

General Description

The 840N021 is a LVCMOS/LVTTL clock synthesizer designed for Ethernet applications. The device generates a 125MHz clock signal from a 25MHz crystal with excellent phase jitter performance. The device uses IDT's fourth generation FemtoClock® NG technology for an optimum of high clock frequency, low phase noise performance and low power consumption. The device supports 2.5V or 3.3V voltage supply and is packaged in a small, lead-free (RoHS 6) 8-lead TSSOP package. The extended temperature range supports wireless infrastructure, telecommunication and networking end equipment requirements. The device is a member of the high-performance clock family from IDT.

Frequency Table

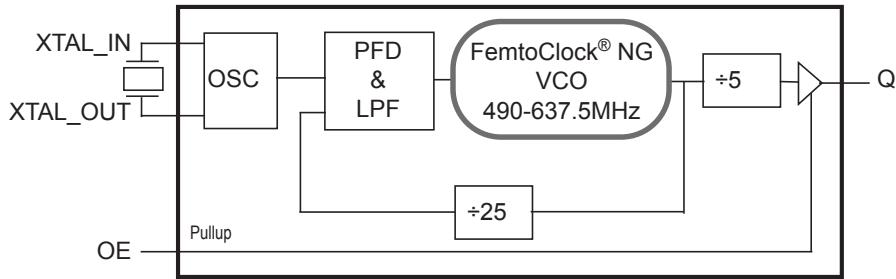

f_{XTAL} (MHz)	Q Output Frequency (MHz)
20	100
25	125

Function Table

Input	Output Enable
OE	
0	Output Q is disabled in high-impedance state
1 (default)	Output Q is enabled.

NOTE: OE is an asynchronous control.

Block Diagram

Features

- Fourth generation FemtoClock® NG technology
- 125MHz output clock synthesized from a 25MHz fundamental mode crystal
- One 2.5V or 3.3V LVCMOS/LVTTL clock output
- Crystal interface designed for a 12pF parallel resonant crystal
- RMS phase jitter @ 125MHz, using a 25MHz crystal (1.875MHz - 20MHz): 0.156ps (maximum)
- RMS phase jitter @ 100MHz, using a 20MHz crystal (12kHz - 20MHz): 0.451ps (maximum)
- LVCMOS interface level for the output enable input
- Full 2.5V or 3.3V supply voltage
- Lead-free (RoHS 6) packaging
- -40°C to 85°C ambient operating temperature
- **Use replacement part 840N202CKI-dddLF**

Pin Descriptions and Characteristics

Table 1. Pin Descriptions

Number	Name	Type		Description
1	V_{DDA}	Power		Analog power supply.
2	OE	Input	Pullup	Output enable pin. LVCMS interface levels.
3, 4	XTAL_OUT, XTAL_IN	Input		Crystal oscillator interface. XTAL_IN is the input, XTAL_OUT is the output.
5	DNU			Do not use. Do not connect.
6	GND	Power		Power supply ground.
7	Q	Output		Single-ended clock output. LVCMS/LVTTL interface levels.
8	V_{DD}	Power		Core supply pin.

NOTE: *Pullup* refers to an internal input resistor. See Table 2, *Pin Characteristics*, for typical values.

Table 2. Pin Characteristics

Symbol	Parameter	Test Conditions	Minimum	Typical	Maximum	Units
C_{IN}	Input Capacitance	OE		3.5		pF
C_{PD}	Power Dissipation Capacitance	$V_{DD} = 3.465V$		11		pF
		$V_{DD} = 2.625V$		9		pF
R_{PULLUP}	Input Pullup Resistor			51		k Ω
R_{OUT}	Output Impedance	$V_{DD} = 3.3V$		15		Ω
		$V_{DD} = 2.5V$		19		Ω

Absolute Maximum Ratings

NOTE: Stresses beyond those listed under *Absolute Maximum Ratings* may cause permanent damage to the device. These ratings are stress specifications only. Functional operation of product at these conditions or any conditions beyond those listed in the *DC Characteristics* or *AC Characteristics* is not implied. Exposure to absolute maximum rating conditions for extended periods may affect product reliability.

