3 in SD_INFO1 is set to 1. (It is cleared to by writing 0.)

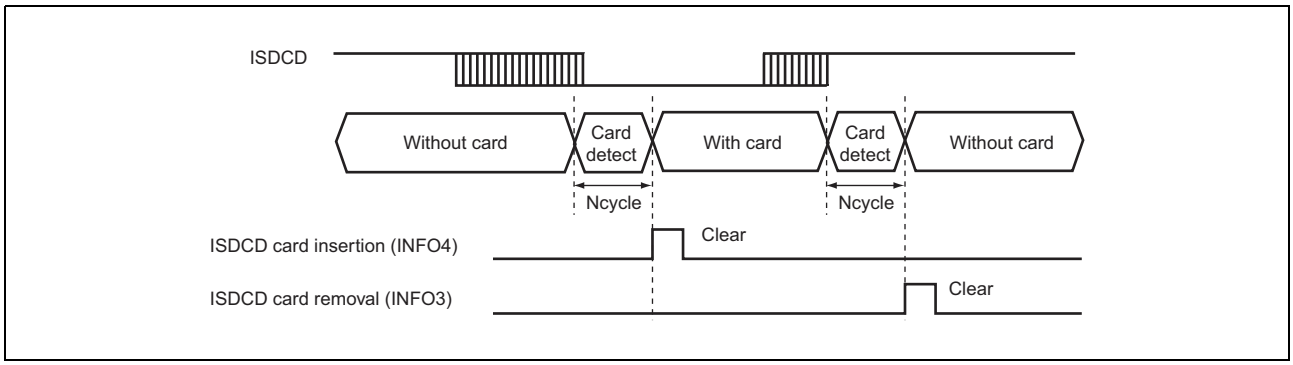

**Figure 50.6 Example of Card Detect with SD_CD**

- SD card detect with SD_D3
  Figure 50.7 shows the timing chart when the SD card is detected with SD_D3. In addition, SD_D3 is pulled down by the host device, and the resistance value for pulling down is decided by the specification of SD host device.

[Card insertion]
When an SD card is inserted, SD_D3 is pulled up. Accordingly, INFO9 in SD_INFO1 is set to 1. (It is cleared to by writing 0.)
[Card removal]
When an SD card is removed, SD_D3 is pulled down. Accordingly, INFO8 in SD_INFO1 is set to 1. (It is cleared to by writing 0.)

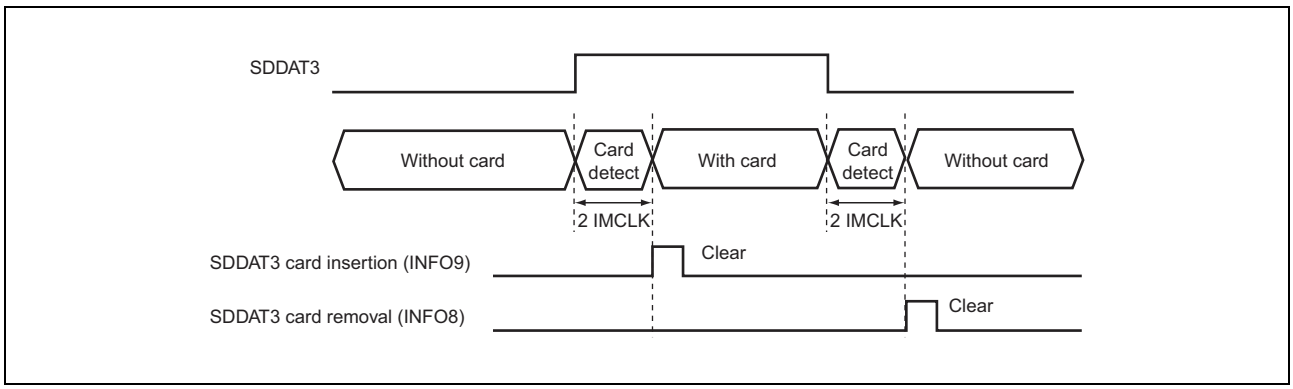

**Figure 50.7 SD Card Detect with SD_D3**

- Power-Down mode at Card removal
  SD Host Interface module is halted by the MSTP123 bit to MSTP120 bit in Standby Control Register 12 (STBCR12). If these bits of each channel in STBCR12 are set to 10, low power consumption is achieved at Card removal. See section 55, Power-Down Modes.

|---|---|---|---|---|
| 3 | MSTP123 | 1 | R/W | SD Host Interface 0 Module Stop<br>00: SD Host Interface 0 Module runs.<br>01: Setting prohibited<br>10: Only card detect block in SD Host Interface 0 Module runs.<br>11: Clock supply to SD Host Interface 0 Module is halted. |

| 0 | MSTP120 | 1 | | |

### (2) Write Protect

The SD host interface has two types of write protect functions.

- Write protect with SD_WP
  SD_WP is connected to the card socket, and pulled up or pulled down by the card insertion. The selection of pulling up or pulling down and the resistance value is decided by the specification of SD host device. As the SD_WP state is reflected to INFO7 in SD_INFO1, the write protect is decided after the SD card is inserted.
- Write protect with command
  The card's internal write protection and the card lock/unlock operation are realized by the command.

### 50.3.3 Interrupt Request and DMA Transfer Request

#### (1) Interrupt Request

The SD host interface has three interrupt requests. Table 50.4 shows the relationship between the interrupt flag registers and the interrupt mask registers. When a bit in an interrupt mask register is set to 0, an interrupt occurs by setting the corresponding bit in the interrupt flag register to 1.
To clear a flag, write 0 to the bit to be cleared and 1 to the other bits.

**Table 50.4 Interrupt Request**

| | Interrupt Flag Register | | Interrupt Mask Register | |
|---|---|---|---|---|
| **Interrupt Request** | **Register Name** | **Bit Name** | **Register Name** | **Bit Name** |
| Card access interrupt (SDHI0) | SD_INFO1 | INFO2 | SD_INFO1_MASK | IMASK2 |

| | | INFO8 | | IMASK8 |
| | | INFO4 | | IMASK4 |
| | | INFO3 | | IMASK3 |

### (2) DMA Transfer Request

The SD host interface has two types of DMA transfer requests. The DMA transfer requests are described in the following passages.

- SD_BUF write DMA transfer request
  - When the buffer is empty while the DMASDRW bit in CC_EXT_MODE is set to 1, the SD_BUF write DMA transfer request is asserted.
  - The SD_BUF write DMA transfer request is negated when the last data in one block (= the transfer data size set in SD_SIZE) is transferred. The SD_BUF write DMA transfer request is also negated by clearing the SDRST bit in SOFT_RST to 0 or setting the STP bit in SD_STOP to 1. Note that if a communications error or timeout occurs at the DMA transfer, the SD_BUF write DMA transfer request is not negated.
  - The number of DMA transfers should be n x one block. (n = integer, one block = the transfer data size set in SD_SIZE)
  - When the IOABT bit in SDIO_MODE is set to 1, the SD_BUF write DMA transfer request is negated.
  - The DMA transfer request is also negated by clearing the DMASDRW bit to 0. However, note that the DMA transfer request is asserted again when the DMASDRW bit is set to 1 before writing to SD_CMD.
- SD_BUF read DMA transfer request
  - When the buffer is full while the DMASDRW bit in CC_EXT_MODE is set to 1, the SD_BUF read DMA transfer request is asserted.
  - The SD_BUF read DMA transfer request is negated when the last data in one block (= the transfer data size set in SD_SIZE) is transferred. The SD_BUF read DMA transfer request is also negated by clearing the SDRST bit in SOFT_RST to 0 or setting the STP bit in SD_STOP to 1. Note that if a communications error or timeout occurs at the DMA transfer, the SD_BUF read DMA transfer request is not negated.
  - The number of DMA transfers should be n x one block. (n = integer, one block = the transfer data size set in SD_SIZE)
  - When the IOABT bit in SDIO_MODE is set to 1, the SD_BUF read DMA transfer request is negated.
  - The DMA transfer request is also negated by clearing the DMASDRW bit to 0. However, note that the DMA transfer request is asserted again when the DMASDRW bit is set to 1 before writing to SD_CMD.
  - The number of cycles at one DMA transfer will be more than P1φ × 10. If SD_CLK is high frequency and SD_BUF is not empty, SD_CLK is stopped until SD_BUF is empty.

### 50.3.4 Communications Errors and Timeouts

- Communications Errors and Timeouts
  Table 50.5 and Table 50.6 show the relationships between the SD card interrupt flag register and SD error status register for communications errors and timeouts, respectively. When a bit in the SD card interrupt flag register is set to 1, the corresponding bit in the SD error status register is set to 1. The values of the SD error status register are cleared by writing to SD_CMD or writing 0 to the SDRST bit in SOFT_RST.

**Table 50.5 Communications Errors**

| | SD Card Interrupt Flag Register | | SD Error Status Register | | |
|---|---|---|---|---|---|
| **Communication Error** | **Register Name** | **Bit Name** | **Register Name** | **Bit Name** | **Description** |
| END error | SD_INFO2 | ERR2 | SD_ERR_STS1 | E5 | When an error occurs in the CRC status length |
| | | | | E4 | When an error occurs in read data length |
| | | | | E3 | When an error occurs in the response length to a command issued within a command sequence |
| | | | | E2 | When an error occurs in the response length (other than a response to a command issued within a command sequence) |
| CRC error | | ERR1 | | E11 | When an error occurs in the CRC status |
| | | | | E10 | When a CRC error occurs in the read data |
| | | | | E9 | When a CRC error occurs in the response to a command issued within a command sequence |
| | | | | E8 | When a CRC error occurs in the response (other than a response to a command issued within a command sequence) |
| CMD error | | ERR0 | | E1 | The command index of the transmitted command differed from the command index of the received response (for a command issued within a command sequence). |
| | | | | E0 | The command index of the transmitted command differed from the command index of the received response (for a command issued other than within a command sequence) |

**Table 50.6 Timeouts**

| Timeout | SD Card Interrupt Flag Register | | SD Error Status Register | | Description |
|---|---|---|---|---|---|
| | Register Name | Bit Name | Register Name | Bit Name | |
| Response timeout | SD_INFO2 | ERR6 | SD_ERR_STS2 | E1 | When the response to a command issued within a command sequence is not received though a longer time than 640 cycles of SD_CLK has elapsed |
| | | | | E0 | When the response (other than a response to a command issued within a command sequence) is not received though a longer time than 640 cycles of SD_CLK has elapsed |
| Data timeout (other than response timeout) | | ERR3 | | E6 | When the busy state (SD_D0 = 0) continues for longer than Ncycle after the CRC status |
| | | | | E5 | When the CRC status is not received though a longer time than Ncycle has elapsed after data writing |
| | | | | E4 | When read data is not received though a longer time than Ncycle has elapsed after read command |
| | | | | | When read data for the next block are not received though a longer time than Ncycle has elapsed after the reception of read data |
| | | | | | When read data for the next block are not received though a longer time than Ncycle has elapsed after release of the read wait state |
| | | | | E3 | When the busy state (SD_D0 = 0) for longer than Ncycle continues after CMD12 has been issued within a command sequence. |
| | | | | E2 | When the busy state (SD_D0 = 0) for longer than Ncycle continues after R1b response |

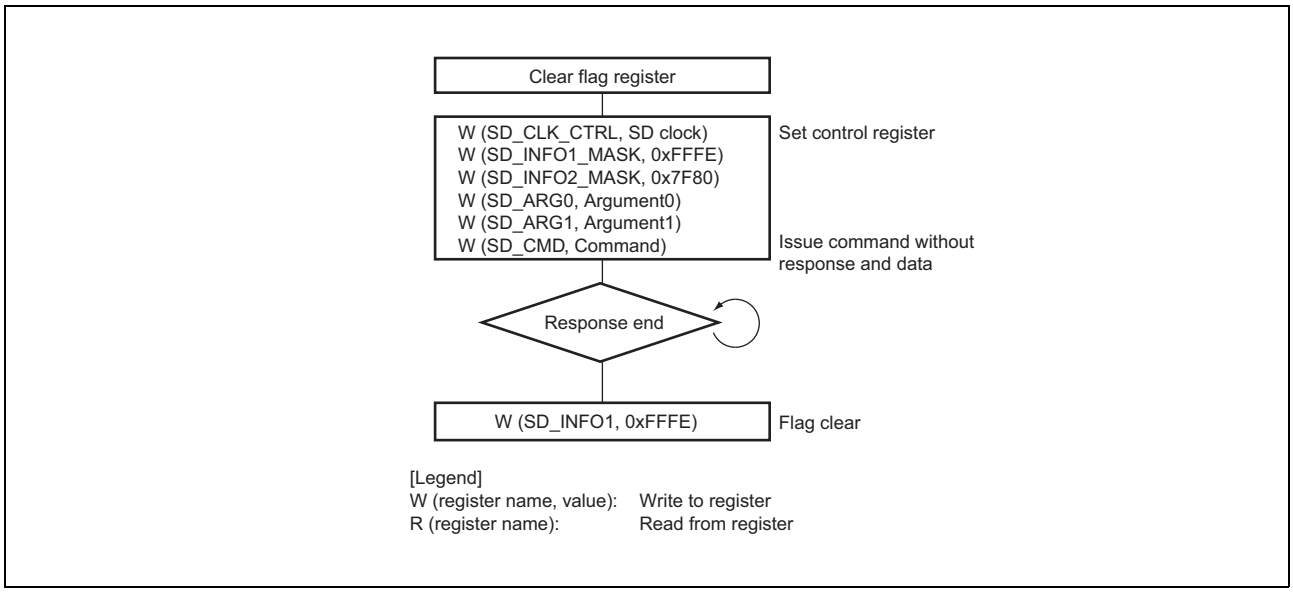

**Figure 50.8 Flow Example of Command Without Response and Data**

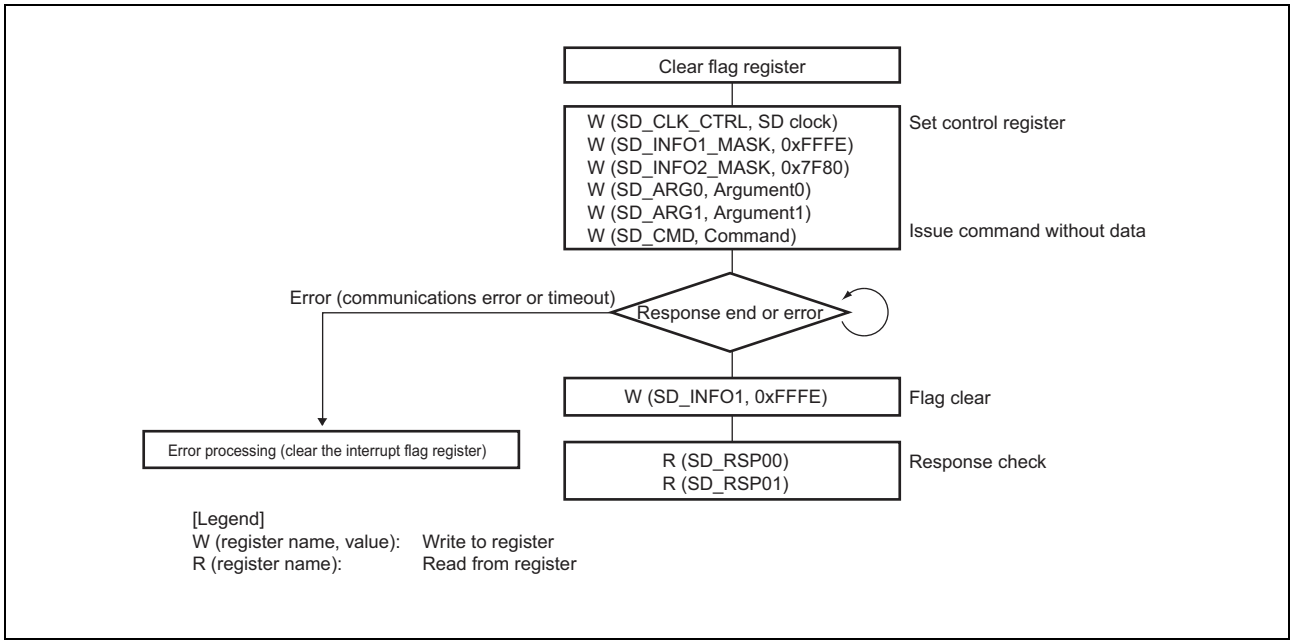

**Figure 50.9 Flow Example of Command Without Data**

(2) Operation for Command without Data Transfer: The operation of the command without data transfer is described in the following.

- Command without response and data
  - Flag register clear
    First, clear the bits in the flag register. (SD_INFO1 and SD_INFO2)
  - Control register set
    Set the SD clock (SD_CLK), interrupt mask, and so on. (SD_CLK_CTRL, SD_INFO1_MASK, and SD_INFO2_MASK)
  - Command issue
    Set CMD Argument in SD_ARG0 and SD_ARG1 and write to SD_CMD.
    Accordingly, CMD is issued, and the operation is started.
  - Flag clear
    When transmission of a command is completed, INFO0 (response end) in SD_INFO1 is set to 1 to generate an interrupt. Clear INFO0 to 0.

- Command without data
  - Flag register clear
    First, clear the bits in the flag register. (SD_INFO1 and SD_INFO2)
  - Control register set
    Set the SD clock (SD_CLK), interrupt mask, and so on. (SD_CLK_CTRL, SD_INFO1_MASK, and SD_INFO2_MASK)
  - Command issue
    Set CMD Argument in SD_ARG0 and SD_ARG1 and write to the SD_CMD.
    Accordingly, CMD is issued, and the operation is started.
  - Flag clear
    When a response is received, INFO0 (response end) in SD_INFO1 is set to 1 to generate an interrupt. Clear INFO0 to 0.
  - Read a response from SD_RSP00 and SD_RSP01.

Furthermore, perform error processing (clear the interrupt flag register) if an error occurs (a communications error or timeout).

## 50.4.2 Single Block Read

### (1) Flowchart

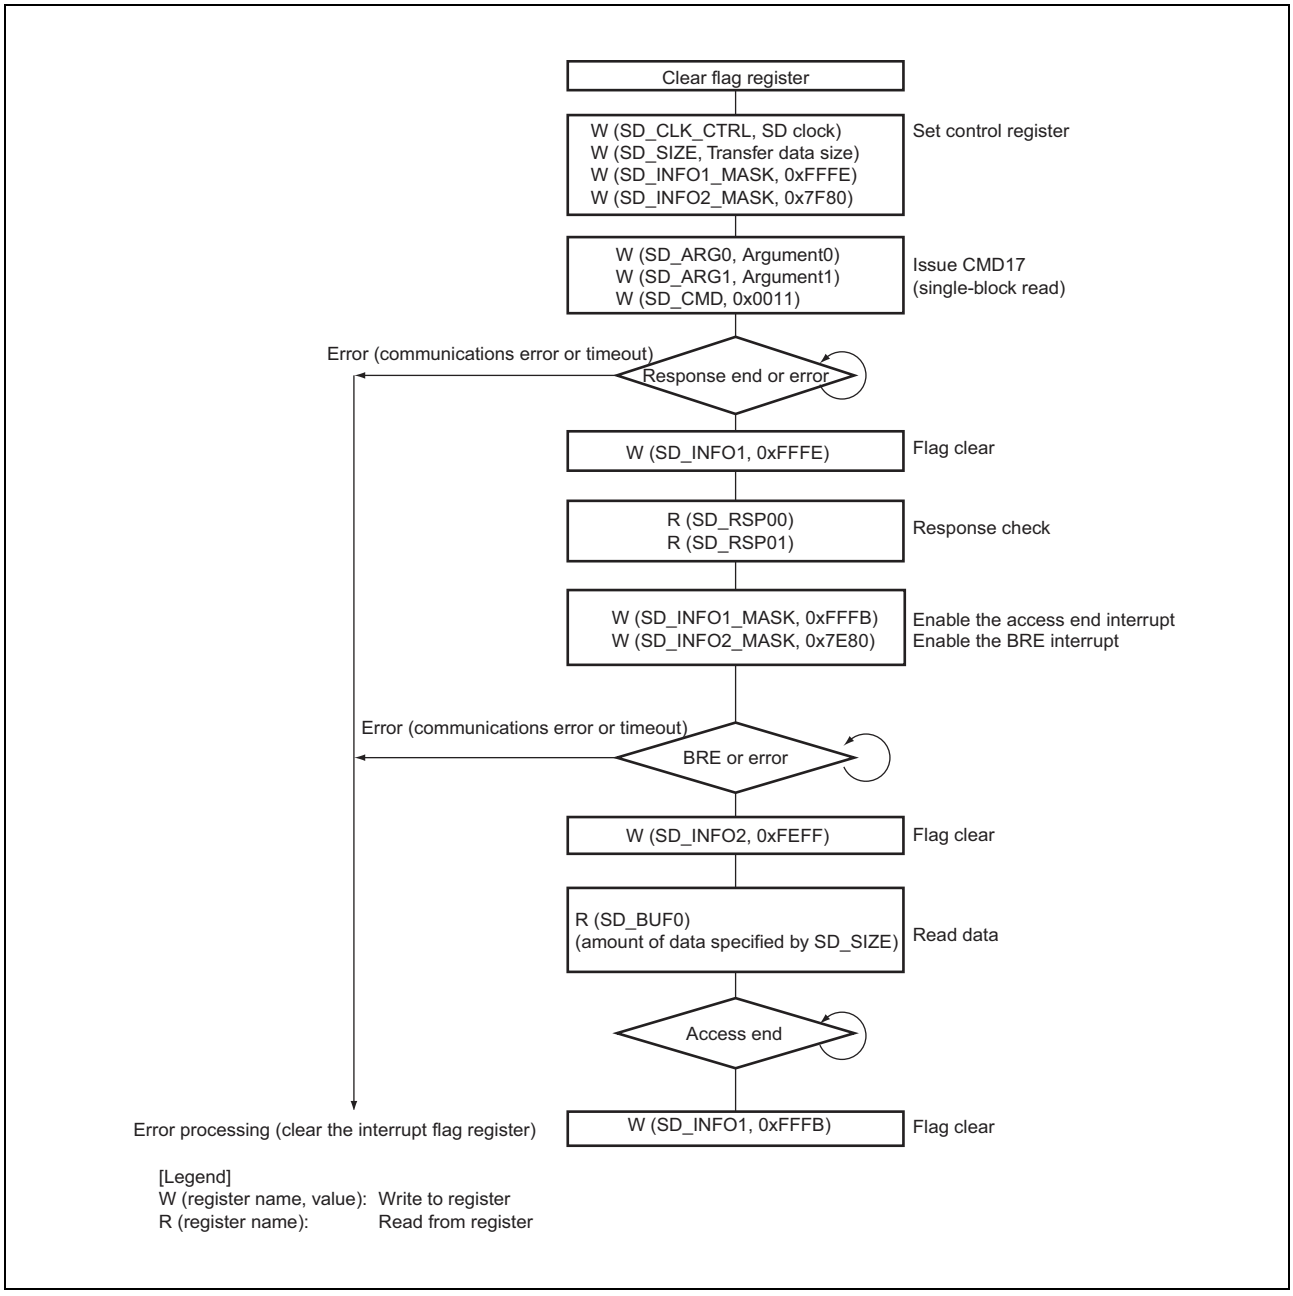

**Figure 50.10 Single Block Read Flowchart Example**

(2) Operation for Single Block Read: The operation of the single block read is described in the following.

– Flag register clear
First, clear the bits in the flag register. (SD_INFO1 and SD_INFO2)

– Control register set
Set the SD clock (SD_CLK), transfer data size, interrupt mask, and so on. (SD_CLK_CTRL, SD_SIZE, SD_INFO1_MASK, and SD_INFO2_MASK)

– Command issue (CMD17)
Set CMD17 Argument in SD_ARG0 and SD_ARG1 and write 0x0011 to SD_CMD.
Accordingly, CMD17 is issued, and the single block read operation is started.

– Response check
On receiving the response, INFO0 (response end) in SD_INFO1 is set to 1 to generate an interrupt. Clear INFO0 to 0 and read the response from SD_RSP00 and SD_RSP01.
If the result of response decoding is an error, the command sequence can be halted by setting the STP bit in SD_STP or the IOABT bit in SDIO_MODE to 1. Furthermore, this causes CMD12 and CMD52 to not be issued.
If the INFO2 bit (access end) in SD_INFO has been set, halting the command sequence will also lead to the generation of an interrupt.

– Data receive from SD card and data read
Write 0xFFFB to SD_INFO1_MASK to enable the access end interrupt. In addition, write 0x7E80 to SD_INFO2_MASK to enable the BRE interrupt. When the data receive from the SD card is completed, the BRE bit in SD_INFO2 is set to 1 to generate an interrupt. Clear the BRE bit to 0 and read the amount of data specified by SD_SIZE from SD_BUF0.
However, a communications error or timeout may be generated if data are being received while reading of SD_BUF0 is in progress.

– Operation complete
When the data read from SD_BUF0 is completed, INFO2 (access end) in SD_INFO1 is set to 1 to generate an interrupt. Clear INFO2 to 0 to end the single block read operation.

Furthermore, perform error processing (clear the interrupt flag register) if an error occurs (a communications error or timeout).

### 50.4.3 Single Block Write

#### (1) Flowchart

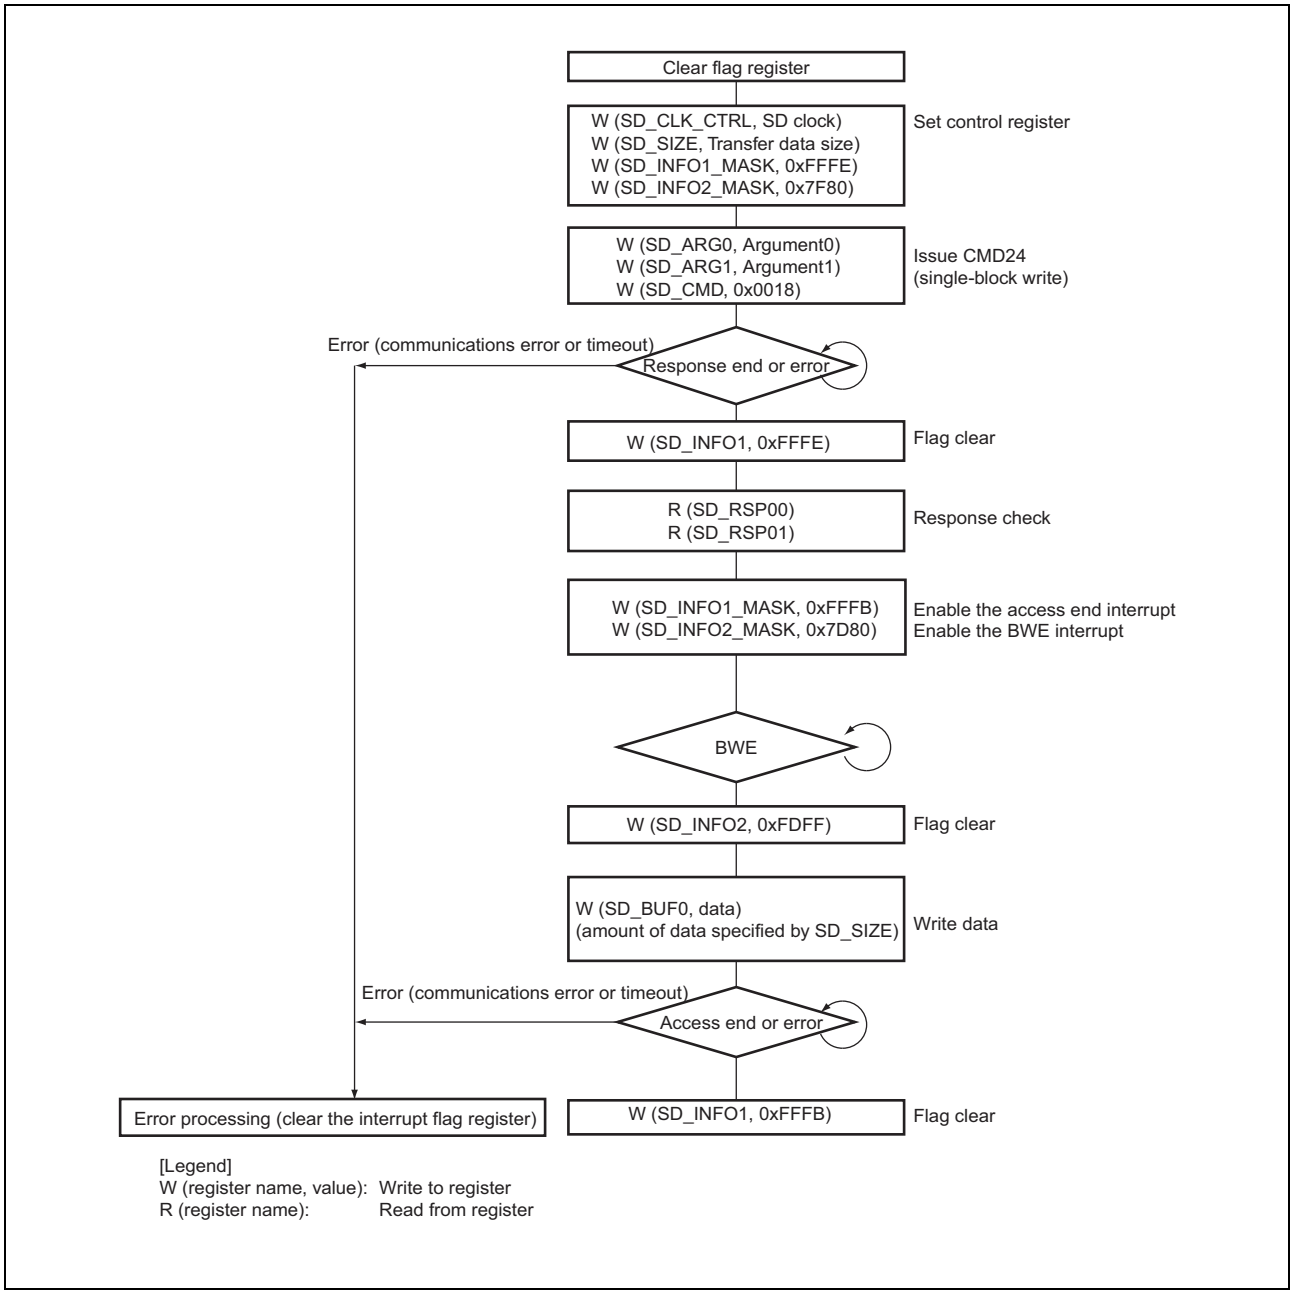

**Figure 50.11 Single Block Write Flowchart Example**

(2) Operation for Single Block Write: The operation of the single block write is described in the following.

– Flag register clear
First, clear the bits in the flag register. (SD_INFO1 and SD_INFO2)

– Control register set
Set the SD clock (SD_CLK), transfer data size, interrupt mask, and so on. (SD_CLK_CTRL, SD_SIZE, SD_INFO1_MASK, and SD_INFO2_MASK)

– Command issue (CMD24)
Set CMD24 Argument in SD_ARG0 and SD_ARG1 and write 0x0018 to SD_CMD.
Accordingly, CMD24 is issued, and the single block write operation is started.

– Response check
On receiving the response, INFO0 (response end) in SD_INFO1 is set to 1 to generate an interrupt. Clear INFO0 to 0 and read the response from SD_RSP00 and SD_RSP01.
If the result of response decoding is an error, the command sequence can be halted by setting the STP bit in SD_STP or the IOABT bit in SDIO_MODE to 1. Furthermore, this causes CMD12 and CMD52 to not be issued.
If the INFO2 bit (access end) in SD_INFO has been set, halting the command sequence will also lead to the generation of an interrupt.

– Data write and data transmit to SD card
Write 0xFFFB to SD_INFO1_MASK to enable the access end interrupt. In addition, write 0x7D80 to SD_INFO2_MASK to enable the BWE interrupt. When SD_BUF0 is ready for the data to be written, the BWE bit in SD_INFO2 is set to 1 to generate an interrupt. Clear the BWE bit to 0 and write the amount of data specified by SD_SIZE to SD_BUF0. When the data write to SD_BUF0 is completed, data is transmitted to the SD card. Then, the CRC status and busy state are received from the SD card.
However, a communications error or timeout may be generated if data are being transmitted after writing to SD_BUF0.

– Operation complete
When the CRC status and busy state are received from the SD card, INFO2 (access end) in SD_INFO1 is set to 1 to generate an interrupt. Clear the INFO2 bit to 0 to end the single block write operation.

Furthermore, perform error processing (clear the interrupt flag register) if an error occurs (a communications error or timeout).

### 50.4.4 Multiple Block Read

#### (1) Flowchart

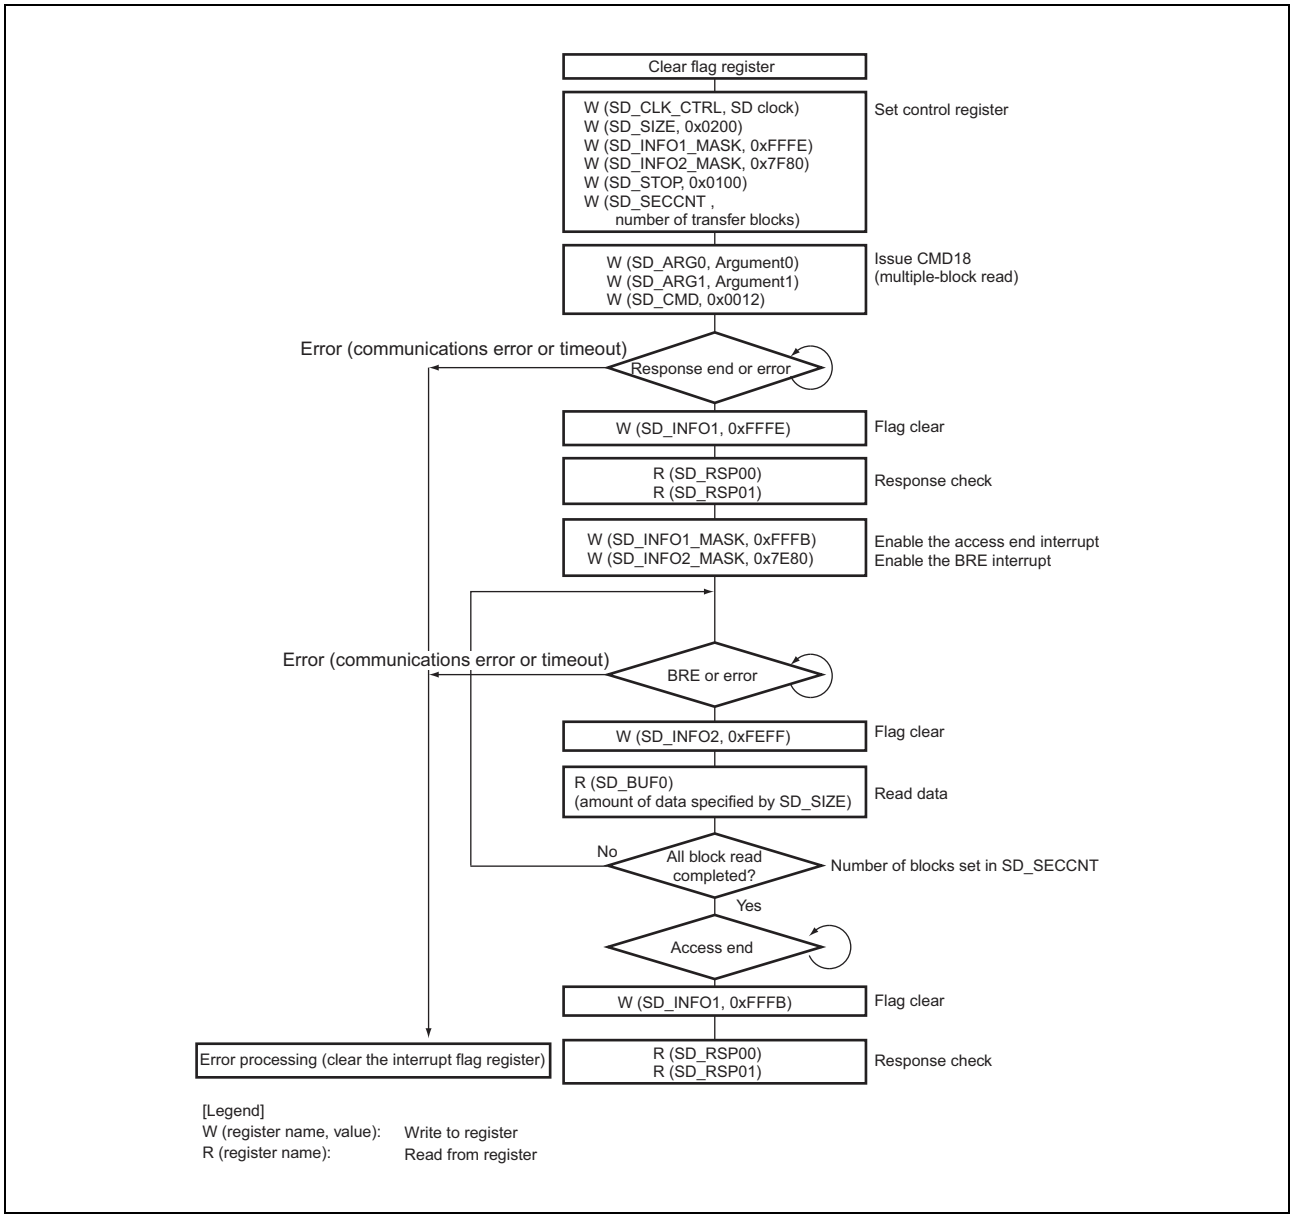

**Figure 50.12 Multiple Block Read Flowchart Example**

(2) Operation for Multiple Block Read: The operation of the multiple block read is described in the following.

– Flag register clear
First, clear the bits in the flag register. (SD_INFO1 and SD_INFO2)

– Control register set
Set the SD clock (SD_CLK), transfer data size, interrupt mask, and so on. (SD_CLK_CTRL, SD_SIZE, SD_INFO1_MASK, and SD_INFO2_MASK)
Set SEC in SD_STOP to 1, and set the number of transfer blocks in SD_SECCNT.

– Command issue (CMD18)
Set CMD18 Argument in SD_ARG0 and SD_ARG1 and write 0x0012 to SD_CMD.
Accordingly, CMD18 is issued, and the multiple block read operation is started.

– Response check
On receiving the response, INFO0 (response end) in SD_INFO1 is set to 1 to generate an interrupt. Clear INFO0 to 0 and read the response from SD_RSP00 and SD_RSP01.
If the result of response decoding is an error, the command sequence can be halted by setting the STP bit in SD_STP to 1. Setting the STP bit to 1 also causes CMD12 to be issued and the response received. When this happens, the arguments for the CMD12 command are set in SD_ARG0 and SD_ARG1. If the command sequence is halted because the access end interrupt has been enabled, an interrupt will be generated by setting of the INFO2 bit (access end) bit in SD_INFO1 to 1 when reception of the response has been completed.
Clear the INFO2 bit to 0 and read the response.

– Data receive from SD card and data read
Write 0xFFFB to SD_INFO1_MASK to enable the access end interrupt. In addition, write 0x7E80 to SD_INFO2_MASK to enable the BRE interrupt. When one-block data receive from the SD card is completed, the BRE bit in SD_INFO2 is set to 1 to generate an interrupt. Clear the BRE bit to 0 and read the amount of data specified by SD_SIZE from SD_BUF0. Doing this repeats transfer of the number of blocks set in SD_SECCNT. However, a communications error or timeout may be generated if data are being received while reading of SD_BUF0 is in progress. When reception of the last block of data is completed, CMD12 is automatically issued and the response is received.
At this point, the arguments of CMD12 are reflected as the arguments of CMD18.

– Operation complete
When all-block data read and the CMD12 response receive are completed, INFO2 (access end) in SD_INFO1 is set to 1 to generate an interrupt. Clear INFO2 to 0 to read the response. This is the end of multiple block read operation.

Furthermore, perform error processing (clear the interrupt flag register) if an error occurs (a communications error or timeout).

### 50.4.5 Multiple Block Write

#### (1) Flowchart

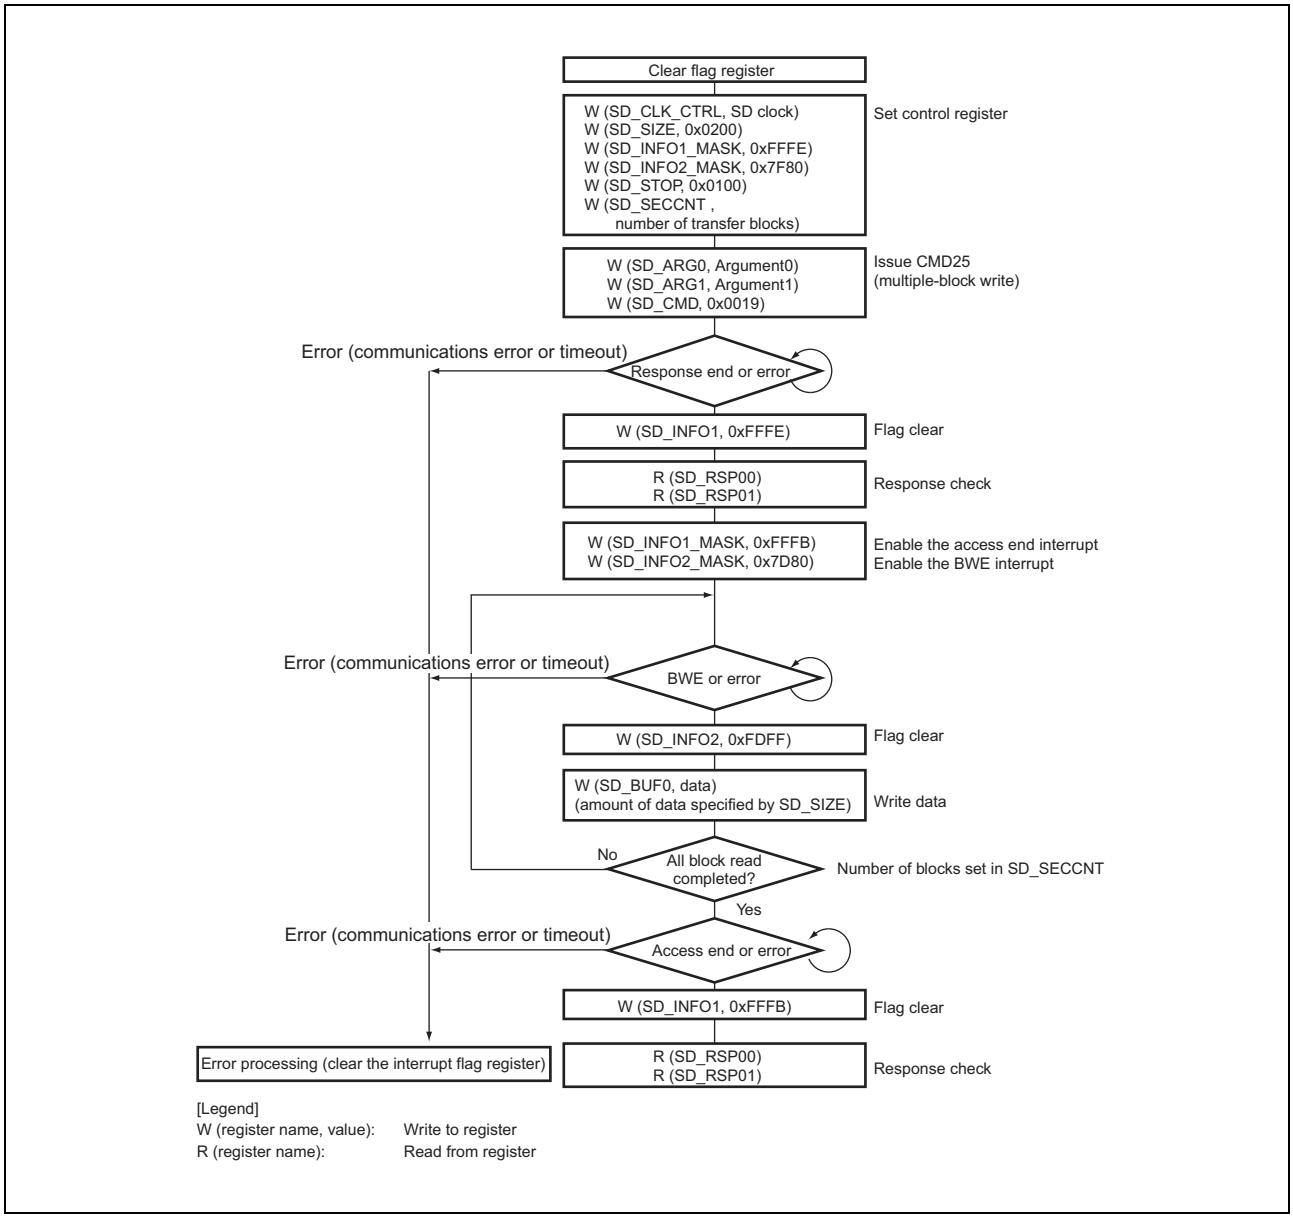

**Figure 50.13 Multiple Block Write Flowchart Example**

(2) Operation for Multiple Block Write: The operation of the multiple block write is described in the following.

– Flag register clear
First, clear the bits in the flag register. (SD_INFO1 and SD_INFO2)

– Control register set
Set the SD clock (SD_CLK), transfer data size, interrupt mask, and so on. (SD_CLK_CTRL, SD_SIZE, SD_INFO1_MASK, and SD_INFO2_MASK)
Set the SEC bit in SD_STOP to 1, and set the number of transfer blocks in SD_SECCNT.

– Command issue (CMD25)
Set CMD25 Argument in SD_ARG0 and SD_ARG1 and write 0x0019 to SD_CMD.
Accordingly, CMD25 is issued, and the multiple block write operation is started.

– Response check
On receiving the response, the INFO0 bit (response end) in SD_INFO1 is set to 1 to generate an interrupt. Clear the INFO0 bit to 0 and read the response from SD_RSP00 and SD_RSP01.
If the result of response decoding is an error, the command sequence can be halted by setting the STP bit in SD_STP to 1. Setting the STP bit to 1 also causes CMD12 to be issued and the response received. When this happens, the arguments for the CMD12 command are set in SD_ARG0 and SD_ARG1. If the command sequence is halted because the access end interrupt has been enabled, an interrupt will be generated by setting of the INFO2 bit (access end) bit in SD_INFO1 to 1 when reception of the response has been completed.
Clear the INFO2 bit to 0 and read the response.

– Data write and data transmit to SD card
Write 0xFFFB to SD_INFO1_MASK to enable the access end interrupt. In addition, write 0x7D80 to SD_INFO2_MASK to enable the BWE interrupt. When SD_BUF0 is ready for the data to be written, the BWE bit in the SD_INFO2 resister is set to 1 to generate an interrupt. Clear the BWE bit to 0 and write the amount of data specified by SD_SIZE to SD_BUF0. When the data write to SD_BUF0 is completed, data is transmitted to the SD card. Then, the CRC status and busy state are received from the SD card. Doing this repeats transfer of the number of blocks set in SD_SECCNT. However, a communications error or timeout may be generated if data are being received while writing to SD_BUF0 is in progress. When reception of the last block of data is completed, CMD12 is automatically issued and the response is received.
At this point, the arguments of CMD12 are reflected as the arguments of CMD25.

– Operation complete
When all-block data transmit and the CRC status receive are completed, the INFO2 bit (access end) in SD_INFO1 is set to 1 to generate an interrupt. Clear the INFO2 bit to 0 to read the response. This is the end of multiple block write operation.

Furthermore, perform error processing (clear the interrupt flag register) if an error occurs (a communications error or timeout).

## 50.5 Usage Note

### (1) SD_BUF Illegal Write Access

When writing data to SD_BUF0 after the single block write or multi block write command is issued, the data of the size specified by SD_SIZE must be written to.
If the data of the size which exceeds the size specified by SD_SIZE is written to, the ERR4 bit in SD_INFO2 is set to 1. In addition, the data written to SD_BUF0 may not be transmitted and it causes the SCLKDIVEN bit in SD_INFO2 to hold the value of 0. In such cases, clearing the SDRST bit in SOFT_RST to 0 and then restoring its value to 1 clears the SCLKDIVEN bit to 1.
However, for the single byte or three bytes when the number of bytes setting in SD_SIZE is odd, or the fraction of bytes when the number of bytes setting in SD_SIZE is even, since the portion of dummy data writing is regarded as excess data and ignored, it is not within the scope of the above description (the fraction of bytes: the two bytes that are not in a four-byte unit).

### (2) Block Number Limitation for Multiple Block Read

When performing a multiple block read of one or two blocks, depending on the timing with which the response register is read, the response value may not be read properly. When receiving one or two blocks of data, use single block read operation.
Figure 50.23 shows the processing flows of SD host interface (hardware) operation and software operation when a multiple block read is performed on two blocks. As shown in the incorrect operation of Figure 50.23, when an interrupt is generated on reception of the CMD18 response and the timing with which the response register is read by the interrupt is delayed, the data during the CMD12 response reception or the CMD12 response may be read. In the case of a multiple block read of three or more blocks, CMD12 is not issued until the block of data has been read, so this problem does not arise. Furthermore, in the case of a multiple block write, since the CMD25 response is read before the block of data is sent, the problem does not arise.

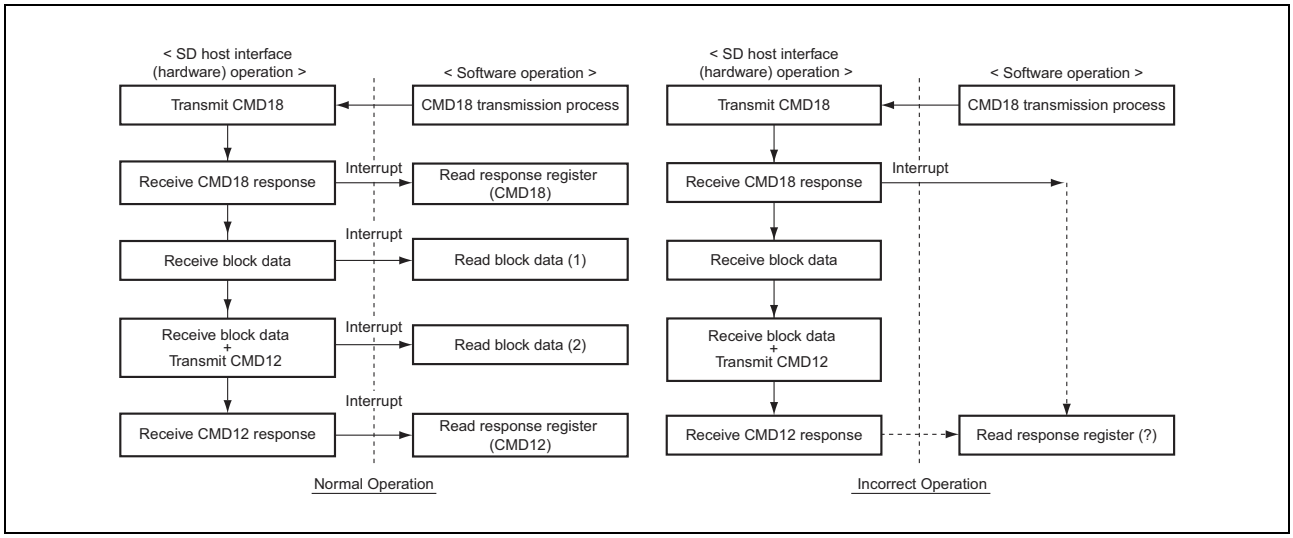

**Figure 50.23 Flowcharts for Multiple Block Read Operation (Two Blocks)**

### (3) Automatic Control of SD_CLK Output

In the SD Card standard, 74 cycles of SD_CLK must be output before initialization of the card. For this reason, use automatic control of SD_CLK output after 74 cycles of SD_CLK have been output. Furthermore, if automatic control of SD_CLK output was in use, SD_CLK output is stopped on completion of the sequence for a communications error or timeout. Thus, in cases where state transitions within the SD card are necessary and so on after completion of the sequence, release automatic control of SD_CLK output and restart supply of SD_CLK to the SD card.

### (4) Control of the C52PUB Setting for Multiple Block Write

If the C52PUB bit in SDIO_MODE is set to 1 during a sequence of multiple block write due to CMD53, CMD52 is not issued until SD_BUF becomes empty. For this reason, set the C52PUB bit after suspending writing to SD_BUF by following the appropriate procedure below.

- When DMA transfer is not in use

1. Before setting the C52PUB bit, suspend writing to SD_BUF by making the setting in SD_INFO2 to disable BWE interrupts.
2. Set the C52PUB bit in SDIO_MODE to 1 (so that CMD52 is issued when SD_BUF becomes empty).
3. After the INFO0 interrupt processing in SD_INFO1 due to the issuing of CMD52 has been completed, restart writing to SD_BUF by making the setting in SD_INFO2 to enable BWE interrupts.

- When DMA transfer is in use

1. Every time DMA transfer of the value set in SD_SIZE × n blocks (where n = 1, 2, ...) proceeds, suspend writing to SD_BUF by DMA transfer before the C52PUB bit is set.
2. Set the C52PUB bit in SDIO_MODE to 1 (so that CMD52 is issued when SD_BUF becomes empty).
3. After the INFO0 interrupt processing in SD_INFO1 due to the issuing of CMD52 has been completed, restart writing to SD_BUF by DMA transfer.

### (5) Erroneous Detection of SDIO interrupts

The SD host interface erroneously detects an SDIO interrupt when all of the following conditions are satisfied.

1. SDIO access
2. The SDIO device supports the SDIO interrupt (an optional part of the standard).
3. The SDIO device supports 4-bit width multi-block read of CMD53 (an optional part of the standard).
4. The SDIO device does not support the SDIO interrupt between 4-bit width data blocks (an optional part of the standard).

Avoid this problem by following the procedure below when the values of the SMB and S4MI bits in the card capability register of the SDIO device are 1 and 0, respectively.

1. Immediately before executing the multiple block read command, clear (to 0) the IOMOD bit of the SDIO_MODE register.
2. Execute the command.
3. Set (to 1) the IOMOD bit of the SDIO_MODE register immediately after multiple block read operation is completed.

### (6) Setting STP bit during multiple read

During multiple block read with auto CMD12 setting 1 to SEC bit of SD_STOP, if performing a force-quit by setting 1 to STP bit of SD_STOP, the command sequence is not terminated depending on the timing of setting 1 to STP bit of SD_STOP.
To avoid this, if setting STP bit of SD_STOP during multiple block transfer, setting 0 to SEC bit of SD_STOP at the same time.
Switching the value of SEC bit of SD_STOP from 1 to 0, even if CBSY bit of SD_INFO2 is 1.
In case the command sequence is not terminated because of not setting 0 to SEC bit of SD_STOP at the same time, setting SDRST bit of SOFT_RST is also available to terminate the command sequence.
If performing a force-quit by setting 1 to IOABT bit of SDIO_MODE during CMD53 multiple block transfer, leave the value (=1) of SEC bit of SD_STOP as it is.

### (7) Software Reset

For transitions to the software reset state by the SDRST bit in the SOFT_RST register, see section 55.3.6, Software Reset. However, where the procedure refers to the SRST bit, read this as the SDRST bit in the SOFT_RST register.

# 51. MMC Host Interface

The MMC host interface is a host controller conforming to the JEDEC Standard JESD84-A441 that allows connection with devices with the MMC interface.

## 51.1 Features

- Supports 1/4/8-bit MMC bus
- Supports the Single Data Rate only
- MMC clock frequency = P1ϕ frequency/$2^n$ (n = 1 to 10)
- Supports High Priority Interrupt (HPI)*
- Supports background operation
- Data buffer: 512 bytes × 2
- Three types of interrupt requests: normal operation, error/timeout, card detection
- DMA transfer requests: buffer write and buffer read
- Card detection function

Note: * Supports HPI in the sequences of CMD6, CMD24, CMD25 (pre-defined), and CMD38.

Figure 51.1 shows a block diagram of this module.

### 51.3.1 Command Setting Register (CE_CMD_SET)

CE_CMD_SET sets a command sequence.
The command sequence starts when the settings have been made in bits 31 to 16. Note that writing to CE_CMD_SET is disabled while a command sequence is proceeding (i.e., the value of CMDSEQ in CE_HOST_STS1 is 1).
CE_CMD_SET should be set according to the description in section 51.7.12, Setting Values of CE_CMD_SET. This register should be accessed in 16 bits. (The address of bits 31 to 16 is H'E804C800 and that of bits 15 to 0 is H'E804C802.)

### 51.3.2 Argument Register (CE_ARG)

CE_ARG sets the argument for the command to be transmitted. Set CE_ARG before starting the command sequence.

| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

### 51.3.3 Argument Register for Automatically-Issued CMD12 (CE_ARG_CMD12)

CE_ARG_CMD12 is used to set the argument for the automatically-issued CMD12 in multi-block transfer. For the automatically-issued CMD12, see section 51.6.4, Automatic CMD12 Issuance. Set CE_ARG_CMD12 before starting the command sequence.

| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

### 51.3.4 Command Control Register (CE_CMD_CTRL)

CE_CMD_CTRL is used to terminate a command sequence forcibly.

| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

| 0 | BREAK | 0 | R/W | Forcible Termination of Command Sequence<br>To discontinue the current command sequence, write 1 to this bit while the bit is 0 and then write 0.<br>After the above procedure, check if the value of the CMDSEQ bit in CE_HOST_STS1 has become 0 and then perform a software reset.<br>Note: Since a software reset returns the register value to the initial value, the register needs be set again. |

### 51.3.5 Transfer Block Setting Register (CE_BLOCK_SET)

CE_BLOCK_SET specifies the size of the block and the number of blocks for the data to be transferred. Set CE_BLOCK_SET before starting the command sequence.

| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

|---|---|---|---|---|
| 31 to 16 | BLKCNT [15:0] | H'0000 | R/W | Number of Blocks for Transfer<br>Note: This setting is valid for multi-block transfer. |
| 15 to 0 | BLKSIZ [15:0] | H'0200 | R/W | Transfer Block Size<br>Note: Transfer block size should be set as follows.<br>• Single-block transfer: 1 to 512 bytes<br>• Multi-block transfer: 512 bytes |

### 51.3.6 Clock Control Register (CE_CLK_CTRL)

CE_CLK_CTRL controls the MMC clock and sets timeout values. Do not change the setting of this register while a command sequence is in progress.

| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

### 51.3.7 Buffer Access Configuration Register (CE_BUF_ACC)

CE_BUF_ACC configures the method of accessing data registers and mode of DMA transfer. Do not change the setting of this register while a command sequence is in progress. For explanation of the buffers, see section 51.6.3, Buffer Structure and Buffer Accesses.

| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

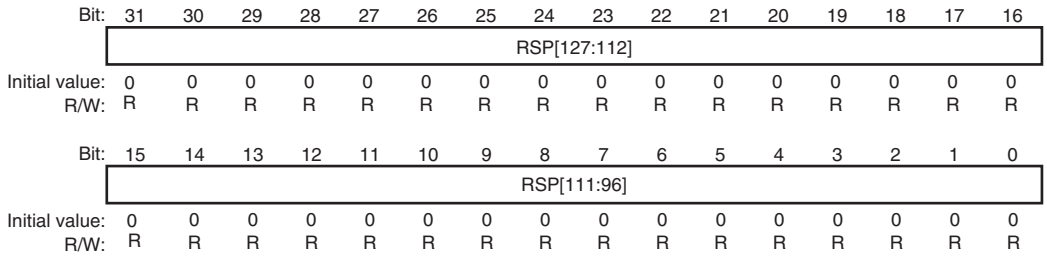
## 51.3.8 Response Registers 3 to 0 (CE_RESP3 to CE_RESP0)

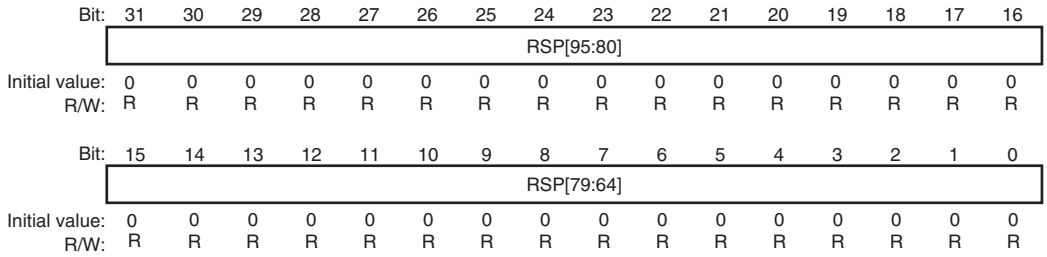
CE_RESP3 to CE_RESP0 are the registers for storing the response that has been received. For the formats of response values, see section 51.6.1, Command/Response Formats.

