

RH850/E2x-FCC2

User's Manual: Hardware

Renesas microcontroller
RH850 Family

All information contained in these materials, including products and product specifications, represents information on the product at the time of publication and is subject to change by Renesas Electronics Corp. without notice. Please review the latest information published by Renesas Electronics Corp. through various means, including the Renesas Electronics Corp. website (<http://www.renesas.com>).

Notice

1. Descriptions of circuits, software and other related information in this document are provided only to illustrate the operation of semiconductor products and application examples. You are fully responsible for the incorporation or any other use of the circuits, software, and information in the design of your product or system. Renesas Electronics disclaims any and all liability for any losses and damages incurred by you or third parties arising from the use of these circuits, software, or information.
2. Renesas Electronics hereby expressly disclaims any warranties against and liability for infringement or any other claims involving patents, copyrights, or other intellectual property rights of third parties, by or arising from the use of Renesas Electronics products or technical information described in this document, including but not limited to, the product data, drawings, charts, programs, algorithms, and application examples.
3. No license, express, implied or otherwise, is granted hereby under any patents, copyrights or other intellectual property rights of Renesas Electronics or others.
4. You shall be responsible for determining what licenses are required from any third parties, and obtaining such licenses for the lawful import, export, manufacture, sales, utilization, distribution or other disposal of any products incorporating Renesas Electronics products, if required.
5. You shall not alter, modify, copy, or reverse engineer any Renesas Electronics product, whether in whole or in part. Renesas Electronics disclaims any and all liability for any losses or damages incurred by you or third parties arising from such alteration, modification, copying or reverse engineering.
6. Renesas Electronics products are classified according to the following two quality grades: "Standard" and "High Quality". The intended applications for each Renesas Electronics product depends on the product's quality grade, as indicated below.

"Standard": Computers; office equipment; communications equipment; test and measurement equipment; audio and visual equipment; home electronic appliances; machine tools; personal electronic equipment; industrial robots; etc.

"High Quality": Transportation equipment (automobiles, trains, ships, etc.); traffic control (traffic lights); large-scale communication equipment; key financial terminal systems; safety control equipment; etc.

Unless expressly designated as a high reliability product or a product for harsh environments in a Renesas Electronics data sheet or other Renesas Electronics document, Renesas Electronics products are not intended or authorized for use in products or systems that may pose a direct threat to human life or bodily injury (artificial life support devices or systems; surgical implantations; etc.), or may cause serious property damage (space system; undersea repeaters; nuclear power control systems; aircraft control systems; key plant systems; military equipment; etc.). Renesas Electronics disclaims any and all liability for any damages or losses incurred by you or any third parties arising from the use of any Renesas Electronics product that is inconsistent with any Renesas Electronics data sheet, user's manual or other Renesas Electronics document.

No semiconductor product is absolutely secure. Notwithstanding any security measures or features that may be implemented in Renesas Electronics hardware or software products, Renesas Electronics shall have absolutely no liability arising out of any vulnerability or security breach, including but not limited to any unauthorized access to or use of a Renesas Electronics product or a system that uses a Renesas Electronics product. RENASAS ELECTRONICS DOES NOT WARRANT OR GUARANTEE THAT RENASAS ELECTRONICS PRODUCTS, OR ANY SYSTEMS CREATED USING RENASAS ELECTRONICS PRODUCTS WILL BE INVULNERABLE OR FREE FROM CORRUPTION, ATTACK, VIRUSES, INTERFERENCE, HACKING, DATA LOSS OR THEFT, OR OTHER SECURITY INTRUSION ("Vulnerability Issues"). RENASAS ELECTRONICS DISCLAIMS ANY AND ALL RESPONSIBILITY OR LIABILITY ARISING FROM OR RELATED TO ANY VULNERABILITY ISSUES. FURTHERMORE, TO THE EXTENT PERMITTED BY APPLICABLE LAW, RENASAS ELECTRONICS DISCLAIMS ANY AND ALL WARRANTIES, EXPRESS OR IMPLIED, WITH RESPECT TO THIS DOCUMENT AND ANY RELATED OR ACCOMPANYING SOFTWARE OR HARDWARE, INCLUDING BUT NOT LIMITED TO THE IMPLIED WARRANTIES OF MERCHANTABILITY, OR FITNESS FOR A PARTICULAR PURPOSE.

7. When using Renesas Electronics products, refer to the latest product information (data sheets, user's manuals, application notes, "General Notes for Handling and Using Semiconductor Devices" in the reliability handbook, etc.), and ensure that usage conditions are within the ranges specified by Renesas Electronics with respect to maximum ratings, operating power supply voltage range, heat dissipation characteristics, installation, etc. Renesas Electronics disclaims any and all liability for any malfunctions, failure or accident arising out of the use of Renesas Electronics products outside of such specified ranges.
8. Although Renesas Electronics endeavors to improve the quality and reliability of Renesas Electronics products, semiconductor products have specific characteristics, such as the occurrence of failure at a certain rate and malfunctions under certain use conditions. Unless designated as a high reliability product or a product for harsh environments in a Renesas Electronics data sheet or other Renesas Electronics document, Renesas Electronics products are not subject to radiation resistance design. You are responsible for implementing safety measures to guard against the possibility of bodily injury, injury or damage caused by fire, and/or danger to the public in the event of a failure or malfunction of Renesas Electronics products, such as safety design for hardware and software, including but not limited to redundancy, fire control and malfunction prevention, appropriate treatment for aging degradation or any other appropriate measures. Because the evaluation of microcomputer software alone is very difficult and impractical, you are responsible for evaluating the safety of the final products or systems manufactured by you.
9. Please contact a Renesas Electronics sales office for details as to environmental matters such as the environmental compatibility of each Renesas Electronics product. You are responsible for carefully and sufficiently investigating applicable laws and regulations that regulate the inclusion or use of controlled substances, including without limitation, the EU RoHS Directive, and using Renesas Electronics products in compliance with all these applicable laws and regulations. Renesas Electronics disclaims any and all liability for damages or losses occurring as a result of your noncompliance with applicable laws and regulations.
10. Renesas Electronics products and technologies shall not be used for or incorporated into any products or systems whose manufacture, use, or sale is prohibited under any applicable domestic or foreign laws or regulations. You shall comply with any applicable export control laws and regulations promulgated and administered by the governments of any countries asserting jurisdiction over the parties or transactions.
11. It is the responsibility of the buyer or distributor of Renesas Electronics products, or any other party who distributes, disposes of, or otherwise sells or transfers the product to a third party, to notify such third party in advance of the contents and conditions set forth in this document.
12. This document shall not be reprinted, reproduced or duplicated in any form, in whole or in part, without prior written consent of Renesas Electronics.
13. Please contact a Renesas Electronics sales office if you have any questions regarding the information contained in this document or Renesas Electronics products.

(Note 1) "Renesas Electronics" as used in this document means Renesas Electronics Corporation and also includes its directly or indirectly controlled subsidiaries.

(Note 2) "Renesas Electronics product(s)" means any product developed or manufactured by or for Renesas Electronics.

Notes for CMOS devices

- (1) Voltage application waveform at input pin:** Waveform distortion due to input noise or a reflected wave may cause malfunction. If the input of the CMOS device stays in the area between VIL (MAX) and VIH (MIN) due to noise, etc., the device may malfunction. Take care to prevent chattering noise from entering the device when the input level is fixed, and also in the transition period when the input level passes through the area between VIL (MAX) and VIH (MIN).
- (2) Handling of unused input pins:** Unconnected CMOS device inputs can be cause of malfunction. If an input pin is unconnected, it is possible that an internal input level may be generated due to noise, etc., causing malfunction. CMOS devices behave differently than Bipolar or NMOS devices. Input levels of CMOS devices must be fixed high or low by using pull-up or pull-down circuitry. Each unused pin should be connected to power supply or GND via a resistor if there is a possibility that it will be an output pin. All handling related to unused pins must be judged separately for each device and according to related specifications governing the device.
- (3) Precaution against ESD:** A strong electric field, when exposed to a MOS device, can cause destruction of the gate oxide and ultimately degrade the device operation. Steps must be taken to stop generation of static electricity as much as possible, and quickly dissipate it when it has occurred. Environmental control must be adequate. When it is dry, a humidifier should be used. It is recommended to avoid using insulators that easily build up static electricity. Semiconductor devices must be stored and transported in an anti-static container, static shielding bag or conductive material. All test and measurement tools including work benches and floors should be grounded. The operator should be grounded using a wrist strap. Semiconductor devices must not be touched with bare hands. Similar precautions need to be taken for PW boards with mounted semiconductor devices.
- (4) Status before initialization:** Power-on does not necessarily define the initial status of a MOS device. Immediately after the power source is turned ON, devices with reset functions have not yet been initialized. Hence, power-on does not guarantee output pin levels, I/O settings or contents of registers. A device is not initialized until the reset signal is received. A reset operation must be executed immediately after power-on for devices with reset functions.
- (5) Power ON/OFF sequence:** In the case of a device that uses different power supplies for the internal operation and external interface, as a rule, switch on the external power supply after switching on the internal power supply. When switching the power supply off, as a rule, switch off the external power supply and then the internal power supply. Use of the reverse power on/off sequences may result in the application of an overvoltage to the internal elements of the device, causing malfunction and degradation of internal elements due to the passage of an abnormal current. The correct power on/off sequence must be judged separately for each device and according to related specifications governing the device.
- (6) Input of signal during power off state:** Do not input signals or an I/O pull-up power supply while the device is not powered. The current injection that results from input of such a signal or I/O pull-up power supply may cause malfunction and the abnormal current that passes in the device at this time may cause degradation of internal elements. Input of signals during the power off state must be judged separately for each device and according to related specifications governing the device.

Table of Contents

Section 1 Overview	90
1.1 Outline	90
1.2 Features.....	92
1.3 Application Fields.....	99
1.4 Ordering Information.....	99
1.5 Differences in the Specifications of FCC Products.....	100
1.6 Pin Connection Diagram (Top View)	103
1.7 Functional Block Configuration.....	109
Section 2 Pin Function	112
2.1 Features of Pin Function.....	113
2.1.1 Port Group.....	113
2.1.2 Register Base Addresses	116
2.1.3 Clock Supplies	116
2.1.4 Interrupt Requests.....	116
2.1.5 Reset Sources.....	117
2.2 Overview.....	118
2.2.1 Functional Overview.....	118
2.2.1.1 Terms.....	118
2.2.1.2 Overview of Pin Functions.....	118
2.2.1.3 Pin Data Input/Output	121
2.3 Port Types	123
2.3.1 Pin Configuration.....	123
2.3.2 Port Control Logic	124
2.4 Registers.....	125
2.4.1 List of Registers	125
2.4.2 Port Group Unit Register Explanation.....	127
2.4.2.1 Configuration of PORT	127
2.4.2.2 Configuration of Pin Data Input/Output.....	137
2.4.2.3 Configuration of Electrical Characteristic.....	146
2.4.2.4 Other Registers.....	154
2.4.3 Pin-Unit Register Explanation	162
2.4.3.1 PCRn_m/JPCRn_m — Port Control Register	162
2.4.4 Port Setting Procedures	164
2.4.4.1 Batch Setting.....	165
2.4.4.2 Individual Setting.....	166
2.4.4.3 Protection Setting.....	170
2.4.5 Functional Selection.....	171
2.4.5.1 Register Configuration When Using Alternative Functions.....	171
2.4.5.2 Alternative Functions That Can Be Used in Direct I/O Control Alternative Mode ..	171
2.4.5.3 Register Setting When Using an Analog Input Pin	173
2.4.5.4 Register Setting to Use the LVDS Buffer.....	174
2.4.5.5 Setting Flow of LVDS function	175

2.4.5.6	Selecton of Function for JTAG Port	175
2.4.5.7	Setting of the ERROROUT_C loopback	175
2.5	Organization of Port Groups	176
2.5.1	List of Port Functions	176
2.5.2	List of Alternative Functions	176
2.6	Functions	177
2.6.1	Digital Noise Filter	177
2.6.1.1	Example of Noise Elimination	177
2.6.1.2	Peripheral Function DNF	178
2.6.1.3	Edge Detection DNF	184
2.6.2	Port Safe State Mode	198

2.6.6	Dedicated Analog Pin Table	205
2.6.7	ICUM Select Function	209
2.6.7.1	Block Diagram	209
2.6.8	RES_OUT Function	210
2.6.8.1	Overview	210
2.7	List of Pin Function	212
2.7.1	Overview	212
2.7.2	Details Function	213
2.8	Pins Status	238
2.9	Handling of The Unused Pins	243
2.9.1	Handling of Thermal Area Pins	247
2.9.1.1	The Case of using Emulation/Instrumentation RAM (SYSVCC and EMUVDD are always supplied)	247
2.9.1.2	The Case of using Emulation/Instrumentation RAM and Aurora I/F (EMUVCC and EMUVDD are always supplied)	248
2.9.1.3	The Case of using Emulation/Instrumentation RAM (EMUVCC and EMUVDD are always supplied)	249
2.9.1.4	The Case of Pin Assignment for Mass Production	250
Section 3 CPU System		251
3.1	Overview	251
3.1.1	Block Diagram	251
3.2	CPU	253
3.2.1	Core Functions	253
3.2.1.1	Features	253
3.2.2	Processor Model	253

3.2.2.1	CPU Operating Modes.....	254
3.2.2.2	Instruction Execution.....	260
3.2.2.3	Exceptions and Interrupts	262
3.2.2.4	Coprocessors.....	264
3.2.2.5	Registers.....	265
3.2.2.6	Data Types.....	268
3.2.2.7	Address Space.....	275
3.2.2.8	Execution Timing of a Store Instruction.....	284
3.2.2.9	Memory Ordering	284
3.2.2.10	Acquiring the CPU Number	284
3.2.2.11	System Protection Identifier (SPID).....	284
3.2.2.12	Timestamp Counter	285
3.2.2.13	Performance Measurement Function	286
3.2.3	Register Set	287
3.2.3.1	Program Registers.....	287
3.2.3.2	Basic System Registers.....	289
3.2.3.3	Interrupt Function Registers	313
3.2.3.4	FPU Function Registers.....	317
3.2.3.5	FXU Function Registers.....	324
3.2.3.6	MPU Function Registers.....	333
3.2.3.7	Cache Operation Function Registers.....	341
3.2.3.8	Count Function Registers	349
3.2.3.9	Hardware Function Registers	357
3.2.4	Exceptions and Interrupts	361
3.2.4.1	Outline of Exceptions.....	361
3.2.4.2	Operation when Acknowledging an Exception	372
3.2.4.3	Return from Exception Handling.....	375
3.2.4.4	Exception Handler Address	377
3.2.4.5	Register Bank Function	387
3.2.4.6	List of Memory Access Exceptions	395
3.2.5	Memory Management.....	396
3.2.5.1	Memory Protection Unit (MPU).....	396
3.2.5.2	Cache.....	407
3.2.6	Coprocessor.....	416
3.2.6.1	Floating-Point Operation.....	416
3.2.6.2	Extended Floating-Point Operation.....	433
3.2.7	Hazard Control.....	446
3.2.7.1	Synchronization Processing	446
3.2.7.2	Guaranteeing the Completion of Store Instruction	448
3.2.7.3	Hazard Management after System Register Update.....	452
3.2.8	Reset.....	457
3.2.8.1	Status of Registers After Reset	457
3.2.9	Ensuring Coherency after Code Flash Programming.....	458
3.2.9.1	Registers.....	458
3.3	Inter-CPU Overview.....	461
3.3.1	Features.....	461
3.3.1.1	Number of Units.....	461
3.3.1.2	Register Base Addresses	462
3.3.1.3	Clock Supplies	462
3.3.1.4	Interrupt Requests	463
3.3.1.5	Reset Sources	463

3.3.1.6	External Input/Output Signals	463
3.3.2	Processor Element Identifier	464
3.4	Inter-Processor Interrupts	465
3.4.1	Inter-Processor Interrupts Overview	465
3.4.2	Inter-Processor Interrupts Registers	465
3.4.2.1	List of Registers	465
3.4.2.2	Self Region	466
3.4.2.3	IPI _n EN _m — IPIR _n Inter-PE Interrupt Enable Register m (n = 0 to 3)	467
3.4.2.4	IPI _n FLG _m — IPIR _n Inter-PE Interrupt Flag Register m (n = 0 to 3)	468
3.4.2.5	IPI _n FCLR _m — IPIR _n Inter-PE Interrupt Clear Register m (n = 0 to 3)	469
3.4.2.6	IPI _n REQ _m — IPIR _n Inter-PE Interrupt Request Register m (n = 0 to 3)	470
3.4.2.7	IPI _n RCLR _m — IPIR _n Inter-PE Interrupt Request Clear Register m (n = 0 to 3)	471
3.4.3	Inter-Processor Interrupts Function	472
3.4.3.1	Initial Setting	472
3.4.3.2	Inter-PE Interrupt Request	473
3.4.3.3	Request Mask Function	478
3.4.3.4	Inter-PE Interrupt Requests of Multiple Systems	478
3.4.3.5	Inter-PE Interrupt Request Clear Function	479
3.5	Mutual Exclusion	480
3.5.1	Mutual Exclusion Overview	480
3.5.2	Mutual Exclusion Registers	481
3.5.2.1	List of Registers	481
3.5.2.2	GOMEV _n — Mutual Exclusion Variable Register n (n = 0 to 31)	482
3.5.3	Mutual Exclusion Function	483
3.5.3.1	Operation Example Using Mutual Exclusion Variable Register (MEV)	483
3.5.3.2	Shared Data that does not Require Mutual Exclusion Processing	486
3.5.3.3	Operation of the LDL and STC Instructions	487
3.5.3.4	Performing Mutual Exclusion by Using the SET1 Instruction	489
3.5.3.5	Performing Mutual Exclusion by Using the CAXI Instruction	490
3.6	Barrier-Synchronization	491
3.6.1	Barrier-Synchronization Overview	491
3.6.2	Barrier-Synchronization Registers	492
3.6.2.1	List of Registers	492
3.6.2.2	Self Region	492
3.6.2.3	BR _n INIT — Barrier-Synchronization n Initialization Register	493
3.6.2.4	BR _n EN — Barrier-Synchronization n Barrier Participating PE Setting Register	494
3.6.2.5	BR _n CHK _m — Barrier-Synchronization n Barrier Check Register m	495
3.6.2.6	BR _n SYNC _m — Barrier-Synchronization n Barrier Synchronization Completion Register m	496
3.6.3	Barrier-Synchronization Function	497
3.6.3.1	Initial Setting	497
3.6.3.2	Barrier Synchronization	498
3.7	TPTM	499
3.7.1	TPTM Overview	499
3.7.2	TPTM Registers	500
3.7.2.1	List of Registers	500
3.7.2.2	Self Region	502
3.7.2.3	TPTM _n IRUN — Counter Start Register of Interval Timer for PEn (n = 0 to 5)	504

3.7.2.4	TPTMnIRRUN — Counter Restart Register of Interval Timer for PEn (n = 0 to 5).....	505
3.7.2.5	TPTMnIISTP — Counter Stop Register of Interval Timer for PEn (n = 0 to 5).....	506
3.7.2.6	TPTMnIISTR — Counter Status Register of Interval Timer for PEn (n = 0 to 5).....	507
3.7.2.7	TPTMnIIEN — Interrupt Enable Register of Interval Timer for PEn (n = 0 to 5)	508
3.7.2.8	TPTMnIUSTR — Underflow Status Register of Interval Timer for PEn (n = 0 to 5).....	509
3.7.2.9	TPTMnIDIV — Divider Register of Interval Timer for PEn (n = 0 to 5).....	510
3.7.2.10	TPTMnFRUN — Counter Start Register of Free-run Timer for PEn (n = 0 to 5)....	511
3.7.2.11	TPTMnFRRUN — Counter Restart Register of Free-run Timer for PEn (n = 0 to 5).....	512
3.7.2.12	TPTMnFSTP — Counter Stop Register of Free-run Timer for PEn (n = 0 to 5)....	513
3.7.2.13	TPTMnFSTR — Counter Status Register of Free-run Timer for PEn (n = 0 to 5).....	514
3.7.2.14	TPTMnFDIV — Divider Register of Free-run Timer for PEn (n = 0 to 5).....	515
3.7.2.15	TPTMnICNTm — Counter Channel m Register of Interval Timer for PEn (n = 0 to 5, m = 0 to 3)	516
3.7.2.16	TPTMnILDm — Load Channel m Register of Interval Timer for PEn (n = 0 to 5, m = 0 to 3).....	517
3.7.2.17	TPTMnFCNT — Counter Register of Free-run Timer for PEn (n = 0 to 5).....	518
3.7.3	TPTM Function.....	519
3.7.3.1	Normal Operation.....	519
3.7.3.2	Operation during a Restart	521
3.7.3.3	Operation during an Underflow.....	522
3.8	Usage Notes	523
3.8.1	Synchronization of Store Instruction Completion and Subsequent Instruction Generation	523
3.8.1.1	When Updated Results in the Control Registers or Memory are Reflected in the Implementation of a Subsequent Instruction	523
3.8.1.2	When the Updated Results in the Control Registers and Memories are Reflected in the Instruction Fetch of a Subsequent Instruction	524
3.8.1.3	Product information of SYNCM.....	524
3.8.1.4	Product information of Waiting for the Completion of Storage	524
3.8.2	Synchronization of Load Instruction Completion and Subsequent Instruction Generation	525
3.8.3	Accesses to Registers by Bit-Manipulation Instructions	525
3.8.4	Ensuring Coherency after Code Flash Programming	525
3.8.5	Overwriting Context when Acknowledging Multiple Exceptions	525
3.8.6	Usage Notes on Prefetching	526
3.8.7	Product Information of Initial Value for G4MH Register.....	527
3.8.8	Product Information of SYSERR Factor	528
3.8.9	Product Information of Cache Structure	528
3.8.10	Product Information of Fetch Size.....	528
3.8.11	Register Initialization.....	529
Section 4 Address MAP		530
4.1	Address MAP.....	530
4.2	Address Space Viewed from Each Bus Master.....	538

4.2.1	Space in which Instructions can be Fetched	538
4.2.2	Data Space Accessible by CPU0, CPU1, CPU2, CPU3, CPU4, CPU5	539
4.2.3	Data Space Accessible by ICUM	540
4.2.4	Data Space Accessible by DMA (sDMAC, DTS)	540
4.2.5	Data Space Accessible by H-Bus Master	540
4.3	Cluster RAM and Retention RAM	543
4.4	Cluster Division of Code Flash	545
Section 5	Operating Modes	550
5.1	Features	550
5.1.1	Normal Operation Mode	551
5.1.2	User Boot Mode	551
5.1.3	Serial Programming Mode	551
5.2	Input Pins	552
5.3	Register Description	553
5.3.1	List of Registers	553
5.3.2	MODE — Mode Register	554
5.3.3	FHVE3 — FHVE3 Control Register	555
5.3.4	FHVE15 — FHVE15 Control Register	555
5.4	Mode Error	556
Section 6	Interrupts	557
6.1	Features of Interrupt Units	557
6.1.1	Units and Channels	557
6.1.2	Register Base Address	559
6.1.3	Clock Supply	559
6.1.4	Interrupt Requests	559
6.1.5	Reset Sources	560
6.1.6	External Input/Output Signals	560
6.2	Overview	561
6.2.1	Outline	561
6.2.2	Functional Overview	562
6.2.3	Interrupt Sources	563
6.2.3.1	FE Level Non-Maskable Interrupts	563
6.2.3.2	FE Level Maskable Interrupts	563
6.2.3.3	EI Level Maskable Interrupts	564
6.2.4	Block Diagram	565
6.3	Registers	566
6.3.1	List of Registers	566
6.3.2	EIC0 to EIC695 — EI Level Interrupt Control Register 0 to 695	567
6.3.3	IMR0 to IMR21 — EI Level Interrupt Mask Register 0 to 21	569
6.3.4	EIBD0 to EIBD31 — EI Level Interrupt Bind Register 0 to 31	570
6.3.5	EIBD32 to EIBD695 — EI Level Interrupt Bind Register 32 to 695	571

6.3.6	NMICTL — NMI Interrupt Control Register	572
6.3.7	EXINTCTL — External Interrupt Control Register	573
6.3.8	EXINTCTL1 — External Interrupt Control Register 1	574
6.3.9	EXINTSTR — External Interrupt Status Register	575
6.3.10	EXINTSTR1 — External Interrupt Status Register 1	576
6.3.11	EXINTSTC — External Interrupt Status Clear Register.....	577
6.3.12	EXINTSTC1 — External Interrupt Status Clear Register 1.....	578
6.3.13	SINTR0 to SINTR3 — Software Interrupt Register.....	579
6.3.14	PINTn + x — Peripheral Interrupt Status Register.....	580
6.3.15	PINTCLRn + x — Peripheral Interrupt Status Clear Register.....	581
6.3.16	TPTMSEL — TPTM Interrupt FE EI Select Register	582
6.4	Interrupt Operation.....	583
6.4.1	Level Interrupts	583
6.4.2	External Interrupts (NMI / IRQ)	583
6.4.3	Inter-Processor Interrupts	583
6.4.4	Broadcast Interrupts.....	583
6.4.5	Software Interrupts.....	583
6.4.6	DTS Interrupt Merge Function	583
6.4.7	Priority Level Handling	584
6.5	Interrupt Processing Flow	585

18.2.1	Functional Overview	939
18.2.2	Functional Overview Description	940
18.2.3	Block Diagram.....	941
18.3	Registers.....	942
18.3.1	List of Registers	942
18.3.2	CSIHnCTL0 — CSIHn Control Register 0	945
18.3.3	CSIHnCTL1 — CSIHn Control Register 1	946
18.3.4	CSIHnCTL2 — CSIHn Control Register 2	949
18.3.5	CSIHnSTR0 — CSIHn Status Register 0	951
18.3.6	CSIHnSTCR0 — CSIHn Status Clear Register 0	953
18.3.7	CSIHnCFGx — CSIHn Configuration Register x (x = 0 to 5).....	954
18.3.8	CSIHnTX0W — CSIHn Transmit Data Register 0 for Word Access	959
18.3.9	CSIHnTX0H — CSIHn Transmit Data Register 0 for Half Word Access.....	961
18.3.10	CSIHnRX0W — CSIHn Receive Data Register 0 for Word Access	962
18.3.11	CSIHnRX0H — CSIHn Receive Data Register 0 for Half Word Access	963
18.3.12	CSIHnBRSy — CSIHn Baud Rate Setting Register y (y = 0 to 3).....	964
18.3.13	CSIHnEIE — CSIHn Interrupt Control Register.....	965
18.3.14	CSIHnECTL0 — CSIHn Extended Communication Control Register 0	966
18.3.15	CSIHnECTL1 — CSIHn Extended Communication Control Register 1	967
18.3.16	CSIHnETXDAm — CSIHn Extended Communication Transmit Data Register m (m = 0 to 15).....	969
18.3.17	CSIHnERXDAm — CSIHn Extended Communication Receive Data Register m (m = 0 to 15).....	970
18.3.18	CSIHnESTT — CSIHn Extended Communication Stop Trigger Register	971
18.3.19	CSIHnESTF — CSIHn Extended Communication Status Register.....	972
18.3.20	List of Cautions	973
18.4	Interrupt Sources	976
18.4.1	Overview	976
18.4.2	Interrupt Delay.....	977
18.4.3	INTCSIHTIC (Communication Status Interrupt).....	978
18.4.3.1	INTCSIHTIC in Direct Access Mode.....	978
18.4.3.2	INTCSIHTIC in Job Mode	980
18.4.4	INTCSIHTIR (Reception Status Interrupt)	981
18.4.4.1	INTCSIHTIR in Direct Access Mode.....	981
18.4.5	INTCSIHTIRE (Communication Error Interrupt)	982
18.4.6	INTCSIHTIJC (Job Completion Interrupt)	983
18.5	Operation	984
18.5.1	Operating Modes (Master/Slave).....	984
18.5.1.1	Master Mode	984
18.5.1.2	Slave Mode	985
18.5.2	Master/Slave Connections	986
18.5.2.1	One Master and One Slave	986
18.5.2.2	One Master and Multiple Slaves.....	986

18.5.3	Chip Selection (CS) Features	987
18.5.3.1	Configuration Registers	987
18.5.3.2	CS Example	989
18.5.3.3	Job Concept.....	990
18.5.4	Details of Chip Select Timing.....	991
18.5.4.1	Changing the Clock Phase	991
18.5.4.2	Changing the Data Phase.....	993
18.5.5	Transmission Clock Selection.....	994
18.5.5.1	Transfer Clock Frequency Calculation.....	994
18.5.5.2	Transfer Clock Frequency Upper and Lower Limits	995
18.5.6	Data Transfer Modes	995
18.5.6.1	Transmit-Only Mode	995
18.5.6.2	Receive-Only Mode	995
18.5.6.3	Transmit/Receive Mode.....	995
18.5.6.4	Summary.....	995
18.5.7	Data Length Selection.....	996
18.5.7.1	Data Length from 2 to 16 Bits.....	996
18.5.7.2	Data Length Greater than 16 Bits	997
18.5.8	Serial Data Direction Selection	999
18.5.9	Slave Select (SS) Function	1000
18.5.9.1	Communication Timing Using SS Function	1000
18.5.9.2	CSIHTSSO Operation.....	1001
18.5.10	Handshake Function	1002
18.5.10.1	Slave Mode	1002
18.5.10.2	Master Mode.....	1004
18.5.11	Error Detection	1005
18.5.11.1	Data Consistency Check	1005
18.5.11.2	Parity Check.....	1007
18.5.11.3	Overrun Error	1008
18.5.12	Loop-Back Mode.....	1009
18.5.13	Enforced Chip Select Idle Setting	1010
18.5.14	Extended Communication Function	1011
18.5.14.1	Data Transfer Direction Selection Function.....	1011
18.5.14.2	Extended Communication Stop Function	1014
18.5.14.3	Extended Communication Status	1015
18.5.14.4	Extended Interrupt Control Function.....	1017
18.6	Operating Procedures.....	1018
18.6.1	Procedures in Direct Access Mode.....	1018
18.6.1.1	Transmit/Receive in Master Mode when Job Mode Is Disabled	1018
18.6.1.2	Transmit/Receive in Master Mode when Job Mode is Enabled	1020
18.6.2	Procedures in Extended Communication Function Mode	1022
18.6.2.1	Trigger to Start Extended Communication	1028
18.6.2.2	Storage Address of Received Data in Extended Communication	1031
Section 19	Serial Communication Interface 3 (SCI3).....	1032
19.1	Features of SCI3.....	1032
19.1.1	Units and Channels.....	1032
19.1.2	Register Base Address	1032

19.1.3	Clock Supply	1033
19.1.4	Interrupt Requests.....	1033
19.1.5	Reset Sources.....	1033
19.1.6	External Input / Output Signals	1034
19.2	Overview.....	1035
19.2.1	Functional Overview	1035
19.2.2	Serial Communication Modes.....	1036
19.2.3	Block Diagram.....	1037
19.3	Registers.....	1038
19.3.1	List of Registers	1038
19.3.2	SCI3nRSR — Receive Shift Register	1039
19.3.3	SCI3nRDR — Receive Data Register	1039
19.3.4	SCI3nTDR — Transmit Data Register.....	1039
19.3.5	SCI3nTSR — Transmit Shift Register.....	1039
19.3.6	SCI3nSMR — Serial Mode Register.....	1040
19.3.7	SCI3nSCR — Serial Control Register.....	1041
19.3.8	SCI3nSSR — Serial Status Register	1043
19.3.9	SCI3nSCMR — Serial Transfer Format Register	1045
19.3.10	SCI3nSEMR — Serial Extended Mode Register	1046
19.3.11	SCI3nBRR — Bit Rate Register.....	1047
19.3.12	SCI3nMDDR — Modulation Duty Register	1050
19.4	Operation in Asynchronous Mode	1051
19.4.1	Transmission / Reception Format.....	1052
19.4.2	Receive Data Sampling Timing and Reception Margin	1053
19.4.3	Clock	1054
19.4.4	Double-Speed Operation	1054
19.4.5	SCI3 Initialization (Asynchronous Mode).....	1055
19.4.6	Serial Data Transmission (Asynchronous Mode)	1056
19.4.7	Serial Data Reception (Asynchronous Mode).....	1061
19.5	Multi-Processor Communication Function.....	1065
19.5.1	Overview and Sample Connection.....	1065
19.5.2	Multi-Processor Serial Data Transmission.....	1066
19.5.3	Multi-Processor Serial Data Reception	1067
19.6	Operation in Clock Synchronous Mode	1071
19.6.1	Clock	1071
19.6.2	SCI3 Initialization (Clock Synchronous Mode).....	1072
19.6.3	Serial Data Transmission (Clock Synchronous Mode)	1073
19.6.4	Serial Data Reception (Clock Synchronous Mode)	1076
19.6.5	Simultaneous Serial Data Transmission and Reception (Clock Synchronous Mode).....	1078
19.7	Bit Rate Modulation Function	1080
19.8	Interrupt Sources	1081
19.9	Usage Notes	1083

19.9.1	Break Detection and Processing.....	1083
19.9.2	Mark State and Production of Breaks	1083
19.9.3	Receive Error Flags and Transmit Operations in Clock Synchronous Mode	1083
19.9.4	Relationship between Writing to SCI3nTDR and the TDRE Flag.....	1083
19.9.5	Restrictions on Using an External Clock for Transmission in Clock Synchronous Mode	1084
19.9.6	External Clock Input in Clock Synchronous Mode.....	1084
Section 20	LIN/UART Interface (RLIN3)	1085
20.1	Features of RLIN3	1085
20.1.1	Units and Channels.....	1085
20.1.2	Register Base Addresses	1086
20.1.3	Clock Supply	1086
20.1.4	Interrupt Requests.....	1087
20.1.5	Reset Sources.....	1089
20.1.6	External Input/Output Signals	1089
20.2	Overview.....	1090
20.2.1	Functional Overview	1090
20.2.2	Block Diagram.....	1093
20.2.3	Terms Used in Block Diagram	1093
20.3	Registers.....	1094
20.3.1	List of Registers	1094
20.3.2	LIN Master Related Registers.....	1095
20.3.2.1	RLN3nLWBR — LIN Wake-Up Baud Rate Select Register	1095
20.3.2.2	RLN3nLBRP0 — LIN Baud Rate Prescaler 0 Register	1096
20.3.2.3	RLN3nLBRP1 — LIN Baud Rate Prescaler 1 Register	1097
20.3.2.4	RLN3nLSTC — LIN Self-Test Control Register.....	1098
20.3.2.5	RLN3nLMD — LIN Mode Register	1099
20.3.2.6	RLN3nLBFC — LIN Break Field Configuration Register	1101
20.3.2.7	RLN3nLSC — LIN Space Configuration Register	1102
20.3.2.8	RLN3nLWUP — LIN Wake-Up Configuration Register.....	1103
20.3.2.9	RLN3nLIE — LIN Interrupt Enable Register	1104
20.3.2.10	RLN3nLEDE —LIN Error Detection Enable Register	1106
20.3.2.11	RLN3nLCUC — LIN Control Register.....	1108
20.3.2.12	RLN3nLTRC — LIN Transmission Control Register	1109
20.3.2.13	RLN3nLMST — LIN Mode Status Register	1110
20.3.2.14	RLN3nLST — LIN Status Register	1111
20.3.2.15	RLN3nLEST — LIN Error Status Register.....	1113
20.3.2.16	RLN3nLDFC — LIN Data Field Configuration Register.....	1115
20.3.2.17	RLN3nLIDB — LIN ID Buffer Register.....	1117
20.3.2.18	RLN3nLCBR — LIN Checksum Buffer Register.....	1118
20.3.2.19	RLN3nLDBRb — LIN Data Buffer b Register (b = 1 to 8)	1119
20.3.3	LIN Slave Related Registers.....	1120
20.3.3.1	RLN3nLWBR — LIN Wake-Up Baud Rate Select Register	1120
20.3.3.2	RLN3nLBRP01 — LIN Baud Rate Prescaler 01 Register	1122
20.3.3.3	RLN3nLSTC — LIN Self-Test Control Register.....	1123
20.3.3.4	RLN3nLMD — LIN Mode Register	1124

20.3.3.5	RLN3nLBFC — LIN Break Field Configuration Register	1125
20.3.3.6	RLN3nLSC — LIN Space Configuration Register	1126
20.3.3.7	RLN3nLWUP — LIN Wake-Up Configuration Register	1127
20.3.3.8	RLN3nLIE — LIN Interrupt Enable Register	1128
20.3.3.9	RLN3nLEDE — LIN Error Detection Enable Register	1130
20.3.3.10	RLN3nLCUC — LIN Control Register.....	1132
20.3.3.11	RLN3nLTRC — LIN Transmission Control Register	1133
20.3.3.12	RLN3nLMST — LIN Mode Status Register	1135
20.3.3.13	RLN3nLST — LIN Status Register	1136
20.3.3.14	RLN3nLEST — LIN Error Status Register.....	1138
20.3.3.15	RLN3nLDFC — LIN Data Field Configuration Register.....	1140
20.3.3.16	RLN3nLIDB — LIN ID Buffer Register.....	1142
20.3.3.17	RLN3nLCBR — LIN Checksum Buffer Register.....	1143
20.3.3.18	RLN3nLDBRb — LIN Data Buffer b Register (b = 1 to 8)	1144
20.3.4	UART Related Registers.....	1145
20.3.4.1	RLN3nLWBR — UART Wake-Up Baud Rate Select Register	1145
20.3.4.2	RLN3nLBRP01 — UART Baud Rate Prescaler 01 Register	1146
20.3.4.3	RLN3nLMD — UART Mode Register	1147
20.3.4.4	RLN3nLBFC — UART Configuration Register	1148
20.3.4.5	RLN3nLSC — UART Space Configuration Register	1150
20.3.4.6	RLN3nLEDE —UART Error Detection Enable Register.....	1151
20.3.4.7	RLN3nLCUC — UART Control Register	1153
20.3.4.8	RLN3nLTRC — UART Transmission Control Register	1154
20.3.4.9	RLN3nLMST — UART Mode Status Register.....	1155
20.3.4.10	RLN3nLST — UART Status Register.....	1156
20.3.4.11	RLN3nLEST — UART Error Status Register	1158
20.3.4.12	RLN3nLDFC — UART Data Field Configuration Register	1160
20.3.4.13	RLN3nLIDB — UART ID Buffer Register.....	1161
20.3.4.14	RLN3nLUDB0 — UART Data Buffer 0 Register.....	1162
20.3.4.15	RLN3nLDBRb — UART Data Buffer b Register (b = 1 to 8)	1163
20.3.4.16	RLN3nLUOER — UART Operation Enable Register	1164
20.3.4.17	RLN3nLUOR1 — UART Option Register 1	1165
20.3.4.18	RLN3nLUTDR — UART Transmission Data Register.....	1167
20.3.4.19	RLN3nLURDR — UART Reception Data Register	1168
20.3.4.20	RLN3nLUWTDR — UART Wait Transmission Data Register	1169
20.4	Interrupt Sources	1170
20.5	Operation	1171
20.5.1	Modes	1171
20.5.2	LIN Reset Mode	1173
20.5.3	LIN Mode.....	1174
20.5.3.1	LIN Master Mode	1177
20.5.3.2	LIN Slave Mode	1181
20.5.3.3	Data Transmission/Reception.....	1189
20.5.3.4	Transmission/Reception Data Buffering	1191
20.5.3.5	Wake-up Transmission/Reception	1194
20.5.3.6	Status	1196
20.5.3.7	Error Status.....	1198
20.5.4	UART Mode	1202
20.5.4.1	Transmission.....	1202
20.5.4.2	Reception.....	1211
20.5.4.3	Expansion Bits	1213

20.5.4.4	Status	1217
20.5.4.5	Error Status	1218
20.5.5	LIN Self-Test Mode	1219
20.5.5.1	Transitioning to LIN Self-Test Mode	1221
20.5.5.2	Transmission in LIN Master Self-Test Mode	1222
20.5.5.3	Reception in LIN Master Self-Test Mode	1224
20.5.5.4	Transmission in LIN Slave Self-Test Mode	1226
20.5.5.5	Reception in LIN Slave Self-Test Mode	1228
20.5.5.6	Terminating LIN Self-Test Mode	1230
20.5.6	Baud Rate Generator	1231
20.5.6.1	LIN Master Mode	1232
20.5.6.2	LIN Slave Mode	1233
20.5.6.3	UART Mode	1234
20.5.7	Noise Filter	1235
Section 21	CANFD Interface (RS-CANFD)	1237
21.1	Features of RS-CANFD	1237
21.1.1	Units and Channels	1237
21.1.2	Register Base Address	1240
21.1.3	Clock Supply	1240
21.1.4	Interrupt Requests	1241
21.1.5	Reset Sources	1246
21.1.6	External Input/Output Signals	1246
21.2	Overview	1247
21.2.1	Functional Outline	1247
21.2.2	Interface Modes	1249
21.2.3	CAN FD Protocol	1249
21.2.4	Block Diagram	1250
21.3	Registers (Classical CAN Mode)	1251
21.3.1	List of Registers	1251
21.3.2	Details of Interface Mode-Related Registers	1256
21.3.2.1	RSCANnGRMCFG — Global Interface Mode Select Register	1256
21.3.3	Details of Channel-Related Registers	1257
21.3.3.1	RSCANnCmCFG — Channel m Configuration Register	1257
21.3.3.2	RSCANnCmCTR — Channel m Control Register	1259
21.3.3.3	RSCANnCmSTS — Channel m Status Register	1264
21.3.3.4	RSCANnCmERFL — Channel m Error Flag Register	1266
21.3.4	Details of Global-Related Registers	1270
21.3.4.1	RSCANnGCFG — Global Configuration Register	1270
21.3.4.2	RSCANnGCTR — Global Control Register	1273
21.3.4.3	RSCANnGSTS — Global Status Register	1275
21.3.4.4	RSCANnGERFL — Global Error Flag Register	1276
21.3.4.5	RSCANnGTSC — Global Timestamp Counter Register	1278
21.3.4.6	RSCANnGTINTSTS0 — Global TX Interrupt Status Register 0	1279
21.3.4.7	RSCANnGTINTSTS1 — Global TX Interrupt Status Register 1	1282
21.3.4.8	RSCANnGFDCFG — Global FD Configuration Register	1284
21.3.5	Details of Receive Rule-Related Registers	1285

21.3.5.1	RSCANnGAFLECTR — Receive Rule Entry Control Register	1285
21.3.5.2	RSCANnGAFLCFG0 — Receive Rule Configuration Register 0	1286
21.3.5.3	RSCANnGAFLCFG1 — Receive Rule Configuration Register 1	1287
21.3.5.4	RSCANnGAFLIDj — Receive Rule ID Register j	1288
21.3.5.5	RSCANnGAFLMj — Receive Rule Mask Register j	1289
21.3.5.6	RSCANnGAFLP0_j — Receive Rule Pointer 0 Register j	1290
21.3.5.7	RSCANnGAFLP1_j — Receive Rule Pointer 1 Register j	1292
21.3.6	Details of Receive Buffer-Related Registers	1293
21.3.6.1	RSCANnRMNB — Receive Buffer Number Register	1293
21.3.6.2	RSCANnRMNDy — Receive Buffer New Data Register y	1294
21.3.6.3	RSCANnRMIDq — Receive Buffer ID Register q	1295
21.3.6.4	RSCANnRMPTRq — Receive Buffer Pointer Register q	1296
21.3.6.5	RSCANnRMDf0_q — Receive Buffer Data Field 0 Register q	1297
21.3.6.6	RSCANnRMDf1_q — Receive Buffer Data Field 1 Register q	1298
21.3.7	Details of Receive FIFO Buffer-Related Registers	1299
21.3.7.1	RSCANnRFCCx — Receive FIFO Buffer Configuration and Control Register x	1299
21.3.7.2	RSCANnRFSTsx — Receive FIFO Buffer Status Register x	1301
21.3.7.3	RSCANnRFPCTRx — Receive FIFO Buffer Pointer Control Register x	1303
21.3.7.4	RSCANnRFIDx — Receive FIFO Buffer Access ID Register x	1304
21.3.7.5	RSCANnRFPTRx — Receive FIFO Buffer Access Pointer Register x	1305
21.3.7.6	RSCANnRFDF0_x — Receive FIFO Buffer Access Data Field 0 Register x	1306
21.3.7.7	RSCANnRFDF1_x — Receive FIFO Buffer Access Data Field 1 Register x	1307
21.3.8	Details of Transmit/Receive FIFO Buffer-Related Registers	1308
21.3.8.1	RSCANnCFCCk — Transmit/Receive FIFO Buffer Configuration and Control Register k	1308
21.3.8.2	RSCANnCFSTSk — Transmit/Receive FIFO Buffer Status Register k	1312
21.3.8.3	RSCANnCFPCTRk — Transmit/Receive FIFO Buffer Pointer Control Register k	1315
21.3.8.4	RSCANnCFIDk — Transmit/Receive FIFO Buffer Access ID Register k	1316
21.3.8.5	RSCANnCFPTRk — Transmit/Receive FIFO Buffer Access Pointer Register k	1318
21.3.8.6	RSCANnCFDF0_k — Transmit/Receive FIFO Buffer Access Data Field 0 Register k	1320
21.3.8.7	RSCANnCFDF1_k — Transmit/Receive FIFO Buffer Access Data Field 1 Register k	1321
21.3.9	Details of FIFO Status-Related Registers	1322
21.3.9.1	RSCANnFESTS — FIFO Empty Status Register	1322
21.3.9.2	RSCANnFFSTS — FIFO Full Status Register	1324
21.3.9.3	RSCANnFMSTS — FIFO Message Lost Status Register	1326
21.3.9.4	RSCANnRFISTS — Receive FIFO Buffer Interrupt Flag Status Register	1328
21.3.9.5	RSCANnCFRISTS — Transmit/Receive FIFO Buffer Receive Interrupt Flag Status Register	1329
21.3.9.6	RSCANnCFTISTS — Transmit/Receive FIFO Buffer Transmit Interrupt Flag Status Register	1330
21.3.10	Details of Transmit Buffer-Related Registers	1331
21.3.10.1	RSCANnTMCp — Transmit Buffer Control Register p	1331
21.3.10.2	RSCANnTMSTSp — Transmit Buffer Status Register p	1333
21.3.10.3	RSCANnTMIDp — Transmit Buffer ID Register p	1335
21.3.10.4	RSCANnTMPTRp — Transmit Buffer Pointer Register p	1336
21.3.10.5	RSCANnTMDF0_p — Transmit Buffer Data Field 0 Register p	1337
21.3.10.6	RSCANnTMDF1_p — Transmit Buffer Data Field 1 Register p	1338

21.3.10.7	RSCANnTMIECy — Transmit Buffer Interrupt Enable Configuration Register y	1339
21.3.11	Details of Transmit Buffer Status-Related Registers	1341
21.3.11.1	RSCANnTMTRSTSy — Transmit Buffer Transmit Request Status Register y	1341
21.3.11.2	RSCANnTMTARSTSy — Transmit Buffer Transmit Abort Request Status Register y	1343
21.3.11.3	RSCANnTMTTCSTSy — Transmit Buffer Transmit Complete Status Register y ..	1345
21.3.11.4	RSCANnTMTASTSy — Transmit Buffer Transmit Abort Status Register y	1347
21.3.12	Details of Transmit Queue-Related Registers	1349
21.3.12.1	RSCANnTXQCCm — Transmit Queue Configuration and Control Register m ...	1349
21.3.12.2	RSCANnTXQSTSm — Transmit Queue Status Register m	1351
21.3.12.3	RSCANnTXQPCTRM — Transmit Queue Pointer Control Register m	1353
21.3.13	Details of Transmit History-Related Registers	1354
21.3.13.1	RSCANnTHLCCm — Transmit History List Configuration and Control Register m	1354
21.3.13.2	RSCANnTHLSTSm — Transmit History List Status Register m	1356
21.3.13.3	RSCANnTHLPCTRM — Transmit History List Pointer Control Register m	1358
21.3.13.4	RSCANnTHLACCm — Transmit History List Access Register m	1359
21.3.14	Details of Test-Related Registers	1360
21.3.14.1	RSCANnGTSTCFG — Global Test Configuration Register	1360
21.3.14.2	RSCANnGTSTCTR — Global Test Control Register	1362
21.3.14.3	RSCANnGLOCKK — Global Lock Key Register	1363
21.3.14.4	RSCANnRPGACCr — RAM Test Page Access Register r	1364
21.4	Registers (CAN FD Mode)	1365
21.4.1	List of Registers	1365
21.4.2	Details of Interface Mode-Related Registers	1371
21.4.2.1	RSCFDnCFDGRMCFG — Global Interface Mode Select Register	1371
21.4.3	Details of Channel-Related Registers	1372
21.4.3.1	RSCFDnCFDCmNCFG — Channel m Nominal Bit Rate Configuration Register	1372
21.4.3.2	RSCFDnCFDCmCTR — Channel m Control Register	1374
21.4.3.3	RSCFDnCFDCmSTS — Channel m Status Register	1379
21.4.3.4	RSCFDnCFDCmERFL — Channel m Error Flag Register	1381
21.4.3.5	RSCFDnCFDCmDCFG — Channel m Data Bit Rate Configuration Register	1385
21.4.3.6	RSCFDnCFDCmFDCFG — Channel m CAN FD Configuration Register	1388
21.4.3.7	RSCFDnCFDCmFDCTR — Channel m CAN FD Control Register	1392
21.4.3.8	RSCFDnCFDCmFDSTS — Channel m CAN FD Status Register	1393
21.4.3.9	RSCFDnCFDCmFDCRC — Channel m CAN FD CRC Register	1395
21.4.4	Details of Global-Related Registers	1396
21.4.4.1	RSCFDnCFDGCFG — Global Configuration Register	1396
21.4.4.2	RSCFDnCFDGCTR — Global Control Register	1399
21.4.4.3	RSCFDnCFDGSTS — Global Status Register	1401
21.4.4.4	RSCFDnCFDGERFL — Global Error Flag Register	1402
21.4.4.5	RSCFDnCFDGTSC — Global Timestamp Counter Register	1404
21.4.4.6	RSCFDnCFDGTINTSTS0 — Global TX Interrupt Status Register 0	1405
21.4.4.7	RSCFDnCFDGTINTSTS1 — Global TX Interrupt Status Register 1	1408
21.4.4.8	RSCFDnCFDGFDCFG — Global FD Configuration Register	1410
21.4.5	Details of Receive Rule-Related Registers	1411
21.4.5.1	RSCFDnCFDGAFLCTR — Receive Rule Entry Control Register	1411
21.4.5.2	RSCFDnCFDGAFLCFG0 — Receive Rule Configuration Register 0	1412

21.4.5.3	RSCFDnCFDGAFLCFG1 — Receive Rule Configuration Register 1	1413
21.4.5.4	RSCFDnCFDGAFLIDj — Receive Rule ID Register j	1414
21.4.5.5	RSCFDnCFDGAFLMj — Receive Rule Mask Register j	1415
21.4.5.6	RSCFDnCFDGAFLP0_j — Receive Rule Pointer 0 Register j	1416
21.4.5.7	RSCFDnCFDGAFLP1_j — Receive Rule Pointer 1 Register j	1418
21.4.6	Details of Receive Buffer-Related Registers	1419
21.4.6.1	RSCFDnCFDRMNB — Receive Buffer Number Register	1419
21.4.6.2	RSCFDnCFDRMNDy — Receive Buffer New Data Register y	1420
21.4.6.3	RSCFDnCFDRMIDq — Receive Buffer ID Register q	1421
21.4.6.4	RSCFDnCFDRMPTRq — Receive Buffer Pointer Register q	1422
21.4.6.5	RSCFDnCFDRMFDSTSq — Receive Buffer CAN FD Status Register q	1424
21.4.6.6	RSCFDnCFDRMDFb_q — Receive Buffer Data Field b Register q	1425
21.4.7	Details of Receive FIFO Buffer-Related Registers	1426
21.4.7.1	RSCFDnCFDRFCCx — Receive FIFO Buffer Configuration and Control Register x	1426
21.4.7.2	RSCFDnCFDRFSTSx — Receive FIFO Buffer Status Register x	1428
21.4.7.3	RSCFDnCFDRFPCTRx — Receive FIFO Buffer Pointer Control Register x	1430
21.4.7.4	RSCFDnCFDRFIDx — Receive FIFO Buffer Access ID Register x	1431
21.4.7.5	RSCFDnCFDRFPTRx — Receive FIFO Buffer Access Pointer Register x	1432
21.4.7.6	RSCFDnCFDRFFDSTSx — Receive FIFO CAN FD Status Register x	1433
21.4.7.7	RSCFDnCFDRFDFd_x — Receive FIFO Buffer Access Data Field d Register x	1434
21.4.8	Details of Transmit/Receive FIFO Buffer Related Registers	1435
21.4.8.1	RSCFDnCFDCFCCK — Transmit/Receive FIFO Buffer Configuration and Control Register k	1435
21.4.8.2	RSCFDnCFDCFSTSx — Transmit/Receive FIFO Buffer Status Register k	1439
21.4.8.3	RSCFDnCFDCFPCTRk — Transmit/Receive FIFO Buffer Pointer Control Register k	1442
21.4.8.4	RSCFDnCFDCFIDk — Transmit/Receive FIFO Buffer Access ID Register k	1444
21.4.8.5	RSCFDnCFDCFPTRk — Transmit/Receive FIFO Buffer Access Pointer Register k	1446
21.4.8.6	RSCFDnCFDCFFDCSTSx — Transmit/Receive FIFO CAN FD Configuration/Status Register k	1448
21.4.8.7	RSCFDnCFDCFDFd_k — Transmit/Receive FIFO Buffer Access Data Field d Register k	1450
21.4.9	Details of FIFO Status-Related Registers	1451
21.4.9.1	RSCFDnCFDFESTS — FIFO Empty Status Register	1451
21.4.9.2	RSCFDnCFDFFSTS — FIFO Full Status Register	1453
21.4.9.3	RSCFDnCFDFMSTS — FIFO Message Lost Status Register	1455
21.4.9.4	RSCFDnCFDRFISTS — Receive FIFO Buffer Interrupt Flag Status Register	1457
21.4.9.5	RSCFDnCFDCFRISTS — Transmit/Receive FIFO Buffer Receive Interrupt Flag Status Register	1458
21.4.9.6	RSCFDnCFDCFTISTS — Transmit/Receive FIFO Buffer Transmit Interrupt Flag Status Register	1459
21.4.10	Details of FIFO DMA-Related Registers	1460
21.4.10.1	RSCFDnCFDCDTCT — DMA Enable Register	1460
21.4.10.2	RSCFDnCFDCDTSTS — DMA Status Register	1462
21.4.11	Details of Transmit Buffer-Related Registers	1464
21.4.11.1	RSCFDnCFDTMCp — Transmit Buffer Control Register p	1464
21.4.11.2	RSCFDnCFDTMSTSp — Transmit Buffer Status Register p	1466
21.4.11.3	RSCFDnCFDTMIDp — Transmit Buffer ID Register p	1468
21.4.11.4	RSCFDnCFDTMPTRp — Transmit Buffer Pointer Register p	1469

21.4.11.5	RSCFDnCFDTMFDCTR _p — Transmit Buffer CAN FD Configuration Register p.....	1471
21.4.11.6	RSCFDnCFDTMDFb _p — Transmit Buffer Data Field b Register p.....	1472
21.4.11.7	RSCFDnCFDTMIECy — Transmit Buffer Interrupt Enable Configuration Register y.....	1473
21.4.12	Details of Transmit Buffer Status-Related Registers	1475
21.4.12.1	RSCFDnCFDTMTRST _{Sy} — Transmit Buffer Transmit Request Status Register y.....	1475
21.4.12.2	RSCFDnCFDTMTARST _{Sy} — Transmit Buffer Transmit Abort Request Status Register y.....	1477
21.4.12.3	RSCFDnCFDTMTCST _{Sy} — Transmit Buffer Transmit Complete Status Register y.....	1479
21.4.12.4	RSCFDnCFDTMTAST _{Sy} — Transmit Buffer Transmit Abort Status Register y.....	1481
21.4.13	Details of Transmit Queue-Related Registers	1483
21.4.13.1	RSCFDnCFDTXQCC _m — Transmit Queue Configuration and Control Register m.....	1483
21.4.13.2	RSCFDnCFDTXQST _{Sm} — Transmit Queue Status Register m	1485
21.4.13.3	RSCFDnCFDTXQPCTR _m — Transmit Queue Pointer Control Register m.....	1487
21.4.14	Details of Transmit History-Related Registers.....	1488
21.4.14.1	RSCFDnCFDTHLCC _m — Transmit History List Configuration and Control Register m.....	1488
21.4.14.2	RSCFDnCFDTHLST _{Sm} — Transmit History List Status Register m.....	1490
21.4.14.3	RSCFDnCFDTHLPCTR _m — Transmit History List Pointer Control Register m ..	1492
21.4.14.4	RSCFDnCFDTHLACC _m — Transmit History List Access Register m.....	1493
21.4.15	Details of Test-Related Registers	1494
21.4.15.1	RSCFDnCFDGTSTCFG — Global Test Configuration Register.....	1494
21.4.15.2	RSCFDnCFDGTSTCTR — Global Test Control Register.....	1496
21.4.15.3	RSCFDnCFDGLOCKK — Global Lock Key Register.....	1497
21.4.15.4	RSCFDnCFDRPGACCr — RAM Test Page Access Register r.....	1498
21.5	Interrupt Sources and DMA Trigger.....	1499
21.5.1	Interrupt Sources.....	1499
21.5.2	DMA Triger (Only in CAN FD Mode).....	1502
21.6	CAN Modes	1503
21.6.1	Global Modes	1503
21.6.1.1	Global Stop Mode	1504
21.6.1.2	Global Reset Mode	1504
21.6.1.3	Global Test Mode.....	1505
21.6.1.4	Global Operating Mode.....	1505
21.6.2	Channel Modes	1506
21.6.2.1	Channel Stop Mode	1507
21.6.2.2	Channel Reset Mode	1507
21.6.2.3	Channel Halt Mode	1508
21.6.2.4	Channel Communication Mode	1508
21.6.2.5	Bus Off State.....	1509
21.6.3	Initializing Registers by Transition to CAN Mode.....	1510
21.7	Reception Functions	1512
21.7.1	Data Processing Using the Receive Rule Table.....	1512
21.7.1.1	Acceptance Filter Processing	1513

21.7.1.2	DLC Filter Processing	1514

22.3.6.7	FLXAnFRMHDC — FlexRay MHD Configuration Register.....	1637
22.3.6.8	FLXAnFRGTUC1 — FlexRay GTU Configuration Register 1.....	1638

22.3.6.9	FLXAnFRGTUC2 — FlexRay GTU Configuration Register 2	1639
22.3.6.10	FLXAnFRGTUC3 — FlexRay GTU Configuration Register 3	1640
22.3.6.11	FLXAnFRGTUC4 — FlexRay GTU Configuration Register 4	1642
22.3.6.12	FLXAnFRGTUC5 — FlexRay GTU Configuration Register 5	1643
22.3.6.13	FLXAnFRGTUC6 — FlexRay GTU Configuration Register 6	1645
22.3.6.14	FLXAnFRGTUC7 — FlexRay GTU Configuration Register 7	1646
22.3.6.15	FLXAnFRGTUC8 — FlexRay GTU Configuration Register 8	1647
22.3.6.16	FLXAnFRGTUC9 — FlexRay GTU Configuration Register 9	1648
22.3.6.17	FLXAnFRGTUC10 — FlexRay GTU Configuration Register 10	1650
22.3.6.18	FLXAnFRGTUC11 — FlexRay GTU Configuration Register 11	1651
22.3.7	CC Status Registers	1653
22.3.7.1	FLXAnFRCCSV — FlexRay CC Status Vector Register	1653
22.3.7.2	FLXAnFRCCEV — FlexRay CC Error Vector Register	1657
22.3.7.3	FLXAnFRSCV — FlexRay Slot Counter Value Register	1659
22.3.7.4	FLXAnFRMTCCV — FlexRay Macrotick and Cycle Counter Value Register	1660
22.3.7.5	FLXAnFRRCV — FlexRay Rate Correction Value Register	1661
22.3.7.6	FLXAnFROCV — FlexRay Offset Correction Value Register	1662
22.3.7.7	FLXAnFRSFS — FlexRay Sync Frame Status Register	1663
22.3.7.8	FLXAnFRSWNIT — FlexRay Symbol Window and NIT Status Register	1666
22.3.7.9	FLXAnFRACS — FlexRay Aggregated Channel Status Register	1669
22.3.7.10	FLXAnFRESIDm — FlexRay Even Sync ID Register m (m = 1 to 15)	1673
22.3.7.11	FLXAnFROSIDm — FlexRay Odd Sync ID Register m (m = 1 to 15)	1675
22.3.7.12	FLXAnFRNMVm — FlexRay Network Management Vector Register m (m = 1 to 3)	1677
22.3.8	Message Buffer Control Registers	1678
22.3.8.1	FLXAnFRMRC — FlexRay Message RAM Configuration Register	1678
22.3.8.2	FLXAnFRFRF — FlexRay FIFO Rejection Filter Register	1682
22.3.8.3	FLXAnFRFRFM — FlexRay FIFO Rejection Filter Mask Register	1684
22.3.8.4	FLXAnFRFCL — FlexRay FIFO Critical Level Register	1685
22.3.9	Message Buffer Status Registers	1686
22.3.9.1	FLXAnFRMHDS — FlexRay Message Handler Status Register	1686
22.3.9.2	FLXAnFRLDTS — FlexRay Last Dynamic Transmit Slot Register	1689
22.3.9.3	FLXAnFRFSR — FlexRay FIFO Status Register	1690
22.3.9.4	FLXAnFRMHDF — FlexRay Message Handler Constraints Flags Register	1692
22.3.9.5	FLXAnFRTXRQi — FlexRay Transmission Request Register i (i = 1 to 4)	1696
22.3.9.6	FLXAnFRNDATi — FlexRay New Data Register i (i = 1 to 4)	1697
22.3.9.7	FLXAnFRMBSCi — FlexRay Message Buffer Status Changed Register i (i = 1 to 4)	1698
22.3.10	Input Buffer	1699
22.3.10.1	FLXAnFRWRDSx — FlexRay Write Data Section Register x (x = 1 to 64)	1699
22.3.10.2	FLXAnFRWRHS1 — FlexRay Write Header Section Register 1	1701
22.3.10.3	FLXAnFRWRHS2 — FlexRay Write Header Section Register 2	1703
22.3.10.4	FLXAnFRWRHS3 — FlexRay Write Header Section Register 3	1704
22.3.10.5	FLXAnFRIBCM — FlexRay Input Buffer Command Mask Register	1705
22.3.10.6	FLXAnFRIBCR — FlexRay Input Buffer Command Request Register	1707
22.3.11	Output Buffer	1709
22.3.11.1	FLXAnFRRDDSx — FlexRay Read Data Section Register x (x = 1 to 64)	1709
22.3.11.2	FLXAnFRRDHS1 — FlexRay Read Header Section Register 1	1710
22.3.11.3	FLXAnFRRDHS2 — FlexRay Read Header Section Register 2	1712
22.3.11.4	FLXAnFRRDHS3 — FlexRay Read Header Section Register 3	1714
22.3.11.5	FLXAnFRMBS — FlexRay Message Buffer Status Register	1716
22.3.11.6	FLXAnFROBCM — FlexRay Output Buffer Command Mask Register	1722

22.3.11.7	FLXAnFROBCR — FlexRay Output Buffer Command Request Register.....	1724
22.3.12	Data Transfer Control Register	1726
22.3.12.1	FLXAnFRITC — FlexRay Input Transfer Configuration Register.....	1726

27.2.1	Functional Overview	2223
27.2.1.1	Terms	2224
27.3	Registers.....	2227
27.3.1	List of Registers	2227
27.3.1.1	Common Register/Config	2227
27.3.2	Common Register/Config.....	2240
27.3.2.1	PSI5SPUOEB — PSI5-S/UART Operation Enable Register.....	2240
27.3.2.2	PSI5SPUOMD — PSI5-S/UART Operation Mode Register	2241
27.3.2.3	PSI5SPUOS — PSI5-S/UART Operation Status Register	2242
27.3.2.4	PSI5SPUNFST — PSI5-S/UART Noise Filter Set Register	2243
27.3.2.5	PSI5SPUSWR — PSI5-S/UART Software Reset Register	2244
27.3.2.6	PSI5SPRMBC — PSI5-S Receive MailBox Data Clear Register	2245
27.3.2.7	PSI5SPUCLB — PSI5-S/UART Communication Loop Back Register	2246
27.3.2.8	PSI5SPUPTS — PSI5-S/UART Rx/Tx Parity Set Register	2247

27.3.2.9	PSI5SPUBCE — PSI5-S/UART Baud Rate Clock Enable Register	2248
27.3.2.10	PSI5SPUBPR — PSI5-S/UART Baud Rate Paramater Register	2249
27.3.2.11	PSI5SPTPS — PSI5-S Timestamp Prescaler Register.....	2250
27.3.2.12	PSI5SPTCAS — PSI5-S Timestamp Counter A Select Register.....	2251
27.3.2.13	PSI5SPTCBS — PSI5-S Timestamp Counter B Select Register.....	2252
27.3.2.14	PSI5SPTCAE — PSI5-S Timestamp Counter A Enable Register.....	2253
27.3.2.15	PSI5SPTCAC — PSI5-S Timestamp Counter A Clear Register	2254
27.3.2.16	PSI5SPTCBE — PSI5-S Timestamp Counter B Enable Register.....	2255
27.3.2.17	PSI5SPTCBC — PSI5-S Timestamp Counter B Clear Register	2256
27.3.2.18	PSI5SPATCE — PSI5-S All Timestamp Counter Enable Register	2257
27.3.2.19	PSI5SPATCC — PSI5-S All Timestamp Counter Clear Register	2258
27.3.2.20	PSI5SUCRIE — UART Communication Rx Interrupt Enable.....	2259
27.3.2.21	PSI5SUCTIE — UART Communication Tx Interrupt Enable	2260
27.3.2.22	PSI5SUCDRE — UART Communication DMA Request Enable Register	2261
27.3.3	Common Register/Rx.....	2262
27.3.3.1	PSI5SUCRD — UART Communication Rx Data Register	2262
27.3.3.2	PSI5SUCRS — UART Communication Rx Status Register.....	2263
27.3.3.3	PSI5SUCRSC — UART Communication Rx Status Clear Register	2265
27.3.4	Common Register/Tx.....	2266
27.3.4.1	PSI5SPTFST — PSI5-S Tx Frame Start Register.....	2266
27.3.4.2	PSI5SPTFNM — PSI5-S Tx Frame Number Register	2267
27.3.4.3	PSI5SPTFD1 — PSI5-S Tx Frame Data1 Register.....	2268
27.3.4.4	PSI5SPTFD2 — PSI5-S Tx Frame Data2 Register.....	2269
27.3.4.5	PSI5SPTFS — PSI5-S Tx Frame Status Register	2270
27.3.4.6	PSI5SPTFIS — PSI5-S Tx FIFO Status Register	2271
27.3.4.7	PSI5SUCTD — UART Communication Tx Data Register.....	2272
27.3.4.8	PSI5SUCTM — UART Communication Tx Monitoring Register	2273
27.3.4.9	PSI5SUCTS — UART Communication Tx Status Register.....	2274
27.3.4.10	PSI5SUCTSC — UART Communication Tx Status Clear Register	2275
27.3.5	Ch0 Register/Config.....	2276
27.3.5.1	PSI5SPRCF10 — PSI5-S Receive Config1 Ch0 Register	2276
27.3.5.2	PSI5SPRCF20 — PSI5-S Receive Config2 Ch0 Register	2279
27.3.5.3	PSI5SPWDE0 — PSI5-S WDT Enable Ch0 Register	2281
27.3.5.4	PSI5SPWDP0 — PSI5-S WDT Prescaler Ch0 Register	2282
27.3.5.5	PSI5SPWDEV0 — PSI5-S WDT Expiration Value Ch0 Register.....	2283
27.3.5.6	PSI5SPCIE0 — PSI5-S CPU Interrupt Enable Ch0 Register.....	2284
27.3.5.7	PSI5SPDRE0 — PSI5-S DMA Transfer Request Enable Ch0 Register	2286
27.3.6	Ch0 Register/Rx.....	2287
27.3.6.1	PSI5SPRES0 — PSI5-S Receive Error Status Ch0 Register	2287
27.3.6.2	PSI5SPRESC0 — PSI5-S Receive Error Status Clear Ch0 Register	2288
27.3.6.3	PSI5SPTCDT0 — PSI5-S Timestamp Capture Data Ch0 Register	2289
27.3.6.4	PSI5SPTCDC0 — PSI5-S Timestamp Capture Data Clear Ch0 Register	2290
27.3.7	Ch0 Register/Interrupt.....	2291
27.3.7.1	PSI5SPCIS0 — PSI5-S CPU Interrupt Status Ch0 Register.....	2291
27.3.7.2	PSI5SPCISC0 — PSI5-S CPU Interrupt Status Clear Ch0 Register	2294
27.3.8	Ch n Register/Config (n: 1 to 7).....	2296
27.3.8.1	PSI5SPRCF1n — PSI5-S Receive Config1 Chn Register (n: 1 to 7).....	2296
27.3.8.2	PSI5SPRCF2n — PSI5-S Receive Config2 Chn Register	2299
27.3.8.3	PSI5SPWDEn — PSI5-S WDT Enable Chn Register	2302
27.3.8.4	PSI5SPWDPn — PSI5-S WDT Prescaler Chn Register	2303
27.3.8.5	PSI5SPWDEVn — PSI5-S WDT Expiration Value Chn Register.....	2304
27.3.8.6	PSI5SPTCDn — PSI5-S Tx Command Data Chn Register	2305

27.3.8.7	PSI5SPCIEn — PSI5-S CPU Interrupt Enable Chn Register.....	2306
27.3.8.8	PSI5SPDREn — PSI5-S DMA Transfer Request Enable Chn Register	2308
27.3.8.9	PSI5SPSTPn — PSI5-S Sync Trigger Prescaler Chn Register	2309
27.3.8.10	PSI5SPSTEVn — PSI5-S Sync Trigger Expiration Value Chn Register.....	2310
27.3.8.11	PSI5SPSTS _n — PSI5-S Sync Trigger Select Ch n Register	2311
27.3.9	Ch n Register/Rx (n: 1 to 7)	2312
27.3.9.1	PSI5SPRES _n — PSI5-S Receive Error Status Chn Register	2312
27.3.9.2	PSI5SPRESC _n — PSI5-S Receive Error Status Clear Chn Register	2314
27.3.9.3	PSI5SPTCDT _n — PSI5-S Timestamp Capture Data Chn Register	2316
27.3.9.4	PSI5SPTCDC _n — PSI5-S Timestamp Capture Data Clear Chn Register	2317
27.3.10	Ch n Register/Tx (n: 1 to 7).....	2318
27.3.10.1	PSI5SPDDTP _n — PSI5-S DDSR Type Chn Register	2318
27.3.10.2	PSI5SPDD _n — PSI5-S DDSR Data Chn Register	2319
27.3.10.3	PSI5SPDD _S _n — PSI5-S DDSR Status Chn Register	2320
27.3.10.4	PSI5SPDDSP _n — PSI5-S DDSR Stop Chn Register	2321
27.3.11	Ch n Register/Interrupt (n: 1 to 7)	2322
27.3.11.1	PSI5SPCIS _n — PSI5-S CPU Interrupt Status Chn Register.....	2322
27.3.11.2	PSI5SPCISC _n — PSI5-S CPU Interrupt Status Clear Chn Register	2325
27.3.12	Ch 0 Frm m MB Data (m: 1, 2).....	2328
27.3.12.1	PSI5SPMB0mS — PSI5-S Receive MailBox Ch0 Frm m Status Register.....	2328
27.3.12.2	PSI5SPMB0mD — PSI5-S Receive MailBox Ch0 Frm m Data Register	2330
27.3.12.3	PSI5SPMB0mT — PSI5-S Receive MailBox Ch0 Frm m Timestamp Register ...	2331
27.3.13	Ch n Frm m MB Data (n: 1 to 7) (m: 1 to 6).....	2332
27.3.13.1	PSI5SPMBnmS — PSI5-S Receive MailBox ch n Frm m Status Register	2332
27.3.13.2	PSI5SPMBnmD — PSI5-S Receive MailBox Ch0 Frm m Data Register	2334
27.3.13.3	PSI5SPMBnmT — PSI5-S Receive MailBox Chn Frm m Timestamp Register ...	2335
27.4	Operation Modes	2336

39.2.3	Overall Configuration of the FIFO Macro	3919
39.2.4	Data Format	3920
39.2.5	Filtering Circuit	3921
39.2.5.1	FIR Filter	3921
39.2.5.2	IIR Filter	3921
39.2.6	Dispatch Circuit.....	3922
39.2.7	Accumulation Circuit	3923
39.2.8	Subtraction Circuit.....	3923
39.2.9	Peak-Hold (PH) Circuit.....	3923
39.2.10	Output Circuit	3925
39.2.11	Intermediate Values Output Circuit.....	3925
39.2.12	Capture Circuit	3925
39.2.13	Buffer A Circuit.....	3925
39.2.14	Buffer B Circuit.....	3925
39.2.15	Terms	3926
39.3	Control Registers	3929
39.3.1	List of Registers for DFE Macro.....	3929
39.3.2	List of Registers for the FIFO Macro.....	3938
39.3.3	DFEjCTLACHn — Control Register A n (n = 0 to 15 for DFE0, n = 0 to 3 for DFE1).....	3939
39.3.4	DFEjCTLBCHn — Control Register B n (n = 0 to 15 for DFE0, n = 0 to 3 for DFE1).....	3942
39.3.5	DFEjDOCHn — Output Data Register n (n = 0 to 15 for DFE0, n = 0 to 3 for DFE1).....	3947
39.3.6	DFEjPHCHn — Peak-Hold Result Register n (n = 0 to 15 for DFE0, n = 0 to 3 for DFE1)	3948

39.3.7	DFEjPHINDCHn — Peak-Hold Index Register n (n = 0 to 15 for DFE0, n = 0 to 3 for DFE1)	3949
39.3.8	DFEjSTCHn — Status Register n (n = 0 to 15, for DFE0, n = 0 to 3 for DFE1)	3951
39.3.9	DFEjCLRSTCHn — Clear Status Register n (n = 0 to 15 for DFE0, n = 0 to 3 for DFE1)	3955
39.3.10	DFEjERMCHn — Error Mask Register n (n = 0 to 15 for DFE0, n = 0 to 3 for DFE1)	3957
39.3.11	DFEjTRGCHn — Trigger Setting Register n (n = 0 to 15 for DFE0, n = 0 to 3 for DFE1)	3958
39.3.12	DFEjTMRGCHn — Timer Trigger Setting Register n (n = 0 to 15 for DFE0, n = 0 to 3 for DFE1)	3961
39.3.13	DFEjTRHCHn — Trigger History Register n (n = 0 to 15 for DFE0, n = 0 to 3 for DFE1)	3964
39.3.14	DFEjCPA to DFEjCPD — Comparison Value Setting Register	3966
39.3.15	DFEjPHIA to DFEjPHID — Peak-Hold Initial Value Setting Register	3967
39.3.16	DFEjACA to DFEjACD — Accumulation/Decimation Count Setting Register	3968
39.3.17	DFEjDI — Software Input Data Register	3969
39.3.18	DFEjTRG — Software Trigger Register	3970
39.3.19	DFEjST — DFE Status Register	3971
39.3.20	DFEjEST — DFE Error Status Register	3972
39.3.21	DFEjPMITRG0 — Peak-Hold Mask-Start/End Timer Trigger Select Register 0	3973
39.3.22	DFEjPMITRG1 — Peak-Hold Mask-Start/End Timer Trigger Select Register 1	3975
39.3.23	DFEjPITRG — Peak-Hold Initialization/End Timer Trigger Select Register	3976
39.3.24	DFEjPITRG1 — Peak-Hold Initialization/End Timer Trigger Select Register 1	3978
39.3.25	DFEjMITRG — Accumulation/Decimation Initialization/Prohibition Timer Trigger Select Register	3979
39.3.26	DFEjMITRG1 — Accumulation/Decimation Initialization/Prohibition Timer Trigger Select Register 1	3981
39.3.27	DFEjFITRG — Filter Initialization Timer Trigger Select Register	3982
39.3.28	DFEjFITRG1 — Filter Initialization Timer Trigger Select Register 1	3984
39.3.29	DFEjPHUPDCn — Peak-Hold Update Notification Setting Register n (n = 0 to 3)	3985
39.3.30	DFEjHOLCHn — Intermediate Value Output Register L n (n = even channels)	3986
39.3.31	DFEjHOHCHn — Intermediate Value Output Register H n (n = even channels)	3987
39.3.32	DFEjHOLMCHn — Intermediate Value Output Mirror Register L n (n = even channels)	3988
39.3.33	DFEjGAINCHn — IIR Filter Gain Setting Register n (n = 0 to 15 for DFE0, n = 0 to 3 for DFE1)	3989
39.3.34	DFEjCPOFSTn — Comparison Offset Value Setting Register n (n = 0 to 2)	3991
39.3.35	DFEjPH23CCTL0 — Peak-Hold 23 Common Control Register 0	3992
39.3.36	DFEjPH2CTL0 — Peak-Hold 2 Control Register 0	3993
39.3.37	DFEjPH3CTL0 — Peak-Hold 3 Control Register 0	3995
39.3.38	DFEjPH20 — Peak-Hold 2 Result Register 0	3997
39.3.39	DFEjPH30 — Peak-Hold 3 Result Register 0	3998
39.3.40	DFEjPH2IND0 — Peak-Hold 2 Index Register 0	3999

39.3.41	DFEjPH3IND0 — Peak-Hold 3 Index Register 0	4001
39.3.42	DFEjSUBCTLCHn — Subtraction Control Register n (n = 0 to 2)	4003
39.3.43	DFEjSUBDOCHn — Subtraction Result Register n (n = 0 to 2)	4005
39.3.44	DFEjSUBSTCHn — Subtraction Status Register n (n = 0 to 2)	4006
39.3.45	DFEjSUBCLRSTCHn — Subtraction Clear Status Register n (n = 0 to 2)	4008
39.3.46	DFEjSUBERMCHn — Subtraction Error Mask Register n (n = 0 to 2)	4009
39.3.47	DFEjSUBTRGCHn — Subtraction Trigger Setting Register n (n = 0 to 2)	4010
39.3.48	DFEjSUBTRHCHn — Subtraction Trigger History Register n (n = 0 to 2)	4012
39.3.49	DFEjSUBTRG0 — Subtraction Start/End Timer Trigger Select Register 0	4013
39.3.50	DFEjCAPCTLCHn — Capture Control Register n (n = 0 to 2)	4014
39.3.51	DFEjCAPDOCHn — Capture Result Register n (n = 0 to 2)	4015
39.3.52	DFEjCAPSTCHn — Capture Status Register n (n = 0 to 2)	4016
39.3.53	DFEjCAPCLRSTCHn — Capture Clear Status Register n (n = 0 to 2)	4017
39.3.54	DFEjCAPERMCHn — Capture Error Mask Register n (n = 0 to 2)	4018
39.3.55	DFBFACCTL — Buffer A Common Control Register	4019
39.3.56	DFBFACCTLCHn — Buffer A Control Register n (n = 0 to 7)	4020
39.3.57	DFBFADOCHn — Buffer A Output Register n (n = 0 to 7)	4021
39.3.58	DFBFACLR — Buffer A Clear Register	4024
39.3.59	DFBFACST — Buffer A Common Status Register	4025
39.3.60	DFBFBCTL — Buffer B Control Register	4026
39.3.61	DFBFBDO — Buffer B Output Register	4027
39.3.62	DFBFBCLR — Buffer B Clear Register	4028
39.3.63	DFBFBST — Buffer B Status Register	4029
39.4	Operation	4030
39.4.1	Overview of Operation	4030
39.4.1.1	DFE Macro	4030
39.4.1.2	FIFO Macro	4032
39.4.2	Operating Procedures	4034
39.4.2.1	Channel Start Procedure	4034
39.4.2.2	Channel Stop Procedure	4037
39.4.2.3	Error Processing Procedure	4039
39.5	Details	4044
39.5.1	Data Flow	4044
39.5.1.1	DFE Macro	4044
39.5.1.2	FIFO Macro	4045
39.5.2	Address Map	4046
39.5.2.1	DFE Macro	4046
39.5.2.2	FIFO Macro	4046
39.5.3	Memory	4047
39.5.4	Format of Coefficient Memory	4048
39.5.5	Format of Data Memory	4049
39.5.6	Setting Control Registers	4050
39.5.6.1	FIR (Fixed-Point)	4050
39.5.6.2	FIR (Integer)	4051
39.5.6.3	IIR (Fixed-Point)	4052

39.5.7	Trigger Control	4053
39.5.7.1	Timer Trigger Input	4053
39.5.7.2	Trigger Flag Functions	4057
39.5.7.3	Trigger Flag Functions and Processing	4061
39.5.7.4	Automatic Initialization of the Channel	4062
39.5.8	Input Data Control	4064
39.5.8.1	AD Input	4064
39.5.8.2	Cascade Input	4064
39.5.8.3	Software Input	4066
39.5.8.4	Dispatch	4066
39.5.9	Filtering Circuit	4068
39.5.9.1	FIR (8, 16, 24, 32 Taps)	4068
39.5.9.2	FIR (64 Taps)	4070
39.5.9.3	One-Stage IIR	4071
39.5.9.4	Two-Stage IIR	4073
39.5.9.5	Three-Stage IIR	4075
39.5.9.6	Errors in the Filtering Circuit	4077
39.5.10	Accumulation Circuit	4077
39.5.10.1	Absolute Value Calculation	4077
39.5.10.2	Summary of Accumulation Processing	4077
39.5.10.3	Operation of Accumulation Processing	4078
39.5.10.4	Operation of Accumulation Processing (with Trigger Flag)	4080
39.5.10.5	Summary of Decimation Processing	4082
39.5.10.6	Operation for Decimation Processing	4082
39.5.10.7	Operation of Decimation Processing (with Trigger Flag)	4084
39.5.11	Subtraction Circuit	4086
39.5.11.1	Summary of the Subtraction Circuit	4087
39.5.11.2	Operation of the Subtraction Circuit	4088
39.5.11.3	Operation of Subtraction Circuit (with Subtraction Start Trigger)	4093
39.5.11.4	Operation of Subtraction Circuit (with Subtraction End Trigger)	4094
39.5.11.5	Operation of Subtraction Circuit (Stop by DFEjSUBCTLCHn.SEN)	4095
39.5.12	Peak-Hold Circuit	4097
39.5.12.1	Summary of Peak-Hold Processing	4097
39.5.12.2	Operation of Peak-Hold Processing	4098
39.5.12.3	Operation of Peak-Hold Processing (Trigger Flag is Enabled)	4100
39.5.12.4	Operation of Peak-Hold Mask Processing (Trigger Flag is Enable)	4102
39.5.12.5	Operation of Comparison Processing	4104
39.5.12.6	Operation of the Peak-Hold Index Register	4105
39.5.12.7	Reading of the Peak-Hold Index Register and Operation	4107
39.5.12.8	Operation When Both Peak-Hold Processing and Comparison Processing Are Executed	4109
39.5.12.9	Summary of Peak-Hold-23 Processing	4111
39.5.12.10	Operation of Peak-Hold-23 Function	4112
39.5.12.11	Operation of the Peak-Hold Index Register When Peak-Hold-23 is Enabled	4119
39.5.12.12	Status of Peak-Hold-23 Function	4119
39.5.12.13	Operation of Peak-Hold-23 Function (Trigger Flag is enable)	4120
39.5.12.14	Setting Example of Peak-Hold-23 Function	4121
39.5.13	Output Circuit	4123
39.5.13.1	Floating-Point Conversion Circuit	4123
39.5.13.2	Output Register Circuit	4123

39.5.13.3	Floating Point Conversion Circuits for the Intermediate Value Output Registers L and H	4123
39.5.13.4	Intermediate Value Output Register Circuits	4123
39.5.14	Capture Circuit	4124
39.5.14.1	Summary of Capture Circuit	4124
39.5.15	Buffer A Circuit	4125
39.5.15.1	Summary of Buffer A Circuit	4125
39.5.15.2	Operation of Output Data Register Enable Flag and Buffer A Data Update Flag	4126
39.5.15.3	Initialization of the Buffer A Circuit	4127
39.5.15.4	Overwriting of FIFO When There is an Overflow	4127
39.5.16	Buffer B Circuit	4128
39.5.16.1	Summary of Buffer B Circuit	4128
39.5.16.2	Operation of Output Data Register Enable Flag	4129
39.5.16.3	Initialization for Buffer B Circuit	4129
39.5.17	Status Register	4130
39.5.17.1	Conditions for Setting and Clearing the DOEN Flag	4131
39.5.18	Error Mask Registers	4133
39.5.19	Subtraction Status Register	4133
39.5.20	Subtraction Error Mask Registers	4134
39.5.21	Capture Status Register	4134
39.5.22	Capture Error Mask Register	4134
39.5.23	Buffer A Status Register	4135
39.5.24	Buffer A Clear Register	4135
39.5.25	Buffer B Status Register	4135
39.5.26	Buffer B Clear Register	4135
39.5.27	Interrupt Requests	4136
39.5.27.1	DFE Macro	4136
39.5.27.2	FIFO Macro	4143
39.6	Notes and Restrictions	4145
39.6.1	Processing Time	4145
39.6.1.1	Processing Time for One Channel	4145
39.6.1.2	Termination Processing Time	4145
39.6.2	DFE Activation Input Interval	4145
39.6.2.1	DFE Processing Time	4146
39.6.3	Trigger Input	4147
39.6.4	Channel Tag and AD Tag	4148
39.6.5	Input Data Format and Calculation Restrictions	4148
39.6.6	Restrictions on Cascade Processing	4148
39.6.7	Operation when the Given Channel is Disabled	4149
39.6.7.1	Channel Enable Bits and Invalidation	4149
39.6.8	Restrictions on FIR 64TAP	4150
39.6.9	Restrictions on Memory Access	4150
39.6.10	Restrictions on Trigger Setting Registers	4150
39.6.11	Setting of Peak-Hold Processing Disable Bit and Accumulation/Decimation Processing Disable Bit	4150

40.3.3.5	CFCECCCTL — ECC Control Register.....	4164
40.3.3.6	CFSECCCTL — ECC Control Register.....	4165
40.3.3.7	CF_ERRINT — Error Notification Control Register	4166
40.3.3.8	CF_SSTCLR — 1-bit Error Status Clear Register.....	4167
40.3.3.9	CF_DSTCLR — Fatal Error Status Clear Register.....	4168
40.3.3.10	CF_OVFCLR — 1-bit Error Overflow Status Clear Register	4169
40.3.3.11	CF_SERSTR — 1-bit Error Status Register	4170
40.3.3.12	CF_DERSTR — Fatal Error Status Register.....	4171
40.3.3.13	CF_OVFSTR — 1-bit Error Overflow Status Register.....	4172
40.3.3.14	CF_SERINF — 1-bit Error Location Information Register	4173
40.3.3.15	CF_nSEADR — n-th 1-bit Error Address Register (n = 00 to 03)	4174
40.3.3.16	CF_00DEADR — 1st Fatal Error Address Register	4176
40.3.3.17	Test Function	4178
40.3.4	Data Flash ECC	4179
40.3.4.1	Overview	4179
40.3.4.2	List of Registers	4179
40.3.4.3	DFECCCTL — Data Flash ECC Control Register.....	4180

40.3.4.4	DFERSTR — Data Flash Error Status Register	4181
40.3.4.5	DFERSTC — Data Flash Error Status Clear Register	4182
40.3.4.6	DFOVFSTR — Data Flash Error Overflow Status Register	4183
40.3.4.7	DFOVFSTC — Data Flash Error Overflow Status Clear Register	4184
40.3.4.8	DFERRINT — Data Flash Error Notification Control Register	4185
40.3.4.9	DFEADR — Data Flash 1st Error Address Register	4186
40.3.4.10	DFTSTCTL — Data Flash Test Control Register	4187
40.3.4.11	DFKCPROT — Data Flash ECC Key Code Protection Register	4188
40.3.4.12	Test Function	4189
40.3.5	Local RAM ECC and Address Feedback	4190
40.3.5.1	Overview	4190
40.3.5.2	Register Base Address	4192
40.3.5.3	List of Registers	4193
40.3.5.4	LRECCCTL — ECC Control Register	4196
40.3.5.5	LRECCTSTCTL — ECC Test Control Register	4197
40.3.5.6	LRAFINV — Address Feedback Test Control Register	4198
40.3.5.7	LRTDATBFECF — ECC Read Buffer Register	4199
40.3.5.8	LR0_ERRINT — Error Notification Control Register	4200
40.3.5.9	LR0_SSTCLR — 1-bit Error Status Clear Register	4201
40.3.5.10	LR0_DSTCLR — Fatal Error Status Clear Register	4202
40.3.5.11	LR0_OVFCLR — 1-bit Error Overflow Status Clear Register	4203
40.3.5.12	LR0_SERSTR — 1-bit Error Status Register	4204
40.3.5.13	LR0_DERSTR — Fatal Error Status Register	4205
40.3.5.14	LR0_OVFSTR — 1-bit Error Overflow Status Register	4206
40.3.5.15	LR0_SERINF — 1-bit Error Location Information Register	4207
40.3.5.16	LR0_nSEADR — n-th 1-bit Error Address Register (n = 00 to 07)	4208
40.3.5.17	LR0_00DEADR — 1st Fatal Error Address Register	4209
40.3.5.18	LR1_ERRINT — Error Notification Control Register	4210
40.3.5.19	LR1_SSTCLR — 1-bit Error Status Clear Register	4211
40.3.5.20	LR1_DSTCLR — Fatal Error Status Clear Register	4212
40.3.5.21	LR1_OVFCLR — 1-bit Error Overflow Status Clear Register	4213
40.3.5.22	LR1_SERSTR — 1-bit Error Status Register	4214
40.3.5.23	LR1_DERSTR — Fatal Error Status Register	4215
40.3.5.24	LR1_OVFSTR — 1-bit Error Overflow Status Register	4216
40.3.5.25	LR1_SERINF — 1-bit Error Location Information Register	4217
40.3.5.26	LR1_nSEADR — n-th 1-bit Error Address Register (n = 00 to 07)	4218
40.3.5.27	LR1_00DEADR — 1st Fatal Error Address Register	4219
40.3.5.28	Test Function	4220
40.3.6	Cluster RAM ECC and Address Feedback	4222
40.3.6.1	Overview	4222
40.3.6.2	Register Base Address	4223
40.3.6.3	List of Registers	4224

Section 1 Overview

The RH850/E2x-FCC2, RH850/E2UH and RH850/E2H are products of the single-chip microcontroller RH850 series from Renesas Electronics.

This section gives an overview of the RH850/E2x-FCC2, RH850/E2UH and RH850/E2H.

1.1 Outline

This product is a 32-bit single-chip microcontroller that incorporates multiple CPUs of the RH850 architecture, code flash, data flash, RAM, DMA controllers, high-speed communication interfaces including RHSB (microsecond bus), CAN, FlexRay, Ethernet, RHSIF, LIN, SENT, PSI5-S, PSI5*¹, three types (sequential conversion type, delta-sigma type and cyclic type) of A/D converters, peripheral functions including digital filter processing, an advance timer unit (ATU-V) and GTM that are best suited for high-speed accurate power train control. This product also conforms to the Automotive Safety Integrity Level (ASIL) that is currently in high demand in the automotive field.

(1) Includes multiple RH850 cores

This product contains multi RH850G4MH cores (each CPU is referred to as CPU0 to CPU5 (E2H: CPU0 to CPU3) hereafter). CPU0 to CPU5 (E2H: CPU0 to CPU3) support RISC-type instruction sets and have significantly improved the instruction execution speed with basic instructions (one clock cycle per instruction) and optimized 10-stage pipeline configurations. Furthermore, this product also supports multiplication instructions using a 32-bit hardware multiplier, saturated product-sum operation instructions, and bit manipulation instructions as instructions best suited for various applications such as automobile power train control.

Two-byte basic instructions and high-level language instructions improve object code efficiency for the C compiler and reduce the program size. Furthermore, this product is suited for advanced real-time control applications by offering a high-speed interrupt response time including the processing time of the on-chip interrupt controller.

(2) On-chip code flash and data flash

This product incorporates a 16-MB (E2H: 12MB) code flash allowing high-speed access, which enables each CPU to access this flash memory efficiently. This memory can be reprogrammed while placed in an application system. This can shorten the system development period and significantly improve serviceability after the system is delivered.

This product also has a 320-KB (E2H: 288-KB) data flash that is available for storing EEPROM data.

(3) A variety of peripheral functions

This product incorporates timers, a Digital Filter Engine (DFE), three types of A/D converters (SAR-ADC, DS-ADC, and Cyclic ADC) and other functions that are best suited for reducing hardware and software control loads in the automobile power train control (e.g. engine, transmission). In addition, this product incorporates standard peripheral functions (UART, CAN, and RHSB) for automotive applications. It also has the global standard on-chip NEXUS JTAG as a debug interface. This allows construction of systems without the need to provide these functions externally, which reduces cost, quantity of components and PCB footprint.

(4) Functional safety support

This product provides with several dedicated functionalities including a Lock-Step Dual Core configuration for the CPU, memory protection with ECC, bus protection with ECC/EDC, peripheral module protection, and voltage/clock monitors to support the functional safety standard (ISO26262) required in automotive applications.

(5) Security support

This product provides various security features and utilizes the Intelligent Cryptographic Unit/Master (ICUMD) as an on-chip Hardware Security Module (HSM).

Note 1. Not supported in E2H

1.2 Features

CPU core	RH850G4MH: 6 units (E2H: 4 units) (for high-speed operation and control)
CPU cache memory	16 KB
Minimum CPU instruction execution time	2.5 ns (during internal 400 MHz operation)
General CPU registers	Thirty-two 32-bit registers
FP-SIMD	<p>CPU0 and CPU2 have their own respective FP-SIMD units</p> <p>32-bit x 1/2/4-way operations</p> <p>Thirty-two 128-bit dedicated registers independent from CPU/FPU</p> <p>Supports single-precision (32-bit) only</p> <p>Supports IEEE754 compliant data types and exceptions</p> <p>Exceptions can be enabled/disabled individually</p> <p>Rounding modes: To nearest/Toward 0/Toward + ∞/Toward - ∞</p> <p>Handling of denormalized numbers: Truncation to zero / IEEE754 compliant exception</p>
CPU instruction sets	<p>Signed multiplication (32 bits × 32 bits → 64 bits): 1 to 2 CPU clocks</p> <p>Saturated operation instructions (with overflow/underflow detection function)</p> <p>32-bit arithmetic/logical shift instructions: 1 CPU clock</p> <p>Bit manipulation instructions</p> <p>Load/store instructions with long/short formats</p> <p>Signed load instructions</p>
Memory space	4-GB address space (common to program and data)
Code flash	<p>Two types of memory area</p> <ul style="list-style-type: none"> • User area: 16 MB (E2H: 12 MB) (common to each CPU, ICUMD) • User boot area: 64 KB high-speed reading through cache enabled <p>OTA (Over-The-Air) update support (E2UH/E2H Only)</p>
Data flash	320 KB (E2H: 288 KB) (common to each CPU and ICUMD)
RAM	<p>Local RAM: 64 KB (E2H: 32 KB) (each CPU)</p> <p>Cluster RAM: 1664 KB (E2H: 1024 KB) (common to each CPU) (128 KB: Retention RAM)</p> <p>Cluster Emulation RAM: 3 MB (1 MB for each cluster) (E2x-FCC2 only)</p> <p>Global Emulation RAM: 2 MB (E2x-FCC2 only)</p>
Interrupts/exceptions	<p>1 nonmaskable interrupt (NMI pin)</p> <p>2 FE level interrupts</p> <p>768 maskable interrupts (high-speed: 32, low-speed: 736)</p> <p>Simultaneous distribution of interrupt sources to multiple cores (each CPU)</p> <ul style="list-style-type: none"> • Applicable sources: non-maskable interrupt (NMI pin), FE level interrupts, 32 high-speed maskable interrupts <p>External interrupt input function (IRQ pins)</p> <p>Software interrupt function (SINT)</p> <p>Inter-processor interrupt function (IPIR)</p> <p>16-level priority specifiable for maskable interrupts</p> <p>For RH850 G4MH exceptions, see Section 3, CPU system.</p>
sDMAC controller	<p>32 channels incorporated (16 channels × 2 units)</p> <p>Transfer data length: 1 byte, 2 bytes, 4 bytes, 8 bytes, 16 bytes, 32 bytes, 64 bytes</p> <p>Parallel reads and writes (fly-by)</p> <p>Address mode: dual address mode</p> <p>Transfer requests: auto request, peripheral hardware request</p> <p>Bus modes: normal speed mode, slow speed mode</p> <p>Arbitration modes: fixed priority mode, round-robin mode</p> <p>Interrupt requests: termination of descriptor step, termination of data transfer, occurrence of address error</p> <p>Descriptor memory: 8 KB (shared among all channels)</p> <p>Scatter-gather transfer</p> <p>Transfer target: On-chip memory, on-chip peripheral modules (excluding the DTS and sDMAC)</p>

DTS controller	<p>128 channels incorporated</p> <p>Transfer unit: 8 bits/16 bits/32 bits/64 bits/128 bits</p> <p>64-bit × 2-burst transfer</p> <p>Dual-address transfer mode</p> <p>Address reloading function</p> <p>Chain transfer function</p> <p>Three transfer modes: Single transfer, block transfer 1 (specified by number of transfer times), and block transfer 2 (specified by address count)</p> <p>Transfer target: On-chip memory, on-chip peripheral modules (excluding the DTS and sDMAC)</p> <p>Transfer requests can be set by interrupt sources and software</p>
I/O	<p>Output driving ability of specific input/output pins is selectable</p> <p>Inversion or non-inversion of output values of specific input/output pins is selectable</p> <p>Pull-down or pull-down off of specific input/output pins is selectable</p>
Safety functions	<p>Flash memory ECC error detection function</p> <p>RAM ECC error detection function</p> <p>Peripheral module RAM ECC error detection function (e.g. DTS, CAN, FlexRay, DFE)</p> <p>Clock monitor</p> <p>Error Control Module (ECM)</p> <p>Duplexing of modules (e.g. CPUs, ECM, error output pins)</p> <p>Automatic Power-on BIST execution after reset</p> <p>Shut-down BIST execution selection after System Reset 2</p>
Error Control Module (ECM)	<p>Collects information for each error check system and safety function and indicates error status</p> <p>When an error is detected, an error signal can be output from the error pin to an outside</p> <p>Interrupts and internal reset signals can be generated upon detection of an error</p> <p>Provided with a function to generate a pseudo-error for debugging and self-diagnosis</p>
Data CRC function B (DCRB)	<p>The data CRC (Cyclic Redundancy Check) function can verify or generate data streams protected by a CRC with various lengths and different bit widths</p>
Multi-Input Signature Generator (MISG)	<p>Monitors write access to specific addresses by the respective CPUs, and generate a 64-bit signature using the write data</p>
Window Watchdog Timer (WDTB)	<p>6 units incorporated (E2H: 4 units)</p> <p>Can generate a signal to the ECM when a counter overflows (timer expires)</p> <p>Can generate an interrupt at 75% of the counter overflow value</p> <p>An interrupt request can be generated at any function of the counter value</p> <p>A window open period can be set to any function of the counter value</p>
Advanced Timer Unit V (ATU-V)	<p>Timer A: 32-bit input capture × 8 channels</p> <p>Timer B: Angle clock generating timer × 1 channel</p> <p>Timer C: 32-bit input capture/output compare × 56 channels</p>
(ATU and GTM cannot be used at the same time)	<p>Timer D: 32-bit one-shot pulse × 60 channels 32-bit input capture × 60 channels 32-bit output compare × 60 channels</p> <p>Timer E: 24-bit PWM × 40 channels</p> <p>Timer F: 32-bit event counter × 20 channels</p> <p>Timer G: 32-bit interval timer × 10 channels</p>
OS Timer (OSTM)	<p>7 units incorporated (E2H: 5 units)</p> <ul style="list-style-type: none"> • A 32-bit timer assuming use by an OS • Interval timer mode or free-running timer mode selectable • Synchronous start between units available
Peripheral Interconnection function (PIC1)	<p>One unit incorporated</p> <ul style="list-style-type: none"> • Synchronous operation between the OSTM timer and other timer input/outputs can be connected
Peripheral Interconnection function (PIC2)	<p>Two units incorporated</p> <ul style="list-style-type: none"> • Maps peripheral IP outputs to triggers
Serial Communication Interface 3 (SCI3)	<p>4 channels incorporated</p> <ul style="list-style-type: none"> • Clock synchronization or start-stop system selectable • Full-duplex communication enabled • Arbitrary bit rate selectable by the on-chip baud rate generator • LSB first or MSB first selectable

Clocked Serial Interface H (CSIH)	<p>8 channels incorporated</p> <ul style="list-style-type: none"> • Three-wire serial synchronous data transfer • Master mode or slave mode selectable • Six or four chip select output signals are selectable • Arbitrary bit rate is selectable by the on-chip baud rate generator
CANFD interface (RS-CANFD)	<p>10 channels incorporated (E2H: 6 channels)</p> <ul style="list-style-type: none"> • RS-CAN mode (RS-CAN software compatibility mode) <ul style="list-style-type: none"> – Conforming to CAN ISO-11898-1 (2003) – Transfer speed up to 1 Mbps – A total of 800 message buffers provided for 10 channels – A total of 480 message buffers provided for 6 channels (E2H) – Reception filtering • CAN-FD mode <ul style="list-style-type: none"> – Conforming to CAN-FD ISO 11898-1 (2015) – Transfer speed up to 8 Mbps – A total of 800 message buffers provided for 10 channels – A total of 480 message buffers provided for 6 channels (E2H) – Reception filtering
FlexRay (FLXA)	<p>2 units incorporated (E2H: 1 unit)</p> <ul style="list-style-type: none"> • Conforming to Protocol Specification v2.1 • Buffer size: A 8-KB space is divided into up to 128 sections (for transmission, reception, and receive FIFO) • Message filtering: ID filter, channel filter, cycle counter filter • Bit rate: 10 Mbps
LIN/UART interface (RLIN3)	<p>8 channels incorporated (E2H: 6 channels)</p> <ul style="list-style-type: none"> • Conforming to LIN Protocol Spec versions 1.3, 2.0, 2.1, 2.2, and SAE J2602 • Three operating modes <ul style="list-style-type: none"> – LIN Master mode – LIN Slave mode – UART mode (half-duplex, full-duplex) • Arbitrary bit rate is selectable by the on-chip baud rate generator • LIN Self-test mode with internal data loop back
Renesas High-Speed Bus (RHSB)	<p>4 channels incorporated (E2H: 3 channels)</p> <p>Communication module supporting Micro-Second Bus channels</p> <ul style="list-style-type: none"> • Down-stream communication • Up to two slaves selectable and configurable individually • Functions for emergencies
Single Edge Nibble Transmission (RSENT)	<p>20 channels incorporated</p> <ul style="list-style-type: none"> • Conforming to the SENT (Single Edge Nibble Transmission) protocol specified in the SAE J2716_201604 standard and the SPC (Short PWM Code) extension to the SENT specification • Unidirectional or bidirectional transfer is possible through a single pin • Bidirectional transfer is possible through two pins • Data transfer protected by a CRC is possible
High Speed Serial Peripheral Interface (HS-SPI)	<p>1 channel incorporated</p> <ul style="list-style-type: none"> • Three-wire serial synchronous data transfer • Master mode or Slave mode selectable • Built in DMA for communication data transfer
Peripheral Sensor Interface 5 serial communication module (PSI5-S)	<p>1 channel incorporated</p> <ul style="list-style-type: none"> • Support the UART based communication for PSI5 transceiver • Conformance with PSI5 protocol specification V2.2 • Generate a PSI5 message from the UART transfer data • The bit rate of the UART can be set by the built-in baud rate generator
Peripheral Sensor Interface 5 (PSI5)	<p>1channel incorporated (E2UH only)</p> <ul style="list-style-type: none"> • Conformance with PSI5 protocol specification V2.0

RHSIF	<p>1 channel incorporated</p> <ul style="list-style-type: none"> • Asynchronous high speed LVDS interface based on IEEE 1596.3-1996 reduced range link • Asynchronous high speed LVDS interface supporting maximum data rates of 320 Mbps • Four channels, including one channel with data streaming capability • Bus master interface that is used by a target node to access shared memory
Ethernet Controller (ETNC)	<p>1 channel incorporated</p> <ul style="list-style-type: none"> • Conformance with the IEEE 802.3 MAC layer standard • PHY interface: MII (Media Independent Interface) and RMII (Reduced Media Independent Interface) • Supports 10 Mbps and 100 Mbps • Supports full-duplex and half-duplex modes • Built-in DMA transfer function
External Bus Interface	<p>1 channel incorporated</p> <ul style="list-style-type: none"> • Supports external memory access (Devices with a conventional SRAM interface are directly connectable) • 16/32 bit data bus of each channel can be selected (E2H: 16 bit data bus) • Address and access control timings are configurable • The idle cycle is independently programmable for after the read and after the write bus cycles
Analog to Digital Converter (ADCH)	<p>96 channels incorporated</p> <ul style="list-style-type: none"> • A/D conversion method: Successive approximation • Configuration of analog input pins <ul style="list-style-type: none"> ADCH0/ADCH1 dedicated inputs: 20/12 ADCH0/ADCH1 shared inputs: 8 ADCH2/ADCH3 dedicated inputs: 24/24 ADCH2/ADCH3 shared inputs: 8 • Resolution: 12-bit/10-bit • Conversion speed: 1.0 μs • Scan groups for five systems for each converter • Two scan modes (multicycle scan mode and continuous scan mode) • ADCH0: Up to 40 virtual channels • ADCH2: Up to 40 virtual channels • ADCH1: Up to 40 virtual channels • ADCH3: Up to 40 virtual channels • Two types of A/D conversion and addition functions incorporated • Converts the converted results to floating-point format • Can enter data directly to the digital filter and the ADC summation function and the Generic Timer Module • Safety functions • Supports an upper/lower-limit-excess-notice-function for the ADC Voltage Monitor Secondary Error Generator or ADC Boundary Flag Generator in each virtual channel

Delta-Sigma Analog to Digital Converter (DSADC)	<p>38 channels incorporated</p> <ul style="list-style-type: none"> • A/D conversion method: Delta-Sigma modulation method • Configuration of analog input pins <ul style="list-style-type: none"> DSADC00: 8 single-ended inputs/4 differential inputs DSADC10: 4 single-ended inputs/2 differential inputs DSADC20: 2 single-ended inputs/1 differential inputs DSADC12: 4 single-ended inputs/2 differential inputs DSADC13: 4 single-ended inputs/2 differential inputs DSADC11: 4 single-ended inputs/2 differential inputs DSADC15: 4 single-ended inputs/2 differential inputs DSADC14: 8 single-ended inputs/4 differential inputs DSADC22: 2 single-ended inputs/1 differential inputs DSADC21: 2 single-ended inputs/1 differential inputs • Input type: Single-end input and differential input • Input gain function (PGA): $\times 1$, $\times 2$, $\times 4$, or $\times 8$ selectable • Calibration function • Can enter data directly to the digital filter and the Generic Timer Module. • Timestamp function • Supporting a boundary flag generating signal to the ADC Boundary Flag Generator • Safety functions
Cyclic Analog to Digital Converter (CADC)	<p>8 channels incorporated</p> <ul style="list-style-type: none"> • A/D conversion method: Cyclic conversion method • Configuration of analog input pins <ul style="list-style-type: none"> CADC00: 8 single-ended inputs /4 differential inputs • Input type: Single-ended input and differential input • Calibration function • Can enter data directly to the digital filter and the Generic Timer Module • Supporting a boundary flag generating signal to the ADC Boundary Flag Generator • Safety functions
Power supply	<p>E2x supports both the 5 V and 3.3 V power supplies with the exception of the core supply. The Power on/off sequence has no constraints</p>
Power supply voltage monitor	<ul style="list-style-type: none"> • The power supply voltage monitor is used for monitoring power domains E0VCC, VCC and VDD • The power supply voltage monitor has High-side (HDET) and Low-side (LDET) voltage detectors, which detect if the monitored voltage is higher or lower than the specified voltage • The Power supply voltage monitors have two types of detection functions, Primary detection and Secondary detection • The Primary detection function is performed by Voltage Monitor. The Secondary detection function is performed by the SAR-ADC • The Delay Monitor (DMON) assists the VMON, which detects the Low-side voltage of VDD • Primary power supply voltage monitor can control on or off for the VMON high level and low level detection of VDD, and the high level detection of VCC and E0VCC • The Primary detection voltage value is fixed, the secondary detection voltage value can be set by the SAR-ADC • If the Secondary power supply voltage monitor detects voltage failures, it notifies the error to the ECM. Based on the settings in the ECM, it is possible to generate an interrupt or reset
Digital Filter Engine (DFE)	<p>20-channel digital filtering (FIR/IIR) functions</p> <ul style="list-style-type: none"> • FIR with up to 64 taps selectable • Up to a 6-order IIR is selectable • Filter coefficients and data are stored in the RAM to be connected • For filtered data: <ul style="list-style-type: none"> Accumulation processing or decimation processing can be enabled Peak-hold processing or comparison processing can be enabled • Directly inputs converted data from the SAR A/D converter or Delta-Sigma A/D converter or cyclic A/D converter to perform automatic filtering
Secure Watchdog Timer (SWDT)	<p>1 unit incorporated</p> <p>Can generate an error signal for the Reset Controller in response to an error</p> <p>Confirmation of matching with a specified Program Counter (PC) value of the CPU0</p>

Intelligent Cryptographic Unit Master (ICUMD)	The ICUMD is an on-chip Hardware Security Module (HSM) The ICUMD supports user-defined security services to the overall system based on cryptographic primitives
On-Chip Debugging unit (OCD)	NEXUS JTAG: One channel incorporated LPD (4-pin): One channel incorporated CAN Debug interface: One channel incorporated Aurora Trace Interface: One channel incorporated (E2x-FCC2 only)
Boundary scan	Supports boundary scan conforming to the IEEE1149.1 standard
Clock controller	The user is able to select the crystal resonance frequency (20 MHz or 40 MHz) Incorporates a crystal resonator circuit (Main OSC), which is used as a reference clock for the PLL Incorporates an internal oscillator, which is used as the start-up clock and backup clock Incorporates a PLL circuit to generate high speed internal clocks by multiplying the Main OSC input Generates clock pulses used inside the chip from the internal oscillator, main oscillator and PLL Software configurable external clock output
Operating modes	Operating modes <ul style="list-style-type: none"> • Normal Operating Mode • User Boot Mode • Serial Programming Mode
Standby controller	This product supports various power-down modes The power consumption of the device can be reduced by selecting one of the following modes: <ul style="list-style-type: none"> • Power off standby mode • HALT Mode • Emulation/Instrumentation RAM and Aurora retention Mode (E2x-FCC2 only) Module standby
Reset controller	6 reset functions <ul style="list-style-type: none"> – Power Up Reset – System Reset 1 – System Reset 2 – Application Reset – Module Reset – JTAG Reset External reset output pin: $\overline{\text{RES_OUT}}$ Automatic RAM initialization after reset
Clock monitor	<ul style="list-style-type: none"> • Up to 11 clock monitors (E2H: up to 9 clock monitors) depending on the device configuration • Detects clock disturbances that results in a frequency lower or higher than the target frequency, and sends an error notification to the ECM Supports the self-diagnosis function
Temperature sensor	1 sensor incorporated <ul style="list-style-type: none"> • Out of range detection of temperature • Operating modes <ul style="list-style-type: none"> – Single measurement mode – Continuous measurement mode • Interrupt generation <ul style="list-style-type: none"> – Temperature Measurement End Interrupt (INTOTSOTI) – Temperature Rise/Drop Interrupt (INTOTSOTULI) – Temperature Alarm Error (INTOTSOTABE) – Temperature Sensor Error (INTOTSOTE)

Generic Timer Module (GTM) (ATU and GTM cannot be used at the same time)	<p>GTM v3.1.5.1 is a modular timer unit and consists of the following submodules.</p> <ul style="list-style-type: none"> • Advanced Routing Unit (ARU) • Broadcast Module (BRC) • Parameter Storage Module (PSM) • Clock Management Unit (CMU) • Cluster Configuration Module (CCM) • Time Base Unit (TBU) • Timer Input Module (TIM) • Timer Output Module (TOM) • ARU-connected Timer Output Module (ATOM) • Dead Time Module (DTM) • Multi Channel Sequencer (MCS) • Memory Configuration (MCFG) • TIM0 Input Mapping Module (MAP) • Digital PLL (DPLL) • Sensor Pattern Evaluation (SPE) • Interrupt Concentrator Module (ICM) • Output Compare Unit (CMP) • Monitoring Unit (MON)
Encoder Timer (ENCA)	<ul style="list-style-type: none"> • Generation of the counter control signal from the encoder input signal, and count operation • Capture function for capturing the counter value with an external trigger signal • Compare function for compare match judgment with the count value • Two capture compare registers that can be set separately for capture operation and for compare operation • Interrupt mask function for masking the interrupt request signal output as a result of the compare match judgment during compare operation • Function for loading the value of the capture compare register to the counter upon underflow occurrence • The Encoder input signal can be applied to the timer counter clear condition • Edge or level can be selected for clearing the encoder input signal of the timer counter clear condition • Detection of counter overflow and underflow and output of error flags and error occurrence interrupts • Five interrupts: two capture compare interrupts, one counter clear interrupt, one overflow interrupt, and one underflow interrupt
Package	<p>[E2x-FCC2] 468-pin plastic FBGA (0.8 mm ball pitch) (25mm × 25mm package size) 373-pin plastic FBGA (0.8 mm ball pitch) (21mm × 21mm package size)</p> <p>[E2UH] 468-pin plastic FBGA (0.8 mm ball pitch) (25mm × 25mm package size) 373-pin plastic FBGA (0.8 mm ball pitch) (21mm × 21mm package size)</p> <p>[E2H] 468-pin plastic FBGA (0.8 mm ball pitch) (25mm × 25mm package size) 373-pin plastic FBGA (0.8 mm ball pitch) (21mm × 21mm package size)</p>

1.3 Application Fields

- Automotive field (including engine control system and transmission control system)

1.4 Ordering Information

Table 1.1 Product Name List

Product Name	Package	On-Chip ROM	Operating Temperature (Tj)	External Oscillator	Maximum Operating Frequency
R7F702012AEABG (RH850/E2UH)	Plastic FBGA-468 0.8-mm ball pitch 25 mm × 25 mm	16 MB	max. 150°C	20/40 MHz	400 MHz
R7F702012AEABA (RH850/E2UH)	Plastic FBGA-373 0.8-mm ball pitch 21 mm × 21 mm	16 MB	max. 150°C	20/40 MHz	400 MHz
R7F702011EABG (RH850/E2H)	Plastic FBGA-468 0.8-mm ball pitch 25 mm × 25 mm	12 MB	max. 150°C	20/40 MHz	400 MHz
R7F702011EABA (RH850/E2H)	Plastic FBGA-373 0.8-mm ball pitch 21 mm × 21 mm	12 MB	max. 150°C	20/40 MHz	400 MHz

FBGA is hereafter referred to as BGA unless the complete abbreviation is required.

The RH850/E2x-FCC2 has 4 variants. Select the proper product according to the table below.

Table 1.2 RH850/E2x-FCC2 List

Frequency	Package	
	FBGA-468	FBGA-373
400 MHz	R7F702Z12AEDBG (for E2UH) R7F702Z11AEDBG (for E2H)	R7F702Z12AEDBA (for E2UH) R7F702Z11AEDBA (for E2H)

1.5 Differences in the Specifications of FCC Products

The table below lists the differences in the specifications of FCC products.

Product		RH850/E2x-FCC2		RH850/E2UH	RH850/E2H	
		For E2UH	For E2H			
CPU	Frequency		400	400	400	400
	Main Core		6	4	6	4
	Lockstep		4	2	4	2
	FPU		6	4	6	4
	Cache (per Main core)	instruction	16 KB (PBS 4w)	16 KB (PBS 4w)	16 KB (PBS 4w)	16 KB (PBS 4w)
		data	4 line (256 bit/line)	4 line (256 bit/line)	4 line (256 bit/line)	4 line (256 bit/line)

1.7 Functional Block Configuration

Internal Block Diagram

Figure 1.7 Internal Block Diagram (E2x-FCC2)

Figure 1.8 Internal Block Diagram (E2UH)

Figure 1.9 Internal Block Diagram (E2H)

Each CPU has its own set of CPU peripherals. These CPU peripherals are assigned to the common address: CPU peripheral (self), separately from their respective address. For example, access by CPU0 to a register of a CPU peripheral (self) is to the register in the CPU peripheral of CPU0; access by CPU1 to a register of a CPU peripheral (self) is to the register in the CPU peripheral of CPU1.

Section 2 Pin Function

This section contains a generic description of the Pin Function Controller (the unit name is defined as PORT in this section). The first part of this section describes the features specific to RH850/E2x-FCC2 microcontrollers, including register base addresses and input/output signals. The ensuing sections describe the functions and registers of PORT.

CAUTION

Some pin functions may be absent from other mass-produced products even if the PKG is the same shape as the FCC2. For information regarding which pin functions are and are not present, see the user's manual for the product you are using.

2.1 Features of Pin Function

2.1.1 Port Group

This product has the following numbers of port groups.

Table 2.1 Indices

Index	Description
n	Throughout this section, each port group is identified by “n” (n = 00 to 57). For example, PMCN indicates the port mode control register of the Pn port.
m	Throughout this section, each port pin is identified by the index “m” (m = 0 to 15) For example, P00_7 indicates pin 7 of port group 00.

Table 2.2 Port Groups in This Product

Product Name	E2xFCC2			E2UH		E2H	
	BGA468(E2UH)	BGA468(E2H)	BGA373(E2UH) BGA373(E2H)	BGA468	BGA373	BGA468	BGA373
Number of Port Groups	24	23	22	24	22	23	22
Port Group Name	P00_m	m = 0 to 11	m = 0 to 11	m = 0 to 11	m = 0 to 11	m = 0 to 11	m = 0 to 11
	P01_m	m = 3 to 15	m = 3 to 15	m = 3 to 7	m = 3 to 15	m = 3 to 15	m = 3 to 7
	P02_m	m = 0 to 11	m = 0 to 11	m = 0 to 11	m = 0 to 11	m = 0 to 11	m = 0 to 11
	P10_m	m = 0 to 14	m = 0 to 14	m = 0 to 14	m = 0 to 14	m = 0 to 14	m = 0 to 14
	P11_m	m = 0 to 10	m = 0 to 10	m = 0 to 10	m = 0 to 10	m = 0 to 10	m = 0 to 10
	P12_m	m = 0 to 9	m = 0 to 9	m = 0 to 9	m = 0 to 9	m = 0 to 9	m = 0 to 9
	P13_m	m = 0 to 14	m = 0 to 14	m = 0 to 14	m = 0 to 14	m = 0 to 14	m = 0 to 14
	P14_m	m = 0 to 12	m = 0 to 12	m = 0 to 12	m = 0 to 12	m = 0 to 12	m = 0 to 12
	P15_m	m = 0 to 8	m = 0 to 8	m = 0 to 8	m = 0 to 8	m = 0 to 8	m = 0 to 8
	P20_m	m = 0 to 7	m = 0 to 7	m = 0 to 7	m = 0 to 7	m = 0 to 7	m = 0 to 7
	P21_m	m = 2 to 5	m = 2 to 5	m = 2 to 5	m = 2 to 5	m = 2 to 5	m = 2 to 5
	P22_m	m = 0 to 13	m = 0 to 13	m = 0 to 13	m = 0 to 13	m = 0 to 13	m = 0 to 13
	P23_m	m = 0 to 7	m = 0 to 7	m = 0 to 7	m = 0 to 7	m = 0 to 7	m = 0 to 7
	P24_m	m = 0 to 15	m = 0 to 15	m = 0 to 15	m = 0 to 15	m = 0 to 15	m = 0 to 15
	P25_m	m = 0 to 15	m = 0 to 8	m = 0 to 6	m = 0 to 15	m = 0 to 8	m = 0 to 6
	P26_m	m = 0 to 1	—	—	m = 0 to 1	—	—
	P27_m	m = 0*1	m = 0*1	m = 0*1	m = 0*1	m = 0*1	m = 0*1
	P30_m	m = 0 to 15	m = 0 to 3	m = 0 to 3	m = 0 to 15	m = 0 to 3	m = 0 to 3
	P31_m	m = 0 to 15	m = 0 to 3	—	m = 0 to 15	m = 0 to 3	—
	P32_m	m = 0 to 6	m = 0 to 6	m = 0 to 6	m = 0 to 6	m = 0 to 6	m = 0 to 6
	P33_m	m = 0 to 13	m = 0 to 13	m = 0 to 13	m = 0 to 13	m = 0 to 13	m = 0 to 13
	P34_m	m = 0 to 4	m = 0 to 4	m = 0 to 4	m = 0 to 4	m = 0 to 4	m = 0 to 4
	P40_m	m = 0 to 15	m = 0 to 15	m = 0 to 15	m = 0 to 15	m = 0 to 15	m = 0 to 15
	JP0_m	m = 0 to 3, 5*2	m = 0 to 3, 5*2	m = 0 to 3, 5*2	m = 0 to 3, 5*2	m = 0 to 3, 5*2	m = 0 to 3, 5*2

Note 1. The P27 port group does not have an input function and can only be used when the Option Byte PFC_RESO_CFG = 1 (See **Section 2.6.8, RES_OUT Function** for details). In addition, this port can only be used for debugger handshaking.

Note 2. TCK does not support port output; it only has a port input function.

If TDI/JP0_0 pin is used as debug interface, JPM0_0 and JPIBC0_0 must be set value after reset (JPM0_0 = 1, JPIBC0_0 = 1).

Table 2.3 Virtual Port Groups in This Product

	P53_m	m = 0 to 15	m = 0 to 15	m = 0 to 15	m = 0 to 15	m = 0 to 15	m = 0 to 15	m = 0 to 15
	P54_m	m = 0 to 15	m = 0 to 15	m = 0 to 15	m = 0 to 15	m = 0 to 15	m = 0 to 15	m = 0 to 15
	P55_m	m = 0 to 15	m = 0 to 15	m = 0 to 15	m = 0 to 15	m = 0 to 15	m = 0 to 15	m = 0 to 15
	P56_m	m = 0 to 15	m = 0 to 15	m = 0 to 15	m = 0 to 15	m = 0 to 15	m = 0 to 15	m = 0 to 15
	P57_m	m = 0 to 15	m = 0 to 15	m = 0 to 15	m = 0 to 15	m = 0 to 15	m = 0 to 15	m = 0 to 15

Note: A virtual port is a port group that is not connected to an external pin, but is instead connected to an internal function. (See **Section 2.6.3, Virtual Port Function via RHSB (XBAR)**, **Section 2.6.4, Virtual Port Function via HSSPI** and **Section 2.6.5, Virtual Port Function via Analog** for details.)

2.1.2 Register Base Addresses

The PORT base addresses are shown in the following table. All port register addresses are expressed as offsets of the base address.

Table 2.4 Register Base Addresses

Base Address Name	Base Address	Bus Group
<PORT0_Base>	FF61 0000 _H	Peripheral Group 6
<JPORT0_Base>	FF62 0000 _H	Peripheral Group 6
<PORT1_Base>	FFC1 0000 _H	Peripheral Group 6
<JPORT1_Base>	FFC2 0000 _H	Peripheral Group 6

2.1.3 Clock Supplies

The PORT clock supplies are shown in the following table.

Table 2.5 Clock Supplies

Unit Name	Unit Clock Name	Supply Clock Name
PORT0	PCLK	CLK_LSB
JPORT0	PCLK	CLK_LSB
PORT1	PCLK	CLK_LSB
JPORT1	PCLK	CLK_LSB

Note: For details of port unit names refer to **Section 2.4, Registers**.

2.1.4 Interrupt Requests

The PORT interrupt requests from external pins are shown in the following table.

Table 2.6 Interrupt Requests

Interrupt Symbol Name	Unit Interrupt Signal	Outline	Interrupt Number	sDMA Trigger Number	DTS Trigger Number
INTP00	IRQ0	External interrupt 0	504	206	114
INTP01	IRQ1	External interrupt 1	505	207	115
INTP02	IRQ2	External interrupt 2	506	208	116
INTP03	IRQ3	External interrupt 3	507	209	117
INTP04	IRQ4	External interrupt 4	508	210	118
INTP05	IRQ5	External interrupt 5	509	211	119
INTP06	IRQ6	External interrupt 6	510	212	120
INTP07	IRQ7	External interrupt 7	511	213	121
INTP08	IRQ8	External interrupt 8	692	214	122
INTP09	IRQ9	External interrupt 9	693	215	123
INTP10	IRQ10	External interrupt 10	694	216	124
INTP11	IRQ11	External interrupt 11	695	217	125

2.1.5 Reset Sources

The PORT reset sources are shown below.

PORT is initialized by the following reset sources.

Table 2.7 Reset Sources

Unit Name	Register Name	Reset Condition					
		Power Up Reset	System Reset 1	System Reset 2	Application Reset	Module Reset	JTAG Reset
PORT0	All registers	✓	✓	✓	✓	—	—
JPORT0	All registers	✓	✓	✓	✓	—	—
PORT1	All registers	✓	✓	✓	✓	—	—
JPORT1	All registers	✓	✓	✓	✓	—	—

2.2 Overview

This product has various pins for input/output (I/O) functions, known as ports. The ports are organized into port groups. This product also has several control registers to allocate functions other than general-purpose I/O functions to the corresponding pins. See below for definitions of pin, port, and port group.

2.2.1 Functional Overview

2.2.1.1 Terms

The terms described in this section are defined as follows.

- Port group:

One port can have up to 16 pins, and the number of pins differs according to the port. All pins of a port share the same control registers.
- Port mode/Port:

In port mode, a pin functions as a general-purpose I/O pin.
- Alternative mode:

In alternative mode, a pin functions as an I/O pin of a peripheral function. Multiple peripheral functions may be multiplexed on a single pin, and control registers select the peripheral function to be used.

2.2.1.2 Overview of Pin Functions

Pins can operate in the following four different modes:

- Port mode (PMn.PMn_m = 0)

The pin operates as a general purpose I/O port in port mode. PMn.PMn_m selects input or output.
- S/W I/O control alternative mode (PMn.PMn_m = 1, PIPn.PIPn_m = 0)

The pin is operated by an alternative function in S/W I/O control alternative mode.

The selection between input and output is made by S/W via the PMn.PMn_m control bits.
- Direct I/O control alternative mode (PMn.PMn_m = 1, PIPn.PIPn_m = 1)

The pin is operated by an alternative function in direct I/O control alternative mode.

In contrast to S/W I/O control alternative mode, input/output is directly controlled by the alternative function in this mode.
- When the input buffer is disabled (PMn.PMn_m = 0, PMn.PMn_m = 1, PIBn.PIBn_m = 0)

A shoot-through current does not flow even if the pin level is in the Hi-Z state. Thus the pin does not need to be fixed to a high or low level externally.

Table 2.8 Pin Function Configuration (Outline)

Unit Name	Bit			I/O
	PMC	PM	PIPC	
Port mode	0	0	0/1	Output mode
		1	0/1	Input mode*1
S/W I/O control alternative mode	1	0	0	Output mode
		1	0	Input mode*2
Direct I/O control alternative mode		0/1	1	Controlled by alternative function*2

Note 1. The input buffer should be enabled (PIBCn_m = 1).

Note 2. When used as an input pin in alternative mode, be sure to set PIBCN_m = 0.

When a pin is operated in alternative mode (PMcn.PMCn_m = 1), one of many different alternative functions (up to 16) can be selected by the PFCn, PFCEn, PFCAEn, and PFCEAEn registers as shown in the following table.

- S/W I/O control alternative mode (PIPCn.PIPCn_m = 0):

Outputs (PMn_m = 0): ALT-OUT1 to ALT-OUT16

Inputs (PMn_m = 1): ALT-IN1 to ALT-IN16

- Direct I/O control alternative mode (PIPCn.PIPCn_m = 1):

Input/Output of ALT-OUT1 to ALT-IN16 is directly selected by the alternative function.

Table 2.9 Outline of Alternative Mode Selection (PM_{Cn}.PM_{Cn_m} = 1)

Bit					Function
PFCEAE* ²	PFAE* ²	PFCE* ²	PFC* ²	PM* ¹	
0	0	0	0	0	Alternative output mode 1 (ALT-OUT1)
				1	Alternative input mode 1 (ALT-IN1)
			1	0	Alternative output mode 2 (ALT-OUT2)
				1	Alternative input mode 2 (ALT-IN2)
		1	0	0	Alternative output mode 3 (ALT-OUT3)
				1	Alternative input mode 3 (ALT-IN3)
			1	0	Alternative output mode 4 (ALT-OUT4)
				1	Alternative input mode 4 (ALT-IN4)
	1	0	0	0	Alternative output mode 5 (ALT-OUT5)
				1	Alternative input mode 5 (ALT-IN5)
			1	0	Alternative output mode 6 (ALT-OUT6)
				1	Alternative input mode 6 (ALT-IN6)
		1	0	0	Alternative output mode 7 (ALT-OUT7)
				1	Alternative input mode 7 (ALT-IN7)
			1	0	Alternative output mode 8 (ALT-OUT8)
				1	Alternative input mode 8 (ALT-IN8)
1	0	0	0	0	Alternative output mode 9 (ALT-OUT9)
				1	Alternative input mode 9 (ALT-IN9)
			1	0	Alternative output mode 10 (ALT-OUT10)
				1	Alternative input mode 10 (ALT-IN10)
		1	0	0	Alternative output mode 11 (ALT-OUT11)
				1	Alternative input mode 11 (ALT-IN11)
			1	0	Alternative output mode 12 (ALT-OUT12)
				1	Alternative input mode 12 (ALT-IN12)
	1	0	0	0	Alternative output mode 13 (ALT-OUT13)
				1	Alternative input mode 13 (ALT-IN13)
			1	0	Alternative output mode 14 (ALT-OUT14)
				1	Alternative input mode 14 (ALT-IN14)
		1	0	0	Alternative output mode 15 (ALT-OUT15)
				1	Alternative input mode 15 (ALT-IN15)
			1	0	Alternative output mode 16 (ALT-OUT16)
				1	Alternative input mode 16 (ALT-IN16)

Note 1. When PIP_{Cn}.PIP_{Cn_m} = 1, the I/O direction is directly controlled by the peripheral (alternative) function and PM is ignored

Note 2. When the bit is a reserved bit, it is defined as 0 in the above table.

2.2.1.3 Pin Data Input/Output

(1) Output Data

In port mode (PMnCn.PMCn_m = 0), the value of Pn.Pn_m is output from the Pn_m pin.

(2) Input Data

Reading the PPRn register returns either the value of the Pn_m pin, the associated bit of port register Pn.Pn_m, or the data output by an alternative function.

The source of the data read via PPRn depends on the pin mode and the setting of several control bits as shown in the following table.

Table 2.10 Mode Description and PPRn_m Read Values for Each Mode

PMC n_m	PM n_m	Bit				Mode	PPR Read Value			
		PIBC n_m	PIPC n_m	PODCE n_m	PODC n_m					
0	1	0	X	X	X	Port input, input buffer disabled	Pn.Pn_m bit			
		1		X	X	Port input, input buffer enabled	Pn_m pin			
	0	X		0	0	0	Port push-pull output	Pn.Pn_m bit*1		
					1	1	Port N-ch open drain output			
					1	0	Port push-pull output			
					1	1	Port P-ch open drain output			
1	1		X		0	X	X		S/W I/O control alternative input	Pn_m pin
						0	0		0	S/W I/O control alternative push-pull output
		1		1			S/W I/O control alternative N-ch open drain output			
		1		0			S/W I/O control alternative push-pull output			
	1	1		S/W I/O control alternative P-ch open drain output						
	X	X		1		1	0	0	Direct I/O control alternative push-pull enable	I/O port in alternative mode • Input: Pn_m pin • Output: Alternative function Internal output signal*1
1			1		Direct I/O control alternative N-ch open drain enable					
1			0		Direct I/O control alternative push-pull enable					
1			1		Direct I/O control alternative P-ch open drain enable					

Note 1. When PBDCn_m = 1, the Pn_m pin level is read via the PPRn_m bit.

- PMnCn.PMCn_m

This bit selects either port mode (PMnCn_m = 0) or alternative function mode (PMnCn_m = 1).

- PMn.PMn_m

This bit selects input (PMn_m = 1) or output (PMn_m = 0) in port mode (PMnCn_m = 0) and S/W I/O control alternative mode (PMnCn_m = 1, PIPCn_m = 0).

- PIBCn.PIBCn_m

This bit disables (PIBCn_m = 0) or enables (PIBCn_m = 1) the input buffer in input port mode (PMcn_m = 0 and PMn_m = 1). When the input buffer is disabled, PPRn_m reads the Pn.Pn_m bit; otherwise the Pn_m pin level is returned.

- PIPcn.PIPcn_m

This bit selects either the S/W or direct I/O control alternative mode.

- PBDCn.PBDCn_m

Setting this bit to 1 in output mode enables bidirectional mode for the pin. In bidirectional mode, the level on pin Pn_m can be read from PPPn.PPRn_m.

- PODCn.PODCn_m, PODCEn.PODCEn_m

This bit selects either push-pull output (PODCn_m = 0), N-ch open drain output (PODCn_m = 1, PODCEn_m = 0) or P-ch open drain output (PODCn_m = 1, PODCEn_m = 1).

(3) Writing to the Pn Register

The data to be output in port Pn_m in port mode (PMcn.PMCn_m = 0) is held in port register Pn.

Pn data can be rewritten in the following two different ways:

- Direct write to the Pn register

New data can be directly written to the Pn register.

- Indirect operation on the Pn bit (SET/RESET/NOT)

An indirect operation on Pn is possible by using the following two registers:

- Port set/reset register: PSRn

When $PSRn.PSRn_{(m+16)} = 1$, the value of $PSRn.PSRn_m$ determines the value of $Pn.Pn_m$. Thus Pn_m can be set/reset without a direct write to Pn.

- Port NOT register: PNOTn

Setting $PNOTn.PNOTn_m = 1$ inverts the $Pn.Pn_m$ bit without a direct write to Pn.

The indirect Pn SET/RESET/NOT operation provides access to single bits (not limited to one bit) of the Pn register while leaving all other Pn bits untouched.

2.3 Port Types

2.3.1 Pin Configuration

The following figure shows the overall configuration of the pins.

Figure 2.1 Block Diagram of Pin Configuration

2.3.2 Port Control Logic

The following figure shows the logical circuitry of the port control functions. The diagram is only a logical reference and does not show the real circuitry.

Figure 2.2 Block Diagram of Port Control Logic

2.4 Registers

2.4.1 List of Registers

The PORT registers are listed in the following table.

For details of the PORT base addresses, see **Section 2.1.2, Register Base Addresses**.

Table 2.11 List of Registers (1/2)

Module Name	Register Name	Symbol	Register Access Unit	Address	Access	Access Protection*1	
						Excluding P21, 27	P21, 27 only*2,*3
PORT0	Port register	Pn	Port Group	<PORT0_base> + 0000 _H + n × 40 _H	16	—	PWE
	Port set/reset register	PSRn	Port Group	<PORT0_base> + 0004 _H + n × 40 _H	32	—	PWE
	Port NOT register	PNOTn	Port Group	<PORT0_base> + 0008 _H + n × 40 _H	16	—	PWE
	Port pin read register	PPRn	Port Group	<PORT0_base> + 000C _H + n × 40 _H	16	—	—
	Port mode register	PMn	Port Group	<PORT0_base> + 0010 _H + n × 40 _H	16	—	PWE
	Port mode control register	PMcN	Port Group	<PORT0_base> + 0014 _H + n × 40 _H	16	—	PWE
	Port function control register	PFcN	Port Group	<PORT0_base> + 0018 _H + n × 40 _H	16	—	PWE
	Port function control expansion register	PFCEn	Port Group	<PORT0_base> + 001C _H + n × 40 _H	16	—	PWE
	Port mode set/reset register	PMSRn	Port Group	<PORT0_base> + 0020 _H + n × 40 _H	32	—	PWE

	JPORT0	Port control register	JPCR _{n_m}	Pin	<JPORT0_base> + 2000 _H + n × 40 _H + m × 4 _H	32	—	—
	PORT0	Port Keycode Protection register	PKCPROT	—	<PORT0_base> + 2F40 _H	32	—	—
Port Write enable register		PWE	—	<PORT0_base> + 2F44 _H	32	PKCPROT	PKCPROT	
LVDS control A register		LVDSCTRLA	—	<PORT0_base> + 2F50 _H	32	—	—	
LVDS control B register		LVDSCTRLB	—	<PORT0_base> + 2F54 _H	32	—	—	
LVDS control C register		LVDSCTRLC	—	<PORT0_base> + 2F58 _H	32	—	—	
LVDS control D register		LVDSCTRLD	—	<PORT0_base> + 2F60 _H	32	—	—	
LVDS control F register*4		LVDSCTRLF	—	<PORT0_base> + 2F68 _H	32	—	—	

Note: n: port number, m: port bit number

Note 1. Write protect only.

Note 2. The P21 port group register is protected from all write accesses to prevent accidental register access. This is because in addition to their port function, the P21_* pins are multiplexed with the RHSIF function; however, these functions do not use the same power domain. This means that I/O of the P21 port group must be disabled when RHSIF is used

Note 3. P27_0 is assigned RES_OUT function as exclusive use, then all write access of P27 port group register is protected.

Note 4. LVDSCTRLF is implemented only in E2x-FCC2 and E2UH (it is not supported in E2H).

2.4.2 Port Group Unit Register Explanation

2.4.2.1 Configuration of PORT

(1) PMC/JPMC — Port Mode Control Register Group

(a) PMCn/JPMC0 — Port Mode Control Register

This register specifies whether the individual pins of port group n are in port mode or in alternative mode.

CAUTION

PMC21 and PMC27 are write-protected by PWE.

See **Section 2.4.2.4, Other Registers** for details.

Value after reset: Refer to **Section 2.5.1, List of Port Functions**

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	PMCn_15	PMCn_14	PMCn_13	PMCn_12	PMCn_11	PMCn_10	PMCn_9	PMCn_8	PMCn_7	PMCn_6	PMCn_5	PMCn_4	PMCn_3	PMCn_2	PMCn_1	PMCn_0
Value after reset	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1
	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Note 1. Refer to **Section 2.5.1, List of Port Functions**.

Table 2.12 PMCn Register Contents

Bit Position	Bit Name	Function
15 to 0	PMCn_[15:0]	These pins specify the operation mode of the corresponding pin: 0: Port mode 1: Alternative mode

NOTE

The control bits of the JTAG Port Mode Control Register (JPMC0) are JPMC0_[7:0].

(b) PMCSRn/JPMCSR0 — Port Mode Control Set/Reset Register

This register provides an alternative method for writing data to a bit in the PMCn register.

The 16 higher bits of PMCSRn specify whether the data in the 16 lower bits of PMCSRn are written to PMCn.PMCn_m.

Even when pins being used by multiple programs belong to the same port group, the PMCSRn register allows masking of the unused bits when overwriting so that independent setting of the corresponding bits by each program is possible.

CAUTION

PMCSR21 and PMCSR27 are write-protected by PWE.

See **Section 2.4.2.4, Other Registers** for details.

Value after reset: Refer to **Section 2.5.1, List of Port Functions**

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	PMCSR _{n_31}	PMCSR _{n_30}	PMCSR _{n_29}	PMCSR _{n_28}	PMCSR _{n_27}	PMCSR _{n_26}	PMCSR _{n_25}	PMCSR _{n_24}	PMCSR _{n_23}	PMCSR _{n_22}	PMCSR _{n_21}	PMCSR _{n_20}	PMCSR _{n_19}	PMCSR _{n_18}	PMCSR _{n_17}	PMCSR _{n_16}
Value after reset	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1
	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	PMCSR _{n_15}	PMCSR _{n_14}	PMCSR _{n_13}	PMCSR _{n_12}	PMCSR _{n_11}	PMCSR _{n_10}	PMCSR _{n_9}	PMCSR _{n_8}	PMCSR _{n_7}	PMCSR _{n_6}	PMCSR _{n_5}	PMCSR _{n_4}	PMCSR _{n_3}	PMCSR _{n_2}	PMCSR _{n_1}	PMCSR _{n_0}
Value after reset	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1
	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Note 1. Refer to **Section 2.5.1, List of Port Functions**.

Table 2.13 PMCSRn Register Contents

Bit Position	Bit Name	Function
31 to 16	PMCSRn_[31:16]	These bits specify whether the value of the corresponding lower bit of PMCn_m is written to PMCn_m: 0: PMCn_m does not depend on PMCSRn_m. 1: The value of PMCn_m is the same as that of PMCSRn_m. Example: When PMCSRn.PMCSRn_31 = 1, the value of bit PMCSRn.PMCSRn_15 is written to bit PMCn.PMCn_15. When read, 0000 _H is always returned.
15 to 0	PMCSRn_[15:0]	These bits specify the PMCn_m value when the corresponding upper bit PMCSRn_(m+16) is 1: 0: PMCn_m = 0 1: PMCn_m = 1 When read, the PMCn register value is returned.

NOTE

The control bits of the JTAG Port Mode Control Set/Reset Register (JPMCSR0) are JPMCSR0_[31:0].

(2) PIPCN/JPIPC0 — Port IP Control Register

This register specifies whether the I/O direction of the Pn_m pin is controlled by port mode register PMn.PMn_m or by an alternative function.

When the Pn_m pin is operated in alternative mode (PMn.PMn_m = 1) and the alternative function directly controls the I/O direction of Pn_m. In this case, PIPCN.PIPCN_m must be set to 1 as well. This hands over I/O control to the alternative function and overrules the PMn.PMn_m setting.

CAUTION

PIPC21 and PIPC27 are write-protected by PWE.

See **Section 2.4.2.4, Other Registers** for details.

Value after reset: Refer to **Section 2.5.1, List of Port Functions**

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	PIPCn_15	PIPCn_14	PIPCn_13	PIPCn_12	PIPCn_11	PIPCn_10	PIPCn_9	PIPCn_8	PIPCn_7	PIPCn_6	PIPCn_5	PIPCn_4	PIPCn_3	PIPCn_2	PIPCn_1	PIPCn_0
Value after reset	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1
	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Note 1. Refer to **Section 2.5.1, List of Port Functions**.

Table 2.14 PIPCN Register Contents

Bit Position	Bit Name	Function
15 to 0	PIPCn_[15:0]	These bits specify the I/O control mode: 0: I/O mode is selected by PMn.PMn_m (S/W I/O control alternative mode). 1: I/O mode is selected by peripheral function (direct I/O control alternative mode).

NOTE

The control bits of the JTAG Port IP Control Register (JPIPC0) are JPIPC0_[7:0].

(3) PM/JPM — Port Mode Register Group

(a) PMn/JPM0 — Port Mode Register

The PMn register specifies whether the individual pins of port group n are in input mode or in output mode.

CAUTION

PM21 and PM27 are write-protected by PWE.

See **Section 2.4.2.4, Other Registers** for details.

Value after reset: Refer to **Section 2.5.1, List of Port Functions**

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	PMn_15	PMn_14	PMn_13	PMn_12	PMn_11	PMn_10	PMn_9	PMn_8	PMn_7	PMn_6	PMn_5	PMn_4	PMn_3	PMn_2	PMn_1	PMn_0
Value after reset	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Note 1. Refer to **Section 2.5.1, List of Port Functions**.

Table 2.15 PMn Register Contents

Bit Position	Bit Name	Function
15 to 0	PMn_[15:0]	These bits specify input/output mode of the corresponding pin: 0: Output mode (output enabled) 1: Input mode (output disabled)

NOTE

- To use a pin in input port mode (PMn.PMn_m = 0 and PMn.PMn_m = 1), the input buffer must be enabled (PIBCn.PIBCn_m = 1).
- PMn_m specifies the I/O direction in port mode (PMn.PMn_m = 0) and alternative mode (PMn.PMn_m = 1) because PIPCN.PIPCN_m = 0 after reset.
- The control bits of the JTAG Port Mode Register (JPM0) are JPM0_[7:0].

(b) PMSRn/JPMSR0 — Port Mode Set/Reset Register

This register provides an alternative method for setting a bit in the PMn register.

The 16 higher bits of PMSRn specify whether the data in the 16 lower bits of PMSRn are written to PMn.PMn_m.

Even when pins being used by multiple programs belong to the same port group, the PMSRn register allows masking of the unused bits when overwriting so that independent setting of the corresponding bits by each program is possible.

CAUTION

PMSR21 and PMSR27 are write-protected by PWE.

See **Section 2.4.2.4, Other Registers** for details.

Value after reset: Refer to **Section 2.5.1, List of Port Functions**

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	PMSRn_31	PMSRn_30	PMSRn_29	PMSRn_28	PMSRn_27	PMSRn_26	PMSRn_25	PMSRn_24	PMSRn_23	PMSRn_22	PMSRn_21	PMSRn_20	PMSRn_19	PMSRn_18	PMSRn_17	PMSRn_16
Value after reset	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1
	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	PMSRn_15	PMSRn_14	PMSRn_13	PMSRn_12	PMSRn_11	PMSRn_10	PMSRn_9	PMSRn_8	PMSRn_7	PMSRn_6	PMSRn_5	PMSRn_4	PMSRn_3	PMSRn_2	PMSRn_1	PMSRn_0
Value after reset	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1
	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Note 1. Refer to **Section 2.5.1, List of Port Functions**.

Table 2.16 PMSRn Register Contents

Bit Position	Bit Name	Function
31 to 16	PMSRn_[31:16]	<p>These bits specify whether the value of the corresponding lower bit of PMSRn_m is written to PMn_m:</p> <p>0: PMn_m does not depend on PMSRn_m.</p> <p>1: The value of PMn_m is the same as that of PMSRn_m.</p> <p>Example:</p> <p>When PMSRn.PMSRn_31 = 1, the value of bit PMSRn.PMSRn_15 is written to bit PMn.PMn_15.</p> <p>When read, 0000_H is always returned.</p>
15 to 0	PMSRn_[15:0]	<p>These bits specify the PMn_m value when the corresponding upper bit PMSRn_(m+16) is 1:</p> <p>0: PMn_m = 0</p> <p>1: PMn_m = 1</p> <p>When read, the PMn register value is returned.</p>

NOTE

The control bits of the JTAG Port Mode Set/Reset Register (JPMSR0) are JPMSR0_[31:0].

(4) PIBCn/JPIBC0 — Port Input Buffer Control Register

When a pin is being used in input port mode ($PMCn.PMCn_m = 0$ and $PMn.PMn_m = 1$), this register enables or disables the input buffer. However, when the pin is used as an input pin in S/W I/O control alternative mode ($PMCn.PMCn_m = 1$ and $PIPCn.PIPCn_m = 0$) or direct I/O control alternative mode ($PMCn.PMCn_m = 1$ and $PIPCn.PIPCn_m = 1$), set $PIBCn.PIBCn_m = 0$.

When pins are in bidirectional mode ($PBDCn.PBDCn_m = 1$), the shared output level loop-back function and pin output level-read function can be selected by setting $PIBCn.PIBCn_m$. Refer to **Section 2.4.2.2(1), PBDCn/JPBDC0 — Port Bidirectional Control Register**.

CAUTION

PIBC21 and PIBC27 are write-protected by PWE.
See **Section 2.4.2.4, Other Registers** for details.

Value after reset: Refer to **Section 2.5.1, List of Port Functions**

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	PIBCn_15	PIBCn_14	PIBCn_13	PIBCn_12	PIBCn_11	PIBCn_10	PIBCn_9	PIBCn_8	PIBCn_7	PIBCn_6	PIBCn_5	PIBCn_4	PIBCn_3	PIBCn_2	PIBCn_1	PIBCn_0
Value after reset	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Note 1. Refer to **Section 2.5.1, List of Port Functions**.

Table 2.17 PIBCn Register Contents

Bit Position	Bit Name	Function
15 to 0	PIBCn_[15:0]	These bits are used to enable and disable the input buffer in input port mode. 0: Input buffer is disabled. 1: Input buffer is enabled.

NOTES

- When the input buffer is disabled, a shoot-through current does not flow even if the pin level is in Hi-Z state. Thus the pin does not need to be fixed to a high or low level externally.
- When the input buffer is enabled in alternative mode ($PMCn.PMCn_m = 1$, $PMn.PMn_m = 1$), there is a possibility that a shoot-through current may flow even if the pin level is Hi-Z state. Then take appropriate measures, such as pull-up/pull-down.
- The control bits of the JTAG Port Input Buffer Control Register (JPIBC0) are JPIBC0_[7:0].

(5) PFC — Port Function Control Register Group

(a) PFCn — Port Function Control Register

This register, together with the PFCEn, PFCAEn and PFCEAEn registers, specifies an alternative function of the pins.

Some alternative functions directly control input/output of pin Pn_m. For such alternative functions PIPCn.PIPCn_m must be set to 1 as well.

For other alternative functions, input/output must be specified by PMn.PMn_m.

CAUTION

PFC21 and PFC27 are protected by PWE.

See **Section 2.4.2.4, Other Registers** for details.

Value after reset: Refer to **Section 2.5.1, List of Port Functions**

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	PFCn_15	PFCn_14	PFCn_13	PFCn_12	PFCn_11	PFCn_10	PFCn_9	PFCn_8	PFCn_7	PFCn_6	PFCn_5	PFCn_4	PFCn_3	PFCn_2	PFCn_1	PFCn_0

Note 1. Refer to **Section 2.5.1, List of Port Functions**.

Table 2.18 PFCn Register Contents

Bit Position	Bit Name	Function
15 to 0	PFCn_[15:0]	These bits specify an alternative function of a pin. For detailed information, refer to Table 2.9, Outline of Alternative Mode Selection (PMCn.PMCn_m = 1) .

(b) PFCEn — Port Function Control Expansion Register

This register, together with the PFCn, PFCAEn and PFCEAEn registers, specifies an alternative function of the pins.

Some alternative functions directly control input/output of pin Pn_m. For such alternative functions PIPCN.PIPCN_m must be set to 1 as well.

For other alternative functions, input/output must be specified by PMn.PMn_m.

CAUTION

PFCE21 and PFCE27 are write-protected by PWE.

See **Section 2.4.2.4, Other Registers** for details.

Value after reset: Refer to **Section 2.5.1, List of Port Functions**

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	PFCEn _15	PFCEn _14	PFCEn _13	PFCEn _12	PFCEn _11	PFCEn _10	PFCEn _9	PFCEn _8	PFCEn _7	PFCEn _6	PFCEn _5	PFCEn _4	PFCEn _3	PFCEn _2	PFCEn _1	PFCEn _0

Note 1. Refer to **Section 2.5.1, List of Port Functions**.

Table 2.19 PFCEn Register Contents

Bit Position	Bit Name	Function
15 to 0	PFCEn_[15:0]	These bits specify an alternative function of a pin. For detailed information, refer to Table 2.9, Outline of Alternative Mode Selection (PMCN.PMCN_m = 1) .

(c) PFCAEn — Port Function Control Additional Expansion Register

This register, together with the PFCn, PFCEn and PFCEAEn registers, specifies an alternative function of the pins.

Some alternative functions directly control input/output of pin Pn_m. For such alternative functions PIPCN.PIPCN_m must be set to 1 as well.

For other alternative functions, input/output must be specified by PMn.PMn_m.

CAUTION

PFCAE21 and PFCAE27 are write-protected by PWE.

See **Section 2.4.2.4, Other Registers** for details.

Value after reset: Refer to **Section 2.5.1, List of Port Functions**

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	PFCAE n_15	PFCAE n_14	PFCAE n_13	PFCAE n_12	PFCAE n_11	PFCAE n_10	PFCAE n_9	PFCAE n_8	PFCAE n_7	PFCAE n_6	PFCAE n_5	PFCAE n_4	PFCAE n_3	PFCAE n_2	PFCAE n_1	PFCAE n_0

	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Note 1. Refer to **Section 2.5.1, List of Port Functions**.

Table 2.20 PFCAEn Register Contents

Bit Position	Bit Name	Function
15 to 0	PFCAEn_[15:0]	These bits specify an alternative function of a pin. For detailed information, refer to Table 2.9, Outline of Alternative Mode Selection (PMCN.PMCN_m = 1) .

(d) PFCEAEn — Port Function Control Extra Additional Expansion Register

This register, together with the PFCn, PFCEn, and PFCAEn registers, specifies an alternative function of the pins.

Some alternative functions directly control input/output of pin Pn_m. For such alternative functions PIPCN.PIPCN_m must be set to 1 as well.

For other alternative functions, input/output must be specified by PMn.PMn_m.

CAUTION

PFCEAE21 and PFCEAE27 are write-protected by PWE.

See **Section 2.4.2.4, Other Registers** for details.

Value after reset: Refer to **Section 2.5.1, List of Port Functions**

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	PFCEA En_15	PFCEA En_14	PFCEA En_13	PFCEA En_12	PFCEA En_11	PFCEA En_10	PFCEA En_9	PFCEA En_8	PFCEA En_7	PFCEA En_6	PFCEA En_5	PFCEA En_4	PFCEA En_3	PFCEA En_2	PFCEA En_1	PFCEA En_0
Value after reset	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1
	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Note 1. Refer to **Section 2.5.1, List of Port Functions**.

Table 2.21 PFCEAEn Register Contents

Bit Position	Bit Name	Function
15 to 0	PFCEAEn_[15:0]	These bits specify an alternative function of a pin. For detailed information, refer to Table 2.9, Outline of Alternative Mode Selection (PMCN.PMCN_m = 1) .

2.4.2.2 Configuration of Pin Data Input/Output

(1) PBDCn/JPBDC0 — Port Bidirectional Control Register

This register enables the input buffer when a pin is used in output mode, and permits bidirectional mode. The Pn_m pin level is read via PPRn.PPRn_m in bidirectional mode.

- Alternative output level loopback function

When the Pn_m pin is used as the alternative output function, the actual pin output level based on the alternative output function can be looped back to the alternative input side by setting PBDCn.PBDCn_m = 1 and

PIBCn.PIBCn_m = 0. For example, the pin output level based on the first alternative function can be looped back to the same alternative input side. Also the pin output level can be read via PPRn.PPRn_m.

- Pin output level read function

When the Pn_m pin is used as the general output port function or the alternative output function, the actual pin output level can be read via PPRn.PPRn_m by setting PBDCn.PBDCn_m = 1 and PIBCn.PIBCn_m = 1. Under this setting, the pin output level will never be looped back to the alternative input side even in alternative output mode.

CAUTION

PBDC21 and PBDC27 are write-protected by PWE.

See **Section 2.4.2.4, Other Registers** for details.

Value after reset: Refer to **Section 2.5.1, List of Port Functions**

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	PBDCn _15	PBDCn _14	PBDCn _13	PBDCn _12	PBDCn _11	PBDCn _10	PBDCn _9	PBDCn _8	PBDCn _7	PBDCn _6	PBDCn _5	PBDCn _4	PBDCn _3	PBDCn _2	PBDCn _1	PBDCn _0

Note 1. Refer to **Section 2.5.1, List of Port Functions**.

Table 2.22 PBDCn Register Contents

Bit Position	Bit Name	Function
15 to 0	PBDCn_[15:0]	These bits enable/disable bidirectional mode of the corresponding pin: 0: Bidirectional mode is disabled. 1: Bidirectional mode is enabled.

NOTE

The control bits of the JTAG Port Bidirectional Control Register (JPBC0) are JPBC0_[7:0].

(2) PPRn/JPPR0 — Port Pin Read Register

This register reflects an actual Pn_m pin level, a Pn.Pn_m bit value, or an output level of the alternative function. The value to be read depends on various control settings as described in **Table 2.10, Mode Description and PPRn_m Read Values for Each Mode**.

Value after reset: Refer to **Section 2.5.1, List of Port Functions**

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	PPRn_15	PPRn_14	PPRn_13	PPRn_12	PPRn_11	PPRn_10	PPRn_9	PPRn_8	PPRn_7	PPRn_6	PPRn_5	PPRn_4	PPRn_3	PPRn_2	PPRn_1	PPRn_0

R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Note 1. Refer to **Section 2.5.1, List of Port Functions**.

Table 2.23 PPRn Register Contents

Bit Position	Bit Name	Function
15 to 0	PPRn_[15:0]	These bits indicate the Pn_m pin level, Pn.Pn_m value, or alternative function output level.

NOTE

The control bits of the JTAG Port Pin Read Register (JPPR0) are JPPR0_[7:0].

(3) P/JP — Port Register Group

(a) Pn/JP0 — Port Register

This register sets and holds the Pn.Pn_m data to be output via the related Pn_m port in output port mode (PMcn.PMCn_m = 0 and PMn.PMn_m = 0).

CAUTION

P21 and P27 are write-protected by PWE.
See **Section 2.4.2.4, Other Registers** for details.

Value after reset: Refer to **Section 2.5.1, List of Port Functions**

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	Pn_15	Pn_14	Pn_13	Pn_12	Pn_11	Pn_10	Pn_9	Pn_8	Pn_7	Pn_6	Pn_5	Pn_4	Pn_3	Pn_2	Pn_1	Pn_0
Value after reset	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1
	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Note 1. Refer to **Section 2.5.1, List of Port Functions**.

Table 2.24 Pn Register Contents

Bit Position	Bit Name	Function
15 to 0	Pn_[15:0]	These bits set the output level of pin m (m = 0 to 15): 0: Low level output 1: High level output

NOTES

- Bits of this register can be manipulated by various means. Refer to the subsection, "Writing to the Pn Register" in **Section 2.2.1.3, Pin Data Input/Output** for details.
- The control bits of the JTAG Port Register (JP0) are JP0_[7:0].

(b) PSRn/JPSR0 — Port Set/Reset Register

This register provides an alternative method for setting a bit in the Pn register.

The 16 higher bits of PSRn specify whether the data in the 16 lower bits of PSRn are written to Pn.Pn_m.

Even when pins being used by multiple programs belong to the same port group, the PSRn register allows masking of the unused bits when overwriting so that independent setting of the corresponding bits by each program is possible.

CAUTION

PSR21 and PSR27 are write-protected by PWE.

See **Section 2.4.2.4, Other Registers** for details.

Value after reset: Refer to **Section 2.5.1, List of Port Functions**

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	PSRn_31	PSRn_30	PSRn_29	PSRn_28	PSRn_27	PSRn_26	PSRn_25	PSRn_24	PSRn_23	PSRn_22	PSRn_21	PSRn_20	PSRn_19	PSRn_18	PSRn_17	PSRn_16

Note 1. Refer to **Section 2.5.1, List of Port Functions**.

Table 2.25 PSRn Register Contents

Bit Position	Bit Name	Function
31 to 16	PSRn_[31:16]	These bits specify whether the value of the corresponding lower bit of PSRn_m is written to Pn_m: 0: Pn_m does not depend on PSRn_m. 1: The value of Pn_m is the same as that of PSRn_m. Example: When PSRn.PSRn_31 = 1, the value of bit PSRn.PSRn_15 is written to bit Pn.Pn_15 and output. When read, 0000 _H is always returned.
15 to 0	PSRn_[15:0]	These bits specify the Pn_m value when the corresponding upper bit PSRn_(m+16) is 1: 0: Pn_m = 0 1: Pn_m = 1 When read, the Pn register value is returned.

NOTE

The control bits of the JTAG Port Set/Reset Register (JPSR0) are JPSR0_[31:0].

(4) PNOTn/JPNOT0 — Port NOT Register

This register enables inverting the Pn_m bit of the port register without directly writing to Pn.

CAUTION

PNOT21 and PNOT27 are write-protected by PWE.

See **Section 2.4.2.4, Other Registers** for details.

Value after reset: Refer to **Section 2.5.1, List of Port Functions**.

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	PNOTn _15	PNOTn _14	PNOTn _13	PNOTn _12	PNOTn _11	PNOTn _10	PNOTn _9	PNOTn _8	PNOTn _7	PNOTn _6	PNOTn _5	PNOTn _4	PNOTn _3	PNOTn _2	PNOTn _1	PNOTn _0

R/W	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W

Note 1. Refer to **Section 2.5.1, List of Port Functions**.

Table 2.26 PNOTn Register Contents

Bit Position	Bit Name	Function
15 to 0	PNOTn_[15:0]	These bits specify if Pn.Pn_m is inverted or not: 0: Pn.Pn_m is not inverted (Pn_m → Pn_m). 1: Pn.Pn_m is inverted ($\overline{Pn_m}$ → Pn_m)

NOTE

The control bits of the JTAG Port NOT Register (JPNOT0) are JPNOT0_[7:0].

(5) PINVn/JPINV0 — Port Output Level Inversion Register

This register enables inverting the output level from a pin. This is valid when the pin is in output mode regardless of port output mode or alternative output mode. It is not valid when Port safe state or the ICUM function are active.

CAUTION

These registers are write-protected by PWE.

See **Section 2.4.2.4, Other Registers** for details.

Value after reset: Refer to **Section 2.5.1, List of Port Functions**

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	PINVn_15	PINVn_14	PINVn_13	PINVn_12	PINVn_11	PINVn_10	PINVn_9	PINVn_8	PINVn_7	PINVn_6	PINVn_5	PINVn_4	PINVn_3	PINVn_2	PINVn_1	PINVn_0

	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Note 1. Refer to **Section 2.5.1, List of Port Functions**.

Table 2.27 PINVn Register Contents

Bit Position	Bit Name	Function
15 to 0	PINVn_[15:0]	These bits specify whether the output level from a pin is inverted or not. 0: Pin output level is not inverted. 1: Pin output level is inverted.

NOTE

The control bits of the JTAG Port Output Level Inversion Register (JPINV0) are JPINV0_[7:0].

(6) PSFS — Port Safe State Register Group**(a) PSFSCn — Port Safe State Control Register**

All Port Groups have Port Safe State Function implemented. Each of these Port Groups has its own Port safe state enable bit that is located in the PSFSCn_m register.

CAUTION

These registers are write-protected by PWE.
See **Section 2.4.2.4, Other Registers** for details.

Value after reset: Refer to **Section 2.5.1, List of Port Functions**

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	PSFSC n_15	PSFSC n_14	PSFSC n_13	PSFSC n_12	PSFSC n_11	PSFSC n_10	PSFSC n_9	PSFSC n_8	PSFSC n_7	PSFSC n_6	PSFSC n_5	PSFSC n_4	PSFSC n_3	PSFSC n_2	PSFSC n_1	PSFSC n_0
Value after reset	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1
	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Note 1. Refer to **Section 2.5.1, List of Port Functions**.

Table 2.28 PSFSC Register Contents

Bit Position	Bit Name	Function
15 to 0	PSFSCn_[15:0]	These bits enable/disable Port Safe State Function of pin m (m = 0 to 15).
	PSFSCn_m	Description
	0	Port Safe State Function is disabled Output control still remains. (Port mode or alternative control mode.)
	1	Port Safe State Function is enabled. Output control is changed to Port safe state mode.

(b) PSFSDn — Port Safe State Data Register

When the Port safe state trigger signal becomes active, the port register (Pn_m) is disconnected and switched to the Port Safe State Data register (PSFSDn_m), and the Port Safe State Output Enable register (PSFSOEn_m) takes over output enable control.

CAUTION

These registers are write-protected by PWE.
See **Section 2.4.2.4, Other Registers** for details.

Value after reset: Refer to **Section 2.5.1, List of Port Functions**

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	PSFSD n_15	PSFSD n_14	PSFSD n_13	PSFSD n_12	PSFSD n_11	PSFSD n_10	PSFSD n_9	PSFSD n_8	PSFSD n_7	PSFSD n_6	PSFSD n_5	PSFSD n_4	PSFSD n_3	PSFSD n_2	PSFSD n_1	PSFSD n_0

Note 1. Refer to **Section 2.5.1, List of Port Functions**.

Table 2.29 PSFSD Register Contents

Bit Position	Bit Name	Function
15 to 0	PSFSDn_[15:0]	These bits set the output level of pin m (m = 0 to 15) in Port safe state mode.
	PSFSDn_m	Data Bus Width
	0	Low level output in Port safe state mode
	1	High level output in Port safe state mode

(c) PSFSOEn — Port Safe State Output Enable Register

When the Port safe state trigger signal becomes active, the port register (Pn_m) is disconnected and switched to the Port Safe State Data register (PSFSDn_m), and the Port Safe State Output Enable register (PSFSOEn_m) takes over output enable control.

CAUTION

These registers are write-protected by PWE.
See **Section 2.4.2.4, Other Registers** for details.

Value after reset: Refer to **Section 2.5.1, List of Port Functions**

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Note 1. Refer to **Section 2.5.1, List of Port Functions**.

Table 2.30 PSFSOE Register Contents

Bit Position	Bit Name	Function
15 to 0	PSFSOEn_[15:0]	These bits set the output enable level of pin m (m = 0 to 15) in Port safe state mode.
	PSFSOEn_m	Data Bus Width
	0	Output disabled in Port safe state mode
	1	Output enabled in Port safe state mode

2.4.2.3 Configuration of Electrical Characteristic

(1) PUD/JPU0 — Pull-Up/Down Register Group

(a) PUn/JPU0 — Pull-Up Option Register

This register specifies whether an on-chip pull-up resistor is connected to an input pin.

CAUTION

PU21 and PU27 are write-protected by PWE.
See **Section 2.4.2.4, Other Registers** for details.

Value after reset: Refer to **Section 2.5.1, List of Port Functions**

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	PUn_15	PUn_14	PUn_13	PUn_12	PUn_11	PUn_10	PUn_9	PUn_8	PUn_7	PUn_6	PUn_5	PUn_4	PUn_3	PUn_2	PUn_1	PUn_0
Value after reset	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1
	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Note 1. Refer to **Section 2.5.1, List of Port Functions**.

Table 2.31 PUn Register Contents

Bit Position	Bit Name	Function	
15 to 0	PUn_[15:0]	These bits specify whether an on-chip pull-up resistor is connected to the corresponding pin in combination with the PDn register. For the electrical characteristics for each setting, see <i>the RH850/E2x-FCC2 Electrical Characteristics, User's Manual: Hardware</i> .	
	PUn_m	PDn_m	Description
	0	0	No on-chip input pull-up/pull-down resistor is connected.
	0	1	On-chip pull-down resistor is connected.
	1	0	On-chip pull-up resistor is connected.
	1	1	Setting is prohibited

NOTES

- Do not set PUn.PUn_m = 1 and PDn.PDn_m = 1 to a single pin.
- The on-chip pull-up resistor has no effect when the pin is operated in output mode.
- The control bits of the JTAG Pull Up Option Register (JPU0) are JPU0_[7:0]

(b) PDn/JPD0 — Pull-Down Option Register

This register specifies whether an on-chip pull-down resistor is connected to an input pin.

CAUTION

PD21 and PD27 are write-protected by PWE.
See **Section 2.4.2.4, Other Registers** for details.

Value after reset: Refer to **Section 2.5.1, List of Port Functions**

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	PDn_15	PDn_14	PDn_13	PDn_12	PDn_11	PDn_10	PDn_9	PDn_8	PDn_7	PDn_6	PDn_5	PDn_4	PDn_3	PDn_2	PDn_1	PDn_0

Note 1. Refer to **Section 2.5.1, List of Port Functions**.

Table 2.32 PDn Register Contents

Bit Position	Bit Name	Function
15 to 0	PDn_[15:0]	These bits set pull-down resistor of input port pins in combination with the PUn register. See Table 2.31, PUn Register Contents .

NOTES

- Do not set PUn.PUn_m = 1 and PDn.PDn_m = 1 to a single pin.
- The on-chip pull-down resistor has no effect when the pin is operated in output mode.
- The control bits of the JTAG Pull Down Option Register (JPD0) are JPD0_[7:0]

(2) PODC/JPODC — Port Open Drain Control Register Group**(a) PODCn/JPODC0 — Port Open Drain Control Register**

This register selects port pin's output buffer function as push-pull type or emulated open drain type.

CAUTION

These registers are write-protected by PWE.

See **Section 2.4.2.4, Other Registers** for details.

Value after reset: Refer to **Section 2.5.1, List of Port Functions**

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	PODCn _15	PODCn _14	PODCn _13	PODCn _12	PODCn _11	PODCn _10	PODCn _9	PODCn _8	PODCn _7	PODCn _6	PODCn _5	PODCn _4	PODCn _3	PODCn _2	PODCn _1	PODCn _0

Note 1. Refer to **Section 2.5.1, List of Port Functions**.

Table 2.33 PODCn Register Contents

Bit Position	Bit Name	Function															
15 to 0	PODCn_[15:0]	These bits enable/disable N-ch or P-ch open drain function of pin m (m = 0 to 15) in combination with the PODCEn register.															
		<table border="1"> <thead> <tr> <th>PODCEn_m</th> <th>PODCn_m</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0</td> <td>0</td> <td>Output buffer operates as push-pull driver</td> </tr> <tr> <td>0</td> <td>1</td> <td>Output buffer operates as N-ch open drain driver</td> </tr> <tr> <td>1</td> <td>0</td> <td>Output buffer operates as push-pull driver</td> </tr> <tr> <td>1</td> <td>1</td> <td>Output buffer operates as P-ch open drain driver</td> </tr> </tbody> </table>	PODCEn_m	PODCn_m	Description	0	0	Output buffer operates as push-pull driver	0	1	Output buffer operates as N-ch open drain driver	1	0	Output buffer operates as push-pull driver	1	1	Output buffer operates as P-ch open drain driver
PODCEn_m	PODCn_m	Description															
0	0	Output buffer operates as push-pull driver															
0	1	Output buffer operates as N-ch open drain driver															
1	0	Output buffer operates as push-pull driver															
1	1	Output buffer operates as P-ch open drain driver															

NOTE

The control bits of the JTAG Port Open Drain Control Register (JPODC0) are JPODC0_[7:0].

(b) PODCEn/JPODCE0 — Port Open Drain Control Expansion Register

This register selects port pin's output buffer function as push-pull type or emulated open drain type.

CAUTION

These registers are write-protected by PWE.

See **Section 2.4.2.4, Other Registers** for details.

Value after reset: Refer to **Section 2.5.1, List of Port Functions**

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	PODCE n_15	PODCE n_14	PODCE n_13	PODCE n_12	PODCE n_11	PODCE n_10	PODCE n_9	PODCE n_8	PODCE n_7	PODCE n_6	PODCE n_5	PODCE n_4	PODCE n_3	PODCE n_2	PODCE n_1	PODCE n_0

Note 1. Refer to **Section 2.5.1, List of Port Functions**.

Table 2.34 PODCEn Register Contents

Bit Position	Bit Name	Function
15 to 0	PODCEn_[15:0]	These bits select port pin's output buffer function as push-pull type or emulated open drain type in combination with the PODCn register. See Table 2.33, PODCn Register Contents for register setting and port pin's output buffer function.

NOTE

The control bits of the JTAG Port Open Drain Control Expansion Register (JPODCE0) are JPODCE0_[7:0].

(3) PDSC/JPDSC — Port Drive Strength Control Register Group

(a) PDSCn/JPDSC0 — Port Drive Strength Control Register

This register is used to configure the driving ability (driving strength) of output port pins and multiplexed output pin functions in combination with the PUCcN register. Specific driving ability settings may be required, depending on the pin function to be used. For details, see *the RH850/E2x-FCC2 Electrical Characteristics, User's Manual: Hardware*.

CAUTION

These registers are write-protected by PWE.
See **Section 2.4.2.4, Other Registers** for details.

Value after reset: Refer to **Section 2.5.1, List of Port Functions**

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	PDSCn _15	PDSCn _14	PDSCn _13	PDSCn _12	PDSCn _11	PDSCn _10	PDSCn _9	PDSCn _8	PDSCn _7	PDSCn _6	PDSCn _5	PDSCn _4	PDSCn _3	PDSCn _2	PDSCn _1	PDSCn _0
Value after reset	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1
	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Note 1. Refer to **Section 2.5.1, List of Port Functions**.

Table 2.35 PDSCn Register Contents

Bit Position	Bit Name	Function	
15 to 0	PDSCn_[15:0]	These bits set driving ability of output port pins and multiplexed output pin functions in combination with the PUCcN register. For the electrical characteristics for each setting, see <i>the RH850/E2x-FCC2 Electrical Characteristics, User's Manual: Hardware</i> .	
	PUCcN_m	PDSCn_m	Output Driving Ability
	0	0	Drive strength 1 (Very Low)
	0	1	Drive strength 2 (Low)
	1	0	Drive strength 3 (Mid)
	1	1	Drive strength 4 (High)

NOTE

The control bits of the JTAG Port Drive Strength Control Register (JPDSC0) are JPDSC0_[7:0].

(b) PUCcN/JPUCc0 — Port Universal Control Register

This register is used to configure the driving ability (driving strength) of output port pins and multiplexed output pin functions in combination with the PDSCn register. Specific driving ability settings may be required, depending on the pin function to be used. For details, see *the RH850/E2x-FCC2 Electrical Characteristics, User's Manual: Hardware*.

CAUTION

These registers are write-protected by PWE.

See **Section 2.4.2.4, Other Registers** for details.

Value after reset: Refer to **Section 2.5.1, List of Port Functions**

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	PUCcN _15	PUCcN _14	PUCcN _13	PUCcN _12	PUCcN _11	PUCcN _10	PUCcN _9	PUCcN _8	PUCcN _7	PUCcN _6	PUCcN _5	PUCcN _4	PUCcN _3	PUCcN _2	PUCcN _1	PUCcN _0
Value after reset	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1

Note 1. Refer to **Section 2.5.1, List of Port Functions**.

Table 2.36 PUCcN Register Contents

Bit Position	Bit Name	Function
15 to 0	PUCcN_[15:0]	These bits set driving ability of output port pins and multiplexed output pin functions in combination with the PDSCn register. See Table 2.35, PDSCn Register Contents for register setting and output driving ability.

NOTE

The control bits of the JTAG Port Universal Control Register (JPUCc0) are JPUCc0_[7:0].

(4) PIS/JPIS — Port Input Buffer Selection Register Group

(a) PISn/JPIS0 — Port Input Buffer Selection Register

This register and the PISAn register select the port pin's input buffer characteristics. Specific input characteristic settings may be required, depending on the pin function to be used. For details, see *the RH850/E2x-FCC2 Electrical Characteristics, User's Manual: Hardware*.

CAUTION

PIS21 and PIS27 are write-protected by PWE.

See **Section 2.4.2.4, Other Registers** for details.

Value after reset: Refer to **Section 2.5.1, List of Port Functions**

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	PISn_15	PISn_14	PISn_13	PISn_12	PISn_11	PISn_10	PISn_9	PISn_8	PISn_7	PISn_6	PISn_5	PISn_4	PISn_3	PISn_2	PISn_1	PISn_0
Value after reset	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Note 1. Refer to **Section 2.5.1, List of Port Functions**.

Table 2.37 PISn Register Contents

Bit Position	Bit Name	Function	
15 to 0	PISn_[15:0]	These bits select input buffer type of pin m (m = 0 to 15) in combination with the PISAn register.	
	PISAn_m	PISn_m	Description
	0	0	Input buffer type is Schmitt 1
	0	1	Input buffer type is Schmitt MSC (Setting prohibited except for SchmittMSC pins.)
	1	x	Input buffer type is TTL

NOTES

- The control bits of the JTAG Port Input Buffer Selection Register (JPIS0) are JPIS0_[7:0].
- Schmitt MSC input is supported by P10_2, P10_4, P10_5, P12_0, P12_1, P12_2, P12_3, P12_4, P13_12, P13_14, P14_7, P14_9, P12_7, P14_4, P15_4, P15_5, P15_6, P25_7*1, P25_8*1, P25_9 only. These pins are multiplexed with the function of RHSBnSix, RHSBnEMRG [n = 0, 1, 2, 3*1, x = 0, 1, 2, 3*1].
- TTL input is not supported with P40 port group.
- For details of selectable input characteristics, refer to *the RH850/E2x-FCC2 Electrical Characteristics, User's Manual: Hardware*.
- Input buffer type of TDI, TCK and TMS is selected to TTL type when these pins are used as Nexus, LPD-4 pin and Boundary SCAN interface.

Note 1. Schmitt MSC inputs with P25_7 and P25_8 are supported for E2H although there is no RHSB3 function in E2H.

(b) PISAn/JPISA0 — Port Input Buffer Selection Advanced Register

This register and the PISn register select the port pin's input buffer characteristics. Specific input characteristic settings may be required, depending on the pin function to be used. For details, see *the RH850/E2x-FCC2 Electrical Characteristics, User's Manual: Hardware*.

CAUTION

PISA21 and PISA27 are write-protected by PWE.
See **Section 2.4.2.4, Other Registers** for details.

Value after reset: Refer to **Section 2.5.1, List of Port Functions**

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	PISAn_15	PISAn_14	PISAn_13	PISAn_12	PISAn_11	PISAn_10	PISAn_9	PISAn_8	PISAn_7	PISAn_6	PISAn_5	PISAn_4	PISAn_3	PISAn_2	PISAn_1	PISAn_0
Value after reset	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1
	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Note 1. Refer to **Section 2.5.1, List of Port Functions**.

Table 2.38 PISAn Register Contents

Bit Position	Bit Name	Function
15 to 0	PISAn_[15:0]	These bits set input buffer selection in combination with the PISn register. See Table 2.37, PISn Register Contents for the register settings and selected input type.

NOTES

- The control bits of the JTAG Port Input Buffer Selection Advanced Register (JPISA0) are JPISA0_[7:0].
- Schmitt MSC input is supported by P10_2, P10_4, P10_5, P12_0, P12_1, P12_2, P12_3, P12_4, P13_12, P13_14, P14_7, P14_9, P12_7, P14_4, P15_4, P15_5, P15_6, P25_7*1, P25_8*1, P25_9 only. These pins are multiplexed with RHSBnSlx, RHSBnEMRG [n = 0, 1, 2, 3*1, x = 0, 1, 2, 3*1].
- TTL input is not supported with P40 port group.
- For details of selectable input characteristics, refer to *the RH850/E2x-FCC2 Electrical Characteristics, User's Manual: Hardware*.
- Input buffer type of TDI, TCK and TMS is selected to TTL type when these pins are used as Nexus, LPD-4 pin and Boundary SCAN interface.

Note 1. Schmitt MSC inputs with P25_7 and P25_8 are supported for E2H although there is no RHSB3 function in E2H.

2.4.2.4 Other Registers

(1) PKCPROT — Port Keycode Protection Register

This register is used for protection against writing registers that may have a material effect on the system so that the application system is not incorrectly stopped due to program malfunction and the like.