Item	Rating
Supply Voltage, V_{DD}	3.63V
Inputs, V_I XTAL_IN Other Inputs	0V to 2V -0.5V to $V_{DD} + 0.5V$
Outputs, V_O	-0.5V to $V_{DD} + 0.5V$
Package Thermal Impedance, θ_{JA}	117°C/W (0 mps)
Storage Temperature, T_{STG}	-65°C to 150°C

DC Electrical Characteristics

Table 3A. Power Supply DC Characteristics, $V_{DD} = 3.3V \pm 5\%$ or $2.5V \pm 5\%$, $T_A = -40^\circ C$ to $85^\circ C$

Symbol	Parameter	Test Conditions	Minimum	Typical	Maximum	Units
V_{DD}	Core Supply Voltage		2.375	3.3	3.465	V
V_{DDA}	Analog Supply Voltage		$V_{DD} - 0.18$	3.3	V_{DD}	V

odc	Output Duty Cycle		48		52	%

NOTE: Electrical parameters are guaranteed over the specified ambient operating temperature range, which is established when the device is mounted in a test socket with maintained transverse airflow greater than 500 lfpm. The device will meet specifications after thermal equilibrium has been reached under these conditions.

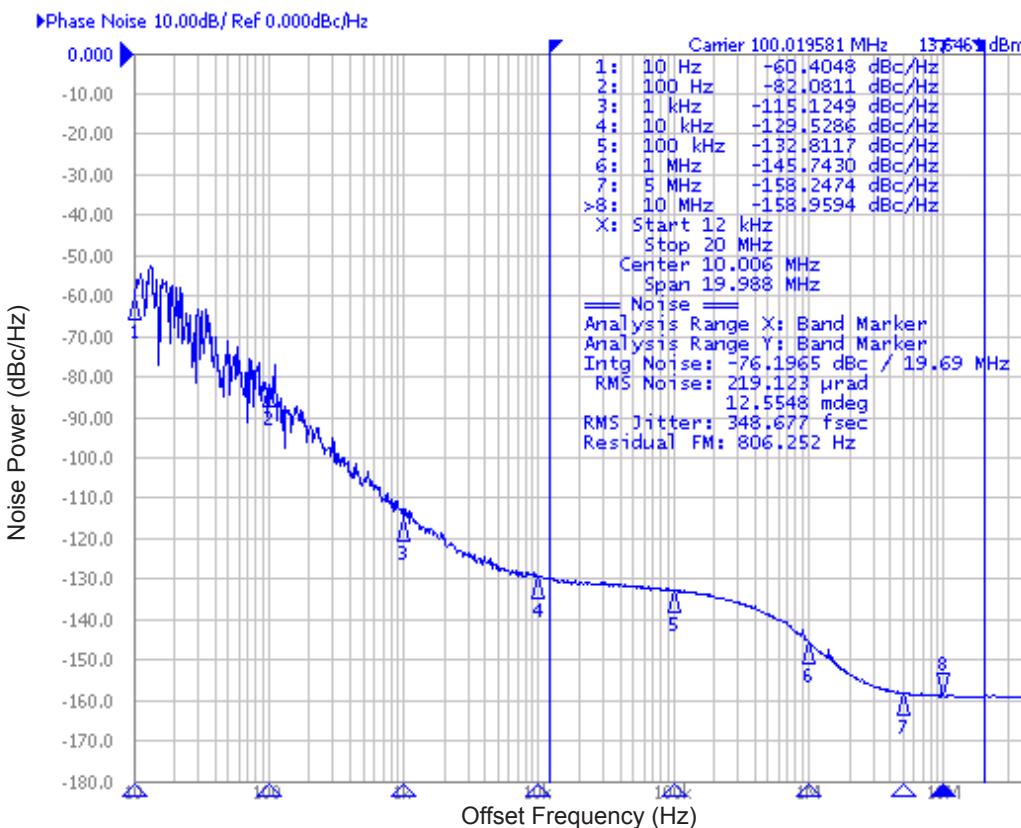

NOTE: Characterized with 20MHz and 25MHz crystals.

NOTE 1: Please refer to the phase noise plots.