- CE_RESP3



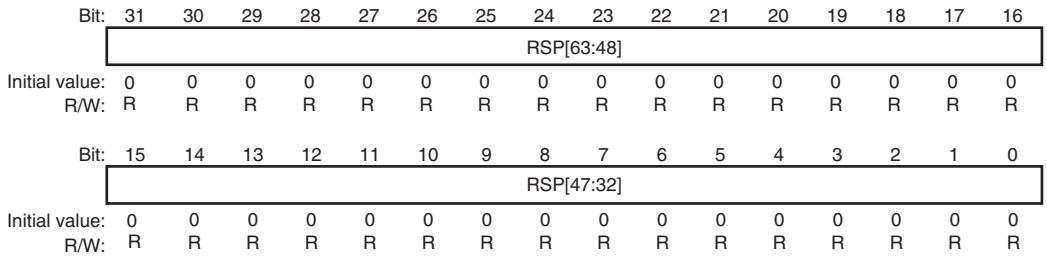
| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| 31 to 0 | RSP[127:96] | H'00000000 | R | [127:96] of a 17-byte response are stored. |

- CE_RESP2



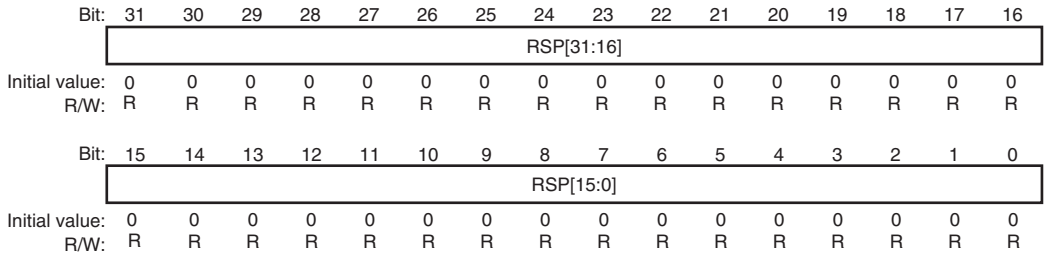
| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| 31 to 0 | RSP[95:64] | H'00000000 | R | [95:64] of a 17-byte response are stored. |

- CE_RESP1



| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| 31 to 0 | RSP[63:32] | H'00000000 | R | [63:32] of a 17-byte response are stored. |

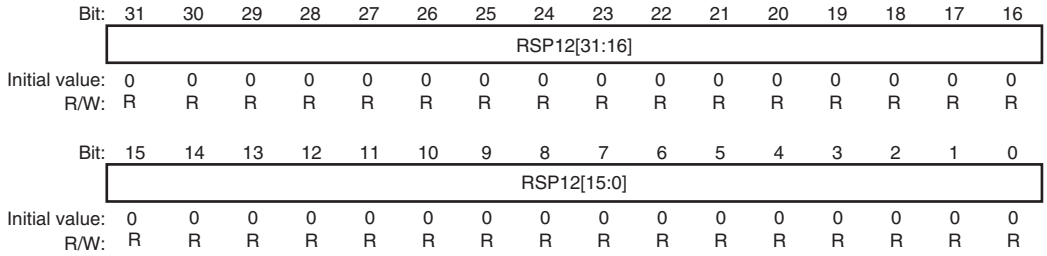
- CE_RESP0



| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| 31 to 0 | RSP[31:0] | H'00000000 | R | [39:8] of a 6-byte response or [31:0] of a 17-byte response are stored.<br>Note: The response to the automatically-issued CMD12 is stored in CE_RESP_CMD12. |

## 51.3.9 Response Register for Automatically-Issued CMD12 (CE_RESP_CMD12)

CE_RESP_CMD12 is the register for storing the response to the automatically-issued CMD12.

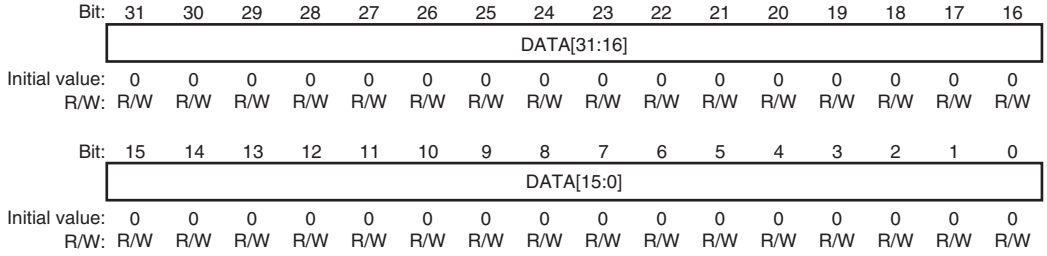


| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| 31 to 0 | RSP12[31:0] | H'00000000 | R | [39:8] of a response to the automatically-issued CMD12 are stored. |

## 51.3.10 Data Register (CE_DATA)

CE_DATA is used to access the buffers of this module.

For the write/read data formats, see section 51.6.2, Data Block Format.



| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| 31 to 0 | DATA[31:0] | H'00000000 | R/W | Buffer write/read data [31:0] |

## 51.3.11 Interrupt Flag Register (CE_INT)

CE_INT indicates various status during execution of a command sequence. Each bit is set to 1 when its setting condition has been met. To clear flag(s), write 0 only to the bit(s) to be cleared and write 1 to the other bits.
For the operation in the case of an error or timeout, see section 51.6.7, Operation in the Case of Error/Timeout.

### 51.3.12 Interrupt Enable Register (CE_INT_EN)

CE_INT_EN controls output of the CE_INT-related interrupt signals. If a flag in CE_INT is set to 1 while its corresponding bit in CE_INT_EN is set to 1, an interrupt request is output. For details on interrupt requests, see section 51.4, Interrupt Requests.

## 51.4 Interrupt Requests

Table 51.3 shows the interrupt request specifications of this module.
This module generates three types of interrupt requests: normal operation, error/timeout, and card detection. When an interrupt flag is set to 1 and also the corresponding interrupt is enabled, an interrupt request is asserted.

**Table 51.3 Specifications of Interrupt Requests**

| Flag Register | Bit | Mask Register | Bit | Interrupt Request |
|---|---|---|---|---|
| CE_INT | CMD12DRE | CE_INT_EN | MCMD12DRE | Normal operation interrupt (MMC2) |

## 51.5 DMA Specifications

This module provides two channels for DMA transfer requests: one for buffer reading and the other for buffer writing.

### 51.5.1 DMA for Buffer Writing

The DMA transfer request is asserted for buffer writing when the buffer has become empty while the DMAWEN bit in CE_BUF_ACC is 1.

The DMA transfer request stays asserted for the amount of data specified by BLKSIZ (the block size set in CE_BLOCK_SET) × BLKCNT (the number of blocks for transfer set in CE_BLOCK_SET), and negated after the last block has been transferred. Note that the BUFWEN bit in CE_INT will not be asserted in this case.

If an error occurs during DMA transfer or DMA transfer is forcibly terminated, the command sequence is stopped automatically, which causes the DMA transfer request to be negated.

### 51.5.2 DMA for Buffer Reading

The DMA transfer request is asserted for buffer reading when the buffer stores data of the block size specified in CE_BLOCK_SET while the DMAREN bit in CE_BUF_ACC is 1.

The DMA transfer request stays asserted for the amount of data specified by BLKSIZ (the block size set in CE_BLOCK_SET) × BLKCNT (the number of blocks for transfer set in CE_BLOCK_SET), and negated after the last block has been transferred. Note that the BUFREN bit in CE_INT will not be asserted in this case.

If an error occurs during DMA transfer or DMA transfer is forcibly terminated, the command sequence is stopped automatically, which causes the DMA transfer request to be negated.

## 51.6 Operation

### 51.6.1 Command/Response Formats

Figure 51.2 shows the format of the command to be transferred. The command index that is set in CMD[5:0] of CE_CMD_SET and the argument set in ARG[31:0] of CE_ARG are reflected in the command.

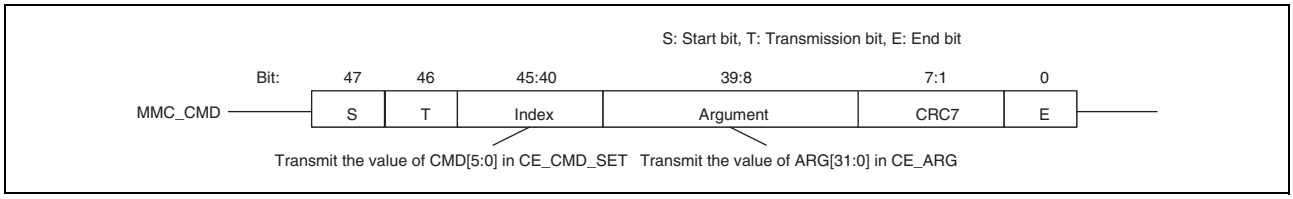

**Figure 51.2 Command Format**

Figure 51.3 and Figure 51.4 show the formats when a 6-byte response and 17-byte response (R2) are received, respectively. The response index is stored in RSPIDX[5:0] of CE_HOST_STS1, and the status value of the response is stored to CE_RESP0 or CE_RESP3 to CE_RESP0.

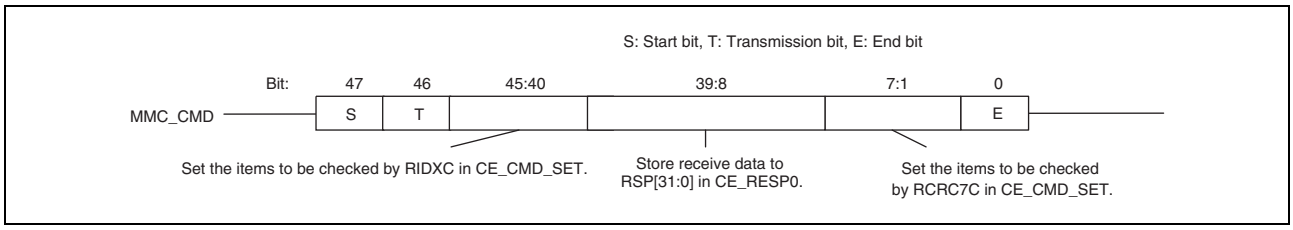

**Figure 51.3 Format of 6-Byte Response**

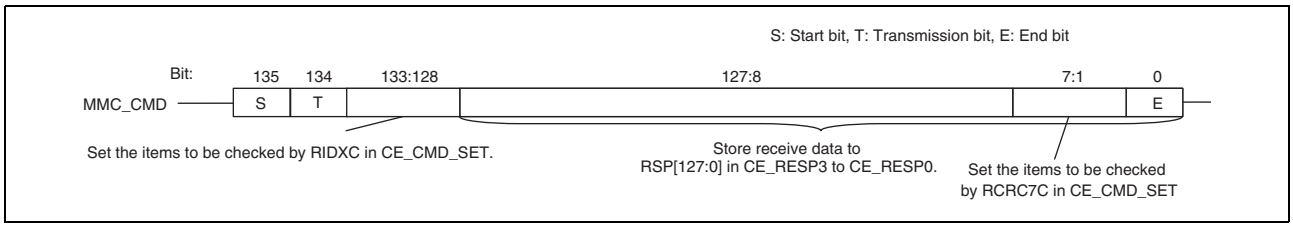

**Figure 51.4 Format of 17-Byte Response (R2)**

## 51.6.2 Data Block Format

Figure 51.5 shows the format of data blocks. For details on D0 to D3 in Figure 51.5, see section 51.6.3, Buffer Structure and Buffer Accesses. When data is written to a card, data stored in the buffer is transmitted. When data is read from a card, receive data is stored to the buffer.

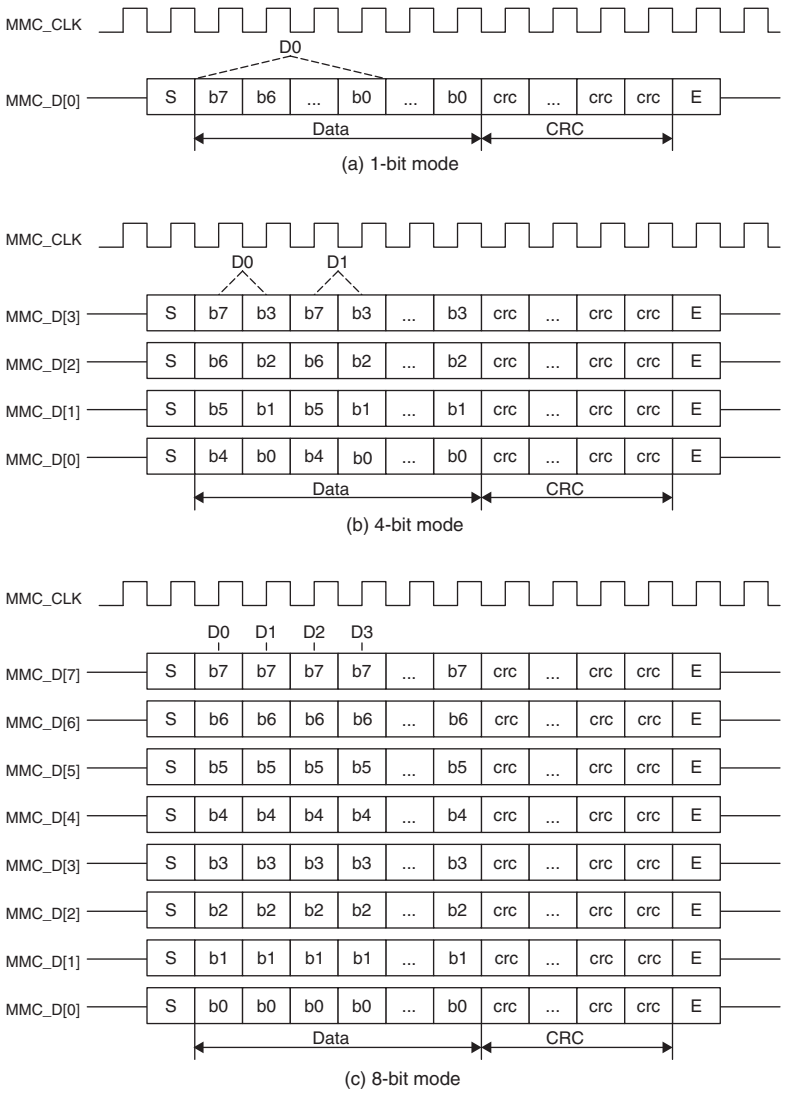

**Figure 51.5 Data Block Format**

### 51.6.3 Buffer Structure and Buffer Accesses

This module has two units of 512-byte RAM as shown in Figure 51.6. Therefore, for multi-block writing, if one block of data (512 bytes) stored in one buffer has been transmitted but the other buffer is full, the next block of data can be continuously transmitted. For multi-block reading, if one block of receive data (512 bytes) has been stored in one buffer but the other buffer is empty, the next block of receive data can be continuously stored in the buffer.

If neither of the buffers is empty for multi-block reading, the MMC clock is stopped and reception is suspended. When one of the buffers becomes empty, the MMC clock supply is started to start reception.

The buffer is accessed with CE_DATA. CE_DATA should be accessed for 4 × (n + 1) bytes (n = 0, 1, 2, 3, …, 127).

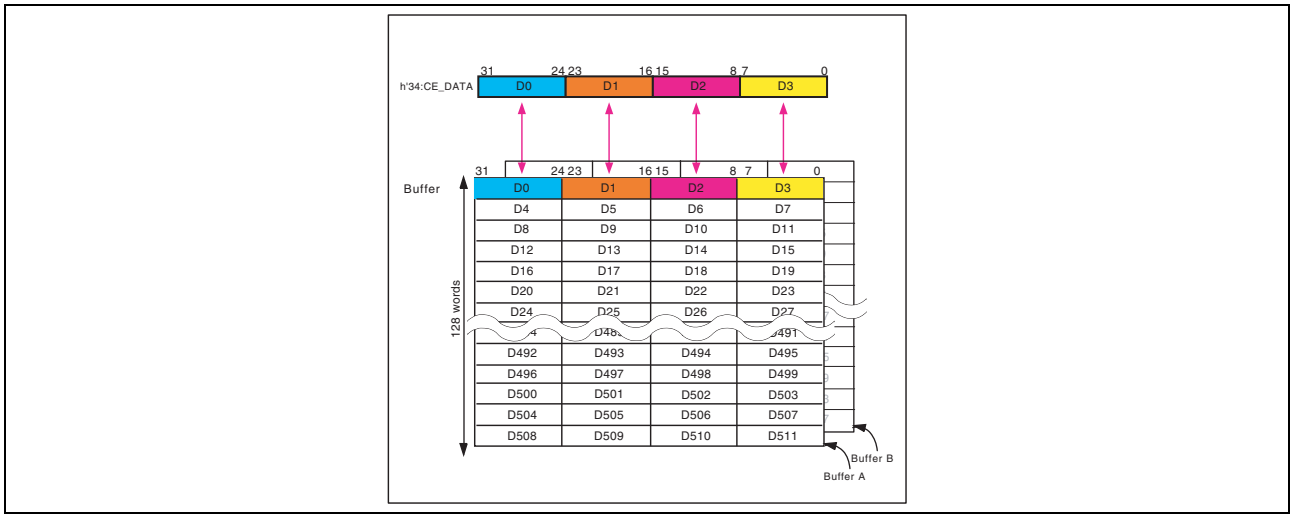

**Figure 51.6 Double Buffer Structure**

The buffer access select function allows byte-wise swapping of data when the buffer is accessed by writing to or reading from CE_DATA. This function is enabled by the setting of CE_BUFF_ACC. Figure 51.7 shows the specification of byte-wise swapping.

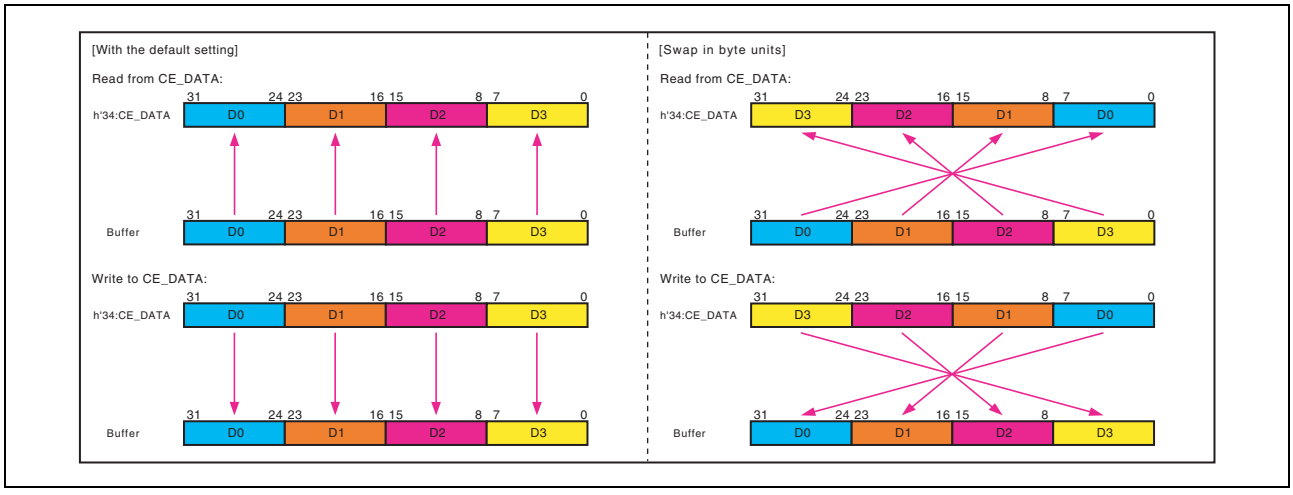

**Figure 51.7 Specification of Byte-Wise Swapping**

### 51.6.4 Automatic CMD12 Issuance

This module automatically issues CMD12 when multi-block transfer is performed with the CMD12EN bit in CE_CMD_SET set to 1.

Figure 51.8 shows the timing of automatic CMD12 issuance in multi-block read. CMD12 is issued such that the end bit of the command is sent two bits before the end bit of the data during reception of the last block.

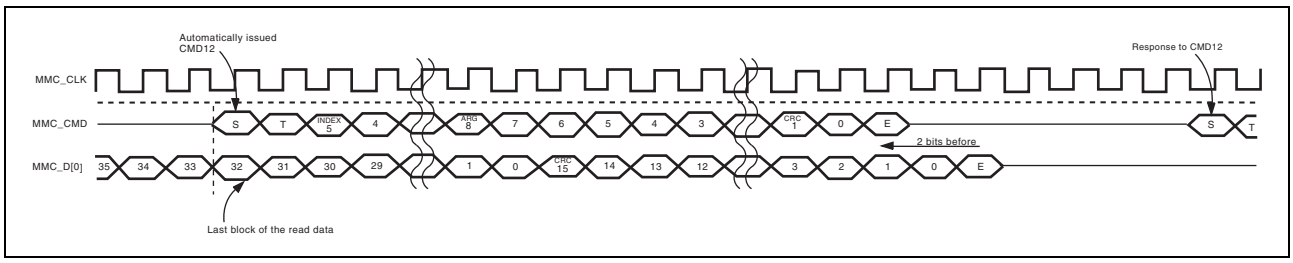

**Figure 51.8 Timing of Automatically-Issued CMD12 in Multi-Block Read (1-Bit Mode)**

Figure 51.9 shows the timing of automatic CMD12 issuance in multi-block write. CMD12 is issued after the data busy after transmission of the last block has ended.

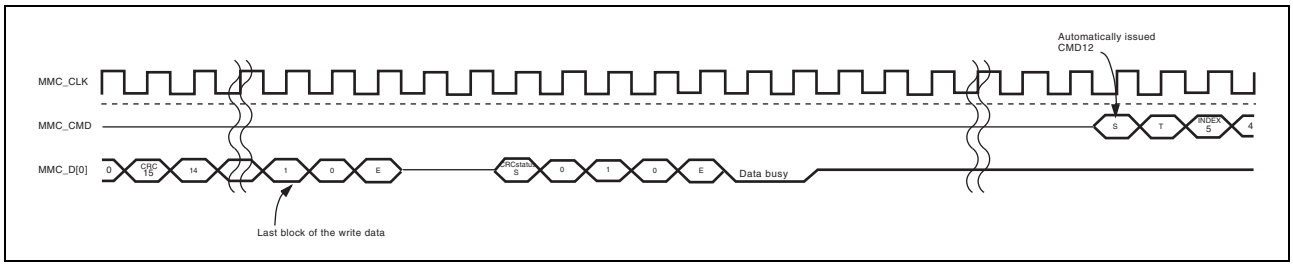

**Figure 51.9 Timing of Automatically-Issued CMD12 in Multi-Block Write (1-Bit Mode)**

The argument of the automatically-issued CMD12 is set by CE_ARG_CMD12. The value of [39:8] of the response to CMD12 is stored to CE_RESP_CMD12. The busy status on response reception is received.

### 51.6.5 High Priority Interrupt (HPI)

HPI should be executed as described below with reference to section 51.3, Register Descriptions and section 51.7, Examples of Setting.

#### (1) When HPI is executed during a write to the device

(a) Terminate the command sequence forcibly.
(b) Wait for the CMDSEQ bit in CE_HOST_STS1 to be cleared to 0.
(c) Issue CMD12 (R1) to make the device in the rcv state enter the prg state. Note that the device does not output the response when the device is in the prg state before issuance of CMD12(R1).
(d) Issue CMD13 (R1).
(e) Issue the HPI command.

#### (2) When HPI is executed during response busy while not writing to the device

(a) Terminate the command sequence forcibly.
(b) Wait for the CMDSEQ bit in CE_HOST_STS1 to be cleared to 0.
(c) Issue CMD13 (R1).
(d) Issue the HPI command*.

The procedure above is for HPI generated in the CMD6, CMD24, CMD25 (Pre-defined), or CMD38 sequence.

Note: * CMD12 (R1b) or CMD13 (R1b) depending on the device connected

### 51.6.6 Background Operation

Background operation should be executed as described below with reference to section 51.3, Register Descriptions and section 51.7, Examples of Setting.

To execute background operation, issue CMD6 (R1) to write to the BKOPS_START byte in the EXT_CSD register of the device.

Completion of background operation can be determined by checking the device state with CMD13 (R1) issued after CMD6 (R1) or by polling MMCDAT[0]. When the device state is indicated as “tran” or MMCDAT[0] is high, background operation is determined to be completed.

To suspend background operation, use HPI described in section 51.6.5.

### 51.6.7 Operation in the Case of Error/Timeout

This module may not be stopped in case of error occurrence. If the command sequence is in progress when an error occurs (check the CMDSEQ bit in CE_HOST_STS1), terminate the sequence forcibly and perform a software reset. The data for transmission or received data that had been stored in the buffers at the time of error occurrence are not guaranteed.

This module is not stopped when a timeout has occurred. To execute the next command after a timeout error has occurred, terminate the sequence forcibly, perform a software reset.

For forcible termination, refer to section 51.7.11, Forcible Termination.

## 51.7 Examples of Setting

This section shows the procedures for executing typical command sequences.

## 51.8 Usage Note

### 51.8.1 Card Detection

The CDRISE and CDFALL bits in CE_DETECT which are used for the card detection function do not have a chattering elimination function. The chattering elimination processing should be implemented by software.

### 51.8.2 Multi-Block Transfer

When HPI is executed, use pre-defined multi-block transfer.

### 51.8.3 Software Reset

For transitions to the software reset state by the SWRST bit in the CE_VERSION register, see section 55.3.6, Software Reset. However, where the procedure refers to the SRST bit, read this as the SWRST bit in the CE_VERSION register.

# 52. Motor Control PWM Timer

This LSI has two channels of on-chip motor control PWM (pulse width modulator) timer with a maximum capability of eight pulse outputs for each channel.

## 52.1 Features

- Maximum of 16 pulse outputs
  — Two 10-bit PWM channels, each with eight outputs
  — 10-bit counter (PWCNT) and cycle register (PWCYR)
  — Duty and output polarity can be set for each output.
- Automatic data transfer in every cycle
  — Each of four duty registers (PWDTR) is provided with buffer registers (PWBFR), with data transferred automatically every cycle.
- Duty cycle configurable
  — A duty cycle of 0% to 100% can be configured by means of a duty register.
- Counting clock selectable
  — There is a choice of five counting clocks (P0ϕ, P0ϕ/2, P0ϕ/4, P0ϕ/8, P0ϕ/16).
- High-speed access via internal 16-bit bus
- Two interrupt sources
  — An interrupt can be requested independently for each channel by a cycle register compare match.
- Automatic transfer of register data
  — Block transfer and one-word data transfer are available by activating the direct memory access controller.
- Module stop mode can be set

Figure 52.1 shows a block diagram of the motor control PWM timer.

### 52.3.1 PWM Control Register_n (PWCR_n) (n = 1, 2)

PWCR_n performs interrupt control, starting/stopping of the counter, and counter clock selection. It also contains a flag that indicates a compare match with the cycle register.

### 52.3.2 PWM Polarity Register_n (PWPR_n) (n = 1, 2)

PWPR_n selects the PWM output polarity.

| 0 | OPSnA | 0 | R/W | |

(n = 1, 2)

### 52.3.3 PWM Counter_n (PWCNT_n) (n = 1, 2)

PWCNT_n is a 10-bit up-counter incremented by the input clock. The input clock is selected by clock select bits CKS2 to CKS0 in PWCR_n.

PWCNT_n can not be directly accessed by the CPU. PWCNT_n is initialized to H'FC00, when the CST bit in PWCR_n is cleared to 0.

### 52.3.4 PWM Cycle Register_n (PWCYR_n) (n = 1, 2)

PWCYR_n is a 16-bit readable/writable register that sets the PWM conversion cycle.

| Bit: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 |
|---|---|---|---|---|---|---|---|---|
| | PWCY15 | PWCY14 | PWCY13 | PWCY12 | PWCY11 | PWCY10 | PWCY9 | PWCY8 |
| Initial value: | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 |
| R/W: | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |
| Bit: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |

| R/W: | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |

When a PWCYR_n compare match occurs, PWCNT_n is cleared and data is transferred from the buffer register (PWBFR_n) to the duty register (PWDTR_n).

PWCYR_n should be written to only while PWCNT_n is stopped. A value of H'FC00 must not be set to PWCYR_n.

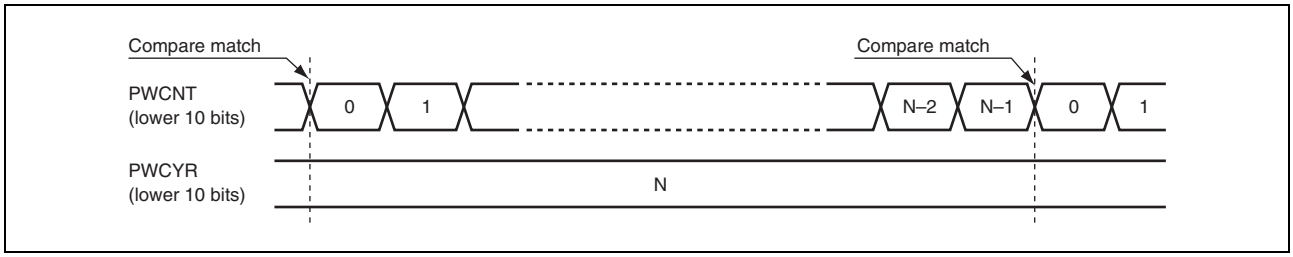

**Figure 52.2 Cycle Register Compare Match**

### 52.3.5 PWM Duty Registers_nA, nC, nE, nG (PWDTR_nA, PWDTR_nC, PWDTR_nE, PWDTR_nG) (n = 1, 2)

There are four PWDTR_n registers (PWDTR_nA, PWDTR_nC, PWDTR_nE, and PWDTR_nG). The PWDTR_nA is used for outputs PWMnA and PWMnB, PWDTR_nC for outputs PWMnC and PWMnD, PWDTR_nE for outputs PWMnE and PWMnF, and PWDTR_nG for outputs PWMnG and PWMnH.
PWDTR_n can not be directly accessed by the CPU. When a PWCYR_n compare match occurs, data is transferred from the buffer register (PWBFR_n) to the duty register (PWDTR_n). PWDTR_n is initialized to H'0000 when the CST bit is cleared to 0.

## 52.4 Bus Master Interface

### 52.4.1 16-Bit Data Registers

PWCYR_n and PWBFR_n are 16-bit registers. These registers are linked to the bus master by a 16-bit data bus, and can be read or written in 16-bit units. They cannot be read or written by 8-bit access; 16-bit access must always be used.

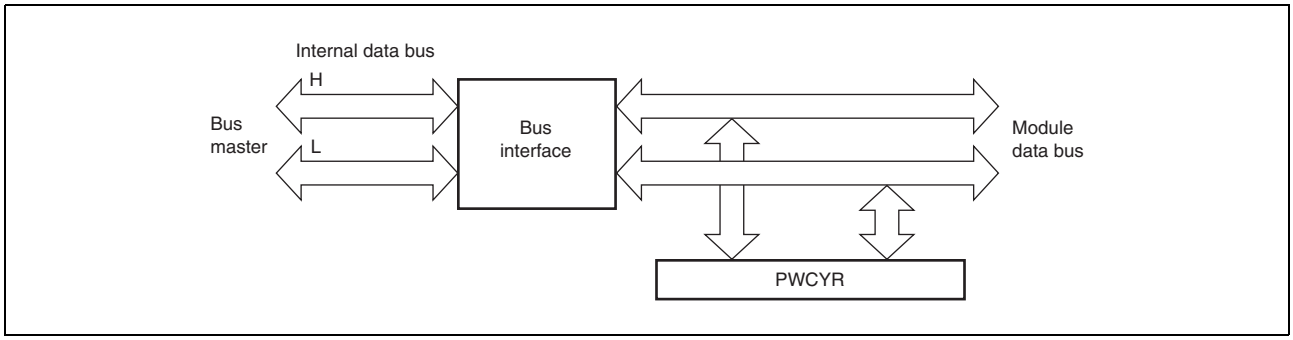

**Figure 52.5 16-Bit Register Access Operation (Bus Master ↔ PWCYR_n (16 Bits))**

### 52.4.2 8-Bit Data Registers

PWCR_n, PWPR_n, and PWBTCR are 8-bit registers that can be read and written to in 8-bit units. These registers are linked to the bus master by a 16-bit data bus, and can be read or written by 16-bit access; in this case, the lower eight bits are read as H'FF.

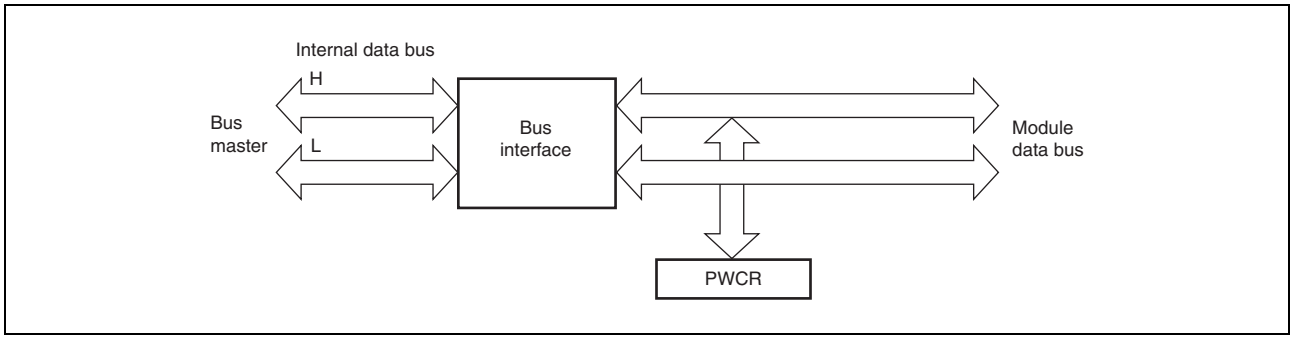

**Figure 52.6 8-Bit Register Access Operation (Bus Master ↔ PWCR_n (Upper Eight Bits))**

## 52.5 Operation

### 52.5.1 PWM Operation

PWM waveforms are output from pins PWM1A to PWM1H and PWM2A to PWM2H as shown in Figure 52.7.

#### (1) Initial Settings

Set the PWM output polarity in PWPR_n; select the clock to be input to PWCNT_n with the CKS2 to CKS0 bits in PWCR_n; set the PWM conversion cycle in PWCYR_n; and set the first frame of data in PWBFR_nA, PWBFR_nC, PWBFR_nE, and PWBFR_nG.

#### (2) Activation

When the CST bit in PWCR_n is set to 1, PWCNT_n starts counting up. On compare match between PWCNT_n and PWCYR_n, data is transferred from the buffer register to the duty register and the CMF bit in PWCR_n is set to 1. At the same time, if the IE bit in PWCR_n has been set to 1, an interrupt can be requested or the direct memory access controller can be activated.

#### (3) Waveform Output

The PWM outputs selected by the OTS bits in PWDTR_nA, PWDTR_nC, PWDTR_nE, and PWDTR_nG go high when a compare match occurs between PWCNT_n and PWCYR_n. The PWM outputs not selected by the OTS bit are low. When a compare match occurs between PWCNT_n and PWDTR_nA, PWDTR_nC, PWDTR_nE, or PWDTR_nG, the corresponding PWM output goes low. If the corresponding bit in PWPR_n is set to 1, the output is inverted.

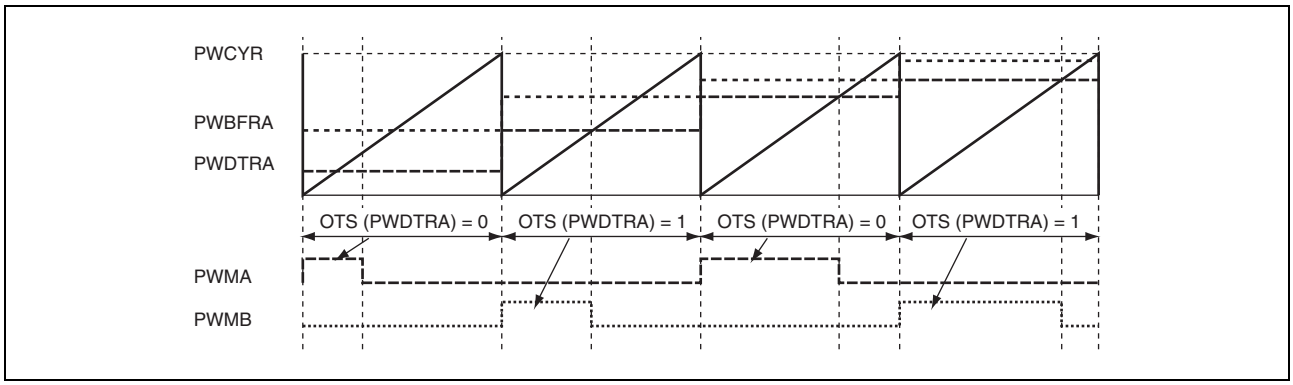

**Figure 52.7 PWM Operation**

#### (4) Next Frame

When a compare match occurs between PWCNT_n and PWCYR_n, data is transferred from the buffer register to the duty register. PWCNT_n is reset and starts counting up from H'000. The CMF bit in PWCR_n is set, and if the IE bit in PWCR_n has been set, an interrupt can be requested or the direct memory access controller can be activated.

#### (5) Stopping

When the CST bit in PWCR_n is cleared to 0, PWCNT_n is reset and stops. All PWM outputs go low (or high if the corresponding bit in PWPR_n is set to 1).

### 52.5.2 Buffer Transfer Control

Setting a corresponding bit in the PWM buffer transfer control register disables a buffer transfer on compare match. This prevents the output from changing when compare match occurs while the buffer register is being changed. A buffer transfer on compare match is resumed after cleaning the bit.

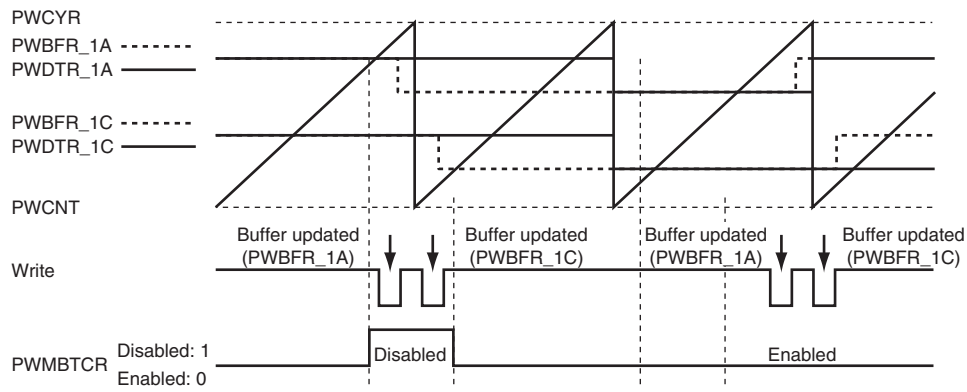

**Figure 52.8 Disabling Buffer Transfer**

## 52.6 Usage Note

### 52.6.1 Conflict between Buffer Register Write and Compare Match

If a PWBFR_n write is performed in the state immediately after a cycle register compare match, the buffer register and duty register are both modified. PWM output changed by the cycle register compare match is not changed by modification of the duty register due to conflict. This may result in unanticipated duty output.
Buffer register modification must be completed before automatic transfer by the direct memory access controller, exception handling due to a compare match interrupt, or the occurrence of a cycle register compare match on detection of the rise of CMF (compare match flag) in PWCR_n.

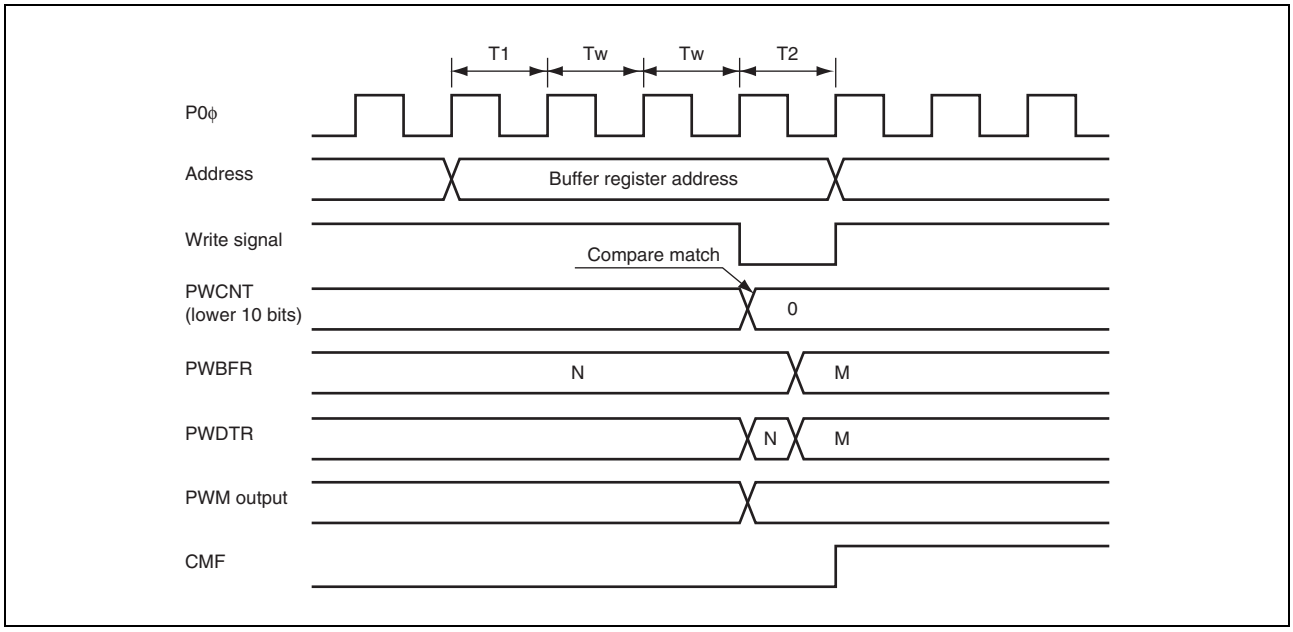

**Figure 52.9 Conflict between Buffer Register Write and Compare Match**

# 53. On-Chip RAM

This LSI has an on-chip large-capacity RAM for display area and work area (128 Kbytes of this RAM are shared with the on-chip data retention RAM) and an on-chip data retention RAM, which can retain data in deep standby mode. These memory units can be used to store instructions or data.
The operation and write access to the large-capacity RAM (including on-chip data retention RAM) can be enabled or disabled through the RAM enable bits and RAM write enable bits.
The on-chip data retention RAM is assigned to page 0 in the on-chip large-capacity RAM. Retention or non-retention of data by the on-chip data retention RAM in deep standby mode is selectable on a per-page basis.

## 53.1 Features

- Page
  - The on-chip large-capacity RAM consists of five pages.
  - The on-chip data retention RAM consists of four pages. Page 0 has 16-Kbytes, page 1 has 16-Kbytes, page 2 has 32-Kbytes, and page 3 has 64-Kbytes.
- Memory map
  The on-chip RAM is located in the address spaces shown in tables 53.1 and 53.2 Each page of the large-capacity RAM in products with a 10-Mbyte on-chip RAM has a capacity of 2 Mbytes, while each page of the large-capacity RAM in products with a 5-Mbyte on-chip RAM has a capacity of 1 Mbyte. Except for the size, the address maps for products with a 5-Mbyte on-chip RAM and with a 10-Mbyte on-chip RAM are compatible. Furthermore, to obtain a continuous address space for 5-Mbyte RAM compatibility when a 10-Mbyte RAM is in use, each page of the latter is divided into two. If you wish to use the pages continuously when using a 10-Mbyte RAM, use mirror addresses.

"Bank" in the above table indicates the physical configuration of the RAM for each page.
The RAM of the RZ/A1H is in a two-bank configuration, consisting of bank 0 and bank 1.
The RAM of the RZ/A1M is in a one-bank configuration, consisting only of bank 0.

- Ports
  Each page of the on-chip large-capacity RAM has one read and write port and is connected to the AXI bus. The on-chip RAM for data retention, which has a port independent of the port in page 0, is shared with the read and write port in four pages.
- Method of arbitration
  When the same port of the on-chip large-capacity RAM is accessed from different masters simultaneously, the AXI bus performs arbitration in round-robin mode.
- Number of access cycles
  The number of cycles for access to read or write is one cycle of Bϕ.

## 53.2 Usage Notes

### 53.2.1 Page Conflict

When the same page of the on-chip large-capacity RAM is accessed from different masters simultaneously, a conflict on the page occurs. Although each access is completed correctly, this kind of conflict degrades the memory access speed. Therefore, it is advisable to provide software measures to prevent such conflicts as far as possible. For example, no conflict will arise if different pages are accessed by each master.

### 53.2.2 Data Retention

Data in the large-capacity RAM (including on-chip data retention RAM) are retained in the states other than power-on reset and deep standby mode. In power-on reset and deep standby mode, these RAMs operate as described below.

#### (1) Power-on Reset

##### (a) On-Chip Large-Capacity RAM (Excluding On-Chip Data Retention RAM)

Data are retained on a power-on reset by disabling the setting of either the VRAME or VRAMWE bit.
Data are not retained when the setting of the VRAME and VRAMWE bits are both enabled.

##### (b) On-Chip Data Retention RAM

Data are retained on a power-on reset by disabling the setting of any of the VRAME, VRAMWE, or RRAMWE, excluding the case that deep standby mode is canceled by power-on reset.
Data are not retained when the setting of the VRAME, VRAMWE and RRAMWE bits are all enabled.

#### (2) Deep Standby Mode

##### (a) On-Chip Large-Capacity RAM (Excluding On-Chip Data Retention RAM)

Data are not retained.

##### (b) On-Chip Data Retention RAM

Data are retained in deep standby mode by enabling the setting of the RRAMKP bit, excluding the case that deep standby mode is canceled by power-on reset. In the case that deep standby mode is canceled by interrupt or pins for cancelling, power-on reset exception handling is executed, but the data are retained.

# 54. Ports

## 54.1 Features

The 256-pin version of this LSI has eleven ports (JP0 and P0 to P9) and the 324-pin version has thirteen ports (JP0 and P0 to P11). All port pins are multiplexed with other peripheral module pin functions, and by setting the control registers, multiplexed pin functions (alternative functions) can be selected.

### 54.1.1 Port group

This LSI has the following number of port groups.

**Table 54.1 Port Group**

| Package | Number | Name |
|---|---|---|
| 256-pin | 11 | P0 to P9, JP0 |
| 324-pin | 13 | P0 to P11, JP0 |

### 54.1.2 Port group index n

Throughout this section, the individual port groups are identified by the index "n" (n = 0 to 11), for example PMCn for the port mode control register, which is used for the Pn pin.

### 54.1.3 Base address

The addresses of the registers used to control the JTAG ports are given as addresses offset from the base address <JPORTn_base>. The addresses of the other registers used to control the general ports are given as addresses offset from the base address <PORTn_base>.

**Table 54.2 Base Addresses <PORTn_base> and <JPORTn_base>**

| <PORTn_base> address | <JPORTn_base> address |
|---|---|
| H'FCFE 3000 | H'FCFE 7B00 |

## 54.2 Functional Overview

### 54.2.1 Mode of Pin Functions

Pins can operate in three modes.

Port mode (PMCn.PMCnm bit = 0)
A pin in port mode operates as a general purpose input/output pin. The I/O mode is selected by setting the PMn.PMnm bit.
Software I/O control alternative mode (PMCn.PMCnm bit = 1, PIPCn.PIPCnm bit = 0)
In this mode, the pins operate as alternative functions.
The I/O mode is selected by setting the PMn.PMnm bit by using software.
Direct I/O control alternative mode (PMCn.PMCnm bit = 1, PIPCn.PIPCnm bit = 1)
In this mode, the pins operate as alternative functions.
Unlike the software I/O alternative mode, however, the I/O mode is selected by the alternative function.

An overview of the register settings is given in the tables below.

**Table 54.3 Pin Function Configuration (Overview)**

| | Bit | | | |
|---|---|---|---|---|
| **Mode** | **PMCn. PMCnm** | **PMn. PMnm** | **PIPCn. PIPCnm** | **I/O** |
| Port mode | 0 | 0 | X | O |
| | | 1*1 | | I |
| Software I/O control alternative mode | 1*2 | 0 | 0 | O |
| | | 1 | | I |
| Direct I/O control alternative mode | | X | 1 | Controlled by the alternative function |

Note 1. The input buffer can be enabled in the port mode only when the PIBCn.PIBCnm bit is set to 1.
Note 2. When the pins are in alternative mode (PMCn.PMCnm = 1), one of the eight alternative functions is selected by the PFCn, PFCEn, and PFCAEn registers. For details, see Table 54.6, Alternative Mode Selection*2.

### 54.2.2 Pin Data Input/Output

The registers used for data input/output are described below. The location that is read via the PPRn register differs depending on the pin mode.

- Output data
  In the port mode (PMCn.PMCnm = 0), the value of the Pn.Pnm bit is output from the Pn_m pin.

- Input data
  When the PPRn register is read, either the value of the Pn_m pin, the value of the Pn.Pnm bit, or the value output by the alternative function is returned. Which value is returned depends on the pin mode and setting of several control bits. The different PPRn read values are shown in the table below.

**Table 54.4 PPRnm Read Values**

| PMCn. PMCnm | PMn. PMnm | PIBCn. PIBCnm | PIPCn. PIPCnm | Mode | PPRnm Read Value |
|---|---|---|---|---|---|
| 0 | 1 | 0 | X | Port input, input buffer disabled | Pn.Pnm register |
| | | 1 | | Port input, input buffer enabled | Pn_m pin |
| | 0 | X | | Port output | Pn.Pnm register*1 |
| 1 | 1 | X | 0 | Software I/O control alternative function input | Pn_m pin |
| | 0 | | | Software I/O control alternative function output | Alternative-function internal output signal*1 |
| | X | | 1 | Direct I/O control alternative function | I/O port in alternative mode:<br>• Input: Pn_m pin<br>• Output: Alternative-function internal output signal*1 |

Note 1. When the PBDCn.PBDCnm bit is 1, the level of the Pn_m pin is returned by the PPRn.PPRnm bit.

## 54.3 Register Description

The following registers are used for setting the individual pins of the port groups:

**Table 54.5 Register Configuration**

| Symbol | Register Name | R/W | 16 Bit Access | 32 Bit Access | Address |
|---|---|---|---|---|---|
| Pn | Port register | R/W | √ | — | <PORTn_base> + 0000H + n × 4 |

### 54.3.1 Port Register (Pn)

In output port mode (PMCn.PMCnm = 0 and PMn.PMnm = 0), this register holds the Pn.Pnm data to be output via the Pn_m pin.

| Bit: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|

| R/W: | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |

| Bit Position | Bit Name | Function |
|---|---|---|
| 15 to 0 | Pn[15:0] | These bits set the output level of the Pn_m pin (m = 0 to 15).<br>0: Outputs low level<br>1: Outputs high level |

### 54.3.2 Port Set and Reset Register (PSRn)

This register provides an alternative method for writing data to the Pn register.
The higher 16 bits of the PSRn register specify whether data can be written to the Pn.Pnm bit specified by the lower 16 bits of the PSRn register.
When reading, the higher 16 bits are read as 0000H. The lower 16 bits are read as the value of the Pn register.

| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | PSRn 31 | PSRn 30 | PSRn 29 | PSRn 28 | PSRn 27 | PSRn 26 | PSRn 25 | PSRn 24 | PSRn 23 | PSRn 22 | PSRn 21 | PSRn 20 | PSRn 19 | PSRn 18 | PSRn 17 | PSRn 16 |
| R/W: | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |

| Bit: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|

| Bit Position | Bit Name | Function |
|---|---|---|
| 31 to 16 | PSRn[31:16] | These are enable bits that specify whether the value of the corresponding lower bit of the PSRn.PSRnm bits is written to the corresponding Pn.Pnm bit.<br>0: Pn.Pnm is independent of PSRn.PSRnm<br>1: Pn.Pnm becomes the value of the PSRn.PSRnm bit.<br>Example:<br>If PSRn.PSRn31 = 1, the value of PSRn.PSRn15 is written to Pn.Pn15. |
| 15 to 0 | PSRn[15:0] | These are data bits that specify the value of the Pn.Pnm bit if the corresponding higher bit, PSRn.PSRn (m+16), is 1.<br>0: Pn.Pnm = 0<br>1: Pn.Pnm = 1 |

### 54.3.3 Port Pin Read Register (PPRn/JPPR0)

The PPRn register reflects either the level of the Pn_m pin, the value of the Pn.Pnm bit, or the output level of the alternative function. The value read depends on various register settings as described in Table 54.4, PPRnm Read Values.

| Bit: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | PPRn 15 | PPRn 14 | PPRn 13 | PPRn 12 | PPRn 11 | PPRn 10 | PPRn9 | PPRn8 | PPRn7 | PPRn6 | PPRn5 | PPRn4 | PPRn3 | PPRn2 | PPRn1 | PPRn0 |
| R/W: | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |

| Bit Position | Bit Name | Function |
|---|---|---|
| 15 to 0 | PPRn[15:0] | The value of the Pn_m pin, the value of the Pn.Pnm bit, or the output level of the alternative function. |

Notes: 1. For the PPRn register read value, see section 54.2.2, Pin Data Input/Output.
2. The JPPR0[1:0] bits are control bits in the JTAG port pin read register (JPPR0).

### 54.3.4 Port Mode Register (PMn)

The PMn register specifies whether the Pn_m pins are in input mode or in output mode.

| Bit: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | PMn15 | PMn14 | PMn13 | PMn12 | PMn11 | PMn10 | PMn9 | PMn8 | PMn7 | PMn6 | PMn5 | PMn4 | PMn3 | PMn2 | PMn1 | PMn0 |
| R/W: | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |

| Bit Position | Bit Name | Function |
|---|---|---|
| 15 to 0 | PMn[15:0] | Specifies input/output mode of the corresponding pin:<br>0: Output mode (output enabled)<br>1: Input mode (output disabled) |

Notes: 1. To use the Pn_m pin in input port mode (PMCn.PMCnm = 0 and PMn.PMnm = 1), the input buffer must be enabled by setting the PIBCn.PIBCnm bit to 1.

2. After reset is issued, the PIPCn.PIPCnm bit is set to 0 and the PMn.PMnm bit specifies the I/O direction for port mode (PMCn.PMCnm = 0) and alternative mode (PMCn.PMCnm = 1). For the pins whose functions are automatically selected in boot mode (see Table 8.3, Initial States by Areas in Boot Modes 0, 1, and 2 to 5), the I/O direction is controlled by the alternative functions instead of the PMn register.

### 54.3.5 Port Mode Control Register (PMCn/JPMC0)

This register is used to specify whether the Pn_m pins are in port mode or in alternative mode.

| Bit: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | PMCn15 | PMCn14 | PMCn13 | PMCn12 | PMCn11 | PMCn10 | PMCn9 | PMCn8 | PMCn7 | PMCn6 | PMCn5 | PMCn4 | PMCn3 | PMCn2 | PMCn1 | PMCn0 |
| R/W: | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |

| Bit Position | Bit Name | Function |
|---|---|---|
| 15 to 0 | PMCn[15:0] | Specifies the operation mode of the corresponding pin:<br>0: Port mode<br>1: Alternative mode |

Caution: The input/output control is not performed just by setting alternative mode (PMCn.PMCnm). Set 1 in the PIPCn.PIPCnm bit too when the I/O control is to be performed by using the alternative function.

Note: The JPMC0[1:0] bits are control bits in the JTAG port mode control register (JPMC0).

### 54.3.6 Port Function Control Register (PFCn)

This register, together with the PFCEn and PFCAEn register, specifies the alternative function of the pins.
The I/O direction of several alternative functions can be controlled directly by using the Pn_m pin. For these alternative functions, the PIPCn.PIPCnm bit must be set to 1.
For all other alternative functions, the I/O direction is specified by using the PMn.PMnm bit.

| Bit: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | PFCn 15 | PFCn 14 | PFCn 13 | PFCn 12 | PFCn 11 | PFCn 10 | PFCn9 | PFCn8 | PFCn7 | PFCn6 | PFCn5 | PFCn4 | PFCn3 | PFCn2 | PFCn1 | PFCn0 |
| R/W: | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |

| Bit Position | Bit Name | Function |
|---|---|---|
| 15 to 0 | PFCn[15:0] | Specifies the alternative function of a pin. |

**Table 54.6 Alternative Mode Selection*2**

| PMCn. PMCnm | PFCAEn. PFCAEnm | PFCEn. PFCEnm | PFCn. PFCnm | PMn. PMnm*1 | Function |
|---|---|---|---|---|---|
| 0 | X | X | X | 1 | Port mode/input |
| | | | | 0 | Port mode/output |
| 1 | 0 | 0 | 0 | 1 | Alternative mode/1st alternative function/input |
| | | | | 0 | Alternative mode/1st alternative function/output |
| | | | 1 | 1 | Alternative mode/2nd alternative function/input |
| | | | | 0 | Alternative mode/2nd alternative function/output |
| | | 1 | 0 | 1 | Alternative mode/3rd alternative function/input |
| | | | | 0 | Alternative mode/3rd alternative function/output |
| | | | 1 | 1 | Alternative mode/4th alternative function/input |
| | | | | 0 | Alternative mode/4th alternative function/output |
| | 1 | 0 | 0 | 1 | Alternative mode/5th alternative function/input |
| | | | | 0 | Alternative mode/5th alternative function/output |
| | | | 1 | 1 | Alternative mode/6th alternative function/input |
| | | | | 0 | Alternative mode/6th alternative function/output |
| | | 1 | 0 | 1 | Alternative mode/7th alternative function/input |
| | | | | 0 | Alternative mode/7th alternative function/output |
| | | | 1 | 1 | Alternative mode/8th alternative function/input |
| | | | | 0 | Alternative mode/8th alternative function/output |

Note 1. When the PIPCn.PIPCnm bit is set to 1, the I/O direction is directly controlled by the alternative function and the setting of the PMn.PMnm bit becomes invalid.
Note 2. Use alternative functions that are open to users. If a mode to which no alternative function is assigned is selected, correct operation is not guaranteed.

### 54.3.7 Port Function Control Expansion Register (PFCEn)

This register, together with the PFCn and PFCAEn register, specifies the alternative function of the pins.
The I/O direction of several alternative functions can be controlled directly by using the Pn_m pin. For these alternative functions, the PIPCn.PIPCnm bit must be set to 1.
For all other alternative functions, the I/O direction is specified by using the PMn.PMnm bit.

| Bit: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | PFCEn 15 | PFCEn 14 | PFCEn 13 | PFCEn 12 | PFCEn 11 | PFCEn 10 | PFCEn 9 | PFCEn 8 | PFCEn 7 | PFCEn 6 | PFCEn 5 | PFCEn 4 | PFCEn 3 | PFCEn 2 | PFCEn 1 | PFCEn 0 |
| R/W: | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |

| Bit Position | Bit Name | Function |
|---|---|---|
| 15 to 0 | PFCEn[15:0] | Specifies the alternative function of a pin. |

### 54.3.8 Port NOT Register (PNOTn)

This register allows a Pn.Pnm bit to be inverted without directly writing to the Pn register.

| Bit: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|

| R/W: | W | W | W | W | W | W | W | W | W | W | W | W | W | W | W | W |

| Bit Position | Bit Name | Function |
|---|---|---|
| 15 to 0 | PNOTn[15:0] | Specifies whether to invert Pn.Pnm.<br>0: Pn.Pnm is not inverted (Pnm → Pnm)<br>1: Pn.Pnm is inverted ($\overline{\text{Pnm}}$ → Pnm) |

### 54.3.9 Port Mode Set and Reset Register (PMSRn)

This register provides an alternative method for writing data to the PMn register.
The higher 16 bits of the PMSRn register specify whether data can be written to the PMn.PMnm bit specified by the lower 16 bits of the PMSRn register.
When reading, the higher 16 bits are read as 0000H. The lower 16 bits are read as the value of the PMn register.

| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

### 54.3.10 Port Mode Control Set and Reset Register (PMCSRn/JPMCSR0)

This register provides an alternative method for writing data to the PMCn register.

