

## Description

The ICS557-05A is a spread-spectrum clock generator that supports PCI-Express requirements. It is used in PC or embedded systems to substantially reduce electro-magnetic interference (EMI). The device provides four differential HCSL or LVDS high-frequency outputs with spread spectrum capability. The output frequency and spread type are selectable using external pins.

## Features

- Packaged in 20-pin TSSOP
- RoHS 5 (green) or RoHS 6 (green and lead free) compliant package
- Supports PCI-Express applications
- Four differential spread spectrum clock outputs
- Spread spectrum for EMI reduction
- Uses external 25 MHz clock or crystal input
- Power down pin turns off chip
- OE control tri-states outputs
- Spread and frequency selection via external pins
- Spread Bypass option available
- Industrial temperature range available
- **For PCIe Gen2 applications, see the 5V41066**
- **For PCIe Gen3 applications, see the 5V41236**

## Application Information

### Decoupling Capacitors

As with any high-performance mixed-signal IC, the ICS557-05A must be isolated from system power supply noise to perform optimally.

Decoupling capacitors of  $0.01\mu\text{F}$  must be connected between each VDD and the PCB ground plane.

### PCB Layout Recommendations

For optimum device performance and lowest output phase noise, the following guidelines should be observed.

Each  $0.01\mu\text{F}$  decoupling capacitor should be mounted on the component side of the board as close to the VDD pin as possible. No vias should be used between decoupling capacitor and VDD pin. The PCB trace to VDD pin should be kept as short as possible, as should the PCB trace to the ground via. Distance of the ferrite bead and bulk decoupling from the device is less critical.

2) An optimum layout is one with all components on the same side of the board, minimizing vias through other signal layers (the ferrite bead and bulk decoupling capacitor can be mounted on the back). Other signal traces should be routed away from the ICS557-05A.

This includes signal traces just underneath the device, or on layers adjacent to the ground plane layer used by the device.

### External Components

A minimum number of external components are required for proper operation. Decoupling capacitors of  $0.01\mu\text{F}$  should be connected between VDD and GND pairs (1,9 and 15,16) as close to the device as possible.

**On chip capacitors-** Crystal capacitors should be connected from pins X1 to ground and X2 to ground to optimize the initial accuracy. The value (in pf) of these crystal caps equal  $(C_L - 12) \times 2$  in this equation,  $C_L$ =crystal load capacitance in pf. For example, for a crystal with a 16 pf load cap, each external crystal cap would be 8 pf.  $[(16-12) \times 2] = 8$ .

### Current Reference Source $R_r$ (Iref)

If board target trace impedance ( $Z$ ) is  $50\Omega$  then  $R_r = 475\Omega$  (1%), providing IREF of 2.32 mA, output current ( $I_{OH}$ ) is equal to  $6 \times \text{IREF}$ .

### Load Resistors $R_L$

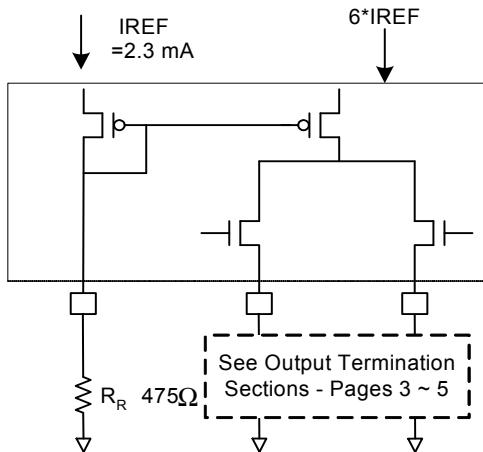

Since the clock outputs are open source outputs, 50 ohm external resistors to ground are to be connected at each clock output.

### Output Termination

The PCI-Express differential clock outputs of the ICS557-05A are open source drivers and require an external series resistor and a resistor to ground. These resistor values and their allowable locations are shown in detail in the **PCI-Express Layout Guidelines** section.

The ICS557-05A can also be configured for LVDS compatible voltage levels. See the **LVDS Compatible Layout Guidelines** section.

## Output Structures

## General PCB Layout Recommendations

For optimum device performance and lowest output phase noise, the following guidelines should be observed.

1. Each  $0.01\mu\text{F}$  decoupling capacitor should be mounted on the component side of the board as close to the VDD pin as possible.
2. No vias should be used between decoupling capacitor and VDD pin.
3. The PCB trace to VDD pin should be kept as short as possible, as should the PCB trace to the ground via. Distance of the ferrite bead and bulk decoupling from the device is less critical.
4. An optimum layout is one with all components on the same side of the board, minimizing vias through other signal layers (any ferrite beads and bulk decoupling capacitors can be mounted on the back). Other signal traces should be routed away from the ICS557-05A. This includes signal traces just underneath the device, or on layers adjacent to the ground plane layer used by the device.