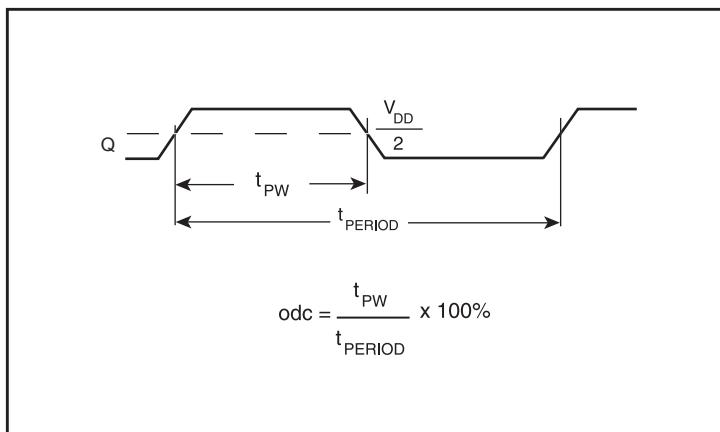

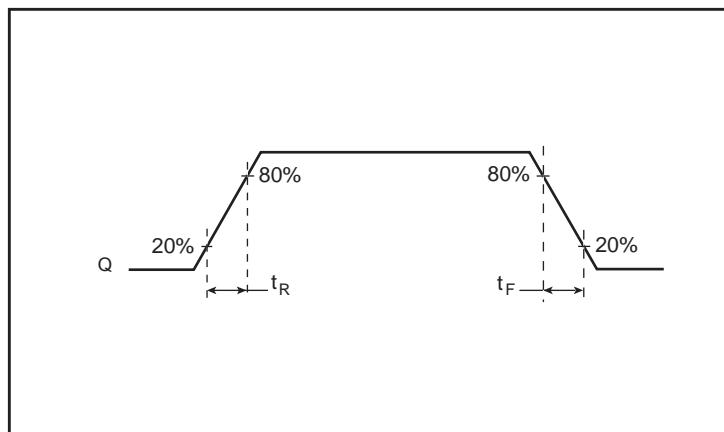

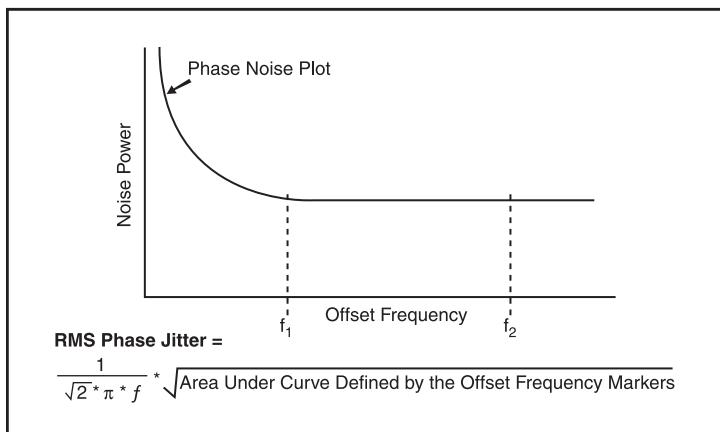

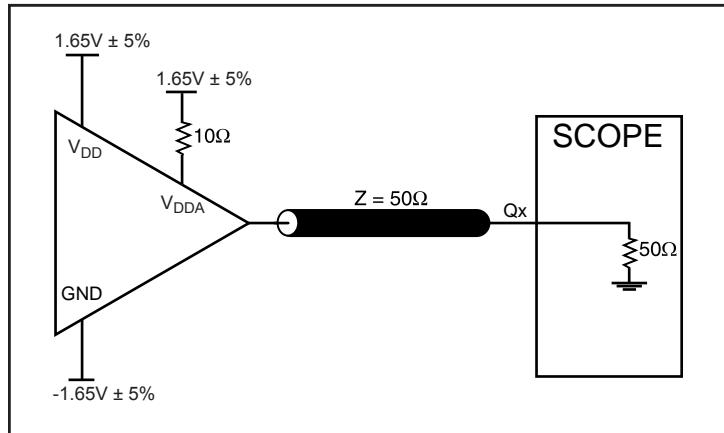

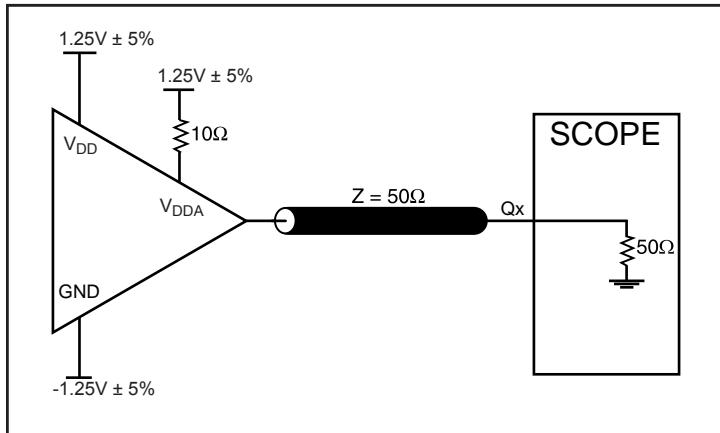

Typical Phase Noise at 125MHz

Typical Phase Noise at 100MHz

Parameter Measurement Information

Applications Information

Overdriving the XTAL Interface

The XTAL_IN input can be overdriven by an LVCMS driver or by one side of a differential driver through an AC coupling capacitor. The XTAL_OUT pin can be left floating. The amplitude of the input signal should be between 500mV and 1.8V and the slew rate should not be less than 0.2V/ns. For 3.3V LVCMS inputs, the amplitude must be reduced from full swing to at least half the swing in order to prevent signal interference with the power rail and to reduce internal noise. *Figure 1A* shows an example of the interface diagram for a high speed 3.3V LVCMS driver. This configuration requires that the sum of the output impedance of the driver (Z_o) and the series resistance (R_s) equals the transmission line impedance. In addition, matched termination at the crystal input will attenuate the signal in half. This