The higher bits of the PMCSRn register specify whether data can be written to the PMCn.PMCnm bit specified by the lower bits of the PMCSRn register.

When reading, the higher 16 bits are read as 0000H. The lower 16 bits are read as the value of the PMCn register.

Note: The JPMCSR0[1:0] bits are control bits in the JTAG port mode control set/reset register (JPMCSR0).

### 54.3.11 Port Function Control Additional Expansion Register (PFCAEn)

This register, together with the PFCn and PFCEn register, specifies the alternative function of the pins.

The I/O direction of several alternative functions can be controlled directly by using the Pn_m pin. For these alternative functions, the PIPCn.PIPCnm bit must be set to 1.

For all other alternative functions, the I/O direction is specified by using the PMn.PMnm bit.

After selecting an alternative function by the PFCn.PFCnm, PFCEn.PFCEnm, or PFCAEn.PFCAEnm bit, set the PMCn.PMCnm bit to 1.

| Bit: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | PFCAEn15 | PFCAEn14 | PFCAEn13 | PFCAEn12 | PFCAEn11 | PFCAEn10 | PFCAEn9 | PFCAEn8 | PFCAEn7 | PFCAEn6 | PFCAEn5 | PFCAEn4 | PFCAEn3 | PFCAEn2 | PFCAEn1 | PFCAEn0 |
| R/W: | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |

| Bit Position | Bit Name | Function |
|---|---|---|
| 15 to 0 | PFCAEn[15:0] | Specifies the alternative function of a pin. |

Caution: Although some alternative functions are assigned to multiple pins in this LSI, only one of the pins can be used for each alternative function. Do not set the same alternative function in multiple pins. For example, when the a/b/c pin is used as the b pin, the b/d/e pin cannot be used as the b pin. Before using the b/d/e pin, set the pin as an alternative function other than b.

Note: For the allocation of the alternative functions, see the table of the pin functions of each port.

## 54.3.12 Port Input Buffer Control Register (PIBCn/JPIBC0)

In input port mode (PMCn.PMCnm = 0 and PMn.PMnm = 1 or JPMC0.JPMC0 = 0), this register enables or disables the input buffer for the Pn_m pin.

| Bit: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | PIBCn 15 | PIBCn 14 | PIBCn 13 | PIBCn 12 | PIBCn 11 | PIBCn 10 | PIBCn 9 | PIBCn 8 | PIBCn 7 | PIBCn 6 | PIBCn 5 | PIBCn 4 | PIBCn 3 | PIBCn 2 | PIBCn 1 | PIBCn 0 |
| R/W: | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |

| Bit Position | Bit Name | Function |
|---|---|---|
| 15 to 0 | PIBCn[15:0] | These bits enable or disable the input buffer.<br>0: Input buffer disabled<br>1: Input buffer enabled |

Note: When the input buffer is disabled, through current does not flow even when the pin level is Hi-Z. Thus the pin does not need to be fixed to a high or low level externally (except for P2_12, P2_15, P3_1, P3_3, P3_9, P5_09, P6_2, P6_4, P7_8, P8_02, P8_7, and P9_1).
The JPIBC0[1:0] bits are control bits in the JTAG port input buffer control register (JPIBC0).

Caution: When the output buffer is enabled and the PBDCn.PBDCnm bit is 1, the input buffer is enabled regardless of this register setting.

## 54.3.13 Port Bidirection Control Register (PBDCn)

This register enables or disables the input buffer while the output buffer is enabled. When the input buffer is enabled while the output buffer is enabled, the bidirectional mode is entered, allowing the level of the Pn_m pin to always be read via the PPRn.PPRnm bit.

| Bit: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | PBDCn 15 | PBDCn 14 | PBDCn 13 | PBDCn 12 | PBDCn 11 | PBDCn 10 | PBDCn 9 | PBDCn 8 | PBDCn 7 | PBDCn 6 | PBDCn 5 | PBDCn 4 | PBDCn 3 | PBDCn 2 | PBDCn 1 | PBDCn 0 |
| R/W: | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |

| Bit Position | Bit Name | Function |
|---|---|---|
| 15 to 0 | PBDCn[15:0] | Enables/disables bidirectional mode of the corresponding pin:<br>0: Bidirectional mode disabled<br>1: Bidirectional mode enabled |

Caution: When using the Pn_m bit as the output of an alternative function (PMCn.PMCnm = 1, PMn.PMnm = 0), the level of the Pn_m pin can be read at the PPRn.PPRnm bit by setting the PBDCn.PBDCnm bit to 1. Note, however, that in this case, the level of the Pn_m pin will be conveyed to the input of the alternative function that the Pn_m pin is being used as.

### 54.3.14 Port IP Control Register (PIPCn)

This register is used to specify whether the I/O direction of the Pn_m pin is controlled by the PMn.PMnm bit or by the alternative function in alternative mode (the PMCn.PMCnm bit is 1).
When using an alternative function shown in Table 54.7, set the PIPCn.PIPCnm bit to 0. When using an alternative function that is not shown in Table 54.7, set the PIPCn.PIPCnm bit to 1. When the PIPCn.PIPCnm bit is set to 1, the alternative function controls the I/O direction and the PMn.PMnm bit setting becomes invalid.

| Bit: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |

### 54.3.15 Serial Sound Interface Noise Canceler Control Register (SNCR)

This register controls the noise canceler in the input route from the LSI pin to a serial sound interface and the pins for MII supported in the Ethernet. Six lower-order bits can be set only when slave mode is selected for the corresponding channel of the serial sound interface.
In master mode, the bit corresponding to the channel of the serial sound interface must be set to 0.

## 54.18 Port Control Logical Diagram

The following shows a logical diagram of the port control function.
Note: This figure shows the logic for reference, not the circuit.

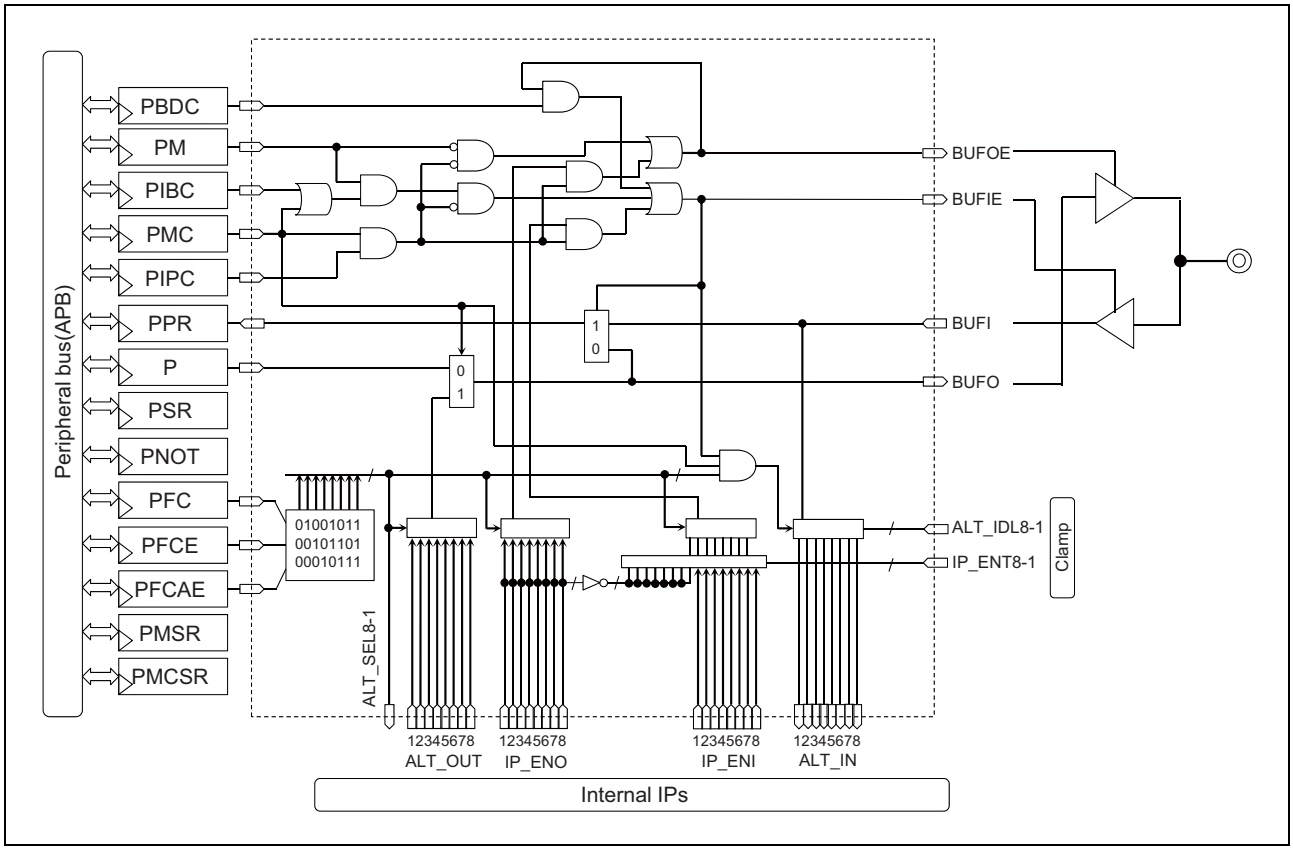

**Figure 54.1 Logical Diagram of Port Control**

## 54.19 Flowchart Examples of Port Setting

A flowchart example for setting the Pn_m pin to port mode is shown in (a), an example for setting software I/O control alternative mode is shown in (b), and an example for setting direct I/O control alternative mode is shown in (c).

### (a) Port settings for port mode

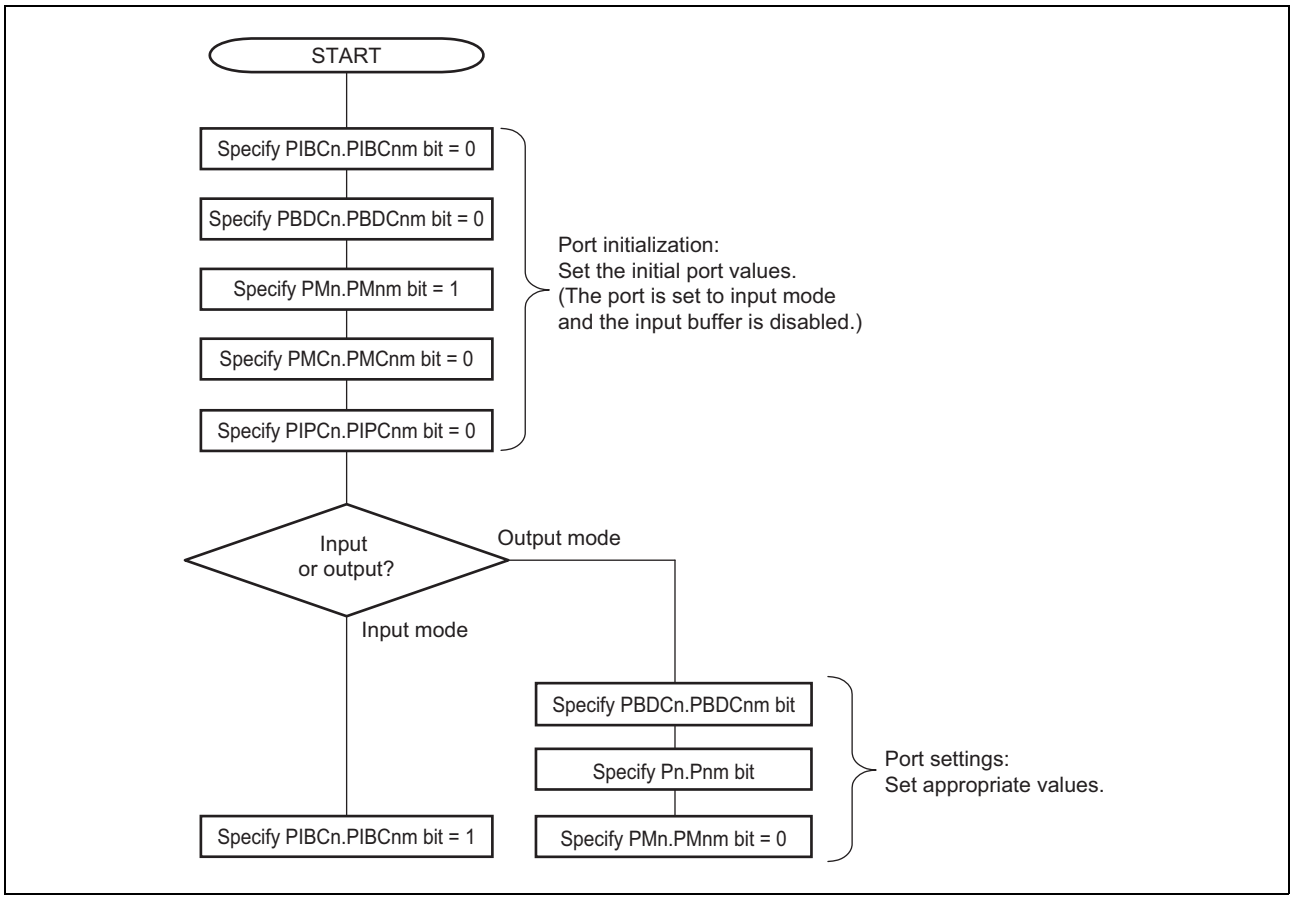

**Figure 54.2 Example of Port Settings (in Port Mode) (1/3)**

(b) Port settings for software I/O control alternative mode

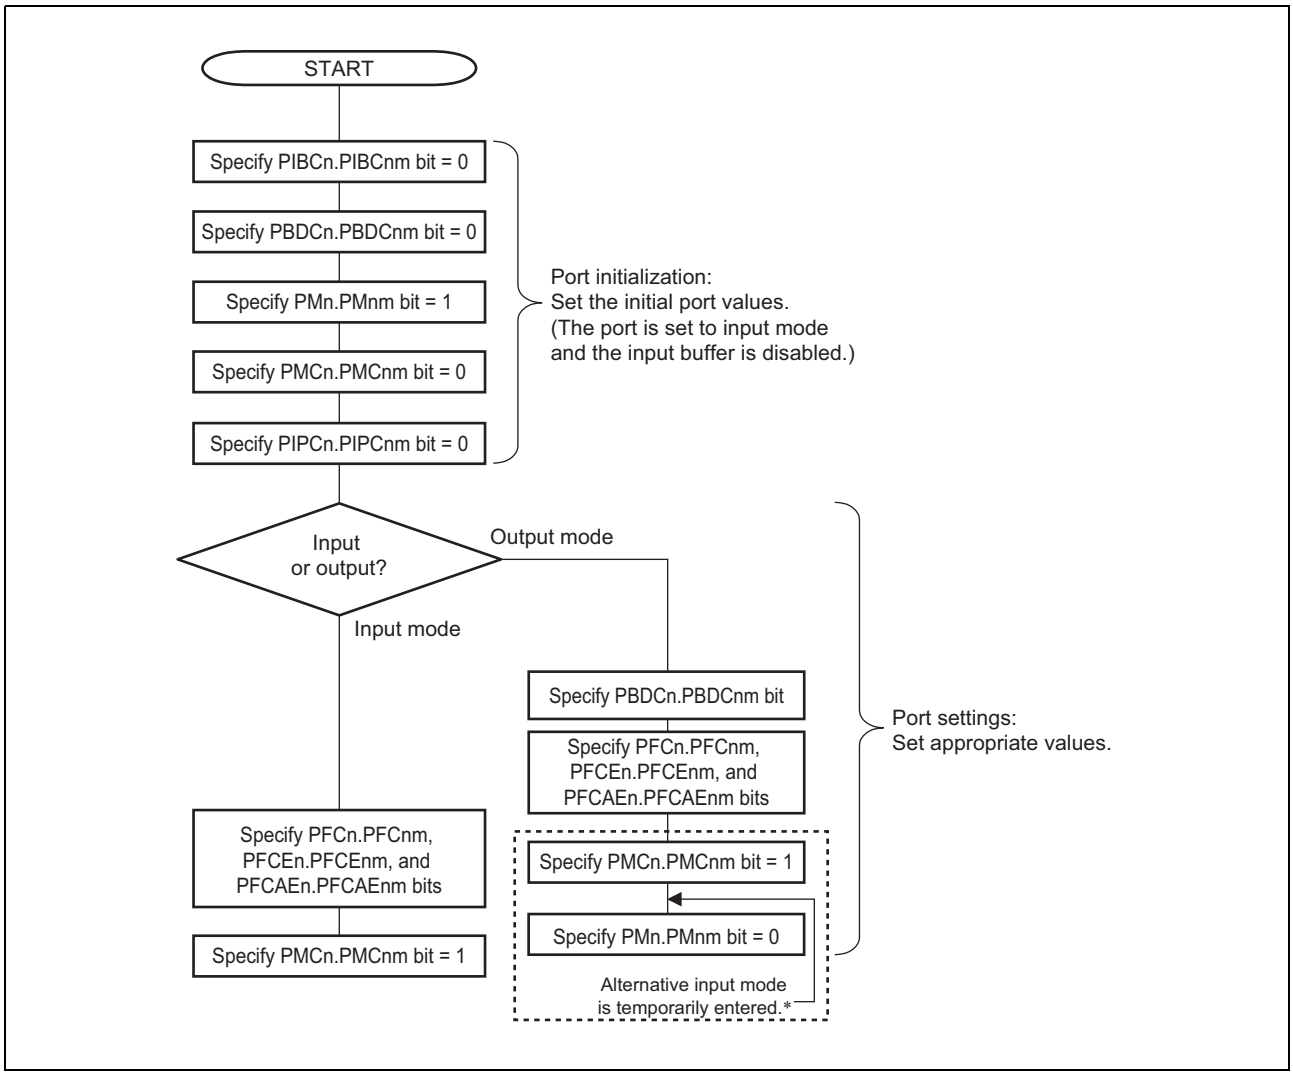

**Figure 54.3 Example of Port Settings (in Software I/O Control Alternative Mode) (2/3)**

Note: * When the Pn_m pin is set to the output mode in software I/O control alternative mode, the alternative input mode is temporarily entered after the PMCn.PMCnm bit is set to 1 until the PMn.PMnm bit is cleared to 0. Therefore, when an interrupt-related signal is selected as the alternative function for the port pin, appropriate settings should be made so that the interrupt does not occur or is ignored.

(c) Port settings for direct I/O control alternative mode

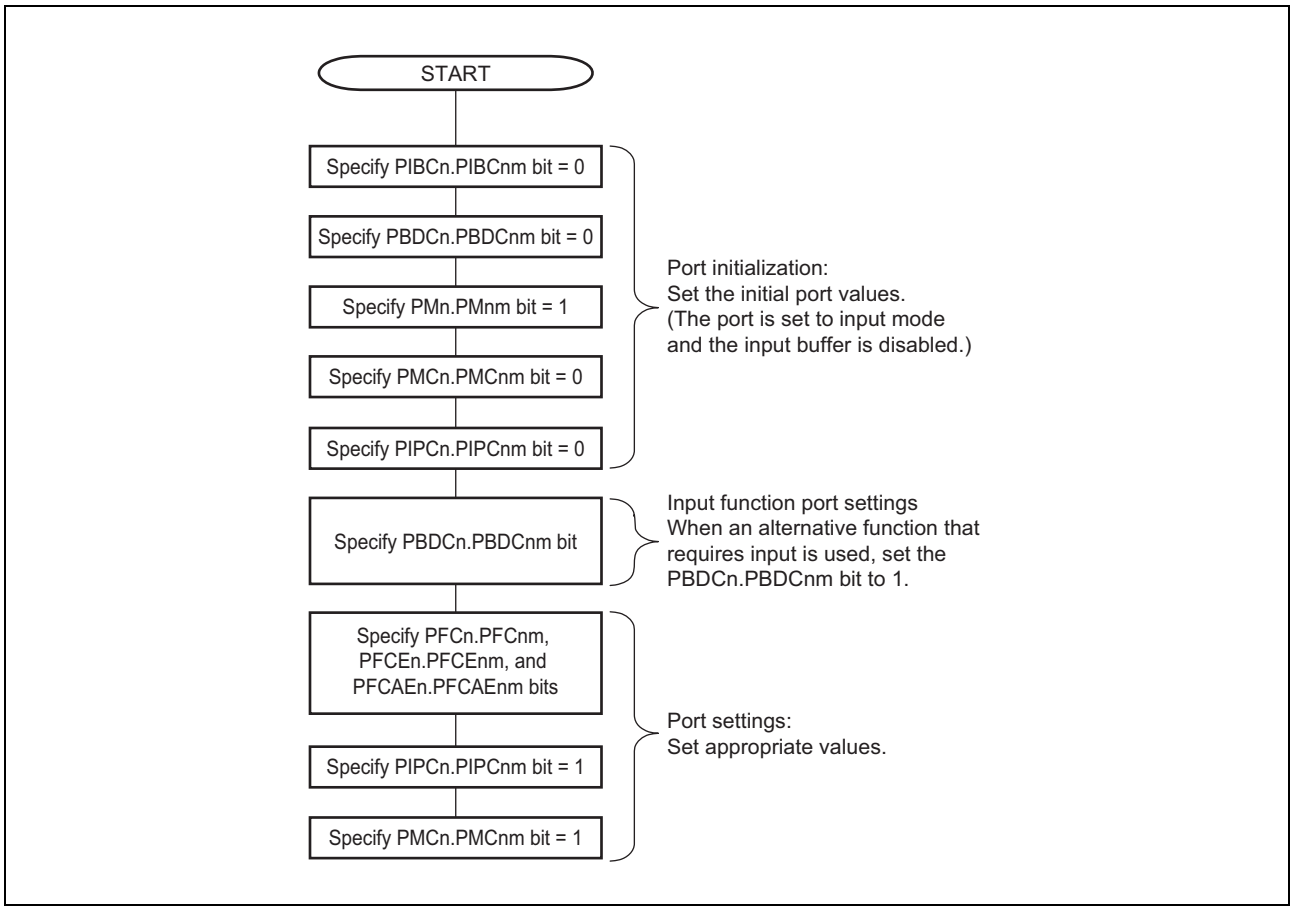

**Figure 54.4 Example of Port Settings (in Direct I/O Control Alternative Mode) (3/3)**

# 55. Power-Down Modes

This LSI supports sleep mode, software standby mode, deep standby mode, and module standby mode. In power-down modes, functions of CPU, clocks, on-chip memory, or part of on-chip peripheral modules are halted or the power-supply is turned off, through which low power consumption is achieved. These modes are canceled by a reset or interrupt.

## 55.1 Features

### 55.1.1 States of Processing and Power-Down Modes

#### (1) States of processing

This LSI has three general states of processing: the reset state, the program execution state, and the power-down modes. Figure 55.1 shows transitions between these states.

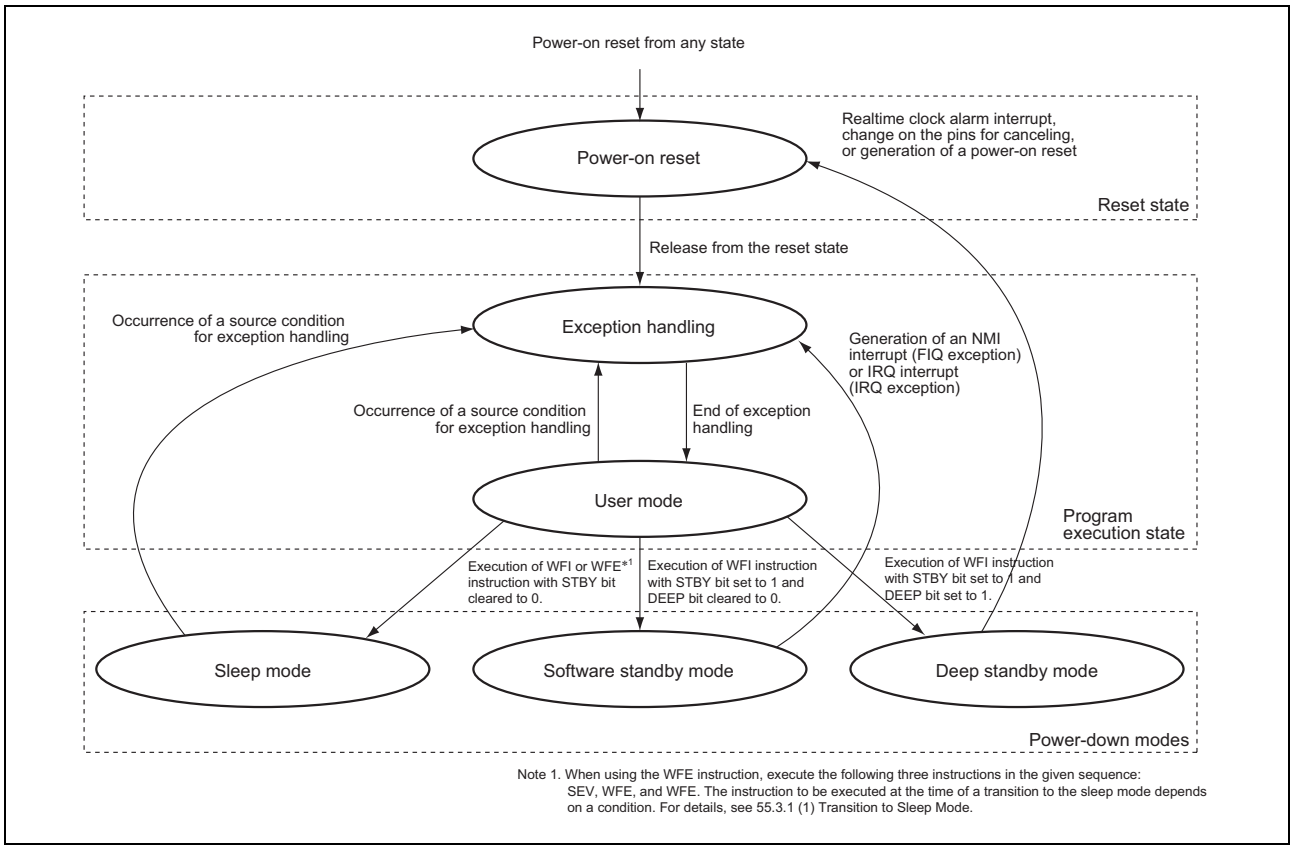

**Figure 55.1 Transitions between Processing States**

#### (2) Power-down modes

This LSI has the following power-down modes and function:

1. Sleep mode
2. Software standby mode
3. Deep standby mode
4. Module standby function

Table 55.1 shows the transition conditions for entering the modes from the program execution state, as well as the CPU and peripheral module states in each mode and the procedures for canceling each mode.

**Table 55.1 States of Power-Down Modes**

| | | State | | | | | | | |
|---|---|---|---|---|---|---|---|---|---|
| **Power-Down Mode** | **Transition Conditions** | **CPU, CPU Register, Primary Cache, TLB** | **Secondary Cache** | **Large-Capacity On-Chip RAM (including on-chip data-retention RAM)** | **On-Chip Peripheral Modules** | **Realtime Clock** | **Internal Power Supply** | **External Memory** | **Canceling Procedure** |
| Sleep mode | Execute WFI or WFE*6 instruction with STBY bit in STBCR1 cleared to 0 | Halted Contents are held.*4 | Running | Running | Running | Running*1 | Applied | Auto-refresh | • Interrupt<br>• Power-on reset |
| Software standby mode | Execute WFI instruction with STBY and DEEP bits in STBCR1 set to 1 and 0, respectively | Halted Contents are held.*4 | Halted Contents are held.*4 | Halted Contents are held.*5 | Halted | Running*1 | Applied | Self-refresh | • NMI or IRQ interrupt<br>• Power-on reset |
| Deep standby mode | Execute WFI instruction with STBY and DEEP bits in STBCR1 set to 1 | Halted Contents are not held. | Halted Contents are not held. | Halted Contents in on-chip data-retention RAM are held*2, and the other contents in large-capacity on-chip RAM are not held. | Halted | Running*1 | Shut off | Self-refresh | • Power-on reset*3<br>• Realtime clock alarm interrupt*3<br>• Change on the pins for canceling*3 |
| Module standby mode | Set the MSTP bits in STBCR2 to STBCR13 to 1 | Running | Running | Running | Specified module halted | Halted | Applied | Auto-refresh | • Clear MSTP bit to 0 |

Note 1. The realtime clock operates when the START bit in the RCR2 register is set to 1. For details, see section 13, Realtime Clock. When deep standby mode is canceled by a power-on reset, the running state cannot be retained. Make the initial setting for the realtime clock again.

Note 2. Setting the bits RRAMKP3 to RRAMKP0 in the RRAMKP register to 1 enables to retain the data in the corresponding area on the on-chip data-retention RAM during the transition to deep standby mode. When the deep standby mode is canceled by a power-on reset, the retained contents are initialized.

Note 3. Deep standby mode can be canceled by a power-on reset, a realtime clock alarm interrupt, or change on the pins for canceling (P2_12, P2_15, P3_1, P3_3, P3_9, P5_9, P6_2, P6_4, P7_8, P8_2, P8_7, P9_1, and NMI). Even when deep standby mode is canceled by a source other than a power-on reset, the reset exception handling is executed instead of the interrupt exception handling.

Note 4. When sleep mode or software standby mode is canceled by a power-on reset, the retained contents are initialized.

Note 5. By setting the VRAME bit in the SYSCR1 register or VRAMWE bit in the SYSCR2 register to enable accesses, the retained contents are initialized when software standby mode is canceled by a power-on reset. By setting the VRAME bit in the SYSCR1 register or VRAMWE bit in the SYSCR2 register to disable accesses, contents in the large-capacity on-chip RAM (including on-chip data-retention RAM) can be retained when software standby mode is canceled by a power-on reset. Note that the area at addresses from H'2002_0000 to H'2002_3FFF is used as working memory for the boot program in boot modes 3 to 5. In boot modes 4 and 5, a 28-Kbyte program is transferred from the external flash memory to the area at addresses from H'2002_4000 to H'2002_AFFF. For details, see section 3, Boot Mode.

Note 6. When using the WFE instruction, execute the following three instructions in the given sequence: SEV, WFE, and WFE. The instruction to be executed at the time of a transition to the sleep mode depends on a condition. For details, see 55.3.1 (1) Transition to Sleep Mode.

Note 1. The transition to and release from module stop mode proceed in the steps described in section 55.3.5, Module Standby Function.

## 55.2.7 Standby Control Register 7 (STBCR7)

STBCR7 is an 8-bit readable/writable register that controls the operation of each module.

Note: • When writing to this register, see section 55.4, Usage Notes.

Note: For details on this register, see section 50.3.2, Card Detect/Write Protect.

## 55.2.13 Standby Control Register 13 (STBCR13)

STBCR13 is an 8-bit readable/writable register that controls the operation of each module.

Note: • When writing to this register, see section 55.4, Usage Notes.

## 55.2.16 Software Reset Control Register 3 (SWRSTCR3)

SWRSTCR3 is an 8-bit readable/writable register that controls a software reset for each module.

Note: • When writing to this register, see section 55.4, Usage Notes.

| Bit: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |

### 55.2.17 System Control Register 1 (SYSCR1)

SYSCR1 is an 8-bit readable/writable register that enables or disables access (read and write) to a specified page in the large-capacity on-chip RAM.

When a VRAMEn (n = 0 to 4) bit in SYSCR1 is set to 1, access to page n is enabled. When a VRAMEn bit is cleared to 0, page n cannot be accessed. In this case, an undefined value is returned when reading data or fetching an instruction from page n, and writing to page n is ignored. The initial value of a VRAMEn bit is 1.

SYSCR1 should be set with a program located in an area other than the large-capacity on-chip RAM. Furthermore, an instruction to read SYSCR1 should be located immediately after the instruction to write to SYSCR1. If not, normal access is not guaranteed.

Note: • When writing to this register, see section 55.4, Usage Notes.

| Bit: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|
| | - | - | - | VRAME4 | VRAME3 | VRAME2 | VRAME1 | VRAME0 |
| Initial value: | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 |

| 2 | VRAME2 | 1 | R/W | RAM Enable 2 (corresponding area: page 2*1 in large-capacity on-chip RAM)<br>0: Access to page 2 is disabled.<br>1: Access to page 2 is enabled. |
| 1 | VRAME1 | 1 | R/W | RAM Enable 1 (corresponding area: page 1*1 in large-capacity on-chip RAM)<br>0: Access to page 1 is disabled.<br>1: Access to page 1 is enabled. |
| 0 | VRAME0 | 1 | R/W | RAM Enable 0 (corresponding area: page 0*1 in large-capacity on-chip RAM)<br>0: Access to page 0 is disabled.<br>1: Access to page 0 is enabled. |

Note 1. For addresses in each page, see section 53, On-Chip RAM.

### 55.2.18 System Control Register 2 (SYSCR2)

SYSCR2 is an 8-bit readable/writable register that enables or disables writing to a specified page in the large-capacity on-chip RAM.

When a VRAMWEn (n = 0 to 4) bit in SYSCR2 is set to 1, writing to page n is enabled. When a VRAMWEn bit is cleared to 0, writing to page n is ignored. The initial value of a VRAMWEn bit is 1.

SYSCR2 should be set with a program located in an area other than the large-capacity on-chip RAM. Furthermore, an instruction to read SYSCR2 should be located immediately after the instruction to write to SYSCR2. If not, normal access is not guaranteed.

Note: • When writing to this register, see section 55.4, Usage Notes.

Note 1. For addresses in each page, see section 53, On-Chip RAM.

## 55.2.19 System Control Register 3 (SYSCR3)

SYSCR3 is an 8-bit readable/writable register that enables or disables writing to a specified page in the on-chip data-retention RAM.

When a RRAMWEn (n = 0 to 3) bit in SYSCR3 is set to 1, writing to page n is enabled. When a RRAMWEn bit is cleared to 0, writing to page n is ignored. The initial value of a RRAMWEn bit is 0.

SYSCR3 should be set with a program located in an area other than the on-chip data-retention RAM.

Note: • When writing to this register, see section 55.4, Usage Notes.

| Bit: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|
| | - | - | - | - | RRAMWE3 | RRAMWE2 | RRAMWE1 | RRAMWE0 |

Note 1. For addresses in each page, see section 53, On-Chip RAM.

Note 2. When the VRAME0 bit in SYSCR1 is cleared to 0 (access to page 0 in large-capacity on-chip RAM is invalid), the on-chip data-retention RAM cannot be accessed (read and written), regardless of the setting of this bit.
When the VRAMWE0 bit in SYSCR2 is cleared to 0 (writing to page 0 in large-capacity on-chip RAM is invalid), the on-chip data-retention RAM cannot be written, regardless of the setting of this bit.

## 55.2.20 CPU Status Register (CPUSTS)

CPUSTS is an 8-bit readable register that indicates the status of the CPU.

| Bit: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|
| | - | - | - | ISBUSY | - | - | - | - |

| 3 to 0 | — | All 0 | R | Reserved<br>These bits are always read as 0. |

## 55.2.21 Standby Request Register 1 (STBREQ1)

This register is used to request notification of whether a CPU or peripheral module is ready for standby. The CPU or peripheral module returns a standby acknowledgement on receipt of a request for notification if it is ready for standby.

Note: • When writing to this register, see section 55.4, Usage Notes.

Note 1. When the MSTP bit for the corresponding module is 1, writing 1 to the STBRQ bit has no effect.

## 55.2.22 Standby Request Register 2 (STBREQ2)

This register is used to request notification of whether a peripheral module is ready for standby. The peripheral module returns a standby acknowledgement on receipt of a request for notification if it is ready for standby.

Note: • When writing to this register, see section 55.4, Usage Notes.

Note 1. When the MSTP bit for the corresponding module is 1, writing 1 to the STBRQ bit has no effect.

## 55.2.23 Standby Acknowledge Register 1 (STBACK1)

This register is used to provide notification that a CPU or peripheral module is in the standby ready state. The CPU or peripheral module returns a standby acknowledgement on reception of a standby notification request if it is ready for standby. This register is a read-only register.

| Bit: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |

Note 1. The bits in STBACK1 are set to 1 when a standby acknowledgement is transmitted from the module while the MSTP bit for the corresponding module is set to 0.

## 55.2.24 Standby Acknowledge Register 2 (STBACK2)

This register is used to provide notification that a peripheral module is in the standby ready state. The peripheral module returns a standby acknowledgement on reception of a standby notification request if it is ready for standby. This register is a read-only register.

Note 1. The bits in STBACK2 are set to 1 when a standby acknowledgement is transmitted from the module while the MSTP bit for the corresponding module is set to 0.

### 55.2.25 On-Chip Data-Retention RAM Area Setting Register (RRAMKP)

RRAMKP is an 8-bit readable/writable register that selects whether the contents of the corresponding area of the on-chip data-retention RAM are retained or not in deep standby mode.

When the RRAMKP3 to RRAMKP0 bits are set to 1, the contents of the corresponding area of the on-chip data-retention RAM are retained in deep standby mode. When these bits are cleared to 0, the contents of the corresponding area of the on-chip data-retention RAM are not retained in deep standby mode.

Note: • When writing to this register, see section 55.4, Usage Notes.

Note 1. For addresses in each page, see section 53, On-Chip RAM.

## 55.2.26 Deep Standby Control Register (DSCTR)

DSCTR is an 8-bit readable/writable register that selects whether the states of the external memory control pins are retained or not when returning from deep standby mode and specifies the method to start the LSI.

Note: • When writing to this register, see section 55.4, Usage Notes.

## 55.2.27 Deep Standby Cancel Source Select Register (DSSSR)

DSSSR is a 16-bit readable/writable register that consists of the bits for selecting a source to cancel deep standby mode. The realtime clock alarm interrupt or change on the pins for canceling (P2_12, P2_15, P3_1, P3_3, P3_9, P5_9, P6_2, P6_4, P7_8, P8_2, P8_7, and P9_1) can be selected as a cancel source. The pins for canceling can be used for canceling deep standby, regardless of pin function settings in the general I/O port.

Note: • When writing to this register, see section 55.4, Usage Notes.

## 55.2.28 Deep Standby Cancel Edge Select Register (DSESR)

DSESR is a 16-bit readable/writable register that consists of the bits for selecting an edge to be detected for the pin specified as a deep standby cancel source with DSSSR. This register setting is always valid for canceling deep standby, regardless of the interrupt controller setting.

Note: • When writing to this register, see section 55.4, Usage Notes.

## 55.2.29 Deep Standby Cancel Source Flag Register (DSFR)

DSFR is a 16-bit readable/writable register composed of two types of bits. One is the flag that confirms which source canceled deep standby mode. The other is the bit that releases the state of pins after canceling deep standby mode. When deep standby mode is canceled by an interrupt (NMI or realtime clock alarm interrupt) and changes on the pins for canceling, this register retains the previous data although power-on reset exception handling is executed. When deep standby mode is canceled by a power-on reset, this register is initialized to H'0000.
All flags must be cleared immediately before transition to deep standby mode.

Note: • When writing to this register, see section 55.4, Usage Notes.

## 55.2.30 XTAL Crystal Oscillator Gain Control Register (XTALCTR)

XTALCTR is an 8-bit readable/writable register that controls the gain of the crystal oscillator for XTAL and the realtime clock.

If the realtime clock uses the EXTAL input, the GAIN0 bit retains the previous value when software standby mode or deep standby mode is canceled by a source other than a power-on reset. If the realtime clock does not use the EXTAL input, this bit is initialized to 0 when software standby or deep standby mode is entered.

If the realtime clock uses the RTC_X1 or RTC_X3 input, the GAIN1 bit retains the previous value when software standby mode or deep standby mode is canceled by a source other than a power-on reset. If the realtime clock does not use the RTC_X1 or RTC_X3 input, this bit is initialized to 0 when software standby or deep standby mode is entered.

This bit is initialized to H'00 when software standby or deep standby mode is canceled by a power-on reset.

Note: • When writing to this register, see section 55.4, Usage Notes.

## 55.3 Operation

### 55.3.1 Sleep Mode

#### (1) Transition to Sleep Mode

When causing the device to make a transition from the program execution state to sleep mode, follow procedure (a) or (b) depending on the condition described following the description of the procedures.

(a) Execute the WFI instruction while the STBY bit in STBCR1 is 0.
(b) While the STBY bit in STBCR1 is 0 and bits I and F in the current program status register (CPSR) corresponding to the interrupt source to trigger release from the sleep mode are 0 (mask disabled), execute the following three instructions in the given sequence: SEV, WFE, and WFE.

When the following condition is met, follow procedure (b) and do not use the WFI instruction other than to initiate a transition to software standby or deep standby.

- Software standby is also being used.
- When software standby is not being used, deep standby is being used, and the procedure (a) in 55.3.4 (1) Transition to Deep Standby Mode is followed to initiate the transition to deep standby.

Although the CPU halts immediately after a transition to the sleep mode, the contents of its internal registers remain unchanged. The on-chip peripheral modules continue to run. The clock output from the CKIO pin is continued.

Note: • When writing to STBCR1 register, see section 55.4, Usage Notes.

#### (2) Canceling Sleep Mode

Sleep mode is canceled by an interrupt (NMI, IRQ, and on-chip peripheral module) or a power-on reset.

- Canceling by an interrupt
  When an NMI, IRQ, or on-chip peripheral module interrupt occurs, sleep mode is canceled and interrupt exception handling is executed. When the priority level of the generated interrupt is lower than the setting of the interrupt controller execution priority register, or the interrupt by the on-chip peripheral module is disabled on the module side, the interrupt request is not accepted and sleep mode is not canceled. When procedure (a) in 55.3.1 (1) Transition to Sleep Mode is followed and an interrupt request occurs with an interrupt masked by bits 6 (the FIQ mask bit) and 7 (the IRQ mask bit) in the CPSR register in the CPU, sleep mode is canceled but interrupt exception handling is not executed.
- Canceling by a reset
  Sleep mode is canceled by a power-on reset.

## 55.3.2 Software Standby Mode

### (1) Transition to Software Standby Mode

The LSI switches from a program execution state to software standby mode by executing the WFI instruction when the STBY bit and DEEP bit in STBCR1 are 1 and 0 respectively. In software standby mode, not only the CPU but also the clock and on-chip peripheral modules halt. The clock output from the CKIO pin also stops.
The contents of the CPU and cache registers remain unchanged. Some registers of on-chip peripheral modules are, however, initialized. As for the states of on-chip peripheral module registers in software standby mode, see section 58.3, Register States.
The CPU takes one cycle to finish writing to STBCR1, and then executes processing for the next instruction. However, it takes one or more cycles to actually write. Therefore, execute a WFI instruction after reading STBCR1 to have the values written to STBCR1 by the CPU to be definitely reflected in the WFI instruction.
After a WFI instruction is issued, the hardware automatically stops the bus master following the wait for completion of the issuing-finished request from the bus master and the transition to software standby proceeds.
Since the transition to software standby is not possible if completion of the issuing-finished request is not possible at this time, do not proceed with access to the registers of modules in the module-standby state and so on.
Furthermore, as the issuing of unintended requests by the bus master is inhibited, using software to stop all bus masters in preparation for the procedure for the transition to software standby is also effective.

The procedure for switching to software standby mode is as follows:

1. Set the standby_mode_en bit of the power control register in the PL310 to 1. For the details of this register, see CoreLink Level 2 Cache Controller L2C-310 Technical Reference Manual issued by Arm Ltd.
2. Clear the TME bit in the watchdog timer control/status register (WTCSR) of the watchdog timer to 0 to stop the watchdog timer.
3. Set the CKS[2:0] bits of the WTCSR register and the watchdog timer counter (WTCNT) to appropriate values so that the watchdog timer overflow period will be at least the oscillation settling time on return from standby.
4. After setting the STBY and DEEP bits in STBCR1 to 1 and 0 respectively, read STBCR1. Then, execute a WFI instruction.

### (2) Canceling Software Standby Mode

Software standby mode is canceled by interrupts (NMI or IRQ) or a reset (power-on reset). Clock signal starts to be output from the CKIO pin.

- Canceling by an interrupt
  When the falling edge or rising edge of the NMI pin (selected by the NMI edge select bit (NMIE) in the interrupt control register 0 (ICR0) of the interrupt controller) or the falling edge or rising edge of an IRQ pin (IRQ7 to IRQ0) (selected by the IRQn sense select bits (IRQn1S and IRQn0S) in interrupt control register 1 (ICR1) of the interrupt controller) is detected, clock oscillation is started. This clock pulse is supplied only to the oscillation settling counter (watchdog timer) used to count the oscillation settling time.
  After the elapse of the time set in the clock select bits (CKS[2:0]) in the watchdog timer control/status register (WTCSR) of the watchdog timer before the transition to software standby mode, the watchdog timer overflow occurs. Since this overflow indicates that the clock has been stabilized, the clock pulse will be supplied to the entire chip after this overflow. Software standby mode is thus cleared and NMI interrupt exception handling (IRQ interrupt exception handling in case of IRQ) is started. If the priority level of the generated interrupt is lower than the setting of the interrupt controller execution priority register, the interrupt request is not accepted and sleep mode is entered. So, cancel software standby mode by an interrupt whose priority level is higher than the setting of the interrupt controller execution priority register.
  When canceling software standby mode by the NMI interrupt or IRQ interrupt, set the CKS[2:0] bits so that the watchdog timer overflow period will be equal to or longer than the oscillation settling time.
  The clock output phase of the CKIO pin may be unstable immediately after detecting an interrupt and until software standby mode is canceled.

- Canceling by a reset
  When the $\overline{\text{RES}}$ pin is driven low, software standby mode is canceled and the LSI enters the power-on reset state. After that, if the $\overline{\text{RES}}$ pin is driven high, the power-on reset exception handling is started.
  Keep the $\overline{\text{RES}}$ pin low until the clock oscillation settles. The internal clock will continue to be output to the CKIO pin.

### (3) Note on Transition to Software Standby Mode

Release from software standby mode is triggered by interrupts (NMI or IRQ) or a power-on reset. If, however, a WFI instruction and an interrupt other than NMI and IRQ are generated at the same time, software standby mode may be canceled due to acceptance of the interrupt.
When initiating a transition to software standby mode, make settings so that interrupts other than NMI and IRQ are not generated before execution of the WFI instruction.

### (4) Note on Canceling Software Standby Mode

After software standby mode is canceled, unstable clock pulses are output from the CKIO pin during oscillation settling time. To prevent malfunction due to the unstable pulses, the CKOEN[1:0] bits in FRQCR should be modified.

### 55.3.3 Software Standby Mode Application Example

This example describes a transition to software standby mode on the falling edge of the NMI signal, and cancellation on the rising edge of the NMI signal. The timing is shown in Figure 55.2.

When the NMI pin is changed from high to low level while the NMI edge select bit (NMIE) in the interrupt control register 0 (ICR0) is set to 0 (falling edge detection), the NMI interrupt is accepted. When the NMIE bit is set to 1 (rising edge detection) by the NMI exception service routine, the STBY and DEEP bits in STBCR1 are set to 1 and 0 respectively, and a WFI instruction is executed, software standby mode is entered. Thereafter, software standby mode is canceled when the NMI pin is changed from low to high level.

Note: • When writing to STBCR1 register, see section 55.4, Usage Notes.

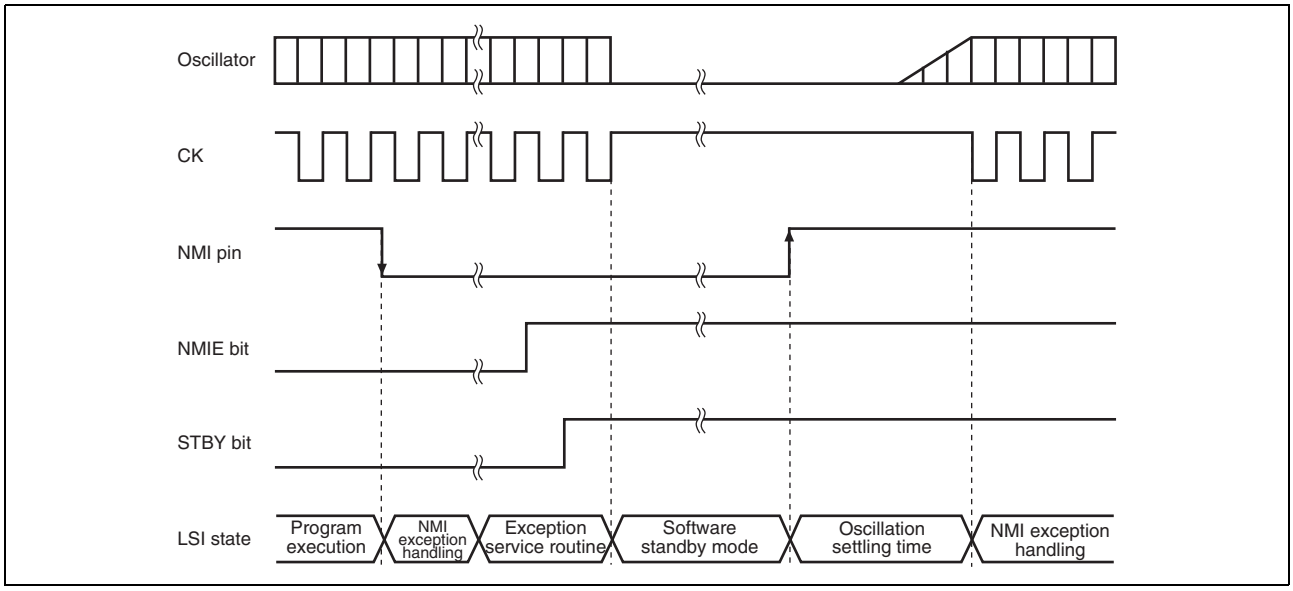

**Figure 55.2 NMI Timing in Software Standby Mode (Application Example)**

### 55.3.4 Deep Standby Mode

#### (1) Transition to Deep Standby Mode

The LSI switches from a program execution state to deep standby mode by executing the WFI instruction when the STBY bit and DEEP bit in STBCR1 are set to 1. In deep standby mode, not only the CPU, clocks, and on-chip peripheral modules but also power supply is turned off excluding the on-chip data-retention RAM area specified by the RRAMKP3 to RRAMKP0 bits in RRAMKP and realtime clock. This can significantly reduce power consumption. Therefore, data in the registers of the CPU, cache, and on-chip peripheral modules are not retained. Pin state values immediately before the transition to deep standby mode are retained.
The CPU takes one cycle to finish writing to STBCR1, and then executes processing for the next instruction. However, it actually takes one or more cycles to write. Therefore, execute a WFI instruction after reading STBCR1 to reflect the values written to STBCR1 by the CPU in the WFI instruction without fail.
After a WFI instruction is issued, the hardware automatically stops the bus master following the wait for completion of the issuing-finished request from the bus master and the transition to deep standby proceeds.
Since the transition to deep standby is not possible if completion of the issuing-finished request is not possible at this time, do not proceed with access to the registers of modules in the module-standby state and so on.
Furthermore, as the issuing of unintended requests by the bus master is inhibited, using software to stop all bus masters in preparation for the procedure for the transition to deep standby is also effective.

The procedure for switching to deep standby mode is as follows. Figure 55.3 also shows its flowchart.

1. Set the standby_mode_en bit of the power control register in the PL310 to 1. For the details of this register, see CoreLink Level 2 Cache Controller L2C-310 Technical Reference Manual issued by Arm Ltd.
2. Set the RRAMKP3 to RRAMKP0 bits in RRAMKP for the corresponding on-chip data-retention RAM area that must be retained. Transfer the programs to be retained to the specified areas of the on-chip data-retention RAM.
3. Set the RAMBOOT and EBUSKEEPE bits in DSCTR to specify the activation method for returning from deep standby mode and to select whether the external memory control pin status is retained or not.
4. When canceling deep standby mode by an interrupt, set the corresponding bit in DSSSR to select the pin or source to cancel deep standby mode. In this case, specify the input signal detection mode for the selected pin with the corresponding bit in DSESR.
5. Execute read and write of an arbitrary but the same address for each page in the on-chip data-retention RAM area. When this is not executed, data last written may not be written to the on-chip data-retention RAM. If there is a write to the on-chip data-retention RAM after this time, execute this processing after the last write to the on-chip data-retention RAM.

The procedures for steps 6 to 8 are as listed under (a) or (b), and which procedure is correct depends on the condition described after the procedures.

(a)

6. Set the STBY and DEEP bits in the STBCR1 register to 1, and then read this register.
7. Clear the flag in the DSFR register.
8. Set the CPU interface control register (ICCICR) of the interrupt controller to 0 so that the CPU is not notified of interrupts other than NMIs. Then, read the ICCICR register.

(b)

6. Clear the flag in the DSFR register.
7. Set the CPU interface control register (ICCICR) of the interrupt controller to 0 so that the CPU is not notified of interrupts other than NMIs. Then, read the ICCICR register.
8. Set the STBY and DEEP bits in the STBCR1 register to 1, and then read this register.

When the condition below is met, follow procedure (b).

- Software standby is not being used, the sleep mode is being used, and procedure (a) in section 55.3.1 (1) Transition to Sleep Mode is followed to initiate the transition to sleep mode.

9. Execute the WFI instruction.
10. The conflict between the instruction and the NMI interrupt may prevent transition to deep standby mode. After executing the WFI instruction, locate the branch instruction to return to step 9.

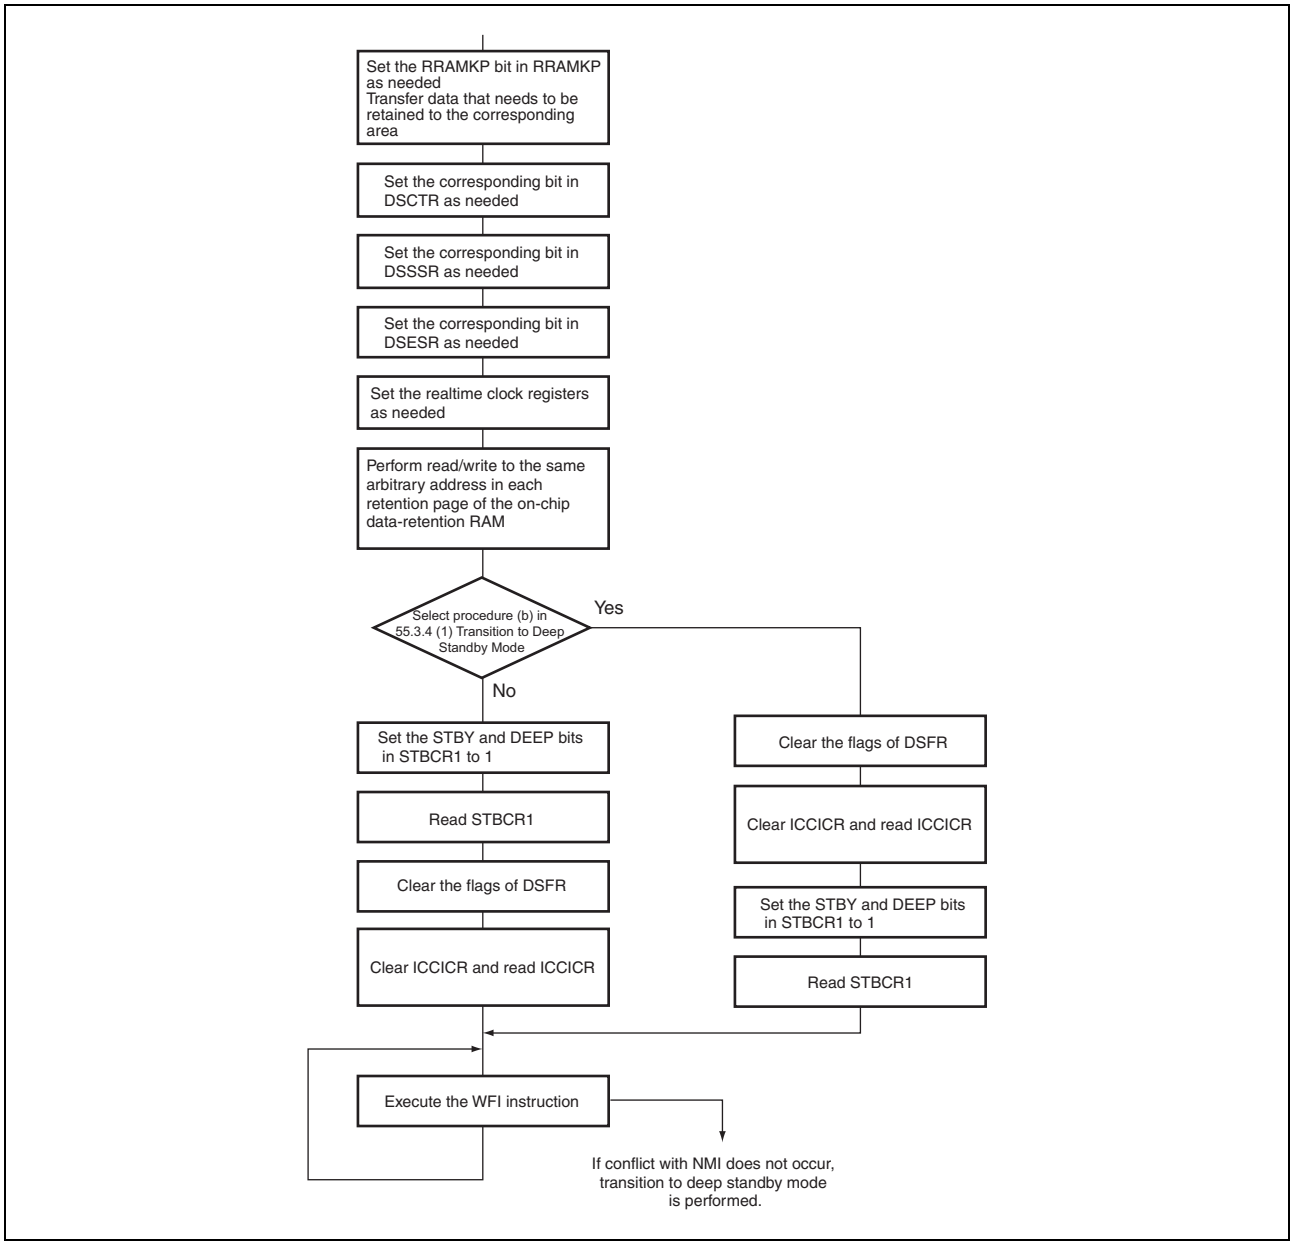

**Figure 55.3 Flowchart of Transition to Deep Standby Mode**

### (2) Canceling Deep Standby Mode

Deep standby mode is canceled by interrupts (NMI or realtime clock alarm interrupt), change on the pins for canceling, or a reset (power-on reset). The realtime clock alarm interrupt can always cancel deep standby mode regardless of the setting of the execution priority register for the interrupt controller and of the alarm interrupt enable flag (RCR1.AIE). This interrupt can also always cancel this mode do regardless of the states of bit 6 (the FIQ mask bit) and bit 7 (the IRQ mask bit) in the CPSR register of the CPU. When canceling the mode by a source other than a reset, a power-on reset exception handling is executed instead of an interrupt exception handling.
Figure 55.4 shows the flowchart of canceling deep standby mode.