For how to set protection, see **Section 2.4.4, Port Setting Procedures**.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	PKCPR OT_31	PKCPR OT_30	PKCPR OT_29	PKCPR OT_28	PKCPR OT_27	PKCPR OT_26	PKCPR OT_25	PKCPR OT_24	PKCPR OT_23	PKCPR OT_22	PKCPR OT_21	PKCPR OT_20	PKCPR OT_19	PKCPR OT_18	PKCPR OT_17	PKCPR OT_16
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W

	PKCPR OT_15	PKCPR OT_14	PKCPR OT_13	PKCPR OT_12	PKCPR OT_11	PKCPR OT_10	PKCPR OT_9	PKCPR OT_8	PKCPR OT_7	PKCPR OT_6	PKCPR OT_5	PKCPR OT_4	PKCPR OT_3	PKCPR OT_2	PKCPR OT_1	PWEE
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W	R/W

Table 2.39 PKCPROT Register Contents

Bit Position	Bit Name	Function
31 to 1	PKCPROT_[31:1]	These bits enable or disable modification of the PWEE bit. The value written is not retained. These bits are always read as 0.*1
0	PWEE	PWE Enable bit 0: Disable write access of PWE register. 1: Enable write access of PWE register.

Note 1. Set A5A5 A500_H with {PKCPROT[31:1], PWEE} to disable writing the PWE register.
Set A5A5 A501_H with {PKCPROT[31:1], PWEE} to enable writing PWE register.

(2) PWE — Port Write Enable Register

This register is used to control which port's protected registers can be written. When PKCPROT.PWEE = 1, this register can be written. When PKCPROT.PWEE = 0, this register cannot be written.

For how to set protection, see **Section 2.4.4, Port Setting Procedures**.

Value after reset: 0000 0000_H

1	PWEP01	Port Write enable for P01 0: Disable write access 1: Enable write access
0	PWEP00	Port Write enable for P00 0: Disable write access 1: Enable write access

Note. Register protection is not supported for virtual port groups.

Note 1. This port group is not supported in the E2H product.

(3) LVDSCTRLA — LVDS Control A Register

This register specifies whether to use the LVDS function.

For details, refer to **Section 2.4.5.4, Register Setting to Use the LVDS Buffer.**

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	LVDSCTRLA_16
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	LVDSCTRLA_3	—	—	LVDSCTRLA_0
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R	R	R/W

Table 2.41 LVDSCTRLA Register Contents

Bit Position	Bit Name	Function
31 to 17	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
16	LVDSCTRLA_[16]	This bit specify the voltage for the LVDS input function: 0: LVDS input function of P21_2 and P21_3 pin is used in 5V mode. 1: LVDS input function of P21_2 and P21_3 pin is used in 3V mode.
15 to 4	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
3	LVDSCTRLA_[3]	This bit specify whether to use the LVDS function: 0: Disable LVDS output function of P21_4 and P21_5 pin. 1: Enable LVDS output function of P21_4 and P21_5 pin.
2, 1	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
0	LVDSCTRLA_[0]	This bit specify whether to use the LVDS function: 0: Disable LVDS input function of P21_2 and P21_3 pin. 1: Enable LVDS input function of P21_2 and P21_3 pin.

(4) LVDSCTRLB — LVDS Control B Register

This register specifies whether to use the LVDS function.

For details, refer to **Section 2.4.5.4, Register Setting to Use the LVDS Buffer.**

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R	R	R/W

Table 2.42 LVDSCTRLB Register Contents

Bit Position	Bit Name	Function
31 to 6	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
5	LVDSCTRLB_5	This bit specify whether to use the LVDS function: 0: Disable LVDS output function of P13_0 and P13_1 pin. 1: Enable LVDS output function of P13_0 and P13_1 pin.
4	LVDSCTRLB_4	This bit specify whether to use the LVDS function: 0: Disable LVDS input function of P13_0 and P13_1 pin. 1: Enable LVDS input function of P13_0 and P13_1 pin.
3	LVDSCTRLB_3	This bit specify whether to use the LVDS function: 0: Disable LVDS output function of P13_2 and P13_3 pin. 1: Enable LVDS output function of P13_2 and P13_3 pin.
2, 1	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
0	LVDSCTRLB_0	This bit specify whether to use the LVDS function: 0: Disable LVDS input function of P14_4 and P14_5 pin. 1: Enable LVDS input function of P14_4 and P14_5 pin.

(5) LVDSCTRLC — LVDS Control C Register

This register specifies whether to use the LVDS function.

For details, refer to **Section 2.4.5.4, Register Setting to Use the LVDS Buffer.**

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R	R/W	R

Table 2.43 LVDSCTRLC Register Contents

Bit Position	Bit Name	Function
31 to 4	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
3	LVDSCTRLC_3	This bit specify whether to use the LVDS function: 0: Disable LVDS output function of P10_2 and P10_3 pin. 1: Enable LVDS output function of P10_2 and P10_3 pin.
2	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
1	LVDSCTRLC_1	This bit specify whether to use the LVDS function: 0: Disable LVDS output function of P10_0 and P10_1 pin. 1: Enable LVDS output function of P10_0 and P10_1 pin.
0	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.

(6) LVDSCTRLD — LVDS Control D Register

This register specifies whether to use LVDS function.

For details, refer to **Section 2.4.5.4, Register Setting to Use the LVDS Buffer.**

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

	—	—	—	—	—	—	—	—	—	—	—	—	LVDSCTRLD_3	—	LVDSCTRLD_1	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R	R/W	R

Table 2.44 LVDSCTRLD Register Contents

Bit Position	Bit Name	Function
31 to 4	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
3	LVDSCTRLD_3	This bit specify whether to use the LVDS function: 0: Disable LVDS output function of P13_6 and P13_7 pin. 1: Enable LVDS output function of P13_6 and P13_7 pin.
2	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
1	LVDSCTRLD_1	This bit specify whether to use the LVDS function: 0: Disable LVDS output function of P13_4 and P13_5 pin. 1: Enable LVDS output function of P13_4 and P13_5 pin.
0	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.

(7) LVDSCTRLF — LVDS Control F Register

This register specifies whether to use LVDS function.

For details, refer to **Section 2.4.5.4, Register Setting to Use the LVDS Buffer.**

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 2.45 LVDSCTRLF Register Contents

Bit Position	Bit Name	Function
31 to 6	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
5	LVDSCTRLF_5	This bit specify whether to use the LVDS function: 0: Disable LVDS output function of P25_12 and P25_13 pin. 1: Enable LVDS output function of P25_12 and P25_13 pin.
4	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
3	LVDSCTRLF_3	This bit specify whether to use the LVDS function: 0: Disable LVDS output function of P25_14 and P25_15 pin. 1: Enable LVDS output function of P25_14 and P25_15 pin.
2 to 0	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.

2.4.3 Pin-Unit Register Explanation

2.4.3.1 PCRn_m/JPCRn_m — Port Control Register

Each register of a port group can be accessed via this register and the PCRn_m register can set all the functions of a single pin. For example, setting bit 6 of the PCRn_m register to 1 sets bit m of the PMCN register to 1 also.

Multiple bits in the PCRn_m register can be batch-set within the ranges described in **Section 2.4.4, Port Setting Procedures**, Individual Setting.

CAUTION

These registers are write-protected by PWE.
See **Section 2.4.2.4, Other Registers** for details.

Value after reset: Refer to **Section 2.5.1, List of Port Functions**.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	PINV	—	PODC	PODCE	—	PUCC	PDSC	—	PISA	—	PIS	PU	PD	PBDC	PIBC
Value after reset	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1
R/W	R	R/W	R	R/W	R/W	R	R/W	R/W	R	R/W	R	R/W	R/W	R/W	R/W	R/W
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	PSFSOE	PSFSD	PSFSC	P	—	—	—	PPR	—	PMC	PIPC	PM	PFCEAE	PFCAE	PFCE	PFC
Value after reset	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1
R/W	R/W	R/W	R/W	R/W	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Note 1. Refer to **Section 2.5.1, List of Port Functions**.

Table 2.46 PCRn_m Register Contents (1/2)

Bit Position	Bit Name	Function
31	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
30	PINV	Same function as bit m of the PINVn register
29	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
28	PODC	Same function as bit m of the PODCn register
27	PODCE	Same function as bit m of the PODCEn register
26	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
25	PUCC	Same function as bit m of the PUCCn register
24	PDSC	Same function as bit m of the PDSCn register
23	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
22	PISA	Same function as bit m of the PISAn register
21	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
20	PIS	Same function as bit m of the PISn register
19	PU	Same function as bit m of the PUn register
18	PD	Same function as bit m of the PDn register

Table 2.46 PCRn_m Register Contents (2/2)

Bit Position	Bit Name	Function
17	PBDC	Same function as bit m of the PBDCn register
16	PIBC	Same function as bit m of the PIBCn register
15	PSFSOE	Same function as bit m of the PSFSOEn register
14	PSFSD	Same function as bit m of the PSFSDn register
13	PSFSC	Same function as bit m of the PSFSCn register
12	P	Same function as bit m of the Pn register
11 to 9	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
8	PPR	Same function as bit m of the PPRn register
7	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
6	PMC	Same function as bit m of the PMCn register
5	PIPC	Same function as bit m of the PIPCn register
4	PM	Same function as bit m of the PMn register
3	PFCEAE	Same function as bit m of the PFCEAEn register
2	PFCAE	Same function as bit m of the PFCAEn register
1	PFCE	Same function as bit m of the PFCEn register
0	PFC	Same function as bit m of the PFCn register

NOTE

The control registers of the JTAG Port Control Register (JPCR0) are JPCR0_m (m = 0 to 3, 5)

2.4.4 Port Setting Procedures

Examples of port setting procedures are shown below.

For the procedures for setting the digital noise filter of a port, see **Section 2.6.1, Digital Noise Filter**.

For the procedures for setting the Port safe state mode, see **Section 2.6.2.3, Configuration Flow**.

CAUTION

Even if a port is used in S/W I/O control alternative mode in a batch setting, the PMn_m register should be set at the end of the process in order to prevent output glitches.

In a PCR configuration, do not change the value of the invert value register (PINVn_m) and output value register (Pn_m) at the same time after output enable is active. If these registers are changed, set them again from the start of the register setting flow.

When returning to the “Port initializing” state after port setting has been configured, please set port register again in the inverse order with Port Group Unit register. At that case, it can not be used with Pin Unit register.

NOTE

When writing a reserved bit in virtual port registers, any value can be set—not just the value after reset. For details of reserved bits, refer to **Section 2.5.1, List of Port Functions**.

2.4.4.1 Batch Setting

The following shows an example of collectively setting a port group.

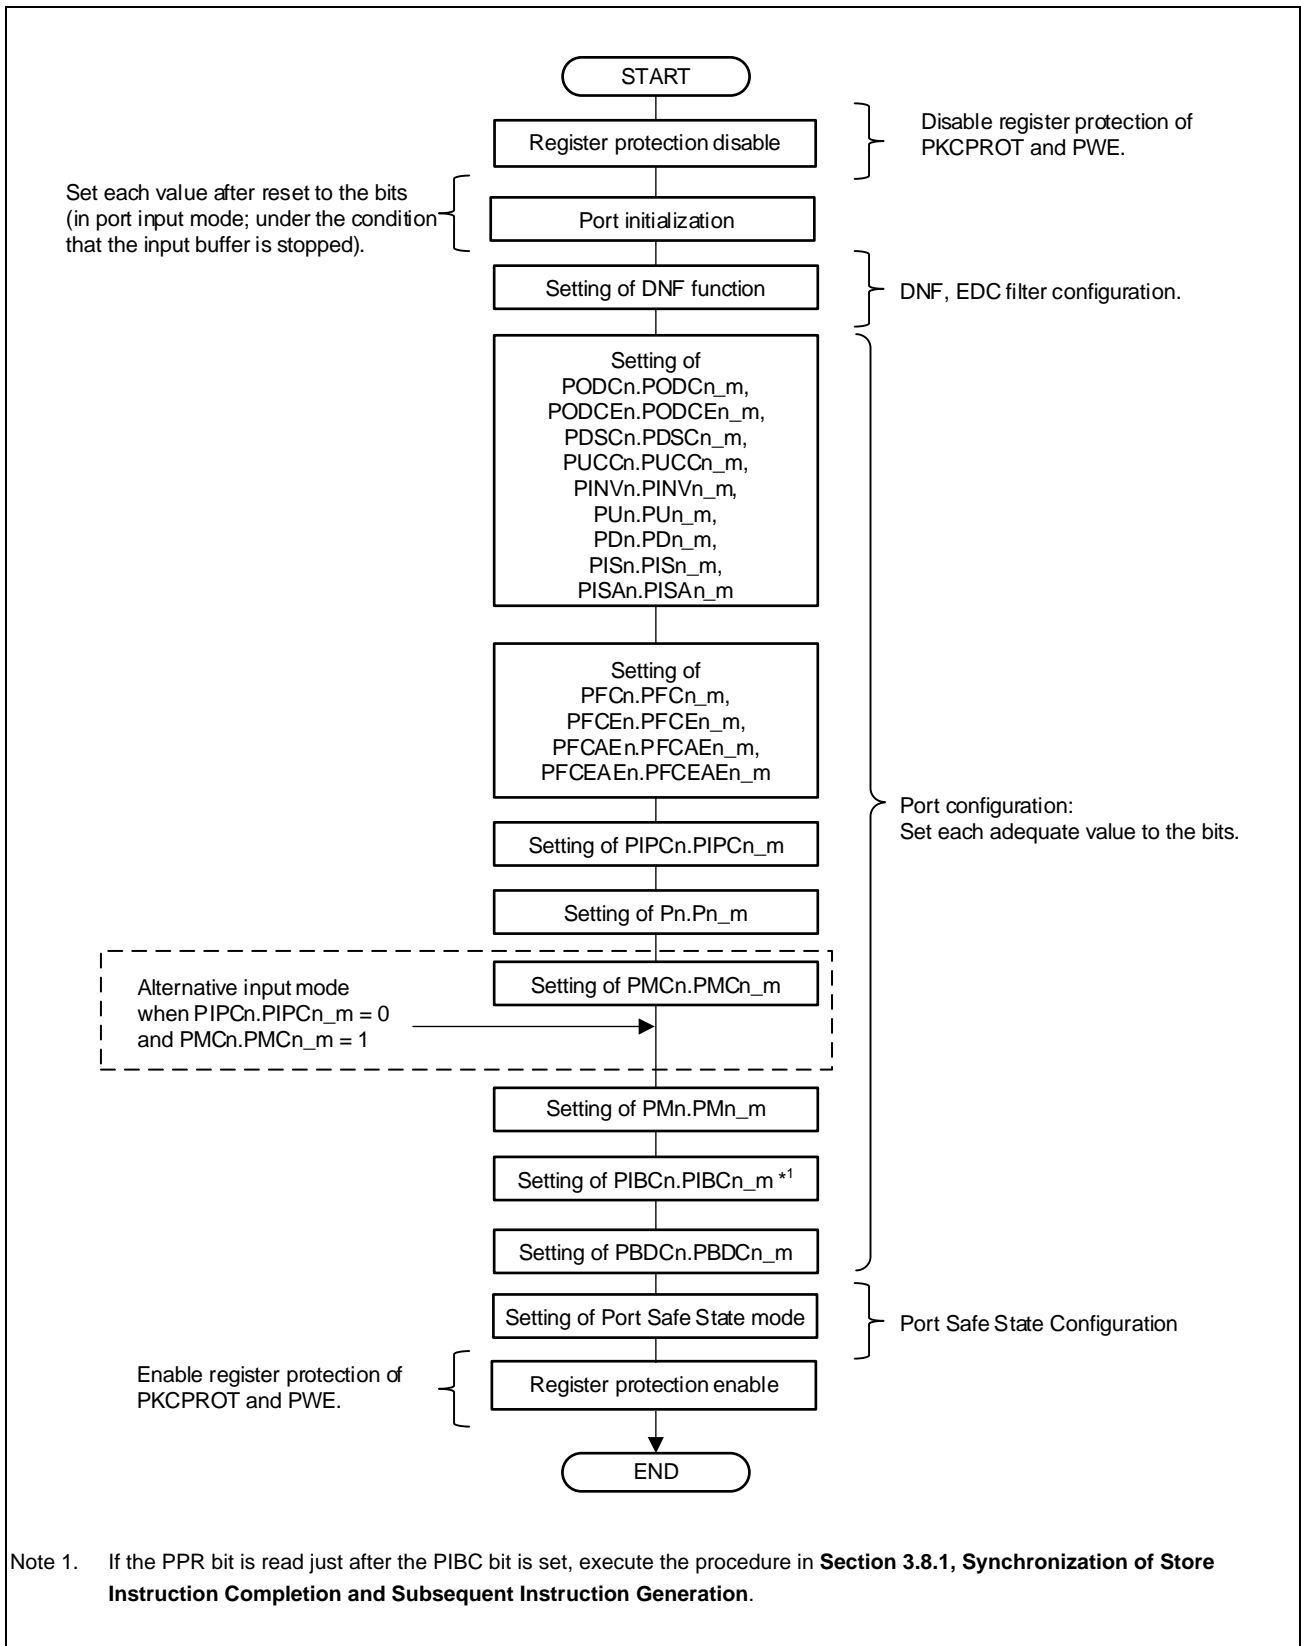

Figure 2.3 Port Setting Flow (Batch Setting)

2.4.4.2 Individual Setting

The following shows an example of individually setting a port group.

Bits can be set simultaneously within the settable range described below by using the PCRn_m register.

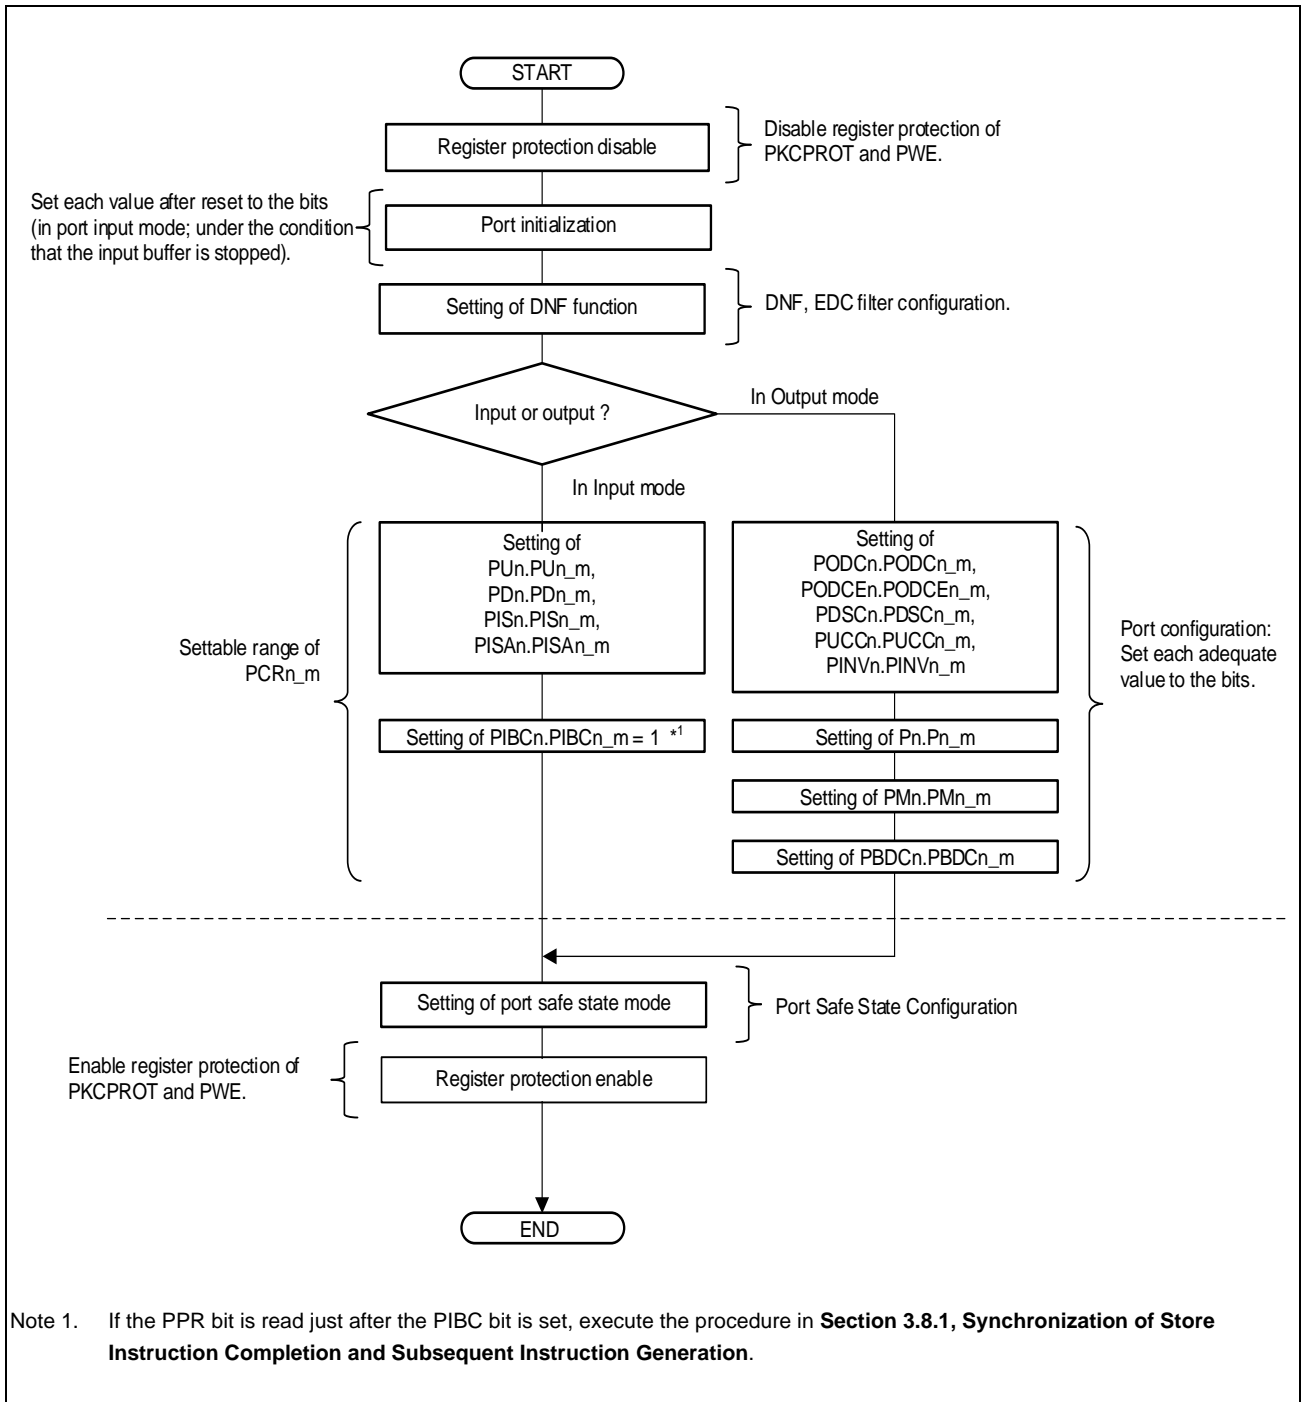

Figure 2.4 Port Setting Flow (in Port Mode)

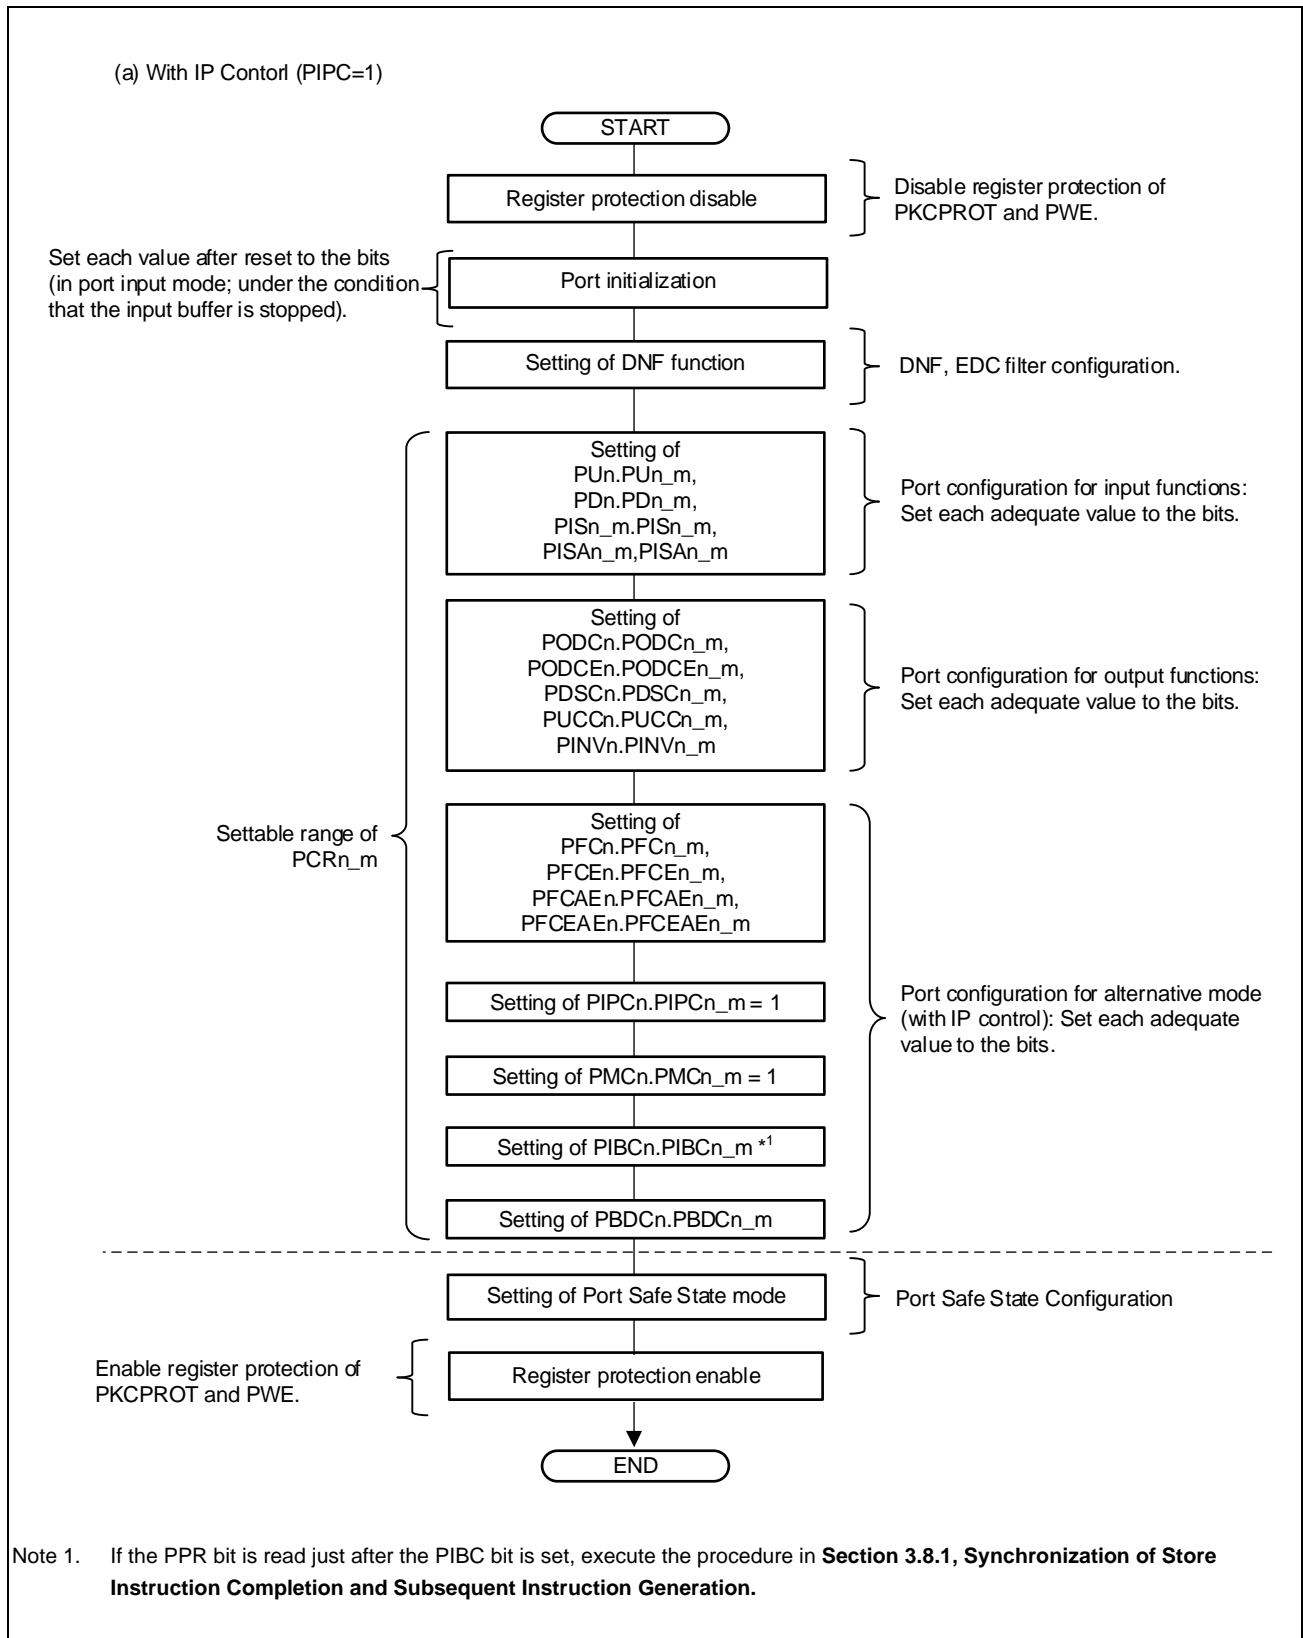

Figure 2.5 Port Setting Flow (in Alternative Mode) (1/3)

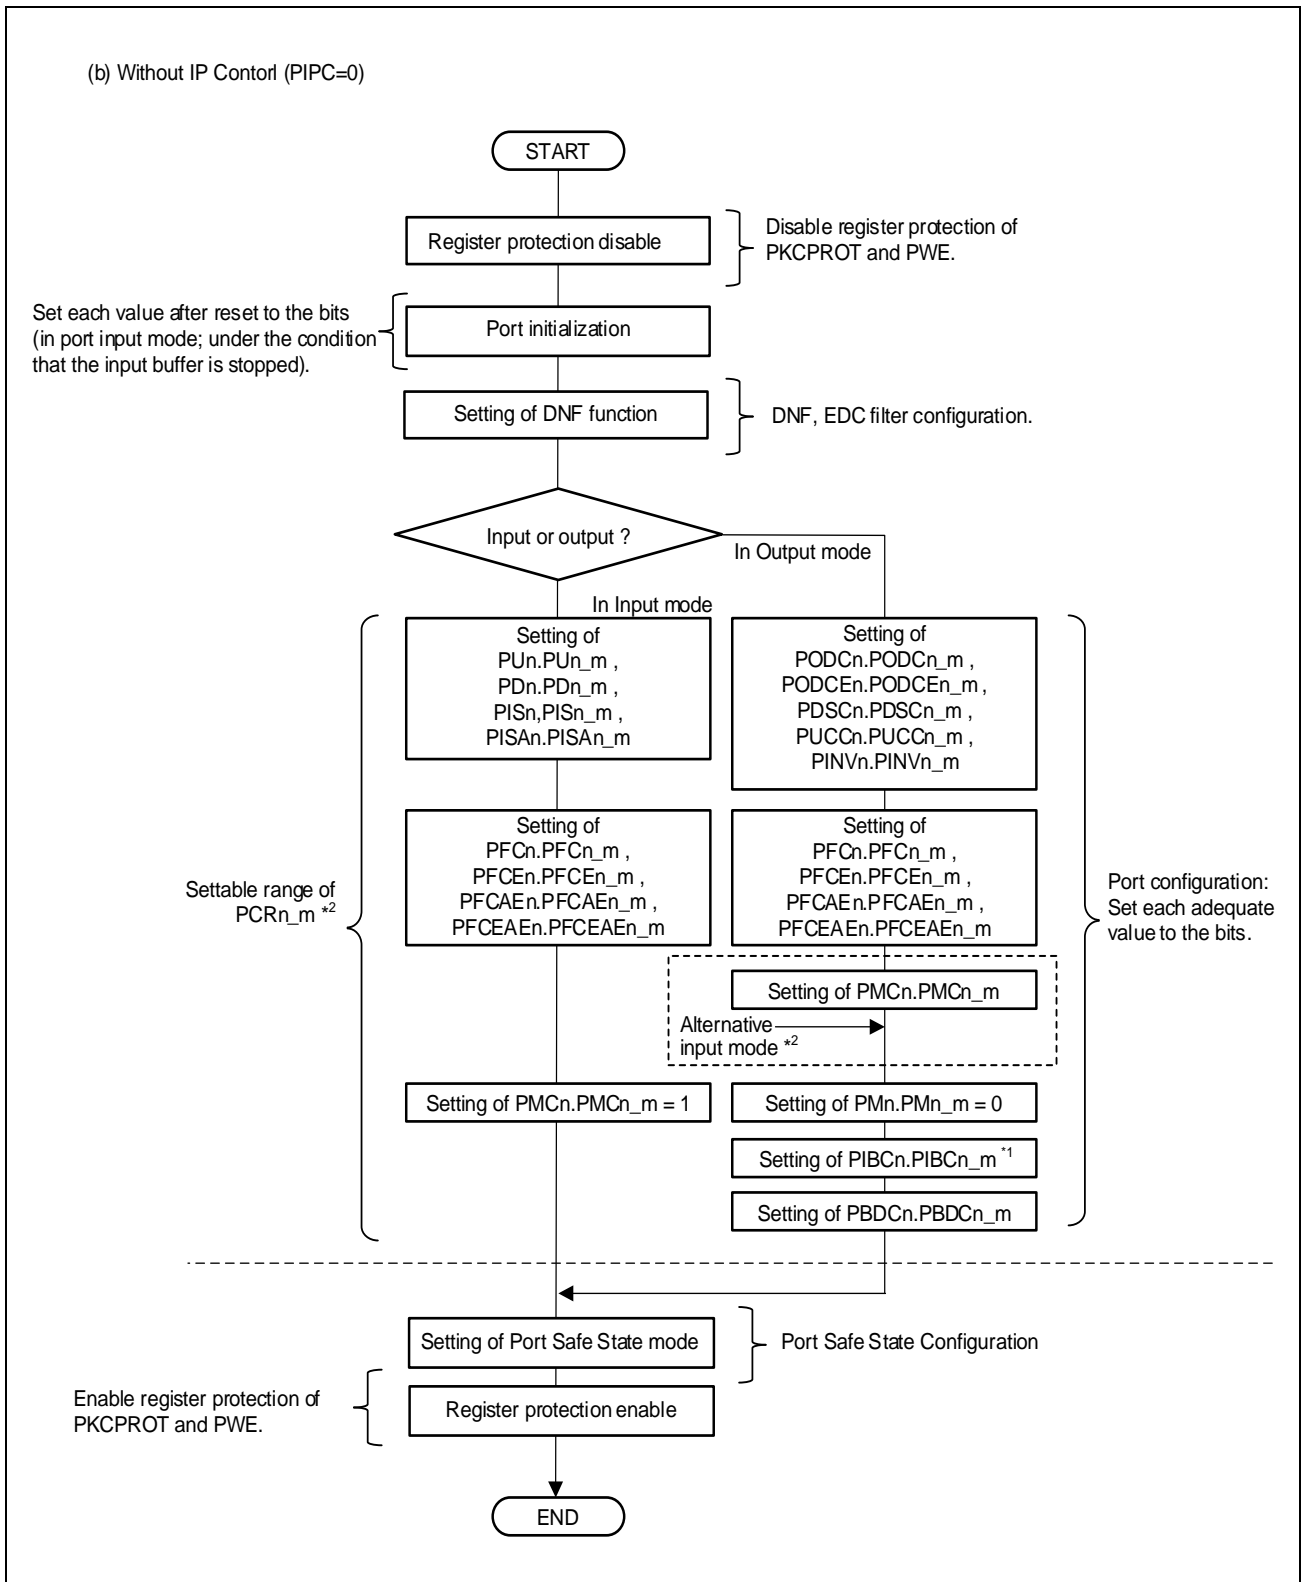

Figure 2.5 Port Setting Flow (in Alternative Mode) (2/3)

- Note 1. If the PPR bit is read just after the PIBC bit is set, execute the procedure in **Section 3.8.1, Synchronization of Store Instruction Completion and Subsequent Instruction Generation**.
- Note 2. In case of port configuration of the following alternative functions, there is a possibility that ECM Error Source Status for $\overline{\text{ERRORIN}}$ is set in ECMmESSTRn, and $\overline{\text{ERROROUT_M}}$ and $\overline{\text{ERROROUT_C}}$ output Low Level. ECM Error Source Status can be cleared by ECMESSTCn. $\overline{\text{ERROROUT_M}}$ and $\overline{\text{ERROROUT_C}}$ can be masked by ECMEMKn. Please set ECMEMK7 bit27 before port configuration of the following alternative function. Please clear ECMEMK7 bit27 after port configuration of that function if $\overline{\text{ERRORIN}}$ function is used.
- About ECMmESSTRn, ECMEMKn and ECMESSTCn, refer to **Section 41, Error Control Module (ECM)**.
- In case of Port configuration by Port Group Unit Register
P32_5: MSTCSZ0
- In case of Port configuration by Pin-Unit Register
P02_10: ATOM1_6 and ATOM5_2N
P15_6: TIM3_6, ATOM6_6 and ATOM7_6
P21_2: ATOM4_0 and ATOM2_4N
P32_5: ATOM3_5N and MSTCSZ0

Figure 2.5 Port Setting Flow (in Alternative Mode) (3/3)

2.4.4.3 Protection Setting

The following shows an example of setting register protection.

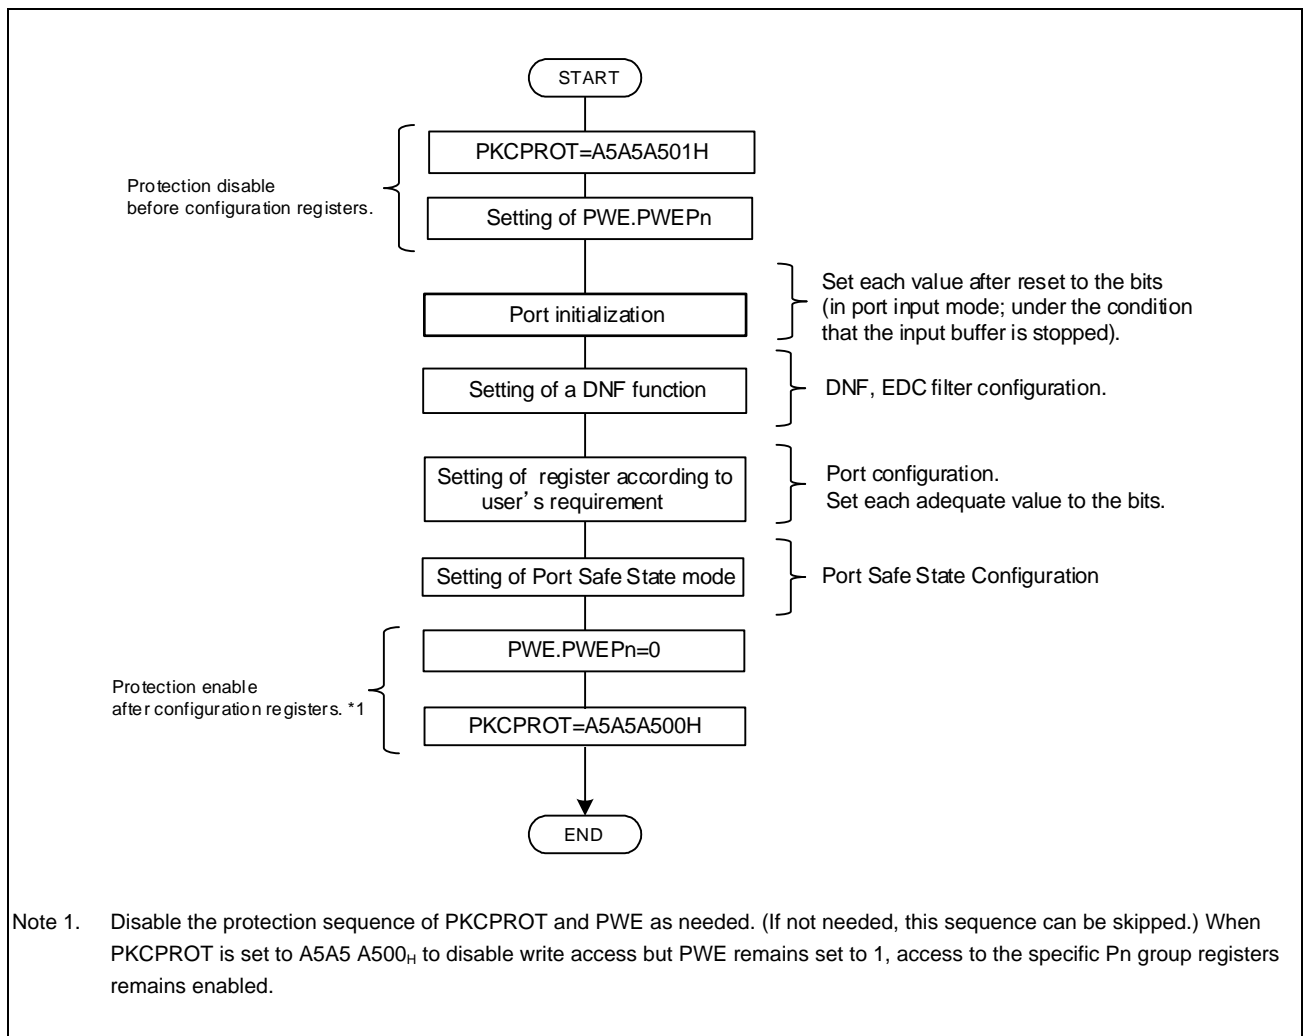

Figure 2.6 Protection Setting Flow

2.4.5 Functional Selection

2.4.5.1 Register Configuration When Using Alternative Functions

When the pin alternative function is used, set $PMn_m = 1$ and select the relevant alternative function by using the $PFCn_m$, $PFCEn_m$, $PFCAEn_m$ and $PFCEAEn_m$ bits.

For several peripheral functions, a single alternative I/O function is allocated to multiple pins. However, input functions should not be enabled on multiple pins at the same time.

2.4.5.2 Alternative Functions That Can Be Used in Direct I/O Control Alternative Mode

The following table shows alternative functions that can be used in direct I/O control alternative mode. To use these functions, set $PIPCn_m = 1$.

When $PIPCn_m = 1$, the set PMn_m value is ignored because the peripheral function controls the input and output of the buffer.

In addition, set $PIPCn_m = 0$ if you are using an alternative function not listed in following table.

When the LVDS buffer is to be used, $PIPCn_m$ register must not be set 1.

Table 2.47 List of Alternative Functions That Can Be Used in Direct I/O Control Alternative Mode (Must Set PIPCn_m = 1)

Category	Pin Name	I/O	Pin Function	Input/Output Control by Peripheral Functions
SCI3n	SCInRxD	I	Receive data input	Input through the pin is enabled when the SCInSCR.RE bit is set to enable reception by SCI3.
	SCInTxD	O	Transmit data output	Output through the pin is enabled when the SCInSCR.TE bit is set to enable transmission by SCI3.
	SCInSCK	I/O	Serial clock input/output	The SCInSCR.CKE[1:0] bits determine whether the pin is an input or output. <ul style="list-style-type: none"> Asynchronous transfer CKE[1:0] = 00: Both input and output through the pin are disabled. CKE[1:0] = 01: The pin is an output. CKE[1:0] = 1x: Prohibited settings Synchronous transfer CKE[1:0] = 0x: The pin is an output.
CSIHn	CSIHnTSSO	O	Transmit data output (data integrity verification)	<ul style="list-style-type: none"> Output control See “CSIHTSSO Operation for Slave Mode”, in Section 18, Clocked Serial Interface H (CSIH). Input control When the CSIHnCTL1.DCS bit is set to enable checking the consistency of data through CSIH, enabling the input buffer for the pin leads to the actual output level of the pin being looped back within the device.
	CSIHnTSCK	I/O	Serial clock input/output	When the setting of CSIHnCTL2 is for CSIH operation in slave mode, this pin is an input. When the setting is for master mode, it is an output.
	CSIHnTRY	I/O	Handshake signal input/output	When the setting of CSIHnCTL2 is for CSIH operation in slave mode, this pin is an output. When the setting is for master mode, it is an input.
ATU-V timer C	TIOCn0 to TIOCn3	I/O	Input capture trigger input, output compare output	This pin is an output when ATU-V timer C is set to a compare-match operation by the TIOCx register. This pin is an input when the setting is for an input capture operation.
HSSPIn	HSSPIn_TXD	O	Transmit data output	For details of output control and input control, see “Control of the HS-SPI Pins”, in Section 28, High Speed Serial Peripheral Interface (HS-SPI) .
	HSSPIn_CLK	I/O	Serial clock input/output	
	HSSPIn_SSLI	I	Slave selection input signal	
	HSSPIn_SSL	O	Slave selection output signal	
Ethernet	MDIO	I/O	PHY chip set I/F data input/output.	Input through the pin is enabled when the ETNCnPIR.MMD and ETNCnPIR.MDI bits are enabled. Output through the pin is enabled when the ETNCnPIR.MMD and ETNCnPIR.MDO bits are enabled.
EXBC	D0 – D31	I/O	Data input/output	See Section 17, External Bus Controller .

Note: n indicates the number of a given peripheral module.

2.4.5.3 Register Setting When Using an Analog Input Pin

It is not necessary to set a port register to select a pin function since ANxxx (SAR-A/D), DSANxxxP, DSANxxxN (DS-A/D), CANxxxP and CANxxxN (Cyclic-A/D) for an analog input are always connected to the A/D converter.

However, some analog input ports are multiplexed with general input ports, so to use the ports as analog input ports, set $PMCn_m = 0^{*1}$ and $PIBCn_m = 0$ (the value after reset of the port register). This prevents shoot-through current from the input buffer on the digital side during an analog voltage input. The relevant pins of this product are port groups P40_m.

Note 1. Some pins may not be equipped with a PMC40_m bit. For further details, see **Section 2.5, Organization of Port Groups**.

2.4.5.4 Register Setting to Use the LVDS Buffer

When the LVDS buffer is to be used, set the LVDSCTRL[A,B,C,D,F] register to enable input/output. Also, set whether the supply voltage of LVDS buffer is 3V or 5V.

CAUTION

Input/output from the LVDS buffer actually being enabled/disable takes at least 10 μ s after setting LVDSCTRL[A,B,C,D,F].

Following pins have LVDS buffer and also port functions, but these can not be used at the same time. Be sure to set value after reset to each registers*1 as initialization in case LVDS buffer is used. In case of LVDS input mode, PFCn.PFCn_m, PFCEn.PFCEn_m and PMCn.PMCn_m can be set after IE bit of LVDSCTRL[A, B] is set. In case of LVDS output mode, PFCn.PFCn_m, PFCEn.PFCEn_m and PMCn.PMCn_m can be set before OE bit of LVDSCTRL[A, B, C, D, F] is set. And PMn.PMn_m and PSFSCn.PSFSCn_m can be set after OE bit of LVDSCTRL[A, B, C] is set. Refer to Section 2.4.5.5 Setting flow of LVDS function for more detail.

Note 1. Set PIBCn.PIBCn_m = 0, PBDCn.PBDCn_m = 0, PMn.PMn_m = 1, PMCn.PMCn_m = 0, PIPCn, PIPCn_m = 0, PFCn.PFCn_m = 0, PFCEn.PFCEn_m = 0, PFCAEn.PFCAEn_m = 0, PFCEAEn.PFCEAEn_m = 0, PDn.PDn_m = 0, PUn.PUn_m = 0, PSFSCn.PSFSCn_m = 0, PSFSDn.PSFSDn_m = 0, PSFSOEn.PSFSOEn_m = 0.

The LVDS setting registers are shown in the following table.

Table 2.48 LVDS Enable Register

Port Register	Register Bit	Power Domain	I/F	Pin Name (A pair of Pch, Nch)	I/O	Control*1	Related Function (A pair of Pch, Nch)	E2x-FCC2			E2UH		E2H

Note 1. OE: Output Enable, IE: Input Enable. VSEL: Supply Voltage Select.

Note 2. LVDSCTRLF is implemented only in E2x-FCC2 and E2UH (it is not supported in E2H).

2.4.5.5 Setting Flow of LVDS function

The following shows the flow to use LVDS function.

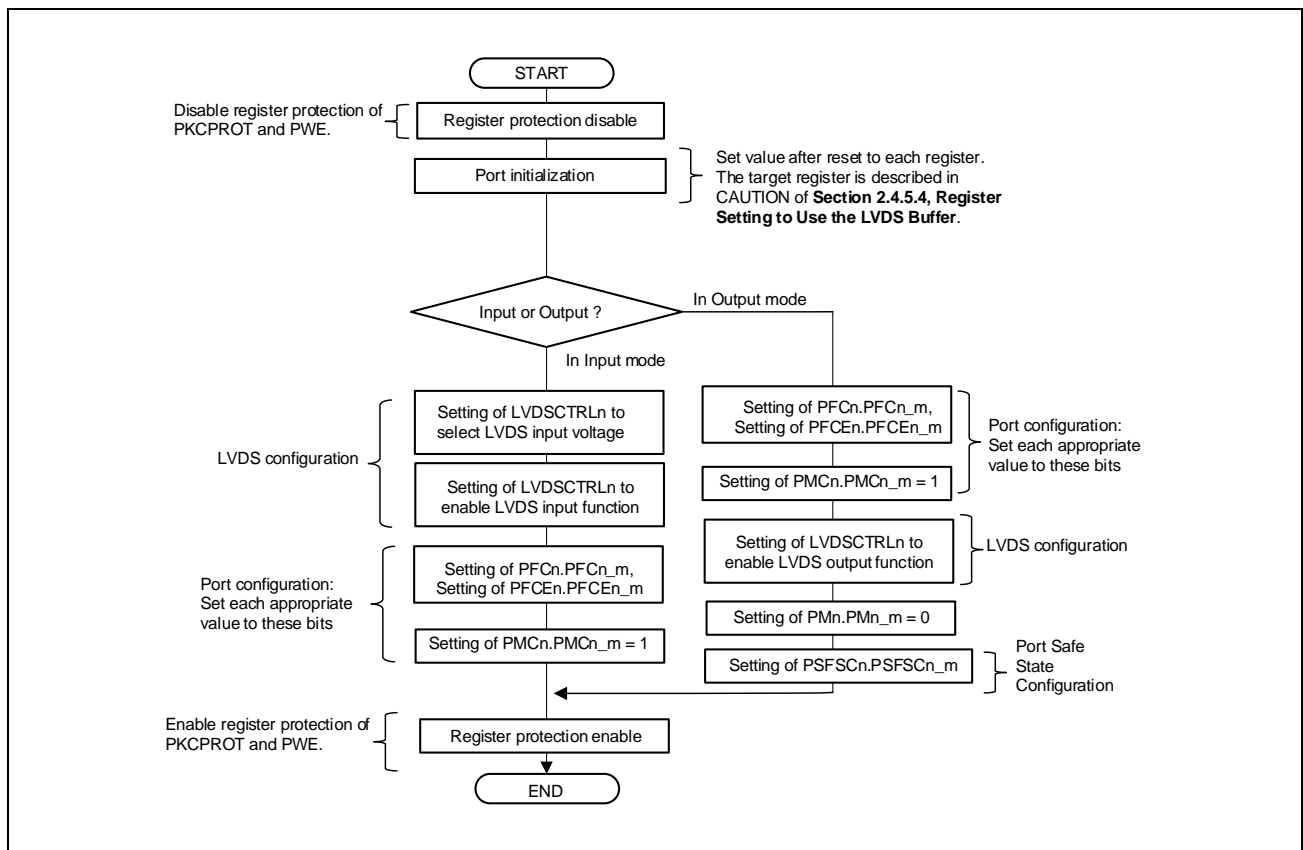

Figure 2.7 LVDS Configuration Flow

2.4.5.6 Selecton of Function for JTAG Port

To enable connection of multiple tools to the JTAG port, the operation mode can be defined by a combination of mode pin and option byte settings. For details, see **Section 47, Debugging and Calibration**.

2.4.5.7 Setting of the ERROROUT_C loopback

When the pin level of ERROROUT_C is confirmed by ECM Checker Error Source Status register, set $PBDCn_m = 1$ to enable the alternative output level loopback function.

See **Section 2.4.2.2(1), PBDCn/JPBDC0 — Port Bidirectional Control Register** for details.

2.5 Organization of Port Groups

2.5.1 List of Port Functions

For detailed information on the control registers, refer to Appendix “*E02-02_List of Port Functions.xlsx*”.

In the bitmap field, “x” means an effective bit and “—” means a reserved bit. Reserved areas are always read as the values after reset. The write value also should be the value after reset. The registers of unimplemented pins should not be modified after reset.

2.5.2 List of Alternative Functions

For detailed information on the alternative functions of each pin, refer to Appendix “*E02-01_List of Alternative Functions.xlsx*”.

In the file, “—” means a reserved function, and this function should not be selected. The functions of unimplemented ports cannot be selected and the registers of these unimplemented pins should not be modified after reset.

2.6 Functions

2.6.1 Digital Noise Filter

The Digital Noise Filter (DNF) eliminates digital noise from external input signals. This product includes two types of DNF: a peripheral function DNF and an edge detection DNF.

2.6.1.1 Example of Noise Elimination

Figure 2.8 Timing Chart of Digital Noise Elimination shows an example of noise elimination using a peripheral function DNF and an edge detection DNF. In this example, the sampling clock is set to 1/2 of the DNF input clock, the sampling count is set to two (twice), and the current output level is set to low level. “○” in the figure means that high level is detected.

In input examples 1, 2, and 3, the output level changes from low to high because the same level is detected twice in a row through sampling. In input examples 4, 5, and 6, on the other hand, the same level is not detected twice consecutively. Therefore, these inputs are regarded as noise and the input signal state is eliminated.

Figure 2.8 Timing Chart of Digital Noise Elimination

2.6.1.2 Peripheral Function DNF

(1) Function Overview

This DNF eliminates noise from the input pins for peripheral functions.

The peripheral function DNF has the following functions:

- Eliminates digital noise from input signals and outputs noiseless signals.
- Selects whether to output signals from which digital noise is eliminated or signals containing digital noise.
- Selects the digital noise elimination width from 2, 3, 4, and 5 counts of the sampling clock.
- Selects from the five types of sampling frequency shown below:
 - 1/1, 1/2, 1/4, 1/8, and 1/16 of the DNF input clock.
- The conditions for noise elimination can be set by each channel via registers.
- The DNF input clock of DNF group number 0, 2 and 3 is a low-speed peripheral clock.
- The DNF input clock of DNF group number 1 is a high-speed peripheral clock.

(2) DNF Register Base Addresses

The following table shows base addresses of DNF.

Table 2.49 Base Addresses of Peripheral Function DNF

Base Address Name	Base Address	Bus Group
<DNF0_Base>	FFC3 0000 _H	Peripheral Group 6
<DNF1_Base>	FFC3 0040 _H	Peripheral Group 6
<DNF2_Base>	FFC3 0080 _H	Peripheral Group 6
<DNF3_Base>	FFC3 00C0 _H	Peripheral Group 6

(3) DNF Clock Supplies

The peripheral function DNF clock supplies are shown in the following table.

Table 2.50 Clock Supplies of Peripheral Function DNF

Unit Name	Unit Clock Name	Supply Clock Name
DNF0	PCLK	CLK_LSB
DNF1	PCLK	CLK_HSB
DNF2	PCLK	CLK_LSB
DNF3	PCLK	CLK_LSB

(4) DNF Reset Sources

The peripheral function DNF reset sources are shown below.

The peripheral function DNF is initialized by the following reset sources.

Table 2.51 Reset Sources of Peripheral Function DNF

Unit Name	Register Name	Reset Condition					
		Power Up Reset	System Reset 1	System Reset 2	Application Reset	Module Reset	JTAG Reset
DNF0	All registers	✓	✓	✓	✓	—	—
DNF1	All registers	✓	✓	✓	✓	—	—
DNF2	All registers	✓	✓	✓	✓	—	—
DNF3	All registers	✓	✓	✓	✓	—	—

(5) List of Peripheral Function DNF Registers

Table 2.52 List of Registers

Module Name	Register Name	Symbol	Address	Value after reset	Access	Access Protection
DNFn	DNF Control Register	DNFP01nCTLm	<DNFn_base> + 04 _H × m	00 _H	8	—

Note: n: DNF group number, m: channel number

(6) DNFP01nCTLm — DNF Control Register

This register sets conditions for noise elimination of channel number m in DNF group number n.

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	NFEN	SLST[1:0]		—	—	PRS[2:0]		
Value after reset	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R	R	R/W	R/W	R/W

Table 2.53 DNFP01nCTLm Register Contents

Bit Position	Bit Name	Function
7	NFEN	This bit enables/disables digital noise elimination. 0: Digital noise is not eliminated. 1: Digital noise is eliminated.
6, 5	SLST[1:0]	These bits specify the sampling count for digital noise elimination. 00: Sampling count = 2 01: Sampling count = 3 10: Sampling count = 4 11: Sampling count = 5
4, 3	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
2 to 0	PRS[2:0]	These bits specify the sampling clock division ratio for digital noise elimination. 000: DNF input clock/1 001: DNF input clock/2 010: DNF input clock/4 011: DNF input clock/8 100: DNF input clock/16 Other than the above: Setting is prohibited.

(7) Setting Flow of Peripheral Function DNF

The following shows the procedures to set the peripheral function DNF.

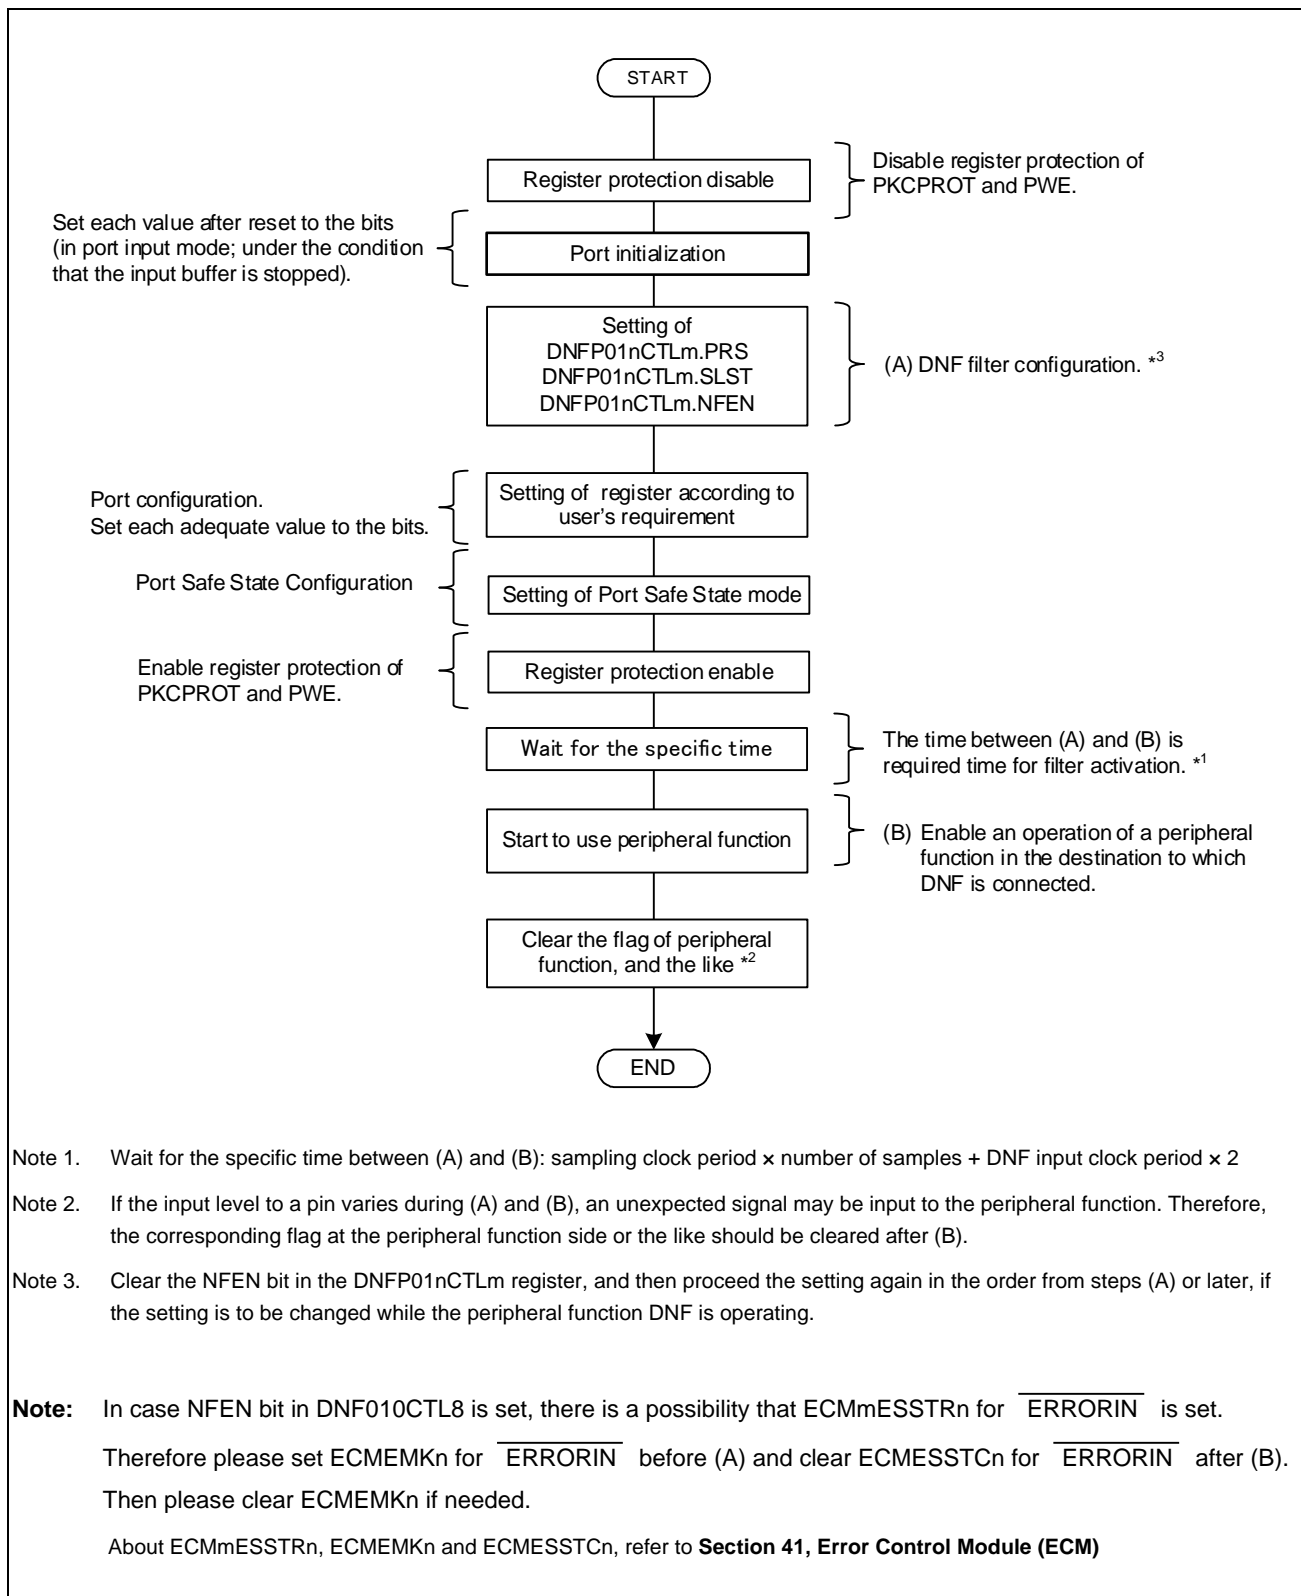

Figure 2.9 Peripheral Function DNF Setting Flow

(8) List of Pins on Which a DNF Is Inserted

The following table shows the pins on which a DNF is inserted.

Table 2.54 DNF Insertion Targets (1/2)

DNF Group	DNF Channel Number (m)	DNF Insertion Target Pin			E2x-FCC2			E2UH		E2H	
		Pin Name	Pin Function	Peripheral Function	BGA 468 (E2UH)	BGA468 (E2H)	BGA373 (E2UH) BGA373 (E2H)	BGA 468	BGA 373	BGA 468	BGA 373
DNF0	0	IRQ0	External interrupt input	INTC	✓	✓	✓	✓	✓	✓	✓

2.6.1.3 Edge Detection DNF

(1) Function Overview

This DNF detects the valid edge of a pin input signal. The signals to be used for edge detection can be selected either before or after noise elimination.

The edge detection DNF has the following functions:

- Eliminates digital noise from input signals and outputs noiseless signals.
- Selects whether to output signals from which digital noise is eliminated or signals containing digital noise.
- Selects the digital noise elimination width from 2, 3, 4, and 5 counts of the sampling clock.
- Selects from the five types of sampling frequency shown below: 1/1, 1/2, 1/4, 1/8, and 1/16 of the DNF input clock.
- The conditions for noise elimination can be set for all channels collectively by a register.
- The DNF input clock is a low-speed peripheral clock.

(2) Edge Detection DNF Register Base Addresses

The following table shows the base addresses of the edge detection DNF. “n” indicates the number of the DNF group.

Table 2.55 Base Addresses of Edge Detection DNF

Base Address Name	Base Address	Bus Group	E2x-FCC2			E2UH		E2H

(5) List of Edge Detection DNF Registers

Table 2.58 List of Registers

Module Name	Register Name	Symbol	Address	Value after reset	Access	Access Protection
EDCn	DNF Control Register	DNFP02nCTL	<EDCn_base> + 00 _H	00 _H	8	—
	Edge detection control Register	DNFP02nEDCm	<EDCn_base> + 04 _H + 08 _H × m	00 _H	8	—
	Edge detection Flag Register	DNFP02nEDFm	<EDCn_base> + 08 _H + 08 _H × m	00 _H	8	—

Note: n: DNF group number, m: channel number

(6) DNFP02nCTL — DNF Control Register

This register sets noise elimination conditions which are commonly used for all channels in DNF group number n.

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	SLST[1:0]		—	—	PRS[2:0]		
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R/W	R/W	R	R	R/W	R/W	R/W

Table 2.59 DNFP02nCTL Register Contents

Bit Position	Bit Name	Function
7	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
6, 5	SLST[1:0]	These bits specify the sampling count for digital noise elimination. 00: Sampling count = 2 01: Sampling count = 3 10: Sampling count = 4 11: Sampling count = 5
4, 3	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
2 to 0	PRS[2:0]	These bits specify the sampling clock division ratio for digital noise elimination. 000: DNF input clock/1 001: DNF input clock/2 010: DNF input clock/4 011: DNF input clock/8 100: DNF input clock/16 Other than the above: Setting is prohibited.

(7) DNFP02nEDCm — Edge Detection Control Register

This register controls edge detection of channel number m in DNF group number n.

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	NFEN	—	—	DMD[1:0]		—	—	—
Value after reset	0	0	0	0	0	0	0	0
R/W	R/W	R	R	R/W	R/W	R	R	R

Table 2.60 DNFP02nEDCm Register Contents

Bit Position	Bit Name	Function
7	NFEN	This bit enables/disables digital noise elimination. 0: Edge is detected for signals containing digital noise. 1: Edge is detected for signals from which digital noise is eliminated
6, 5	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
4, 3	DMD[1:0]	This bit enables/disables edge detection and sets edge to be detected 00: Edge detection is disabled. 01: Rising edge is detected. 10: Falling edge is detected. 11: Both edges are detected.
2 to 0	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.

(8) DNFP02nEDFm — Edge Detection Flag Register

This register has an edge detection flag and a flag clear bit of channel number m in DNF group number n.

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	EDF	—	—	—	—	—	—	CLED
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R/W

Table 2.61 DNFP02nEDFm Register Contents

Bit Position	Bit Name	Function
7	EDF	This bit holds a result of edge detection based on the edge detection setting for channel number m. This bit is cleared by writing 1 to the CLED bit and continues to hold 1 unless it is cleared. Its state does not change while 1 is held, even if an edge is detected. 0: Valid edge has not been detected. 1: Valid edge has been detected.
6 to 1	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
0	CLED	Writing 1 to this bit clears the status flag of EDF, bit 7. In case of contention between the writing of 1 and a setting source of bit 7, EDF clearing takes priority. Even writing 0 cannot change the state. The read value is always 0.

(9) Setting Flow of Edge Detection DNF

The following shows the procedures to set edge detection DNF.

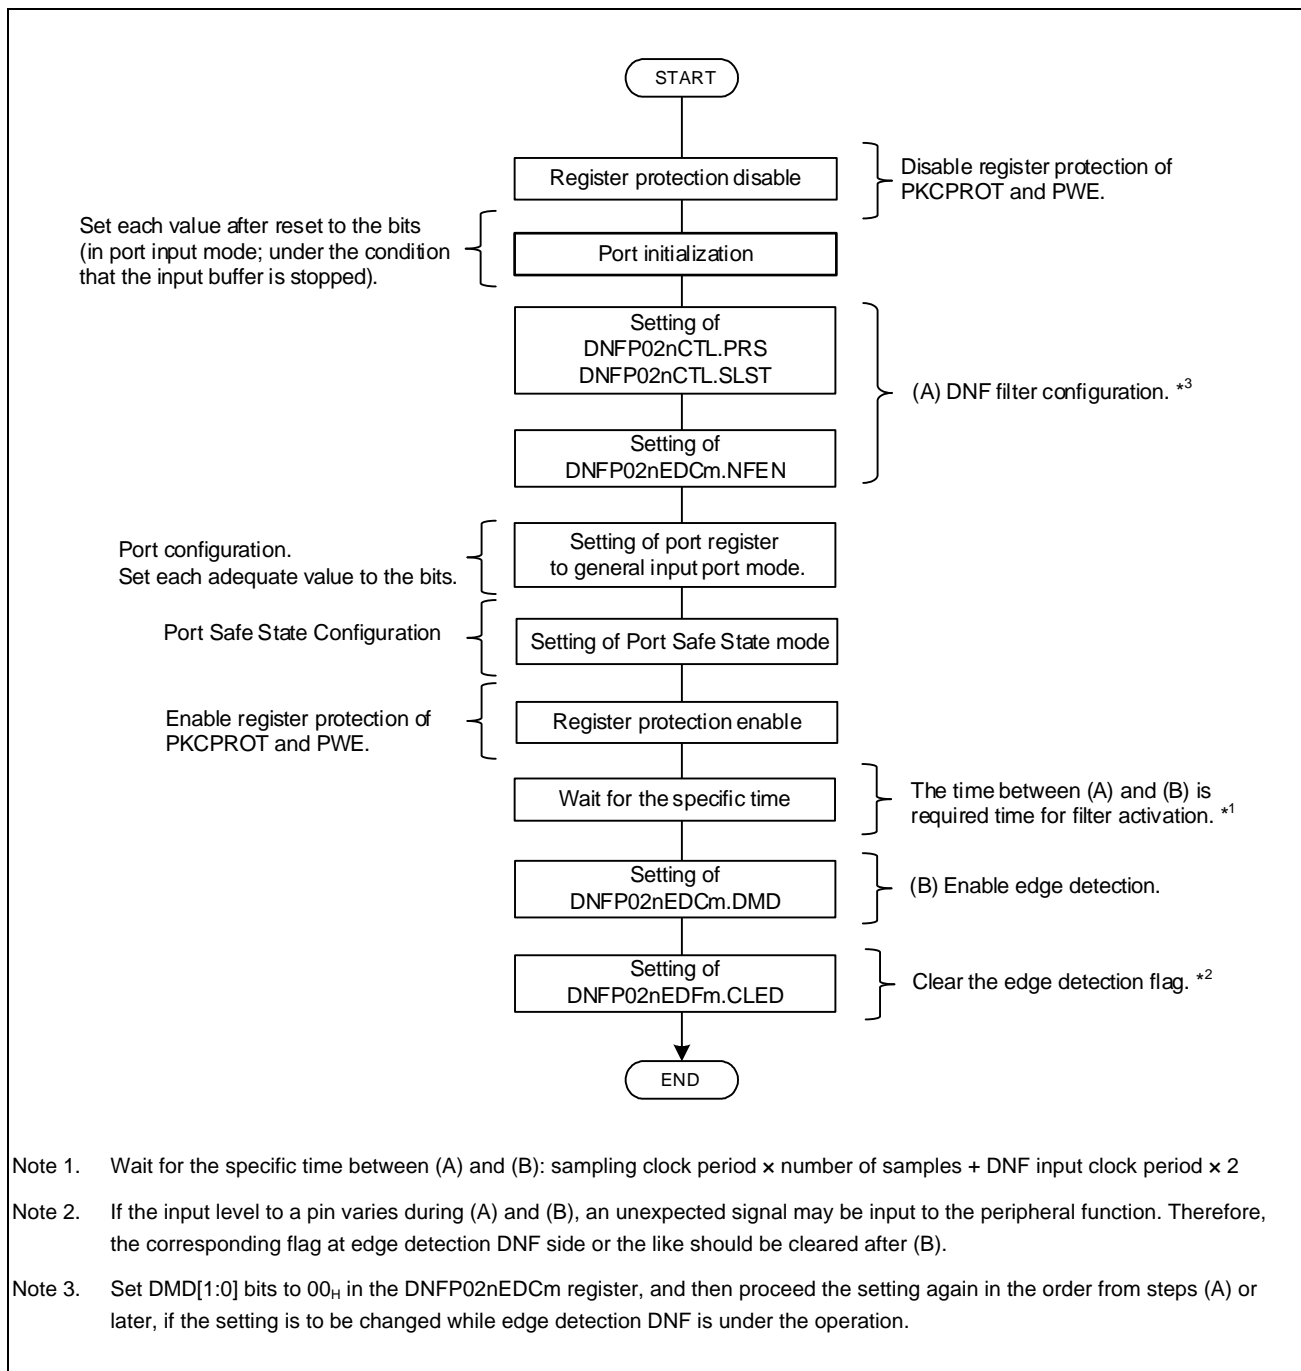

Figure 2.10 Edge Detection DNF Setting Flow

(10) List of Pins on Which an Edge Detection DNF Is Inserted

All port groups are the targets of edge detection DNF insertion. For details, see the following tables.

Table 2.62 DNF Insertion Target Pins (1/7)

2.6.2 Port Safe State Mode

All Port Groups have a Port Safe State Function implemented. Each of these Port Groups has its own Port safe state enable bit that is located in the PSFSCn_m register. When Port safe state trigger signal named ERROROUTZ controlled by the Error Control Module becomes active, the port behavior is changed to the following states.

- Case of PSFSCn_m = 0

The output control still remains. (Port mode or alternative control mode.)

- Case of PSFSCn_m = 1

The output control is changed to Port Safe State mode. The Port register (Pn_m) is disconnected and switched to the Port Safe State Data register (PSFSDn_m), and the Port mode register (PMn_m) is switched to the Port Safe State Output Enable register (PSFSOEn_m) which takes over output enable control.

NOTES

1. Do not set PSFSOEn_m = 1 if the target port is used in input mode.
2. Do not set PSFSOEn_m = 1 and PSFSDn_m = 1 if the target port is used in LVDS output mode.
3. The source of Port safe state trigger signal is an error output signal named ERROROUTZ in the Error Control Module (ECM). It can be controlled by the ECMmESET and ECMmECLR registers. Port safe state mode must be set after the error signal is cleared by the ECMmECLR register. For details, refer to **Section 41.3.3, ECMmECLR — ECM Master/Checker Error Clear Trigger Register (m = M/C)**.
4. When the Port safe state function is enabled for dynamically toggled pins such as the serial communication, these pins may output unexpected signals as normal communication because the state of target pins is fixed as soon as the error has been detected. But in that case, this function can block abnormal output signals immediately by fixing these ports to Port safe state.

In case output level is set to High or Low by using the Port safe state function, the number of pins which can be applied to this function is restricted to 5 pins or less in each group.

(PSFSCn.PSFSCn_m = 1 and PSFSOEn.PSFSoEn_m = 1)

On the other hand, the number of these pins is not restricted if output level is set to Hi-z.

(PSFSCn.PSFSCn_m = 1 and PSFSOEn.PSFSoEn_m = 0)

For each pin group, refer to Note 3 of Section 1.2.6 Output Voltage Characteristics in *RH850/E2x-FCC2 Electrical Characteristics, User's Manual: Hardware*.

2.6.2.1 Block Diagram

The following figure shows an overview of the Port Safe State Function.

Figure 2.11 Block Diagram of Port Safe State

2.6.2.2 Supported Pins

All port groups are the target of the Port Safe State function. (See **Section 2.1.1, Port Group** for the supported port groups). The following table shows a list of pins not subject to the Port Safe State function.

Table 2.63 Pins Not Subject to Port Safe State Function

Category	Pin Name
Reference voltage pins of A/D converters	ADSVREFH, ADSVREFL, A0VREFH, A1VREFH, A2VREFH, A3VREFH
Analog input pins	ANxxx, CANxxxN, CANxxxP, DSANxxxN, DSANxxxP
Pins connected to capacitors	ADSVCL, RAMSVCL
External reset input pins	$\overline{\text{RES_IN}}$
Non-maskable input pins	NMI
Debug control pins	TCK, TDI, TDO, TMS, $\overline{\text{TRST}}$, $\overline{\text{DRDY}}$, $\overline{\text{AURORÉS}}$, CICLEFP, CICLEFN, TODP0, TODN0
Mode setting pins	MD0, MD1
Crystal pins	XTAL, EXTAL
Error output pins	$\overline{\text{ERROROUT_M}}$ *1

Note 1. When Port safe state trigger signal becomes active, the status of $\overline{\text{ERROROUT_M}}$ will be changed to Low output as the Port safe state depends on the ECM setting. Refer to **Section 41, Error Control Module (ECM)** for details.

2.6.2.3 Configuration Flow

The following shows the flow to use Port safe state mode.

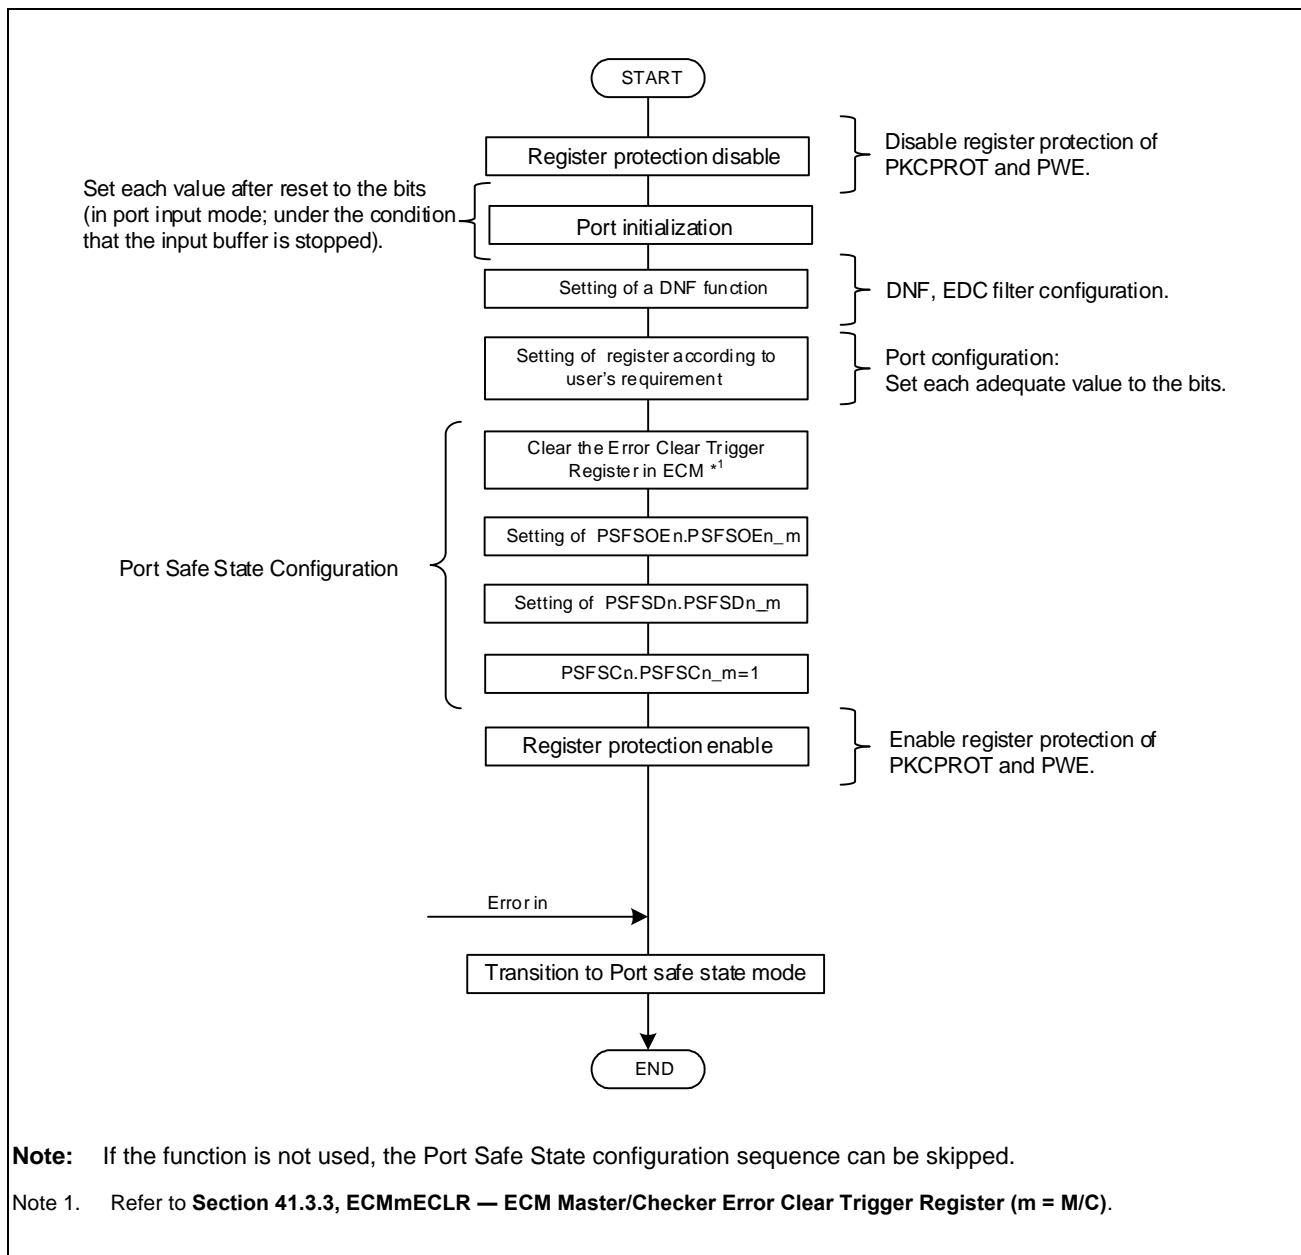

Figure 2.12 Setting Flow of Port Safe State

2.6.3 Virtual Port Function via RHSB (XBAR)

Virtual ports are port groups that are not connected to external pins but are instead connected to internal functions. Port groups P50, P51, P52 and P53 are virtual ports for the XBAR function of RHSB. Configurable output signals are 64 bits in total (each port group has 16 bits x 4 groups), and it is possible to transfer these data serially to other devices via XBAR in the same way as with a port register setting (XBAR function, see **Section 23.6, Cross Bar (XBAR)**).

- The output data (64 bits) of P50, P51, P52 and P53 is transferring to input of XBAR function.
- Output pins of P50, P51, P52 and P53 are connected to XBAR function instead of IO output buffer.
- The data from XBAR function is transferred to RHSB.

2.6.3.1 Block Diagram

The following figure shows the use of coordination with XBAR Function.

Figure 2.13 Block Diagram of Virtual Port Function via RHSB

2.6.4 Virtual Port Function via HSSPI

Virtual ports are port groups that are not connected to external pins but are instead connected to internal functions. Port groups of P54, P55, P56 and P57 are virtual port groups for HSSPI I/F. Their function is to transfer the received serial data from HSSPI I/F to GTM/ATU, as the inverted function of delivering the serial data to XBAR described in **Section 2.6.3, Virtual Port Function via RHSB (XBAR)**.

About HSSPI function, see **Section 28, High Speed Serial Peripheral Interface (HS-SPI)**.

- The data (max 64 bits) from HSSPI is transferred to the input pins of P54, P55, P56 and P57.
- The input pins of P54, P55, P56 and P57 are connected to HSSPI instead of the IO input buffer.
- The data from HSSPI is transferred to GTM/ATU via the port function (pin multiplexed table, see **Section 2.5.2, List of Alternative Functions**).
- The 64 bits of data from HSSPI can be divided by 8 bits per frame.
- For example, the received data is $8*n$ bits ($n = 1, 2, 3, \dots, 8$)

2.6.4.1 Block Diagram

The following figure shows the use of P54, P55, P56 and P57. It may look like that the data for GTM/ATU is from P54, P55, P56 and P57, but in actually, the data is from HSSPI.

Figure 2.14 Block Diagram of Virtual Port Function via HSSPI

2.6.5 Virtual Port Function via Analog

Virtual ports are port groups that are not connected to external pins but are instead connected to internal functions. The target port groups are P41, P42 and P43. This function is to transfer the received serial data from Analog Boundary Flag generator to GTM/ATU, as the inverted function of delivering the serial data to XBAR described in **Section 2.6.3, Virtual Port Function via RHSB (XBAR)**.

About Analog Boundary Flag generator, see **Section 36, Analog to Digital Converter (ADCH)**, **Section 37, Delta-Sigma Analog to Digital Converter (DSADC)** and **Section 38, Cyclic Analog to Digital Converter (CADC)**.

- The data (max 48 bits for E2x-FCC2) from Analog Boundary Flag generator is transferring to input pins of P41, P42 and P43.
- Input pins of virtual ports are connected to Analog Boundary Flag generator instead of IO input buffer.
- The data from Analog Boundary Flag generator is transferred to GTM/ATU via port function (pin multiplexed table, see **Section 2.5.2, List of Alternative Functions**).

2.6.5.1 Block Diagram

The following figure shows the use of virtual ports. It may look like the data for GTM/ATU is from a virtual port, but actually, the data is from the analog module.

Figure 2.15 Block Diagram of Virtual Port Function via Analog

2.6.6 Dedicated Analog Pin Table

2.6.7 ICUM Select Function

For the ICUM select function, ports are controlled by ICUM even if the port is in alternative mode or Port safe state mode. Then no matter what function is selected for the port, the ICUM selection function is always active. The control from ICUM is asynchronous to the clock bus. The priority of the ICUM select function is higher than GPIO control and IP control, but lower than reset.

ICUM select function target pin: P22_11.

For information on how to use the ICUM function, refer to the separate User Manual: *Intelligent Cryptographic Unit*.

Figure 2.16 Block Diagram of ICUM Function

2.6.8 RES_OUT Function

2.6.8.1 Overview

This product has a $\overline{\text{RES_OUT}}$ pin to handshake with a debugger. The behavior of this signal's output can be selected by using an Option Byte as follows. For detailed information about Option Bytes, refer to the **Section 44, Basic Hardware Protection (BHP)**.

(1) Option Byte PFC_RESO_CFG = 1

- $\overline{\text{RES_OUT}}$ pin is assign P27 group (P27_0 only) supported with output in order to handshake to debugger only.
- This port setting is configurable as a high/low output with push-pull and open drain modes that are the same as other port. However, all of the P27 registers are protected by a key code register.
- The output signal is low when reset factor (see **Section 2.1.5, Reset Sources** for details) is asserted. It will hold the low output until port setting is changed by user SW command.
- This pin shows the internal reset state, so can be used as handshake for external devices like debugger.

The following figure shows the use of RES_OUT function.

Figure 2.17 Timing Chart for RES_OUT Function for Each Reset Factor (PFC_RESO_CFG = 1).

(2) Option Byte PFC_RESO_CFG = 0

- $\overline{\text{RES_OUT}}$ pin is not assigned to a port group, so the port setting is not configurable.
- The output signal is low when reset factor (see **Section 2.1.5, Reset Sources** for details.) is asserted. And the terminal state is automatically changed from low to high after internal reset.

The following figure shows the use of $\overline{\text{RES_OUT}}$ function.

Figure 2.18 Timing Chart for $\overline{\text{RES_OUT}}$ Function for Each Reset Factor (PFC_RESO_CFG = 0).

2.7 List of Pin Function

2.7.1 Overview

Table 2.65 list the functions of each pin. “✓” indicates that the pin support the relevant function and “—” indicates that it does not. Do not use pins that do not support the relevant functions.

Note 1. These functions are multiplexed via virtual ports, so they can only be used in input mode. (See **Section 2.5.2, List of Alternative Functions** for details.) About the pins that support port groups, refer to **Section 2.1.1, Port Groups**.

2.8 Pins Status

See the description of the pin states in **Section 10, Reset Controller** for the definition of each reset state.

The following table describes the condition definition for pin states, such as Condition A is External Reset State.

		$\overline{\text{TRST}}$	I (pull-down)	I (pull-down)	I (pull-down)	I (pull-down)	I (pull-down)	I (pull-down)
		$\overline{\text{DRDY}}$ / JP0_5	Z	Z	Z	Z	Z	Z

Note: I: Input

O: Output

H: Output High

L: Output Low

Z: High impedance

Pull-up: On-chip pull-up resistor

Pull-down: On-chip pull-down resistor

Note: The port pin's input structures is designed in a way that during reset and after reset, unconnected pins do not tend to oscillate, draw excessive current, or exhibit unintended crosscoupling effects on other port pins.

Note 1. Boundary Scan I/F mode is not support with Serial Programming Mode.

Note 2. This condition is support with CAN/CAN-FD debug I/F mode in Serial Programming Mode only (About CAN/CAN-FD mode, see **Section 5, Operating Modes** for details.).

Note 3. When the Option Byte PFC_RESO_CFG = 0, $\overline{\text{RES_OUT}}$ pin output is changed to high after internal reset release. (See **Section 2.6.8, RES_OUT Function** for details.)

Note 4. $\overline{\text{DRDY}}$ pin status depends on the NEXUS/JTAG state. WAIT state is high, and IDLE state is low.

Note 5. $\overline{\text{ERROROUT_M}}$ pin status depends on the output signal from Error Control Module. (See **Section 41, Error Control Module (ECM)** for details.)

Note 6. The condition M is the same as the previous condition just before system reset 2 is asserted.

Note 7. When the status is changed from condition F, $\overline{\text{DRDY}}$ pin depends on the NEXUS/JTAG state. WAIT state is high, and IDLE state is low.

Note 8. When the status is changed from condition E or F or M, TDO and $\overline{\text{DRDY}}$ pins are the same as the previous condition.

2.9 Handling of The Unused Pins

Examples of the handling of unused pins are listed in following table.

Table 2.69 Examples of the Handling of Unused Pins (1/3)

Classification	Pin Name	IO	Examples of Handling of Unused Pins	On-chip Pull-down/Pull-up Resistor
Clock	XTAL	O	This pin can be left open.	None
	EXTAL	I	(This pin will always be used.)	None
System control	RES_IN	I	(This pin will always be used.)	This pin is equipped with an internal pull-down resistor.
	RES_OUT	O	This pin can be left open.	None
	MD0	I	(This pin will always be used.)	This pin is equipped with an internal pull-down resistor.
	MD1	I	This pin must be connected to VSS via individual resistor.	This pin is equipped with an internal pull-down resistor.
Interrupt	NMI	I	This pin must be connected to VSS via individual resistor.	This pin is equipped with an internal pull-down resistor.
ECM	ERROROUT_M	O	This pin can be left open.	None
General input/output port	Pn_m	IO	<p>[Input mode] These pins can be left open and the settings are to disable input (values after reset are PMCn_m = 0, PMn_m = 1, PIBCn_m = 0) These pins can be left open and the settings are to enable on-chip pull-up/pull-down resistors (use PUn_m, PDn_m) These pins must be connected to power supply or ground of each pin via individual resistor.</p> <p>[Output mode] These pins can be left open.</p>	The pins are equipped with internal pull-up or pull-down resistors which can be enabled by register settings.
ADC, DS-ADC	Analog input-only AN0xx, AN1xx, AN2xx, AN3xx (excluding AN00x, AN01x, AN20x, AN21x)	I	These pins can be left open.	None
	Alternative analog input and digital input. AN00x, AN01x, AN20x, AN21x	I	These pins can be left open with the settings are to disable input (values after reset are PMCn_m = 0, and PIBCn_m = 0)	None

Table 2.69 Examples of the Handling of Unused Pins (2/3)

Classification	Pin Name	IO	Examples of Handling of Unused Pins	On-chip Pull-down/Pull-up Resistor	
Debug	AUORES ^{*1}	I	Refer to Section 2.9.1, Handling of Thermal Area Pins.	Refer to Section 2.9.1, Handling of Thermal Area Pins.	
	CICREFP ^{*1}	I	Refer to Section 2.9.1, Handling of Thermal Area Pins.	Refer to Section 2.9.1, Handling of Thermal Area Pins.	
	CICREFN ^{*1}	I	Refer to Section 2.9.1, Handling of Thermal Area Pins.	Refer to Section 2.9.1, Handling of Thermal Area Pins.	
	TODP0 ^{*1}	O	Refer to Section 2.9.1, Handling of Thermal Area Pins.	Refer to Section 2.9.1, Handling of Thermal Area Pins.	
	TODN0 ^{*1}	O	Refer to Section 2.9.1, Handling of Thermal Area Pins.	Refer to Section 2.9.1, Handling of Thermal Area Pins.	
	TDI/LPDI/JP0_0/FPDR	TDI	I	This pin can be left open. If it is connected, this pin must also be connected to VCC via an individual resistor	This pin is equipped with an internal pull-up resistor.
		LPDI	I	This pin can be left open. If it is connected, this pin must also be connected to VCC via an individual resistor	This pin is equipped with an internal pull-up resistor.
		JP0_0/FPDR	I	Do not select the JP0_0/FPDR pin function if the pin is not use in use.	(The pins are equipped with internal pull-up or pull-down resistors which can be enabled by register settings.) The internal pull-up resistor is enabled in booting up by the boot firmware.
	TDO/LPDO / JP0_1/FPDT	TDO	O	This pin can be left open	None
		LPDO	O	This pin can be left open	None
		JP0_1/FPDT	O	Do not select the JP0_1/FPDT pin function if the pin is not use in use.	(The pins are equipped with internal pull-up or pull-down resistors which can be enabled by register settings.) None
	TCK/LPDCLKI/JP0_2/FPCK	TCK	I	This pin can be left open. If it is connected, this pin must also be connected to VCC via an individual resistor	This pin is equipped with an internal pull-up resistor.
		LPDCLKI	I	This pin can be left open. If it is connected, this pin must also be connected to VCC via an individual resistor	This pin is equipped with an internal pull-up resistor.
		JP0_2/FPCK	I	Do not select the JP0_2/FPCK pin function if the pin is not use in use.	(The pins are equipped with internal pull-up resistors which can be enabled by register settings.) None
	TMS / JP0_3	TMS	I	This pin can be left open. If it is connected, this pin must also be connected to VCC via an individual resistor	This pin is equipped with an internal pull-up resistor.
TRST / LPDRST		I	This pin must be connected to VSS via individual resistor.	This pin is equipped with an internal pull-down resistor.	
DRDY / LPDCLKO / JP0_5	DRDY	O	This pin can be left open.	None	
	LPDCLKO	O	This pin can be left open.	None	
NC	NC	—	This pin must be open and soldering with printed circuit board is recommended.	None	
VSS(NC)	VSS(NC)	—	Connecting this pin to VSS is recommended from the point of view of power stabilization. (It is connected to VSS in PKG.) However, it can be left open. Soldering with printed circuit board is recommended even if open.	None	
A0VSS(NC)	A0VSS(NC)	—	Connecting this pin to A0VSS is recommended from the point of view of power stabilization. (It is connected to A0VSS in PKG.) However, it can be left open. Soldering with printed circuit board is recommended even if open.	None	
VDD(NC)	VDD(NC)	—	Refer to Section 2.9.1, Handling of Thermal Area Pins.	Refer to Section 2.9.1, Handling of Thermal Area Pins.	

Table 2.69 Examples of the Handling of Unused Pins (3/3)

Classification	Pin Name	Examples of Handling of Unused Pins	On-chip Pull-down/Pull-up Resistor
Power supply	E0VCC/E1VCC/E2VCC	(This pin will always be used.)	—
	SYSVCC	(This pin will always be used.)	—

A1VREFH: This pin must be connected to E0VCC. A2VCC: This pin must be connected to E0VCC. A2VSS: This pin must be connected to VSS. A2VREFH: This pin must be connected to E0VCC. A3VCC: This pin must be connected to E0VCC. A3VSS: This pin must be connected to VSS. A3VREFH: This pin must be connected to E0VCC.</p>	—	

Note: For the correspondences between the various pins and the power supply or ground, see *the RH850/E2x-FCC2 Electrical Characteristics, User's Manual: Hardware.*

Note: Use a resistor with a value of at least 1 kΩ for externally pulling pins up or down.

Note: Take care regarding the resistive division effect when using an external resistor to pull up or pull down a pin that is equipped with an internal pull-up or pull-down resistor.

Note 1. The pin is implemented only in E2x-FCC2.

2.9.1 Handling of Thermal Area Pins

2.9.1.1 The Case of using Emulation/Instrumentation RAM (SYSVCC and EMUVDD are always supplied)

Emulation/Instrumentation RAM is available.

Emulation/Instrumentation RAM can be retained when power-off standby (see **Section 16.2.1, Power Off Standby Mode** for details).

Aurora I/F is can not be used ($\overline{\text{AURORES}} = \text{VSS}$).

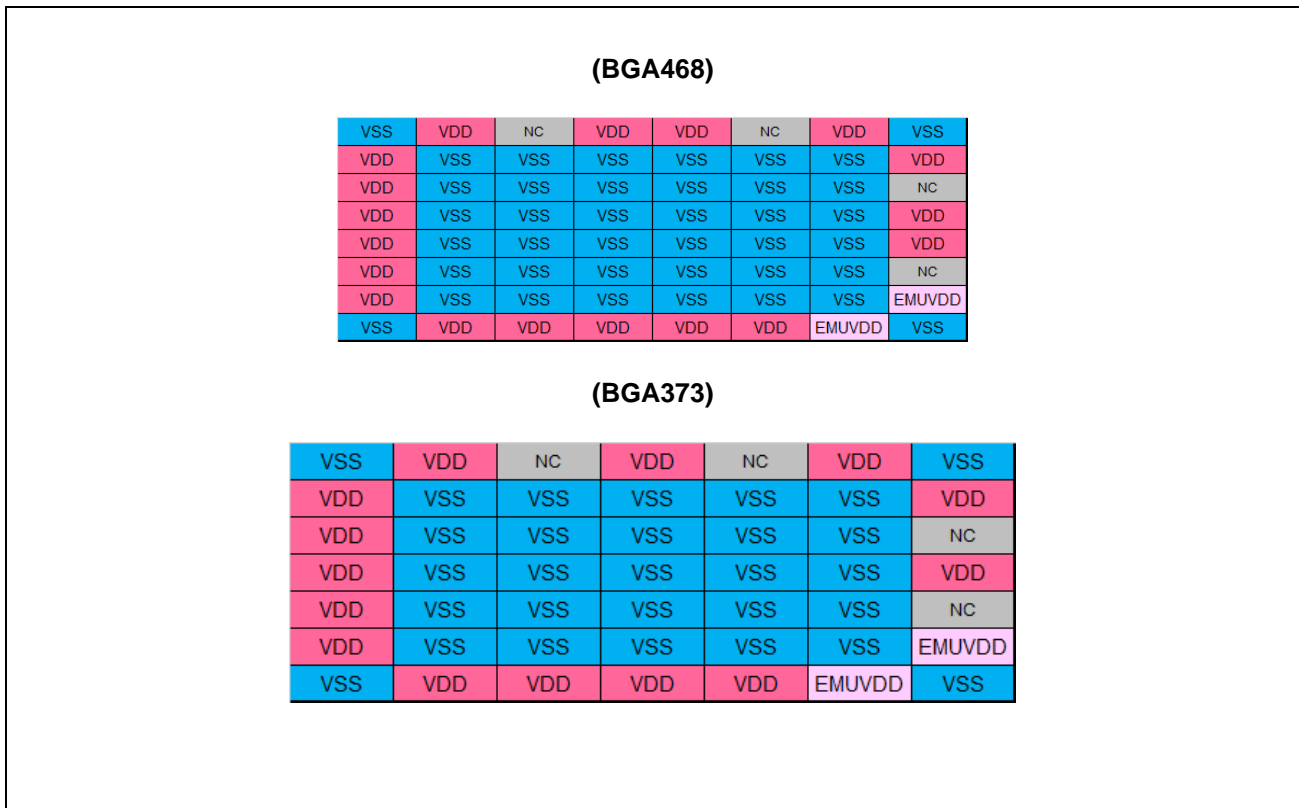

Figure 2.20 Thermal Area Pin Connection Diagram

Table 2.70 Example of the Handling of Unused Pins for Thermal Area

Classification	Pin Name	Debug tool is used.	Debug tool is not used.*1	On-chip Pull-down / Pull-up Resistor
Power supply	EMUVDD	(This pin will always be used.)	This pin can be left open.	—

Note 1. It indicate that Emulation/Instrumentation RAM is not need to be retained. If some of these pins are left open, then all of these pins must be left open.

2.9.1.2 The Case of using Emulation/Instrumentation RAM and Aurora I/F (EMUVCC and EMUVDD are always supplied)

Emulation/Instrumentation RAM and Aurora I/F is available.

Emulation/Instrumentation RAM can be retained when Emulation/Instrumentation RAM and Aurora Retention Mode. (see **Section 16.2.2, Emulation/Instrumentation RAM and Aurora Retention Mode** for details).

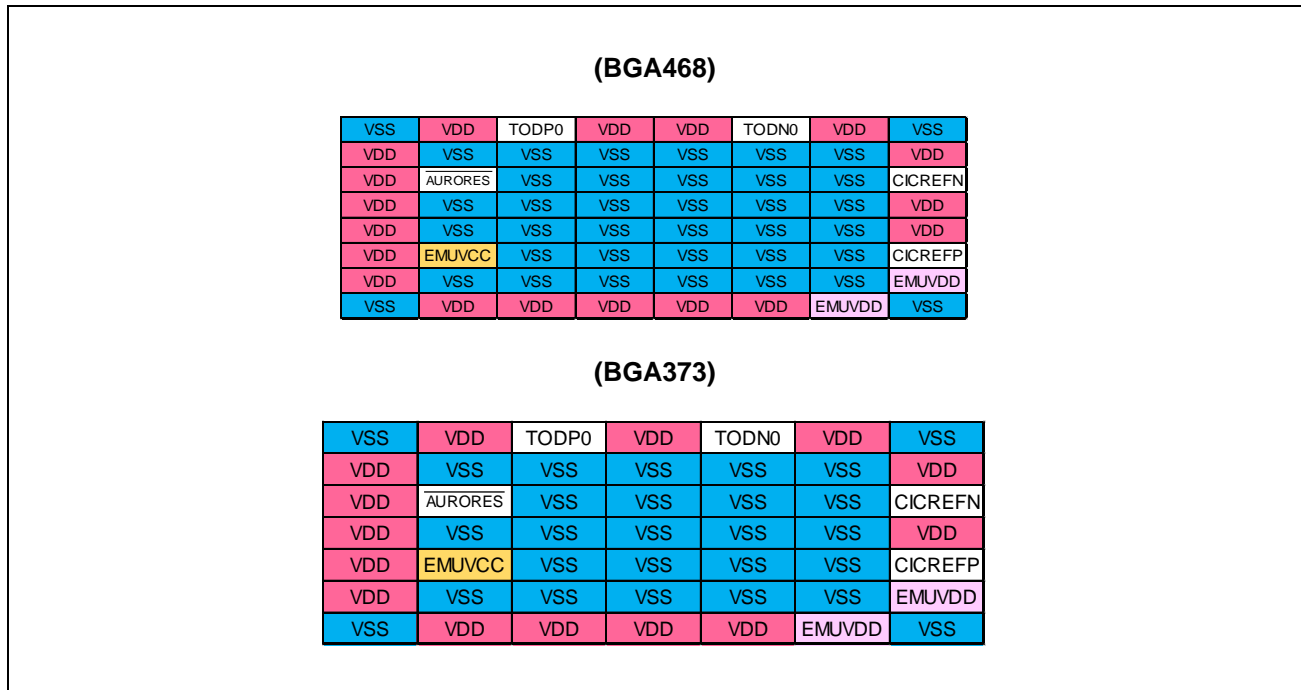

Figure 2.21 Thermal Area Pin Connection Diagram

Table 2.71 Examples of the Handling of Unused Pins for Thermal Area

Classification	Pin Name	Debug tool is used.	Debug tool is not used. *1	On-chip Pull-down / Pull-up Resistor
Debug	AUORES	(This pin will always be used.)	This pin can be left open.	This pin is equipped with an internal pull-down resistor.
	CICREFP	(This pin will always be used.)	This pin can be left open.	—
	CICREFN			
	TODP0 TODNO			
Power supply	EMUVCC	(This pin will always be used.)	This pin can be left open.	—
	EMUVDD	(This pin will always be used.)	This pin can be left open.	—

Note 1. It indicate that AURORA I/F is not used and Emulation/Instrumentation RAM is not need to be retained. If some of these pins are left open, then all of these pins must be left open.

2.9.1.3 The Case of using Emulation/Instrumentation RAM (EMUVCC and EMUVDD are always supplied)

Emulation/Instrumentation RAM is available.

Emulation/Instrumentation RAM can be retained when Emulation/Instrumentation RAM and Aurora Retention Mode. (see **Section 16.2.2, Emulation/Instrumentation RAM and Aurora Retention Mode** for details).

Aurora I/F can not be used ($\overline{\text{AURORES}} = \text{VSS}$).

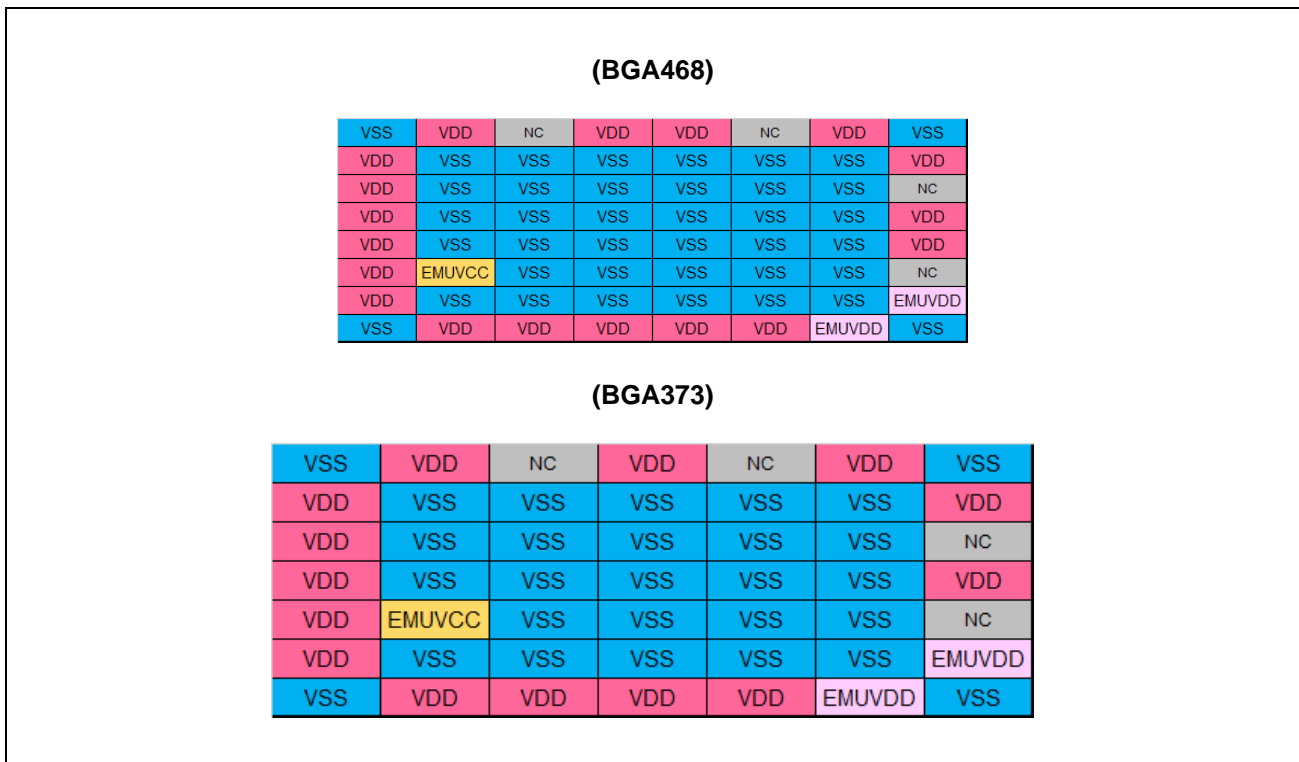

Figure 2.22 Thermal Area Pin Connection Diagram

Table 2.72 Examples of the Handling of Unused Pins for Thermal Area

Classification	Pin Name	Debug tool is used.	Debug tool is not used.*1	On-chip Pull-down / Pull-up Resistor
Power supply	EMUVCC	(This pin will always be used.)	This pin can be left open.	—
	EMUVDD	(This pin will always be used.)	This pin can be left open.	—

Note 1. It indicate that the Emulation/Instrumentation RAM and Aurora configuration are not need to be retained. If some of these pins are left open, then all of these pins must be left open.

2.9.1.4 The Case of Pin Assignment for Mass Production

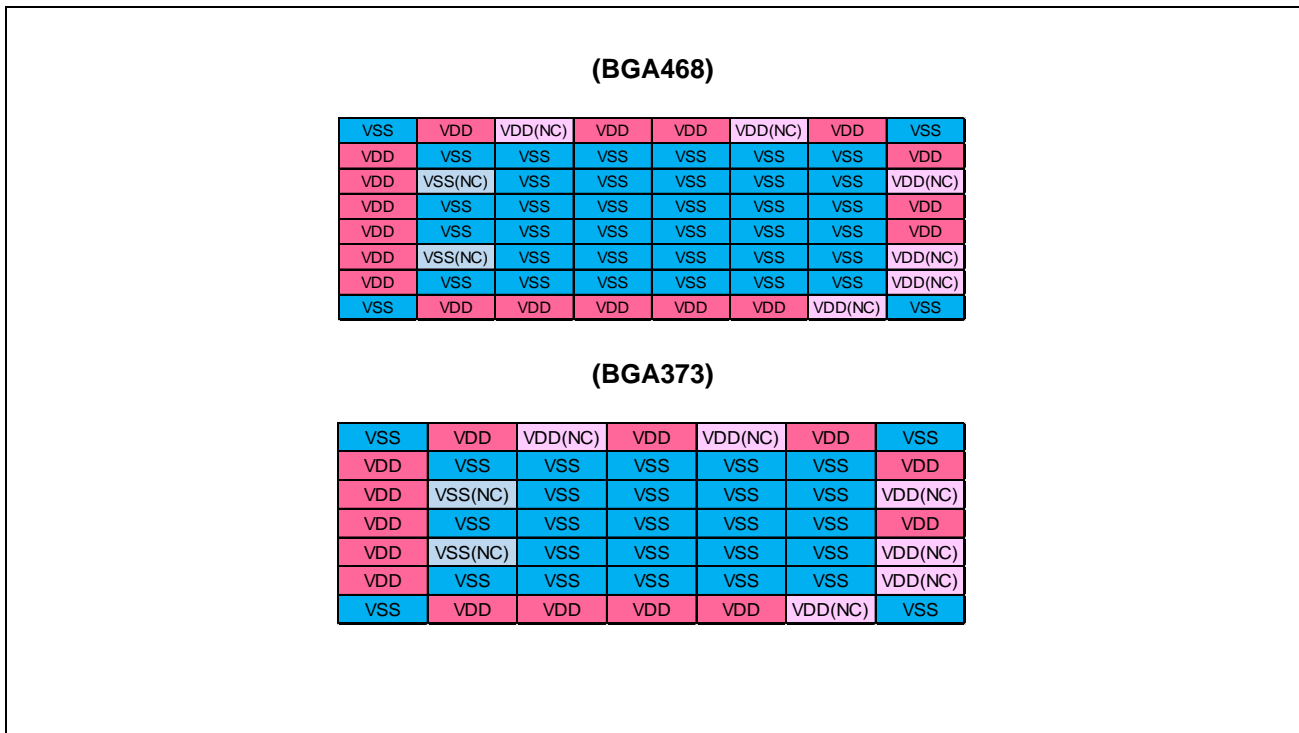

Figure 2.23 Thermal Area Pin Connection Diagram

Table 2.73 Examples of the Handling of Unused Pins for Thermal Area

Classification	Pin Name	Examples of Handling of Unused Pins.	On-chip Pull-down / Pull-up Resistor
Power supply	VDD(NC)	Connecting this pin to VDD is recommended from the point of view of power stabilization. (It is connected to VDD in PKG.) However, it can be left open. Soldering with printed circuit board is recommended even if open.	—
	VSS(NC)	Connecting this pin to VSS is recommended from the point of view of power stabilization. (It is connected to VSS in PKG.) However, it can be left open. Soldering with printed circuit board is recommended even if open.	—

Section 3 CPU System

3.1 Overview

3.1.1 Block Diagram

For the block diagram of the CPU system, see **Figure 1.7** to **Figure 1.9** in **Section 1, Overview**.

The CPU system consists of the following modules.

CPU0 (PE0), CPU1 (PE1), CPU2 (PE2), CPU3 (PE3), CPU4 (PE4), CPU5 (PE5)

The RH850 G4MH core is included as the main CPU. The CPUs also include a checker core for safety assurance (except CPU2 and CPU3).

NOTE

CPU4 and CPU5 are unmounted in E2H.

ICUMD

Refer to *the E2x ICUMD User's Manual*.

Local RAM

Each PE has a high-speed accessible local RAM.

Cluster RAM

The cluster RAM is a mass on-chip RAM that all PEs share. Some areas of this RAM function as the retention RAM.

Code Flash

A mass code flash is included for program storage. PE0, PE1, PE2, PE3, PE4, PE5 and ICUMD share the code flash and they are connected with each other via the code flash interface.

Emulation RAM

This is RAM to emulate the code flash. The programs can be replaced by control from an external tool without rewriting the code flash. It is supported in E2x-FCC2.

Data Flash

This is a flash memory rewritable by the CPU.

P-Bus and H-Bus and I-Bus

Peripheral IPs are connected on P-Bus, H-Bus and I-Bus.

E2x-FCC2: The P-Bus consists of 10 groups, Peripheral Group 0 to 9.

The H-Bus consists of 5 groups, H-Bus Group 0 to 2,4, and 5.

The I-Bus consists of 4 groups, I-Bus Group 0 to 3.

E2UH: The P-Bus consists of 10 groups, Peripheral Group 0 to 9.
The H-Bus consists of 5 groups, H-Bus Group 0 to 2,4, and 5.
The I-Bus consists of 4 groups, I-Bus Group 0 to 3.

E2H: The P-Bus consists of 10 groups, Peripheral Group 0 to 9.
The H-Bus consists of 4 groups, H-Bus Group 0 to 2 and 5.
The I-Bus consists of 4 groups, I-Bus Group 0 to 3.

Refer to each section on peripheral IPs for information on bus groups.

INTC1, INTC2

INTC1 is an interrupt controller exclusive to each PE. INTC2 is a common interrupt controller that all PEs can share, which is able to set the destination PE for binding interrupt requests by the registers.

DMA

Two DMA transfer modules, sDMAC and DTS, are included. DTS includes the checker logic for safety assurance.

3.2 CPU

3.2.1 Core Functions

3.2.1.1 Features

Table 3.1 lists the features of the RH850G4MH core. See *the RH850G4MH User's Manual: Software*.

Table 3.1 Features of the RH850G4MH Core

Item	Feature
CPU	<ul style="list-style-type: none"> • High performance 32-bit architecture for embedded control • 32-bit internal data bus • Thirty-two 32-bit general-purpose registers • RISC-type instruction sets <ul style="list-style-type: none"> – Long/short type load/store instructions – Three-operand instructions – Instruction sets based on C • CPU operating modes <ul style="list-style-type: none"> – User mode, supervisor mode • Address space: 4-GB linear space for both data and instructions • Out-of-Order execution
Coprocessor	<ul style="list-style-type: none"> • A floating point operation coprocessor (FPU) <ul style="list-style-type: none"> – Supports single precision (32-bits) and double precision (64-bits). – Supports IEEE754-compliant data types and exceptions. – Rounding mode: Nearest, 0 direction, $+\infty$ direction, and $-\infty$ direction – Handling of non-normalized numbers: These are truncated to 0, or an exception is reported to comply with IEEE754. • An extended floating-point operation coprocessor (FXU) <ul style="list-style-type: none"> – Supports 4 single-precision (32-bit) parallel operations (FP-SIMD) – Supports IEEE754-compatible data types and exceptions – Rounding modes: Nearest, 0 direction, $+\infty$ direction, and $-\infty$ direction – Handling of non-normalized numbers: These are truncated to 0, or an exception is reported to comply with IEEE754.
Exception/Interrupt	<ul style="list-style-type: none"> • 16-level interrupt priority that can be specified for each channel • Vector selection method that can be selected according to performance requirements and the amount of consumed memory <ul style="list-style-type: none"> – Direct branch method exception vector (direct vector method) – Address-table-referencing indirect branch method exception vector (table reference method) • Support for high-speed context save and restore processing on interrupt by using dedicated instructions (PUSHSP, POPSP) • Support for high-speed context save on interrupt by using the register bank feature • Support for restoration from the register bank using a dedicated instruction (RESBANK)
Memory Management	<ul style="list-style-type: none"> • Memory protection function (MPU): 24 areas settable.
Cache	<ul style="list-style-type: none"> • Instruction cache 16 KB

3.2.2 Processor Model

This CPU defines a processor model that has basic operation functions, registers, and an exception management function.

This section describes the unique features of the processor model of this CPU.

3.2.2.1 CPU Operating Modes

This CPU has two operating modes of the supervisor mode (SV) and the user mode (UM). Whether the system is in supervisor mode or user mode is indicated by the UM bit in the PSW register.

- Supervisor mode (PSW.UM = 0): All hardware functions can be managed or used.
- User mode (PSW.UM = 1): The usable hardware functions are restricted.

(1) Definition of CPU Operating Modes

(a) Supervisor Mode (SV)

All hardware functions can be managed or used in this mode. The system always starts up in supervisor mode after a reset.

(b) User Mode (UM)

This operating mode makes up a pair with the supervisor mode. In user mode, address spaces to which access is permitted by the supervisor and the system registers defined as user resources can be used. Supervisor-privileged instructions cannot be executed and result in exceptions.

Restriction in user mode (PSW.UM = 1)

- Privileged instruction violations due to SV-privileged-instruction operating restrictions
(→ PIE exceptions)

For details about privileged-instruction operating restrictions, see **Section 3.2.2.1(3), CPU Operating Mode and Privileges**.

(2) CPU Operating Mode Transition

The CPU operating mode changes due to three events.

(a) Change due to Acknowledging an Exception

When an exception is acknowledged in user mode, the CPU operating mode changes to privileged mode.

When an exception is acknowledged in supervisor mode, the CPU operating mode remains as is.

(b) Change due to a Return Instruction

When a return instruction is executed, the PSW value is restored according to the value of the corresponding bit backed up to EIPSW and FEPSW.

(c) Change due to a System Register Instruction

The CPU operating mode changes when an LDSR instruction is used to directly overwrite the PSW operating mode bits.

CAUTION

The CPU operating mode cannot be changed in user mode because the higher-order 31 to 5 bits of the PSW register cannot be overwritten while the mode can be changed in supervisor mode. This CPU guarantees that if an LDSR instruction is used to update the PSW register, the new setting will be reflected when the subsequent instruction is executed. However, this CPU does not guarantee that the new setting will be reflected in the memory protection by the MPU for instruction fetch of the subsequent instruction. Therefore, for changing the higher-order 31 to 5 bits of the PSW register, it is recommended to use a return instruction. For details, see **Section 3.2.7.3, Hazard Management after System Register Update**.

(3) CPU Operating Mode and Privileges

In this CPU, the usable functions can be restricted according to usage permission settings for specific resources and the CPU operating mode. Specific instructions (including instructions that update specific system registers) can only be executed in the defined operating mode. The permissions necessary to execute these specific instructions are called “privileges”. In operating modes that do not have privileges, these instructions are not executed and exceptions occur.

This CPU defines the following two types of privileges (usage permission).

- Supervisor (SV) privilege: Privilege necessary for important system resources operation, fatal error processing, and user-mode program execution management
- Coprocessor use permissions: Permissions necessary to use a coprocessor

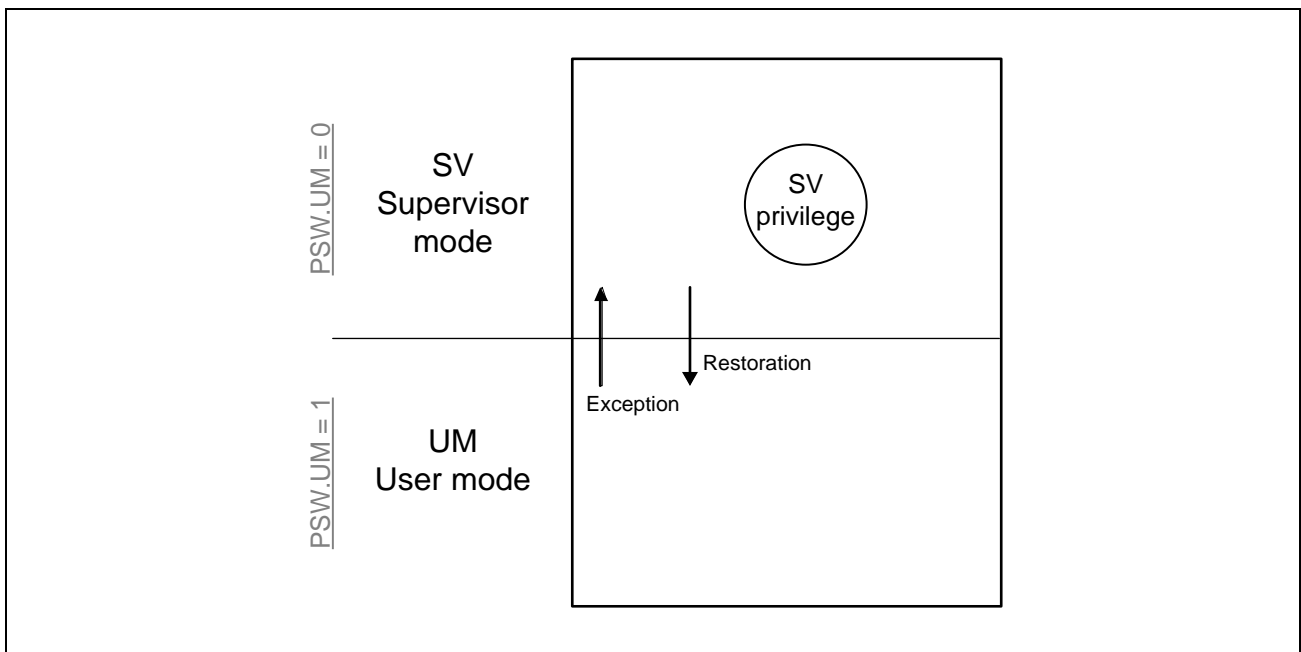

Figure 3.1 CPU Operating Modes and Privileges

(a) Supervisor Privilege (SV Privilege)

The privilege necessary to perform the operation for important system resources, fatal error processing, and user-mode program execution management is called the supervisor privilege (SV privilege). This privilege is available in supervisor mode. The SV privilege is generally necessary to execute instructions used to perform the operation for important system resources, and these instructions are sometimes called SV privileged instructions.

(b) Coprocessor Use Permissions

Regardless of the CPU operating mode, it is possible to specify whether coprocessors can be used.

The CU2 to CU0 bits in the PSW register are used by a supervisor to specify whether coprocessors can be used by each program. If the CU 2 to CU0 bits are not set to 1, a coprocessor unusable exception occurs when the corresponding coprocessor instruction is executed or the system register is accessed.

If no coprocessor is installed, it is not possible to set the corresponding CU bits to 1. The setting of the CU2 to CU0 bits is valid regardless of the CPU operating mode, and, if the supervisor accesses coprocessor system registers, it is necessary to set the CU2 to CU0 bits to enable coprocessor use.

(c) Operation when there is a Privilege Violation

When a privileged instruction is executed by someone who does not have the required privilege, or when a system register for which access permission is specified is accessed by someone who does not have the required permission, a PIE exception or UCPOP exception occurs.

The relationship between instructions that can be executed according to operating mode and use permission are shown in **Table 3.2**, and the relationship between system registers that can be accessed according to operating mode and use permission are shown in **Table 3.3**.

Table 3.2 Operation when Violating Execution Permission

Instruction		PSW				Whether Instructions can be Executed
Execution Permission	Classification	UM	CU2	CU1	CU0	
SV privilege	*1	0	—	—	—	Possible
		1	—	—	—	Not possible (PIE exception occurs)
User	Coprocessor 0 instruction	—	—	—	0	Not possible (UCPOP exception occurs)
		—	—	—	1	Possible
	Coprocessor 1 instruction	—	—	0	—	Not possible (UCPOP exception occurs)
		—	—	1	—	Possible
	Coprocessor 2 instruction	—	0	—	—	Not possible (UCPOP exception occurs)
		—	1	—	—	Possible
Other than above	—	—	—	—	Possible	

Remark: —: 0 or 1

Note 1. Coprocessor instructions with SV privilege are not defined in this CPU.

Table 3.3 Operation When Violating Access Permission to System Registers

System Register		PSW				Whether Instructions can be Executed
Access Permission	Classification	UM	CU2	CU1	CU0	
SV permission	Coprocessor 0 Permission	0	—	—	0	Inaccessible (UCPOP exception occurs)
		0	—	—	1	Accessible
		1	—	—	0	Inaccessible (UCPOP exception occurs)
		1	—	—	1	Inaccessible (PIE exception occurs)
	Coprocessor 1 Permission	0	—	0	—	Inaccessible (UCPOP exception occurs)
		0	—	1	—	Accessible
		1	—	0	—	Inaccessible (UCPOP exception occurs)
		1	—	1	—	Inaccessible (PIE exception occurs)
	Coprocessor 2 Permission	0	0	—	—	Inaccessible (UCPOP exception occurs)
		0	1	—	—	Accessible
		1	0	—	—	Inaccessible (UCPOP exception occurs)
		1	1	—	—	Inaccessible (PIE exception occurs)
	Other than above	0	—	—	—	Accessible
		1	—	—	—	Inaccessible (PIE exception occurs)
UM permission	Coprocessor 0 Permission	—	—	—	0	Inaccessible (UCPOP exception occurs)
		—	—	—	1	Accessible
	Coprocessor 1 Permission	—	—	0	—	Inaccessible (UCPOP exception occurs)
		—	—	1	—	Accessible
	Coprocessor 2 Permission	—	0	—	—	Inaccessible (UCPOP exception occurs)
		—	1	—	—	Accessible
	Other than above	—	—	—	—	Accessible

Remark: —: 0 or 1

(4) Halt State by a HALT Instruction

Executing a HALT instruction brings the CPU core to a HALT state.

A HALT state is terminated when a request for a terminating exception is made to the CPU. At this point, if the conditions for acknowledging the terminating exception are met, control is transferred to the exception handler address. Even if they are not met, the HALT state is terminated when the request is made; therefore, operation is resumed from the instruction following the HALT instruction.

(5) Temporary Halt State by a SNOOZE instruction

A SNOOZE instruction is an instruction to reduce the use of bus bandwidth during a spinlock. After this instruction is completed, the CPU core is brought to a temporary halt state to restrict the execution of the subsequent instructions. Programmers can avoid the unnecessary use of bus bandwidth that results from short-term repetition of a locking process, by inserting this instruction into a spinlock loop.

A temporary halt state is terminated if any of the following conditions is met:

- After the time specified by the SNZCFG register elapsed, the execution of the subsequent instructions is resumed.
- The occurrence of a terminating exception causes control to be transferred to the exception handler address. If the conditions for acknowledging the exception are not met, execution is resumed from the instruction following the SNOOZE instruction. Also, if the exception is acknowledged, the instruction following the SNOOZE instruction is interrupted, and the PC restored indicates the instruction following the SNOOZE instruction.

3.2.2.2 Instruction Execution

The instruction execution flow of this CPU is shown below.

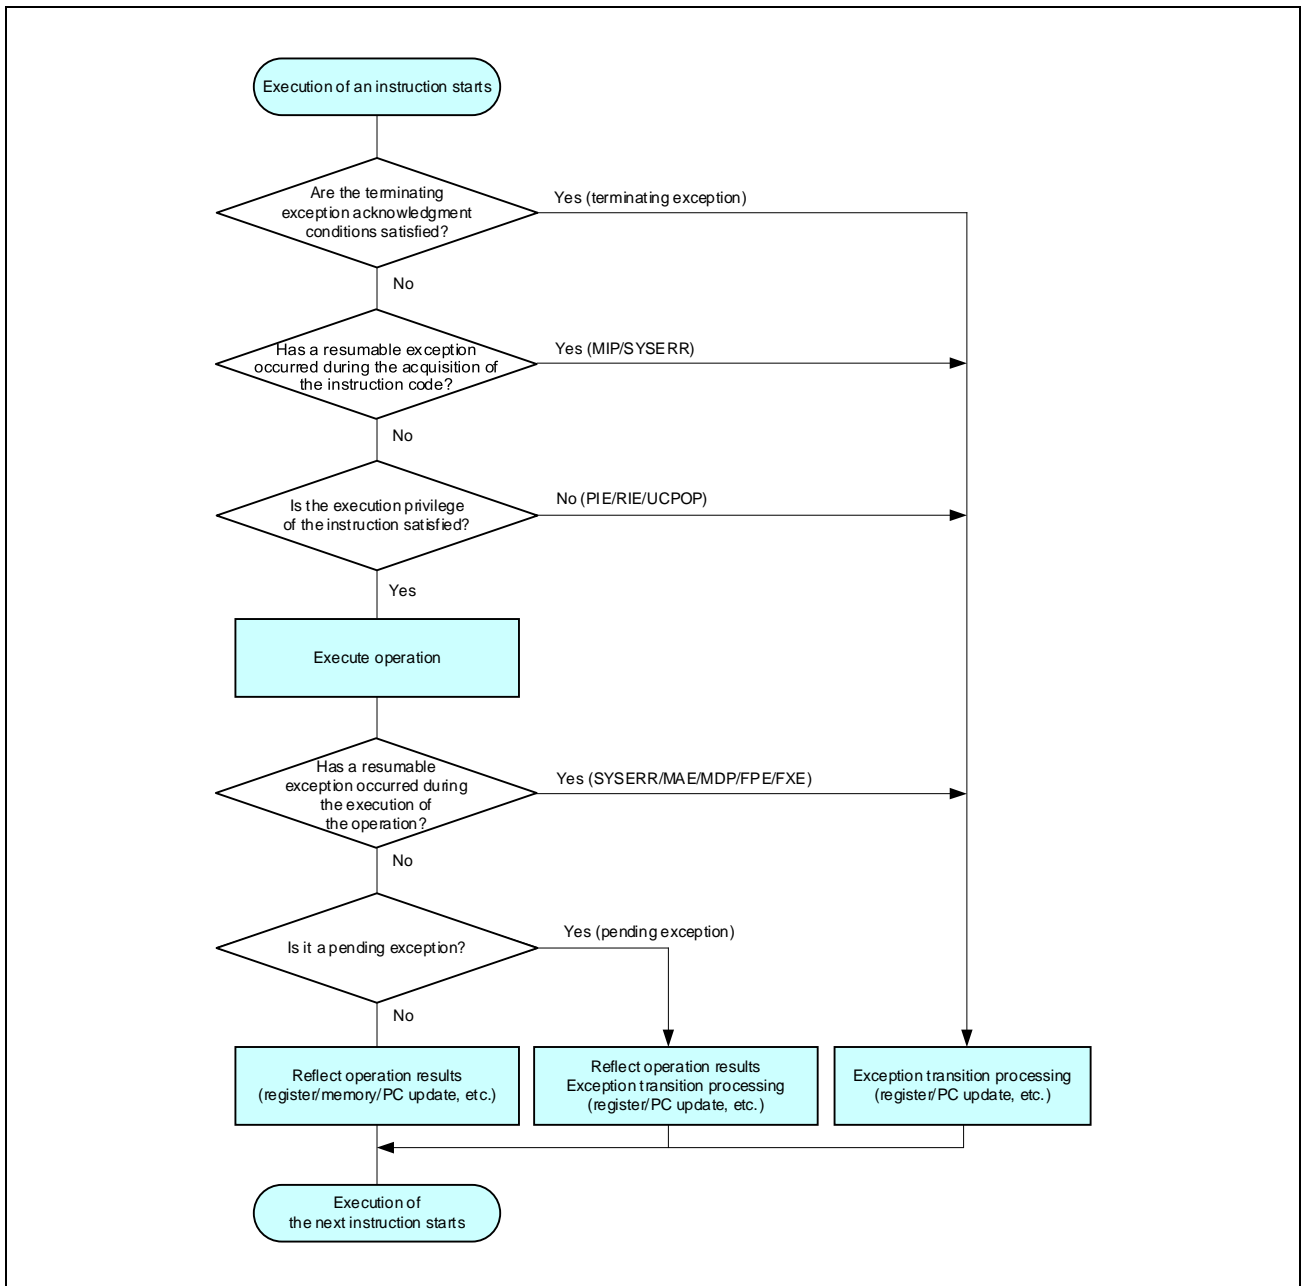

Figure 3.2 Instruction Execution Flow

If terminating exceptions can be acknowledged, if an exception is detected during the acquisition of instruction code, or if the execution privilege of the instruction is not satisfied, an exception occurs before the instruction is executed. If a resumable exception occurs while the CPU is executing the operation, it interrupts the execution of the operation and acknowledges the exception. In these cases, the result of instruction operation is, in principle, not reflected in registers or memory and the CPU retains its state that is established before executing the instruction.*¹

For a pending exception such as a software exception, the exception is acknowledged after the result of instruction execution has been reflected.

For details of the types of exceptions, refer to **Section 3.2.2.3, Exceptions and Interrupts**.

Note 1. If an exception is acknowledged during the execution of the following instructions, intermediate results may be applied to memory or general-purpose registers. However, SP/EP is not updated.

- PREPARE, DISPOSE, PUSHSP, POPSP

3.2.2.3 Exceptions and Interrupts

Exceptions and interrupts are exceptional events that cause the program under execution to branch to another program. Exceptions and interrupts are triggered by various sources, including interrupts from peripherals and program abnormalities.

For details, see **Section 3.2.2.3, Exceptions and Interrupts**.

(1) Types of Exceptions

The exceptions of this CPU are divided into the following three types according to the purpose of the exceptions.

- Terminating exception
- Resumable exception
- Pending exception

(a) Terminating Exception

A terminating exception is an exception that is acknowledged by interrupting an instruction before the execution of the operation for the instruction. Terminating exceptions include interrupts, etc.

This type of exceptions, such as an interrupt or hardware error, start another program irrelevant to the currently processed program.

(b) Resumable Exception

A resumable exception is an exception that occurs during the execution of the operation for an instruction and that is acknowledged without the completion of the instruction. It is also referred to as a precise exception because it is precisely acknowledged without the completion of the relevant instruction or the execution of the subsequent instruction.

Unlike a terminating exception, a resumable exception occurs during the execution of an instruction, and cancel the execution of the instruction, and so it allows the instruction to be executed again after exception handling. Therefore, it is possible to perform complex memory management while maintaining the consistency of the logical operation of programs, by executing the same instruction again after appropriate configuration by exception handling.

(c) Pending Exception

A pending exception is an exception that occurs as a result of the execution of the operation for an instruction, and that is acknowledged after the completion of the instruction. Pending exceptions include software exceptions, etc.

The occurrence of a pending exception is defined as a normal operation of an instruction; therefore, unlike a resumable exception, a pending exception normally completes the instruction that caused it, and never re-executes the instruction. This exception is intended mainly for use in call gates, for example, for calling a management program.

(2) Exception Level

In this CPU, if an exception with a high degree of urgency occurs while another exception is being processed, the urgent exception will be processed. To make it possible to return to the interrupted exception handling after acknowledging the urgent exception, even if the context had not been saved to the memory, exception causes are managed in the following two hierarchical levels.

- EI level exception
- FE level exception

EI level exceptions are used for processing such as regular user processing, interrupt servicing, and OS processing. FE level exceptions are used to enable interrupts with a high degree of urgency for the system or exceptions from the memory management function that might occur during OS processing to be acknowledged even while an EI level exception is being processed.

3.2.2.4 Coprocessors

In this CPU, single-precision and double-precision floating-point unit (FPU) and extended floating-point operation unit (FXU) are incorporated. Note that these coprocessors may not be available depending on the specification of the product.

(1) Coprocessor Use Permissions

To execute a coprocessor instruction, permission to use the corresponding coprocessor instruction is necessary. Coprocessor use permissions are specified by the PSW.CU2 to PSW.CU0 bits, and, if an attempt is made to execute an instruction for which the corresponding coprocessor use permission is cleared to 0, a coprocessor unusable exception (UCPOP) occurs.

In the following cases, the values of the PSW.CU2 to CU0 bits are fixed at 0 and cannot be changed.

- Coprocessor functions are not incorporated in the product
- Coprocessor functions are made unavailable according to the functions of the product

(2) Correspondences between Coprocessor Use Permissions and Coprocessors

This CPU defines coprocessor use permissions to control the availability of the coprocessor for each program during CPU operation. There are three coprocessor use permissions (CU0 to CU2), and their correspondences with the coprocessors are shown in the following table. This CPU does not have a coprocessor function with the coprocessor use permission CU2. The coprocessor use permission CU2 is a function reserved for future CPUs that have compatibility with this CPU.

Table 3.4 Correspondences between Coprocessor Use Permissions and Coprocessors

Coprocessor Use Permission	Coprocessor	Exception Cause Code
CU0	Single-precision FPU	80 _H
	Double-precision FPU	
CU1	FXU	81 _H
CU2	Reserved	82 _H

(3) Coprocessor Unusable Exceptions

A coprocessor unusable exception occurs if an attempt is made to execute a coprocessor instruction or access a system register of the coprocessor without having the corresponding coprocessor use permission (PSW.CUn = 0).

For details about the opcodes of the coprocessor instructions, see *the RH850G4MH User's Manual: Software*. For details about the system registers of the coprocessors, see **Section 3.2.3.4, FPU Function Registers** and **Section 3.2.3.5, FXU Function Registers**.

If the register bank function is used, the FPSR register, which is a system register of the FPU, is accessed when the automatic context saving and the RESBANK instruction is executed. In this case, even if the coprocessor use permission is not given (PSW.CU0 = 0), a coprocessor unusable exception does not occur.

(4) System Registers

Some coprocessor functions have system registers as the part of their functions. The coprocessor use permission is necessary to access the system register of a coprocessor function. For some system registers, the supervisor privilege (SV privilege) is necessary in addition to the coprocessor use permission.

For details about the permissions necessary to access system registers, see **Section 3.2.2.5, Registers**.

3.2.2.5 Registers

This CPU defines program registers (general-purpose registers and the program counter PC) and system registers for controlling the status and storing exception information.

(1) Program Registers

The program registers include general-purpose registers (r0 to r31) and the program counter (PC).

Table 3.5 Program Registers

Category	Access Permission	Name
Program counter	UM	PC
General-purpose registers	UM	r0-r31

Note: Access to the registers with UM (user mode) access permission is always allowed.

For details about program registers, see **Section 3.2.3.1, Program Registers**.

(2) System Registers

System registers are placed in dedicated address spaces defined based on two types of address information: selection ID and register number. Up to 32 selection ID can be defined, and one selection ID includes up to 32 system registers. Therefore, up to 1024 system registers can be defined in the address spaces for system registers. Basically this CPU allocates selection ID as shown below:

- Selection ID 0 to 3: Registers related to basic functions
- Selection ID 4 and 5: Registers related to the memory management function
- Selection ID 10 and 11: Registers related to functions expanded from the legacy architecture
- Selection ID 12 and 13: Registers related to this CPU specific hardware functions
- Other ID: Reserved for future expansion of CPUs compatible with this CPU

For details about system registers, see the relevant sections in **Section 3.2.3, Register Set**.

(3) Register Updating

There are several methods used to update registers. Normally, no particular restrictions apply when updating register by using an instruction. However, when updating registers by using the following instructions, some restrictions might apply, depending on the operating mode.

- LDSR
- STSR

(a) LDSR and STSR

The LDSR and STSR instructions can access all the system registers.

However, if a system register is accessed without the proper permission, a PIE exception or UCPOP exception might occur. For details about the access permission for each register, see the description of system registers in **Section 3.2.3, Register Set**. For details about behaviors when a privilege violation occurs, see **Section 3.2.2.1(3), CPU Operating Mode and Privileges**.

Figure 3.3 shows the flow of executing the LDSR and STSR instructions.

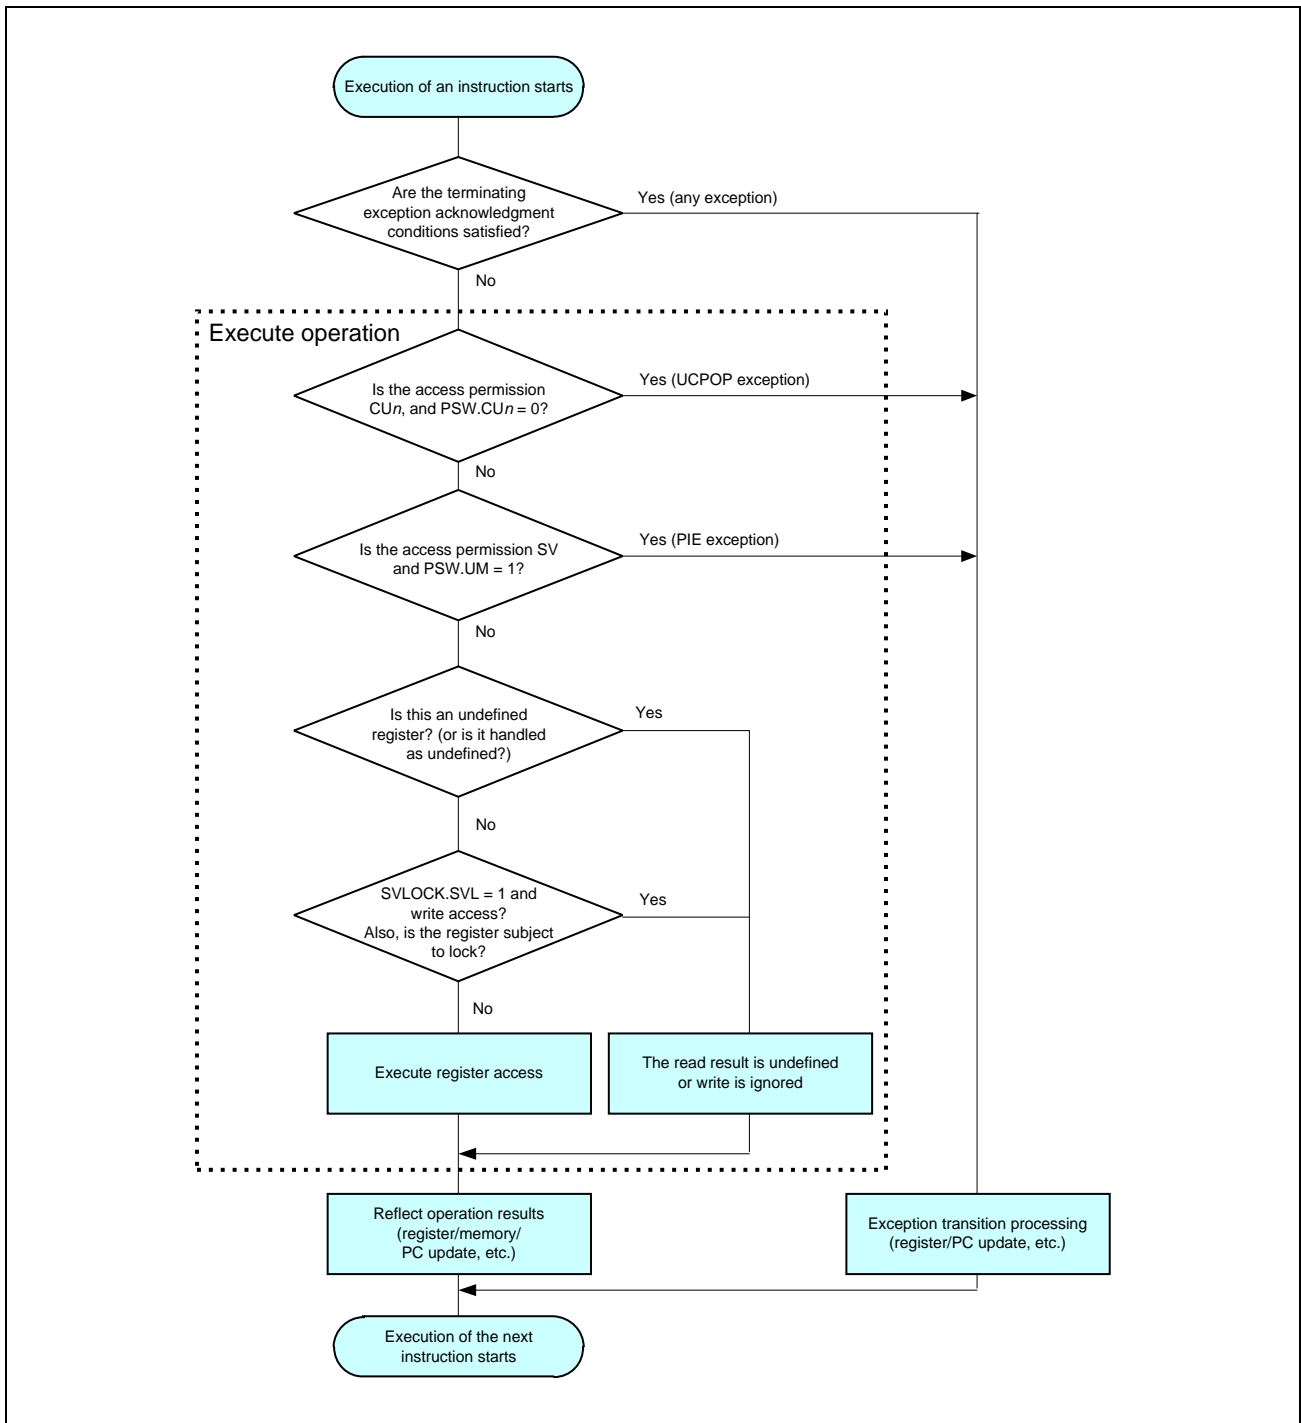

Figure 3.3 Flow of Executing the LDSR and STSR Instructions

(4) Accessing Undefined Registers

If a system register number without any register assigned is accessed or if an inaccessible register is accessed, the following results occur.

- Undefined registers are handled as having the SV permission. When they are accessed by an LDSR or STSR instruction in user mode (PSW.UM = 1), a PIE exception occurs.
- For a read operation, the read result is undefined. If the read value is used in a program, unexpected behaviors might occur.
- For a write operation, the write operation is ignored.

(5) Supervisor Lock Setting

If the SVLOCK.SVL bit is set (1), the following system registers cannot be updated even in supervisor mode:

SPID, MPM, MPLA, MPUA, MPAT, and MPIDn

However, if the SVLOCK.SVL bit is set (1), an attempt to update the system registers above does not cause a PIE exception.

Also, even if the SVLOCK.SVL bit is set (1), it is possible to read the system registers above.

This function is intended for the safety of systems that incorporate this CPU. It prevents a program running in supervisor mode from abruptly changing memory protection setting due to a programming error, etc., to make illegal memory access possible, and to impair safety.

3.2.2.6 Data Types

(1) Data Formats

This CPU handles data in little endian format. This means that byte 0 of a halfword or a word is always the least significant (rightmost) byte.

The supported data format is as follows.

- Byte (8-bit data)
- Halfword (16-bit data)
- Word (32-bit data)
- Double-word (64-bit data)
- Quad-word (128-bit data)
- Bit (1-bit data)

In this CPU, a memory access of double-word data is divided into two non-atomic memory accesses of word data, and a memory access of quad-word data is divided into four non-atomic memory accesses of word data.

(a) Byte

A byte is 8 consecutive bits of data that starts from any byte boundary. Numbers from 0 to 7 are assigned to these bits, with bit 0 as the LSB (least significant bit) and bit 7 as the MSB (most significant bit). The byte address is specified as “A”.

(b) Halfword

A halfword is two consecutive bytes (16 bits) of data that starts from any byte boundary. Numbers from 0 to 15 are assigned to these bits, with bit 0 as the LSB and bit 15 as the MSB. The bytes in a halfword are specified using address “A”, so that the two addresses comprise byte data of “A” and “A + 1”.

(c) Word

A word is four consecutive bytes (32 bits) of data that starts from any byte boundary. Numbers from 0 to 31 are assigned to these bits, with bit 0 as the LSB (least significant bit) and bit 31 as the MSB (most significant bit). A word is specified by address “A” and consists of byte data of four addresses: “A”, “A + 1”, “A + 2”, and “A + 3”.

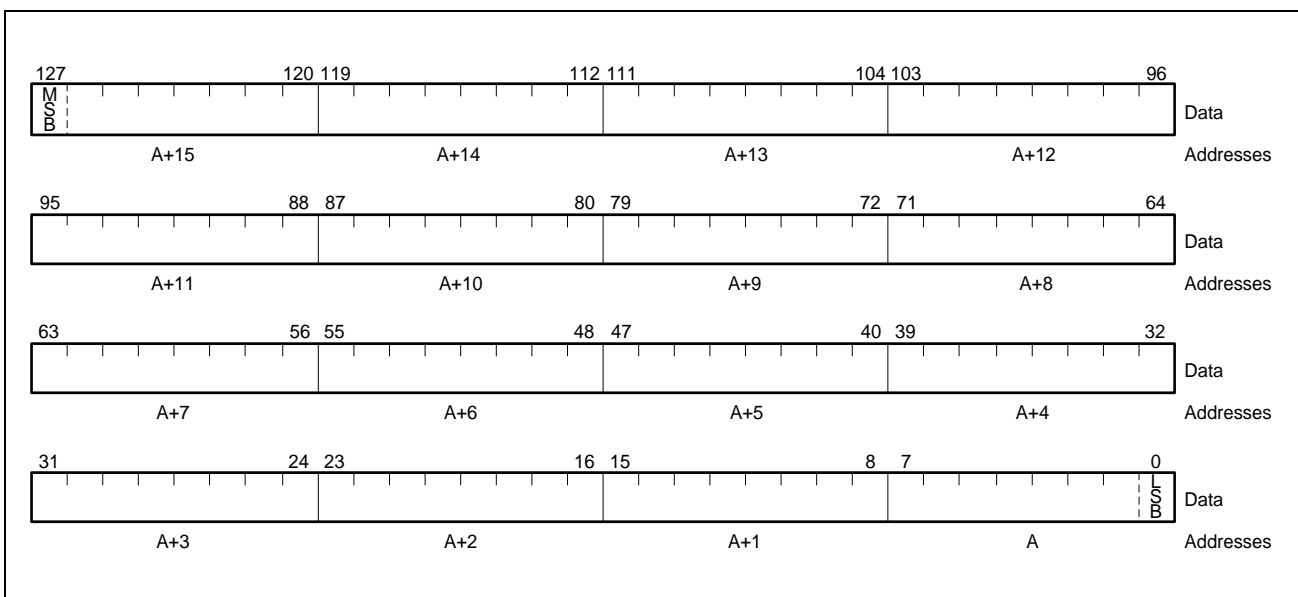

(d) Double-word

A double-word is eight consecutive bytes (64 bits) that start from any 4-byte boundary. Numbers from 0 to 63 are assigned to these bits, with bit 0 as the LSB and bit 63 as the MSB. A double-word is specified by address “A” and consists of byte data of eight addresses: “A”, “A + 1”, “A + 2”, “A + 3”, “A + 4”, “A + 5”, “A + 6”, and “A + 7”.

(e) Quad-word

A quad-word is sixteen consecutive bytes (128 bits) that start from any 8-byte boundary. Numbers from 0 to 127 are assigned to these bits, with bit 0 as the LSB and bit 127 as the MSB. A quad-word is specified by address “A” and consists of byte data of sixteen addresses: “A”, “A + 1”, ..., and “A + 15”.

(f) Bit

A bit is bit data at the nth bit within 8-bit data that starts from any byte boundary. Each bit is specified using its byte address “A” and its bit number “n” (n = 0 to 7).

(2) Data Representation

(a) Integers

Integers are represented as binary values using 2's complement, and are used in one of four lengths: 64 bits, 32 bits, 16 bits, or 8 bits. Regardless of the length of an integer, its place uses bit 0 as the LSB, and this place gets higher as the bit number increases. Because this is a 2's complement representation, the MSB is used as a sign bit.

The integer ranges for various data lengths are as follows.

- Double-word (64 bits): -9223372036854775808 to +9223372036854775807
- Word (32 bits): -2147483648 to +2147483647
- Halfword (16 bits): -32768 to +32767
- Byte (8 bits): -128 to +127

Although data format of quad-word (128 bits) is defined, data representation of quad-word is not used in this CPU. This is because quad-word data consists of four-word data or two-double-word data, but this CPU does not process quad-word data directly.

(b) Unsigned Integers

In contrast to “integers” which are data that can take either a positive or negative sign, “unsigned integers” are never negative integers. Like integers, unsigned integers are represented as binary values, and are used in one of four lengths: 64 bits, 32 bits, 16 bits, or 8 bits. Also like integers, the positioning of unsigned integers uses bit 0 as the LSB and gets higher as the bit number increases. However, unsigned integers do not use a sign bit.

The unsigned integer ranges for various data lengths are as follows.

- Double-word (64 bits): 0 to 18446744073709551615
- Word (32 bits): 0 to 4294967295
- Halfword (16 bits): 0 to 65535
- Byte (8 bits): 0 to 255

(c) Bits

Bit data are handled as single-bit data with either of two values: cleared (0) or set (1). There are four types of bit-related operations (listed below), which target only single-byte data in the memory space.

- Set
- Clear
- Invert
- Test

(3) Data Alignment

In this CPU, misaligned data allocation is inhibited. When the result of address calculation is a misaligned address, a misalignment exception (MAE) occurs.

Misaligned access indicates the accesses to the data size with the addresses listed below:

- Halfword size: The access to an address that is not at the halfword boundary (where LSB of the address = 0)
- Word size: The access to an address that is not at the word boundary (where the lowest two bits of the address = 0).
- Double-word size: The access to an address that is not at the double-word boundary (where the lowest three bits of the address = 0).
- Quad-word size: The access to an address that is not at the quad-word boundary (where the lowest four bits of the address = 0)

For the double-word format only, a misaligned access exception does not occur when data is placed at the word boundary but not at the double-word boundary, and data can be normally accessed in double word.

CAUTIONS

1. The following instructions might possibly cause misaligned access. For details, see the relevant descriptions in *the RH850G4MH User's Manual: Software*.
 - LD.H, LD.HU, LD.W, LD.DW
 - SLD.H, SLD.HU, SLD.W
 - ST.H, ST.W, ST.DW
 - SST.H, SST.W
 - LDL.HU, LDL.W, STC.H, STC.W, CAXI
 - LDV.W, LDV.DW, LDV.QW, STV.W, STV.DW, STV.QW
 - LDVZ.H4, STVZ.H4
2. The following instructions do not cause misaligned access, because the address is rounded as the instruction specification when a misaligned address is specified.
 - PREPARE, DISPOSE
 - PUSHSP, POPSP

(a) Byte Access

(b) Halfword Access

(c) Word Access

(d) Double-word Access

Note 1. No misalignment exception (MAE) occurs for LD.DW and ST.DW instructions. For details, see LD.DW and ST.DW in the *RH850G4MH User's Manual: Software*. An MAE occurs for other double-word access instructions.

Figure 3.4 Example of Data Placement for Misaligned Access (1/2)

Figure 3.4 Example of Data Placement for Misaligned Access (2/2)

3.2.2.7 Address Space

This CPU supports a linear address space of up to 4 Gbytes. Both memory and I/O can be mapped to this address space (using the memory mapped I/O method). The CPU outputs a 32-bit address for memory and I/O, in which the highest address number is “ $2^{32} - 1$ ”.

The byte data placed at various addresses is defined with bit 0 as the LSB and bit 7 as the MSB. When the data is comprised of multiple bytes, it is defined so that the byte data at the lowest address is the LSB and the byte data at the highest address is the MSB (i.e., in little endian format).

This manual stipulates that, when representing data comprised of multiple bytes, the right edge must be represented as the lower-order addresses and the left side as the higher-order addresses, as shown below.

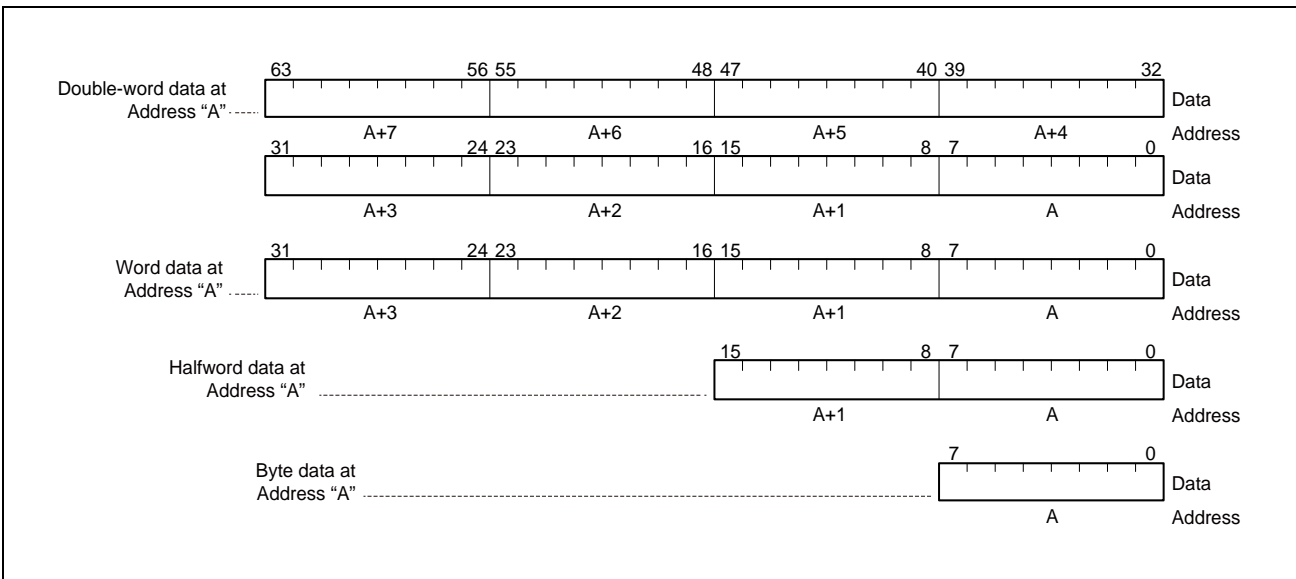

Figure 3.5 Address Space Byte Format

(1) Memory Map

This CPU is 32-bit architecture and supports a linear address space of up to 4 Gbytes. The whole range of this 4-Gbyte address space can be addressed by instruction addressing (instruction fetch access) and data addressing (data access).

A memory map is shown in **Figure 3.6**.

Figure 3.6 Memory Map (Address Space)

(2) Instruction Addressing

The instruction address is determined based on the contents of the program counter (PC), and is automatically incremented according to the number of bytes in the executed instruction. When a branch instruction is executed, the addressing shown below is used to set the branch destination address to the PC.

If the result of address calculation exceeds the positive maximum value $FFFF\ FFFF_H$ by addition, it is wrapped around to $0000\ 0000_H$. If the result of address calculation falls below the positive minimum value $0000\ 0000_H$ by subtraction, it is wrapped around to $FFFF\ FFFF_H$.

(a) Relative Addressing (PC Relative)

Signed N-bit data (displacement: disp N) in the instruction code is added to the program counter (PC). In this case, displacement is handled as 2's complement data, and the MSB is a sign bit (S). If the displacement is less than 32 bits, the higher-order bits are sign-extended (N differs from one instruction to another).

The JARL, JR, and Bcond instructions are used with this type of addressing.

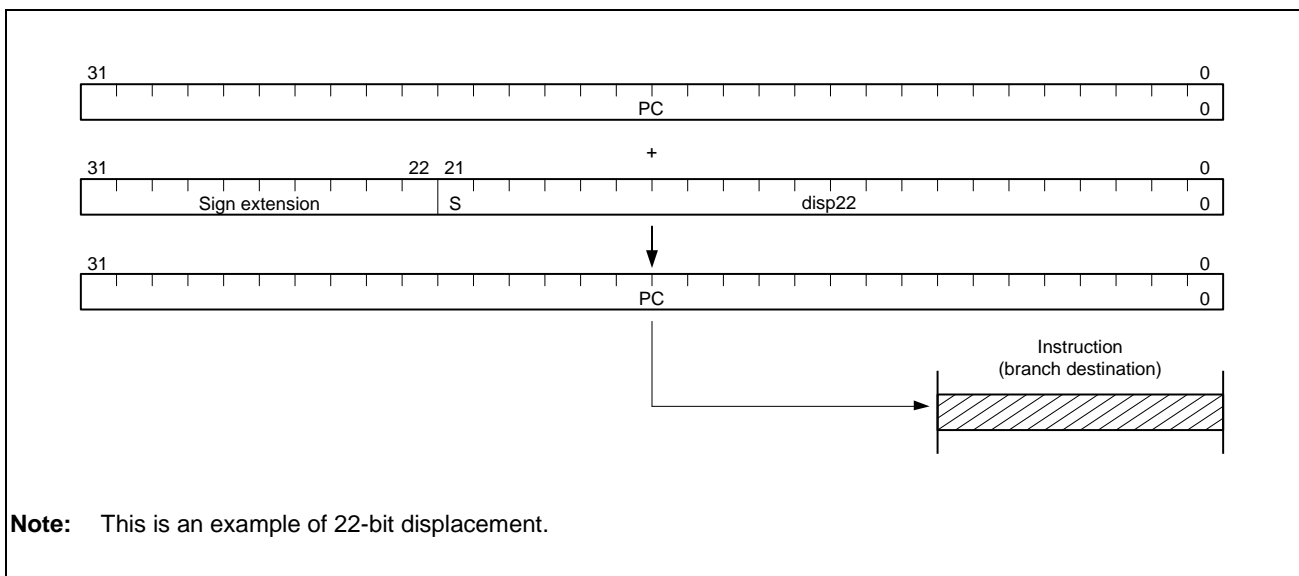

Figure 3.7 Relative Addressing

(b) Register Addressing (Register Indirect)

The contents of the general-purpose register (reg1) or system register (regID) specified by the instruction are transferred to the program counter (PC).

The JMP, CTRET, EIRET, FERET, and DISPOSE instructions are used with this type of addressing.

Figure 3.8 Register Addressing

(c) Based Addressing

The contents of the general-purpose register (reg1) and the N-bit displacement (dispN) specified by the instruction are added and transferred to the program counter (PC). At this time, the displacement is handled as a 2's complement data, and the MSB is a sign bit (S). If the displacement is less than 32 bits, the higher bits are sign-extended (N differs from one instruction to another).

The JMP instruction is used with this type of addressing.

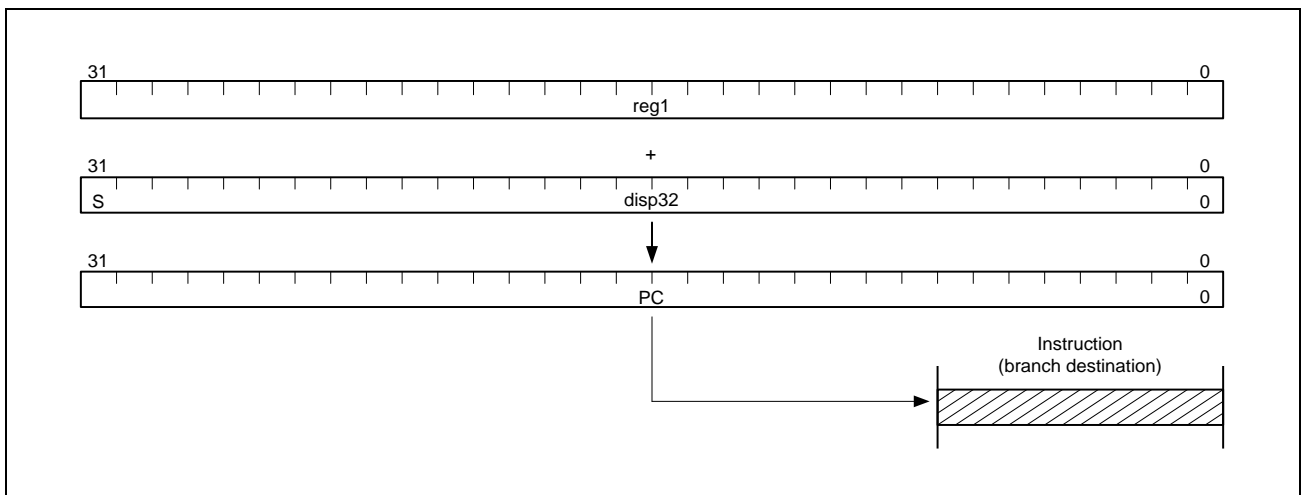

Figure 3.9 Based Addressing

(d) Other Addressing

A value specified by an instruction is transferred to the program counter (PC). How a value is specified is explained in [Operation] or [Description] of each instruction.

The CALLT, SYSCALL, TRAP, FETRAP, and RIE instructions, and branch in case of an exception are used with this type of addressing.

(3) Data Addressing

The following methods can be used to access the target registers or memory when executing an instruction.

If the result of address calculation exceeds the positive maximum value $FFFF\ FFFF_H$ by addition, it is wrapped around to $0000\ 0000_H$. If the result of address calculation falls below the positive minimum value $0000\ 0000_H$ by subtraction, it is wrapped around to $FFFF\ FFFF_H$.

(a) Register Addressing

This addressing method accesses the general-purpose register or system register specified in the general-purpose register field as an operand.

Any instruction that includes the operand `reg1`, `reg2`, `reg3`, or `regID` is used with this type of addressing.

(b) Immediate Addressing

This address mode uses arbitrary size data as the operation target in the instruction code.

Any instruction that includes the operand `imm5`, `imm16`, `vector`, or `cccc` is used with this type of addressing.

NOTE

vector: This is immediate data that specifies the exception vector (00_H to $1F_H$), and is an operand used by the TRAP, FETRAP, and SYSCALL instructions. The data width differs from one instruction to another.

cccc: This is 4-bit data that specifies a condition code, and is an operand used in the Bcond instruction, CMOV instruction, SASF instruction, and SETF instruction.

(c) Based Addressing

There are two types of based addressing, as described below.

3.2.2.7.3.c.1 Type 1

The contents of the general-purpose register (reg1) specified at the addressing specification field in the instruction code are added to the N-bit displacement (dispN) data sign-extended to word length to obtain the operand address, and the target memory is accessed using the operand address. At this time, the displacement is handled as a 2's complement data, and the MSB is a sign bit (S). If the displacement is less than 32 bits, the higher bits are sign-extended (N differs from one instruction to another).

The LD, ST, LDV and STV instructions are used with this type of addressing.

Figure 3.10 Based Addressing (Type 1)

3.2.2.7.3.c.2 Type 2

The contents of the element pointer (r30) are added to the N-bit displacement data (dispN) zero-extended to a word length to obtain the operand address, and target memory is accessed using the operand address. If the displacement is less than 32 bits, the higher bits are zero-extended (N differs from one instruction to another).

The SLD and SST instructions are used with this type of addressing.

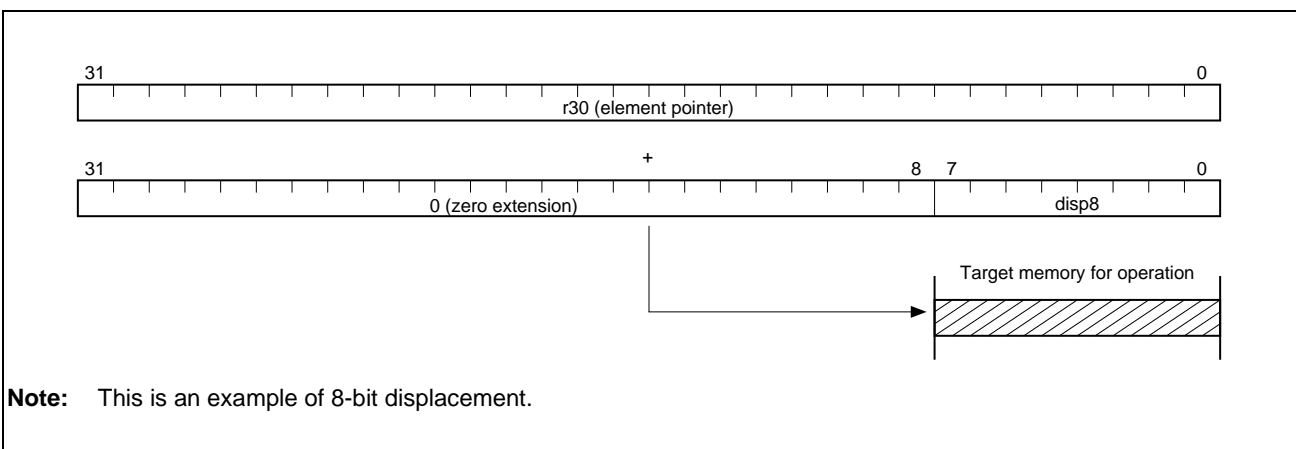

Figure 3.11 Based Addressing (Type 2)

(d) Bit Addressing

The contents of the general-purpose register (reg1) are added to the N-bit displacement (dispN) data sign-extended to word length to obtain the operand address, and one bit (as specified by 3-bit data “bit #3”) in one byte of the target memory is accessed using the operand address. At this time, the displacement is handled as a 2’s complement data, and the MSB is a sign bit (S). If the displacement is less than 32 bits, the higher bits are sign-extended (N differs from one instruction to another).

The CLR1, SET1, NOT1, and TST1 instructions are used with this type of addressing.

Figure 3.12 Bit Addressing

(e) Post Index Increment/Decrement Addressing

The contents of the general-purpose register (reg1) are used as an operand address to access the target memory, and then the general-purpose register (reg1) is updated. There are two types of the general-purpose register updating, by incrementing or decrementing.

If the result of incrementing the general-purpose register (reg1) value exceeds the positive maximum value $FFFF\ FFFF_H$, the result wraps around to $0000\ 0000_H$, and, if the result of decrementing the general-purpose register value is less than the positive minimum value $0000\ 0000_H$, the result wraps around to $FFFF\ FFFF_H$.

3.2.2.7.3.e.1 Type 1

The general-purpose register (reg1) is updated by adding a constant that depends on the type of accessed data (the size of the accessed data) to the contents of the general-purpose register (reg1). If the type of accessed data is a byte, 1 is added, if the type is a halfword, 2 is added, if the type is a word, 4 is added, and if the type is a double-word, 8 is added.

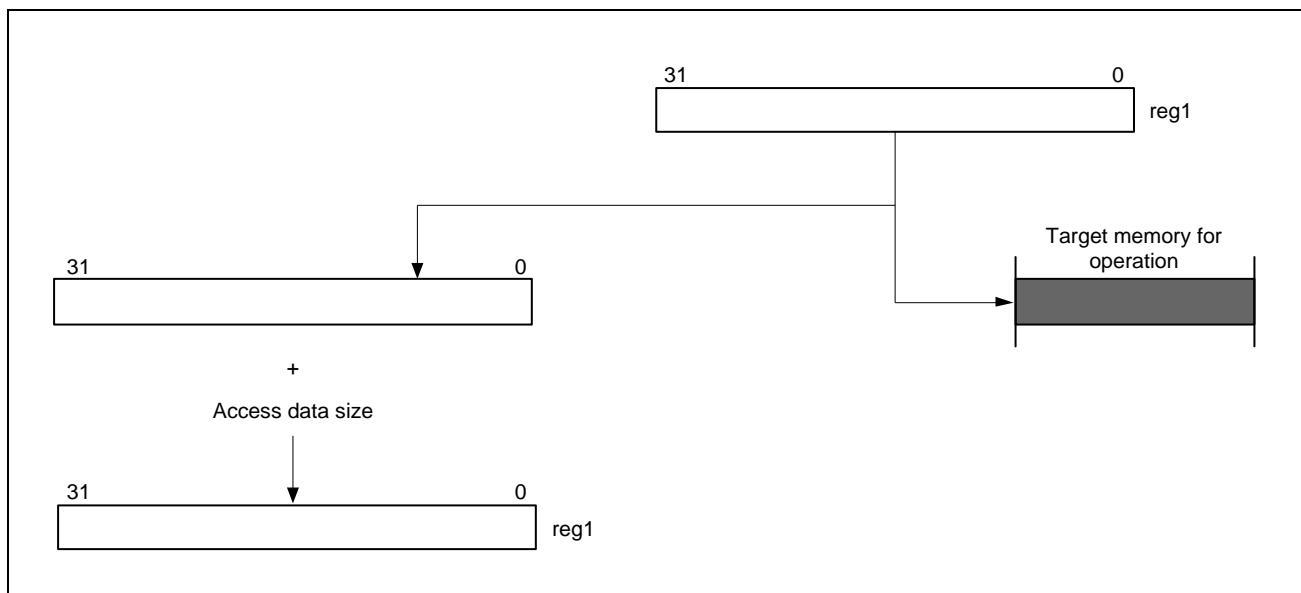

Figure 3.13 Post Index Increment/Decrement Addressing (Type 1)

3.2.2.7.3.e.2 Type 2

The general-purpose register (reg1) is updated by subtracting a constant that depends on the size of the accessed data from the contents of the general-purpose register (reg1). If the size of accessed data is a byte, 1 is subtracted, if the size is a halfword, 2 is subtracted, if the size is a word, 4 is subtracted, and if the size is a double-word, 8 is subtracted.

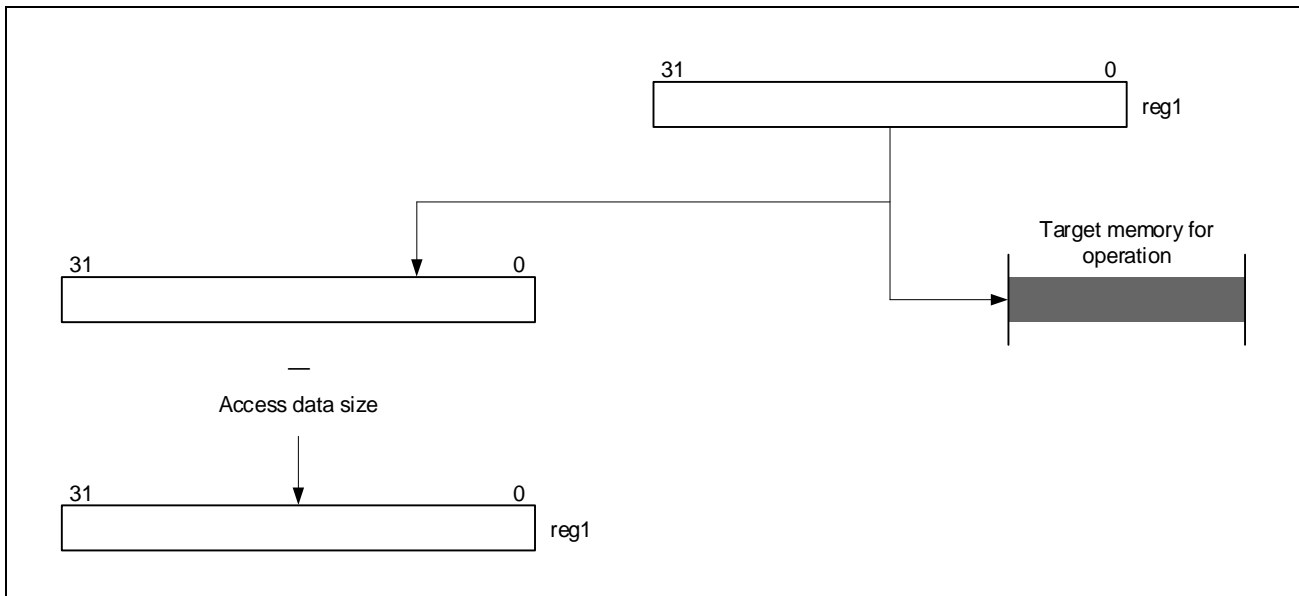

Figure 3.14 Post Index Increment/Decrement Addressing (Type 2)

(f) Other Addressing

The target memory is accessed using a value specified by an instruction as the operand address. How a value is specified is explained in [Operation] or [Description] of each instruction.

The SWITCH, CALLT, SYSCALL, PREPARE, DISPOSE, PUSHSP, and POPSP instructions are used with this type of addressing.

3.2.2.8 Execution Timing of a Store Instruction

Completion of writing by a store instruction may differ depending on the type of the memory to be accessed. For details, see **Section 3.2.7.2, Guaranteeing the Completion of Store Instruction**.

3.2.2.9 Memory Ordering

This CPU guarantees that memories are accessed in the programmed order. However, in the system that incorporates multiple bus masters such as the bus system with DMA or multi-core, the order of accesses to memories needs to be considered. For these cases, see **Section 3.2.7.1, Synchronization Processing**.

3.2.2.10 Acquiring the CPU Number

This CPU provides a method for identifying CPUs in a multi-processor system.

In the multi-processor configuration, you can identify which CPU core is running a program by referencing the PEID register. A unique number within a multi-processor system is assigned to the PEID register according to the specification of the product.

3.2.2.11 System Protection Identifier (SPID)

In this CPU, memory resources and peripheral devices are managed by system protection groups. By specifying the group to which the program being executed belongs, you can assign accessible memory resources and peripheral devices to the program.

The program being executed belongs to the group specified by the SPID, and whether the memory resources and peripheral devices are accessible is decided using the SPID. A value can be set to the SPID register by the supervisor.