can be done in one of two ways. First, R_1 and R_2 in parallel should equal the transmission line impedance. For most 50Ω applications, R_1 and R_2 can be 100Ω . This can also be accomplished by removing R_1 and changing R_2 to 50Ω . The values of the resistors can be increased to reduce the loading for a slower and weaker LVCMS driver. *Figure 1B* shows an example of the interface diagram for an LVPECL driver. This is a standard LVPECL termination with one side of the driver feeding the XTAL_IN input. It is recommended that all components in the schematics be placed in the layout. Though some components might not be used, they can be utilized for debugging purposes. The datasheet specifications are characterized and guaranteed by using a quartz crystal as the input.

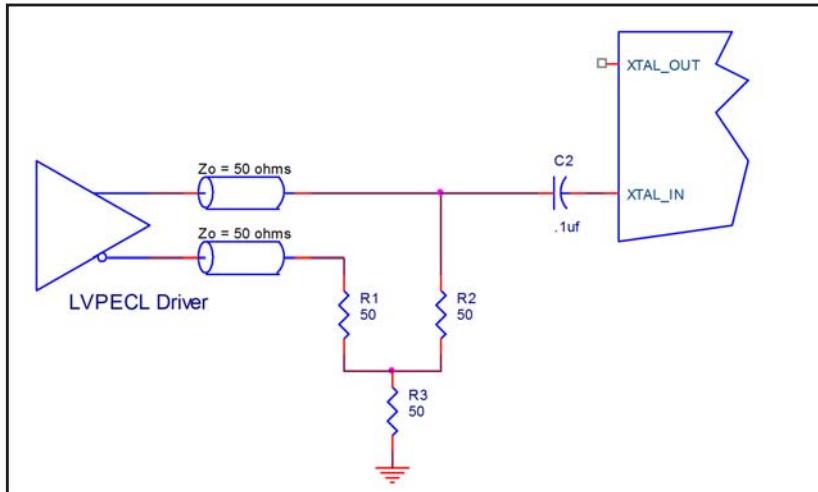

Figure 1B. General Diagram for LVPECL Driver to XTAL Input Interface

Schematic Example

Figure 2 shows an example 840N021 application schematic in which the device is operated at $V_{DD} = V_{DDA} = +3.3V$. The schematic example focuses on functional connections and is intended as an example only and may not represent the exact user configuration. Refer to the pin description and functional tables in the datasheet to ensure the logic control inputs are properly set. For example OE can be configured from an FPGA instead of set with pull up and pull down resistors as shown.