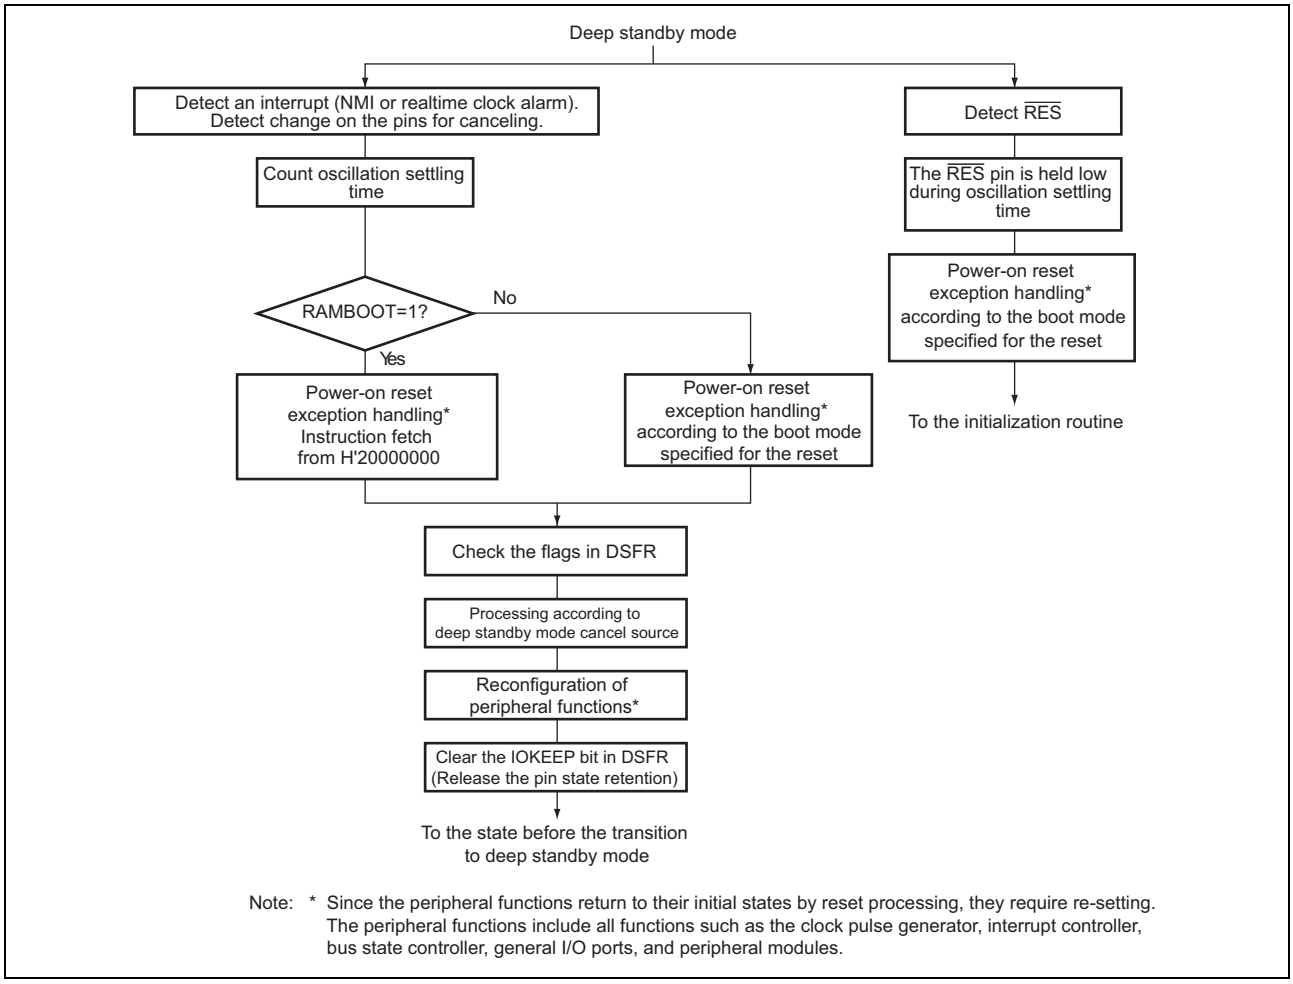

**Figure 55.4 Flowchart of Canceling Deep Standby Mode**

- Canceling by a source other than a reset
  When the falling or rising edge of the NMI pin (selected by a corresponding bit in DSESR) or falling or rising edge of the pins for canceling (selected by a corresponding bit in DSESR) is detected or the realtime clock alarm interrupt (see section 13.4.4, Alarm Function) is generated, clock oscillation is started after the wait time for the oscillation settling time. After the oscillation settling time has elapsed, deep standby mode is cancelled and the power-on reset exception handling is executed.
  The clock output phase of the CKIO pin may be unstable immediately after detecting a cancel source and until deep standby mode is canceled.
  The detecting of the NMI pin, the pins for canceling, and the realtime clock alarm interrupt becomes enable when the corresponding bits in DSSSR are set. The detected cancel sources are kept, but they are reflected to DSFR after canceling the deep standby mode. When the CPU accepts any interrupts and reads the interrupt response register (ICCIAR), all of the cancel sources that are kept are cleared. When the CPU enters the deep standby mode as the

detected cancel sources are kept, the deep standby mode is canceled immediately after the CPU enters the deep standby mode.

- Canceling with a reset
  Driving the $\overline{\text{RES}}$ pin low cancels deep standby mode and causes a transition to the power-on reset state. After this, driving the $\overline{\text{RES}}$ pin high initiates power-on reset exception handling. Output of the internal clock from the CKIO pin also starts by driving the $\overline{\text{RES}}$ pin low.
  Keep the $\overline{\text{RES}}$ pin low until the clock oscillation has settled.

### (3) Operation after Canceling Deep Standby Mode

After canceling deep standby mode, the LSI can be activated through the external memory or from the on-chip data-retention RAM, which can be selected by setting the RAMBOOT bit in DSCTR. By setting the EBUSKEEPE bit, the states of the external memory control pins can be retained even after cancellation of deep standby mode. Table 55.3 shows the pin states after cancellation of deep standby mode according to the setting of each bit. Table 55.4 lists the external memory control pins.

**Table 55.3 Pin States after Cancellation of Deep Standby Mode and System Activation Method by the DSCTR Settings**

|---|---|---|---|
| 0 | 0 | External memory | The states of the external memory control pins are not retained.<br>For other pins, the retention of their states is cancelled when the IOKEEP bit is cleared. |

When deep standby mode is canceled by interrupts (NMI or realtime clock alarm) or changes on the pins for canceling, the deep standby cancel source flag register (DSFR) can be used to confirm which source has canceled the mode.
Pins retain the state immediately before the transition to deep standby mode. However, in system activation through the external memory, the retention of the states of the external memory control pins is cancelled so that programs can be fetched after cancellation of deep standby mode. Other pins, after cancellation of deep standby mode, continue to retain the pin states until writing 0 to the IOKEEP bit in DSFR after reading 1 from the same bit. In system activation from the on-chip data-retention RAM, after cancellation of deep standby mode, both the external memory control pins and other pins continues to retain the pin states until writing 0 to the IOKEEP bit in DSFR after reading 1 from the same bit.
Reconfiguration of peripheral functions is required to return to the previous state of deep standby mode. Peripheral functions include all functions such as the clock pulse generator, interrupt controller, general I/O ports, and peripheral modules. After the reconfiguration, the retention of the pin state can be canceled and the LSI returns to the state prior to the transition to deep standby mode by reading 1 from the IOKEEP bit in DSFR and then writing 0 to it.

### (4) Notes on Transition to Deep Standby Mode

If multiple canceling sources have been specified and multiple canceling sources are input, multiple cancel source flags will be set.

## 55.3.5 Module Standby Function

### (1) Transition to Module Standby Function

Setting an MSTP bit in a standby control register to 1 halts supply of the clock signal to the corresponding on-chip peripheral module. This function can be used to reduce power consumption both while a program is running and in sleep mode. Disable a module before placing it in the module standby state. If interrupt requests are enabled, set the respective register in the target module or in the interrupt controller to disable interrupt requests. If DMA transfer requests are enabled, set the respective register in the target module to disable DMA transfer requests from the module and then set the respective register in the direct memory access controller to stop DMA transfers. In addition, do not attempt to access a module's registers while it is in the module standby state. The procedure for transitions to the module standby state depends on whether the STBREQ register has a bit for the corresponding module.

(a) Procedure for transition to module standby of modules for which the STBREQ register does not have a corresponding bit

1. Set the MSTP bit of the corresponding module to 1.

(b) Procedure for transition to module standby of modules for which the STBREQ register has a corresponding bit

1. Set the corresponding bit in the STBREQ register to 1 to generate a request to stop the module.
2. Confirm that the module is ready to be stopped by the corresponding bit in the STBACK register being set to 1.
3. Set the MSTP bit of the corresponding module to 1.

For states of registers in the module standby function, see section 58.3, Register States.

### (2) Canceling Module Standby Function

Release from the module standby state can be achieved in two ways: starting the module by a power-on reset while the MSTP bit is set to 1, then clearing the MSTP bit to 0, or setting the MSTP bit to 0 to activate the module, setting the MSTP bit to 1 to place the module in the standby state, and then setting the MSTP bit to 0 again. If you use the latter approach, the procedure for release from module standby depends on whether the STBREQ register has a bit for the corresponding module.

- Release from the module standby state after the activation of the module by a power-on reset while the MSTP bit is set to 1

1. Clear the MSTP bit to 0.
2. After that, dummy-read the same register.

- Release from the module standby state after a transition to standby following activation of the module

(a) Procedure for release from module standby of modules for which the STBREQ register does not have a corresponding bit

1. Clear the MSTP bit to 0, then dummy-read the same register.

(b) Procedure for release from module standby of modules for which the STBREQ register has a corresponding bit

1. Clear the MSTP bit to 0, then dummy-read the same register.
2. Clear the corresponding bit in the STBREQ register to 0 to cancel the request to stop the module.
3. Confirm that the corresponding bit in the STBACK register has been cleared to 0, indicating the completion of release from standby.

### 55.3.6 Software Reset

Initialization equivalent to a power-on reset is only applied to the selected modules. The procedure for transitions to the software reset state varies according to whether the STBREQ register has a bit for the corresponding module. Follow the procedures below according to whether this is or is not the case. If DMA transfer requests are enabled, make the settings to stop the DMA transaction for the corresponding channel before transitions to the software reset state. For stopping the DMA transaction, see section 9.7.11, Transfer Status.

(1) Transition to Software Reset State

(a) Procedure for transition to the software reset state of modules for which the STBREQ register does not have a corresponding bit

1. Set the SRST bit of the corresponding module to 1, then dummy-read the same register.

(b) Procedure for transition to the software reset state of modules for which the STBREQ register has a corresponding bit

1. Set the corresponding bit in the STBREQ register to 1 to generate a request to stop the module.
2. Confirm that the corresponding bit in the STBACK register has been set to 1.
3. Set the SRST bit of the corresponding module to 1, then dummy-read the same register.

(2) Canceling Software Reset

(a) Procedure for release from the software reset state of modules for which the STBREQ register does not have a corresponding bit

1. Clear the SRST bit of the corresponding module to 0, then dummy-read the same register.

(b) Procedure for release from the software reset state of modules for which the STBREQ register has a corresponding bit

1. Clear the SRST bit of the corresponding module to 0, then dummy-read the same register.
2. Clear the corresponding bit in the STBREQ register to 0 to cancel the request to stop the module.
3. Confirm that the corresponding bit in the STBACK register has been cleared to 0.

### 55.3.7 Adjustment of XTAL Crystal Oscillator Gain

The gain of the crystal oscillator for XTAL and the realtime clock can be adjusted using the GAIN1 and GAIN0 bits in XTALCTR. To modify the gain of the signal on the EXTAL or XTAL pin, PLL settling time is needed. The settling time is counted using the on-chip watchdog timer. Counting to secure the PLL settling time is not needed when the gain of the signal on the RTC_X3 or RTC_X4 pin is changed.

After a change to the value of the GAIN0 bit, the hardware automatically stops the bus master following the wait for completion of the issuing-finished request from the bus master and the change to the gain for the crystal oscillator in use with XTAL proceeds.

Since the change to the gain for the crystal oscillator in use with XTAL cannot start if completion of the issuing-finished request is not possible at this time, do not proceed with access to the registers of modules in the module-standby state and so on.

Furthermore, as the issuing of unintended requests by the bus master is inhibited, using software to stop all bus masters in preparation for the procedure to change the gain for the crystal oscillator in use with XTAL is also effective.

1. The large gain is selected in the initial state.
2. Set the standby_mode_en bit of the power control register in the PL310 to 1. For the details of this register, see CoreLink Level 2 Cache Controller L2C-310 Technical Reference Manual issued by Arm Ltd.
3. Set the watchdog timer so that the specified settling time should be obtained and stop the watchdog timer. Specifically, the following settings are necessary:
   TME in WTCSR = 0: Stop the watchdog timer.
   CKS[2:0] in WTCSR: Division ratio for watchdog timer count clock
   WTCNT: Initial counter value
   (The watchdog timer starts counting on the set clock.)
4. Set the GAIN0 bit to the desired value.
5. The LSI is internally stopped and the watchdog timer starts counting. The clock is supplied only to the watchdog timer and other internal clocks are stopped. In this state, the CKIO pin continues to output an unstable clock. To avoid malfunction due to the unstable clock, modify the CKOEN2 bit in FRQCR appropriately. Since this state is equivalent to the software standby mode state, some registers of on-chip peripheral modules are initialized. For details, see section 58.3, Register States.
6. When an overflow occurs on the watchdog timer, the specified clock supply is started and the LSI starts operation. The watchdog timer stops after an overflow.

## 55.4 Usage Notes

### 55.4.1 Usage Notes on Setting Registers

When writing to the registers related to power-down modes, note the following.
When writing to the register related to power-down modes, the CPU, after executing a write instruction, executes the next instruction without waiting for the write operation to complete.
Therefore, to reflect the change specified by writing to the register while the next instruction is executed, insert a dummy read of the same register between the register write instruction and the next instruction.

### 55.4.2 Usage Notes when the Realtime Clock is not Used

When the realtime clock is not used, set the MSTP60 bit in STBCR6 to 1 after setting the bits in registers of the realtime clock. For details, see section 55.2.6, Standby Control Register 6 (STBCR6).

- Set the RTCEN bit in the control register 2 (RCR2) to 0
- Set the RCKSEL[1:0] bits in the control register 5 (RCR5) to 00.

### 55.4.3 Usage Notes Applying when the USB_X1 Pin is not to be Used

When a 48 MHz clock is not being supplied to the USB_X1 pin, set registers according to the below procedure in the initial settings after release from the power-on reset state or deep standby mode.

#### (1) When the USB2.0 host/function module is not to be used

1. Set the MSTP71 bit in the STBCR7 register to 0 and dummy-read STBCR7.
2. Set the UCKSEL bit in the SYSCFG0_0 register to 1.
3. Wait for at least 20 cycles of the EXTAL clock.
4. Set the MSTP71 bit in the STBCR7 register to 1 and dummy-read STBCR7.

#### (2) When the USB2.0 host/function module is to be used

Set the MSTP71 bit* in the STBCR7 register to 0 and dummy-read STBCR7.
Set the UCKSEL bit in the SYSCFG0_0 register to 1.
Follow the procedure of example 1 in 29.4.1 (5) Setting the Clock Supply for the USB Module
Make the initial settings of the USB2.0 host/function module.
Note: * When channel 1 of the USB2.0 host/function module is to be used, also set the MSTP70 bit to 0.

### 55.4.4 Notes on Using IRQ Pins as Triggers for Release from Standby when Software Standby is in Use

To use an IRQ pin as the trigger for release from standby when software standby is in use, see section 7.8.4, Notes on Using IRQ Pins as Triggers for Release from Standby when Software Standby is in Use.

# 56. Debugger Interface

This LSI incorporates a debugger interface to support the boundary scan function and connection to the emulator.

## 56.1 Features

The debugger interface is a serial input/output interface which has a JTAG (Joint Test Action Group, IEEE Std.1149.1 and IEEE Standard Test Access Port and Boundary-Scan Architecture) interface and CoreSight debug interface.

This module has TAP controllers for the boundary scan and CoreSight debug function.

Driving the BSCANP pin high selects the boundary-scan TAP controller, and driving the BSCANP pin low selects the CoreSight debug TAP controller.

Figure 56.1 is a block diagram of this module and Table 56.1 shows the JTAG pin mode.

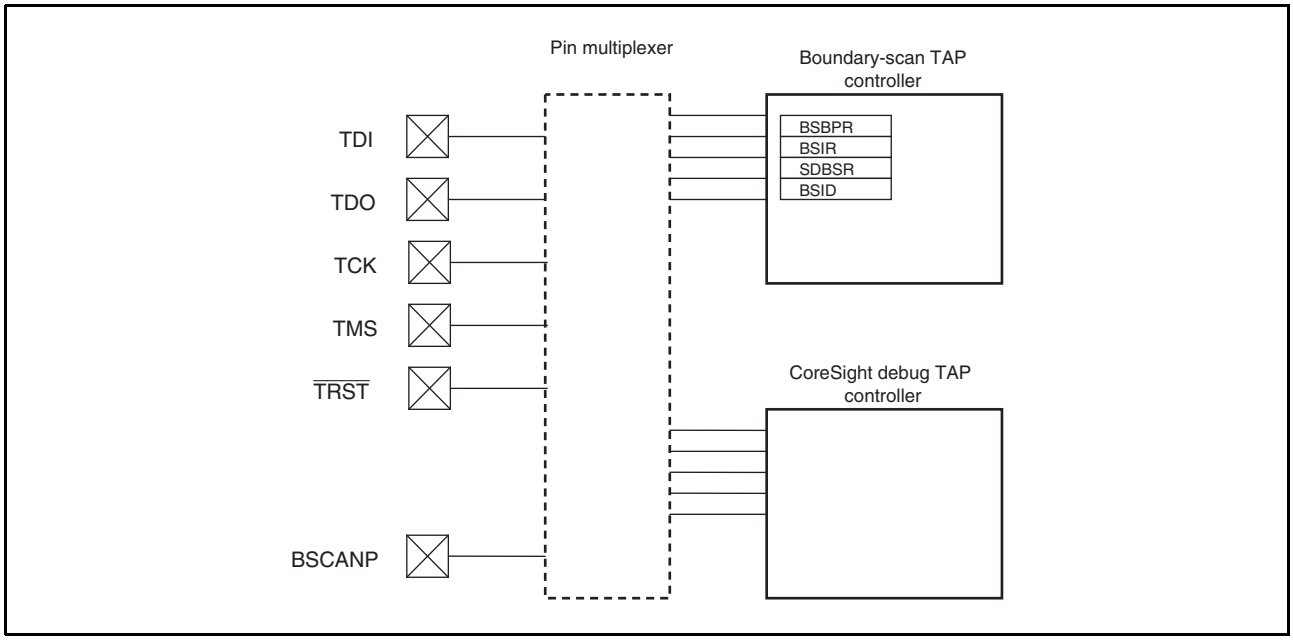

**Figure 56.1 Block Diagram**

**Table 56.1 JTAG Pin Mode**

| BSCANP | JTAG Pin Mode |
|---|---|
| 0 | Normal operation (CoreSight debug mode) |
| 1 | Boundary-scan mode |

The following lists the features of CoreSight.

- JTAG interface
  Supports JTAG and serial wire debug mode (SWD)
- Trace interface
  Outputs 4-bit × 66-Mbps (33-MHz DDR) trace data
  4-Kbyte Embedded Trace FIFO (ETF)
- Controls by ICE registers
  Control of resetting, debug-enable signal supplied to the CPU, and disabling power shut-off in deep-standby mode during debugging (fake debug mode)

Figure 56.2 is a block diagram of CoreSight, Table 56.2 to Table 56.5 show the input/output pins of the cross-trigger interface (CTI), and Table 56.6 shows the address map for CoreSight. For details of CoreSight other than ICE registers, see the technical reference manual issued by Arm Ltd.

## 56.2 Input/Output Pins

Table 56.7 shows the pin configuration of the debugger interface.

**Table 56.7 Pin Configuration**

| Name | Pin Name | Input/ Output | Function |
|---|---|---|---|
| Test clock | TCK/SWDCLK | Input | Data is input in serial to this module via the data input pin (TDI) or data is output via the data output pin (TDO) in synchronization with this signal.<br>Functions as the SWDCLK pin in serial wire debug (SWD) mode. |
| Test mode select | TMS/SWDIO | Input, Input/ Output | Changing this signal in synchronization with the TCK signal determines the state of the TAP controller circuit.<br>Its protocol conforms to the subset of the JTAG standard (IEEE standard 1149.1).<br>Functions as the SWDIO pin in serial wire debug (SWD) mode. |
| Test reset | $\overline{\text{TRST}}$* | Input | This signal is received asynchronously with the TCK signal. Asserting this signal resets this module. When power is supplied, this pin should be asserted for a given period regardless of whether or not this module function is used.<br>For details on resetting, see section 56.5.2, Reset Signal Setting. |
| Test data input | TDI | Input | Data is sent to this module by changing this signal in synchronization with the TCK signal. |
| Test data output | TDO | Output | Data is read from this module by reading this signal in synchronization with the TCK signal.<br>This pin also functions as an output pin in the serial wire debug (SWD) mode. However, a fixed value (the high level) is output because this product does not support the SWO function. |
| Boundary scan setting | BSCANP | Input | Input a high-level signal during boundary-scan testing.<br>Input a low-level signal during normal use. |
| Clock output | TRACECLK | Output | Trace clock output pin |
| Enable output | TRACECTL | Output | Trace enable output pin |
| Data output | TRACEDAT3 to TRACEDATA0 | Output | Trace data output pins |

Note: * When designing a board that can use an emulator, the $\overline{\text{RES}}$ and $\overline{\text{TRST}}$ pin circuits should be designed so that they can be set low and the $\overline{\text{TRST}}$ pin can be controlled independently at power-on. When the $\overline{\text{TRST}}$ pin is not in use, it should be either fixed to low level or connected to the $\overline{\text{RES}}$ pin (or another pin which operates in the same manner as the $\overline{\text{RES}}$ pin).

## 56.3 Registers for Boundary-Scan TAP Controller

The boundary-scan TAP controller has the following registers.

**Table 56.8 List of Registers of Boundary-Scan TAP Controller**

| Register Name | Abbreviation | R/W | Initial Value | Address | Access Size |
|---|---|---|---|---|---|
| Bypass register | BSBPR | — | — | — | — |
| Instruction register | BSIR | — | H'55 | — | — |
| Boundary scan register | SDBSR | — | — | — | — |
| ID register | BSID | — | H'08178447 *1<br>H'0821D447 *2 | — | — |

Note 1. RZ/A1H
Note 2. RZ/A1M

### 56.3.1 Bypass Register (BSBPR)

BSBPR is a 1-bit register that cannot be accessed by the CPU. When BSIR is set to BYPASS mode, BSBPR is connected between the TDI and TDO pins. The initial value is undefined.

### 56.3.2 Instruction Register (BSIR)

BSIR is an 8-bit register. This register is initialized by $\overline{\text{TRST}}$ assertion or in the TAP test-logic-reset state. BSIR cannot be accessed by the CPU.

| Bit | Bit Name | Initial Value | R/W | Description |
|---|---|---|---|---|
| 7 to 0 | TI[7:0] | 01010101 | — | Test Instruction<br>The instruction of this module is transferred to BSIR through a serial input from the TDI pin.<br>For commands, see Table 56.9. |

**Table 56.9 Commands Supported for Boundary Scan TAP Controller**

| Bits 7 to 0 | | | | | | | | Description |
|---|---|---|---|---|---|---|---|---|
| TI7 | TI6 | TI5 | TI4 | TI3 | TI2 | TI1 | TI0 | |
| 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | EXTEST |

| 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | BYPASS |
| Other than above | | | | | | | | Reserved |

### 56.3.3 Boundary Scan Register (SDBSR)

SDBSR is a shift register, located on the PAD, for controlling the input/output pins of this LSI. SDBSR cannot be accessed by the CPU. The initial value is undefined. Using the EXTEST, SAMPLE/PRELOAD, CLAMP, and HIGHZ commands, a boundary scan test conforming to the JTAG standard can be carried out. Table 56.10 shows the correspondence between the pins of this LSI and bits of the boundary scan register.

Note 1. The pin names are as listed in the “Port function/dedicated function” column of Table 1.4, List of Pins in section 1.6, List of Pins.
Note 2. Open-drain pin. Setting the data bit for the pin to 0 makes the pin output a low-level signal and setting the data bit for the pin to 1 places the pin in the hi-Z state.
Note 3. Bits of type “control” are active low. When the control bit is at the low level, the corresponding pin becomes an output.
Note 4. This pin only operates when data are shifted through during a boundary scan test by a boundary scan register that is not related to a specific pin.

### 56.3.4 ID Register (BSID)

BSID is a 32-bit read-only register that cannot be accessed by the CPU. BSID can only be read from the pins when the IDCODE command is set.

## 56.5 Operation

### 56.5.1 TAP Controller

Figure 56.3 shows the internal states of the TAP controller. State transitions basically conform to the JTAG standard.

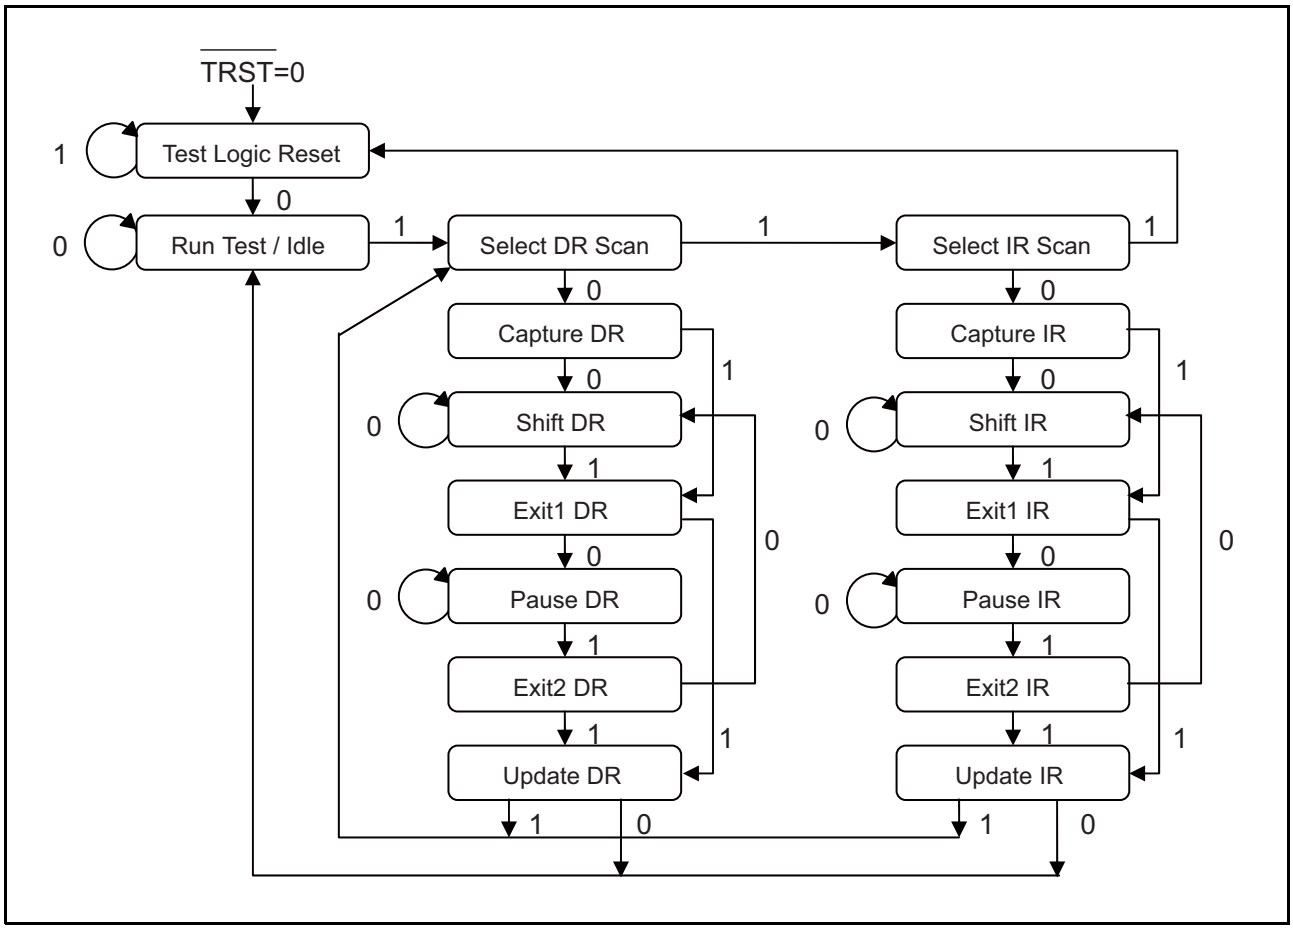

**Figure 56.3 State Transitions of TAP Controller**

Note: State transition occur according to the TMS value at the rising edge of the TCK signal. The TDI value sampled at the rising edge of the TCK signal and shifted at the falling edge of the TCK signal. TDO value is output at the rising edge of the TCK signal. The TDO signal is in a Hi-Z state for TAP controller states other than Shift-DR and Shift-IR. A transition to the Test-Logic-Reset state by clearing $\overline{\text{TRST}}$ to 0 is performed asynchronously with the TCK signal.

### 56.5.2 Reset Signal Setting

**Table 56.12 Reset Signal Setting**

| $\overline{\text{RES}}$ | $\overline{\text{TRST}}$ | Chip State |
|---|---|---|
| L | L | The chip is power-on reset and this module is reset.*1 |
| | H | The chip is power-on reset.*1 |
| H | L | This module is only reset.*2 |
| | H | Normal operation*2 |

Note 1. By asserting the $\overline{\text{RES}}$ and $\overline{\text{TRST}}$ signals, the CPU and CoreSight enter the reset state. Set the debugging function while asserting the $\overline{\text{RES}}$ signal after negating the $\overline{\text{TRST}}$ signal.
Note 2. Do not negate the $\overline{\text{TRST}}$ signal while the $\overline{\text{RES}}$ signal is at the high-level.
Note 3. When the $\overline{\text{TRST}}$ pin is to be negated, make sure that the specification for $\overline{\text{RES}}$ input rise time ($t_{RSr}$) or $\overline{\text{RES}}$ negating hold time ($t_{RSNH}$) in Table 59.6, Control Signal Timing, is satisfied.

## 56.6 Boundary Scan

Commands can be set in BSIR by this module to place this module's pins in boundary scan mode stipulated by JTAG.

### 56.6.1 Supported Instructions

This LSI supports three mandatory instructions stipulated by JTAG standard (BYPASS, SAMPLE/PRELOAD, and EXTEST) and three option instructions (IDCODE, CLAMP, and HIGHZ).

(1) BYPASS

BYPASS is a mandatory instruction that operates the bypass register. This instruction is used to shorten the shift path to speed up serial data transfer involving other LSI on the printed circuit board. This LSI's system circuits are not affected by execution of this instruction.

(2) SAMPLE/PRELOAD

SAMPLE/PRELOAD is used to input data from this LSI’s internal circuit to the boundary scan register, outputs data from the scan path, and loads data onto the scan path. While this instruction is being executed, signals input to this LSI pins are transmitted directly to the internal circuit, and the values of the internal circuit are directly output externally from the output pins. This LSI's system circuits are not affected by execution of this instruction.

In a SAMPLE operation, a snapshot of a value to be transferred from an input pin to the internal circuit, or a value to be transferred from the internal circuit to an output pin, is latched into the boundary scan register and read from the scan path. Snapshot latching is performed in synchronization with the rising edge of the TCK signal in the Capture-DR state. Snapshot latching does not affect normal operation of this LSI.

In a PRELOAD operation, an initial value is set in the parallel output latch of the boundary scan register from the scan path prior to the EXTEST instruction. Without a PRELOAD operation, when the EXTEST instruction was executed, an undefined value would be output from the output pin until completion of the initial scan sequence (transfer to the output latch) (with the EXTEST instruction, the parallel output latch value is constantly output to the output pin).

(3) EXTEST

This instruction is provided to test external circuit when this LSI is mounted on a printed circuit board. When this instruction is executed, output pins are used to output test data (previously set by the SAMPLE/PRELOAD instruction) from the boundary scan register to the printed circuit board, and input pins are used to latch test results into the boundary scan register from the printed circuit board. If testing is carried out by using the EXTEST instruction N times, the Nth test data is scanned-in when test data (N-1) is scanned out. The data loaded into the output pin boundary scan register in the Capture-DR state are not used for external circuit testing (data are replaced by the shift operation).

(4) IDCODE

Commands can be set in BSIR via pins of this module to place the module’s pins in the IDCODE mode stipulated by JTAG. When this module is initialized ($\overline{\text{TRST}}$ is asserted or TAP is in the Test-Logic-Reset state), the IDCODE mode is entered.

(5) CLAMP, HIGHZ

Commands can be set in BSIR via pins of this module to place the module’s pins in the CLAMP or HIGHZ mode stipulated by JTAG.

### 56.6.2 Points for Attention

1. Boundary scan mode does not cover clock-related signals (EXTAL, XTAL, CKIO, AUDIO_X1, AUDIO_X2, USB_X1, USB_X2, RTC_X1, and RTC_X2).
2. Boundary scan mode does not cover reset-related signal ($\overline{\text{RES}}$).
3. Boundary scan mode does not cover this module's signals (TCK, TDI, TDO, TMS, $\overline{\text{TRST}}$, and BSCANP).
4. Boundary scan mode does not cover USB-related signals (DP0, DP1, DM0, DM1, VBUS0, VBUS1, and REFRIN).
5. Boundary scan mode does not cover P0_3.
6. Boundary scan mode does not cover the digital video decoder related signals (VIN1A, VIN2A, VIN1B, VIN2B, VIDEO_X1, VIDEO_X2, VRP, VRM, and REXT).
7. Boundary scan mode does not cover AVref (reference voltage pin for the A/D converter).

## 56.7 Usage Notes

1. Once a command of this module is set, it will not be modified unless another command is reissued. If the same command is given continuously, the command must be set after a command (BYPASS, etc.) that does not affect LSI operations is once set.
2. Regardless of whether or not this module is to be used, it should be initialized by asserting the $\overline{\text{TRST}}$ signal when power is supplied and on release from deep standby mode (excluding fake debug mode) through assertion of the $\overline{\text{RES}}$ signal.
3. Be sure to wait for at least 200 ns after negating the $\overline{\text{TRST}}$ signal before starting TAP controller operation.
4. Be sure to fix the TMS pin to the high level until 200 ns have elapsed after negation of the $\overline{\text{TRST}}$ signal.

# 57. EthernetAVB

## 57.1 Overview

The EthernetAVB incorporates an Ethernet controller (E-MAC) that conforms to the definition of the MAC (Media Access Control) layer for Ethernet in the IEEE 802.3 standard.

When connected with a physical-layer LSI chip (PHY-LSI) that complies with the standard, the E-MAC is able to transmit and receive Ethernet (IEEE 802.3) frames. The E-MAC has a single MAC layer interface.

The EthernetAVB has a dedicated direct memory access controller (AVB-DMAC) for transferring transmitted Ethernet frames to and received Ethernet frames from respective storage areas in the on-chip RAM at high speed.

The AVB-DMAC is compliant with the following three standards formulated for IEEE 802.1BA: the IEEE 802.1AS timing and synchronization protocol, the IEEE 802.1Qav real-time transfer, and the IEEE 802.1Qat stream reservation protocol.

For the on-chip RAM, see section 53, On-Chip RAM.

### 57.1.1 Specifications (Functions)

Table 57.1 lists the specifications of the EthernetAVB module.

**Table 57.1 Specifications (Functions)**

#### FCE (Flow Control Enable) Bit

This bit enables flow control by the E-MAC.

Writing to this bit is only possible when the current operating mode is configuration mode.

### LBME (Loopback Mode Enable) Bit

This bit enables loopback mode.

In loopback mode, the transmission lines are internally connected to the reception lines. When loopback mode is to be used, the Ethernet transmission clock must be supplied to the MII interface. A received clock signal is not required. Writing to this bit is only possible when the current operating mode is configuration mode.

CAUTION

Data for transmission are still output normally. To eliminate effects on external modules, pin control should be applied to block the output of data. For pin control, see Section 54, Ports.

### BOC (First Byte Specification) Bit

Specifies the allocation of the first byte from a received Ethernet frame to the on-chip RAM.

This configuration setting does not affect the format and filter parameters of the descriptor in the on-chip RAM.

Writing to this bit is only possible when the current operating mode is configuration mode.

Figure 57.2 to Figure 57.4 show how data from frames received via the Ethernet connection are stored in the on-chip RAM.

#### CSEL[1:0] (gPTP Clock Select) Bits

These bits select the clock source for the gPTP timer.

Writing to these bits is only possible when the current operating mode is configuration mode.

#### DTSR (Data Transfer Suspend Request) Bit

This bit can suspend access to the on-chip RAM.

The access is suspended on completion of the transfer of the frame currently being transferred.

This function disables access to the on-chip RAM without affecting normal operation of the AVB-DMAC. Use this bit when exclusive control over the contents of the on-chip RAM is necessary, for example, in checking its integrity.

Note that the transmission and reception queues are not processed while access is suspended.

Change neither the AVB-DMAC settings nor the mode from when this bit is set to 1 to complete suspension until when the data transfer suspend status bit (CSR.DTS) is set to 1.

#### OPC[1:0] (Operating Mode Configuration) Bits

These bits specify the operating mode.

For the operating modes, see Section 57.3.1.1, Operating Modes.

Writing to this bit is possible in any of the operating modes, but should not be done after the standby request has been issued to the EthernetAVB. For issuance of the standby request to the EthernetAVB, see section 55, Power-Down Modes.

## 57.2.2 Descriptor Base Address Table Register (DBAT)

The DBAT register is used to set the base address of the descriptor table.

CAUTION

The setting of this bit must be a multiple of four (i.e. b0 and b1 must be set to 0).

**TAL3[1:0] (Table Address) Bits**

These bits specify the base address of the descriptor table in the on-chip RAM.

For the structure of this table, see Section 57.3.3, Descriptors.

Writing to this bit is only possible when the current operating mode is configuration mode.

### 57.2.3 Descriptor Base Address Load Request Register (DLR)

The DLR register is used to issue a request to load the values from the current descriptor address register q (CDARq) for each queue to the descriptor base address table register (DBAT).

**LBAq (Base Address Load Request) Bits**

Each bit is used to issue requests to load base addresses and to indicate that a base address is currently being loaded.

Setting a bit to 1 issues a request for loading the descriptor base address for the queue q (q = 0 to 21), to change the current descriptor address bit (CDARq.CDA) to DBAT.TA + 8*q.

If transfer is currently in progress, loading is executed on completion of transfer for the current frame.

Completion of loading leads to automatic setting of the corresponding bit to 0.

For the transmission queues, base address load requests are executed even while fetching is in progress (the transmit start request bit in the transmit configuration control register (TCCR.TSRQt) is 1). Therefore, be sure to check that fetching is not in progress before issuing a request.

Writing to a bit of this register is only possible when the current operating mode is configuration mode.

Only 1 can be written to this bit.

### 57.2.4 AVB-DMAC Status Register (CSR)

The CSR register is used to indicate the operating mode in which the AVB-DMAC is running and the individual communications states.

| Bit | b31 | b30 | b29 | b28 | b27 | b26 | b25 | b24 | b23 | b22 | b21 | b20 | b19 | b18 | b17 | b16 |

#### RPO (Receive Process Status) Bit

This bit indicates whether a reception queue contains an unread received frame.

This bit being set to 1 indicates that a received frame is yet to be stored in the on-chip RAM.

- [Clearing conditions]
  The current operating mode is not operation mode.
  Received frames in the reception FIFO all being stored in the on-chip RAM.
- [Setting condition]
  A received frame being stored in the reception FIFO (but not yet in the on-chip RAM)

#### TPO3 (Transmit Process Status 3) Bit

This bit indicates whether a class A stream is being transmitted.

This bit being set to 1 indicates that the AVB-DMAC is fetching data for transmission from the on-chip RAM, or the E-MAC is transmitting data.

- [Clearing conditions]
  The current operating mode is not operation mode.
  Completion of transfer of all frames for transmission from the transmission FIFO (the transmit start request bit in the transmit configuration control register (TCCR.TSRQ3) is 0)
- [Setting condition]
  Transmission being started (by writing 1 to the transmit start request bit in the transmit configuration control register (TCCR.TSRQ3))

#### TPO2 (Transmit Process Status 2) Bit

This bit indicates whether a class B stream is being transmitted.

This bit being set to 1 indicates that the AVB-DMAC is fetching data for transmission from the on-chip RAM, or the E-MAC is transmitting data.

- [Clearing conditions]
  The current operating mode is not operation mode.
  Completion of transfer of all frames for transmission from the transmission FIFO (the transmit start request bit in the transmit configuration control register (TCCR.TSRQ2) is 0)
- [Setting condition]
  Transmission being started (by writing 1 to the transmit start request bit in the transmit configuration control register (TCCR.TSRQ2))

#### TPO1 (Transmit Process Status 1) Bit

This bit indicates whether a network control is being transmitted.

This bit being set to 1 indicates that the AVB-DMAC is fetching data for transmission from the on-chip RAM, or the E-MAC is transmitting data.

- [Clearing conditions]
  The current operating mode is not operation mode.
  Completion of transfer of all frames for transmission from the transmission FIFO (the transmit start request bit in the transmit configuration control register (TCCR.TSRQ1) is 0)
- [Setting condition]
  Transmission being started (by writing 1 to the transmit start request bit in the transmit configuration control register (TCCR.TSRQ1))

#### TPO0 (Transmit Process Status 0) Bit

This bit indicates whether a best effort is being transmitted.

This bit being set to 1 indicates that the AVB-DMAC is fetching data for transmission from the on-chip RAM, or the E-MAC is transmitting data.

- [Clearing conditions]
  The current operating mode is not operation mode.
  Completion of transfer of all frames for transmission from the transmission FIFO (the transmit start request bit in the transmit configuration control register (TCCR.TSRQ0) is 0)
- [Setting condition]
  Transmission being started (by writing 1 to the transmit start request bit in the transmit configuration control register (TCCR.TSRQ0))

#### DTS (Data Transfer Suspend Status) Bit

This bit indicates whether access to the on-chip RAM is enabled.

- [Clearing condition]
  The current operating mode is not operation mode.
  The data transfer suspend request bit in the AVB-DMAC mode register (CCC.DTSR) being 0.
- [Setting condition]
  Access to the on-chip RAM not proceeding while the data transfer suspend request bit (CCC.DTSR) in the AVB-DMAC mode register (CCC) is 1 (if the on-chip RAM is being accessed, this bit is set to 1 on completion of access).

#### OPS[3:0] (Operating Mode Status) Bits

These bits indicate the current operating mode.

For the operating modes, see Section 57.3.1.1, Operating Modes.

## 57.2.5 Current Descriptor Address Register q (CDARq) (q = 0 to 21)

The CDARq register indicates the current descriptor address.

**Table 57.9 CDARq (q = 0 to 21) register contents**

| Bit Position | Bit Name | Function |
|---|---|---|
| b31 to b0 | CDA[31:0] | Current Descriptor Address<br>The address of the current descriptors for the transmission queues |

### CDA[31:0] (Current Descriptor Address) Bits

CDAR0 to CDAR3 indicate the addresses of the current descriptors for the corresponding transmission queues while CDAR4 to CDAR21 indicate the addresses of the current descriptors for the corresponding reception queues.

If the operating mode is changed to operation mode, the contents of the register for the queue to be used are set in the descriptor base address table register (DBAT).

Also, when the descriptor base address load request register (DLR) issues a load request, the contents of the corresponding register are set in the descriptor base address table register (DBAT).

### Conditions for updating:

These bits are set to 0 when the operating mode is not operation mode.

This register is updated in response to processing of the descriptor for a queue.

## 57.2.6 Error Status Register (ESR)

The ESR register indicates the error status in the AVB-DMAC.

| b7 to b5 | — | Reserved<br>These bits are read as 0. The write value should be 0. |
| b4 to b0 | EQN[4:0] | Error Queue Number<br>Error queue number. |

### EIL (Error Information Lost) Bit

This bit indicates that error information has been lost because a new error was detected when the previous error remained unprocessed.

### Conditions for updating:

This bit is set to 0 when the operating mode is not operation mode.
This bit is also set to 0 when 0 is written to the queue error interrupt status bit in the error interrupt status register (EIS.QEF).

This bit is set to 1 when the condition for setting the queue error interrupt status bit in the error interrupt status register (EIS.QEF) to 1 is satisfied when the queue error interrupt status bit in the error interrupt status register (EIS.QEF) is 1.

### ET[3:0] (Error Type) Bits

These bits indicate the detail of the error detected.
When the detected error is related to descriptor reading (ESR.ET = B'0000 or B'0010), the current descriptor address bits in the current descriptor address register q (CDARq.CDA) are not updated thus the same descriptor is processed again. To handle this, correct the descriptor.

When the detected error is related to descriptor writing (ESR.ET = B'0001), the current descriptor address bits in the current descriptor address register q (CDARq.CDA) and the transmit start request bit in the transmit configuration control register (TCCR.TSRQt) are updated as in the normal case thus the descriptor chain processing is not affected.
The other errors are temporary and might be eliminated by transfer continuation. For details, refer to Section 57.3.2.3, Checking Integrity.

This bit should be referred to only when the queue error interrupt status bit in the error interrupt status register (EIS.QEF) is 1.

**Conditions for updating:**

These bits are updated when the condition for setting the queue error interrupt status bit in the error interrupt status register (EIS.QEF) to 1 is satisfied when the queue error interrupt status bit in the error interrupt status register (EIS.QEF) is 0.

**EQN (Error Queue Number) Bits**

These bits indicate the queue number in which the error has been detected.
When ESR.EQN is 0 to 3, it means that the related queue is a transmission queue and the EQN value is the transmission queue number. When ESR.EQN is 4 or larger, it means that the related queue is a reception queue and the "ESR.EQN – 4" is the reception queue number r.
Refer to these bits only when the queue error interrupt status bit in the error interrupt status register (EIS.QEF) is 1.

**Conditions for updating:**

These bits are updated when the condition for setting the queue error interrupt status bit in the error interrupt status register (EIS.QEF) to 1 is satisfied when the EIS.QEF bit is 0.

## 57.2.7 Receive Configuration Register (RCR)

The RCR register is used to make settings related to reception for the AVB-DMAC.

#### RFCL[12:0] (Receive FIFO Caution Level) Bits

These bits set the caution level for the reception FIFO and are used to maintain the priority order of the storage of received data and the fetching of data for transmission.

If the reception FIFO contains less data than this level, processing of both transmission and reception queues becomes pending.

If the reception FIFO contains more data than this level, only data in the reception queue are transferred, and processing of the transmission queue becomes pending.

Writing to this bit is only possible when the current operating mode is configuration mode.

CAUTION

- In the case of this LSI chip, set these bits to H'1800.

#### ETS2 (Time Stamp Enable (Stream)) Bit

Enables the inclusion of time-stamp information in reception queues 2 to 17.

The descriptor structure differs depending on whether time-stamp information is included or not. The reception queue in which time-stamp information is enabled uses the extended descriptor.

Writing to this bit is only possible when the current operating mode is configuration mode.

#### ETS0 (Time Stamp Enable (Best Effort)) Bit

Enables the inclusion of time-stamp information in reception queue 0.

The descriptor structure differs depending on whether time-stamp information is included or not. The reception queue 0 in which time-stamp information is enabled uses the extended descriptor.

Writing to this bit is only possible when the current operating mode is configuration mode.

#### ESF[1:0] (Stream Filtering Select) Bits

These bits select separation filtering for reception queues 2 to 17.

The queue-dependent separation filter can be used in combination with the identification of AVB stream frames.

When the value is B'00, filtering is disabled and frames from streams are processed in reception queue 0 (best effort).

When the value is B'01, the separation filter is enabled for both AVB stream frames and non-AVB stream frames; frames from non-matching streams are processed in reception queue 0 (best effort).

When the value is B'10, the separation filter is enabled for AVB stream frames; frames from non-matching streams are discarded.

When the value is B'11, the separation filter is enabled for AVB stream frames; frames from non-matching streams are processed in reception queue 0 (best effort).

For separation filtering, see 57.3.4.1 (1) Separation Filtering.

Writing to this bit is only possible when the current operating mode is configuration mode.

#### ENCF (Enable Network Control Filtering) Bit

Enables the AVB network control frame for reception queue 1.

When reception queue 1 is disabled, a received frame is stored in reception queue 0 (best effort).

Writing to this bit is only possible when the current operating mode is configuration mode.

#### EFFS (Enable Error Frame) Bit

Enables or disables the reception of frames that have been classified as error frames by the E-MAC.

Received error frames are stored in reception queue 0 (best effort).

An indicator of error detection by the E-MAC during reception is stored in the descriptor (DESCR.MS).

Writing to this bit is only possible when the current operating mode is configuration mode.

## 57.2.8 Receive Queue Configuration Register i (RQCi) (i = 0 to 4)

The RQC0 register is used to set up reception queues 0 to 3.

The RQC1 register is used to set up reception queues 4 to 7.

The RQC2 register is used to set up reception queues 8 to 11.

The RQC3 register is used to set up reception queues 12 to 15.

The RQC4 register is used to set up reception queues 16 to 17.

### UFCCr[1:0] (r = 0 to 17) Unread Frame Counter Configuration Bits

These bits set the unread frame counter for reception queue r.

With the AVB-DMAC, four patterns of settings are available for the unread frame counter. Use the unread frame counter stop level configuration register (UFCS) to set the stop level of the unread frame counter.

When these bits are set to B’00, the stop function is disabled.

Writing to the bits is only possible when the current operating mode is configuration mode.

### RSMr[1:0] (r = 0 to 17) Receive Synchronous Mode Bits

These bits set receive synchronous mode.

Set B’00 in this bit.

Writing to the bits is only possible when the current operating mode is configuration mode.

## 57.2.9 Receive Padding Configuration Register (RPC)

The RPC register is used to set padding for received frames.

| b10 to b8 | PCNT[2:0] | Stored Padding Counter<br>These bits indicate the amount of padding to be stored in data areas for descriptors. The setting is in words.<br>I.e. 1 in the counter indicates 1 word (4 bytes). |
| b7 to b0 | — | Reserved<br>These bits are read as 0. The write value should be 0. |

CAUTION

Padding can be used to extend frame lengths, but frame lengths should not exceed 4 Kbytes.

### DCNT[7:0] Stored Data Counter Bits

These bits specify the amount of the frame data (1 to 255) to be stored following the padding. Counting by one indicates one word (4 bytes). For example, when these bits are set to 47, the amount of data is 47 words (= 188 bytes).

When these bits are 0, all received data have been stored following the initial padding.

Writing to the bits is only possible when the current operating mode is configuration mode.

For details on padding, see section 57.3.4.3 (c) Padding.

**PCNT[2:0] Stored Padding Counter Bits**

These bits specify the amount of padding to be appended to the on-chip RAM. Counting by one indicates one word (4 bytes). For example, when these bits are set to 1, the amount of padding is one word (= 4 bytes).

Writing to the bits is only possible when the current operating mode is configuration mode.

For details on padding, see section 57.3.4.3 (c) Padding.

## 57.2.10 Unread Frame Counter Stop Level Configuration Register (UFCS)

The UFCS register sets the stop levels for unread frames.

### SL0 to SL3[5:0] Stop Level 0 to 3 Bits

These bits set the stop levels for unread frames.

One of the four stop levels from 0 to 3 can be set for each reception queue. When these bits are set to 0, the stop function is disabled. The level to be used is specified by the receive queue configuration register i (RQCi) (i = 0 to 4).

Writing to the bits is only possible when the current operating mode is configuration mode.

## 57.2.11 Unread Frame Counter Register i (UFCVi) (i = 0 to 4)

The UFCV0 register indicates the number of unread frames in reception queues 0 to 3.

The UFCV1 register indicates the number of unread frames in reception queues 4 to 7.

The UFCV2 register indicates the number of unread frames in reception queues 8 to 11.

The UFCV3 register indicates the number of unread frames in reception queues 12 to 15.

The UFCV4 register indicates the number of unread frames in reception queues 16 and 17.

### CVr[5:0] Unread Frame Count r (r = 0 to 17) Bits

These bits indicate the number of unread frames in reception queue r.

The number of unread frames is decremented by the value that is written to the unread frame counter decrement register i (UFCDi).

For a description of how to use unread frames, refer to Section 57.3.4.4, Unread Frame Counters.

**Conditions for updating:**

The bits are set to 0 when the operating mode is not operation mode and when the descriptor base address load request register (DLR) issues a base address load request.

The value of these bits is incremented when a frame is stored in reception queue r normally and a write transaction to the corresponding descriptor is issued. (The maximum setting is H’3F. If the value exceeds H’3F, incrementation will not proceed.) Note that the value is incremented without waiting for response to the write transaction. Therefore confirm that the descriptor type (DESCR.DT) of the corresponding descriptor has been updated before processing the received data.

The value is decremented by the value written to the unread frame counter decrement register i

(UFCDi). Confirm that the descriptor types (DESCR.DT) of all the target descriptors for decrementing have been updated before decrementing.

## 57.2.12 Unread Frame Counter Decrement Register i (UFCDi) (i = 0 to 4)

The UFCD0 register is used to decrement unread counters in reception queues 0 to 3.

The UFCD1 register is used to decrement unread counters in reception queues 4 to 7.

The UFCD2 register is used to decrement unread counters in reception queues 8 to 11.

The UFCD3 register is used to decrement unread counters in reception queues 12 to 15.

The UFCD4 register is used to decrement unread counters in reception queues 16 and 17.

### DVr[5:0] Unread Frame Decrement Value r (r = 0 to 17) Bits

These bits set the decrement value for unread frames in reception queue r. The value of an unread frame counter register i (UFCVi) (i = 0 to 4) is decremented by the value set in the corresponding bits of this register.

Write H’3F to these bits to reset the unread counters in reception queue r.

These bits are always read as 0.

## 57.2.13 Separation Filter Offset Register (SFO)

The SFO register sets an offset into frames for use by the separation filter.

| b5 to b0 | FBP[5:0] | First Byte Position<br>Position in Ethernet frames of the first byte of the bytes to be used by the separation filter |

### FBP[5:0] First Byte Position Bits

These bits set the position in Ethernet frames of the first byte of the bytes to be used by the separation filter.

When these bits are 0, the separation filter starts from the start of each Ethernet frame (first byte of the destination address). For bytes in Ethernet frames, see Figure 57.2 Data for Reception in an Ethernet Frame, in Section 57.2.1, AVB-DMAC Mode Register (CCC).

Writing to the bits is only possible when the current operating mode is configuration mode.

For separation filtering, see section 57.3.4.1 (1) Separation Filtering.

CAUTION

Received frames having fewer bytes than the setting of these bits + 8 bytes are judged to be non-matching by the separation filter. In this case, the data will either be sorted into a reception queue or discarded in accord with the setting of the separation filtering select bits in the receive configuration register (RCR.ESF).

## 57.2.14 Separation Filter Pattern Register i (SFPi) (i = 0 to 31)

Pairs of SFPi registers set the pattern for the separation filters to be used by the corresponding reception queues 2 to 17.

### FPs[63:0](s = i/2) Separation Filter Pattern Bits

These bits set the pattern for a separation filter to be used with reception queues 2 to 17 (for streams 0 to 15).

Each queue has a 64-bit setting; reception queue 2 (for stream 0) uses SFP0 and SFP1, reception queue 17 (for stream 15) uses SFP30 and SFP31, and so on.

SFPi.FPs[7:0] (where i is an even number) are used for the byte of Ethernet frame data specified by the separation filter offset register, while SFPi.FPs[63:56] (where i is the corresponding odd number) are used for the byte at the address specified by the separation filter offset register (SFO) + 7.

Data from received frames passes the separation filter when the following formula is satisfied.

(Data from received frames & SFMi.CFM) == SFPi.FPs

Eight bytes from the position specified by the start byte position bits (SFO.FBP) of data in the received frames are used by the separation filter.

Writing to the bits is only possible when the current operating mode is configuration mode.

For separation filtering, see section 57.3.4.1 (1) Separation Filtering.

## 57.2.15 Separation Filter Mask Register i (SFMi) (i = 0 or 1)

A pair of SFMi registers sets the mask value for the separation filter used by the corresponding reception queue 2 to 17.

### CFM[63:0] Separation Filter Mask Bits

These bits set the mask value for the separation filter for use with the corresponding reception queue 2 to 17 (stream 0 to 15).

SFM0.CFM[7:0] are used for bytes of Ethernet frame data specified by the separation filter offset register, while SFM1.CFM[63:56] are used for the separation filter offset register (SFO) + 7.

Writing to the bits is only possible when the current operating mode is configuration mode.

For separation filtering, see section 57.3.4.1 (1) Separation Filtering.

## 57.2.16 Transmit Configuration Register (TGC)

The TGC register is used to make settings related to transmission for the AVB-DMAC.

### TBD0 to TBD3[1:0] Transmit FIFO Size (Stream Class A/ Stream Class B/Network Control/Best Effort) Bits

These bits set the sizes of the transmission FIFO buffers for use with each of the transmission queues.

Writing to these bits is only possible when the current operating mode is configuration mode.

Set these bits to 2.

### TQP[1:0] Transmit Queue Priority Bits

These bits set the priority of the transmission queues.

B’00: Non-AVB mode: Q3→Q2→Q1→Q0

B’01: AVB mode 1: Q3 (CBS)→Q2 (CBS)→Q1→Q0

B’10: Setting prohibited

B’11: AVB mode 2: Q1→Q3 (CBS)→Q2 (CBS)→Q0

For the credit-based shaping (CBS) algorithm, see Section 57.3.6, CBS (Credit-Based Shaping).

The CBS algorithm is not applied in non-AVB mode (i.e. when the value is B’00).

Writing to the bits is only possible when the current operating mode is configuration mode.

### TSM0 to TSM3 Transmit Synchronous Bits

Set these bits to 0.

## 57.2.17 Transmit Configuration Control Register (TCCR)

The TCCR register controls transmission by the AVB-DMAC and is used to make related settings.

### TFR Time Stamp FIFO Release Bit

This bit releases the oldest entry in the time-stamp FIFO.

When 1 is written to this bit, the TFAi register is updated by the oldest entry in the time-stamp FIFO.

For a description of how to use the time-stamp FIFO, see Section 57.3.5.4, Time Stamping in Transmission.

This bit is always read as 0.

When the time stamp FIFO count bits (TSR.TFFL) are set to B’000, 1 should not be written to this bit.

#### TFEN Time Stamp FIFO Enable Bit

This bit enables storage in the time-stamp FIFO.

When it is set, time-stamp information is stored for descriptors with DESCR.TSR set to 1 (for DESCR.TSR, see section 57.3.5.2 (2) Configuration of Transmission Frame Data Descriptors.

When 0 is set in this bit, no entries are made in the time-stamp FIFO.

For a description of how to use the time-stamp FIFO, see Section 57.3.5.4, Time Stamping in Transmission.

#### TSRQt Transmit Start Request (Queue t) (t = 0 to 3) Bit

This bit issues a request to start transmission for transmission queue t.

When read, this bit being set to 1 indicates that transmission queue t has a frame that has not yet been fetched to the transmission FIFO.

Frame transmission by the E-MAC is processed independently from fetching to the transmission FIFO. The timing of transmission from a queue depends on the priority order of transmission.

For the scheduling of transmission queues, see Section 57.3.5.1, Transmission Modes.

Writing to this bit is only possible when the current operating mode is configuration mode.

Only 1 can be written to the bit. Writing 0 to the bit has no effect.

#### Conditions for updating:

The bit is set to 0 when the operating mode is not operation mode, when a descriptor of type EEMPTY, FEMPTY, or LEMPTY (no usable data) is processed, when an EOS descriptor is processed, and when a descriptor with defective data is processed.

## 57.2.18 Transmit Status Register (TSR)

The TSR register indicates the state of transmission by the AVB-DMAC.

### TFFL[3:0] Time Stamp FIFO Count Bits

These bits indicate the number of time stamps in the time-stamp FIFO.

The values 0 and 2 indicate that the time-stamp FIFO is empty and full, respectively (values 3 to 7 are reserved).

Conditions for updating:

The bits are set to 0 when the operating mode is not operation mode and when the time stamp FIFO enable bit in the transmit configuration control register (TCCR.TFEN) = 0.

When the time stamp FIFO enable bit (TCCR.TFEN) is 1 and these bits are not 2, the value of these bits is incremented after a frame with DESCR.TSR set has been transmitted by the E-MAC (for DESCR.TSR, see Section 57.3.5.2 (2) Configuration of Transmission Frame Data Descriptors.

The value of these bits is decremented if it is not 0 when 1 is written to the time stamp FIFO release bit in the transmit configuration control register (TCCR.TFR).