CAUTION

According to the value of the SPID, how operations are assigned to memory resources and peripheral devices is determined by the specifications of the product.

3.2.2.12 Timestamp Counter

This CPU has a 64-bit timestamp counter. It can measure long time, and so can be used as specific information for time identification.

Since the timestamp counter is allocated to system registers, it can be accessed quickly by using a LDSR/STSR instruction.

If an overflow occurs during counting operation, no exception will occur.

(1) How to Operate the Timestamp Counter

The value of the timestamp counter is initialized to 0 by a reset. Therefore, if you want to retain the value of the counter across a reset, then before the reset, save the value of the counter in a memory that is not initialized by the reset, restore the value to the counter after the reset, and restart counting.

The counter is 64-bit width, so the counter consists of two 32-bit system registers, TSCOUNTL and TSCOUNTH. Both registers need to be accessed by using LDSR/STSR instructions.

When the counter is not running (the value of the TSCTRL.CEN bit is 0), no special care is needed to access the two registers.

However, if the counter is running (the value of the TSCTRL.CEN bit is 1), it is not recommended to update the counter by using LDSR instructions. In this case, the timing of update of the counter is not guaranteed. It is recommended to update the counter when it is not running.

Also, when reading the value of the counter by using STSR instructions while it is running, it is recommended to follow the procedure below.

TSCNTRD:			
STSR	1, r21, 11	--	Read the upper side of the counter
STSR	0, r20, 11	--	Read the lower side of the counter
STSR	1, r22, 11	--	Read again the upper side of the counter
CMP	r21, r22	--	Compare the two values read from the upper side of the counter
BNE	TSCNTRD	--	If they are not identical, a carry has occurred. Read again.

Even if the CPU core is not in operation after the execution of a HALT or SNOOZE instruction, the timestamp counter continues counting.

3.2.2.13 Performance Measurement Function

This CPU has the performance measurement function. The performance measurement function can measure the performance of programs executed, the effects of interrupts generated during operation, etc. by counting the occurrence of the event specified by the PMCTRLn.CND bit.

The system registers used by the performance measurement function can be accessed only in supervisor mode after a reset. However, it can be accessed in user mode by changing the setting of the PMUMCTRL register.

The performance measurement function itself works in user mode regardless of the setting of the PMUMCTRL register. Even if all performance measurement channels are made inaccessible in user mode by using the PMUMCTRL register, configuration in supervisor mode allows performance measurement during operation in user mode.

This CPU has four channels of system register set for the performance measurement function.

3.2.3 Register Set

This chapter describes the program register and system register mounted on this CPU.

3.2.3.1 Program Registers

Program registers includes general-purpose registers (r0 to r31) and the program counter (PC). r0 always retains 0. The values of the general-purpose registers r1 to r31 after a reset are undefined. The value of the PC after a reset is the value of RBASE register.

Table 3.6 Program Registers

Program Register	Name	Function	Description
General-purpose registers	r0	Zero register	Always retains 0
	r1	Assembler reserved register	Used as working register for generating addresses
	r2	Register for address and data variables (used when the real-time OS used does not use this register)	
	r3	Stack pointer (SP)	Used for generating a stack frame when a function is called
	r4	Global pointer (GP)	Used for accessing a global variable in the data area
	r5	Text pointer (TP)	Used as a register that indicates the start of the text area (area where program code is placed)
	r6 to r29	Register for addresses and data variables	
	r30	Element pointer (EP)	Used as a base pointer for generating addresses when accessing memory
	r31	Link pointer (LP)	Used when the compiler calls a function
Program counter	PC	Retains instruction addresses during execution of programs	

Note: For further descriptions of r1, r3 to r5, and r31 used for an assembler and/or C compiler, see the manual of each software development environment.

(1) General-purpose Registers

A total of 32 general-purpose registers (r0 to r31) are provided. All of these registers can be used for either data variables or address variables.

Of the general-purpose registers, r0 to r5, r30, and r31 are assumed to be used for special purposes in software development environments, so it is necessary to note the following when using them.

(a) r0, r3, and r30

These registers are implicitly used by instructions.

r0 is a register that always retains 0. It is used for operations that use 0, addressing with base address being 0, etc.

r3 is implicitly used by the PREPARE, DISPOSE, PUSHSP, and POPSP instructions.

r30 is used as a base pointer when the SLD instruction or SST instruction accesses memory.

(b) r1, r4, r5, and r31

These registers are implicitly used by the assembler and C compiler.

When using these registers, register contents must first be saved so they are not lost and can be restored after the registers are used.

(c) r2

This register is used by a real-time OS in some cases. If the real-time OS that is being used is not using r2, r2 can be used as a register for address variables or data variables.

(2) PC — Program Counter

The PC retains the address of the instruction being executed.

Table 3.7 PC Register Contents

Bit	Name	Description	R/W	Value after Reset
31 to 1	PC31 to PC1	These bits indicate the address of the instruction being executed.	R/W	*1
0	PC0	This bit is fixed to 0. Branching to an odd number address is disabled.	R/W	0

Note 1. For details, see **Section 4, Address MAP**.

3.2.3.2 Basic System Registers

The basic system registers are used to control CPU status and to retain exception information.

The basic system registers are read from or written to by using the LDSR and STSR instructions and specifying the system register number, which is made up of a register number and selection ID.

Table 3.8 Basic System Registers

Register No. (regID, selID)	Symbol	Function	Access Permission
SR0, 0	EIPC	Status save registers when acknowledging EI level exception	SV
SR1, 0	EIPSW	Status save registers when acknowledging EI level exception	SV
SR2, 0	FEPC	Status save registers when acknowledging FE level exception	SV
SR3, 0	FEPSW	Status save registers when acknowledging FE level exception	SV
SR5, 0	PSW	Program status word	*1
SR6, 0	FPSR	(See Section 3.2.3.4, FPU Function Registers)	CU0 and SV
SR7, 0	FPEPC	(See Section 3.2.3.4, FPU Function Registers)	CU0 and SV
SR8, 0	FPST	(See Section 3.2.3.4, FPU Function Registers)	CU0
SR9, 0	FPCC	(See Section 3.2.3.4, FPU Function Registers)	CU0
SR10, 0	FPCFG	(See Section 3.2.3.4, FPU Function Registers)	CU0
SR13, 0	EIIC	EI level exception cause	SV
SR14, 0	FEIC	FE level exception cause	SV
SR16, 0	CTPC	CALLT execution status save register	UM
SR17, 0	CTPSW	CALLT execution status save register	UM
SR20, 0	CTBP	CALLT base pointer	UM
SR21, 0	SNZCFG	SNOOZE control register	SV
SR28, 0	EIWR	EI level exception working register	SV
SR29, 0	FEWR	FE level exception working register	SV
SR0, 1	SPID	System protection identifier	SV
SR1, 1	SPIDLIST	List of system protection identifiers that can be specified in SPID	SV
SR2, 1	RBASE	Reset vector base address	SV
SR3, 1	EBASE	Exception handler vector address	SV
SR4, 1	INTBP	Base address of the interrupt handler "address" table	SV
SR5, 1	MCTL	CPU control	SV
SR6, 1	PID	Processor ID	SV
SR8, 1	SVLOCK	Supervisor lock	SV
SR11, 1	SCCFG	SYSCALL operation setting	SV
SR12, 1	SCBP	SYSCALL base pointer	SV
SR0, 2	PEID	Processor element identifier	SV
SR1, 2	BMID	Bus master identifier	SV
SR6, 2	MEA	Memory error address	SV
SR8, 2	MEI	Memory error information	SV
SR15, 2	RBCR0	Register bank control 0	SV
SR16, 2	RBCR1	Register bank control 1	SV
SR17, 2	RBNR	Register bank number	SV
SR18, 2	RBIP	Register bank initial pointer	SV

Note 1. The access permission differs depending on the bit. For details, see **Section 3.2.3.2(5), PSW — Program Status Word**.

(1) EIPC — Status Save Register when Acknowledging EI Level Exception

When an EI level exception is acknowledged, the address of the instruction that was being executed when the EI level exception occurred, or of the next instruction, is saved to the EIPC register (see **Section 3.2.4.1(3), Types of Exceptions**).

Because there is only one pair of EI level exception status save registers, when processing multiple exceptions, the contents of these registers must be saved by a program.

Be sure to set an even-numbered address to the EIPC register. An odd-numbered address must not be specified.

Table 3.9 EIPC Register Contents

Bit	Name	Description	R/W	Value after Reset
31 to 1	EIPC31 to EIPC1	These bits indicate the PC saved when an EI level exception is acknowledged.	R/W	Undefined
0	EIPC0	This bit indicates the PC restored when an EI level exception is acknowledged. Always set this bit to 0. Even if it is set to 1, the value transferred to the PC when the EIRET instruction is executed is 0.	R/W	Undefined

(3) FEPC — Status Save Register when Acknowledging FE Level Exception

When an FE level exception is acknowledged, the address of the instruction that was being executed when the FE level exception occurred, or of the next instruction, is saved to the FEPC register (see **Section 3.2.4.1(3), Types of Exceptions**). Because there is only one pair of FE level exception status save registers, when processing multiple exceptions, the contents of these registers must be saved by a program.

Be sure to set an even-numbered address to the FEPC register. An odd-numbered address must not be specified.

Table 3.11 FEPC Register Contents

Bit	Name	Description	R/W	Value after Reset
31 to 1	FEPC31 to FEPC1	These bits indicate the PC saved when an FE level exception is acknowledged.	R/W	Undefined
0	FEPC0	This bit indicates the PC saved when an FE level exception is acknowledged. Always set this bit to 0. Even if it is set to 1, the value transferred to the PC when the FERET instruction is executed is 0.	R/W	Undefined

(4) FEPSW — Status Save Register when Acknowledging FE Level Exception

When an FE level exception is acknowledged, the current PSW setting is saved to the FEPSW register.

Because there is only one pair of FE level exception status save registers, when processing multiple exceptions, the contents of these registers must be saved by a program.

Table 3.12 FEPSW Register Contents

Bit	Name	Description	R/W	Value after Reset
31	—	(Reserved for future expansion. Be sure to set to 0.)	R	0
30	UM	This bit stores the PSW.UM bit setting when an FE level exception is acknowledged.	R/W	0
29 to 19	—	(Reserved for future expansion. Be sure to set to 0.)	R	0
18 to 16	CU2 to CU0	These bits store the PSW.CU2-0 field setting when an FE level exception is acknowledged*1.	R/W	0
15	EBV	This bit stores the PSW.EBV bit setting when an FE level exception is acknowledged.	R/W	0
14 to 8	—	(Reserved for future expansion. Be sure to set to 0.)	R	0
7	NP	This bit stores the PSW.NP bit setting when an FE level exception is acknowledged.	R/W	0
6	EP	This bit stores the PSW.EP bit setting when an FE level exception is acknowledged.	R/W	0
5	ID	This bit stores the PSW.ID bit setting when an FE level exception is acknowledged.	R/W	1
4	SAT	This bit stores the PSW.SAT bit setting when an FE level exception is acknowledged.	R/W	0
3	CY	This bit stores the PSW.CY bit setting when an FE level exception is acknowledged.	R/W	0
2	OV	This bit stores the PSW.OV bit setting when an FE level exception is acknowledged.	R/W	0
1	S	This bit stores the PSW.S bit setting when an FE level exception is acknowledged.	R/W	0
0	Z	This bit stores the PSW.Z bit setting when an FE level exception is acknowledged.	R/W	0

Note 1. CU2 is reserved for future CPUs that are to be made compatible with this CPU. It is always set to 0 in this CPU.

Table 3.14 PSW Register Contents (2/2)

Bit	Name	Description	R/W	Value after Reset
15	EBV	This bit indicates the reset vector and exception vector operation. See Section 3.2.3.2(16), RBASE — Reset Vector Base Address and Section 3.2.3.2(17), EBASE — Exception Handler Vector Address .	R/W	0
14 to 8	—	(Reserved for future expansion. Be sure to set to 0.)	R	0
7	NP	This bit disables the acknowledgement of FE level exception. When an FE level exception is acknowledged, this bit is set to 1 to disable the acknowledgement of EI level and FE level exceptions. As for the exceptions which the NP bit disables the acknowledgment, see Table 3.95, Exception Cause List . 0: The acknowledgement of FE level exception is enabled. 1: The acknowledgement of FE level exception is disabled.	R/W	0
6	EP	This bit indicates that an exception other than an interrupt is being serviced. It is set to 1 when the corresponding exception occurs. This bit does not affect acknowledging an exception request even when it is set to 1. 0: An exception other than an interrupt is not being serviced. 1: An exception other than an interrupt is being serviced.	R/W	0
5	ID	This bit disables the acknowledgement of EI level exception. When an EI level or FE level exception is acknowledged, this bit is set to 1 to disable the acknowledgement of EI level exception. As for the exceptions which the ID bit disables the acknowledgment, see Table 3.95, Exception Cause List . This bit is also used to disable EI level exceptions from being acknowledged as a critical section while an ordinary program or interrupt is being serviced. It is set to 1 when the DI instruction is executed, and cleared to 0 when the EI instruction is executed. The change of the ID bit by the EI or ID instruction will be enabled from the next instruction. 0: The acknowledgement of EI level exception is enabled. 1: The acknowledgement of EI level exception is disabled.	R/W	1
4	SAT*2	This bit indicates that a saturation arithmetic operation instruction resulted in overflow and saturation processing is applied to the result. This is a cumulative flag, that is, it is set (1) once a saturation occurs and not cleared (0) by subsequent instructions with unsaturated results. This bit is cleared by the LDSR instruction. Note that execution of an arithmetic operation instruction neither set nor clear this flag. 0: The result was not saturated 1: The result was saturated	R/W	0
3	CY	This bit indicates whether a carry or borrow has occurred in the operation result. 0: Carry and borrow have not occurred. 1: Carry or borrow has occurred.	R/W	0
2	OV*2	This bit indicates whether or not an overflow has occurred during an operation. 0: Overflow has not occurred. 1: Overflow has occurred.	R/W	0
1	S*2	This bit indicates whether or not the result of an operation is negative. 0: Result of operation is positive or 0. 1: Result of operation is negative.	R/W	0
0	Z	This bit indicates whether or not the result of an operation is 0. 0: Result of operation is not 0. 1: Result of operation is 0.	R/W	0

Note 1. The coprocessor use permission CU2 is reserved for future CPUs that are to be made compatible with this CPU.

Note 2. Saturation processing is applied to the operation result in accordance with the contents of the OV and S flags. The SAT flag is set (1) only when the OV flag is set (1) in the saturation arithmetic operation.

Operation Result Status	Flag Status			Operation Result after Saturation Processing
	SAT	OV	S	
Exceeded positive maximum value	1	1	0	7FFF FFFF _H
Exceeded negative maximum value	1	1	1	8000 0000 _H
Positive (maximum value not exceeded)	Value prior to operation is retained	0	0	Operation result as is
Negative (maximum value not exceeded)			1	

(6) EIIC — EI Level Exception Cause

The EIIC register retains the cause of any EI level exception that occurs. The value retained in this register is an exception code corresponding to a specific exception cause (see **Table 3.95, Exception Cause List**).

Table 3.15 EIIC Register Contents

Bit	Name	Description	R/W	Value after Reset
31 to 0	EIIC31 to EIIC0	These bits store the exception cause code when an EI level exception occurs. The EIIC15-0 field stores the exception cause codes shown in Table 3.95 . The EIIC31-16 field stores detailed exception cause codes defined individually for each exception. If there is no particular definition, these bits are set to 0.	R/W	0

(7) FEIC — FE Level Exception Cause

The FEIC register retains the cause of any FE level exception that occurs. The value retained in this register is an exception code corresponding to a specific exception cause (see **Table 3.95, Exception Cause List**).

Table 3.16 FEIC Register Contents

Bit	Name	Description	R/W	Value after Reset
31 to 0	FEIC31 to FEIC0	These bits store the exception cause code when an FE level exception occurs. The FEIC15-0 field stores the exception cause codes shown in Table 3.95 . The FEIC31-16 field stores detailed exception cause codes defined individually for each exception. If there is no particular definition, these bits are set to 0.	R/W	0

(8) CTPC — Status Save Register when Executing CALLT

When a CALLT instruction is executed, the address of the next instruction after the CALLT instruction is saved to CTPC.

Be sure to set an even-numbered address to the CTPC register. An odd-numbered address must not be specified.

Table 3.17 CTPC Register Contents

Bit	Name	Description	R/W	Value after Reset
31 to 1	CTPC31 to CTPC1	These bits indicate the PC of the instruction after the CALLT instruction.	R/W	Undefined
0	CTPC0	This bit indicates the PC of the instruction after the CALLT instruction. Always set this bit to 0. Even if it is set to 1, the value transferred to the PC when the CTRET instruction is executed is 0.	R/W	Undefined

(9) CTPSW — Status Save Register when Executing CALLT

When a CALLT instruction is executed, some of the PSW (program status word) settings are saved to CTPSW.

Table 3.18 CTPSW Register Contents

Bit	Name	Description	R/W	Value after Reset
31 to 5	—	(Reserved for future expansion. Be sure to set to 0.)	R	0
4	SAT	This bit stores the PSW.SAT bit setting when the CALLT instruction is executed.	R/W	0
3	CY	This bit stores the PSW.CY bit setting when the CALLT instruction is executed.	R/W	0
2	OV	This bit stores the PSW.OV bit setting when the CALLT instruction is executed.	R/W	0
1	S	This bit stores the PSW.S bit setting when the CALLT instruction is executed.	R/W	0
0	Z	This bit stores the PSW.Z bit setting when the CALLT instruction is executed.	R/W	0

(10) CTBP — CALLT Base Pointer

The CTBP register is used to specify table addresses of the CALLT instruction and generate target addresses.

Be sure to set the CTBP register to a halfword address.

Table 3.19 CTBP Register Contents

Bit	Name	Description	R/W	Value after Reset
31 to 1	CTBP31 to CTBP1	These bits indicate the base pointer address of the CALLT instruction. These bits indicate the start address of the table used by the CALLT instruction.	R/W	0
0	CTBP0	This bit indicates the base pointer address of the CALLT instruction. This bit indicates the start address of the table used by the CALLT instruction. Always set this bit to 0.	R	0

(11) SNZCFG — SNOOZE Configuration

The SNZCFG register is used to configure the operation of the SNOOZE instruction.

Table 3.20 SNZCFG Register Contents

Bit	Name	Description	R/W	Value after Reset
31 to 8	—	(Reserved for future expansion. Be sure to set to 0.)	R	0
7 to 0	SNZCNT	These bits specify the number of clock cycles in which execution is to be temporarily halted by the SNOOZE instruction.	R/W	20 _H

(12) EIWR — EI Level Exception Working Register

The EIWR register is used as a working register when an EI level exception has occurred.

Table 3.21 EIWR Register Contents

Bit	Name	Description	R/W	Value after Reset
31 to 0	EIWR31 to EIWR0	These bits constitute a working register that can be used for any purpose during the processing of an EI level exception. Use this register for purposes such as storing the values of general-purpose registers.	R/W	Undefined

(13) FEWR — FE Level Exception Working Register

The FEWR register is used as a working register when an FE level exception has occurred.

Table 3.22 FEWR Register Contents

Bit	Name	Description	R/W	Value after Reset
31 to 0	FEWR31 to FEWR0	These bits constitute a working register that can be used for any purpose during the processing of an FE level exception. Use this register for purposes such as storing the values of general-purpose registers.	R/W	Undefined

(14) SPID — System Protection Identifier

The SPID register holds the system protection identifier of the CPU.

Table 3.23 SPID Register Contents

Bit	Name	Description	R/W	Value after Reset
31 to 5	—	(Reserved for future expansion. Be sure to set to 0.)	R	0
4 to 0	SPID	These bits indicate the system protection identifier. The system protection identifier is a variable ID that is used for access protection in a product which consists of two or more bus masters including this CPU. For its uses and constraints on its value, see Section 3.8.7, Product Information of Initial Value for G4MH Register . Within this CPU, the SPID is used to check for area matching by the MPU. It allows the system specifications defined for the product to be reflected in the MPU's protection feature. The settable system protection identifiers are given by the SPIDLIST register. If an attempt is made to set an illegal system protection identifier, the SPID register is not updated and retains the original value.	R/W	*1

Note 1. See **Section 3.8.7, Product Information of Initial Value for G4MH Register**.

(15) SPIDLIST — Legitimate System Protection Identifier List

The SPIDLIST register contains a list of system protection identifiers that can be set to the SPID register.

The bits corresponding to the settable system protection identifiers are set to 1. The bits corresponding to illegal system protection identifiers are cleared to 0. These values are set outside the CPU as system specifications and cannot be altered by this CPU.

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Table 3.24 SPIDLIST Register Contents

Bit	Name	Description	R/W	Value after Reset
31	SL31	This bit indicates whether or not 31 can be set as a system protection identifier.	R	*1
30	SL30	This bit indicates whether or not 30 can be set as a system protection identifier.	R	*1
29	SL29	This bit indicates whether or not 29 can be set as a system protection identifier.	R	*1
28	SL28	This bit indicates whether or not 28 can be set as a system protection identifier.	R	*1
27	SL27	This bit indicates whether or not 27 can be set as a system protection identifier.	R	*1
26	SL26	This bit indicates whether or not 26 can be set as a system protection identifier.	R	*1
25	SL25	This bit indicates whether or not 25 can be set as a system protection identifier.	R	*1
24	SL24	This bit indicates whether or not 24 can be set as a system protection identifier.	R	*1
23	SL23	This bit indicates whether or not 23 can be set as a system protection identifier.	R	*1
22	SL22	This bit indicates whether or not 22 can be set as a system protection identifier.	R	*1
21	SL21	This bit indicates whether or not 21 can be set as a system protection identifier.	R	*1
20	SL20	This bit indicates whether or not 20 can be set as a system protection identifier.	R	*1
19	SL19	This bit indicates whether or not 19 can be set as a system protection identifier.	R	*1
18	SL18	This bit indicates whether or not 18 can be set as a system protection identifier.	R	*1
17	SL17	This bit indicates whether or not 17 can be set as a system protection identifier.	R	*1
16	SL16	This bit indicates whether or not 16 can be set as a system protection identifier.	R	*1
15	SL15	This bit indicates whether or not 15 can be set as a system protection identifier.	R	*1
14	SL14	This bit indicates whether or not 14 can be set as a system protection identifier.	R	*1
13	SL13	This bit indicates whether or not 13 can be set as a system protection identifier.	R	*1
12	SL12	This bit indicates whether or not 12 can be set as a system protection identifier.	R	*1
11	SL11	This bit indicates whether or not 11 can be set as a system protection identifier.	R	*1
10	SL10	This bit indicates whether or not 10 can be set as a system protection identifier.	R	*1
9	SL9	This bit indicates whether or not 9 can be set as a system protection identifier.	R	*1
8	SL8	This bit indicates whether or not 8 can be set as a system protection identifier.	R	*1
7	SL7	This bit indicates whether or not 7 can be set as a system protection identifier.	R	*1
6	SL6	This bit indicates whether or not 6 can be set as a system protection identifier.	R	*1
5	SL5	This bit indicates whether or not 5 can be set as a system protection identifier.	R	*1
4	SL4	This bit indicates whether or not 4 can be set as a system protection identifier.	R	*1
3	SL3	This bit indicates whether or not 3 can be set as a system protection identifier.	R	*1
2	SL2	This bit indicates whether or not 2 can be set as a system protection identifier.	R	*1
1	SL1	This bit indicates whether or not 1 can be set as a system protection identifier.	R	*1
0	SL0	This bit indicates whether or not 0 can be set as a system protection identifier.	R	*1

Note 1. See **Section 3.8.7, Product Information of Initial Value for G4MH Register**.

(16) RBASE — Reset Vector Base Address

This register indicates the reset vector address when there is a reset. If the PSW.EBV bit is 0, this register indicates the exception handler vector address and the selection method of exception handler address.

Table 3.25 RBASE Register Contents

Bit	Name	Description	R/W	Value after Reset
31 to 9	RBASE31 to RBASE9	These bits indicate the reset vector when there is a reset. When PSW.EBV = 0, this address is also used as the exception vector. The RBASE8 to RBASE0 bits are not assigned as names because these bits are always 0.	R	*1
8 to 2	—	(Reserved for future expansion. Be sure to set to 0.)	R	0
1	DV	When the DV bit is set, the exception handler address for interrupt is determined by using the direct vector method. For details, see Section 3.2.4.4(1)(b), Table Reference Method . This bit is valid when PSW.EBV = 0.	R	*1
0	RINT	When the RINT bit is set, the exception handler address for interrupt processing is reduced. See Section 3.2.4.4(1)(a), Direct Vector Method . This bit is valid when PSW.EBV = 0.	R	*1

Note 1. See **Section 3.8.7, Product Information of Initial Value for G4MH Register**.

(17) EBASE — Exception Handler Vector Address

This register indicates the exception handler vector address and the selection method of exception handler address. This register is valid when the PSW.EBV bit is 1.

Table 3.26 EBASE Register Contents

Bit	Name	Description	R/W	Value after Reset
31 to 9	EBASE31 to EBASE9	The exception handler routine address is changed to the address resulting from adding the offset address of each exception to the base address specified for this register. The EBASE8 to EBASE0 bits are not assigned as names because these bits are always 0.	R/W	Undefined
8 to 2	—	(Reserved for future expansion. Be sure to set to 0.)	R	0
1	DV	When the DV bit is set, the exception handler address for interrupt is determined by using the direct vector method. For details, see Section 3.2.4.4(1)(b), Table Reference Method .	R/W	Undefined
0	RINT	When the RINT bit is set, the exception handler address for interrupt processing is reduced. See Section 3.2.4.4(1)(a), Direct Vector Method .	R/W	Undefined

(18) INTBP — Base Address of the Interrupt Handler Address Table

This register indicates the base address of the table when the table reference method is selected as the interrupt handler address selection method.

Table 3.27 INTBP Register Contents

Bit	Name	Description	R/W	Value after Reset
31 to 9	INTBP31 to INTBP9	These bits indicate the base pointer address for an interrupt when the table reference method is used. The value indicated by these bits is the first address in the table used to determine the exception handler when the interrupt specified by the table reference method (EIINT n) is acknowledged. The INTBP8 to INTBP0 bits are not assigned as names because these bits are always 0.	R/W	Undefined
8 to 0	—	(Reserved for future expansion. Be sure to set to 0.)	R	0

(19) MCTL — Machine Control

The MCTL register is used to control the CPU.

Table 3.28 MCTL Register Contents

Bit	Name	Description	R/W	Value after Reset
31 to 1	—	(Reserved for future expansion. Be sure to set to 0.)	R	0
0	UIC	This bit is used to control the interrupt enable/disable operation in user mode. When this bit is set to 1, executing the EI/DI instruction in user mode become possible.	R/W	0

(20) PID — Processor ID

The PID register retains a processor identifier that is unique to the CPU. The PID register is a read-only register.

CAUTION

The PID register indicates information used to identify the incorporated CPU core and CPU core configuration. Usage such that the software behavior varies dynamically according to the PID register information is not assumed.

Table 3.29 PID Register Contents

Bit	Name	Description	R/W	Value after Reset
31 to 24	PID	Architecture Identifier This identifier indicates the architecture of the processor.	R	*1
23 to 8		Function Identifier This identifier indicates the functions of the processor. These bits indicate whether or not functions defined per bit are implemented (1: implemented, 0: not implemented). Bit 23 to19: Reserved Bit 18: Register bank Bit 17 to12: Reserved Bit 11: Extended floating-point operation function Bit 10: Double-precision floating-point operation function Bit 9: Single-precision floating-point operation function Bit 8: Memory protection unit (MPU) function	R	*1
7 to 0		Version Identifier This identifier indicates the version of the processor.	R	*1

NOTE: If a double-precision floating-point operation function is implemented (when bit 10 is 1), a single-precision floating-point operation function is also always implemented (bit 9 is 1).

Note 1. For details, see **Section 3.8.7, Product Information of Initial Value for G4MH Register.**

(21) SVLOCK — Supervisor Lock

The SVLOCK register is used to restrict the CPU operation in supervisor mode.

Table 3.30 SVLOCK Register Contents

Bit	Name	Description	R/W	Value after Reset
31 to 1	—	(Reserved for future expansion. Be sure to set to 0.)	R	0
0	SVL	This bit specifies whether to restrict the CPU operation in supervisor mode. 0: Does not restrict the CPU operation in supervisor mode. 1: Restrict the CPU operation in supervisor mode. If the SVL bit is set to 1, the following system registers* ¹ cannot be updated even when the CPU is in supervisor mode: SPID, MPM, MPLA, MPUA, MPAT, MPID _n For details, see Section 3.2.2.5(5), Supervisor Lock Setting.	R/W	0

Note 1. The target system registers are those registers that are associated with memory accessing. This register prevents these registers from being rewritten carelessly and unintentional memory access from being performed outside the CPU.

(22) SCCFG — SYSCALL Operation Setting

This register is used to set operations related to the SYSCALL instruction. Be sure to set an appropriate value to this register before using the SYSCALL instruction.

Table 3.31 SCCFG Register Contents

Bit	Name	Description	R/W	Value after Reset
31 to 8	—	(Reserved for future expansion. Be sure to set to 0.)	R	0
7 to 0	SIZE	These bits specify the maximum number of entries of a table that the SYSCALL instruction references. The maximum number of entries the SYSCALL instruction references is 1 if SIZE is 0, and 256 if SIZE is 255. By setting the maximum number of entries appropriately in accordance with the number of functions branched by the SYSCALL instruction, the memory area can be effectively used. If a vector exceeding the maximum number of entries is specified for the SYSCALL instruction, the first entry is selected. Place an error processing routine at the first entry.	R/W	0

(23) SCBP — SYSCALL Base Pointer

The SCBP register is used to specify a table address of the SYSCALL instruction and generate a target address. Be sure to set an appropriate value to this register before using the SYSCALL instruction.

Be sure to set a word address to the SCBP register.

Table 3.32 SCBP Register Contents

Bit	Name	Description	R/W	Value after Reset
31 to 2	SCBP31 to SCBP2	These bits indicate the base pointer address of the SYSCALL instruction. These bits indicate the start address of the table used by the SYSCALL instruction.	R/W	0
1, 0	SCBP1, SCBP0	These bits indicate the base pointer address of the SYSCALL instruction. These bits indicate the start address of the table used by the SYSCALL instruction. Always set these bits to 0.	R	0

(24) PEID — Processor Element Identifier

Table 3.33 PEID Register Contents

Bit	Name	Description	R/W	Value after Reset
31 to 3	—	(Reserved for future expansion. Be sure to set to 0.)	R	0
2 to 0	PEID	These bits indicate the processor element identifier.	R	*1

Note 1. The processor element identifier of the CPU which is defined by the product specification is read. Writing to these bits is not possible. For details, see **Section 3.8.7, Product Information of Initial Value for G4MH Register**.

(25) BMID — Bus Master Identifier

Table 3.34 BMID Register Contents

Bit	Name	Description	R/W	Value after Reset
31 to 5	—	(Reserved for future expansion. Be sure to set to 0.)	R	0
4 to 0	BMID	These bits indicate the bus master identifier.	R	*1

Note 1. The bus master identifier of the CPU which is defined by the product specification is read. Writing to these bits is not possible. For details, see **Section 3.8.7, Product Information of Initial Value for G4MH Register**.

(26) MEA — Memory Error Address

Table 3.35 MEA Register Contents

Bit	Name	Description	R/W	Value after Reset
31 to 0	MEA	These bits holds the address in which an MAE (misalignment) or MPU violation occurred.	R/W	Undefined

(27) MEI — Memory Error Information

The MEI register holds the information about the instruction that caused a misalignment exception (MAE) or memory protection exception (MDP). The information can be used as hint information for the emulation by software.

Table 3.36 MEI Register Contents

Bit	Name	Description	R/W	Value after Reset
31 to 28	LEN	These bits indicate the code size of the instruction that causes the exception. 0: Non-instruction factor 2: 16 bits 4: 32 bits 6: 48 bits 8 :64 bits Values other than those listed above are reserved for future use and never stored here. For details, see Table 3.37 .	R/W	Undefined
27 to 21	—	(Reserved for future expansion. Be sure to set to 0.)	R	0
20 to 16	REG	These bits indicate the source register number or destination register number of the instruction that caused the exception. For details, see Table 3.37 .	R/W	Undefined
15 to 12	—	(Reserved for future expansion. Be sure to set to 0.)	R	0
11 to 9	DS	These bits indicate the data type of the instruction that caused the exception*1. 0: Byte (8 bits) 1: Halfword (16 bits) 2: Word (32 bits) 3: Double-word (64 bits) 4: Quad-word (128 bits) Values other than those listed above are reserved for future use and never stored here. For details, see Table 3.37 .	R/W	Undefined
8	U	This bit indicates the sign extension method of the instruction that caused the exception. 0: Signed 1: Unsigned For details, see Table 3.37 .	R/W	Undefined
7 to 6	—	(Reserved for future expansion. Be sure to set to 0.)	R	0
5 to 1	ITYPE	These bits indicate the instruction that caused the exception. For details, see Table 3.37 .	R/W	Undefined
0	RW	This bit indicates whether the operation performed by the instruction that caused the exception is a read (Load-memory) or a write (Store-memory). 0: Read (Load-memory) 1: Write (Store-memory) For details, see Table 3.37 .	R/W	Undefined

Note 1. Even if the data is divided and access is made several times due to the specifications of the hardware, the original data type indicated by the instruction is stored.

STVZ.H4 (disp16)	6 (48 bits)	src	3 (Double-word)	0 (Signed)	1 (Write)	11111 _B

Remarks: dst: Destination register number; src: Source register number

Note 1. Specific to this CPU.

Note 2. This exception occurs when the instruction executes a read access.

Note 3. When the destination is r3, 0 is stored.

Note 4. When an exception occurs during a table reference that is triggered by an interrupt for which the table reference method is selected,

Note 5. In instruction format (1), "4 (32 bits)" is set.

Note 6. In instruction format (2), the value is selected as follows according to the value of the ff field in the instruction code:

ff = 00_B: 4 (32 bits)

ff = 01_B: 6 (48 bits)

ff = 10_B: 6 (48 bits)

ff = 11_B: 8 (64 bits)

(28) RBCR0 — Register Bank Control 0

Table 3.38 RBCR0 Register Contents

Bit	Name	Description	R/W	Value after Reset
31 to 17	—	(Reserved for future expansion. Be sure to set to 0.)	R	0
16	MD	This bit specifies the save mode of the register bank. 0: Save mode 0 1: Save mode 1	R/W	0
List of Registers to be Saved

PC		✓	✓	
PSW		✓	✓	
EIIC		✓	✓	
FPSR		✓	✓	
r1-r19		✓	✓	
r20-r29		—	✓	
r30		✓	✓	
r31		—	✓	
✓: Saved —: Not saved				
15 to 0	BE15 to BE0	These bits specify the priority level of the interrupt on which the register bank is to be used. 0: Do not use the register bank on an interrupt of the level corresponding to this bit. 1: Use the register bank on an interrupt of the level corresponding to this bit.	R/W	0
The bit positions correspond to the priority levels of the interrupts as follows:				
Bit	Priority Level			
0	Level 0 (highest priority)			
1	Level 1			
	:			
14	Level 14			
15	Level 15 (lowest priority)			
The register bank is used when an interrupt (EIINT _n) of a level is accepted while the bit corresponding to that level is set (1).				

(29) RBCR1 — Register Bank Control 1

Table 3.39 RBCR1 Register Contents

Bit	Name	Description	R/W	Value after Reset
31 to 16	—	(Reserved for future expansion. Be sure to set to 0.)	R	0
15 to 0	NC15 to NC0	These bits specify the values to be set to the PSW.ID bit when an interrupt (EIINT _n) of the priority level corresponding to the bit position is accepted. 0: PSW.ID is set to 0 when an interrupt of the priority level corresponding to the bit position is accepted. 1: PSW.ID is set to 1 when an interrupt of the priority level corresponding to the bit position is accepted (initial value).	R/W	FFFF _H

This setting, however, is enabled only when the interrupt handler address selection method is set to the table reference method and the use of the register banks is enabled.

The bit positions correspond to the priority levels of the interrupts as follows:

Bit	Priority Level
0	Level 0 (highest priority)
1	Level 1
:	
14	Level 14
15	Level 15 (Lowest priority)

(30) RBNR — Register Bank Number

Table 3.40 RBNR Register Contents

Bit	Name	Description	R/W	Value after Reset
31 to 5	—	(Reserved for future expansion. Be sure to set to 0.)	R	0
4 to 0	BN	These bits indicate the number of the register bank to be used next. The value in these bits is incremented by 1 when an interrupt (EIINT _n) that uses a register bank is accepted. If an interrupt that uses a register bank occurs when the value of BN is greater than 15, the interrupt is not accepted and held pending, and a SYSERR exception is generated. The value of BN is decremented by 1 when a RESBANK instruction is executed. If the RESBANK instruction is executed when the value of BN is 0, the instruction is not executed and a SYSERR exception is generated. In this case, BN is not updated and its value remains the same. If an attempt is made to write a value of 16 or greater to these bits, the value of BN becomes 16.	R/W	0

(31) RBIP — Register Bank Initial Pointer

Table 3.41 RBIP Register Contents

Bit	Name	Description	R/W	Value after Reset
31 to 4	RBIP31 to RBIP4	<p>These bits indicate the initial pointer to the register bank.</p> <p>The values of RBCR0.MD and RBNR.BN together with this value determine the memory address to which the next register bank to be used is allocated as follows.</p> <ul style="list-style-type: none"> • Save mode 0 (RBCR0.MD = 0): $RBIP - RBNR.BN \times 60_H$ • Save mode 1 (RBCR0.MD = 1): $RBIP - RBNR.BN \times 90_H$ 	R/W	Undefined
3 to 0	—	(Reserved for future expansion. Be sure to set to 0.)	R	0

3.2.3.3 Interrupt Function Registers

(1) Interrupt Function System Registers

Interrupt function system registers are read from or written to by using the LDSR and STSR instructions and specifying the system register number, which is made up of a register number and selection ID.

Table 3.42 Interrupt Function System Registers

Register No. (regID, selID)	Symbol	Function	Access Permission
SR10, 2	ISPR	Priority of interrupt being serviced	SV
SR12, 2	ICSR	Interrupt control status	SV
SR13, 2	INTCFG	Interrupt function setting	SV
SR14, 2	PLMR	Interrupt priority masking	SV

(a) ISPR — Priority of Interrupt being Serviced

The ISPR register holds the priority levels of the EIINT n interrupts that are being processed by the CPU so that priority sealing can be performed based on interrupt priorities when multiple interrupts occurred.

Table 3.43 ISPR Register Contents

Bit	Name	Description	R/W	Value after Reset
31 to 16	—	(Reserved for future expansion. Be sure to set to 0.)	R	0
15 to 0	ISP15 to ISP0	These bits indicate the acknowledgment status of an EIINT n interrupt with a priority* ¹ that corresponds to the relevant bit position. 0: An interrupt request for an interrupt whose priority corresponds to the relevant bit position has not been acknowledged. 1: An interrupt request for an interrupt whose priority corresponds to the relevant position is being serviced by the CPU core.	R* ³	0

The bit positions correspond to the priority levels of the interrupts as follows:

Bit	Priority
0	Priority 0 (highest)
1	Priority 1
:	
14	Priority 14
15	Priority 15 (lowest)

When an interrupt request (EIINT n) is acknowledged, the bit corresponding to the acknowledged interrupt request is automatically set to 1. If PSW.EP is 0 when the EIRET instruction is executed, the bit with the highest priority among the ISP15 to ISP0 bits that are set (0 is the highest priority) is cleared to 0*². While a bit in this register is set to 1, same or lower priority interrupts (EIINT n) are masked. Priority level judgment is therefore not performed when the system is determining whether to acknowledge an exception, meaning that exceptions will not be acknowledged.

For details, see **Section 3.2.4.1(5), Interrupt Exception Priority and Priority Masking.**

When performing software-based priority control using the PLMR register, be sure to clear this register by using the INTCFG.ISPC bit.

Note 1. For details, see **Section 3.2.4.1(5), Interrupt Exception Priority and Priority Masking.**

Note 2. Interrupt acknowledgment and auto-updating of values when the EIRET instruction is executed are disabled by setting (1) the INTCFG.ISPC bit. It is recommended to enable auto-updating of values, so in normal cases, the INTCFG.ISPC bit should be cleared to 0.

Note 3. This is R or R/W, depending on the setting of the INTCFG.ISPC bit. It is recommended to use this register as a read-only (R) register.

(d) PLMR — Interrupt Priority Level Mask

This register masks the interrupts (EIINT n) whose priority level is not higher than the level specified by these bits.

Table 3.46 PLMR Register Contents

Bit	Name	Description	R/W	Value after Reset
31 to 5	—	(Reserved for future expansion. Be sure to set to 0.)	R	0
4 to 0	PLM	These bits are used to mask the interrupts (EIINT n) whose priority level is not higher than the level specified by these bits. When an interrupt (EIINT n) is masked by this register, it is not accepted.	R/W	10 _H

The correspondence between the value of the PLM bit and the highest priority of interrupts to be masked is shown below.

Value of PLM Bit	Highest Priority of Interrupts to be Masked
0	Priority 0 (highest priority)
1	Priority 1
:	
14	Priority 14
15	Priority 15 (lowest priority)
16 or greater	No mask

Since the highest priority level of an interrupt that is defined for this CPU is 0, if 0 is specified in the PLM bit, all interrupts (EIINT n) are masked by this register. Since the lowest priority level that is defined for this CPU is 15, no interrupts are masked by this register if 16 or greater value is specified in the PLM bit.

If the value of PLMR is altered by the LDSR instruction, the new PLMR value is reflected in the instructions following that LDSR instruction.

3.2.3.4 FPU Function Registers

(1) Floating-Point Registers

The FPU uses the CPU general-purpose registers (r0 to r31). There are no register files used only for floating-point operations.

- Single-precision floating-point instruction:
Thirty-two 32-bit registers can be specified. These general-purpose registers correspond to r0 to r31.
- Double-precision floating-point instruction:
Sixteen 64-bit registers can be specified. Paired general-purpose registers are used as register pairs ({r1, r0}, {r3, r2} ... {r31, r30}). Each register pair is specified in the instruction format with an even numbered register. Because r0 is a zero register (always holds 0), in principle {r1, r0} cannot be used by a double-precision floating-point instruction.

(2) Floating-Point Function System Registers

The FPU can use the following system registers to control floating-point operations. Floating-point function system registers are read from or written to by using the LDSR and STSR instructions and specifying the system register number, which is made up of a register number and selection ID.

- FPSR: This register is used to control and monitor exceptions. It also holds the result of compare operations, and sets the FPU operation mode. Its bits are used to set condition code, subnormal number flush enable, rounding mode control, cause, exception enable, and preservation.
- FPEPC: This register stores the program counter value for the instruction where a floating-point operation exception has occurred.
- FPST: This register reflects the contents of the FPSR register bits related to the operation status.
- FPCC: This register reflects the contents of the FPSR.CC (7:0) bits.
- FPCFG: This register reflects the contents of the FPSR register bits related to the operation settings.

Table 3.47 FPU System Registers

Register No. (regID, selID)	Symbol	Function	Access Permission
SR6, 0	FPSR	Floating-point operation configuration/status	CU0 and SV
SR7, 0	FPEPC	Floating-point operation exception program counter	CU0 and SV
SR8, 0	FPST	Floating point operation status	CU0
SR9, 0	FPCC	Floating-point operation comparison result	CU0
SR10, 0	FPCFG	Floating-point operation configuration	CU0

(a) FPSR — Floating-point Configuration/Status

This register indicates the execution status of floating-point operations and any exceptions that occur. For details about exception, see **Section 3.2.6.1(5), Floating-Point Operation Exceptions**.

Note 1. See the descriptions of each bit.

Table 3.48 FPSR Register Contents (1/2)

Bit	Name	Description	R/W	Value after Reset																						
31 to 24	CC7 to CC0	These are the CC (condition) bits. They store the results of floating-point comparison instructions. The CC7 to CC0 bits are not affected by any instructions except the comparison instruction and LDSR instruction. 0: Comparison result is false 1: Comparison result is true	R/W	Undefined																						
23	FN	This bit enables flush-to-nearest mode. When the FN bit is set to 1, if the rounding mode is RN and the operation result is a subnormal number, the number is flushed to the nearest number. For details, see Section 3.2.6.1(9), Flush to Nearest .	R/W	0																						
22	IF	This bit accumulates and indicates information about the flushing of input operands. For details about flushing subnormal numbers, see Section 3.2.6.1(8), Flushing Subnormal Numbers .	R/W	0

15 to 10	XC (E,V,Z,O,U,I)	These are the cause bits. For details, see Section 3.2.3.4.2.a.1, Cause Bits (XC) .	R/W	Undefined																			
9 to 5	XE (V,Z,O,U,I)	These are the enable bits. For details, see Section 3.2.3.4.2.a.2, Enable Bits (XE) .	R/W	0																			
4 to 0	XP (V,Z,O,U,I)	These are the preservation bits. For details, see Section 3.2.3.4.2.a.3, Preservation Bits (XP) .	R/W	Undefined																			

3.2.3.4.2.a.1 Cause Bits (XC)

Bits 15 to 10 in the FPSR register are cause bits, which indicate the occurrence and cause of a floating-point operation exception. If an exception defined by IEEE754 is generated, when an enable bit is set to 1 corresponding to the exception, a cause bit is set, and the exception then occurs. When two or more exceptions occur during a single instruction, each corresponding bit is set to 1.

If two or more exceptions are detected, as long as the enable bit corresponding to one of the exceptions is set to 1, the exception occurs. In this case, the cause bits of all the detected exceptions, including exceptions whose enable bits are cleared to 0, are set to 1.

The cause bits are rewritten by a floating-point instruction (except the TRFSR instruction) where the floating-point operation exception occurred. The E bit is set to 1 when software emulation is required, otherwise it is cleared to 0. Other bits are set to 1 or cleared to 0 depending on whether or not an IEEE754-defined exception has occurred.

When a floating-point operation exception has occurred, the operation result is not stored, and only the cause bits are affected.

When the cause bits are set to 1 by an LDSR instruction, a floating-point operation exception does not occur.

3.2.3.4.2.a.2 Enable Bits (XE)

Bits 9 to 5 in the FPSR register are the enable bits, which enable floating-point operation exceptions. When an IEEE754-defined exception occurs, a floating-point operation exception occurs if the enable bit corresponding to the exception has been set to 1.

There are no enable bits corresponding to an unimplemented operation exception (E). An unimplemented operation exception (E) always occurs as a floating-point operation exception.

If the corresponding enable bit has not been set to 1, no exception occurs and the default result defined by IEEE754 is stored.

3.2.3.4.2.a.3 Preservation Bits (XP)

Bits 4 to 0 in the FPSR register are preservation bits. These bits store and indicate the detected exception after reset. An exception defined by IEEE754 occurs, and if a floating-point operation exception is not generated, the preservation bit is set to 1, otherwise it does not change. The preservation bits are not cleared to 0 by the floating-point operation. However, these bits can be set and cleared by software when an LDSR instruction is used to write a new value to the FPSR register.

There are no preservation bits corresponding to unimplemented operation exceptions (E). An unimplemented operation exception (E) always occurs as a floating-point operation exception.

NOTE

For details about the exception types and how they relate to particular bits, see **Figure 3.37, Cause, Enable, and Preservation Bits of FPSR Register**.

(b) FPEPC — Floating-point Exception Program Counter

When an exception that is enabled by an enable bit occurs, the program counter (PC) of the instruction that caused the exception is stored.

Table 3.49 FPEPC Register Contents

Bit	Name	Description	R/W	Value after Reset
31 to 1	FPEPC31 to FPEPC1	These bits store the program counter (PC) of the floating-point instruction that caused the exception when a floating-point operation exception that is enabled by an enable bit occurs.	R/W	Undefined
0	FPEPC0	This bit stores the program counter (PC) of the floating-point instruction that caused the exception when a floating-point operation exception that is enabled by an enable bit occurs.	R	0

(c) FPST — Floating-point Operation Status

This register reflects the contents of the FPSR register bits related to the operation status.

Table 3.50 FPST Register Contents

Bit	Name	Description	R/W	Value after Reset
31 to 14	—	(Reserved for future expansion. Be sure to set to 0.)	R	0
13 to 8	XC (E, V, Z, O, U, I)	These are cause bits. For details, see Section 3.2.3.4.2.a.1, Cause Bits (XC) . Values written to these bits are reflected in FPSR.XC bits.	R/W	Undefined
7, 6	—	(Reserved for future expansion. Be sure to set to 0.)	R	0
5	IF	This bit accumulates and indicates information about the flushing of input operands. For details about flushing subnormal numbers, see Section 3.2.6.1(8), Flushing Subnormal Numbers . Value written to this bit is reflected in FPSR.IF bit.	R/W	0
4 to 0	XP (V, Z, O, U, I)	These are preservation bits. For details, see Section 3.2.3.4.2.a.3, Preservation Bits (XP) . Values written to these bits are reflected in FPSR.XP bits.	R/W	Undefined

(d) FPCC — Floating-point Operation Comparison Result

This register reflects the contents of the FPSR.CC7 to FPSR.CC0 bits.

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

3.2.3.5 FXU Function Registers

(1) Vector Registers

32 vector registers (wr0-wr31) are provided as data registers dedicated to the extended floating-point operation unit (FXU). All of these registers can be used to store data variables. The data width of these registers is 128 bits. The values of the vector registers wr0 to wr31 after reset are undefined.

As shown in **Figure 3.15** and **Table 3.53**, one vector register consists of 4 arithmetic ways. One single-precision floating-point data is stored in one arithmetic way. This allows four single-precision floating-point operations to be performed with one extended floating-point operation instruction.

Figure 3.15 Vector Register Configuration

Table 3.53 Way Configuration of Vector Registers

Name	Bits	Function
W0	[31:0]	Way 0 data
W1	[63:32]	Way 1 data
W2	[95:64]	Way 2 data
W3	[127:96]	Way 3 data

(2) Extended Floating-point Function System Registers

The FXU can use the following system registers to control arithmetic operations. Extended floating-point function system registers are read from or written to by using the LDSR and STSR instructions and specifying the system register number, which is made up of a register number and selection ID.

- **FXSR:** This register is used to control and monitor the extended floating-point operation exceptions. It is also used to set the operation mode of the FXU. It has bits for subnormal flush enabling, rounding mode control, exception cause, exception enabling and preservation.
- **FXST:** This register reflects the contents of the FXSR register bits related to the operation status.
- **FXINFO:** This register holds the information about the configuration of the FXU.
- **FXCFG:** This register reflects the contents of the FXSR register bits related to the operation settings.
- **FXXC:** This register holds the XC (cause) bits of extended floating-point operation exceptions for each arithmetic way.
- **FXXP:** This register holds the XP (preservation) bits of extended floating-point operation exceptions for each arithmetic way.

Table 3.54 List of Extended Floating-point Function System Registers

Register Number (regID, selID)	Name	Function	Access Permission
SR6, 10	FXSR	Extended floating-point operation configuration/status	CU1 and SV
SR8, 10	FXST	Extended floating-point operation status	CU1
SR9, 10	FXINFO	FXU configuration information	CU1
SR10, 10	FXCFG	Extended floating-point operation configuration	CU1
SR12, 10	FXXC	XC (cause) bits for each arithmetic way	CU1
SR13, 10	FXXP	XP (preservation) bits for each arithmetic way	CU1

(a) FXSR — Extended Floating-point Operation Configuration/Status

The FXSR register indicates the execution status of extended floating-point operations and occurrence of exceptions.

If the value is exactly in-between the two nearest representable values, the result is rounded toward the value whose least significant bit is 0.	0	1	RZ	Rounds the result toward 0. The result is the nearest to the value that does not exceed the absolute value of the result with infinite accuracy.	1	0	RP	Rounds the result toward $+\infty$. The result is nearest to a value equal to or greater than the accurate result with infinite accuracy.	1	1	RM	Rounds the result toward $-\infty$. The result is nearest to a value equal to or less than the accurate result with infinite accuracy.		
RM Bits		Mnemonic	Description																							
19	18																									
0	0	RN	Rounds the result to the nearest representable value. If the value is exactly in-between the two nearest representable values, the result is rounded toward the value whose least significant bit is 0.																							
0	1	RZ	Rounds the result toward 0. The result is the nearest to the value that does not exceed the absolute value of the result with infinite accuracy.																							
1	0	RP	Rounds the result toward $+\infty$. The result is nearest to a value equal to or greater than the accurate result with infinite accuracy.																							
1	1	RM	Rounds the result toward $-\infty$. The result is nearest to a value equal to or less than the accurate result with infinite accuracy.																							
17	FS	This bit enables values that could not be normalized (subnormal numbers) to be flushed. If the FS bit is set, input operands and operation results that are subnormal numbers are flushed without causing an unimplemented operation exception (E). An input operand that is a subnormal number is flushed to 0 with the same sign. Operation results that are subnormal numbers either become 0 or the minimum normalized number, depending on the rounding mode.	R/W	1																						
		<table border="1"> <thead> <tr> <th rowspan="2">Operation Result that is a Subnormal Number</th> <th colspan="4">Rounding Mode and Value after Flushing</th> </tr> <tr> <th>RN*1</th> <th>RZ</th> <th>RP</th> <th>RM</th> </tr> </thead> <tbody> <tr> <td>Positive</td> <td>+0</td> <td>+0</td> <td>$+2^{E_{min}}$</td> <td>+0</td> </tr> <tr> <td>Negative</td> <td>-0</td> <td>-0</td> <td>-0</td> <td>$-2^{E_{min}}$</td> </tr> </tbody> </table>	Operation Result that is a Subnormal Number	Rounding Mode and Value after Flushing				RN*1	RZ	RP	RM	Positive	+0	+0	$+2^{E_{min}}$	+0	Negative	-0	-0	-0	$-2^{E_{min}}$

<p>Note 1. If the rounding mode is RN and the FXSR.FN bit is set, flushing will occur in the direction of higher accuracy. For details, see Section 3.2.6.2(9), Flush to Nearest.</p>																										

Table 3.55 FXSR Register Contents (2/2)

Bit	Name	Description	R/W	Value after Reset
16	—	(Reserved for future expansion. Be sure to set to 0.)	R	0
15 to 10	XC (E,V,Z,O,U,I)	These are the cause bits. For details, see Section 3.2.3.5.2.a.1, Cause Bits (XC) .	R/W	Undefined
9 to 5	XE (V,Z,O,U,I)	These are the enable bits. For details, see Section 3.2.3.5.2.a.2, Enable Bits (XE) .	R/W	0
4 to 0	XP (V,Z,O,U,I)	These are the preservation bits. For details, see Section 3.2.3.5.2.a.3, Preservation Bits (XP) .	R/W	Undefined

3.2.3.5.2.a.1 Cause Bits (XC)

Bits 15 to 10 in the FXSR register are cause bits, which indicate the occurrence and cause of an extended floating-point operation exception. The FXSR.XC bits hold the OR of the detection results of extended floating-point operation exceptions that occurred in the arithmetic ways. If an exception defined by IEEE754 is generated, when an enable bit is set to 1 corresponding to the exception, a cause bit is set, and the exception then occurs. When two or more exceptions occur during a single instruction, each corresponding bit is set to 1.

If two or more exceptions are detected, as long as the enable bit corresponding to one of the exceptions is set to 1, the exception occurs. In this case, the cause bits of all the detected exceptions, including exceptions whose enable bits are cleared to 0, are set to 1.

The cause bits are rewritten by the extended floating-point operation instruction that caused the extended floating-point operation exception. The E bit is set to 1 when software emulation is required, otherwise it is cleared to 0. Other bits are set to 1 or cleared to 0 depending on whether or not an IEEE754-defined exception has occurred.

When an extended floating-point operation exception has occurred, the operation result is not stored, and only the cause bits are affected.

When the cause bits are set to 1 by an LDSR instruction, no extended floating-point operation exception occurs.

3.2.3.5.2.a.2 Enable Bits (XE)

Bits 9 to 5 in the FXSR register are the enable bits, which enable extended floating-point operation exceptions. When an IEEE754-defined exception occurs, an extended floating-point operation exception occurs if the enable bit corresponding to the exception has been set to 1.

There are no enable bits corresponding to an unimplemented operation exception (E). An unimplemented operation exception (E) always occurs as an extended floating-point operation exception.

The FXSR.XE bits cannot be set on an arithmetic way basis. The same setting is used for the all arithmetic ways.

If the corresponding enable bit has not been set to 1, no exception occurs and the default result defined by IEEE754 is stored.

3.2.3.5.2.a.3 Preservation Bits (XP)

Bits 4 to 0 in the FXSR register are preservation bits and accumulate and indicate the exceptions that have been detected since a reset. An exception defined by IEEE754 occurs, and if an extended floating-point operation exception is not generated, the preservation bit is set to 1, otherwise it does not change. The preservation bits are not cleared to 0 by the extended floating-point operation. However, these bits can be set and cleared by software when an LDSR instruction is used to write a new value to the FXSR register.

There are no preservation bits corresponding to unimplemented operation exceptions (E). An unimplemented operation exception (E) always occurs as an extended floating-point operation exception.

NOTE

For details about the exception types and how they relate to particular bits, see **Figure 3.38, Relationship among the Cause and Enable Bits of the FXSR and FXXC Registers** and **Figure 3.39, Relationship among the Preservation and Enable Bits of the FXSR and FXXP Registers**.

(b) FXST — Extended Floating-point Operation Status

This register reflects the contents of the FXSR register bits related to the operation status.

3.2.3.6 MPU Function Registers

(1) MPU Function System Registers

MPU function system registers are read from or written to by using the LDSR and STSR instructions and specifying the system register number, which is made up of a register number and selection ID.

Table 3.61 MPU Function System Registers

Register No. (regID, selID)	Symbol	Function	Access Permission
SR0, 5	MPM	Memory protection operation mode setting	SV
SR2, 5	MPCFG	MPU configuration	SV
SR8, 5	MCA	Memory protection setting check address	SV
SR9, 5	MCS	Memory protection setting check size	SV
SR10, 5	MCC	Memory protection setting check command	SV
SR11, 5	MCR	Memory protection setting check result	SV
SR12, 5	MCI	Memory protection setting check SPID	SV
SR16, 5	MPIDX	Index of memory protection setting registers to be accessed	SV
SR20, 5	MPLA	Protection area minimum address	SV
SR21, 5	MPUA	Protection area maximum address	SV
SR22, 5	MPAT	Protection area attribute	SV
SR24, 5	MPID0	SPID which can access protection area	SV
SR25, 5	MPID1	SPID which can access protection area	SV
SR26, 5	MPID2	SPID which can access protection area	SV
SR27, 5	MPID3	SPID which can access protection area	SV
SR28, 5	MPID4	SPID which can access protection area	SV
SR29, 5	MPID5	SPID which can access protection area	SV
SR30, 5	MPID6	SPID which can access protection area	SV
SR31, 5	MPID7	SPID which can access protection area	SV

(a) MPM — Memory Protection Operation Mode

The memory protection operation mode register is used to define the basic operation mode of the memory protection function.

Table 3.62 MPM Register Contents

Bit	Name	Description	R/W	Value after Reset
31 to 2	—	(Reserved for future expansion. Be sure to set to 0.)	R	0
1	SVP	In SV mode (when PSW.UM = 0), this bit is used to specify whether to restrict access according to the SX, SW, and SR bits of the MPAT register for each protection area.*1 0: Enable all accesses in SV mode. 1: Restrict access according to the SX, SW, and SR bits in SV mode.*2	R/W	0
0	MPE	This bit is used to specify whether to enable or disable MPU function. 0: Disable 1: Enable	R/W	0

Note 1. When the SVP bit is set to 1 by an LDSR instruction, the setting is effective from the operand access by the subsequent instruction. On the other hand, since the instruction fetch access is executed independently from the setting of the SVP bit, it is not possible to identify the timing when the new setting is applied to the instruction fetch access. In this case, make settings of the protection area in advance so that the program which sets the SVP bit itself will not be blocked.

Note 2. If the SVP bit is set to 1, the MDP or MIP exception handler cannot be executed if it is not permitted to access to the necessary memory areas. Be sure to make settings of the protection area in advance so that the necessary memory areas can be accessed by the exception handler.

(b) MPCFG — MPU Configuration

This register holds the information about the configuration of the MPU.

Table 3.63 MPCFG Register Contents

Bit	Name	Description	R/W	Value after Reset
31 to 20	—	(Reserved for future expansion. Be sure to set to 0.)	R	0
19 to 16	ARCH	These bits indicate the version of the MPU architecture specifications. A value of 1 is read for this CPU.	R	1
15 to 5	—	(Reserved for future expansion. Be sure to set to 0.)	R	0
4 to 0	NMPUE	These bits indicate the number of MPU entries implemented in this CPU minus 1. A value of 23 is read since this CPU incorporates 24 MPU entries.	R	23

(c) MCA — Memory Protection Setting Check Address

This register is used to specify the base address of the area for which a memory protection setting check is to be performed.

Table 3.64 MCA Register Contents

Bit	Name	Description	R/W	Value after Reset
31 to 0	MCA31 to MCA0	These bits are used to specify the starting address of the memory area which subjects to a memory protection setting check in bytes.	R/W	Undefined

(d) MCS — Memory Protection Setting Check Size

This register is used to specify the size of the area for which a memory protection setting check is to be performed.

Table 3.65 MCS Register Contents

Bit	Name	Description	R/W	Value after Reset
31 to 0	MCS31 to MCS0	These bits are used to specify the size of the memory area in bytes which subjects to a memory protection setting check. Because the specified size is assumed to represent an unsigned integer, it is not possible to check an area in the direction in which the address value decreases relative to the MCA register value.	R/W	Undefined

(e) MCC — Memory Protection Setting Check Command

This command register is used to start a memory protection setting check.

Table 3.66 MCC Register Contents

Bit	Name	Description	R/W	Value after Reset
31 to 0	MCC31 to MCC0	When any value is written to the MCC register, a memory protection setting check starts. By setting up the MCA / MCS register and then writing to the MCC register, results are stored in MCR. Because the check is started by any written value, a check can be started by using r0 as the source register without using any unnecessary registers. Note that, for the check, the results are applied according to each area setting regardless of the state of the PSW.UM bit. When the MCC register is read, value 0000 0000 _H is always returned.	R/W	0

(f) MCR — Memory Protection Setting Check Result

This register is used to store the results of a memory protection setting check.

When the MCC register is written, the value of the MPIDn registers (n = 0 to 7), the WMPIDn bits (n = 0 to 7) (for write permission) and the RMPIDn bits (n = 0 to 7) (for execution and read permission) of each MPAT register are checked to verify that the SPID specified by the MCI register matches the SPID for which the access is permitted.

However, if the WG bit or RG bit of the MPAT register is set to 1, it is assumed that the SPID specified by the MCI register matches the SPID for which write or execution and read access is permitted regardless of the SPID matching result above.

If an SPID match is found, protection attributes of the protection area which includes the address area specified by the MCA and MCS registers are stored in the corresponding attribute bits of the MCR register. If multiple protection areas include the specified address area, and if an access is permitted by any of the protection areas, 1, which indicates the access is permitted, is stored in the corresponding attribute bits of the MCR register.

If no SPID match is found or no protection area including the specified address area exists, 0, which indicates the access is not permitted, is stored in each attribute bit of the MCR register.

CAUTION

If the specified area to be checked crosses 0000 0000_H or 7FFF FFFF_H, it is judged as an area setting error, and the MCR.OV bit is set to 1. This means that the MCR.OV bit must be read to confirm that the result is not invalid (OV = 0) before referencing the check result of each attribute bit. When the MCR.OV bit is set to 1, all attribute bits are cleared to 0 unless the MPM.SVP bit is 0. If the MPM.SVP bit is 0, the MCR.SXE, SWE and SRE bits are set to 1, even if the MCR.OV bit is set to 1. Even when no SPID match is found, the MCR.OV bit is set to 1 if the area setting is wrong.

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
MCR	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 3.67 MCR Register Contents (1/2)

Bit	Name	Description	R/W	Value after Reset
31 to 9	—	(Reserved for future expansion. Be sure to set to 0.)	R	0
8	OV	If the specified area includes 0000 0000 _H or 7FFF FFFF _H , 1 is stored in this bit. In other cases, 0 is stored in this bit.	R/W	Undefined
7, 6	—	(Reserved for future expansion. Be sure to set to 0.)	R	0
5	SXE	If the specified area is contained within one protection area and execution is permitted for that area in supervisor mode, 1 is stored in this bit. In other cases, 0 is stored in this bit.	R/W	Undefined
4	SWE	If the specified area is contained within one protection area and writing to that area is permitted in supervisor mode, 1 is stored in this bit. In other cases, 0 is stored in this bit.	R/W	Undefined
3	SRE	If the specified area is contained within one protection area and reading from that area is permitted in supervisor mode, 1 is stored in this bit. In other cases, 0 is stored in this bit.	R/W	Undefined
2	UXE	If the specified area is contained within one protection area and execution is permitted for that area in user mode, 1 is stored in this bit. In other cases, 0 is stored in this bit.	R/W	Undefined

Table 3.67 MCR Register Contents (2/2)

Bit	Name	Description	R/W	Value after Reset
1	UWE	If the specified area is contained within one protection area and writing from that area is permitted in user mode, 1 is stored in this bit. In other cases, 0 is stored in this bit.	R/W	Undefined
0	URE	If the specified area is contained within one protection area and reading from that area is permitted in user mode, 1 is stored in this bit. In other cases, 0 is stored in this bit.	R/W	Undefined

(g) MCI — Memory Protection Setting Check SPID

This register is used to specify the SPID for which a memory protection settings check is to be performed.

Table 3.68 MCI Register Contents

Bit	Name	Description	R/W	Value after Reset
31 to 5	—	(Reserved for future expansion. Be sure to set to 0.)	R	0
4 to 0	SPID	These bits specify the SPID for which a memory protection settings check is to be performed.	R/W	Undefined

(h) MPIDX — Index of Memory Protection Setting Registers to be Accessed

This register is used to specify the index of memory protection setting registers to be accessed.

Table 3.69 MPIDX Register Contents

Bit	Name	Description	R/W	Value after Reset
31 to 5	—	(Reserved for future expansion. Be sure to set to 0.)	R	0
4 to 0	IDX	These bits specify the index of the MPLA, MPUA, and MPAT registers to be accessed by the LDSR or STSR instruction. The result of changing the value of this register is reflected in the instruction immediately following. This CPU provides 24 channels of protection areas, so that IDX may be set to a value from 0 to 23. If a value from 24 to 31 is set to IDX and the MPLA, MPUA, or MPAT register is accessed by the LDSR or STSR instruction, it is handled as an undefined register.	R/W	0

(i) MPLA — Protection Area Minimum Address

This register indicates the minimum address of a protection area. The value written into this register with the LDSR instruction is set as the minimum address of area n ($n = 0$ to 23) specified in the MPIDX register. The value read from this register with the STSR instruction is the minimum address of area n specified in the MPIDX register. It is impossible to manipulate the minimum address of area n without using the MPIDX register and this register.

This CPU provides 24 channels of protection areas, so that the MPLA register can be used specifying a value from 0 to 23 in the MPIDX register. If a value from 24 to 31 is specified in the MPIDX register, the register is handled as an undefined register.

Table 3.70 MPLA Register Contents

Bit	Name	Description	R/W	Value after Reset
31 to 2	MPLA31 to MPLA2	These bits specify the minimum address of area n ($n = 0$ to 23) specified by the MPIDX register. The specified minimum address is included in the range of area matching.	R/W	Undefined
1, 0	—	(Reserved for future expansion. Be sure to set to 0.)	R	0

(j) MPUA — Protection Area Maximum Address

This register indicates the maximum address of a protection area. The value written into this register with the LDSR instruction is set as the maximum address of area n ($n = 0$ to 23) specified in the MPIDX register. The value read from this register with the STSR instruction is the maximum address of area n specified in the MPIDX register. It is impossible to manipulate the maximum address of area n without using the MPIDX register and this register.

This CPU provides 24 channels of protection areas, so that the MPUA register can be used specifying a value from 0 to 23 in the MPIDX register. If a value from 24 to 31 is specified in the MPIDX register, the register is handled as an undefined register.

Table 3.71 MPUA Register Contents

Bit	Name	Description	R/W	Value after Reset
31 to 2	MPUA31 to MPUA2	These bits specify the maximum address of area n ($n = 0$ to 23) specified by the MPIDX register. The specified maximum address is included in the range of area matching. Bits 1 and 0 of the maximum address are handled as 1.	R/W	Undefined
1, 0	—	(Reserved for future expansion. Be sure to set to 0.)	R	0

Table 3.72 MPAT Register Contents (2/2)

Bit	Name	Description	R/W	Value after Reset
3	SR	This bit indicates the read permission in the supervisor mode for area n (n = 0 to 23) specified by the MPIDX register.*1,*2 0: Reading is disabled. 1: Reading is enabled.	R/W	Undefined
2	UX	This bit indicates the execution permission in the user mode for area n (n = 0 to 23) specified by the MPIDX register. 0: Execution is disabled. 1: Execution is enabled.	R/W	Undefined
1	UW	This bit indicates the write permission in the user mode for area n (n = 0 to 23) specified by the MPIDX register. 0: Writing is disabled. 1: Writing is enabled.	R/W	Undefined
0	UR	This bit indicates the read permission in the user mode for area n (n = 0 to 23) specified by the MPIDX register.*2 0: Reading is disabled. 1: Reading is enabled.	R/W	Undefined

Note 1. If access is restricted in SV mode, the MDP or MIP exception handler might not be executed depending on the settings. Be sure to make settings of the protection area in advance so that the necessary memory areas can be accessed by the exception handler.

Note 2. For the CALLT, SWITCH, and SYSCALL instructions and interrupts in table reference method, an MDP exception occurs if reading the address where the table is stored is not permitted. Permission for the SYSCALL instruction and interrupts in table reference method are judged after the operation mode of the CPU is transitioned to the supervisor mode. Therefore, when the MPM.SVP bit is set (1), the SR bit need to be set (1) as well.

(I) MPIDn —SPID which can Access Protection Area

This register specifies the SPID which can access protection area. The accessibility for the specified SPID is determined in conjunction with the WMPIDn and RMPIDn bits (n = 0 to 7) which are specified via the MPAT register.

This CPU has 8 MPID registers.

Table 3.73 MPIDn Register Contents

Bit	Name	Description	R/W	Value after Reset
31 to 5	—	(Reserved for future expansion. Be sure to set to 0.)	R	0
4 to 0	SPID	These bits specify the SPID which can access protection area.	R/W	Undefined

3.2.3.7 Cache Operation Function Registers

(1) Cache Control Function System Registers

Cache control function system registers are read from or written to by using the LDSR and STSR instructions and specifying the system register number, which is made up of a register number and selection ID.

Table 3.74 Cache Control Function System Registers

Register No. (regID, selID)	Symbol	Function	Access Permission
SR16, 4	ICTAGL	Instruction cache tag Lo access	SV
SR17, 4	ICTAGH	Instruction cache tag Hi access	SV
SR18, 4	ICDATL	Instruction cache data Lo access	SV
SR19, 4	ICDATH	Instruction cache data Hi access	SV
SR24, 4	ICCTRL	Instruction cache control	SV
SR26, 4	ICCFG	Instruction cache configuration	SV
SR28, 4	ICERR	Instruction cache error	SV

(a) ICTAGL — Instruction Cache Tag Lo Access

This register is used by the CIST/CILD instruction in relation to the instruction cache. During execution of the CIST instruction, values that are stored to the tag RAM for the instruction cache are stored. During execution of the CILD instruction, values read from the tag RAM for the instruction cache are stored.

Table 3.75 ICTAGL Register Contents

Bit	Name	Description	R/W	Value after Reset
31 to 11	LPN	These bits hold address bits 27 to 11. Bits 31 to 28 must always be set to 0. Bits 27 to 11 are held if the cache size is 8 Kbytes. Bits 27 to 12 are held and bit 11 is always set to 0 if the cache size is 16 Kbytes.*1	R/W	Undefined
10 to 6	—	(Reserved for future expansion. Be sure to set to 0.)	R	0
5, 4	LRU	These bits indicate LRU information of specified cache line. LRU information cannot be freely changed to any value by the CIST instruction.	R/W	Undefined
3	—	(Reserved for future expansion. Be sure to set to 0.)	R	0
2	L	This bit holds the lock information.*2 0: The cache line is not locked. 1: The cache line is locked.	R/W	Undefined
1	—	(Reserved for future expansion. Be sure to set to 0.)	R	0
0	V	This bit holds valid/invalid information of specified cache line.*2 0: The cache line is disabled. 1: The cache line is enabled.	R/W	Undefined

Note 1. Bit 11 cannot be written with any value by an LDSR instruction if the cache size is 16 Kbytes. It is always set to 0.

Note 2. If a tag RAM is set by a CIST instruction, the settings of other bits are valid only when the V bit is enabled. When the V bit is disabled, the cache line is always judged as a cache miss regardless of the value in the LPN bit. Also, when the V bit is disabled, even if the cache line is locked by the setting of the L bit, the cache line becomes the target to be replaced.

(b) ICTAGH — Instruction Cache Tag Hi Access

This register is used by the CIST/CILD instruction in relation to the instruction cache. During execution of the CIST instruction, values that are stored to the ECC for the tag RAM and the Data RAM for the instruction cache are stored. During execution of the CILD instruction, values read from the ECC for the tag RAM and the Data RAM for the instruction cache are stored.

Table 3.76 ICTAGH Register Contents

Bit	Name	Description	R/W	Value after Reset
31	WD	This bit specifies whether the data RAM of the cache is updated during execution of the CIST instruction. 0: Data RAM of the cache is not updated. 1: Data RAM of the cache is updated.	R/W	0
30	PD	This bit specifies the data to be written to the ECC of the data RAM when the WD bit is set to 1 and the CIST instruction is executed. 0: ECC automatically generated from the write data is written to the ECC of the data RAM. 1: Values in the DATAECC field are written to the ECC of the data RAM.	R/W	0
29	WT	This bit specifies whether the tag RAM of the cache is updated during execution of the CIST instruction. When this bit is set to 1, the V bit and L bit of the cache line are also updated. 0: Tag RAM of the cache is not updated. 1: Tag RAM of the cache is updated.	R/W	0
28	PT	This bit specifies the data to be written to the ECC of the tag RAM when the WT bit is set to 1 and the CIST instruction is executed. 0: ECC automatically generated from the write data is written to the ECC of the tag RAM. 1: Values in the TAGECC field are written to the ECC of the tag RAM.	R/W	0
27 to 24	—	(Reserved for future expansion. Be sure to set to 0.)	R	0
23 to 16	DATAECC	These bits hold ECC for data RAM.	R/W	Undefined
15 to 8	TAGECC	These bits hold ECC for tag RAM. Bit 15 is fixed to 0.	R/W	Undefined
7 to 0	—	(Reserved for future expansion. Be sure to set to 0.)	R	0

(c) ICDATL — Instruction Cache Data Lo Access

This register is used by the CIST/CILD instruction in relation to the instruction cache. During execution of the CIST instruction, values that are stored to the data RAM for the instruction cache are stored. During execution of the CILD instruction, values read from the data RAM for the instruction cache are stored.

Table 3.77 ICDATL Register Contents

Bit	Name	Description	R/W	Value after Reset
31 to 0	DATAL	<p>These bits hold the lower-order 32 bits of the 64-bit instruction data*¹ in the block in the specified cache line. The bits to be held is specified by offset of the index.*²</p> <p>Offset of index = 00: Bits 31 to 0*³</p> <p>Offset of index = 01: Bits 95 to 64*³</p> <p>Offset of index = 10: Bits 159 to 128*³</p> <p>Offset of index = 11: Bits 223 to 192*³</p>	R/W	Undefined

Note 1. Data alignment of the instruction data in the block in the cache line is different from the data alignment of memory. For details, see **Section 3.2.5.2(10), Configuration of Instruction Cache**.

Note 2. For details on how to specify Offset, see **Section 3.2.5.2(6), Cache Index Specification Method**.

Note 3. For details on the bit position, see **Figure 3.31** in **Section 3.2.5.2(10), Configuration of Instruction Cache**.

(d) ICDATH — Instruction Cache Data Hi Access

This register is used by the CIST/CILD instruction in relation to the instruction cache. During execution of the CIST instruction, values that are stored to the data RAM for the instruction cache are stored. During execution of the CILD instruction, values read from the data RAM for the instruction cache are stored.

Table 3.78 ICDATH Register Contents

Bit	Name	Description	R/W	Value after Reset
31 to 0	DATAH	These bits hold the upper-order 32 bits of the 64-bit instruction data* ¹ in the block in the specified cache line. The bits to be held is specified by offset of the index.* ² Offset of index = 00: Bits 63 to 32* ³ Offset of index = 01: Bits 127 to 96* ³ Offset of index = 10: Bits 191 to 160* ³ Offset of index = 11: Bits 255 to 224* ³	R/W	Undefined

Note 1. Data alignment of the instruction data in the block in the cache line is different from the data alignment of memory. For details, see **Section 3.2.5.2(10), Configuration of Instruction Cache**.

Note 2. For details on how to specify Offset, see **Section 3.2.5.2(6), Cache Index Specification Method**.

Note 3. For details on the bit position, see **Figure 3.31 in Section 3.2.5.2(10), Configuration of Instruction Cache**.

(e) ICCTRL — Instruction Cache Control

This register is used to control the instruction cache.

Table 3.79 ICCTRL Register Contents

Bit	Name	Description	R/W	Value after Reset
31 to 17	—	(Reserved for future expansion. Be sure to set to 0.)	R	0
16	—	(Reserved for future expansion. Be sure to set to 1.)	R	1
15 to 9	—	(Reserved for future expansion. Be sure to set to 0.)	R	0
8	ICHCLR	When this bit is set to 1, the entire instruction cache is cleared. This clears the V and L bits (to 0) and initializes the LRU information. This bit is always read as 0.	R/W	0
7 to 3	—	(Reserved for future expansion. Be sure to set to 0.)	R	0
2	ICHEIV	When this bit is set to 1, the instruction cache is automatically set as invalid (the ICHEN bit is cleared to 0) whenever a cache error* ² occurs.	R/W	0
1	ICHEMK	When this bit is set to 1, it masks notification of cache error exceptions for the CPU after a cache error* ² has occurred.	R/W	1
0	ICHEN	This bit indicates valid/invalid status of instruction cache. 0: Instruction cache is invalid 1: Instruction cache is valid	R/W	*1

Note 1. The value after reset is determined by the hardware specifications. For details, see **Section 3.8.7, Product Information of Initial Value for G4MH Register**.

Note 2. For details on the cache error, see **Section 3.2.5.2(10), Configuration of Instruction Cache**.

(f) ICCFG — Instruction Cache Configuration

This register indicates the instruction cache configuration.

Table 3.80 ICCFG Register Contents

Bit	Name	Description	R/W	Value after Reset
31 to 15	—	(Reserved for future expansion. Be sure to set to 0.)	R	0
14 to 8	ICHSIZE	These bits indicate the size (in Kbytes) of the instruction cache. 000 1000: 8 Kbytes 001 0000: 16 Kbytes Other than above: Setting prohibited	R	*1
7 to 4	ICHLINE	These bits indicate the number of lines for each way in the instruction cache. 0010: 64 lines 0100: 128 lines Other than above: Setting prohibited	R	*1
3 to 0	ICHWAY	These bits indicate the number of ways in the instruction cache. 0100: 4 ways Other than above: Setting prohibited	R	*1

Note 1. The value after reset is determined by the hardware specifications. For details, see **Section 3.8.7, Product Information of Initial Value for G4MH Register**.

(g) ICERR — Instruction Cache Error

This register is used to store cache error information for the instruction cache.

After the ICHERR bit is set to 1, any subsequent cache error information that is generated is not stored until this setting is explicitly cleared to 0. However, information on error status (ESAFE, ESMH, ESPBSE, ESTE1, ESTE2, ESDC, and ESDE) is accumulated.

Table 3.81 ICERR Register Contents

Bit	Name	Description	R/W	Value after Reset
31	CISTW	This bit is set to indicate that the destination way specified for a CISTI instruction was in error. Although the entry information is overwritten so that writing is completed, the V bit will be cleared the next time the cache line is read (i.e. reading will be judged to have missed the cache). However, setting of this bit is not accompanied by an exception for the CPU.	R/W	Undefined
30	ESAFE	Error status: Address feedback error	R/W	Undefined
29	ESMH	Error status: Multi hit	R/W	Undefined
28	ESPBSE	Error status: WAY error	R/W	Undefined
27	ESTE1	Error status: Tag RAM 1-bit error	R/W	Undefined
26	ESTE2	Error status: Tag RAM 2-bits error	R/W	Undefined
25	ESDC	Error status: Data RAM 1-bit error	R/W	Undefined
24	ESDE	Error status: Data RAM 2-bits error	R/W	Undefined
23	—	(Reserved for future expansion. Be sure to set to 0.)	R	0
22	ERMAFE	Error exception notification mask: Address feedback error ^{*3}	R/W	0
21	ERM MH	Error exception notification mask: Multi hit ^{*3}	R/W	0
20	ERMPBSE	Error exception notification mask: WAY error ^{*3}	R/W	0
19	ERMTE1	Error exception notification mask: Tag RAM 1-bit error ^{*3}	R/W	0
18	ERMTE2	Error exception notification mask: Tag RAM 2-bits error ^{*3}	R/W	0
17	ERMDC	Error exception notification mask: Data RAM 1-bit error ^{*3}	R/W	0
16	ERMDE	Error exception notification mask: Data RAM 2-bits error ^{*3}	R/W	0
15 to 13	ICHEWY	These bits hold the way number where a cache error occurred. Bit 15 is always set to 0.	R/W	Undefined
12 to 5	ICHEIX	These bits hold the cache index where a cache error occurred. Bits 10 to 5 are held and bits 12 and 11 are fixed to 0 for a cache size of 8 Kbytes.*1 Bits 11 to 5 are held and bit 12 is fixed to 0 for a cache size of 16 Kbytes.*2	R/W	Undefined
4	ICHERQ	When this bit is set to 1, this bit indicates that cache error exception notification is in progress. However, if cache error exception notification has been masked, the CPU is not notified even when 1 has been set to this bit.	R/W	0
3	ICHED	This bit indicates that an error has occurred in data RAM.	R/W	0
2	ICHET	This bit indicates that an error has occurred in tag RAM.	R/W	0
1	—	(Reserved for future expansion. Be sure to set to 0.)	R	0
0	ICHERR	This bit is set to 1 when a cache error has occurred.	R/W	0

Note 1. Bits 12 and 11 cannot be written with any value by an LDSR instruction if the cache size is 8 Kbytes. They are always set to 0.

Note 2. Bit 12 cannot be written with any value by an LDSR instruction if the cache size is 16 Kbytes. It is always set to 0.

- Note 3. While the error exception notification mask bit for each error cause is cleared (to 0), if the corresponding error occurs, the ICHERR, ICHERQ, ICHED/ICHET, ICHEIX, and ICHEWY bits are updated and the corresponding error status bit is set (to 1). While the error exception notification mask bit is set (to 1), if the corresponding error occurs, only the corresponding error status bit is set (to 1).

3.2.3.8 Count Function Registers

(1) Count Function System Registers

Count function system registers are read from or written to by using the LDSR and STSR instructions and specifying the system register number, which is made up of a register number and selection ID.

Table 3.82 Count Function System Registers

Register No. (regID, selID)	Symbol	Function	Access Permission
SR0, 11	TSCOUNTL	Timestamp count L register	UM*1
SR1, 11	TSCOUNTH	Timestamp count H register	UM*1
SR2, 11	TSCTRL	Timestamp count control register	SV
SR8, 11	PMUMCTRL	Performance counter user mode control register	SV
SR16, 11	PMCOUNT0	Performance count 0 register	UM*2
SR17, 11	PMCTRL0	Performance count control 0 register	UM*2
SR18, 11	PMCOUNT1	Performance count 1 register	UM*2
SR19, 11	PMCTRL1	Performance count control 1 register	UM*2
SR20, 11	PMCOUNT2	Performance count 2 register	UM*2
SR21, 11	PMCTRL2	Performance count control 2 register	UM*2
SR22, 11	PMCOUNT3	Performance count 3 register	UM*2
SR23, 11	PMCTRL3	Performance count control 3 register	UM*2

Note 1. Only reads are permitted in user mode. A PIE exception will occur if an attempt is made to write in user mode. Reads and writes are permitted in supervisor mode.

Note 2. Accessing in user mode becomes possible by configuring the PMUMCTRL register.

(a) TSCOUNTL — Timestamp Count L

This register, together with the timestamp count H register, implements a 64-bit counter. This register serves as the lower-order 32 bits of the 64-bit counter.

This register can be read only in user mode. A PIE exception will occur if an attempt is made to write this register in user mode. This register can be read and written in supervisor mode.

Table 3.83 TSCOUNTL Register Contents

Bit	Name	Description	R/W	Value after Reset
31 to 0	TSCNTL31 to TSCNTL0	<p>These bits account for the lower-order 32 bits of the 64-bit counter.</p> <p>If counting is enabled by the TSCTRL register, the value of this register is incremented by 1 on every clock cycle.</p> <p>When this register counts up from FFFF FFFF_H, the TSCOUNTH register is incremented by 1 as a carryover and this register wraps around to 0000 0000_H.</p> <p>This register is accessible at an arbitrary timing regardless of whether counting is enabled or disabled. In addition, it is possible to start counting at an arbitrary count by loading that value in this register before starting to count.</p>	R/W*1	0

Note 1. To use this register for making up an accurate 64-bit counter, see **Section 3.2.2.12, Timestamp Counter**.

(b) TSCOUNTH — Timestamp Count H

This register, together with the timestamp count L register, implements a 64-bit counter. This register serves as the higher-order 32 bits of the 64-bit counter.

This register can be read only in user mode. A PIE exception will occur if an attempt is made to write this register in user mode. This register can be read and written in supervisor mode.

Table 3.84 TSCOUNTH Register Contents

Bit	Name	Description	R/W	Value after Reset
31 to 0	TSCNTH31 to TSCNTH0	<p>These bits account for the higher-order 32 bits of the 64-bit counter.</p> <p>If counting is enabled by the TSCTRL register, the value of this register is incremented by 1 when the TSCOUNTL register counts up and generates a carryover.</p> <p>If a carryover occurs in the TSCOUNTL register when this register holds a value of FFFF FFFF_H, the TSCTRL.OVF bit is set to 1 and this register wraps around to 0000 0000_H.</p> <p>This register is accessible at an arbitrary timing regardless of whether counting is enabled or disabled. In addition, it is possible to start counting at an arbitrary count by loading that value in this register before starting to count.</p>	R/W*1	0

Note 1. To use this register for making up an accurate 64-bit counter, see **Section 3.2.2.12, Timestamp Counter**.

(e) PMCOUNTn — Performance Count

This register counts the number of occurrences of various events, which are specified by the PMCTRLn register. This CPU has 4 channels (n = 0 to 3) of performance count registers.

Table 3.87 PMCOUNTn Register Contents

Bit	Name	Description	R/W	Value after Reset
31 to 0	PMCNT31 to PMCNT0	<p>These bits form a 32-bit counter register.</p> <p>The counter counts the number of occurrences of the event that is specified by the PMCTRLn.CND bit.</p> <p>When this register counts up from FFFF FFFF_H, the PMCTRLn.OVF bit is set to 1 and the register wraps around to 0000 0000_H.</p> <p>This register is accessible at an arbitrary timing regardless of whether counting is enabled or disabled. In addition, it is possible to start counting at an arbitrary count by loading that value in this register before starting to count.</p>	R/W	0

Table 3.88 PMCTRLn Register Contents (2/2)

Bit	Name	Description	R/W	Value after Reset
0	CEN	This bit enables or disables the count operation of the PMCOUNTERn register. 0: Disables count operation. 1: Enables count operation. If this bit is written with a 1 when it is set to 0, the counter starts counting immediately. If this bit is written with a 0 when it is set to 1, the counter stops counting immediately. If this bit is 0, the values of the PMCOUNTERn register is preserved. There is no factor that will automatically change the value of this bit.	R/W	0
Note 1.		For the events for which speculative operation column is "Yes", events whose execution results are cancelled are also counted.		
Note 2.		All clock cycles from the start of counting until the end, including the period during which no instruction is executed, are counted.		
Note 3.		The LDSR instruction which starts counting is not included but the LDSR instruction which stops counting is included in this number.		
Note 4.		Applicable instructions are JR, JMP, Bcond (only if condition is met), JARL, LOOP (only if condition is met), CALLT, DISPOSE, SWITCH, SYSCALL, CTRET, EIRET and FERET instructions. Other instructions with branch processing are not counted. Bcond and LOOP instructions are not counted if condition is not met.		
Note 5.		It is possible to obtain the branch prediction miss rate (hit rate) by measuring the numbers of executions of conditional branch instructions and branch prediction misses. Note that the unconditional branch (BR) of the Bcond instruction is counted in "Number of executions of conditional branch instructions" (CND = 19 _H), but it is not counted in "Number of branch prediction misses of conditional branch instructions" (CND = 1A _H).		
Note 6.		In EIINTn with table reference method, an exception which is detected during reading of the table or automatically saving the context to the register bank is not included in this number.		
Note 7.		Since this event presumes that the ISPR register is automatically updated on the acceptance of and returning from interrupt, it cannot be measured correctly if it is used with the INTCFG.ISPC bit set to 1.		
Note 8.		This CPU acquires the instruction code in 64-bit units. Every 64-bit acquisition is counted as a request for a single instruction fetching. Note that this is not the number of instructions. Instruction fetching by the CACHE instruction is not counted.		
Note 9.		In this CPU, a cache hit indicates the number of requests for a single instruction fetching but not the number of instructions. Cache operation by the CACHE instruction is not counted.		
Note 10.		Instruction issue stall occurs when issuing of an instruction (starting execution of an instruction) is stalled if the CPU satisfies any of the following conditions. <ul style="list-style-type: none"> At execution of an STSR instruction that reads the PSW register, issue of the instruction is stalled until completion of all preceding instructions. At execution of a SYNCP, SYNCM, or SYNCI instruction, issue of the instruction is stalled until waiting conditions for the instruction are cleared. For details on the waiting conditions, see Section 3.2.7.1, Synchronization Processing. At execution of an LDSR instruction or STSR instruction that manipulates the cache control function system registers, issue of the instruction is stalled until completion of all preceding CACHE instructions. At execution of an LDSR instruction or STSR instruction that manipulates the FPU system registers, issue of the instruction is stalled until completion of all preceding FPU instructions. At execution of an LDSR instruction or STSR instruction that manipulates the FXU system registers, issue of the instruction is stalled until completion of all preceding FXU instructions. If an LDSR instruction updates the system register which guarantees reflection of its update to the subsequent instruction, issue of the instruction is stalled until the update of the system register is completed. For details, see Section 3.2.7.3, Hazard Management after System Register Update. If execution of an STSR instruction is started after execution of an LDSR instruction is started, issue of the STSR instruction is stalled until completion of the LDSR instruction. (This applies even if the system register numbers of the LDSR and STSR instructions do not match). When a HALT instruction is executed, issue of the subsequent instruction is stalled until conditions for releasing the halt state are generated. When a SNOOZE instruction is executed, issue of the subsequent instruction is stalled until conditions for releasing the snooze state are generated. When any of the following instructions that includes branching is executed, issue of the subsequent instruction is stalled until completion of the branching and cancellation of execution of the subsequent instruction. SYSCALL, CALLT, EIRET, FERET, CTRET, TRAP, FETRAP, SYNCI 		

- When any of the following exceptions is detected, issue of the subsequent instruction is stalled until acknowledgement of the exception is completed and cancellation of execution of the subsequent instruction.
MIP, SYSERR (resumable), RIE, UCPOP, PIE

- Note 11. Actual Flash ROM access requests are counted. If an instruction fetch request hits the instruction cache, it is not counted. Instruction fetch requests to Flash ROM by the CACHE and PREF instructions are counted. Instruction pre-fetching to Flash ROM is also counted.
- Note 12. Actual Flash ROM access requests are counted. If a data read request hits the ROM data buffer, it is not counted. Pre-fetching to Flash ROM is counted. Note that the number of data read requests to Flash ROM is different from the number of Flash ROM accesses by instructions.
- Note 13. Since the number of instruction fetch request (30_H) and the number of instruction cache hits (31_H) include the speculative instruction fetching, the number of hits divided by the number of requests may not be the accurate instruction cache hit rate of this CPU. The instruction cache hit rate of this CPU can be calculated by the number of instruction fetch requests and the number of instruction fetch requests to Flash ROM (50_H). In this case, the number of instruction fetch request reduced by the number of instruction fetch requests to Flash ROM will be the number of instruction cache hits. However, even in this case, the number of instruction cache hits includes the speculative instruction fetching. Pre-fetching by the PREF instruction is counted as the number of instruction fetch requests, though accessing non-cacheable area is not counted as the number of instruction fetch requests to Flash ROM.

3.2.3.9 Hardware Function Registers

(1) Hardware Function System Registers

Hardware function system registers are read from or written to by using the LDSR and STSR instructions and specifying the system register number, which is made up of a register number and selection ID.

Table 3.89 Hardware Function System Registers

Register No. (regID, selID)	Symbol	Function	Access Permission
SR 0, 12	LSTEST0	Lock-step function self-diagnosis register 0	SV
SR1, 12	LSTEST1	Lock-step function self-diagnosis register 1	SV
SR5, 12	IFCR	Instruction fetch control register	SV
SR8, 12	BRPCTRL0	Branch prediction function control register	SV
SR24, 13	RDBCR	ROM data buffer control register	SV

(a) LSTEST0 — Lock-step Function Self-diagnosis Register 0

This register is for the self-diagnosis of the lock-step function. It can be used for the self-diagnosis of the lock-step function in combination with the LSTEST1 register. For details of the lock-step function and its availability, see **Section 40, Functional Safety**.

Table 3.90 LSTEST0 Register Contents

Bit	Name	Description	R/W	Value after Reset
31 to 0	LSTEST0 31 to LSTEST0 0	[Write] Write any value to bits of the LSTEST0 register. [Read] Value in LSTEST0 is read by the master CPU of the lock-stepped CPU. Value in LSTEST1 is read by the checker CPU of the lock-stepped CPU.	R/W	0

(b) LSTEST1 — Lock-step Function Self-diagnosis Register 1

This register is for the self-diagnosis of the lock-step function. It can be used for the self-diagnosis of the lock-step function in combination with the LSTEST0 register. For details of the lock-step function and its availability, see **Section 40, Functional Safety**.

Table 3.91 LSTEST1 Register Contents

Bit	Name	Description	R/W	Value after Reset
31 to 0	LSTEST1 31 to LSTEST1 0	[Write] Write any value to bits of the LSTEST1 register. [Read] Value in LSTEST1 is read by the master CPU of the lock-stepped CPU. Value in LSTEST0 is read by the checker CPU of the lock-stepped CPU.	R/W	0

3.2.4 Exceptions and Interrupts

An exception is a particular event that forces branching of operation from the current program to another program.

The program at the branch destination of a given exception is called an “exception handler”.

CAUTION

This CPU handles interrupts as types of exception.

3.2.4.1 Outline of Exceptions

This section describes the elements that assign properties to exceptions, and shows how exceptions work.

(1) Exception Cause List

This CPU supports the following exceptions.

Table 3.95 Exception Cause List

Exception	Name	Source	Type*1	Saved Resource	Return/ Restoration	Exception Cause Code*2	Priority Order*3		Acknowledgment Condition (PSW)		Update (PSW)			
							Priority Level	Priority	ID	NP	UM	ID	NP	EP
RESET	Reset	Reset input	Terminating	—	—	None	1	—	x	0	1	0	0	0
MDP	Memory protection exception (access privilege)	Memory protection violation due to an interrupt using the table reference method	Terminating	FE	Yes	95H	2*7	—	x	0	1	1	1	s
FENMI	FENMI interrupt	Interrupt input terminal	Terminating	FE	No	E0H	4	1	x	0	1	1	0	s
FEINT	FEINT interrupt	Interrupt input terminal	Terminating	FE	Yes	F0H-FFH	4	2	x	0	1	1	0	s
SYSERR	System error	Error due to context saving to the register bank	Terminating	FE	No	1CH	4	3	x	0	1	1	1	s
EIINT0-2047	User interrupt	Interrupt input terminal	Terminating	EI	Yes	1000H-17FFH*5	5	*10	0	0	*9	s	0	s
MIP	Memory protection exception (execution privilege)	Memory protection violation due to instruction fetching	Resumable	FE	Yes	90H	7	1	x	0	1	1	1	s
SYSERR	System error	Error due to instruction fetching	Resumable	FE	No	10H-1FH*4	7	2	x	0	1	1	1	s
UCPOP	Coprocessor unusable exception	Execution of a coprocessor instruction/access permission violation	Resumable	FE	Yes	80H-82H*6	7	3	x	0	1	1	1	s
RIE	Reserved instruction exception	Execution of a reserved instruction	Resumable	FE	Yes	60H	7	4	x	0	1	1	1	s
PIE	Privilege instruction exception	Execution of a privileged instruction/access permission violation	Resumable	FE	Yes	A0H	7	5	x	0	1	1	1	s
SYSERR	System error	Error prior to context restoration from the register bank	Resumable	FE	No	1DH	7	6	x	0	1	1	1	s
MAE	Misalignment exception	Misaligned access occurrence	Resumable	FE	Yes	C0H	8	1	x	0	1	1	1	s
MDP	Memory protection exception (access privilege)	Memory protection violation due to operand access	Resumable	FE	Yes	91H	8	2	x	0	1	1	1	s
FPE	FPU exception (precise)	Execution of an FPU instruction	Resumable	EI	Yes	71H	8	3	x	0	1	s	1	s
FXE	FXU exception (precise)	Execution of an FXU instruction	Resumable	EI	Yes	75H	8	4	x	0	1	s	1	s
SYSCALL	System call	Execution of the SYSCALL instruction	Pending	EI	Yes	8000H-80FFH	9	*8	x	0	1	s	1	s
FETRAP	FE level trap	Execution of the FETRAP instruction	Pending	FE	Yes	31H-3FH	9		x	0	1	1	1	s
TRAP0	EI level trap 0	Execution of the TRAP instruction	Pending	EI	Yes	40H-4FH	9		x	0	1	s	1	s
TRAP1	EI level trap 1	Execution of the TRAP instruction	Pending	EI	Yes	50H-5FH	9		x	0	1	s	1	s

Note: s: Retained, x: Not an acknowledgment condition

Note 1. For details, see Section 3.2.4.1(3), Types of Exceptions.

Note 2. Represents lower-order 16 bits of the exception cause code. The higher-order 16 bits of the exception cause code are loaded with a detail code which is defined for each exception. The code is 0000H, unless it is specifically described in the individual functional descriptions.

Note 3. The acknowledgment priority for exceptions is checked by the priority level, and then priority. A smaller value has a higher priority. For details, see Section 3.2.4.1(4), Exception Acknowledgment Conditions and Priority Order.

Note 4. For details, see Section 3.2.4.1(2), Overview of Exception Causes.

- Note 5. 1000_H-17FF_H (channels 0 to 2047) are selected according to the channel.
- Note 6. 80_H-82_H correspond to the coprocessor use permissions (CU0-CU2), respectively.
- Note 7. The case in which an MDP exception occurs during the processing (table read or automatic context saving onto the register bank) which is performed after a table reference method interrupt (EIINT_n) is selected as the result of priority determination. The occurrence of this type of exceptions takes precedence over that of the terminating-type exceptions except the reset. For details, see **Section 3.2.4.1(2), Overview of Exception Causes**.
- Note 8. Occurs in an exclusive manner as it is caused by the execution of an instruction. There is no priority difference within the same priority level.
- Note 9. There are cases in which the PSW.ID bit is set to 0 on interrupts of table reference method in which the register bank is used. For details, see **Section 3.2.4.5(2), Automatic Context Saving**.
- Note 10. The priority of EIINT0-EIINT2047 varies depending on settings of the interrupt controller. For details, see **Section 3.2.4.1(5), Interrupt Exception Priority and Priority Masking**.

(2) Overview of Exception Causes

The following is an overview of the exception causes handled by the CPU.

(a) RESET

RESET is generated when inputting a reset signal. For details, see **Section 3.2.8, Reset**.

(b) FENMI, FEINT, and EIINT

These are interrupts generated by interrupt signals from the interrupt controller to activate a certain program. For details about the interrupt functions, see **Section 3.2.3.3, Interrupt Function Registers** and the specifications of the interrupt controller incorporated in your product.

(c) SYSERR

This is a system error exception.

An error occurring during automatic context saving using the register bank function is notified as a terminating-type SYSERR exception. In this case, as with the case of acknowledging an interrupt, the PC of the instruction that is interrupted when the exception occurred is loaded in the FEPC and the PSW at that time in the FEPSW, respectively. An error occurring during the restoration of the context with the RESBANK instruction is notified as a resumable-type SYSERR exception. In this case, the PC of the RESBANK instruction is loaded in the FEPC and the PSW at that time in the FEPSW, respectively.

An error that occurs at an instruction fetch access is notified as a resumable-type SYSERR exception. In this case, the PC of the instruction to be fetched is loaded in the FEPC and the PSW at that time in the FEPSW, respectively.

Table 3.96 lists the exception cause codes that are loaded in the lower-order 16 bits of the FEIC register when SYSERR exceptions occur. The higher-order 16 bits of the exception cause code are padded with 0s.

Table 3.96 Lower-order 16 Bits of the Exception Cause Codes Associated with the SYSERR Exception

Exception Cause Code	Cause
11 _H	A response error occurred in a bus slave at the time of instruction fetching.* ¹
13 _H	An error within the scope of safety functions, such as an ECC error or parity error, occurred at the time of instruction fetching.* ^{1,*2}
1C _H	An error occurred when automatically saving context to the register bank.
1D _H	An error occurred at the time of context restoration from the register bank (during the execution of the RESBANK instruction).

Note 1. For details, see **Section 3.8.8, Product Information of SYSERR Factor**.

Note 2. When an ECC or parity error is found in fetching from the instruction cache, it is handled as a cache miss so a SYSERR exception does not occur.

All the causes that generate a SYSERR exception for this CPU are listed in **Table 3.96**. An error that is detected externally to the CPU does not generate a SYSERR exception.

(d) FPE

These are exceptions that occur when a floating-point instruction is being executed. For details, see **Section 3.2.6.1, Floating-Point Operation**.

(e) FXE

These are exceptions that occur when an extended floating-point instruction is being executed. For details, see **Section 3.2.6.2, Extended Floating-Point Operation**.

(f) MIP and MDP

These are exceptions that occur when the MPU detects a violation. Detecting an exception is performed when the address at which the instruction will access the memory is calculated. For details, see **Section 3.2.5.1, Memory Protection Unit (MPU)**.

There are cases in which an MDP exception is detected during a table read or automatic context saving onto the register bank when a table reference method interrupt (EIINT n) is selected as the result of determining the priority level of the terminating-type exception. In such a case, the execution of the instruction is interrupted and an MDP exception (terminating-type) is generated as with an ordinary interrupt. In this case, the PC of the instruction that is interrupted is saved in the FEPC and the PSW that is established before the interrupt is accepted is saved in the FEPSW, respectively. For the table reference method, see **Section 3.2.4.4, Exception Handler Address**.

(g) RIE

This is a reserved instruction exception. This exception occurs when an attempt is made to execute the opcode of an instruction other than an instruction whose operation is defined. The operation is the same as the RIE instruction. For details, see *the RH850G4MH User's Manual: Software*.

(h) PIE

This is a privilege instruction exception. This exception occurs when an attempt is made to execute an instruction that does not have the required privilege. For details, see **Section 3.2.2.1(3), CPU Operating Mode and Privileges**, **Section 3.2.2.2, Instruction Execution**, and **Section 3.2.2.5(3)(a), LDSR and STSR**.

(i) UCPOP

This is an exception that occurs when an attempt is made to execute a coprocessor instruction when the coprocessor in question is not usable. For details, see **Section 3.2.2.4, Coprocessors**.

(j) MAE

This is an exception that occurs when the result of address calculation is a misaligned address. For details, see **Section 3.2.2.6(3), Data Alignment**.

(k) TRAP, FETRAP, and SYSCALL

These are exceptions that occur according to the result of instruction execution. For details, see *the RH850G4MH User's Manual: Software*.

(3) Types of Exceptions

This CPU divides exceptions into the following three types according to how they are executed.

- Terminating exceptions
- Resumable exceptions
- Pending exceptions

(a) Terminating Exceptions

In the case of an exception of this type, the exception is acknowledged by interrupting the current instruction before its operation is executed. These exceptions include interrupts, etc.

In the case of interrupts, their occurrence is not dependent upon the result of executing the current instruction, that is, generation is not related to that instruction. When an interrupt occurs, the PSW.EP bit is cleared to 0, unlike other exceptions. Consequently, termination of the exception handler routine is reported to the external interrupt controller when the return instruction is executed. Be sure to execute a return instruction from an interrupt while the PSW.EP bit is cleared to 0.

CAUTIONS

1. The PSW.EP bit is cleared to 0 only when an interrupt (EIINT n , FEINT, or FENMI) is acknowledged. It is set to 1 when any other exception occurs.
If a return instruction from the exception handler routine that has been started by an interrupt is executed while the PSW.EP bit is set to 1, the resources on the external interrupt controller might not be released, causing malfunctioning.
2. A terminating exception may be accepted during the execution of an instruction that performs multiple memory accesses. In this case, although the execution of the instruction is terminated, the result of memory accesses that have been already completed are not canceled. For example, memory is updated by the PREPARE instruction and the general-purpose registers are updated by the DISPOSE instruction. However, it is guaranteed that the PC and SP retain the original values required to re-execute the instruction. For details, see *the RH850G4MH User's Manual: Software*. The relevant instructions are listed below.
 - PREPARE, DISPOSE, PUSHSP, POPSP, RESBANK
3. For the instructions that perform load-access and branch, a terminating exception may be accepted after the load-access is completed. However, it is guaranteed that the PC and the system registers (such as CTPC) that are updated on completion of the instruction retain the original values required to re-execute the instruction. For details, see *the RH850G4MH User's Manual: Software*. The relevant instructions are listed below.
 - CALLT, SYSCALL, SWITCH

(b) Resumable Exceptions

A resumable exception is the one that occurs during the operation of an instruction and that is accepted without the completion of that instruction. It is also called a precise exception because it is accepted precisely without the completion of the instruction that was being executed and without the execution of the subsequent instructions. The occurrence of this exception suppresses the update of the general-purpose and system registers. In addition, since the return PC of the exception points to the very instruction that caused the exception, it is possible to resume the execution at the point before the exception occurred.

The return PC of a resumable exception is the PC of the instruction which caused the exception (current PC).

(c) Pending Exceptions

This is an exception acknowledged after the execution of an instruction finishes as a result of executing the instruction operation. Pending exceptions include software exceptions. Because pending exceptions occur as a result of normal instruction execution, the processing resumes with the instruction following the instruction that caused the pending exceptions when processing control is returned. The original processing can be normally continued after the exception handling.

The return PC of a pending exception is the PC of the next instruction (next PC).

(4) Exception Acknowledgment Conditions and Priority Order

This CPU acknowledges only one exception at specific timing based on the exception acknowledgment conditions and priority order. The exception to be acknowledged is determined based on the exception acknowledgment conditions and priority order, as shown in **Figure 3.16** below.

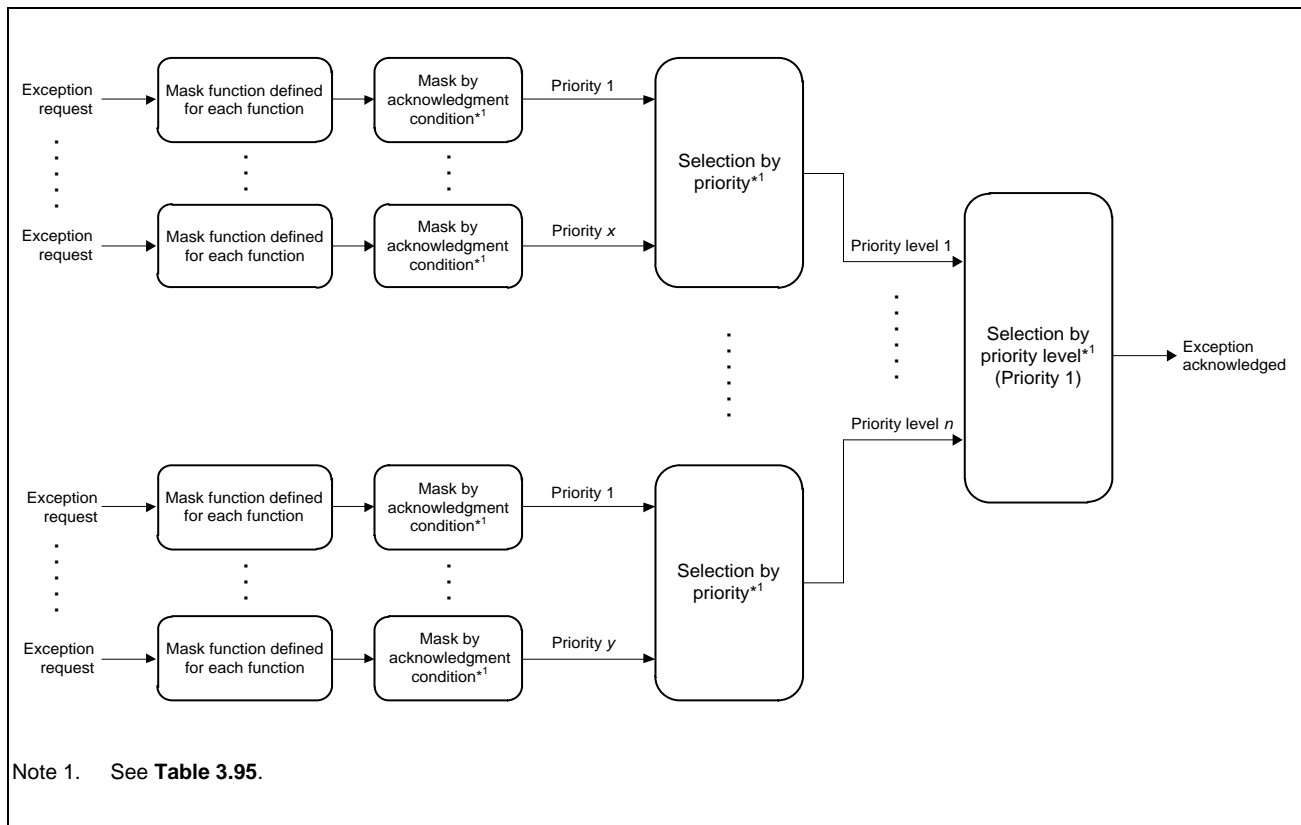

Figure 3.16 Exception Acknowledgment Conditions and Priority Order

In **Table 3.95**, an exception with “0” in the acknowledgment condition column can be acknowledged when the corresponding bit is “0”. This kind of exception is not accepted when the corresponding bit is “1”. When it changes to “0” and the acknowledgment conditions are met, acknowledgment of the exception becomes possible. If no value is specified for a bit, it is not an acknowledgment condition. If multiple bits are specified as conditions, all the conditions must be met simultaneously.

Some exceptions are provided with dedicated mask functions that are unique to their functionality. The decision on the acceptability of the exceptions based on the individually defined mask function is made before the decision on the acknowledgement (acceptance) conditions listed in **Table 3.95**. For details, see the description of the cause of the individual exceptions.

If more than two exceptions satisfy the acknowledgment conditions simultaneously, one exception is selected according to the priority order. The priority order is determined in multiple stages; priority level, and then priority. A smaller number has a higher priority.

When this CPU accepts an exception, it returns an acceptance response to the requesting module.

If a terminating-type exception is not accepted, the request for that exception is not made pending by this CPU. To keep the exception request pending for acceptance, the module such as the interrupt controller that issued the terminating-type exception request to the CPU makes the exception request pending.

Any exceptions that occur at the same time as a reset are not accepted. For details, see **Section 3.2.4.2(1), Special Operations**.

For details about acknowledgment conditions, priority level, and priority, see **Table 3.95**.

(5) Interrupt Exception Priority and Priority Masking

An interrupt (EIINT n) can be masked for each exception priority or interrupt priority by setting registers. This function allows the software implementation of an interrupt ceiling with a more flexible software structure and no maintenance.

Figure 3.17 shows an overview of the functions of interrupt exception priority and priority masking.

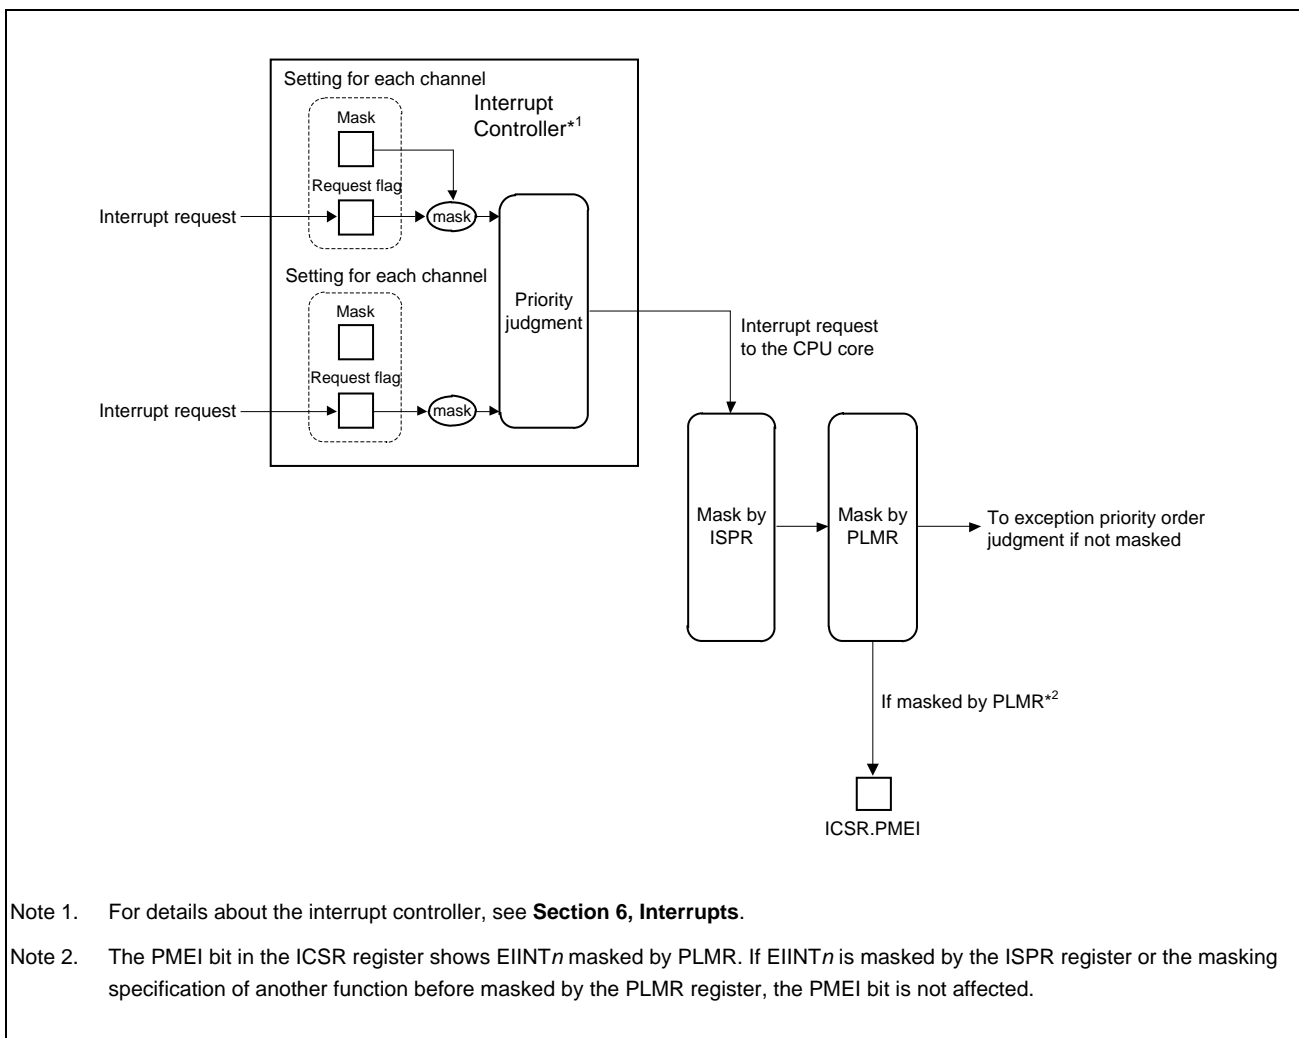

Figure 3.17 Interrupt Exception Priority and Priority Masking

(a) Interrupt Priority

This CPU supports a maximum of 16 priority levels for interrupts (EIINT n). For the details on the procedure to set interrupt priority, see **Section 6, Interrupts**.

(b) Interrupt Priority Mask

EIINT n might be masked at different priorities by the ISPR register and PLMR register. These registers should be used as follows.

For the ISPR register, the bit corresponding to the priority is set to 1 when the hardware acknowledges an interrupt, and interrupts with the same or lower priority are masked. When the EIRET instruction corresponding to the interrupt is executed, the corresponding bit of the ISPR register is cleared to 0 to clear the mask.

This automatic interrupt ceiling makes multiple interrupts servicing easy without using software control.

The PLMR register allows you to mask specific interrupt priorities with software. Use it to raise the priority level of the interrupt ceiling temporarily in a program. The mask setting specified by the ISPR register and the mask setting of PLMR might overlap, and an interrupt is masked if it is masked with one or the other of them. Normally, use the PLMR register to raise the ceiling value from the ceiling value of the ISPR register.

The function of the INTCFG register allows you to disable automatic update of the ISPR register upon acknowledgment of and return from an interrupt. To perform interrupt ceiling control by using software without using the function of the ISPR register, set the ISPC bit in the INTCFG register to 1, clear the ISPR register, and then control the ceiling value with software by using the PLMR register.

Also, when you are using the PLMR register, you can check if any interrupt is masked with the PLMR register by using the ICSR register.

(6) Return and Restoration

When exception handling has been performed, it might affect the original program that was interrupted by the acknowledged exception. This effect is indicated from two perspectives: “Return” and “Restoration”.

- Return: Indicates whether or not the original program can be re-executed from where it was interrupted.
- Restoration: Indicates whether or not the processor statuses (status of processor resources such as general-purpose registers and system registers) can be restored as they were when the original program was interrupted.

An exception that cannot be returned or restored from (“No” in **Table 3.95**) might cause the return PC to be lost, making it impossible to return from the exception to the original processing by using a return instruction. An exception whose trigger cannot be selected is an unreturnable or unrestorable exception.

For an unrestorable exception, it is possible to return to the original program flow. However, because the state before the occurrence of the exception cannot be restored at that point, care must be taken in continuing subsequent program operation.

(7) Context Saving

To save the current program sequence when an exception occurs, appropriately save the following resources according to the function definitions. There are resources that are automatically saved by hardware and resources that need to be saved by software.

- Program counter (PC)
- Program status word (PSW)
- Exception cause code (EIIC, FEIC)
- Work system register (EIWR, FEWR)

The resource to use as the saving destination is determined according to the exception type. Saved resource determination is described below.

For exceptions that use the register bank function, specific resources are automatically saved. For details, see **Section 3.2.4.5, Register Bank Function**.

(a) Context Saving

Exceptions with certain acknowledgment conditions might not be acknowledged at the start of exception handling, based on the pending bits (PSW.ID and NP bits) that are automatically set when another exception is acknowledged.

To enable multiple exception processing which makes exceptions of the same level acceptable again, the return registers and certain information about the corresponding exception causes must be saved, such as to a stack. This information that must be saved is called the “context”.

In principle, it is necessary to make sure that no exceptions of the same level can occur before saving the context.

The working system registers that can be used in the work of saving contexts and those for which the values are saved to enable the handling of multiple exceptions as required are referred to as the basic context registers.

These basic context registers are provided for each exception level. For this reason, it is possible to precisely return from the current exception since its context will not be overwritten when an exception of a different level occurs before saving the current context.

Table 3.97 Basic Context Registers

Exception Level	Basic Context Registers
EI level	EIPC, EIPSW, EIIC, EIWR
FE level	FEPC, FEPSW, FEIC, FEWR

See **Section 3.2.2.3(2), Exception Level**.

3.2.4.2 Operation when Acknowledging an Exception

Check whether each exception that is reported during instruction execution is acknowledged according to the priority. The procedure for exception-specific acknowledgment operation is shown below.

- <1> Check whether the acknowledgment conditions are satisfied and whether exceptions are acknowledged according to their priority.
- <2> Calculate the exception handler address according to the current PSW value*¹
- <3> For FE level exceptions, the following processing is performed.
 - Saving the PC to FEPC
 - Saving the PSW to FEPSW
 - Storing the exception cause code in FEIC
 - Updating the PSW*²
 - Store the exception handler address calculated in (2) in the PC, and then pass control to the exception handler.
- <4> For EI level exceptions, the following processing is performed.
 - Saving the PC to EIPC
 - Saving the PSW to EIPSW
 - Storing the exception cause code in EIIC
 - Updating the PSW*²
 - Store the exception handler address calculated in (2) in the PC, and then pass control to the exception handler.
 - When the exception is an interrupt that uses the register bank, save the context automatically^{Note 3}.

Note 1. For details, see **Section 3.2.4.4, Exception Handler Address**.

Note 2. For the values to be updated, see **Table 3.95**.

Note 3. For details on register banks, see **Section 3.2.4.5, Register Bank Function**.

Figure 3.18 shows the steps <1> to <4>.

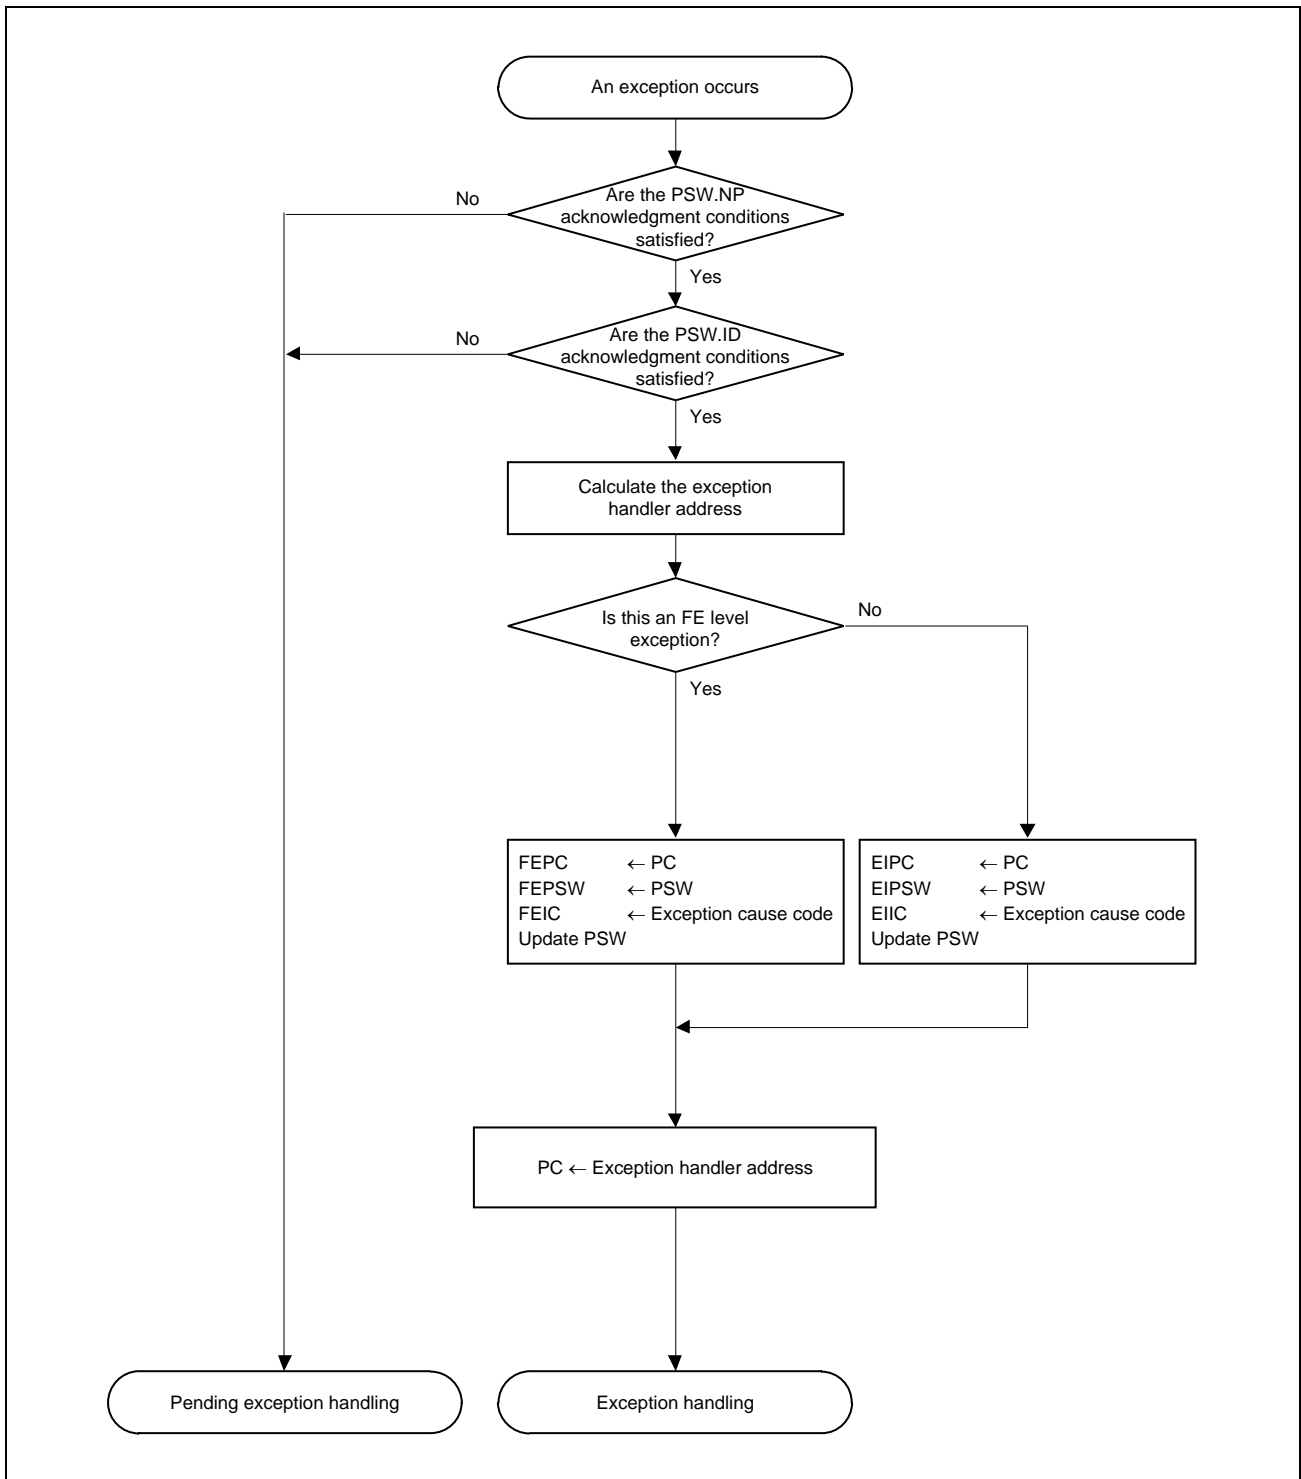

Figure 3.18 Operation When Acknowledging an Exception

(1) Special Operations

(a) EP Bit of PSW Register

If an interrupt is acknowledged, the PSW.EP bit is cleared to 0. If an exception other than an interrupt is acknowledged, the PSW.EP bit is set to 1.

The operation of the CPU when executing the EIRET and FERET instructions depends on the state of the EP bit. If the EP bit is cleared to 0, the CPU notifies the external interrupt controller of the termination of the exception processing routine. This function is necessary to properly control the request flag in the interrupt controller and other resources upon return from the interrupt. When the EP bit is cleared to 0, and the EIRET instruction is executed, the bit with the highest priority (0 is the highest) among the bits set to 1 in ISPR.ISP15 to ISPR.ISP0 is cleared to 0.

To return from an interrupt, be sure to execute the return instruction with the EP bit cleared to 0.

(b) Coprocessor Unusable Exception

For coprocessor unusable exceptions, the opcodes that cause the exception depend on the status of the CU bit of the PSW register.

When a coprocessor is not included in the product or it is not usable, if an attempt is made to execute a coprocessor instruction corresponding to the coprocessor, a coprocessor unusable exception (UCPOP) immediately occurs. If an LDSR or STSR instruction attempts to access a system register of the coprocessor, a coprocessor unusable exception (UCPOP) immediately occurs too.

For details, see **Section 3.2.2.4(3), Coprocessor Unusable Exceptions**.

(c) Reserved Instruction Exception

If an opcode that is reserved for future function extension and for which no instruction is defined is executed, a reserved instruction exception (RIE) occurs.

The opcode that always generates a reserved instruction exception is defined as the RIE instruction.

(d) Reset

Reset is performed in the same way as exception handling, but it is not regarded as EI level exception or FE level exception. The reset operation is the same that of an exception without acknowledgment conditions, but the value of each register is changed to the value after reset. In addition, returning to the original program from the reset is not possible.

All exceptions that have occurred at the same time as CPU initialization are canceled and not acknowledged even after CPU initialization.

For details, see **Section 3.2.8, Reset**.

3.2.4.3 Return from Exception Handling

To return from exception handling, execute the return instruction (EIRET or FERET) corresponding to the relevant exception level.

When a context has been saved, such as to a stack, the context must be restored before executing the return instruction. When execution is returned from an unrestorable exception, the status before the exception occurs in the original program cannot be restored. Consequently, the execution result might differ from that when the exception does not occur.

The EIRET instruction is used to return from EI level exception handling and the FERET instruction is used to return from FE level exception handling.

When the EIRET or FERET instruction is executed, the CPU performs the following processing and then passes control to the return PC address.

- <1> If the PSW.EP bit is set to 0, the CPU notifies the interrupt controller of the termination of the exception routine.
- <2> When the EIRET instruction is executed while PSW.EP = 0 and INTCFG.ISPC = 0, the CPU updates the ISPR register.
When the FERET instruction is executed, the CPU does not update the ISPR register.
- <3> When the EIRET instruction is executed, return PC and PSW are loaded from the EIPC and EIPSW registers. When the FERET instruction is executed, return PC and PSW are loaded from the FEPC and FEPSW registers.
- <4> Control is passed to the address indicated by the return PC that were loaded.

Figure 3.19 shows the flow for returning from exception handling using the EIRET or FERET instruction.

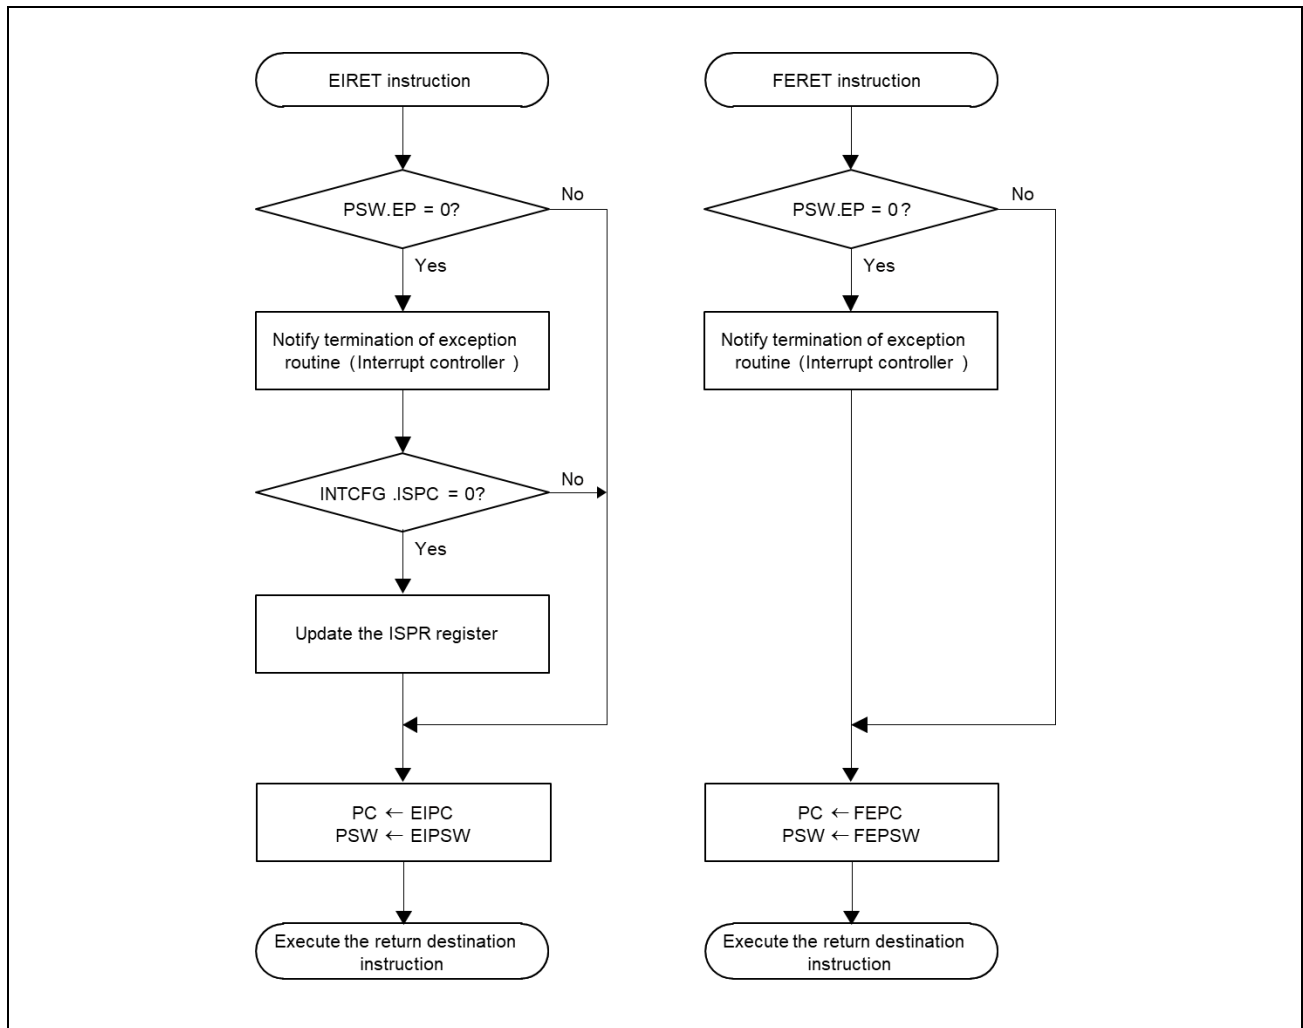

Figure 3.19 Return Instruction-Based Exception Return Flow

3.2.4.4 Exception Handler Address

For this CPU, the exception handler address used for execution during reset input, exception acknowledgment, or interrupt acknowledgment can be changed according to the settings.

(1) Resets, Exceptions, and Interrupts

The exception handler address for resets and exceptions is determined by using the direct vector method, in which the reference point of the exception handler address can be changed by using the PSW.EBV bit, RBASE register, and EBASE register. For interrupts, the direct vector method and table reference method can be specified. If the table reference method is selected, execution can branch to the address indicated by the exception handler table allocated in the memory.

(a) Direct Vector Method

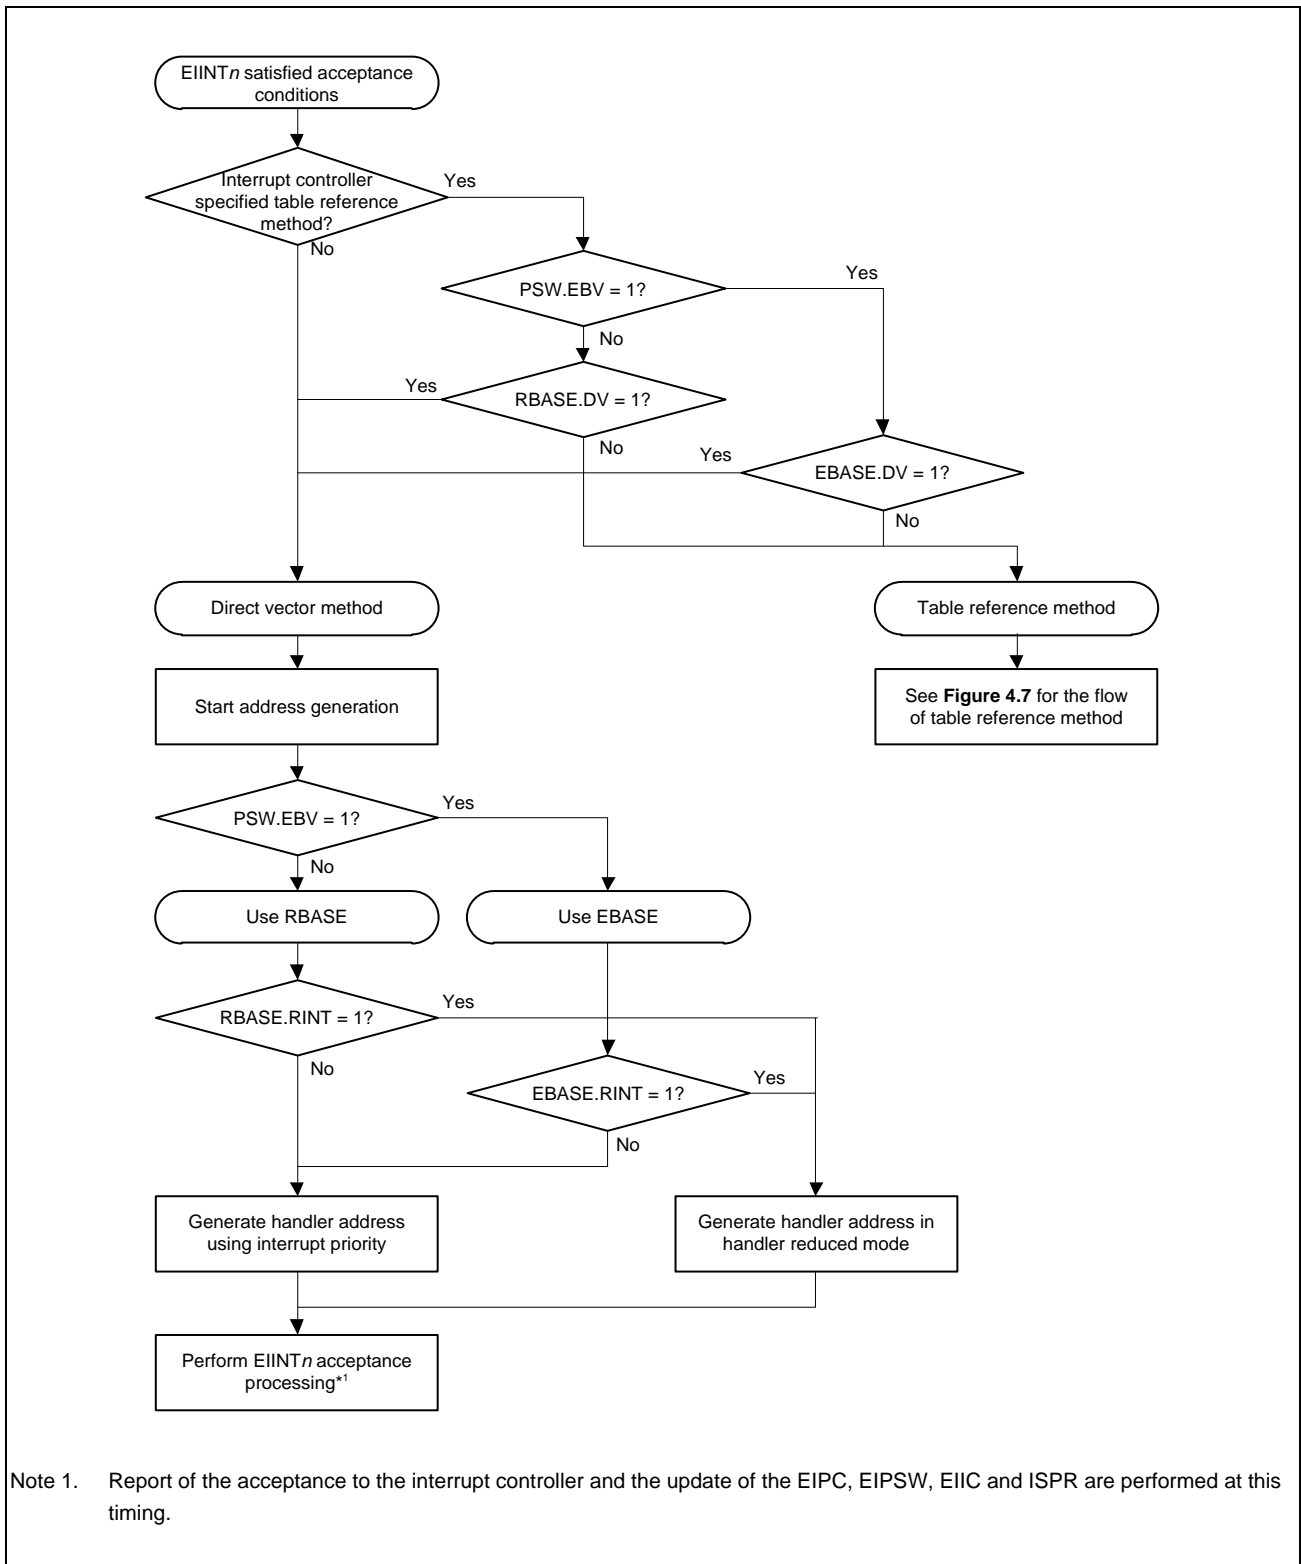

This CPU uses the result of adding the offset address shown in **Table 3.98** to the base address indicated by the RBASE or EBASE register as the exception handler address.

Whether to use the RBASE or EBASE register as the base address is selected according to the PSW.EBV bit. If the PSW.EBV bit is set to 1, the EBASE register value is used as the base address. If the bit is cleared to 0, the RBASE register value is used as the base address.

However, reset input always refers to the RBASE register.

In addition, user interrupts (EIINT n) refer to the RINT bit of the selected base register, and reduce the offset address according to the value of the bit. If the RBASE.RINT bit or EBASE.RINT bit is set to 1, all user interrupts are handled using an offset address of 100_H. If the bit is cleared to 0, the offset address is determined according to **Table 3.98**.

Figure 3.20 shows the flow of generating a handler address for the direct vector method.

Note 1. Report of the acceptance to the interrupt controller and the update of the EIPC, EIPSW, EIIC and ISPR are performed at this timing.

Figure 3.20 Flow of Generating a Handler Address of the Direct Vector Method

Figure 3.21 Direct Vector Method

The table below shows how base register is selected and offset address for each exception. The value of the PSW register used to determine the exception handler address is the value after being updated due to the acknowledgment of an exception.

Table 3.98 Selection of Base Register/Offset Address

	PSW.EBV = 0	PSW.EBV = 1	RINT = 0	RINT = 1
	Base Register		Offset Address	
RESET	RBASE	None*1	000 _H	000 _H
SYSERR		EBASE	010 _H	010 _H
(R.F.U.)			020 _H	020 _H
FETRAP			030 _H	030 _H
TRAP0			040 _H	040 _H
TRAP1			050 _H	050 _H
RIE			060 _H	060 _H
FPE/FXE			070 _H	070 _H
UCPOP			080 _H	080 _H

Note 1. An exception generated to update EBV to 0.

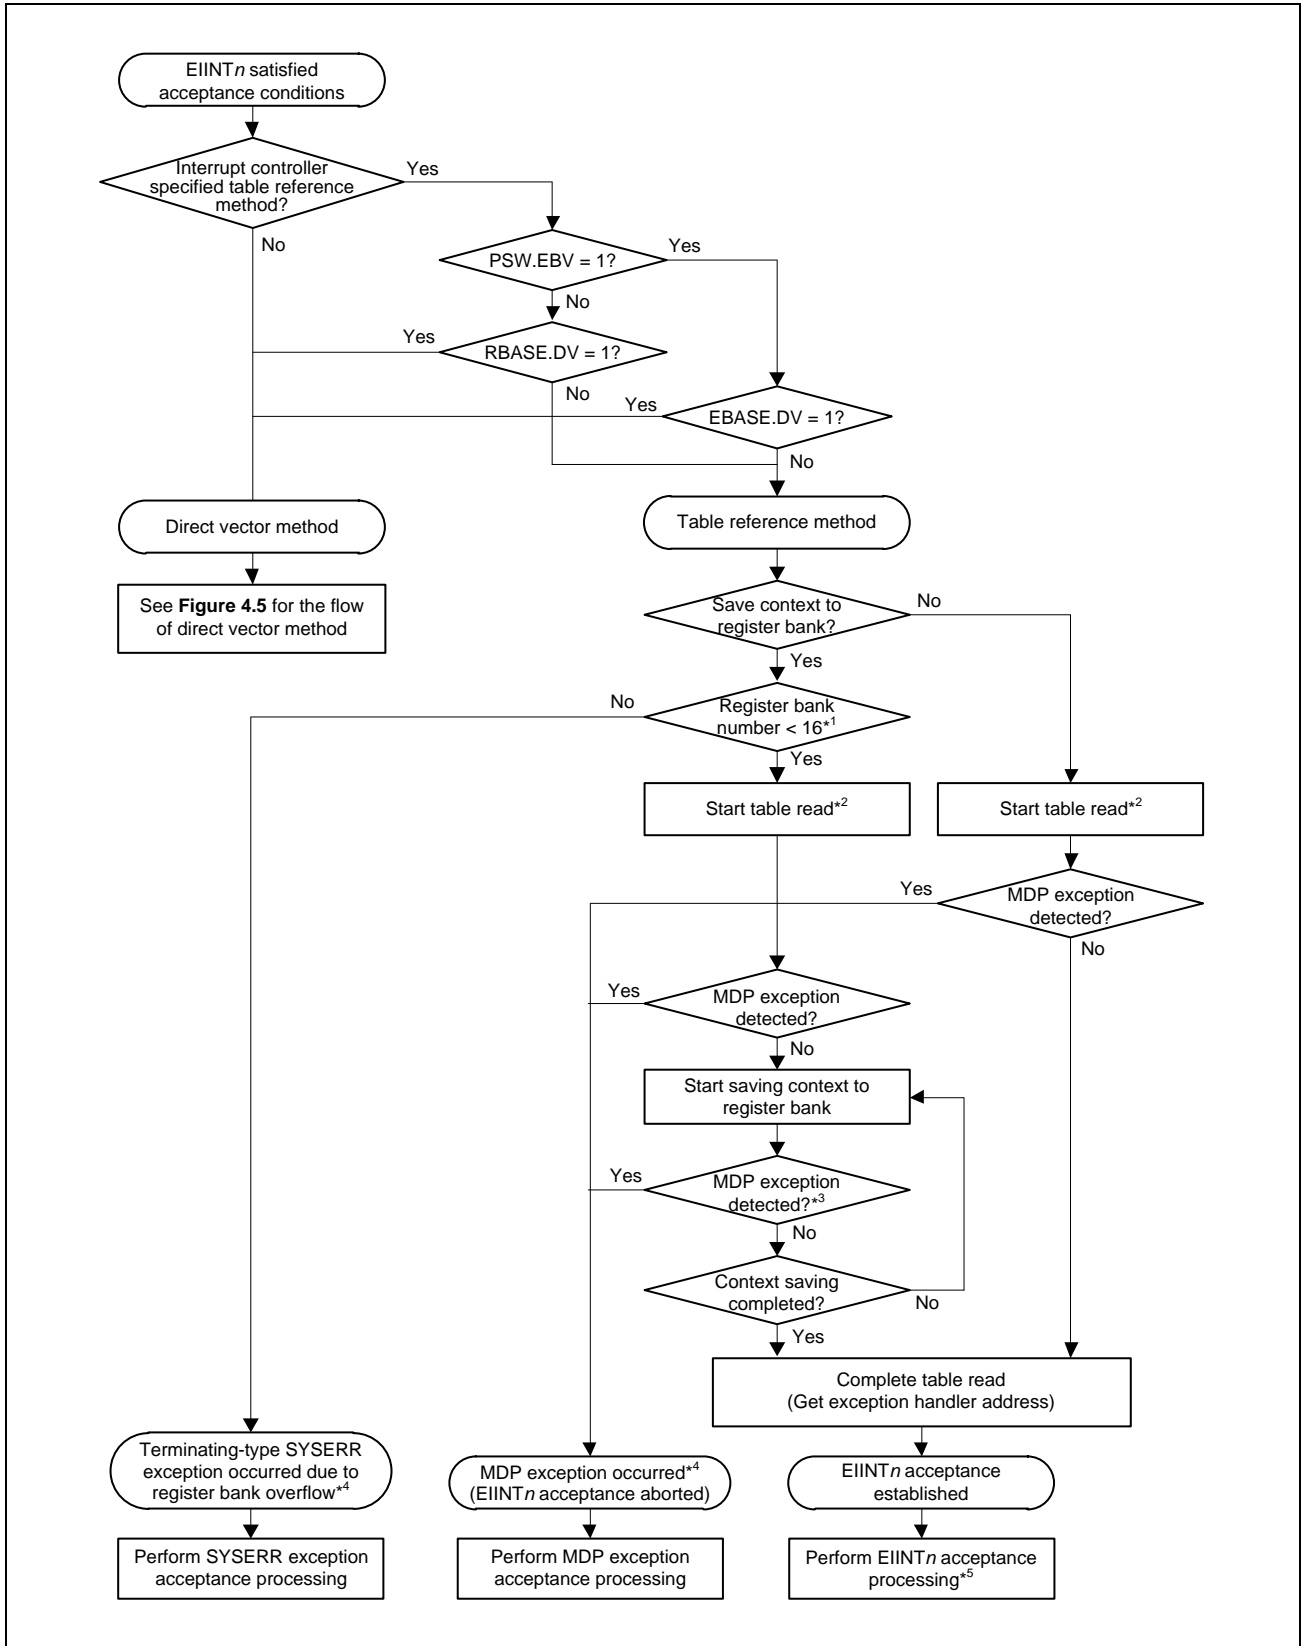

The user interrupt offset address reduction function is used to reduce the memory size required by the exception handler for specific operating modes of the system. The main purpose of this is to minimize the amount of memory consumed in operating modes that use only the minimum functionality, for example, during system maintenance and diagnosis.

(b) Table Reference Method

In the direct vector method, there is one user-interrupt exception handler for each interrupt priority, and user-interrupts with the same priority branch to the same interrupt handler, but some users might want to use code areas that differ from the start time for each interrupt handler.

This CPU defines a table reference method to accommodate to such uses.

Figure 3.22 shows the flow of generating a handler address for the table reference method.

- Note 1. For automatic context saving onto the register bank, the operation condition judgment is necessary. For details, see **Figure 3.24**.
- Note 2. This CPU updates the EIPC and EIPSW at this timing.
- Note 3. Detection of an MDP exception is performed every time an individual context is saved. An MDP exception occurs when an MDP violation is detected when saving an individual context rather than after all context saving is completed.
- Note 4. The PC of the instruction interrupted by the interrupt and the value of the PSW at that time are saved to the FEPC and the FEPSW respectively. These values are the same as the values saved to the EIPC and the EIPSW at the timing of Note 2. Therefore, when returning from the exception handler, it is possible to return exactly to the interrupted instruction. In addition, because no acceptance response has been reported to the interrupt controller, unless canceling the interrupt request in the exception handler, the interrupt request will remain held and interrupt acceptance processing will start again.
- Note 5. Report of the acceptance to the interrupt controller and the update of the EIIC and ISPR are performed at this timing.

Figure 3.22 Flow of Generating a Handler Address of Table Reference Method

- <1> In any of the following cases, the exception handler address is determined by using the direct vector method.
- When the interrupt channel setting is not the table reference method
 - When PSW.EBV = 0 and RBASE.DV = 1
 - When PSW.EBV = 1 and EBASE.DV = 1
- <2> In cases other than <1>, calculate the table read position.
Exception handler address read position = INTBP register + channel number × 4 bytes
- <3> Read word data starting at the exception handler address read position calculated in <2>.
- <4> Use the word data read in <3> as the exception handler address.
- <5> The acceptance of the interrupt is established when the exception handler address has been got. In addition to the exception acceptance processing shown in **Figure 3.18**, the CPU returns an acceptance response to the interrupt controller and updates the ISPR.

CAUTIONS

1. For details about the interrupt channel settings, see **Section 6, Interrupts**.
2. There are cases in which a memory protection exception (MDP) occurs while reading word data from the exception handler address read position depending on the memory protection settings. In such a case, the acceptance of the interrupt is temporarily cancelled. Since no acceptance response is returned to the interrupt controller, the interrupt request is held pending and is become acceptable again when execution is returned from the memory protection exception processing.
3. If a memory protection exception occurs during a word data read from the exception handler address read position, the PC of the instruction that is interrupted by the interrupt is saved in the FEPC. Since the acceptance of the interrupt is cancelled, the value of the PSW established when the interrupt occurred (which should have been saved in the EIPSW) is saved in the FEPSW.

Exception handler address read positions corresponding to interrupt channels and the placement of the interrupt handler address table in memory are shown below.

Table 3.99 Exception Handler Address Read Position

Type	Exception Handler Address Read Position
EIINT interrupt channel 0	INTBP + 0 × 4
EIINT interrupt channel 1	INTBP + 1 × 4
:	:
EIINT interrupt channel 2046	INTBP + 2046 × 4
EIINT interrupt channel 2047	INTBP + 2047 × 4

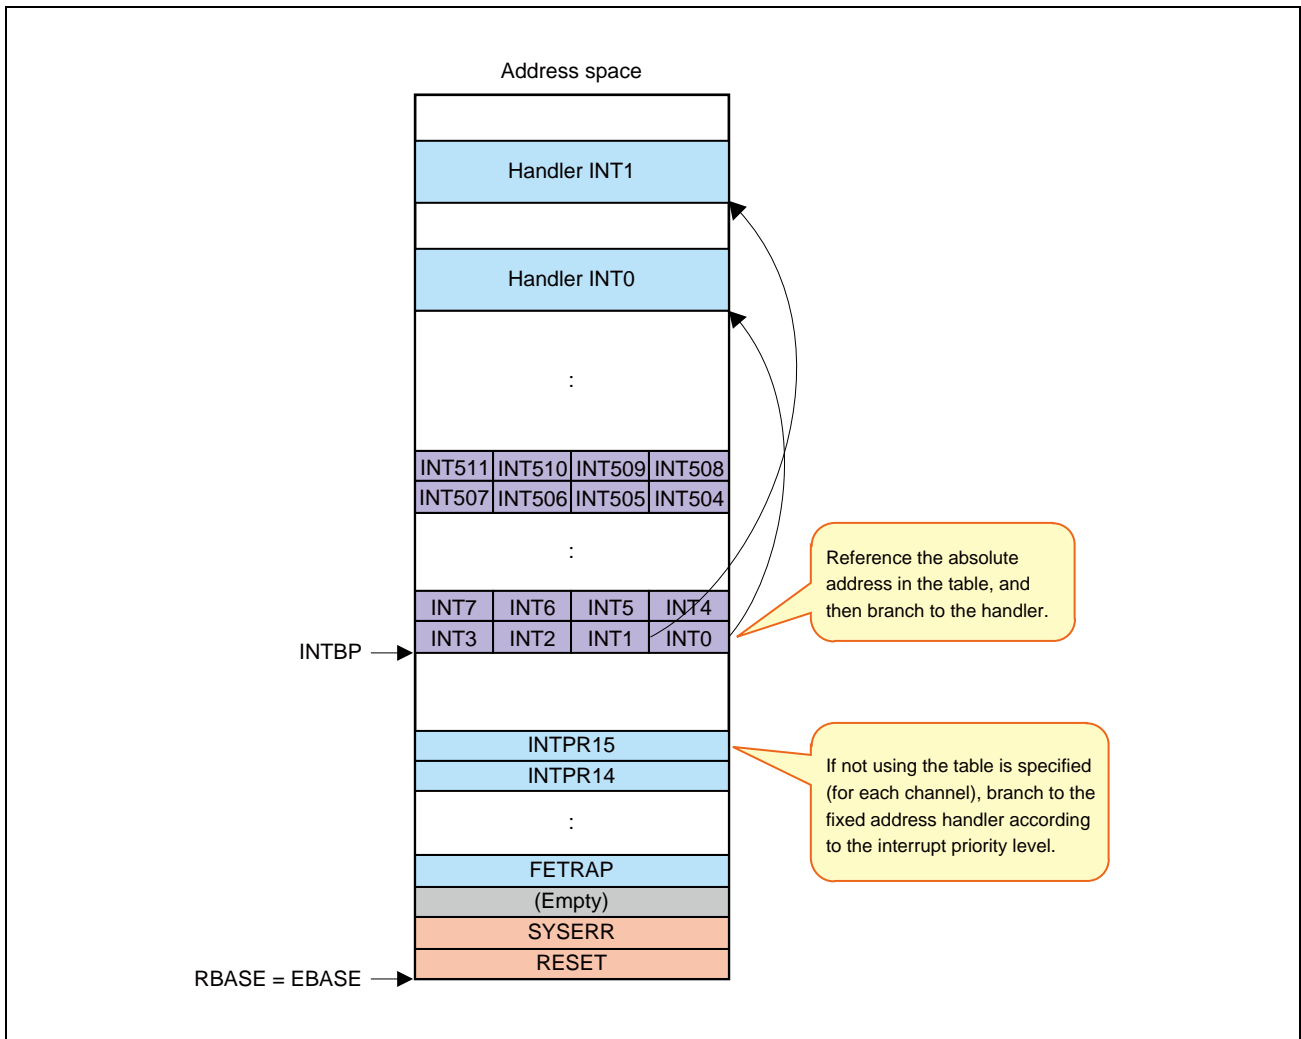

Figure 3.23 Placement of the Interrupt Handler Address Table in Memory

For details about the exception handler address selection method settings for each interrupt channel, see **Section 6, Interrupts**.

(2) System Calls

For system call exceptions, the referenced table entry is selected according to the value of the vector specified by the SYSCALL instruction and the value of the SCCFG.SIZE bit, and the exception handler address is calculated according to the contents of the table entry and the SCBP register value.

As an example, if table size n is specified by SCCFG.SIZE, the table entry is selected as shown below. Note that if the vector specified by the SYSCALL instruction (vector 8) is greater than table size n , the table entry referenced by vector $n + 1$ to 255 is table entry 0.

Table 3.100 System Calls

Vector	Exception Cause Code	Referenced Table Entry
0	0000 8000 _H	Table entry 0
1	0000 8001 _H	Table entry 1
2	0000 8002 _H	Table entry 2
(Omitted)	:	:
$n - 1$	0000 8000 _H + ($n - 1$) _H	Table entry $n - 1$
n	0000 8000 _H + n _H	Table entry n
$n + 1$	0000 8000 _H + ($n + 1$) _H	Table entry 0
(Omitted)	:	:
254	0000 80FE _H	Table entry 0
255	0000 80FF _H	Table entry 0

CAUTION

Because table entry 0 is selected if a vector that exceeds the table size specified by SCCFG.SIZE is specified, allocate the error processing routine at table entry 0.

3.2.4.5 Register Bank Function

This CPU provides the register bank function that automatically saves the context when it accepts an interrupt (EIINT n). Since the saving of the context proceeds in parallel with the interrupt acceptance processing, this function enables the CPU to make high-speed interrupt response.

(1) Outline of the Register Bank Function

The register bank function that this CPU provides has the following features:

- Automatically saves the context upon acceptance of an interrupt (EIINT n) meeting some conditions (see **Section 3.2.4.5(2), Automatic Context Saving.**)
- The destination of the context saving is not dedicated memory but an area of ordinary memory installed in this CPU (specified by the RBIP register).
- The context to be saved can be selected from two groups (specified by the RBCR0.MD bit).
- Supports a maximum of 16 levels of multiple interrupts (the RBNR.BN bits indicate the number of accepted interrupts).
- The context is restored from the register bank by executing the RESBANK instruction (no automatic restoration function).

(2) Automatic Context Saving

Automatic context saving is carried out when the following conditions are satisfied for an interrupt request (EIINT n) notified:

- Table reference method is specified for the interrupt request*¹.
- The use of the register bank is specified by the RBCR0.BE[i] bit which is associated with the priority (i) of the interrupt request (the automatic context saving onto the register bank is enabled).
- The RBNR.BN bits have a value no greater than 15 (the number of register banks in use is not greater than 15).

Note 1. See **Section 6, Interrupts** for the procedure to specify the table reference method.

Automatic context saving is not carried out if the table reference method is not specified for the interrupt request (EIINT n) or the use of the register bank is not specified by the RBCR0.BE[i] bit associated with the interrupt priority (i).

In addition, no automatic context saving is carried out if the value of the RBNR.BN bits are greater than 15. In such a case, it is assumed that an unexpected interrupt acceptance processing is being performed and a terminating-type SYSERR exception is notified for error processing.

Figure 3.24 shows the flow of checking the conditions for automatic context saving.

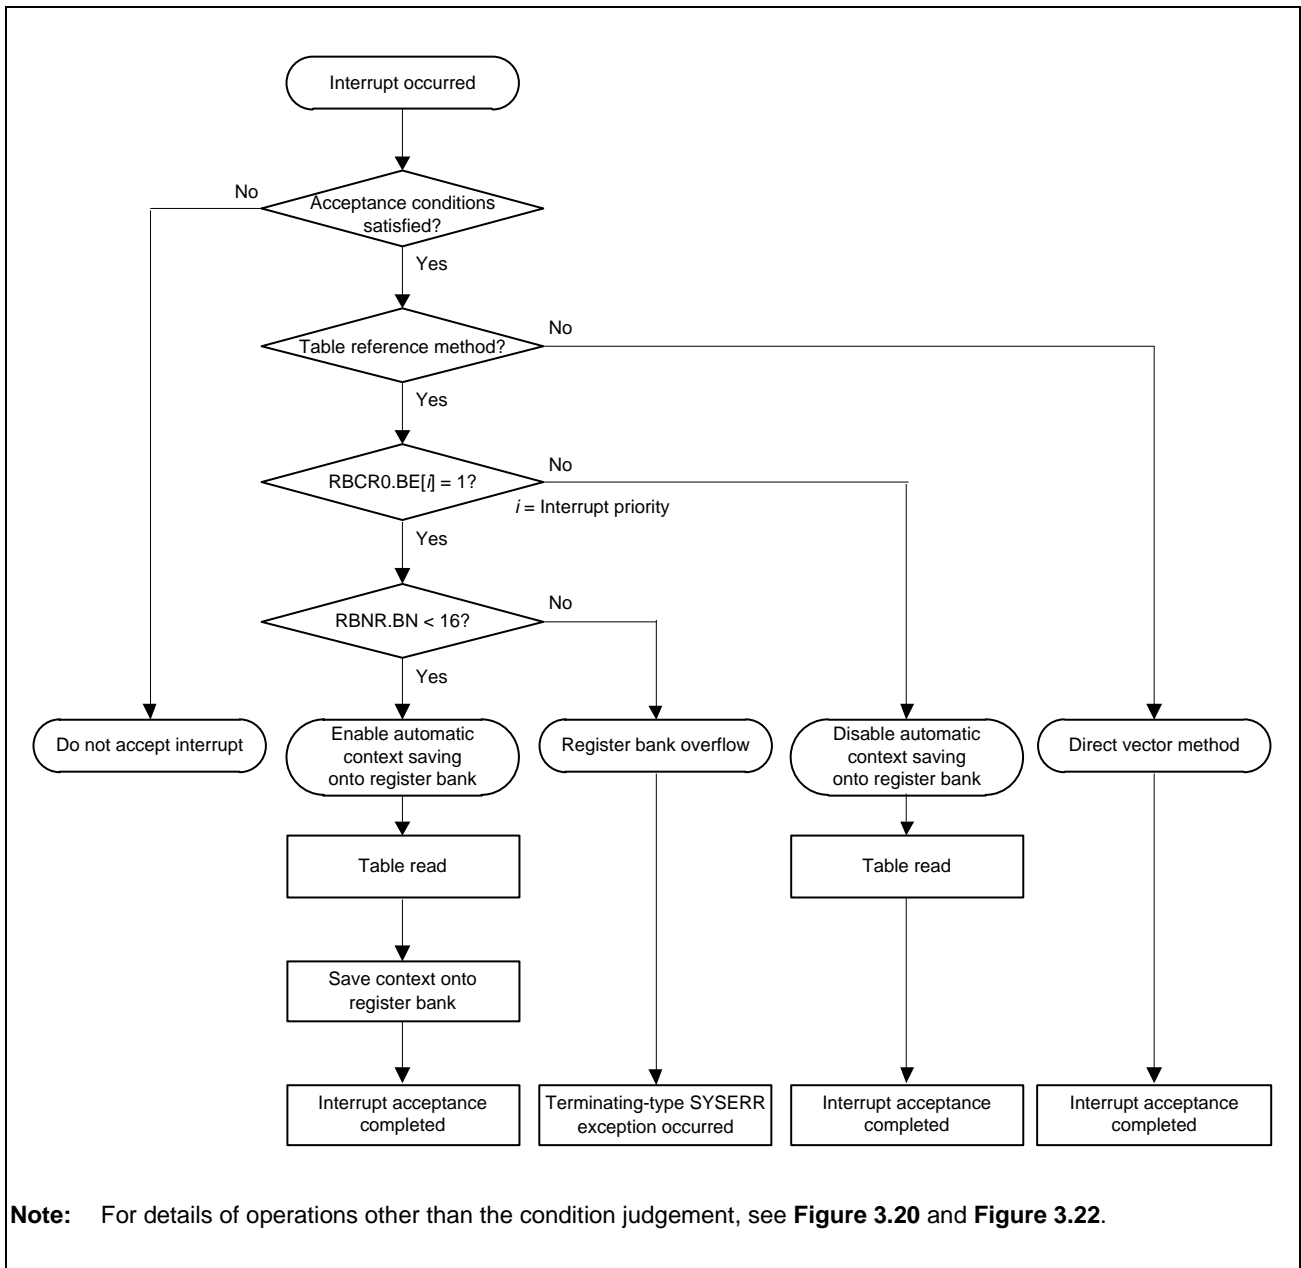

Figure 3.24 Flow of Checking the Conditions for Automatic Context Saving

(a) Automatic Context Saving

Shown below is the processing of automatic context saving onto the register bank.

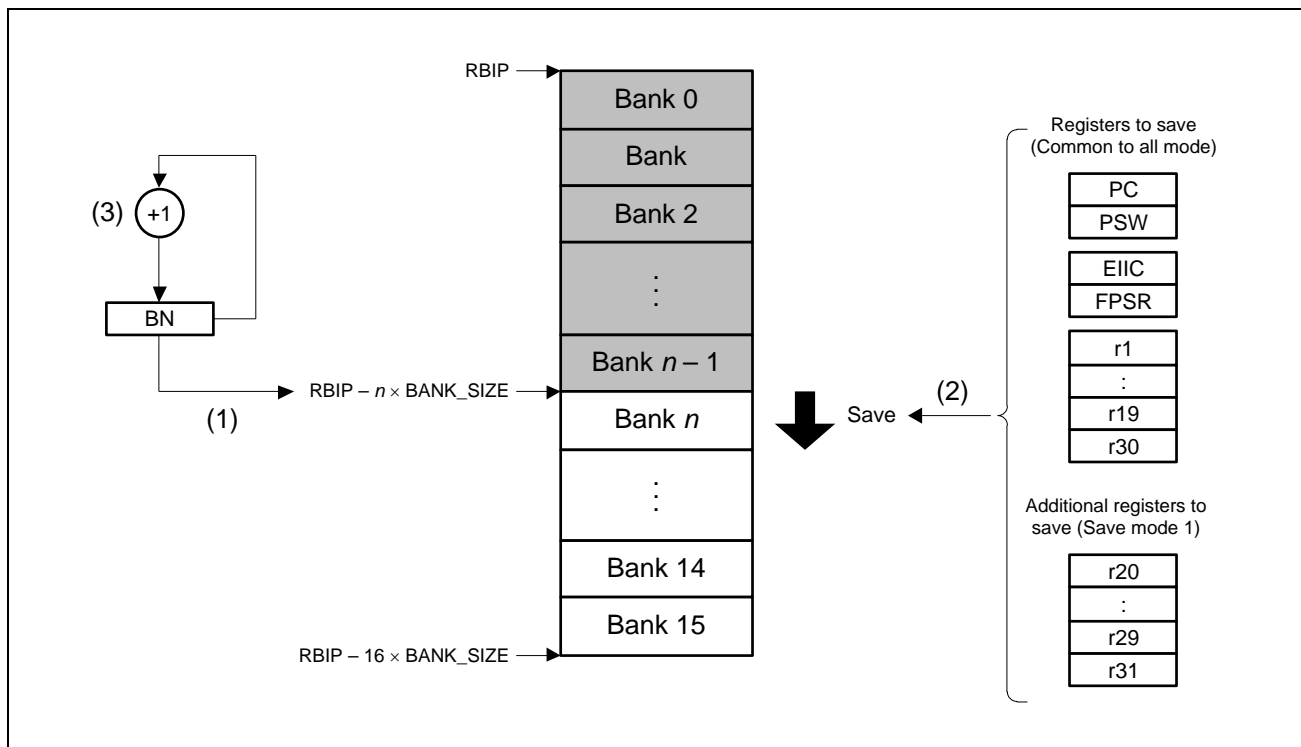

Figure 3.25 Processing of Automatic Context Saving

1. Calculate the start address of register bank n on which the context is to be saved based on the value of the register bank initial pointer (RBIP) and the value (n) of the BN bits of the register bank number register (RBNR) established upon acceptance of the interrupt. The size (BANK_SIZE) of the register bank differs depending on the save mode that is selected.
 - Start address:

$$RBIP - n \times BANK_SIZE$$
 - BANK_SIZE:
 - Save mode 0: 60H
 - Save mode 1: 90H
2. Save the target registers onto the register bank n specified by the RBNR.BN bits according to the save mode specified by the RBCR0.MD bit*1. **Table 3.101** shows a list of the registers to save, their addresses, and save order.
3. Increment the value of the RBNR.BN bits by 1. This terminates the register bank saving processing*2 and initiates the execution of the interrupt handler*3.

Note 1. MDP exceptions (terminating-type) might be caused by memory accesses made during the register bank saving processing. The other types of interrupts and exceptions cannot be accepted.

Note 2. The saving of the registers into the memory area specified as the register bank does not have always been completed. To ensure the completion of register saving, this CPU can employ a procedure similar to the one with the ordinary store instruction. For details, see **Section 3.2.7.2, Guaranteeing the Completion of Store Instruction.**

Note 3. Exceptions of higher priorities can be accepted after the saving onto the register bank is finished.

Table 3.101 List of Registers to Save, Addresses, Save Order, and Restore Order

Addresses	Save mode 0	Save mode 1	Save Order	Restore Order
RBIP – n × BANK_SIZE	(MD = 0)	(MD = 1)	*1, *2	*1, *3
-04 _H	PC	PC	1	24 / 35
-08 _H	PSW	PSW	2	23 / 34
-0C _H	EIIC	EIIC	3	22 / 33
-10 _H	FPSR	FPSR	4	21 / 32
-14 _H	r1	r1	5	20 / 31
-18 _H	r2	r2	6	19 / 30
-1C _H	r3	r3	7	18 / 29
-20 _H	r4	r4	8	17 / 28
-24 _H	r5	r5	9	16 / 27
-28 _H	r6	r6	10	15 / 26
-2C _H	r7	r7	11	14 / 25
-30 _H	r8	r8	12	13 / 24
-34 _H	r9	r9	13	12 / 23
-38 _H	r10	r10	14	11 / 22
-3C _H	r11	r11	15	10 / 21
-40 _H	r12	r12	16	9 / 20
-44 _H	r13	r13	17	8 / 19
-48 _H	r14	r14	18	7 / 18
-4C _H	r15	r15	19	6 / 17
-50 _H	r16	r16	20	5 / 16
-54 _H	r17	r17	21	4 / 15
-58 _H	r18	r18	22	3 / 14
-5C _H	r19	r19	23	2 / 13
-60 _H	r30	r20	24	1 / 12
-64 _H	*4	r21	25	11
-68 _H		r22	26	10
-6C _H		r23	27	9
-70 _H		r24	28	8
-74 _H		r25	29	7
-78 _H		r26	30	6
-7C _H		r27	31	5
-80 _H		r28	32	4
-84 _H		r29	33	3
-88 _H		r30	34	2
-8C _H		r31	35	1
-90 _H		*5		
-94 _H		*6		

Note 1. Register saving and restoration start sequentially at sequence number 1.

Note 2. The target registers to be saved in save mode 0 (RBCR0.MD = 0) are the registers up to r30 with a save sequence number of 24.

Note 3. The restoration sequence numbers shown on the left side are for save mode 0 and those shown on the right side are for save mode 1.

Note 4. In save mode 0, the next bank (n + 1) starts from this address.

Note 5. In save mode 1, no register is saved in this address. This address is not used.

Note 6. In save mode 1, the next bank (n + 1) starts from this address.

(b) Suppressing the Update of the PSW.ID Bit

When an interrupt (EIINT n) is accepted in the normal state, the PSW.ID bit is set to 1 and interrupts of the same EI level cannot be accepted unless the acceptance of interrupts is enabled explicitly with the EI instruction.

For interrupts that make use of the register bank (satisfying the automatic context saving conditions), on the other hand, by clearing the RBCR1.NC[i] bit associated with the interrupt priority (i) to 0, the PSW.ID bit keeps its value 0 without being set to 1 when an interrupt is accepted. This makes it possible to accept interrupts of higher priorities without software intervention after the end of automatic context saving. Since necessary registers are automatically saved, the CPU can return to the original interrupt processing precisely.

(3) Context Restoration

The context automatically saved onto the register bank need to be restored before returning from the interrupt processing to the original program. Although the context saving onto the register bank is automatically done, its restoration needs to be accomplished explicitly by software executing the RESBANK instruction.

(a) Conditions for Executing the RESBANK Instruction

The RESBANK instruction must be executed to restore the context from the register bank. The RESBANK instruction is a supervisor-privileged instruction. A PIE exception will occur if it is executed in user mode.

A resumable-type SYSERR exception will occur if the RESBANK instruction is executed when the value of the RBNR.BN bits are 0. A 0 in the RBNR.BN bits means that no context has automatically been saved onto the register bank. Accordingly, an invalid value will be restored if the RESBANK instruction is executed in such case.

The above-mentioned operating conditions are summarized in **Figure 3.26**.

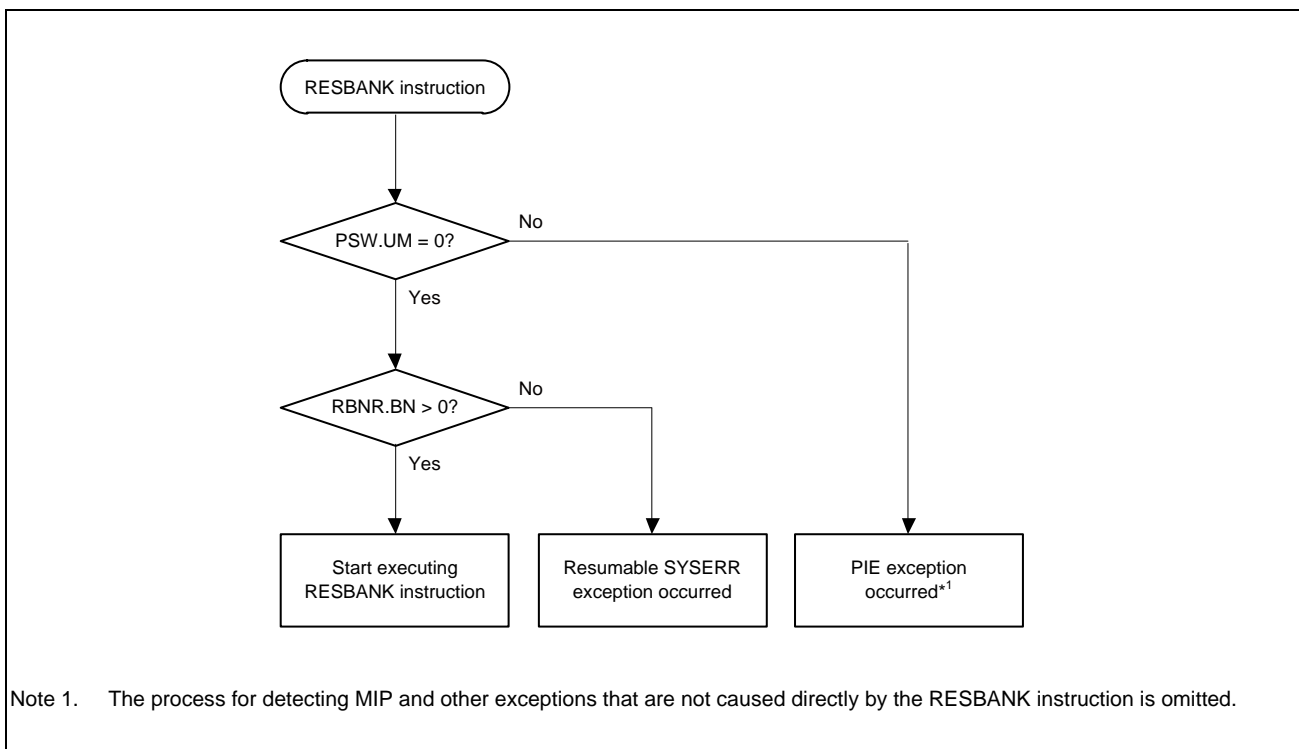

Figure 3.26 Flow of Checking the Conditions for Executing the RESBANK Instruction

(b) Context Restoration

The figure below shows the processing of the RESBANK instruction for restoring the context from the register bank.