As with any high speed analog circuitry, the power supply pins are vulnerable to random noise, so to achieve optimum jitter performance isolation of the V_{DD} pin from power supply is required. In order to achieve the best possible filtering, it is recommended that the placement of the filter components be on the device side of the PCB as close to the power pins as possible. If space is limited, the

0.1 μ F capacitor on the V_{DD} pin must be placed on the device side with direct return to the ground plane though vias. The remaining filter components can be on the opposite side of the PCB.

Power supply filter component recommendations are a general guideline to be used for reducing external noise from coupling into the devices. The filter performance is designed for a wide range of noise frequencies. This low-pass filter starts to attenuate noise at approximately 10kHz. If a specific frequency noise component is known, such as switching power supplies frequencies, it is recommended that component values be adjusted and if required, additional filtering be added. Additionally, good general design practices for power plane voltage stability suggests adding bulk capacitance in the local area of all devices.

Power Considerations

This section provides information on power dissipation and junction temperature for the 840N021. Equations and example calculations are also provided.

1. Power Dissipation.

The total power dissipation for the 840N021 is the sum of the core power plus the analog power plus the power dissipated in the load(s). The following is the power dissipation for $V_{DD} = 3.3V + 5\% = 3.465V$, which gives worst case results.

- Power (core)_{MAX} = $V_{DD_MAX} * (I_{DD} + I_{DDA}) = 3.465V * (67mA + 18mA) = 294.53mW$
- Output Impedance R_{OUT} Current due to Loading 50Ω to $V_{DD}/2$
Output Current $I_{OUT} = V_{DD_MAX} / [2 * (50\Omega + R_{OUT})] = 3.465V / [2 * (50\Omega + 15\Omega)] = 26.7mA$
- Power Dissipation on the R_{OUT} per LVC MOS output
Power (R_{OUT}) = $R_{OUT} * (I_{OUT})^2 = 15\Omega * (26.7mA)^2 = 10.7mW$ per output
- Total Power (R_{OUT}) = $10.7mW * 1 = 10.7mW$

Dynamic Power Dissipation at 125MHz

$$\text{Power (125MHz)} = C_{PD} * \text{Frequency} * (V_{DD})^2 = 11pF * 125MHz * (3.465V)^2 = 16.51mW \text{ per output}$$

$$\text{Total Power (125MHz)} = 16.51mW * 1 = 16.51mW$$

Total Power Dissipation

- **Total Power**
= Power (core)_{MAX} + Power (R_{OUT}) + Power (125MHz)
= $294.53mW + 10.7mW + 16.51mW$
= $321.74mW$

2. Junction Temperature.

Junction temperature, T_j , is the temperature at the junction of the bond wire and bond pad directly affects the reliability of the device. The maximum recommended junction temperature is 125°C . Limiting the internal transistor junction temperature, T_j , to 125°C ensures that the bond wire and bond pad temperature remains below 125°C .

The equation for T_j is as follows: $T_j = \theta_{JA} * P_{d_total} + T_A$

T_j = Junction Temperature

θ_{JA} = Junction-to-Ambient Thermal Resistance

P_{d_total} = Total Device Power Dissipation (example calculation is in section 1 above)

T_A = Ambient Temperature

In order to calculate junction temperature, the appropriate junction-to-ambient thermal resistance θ_{JA} must be used. Assuming no air flow and a multi-layer board, the appropriate value is 117°C/W per Table 5 below.

Therefore, T_j for an ambient temperature of 85°C with all outputs switching is:

$$85^\circ\text{C} + 0.322W * 117^\circ\text{C/W} = 122.7^\circ\text{C}. \text{ This is below the limit of } 125^\circ\text{C}.$$

This calculation is only an example. T_j will obviously vary depending on the number of loaded outputs, supply voltage, air flow and the type of board (multi-layer).