#### CCS0 and CCS1[1:0] CBS Counter Status 0 and 1 Bits

These bits indicate the CBS (credit-based shaping) state of stream data transmission queues 0 and 1. If the calculated credit value is outside the range specified by CBS upper limit register c (CULc) and CBS lower limit register c (CLLc), it falls outside the range for CBS.

Conditions for updating:

The bits are set to B’00 when the operating mode is not operation mode.

The bits are set to B’00 when the credit value calculated by the CBS is within the range specified by the CBS upper limit register c (CULc) (c = 0, 1) and the CBS lower limit register c (CLLc) (c = 0, 1).

The bits are set to B’01 if the credit value calculated by the CBS is lower than the value in CBS lower limit register c (CLLc).

The bits are set to B’10 if the credit value calculated by the CBS is higher than the value in CBS upper limit register c (CULc).

## 57.2.19 Time Stamp FIFO Access Register 0 (TFA0)

TFA0 indicates the time stamp value.

### TSV[79:0] Time Stamp Value Bits

These 80 bits consist of TFA0.TSV[31:0], TFA1.TSV[63:32], and TFA2.TSV[79:64], which together indicate the oldest time stamp value stored in the time-stamp FIFO.

Once the time-stamp FIFO is full, no further time-stamp values are stored.

Conditions for updating:

The bits are set to H'0000 0000 when the operating mode is not operation mode.

The register is updated whenever a value is stored in the time-stamp FIFO (when the time-stamp FIFO count bit in the transmit status register (TSR.TFFL) changes from 0 to 1).

The register is updated when the oldest entry is released (when the time stamp FIFO release bit in the transmit configuration control register (TCCR.TFR) is set to 1).

## 57.2.20 Time Stamp FIFO Access Register 1 (TFA1)

The TFA1 register indicates the time-stamp value.

For details, see Section 57.2.19, Time Stamp FIFO Access Register 0 (TFA0).

## 57.2.21 Time Stamp FIFO Access Register 2 (TFA2)

The TFA2 register indicates the time-stamp tag and part of the time-stamp value.

### TST[9:0] Time Stamp Tag Bits

These bits indicate the contents of the DESCR.TAG bit within the descriptor for frame transmission. These values are used to check the correlation between frames within the transmission queue and the time-stamp values (accessible through time stamp FIFO access register i (TFAi.TSV, i = 0 to 2)) which can be placed in the FIFO.

For the tagging of frames in transmission, see Section 57.3.5.4, Time Stamping in Transmission.

When the time stamp FIFO count bits (TSR.TFFL) are 0, do not refer to these bits.

Conditions for updating:

The bits are set to H'000 when the operating mode is not operation mode.

Updated when a value is stored in the time-stamp FIFO (when the value of the time stamp FIFO count bit in the transmit status register (TSR.TFFL) changes from 0 to 1).

Updated when the oldest entry has been released (1 is set in the time stamp FIFO release bit in the transmit configuration control register (TCCR.TFR)).

### TSV[73:64] Time Stamp Value Bits

For details, see Section 57.2.19, Time Stamp FIFO Access Register 0 (TFA0).

## 57.2.22 CBS Increment Value Register c (CIVRc) (c = 0 or 1)

The CIVR0 register sets the increment in the CBS algorithm for transmission queue 2 (for stream class B).

The CIVR1 register sets the increment in the CBS algorithm for transmission queue 3 (for stream class A).

### CIV[31:0] CBS Increment Value Bits

These bits set the increment for the CBS algorithm.

Set a value in the range from 1 to 65535 (H'0000 0001 to H'0000 FFFF).

The value to be written to these bits depends on the Ethernet bit rate and Bϕ (internal bus clock). For details, see Section 57.3.6, CBS (Credit-Based Shaping).

## 57.2.23 CBS Decrement Value Register c (CDVRc) (c = 0 or 1)

The CDVR0 register sets the decrement in the CBS algorithm for transmission queue 2 (for stream class B).

The CDVR1 register sets the decrement in the CBS algorithm for transmission queue 3 (for stream class A).

### CDV[31:0] CBS Decrement Value Bits

These bits set the decrement for the CBS algorithm.

Set a negative value from -1 to -65536 (H'FFFF FFFF to H'FFFF 0000).

The value to be written to these bits depends on the Ethernet bit rate and Bϕ (internal bus clock). For details, see Section 57.3.6, CBS (Credit-Based Shaping).

## 57.2.24 CBS Upper Limit Register c (CULc) (c = 0 or 1)

The CUL0 register sets the upper limit for credit values calculated by using the CSB algorithm for transmission queue 2 (for stream class B).

The CUL1 register sets the upper limit for credit values calculated by using the CSB algorithm for transmission queue 3 (for stream class A).

### ULV[31:0] CBS Upper Limit Bits

These bits set the upper limit for credit values calculated by using the CBS algorithm.

The setting is a limiting value for error detection and does not normally affect operation of the algorithm.

Write a positive value to these bits.

For details, see Section 57.3.6, CBS (Credit-Based Shaping).

### 57.2.25 CBS Lower Limit Register c (CLLc) (c = 0 or 1)

The CUL0 register sets the lower limit for credit values calculated by using the CSB algorithm for transmission queue 2 (for stream class B).

The CUL1 register sets the lower limit for credit values calculated by using the CSB algorithm for transmission queue 3 (for stream class A).

#### LLV[31:0] CBS Lower Limit Bits

These bits set the lower limit for credit values calculated by using the CBS algorithm.

The setting is a limiting value for error detection and does not normally affect operation of the algorithm.

Write a negative value to these bits.

For details, see Section 57.3.6, CBS (Credit-Based Shaping).

## 57.2.26 Descriptor Interrupt Control Register (DIC)

The DIC register is used to control descriptor interrupts 1 to 15.

### RPE1 to RPE15 Descriptor Interrupt Enable Bits 1 to 15

When an interrupt source flag is set (a bit from among the DPF1 to DPF15 bits in the descriptor interrupt status register (DIS) = 1) while the interrupt is enabled, the interrupt is issued.

## 57.2.27 Descriptor Interrupt Status Register (DIS)

The DIS register indicates the state of descriptor interrupts.

### DPF1 to DPF15 Descriptor Interrupt Status Bits

The corresponding bit indicates completion of the processing of a descriptor with DESCR.DIE set to the corresponding number from 1 to 15 within the reception or transmission queue.

When DESCR.DIE is 0, the descriptor interrupt is not generated.

Only 0 can be written to these bits.

[Conditions for Changing]

A bit is set to 0 when the operating mode is not operation mode.

A bit is set to 1 when a descriptor with DESCR.DIE set to the corresponding number from 1 to 15 is processed and a write transaction to the corresponding descriptor is issued. Note that the bit is set to 1 without waiting for response to the write transaction. Therefore confirm that the descriptor type (DESCR.DT) of the corresponding descriptor has been updated before post-processing the processed descriptor.

## 57.2.28 Error Interrupt Control Register (EIC)

The EIC register controls the AVB-DMAC-related error interrupts.

### TFFE Time Stamp FIFO Full-Error Interrupt Enable Bits

When the time stamp FIFO is full (TFFF in the error interrupt status register (EIS) = 1) and the interrupt is enabled, the interrupt is issued.

### CULE1 CBS Upper Limit Error Interrupt Enable Bit (Class A)

When the Class A CBS reaches its upper limit (CULF1 in the error interrupt status register (EIS) = 1) and the interrupt is enabled, the interrupt is issued.

#### CULE0 CBS Upper Limit Error Interrupt Enable Bit (Class B)

When the Class B CBS reaches its upper limit (CULF0 in the error interrupt status register (EIS) = 1) and the interrupt is enabled, the interrupt is issued.

#### CLLE1 CBS Lower Limit Error Interrupt Enable Bit (Class A)

When the Class A CBS reaches its lower limit (CLLF1 in the error interrupt status register (EIS) = 1) and the interrupt is enabled, the interrupt is issued.

#### CLLE0 CBS Lower Limit Error Interrupt Enable Bit (Class B)

When the Class B CBS reaches its lower limit (CLLF0 in the error interrupt status register (EIS) = 1) and the interrupt is enabled, the interrupt is issued.

#### SEE Separation Filter Error Interrupt Enable Bit

When the separation filter error is detected (SEF in the error interrupt status register (EIS) = 1) and the interrupt is enabled, the interrupt is issued.

#### QEE Queue Error Interrupt Enable Bit

When the queue error is detected (QEF in the error interrupt status register (EIS) = 1) and the interrupt is enabled, the interrupt is issued.

## 57.2.29 Error Interrupt Status Register (EIS)

The EIS register indicates the states of AVB-DMAC-related error interrupts.

#### QFS Queue Full Error Status Bit

With the interrupts enabled, this bit indicates that a queue is full (the receive queue r full interrupt status bit (QFFr) or the receive FIFO full interrupt status bit (RFFF) in receive interrupt status register 2 (RIS2) = 1).

[Conditions for Changing]

If the receive queue r full interrupt status bit (RIS2.QFFr) and the receive queue r full interrupt enable bit in the receive interrupt control register 2 (RIC2.QFEr) are updated, this bit is also updated.

If the receive FIFO full interrupt status bit (RIS2.RFFF) and the receive FIFO full interrupt enable bit (RIC2.RFFE) are updated, this bit is also updated.

#### TFFF Time Stamp FIFO Full-Error Interrupt Status Bit

This bit indicates that a new transmission time stamp has been discarded due to the time-stamp FIFO being full (i.e. has reached the overflow state).

Only 0 can be written to the bit.

[Conditions for Changing]

The bit is set to 0 when the operating mode is not operation mode.

The bit is set to 1 when a frame with DESCR.TSR set is transmitted while the time stamp FIFO enable bit in the transmit configuration control register (TCCR.TFEN) is set to 1 and the time stamp FIFO count bit in the transmit status register (TSR.TFFL) is set to 2.

#### CULF1 CBS Upper Limit Error Interrupt Status Bit (Class A)

This bit indicates that CBS counter 1 has exceeded the set upper limit (CUL1.ULV in the CBS upper limit register c (CULc)).

Only 0 can be written to the bit.

[Conditions for Changing]

This bit is set to 0 when the operating mode is not operation mode.

This bit is set to 1 when the value of the CBS counter status 1 (Class A) bits in the transmit status register (TSR.CCS1) change from 00 (indicating a value within the range between the limits) to 10 (indicating a value over the upper limit).

#### CULF0 CBS Upper Limit Error Interrupt Status Bit (Class B)

This bit indicates that CBS counter 0 has exceeded the set upper limit (CUL0.ULV in the CBS upper limit register c (CULc)).

Only 0 can be written to the bit.

[Conditions for Changing]

The bit is set to 0 when the operating mode is not operation mode.

The bit is set to 1 when the value of the CBS counter status 0 (Class B) bit in the transmit status register changes from 00 (indicating a value within the range between the limits) to 10 (indicating a value over the upper limit).

#### CULF1 CBS Lower Limit Error Interrupt Status Bit (Class A)

This bit indicates that CBS counter 1 has fallen below the set lower limit (CLL1.LLV in CBS lower limit register c (CLLc)).

Only 0 can be written to the bit.

[Conditions for Changing]

The bit is set to 0 when the operating mode is not operation mode.

The bit is set to 1 when the value of the CBS counter status 1 (Class A) bit in the transmit status register (TSR.CCS1) changes from 00 (indicating a value within the range between the limits) to 01 (indicating a value less than the lower limit).

#### CLLF0 CBS Lower Limit Error Interrupt Status Bit (Class B)

This bit indicates that CBS counter 0 has fallen below the set lower limit (CLL0.LLV in the CBS lower limit register c (CLLc)).

Only 0 can be written to the bit.

[Conditions for Changing]

The bit is set to 0 when the operating mode is not operation mode.

The bit is set to 1 when the value of the CBS counter status 0 (Class B) bit in the transmit status register (TSR.CCS0) changes from 00 (indicating a value within the range between the limits) to 01 (indicating a value less than the lower limit).

#### SEF Separation Filter Error Interrupt Status Bit

This bit indicates that a received frame has been discarded due to non-matching of the defined separation filter.

Only 0 can be written to this bit.

[Conditions for Changing]

The bit is set to 0 when the operating mode is not operation mode.

If the stream filtering select bits in the receive configuration register (RCR.ESF) are B'10, this bit is set to 1 when the received frame is discarded because the received AVB stream data frame has not match any of the separation filters.

#### QEF Queue Error Interrupt Status Bit

This bit indicates that an error is detected when the transmission and reception queues are processed. For details, see Section 57.3.2.3, Checking Integrity.

Only 0 can be written to this bit.

[Conditions for Changing]

The bit is set to 0 when the operating mode is not operation mode.

If an error in the transmission and reception queues is detected, this bit is set to 1.

## 57.2.30 Receive Interrupt Control Register 0 (RIC0)

The RIC0 register controls the AVB-DMAC receive interrupts.

### FRE0 to FRE17 Receive Frame Interrupt Enable Bits 0 to 17

When an interrupt source flag is set (a bit from among the receive interrupt status bits in the receive interrupt status register (RIS0.FRF0 to 17) = 1) while the interrupt is enabled, the interrupt is issued.

## 57.2.31 Receive Interrupt Status Register 0 (RIS0)

The RIS0 register indicates the states of the AVB-DMAC receive interrupts.

### FRF0 to FRF17 Receive Frame Interrupt Status Bits 0 to 17

Each bit indicates that a corresponding frame has been stored normally in reception queues 0 to 17 and that data are ready for CPU processing.

Only 0 can be written to the bit.

[Conditions for Changing]

A bit is set to 0 when the operating mode is not operation mode.

A bit is set to 0 when a value is written to the unread frame counter decrement register i (UFCDi) (i = 0 to 4), and this decrements the value of unread frame counter register i (UFCVi) (i = 0 to 4) to 0.

When a frame is stored in reception queue normally and a write transaction to the corresponding descriptor is issued, the corresponding bit is set to 1. Note that the bit is set to 1 without waiting for response to the write transaction. Therefore confirm that the descriptor type (DESCR.DT) of the corresponding descriptor has been updated before processing the received data.

## 57.2.32 Receive Interrupt Control Register 1 (RIC1)

The RIC1 register controls the AVB-DMAC receive interrupts.

### RFWE Receive FIFO Warning Interrupt Enable Bit

If the reception FIFO reaches the caution level (the value set in the receive FIFO caution level bits in the receive configuration register (RCR.RFCL) with the corresponding interrupt enabled, the interrupt is issued.

## 57.2.33 Receive Interrupt Status Register 1 (RIS1)

The RIS1 register indicates the states of the AVB-DMAC receive interrupts.

### RFWF Receive FIFO Warning Interrupt Status Bit

This bit indicates that the reception FIFO has reached the set caution level (the value set in the receive FIFO caution level bits in the receive configuration register (RCR.RFCL)).

Only 0 can be written to the bit.

[Conditions for Changing]

The bit is set to 0 when the operating mode is not operation mode.

The bit is set to 1 when the reception FIFO exceeds the set caution level (the value set in the receive FIFO caution level bits in the receive configuration register (RCR.RFCL)).

## 57.2.34 Receive Interrupt Control Register 2 (RIC2)

The RIC2 register controls the AVB-DMAC receive interrupts.

### RFFF Receive FIFO Full Interrupt Status Bit

This bit indicates that a frame was received but storing it was not possible due to the reception FIFO being full.

When receiving a frame is not possible, the frame will be discarded.

Other information regarding discarded frames is not retained. Even if the frame is not discarded, this bit may also be set to 1 if the E-MAC determines that the frame is an error frame

Only 0 can be written to the bit.

[Conditions for Changing]

The bit is set to 0 when the operating mode is not operation mode.

The bit is set to 1 when the reception FIFO cannot hold received data.

### QFF0 to 17 Receive 0 to 17 Full Interrupt Status Bits

These bits indicate that reception queue r did not have space for storing a received frame.

A reception queue is treated as full when it has no descriptors (descriptor type (DESCR.DT) = FEMPTY, FEMPTY_IS, FEMPTY_IC, or FEMPTY_ND) available or reaches the set level for stopping.

CAUTION

If no FEMPTY descriptors or no empty space for descriptors remains in the queue during storing of a divided frame (see Section 57.3.4.3 (b) Divided Frames), an error frame is stored in the queue. Such error frames are treated as descriptor sequence errors.

**[Conditions for Changing]**

A bit is set to 0 when the operating mode is not operation mode.

A bit is set to 1 when reception queue r has no space available for storage.

A bit is set to 1 when the unread frame counter (unread frame counter register i (UFCVi) (i = 0 to 4)) reaches the set level for stopping.

A bit is set to 1 when the unread frame counter reaches the level for stopping before the subsequent received frame is discarded.

## 57.2.36 Transmit Interrupt Control Register (TIC)

The TIC register controls the AVB-DMAC transmit interrupts.

### TFWE Time Stamp FIFO Warning Interrupt Enable Bit

When the time-stamp FIFO reaches the warning level while the interrupt is enabled, the interrupt is issued.

### TFUE Time Stamp FIFO Update Interrupt Enable Bit

When the time-stamp FIFO is updated while the interrupt is enabled, the interrupt is issued.

## 57.2.37 Transmit Interrupt Status Register (TIS)

The TIS register indicates the states of the AVB-DMAC transmit interrupts.

| b7 to b0 | — | Reserved<br>These bits are read as 0. The write value should be 0. |

### TFWF Time Stamp FIFO Warning Interrupt Status Bit

This bit indicates that the transmission time-stamp FIFO has reached the warning level.

Only 0 can be written to the bit.

[Conditions for Changing]

The bit is set to 0 when the operating mode is not operation mode and when the time stamp FIFO enable bit in the transmit configuration control register (TCCR.TFEN) is 0.

The bit is set to 1 after a frame including DESCR.TSR set has been transmitted and one entry has already been stored in the time-stamp FIFO.

#### TFUF Time Stamp FIFO Update Interrupt Status Bit

This bit indicates that the transmission time-stamp FIFO has been updated.

Only 0 can be written to the bit.

[Conditions for Changing]

The bit is set to 0 when the operating mode is not operation mode, when the time stamp FIFO enable bit in the transmit configuration control register (TCCR.TFEN) is 0, and when 1 is written to the time stamp FIFO release bit in the transmit configuration control register (TCCR.TFR).

The bit is set to 1 when the time stamp FIFO enable bit (TCCR.TFEN) is 1 after a frame including DESCR.TSR set has been transmitted.

## 57.2.38 Interrupt Summary Status Register (ISS)

The ISS register gives a summary of the states of AVB-DMAC-related interrupts.

#### DPS1 to DPS15 Descriptor Interrupt 1 to 15 Summary Bits

These bits are set to 1 when the given descriptor interrupt enable bit (DIC.DPE1 to DPE15) and descriptor interrupt status flag (DIS.DPF1 to DPF15) are both 1.

#### CGIS gPTP Interrupt Summary Bit

This bit is set to 1 when either interrupt-related bit in the two gPTP-related interrupt registers (GIC and GIS) is 1.

#### RFWS Receive FIFO Warning Interrupt Summary Bit

This bit is set to 1 when the receive FIFO warning interrupt enable bit (RIC1.RFWE) and receive FIFO warning interrupt status flag (RIS1.RFWF) are both 1.

#### TFWS Time Stamp FIFO Warning Interrupt Summary Bit

This bit is set to 1 when the time stamp FIFO warning interrupt enable bit (TIC.TFWE) and time stamp FIFO warning interrupt status flag (TIS.TFWF) are both 1.

#### TFUS Time Stamp FIFO Update Interrupt Summary Bit

This bit is set to 1 when the time stamp FIFO update interrupt enable bit (TIC.TFUE) and time stamp FIFO update interrupt status flag (TIS.TFUF) are both 1.

#### MS E-MAC Interrupt Summary Bit

This bit is set to 1 when an E-MAC interrupt is issued.

#### ES Error Interrupt Summary Bit

This bit is set to 1 when any of the valid flags in the error interrupt status register (EIS) is 1 or the queue full error interrupt status bit (EIS.QFS) in the error interrupt status register (EIS) is 1.

## 57.2.39 gPTP Configuration Control Register (GCCR)

The GCCR register is used to set and control the gPTP (generalized precision time protocol).

#### TCSS[1:0] Timer Capture Source Select Bits

These bits select the source used for updating the captured timer register (gPTP timer capture register (GCTi.CTV)).

These bits should still be controlled when timer control is not being requested (GCCR.TCR = B'00).

#### LMTT Maximum Transit Time Configuration Request Bit

This bit issues requests for configuring the gPTP maximum transit time configuration register (GMTT).

Only 1 can be written to the bit.

[Conditions for Changing]

The bit is set to 1 when the operating mode is not operation mode.

The bit is set to 0 when the value of the gPTP maximum transit time configuration register (GMTT) is reflected in the gPTP timer.

#### LPTC Presentation Time Compare Value Configuration Request Bit

This bit issues requests for configuring the gPTP presentation time comparison register (GPTC).

Only 1 can be written to the bit.

[Conditions for Changing]

The bit is set to 1 when the operating mode is not operation mode.

The bit is set to 0 when the value of the gPTP presentation time comparison register (GPTC) is reflected in the gPTP timer.

#### LTI Timer Increment Value Configuration Request Bit

This bit issues requests for configuring the gPTP timer increment configuration register (GTI).

Only 1 can be written to the bit.

[Conditions for Changing]

The bit is set to 1 when the operating mode is not operation mode.

The bit is set to 0 when the value of the gPTP timer increment configuration register (GTI) is reflected in the gPTP timer.

#### LTO Timer Offset Value Configuration Request Bit

This bit issues requests for configuring gPTP timer offset configuration register i (GTOi).

Only 1 can be written to the bit.

[Conditions for Changing]

The bit is set to 1 when the operating mode is not operation mode.

The bit is set to 0 when the value of gPTP timer offset configuration register i (GTOi) is reflected in the gPTP timer.

#### TCR[1:0] Timer Control Request Bits

These bits issue requests for controlling the gPTP timer.

Writing to the bits is only possible when the current operating mode is operation mode and the bits are B’00.

Do not write to the bit when the gPTP timer clock select bit in the AVB-DMAC mode register is B’00.

[Conditions for Changing]

The bits are set to B’00 when the operating mode is not operation mode and on completion of the requested processing.

## 57.2.40 gPTP Maximum Transit Time Configuration Register (GMTT)

The GMTT register sets the maximum time for transitions of the gPTP timer.

### MTTV[31:0] Maximum Transit Time Bits

These bits set the maximum transition time for use in calculating AVTP presentation times.

Write the desired setting to the bits, then issue the configuration request by setting the maximum transit time configuration request bit in the gPTP configuration control register (GCCR.LMTT) to 1.

CAUTION

Do not write a value to these bits when the operating mode is operation mode and the maximum transit time configuration request bit (GCCR.LMTT) is 1.

## 57.2.41 gPTP Presentation Time Comparison Register (GPTC)

The GPTC register sets a value for comparison with presentation times in the gPTP timer.

### PTCV[31:0] Presentation Time Comparison Value Bits

These bits set a value for comparison with AVTP timer values to which a maximum transit time is not appended.

Write the desired setting to the bits, then issue the configuration request by setting the presentation time comparison value configuration request bit in the gPTP configuration control register (GCCR.LPTC) to 1.

CAUTION

Do not write a value to these bits when the operating mode is operation mode and the presentation time comparison value configuration request bit (GCCR.LPTC) is 1.

Do not set these bits to a value in the range from x-1 to x+1 (x is the setting value of the gPTP timer increment value bits (GTI.TIV)).

## 57.2.42 gPTP Timer Increment Configuration Register (GTI)

The GTI register sets the increment for the gPTP timer.

| b27 to b0 | TIV[27:0] | gPTP Timer Increment Value<br>Increment for the gPTP timer |

### TIV[27:0] Bits (gPTP Timer Increment Value)

When the gPTP clock select bits in the AVB-DMAV mode register (CCC.CSEL) are selecting a clock signal, these bits set the value by which the timer is incremented each time a cycle of that clock signal elapses.

Write the desired setting to the bits, then issue the configuration request by setting the timer increment value configuration request bit in the gPTP configuration control register (GCCR.LTI) to 1.

CAUTION

Do not write a value to these bits when the operating mode is operation mode and the timer increment value configuration request bit (GCCR.LTI) is 1.

Do not write 0 to the bits.

## 57.2.43 gPTP Timer Offset Configuration Register i (GTOi) (i = 0 to 2)

The GTOi register sets an offset value for the gPTP timer.

The offset value is added to the combination of bits 0 to 31 in GTO0, 32 to 63 in GTO1, and 64 to 79 in GTO2, which together make up the gPTP timer.

|---|---|---|
| b31 to b0 | TOV[31+32*i:32*i] | Timer Offset Value<br>Offset value for the gPTP timer |

### TOV[79:0] Timer Offset Value Bits

This is an 80-bit value consisting of the settings in GTO0.TOV[31:0], GTO1.TOV[63:32], and GTO2.TOV[79:64], and is used to set an offset for adding to the value of the gPTP timer.

Write the desired setting to the bits, then issue the configuration request by setting the timer offset value configuration request bit in the gPTP configuration control register (GCCR.LTO) to 1.

CAUTION

Do not write a value to these bits when the operating mode is operation mode and the timer offset value configuration request bit (GCCR.LTO) is 1.

Write H'0000 to GTO2.TOV[95:80].

Set a value in the range from 0 to $10^9$-1 (H'0000 0000 to H'3B9A C9FF) in GTO0.TOV[31:0].

## 57.2.44 gPTP Interrupt Control Register (GIC)

The GCI register is used to control gPTP-related interrupts.

### PTME Presentation Time Match Interrupt Enable Bit

When this bit is 1, setting of the presentation time match interrupt flag in the gPTP interrupt status register (GIS.PTMF) to 1 leads to generation of that interrupt.

### PTOE Presentation Time Overrun Interrupt Enable Bit

When this bit is 1, setting of the presentation time overrun interrupt flag in the gPTP interrupt status register (GIS.PTOF) to 1 leads to generation of that interrupt.

### PTCE Presentation Time Capture Interrupt Enable Bit

When this bit is 1, setting of the presentation time capture interrupt flag in the gPTP interrupt status register (GIS.PTCF) to 1 leads to generation of that interrupt.

## 57.2.45 gPTP Interrupt Status Register (GIS)

The GIC register indicates the state of the gPTP-related interrupt.

### PTMF Presentation Time Match Interrupt Flag Bit

This bit indicates that the value of the AVTP timer exceeds the value of the gPTP presentation time comparison register (GPTC).

Only 0 can be written to the bit.

[Conditions for Changing]

The bit is set to 0 when the operating mode is not operation mode.

The bit is set to 1 when the AVTP timer value is greater than or equal to the value of the gPTP presentation time comparison register (GPTC).

### PTOF Presentation Time Overrun Interrupt Flag Bit

This bit indicates that an external capture event (rising signal on the AVB_CAPTURE pin) is generated before completion of the previous capture process.

Only 0 can be written to the bit.

[Conditions for Changing]

The bit is set to 0 when the operating mode is not operation mode.

The bit is set to 0 when the presentation time capture interrupt flag bit (GIS.PTCF) is set to 0. The bit is set to 1 when an external capture event is generated while the value of the presentation time capture interrupt flag bit (GIS.PTCF) is 1.

**PTCF Presentation Time Capture Interrupt Flag Bit**

This bit indicates that an external capture event (rising signal on the AVB_CAPTURE pin) is generated.

Only 0 can be written to the bit.

[Conditions for Changing]

The bit is set to 0 when the operating mode is not operation mode.

The bit is set to 1 when an external capture event is generated.

CAUTION

To generate an external capture event, the AVB_CAPTURE pin should be held high for at least two cycles of the clock specified by the gPTP clock select bits (CCC.CSEL).

## 57.2.46 gPTP Presentation Time Capture Register (GCPT)

The GCPT register indicates the captured presentation time.

**Table 57.50 GCPT register contents**

| Bit Position | Bit Name | Function |
|---|---|---|
| b31 to b0 | CPTV[31:0] | Presentation Time Capture<br>Presentation time value |

### CPTV[31:0] Presentation Time Capture Bits

These bits indicate the AVTP presentation time captured in response to an external capture event (rising signal on the AVB_CAPTURE pin). Read the time value from these bits and clear the presentation time capture interrupt flag bit (GIS.PTCF) before triggering a next capture.

Whether capturing a correct value was possible can be confirmed by following the procedure below.

1. Read these bits.
2. Read the presentation time overrun interrupt flag bit (GIS.PTOF).
3. Read these bits again.
4. Check whether the presentation time overrun interrupt flag bit (GIS.PTOF) is set to 1 and whether the value read from these bits has changed. If either of the two conditions is met, a correct value has not been captured.

   [Conditions for Changing]

   The bits are set to H’00000000 when the operating mode is not operation mode.

   When an external capture event occurs, the bits are updated with the AVTP presentation time value at the time of the event.

CAUTION

To generate an external capture event, the AVB_CAPTURE pin should be held high for at least two cycles of the clock specified by the gPTP clock select bits (CCC.CSEL).

## 57.2.47 gPTP Timer Capture Register i (GCTi) (i = 0 to 2)

The GCTi registers form an 80-bit register that captures the gPTP timer value.

| Bit Position | Bit Name | Function |
|---|---|---|
| b31 to b0 | CTV[31+32*i:32*i] | gPTP Timer Capture Value<br>Captured timer value |

### CTV[79:0] gPTP Timer Capture Value Bits

These 80 bits consist of GCT0.CTV[31:0], GCT1.CTV[63:32] and GCT2.CTV[79:64], which together indicate captured timer values.

When B’00 (value of the gPTP timer) or B'01 (corrected gPTP timer value) is selected by the timer capture source select bits in the gPTP configuration control register (GCCR.TCSS), the corresponding 80-bit values are stored in GCT0.CTV[31:0], GCT1.CTV[63:32], and GCT2.CTV[79:64].

When B’10 (AVTP presentation time) is selected by the timer capture source select bit (GCCR.TCSS), the corresponding 32-bit values are stored in GCT0.CTV[31:0].

Actual writing of the timer value specified by the timer capture source select bits (GCCR.TCSS) proceeds when B’11 (timer capture request) is written to the timer control request bits in the gPTP configuration control register (GCCR.TCR).

Do not read the value while the value of the timer control request bits (GCCR.TCR) is B’11, because this indicates that storage is still in progress.

When operating mode is not operation mode, the bits are set to H’00000000.

## 57.2.48 E-MAC Mode Register (ECMR)

ECMR is used to specify the operating mode of the E-MAC. The settings in this register are normally made in the initialization process following a reset.

The operating mode settings must not be changed while transmission or reception is enabled (i.e. while the RE or TE bit in this register is 1).

### TRCCM Counter Clear Mode Bit

This bit sets the method for clearing the counter register. Refer to the descriptions of the counter registers.

### RCSC Checksum Calculation Bit

Setting this bit to 1 enables automatic calculation of checksums for data in received frames.

Only the data field of an Ethernet frame is in the scope of checksum calculation. Specifically, the checksum is calculated from the data field, which follows the length/type field and is followed by the CRC field. Calculation only involves 16-bit addition; it does not involve bit inversion.

### DPAD Data Padding Control Bit

This bit specifies padding or non-padding of data when less than 60 bytes are to be transmitted.

When this bit is set to 1, data are transmitted without padding; when it is set to 0, data are padded to make up 60-byte units for transmission.

#### RZPF (PAUSE Frame Reception with Time = 0) Bit

When the RZPF bit is set to 0, received PAUSE frames with the Timer value 0 are discarded.

When the RZPF bit is set to 1, release from the transmission wait state follows reception of a PAUSE frame with the Timer value 0.

#### ZPF (PAUSE Frame Usage with TIME = 0 Enable) Bit

When the ZPF bit is set to 0, the next frame to be transmitted is not transmitted until the time specified by the Timer value has elapsed.

Received PAUSE frames with the Timer value 0 are discarded.

When the ZPF bit is set to 1, if the amount of data in the reception FIFO becomes less than the setting of the receive FIFO critical level bits (RCR.RFCL) before the time specified by the Timer value elapses, a PAUSE frame with a Timer value of 0 is automatically transmitted. If the interface is in the transmission wait state, it is released from that state on receiving a PAUSE frame with a Timer value of 0.

#### PFR PAUSE Frame Receive Mode Bit

This bit specifies whether PAUSE frames are transferred to the AVB-DMAC.

#### RXF (Operating Mode for Flow Control in Reception) Bit

When the RXF bit is set to 1 and a PAUSE frame is received, a next frame to be transmitted is not transmitted until the time indicated by the Timer value in the PAUSE frame has elapsed. However, the transmission of a current frame is continued. The number of received PAUSE frames is also counted. For details, see Section 57.2.56, PAUSE Frame Receive Counter (PFRCR).

Setting this bit to 0 disables PAUSE frame detection.

#### TXF (Operating Mode for Flow Control in Transmission) Bit

The TXF bit enables or disables flow control in transmission by the port.

Setting this bit to 0 disables PAUSE frame detection.

#### RE Reception Enable Bit

If this bit is switched from reception being enabled (RE = 1) to reception being disabled (RE = 0) while a frame is being received, reception will continue until reception of that frame is completed.

#### TE Transmission Enable Bit

If this bit is switched from transmission being enabled (TE = 1) to transmission being disabled (TE = 0) while a frame is being transmitted, transmission will continue until transmission of that frame is completed.

#### DM Full-Duplex Transfer Enable Bit

This bit enables or disables full-duplex transfer.

#### PRM Promiscuous Mode Bit

Setting the PRM bit enables all Ethernet frames to be received. All Ethernet frames means all receivable frames, irrespective of differences or enabled/disabled status (destination address, broadcast address, multicast bit, etc.).

## 57.2.49 Receive Frame Length Register (RFLR)

The RFLR register specifies the maximum length (in bytes) of frames that can be received by this LSI. Settings in this register must not be changed while reception is enabled (while the RE bit in the E-MAC mode register (EMCR) is 1).

| Bit | b31 | b30 | b29 | b28 | b27 | b26 | b25 | b24 | b23 | b22 | b21 | b20 | b19 | b18 | b17 | b16 |

### RFL[17:0] Receive Frame Length Bits

Frame data described here refers to all fields from the destination address up to the CRC data. Frame contents from the destination address up to the data are actually transferred to memory. CRC data are not included in the transfer. When more data than the specified number of bytes are received, the portion of data that exceeds the specified value is discarded.

## 57.2.50 E-MAC Status Register (ECSR)

The ECSR register indicates the state of the E-MAC. The CPU can be notified of the state. For bits associated with interrupts, the interrupt can be enabled or disabled by the corresponding bit in the E-MAC Interrupt Permission Register (ECSIPR) described in Section 57.2.51.

| b0 | ICD | Illegal Carrier Detection<br>0: PHY-LSI has not detected an illegal carrier on the line.<br>1: PHY-LSI has detected an illegal carrier on the line. |

### PFROI PAUSE Frame Retransmit Retry Over Bit

This bit indicates that retransmission count has exceeded the retransmit upper limit set in the PAUSE frame retransmission count register (TPAUSER) during PAUSE frame retransmission when the flow control is enabled.

Writing 1 to this bit clears it to 0.

### ICD Illegal Carrier Detection Bit

This bit indicates that the PHY-LSI has detected an illegal carrier on the line. If a change in the signal input from the PHY-LSI occurs in a period shorter than the software recognition period, the correct information may not be obtained. Refer to the timing specification for the PHY-LSI used.

Writing 1 to this bit clears it to 0.

## 57.2.51 E-MAC Interrupt Permission Register (ECSIPR)

The ECSIPR register enables or disables the states indicated by the ECSR register as interrupt sources. Each effective bit disables or enables interrupts corresponding to the bits in ECSR.

| Bit | b31 | b30 | b29 | b28 | b27 | b26 | b25 | b24 | b23 | b22 | b21 | b20 | b19 | b18 | b17 | b16 |

| b0 | ICDIP | Illegal Carrier Detect Interrupt Enable<br>0: Interrupts on setting of the ICD bit is disabled.<br>1: Interrupt on setting of the ICD bit is enabled. |

### PFROIP PAUSE Frame Retransmit Interrupt Enable Bit

Setting this bit to 1 selects interrupt generation on setting of the PAUSE frame retransmit retry over bit (ECSR.PFROI) in the E-MAC status register to 1.

### ICDIP Illegal Carrier Detect Interrupt Enable Bit

Setting this bit to 1 selects interrupt generation on setting of the illegal carrier detection bit (ECSR.ICD) in the E-MAC status register to 1.

## 57.2.52 PHY Interface Register (PIR)

The PIR register provides a means of access to the PHY-LSI internal registers via the MII.

| Bit | b31 | b30 | b29 | b28 | b27 | b26 | b25 | b24 | b23 | b22 | b21 | b20 | b19 | b18 | b17 | b16 |

### MDI MII Management Data-In Bit

This bit indicates the level of the ET_MDIO pin.

### MDO MII Management Data-Out Bit

This bit holds data for output from the ET_MDIO pin.

The ET_MDIO pin outputs a value set in this bit when the MMD bit is set to 1 (to specify writing as the direction). Data are not output while the MMD bit is set to 0 (to specify reading as the direction).

### MMD MII Management Mode Bit

This bit specifies the direction for data through MDIO (reading or writing).

### MDC MII Management Data Clock Bit

Values set in this bit are output on the ET_MDC pin to supply the MII with the management data clock. For the method of access to the MII registers, see Section 57.3.12, Connection to PHY-LSI.

## 57.2.53 Automatic PAUSE Frame Register (APR)

The APR register is used to set the value for the TIME parameter of automatically transmitted PAUSE frames. When a PAUSE frame is automatically transmitted, the value set in this register is used as its TIME parameter.

| Bit | b31 | b30 | b29 | b28 | b27 | b26 | b25 | b24 | b23 | b22 | b21 | b20 | b19 | b18 | b17 | b16 |

### AP[15:0] Automatic PAUSE Bit

These bits set the value of the TIME parameter in automatically transmitted PAUSE frames. The unit for the setting is 512-bit periods.

Set these bits to a value other than H'0000 when the flow control in transmission (PAUSE frame transmission) is enabled (ECMR.TXF = 1).

## 57.2.54 Manual PAUSE Frame Register (MPR)

The MPR register is used to set the value for the TIME parameter of manually generated PAUSE frames. When a PAUSE frame is manually transmitted, the value set in this register is used as its TIME parameter.

### MP[15:0] Manual PAUSE Bits

These bits set the value of the TIME parameter in manually generated PAUSE frames.

The unit for the setting is 512 bit periods.

## 57.2.55 PAUSE Frame Transmit Counter (PFTCR)

The PFTCR register is a counter that indicates the number of times PAUSE frames have been transmitted.

| Bit | b31 | b30 | b29 | b28 | b27 | b26 | b25 | b24 | b23 | b22 | b21 | b20 | b19 | b18 | b17 | b16 |

| b15 to b0 | PFTXC[15:0] | PAUSE Frame Transmit Counter<br>Counter for counting the number of transmitted PAUSE frames |

### PFTXC[15:0] PAUSE Frame Transmit Counter Bits

These bits indicate the total number of PAUSE frames that have been transmitted (both manually and automatically).

The bits are cleared to 0 when they are read.

If counting up and clearing of the counter coincide, clearing the counter takes priority.

## 57.2.56 PAUSE Frame Receive Counter (PFRCR)

The RFRCR register is a counter that indicates the number of times PAUSE frames have been received.

| Bit | b31 | b30 | b29 | b28 | b27 | b26 | b25 | b24 | b23 | b22 | b21 | b20 | b19 | b18 | b17 | b16 |

| b15 to b0 | PFRXC[15:0] | PAUSE Frame Receive Counter<br>Counter for counting the number of received PAUSE frames |

### PFRXC[15:0] PAUSE Frame Receive Counter Bits

These bits indicate the number of PAUSE frames that have been received when flow control in reception is enabled (the RXF bit in ECMR = 1).

The bits are cleared to 0 when they are read.

If counting up and clearing the counter coincide, clearing the counter takes priority.

## 57.2.57 Automatic PAUSE Frame Retransmission Count Register (TPAUSER)

The TPAUSER register sets the upper limit of automatic PAUSE frame retransmission count.

| Bit | b31 | b30 | b29 | b28 | b27 | b26 | b25 | b24 | b23 | b22 | b21 | b20 | b19 | b18 | b17 | b16 |

### TPAUSE[15:0] Automatic PAUSE Frame Retransmission Count Upper Limit Bits

The bits set the upper limit of automatic PAUSE frame retransmission count.

The setting in the bits must not be changed while transmission is enabled (EMCR.TE = 1).

## 57.2.58 MAC Address High Register (MAHR)

The MAHR register specifies the 32 higher-order bits of the 48-bit MAC address. The settings in this register are normally made in the initialization process after a reset.

The settings in this register must not be changed while transmission or reception is enabled.

| Bit | b31 | b30 | b29 | b28 | b27 | b26 | b25 | b24 | b23 | b22 | b21 | b20 | b19 | b18 | b17 | b16 |

### MA[47:16] MAC Address Bits 47 to 16

These bits are used to set the 32 higher-order bits of the MAC address.

For example, if the MAC address is 01-23-45-67-89-AB (hexadecimal), set H'0123 4567 in the MAHR register.

## 57.2.59 MAC Address Low Register (MALR)

The MALR register specifies the 16 lower-order bits of the 48-bit MAC address. The settings in this register are normally made in the initialization process after a reset.

The settings in this register must not be changed while transmission or reception is enabled.

| Bit | b31 | b30 | b29 | b28 | b27 | b26 | b25 | b24 | b23 | b22 | b21 | b20 | b19 | b18 | b17 | b16 |

### MA[15:0] MAC Address Bits 15 to 0

These bits are used to set the 16 lower-order bits of the MAC address.

For example, if the MAC address is 01-23-45-67-89-AB (hexadecimal), set H'89AB in the MALR register.

## 57.2.60 CRC Error Frame Receive Counter Register (CEFCR)

The CEFCR register is a counter that indicates the number of times frames with CRC errors were received. Counting up stops when the value in this register reaches H'FFFF FFFF.

| Bit | b31 | b30 | b29 | b28 | b27 | b26 | b25 | b24 | b23 | b22 | b21 | b20 | b19 | b18 | b17 | b16 |

|---|---|---|
| b31 to b0 | CEFC[31:0] | CRC Error Frame Counter<br>These bits indicate the number of CRC error frames received. |

### CEFC[31:0] CRC Error Frame Counter Bits

These bits indicate the number of received frames having CRC errors.

The bits are cleared to 0 when they are read while the counter clear mode bit (TRCCM) in the E-MAC mode register is set to 1.

When TRCCM = 0, they are cleared to 0 by the writing of any value to this register.

## 57.2.61 Frame Receive Error Counter Register (FRECR)

The FRECR register is a counter that indicates the number of frames for which receive errors were generated by input on the ET_RXER pin from the PHY-LSI. Counting up stops when the value in this register reaches H'FFFF FFFF.

| Bit | b31 | b30 | b29 | b28 | b27 | b26 | b25 | b24 | b23 | b22 | b21 | b20 | b19 | b18 | b17 | b16 |

### FREC[31:0] Frame Receive Error Counter Bits

These bits indicate the number of errors during frame reception.

The bits are cleared to 0 when they are read while the counter clear mode bit (TRCCM) in the E-MAC mode register is set to 1.

When TRCCM = 0, they are cleared to 0 by the writing of any value to this register.

## 57.2.62 Too-Short Frame Receive Counter Register (TSFRCR)

The TSFRCR register is a counter that indicates the number of received frames that were fewer than 64 bytes in length. Counting stops when the value in this register reaches H'FFFF FFFF.

### TSFRC[31:0] Too-Short Frame Receive Counter Bits

These bits indicate the number of received frames that were fewer than 64 bytes in length.

The bits are cleared to 0 when they are read while the counter clear mode bit (TRCCM) in the E-MAC mode register is set to 1.

When TRCCM = 0, they are cleared to 0 by the writing of any value to this register.

## 57.2.63 Too-Long Frame Receive Counter Register (TLFRCR)

The TLFRCR register is a counter that indicates the number of received frames that were longer than the value specified in the receive frame length register (RFLR). Counting up stops when the value in the TLFRCR register reaches H'FFFF FFFF.

| Bit | b31 | b30 | b29 | b28 | b27 | b26 | b25 | b24 | b23 | b22 | b21 | b20 | b19 | b18 | b17 | b16 |

### TLFC[31:0] Too-Long Frame Receive Counter Bits

These bits indicate the number of received frames that were longer than the value in RFLR.

The bits are cleared to 0 when they are read while the counter clear mode bit (TRCCM) in the E-MAC mode register is set to 1.

When TRCCM = 0, they are cleared to 0 by the writing of any value to this register.

## 57.2.64 Residual-Bit Frame Receive Counter Register (RFCR)

The RFCR register is a counter that indicates the number of received frames containing “residual bits” (trailing bits not making up an 8-bit unit). Counting up stops when the value in this register reaches H’FFFF FFFF.

| Bit | b31 | b30 | b29 | b28 | b27 | b26 | b25 | b24 | b23 | b22 | b21 | b20 | b19 | b18 | b17 | b16 |

### RFC[31:0] Residual-Bit Frame Receive Counter Bits

These bits indicate the number of received frames containing residual bits.

The bits are cleared to 0 when they are read while the counter clear mode bit (TRCCM) in the E-MAC mode register is set to 1.

When TRCCM = 0, they are cleared to 0 by the writing of any value to this register.

## 57.2.65 Multicast Address Frame Receive Counter Register (MAFCR)

The MAFCR register is a counter that indicates the number of received frames for which a multicast address was specified. Counting up stops when the value in this register reaches H'FFFF FFFF.

| Bit | b31 | b30 | b29 | b28 | b27 | b26 | b25 | b24 | b23 | b22 | b21 | b20 | b19 | b18 | b17 | b16 |

### MAFC[31:0] Multicast Address Frame Counter Bits

These bits indicate the number of multicast frames that have been received.

The bits are cleared to 0 when they are read while the counter clear mode bit (TRCCM) in the E-MAC mode register is set to 1.

When TRCCM = 0, they are cleared to 0 by the writing of any value to this register.

## 57.3 Operation

The EthernetAVB consists of the following functional units:

- DMA transfer controller (AVB-DMAC): Handles DMA transfer between the data storage areas for reception and transmission in the on-chip RAM and the reception and transmission FIFO buffers
- MAC controller (E-MAC): Handles transfer between the reception and transmission FIFO buffers and the MII

Using its direct memory access (DMA) function, the AVB-DMAC handles DMA transfer of frame data between the destinations for storing Ethernet frame data for transmission and reception in the on-chip RAM and the FIFO buffers for reception and transmission. Data cannot be directly read from or written to the FIFO buffers.

To handle DMA transfer, the AVB-DMAC requires information that includes the addresses for storage of data for transmission and received data. These data are referred to as descriptors. The AVB-DMAC reads data for transmission from the storage area for data to be transmitted according to the information in descriptors and writes received data to the storage area for received data accompanied by information in descriptors. The descriptors are placed in the on-chip RAM. Arranging multiple descriptors in descriptor lists allows the continuous reception or transmission of multiple Ethernet frames.

The E-MAC supports an MII, which provides an interface format for the externally connected PHY-LSI. The E-MAC constructs Ethernet frames from data written to the transmission FIFO and transmits these frames to the MII. It also performs CRC checking of Ethernet frames received from the MII and writes the frames to the reception FIFO.

### 57.3.1 AVB-DMAC Operating Modes

Figure 57.5 illustrates the operating modes of the AVB-DMAC.

Transitions of AVB-DMAC operating mode are under the control of the items listed below.

- CPU operating mode (power-on reset)
- Configuration of the operating mode configuration bits (CCC.OPC) in the AVB-DMAC mode register

The current operating mode can be determined by reading the operating mode status bits in the AVB-DMAC status register (CSR.OPS).

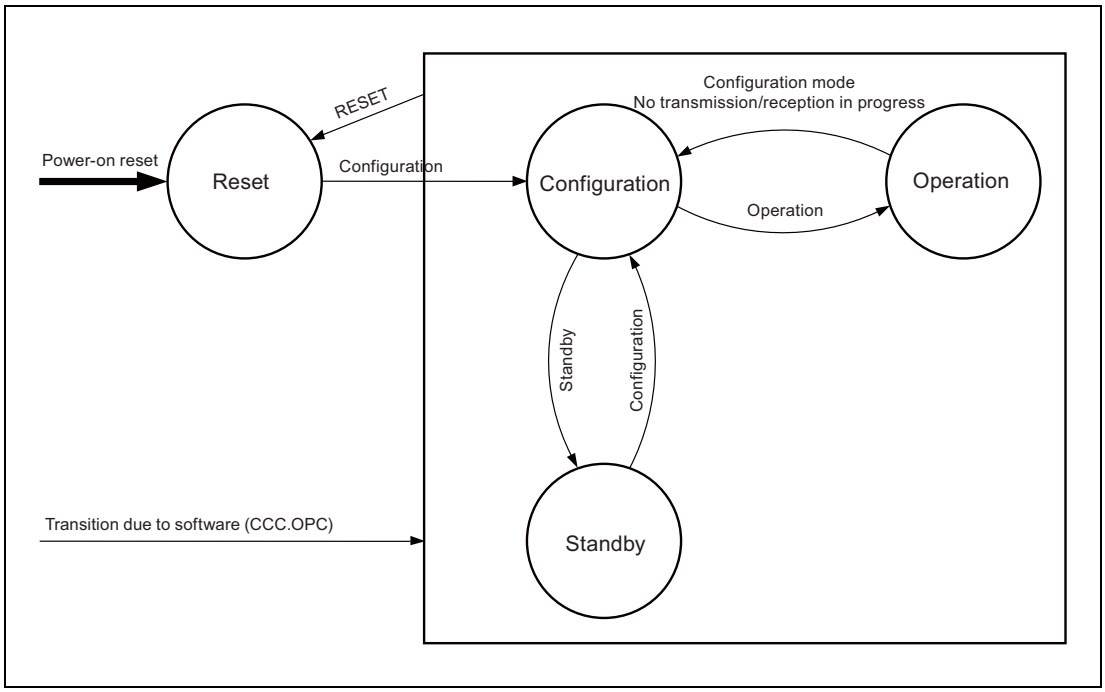

**Figure 57.5 Operating Mode of AVB-DMAC**

#### 57.3.1.1 Operating Modes

(1) Reset mode

After a power-on reset, the AVB-DMAC enters reset mode.
In reset mode, only the AVB-DMAC operating mode control function is controllable and other functions are all stopped. This mode is designed for reduced power when the Ethernet function is not necessary.

(2) Configuration mode

In configuration mode, various settings for the AVB-DMAC can be made.
The operation of most functions is stopped and all status registers are initialized to their reset values.
The E-MAC functions in this mode.

(3) Operation mode

In operation mode, all functions of the AVB-DMAC can operate.
Ethernet communications can only proceed in this mode.

(4) Standby mode

In standby mode, only the operating mode control function and E-MAC can be used. Other functions cannot be used.

### 57.3.1.2 How to Set the Operating Mode

Set the operating mode configuration bits in the AVB-DMAC status register (CSR.OPC) to select the operating mode. Furthermore, the current operating mode can be checked by reading the operating mode status bits in the AVB-DMAC status register (CSR.OPS).

Transitions other than from operation mode to configuration mode are made after the value is written to the operating mode configuration bits (CCC.OPC) (Figure 57.6).

For transitions from operation mode to configuration mode, follow the procedure in Figure 57.7 because any transmission and reception in progress will be executed before the transition to configuration mode.

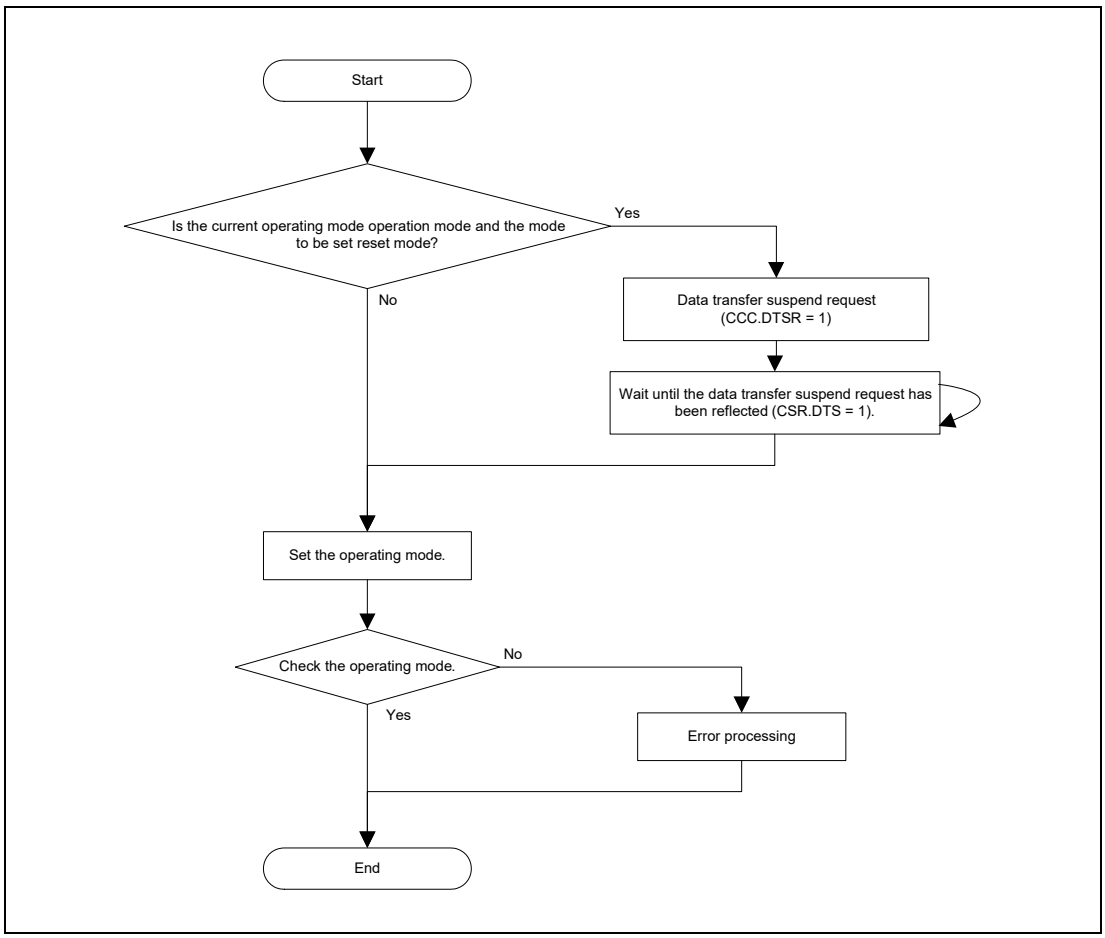

**Figure 57.6 Flow for Transitions of Operating Mode (Other than from Operation Mode to Configuration Mode)**

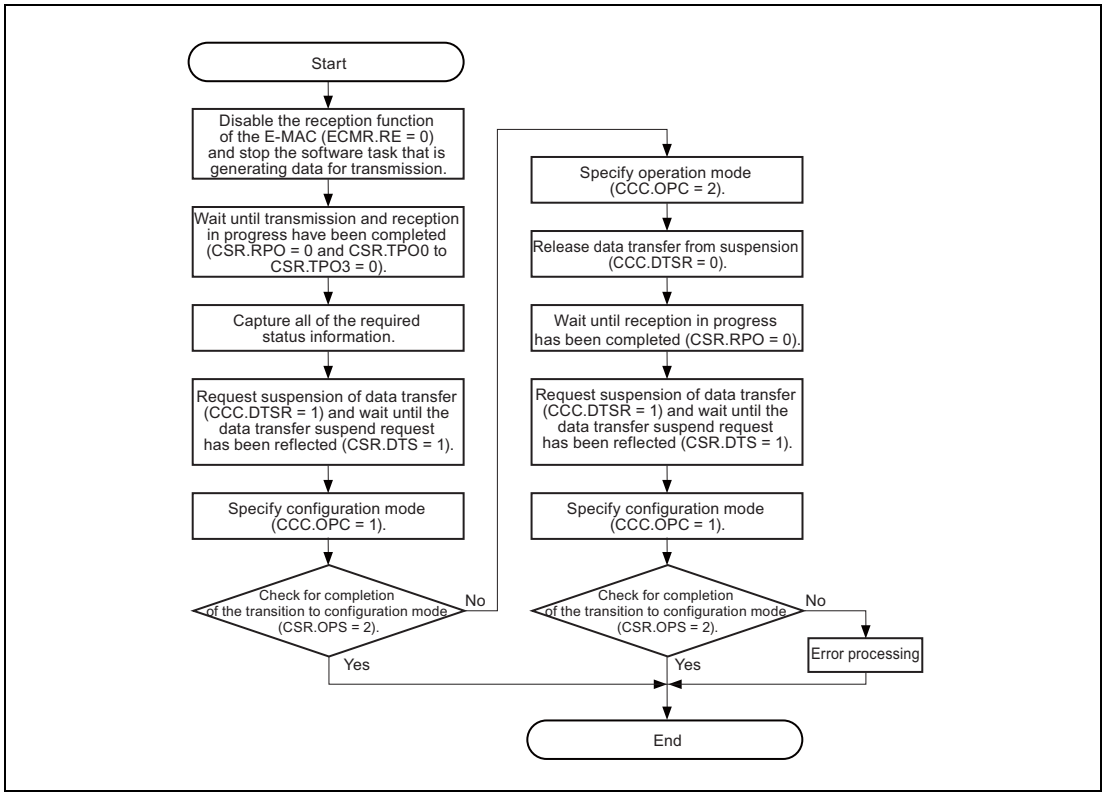

**Figure 57.7 Flow for Transitions of Operating Mode (from Operation Mode to Configuration Mode)**

In the transition from operation mode to configuration mode, the AVB-DMAC executes the following operations before the transition is completed. Read the operating mode status bits in the AVB-DMAC status register (CSR.OPS) to check that the transition to configuration mode has been completed.

- If the transfer of a frame between the reception FIFO and on-chip RAM is in progress, this is completed
  (other received frames remaining in the FIFO and any frames that are subsequently received by the E-MAC are discarded).
- If the transfer of a frame is in progress between the transmission FIFO and on-chip RAM, this is completed
  (frames for transmission remaining in the on-chip RAM will not be transmitted).
- All frames for transmission in the transmission FIFO are transferred to the E-MAC.

**Notes:**

When the operating mode shifts to configuration mode, all status registers are cleared.

We recommend following the procedure below in the case of this transition.

1. Disable reception.
2. Since reception actually stopping after being disabled requires time, wait for an interval equivalent to that for reception of a maximum length packet.
3. Stop the software task that is generating data for transmission.
4. Wait until the receive process status bit (CSR.RPO) and the transmit process status bits (CSR.TPO0 to 3) in the AVB-DMAC status register are set to 0.
5. Capture all of the required status information.

6. Set the operating mode configuration bits in the AVB-DMAC mode register (CCC.OPC) to initiate the transition to configuration mode.

#### 57.3.1.3 Operating Mode Transitions Due to Hardware

The following hardware factors can also initiate transitions of the AVB-DMAC operating mode.

(1) Power-on reset

Resetting of the LSI chip leads to resetting of the entire EthernetAVB module. The operating mode shifts to reset mode.

## 57.3.2 Common Control for Transmission and Reception

### 57.3.2.1 Initialization Procedure

Figure 57.8 shows the overall initialization procedure in outline.