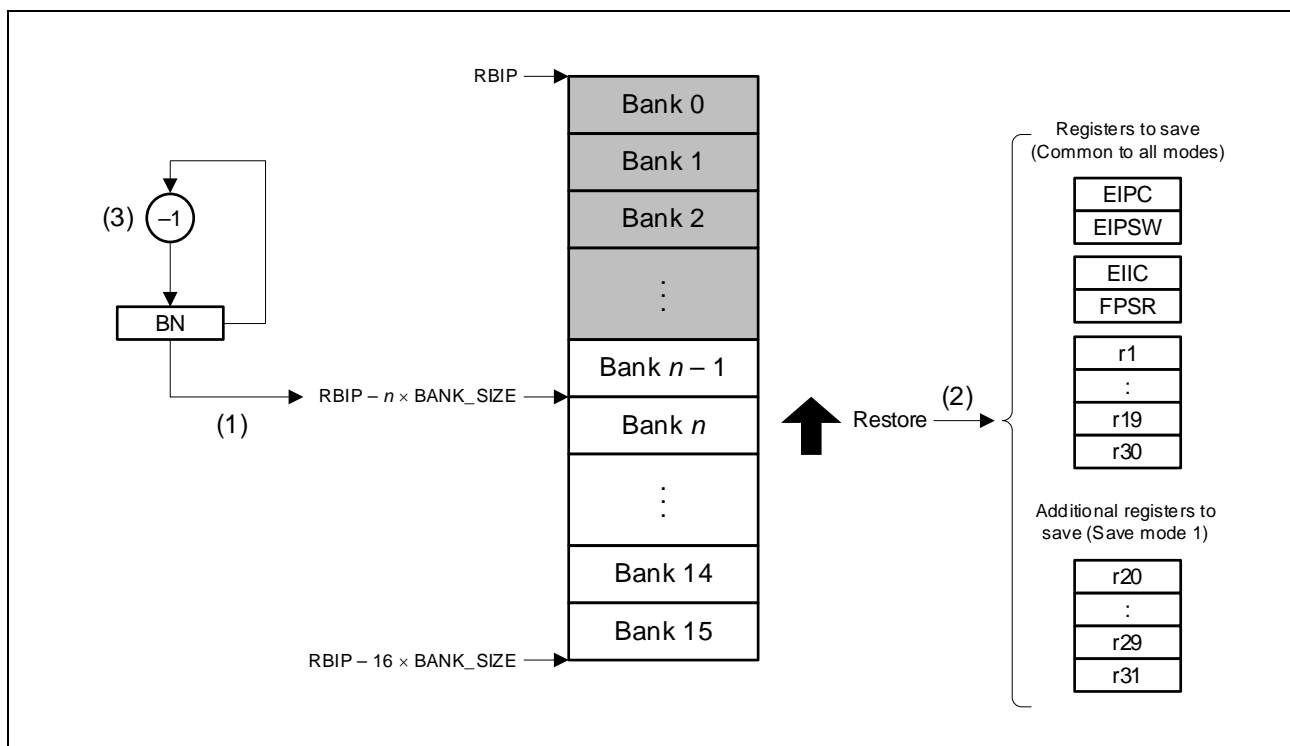

Figure 3.27 Processing of Context Restoration

1. Calculate the start address of register bank $n-1$ from which the context is to be restored based on the value of the register bank initial pointer (RBIP) and the value (n) of the BN bits of the register bank number register (RBNR) established upon acceptance of the interrupt. Unlike in the case of saving the context, the start address to be referenced when restoring the context is the lower-limit side of the register bank addresses. The size (BANK_SIZE) of the register bank differs depending on the save mode that is selected.

Start address:

$$RBIP - n \times BANK_SIZE$$

BANK_SIZE :

Save mode 0: 60_H

Save mode 1: 90_H

2. Restore the context from the register bank $n-1$ in the target registers according to the save mode specified by the RBCR0.MD bit*¹. **Table 3.101** shows a list of the registers to restore, their addresses, and restore order.
3. Decrement the value of the RBNR.BN bits by 1*². This terminates the register bank restoration processing and completes the execution of the RESBANK instruction*³.

Note 1. The CPU can accept terminating-type exceptions while restoring the context from the register bank. MDP exceptions (resumable-type) might be caused by memory accesses made during the register bank restoration processing.

Note 2. When the CPU accepts an exception before the value of RBNR.BN is updated, it stops the execution of the RESBANK instruction even if the restoration of all registers is not yet completed. In this case, though there are some registers of which restoration has been completed, the CPU cannot know what registers have been restored. Since the return PC of the exception is the PC of this RESBANK instruction, the CPU can re-execute

precisely the RESBANK instruction if none of the resources related to the RESBANK instruction are altered during the exception processing.

Note 3. After the RESBANK instruction is executed, execute the EIRET instruction to return from the interrupt handler.

3.2.4.6 List of Memory Access Exceptions

Table 3.102 shows a list of instructions and exceptions that make memory accesses and the exceptions that can be detected. Exceptions identified by the symbol “✓” can be detected during the memory accesses that are made during the processing of the listed instructions and exceptions. Exceptions identified by the symbol × are not detected.

Table 3.102 List of Memory Access Exceptions

Instruction/Exception	MAE	MDP	Instruction/Exception	MAE	MDP
SLD.B	×	✓	TST1	×	✓
SLD.BU	×	✓	PREPARE	×	✓
SLD.H	✓	✓	DISPOSE	×	✓
SLD.HU	✓	✓	PUSHSP	×	✓
SLD.W	✓	✓	POPSP	×	✓
SST.B	×	✓	SWITCH	×	✓
SST.H	✓	✓	CALLT	×	✓
SST.W	✓	✓	SYSCALL	×	✓
LD.B	×	✓	LDV.W	✓	✓
LD.BU	×	✓	LDV.DW	✓	✓
LD.H	✓	✓	LDV.QW	✓	✓
LD.HU	✓	✓	STV.W	✓	✓
LD.W	✓	✓	STV.DW	✓	✓
LD.DW	✓	✓	STV.QW	✓	✓
ST.B	×	✓	LDVZ.H4	✓	✓
ST.H	✓	✓	STVZ.H4	✓	✓
ST.W	✓	✓	CACHE (CHBII)	×	✓
ST.DW	✓	✓	CACHE (CIBII)	×	×
LDL.BU	×	✓	CACHE (CFALI)	×	✓
LDL.HU	✓	✓	CACHE (CISTI)	×	×
LDL.W	✓	✓	CACHE (CILDII)	×	×
STC.B	×	✓	CACHE (other commands)	×	×
STC.H	✓	✓	PREF (PREFI)	×	×*1
STC.W	✓	✓	PREF (other commands)	×	×
CAXI	✓	✓	Table reference type EIINT n	×	✓*2
SET1	×	✓	Register bank saving processing	×	✓*2
CLR1	×	✓	RESBANK	×	✓
NOT1	×	✓			

Note 1. When a violation is detected during the execution of the PREF instruction, no MDP exception is generated but the memory access is suppressed. Read access is not performed.

Note 2. Both of table read accesses due to table reference method interrupts and write accesses for automatically saving the context onto the register bank occur independently of the execution of an instruction. This CPU handles any MDP exception that is caused by these accesses as a terminating-type exception. The exception cause code of this MDP exception differs from that of resumable-type MDP exceptions. For details see **Table 3.95**.

3.2.5 Memory Management

This CPU provides the following functions for managing memory.

- Memory protection unit (MPU)
- Instruction cache function
- Mutual exclusion function
- Special instructions for synchronization processing
- Guaranteeing the completion of store instructions

3.2.5.1 Memory Protection Unit (MPU)

Memory protection functions are provided in an MPU (memory protection unit) to maintain a smooth system by detecting and preventing unauthorized use of system resources by unreliable programs, runaway events, etc.

(1) Features

(a) Memory Access Control

Multiple protection areas can be assigned to the address space. Consequently, unauthorized program execution or data manipulation by user programs can be detected and prevented. The upper and lower limit addresses of each area can be specified so that the address space can be used precisely and efficiently.

(b) Access Management for Each CPU Operation Mode

In this CPU, several status bits are used to control access to resources, and these bits are used in combination to perform protection that is appropriate, according to each program's level of reliability.

(c) Protection with the System Protection Identifier (SPID)

This CPU can use the system protection identifier (SPID) to check for area matching. The usage and limitations on settings of the SPID register depend on the system specifications of the product in which this CPU is mounted. Reflecting such system specifications in the control of memory access can enable the efficient management of access.

(2) Protection Area Settings

(a) Protection Area Attribute Settings

Set the respective protection areas appropriately. For details about registers, see **Section 3.2.3, Register Set**.

3.2.5.1.2.a.1 E bit

This sets the target protection area setup as enabled or disabled. When disabled, all settings are disabled. Make sure valid setting values have been stored for other protection area settings (MPUA, MPLA, and MPAT) at the time when this bit is set to 1.

3.2.5.1.2.a.2 UX, UR, and UW bits

These bits indicate the access privileges for the target protection area during user mode. A 1 in these bits indicates the presence of the corresponding access privilege.

3.2.5.1.2.a.3 SX, SR, and SW bits

These bits indicate the access privileges for the target protection area during supervisor mode. These bits, in addition to the E bit, are valid only when the MPM.SVP bit has been set to 1. If the MPM.SVP bit has been cleared to 0, even when the E bit is set to 1, protection is not performed while in supervisor mode, regardless of the values of the SX, SR, and SW bits, and the entire address space becomes access-enabled.

3.2.5.1.2.a.4 WG and WMPIDn bits and MPIDn registers (n = 0 to 7)

These bits indicate how to reference the system protection identifier (SPID) during the check for the permission to write to a protection area.

When the WG bit is set (to 1), the access permission for all write accesses is judged only by the settings of the UW or SW bit regardless of the value of the SPID that is set.

When the WG bit is cleared (to 0), if the value of the SPID register matches any of the values specified in the MPIDn registers and if the WMPIDn bit corresponding to the matching MPIDn register is set (to 1), the access permission is judged according to the settings of the UW or SW bit. If the value of the SPID register matches none of the values specified in the MPIDn registers or if the WMPIDn bit corresponding to the matching MPIDn register is cleared (to 0), the access permission is judged to be “write-disabled” regardless of the settings of the UW or SW bit.

In addition, when the values of multiple MPIDn registers match the value of the SPID register, writing is possible if any of the corresponding WMPIDn bit is set (to 1).

3.2.5.1.2.a.5 RG bit, RMPIDn bit, and MPIDn registers (n = 0 to 7)

These bits indicate how to reference the system protection identifier (SPID) during the check for the permission to read from a protection area.

When the RG bit is set (to 1), the access permission for all read accesses is judged only by the settings of the UX and UR bits or the SX and SR bits regardless of the value of the SPID that is set. When the RG bit is cleared (to 0), if the value of the SPID register matches any of the values specified in the MPIDn registers and if the RMPIDn bit corresponding to the matching MPIDn register is set (to 1), the access permission is judged according to the settings of the UX and UR bits or the SX and SR bits. If the value of the SPID register matches none of the values specified in the MPIDn registers or if the RMPIDn bit corresponding to the matching MPIDn register is cleared (to 0), the access permission is judged to be “read-disabled” regardless of the settings of the UX and UR bits or the SX and SR bits.

In addition, when the values of multiple MPIDn registers match the value of the SPID register, reading is possible if any of the corresponding RMPIDn bit is set (to 1).

(3) Caution Points for Protection Area Setup

(a) Crossing Protection Area Boundaries

When the specified protection areas overlap, the access control settings for the overlapping parts are set to “allow most”.

In other words, when multiple protection areas have been specified, if access is enabled for either of the protection areas, access is judged to be enabled.

(b) Invalid Protection Area Settings

Protection area settings are invalid in the following case.

- When value set to lower-limit address is larger than value set to upper-limit address

CAUTION

Addresses are handled as unsigned integers (0_H to FFFF FFFF_H).

For example, the following settings alone cannot make the target area accessible (MPAT is omitted):

MPLA0 = FFFF FF80_H, MPUA0 = 0000 00FC_H

This setting should be divided into the following two protection area settings.

MPLA0 = FFFF FF80_H, MPUA0 = FFFF FFFC_H

MPLA1 = 0000 0000_H, MPUA1 = 0000 00FC_H

MPLA0 refers to the MPLA register for the protection area 0. The same holds true for the other registers.

(c) Lower- and Upper-Limit Addresses Referenced during Protection Violation Checks

Table 3.103 lists the lower-limit addresses that are compared with MPLA and the upper-limit addresses that are compared with MPUA during the protection violation check.

Table 3.103 Lower- and Upper-limit Addresses Referenced during the Protection Violation Check

Instruction/Event	Access size	Lower-Limit Address	Upper-Limit Address
SLD, SST, LD, ST, LDL, STC, LDV, STV	Byte	Address calculated according to the addressing specified in the instruction	Same as lower-limit address
	Half word		Lower-limit address + 1
	Word		Lower-limit address + 3
	Double word* ¹		Lower-limit address + 7
	Quad word* ¹		Lower-limit address + 15
CAXI	Word	Value of reg1	Lower-limit address + 3
SET1, NOT1, CLR1, TST1	Byte	Address calculated according to the addressing specified in the instruction	Same as lower-limit address
PREPARE, DISPOSE, PUSHSP, POPSP	Word* ²	Address calculated from the value of the SP and the number of accesses	Lower-limit address + 3
SWITCH, CALLT	Half word	Address calculated according to the addressing specified in the instruction	Lower-limit address + 1
SYSCALL	Word	Address calculated according to the default addressing	Lower-limit address + 3
CACHE (CHBII, CFALI), PREF	Cache line size* ³	reg1 value rounded by cache line size	Lower-limit address + Cache line size – 1
Table reference EIINT _n	Word	Address from which the exception handler address is read when table reference method is selected	Lower-limit address + 3
Automatic context saving onto a register bank	Word* ²	Address calculated from the values of the RBIP and the RBNR.BN bit	Lower-limit address + 3
RESBANK	Word* ²	Address calculated from the values of the RBIP and the RBNR.BN bit	Lower-limit address + 3
Memory protection configuration check function	Value of MCS	Value of MCA	Value of MCA + MCS – 1
Instruction fetch	Instruction fetch size* ⁴	PC rounded by the instruction fetch size	Lower-limit address + Instruction fetch size – 1

Note 1. Since the minimum protection area unit is word-size, there are cases in which the lower- or upper-limit address specified for a double or quad word access does not fall within the address range designated by a single protection area setting. If either one of the lower- and upper-limit addresses does not fall within the specified address range, a protection violation is detected and an MDP exception is generated. See **Section 3.2.5.1(3)(d), Memory Access Spanning Contiguous Protection Areas** for the operation for two contiguous protection area settings.

Note 2. The instruction accesses contiguous multi-byte area, however, memory accesses for a single register are carried out on word-size basis. Memory protection is effected on each of these word-size accesses. For this reason, there are cases in which a data protection violation is detected when some of word-size memory access are executed and there still are memory accesses that are yet to be executed. In these cases, an MDP exception occurs during the processing of the instruction, and the instruction is aborted. Memory or registers are updated by the completed processing of the instruction.

Note 3. For the cache line size, see **Section 3.8.9, Product Information of Cache Structure**.

Note 4. For the instruction fetch size, see **Section 3.8.10, Product Information of Fetch Size**.

(d) Memory Access Spanning Contiguous Protection Areas

With respect to the memory protection against an operand access, it is necessary that the associated memory access is encompassed entirely in a single access enabled area. No accesses that span over two or more areas are allowed even when the access enabled areas are allocated in contiguous spaces. In this CPU, since the minimum protection area unit is word-size and misaligned accesses cannot be executed, memory accesses spanning over areas can occur during double word size memory accesses (LD.DW, ST.DW, LDV.DW, and STV.DW) or quad-word memory access (LDV.QW, STV.QW).

On the other hand, the memory accesses associated with the instructions PREPARE, DISPOSE, PUSHSP, POPSP, and RESBANK and the memory accesses associated with the automatic context saving onto a register bank may span over two or more access enabled areas since they are handled as repetitions of two or more word size accesses.

With respect to the memory protection against an instruction fetch, if a fetch access spans over protection areas, the instruction codes that are fetched are given the result of judging the memory protection which is made with the word size as a delimiter. Since only a specific part of the instruction codes that are fetched is required to execute the instruction, even if an instruction fetch which spans over enabled and disabled areas is made, the instruction code in the enabled area can be executed. If the instruction code in the disabled area is used, an MIP exception will occur.

Since the instruction codes are allocated on a half word basis, for an instruction whose instruction length is the word size or longer, there are cases in which the instruction itself spans over protection areas. In such a case, the instruction may be executed if both areas are enabled. If one area is disabled, however, the instruction cannot be executed even if the other area is enabled.

Table 3.104 below shows the examples of operand accesses which span over protection areas. **Table 3.105** below shows the examples of instruction fetches which span over protection areas. In the following examples, the LD.DW, DISPOSE instructions and the instruction fetch start to access address 0000 00FC_H and proceed in the direction of increasing addresses. The PREPARE instruction starts to access address 0000 0100_H and proceeds in the direction of decreasing addresses. The memory protection setting check function checks the area that begins from 0000 00FC_H and goes beyond the boundary of the protection area. In the examples, following two protection areas are set.

Protection area setting 0: MPLA0 = 0000 0000_H, MPUA0 = 0000 00FC_H

Protection area setting 1: MPLA1 = 0000 0100_H, MPUA1 = 0000 01FC_H

Table 3.104 Examples of Operand Memory Accesses Spanning Over Contiguous Protection Areas

Protection Setting		Operation			
Setting 0	Setting 1	LD.DW, etc.	PREPARE, etc. (save context)	DISPOSE, etc. (restore context)	Memory Protection Setting Check
Disabled	Disabled	MDP	MDP	MDP	Prohibited (0) ^{*5}
Disabled	Enabled	MDP	MDP ^{*1}	MDP ^{*3}	Prohibited (0) ^{*5}
Enabled	Disabled	MDP	MDP ^{*2}	MDP ^{*4}	Prohibited (0) ^{*5}
Enabled	Enabled	MDP	Access executed	Access executed	Prohibited (0) ^{*5}

- Note 1. Accesses made to addresses in the protection area setting 1 are enabled and update the memory. When an access is made to an address in the protection area setting 0, an MDP exception occurs and the execution of the instruction is aborted. The MEA register holds the address at which the first data protection violation is detected.
- Note 2. Since the address at which accessing is to start is disabled, an MDP exception occurs without the execution of any memory access.
- Note 3. Since the address at which accessing is to start is disabled, an MDP exception occurs without the execution of any memory access.
- Note 4. Accesses made to addresses in the protection area setting 0 are enabled and update the registers. When an access is made to an address in the protection area setting 1, an MDP exception occurs and the execution of the instruction is aborted. The MEA register holds the address at which the first data protection violation is detected.
- Note 5. The memory protection setting check function sets "Prohibited (0)" to the corresponding bits of the MCR register unless the target area falls within a single protection area.

Table 3.105 Examples of Instruction Fetch Memory Accesses Spanning Over Contiguous Protection Areas

Protection Setting		Operation			
Setting 0	Setting 1	Execute Instructions Covered by Only Setting 0	Execute Instructions Covered by Only Setting 1	Execute Instructions Spanning Over Settings 0 and 1	Manipulate Instruction Cache with CACHE Instruction/Prefetching by the PREF Instruction
Disabled	Disabled	MIP	MIP	MIP	MDP ^{*1} /Disabled ^{*2}
Disabled	Enabled	MIP	Instruction executed	MIP	MDP ^{*1} /Disabled ^{*2}
Enabled	Disabled	Instruction executed	MIP	MIP	MDP ^{*1} /Disabled ^{*2}
Enabled	Enabled	Instruction executed	Instruction executed	Instruction executed	MDP ^{*1} /Disabled ^{*2}

- Note 1. An MDP exception occurs when a memory protection violation is detected for the CACHE instruction which manipulates the instruction cache using the address specification method.
- Note 2. An MDP exception does not occur, and prefetching is disabled when a PREF instruction leads to a violation of memory protection.

(e) Memory Access which Spans Over Address 0000 0000_H

Table 3.106 summarizes the operations that are performed when a memory access which spans over addresses FFFF FFFF_H to 0000 0000_H is made with the protection setting such that all the address spaces are enabled by the following single protection area setting:

Protection area setting 0: MPLA0 = 0000 0000_H, MPUA0 = FFFF FFFC_H

Table 3.106 Operations of Memory Access That Span Over Address 0000 0000_H

Instruction/Event	Operation
LD.DW, ST.DW	MDP exception
PREPARE, DISPOSE, PUSHSP, POPSP, RESBANK, Automatic context saving onto a register bank	Access executed

For instructions and events other than those mentioned above, no memory access which spans over address 0000 0000_H is generated by a single instruction or event.

(4) Access Control

In this CPU, accesses are controlled appropriately according to the settings described in **Section 3.2.5.1(2), Protection Area Settings**. In any of the cases listed below, the CPU ensures logical integrity by limiting actual access, detecting violations before instruction execution is completed, and setting up exceptions.

- When about to execute an instruction at an address outside the executable area
- When about to execute an instruction that reads from an address outside the read-accessible area
- When about to execute an instruction that writes to an address outside the write-accessible area

The specifics of access control are as follows.

- The result of the access which is judged as prohibited is not reflected in memory or I/O devices.
- The result of the access which is judged as enabled is reflected in memory or I/O devices.

CAUTIONS

1. Even when access is enabled, there might be cases where access is blocked by another function that prohibits it.
2. In some cases, access judged to be prohibited may be executed for a memory. The cases are as listed below.
 - Reading local RAM
 - Reading of code flash memory by instruction prefetching of the instruction cache

Since execution of the instructions that read from the local RAM or execute the prefetched instruction is inhibited by an exception, such access does not affect the execution of instructions. However, when a debugger is monitoring access to the local RAM or code flash memory, it may observe access judged to be prohibited.

(5) Violations and Exceptions

In this CPU, violations are detected during instruction fetch access or operand access according to the protection area settings, and an exception is generated.

- Execution protection violation (during instruction fetch access)
- Data protection violation (during operand access)

(a) Execution Protection Violation (MIP Exception)

This violation is detected when an instruction is executed. An execution protection violation is detected when attempting to execute an instruction that has been placed in a non-executable area.

When an execution protection violation is detected, an MIP exception always occurs.

(b) Data Protection Violation (MDP Exception)

This violation is detected during operand access. A data protection violation is detected when a memory access instruction, etc. attempts to access data from an access-prohibited area.

When a data protection violation is detected, an MDP exception always occurs.

(c) Exception Cause Code and Exception Address

When an execution protection violation or data protection violation has been detected, the exception cause code is determined as shown in **Table 3.107**. The determined exception cause code is set to the FEIC register.

The MEA register is used to store either the PC of the instruction that detected the execution protection violation or the access address used when the data protection violation occurred. The MEA register is shared by MIP and MDP exceptions since these exceptions do not occur simultaneously. Also, when a data protection violation occurs, the information of the instruction or event that caused the violation is stored in the MEI register.

Table 3.107 Exception Cause Code of Memory Protection Violation

Exception	Operation Mode When Violation Occurred	Bit Number and Bit Name										
		31-25	24	23	22	21	20	19	18	17	16	15-0
		—	MS	BL	RMW	SX	SW	SR	UX	UW	UR	—
MIP	User mode	0	0	0	0	0	0	0	1	0	0	90 _H
	Supervisor mode	0	0	0	0	1	0	0	0	0	0	90 _H
MDP	User mode	0	*5	*4	*3	0	0	0	0	*2	*1	91 _H
	Supervisor mode	0				0	*2	*1	0	0	0	91 _H *6

- Remarks:**
- UR: A violation is detected during a read operation in user mode (PSW.UM = 1).
 - UW: A violation is detected during a write operation in user mode (PSW.UM = 1).
 - UX: A violation is detected during instruction execution in user mode (PSW.UM = 1).
 - SR: A violation is detected during a read operation in supervisor mode (PSW.UM = 0).
 - SW: A violation is detected during a write operation in supervisor mode (PSW.UM = 0).
 - SX: A violation is detected during instruction execution in supervisor mode (PSW.UM = 0).
 - RMW: Set to 1 when the instruction causing the violation contains a read-modify-write operation (SET1, NOT1, CLR1, or CAXI).
 - BL: Set to 1 when the instruction causing the violation performs a block transfer (PREPARE, DISPOSE, PUSHSP, or POPSP).
 - MS: Set to 1 when the instruction causing the violation performs a misaligned access.

Note 1. When a read violation is caused by an instruction that includes a read operation, either the SR or UR bit is set to 1.

Note 2. When a write violation is caused by an instruction that includes a write operation, either the SW or UW bit is set to 1.

Note 3. This bit is set to 1 when a violation is caused by the SET1, NOT1, CLR1, or CAXI instruction.

Note 4. This bit is set to 1 when a violation is caused by the PREPARE, DISPOSE, PUSHSP, or POPSP instruction.

Note 5. This bit is set to 1 when the instruction causing the violation performs a misaligned access.

Note 6. These bits are loaded with 95_H for a data protection violation that is detected during a table read initiated by table reference EIINTn or automatic context saving onto a register bank. These are executed only in supervisor mode.

(6) Memory Protection Setting Check Function

For the programs, such as OS, that provide services, this CPU provides a memory protection setting check function to enable implementation of a service protection function that checks in advance whether or not the address area to be used for the requested operations is within an area that is accessible by the source that requested the service. By using this function, when verifying the validity of the user-supplied parameters for a system service, the OS can complete the verification in a shorter time than by repeating reading and checking the area settings by software.

(a) Check Details

The memory protection setting check function checks what access permission settings are made for the specified address area according to the protection area settings that are stored in the MPU.

If the address area specified by the MCA and MCS registers is contained within one protection area (specified by a pair of the MPLA and MPUA registers) and the instruction execution (instruction fetch)/write access/read access for the SPID specified by the MCI register is permitted in supervisor mode/user mode, the corresponding bit in the MCR register is set (to 1).

If the specified address area is not contained within one protection area or an access for the specified SPID is not permitted in an operation mode, the corresponding bit in the MCR register is cleared (to 0).

This check operation is realized by executing the same memory protection judgement procedure that is applied to the operand access or instruction fetch access to the specified address area and SPID. Therefore, when the checked address area is accessed by a load instruction, store instruction or instruction fetch, the access is judged as permitted or a memory protection exception occurs according to the check result.

CAUTIONS

1. For the memory protection setting check function to judge the access as permitted, it is necessary that the specified address area is contained within one protection area. For example, when two contiguous protection areas are set as access permitted (see **Section 3.2.5.1(3)(d), Memory Access Spanning Contiguous Protection Areas**), the memory protection setting check result for the address area spanning over the contiguous protection areas becomes "access prohibited (0)". Therefore, if there are such memory protection settings, there may be a difference between the actual access result by PREPARE instruction, instruction fetch, etc. and the result of memory protection setting check function.
2. The memory protection check function makes the same judgement as the memory protection judgement that is applied to the actual memory accesses. For example, if the MPM.MPE bit is cleared (to 0), all check results are always set to "access permitted (1)". If the MPM.SVP bit is cleared (to 0), the bits MCR.SXE, SWE, and SRE are always set to "access permitted (1)". Or if the MPM.MPE bit is set (to 1) (MPM.SVP is assumed to be cleared) and the MPAT.E bit of all protection area settings is cleared (to 0), the MCR.UXE, UWE, and URE bits are always set to "access prohibited (0)".

(b) Checking Procedure

Set the base address (lower limit) of the target address area to the MCA register, the size of the target area to the MCS register, and the system protection identifier (SPID) of the source requesting the service to the MCI register, then use the LDSR instruction (r0 specification is recommended) to access the MCC register and execute a check. The results can be read from the MCR register by the STSR instruction.

CAUTION

If the specified area to be checked crosses 0000 0000_H or 7FFF FFFF_H, it is judged as an area setting error, and the MCR.OV bit is set to 1. This means that the MCR.OV bit must be checked before accessing the check results. Do not use the check result until it is confirmed that the result is not invalid (OV = 0).

(c) Sample Code

It is assumed that the memory protection setting check function will be used for the following operations.

```

_service_protection:
    ...
    MOV     ADDRESS, r10           // Store the start address of the area to be checked to r10
    MOV     SIZE, r11             // Store the size of the area to be checked to r11
    MOV     SPID, r12             // Store the system protection identifier to r12
    DI
    LDSR    r10, sr8, 5           // Set the address to MCA
    LDSR    r11, sr9, 5           // Set the size to MCS
    LDSR    r12, sr12, 5          // Set the system protection identifier to MCI
    LDSR    r0, sr10, 5           // Start checking with MCC
    STSR    sr11, r13, 5         // Get the results from MCR
    EI
    ANDI    0x0100, r13, r0
    BNZ     _overflow            // Processing of invalid input when OV = 1
    BR     _result_check         // Otherwise, result is checked

```

(d) Method of Calculating Address Areas

The address area to be checked is treated as follows and compared with the memory protection setting.

Lower-limit address of the area: MCA setting

Upper-limit address of the area: Value calculated from $MCA + (MCS - 1)$

In addition, when MCS is set to 0000 0000_H, the value of “MCS – 1” is treated as FFFF FFFF_H. Moreover, if the result of calculating an upper address exceeds FFFF FFFF_H, it will be calculated as a 33-bit value, but the most significant bit, which represents an overflow, is discarded.

When MCA is 0000 0000_H and MCS is 0000 0000_H, the upper-limit address is FFFF FFFF_H.

When MCA is FFFF FFFF_H and MCS is 0000 0002_H, the upper-limit address is 0000 0001_H.

(e) Checking Results of the Memory Protection Setting Checking Function

Table 3.108 lists the results of the memory protection setting checking function for various settings.

Table 3.108 List of Checking Results of Memory Protection Setting Checking Function

MPM Setting		Check Setting (MCA, MCS, MCI)		Operation in the Various Types of Protected Area					Final Result of Checking (in the MCR) ^{*2}			
				Protection Setting			Result of Checking for One Protected Area ^{*1}					
MPE	SVP	Address	MCI, MPIDn	E	Address	xMPIDn ^{*3}	SXE, SWE, SRE	UXE, UWE, URE	OV	SXE, SWE, SRE	UXE, UWE, URE	
0	—	—	—	—	—	—	—	—	0	All bits are set to 1	All bits are set to 1	
1	0	Spanning 0000 0000 _H	—	—	—	—	—	—	1	All bits are set to 1	All bits are set to 0	
		Spanning 7FFF FFFF _H	—	—	—	—	—	—	1	All bits are set to 1	All bits are set to 0	
		Other than above	*4	*4	*4	*4	All bits are set to 1	*4	0	All bits are set to 1	*4	
	1	Spanning 0000 0000 _H	—	—	—	—	—	—	—	1	All bits are set to 0	All bits are set to 0
			Spanning 7FFF FFFF _H	—	—	—	—	—	—	1	All bits are set to 0	All bits are set to 0
			Other than above	Mismatch	—	—	—	All bits are set to 0	All bits are set to 0	0	All bits are set to 0	All bits are set to 0
		Match	0	—	—	—	All bits are set to 0	All bits are set to 0	0	Results for each of the areas	Results for each of the areas	
			1	Not included	—	—	All bits are set to 0	All bits are set to 0	0	Results for each of the areas	Results for each of the areas	
				—	Disabled	—	—	All bits are set to 0	All bits are set to 0	0	Results for each of the areas	Results for each of the areas
Included	Enabled	—	—	Results corresponding to the setting	Results corresponding to the setting	0	Results for each of the areas	Results for each of the areas				

Note 1. For the MPM and other settings, this indicates the result produced by a single protection-setting area, but it cannot be directly monitored.

Note 2. The values to be stored in each bit of the MCR are the overall results for all areas covered by the given protection setting. “Results for each of the areas” will be enabled if the result of checking for even one area is enabled. However, for the value of the OV bit or all bits being set to 1 or 0, the result is as defined regardless of the result of each protection setting area.

Note 3. This indicates the result of enabling when the WG or RG bit is set (to 1), or the collective results of enabling or disabling by the individual WMPIDn and RMPIDn bits.

Note 4. When the MPM.MPE bit is set (to 1) and the MPM.SVP bit is cleared (0), access to all memory in supervisor mode is enabled. On the other hand, the judgment in user mode is different. The results obtained in accord with the settings for checking and protection are stored in the same way as the results when both the MPM.MPE and MPM.SVP bits are set (to 1).

3.2.5.2 Cache

This section describes the function to control the cache memory that is installed in this CPU.

In normal operation, the cache memory is used implicitly in instruction fetching by the CPU. However, if the setting is to be changed or the state of the cache memory is directly manipulated by the CACHE instruction, consistency with the normal operation of CPU must be maintained. In many cases, the hardware makes adjustments so that inconsistencies between the normal operation of the CPU and the manipulation of the cache do not arise. However, to make sure that the results of cache manipulation are the intended state, take care that the manipulation does not affect the implicit operation.

For a detailed description of the cache memory that is installed in the individual products, see **Section 3.8.9, Product Information of Cache Structure**.

(1) Features

A 16-KB and parity-based way select (PBS) 4-way set associative instruction cache is placed between the CPU and the code flash. The instruction cache and the code flash are connected to each other via a 256-bit dedicated bus to minimize penalties caused by a cache miss. A data buffer is also mounted between the CPU and the code flash to achieve high-speed data access. The 256-MB area from 0000 0000_H to 0FFF FFFF_H in the address space is intended for the instruction cache and data buffer.

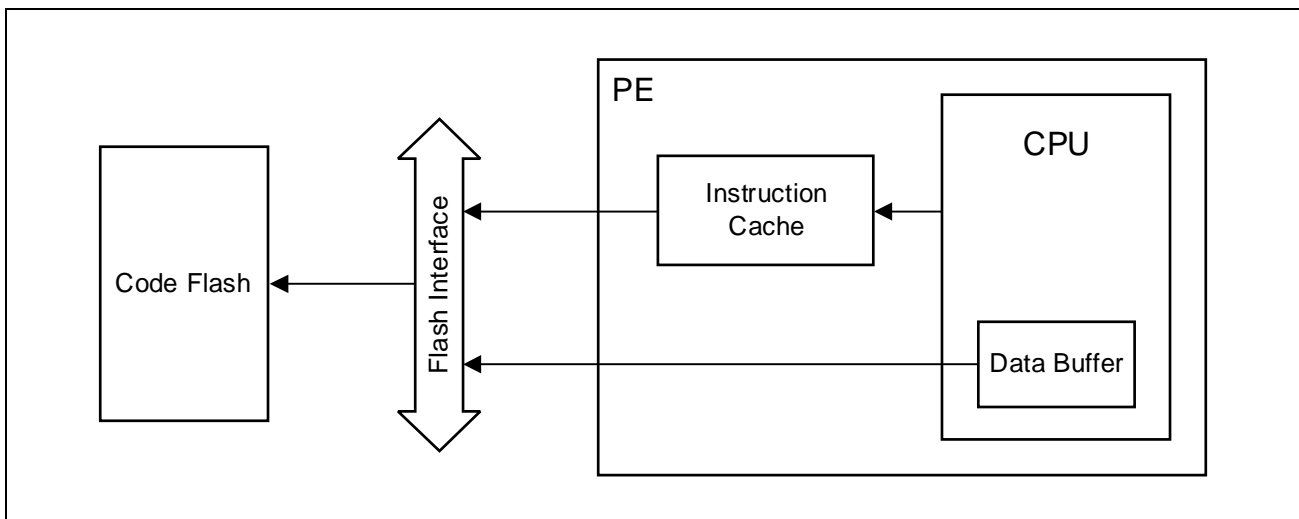

Figure 3.28 Instruction Cache and Data Buffer

(2) Cache Operation Registers

Figure 3.29 shows the system registers for cache operation. The supervisor privilege is required for the operation.

Figure 3.29 Cache Operation Registers

(3) Change Cache Use Mode

(a) Change Use Mode of Instruction Cache

The instruction cache use mode can be changed by using the ICCTRL.ICHEN bit. To enable an instruction cache, set the ICHEN bit to 1.

To disable the instruction cache, clear the ICHEN bit to 0.

Completion of the LDSR instruction that sets ICHEN might not coincide with completion of the instruction cache setting change. As in the following sample code, by executing the SYNCI instruction after the LDSR instruction, it is ensured that the change of the instruction cache setting takes effect after the SYNCI instruction.

```
LDSR r10, sr24, 4 // Change the instruction cache settings (ICCTRL)(setting value is stored in r10)
SYNCI // Wait for completion of the LDSR instruction, then refetch the subsequent
instructions.
```

(4) Cache Operations Using CACHE Instruction

The CACHE instruction manipulates the specified data in the cache memory.

Such data manipulation by the CACHE instruction starts after updating of the cache memory by all preceding memory access has been completed. Consequently, the result of preceding memory access is guaranteed to be the target for operations using the CACHE instruction. Additionally, a suitable synchronization operation is needed following execution of the CACHE instruction to ensure that the results are reflected in subsequent instructions.

The CACHE instruction can manipulate the cache memory even when the cache is disabled.

(a) Specification Method for Target of CACHE Instruction

There are basically two ways to specify the target for operations.

- Directly specify the address to be accessed:
In this CPU, this is called the address specification method. In this case, the cache line containing the specified address is subject to operation.
- Directly specify the cache memory's way number and line number:
In this CPU, this is called the index specification method. In this case, no hit judgment for the cache is performed, and the operation is performed on the specified cache index. For details about the cache index specification method, see **Section 3.2.5.2(6), Cache Index Specification Method**.

(b) Operations Performed using the CACHE Instruction

The operations performed on the cache memory are divided into the following. For details about each operation, see *the RH850G4MH User's Manual: Software*.

3.2.5.2.4.b.1 Cache Hit Block Invalidate / Cache Indexed Block Invalidate (CHBI / CIBI)

This disables the specified cache line. When using the address specification method, the cache line is disabled only when there is a hit. When using the index method, specified cache line is disabled. If the specified cache line is locked, it is unlocked. This operation can be used in cases such as when the entire memory cache is initialized by software.

Disabling a cache line refers to the process of clearing the cache information corresponding to the ICTAGL.V and ICTAGL.L bits (to 0).

3.2.5.2.4.b.2 Cache Fetch and Lock (CFAL)

This stores the data at the specified address to the cache memory. At this time, the cache line where the data is stored is locked. This prevents the cache line from being replaced. If the target cache line has already been stored in the cache memory, it is simply locked. If the target cache line has already been stored in the cache memory and is locked, this operation does nothing.

This operation can be used to improve execution efficiency by reducing variations in instruction execution time that occur due to cache misses in the specified memory area.

Cache lines are locked only when they are enabled. Although enabling and locking of a cache line are carried out simultaneously during the execution of the CFAL instruction, no cache line is locked when only locking is configured using the CIST instruction. For details, see **Section 3.2.3.7(1)(a), ICTAGL — Instruction Cache Tag Lo Access**.

CAUTION

In the instruction cache supported by this CPU, if all the cache lines at the same index in the target way group are locked, the cache lines are not replaced. Care must be taken with respect to the cache lock specifications and the number of cache ways when monopolizing the cache memory efficiently using this operation. For the way group, see **Section 3.2.5.2(10), Configuration of Instruction Cache**.

For details, see **Section 3.8.9, Product Information of Cache Structure**.

3.2.5.2.4.b.3 Cache Indexed Load / Cache Indexed Store (CILD / CIST)

This operation is used to directly access the cache memory. Values can be written and read, via a system register, at a position in the cache memory specified by using an index. Because cache data and cache tags can be accessed directly, this operation can be used for purposes such as software debugging.

(5) Cache Operation by the PREF Instruction

The PREF instruction is provided to realize efficient cache access by advising the CPU that an address is likely to be used in the near future. Getting the CPU to prefetch data into the cache memory before using the data can reduce the read wait time caused by a cache miss.

Assuming support by compilers and other tools, the PREF instruction can be executed regardless of the CPU operating mode. Execution of the PREF instruction does not cause an exception generated by the MPU, and has no effect on logical operations, just like the NOP instruction.

CAUTION

Because a data read request by the PREF instruction is rather speculative, it might not be executed depending on the system conditions. No cache fill is performed if all the cache lines at the same index in the target way group are locked. If an area outside the cacheable area is specified, the read itself is not carried out.

(6) Cache Index Specification Method

For a cache instruction that uses the index specification method, explicitly specify the cache memory subject to operation in the format shown in **Figure 3.30**, instead of specifying an address. The bit positions of each field depend on the size of the cache memory incorporated in the CPU core. Information about the incorporated cache memory and size can be read from the ICCFG register.

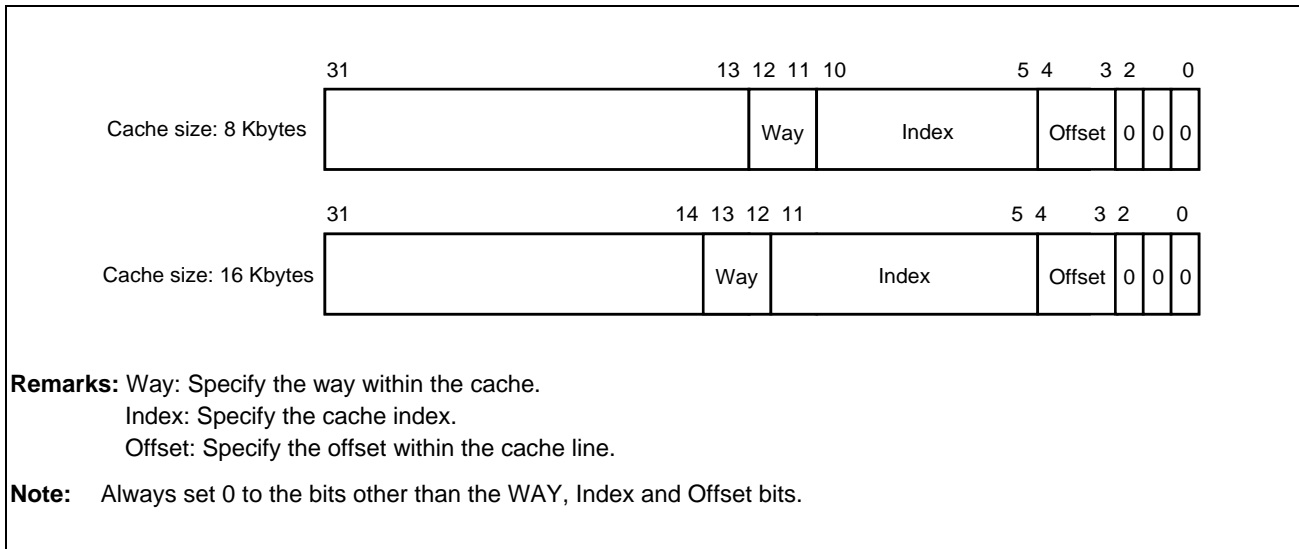

Figure 3.30 Cache Index Specification Method

NOTE

The Offset field indicates the byte position within the cache line. This setting is not required (i.e., ignored) in normal index specification operations. For a CILD/CIST operation, it is used to specify a position within the cache line because the ICDATH/ICDATL register is shorter than the cache line length.

(7) Execution Privilege of the CACHE/PREF Instruction

Because the CACHE instruction directly manipulates the contents of the cache memory, privileges are specified according to the type of operation. When the CACHE instruction is executed without the privilege required for the CACHE operation, a privilege instruction exception (PIE) occurs.

On the other hand, the PREF instruction provides information for speculative execution, so it can be executed in any mode.

The privileges required by the different operations performed by the CACHE instruction are shown below.

(a) Operations allowed with the user privilege

Among address specification method operations, operations without a cache lock (CHBI) can be executed in any operation mode.

(b) Operations requiring the supervisor privilege

Among address specification method operations, operations with a cache lock (CFAL) require the supervisor privilege.

In addition, index specification method operations also require the supervisor privilege.

(8) Memory Protection for the CACHE and PREF Instructions

The memory protection judgment for the CACHE and PREF instructions proceeds in accord with the operating mode when the instruction is executed. These instructions are handled as read access. When memory protection is enabled and the MPAT.SR or UR bit is set (to 1), the instruction can be executed according to the operating mode.

The CACHE instructions using the address specification mode are subject to the memory protection provided by the MPU. If a protection violation is detected, the cache operation is not executed and an MDP exception occurs.

On the other hand, since the CACHE instructions using the index specification method specify the position of data in the instruction cache but not the memory address, they are not subject to the memory protection. No matter what value is specified for the index, an MDP exception does not occur.

If a protection violation for a PREF instruction is detected, the prefetching is not performed and an MDP exception does not occur.

For both CACHE and PREF instructions, if operation is undefined for the specified opcode, cache operation and memory access are not performed at all, so they are not subject to the memory protection.

Table 3.109 shows the correspondence between operations and access permissions.

Table 3.109 Relationship between Cache Operations and Permissions

Instruction	Address/Index	Instruction Execution Privilege	Access Permission
CHBII	Address	UM	Read
CIBII	Index	SV	—
CFALI	Address	SV	Read
CISTI	Index	SV	—
CILDI	Index	SV	—
PREF	Address	UM	Read

(9) Example of Using the CACHE Instruction to Manipulate Cache Memory

This section gives an example of cache memory manipulation by the CACHE instruction, with setting up self-modifying code as the intention.

In the following example, an instruction code is generated in memory that is being cached in the instruction cache, and the instruction cache is disabled. Regarding whether memory that supports such cache memory manipulation is present, see **Section 3.8.9, Product Information of Cache Structure**.

```

ST.W r20, 0[r10]      // Write the target data to memory
SYNCM                 // Wait for the completion of memory writing
CACHE 0x00, [r10]    // CHBII: Disable caching of the target area by the instruction cache
SYNCI                 // Wait for the completion of instruction cache manipulation
JMP [r12]             // Branch to the target area and execute the updated instruction code

```

(10) Configuration of Instruction Cache

This section describes the configuration of instruction cache mounted for this CPU. For more information, see **Section 3.8.9, Product Information of Cache Structure**.

This CPU supports an instruction cache in the following configuration.

- Four ways
- 256-bit cache line size (unit of filling)
- 256-Mbyte target area for caching
- ECC protection
- Cache error notification

(a) Four ways

Since the instruction cache mounted for this CPU is configured with four ways, the capacity of each way is one-quarter of the capacity of the whole cache.

The four ways are divided into two way groups; way 0 and way 1 belong to way group A, and way 2 and way 3 belong to way group B. As for the access address, if the parity of the bits to be stored in the tag is 0, way group A is used, whereas way group B is used if the parity is 1.

When storing data in a new cache line, the LRU (least recently used) method determines the destination way for storage from within the given way group.

(b) Cache line size

The cache line size (unit of filling) is the amount of data that is stored in one line of the cache, and is 256 bits in the instruction cache for this CPU.

(c) Allocation of cache data

Data from memory are allocated to the cache memory in the way shown in **Figure 3.31**.

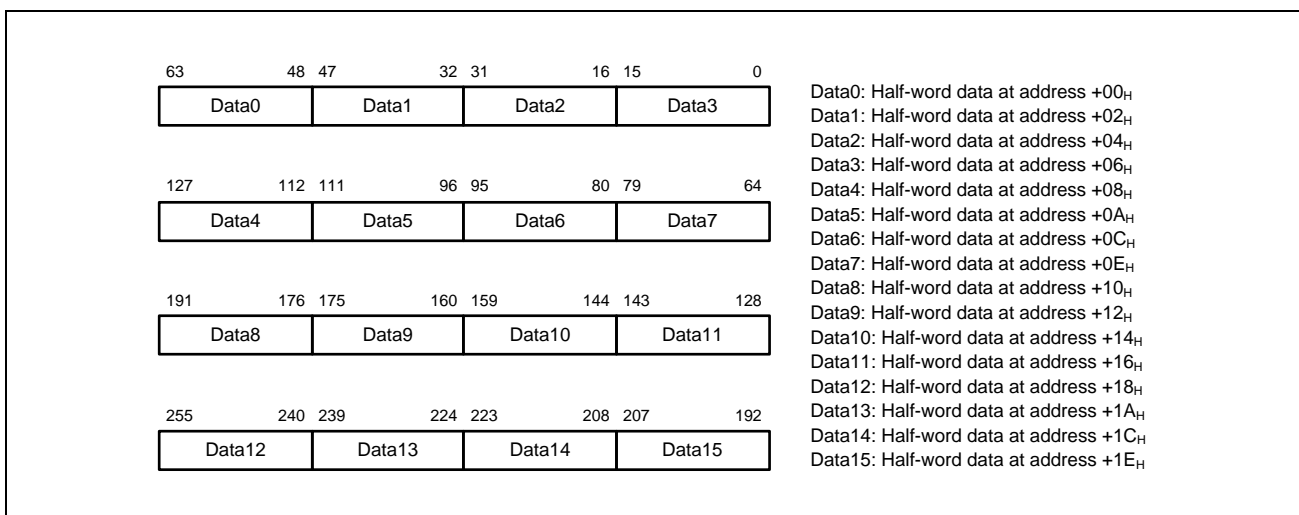

Figure 3.31 Allocation of Data to the Cache

(d) Cacheable area

The cacheable area for the instruction cache of this CPU is the 256 Mbytes from 0000 0000_H to 0FFF FFFF_H. Although instructions can be fetched from locations beyond the above area, they are never stored in the instruction cache in that case.

(e) ECC protection

The data RAM and the tag RAM of the instruction cache for this CPU are protected by ECCs. Upon detection of an ECC error in either area of RAM, the target line is disabled, and the CPU provides external notification of the occurrence of the error at the same time as re-fetching proceeds.

For details on the ECC protection, refer to **Section 40, Functional Safety**.

(f) Cache error notification

The instruction cache for this CPU detects the following five types of errors. A cache error is detected at the time of read operation by the instruction fetching or the CACHE instruction using the address specification method. In addition to the read operation, an address-feedback error is also detected at the time of write operation by cache fill. This CPU provides external notification of these errors. For the operation in cases of these errors occurring, refer to **Section 40, Functional Safety**.

- ECC error of data RAM
- ECC error of tag RAM
- Multi-hit error
- Way error
- Address-feedback error

A multi-hit error is detected when access to an address hits two ways in a way group at the same time. Upon detection of a multi-hit error, the target line is disabled, and the CPU provides external notification of the occurrence of the error at the same time as re-fetching proceeds.

A way error is detected when the parity in a way group does not match the parity of data stored in the tag RAM. Upon detection of a way error, the target line is disabled, and the CPU provides external notification of the occurrence of the error at the same time as re-fetching proceeds.

An address-feedback error is detected when the address for access to the RAM does not match the feedback address. When the error is detected at the time of cache reading, the target line is disabled, and the CPU provides external notification of the occurrence of the error at the same time as re-fetching proceeds. When the error is detected at the time of cache writing, the target line is disabled, and the CPU provides external notification of the occurrence of the error.

(11) Data Buffer Function

The four-line buffer with 256 bits per line is mounted as a data buffer. 256-bit data read from the code flash is stored in the data buffer in 256-bit units. When the data buffer hit occurs, the data is read out from the data buffer, so the code flash is not accessed again.

3.2.6 Coprocessor

3.2.6.1 Floating-Point Operation

The floating-point unit (FPU) operates as the CPU coprocessor, and executes floating-point instructions.

Either single-precision (32-bit) or double-precision (64-bit) data can be used. In addition, the conversion between a floating point type and an integer type is possible.

The FPU of this CPU conforms to ANSI/IEEE standard 754-2008 (IEEE Standard for Floating-Point Arithmetic).

(1) Configuration of Floating-Point Operation Function

(a) Not implemented

If the floating-point operation function is not implemented, all the floating-point instructions cannot be used. If an attempt is made to execute such an instruction, a coprocessor unusable exception occurs. In addition, all the floating-point system registers become inaccessible, and if an attempt is made to access any of the registers using LDSR/STSR instruction, a coprocessor unusable exception occurs.

(b) Implementing only single precision

If only the floating-point operation function with single precision is implemented, only floating-point instructions classified as single precision*¹ can be used. If an attempt is made to execute a floating-point instruction classified as double precision*², a coprocessor unusable exception occurs. All the floating-point system registers supply the function described in **Section 3.2.3.4, FPU Function Registers**.

Note 1. The single-precision floating-point instruction is the instruction described as (Single) in the description of each instruction in *the RH850G4MH User's Manual: Software*.

Note 2. The double-precision floating-point instruction is the instruction described as (Double) in the description of each instruction in *the RH850G4MH User's Manual: Software*.

(c) Implementing single precision and double precision

All the floating-point instructions can be used when floating-point instructions of single precision and double precision are implemented. All the floating-point system registers supply the functions described in **Section 3.2.3.4, FPU Function Registers**.

(2) Data Types

(a) Floating-point format

The FPU supports 32-bit (single precision) and 64-bit (double precision) IEEE754 floating-point operations.

The single-precision floating-point format consists of a 24-bit signed fraction (s + f) and an 8-bit exponent (e), as shown in **Figure 3.32**.

Figure 3.32 Single-Precision Floating-Point Format

The double-precision floating-point format consists of a 53-bit signed fraction (s + f) and an 11-bit exponent (e), as shown in **Figure 3.33**.

Figure 3.33 Double-precision Floating-Point Format

A numerical value in the floating-point format includes the following three areas.

- Sign bit: s
- Exponent: $e = E + \text{bias value}$
- Fraction: $f = .b_1b_2\dots b_{p-1}$ (value lower than the first decimal place)

The bias value for the single-precision format is 127. For double-precision format, the bias value is 1023.

The range of the exponent value E when unbiased covers all integers from E_{\min} to E_{\max} , along with two reserved values, $E_{\min} - 1$ (± 0 or subnormal number), and $E_{\max} + 1$ ($\pm \infty$ or NaN: not-a-number). A numeric value other than 0 is represented in one format, depending on the single-precision and double-precision formats.

The numeric value (v) represented in this format can be calculated by the expression shown in **Table 3.110**.

Table 3.110 Calculation Expression of Floating-Point Value

Type	Calculation Expression	
NaN (not-a-number)	If $E = E_{\max} + 1$ and $f \neq 0$	then $v = \text{NaN}$ regardless of s
$\pm \infty$ (infinite number)	If $E = E_{\max} + 1$ and $f = 0$	then $v = (-1)^s \infty$
Normalized number	If $E_{\min} \leq E \leq E_{\max}$	then $v = (-1)^s 2^E (1.f)$
Subnormal number	If $E = E_{\min} - 1$ and $f \neq 0$	then $v = (-1)^s 2^{E_{\min}} (0.f)$
± 0 (zero)	If $E = E_{\min} - 1$ and $f = 0$	then $v = (-1)^s 0$

- NaN (not-a-number)

IEEE754 defines a floating-point value called NaN (not-a-number). Because this value is not a numerical value, it does not have any “greater than” or “less than” relationships to other values.

If v is NaN in all of the floating-point formats, it might be either SignalingNaN (S-NaN) or QuietNaN (Q-NaN), depending on the value of the most significant bit of “f”. If the most significant bit of “f” is set, v is QuietNaN; if the most significant bit is cleared, it is SignalingNaN.

Table 3.111 shows the value of each parameter defined in floating-point formats.

Table 3.111 Floating-Point Formats and Parameter Values

Parameter	Format	
	Single Precision	Double Precision
E _{max}	+127	+1023
E _{min}	-126	-1022
Bias value of exponent	+127	+1023
Length of exponent (number of bits)	8	11
Integer bits	Cannot be seen	Cannot be seen
Length of fraction (number of bits)	23	52
Length of format (number of bits)	32	64

Table 3.112 shows the minimum and maximum values that can be represented in floating-point formats.

Table 3.112 Floating-Point Minimum and Maximum Values

Type	Value
Minimum value of single-precision floating point	1.40129846e - 45
Minimum value of single-precision floating point (normal)	1.17549435e - 38
Maximum value of single-precision floating point	3.40282347e + 38
Minimum value of double-precision floating point	4.9406564584124654e - 324
Minimum value of double-precision floating point (normal)	2.2250738585072014e - 308
Maximum value of double-precision floating point	1.7976931348623157e + 308

(b) Fixed-point formats

The value of a fixed point is held in the format of 2's complement. **Figure 3.34** shows a 32-bit fixed-point format and **Figure 3.35** shows a 64-bit fixed-point format. No signed bits exist in the unsigned fixed-point format, and all bits represent the integer value.

Figure 3.34 32-bit Fixed-Point Format

Figure 3.35 64-bit Fixed-Point Format

(c) Expanded floating-point format

This CPU supports the 16-bit (half-precision) IEEE754 floating-point format as a floating-point format for storing data. The half-precision floating-point format is used to decrease the amount of data; it is not supported for arithmetic operations. Instructions are available for converting single-precision floating-point format data into half-precision floating-point data and vice-versa. The half-precision floating-point format consists of an 11-bit signed fraction (s + f) and a 5-bit exponent (e), as shown in **Figure 3.36**.

Figure 3.36 Half-Precision Floating-Point Format

Like other floating-point formats, the numeric values represented in this format can be calculated by using the expressions shown in **Table 3.110**. The values of the parameters defined by the half-precision floating-point format are shown in **Table 3.113**.

Table 3.113 Half-Precision Floating-Point Format and Parameter Values

Parameter	Half Precision
E _{max}	+15
E _{min}	-14
Bias value of exponent	+15
Length of exponent (number of bits)	5
Integer bits	Cannot be seen
Length of fraction (number of bits)	10
Length of format (number of bits)	16

Table 3.114 shows the minimum and maximum values that can be represented in the half-precision floating-point format.

Table 3.114 Half-Precision Floating-Point Minimum and Maximum Values

Type	Value
Minimum value of half-precision floating point	5.96046e - 8
Maximum value of half-precision floating point (normal)	6.10352e - 5
Maximum value of half-precision floating point	65504

(3) Register Set

For details about the register set, see **Section 3.2.3.4, FPU Function Registers**.

(4) Floating-Point Instructions

Floating-point instructions are divided into single-precision instructions (single) and double-precision instructions (double).

For details about the floating-point instructions, see *the RH850G4MH User's Manual: Software*.

(5) Floating-Point Operation Exceptions

This section describes how the FPU processes floating-point operation exceptions.

(a) Types of exceptions

When floating-point operations or processing of operation results cannot be done using the ordinary method, a floating-point operation exception occurs.

One of the following two operations is performed when a floating-point operation exception has occurred.

- When exceptions are enabled
The cause bit is set in the floating-point configuration/status register (FPSR), and processing (by software) is passed to the exception handler routine.
- When exceptions are prohibited
The preservation bit is set in the floating-point configuration/status register (FPSR), an appropriate value (initial value) is stored in the FPU destination register, then execution is continued.

The FPU uses cause bits, enable bits, and preservation bits (status flags) to support the following five types of IEEE754-defined exception causes.

- Inexact operation (I)
- Overflow (O)
- Underflow (U)
- Division by zero (Z)
- Invalid operation (V)

The sixth type of exception cause is unimplemented operation (E), which causes an exception when a floating-point operation cannot be executed. This exception requires processing by software. An unimplemented operation exception (E) occurs when exceptions are always enabled, rather than by using properties, enable bits, or preservation bits.

Figure 3.37 shows the FPSR register bits that are used to support exceptions.

Figure 3.37 Cause, Enable, and Preservation Bits of FPSR Register

The five exceptions (V, Z, O, U, and I) defined by IEEE754 are enabled when the corresponding enable bits are set. When an exception occurs, if the corresponding enable bit has been set, the FPU sets the corresponding cause bit. If the exception can be acknowledged, processing is passed to the exception handler routine. If exceptions are prohibited, the exception corresponding preservation bit is set, and processing is not passed to the exception handler routine.

(b) Exception handling

When a floating-point operation exception occurs, the cause bits of the FPSR register indicate the cause of the floating-point operation exception.

3.2.6.1.5.b.1 Status flag

A corresponding preservation bit is available for each IEEE754-defined exception. The preservation bit is set when the corresponding exception is prohibited but the exception condition has been detected. The preservation bit is set or reset whenever new values are written to the FPSR register by the LDSR instruction.

If an exception is prohibited by an enable bit, predetermined processing is performed by the FPU. This processing provides an initial value as the result, rather than a floating-point operation result. This initial value is determined according to the type of exception. For an overflow exception or underflow exception, the initial value also differs depending on the current rounding mode. **Table 3.115** shows the initial values provided for each of the FPU IEEE754-defined exceptions.

Table 3.115 FPU Initial Values for IEEE754-Defined Exceptions

Area	Description	Rounding Mode	Initial Value
V	Invalid operation	—	Quiet not-a-number (Q-NaN)
Z	Division by zero	—	Correctly signed ∞
O	Overflow	RN	∞ with sign of intermediate result
		RZ	Maximum normalized number with sign of intermediate result
		RP	Negative overflow: Maximum negative normalized number Positive overflow: $+\infty$
		RM	Positive overflow: Maximum positive normalized number Negative overflow: $-\infty$
U	Underflow*1	RN*2	0 with sign of intermediate result
		RZ	0 with sign of intermediate result
		RP	Positive underflow: Minimum positive normalized number Negative underflow: 0
		RM	Negative underflow: Minimum negative normalized number Positive underflow: 0
I	Inexact operation	—	Rounded result

Note 1. If the FPSR.FS bit is cleared, an unimplemented operation exception (E) will occur if an underflow occurs in the rounded result; an underflow exception (U) will not occur. If the FS bit of the FPSR register is set, the flushed result is used as the initial value.

Note 2. If the rounding mode is RN and the FN bit of the FPSR register is set, flushing will occur in the direction of higher accuracy. For details, see **Section 3.2.6.1(9), Flush to Nearest**.

(6) Exception Details

The following describes the conditions under which each of the FPU exceptions occurs and the FPU responses.

(a) Inexact exception (I)

In the following cases, the FPU detects an inexact exception.

- When the precision of the rounded result is dropped
- When the rounded result overflows while overflow exceptions are prohibited
- When the rounded result underflows while underflow exceptions are prohibited
- When the operand that is a subnormal number is flushed, neither an invalid operation exception (V) nor a division by zero exception (Z) is detected, and the other operands are not Q-NaN

CAUTION

If the FS bit of the FPSR register is cleared and the operation result underflows, an unimplemented operation exception (E) occurs. In such cases, the underflow exception is not detected, so the inexact exception is not detected either.

3.2.6.1.6.a.1 If exception is enabled

The contents of the destination register are not changed, contents of the source register are saved, and an inexact exception occurs.

3.2.6.1.6.a.2 If exception is not enabled

If no other exception occurs, the rounded result or the result that underflows or overflows is stored in the destination register.

(b) Invalid operation exception (V)

An invalid operation exception occurs when either or both of the operands are invalid.

- Arithmetic operation with S-NaN included in operands. The conditional move instruction (CMOV), absolute value (ABS), and arithmetic negation (NEG) are not handled as arithmetic operations, but minimum value (MIN) and maximum value (MAX) are handled as arithmetic operations.
- Multiplication: $\pm 0 \times \pm \infty$ or $\pm \infty \times \pm 0$
- Fused-multiply-add: $(\pm 0 \times \pm \infty) + c$ or $(\pm \infty \times \pm 0) + c$. But only if c is not Q-NaN.
- Addition/subtraction or multiply-add operation*¹:
Addition of infinite values with different signs or subtraction of infinite values with the same sign
- Division: $\pm 0 \div \pm 0$ or $\pm \infty \div \pm \infty$
- Square root: When operand is less than 0
- Conversion to integer when source is outside of integer range.
- Comparison: With condition codes 8 to 15, if the operand is unordered (see *the RH850G4MH User's Manual: Software*)

Note 1. When the multiplication result is infinite or when adding or subtracting between infinities.

3.2.6.1.6.b.1 If exception is enabled

The contents of the destination register are not changed, contents of the source register are saved, and an invalid operation exception occurs.

3.2.6.1.6.b.2 If exception is not enabled

If no other exception occurs, and the destination is a floating-point format, Q-NaN is stored in the destination register. If the destination has an integer format, see the operation result description of each instruction for the value to be stored in the destination register.

(c) Division by zero exception (Z)

A division by zero exception occurs when a divisor is 0 and a dividend is a finite number other than 0.

3.2.6.1.6.c.1 If exception is enabled

The contents of the destination register are not changed, contents of the source register are saved, and a division by zero exception occurs.

3.2.6.1.6.c.2 If exception is not enabled

If no other exception occurs, a correctly signed infinite number ($\pm \infty$) is stored in the destination register.

(d) Overflow exception (O)

An overflow exception is detected if the exponent range is infinite and if the result of the rounded floating point is greater than maximum finite number in the destination format.

3.2.6.1.6.d.1 If exception is enabled

The contents of the destination register are not changed, the contents of the source register are saved, and an overflow exception occurs.

3.2.6.1.6.d.2 If exception is not enabled

If no other exception occurs, the initial value that is determined by the rounding mode and the sign of the intermediate result is stored in the destination register (see **Table 3.115, FPU Initial Values for IEEE754-Defined Exceptions**).

(e) Underflow exception (U)

If the operation result is $-2^{E_{min}}$ to $+2^{E_{min}}$ (but not zero), an underflow exception is detected.

Although IEEE754 defines several methods for detecting an underflow, the same method should be used to detect underflows, regardless of the processing to be performed.

The following two methods can be used to detect an underflow for binary floating point numbers.

- The result calculated after rounding and using an infinite exponent range is not zero and is within $\pm 2^{E_{min}}$.
- The result calculated before rounding and using an infinite exponent range and precision is not zero and is within $\pm 2^{E_{min}}$.

In this CPU, an underflow is detected before rounding. Or the rounded result is one of the following, an inexact result is detected.

- When a given result differs from the result calculated when the exponent range and precision are infinite

In this CPU, the behavior when an inexact result is detected differs as follows depending on whether underflow exceptions are enabled or disabled:

3.2.6.1.6.e.1 If exception is enabled

When the FS bit of the FPSR register has been set, if underflow exceptions are enabled, an underflow exception (U) occurs. When the FS bit of the FPSR register has been set, if underflow exceptions are not enabled but inexact exceptions are enabled, an inexact exception (I) occurs.

3.2.6.1.6.e.2 If exception is not enabled

If the FS bit of the FPSR register has been set, the initial value determined according to the rounding mode and intermediate result value is stored in the destination register (see **Table 3.115, FPU Initial Values for IEEE754-Defined Exceptions**).

CAUTION

If the FS bit of the FPSR register has not been set, an unimplemented operation exception (E) occurs regardless of whether or not exceptions are enabled. Because an unimplemented operation exception (E) must occur, an underflow exception (U) does not occur.

(f) Unimplemented operation exception (E)

The E bit is set and an unimplemented operation exception (E) occurs when an abnormal operand or abnormal result that cannot be correctly processed by hardware has been detected. The operand and destination register contents do not change.

If the FS bit of the FPSR register has been set, an unimplemented operation exception (E) will not occur.

If the FS bit of the FPSR register has been cleared, an unimplemented operation exception (E) will occur under the following conditions (except for CMOVF.D, CMOVF.S, CMPF.D, CMPF.S, CVTF.HS, ABSF.D, ABSF.S, MAXF.D, MAXF.S, MINF.D, MINF.S, NEGF.D, and NEGF.S instructions).

- When the operand is a subnormal number
- When the operation result is a subnormal number, or an underflow has occurred

CAUTION

If the FS bit of the FPSR register is set to 1, an unimplemented operation exception (E) will not occur under any circumstances.

(7) Saving and Returning Status

When a floating-point operation exception occurs, the PC and PSW are saved to the EIPC and EIPSW registers respectively, and the exception cause code is saved to the EIIC register.

The exception cause code of the floating-point operation exception is 71_H.

When an EI level exception is acknowledged while processing a floating-point operation exception, an EIPC register override occurs, which prevents the returning to the instruction that caused the floating-point operation exception to occur. When acknowledgment of EI level exceptions is required, the contents of the EIPC, EIPSW, and EIIC registers must be saved, such as to a stack.

When a floating-point instruction is used in a floating-point operation exception handler routine, the FPSR and FPEPC registers will be overridden if another floating-point operation exception occurs. In such cases, the FPSR and FPEPC registers should be saved at the start of the floating-point operation exception handler processing, and should be returned at the end of the handler processing.

The cause bits of the FPSR register hold the results from only one enabled exception. In any case, the previous results are held until the next enabled exception occurs.

(8) Flushing Subnormal Numbers

This CPU can process subnormal numbers—very small numbers that are lower than the minimum normalized number—in one of the following two ways:

- Normalize the operand or operation result and continue executing arithmetic processing
- Generate an unimplemented operation exception (E) and execute exception handling

Executing software-based exception handling will obtain a more accurate result, but the amount of time required to obtain the result will vary depending on the input value. In control systems that require a real-time performance, therefore, this is usually unacceptable. In this case, it is important to obtain the result within a certain amount time rather than focus on accuracy.

(a) Normalize the subnormal numbers and continue executing arithmetic processing

By setting the FS bit of the FPSR register to 1, this CPU can normalize the operand or operation result to a specific value and continue executing arithmetic processing if a subnormal number is input as the operand or obtained as the operation result. At this time, extremely small differences in values might not appear in the operation result.

For the operand and operation result, the values to which subnormal numbers are flushed when the FS bit is set (1) are shown in **Table 3.116** and **Table 3.117** below.

Table 3.116 Rounding Mode and Flush Value of Input Operand

Sign of Subnormal Operand	Rounding Mode and Value to Which Input Operand Is Flushed			
	RN	RZ	RP	RM
+			+0	
-			-0	

Table 3.117 Rounding Mode and Flush Value of Operation Result

Sign of Subnormal Operand Result	Rounding Mode and Value to Which Operation Result Is Flushed			
	RN*1	RZ	RP	RM
+	+0	+0	+2 ^{E_{min}}	+0
-	-0	-0	-0	-2 ^{E_{min}}

Note 1. If the rounding mode is RN and the FN bit of the FPSR register is set, flushing will occur in the direction of higher accuracy. For details, see **Section 3.2.6.1(9), Flush to Nearest**.

Whether an input operand that is a subnormal number has been flushed or not can be checked by referencing the IF bit of the FPSR register. Whether an operation result that is a subnormal number has been flushed or not can be checked by referencing the U bit of the FPSR register.

CAUTIONS

1. In control systems that require a real-time performance, it is recommended to always set the FS bit of the FPSR register to 1.
2. If the FS bit of the FPSR register is set to 1, an unimplemented operation exception (E) will not occur under any circumstances.
3. Whether the operation result is a subnormal number is judged by using the value before rounding.
4. The IF bit of the FPSR register also accumulates and indicates information about flushing instructions that have caused a floating-point operation exception.

(b) Generate an unimplemented operation exception (E) and execute exception handling

By clearing the FS bit of the FPSR register to 0, an unimplemented operation exception (E) will occur if a subnormal number is input as the operand or obtained as the operation result. When an unimplemented operation exception occurs, software-based progressive underflow processing is performed in the floating-point operation exception handling routine, enabling a more accurate result to be obtained. In this case, however, a real-time processing performance might not be realized due to the software processing load.

(c) Instructions that can handle subnormal numbers

The following instructions can be executed without causing an unimplemented operation exception (E) even if an operand that is a subnormal number is input while the FS bit of the FPSR register is 0.

- Conditional move instruction (CMOV), absolute value (ABS), arithmetic negation (NEG)
- Minimum value (MIN), maximum value (MAX), compare (CMPF)
- Conversion from half-precision to single-precision (CVTF.HS)

(d) Instructions that are not affected by flushing subnormal numbers

For the following instructions, flushing does not occur even an operand that is a subnormal number is input while the FS bit of the FPSR register is 1.

- Conditional move instruction (CMOV), absolute value (ABS), arithmetic negation (NEG)
- Minimum value (MIN), maximum value (MAX), compare (CMPF)
- Conversion from half-precision to single-precision (CVTF.HS)

(9) Flush to Nearest

This CPU provides flush-to-nearest mode, a feature for flushing to the nearest number with higher accuracy when a flushing operation results subnormal number. Flush-to-nearest mode is enabled when the rounding mode is RN and the FN bit of the FPSR register is set (1). When this mode is used, the FPU determines the value to which to flush the subnormal number based on the number of the operation result and not just the sign. This feature has no effect in rounding modes other than RN or on the result of flushing an input operand.

Table 3.118 Rounding Mode and Value to Which Operation Result is Flushed

Value of Subnormal Operation Result	Rounding Mode and Value to Which Operation Result Is Flushed				
	RN		RZ	RP	RM
	FN = 1	FN = 0			
$+2^{E_{min}-1} \leq \text{Operation result} < +2^{E_{min}}$	$+2^{E_{min}}$	+0	+0	$+2^{E_{min}}$	+0
$+0 < \text{Operation result} < +2^{E_{min}-1}$	+0				
$-2^{E_{min}-1} < \text{Operation result} < -0$	-0	-0	-0	-0	$-2^{E_{min}}$
$-2^{E_{min}} < \text{Operation result} \leq -2^{E_{min}-1}$	$-2^{E_{min}}$				

CAUTION

Whether the operation result is a subnormal number is judged by using the value before rounding.

(10) Limitation on the Floating-Point Operation Result

There is a limitation on the floating-point operation result of this CPU.

(a) Operation instruction result when the input data is NaN (not-a-number)

When the input data is NaN (not-a-number), the operation instruction result will be as shown in **Table 3.119**.

Table 3.119 Operation Result when Input data is NaN

Input Data*3	Single-precision Operation Result	Double-precision Operation Result
SNaN and QNaN mixed	7FFF FFFF _H	7FFF FFFF_FFFF FFFF _H
Only SNaN	7FFF FFFF _H	7FFF FFFF_FFFF FFFF _H
Only QNaN	*1	*1
SNaN and real number	7FFF FFFF _H	7FFF FFFF_FFFF FFFF _H
QNaN and real number	*1,*4	*1,*4
Other than above*2	7FFF FFFF _H	7FFF FFFF_FFFF FFFF _H

Note 1. If the input data contains QNaN, QNaN in the input data is selected as the operation result by the priority of reg2, reg1, and reg3.

Note 2. In this case, input data contains real numbers only, and the operation result is invalid.

Note 3. When the operand of an ABSF.S, ABSF.D, NEGF.S, or NEGF.D instruction is NaN, the result of the operation will be the value obtained by the operation on the sign bit alone.

Note 4. When one of the operands of an MAXF.S, MAXF.D, MINF.S, and MINF.D instruction is QNaN, the result of the operation will be whichever operand is a real number.

(b) Results of conversion instructions when the operand is NaN (not-a-number)

When the operand is NaN (not-a-number), the results of conversion are as shown in **Table 3.120**.

Table 3.120 Results of Conversion when the Operand is NaN (not-a-number)

Input Data	Output Format	Results of Conversion
Half-precision SNaN	Single precision	7FFF FFFF _H
Half-precision QNaN	Single precision	The QNaN value with the same sign. Bits 12 to 0 in the fractional part of the output value are 0.
Single-precision SNaN	Word (signed)	8000 0000 _H
	Word (unsigned)	0000 0000 _H
	Long (signed)	8000 0000_0000 0000 _H
	Long (unsigned)	0000 0000_0000 0000 _H
	Half precision	7FFF _H
	Double precision	7FFF FFFF_FFFF FFFF _H
Single-precision QNaN	Word (signed)	8000 0000 _H
	Word (unsigned)	0000 0000 _H
	Long (signed)	8000 0000_0000 0000 _H
	Long (unsigned)	0000 0000_0000 0000 _H
	Half precision	The QNaN value with the same sign. Bits 12 to 0 in the fractional part of the operand are truncated.
	Double precision	The QNaN value with the same sign. Bits 28 to 0 in the fractional part of the output value are 0.
Double-precision SNaN	Word (signed)	8000 0000 _H
	Word (unsigned)	0000 0000 _H
	Long (signed)	8000 0000_0000 0000 _H
	Long (unsigned)	0000 0000_0000 0000 _H
	Single precision	7FFF FFFF _H
	Double precision	7FFF FFFF_FFFF FFFF _H
Double-precision QNaN	Word (signed)	8000 0000 _H
	Word (unsigned)	0000 0000 _H
	Long (signed)	8000 0000_0000 0000 _H
	Long (unsigned)	0000 0000_0000 0000 _H
	Single precision	The QNaN value with the same sign. Bits 28 to 0 in the fractional part of the operand are truncated.
	Double precision	The QNaN value with the same sign. Bits 28 to 0 in the fractional part of the output value are 0.

(c) When 0 comparison is performed by MAXF and MINF

When both reg1 and reg2 are either +0 or -0, the operation will be as follows.

MINF.S, MINF.D: The value of reg1 is stored in reg3.

MAXF.S, MAXF.D: The value of reg2 is stored in reg3.

(d) In the case of the precision instruction (RECIPF)

The operation results of RECIPF.S and RECIPF.D are the same as the operation results of 1/x by DIVF.S and DIVF.D.

3.2.6.2 Extended Floating-Point Operation

The extended floating-point operation unit (FXU) operates as a coprocessor of the CPU, and executes an extended floating-point operation instruction.

The execution of one extended floating-point operation instruction allows the execution of four single-precision floating-point (vector data) operations. This is an operation generally referred to as an SIMD (Single Instruction Multiple Data) operation.

Also, conversion is possible between a floating-point type and an integer type. In extended floating-point operation by this CPU, the floating-point is handled according to the ANSI/IEEE standard 754-2008 “IEEE Standard for Floating-point Arithmetic”.

The FXU consists of an extended floating-point operation block and vector registers where vector data is stored. There are 32 vector registers and the data width is 128 bits.

An extended floating-point operation instruction is executed by the extended floating-point operation block. The extended floating-point operation block performs 32-bit x 4 vector data operation on 128-bit vector registers. This is an operation method generally referred to as SIMD execution.

(1) Configuration of Extended Floating-Point Operation Function

(a) Not implemented

If the extended floating-point operation function is not implemented, any extended floating-point operation instruction cannot be used, and any attempt to execute an extended floating-point operation instruction will result in a coprocessor unusable exception. Also, any extended floating-point system register cannot be accessed, and any attempt to manipulate an extended floating-point system register by means of the LDSR/STSR instruction will result in a coprocessor unusable exception.

(b) Implemented

If the extended floating-point operation function is implemented, any extended floating-point operation instruction can be used. Also, all vector registers and extended floating-point system registers provide the functions described in **Section 3.2.3.5, FXU Function Registers**.

(2) Data Types

The FXU supports the single-precision floating-point formats specified by IEEE 754. For details of the single-precision floating-point formats, see **Section 3.2.6.1(2), Data Types**.

The FXU does not support the double-precision floating-point formats.

(3) Register Set

For details of the register set, see **Section 3.2.3.5, FXU Function Registers**.

(4) Extended Floating-Point Operation Instructions

Extended floating-point operation instructions consist of extended floating-point vector operation instructions and extended floating-point vector manipulation instructions. For details of the extended floating-point operation instructions, see *the RH850G4MH User's Manual: Software*.

(5) Extended Floating-Point Operation Exceptions

This section describes how the FXU handles extended floating-point operation exceptions.

(a) Types of Exceptions

When it becomes impossible to perform floating-point operation or handle operation results on any operation way during the execution of an extended floating-point operation instruction, an extended floating-point operation exception occurs.

One of the following two operations is performed when an extended floating-point operation exception has occurred.

- When exceptions are enabled

The exception cause of each operation way is set in the FXXC register, and the logical OR of the extended floating-point operation exception that has occurred on each operation way is saved into the cause bits of the extended floating-point configuration/status register FXSR.

Control (software control) is transferred to the exception handler routine.

- When exceptions are disabled

The exception cause of each operation way is set in the FXXP register, and the logical OR of the extended floating-point operation exception that has occurred on each operation way is saved into the preservation bits of the extended floating-point configuration/status register FXSR.

An appropriate value (initial value) is stored in the destination register for an instruction that has caused an exception, and execution is continued.

The FXU uses cause bits, enable bits, and preservation bits (status flags) to support the following five types of IEEE754-defined exception causes.

- Inexact operation (I)
- Overflow (O)
- Underflow (U)
- Division by zero (Z)
- Invalid operation (V)

The sixth type of exception cause is unimplemented operation (E), which causes an exception when an extended floating-point operation cannot be executed. This exception requires processing by software. An unimplemented operation exception (E) occurs when exceptions are always enabled, rather than by using properties, enable bits, or preservation bits.

Figure 3.38 shows the relationship among the enable bits and the cause bits of the FXSR register and the cause bits of the FXXC register; these bits are used to support exceptions. **Figure 3.39** shows the relationship among the enable bits and the preservation bits of the FXSR register and the preservation bits of the FXXP register.

Figure 3.38 Relationship among the Cause and Enable Bits of the FXSR and FXXC Registers

Figure 3.39 Relationship among the Preservation and Enable Bits of the FXSR and FXXP Registers

The five exceptions (V, Z, O, U, and I) defined by IEEE754 are enabled when the corresponding enable bits are set. All operation ways share the enable bits of the FXSR register, but detection of an exception is performed for each operation way. Therefore, different exceptions may be detected on multiple operation ways. In this case, one extended floating-point operation exception occurs.

If an exception has been detected on an operation way with its corresponding enable bit set, the FXU sets the cause bit of the operation way in the FXXC register. Also, it obtains the logical OR of the cause bits of all operation ways and sets the corresponding cause bits in the FXSR register. If the exception can be acknowledged, control is transferred to the exception handler routine.

If exceptions are prohibited, the preservation bit of that operation way in the FXXP register is set. Also, the logical OR of the preservation bits of all operation ways is obtained to set the corresponding preservation bits in the FXSR register. In this case, control is not transferred to the exception handler routine.

(b) Exception handling

When an extended floating-point operation exception occurs, the cause bits of the FXSR register indicate the cause of the extended floating-point operation exception.

3.2.6.2.5.b.1 Status flag

A corresponding preservation bit is available for each IEEE754-defined exception. The preservation bit is set when the corresponding exception is prohibited but the exception condition has been detected. The preservation bit is set or reset whenever new values are written to the FXSR register by the LDSR instruction.

If an exception is prohibited by an enable bit, predetermined processing is performed by the FXU. This processing provides an initial value as the result, rather than a floating-point operation result. This initial value is determined according to the type of exception. For an overflow exception or underflow exception, the initial value also differs depending on the current rounding mode. **Table 3.121** shows the initial values provided for each of the IEEE754-defined exceptions.

Note that initial values are stored only for operation ways where an exception has been detected. If different exceptions have been detected on multiple operation ways, the initial value corresponding to each exception is stored in the destination of each operation way.

Table 3.121 FXU Initial Values for IEEE754 Defined Exceptions

Area	Description	Rounding Mode	Initial Value
V	Invalid operation	—	Quiet not-a-number (Q-NaN)
Z	Division by zero	—	Correctly signed ∞
O	Overflow	RN	∞ with sign of intermediate result
		RZ	Maximum normalized number with sign of intermediate result
		RP	Negative overflow: Maximum negative normalized number Positive overflow: $+\infty$
		RM	Positive overflow: Maximum positive normalized number Negative overflow: $-\infty$
U	Underflow* ¹	RN* ²	0 with sign of intermediate result
		RZ	0 with sign of intermediate result
		RP	Positive underflow: Minimum positive normalized number Negative underflow: 0
		RM	Negative underflow: Minimum negative normalized number Positive underflow: 0
I	Inexact operation	—	Rounded result

Note 1. If the FXSR.FS bit is cleared, an underflow in the rounded result will cause an unimplemented operation exception (E); therefore, in this case, an underflow exception (U) will not occur. If the FXSR.FS bit is set, the flushed result is used as the initial value.

Note 2. If the rounding mode is RN and FXSR.FN is set, flushing will occur in the direction of higher accuracy. For details, see **Section 3.2.6.1(9), Flush to Nearest**.

(6) Exception Details

The following describes the conditions under which each extended floating-point operation exception occurs and how the FXU handles it.

(a) Inexact exception (I)

If any of the following conditions is detected on any operation way, the FXU detects an inexact exception.

- When the precision of the rounded result is dropped
- When the rounded result overflows while overflow exceptions are prohibited
- When the rounded result underflows while underflow exceptions are prohibited
- When the operand that is a subnormal number is flushed, neither an invalid operation exception (V) nor a division by zero exception (Z) is detected, and the other operands are not Q-NaN

CAUTION

If the FXSR.FS bit is cleared and the operation result underflows, an unimplemented operation exception (E) occurs. In such cases, the underflow exception is not detected, so the inexact exception is not detected either.

3.2.6.2.6.a.1 If exception is enabled

The contents of the destination register are not changed, the contents of the source register are saved, and an inexact exception occurs.

3.2.6.2.6.a.2 If exception is not enabled

If no other exception occurs, the rounded result or the result that underflows or overflows is stored in the destination register.

(b) Invalid operation exception (V)

If either or both of the operands are invalid on any operation way, an invalid operation exception is detected.

- Arithmetic operation with S-NaN included in operands. The conditional move instruction (CMOV), absolute value (ABS), and arithmetic negation (NEG) are not handled as arithmetic operations, but minimum value (MIN) and maximum value (MAX) are handled as arithmetic operations.
- Multiplication: $\pm 0 \times \pm \infty$ or $\pm \infty \times \pm 0$
- Fused-multiply-add: $(\pm 0 \times \pm \infty) + c$ or $(\pm \infty \times \pm 0) + c$. But only if c is not Q-NaN.
- Addition/subtraction or multiply-add operation*¹:
Addition of infinite values with different signs or subtraction of infinite values with the same sign.
- Division: $\pm 0 \div \pm 0$ or $\pm \infty \div \pm \infty$
- Square root: When operand is less than 0.
- Conversion to integer when source is outside of integer range.
- Comparison: With condition codes 8 to 15, if the operand is unordered (see *the RH850G4MH User's Manual: Software*)

Note 1. When the multiplication result is infinite or when adding or subtracting between infinities.

3.2.6.2.6.b.1 If exception is enabled

The contents of the destination register are not changed, the contents of the source register are saved, and an invalid operation exception occurs.

3.2.6.2.6.b.2 If exception is not enabled

If no other exception occurs, and the destination is a floating-point format, Q-NaN is stored in the destination register. If the destination has an integer format, see the operation result description of each instruction for the value to be stored in the destination register.

(c) Division by zero exception (Z)

A division by zero exception occurs if, on any operation way, a divisor is 0 and a dividend is a finite number other than 0.

3.2.6.2.6.c.1 If exception is enabled

The contents of the destination register are not changed, the contents of the source register are saved, and a division by zero exception occurs.

3.2.6.2.6.c.2 If exception is not enabled

If no other exception occurs, a correctly signed infinite number ($\pm \infty$) is stored in the destination register.

(d) Overflow exception (O)

An overflow exception is detected if, on any operation way, the exponent range is infinite and if the result of the rounded floating-point is greater than maximum finite number in the destination format.

3.2.6.2.6.d.1 If exception is enabled

The contents of the destination register are not changed, the contents of the source register are saved, and an overflow exception occurs.

3.2.6.2.6.d.2 If exception is not enabled

If no other exception occurs, the initial value that is determined by the rounding mode and the sign of the intermediate result is stored in the destination register (see **Table 3.121, FXU Initial Values for IEEE754 Defined Exceptions**).

(e) Underflow exception (U)

If, on any operation way, the operation result is $-2^{E_{min}}$ to $+2^{E_{min}}$ (but not zero), an underflow exception is detected.

Although IEEE754 defines several methods for detecting an underflow, the same method should be used to detect underflows, regardless of the processing to be performed.

The following two methods can be used to detect an underflow for binary floating-point numbers.

- The result calculated after rounding and using an infinite exponent range is not zero and is within $\pm 2^{E_{min}}$
- The result calculated before rounding and using an infinite exponent range and precision is not zero and is within $\pm 2^{E_{min}}$.

In this CPU, an underflow is detected before rounding.

Also, if the rounded result is one of the following, an inexact result is detected.

- When a given result differs from the result calculated when the exponent range and precision are infinite

In this CPU, the behavior when an inexact result is detected differs as follows depending on whether underflow exceptions are enabled or disabled.

3.2.6.2.6.e.1 If exception is enabled

When the FXSR.FS bit has been set, if underflow exceptions are enabled, an underflow exception (U) occurs. When the FXSR.FS bit has been set, if underflow exceptions are not enabled but inexact exceptions are enabled, an inexact exception (I) occurs.

3.2.6.2.6.e.2 If exception is not enabled

If the FXSR.FS bit has been set, the initial value determined according to the rounding mode and intermediate result value is stored in the destination register (see **Table 3.121 FXU Initial Values for IEEE754 Defined Exceptions**).

CAUTION

If the FXSR.FS bit has not been set, an unimplemented operation exception (E) occurs regardless of whether or not exceptions are enabled. Because an unimplemented operation exception (E) must occur, an underflow exception (U) does not occur.

(f) Unimplemented operation exception (E)

The E bit is set and an unimplemented operation exception (E) occurs when, on any operation way, an abnormal operand or abnormal result that cannot be correctly processed by hardware has been detected. The operand and destination register contents do not change.

If the FXSR.FS bit has been set, an unimplemented operation exception (E) will not occur.

If the FXSR.FS has been cleared, an unimplemented operation exception (E) will occur under the following conditions (except for ABSF.S4, CMOVF.W4, CMPF.S4, CVTF.HS4, MAXF.S4, MAXRF.S4, MINF.S4, MINRF.S4, and NEGF.S4 instructions).

- When the operand is a subnormal number
- When the operation result is a subnormal number, or an underflow has occurred

CAUTION

If the FXSR.FS bit has not been set, an unimplemented operation exception (E) occurs regardless of whether or not exceptions are enabled. Because an unimplemented operation exception (E) must occur, an underflow exception (U) does not occur.

(7) Saving and Restoring Status

When an extended floating-point operation exception occurs, the PC and PSW are saved to the EIPC and EIPSW registers respectively, and the exception cause code is saved to the EIIC register.

The exception cause code of the extended floating-point operation exception is 75_H.

When an EI level exception is acknowledged while processing an extended floating-point operation exception, an EIPC register override occurs, which prevents the returning to the instruction that caused the extended floating-point operation exception to occur. Therefore, when acknowledgment of EI level exceptions is required, the contents of the EIPC, EIPSW, and EIIC registers must be saved in advance into a stack or the like.

When an extended floating-point operation instruction is used in an extended floating-point operation exception handler routine, the FXSR and FXXC registers will be overridden if another floating-point operation exception occurs. In such cases, the FXSR and FXXC registers should be saved at the start of the extended floating-point operation exception handler processing, and should be restored at the end of the handler processing.

The cause bits of the FXSR register hold the results from only one enabled exception. In any case, the previous results are held until the next enabled exception occurs.

(8) Flushing Subnormal Numbers

This CPU can process subnormal numbers—very small numbers that are lower than the minimum normalized number—in one of the following two ways:

- Normalize the operand or operation result and continue executing arithmetic processing
- Generate an unimplemented operation exception (E) and execute exception handling

Executing software-based exception handling will obtain a more accurate result, but the amount of time required to obtain the result will vary depending on the input value. In control systems that require a real-time performance, therefore, this is usually unacceptable. In this case, it is important to obtain the result within a certain amount of time rather than focus on accuracy.

(a) Normalize the subnormal numbers and continue executing arithmetic processing

By setting the FS bit of the FXSR register to 1, this CPU can normalize the operand or operation result to a specific value and continue executing arithmetic processing even if a subnormal number is input as the operand or obtained as the operation result. At this time, extremely small differences in values might not appear in the operation result.

For the operand and operation result, the values to which subnormal numbers are flushed when the FS bit is set to 1 are shown in **Table 3.122** and **Table 3.123** below.

Table 3.122 Rounding Mode and Flush Value of Input Operand

Sign of Subnormal Operand	Rounding Mode and Value to Which Input Operand is Flushed			
	RN	RZ	RN	RM
+			+0	
-			-0	

Table 3.123 Rounding Mode and Flush Value of Operation result

Sign of Subnormal Operation Result	Rounding Mode and Value to Which Operation Result is Flushed			
	RN*1	RZ	RN*1	RM
+	+0	+0	+2 ^{E_{min}}	+0
-	-0	-0	-0	-2 ^{E_{min}}

Note 1. If the rounding mode is RN and FXSR.FN is set, flushing will occur in the direction of higher accuracy. For details, see **Section 3.2.6.1(9), Flush to Nearest**.

Whether an input operand that is a subnormal number has been flushed or not can be checked by referencing the IF bit of the FXSR register. Whether an operation result that is a subnormal number has been flushed or not can be checked by referencing the U bit of the FXSR register.

CAUTIONS

1. In control systems that require a real-time performance, it is recommended to always set the FS bit of the FXSR register to 1.
2. If the FS bit of the FXSR register is set to 1, an unimplemented operation exception (E) will not occur under any circumstances.
3. Whether the operation result is a subnormal number is judged by using the value before rounding.
4. The IF bit of the FXSR register also accumulates and indicates information about flushing instructions that have caused an extended floating-point operation exception.

(b) Generate an unimplemented operation exception (E) and execute exception handling

Clearing the FS bit of the FXSR register to 0 will cause an unimplemented operation exception (E) if a subnormal number is input as the operand or obtained as the operation result. When an unimplemented operation exception occurs, software-based progressive underflow processing is performed in the floating-point operation exception handling routine, enabling a more accurate result to be obtained. In this case, however, a real-time processing performance might not be ensured depending on the software processing load.

(c) Instructions that can handle subnormal numbers

The following instructions can be executed without causing an unimplemented operation exception (E) even if an operand that is a subnormal number is input while the FS bit of the FXSR register is 0.

- Conditional move instruction (CMOV), absolute value (ABS), arithmetic negation (NEG)
- Minimum value (MIN), maximum value (MAX), compare (CMPF)
- Conversion from half-precision to single-precision (CVTF.HS4)

(d) Instructions that are not affected by flushing subnormal numbers

For the following instructions, flushing does not occur even if an operand that is a subnormal number is input while the FS bit of the FXSR register is 1.

- Conditional move instruction (CMOV), absolute value (ABS), arithmetic negation (NEG)
- Minimum value (MIN), maximum value (MAX), compare (CMPF)
- Conversion from half-precision to single-precision (CVTF.HS4)

(9) Flush to Nearest

This CPU provides flush-to-nearest mode, a feature for flushing to the nearest number with higher accuracy when a flushing operation results subnormal number. Flush-to-nearest mode is enabled when the rounding mode is RN and FXSR.FN is set to 1. When this mode is used, the FXU determines the value to which to flush the subnormal number based on the number of the operation result and not just the sign. This feature has no effect in rounding modes other than RN or on the result of flushing an input operand.

Table 3.124 Rounding Mode and Value to Which Operation Result is Flushed

Value of Subnormal Operation Result	Rounding Mode and Value to Which Operation Result is Flushed				
	RN		RZ	RP	RM
	FN = 1	FN = 0			
$+2^{E_{min}-1} \leq \text{Operation result} < +2^{E_{min}}$	$+2^{E_{min}}$	+0	+0	$+2^{E_{min}}$	+0
$+0 < \text{Operation result} < +2^{E_{min}-1}$	+0				
$-2^{E_{min}-1} < \text{Operation result} < -0$	-0	-0	-0	-0	$-2^{E_{min}}$
$-2^{E_{min}} < \text{Operation result} \leq -2^{E_{min}-1}$	$-2^{E_{min}}$				

CAUTION

Whether the operation result is a subnormal number is judged by using the value before rounding.

(10) Limitation on the Floating-Point Operation Result

There is a limitation on the floating-point operation result of this CPU.

(a) Operation instruction result when the input data is NaN (not-a-number)

When the input data is NaN (not-a-number), the operation instruction result will be as shown in **Table 3.125**.

Table 3.125 Operation Result when Input data is NaN

Input Data*3	Operation Result
SNaN and QNaN mixed	7FFF FFFF _H
Only SNaN	7FFF FFFF _H
Only QNaN	*1,*4
SNaN and real number	7FFF FFFF _H
QNaN and real number	*1,*4
Other than above*2	7FFF FFFF _H

Note 1. If the input data contains QNaN, QNaN in the input data is selected as the operation result by the priority of wreg2, wreg1, and wreg3.

Note 2. In this case, input data contains real numbers only, and the operation result is invalid.

Note 3. When the operand of an ABSF.S4 or NEGF.S4 instruction is NaN, the result of the operation will be the value obtained by the operation on the sign bit alone.

Note 4. When one of the operands of a MAXF.S4, MAXRF.S4, MINF.S4, and MINRF.S4 instruction is QNaN, the result of the operation will be whichever operand is a real number.

(b) Results of conversion instructions when the operand is NaN (not-a-number)

When the operand is NaN (not-a-number), the results of conversion are as shown in **Table 3.126**.

Table 3.126 Results of Conversion when the Operand is NaN (not-a-number)

Input Data	Output Format	Results of Conversion
Half-precision SNaN	Single precision	7FFF FFFF _H
Half-precision QNaN	Single precision	The QNaN value with the same sign. Bits 12 to 0 in the fractional part of the output value are 0.
Single-precision SNaN	Word (signed)	8000 0000 _H
	Word (unsigned)	0000 0000 _H
	Half precision	7FFF _H
Single-precision QNaN	Word (signed)	8000 0000 _H
	Word (unsigned)	0000 0000 _H
	Half precision	The QNaN value with the same sign. Bits 12 to 0 in the fractional part of the operand are truncated.

(c) When 0 comparison is performed by MAXF and MINF

When wreg1 and wreg2 elements are either +0 or -0, the operation will be as follows.

MINF.S4: The values of wreg1 elements are stored in wreg3 elements.

MAXF.S4: The values of wreg2 elements are stored in wreg3 elements.

MINRF.S4: The values of wreg1 and wreg2 even elements are stored in wreg3 elements.

MAXRF.S4: The values of wreg1 and wreg2 odd elements are stored in wreg3 elements.

(d) In the case of the precision instruction (RECIPIF)

The operation result of RECIPIF.S4 is the same as the operation result of 1/x by DIVF.S.

3.2.7 Hazard Control

3.2.7.1 Synchronization Processing

In order to increase the processing performance, this CPU executes subsequent instructions without waiting for completion of the processing of preceding instructions, as long as there is no dependence relationship between a preceding instruction and a subsequent instruction. For example, when a store instruction is to update the value of a control register of a peripheral device which operates more slowly than the CPU, even when updating of the register is not completed while the bus system is still handling processing to store the value, the execution of a subsequent instruction will proceed. For this reason, if a subsequent instruction should certainly be made to wait for completion of processing of a preceding instruction by software, procedures for synchronization processing are required.

Moreover, when a single CPU is executing multiple load and store instructions, the results of execution are guaranteed to be in the order of the instructions of the program. However, in order to guarantee the order of data accesses among multiple bus masters outside a mutual exclusion control section, synchronization processing should be performed before the subsequent data access. For details of synchronization processing, refer to **Section 3.8.1, Synchronization of Store Instruction Completion and Subsequent Instruction Generation** and **Section 3.8.2, Synchronization of Load Instruction Completion and Subsequent Instruction Generation**.

This CPU provides four instructions dedicated for synchronization processing.

In addition, since a wait for the result of preceding load processing depends on general-purpose registers and handled automatically by hardware, no synchronization processing is required by software.

(1) SYNCNP

The SYNCNP instruction is a special instruction for pipeline synchronization processing, which makes pipelines wait for the result of executing a preceding instruction is reflected before starting to execute a subsequent instruction. Though the SYNCNP instruction causes a wait for the results of executing all preceding load processing (up to storing of the loaded values in general-purpose registers), it does not cause waiting for the results of executing store processing (updating of the destination memory locations for storage and of memory-mapped control registers). For how to be sure that the results of executing store processing are reflected for subsequent instructions, see **Section 3.2.7.2, Guaranteeing the Completion of Store Instruction**.

(2) SYNCNM

The SYNCNM instruction is a special instruction for memory-access synchronization processing, and causes a wait for the results of executing all preceding load processing (up to storage of the loaded values in general-purpose registers) and for the results of executing all preceding store processing (updating of the destination memory locations for storage and memory-mapped control registers). However, for those bus systems and peripheral devices for which storage is speculatively completed (resulting in delays in the completion of writing to the memory and control registers), the SYNCNM instruction does not guarantee completion of the execution of store instructions. For how to be sure that the results of executing store processing are reflected for subsequent instructions in such cases, see **Section 3.2.7.2, Guaranteeing the Completion of Store Instruction**.

(3) SYNCNI

The SYNCNI instruction is a special instruction for the synchronization of instruction fetching. It causes subsequent instructions that have already been fetched into the pipeline but not executed to be discarded, and restarts instruction fetching from the earliest of the discarded instructions to have been fetched. This instruction is used when the result of a preceding instruction must be reflected in processing by subsequently fetched instructions. Though the SYNCNI instruction causes a wait for the results of executing all preceding load processing (up to storing of the loaded values in

general-purpose registers), it does not cause waiting for the results of executing store processing (updating of the destination memory locations for storage and of memory-mapped control registers). If a cache instruction has been issued, this instruction also causes a wait for the completion of the instruction cache operation.

The SYNCI instruction should be executed after changes to the CPU operating mode or reflection of changes to the memory protection settings if this will be required in subsequent instruction fetching. For details, see **Section 3.2.7.3(1), Updating the Settings Related to Instruction Fetching**.

When reflecting the results of executing store instructions in subsequent instruction fetching is required, due to changes to self-modifying code or switching between areas of the code-flash memory, execute a dummy read before the SYNCI instruction. This causes a wait for the results of executing store instructions, resulting in these being reflected in subsequent instruction fetching. For details, see **Section 3.2.7.2, Guaranteeing the Completion of Store Instruction**.

(4) SYNCE

The SYNCE instruction of this CPU does not perform processing related to synchronization.

The effects of the four synchronization processing instructions are summarized in **Table 3.127**.

Table 3.127 Effects of Synchronization Processing Instructions

Synchronization Processing Instruction	Guaranteed Synchronization Processing				
	Instruction Fetching		Instruction Execution		
	Subsequent Instructions	Cache Operations* ¹	Load Instructions	Store Instructions	Instructions for Other Operations
SYNCP	—	—	Execution completed* ³	—	Execution completed
SYNCM	—	—	Execution completed* ³	Execution completed* ⁴	Execution completed
SYNCI	Re-fetching* ²	Execution completed	Execution completed* ³	—	Execution completed
SYNCE	—	—	—	—	—

Note 1. This indicates the execution of cache instructions. The LDSR instruction to update the function registers for cache operations is included among the instructions for other operations.

Note 2. This CPU speculatively fetches instructions, so even if the next instruction from the SYNCI instruction has already been fetched, it is fetched again.

Note 3. This indicates the processing up to the storing of loaded data in general-purpose registers

Note 4. This indicates the processing up to updating of the destination memory locations and memory-mapped control registers for storage. However, updating may not be guaranteed. This depends on the specification of the destination for writing. For details, see **Section 3.2.7.2, Guaranteeing the Completion of Store Instruction**.

3.2.7.2 Guaranteeing the Completion of Store Instruction

Instructions for storage may appear to be completed faster than those for loading given the same address. However, the data for storage may not actually have been stored when the instruction has been completed. For example, in the synchronization of multiple cores or the manipulation of peripheral devices, processing related to the stored values should only proceed after storage in the target locations is confirmed. This should be checked by software after the execution of instructions for storage.

This CPU provides two approaches to waiting for the progress of storage at different stages.

(1) Using the SYNCM Instruction to Wait for the Completion of Storage

Executing the SYNCM instruction causes operations to wait until the results of preceding store instructions will be correctly read by subsequent reading. This guarantees confirmed execution when an instruction stored in the memory is to be executed or data are to be transferred to the other CPU core or by DMA via the memory.

In the following example, after waiting for the execution of the two store instructions that proceed the SYNCM instruction, the processing for which waiting was required proceeds in “Operations” below. Processing to branch to an address where an instruction code is stored, for notification of the other CPU, and so on, falls into the category of “Operations”.

ST.W	r21, 0[r1]	//	Store data 1
ST.W	r22, 4[r1]	//	Store data 2
SYNCM		//	Wait for completion of the store instructions
Operation		//	Processing after waiting for completion of the store instructions

However, the SYNCM instruction does not guarantee that the results of preceding store instructions will have already been reflected at the destinations. For example, when storing a value in a register of a peripheral device, the register of the peripheral device may not have been updated when waiting due to the SYNCM instruction has finished, and the resulting may be operation that is not as desired. In such cases, use dummy reading to cause the wait. This is described in **Section 3.2.7.2(2), Using Dummy Reading to Wait for the Completion of Storage**.

In addition, since the SYNCM instruction requires hardware operations to wait in response to its execution, it is only effective in access to bus slaves where the CPU can recognize the progress of processing for storage. If a bus slave is capable of arbitrating requests from multiple bus masters, or is connected to the bus via a bus bridge, the CPU is unable to recognize the progress of storage, so using the SYNCM instruction to cause the wait may not be effective.

The bus slaves (address groups) that support using the SYNCM instruction to wait for the completion of storage in this CPU are listed in **Table 3.128**.

Table 3.128 Bus Slaves that Support Using the SYNCM Instruction to Wait for the Completion of Storage in This CPU

Bus Slaves	Description
L1RAM (given CPU)	Waiting for the updating of memory is also possible.*1
L1RAM (other CPU)	A configuration of two CPU cores can be assumed for this device. For configurations with three or more cores, refer to Section 3.8.1.3, Product information of SYNCM.
L2RAM	A configuration of two CPU cores with a single shared L2RAM can be assumed for this device. For configurations with three or more cores or having multiple L2RAMs, refer to Section 3.8.1.3, Product information of SYNCM.
INTC1	This is the dedicated interrupt controller for connection with the CPU.
Others	Depends on the specifications of the connected bus or slave. For details, refer to Section 3.8.1.3, Product information of SYNCM.

Note 1. For details, **Section 3.2.7.2(2), Using Dummy Reading to Wait for the Completion of Storage.**

The instructions for which the SYNCM instruction causes a wait are all preceding instructions for storing and loading. Multiple instructions for storing and loading running at the same time raises the possibility of the wait being longer than is necessary.

One SYNCM instruction per store instruction is not required. Following consecutive storage in a specific bus slave in units of memory type, peripheral device, and so on, a single SYNCM instruction after the last store instruction leads to a wait for the completion of all preceding store instructions. In the above example, one SYNCM instruction is executed after the execution of two store instructions.

(2) Using Dummy Reading to Wait for the Completion of Storage

Executing a load instruction for the same address immediately after a store instruction can also be used to wait for the completion of a store instruction. This approach is unlike using the SYNCM instruction to cause waiting, since it involves actually waiting for the result of the store instruction to be reflected. On the other hand, this approach may require more cycles than using the SYNCM instruction.

Specifying r0 as the destination for storage of the value loaded by the dummy read enables discarding of the loaded values when they are unnecessary, without destroying the other register values. The following is an example of code for this.

ST.W	r21, 0[r1]	//	Store data 1
ST.W	r22, 4[r1]	//	Store data 2
LD.W	4[r1], r0	//	Load data from the target for access (dummy read).
SYNCP		//	Wait for loading to be completed.
Operation		//	Processing after waiting for completion of the store instructions

Unlike using the SYNCM instruction, this approach combines functions of the CPUs to cause the wait. Since it does not require dedicated hardware, it may be used with many bus slaves.

On the other hand, if a cache for temporarily storing data is present in the bus system along the path to the destination, a value to be stored will be read by a subsequent load instruction even if it has not yet reached its destination, so this method cannot guarantee the completion of store instructions in such cases. Also, depending on the specifications of peripheral devices, a predetermined time after a change to a setting by a store instruction may have to elapse before the desired value can be read. In addition to this approach, such cases require processing to wait for the predetermined time.

Though this CPU does not include such cache functions or peripheral functions with limits on the time to elapse before reading, the situation depends on the product. For details, refer to **Section 3.8.1.4, Product information of Waiting for the Completion of Storage**.

As with using the SYNCM instruction, in using dummy reading, following consecutive storage in a particular bus slave, only a single load instruction following the final store instruction is effective in waiting for the execution of all preceding store instructions to be complete.

Table 3.129 lists the bus slaves for which using dummy reading to wait is effective.

Table 3.129 Bus Slaves for which Using Dummy Reading to Wait is Effective

Bus Slaves	Description
L1RAM (other CPU)	
L2RAM	
INTC1	
Others	Depends on the specifications of the connected bus or slave. For details, refer to Section 3.8.1.4, Product information of Waiting for the Completion of Storage .

In the case of access to the L1RAM of a given CPU, for the sake of the efficiency of processing, execution of the load instruction may be completed before the memory is actually updated. On the other hand, it is possible to execute a SYNCM instruction to cause the wait for completion of the updating of memory. Therefore, use the SYNCM instruction to cause the wait for the completion of instructions for storage in the L1RAM of a given CPU.

When reflecting the results of executing store instructions in subsequent instruction fetching is required, due to changes to self-modifying code or switching between areas of the code-flash memory, execute a SYNCI instruction rather than a SYNCP instruction after the dummy read. This causes a wait for the results of executing store instructions, resulting in these being reflected in subsequent instruction fetching. The following shows an example of code for this.

ST.W	r21, 0[r1]	//	A change relating to instruction fetching
LD.W	0[r1], r0	//	Load data from the target for access (dummy read).
SYNCI		//	Synchronization of the wait for the execution of loading and instruction fetching
Operation		//	Processing after the change to instruction fetching operations

3.2.7.3 Hazard Management after System Register Update

If an LDSR instruction is executed to update the setting of a system register before an STSR instruction is executed to read the system register or before a CALLT instruction or the like, which uses the system register, is executed, then the new setting must be reflected in order to perform the desired operation.

This CPU guarantees that if an LDSR instruction is used to update system registers shown in **Table 3.130**, the new register setting will be applied when the subsequent instruction is executed. However, it does not guarantee that the new setting will be applied in instruction fetching. In this case, synchronization process is required. Also, the execution of an EI or DI instruction is treated in the same way as the update of PSW by an LDSR instruction; that is, it is guaranteed that the values updated by an EI or DI instruction is applied to the subsequent instruction.

Table 3.130 System Registers that Guarantee Reflection of their Updates by LDSR Instruction to the Subsequent Instruction

selID*1	System Register*2							
0	EIPC	EIPSW	FEPC	FEPSW	PSW	FPSR	FPEPC	FPST
	FPCC	FPCFG	EIIC	FEIC	CTPC	CTPSW	CTBP	SNZCFG
	EIWR	FEWR						
1	SPID	SPIDLIST	RBASE	EBASE	INTBP*3	MCTL	PID	SVLOCK
	SCCFG	SCBP						
2	PEID	BMID	MEA	MEI	ISPR*3	ICSR	INTCFG*3	PLMR*3
	RBCR0*4	RBCR1*4	RBNR*4	RBIP*4				
5	MPM	MPCFG	MCA	MCS	MCC	MCR	MCI	MPIDX*5
10	FXSR	FXST	FXINFO	FXCFG	FXXC	FXXP		
13	RDBCR							

Note 1. In the representation of LDSR and STSR instructions, selection ID are represented as selID.

Note 2. This table includes a register whose value cannot be updated and a register that has a bit whose value cannot be updated.

Note 3. If these registers, which control the acceptance of interrupts, are updated, interrupts will be accepted with the new register settings if interrupt requests are present at the time of executing the subsequent instruction.

Note 4. If these registers, which control the register bank function, are updated, interrupts will be accepted with the new register settings if interrupt requests are present at the time of executing the subsequent instruction. However, when the RESBANK instruction is executed after updating the RBCR0.MD, a synchronization process is required.

Note 5. If an LDSR instruction is executed to update the MPLA, MPUA, or MPAT register immediately after another LDSR instruction is executed to update the MPIDX register, it is guaranteed that the new setting of MPIDX is reflected in the subsequent instructions. In order to read the MPLA, MPUA, or MPAT register by using a STSR instruction after the update of the MPIDX register, a synchronization process is required.

If the settings related to instruction fetch or a system register that is not shown in **Table 3.130** is updated, the new register setting can be reflected by performing any of the following synchronization processes immediately after the LDSR instruction. The appropriate synchronization process should be decided according to details of the new register setting and the subsequent operation.

For SYNCI or SYNCP instruction, that are used for synchronization process, see **Section 3.2.7.1, Synchronization Processing**.

(1) Updating the Settings Related to Instruction Fetching

To effectively supply instruction codes read from the memory to the instruction execution unit, operations of instruction fetching are independent from those of the instruction execution unit and are speculative. This means that the progress of reading the subsequent instruction code by instruction fetching is not known on completion of the system register update. In other words, the result from which instruction fetching is applied to the new setting of the system register is not known. Therefore, an explicit synchronization process is required for updates of the system registers which are related to instruction fetching. This process is also necessary for updates of the system registers listed in **Table 3.130** in order to ensure that the updates are reflected in instruction fetching.

The system registers related to instruction fetching are listed below:

CPU operating mode:	PSW.UM, PSW.CU1, PSW.CU0
Access protection:	SPID
Memory protection:	MPU function registers
Instruction cache:	Cache operation function registers
Instruction fetch:	Instruction fetch control registers

If the settings of the system registers listed above are updated, by executing the SYNCI, EIRET, or FERET instruction, the new settings are surely reflected when the subsequent instruction is fetched. Here, these instructions are called “Instruction fetch synchronization instructions”. For usage of the EIRET and FERET instructions, see **Section 3.2.7.3(7), Use of EIRET and FERET Instructions in Synchronization Process**.

For fetching the instruction fetch synchronization instructions themselves, whether the updates of the system registers are reflected or not cannot be decided. In these cases, the following cares must be taken.

(a) Updating PSW.UM

When an LDSR instruction is used to update PSW, especially by setting PSW.UM (to 1), which in response enables memory protection function, be sure that fetching of the SYNCI instruction, which is used for synchronizing the instruction fetch, does not cause a memory protection violation. Also note that setting PSW.UM disables execution of some instructions and updating of some system registers.

On the other hand, when an EIRET or FERET instruction is executed, the value in EIPSW or FEPSW is transferred to PSW as the operation of the instruction. This means that fetching of the instruction takes place before updating of PSW.UM by the instruction itself. For these reasons, updating of PSW.UM by an EIRET or FERET instruction is recommended.

(b) Updating PSW.CU1 and PSW.CU0

After PSW.CU1 or PSW.CU0 is updated, if a FXU or FPU instruction is executed without synchronization process, a coprocessor unusable exception (UCPOP) may not be properly detected. To avoid this, execute a SYNCI instruction for synchronization after updating these bits. Unlike updating of PSW.UM, updating of PSW.CU1 or PSW.CU0 and detection of a coprocessor unusable exception can be surely synchronized by a SYNCI instruction.

For updating PSW.CU1 or PSW.CU0 and PSW.UM at the same time, use of an EIRET or FERET instruction described in **Section 3.2.7.3(1)(a), Updating PSW.UM** is recommended.

(c) Updating SPID

SPID is referenced by memory protection function and the bus system outside the CPU. If an ID without access permission to the memory resources or peripheral devices is set to SPID, instruction fetching does not take place correctly. Be sure to set an appropriate ID to SPID. To ensure that the bus system references any updates on SPID, the instruction cache must be disabled once.

(d) Updating MPU Function Registers

Updating the settings of memory protection by manipulating the MPU function registers is detailed in **Section 3.2.7.3(2), Updating the Memory Protection Settings of MPU.**

For reflecting the updated settings in fetching of the subsequent instruction, execute either of the SYNCI, EIRET, and FERET instructions. Note, however, that whether the instruction fetch synchronization instruction itself is fetched with the new protection settings or not is not known. In this case, the following operations are required.

- i) Enable memory protection in user mode only and update the settings in supervisor mode.
- ii) Update the settings of memory protection in the area where execution of instructions are allowed.
- iii) Surely set execution of instructions for the memory area including those for instruction fetch synchronization instruction to be enabled

For updating PSW.UM with operation i) above, use of an EIRET or FERET instruction described in **Section 3.2.7.3(1)(a), Updating PSW.UM** is recommended.

(e) Updating Cache Operation Function Registers

Updating these registers by an instruction does not require certain synchronization process. However, if you want to make sure that the disabled state of the instruction cache is reflected in fetching of the subsequent instruction, execute an instruction fetch synchronization instruction after the update of the cache operation function registers.

(f) Updating Instruction Fetch Control Registers

Updating these registers by an instruction does not require certain synchronization process.

(2) Updating the Memory Protection Settings of MPU

The system registers of MPU that are shown in **Table 3.130** guarantee that their latest settings are reflected in the subsequent instruction, but this does not apply to other system registers (MPIDX, MPLA, MPUA, MPAT, and MPIDn (n = 0 to 7) that configure the settings of protection areas.

In order to read settings updated by an LDSR instruction by using the subsequent STSR instruction, the synchronization process described in **Section 3.2.7.3(4), Updating Register Bank Function-Related System Registers** is required.

For reflecting the updated memory protection settings in the instruction fetch, see **Section 3.2.7.3(1), Updating the Settings Related to Instruction Fetching**.

For reflecting the updated memory protection setting in the instruction that makes operand accesses, execute a SYNCI or SYNCP instruction after the update. This ensures that the new protection setting is reflected in the operand accesses by the subsequent instructions.

The EIRET and FERET instructions can be used instead of the SYNCI and SYNCP instructions. Especially, for the case of updating memory protection settings related to instruction fetch as well as making operand accesses, use of an EIRET or FERET instruction is recommended.

(3) Updating Interrupt-Related System Registers

As shown in **Table 3.130**, when the system registers related to interrupts (ISPR, INTCFG, PLMR) are updated, it is guaranteed that the updates are reflected when the subsequent instruction is executed.

However, when updating the setting of INTCFG to stop automatic update of ISPR, for example, if an interrupt is generated after INTCFG is updated and before an LDSR instruction that updates ISPR is executed, only the update in INTCFG is reflected in the interrupt handling. As the update of ISPR is not reflected, the desired interrupt handling cannot be performed.

To avoid this, when updating the system registers related to interrupts, it is recommended to disable interrupts by setting PSW.ID to 1.

We also recommend that updating of PSW.EBV and EBASE, which specify vector address of an interrupt handler, are executed while interrupts are disabled. For details, see **Section 3.2.7.3(8), Updating PSW.EBV and EBASE**.

(4) Updating Register Bank Function-Related System Registers

As shown in **Table 3.130**, when the system registers related to the register bank function (RBCR0, RBCR1, RBNR, RBIP) are updated, it is guaranteed that the updates are reflected when the subsequent instruction is executed. For example, if an interrupt is generated after an LDSR instruction that updates RBIP is executed, the automatic context saving to the register bank is executed using the updated value of RBIP.

However, when updating the settings of RBCR0 and RBCR1, for example, if an interrupt is generated after RBCR0 is updated and before an LDSR instruction that updates RBCR1 is executed, only the update in RBCR0 is reflected in the automatic context saving to the register bank. As the update of RBCR1 is not reflected, the desired processing cannot be performed.

To avoid this, when updating the system registers related to the register bank function, it is recommended to disable interrupts by setting PSW.ID to 1.

For RBCR0 only, synchronization process by the SYNCI instruction is necessary to surely reflect the new setting of the register to the subsequent RESBANK instruction. The following shows an example of code for this.

DI		// Disable interrupt
LDSR	r20, 15, 2	// Update RBCRO
SYNCI		// Synchronization of instruction fetching
RESBANK		// Execute RESBANK using updated RBCRO

(5) Reading a System Register by Using an STSR Instruction

After executing an LDSR instruction to update a system register, execute a SYNCP instruction before executing an STSR instruction for read operation. Since the SYNCP instruction waits until the execution of the preceding LDSR instruction is completed, it is ensured that the new register setting is read.

For the system registers shown in **Table 3.130**, the new register settings are read without synchronization process by SYNCP instruction.

(6) Referencing a System Register by the Subsequent Instruction

After executing an LDSR instruction to update a system register, execute a SYNCP instruction before executing an instruction to refer to the system register. Since the SYNCP instruction waits until the execution of the preceding LDSR instruction is completed, it is ensured that the new register setting is reflected.

(7) Use of EIRET and FERET Instructions in Synchronization Process

The EIRET and FERET instructions are defined as return instructions from the exception handler of their corresponding exception levels. These instructions can set any PC and PSW at the same time and therefore usable as instructions for synchronization process in this CPU.

To use an EIRET instruction for synchronization process, set appropriate values to EIPC and EIPSW and execute the instruction. To use an FERET instruction for synchronization process, set appropriate values to FEPC and FEPSW and execute the instruction.

Set values to EIPC and FEPC that is the PCs after these instructions are executed. Set values to EIPSW and FEPSW that is the PSW after these instructions are executed.

Note that these instructions are supervisor privileged instructions. That means, the state of PSW.UM can be changed only from 0 (clear) to 1 (set), supervisor mode to user mode.

For details on the EIRET and FERET instructions, see *the RH850G4MH User's Manual: Software*.

(8) Updating PSW.EBV and EBASE

EBASE is a register that indicates the vector address of the exception handler. This is enabled when PSW.EBV is set (to 1). The recommended updating procedure is as follows.

- 1) Set PSW.ID to 1
- 2) Clear PSW.EBV to 0 (updating at the same time with PSW.ID is possible)
- 3) Update EBASE
- 4) Set PSW.EBV to 1
- 5) Clear PSW.ID to 0 (updating at the same time with PSW.EBV is possible)

For updating PSW.UM in the procedure above as well, use of an EIRET or FERET instruction described in **Section 3.2.7.3(1)(a), Updating PSW.UM** is recommended.

3.2.8 Reset

3.2.8.1 Status of Registers After Reset

If a reset signal is input by a method defined by the hardware specifications, the program registers and system registers are placed in the status shown by the value after reset of each register in **Section 3.2.3, Register Set**, and program execution is started. Set the contents of each register to an appropriate value in the program.

The CPU executes a reset to start execution of a program from the reset address specified by **Section 3.2.4.4, Exception Handler Address**.

Note that because the PSW.ID bit is set to 1 immediately after a reset, conditional EI level exceptions will not be acknowledged. To acknowledge conditional EI level exceptions, clear the PSW.ID bit to 0.

3.2.9 Ensuring Coherency after Code Flash Programming

The CPU has an efficient instruction cache and data buffer for the code flash area.

Therefore, after using self-programming to program the code flash memory, clear the instruction cache and data buffer to ensure coherency. The instruction cache and data buffer can be cleared by using the ICCTRL register and the RDBCR register, respectively. The entire CPU's instruction cache and data buffer can also be cleared at the same time by using the TM_CC register. For details on the ICCTRL and RDBCR register, see **Section 3.2.3.7, Cache Operation Function Registers** and **Section 3.2.3.9, Hardware Function Registers**. For details on the TM_CC register, see **Section 3.2.9.1, Registers**.

3.2.9.1 Registers

(1) Register Base Address

The GCFU base address is listed in the following table. The GCFU register addresses are given as offsets from the base addresses.

Table 3.131 Register Base Address

Base Address Name	Base Address	Bus Group
<GCFU_base>	FFFB 1400 _H	Peripheral Group 0

(2) Clock Supply

Clock supply by and to GCFU is listed in the following table.

Table 3.132 Clock Supply

Unit Name	Unit Clock Name	Clock Supply Name
GCFU	PCLK	CLK_HBUS

(3) List of Registers

Table 3.133 List of Registers

Module Name	Register Name	Symbol	Address	Access
GCFU	Cache Clear Operation Register	TM_CC	<GCFU_base> + 08 _H	32

(4) TM_CC — Cache Clear Operation Register

The TM_CC register is used to issue requests for clearing of the unit (instruction cache or data buffer) that holds data from the code flash.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Indicates that a data buffer clear request is currently being processed (when read).</p>

3.3 Inter-CPU Overview

This subsection contains a Barrier-Synchronization (BARR), Inter-Processor Interrupts (IPIR), Mutual Exclusion (MEV) and Time Protection Timer (TPTM). The first part of this subsection describes this product's specific properties, such as the number of units, register base addresses, etc. The remainder of the subsection shows the functions and registers.

3.3.1 Features

3.3.1.1 Number of Units

Table 3.135 Number of Units

Product Name		RH850/E2x-FCC2	
		468 pins	373 pins
BARR	Number of units	1	1
	Name of unit	BARR	
IPIR	Number of units	1	1
	Number of channels for each CPU	4	4
	Name of unit	IPIR	
MEV	Number of units	1	1
	Number of registers in a unit	32	32
	Name of unit	MEV	
TPTM	Number of units	1	1
	Number of channels for each CPU	4 interval timers 1 free-run timer	4 interval timers 1 free-run timer
	Name of unit	TPTM	

Product Name		RH850/E2UH	
		468 pins	373 pins

3.3.1.2 Register Base Addresses

Table 3.136 Register Base Addresses

Base Address Name	Base Address	Bus Group
<BARR_base>	FFFB 8000 _H	I-Bus Group2
<IPIR_base>	FFFB 9000 _H	I-Bus Group1
<MEV_base>	FFFB A000 _H	I-Bus Group0
<TPTM_base>	FFFB B000 _H	I-Bus Group3

3.3.1.3 Clock Supplies

The clock supplies are listed in the following table.

Table 3.137 Clock Supplies

Unit Name	Unit Clock Name	Supply Clock Name
BARR	cpu_clk	CLK_CPU
IPIR	cpu_clk	CLK_CPU
MEV	cpu_clk	CLK_CPU
TPTM	cpu_clk	CLK_CPU

3.3.1.4 Interrupt Requests

The interrupt requests are listed in the following table.

Table 3.138 Interrupt Requests

Interrupt Symbol Name	Unit Interrupt Signal	Description	Interrupt Number	sDMA Trigger Number	DTS Trigger Number
INTIPIR0	ipir_int_ch0	IPIR CH0 interrupt	EIINT0	—	—
INTIPIR1	ipir_int_ch1	IPIR CH1 interrupt	EIINT1	—	—
INTIPIR2	ipir_int_ch2	IPIR CH2 interrupt	EIINT2	—	—
INTIPIR3	ipir_int_ch3	IPIR CH3 interrupt	EIINT3	—	—
FEINT1 or INTTPTM* ¹	TPTM_IRQ	TPTM interval interrupt	FEINT1 or EIINT31* ¹	—	—

Note 1. This interrupt can be selected for use as FEINT1 or EIINT31. See **Section 6.3.16, TPTMSEL — TPTM Interrupt FE EI Select Register**.

3.3.1.5 Reset Sources

The reset sources are shown below. These modules are initialized by the following reset sources.

Table 3.139 Reset Sources

Unit Name	Register Name	Reset Condition					
		Power Up Reset	System Reset 1	System Reset 2	Application Reset	Module Reset	JTAG Reset
BARR	All registers	✓	✓	✓	✓	—	—
IPIR	All registers	✓	✓	✓	✓	—	—
MEV	All registers	✓	✓	✓	✓	—	—
TPTM	All registers	✓	✓	✓	✓	—	—

3.3.1.6 External Input/Output Signals

This module has no external input/output signals.

3.3.2 Processor Element Identifier

The PEID, the ID number of a processor element, can be read from the PEID register. Which CPU core performs a specific program can be known by referring to the PEID. The following shows the PEIDs of this product.

For the PEID register, see **Section 3.2.3.2, Basic System Registers**.

CPU Core	PEID
CPU0 (PE0)	000 _B
CPU1 (PE1)	001 _B
CPU2 (PE2)	010 _B
CPU3 (PE3)	011 _B
CPU4 (PE4)	100 _B
CPU5 (PE5)	101 _B

3.4 Inter-Processor Interrupts

3.4.1 Inter-Processor Interrupts Overview

Inter Processor Interrupt Register (IPIR) is a function that controls fast interrupt requests between PEs. Use of IPIR achieves faster processing of inter-PE interrupts than setting a request flag for the INTC2 interrupt channel by using software.

IPIR has the following features.

- Support of inter-PE interrupt function of 4 channels
- Level detection of interrupts. Edge detection is not supported.
- Accessible from all clusters and all PEs
- Identification of interrupt request source PE is possible.
- Unintended inter-PE interrupts can be prevented by masking interrupt requests.
- SET1, CLR1, and NOT1 can be executed as atomic operation instructions to IPIR.
 - Read-modify-write operations using the LD instruction and the ST instruction are also possible, but not as atomic operations.

3.4.2 Inter-Processor Interrupts Registers

3.4.2.1 List of Registers

Table 3.140 List of Registers

Module Name	Register Name	Register Symbol	Address	Access	Access Protection
IPIR	IPIRn*2 Inter-PE Interrupt Enable Self-Register*1	IPIInENS	<IPIR_base> + 000 _H + 020 _H × n	8	—
	IPIRn*2 Inter-PE Interrupt Flag Self-Register*1	IPIInFLGS	<IPIR_base> + 004 _H + 020 _H × n	8	—
	IPIRn*2 Inter-PE Interrupt Clear Self-Register*1	IPIInFCLRS	<IPIR_base> + 008 _H + 020 _H × n	8	—
	IPIRn*2 Inter-PE Interrupt Request Self-Register*1	IPIInREQS	<IPIR_base> + 010 _H + 020 _H × n	8	—
	IPIRn*2 Inter-PE Interrupt Request Clear Self-Register*1	IPIInRCLRS	<IPIR_base> + 014 _H + 020 _H × n	8	—
	IPIRn*2 Inter-PE Interrupt Enable Register m*3	IPIInENm	<IPIR_base> + 800 _H + 020 _H × n + 100 _H × m	8	—
	IPIRn*2 Inter-PE Interrupt Flag Register m*3	IPIInFLGm	<IPIR_base> + 804 _H + 020 _H × n + 100 _H × m	8	—
	IPIRn*2 Inter-PE Interrupt Clear Register m*3	IPIInFCLRm	<IPIR_base> + 808 _H + 020 _H × n + 100 _H × m	8	—
	IPIRn*2 Inter-PE Interrupt Request Register m*3	IPIInREQm	<IPIR_base> + 810 _H + 020 _H × n + 100 _H × m	8	—
	IPIRn*2 Inter-PE Interrupt Request Clear Register m*3	IPIInRCLRm	<IPIR_base> + 814 _H + 020 _H × n + 100 _H × m	8	—

Note 1. When PE accesses the self register, PE can access the corresponding register for each PE. For example, when PE1 accesses the IPIOREQS register, PE1 can also access the IPIOREQ1 register.

Note 2. n = 0 to 3. n is the channel number of IPIR.

Note 3. m = 0 to 5. m is the PEID.

3.4.2.2 Self Region

The self region contains the following five types of registers.

- IPIInENS — IPIIn Inter-PE Interrupt Enable Self-Register
- IPIInFLGS — IPIIn Inter-PE Interrupt Flag Self-Register
- IPIInFCLRS — IPIIn Inter-PE Interrupt Clear Self-Register
- IPIInREQS — IPIIn Inter-PE Interrupt Request Self-Register
- IPIInRCLRS — IPIIn Inter-PE Interrupt Request Clear Self-Register

The self-registers are virtual registers that do not physically exist. Access from each PE to self-registers is routed to the actual register corresponding to the access source PE. **Table 3.141** lists the access source PEs and routing destination registers. For the functions of each register bit, refer to the specifications of the routing destination register. When the masters except PEx access the self-registers, the registers return 0_B, and write access is ignored.

It is basically assumed that the IPIIn registers are accessed from PEs via self region when PEs use the IPIIn function. This allows PEs to use the same code because it is not necessary to specify different register addresses for each PE.

It is also possible to directly access registers by specifying the address of the actual register without using the self-registers. In this case, the purpose is assumed to be to check the status of registers for another PE, or to reference the individual registers by a debugging tool.

Table 3.141 Self Region Register Routing List

Self Register	Access Source PE					
	PE0	PE1	PE2	PE3	PE4	PE5
IPIInENS	IPIInEN0	IPIInEN1	IPIInEN2	IPIInEN3	IPIInEN4	IPIInEN5
IPIInFLGS	IPIInFLG0	IPIInFLG1	IPIInFLG2	IPIInFLG3	IPIInFLG4	IPIInFLG5
IPIInFCLRS	IPIInFCLR0	IPIInFCLR1	IPIInFCLR2	IPIInFCLR3	IPIInFCLR4	IPIInFCLR5
IPIInREQS	IPIInREQ0	IPIInREQ1	IPIInREQ2	IPIInREQ3	IPIInREQ4	IPIInREQ5
IPIInRCLRS	IPIInRCLR0	IPIInRCLR1	IPIInRCLR2	IPIInRCLR3	IPIInRCLR4	IPIInRCLR5

3.4.2.3 IPIInENm — IPIRn Inter-PE Interrupt Enable Register m (n = 0 to 3)

The IPIRn Inter-PE Interrupt Enable Register m (IPIInENm) is an 8-bit read/write register that sets the transmitting PE allowed to issue inter-PE interrupt requests to PEm.

This register is used to enable inter-PE interrupt requests of PE (PE_x) by the receiving PE (PE_m) itself.

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0	
	—	—	EN						
Value after reset	0	0	0	0	0	0	0	0	
R/W	R	R	R/W	R/W	R/W	R/W	R/W	R/W	

Table 3.142 IPIInENm Register Contents

Bit Position	Bit Name	Function
7 to 6	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
5 to 0	EN	Inter-PE Interrupt Enable. Write 1 to the x-th bit to enable the issuance of inter-PE interrupt requests from PE _x to PE _m . Write 0 to the x-th bit to disable the issuance of inter-PE interrupt requests from PE _x to PE _m . Bit 0: PE0 Bit 1: PE1 : Bit 5: PE5

3.4.2.4 IPIInFLGm — IPIRn Inter-PE Interrupt Flag Register m (n = 0 to 3)

The IPIRn Inter-PE Interrupt Flag Register m (IPIInFLGm) is an 8-bit read only register that indicates the transmitting PE that issued an inter-PE interrupt request to PEm.

This register is used to distinguish the requesting PE by PEm when PEm has received an inter-PE interrupt request.

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0	
	—	—	FLG						
Value after reset	0	0	0	0	0	0	0	0	
R/W	R	R	R	R	R	R	R	R	

Table 3.143 IPIInFLGm Register Contents

Bit Position	Bit Name	Function
7 to 6	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
5 to 0	FLG	Inter-PE Interrupt Request Flag. This register indicates the status of Inter-PE Interrupt request from other PEs. The x-th bit is automatically updated according to the IPIInREQx[m] change while the value of the IPIInENm[x] bit is 1. The x-th bit is not set if IPIInENm[x] is 0, even if IPIInREQx[m] is set. The x-th bit is also cleared when the IPIInFCLRm[x] bit is set. Bit 0: PE0 Bit 1: PE1 : Bit 5: PE5

3.4.2.5 IPInFCLRm — IPIRn Inter-PE Interrupt Clear Register m (n = 0 to 3)

The Inter-PE Interrupt Clear Register m (IPInFCLRn) is an 8-bit write only register that clears inter-PE interrupt requests to PEm.

This register is used to clear the request flag by PEm after receiving the Inter-PE interrupt request from another PE.

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0	
	—	—	FCLR						
Value after reset	0	0	0	0	0	0	0	0	
R/W	R	R	W	W	W	W	W	W	

Table 3.144 IPInFCLRm Register Contents

Bit Position	Bit Name	Function
7 to 6	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
5 to 0	FCLR	Inter-PE Interrupt Request Flag Clear IPInFLGm[x] can be cleared by writing 1 to this bit. Writing 0 is ignored. Bit 0: PE0 Bit 1: PE1 : Bit 5: PE5

3.4.2.6 IPIInREQm — IPIRn Inter-PE Interrupt Request Register m (n = 0 to 3)

The Inter-PE Interrupt Request Register m is an 8-bit read/write register that controls Inter-PE interrupt request from PEm to other PEs.

Value after reset: 00H

Bit	7	6	5	4	3	2	1	0
	—	—	REQ					
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R/W	R/W	R/W	R/W	R/W	R/W

Table 3.145 IPIInREQm Register Contents

Bit Position	Bit Name	Function
7 to 6	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
5 to 0	REQ	<p>When 1 is written to the x-th bit while the value of the IPIInENx[m] bit is 1: The value of the x-th bit becomes 1. The high level is output to the inter-PE interrupt request for PEx, and IPIInFLGx[m] is automatically set to 1.</p> <p>When 1 is written to the x-th bit while the value of the IPIInENx[m] bit is 0: The value of the x-th bit becomes 1. There are no other operations.</p> <p>When 0 is written to the x-th bit: Writing 0 is ignored.</p> <p>When read: The register value is read out.</p> <p>Bit 0: PE0 Bit 1: PE1 : Bit 5: PE5</p>

3.4.2.7 IPIInRCLRm — IPIInR Inter-PE Interrupt Request Clear Register m (n = 0 to 3)

The Inter-PE Interrupt Request Clear Register m (IPIInRCLRm) is an 8-bit write only register that clears inter-PE interrupt requests for other PEs by PEm.

This register is assumed to be used to clear inter-PE interrupt requests that are set unintentionally while IPIInENm is 0.

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	RCLR					
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	W	W	W	W	W	W

Table 3.146 IPIInRCLRm Register Contents

Bit Position	Bit Name	Function
7 to 6	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
5 to 0	RCLR	Inter-PE Interrupt Request Clear Writing 1 to the x-th bit clears the IPIInREQm[x] bit. If the value of the IPIInENx[m] bit is 1, the IPIInFLGx[m] bit is also cleared at the same time. The transmitting PE allowed to issue inter-PE interrupt requests by the IPIInENm register can also cancel an inter-PE interrupt request by using this bit, but the receiving PE may in some cases accept the inter-PE interrupt request while the cancellation processing takes place. Writing 0 is ignored. This bit always returns 0 when read. Bit 0: PE0 Bit 1: PE1 : Bit 5: PE5

3.4.3 Inter-Processor Interrupts Function

E2UH has only PE0, PE1, PE2, PE3, PE4 and PE5, but this subsection includes examples of PE0 to PE7.

E2H has only PE0, PE1, PE2 and PE3, but this subsection includes examples of PE0 to PE7.

3.4.3.1 Initial Setting

Initial setting of authorized PEs by the IPIInENm register must be made before IPIR is used. An example of initial setting is given below.

(1) Initial Setting by Receiving PE

Figure 3.40 shows an example of the initial setting of IPIR channel 0 by PE1, which is a receiving PE. In this figure, bits PE4 to 7 of each register are omitted.

First, if IPIR has already been used and the values of bits IPIOREQ0 to 7[1] and the value of the IPIOFLG1 register have changed from the initial values, PE1 writes FF_H*1 to the IPIOFCLRS (= IPIOFCLR1) register to clear bits IPIOREQ0 to 7[1] and the IPIOFLG1 register. If the values of bits IPIOREQ0 to 7[1] and the IPIOFLG1 register are the initial values, for example after hardware reset, this clearing operation is not required.

Next, PE1 writes 01_H to the IPIOENS (= IPIOEN1) register to accept interrupt requests from PE0 to PE1. Like for the clear register, upon completion of setting of the enable register, PE1 can accept interrupt requests from PE0.

Note 1. As this product has only PE0 and PE1, PE1 writes 03_H to IPIOFCLRS register to clear.

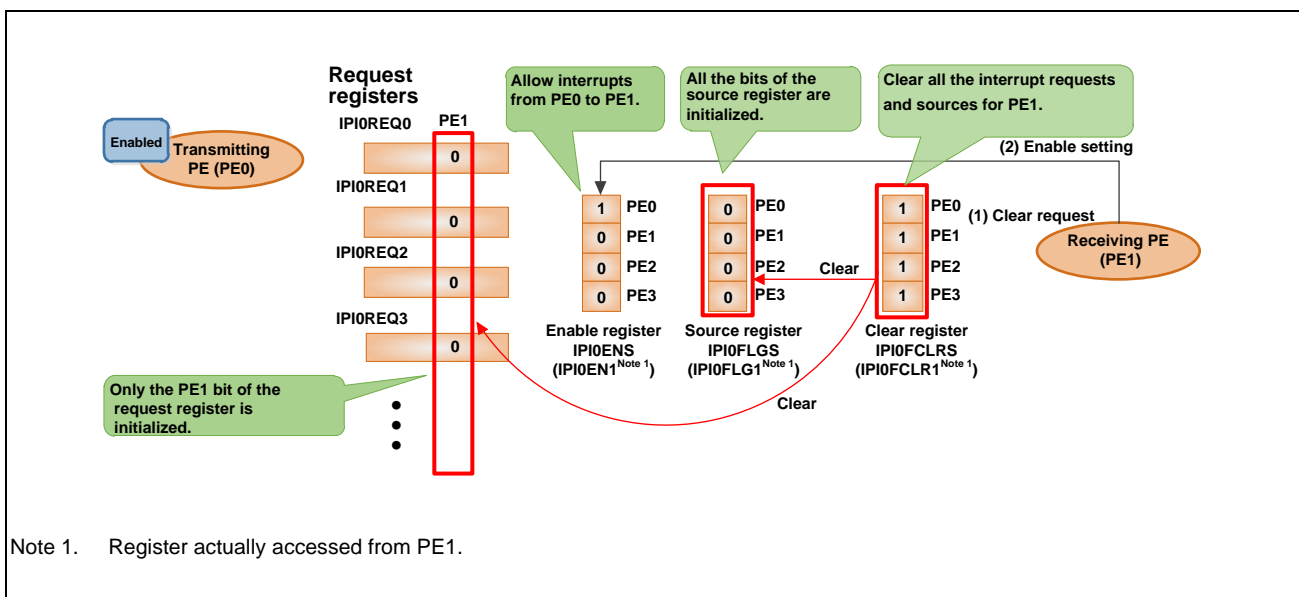

Figure 3.40 Example of Initial Setting of IPIR Channel 0 by Receiving PE (PE1)

(2) Initial Setting by Control PE

An example of initial setting from a PE other than a receiving PE is shown below. In this section, the PE that performs the initial setting is called the control PE for the sake of convenience. **Figure 3.41** shows an example of the initial setting of IPIR channel 0 by PE3, which is the control PE. In this figure, bits PE4 to 7 of each register are omitted.

First, if IPIR has already been used and the values of bits IPIOREQ0 to 7[1] and the value of the IPIOFLG1 register have changed from the initial values, PE3 writes FF_H to the IPIOFCLR1 register to clear bits IPIOREQ0 to 7[1] and the IPIOFLG1 register. If the values of bits IPIOREQ0 to 7[1] and the IPIOFLG1 register are the initial values, for example after hardware reset, this clearing operation is not required.

Next, PE3 writes 01_H to the IPIOEN1 register to accept interrupt requests from PE0 to PE1. Like for the clear register, upon completion of setting of the enable register, PE1 can accept interrupt requests from PE0.

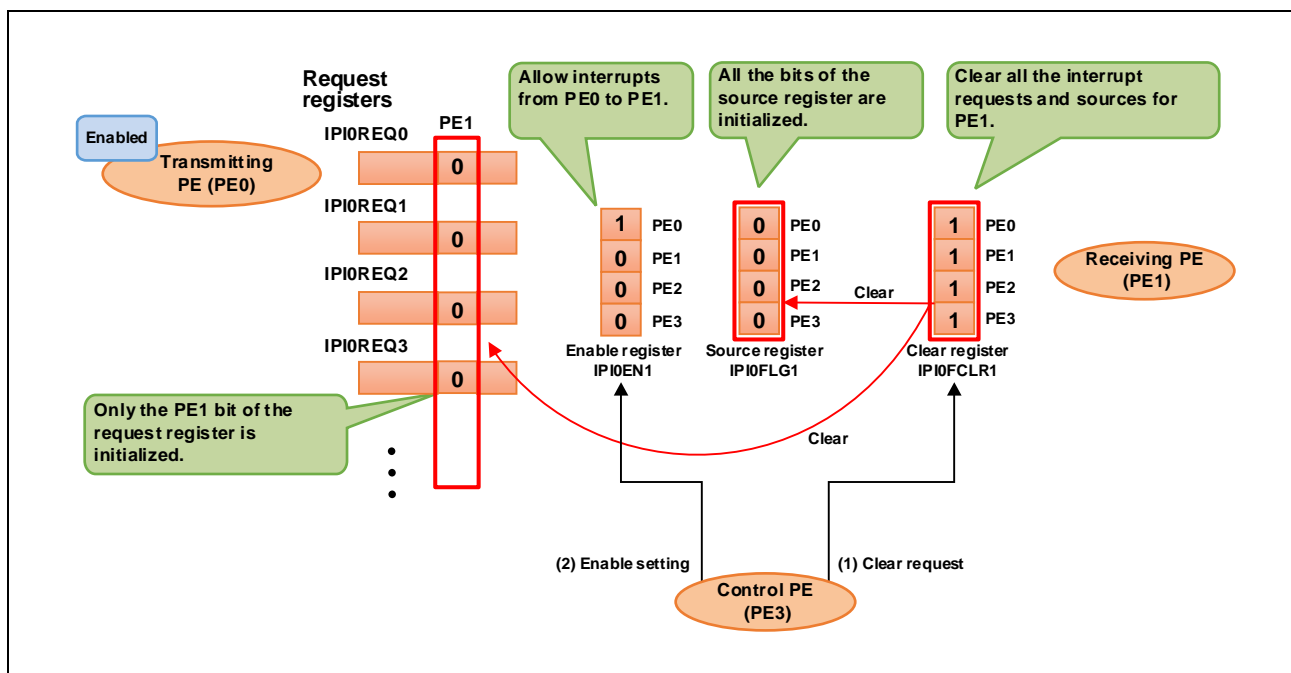

Figure 3.41 Example of Initial Configuration of IPIR Channel 0 by Control PE (PE3)

3.4.3.2 Inter-PE Interrupt Request

Figure 3.42 shows an example of the operation when PE0 sends an inter-PE interrupt request to PE1 using IPIR channel 0. In this figure, bits PE4 to 7 of each register are omitted. In this example, the initial setting is set to IPIOEN1 in advance to enable inter-PE interrupt requests from PE0. For an operation example of the initial setting, see **Section 3.4.3.1, Initial Setting**. The following describes an example of accessing the registers through the self-register.

First, PE0, which is the transmitting PE, reads the IPIOREQS (= IPIOREQ0) register and checks that the value of the IPIOREQS[1] (= IPIOREQ0[1]) bit is 0_B. If the value of the IPIOREQS[1] (= IPIOREQ0[1]) bit is 1_B, this means that the previous inter-PE interrupt request from PE0 to PE1 has not been accepted by PE1, and thus a new inter-PE interrupt request cannot be issued. If it is confirmed that the value of the IPIOREQS[1] (= IPIOREQ0[1]) bit is 0_B and thus an inter-PE interrupt request from PE0 to PE1 is enabled, PE0 sets the IPIOREQS[1] (= IPIOREQ0[1]) bit to 1_B to issue an inter-PE interrupt request from PE1. Because inter-PE interrupts from PE0 to PE1 are enabled by the IPIOEN1 register, when PE0 sets the IPIOREQS[1] (= IPIOREQ0[1]) bit to 1_B, the IPIOFLG1[1] bit is automatically set to 1_B, and an inter-PE interrupt request signal is output to PE1 from IPIR.

Figure 3.43 shows an example of the operation when PE1 receives an inter-PE interrupt request from PE0 using IPIR channel 0. When PE1, which is the receiving PE, receives an inter-PE interrupt signal, it reads the IPIOFLGS (= IPIOFLG1) register, and because the value of the IPIOFLGS[0] (= IPIOFLG1[0]) bit is 1_B, it recognizes that the inter-PE interrupt request has been sent from PE0. But if the request side clears the request, the value of it is 0_B. After verifying the source of the inter-PE interrupt, PE1 sets the IPIOFCLRS[0] (= IPIOFCLR1[0]) bit to 1_B, and the processing transitions to the inter-PE interrupt processing. The IPIOREQS[1] (= IPIOREQ0[1]) bit and the IPIOFLGS (= IPIOFLG1) bit are automatically cleared when the IPIOFCLRS[0] (= IPIOFCLR1[0]) bit is set to 1_B by PE1.

Figure 3.44 shows the operation flow from initial setting of IPIR by the receiving PE (PE1), to sending of an inter-PE interrupt request by the transmitting PE (PE1), and completion of reception of that inter-PE interrupt request by the receiving PE (PE1).

Note that if a new inter-PE interrupt request is generated to the same receiving PE before the source register is cleared by the receiving PE with the clear register, the bit corresponding to the new transmitting PE in the source register will be set to 1_B, but the inter-PE interrupt request signal being retained high, the second and subsequent inter-PE interrupt requests will not be output. Therefore, the processing when multiple sources occur when the receiving PE has received an inter-PE interrupt request must be controlled by software.

The transmitting PE can detect whether the preceding inter-PE interrupt request was successfully received by the receiving PE, by checking the value of the request register. To monitor the request register with a polling loop, it is recommended to curb the bus load by executing the snooze instruction within the polling loop in order to avoid the bus system occupation for extended periods of time.

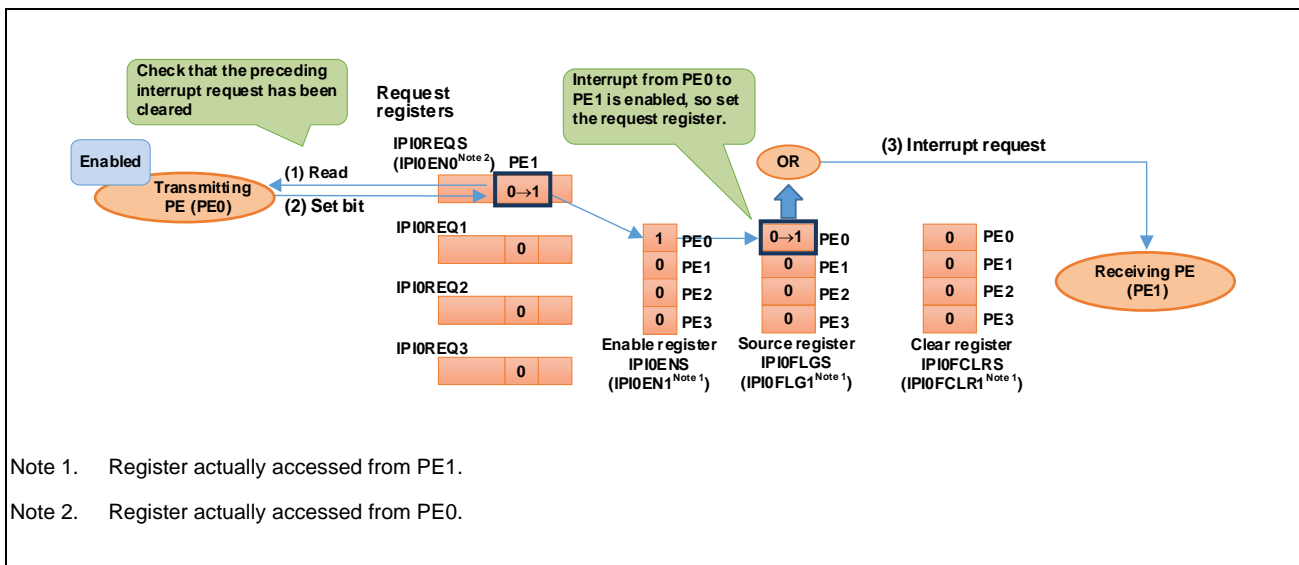

Figure 3.42 Example of Inter-PE Interrupt Transmission Operation

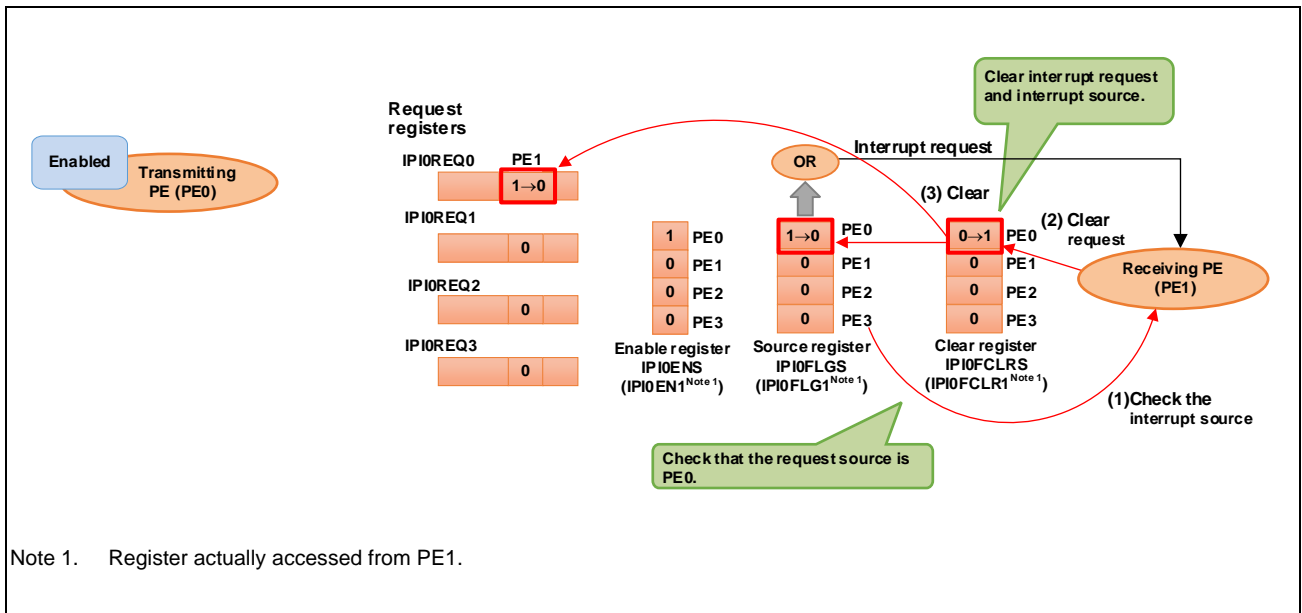

Figure 3.43 Example of Inter-PE Interrupt Reception Operation

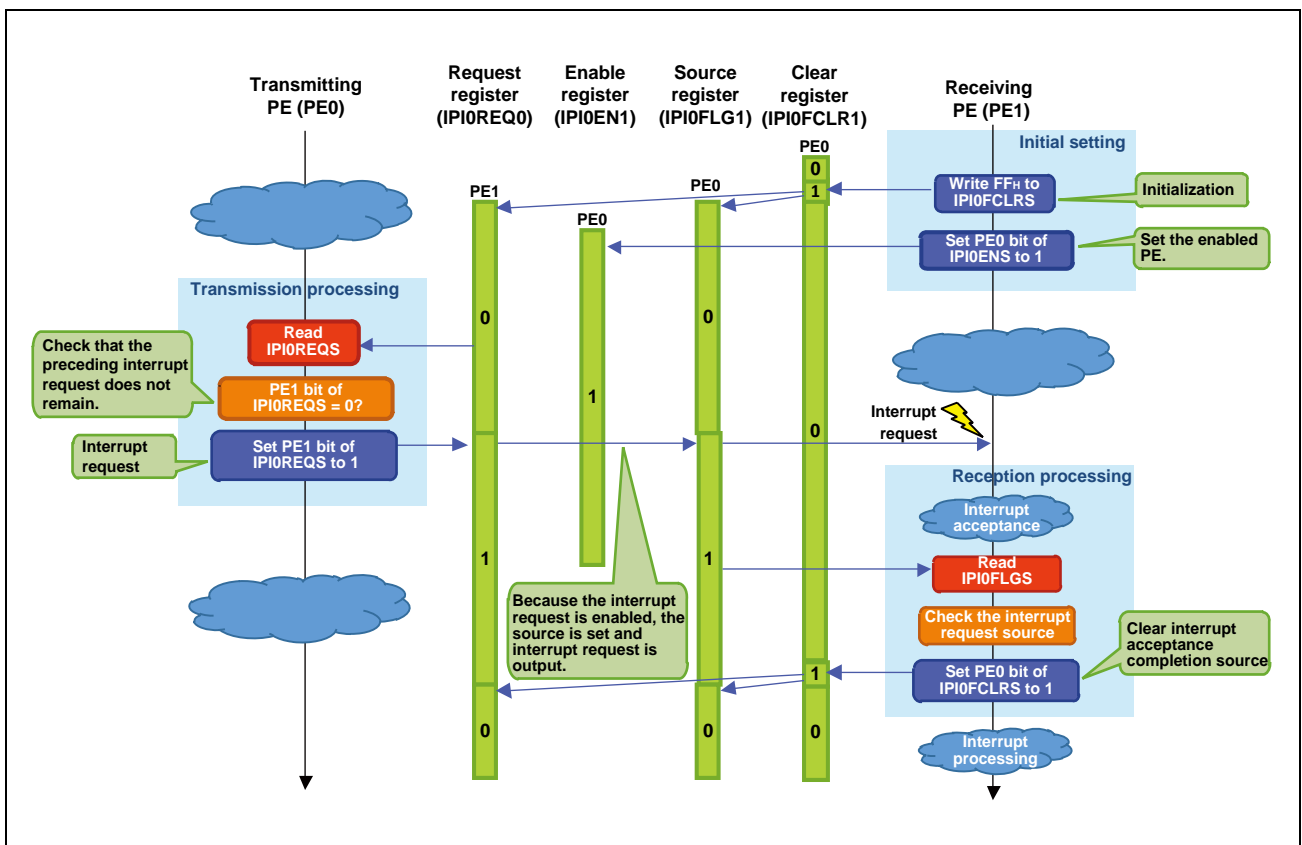

Figure 3.44 Operation Flow of Inter-PE Interrupt

(1) Sample Code**(a) Transmission Processing**

Figure 3.45 shows a sample flowchart of the inter-PE interrupt request transmission processing using IPIR channel 0.

Figure 3.45 Flowchart of Inter-PE Interrupt Request Transmission Processing

(b) Reception Processing

Figure 3.46 shows a sample flowchart of the inter-PE interrupt request reception processing using IPIR channel 0. To prevent source flag loss, the source flag & source clear register configuration is used.

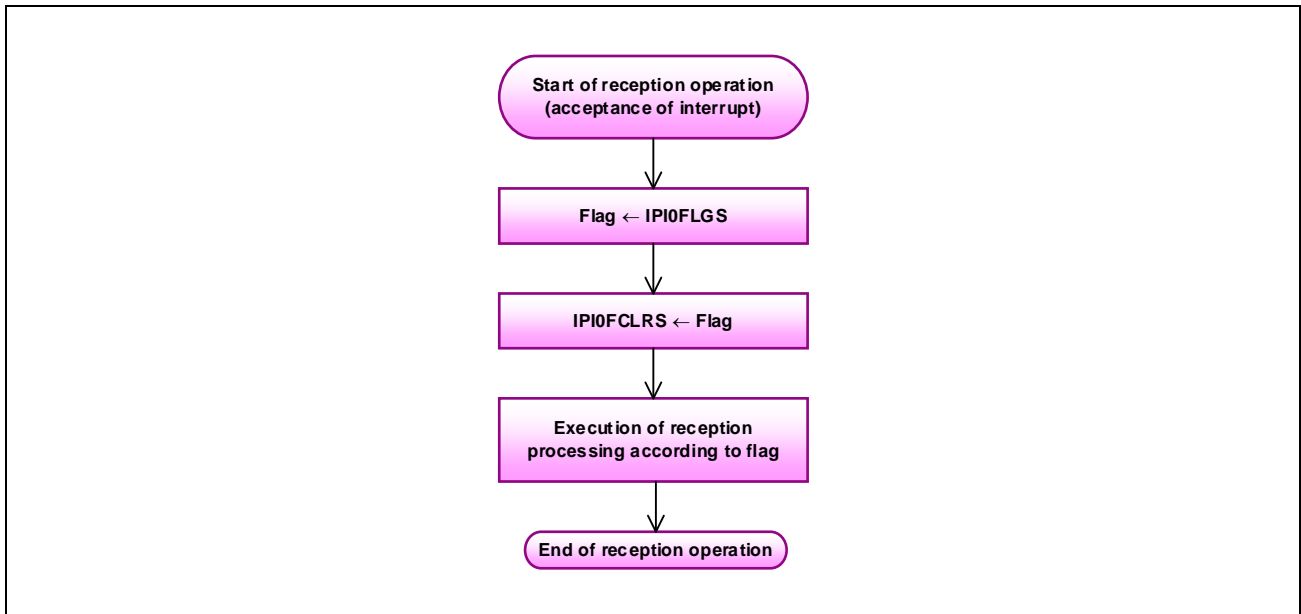

Figure 3.46 Flowchart of Inter-PE Interrupt Request Transmission Processing

3.4.3.3 Request Mask Function

Inter-PE interrupt requests disabled by the $IPInENm$ register setting are ignored. **Figure 3.47** shows an example of the operation when an inter-PE interrupt is requested from a disabled PE. In this figure, bits PE4 to 7 of each register are omitted. In this example, the initial setting is set to $IPIOEN1$ in advance to prohibit inter-PE interrupt requests from PE2 to PE1. For an operation example of the initial setting, see **Section 3.4.3.1, Initial Setting**.

Even if PE2 sets $IPIOREQS[1]$ (= $IPIOREQ2[1]$) to 1_B to request PE1 to issue an inter-PE interrupt, inter-PE interrupts from PE2 to PE1 are prohibited, so the $IPInFLG1[2]$ bit remains 0_B and no interrupt request signal is output.

If the transmitting PE disabled by the $IPInENm$ register setting unintentionally writes 1_B to the $IPIOREQm$ register, the $IPIOREQm$ register can be cleared by using the $IPInRCLRm$ register. For details, see **Section 3.4.3.5, Inter-PE Interrupt Request Clear Function**.

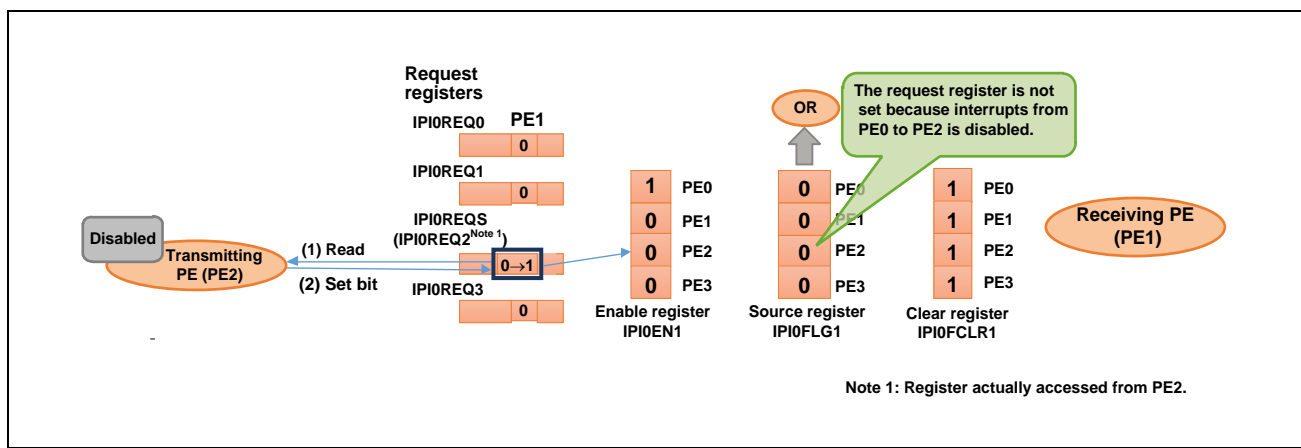

Figure 3.47 Request Mask Operation Example

3.4.3.4 Inter-PE Interrupt Requests of Multiple Systems

If the combination of the transmitting PE and receiving PE differs, multiple inter-PE interrupt requests can be output simultaneously on one channel of IPIR. For example it is possible to output inter-PE interrupt request A (PE0 to PE1) and inter-PE interrupt request B (PE1 to PE0) on channel 1 of IPIR simultaneously. Each register operates independently when the combination of the transmitting PE and receiving PE differs, so multiple inter-PE interrupt requests can be output simultaneously.

3.4.3.5 Inter-PE Interrupt Request Clear Function

The IPIInREQm[x] bit can be cleared by setting the IPIInRCLRm[x] bit to 1_B, allowing you to cancel inter-PE interrupt requests from the transmitting PE. If inter-PE interrupt requests from the transmitting PE are enabled by the IPIInENx[m] bit, the IPIInFLGx[m] bit is also cleared at the same time as the IPIInREQm[x] bit is cleared. However, the receiving PE may in some cases accept the inter-PE interrupt while the cancellation processing takes place.

Figure 3.48 shows an example of the operation to clear inter-PE interrupt requests from PE0 and PE2 to PE1. When PE0 writes 1_B to the IPIORCLRS[1] (= IPIORCLR0[1]) bit, the IPIOREQ0[1] bit is cleared. Moreover, because inter-PE interrupt requests from PE0 to PE1 are enabled by the IPIOEN1 register setting, IPIOFLG1[0] is also cleared.

When PE2 writes 1_B to the IPIORCLRS[1] (= IPIORCLR2[1]) bit, the IPIOREQ2[1] bit is cleared. Here, inter-PE interrupt requests from PE2 to PE1 are disabled by the IPIOEN1 register setting, so the IPIORCLR2 register does not affect the value of the IPIOFLG1 register.

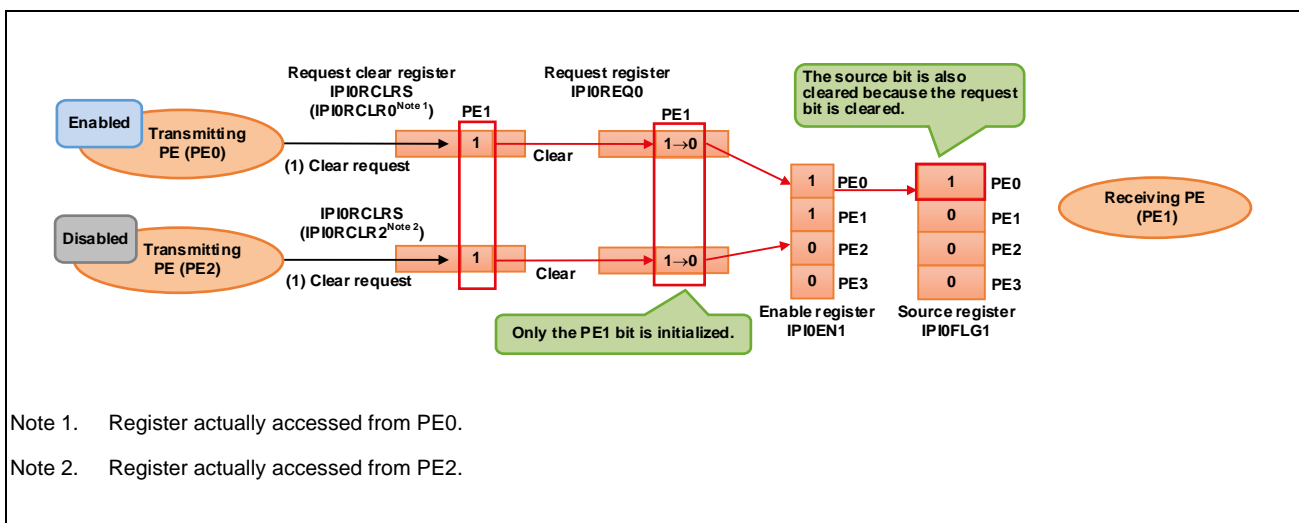

Figure 3.48 Example of Inter-PE Interrupt Request Clear Function Operation

3.5 Mutual Exclusion

This CPU provides instructions that enable shared resources to be controlled mutually exclusively from multiple programs when the system is operating in a multi- processing environment.

When using mutual exclusion, mutual exclusion variables have to be defined in the memory and all programs must operate in accordance with the appropriate instruction flow.

CAUTION

Embedded CPUs in a single-processor configuration use a programming model in which data coherence is maintained by disabling the acknowledgment of maskable interrupts. This is a very easy and sure method of maintaining data coherence, but naturally in a multi-processor, multiple programs might be executing and attempting to use the data at the same time. In this case it is not possible to maintain data coherence simply by disabling maskable interrupt acknowledgment.

3.5.1 Mutual Exclusion Overview

The local RAM, cluster RAM, and the mutual exclusion variable register (MEV) are available as resources for exclusive control. As atomic operation instructions, the instructions of LDL/STC, CAXI, SET1, CLR1, and NOT1 can be performed for the local RAM and cluster RAM, and the instructions of CAXI, SET1, CLR1, and NOT1 can be performed for the mutual exclusion variable register (MEV). These registers are also accessible by the LD and ST instructions but are not regarded as atomic operation.

These MEV registers support exclusive control for variables shared between PEs (common resources).

- Thirty-two 32-bit MEV registers are included.
- 1-, 8-, 16-, and 32-bit accesses are available for each MEV.
- Accesses from all CPU can be made.
- Atomic operation instructions of CAXI, SET1, CLR1, and NOT1 can be performed.

3.5.2 Mutual Exclusion Registers

3.5.2.1 List of Registers

Table 3.147 List of Registers

Module Name	Symbol	Register Name	Address	Access	Access Protection

3.5.2.2 G0MEVn — Mutual Exclusion Variable Register n (n = 0 to 31)

The Mutual Exclusive variable Register n (G0MEVn) is a 32-bit read/write register that can be used as a mutual exclusive resource.

Value after reset: 0000 0000_H

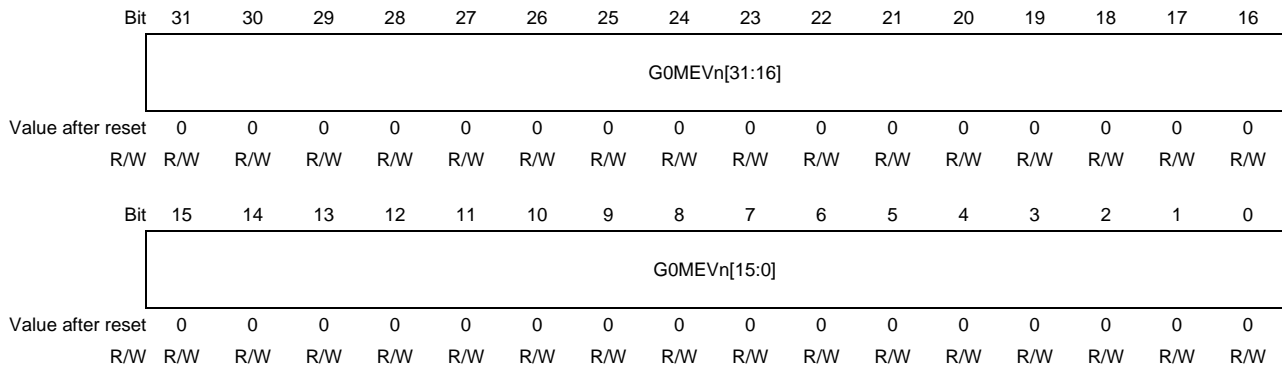

Table 3.148 G0MEVn Register Contents

Bit Position	Bit Name	Function
31 to 0	G0MEVn[31:0]	Mutual Exclusive Variable. These bits can be read and written from all PEs.

3.5.3 Mutual Exclusion Function

3.5.3.1 Operation Example Using Mutual Exclusion Variable Register (MEV)

An example of a flow chart that does mutual exclusion of a shared resource by spin lock with MEV is given in the following figure. When the value of MEV is 1_B in this example, a shared resource shows that it is lock status. It is recommended that reading or writing to MEV be carried out by atomic operation because MEV itself is also a shared resource.

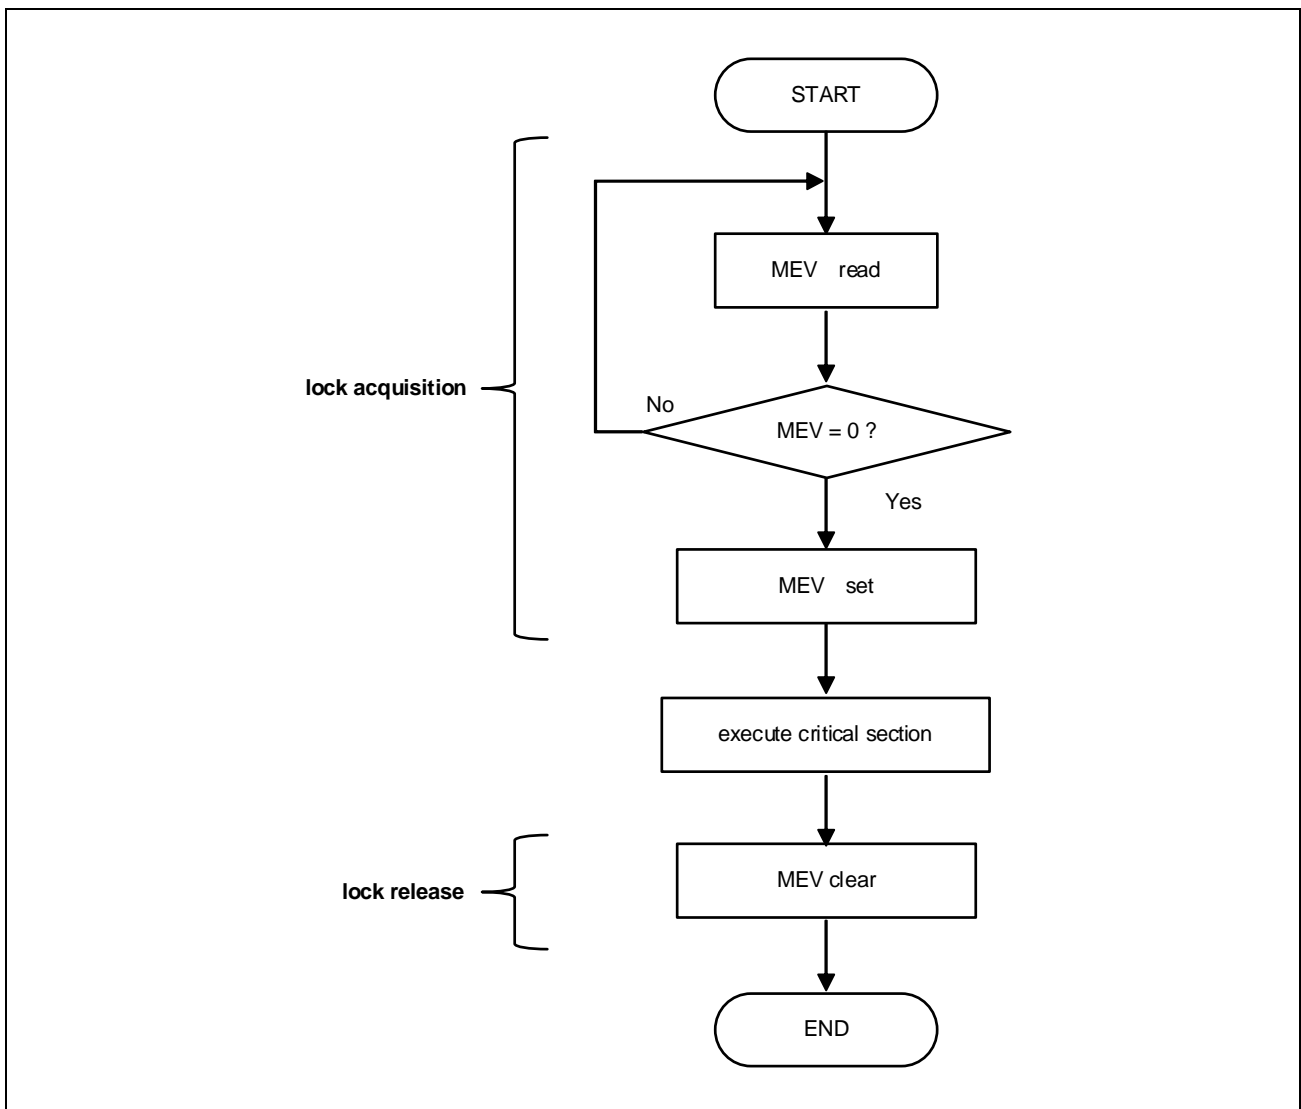

Figure 3.49 Spin Lock Examples of Lock Step Using MEV

A CAXI operation can be used for atomic operation which extends over more than one data column in G4MH. The sample code which does lock acquisition/release using MEV below is indicated. “lock_adr” is equivalent to the address of MEV by this example.

Lock Acquisition

```
MOV    lock_adr, r20
Lock:  MOV    1, r21
      CAXI   [r20], r0, r21
      BZ    Lock_succes
      SNOOZE
      BR    Lock
Lock_succes:
```

Lock Release

```
MOV    lock_adr, r20
ST.W   r0, 0[r20]
```

Figure 3.50 shows an operation example that does mutual exclusion of a shared resource between PE0 and PE1. The lock status of a shared resource is indicated by the value of MEV that corresponds to each PE, and MEV has lock status at 1_B by this example.

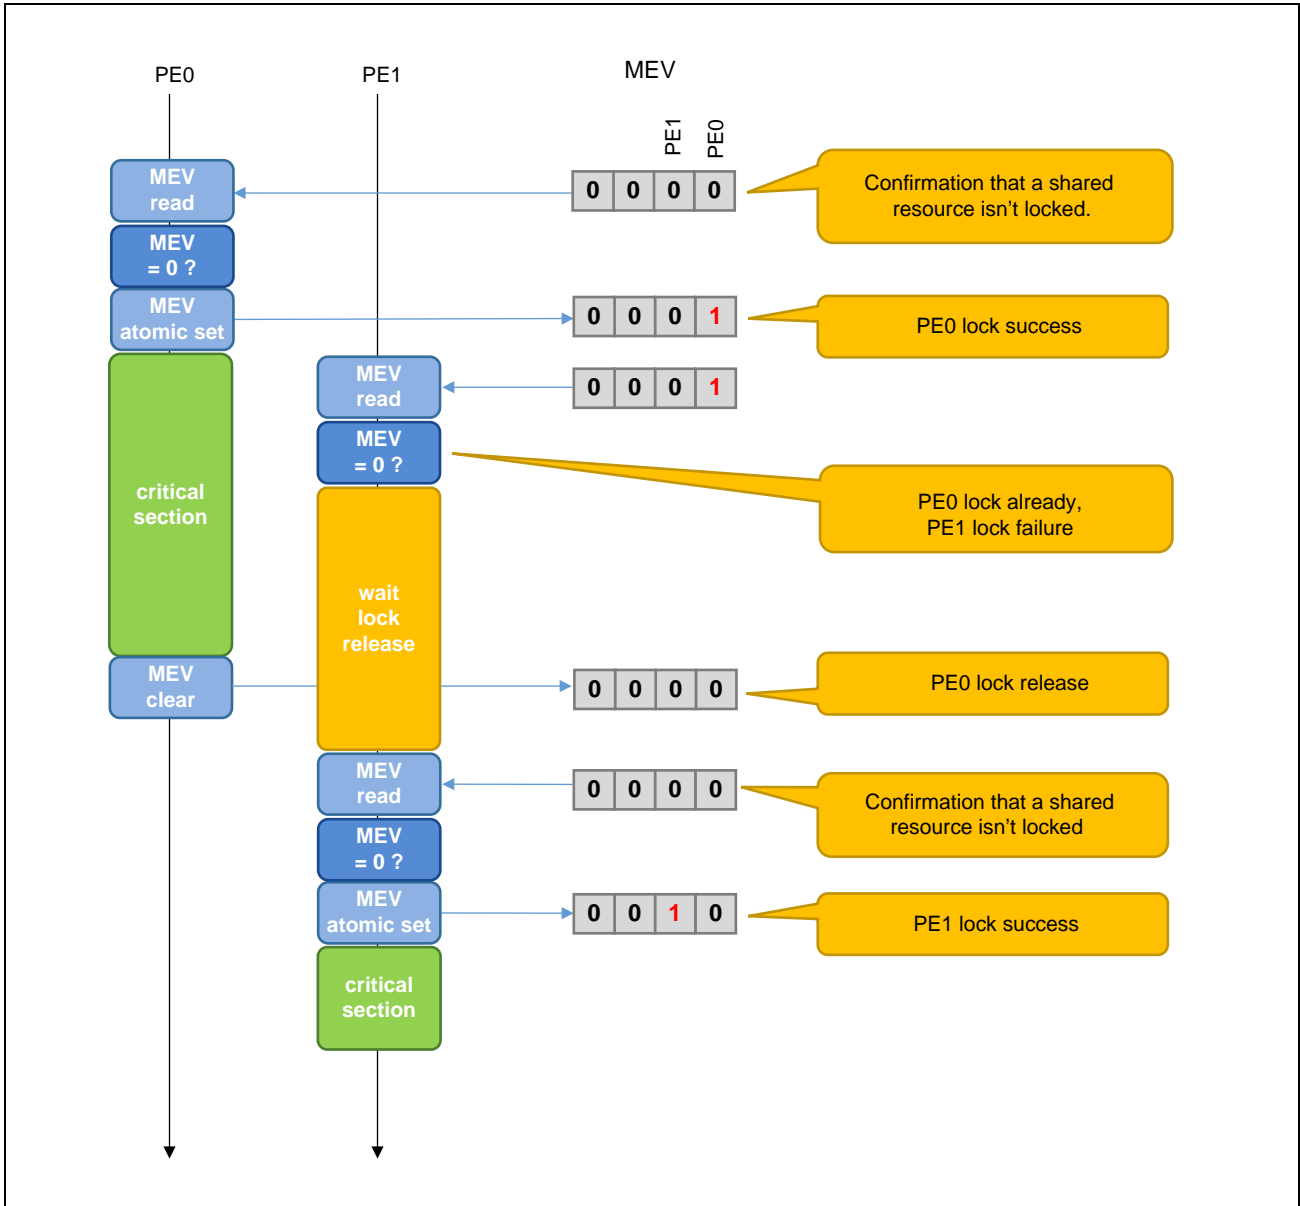

Figure 3.50 MEV Usage Sample

3.5.3.2 Shared Data that does not Require Mutual Exclusion Processing

This CPU maintains data access coherence for the following types of data access even in a multi-processor environment.