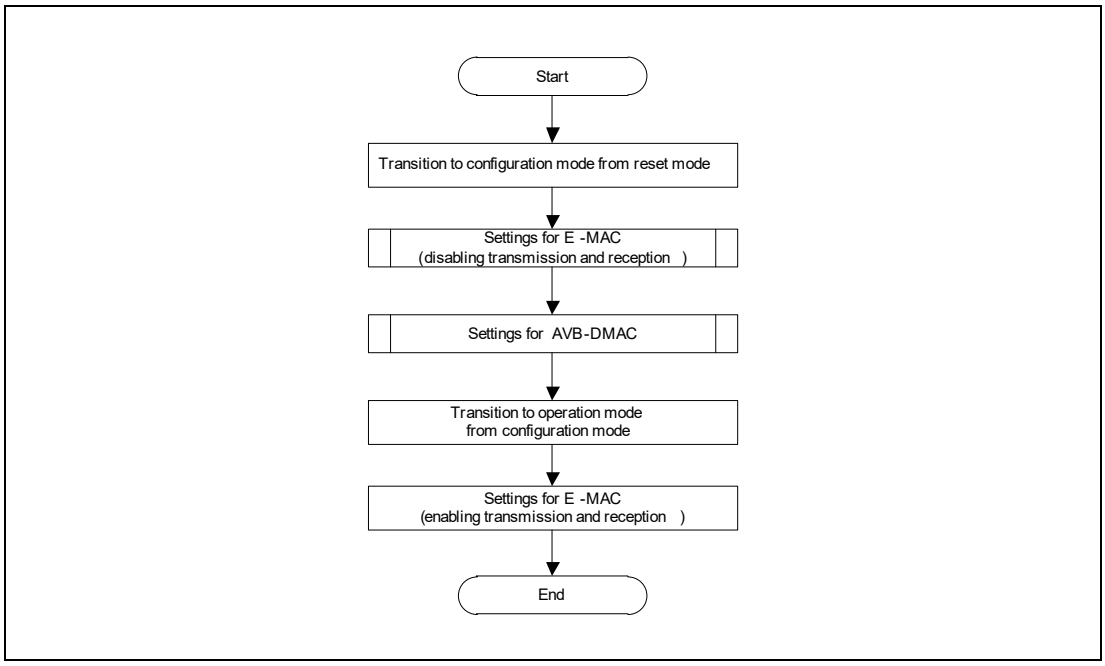

**Figure 57.8 Outline of the Initialization Procedure**

(1) Initializing the Receiver Section

Before starting reception, follow the procedure below.

Set the operating mode to operation mode or standby mode, and do not enable reception until the settings for the AVB-DMAC are completed.

- Set the operating mode to configuration mode.
- Set AVB filtering for network control frames and AVB stream frames to suit the specifications of the product the chip will be used in.
- Create a descriptor chain for each queue to be used.
- Set the base address for the descriptor table in the descriptor base address table register (DBAT).
- Specify the maximum frame length with the receive frame length upper limit register (RFLR).
- Specify whether padding is to be used with the receive padding configuration register (RPC).
- Set the unread frame counter for each queue with unread frame counter registers 0 to 4.

(2) Initializing the Transmitter Section

(4) Initialization of the AVB-DMAC Unit

Figure 57.11 illustrates initialization of the AVB-DMAC unit.

For a description of how to set up the descriptors and the CBS, see Section 57.3.3, Descriptors, and Section 57.3.6, CBS (Credit-Based Shaping).

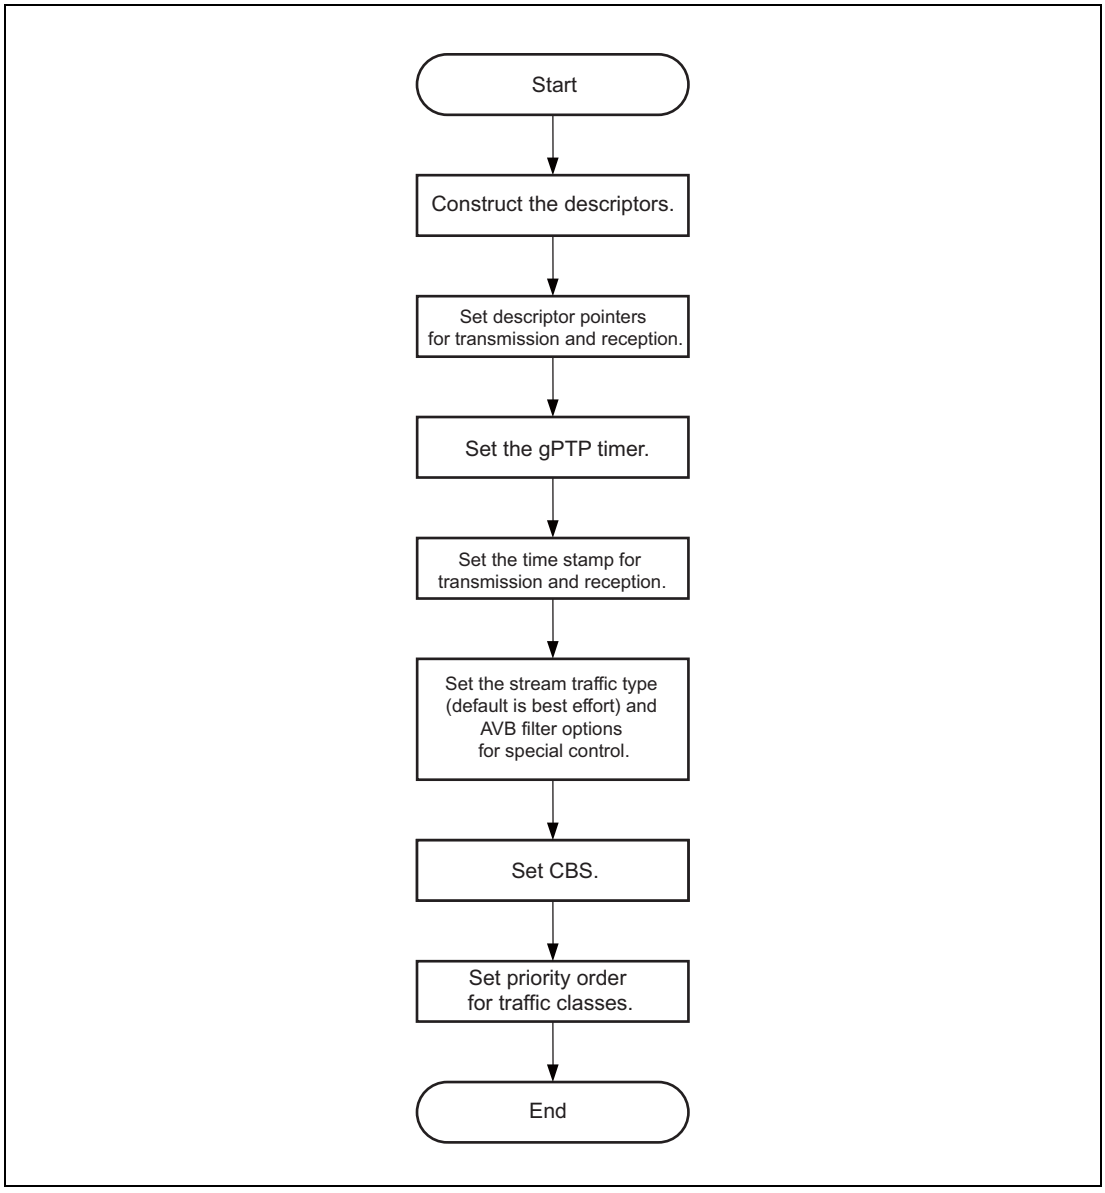

**Figure 57.11 Procedure for Initializing the AVB-DMAC Unit**

### 57.3.2.2 Scheduling Reception and Transmission

The EthernetAVB normally has independent buses for transmission and reception. Furthermore, the four processes of fetching, storing, transmission and reception are basically independent of one another. Fetching and storing, however, share the same bus master so cannot be executed simultaneously. Access to the bus master is controlled by the scheduler.

Figure 57.12 is a schematic view of EthernetAVB operations in transmission and reception.

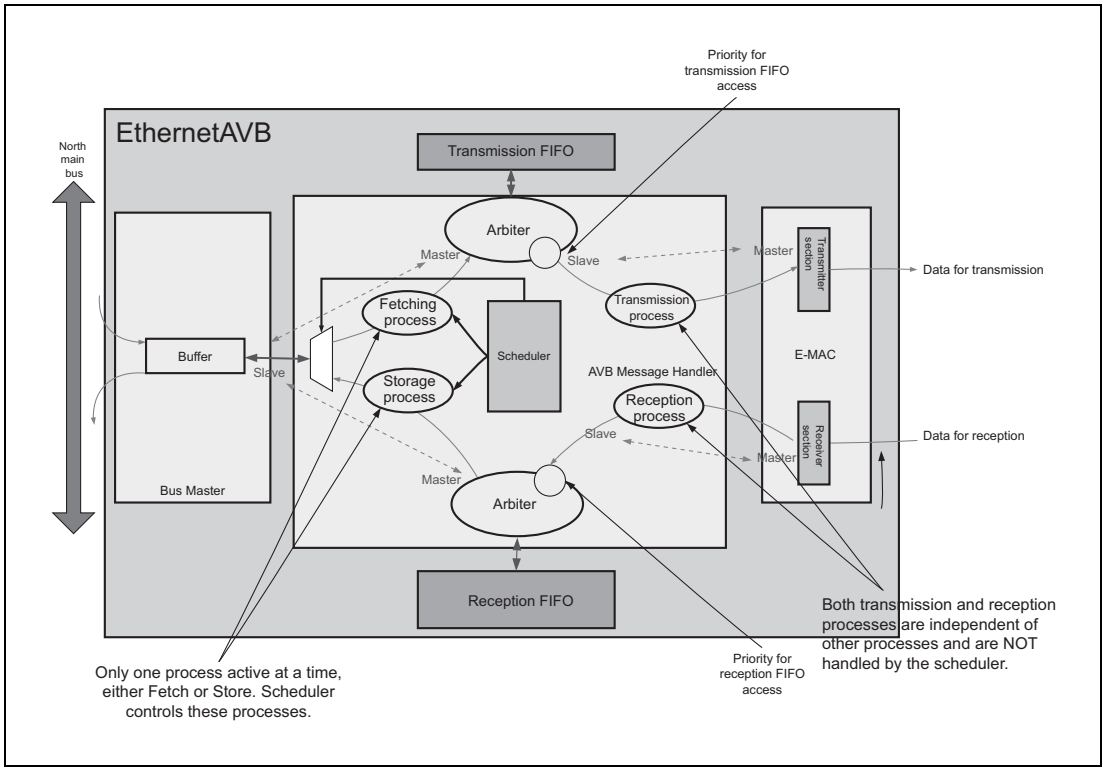

**Figure 57.12 Schematic View of EthernetAVB Operations in Transmission and Reception**

Storing and fetching are alternately performed. When the number of frames held by the reception FIFO reaches the warning level, storing takes precedence over fetching.

(1) Relationship between Transmission Queue Numbers and Traffic Classes

In fetching, the relationships between the transmission queues and traffic classes are fixed, so the priority specified by the transmit queue priority bits in the transmit configuration register (TGC.TQP) has no effect.

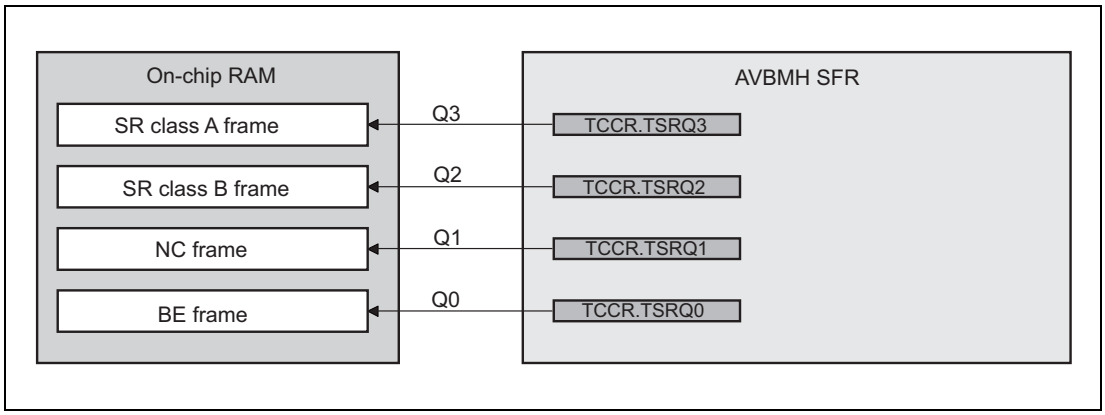

**Figure 57.13 Class Associations of Queues for the Scheduler**

In fetching, the credit values for stream classes A and B are not taken into account. Behavior depends on the setting of the transfer FIFO size configuration bits in the transfer configuration registers (TGC.TBDt).

When the transmit queue priority bits in the transmit configuration register (TGC.TQP) are B’00 or B'01, the priority order is Q3 → Q 2 → Q1 → Q0.

When the transmit queue priority bits in the transmit configuration register (TGC.TQP) are B’11, the priority order is Q1 → Q3 → Q2 → Q0.

### 57.3.2.3 Checking Integrity

The EthernetAVB is capable of detecting and identifying errors produced in the processing of Ethernet frames and in the transfer of frame data for transmission and reception.

(1) Items for Monitoring in Both Reception and Transmission

(a) Errors in access to the on-chip RAM for reading of descriptors

- The error type bits (ESR.ET) are set to B'0000, and the queue number being processed is set to the error queue number bits (ESR.EQN).
- The same descriptor may be processed again because the current descriptor address (CDARq.CDA) was not changed.
- If this problem occurs in a divided frame, the sequence may be broken.

**In reception**

- The received frame will be lost.
- The same problem will occur for the next frame of data received for the same queue.

**In transmission**

- The transmit start request bit in the transmit configuration control register (TCCR.TSRQt) is set to 0.
- The frame will be lost from the transmission FIFO.

(b) Illegal configuration of a descriptor

- The error type bits (ESR.ET) are set to B'0010, and the queue number being processed is set to the error queue number bits (ESR.EQN).
- The same descriptor may be processed again because the current descriptor address (CDARq.CDA) was not changed.
- If this problem occurs in a divided frame, the sequence may be broken.

**In reception**

- The received frame will be lost.
- The same problem will occur for the next frame of data received for the same queue.

**In transmission**

- The transmit start request bit in the transmit configuration control register (TCCR.TSRQt) is set to 0.
- The frame will be lost from the transmission FIFO.

(c) Errors in access to the on-chip RAM for writing of descriptors

- The error type bits (ESR.ET) are set to B'0001, and the queue number being processed is set to the error queue number bits (ESR.EQN).
- As in the case where no error occurs, the current descriptor address (CDARq.CDA) and the transmit start request bit in the transmit configuration control register (TCCR.TSRQt) are updated.

- As DESCR.DT was not updated, hardware and software synchronization may have been lost.

(2) Items for Monitoring in Reception

(a) Errors in access to the on-chip RAM for writing of data or time stamps

- The error type bits (ESR.ET) are set to B'0101, and the queue number being processed is set to the error queue number bits (ESR.EQN).
- As in the case where no error occurs, the current descriptor address (CDARq.CDA) is updated.
- DESCR.EI is set to 1 to indicate error detection.
- This problem occurring in a divided frame may break the descriptor sequence, making the queue unusable.

(b) Overflow of the Reception FIFO

- The reception FIFO full interrupt status bit (RIS2.RFFF) is set to 1.
- The received frames are all invalidated. The frames stored in the reception FIFO must be discarded according to the following procedure.

1. Stop reception and enter configuration mode according to the flow shown in Figure 57.7, Flow for Transitions of Operating Mode (from Operation Mode to Configuration Mode).
2. Discard all the unprocessed received data stored in the on-chip RAM.

(3) Items for Monitoring in Transmission

(a) Errors in Access for Reading Data from the on-chip RAM

- The error type bits (ESR.ET) are set to B'0100, and the queue number being processed is set to the error queue number bits (ESR.EQN).
- Data that have already been fetched are discarded from the transmission FIFO.
- When an error of this type occurs during processing of an FSINGLE or FEND descriptor:
  As in the case where no error occurs, the current descriptor address (CDARq.CDA) and the transmit start bit in the transmit configuration control register (TCCR.TSRQt) are updated. Fetching resumes after the error frame.
- When an error of this type occurs during processing of an FSTART or FMID descriptor:
  - The current descriptor address (CDARq.CDA) is not updated.
  - The transmit start bit in the transmit configuration control register (TCCR.TSRQt) is set to 0.

(b) Overflow of the Transmission FIFO

- The error type bits (ESR.ET) are set to B'1010, and the queue number being processed is set to the error queue number bits (ESR.EQN).
- As in the case where no error occurs, the current descriptor address (CDARq.CDA) and the transmit start bit in the transmit configuration control register (TCCR.TSRQt) are updated. Fetching resumes after the error frame.
- The frame will be discarded from the FIFO.

(c) Frame size error during transmission

- The error type bits (ESR.ET) are set to B'1001, and the queue number being processed is set to the error queue number bits (ESR.EQN).
- As in the case where no error occurs, the current descriptor address (CDARq.CDA) and the transmit start bit in the transmit configuration control register (TCCR.TSRQt) are updated. Fetching resumes after the error frame.

A transmit frame size error is detected when the size setting in one or more (in the case of a divided frame) descriptors for frame transmission is more than 1996 bytes. Such frames are cut out and transmitted.

## 57.3.3 Descriptors

### 57.3.3.1 Data Representation in On-chip RAM

The AVB-DMAC transfers data for transmission and received data to and from the application software via the on-chip RAM.

Control structures referred to as descriptors and the frame data referred to as descriptor data area are allocated to the on-chip RAM. Dividing into a control area and data area allows the flexible allocation of frame data to the on-chip RAM.

Figure 57.14 shows an example of the memory maps for descriptors and the descriptor data area in the on-chip RAM.

A descriptor consists of its type (DESCR.DT), which controls the descriptor functions, a descriptor pointer (DESCR.DPTR) indicating the start address for storage of the frame data in the descriptor area, and the data size field (DESCR.DS), indicating the amount of frame data. Post-processing interrupt generation can be set up for each descriptor. Enabling and disabling of the interrupt is controlled by the descriptor interrupt enable bits (DESCR.DIE).

The descriptor may also hold information related to content. This information does not affect general descriptor functions. It provides information other than the frame data proper, such as on the state of reception.

For details, see Section 57.3.4.2, Setting Up Reception Descriptors, and Section 57.3.5.2, Setting Up Transmission Descriptors.

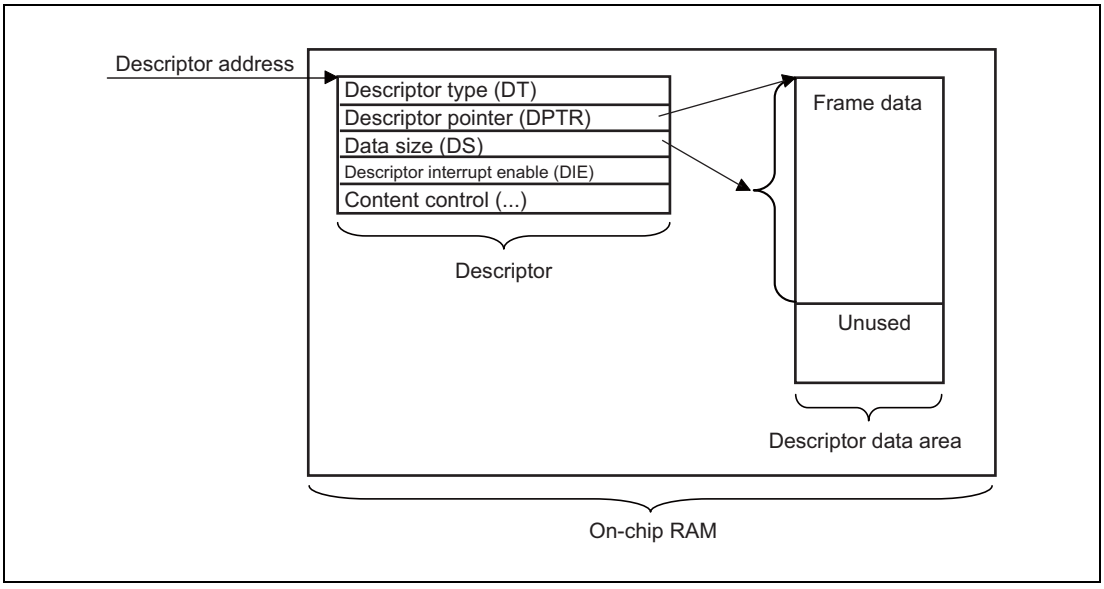

**Figure 57.14 Example of On-chip RAM Memory Map**

The descriptor must be aligned with a 32-bit boundary in the on-chip RAM.

Descriptors are generally configured of 64 bits, but are configured of 160 bits when reception and storage of gPTP time stamps is enabled.

The frame data must also be aligned with a 32-bit boundary in the on-chip RAM.

The amount of data in the frame is defined by the data size bits (DESCR.DS). In reception, these bits indicate the upper limit on the size of frames to be received. If the data size is not aligned with a 32-bit boundary, the bytes to the next 32-bit boundary in the data area will be an unused area.

### 57.3.3.2 Using Descriptor Chains in Queues

Transmission and reception descriptors in the on-chip RAM are grouped into queues. Each queue handles frames so that they are transmitted in order of priority and received separately. A queue is capable of controlling one or more frames. Accordingly, multiple descriptors can be assigned to one queue. A combination of multiple descriptors is referred to as a descriptor chain.

For a descriptor chain, the three general descriptor types listed below are defined. For details on these descriptor types, see Section 57.3.3.6, Descriptor Type.

- Descriptors that define frame data
- Descriptors that control the descriptor chain itself (e.g. LINK, EOS).
- Descriptors that arbitrate access by hardware or software

Figure 57.15 shows the two basic topologies for descriptor chains. In the simplified examples in the figure, all descriptors allocated to the chain are stored in the array.

- For a linear descriptor chain, the last descriptor in the array is a control descriptor indicating the end of the descriptors (e.g. EEMPTY).
- For a cyclic descriptor chain, the last descriptor in the array is a control descriptor that returns to the first descriptor in the array (e.g. LINK).

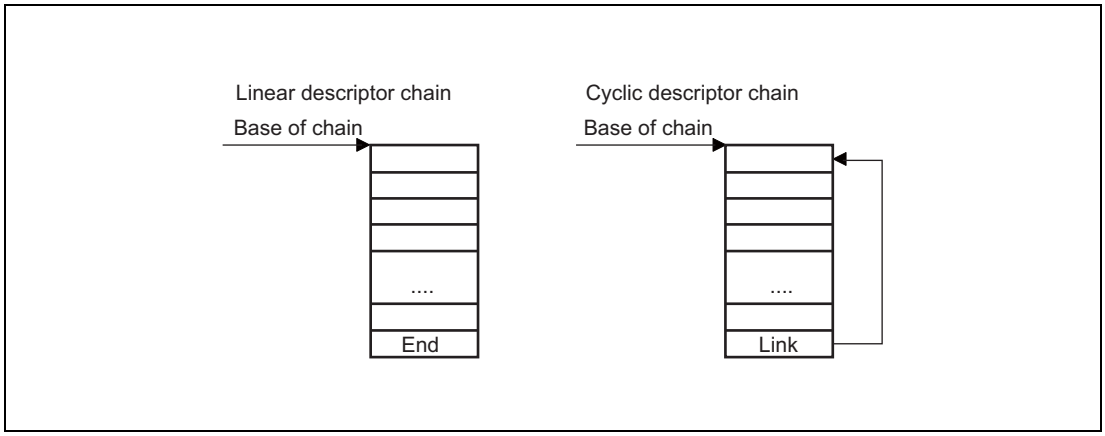

**Figure 57.15 Outline of the Basic Descriptor Chains**

The relationship between queues and descriptor chains is defined by the base addresses of chains. A queue is connected to one descriptor chain over one round of processing. There is also a method of switching to a different chain while in operation mode.

There are no restrictions on the number of link descriptors and their locations within the chain. The last descriptor of a designed chain determines the topology.

Which chain structure is to be used or which topology is suitable depends on the application. A description of how to design descriptor chains to suit various applications is given in Section 57.3.4.2. Procedure for Setting Reception Descriptors, and Section 57.3.5.2, Setting Up Transmission Descriptors.

### 57.3.3.3 Descriptor Base Address Table

The base address table in the on-chip RAM contains the address of the first descriptor of all chains to be handled by the respective queues.

Entries 0 to 3 are used to access transmission queues 0 to 3. Subsequent entries are used to access reception queues. Entry 4 thus corresponds to reception queue 0.

The configuration of entries in the base address table is the same as the configuration of link descriptors. We recommend using the descriptor type (DESCR.DT) LINKFIX. Processing of this link descriptor does not change it, so it does not require updating. The first descriptor of a chain performs hardware and software synchronization. If the application requires hardware and software synchronization for the base addresses, use the descriptor type (DESCR.DT) LINK.

The CPU is only capable of using LINKFIX and LINK as descriptor types (DESCR.DT) of descriptors in the base address table.

Set the location of the base address table in the on-chip RAM in the descriptor base address table register (DBAT).

Figure 57.16 shows an example of a base address table for controlling four transmission and three reception queues. The boxes to the right of the table represent descriptor chains with the desired topologies.

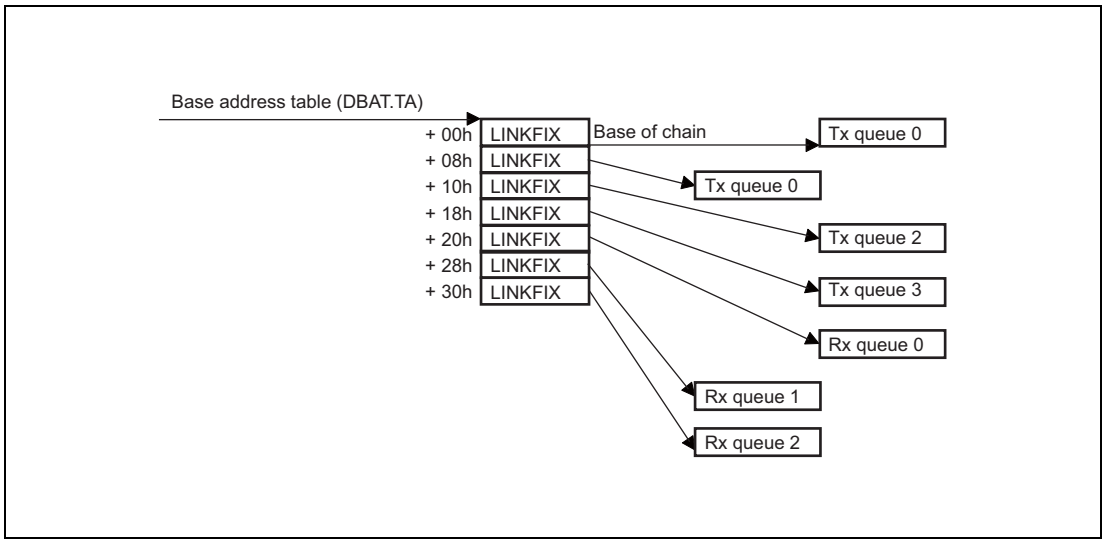

**Figure 57.16 Example of a Base Address Table for Reception and Transmission Queues**

CAUTION

The size of the descriptors in the base address table is always eight bytes even if the queue itself includes extended descriptors.

#### 57.3.3.4 Descriptor Chain Processing

When a descriptor is currently being processed or the queue for a descriptor is active, the current descriptor is a descriptor to be processed. The current descriptor address for use by a queue q can be checked in the current descriptor address register q (CDARq).

Current descriptors are:

- set in the descriptor base table address bits (DBAT.TA) +8*q for all q queues when the operating mode shifts to operation mode.
- set in the descriptor base table address bits (DBAT.TA) +8*q when a base address load request is issued for a queue q by setting the corresponding bit (DLR.LBAq) in the descriptor base address load request register (DLR).
- set in DESCR.DPTR for a link descriptor (LINK, LINKFIX) to be processed.
- incremented by the size of the descriptors (8 bytes for normal descriptors and 20 bytes for extended descriptors) after a descriptor has been processed. In this case, the AVB-DMAC updates the descriptor type and informs the CPU that the descriptor has been processed.

In other cases (for illegal descriptor processing and so on), the current descriptor address register q (CDARq) is not updated.

### 57.3.3.5 Descriptor Interrupts

A descriptor is able to issue a descriptor interrupt on completion of its processing. The setting of the descriptor interrupt enable bits (DESCR.DIE) in each descriptor can disable the descriptor interrupts or select the specific descriptor interrupt to be generated.

The descriptor interrupt is a common resource that is shared between reception and transmission queues.

Figure 57.17 illustrates the way in which the AVB-DMAC generates descriptor interrupts (or sets bits in the descriptor interrupt status register (DIS.DPFi)). Processing of a descriptor with the value i in the descriptor interrupt enable bits (DESCR.DIE) leads to the corresponding bit in the descriptor interrupt status register (DIS.DPFi) being set.

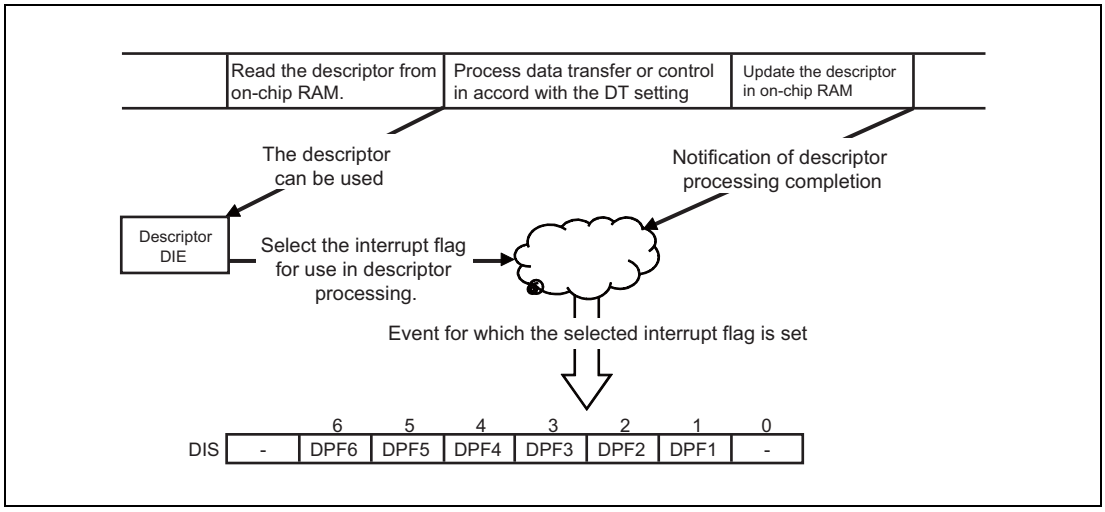

**Figure 57.17 Method of Descriptor Interrupt Generation**

#### 57.3.3.6 Descriptor Type

The descriptor types (indicated by the DESCR.DT bits) supported by the AVB-DMAC fall into the following three categories.

- Definitions of frame data
- Control of descriptor chains
- Hardware and software arbitration

Table 57.70 is a summary of the descriptor types available for the AVB-DMAC. Entries under “Name” are the names of the descriptor types and the values under “DT” are the corresponding values to be set in the descriptor type field (DESCR.DT). A given descriptor may be handled differently according to whether it is in a transmission or reception queue, so the transmission and reception columns list the scopes of control and processing of the descriptor types.

The abbreviations defined below are used in the transmission and reception columns.

**Definition of SW:**

- The descriptor is processed by software.
- Software has access to and may modify the descriptor and descriptor data area.
- This descriptor cannot be changed by hardware (AVB-DMAC).

**Definition of HW:**

- The descriptor is processed by hardware (AVB-DMAC).
- Software must modify neither the descriptor nor the descriptor data area.
- Hardware (AVB-DMAC) processes this descriptor and subsequently changes the descriptor type.

**Invalid:**

This descriptor type is not used in transfer in the given direction (transmission or reception).

Do not write this value to the descriptor type (DESCR.DT) field for transfer in the given direction.

Hardware does not process these descriptor types in the cases listed as invalid. The current descriptor address (CDARq.CDA) will not be changed when processing of a queue for the given direction arrives at a descriptor with this type setting.

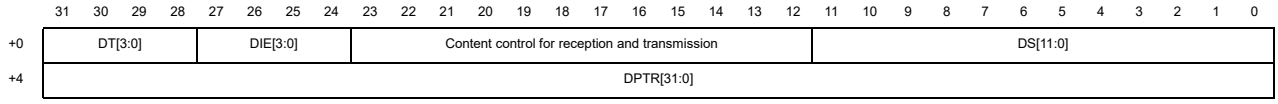
### (1) Layout of General Descriptors in the On-chip RAM

The AVB-DMAC updates processed descriptors in the on-chip RAM. The field to be changed in a descriptor being updated depends upon whether the direction is transmission or reception and the queue mode. Other fields will not be changed. There are no restrictions on the values set in unused descriptor fields (indicated by "—" in the figure).

### (2) Frame Data Descriptors

The allocation of bits in the frame data descriptors (FSTART, FMID, FEND, and FSINGLE) is shown below.

- Normal descriptor (usable in both reception and transmission)



- Extended descriptor (usable only in reception)

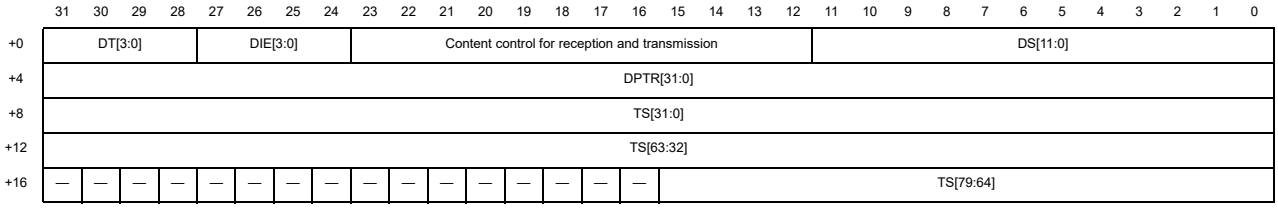


**Table 57.71 Contents of Frame Data Descriptors (DESCR)**

| Bit Name | Function |

| TS[79:0] | Time Stamp<br>Time stamp of the received frame (only available in extended descriptors) |

CAUTION

Register an address aligned with a 32-bit boundary as the descriptor pointer (DESCR.DPTR).

H'0000 is written to the reserved bits in an extended descriptor (bits 31 to 16 in DESCR) when the time stamp is stored.

(3) Hardware/Software Arbitration Descriptors (Only for Reception)

The allocation of bits in the descriptors for hardware/software arbitration (FEMPTY, FEMPTY_IS, FEMPTY_IC, and FEMPTY_ND) is shown below.

- Normal descriptor

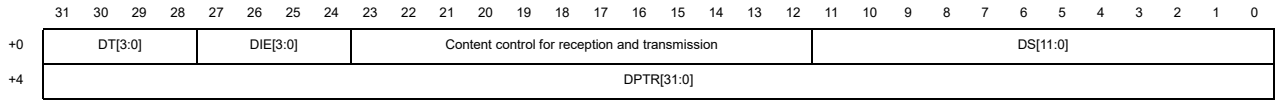

**Table 57.72 Contents of Hardware/Software Arbitration Descriptors (DESCR)**

| Bit Name | Function |
|---|---|
| DT[3:0] | Descriptor Type<br>12: FEMPTY<br>13: FEMPTY_IS<br>14: FEMPTY_IC<br>15: FEMPTY_ND<br>For details, see Table 57.70, Summary of Descriptor Types. |
| DIE[3:0] | Descriptor Interrupt Enable<br>B'0000: Descriptor interrupt is disabled.<br>B'0001 to B'1111: The corresponding descriptor interrupt is generated (DIS.DPFi). |

| DS[11:0] | Data Size<br>Size of the data area/frame data for the descriptor (in bytes) |
| DPTR[31:0] | Descriptor Pointer<br>Pointer to the data area for the descriptor<br>Register an address on a 32-bit boundary. |

CAUTIONS

Register an address aligned with a 32-bit boundary as the descriptor pointer (DESCR.DPTR).

When an extended descriptor is used, a 12-byte unused area is added.

In an FEMPTY descriptor, the descriptor type (DT), descriptor interrupt enable (DIE), data size (DS), and descriptor pointer (DPTR) fields are used.

In an FEMPTY_IS descriptor, the descriptor type (DT), descriptor interrupt enable (DIE), and descriptor pointer (DPTR) fields are used.

In an FEMPTY_IC descriptor, the descriptor type (DT) and descriptor interrupt enable (DIE) are used.

In an FEMPTY_ND descriptor, the descriptor type (DT), descriptor interrupt enable (DIE), and data size (DS) are used.

(4) Link Descriptors

The allocation of bits in the link descriptors (LINK and LINKFIX) is shown below.

- Normal descriptor

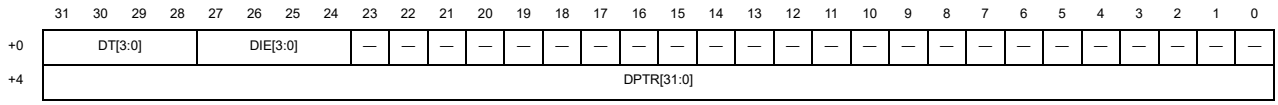

**Table 57.73 Contents of Link Descriptors (DESCR)**

| Bit Name | Function |
|---|---|
| DT[3:0] | Descriptor Type<br>8: LINK<br>9: LINKFIX<br>For details, see Table 57.70, Summary of Descriptor Types. |

| DPTR[31:0] | Descriptor Pointer<br>Pointer to the data area for the next descriptor<br>Register an address on a 32-bit boundary. |

CAUTION

Register an address aligned with a 32-bit boundary as the descriptor pointer (DESCR.DPTR).

When an extended descriptor is used, a 12-byte unused area is added.

### (5) Other Descriptors

The allocation of bits in the other descriptors (EOS, FEMPTY (only for transmission), LEMPTY, and EEMPTY) is shown below.

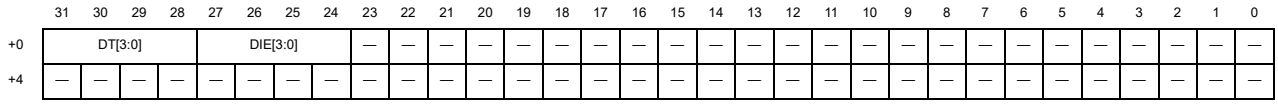

**Table 57.74 Contents of Other Descriptors (DESCR)**

| Bit Name | Function |
|---|---|
| DT[3:0] | Descriptor Type<br>10: EOS<br>12: FEMPTY (only for transmission)<br>2: LEMPTY<br>3: EEMPTY<br>For details, see Table 57.70, Summary of Descriptor Types. |
| DIE[3:0] | Descriptor Interrupt Enable<br>B'0000: Descriptor interrupt is disabled.<br>B'0001 to B'1111: The corresponding descriptor interrupt is generated (DIS.DPFi). |

CAUTION

When an extended descriptor is used, a 12-byte unused area is added.

### (6) How to Use Frame Data Descriptors

The descriptor data area size field (DESCR.DS) can specify up to 2048 bytes of Ethernet frame data per data area. Settings higher than 2048 (bytes) cannot be made.

In general, Ethernet frames are not of uniform length. The AVB-DMAC is capable of dividing frame data into multiple descriptors in order to minimize the memory capacity for frame data. This function allows processing of frames that are longer than the limit for descriptor data areas. Division can also be applied to frames on the basis of their data structures.

To handle both frames divided up into multiple data areas and descriptors for complete single frames, four types (DESCR.DT) FSTART, FEND, FMID, and FSINGLE are defined.

Figure 57.18 shows the mapping of frame data by frame data descriptors. The descriptor data areas are allocated to the on-chip RAM. For frames that require division into four or more data areas, additional FMID descriptors can be added as required.

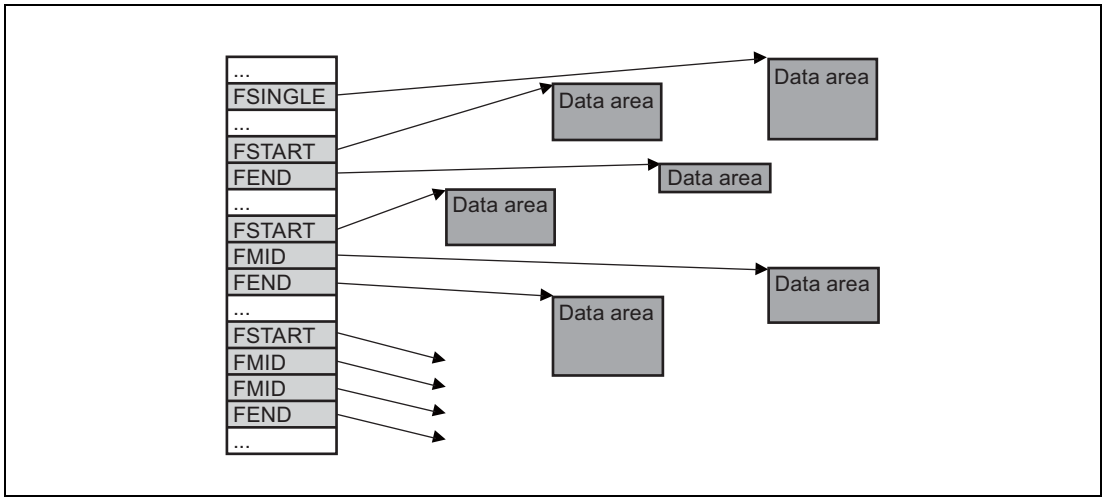

**Figure 57.18 Mapping of Frame Data**

For reception, set the descriptor data areas to the maximum size (i.e. give DESCR.DS its maximum value). The AVB-DMAC will store received frame data in the given area. If a received frame has more data than the maximum size, the AVB-DMAC will divide the data up.

For transmission, set the frame data size to the actual data size. The AVB-DMAC modifies the descriptor type (DESCR.DT) to FEMPTY after processing the relevant descriptor. The data size (DESCR.DS) and descriptor pointer (DESCR.PTR) fields retain their settings.

A descriptor data area including unused space produces an empty space between data areas. In reception, an "incremental data area" can be used to prevent empty spaces. For incremental data areas, see Section 57.3.4.3 (2) Incremental Data Areas.

As well as reducing the memory capacity taken up by the descriptor area in the on-chip RAM, division into frames can be used to identify different sections of data (e.g. for separating a header and data).

### (7) How to Use Chain Control Descriptors

#### (a) Link Descriptors

The link descriptors can be used to set up cyclic descriptor chains (for details, see Section 57.3.3.2, Using Descriptor Chains in Queues).

After a LINK descriptor is processed, its descriptor type (DESCR.DT) is changed to LEMPTY. The descriptor pointer (DESCR.PTR) retains its setting.

After processing of a LINKFIX descriptor, the descriptor type (DESCR.DT) is not updated. Software can change the descriptor type (DESCR.DT), descriptor interrupt enable (DESCR.DIE), and descriptor pointer (DESCR.DPTR). Take care, however, to check the current descriptor address register (CDARq.CDA) before changing the descriptor pointer (DESCR.DPTR).

#### (b) EOS Descriptor

Use the EOS descriptor to divide a descriptor chain into various segments. The queue can continue even after an EOS descriptor.

In transmission, the response to an EOS descriptor is clearing of the transmit start request bit in the transmit configuration control register (TCCR.TSRQq) to 0.

In reception, the response is generation of a receive queue full interrupt (RIS2.QFFr), although if the frame currently being received is being divided for storage (received data being stored in FMID- or FEND-type frames), the data are not completely stored.

### (8) How to Use Hardware and Software Arbitration Descriptors

In hardware processing of descriptors, the empty descriptor types (FEMPTY, LEMPTY, and EEMPTY) are defined to distinguish various descriptors. For software, they can be used to initiate checking for empty spaces, etc.

#### (a) FEMPTY, FEMPTY_IS, FEMPTY_IC, and FEMPTY_ND

These descriptor types (DESCR.DT) are used for descriptors that do not contain effective data. Of these, only FEMPTY is used in transmission.

These descriptor pointers (DESCR.DPTR) indicate the descriptor data area.

#### (b) LEMPTY

This descriptor type (DESCR.DT) is assigned to LINK descriptors after they have been processed.

The descriptor pointer (DESCR.DPTR) of an LEMPTY descriptor still points to the linked descriptor.

#### (c) EEMPTY

This descriptor type (DESCR.DT) is assigned to EOS descriptors after they have been processed.

The descriptor pointer (DESCR.DPTR) of an EEMPTY descriptor is not used, and thus points to nothing.

(9) Relationship between Descriptor Access by Hardware and Software

In the EthernetAVB, the allocation of descriptor types (DESCR.DT) to the on-chip RAM can be used. This makes it possible to minimize access to the EthernetAVB registers via the CPU, leading to higher performance.

- Each descriptor type in the set is exclusively for processing by hardware or software, depending on the direction of transfer (see Table 57.70, Summary of Descriptor Types).
- Software must not change a descriptor assigned to hardware processing (the hardware does not change descriptors assigned to software processing).

In the case of software processing, the software must process the information in the descriptor and the corresponding frame data before changing the descriptor type. If a descriptor type for hardware is set in DESCR.DT, the software should not change any part of the descriptor or of the corresponding frame data.

### 57.3.3.7 Optimization of Bus Performance when Using Descriptors

The following items are recommended as ways to ensure the optimal use of data structures in the on-chip RAM.

They are not requirements, but using a different approach may increase the load on the system bus within the LSI chip.

- Register descriptors with 64-bit alignment (this does not apply to extended descriptors).
- While in operation mode, use LINKFIX instead of LINK whenever a descriptor need not be changed. Hardware modifies the descriptor type (DESCR.DT) fields of LINK descriptors.
- Restrict frame data to a maximum size of 128 bytes.
- Minimize parallelism of processing to the descriptor chains.
  This helps in arranging the different segments exclusively for access by software or hardware by dividing the chains so as to be allocated to different on-chip RAM pages.
- Minimize the number of divided frames. This can reduce the overhead of descriptor handling.

### 57.3.4 Control in Reception

The point of the AVB-DMAC is to transfer data between the E-MAC and on-chip RAM without intervention by the CPU.

Create descriptors that define the amounts of frame data to be stored and the locations. After the E-MAC receives a frame, it stores the received frame data and the conditions of reception as the MAC state. If the descriptor is extended, the time stamp is also stored. For a description of how to set up descriptors for use in reception, see Section 57.3.4.2, Setting Up Reception Descriptors.

The AVB-DMAC filters received frames to separate them into various classifications (separation filtering). More specifically, this is done to separate received frames into the various reception queues and to set the priorities of different classes of received frames. For more on separation filtering, see Section 57.3.4.1 (1) Separation Filtering.

Figure 57.19 shows the reception data bus and the selection of queues for use in reception.

Each frame received from the E-MAC is stored in the reception FIFO; in parallel with this, the frame is analyzed to identify its type and the target queue number. After the E-MAC completes reception, the target queue number is generated and stored in the reception FIFO. A reception flag is applied to each reception queue in the on-chip RAM, and the unread frame counter (UFC) is also applied to each reception queue.

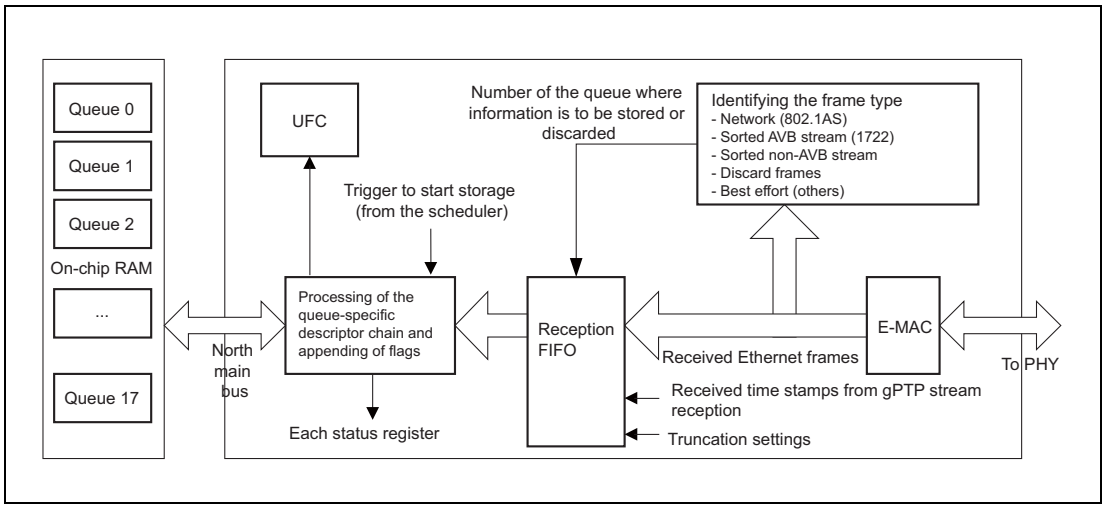

**Figure 57.19 Mechanism of General Reception Queue Selection**

### 57.3.4.1 Reception Queues

The AVB-DMAC applies its separation filtering mechanism to select the reception queue for storing a received frame. The AVB-DMAC stores all received frames in the on-chip RAM.

There are two conditions for the AVB-DMAC to discard a received frame.

- Detection of an error during reception by the E-MAC
  - Whether error frames are discarded or stored in reception queue 0 (best effort) can be set by the error frame enable bit in the receive configuration register (RCR.EFFS). If error frames are to be stored (RCR.EFFE = 1), they are always stored in queue 0 (best effort). In this case, parameters of each queue (e.g. truncation) may not match. If the storage of time stamps for reception queue 0 (best effort) is enabled (the time stamp enable bit in the receive configuration register RCR.ETS0 = 1), time stamps are stored even for error frames.
- Non-matching determination conditions of the separation filter
  - Whether non-matching frames are discarded or stored in reception queue 0 (best effort) can be set by the stream filtering select bit in the receive configuration register (RCR.ESF).

The flowchart in Figure 57.20 shows how the AVB-DMAC selects the reception queue in accord with the frame type, including judgment by the separation filter. Selection of the queue starts when the E-MAC completes frame reception. The result is storage of the frame in the proper queue or the frame being discarded.

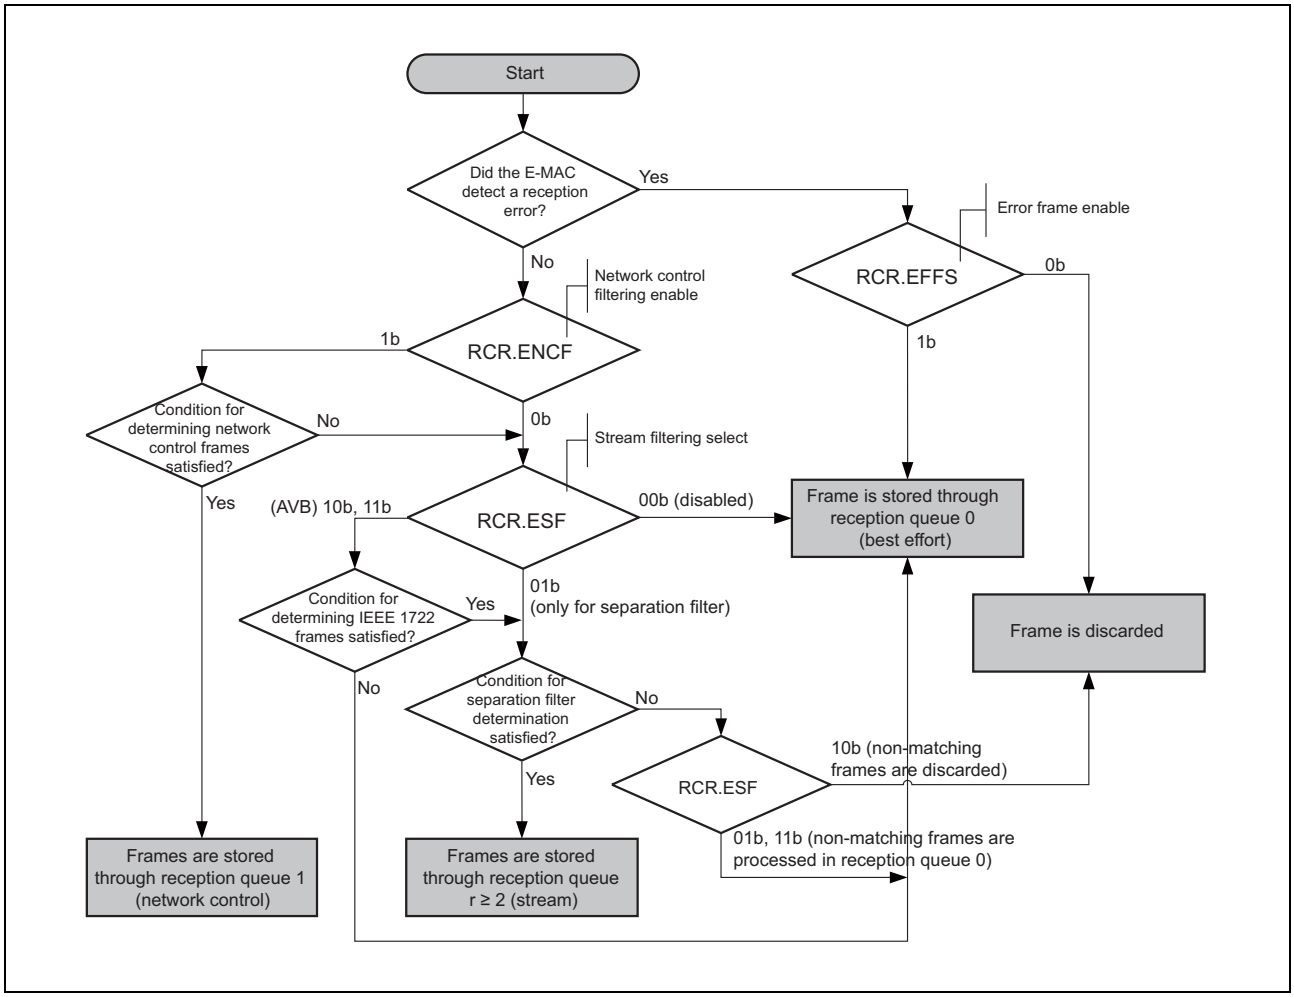

**Figure 57.20 Flow of Reception Queue Selection**

**Notes on the description of entries in the flowchart**

- “Condition for determining network control frames”
  The Ethernet destination address (DA) is 01:80:C2:00:00:0E, and
  The Ethernet type (ET) is 88:F7.
- “Condition for determining IEEE 1722 frames”
  The Ethernet destination address (DA) is in the range from 91:E0:F0:00:00:00 to 91:E0:F0:00:FE:FF,
  The VLAN tagged TPID (tag protocol identifier) field (VL) is 81:00, and
  The Ethernet type (ET) is 22:F0.
- “Condition for separation filter determination”
  See Section 57.3.4.1 (1) Separation Filtering.

Figure 57.21 shows the allocation of data in Ethernet frames used for determination of Network Control frame and IEEE1722 frame. The preambles of Ethernet frames are not taken into account.

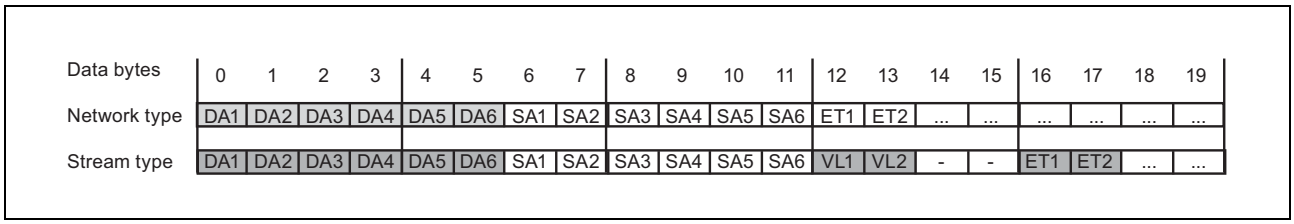

**Figure 57.21 Data Allocation of Ethernet Frames Used in Frame Determination**

### (1) Separation Filtering

Separation filtering involves the checking of 64 bits (eight successive bytes) in received Ethernet frames. The setting for the first byte (i.e. the setting of the separation filter offset configuration register (SFO.FBP)), selects the part of frames to be used in separation filtering. There is also a common filter mask (set in the separation filter mask configuration register (SFMi.CFM)) that can filter less than the number of bytes and mask particular bits.

**Examples**

To use only the first byte from the top in separation filter, set separation filter mask configuration register 0 (SFM0.CFM) to H’0000 00FF and separation filter mask configuration register 1 (SFM1.CFM) to H’0000 0000.

To use seven bytes from the top in separation filter, set separation filter mask configuration register 0 (SFM0.CFM) to H’FFFF FFFF and separation filter mask configuration register 1 (SFM1.CFM) to H’00FF FFFF.

CAUTION

If bits are set to 0 in the separation filter mask, in order to match with the pattern, the bits at the corresponding positions of the pattern must also be set to 0. Only when "the received frame data & the separation filter mask register (SFMi.CFM) = the separation filter pattern register (SFPi.FPs)", it is judged that the bits match with the pattern.

Figure 57.22 shows separation filtering. The selected data from a received frame (Rx_Frame[63:0]) are masked by the common filter mask. This value is compared with all filter patterns. The AVB-DMAC selects the queue having the smallest queue number from among the matched filter patterns.

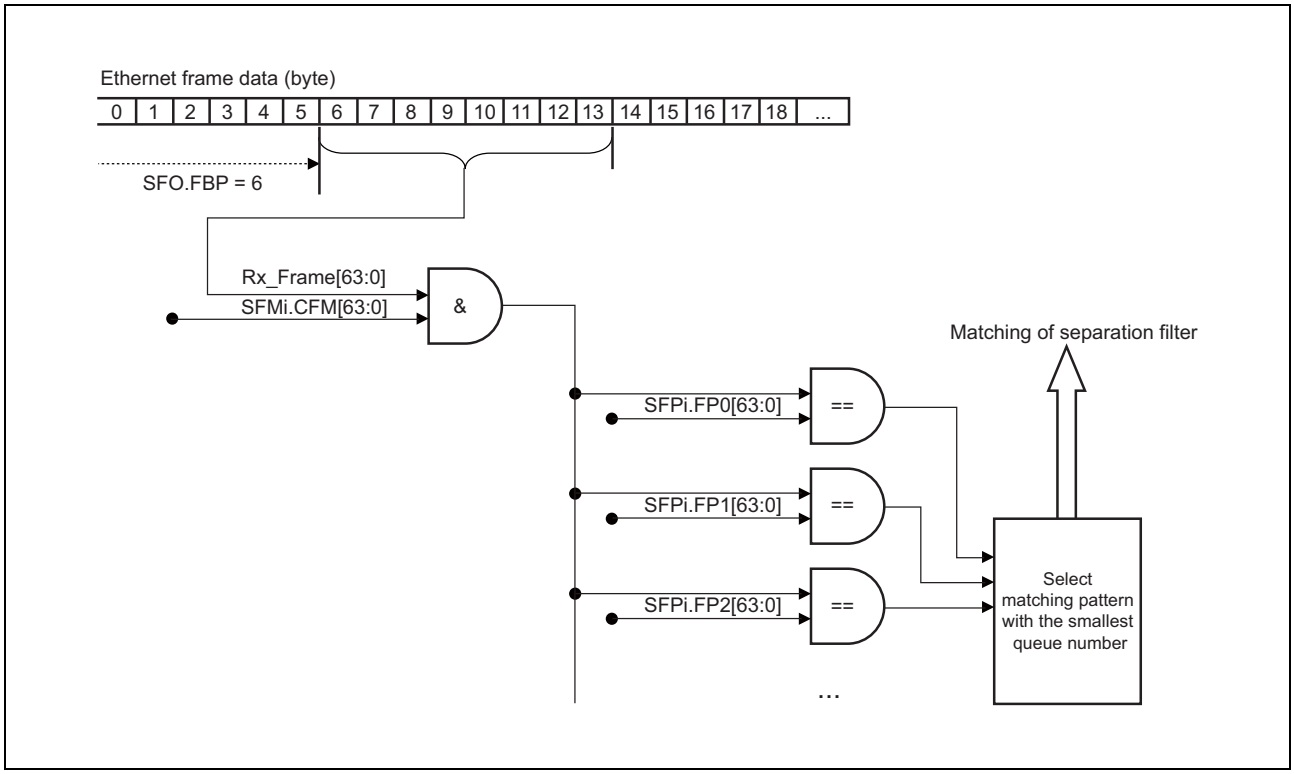

**Figure 57.22 Overview of Separation Filtering (when SFO.FBP = 6)**

### (a) Restrictions on Number of Filters Used

The AVB-DMAC always checks all the separation filter patterns. When it is not necessary to use all the reception queues, providing a special pattern can prevent data from being stored in the unused reception queue.