- Access in which the data is aligned to the size that matches the data type (aligned access)
 - LD, ST, SLD, SST, LDL, STC, and bit manipulation instructions (TST1)
- Access by using a bit manipulation instruction (SET1, CLR1, or NOT1) (read-modify-write)
- Access by using the CAXI instruction (read-modify-write)

NOTE

Whether an instruction is atomically executed or not depends on the data format. Please refer to **Section 3.2.2.6, Data Types**.

With some exceptions, mutual exclusion is achieved by using these types of data access. In other words, it is guaranteed that while one CPU is executing the instructions that perform the above data accesses, another CPU is not accessing the data. This is known as an instruction being executed atomically or an instruction guaranteeing the atomicity.

Note that the atomic execution of an instruction means that a data access bus transaction completes with no disruption; it does not necessarily mean that a series of transactions has been completed

CAUTION

The extent to which coherency is guaranteed might be limited, depending on the hardware specifications. For example, for some memories, coherency might not be guaranteed even if aligned access is used. For details, see **Section 3.5.1, Mutual Exclusion Overview** and **Section 3.8.3, Accesses to Registers by Bit-Manipulation Instructions**.

3.5.3.3 Operation of the LDL and STC Instructions

The LDL and STC instructions can be used to obtain atomic read-modify-write operations for accurate processing in the updating of memory by multicore systems. The LDL and STC instructions operate as follows. For the operation of the LDL and STC instructions, refer to the RH850G4MH User's Manual: Software.

(1) Link

Only one link (LLbit) can be created per CPU. The link includes information on the address for which it was created, and control is applied according to whether an STC instruction succeeds or fails at this address and whether the link is lost. The link also includes the data size information when it the link is created and therefore any STC instruction which has a data size different from that of the LDL instruction that created a link always fails, and the link is deleted.

(2) Link generation

Each CPU is capable of generating a link to the local RAM and the cluster RAM. Executing the LDL instruction on the target RAM for the operation leads to the link address being registered, the link flag being set, and a link being generated in response to reading by the instruction.

- (a) The local RAM for the given processor
- (b) The cluster RAM

Each CPU is capable of generating a link to either (a) or (b).

(3) Success in storing

After a link has been generated, storing will only proceed in response to executing an STC instruction corresponding to the generated link.

(4) Failure in storing

If a link is lost, storing does not proceed even when an STC instruction for the corresponding address is processed. Storing also does not proceed when an STC instruction that does not correspond to the link is processed.

(5) Condition for successful storing

If the following condition is met, the STC instruction is judged to be for the address corresponding to the link.

- The address and size for the LDL instruction that generated the link matches that for the STC instruction.

(6) Loss of the link

A link is lost when certain event or address conditions are satisfied. **Table 3.149** shows the link loss conditions. A link is lost if any of the conditions shown in this table satisfied.

Table 3.149 Link Loss Conditions

Event Condition	Remark
Store operation to a 32-byte-aligned address range that includes the address of the existing link*1	The following operations by both the CPU for which the link was generated and another bus master (e.g. CPU) correspond. <ul style="list-style-type: none"> • ST, SST, STC, and STV instructions • SET1, NOT1, CLR1, and CAXI instructions • PREPARE and PUSHSP instructions
Execution of STC instruction for a location corresponding to the existing link within its own CPU	The corresponding link (for (1) or (2) above) will be lost whether the result of the instruction was success or fail.
Execution of LDL instruction for a location corresponding to the existing link within its own CPU	The link generated by a CPU in response to the its preceding LDL instruction will be lost, and the link in response to the following LDL instruction is generated.
Execution of CLL instruction	
Exception acknowledgment	
Execution of EIRET instruction	
Execution of FERET instruction	
Bus access error of LDL	

Note 1. In the local RAM, if the store instruction except STC/CAXI instruction is executed, the Link is not always lost. Therefore, use the program flow which does not need that these instructions cause the Link Loss. For example, in the sample code (7), after reading the Lock variable using the LDL instruction, by executing the STC instruction only if nobody has the Lock, the program flow does not need the Link Loss caused by the store instruction for the Lock Release.

(7) Sample Code

The sample code of a spinlock executed by using the LDL.W and STC.W instructions is shown below.

Lock Acquisition

```

        MOV        lock_adr, r20
Lock:   LDL.W     [r20], r21
        CMP        r0, r21
        BNZ       Lock_wait
        MOV        1, r21
        STC.W     r21, [r20]
        CMP        r0, r21
        BNZ       Lock_success
Lock_wait:
        SNOOZE
        BR        Lock
Lock_success:

```

Lock Release

```

        ST.W     r0, 0[r20]

```

3.5.3.4 Performing Mutual Exclusion by Using the SET1 Instruction

The SET1 instruction can be used to perform mutual exclusion over multiple data arrays. By executing the SET1 instruction on the same bit in the memory and then checking the PSW.Z flag, which indicates the execution result, it can be determined whether lock acquisition succeeded or failed.

CAUTIONS

1. Depending on the hardware specifications, the system performance might drop if exclusive control is executed frequently by using the SET1 instruction, because this causes the bus to be occupied for a long time. It is therefore recommended to execute exclusive control by using the LDL/STC instructions as much as possible.
2. When performing mutual exclusion by using the SET1 instruction, to prevent the problem of excessive bus occupancy described in Caution 1 above, execute the SNOOZE instruction before attempting to acquire a lock again after lock acquisition has failed, and adjust the lock acquisition loop execution interval.

(1) Sample Code

The sample code of a spinlock executed by using the SET1 instruction is shown below.

Lock Acquisition

```
        MOV        lock_adr, r20
Lock:   SET1       0, 0[r20]
        BZ         Lock_success
        SNOOZE
        BR         Lock
Lock_success:
```

Lock Release

```
        CLR1      0, 0[r20]
```

3.5.3.5 Performing Mutual Exclusion by Using the CAXI Instruction

The CAXI instruction can be used to perform mutual exclusion over multiple data arrays. By executing the CAXI instruction on the same word in the memory and then checking the destination register, it can be determined whether lock acquisition succeeded or failed.

CAUTIONS

1. Depending on the hardware specifications, the system performance might drop if exclusive control is executed frequently by using the CAXI instruction, because this causes the bus to be occupied for a long time. It is therefore recommended to execute exclusive control by using the LDL/STC instructions as much as possible.
2. When performing mutual exclusion by using the CAXI instruction, to prevent the problem of excessive bus occupancy described in Caution 1 above, execute the SNOOZE instruction before attempting to acquire a lock again after lock acquisition has failed, and adjust the lock acquisition loop execution interval.

(1) Sample Code

The sample code of a spinlock executed by using the CAXI instruction is shown below.

Lock Acquisition

```

MOV      lock_adr, r20
Lock:    MOV      1, r21
         CAXI    [r20], r0, r21
         BZ     Lock_success
         SNOOZE
         BR     Lock
Lock_success:

```

Lock Release

```

ST.W    r0, 0[r20]

```

3.6 Barrier-Synchronization

3.6.1 Barrier-Synchronization Overview

When parallel processing is performed using a multicore processor, it may be necessary to make the cores wait until the data required for the next processing is ready, at which point the processing can proceed to the next processing.

Typically, control that sets up a barrier that prevents the next process from starting before all the applicable cores complete the predetermined processing is called barrier synchronization. It is possible to implement barrier synchronization just using software, but this may degrade system processing performance due to the concentration of barrier arrival notifications from the various cores and memory access from the various cores for verification purposes.

Barrier synchronization registers enable easy barrier synchronization by detecting whether all the applicable cores have completed the required processing through the reception of completion notifications from the various PEs, while also providing a barrier synchronization support function that automatically clears completion notifications from the various PEs in preparation for the next barrier synchronization. This function makes it possible to reduce the number of memory accesses for barrier synchronization, thereby minimizing the negative impact of barrier synchronization on processing performance. This function can also be used for barrier synchronization between PEs forming a cluster.

The barrier synchronization register has the following features.

- The 16-ch barrier synchronization registers are provided.
- Barrier synchronization can be implemented using the same code for all the cores.
- Accessible from all clusters and all PEs within the system

3.6.2 Barrier-Synchronization Registers

3.6.2.1 List of Registers

Table 3.150 List of Registers

Module Name	Register Name	Register Symbol	Address	Access	Access Protection
BARR	Barrier-Synchronization n*2 Barrier Participating PE Setting Register	BRnEN	<BARR_base> + 004 _H + 010 _H × n	8	—
	Barrier-Synchronization n*2 Initialization Register	BRnINIT	<BARR_base> + 000 _H + 010 _H × n	8	—
	Barrier-Synchronization n*2 Barrier Check Register Self*1	BRnCHKS	<BARR_base> + 100 _H + 010 _H × n	8	—
	Barrier-Synchronization n*2 Barrier Synchronization Completion Register Self*1	BRnSYNCS	<BARR_base> + 104 _H + 010 _H × n	8	—
	Barrier-Synchronization n*2 Barrier Check Register m*3	BRnCHKm	<BARR_base> + 800 _H + 010 _H × n + 100 _H × m	8	—
	Barrier-Synchronization n*2 Barrier Synchronization Completion Register m*3	BRnSYNCSm	<BARR_base> + 804 _H + 010 _H × n + 100 _H × m	8	—

Note 1. When PE accesses the self register, PE can access the corresponding register for each PE. For example, when PE1 accesses BR0CHKS register, PE1 can access BR0CHK1 register.

Note 2. n = 0 to 15. n is the Barrier-Synchronization channel number.

Note 3. m = 0 to 5. m is the value of PEID.

3.6.2.2 Self Region

The self region contains the following two types of registers.

- BRnCHKS — Barrier-Synchronization n - Barrier Check Self-Register
- BRnSYNCS — Barrier-Synchronization n – Barrier Synchronization Completion Self-Register

The self registers are virtual registers that do not physically exist. Access from each PE to self registers is routed to the actual register corresponding to the access source PE. **Table 3.151** lists the access source PEs and routing destination registers. For the functions of each register bit, refer to the specifications of the routing destination register. When masters except PEx access the self registers, the register returns 0, and write access is ignored.

It is basically assumed that the barrier synchronization registers are accessed from PEs via self region when PEs use the barrier synchronization function. This allows PEs to use same code because it is not necessary to specify different register address for each PE.

It is also possible to directly access registers by specifying the address of the actual register without using the self register. In this case, the purpose is assumed to check the status of registers for another PE, or referencing of individual registers by a debugging tool.

Table 3.151 Self Region Register Routing List

Self Register	Access Source PE					
	PE0	PE1	PE2	PE3	PE4	PE5
BRnCHKS	BRnCHK0	BRnCHK1	BRnCHK2	BRnCHK3	BRnCHK4	BRnCHK5
BRnSYNCS	BRnSYNCS0	BRnSYNCS1	BRnSYNCS2	BRnSYNCS3	BRnSYNCS4	BRnSYNCS5

3.6.2.3 BRnINIT — Barrier-Synchronization n Initialization Register

The Barrier-Synchronization n Initialization Register (BRnINIT) is an 8-bit write only register that initializes the Barrier-Synchronization channel n (n = 0 to 15). This register clears the BRnCHKm register and BRnSYNCm register of channel n.

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	BRINIT
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	W

Table 3.152 BRnINIT Register Contents

Bit Position	Bit Name	Function
7 to 1	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
0	BRINIT	Barrier-Synchronization n initialize Writing 1 to this bit clears registers BRnCHK0 to 5 and registers BRnSYNC0 to 5 of the same channel. This bit always returns 0 when read.

3.6.2.4 BRnEN — Barrier-Synchronization n Barrier Participating PE Setting Register

The Barrier-Synchronization n Barrier Participating PE Setting Register (BRnEN) is an 8-bit read/write register that enables Barrier-Synchronization Participation in channel n for PEs.

Value after reset: 00H

Bit	7	6	5	4	3	2	1	0	
	—	—	BREN[5:0]						
Value after reset	0	0	0	0	0	0	0	0	
R/W	R	R	R/W	R/W	R/W	R/W	R/W	R/W	

Table 3.153 BRnEN Register Contents

Bit Position	Bit Name	Function
7 to 6	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
5 to 0	BREN[5:0]	Barrier-Synchronization Participation enable for channel n Writing 1 to the x-th bit enables the barrier synchronization support function for PEx. Writing 0 to the x-th bit disables the barrier synchronization support function for PEx. Bit 0: PE0 Bit 1: PE1 : Bit 5: PE5

3.6.2.5 BRnCHKm — Barrier-Synchronization n Barrier Check Register m

The Barrier-Synchronization n Barrier Check Register (BRnCHKm) is an 8-bit read/write register that is used for PEm to notify that PEm has arrived at the barrier of channel n. The PE that has arrived at the barrier is to write the BRCHK bit of this register.

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	BRCHK
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R/W

Table 3.154 BRnCHKm Register Contents

Bit Position	Bit Name	Function
7 to 1	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
0	BRCHK	Barrier Check Bit of channel n This bit can be updated by both software and hardware. Software: When the BRnCHKm register is written, the value of this bit becoming 1 regardless of the writing value. This bit can be set even if the BRnEN.BRENm bit is 0, but it does not affect the barrier - synchronization of channel n. Hardware: This bit is cleared by the hardware when the barrier-synchronization is established at the condition that all the BRnCHKm.BRCHK bits of participating PEs, which are enabled by the BRnEN register, are set. At the same time, the BRnSYNCm.BRSYNC bits of all participating PEs are set. This bit is cleared by writing 1 to the BRnINIT.BRINIT bit.

NOTE

If all bits of the BRnEN register are 0 (no PE participates the barrier synchronization), BRCHK bit cannot be set.

3.6.2.6 BRnSYNCm — Barrier-Synchronization n Barrier Synchronization Completion Register m

The Barrier-Synchronization n Barrier Synchronization Completion Register is an 8-bit read/write register that indicates that all the PEs that participate in the barrier of channel n have arrived at the barrier of channel n.

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	BRSYNC
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R/W

Table 3.155 BRnSYNCm Register Contents

Bit Position	Bit Name	Function
7 to 1	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
0	BRSYNC	Barrier synchronization completion This bit can be updated by both software and hardware. Software: When the BRnSYNCm register is written, this bit is updated with the write data. Hardware: If the BRnEN.BRENm bit is 1, this bit is automatically set when the barrier-synchronization is established at the condition that all the BRnCHKm.BRCHK bits of participating PEs, which are enabled by the BRnEN register, are set. If the BRnEN.BRENm bit is 0, this bit is not updated by the hardware. This bit is cleared by writing 1 to the BRnINIT.BRINIT bit.

3.6.3 Barrier-Synchronization Function

E2UH has PE0, PE1, PE2, PE3, PE4 and PE5, but this subsection show examples with PE0 to PE3.

E2H has PE0, PE1, PE2 and PE3, but this subsection show examples with PE0 to PE3.

3.6.3.1 Initial Setting

Before the barrier synchronization register is used, initial settings must be made in the BRnEN register. **Figure 3.51** shows an example of the initial setting of synchronization register channel 0 by PE0.

First, to clear the setting of the previous operation, the BR0EN register is cleared by write operation. After clearing of the BR0EN register, write 07_H to the BR0EN register to participate PE0, PE1 and PE2 in barrier synchronization. Lastly, PE0 writes 1_B to the BR0INIT register to clear registers BR0CHK0 to 3 and registers BR0SYNC0 to 3. Upon completion of setting of the participating PE setting register and initialization, barrier synchronization using the barrier synchronization register is possible.

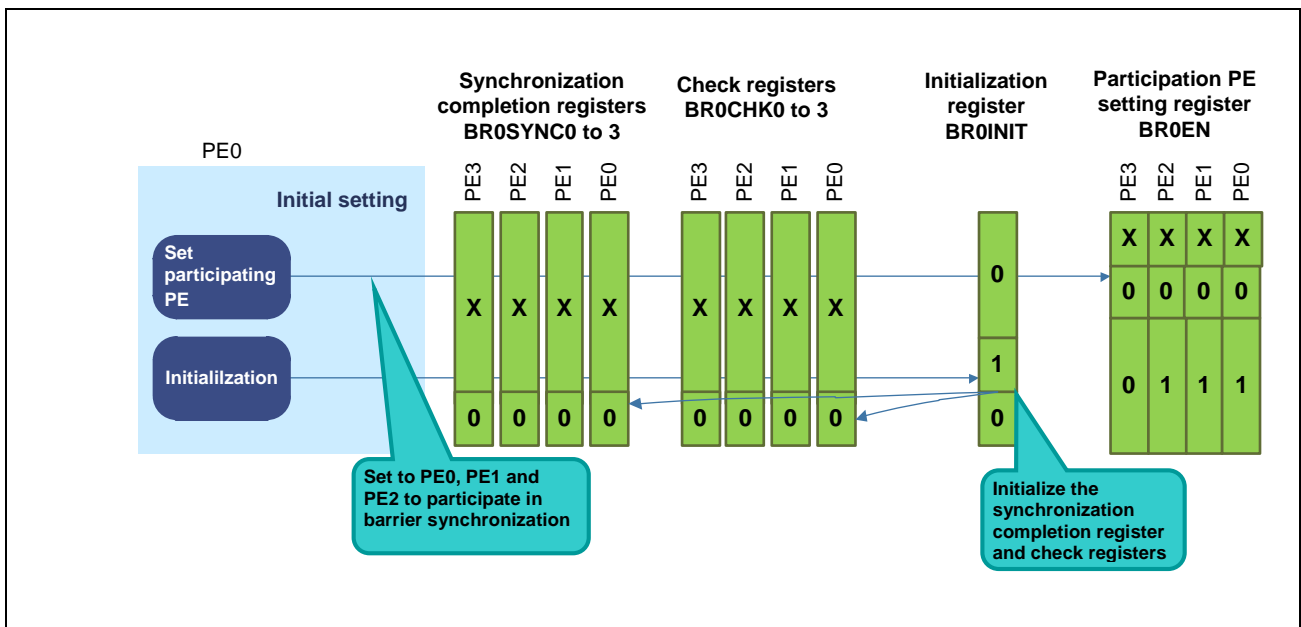

Figure 3.51 Example of Initial Setting of Barrier Synchronization Register

3.6.3.2 Barrier Synchronization

Figure 3.52 shows an example of the operation executing barrier synchronization of PE0, PE1, and PE2 using barrier synchronization register channel 0. In this example, PE0, PE1, and PE2 are set by the BR0EN register in advance to participate in barrier synchronization by the initial setting processing described in **Section 3.4.3.1, Initial Setting**.

When PE0, PE1, and PE2, which are set to participate in barrier synchronization by the BR0EN register, arrive at the barrier, they each write data to the BR0CHKS register, setting it to 1_B. Note that the BR0CHKS register is set to 1_B when it is written to, regardless of the write value. Each of the PEs, upon arriving at the barrier, polls the BR0SYNCS register and waits for all the other PEs participating in barrier synchronization to arrive at the barrier. When all the PEs participating in barrier synchronization arrive at the barrier and the values of registers BR0CHK0 to 2 have all become 1_B, registers BR0CHK0 to 3 are automatically cleared, and 1_B is automatically set to registers BR0SYNCS0 to 2 (= BR0SYNCS). When a PE that arrives at the barrier detects that the BR0SYNCS register has been set to 1_B, it considers that all the PEs participating in barrier synchronization have arrived at the barrier, and it clears the respective BR0SYNCS registers to 0_B to allow transition to the next processing. When the values of registers BR0CHK0 to 2 have all become 1_B, registers BR0CHK0 to 3 are automatically cleared, so each PE is able to move on to the next cycle as soon as the BR0SYNCS register is cleared.

- Note 1. Register actually accessed from PE0.
- Note 2. Register actually accessed from PE1.
- Note 3. Register actually accessed from PE2.
- Note 4. Register actually accessed from PE3.

Figure 3.52 Example of Operation of Barrier Synchronization Using Barrier Synchronization Register

3.7 TPTM

3.7.1 TPTM Overview

Time Protection Timer (TPTM) is sets of CPU dedicated timers used to achieve high performance and functionality of timing protection. One timer set is assigned to each CPU respectively.

TPTM has the following features.

- Interval timer × 4ch (down counter)
- Free-run timer × 1ch (up counter)
- Start, Stop and Restart of counter for both of the interval timers and the free-run timer.
- Divided counter of the timers can be configured for the interval timers and the free-run timer respectively.
- Simultaneous count control for the interval timers.
- Underflow interrupt for the interval timers.

3.7.2 TPTM Registers

3.7.2.1 List of Registers

Table 3.156 List of Registers (1/2)

Module Name	Register Name	Register Symbol	Address	Access	Access Protection
TPTM self*1	Counter Start Register of Interval Timer Self	TPTMSIRUN	<TPTM_base> + 000 _H	8, 16, 32	—

	Counter Restart Register of Free-run Timer for PEn	TPTMnFRRUN	<TPTM_base> + 124 _H + (100 _H × n)	8, 16, 32	—
	Counter Stop Register of Free-run Timer for PEn	TPTMnFSTP	<TPTM_base> + 128 _H + (100 _H × n)	8, 16, 32	—
	Counter Status Register of Free-run Timer for PEn	TPTMnFSTR	<TPTM_base> + 12C _H + (100 _H × n)	8, 16, 32	—
	Divider Register of Free-run Timer for PEn	TPTMnFDIV	<TPTM_base> + 130 _H + (100 _H × n)	8, 16, 32	—
	Counter Channel 0 Register of Interval Timer for PEn	TPTMnCNT0	<TPTM_base> + 180 _H + (100 _H × n)	32	—
	Load Channel 0 Register of Interval Timer for PEn	TPTMnILD0	<TPTM_base> + 184 _H + (100 _H × n)	32	—
	Counter Channel 1 Register of Interval Timer for PEn	TPTMnCNT1	<TPTM_base> + 188 _H + (100 _H × n)	32	—
	Load Channel 1 Register of Interval Timer for PEn	TPTMnILD1	<TPTM_base> + 18C _H + (100 _H × n)	32	—
	Counter Channel 2 Register of Interval Timer for PEn	TPTMnCNT2	<TPTM_base> + 190 _H + (100 _H × n)	32	—
	Load Channel 2 Register of Interval Timer for PEn	TPTMnILD2	<TPTM_base> + 194 _H + (100 _H × n)	32	—
	Counter Channel 3 Register of Interval Timer for PEn	TPTMnCNT3	<TPTM_base> + 198 _H + (100 _H × n)	32	—
	Load Channel 3 Register of Interval Timer for PEn	TPTMnILD3	<TPTM_base> + 19C _H + (100 _H × n)	32	—
	Counter Register of Free-run Timer for PEn	TPTMnFCNT	<TPTM_base> + 1A0 _H + (100 _H × n)	32	—

Note 1. When PE accesses the self register, PE can access the corresponding register for each PE. For example, when PE1 accesses TPTMSIRUN register, PE1 can access the TPTM1IRUN register.

Note 2. n = 0 to 5. n is the PEID number.

3.7.2.2 Self Region

The self region contains the following registers.

- TPTMSIRUN — Counter Start Register of Interval Timer
- TPTMSIRRUN — Counter Restart Register of Interval Timer
- TPTMSISTP — Counter Stop Register of Interval Timer
- TPTMSISTR — Counter Status Register of Interval Timer
- TPTMSIEN — Interrupt Enable Register of Interval Timer
- TPTMSIISTR — Underflow Status Register of Interval Timer
- TPTMSIDIV — Divider Register of Interval Timer
- TPTMSFRUN — Counter Start Register of Free-run Timer
- TPTMSFRRUN — Counter Restart Register of Free-run Timer
- TPTMSFSTP — Counter Stop Register of Free-run Timer
- TPTMSFSTR — Counter Status Register of Interval Timer
- TPTMSFDIV — Divider Register of Free-run Timer
- TPTMSICNT0 — Counter Channel 0 Register of Interval Timer
- TPTMSILD0 — Load Channel 0 Register of Interval Timer
- TPTMSICNT1 — Counter Channel 1 Register of Interval Timer
- TPTMSILD1 — Load Channel 1 Register of Interval Timer
- TPTMSICNT2 — Counter Channel 2 Register of Interval Timer
- TPTMSILD2 — Load Channel 2 Register of Interval Timer
- TPTMSICNT3 — Counter Channel 3 Register of Interval Timer
- TPTMSILD3 — Load Channel 3 Register of Interval Timer
- TPTMSFCNT — Counter Register of Free-run Timer

Table 3.157 Self Region Register Routing List

Self Region Register	Access source PE					
	PE0	PE1	PE2	PE3	PE4	PE5
TPTMSIRUN	TPTM0IRUN	TPTM1IRUN	TPTM2IRUN	TPTM3IRUN	TPTM4IRUN	TPTM5IRUN

3.7.2.3 TPTMnIRUN — Counter Start Register of Interval Timer for PEn (n = 0 to 5)

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	IRUN3	IRUN2	IRUN1	IRUN0
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	W	W	W	W

Table 3.158 TPTMnIRUN Register Contents

Bit Position	Bit Name	Function
31 to 4	—	Reserved. When read, the value after reset is returned. When writing, write the value after reset.
3	IRUN3	Start command bit of interval timer channel 3 0: No action 1: Start counter When writing 1 to the bit, the value of TPTMnILD3 is loaded in TPTMnICNT3. This bit is always read as 0.
2	IRUN2	Start command bit of interval timer channel 2 0: No action 1: Start counter When writing 1 to the bit, the value of TPTMnILD2 is loaded in TPTMnICNT2. This bit is always read as 0.
1	IRUN1	Start command bit of interval timer channel 1 0: No action 1: Start counter When writing 1 to the bit, the value of TPTMnILD1 is loaded in TPTMnICNT1. This bit is always read as 0.
0	IRUN0	Start command bit of interval timer channel 0 0: No action 1: Start counter When writing 1 to the bit, the value of TPTMnILD0 is loaded in TPTMnICNT0. This bit is always read as 0.

3.7.2.4 TPTMnIRRUN — Counter Restart Register of Interval Timer for PEn (n = 0 to 5)

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	IRRUN3	IRRUN2	IRRUN1	IRRUN0
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	W	W	W	W

Table 3.159 TPTMnIRRUN Register Contents

Bit Position	Bit Name	Function
31 to 4	—	Reserved. When read, the value after reset is returned. When writing, write the value after reset.
3	IRRUN3	Restart command bit of interval timer channel 3 0: No action 1: Restart counter When writing 1 to the bit, the counter is restarted from current value of TPTMnICNT3. This bit is always read as 0.
2	IRRUN2	Restart command bit of interval timer channel 2 0: No action 1: Restart counter When writing 1 to the bit, the counter is restarted from current value of TPTMnICNT2. This bit is always read as 0.
1	IRRUN1	Restart command bit of interval timer channel 1 0: No action 1: Restart counter When writing 1 to the bit, the counter is restarted from current value of TPTMnICNT1. This bit is always read as 0.
0	IRRUN0	Restart command bit of interval timer channel 0 0: No action 1: Restart counter When writing 1 to the bit, the counter is restarted from current value of TPTMnICNT0. This bit is always read as 0.

3.7.2.5 TPTMnISTP — Counter Stop Register of Interval Timer for PEn (n = 0 to 5)

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	ISTP3	ISTP2	ISTP1	ISTP0
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	W	W	W	W

Table 3.160 TPTMnISTP Register Contents

Bit Position	Bit Name	Function
31 to 4	—	Reserved. When read, the value after reset is returned. When writing, write the value after reset.
3	ISTP3	Stop command bit of interval timer channel 3 0: No action 1: Stop counter When writing 1 to the bit, the counter is stopped at the value of TPTMnCNT3. This bit is always read as 0.
2	ISTP2	Stop command bit of interval timer channel 2 0: No action 1: Stop counter When writing 1 to the bit, the counter is stopped at the value of TPTMnCNT2. This bit is always read as 0.
1	ISTP1	Stop command bit of interval timer channel 1 0: No action 1: Stop counter When writing 1 to the bit, the counter is stopped at the value of TPTMnCNT1. This bit is always read as 0.
0	ISTP0	Stop command bit of interval timer channel 0 0: No action 1: Stop counter When writing 1 to the bit, the counter is stopped at the value of TPTMnCNT0. This bit is always read as 0.

3.7.2.6 TPTMnISTR — Counter Status Register of Interval Timer for PEn (n = 0 to 5)

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	ISTR3	ISTR2	ISTR1	ISTR0
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 3.161 TPTMnISTR Register Contents

Bit Position	Bit Name	Function
31 to 4	—	Reserved. When read, the value after reset is returned. When writing, write the value after reset.
3	ISTR3	Status bit of interval timer channel 3 0: Counter is stopped. 1: Counter is running.
2	ISTR2	Status bit of interval timer channel 2 0: Counter is stopped. 1: Counter is running.
1	ISTR1	Status bit of interval timer channel 1 0: Counter is stopped. 1: Counter is running.
0	ISTR0	Status bit of interval timer channel 0 0: Counter is stopped. 1: Counter is running.

3.7.2.7 TPTMnIIEN — Interrupt Enable Register of Interval Timer for PEn (n = 0 to 5)

This register controls enabling/disabling of interrupt request by TPTM_IRQ[n].

When underflow occurs in interval timer channel m in TPTMn, TPTMnIUSTR.IUSTRm bit is set whether IIENm bit is set or not. If IIENm bit is set, TPTM_IRQ[n] is asserted.

Note that TPTM_IRQ[n] will be asserted immediately after IIENm bit is set if TPTMnIUSTR.IUSTRm holds 1.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	IIEN3	IIEN2	IIEN1	IIEN0
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W

Table 3.162 TPTMnIIEN Register Contents

Bit Position	Bit Name	Function
31 to 4	—	Reserved. When read, the value after reset is returned. When writing, write the value after reset.
3	IIEN3	Interrupt enable bit of interval timer channel 3 0: Disable. 1: Enable.
2	IIEN2	Interrupt enable bit of interval timer channel 2 0: Disable. 1: Enable.
1	IIEN1	Interrupt enable bit of interval timer channel 1 0: Disable. 1: Enable.
0	IIEN0	Interrupt enable bit of interval timer channel 0 0: Disable. 1: Enable.

3.7.2.8 TPTMnIUSTR — Underflow Status Register of Interval Timer for PEn (n = 0 to 5)

This register indicates the status of underflow occurrence of interval timers in TPTMn.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	IUSTR3	IUSTR2	IUSTR1	IUSTR0
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W

Table 3.163 TPTMnIUSTR Register Contents

Bit Position	Bit Name	Function
31 to 4	—	Reserved. When read, the value after reset is returned. When writing, write the value after reset.
3	IUSTR3	Underflow flag bit of interval timer channel 3 0: Underflow did not occur. 1: Underflow occurred. When writing 0 to the bit, IUSTR3 is cleared. Writing 1 to the bit is ignored.
2	IUSTR2	Underflow flag bit of interval timer channel 2 0: Underflow did not occur. 1: Underflow occurred. When writing 0 to the bit, IUSTR2 is cleared. Writing 1 to the bit is ignored.
1	IUSTR1	Underflow flag bit of interval timer channel 1 0: Underflow did not occur. 1: Underflow occurred. When writing 0 to the bit, IUSTR1 is cleared. Writing 1 to the bit is ignored.
0	IUSTR0	Underflow flag bit of interval timer channel 0 0: Underflow did not occur. 1: Underflow occurred. When writing 0 to the bit, IUSTR0 is cleared. Writing 1 to the bit is ignored.

3.7.2.9 TPTMnIDIV — Divider Register of Interval Timer for PEn (n = 0 to 5)

Value after reset: 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	IDIV[7:0]							
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 3.164 TPTMnIDIV Register Contents

Bit Position	Bit Name	Function
31 to 8	—	Reserved. When read, the value after reset is returned. When writing, write the value after reset.
7 to 0	IDIV[7:0]	Clock dividing setting of interval timer for all channels Counter clock ratio is specified by the following expression. $count_clock = clk_cpu / (IDIV[7:0] + 1)$

CAUTIONS

- To avoid unintended timer behavior, the TPTMnIDIV register should be written while all channels of TPTMnCNTm are in stop state.
- It is prohibited to access this register by bit-manipulation instruction.

3.7.2.10 TPTMnFRUN — Counter Start Register of Free-run Timer for PEn (n = 0 to 5)

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	FRUN
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	W

Table 3.165 TPTMnFRUN Register Contents

Bit Position	Bit Name	Function
31 to 1	—	Reserved. When read, the value after reset is returned. When writing, write the value after reset.
0	FRUN	Start command bit of free-run timer 0: No action 1: Start counter When writing 1 to the bit during the counter stopping, the value of 0000 0000 _H is loaded in TPTMnFCNT and the counter is started. When writing 1 to the bit during the counter working, the value of 0000 0000 _H is loaded in TPTMnFCNT and the counter is re-started. This bit is always read as 0.

3.7.2.11 TPTMnFRRUN — Counter Restart Register of Free-run Timer for PEn (n = 0 to 5)

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	FRRUN
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	W

Table 3.166 TPTMnFRRUN Register Contents

Bit Position	Bit Name	Function
31 to 1	—	Reserved. When read, the value after reset is returned. When writing, write the value after reset.
0	FRRUN	Restart command bit of free-run timer 0: No action 1: Restart counter When writing 1 to the bit, the counter is restarted from current value of TPTMnFCNT. This bit is always read as 0.

3.7.2.12 TPTMnFSTP — Counter Stop Register of Free-run Timer for PEn (n = 0 to 5)

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	FSTP
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	W

Table 3.167 TPTMnFSTP Register Contents

Bit Position	Bit Name	Function
31 to 1	—	Reserved. When read, the value after reset is returned. When writing, write the value after reset.
0	FSTP	Stop command bit of free-run timer 0: No action 1: Stop counter When writing 1 to the bit, the counter is stopped at the value of TPTMnFCNT. This bit is always read as 0.

3.7.2.13 TPTMnFSTR — Counter Status Register of Free-run Timer for PEn (n = 0 to 5)

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	FSTR
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 3.168 TPTMnFSTR Register Contents

Bit Position	Bit Name	Function
31 to 1	—	Reserved. When read, the value after reset is returned. When writing, write the value after reset.
0	FSTR	Status bit of Free- run timer 0: Counter is stopped. 1: Counter is running.

3.7.2.14 TPTMnFDIV — Divider Register of Free-run Timer for PEn (n = 0 to 5)

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	FDIV[7:0]							
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 3.169 TPTMnFDIV Register Contents

Bit Position	Bit Name	Function
31 to 8	—	Reserved. When read, the value after reset is returned. When writing, write the value after reset.
7 to 0	FDIV[7:0]	Clock dividing setting of free-run timer Counter clock ratio is specified by the following expression. $\text{count_clock} = \text{clk_cpu} / (\text{FDIV}[7:0] + 1)$

CAUTIONS

- To avoid unintended timer behavior, the TPTMnFDIV register should be written while TPTMnFCNT is in stop state.
- It is prohibited to access this register by bit-manipulation instruction.

3.7.2.15 TPTMnICNTm — Counter Channel m Register of Interval Timer for PEn (n = 0 to 5, m = 0 to 3)

Value after reset: Undefined

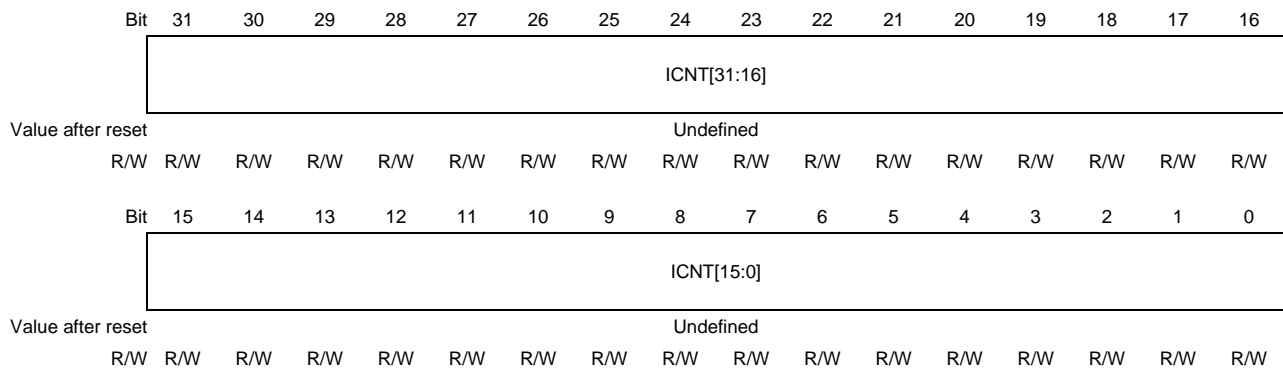

Table 3.170 TPTMnICNTm Register Contents

Bit Position	Bit Name	Function
31 to 0	ICNT[31:0]	Counter value of interval timer channel m for PEn When writing 1 _B to TPTMnIRUN.IRUNm, the value of TPTMnILDm is loaded in this register and this register starts to count down from this value. Also, when an underflow of this register occurs, the value of TPTMnILDm is reloaded in this register and this register continues to count down from this value.

CAUTION

To avoid unintended timer behavior, the TPTMnICNTm register should be written while in stop state.

3.7.2.16 TPTMnILDm — Load Channel m Register of Interval Timer for PEn (n = 0 to 5, m = 0 to 3)

Value after reset: Undefined

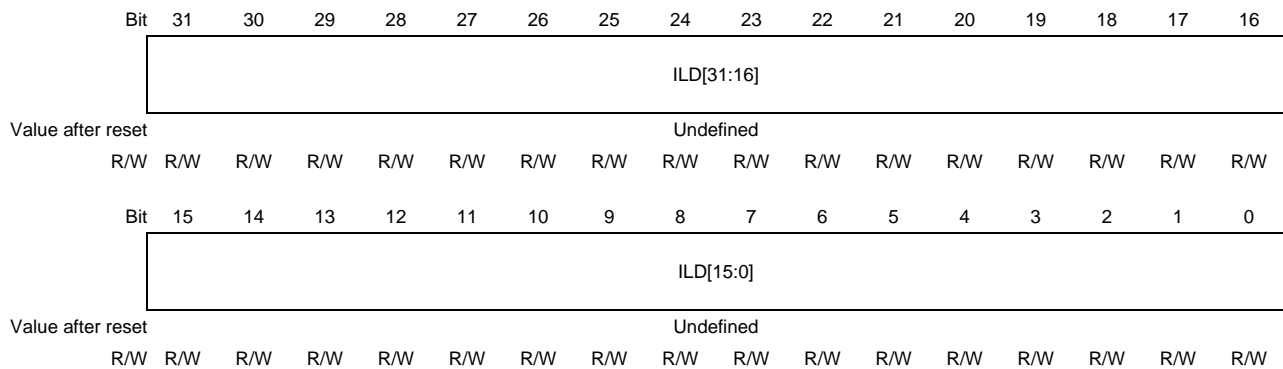

Table 3.171 TPTMnILDm Register Contents

Bit Position	Bit Name	Function
31 to 0	ILD[31:0]	Load data value of interval timer channel m for PEn At the timing of writing 1 to TPTMnIRUNm, the value of this register is loaded in TPTMnCnTm. Also, when an underflow of TPTMnCnTm occurs, the value of this register is reloaded in TPTMnCnTm.

CAUTION

To avoid unintended timer behavior, the TPTMnILDm register should be written while TPTMnCnTm of corresponding channel is in stop state.

3.7.2.17 TPTMnFCNT — Counter Register of Free-run Timer for PEn (n = 0 to 5)

Value after reset: Undefined

Table 3.172 TPTMnFCNT Register Contents

Bit Position	Bit Name	Function
31 to 0	FCNT[31:0]	Counter value of free-run timer for PEn When writing 1 _B to TPTMnFRUN.FRUN, the value of 0000_0000 _H is loaded in this register and this register starts to count up from this value. Also, when an overflow of this register occurs, the value of 0000_0000 _H is reloaded in this register and this register continues to count up from this value.

CAUTION

To avoid unintended timer behavior, the TPTMnFCNT register should be written while in stop state.

3.7.3 TPTM Function

CAUTION

If interruption is used as EI level instead of FE level, set the TPTMSEL register before TPTM starts. It is prohibited to change the setting value of the TPTMSEL register after TPTM start.

3.7.3.1 Normal Operation

The normal operation flow is shown in **Figure 3.53**.

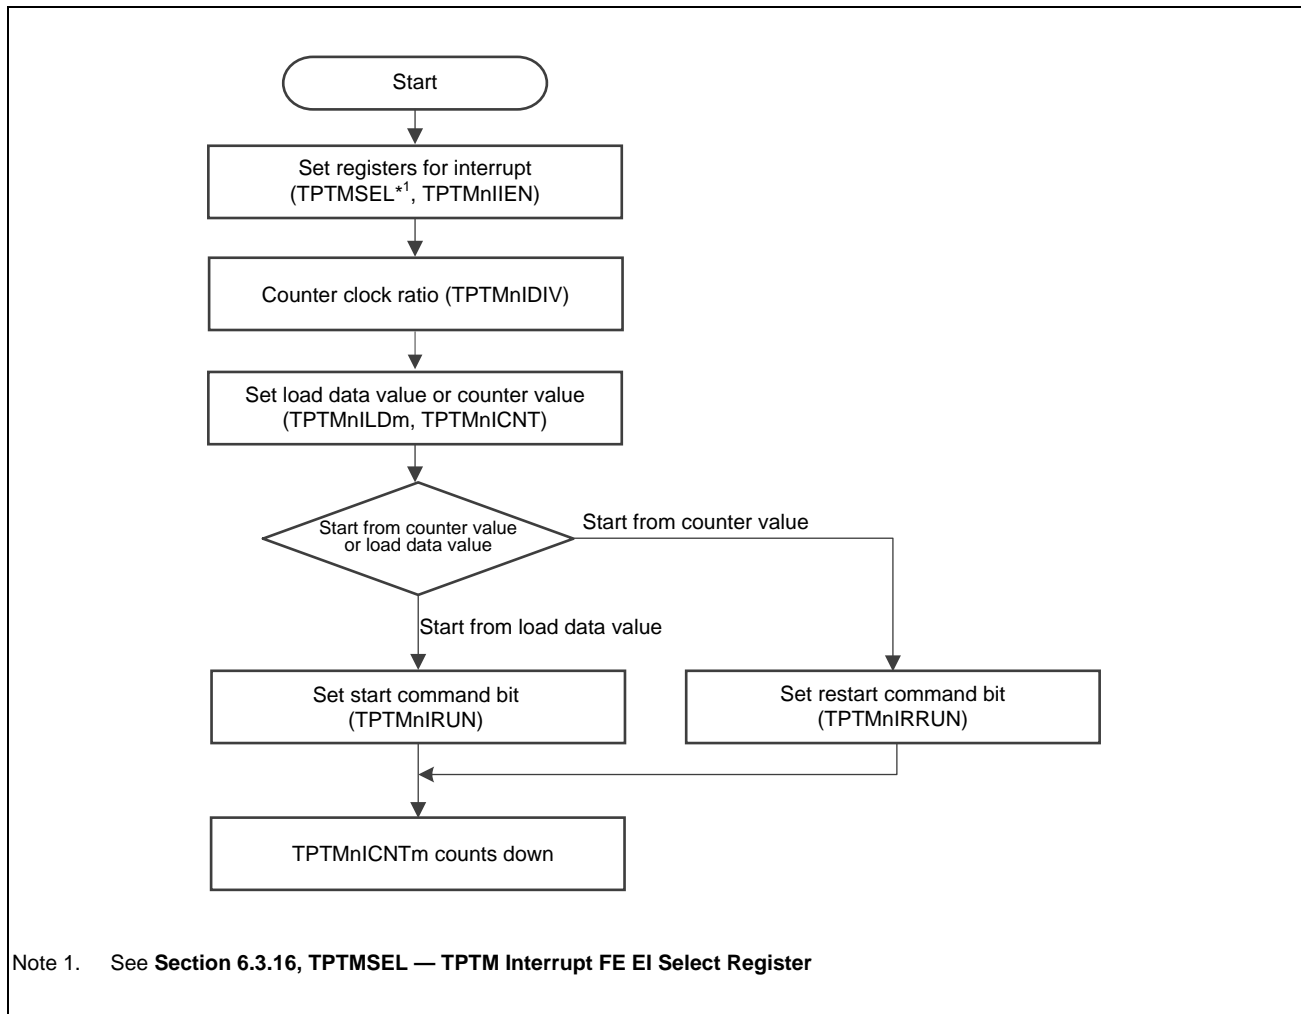

Figure 3.53 Flow of Normal Operation

It shows the timing chart of normal operation of interval timer in case that counter clock ratio is a 1/2 period of CPU_CLK and load data value is 0000 0004_H in **Figure 3.54**.

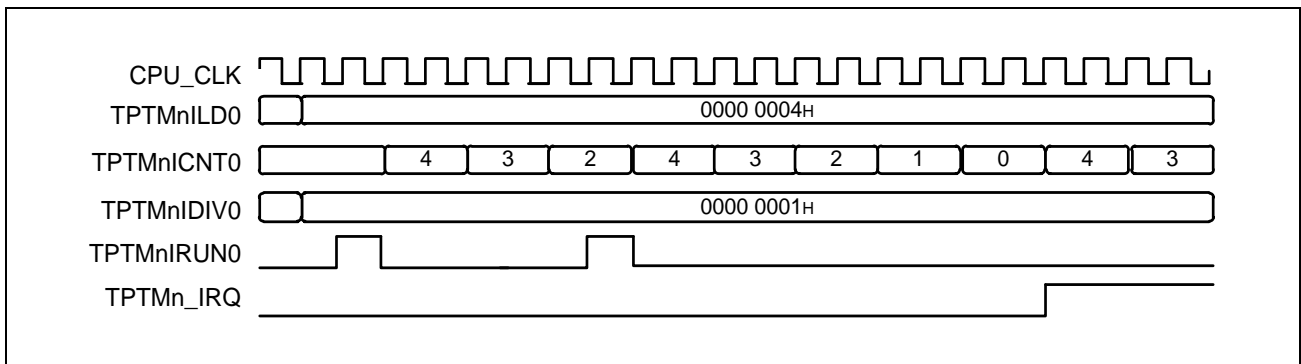

Figure 3.54 Normal Operation (TPTMnDIV = 0000 0001_H, TPTMnILD = 0000 0004_H)

3.7.3.2 Operation during a Restart

The flow of operation during a restart is shown in **Figure 3.55**.

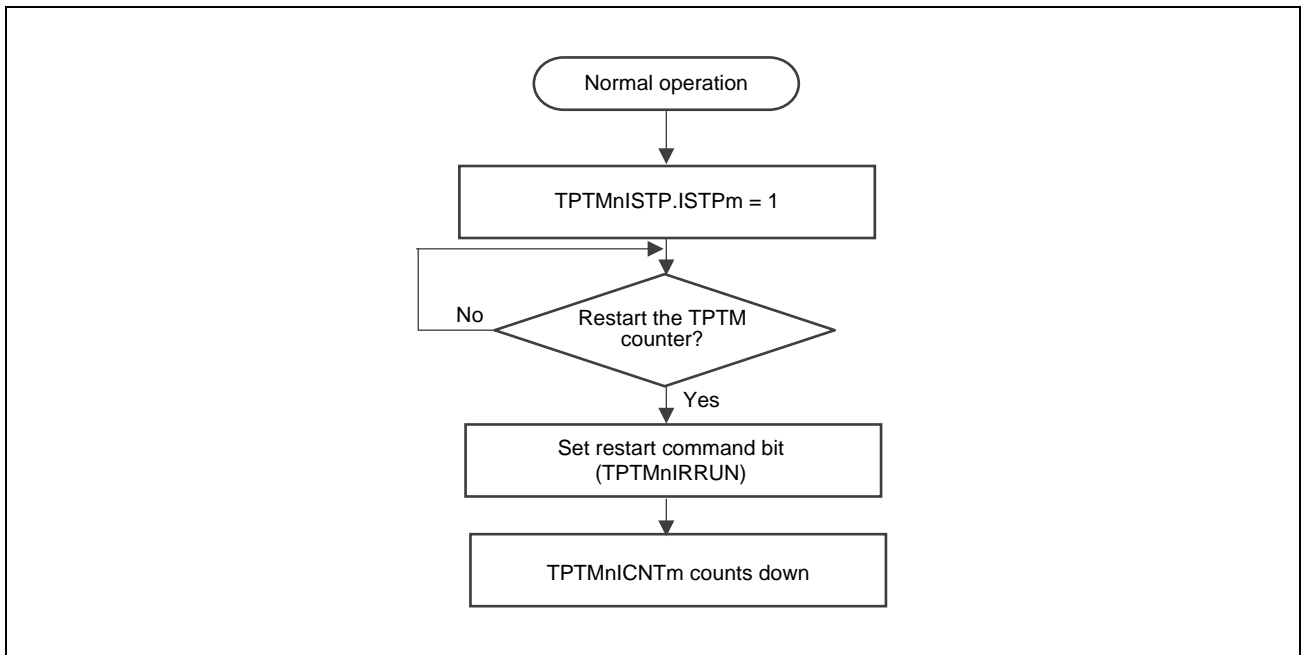

Figure 3.55 Flow of Operation during a Restart

TPTMnCNTm starts countdown at the next cycle after setting TPTMnIRUN.

TPTMnCNTm stops countdown at the next cycle after setting TPTMnISTP during countdown.

TPTMnCNTm restarts countdown from the current counter value at the next cycle after setting TPTMnIRRUN during countdown stop.

The timing chart of interval timer operation at the time of restart when the counter clock ratio is 1/2 period of CPU_CLK and load data value is 0000 0004_H is shown in **Figure 3.54**.

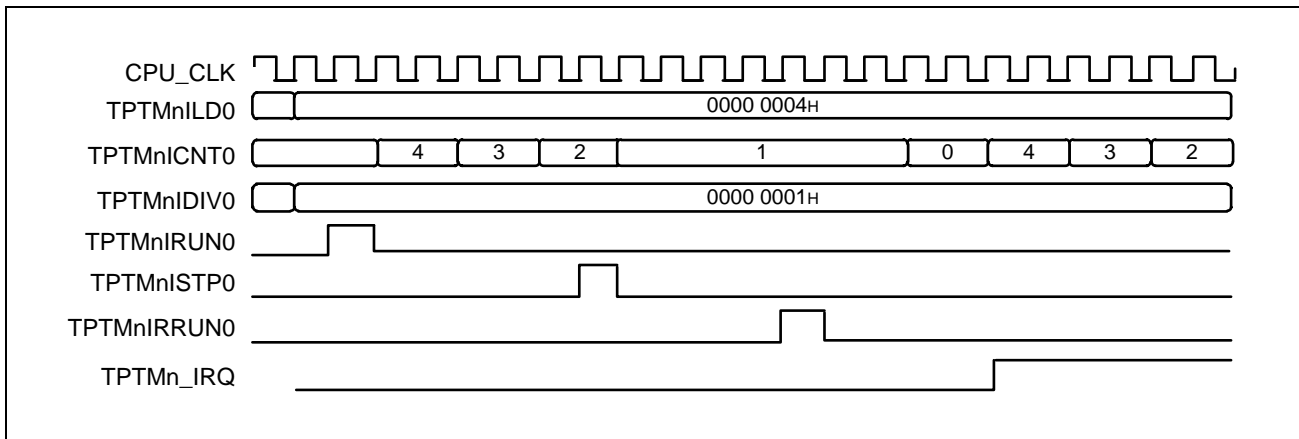

Figure 3.56 Operation during a Restart (TPTMnIDIV = 0000 0001H, TPTMnILD = 0000 0004H)

3.7.3.3 Operation during an Underflow

When TPTMnIIEN.IIENm is 1_B, an interrupt is enabled, TPTMnIUSTR.IUSTRm is set and TPTMn_IRQ is asserted at the next cycle after TPTMnCNTm becomes 0000 0000_H.

When CPU has finished interrupt processing of TPTM, it needs to clear TPTMnIUSTR.IUSTRm.

Cycles of TPTMn Interrupt

The cycles of TPTMn Interrupt are as follows.

- TPTMn Interrupt generation cycle = TPTMnCNTm × Counter-Clock cycle*

$$*Counter-Clock\ cycle = CPU_CLK \times (TPTMnIDIV + 1)$$

When TPTMnIIEN.IIENm is 0, an interrupt is disabled, TPTMnIUSTR.IUSTRm is set but TPTMn_IRQ is not asserted at the next cycle after TPTMnCNTm becomes 0000 0000_H. In this case, TPTMn_IRQ is asserted if TPTMnIIEN.IIENm is set before TPTMnIUSTR.IUSTRm is cleared.

3.8 Usage Notes

3.8.1 Synchronization of Store Instruction Completion and Subsequent Instruction Generation

When a control register is updated by a store instruction, there is a time lag from execution of the store instruction by the CPU to actual updating of the control register. Therefore, appropriate processing for synchronization is required to ensure that control registers reflect updated values before execution of subsequent instructions. The processing for synchronization is shown below.

For details on the procedure regarding updating of the system registers by the LDSR instruction and synchronization with subsequent instructions, refer to **Section 3.2.7.3, Hazard Management after System Register Update**.

3.8.1.1 When Updated Results in the Control Registers or Memory are Reflected in the Implementation of a Subsequent Instruction

Example 1) An interrupt may be enabled by implementation of an EI instruction after an interrupt request is cleared by access from the control register in the INTC2 and the peripheral circuits. Proceed as follows in this case.

- (1) Store instruction to update a control register (ST.W, etc.)
- (2) Dummy reading of the above-mentioned control register (LD.W, etc.)*¹
- (3) SYNCP
- (4) Subsequent instruction (EI, etc.)

Example 2) Implement the same processing even when the access required after waiting to secure the updating of a given control register (register A) is to another control register (register B). This includes the following cases: the interlinked operation of different peripheral modules and when releasing the interrupt mask in INTC after making peripheral module settings.

However, this processing is unnecessary if control registers A and B are in the same peripheral group.

For the correspondence between the peripheral groups and the peripheral modules/registers, see each section.

- (1) Store instruction to update control register A (ST.W, etc.)
- (2) Dummy reading of the above-mentioned control register (LD.W, etc.)*¹
- (3) SYNCP
- (4) Store/Load instruction to access control register B (ST.W, LD.W, etc.)

The same processing is also required when access to control registers and memory within the scope of protection starts after waiting for the completion of settings for safety functions such as memory protection, ECC checking, and so on.

Moreover, the same processing is also required when guarantee the completion of store accesses to memory.

Note 1. Dummy reading of any register of the same peripheral group can be used instead.

3.8.1.2 When the Updated Results in the Control Registers and Memories are Reflected in the Instruction Fetch of a Subsequent Instruction

1. If you wish to write an instruction to the RAM and then branch to the RAM to execute the written instruction, do this as follows.
 - (1) Store instruction to update a memory (ST.W, etc.)
 - (2) Dummy reading of the above-mentioned memory (LD.W, etc.)
 - (3) SYNCI
 - (4) Subsequent instruction (branch instruction, etc.)

2. When branching to a target memory after waiting for the completion of updating the control registers for memory protection and ECC, do this as follows.
 - (1) Store instruction to update a control register (ST.W, etc.)
 - (2) Dummy reading of the control register (LD.W, etc.)
 - (3) SYNCI
 - (4) Subsequent instruction (branch instruction, etc.)

3.8.1.3 Product information of SYNCM

Table 3.173 shows the correspondence between the module names given in *the RH850G4MH User's Manual: Software* and the module names in this product information document.

Table 3.173 Module Name Correspondence in this Product Information Document

Module Name	Module Name of This Product Information Document
L1RAM (given CPU)	Local RAM (own core)
L1RAM (other CPU)	Local RAM (other core)
L2RAM	Cluster0/1/2 RAM
INTC1	INTC1
Others	There is no module corresponding to "Others" in this product

3.8.1.4 Product information of Waiting for the Completion of Storage

Table 3.174 Bus Slaves for which Using Dummy Reading to Wait is Effective

Bus Slaves	Description
L1RAM (given CPU)	Local RAM (own core)
L1RAM (other CPU)	Local RAM (other core)
L2RAM	Cluster0/1/2 RAM
INTC1	INTC1
Others	All peripheral module

3.8.2 Synchronization of Load Instruction Completion and Subsequent Instruction Generation

When a control register and memory is accessed by a load instruction, the order of data accesses does not guarantee the same order of program. Therefore, appropriate processing for synchronization is required to ensure the completion of a load instruction for the subsequent data access instructions. However, the synchronization processing is not necessary for accesses to some target data space. For details on target data space, refer to **Section 4.2.2, Data Space Accessible by CPU0, CPU1, CPU2, CPU3, CPU4, CPU5**. The processing for load synchronization is shown below.

Example) It is necessary to wait for the completion of a load access to an address A before an access to other address B, proceed as follows in this case.

- (1) Load instruction to refer Address A (LD.W, etc.)
- (2) SYNC
- (3) Store/Load instruction to access Address B (ST.W, LD.W, etc.)

3.8.3 Accesses to Registers by Bit-Manipulation Instructions

Processing of a bit-manipulation instruction takes the form of atomic reading, modification, and writing of an eight-bit unit. Thus, access by a bit-manipulation instruction is only possible for registers for which reading and writing in 8-bit units is possible. However, take care in the cases of registers that contain multiple flag bits, since the read-modify-write cycle may also clear flags other than those which were for clearing.

Write access to H-Bus group registers by using bit-manipulation instructions is not atomic. Access by other masters may interrupt the read-modify-write processing of these instructions.

3.8.4 Ensuring Coherency after Code Flash Programming

For PE0 and PE1, see **Section 3.2.9, Ensuring Coherency after Code Flash Programming**.

For ICUMD, see *the E2x ICUMD User's Manual*.

3.8.5 Overwriting Context when Acknowledging Multiple Exceptions

Exceptions may be acknowledged regardless of the states of the ID or NP bits of the PSW register. This depends on the type of exception. When multiple exceptions occur, the contents of the system registers which hold the context information are overwritten. Regarding the conditions for acknowledging exceptions from each source and the possibility of return and recovery, see **Section 3.2.4, Exceptions and Interrupts**.

3.8.6 Usage Notes on Prefetching

CPU executes speculative instruction fetching from locations after the current value of the program counter to maintain the throughput of instruction fetches. Reading from memory due to such prefetching may proceed even from locations to which instruction codes have not been assigned (Note 1. in **Figure 3.57**). Note the following and keep in mind that the CPU does not execute values read in such cases.

The following notes apply to instruction fetching from memory in general.

- Occurrence of ECC errors due to values in memory being undefined

This prefetching may lead to an ECC error in case of reading from the code flash memory after it has been erased or from the Local RAM or Cluster RAM before initialization. When instruction codes are assigned to memory, initialize said area with values as desired (Note 1. in **Figure 3.57**).

- Detection of illegal access by the CRG

The CRG may detect such prefetching as illegal access. To prevent prefetching being detected as an illegal access, do not allow any region of overlap area with said areas (Note 1. in **Figure 3.57**) and areas to which access is prohibited by the CRG. Reading from an area protected by the MPU does not cause a memory protection exception.

- Access to Access Prohibited Area

Assign instruction codes to memory without allowing any overlap between said area (Note 1. in **Figure 3.57**) and an access-prohibited area.

- Speculative read operation by Prefetch

Depending on the decode result of prefetch instruction, the CPU may issue speculative read request to Local RAM (own core), Local RAM (other core), Cluster RAM or Code Flash. The lockstep error described in **Section 40.4.4, Usage Note** may be occurred by speculative read request. If it is unnecessary as a result of branch instruction, the data is discarded.

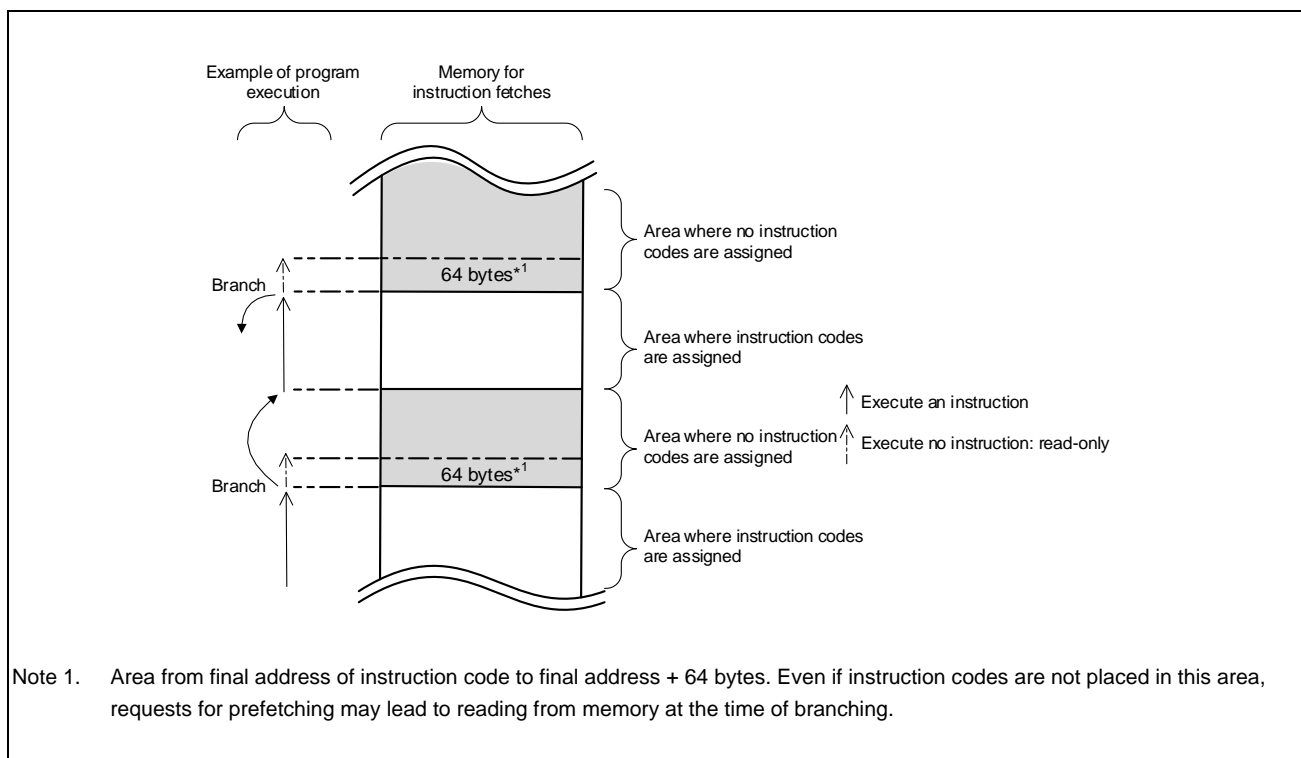

Figure 3.57 Areas that Require Attention Regarding Prefetching

3.8.7 Product Information of Initial Value for G4MH Register

The G4MH register's initial values of the product dependent are shown below.

Register No.	Symbol	Initial value
SR0,1	SPID	*1
SR1,1	SPIDLIST	FFFF FFFF _H
SR2,1	RBASE	*2
SR6,1	PID	*3
SR0,2	PEID	*4
SR1,2	BMID	*5
SR24,4	ICCTRL	0001 0003 _H
SR26,4	ICCFG	*6

Note 1. The initial values of SPID register are listed below.

CPU0: 0000 0000_H
 CPU1: 0000 0001_H
 CPU2: 0000 0002_H
 CPU3: 0000 0003_H
 CPU4: 0000 0004_H
 CPU5: 0000 0005_H

Note 2. See **Section 4, Address MAP** about RBASE register's bit to 31 from 9. Initial value of RBASE.DV bit is 0 and Initial value of RBASE.RINT bit is 0.

Note 3. The initial values of PID register are listed below.

E2x-FCC2 0604 0F01_H(CPU0/CPU2)
 0604 0701_H(CPU1/CPU3/CPU4/CPU5)
 E2UH 0604 0F01_H(CPU0/CPU2)
 0604 0701_H(CPU1/CPU3/CPU4/CPU5)
 E2H 0604 0F01_H(CPU0/CPU2)
 0604 0701_H(CPU1/CPU3)

Note 4. The initial values of PEID register are listed below.

CPU0: 0000 0000_H
 CPU1: 0000 0001_H
 CPU2: 0000 0002_H
 CPU3: 0000 0003_H
 CPU4: 0000 0004_H
 CPU5: 0000 0005_H

Note 5. The initial values of BMID register are listed below.

CPU0: 0000 0000_H
 CPU1: 0000 0001_H
 CPU2: 0000 0002_H
 CPU3: 0000 0003_H
 CPU4: 0000 0004_H
 CPU5: 0000 0005_H

Note 6. The initial values of ICCFG register are listed below.

E2x-FCC2 0000 1044_H
 E2UH 0000 1044_H
 E2H 0000 1044_H

3.8.8 Product Information of SYSERR Factor

The product-dependent SYSERR causes are shown below. Refer to **Section 3.2.4, Exceptions and Interrupts** for details on SYSERR.

Exception Cause Code*1	Cause
11 _H	When any of the following errors occurs in instruction fetch <ul style="list-style-type: none"> • ADDRESS ECC error in Local RAM, Cluster RAM and Code Flash • Guard error in PEG, CRG and security guard.*2 • Address Feedback error in LRAM and Cluster RAM • An unimplemented area is fetch accessed
13 _H	When any of the following errors occurs in instruction fetch <ul style="list-style-type: none"> • Uncorrectable DATA ECC error in Local RAM, Cluster RAM and Code Flash (including cases where 1-bit correction is prohibited) • Address parity error in Code Flash.

Note 1. Refer to **Section 3.2.4, Exceptions and Interrupts** about another exception cause code (excluding 11_H and 13_H).

Note 2. Guard error caused by security setting. Refer to *the E2x ICUMD User's Manual* for details on Security guard.

Note 3. When an error occurs in instruction fetch at the time of cache miss or cache invalid, following ECM error sources may not be notified and following error information registers may not be updated.

< ECM error sources >

- No.200: Code Flash - Address parity error
- No.201: Code Flash - ECC 2bit error
- No.202: Code Flash - ECC 1bit error
- No.203: Code Flash - Error address overflow

< Error information registers >

- ECMmESSTR6
- CF_SERSTR
- CF_DERSTR
- CF_OVFSTR
- CF_SERINF
- CF_nSEADR
- CF_00DEADR

However, by executing the following sequence in the SYSERR exception handler, the above notification and the update can be performed. In that case, please note that the access information will be recorded as load since it is not fetch access.

- Clear(0) RDBCR.RDBEN
- Read memory area from FEPC to FEPC+7 using LD.H instruction

3.8.9 Product Information of Cache Structure

The product-dependent cache structure are shown below.

Cache structure	E2x-FCC2	E2UH	E2H
Total Size	16 KB	16 KB	16 KB
Number of Way	4-way	4-way	4-way
Number of Line	128 line	128 line	128 line

3.8.10 Product Information of Fetch Size

These product's CPU(G4MH) fetch size is 64-Bit.

3.8.11 Register Initialization

The CPU in this product has general purpose registers and system registers which value after reset are undefined. In case of lockstep core, initial value of the master core and checker core after reset may be different. Therefore, these registers must be initialized at first. The registers which need the initialization are shown in **Table 3.175**.

For Usage of Lockstep Error, see **Section 40.4.4, Usage Note**.

Table 3.175 Registers needed to be initialized

Type	Registers
General purpose register	r1 to r31
Basic system register	EIPC, FEPC, CTPC, EIWR, FEWR, EBASE, INTBP, MEA, MEI, RBIP
FPU system register *1	FPSR, FPEPC, FPST, FPCC
MPU function register	MCA, MCS, MCR, MCI, MPLA, MPUA, MPAT, MPID0 to MPID7
FXU Function Registers *2	wr0 to wr31, FXSR, FXST, FXXC, FXXP
Cache operation function register	ICTAGL, ICTAGH, ICDATL, ICDATH, ICERR

Note 1. When the PSW.CU0 is set to 1, initialize the above registers.

Note 2. When the PSW.CU1 is set to 1, initialize the above registers.

Section 4 Address MAP

4.1 Address MAP

Table 4.1 shows the address space of the RH850/E2x-FCC2 (For E2UH) and E2UH (E2x-FCC2 compatible mode).

Table 4.2 shows the address space of the RH850/E2UH single map mode.

Table 4.3 shows the address space of the RH850/E2UH double map mode.

Table 4.4 shows the address space of the RH850/E2x-FCC2 (For E2H) and E2H (E2x-FCC2 compatible mode).

Table 4.5 shows the address space of the RH850/E2H single map mode.

Table 4.6 shows the address space of the RH850/E2H double map mode.

See **Section 43, Flash Memory** for details about E2x-FCC2 compatible mode, single map mode, and double map mode.

When making an access to register space, access the addresses shown in each peripheral IPs section. Do not access an address that is not specified in **Table 4.1**, **Table 4.2**, **Table 4.3**, **Table 4.4**, **Table 4.5**, **Table 4.6**, and an area where any access is prohibited. If an unspecified address or reserved area is accessed, operation is not guaranteed.

Table 4.1 Address MAP of RH850/E2x-FCC2 (For E2UH) and E2UH (E2x-FCC2 Compatible Mode) (1/2)

Address	Address Space Type	Size
0000 0000 _H to 00FF FFFF _H	Code flash (User area)	16 MB
0100 0000 _H to 03FF FFFF _H	Access prohibited area	
0400 0000 _H to 04FF FFFF _H	Code flash (Mirror Area)	16MB
0500 0000 _H to 07FF FFFF _H	Access prohibited area	
0800 0000 _H to 0800 FFFF _H	Code flash (User boot area)	64 KB
0801 0000 _H to 0802 FFFF _H	Access prohibited area	
0803 0000 _H to 0803 7FFF _H	Code flash (Product Info Area)	32 KB
0803 8000 _H to 0804 FFFF _H	Access prohibited area	
0805 0000 _H to 0805 FFFF _H	Code flash (ECC test Area of Bank A)	64 KB
0806 0000 _H to 0834 FFFF _H	Access prohibited area	
0835 0000 _H to 0835 FFFF _H	Code flash (ECC test Area of Bank B)	64 KB
0836 0000 _H to 0864 FFFF _H	Access prohibited area	
0865 0000 _H to 0865 FFFF _H	Code flash (ECC test Area of Bank C)	64 KB
0866 0000 _H to 0894 FFFF _H	Access prohibited area	
0895 0000 _H to 0895 FFFF _H	Code flash (ECC test Area of Bank D)	64 KB
0896 0000 _H to 08C4 FFFF _H	Access prohibited area	
08C5 0000 _H to 08C5 FFFF _H	Code flash (ECC test Area of Bank E)	64 KB
08C6 0000 _H to 08E4 FFFF _H	Access prohibited area	
08E5 0000 _H to 08E5 FFFF _H	Code flash (ECC test Area of Bank F)	64 KB
08E6 0000 _H to 0BFE FFFF _H	Access prohibited area	
0BFF 0000 _H to 0BFF FFFF _H	Code flash (ECC test Area of Global Area)	64 KB
0C00 0000 _H to 0CFF FFFF _H	Code flash (Blank check Area)	16 MB
0D00 0000 _H to 0FFF FFFF _H	Access prohibited area	
1000 0000 _H to 1FFF FFFF _H	H-Bus area	256 MB
2000 0000 _H to 2FFF FFFF _H	External memory area	256 MB
3000 0000 _H to FD1F FFFF _H	Access prohibited area	

Table 4.1 Address MAP of RH850/E2x-FCC2 (For E2UH) and E2UH (E2x-FCC2 Compatible Mode) (2/2)

Address	Address Space Type	Size
FD20 0000 _H to FD20 FFFF _H	Local RAM (CPU5)	64 KB
FD21 0000 _H to FD3F FFFF _H	Access prohibited area	
FD40 0000 _H to FD40 FFFF _H	Local RAM (CPU4)	64 KB
FD41 0000 _H to FD5F FFFF _H	Access prohibited area	
FD60 0000 _H to FD60 FFFF _H	Local RAM (CPU3)	64 KB
FD61 0000 _H to FD7F FFFF _H	Access prohibited area	
FD80 0000 _H to FD80 FFFF _H	Local RAM (CPU2)	64 KB
FD81 0000 _H to FD9F FFFF _H	Access prohibited area	
FDA0 0000 _H to FDA0 FFFF _H	Local RAM (CPU1)	64 KB
FDA1 0000 _H to FDBF FFFF _H	Access prohibited area	
FDC0 0000 _H to FDC0 FFFF _H	Local RAM (CPU0)	64 KB
FDC1 0000 _H to FDDF FFFF _H	Access prohibited area	
FDE0 0000 _H to FDE0 FFFF _H	Local RAM (self)	64 KB
FDE1 0000 _H to FDFE FFFF _H	Access prohibited area	
FE00 0000 _H to FE19 FFFF _H	Cluster RAM	1664 KB
FE1A 0000 _H to FEFF FFFF _H	Access prohibited area	
FF00 0000 _H to FFFB 7FFF _H (FF20 0000 _H to FF24 FFFF _H) (FF30 0000 _H to FF3F FFFF _H)	P-Bus area (Data Flash) (Flash Extra Area)	15.72 MB 320 KB 1 MB
FFFB 8000 _H to FFFB EFFF _H	I-Bus area	28 KB
FFFB F000 _H to FFFB FFFF _H	Access prohibited area	
FFFC 0000 _H to FFFC 3FFF _H	CPU peripheral area (self)	16 KB
FFFC 4000 _H to FFFC 7FFF _H	CPU peripheral area (CPU0)	16 KB
FFFC 8000 _H to FFFC BFFF _H	CPU peripheral area (CPU1)	16 KB
FFFC C000 _H to FFFC FFFF _H	CPU peripheral area (CPU2)	16 KB
FFFD 0000 _H to FFFD 3FFF _H	CPU peripheral area (CPU3)	16 KB
FFFD 4000 _H to FFFD 7FFF _H	CPU peripheral area (CPU4)	16 KB
FFFD 8000 _H to FFFD BFFF _H	CPU peripheral area (CPU5)	16 KB
FFFD C000 _H to FFFF FFFF _H	Access prohibited area	

See **Section 3, CPU System** for details about each area.

See **Section 43.2.3, Mapping of Flash Extra Area** for details about Flash Extra Area.

See **Section 43.2.4, Examples of the Chip Writing** for details about OTP setting.

See *RH850/E2x Safety Application Note* for details about ECC test Area in Code flash.

Table 4.2 Address MAP of RH850/E2UH Single Map Mode

Address	Address Space Type	Size
0000 0000 _H to 00FF FFFF _H	Code flash (User area)	16 MB
0100 0000 _H to 03FF FFFF _H	Access prohibited area	
0400 0000 _H to 04FF FFFF _H	Code flash (Mirror Area)	16MB
0500 0000 _H to 07FF FFFF _H	Access prohibited area	
0800 0000 _H to 0800 FFFF _H	Code flash (User boot area 0)	64 KB
0801 0000 _H to 0802 FFFF _H	Access prohibited area	
0803 0000 _H to 0803 7FFF _H	Code flash (Product Info Area 0)	32 KB
0803 8000 _H to 0804 FFFF _H	Access prohibited area	
0805 0000 _H to 0805 FFFF _H	Code flash (ECC test Area of Bank A)	64 KB
0806 0000 _H to 082F FFFF _H	Access prohibited area	
0830 0000 _H to 0830 FFFF _H	Code flash (User boot area 1)	64 KB
0831 0000 _H to 0832 FFFF _H	Access prohibited area	
0833 0000 _H to 0833 7FFF _H	Code flash (Product Info Area 1)	32 KB
0833 8000 _H to 0834 FFFF _H	Access prohibited area	
0835 0000 _H to 0835 FFFF _H	Code flash (ECC test Area of Bank B)	64 KB
0836 0000 _H to 0864 FFFF _H	Access prohibited area	
0865 0000 _H to 0865 FFFF _H	Code flash (ECC test Area of Bank C)	64 KB
0866 0000 _H to 0894 FFFF _H	Access prohibited area	
0895 0000 _H to 0895 FFFF _H	Code flash (ECC test Area of Bank D)	64 KB
0896 0000 _H to 08C4 FFFF _H	Access prohibited area	
08C5 0000 _H to 08C5 FFFF _H	Code flash (ECC test Area of Bank E)	64 KB
08C6 0000 _H to 08E4 FFFF _H	Access prohibited area	
08E5 0000 _H to 08E5 FFFF _H	Code flash (ECC test Area of Bank F)	64 KB
08E6 0000 _H to 0BFE FFFF _H	Access prohibited area	
0BFF 0000 _H to 0BFF FFFF _H	Code flash (ECC test Area of Global Area)	64 KB
0C00 0000 _H to 0CFF FFFF _H	Code flash (Blank check Area)	16 MB
0D00 0000 _H to 0FFF FFFF _H	Access prohibited area	
1000 0000 _H to FFFF FFFF _H	This address area does not change even in single map mode. Please refer to Table 4.1	

See **Section 3, CPU System** for details about each area.

See **Section 43.2.3, Mapping of Flash Extra Area** for details about Flash Extra Area.

See **Section 43.2.4, Examples of the Chip Writing** for details about OTP setting.

See *RH850/E2x Safety Application Note* for details about ECC test Area in Code flash.

Table 4.3 Address MAP of RH850/E2UH Double Map Mode

Address	Address Space Type	Size
0000 0000 _H to 007F FFFF _H	Code flash (User area Valid Area)	8 MB
0080 0000 _H to 01FF FFFF _H	Access prohibited area	
0200 0000 _H to 027F FFFF _H	Code flash (User area Invalid Area)	8 MB
0280 0000 _H to 03FF FFFF _H	Access prohibited area	
0400 0000 _H to 047F FFFF _H	Code flash (Mirror Area)	8MB
0480 0000 _H to 05FF FFFF _H	Access prohibited area	
0600 0000 _H to 067F FFFF _H	Code flash (Mirror Area)	8MB
0680 0000 _H to 07FF FFFF _H	Access prohibited area	
0800 0000 _H to 0800 FFFF _H	Code flash (User boot area Valid Area)	64 KB
0801 0000 _H to 0802 FFFF _H	Access prohibited area	
0803 0000 _H to 0803 7FFF _H	Code flash (Product Info Area Valid Area)	32 KB
0803 8000 _H to 0804 FFFF _H	Access prohibited area	
0805 0000 _H to 0805 FFFF _H	Code flash (ECC test Area of Bank A or B ^{*1})	64 KB
0806 0000 _H to 0834 FFFF _H	Access prohibited area	
0835 0000 _H to 0835 FFFF _H	Code flash (ECC test Area of Bank C or D ^{*1})	64 KB
0836 0000 _H to 0864 FFFF _H	Access prohibited area	
0865 0000 _H to 0865 FFFF _H	Code flash (ECC test Area of Bank E or F ^{*1})	64 KB
0866 0000 _H to 09FF FFFF _H	Access prohibited area	
0A00 0000 _H to 0A00 FFFF _H	Code flash (User boot area Invalid Area)	64 KB
0A01 0000 _H to 0A02 FFFF _H	Access prohibited area	
0A03 0000 _H to 0A03 7FFF _H	Code flash (Product Info Area Invalid Area)	32 KB
0A03 8000 _H to 0A04 FFFF _H	Access prohibited area	
0A05 0000 _H to 0A05 FFFF _H	Code flash (ECC test Area of Bank A or B ^{*1})	64 KB
0A06 0000 _H to 0A34 FFFF _H	Access prohibited area	
0A35 0000 _H to 0A35 FFFF _H	Code flash (ECC test Area of Bank C or D ^{*1})	64 KB
0A36 0000 _H to 0A64 FFFF _H	Access prohibited area	
0A65 0000 _H to 0A65 FFFF _H	Code flash (ECC test Area of Bank E or F ^{*1})	64 KB
0A66 0000 _H to 0BFE FFFF _H	Access prohibited area	
0BFF 0000 _H to 0BFF FFFF _H	Code flash (ECC test Area of Global Area)	64 KB
0C00 0000 _H to 0CFF FFFF _H	Code flash (Blank check Area)	16 MB
0D00 0000 _H to 0FFF FFFF _H	Access prohibited area	
1000 0000 _H to FFFF FFFF _H	This address area does not change even in double map mode. Please refer to Table 4.1	

Note 1. Mapped Bank is dependent on option byte setting. See **Section 43, Flash Memory**.

See **Section 3, CPU System** for details about each area.

See **Section 43.2.3, Mapping of Flash Extra Area** for details about Flash Extra Area.

See **Section 43.2.4, Examples of the Chip Writing** for details about OTP setting.

See *RH850/E2x Safety Application Note* for details about ECC test Area in Code flash.

Table 4.4 Address MAP of RH850/E2x-FCC2 (For E2H) and E2H (E2x-FCC2 Compatible Mode)

Address	Address Space Type	Size
0000 0000 _H to 00BF FFFF _H	Code flash (User area)	12 MB
00C0 0000 _H to 03FF FFFF _H	Access prohibited area	
0400 0000 _H to 04BF FFFF _H	Code flash (Mirror Area)	12MB
04C0 0000 _H to 07FF FFFF _H	Access prohibited area	
0800 0000 _H to 0800 FFFF _H	Code flash (User boot area)	64 KB
0801 0000 _H to 0802 FFFF _H	Access prohibited area	
0803 0000 _H to 0803 7FFF _H	Code flash (Product Info Area)	32 KB
0803 8000 _H to 0804 FFFF _H	Access prohibited area	
0805 0000 _H to 0805 FFFF _H	Code flash (ECC test Area of Bank A)	64 KB
0806 0000 _H to 0834 FFFF _H	Access prohibited area	
0835 0000 _H to 0835 FFFF _H	Code flash (ECC test Area of Bank B)	64 KB
0836 0000 _H to 0864 FFFF _H	Access prohibited area	
0865 0000 _H to 0865 FFFF _H	Code flash (ECC test Area of Bank C)	64 KB
0866 0000 _H to 0894 FFFF _H	Access prohibited area	
0895 0000 _H to 0895 FFFF _H	Code flash (ECC test Area of Bank D)	64 KB
0896 0000 _H to 0BFE FFFF _H	Access prohibited area	
0BFF 0000 _H to 0BFF FFFF _H	Code flash (ECC test Area of Global Area)	64 KB
0C00 0000 _H to 0CBF FFFF _H	Code flash (Blank check Area)	12 MB
0CC0 0000 _H to 0FFF FFFF _H	Access prohibited area	
1000 0000 _H to 1FFF FFFF _H	H-Bus area	256 MB
2000 0000 _H to 2FFF FFFF _H	External memory area	256 MB
3000 0000 _H to FD5F FFFF _H	Access prohibited area	
FD60 0000 _H to FD60 7FFF _H	Local RAM (CPU3)	32 KB
FD60 8000 _H to FD7F FFFF _H	Access prohibited area	
FD80 0000 _H to FD80 7FFF _H	Local RAM (CPU2)	32 KB
FD80 8000 _H to FD9F FFFF _H	Access prohibited area	
FDA0 0000 _H to FDA0 7FFF _H	Local RAM (CPU1)	32 KB
FDA0 8000 _H to FDBF FFFF _H	Access prohibited area	
FDC0 0000 _H to FDC0 7FFF _H	Local RAM (CPU0)	32 KB
FDC0 8000 _H to FDDF FFFF _H	Access prohibited area	
FDE0 0000 _H to FDE0 7FFF _H	Local RAM (self)	32 KB
FDE0 8000 _H to FDFE FFFF _H	Access prohibited area	
FE00 0000 _H to FE0F FFFF _H	Cluster RAM	1024 KB
FE10 0000 _H to FEFF FFFF _H	Access prohibited area	
FF00 0000 _H to FFFB 7FFF _H	P-Bus area	15.72 MB
(FF20 0000 _H to FF24 7FFF _H)	(Data Flash)	288 KB
(FF30 0000 _H to FF3F FFFF _H)	(Flash Extra Area)	1 MB
FFFB 8000 _H to FFFB EFFF _H	I-Bus area	28 KB
FFFB F000 _H to FFFB FFFF _H	Access prohibited area	
FFFC 0000 _H to FFFC 3FFF _H	CPU peripheral area (self)	16 KB
FFFC 4000 _H to FFFC 7FFF _H	CPU peripheral area (CPU0)	16 KB
FFFC 8000 _H to FFFC BFFF _H	CPU peripheral area (CPU1)	16 KB
FFFC C000 _H to FFFC FFFF _H	CPU peripheral area (CPU2)	16 KB
FFFD 0000 _H to FFFD 3FFF _H	CPU peripheral area (CPU3)	16 KB
FFFD 4000 _H to FFFF FFFF _H	Access prohibited area	

See **Section 3, CPU System** for details about each area.

See **Section 43.2.3, Mapping of Flash Extra Area** for details about Flash Extra Area.

See **Section 43.2.4, Examples of the Chip Writing** for details about OTP setting.

See *RH850/E2x Safety Application Note* for details about ECC test Area in Code flash.

Table 4.5 Address MAP of RH850/E2H Single Map Mode

Address	Address Space Type	Size
0000 0000 _H to 00BF FFFF _H	Code flash (User area)	12 MB
00C0 0000 _H to 03FF FFFF _H	Access prohibited area	
0400 0000 _H to 04BF FFFF _H	Code flash (Mirror Area)	12MB
04C0 0000 _H to 07FF FFFF _H	Access prohibited area	
0800 0000 _H to 0800 FFFF _H	Code flash (User boot area 0)	64 KB
0801 0000 _H to 0802 FFFF _H	Access prohibited area	
0803 0000 _H to 0803 7FFF _H	Code flash (Product Info Area 0)	32 KB
0803 8000 _H to 0804 FFFF _H	Access prohibited area	
0805 0000 _H to 0805 FFFF _H	Code flash (ECC test Area of Bank A)	64 KB
0806 0000 _H to 082F FFFF _H	Access prohibited area	
0830 0000 _H to 0830 FFFF _H	Code flash (User boot area 1)	64 KB
0831 0000 _H to 0832 FFFF _H	Access prohibited area	
0833 0000 _H to 0833 7FFF _H	Code flash (Product Info Area 1)	32 KB
0833 8000 _H to 0834 FFFF _H	Access prohibited area	
0835 0000 _H to 0835 FFFF _H	Code flash (ECC test Area of Bank B)	64 KB
0836 0000 _H to 0864 FFFF _H	Access prohibited area	
0865 0000 _H to 0865 FFFF _H	Code flash (ECC test Area of Bank C)	64 KB
0866 0000 _H to 0894 FFFF _H	Access prohibited area	
0895 0000 _H to 0895 FFFF _H	Code flash (ECC test Area of Bank D)	64 KB
0896 0000 _H to 0BFE FFFF _H	Access prohibited area	
0BFF 0000 _H to 0BFF FFFF _H	Code flash (ECC test Area of Global Area)	64 KB
0C00 0000 _H to 0CBF FFFF _H	Code flash (Blank check Area)	12 MB
0CC0 0000 _H to 0FFF FFFF _H	Access prohibited area	
1000 0000 _H to FFFF FFFF _H	This address area does not change even in single map mode. Please refer to Table 4.4	

See **Section 3, CPU System** for details about each area.

See **Section 43.2.3, Mapping of Flash Extra Area** for details about Flash Extra Area.

See **Section 43.2.4, Examples of the Chip Writing** for details about OTP setting.

See *RH850/E2x Safety Application Note* for details about ECC test Area in Code flash.

Table 4.6 Address MAP of RH850/E2H Double Map Mode

Address	Address Space Type	Size
0000 0000 _H to 005F FFFF _H	Code flash (User area Valid Area)	6 MB
0060 0000 _H to 01FF FFFF _H	Access prohibited area	
0200 0000 _H to 025F FFFF _H	Code flash (User area Invalid Area)	6 MB
0260 0000 _H to 03FF FFFF _H	Access prohibited area	
0400 0000 _H to 045F FFFF _H	Code flash (Mirror Area)	6MB
0460 0000 _H to 05FF FFFF _H	Access prohibited area	
0600 0000 _H to 065F FFFF _H	Code flash (Mirror Area)	6MB
0660 0000 _H to 07FF FFFF _H	Access prohibited area	
0800 0000 _H to 0800 FFFF _H	Code flash (User boot area Valid Area)	64 KB
0801 0000 _H to 0802 FFFF _H	Access prohibited area	
0803 0000 _H to 0803 7FFF _H	Code flash (Product Info Area Valid Area)	32 KB
0803 8000 _H to 0804 FFFF _H	Access prohibited area	
0805 0000 _H to 0805 FFFF _H	Code flash (ECC test Area of Bank A or B ^{*1})	64 KB
0806 0000 _H to 0834 FFFF _H	Access prohibited area	
0835 0000 _H to 0835 FFFF _H	Code flash (ECC test Area of Bank C or D ^{*1})	64 KB
0836 0000 _H to 09FF FFFF _H	Access prohibited area	
0A00 0000 _H to 0A00 FFFF _H	Code flash (User boot area Invalid Area)	64 KB
0A01 0000 _H to 0A02 FFFF _H	Access prohibited area	
0A03 0000 _H to 0A03 7FFF _H	Code flash (Product Info Area Invalid Area)	32 KB
0A03 8000 _H to 0A04 FFFF _H	Access prohibited area	
0A05 0000 _H to 0A05 FFFF _H	Code flash (ECC test Area of Bank A or B ^{*1})	64 KB
0A06 0000 _H to 0A34 FFFF _H	Access prohibited area	
0A35 0000 _H to 0A35 FFFF _H	Code flash (ECC test Area of Bank C or D ^{*1})	64 KB
0A36 0000 _H to 0BFE FFFF _H	Access prohibited area	
0BFF 0000 _H to 0BFF FFFF _H	Code flash (ECC test Area of Global Area)	64 KB
0C00 0000 _H to 0CBF FFFF _H	Code flash (Blank check Area)	12 MB
0CC0 0000 _H to 0FFF FFFF _H	Access prohibited area	
1000 0000 _H to FFFF FFFF _H	This address area does not change even in double map mode. Please refer to Table 4.4	

Note 1. Mapped Bank is dependent on option byte setting. See **Section 43, Flash Memory**.

See **Section 3, CPU System** for details about each area.

See **Section 43.2.3, Mapping of Flash Extra Area** for details about Flash Extra Area.

See **Section 43.2.4, Examples of the Chip Writing** for details about OTP setting.

See *RH850/E2x Safety Application Note* for details about ECC test Area in Code flash.

4.2 Address Space Viewed from Each Bus Master

Figure 4.1 shows address spaces of RH850/E2x-FCC2 (For E2UH) and E2UH viewed from each bus master.

Figure 4.2 shows address spaces of RH850/E2x-FCC2 (For E2H) and E2H viewed from each bus master.

4.2.1 Space in which Instructions can be Fetched

1. Instructions of CPU0, CPU1, CPU2, CPU3, CPU4, CPU5 and ICUM can be fetched from the code flash, local RAM and Cluster RAM.
2. The reset vector (RBASE initial value) of CPU0, CPU1, CPU2, CPU3, CPU4 and CPU5:
 - When starting up from the user boot area, its head address is 0800 0000_H.
 - When starting up from the user area of RH850/E2x-FCC2 and E2UH, its head address is selectable from 0000 0000 to 00FF FFFF_H by Option byte. For details, see **Section 43, Flash Memory**.
 - When starting up from the user area of RH850/ E2H, its head address is selectable from 0000 0000 to 00BF FFFF_H by Option byte. For details, see **Section 43, Flash Memory**.
3. The reset vector (RBASE initial value) of ICUM:
 - See *the E2x ICUMD User's Manual*.

4.2.2 Data Space Accessible by CPU0, CPU1, CPU2, CPU3, CPU4, CPU5

All spaces are accessible.

NOTE

The data accesses inside the following target data space are operated in the same order as the program.

- Code Flash
- H-Bus area Group 0, 1, 2, 4, 5
(H-Bus area Group 4 is not implemented in E2H.)
- External memory area*¹
- P-Bus area Group 0, 1, 2H/2L, 3, 4, 5, 6, 7, 8, 9
- I-Bus area 0, 1, 2, 3
- CPU peripheral area (self, CPU0, CPU1, CPU2, CPU3, CPU4, CPU5)
(CPU4, CPU5 is not implemented in E2H.)
- Cluster RAM Cluster 0, 1, 2*²
(Cluster 2 is not implemented in E2H.)

Note 1. The data accesses within 16 MB boundaries is operated in the same order as the program.
(2000 0000_H to 20FF FFFF_H, 2100 0000_H to 21FF FFFF_H, 2200 0000_H to, ... ,2F00 0000_H to 2FFF FFFF_H)

Note 2. The data accesses between Cluster0 RAM, Cluster1 RAM and Cluster2 RAM are also operated in the same order as the program.

The load accesses inside the following target data space may be operated before the completion of the preceding access (load or store). In order to guarantee the order of accesses, synchronization processing by software for the preceding access is necessary.

- Local RAM (self, CPU0, CPU1, CPU2, CPU3, CPU4, CPU5)
(CPU4, CPU5 is not implemented in E2H.)

For the data accesses between different target spaces, the order of data accesses is not guaranteed as the program order.

In order to guarantee the order of accesses, synchronization processing by software for the preceding access is necessary.

For details of synchronization processing, refer to **Section 3.8.1, Synchronization of Store Instruction Completion and Subsequent Instruction Generation** and **Section 3.8.2, Synchronization of Load Instruction Completion and Subsequent Instruction Generation**.

4.2.3 Data Space Accessible by ICUM

See the *E2x ICUMD User's Manual*.

4.2.4 Data Space Accessible by DMA (sDMAC, DTS)

See **Figure 4.1**, **Figure 4.2** for the accessible spaces from the DMA.

4.2.5 Data Space Accessible by H-Bus Master

See **Figure 4.1**, **Figure 4.2** for the accessible spaces from the H-Bus Master.

NOTE

H-Bus Master can't access to each H-Bus Slave (except RHSIF). See table below about detail of HBUS access.

H-Bus Master \ H-Bus Slave	RHSIF0	FLXA0	ETNC	FLXA1	BSC
RHSIF0	✓	✓	✓	✓	✓
FLXA0	—	—	—	—	✓
HS-SPI0	—	—	—	—	✓
ETNC	—	—	—	—	✓
FLXA1	—	—	—	—	✓

	Access from CPU0/1/2/3/4/5	Access from DMA	Access from H-Bus Master

Fetch and data access available
Data access available
Access prohibited

Figure 4.2 Address Space of RH850/E2x-FCC2 (For E2H) and E2H Viewed from Each Bus Master*1

Note 1. This figure shows the address space of RH850/E2x-FCC2 (For E2H) and E2H (E2x-FCC2 compatible mode). See **Table 4.5** and **Table 4.6** for details on the address of single map mode and double map mode.

Note 2. For usage assignment of instruction codes, see **Section 3.8.6, Usage Notes on Prefetching**.

4.3 Cluster RAM and Retention RAM

The cluster RAM of RH850/E2x-FCC2 (For E2UH) and E2UH is divided into three, Cluster0, Cluster1 and Cluster2. Different clusters can be accessed concurrently. The upper 128 Kbytes of Cluster2 is the retention RAM that retains data even during poweroff standby state.

Figure 4.3 Cluster RAM of RH850/E2x-FCC2 (For E2UH) and E2UH

The cluster RAM of RH850/E2x-FCC2 (For E2H) and E2H is divided into two, Cluster0 and Cluster1. Different clusters can be accessed concurrently. The upper 128 Kbytes of Cluster1 is the retention RAM that retains data even during poweroff standby state.

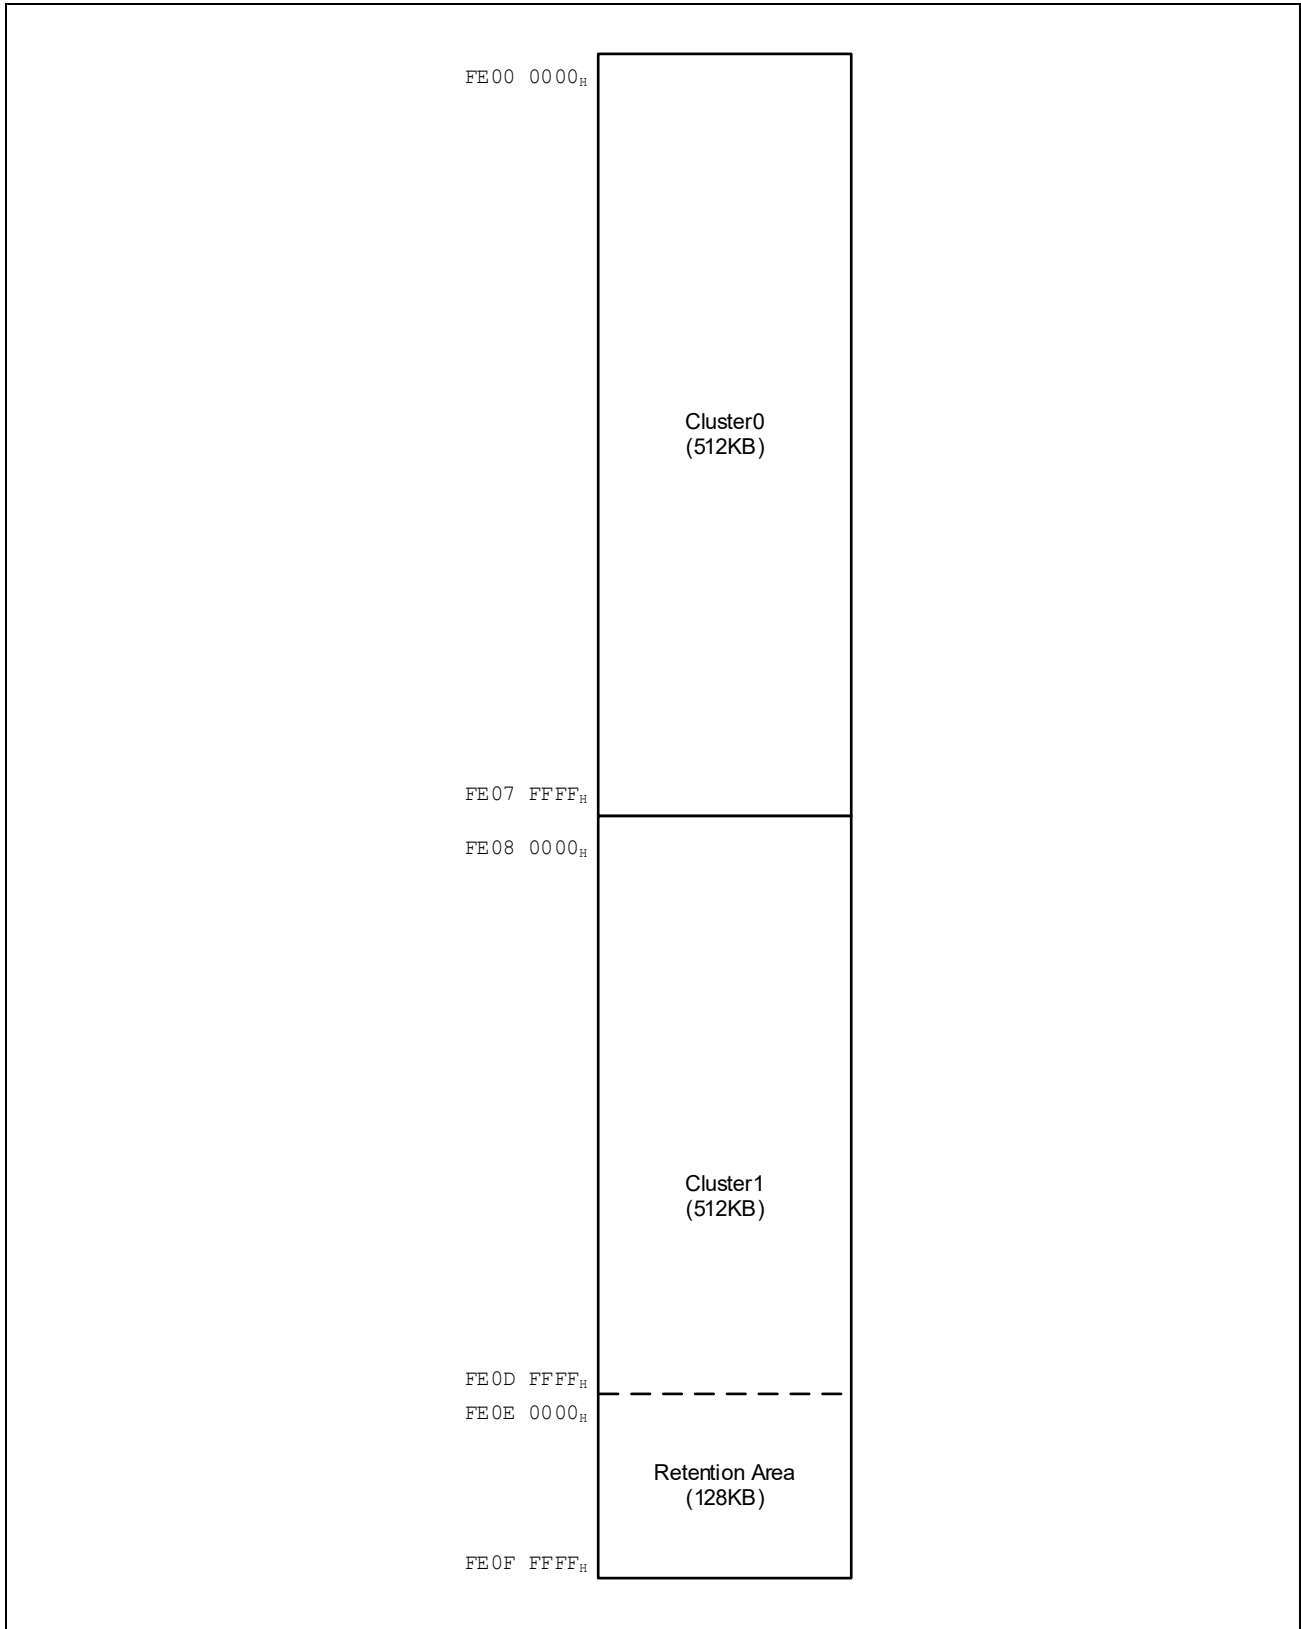

Figure 4.4 Cluster RAM of RH850/E2x-FCC2 (For E2H) and E2H

4.4 Cluster Division of Code Flash

The code flash of RH850/E2x-FCC2 (For E2UH) and E2UH is divided into three, Cluster0, Cluster1 and Cluster2.

Figure 4.5 shows the address map of code flash in RH850/E2x-FCC2 (For E2UH) and E2UH (E2x-FCC2 compatible mode). **Figure 4.6** shows the address map of code flash in RH850/E2UH single map mode. **Figure 4.7** shows the address map of code flash in RH850/E2UH double map mode. The access latency from CPU0 or CPU1 to Cluster0 code flash is faster than the access to Cluster1/2 code flash, because CPU0 and CPU1 are in Cluster0. The access latency from CPU2 or CPU3 to Cluster1 code flash is faster than the access to Cluster0/2 code flash, because CPU2 and CPU3 are in Cluster1. The access latency from CPU4 or CPU5 to Cluster2 code flash is faster than the access to Cluster0/1 code flash, because CPU4 and CPU5 are in Cluster2. For details of code flash, see **Section 43, Flash Memory**.

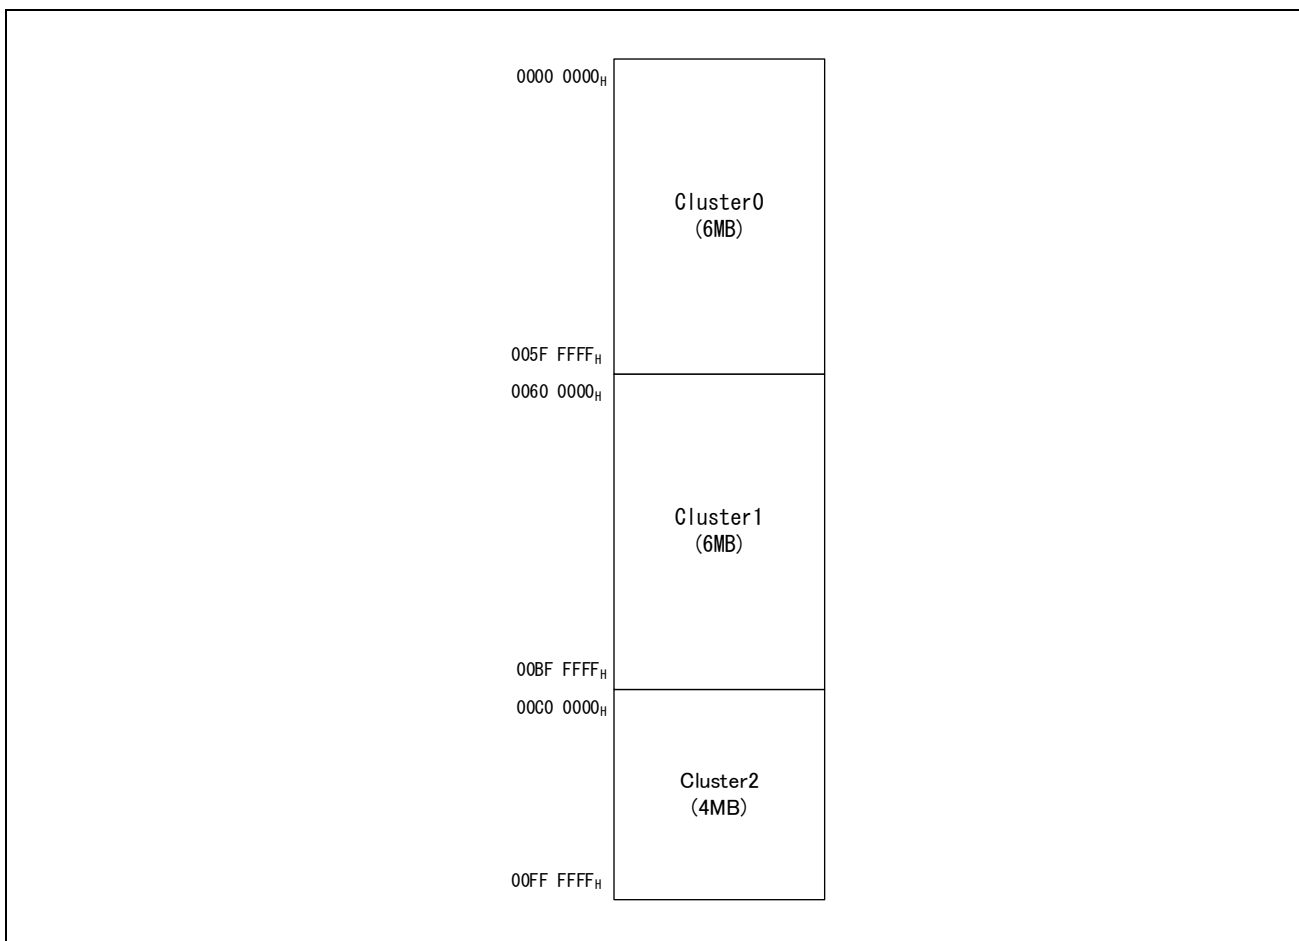

Figure 4.5 Code Flash of RH850/E2x-FCC2 (For E2UH) and E2UH (E2x-FCC2 Compatible Mode)

Figure 4.6 Code Flash of RH850/E2UH Single Map Mode

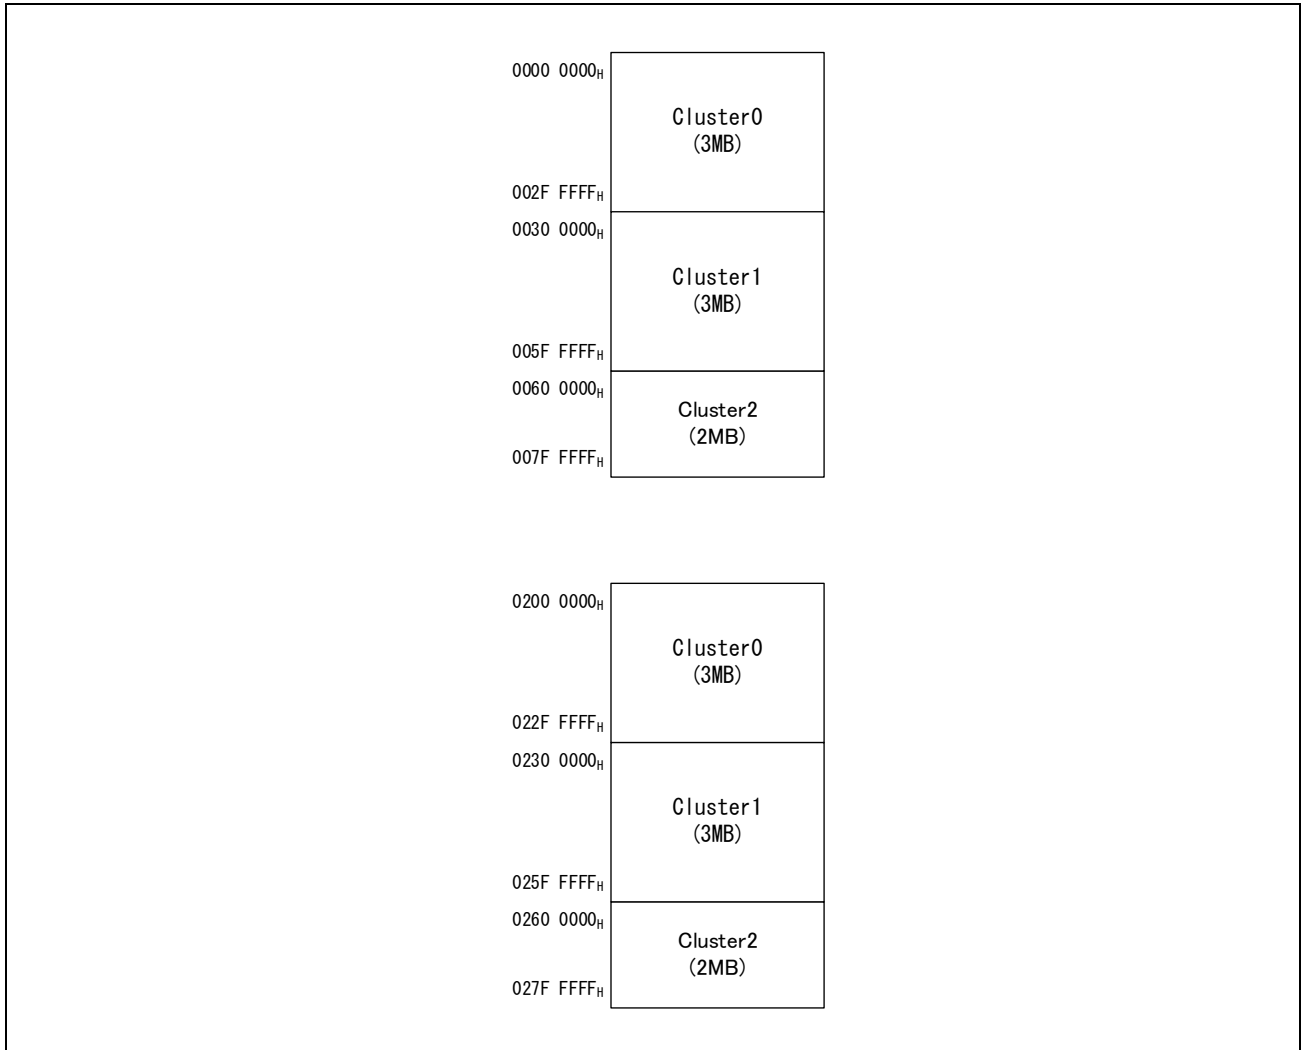

Figure 4.7 Code Flash of RH850/E2UH Double Map Mode

The code flash of RH850/E2x-FCC2 (For E2H) and E2H is divided into two, Cluster0 and Cluster1. **Figure 4.8** shows the address map of code flash in RH850/E2x-FCC2 (For E2H) and E2H (E2x-FCC2 compatible mode). **Figure 4.9** shows the address map of code flash in RH850/E2H single map mode. **Figure 4.10** shows the address map of code flash in RH850/E2H double map mode. The access latency from CPU0 or CPU1 to Cluster0 code flash is faster than the access to Cluster1 code flash, because CPU0 and CPU1 are in Cluster0. The access latency from CPU2 or CPU3 to Cluster1 code flash is faster than the access to Cluster0 code flash, because CPU2 and CPU3 are in Cluster1. For details of code flash, see **Section 43, Flash Memory**.

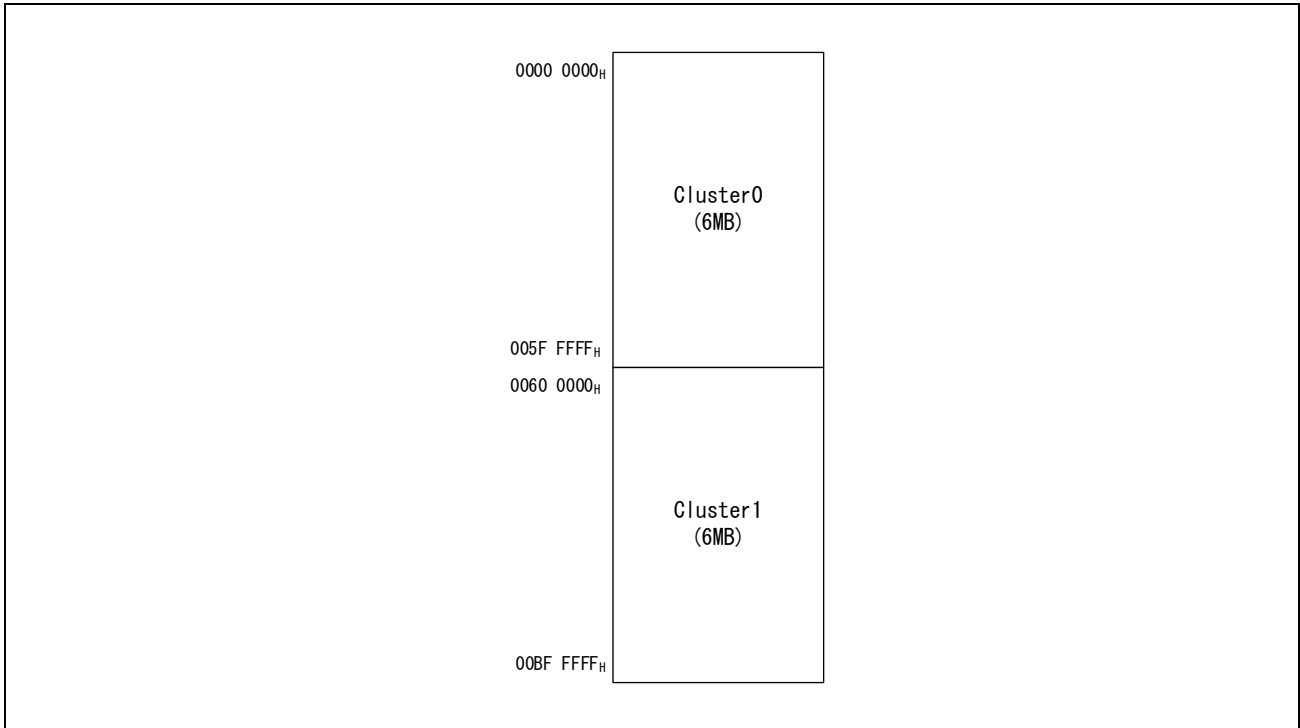

Figure 4.8 Code Flash of RH850/E2x-FCC2 (For E2H) and E2H (E2x-FCC2 Compatible Mode)

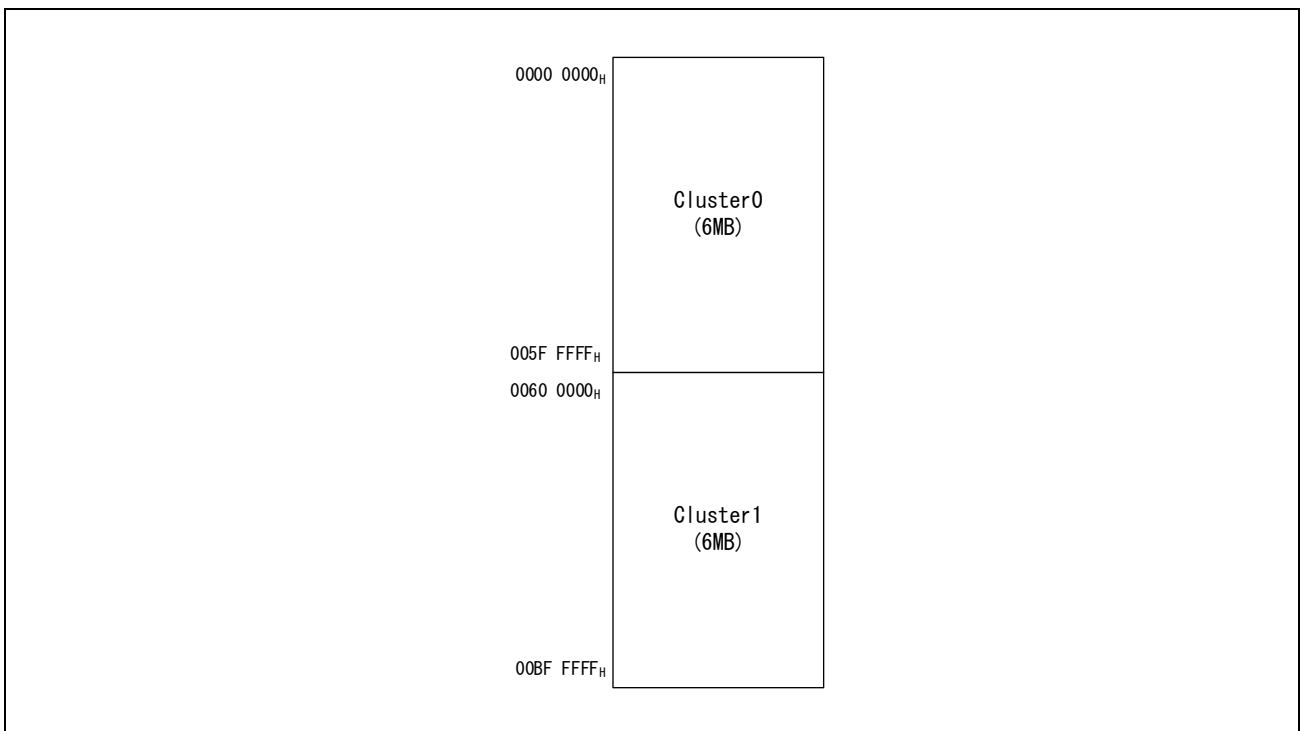

Figure 4.9 Code flash of RH850/E2H Single Map Mode

Figure 4.10 Code flash of RH850/E2H Double Map Mode

Section 5 Operating Modes

5.1 Features

This LSI has multiple operating modes, which can be selected with the three pins (MD1, MD0 and TRST) and the settings of option bytes STMSEL1 / STMSEL0. For the procedures to set STMSEL1 / STMSEL0, see **Section 43, Flash Memory**. **Table 5.1** lists the operating modes. The values of MD0, MD1 and TRST are latched at the rising edge of RES_IN to determine the operating mode. These pins are continually monitored during operation to detect mode errors.

Table 5.1 Mode List

Value Set to Pin			Value Set in Option Byte		Mode	Startup Area	Types of Debug Interface*1,*4	Flash Writer Interface	Remarks
MD1	MD0	TRST	STMS EL1	STMS EL0					
0	0	0	0	0	Normal operation mode	User area*2	Nexus/LPD	—	BIST is available
0	0	0	0	1	User boot mode	User boot area	Nexus/LPD	—	BIST is available
0	0	0	1	X	Serial programming mode	Boot firmware	Nexus/LPD*6	CSI	Serial programming is available
0	0	1*5,*8	X	0	Normal operation mode	User area*2	Nexus/LPD/ Boundary scan*7	—	CPU will not run*5 BIST is not available*8
0	0	1*5,*8	X	1	User boot mode	User boot area	Nexus/LPD/ Boundary scan*7	—	CPU will not run*5 BIST is not available*8
0	1	X	X	X	Serial programming mode	Boot firmware	Nexus/LPD*6	RS-CANFD / RS-CAN, CSI, 2-wire UART*3	Serial programming is available

Note 1. For the correspondence between the pin function and pin state in each debug interface. See **Section 2, Pin Function**.

Note 2. Reset vector address can be set by Option Bytes for the ROM area. See **Section 43, Flash Memory**.

Note 3. Method for changing the serial communication mode is shown in **Section 43, Flash Memory**. CSI is the "Clockless Serial Interface".

Note 4. Nexus/LPD for debug is determined by the TDI level when TRST is released. Nexus shall be selected when Boundary scan runs.

Note 5. CPU will not run after reset release in this mode when TRST = 1. This mode is for the purpose of On-Chip debug or when using a boundary scan. Option bytes can be used to disable the CPU from running after reset. See **Section 44, Basic Hardware Protection (BHP)** and **Section 43, Flash Memory** for details.

Note 6. When RS-CAN or RS-CANFD boot is selected.

Note 7. Boundary scan can be run when the CPU and ICUM are not running. Boundary scan is selected by using JTAG instructions. TDI shall be set 1 when TRST is released for running Boundary scan.

Note 8. BIST will not run when TRST = 1.

5.1.1 Normal Operation Mode

This mode is the default mode for execution of application software. The Boundary scan, Power-Up BIST, Shutdown BIST and the On-chip Debug capabilities also use this mode. After reset release, instruction fetch is carried out from the user area. For the reset vector of each CPU, see **Section 43, Flash Memory**.

The CPU will not autonomously run when TRST = 1. A debugger must be used to cause the CPU to run.

5.1.2 User Boot Mode

This mode is basically the same as Normal Operation Mode except for the fetch area.

This mode is used to provide an alternative boot location for application software.

After release from the reset state, instruction fetch is carried out from the user boot area.

5.1.3 Serial Programming Mode

This mode is initiated by an external programming device. Use it to store application code or application data in the flash memories of the device. After reset release, the MCU boots up from the on-chip boot firmware and establishes a connection in the specified transmission method. For details, see **Section 43, Flash Memory**.

5.2 Input Pins

Table 5.2 shows the pin information for mode setting. The states of all the mode pins are latched in the Mode Register.

Table 5.2 Pin Information for Mode Setting

Pin Name	I/O	Function
MD1	Input	Operating mode select pin
MD0	Input	Operating mode select pin
$\overline{\text{TRST}}$	Input	Shared pin used as Nexus/JTAG reset pin and operating mode select pin

5.3 Register Description

5.3.1 List of Registers

The following table lists the operating mode registers.

Table 5.3 List of Registers

Module Name	Register Name	Symbol	Address	Access	Access Protection
SYCTRL	Mode Register	MODE	FF70 0000 _H	32	
SYCTRL	FHVE3 Control Register	FHVE3	FF70 3800 _H	32	
SYCTRL	FHVE15 Control Register	FHVE15	FF70 3804 _H	32	

Table 5.4 Register Reset Condition

Unit Name	Register Name	Reset Source					
		Power Up Reset	System Reset 1	System Reset 2	Application Reset	Module Reset	JTAG Reset
MODE	ALL Registers	✓	✓*1	—	—	—	—

Note 1. VMON Reset is excluded.

5.3.2 MODE — Mode Register

This register indicates the Operating Mode of the device.

The states of the mode pins and mode select option bytes are latched in this register when the external reset or standby reset is released.

Value after reset: 000x 000x_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	STMSEL1	STMSEL0
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	X	X
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	MD1	MD0	TRST
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	x	x	x
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 5.5 Mode Register Contents

Bit Position	Bit Name	Function
31 to 18	—	Reserved. When read, the value after reset is returned. When writing, write the value after reset.
17	STMSEL1	STMSEL1 This bit indicates the status of the Option byte STMSEL1 0: Low-level detected 1: High-level detected
16	STMSEL0	STMSEL0 This bit indicates the status of the Option byte STMSEL0 0: Low-level detected 1: High-level detected
15 to 3	—	Reserved. When read, the value after reset is returned. When writing, write the value after reset.
2	MD1	MD 1 This bit indicates the level of the signal latched for Mode Pin MD 1 0: Low-level detected 1: High-level detected
1	MD0	MD 0 This bit indicates the level of the signal latched for Mode Pin MD 0 0: Low-level detected 1: High-level detected
0	TRST	TRST This bit indicates the level of the signal latched for Mode Pin TRST 0: Low-level detected 1: High-level detected

5.3.3 FHVE3 — FHVE3 Control Register

Please refer to **Section 43, Flash Memory** for details on this register.

5.3.4 FHVE15 — FHVE15 Control Register

Please refer to **Section 43, Flash Memory** for details on this register.

5.4 Mode Error

This LSI has the ability to notify the ECM when it detects an unintended activation of a different mode or unintended de-activation of the currently selected mode. The MD1, MD0 and TRST pins are monitored, along with the STMSEL0 and STMSEL1 bits to detect unintended changes. If these values change when they are not expected to change, a mode check error occurs.

The unintended modes are as follows. For details, see **Section 41, Error Control Module (ECM)**.

Detectable unintended modes are shown in **Table 5.6**.

Table 5.6 List of Detectable Mode Errors

User Intended Mode	Detectable Mode Error
Normal Operation Mode	Unintended deactivation of Normal Operation Mode
	Unintended activation of User Boot Mode
User Boot Mode	Unintended activation of Normal Operation Mode
	Unintended deactivation of User Boot Mode
Normal Operation Mode / User Boot Mode	Unintended activation of Serial Programming Mode
	Unintended activation of Production Test Mode
Other than On chip debug mode	Unintended Debug Enabled
any mode	The detection of differences between the latched value and from Flash.

NOTE

Although it is possible to change the setting of MD0 or $\overline{\text{TRST}}$ (e.g. for the purpose of selecting communication method) after RES_IN is released, a mode error is also detected when MD0 or TRST is changed after RES_IN is released in serial programming mode. MD1 shall be fixed to "0" in user mode.

Mode check error functions work only when the settings of the external terminals and STMSEL1, STMSEL0 correspond with Normal operation mode or User boot mode under the condition of $\overline{\text{TRST}} = 0$.

Section 6 Interrupts

This section describes the interrupt units.

6.1 Features of Interrupt Units

6.1.1 Units and Channels

This microcontroller has the following number of interrupt units.

Table 6.1 Number of Units (INTC1)

Product Name	RH850/E2x-FCC2	
	468 Pins	373 Pins

6.1.2 Register Base Address

The register base addresses of the interrupt units are listed in **Table 6.13**.

The address of each register in this section is specified as an offset from one of these base addresses.

Table 6.13 Register Base Address

Base Address Name	SELF / PE*	Base Address	Bus Group
<INTC1_base>	INTC1 of SELF	FFFC 0000 _H	—
<INTC1_base>	INTC1 of PE0	FFFC 4000 _H	CPU Peripheral 0
<INTC1_base>	INTC1 of PE1	FFFC 8000 _H	CPU Peripheral 1
<INTC1_base>	INTC1 of PE2	FFFC C000 _H	CPU Peripheral 2
<INTC1_base>	INTC1 of PE3	FFFD 0000 _H	CPU Peripheral 3
<INTC1_base>	INTC1 of PE4	FFFD 4000 _H	CPU Peripheral 4
<INTC1_base>	INTC1 of PE5	FFFD 8000 _H	CPU Peripheral 5
<INTC2_base>	—	FFF8 0000 _H	Peripheral Group 0
<INTIF_base>	—	FF09 0000 _H	Peripheral Group 9
<EINT_base>	—	FFC0 0000 _H	Peripheral Group 6

Note: PE4 and PE5 are not supported for E2H.

6.1.3 Clock Supply

Clock supplies for each interrupt unit are shown in the following table.

Table 6.14 Clock Supply

Unit Name	Unit Clock Name	Supply Clock Name
INTC1	clk	CLK_CPU
INTC2	pe_clk	CLK_CPU
	bus_clk	CLK_HBUS
INTIF	pclk	CLK_HBUS
EINT	clk_lsb	CLK_LSB

6.1.4 Interrupt Requests

The INTC2 interrupt requests are listed in the following table.

Table 6.15 Interrupt Requests

Interrupt Symbol Name	Unit Interrupt Signal	Outline	Interrupt Number	sDMA Trigger Number	DTS Trigger Number
INTBRDC0	INT_BRDC0	Broadcast notification 0	4	—	—
INTBRDC1	INT_BRDC1	Broadcast notification 1	5	—	—
INTBRDC2	INT_BRDC2	Broadcast notification 2	6	—	—
INTBRDC3	INT_BRDC3	Broadcast notification 3	7	—	—
INTEINTSW0	intreq_sint[0]	Software interrupt 0	14	—	—
INTEINTSW1	intreq_sint[1]	Software interrupt 1	15	—	—
INTEINTSW2	intreq_sint[2]	Software interrupt 2	16	—	—
INTEINTSW3	intreq_sint[3]	Software interrupt 3	17	—	—

6.1.5 Reset Sources

The reset sources for initialization of the interrupt units are shown in **Table 6.16**.

Table 6.16 Reset Sources

Unit Name	Register Name	Reset Condition					
		Power Up Reset	System Reset 1	System Reset 2	Application Reset	Module Reset	JTAG Reset
INTC1	All registers*1	✓	✓	✓	✓	—	—
INTC2	All registers*1	✓	✓	✓	✓	—	—
INTIF	All registers*1	✓	✓	✓	✓	—	—
EINT	All registers*1	✓	✓	✓	✓	—	—

Note 1. See **Table 6.20**.

6.1.6 External Input/Output Signals

External input/output signals of the interrupt units are listed below.

Table 6.17 External Input/Output Signals

Unit Signal Name	Direction	Outline	Alternative Port Pin Signal
EINT			
IRQ0	Input	External pin IRQ0	IRQ0
IRQ1	Input	External pin IRQ1	IRQ1
IRQ2	Input	External pin IRQ2	IRQ2
IRQ3	Input	External pin IRQ3	IRQ3
IRQ4	Input	External pin IRQ4	IRQ4
IRQ5	Input	External pin IRQ5	IRQ5
IRQ6	Input	External pin IRQ6	IRQ6
IRQ7	Input	External pin IRQ7	IRQ7
IRQ8	Input	External pin IRQ8	IRQ8
IRQ9	Input	External pin IRQ9	IRQ9
IRQ10	Input	External pin IRQ10	IRQ10
IRQ11	Input	External pin IRQ11	IRQ11
FENMI	Input	Non-maskable interrupt	NMI

6.2 Overview

6.2.1 Outline

INTC features

- Interrupt sources:
 - Non-maskable interrupt (FENMI): 1 channel for each CPU
 - FE level interrupt (FEINT0 to 1): 2 channels for each CPU
 - Low latency EI level interrupt (maskable) EIINT0 to 31:
 - 32 channels for each CPU
 - Inter-processor interrupts: 4 channels shared on channels 0 to 3
 - Broadcast interrupts: 4 channels shared on channels 4 to 7
 - Low speed interrupts (maskable) (EIINT32 to 695):
 - 664 channels shared by all CPUs
- Interrupt priority levels:
 - Up to 16 interrupt priority levels can be set by the interrupt control registers.
- Interrupt detection method:
 - The detection method of FEINT and EIINT interrupts are individually set to edge detection or level detection.
- Register banks:
 - For details about register banks, see **Section 3.2.4.5, Register Bank Function**.

INTC consists of INTC1 and INTC2

- INTC1
 - All CPUs have their own interrupt controller, INTC1. Each CPU accesses the INTC1 that corresponds to that CPU. INTC1 controls low-latency interrupts and has the following functions:
 - Priority setting
 - Interrupt mask setting
- INTC2
 - INTC2 is a common interrupt controller that all the CPUs share. INTC2 controls low-speed interrupts and has the following functions:
 - Priority setting
 - Interrupt mask setting
 - CPU binding setting
 - Broadcast interrupt setting

Others

- INTIF
 - Peripheral interrupt / TPTM interrupt control function
- EINT
 - External interrupt / Software interrupt / NMI control function

6.2.2 Functional Overview

The act of branching from a currently running program to a different program in response to an event is called an exception. This microcontroller supports the following types of exceptions. Exceptions are described in detail in **Section 3.2.4, Exceptions and Interrupts**.

The following three exceptions are called interrupts, and are described in this section:

- FE level Non-Maskable Interrupt (FENMI)

An FENMI interrupt is acknowledged even if another FE level interrupt, FEINT, has been generated.

- An FENMI interrupt is acknowledged even if the CPU system register PSW.NP = 1.
- Return from an FENMI interrupt is not possible and recovery is disabled, when multiple interrupts occur.

- FE level maskable interrupt (FEINT)

An FEINT interrupt can be acknowledged only if an FE level non-maskable interrupt, FENMI, has not been generated.

- An FEINT can be acknowledged if the CPU system register PSW.NP = 0.
- Return is enabled and recovery is enabled.

- EI level maskable interrupt (EIINT)

An EIINT interrupt can be acknowledged only if an FE level interrupt, FENMI or FEINT, has not been generated.

- An EIINT can be acknowledged if the CPU system registers PSW.NP = 0 and PSW.ID = 0, and when the following two conditions are satisfied:
 - The interrupt priority level is higher than the priority level of the acknowledgment status, which is set to the CPU system register ISPR.
 - The interrupt priority level is higher than the priority level, which is set to the CPU system register PLMR.
- Return is enabled and recovery is enabled.
- Interrupt masking can be specified for each interrupt channel.
- One of 16 interrupt priority levels can be specified for each interrupt channel.

For details about the PSW register, see **Section 3.2.3.2(5), PSW — Program Status Word**.

6.2.3 Interrupt Sources

6.2.3.1 FE Level Non-Maskable Interrupts

See **Section 3.2.4, Exceptions and Interrupts** for details about the priority order, return PC, status registers and return instructions.

Table 6.18 Non-Maskable Interrupt Requests

Interrupt	Interrupt Request		Unit	Priority Order	Detection Type	Exception Cause Code	Offset Address
	Symbol	Name					
FENMI	NMI	NMI pin	Port	*1	Edge	0E0 _H	0E0 _H

Note 1. See **Section 3.2.4, Exceptions and Interrupts**.

6.2.3.2 FE Level Maskable Interrupts

See **Section 3.2.4, Exceptions and Interrupts** for details about the priority order, return PC, status registers and return instructions.

Table 6.19 FE Level Interrupt Requests

Interrupt	Interrupt Request		Unit	Priority Order	Detection Type	Exception Cause Code	Offset Address
	Symbol	Cause					
	PE0						
FEINT0	FE level interrupt from the ECM		ECM	*1	Edge	F0 _H	F0 _H
FEINT1	Interrupt from Time Protection Timer for PE0*2		Time Protection Timer	*1	Level	F1 _H	F0 _H
	PE1						
FEINT0	FE level interrupt from the ECM		ECM	*1	Edge	F0 _H	F0 _H
FEINT1	Interrupt from Time Protection Timer for PE1*2		Time Protection Timer	*1	Level	F1 _H	F0 _H
	PE2						
FEINT0	FE level interrupt from the ECM		ECM	*1	Edge	F0 _H	F0 _H
FEINT1	Interrupt from Time Protection Timer for PE2*2		Time Protection Timer	*1	Level	F1 _H	F0 _H
	PE3						
FEINT0	FE level interrupt from the ECM		ECM	*1	Edge	F0 _H	F0 _H
FEINT1	Interrupt from Time Protection Timer for PE3*2		Time Protection Timer	*1	Level	F1 _H	F0 _H
	PE4						
FEINT0	FE level interrupt from the ECM		ECM	*1	Edge	F0 _H	F0 _H
FEINT1	Interrupt from Time Protection Timer for PE4*2		Time Protection Timer	*1	Level	F1 _H	F0 _H
	PE5						
FEINT0	FE level interrupt from the ECM		ECM	*1	Edge	F0 _H	F0 _H
FEINT1	Interrupt from Time Protection Timer for PE5*2		Time Protection Timer	*1	Level	F1 _H	F0 _H

Note: PE4 and PE5 are not supported for E2H.

Note 1. See **Section 3.2.4, Exceptions and Interrupts**.

Note 2. This interrupt can be used as an EIINT. See **Section 6.3.16, TPTMSEL — TPTM Interrupt FE EI Select Register**.

6.2.3.3 EI Level Maskable Interrupts

See **Section 3.2.4, Exceptions and Interrupts** for details about the priority order, return PC and return instructions.

See **Section 6.3.2, EIC0 to EIC695 — EI Level Interrupt Control Register 0 to 695** for details about the control registers.

For details, refer to Appendix file “Interrupt_table.xlsx”.

6.2.4 Block Diagram

The block diagram of the interrupt units is shown in **Figure 6.1**.

Figure 6.1 Block Diagram of Interrupt Units

Note: PE4 and PE5 are not supported for E2H.

6.3 Registers

6.3.1 List of Registers

Table 6.20 List of Registers

Module Name	Register Name	Symbol	Address	Access	Access Protect
INTC1	EI Level Interrupt Control Register* ¹	EICn (n = 0 to 31)	<INTC1_base> + 0000 _H + 02 _H × n	8, 16	—
	EI Level Interrupt Mask Register* ¹	IMR0	<INTC1_base> + 00F0 _H	8, 16, 32	—
	EI Level Interrupt Bind Register* ¹	EIBDn (n = 0 to 31)	<INTC1_base> + 0100 _H + 04 _H × n	32	—
INTC2	EI Level Interrupt Control Register* ¹	EICn (n = 32 to 695)	<INTC2_base> + 0000 _H + 02 _H × n	8, 16	—
	EI Level Interrupt Mask Register* ¹	IMRn (n = 1 to 21)	<INTC2_base> + 1000 _H + 04 _H × n	8, 16, 32	—
	EI Level Interrupt Bind Register* ¹	EIBDn (n = 32 to 695)	<INTC2_base> + 2000 _H + 04 _H × n	32	—
INTIF	Peripheral Interrupt Status Register	PINTn (n = 0 to 7)	<INTIF_base> + 00 _H + 04 _H × n	32	—
	Peripheral Interrupt Status Clear Register	PINTCLRn (n = 0 to 7)	<INTIF_base> + 20 _H + 04 _H × n	32	—
	TPTM Interrupt FE EI Select Register	TPTMSEL	<INTIF_base> + C0 _H	8, 16, 32	—
EINT	NMI Interrupt Control Register	NMICTL	<EINT_base>	8	—
	External Interrupt Control Register	EXINTCTL	<EINT_base> + 10 _H	8, 16	—
	External Interrupt Status Register	EXINTSTR	<EINT_base> + 14 _H	8	—
	External Interrupt Status Clear Register	EXINTSTC	<EINT_base> + 18 _H	8	—
	Software Interrupt Register 0	SINTR0	<EINT_base> + 20 _H	8	—
	Software Interrupt Register 1	SINTR1	<EINT_base> + 24 _H	8	—
	Software Interrupt Register 2	SINTR2	<EINT_base> + 28 _H	8	—
	Software Interrupt Register 3	SINTR3	<EINT_base> + 2C _H	8	—
	External Interrupt Control Register1	EXINTCTL1	<EINT_base> + 50 _H	8, 16	—
	External Interrupt Status Register1	EXINTSTR1	<EINT_base> + 54 _H	8	—
External Interrupt Status Clear Register1	EXINTSTC1	<EINT_base> + 58 _H	8	—	

Note 1. It is recommended to execute a DI instruction to avoid incorrect detection of interrupts when the settings of these registers are changed.

6.3.2 EIC0 to EIC695 — EI Level Interrupt Control Register 0 to 695

These registers define control of EI level interrupts. There is one register for each EI interrupt source. For a complete list of interrupt sources, see Appendix file “Interrupt_table.xlsx”.

CAUTION

If the EIRFn bit is set to 0 immediately after a peripheral module generates the corresponding interrupt request upon detection of an edge (before an interrupt is acknowledged by the CPU), the request may be lost.

If the EIRFn bit is set to 1 immediately after an interrupt is acknowledged by the CPU, a new interrupt request will be generated.

This also applies to bit manipulation instructions (set1, clr1, not1) described in **Section 3.8.3, Accesses to Registers by Bit-Manipulation Instructions**.

Accessing only the lower byte of this register (including EIMKn) by a bit-manipulation instruction does not modify the EIRFn bit.

Value after reset: 008F_H (edge detection), 808F_H (level detection)*1

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	EICTn	—	—	EIRFn	—	—	—	—	EIMKn	EITBn	—	—	EIPn[3:0]			
Value after reset	0/1*1	0	0	0	0	0	0	0	1	0	0	0	1	1	1	1
R/W	R	R	R	R/W	R	R	R	R	R/W	R/W	R	R	R/W	R/W	R/W	R/W

Note 1. Interrupt detection by edge: 0_B
 Interrupt detection by level: 1_B

Table 6.21 EIC0 to EIC695 Register Contents (1/2)

Bit Position	Bit Name	Function
15	EICTn	This bit indicates the type of interrupt detection. This bit is read only. 0: Detection by edge 1: Detection by level When writing in 8-bit or 16-bit units, write the value after a reset.
14, 13	—	Reserved These bits are always read as 0. The write value should always be 0.
12	EIRFn	Interrupt Request Flag Operation varies depending on the interrupt input interface. 0: No interrupt request (Initial value) 1: Interrupt request present <ul style="list-style-type: none"> • Edge detection This flag is automatically cleared to 0 when an interrupt request from its own channel is acknowledged by the CPU core. • Level detection This bit cannot be set or cleared by the software. This is a read-only bit.
11 to 8	—	Reserved These bits are always read as 0. The write value should always be 0.

Table 6.21 EIC0 to EIC695 Register Contents (2/2)

Bit Position	Bit Name	Function
7	EIMKn	<p>Interrupt Mask</p> <p>If this bit is set to 1, interrupt requests set by the interrupt request flag (EIRFn) are masked to inhibit interrupt requests from the channel to the CPU core. The presence of unprocessed interrupts is not reported and the PMEI bit in ICSR is not set for the channel for which this bit is set to 1. Even when interrupt processing is disabled by the setting of this bit, the input of an interrupt signal is not masked and the interrupt request flag is set. The state of this bit is also reflected in the Interrupt Mask Register (IMR).</p> <p>When the interrupt request from the channel is masked with EIMKn = 1, the EIRFn still reflects the interrupt request for the channel and can be polled in software. When the EIMKn bit is cleared, interrupt requests from the channel are issued to the CPU core for subsequent processing. The state of the EIMKn bit is also reflected in the corresponding IMRm register.</p> <p>0: Interrupt processing is enabled. 1: Interrupt processing is disabled. (Initial value)</p>
6	EITBn	<p>Interrupt Vector Method Select</p> <p>0: Direct vector method 1: Table reference method</p>
5, 4	—	<p>Reserved</p> <p>These bits are always read as 0. The write value should always be 0.</p>
3 to 0	EIPn	<p>These bits specify 16 interrupt priority levels (0: highest priority, 15: lowest priority).</p> <p>If two or more EI level interrupt requests are generated simultaneously, the source with a higher priority specified by these bits is selected and is sent to the CPU core. If the priorities specified by these bits are equal, the source with the lower default priority channel number is selected.</p>

Note: n = 0 to 695

The values for the given channel numbers listed as reserved in Appendix file "Interrupt_table.xlsx" must not be set to anything other than their values after a reset.

NOTE

When a channel n is defined as broadcast interrupt (EIBDn.CST = 1), EIMKn and EIRFn bits of the EICn register of the channel must be set to 0 after an initial configuration of the channel. In the period when the EIINTn interrupt is enabled, it is prohibited to mask (EIMKn = 1) an interrupt processing of the channel. When it is necessary to mask a broadcast interrupt, EIC4 to EIC7 registers in INTC1 of each PE can be used to mask the corresponding broadcast interrupt.

6.3.3 IMR0 to IMR21 — EI Level Interrupt Mask Register 0 to 21

These registers are an aggregation of the EIMK bits from the EIC registers. The setting of the EIMK bit in the EIC register is reflected in this register. Also the setting of a bit in this register is reflected in the EIMK bit of the corresponding EIC register.

Value after reset: FFFF FFFF_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 6.22 IMR0 to IMR21 Register Contents

Bit Position	Bit Name	Function
31 to 0	EIMK (m × 32 + 31) to EIMK (m × 32 + 0)	These are interrupt mask bits for EI level maskable interrupt (INT) channels 0 to 695. 0: Interrupt processing enabled 1: Interrupt processing disabled

Note: m = 0 to 21

The value of the EIMK bits for the given channel numbers listed as reserved in Appendix file "Interrupt_table.xlsx" must be set to 1.

NOTE

When writing to the EIMK bit by writing the IMR1 to 21 registers, only access from the PE set in the EIBDn.PEID (n = 32 to 695) register in the corresponding channel is possible. The EIMK bit is not updated when writing from a different PE.

6.3.4 EIBD0 to EIBD31 — EI Level Interrupt Bind Register 0 to 31

These registers are provided for each EI level interrupt source to define binding between interrupt sources and PEs. For details on each of the interrupt sources, see Appendix file “Interrupt_table.xlsx”.

Value after reset: 0000 0000_H (PE0)
 0000 0001_H (PE1)
 0000 0002_H (PE2)
 0000 0003_H (PE3)
 0000 0004_H (PE4)
 0000 0005_H (PE5)

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 6.23 EIBD0 to EIBD31 Register Contents

Bit Position	Bit Name	Function
31 to 3	—	Reserved These bits are always read as 0. The write value should always be 0.
2 to 0	PEID[2:0]	These bits specify the interrupt bind (request) destination. These bits are fixed in EIBD0 to EIBD31 and cannot be modified. 000: Interrupt is bound to PE0. 001: Interrupt is bound to PE1. 010: Interrupt is bound to PE2. 011: Interrupt is bound to PE3. 100: Interrupt is bound to PE4. 101: Interrupt is bound to PE5.

Note: PE4 and PE5 are not supported for E2H.

Note 1. The values for the given channel numbers listed as reserved in Appendix file “Interrupt_table.xlsx” must not be set to anything other than their values after a reset.

NOTE

Changing the corresponding EIBD_n register during the processing of an EIINT request is prohibited.

Note: n = 0 to 31

6.3.5 EIBD32 to EIBD695 — EI Level Interrupt Bind Register 32 to 695

These registers are provided for each EI level interrupt source to define a binding between interrupt sources 32 to 695 and CPU cores. For a list of interrupt sources, see Appendix file “Interrupt_table.xlsx”.

Value after reset: 0000 0000_H

Bit Position	Bit Name	Function
31	CST	Broadcast interrupt enable.
30 to 26	—	Reserved These bits are always read as 0. The write value should always be 0.
25 to 24	BCP[1:0]	When the CST bit is 1, these bits specify a broadcast interrupt port number setting. When the CST bit is 0, these bits do not specify anything.
23 to 3	—	Reserved These bits are always read as 0. The write value should always be 0.
2 to 0	PEID[2:0]	These bits specify the interrupt bind (request) destination. 000: Interrupt is bound to PE0. 001: Interrupt is bound to PE1. 010: Interrupt is bound to PE2. 011: Interrupt is bound to PE3. 100: Interrupt is bound to PE4. 101: Interrupt is bound to PE5. Other than above: Setting prohibited To execute an interrupt of the corresponding source, be sure to set one of the above values.

Note: The values for the given channel numbers listed as reserved in Appendix file “Interrupt_table.xlsx” must not be set to anything other than their values after a reset.

Note: PE4 and PE5 are not supported for E2H.

NOTE

Changing the corresponding EIBD_n register during the processing of an EIINT request is prohibited.

Note: n = 32 to 695

6.3.6 NMICTL — NMI Interrupt Control Register

NMICTL is an 8-bit register used to define the active edge for the NMI interrupt input. The active edge can be either rising or falling.

Value after reset: 00H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	NMIS
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R/W

Table 6.25 NMICTL Register Contents

Bit Position	Bit Name	Function
7 to 1	—	Reserved When read, the value after reset is returned.
0	NMIS	NMI Interrupt Detecting Method Select This bit selects the method of detecting an NMI interrupt signal from either falling edge or rising edge. 0: An interrupt request is detected by the NMI input falling edge. 1: An interrupt request is detected by the NMI input rising edge.

6.3.7 EXINTCTL — External Interrupt Control Register

EXINTCTL is a 16-bit register. This register defines the detection method for external interrupt input pins IRQ0 to IRQ7. Detection methods are edge (rising or falling) or level (low or high).

Value after reset: 0000H

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	IRQ7S		IRQ6S		IRQ5S		IRQ4S		IRQ3S		IRQ2S		IRQ1S		IRQ0S	
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 6.26 EXINTCTL Register Contents

Bit Position	Bit Name	Function
15 to 14	IRQ7S	External Interrupt Detecting Method Select
13 to 12	IRQ6S	These bits select the method of detecting an IRQ7 to IRQ0 interrupt signal from either low level, high level, falling edge, or rising edge.
11 to 10	IRQ5S	
9 to 8	IRQ4S	00: An interrupt request is detected by the IRQn input low level.*1
7 to 6	IRQ3S	01: An interrupt request is detected by the IRQn input high level.*1
5 to 4	IRQ2S	10: An interrupt request is detected by the IRQn input falling edge.
3 to 2	IRQ1S	11: An interrupt request is detected by the IRQn input rising edge.
1 to 0	IRQ0S	n = 0 to 7

Note 1. When level detection is selected, the active level should be retained until an interrupt request is acknowledged.

6.3.8 EXINTCTL1 — External Interrupt Control Register 1

EXINTCTL1 is a 16-bit register. This register defines detection method for external interrupt input pins IRQ8 to IRQ11. Detection methods are edge (rising or falling) or level (low or high).

Value after reset: 0000H

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	IRQ11S		IRQ10S		IRQ9S		IRQ8S	
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 6.27 EXINTCTL1 Register Contents

Bit Position	Bit Name	Function
15 to 8	—	Reserved When read, the value after reset is returned.
7 to 6	IRQ11S	External Interrupt Detecting Method Select
5 to 4	IRQ10S	These bits select an IRQ8 to IRQ11 interrupt signal detecting method from either low level, high level, falling edge, and rising edge.
3 to 2	IRQ9S	
1 to 0	IRQ8S	00: An interrupt request is detected by the IRQn input low level.*1 01: An interrupt request is detected by the IRQn input high level.*1 10: An interrupt request is detected by the IRQn input falling edge. 11: An interrupt request is detected by the IRQn input rising edge. n = 8 to 11

Note 1. When level detection is selected, the active level should be retained until an interrupt request is accepted.

6.3.9 EXINTSTR — External Interrupt Status Register

EXINTSTR is an 8-bit register. This register indicates the presence of external interrupt requests IRQ0 to IRQ7. When an “edge” is specified as the detection method, interrupt requests retained in this register can be cleared by the EXINTSTC register.

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	IRQ7F	IRQ6F	IRQ5F	IRQ4F	IRQ3F	IRQ2F	IRQ1F	IRQ0F
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R

Table 6.28 EXINTSTR Register Contents

Bit Position	Bit Name	Function
7	IRQ7F	External Interrupt Requests
6	IRQ6F	These bits indicate the IRQ7 to IRQ0 interrupt request status.
5	IRQ5F	<ul style="list-style-type: none"> When level detection is selected
4	IRQ4F	<ul style="list-style-type: none"> 0: No IRQn interrupt request is present. 1: IRQn interrupt request is present.
3	IRQ3F	[Clearing condition]
2	IRQ2F	The IRQn input is not at the level corresponding to the conditions specified in IRQnS in EXINTCTL
1	IRQ1F	[Setting condition]
0	IRQ0F	<ul style="list-style-type: none"> The IRQn input is at the level corresponding to the conditions specified in IRQnS in EXINTCTL When edge detection is selected 0: No IRQn interrupt request has been detected 1: IRQn interrupt request has been detected
		[Clearing condition]
		Writing 1 to the IRQnC bit in EXINTSTC
		[Setting condition]
		An edge corresponding to the conditions specified in IRQnS in EXINTCTL is generated

Note: n = 0 to 7

6.3.10 EXINTSTR1 — External Interrupt Status Register 1

EXINTSTR1 is an 8-bit register. This register indicates the presence of external interrupt requests IRQ8 to IRQ11. When an “edge” is specified as the detection method, interrupt requests retained in this register can be cleared by the EXINTSTC1 register.

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	IRQ11F	IRQ10F	IRQ9F	IRQ8F
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R

Table 6.29 EXINTSTR1 Register Contents

Bit Position	Bit Name	Function
7 to 4	—	Reserved When read, the value after reset is returned.
3	IRQ11F	External Interrupt Requests
2	IRQ10F	These bits indicate the the IRQ11 to IRQ8 interrupt request status.
1	IRQ9F	<ul style="list-style-type: none"> When level detection is selected <ul style="list-style-type: none"> 0: No IRQ_n interrupt request is present 1: IRQ_n interrupt request is present
0	IRQ8F	<ul style="list-style-type: none"> When level detection is selected <ul style="list-style-type: none"> 0: No IRQ_n interrupt request is present 1: IRQ_n interrupt request is present [Clearing condition] The IRQ_n input is not at the level corresponding to the conditions specified in IRQ_nS in EXINTCTL1 [Setting condition] The IRQ_n input is at the level corresponding to the conditions specified in IRQ_nS in EXINTCTL1 When edge detection is selected <ul style="list-style-type: none"> 0: No IRQ_n interrupt request has been detected 1: IRQ_n interrupt request has been detected [Clearing condition] Writing 1 to the IRQ_nC bit in EXINTSTC1 [Setting condition] An edge corresponding to the conditions specified in IRQ_nS in EXINTCTL1 is generated

Note: n = 8 to 11

6.3.11 EXINTSTC — External Interrupt Status Clear Register

EXINTSTC is an 8-bit register used to clear IRQ_nF in EXINTSTR when edge detection is selected as the method of detecting IRQ_n. Writing 1 to IRQ_nC clears the corresponding IRQ_nF bit in EXINTSTR.

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	IRQ7C	IRQ6C	IRQ5C	IRQ4C	IRQ3C	IRQ2C	IRQ1C	IRQ0C
Value after reset	0	0	0	0	0	0	0	0
R/W	W	W	W	W	W	W	W	W

Table 6.30 EXINTSTC Register Contents

Bit Position	Bit Name	Function
7	IRQ7C	External Interrupt Request Clear
6	IRQ6C	These bits clear the interrupt request status when the edge detection is selected for detecting IRQ7 to IRQ0 interrupts.
5	IRQ5C	
4	IRQ4C	• When level detection is selected These bits have no function.
3	IRQ3C	• When edge detection is selected
2	IRQ2C	Writing 1 clears the corresponding IRQ _n F bit in the EXINTSTR register.
1	IRQ1C	
0	IRQ0C	

Note: n = 0 to 7

6.3.12 EXINTSTC1 — External Interrupt Status Clear Register 1

EXINTSTC1 is an 8-bit register used to clear IRQnF in EXINTSTR1 when edge detection is selected as the method of detecting IRQn. Writing 1 to IRQnC clears the corresponding IRQnF bit in EXINTSTR1.

Value after reset: 00H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	IRQ11C	IRQ10C	IRQ9C	IRQ8C
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	W	W	W	W

Table 6.31 EXINTSTC1 Register Contents

Bit Position	Bit Name	Function
7 to 4	Reserved	When writing, write the value after reset.
3	IRQ11C	External Interrupt Request Clear
2	IRQ10C	These bits clear the interrupt request status when the edge detection is selected for detecting IRQ11 to IRQ8 interrupts.
1	IRQ9C	
0	IRQ8C	<ul style="list-style-type: none"> When level detection is selected When edge detection is selected These bits have no function. Writing 1 clears the corresponding IRQnF bit in the EXINTSTR1 register.

Note: n = 8 to 11

6.3.13 SINTR0 to SINTR3 — Software Interrupt Register

SINTR0 to SINTR3 are 8-bit registers used to control software interrupts 0 to 3 (SINT0 to SINT3).

Writing 01_H to these registers increments the value of the counter; writing 00_H decrements it. When the value of the counter for any of these registers is 1 or more, the corresponding interrupt from among software interrupts 0 to 3 (SINT0 to SINT3) is generated. When reading the value from any of these registers, the read value is the current value of the counter.

Table 6.32 SINTR0 to SINTR3 Register Contents

Bit Position	Bit Name	Function
7 to 0	SINTCn[7:0]	Software Interrupt Request This bit generates a software interrupt. [Reading operation] The number of SINTn interrupt request counts is read out. [Writing operation] Writing 01 _H : Increments the counter.*1 Writing 00 _H : Decrements the counter.*2

Note 1. When 01_H is written to the register while the value of the counter is FF_H, the counter is not incremented and its value remains FF_H.

Note 2. When 00_H is written to the register while the value of the counter is 00_H, the counter is not decremented and its value remains 00_H.

6.3.14 PINTn + x — Peripheral Interrupt Status Register

All 128 DTS interrupt flags are divided between 8 registers PINT0 to PINT7. Each register contains 32 interrupt flags. Only one bit in each register PINT0 to PINT7 can be set. If multiple DTS channels within the same PINTn register request an interrupt, only the bit of the lowest DTS channel in that register is set.

Value after reset: 0000 0000_H

• PINT n + x (n = 0 to 3, x = 0)

Table 6.37 TPTMSEL Register Contents

Bit Position	Bit Name	Function
31 to 6	—	Reserved These bits are always read as 0. The write value should always be 0.
5	TPTMSEL5* ¹	This bit selects whether the FEINT or the EIINT is the TPTM interrupt of PE5. 0: the TPTM interrupt of PE5 is connected to FEINT. 1: the TPTM interrupt of PE5 is connected to EIINT
4	TPTMSEL4* ¹	This bit selects whether the FEINT or the EIINT is the TPTM interrupt of PE4. 0: the TPTM interrupt of PE4 is connected to FEINT. 1: the TPTM interrupt of PE4 is connected to EIINT
3	TPTMSEL3	This bit selects whether the FEINT or the EIINT is the TPTM interrupt of PE3. 0: the TPTM interrupt of PE3 is connected to FEINT. 1: the TPTM interrupt of PE3 is connected to EIINT
2	TPTMSEL2	This bit selects whether the FEINT or the EIINT is the TPTM interrupt of PE2. 0: the TPTM interrupt of PE2 is connected to FEINT. 1: the TPTM interrupt of PE2 is connected to EIINT
1	TPTMSEL1	This bit selects whether the FEINT or the EIINT is the TPTM interrupt of PE1. 0: the TPTM interrupt of PE1 is connected to FEINT. 1: the TPTM interrupt of PE1 is connected to EIINT
0	TPTMSEL0	This bit selects whether the FEINT or the EIINT is the TPTM interrupt of PE0. 0: the TPTM interrupt of PE0 is connected to FEINT. 1: the TPTM interrupt of PE0 is connected to EIINT

Note 1. PE4 and PE5 are not supported for E2H. These bits are reserved, and these bits are always read as 0, and the write value should always be 0 for E2H.

6.4 Interrupt Operation

6.4.1 Level Interrupts

For the operation of level interrupts, see **Section 6.5.1, Level Interrupt Processing Flow**.

6.4.2 External Interrupts (NMI / IRQ)

NMI and IRQ interrupts are input from external devices. Detection methods for these interrupts can be chosen from four methods (two methods for NMI and all four methods for IRQ).

6.4.3 Inter-Processor Interrupts

For the operation of Inter-Processor Interrupts, see **Section 3.4, Inter-Processor Interrupts**.

6.4.4 Broadcast Interrupts

INTC2 has a function for broadcast interrupts. With this function, the EIINTn request input is transferred to EIINT4-7 of each CPU's INTC1 as a broadcast notification 0-3 with no priority judgement.

The interrupt detection type of the EIINTn must be edge detection if the broadcast function is used. The broadcast function cannot be activated (EIBDn.CST cannot be set) if the interrupt detection type of the EIINTn is configured as level detection.

When EIBDn.CST is set, EIINTn is used as the broadcast interrupt source.

EIBDn.BCP[1:0] determines which port of the broadcast interrupt (EIINT4-7) is triggered. It is prohibited to assign more than one interrupt channel to the same broadcast interrupt (EIINT4-7).

For the operation of broadcast interrupts, see **Section 6.3.5, EIBD32 to EIBD695 — EI Level Interrupt Bind Register 32 to 695** and **Section 6.5.4, Broadcast Interrupt Processing Flow**.

6.4.5 Software Interrupts

For the operation of software interrupts, see **Section 6.3.13, SINTR0 to SINTR3 — Software Interrupt Register** and **Section 6.4.7, Priority Level Handling**.

6.4.6 DTS Interrupt Merge Function

Up to 128 transfer end interrupts and up to 128 transfer count match interrupts are aggregated into one type of interrupt in units of 32 interrupts. 128 bits from all DTS channels are combined into 8 registers, PINT0 to PINT7. If multiple DTS channels within the same status register (PINT0 to PINT7) request an interrupt, only the bit of the lowest DTS channel in that register is set. For additional information see **Section 6.3.14, PINTn + x — Peripheral Interrupt Status Register** and **Section 6.3.15, PINTCLRn + x — Peripheral Interrupt Status Clear Register**.

6.4.7 Priority Level Handling

There is no priority control for FENMI because it has one channel.

FE-level maskable interrupt priority is determined within FEINT0-1. The channel with the lowest number is given priority over other channels.

EI-level maskable interrupt priority is determined within EIINT0-31 and EIINT32-695 in each PE. Priority is determined by 16 interrupt priority levels specified for each interrupt channel (EICn.EIP3-0). In channels with same priority level, the channel with the lowest number is given priority over other channels.

6.5 Interrupt Processing Flow

6.5.1 Level Interrupt Processing Flow

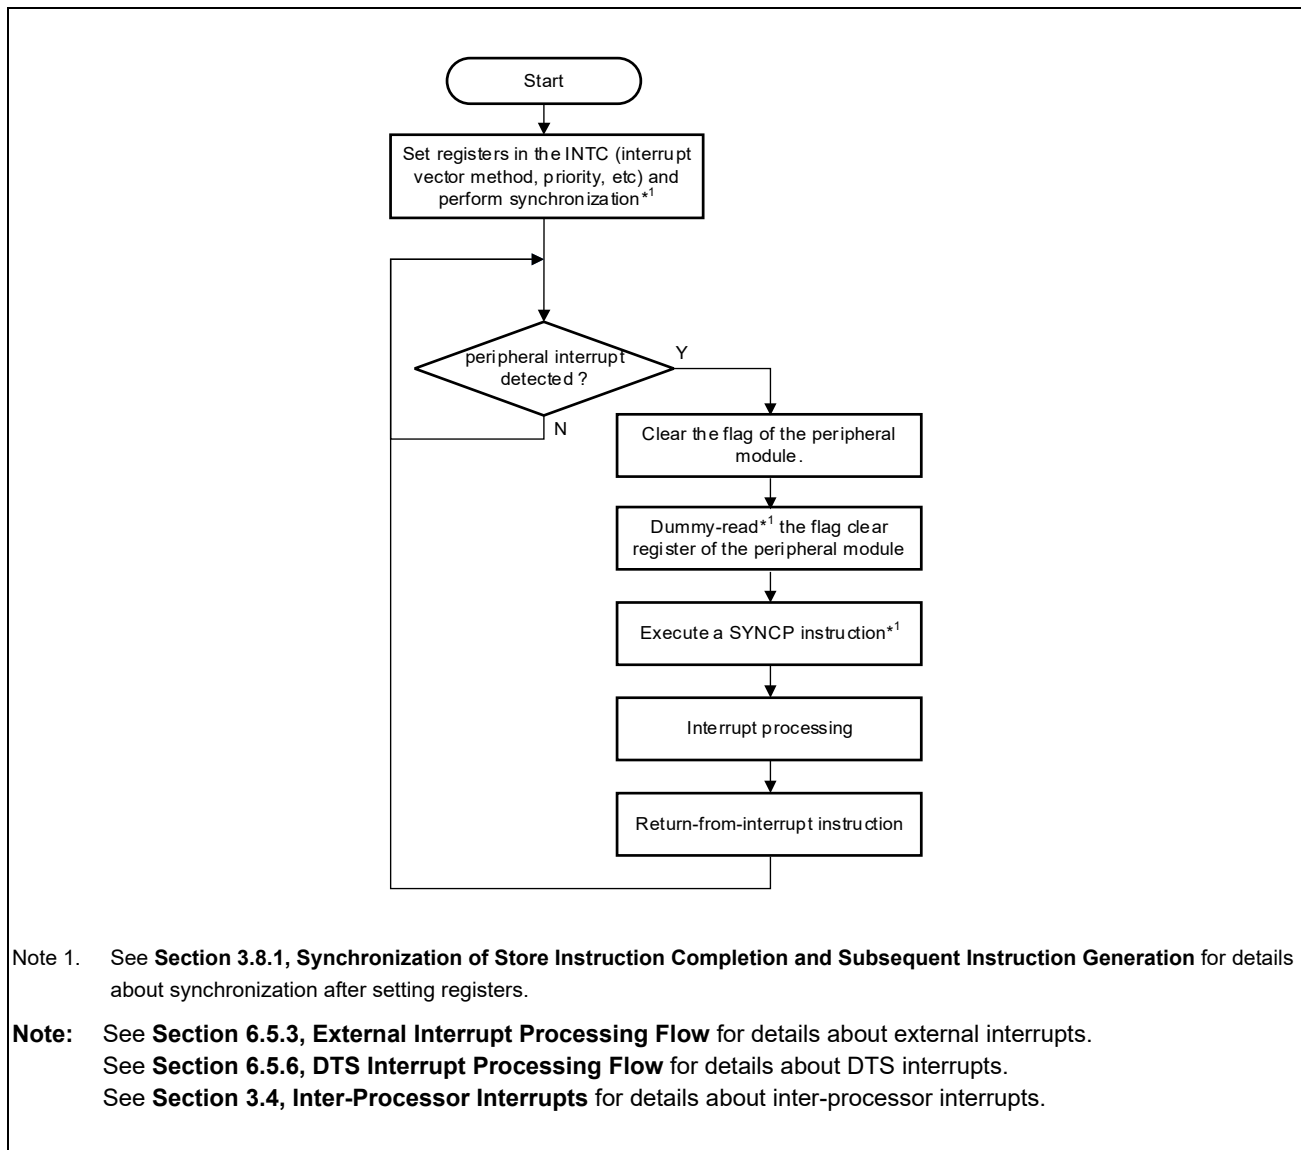

Figure 6.2 Example of the Level Interrupt Processing Flow

6.5.2 NMI Processing Flow

- Select the NMI detection method (falling edge or rising edge) by setting the NMICTL register.
- After an NMI has been detected, an interrupt request is sent to the INTC.
- NMI interrupts are acknowledged as the highest priority even when another FE level interrupts have been generated. NMI interrupts cannot be masked by the PSW.NP in the CPU system register. Recovery or return from an NMI interrupt is not possible.

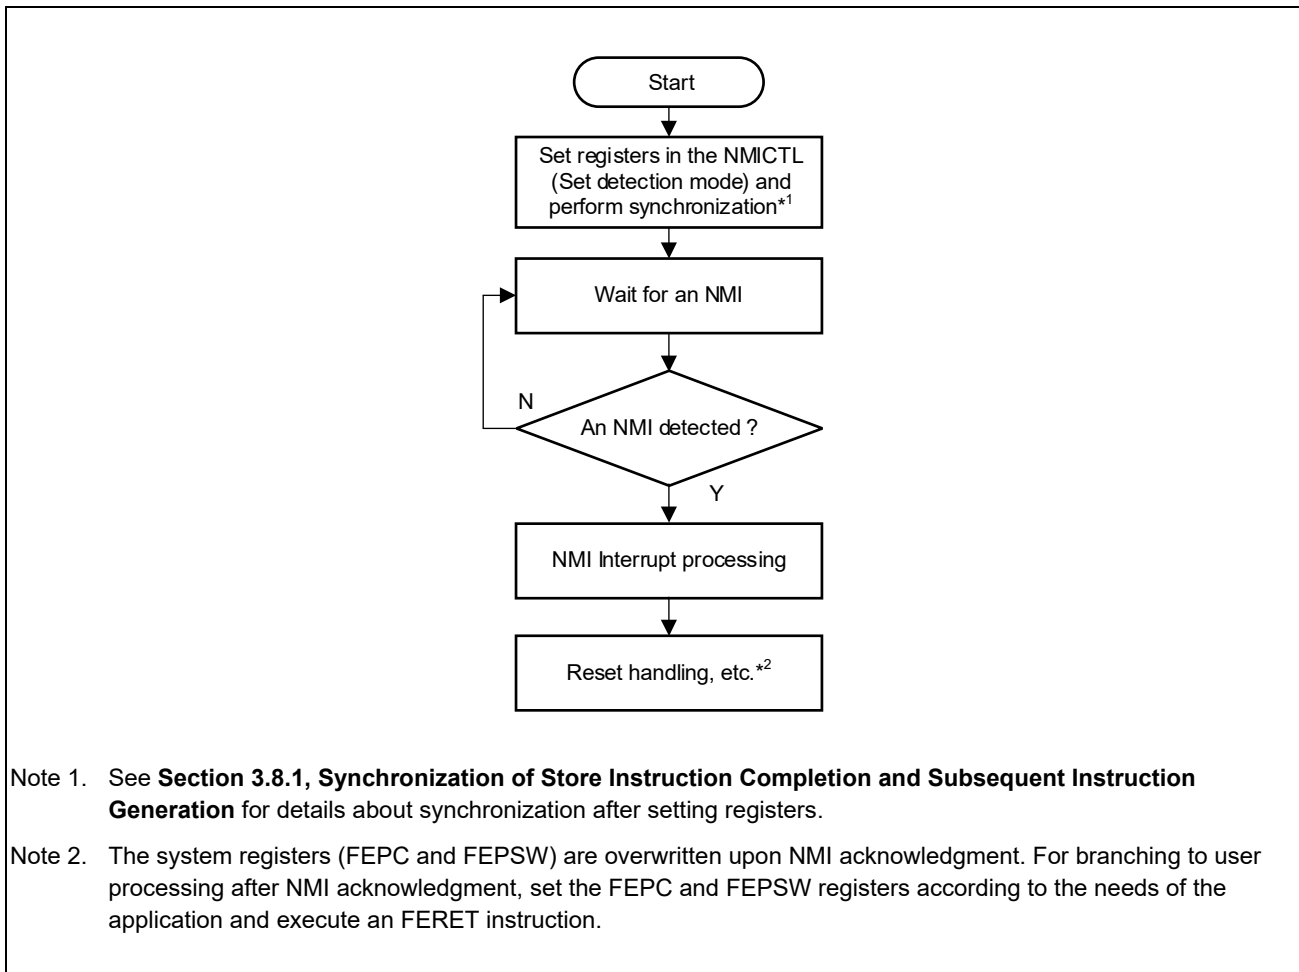

Figure 6.3 Example of the NMI Processing Flow

6.5.3 External Interrupt Processing Flow

- Select the IRQ detection method (edge detection or level detection) by setting the EXINTCTL and the EXINTCTL1 registers.
- After detection of an IRQ, an interrupt request is issued to the INTC.
- If level detection is selected, confirm that the IRQn pin is negated before returning from the interrupt service routine by the return instruction.
- If edge detection is selected, clear the interrupt request before returning from an interrupt service routine by the return instruction. To clear an interrupt request, write to the corresponding bit of the EXINTSTC and the EXINTSTC1 registers.

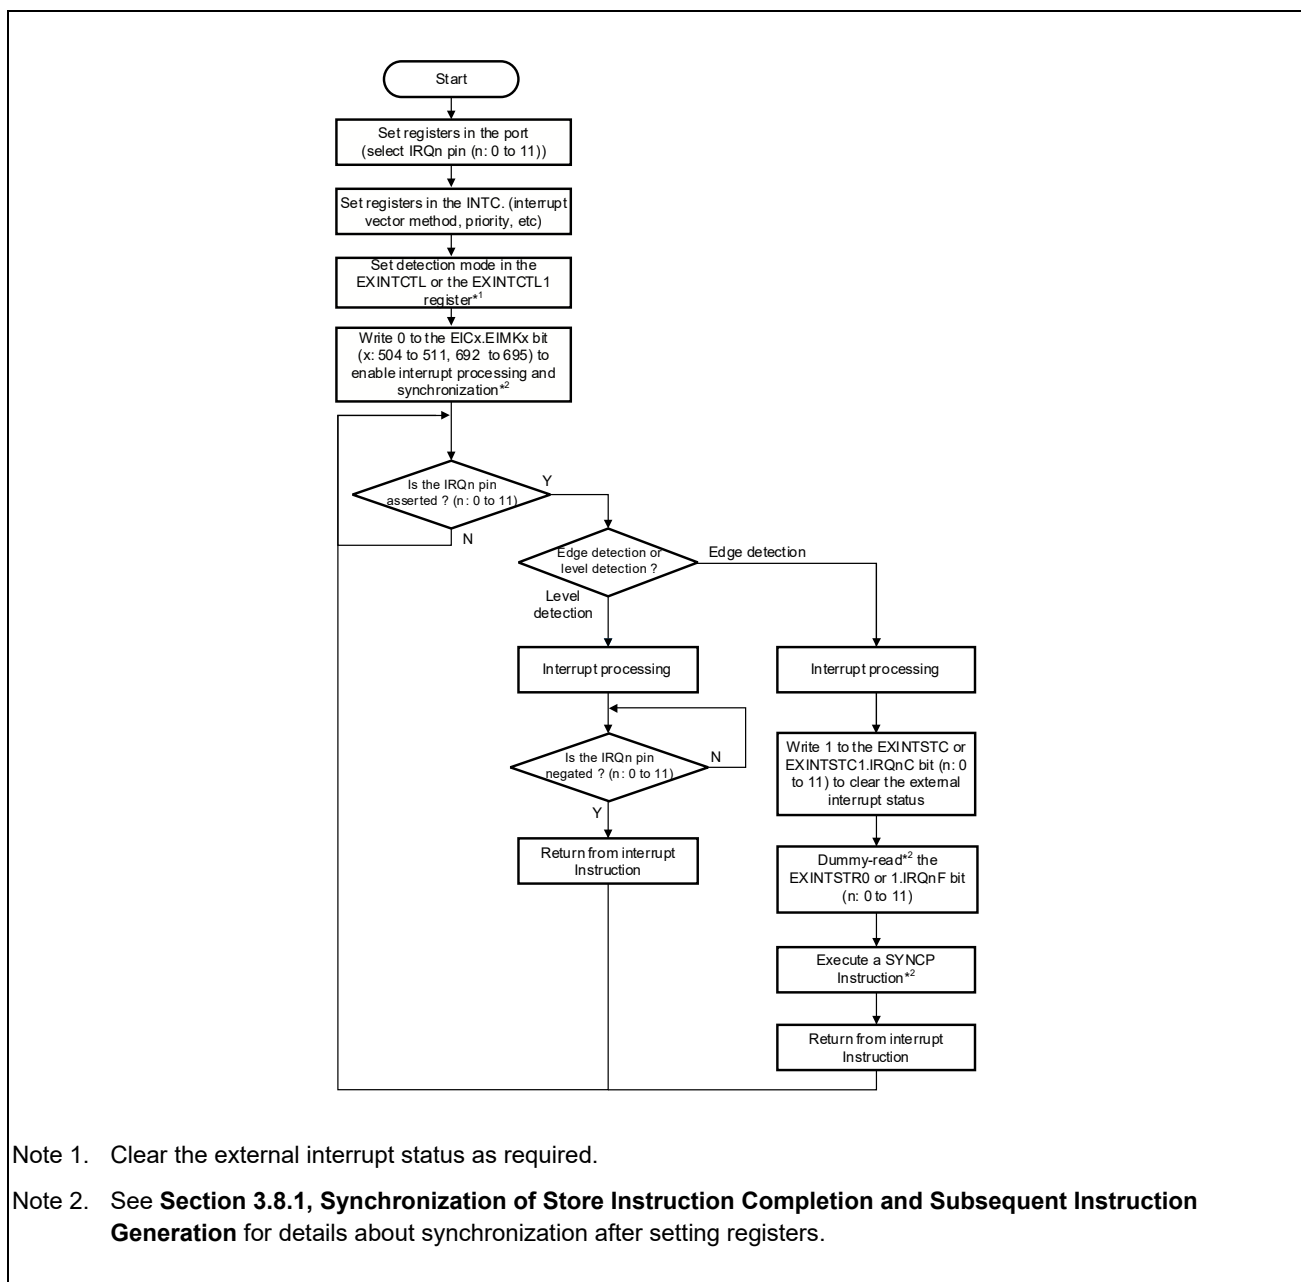

Figure 6.4 Example of the External Interrupt Processing Flow

6.5.4 Broadcast Interrupt Processing Flow

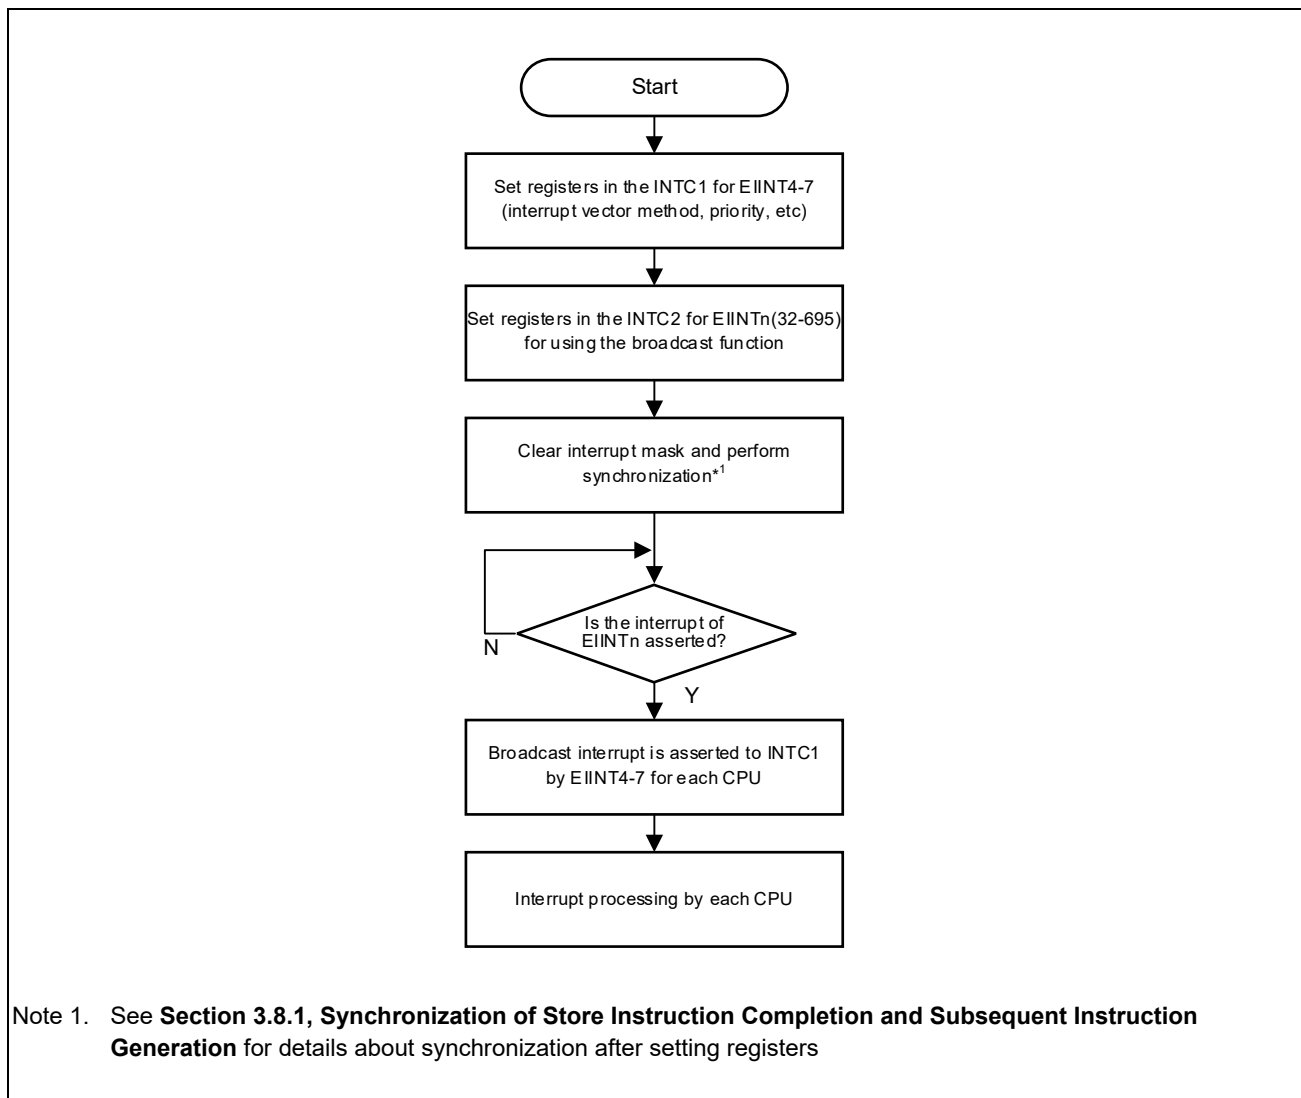

Figure 6.5 Example for the Broadcast Interrupt

NOTE

When using the broadcast function, the EIINTn (n = 32 to 695) interrupts are not generated individually upon the occurrence of each interrupt factor. Interrupts are generated in EIINT4-7 as broadcast interrupts.