Example 1:
Setting a value other than H'FFFF_FFFF_FFFF_FFFF to the separation filter mask register (SFMi.CFM) and setting H'FFFF_FFFF_FFFF_FFFF to the separation filter pattern register (SFPi.FPs) can prevent pattern matching in the unused reception queue.

Example 2:
Setting H'FFFF_FFFF_FFFF_FFFF to the separation filter mask register (SFMi.CFM) and setting the value identical to the pattern in reception queue 2 to the separation filter pattern register (SFPi.FPs) selects, upon a pattern matching, reception queue 2, which has a smaller queue number, thus preventing the unused reception queue from being used.

### (2) Separating Streams

The AVB-DMAC applies separation filtering to sort frames received in streams. An AVB network has a concept of “Talker” and “Listener”. A Talker is an end station that generates one or more streams. A Listener is an end station that has the role of being a sink for at least one stream. The various A/V streams are identified by 8-byte stream IDs.

The number of end stations within an ABV network and their roles differ with the application.

The stream ID is a specific pattern of the AVB network for identifying one stream. Figure 57.23 shows the bit allocation of bits in IEEE1722 Ethernet frames and stream ID fields.

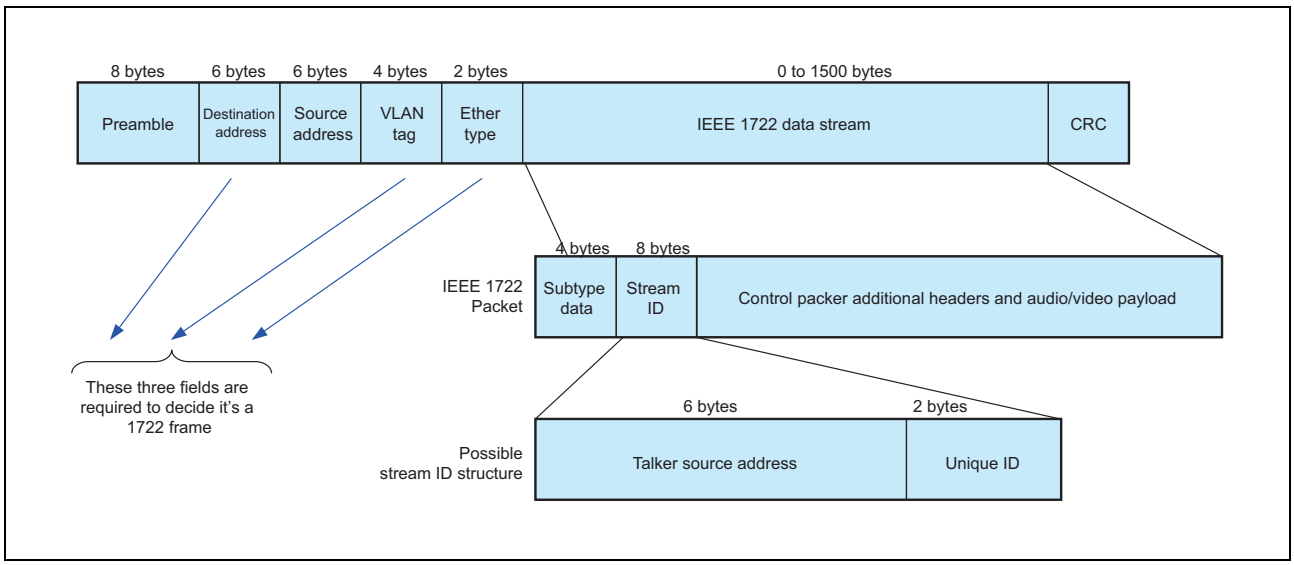

**Figure 57.23 IEEE 1722 Frame Layout and Stream ID**

The IEEE 1722 standard stipulates that the stream ID field starts from the 22nd byte (not counting the preamble). Accordingly, set the separation filter offset (SFO.FBP) to 22 in separations on IEEE 1722 streams. Set the separation filter mask (SFMi) and separation filter pattern (SFPi) in accord with the specification of the application in which the chip is being used.

Example: In the example of a stream ID shown in Figure 57.23, the representative application divides the field into the talker source address and the unique stream ID. The unique ID is used to differentiate between multiple streams from the same talker. Based on this, there are two settings for separation filter masking:

- To divide various streams into individual queues, set SFM0.CFM to H’FFFF FFFF and SFM1.CFM to H’FFFF FFFF.
- To divide streams for each talker into individual queues, set SFM0.CFM to H’FFFF FFFF and SFM1.CFM to H’0000 FFFF. This excludes the unique ID from the filter condition.

### 57.3.4.2 Setting Up Reception Descriptors

For reception, the descriptor as described in Section 57.3.3, Descriptors is used.

This section describes specific operations that are especially required in handling reception queues.

#### (1) Reception Descriptor Type

The type of a descriptor is defined by the descriptor type (DESCR.DT) field.

Table 57.75 shows the descriptor types used in reception. In the table, entries in the write-back column indicate how the AVB-DMAC changes the DESCR.DT field upon completion of descriptor processing.

**Table 57.75 Descriptor Types in Reception**

| Descriptor Type (DESCR.DT) | Operation | Write-back |
|---|---|---|
| **Frame Start** (FSTART) | There is no storage space in a reception queue:<br>The RIS2.QFFr bit indicates that queue r is full and the received frame is not stored.<br>Descriptor processing proceeds again in response to further reception. | Not changed |
| **Frame Middle** (FMID) | Same as FSTART | Not changed |
| **Frame End** (FEND) | Same as FSTART | Not changed |
| **Frame Single** (FSINGLE) | Same as FSTART | Not changed |
| **Link** (LINK) | Processing proceeds to the descriptor specified by DESCR.DPTR. | LEMPTY |
| **Fixed Link** (LINKFIX) | Same as LINK | Not changed |
| **End Of Set** (EOS) | In the case of a divided frame (received frame being stored in FMID or FEND), storing of frames is stopped and the frame is lost. RIS2.QFFr indicates that the frame has been lost.<br>If this happens at the start of a frame (received frame being stored in FSTART or FSINGLE), storing of frames starts from the next descriptor.<br>In either case, processing shifts to the next descriptor in the chain. | EEMPTY |
| **Frame Empty** (FEMPTY) | Used to store received data.<br>Up to DESCR.DS bytes are stored in the descriptor data area.<br>For details, see Section 57.3.4.3 (1) Storing Frame Data in the Descriptor Data Area. | FSTART, FMID, FEND, or FSINGLE |
| Frame Empty Incremental Start (FEMPTY_IS) | Used to store received data.<br>The remaining frame data are all stored in the descriptor's data area.<br>DESCR.DPTR indicates the base address of the incremental data area.<br>For details, see Section 57.3.4.3 (2) Incremental Data Areas. | FEND or FSINGLE |
| Frame Empty Incremental Continue (FEMPTY_IC) | Used to store received data.<br>The remaining bytes of frame data are all stored in the descriptor's data area.<br>DESCR.DPTR is undefined, but the address after processing of previous incremental data becomes the base address.<br>For details, see Section 57.3.4.3 (2) Incremental Data Areas. | FEND or FSINGLE |
| Frame Empty No Data storage (FEMPTY_ND) | Used to store received data.<br>DESCR.DS bytes of spaces are secured in the reception FIFO but not stored. After processing, DESCR.DS is written back as 0.<br>For details, see Section 57.3.4.3 (2) Incremental Data Areas | FSTART, FMID, FEND or FSINGLE |
| Link Empty (LEMPTY) | Same as FSTART | Not changed |
| EOS Empty (EEMPTY) | Same as FSTART | Not changed |

If a reception FIFO read error occurs when FEMPTY_ND is used, it is not reflected in DESCR.EI and queue error interrupt status bit (EIS.QEF).

Therefore, to detect a reception FIFO error also for unnecessary data, FEMPTY should be used.

(2) Configuration of Reception Frame Data Descriptors

Figure 57.24 shows the configuration of descriptors for use with reception queues. The reception-specific fields are the same whether the descriptor is normal or extended. The reception-specific fields (DESCR.MSC, DESCR.PS, DESCR.EI, and DESCR.TR) are described in Table 57.76.

For the other fields and the descriptor types, see Section 57.3.3.6, Descriptor Type.

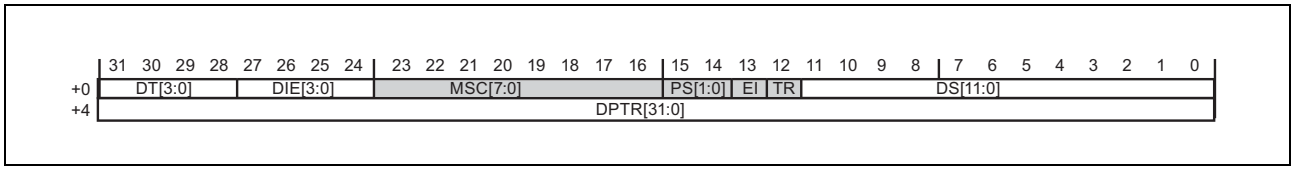

**Figure 57.24 Configuration of Descriptor for a Received Frame**

**Table 57.76 Configuration of a Received Descriptor**

| Bit Name | Function |
|---|---|
| MSC | MAC Status Code<br>These bits indicate errors in reception detected by the E-MAC.<br>These bits are set to the same value between the frames divided by the descriptor.<br>Details of the bits are as follows.<br>MSC[7]: Received frame has a multicast address.<br>MSC[6]: Reserved<br>MSC[5]: Reserved<br>MSC[4]: Received frame has residual bits.<br>MSC[3]: Received frame is too long.<br>MSC[2]: Received frame is too short<br>MSC[1]: Error in frame reception<br>MSC[0]: Received frame has a CRC error. |
| PS | Padding Selection<br>These bits specify whether frame data are to be padded when stored in the incremental data area.<br>Insertion of padding data is in accord with the settings in the receive padding configuration register (RPC).<br>B’00: Padding is not to be inserted.<br>B’01: Padding data may be inserted. This depends on the RPC settings.<br>B'10: Setting prohibited.<br>B'11: Setting prohibited. |
| EI | Error Indication<br>This bit indicates the detection of an error in frame data while a frame was being stored.<br>The bit is set to 1 for a descriptor in which an error has been detected. If the descriptor is for a divided frame, the frame data is discarded.<br>0: No error<br>1: Error is detected |
| TR | Truncation Indication<br>This bit indicates whether frame data received from the E-MAC have been truncated before being stored in the on-chip RAM.<br>These bits are set to the same value between the frames divided by the descriptor.<br>0: Data have not been truncated.<br>1: Data have been truncated. |

CAUTION

The RCR.EFFS bit specifies whether or not frames with errors detected by the E-MAC are to be stored in the on-chip RAM. When the storing of error frames is disabled, error codes are not written to DESCR.MSC.

### 57.3.4.3 Reception Processing

After initialization, the AVB-DMAC is able to select the proper reception queue and store received frames in the data area in the on-chip RAM as indicated by the descriptor. The AVB-DMAC continues to store received data in the on-chip RAM as long as space is available for descriptors and data areas.

Received frames are classified and stored in the reception FIFO in accord with the algorithm described in Section 57.3.4.1 (1) Separation Filtering. A frame will already have been sorted by separation filtering, truncated, or discarded based on reception by the MAC before being stored in the reception FIFO. The following data are stored in the reception FIFO.

- MAC status of received frames
- Length of received frames
- Time stamp of received frames
- Target reception queue
- Received frame data

If the reception FIFO contains even one frame, the scheduler allocates storing in the reception queue (see Section 57.3.2.2, Scheduling Reception and Transmission).

If there is even one empty descriptor in a queue for which reception has started, the storage of frame data starts. Received frames for a queue that is already full (there is no empty frame descriptor or the unread frame counter stop level has been reached) are discarded from the reception FIFO. This ensures that one queue being full does not prevent the processing for data in the other queues.

#### (1) Storing Frame Data in the Descriptor Data Area

Frame data for storage are assumed to be in either of the two patterns described below.

- The data for an entire frame will fit in the descriptor data area.
  - In this case, the descriptor type (DESCR.DT) is FSINGLE.
- Frame data is bigger than the descriptor, so the frame data is divided and stored in the descriptor data area.
  - In this case, FSTART is written to the descriptor type (DESCR.DT) bits of the first of the frame data to arrive and FMID and FEND are written to the type bits of descriptors for subsequent data.

The descriptor type is updated by the AVB-DMAC in the last step of descriptor processing, so software can always access the descriptor written-back to DESCR.DT.

Software can write FEMPTYxxx directly to the descriptor type field after processing the stored frame data. Do not change the descriptor or any part of the descriptor data area after FEMPTYxxx is written to DESCR.DT.

(a) Single Frame

For a frame with an FSINGLE descriptor, all data for the frame are held at the position defined by DESCR.DPTR. DESCR.DS indicates the length of the received frame.

If DESCR.DS is bigger than the actual size of a received frame, the FEMPTY or FEMPTY_ND descriptor is stored in place of the FSINGLE descriptor.

Also, the FEMPTY_IS and FEMPTY_IC descriptors, which always hold the full frame data, are stored in place of the FSINGLE descriptor.

(b) Divided Frames

Divided frames can be processed in the same way as a single frame. A frame stored with divided descriptors must be recombined before use. DESCR.EI and DESCR.TS are only valid in the last descriptor of the sequence for a divided frame.

CAUTION

If the data area size setting in DESCR.DS is not a multiple of four bytes, only the number of bytes set in DESCR.DS is fetched from the reception FIFO and the remaining bytes are used by the next descriptor.

After a received frame is divided into different descriptors, each frame data is processed separately, and the descriptor type is assigned by software after processing. Accordingly, an error frame (FEMPTYxxx instead of FMID or FEND) may exist while a descriptor chain is being processed. In such a case, the CPU must postpone processing of the error frame until the corresponding descriptor has been processed.

(c) No Data

The application specification may lead to some types of received frames being unimportant (for example, when the application only requires stream data from the Ethernet frames). Storing frames in divided form makes separating out the unnecessary parts of Ethernet frames possible.

If part of a divided frame is not required, use the FEMPTY_ND descriptor so that unnecessary data is not stored in the on-chip RAM.

After processing an FEMPTY_ND descriptor, the AVB-DMAC sets DESCR.DS to 0. DESCR.DS = 0 is for the specific flag indicating that the FEMPTY_ND descriptor has been processed.

(2) Incremental Data Areas

Secure space for storing received data in the on-chip RAM. Even when all descriptor data areas of a chain are placed in the contiguous area of the on-chip RAM area, a received frame being shorter than the descriptor data area will lead to an empty space. Figure 57.25 shows an example of settings and the memory map.

In some cases, contiguous data arrangement may be effective (e.g. when received data are to be processed other than by hardware as the A/V codec module). When the length of frames differs for each received frame (e.g. when payloads vary between having one or two A/V packages), the use of a pointer in the descriptor produces empty spaces in the data area. This necessitates additional processing such as copying the frame data to remove the empty spaces.

Accordingly, and to prevent copying data, the AVB-DMAC supports an “incremental data area” function.

When incremental data areas are in use, different descriptors use a contiguous data area. The first descriptor (FEMPTY_IS) from the top defines the base address of the incremental data area and is used to, together with the subsequent descriptor (FEMPTY_IC) within the descriptor chain, hold received data. Figure 57.26 shows an example of settings and the memory map.

When an incremental data area is used, it is also possible to divide a frame into various descriptors in a way that reflects its structure (e.g. one descriptor for the Ethernet header and one for the data payload).

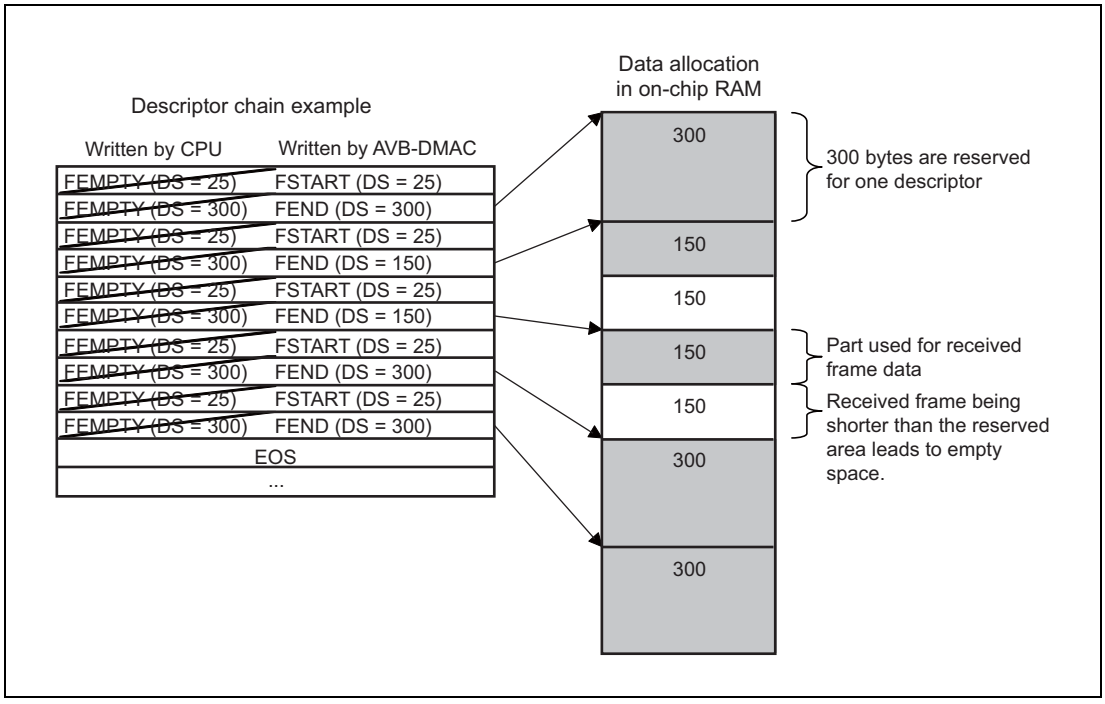

**Figure 57.25 When Individual Descriptor Data Areas are Used**

Figure 57.25 and Figure 57.26 show how control of the data storage areas by a descriptor chain varies according to whether incremental data areas are not in use or in use. The chains are configured for storing received frames consisting of a 25-byte header (in this example, stored in the on-chip RAM area outside the drawing range) and a 150- or 300-byte payload (whether one or two 150-byte data depending on the data source).

In Figure 57.25, an EOS descriptor is added as an example of a re-synchronization point. If a frame larger than 325 bytes is received, the frame will be divided into three descriptors, meaning that synchronization of the header and data sequences is lost. However, a frame is not divided across an EOS descriptor, so adding EOS descriptors can prevent the header and data sequences losing synchronization. While an incremental data area is in use, EOS descriptors are not required because the incremental descriptors always hold all data being processed.

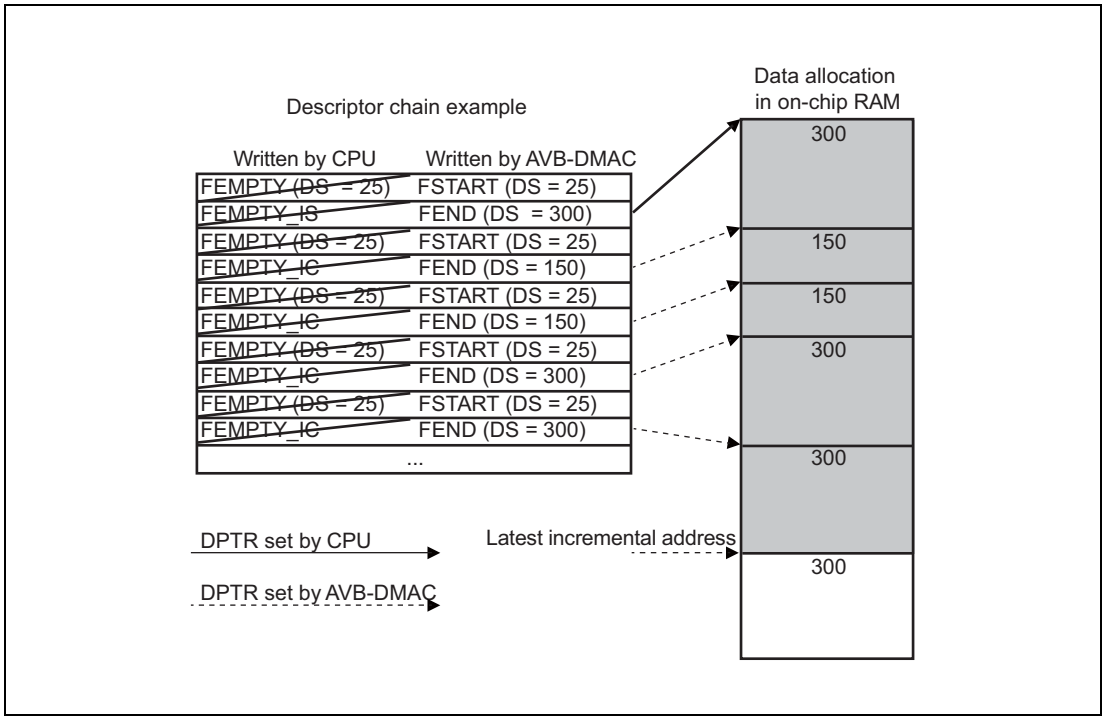

**Figure 57.26 When Incremental Data Area is Used**

As Figure 57.26 shows, when data are stored in an incremental data area, the descriptor pointers in the FEMPTY_IC descriptors (DESCR.DPTR) are updated. Accordingly, the FEND or FSINGLE descriptor written-back by the AVB-DMAC after processing is in the same format as the FEMPTY descriptor after processing.

Software captures contiguous received data, which has no empty spaces, from an incremental data area. The incremental data area must be aligned with a 4-byte boundary. Therefore, when the amount of received data for storage in an incremental data area is not a multiple of four bytes, from one to three bytes of empty space is placed at the end of the incremental data area. DESCR.DS can be read to check for such empty spaces.

For the normal descriptors (FEMPTY and FEMPTY_ND), controlling the amount of received data due to DESCR.DR is possible, but for the incremental descriptors (FEMPTY_IS and FEMPTY_IC), controlling the amount of received data to be stored is not possible. All received data are always stored in an incremental descriptor.

### (a) Setting Up an Incremental Data Area

If a descriptor chain has N descriptors (one FEMPTY_IS and N-1 FEMPTY_IC), an area for storing N times of the maximum received data as the incremental data area must be secured.

As Figure 57.26 shows, DESCR.DPTR of an FEMPTY_IS descriptor indicates the base address of the incremental data area. The subsequent FEMPTY_IC descriptor in the chain indicates that data must be stored in the incremental data area.

### (b) Processing an Incremental Data Area Based on Descriptors

Since data processing by the CPU is the same regardless of how the AVB-DMAC stores the data, data stored in an incremental data area do not require any special handling.

### (c) Padding

Use padding for reception of frame data that are not aligned correctly. Padding can be set individually for each descriptor. Accordingly, in the reception of divided frames, padding can be set to only those frames that require it (e.g. A/V payload data.)

Padding can also be used to effectively use an incremental data area (e.g. to prevent inefficient access by aligning received data with 32-byte boundaries.

Padding can only be used in an incremental data area.

The value H'0000 0000 is always used in padding.

Padding is the addition of the number of words (from one to seven 32-bit words) set in the stored padding counter bit in the receive padding configuration register (RPC.PCNT). This padding is repeatedly inserted for each received data count set to the stored data counter bit (RPC.DCN) (from one to 255 32-bit words). When the stored data counter (RPC.DCNT) reaches 0, however, padding is not repeated.

The first word of padding is always inserted at the position specified by DESCR.DPTR. When divided frames are in use, a padding word can be inserted in accord with each descriptor (e.g. the first descriptor handles a 42-byte header data and the second descriptor holds padded payload data in an incremental data area).

The next figure shows a general example of how padding is inserted and an example of setting up padding. In the figure, A indicates frame data received from the E-MAC, while B indicates frame data stored in the descriptor data area (32-bit word units).

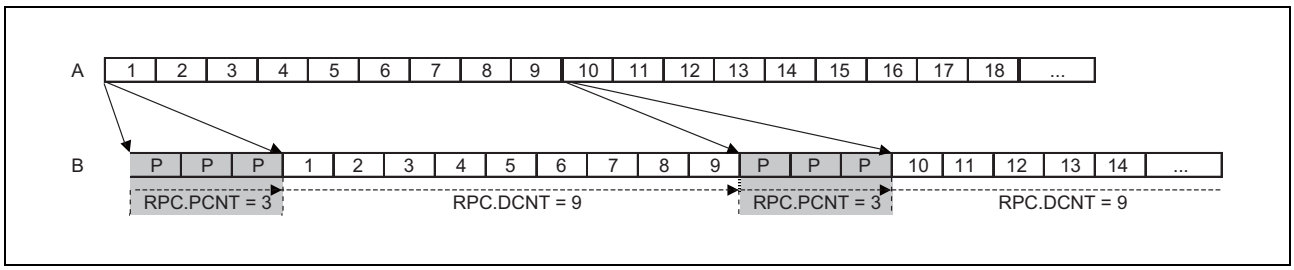

**Figure 57.27 Example of a Padding Setting**

Both padding and received frame data are counted in the descriptor size (DESCR.DS).

### (3) Support for Reception Time Stamps

Capturing reception time stamps is essential for IEEE 802.1AS time synchronization. Other types of received frames may also require that a reception time stamp be appended; this depends on the application. The AVB-DMAC supplies reception time stamps based on the gPTP timer by storing time stamps that have been captured when the start frame delimiter (SFD) for a received frame in the last frame data descriptor (FEND or FSINGLE). For the gPTP timer, see Section 57.3.7.1, gPTP Timer.

When time stamps are to be stored, use extended descriptors for the entire reception queue. Furthermore, time stamps are always stored for reception queue 1 (network control). Time stamps for reception queue 0 (best effort) and reception queue r ($r \geq 2$; for stream data) can be selected by the time stamp enable bits in the receive configuration register (RCR.ETS0 or RCR.ETS2).

### 57.3.4.4 Unread Frame Counters

Each reception queue has an unread frame counter (UFCVi). Use the unread frame counter configuration bits in the receive queue configuration register (RQCi.UFCCr) to select from among the four stop levels for each unread frame counter. The 0 setting disables the stop functions. For how to set this up, see Figure 57.28.

Operations of the AVB-DMAC (hardware) and CPU (software) drive an unread frame counter (UFC) in the following ways.

- The hardware indicates that it has added a new frame to the descriptor chain for the queue (this increments the counter).
- Software indicates how many frames from the descriptor chain it has processed by writing to the corresponding bits of the unread frame counter decrement register for the queue (this decrements the register by the number written).

The unread frame counter is based on the number of frames stored in the on-chip RAM and is only incremented by one even when a received frame is divided into different descriptors. Data failure in a descriptor chain requires care because this may fail in synchronization of the unread frame counter as described in Section 57.3.4.4 (1) Loss of Unread Frame (UFC) Synchronization.

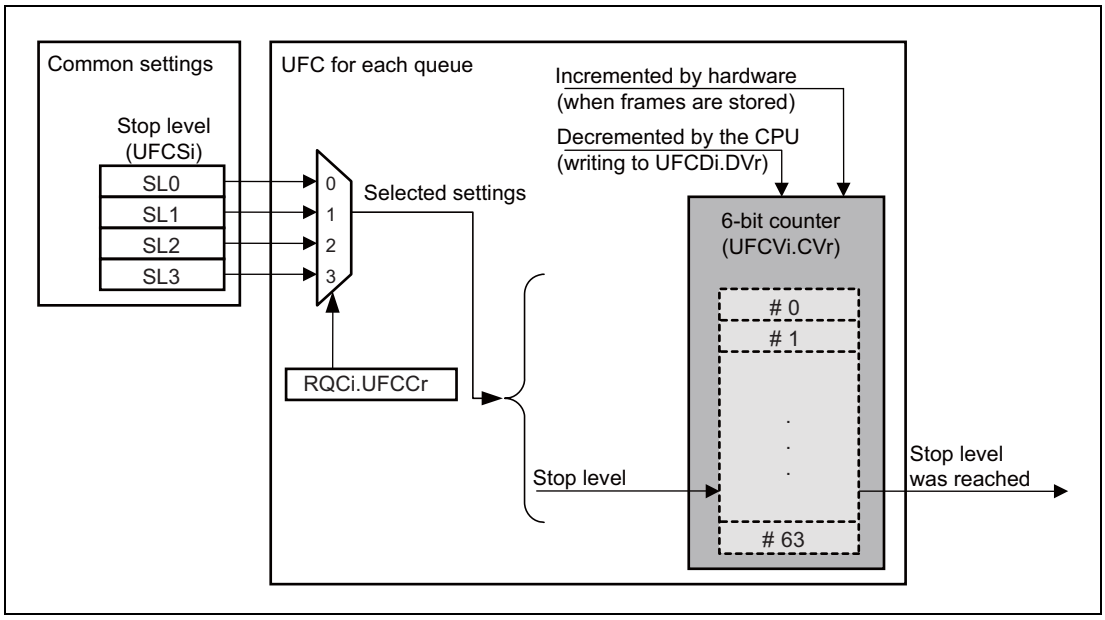

**Figure 57.28 Overview of an Unread Frame Counter**

Unless synchronization of hardware and software is lost, the current unread frame counter value (UFCVi.CVr) indicates the number of unread frames in the queue.

When the stop level has been reached, received frames are not stored in the descriptor chain. Setting 0 as the stop level disables the stop function. Otherwise, further received frames for the queue are discarded once its unread frame counter reaches the stop level. Activation of the unread frame counter stop function is indicating by setting of the receive queue full interrupt flag in the receive interrupt status register 2 (RIS2.QFFr).

Set the unread frame counter stop level configuration register (UFCS) for each reception queue that will use the unread frame counter function while the current operating mode is configuration mode.

### (1) Loss of Unread Frame (UFC) Synchronization

The unread frame counters do not recognize failure to store a frame in the on-chip RAM. In other words, the AVB-DMAC increments the counter for a queue each time it captures a frame for that queue from the reception FIFO whether or not it succeeds in storing the frame normally in the descriptor chain.

In general, synchronization of hardware and software may be lost under the following conditions.

- An unread frame counter reaching its maximum value
  When the value of a counter in an unread frame counter register i (UFCVi) (i = 0 to 4) reaches 63, synchronization for the corresponding queue can be lost.
  It can only be judged that a loss of synchronization has not occurred when the stop level is set to 63.
- A queue not having enough space for a descriptor or the associated data
  In this case, the corresponding receive queue full interrupt flag (RIS2.QFFr) in receive interrupt status register 2 (RIS2) is set.
  If an unread frame counter reaches its stop level, the receive queue full interrupt flag (RIS2.QFFr) in the receive interrupt status register 2 (RIS2) is set.
- A problem occurring during access to memory

The result of a failure in synchronization is the unread frame counter indicating that the corresponding descriptor chain contains more available frames than it actually does. To retrieve the correct starting point for operations, use the descriptor base address load request (DLR.LBAq) for the given queue.

### 57.3.5 Transmission Control

Areas in the on-chip RAM for storing transmission descriptors must also be secured (for descriptors, see Section 57.3.3, Descriptors).

The AVB-DMAC fetches data from the on-chip RAM in accord with the procedure the descriptor describes. The descriptor also retains tag information once the frame has been fetched for transmission. The tag information is used to maintain the relationships between state information and time stamps for the software and the AVB-DMAC. The status and time stamp information for transmitted frames remains accessible after their transmission is completed.

#### 57.3.5.1 Transmission Modes

The AVB-DMAC has two modes of transmission.

- AVB transmission mode
  This mode is selected by the priority level setting for the transmission queue in the transmit configuration register (setting of the TGC.TQP[1:0] bits) being B'01 or B'11.
- Non-AVB transmission mode
  This mode is selected by the priority level setting for the transmission queue in the transmit configuration register (setting of the TGC.TQP[1:0] bits) being B'00.

##### (1) AVB Transmission Mode

AVB transmission supports the control of traffic through the output port to implement various traffic classes.

###### (a) Support for Traffic Classes and Associated Priority

When transmission is in AVB transmission mode, streams of traffic are transmitted in accord with the part of the AVB specification called Forwarding and Queuing for Time Sensitive Streams (FQTSS; for details on this, see the IEEE 802.1Q standard).

In the AVB specification, at least one queue for a reserving stream under the Stream Reservation Protocol (SR stream) and at least one queue for a non-SR stream are present, and the queues for reserved traffic according to the SRP have highest priority.

The AVB-DMAC supports four traffic classes: SR class A, SR class B, network control (NC) traffic (gPTP frames), and best effort (BE) traffic. Allocating a specific queue to network control (NC) frames ensures the control of synchronization.

The AVB-DMAC realizes compliance with the AVB standards by handling queues with the following architecture (in terms of traffic classes).

- Four transmission queues (Q3, Q2, Q1, and Q0) are available.
- Q3 and Q2 are for SR streams (one each for class A and class B).
- Q1 is for low-bandwidth network control (NC) traffic (gPTP frames)
- Q0 is for other types of traffic (MSRPDU*1, MVRPDU*2, best effort (BE), etc.)

CAUTIONS

1. MSRPDU: Multiple Stream Registration Protocol Data Unit
2. MVRPDU: Multiple VLAN Registration Protocol Data Unit

Fetching from queues proceeds in order of priority of the above traffic types. Three systems of priority are available through the setting of the transmit queue priority bits in the transmit configuration register (TGC.TQP[1:0]). In the default priority scheme, which is called AVB mode 1 (selected by TGC.TQP[1:0] = B'01), operation of the AVB-DMAC is fully in accord with the AVB specification. AVB mode 2 (transmit queue priority bits (TGC.TQP[1:0] = B'11) is an alternative priority scheme and varies from the AVB specification. Using this scheme thus requires more care.

**Table 57.77 Default and Alternative Priority Orders in AVB Transmission Mode**

| Priority Schemes (AVB Mode) | Priority Order of Queues |
|---|---|
| AVB mode 1 | Q3 (SR class A) > Q2 (SR class B) > Q1 (NC) > Q0 (BE) |
| AVB mode 2 | Q1 (NC) > Q3 (SR class A) > Q2 (SR class B) > Q0 (BE) |

### (b) Transmission Selecting Algorithm and CBS

The algorithm the AVB-DMAC applies to select frames for transmission is in accord with the IEEE 802.1Q standard. For AVB mode, the CBS (credit-based shaping) algorithm is applied to the class A and class B SR queues (Q3 and Q2). Use of the CBS enables correct handling of the priorities of transmission from the SR queues. For the CBS algorithm, see Section 57.3.6, CBS (Credit-Based Shaping).

When the following conditions are both satisfied, transmission from an SR queue (Q3 or Q2) proceeds at the specified time.

- The queue contains at least one frame ready for transmission.
- The queue has credit.
- Unless an SR queue satisfies the above conditions, a higher priority queue is not present (not ready for transmission).

A non-SR queue (Q1 or Q0) is selected if the conditions below both hold.

- The queue contains at least one frame ready for transmission.
- As well as the above condition, a higher priority queue is not present (not ready for transmission).

Figure 57.29 and Figure 57.30 are flowcharts of selection for transmission in AVB mode 1 and AVB mode 2.

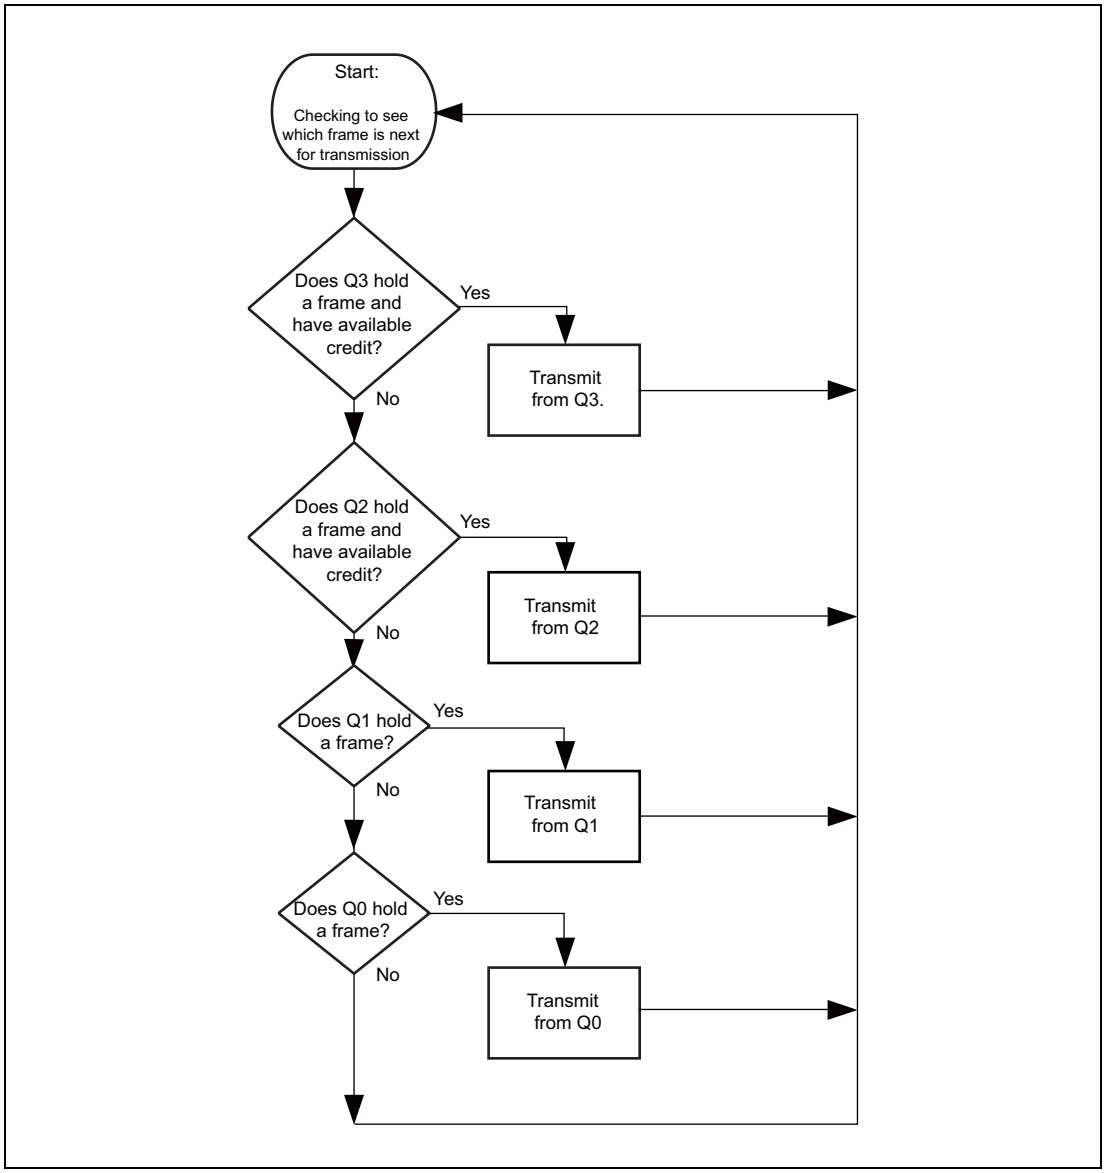

**Figure 57.29 Flow of Selection for Transmission in AVB Mode 1**

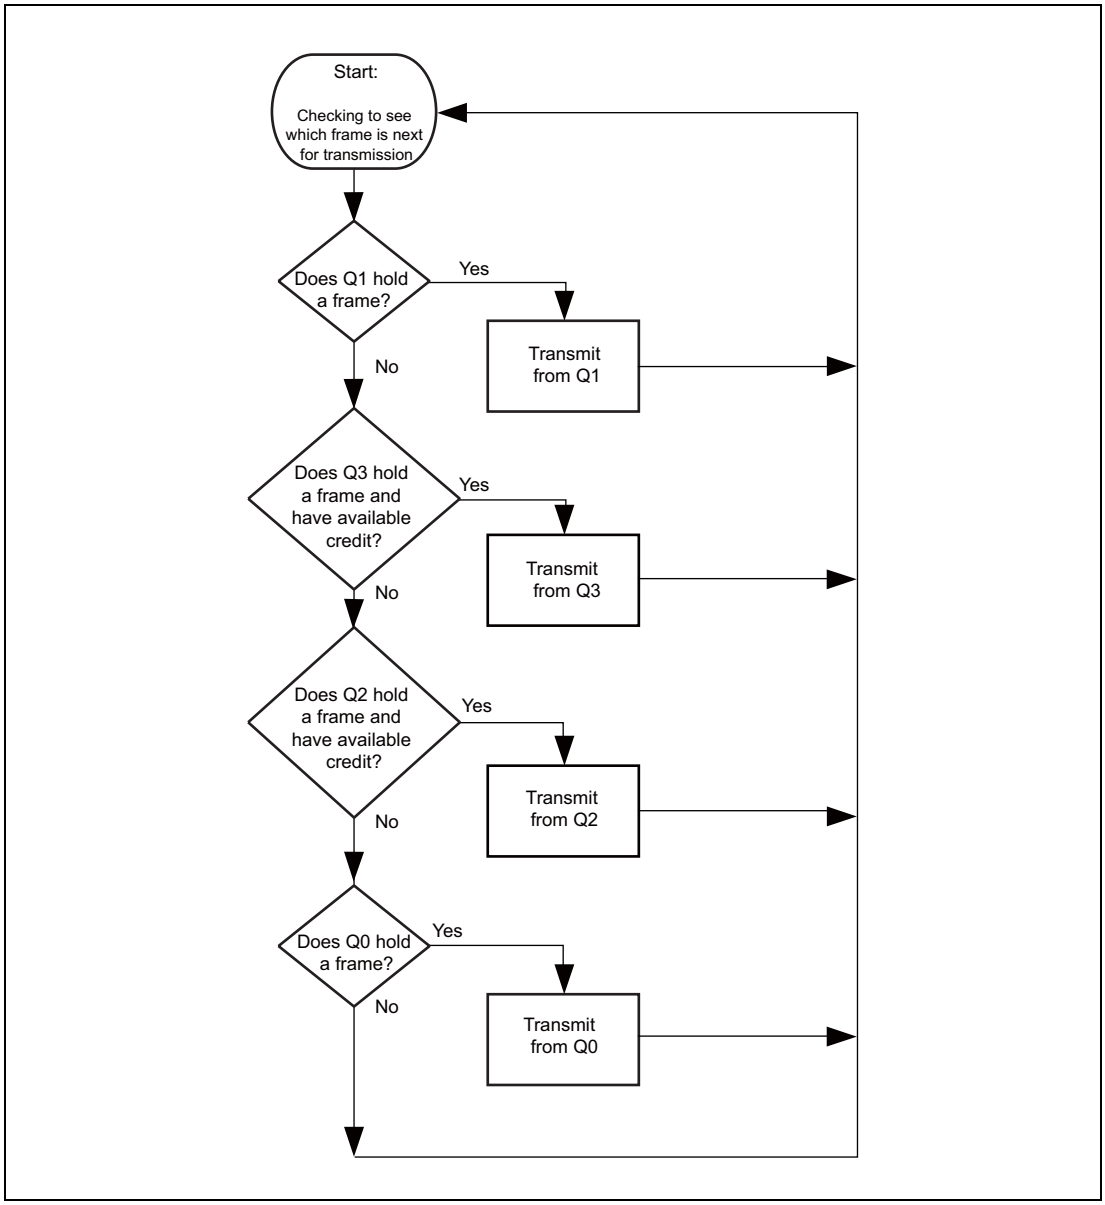

**Figure 57.30 Flow of Selection for Transmission in AVB Mode 2**

(2) Non-AVB Transmission Mode

In non-AVB transmission mode, an absolute priority scheme is used. The SR class is not supported and the CBS algorithm is not used.

In non-AVB transmission mode (when the transmit queue priority bits in the transmit configuration register (TGC.TQP[1:0]) are B'00), data is fetched for transmission in a strict order of priority (Q3 > Q2 > Q1 > Q0).

Figure 57.31 shows the flow of selection in non-AVB transmission mode.

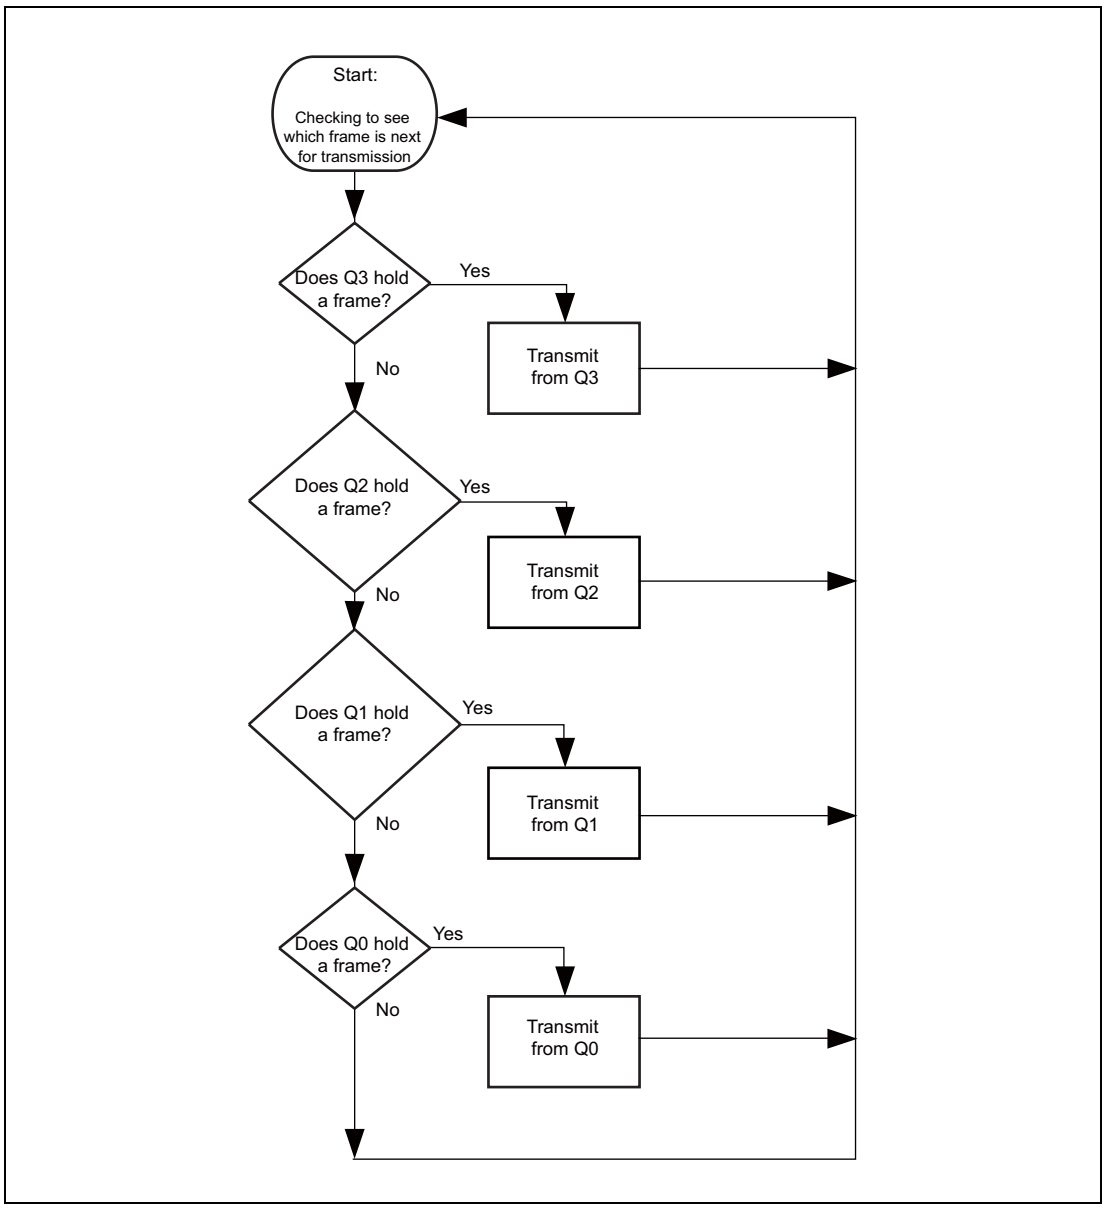

**Figure 57.31 Flow of Selection for Transmission in Non-AVB Mode**

### (3) Setting the Size of the Transmission FIFO

The transmission FIFO is made up of 124 clusters. Each cluster can hold up to 128 bytes.

The size of the part of the transmission FIFO for use by each of the four transmission queues can be set by the corresponding transmit queue configuration q bits in the transmit control register (TGC.TBDq). The maximum number of clusters required can be determined from the maximum length of frames for transmission from the queue q.

Even if queue t already contains data of the frame size specified by TGC.TBDt, the AVB-DMAC fetches the next frame to queue t after the E-MAC starts transfer data from queue t. Therefore, a frame data area of the total of maximum frame sizes set for each transmission queue plus an area for 1 frame must be secured for a cluster.

**General Usage Examples:**

Q0: Frames containing up to 1500 bytes → 1500/128 = 11.7 → 12 clusters

Q1: Frames containing up to 1024 bytes → 1024/128 = 8.0 → 8 clusters

Q3: Frames containing up to 1996 bytes → 1996/128 = 15.6 → 16 clusters

Q4: Frames containing up to 1996 bytes → 1996/128 = 15.6 → 16 clusters

When the depth of all transmission queues is 2, only the following number of clusters is required.

2 * (12 + 8 + 16 + 16) + 16 = 2 * 52 + 16 = 120

Adjust the frame length of each queue so that the number of clusters to be used is no greater than 124.

### 57.3.5.2 Setting Up Transmission Descriptors

#### (1) Transmission Descriptor Type

The type of a descriptor is defined by the descriptor type (DESCR.DT) field.

Table 57.78 shows the descriptor types used in transmission. In the table, entries in the write-back column indicate how the AVB-DMAC changes the DESCR.DT field upon completion of descriptor processing.

**Table 57.78 Descriptor Types in Transmission**

| Descriptor Type (DESCR.DT) | Operation | Write-back |
|---|---|---|
| **Frame Start** (FSTART) | The AVB-DMAC fetches the first of the data for the divided frame and proceeds to the next descriptor. | FEMPTY |
| **Frame Middle** (FMID) | The AVB-DMAC fetches the second or subsequent data for the divided frame and proceeds to the next descriptor. | FEMPTY |
| **Frame End** (FEND) | The AVB-DMAC fetches the last of the data for the divided frame.<br>When the frame of data that has been fetched to the transmission FIFO is ready for transmission by the E-MAC, the AVB-DMAC proceeds to the next descriptor. | FEMPTY |
| **Frame Single** (FSINGLE) | The AVB-DMAC fetches the frame of data.<br>When the frame of data that has been fetched to the transmission FIFO is ready for transmission by the E-MAC, the AVB-DMAC proceeds to the next descriptor. | FEMPTY |
| **Link** (LINK) | Processing proceeds to the descriptor specified by DESCR.DPTR. | LEMPTY |
| **Fixed Link** (LINKFIX) | Same as LINK | Not changed |
| **End Of Set** (EOS) | Clears the transmit start request bit (TCCR.TSRQt), which stops transmission queue.<br>When the TCCR.TSRQt is again set to 1 (a new transmission start request is issued), processing proceeds to the next descriptor. | EEMPTY |
| **Frame Empty** (FEMPTY) | Clears the transmit start request bit (TCCR.TSRQt), which stops transmission queue.<br>When the TCCR.TSRQt is again set to 1 (a new transmission start request is issued), processes this descriptor again. | Not changed |
| **Link Empty** (LEMPTY) | Same as FEMPTY | Not changed |
| **EOS Empty** (EEMPTY) | Same as FEMPTY | Not changed |

(2) Configuration of Transmission Frame Data Descriptors

Figure 57.32 shows the configuration of descriptors for use with transmission queues. The transmission-specific fields (DESCR.TSR and DESCR.TAG) are described in Table 57.79.

For the other fields and the descriptor types, see Section 57.3.3.6, Descriptor Type.

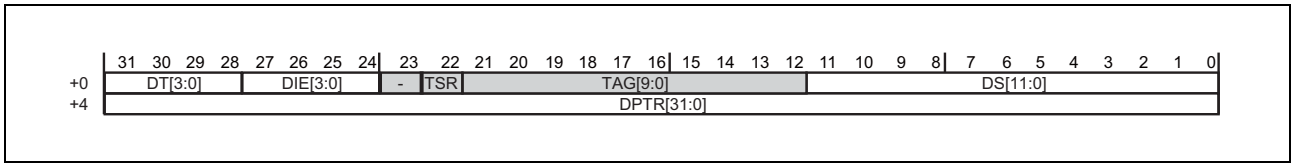

**Figure 57.32 Configuration of Descriptor for a Transmitted Frame**

**Table 57.79 Configuration of a Transmission Descriptor**

| Bit Name | Function |
|---|---|
| TSR | Time Stamp Store Request<br>This bit specifies whether the transmission time stamp together with tag information is to be stored within the EthernetAVB module.<br>0: The time stamp status FIFO within the EthernetAVB module does not retain a transmission time stamp.<br>1: The time stamp status FIFO within the EthernetAVB module retains a transmission time stamp.<br>Only control this bit while the current DESCR.DT is FEND or FSINGLE. |
| TAG | Frame Tag<br>This TAG field is used to associate each frame data status with a time stamp. Frame TAG is not required but is recommended.<br>Only control this bit while the current DESCR.DT is FEND or FSINGLE. |

For the time stamp FIFO function, see Section 57.3.5.4, Time Stamping in Transmission.

### 57.3.5.3 Transmission

#### (1) Transmitting Frames

Setting the transmit start request bit in the transmit configuration control register (TCCR.TSRQt) starts the transfer of frames from the corresponding transmission queue.

The descriptor in the current descriptor address for the queue (CDARq.CDA) is read first.

If this descriptor is a descriptor for frame transmission (FSINGLE, etc.), the AVB-DMAC fetches the frame data from the data area indicated by the descriptor, writes FEMPTY back to the descriptor type (DESCR.DT) bits to indicate completion of this processing, then proceeds to processing of the next descriptor.

If the descriptor is not for transmission, processing is as dictated by the given descriptor (for these descriptors, see the descriptions in Section 57.3.3, Descriptors).

If a base address load request is issued for a descriptor chain while it is being processed (by setting 1 in the LBAq bit for transmission queue q that is currently being processed in the descriptor base address load request register, DLR), processing proceeds to the new descriptor chain (descriptor base table address bits (DBAT.TA) + 8*q). Loading the base address does not interrupt frame fetching, but note that frames that have not been fetched from the old chain remain where they are.

Figure 57.33 shows descriptor processing during transmission. “Fxxx” in the figure indicates the frame data descriptors (FSTART, FMID, FEND, FSINGLE).

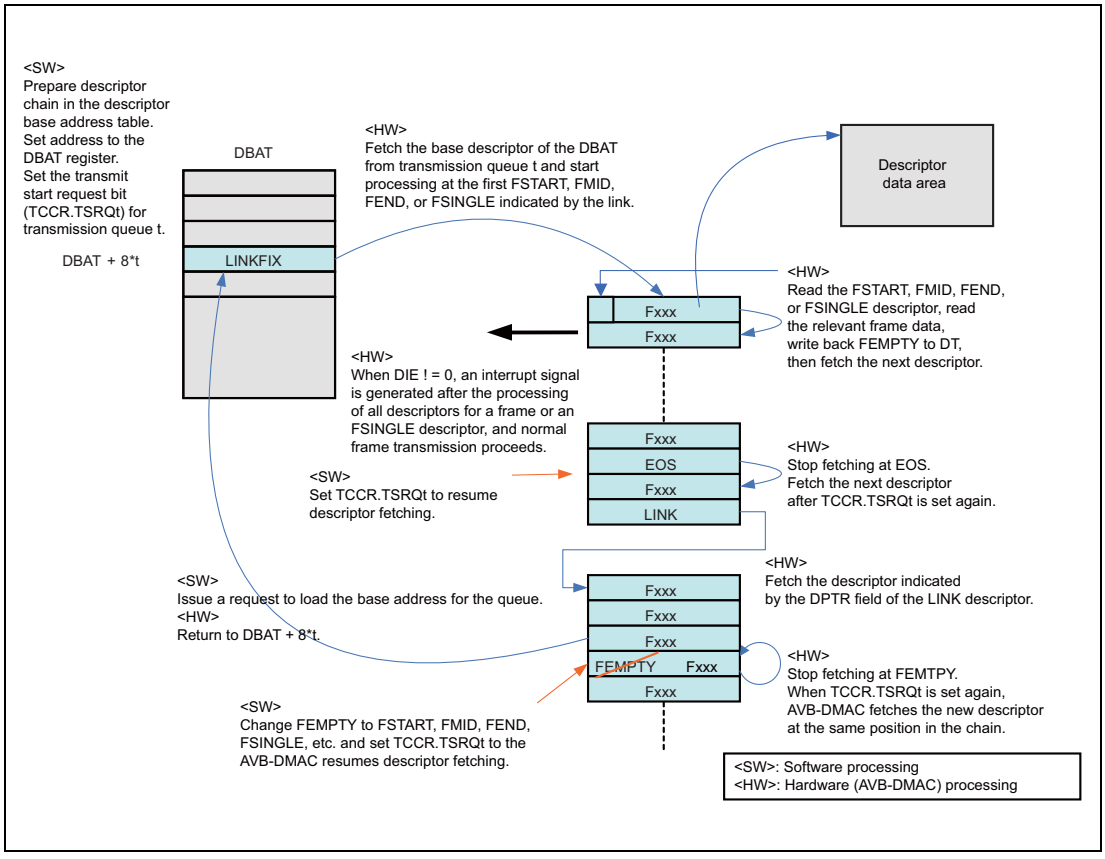

**Figure 57.33 Descriptor Processing During Transmission**

(2) Examples of Descriptor Usage

(a) Immediate Frame Transmission

Immediate frame transmission is a method in which fetching by the AVB-DMAC starts whenever software adds data to a queue. FEMPTY descriptors are used as stop points to keep the hardware and software in synchronization.

As preparation in transmission, software creates descriptor chains that have FEMTPY descriptors.

Figure 57.34 shows the flow for subsequent process.

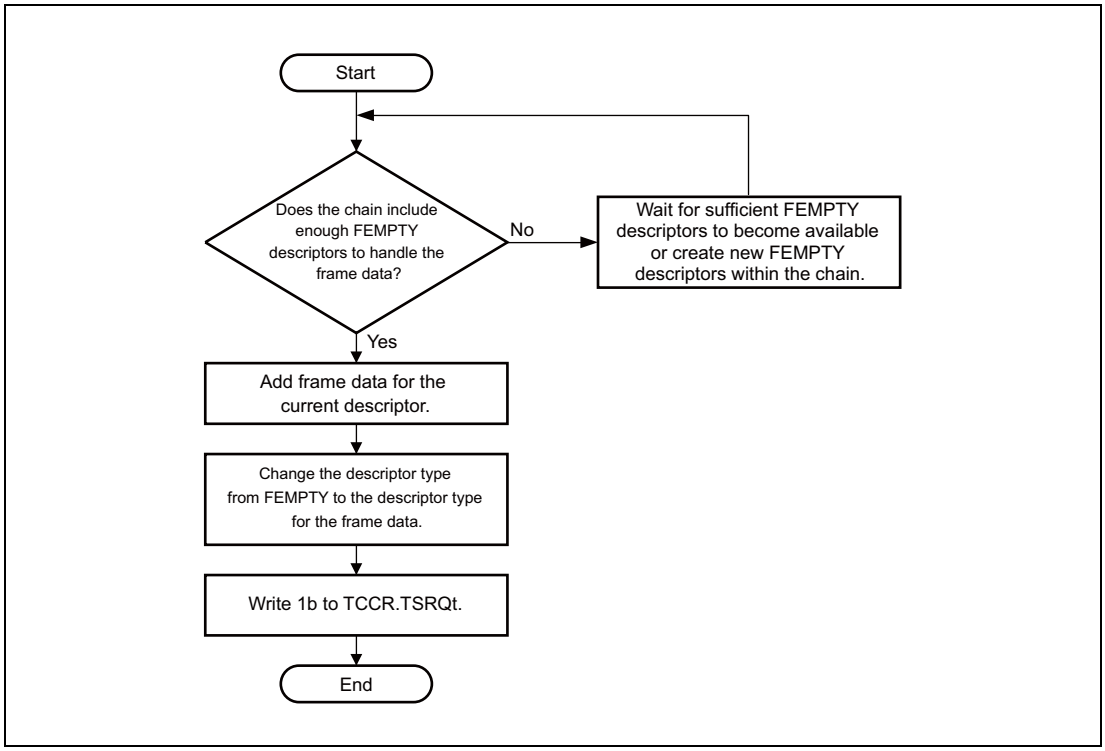

**Figure 57.34 Software Flow for Immediate Frame Transmission**

When processing a divided frame, change the types of descriptors in the backward direction, i.e., from FEND to FSTART. This guarantees all the descriptors including frame data to be ready when the AVB-DMAC starts fetching divided frames.