6.5.5 Software Interrupt Processing Flow

- Software interrupt requests are controlled by writing 00_H or 01_H to the counter registers (SINTR0 to SINTR3).
- Writing 00_H leads to the counter's value being decremented by 1.
- Writing 01_H leads to the counter's value being incremented by 1.
- If the incremented counter value is 1 or above, an interrupt request for the INTC is generated.
- Before returning from the interrupt service routine, decrement the SINTR_n counter by 1. If SINTR_n is 00_H after issuing the instruction to return from the interrupt, wait for the writing of 01_H to SINTR_n.

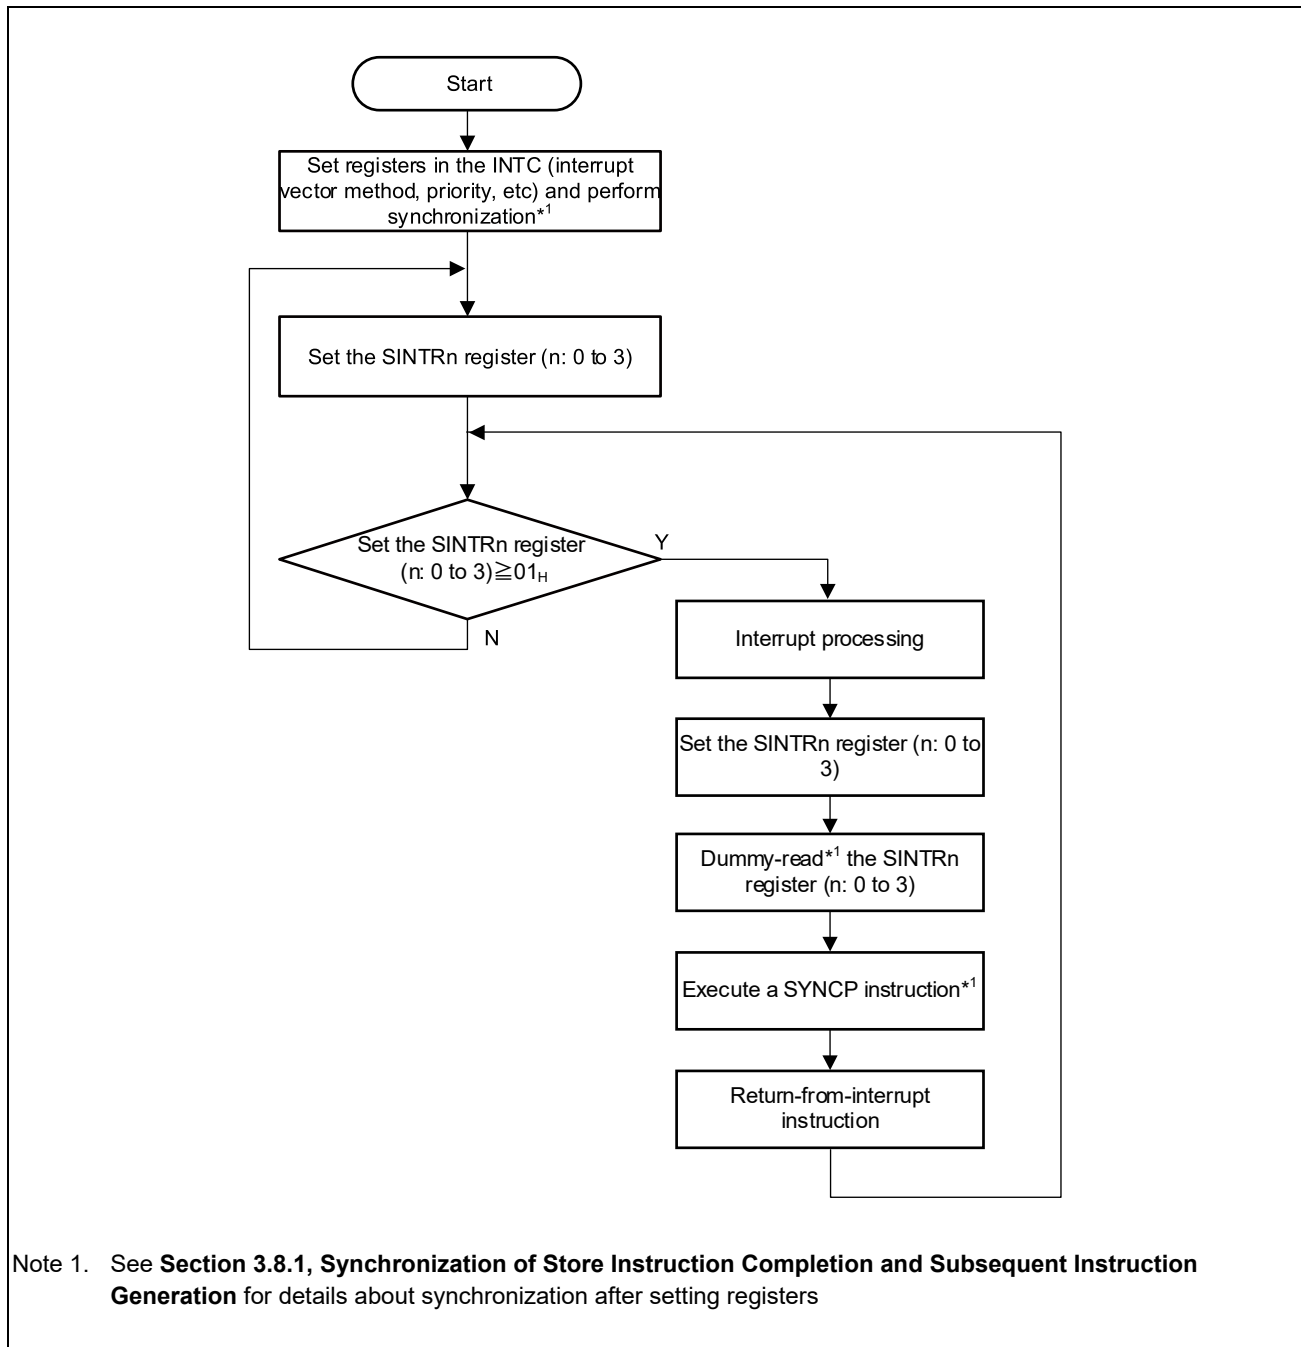

Figure 6.6 Example of the Software Interrupt Processing Flow

6.5.6 DTS Interrupt Processing Flow

- When only one interrupt request is generated out of the bundled 32 interrupt sources:
 - The bit corresponding to the interrupt request in the PINTn register is set to 1 and an interrupt request is output.
 - On completion of interrupt processing, write 1 to the interrupt clear register (PINTCLRn) to clear the interrupt request before issuing the return from interrupt instruction, then wait for the next one.
- When multiple interrupt sources are generated out of the bundled 32 interrupt sources:
 - Only the bit of the DTS channel with the lowest number is set in the PINTn register and the request is generated.
 - On completion of interrupt processing (before returning from the interrupt service routine), write 1 to the corresponding bit in the interrupt clear register (PINTCLRn) to clear the interrupt request.
 - After clearing the interrupt request bit of the first DTS channel, the bit corresponding to the next lowest DTS channel requesting an interrupt is set and the interrupt request is output.
 - These steps are repeated until all interrupt sources bundled into the same 32-bit register are cleared.

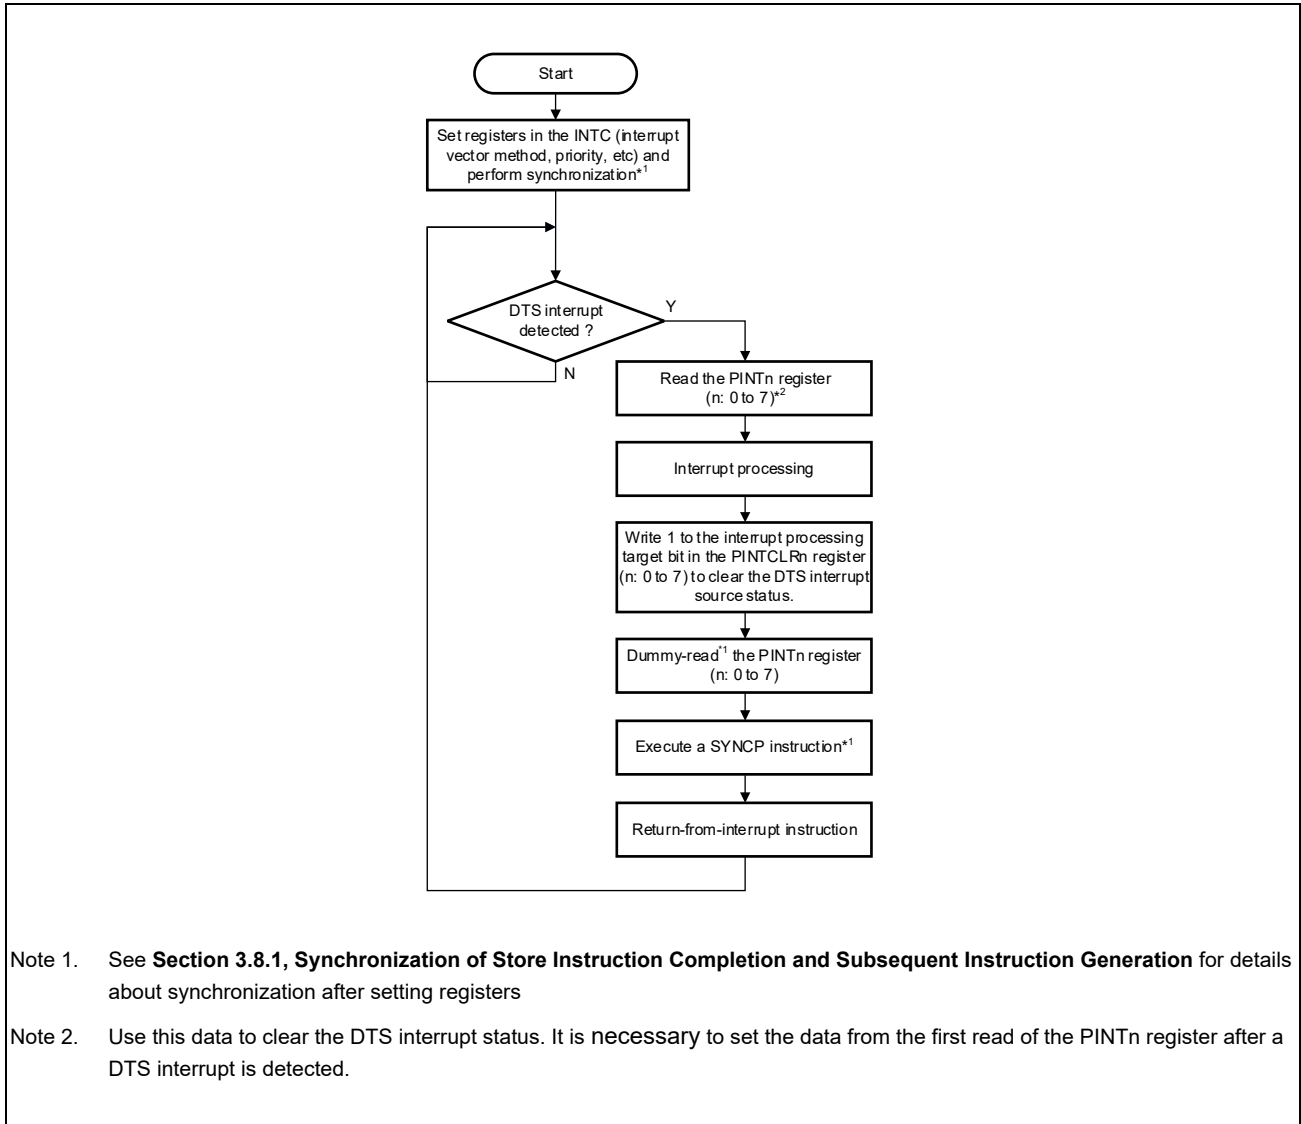

Figure 6.7 Example of the DTS Interrupt Processing Flow

6.6 Interrupt Response Times

Table 6.38 Interrupt Response Times (Min)

Target	Interrupt Request Source		Number of Cycles for Processing			
	INTC Connection	Operating Clock	Synchronization	INTC2	INTC1	In PE0/PE1/PE2/PE3/PE4/PE5
PE0/PE1 PE2/PE3 PE4/PE5	Directly input to INTC1	CLK_CPU	$1 \times I\phi$	—	$2 \times I\phi$ < $1 \times I\phi$ >	See the description under "In PE0/PE1/PE2/PE3/PE4/PE5" below.
		CLK_LSB	$2 \times P\phi + 1 \times S\phi$			
		CLK_LSB (Peripheral Group 2L)	$1 \times L\phi + 2 \times P\phi + 1 \times S\phi$			
		CLK_HSB	—			
		CLK_HBUS	$1 \times P\phi + 1 \times S\phi$			
		CLK_UHSB	—			
	Input via INTC2	CLK_CPU	—	$3 \times P\phi + 2 \times I\phi$ < $2 \times P\phi + 2 \times I\phi$ >	—	
		CLK_LSB	$2 \times P\phi$			
		CLK_LSB (Peripheral Group 2L)	$1 \times L\phi + 2 \times P\phi$			
		CLK_HSB	$1 \times H\phi + 2 \times P\phi$			
		CLK_HSB (Peripheral Group 2H)	$1 \times U\phi + 3 \times P\phi$			
		CLK_HBUS	$1 \times P\phi$			
		CLK_UHSB	$1 \times U\phi + 3 \times P\phi$			

Note: The numbers in < > indicate the numbers of cycles in the case of level detection.

Note: PE4 and PE5 are not supported for E2H.

Note: $I\phi$: CPU clock (CLK_CPU)
 $S\phi$: SBUS clock (CLK_SBUS)
 $P\phi$: HBUS clock (CLK_HBUS)
 $H\phi$: Peripheral high speed clock (CLK_HSB)
 $L\phi$: Peripheral low speed clock (CLK_LSB)
 $U\phi$: Peripheral ultra high speed clock (CLK_UHSB)

Table 6.39 Response Cycles in CPU Operation(Min)

Interrupt Vector Method	Cache HIT/MISS	RBCR 0.MD	In PE0 to PE5 400MHz
Direct Vector	Cache HIT	—	$5 \times I\phi$
	Cache MISS	—	$12 \times I\phi$
Table Reference (The vector code is stored in Code Flash)	Cache HIT	—	$15 \times I\phi$
		0 _B	$19 \times I\phi$
		1 _B	$25 \times I\phi$
	Cache MISS	—	$24 \times I\phi$
		0 _B	$24 \times I\phi$
		1 _B	$25 \times I\phi$

Note: PE4 and PE5 are not supported for E2H.

Note: $I\phi$: CPU clock (CLK_CPU)

Note: See Section 3.2.3.2(28), RBCR0 — Register Bank Control 0 for RBCR0.MD.

Section 7 sDMA Controller (sDMAC)

This section contains a generic description of the sDMA Controller (sDMAC).

The first part of this section describes this product's specific properties, such as the number of units and register base addresses.

The remainder of the section describes the functions and registers of the sDMAC.

7.1 Features of sDMAC

7.1.1 Number of Units

This microcontroller has the following number of sDMAC units.

Table 7.1 Number of Units

Product Name	RH850/E2x-FCC2	
	468 Pins	373 Pins
Number of Units	2	2
Number of Channels per unit	16	16
Unit Name	SDMAC _j (j = 0, 1)	SDMAC _j (j = 0, 1)

Product Name	RH850/E2UH	
	468 Pins	373 Pins
Number of Units	2	2
Number of Channels per unit	16	16
Unit Name	SDMAC _j (j = 0, 1)	SDMAC _j (j = 0, 1)

Product Name	RH850/E2H	
	468 Pins	373 Pins
Number of Units	2	2
Number of Channels per unit	16	16
Unit Name	SDMAC _j (j = 0, 1)	SDMAC _j (j = 0, 1)

Table 7.2 Index

Index	Meaning
j	The individual units are identified by the index "j" (j = 0 to 1).
n	The individual channels are identified by the index "n" (n = 0 to 15).
m	The individual trigger group selection registers are identified by the index "m" (m = 0 to 15).

7.1.2 Register Base Addresses

sDMAC register addresses are given as offsets from the base addresses.

sDMAC base addresses are listed in the following table.

Table 7.3 Register Base Addresses

Base Address Name	Base Address	Bus Group
<SDMAC0_base>	FFF9 0000 _H	Peripheral Group 0
<SDMAC1_base>	FFF9 8000 _H	Peripheral Group 0
<DMATRGSSEL_base>	FF09 0100 _H	Peripheral Group 9

7.1.3 Clock Supply

The sDMAC clock supplies are shown in the following table.

Table 7.4 sDMAC Clock Supply

Unit Name	Clock Name in the Unit	Supply Clock Name	Description
SDMACj	SCLK	CLK_HBUS	System interconnect clock
	PCLK	CLK_HBUS	Register access clock
DMATRGSSEL	PCLK	CLK_HBUS	Register access clock

7.1.4 Interrupts

sDMAC interrupt requests are listed in the following table.

Table 7.5 Interrupt Requests (1/3)

Interrupt Symbol Name	Unit Interrupt Signal	Outline	Interrupt Number
INTSDMAC0CH0	SDMAC0.intreq_ch[0]	sDMAC0 channel 0 transfer end interrupt sDMAC0 channel 0 descriptor step end interrupt sDMAC0 channel 0 address error interrupt	45
INTSDMAC0CH1	SDMAC0.intreq_ch[1]	sDMAC0 channel 1 transfer end interrupt sDMAC0 channel 1 descriptor step end interrupt sDMAC0 channel 1 address error interrupt	46
INTSDMAC0CH2	SDMAC0.intreq_ch[2]	sDMAC0 channel 2 transfer end interrupt sDMAC0 channel 2 descriptor step end interrupt sDMAC0 channel 2 address error interrupt	47
INTSDMAC0CH3	SDMAC0.intreq_ch[3]	sDMAC0 channel 3 transfer end interrupt sDMAC0 channel 3 descriptor step end interrupt sDMAC0 channel 3 address error interrupt	48
INTSDMAC0CH4	SDMAC0.intreq_ch[4]	sDMAC0 channel 4 transfer end interrupt sDMAC0 channel 4 descriptor step end interrupt sDMAC0 channel 4 address error interrupt	49
INTSDMAC0CH5	SDMAC0.intreq_ch[5]	sDMAC0 channel 5 transfer end interrupt sDMAC0 channel 5 descriptor step end interrupt sDMAC0 channel 5 address error interrupt	50
INTSDMAC0CH6	SDMAC0.intreq_ch[6]	sDMAC0 channel 6 transfer end interrupt sDMAC0 channel 6 descriptor step end interrupt sDMAC0 channel 6 address error interrupt	51
INTSDMAC0CH7	SDMAC0.intreq_ch[7]	sDMAC0 channel 7 transfer end interrupt sDMAC0 channel 7 descriptor step end interrupt sDMAC0 channel 7 address error interrupt	52
INTSDMAC0CH8	SDMAC0.intreq_ch[8]	sDMAC0 channel 8 transfer end interrupt sDMAC0 channel 8 descriptor step end interrupt sDMAC0 channel 8 address error interrupt	53

Table 7.5 Interrupt Requests (2/3)

Interrupt Symbol Name	Unit Interrupt Signal	Outline	Interrupt Number
INTSDMAC0CH9	SDMAC0.intreq_ch[9]	sDMAC0 channel 9 transfer end interrupt sDMAC0 channel 9 descriptor step end interrupt sDMAC0 channel 9 address error interrupt	54
INTSDMAC0CH10	SDMAC0.intreq_ch[10]	sDMAC0 channel 10 transfer end interrupt sDMAC0 channel 10 descriptor step end interrupt sDMAC0 channel 10 address error interrupt	55
INTSDMAC0CH11	SDMAC0.intreq_ch[11]	sDMAC0 channel 11 transfer end interrupt sDMAC0 channel 11 descriptor step end interrupt sDMAC0 channel 11 address error interrupt	56
INTSDMAC0CH12	SDMAC0.intreq_ch[12]	sDMAC0 channel 12 transfer end interrupt sDMAC0 channel 12 descriptor step end interrupt sDMAC0 channel 12 address error interrupt	57
INTSDMAC0CH13	SDMAC0.intreq_ch[13]	sDMAC0 channel 13 transfer end interrupt sDMAC0 channel 13 descriptor step end interrupt sDMAC0 channel 13 address error interrupt	58
INTSDMAC0CH14	SDMAC0.intreq_ch[14]	sDMAC0 channel 14 transfer end interrupt sDMAC0 channel 14 descriptor step end interrupt sDMAC0 channel 14 address error interrupt	59
INTSDMAC0CH15	SDMAC0.intreq_ch[15]	sDMAC0 channel 15 transfer end interrupt sDMAC0 channel 15 descriptor step end interrupt sDMAC0 channel 15 address error interrupt	60
INTSDMACERR	SDMAC0.intreq_aerr SDMAC1.intreq_aerr	sDMAC0 address error interrupt sDMAC1 address error interrupt	29
INTSDMAC1CH0	SDMAC1.intreq_ch[0]	sDMAC1 channel 0 transfer end interrupt sDMAC1 channel 0 descriptor step end interrupt sDMAC1 channel 0 address error interrupt	61
INTSDMAC1CH1	SDMAC1.intreq_ch[1]	sDMAC1 channel 1 transfer end interrupt sDMAC1 channel 1 descriptor step end interrupt sDMAC1 channel 1 address error interrupt	62
INTSDMAC1CH2	SDMAC1.intreq_ch[2]	sDMAC1 channel 2 transfer end interrupt sDMAC1 channel 2 descriptor step end interrupt sDMAC1 channel 2 address error interrupt	63
INTSDMAC1CH3	SDMAC1.intreq_ch[3]	sDMAC1 channel 3 transfer end interrupt sDMAC1 channel 3 descriptor step end interrupt sDMAC1 channel 3 address error interrupt	64
INTSDMAC1CH4	SDMAC1.intreq_ch[4]	sDMAC1 channel 4 transfer end interrupt sDMAC1 channel 4 descriptor step end interrupt sDMAC1 channel 4 address error interrupt	65
INTSDMAC1CH5	SDMAC1.intreq_ch[5]	sDMAC1 channel 5 transfer end interrupt sDMAC1 channel 5 descriptor step end interrupt sDMAC1 channel 5 address error interrupt	66
INTSDMAC1CH6	SDMAC1.intreq_ch[6]	sDMAC1 channel 6 transfer end interrupt sDMAC1 channel 6 descriptor step end interrupt sDMAC1 channel 6 address error interrupt	67
INTSDMAC1CH7	SDMAC1.intreq_ch[7]	sDMAC1 channel 7 transfer end interrupt sDMAC1 channel 7 descriptor step end interrupt sDMAC1 channel 7 address error interrupt	68
INTSDMAC1CH8	SDMAC1.intreq_ch[8]	sDMAC1 channel 8 transfer end interrupt sDMAC1 channel 8 descriptor step end interrupt sDMAC1 channel 8 address error interrupt	69
INTSDMAC1CH9	SDMAC1.intreq_ch[9]	sDMAC1 channel 9 transfer end interrupt sDMAC1 channel 9 descriptor step end interrupt sDMAC1 channel 9 address error interrupt	70
INTSDMAC1CH10	SDMAC1.intreq_ch[10]	sDMAC1 channel 10 transfer end interrupt sDMAC1 channel 10 descriptor step end interrupt sDMAC1 channel 10 address error interrupt	71

Table 7.5 Interrupt Requests (3/3)

Interrupt Symbol Name	Unit Interrupt Signal	Outline	Interrupt Number
INTSDMAC1CH11	SDMAC1.intreq_ch[11]	sDMAC1 channel 11 transfer end interrupt sDMAC1 channel 11 descriptor step end interrupt sDMAC1 channel 11 address error interrupt	72
INTSDMAC1CH12	SDMAC1.intreq_ch[12]	sDMAC1 channel 12 transfer end interrupt sDMAC1 channel 12 descriptor step end interrupt sDMAC1 channel 12 address error interrupt	73
INTSDMAC1CH13	SDMAC1.intreq_ch[13]	sDMAC1 channel 13 transfer end interrupt sDMAC1 channel 13 descriptor step end interrupt sDMAC1 channel 13 address error interrupt	74
INTSDMAC1CH14	SDMAC1.intreq_ch[14]	sDMAC1 channel 14 transfer end interrupt sDMAC1 channel 14 descriptor step end interrupt sDMAC1 channel 14 address error interrupt	75
INTSDMAC1CH15	SDMAC1.intreq_ch[15]	sDMAC1 channel 15 transfer end interrupt sDMAC1 channel 15 descriptor step end interrupt sDMAC1 channel 15 address error interrupt	76

7.1.5 sDMAC Transfer Requests

The sDMAC transfer request table lists all sDMAC transfer request factors that can be selected by the DMAjRS_n registers and groups that can be selected by the DMACSELj_m registers.

For details about the sDMAC transfer request table lists, refer to Appendix file “sDMAC_Transfer_request_Table.xlsx”.

7.1.6 Reset Sources

sDMAC reset sources are listed in the following table. The sDMAC is initialized by these reset sources.

Table 7.6 Reset Sources

Unit Name	Register Name	Reset Condition					
		Power Up Reset	System Reset 1	System Reset 2	Application Reset	Module Reset	JTAG Reset
SDMACj	All registers	✓	✓	✓	✓	—	—
DMATRGSSEL	All registers	✓	✓	✓	✓	—	—

7.2 Overview

The sDMAC can be used in place of the CPU to perform high-speed data transfer between on-chip memories.

7.2.1 Functional Overview

The sDMAC has the following features:

- 16 channels
- 4-Gbyte physical address space
 - Source and destination addresses are 32 bits wide
- Connected to the System Bus directly. If a conflict occurs with another bus master in the System Bus, the transfer is arbitrated by round-robin arbitration.
- Physical bus data width: 64 bits
- Transfer data length: 1 byte, 2 bytes, 4 bytes, 8 bytes, 16 bytes, 32 bytes, 64 bytes
- The maximum transfer size: 4,294,967,295 bytes ($2^{32}-1$ bytes)
- Parallel reads and writes (fly-by)
- Address mode: Dual address mode
- Transfer requests:

Two request modes are available. Requests can be triggered by an auto request (a transfer request always occurs) or a peripheral hardware request.
- Bus mode:

Each channel can be set to either normal speed mode or slow speed mode.
- Mode for arbitration between transfer channels:

The arbitration mode can be set to either fixed priority arbitration mode or round-robin arbitration mode.
- Interrupt requests:

CPU interrupts from the sDMAC are triggered by three factors: termination of the descriptor step, termination of a data transfer and occurrence of an address error.
- Functions of the descriptor:

A descriptor contains register settings (source address register, destination address register, transfer size register, transfer mode register and scatter gather registers) and can be chained to the next descriptor. The descriptor memory size is 4 KB. This descriptor memory is shared by all channels.
- Scatter-gather transfer:

Inner and outer loops for transfers with inner and outer address increments are supported. Scattering at the destination interface and gathering at the source interface can be enabled independently and in parallel.

 - Inner and outer address increments are 32 bits wide
- sDMAC has a data RAM as a pending transfer data buffer.

The data RAM size is 2 KB and a DMA channel can use 64 bits × 16 lines for its own transactions.

7.2.2 Block Diagram

The following is a block diagram of sDMAC.

Figure 7.1 Block Diagram of sDMAC

The following block diagram shows sDMAC transfer request source selection by the DMACSELj_m registers.

Figure 7.2 Block Diagram of sDMAC Transfer Request Selection

7.3 Registers of sDMAC

7.3.1 List of Registers

sDMAC registers are listed in the following table.

For details about <SDMACj_base>, see **Section 7.1.2, Register Base Address**.

Table 7.7 List of Registers (1/2)

Module Name	Register Name	Symbol	Address	Access	Access Protection
Global Registers					
SDMACj	DMA Address Error Notification Status Register	DMAjESTA	<SDMACj_base> + 0010 _H	32	—
	DMA Interrupt Status Register	DMAjISTA	<SDMACj_base> + 0020 _H	32	—
	DMA Channel Request Priority Register	DMAjCHPRI	<SDMACj_base> + 0040 _H	32	—
	DMA Operation Register	DMAjOR	<SDMACj_base> + 0060 _H	16	—

7.3.2 DMAjESTA — DMA Address Error Notification Status Register

DMAjESTA is a 32-bit read-only register that indicates the address error notification (INTSDMACERR) status of each channel. Causes of address errors are shown in **Section 7.5(1), Address Errors**. Specification of the error notification routes is shown in **Section 7.4.2, DMA Interrupts**.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	AEN[15:0]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 7.8 DMAjESTA Register Contents

Bit Position	Bit Name	Function
31 to 16	—	Reserved When read, the value after reset is returned.
15 to 0	AEN[15:0]	Channel address error notification INTSDMACERR status These bits reflect the CAE bit status of the channels whose CAEE bit is set to 1. AEN[n]: 0: Channel n address error notification does not occur 1: Channel n address error notification occurs

7.3.3 DMAjISTA — DMA Interrupt Status Register

DMAjISTA is a 32-bit read-only register that indicates the interrupt signal status of each channel. Interrupt routes are shown in **Section 7.4.2, DMA Interrupts**.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	INT[15:0]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 7.9 DMAjISTA Register Contents

Bit Position	Bit Name	Function
31 to 16	—	Reserved When read, the value after reset is returned.
15 to 0	INT[15:0]	Channel interrupt status INT[n]: 0: Channel n interrupt does not occur 1: Channel n Interrupt occurs

7.3.4 DMAjCHPRI — DMA Channel Request Priority Register

DMAjCHPRI is a 32-bit read/write register that specifies the channel request priority count timing.

See **Section 7.4.3(3), Channel Request Priority** for details.

Value after reset: 0000 0010_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	PRICNT[15:0]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 7.10 DMAjCHPRI Register Contents

Bit Position	Bit Name	Function
31 to 16	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
15 to 0	PRICNT[15:0]	Channel Request Priority Count value This bit is used to control the timing of the channel request priority function.

7.3.5 DMAjOR — DMA Operation Register

DMAjOR is a 16-bit read/write register that controls master enable and specifies the priority level of all DMA channels.

Value after reset: 0000_H

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	PR[1:0]		—	—	—	—	—	—	—	DME
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R/W	R/W	R	R	R	R	R	R	R	R/W

Table 7.11 DMAjOR Register Contents

Bit Position	Bit Name	Function
15 to 10	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
9, 8	PR[1:0]	Priority Mode Select the priority level between channels when there are transfer requests for multiple channels simultaneously. 00: CH0 > CH1 > ... > CH14 > CH15 11: Round-robin mode Other than above: Setting prohibited
7 to 1	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
0	DME	DMA Master Enable Enables or disables DMA transfers on all channels. If the DME bit and the DE bit in DMAjCHCR_n are set to 1, DMA transfer is enabled. At this time, the TE bits in DMAjCHSTA_n and the CAE bits in DMAjCHSTA_n must be all 0. If this bit is cleared during transfer, transfers on all channels are terminated. 0: Disable DMA transfers on all channels 1: Enable DMA transfers on all channels

7.3.6 DMAjCHRST — DMA Channel Reset Register

DMAjCHRST register is a 32-bit write-only register that initializes each channel.

When this register is set, the specified channel state is initialized completely and the following registers are initialized.

DMAjSAR_n, DMAjDAR_n, DMAjTSR_n, DMAjTSRB_n, DMAjTMR_n, DMAjCHCR_n, DMAjCHSTP_n, DMAjCHSTA_n, DMAjGIAI_n, DMAjGOAI_n, DMAjSIAI_n, DMAjSOAI_n, DMAjSGCR_n, DMAjRS_n, DMAjBUFCR_n, DMAjDPPTR_n, DMAjDPCR_n

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	CLR[15:0]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W

Table 7.12 DMAjCHRST Register Contents

Bit Position	Bit Name	Function
31 to 16	—	Reserved When writing, write the value after reset.
15 to 0	CLR[15:0]	All registers in the channel can be cleared by writing to these bits. CLR[0] 0: Ignored 1: Channel 0 registers are cleared CLR[1] 0: Ignored 1: Channel 1 registers are cleared ... CLR[15] 0: Ignored 1: Channel 15 registers are cleared Before writing to this register, confirm that channel BUSY is 0.

7.3.7 DMAjCM_n — DMA Channel Master Setting Register

DMAjCM_n is a 32-bit read/write register that configures the DMA master information.

Value after reset: DMA0CM_n: 0000 1C00_H

DMA1CM_n: 0000 1B00_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	SPID[4:0]				—	—	—	—	—	—	—	—	UM
Value after reset	0	0	0	*	*	*	*	*	0	0	0	0	0	0	0	0
R/W	R	R	R	R/W	R/W	R/W	R/W	R/W	R	R	R	R	R	R	R	R/W

Note: This value is 1C_H (sDMAC0) or 1B_H (sDMAC1).

Table 7.13 DMAjCM_n Register Contents

Bit Position	Bit Name	Function
31 to 13	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
12 to 8	SPID	Channel master SPID setting Specifies the SPID information of the master assigned to the channel. Value after reset of DMA0CM_n: 1C _H Value after reset of DMA1CM_n: 1B _H
7 to 1	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
0	UM	Channel master UM setting Specifies the UM information of the master assigned to the channel. 0: Supervisor mode 1: User mode

7.3.8 DMAjSAR_n — DMA Source Address Register

DMAjSAR_n is a 32-bit read/write register that specifies the source address of DMA transfer. During DMA transfer, this register indicates the next source address.

When the selected source address mode is “increment” (SM bit in DMAjTMR_n register is 01_B), the source address can be specified on a byte boundary. Otherwise the source address must be specified on the transaction size boundary (STS bit in DMAjTMR_n register).

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SAR[31:16]																
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SAR[15:0]																
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Note: In case of using the gather transfer function, this register must be set to a multiple of DMA source transaction size which is set to STS bit in the DMAjTMR_n register.

7.3.9 DMAjDAR_n — DMA Destination Address Register

DMAjDAR_n is a 32-bit read/write register that specifies the destination address of DMA transfer. During DMA transfer, this register indicates the next destination address.

When the selected destination address mode is “increment” (DM bit in DMAjTMR_n register is 01_B), the destination address can be specified on a byte boundary. Otherwise the destination address must be specified on the transaction size boundary (DTS bit in DMAjTMR_n register).

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
DAR[31:16]																
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DAR[15:0]																
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

7.3.10 DMAjTSR_n — DMA Transfer Size Register

DMAjTSR_n is a 32-bit read/write register that specifies the DMA transfer size. The total size of DMA transfer is 1 byte when the setting is 0000 0001_H and 4,294,967,295 bytes ($2^{32}-1$ bytes) when FFFF FFFF_H is set. When the setting is 0000 0000_H, transfer does not occur, and TE is set immediately. During DMA transfer, DMAjTSR_n indicates the remaining transfer size.

In DMA transfer, the size of the read transfer and write transfer may differ. This is because the DMAC uses flyby DMA transfer via the data RAM. DMAjTSR_n indicates the read transfer size.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
TSR[31:16]																
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
TSR[15:0]																
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

7.3.11 DMAjTSRB_n — DMA Transfer Size Register B

DMAjTSRB_n is a 32-bit read-only register that indicates the DMA transfer size. During DMA transfer, this register indicates the remaining transfer size (in bytes). When DMAjTSR_n is written, the same value is set in this register.

In DMA transfer, the size of the read transfer and write transfer may differ. This is because the DMAC uses flyby DMA transfer via data RAM. DMAjTSRB_n indicates the write transfer size. The DMAjTSR_n value is copied to the DMAjTSRB_n register when DMA transfer starts.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 7.14 DMAjTMR_n Register Contents (1/2)

Bit Position	Bit Name	Function
31 to 24	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
23 to 20	SLM[3:0]	DMA Transfer Slow Speed mode Specifies the number of clock cycles (bus clock) between two DMA transfers. DMA transfer is executed once every number of clock cycles specified by SLM. 0000: Normal mode 1000: 256 clock cycles 1001: 512 clock cycles 1010: 1024 clock cycles : 1111: 32768 clock cycles Other than above: Setting prohibited
19 to 16	PRI[3:0]	Channel Request Priority Setting These bits set the priority of channel requests. Refer to 7.4.3(3) for details. PRI[3] 0: Channel request priority is disabled. 1: Channel request priority is enabled. PRI[2:0] 111: Highest priority : 000: Lowest priority
15 to 13	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
12	TRS	Transfer request source Specifies which transfer request source will be sent to the DMAC. Before changing transfer request sources, the DMA enable bit (DE) should be set to 0. 0: Auto request 1: Hardware request

Table 7.14 DMAjTMR_n Register Contents (2/2)

Bit Position	Bit Name	Function
11, 10	DM[1:0]	Destination address mode Specify whether the DMA destination address is incremented or fixed, and the amount of increment. 00: Fixed destination address 01: Destination address is incremented based on destination transaction size (DTS) +1 in 1-byte unit transfers +2 in 2-byte unit transfers +4 in 4-byte unit transfers +8 in 8-byte unit transfers +16 in 16-byte unit transfers +32 in 32-byte unit transfers +64 in 64-byte unit transfers Other than above: Setting prohibited
9, 8	SM[1:0]	Source Address Mode Specify whether the DMA source address is incremented or fixed, and the amount of increment. 00: Fixed source address 01: Source address is incremented based on source transaction size (STS) +1 in 1-byte unit transfers +2 in 2-byte unit transfers +4 in 4-byte unit transfers +8 in 8-byte unit transfers +16 in 16-byte unit transfers +32 in 32-byte unit transfers +64 in 64-byte unit transfers Other than above: Setting prohibited
7 to 4	DTS[3:0]	DMA destination transaction size 0000: 1-byte unit transfer 0001: 2-byte unit transfer 0010: 4-byte unit transfer 0011: 8-byte unit transfer 0100: 16-byte unit transfer 0101: 32-byte unit transfer 0110: 64-byte unit transfer Other than above: Setting prohibited
3 to 0	STS[3:0]	DMA source transaction size 0000: 1-byte unit transfer 0001: 2-byte unit transfer 0010: 4-byte unit transfer 0011: 8-byte unit transfer 0100: 16-byte unit transfer 0101: 32-byte unit transfer 0110: 64-byte unit transfer Other than above: Setting prohibited

7.3.13 DMAjCHCR_n — DMA Channel Control Register

DMAjCHCR_n is a 16-bit read/write register that controls DMA transfer.

Value after reset: 0000H

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	DPE	DPB	—	—	—	CAEE	CAIE	DSIE	IE	DE
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R/W	R/W	R	R	R	R/W	R/W	R/W	R/W	R/W

Table 7.15 DMAjCHCR_n Register Contents (1/2)

Bit Position	Bit Name	Function
15 to 10	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
9	DPE	Descriptor enable bit Specifies whether the descriptor is enabled. 0: Disabled Descriptor operation is disabled. 1: Enabled Descriptor operation is enabled. When the DMAjDPPTR_n.CF bit is set to 1, after reading the register setting from the descriptor memory, DMA transfer is continued. Clearing the DPE bit by setting the DMAjCHFCR_n.DPEC bit to 1 terminates the descriptor chain operation.
8	DPB	Descriptor start bit Specifies the configuration to be loaded at the beginning of the descriptor. After reading the descriptor, this bit is cleared. While DE = 1, DPB must not be set to 1. 0: Start the DMA transfer via a register setting. 1: Start DMA transfer after the channel configuration is copied from the descriptor memory. The configurations to copy from the Descriptor memory are specified in the DMAjDPCR_n register.
7 to 5	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
4	CAEE	Channel address error notification INTSDMACERR enable Specifies whether a channel can issue a notification upon the occurrence of an address error. When the CAEE bit and the DMAjCHSTA_n.CAE bit are set to 1, a channel (sDMAC_CH0 to sDMAC_CH15) can issue notifications about address errors. (INTSDMACERR) For details, see Section 7.4.2, DMA Interrupts . 0: Address error notification disabled 1: Address error notification enabled
3	CAIE	Channel address error interrupt INTSDMACjCHn enable Specifies whether a channel can generate an interrupt request upon occurrence of an address error. When the CAIE bit and DMAjCHSTA_n.CAE bit are set to 1, a channel will generate an interrupt request (INTSDMACjCHn) upon the occurrence of an address error. For details, see Section 7.4.2, DMA Interrupts . 0: Interrupt request disabled 1: Interrupt request enabled
2	DSIE	Descriptor step end interrupt master enable Specifies whether a channel can generate an interrupt at the end of a descriptor step. When the DMAjDPPTR_n.DIE bit and DSIE bit are set to 1, a channel will generate an interrupt request (INTSDMACjCHn) upon completion of a descriptor step. See Section 7.5, Usage Notes for details about DMA transfer interrupts. 0: Interrupt request is disabled 1: Interrupt request is enabled

Table 7.15 DMAjCHCR_n Register Contents (2/2)

Bit Position	Bit Name	Function
1	IE	<p>Transfer end interrupt enable</p> <p>Specifies whether or not a channel can generate an interrupt at the end of DMA transfer. Setting this bit to 1 will allow a channel to generate an interrupt request (INTSDMACjCHn) when the DMAjCHSTA_n.TE bit is set to 1. See Section 7.5, Usage Notes for details about DMA transfer interrupts.</p> <p>0: Interrupt request is disabled. 1: Interrupt request is enabled.</p>
0	DE	<p>DMA Enable</p> <p>Enables or disables DMA transfer for the corresponding channel. Clearing the DE bit to 0 by setting the DMAjCHFCR_n.DEC bit to 1 terminates DMA transfer. The DE bit is also cleared automatically when an ongoing DMA transfer is finished or an ECC error of the descriptor RAM occurs. See Section 7.5, Usage Notes for details about DMA transfer interrupts.</p> <p>0: DMA transfer disabled 1: DMA transfer enabled</p>

7.3.14 DMAjCHSTP_n — DMA Channel Stop Register

DMAjCHSTP_n is a 16-bit read/write register that controls the stop condition for DMA transfer.

Value after reset: 0000_H

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	STP
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Table 7.16 DMAjCHSTP_n Register Contents

Bit Position	Bit Name	Function
15 to 1	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
0	STP	DMA transmission stop When this bit is set to 1, packet requests stop immediately. When this bit is set to 0 after transmission has been stopped, the stopped transmission is resumed. 0: No operation 1: DMA transfer stop

7.3.15 DMAjCHSTA_n — DMA Channel Status Register

DMAjCHSTA_n register is a 32-bit read-only register that shows the DMA transfer status.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	OVF	DRQ	—	—	—	—	—	—	—	—	CAE	DSE	TE	BUSY
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 7.17 DMAjCHSTA_n Register Contents (1/2)

Bit Position	Bit Name	Function
31 to 14	—	Reserved When read, the value after reset is returned.
13	OVF	Hardware transfer request overflow flag Indicates that a hardware trigger was asserted before a pending hardware transfer request has been acknowledged. To clear the OVF bit, write 1 to the DMAjCHFCR_n.OVFC bit. 0: No hardware transfer request overflow 1: Hardware transfer request overflow occurred
12	DRQ	Hardware request status If this bit is set, it means that a hardware transfer request exists or is retained. <ul style="list-style-type: none"> This bit shows whether a hardware transfer request is retained. When the transfer specified by DMAjRS_n.TL bits is completed, this bit is automatically cleared. This bit can be cleared by writing 1 to the DMAjCHFCR_n.DRQC bit. This bit changes regardless of the value of the DMAjTMR_n.TRS bit when a hardware DMA transfer request is generated. 0: There is no hardware transfer request 1: There is a hardware transfer request
11 to 4	—	Reserved When read, the value after reset is returned.

Table 7.17 DMAjCHSTA_n Register Contents (2/2)

Bit Position	Bit Name	Function
3	CAE	<p>Address error flag</p> <p>Indicates that an address error interrupt occurred in the DMA transfer. The following conditions can set this bit:</p> <ul style="list-style-type: none"> The transfer source or transfer destination is an invalid space. A GUARD error occurred upon access to a source or a destination address. Channel register setting is prohibited. <p>See section 7.5(1), Address Errors for detail about address errors.</p> <p>If this bit is set, DMA transfer is not enabled for the channel even if the DE bit is set to 1. To clear the CAE bit, write 1 to the DMAjCHFCR_n.CAEC bit.</p> <ul style="list-style-type: none"> 0: Address error interrupt did not occur in the DMA transfer 1: Address error interrupt occurred in the DMA transfer
2	DSE	<p>Descriptor step end flag</p> <p>When the DMAjCHCR_n.DSIE bit is set to 1 and the DMAjDPPTTR_n.DIE bit is set to 1, the DSE bit is set to 1 at the end of DMA transfer. To clear the DSE bit, write 1 to the DMAjCHFCR_n.DSEC bit.</p> <ul style="list-style-type: none"> 0: DMA transfer is in progress or has finished 1: The descriptor step has finished
1	TE	<p>Transfer end flag</p> <p>The TE bit is set to 1 when data transfer ends (DMAjTSR_n becomes 0). When the descriptor is enabled, the TE bit is set to 1 at the end of all descriptor steps.</p> <p>The TE bit is not set to 1 in the following cases:</p> <ul style="list-style-type: none"> DMA transfer ends due to a DMA address error before DMAjTSR_n becomes 0. DMA transfer is terminated by clearing the DE bit and DME bit in DMAjOR. <p>To clear the TE bit, write 1 to the DMAjCHFCR_n.TEC bit. If the DMAjCHCR_n.DE bit is set to 1 while TE bit is set to 1, DMA transfer will not be enabled.</p> <ul style="list-style-type: none"> 0: DMA transfer is in progress or DMA transfer has finished 1: DMA transfer ended at the specified count (TSR = 0)
0	BUSY	<p>Channel Busy flag</p> <p>This bit indicates that the channel is busy. When transfer is started, the BUSY bit is set to 1. After the DMAjCHCR_n.DE bit is cleared or the DMAjCHSTP_n.STP bit is set, the BUSY bit is cleared after receiving the response of all packets.</p> <ul style="list-style-type: none"> 0: Channel status is idle. 1: Channel status is busy.

7.3.16 DMAjCHFCR_n — DMA Channel Flag Clear Register

DMAjCHFCR_n is a 32-bit write-only register that clears the DMA channel status flags.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	W	W	R	R	W	R	R	R	R	R	W	W	W	W

Table 7.18 DMAjCHFCR_n Register Contents (1/2)

Bit Position	Bit Name	Function
31 to 14	—	Reserved When writing, write the value after reset.
13	OVFC	Hardware transfer request overflow flag clear When the OVFC bit is set to 1, the DMAjCHSTA_n.OVF bit is cleared. 0: No operation 1: DMAjCHSTA_n.OVF bit is cleared.
12	DRQC	Hardware transfer request clear When the DRQC bit is set to 1, the DMAjCHSTA_n.DRQ bit is cleared. 0: No operation 1: DMAjCHSTA_n.DRQ bit is cleared.
11 to 10	—	Reserved When writing, write the value after reset.
9	DPEC	Descriptor enable clear When the DPEC bit is set to 1, the DMAjCHCR_n.DPE bit is cleared. The DMAjCHCR_n.DPE bit is the enable condition of the descriptor operation. To suspend DMA transfer at the end of a descriptor step, clear the DPE bit by using this bit. 0: No operation 1: DMAjCHCR_n.DPE bit is cleared
8 to 4	—	Reserved When writing, write the value after reset.
3	CAEC	Address error flag clear When the CAEC bit is set to 1, the DMAjCHSTA_n.CAE bit is cleared. The DMAjCHSTA_n.CAE bit is the stop condition of DMA transfer. To end DMA transfer, clear the DMAjCHCR_n.DE bit before clearing the DMAjCHSTA_n.CAE bit. 0: No operation 1: DMAjCHSTA_n.CAE bit is cleared
2	DSEC	Descriptor step end flag clear When the DSEC bit is set to 1, the DMAjCHSTA_n.DSE bit is cleared. 0: No operation 1: DMAjCHSTA_n.DSE bit is cleared

Table 7.18 DMAjCHFCR_n Register Contents (2/2)

Bit Position	Bit Name	Function
1	TEC	<p>Transfer end flag clear</p> <p>When the TEC bit is set to 1, the DMAjCHSTA_n.TE bit is cleared. The DMAjCHSTA_n.TE bit is the stop condition of DMA transfer. To end DMA transfer, clear the DMAjCHCR_n.DE bit before clearing the DMAjCHSTA_n.TE bit.</p> <p>0: No operation 1: DMAjCHSTA_n.TE bit is cleared</p>
0	DEC	<p>DMA enable clear</p> <p>When the DEC bit is set to 1, the DMAjCHCR_n.DE bit is cleared. The DMAjCHCR_n.DE bit is the enable condition of DMA transfer. To suspend DMA transfer, clear the DE bit by using this bit. See Section 7.5, Usage Notes for details about DMA transfer suspension.</p> <p>0: No operation 1: DMAjCHCR_n.DE bit is cleared</p>

7.3.17 DMAjGIAI_n — DMA Gather Inner Address Increment Register

DMAjGIAI_n is a 32-bit read/write register that specifies the source address increment for the inner loop of a gather transfer.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
GIAI[31:16]																
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Note: This register must be set to a multiple of DMA source transaction size which is set to STS bit in the DMAjTMR_n register.

7.3.18 DMAjGOAI_n — DMA Gather Outer Address Increment Register

DMAjGOAI_n is a 32-bit read/write register that specifies the source address increment for the outer loop of a gather transfer.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
GOAI[31:16]																
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
GOAI[15:0]																
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Note: This register must be set to a multiple of DMA source transaction size which is set to STS bit in the DMAjTMR_n register.

7.3.19 DMAjSIAI_n — DMA Scatter Inner Address Increment Register

DMAjSIAI_n is a 32-bit read/write register that specifies the destination address increment for the inner loop of a scatter transfer.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

7.3.20 DMAjSOAI_n — DMA Scatter Outer Address Increment Register

DMAjSOAI_n is a 32-bit read/write register that specifies the destination address increment for the outer loop of a scatter transfer.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SOAI[31:16]																
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SOAI[15:0]																
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

7.3.21 DMAjSGST_n — DMA Scatter Gather Status Register

DMAjSGST_n is a 32-bit read only register that indicates the count of inner scatter and gather loops. The detailed operation of scatter/gather is explained in **Section 7.4.5, Scatter Gather Transfer**.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	SICNT[13:0]

Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 7.19 DMAjSGST_n Register Contents

Bit Position	Bit Name	Function
31, 30	—	Reserved When read, the value after reset is returned.
29 to 16	SICNT[13:0]	Indicates the current repeat count of the scatter inner DMA loop.
15, 14	—	Reserved When read, the value after reset is returned.
13 to 0	GICNT[13:0]	Indicates the current repeat count of the gather inner DMA loop.

7.3.22 DMAjSGCR_n — DMA Scatter Gather Control Register

DMAjSGCR_n is a 32-bit read/write register that controls scattering on the source side and gathering on the destination side. The operation of scatter/gather is explained in detail in **Section 7.4.5, Scatter Gather Transfer**.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	SEN	ZF	SIRPT[13:0]

Table 7.20 DMAjSGCR_n Register Contents

Bit Position	Bit Name	Function
31	SEN	Scatter enable on source side 0: Scattering is disabled 1: Scattering is enabled
30	ZF	Zero fill 0: Zero fill is disabled 1: Zero fill is enabled
29 to 16	SIRPT[13:0]	Repeat count of the inner DMA loop if scattering is enabled 0: Zero repeats 1: One repeat : 16383: 16383 repeats
15	GEN	Gather enable on destination side 0: Gathering is disabled 1: Gathering is enabled
14	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
13 to 0	GIRPT[13:0]	Repeat count of the inner DMA loop if gathering is enabled 0: Zero repeats 1: One repeat : 16383: 16383 repeats

7.3.23 DMAjRS_n — DMA Resource Select Register

DMAjRS_n is a 32-bit read/write register that specifies the source and control settings for hardware transfer requests. The operation of hardware transfer requests is explained in detail in **Section 7.4.1, DMA Transfer Requests**.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

	—	TL[2:0]			FPT	PLE	DRQI	—	RS[7:0]							
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
	R/W	R	R/W	R/W	R/W	R/W	R/W	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 7.21 DMAjRS_n Register Contents (1/2)

Bit Position	Bit Name	Function
31 to 16	TC[15:0]	Transfer count per hardware request Specify the number of DMA transfers in hardware request mode. This bit is valid only when the DMAjRS_n.TL bit is set to 000 or 001. In this case, setting 0 is prohibited.
15	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
14 to 12	TL[2:0]	Transfer limit per hardware request Specifies the limit of transfers generated by a hardware request. 000: Transaction size indicated by DMAjTMR_n.STS * DMAjRS_n.TC (Setting prohibited when PLE = 1) 001: Transaction size indicated by DMAjTMR_n.DTS * DMAjRS_n.TC (Setting prohibited when PLE = 0) 010: Transfer size indicated by DMAjTSR_n.TSR 011: Until the DSE flag is asserted. (Transfer also ends when the TE flag is asserted.) 100: Until the TE flag is asserted Other than above: Setting prohibited
11	FPT	First pre-load trigger Specifies the trigger to start the first pre-load transfer. If transfer data is not prepared before DE is set, this bit should be set to 1. When the pre-load function is disabled (PLE = 0), this setting is ignored. 0: First pre-load start when DE is set to 1 1: First pre-load start when hardware request is asserted
10	PLE	Pre-load enable When the pre-load function is enabled, the DMAC loads transfer data from the source memory before a hardware request is asserted. 0: Disable 1: Enable
9	DRQI	DMA request initialization when descriptor settings are loaded Specifies whether to initialize the DRQ bits when this register setting is loaded from the descriptor memory. When DRQI is set to 1, the remaining DRQ bits are cleared. The DRQ bits are also cleared when a different source (RS) is loaded. For details, see Section 7.4.6(4)(h), Example 8: Hardware Request Operation with Different Request Source Settings . 0: DRQ initialize disabled 1: DRQ initialize enabled

Table 7.21 DMAjRS_n Register Contents (2/2)

Bit Position	Bit Name	Function
8	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
7 to 0	RS[7:0]	DMA request source See the DMA request resources of on-chip peripheral modules.

7.3.24 DMAjBUFCR_n — DMA Buffer Control Register

DMAjBUFCR_n is a 32-bit read/write register that controls the upper limit of the data RAM buffer. This register specifies the upper limit of the RAM buffer available to a channel for data prefetching. This setting should not be changed unless it is necessary to limit the amount of prefetched data.

Value after reset: 0000 0080_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	ULB[7:0]

R/W	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 7.22 DMAjBUFCR_n Register Contents

Bit Position	Bit Name	Function
31 to 8	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
7 to 0	ULB[7:0]	Upper limit of buffer This register controls the upper limit of a channel's data buffer. A power-of-two setting is recommended. Setting ULB to less than the transaction size (DMAjTMR_n.STS, DMAjTMR_n.DTS) is prohibited. The maximum value is 128 (bytes).

7.3.25 DMAjDPPTR_n — DMA Descriptor Pointer Register

DMAjDPPTR_n is a 32-bit read/write register that specifies the address of the next register setting in the descriptor memory. The operation of descriptors is explained in detail in **Section 7.4.6, Descriptors**.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	PTR[11:2]										DIE	CF
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 7.23 DMAjDPPTR_n Register Contents

Bit Position	Bit Name	Function
31 to 12	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
11 to 2	PTR[11:2]	Address pointer of Descriptor These bits indicate the address of the next register setting in the descriptor memory.
1	DIE	Descriptor interrupt enable When the DMAjCHCR_n.DSIE bit and this bit are set to 1 at the end of the current DMA transfer, the DSE bit in DMAjCHSTA_n set to 1 and the descriptor step end interrupt is issued. 0: Interrupt request is disabled 1: Interrupt request is enabled
0	CF	Continuation flag of descriptor 0: Disable Transfer is not continued. The TE bit in the DMAjCHCR_n register is set to 1 at the termination of the current DMA transfer. 1: Enable When DMA transfer with the current register settings is terminated and DMAjCHCR_n.DPE is set to 1, transfer continues to read the register settings from the DPTR address of the descriptor memory.

7.3.26 DMAjDPCR_n — DMA Descriptor Control Register

DMAjDPCR_n is a 32-bit read/write register that specifies which channel settings will be updated with the contents of the descriptor memory. The operation of descriptors is explained in details in **Section 7.4.6, Descriptors**.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 7.24 DMAjDPCR_n Register Contents

Bit Position	Bit Name	Function
31 to 11	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
10 to 0	UPF[10:0]	Update flag of Descriptor These bits specify the registers to be updated by a descriptor operation. The DMAjDPPTR_n register is always updated. UPF[0]: Enable/disable updating the DMAjSAR_n register UPF[1]: Enable/disable updating the DMAjDAR_n register UPF[2]: Enable/disable updating the DMAjTSR_n register UPF[3]: Enable/disable updating the DMAjTMR_n register UPF[4]: Enable/disable updating the DMAjGIAI_n register UPF[5]: Enable/disable updating the DMAjGOAI_n register UPF[6]: Enable/disable updating the DMAjSIAI_n register UPF[7]: Enable/disable updating the DMAjSOAI_n register UPF[8]: Enable/disable updating the DMAjSGCR_n register UPF[9]: Enable/disable updating the DMAjRS_n register UPF[10]: Enable/disable updating the DMAjBUFCR_n register

7.3.27 Descriptor RAM — Descriptor Memory

See **Section 7.4.6, Descriptor** for details about the descriptor memory.

7.3.28 DMACSELj_m — sDMACj Transfer Request Group Selection Register m (m = 0 to 15)

DMACSELj_m is a 32-bit read/write register that specifies the sDMACj transfer request group for each channel.

Value after reset: DMACSEL0_m: 0000 0000_H
DMACSEL1_m: 5555 5555_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit Name	Function
SELn	0 _B : Select DMA transfer request group 0 1 _B : Select DMA transfer request group 1

7.4 Operation

7.4.1 DMA Transfer Requests

The DMAC starts DMA transfer by accepting a hardware DMA transfer request or software DMA transfer request. The DMA transfer request source (TRS) bit in the DMA transfer mode register (DMAjTMR_n) determines whether a hardware DMA transfer request or a software DMA transfer request is used. How to set up DMA transfer requests is described in **Section 7.7, Setting up DMA Transfer**.

(1) Auto-Request Mode

When the TRS bit in the DMAjTMR_n register is set to 0, a software DMA transfer request can be generated. When the DE bit in DMAjCHCR_n and the DME bit in DMAjOR are set to 1 for the target channel, the transfer begins providing the CAE bit in DMAjCHSTA_n is 0.

(2) Hardware-Request Mode

When the TRS bit in the DMAjTMR_n register is set to 1, if DMA transfer is enabled (DE = 1, DME = 1, TE = 0, CAE = 0), a transfer is performed upon the input of a transfer request signal.

In the case of a hardware DMA transfer request for the DMAC, one out of 256 hardware DMA transfer sources is selected and assigned to each channel of the DMAC in the DMA request control module. This assignment is configured by the resource select (RS) bit in the DMAjRS_n register.

Examples of using hardware request mode are shown below.

(a) Example 1: Hardware Request Operation to Transfer Data from a Peripheral Module

Figure 7.3 and Figure 7.4 show examples of a peripheral module requesting sDMAC transfer from peripheral memory to on-chip memory. When the hardware transfer request triggers a load data transfer (DMAjRS_n.PLE = 0), the DMAjRS_n.TL bit determines the load data transfer limit per hardware transfer request. Store data transfers are executed in auto request mode in this case.

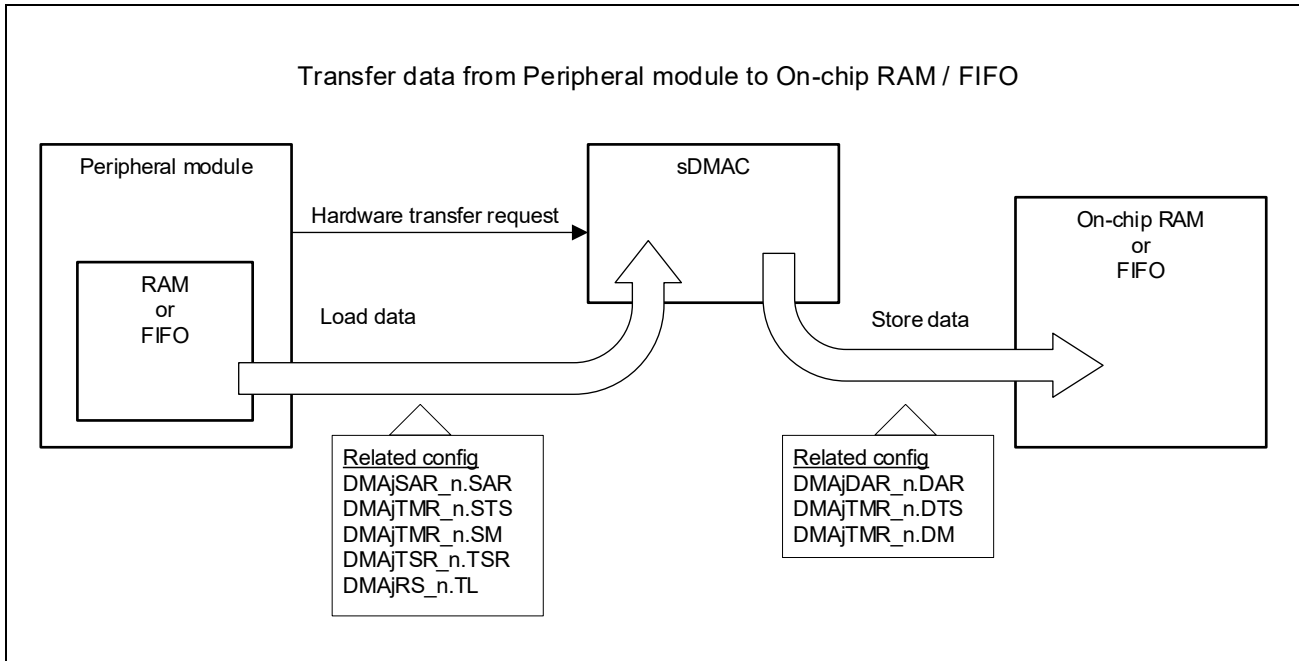

Figure 7.3 Transferring Data from Peripheral Module in Hardware-Request Mode

Figure 7.4 Timing Chart for Transferring Data from Peripheral Module

(b) Example 2: Hardware Request Operation to Transfer Data to a Peripheral Module

Figure 7.5, Figure 7.6, Figure 7.7, and Figure 7.8 show examples of a peripheral module requesting sDMAC transfer from on-chip memory to peripheral module memory. When the pre-load function is enabled ($\text{DMAjRS}_n.\text{PLE} = 1$), a hardware transfer request triggers a store data transfer. The $\text{DMAjRS}_n.\text{TL}$ bit determines the store data transfer limit per hardware transfer request. Load data transfers are executed in auto request mode in this case.

In case the pre-load transfer is triggered before the load data is prepared in the source memory, the pre-load limit can be controlled by setting the ULB bit in DMAjBUFCR_n register as shown in **Figure 7.8**.

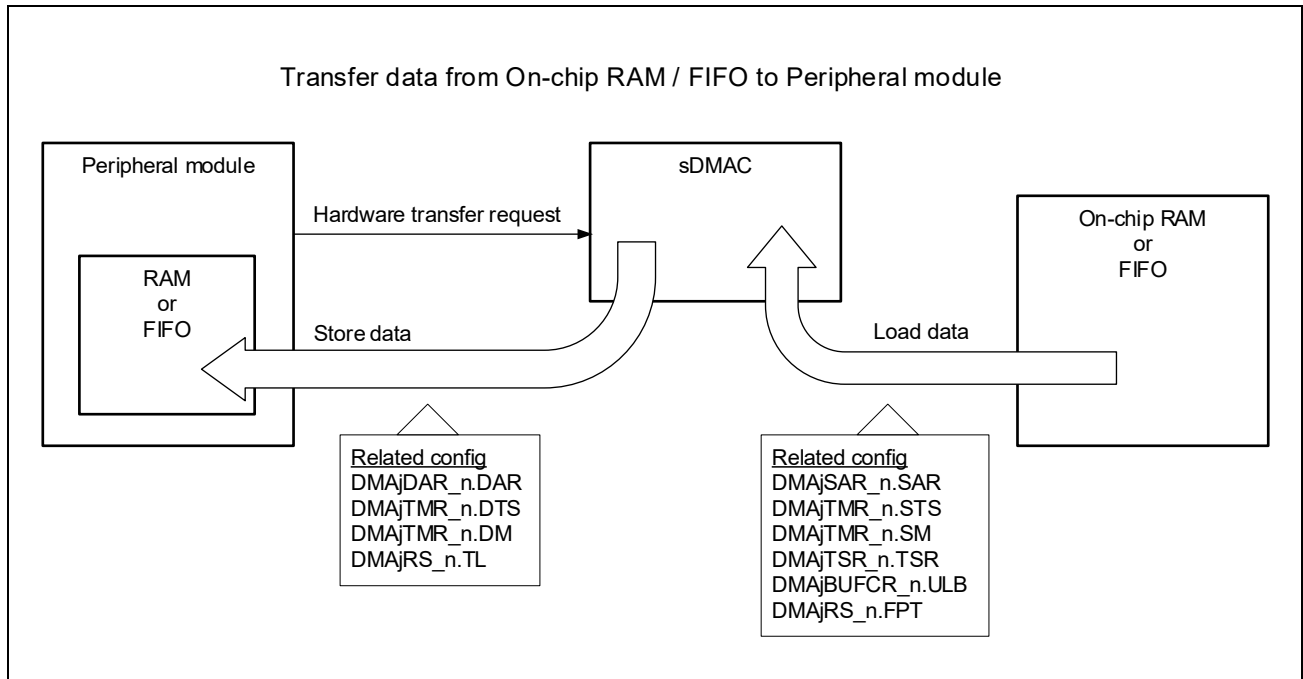

Figure 7.5 Transferring Data to a Peripheral Module in Hardware Request Mode

Figure 7.6 Timing Chart for Pre-Load Function in Hardware Request Mode

Figure 7.7 Timing Chart of Transferring Data to Peripheral Module

Figure 7.8 Timing Chart of Transferring Data with Buffer Control Operation

7.4.2 DMA Interrupts

The routing of sDMAC interrupts is shown in **Figure 7.9**. sDMAC interrupts can be masked by the DMA channel registers.

A channel interrupt request is raised by sDMAC if any of these status bits is set (OR function):

- Transfer end (TE),
- Descriptor step end (DSE)
- Channel address error (CAE).
- Address error notifications are also routed to the CPU by another path.

The status of channel interrupt requests and address errors is indicated in global registers DMAjISTA and DMAjESTA.

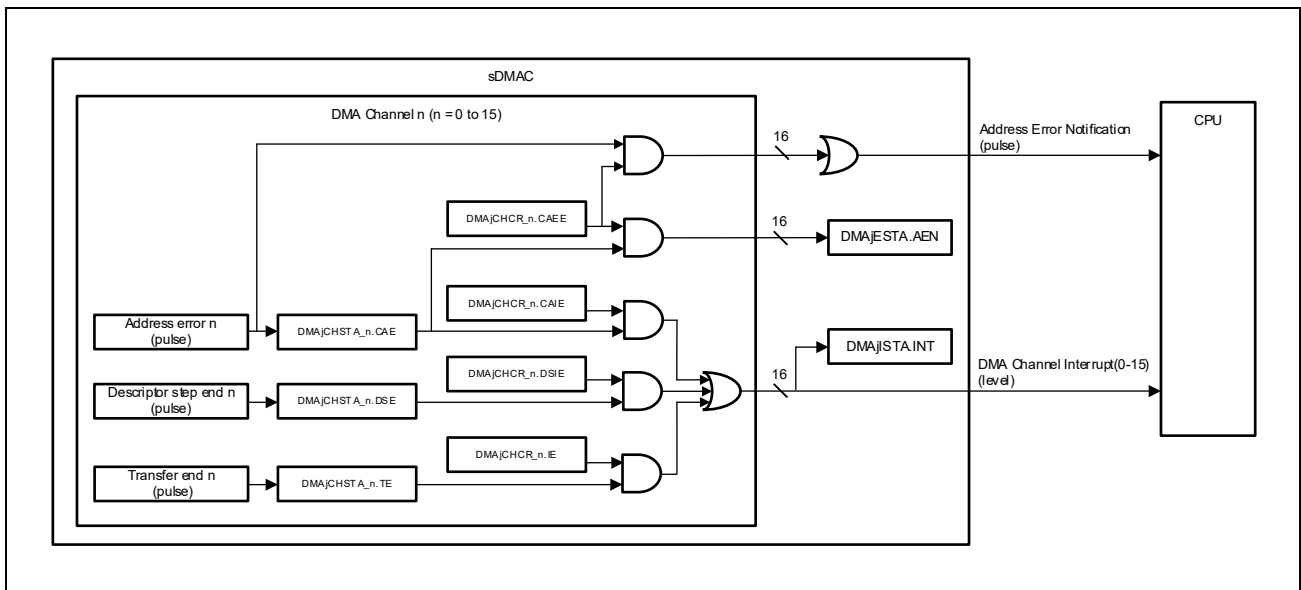

Figure 7.9 Interrupt Routing in sDMAC

7.4.3 Channel Priority

When sDMAC receives transfer requests from multiple channels, it transfers data according to a predetermined priority. One of two modes (fixed mode or round-robin mode) can be selected (DMAjOR.PR[1:0]).

(1) Fixed Mode

In this mode, the priority levels among the channels remain fixed.

CH0 > CH1 > ... > CH14 > CH15

(2) Round-Robin Mode

In round-robin mode, each time data of one transfer unit (1 to 64 byte units) is transferred on one channel, the priority is rotated. The channel on which the transfer has just finished rotates to the bottom of the priority. The priority of round-robin mode is CH0 > CH1 > ... > CH14 > CH15 immediately after reset.

(3) Channel Request Priority

To increase the priority of the specified channel, use the PRI bits in the DMA transfer mode register (DMAjTMR_n). This function is given priority over the PR bits in the DMA operation register (DMAjOR). If a channel request is not accepted, the channel priority counter increases by the count set by the PRICNT bits in the DMA channel request priority register (DMAjCHPRI). The PRICNT bits in the DMA channel request priority register (DMAjCHPRI) are counted up by SCLK. When this priority counter reaches the maximum value (= 7), the highest priority request is accepted. However, if more than one channel has high priority, the requests are arbitrated according to the setting of the PR bits in DMAjOR.

Figure 7.10 shows the channel request priorities.

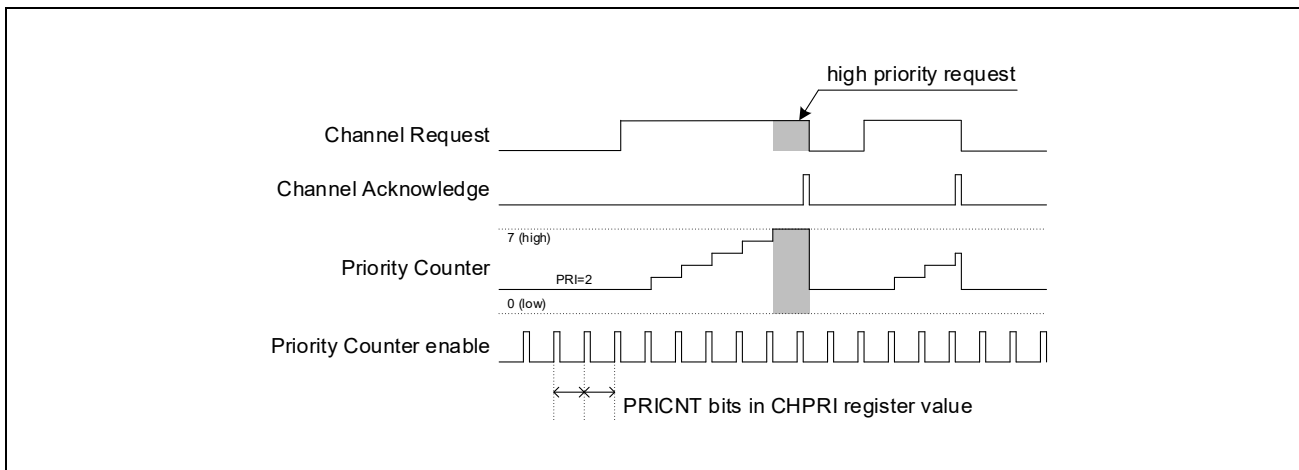

Figure 7.10 Channel Request Priorities

7.4.4 Slow Speed Mode

In slow speed mode, there is a configurable delay between consecutive DMA transfers. The delay (number of clock cycles) is specified by the SLM bit in the DMAjTMR_n register. Slow speed mode can be selected independently for each DMA channel. When one DMA channel operating in slow speed mode is waiting between DMA transfers, another DMA channel operating in slow speed mode can perform DMA transfer.

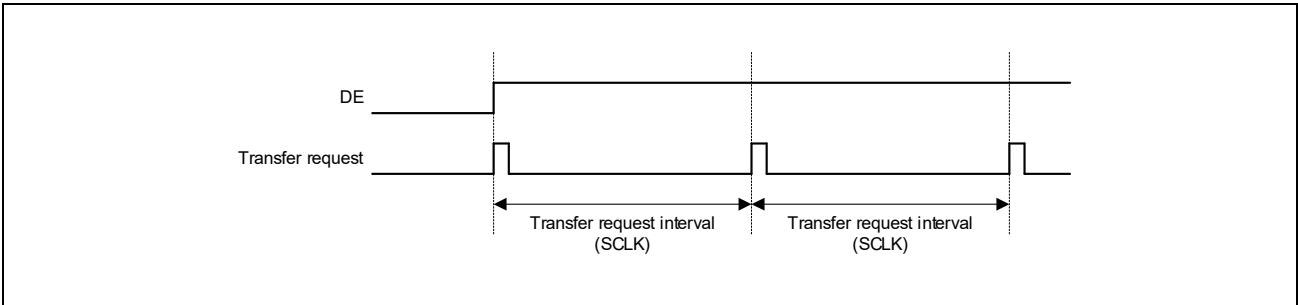

Figure 7.11 Slow Speed Mode

7.4.5 Scatter Gather Transfer

The DMAC supports gathering on the source side and scattering on the destination side.

The gather flow is shown in **Figure 7.12**. It is enabled if the GEN bit in DMAjSGCR_n for the given DMA channel is set to 1. The gather flow supports an inner and an outer loop. The number of iterations of the inner loop is specified by the GIRPT bit in DMAjSGCR_n register. The total of inner and outer loop transfers equals the number of TSR bytes. So the number of iterations of the outer loop is indirectly defined by the TSR register. The inner loop always transfers a data unit the size of an STS byte from the source to the data RAM and the SAR register is updated in the same way as transfers with gathering disabled. Additionally, the source address (SAR bits in DMAjSAR_n register) is increased by the inner address increment (GIAI bits in DMAjGIAI_n register). This procedure is repeated until the value of TSR bits in DMAjTSR_n or the value of GICNT bits in DMAjSGST_n register reaches zero, which concludes the inner loop. Before the inner loop is repeated, the source address (SAR bits in DMAjSAR_n register) is increased by the outer address increment (GOAI bits in DMAjGOAI_n register) and the GICNT bits in DMAjSGST_n register are restored with the value of GIRPT bits in DMAjSGCR_n register. The outer loop is repeated until the value of TSR bits in DMAjTSR_n register reaches zero. **Figure 7.14** shows an example with gathering and scattering enabled. If a transaction error occurs while the gather flow is active, the gather flow restarts at the beginning after the error condition is cleared.

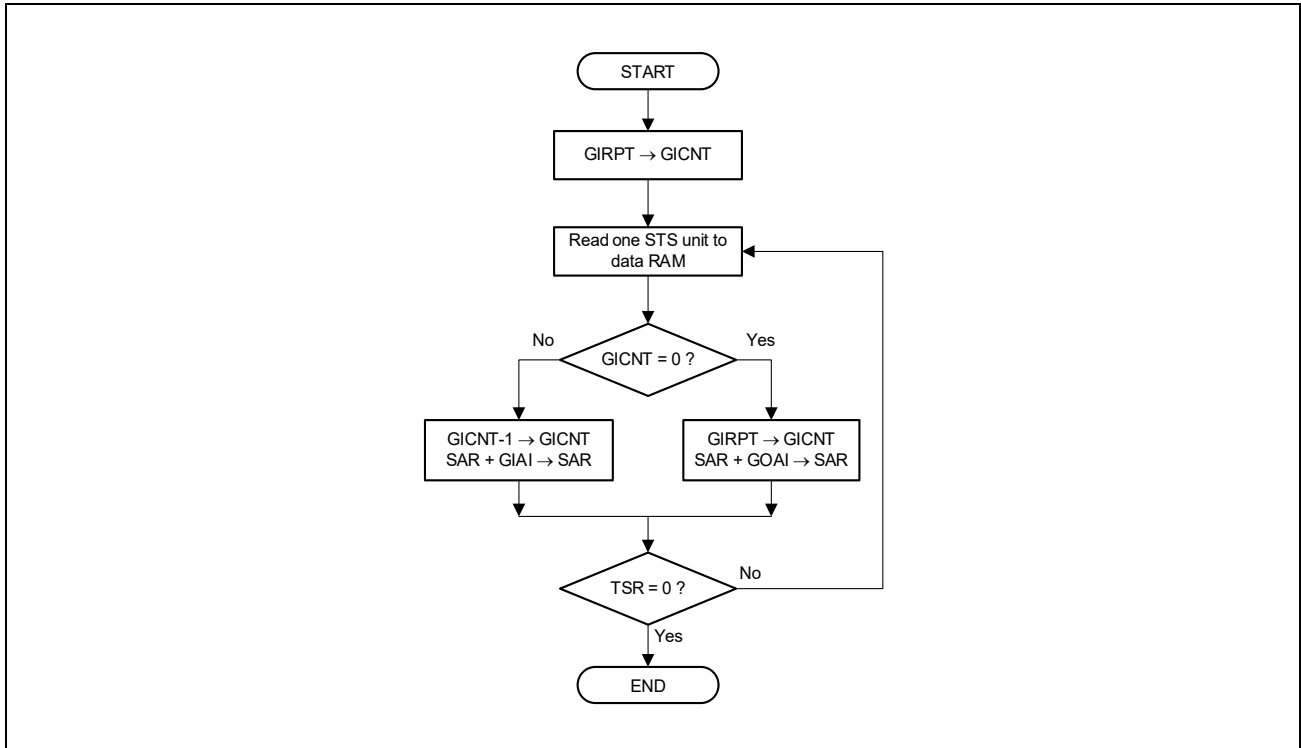

Figure 7.12 Gather Flow at Source Side If GEN = 1

The scatter flow is shown in **Figure 7.13**. It is enabled if the SEN bit in DMAjSGCR_n for the given DMA channel is set to 1. The scatter flow also supports an inner and outer loop. Additionally, zero filling is supported in the inner loop. The number of iterations of the inner loop is specified by the SIRPT register. The total of inner and outer loop transfers equals the number of TSRB bytes. So the number of iterations of the outer loop is indirectly defined by the TSRB register. The inner loop always transfers one data unit of size specified by DTS bits in DMAjTMR_n from the data RAM to the destination address and the DAR bits in DMAjDAR_n register is updated in the same way as for transfers with scattering disabled. If zero filling is disabled by setting ZF bit in DMAjSGCR_n = 0, the destination address (DAR bits in DMAjDAR_n register) is additionally increased by the inner address increment (SIAI bits in DMAjSIAI_n register), resulting in the destination address for the next data unit (the value of DAR bits in DMAjDAR_n register plus the value of SIAI bits in DMAjSIAI_n register). If zero filling is enabled by setting ZF bit in DMAjSGCR_n register = 1, value zero with data units specified by SIAI bits in DMAjSIAI_n register are written to the destination address and the DAR bits in DMAjDAR_n register is updated. This procedure also uses internal register ZFTSR to calculate the remaining zero fill transfer size. This procedure is repeated until the value of TSRW bits in DMAjTSRB_n register or the value of SICNT bits in DMAjSGST_n register reaches zero, which concludes the inner loop. Before the inner loop is repeated, the destination address (DAR bits in DMAjDAR_n register) is increased by the outer address increment (SOAI bits in DMAjSOAI_n register) if zero fill is disabled and the SICNT bits in DMAjSGST_n register is restored with the value of SIRPT bits in DMAjSGCR_n register. The outer loop is repeated until the value of TSRW bits in DMAjTSRB_n reaches zero. **Figure 7.14** shows an example with gathering and scattering enabled. If a transaction error occurs while the scatter flow is active, the scatter flow restarts at the beginning after the error condition is cleared.

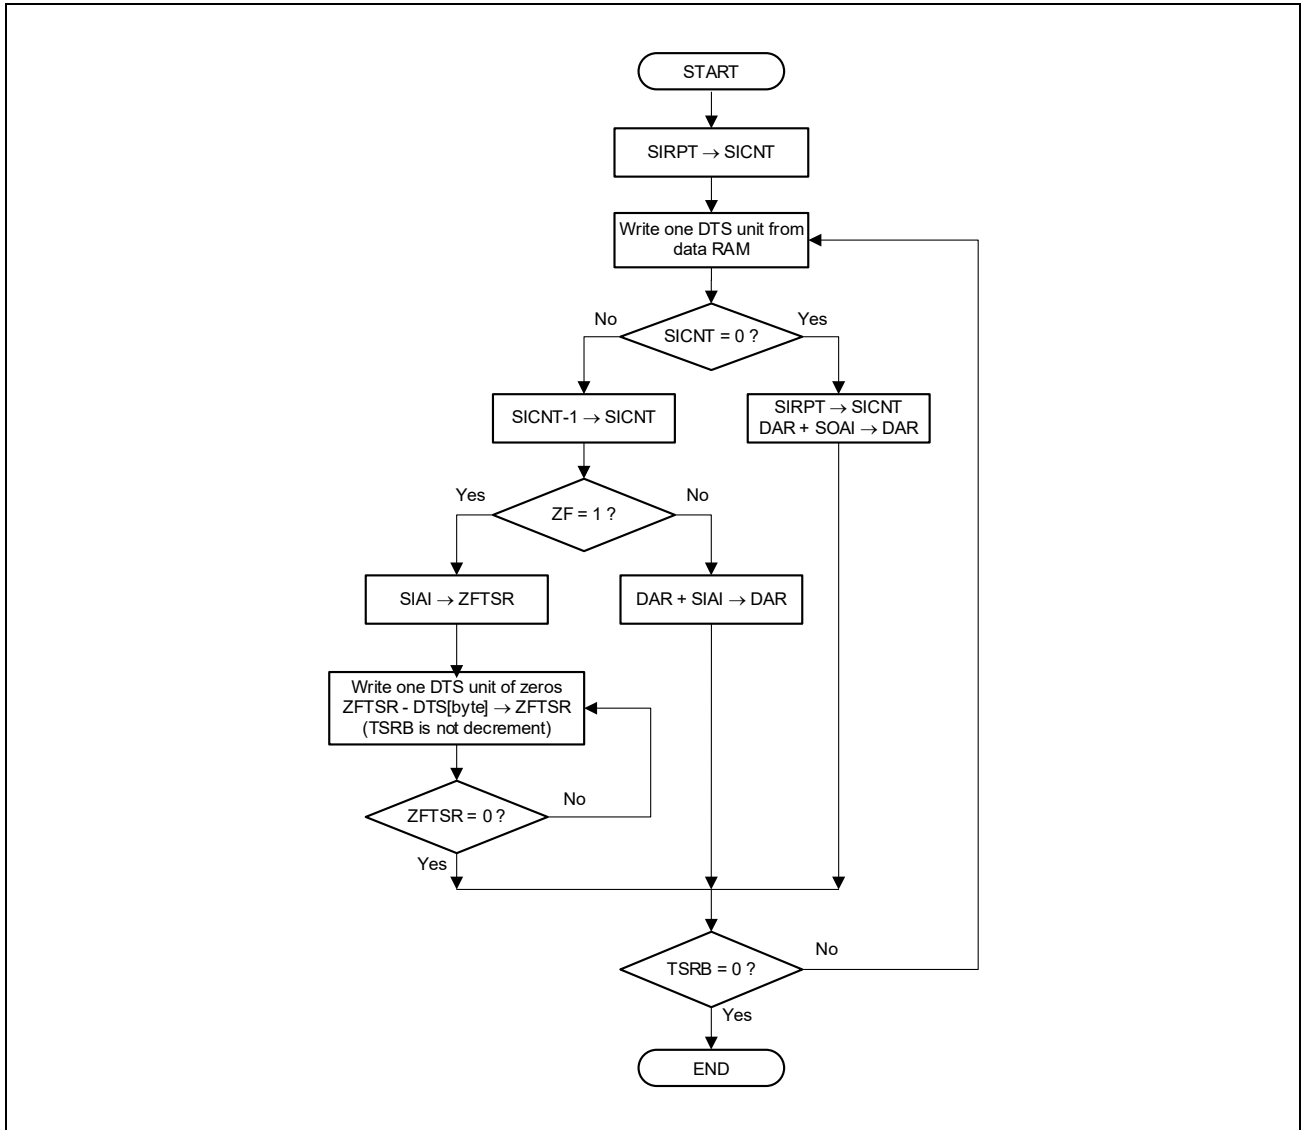

Figure 7.13 Scatter Flow at Destination Side If SEN = 1

Figure 7.14 Examples That Show the Operation of Scatter and Gather Flows

The scatter gather features can be used to realize re-sorting. Transposing a column vector from a source memory address to a row vector at the destination memory address is realized by using gathering at the source side. The inner loop (GIRPT bits in DMAjSGCR_n register) is set to the number of samples in the vector. The data unit size (STS bits or DTS bits in DMAjTMR_n register) is set to the size of one vector element. The inner address offset (GIAI bits in DMAjGIAI_n register) is set to $k \times STS$, where k is the width of the source matrix in the number of elements and STS is

the value of STS bits in DMAjTMR_n register. The same principle can be used to transpose a row vector to a column vector. Here, scattering is used instead of gathering. Gathering and scattering can also be used to read every m-th source address and write it to every n-th destination address. Since gathering and scattering can be enabled independently, any combination is possible. At the destination side, zero filling can be used to set the words between the write addresses to zero.

Finally, the outer loop feature for both gathering and scattering allows the realization of inner and outer DMA loops.

7.4.6 Descriptors

A descriptor contains all the necessary register bits that describe a single transfer task on a channel. A channel can execute multiple descriptors in a chain by reloading the register settings from the descriptor memory. Descriptor operations are enabled by setting DPE bit to 1_B in DMAjCHCR_n. When the DMA transfer defined by the current register setting is finished, the next descriptor is loaded from the descriptor memory. The address of the descriptor to load is defined by the DMAjDPPTR_n.PTR bits. The new descriptor also updates the DMAjDPPTR_n register. This enables an arbitrary chain of descriptors.

Updating of the register list by descriptor operations is shown in **Table 7.26**.

The bit format in the descriptor memory matches the bit format in the corresponding DMA channel registers.

The DMAjSAR_n, DMAjDAR_n and DMAjTSR_n registers are updated during DMA transfer. If the DMAjSAR_n and DMAjDAR_n registers are not updated, the next DMA transfer is started from the final value of the previous DMA transfer. The DMAjTSR_n register is set to 0 after DMA transfer, so DMAjTSR_n register must be updated.

Table 7.26 Register List of Channels to Be Updated

No.	Name	Abbreviation	Bit	DMADPCR.UPF bit
1	DMA source address register	DMAjSAR_n	All bits	UPF[0]
2	DMA destination address register	DMAjDAR_n	All bits	UPF[1]
3	DMA transfer size register	DMAjTSR_n	All bits	UPF[2]
4	DMA transfer mode register	DMAjTMR_n	All bits	UPF[3]
5	DMA gather inner address increment register	DMAjGIAI_n	All bits	UPF[4]
6	DMA gather outer address increment register	DMAjGOAI_n	All bits	UPF[5]
7	DMA scatter inner address increment register	DMAjSIAI_n	All bits	UPF[6]
8	DMA scatter outer address increment register	DMAjSOAI_n	All bits	UPF[7]
9	DMA scatter gather control register	DMAjSGCR_n	All bits	UPF[8]
10	DMA resource select register	DMAjRS_n	All bits	UPF[9]
11	DMA buffer control register	DMAjBUFCR_n	All bits	UPF[10]

Set as follows for each channel that should use the descriptor function:

- Specify the register to be updated in the UPF bits of the DMAjDPCR_n register.
- Set the DMA transfer setting in the descriptor memory.
- If DMA transfer should start when a configuration is copied from the descriptor memory to DMA channel registers
 - set the DMAjDPPTR_n.PTR bits to the first transfer configuration in the descriptor memory
 - set DMAjCHCR_n.DPB to 1
- If DMA transfer should start according to a register setting and continue with the descriptor function.
 - configure the channel registers
 - set the DMAjDPPTR_n.PTR bits to the address of the next transfer configuration in the descriptor memory
 - set DMAjDPPTR_n.CF to 1
 - set DMAjCHCR_n.DPB to 0

The descriptor memory is shared by all DMA channels. Therefore is it important to avoid overlaps of areas used by different DMA channels in common descriptor memory.

(1) Configuration of Descriptor Memory

A DMA transfer configuration can start from any address in the descriptor memory. Register configurations that are not updated should not be written.

Examples of configurations in descriptor memory are shown in the figure below.

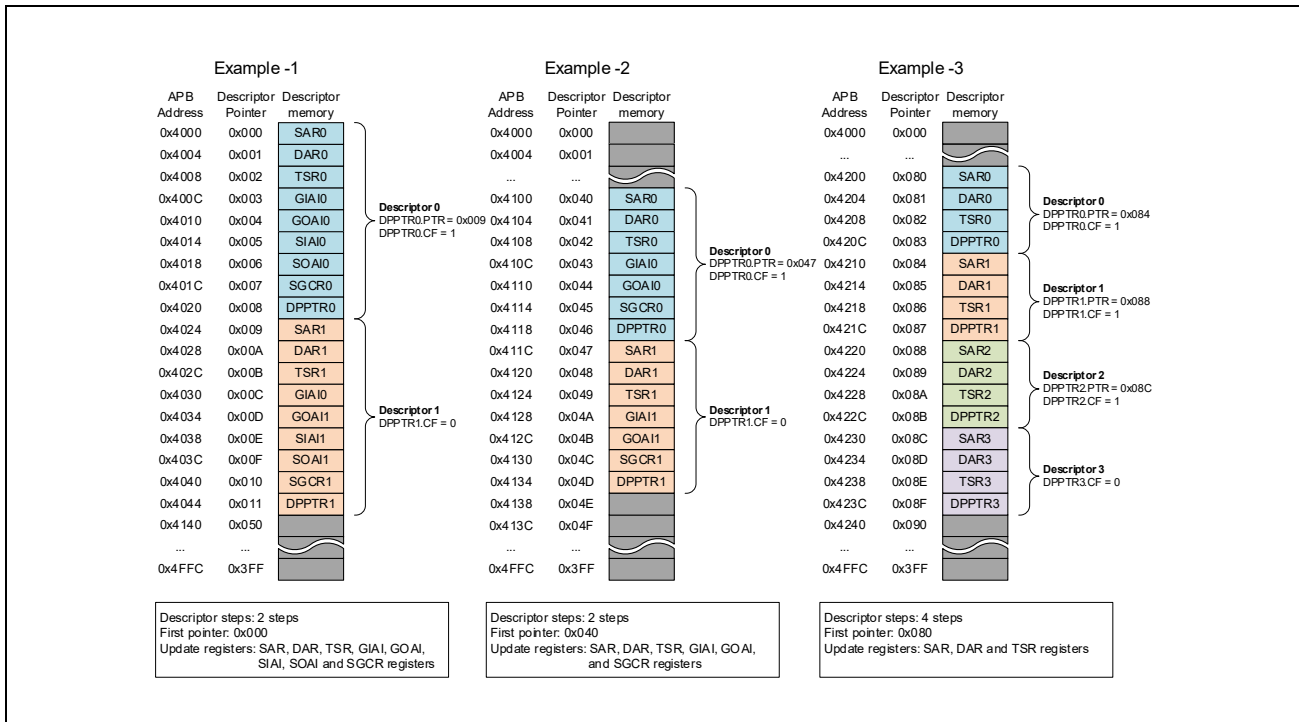

Figure 7.15 Built-in Descriptor Memory Configuration

(2) Flow of Setting Updating by Descriptor Operation

Updating a configuration by using the descriptor function is specified by the UPF bits in the DMAjDPCR_n register. If a register is updated by a descriptor operation, the PTR bit in DMAjDPPTR_n is incremented. Finally the DMAjDPPTR_n register is updated. Therefore, the DMAjDPPTR_n register setting must be always written into the descriptor memory.

This flow is automatically processed by hardware.

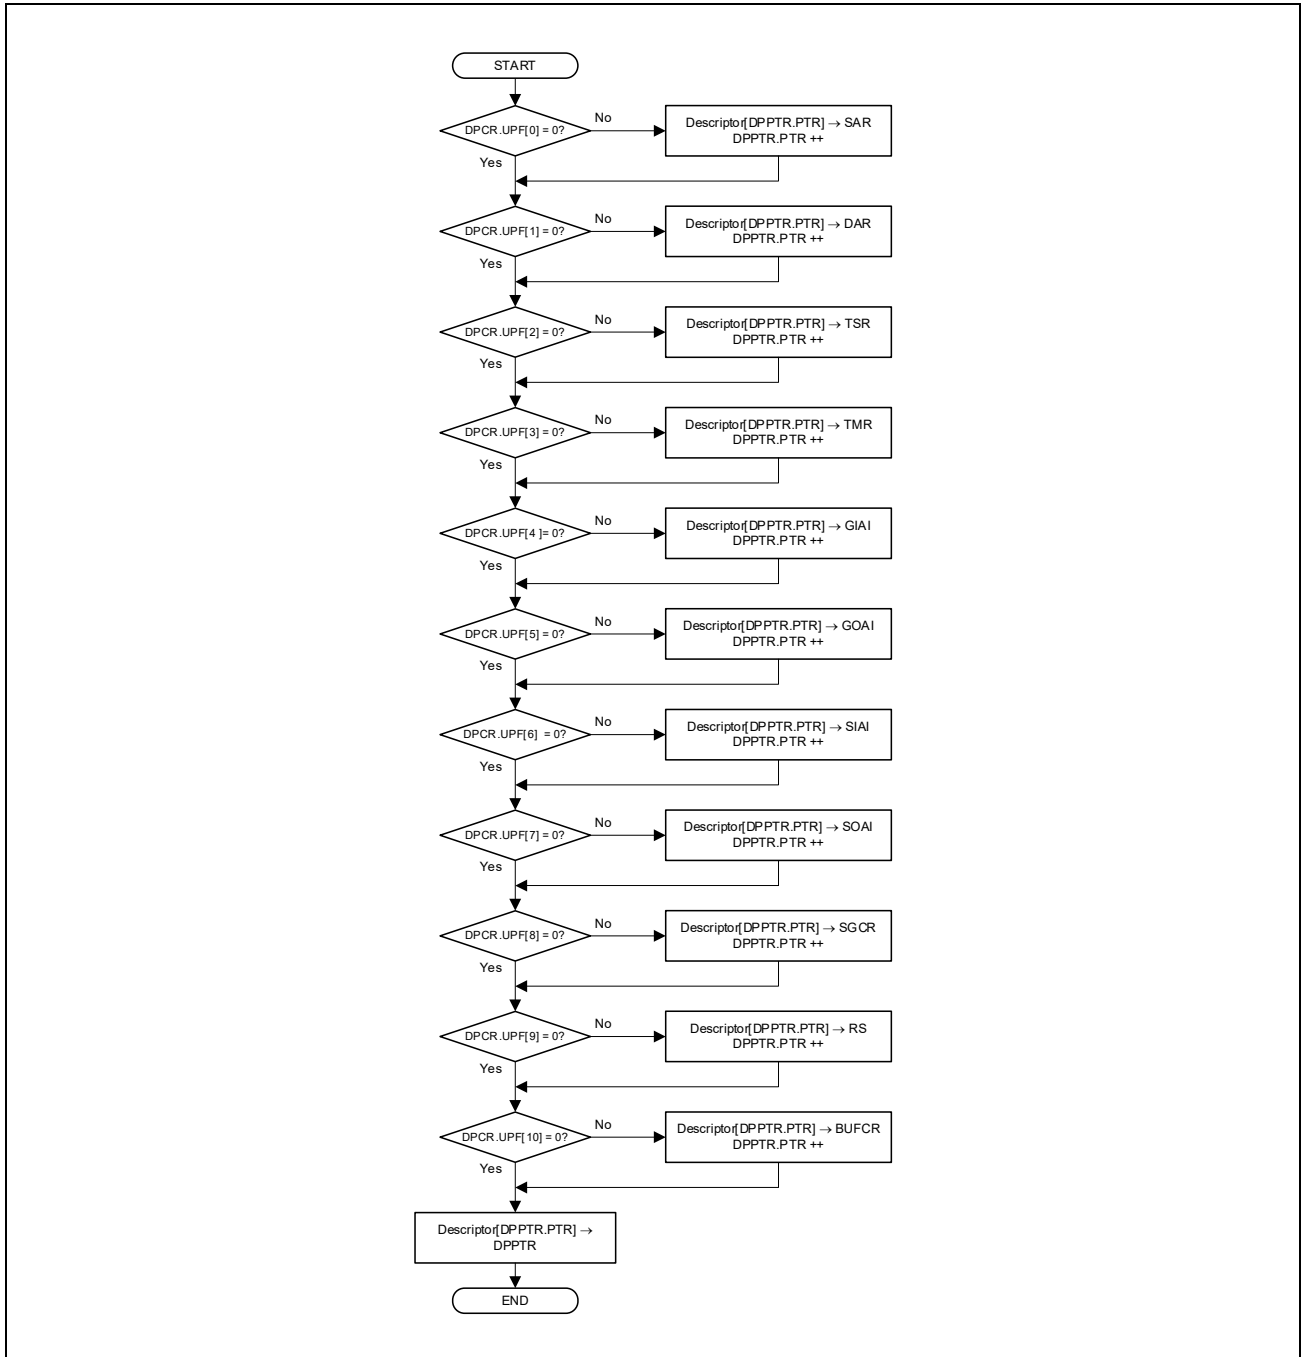

Figure 7.16 Flow of Setting Updating by Descriptor Operation

(3) Descriptor Operational Flow

Figure 7.17 shows the descriptor operational flow.

When the first transfer setting is written in the descriptor memory, the DPB bit in the DMAjCHCR_n register is set to 1. When a DSE interrupt is issued after a step of DMA transfer completion, the DSIE bit in the DMAjCHCR_n register and the DIE bit in DMAjDPPTR_n in the descriptor memory are set to 1. A DSE interrupt can be issued at the optional timing by using this setting. When DSE bit in DMAjCHSTA_n register is set already at the time of a step of DMA transfer completion, the next transfer setting is not read from the descriptor memory. There is a possibility that the next setting is not written in the descriptor memory because the first DSE interrupt has not been processed. The descriptor can be continued by clearing the first DSE interrupt. When the DPE bit in DMAjCHCR_n register is set to 0 or the CF bit in DMAjDPPTR_n register in the Descriptor memory is set to 0 after a step of DMA transfer completion, TE interrupt is issued, and Descriptor is ended.

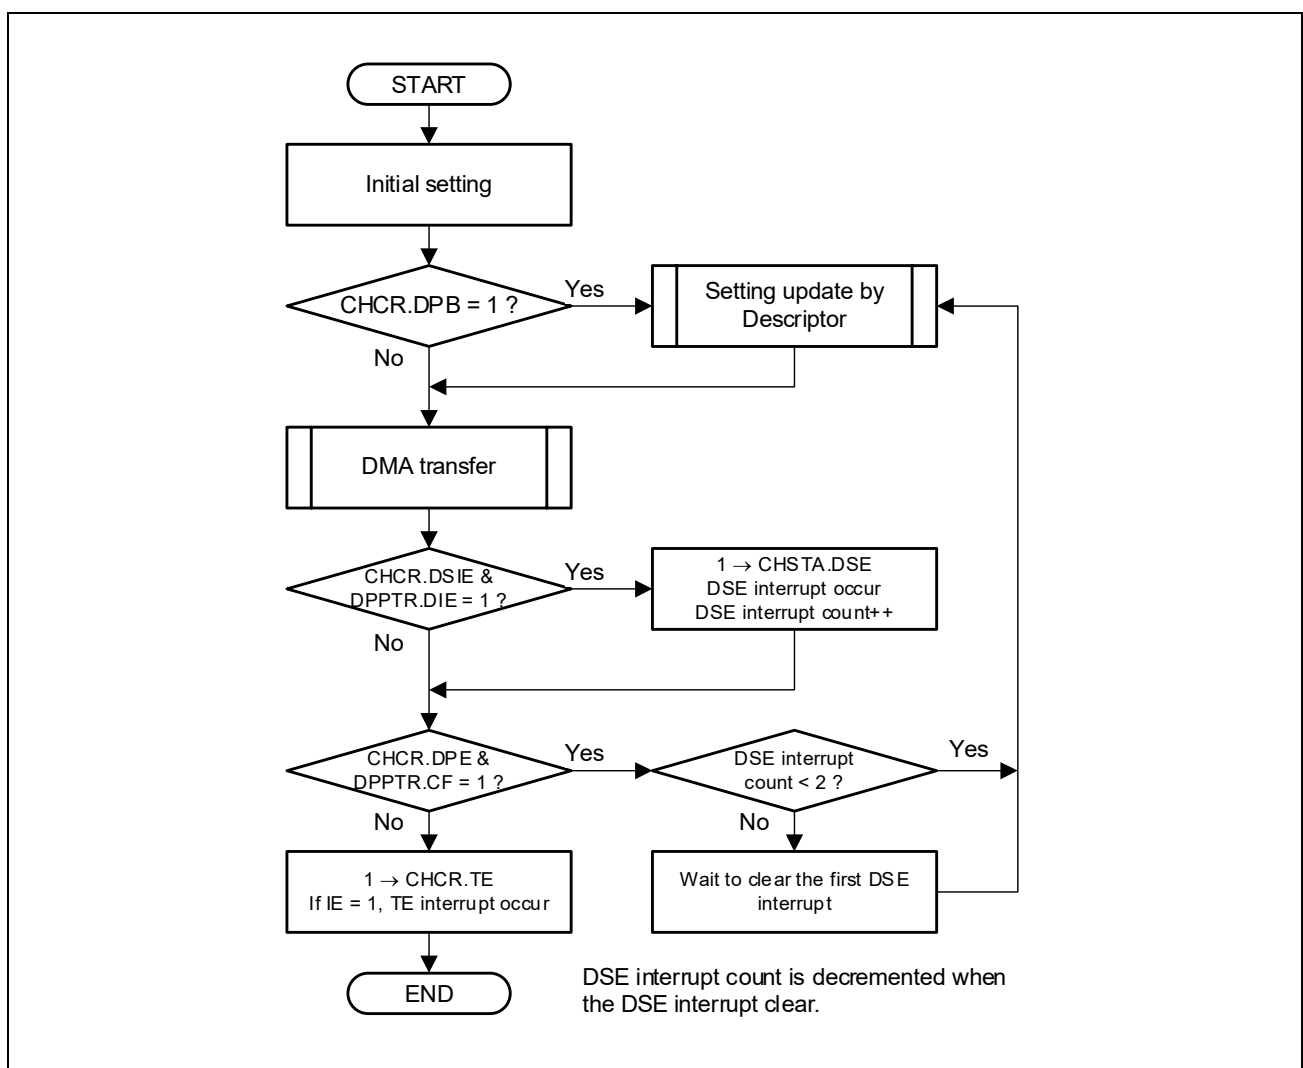

Figure 7.17 Descriptor Operational Flow

(4) Example of descriptor usage

Figure 7.18 to Figure 7.25 show examples of using descriptors operations.

(a) Example 1: Normal Descriptor Operations

The DMAC transfers descriptors in the listed order and generates an interrupt after all of the transfers are complete.

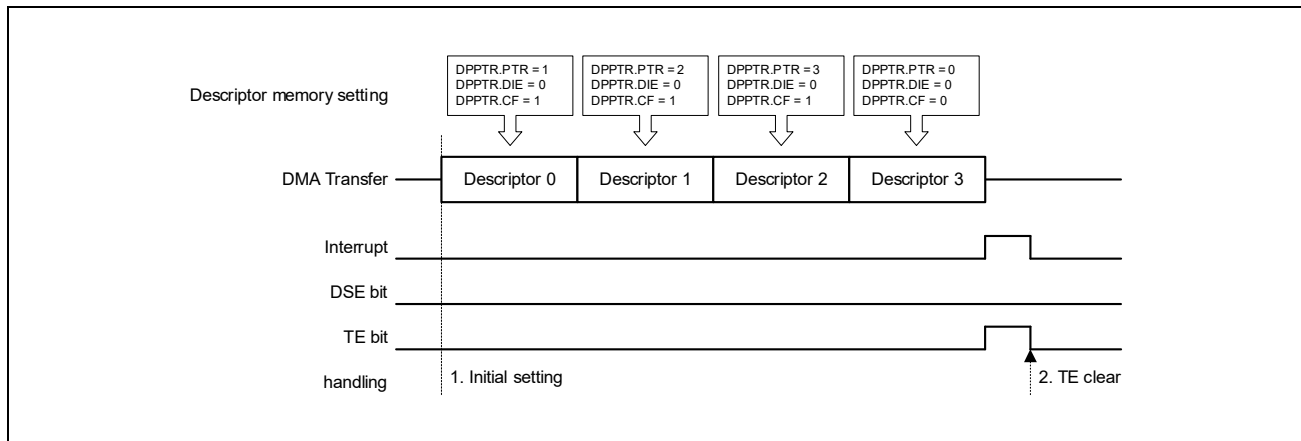

Figure 7.18 Normal Descriptor Operations (Example 1)

No.	Handling	Detail

3	TE clear	<p>Check the interrupt status (read CHSTA)</p> <p>Disable DMA transfer. (CHCR.DE = 0)</p> <p>Clear the transfer end flag. (CHFCR.TEC = 1)</p>

(5) Stopping a Descriptor Operation

Three methods can be used to stop a descriptor operation.

Method 1: Descriptor updating is stopped after completion of the specific DMA transfer.

The specific CF bit in DMAjDPPTR_n in the descriptor memory is set to 0.

The TE interrupt is issued after the end of the specified DMA transfer.

Method 2: Descriptor updating is stopped after the current DMA transfer is complete.

The DPE bit in the DMAjCHCR_n register is set to 0 by writing 1 to the DPEC bit in the DMAjCHFCR_n register. The TE interrupt is issued after the end of the current DMA transfer even if the CF bit is set to 1.

It is not recommended to use the CF bit of the DMAjDPPTR_n register to stop DMA transfer. This bit is updated by the descriptor function.

Method 3: Immediate stop without completing the current DMA transfer.

See **Section 7.5(2), DMA Transfer Suspension** and **Section 7.5(3), Stopping and Restarting DMA Transfer**.

7.4.7 Transfer Flow

Write the transfer condition settings to the DMA source address register (DMAjSAR_n), DMA destination address register (DMAjDAR_n), DMA transfer size register (DMAjTSR_n), DMA transfer mode register (DMAjTMR_n), DMA Channel control register (DMAjCHCR_n), DMA resource select register (DMAjRS_n) and DMA operation register (DMAjOR). The DMAC transfers data in following order.

(1) Auto Request Mode

- A transfer request occurs and the DMAC confirms whether transfer is enabled (DE = 1, DME = 1, TE = 0, CAE = 0). Transfer starts automatically.
- If a transfer request is generated, one transfer unit (specified by STS [3:0] or DTS[3:0]) will be transferred. DMAjTSR_n will be decremented by the transfer unit every time DMA transfer completes.
- When the specified number of transfers are complete (the value of DMAjTSR_n and DMAjTSRB_n is 0), transfer ends normally. At this time if the IE bit of DMAjCHSTA_n is set to 1, a TE interrupt will be issued to the CPU.
- Transfer is terminated if an address error occurs in DMA transfer. In addition, transfer is terminated even if the DE bit of DMAjCHCR_n or the DME bit of DMAjOR is set to 0.

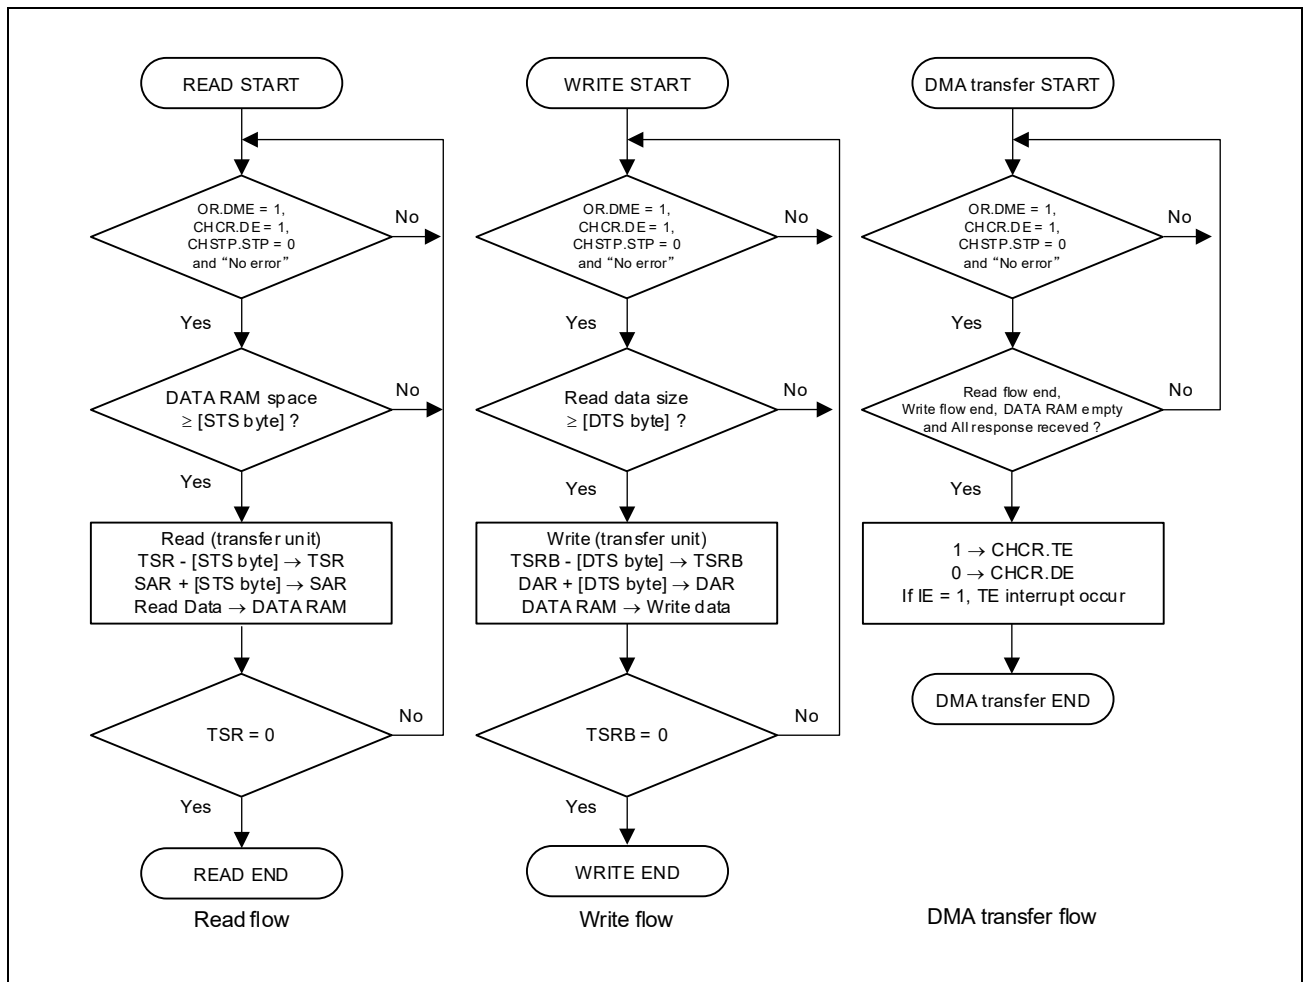

Figure 7.26 Transfer Flow in Auto Request Mode

(2) Hardware Request Mode

- **Figure 7.27** shows the flow in hardware request mode.
- A hardware request can be received when the DMAC confirms whether transfer is enabled (DE = 1, DME = 1, TE = 0, CAE = 0).
- If PLE is set to 1 and FPT is set to 0, pre-loading data from the source memory to the data RAM of sDMAC starts automatically. DMAjTSR_n will be decremented by the transfer unit every time pre-load transfer completes. If FPT is set to 1, pre-loading occurs after the first hardware transfer request is generated and the internal status register (FPS) is set to 0.
- When a hardware transfer request is generated, one transfer unit (specified by TL[2:0]) will be transferred. DMAjTSRB_n will be incremented by the transfer unit every time transfer completes.
- When the specified number of transfers are complete (the value of DMAjTSR_n and DMAjTSRB_n is 0), transfer ends normally. At this time if the IE bit of DMAjCHSTA_n is set to 1, a TE interrupt will be issued to the CPU.
- Transfer is terminated if an address error occurs in DMA transfer. In addition, transfer is terminated even if the DE bit of DMAjCHCR_n or the DME bit of DMAjOR is set to 0.

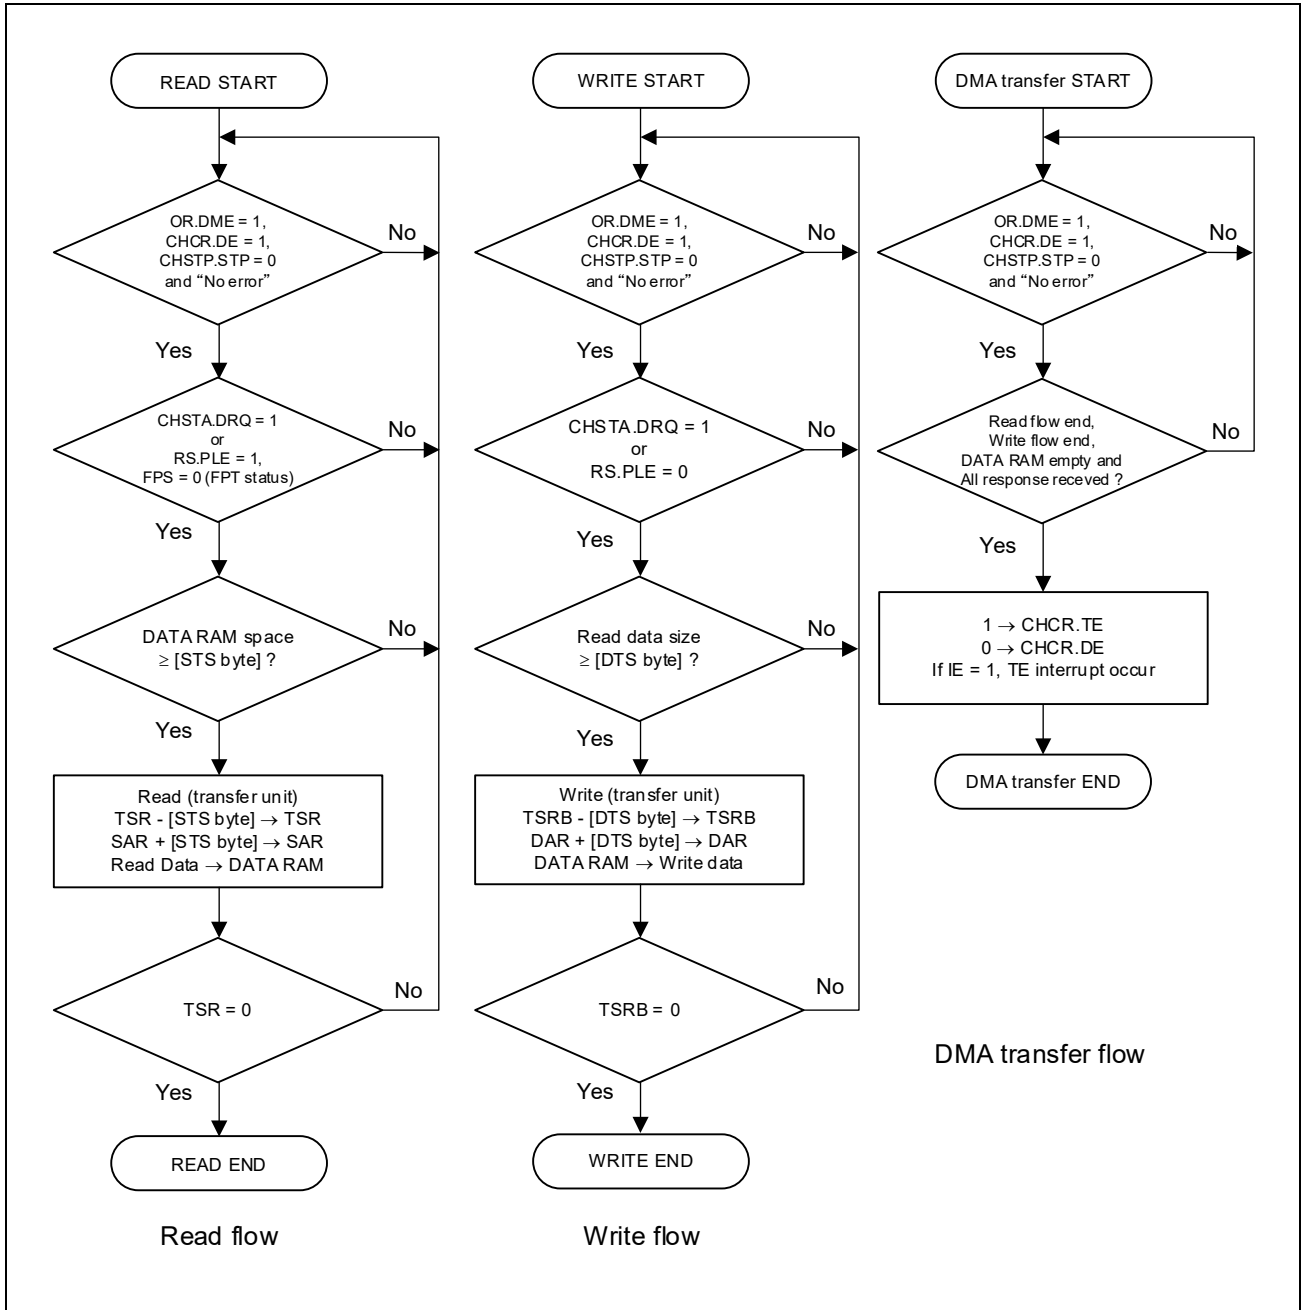

Figure 7.27 Transfer Flow in Hardware Request Mode

7.4.8 Performance

The DMA controller operates on a CLK_HBUS. Read and write transaction requests are issued in parallel on both system interconnect read and write interfaces to enable flyby transfers. Transaction requests are issued without waiting for a reply. So multiple outstanding requests can be in flight on the bus. This is used to hide latencies on the path from the DMA to the slave. The DMA supports 16 outstanding transactions per system interconnect interface (16 reads and 16 writes).

All channels operate in parallel. Arbitration on the read/write interfaces is performed as defined in the operation register DMAJOR. The bus data width is 64 bits (8 bytes). If the unit transfer size (STS/DTS) is larger than 8 bytes, the transaction requests multiple replies in sequence (also called “burst”). The maximum burst size is 8, resulting in a maximum transfer unit size of 64 bytes.

The maximum number of outstanding requests in each DMA channel changes depending on the unit transfer size (STS/DTS). Each DMA channel can use 128 bytes in data RAM as outstanding transfer data buffer. If the unit transfer size (STS/DTS) in a DMA channel is 16 bytes or more, the number of outstanding requests in the DMA channel is 8 or less and the maximum number of outstanding request is 16 or less. Each DMA channel can issue a new transaction request every three clock cycles at best. The frequency at which each DMA channel issues a new transaction request changes depending on the number of outstanding requests in the DMA channel or the number of channels using DMA transfer. If the unit transfer size (STS/DTS) in a DMA channel is 64 bytes, the number of outstanding requests in the DMA channel is 2. In this case, if DMA transfer is operated with one DMA channel and a transaction request is issued twice, a subsequent read transaction request is not issued before previous read and write transaction requests are processed, and the DMA channel cannot issue a new transaction request every three clock cycles.

To utilize the read and write data channels every cycle, two approaches can be used:

- Use three DMA channels. Each channel transfers one third of the required data. The DMAC issues a new request transaction every cycle on the read and write interfaces in parallel.
- Use one DMA channel with a STS/DTS value of 8 bytes. The read/write transaction requests are issued every three cycles.

Both approaches fully utilize the read and write data channels if the data RAM is sufficiently utilized.

7.5 Usage Notes

Pay attention to the following notes when using the DMAC.

(1) Address Errors

When a DMA address error occurs, set the register of the erroneous channel again after DMA transfer suspend shown in **Section 7.5(2), DMA Transfer Suspension** and then start transfer. Address errors are caused by the factors indicated in **Table 7.27**.

Table 7.27 Address Error Factors

Factor	Description
DMA transfer error	The transfer source or transfer destination is invalid space.
	The transfer source or transfer destination is a GUARD error.
Prohibited setting error	DMA source transaction size setting is prohibited. (DMATMR.STS > 0110: 64 bytes)
	DMA destination transaction size setting is prohibited. (DMATMR.DTS > 0110: 64 bytes)
	DMA transfer count is zero in hardware request mode (DMARS.TC = 0 when DMARS.TL = 000, 001)

(2) DMA Transfer Suspension

When suspension DMA transfer, clear the DE bit in the DMA channel control register (DMAjCHCR_n) by using the DEC bit in the DMA channel flag clear register (DMAjCHFCR_n) to disable DMA transfer. After receiving the entire response packet, clear the BUSY bit in the DMA channel status register (DMAjCHSTA_n) to 0. There is a possibility that a TE/DSE interrupt may occur to asynchronous timing after suspension transfer, so it is necessary to assume the following case and take appropriate measures:

- After DMA transfer is suspended, the TE/DSE bit is set to 1 and the BUSY bit is cleared. If the IE/DSIE bit is set to 1 at that time, the DMA interrupt is asserted.

NOTE

If DMA transfer is initialized while the last transfer is executing, this causes a TE/DSE generation delay. In this case, perform a dummy read.

Figure 7.28 shows a processing example when DMA transfer is suspended.

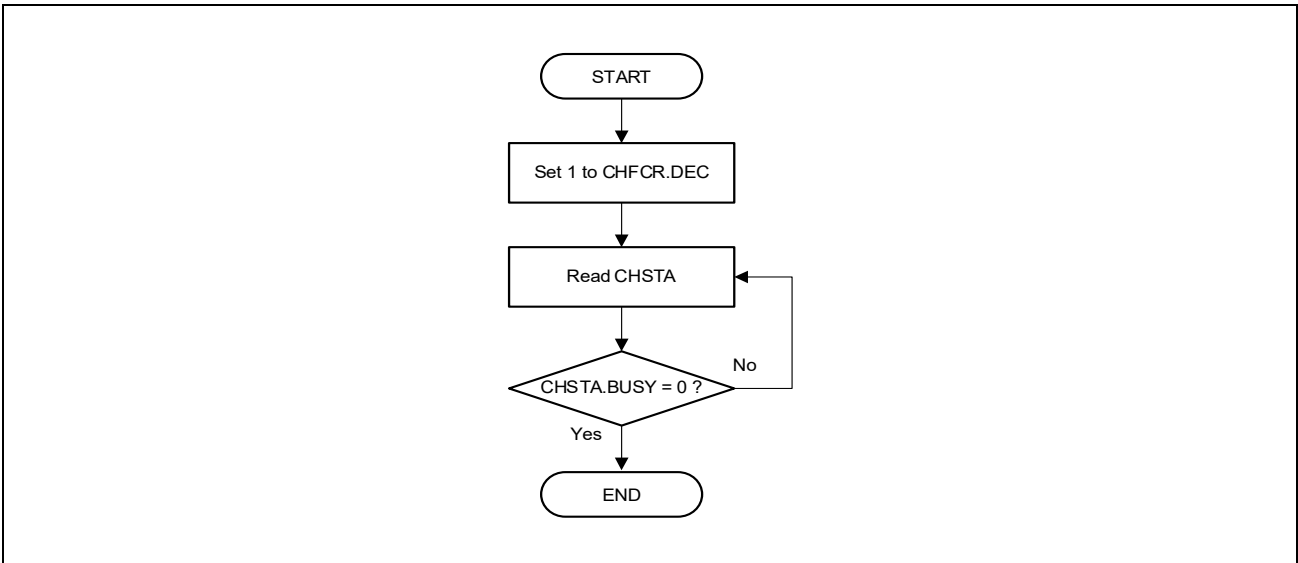

Figure 7.28 Example of DMAC Transfer Suspension Processing

(3) Stopping and Restarting DMA Transfer

To stop DMA transfer temporarily, write 1 to the STP bit in the DMA channel stop register (DMA_jCHSTP_n). Writing to the STP bit stops DMA transfer requests immediately. After receiving the entire response packet, the BUSY bit is cleared to 0. When restarting, set the STP bit to 0.

Figure 7.29 shows a processing example when stopping and restarting DMA transfer.

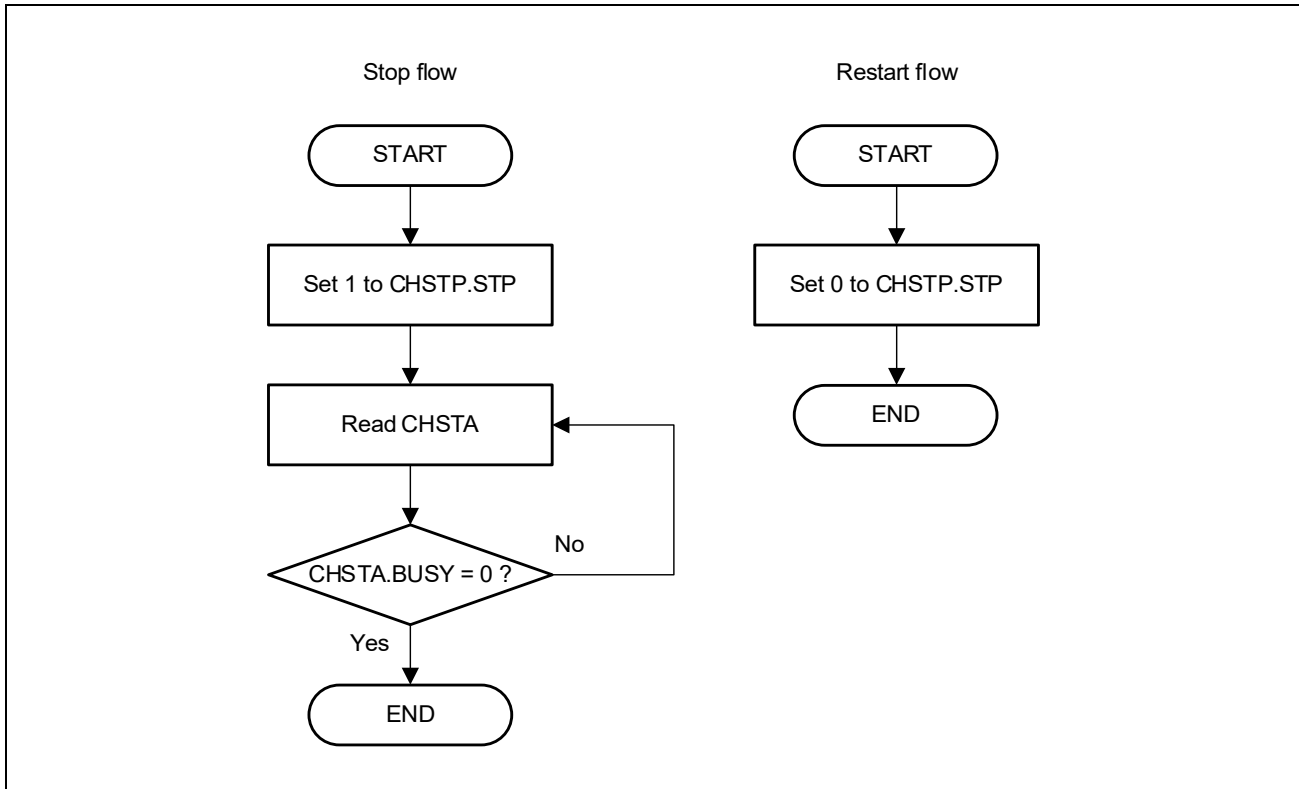

Figure 7.29 Example of DMA Transfer Stop and Restart Processing

(4) Restriction and Impact on the Transfer Unit Size on Addresses and Offsets

The general recommendation is to set the base address (SAR, DAR) and the scatter address increments (SIAI, SOAI) to a multiple of the related transfer unit size (STS, DTS). If this recommendation is not followed, the byte transfers are used instead. This reduces the performance significantly.

In case of using the gather transfer function, the DMA Source Address Register (DMA_jSAR_n), the DMA Gather Inner Address Increment Register (DMA_jGIAI_n) and the DMA Gather Outer Address Increment Register (DMA_jGOAI_n) must be set to multiples of DMA source transaction size which is set to STS bit in the DMA_jTMR_n register.

7.6 Reliability Function

7.6.1 Overview

In this product, the DMAC is a resource used by multiple masters (CPU0 to CPU5). In order for the DMAC to support a multi-core configuration, the following reliability functions are offered.

- Register access protection function
Refer to **Section 40, Functional Safety**.
- Master information inheritance function

7.6.2 Master Information Inheritance Function

In this product, DMA access inherits master information is set by DMAjCM_n register.

The master information that is output from the DMAC is as shown in **Table 7.28** for access guard.

Table 7.28 Master Information That Is Output from DMAC

Meaning	Value that is output from DMAC
UM	Same as the UM bit value in the channel master setting register
SEC	Non secure
SPID	Same as the SPID bit value in the channel master setting register

7.7 Setting up DMA Transfer

7.7.1 Overview of Setting up DMA Transfer

Table 7.29 Overview of Setting up DMA Transfer

No.	Description	Register		Necessity of the Setting
1	Transfer request group selection setting	DMACSELj_m	DMA transfer request group selection register m	Mandatory (if using hardware transfer request mode)
2	Overall DMA operation setting	DMAjCM_n	DMA channel master setting register	Mandatory
3	Channel setting	DMAjSAR_n	DMA source address register	Mandatory
4		DMAjDAR_n	DMA destination address register	Mandatory
5		DMAjTSR_n	DMA transfer size register	Mandatory
6		DMAjTMR_n	DMA transfer mode register	Mandatory
7		DMAjRS_n	DMA resource select register	Mandatory (if using hardware transfer request mode)
8	Status clear	DMAjCHFCR_n	DMA channel flag clear register	Mandatory
9	Channel operation enable	DMAjCHCR_n	DMA channel control register	Mandatory

NOTE

If a transfer request is used to change the transfer request group, it is necessary to set up the registers from the beginning without configuring an overall DMA operation setting.

7.7.2 Setting up the Transfer Request Group Selection

Set up the transfer request group selection before using the sDMAC. The following registers must be set up to configure a transfer request group.

- sDMACj Transfer Request Group Selection Register m (DMACSELj_m) (j = 0 to 1, m = 0 to 15)
This register configures the transfer request group selection

7.7.3 Setting up the Overall DMA Operation

Set up the overall DMA operation before you start using DMA.

The following register must be set up to configure the overall DMA operation.

DMAC channel master setting register (DMAjCM_n)

This register configures the channel assignment. (For details, see **Section 7.6, Reliability Function.**)

If the DMAC channel master setting registers are not properly set, DMA channel setting and DMA transfer cannot be executed properly.

7.7.4 Setting up the DMA Channel Setting

The DMA channel setting defines the transfer information and transfer source for each DMAC channel.

To configure the DMA channel setting, the master allowed to access each channel needs to set up the channel registers.

Follow the procedure below to set up the DMAC channel setting and use the DMAC.

(1) Disabling the DMAC channel operation

If the channel operation enable bit (DE) in the DMA channel control register (DMAjCHCR_n) is set, channel setting up registers must not to be set up. Wait for the previous DMA transfer to finish or be suspended, and then disable the DMAC channel operation.

(2) Setting up the transfer information

When setting up the transfer information for the DMAC, the following registers need to be set up.

- DMA source address register (DMAjSAR_n)
- DMA destination address register (DMAjDAR_n)
- DMA transfer size register (DMAjTSR_n)
- DMA transfer mode register (DMAjTMR_n)

(3) Setting up the DMA transfer request

While setting the transfer information, set the DMA transfer request select (TRS) bit in the DMA transfer mode register (DMAjTMR_n) to define whether a hardware or software DMA transfer request is used.

The hardware and software DMA transfer request cannot be used for the same channel at the same time.

If the hardware DMA transfer request is used, select one source to be used as the hardware DMA transfer request out of the 256 available hardware DMA transfer sources using the resource selection (RS) bit in the DMA resource select register (DMAjRS_n).

The DMA channel may retain a hardware DMA transfer request that came before the hardware DMA transfer source is selected. Clear the hardware DMA transfer request (DMACHSTA_n.DRQ) and overflow flag (DMACHSTA_n.OVF) by using the DMA channel flag clear register (DMAjCHFCR_n) before enabling channel operation.

If the software DMA transfer request is used, disable the hardware DMA transfer request select (TRS) bit in the DMA transfer mode register (DMAjTMR_n).

(4) Clearing the transfer status

The DMA channel status register (DMAjCHSTA_n) may retain the result of the previous DMA transfer. Clear the flags in the DMA transfer status register using the DMA channel flag clear register (DMAjCHFCR_n).

(5) Enabling the DMAC channel operation

Set the DMA channel operation enable bit (DE) in the DMA channel control register (DMAjCHCR_n) to enable the channel operation. After the channel operation enable bit is set, the DMAC can accept a DMA transfer request and start DMA transfer.

Section 8 DTS Controller

This section provides a generic description of the Data Transfer Service (DTS) controller. The first part of this section contains information about product properties such as number of units and register base addresses. The second part of this section describes functions and registers of DTS.

8.1 Features of DTS

8.1.1 Number of Units and Channels

This product has the following number of DTS units.

Table 8.1 Number of Units

Product Name	RH850/E2x-FCC2	
	468 Pins	373 Pins
Number of Units	1	1
Number of Channels	128	128
Name	DTSCNT	DTSCNT

Product Name	RH850/E2UH	
	468 Pins	373 Pins
Number of Units	1	1
Number of Channels	128	128
Name	DTSCNT	DTSCNT

Product Name	RH850/E2H	
	468 Pins	373 Pins
Number of Units	1	1
Number of Channels	128	128
Name	DTSCNT	DTSCNT

Table 8.2 Definition of Indexes

Index	Meaning
nnn	The channel number is identified by the index "nnn". (nnn = 0 to 127)
m	The individual trigger group selection registers are identified by the index "m" (m = 0 to 15).

8.1.2 Register Base Addresses

The DTS base addresses are listed in **Table 8.3**.

The DTS register addresses are specified as offsets from the base addresses.

Table 8.3 Register Base Addresses

Base Address Name	Base Address	Bus Group
<DTS_base>	FFF8 8000 _H	Peripheral Group 0
<DMATRGSSEL_base>	FF09 0100 _H	Peripheral Group 9

8.1.3 Clock Supplies

The DTS clock supplies are shown in the following table.

Table 8.4 Clock Supplies

Unit Name	Clock for the Unit	Supply Clock Name
DTSCNT	clk	CLK_HBUS
DMATRGSEL	PCLK	CLK_HBUS

8.1.4 Interrupt Requests

The DTS interrupt requests are listed in the following table.

Table 8.5 Interrupt Requests

Interrupt symbol name	Unit Interrupt Signal	Outline	Interrupt Number
INTDTS31TO0	INTDTS[31:0]	DTS ch31-0 transfer end	37
INTDTS63TO32	INTDTS[63:32]	DTS ch63-32 transfer end	38
INTDTS95TO64	INTDTS[95:64]	DTS ch95-64 transfer end	39
INTDTS127TO96	INTDTS[127:96]	DTS ch127-96 transfer end	40
INTDTSCT31TO0	INTDTSCT[31:0]	DTS ch31-0 transfer count match	41
INTDTSCT63TO32	INTDTSCT[63:32]	DTS ch63-32 transfer count match	42
INTDTSCT95TO64	INTDTSCT[95:64]	DTS ch95-64 transfer count match	43
INTDTSCT127TO96	INTDTSCT[127:96]	DTS ch127-96 transfer count match	44
INTDTSERR	DTSERR	DTS transfer error	30

8.1.5 DTS Transfer Requests for DTS

The DTS transfer request table lists all DTS transfer request factors for DTS. The DTS transfer request group for DTS can be selected by the DTSSSELm register.

8.1.6 Reset Sources

DTS reset sources are listed in the following table. DTS is initialized by the following reset sources.

Table 8.6 Reset Sources

Unit Name	Register Name	Reset Condition					
		Power Up Reset	System Reset 1	System Reset 2	Application Reset	Module Reset	JTAG Reset
DTSCNT	All registers	✓	✓	✓	✓	—	—
DTSSSEL	All registers	✓	✓	✓	✓	—	—

8.1.7 External Input/Output Signals

This module has no signals mapped to external input/output pins.

8.2 Overview

8.2.1 Functional Overview

The Data Transfer Service (DTS) is a DMA controller used to access data without going through the CPU.

DTS stores transfer information in a dedicated RAM (DTSRAM).

Table 8.7 shows the configuration of DTS.

Table 8.7 Configuration of DTS

Module Name	Number of Units	Number of Channels
DTSCNT	1	128 ch

Functions of DTSFSL are arbitration of incoming the DTS requests, triggering the DTS controller and monitoring ongoing DTS transfers. DTSFSL can handle 128 DTS transfer sources.

The address space that can be used for DTS transfer is a 4 GB address space represented by a 32-bit address. For information about which resource is assigned to a particular area in the 4 GB address space and which area is accessible from DTS, refer to **Section 4, Address Map**.

The DTS is connected to System Bus directly. If a conflict occurs with another bus master in System Bus, the transfer is arbitrated by round-robin arbitration.

8.2.2 Definition of Terms

Table 8.8 shows the terms used in this section.

Table 8.8 List of Term Definitions

Term	Meaning
DTS transfer	A term for data transfer carried out by the DTS controller
DTS cycle	A series of actions that consist of reading an amount of data specified by the transfer size (8/16/32/64/128 bits) from the address specified by the source address and writing it to the address specified by the destination address. The first half of the DTS cycle (reading part) is called a read cycle, and the second half (writing part) is called a write cycle.
Hardware DTS transfer source	A trigger for a DTS transfer request issued by an internal peripheral device
Hardware DTS transfer request	A DTS transfer request issued by a hardware DTS transfer source
Software DTS transfer request	A DTS transfer request issued by writing to a register via software
DTS transfer request	A trigger to start DTS transfer with DTS
Transfer information (TI)	The information required for DTS transfer, including the source address, destination address, transfer data size, and transfer count. The transfer information for DTS is referred to as TI.
DTSRAM	RAM used by DTS to store the transfer information
Single transfer	A DTS transfer consisting of one DTS cycle started by one DTS transfer request
Block transfer 1	A DTS transfer consisting of the number of DTS cycles specified by the transfer count in the transfer information, started by one DTS transfer request
Block transfer 2	A DTS transfer consisting of the number of DTS cycles specified by the address reload count in the transfer information, started by one DTS transfer request
Block transfer	A general term for both block transfer 1 and block transfer 2
Last transfer	The DTS cycle carried out when the transfer count in the transfer information is 1
Address reload transfer	The DTS cycle carried out when the address reload count in the transfer information is 1 if reload function 2 is used
Suspend	An action of pausing a DTS transfer during block transfer. The DTS transfers can be resumed after suspension.
Resume	An action of resuming a suspended DTS transfer
Transfer abort	An action of aborting a DTS transfer before it is finished. Aborted DTS transfers cannot be resumed.

8.3 Registers

8.3.1 List of Registers

Table 8.9 List of Registers

Module Name	Register Name	Symbol	Address	Access	Access Protection
DTSCNT	DTS Control Register 1	DTSCCTL1	<DTS_base> + 0010 _H	32	—
	DTS Control Register 2	DTSCCTL2	<DTS_base> + 0014 _H	32	—
	DTS Status Register	DTSSTS	<DTS_base> + 0018 _H	32	—
	DTS Error Register	DTSER	<DTS_base> + 0024 _H	32	—
	DTS Channel Priority Setting Register 0	DTSPR0	<DTS_base> + 0060 _H	32	—
	DTS Channel Priority Setting Register 1	DTSPR1	<DTS_base> + 0064 _H	32	—
	DTS Channel Priority Setting Register 2	DTSPR2	<DTS_base> + 0068 _H	32	—
	DTS Channel Priority Setting Register 3	DTSPR3	<DTS_base> + 006C _H	32	—
	DTS Channel Priority Setting Register 4	DTSPR4	<DTS_base> + 0070 _H	32	—
	DTS Channel Priority Setting Register 5	DTSPR5	<DTS_base> + 0074 _H	32	—
	DTS Channel Priority Setting Register 6	DTSPR6	<DTS_base> + 0078 _H	32	—
	DTS Channel Priority Setting Register 7	DTSPR7	<DTS_base> + 007C _H	32	—
	DTS Channel Master Setting Register*1	DTSnmmCM	<DTS_base> + "0200 _H + 4 _H × [DTS channel number] (0200 _H to 03FC _H)"	32	—
	DTS Source Address Register	DTSAmm	<DTS_base> + 1000 _H + 40 _H × [channel number]	32	—
	DTS Destination Address Register	DTDAmm	<DTS_base> + 1004 _H + 40 _H × [channel number]	32	—
	DTS Transfer Count Register	DTTCmm	<DTS_base> + 1008 _H + 40 _H × [channel number]	32	—
	DTS Transfer Control Register	DTTCmm	<DTS_base> + 100C _H + 40 _H × [channel number]	32	—
	DTS Reload Source Address Register	DTRSAmm	<DTS_base> + 1010 _H + 40 _H × [channel number]	32	—
	DTS Reload Destination Address Register	DTRDAmm	<DTS_base> + 1014 _H + 40 _H × [channel number]	32	—
	DTS Reload Transfer Count Register	DTRTCmm	<DTS_base> + 1018 _H + 40 _H × [channel number]	32	—
	DTS Transfer Count Compare Register	DTTCmm	<DTS_base> + 101C _H + 40 _H × [channel number]	32	—
	DTSFSL Operation Setting Register	DTFSLmm	<DTS_base> + 1020 _H + 40 _H × [channel number]	32	—
	DTSFSL Transfer Status Register	DTFSTmm	<DTS_base> + 1024 _H + 40 _H × [channel number]	32	—
	DTSFSL Transfer Request Set Register	DTFSSmm	<DTS_base> + 1028 _H + 40 _H × [channel number]	32	—
	DTSFSL Transfer Status Clear Register	DTFSCmm	<DTS_base> + 102C _H + 40 _H × [channel number]	32	—
	DMATRGSEL	DTS Transfer Request Group Selection Register	DTSELm*2	<DMATRGSEL_base> + 100 _H + (m × 4 _H)	8, 16, 32

Note 1. The [channel number] in the offset address is a number from 0 to 127. The “nnn” in the register symbols is a 3-digit number from 000 to 127.

Note 2. m index

8.3.2 Description of Global Registers

8.3.2.1 DTSCCTL1 — DTS Control Register 1

DTS Control Register 1 (DTSCCTL1) is a 32-bit read/write register that controls the DTS global suspension setting.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	DTSUS T
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Table 8.10 DTSCCTL1 Register Contents

Bit Position	Bit Name	Function
31 to 1	—	Reserved. When read, the value after reset is returned. When writing, write the value after reset.
0	DTSUST	DTS suspend This bit shows whether DTS transfers are suspended. If this bit is set to 1, a DTS suspend is requested. 0: DTS is not suspended 1: DTS is suspended or DTS suspension is requested

8.3.2.2 DTSTCTL2 — DTS Control Register 2

DTS Control Register 2 (DTSTCTL2) is a 32-bit write only register that controls DTS transfer abort.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	DTSTIT
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	W

Table 8.11 DTSTCTL2 Register Contents

Bit Position	Bit Name	Function
31 to 1	—	Reserved. When writing, write the value after reset.
0	DTSTIT	DTS transfer abort request Setting this bit to 1 while DTS transfer is suspended aborts the suspended DTS transfer. Writing to this bit while DTS transfer is in progress is ignored. When the suspended DTS transfer is aborted, the DTSSTS.DTSACT bit is cleared. This bit is write only.

8.3.2.3 DTSSTS — DTS Status Register

The DTS Status Register (DTSSTS) is a 32-bit read only register that indicates the DTS status.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	DTSCY C	DTSACH[6:0]						DTSAC T	
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 8.12 DTSSTS Register Contents

Bit Position	Bit Name	Function
31 to 9	—	Reserved. When read, the value after reset is returned.
8	DTSCYC	DTS cycle execution state This bit shows whether a DTS cycle is in progress in DTS. 0: DTS cycle is not in progress. 1: DTS cycle is in progress.
7 to 1	DTSACH	DTS transfer channel If there is a channel in DTS executing a DTS transfer, the channel number is shown. If there is no channel in DTS executing a DTS transfer, the channel number of the last DTS transfer is shown.
0	DTSACT	DTS transfer status This bit shows whether there is a channel in DTS executing a DTS transfer. 0: There is no channel in DTS executing DTS transfer. 1: There is a channel in DTS executing DTS transfer. If DTS is in the suspended state while there is a channel executing DTS transfer, this bit remains 1. If a DTS transfer abort request is made using the DTSCCTL2.DTSTIT bit, the suspended DTS transfer is aborted, and this bit is cleared to 0. When a DTS transfer error occurs and the DTS transfer is aborted, this bit is cleared.

8.3.2.4 DTSER — DTS Error Register

The DTS Error Register (DTSER) is 32-bit read only register that indicates the error status of DTS.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Table 8.13 DTSER Register Contents

Bit Position	Bit Name	Function
31 to 15	—	Reserved. When read, the value after reset is returned.
14 to 8	DTSERCH	DTS error channel These bits show the DTS channel number of the smallest channel number that has a DTS transfer error. These bits are read-only and cannot be cleared.
7 to 2	—	Reserved. When read, the value after reset is returned.
1	DTSERWR	DTS transfer error cycle This bit indicates that a DTS transfer error occurred on the channel indicated by DTSERCH[6-0] in the read cycle or the write cycle. These bits are read-only and cannot be cleared. 0: A DTS transfer error occurred in the read cycle. 1: A DTS transfer error occurred in the write cycle.
0	DTSER	DTS transfer error flag This bit shows whether a DTS transfer error is detected in DTS. 0: A DTS transfer error was not detected in all DTS channels. 1: A DTS transfer error was detected in one of the DTS channels.

Note: In order to clear DTSER, a DTS transfer error of all DTS channels need to be cleared.

8.3.2.5 DTSPRn — DTS Channel Priority Setting Register (n = 0 to 7)

The DTS Channel Priority Setting Register (DTSPRn) is a 32-bit read/write register that defines the priorities for each DTS channel. The priorities are configured from 0 to 3, with 0 being the highest.

8.3.2.6 DTSnnnCM — DTS Channel Master Setting Register (nnn = 000 to 127)

The DTS Channel Master Setting Register (DTSnnnCM) is a 32-bit read/write register that defines the channel master configuration for each DTS channel. The contents of this register is used for the master information inheritance function. For more information about the function, see **Section 8.7, Reliability Functions**.

This register is placed in the DTSRAM and the lower 16-bit field of this register is shared with the DTS transfer count compare register (DTTCCnnn), one of DTS channel register. If this register is written, DTTCCnnn register is updated as well.

Value after reset: 0000 0000_H*¹ RAM initialization is executed.
Undefined*¹ RAM initialization is not executed.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16				
	CHAIN RESTRICT	CHAIN_SPID[4:0]				CHAIN UM	—	—	SPID[4:0]				UM	—						
Value after reset	R/W							Undefined* ¹		R/W							R/W			
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0				
	CMC[15:0]																			
Value after reset	R/W							Undefined* ¹									R/W			

Note 1. The value after reset is dependent on the setting of RAM initialization. See **Section 10.3.6, RAM Initialization** for details.

Table 8.22 DTSnnnCM Register Contents

Bit Position	Bit Name	Function
31	CHAIN_RESTRICT	Chain function restriction setting 0: The chain function is not restricted. A chain from any channel is possible. 1: The chain function is restricted. A chain is permitted only when SPID set by CHAIN_SPID[4:0] is the same as DTSnnnCM.SPID[4:0] of the current channel in the chain and UM set by CHAIN_UM is the same as DTSnnnCM.UM of the current channel in the chain.
30 to 26	CHAIN_SPID[4:0]	Chain permission SPID setting These bits specify the SPID information that permits the chain function.
25	CHAIN_UM	Chain permission UM setting This bit specifies the UM information that permits the chain function.
24 to 23	—	Reserved When read, the value returned is undefined. The write value should be 0.
22 to 18	SPID[4:0]	Channel master SPID setting These bits specify the SPID information used by the master assigned to the channel.
17	UM	Channel master UM setting This bit specifies the UM information of the master assigned to the channel.
16	—	Reserved When read, the value returned is undefined. The write value should be 0.
15 to 0	CMC[15:0]	Transfer count compare In terms of contents, this field is the same as bits[15:0] in Section 8.3.3.2(8), DTTCCnnn — DTS Transfer Count Compare Register .

Note: DTS000CM to DTS127CM configure the channel master information of DTS channels 0 to 127 respectively. For information about the functions this register provides, see **Section 8.7, Reliability Functions**.

The lowest 16 bits of this register are shared with the DTS Transfer Count Compare Register, one of DTS channel registers.

When writing to this register, the DTS Transfer Count Compare Register is updated as well.

Bits 24-23 and 16 of this register are reserved, but these bits are readable and writable. It is recommended to write 0 to these bits and to ignore the value read from these bits.

8.3.3 Description of DTS Channel Registers

8.3.3.1 Transfer Information of DTS (TI)

(1) Structure of TI

The transfer information of DTS is called TI. One TI consists of 8 sets which are called TI-A, TI-B, TI-C, TI-D, TI-E, TI-F, TI-G, and TI-H. Each set consists of a 32-bit word. Eight sets of TI are assigned to each channel.

The following figure shows the structure of TI.

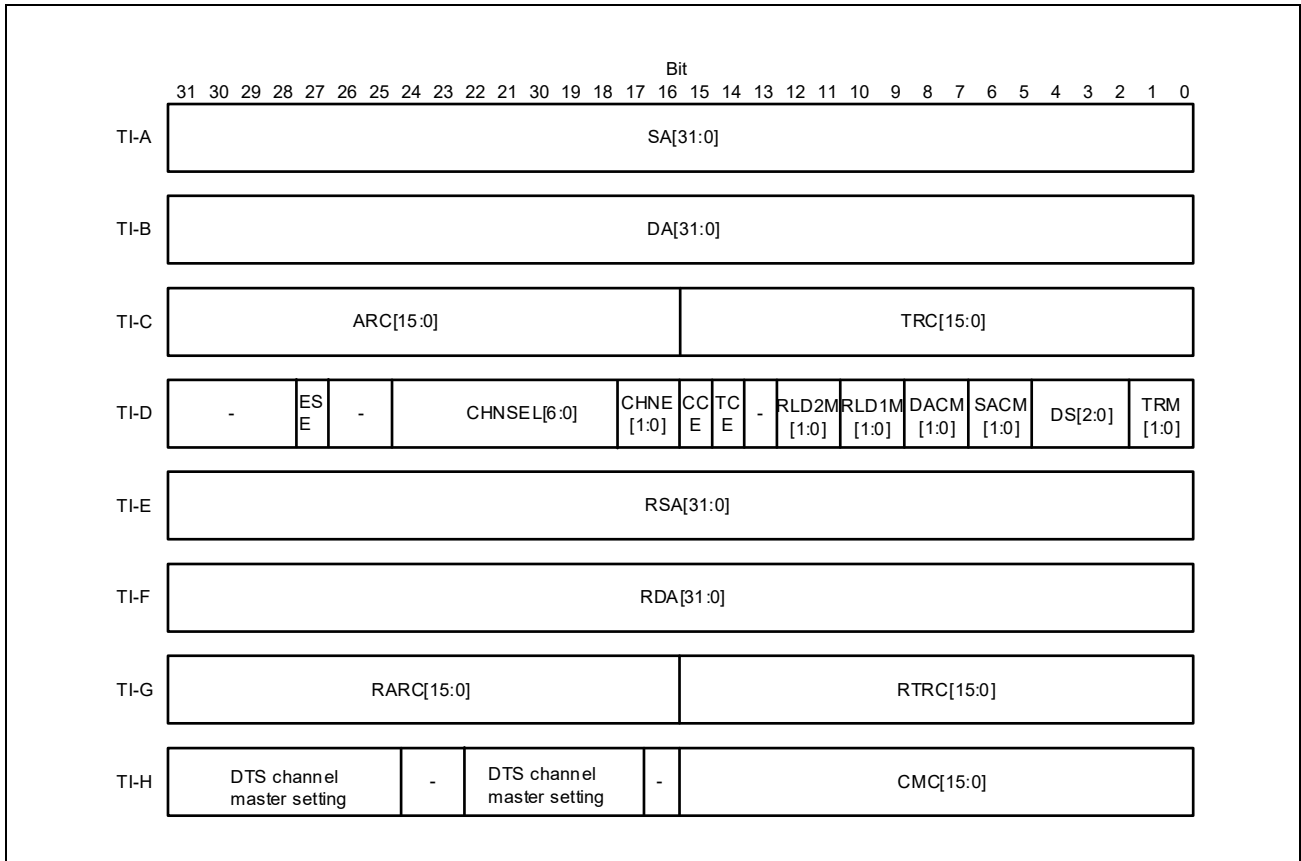

Figure 8.1 Structure of TI

(2) Organization of TI in DTSRAM

The user can indirectly access DTSRAM through the DTS channel registers for each channel and DTS channel master setting registers.

Therefore, direct access to TI structures in DTSRAM is usually not required.

As an exception, when an ECC error occurs while DTSRAM is being accessed, the address at which error occurred is stored in the DTSRAM 1st 1-bit Error Address Register (DR_00SEADR) or the DTSRAM 1st Fatal Error Address Register (DR_00DEADR). It is helpful to understand the address organization of TI in DTSRAM to distinguish which channel/TI has generated the error.

Figure 8.2 shows the address organization of TI in DTSRAM.

DTSRAM address	TI location	
FFC _H	channel 127	TI-H
FF8 _H		TI-G
FF4 _H		TI-F
FF0 _H		TI-E
FEC _H		TI-D
FE8 _H		TI-C
FE4 _H		TI-B
FE0 _H		TI-A
FDC _H	channel 126	TI-H
	channel 2	TI-A
040 _H	channel 1	TI-H
03C _H		TI-G
038 _H		TI-F
034 _H		TI-E
030 _H		TI-D
02C _H		TI-C
028 _H		TI-B
024 _H		TI-A
020 _H	channel 0	TI-H
01C _H		TI-G
018 _H		TI-F
014 _H		TI-E
010 _H		TI-D
00C _H		TI-C
008 _H		TI-B
004 _H		TI-A
000 _H		

Figure 8.2 Organization of TI in DTSRAM

(3) How to Access TI

TI-A can be accessed through the DTS Source Address Register (DTSAnnn) for each channel.

TI-B can be accessed through the DTS Destination Address Register (DTDAnnn) for each channel.

TI-C can be accessed through the DTS Transfer Count Register (DTTCnnn) for each channel.

TI-D can be accessed through the DTS Transfer Control Register (DTTCTnnn) for each channel.

TI-E can be accessed through the DTS Reload Source Address Register (DTRSAnnn) for each channel.

TI-F can be accessed through the DTS Reload Destination Address Register (DTRDAnnn) for each channel.

TI-G can be accessed through the DTS Reload Transfer Count Register (DTRTCnnn) for each channel.

TI-H can be accessed through either the global Channel Master Setting Register (DTSnnnCM) or the channel specific Transfer Count Compare Register (DTTCCnnn).

(4) Cautions on Accessing TI

The value of the DTS Channel Master Setting Register and the value of the DTS Transfer Count Compare Register are both stored in TI-H.

Accessing the DTS Channel Master Setting Register (DTSnnnCM) is performed via a 32-bit access to the entire TI-H.

When writing to the DTS Channel Master Setting Register, the lower 16 bits (DTS transfer count compare or CMC) are also updated. When reading from the DTS Channel Master Setting Register, the lower 16 bits represent the CMC value.

When reading from the DTS Transfer Count Compare Register (DTTCCnnn), hardware performs a 32-bit read access from TI-H but only the lower 16 bits are used for the result of the register read. When writing to the DTS Transfer Count Compare Register (DTTCCnnn), hardware performs a read-modify-write access to TI-H.

Since the contents of TI after reset are undefined, writing to the DTS Transfer Count Compare Register (DTTCCnnn) before writing to the DTS Channel Master Setting Register can result in an ECC error due to the read part of the read-modify-write access.

Some bits of TI-H are reserved. It is recommended to write 0 to these bits and to ignore the value read from these bits.

After reset, the values of TI in DTSRAM are undefined. The first access to TI after reset should be a write access. Otherwise an ECC error will occur.

- DTS Source Address Register (DTSAnnn)
- DTS Destination Address Register (DTDAnnn)
- DTS Transfer Count Register (DTTCnnn)
- DTS Transfer Control Register (DTTCTnnn)
- DTS Reload Source Address Register (DTRSAnnn)
- DTS Reload Destination Address Register (DTRDAnnn)
- DTS Reload Transfer Count Register (DTRTCnnn)
- Channel master setting registers (DTSnnnCM)

After reset a write access to the DTS Transfer Count Compare Register (DTTCCnnn) must follow a write access to the DTS Channel Master Setting Register (DTSnnnCM).

When accessing TI contents while a DTS transfer is in progress, the following implications should be considered.

- TI of the channel should not be updated by the CPU during the ongoing transfer. Otherwise a mismatch between the DTS transfer and the contents of TI may occur.
- If a TI access is requested from the CPU while a TI fetch or TI write back is being executed, the TI access is executed after the completion of the TI fetch or TI write back.
- If a TI fetch or TI write back is requested while a TI access request from the CPU is being processed, the TI fetch or TI write back is executed after the completion of the TI access.

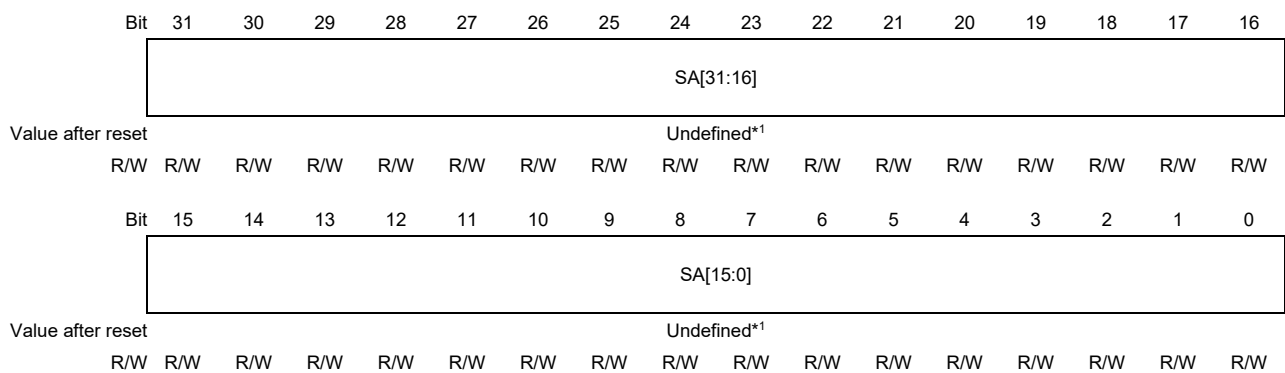

8.3.3.2 Details of DTS Channel Registers

The “nnn” in the register symbols indicates the DTS channel number (nnn = 000 to 127).

(1) DTSA_{nnn} — DTS Source Address Register

The DTS Source Address Register (DTSA_{nnn}) is a 32-bit read/write register that specifies the DTS transfer source address of each channel.

Value after reset: 0000 0000_H*¹ RAM initialization is executed.
 Undefined*¹ RAM initialization is not executed.

Note 1. The value after reset is dependent on the setting of RAM initialization. See **Section 10.3.6, RAM Initialization** for details.

Table 8.23 DTSA_{nnn} Register Contents

Bit Position	Bit Name	Function
31 to 0	SA[31:0]	Source address These bits specify the DTS transfer source address. This register is updated at the timing of TI writeback and retains the DTS transfer source address for the next DTS transfer.

NOTE

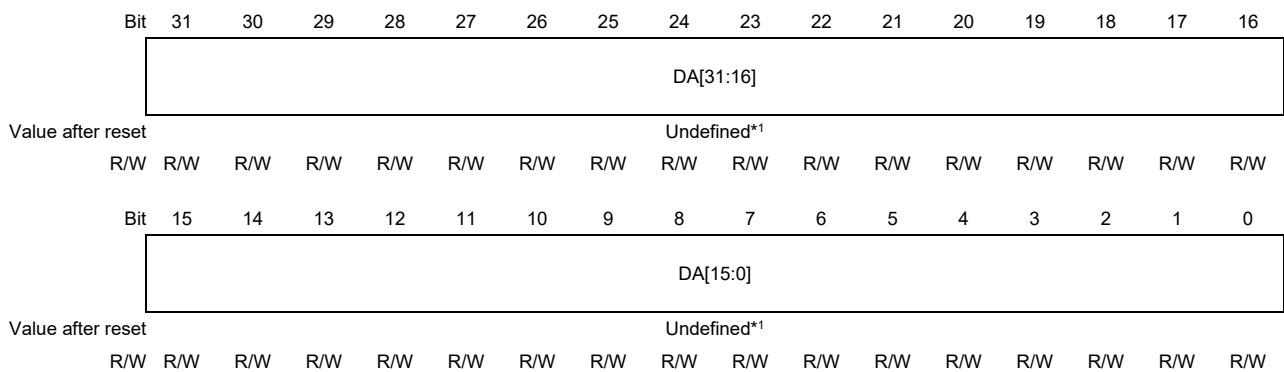

DTS transfer for misaligned data is not supported. The possible lowest four bits of the address for each transfer data size are as follows. The correct operation is not guaranteed if any other setting is specified.

Data Size	SA3	SA2	SA1	SA0
8 bits	0/1	0/1	0/1	0/1
16 bits	0/1	0/1	0/1	0
32 bits	0/1	0/1	0	0
64 bits	0/1	0	0	0
128 bits	0	0	0	0

(2) DTDAnnn — DTS Destination Address Register

The DTS Destination Address Register (DTDAnnn) is a 32-bit read/write register that specifies the DTS transfer destination address of each channel.

Value after reset: 0000 0000_H*¹ RAM initialization is executed.
Undefined*¹ RAM initialization is not executed.

Note 1. The value after reset is dependent on the setting of RAM initialization. See **Section 10.3.6, RAM Initialization** for details.

Table 8.24 DTDAnnn Register Contents

Bit Position	Bit Name	Function
31 to 0	DA[31:0]	Destination address These bits specify the DTS transfer destination address. This register is updated at the timing of TI writeback and retains the DTS transfer destination address for the next DTS transfer.

NOTES

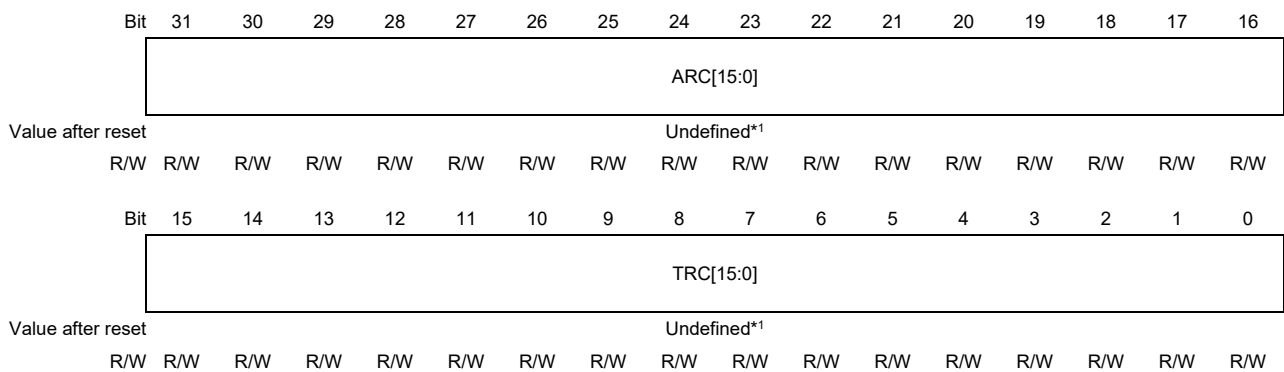

- If a DTS transfer error occurs in the read cycle of a DTS transfer, the write cycle is not executed, but the destination address is updated.
- DTS transfer for misaligned data is not supported. The possible lowest four bits of the address for each transfer data size are as follows. The correct operation is not guaranteed if any other setting is specified.

Data Size	DA3	DA2	DA1	DA0
8 bit	0/1	0/1	0/1	0/1
16 bit	0/1	0/1	0/1	0
32 bit	0/1	0/1	0	0
64 bit	0/1	0	0	0
128 bit	0	0	0	0

(3) DTTCnnn — DTS Transfer Count Register

The DTS Transfer Count Register (DTTCnnn) is a 32-bit read/write register that specifies the DTS transfer count of each channel.

Value after reset: 0000 0000_H*¹ RAM initialization is executed.
Undefined*¹ RAM initialization is not executed.

Note 1. The value after reset is dependent on the setting of RAM initialization. See **Section 10.3.6, RAM Initialization** for details.

Table 8.25 DTTCnnn Register Contents

Bit Position	Bit Name	Function										
31 to 16	ARC[15:0]	<p>Address reload count</p> <p>These bits specify the transfer count for the address reload function. The number is used for both reload function 2 and block transfer 2. When reload function 2 or block transfer 2 is used, ARC[15:0] are decremented by one for every DTS cycle and updated at the timing of TI writeback. When neither reload function 2 nor block transfer 2 is used, ARC[15:0] are not updated.</p> <p>If ARC[15:0] are 0000_H, address reload is not performed and ARC[15:0] are not updated.</p>										
15 to 0	TRC[15:0]	<p>Transfer count</p> <p>These bits configure the transfer count. TRC[15:0] are decremented by one whenever a DTS cycle is executed. These bits are updated at the timing of TI writeback. If the reload function is not used, the value at completion (0000_H) is retained after the completion of the last transfer. If 0000_H is set, DTS transfer is not executed even if a DTS transfer request is accepted.</p> <table border="1"> <thead> <tr> <th>TRC[15:0]</th> <th>Operation</th> </tr> </thead> <tbody> <tr> <td>0000_H</td> <td>Transfer is disabled or complete.</td> </tr> <tr> <td>0001_H</td> <td>The number of transfers or remaining transfers is 1.</td> </tr> <tr> <td>:</td> <td>:</td> </tr> <tr> <td>FFFF_H</td> <td>The number of transfers or remaining transfers is 65535.</td> </tr> </tbody> </table>	TRC[15:0]	Operation	0000 _H	Transfer is disabled or complete.	0001 _H	The number of transfers or remaining transfers is 1.	:	:	FFFF _H	The number of transfers or remaining transfers is 65535.
TRC[15:0]	Operation											
0000 _H	Transfer is disabled or complete.											
0001 _H	The number of transfers or remaining transfers is 1.											
:	:											
FFFF _H	The number of transfers or remaining transfers is 65535.											

NOTE

If a transfer error occurs in the read cycle of DTS transfer, the write cycle is not executed, but the transfer count and address reload count are updated.

(4) DTTCTnnn — DTS Transfer Control Register

The DTS Transfer Control Register (DTTCTnnn) is a 32-bit read/write register that defines DTS transfer configuration of the channel.

Value after reset: 0000 0000_H*1 RAM initialization is executed.
Undefined*1 RAM initialization is not executed.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	ESE	—	—	CHNSEL[6:0]						CHNE[1:0]		
Value after reset	Undefined*1							Undefined*1								
	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	CCE	TCE	—	RLD2M[1:0]	RLD1M[1:0]	DACM[1:0]	SACM[1:0]	DS[2:0]		TRM[1:0]						
Value after reset	Undefined*1							Undefined*1								
	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Note 1. The value after reset is dependent on the setting of RAM initialization. See **Section 10.3.6, RAM Initialization** for details.

Table 8.26 DTTCTnnn Register Contents (1/3)

Bit Position	Bit Name	Function
31 to 28	—	Reserved When read, the value returned is undefined. The write value should be 0.
27	ESE	Setting of DTS error transfer disable This bit specifies whether to abort DTS transfer when a DTS transfer error occurs. If this bit is cleared to 0, DTS transfer continues when a DTS transfer error occurs. If this bit is set to 1, DTS transfer is aborted when a DTS transfer error occurs. 0: DTS transfer continues when a DTS transfer error occurs. 1: DTS transfer is aborted when a DTS transfer error occurs.
26 to 25	—	Reserved When read, the value returned is undefined. The write value should be 0.
24 to 18	CHNSEL[6:0]	Next channel to chain These bits specify the next channel to chain. The next channel must be another channel in DTS. Setting the same channel for the next channel is not allowed. (Correct operation is not guaranteed in this case.)
17 to 16	CHNE[1:0]	Chain enable This bit selects the chain function. 00: Disabled 01: Chain at the last transfer A chain request is generated at the completion of the DTS cycle at which the remaining transfer count is 1. 10: (Setting prohibited) 11: Always chain A chain request is generated at the completion of every DTS cycle.
15	CCE	Transfer count match interrupt enable If this bit is set, a transfer count match interrupt is generated at the completion of the DTS cycle in which the Transfer Count Compare Register and remaining transfer count have the same value.

Table 8.26 DTTCTnnn Register Contents (2/3)

Bit Position	Bit Name	Function															
14	TCE	Transfer completion interrupt enable If this bit is set, a transfer completion interrupt is generated at the completion of the last transfer.															
13	—	Reserved When read, the value returned is undefined. The write value should be 0.															
12, 11	RLD2M[1:0]	Reload function 2 setting These bits configure reload function 2. 00: Reload function 2 is disabled. 01: Reload function 2 is enabled. The source address and address reload count are reloaded at the completion of the DTS cycle in which the address reload count is 1. 10: Reload function 2 is enabled. The destination address and address reload count are reloaded at the completion of the DTS cycle in which address reload count is 1. 11: Reload function 2 is enabled. The source address, destination address, and address reload count are reloaded at the completion of the DTS cycle in which address reload count is 1.															
10 to 9	RLD1M[1:0]	Reload function 1 setting These bits configure reload function 1. 00: Reload function 1 is disabled. 01: Reload function 1 is enabled. The source address and transfer count are reloaded at the completion of the DTS cycle in which remaining transfer count is 1. (If reload function 2 is enabled, the address reload count is also reloaded.) 10: Reload function 1 is enabled. The destination address and transfer count are reloaded at the completion of the DTS cycle in which remaining transfer count is 1. (If reload function 2 is enabled, the address reload count is also reloaded.) 11: Reload function 1 is enabled. The source address, destination address, and transfer count are reloaded at the completion of the DTS cycle in which remaining transfer count is 1. (If reload function 2 is enabled, the address reload count is also reloaded.)															
8 to 7	DACM[1:0]	Destination address count direction These bits specify the count direction of the destination address. <table border="1"> <thead> <tr> <th>DACM1</th> <th>DACM0</th> <th>Direction of Count</th> </tr> </thead> <tbody> <tr> <td>0</td> <td>0</td> <td>Increment</td> </tr> <tr> <td>0</td> <td>1</td> <td>Decrement</td> </tr> <tr> <td>1</td> <td>0</td> <td>Fixed</td> </tr> <tr> <td>1</td> <td>1</td> <td>Prohibited (Operation not guaranteed)</td> </tr> </tbody> </table>	DACM1	DACM0	Direction of Count	0	0	Increment	0	1	Decrement	1	0	Fixed	1	1	Prohibited (Operation not guaranteed)

		0	0	0	8 bits																									
		0	0	1	16 bits																									
		0	1	0	32 bits																									
		0	1	1	64 bits																									
1	0	0	128 bits																											
Other than the above			Prohibited (Operation not guaranteed)																											
1 to 0	TRM[1:0]	Transfer mode These bits specify the DTS transfer mode.																												
		00: Single transfer																												
		01: Block transfer 1 (The number of transfers is specified by the transfer count.)																												
		10: Block transfer 2 (The number of transfers is specified by the address reload count.)																												
		11: Prohibited (Operation not guaranteed)																												

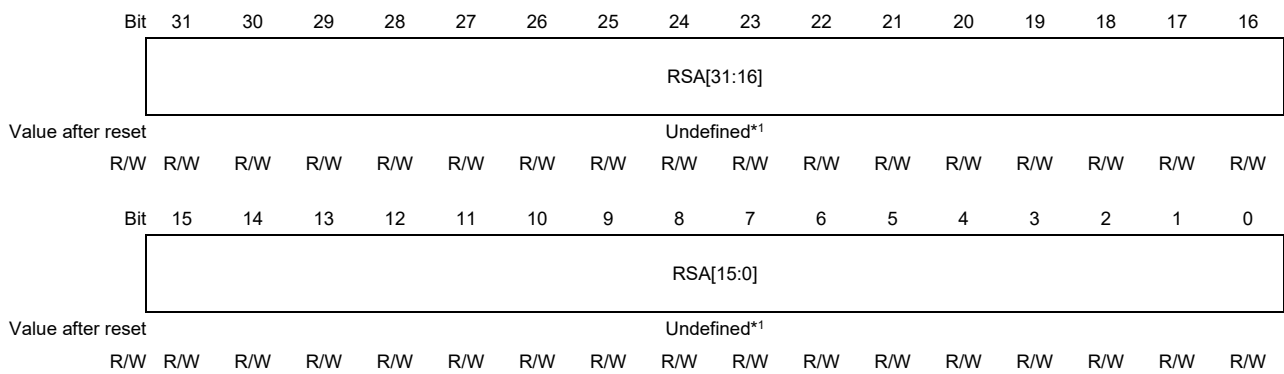

NOTES

1. If prohibited settings are used for some of the bits, the correct operation is not guaranteed.
2. Some bits in this register are unused, but these bits are readable and writable. It is recommended to write 0 to these bits and to ignore the value read from these bits.

(5) DTRSAnn — DTS Reload Source Address Register

The DTS Reload Source Address Register (DTRSAnn) is a 32-bit read/write register that specifies the DTS reload source address of each channel.

Value after reset: 0000 0000_H*1 RAM initialization is executed.
 Undefined*1 RAM initialization is not executed.

Note 1. The value after reset is dependent on the setting of RAM initialization. See **Section 10.3.6, RAM Initialization** for details.

Table 8.27 DTRSAnn Register Contents

Bit Position	Bit Name	Function
31 to 0	RSA[31:0]	Reload source address These bits specify the source address to be reloaded when reload function 1 or reload function 2 is used.

NOTE

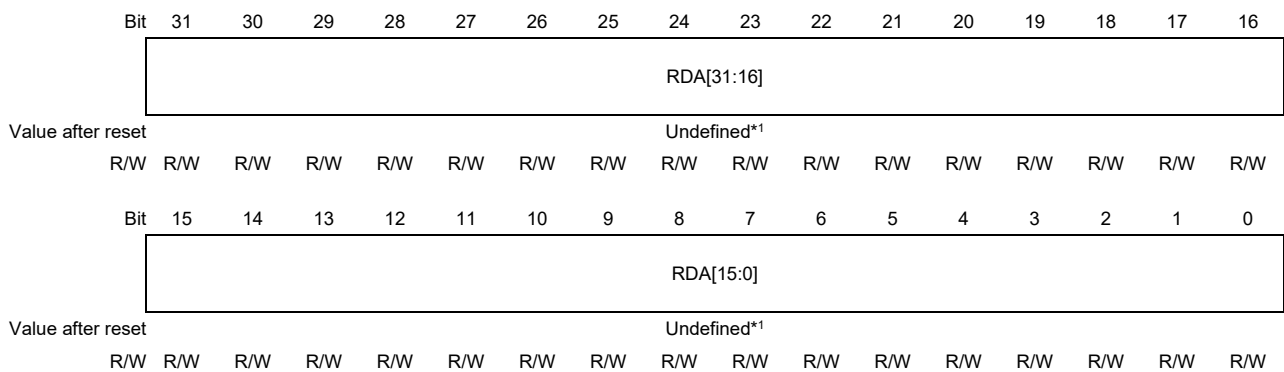

DTS transfer for misaligned data is not supported. The possible lowest four bits of the address for each transfer data size are as follows. The correct operation is not guaranteed if any other setting is specified.

Data Size	RSA3	RSA2	RSA1	RSA0
8 bits	0/1	0/1	0/1	0/1
16 bits	0/1	0/1	0/1	0
32 bits	0/1	0/1	0	0
64 bits	0/1	0	0	0
128 bits	0	0	0	0

(6) DTRDAnnn — DTS Reload Destination Address Register

The DTS Reload Destination Address Register (DTRDAnnn) is a 32-bit read/write register that specifies the DTS reload destination address of each channel.

Value after reset: 0000 0000_H*1 RAM initialization is executed.
Undefined*1 RAM initialization is not executed.

Note 1. The value after reset is dependent on the setting of RAM initialization. See **Section 10.3.6, RAM Initialization** for details.

Table 8.28 DTRDAnnn Register Contents

Bit Position	Bit Name	Function
31 to 0	RDA[31:0]	Reload destination address These bits specify the destination address to be reloaded when reload function 1 or reload function 2 is used.

NOTE

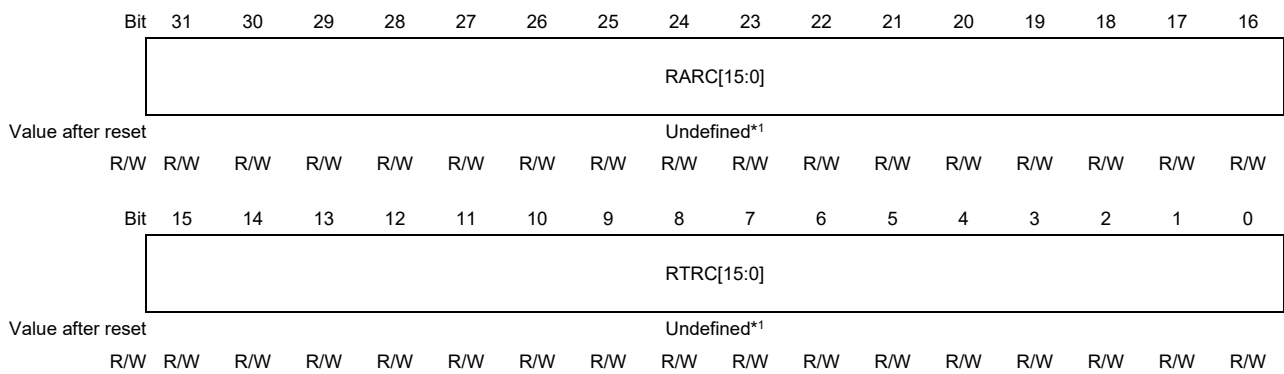

DTS transfer for misaligned data is not supported. The possible lowest four bits of the address for each transfer data size are as follows. The correct operation is not guaranteed if any other setting is specified.

Data Size	RDA3	RDA2	RDA1	RDA0
8 bits	0/1	0/1	0/1	0/1
16 bits	0/1	0/1	0/1	0
32 bits	0/1	0/1	0	0
64 bits	0/1	0	0	0
128 bits	0	0	0	0

(7) DTRTCnnn — DTS Reload Transfer Count Register

The DTS Reload Transfer Count Register (DTRTCnnn) is a 32-bit read/write register that specifies the DTS reload transfer count of each channel.

Value after reset: 0000 0000_H*1 RAM initialization is executed.
 Undefined*1 RAM initialization is not executed.

Note 1. The value after reset is dependent on the setting of RAM initialization. See **Section 10.3.6, RAM Initialization** for details.

Table 8.29 DTRTCnnn Register Contents

Bit Position	Bit Name	Function
31 to 16	RARC[15:0]	Reload address reload count These bits specify the value to be reloaded to the address reload count when reload function 2 is used.
15 to 0	RTRC[15:0]	Reload transfer count These bits specify the value to be reloaded to the transfer count when reload function 1 is used.
	RTRC[15:0]	Operation
	0000 _H	No DTS transfer
	0001 _H	1 transfer
	:	:
	FFFF _H	65535 transfers

(8) DTTCCnnn — DTS Transfer Count Compare Register

The DTS Transfer Count Compare Register (DTTCCnnn) is a 32-bit read/write register which configures the transfer count to be compared to transfer count register.

Value after reset: 0000 0000_H*¹ RAM initialization is executed.
 Undefined*¹ RAM initialization is not executed.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	CMC[15:0]															
Value after reset	Undefined* ¹															
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Note 1. The value after reset is dependent on setting of RAM initialization. See **Section 10.3.6, RAM Initialization** for details.

Table 8.30 DTTCCnnn Register Contents

Bit Position	Bit Name	Function
31 to 16	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
15 to 0	CMC[15:0]	Transfer count compare These bits configure the transfer count to be compared to the Transfer Count Register. If the transfer count match interrupt enable (DTTCTnnn.CCE) bit is 1, the transfer count match interrupt is generated at the completion of the DTS cycle in which remaining transfer count is the same as the value in this register. If CMC[15:0] is 0000H, comparison with the transfer count is disabled. In this case, the transfer count match interrupt is not generated.

Note: This register must be accessed after the DTS channel master setting register is set up. If this register is accessed without setting up the DTS channel master setting register after reset, an ECC error may occur.

(9) DTFSL_{nnn} — DTSFSL Operation Setting Register

The DTSFSL Operation Setting Register (DTFSL_{nnn}) is a 32-bit read/write register that controls the DTS transfer request of each channel.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	REQEN
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Table 8.31 DTFSL_{nnn} Register Contents

Bit Position	Bit Name	Function
31 to 1	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
0	REQEN	DTS transfer request enable This bit specifies whether a DTS transfer request of each channel is used as a candidate for DTS channel arbitration. 0: The DTS transfer request is not used as a candidate for DTS channel arbitration. 1: The DTS transfer request is used as a candidate for DTS channel arbitration. If this bit is 0, the request of the channel is not a candidate of DTS channel arbitration inside DTSFSL. DTS transfer request from the channel is not generated consequently, even if DTSFSL holds a request.

(10) DTFSTnnn — DTSFSL Transfer Status Register

The DTSFSL Transfer Status Register (DTFSTnnn) is a 32-bit read-only register that indicates the status of each channel.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	ERWR	—	—	—	ER	—	CC	TC	—	—	—	DRQ
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 8.32 DTFSTnnn Register Contents (1/2)

Bit Position	Bit Name	Function
31 to 12	—	Reserved When read, the value after reset is returned.
11	ERWR	DTS transfer error cycle When transfer error flag (ER) is set, this bit is also updated. This bit indicates whether a DTS transfer error has occurred in the read cycle or write cycle. If the ER bit is already set, this bit is not updated when another DTS transfer error occurs. This bit is also cleared when the ER bit is cleared. 0: A DTS transfer error occurred in the read cycle. 1: A DTS transfer error occurred in the write cycle
10 to 8	—	Reserved When read, the value after reset is returned.
7	ER	Transfer error flag This bit is set when a DTS transfer error occurs. If this bit is 1 and the DTTCTnnn.ESE bit is set, a DTS transfer is not executed when a DTS transfer request occurs. This bit is cleared by writing 1 to the DTFSCnnn.ERC bit. 0: No DTS transfer error has occurred 1: A DTS transfer error has occurred
6	—	Reserved When read, the value after reset is returned.
5	CC	Transfer count match flag This bit is set at the completion of the DTS transfer in which the remaining transfer count is the same as the value set in the transfer compare register. This bit is cleared by writing 1 to the DTFSCnnn.CCC bit. 0: No compare match with the Transfer Count Compare Register has occurred. 1: A compare match with the Transfer Count Compare Register has occurred.
4	TC	Transfer completion flag This bit is set at the completion of the last transfer and shows whether DTS transfer is complete. This bit is cleared by writing 1 to the DTFSCnnn.TCC bit. 0: DTS transfer is not complete 1: DTS transfer is complete
3 to 1	—	Reserved When read, the value after reset is returned.

Table 8.32 DTFSTnnn Register Contents (2/2)

Bit Position	Bit Name	Function
0	DRQ	<p>DTS transfer request flag</p> <p>This bit shows whether a DTS transfer request of this channel is being held.</p> <p>This bit is set when DTS transfer request is detected, or when the DTFSSnnn.DRQS bit is written by software.</p> <p>This bit is automatically cleared when DTS accepts a transfer request while DTSFSL is requesting DTS transfer for the channel in question. This bit also can be cleared by writing to the DTFSCnnn.DRQC bit.</p> <p>0: A DTS transfer request was not detected.</p> <p>1: A DTS transfer request was detected and is being held in DTSFSL.</p>

(11) DTFSSnnn — DTSFSL Transfer Request Set Register

The DTSFSL Transfer Request Set Register (DTFSSnnn) is 32-bit write-only register that sets the DRQ bit in the DTFSTnnn register.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	DRQS
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	W

Table 8.33 DTFSSnnn Register Contents

Bit Position	Bit Name	Function
31 to 1	—	Reserved When writing, write the value after reset.
0	DRQS	DTS transfer request set Writing 1 to this bit will generate a DTS transfer request.

(12) DTFSCnnn — DTSFSL Transfer Status Clear Register

The DTSFSL Transfer Status Clear Register (DTFSCnnn) is 32-bit write-only register that clears the status flag bits in the DTFSTnnn register.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	ERC	—	CCC	TCC	—	—	—	DRQC
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	W	R	W	W	R	R	R	W

Table 8.34 DTFSCnnn Register Contents

Bit Position	Bit Name	Function
31 to 8	—	Reserved When writing, write the value after reset.
7	ERC	Transfer error flag (ER) clear The DTFSTnnn.ER bit can be cleared by writing 1 to this bit.
6	—	Reserved When writing, write the value after reset.
5	CCC	Transfer count match flag (CC) clear The DTFSTnnn.CC bit can be cleared by writing 1 to this bit.
4	TCC	Transfer completion flag (TC) clear The DTFSTnnn.TC bit can be cleared by writing 1 to this bit.
3 to 1	—	Reserved When writing, write the value after reset.
0	DRQC	DTS transfer request clear The DTFSTnnn.DRQ bit can be cleared by writing 1 to this bit.

8.3.4 Detail DTSSSELm

8.3.4.1 DTSSSELm — DTS Transfer Request Group Selection Register (m = 0 to 15)

DTSSSELm register is 32-bit read/write register. The DTSSSELm register specifies the DTS transfer request group for each channel.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

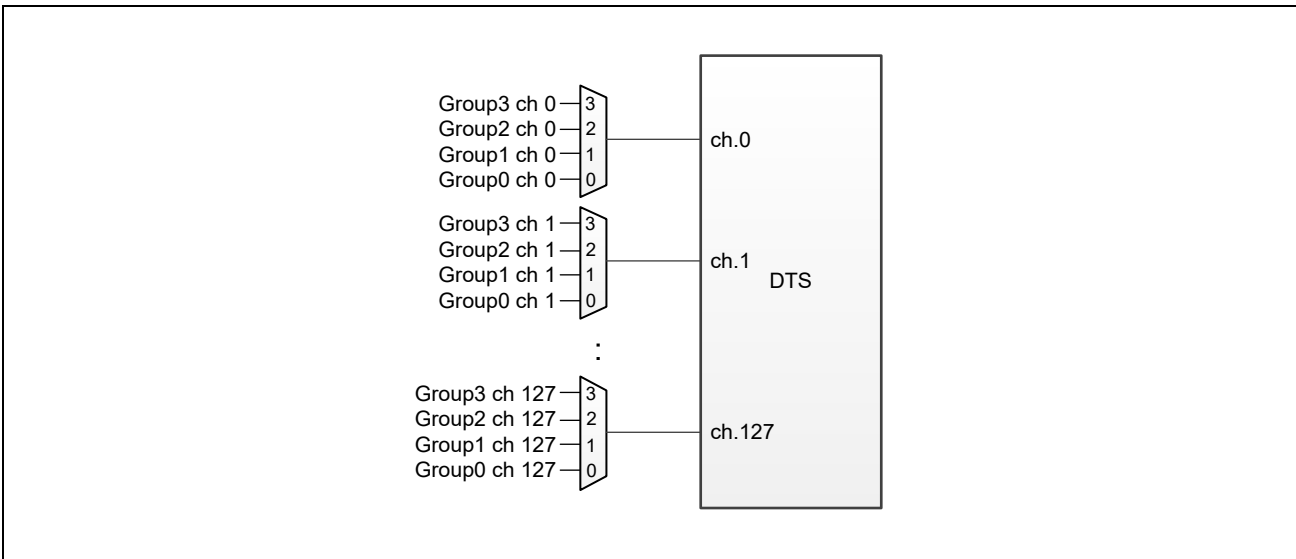

Figure 8.3 DTS Transfer Request Group Selection

8.4 Operation

8.4.1 Basic Operation of DTS Transfer

8.4.1.1 Transfer Mode

DTS has three transfer modes.

(1) Single Transfer

One DTS cycle is executed when a DTS transfer request is accepted.

(2) Block Transfer 1

The number of DTS cycles specified by the TRC bits in the DTS Transfer Count Register are executed when a DTS transfer request is accepted.

(3) Block Transfer 2

The number of DTS cycles specified by the ARC bits in the DTS Transfer Count Register are executed when a DTS transfer request is accepted. If the address reload count (ARC) is larger than the value of the transfer count (TRC), the number of DTS cycles is defined as the value of TRC.

8.4.1.2 Executing a DTS Cycle

DTS always executes the write cycle after the read cycle is complete. For example, if the transfer data size is 128 bits, the write cycle is executed after the read cycle for the 128-bit data is finished. The write cycle never starts before the read cycle is completed.

8.4.1.3 Updating Transfer Information

When a DTS cycle is executed, the DTS updates the transfer information as follows.

(1) Source Address and Destination Address

Transfer information (TI) will be updated as described in **Table 8.36** according to the settings of the DTS Transfer Control Register (DTTCTnnn) such as the source address count direction, the destination address count direction, and the transfer data size.

Table 8.36 Updating the Source Address and the Destination Address

Direction of Count	Transfer Data Size	Address after Update
Increment	8 bit	(address before update) + 0000 0001 _H
	16 bit	(address before update) + 0000 0002 _H
	32 bit	(address before update) + 0000 0004 _H
	64 bit	(address before update) + 0000 0008 _H
	128 bit	(address before update) + 0000 0010 _H
Decrement	8 bit	(address before update) - 0000 0001 _H
	16 bit	(address before update) - 0000 0002 _H
	32 bit	(address before update) - 0000 0004 _H
	64 bit	(address before update) - 0000 0008 _H
	128 bit	(address before update) - 0000 0010 _H
Fixed	—	Same as the address before update.

When the reload function is used, a specific update rule is applied other than the one described in **Table 8.36** for the last transfer and the address reload transfer. For details, see **Section 8.4.3, Reload Function**.

(2) Transfer Count/Address Reload Count

The transfer count is decremented by one for every DTS cycle.

The address reload count is decremented by one for every DTS cycle when reload function 2 or block transfer 2 is used. When neither reload function 2 nor block transfer 2 is used, it is not updated.

If the reload function is used, a specific update rule is applied for the last transfer and the address reload transfer.

For details, see **Section 8.4.3, Reload Function**.

(3) Other Transfer Information

Other transfer information is not updated during execution of a DTS cycle.

8.4.1.4 Last Transfer and Address Reload Transfer

The last transfer means the DTS cycle executed when the value in the Transfer Count Register, which shows the remaining number of transfers, is 1. The last transfer differs in operation compared to the other DTS cycles as follows.

- The transfer completion flag (DTFSTnnn.TC) is set when the last transfer is complete.
- When the transfer completion interrupt output enable is set, a transfer completion interrupt is output when the last transfer is complete.
- When reload function 1 is enabled, reload function 1 is executed at the timing of the last transfer. For details, see **Section 8.4.3, Reload Function.**

Address reload transfer means the DTS cycle executed when reload function 2 is enabled and the address reload count is 1. Reload function 2 is executed after address reload transfer. For details, see **Section 8.4.3, Reload Function.**

8.4.1.5 Transfer Completion Interrupt and Transfer Count Match Interrupt Output

DTS can output a transfer completion interrupt and a transfer count match interrupt to outside DTS.

(1) Transfer Completion Interrupt Output

When the transfer completion interrupt output enable bit (DTTCTn.TCE) is set in the Transfer Control Register, DTS requests a DTS transfer completion interrupt when the last transfer is complete.

(2) Transfer Count Match Interrupt Output

When the transfer count match interrupt enable bit (DTTCTn.CCE) is set in the Transfer Control Register, DTS requests a DTS transfer count match interrupt at the completion of the DTS cycle in which the Transfer Count Compare Register and the transfer count have the same value.

Figure 8.4 shows the operation of the transfer completion interrupt and the transfer count match interrupt.

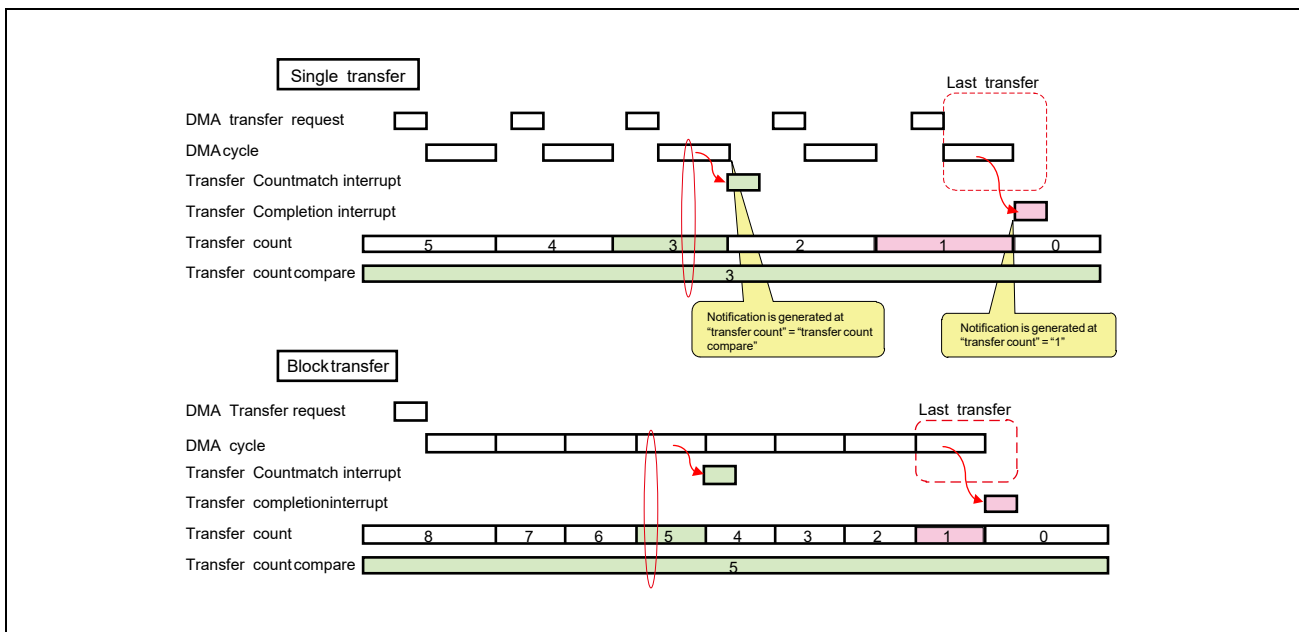

Figure 8.4 Transfer Completion Interrupt and Transfer Count Match Interrupt

8.4.1.6 Continuous Transfer

DTS does not have a configuration that supports continuous transfer.

DTS does not start DTS transfer when a DTS transfer request is generated while the transfer count is 0.

If the reload function 1 is used and the transfer count with the value other than 0 is reloaded to the transfer count bits (TRC[15:0]) in the DTS Transfer Count Register (DTTC_{nnn}) when the last transfer is complete, the DTS can start the transfer after the next DTS transfer request is accepted.

8.4.2 Channel Priority Order

This subsection explains arbitration between multiple DTS channels.

8.4.2.1 DTS Channel Arbitration

If there are DTS transfer requests from multiple DTS channels, DTSFSL arbitrates those DTS channels. For each DTS channel, a priority can be selected from four levels using the DTS channel priority setting registers.

If there are DTS transfer requests from multiple DTS channels, arbitration is executed as follows.

The channel with the higher priority level in the setting of the DTS channel priority setting register has priority.

If two channels have the same priority level specified in the DTS channel priority setting register, the channel with the smaller channel number has priority.

DTSFSL sends DTS a DTS transfer request for the channel selected by arbitration. DTS executes DTS transfer when it accepts the DTS transfer request.

DTS transfer does not allow arbitration between DTS channels in the middle of a block transfer. If a higher priority DTS transfer request is issued during a lower priority block transfer, the higher priority DTS transfer has to wait until the current block transfer is complete*1.

Note 1. Completion of block transfer means either the last transfer or the last transfer for block transfer 1 or the address reload transfer for block transfer 2 is finished.

When the DTS is executing the block transfer 1 or the block transfer 2, a DTS cycle of a DTS channel with a higher priority does not take over the ongoing block transfer until the last transfer is completed.

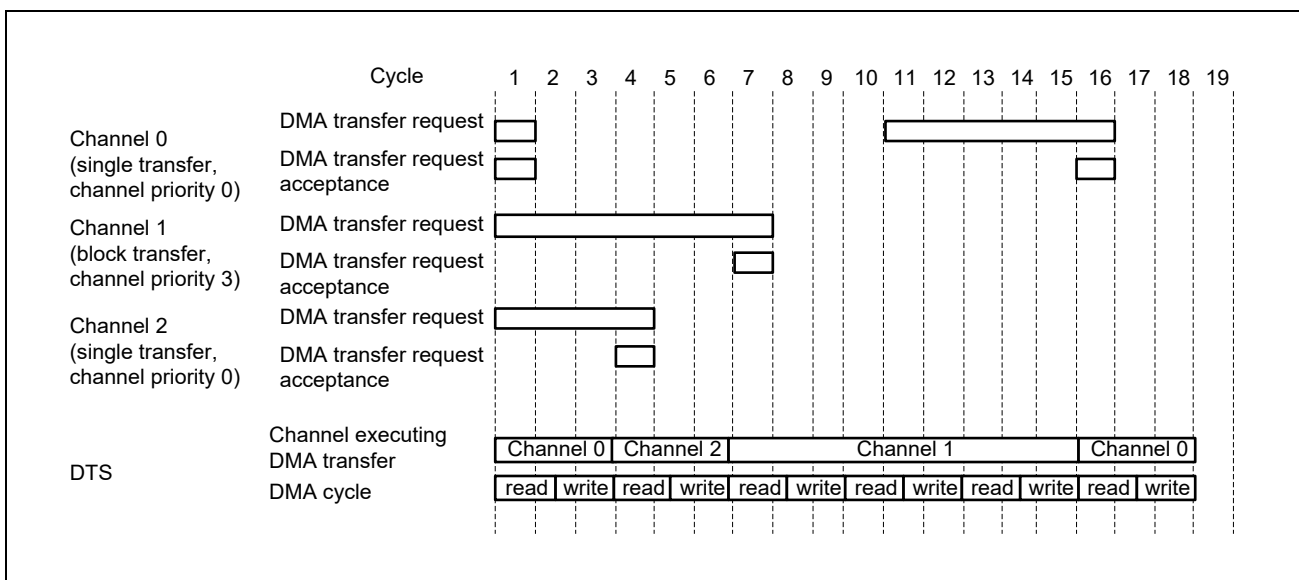

Figure 8.5 DTS Channel Arbitration

Cycle numbers shown in **Figure 8.5** are for explanation purposes only. They do not indicate the actual number of cycles necessary for executing DTS transfer.

In **Figure 8.5**, DTS transfer requests for channels 0, 1, and 2 are generated at Cycle 1. The channel priority for channels 0 and 2 is 0 and is higher than the channel priority for channel 1, which is 3. In addition, if two channels have the same priority, the channel with the smaller channel number has higher priority. Consequently, the priority order for

arbitration is “channel 0 > channel 2 > channel 1”, and a DTS cycle for channel 0 starts because its priority is the highest. As a result of arbitration between channels 1 and 2 at cycle 4, a DTS cycle for channel 2 starts. A DTS cycle for channel 1 starts at Cycle 7, and continuous cycles follow until Cycle 15 because channel 1 uses block transfer. At Cycle 11, a DTS transfer request for channel 0 is generated. The DTS cycle for channel 1 is still ongoing and no arbitration is executed until the block transfer of channel 1 is complete.

At cycle 15, the block transfer of channel 1 is complete. At cycle 16, a DTS cycle for channel 0 starts.

8.4.3 Reload Function

8.4.3.1 Overview of the Reload Function

The reload function updates a portion of the transfer information, more specifically, the source address, destination address, transfer count and address reload count, to predefined values during DTS transfer.

The reload function has two types of functions: reload function 1 and reload function 2.

8.4.3.2 Operation of Reload Function 1

When reload function 1 is enabled, the actions described in **Table 8.37** are executed at the timing of the last transfer according to the reload function 1 settings.

Table 8.37 Operation of Reload Function 1

Reload Function 1 Setting	Register	Action at the Last Transfer
00 (Reload function 1 disabled.)	Source address	Not reloaded.
	Destination address	Not reloaded.
	Transfer count	Not reloaded.
	Address reload count	Not reloaded.
01 (Reload function 1 enabled. Reloading source address and transfer count.)	Source address	The reload source address is copied to this.
	Destination address	Not reloaded.
	Transfer count	The reload transfer count is copied to this.
	Address reload count	If reload function 2 is disabled: Not reloaded. If reload function 2 is enabled: The reload address reload count is copied to this.
10 (Reload function 1 enabled. Reloading destination address and transfer count.)	Source address	Not reloaded.
	Destination address	The reload destination address is copied to this.
	Transfer count	The reload transfer count is copied to this.
	Address reload count	If reload function 2 is disabled: Not reloaded. If reload function 2 is enabled: The reload address reload count is copied to this.
11 (Reload function 1 enabled. Reloading source address, destination address, and transfer count.)	Source address	The reload source address is copied to this.
	Destination address	The reload destination address is copied to this.
	Transfer count	The reload transfer count is copied to this.
	Address reload count	If reload function 2 is disabled: Not reloaded. If reload function 2 is enabled: The reload address reload count is copied to this.

Figure 8.6 shows the operation of reload function 1.

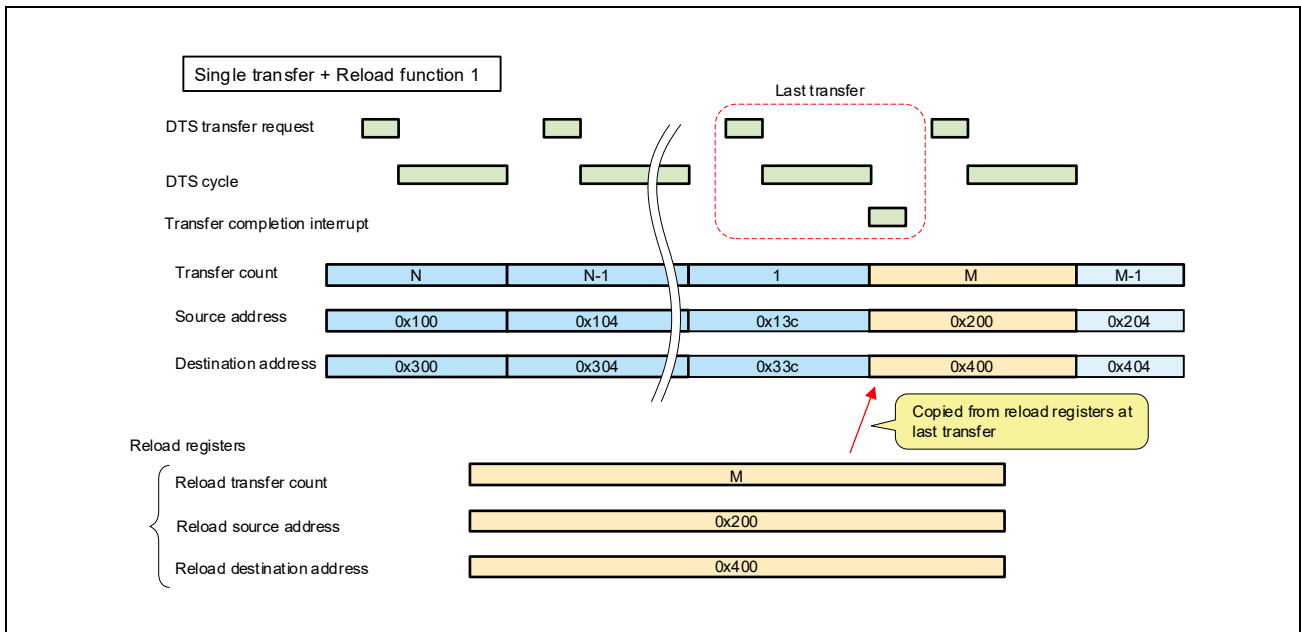

Figure 8.6 Operation of Reload Function 1

8.4.3.3 Reload Function 2

When reload function 2 is enabled, the actions described in **Table 8.38** are executed at the timing of address reload transfer according to the reload function 2 settings.

Table 8.38 Operation of Reload Function 2

Reload Function 2 Setting	Register	Action at Address Reload Transfer
00 (Reload function 2 disabled.)	Source address	Not reloaded.
	Destination address	Not reloaded.
	Address reload count	Not reloaded.
01 (Reload function 2 enabled. Reloading source address.)	Source address	The reload source address is copied to this.
	Destination address	Not reloaded.
	Address reload count	The reload address reload count is copied to this.
10 (Reload function 2 enabled. Reloading destination address.)	Source address	Not reloaded.
	Destination address	The reload destination address is copied to this.
	Address reload count	The reload address reload count is copied to this.
11 (Reload function 2 enabled. Reloading source address and destination address.)	Source address	The reload source address is copied to this.
	Destination address	The reload destination address is copied to this.
	Address reload count	The reload address reload count is copied to this.

Figure 8.7 shows the operation of reload function 2.

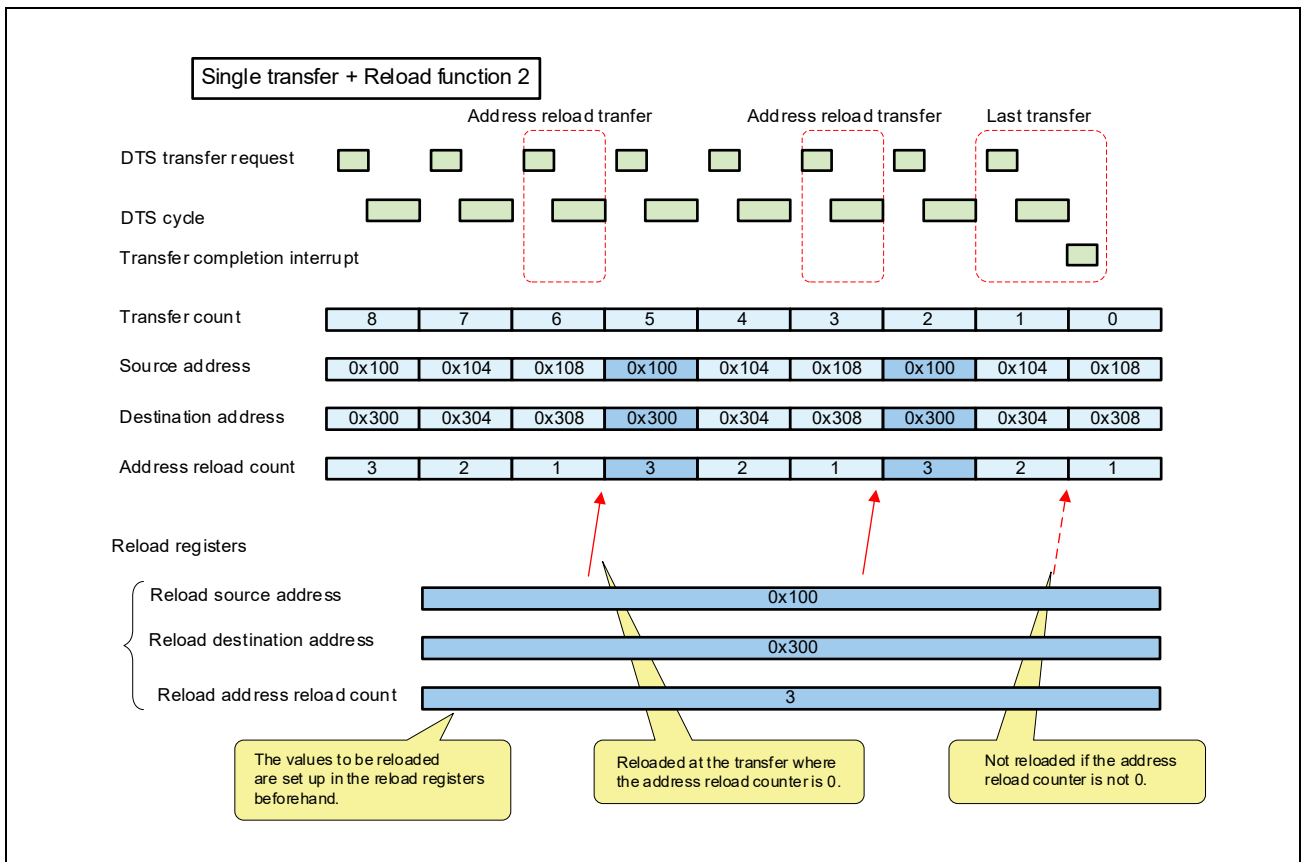

Figure 8.7 Operation of Reload Function 2

Figure 8.8 shows the operation when both reload function 1 and reload function 2 are used simultaneously.

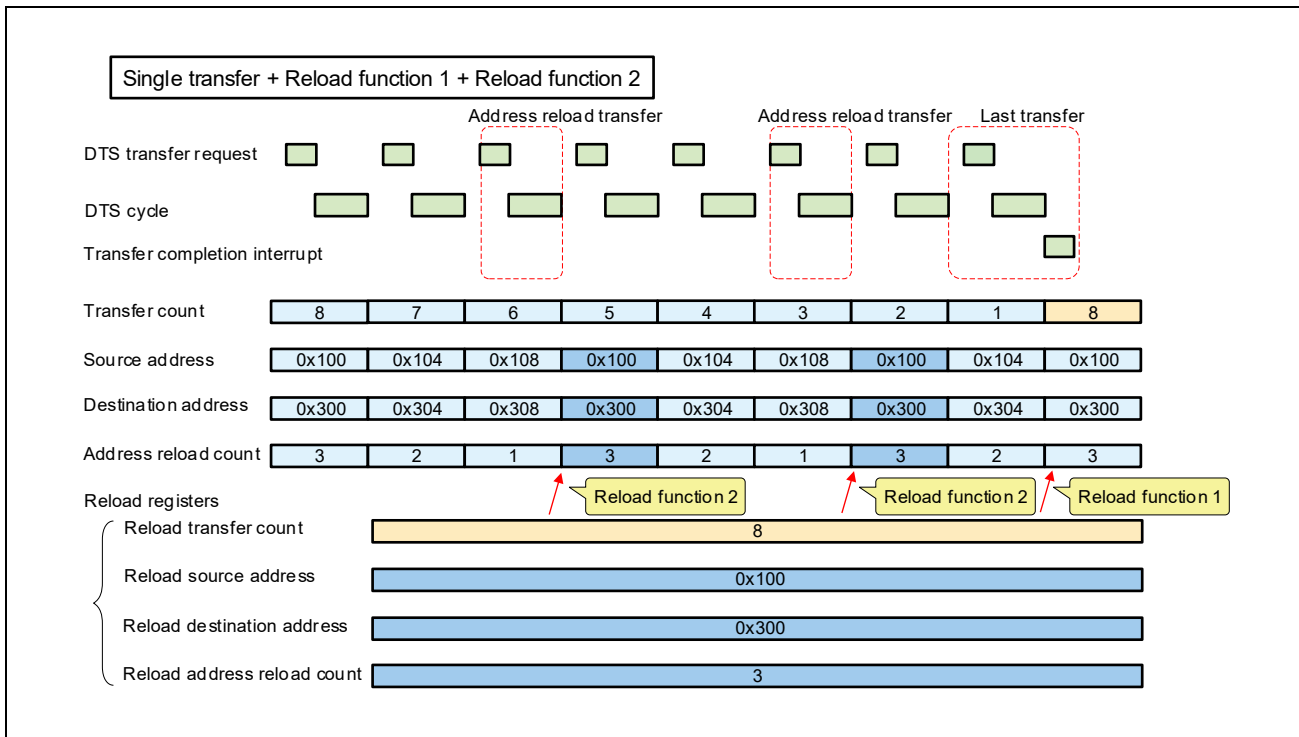

Figure 8.8 Operation When Combining Reload Function 1 and Reload Function 2

8.4.3.4 Timing of Setting DTS Reload Registers

It should be noted that the right timing of setting up the reload source address information, reload destination address information and reload transfer count information differs depending on the transfer mode.

In the single transfer mode, the TI fetched at the beginning of the last transfer or address reload transfer is used for reload at the completion of the DTS cycle. Therefore, if the reload function is used for a single transfer, the reload source address information, reload destination address information, and reload transfer count information in the TI must be set up before the beginning of the last transfer or address reload transfer.

For a block transfer, TI is fetched only at the beginning of the block transfer. The TI is used for the reload function at the last transfer or the address reload transfer. Therefore, when using the reload function for a block transfer, the reload contents in the TI must be set up before the beginning of the block transfer. If the reload contents is updated during the block transfer, those new settings cannot be reflected to the TI nor the next transfer.

8.4.4 Chain Function

8.4.4.1 Overview

DTS provides a function called chain function. When using the chain function, the completion of the DTS cycle or the last transfer for one channel can trigger a DTS transfer request for another channel. The DTS transfer request initiated by the chain function is called a chain request. You can select the condition for generating a chain request from the following two options.

- Always chain: A chain request is generated at the completion of every DTS cycle.
- Chain at the last transfer: A chain request is generated at the completion of the last transfer.

Figure 8.9 shows the operation of the “always chain” option.

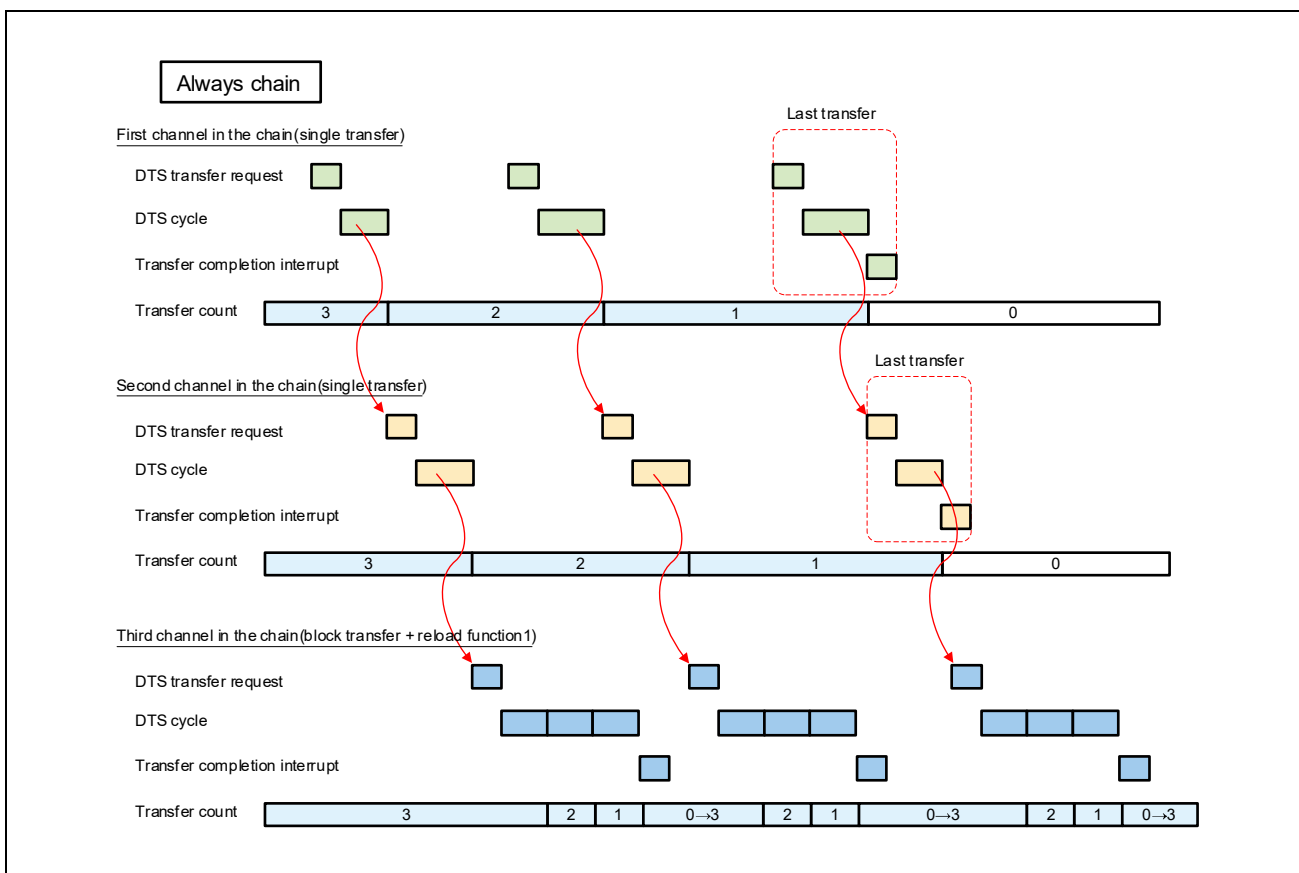

Figure 8.9 Operation of “Always Chain” Option

Figure 8.10 shows the operation of the “chain at the last transfer” option.

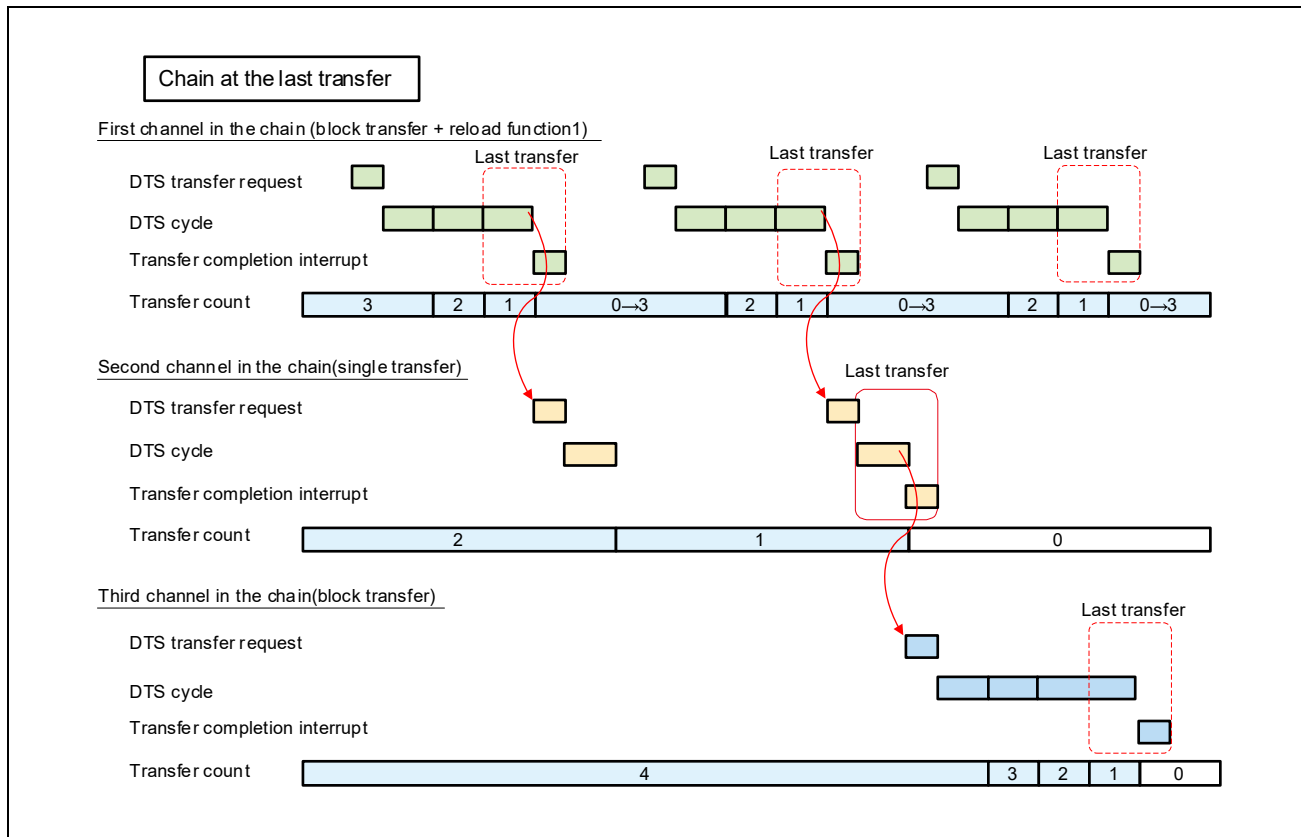

Figure 8.10 Operation of “Chain at the Last Transfer” Option

8.4.4.2 Setting Up the Chain Function

When using the chain function, it has to be enabled by the chain enable (DTTCTn_{nn}.CHNE) and the next channel in the chain has to be specified in the chain selection (DTTCTn_{nn}.CHNSEL) of the DTS Transfer Control Register.

If the reliability functions are required, the chain restriction (DTSn_{nn}CM.CHAIN_RESTRICT, CHAIN_SPID[4:0], CHAIN_UM) also has to be specified in DTS Channel Master Setting Register.

For detailed information about reliability function, see **Section 8.7, Reliability Functions** for details.

8.4.5 DTS Operation

8.4.5.1 Types of DTS Transfer Requests and Assigning DTS Transfer Requests

DTS starts DTS transfer by accepting a hardware DTS transfer request or software DTS transfer request.

A transfer request for DTS is retained in the transfer request pending bit of DTSFSL for each channel.

For DTSFSL, both a hardware DTS transfer request and a software DTS transfer request are retained in the same transfer request pending bit. When executing DTS transfer, DTS does not care whether the DTS transfer request is a hardware DTS transfer request or software DTS transfer request.

8.4.5.2 Generating and Accepting a DTS Transfer Request

DTS only supports edge detection for hardware DTS transfer requests.

When DTSFSL detects a hardware DTS transfer source*¹ input, DTSFSL sets the transfer request pending bit and retains the hardware DTS transfer source as a DTS transfer request. If the transfer request pending bit is set and the transfer request enable bit (DTFSLnnn.REQEN) in the DTSFSL operation setting register is set, DTSFSL notifies DTS of the DTS transfer request.

Software can also generate a DTS transfer request by setting the transfer request pending bit (DTFSTnnn.DRQ) using the DTSFSL transfer request set register (DTFSSnnn).

DTSFSL can retain only one DTS transfer request per channel. If, while the transfer request pending bit for a channel is set, a new hardware DTS transfer source input for the same channel occurs, DTSFSL ignores the new hardware DTS transfer source input.

The transfer request pending bit is automatically cleared when DTS accepts the DTS transfer request. DTSFSL clears the transfer request pending bit automatically when DTS accepts the DTS transfer request regardless of the type of DTS transfer to be executed by DTS.

The transfer request pending bit can also be cleared using the DTSFSL transfer status clear register (DTFSCnnn). If the transfer request pending bit of a channel is cleared before DTS accepts the DTS transfer request, DTS transfer of the channel is not executed.

Note 1. For details, refer to Appendix file "DTS_Transfer_request_Table.xlsx".

8.4.5.3 Executing DTS Transfer

When DTS accepts a DTS transfer request for a channel, DTS executes DTS transfer on the channel. If there are DTS transfer requests from multiple channels, DTSFSL arbitrates the DTS channels and selects the channel for the DTS transfer request.

While DTS is executing DTS transfer, the DTS transfer status (DTSSTS.DTSACT) bit in the DTS status register is set. In addition, the channel number of the currently ongoing DTS transfer is set in the DTS transfer channel (DTSSTS.DTSACH).

When the DTS transfer is complete or aborted because of a DTS transfer error or a register write and no channel is currently executing DTS transfer, the DTS transfer status (DTSSTS.DTSACT) bit is cleared.

8.4.5.4 DTSRAM Access

DTS accesses the DTSRAM when DTS transfer starts and finishes.

The DTS action of reading transfer information from the DTSRAM when DTS transfer starts is called TI fetch.

The DTS action of updating the transfer information on the DTSRAM when DTS transfer finishes is called TI writeback.

A single transfer performs a TI fetch at the beginning of a DTS cycle and a TI writeback at the end of a DTS cycle.

A block transfer performs a TI fetch at the beginning of the first DTS cycle and a TI writeback at the end of the DTS cycle that satisfies the block transfer completion condition (the last transfer or address reload transfer).

Therefore, in the case of a single transfer, the transfer information in DTSRAM is updated during each DTS cycle. In the case of block transfer, the transfer information in DTSRAM is updated after completion of the block transfer. If software reads the transfer information from DTSRAM during execution of a block transfer, the information represents the beginning of the block transfer.

8.5 Suspension, Resume, and Transfer Abort, and Clearing a DTS Transfer Request

8.5.1 Suspend, Resume, and Transfer Abort of a DTS Transfer

A DTS transfer being executed by DTS can be suspended by setting the DTS suspend bit (DTSCTL1.DTSUST) in DTS control register 1. If a DTS cycle is in progress, the DTS transfer is suspended after the DTS cycle is finished. If the current DTS cycle is a single transfer or a transfer that completes a block transfer (the last transfer or address reload transfer), the DTS transfer is suspended after a TI writeback and completion of the DTS cycle.

If the type of the current DTS cycle is other than the above, DTS transfer is suspended after the completion of the DTS cycle without a TI writeback. To resume DTS transfer after suspension, the DTS suspend bit in DTS control register 1 has to be cleared.

To abort DTS transfer by DTS, first suspend DTS as described above and then set the DTS transfer abort request bit (DTSCTL2.DTSTIT) in DTS control register 2. If a transfer is aborted, no TI writeback is executed. In addition, aborting a DTS transfer does not change the value of the DTS suspend bit (DTSCTL1.DTSUST). If it is desired to have the DTS accept another DTS transfer request after the abort, clear the DTS suspend bit.

Figure 8.11 shows an example of suspension, resume, and transfer abort of a DTS transfer.

In **Figure 8.11**, channels 0, 1, and 2 are executing block transfer. At time tick 1, a DTS transfer request for channel 1 is accepted and DTS transfer starts. At time tick 2, DTS transfer requests for channels 0 and 2 are generated. At time tick 3, the last transfer of channel 1 is complete, and as a result of DTS channel arbitration, a DTS transfer request for channel 0 is accepted, and DTS transfer of channel 0 starts because channel 0 has a higher priority than channel 2. At time tick 4, the last transfer of channel 0 is complete, and DTS transfer of channel 2 starts. At time tick 5, DTS is put into the suspended state, and the DTS transfer of channel 2 is suspended. At time tick 6, DTS transfer requests for channels 0 and 1 are generated. At time tick 7, the suspended state for DTS is cleared, and the DTS transfer of channel 2, which was suspended in the middle of a block transfer, is resumed. If DTS transfer is suspended in the middle of a block transfer, no DTS channel arbitration is executed when it is resumed. At time tick 8, the last transfer of channel 2 is complete, and as a result of DTS channel arbitration, a DTS transfer request for channel 0 is accepted and the DTS transfer starts because channel 0 has a higher priority than channel 2. At time tick 9, DTS is put into the suspended state, and at time tick 10, the suspended DTS transfer of channel 0 is aborted. When the suspended state of DTS is cleared at time tick 11, DTS transfer of channel 1 starts because there is no currently ongoing DTS transfer and channel 1 is the only channel with a DTS transfer request.

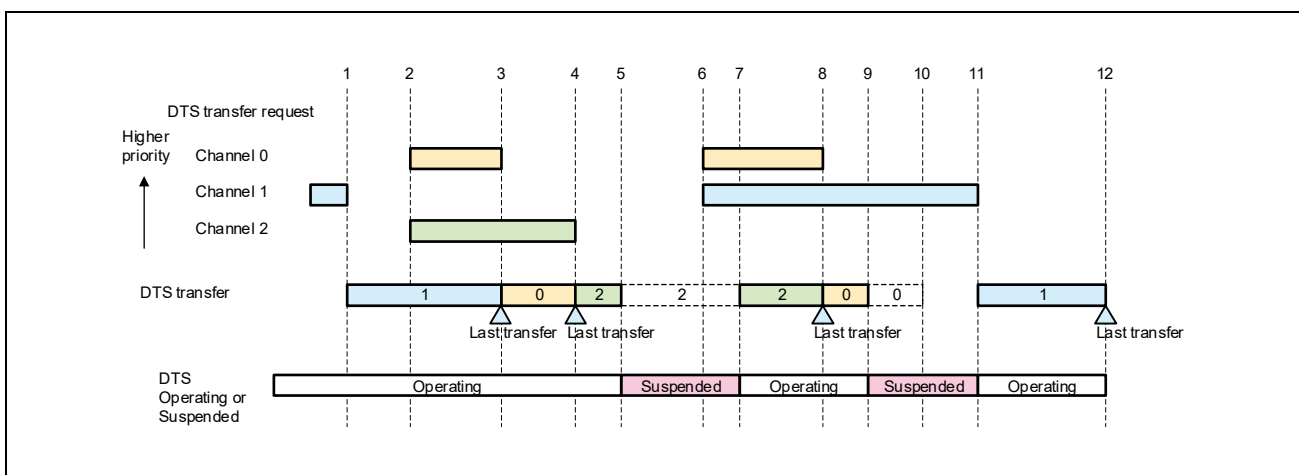

Figure 8.11 Example of Suspension, Resume, and Transfer Abort of a DTS Transfer

8.5.2 Masking and Clearing a Hardware DTS Transfer Request by DTSFSL

A DTS transfer request from a channel to DTS can be temporarily disabled (masked) by clearing the transfer request enable bit (DTFSL_{nnn}.REQEN) in the DTSFSL operation setting register. In this case, the masked channel is excluded from DTSFSL arbitration.

A DTS transfer request held in DTSFSL can be cleared by setting the transfer request clear bit (DTFSC_{nnn}.DRQC) in the DTSFSL transfer request clear register.

DTSFSL monitors hardware transfer source requests regardless of the state of DTS and the transfer request enable bit (DTFSL_{nnn}.REQEN). DTSFSL sets a DTS transfer request for a channel when it detects a hardware transfer source request. When resuming or starting DTS transfer, a hardware DTS transfer request held in DTSFSL should be cleared as required.

8.5.3 List of Suspend, Resume, and Transfer Abort Functions

Table 8.39 List of Suspend, Resume, and Transfer Abort Functions

Function	How to Execute the Function	Operation	Possibility of DTS Transfer Abort
Suspension and resume of DTS	Setting and clearing DTCTL1.DTSUST.	All channels of DTS transfer is suspended.	Possible (by setting DTCTL2.DTSTIT during suspension)

8.6 Error Control

8.6.1 Types of Errors

DTS can generate the following types of errors:

- DTS Transfer Error

This error is generated when an error is detected in the read cycle or write cycle in a DTS cycle or when an error is detected by checking the ECC in the read cycle.

This error can be generated in all DTS channels during execution of DTS transfer.

- DTSRAM ECC Error

This error is generated when an ECC error is detected in the DTSRAM read access by DTS.

This error can be generated in the TI fetch during execution of DTS transfer for DTS or while software is accessing the DTS channel registers.

- DTSRAM Address Feedback Error

This error is generated when an Address Feedback error is detected in the DTSRAM read or write access by DTS.

This error can be generated in the TI fetch or TI writeback during execution of DTS transfer for DTS or while software is accessing the DTS channel registers. See **Section 40, Functional Safety** for details.

8.6.2 DTS Transfer Error

8.6.2.1 Operation of DTS When a DTS Transfer Error Occurs

When a DTS transfer error occurs in DTS, the transfer error flag (DTFSTnnn.ER) in the DTS transfer status register of the channel on which the DTS transfer error occurred is set. The transfer error cycle flag (DTSFSTnnn.ERWR) in the DTS transfer status register of the channel on which the DTS transfer error occurred shows whether the error occurred in the read cycle or the write cycle. The DTS Error register (DTSER) shows the smallest number of DTS channels on which the DTS transfer error occurred.

If a DTS transfer error occurs in a single transfer, a TI writeback is executed to finish the DTS cycle.

If a DTS transfer error occurs in the middle of a block transfer and the DTS error transfer disable bit (DTTCTnnn.ESE) is set, the remaining DTS cycles in the block transfer are not executed, but a TI writeback is executed to finish the DTS cycle. At the same time, the DTS transfer status (DTSSTS.DTSACT) bit in the DTS status register is cleared. If a DTS transfer error occurs in the middle of a block transfer and the DTS error transfer disable bit (DTTCTnnn.ESE) is cleared, the block transfer continues regardless of the DTS transfer error.

If a DTS transfer error occurs during the read cycle of a DTS cycle, the write cycle is not executed. If a DTS transfer error occurs during the write cycle of a DTS cycle, the validity of the write is not guaranteed.

Regardless of whether a DTS transfer error occurs in the read cycle or write cycle of a DTS cycle, the source address, destination address, transfer count, and address reload count registers are updated, and the TI is updated by a TI writeback.

Even if the transfer error flag (DTFSTnnn.ER) in the DTS transfer status register of the channel is set, a TI fetch is executed when DTS accepts a DTS transfer request for the channel. If, as a result of the TI fetch, the DTS error transfer disable bit (DTTCTnnn.ESE) is found to be set, a DTS cycle and a TI writeback are not executed. If the DTS error transfer disable bit (DTTCTnnn.ESE) is cleared, DTS transfer is executed.

8.6.3 DTSRAM Error

There are three types of DTSRAM errors detected in DTSRAM read access: an ECC correctable error, an ECC uncorrectable error and an address feedback error. There is one type of DTSRAM error detected in DTSRAM write access: an address feedback error.

If an ECC correctable 1-bit error is detected during a TI fetch, error corrected data is used, and DTS transfer continues. If an ECC correctable 1-bit error is detected during DTS channel register access from software, error corrected data is returned as read data.

If an ECC uncorrectable error or an address feedback error is detected during a TI fetch, handling of the DTS transfer request is terminated without executing a DTS cycle and TI writeback. If an address feedback error is detected during a TI writeback, the validity of the TI writeback is not guaranteed. If an ECC uncorrectable error or address feedback error is detected during a DTS channel register read from software, a peripheral bus error is reported. If an address feedback error is detected during a DTS channel register write from software, a peripheral bus error is not reported, but the validity of the write access is not guaranteed. In addition to an ECC 2-bit error, an ECC 1-bit error is treated as uncorrectable if 1-bit error correction is disabled in ECC.

8.7 Reliability Functions

8.7.1 Overview

In this product, DTS provides the following reliability functions to support multi-core configurations (multiple master PEs).

- Register access protection function
See **Section 40, Functional Safety**.
- Master information inheritance function
- SPID setting restriction
See **Section 40, Functional Safety**
- Restriction on chain function

8.7.2 Master Information Inheritance Function

The master information inheritance function uses the contents of the channel master setting registers as the sideband information of the data transfer interface.

DTS outputs the sideband information of data transfer for the access guard.

Table 8.40 shows the sideband information that DTS outputs.

Table 8.40 Sideband Information That Is Output from DTS

Meaning	Value Output from DTS
UM	Same as the UM bit value in the channel master setting register
SEC	Non secure
SPID	Same as the SPID bit value in the channel master setting register,

8.7.3 Restriction on Chain Function

The channel configuration of the chain function can be restricted. When chain function restriction is enabled, only a pre-allowed channel in master information can be set as the next channel.

The chain function is not restricted if the CHAIN_RESTRICT bit of the DTS Channel Master Setting Register (DTSnnnCM) is cleared. In this case, DTS channel can specify any other channel to be included in the chain function.

The chain function is restricted if the CHAIN_RESTRICT bit of the DTS Channel Master Setting Register (DTSnnnCM) is set. In this case, only the channels in which CHAIN_SPID[4:0] and CHAIN_UM match can be included into the chain function by DTS channel.

When a chain is executed, DTS compares the channel master settings of the previous and next channels to decide if the chain is permissible.

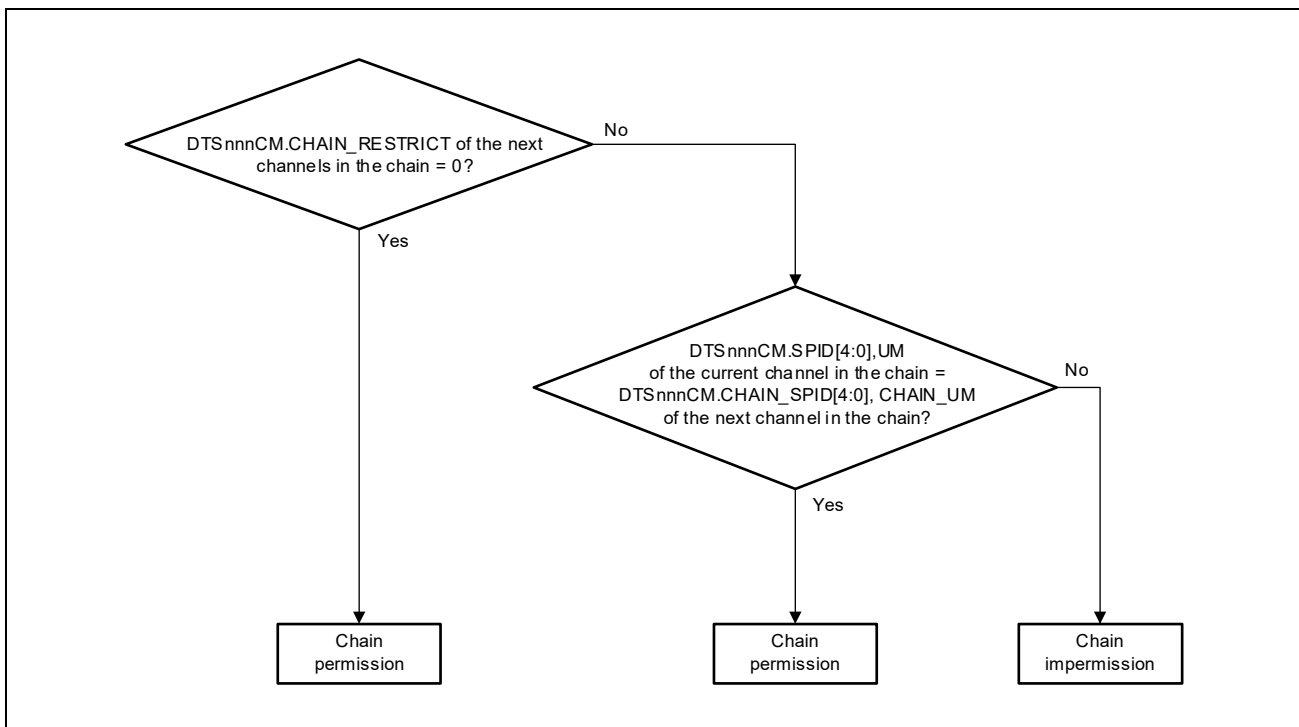

Figure 8.12 Chain Judgement Flow

8.8 Setting up DTS Transfer

8.8.1 Overview of Setting up DTS Transfer

Table 8.41 Overview of Setting up DTS Transfer

Description	Register		Necessity of the Setting
Transfer request group selection setting	DTSSSELm	DTS transfer request group selection	Mandatory (if using a hardware transfer request)
Overall DTS operation setting	DTSPRn	DTS channel priority setting	Mandatory (if DTS is used)
	DTSnnnCM	DTS channel master setting	Mandatory (if DTS is used)
Channel setting	DTSAAnnn	DTS source address	Mandatory
	DTDAnnn	DTS destination address	Mandatory
	DTTCnnn	DTS transfer count	Mandatory
	DTTCTnnn	DTS transfer control	Mandatory
	DTRSAAnnn	DTS reload source address	Mandatory if the reload function is used
	DTRDAAnnn	DTS reload destination address	
	DTRTCnnn	DTS reload transfer count	
	DTTCcnnn	DTS transfer count compare	Mandatory if the transfer count match interrupt is used
Status clear	DTFSCnnn	DTSFSL transfer status clear	Recommended
Transfer request enable	DTFSLnnn	DTSFSL operation setting	Mandatory

8.8.2 Setting up the Transfer Request Group Selection

Set up the transfer request group selection before using DTS. The following registers must be set up to configure the transfer request group.

- DTS Transfer Request group selection Register (DTSSSELm) (m = 0 to 15)
This register configures the transfer request group selection.

8.8.3 Setting up the Overall DTS Operation

Set up the overall DTS operation before using DTS.

The following registers must be set up to configure the overall DTS operation.

- DTS channel priority setting registers (DTSPRn, n = 0 to 7)
These registers configure the priority level of each DTS channel used for DTS channel arbitration.
- DTS channel master setting registers (DTSnmmCM)
These registers configure channel assignment. (For details, see **Section 8.7, Reliability Functions.**)

NOTE

It is important to properly configure the DTS channel master setting registers. Otherwise DTS transfer will not operate as expected.

It is recommended to clear following errors detected while setting up DTS:

- The DTSFSL Transfer Status Register (DTFSTnmm)

NOTE

Channel number information of the channel with error can be obtained by reading the DTS Error Register (DTSER).

8.8.4 Configuring the DTS Channel Settings

The DTS channel settings define the transfer information and transfer source for a DTS channel.

The following procedure shows how to configure the DTS channel settings.

(1) Disable transfer requests by DTSFSL.

Clear the transfer request enable bit (DTFSL_{nnn}.REQEN) in the DTSFSL operation setting register of the DTS channel being configured. This procedure is not mandatory but recommended in order to prevent DTS transfer requests during DTS channel configuration. It is also recommended to check the DTS status register (DTSSTS) and confirm that DTS transfer is not ongoing on the DTS channel being configured.

(2) Configure the transfer information (TI).

The following registers need to be set up to configure DTS channel transfer information.

- DTS Source Address Register (DTSAnnn)
- DTS Destination Address Register (DTDA_{nnn})
- DTS Transfer Count Register (DTTC_{nnn})
- DTS Transfer Control Register (DTTCT_{nnn})
- DTS Reload Source Address Register (DTRSA_{nnn})
- DTS Reload Destination Address Register (DTRDA_{nnn})
- DTS Reload Transfer Count Register (DTRTC_{nnn})
- DTS Transfer Count Compare Register (DTTCC_{nnn})

(3) Set the DTS transfer request.

DTS does not distinguish between hardware and software DTS transfer requests (no specific setting). Both hardware and software DTS transfer requests are retained in the same transfer request pending bit (DTFST_{nnn}.DRQ).

DTSFSL may retain a DTS transfer request that came before the transfer information is set up. If necessary, DTS transfer requests (DTFST_{nnn}.DRQ) retained in DTSFSL can be cleared by using the DTSFSL transfer status clear register (DTFSC_{nnn}).

(4) Enable transfer requests by DTSFSL.

Set the transfer request enable bit (DTFSL_{nnn}.REQEN) in the DTSFSL operation setting register to enable DTS transfer requests for the DTS channel.

After the transfer request enable bit for DTSFSL is set, DTS can accept a DTS transfer request and start DTS transfer.

Section 9 RAM

This section describes the RAM mounted on RH850/E2x-FCC2, E2UH and E2H.

9.1 List of On-Chip RAMs

Table 9.1 shows the list of On-Chip RAMs.

Table 9.1 List of On-Chip RAMs

		RH850/E2x-FCC2 (For E2UH)	RH850/E2x-FCC2 (For E2H)	RH850/E2UH	RH850/E2H
Local RAM per CPU		64 KB	32 KB	64 KB	32 KB
Cluster0 RAM	Total Size (Retention RAM included)	512 KB	512 KB	512 KB	512 KB
	Retention RAM (Included in Cluster0 RAM)	No	No	No	No
Cluster1 RAM	Total Size (Retention RAM included)	512 KB	512 KB	512 KB	512 KB
	Retention RAM (Included in Cluster1 RAM)	No	128 KB	No	128 KB
Cluster2 RAM	Total Size (Retention RAM included)	640 KB	No	640 KB	No
	Retention RAM (Included in Cluster1 RAM)	128 KB	No	128 KB	No
Cluster0 ERAM*1		1 MB	1 MB	No	No
Cluster1 ERAM*1		1 MB	1 MB	No	No
Cluster2 ERAM*1		1 MB	No	No	No
Global ERAM*1		2 MB	2 MB	No	No
Instrumentation RAM*1		96 KB	96 KB	No	No

Note 1. All data are retained in Emulation/Instrumentation RAM and Aurora Retention Mode (E2x-FCC2 Only).

9.2 Features

Access:

The CPU n^{*1} , DMA and H-Bus Master can access the Local RAM (CPU n^{*1}), the Cluster 0/1/2 RAM, the Cluster 0/1/2 ERAM, the Global ERAM and the Instrumentation RAM. The access latency from CPU n to the Local RAM for CPU n^{*1} is the same as the access to the Local RAM (self).

The access latency from CPU0 or CPU1 to Cluster0 RAM is faster than the access latency to Cluster1/2 RAM, because CPU0 and CPU1 are in Cluster0. The access latency from CPU2 or CPU3 to Cluster1 RAM is faster than the access latency to Cluster0/2 RAM, because CPU2 and CPU3 are in Cluster1. The access latency from CPU4 or CPU5 to Cluster2 RAM is faster than the access latency to Cluster0/1 RAM, because CPU4 and CPU5 are in Cluster2.

Note 1. $n = 0$ to 5 (E2x-FCC2 and E2UH), $n = 0$ to 3 (E2H).

RAM Retention:

In RH850/E2x-FCC2, all data in the Cluster ERAM, Global ERAM and Instrumentation RAM are retained in Emulation/Instrumentation RAM and Aurora Retention Mode (E2x-FCC2 Only).

In RH850/E2x-FCC2 and E2UH, 128 Kbytes of data in the Cluster2 RAM are retained in power-off standby mode.

In RH850/E2H, 128 Kbytes of data in the Cluster1 RAM are retained in power-off standby mode.

For details, see **Section 16, Standby Controller**.

ECC:

The Local RAM(CPU0/CPU1/CPU2/CPU3/CPU4/CPU5) and Cluster RAM include the ECC.

The Local RAM(CPU0/CPU1/CPU2/CPU3/CPU4/CPU5) and Cluster RAM also include the address feedback function. For details, see **Section 40, Functional Safety**.

9.3 RAM Data Retention

Simultaneous occurrence of write and reset in the RAM space that retains data is not written as undefined data in power-off standby mode.

9.4 Usage Notes

When ECC error detection/correction is enabled for the Local RAM and Cluster RAM, initialize the RAM using a write instruction with the maximum bit length of its access size before using the RAM.

For the maximum bit length of the RAM access size, see the applicable data width in **Section 40, Functional Safety**.

If the RAM is accessed before its initialization, an ECC error may be detected. Also, if initialization with the maximum bit length is not performed (e.g. if a 32-bit RAM is initialized by an 8-bit or 16-bit access), an ECC error may be detected.

Section 10 Reset Controller

10.1 Features

The Reset Controller controls all factors that affect the reset behavior of the device.

The device has several kinds of reset categories depending on the areas that are reset. Each of the reset categories is triggered by one or multiple reset sources.

The relationship between reset categories and their sources is shown in **Table 10.1**.

Table 10.1 Reset Categories and Reset Sources

Reset Category	Source
Power Up Reset	<ul style="list-style-type: none"> Power Up Reset*¹ (by SYSVCC Voltage level) Debugger Reset (forcible reset by a debugger) For details, see Section 47, Debugging and Calibration .
System Reset 1	<ul style="list-style-type: none"> Standby Reset (exiting power off standby mode using $\overline{\text{RES_IN}}$) External Reset (by $\overline{\text{RES_IN}}$) VMON Reset (by Voltage monitor and Delay monitor)
System Reset 2	<ul style="list-style-type: none"> Software Reset (by SWSRESA, SWSRESA_ICUM) ECM Reset (if RESC0 = 0) SWDT Reset (if RESC1 = 0)
Application Reset	<ul style="list-style-type: none"> Software Reset (by SWARESAS, SWARESAS_ICUM) ECM Reset (if RESC0 = 1) SWDT Reset (if RESC1 = 1) <p>NOTE: This reset is basically identical to System Reset 2 with the following exceptions: Clock configuration is preserved, except that of external clock output. Initial setting of peripheral functions using the option byte is not changed. HW BIST is not executed.</p>
Module Reset	<ul style="list-style-type: none"> Software Module Reset Assertion Register for ICU-M (SWMRESAS_ICUM) ICU-M WDTA Reset For details, see Section 45, Intelligent Cryptographic Unit/Master (ICUMD) .
JTAG Reset	JTAG Reset (by $\overline{\text{TRST}}$)

Note 1. External Reset ($\overline{\text{RES_IN}}$) must be asserted low at power up and power down. For the timing details, see *the RH850/E2x-FCC2 Electrical Characteristics, User's Manual: Hardware*.

10.1.1 Register Base Addresses

Reset base addresses are listed in the following table.

Reset register addresses are given as offsets from the base addresses in general.

Table 10.2 Register Base Addresses

Base Address Name	Base Address	Bus Group
<RESET_base>	FF70 0000 _H	Peripheral Group 6
<BOOT_base>	FFFB 0000 _H	Peripheral Group 0

10.1.2 Input/Output Pins

I/O pins related to reset are shown in **Table 10.3**.

Table 10.3 I/O Pins

Pin Function Name	Direction	Description
$\overline{\text{RES_IN}}$	Input	Reset Input
$\overline{\text{TRST}}$	Input	JTAG Reset Input
$\overline{\text{RES_OUT}}$	Output	Reset Output

10.2 Register Description

10.2.1 Register Protection

Write-protected registers are protected from inadvertent write access due to erroneous program execution, etc. Write-protected registers can be written by releasing the protection of RESKCPR0T.

10.2.2 List of Registers

The registers related to reset are listed in **Table 10.4**.

Table 10.4 List of Registers

Unit Name	Register Name	Symbol	Address	Access size	Access Protection
PFSYSTEM	Boot Control Register	BOOTCTRL	<BOOT_base> + 2000 _H	32	
SYSCTRL	Reset Factor Register	RESF	<RESET_base> + 0480 _H	32	
SYSCTRL	Reset Factor Clear Register	RESFC	<RESET_base> + 0484 _H	32	
SYSCTRL	Software System Reset Assertion Register	SWSRESA	<RESET_base> + 0500 _H	32	RESKCPR0T
SYSCTRL	Software Application Reset Assertion Register	SWARESAS	<RESET_base> + 0504 _H	32	RESKCPR0T
SYSCTRL	Reset Configuration Register	RESC	<RESET_base> + 0580 _H	32	RESKCPR0T
SYSCTRL	RAM Initialization Mode Control Register for DTS RAM	STAC_DTS RAM	<RESET_base> + 0880 _H	32	
SYSCTRL	RAM Initialization Mode Control Register for sDMAC Descriptor RAM	STAC_DPR AM	<RESET_base> + 0888 _H	32	
SYSCTRL	RAM Initialization Mode Control Register for DFE	STAC_DFE	<RESET_base> + 088C _H	32	
SYSCTRL	RAM Initialization Mode Control Register for FlexRay	STAC_FLX A	<RESET_base> + 0894 _H	32	
SYSCTRL	RAM Initialization Mode Control Register for Ethernet	STAC_ETH ER	<RESET_base> + 0898 _H	32	
SYSCTRL	RAM Initialization Mode Control Register for GTM	STAC_GTM	<RESET_base> + 089C _H	32	
SYSCTRL	Reset Controller Register Key Code Protection Register	RESKCPR OT	<RESET_base> + 0FF0 _H	32	

10.2.3 Reset of Registers

The register reset conditions are shown in **Table 10.5**.

Table 10.5 Register Reset Conditions

Register Name	Reset Condition					
	Power Up Reset	System Reset 1	System Reset 2	Application Reset	Module Reset	JTAG Reset
BOOTCTRL	✓	✓	✓	✓	—	—
RESF	✓*1	✓*1	—	—	—	—

STAC_GTM	✓	✓	✓	—	—	—
RESKCPROT	✓	✓	✓	—	—	—

Note 1. For details, see **Section 10.2.5, RESF — Reset Factor Register**.

10.2.4 BOOTCTRL — Boot Control Register

This register controls the startup of each PE. At the time of reset (System Reset 1/2, and Application Reset) release, the PEs are started according to the initial setting of this register, which is defined by a FLASH option byte. After reset release, PEs can be started selectively by asserting the corresponding bit of this register. Only 1 can be written to these bits. Writing 0 is ignored. For details on value of the FLASH option byte, see **Section 43, Flash Memory**.

Value after reset: 0000 000X_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	BC5	BC4	BC3	BC2	BC1	BC0
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	x

Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0	1
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 10.7 RESF Register Contents (1/2)

Bit Position	Bit Name	Function
31 to 18	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
17	ICUMARESFO	ICU-M Software Application Reset Flag This flag is a status flag controlled by ICU-M. For details, see Section 45, Intelligent Cryptographic Unit/Master (ICUMD) . This flag is cleared to 0 by Power Up Reset* ¹ , Standby Reset and VMON Reset. 0: No reset has occurred 1: Reset has occurred
16	ICUMSRESFO	ICU-M Software System Reset Flag This flag is a status flag controlled by ICU-M. For details, see Section 45, Intelligent Cryptographic Unit/Master (ICUMD) . This flag is cleared to 0 by Power Up Reset* ¹ , Standby Reset and VMON Reset. 0: No reset has occurred 1: Reset has occurred
15 to 13	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
12	HWBISTF	HW BIST Execution Flag* ³ This flag will always be asserted after a preceding Power-Up or System Reset if the HW BIST is enabled. In this case, the corresponding Power-Up or System Reset Flag is asserted as well. 0: HW BIST was not executed 1: HW BIST was executed
11	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
10	ARESF2	ECM Application Reset Flag This flag is cleared to 0 by Power Up Reset* ¹ , Standby Reset and VMON Reset. 0: No reset has occurred 1: Reset has occurred
9	ARESF1	SWDT Application Reset Flag This flag is cleared to 0 by Power Up Reset* ¹ , Standby Reset and VMON Reset. 0: No reset has occurred 1: Reset has occurred

Table 10.7 RESF Register Contents (2/2)

Bit Position	Bit Name	Function
8	ARESF0	Software Application Reset Flag This flag is cleared to 0 by Power Up Reset* ¹ , Standby Reset and VMON Reset. 0: No reset has occurred 1: Reset has occurred
7	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
6	SRES2F2	ECM System Reset Flag This flag is cleared to 0 by Power Up Reset* ¹ , Standby Reset and VMON Reset. 0: No reset has occurred 1: Reset has occurred
5	SRES2F1	SWDT System Reset Flag This flag is cleared to 0 by Power Up Reset* ¹ , Standby Reset and VMON Reset. 0: No reset has occurred 1: Reset has occurred
4	SRES2F0	Software System Reset Flag This flag is cleared to 0 by Power Up Reset* ¹ , Standby Reset and VMON Reset. 0: No reset has occurred 1: Reset has occurred
3	SRES1F2	VMON Reset Flag This flag is cleared to 0 by Power Up Reset* ¹ and Standby Reset. 0: No reset has occurred 1: Reset has occurred
2	SRES1F1	External Reset Flag* ² 0: No reset has occurred 1: Reset has occurred
1	SRES1F0	Standby Reset Flag This flag is cleared to 0 by Power Up Reset.* ¹ 0: No reset has occurred 1: Reset has occurred
0	PRESF0	Power Up Reset Flag 0: No reset has occurred 1: Reset has occurred This bit is used to judge Power Up Retention RAM data can not be guaranteed with this bit

Note 1. A Power up reset caused by a debugger also clears this flag.

Note 2. SRES1F1 is a high priority flag. Do not use ARESF2-0 and SRES2F2-0 for judgment when SRES1F1=1 at the time of reset factor judgment.

Note 3. HWBISTF is also set at the condition of "BIST not executed" by setting TRST pin to High. Please refer to **Table 40.431** and **Table 40.432** about the condition.

Table 10.8 Reset Factor Register Value in Usecase

1, 0	RZEROMD[1:0]	RAM Initialization Mode for GTM The value after reset can be set by using the flash option byte. X0 _B : Disabled 01 _B : Setting is prohibited 11 _B : Enabled

10.2.16 RESKCPROT — Reset Controller Register Key Code Protection Register

The RESKCPROT register is used to protect against writing to the registers that may have a material effect on the system so that the application system is not incorrectly stopped due to program malfunction and the like.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	KCPROT[31: 16]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	KCPROT[15: 1]															KCE
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W	R/W

Table 10.19 RESKCPROT Register Contents

Bit Position	Bit Name	Function
31 to 1	KCPROT[31:1]	Enable or disable modification of the KCE bit. The written value is not retained. These bits are always read as 0.*1
0	KCE	Key Code Enable bit 0: Disable write access to protected registers 1: Enable write access to protected registers

Note 1. Write A5A5A500_H to this register to disable writing to protected registers.
Write A5A5A501_H to this register to enable writing to protected registers.

10.3 Operation

10.3.1 Reset Categories

The following are the reset categories of this product.

Each reset category has multiple reset sources (described in the next section). The reset source for each category has a different impact on the system. See the description of resets in the product specifications to determine the exact response of each block to each reset.

Power Up Reset

The Power Up Reset indicates a partial (beginning) power up of the device with SYSVCC. The device begins to function only when a valid SYSVCC is applied while no other power is being supplied. An internal circuit monitors SYSVCC and generates this Power Up Reset signal when SYSVCC transitions to being valid or transitions to being invalid. The external reset pin (RES_IN) must be asserted low during this power up process (when Power Up Reset is negated internally), and during the power down process (when Power Up Reset is asserted internally). Power up Reset can also be triggered by the debugger. All blocks and resources on the device are affected by this reset.

System Reset 1

The System Reset 1 indicates a full power up of the device with all power supplies being applied(excluding EMUVDD and EMUVCC for E2x-FCC2). It also indicates when the external reset (RES_IN) is asserted, even though all of the power supplies remain valid. Internal voltage monitors of all of the supplies can also cause this reset.

For timing details, see *the RH850/E2x-FCC2 Electrical Characteristics, User's Manual: Hardware*. Almost all blocks and resources of this device are affected by this reset. The sources of this reset are as follows:

- Standby Reset
- External Reset
- Voltage Monitor & Delay monitor Reset (VMON Reset)

System Reset 2

System Reset 2 indicates a possible catastrophic software problem that requires a fresh boot of the device.

The sources of this reset are as follows:

- Software Reset by writing the associated register
- Error Control Module Reset (The Reset Category is configured by the Reset Configuration Register)
- Secure Watchdog Timer Reset (The Reset Category is configured by the Reset Configuration Register)

Application Reset

Application Reset is used for fast initialization of the application. This reset is basically identical to System Reset 2 with the following exceptions: Clock configuration is preserved except that of external clock output; the initial setting of peripheral functions using the option byte is not changed; and HW BIST is not executed. This enables fast initialization. Application Reset sources are as follows:

- Software Reset by writing the associated register
- Error Control Module Reset (The Reset Category is configured by the Reset Configuration Register)
- Secure Watchdog Timer Reset (The Reset Category is configured by the Reset Configuration Register)

Module Reset

This is a Software Module Reset for ICUM. For details, see **Section 45, Intelligent Cryptographic Unit/Master (ICUMD)**.

JTAG Reset

JTAG Reset is used for initialization of debug module. For details, see **Section 48, Boundary Scan**.

10.3.2 Reset Sources

Power Up Reset

A power up reset occurs when the SYSVCC power supply becomes valid (within specified limits). An internal power on clear (POC) circuit continuously monitors the voltage level of SYSVCC and asserts an internal power on reset to logic that is powered by SYSVCC. The RESF.PRESF0 bit will be set when this reset occurs.

For details on the POC specifications see *the RH850/E2x-FCC2 Electrical Characteristics, User's Manual: Hardware*.

Debugger Reset

This device (microcontroller) can be forcibly reset by a debugger.

For details, see **Section 47, Debugging and Calibration**.

Standby Reset

A standby reset occurs when returning from power off standby mode to normal operation mode (or user boot mode or serial programming mode). The RESF.SRES1F0 bit will be set when this condition occurs.

For details on standby functionality, see **Section 16, Standby Controller**.

External Reset (by RES_IN)

A dedicated Reset Input pin ($\overline{\text{RES_IN}}$) is available for initialization.

In case of an open reset input, the device will be initialized via the internal pull-down of the Reset Input Buffer.

In the case of Power-up and Power-down, $\overline{\text{RES_IN}}$ should be low. For details on the required $\overline{\text{RES_IN}}$ low period, see *the RH850/E2x-FCC2 Electrical Characteristics, User's Manual: Hardware*.

To activate a reset, $\overline{\text{RES_IN}}$ must be asserted low for a time longer than the noise filter. For details on the required $\overline{\text{RES_IN}}$ low pulse width, see *the RH850/E2x-FCC2 Electrical Characteristics, User's Manual: Hardware*.

VMON Reset

The VMON reset can be asserted as soon as one of the supply voltages is outside the operating range. The execution of the VMON reset can be masked. For details, see **Section 12, Power Supply Voltage Monitor**. The VMON reset operation is independent from External Reset.

ECM Reset

All failures that can be detected by the Error Control Module (ECM) generate dedicated internal resets or interrupts. The failure signals and system behavior can be configured in the ECM (see **Section 41, Error Control Module (ECM)**). Optionally, the device failures can be configured to be used as a Reset Source.

The ECM Reset can generate a System Reset 2 or an Application Reset. The behavior can be configured by the Reset Configuration Register.

SWDT Reset

The Secure Watchdog Timer (SWDT) module can generate a SWDT reset. For details, see **Section 46, Secure Watchdog Timer (SWDT)**.

Software Reset

The device supports multiple software resets that can trigger the reset of dedicated Reset Domains:

- Software System Reset Assertion Register (SWSRESA) triggers a System Reset 2

- Software Application Reset Assertion Register (SWARESA) triggers an Application Reset

Each software reset can be triggered when software writes to the associated Reset Assertion Register.

Each Reset Assertion Register is protected against unintended access by configuring the Key Code protection register. For details, see **Section 40, Functional Safety**.

JTAG Reset

A dedicated Reset Input pin ($\overline{\text{TRST}}$) is available for initialization of the Boundary Scan and debug function.

The Boundary Scan and Debug function are described in **Section 47, Debugging and Calibration** and **Section 48, Boundary Scan**.

The JTAG Reset is active low.

10.3.3 Reset Flags

Any reset root cause can be identified by SW in the Reset Factor Register (RESF). Each reset source will be indicated by one bit when it occurs. The status can be read out after the reset has been executed.

The method for determining the reset factors is shown in **Figure 10.1**.

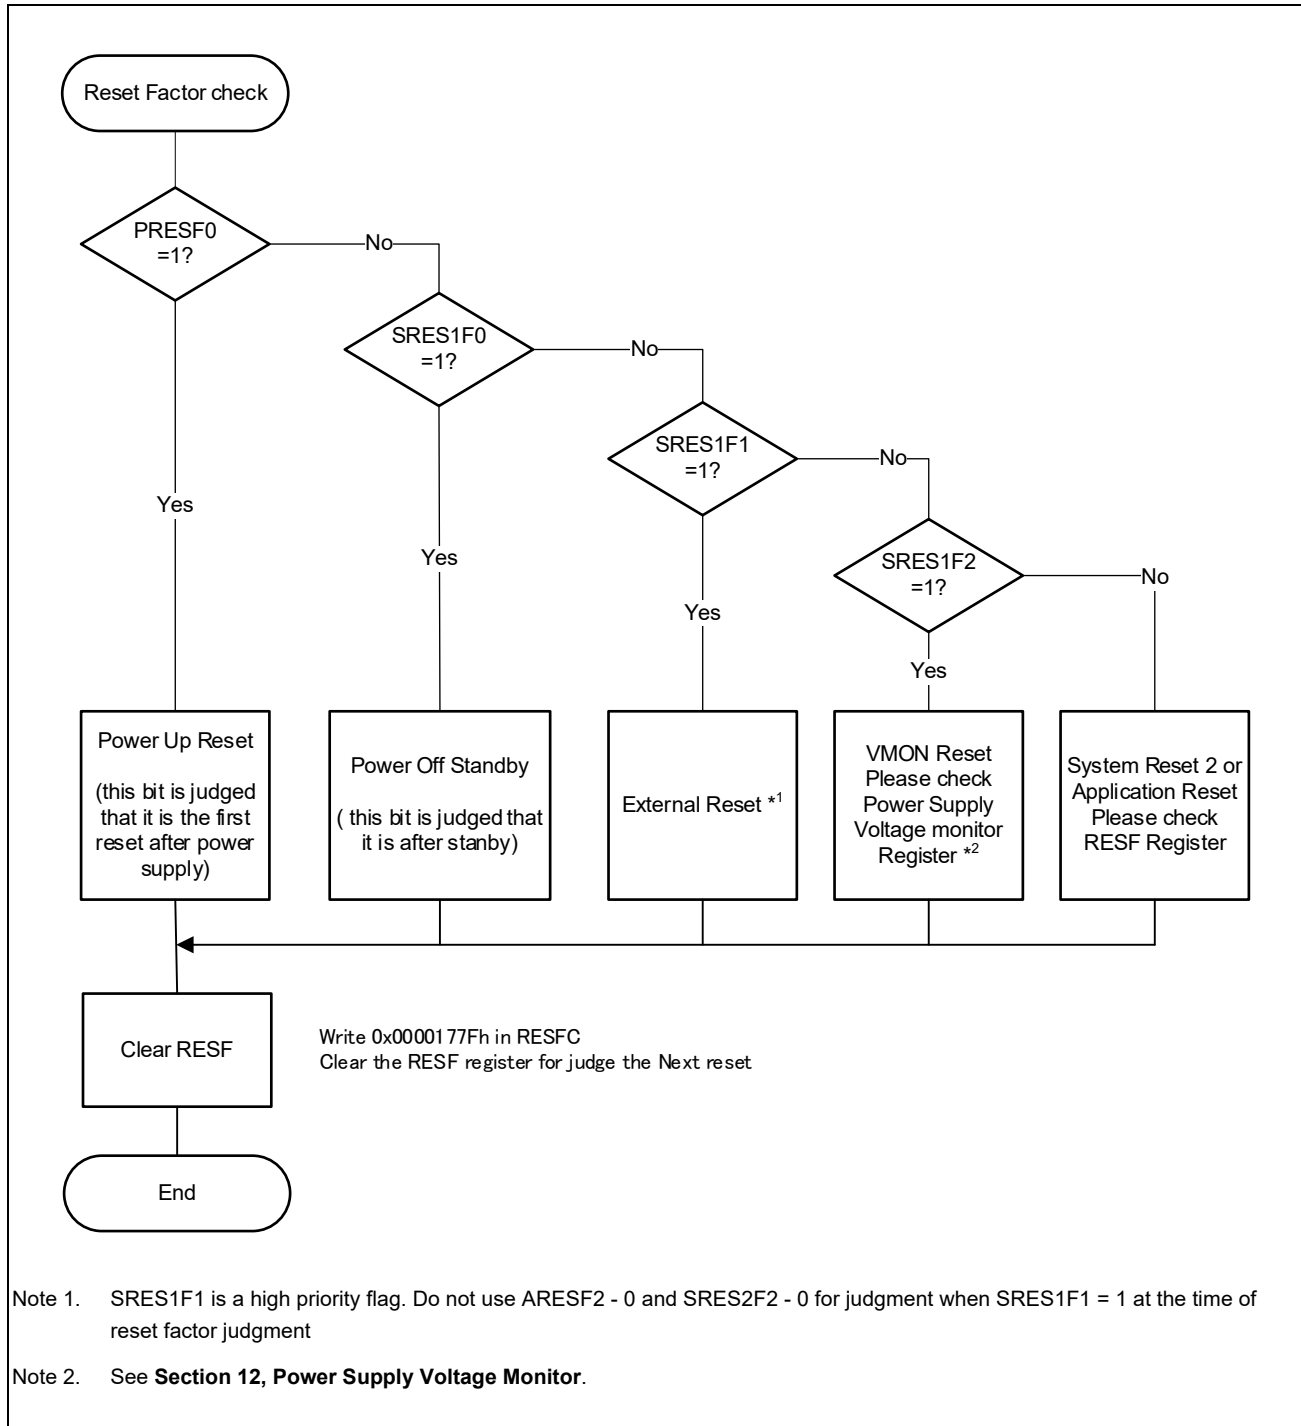

Figure 10.1 Flowchart of Reset Factor Result

10.3.4 FACI Reset Transfer

Transfer of Configuration settings, Block Protection settings, Security settings (Option Bytes) from FLASH memory are executed by System Reset 1 and System Reset 2.

These data become effective with completion of FACI transfer.

If FACI reset transfer Error is detected in Normal operation mode or in User boot mode, the device will be kept in reset state and will not start up.

FACI reset transfer Error is an error factor of the ECM.

Configuration Setting Area/ Block Protection Area/Security Setting Area has two-area (Valid/Invalid area) structure and remain previous settings in Invalid area. If occur unintended switching of Valid/Invalid area, not notify error to ECM. If care regarding in this case, by comparing the read settings and the settings recorded separately, It is possible to detect the influence of unintended switching of Valid/Invalid area. Also, if the command is executed twice that setting the same settings, the settings of the two areas will be the same due to remain previous settings in the invalid area. In this way it is possible to eliminate the influence of unintended switching of Valid/Invalid area.

For details on two-area structure , refer to the RH850/E2x Flash Memory User's Manual: Hardware Interface which this product targets.

10.3.5 HW BIST

HW BIST is executed by System Reset 1 and System Reset 2.

For System Reset 2, HW BIST execution can be disabled. For details, see **Section 40.6, BIST**.

10.3.6 RAM Initialization

RAM data can be initialized (to all 0) according to the setting of a Flash option byte. This initialization, if enabled by the flash option byte, will occur for a system reset 1, a system reset 2, and an application reset (if the value of the STAC register is not changed by using a flash option byte). For an Application Reset and Module Reset, RAM initialization can also be controlled by STAC register. for the Module Reset of ICUM, only RAM data of ICUM can be initialized (to all 0) depending on a STAC register of ICU-M.

A separate flash option byte exists for each major RAM block, so that each block is independently controlled.

Target RAM

- DTS RAM
- sDMAC Descriptor RAM
- DFE RAM
- FlexRay RAM
- Ethernet RAM
- GTM RAM

Local RAM and Cluster RAM are initialized by using a software write instruction.

10.3.7 Reset Output ($\overline{\text{RES_OUT}}$)

A dedicated Reset Output pin $\overline{\text{RES_OUT}}$ is available for indicating when the microcontroller is in reset and for controlling the reset of external devices. It will be asserted by all reset categories (except Module Reset and JTAG Reset).

For the $\overline{\text{RES_OUT}}$ function, refer to **Section 2.6.8, $\overline{\text{RES_OUT}}$ Function.**

10.4 Usage Notes

10.4.1 RAM and Register Data Retention when External Reset Is Asserted

The data of RAM and registers*¹ will not be retained if the operating modes differ when an external reset is asserted or released by a change of the value set to the corresponding external terminal (e.g. MD0, TRST).

Note 1. Registers that are not initialized by External Reset.

Table 10.20 RAM and Register Data Retention when External Reset Is Asserted

Release Timing	Assert Timing		
	Normal Operation Mode	User Boot Mode	Serial Programming Mode
Normal Operation Mode	Retained	Retained	Not retained
User Boot Mode	Retained	Retained	Not retained
Serial Programming Mode	Not retained	Not retained	Retained

Note: The data of MBIST target RAM is not retained in BIST. For details about MBIST target, see **Section 40.6.2.10, MBIST1FTAG0, Section 40.6.2.11, MBIST1FTAG1, Section 40.6.2.12, MBIST1FTAG2, Section 40.6.2.13, MBIST1FTAG3, Section 40.6.2.14, MBIST1FTAG4, Section 40.6.2.15, MBIST1FTAG5 and Section 40.6.2.16, MBIST1FTAG6.**

10.4.2 VMON Reset Assertion

The data of RAM and registers*¹ will not be retained when the VMON reset is asserted.

Note 1. Registers are not initialized by VMON Reset.

Section 11 Power Supply

11.1 Features

This section describes the external voltage connection and internal voltage distribution.

11.2 External Pin List

Table 11.1 shows the list of external pins.

Table 11.1 List of External Pins

Power Supply Name	Power Related Pin Name	Power Combination Condition		Usage
		Operational Voltage Range (3 supply)	Operational Voltage Range (VDD & 5 V)	
E0VCC		4.5 V to 5.5 V	4.5 V to 5.5 V	Port IOs The same power source can be used with each power supply that uses the same voltage range. Refer to Figure 11.1 See the <i>RH850/E2x-FCC2 Electrical Characteristics, User's Manual: Hardware</i> for the supported functions with each voltage range.
E1VCC		3.0 V to 3.6 V or 4.5 V to 5.5 V		
E2VCC		3.0 V to 3.6 V or 4.5 V to 5.5 V		
LVDVCC* ³		3.0 V to 3.6 V or 4.5 V to 5.5 V	4.5 V to 5.5 V	RHSIF LVDS outputs. The power source of LVDVCC should be the same with E0VCC while the GPIO shared with RHSIF is used. Refer to Figure 11.2 .
SYSVCC		3.0 V to 3.6 V	4.5 V to 5.5 V	System logics, retention RAM
VCC		3.0 V to 3.6 V	4.5 V to 5.5 V	Oscillator, PLL, Flash programming
	RAMSVCL	—	—	Stabilizing capacitance for retained RAM
EMUVCC* ¹		3.0 V to 3.6 V	3.0 V to 3.6 V	ERAM / Instrumentation RAM, Aurora
EMUVDD* ¹		1.025 V to 1.155 V* ²	1.025 V to 1.155 V* ²	ERAM / Instrumentation RAM, Aurora (When do not use Aurora IF)
		1.04 V to 1.14 V	1.04 V to 1.14 V	ERAM / Instrumentation RAM ,Aurora (When use Aurora IF)
VDD		1.025 V to 1.155 V	1.025 V to 1.155 V	Core logics
A0VCC		4.5 V to 5.5 V	4.5 V to 5.5 V	SAR-ADC * ³
A1VCC		4.5 V to 5.5 V	4.5 V to 5.5 V	* ³
A2VCC		4.5 V to 5.5 V	4.5 V to 5.5 V	* ³
A3VCC		4.5 V to 5.5 V	4.5 V to 5.5 V	* ³
	A0VREFH	4.5 V to 5.5 V	4.5 V to 5.5 V	Reference voltage for SAR-ADC
	A1VREFH	4.5 V to 5.5 V	4.5 V to 5.5 V	
	A2VREFH	4.5 V to 5.5 V	4.5 V to 5.5 V	
	A3VREFH	4.5 V to 5.5 V	4.5 V to 5.5 V	
ADSVCC		4.5 V to 5.5 V	4.5 V to 5.5 V	DS-ADC, and Cyclic-ADC * ³
	ADSVREFH	4.5 V to 5.5 V	4.5 V to 5.5 V	Reference voltage for power for DS-ADC, and Cyclic-ADC
	ADSVCL	—	—	Stabilizing capacitance for DS-ADC operation

- Note 1. Only E2x-FCC2 supports EMUVCC, EMUVDD.
- Note 2. Only when using Aurora. EMUVDD max = 1.14 V min = 1.04 V when not using Aurora.
- Note 3. The same power source shall be used with each A0VCC, A1VCC, A2VCC, A3VCC, and ADSVCC power supply.
See the application note separately issued.

11.3 Example of Power Supply Connection

11.3.1 Example of Power Supply Connection

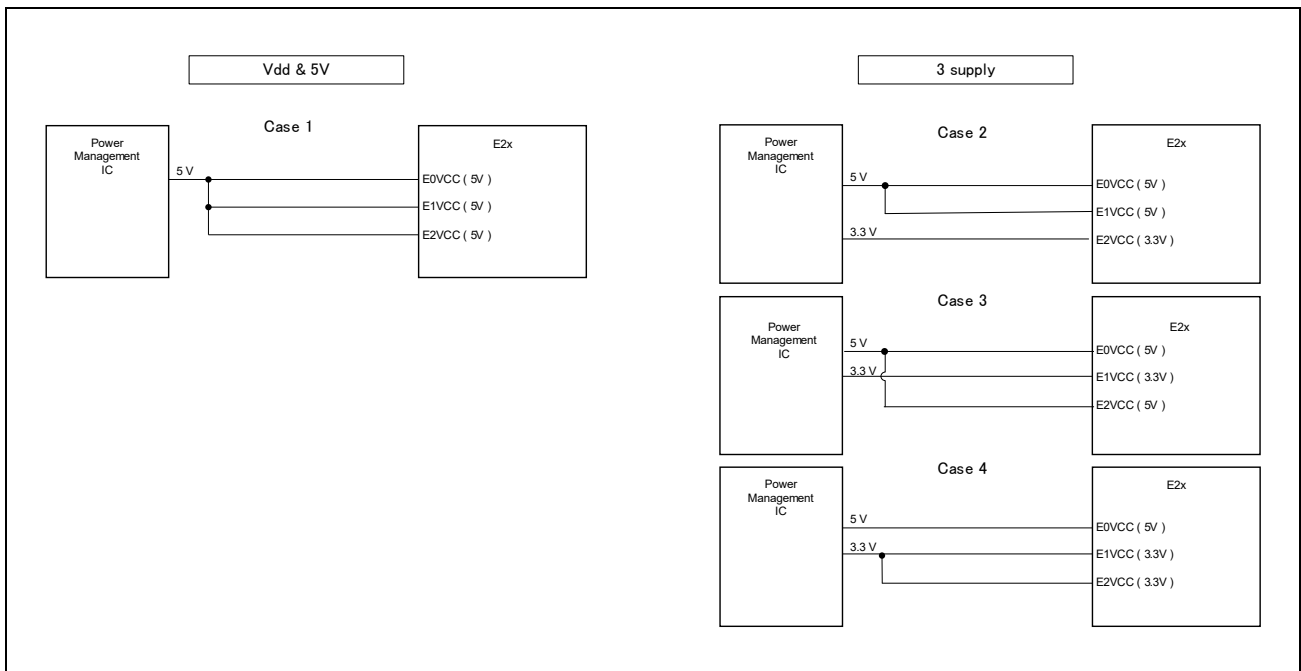

Figure 11.1 Combinations of power connection about EnVCC (n = 0 to 2)

The power source connection policy for EnVCC (n = 0 to 2):

In the case of VDD and 5V, the power source shall be connected as in Case 1.

In the case of 3 power supplies, the power source shall be connected as in Cases 2 to 4.

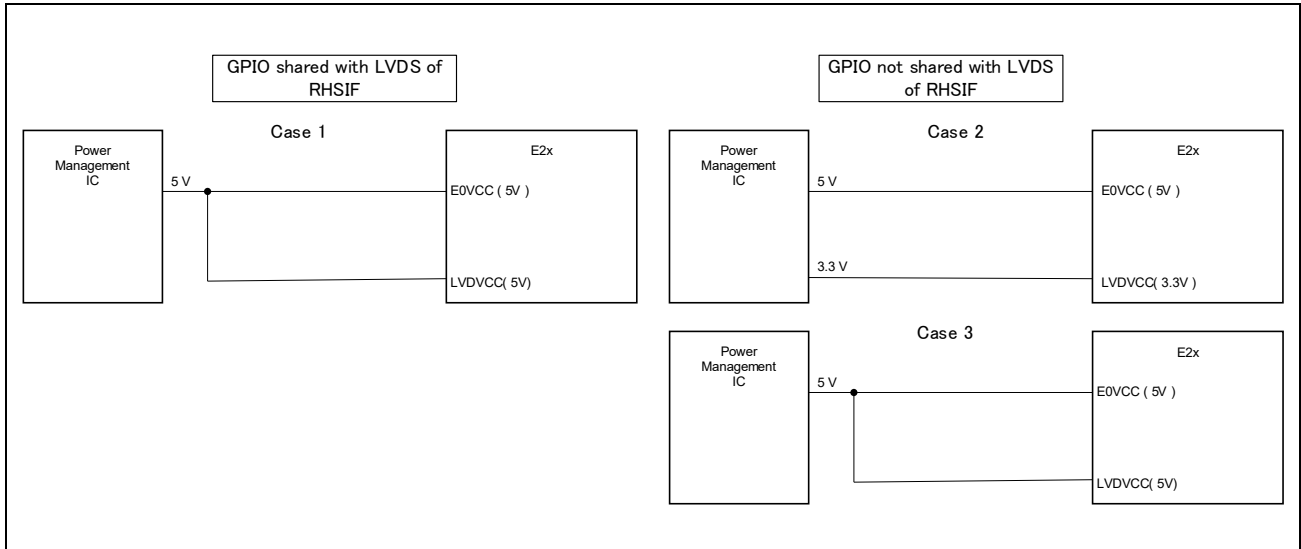

Figure 11.2 Combinations of the power connection about E0VCC and LVDVCC

The power source connection policy about LVDVCC that concerns E0VCC.

i) Case to use GPIO shared with LVDS of RHSIF

The power source of LVDVCC should be the same as the source of E0VCC if the user uses the GPIO shared with the LVDS of RHSIF. The combinations of the power connection are restricted as Case 1 in **Figure 11.2**.

ii) Case NOT to use GPIO shared with the LVDS of RHSIF

The power source of LVDVCC can be set independently of the source of E0VCC (Case 2 or Case 3).

11.4 Power Up/Down Timing

See details in the *RH850/E2x-FCC2 Electrical Characteristics, User's Manual: Hardware*.

11.5 Usage Note

The handling of the power supply pins is described in this section.

For the handling of unused pins, see **Section 2, Pin Function**.

Table 11.2 List of External Pins

Power Supply Name	Power Related Pin Name	Required Setting	Recommended Handling
EnVCC (n = 0 to 2)			Connect an external capacitor to suit the conditions of usage.
SYSVCC		Decoupling capacitor: 0.1 μF $\pm 30\%$	
VCC		Stabilizing capacitor for power: 10 μF $\pm 30\%$ or higher	Decoupling capacitor for each pin
	RAMSVCL	Stabilizing capacitor for power: 0.22 μF $\pm 30\%$	See the application note separately issued.
EMUVCC* ¹		Inductor* ² : 1 μH $\pm 20\%$ including 1 Ω $\pm 5\%$ resistor	Refer to Figure 11.3 as an example.
		Decoupling capacitors* ² : 2.2 μF $\pm 20\%$	
EMUVDD* ¹		Decoupling capacitors* ³ : 0.1 μF $\pm 30\%$ and 0.01 μF $\pm 30\%$	Refer to Figure 11.3 as an example.
VDD		Decoupling capacitors: 0.1 μF $\pm 20\%$ and 10 μF $\pm 20\%$	See the application note separately issued.
LVDVCC			See the application note separately issued.
AnVCC (n = 0 to 3)			See the application note separately issued.
	AnVREFH (n = 0 to 3)		See the application note separately issued.
ADSVCC			See the application note separately issued.
	ADSVREFH		See the application note separately issued.
	ADSVCL		See the application note separately issued.

Note 1. Only E2xFCC2 supports EMUVCC, EMUVDD.

Note 2. When Aurora IF is not used, Ferrite Beads is not required. Use the same capacitor with SYSVCC in that case.

Note 3. When Aurora IF is not used, only 0.1 μF capacitors are required.

Note 1. This resistor is included in the inductor.

Figure 11.3 Filtering and Bypass Condenser Reference Design for EMUVCC and EMUVDD

Section 12 Power Supply Voltage Monitor

12.1 Overall Configuration

12.1.1 Features

- The power supply voltage monitor is used for monitoring the domains E0VCC (hereafter called EVCC in this section), VCC and VDD.
The power supply voltage monitor has H-side (HDET) and L-side (LDET) voltage detectors, which detect if the monitored voltage is higher or lower than the specified voltage. See **Figure 12.1** and **Figure 12.2** for the detection level.
- The power supply voltage monitor has two types of detection functions: Primary detection and Secondary detection
- Primary detection is conducted by Voltage Monitor. For details, refer to **Section 12.2, Primary Detection of Voltage Monitor**.
- Secondary detection is conducted by SAR-ADC. For details, refer to **Section 36, Analog to Digital Converter (ADCH)**.
- Delay Monitor (DMON) assists VMON which detects the L-side voltage of VDD. For details, refer to **Section 12.2.9.2, VCC Primary Low Detection**.
- Delay Monitor (DMON) assists the power supply voltage monitor (VMON) to detect the low level voltage of VDD. For details, refer to **Section 12.3, Delay Monitor (DMON)**.
- Primary power supply voltage monitor can be set ON/OFF for the VMON reset high level and low level detection of VDD, with a high level of VCC and EVCC. Low level detection of VCC and EVCC always raises VMON reset.
- Primary detection voltage value is fixed, secondary detection voltage value can be set by the SAR-ADC.
- If the Secondary power supply voltage monitor detects voltage failures, it notifies the error to the ECM. In this case, it is possible to generate an interrupt or reset by setting the ECM. For details, refer to **Section 41, Error Control Module (ECM)**.
Figure 12.3 shows the construction of the notification with primary and secondary voltage monitor.

Figure 12.1 VMON Detection Level (VDD)

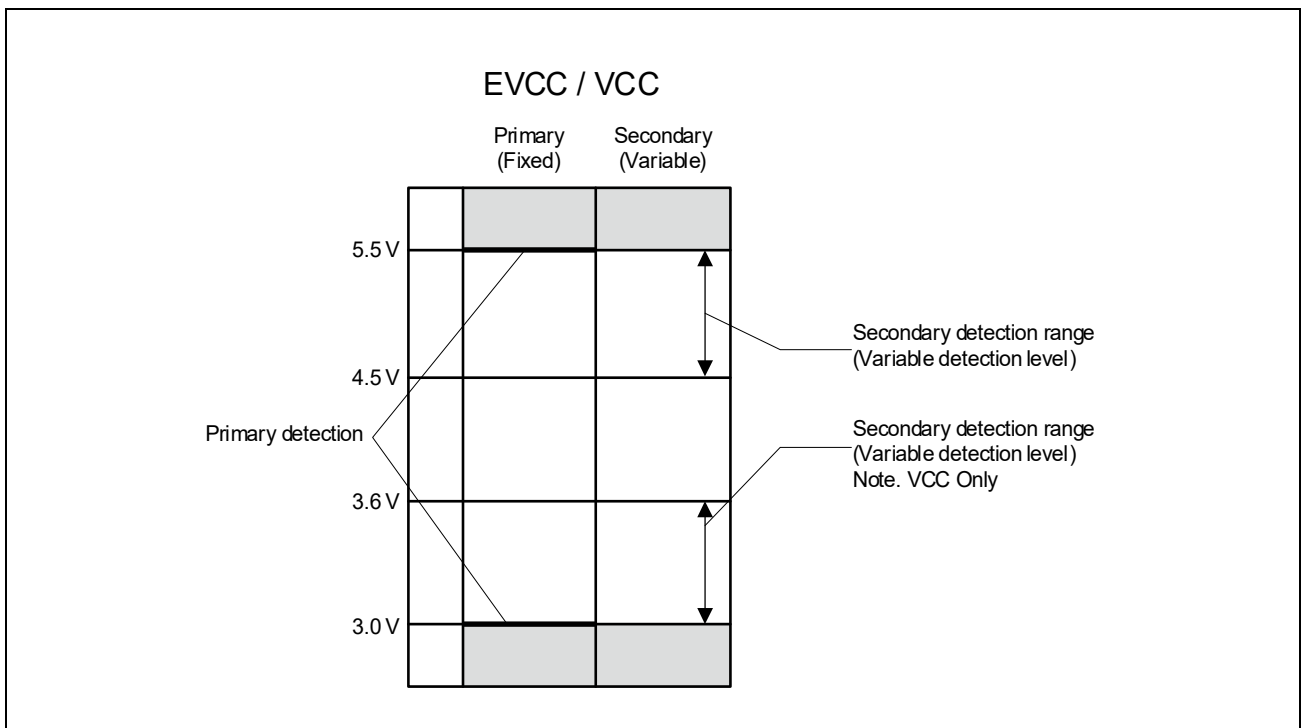

Figure 12.2 VMON Detection Level (EVCC / VCC)

Figure 12.3 Block Diagram of Power Supply Voltage Monitor (Overall)

12.2 Primary Detection of Voltage Monitor (VMON)

12.2.1 Features

- Violation of the operating range of each voltage is indicated by:
 - Error output pin ($\overline{\text{ERROROUT_M}}$)
 - Each power supply voltage high and low-voltage flags
 - VMON Reset
- Diagnostic function:
 - VMON function is testable.
 - High and low-voltage errors can be generated without influencing the voltage itself.
 - VMON error test is done by changing the reference voltage.
 - The signal path to the $\overline{\text{ERROROUT_M}}$ pin can optionally be masked.

12.2.2 Register Base Address

The voltage Monitor base address is given in the following table.

Voltage Monitor register addresses are given as offsets from the base addresses in general.

Table 12.1 Register Base Address

Base Address Name	Base Address	Bus Group
<VMON_base>	FF70 1800 _H	Peripheral Group 6

12.2.3 Clock Supply

The clock supply to VMON is shown in **Table 12.2**.

Table 12.2 Clock Supply

Unit Name	Unit Clock Name	Clock Name
VMON	Digital noise filter clock	CLK_HVIOOSC
	Register access clock	CLK_LSB

12.2.4 Interrupt Requests

This module has no interrupt requests.

12.2.5 External Input and Output Pins

The I/O pin related to reset is given in **Table 12.3**.

Table 12.3 I/O Pin

Pin Function Name	Direction	Description
$\overline{\text{ERROROUT_M}}$	Output	VMON error detection output, ECM error output

12.2.6 Overview

12.2.6.1 Block Diagram

Figure 12.4, Figure 12.5 and Figure 12.6 show the block diagram of the power supply voltage monitor.

Figure 12.4 Block Diagram of the Power Supply Voltage Monitor (VDD)

Figure 12.5 Block Diagram of the Power Supply Voltage Monitor (VCC)

Figure 12.6 Block Diagram of the Power Supply Voltage Monitor (EVCC)

12.2.7 Registers

12.2.7.1 List of Registers

The list of registers related to VMON is shown in **Table 12.4**.

Table 12.4 List of Registers

Unit Name	Register Name	Symbol	Address	Access Size	Access Protection
VMON	VMON Factor Register	VMONF	<VMON_base>+ 000 _H	8	—
VMON	VMONF Clear Register	VMONFC	<VMON_base>+ 004 _H	8	VMONKCPROT
VMON	VMON DIAG Monitor Enable Register	VMONDIAGME	<VMON_base>+ 008 _H	8	—
VMON	VMONDIAGME Write Register* ¹	VMONDIAGMEW	<VMON_base>+ 00C _H	8	VMONKCPROT
VMON	VMON Detection Output Diagnosis MASK Register	VMONDMASK	<VMON_base>+ 010 _H	8	—
VMON	VMON DIAG Mode Setting Register	VMONDIAG	<VMON_base>+ 014 _H	8	—
VMON	VMON DIAG Filter Enable Register	VMONDIAGFE	<VMON_base>+ 018 _H	8	—
VMON	VDD Detection Enable Register	VDDDE	<VMON_base>+ 080 _H	8	VMONKCPROT
VMON	VDD Monitor Filter Control Register	VDDFCR	<VMON_base>+ 084 _H	8	—

EVCCDE	✓	✓*1	—	—	—	—
EVCCFCR	✓	✓*1	—	—	—	—
VMONKCPROT	✓	✓	✓	—	—	—

Note 1. VMON Reset is excluded.

Note 2. Standby reset only

12.2.7.2 VMONF — VMON Factor Register

VMONF register indicates that an error is detected by VMON. Each flag of VMONF can be cleared individually by writing “1” to the corresponding bit in VMONFC.

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	EVCCCHVF	EVCCCLVF	VCCHVF	VCCLVF	VDDHVF	VDDLVF
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R

Table 12.6 VMONF Register Contents

Bit Position	Bit Name	Function
7 to 6	—	Reserved When read, the value after reset is returned.
5	EVCCCHVF	EVCC high voltage detection flag 0: No high EVCC voltage violation detected 1: High EVCC voltage violation occurred
4	EVCCCLVF	EVCC low voltage detection flag 0: No low EVCC voltage violation detected 1: low EVCC voltage violation occurred
3	VCCHVF	VCC high voltage detection flag 0: No high VCC voltage violation detected 1: High VCC voltage violation occurred
2	VCCLVF	VCC low voltage detection flag 0: No low VCC voltage violation detected 1: low VCC voltage violation occurred
1	VDDHVF	VDD high voltage detection flag 0: No high VDD voltage violation detected 1: High VDD voltage violation occurred
0	VDDLVF	VDD low voltage detection flag 0: No low VDD voltage violation detected 1: low VDD voltage violation occurred

12.2.7.3 VMONFC — VMONF Clear Register

VMONFC is a register to clear the VMONF register. The read value of this register is always 00_H.

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	EVCCHVFC	EVCLLVFC	VCCHVFC	VCCLLVFC	VDDHVFC	VDDLVC
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	W	W	W	W	W	W

Table 12.7 VMONFC Register Contents

Bit Position	Bit Name	Function
7 to 6	—	Reserved When writing, write the value after reset.
5	EVCCHVFC	Clear EVCC high voltage detection flag 0: Writing 0 has no effect 1: Writing 1 clears EVCCHVF
4	EVCLLVFC	Clear EVCC low voltage detection flag 0: Writing 0 has no effect 1: Writing 1 clears EVCLLVF
3	VCCHVFC	Clear VCC high voltage detection flag 0: Writing 0 has no effect 1: Writing 1 clears VCCHVF
2	VCCLLVFC	Clear VCC low voltage detection flag 0: Writing 0 has no effect 1: Writing 1 clears VCCLLVF
1	VDDHVFC	Clear VDD high voltage detection flag 0: Writing 0 has no effect 1: Writing 1 clears VDDHVF
0	VDDLVC	Clear VDD low voltage detection flag 0: Writing 0 has no effect 1: Writing 1 clears VDDLVC

12.2.7.4 VMONDIAGME — VMON DIAG Monitor Enable Register

VMONDIAGME is a read only register to control the VMON DIAG function.

This register reflects the settings written to VMONDIAGMEW.

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	VMONDIAGME
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R

Table 12.8 VMONDIAGME Register Contents

Bit Position	Bit Name	Function
7 to 1	—	Reserved When read, the value after reset is returned.
0	VMONDIAGME	Permit DIAG function 0: DIAG function of the Voltage Monitor can be enabled 1: DIAG function of the Voltage Monitor cannot be enabled

12.2.7.5 VMONDIAGMEW — VMONDIAGME Write Register

VMONDIAGMEW is a register to set values of VMONDIAGME. Writing is permitted only once after Standby Reset or External Reset are released. Subsequent write operations are ignored. The read value of this register is always 00_H.

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	VMON DIAGMEW
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	W

Table 12.9 VMONDIAGMEW Register Contents

Bit Position	Bit Name	Function
7 to 1	—	Reserved When writing, write the value after reset.
0	VMONDIAGMEW	The data written in this bit is set to VMONDIAGME.

12.2.7.6 VMONDMASK — VMON Detection Output Diagnosis Mask Register

VMONDMASK is a register to mask VMON_ERROROUT and VMON Reset when VMONDIAGME = 0.

The VMONDMASK setting is ignored if VMONDIAGME.VMONDIAGME = 1.

Writing to VMONDMASK is permitted during the period from External Reset release until writing to VMONDIAGMEW.

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	EVCCRESMD	VCCRESMD	VDDRESMD	—	EVCCERRMD	VCCERRMD	VDDERRMD
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R/W	R/W	R/W	R	R/W	R/W	R/W

Table 12.10 VMONDMASK Register Contents

Bit Position	Bit Name	Function
7	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
6	EVCCRESMD	This bit masks VMON_EVCC_REQ_RESET when VMONDIAGME.VMONDIAGME = 0. 0: VMON_EVCC_REQ_RESET is not masked. 1: VMON_EVCC_REQ_RESET is masked.
5	VCCRESMD	This bit masks VMON_VCC_REQ_RESET when VMONDIAGME.VMONDIAGME = 0. 0: VMON_VCC_REQ_RESET is not masked. 1: VMON_VCC_REQ_RESET is masked.
4	VDDRESMD	This bit masks VMON_VDD_REQ_RESET when VMONDIAGME.VMONDIAGME = 0. 0: VMON_VDD_REQ_RESET is not masked. 1: VMON_VDD_REQ_RESET is masked.
3	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
2	EVCCERRMD	This bit masks VMON_EVCC_ERROROUT when VMONDIAGME.VMONDIAGME = 0. 0: VMON_EVCC_ERROROUT is not masked. 1: VMON_EVCC_ERROROUT is masked.
1	VCCERRMD	This bit masks VMON_VCC_ERROROUT when VMONDIAGME.VMONDIAGME = 0. 0: VMON_VCC_ERROROUT is not masked. 1: VMON_VCC_ERROROUT is masked.
0	VDDERRMD	This bit masks VMON_VDD_ERROROUT when VMONDIAGME.VMONDIAGME = 0. 0: VMON_VDD_ERROROUT is not masked. 1: VMON_VDD_ERROROUT is masked.

12.2.7.7 VMONDIAG — VMON DIAG Mode Setting Register

VMONDIAG forces VMON comparators to output an error. This register is valid only when VMONDIAGME = 0. VMONDIAG's setting is ignored if VMONDIAGME.VMONDIAGME = 1.

Writing to VMONDIAG is permitted during the period from External Reset release until writing to VMONDIAGMEW.

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	EVCCDIAGH	EVCCDIAGL	VCCDIAGH	VCCDIAGL	VDDDIAGH	VDDDIAGL
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R/W	R/W	R/W	R/W	R/W	R/W

Table 12.11 VMONDIAG Register Contents

Bit Position	Bit Name	Function
7, 6	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
5	EVCCDIAGH	This bit can change the detection level of high voltage detector to low level intentionally when VMONDIAGME.VMONDIAGME = 0. 0: EVCC for high voltage monitors normally. 1: EVCC for high voltage will detect violation condition because detection level changes.
4	EVCCDIAGL	This bit can change the detection level of low voltage detector to high level intentionally when VMONDIAGME.VMONDIAGME = 0. 0: EVCC for low voltage monitors normally. 1: EVCC for low voltage will detect violation condition because detection level changes.
3	VCCDIAGH	This bit can change the detection level of high voltage detector to low level intentionally when VMONDIAGME.VMONDIAGME = 0. 0: VCC for high voltage monitors normally. 1: VCC for high voltage will detect violation condition because detection level changes.
2	VCCDIAGL	This bit can change the detection level of low voltage detector to high level intentionally when VMONDIAGME.VMONDIAGME = 0. 0: VCC for low voltage monitors normally. 1: VCC for low voltage will detect violation condition because detection level changes.
1	VDDDIAGH	This bit can change the detection level of high voltage detector to low level intentionally when VMONDIAGME.VMONDIAGME = 0. 0: VDD for high voltage monitors normally. 1: VDD for high voltage will detect violation condition because detection level changes.
0	VDDDIAGL	This bit can change the detection level of low voltage detector to high level intentionally when VMONDIAGME.VMONDIAGME = 0. 0: VDD for low voltage monitors normally. 1: VDD for low voltage will detect violation condition because detection level changes.

12.2.7.8 VMONDIAGFE — VMON DIAG Filter Enable Register

VMONDIAGFE specifies whether the output filter for ERROROUT is enabled.

This register is valid only when VMONDIAGME = 0. The setting of this register is ignored if VMONDIAGME.VMONDIAGME = 1.

Writing to VMONDIAGFE is permitted during the period from External Reset release until writing to VMONDIAGMEW.

VMON reset does not occur when each bit is set to 0.

Value after reset: 07_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	EVCC DIAGFLTEN	VCC DIAGFLTEN	VDD DIAGFLTEN
Value after reset	0	0	0	0	0	1	1	1
R/W	R	R	R	R	R	R/W	R/W	R/W

Table 12.12 VMONDIAGFE Register Contents

Bit Position	Bit Name	Function
7 to 3	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
2	EVCCDIAGFLTEN	Enable output filter for VMON_EVCC_ERROROUT when VMONDIAGME.VMONDIAGME = 0. 0: Disable output filter for VMON_EVCC_ERROROUT 1: Enable output filter for VMON_EVCC_ERROROUT
1	VCCDIAGFLTEN	Enable output filter for VMON_VCC_ERROROUT when VMONDIAGME.VMONDIAGME = 0. 0: Disable output filter for VMON_VCC_ERROROUT 1: Enable output filter for VMON_VCC_ERROROUT
0	VDDDIAGFLTEN	Enable output filter for VMON_VDD_ERROROUT when VMONDIAGME.VMONDIAGME = 0. 0: Disable output filter for VMON_VDD_ERROROUT 1: Enable output filter for VMON_VDD_ERROROUT

12.2.7.9 VDDDE — VDD Detection Enable Register

VDDDE is a register to control VMON reset, VMON signal mask and VMON signal filter.

Bits 3, 1, 0 are set by the flash option byte when Standby Reset or External Reset is released.

Writing to VDDDE is permitted during the period from External Reset release until writing to VMONDIAGMEW.

Value after reset: 0X_H

Bit	7	6	5	4	3	2	1	0
	VDDCIRREN[2:0]			VDDFBISTME	VDDFLTEN	—	VDDHDE	VDDLDE
Value after reset	0	0	0	0	X	0	X	X
R/W	R/W	R/W	R/W	R/W	R	R	R	R

Table 12.13 VDDDE Register Contents

Bit Position	Bit Name	Function
7 to 5	VDDCIRREN[2:0]	Permit VMON reset by VDD detection. VDDCIRREN 2 to 0 101 _B : VMON reset by VDD high voltage detection is permitted 110 _B : VMON reset by VDD low voltage detection is permitted 111 _B : VMON reset by VDD high/low voltage detection is permitted Other value: VMON reset by VDD detection is not permitted
4	VDDFBISTME	When this bit is set to 0, VMON_VDD_ERROROUT and VMON_VDD_REQRESET are masked when BIST is carried out after VMON Reset. When this bit is set to 1, VMON_VDD_ERROROUT and VMON_VDD_REQRESET are not masked when BIST is carried out after VMON Reset. 0 : During BIST the VMON_VDD_ERROROUT and VMON_VDD_REQRESET can be masked 1 : During BIST the VMON_VDD_ERROROUT and VMON_VDD_REQRESET cannot be masked Note: VMON_VDD_ERROROUT output and VMON_VDD_REQRESET are always masked when BIST is carried out after Standby Reset or External Reset. VMON_VDD_ERROROUT output and VMON_VDD_REQRESET are never masked when BIST is carried out after System Reset 2.
3	VDDFLTEN	Enable output filter for $\overline{\text{ERROROUT_M}}$ and VMONF. 0: Disable output filter for $\overline{\text{ERROROUT_M}}$ and VMONF. 1: Enable output filter for $\overline{\text{ERROROUT_M}}$ and VMONF.
2	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
1	VDDHDE	VDD High voltage detection enable 0: Disable VDD high voltage detection 1: Enable VDD high voltage detection
0	VDDLDE	VDD Low voltage detection enable 0: Disable VDD low voltage detection 1: Enable VDD low voltage detection

12.2.7.10 VDDFCR — VDD Monitor Filter Control Register

VDDFCR is a register to adjust the filtering width of VDD Monitor digital noise filter.

This register is set by the flash option byte when Standby Reset or External Reset is released.

Value after reset: 0X_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	VDDFLTW[1:0]		VDDCLKSEL[1:0]	
Value after reset	0	0	0	0	X	X	X	X
R/W	R	R	R	R	R	R	R	R

Table 12.14 VDDFCR Register Contents

Bit Position	Bit Name	Function
7 to 4	—	Reserved When read, the value after reset is returned.
3, 2	VDDFLTW[1:0]	These bits select the minimum filtering width of digital noise filter. (The minimum filtering width is given by cycle-count of the clock selected by VDDCLKSEL1, 0.)
	VDDFLTW[1:0]	Minimum Filtering Width (Cycle)
	00	20 cycles
	01	13 cycles
	10	8 cycles
	11	3 cycle
1, 0	VDDCLKSEL[1:0]	These bits select the clock of the digital noise filter from the following clocks.
	VDDCLKSEL[1:0]	Clock of the Digital Filter
	00	CLK_HVIOSC frequency / 256
	01	CLK_HVIOSC frequency / 128
	10	CLK_HVIOSC frequency / 64
	11	CLK_HVIOSC frequency / 32
CAUTION: The frequency of CLK_HVIOSC is typ. 16 MHz, min. 8 MHz.		

Wait specified time = 10us + Digital noise filter width.

For example, VDDFLTW[1:0] = 00b VDDCLKSEL[1:0] = 00b

Wait specified time = 10us + 20cycle * 256 * 62.5ns = 330us

12.2.7.11 VCCDE — VCC Detection Enable Register

VCCDE is a register to control VMON reset, VMON signal mask and VMON signal filter.

Bits 3, 1 are set by the flash option byte when Standby Reset or External Reset is released.

Writing to VCCDE is permitted during the period from External Reset release until writing to VMONDIAGMEW.

Value after reset: 0X_H

Bit	7	6	5	4	3	2	1	0
	VCCIRREN1	—	VCCIRREN0	—	VCCFLTEN	—	VCCHDE	—
Value after reset	0	0	0	0	X	0	X	0
R/W	R/W	R	R/W	R	R	R	R	R

Table 12.15 VCCDE Register Contents

Bit Position	Bit Name	Function
7	VCCIRREN1	Permit VMON reset by VCC high voltage detection. VCCIRREN1,0 11 _B : VMON reset by VCC high voltage detection is permitted Other value: VMON reset by VCC high voltage detection is not permitted
6	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
5	VCCIRREN0	Refer to bit 7 (VCCIRREN1).
4	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
3	VCCFLTEN	Enable output filter for $\overline{\text{ERROROUT_M}}$ and VMONF. 0: Disable output filter for $\overline{\text{ERROROUT_M}}$ and VMONF. 1: Enable output filter for $\overline{\text{ERROROUT_M}}$ and VMONF.
2	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
1	VCCHDE	VCC high voltage detection enable 0: Disable VCC high voltage detection 1: Enable VCC high voltage detection
0	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.

12.2.7.12 VCCFCR — VCC Monitor Filter Control Register

VCCFCR is a register to adjust the filtering width of the VCC Monitor digital noise filter.

This register is set by the flash option byte when Standby Reset or External Reset is released.

Value after reset: 0X_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	VCCFLTW[1:0]		VCCCLKSEL[1:0]	
Value after reset	0	0	0	0	X	X	X	X
R/W	R	R	R	R	R	R	R	R

Table 12.16 VCCFCR Register Contents

Bit Position	Bit Name	Function
7 to 4	—	Reserved When read, the value after reset is returned.
3, 2	VCCFLTW[1:0]	These bits select the minimum filtering width of digital noise filter. (The minimum filtering width is given by the cycle-count of the clock selected by VCCCLKSEL1, 0.)
	VCCFLTW[1:0]	Minimum Filtering Width (Cycle)
	00	20 cycles
	01	13 cycles
	10	8 cycles
	11	3 cycles
1, 0	VCCCLKSEL[1:0]	These bits select the clock of the digital noise filter from the following clocks.
	VCCCLKSEL[1:0]	Clock of the Digital Filter
	00	CLK_HVIOSC frequency / 256
	01	CLK_HVIOSC frequency / 128
	10	CLK_HVIOSC frequency / 64
	11	CLK_HVIOSC frequency / 32
CAUTION: The frequency of CLK_HVIOSC is typ. 16 MHz, min. 8 MHz.		

Wait specified time = 10us + Digital noise filter width.

For example, VCCFLTW[1:0] = 00b VCCCLKSEL[1:0] = 00b

Wait specified time = 10us + 20cycle * 256 * 62.5ns = 330us

12.2.7.13 EVCCDE — EVCC Detection Enable Register

EVCCDE is register to control VMON reset, VMON signal mask and VMON signal filter.

Bits 3 and 1 are set by the flash option byte when Standby Reset or External Reset is released.

Writing to EVCCDE is permitted during the period from External Reset release until writing to VMONDIAGMEW.

Value after reset: 0X_H

Bit	7	6	5	4	3	2	1	0
	EVCCIRREN1	—	EVCCIRREN0	—	EVCCFLTEN	—	EVCCHDE	—
Value after reset	0	0	0	0	X	0	X	0
R/W	R/W	R	R/W	R	R	R	R	R

Table 12.17 EVCCDE Register Contents

Bit Position	Bit Name	Function
7	EVCCIRREN1	Permit VMON reset by EVCC high voltage detection. EVCCIRREN1,0 11 _B : VMON reset by EVCC high voltage detection is permitted Other value: VMON reset by EVCC high voltage detection is not permitted
6	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
5	EVCCIRREN0	Refer to bit 7 (EVCCIRREN1).
4	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
3	EVCCFLTEN	Enable output filter for $\overline{\text{ERROROUT_M}}$ and VMONF. 0: Disable output filter for $\overline{\text{ERROROUT_M}}$ and VMONF. 1: Enable output filter for $\overline{\text{ERROROUT_M}}$ and VMONF.
2	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
1	EVCCHDE	EVCC high voltage detection enable 0: Disable EVCC high voltage detection 1: Enable EVCC high voltage detection
0	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.

12.2.7.14 EVCCFCR — EVCC Monitor Filter Control Register

EVCCFCR is a register to adjust the filtering width of the EVCC Monitor digital noise filter.

This register is set by the flash option byte when Standby Reset or External Reset is released.

Value after reset: 0X_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	EVCCFLTW[1:0]		EVCCCLKSEL[1:0]	
Value after reset	0	0	0	0	X	X	X	X
R/W	R	R	R	R	R	R	R	R

Table 12.18 EVCCFCR Register Contents

Bit Position	Bit Name	Function
7 to 4	—	Reserved When read, the value after reset is returned.
3, 2	EVCCFLTW[1:0]	These bits select the minimum filtering width of digital noise filter. (The minimum filtering width is given by the cycle-count of the clock selected by EVCCCLKSEL1, 0)
	EVCCFLTW[1:0]	Minimum Filtering Width (Cycle)
	00	20 cycles
	01	13 cycles
	10	8 cycles
	11	3 cycles
1, 0	EVCCCLKSEL[1:0]	These bits select the clock of the digital noise filter from the following clocks.
	EVCCCLKSEL[1:0]	Clock of the Digital Filter
	00	CLK_HVIOSC frequency / 256
	01	CLK_HVIOSC frequency / 128
	10	CLK_HVIOSC frequency / 64
	11	CLK_HVIOSC frequency / 32
CAUTION: The frequency of CLK_HVIOSC is typ. 16 MHz, min 8 MHz.		

Wait specified time = 10us + Digital noise filter width.

For example, EVCCFLTW[1:0] = 00b EVCCCLKSEL[1:0] = 00b

Wait specified time = 10us + 20cycle * 256 * 62.5ns = 330us

12.2.7.15 VMONKCPROT — VMON Register Key Code Protection Register

The VMONKCPROT register is used for protection against writing operation to the registers that may have a material effect on the system so that the application system is not incorrectly stopped due to program malfunctions and the like.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	KCPROT[31:16]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	KCPROT[15:1]															KCE
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W	R/W

Table 12.19 VMONKCPROT Register Contents

Bit Position	Bit Name	Function
31 to 1	KCPROT[31:1]	Enable or disable modification of the KCE bit. The written value is not retained. These bits are always read as 0.*1
0	KCE	Key Code Enable bit 0: Disable write access to protected registers 1: Enable write access to protected registers

Note 1. Write A5A5A500_H to this register to disable writing to protected registers.
Write A5A5A501_H to this register to enable writing to protected registers.

12.2.8 Operation

12.2.8.1 VMON Basic Function

VMON watches VDD, VCC and EVCC voltage.

VMON has a high and low voltage detection circuit. If it detects a voltage error, it records the error to the VMONF register and notifies the error to the outside via the $\overline{\text{ERROROUT_M}}$ pin. It also generates internal reset (VMON reset) triggered by detection of voltage error.

(1) VMON detection flag

VMONF.VDDHF is set to “1” when VDD becomes higher than high voltage detection level of VMON.

VMONF.VCCHF is set to “1” when VCC becomes higher than high voltage detection level of VMON.

VMONF.EVCCHF is set to “1” when EVCC becomes higher than high voltage detection level of VMON.

Similarly, VMONF.VDDLf is set to “1” when VDD becomes lower than low voltage detection level of VMON.

VMONF.VCCLf is set to “1” when VCC becomes lower than low voltage detection level of VMON.

VMONF.EVCCLf is set to “1” when EVCC becomes lower than low voltage detection level of VMON.

These flags can be cleared to “0” by writing in the corresponding bit of VMONFC.

These flags are also cleared by Standby Reset (not cleared by other resets). **Figure 12.7** shows an operation example of VMONF.

(2) $\overline{\text{ERROROUT_M}}$ pin

While monitor voltage is higher than the high voltage detection level or lower than the low voltage detection level of VMON, the $\overline{\text{ERROROUT_M}}$ pin outputs a low level.

If VMON does not detect voltage error and ECM does not detect error, $\overline{\text{ERROROUT_M}}$ pin outputs a high level.

To avoid unwanted operation of the VMON circuit caused by instable power supply at power up, $\overline{\text{ERROROUT_M}}$ is fixed to low during the External Reset period and Standby Reset period.

$\overline{\text{ERROROUT_M}}$ outputs the error detection result during other reset periods.

The status of $\overline{\text{ERROROUT_M}}$ is readable from ECM. For details, refer to **Section 41, Error Control Module (ECM)**.

Figure 12.7 shows an operation example of $\overline{\text{ERROROUT_M}}$.

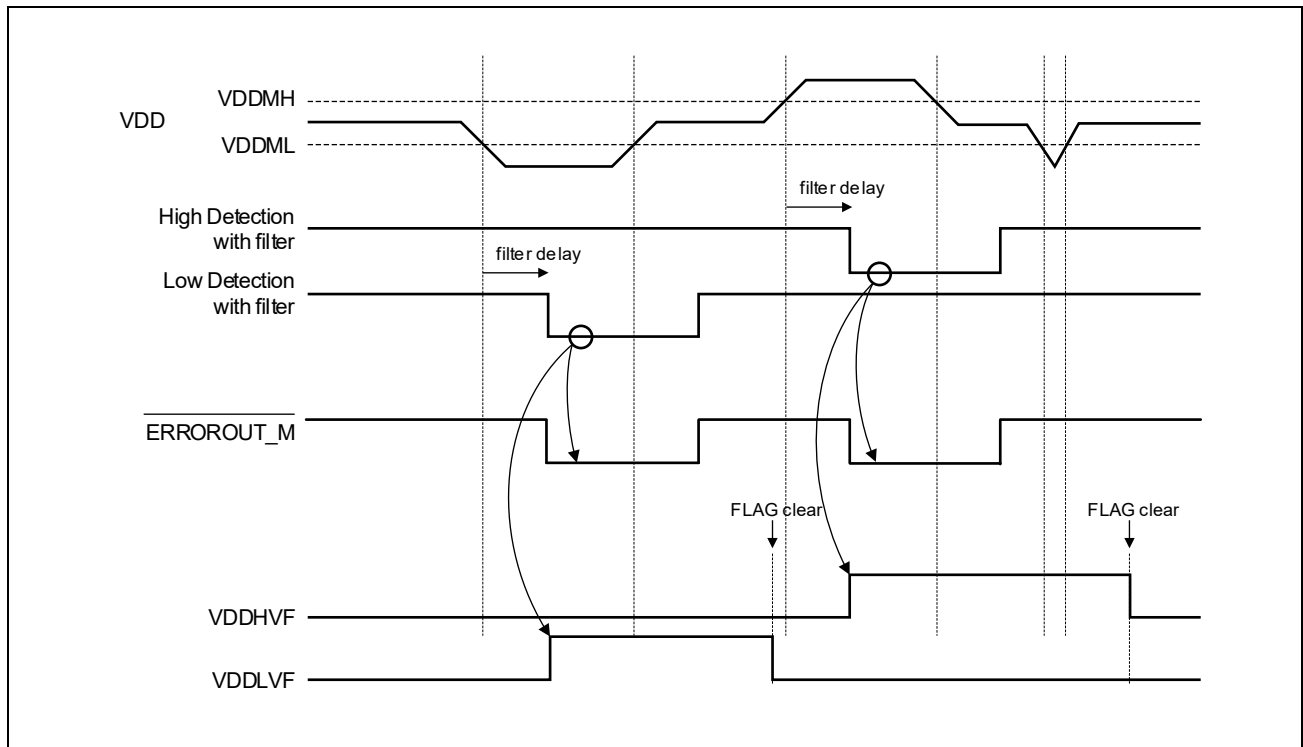

Figure 12.7 Example of VMONF and $\overline{\text{ERROROUT_M}}$ Operation (VDD)

(3) VMON reset

If VDD voltage becomes higher than high voltage detection level of VMON when “101_H” or “111_H” were set to VDDDE.VDDCIRREN[2:0] in advance, VMON reset occurs.

If VDD voltage becomes lower than low voltage detection level of VMON when “110_H” or “111_H” were set to VDDDE.VDDCIRREN[2:0] in advance, VMON reset occurs.

If VCC voltage or EVCC voltage becomes higher than high voltage detection level of VMON when “11_H” was set to VCCDE.VCCCIRREN1, 0*¹ or EVCCDE.EVCCIRREN1, 0*¹ in advance respectively, VMON reset occurs.

VMON reset is released after the specified time has been passed since VMON detects the normal voltage. **Figure 12.8** shows an operation example of VMON reset.

Note 1. LDET of VCC / EVCC will always generate the VMON RESET at the time of low voltage detection, except during diagnosis.

NOTE

Notes on before enabling VMON after reset release. Before the self-diagnosis is completed, VMON operation is out of guarantee, but the actual operation at normal case is as follows. According to the initial value of the register, when LDET of VCC and EVCC is detected, VMON reset occurs, and when HDET of VCC and EVCC is detected, VMON reset doesn't occur.

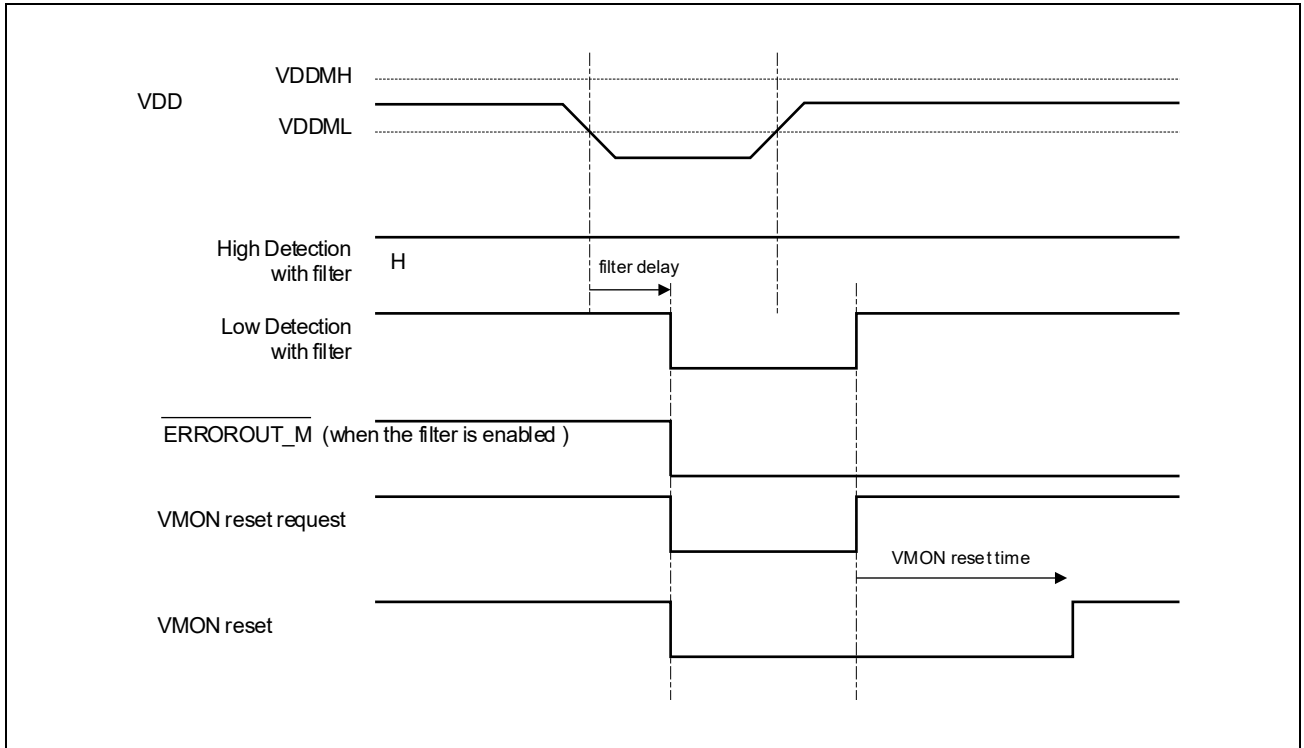

Figure 12.8 Example of VMON Reset Operation (VDD)

(4) Digital Noise Filter

The output signal of the voltage detector passes through a digital noise filter to remove unintended glitches. See *the RH850/E2x-FCC2 Electrical Characteristics, User's Manual: Hardware* for further information on the filter characteristics.

The digital noise filter clock and the cycle are controlled by setting of the following registers. (These register are read only and set by flash option byte.)

- VDDFCR
- VCCFCR
- EVCCFCR

The relation of filter enable is shown in **Figure 12.4**, **Figure 12.5** and **Figure 12.6**.

12.2.8.2 VMON Function in BIST (Mask of VMON_VDD_ERROROUT and VMON_VDDREQRESET)

It is possible to mask VMON_ERROROUT output and VMON reset by VDDDE.VDDFBISTME when BIST is carried out after VMON Reset.

In this case, VMON_VDD_ERROROUT is fixed at a high level, and VMON_VDD_REQRESET does not occur.

When VDDDE.VDDFBISTME is set to “1”, VMON_VDD_ERROROUT and VMON_VDD_REQRESET are not masked when BIST is carried out after VMON Reset.

NOTE

VMON_VDD_ERROROUT output and VMON_VDD_REQRESET are always masked when BIST is carried out after Standby Reset or External Reset.

VMON_VDD_ERROROUT output and VMON_VDD_REQRESET are never masked when BIST is carried out after System Reset 2.

12.2.8.3 VMON Diagnosis Function

(1) Change of VMON detection level for the error injection

When VMONDIAGME.VMONDIAGME is “0”, VDD detection level can be changed by VMONDIAG.VDDDIAGH or VMONDIAG.VDDDIAGL.

When VMONDIAGME.VMONDIAGME is “0”, VCC detection level can be changed by VMONDIAG.VCCDIAGH or VMONDIAG.VCCDIAGL.

When VMONDIAGME.VMONDIAGME is “0”, EVCC detection level can be changed by VMONDIAG.EVCCDIAGH or VMONDIAG.EVCCDIAGL.

VMON error detection signal can be intentionally generated by setting these registers even when each power supply voltage is in the operating range.

NOTE

During self-diagnosis, VMON detection by abnormal voltage can not be operated. As ERROROUT is injected with error in VMON Diagnosis Function, it can not detect VMON by abnormal voltage and ERROROUT output high level.

(2) Mask of VMON_ERROROUT and VMON reset

When VMONDIAGME.VMONDIAGME is “0” and VMONDMASK.VDDERRMD is set to “1”, VMON_VDD_ERROROUT can be masked.

When VMONDIAGME.VMONDIAGME is “0” and VMONDMASK.VCCERRMD is set to “1”, VMON_VCC_ERROROUT can be masked.

When VMONDIAGME.VMONDIAGME is “0” and VMONDMASK.EVCCERRMD is set to “1”, VMON_EVCC_ERROROUT can be masked.

If above three settings are done, $\overline{\text{ERROROUT_M}}$ is dependent on the setting of ECM and DMON during diagnosis.

When VMONDIAGME.VMONDIAGME is “0” and VMONDMASK.VDDRESMD is set to “1”, VMON_VDD_REQ_RESET can be masked.

When VMONDIAGME.VMONDIAGME is “0” and VMONDMASK.VCCRESMD is set to “1”, VMON_VCC_REQ_RESET can be masked.

When VMONDIAGME.VMONDIAGME is “0” and VMONDMASK.EVCCRESMD is set to “1”, VMON_EVCC_REQ_RESET can be masked.

(3) Flow of VMON diagnosis application

VMONDIAGME.VMONDIAGME is initialized to “0” by Standby Reset or External Reset. Therefore, VMON diagnosis function is enabled at start-up after these resets.

The user’s application controls the diagnostic function by VMONDMASK, VMONDIAG and VMONDIAGFE.

Figure 12.9 shows an example of the diagnosis application.

After diagnosis application is finished, write “1” to VMONDIAGME.VMONDIAGME and disable VMON diagnosis function immediately.

This function protects each flag against erroneous operation when each power supply is out of the operating range.

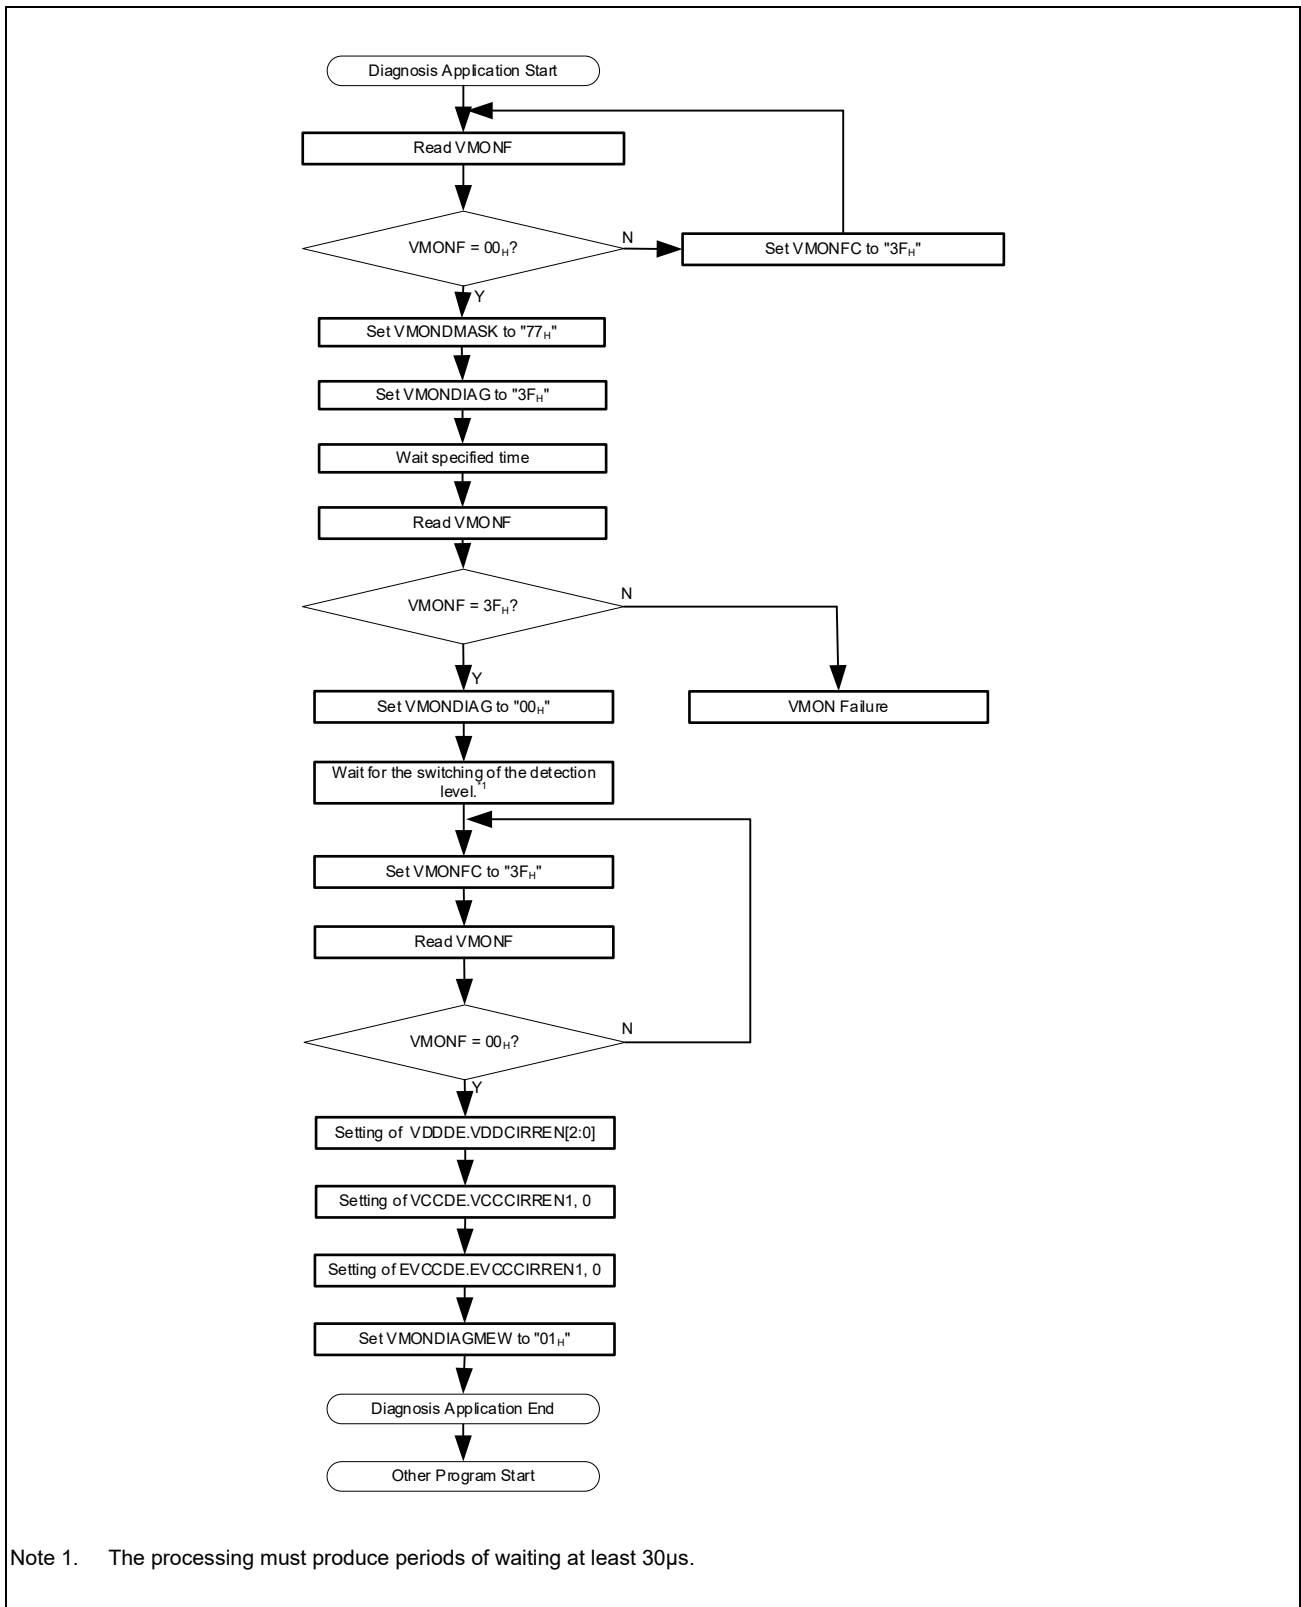

Figure 12.9 Example of the Flowchart of VMON Diagnosis Application

Wait specified time = 10 μ s + Digital noise filter width.

Please refer VDDFCR and VCCFCR and EVCCFCR for “Wait specified time”

12.2.9 Usage Notes

12.2.9.1 Flag Bit (VMONF)

Setting 1 to VMONF by error detection is prior to clearing VMONF by VMONFC.

These functions protect each flag against erroneous operation when each power supply is out of the operating range.

When Monitor voltages are recovered to the operating range, the MCU needs to be initialized by External Reset or VMON reset, or the MCU may still continue erroneous operation and then unintended flag clearing may occur.

12.2.9.2 VCC Primary Low Detection

Because of internal circuit guard of this LSI, VMON Reset might occur in a shorter time than the filter width when VCC voltage is lower than the lowest level of VCC primary low detection range*¹.

In that case, VCCLVF will not be set by the VCC primary low detection.

Note 1. VCC primary low detection level has some width. For details, refer to *the RH850/E2x-FCC2 Electrical Characteristics, User's Manual: Hardware*.

12.2.9.3 External Reset occurs during self-diagnosis

If the External Reset conflicts with the VCC and EVCC low voltage detection of self-diagnosis, Standby Reset will occur.

12.3 Delay Monitor (DMON)

12.3.1 Features

DMON can detect abnormalities in the delay time of transistor devices by using an on-chip delay monitor while the microcontroller is operating. DMON can only monitor the delay time on the VDD domain. It detects an error if the monitored delay time is lower than the threshold according to the fabrication process conditions.

DMON assists the power supply voltage monitor (VMON), which detects the low level voltage of VDD.

When DMON detects a delay error within the ranges of VMON detection, it notifies VMON about the error detection to operate VMON reset normally.

12.3.2 Register Base Addresses

The Delay Monitor base address is given in the following table.

Delay Monitor register addresses are given as offsets from the base addresses in general.

Table 12.20 Register Base Addresses

Base Address Name	Base Address	Bus Group
<DMON_base>	FF70 1C00 _H	Peripheral Group 6

12.3.3 Clock Supply

The clock supply to DMON is shown in the following table.

Table 12.21 Clock Supply

Unit Name	Clock Name	Symbol
DMON	Main OSC	CLK_MOSC
	Peripheral low speed clock	CLK_LSB

12.3.4 Interrupt and DMA/DTS Requests

This module has no interrupt and DMA/DTS requests.

12.3.5 External Input and Output Pins

This module has no external input/output pins.

12.3.6 Overview

12.3.6.1 Functional Overview

The On-Chip delay monitor measures the delay time related to the power supply voltage. It converts analog delay time into digital codes (DCODE) and outputs the DCODE into a comparator. The DCODE is compared with the threshold, which is a fixed value. When the DCODE becomes lower than the threshold, an error output signal (DMON_ERROROUT) and a reset request signal (DMON_REQRESET) are generated to notify the VMON.

12.3.6.2 Block Diagram

Figure 12.10 Block Diagram of Delay Monitor

12.3.7 Registers

12.3.7.1 List of Registers

The register list related to DMON is shown in **Table 12.22**.

Table 12.22 List of Registers (DMON)

Unit Name	Register Name	Symbol	Address	Access Size	Access Protection
DMON	DMON Factor Register	DMONF	<DMON_base> + 000 _H	32	
DMON	DMONF Clear Register	DMONFC	<DMON_base> + 004 _H	32	DMONKCPR00
DMON	DMON DIAG Monitor Enable Register	DMONDIAGME	<DMON_base> + 008 _H	32	
DMON	DMONDIAGME Write Register* ¹	DMONDIAGMEW	<DMON_base> + 00C _H	32	DMONKCPR00
DMON	DMON Detection Output Diagnosis Mask Register	DMONDMASK	<DMON_base> + 010 _H	32

DMONKCPR00	✓	✓	✓	✓	—	—

Note 1. Standby Reset only.

12.3.7.2 DMONF — DMON Factor Register

The DMONF register indicates that an error is detected by DMON. Each flag of DMONF can be cleared individually by writing “1” to the corresponding bit in DMONFC.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	DMON LVF
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 12.24 DMONF Register Contents

Bit Position	Bit Name	Function
31 to 1	—	Reserved When read, the value after reset is returned.
0	DMONLVF	Lower limit delay detection flag 0: No lower limit delay error detected 1: Lower limit delay error occurred

12.3.7.3 DMONFC — DMONF Clear Register

DMONFC is a register to clear the DMONF register. The read value of this register is always 0000 0000_H.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

0	DMONDIAGME	Permit DIAG function 0: DIAG function of the DMON can be enabled 1: DIAG function of the DMON cannot be enabled

12.3.7.5 DMONDIAGMEW — DMONDIAGME Write Register

DMONDIAGMEW is a register to set values of DMONDIAGME. Writing is permitted only once after System Reset 1/2 is released. Subsequent write operations are ignored. The read value of this register is always 0000 0000_H.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Table 12.27 DMONDIAGMEW Register Contents

Bit Position	Bit Name	Function
31 to 1	—	Reserved When writing, write the value after reset.
0	DMONDIAGMEW	The data written in this bit is set to DMONDIAGME.DMONDIAGME.

12.3.7.6 DMONDIAG — DMON DIAG Mode Setting Register

The DMONDIAG register is used for controlling the diagnostic function of DMON.

This register is valid only when DMONDIAGME.DMONDIAGME = 0. The setting of DMONDIAG is ignored if DMONDIAGME.DMONDIAGME = 1.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 12.28 DMONDIAG Register Contents

Bit Position	Bit Name	Function
31 to 1	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
0	DMONDIAGL	This bit is used for error injection of diagnosis function when DMONDIAGME = 0. 0: Normal operation. 1: Execute error injection.

12.3.7.7 DMONDMASK — DMON Detection Output Diagnosis Mask Register

DMONDMASK is a register to mask DMON_REQRESET and DMON_ERROROUT when DMONDIAGME.DMONDIAGME = 0. DMONDMASK setting is ignored if DMONDIAGME.DMONDIAGME = 1.

Value after reset: 0000 0011_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	DMON RESMD	—	—	—	DMON ERRMD
Value after reset	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	1
R/W	R	R	R	R	R	R	R	R	R	R	R	R/W	R	R	R	R/W

Table 12.29 DMONDMASK Register Contents

Bit Position	Bit Name	Function
31 to 5	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
4	DMONRESMD	This bit masks DMON_REQRESET when DMONDIAGME.DMONDIAGME = 0. 0: DMON_REQRESET is not masked. 1: DMON_REQRESET is masked.
3 to 1	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
0	DMONERRMD	This bit masks DMON_ERROROUT when DMONDIAGME.DMONDIAGME = 0. 0: DMON_ERROROUT is not masked. 1: DMON_ERROROUT is masked.

12.3.7.8 DMONDE — DMON Detection Enable Register

DMONDE is a register to control DMON detection, the DMON signal mask and DMON signal filter.

Writing in DMONDE is permitted during the period before writing in DMONDIAGMEW after System Reset 1/2 is released. Writing in this register is ignored after writing in DMONDIAGMEW.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 12.30 DMONDE Register Contents

Bit Position	Bit Name	Function
31 to 8	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
7	DMONCIRREN1	Permit DMON_REQRESET notification. DMONCIRREN1, 0 00 _B , 01 _B , 10 _B : DMON_REQRESET is not permitted 11 _B : DMON_REQRESET is permitted
6	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
5	DMONCIRREN0	Refer to bit 7 (DMONCIRREN1).
4	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
3	DMONFLTEN	Enable output filter for DMON_ERRORROUT and DMON Error Detection Flag 0: Disable output filter for DMON_ERRORROUT and DMON Error Detection Flag 1: Enable output filter for DMON_ERRORROUT and DMON Error Detection Flag
2 to 1	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
0	DMONLDE	DMON Low delay detection enable 0: Disable DMON lower limit delay detection 1: Enable DMON lower limit delay detection

12.3.7.9 DMONFCR — DMON Filter Control Register

DMONFCR is a register to adjust the filtering width of the DMON digital noise filter.

Writing in DMONFCR is permitted during the period before writing in DMONDIAGMEW after System Reset 1/2 is released. Writing in this register is ignored after writing in DMONDIAGMEW.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 12.31 DMONFCR Register Contents

Bit Position	Bit Name	Function
31 to 3	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
2 to 0	DMONFLTW	These bits select the minimum filtering width of the digital noise filter. The minimum filtering width is given as a number of sampling times. 000: 1 sampling times 001: 2 sampling times 010: 4 sampling times 011: 8 sampling times 100: 16 sampling times 101: 32 sampling times 110: 64 sampling times 111: 128 sampling times

CAUTION: The sampling period is 4 μ s.

12.3.7.10 DMONKCPROT0 — DMON Register Key Code Protection Register 0

The DMONKCPROT0 register is used for protection against writing operation to the registers that may have a material effect on the system so that the application system is not incorrectly stopped due to program malfunction and the like.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	KCPROT[31:16]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	KCPROT[15:1]															KCE
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W	R/W

Table 12.32 DMONKCPROT0 Register Contents

Bit Position	Bit Name	Function
31 to 1	KCPROT[31:1]	Enable or disable modification of the KCE bit. The written value is not retained. These bits are always read as 0.*1
0	KCE	Key Code Enable bit 0: Disable write access to protected registers 1: Enable write access to protected registers

Note 1. Write A5A5A500_H to this register to disable writing to protected registers.
Write A5A5A501_H to this register to enable writing to protected registers.

12.3.8 Operation

12.3.8.1 DMON Basic Function

DMON monitors the delay time depending on the VDD supply voltage.

If it detects a delay error, it records the error to DMONF register. It also generates DMON_ERROROUT and DMON_REQRESET triggered by detection of the lower limit delay, and notifies the error to VMON.

Figure 12.11 shows the flowchart of starting up DMON. DMON begins to operate after VMON starts up and the Clock Monitor confirms that Main OSC clock is normally operating. The user must invoke DMON after starting up VMON and checking Clock Monitor to see whether or not Main OSC clock is operating normally. After DMON starts up, the system clock needs to be changed to PLL and the clock gear up is carried out.

The timing chart of DMON operation is shown in **Figure 12.12**.

When Power Up Reset or System Reset 1/2 is asserted, DMON is also initialized by these resets. After restart from the reset, the start-up sequence needs to be executed again.

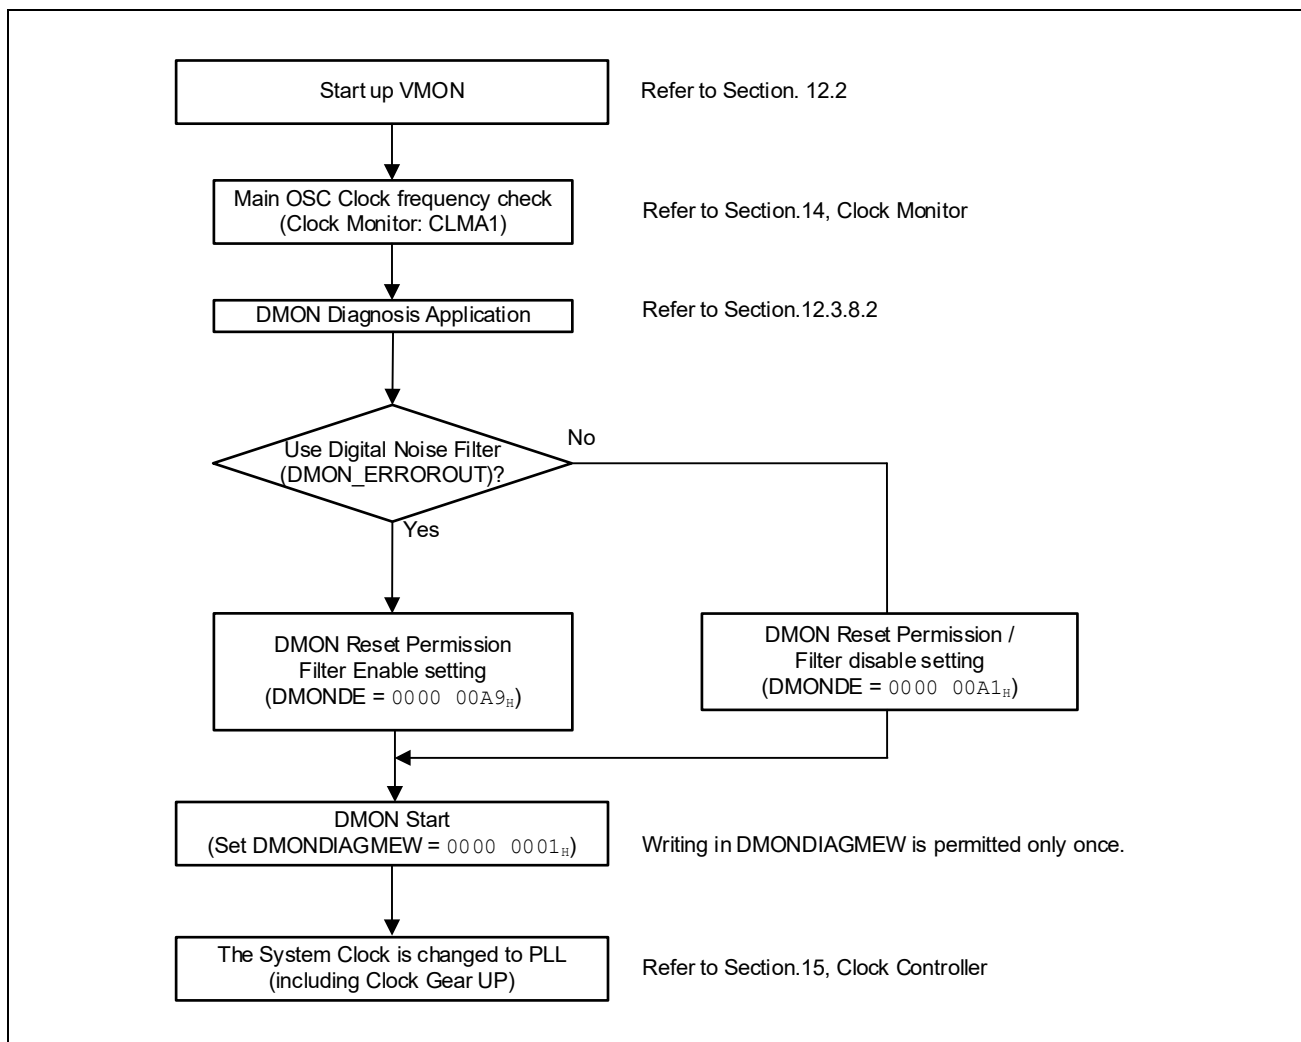

Figure 12.11 Flowchart of DMON Start-Up

Figure 12.12 Timing Chart of the DMON Function

DMON generates the sampling period from Main OSC clock (CLK_MOSC). If the frequency of Main OSC is faster than the spec, the DCODE will become smaller than the expected value due to shortening of the sampling period. Therefore, there is a possibility that DMON detects the delay error before the error detection of clock monitor for Main OSC and the MCU is initialized by VMON reset. If the user distinguishes between the failure of Main OSC and the reset factor caused by DMON error after the MCU restarts from VMON reset, the user needs to confirm the DMON error flag and check the frequency of Main OSC by clock monitor (CLMA1). **Figure 12.13** shows an example of a flowchart to identify the reset factor.

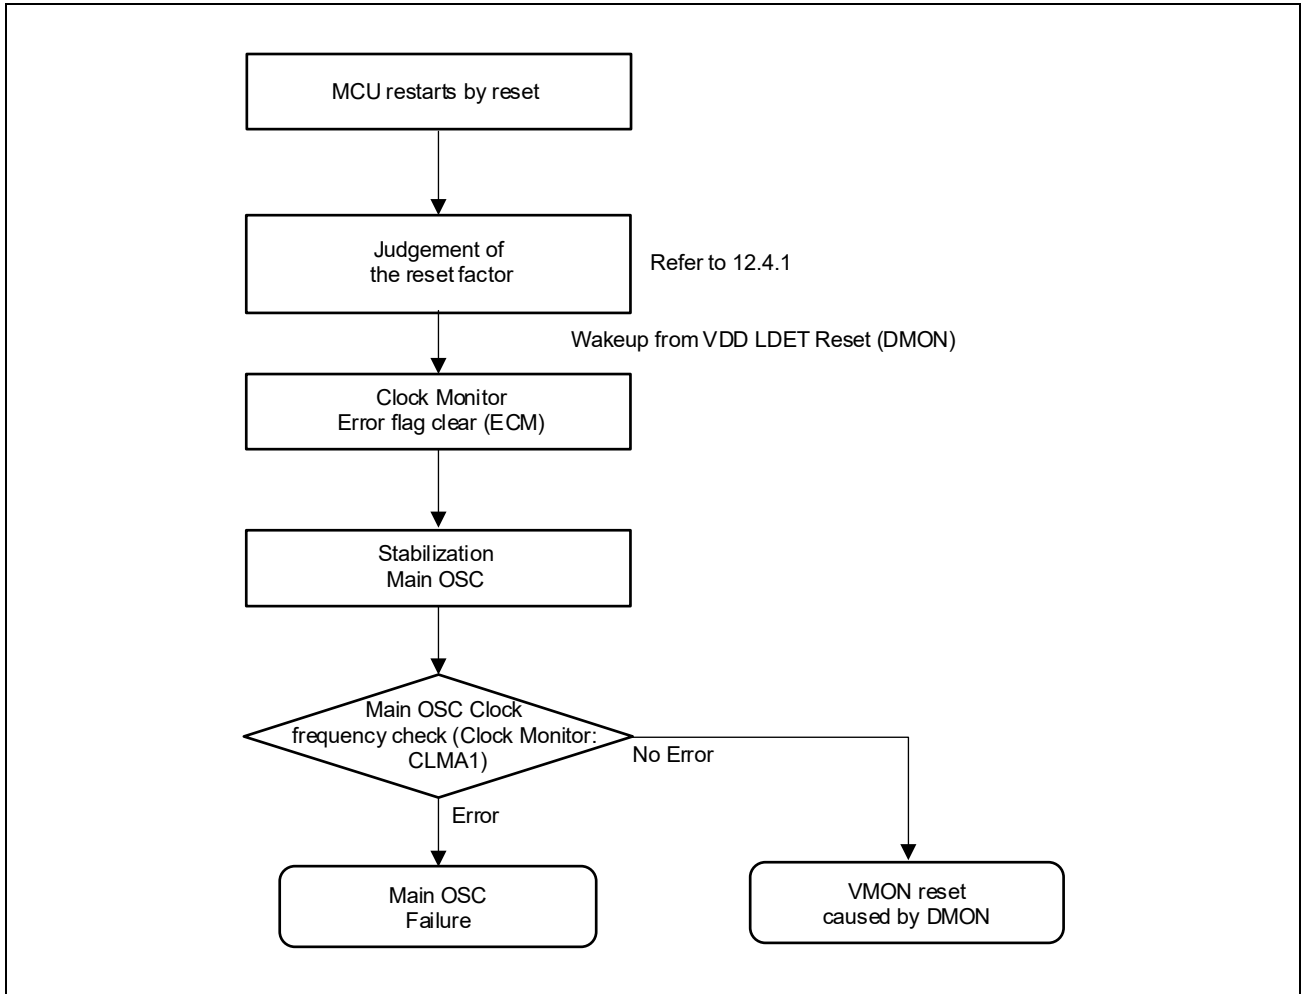

Figure 12.13 Example of Flowchart to Identify the Failure of Main OSC

(1) DMON Error Detection Flag

DMON sets “1” to DMONF.DMONLVF when the DCODE becomes lower than the low detection threshold level.

The flag can be cleared to “0” by writing to the corresponding bit of DMONFC.

The flag is also cleared by power up reset and standby reset (not cleared by other resets). **Figure 12.14** shows an operation example of DMONF.

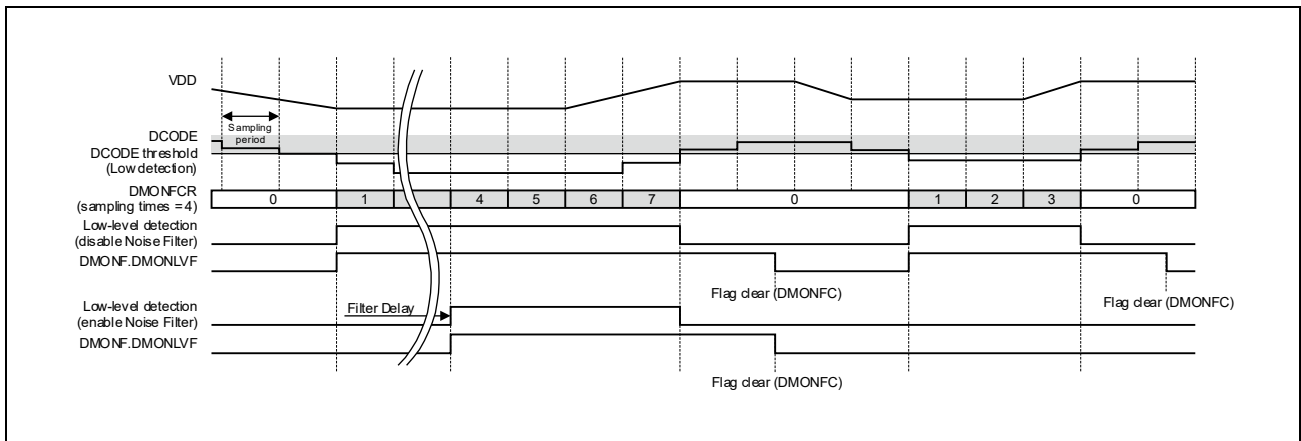

Figure 12.14 DMON Error Detection Flag

(2) DMON_REQRESET Output

If the DCODE value becomes lower than the DCODE threshold level when DMONDE.DMONCIRREN is set to “11_B”, DMON notifies VMON that the DMON_REQRESET has occurred. After that, VMON reset occurs and the MCU including DMON is initialized. DMON continues to hold the DMON_REQRESET state until DMON is initialized by VMON reset. **Figure 12.15** shows an operation example of DMON_REQRESET.