Figure 57.35 shows software and AVB-DMAC operations for divided frame transmission. In the figure, software and hardware independently perform processing. This allows software to prepare the descriptor for frame n + 1 even when the AVB-DMAC is currently fetching frame n.

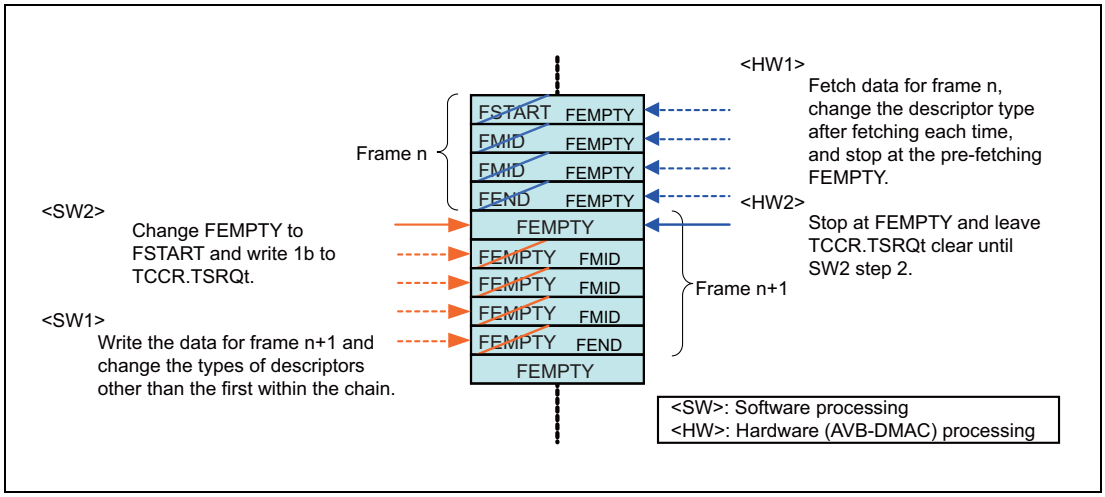

**Figure 57.35 Software and AVB-DMAC Operation Examples for Immediate Frame Transmission (divided frames)**

(b) Frame Set Transmission with Switching of the Active Descriptor Chain

This method is used when data are transmitted with a delay for software control to secure bandwidth or for other reasons, rather than immediately transmitted. EOS descriptors are used for the stop points.

As preparation in transmission, software creates descriptor chains that have FEMTPY descriptors.

Figure 57.36 shows the flow for subsequent process.

In the first task, software creates and adds a transmission frame to the descriptor chain, which is followed by EOS descriptor insertion.
In the second task, software processes the transmission trigger for the transmission descriptor prepared. This guarantees transmission of a frame set per trigger.
No particular operation is necessary for synchronization between two tasks. If not enough frame sets are prepared when the transmit start request bit in the transmit configuration control register (TCCR.TSRQt) is set, only the prepared frame sets are transmitted. If nothing is prepared in the queue, only clearance of a transmission request is performed.

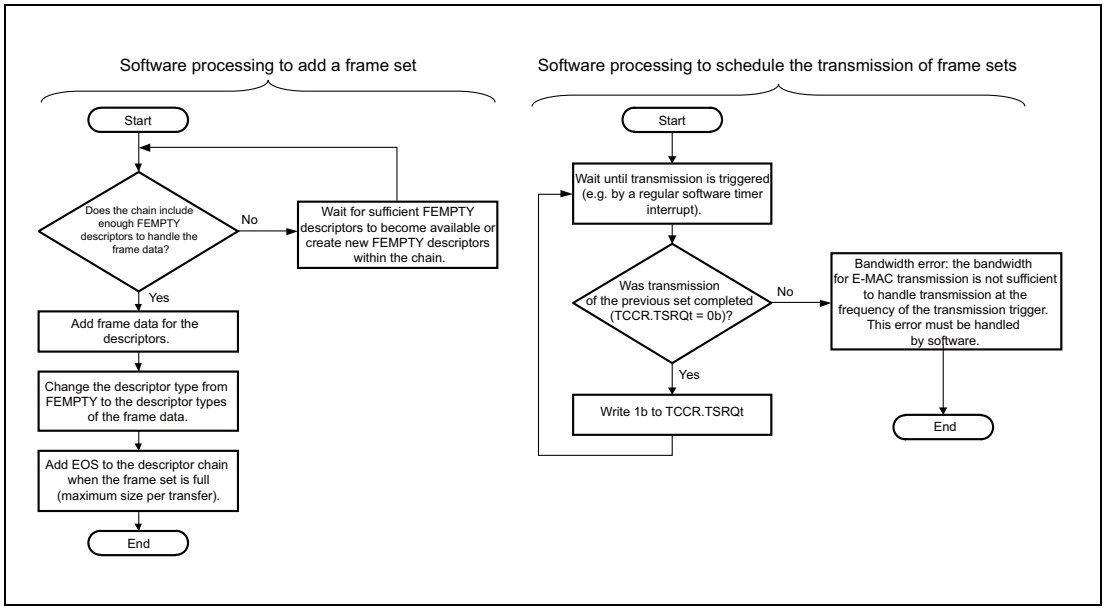

**Figure 57.36 Software Flow for Frame Set Transmission with Switching of the Active Descriptor Chain**

In a given time, the AVB-DMAC does not use the descriptor chain area currently being updated by software; therefore, descriptor types for a divided frame can be changed in any order.

Figure 57.37 shows software and AVB-DMAC operation examples in this method.

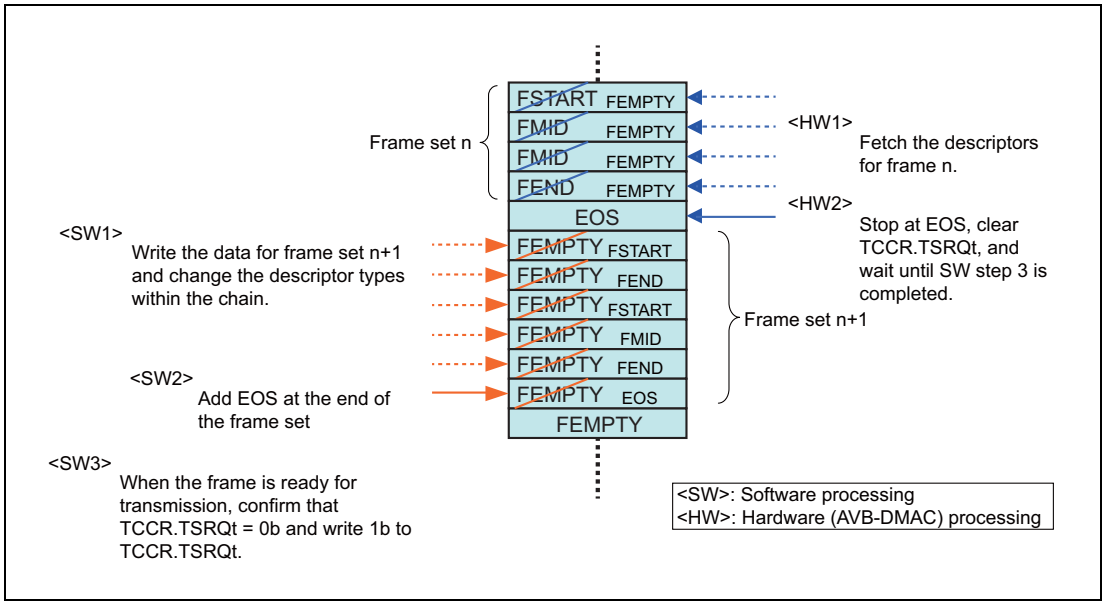

**Figure 57.37 SW and AVB-DMAC Operation Examples for Frame Set Transmission with Switching of the Active Descriptor Chain**

### (c) Frame Set Transmission Using a Shadow Descriptor Chain

This method is used when data are transmitted with a delay for software control to secure bandwidth or for other reasons, rather than immediately transmitted. Two or more descriptor chains are used. The chains are classified as active or shadow chains. Software prepares frame data in shadow chain and descriptor while hardware processes active chain. EOS or FEMPTY descriptors are used for the stop points.

As preparation in transmission, software creates a shadow descriptor chain that has a FEMPTY descriptor, and creates a frame data descriptor in an active chain. Software then sets the transmit start request bit (TCCR.TSRQt) to start transmission of the active chain. During active chain transmission, software can prepare frame data for the shadow chain.

Figure 57.38 shows the flow for software implementing this method.

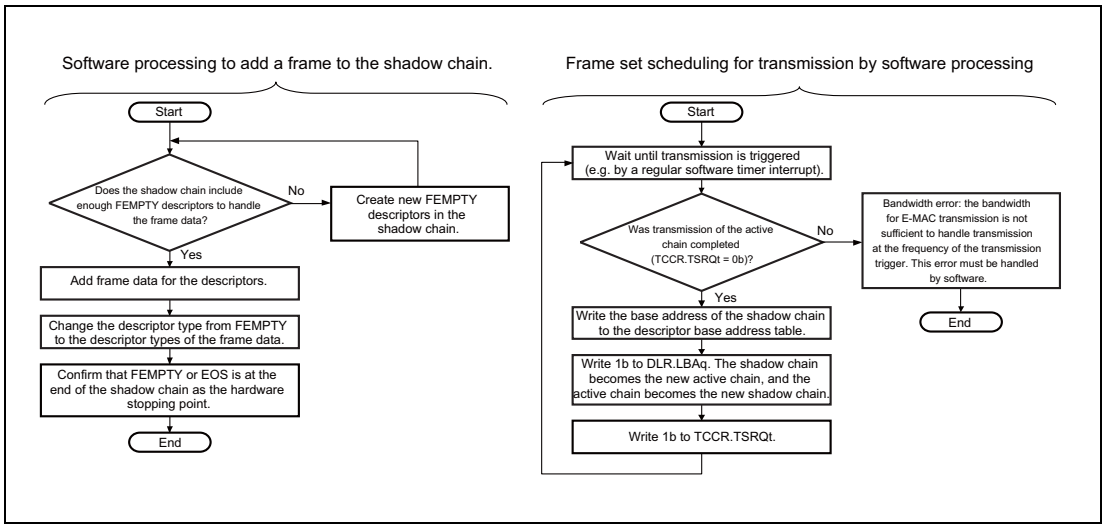

**Figure 57.38 Software Flow for Frame Set Transmission Using the Shadow Descriptor Chain**

Figure 57.39 shows software and AVB-DMAC operation examples in this method.

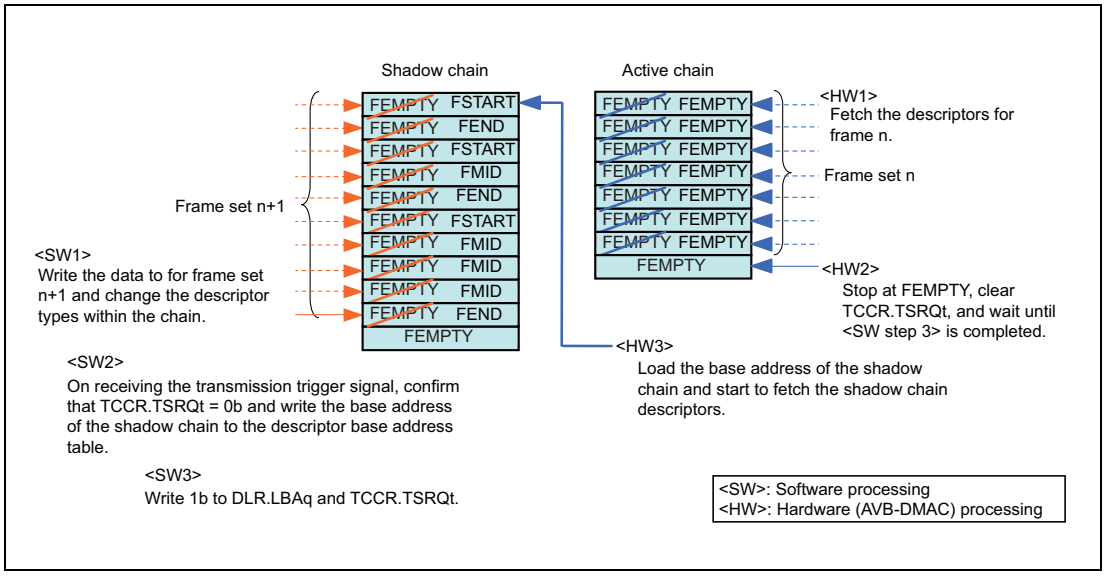

**Figure 57.39 SW and AVB-DMAC Operation Examples for Frame Set Transmission Using the Shadow Descriptor Chain**

#### 57.3.5.4 Time Stamping in Transmission

Transmission time stamps are important in performing timing and synchronization processing of the IEEE 802.1AS standard. Reference to the transmission time stamps can also be useful to other applications and so on. The AVB-DMAC supplies the time-stamp values based on the gPTP timer by storing the time stamps captured at the same time as sending of the Start of Frame Delimiter (SFD) for transmitted frames.

When the time stamp storage request field (DESCR.TSR) is set to 1, selecting storage of a time stamp, the tag number defined in the tag field (DESCR.TAG) of the last descriptor in a set (FEND) or of an FSINGLE descriptor for the frame being transmitted is stored with the time stamp. This eases identification and association. The time-stamp FIFO is accessible at any time.

The method of using this function is described below:

1. Create descriptor and frame data in the on-chip RAM for the frame requiring time stamping. Write the tag number of the frame to the frame tag field (DESCR.TAG) and set the time stamp storage request field (DESCR.TSR) to 1.
2. The AVB-DMAC fetches and analyzes the descriptor. When the time stamp storage request field (DESCR.TSR) is 1, the AVB-DMAC recognizes that transmitting this frame also requires storage of the time stamp.
3. The AVB-DMAC fetches the frame data and stores the frame data in the transmission FIFO for scheduling.
4. Under the control of priority settings according to credit-based shaping (CBS) or another scheme, the transmission scheduler decides it is time to transmit frame.
5. The EthernetAVB starts transmission of frame.
6. The gPTP time stamp is captured at the start of sending the frame delimiter (SFD) for transmission and stored with the tag frame field (DESCR, TAG) in the time-stamp FIFO upon completion of the frame transmission. When the time stamp update interrupt is enabled, update of time stamp is notified by an interrupt.
7. The time stamp can now be acquired from the time-stamp FIFO.

Use the time-stamp FIFO for the timing and synchronization of frames with IEEE 802.1AS compliance.

Time stamping can also be used with other frames, but take care not to allow the time-stamp FIFO to overflow. When the time-stamp FIFO is full, further time stamps in subsequent transmissions are not stored.

Figure 57.40 shows software flow in time-stamp FIFO operation. The time stamp FIFO update interrupt status bit (TIS.TFUF) and the time stamp FIFO warning interrupt status bit (TIS.TFWF) are used for the start flag of the START block in the figure.

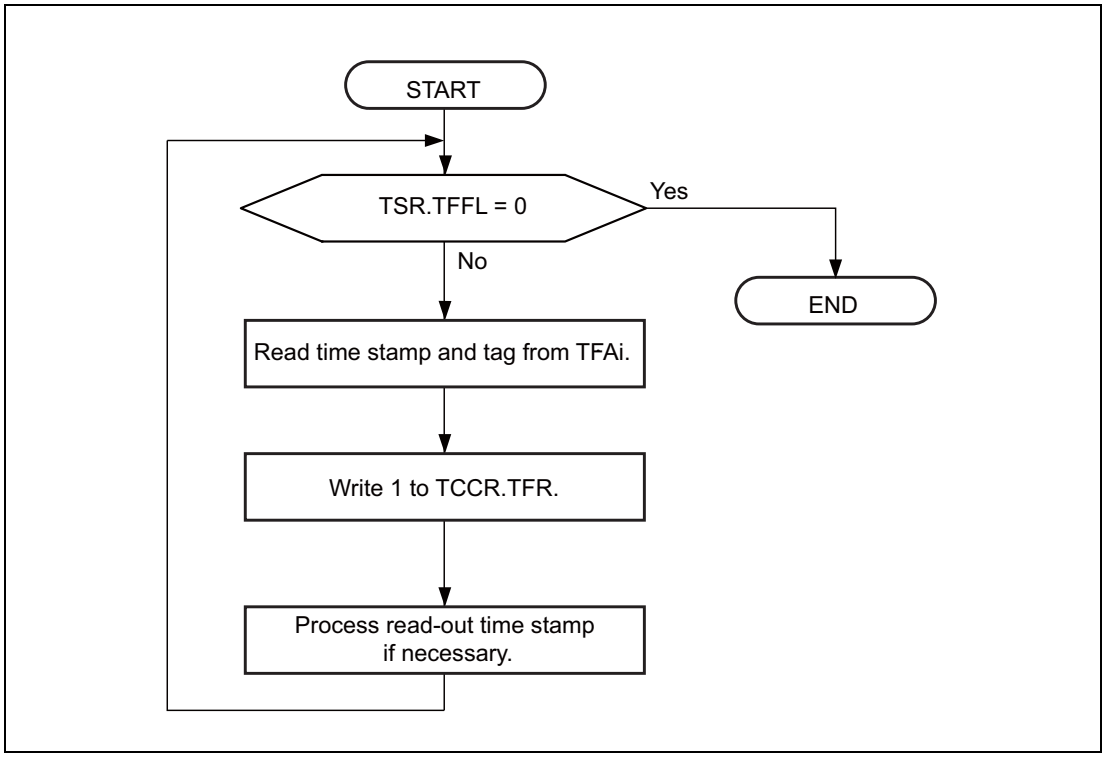

**Figure 57.40 Flow of Transmission Time Stamping**

When all the entries in the time-stamp FIFO are released, the time stamp FIFO update interrupt status bit (TIS.TFUF) and time stamp FIFO warning interrupt status bit (TIS.TFWF) are cleared by the AVB-DMAC. Therefore, clearing the interrupt flags is not necessary.

When multiple frames are transmitted with time stamps but from different queues, the order of storage in the time-stamp FIFO buffer depends on the order of frames in transmission.

### 57.3.6 CBS (Credit-Based Shaping)

In AVB transmission mode (i.e. when the transmit queue priority field in the transmit configuration register (TGC.TQP) is B'01 or B'11), transmission queues Q3 and Q2 are respectively assigned to class A and class B stream traffic and the CBS (Credit Based Shaping) algorithm is used to select the transmission queues in order to satisfy the Forwarding and Queuing for Time Sensitive Streams (FQTSS) specification (see section 8.6.8 or section 34 in IEEE 802.1Q).

The CBS algorithm is based on the concept of transmission credit for each queue. Credit can be thought of as the degree to which a queue has the "right" to transmit at a given time. In addition, in AVB transmission mode as specified in IEEE 802.1Q, queues that are subject to the CBS algorithm are able to transmit when the following conditions are met.

- At least one frame is stored in the queue.
- The credit for the queue is 0 or a positive value.

The credit for a transmission queue is incremented while one or more frames from the queue are present in the transmission FIFO but transmission of these frames is not proceeding. This state is indicated by the transmission process status bit for queue t in the AVB-DMAC status register (CSR.TPOt) being clear (0). The credit is decremented while transmission of a frame from the queue is in progress. This mechanism is used to control transmission so that the amount of data for transmission for each queue does not exceed the specified maximum bandwidths.

IEEE 802.1Q defines the following parameters for queues under the control of the CBS algorithm.

**portTransmitRate:** Maximum transmission data rate of an external port. The E-MAC determines this parameter.

**bandwidthFraction:** Maximum fraction of portTransmitRate that can be used for a queue.

**idleSlope**: Rate of change of credit for a queue when transmission of frames from the queue is not proceeding so the credit value (in bits per second) is increasing. idleSlope is also equal to the maximum fraction of the total bandwidth (portTransmitRate) that is available to the given queue under a specified condition (frames from the queue can be placed in a continuous stream. See Annex L of IEEE 802.Q.
idleSlope = bandwidthFraction * portTransmitRate

**sendSlope**: Rate of change of credit (in bits per second) for a queue while transmission of a frame from the queue is in progress so the credit value is decreasing.
The value of sendSlope is defined as follows:
sendSlope = idleSlope - portTransmitRate

Furthermore, the values below are used to define individual traffic classes (or queues for the classes) under control of the algorithm. See Annex L of IEEE 802.Q.

**maxFrameSize:** Maximum size of frames (in bits) of the corresponding traffic class that can be transmitted from a port

**maxInterferenceSize:** Maximum burst size (in bits) by which delays for the corresponding traffic class can be allowed

**hiCredit:** Maximum credit value (positive number). Can be calculated by using the following equation: hiCredit = maxInterferenceSize * (idleSlope / portTransmitRate)

**loCredit:** Minimum credit value (negative number). Can be calculated by using the following equation: loCredit = maxFrameSize * (sendSlope / portTransmitRate)

Figure 57.41 shows how the CBS algorithm works and the meaning of the above parameters. When there is no frame to be transmitted in the queue in the transmit-enabled state, the credit value is 0 (after Frame 0 transmission in the figure).

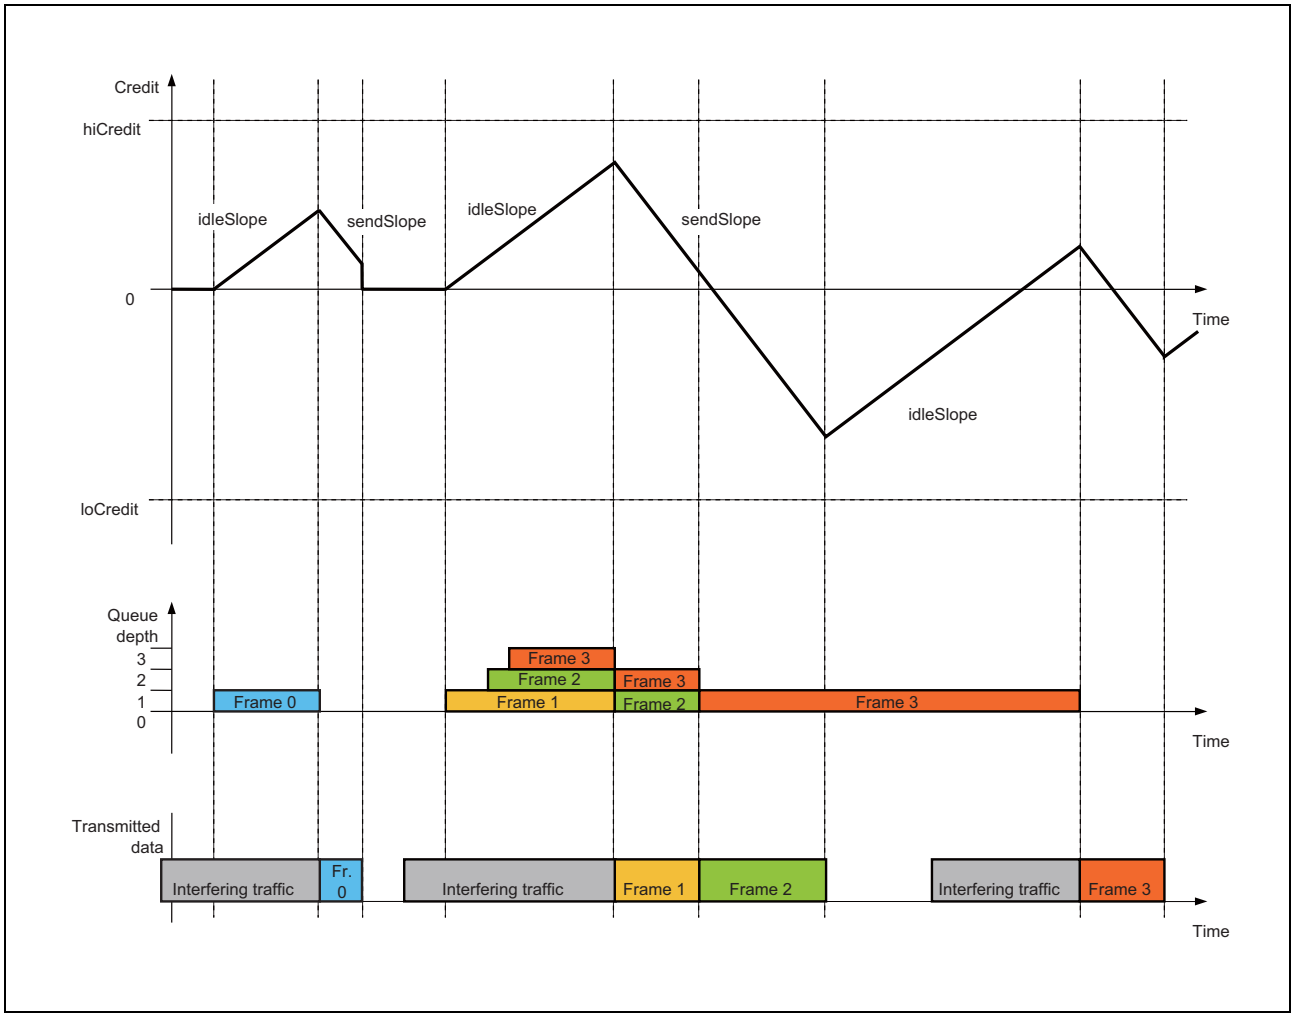

**Figure 57.41 CBS (Credit-Based Shaping) Operation**

Figure 57.42 shows the operation of CBS (Credit Based Shaping) in the AVB-DMAC.

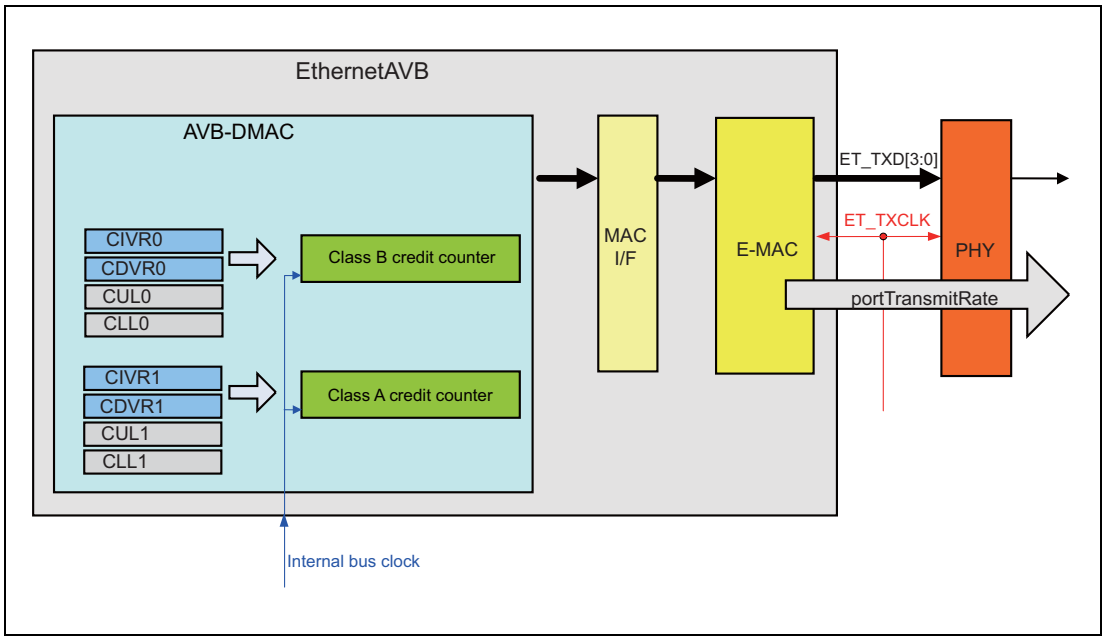

**Figure 57.42 CBS (Credit-Based Shaping) Operation in the AVB-DMAC**

The CBS operation in the AVB-DMAC is based on “credit counters” for the respective traffic classes (SR class A and class B). The following parameters apply for these classes.

CBS increment value (CIV): Signed positive number
The credit is incremented by this amount every internal bus clock cycle while a frame from the queue is pending but transmission has not started (idleSlope).

CBS decrement value (CDV): Signed negative number
The credit is decremented by this amount every internal bus clock cycle while transmission of a frame from the queue is proceeding (sendSlope).

The CBS increment value (CIV) and CBS decrement value (CDV) are defined as follows.

CIV = idleSlope * Mfactor

CDV = sendSlope * Mfactor

Mfactor is a multiplier factor to ensure accuracy for CIV and CDV. CIV and CDV are finally calculated by using the following equations.

CIV = (portTransmitRate/Bϕ) * bwFraction * Mfactor

CDV = (portTransmitRate/Bϕ) * (bwFraction - 1) * Mfactor

The credit counters are driven by the internal bus clock (Bϕ), so calculating the slope parameters for CBS requires (1/Bϕ).

Mfactor must be calculated for the CBS parameters. All queues for the same class must have the same CBS parameters. Mfactor for a certain class can be changed during operation, unless transmission is pending for that class (i.e. the transmit process status bit in the AVB-DMAC status register (CSR.TPOt) = 0). At that time, the credit counter values for class are 0. Note that the credit value will

not match a new incrementation or decrementation parameter if Mfactor is changed while the credit counter value is non-zero. Mfactor configuration register is not present in the AVB-DMAC.

Set the CIV and CDV parameters in the CBS increment value registers (CIVRc) and the CBS decrement value registers (CDVRc). They should be dynamically updated when streams are registered and erased in accord with IEEE 802.1Qat.

Although the credit counters operate with the internal bus clock (Bφ), a transmission clock is used in frame transmission. Therefore, time lags occur when frame transmission starts and ends.

For this reason, an extra credit is stored after a frame is transmitted. The maximum value of the credit to be stored is the credit value incremented for one cycle of the Bφ clock and equals the Tx port transmission rate in Mbps * Bφ.

Bandwidth needs to be secured by software taking this into account.

The AVB-DMAC also has CBS upper limit registers (CULc) (the upper limit registers for classes A and B) and CBS lower limit registers (CLLc) (the lower limit registers for classes A and B). Multiply the upper limit (hiCredit) and the lower limit (loCredit) by Mfactor for each class as defined above so that the resulting values agree with the credit values.

CUL = hiCredit * Mfactor = maxInterferenceSize * bwFraction * Mfactor

CLL = loCredit * Mfactor = maxFrameSize * (bwFraction - 1) * Mfactor

**Example:**

Assume that portTransmitRate = 100 Mbps, Bϕ = 130 MHz and bwFraction = 3%. Then idleSlope and sendSlope represented as one bit vs. cycles of the peripheral bus clock are as follows.

idleSlope = (portTransmitRate/Bϕ) * bwFraction = 100/130 (Mbps/MHz) * 3% = 0.023 (bit/Bϕ)

sendSlope = idleSlope - (portTransmitRate / Bϕ) = -0.746 (bit/Bϕ)

Let Mfactor be 100, then CIV and CDV parameters are determined as follows.

CIV = idleSlope * Mfactor = 23

CDV = sendSlope * Mfactor = -74.6

### 57.3.6.1 Restrictions on CIV, CDV and Mfactor

The maximum value (the minimum value for negative numbers) up to which the credit counter will not overflow determines the maximum values of CIV and CDV that can be set in the CBS registers. This maximum credit value is equivalent to the worst case of the hiCredit value, and the maximum values for class A and class B are calculated as follows.

<Conditions>

- Class A maximum value (hiCredit_max_classA)
  classA bwFraction ≅ 100%
  Maintaining the proper relations in the transmission priority order requires waiting for a period equivalent to the one maximum sized frame.
  hiCredit_max_classA ≅ maxInterferenceSize for class A = Waiting for a period equivalent to one maximum sized frame = header + maximum size payload + CRC (2000 bytes) + preamble (8 bytes) + IFG (12 bytes) + processing_delay (≅ 80 bytes) ≅ 2100 bytes
- Class B maximum value (hiCredit_max_classB)
  classB bwFraction ≅ 100%
  Maintaining the proper relations in the transmission priority order requires waiting for a period equivalent to the respective one maximum sized frame in the class A transmission queue and other transmission queues.
  hiCredit_max_classB ≅ maxInterferenceSize for class B = Waiting for a period equivalent to two maximum sized frames = 2* hiCredit_max_classA ≅ 4200 bytes

In bit units, calculated as follows:

hiCredit_max_classA = 16800

hiCredit_max_classB = 33600

The 32-bit signed counter can handle from $-2^{31}$ to $2^{31}-1$, so the specifiable maximum values of Mfactor without overflow are:

Mfactor_max_classA = $2^{31}-1$ / hiCredit_max_classA ≅ 127826 and
Mfactor_max_classB = $2^{31}-1$ / hiCredit_max_classB ≅ 63913.

A high degree of accuracy can be achieved even with a low bandwidth. In class B, bandwidthFraction = 0.05% and the bandwidth error < 0.1%.

The maximum value of CIV is calculated from the following equation.

CIV = idleSlope x Mfactor = (portTransmitRate / Bϕ) * bandwidthFraction × Mfactor

When Mfactor is the maximum value and bandwidthFraction is the maximum value (up to 100%):

CIV_max_classA = (portTransmitRate / Bϕ) * Mfactor_max_classA and
CIV_max_classB = (portTransmitRate / Bϕ) * Mfactor_max_classB.

The maximum values when portTransmitRate = 100 Mbps and Bϕ = 130 MHz are as follows:

CIV_max_classA ≅ 98328

CIV_max_classB ≅ 49164

Table 57.80 shows examples of values for portTransmitRate and internal bus clock frequency. The values in this table are just the results of calculation, so when actually setting values, the CIV values must be limited so that the 32-bit credit counter will not overflow. In the AVB-DMAC, the CIV parameters are implemented as 16 bits + a sign bit, so CIV ≤ 65535 should be applied to both class A and class B.

**Table 57.80 Example of Maximum Values for Class A and Class B CIV Parameters**

| portTransmitRate | Bϕ [MHz] | CIV_max_classA | CIV_max_classB |
|---|---|---|---|
| 100 Mbps | 100 | 127826 | 63913 |
| 100 Mbps | 125 | 102260 | 51130 |
| 100 Mbps | 133 | 96109 | 48054 |

### 57.3.6.2 Credit Incrementation (IFGs)

In the CBS credit counter in the AVB-DMAC, the inter-frame gap (IFG) after a frame is transmitted is not treated as part of frame transmission. During an IFG, the credit is incremented for all SR queues that have pending frames or negative credit. Figure 57.43 illustrates credit operations during IFGs.

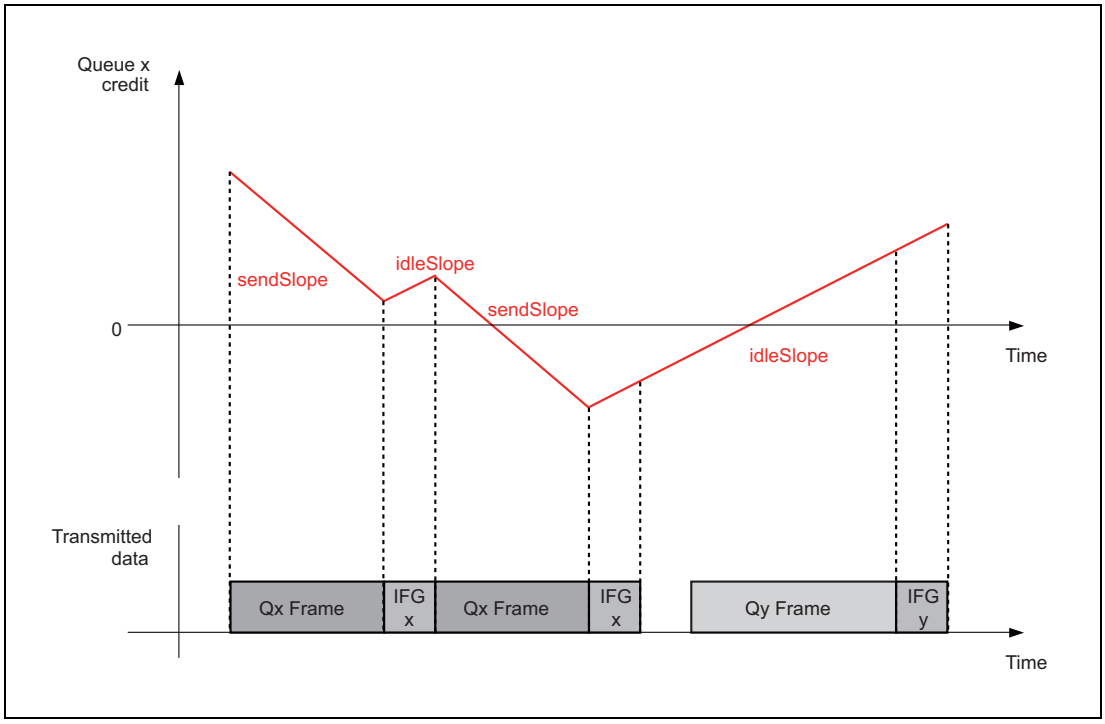

**Figure 57.43 Credit Operations during IFGs**

The IFG need not be included in calculation of the bandwidth for the specified SR class when deciding the idleSlope, sendSlope, and CIV and CDV parameters. However, IFG must also be included in the calculation in order to confirm that the total bandwidth allocated to all SR classes does not exceed 100% of portTransmitRate.

### 57.3.6.3 CBS Setting Example

The case of a class A 48-kHz stereo audio stream among Ethernet frames is described as an example.

After every class A measurement interval (125 us), 80 octets consisting of two sets of six 32-bit samples plus a 32-octet header are stored as audio data within a frame. The IEEE 802.3 also imposes a 42-octet media-specific frame overhead (an 8-octet preamble, 14-octet IEEE 802.3 header, 4-octet IEEE 802.1Q priority/VID Tag, 4-octet CRC, and 12-octet IFG) are also added. Accordingly, the total frame size is 80 + 42 = 122, and one such frame is transmitted after every class measurement interval.

This represents a total bandwidth of about 7.8 Mbits per second (122 octets × 8 bits per octet × 8000 frames per second) for this class. The E-MAC runs at 100 Mbps (portTransmitRate), so the allocation of the total bandwidth to each class A queue corresponds to 7.8%. If other traffic classes are to share the total transmission bandwidth, checking that the total allocation of bandwidth with this 7.8% allocation does not exceed 100% of portTransmitRate is required.

To obtain the CIV and CDV parameters for a given class, the IFG must not be taken into account in calculation of the frame size. For this case, therefore, we obtain the total bandwidth for the class = about 7.04 Mbps (110 octets × 8 bits per octet × 8000 frames per second) = 7.04% of portTransmitRate.

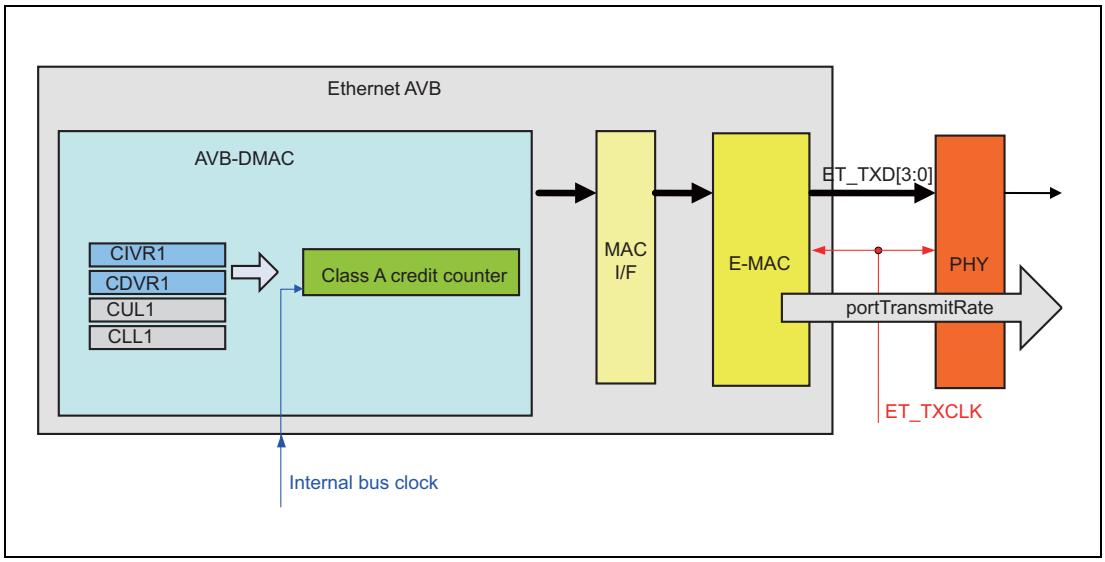

**Figure 57.44 Example of CBS Settings**

In this setting example, operating frequency and so on in each section are as follows:

- the E-MAC runs at 100 Mbps, so portTransmitRate = 100 Mbps and
- high-speed internal bus clock (operating clock for the credit counter) frequency = 133 MHz,

securing a bandwidth of 7.04 Mbits/sec for class A requires configuring the CBS parameters as follows.

- bandwidthFraction = 7.04%
- idleSlope = (portTransmitRate / Bϕ) * bandwidthFraction ≅ 0.05293 bits per Bϕ
- sendSlope = idleSlope – (portTransmitRate / Bϕ) ≅ -0.69895 bits per Bϕ

When Mfactor = 10000, the parameters are as follows.

- CIV = idleSlope × Mfactor = 529 bits per Bϕ

- CDV = sendSlope × Mfactor = -6989 bits per Bϕ

These are the final values for setting in the CIVR1 and CDVR1 registers.

## 57.3.7 IEEE802.1: gPTP

### 57.3.7.1 gPTP Timer

An 84-bit timer is provided to support the gPTP function. Figure 57.45 shows the overview of the timer.

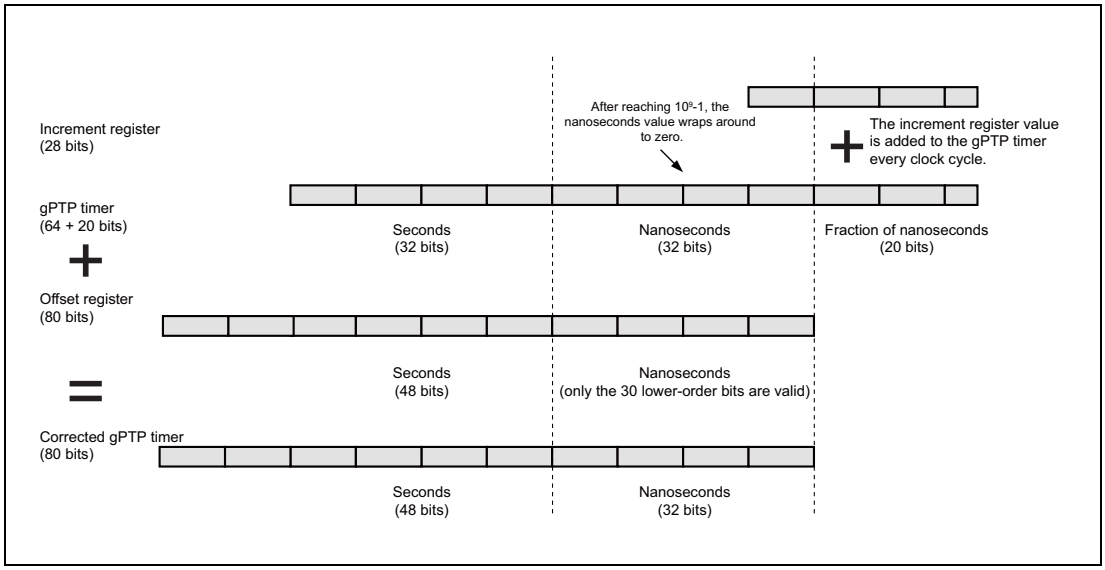

**Figure 57.45 gPTP Timer**

The higher-order 32 bits indicate seconds. For the next 32 bits indicate nanoseconds. The lower-order 20 bits indicate fractional nanoseconds. Software can only read the 32 higher-order bits, indicating seconds, and the subsequent 32-bits, indicating nanoseconds. The 20 lower-order 20 bits, representing less than 1 ns, are provided within the AVB-DMAC to maintain accuracy in time measurement, and cannot be referenced.

The timer can be reset by setting the timer control request bits in the gPTP configuration control register (GCCR.TCR[1:0]) to B'01. These bits are set to B'00 on completion of normal resetting of the timer.

After the timer starts, the value in the gPTP timer increment value bit (GTI.TIV) is added to the value of the gPTP timer every clock cycle. When the value of the nanosecond part reaches $10^9$ - 1, it returns to 0 when the next 1 nanosecond is counted. The fractional nanosecond value is represented by 20 bits and can be adjusted in precision of $1/2^{20}$ (1/1048576) nanosecond.

Before setting a value in the gPTP timer increment value bit (GTI.TIV), set the timer increment value setting request bit in the gPTP configuration control register (GCCR.LTI) to 1. If this bit is not set to 1, new values that are written will not be reflected in the register. This bit returns to 0 after the setting is completed.

An offset to the gPTP timer is also available. If this is required, set the value in the timer offset value bit (GTO.TOV). Before setting a value in this register, set the timer offset value setting request bit in the gPTP configuration control register (GCCR.LTO) to 1. If this bit is not set to 1, new values that are written will not be reflected in the register. This bit returns to 0 after the setting is completed. Set the value from 0 to $10^9$ - 1 to the timer offset value bits (GTO0.TOV[31:0]) in the nanoseconds portion. When adding an offset, take care that the calculation result with the offset added does not exceed 80 bits.

The value of the gPTP timer can be read from the gPTP timer capture value bit (GCTi.CTV) by setting the timer control request bits in the gPTP timer control register (GCCR.TCR[1:0]) to B'11. Set the timer capture source select bits in the gPTP configuration control register (TCCR.TCSS) to select the timer value for capture as the value of the gPTP timer, the corrected value of the gPTP timer (value with the offset added), or the AVTP presentation time. Setting the timer control request bits in the gPTP configuration control register (GCCR.TCR[1:0]) to B'11 initiates the capture. Once normal capture of the timer is complete, the value of the timer control request bits in the gPTP configuration control register (GCCR.TCR[1:0]) returns to B'00.

The timer for gPTP operates as a free-running timer but can be synchronized with the Grandmaster clock.

The timer clock source can be selected from the internal bus clock and Ethernet transmission clock by setting the gPTP clock select bits (CCC.CSEL[1:0]).

#### 57.3.7.2 Free-Running Operation

The IEEE 802.1 AS standard does not prescribe the adjustment of local clocks to the Grandmaster clock. To avoid negative effects from the correction procedure, we recommend the use of a free-running timer.

As a free-running timer, the timer counts the local clock based on the local time. The gPTP timer increment value bit (GTI.TIV) is set to 1 ns (the setting value = H'0010 0000) and the timer offset value bit (GTOi.TOV) is set to 0. The ratio information captured at the time of the gPTP delay measurement and synchronization procedures is used to correct the frequency ratio to that of the Grandmaster clock. The Grandmaster clock can be calculated from the local clock by using the information collected during the gPTP measurement and synchronization procedures.

#### 57.3.7.3 Synchronization with the Grandmaster Clock

In situations requiring physical synchronization of the local clock with the Grandmaster clock, the fractional nanoseconds value (the 20 lower-order bits of the gPTP timer) is used to make the adjustment. Specifically, the increment value is finely adjusted to correct for deviations of the clock frequency from that of the Grandmaster clock.

Use the timer offset value bit (GTOi.TOV) to correct for offsets for comparing with the absolute time and so on from start-up. The sum of the timer value and the offset register is the corrected gPTP timer value.

Set the value from 0 to $10^9$ - 1 to the timer offset value bits (GTOi.TOV[31:0]) for setting the nanoseconds portion of the offset.

The following equation gives a method of calculating the increment (GTI.TIV) from the frequency of the gPTP clock and its deviation from that of the Grandmaster clock. Variable d is the deviation (d = $10^{-6}$ for 1 ppm).

$$GTI.TIV = round\left(\frac{2^{20}GHz}{f_{GPTP}} * (1+d)\right)$$

After adjusting for the current deviation of clock frequency, re-set the gPTP timer increment register (GTI.TIV).

After calculating the new offset value, re-set the timer offset configuration register (GTOi.TOV).

- Sample setting 1

When $f_{GPTP}$ = 100 MHz ± 0 ppm (device used is guaranteed by the Grandmaster clock)

gPTP is updated every 10 ns.

Set the gPTP timer increment value bits (GTI.TIV) to H’00A0_0000.

- Sample setting 2

When $f_{GPTP}$ = 100 MHz - 10 ppm

gPTP is updated every 10 ns.

Set the gPTP timer increment value bits (GTI.TIV) to H’00A0_0069 (10485864.8576 before rounded off). Rounding off the value causes a frequency error less than 1 ppm.

### 57.3.7.4 Support Provided by the gPTP Timer in Transmission and Reception

The timer value described above is used in the time-stamp values captured when start frame delimiters are detected in reception and generated in transmission.

Captured time stamp values for received frames are stored in the corresponding descriptors. Those for transmitted frames are stored with tag information in the time-stamp FIFO. The time stamp values are thus correlated with both transmitted and received frames.

Note that the use of corrected gPTP timer values can introduce an error due to the offset correction in the gPTP synchronization procedure.

Errors due to SFD notification and the interface between the timer modules must also be taken into account. Although SFDs for transmission and reception are detected in synchronization with the transmission and reception clocks, respectively, the gPTP operates with a gPTP clock. Therefore, an error of ± 1 GTI.TIV + 1 Bφ is generated.

### 57.3.8 Support for IEEE 1722

For IEEE 1722, the following two functions are supported.

- Output and capture of values in the IEEE 1722 AVTP (Audio/Video Transport Protocol) presentation time format
- Comparison of IEEE 1722 AVTP presentation time stamps

The 32-bit AVTP time stamp field of IEEE 1722 frames holds the AVTP presentation time when the AVTP time-stamp enable bit in the frame is 1. The AVTP time stamp field is generated from the pPTP timer and is given as seconds (gPTP_seconds) and nanoseconds (gPTP_nanoseconds) according to the following equation.

AVTP time stamp = (gPTP_seconds * $10^9$ + gPTP_nanoseconds) modulo $2^{32}$

The AVTP presentation time can be read from the gPTP timer capture value bit (GCTi.CTV). Set the timer capture source select bits in the gPTP configuration control register (TCCR.TCSS) to select the timer value for capture as the AVTP presentation time. Setting the timer control request bits in the gPTP configuration control register (GCCR.TCR[1:0]) to B’11 initiates the capture. The value stored as the capturing result is obtained by adding the maximum transit time defined in the maximum transit time bits (GMTT.MTTV) to the corrected gPTP timer value. The AVTP presentation time wraps around approximately every four seconds.

CAUTION

The AVTP presentation time captured in GCTi.CTV is only valid when the corrected gPTP timer value is in synchronization with the Grandmaster clock. That is, the timer increment and timer offset values for the corrected gPTP timer value must be adjusted by the synchronization procedure so that the corrected gPTP clock is adjusted to match the time kept by the Grandmaster clock.

### 57.3.9 Flow Control

The E-MAC supports flow control for full-duplex operation in compliance with the IEEE 802.3 standards. This flow control is applicable to both reception and transmission. In regard to the transmission of PAUSE frames, flow control operates in the following ways.

(1) Automatic PAUSE Frame Transmission

For the received frames, PAUSE frames are automatically transmitted when the amount of data having been written in the reception FIFO reaches the value specified by the receive FIFO caution level bits in the receive configuration register (RCR.RFCL). The TIME parameter contained in the PAUSE frame can be specified by the automatic PAUSE frame register (APR). If the maximum count of PAUSE frame retransmission times is not specified, PAUSE frames are automatically transmitted repeatedly until the data is read from the reception FIFO and the remaining data amount becomes smaller than the value specified by the RCR.RFCL. As the maximum count of PAUSE frame retransmission times, any value from 1 to 65535 can be specified by the PAUSE frame retransmission count register (TPAUSER). In this case, PAUSE frames are automatically transmitted repeatedly until the remaining data amount becomes smaller than the value specified by the RCR.RFCL or the count of retransmission times reaches the value specified by the TPAUSER. The retransmit counter is cleared to 0 when the next PAUSE frame is transmitted once the data amount in the reception FIFO becomes smaller than the value specified by the RCR.RFCL.

Automatic PAUSE frame transmission is enabled when the operating mode bit for flow control in transmission in the E-MAC mode register (ECMR.TXF) is 1.

(2) Manual PAUSE Frame Transmission

PAUSE frames can also be transmitted in response to software operations. Writing a timer value to the manual PAUSE frame register (MPR) starts the transmission of a PAUSE frame. This only causes the transmission of one PAUSE frame.

(3) PAUSE Frame Reception

After reception of a PAUSE frame, transmission of the next frame does not proceed until the time indicated by the Timer value elapses. However, transmission of a frame currently being transmitted continues. PAUSE frames are only received while the operating mode for flow control in reception bit in the E-MAC mode register (ECMR.RXF) is set to 1. The number of received PAUSE frames is counted.

(4) 0 TIME PAUSE Frame Control

The setting of the PAUSE frame usage with TIME = 0 enable bit in the E-MAC mode register (ECMR.ZPF) enables or disables the transmission of PAUSE frames with the TIME parameter value 0. The setting of the PAUSE frame reception with time = 0 bit in the E-MAC mode register (ECMR.RZPF) enables or disables the reception of PAUSE frames with the TIME parameter value 0.

- Operation for transmission
  When the 0-time PAUSE frame control is enabled, PAUSE frame with the TIME parameter value 0 is transmitted when the capacity of the reception FIFO is less than the value of the receive FIFO caution level bits in the receive configuration register (RCR.RFCR) while the time indicated by the TIME parameter value has not elapsed.
  When the 0-time PAUSE frame control is disabled, PAUSE frames with the TIME parameter value 0 are not transmitted.
- Operation for reception

When the 0-time PAUSE frame reception is enabled, frame transmission wait state is released when PAUSE frame with the TIME parameter value 0 is received.
When the 0-time PAUSE frame reception is disabled, received PAUSE frames with the TIME parameter value 0 are discarded.

### 57.3.10 Interrupts

The EthernetAVB module has four interrupts: three interrupts from the AVB-DMAC and one interrupt from the E-MAC. The three interrupts from the AVB-DMAC are generated when the AVB-DMAC is placed in operation mode, and the one interrupt from the E-MAC is generated when the AVB-DMAC is placed in configuration, operation, or standby mode.

Table 57.81 is a list of the interrupts.

**Table 57.81 EthernetAVB Interrupts**

| Interrupt Source Name | Remarks |
|---|---|
| AVB_DATA | Transmit/receive data management interrupt |
| AVB_ERROR | Error management interrupt |
| AVB_MANAGE | Other management (FIFO caution level, etc.) interrupt |
| AVB_MAC | E-MAC interrupt |

The AVB-DMAC related interrupts include descriptor interrupts (15 sources), error interrupts (5 sources), reception interrupts (37 sources), transmission interrupts (2 sources), and gPTP interrupts (3 sources). From the CPU's perspective, each appears as one of the above four interrupt sources.

The states of an AVB-DMAC-related interrupt sources can be checked in the following registers.

- Descriptor interrupt status register (DIS)
- Error interrupt status register (EIS)
- Receive interrupt status register (RISi)
- Transmit interrupt status register (TIS)
- gPTP interrupt status register (GIS)

The interrupts are controlled by the corresponding interrupt enable bits. However, the status flags operate independently of the settings of the enable bits.

The states of grouped interrupts can be checked by reading the interrupt summary status register (ISS) and the queue full error interrupt status bit in the error interrupt status register (EIS.QFS).

#### 57.3.10.1 Transmit/Receive Data Management Interrupt

The management interrupt for transmission and reception is conveyed when the interrupt conditions corresponding to the following sources are satisfied.

- Receive frame interrupt in the receive interrupt status register 0 (RIS0.FRFr)
- Descriptor interrupt in the descriptor interrupt status register (DIS.DPFi)

#### 57.3.10.2 Error Management Interrupt

The error management interrupt is conveyed when interrupt conditions corresponding to the following sources are satisfied.

- Time stamp FIFO full error interrupt in the error interrupt status register (EIS.TFFF)
- CBS limitation value error interrupts in the error interrupt status register (EIS.CULF1, EIS.CULF0, EIS.CLLF1, EIS.CLLF0)
- Receive FIFO full interrupt in the receive interrupt status register 2 (RIS2.RFFF)
- Receive queue full interrupt in the receive interrupt status register 2 (RIS2.QFFr)

#### 57.3.10.3 Other Management (FIFO Warning, etc.) Interrupts

The other management (FIFO warning, etc.) interrupt is conveyed when interrupt conditions corresponding to the following sources are satisfied.

(1) Reception related interrupt

Receive FIFO warning interrupt in the receive interrupt status register 1 (RIS1.RFWF)

(2) Transmission related interrupts

Time stamp FIFO warning interrupt in the transmit interrupt status register (TIS.TSWF)

Time stamp FIFO update interrupt in the transmit interrupt status register (TIS.TSUF)

(3) gPTP related interrupts

Presentation time match interrupt in the gPTP interrupt status register (GIS.PTMF)

#### 57.3.10.4 E-MAC Interrupt

The E-MAC interrupt is conveyed when the following E-MAC interrupt sources are generated.

- PAUSE frame retransmit retry over interrupt in the E-MAC status register (ECSR.PFROI)
- Illegal carrier detection interrupt in the E-MAC status register (ECSR.ICD)

| Write | 1..1 | 01 | 01 | 00001 | RRRRR | 10 | D..D | X |

[Legend]

PRE: 32 consecutive 1s
ST: Write of 01 indicating start of frame
OP: Write of code indicating access type
PHYAD: Write of 0001 if the PHY-LSI address is 1 (sequential write starting with the MSB).
This bit changes depending on the PHY-LSI address.
REGAD: Write of 000q if the register address is 1 (sequential write starting with the MSB).
This bit changes depending on the PHY-LSI register address.
TA: Time for switching data transmission source on MII interface
(a) Write: 10 written
(b) Read: Bus release (notation: Z0) performed
DATA: 16-bit data. Sequential write or read from MSB
(a) Write: 16-bit data write
(b) Read: 16-bit data read
IDLE: Wait time until next MII management format input
(a) Write: Independent bus release (notation: X) performed
(d) Read: Bus already released in TA: control unnecessary

### (2) MII Register Access Procedure

The program accesses MII registers via PIR. Access is implemented by a combination of 1-bit-unit data write, 1-bit-unit data read, bus release, and independent bus release. Figure 57.65 to Figure 57.68 show the MII register access timing. The timing will differ depending on the PHY-LSI type.

## 57.3.13 Usage Notes

### 57.3.13.1 Checksum Calculation of Ethernet Frames

This LSI is capable of calculating the checksum data of the received frames. Only the data fields of the Ethernet frames are subject to checksum calculation. Specifically, a data field follows the length/type field and is followed by the CRC field. Figure 57.69 shows schematics indicating which parts of the Ethernet frames are calculated. Calculation involves 16-bit addition only; it does not involve bit inversion. Note that when the checksum data is valid, the CRC data (4 bytes) is not transferred as a receive frame, and the checksum data (sum data) is added automatically. Figure 57.70 shows schematics of Ethernet frames to which the checksum data has been added.

CAUTION

Also for the frames with VLANtag inserted, the 15th byte from the top and the following bytes before the CRC field are subject to calculation.