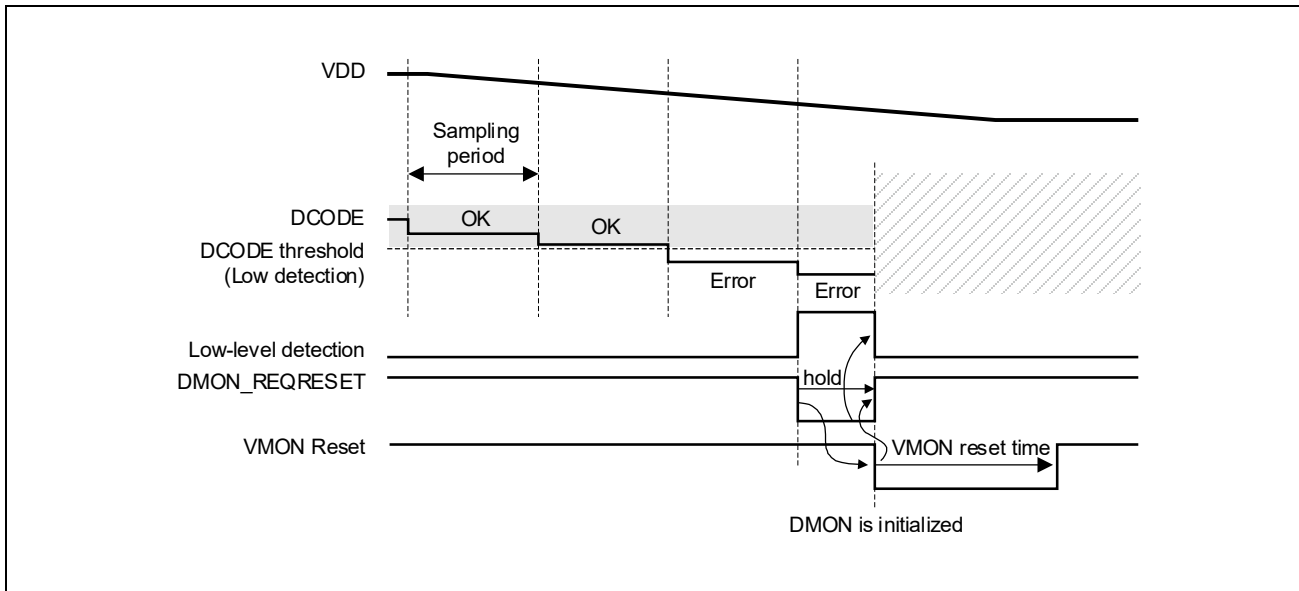

Figure 12.15 DMON_REQRESET Operation

(3) Digital Noise Filter

The output signal of the DMON comparators passes through a digital noise filter to remove unintended glitches.

Whether to use filtered output or to bypass the filter is selectable by DMONDE.DMONFLTEN.

The digital noise filter period can be changed by the DMONFCR register.

12.3.8.2 DMON Diagnosis Function

(1) Change of DMON detection level for error injection

When DMONDIAGME.DMONDIAGME is set to “0”, the Lower limit delay threshold level can be changed by DMONDIAG.DMONDIAGL.

The DMON error detection signal can be intentionally generated by setting this register when VMON did not detect a voltage error and the clock monitor CLMA1 did not detect frequency abnormalities.

(2) Mask of DMON_ERROROUT and DMON_REQRESET

When DMONDIAGME.DMONDIAGME is set to “0” and DMONDMASK.DMONERRMD is set to “1”, DMON_ERROROUT can be masked.

When DMONDIAGME.DMONDIAGME is set to “0” and DMONDMASK.DMONRESMD is set to “1”, DMON_REQRESET can be masked.

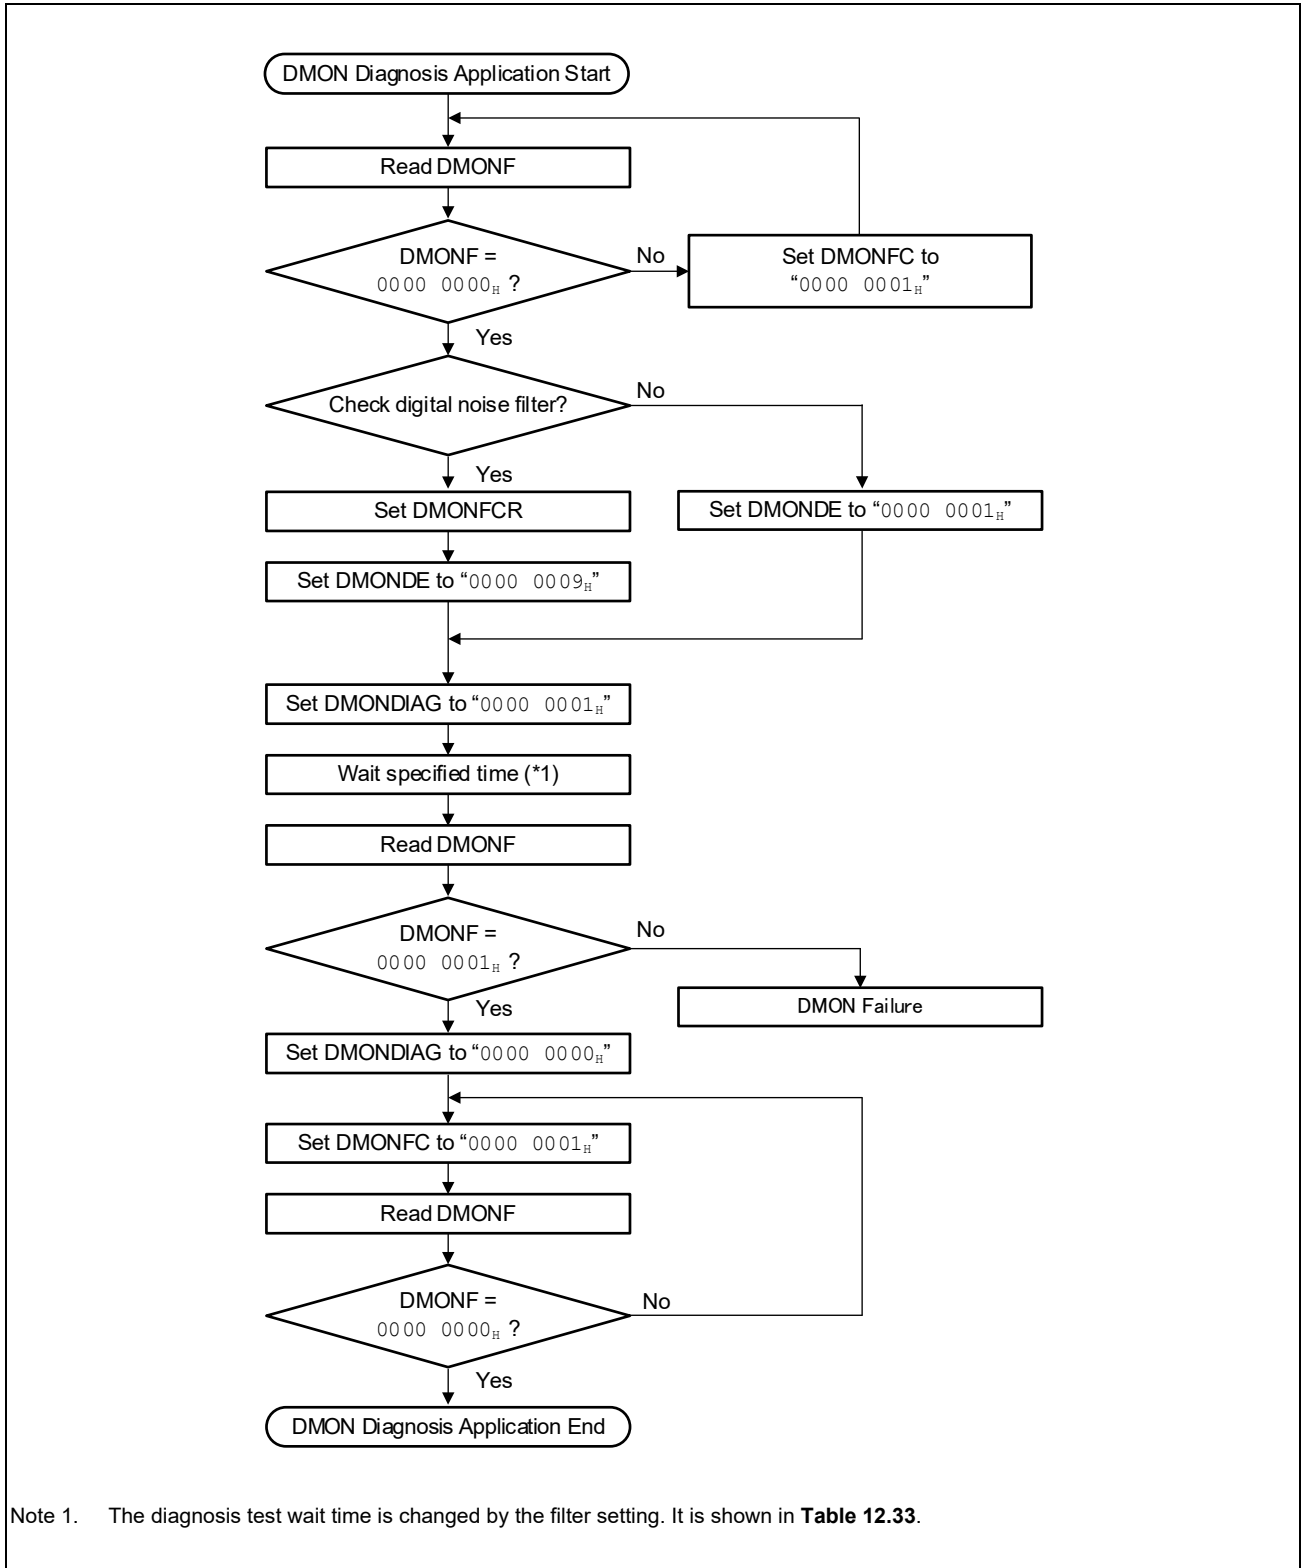

(3) Flow of DMON diagnosis application

DMONDIAGME.DMONDIAGME is initialized to “0” by Power Up Reset or System Reset 1/2. Therefore, the DMON diagnosis function is enabled at start-up after these resets.

The user’s application controls the diagnostic function by DMONDMASK and DMONDIAG. **Figure 12.16** shows the example of the diagnosis application.

After diagnosis application is finished, write “1” to DMONDIAGMEW.DMONDIAGMEW and disable the DMON diagnosis function immediately.

This function protects each flag against erroneous operation when each power supply is out of the operating range.

Note 1. The diagnosis test wait time is changed by the filter setting. It is shown in **Table 12.33**.

Figure 12.16 Example of Flowchart of DMON Diagnosis Application

Table 12.33 Wait Times of Diagnosis Test

DMONFCR.DMONFLTW	Wait time
000	12 us
001	16 us
010	24 us
011	40 us
100	72 us
101	136 us
110	264 us
111	520 us

12.4 Usage Notes

12.4.1 Judgment Method of Reset Factors for Voltage Monitor

If RESF.SRES1F2 bit is “1”, this product is woken up

Check the VMONF and DMONF for the detection power.

The judgment method of the reset factors is shown in **Figure 12.17**.

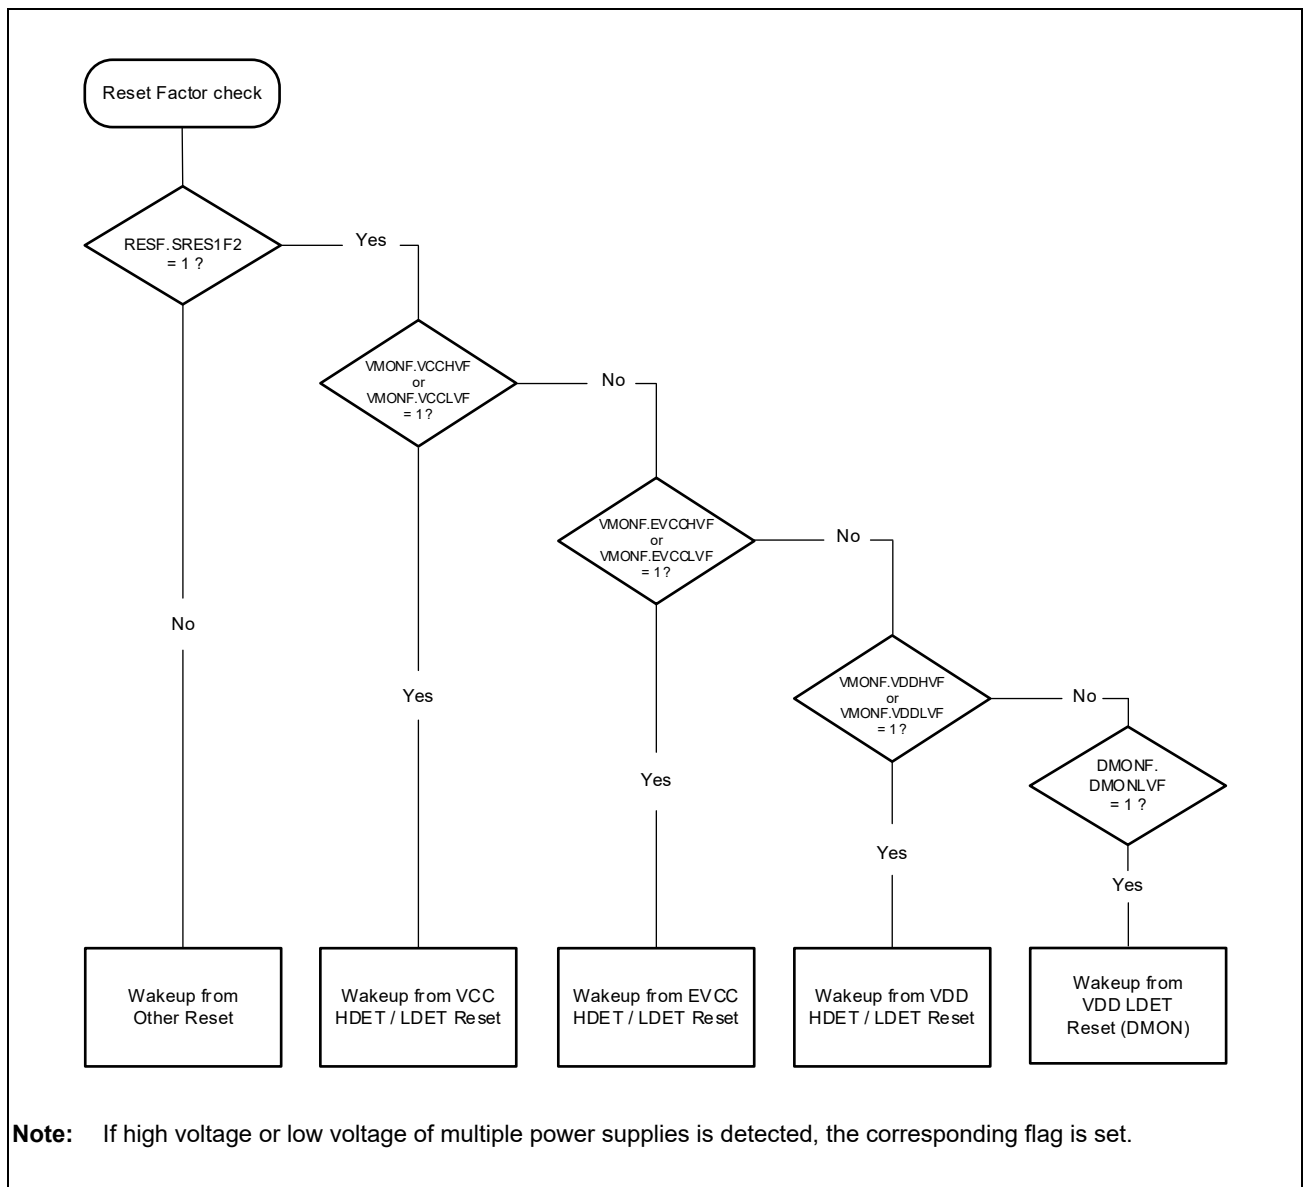

Figure 12.17 Flowchart of Reset Factor Judgment

Section 13 Temperature Sensor

13.1 Features

13.1.1 Number of Channels

Table 13.1 Number of Channels

Temperature Sensor	
Number of Channels	1
Name	OTS0

13.1.2 Register Base Address

Table 13.2 Register Base Addresses

Base Address Name	Base Address	Bus Group
<OTS0_base>	FF70 A000 _H	Peripheral Group 6

13.1.3 Clock Supply

The clocks supplied to the temperature sensor are listed in the following table.

Table 13.3 Clock Supply

Unit Name	Unit Clock Name	Clock Name
OTS0	Operation clock	CLK_LSB
	Register access clock	CLK_LSB

13.1.4 Interrupt Requests

The temperature sensor interrupt requests are listed in the following table.

Table 13.4 Interrupt Requests

Unit Interrupt Name	Unit Interrupt Signal Outline	Interrupt Number
INTOTSOTE	Temperature sensor error interrupt	501
INTOTSOTI	Temperature measurement end interrupt	502
INTOTSOTULI	Triggered if the state machine changes the state due to a temperature rise or drop in the guaranteed temperature range	503*1
INTOTSOTABE	Abnormal temperature error interrupt	503*1

Note 1. INTOTSOTULI and INTOTSOTABE are merged.

13.1.5 External Input and Output Pins

This module has no external input/output pin.

13.2 Overview

13.2.1 Functional Overview

The following describes the features of the temperature sensor.

- Temperature data register

A temperature data register stores a temperature measurement value.

- Temperature measurement mode

Single measurement mode: Used to measure temperature only once.

Continuous measurement mode: Used to measure temperature continuously.

- Supporting temperature measurement end interrupt

Each time temperature measurement ends, the temperature sensor can generate an interrupt request (INTOTSOTI) to be sent to the INTC.

- Supporting temperature alarm error interrupt and temperature rise/drop interrupt

Six temperature threshold values (high-temperature border AU > high-temperature border AL > high-temperature border BU > high-temperature border BL > low-temperature border AU > low-temperature border AL) should be set in advance. Furthermore, the temperature sensor has four temperature states (high temperature A, high temperature B, normal temperature, and low temperature A). The temperature state is updated at each temperature measurement according to six temperature threshold values. The following describes the conditions for generating a temperature alarm error interrupt and a temperature rise/drop interrupt.

- A temperature alarm error interrupt (INTOTSOTABE) is output at a transition from a state other than high temperature A to high temperature A or at a transition from a state other than low temperature A to low temperature A.
- A temperature rise/drop interrupt (INTOTSOTULI) is output at a transition from high temperature A to high temperature B or normal temperature, or at a transition from high temperature B to normal temperature, that is, when the temperature drops.
- A temperature rise/drop interrupt (INTOTSOTULI) is output at a transition from low temperature A to high temperature B or normal temperature, or at a transition from normal temperature to high temperature B, that is, when the temperature rises.

Temperature status can be monitored by reading the temperature status register.

- Diagnosis function

When temperature is measured in continuous measurement mode, if the difference between the measured value and the previously measured value is larger than the specified temperature difference limit value, a temperature sensor error interrupt (INTOTSOTE) is output.

- Reducing errors by temperature correction

Three temperature correction coefficients are stored during device manufacturing in coefficient registers A to C.

13.2.2 Block Diagram

Figure 13.1 shows a block diagram of the temperature sensor.

Figure 13.1 Temperature Sensor Block Diagram

13.3 Register

13.3.1 List of registers

The following table lists the registers of the temperature sensor.

<OTSn_base> is defined in **Section 13.1.2, Register Base Address**.

Table 13.5 List of Registers

Unit Name	Register Name	Symbol	Address	Access Size
OTSn	Temperature Measurement Start Control Register	OTSnOTSTCR	<OTSn_base> + 00 _H	8
OTSn	Temperature Measurement End Control register	OTSnOTENDCR	<OTSn_base> + 04 _H	8
OTSn	Temperature Sensor Control Register	OTSnOTCR	<OTSn_base> + 08 _H	8
OTSn	Temperature Sensor Flag Clear Register	OTSnOTFCR	<OTSn_base> + 0C _H	8
OTSn	Temperature Sensor Flag Register	OTSnOTFR	<OTSn_base> + 10 _H	8
OTSn	Temperature Status Register	OTSnOTSTR	<OTSn_base> + 14 _H	8
OTSn	Temperature Data Register	OTSnOTDR	<OTSn_base> + 18 _H	16
OTSn	High-Temperature Border AU Register	OTSnHTBRAU	<OTSn_base> + 1C _H	16
OTSn	High-Temperature Border AL Register	OTSnHTBRAL	<OTSn_base> + 20 _H	16
OTSn	High-Temperature Border BU Register	OTSnHTBRBU	<OTSn_base> + 24 _H	16
OTSn	High-Temperature Border BL Register	OTSnHTBRBL	<OTSn_base> + 28 _H	16
OTSn	Low-Temperature Border AU Register	OTSnLTBRAU	<OTSn_base> + 2C _H	16

OTSn	Coefficient A Register	OTSnCOEFFRA	<OTSn_base> + 38 _H	16
OTSn	Coefficient B Register	OTSnCOEFFRB	<OTSn_base> + 3C _H	16
OTSn	Coefficient C Register	OTSnCOEFFRC	<OTSn_base> + 40 _H	16

Note: (n = 0)

13.3.2 Reset of Registers

Table 13.6 Register Reset Conditions

Register Name	Reset Source					
	Power Up Reset	System Reset 1	System Reset 2	Application Reset	Module Reset	JTAG Reset
All registers	✓	✓	✓	✓	—	—

13.3.3 OTS0OTSTCR — Temperature Measurement Start Control Register

OTS0OTSTCR is an 8-bit write-only control register to start the temperature sensor.

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	OTST
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	W

Table 13.7 OTS0OTSTCR Register Contents

Bit Position	Bit Name	Function
7 to 1	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
0	OTST	Temperature Measurement Start Condition for starting temperature measurement by OTST. Write 1 to OTST when OFACT = 0

13.3.4 OTS0OTENDCR — Temperature Measurement End Control Register

OTS0OTENDCR is an 8-bit write-only control register to terminate the temperature sensor.

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	OTEND
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	W

Table 13.8 OTS0OTENDCR Register Contents

Bit Position	Bit Name	Function
7 to 1	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
0	OTEND	Temperature Measurement End Condition for terminating temperature measurement by OTEND. Write 1 to OTEND and then wait for 2 cycles of the OTS clock.

13.3.5 OTS0OTCR — Temperature Sensor Control Register

OTS0OTCR is an 8-bit readable/writable register to control the temperature sensor.

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	OTEE	OTULIE	OTABEE	SDE	OTMD
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R/W	R/W	R/W	R/W	R/W

Table 13.9 OTS0OTCR Register Contents

Bit Position	Bit Name	Function
7 to 5	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
4	OTEE	Temperature Sensor Error Enable 0: Disabled 1: Enabled When OTMD = 0 (single measurement mode) or SDE = 0 (diagnosis disabled), no temperature sensor error is generated regardless of the OTEE setting.
3	OTULIE	Temperature Rise/Drop Interrupt Enable 0: Disabled 1: Enabled
2	OTABEE	Temperature Alarm Error Enable 0: Disabled 1: Enabled
1	SDE	Diagnosis Enable 0: Disabled 1: Enabled When OTMD = 0 (single measurement mode), diagnosis is not performed regardless of the SDE setting.
0	OTMD	Temperature Measurement Mode 0: Single temperature measurement mode 1: Continuous temperature measurement mode

CAUTION

To prevent malfunction, set OTS0OTCR while the OTACT bit in OTS0OTFR is 0.

13.3.6 OTS0OTFCR — Temperature Sensor Flag Clear Register

OTS0OTFCR is an 8-bit write-only register to clear the OTS0OTFR register.

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	SDERC	—	OTFC
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	W	R	W

Table 13.10 OTS0OTFCR Register Contents

Bit Position	Bit Name	Function
7 to 3	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
2	SDERC	Diagnosis Error Clear Writing 0: Does not clear the diagnosis error. Writing 1: Clears the diagnosis error.
1	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
0	OTFC	Temperature Measurement End Flag Clear Writing 0: Does not clear the temperature measurement end flag. Writing 1: Clears the temperature measurement end flag.

13.3.7 OTS0OTFR — Temperature Sensor Flag Register

OTS0OTFR is an 8-bit read-only register to indicate temperature sensor flags.

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	SDER	OTACT	OTF
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R

Table 13.11 OTS0OTFR Register Contents

Bit Position	Bit Name	Function
7 to 3	—	Reserved When read, the value after reset is returned.
2	SDER	Diagnosis Error Setting condition A diagnosis error occurred. Clearing condition Write SDERC to 1 in OTS0OTFCR
1	OTACT	Temperature Sensor Status 0: The temperature sensor is in the idle state. 1: The temperature sensor is operating.
0	OTF	Temperature Measurement End Flag Setting condition A temperature measurement value is written to OTS0OTDR Clearing condition Write OTFC to 1 in OTS0OTFCR. Reading of the OTS0OTDR register.

CAUTION

SDER is updated when a temperature measurement value is written to OTS0OTDR.

13.3.8 OTS0OTSTR — Temperature Status Register

OTS0OTSTR is an 8-bit read-only register to indicate temperature sensor status.

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	TSTAT[1:0]	
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R

Table 13.12 OTS0OTSTR Register Contents

Bit Position	Bit Name	Function
7 to 2	—	Reserved When read, the value after reset is returned.
1 to 0	TSTAT[1:0]	Temperature Status 00: Normal temperature (value after reset) 01: High temperature B 10: High temperature A 11: Low temperature A When temperature is measured, temperature status is determined by the temperature measurement value and the status is reflected in TSTAT[1:0]. Figure 13.2 shows the status transitions of TSTAT, and Table 13.13 shows the temperature alarm error and temperature rise/drop interrupt generating conditions.

CAUTION

The TSTAT[1:0] bits are updated when a temperature measurement value is written to OTS0OTDR.

Figure 13.2 Temperature Status and Transition States

Table 13.13 Conditions for Generating Temperature Alarm Error and Temperature Rise/Drop Interrupts

		After Status Transition			
		High temp. A	High temp. B	Normal temp.	Low temp. A
Before status transition	High temp. A	N/A	INTOTSOTULI	INTOTSOTULI	INTOTSOTABE
	High temp. B	INTOTSOTABE	N/A	INTOTSOTULI	INTOTSOTABE
	Normal temp.	INTOTSOTABE	INTOTSOTULI	N/A	INTOTSOTABE
	Low temp. A	INTOTSOTABE	INTOTSOTULI	INTOTSOTULI	N/A

[Legend]

INTOTSOTABE: Occurrence of temperature alarm error

INTOTSOTULI: Occurrence of temperature rise or drop interrupt

N/A: Neither INTOTSOTABE nor INTOTSOTULI occurs.

13.3.9 OTS0OTDR — Temperature Data Register

OTS0OTDR is a 16-bit read-only register that stores a temperature measurement value.

Value after reset: 0000_H

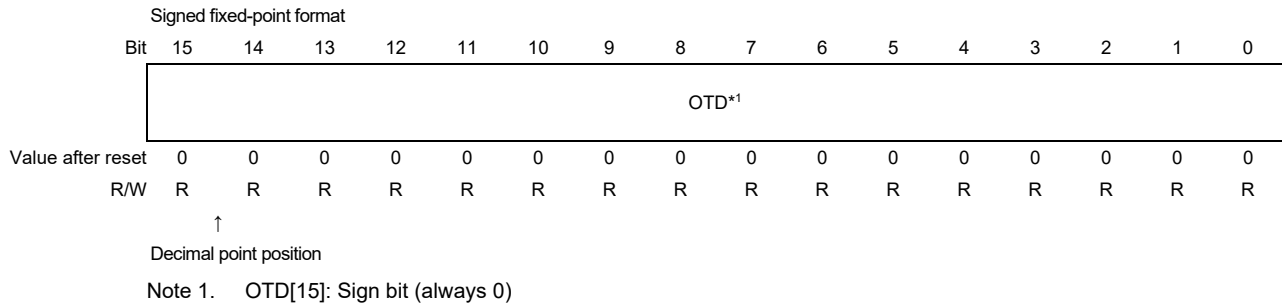

Table 13.14 OTS0OTDR Register Contents

Bit Position	Bit Name	Function
15 to 0	OTD	Temperature Data Value These bits specify a value for temperature data. OTD[15] is always 0.

NOTE

When the CPU reads the register while the temperature sensor module is updating the register, the value before updating will be read. **Figure 13.4** show the updating of this register.

13.3.10 OTS0HTBRmn — High-Temperature Border mn Register (m = A or B, n = U or L)

OTS0HTBRmn is a 16-bit readable/writable register to specify the temperature border of high temperature m.

Value after reset: 0000_H

Note 1. HTBmn[15]: Sign bit (always 0)

Table 13.15 OTS0HTBRmn Register Contents

Bit Position	Bit Name	Function
15 to 0	HTBmn	<p>High-Temperature Border mn</p> <p>These bits specify the high-temperature border mn. Specify it so that the following condition is met.</p> <p style="padding-left: 40px;">OTS0HTBRAU > OTS0HTBRAL > OTS0HTBRBU > OTS0HTBRBL > OTS0LTBRAU > OTS0LTBRAL</p> <p>The HTBmn format is the same as the OTS0OTDR format. HTBmn[15] is always 0.</p> <p>For details, see Section 13.3.8, OTS0OTSTR — Temperature Status Register.</p>

CAUTION

To prevent malfunction, set OTS0HTBRmn while the OTACT bit in OTS0OTFR is 0.

13.3.11 OTS0LTBRAn — Low-Temperature Border An Register (n = U or L)

OTS0LTBRAn is a 16-bit readable/writable register to specify the temperature border of low temperature A.

Value after reset: 0000_H

Note 1. LTBA_n[15]: Sign bit (always 0)

Table 13.16 OTS0LTBRAn Register Contents

Bit Position	Bit Name	Function
15 to 0	LTBA _n	<p>Low-Temperature Border An</p> <p>These bits specify the low-temperature border An. Specify it so that the following condition is met.</p> <p style="padding-left: 20px;">OTS0HTBRAU > OTS0HTBRAL > OTS0HTBRBU > OTS0HTBRBL > OTS0LTBRAU > OTS0LTBRAL</p> <p>The LTBA_n format is the same as the OTS0OTDR format. LTBA_n[15] is always 0.</p> <p>For details, see Section 13.3.8, OTS0OTSTR — Temperature Status Register.</p>

CAUTION

To prevent malfunction, set OTS0LTBRAn while the OTACT bit in OTS0OTFR is 0.

13.3.12 OTS0TDLR — Temperature Difference Limiting Register

OTS0TDLR is a 16-bit readable/writable register to specify the temperature difference limit value for self-diagnosis.

Value after reset: 7FFF_H

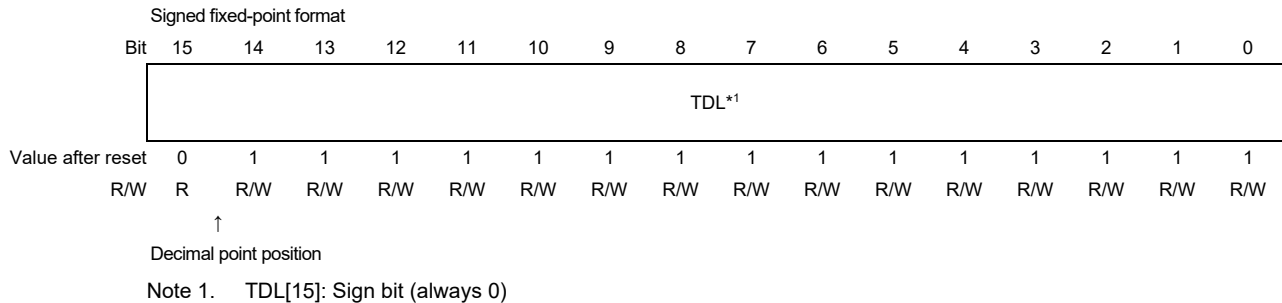

Table 13.17 OTS0TDLR Register Contents

Bit Position	Bit Name	Function
15 to 0	TDL	<p>Temperature Difference Limit Value</p> <p>These bits specify a value for limiting the temperature difference between present temperature measurement value and previous temperature measurement value in continuous measurement mode. When the following condition is met, SDER (diagnosis error) is set to 1.</p> $\text{OTS0TDLR} < \text{present temperature measurement value} - \text{previous temperature measurement value} $ <p>To calculate from the temperature, calculate back from the formula described in the OTS0COEFFRn register ($T[\text{K}] = AX^2 + BX + C$). For details, see Section 13.3.13, OTS0COEFFRn — Coefficient n Register (n = A, B, C).</p> <p>The TDL format is the same as the OTS0OTDR format. TDL[15] is always 0. For details, see Section 13.3.8, OTS0OTSTR — Temperature Status Register.</p>

CAUTION

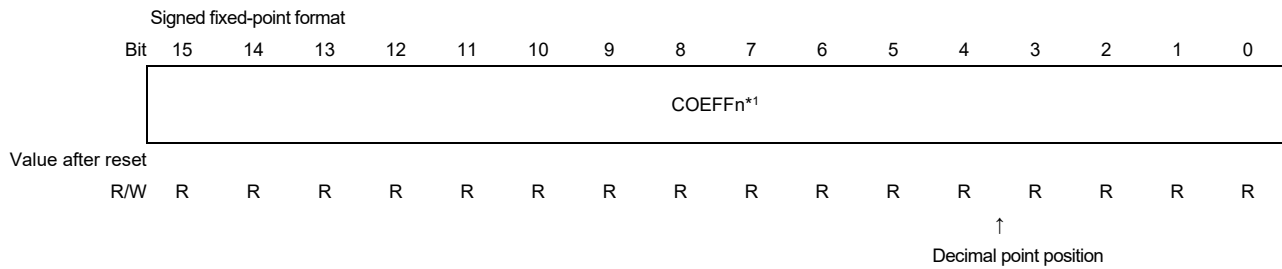

To prevent malfunction, set OTS0TDLR while the OTACT bit in OTS0OTFR is 0.

13.3.13 OTS0COEFFRn — Coefficient n Register (n = A, B, C)

OTS0COEFFRn is a 16-bit read-only register to store coefficients for correction calculation.

Coefficients are stored in OTS0COEFFRn during device manufacturing.

Value after reset: The value after reset will be stored at delivery inspection for each device.

Note 1. COEFFn[15]: Sign bit (always 0)

Table 13.18 OTS0COEFFRn Register Contents

Bit Position	Bit Name	Function
15 to 0	COEFFn	Coefficient values for correction calculation These bits specify the values of the coefficients. COEFFn[15] is always 0.

- Reducing errors by temperature correction

Three temperature correction coefficients are stored during device manufacturing in coefficient registers A to C.

Errors in temperature measurement values can be reduced by making a correction by using the temperature correction calculation formula that uses the temperature correction coefficients. However, temperature corrections must be made by the CPU. By using this process, the Temperature Border setting can be improved.

- Correction calculation formula: $T[K] = AX^2 + BX + C$

- T: Temperature value after correction
- X: Temperature value before correction (OTS0OTDR)
- A to C: Coefficients A to C (OTS0COEFFRn n = A, B, C)

For example

$$\text{OTS0OTDR} = 36\text{DA}_\text{H}, \text{OTS0COEFFRA} = 2106_\text{H}, \text{OTS0COEFFRB} = 2\text{D}87_\text{H}, \text{OTS0COEFFC} = 0040_\text{H}$$

$$X = \text{OTS0OTDR} / (2^{15}) = 0.428528$$

$$A = \text{OTS0COEFFRA} / (2^4) = 528.375$$

$$B = \text{OTS0COEFFRB} / (2^4) = 728.4375$$

$$C = \text{OTS0COEFFRC} / (2^4) = 4$$

$$T[^\circ\text{C}] = T[\text{K}] - 273.15 = AX^2 + BX + C - 273.15 = 140.035^\circ\text{C}$$

13.4 Operation

13.4.1 Temperature Measurement Sequence

The temperature sensor is equipped with a Single measurement mode and a Continuous measurement mode.

The measurement start trigger and measurement end trigger of each mode is shown below.

Table 13.19 Measurement Start/End Trigger

Measurement Mode	Measurement Start Trigger	Measurement End Trigger
Single measurement mode OTS0OTCR.OTMD = 0	Write 1 _B in OTS0OTSTCR.OTST.	1) Automatic stop after one temperature measurement ends 2) Write 1 _B in OTS0OTENDCR.OTEND.*1 *2
Continuous measurement mode OTS0OTCR.OTMD = 1	Write 1 _B in OTS0OTSTCR.OTST.	Write 1 _B in OTS0OTENDCR.OTEND.*1

Note 1. If the temperature measurement has been stopped by the OTS0OTENDCR.OTEND, data during the measurement will be discarded.

Note 2. If the temperature measurement has been stopped by the OTS0OTENDCR.OTEND before the first measurement has been completed, the measurement operation will not output the measurement result at all.

The time until the temperature data is output requires 512 states (9.984 ms.) of the OTS clock to convert the measured temperature to digital data.

There is a measurement stabilization period of 3 OTS clock states before the temperature is sampled after the measurement process is started by writing to the OTS0OTSSTCR.OTST bit.

In Single measurement mode, to update the temperature measurement result requires 515 OTS clock states, including the measurement preparation period, until the temperature measurement operation ends.

In Continuous measurement mode, 515 of the OTS clock states, including the 3-state measurement stabilization period, are required only for the first temperature measurement, the second and subsequent updates of the temperature measurement result require 512 states, and the measurement operation is repeated until 1 is written to OTENDCR.OTEND.

13.4.2 Examples of Temperature Measurement Operation

The following figure shows the temperature measurement operation in single measurement mode.

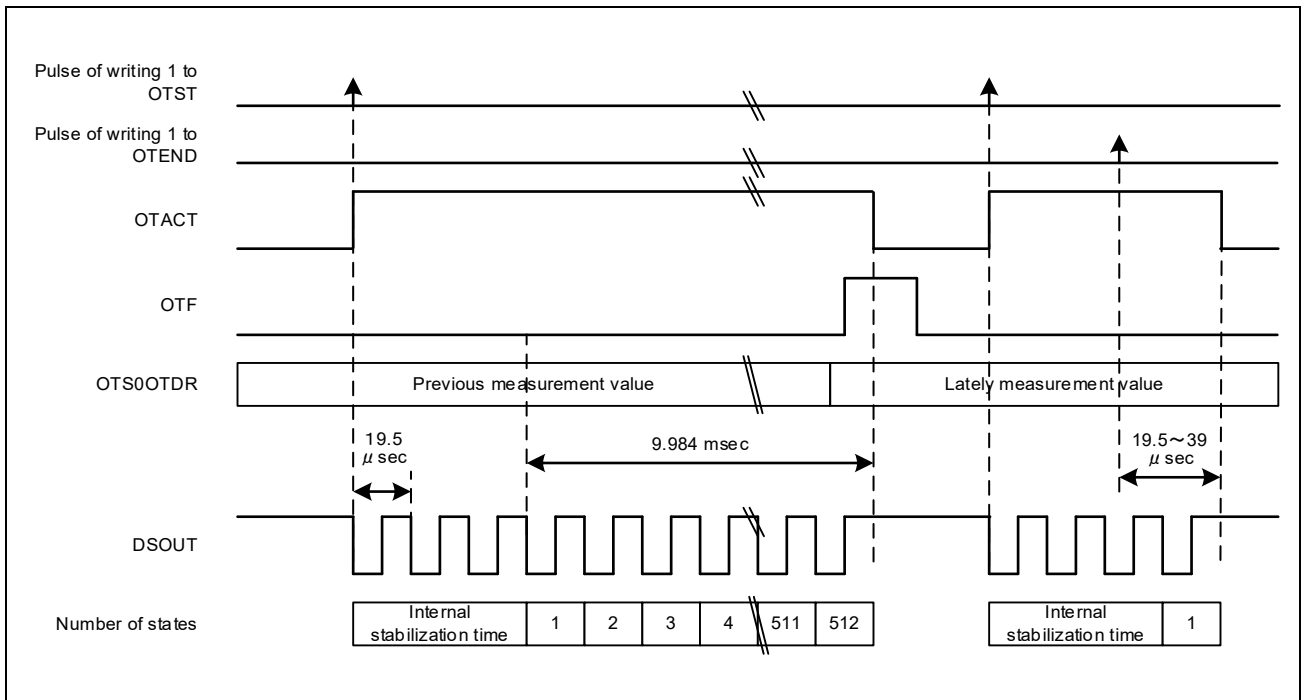

Figure 13.3 Example of Temperature Measurement Operation (Single Measurement Mode)

NOTE

If "1" is written to OTENDCR.OTEND at the time of internal cycle 511 or 512, request INTOTSOTI is issued and OTS0OTFR.OTF is set after updating the temperature measurement result as with the case of automatic stop after the temperature measurement.

DSOUT is the operation clock of the temperature sensor obtained by dividing CLK_LSB.

The period of DSOUT is 19.5 μs (When CLK_LSB 40 MHz)

The following figure shows temperature measurement operation in continuous measurement mode. There is no internal stabilization time in the second and subsequent temperature measurements.

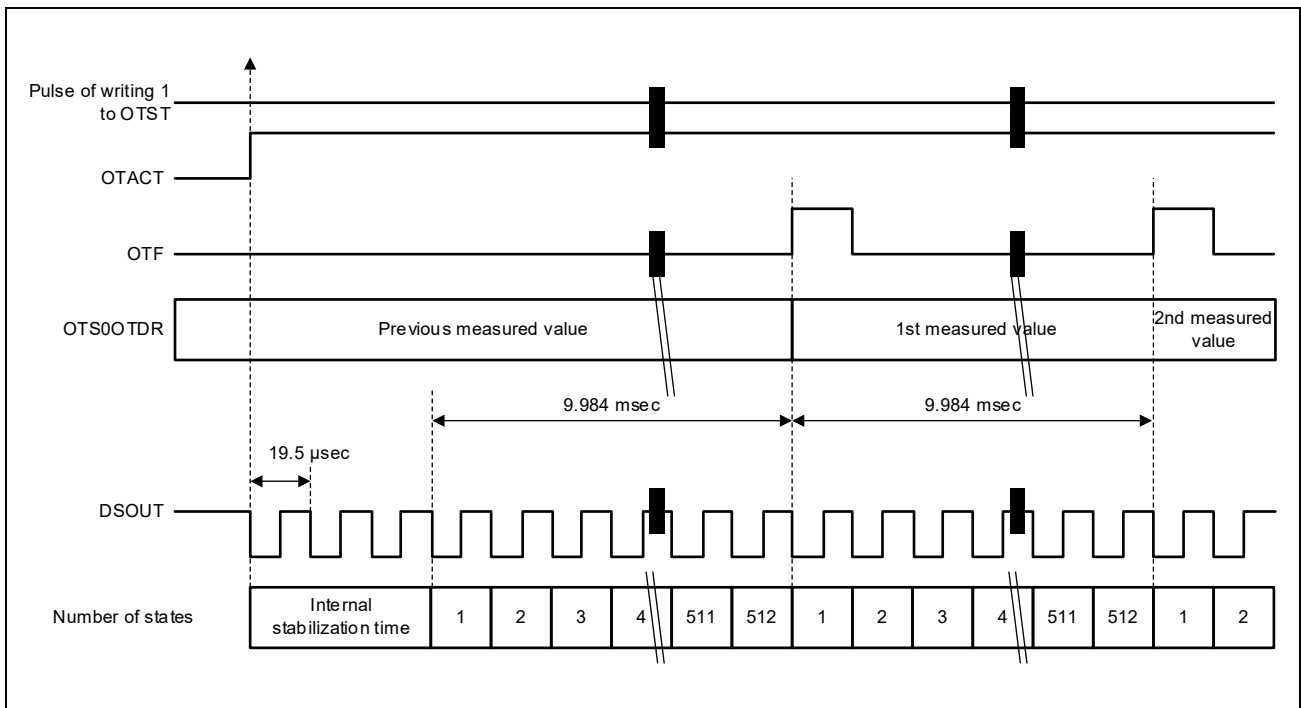

Figure 13.4 Example of Temperature Measurement Operation (Continuous Measurement Mode)

13.4.3 Temperature Measurement End Interrupt Request

The temperature sensor can generate a temperature measurement end interrupt request (INTOTSOTI) to be sent to the INTC. At this time, the OTS0OTFR.OTF is set.

The table below shows the assertion condition and negated conditions of INTOTSOTI and OTS0OTFR.OTF.

Table 13.20 Temperature Measurement End Conditions

Measurement End Notification Signal	Assert Conditions	Negated Conditions	Enable Control
Temperature measurement end interrupt (INTOTSOTI)	Each time temperature measurement ends	After the assertion, one cycle after the register access clock	No enable control bit.
Temperature measurement end flag (OTS0OTFR.OTF)	Each time temperature measurement ends	1) Reading of the OTS0OTDR register 2) Write 1 _B in OTS0OTFCR.OTFC	No enable control bit.

For the OTS0OTFR.OTF bit, if the assertion conditions and negated conditions conflict, negated condition takes precedence.

If the temperature measurement has been stopped by the OTS0OTENDCR.OTEND, neither the INTOTSOTI nor the OTS0OTFR.OTF will occur.

However, after writing “1” to the OTS0OTENDCR.OTEND, when the measurement is within 2 OTS clock cycles of being completed, the measurement result is updated and the INTOTSOTI and OTS0OTFR.OTF are asserted.

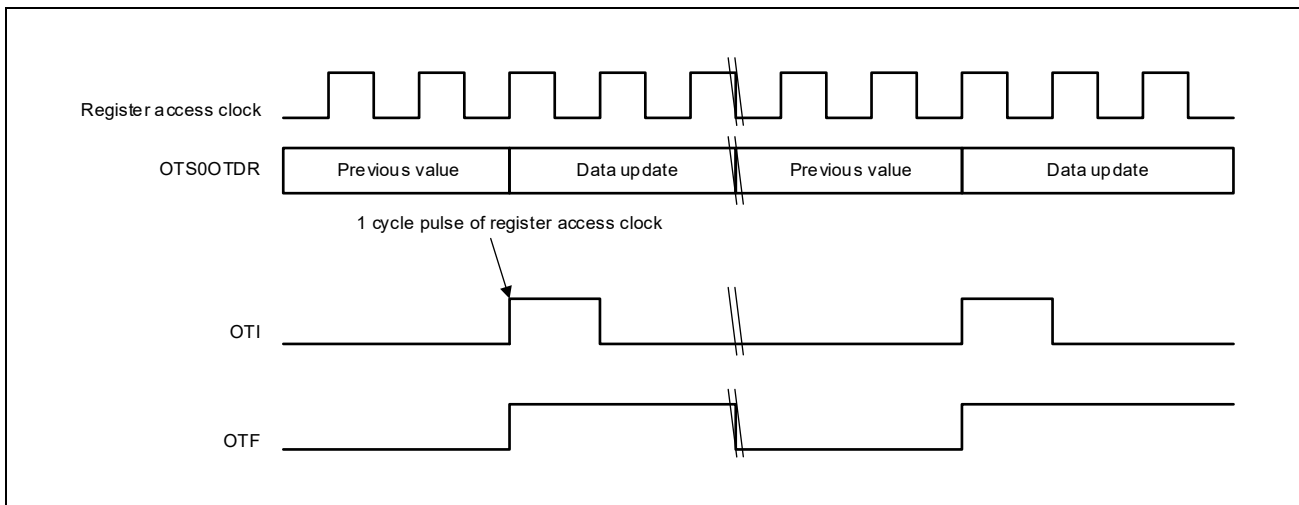

Figure 13.5 Example of Occurrence of a Temperature Measurement End Interrupt

13.4.4 Temperature Alarm Error and Temperature Rise/Drop Interrupt and Temperature Sensor Error Interrupt Requests

The temperature sensor can generate a temperature rise or drop interrupt request (INTOTSOTULI), a temperature sensor error interrupt request (INTOTSOTE) and a temperature alarm error (INTOTSOTABE) to be sent to the INTC. Setting OTULIE in OTS0OTCR to 1 enables INTOTSOTULI. Setting OTULIE to 0 disables INTOTSOTULI. Setting OTEE in OTS0OTCR to 1 enables INTOTSOTE. Setting OTEE to 0 disables INTOTSOTE. Setting OTABEE in OTS0OTCR to 1 enables INTOTSOTABE. Setting OTABEE to 0 disables INTOTSOTABE.

The table below shows the assert conditions and negated conditions of INTOTSOTULI and INTOTSOTABE.

Table 13.21 Temperature Sensor Interrupts

Temperature State Transition Notification Signal	Assert Conditions	Negated Conditions	Enable Control
Temperature rise or drop interrupt (INTOTSOTULI)	Temperature state transition from a state other than the high temperature B to high temperature B. Temperature state transition from a state other than the normal temperature to normal temperature.	After the assertion, one cycle after the register access clock	OTS0OTCR.OTULIE
Temperature alarm error (INTOTSOTABE)	Temperature state transition from a state other than the high temperature A to high temperature A. Temperature state transition from a state other than the low temperature A to low temperature A.	After the assertion, one cycle after the register access clock	OTS0OTCR.OTABEE
Temperature sensor error interrupt (INTOTSOTE)	After the OTDR register is updated, when the difference between the temperature measurements exceeds a set value TDL.	After the assertion, one cycle after the register access clock	OTS0OTCR.OTEE and OTS0OTCR.SDE
Diagnostic error flag (OTS0OTFR.SDER)	After the OTDR register is updated, when the difference between the temperature measurements exceeds a set value TDL.	Write 1 _B in OTS0OTFCR.SDERC	OTS0OTCR.SDE

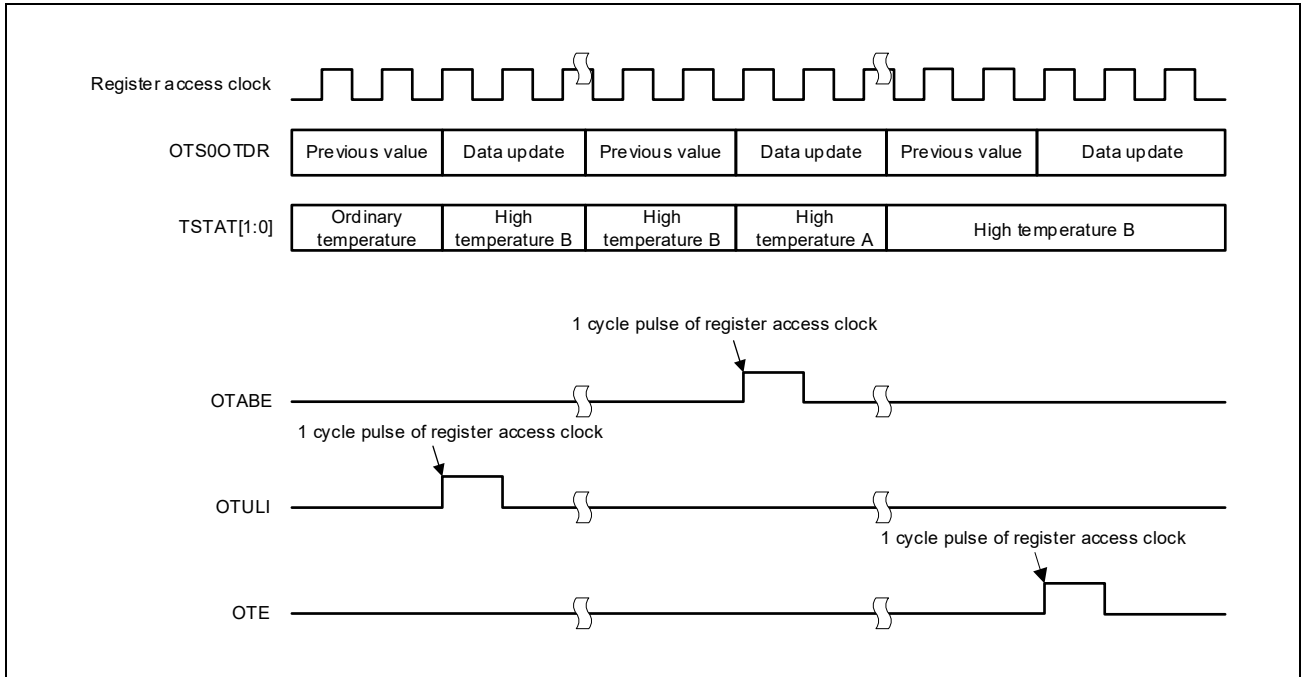

Figure 13.6 Example of Occurrence of a Temperature Alarm Error, a Temperature Rise/Drop Interrupt and a Temperature Sensor Error Interrupt

Section 14 Clock Monitor

14.1 Features

This section contains a generic description of clock monitor A (CLMA).

The first part of this section indicates all this product's specific properties, such as the number of channels and register base addresses.

The remainder of the section describes the functions and registers of CLMA.

14.1.1 Number of Channels

Table 14.1 Number of Channels

Clock Monitor	
Number of Channels	11
Name	CLMA _n (n = 0 to 10)

Note: CLMA4 is for the ICU-M. For details, refer to the relevant document. CLMA9 and CLMA10 are not supported in E2H.

14.1.2 Register Base Addresses

Table 14.2 Register Base Addresses

Base Address Name	Base Address	Bus group
<CLMAC_base>	FF70 2000 _H	Peripheral Group 6
<CLMA0_base>	FF70 2100 _H	Peripheral Group 6
<CLMA1_base>	FF70 2200 _H	Peripheral Group 6
<CLMA2_base>	FF70 2300 _H	Peripheral Group 6
<CLMA3_base>	FF70 2400 _H	Peripheral Group 6
<CLMA5_base>	FF70 2500 _H	Peripheral Group 6
<CLMA6_base>	FF70 2600 _H	Peripheral Group 6
<CLMA7_base>	FF70 2700 _H	Peripheral Group 6
<CLMA8_base>	FF70 2800 _H	Peripheral Group 6
<CLMA9_base>	FF70 2900 _H	Peripheral Group 6
<CLMA10_base>	FF70 2A00 _H	Peripheral Group 6

14.1.3 Clock Supply

The clocks monitored by CLMA and the CLMA sampling clocks are indicated below.

For each clock frequency, see **Section 15, Clock Controller**.

Table 14.3 Clock Supply

Unit Name	CLMATMON (monitored clock)	CLMATSM (sampling clock)	Register access clock
CLMA0	CLK_IOSC	CLK_MOSC / 8	CLK_LSB
CLMA1	CLK_MOSC	CLK_IOSC / 400	CLK_LSB
CLMA2	CLK_LSB	CLK_MOSC / 8	CLK_LSB
CLMA3	CLK_UHSB	CLK_MOSC / 8	CLK_LSB
CLMA5	CLK_CPU (PE0) / 4	CLK_MOSC / 8	CLK_LSB
CLMA6	CLK_CPU (PE1) / 4	CLK_MOSC / 8	CLK_LSB
CLMA7	CLK_CPU (PE2) / 4	CLK_MOSC / 8	CLK_LSB
CLMA8	CLK_CPU (PE3) / 4	CLK_MOSC / 8	CLK_LSB
CLMA9	CLK_CPU (PE4) / 4	CLK_MOSC / 8	CLK_LSB
CLMA10	CLK_CPU (PE5) / 4	CLK_MOSC / 8	CLK_LSB

14.1.4 Interrupt Requests

This module has no interrupt requests.

14.1.5 External Input and Output Pins

This module has no external input/output pins.

14.2 Overview

This product incorporates the clock monitors (CLMA) to monitor the clock operation by detecting the abnormal frequency of the clock to be monitored. The clock monitors provide the following functions.

- Monitors to see if the frequency of the clock to be monitored is within the specified range based on the sampling clock.
- Issues an error notice to the ECM upon detection of the abnormal state of the clock.

14.2.1 Functional Overview

Clock monitor CLMA detects frequency abnormalities in the monitored clock. It uses sampling clock CLMATSMPL to monitor whether the frequency of input clock CLMATMON is within a specific range.

Upon detection of an abnormal clock, it outputs a reset request signal.

14.2.2 Block Diagram

Figure 14.1 shows the block diagram of each clock monitor.

Figure 14.1 Block Diagram of Each Clock Monitor

14.3 Register

14.3.1 Register Protection

Write protected registers are protected from inadvertent write access due to erroneous program execution, etc.

By releasing the protection of CLMAKCPROT, they can be written. For details, see **Section 40, Functional Safety**.

14.3.2 List of Registers

The following table lists the CLMA registers.

<CLMAC_base> and <CLMA_n_base> are defined in **Section 14.1.2, Register Base Addresses**.

Table 14.4 List of Registers

Unit Name	Register Name	Symbol	Address	Access Size	Access Protection
CLMA _n	CLMA _n Control Register	CLMA _n CTL	<CLMA _n _base> + 000 _H	8	CLMAKCPROT
CLMA _n	CLMA _n Compare Register L	CLMA _n CMPL	<CLMA _n _base> + 008 _H	16	—
CLMA _n	CLMA _n Compare Register H	CLMA _n CMPH	<CLMA _n _base> + 00C _H	16	—
CLMAC	Clock Monitor Test Register	CLMATEST	<CLMAC_base> + 000 _H	32	CLMAKCPROT
CLMAC	Clock Monitor Test Status Register	CLMATESTS	<CLMAC_base> + 004 _H	32	—
CLMAC	Clock Monitor Backup Clock Enable Register	CLMABCE	<CLMAC_base> + 008 _H	8	CLMAKCPROT
CLMAC	Clock Monitor Register Key Code Protection Register	CLMAKCPROT	<CLMAC_base> + F00 _H	32	—

Note: (n = 0 to 3, 5 to 10)

14.3.3 Resetting the Registers

Table 14.5 Register Reset Conditions

Register Name	Reset Source					
	Power Up Reset	System Reset 1	System Reset 2	Application Reset	Module Reset	JTAG Reset
All registers	✓	✓	✓	✓	—	—

Each clock monitor (CLMA_n) can also be reset by CLMATEST.RESCLM. In this case, it is necessary to perform a special procedure and reconfigure the CLMA_n parameters before the clock frequency is changed by the register for the operating clock.

For details about this special procedure, see **Section 14.5.2, Reset Procedure Using CLMATEST.RESCLM.**

Table 14.6 Individual Reset Conditions

Channel Name	CLMATEST.RESCLM Reset Target									
	CLMA0TES EN = 1	CLMA1TES EN = 1	CLMA2TES EN = 1	CLMA3TES EN = 1	CLMA5TES EN = 1	CLMA6TES EN = 1	CLMA7TES EN = 1	CLMA8TES EN = 1	CLMA9TES EN = 1	CLMA10TE SEN = 1

14.3.4 CLMA_nCTL — CLMA_n Control Register

This register enables the clock monitor CLMA_n.

CLMA₉ and CLMA₁₀ are not supported in E2H.

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	CLMA _n CLME
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R/W

Table 14.7 CLMA_nCTL*¹ Register Contents

Bit Position	Bit Name	Function
7 to 1	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
0	CLMA _n CLME	Enables or disables the clock monitor: 0: Disables CLMA _n . 1: Enables CLMA _n . This bit can only be cleared by a reset

Note 1. CLMA₉CTL and CLMA₁₀CTL are reserved register in E2H. When reading, the value after reset is returned, write the value after reset.

14.3.5 CLMA_nCMPL — CLMA_n Compare Register L

This register specifies the lower limit of the monitored clock frequency.

Write access is permitted only when CLMA_n is disabled (CLMA_nCTL.CLMA_nCLME = 0).

CLMA9 and CLMA10 are not supported in E2H.

Value after reset: 0001_H

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	CLMA _n CMPL[11:0]											
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1
	R/W	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 14.8 CLMA_nCMPL*¹ Register Contents

Bit Position	Bit Name	Function
15 to 12	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
11 to 0	CLMA _n CMPL[11:0]	Specify the lower threshold. When CLMA is used, these bits must be set appropriately. CLMA0: 25F _H CLMA1: 4BB _H CLMA2: FE _H CLMA3: 3FB _H CLMA5: 27D _H (400 MHz) CLMA6: 27D _H (400 MHz) CLMA7: 27D _H CLMA8: 27D _H CLMA9: 27D _H CLMA10: 27D _H The above is an example of setting when using EXTAL. (Clock condition EXTAL +0%/-0.5%, Internal OSC ±5%, PLL ±0.05% (Long term jitter)) When CLMA is not used, these bits must retain their values after a reset.

Note 1. CLMA9CMPL and CLMA10CMPL are reserved register in E2H. When reading, the value after reset is returned, write the value after reset.

14.3.6 CLMA_nCMPH — CLMA_n Compare Register H

This register specifies the upper limit of monitored clock frequency.

Write access is permitted only when the CLMA_n is disabled (CLMA_nCTL.CLMA_nCLME = 0).

CLMA9 and CLMA10 are not supported in E2H.

Value after reset: 03FF_H

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	CLMA _n CMPH[11:0]											
Value after reset	0	0	0	0	0	0	1	1	1	1	1	1	1	1	1	1
	R/W	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 14.9 CLMA_nCMPH*¹ Register Contents

Bit Position	Bit Name	Function
15 to 12	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
11 to 0	CLMA _n CMPH[11:0]	Specify the upper threshold. When CLMA is used, these bits must be set appropriately.. CLMA0: 2A5 _H CLMA1: 545 _H CLMA2: 102 _H CLMA3: 40A _H CLMA5: 286 _H (400 MHz) CLMA6: 286 _H (400 MHz) CLMA7: 286 _H CLMA8: 286 _H CLMA9: 286 _H CLMA10: 286 _H The above is an example of setting when using EXTAL. (Clock condition EXTAL +0%/-0.5%, Internal OSC ±5%, PLL ±0.05% (Long term jitter)) When CLMA is not used, these bits must retain their values after a reset.

Note 1. CLMA9CMPH and CLMA10CMPH are reserved register in E2H. When reading, the value after reset is returned, write the value after reset.

14.3.7 CLMATEST — Clock Monitor Test Register

This register is used for the self-test of the clock monitors. Each Clock Monitor can be tested individually.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 14.10 CLMATEST Register Contents (1/2)

Bit Position	Bit Name	Function
31 to 13	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
12	CLMA10TESEN ^{*2}	CLMA10 self-test enable/disable 0: Test disabled. 1: Test enabled.
11	CLMA9TESEN ^{*2}	CLMA9 self-test enable/disable 0: Test disabled. 1: Test enabled.
10	CLMA8TESEN	CLMA8 self-test enable/disable 0: Test disabled. 1: Test enabled.
9	CLMA7TESEN	CLMA7 self-test enable/disable 0: Test disabled. 1: Test enabled.
8	CLMA6TESEN	CLMA6 self-test enable/disable 0: Test disabled. 1: Test enabled.
7	CLMA5TESEN	CLMA5 self-test enable/disable 0: Test disabled. 1: Test enabled.
6	CLMA3TESEN	CLMA3 self-test enable/disable 0: Test disabled. 1: Test enabled.
5	CLMA2TESEN	CLMA2 self-test enable/disable 0: Test disabled. 1: Test enabled.
4	CLMA1TESEN	CLMA1 self-test enable/disable 0: Test disabled. 1: Test enabled.

Table 14.10 CLMATEST Register Contents (2/2)

Bit Position	Bit Name	Function
3	CLMA0TESEN	CLMA0 self-test enable/disable 0: Test disabled. 1: Test enabled.
2	ERRMSK* ¹	Masks an error notification to the ECM when CLMAn detects an error. When the ERRMSK is set for a certain CLMAn, the associated CLMAn does not issue an error notification to the ECM even if it detects an error. 0: Does not mask an error notification to the ECM. 1: Masks an error notification to the ECM.
1	MONCLKMSK* ¹	Fixes the level of the clock input to the CLMAn that should be monitored, to the low level. 0: Does not fix the clock input to the CLMAn that should be monitored to the low level. 1: Fixes the clock input to the CLMAn that should be monitored to the low level.
0	RESCLM* ¹	Initializes CLMAn forcibly. 0: Does not initialize CLMAn. 1: Initializes CLMAn.

Note 1. These bits are valid for CLMAn that is in self-diagnosis mode by setting "1" to CLMAnTESEN.

Note 2. These bits are reserved bit in E2H. When reading, the value after reset is returned, write the value after reset.

14.3.8 CLMATESTS — Clock Monitor Test Status Register

This register is used for the self-test of the clock monitors. It monitors the error detection flags that are otherwise forwarded to the ECM module. Once error is detected, this register keeps the status until CLMA_n is reset.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

3	CLMA3ERRS	CLMA3 error status 0: No error detected 1: Error detected
2	CLMA2ERRS	CLMA2 error status 0: No error detected 1: Error detected
1	CLMA1ERRS	CLMA1 error status 0: No error detected 1: Error detected

Table 14.11 CLMATESTS Register Contents (2/2)

Bit Position	Bit Name	Function
0	CLMA0ERRS	CLMA0 error status 0: No error detected 1: Error detected

Note 1. These bits are reserved bit in E2H. When reading,the value after reset is returned,write the value after reset.

14.3.9 CLMABCE — Clock Monitor Backup Clock Enable Register

This register is a backup clock switching control register.

When CLMA1 or CLMA5 detects an error, the selector to select the startup clock source (CLK_IOOSC) or PLL Clock will be switched to choose the startup clock source (CLK_IOOSC).

For switching points, see **Section 15, Clock Controller**.

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	CLMABCE
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R/W

Table 14.12 CLMABCE Register Contents

Bit Position	Bit Name	Function
7 to 1	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
0	CLMABCE	Backup clock switching control 0: Disable the backup clock function 1: Enable the backup clock function

14.3.10 CLMAKCPROT — Clock Monitor Register Key Code Protection Register

The CLMAKCPROT register is used for protection against writing operation to the registers that may have a material effect on the system so that the application system is not incorrectly stopped due to program malfunction and the like.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	KCPROT[31:16]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	KCPROT[15:1]															KCE
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W	R/W

Table 14.13 CLMAKCPROT Register Contents

Bit Position	Bit Name	Function
31 to 1	KCPROT[31:1]	Enable or disable modification of the KCE bit. The written value is not retained. These bits are always read as 0. *1
0	KCE	Key Code Enable bit 0: Disable write access to protected registers 1: Enable write access to protected registers

Note 1. Write A5A5 A500_H to this register to disable writing to protected registers.
Write A5A5 A501_H to this register to enable writing to protected registers.

14.4 Functional Description

The Clock Monitor CLMAn is used to verify whether the frequency of a clock (CLMATMON) is within the specified range.

14.4.1 Detection of Abnormal Clock Frequencies

Detection Method

- (1) CLMAn counts the rising edges of the monitored clock CLMATMON within 16 cycles of the sampling clock CLMATSMPL and then compares the count with the configured thresholds:
 - CLMAnCMPL.CLMAnCMPL[11:0] defines the lower threshold.
 - CLMAnCMPH.CLMAnCMPH[11:0] defines the upper threshold.
- (2) When the frequency of CLMATMON is too low*¹, the count falls below CLMAnCMPL.CLMAnCMPL.
- (3) When the frequency of CLMATMON is too high, the count exceeds CLMAnCMPH.CLMAnCMPH.

Note 1. If the monitored clock stops completely, an error may not be detected.

Figure 14.2 Example: f_{CLMATMON} is Lower than the Specified Limit.

Figure 14.3 Example: $f_{CLMATMON}$ is Higher than the Specified Limit.

NOTE

Even if the $f_{CLMATMON}$ exceeds or falls below the specified limits during a sampling period, the count value may be within the valid range.
 Abnormal $f_{CLMATMON}$ is detected in the next sampling period.

Calculation of thresholds

For the compare registers CLMAnCMPL and CLMAnCMPH, specify the minimum and maximum number of CLMATMON clock cycles to occur within 16 cycles of the sampling clock CLMATSMPL that defines the normal range of CLMATMON.

The number of CLMATMON clock cycles to occur within 16 cycles of CLMATSMPL is denoted by N .

$$\frac{16}{f_{CLMATSMPL}} = \frac{N}{f_{CLMATMON}}$$

$$N = \frac{f_{CLMATMON}}{f_{CLMATSMPL}} \times 16$$

Considering the allowed frequency deviations of CLMATMON and CLMATSMPL, the threshold values can be calculated by the following formulas:

$$\begin{aligned} \text{Lower threshold} &= N_{min} \\ &= \frac{f_{CLMATMON(min)}}{f_{CLMATSMPL(max)}} \times 16 - 1 \end{aligned}$$

$$\begin{aligned} \text{Upper threshold} &= N_{max} \\ &= \frac{f_{CLMATMON(max)}}{f_{CLMATSMPL(min)}} \times 16 + 1 \end{aligned}$$

<Example>

For $f_{CLMATSMPL} = 250 \text{ kHz} (\pm 5\%)$ and $f_{CLMATMON} = 20 \text{ MHz} (\pm 0.1\%)$, the recommended threshold values are the following:

$$\begin{aligned} N_{min} &= 19.98 / 0.2625 \times 16 - 1 \\ &= 1216.83 \\ \text{CLMAnCMPL} &= 1216 = 04C0_H \\ \\ N_{max} &= 20.02 / 0.2375 \times 16 + 1 \\ &= 1348.72 \\ \text{CLMAnCMPH} &= 1349 = 0545_H \end{aligned}$$

<Minimum thresholds>

The following restrictions must be taken into account:

- CLMAnCMPL \geq 0001_H
- CLMAnCMPH \geq CLMAnCMPL + 0003_H

14.4.2 Error Notification

When the frequency of the monitored clock (CLMATMON) becomes too low or too high and an error is detected, CLMA_n sends an error notification to ECM. In addition, the error notification is not canceled until CLMA_n is reset.

When CLMA1 or CLMA5 detects an error, the selector to select the startup clock source (CLK_IOSC) or PLL Clock will be switched to choose the startup clock source (CLK_IOSC).

After the clock source is switched to CLK_IOSC when CLMA1 or CLMA5 detect an error, the clock source cannot be switched with the selection of CKSC0C.

NOTES

1. When CLK_IOSC is selected due to the back-up clock function, CLMA2 to CLMA10 will begin to detect errors.
2. Even if the monitor clock stops completely, the clock source may not be switched to startup clock source (CLK_IOSC). In addition, reset or interrupt may not occur from the ECM.

14.4.3 Self-Diagnosis

This LSI implements a self-diagnosis function for the clock monitors. It allows isolating the clock monitor from the system and executing functional test patterns via software. Each clock monitor can be tested individually. For performing these tests, the clock monitor inputs can be controlled by dedicated control registers, while its outputs can be observed in status registers.

Two registers are implemented for the self-diagnosis of the clock monitors, the Clock Monitor Test Register (CLMATEST) and the Clock Monitor Test Status Register (CLMATESTS). Refer to the corresponding register descriptions for details.

14.5 Operation

14.5.1 Procedures to Enable CLMA_n

[Procedure]

- (1) Enable write access of protected registers by setting CLMAKCPROT = A5A5 A501_H according to CLMA targets.
- (2) Set the minimum and maximum number of clock cycles to CLMA_nCMPL and CLMA_nCMPLH.
- (3) Set enable/disable of back up clock switching to the CLMABCE register.
- (4) Enable CLMA_n by setting 01_H to CLMA_nCTL.CLMA_nCLME.
- (5) Disable write access of protected registers by setting CLMAKCPROT.KCE = A5A5 A500_H according to CLMA targets.

CAUTION

- CLMA_n (n = 0, 1) operation must be started after users check stable state of MainOSC by referring to MOSCS.MOSCSTAB = 1.
- CLMA_n (n = 2 to 10) operation must be started after users check that the clock gear-up procedure has been finished.
- When Startup BIST is not executed by flash option at the reset of Power Up Reset, Standby Reset and VMON Reset with using crystal resonator, as soon as CPU boot up and wait until MOSCS.MOSCSTAB = 1, it is necessary to initialize CLMA_n (n = 0, 2 to 10) according to the procedure of **Section 14.5.2, Reset Procedure Using CLMATEST.RESCLM** and then clear all CLMA_n (n = 0, 2 to 10) related error flags presented in ECM master/checker error source status registers. For details of these error registers and how to clear them, please see **Section 41, Error Control Module (ECM)**.

14.5.2 Reset Procedure Using CLMATEST.RESCLM

Each clock monitor (CLMA0/1/2/3/5/6/7/8/9/10) can also be reset by CLMATEST.RESCLM. In this case, it is necessary to perform the following procedure and reconfigure the CLMA_n parameters before the clock frequency is changed by the register for the operating clock.

[Procedure]

Example: Resetting CLMA0

1. CLMATEST.CLMA0TESEN = 1 (write data: 0000 0008_H)
2. CLMATEST.ERRMSK = 1 (write data: 0000 000C_H)
3. CLMATEST.MONCLKMSK = 1 (write data: 0000 000E_H)
4. CLMATEST.RESCLM = 1 (write data: 0000 000F_H)
5. CLMATEST.RESCLM = 0 (write data: 0000 000E_H)
6. CLMATEST.MONCLKMSK = 0 (write data: 0000 000C_H)
7. CLMATEST.ERRMSK = 0 (write data: 0000 0008_H)
8. CLMATEST.CLMA0TESEN = 0 (write data: 0000 0000_H)

14.5.3 Procedures to do Self-Diagnosis

Self-diagnosis of the clock monitor is available as described below. In the description, the clock monitor to be self-diagnosed is operating.

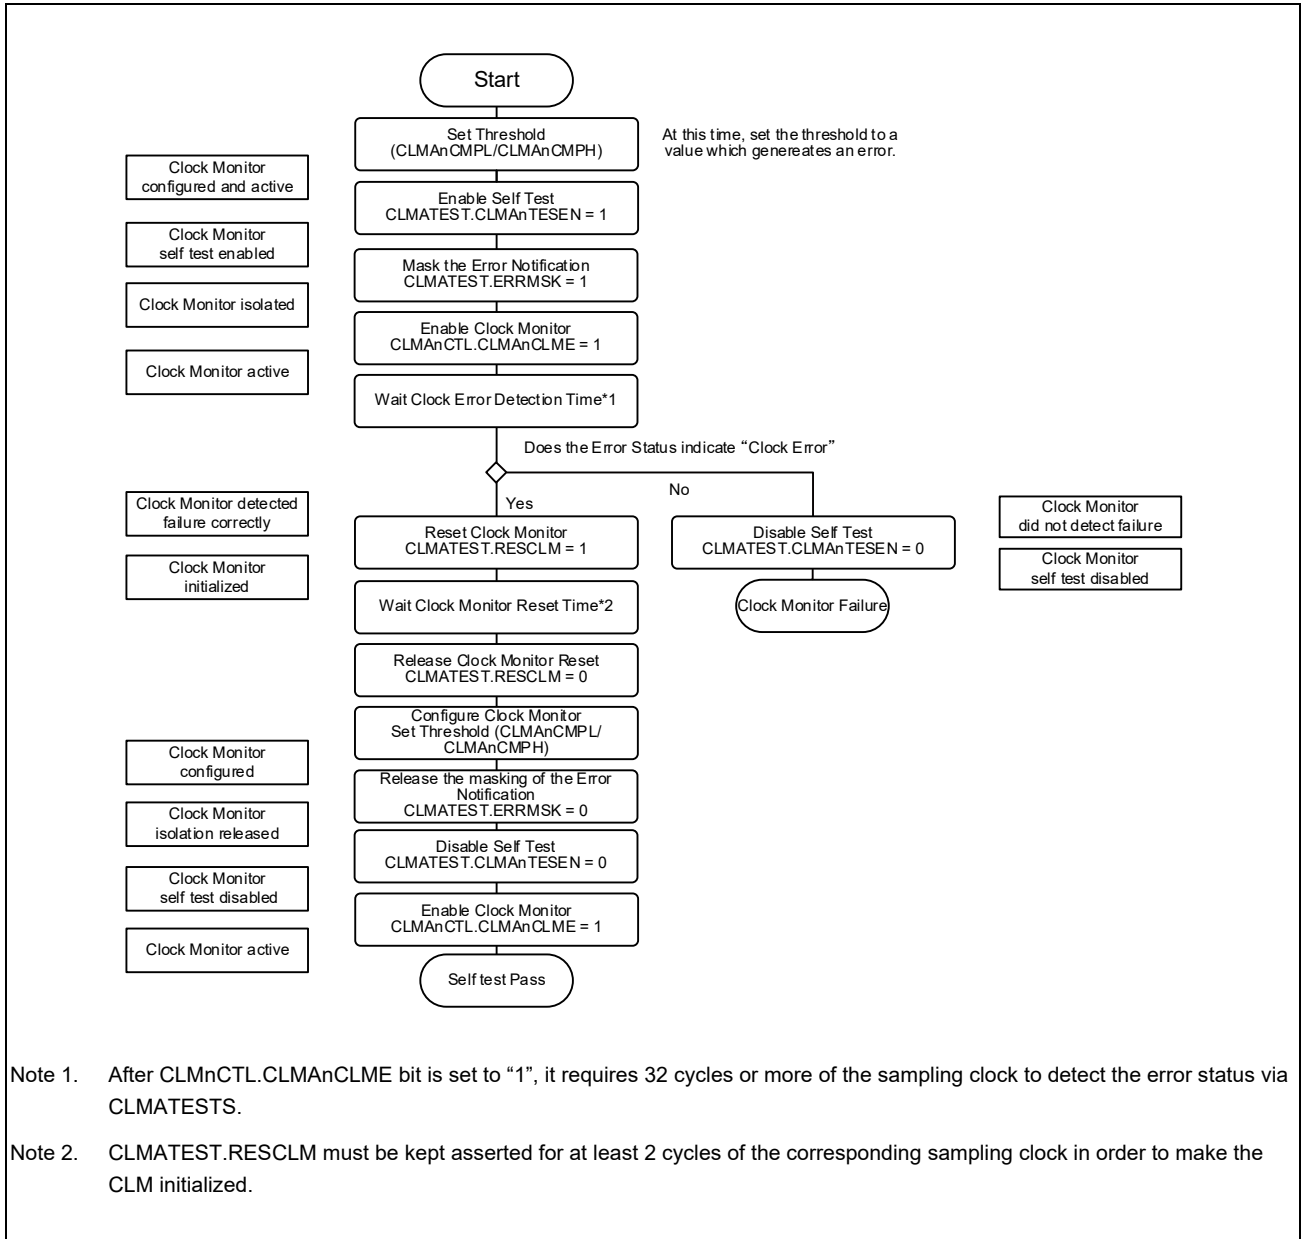

Figure 14.4 Flow Chart of Self-Diagnosis

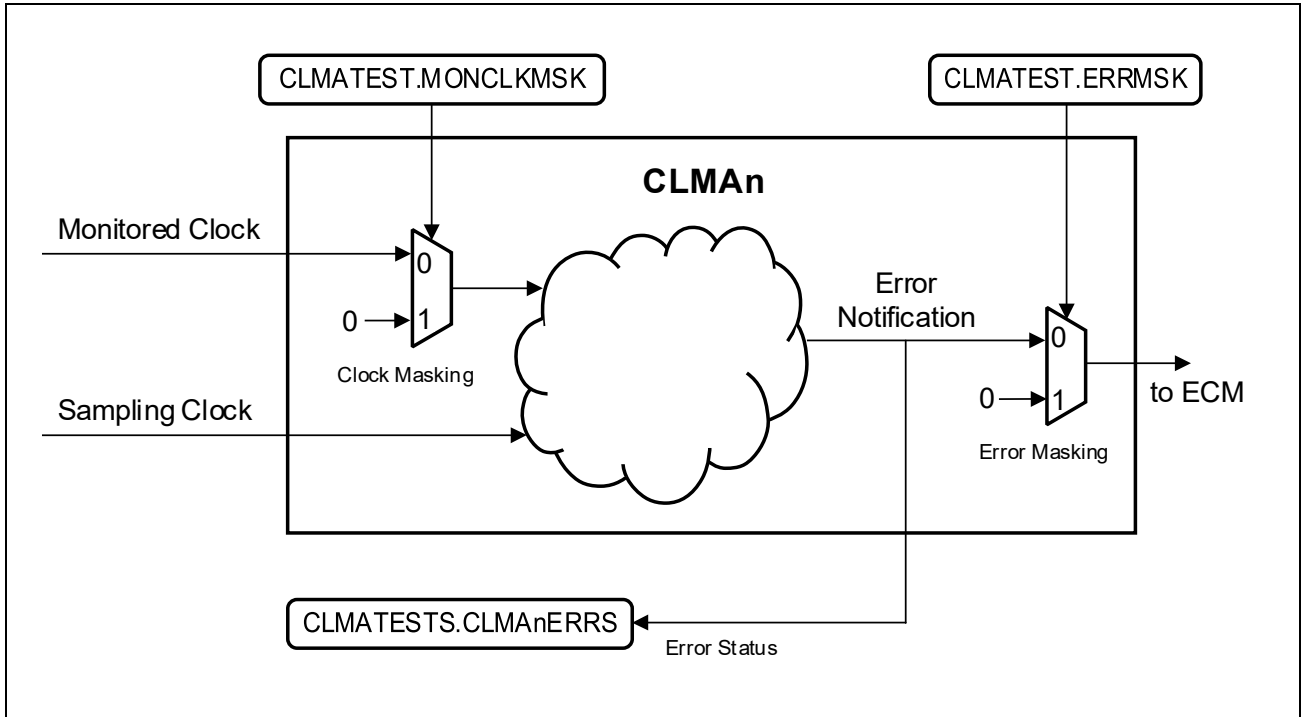

Figure 14.5 Self-Diagnosis of the Clock Monitor

Section 15 Clock Controller

The clock controller generates several clocks that are supplied to peripherals and to external pins for use by other devices. The clock controller consists of a main oscillator circuit (Main OSC), an internal oscillator, a Phase Locked Loop circuit (PLL), clock dividers and clock selectors. PLL uses the Main OSC as a reference clock. Use of Main OSC is mandatory.

15.1 Features

- Crystal resonator circuit (Main OSC), used as a PLL reference clock
- Internal oscillator, used as the startup and backup clock
- PLL circuit to generate high speed internal clocks by multiplying the Main OSC input
- Software configurable external clock output
- Clock controller can generate clock pulses from internal oscillator, main oscillator and PLL
- MainOsc Configuration is variable by OPBT7. Please refer to **Section 15.4.3, Main OSC Configuration and Stabilization Sequence** and **Section 15.4.4, OSC Monitor Mode**

15.1.1 Register Base Addresses

The clock controller base address is shown in the following table.

Clock controller register addresses are given as offsets from the base addresses in general.

Table 15.1 Register Base Addresses

Base Address Name	Base Address	Bus Group
<CLK_base>	FF70 3000 _H	Peripheral Group 6

15.1.2 External Input / Output Pins

Table 15.2 shows the pins related to the clock controller.

Table 15.2 Pins Related to the Clock Controller

Pin Function Name	Direction	Function
EXTAL	Input	Main OSC crystal resonator / external clock input
XTAL	Output	Main OSC crystal resonator
CK	Output	External clock out (divider 2)

15.2 Overview

15.2.1 Types of Clocks

The clock sources are listed in **Table 15.3**, and the clock frequencies based on different clock sources are listed in **Table 15.4** and **Table 15.5**.

Table 15.3 List of Clock Sources

Clock Name	Symbol	Clock Frequency (MHz)	Remarks
EXTAL, XTAL	EXTAL, XTAL	20/40	The frequency of EXTAL can be selected by using an option byte.* ¹ Main OSC crystal resonator or external clock input
MainOSC	CLK_MOSC	20	CLK_MOSC is the 20MHz clock after selected by using an option byte.* ¹
Internal OSC	CLK_IOSC	100	
WDTB/SWDT counter clock	CLK_WDT	0.25	WDTB / SWDT counter clock source can be selected by using an option byte.* ¹ Clock source: CLK_MOSC* ² or CLK_IOSC
ICU-M (WDTA) counter clock / ECM counter clock	CLK_WDTICUM	0.25	Clock source: CLK_IOSC
HVIOSC (VMON filter clock)	CLK_HVIOSC	16	
External clock out	CK	Divider 2 setting Maximum output frequency: 4 MHz	Clock source: CLK_MOSC or CLK_LSB

Note 1. See **Section 43, Flash Memory** for target values.

Note 2. WDTB auto-start by CLK_MOSC is prohibited if BIST is not executed.

Table 15.4 Clock Frequencies with PLL as the Clock Source

Clock Name	Symbol	Clock Frequency Mode (MHz)		Remarks
		400 MHz Mode		
CPU clock	CLK_CPU	400		The clock frequency can be divided by Divider 0 (CLKD0DIV) settings. Clock source: PLL clock
System Bus clock	CLK_SBUS	200		
H-Bus clock	CLK_HBUS	100		
Peripheral ultra high speed clock	CLK_UHSB	160		
Peripheral high speed clock	CLK_HSB	80		
Peripheral low speed clock	CLK_LSB	40		
RHSB clock	CLK_RHSB	80/160		The RHSB clock source can be selected by using an option byte.* ¹ Clock source: CLK_HSB or CLK_UHSB

Note 1. See **Section 43, Flash Memory** for target values.

Table 15.5 Clock Frequencies with Internal OSC as the Clock Source

Clock Name	Symbol	Clock Frequency Mode (MHz)		Remarks
		400 MHz Mode		
CPU clock	CLK_CPU	100		If the source clock is CLK_IOSC, then the CPU clock is 100 MHz in all modes, but the peripheral clocks are different in each mode. This is because the division ratio between the CPU clock and peripheral clocks is fixed in each mode.
System Bus clock	CLK_SBUS	50		
H-Bus clock	CLK_HBUS	25		
Peripheral ultra high speed clock	CLK_UHSB	40		
Peripheral high speed clock	CLK_HSB	20		
Peripheral low speed clock	CLK_LSB	10		
RHSB clock	CLK_RHSB	20/40		The RHSB clock source can be selected by using the option bytes.* ¹ Clock source: CLK_HSB or CLK_UHSB

Note 1. Refer to **Section 43, Flash Memory** for target values

15.2.2 Block Diagram

A block diagram of the clock controller is shown in **Figure 15.1**.

Figure 15.1 Block Diagram of Clock Controller

15.3 Register Description

15.3.1 Register Protection

Write protection prevents inadvertent changing of register content due to erroneous software execution.

The CLKKCPROT0 and CLKKCPROT1 registers have to be written first in order to unlock protected registers and allow changing the register content.

15.3.2 List of Registers

The following table lists the clock controller registers.

Table 15.6 List of Clock Controller Registers

Unit Name	Register Name	Symbol	Address	Access Size	Access Protection
SYCTRL	Clock Divider 0 Divisor Register	CLKD0DIV	<CLK_base> + 000 _H	32	CLKKCPROT0
SYCTRL	Clock Divider 0 Status Register	CLKD0STAT	<CLK_base> + 004 _H	32	—
SYCTRL	Clock Divider 2 Divisor Register	CLKD2DIV	<CLK_base> + 010 _H	32	CLKKCPROT0
SYCTRL	Clock Divider 2 Status Register	CLKD2STAT	<CLK_base> + 014 _H	32	—
SYCTRL	Clock Selector 0 Control Register	CKSC0C	<CLK_base> + 100 _H	32	CLKKCPROT0
SYCTRL	Clock Selector 0 Status Register	CKSC0S	<CLK_base> + 108 _H	32	—
SYCTRL	Clock Selector 2 Control Register	CKSC2C	<CLK_base> + 180 _H	32	CLKKCPROT0
SYCTRL	Clock Selector 2 Status Register	CKSC2S	<CLK_base> + 188 _H	32	—
SYCTRL	PLL Oscillation Status Register	PLLCLKS	<CLK_base> + 200 _H	32	—
SYCTRL	Main Oscillation Status Register	MOSCS	<CLK_base> + 400 _H	32	—
SYCTRL	OSC Monitor Mode Entry Register	OSCMONMD	<CLK_base> + 404 _H	32	CLKKCPROT1
SYCTRL	Clock Controller Register Key Code Protection Register 0	CLKKCPROT0	<CLK_base> + 700 _H	32	—
SYCTRL	Clock Controller Register Key Code Protection Register 1	CLKKCPROT1	<CLK_base> + 710 _H	32	—

15.3.3 Reset of Registers

Table 15.7 Reset Sources Applicable to Each Register

Symbol	Reset Source

Table 15.9 CLKD0STAT Register Contents

Bit Position	Bit Name	Function
31 to 2	—	Reserved When read, the value after reset is returned.
1	CLKD0SYNC	Divider clock synchronized 0: The system and peripheral clock do not correspond to the division ratio setting in CLKD0DIV. 1: The system and peripheral clock correspond to the division ratio setting in CLKD0DIV.
0	—	Reserved When read, the value after reset is returned.

15.3.6 CLKDnDIV — Clock Divider Divisor Register (n = 2)

This register defines the division ratio of clock divider n (n = 2) used for the external clock.

This register must not be written with a new value while CLKDnSYNC is deasserted.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 15.12 CLKDnSTAT Register Contents

Bit Position	Bit Name	Function
31 to 2	—	Reserved When read, the value after reset is returned.
1	CLKDnSYNC	Divider clock synchronized 0: The external clock does not correspond to the division ratio setting in CLKDnDIV. 1: The external clock corresponds to the division ratio setting in CLKDnDIV.
0	CLKDnCLKACT	Divider clock active 0: The external clock is inactive (CLKDnDIV[4:0] = 00000 _B) 1: The external clock is active

15.3.8 CKSC0C — Clock Selector 0 Control Register

This register selects the clock that drives the system and peripheral clock trees.

This register must not be written with a new value while CKSC0S shows a different ID.

Value after reset: 0000 0002_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 15.14 CKSC0S Register Contents

Bit Position	Bit Name	Function
31 to 3	—	Reserved When read, the value after reset is returned.
2 to 0	CLKACT0[2:0]	Clock source status Indicates the ID of the selected clock source of the system and peripheral clock. The value indicated by these bits shows the actual ID that is currently selected or currently waiting to be changed to another ID. ID = 001 _B : PLL ID = 010 _B : Internal OSC

15.3.10 CKSCnC — Clock Selector Control Register (n = 2)

This register selects the clock that drives the CK clock .

This register must not be written with a new value while CKSCnS shows a different ID.

Value after reset: 0000 0003_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 15.16 CKSCnS Register Contents

Bit Position	Bit Name	Function
31 to 3	—	Reserved When read, the value after reset is returned.
2 to 0	CLKACTn[2:0]	Clock source status Indicates the ID of the selected clock source of the external clock. The value indicated by these bits shows the actual ID that is currently selected or currently waiting to be changed to another ID. ID = 011 _B : CLK_MOSC ID = 100 _B : CLK_LSB

15.3.12 PLLCLKS — PLL Oscillation Status Register

This register indicates the PLL oscillation status.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	CLK STAB	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0*1	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Note 1. Depends on the read timing after the CPU starts operation.

Table 15.17 PLLCLKS Register Contents

Bit Position	Bit Name	Function
31 to 2	—	Reserved When read, the value after reset is returned.
1	CLKSTAB	PLL clock stable state 0: PLL is unstable. 1: PLL is stable.
0	—	Reserved When read, the value after reset is returned.

15.3.13 MOSCS — Main Oscillation Status Register

This register indicates the main oscillator status.

Value after reset: 0000 000x_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	MOSC STAB
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0*1
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Note 1. Depends on the read timing after the CPU starts operation.

Table 15.18 MOSCS Register Contents

Bit Position	Bit Name	Function
31 to 1	—	Reserved When read, the value after reset is returned.
0	MOSCSTAB	Main OSC clock stable state 0: Main OSC clock is unstable. 1: Main OSC clock is stable.

15.3.14 OSCMONMD — OSC Monitor Mode Entry Register

This register enables OSC monitor mode.

Writing to this register is enabled when CKSC0C.CKSC0[2:0] = 2_H.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	OSCMONMD
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Table 15.19 OSCMONMD Register Contents

Bit Position	Bit Name	Function
31 to 1	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
0	OSCMONMD	OSC Monitor mode entry bit 0: Disable OSC monitor mode 1: Enable OSC monitor mode

15.3.15 CLKKCPROT0 — Clock Controller Register Key Code Protection Register 0

The CLKKCPROT0 register is used to protect against writing to registers that may have a material effect on the system, so that the application system is not incorrectly stopped by a program malfunction, etc.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	KCPROT[31:16]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	KCPROT[15:1]															KCE
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W	R/W

Table 15.20 CLKKCPROT0 Register Contents

Bit Position	Bit Name	Function
31 to 1	KCPROT[31:1]	Enable or disable modification of the KCE bit. The written value is not retained. These bits are always read as 0.*1
0	KCE	Key Code Enable bit 0: Disable write access to protected registers 1: Enable write access to protected registers

Note 1. Write A5A5 A500_H to this register to disable writing protected registers.
Write A5A5 A501_H to this register to enable writing protected registers.

15.3.16 CLKKCPROT1 — Clock Controller Register Key Code Protection Register 1

The CLKKCPROT1 register is used to protect against writing to registers that may have a material effect on the system, so that the application system is not incorrectly stopped by a program malfunction, etc.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	KCPROT[31:16]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	KCPROT[15:1]															KCE
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W	R/W

Table 15.21 CLKKCPROT1 Register Contents

Bit Position	Bit Name	Function
31 to 1	KCPROT[31:1]	Enable or disable modification of the KCE bit. The written value is not retained. These bits are always read as 0. *1
0	KCE	Key Code Enable bit 0: Disable write access to protected registers 1: Enable write access to protected registers

Note 1. Write A5A5 A500_H to this register to disable writing protected registers.
Write A5A5 A501_H to this register to enable writing protected registers.

15.4 Operation

15.4.1 Sequence for Shifting the Clock Gear Up

To switch the clock signals, follow the procedure shown in **Figure 15.2**.

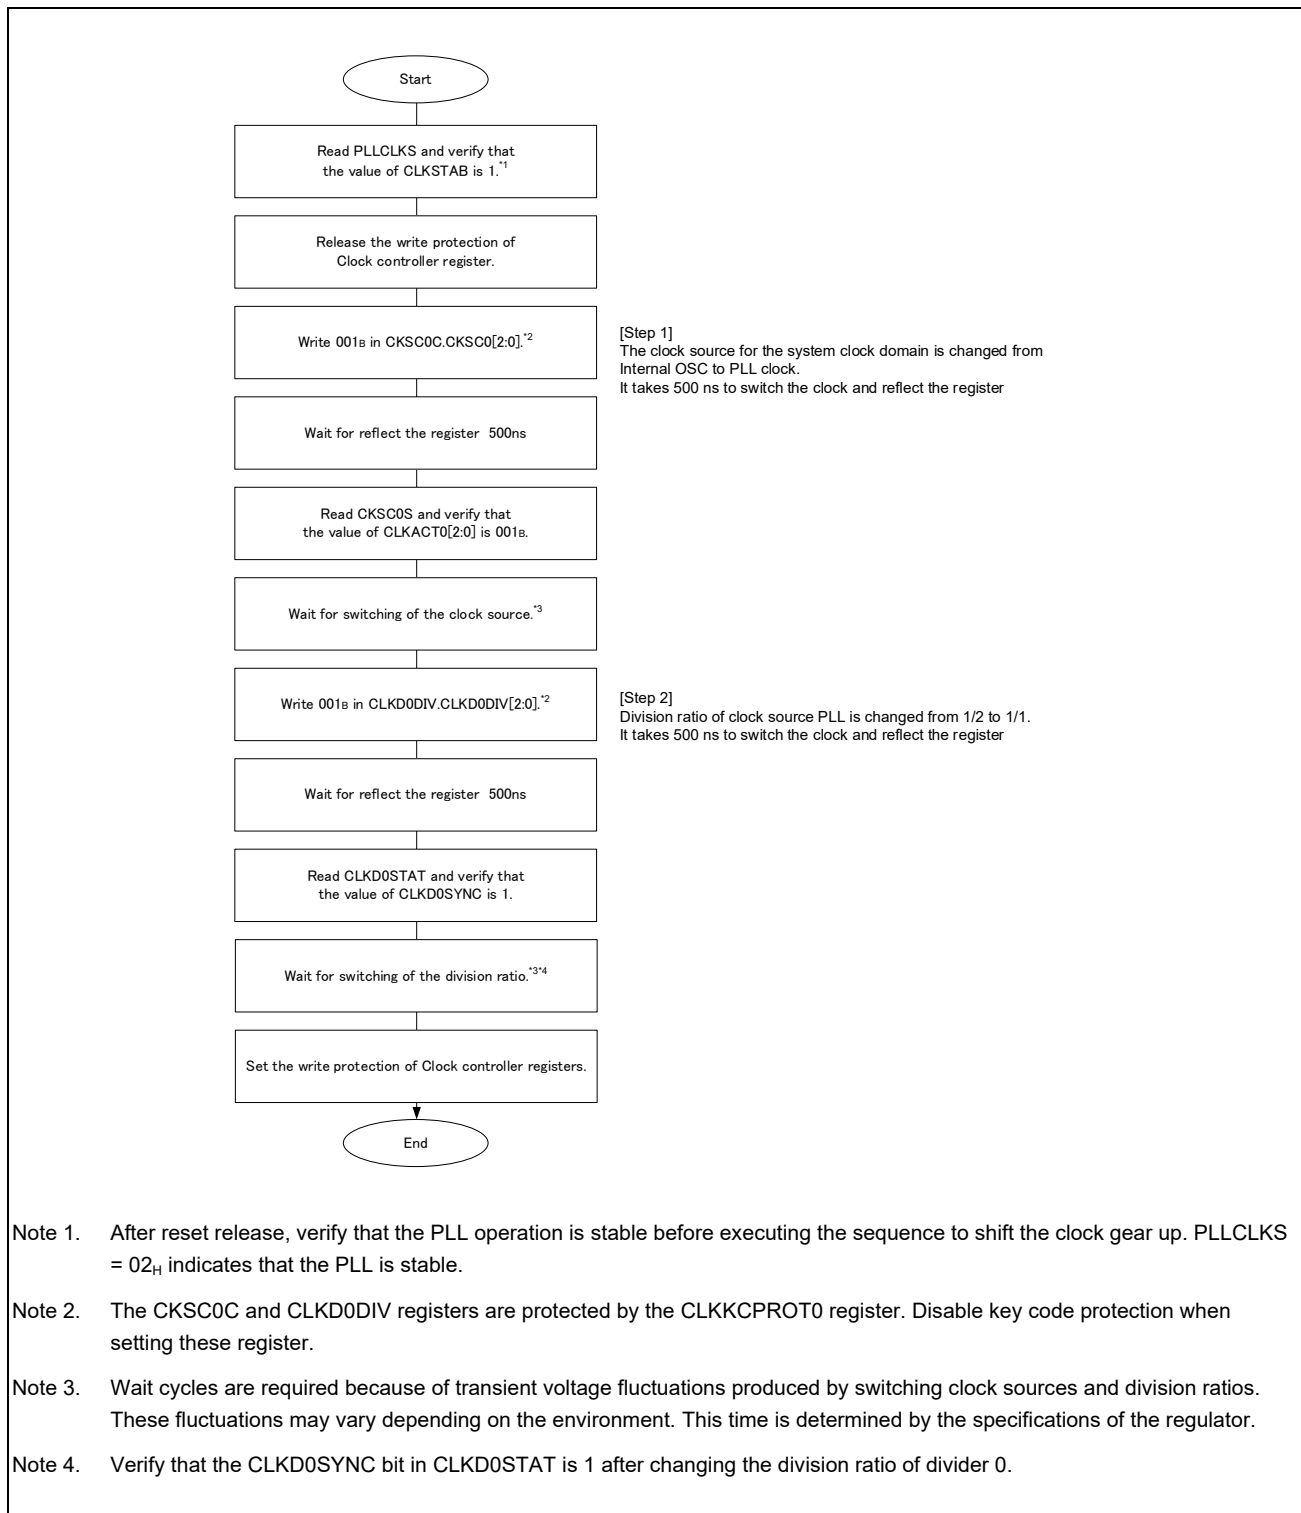

Figure 15.2 Example of Shifting Clock Gear Up

15.4.2 External Clock Output Pins (CK)

The device provides an external clock that can be used as clock supply for other external circuits. For details, see **Section 15.3.6, CLKDnDIV — Clock Divider Divisor Register (n = 2)**, **Section 15.3.7, CLKDnSTAT — Clock Divider Status Register (n = 2)**, **Section 15.3.10, CKSCnC — Clock Selector Control Register (n = 2)**, and **Section 15.3.11, CKSCnS — Clock Selector Status Register (n = 2)**.

- Clock signals can be output from the external pin CK.
- Output clock frequencies can be divided by the divider by configuring register settings.
- The source of the external clock can be configured as CLK_MOSC or CLK_LSB.
- It is recommended that the external clock be configured after clock gearup is complete.

NOTES

1. Stop the external clock before changing the clock source.
 2. CLK_LSB becomes the backup clock if changing to a backup clock was triggered by an error detected in CLMA.
-

15.4.3 Main OSC Configuration and Stabilization Sequence

The block diagram of MainOSC setting and the sequence of MainOSC stabilization are shown in **Figure 15.3** and **Figure 15.4**, respectively.

Figure 15.3 Block Diagram of MainOSC Configuration

Figure 15.4 Sequence of MainOSC Stabilization

15.4.4 OSC Monitor Mode

This mode is used for characterization of the main oscillator crystal.

OSC monitor mode is enabled if the OSCMONMD.OSCMONMD bit is set to 1.

Steps required to prevent the system from stopping when in OSC monitor mode:

- Disable auto start of WDTB and SWDT.
- Wait six cycles (CLK_LSB) to transition to OSC monitor mode.
- Be sure to execute the HALT instruction in each CPU after transitioning to OSC monitor mode.
- Return from OSC monitor mode should be done by External Reset.

The recommended characterization flow is shown in **Figure 15.6**.

Figure 15.5 Block Diagram of OSC Monitor Mode

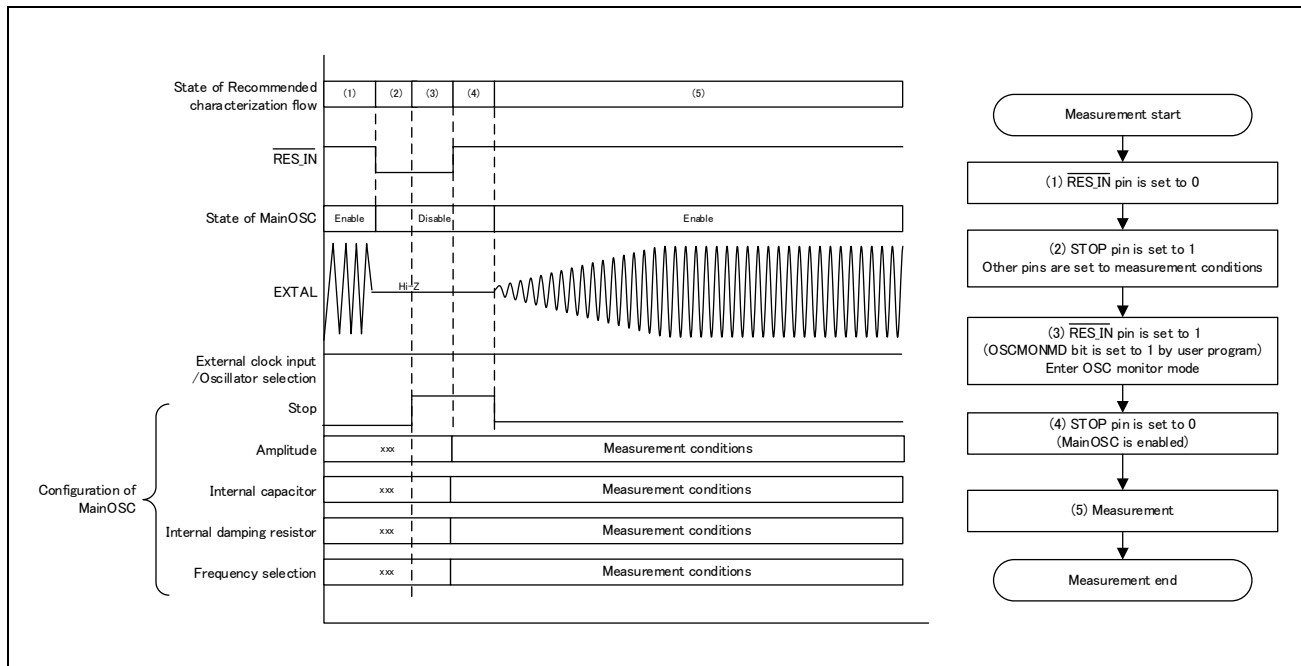

Figure 15.6 Recommended Characterization Flow

Table 15.22 OSC Monitor Mode Pins

Signal Name	Option Byte* ¹	OSC Monitor Mode		Description
		Setting Pins	I/O	
STOP	—	P14_2	Input	MOSC enable/disable 0: MOSC is enabled. 1: MOSC is stopped.
EXCLK	MOSC_EXCLKINPUTZ	Oscillator	Input	External clock input/Oscillator selection 0: MOSC outputs the clock from EXTAL as is, without going through AMP. (External clock) 1: Normal oscillation (Oscillator)
FREQ_SEL	MOSC_40MHz	—	Input	Frequency selection 0: 20 MHz 1: 40 MHz
CAPSEL[3:0]	MOSC_CAP_SEL[3:0]	P22_5, P22_6, P22_9, P14_4	Input	This bit controls the OSC internal capacitance.* ²
SHTSTBY_A	MOSC_SHTSTBY_A	P14_1	Input	Amplitude (x_A: unstable / x_B: stable) This bit controls OSC drivability during oscillation stabilization.* ² When Start-up, SHTSTBY_A must be "1". After oscillation becomes stable, SHTSTBY_B must be "0".
SHTSTBY_B	MOSC_SHTSTBY_B			
AMPSEL_A[2:0]	MOSC_AMP_SEL_A[2:0]	P22_12, P22_2, P22_3	Input	Damping resistor configuration. (x_A: Unstable / x_B: Stable) This bit controls the damping resistor.* ²
AMPSEL_B[2:0]	MOSC_AMP_SEL_B[2:0]			
RDSEL_A[2:0]	MOSC_RD_SEL_A[2:0]	P14_7, P15_0, P15_4	Input	Damping resistor configuration. (x_A: Unstable / x_B: Stable) This bit controls the damping resistor.* ²
RDSEL_B[2:0]	MOSC_RD_SEL_B[2:0]			
OSCOUT	—	P20_3	Output	MainOSC clock output

Note 1. For details on the option byte, see **Section 43, Flash Memory**.

Note 2. For details, see *RH850/E2x-FCC2 Electrical Characteristics, User's Manual: Clock Timing*.

15.5 Usage Notes

15.5.1 Main OSC setting

In the initial state of the product to be shipped, Option Bytes are fixed.

In case of the mismatch between the EXTAL/XTAL parameter condition and Main OSC Option Bytes setting relationship, Option Bytes should be written in Serial programming mode to be matched against the EXTAL/XTAL parameter condition.

15.5.2 Clock Gear Up

The operational settings for each peripheral function should be configured after clock gearup is complete.

(Except for when each function has a specified usage.)

The operation of each peripheral function is guaranteed only in the clock gear up state.

(Except when permitted by each peripheral function)

It must be set according to the procedure in **Figure 15.2**.

It is recommended to set the external clock output after clock gearup because CLK_MOSC is not stable and CLK_LSB has a different frequency.

15.5.3 FPU Operation Notes

Operations that require the FPU or FPSIMD should not be used when the division ratio is being changed. Increased current fluctuation as a result of using the FPU or FPSIMD can make the division ratio change unstable.

15.5.4 Board Design Notes

Other signal lines should not cross over EXTAL and XTAL because induction may prevent proper oscillation. See **Figure 15.7**.

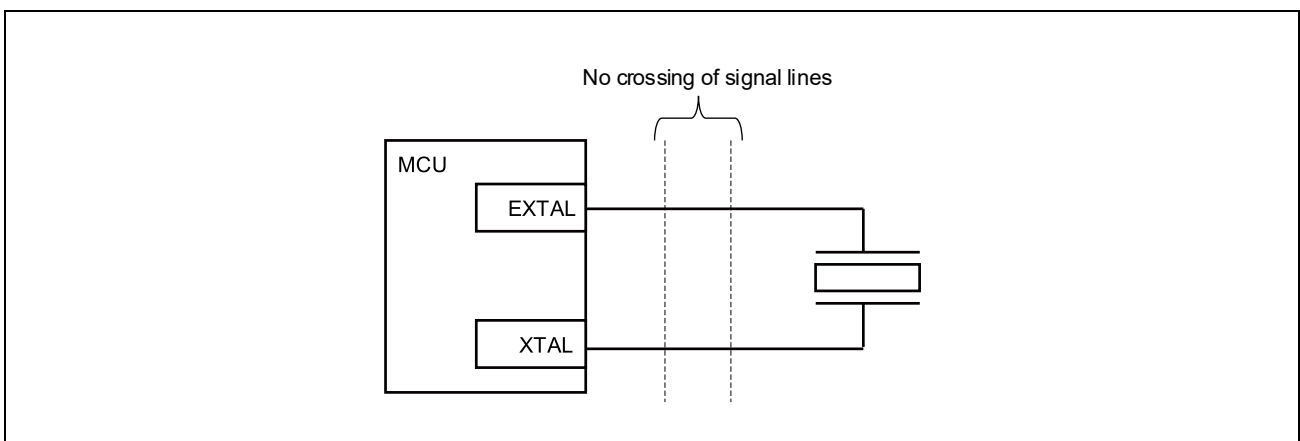

Figure 15.7 Board Design Notes

Section 16 Standby Controller

16.1 Features

This product supports various power-down modes such as power off standby mode, Emulation/Instrumentation RAM and Aurora retention mode (E2x-FCC2 Only), HALT mode, and module standby mode.

The power consumption of the LSI can be reduced by applying a suitable power-down mode for the application.

16.1.1 Register Base Addresses

Standby controller base address is listed in the following table.

Standby controller register addresses are given as offsets from the base addresses in general.

Table 16.1 Register Base Addresses

Base Address Name	Base Address	Bus Group
<MSTB_base>	FF70 1000 _H	Peripheral Group 6

16.2 Power Down Modes

16.2.1 Power Off Standby Mode

In Power Off Standby Mode, only the retention RAM of the Global (Cluster) RAM is powered. All clocks are stopped. All power supplies except SYSVCC can be turned off.

Power Off Standby Mode is entered by asserting the RES_IN pin low, and then turning off all power supplies except SYSVCC.

Power Off Standby Mode is exited by turning all the power supplies on, waiting for the required time for clock stabilization and then negating RES_IN. See *the RH850/E2x-FCC2 Electrical Characteristics, User's Manual: Hardware* for timing details.

If the EMUVDD is supplied, the data in Emulation/Instrumentation RAM is also retained. For RAM retention targets, see the section about RAM.

16.2.2 Emulation/Instrumentation RAM and Aurora Retention Mode (E2x-FCC2 Only)

In Emulation/Instrumentation RAM and Aurora Retention Mode, only the Emulation/Instrumentation RAM and Aurora configuration are retained. All power supplies except EMUVCC and EMUVDD can be turned off.

Emulation/Instrumentation RAM and Aurora Retention Mode is entered by asserting the RES_IN pin low, and then turning off all power supplies except EMUVCC and EMUVDD.

Emulation/Instrumentation RAM and Aurora Retention Mode is exited by turning all the power supplies on, waiting for the required time for clock stabilization and then negating RES_IN.

See *the RH850/E2x-FCC2 Electrical Characteristics, User's Manual: Hardware* for timing details.

16.2.3 HALT Mode

When the HALT instruction is executed, the CPU transits to HALT mode and stops instruction execution.

Each CPU (PE0, PE1, PE2, PE3, PE4, PE5) can be controlled individually.

The CPU returns from this state by the occurrence of an all resets (except Module Reset and JTAG Reset), interrupt or exception.

16.2.4 Module Standby

This function stops the clocks for the selected peripherals to reduce power consumption. After reset (see **Table 16.2, Table 16.3**) is released, All the peripheral modules except for WDTB, $\Delta\Sigma$ -ADC and Cyclic-ADC enter the module standby mode.

Set the bit of the target register to 0 to release the module standby mode

Set the bit of the target register to 1 to set the module standby mode

NOTES

1. It is recommended to set WDTB module standby before clock gear-up (if WDTB has not been auto-started or has not triggered by software yet)
2. These registers should only be written one time after reset. Operation is not guaranteed for subsequent writes.

16.3 Description of Registers

16.3.1 Register Protection

Write-protected registers are protected from inadvertent write access due to erroneous program execution, etc.

Write-protected registers can be written by releasing the protection of MSRKCProt.

16.3.2 List of Registers

The following table lists the standby controller registers.

Table 16.2 List of Registers

Unit Name	Register Name	Symbol	Address	Access size	Access Protection
MSTB	Module Standby Register for ATU5	MSR_ATU* ¹	<MSTB_base> + 000 _H	32	MSRKCPROT
MSTB	Module Standby Register for GTM	MSR_GTM* ¹	<MSTB_base> + 000 _H	32	MSRKCPROT
MSTB	Module Standby Register for OSTM	MSR_OSTM	<MSTB_base> + 010 _H	32	MSRKCPROT
MSTB	Module Standby Register for WDTB	MSR_WDT	<MSTB_base> + 020 _H	32	MSRKCPROT
MSTB	Module Standby Register for SCI3	MSR_SCI	<MSTB_base> + 030 _H	32	MSRKCPROT
MSTB	Module Standby Register for HSSPI	MSR_HSSPI	<MSTB_base> + 040 _H	32	MSRKCPROT
MSTB	Module Standby Register for RLIN3	MSR_RLIN	<MSTB_base> + 050 _H	32	MSRKCPROT
MSTB	Module Standby Register for CSIH	MSR_CSIH	<MSTB_base> + 060 _H	32	MSRKCPROT
MSTB	Module Standby Register for RHSIF	MSR_RHSIF	<MSTB_base> + 070 _H	32	MSRKCPROT
MSTB	Module Standby Register for RHSB	MSR_RHSB	<MSTB_base> + 080 _H	32	MSRKCPROT
MSTB	Module Standby Register for CAN	MSR_CAN	<MSTB_base> + 090 _H	32	MSRKCPROT
MSTB	Module Standby Register for FlexRay	MSR_FLXA	<MSTB_base> + 0A0 _H	32	MSRKCPROT
MSTB	Module Standby Register for Ethernet controller	MSR_ETHER	<MSTB_base> + 0B0 _H	32	MSRKCPROT
MSTB	Module Standby Register for RSENT	MSR_RSENT	<MSTB_base> + 0C0 _H	32	MSRKCPROT
MSTB	Module Standby Register for PSI5	MSR_PSI5	<MSTB_base> + 0D0 _H	32	MSRKCPROT
MSTB	Module Standby Register for PSI5S	MSR_PSI5S	<MSTB_base> + 0E0 _H	32	MSRKCPROT
MSTB	Module Standby Register for DFE	MSR_DFE	<MSTB_base> + 100 _H	32	MSRKCPROT
MSTB	Module Standby Register for DS-ADC	MSR_DAD	<MSTB_base> + 110 _H	32	MSRKCPROT
MSTB	Module Standby Register for Cyclic-ADC	MSR_CAD	<MSTB_base> + 120 _H	32	MSRKCPROT
MSTB	Module Standby Register for SAR-ADC	MSR_SAD	<MSTB_base> + 130 _H	32	MSRKCPROT
MSTB	Module Standby Register for ENCA	MSR_ENCA	<MSTB_base> + 140 _H	32	MSRKCPROT
MSTB	Module Standby Register Key Code Protection Register	MSRKCPROT	<MSTB_base> + 700 _H	32	—

Note 1. MSR_ATU, MSR_GTM switch in OPBT. See **Section 43, Flash Memory**.

16.3.3 Reset of Registers

Table 16.3 Register Reset Conditions

	Reset Source					
	Power Up Reset	System Reset 1	System Reset 2	Application Reset	Module Reset	JTAG Reset
All registers	✓	✓	✓	✓	—	—

16.3.4 MSR_ATU — Module Standby Register for ATU5

This register is used to control the Stop Mode of the ATU5.

Value after reset: FFFF FFFF_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	MS_GTM
Value after reset	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Table 16.5 MSR_GTM Register Contents

Bit Position	Bit Name	Function
31 to 1	—	Reserved When reading, the value after reset is returned. When writing, write the value after reset.
0	MS_GTM	Setting this bit to 1 stops clock supply to GTM. 0: Put GTM in operating mode. 1: Put GTM in standby mode (stop clocks to GTM).

16.3.6 MSR_OSTM — Module Standby Register for OSTM

This register is used to control the Stop Mode of the OSTM.

Value after reset: FFFF FFFF_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

Table 16.6 MSR_OSTM Register Contents

Bit Position	Bit Name	Function
31 to 7	—	Reserved When reading, the value after reset is returned. When writing, write the value after reset.
6	MS_OSTM6*1	Setting this bit to 1 stops clock supply to OSTM6 0: Put OSTM6 in operating mode. 1: Put OSTM6 in standby mode (stop clocks to OSTM6).
5	MS_OSTM5*1	Setting this bit to 1 stops clock supply to OSTM5 0: Put OSTM5 in operating mode. 1: Put OSTM5 in standby mode (stop clocks to OSTM5).
4	MS_OSTM4	Setting this bit to 1 stops clock supply to OSTM4 0: Put OSTM4 in operating mode. 1: Put OSTM4 in standby mode (stop clocks to OSTM4).
3	MS_OSTM3	Setting this bit to 1 stops clock supply to OSTM3 0: Put OSTM3 in operating mode. 1: Put OSTM3 in standby mode (stop clocks to OSTM3).
2	MS_OSTM2	Setting this bit to 1 stops clock supply to OSTM2. 0: Put OSTM2 in operating mode. 1: Put OSTM2 in standby mode (stop clocks to OSTM2).
1	MS_OSTM1	Setting this bit to 1 stops clock supply to OSTM1. 0: Put OSTM1 in operating mode. 1: Put OSTM1 in standby mode (stop clocks to OSTM1).
0	MS_OSTM0	Setting this bit to 1 stops clock supply to OSTM0. 0: Put OSTM0 in operating mode. 1: Put OSTM0 in standby mode (stop clocks to OSTM0).

Note 1. This bit is a reserved bit in E2H. When reading, the value after reset is returned. When writing, write the value after reset.

16.3.7 MSR_WDT — Module Standby Register for WDTB

This register is used to control the Stop Mode of the WDTB.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	MS_WDT5*1	MS_WDT4*1	MS_WDT3	MS_WDT2	MS_WDT1	MS_WDT0
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W

Table 16.7 MSR_WDT Register Contents

Bit Position	Bit Name	Function
31 to 6	—	Reserved When reading, the value after reset is returned. When writing, write the value after reset.
5	MS_WDT5*1	Setting this bit to 1 stops clock supply to WDTB5 0: Put WDTB5 in operating mode. 1: Put WDTB5 in standby mode (stop clocks to WDTB5).
4	MS_WDT4*1	Setting this bit to 1 stops clock supply to WDTB4 0: Put WDTB4 in operating mode. 1: Put WDTB4 in standby mode (stop clocks to WDTB4).
3	MS_WDT3	Setting this bit to 1 stops clock supply to WDTB3 0: Put WDTB3 in operating mode. 1: Put WDTB3 in standby mode (stop clocks to WDTB3).
2	MS_WDT2	Setting this bit to 1 stops clock supply to WDTB2 0: Put WDTB2 in operating mode. 1: Put WDTB2 in standby mode (stop clocks to WDTB2).
1	MS_WDT1	Setting this bit to 1 stops clock supply to WDTB1. 0: Put WDTB1 in operating mode. 1: Put WDTB1 in standby mode (stop clocks to WDTB1).
0	MS_WDT0	Setting this bit to 1 stops clock supply to WDTB0. 0: Put WDTB0 in operating mode. 1: Put WDTB0 in standby mode (stop clocks to WDTB0).

Note 1. This bit is a reserved bit in E2H. When reading, the value after reset is returned. When writing, write the value after reset.

16.3.8 MSR_SCI — Module Standby Register for SCI3

This register is used to control the Stop Mode of the SCI3.

Value after reset: FFFF FFFF_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	MS_SCI33	MS_SCI32	MS_SCI31	MS_SCI30
Value after reset	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W

Table 16.8 MSR_SCI Register Contents

Bit Position	Bit Name	Function
31 to 4	—	Reserved When reading, the value after reset is returned. When writing, write the value after reset.
3	MS_SCI33	Setting this bit to 1 stops clock supply to SCI33. 0: Put SCI3 in operating mode. 1: Put SCI3 in standby mode (stop clocks to SCI33).
2	MS_SCI32	Setting this bit to 1 stops clock supply to SCI32. 0: Put SCI2 in operating mode. 1: Put SCI2 in standby mode (stop clocks to SCI32).
1	MS_SCI31	Setting this bit to 1 stops clock supply to SCI31. 0: Put SCI1 in operating mode. 1: Put SCI1 in standby mode (stop clocks to SCI31).
0	MS_SCI30	Setting this bit to 1 stops clock supply to SCI30. 0: Put SCI0 in operating mode. 1: Put SCI0 in standby mode (stop clocks to SCI30).

16.3.9 MSR_HSSPI — Module Standby Register for HSSPI

This register is used to control the Stop Mode of the HSSPI.

Value after reset: FFFF FFFF_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	MS_HSSPI0
Value after reset	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Table 16.9 MSR_HSSPI Register Contents

Bit Position	Bit Name	Function
31 to 1	—	Reserved When reading, the value after reset is returned. When writing, write the value after reset.
0	MS_HSSPI0	Setting this bit to 1 stops clock supply to HSSPI0. 0: Put HSSPI0 in operating mode. 1: Put HSSPI0 in standby mode (stop clocks to HSSPI0).

16.3.10 MSR_RLIN — Module Standby Register for RLIN3

This register is used to control the Stop Mode of the RLIN3.

Value after reset: FFFF FFFF_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	MS_RLIN7*1	MS_RLIN6*1	MS_RLIN5	MS_RLIN4	MS_RLIN3	MS_RLIN2	MS_RLIN1	MS_RLIN0
Value after reset	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1
R/W	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 16.10 MSR_RLIN Register Contents

Bit Position	Bit Name	Function
31 to 8	—	Reserved When reading, the value after reset is returned. When writing, write the value after reset.
7	MS_RLIN7*1	Setting this bit to 1 stops clock supply to RLIN7 0: Put RLIN7 in operating mode. 1: Put RLIN7 in standby mode (stop clocks to RLIN7).
6	MS_RLIN6*1	Setting this bit to 1 stops clock supply to RLIN6 0: Put RLIN6 in operating mode. 1: Put RLIN6 in standby mode (stop clocks to RLIN6).
5	MS_RLIN5	Setting this bit to 1 stops clock supply to RLIN5. 0: Put RLIN5 in operating mode. 1: Put RLIN5 in standby mode (stop clocks to RLIN5).
4	MS_RLIN4	Setting this bit to 1 stops clock supply to RLIN4. 0: Put RLIN4 in operating mode. 1: Put RLIN4 in standby mode (stop clocks to RLIN4).
3	MS_RLIN3	Setting this bit to 1 stops clock supply to RLIN3. 0: Put RLIN3 in operating mode. 1: Put RLIN3 in standby mode (stop clocks to RLIN3).
2	MS_RLIN2	Setting this bit to 1 stops clock supply to RLIN2. 0: Put RLIN2 in operating mode. 1: Put RLIN2 in standby mode (stop clocks to RLIN2).
1	MS_RLIN1	Setting this bit to 1 stops clock supply to RLIN1. 0: Put RLIN1 in operating mode. 1: Put RLIN1 in standby mode (stop clocks to RLIN1).
0	MS_RLIN0	Setting this bit to 1 stops clock supply to RLIN0. 0: Put RLIN0 in operating mode. 1: Put RLIN0 in standby mode (stop clocks to RLIN0).

Note 1. This bit is a reserved bit in E2H. When reading, the value after reset is returned. When writing, write the value after reset.

16.3.11 MSR_CSIH — Module Standby Register for CSIH

This register is used to control the Stop Mode of the CSIH.

Value after reset: FFFF FFFF_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	MS_CSIH7	MS_CSIH6	MS_CSIH5	MS_CSIH4	MS_CSIH3	MS_CSIH2	MS_CSIH1	MS_CSIH0
Value after reset	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1
R/W	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 16.11 MSR_CSIH Register Contents

Bit Position	Bit Name	Function
31 to 8	—	Reserved When reading, the value after reset is returned. When writing, write the value after reset.
7	MS_CSIH7	Setting this bit to 1 stops clock supply to CSIH7 0: Put CSIH7 in operating mode. 1: Put CSIH7 in standby mode (stop clocks to CSIH7).
6	MS_CSIH6	Setting this bit to 1 stops clock supply to CSIH6 0: Put CSIH6 in operating mode. 1: Put CSIH6 in standby mode (stop clocks to CSIH6).
5	MS_CSIH5	Setting this bit to 1 stops clock supply to CSIH5. 0: Put CSIH5 in operating mode. 1: Put CSIH5 in standby mode (stop clocks to CSIH5).
4	MS_CSIH4	Setting this bit to 1 stops clock supply to CSIH4. 0: Put CSIH4 in operating mode. 1: Put CSIH4 in standby mode (stop clocks to CSIH4).
3	MS_CSIH3	Setting this bit to 1 stops clock supply to CSIH3. 0: Put CSIH3 in operating mode. 1: Put CSIH3 in standby mode (stop clocks to CSIH3).
2	MS_CSIH2	Setting this bit to 1 stops clock supply to CSIH2. 0: Put CSIH2 in operating mode. 1: Put CSIH2 in standby mode (stop clocks to CSIH2).
1	MS_CSIH1	Setting this bit to 1 stops clock supply to CSIH1. 0: Put CSIH1 in operating mode. 1: Put CSIH1 in standby mode (stop clocks to CSIH1).
0	MS_CSIH0	Setting this bit to 1 stops clock supply to CSIH0. 0: Put CSIH0 in operating mode. 1: Put CSIH0 in standby mode (stop clocks to CSIH0).

16.3.12 MSR_RHSIF — Module Standby Register for RHSIF

This register is used to control the Stop Mode of the RHSIF.

Value after reset: FFFF FFFF_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	MS_RHSIF0
Value after reset	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Table 16.12 MSR_RHSIF Register Contents

Bit Position	Bit Name	Function
31 to 1	—	Reserved When reading, the value after reset is returned. When writing, write the value after reset.
0	MS_RHSIF0*1.	Setting this bit to 1 stops clock supply to RHSIF0. 0: Put RHSIF0 in operating mode. 1: Put RHSIF0 in standby mode (stop clocks to RHSIF0).

Note 1. Access to RHSIF is required waiting period of at least 12 cycles in the CPU clock after standby release.

16.3.13 MSR_RHSB — Module Standby Register for RHSB

This register is used to control the Stop Mode of the RHSB.

Value after reset: FFFF FFFF_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	MS_RHSB3 ^{*1}	MS_RHSB2	MS_RHSB1	MS_RHSB0
Value after reset	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W

Table 16.13 MSR_RHSB Register Contents

Bit Position	Bit Name	Function
31 to 4	—	Reserved When reading, the value after reset is returned. When writing, write the value after reset.
3	MS_RHSB3 ^{*1}	Setting this bit to 1 stops clock supply to RHSB3 0: Put RHSB3 in operating mode. 1: Put RHSB3 in standby mode (stop clocks to RHSB3).
2	MS_RHSB2	Setting this bit to 1 stops clock supply to RHSB2 0: Put RHSB2 in operating mode. 1: Put RHSB2 in standby mode (stop clocks to RHSB2).
1	MS_RHSB1	Setting this bit to 1 stops clock supply to RHSB1. 0: Put RHSB1 in operating mode. 1: Put RHSB1 in standby mode (stop clocks to RHSB1).
0	MS_RHSB0	Setting this bit to 1 stops clock supply to RHSB0. 0: Put RHSB0 in operating mode. 1: Put RHSB0 in standby mode (stop clocks to RHSB0).

Note 1. This bit is a reserved bit in E2H. When reading, the value after reset is returned. When writing, write the value after reset.

16.3.14 MSR_CAN — Module Standby Register for CAN

This register is used to control the Stop Mode of the CAN.

Value after reset: FFFF FFFF_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	MS_RSCFD ₁ *1	MS_RSCFD ₀
Value after reset	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W

Table 16.14 MSR_CAN Register Contents

Bit Position	Bit Name	Function
31 to 2	—	Reserved When reading, the value after reset is returned. When writing, write the value after reset.
1	MS_RSCFD1*1	Setting this bit to 1 stops clock supply to RSCFD1 0: Put RSCFD1 in operating mode. 1: Put RSCFD1 in standby mode (stop clocks to RSCFD1).
0	MS_RSCFD0	Setting this bit to 1 stops clock supply to RSCFD0. 0: Put RSCFD0 in operating mode. 1: Put RSCFD0 in standby mode (stop clocks to RSCFD0).

Note 1. This bit is a reserved bit in E2H. When reading, the value after reset is returned. When writing, write the value after reset.

16.3.15 MSR_FLXA — Module Standby Register for FlexRay

This register is used to control the Stop Mode of the FlexRay.

Value after reset: FFFF FFFF_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	MS_FLXA1*1	MS_FLXA0
Value after reset	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W

Table 16.15 MSR_FLXA Register Contents

Bit Position	Bit Name	Function
31 to 2	—	Reserved When reading, the value after reset is returned. When writing, write the value after reset.
1	MS_FLXA1*1	Setting this bit to 1 stops clock supply to FLXA1 0: Put FLXA1 in operating mode. 1: Put FLXA1 in standby mode (stop clocks to FLXA1).
0	MS_FLXA0	Setting this bit to 1 stops clock supply to FLXA0. 0: Put FLXA0 in operating mode. 1: Put FLXA0 in standby mode (stop clocks to FLXA0).

Note 1. This bit is a reserved bit in E2H.

16.3.16 MSR_ETHER — Module Standby Register for Ethernet controller

This register is used to control the Stop Mode of the Ethernet controller.

Value after reset: FFFF FFFF_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	MS_ETHER
Value after reset	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Table 16.16 MSR_ETHER Register Contents

Bit Position	Bit Name	Function
31 to 1	—	Reserved When reading, the value after reset is returned. When writing, write the value after reset.
0	MS_ETHER	Setting this bit to 1 stops clock supply to Ethernet controller. 0: Put ETHER in operating mode. 1: Put ETHER in standby mode (stop clocks to Ethernet controller).

16.3.17 MSR_RSENT — Module Standby Register for RSENT

This register is used to control the Stop Mode of the RSENT.

Value after reset: FFFF FFFF_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	MS_RS ENT19	MS_RS ENT18	MS_RS ENT17	MS_RS ENT16
Value after reset	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	MS_RS ENT15	MS_RS ENT14	MS_RS ENT13	MS_RS ENT12	MS_RS ENT11	MS_RS ENT10	MS_RS ENT9	MS_RS ENT8	MS_RS ENT7	MS_RS ENT6	MS_RS ENT5	MS_RS ENT4	MS_RS ENT3	MS_RS ENT2	MS_RS ENT1	MS_RS ENT0
Value after reset	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 16.17 MSR_RSENT Register Contents (1/2)

Bit Position	Bit Name	Function
31 to 20	—	Reserved When reading, the value after reset is returned. When writing, write the value after reset.
19	MS_RSENT19	Setting this bit to 1 stops clock supply to RSENT19 0: Put RSENT19 in operating mode. 1: Put RSENT19 in standby mode (stop clocks to RSENT19).
18	MS_RSENT18	Setting this bit to 1 stops clock supply to RSENT18 0: Put RSENT18 in operating mode. 1: Put RSENT18 in standby mode (stop clocks to RSENT18).
17	MS_RSENT17	Setting this bit to 1 stops clock supply to RSENT17 0: Put RSENT17 in operating mode. 1: Put RSENT17 in standby mode (stop clocks to RSENT17).
16	MS_RSENT16	Setting this bit to 1 stops clock supply to RSENT16. 0: Put RSENT16 in operating mode. 1: Put RSENT16 in standby mode (stop clocks to RSENT16).
15	MS_RSENT15	Setting this bit to 1 stops clock supply to RSENT15. 0: Put RSENT15 in operating mode. 1: Put RSENT15 in standby mode (stop clocks to RSENT15).
14	MS_RSENT14	Setting this bit to 1 stops clock supply to RSENT14. 0: Put RSENT14 in operating mode. 1: Put RSENT14 in standby mode (stop clocks to RSENT14).
13	MS_RSENT13	Setting this bit to 1 stops clock supply to RSENT13. 0: Put RSENT13 in operating mode. 1: Put RSENT13 in standby mode (stop clocks to RSENT13).
12	MS_RSENT12	Setting this bit to 1 stops clock supply to RSENT12. 0: Put RSENT12 in operating mode. 1: Put RSENT12 in standby mode (stop clocks to RSENT12).
11	MS_RSENT11	Setting this bit to 1 stops clock supply to RSENT11. 0: Put RSENT11 in operating mode. 1: Put RSENT11 in standby mode (stop clocks to RSENT11).

Table 16.17 MSR_RSENT Register Contents (2/2)

Bit Position	Bit Name	Function
10	MS_RSENT10	Setting this bit to 1 stops clock supply to RSENT10. 0: Put RSENT10 in operating mode. 1: Put RSENT10 in standby mode (stop clocks to RSENT10).
9	MS_RSENT9	Setting this bit to 1 stops clock supply to RSENT9. 0: Put RSENT9 in operating mode. 1: Put RSENT9 in standby mode (stop clocks to RSENT9).
8	MS_RSENT8	Setting this bit to 1 stops clock supply to RSENT8. 0: Put RSENT8 in operating mode. 1: Put RSENT8 in standby mode (stop clocks to RSENT8).
7	MS_RSENT7	Setting this bit to 1 stops clock supply to RSENT7. 0: Put RSENT7 in operating mode. 1: Put RSENT7 in standby mode (stop clocks to RSENT7).
6	MS_RSENT6	Setting this bit to 1 stops clock supply to RSENT6. 0: Put RSENT6 in operating mode. 1: Put RSENT6 in standby mode (stop clocks to RSENT6).
5	MS_RSENT5	Setting this bit to 1 stops clock supply to RSENT5. 0: Put RSENT5 in operating mode. 1: Put RSENT5 in standby mode (stop clocks to RSENT5).
4	MS_RSENT4	Setting this bit to 1 stops clock supply to RSENT4. 0: Put RSENT4 in operating mode. 1: Put RSENT4 in standby mode (stop clocks to RSENT4).
3	MS_RSENT3	Setting this bit to 1 stops clock supply to RSENT3. 0: Put RSENT3 in operating mode. 1: Put RSENT3 in standby mode (stop clocks to RSENT3).
2	MS_RSENT2	Setting this bit to 1 stops clock supply to RSENT2. 0: Put RSENT2 in operating mode. 1: Put RSENT2 in standby mode (stop clocks to RSENT2).
1	MS_RSENT1	Setting this bit to 1 stops clock supply to RSENT1. 0: Put RSENT1 in operating mode. 1: Put RSENT1 in standby mode (stop clocks to RSENT1).
0	MS_RSENT0	Setting this bit to 1 stops clock supply to RSENT0. 0: Put RSENT0 in operating mode. 1: Put RSENT0 in standby mode (stop clocks to RSENT0).

16.3.18 MSR_PSI5 — Module Standby Register for PSI5

This register is used to control the Stop Mode of the PSI5.

Value after reset: FFFF FFFF_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Value after reset	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W

Table 16.24 MSR_ENCA Register Contents

Bit Position	Bit Name	Function
31 to 2	—	Reserved When reading, the value after reset is returned. When writing, write the value after reset.
1	MS_ENCA1	Setting this bit to 1 stops clock supply to ENCA1. 0: Put ENCA1 in operating mode. 1: Put ENCA1 in standby mode (stop clocks to ENCA1).
0	MS_ENCA0	Setting this bit to 1 stops clock supply to ENCA0. 0: Put ENCA0 in operating mode. 1: Put ENCA0 in standby mode (stop clocks to ENCA0).

16.3.25 MSRKCPROT — Module Standby Register Key Code Protection Register

The MSRKCPROT register is used to protect against writing to the registers that may have a material effect on the system so that the application system is not incorrectly stopped due to program malfunction and the like.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	KCPROT[31:16]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	KCPROT[15:1]															KCE
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W	R/W

Table 16.25 MSRKCPROT Register Contents

Bit Position	Bit Name	Function
31 to 1	KCPROT[31:1]	Enable or disable modification of the KCE bit. The written value is not retained. These bits are always read as 0.*1
0	KCE	Key Code Enable bit 0: Disable write access to protected registers 1: Enable write access to protected registers

Note 1. Write A5A5A500_H to this register to disable writing protected registers.
Write A5A5A501_H to this register to enable writing protected registers.

Section 17 External Bus Controller

This section contains a generic description of the external bus controller (EXBC).

The first part in this section describes the features specific to this product, including register base addresses and input/output signals. The ensuing sections describe the functions and registers of EXBC.

17.1 Features of EXBC

17.1.1 Products that Incorporate EXBC

EXBC is incorporated in the following products.

Table 17.1 Products that Incorporate EXBC

Product Name	RH850/E2x-FCC2	
	468 pins	373 pins
Number of Units	1	1
Unit Name	EXBC	EXBC

Table 17.2 Products that Incorporate EXBC

Product Name	RH850/E2UH	
	468 pins	373 pins
Number of Units	1	1
Unit Name	EXBC	EXBC

Table 17.3 Products that Incorporate EXBC

Product Name	RH850/E2H	
	468 pins	373 pins
Number of Units	1	1
Unit Name	EXBC	EXBC

Table 17.4 Indices

Index	Description
m	Throughout this section, the individual EXBC units are identified by the index "m" (m = 0).
n	Throughout this section, chip select areas are identified by "n" (n = 0 to 3). For example, the external memory area of CSn is described as the CSn area.

Table 17.5 External Bus Controller Functions

Control Signal Name	RH850/E2x-FCC2	
	468 pins	373 pins
Address	23 bit	23 bit
Chip select output	4	4
Data bus	32 bits	16 bits

Table 17.6 External Bus Controller Functions

Control Signal Name	RH850/E2UH	
	468 pins	373 pins
Address	23 bit	23 bit
Chip select output	4	4
Data bus	32 bits	16 bits

Table 17.7 External Bus Controller Functions

Control Signal Name	RH850/E2H	
	468 pins	373 pins
Address	23 bit	23 bit
Chip select output	4	4
Data bus	16 bits	16 bits

17.1.2 Register Base Address

The EXBC base address is shown in the following table.

The EXBC register addresses are expressed as offsets from the base address.

Table 17.8 Register Base Address

Base Address Name	Base Address	Bus Group
<EXBC_base>	1003 0000 _H	H-Bus Group 5

17.1.3 Clock Supply

The EXBC clock supply is shown in the following table.

Table 17.9 Clock Supply

Unit Name	Unit Clock Name	Supply Clock Name
EXBC	HCLK	CLK_LSB

17.1.4 Reset Sources

The EXBC reset sources are shown below. EXBC is initialized by the following reset sources.

Table 17.10 Reset Sources

Unit Name	Register Name	Reset Condition					
		Power Up Reset	System Reset 1	System Reset 2	Application Reset	Module Reset	JTAG Reset
EXBC	All registers	✓	✓	✓	✓	—	—

17.1.5 External Input/Output Signals

External input/output signals of EXBC are listed below.

Table 17.11 External Input/Output Signals

Unit Signal Name	Description	Alternative Port Pin Signal Name
EXBC		
A[23:1]	Address bus signal	A[23:1]
D[15:0]	Data bus I/O signal	D[15:0]
D[31:16] ^{*3}	Data bus I/O signal	D[31:16] ^{*3}
MSTBENZ[1:0]	Byte enable output signal	$\overline{\text{MSTBENZ}}[1:0]$
MSTBENZ[3:2] ^{*3}	Byte enable output signal	$\overline{\text{MSTBENZ}}[3:2]$ ^{*3}
MSTCSZ[1:0]	Chip select output signal	$\overline{\text{MSTCSZ}}[1:0]$
MSTCSZ[3:2] ^{*3}	Chip select output signal	$\overline{\text{MSTCSZ}}[3:2]$ ^{*3}
MSTOEZ	Read strobe output signal	$\overline{\text{MSTOEZ}}$
MSTWAITZ	External wait request input signal	$\overline{\text{MSTWAITZ}}$
MSTWEZ	Write strobe output signal	$\overline{\text{MSTWEZ}}$

Note 1. For the port to be used as EXBC, set the output driver strength to drive strength 2 (PUCCN_m = 0, PDSCN_m = 1).

Note 2. For "Data bus I/O signal" (D signal), fix the input level by pull-up or pull-down. Also, when "External wait request input signal" (MSTWAITZ signal) is not used, fix the input level by the pull-up.

Note 3. Not supported for 373 pins, and 468 pins in E2H.

17.2 Overview

The external memory access controller provides four chip select areas, and wait time is selectable in each chip select area.

17.2.1 Functional Overview

The main features of the external memory access controller:

- Supports external memory access (Devices with conventional SRAM interface directly connectable)
- Address/Data separate interface
- Up to 8 or 16 Mbyte linear address space for each CS
- Configurable 8, 16 and 32 bit data transfer are supported
- Four chip select areas and 16 or 32-bit bus width
- Accepted little endian
- Various wait functions can be set individually for each chip select area
- External wait on SRAM access cycle

17.2.1.1 Separate Bus Mode

This is an operation mode that connects address output and data input/output to external memory using independent signal lines. By using this mode, SRAM can be connected to individual chip select areas.

17.2.1.2 Chip Select Output Function

The external bus area of the memory space is divided into four chip select areas, and a chip select signal can be output for each chip select area. The allocation of these chip select areas is fixed by the system and cannot be changed through programming.

17.2.1.3 Data Bus Size

The data bus size for accessing each chip select area is selected to 16 or 32 bits.

17.2.1.4 Data Endian Setting Function

Only little endian is supported.

17.2.1.5 Programmable Wait Setting Functions

This microcontroller has the following wait functions, which can be set for each chip select area.

- Programmable data wait
- Data hold wait
- Address setup wait
- Idle cycle

17.2.1.6 External Wait Function

When accessing SRAM data in a write cycle, waits of any width can be inserted externally from the $\overline{\text{MSTWAITZ}}$ pin. The $\overline{\text{MSTWAITZ}}$ pin is sampled just before the data output cycle, and the data latch timing can be delayed by any amount.

17.2.2 Block Diagram

The following block diagram shows the main components of the EXBC.

Figure 17.1 EXBC Block Diagram

17.3 Registers

17.3.1 List of Registers

The EXBC registers are listed in the following table.

For details on <EXBC_base>, see **Section 17.1.2, Register Base Address**.

Table 17.12 List of Registers

Module Name	Register Name	Symbol	Address	Initial Value	Access	Access Protection
EXBC	Control register of size of bus	BSC	<EXBC_base> + 04 _H	0000 5555 _H	32	—
	Static memory control register 0	SMC0	<EXBC_base> + 08 _H	0000 FFFF _H	32	—
	Static memory control register 1	SCM1	<EXBC_base> + 0C _H	0000 FFFF _H	32	—
	Static memory control register 2	SMC2	<EXBC_base> + 10 _H	0000 FFFF _H	32	—
	Static memory control register 3	SMC3	<EXBC_base> + 14 _H	0000 FFFF _H	32	—

17.3.2 Register Explanation

17.3.2.1 BSC — Bus Size Controller Register

The BSC register is a 32 bit register that controls the data bus width of the memory. The SBS3-SBS0 bits are for SRAM channels 0-3.

Value after reset: 0000 5555_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

17.3.2.2 SMCn — Static Memory Control Register 0-3

The SMCn register is a 32 bit register that controls the SRAM chip select ($\overline{\text{MSTCSZ3}} - \overline{\text{MSTCSZ0}}$) area wait cycle. “n” in the register name indicates the SRAM channel, 0-3. (n = 3, 2, 1, 0)

Value after reset: 0000 FFFF_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

	1110	14
	1111	15 (initial value)

CAUTION: The number of write address setting wait cycles cannot be set to 0 cycles.

17.4 Functions

17.4.1 Bus Control Functions

17.4.1.1 Chip Select Output Function

The connected external memory area is divided into and managed in 4 chip select areas, as shown in **Figure 17.2 External Memory Map**.

When a bus cycle is generated for the external bus, this microcontroller activates (low level) the $\overline{\text{MSTCSZ}}[3:0]$ output pin corresponding to the access target address, along with outputting the access target address from the A[23:1]

The various settings for the external bus, such as the number of wait/idle states, can all be made for each chip select area.

By using these functions, different types of memory can be connected to each chip select area.

The allocation of the chip select areas is fixed by the system and cannot be changed through programming.

The memory map is shown below.

Figure 17.2 External Memory Map

17.4.2 Wait Functions

The wait functions are listed below.

Table 17.15 Wait Functions

Wait Function	Data Wait		Data Hold Wait	Address Wait	Idle State
	Programmable	External Pin			
Read access	✓	✓	—	✓	✓
Write access	✓	✓	✓	✓	—
Setting register	DWn	—	WWn	ACn	IWn
Max. number of waits	15	—	15	15	15

Note: n = 0, 1, 2, 3

17.4.2.1 Programmable Data Wait Function

This wait function is used to delay the data latch timing by extending the read strobe and write strobe periods.

This function is enabled during data transfer. Up to 15 cycles can be inserted.

Data waits can be set for each chip select area using the DWn bits of SMCn register.

Figure 17.3 Bus Cycles when Inserting Programmable Data Waits

17.4.2.2 External Wait Function

Data waits of any length can be inserted from the $\overline{\text{MSTWAITZ}}$ pin.

The data wait cycles obtained by ORing the programmable data wait set by data wait control register (D_{Wn} bits of SMC_n register) and the external wait set by the $\overline{\text{MSTWAITZ}}$ pin input are inserted.

Figure 17.4 Internal Data Wait Generator

Figure 17.5 Bus Cycles when Inserting Programmable Data Waits and External Waits

17.4.2.3 Data Hold Wait Function

This function inserts a wait in the state following the rising edge of the write strobe signal in order to secure the hold time for the data write strobe.

This microcontroller always inserts 1 data hold wait state upon occurrence of a write cycle. This data hold wait can be extended by up to 15 cycles by setting the WW_n bits of SMC_n register.

The number of cycles to extend the data hold wait can be set for each chip select area with the WW_n bits of SMC_n register.

Figure 17.6 Bus Cycles when Inserting Data Hold Waits

17.4.2.4 Address Setup Wait Function

The address setup wait function inserts a wait before the address transfer state in order to secure the setup time for the address strobe.

Up to 15 wait cycles can be inserted for each chip select area by setting the ACn bits of SMCn register.

Figure 17.7 Bus Cycles when Inserting Address Setup Waits

17.4.2.5 Idle Insertion Function

This function inserts an idle state after the last state of each cycle in order to prevent bus conflicts between cycles.

This function can be set independently after a read cycle for each chip select area by setting the IWn bits of SMCn register.

Figure 17.8 Bus Cycles when Inserting Idle States

17.4.3 Memory Connection Example

17.4.3.1 SRAM Connection Example

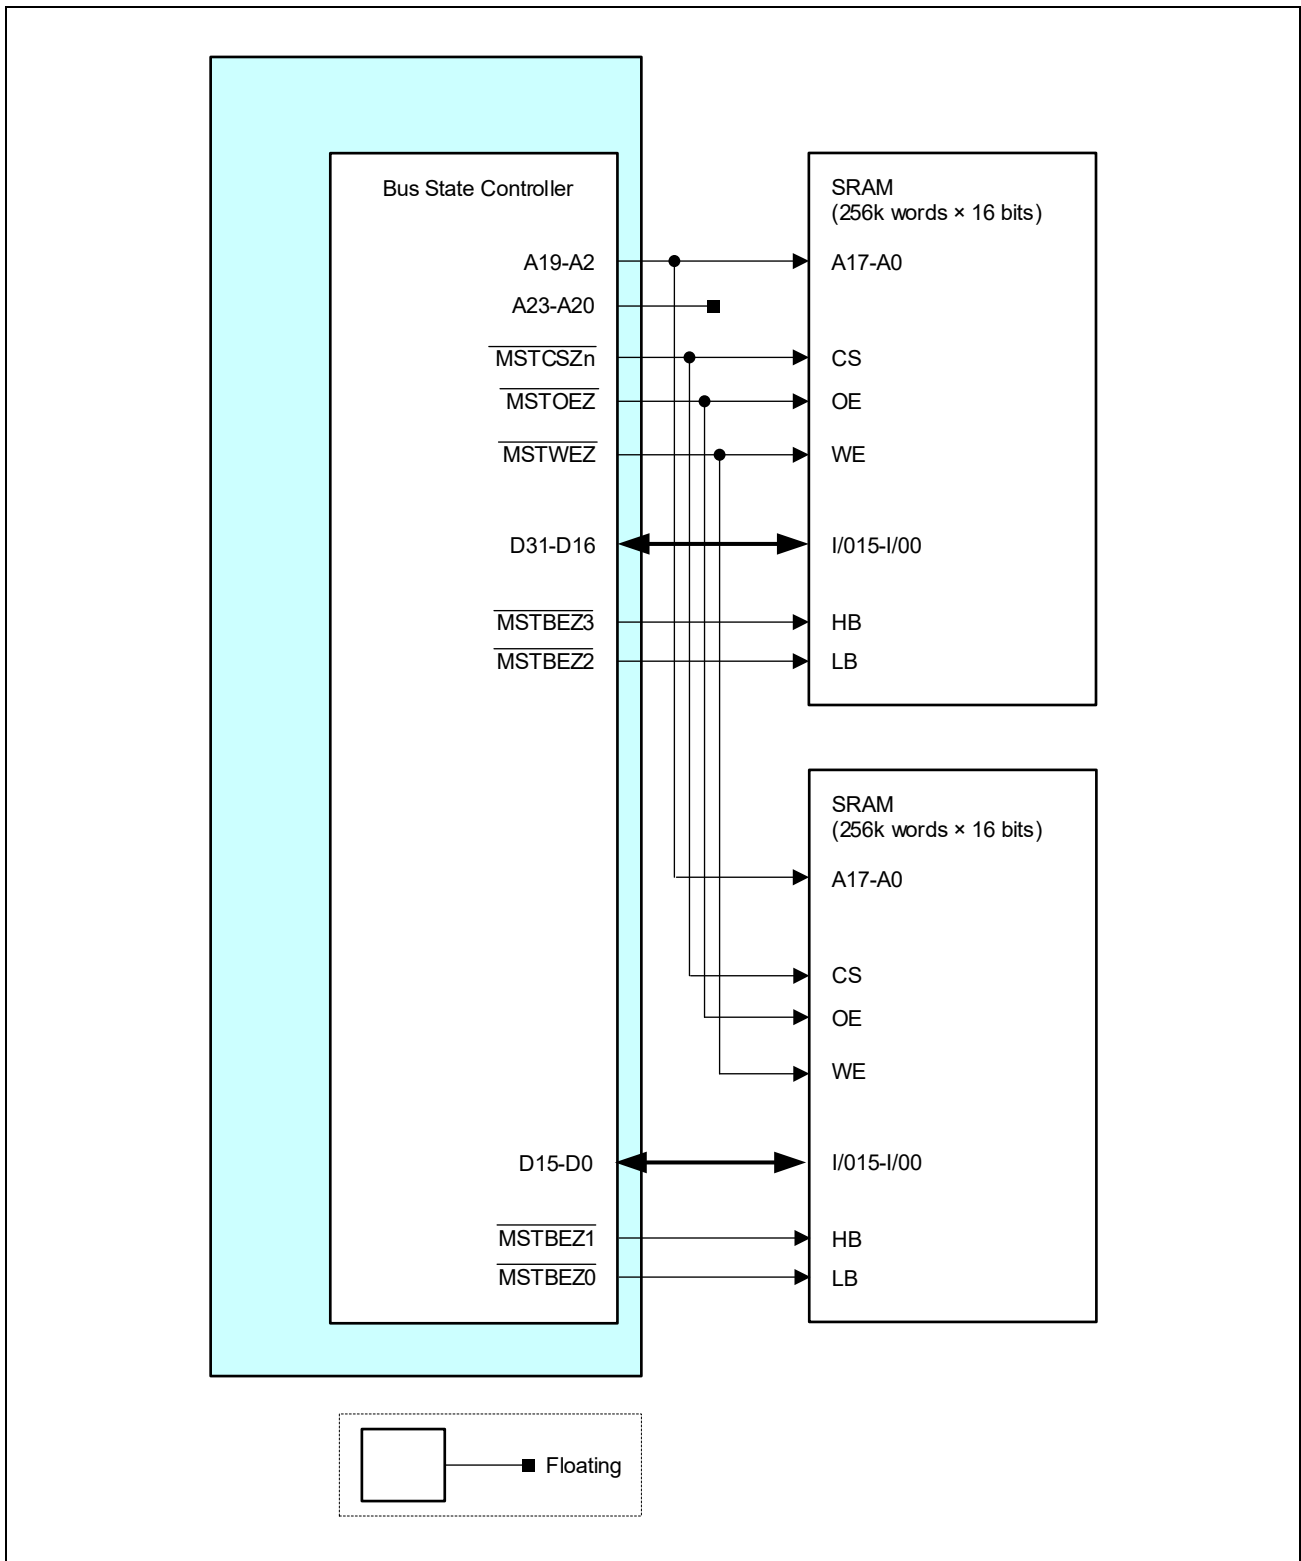

Figure 17.9 SRAM (32 Bits) Connection Example

Figure 17.10 SRAM (16 Bits) Connection Example

NOTES

1. 2 byte unit address is output from EXBC.
2. When 32 bit access is performed at the 16 bit setting, 16 bit access is performed twice.

Section 18 Clocked Serial Interface H (CSIH)

18.1 Features of CSIH

18.1.1 Units and Channels

This microcontroller has the following number of CSIH channels.

Table 18.1 Number of Channels

Product Name	RH850/E2x-FCC2 series	
	468 pins	373 pins
Number of Channels	8	
Unit Name	CSIHn (n = 0 to 7)	

Table 18.2 Index

Index	Description
m	A variable used for explanation is identified by the index "m": for example, CSIHnETXDAm and CSIHnERXDAm are a non-specified baud rate setting register of CSIHn.
n	Throughout this section, the individual CSIH units are identified by the index "n" ("n" is channel numbers.): for example, CSIHnCTL0 is the CSIHn control register 0.
x	CSIHn has a maximum of 6 chip select signals. Throughout this section, the individual chip select signals are identified by the index "x": that is, CSx denotes a non-specified chip select signal.
y	A variable used for explanation is identified by the index "y": for example, CSIHnBRSy is the baud rate setting register of CSIHn.

The numbers of chip select signals for each of the CSIH units are listed in the following table.

Table 18.3 Number of Chip Select Signals

Unit Name	Chip Select Index
CSIH0	CSx (x = 0 to 5)
CSIH1	CSx (x = 0 to 3)
CSIH2	CSx (x = 0 to 3)
CSIH3	CSx (x = 0 to 3)
CSIH4	CSx (x = 0 to 3)
CSIH5	CSx (x = 0 to 3)
CSIH6	CSx (x = 0 to 3)
CSIH7	CSx (x = 0 to 3)

18.1.2 Register Base Address

CSIH base addresses are listed in the following table.

CSIH register addresses are given as offsets from the base addresses.

Table 18.4 Register Base Addresses

Base Address Name	Base Address	Bus Group
<CSIH0_base>	FFD8 0000 _H	Peripheral Group 4
<CSIH1_base>	FFD8 2000 _H	Peripheral Group 4
<CSIH2_base>	FFD8 4000 _H	Peripheral Group 4
<CSIH3_base>	FFD8 6000 _H	Peripheral Group 4
<CSIH4_base>	FFD8 8000 _H	Peripheral Group 3
<CSIH5_base>	FFD8 A000 _H	Peripheral Group 3
<CSIH6_base>	FFD8 C000 _H	Peripheral Group 3
<CSIH7_base>	FFD8 E000 _H	Peripheral Group 3

18.1.3 Clock Supply

The CSIH clock supply is shown in the following table.

Table 18.5 Clock Supply

Unit Name	Unit Clock Name	Supply Clock Name
CSIHn	PCLK	CLK_HSB

18.1.4 Interrupt Requests

CSIH interrupt requests are listed in the following table.

Table 18.6 Interrupt Requests (1/2)

Interrupt symbol name	Unit Interrupt Signal	Outline	Interrupt Number	sDMA Trigger Number	DTS Trigger Number

18.2 Overview

18.2.1 Functional Overview

- Three-wire serial synchronous data transfer well known as SPI
- Either master mode or slave mode can be selected
- Multiple slaves configuration and RCB (Recessive Configuration for Broadcasting) are possible since there are six configurable chip select output signals
- Slave select input signal ($\overline{\text{CSIHTSSI}}$) is usable
- Built-in baud rate generator
- Transfer clock frequency is adjustable in master mode, whereas it is determined by the input clock in slave mode.
- Maximum transfer clock frequency:
 - Master mode: 10.0 MHz (however, it must be equal to or lower than PCLK/8)
 - Slave mode: 4.0 MHz (however, it must be equal to or lower than PCLK/20)
- Clock phase and data phase are selectable
- Data transfer with MSB first or LSB first is selectable
- Transfer data length is selectable from 2 to 16 bits in 1-bit units
- Built-in EDL (extended data length) function for transferring more than 16 bits of data
- Three selectable transfer modes:
 - transmit-only mode
 - receive-only mode
 - transmit/receive mode
- Built-in handshake function
- Built-in error detection (data consistency check, parity, and overrun)
- Support of job concept
- Four different interrupt request signals (INTCSIHTIC, INTCSIHTIR, INTCSIHTIRE, INTCSIHTIJC)
- Three different DMA request signals (INTCSIHTIC, INTCSIHTIR, INTCSIHTIJC)
- Built-in LBM (loop back mode) function for self-test
- Enforced chip select idle setting
- Built-in JOB enable control bit for AUTOSAR
- CSIH has an extended communication function that can perform 8, 16, 32-bit SPI communication.
 - Extended communication data registers can use up to 16 stages.

18.2.2 Functional Overview Description

The CSIH uses three signals for communication:

- Transmission clock CSIH_TSCK (output in master mode, input in slave mode)
- Data output signal CSIH_TSO
- Data input signal CSIH_TSI

Additional signals are available for external control and monitoring:

- $\overline{\text{CSIH}}\text{TSSI}$: Slave select input signal
- CSIH_TRYO: Ready/busy output signal (handshake signal)
- CSIH_TRYI: Ready/busy input signal (handshake signal)
- CSIH_TCSS[5:0]: Chip select signals

Data transmission is bit-wise and serial, and performed synchronously with the transmission clock.

The following table shows the most important registers for setting up the CSIH.

Table 18.11 Main Registers of CSIH

Register	Function
CSIH _n CTL0	Enables/disables serial clock, and permits/prohibits data transmission and data reception. Defines end-of-job behavior and enables/disables (bypass) buffering.
CSIH _n CTL1	Controls options like interrupt timing, extended data length, job feature, loop-back mode, handshake, etc. such as
CSIH _n CTL2	Selects master or slave mode, and the transfer clock frequency of the built-in baud rate generator (BRG) in master mode.
CSIH _n BRSy	Specifies the transfer clock frequency for each chip select signal.
CSIH _n CFGx	Configures the communication protocol for each chip select signal.

18.2.3 Block Diagram

The following block diagram shows the main components of the CSIH.

Figure 18.1 CSIH Block Diagram

In master mode, the transmission clock CSIHSSCK is generated by the built-in baud rate generator (BRG). In slave mode, the transmission clock is supplied by an external source.

The loop back circuit disconnects the CSIH completely from the ports and supports internal self-test.

NOTE

This section describes the following modes:

- The “operating mode” is either master mode or and slave mode. In this context, only a master can control and communicate with several slaves (for details, see **Section 18.5.1, Operating Modes (Master/Slave)**).
- The “job mode” is related to the AUTOSAR job concept (for details, see **Section 18.5.3.3, Job Concept**).
- The “data transfer mode” specifies the type of communication – transmit-only, receive-only, or transmit/receive (for details, see **Section 18.5.6, Data Transfer Modes**).

18.3 Registers

18.3.1 List of Registers

CSIH registers are listed in the following table.

For details about <CSIHn_base>, see **Section 18.1.2, Register Base Address**.

Table 18.12 List of Registers (1/3)

Module Name	Register Name	Symbol	Address	Access Size	Access Protection
CSIHn	CSIHn Control Register 0	CSIHnCTL0	<CSIHn_base> + 0000 _H	8	—
	CSIHn Control Register 1	CSIHnCTL1	<CSIHn_base> + 0010 _H	32	—
	CSIHn Control Register 2	CSIHnCTL2	<CSIHn_base> + 0014 _H	16	—
	CSIHn Status Register 0	CSIHnSTR0	<CSIHn_base> + 0004 _H	32	—
	CSIHn Status Clear Register 0	CSIHnSTCR0	<CSIHn_base> + 0008 _H	16	—
	CSIHn Configuration Register 0	CSIHnCFG0	<CSIHn_base> + 1044 _H	32	—
	CSIHn Configuration Register 1	CSIHnCFG1	<CSIHn_base> + 1048 _H	32	—
	CSIHn Configuration Register 2	CSIHnCFG2	<CSIHn_base> + 104C _H	32	—
	CSIHn Configuration Register 3	CSIHnCFG3	<CSIHn_base> + 1050 _H	32	—
	CSIHn Configuration Register 4	CSIHnCFG4	<CSIHn_base> + 1054 _H	32	—
	CSIHn Configuration Register 5	CSIHnCFG5	<CSIHn_base> + 1058 _H	32	—
	CSIHn Transmit Data Register 0 for Word Access	CSIHnTX0W	<CSIHn_base> + 1008 _H	32	—
	CSIHn Transmit Data Register 0 for Half Word Access	CSIHnTX0H	<CSIHn_base> + 100C _H	16	—
	CSIHn Receive Data Register 0 for Word Access	CSIHnRX0W	<CSIHn_base> + 1010 _H	32	—
	CSIHn Receive Data Register 0 for Half Word Access	CSIHnRX0H	<CSIHn_base> + 1014 _H	16	—
	CSIHn Baud Rate Setting Register 0	CSIHnBRS0	<CSIHn_base> + 1068 _H	16	—
	CSIHn Baud Rate Setting Register 1	CSIHnBRS1	<CSIHn_base> + 106C _H	16	—
	CSIHn Baud Rate Setting Register 2	CSIHnBRS2	<CSIHn_base> + 1070 _H	16	—
	CSIHn Baud Rate Setting Register 3	CSIHnBRS3	<CSIHn_base> + 1074 _H	16	—
	CSIHn Interrupt Control Register	CSIHnEIE	<CSIHn_base> + 1100 _H	8,16,32	—
	CSIHn Extended Communication Control Register 0	CSIHnECTL0	<CSIHn_base> + 1104 _H	8,16,32	—
	CSIHn Extended Communication Control Register 1	CSIHnECTL1	<CSIHn_base> + 1108 _H	8,16,32	—
	CSIHn Extended Communication Transmit Data Register 0	CSIHnETXDA0	<CSIHn_base> + 110C _H	8,16,32	—
	CSIHn Extended Communication Transmit Data Register 1	CSIHnETXDA1	<CSIHn_base> + 1110 _H	8,16,32	—

	CSIHn Extended Communication Stop Trigger Register	CSIHnESTT	<CSIHn_base> + 1190 _H	8,16,32	—

Table 18.12 List of Registers (3/3)

Module Name	Register Name	Symbol	Address	Access Size	Access Protection
CSIHn	CSIHn Extended Communication Status Register	CSIHnESTF	<CSIHn_base> + 1194 _H	8,16,32	—

18.3.2 CSIHnCTL0 — CSIHn Control Register 0

This register controls the operation clock, enables/disables transmission/reception, and enables/disables the memory allocated for transmission and/or reception. It forces the stop of communication at the end of the current job.

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	CSIHnPWR	CSIHnTXE	CSIHnRXE	—	—	—	CSIHnJOBE	CSIHnMBS
Value after reset	0	0	0	0	0	0	0	0
	R/W	R/W	R/W	R	R	R	R/W	R/W

Table 18.13 CSIHnCTL0 Register Contents

Bit Position	Bit Name	Function
7	CSIHnPWR	Controls the operation clock. 0: Stops operation clock. 1: Supplies operation clock. Clearing CSIHnPWR to 0 resets the internal circuits, stops operation, and sets CSIH to standby state. Clock supply to internal circuits stops. If CSIHnPWR is cleared to 0 during communication, ongoing communication is immediately aborted. In this case, the communication setting must be reconfigured.
6	CSIHnTXE	Permits or prohibits transmission. 0: Prohibits transmission. 1: Permits transmission.
5	CSIHnRXE	Permits or prohibits reception. 0: Prohibits reception. 1: Permits reception.
4 to 2	—	Reserved When read, the value after reset is read. When writing to these bits, write the value after reset.
1	CSIHnJOBE	Stops communication at the end of the current job (communication ends if data is written to the transmission buffer when CSIHnTX0W.CSIHnEOJ = 1 (job completion)). 0: Communication stop is not requested. 1: Stops communication. This bit can be used to abort an ongoing job. This bit is cleared to 0 automatically. Even if this bit is set to 1, the read value is always 0.
0	CSIHnMBS	Enables direct access mode. 0: CSIH transmit/receive operation is prohibited. 1: Direct access mode Write 1 in CSIHnMBS bit for transmission/reception via the CSIH.

CAUTIONS

- Do not modify any of CSIHnTXE, CSIHnRXE, CSIHnJOBE, and CSIHnMBS bits while CSIHnPWR = 0.
Do not modify the CSIHnMBS bit when CSIHnPWR = 1.
The CSIHnTXE, CSIHnRXE, and CSIHnMBS bits can be modified when the CSIHnPWR bit is changed from 0 to 1.
To change the CSIHnMBS bit, do so at the same time as when the CSIHnPWR bit is changed from 0 to 1.
- Do not modify CSIHnTXE, CSIHnRXE, or CSIHnMBS while data transmission is pending or going on, i.e. if CSIHnSTR0.CSIHnTSF = 1.

When setting this register, see **Table 18.34, Notes on Setting Registers**.

18.3.3 CSIHnCTL1 — CSIHn Control Register 1

This register specifies the interrupt timing and the interrupt delay mode. It also enables/disables extended data length control, loop-back mode, handshake functionality, and job mode. It selects the active output level of each chip select signal and the behavior of the chip select signals after the transfer of the final data.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 18.14 CSIHnCTL1 Register Contents (1/2)

Bit Position	Bit Name	Function
31 to 18	—	Reserved When read, the value after reset is read. When writing to these bits, write the value after reset.
17	CSIHnCKR	CSIHnTSCCK Clock Inversion Function 0: The default level of CSIHnTSCCK is high 1: The default level of CSIHnTSCCK is low For details, see Section 18.3.7, CSIHnCFGx — CSIHn Configuration Register x . CAUTION: Clear the CSIHnCKPx bit in CSIHnCFGx to 0 when this bit is used without the chip select function.
16	CSIHnSLIT	Selects the timing of interrupt INTCSIHnTIC. 0: Normal interrupt timing (interrupt is generated after the transfer) 1: As soon as the contents of the CSIHnTX0W/H register are transferred to the shift register, an interrupt is generated. For details, see Section 18.4.3, INTCSIHnTIC (Communication Status Interrupt) .
15 to 14	—	Reserved When read, the value after reset is read. When writing to these bits, write the value after reset.
13 to 8	CSIHnCSLx	Selects the active output level of chip select signal x (CSIHnTCSLx). 0: Chip select is active low. 1: Chip select is active high. For details, see Section 18.5.3, Chip Selection (CS) Features .
7	CSIHnEDLE	Enables/disables extended data length (EDL) mode. 0: Disables extended data length mode. 1: Enables extended data length mode. For details, see Section 18.5.7.2, Data Length Greater than 16 Bits .

Table 18.14 CSIHnCTL1 Register Contents (2/2)

Bit Position	Bit Name	Function
6	CSIHnJE	<p>Enables/disables job mode.</p> <p>0: Disables job mode. 1: Enables job mode.</p> <p>For details, see Section 18.5.3.3, Job Concept.</p> <p>The CSIHnCTL0.CSIHnJOBE, and CSIHnTX0W.CSIHnEOJ bits are enabled only when CSIHnJE = 1.</p> <p>Setting this bit in slave mode is prohibited.</p> <p>When CSIHnJE = 0, interrupt INTCSIHTIC is generated after one unit of data transmission is completed.</p> <p>When CSIHnJE = 1, interrupt INTCSIHTIC is also generated after one unit of data transmission is completed.</p> <p>In the case of CSIHnTX0W.CSIHnEOJ = 1 and CSIHnCTL0.CSIHnJOBE = 1, however, interrupt INTCSIHTIJC is generated instead of INTCSIHTIC.</p>
5	CSIHnDCS	<p>Enables/disables data consistency check.</p> <p>0: Disables data consistency check. 1: Enables data consistency check.</p> <p>For details, see Section 18.5.11.1, Data Consistency Check.</p>
4	CSIHnCSRI	<p>Defines chip select signal behavior after last data transfer.</p> <p>0: Chip select signal retains the active level. 1: Chip select signal returns to the inactive level.</p> <p>The last data is determined at the interrupt timing when CSIHnCTL1.CSIHnSLIT is 1.</p>
3	CSIHnLBM	<p>Controls loop-back mode (LBM).</p> <p>0: Deactivates loop-back mode. 1: Activates loop-back mode.</p> <p>For details, see Section 18.5.12, Loop-Back Mode.</p>
2	CSIHnSIT	<p>Selects interrupt delay mode.</p> <p>0: No delay is generated. 1: Half clock delay is generated for all interrupts.</p> <p>This bit is only valid in master mode. In slave mode, no delay is generated.</p> <p>For details, see Section 18.4.2, Interrupt Delay.</p>
1	CSIHnHSE	<p>Enables/disables the handshake function.</p> <p>0: Disables the handshake function. 1: Enables the handshake function.</p> <p>For details, see Section 18.5.10, Handshake Function.</p>
0	CSIHnSSE	<p>Enables/disables the slave select function.</p> <p>0: Input signal $\overline{\text{CSIHTSSI}}$ is disabled. 1: Input signal $\overline{\text{CSIHTSSI}}$ is recognized.</p> <p>If the slave select function is not used, this bit must be set to 0 (see also Section 18.5.2, Master/Slave Connections).</p>

Details about CSIHnCTL1.CSIHnSSE are shown in the following tables.

Table 18.15 Operation of the Slave Select Function during Reception

CSIHnCTL0. CSIHnRXE	CSIHnCTL1. CSIHnSSE	$\overline{\text{CSIHTSSI}}$	Receive Operation
0	—	—	Reception is prohibited
1	0	—	Possible
1	1	0	Possible
1	1	1	Disabled

Table 18.16 Operation of the Slave Select Function during Transmission

CSIHnCTL0. CSIHnTXE	CSIHnCTL1. CSIHnSSE	$\overline{\text{CSIHTSSI}}$	Transmit Operation
0	—	—	Transmission is prohibited
1	0	—	Possible
1	1	0	Possible
1	1	1	Disabled

CAUTION

When setting this register, see **Table 18.34, Notes on Setting Registers.**

18.3.4 CSIHnCTL2 — CSIHn Control Register 2

This register selects operating mode and the reference clock value, and specifies the transfer clock frequency.

For details, see **Section 18.5.5, Transmission Clock Selection**.

Value after reset: E000_H

Table 18.17 CSIHnCTL2 Register Contents

Bit Position	Bit Name	Function																																				
15 to 13	CSIHnPRS[2:0]	These bits select the operation mode and the reference clock value.																																				
		<table border="1"> <thead> <tr> <th>CSIHnPRS2</th> <th>CSIHnPRS1</th> <th>CSIHnPRS0</th> <th>Selection of Reference Clock (PRSOUT)</th> </tr> </thead> <tbody> <tr> <td>0</td> <td>0</td> <td>0</td> <td>PCLK (Master mode)</td> </tr> <tr> <td>0</td> <td>0</td> <td>1</td> <td>PCLK/2 (Master mode)</td> </tr> <tr> <td>0</td> <td>1</td> <td>0</td> <td>PCLK/4 (Master mode)</td> </tr> <tr> <td>0</td> <td>1</td> <td>1</td> <td>PCLK/8 (Master mode)</td> </tr> <tr> <td>1</td> <td>0</td> <td>0</td> <td>PCLK/16 (Master mode)</td> </tr> <tr> <td>1</td> <td>0</td> <td>1</td> <td>PCLK/32 (Master mode)</td> </tr> <tr> <td>1</td> <td>1</td> <td>0</td> <td>PCLK/64 (Master mode)</td> </tr> <tr> <td>1</td> <td>1</td> <td>1</td> <td>External clock via CSIHnTSCk(in) (Slave mode)</td> </tr> </tbody> </table>	CSIHnPRS2	CSIHnPRS1	CSIHnPRS0	Selection of Reference Clock (PRSOUT)	0	0	0	PCLK (Master mode)	0	0	1	PCLK/2 (Master mode)	0	1	0	PCLK/4 (Master mode)	0	1	1	PCLK/8 (Master mode)	1	0	0	PCLK/16 (Master mode)	1	0	1	PCLK/32 (Master mode)	1	1	0	PCLK/64 (Master mode)	1	1	1	External clock via CSIHnTSCk(in) (Slave mode)
CSIHnPRS2	CSIHnPRS1	CSIHnPRS0	Selection of Reference Clock (PRSOUT)																																			
0	0	0	PCLK (Master mode)																																			
0	0	1	PCLK/2 (Master mode)																																			
0	1	0	PCLK/4 (Master mode)																																			
0	1	1	PCLK/8 (Master mode)																																			
1	0	0	PCLK/16 (Master mode)																																			
1	0	1	PCLK/32 (Master mode)																																			
1	1	0	PCLK/64 (Master mode)																																			
1	1	1	External clock via CSIHnTSCk(in) (Slave mode)																																			
		CAUTION: Max baud rate configuration is as follows.																																				
		<ul style="list-style-type: none"> • Master mode is PCLK/8. • Slave mode is PCLK/20. 																																				
12 to 0	—	Reserved When read, the value after reset is read. When writing to these bits, write the value after reset.																																				

In master mode, the following bits are used to set the transfer clock frequency:

CSIHnCTL2.CSIHnPRS[2:0], CSIHnCFGx.CSIHnBRSSx[1:0], CSIHnBRSy.CSIHnBRS[11:0]

In addition, any of the four different transfer clock frequency settings that are specified by the CSIHnBRSy.CSIHnBRS[11:0] bits are selected for each chip select signal. To select the transfer clock frequency setting for each chip select signal, use the CSIHnCFGx.CSIHnBRSSx[1:0] bits.

The following table shows the relationship between CSIHnCFGx.CSIHnBRSSx[1:0] and CSIHnBRSy.CSIHnBRS[11:0].

CSIHnCFGx. CSIHnBRSSx[1:0]	Transfer Clock Frequency Setting Bit to be Selected
00	CSIHnBRS0.CSIHnBRS[11:0]
01	CSIHnBRS1.CSIHnBRS[11:0]
10	CSIHnBRS2.CSIHnBRS[11:0]
11	CSIHnBRS3.CSIHnBRS[11:0]

The following table shows the relationship between the transfer clock frequency and the transfer clock frequency setting (CSIHnBRSy[11:0]) selected by the CSIHnBRSSx[1:0] bits when the bit value of the CSIHnPRS[2:0] bits is α .

CSIHnBRSy[11:0]	Transfer clock frequency
0	BRG stopped
1	$PCLK / (2^\alpha \times 1 \times 2)$
2	$PCLK / (2^\alpha \times 2 \times 2)$
3	$PCLK / (2^\alpha \times 3 \times 2)$
4	$PCLK / (2^\alpha \times 4 \times 2)$
...	...
4095	$PCLK / (2^\alpha \times 4095 \times 2)$

CAUTION

Changing the contents of this register is only permitted when CSIHnCTL0.CSIHnPWR = 0.

When setting this register, see **Table 18.34, Notes on Setting Registers**.

18.3.5 CSIHnSTR0 — CSIHn Status Register 0

This register indicates the status of CSIH.

Value after reset: 0000 0010_H

Transmit/receive mode																				
Receive-only mode																				
Slave Mode	Timing to Set	Timing to Clear																		
Transmit-only mode	Data is written to a transmit register (CSIHnTX0W/CSIHnTX0H)	Within a half clock cycle of the last serial clock edge																		
Transmit/receive mode																				
Receive-only mode	Input timing of CSIHnTSCK																			
6 to 4	—	Reserved When read, the value after reset is read.																		
3	CSIHnDCE	Data Consistency Check Error Flag 0: No data consistency error is detected. 1: Data consistency error is detected. This bit is cleared by writing 1 to CSIHnSTCR0.CSIHnDCEC. When this bit is set to 1 and cleared to 0 simultaneously, setting to 1 is prioritized. This bit is initialized when CSIHnCTL0.CSIHnPWR is changed from 0 to 1 or from 1 to 0.																		
2	—	Reserved When read, the value after reset is read.																		
1	CSIHnPE	Parity Error Flag 0: No parity error is detected. 1: Parity error is detected. This bit is cleared by writing 1 to CSIHnSTCR0.CSIHnPEC. When this bit is set to 1 and cleared to 0 simultaneously, setting to 1 is prioritized. This bit is initialized when CSIHnCTL0.CSIHnPWR changes from 0 to 1 or from 1 to 0.																		

Table 18.18 CSIHnSTR0 Register Contents (2/2)

Bit Position	Bit Name	Function
0	CSIHnOVE	Overrun Error Flag 0: No overrun error is detected. 1: Overrun error is detected. For details, see Section 18.5.11.2 , Parity Check. This bit is cleared by writing 1 to CSIHnSTCR0.CSIHnOVEC. When this bit is set to 1 and cleared to 0 simultaneously, setting to 1 is prioritized. This bit is initialized when CSIHnCTL0.CSIHnPWR changes from 0 to 1 or from 1 to 0.

Table 18.19 Behaviors in Various Direct Access Modes

Bit Name	Bit Position	Direct Access Mode
CSIHnTSF	7	0: Idle state 1: Communication is in progress or being prepared
CSIHnDCE	3	0: No error is detected. 1: An error is detected.
CSIHnPE	1	0: No error is detected. 1: An error is detected.
CSIHnOVE	0	0: No error is detected. 1: An error is detected.

CAUTION

When setting this register, see **Table 18.34, Notes on Setting Registers**.

18.3.6 CSIHnSTCR0 — CSIHn Status Clear Register 0

This register clears the status flags of the CSIHnSTR0 status register.

Value after reset: 0000_H

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	CSIHn DCEC	—	CSIHn PEC	CSIHn OVEC
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R	R/W	R/W

Table 18.20 CSIHnSTCR0 Register Contents

Bit Position	Bit Name	Function
15 to 4	—	Reserved When read, the value after reset is read. When writing to these bits, write the value after reset.
3	CSIHnDCEC	Controls the data consistency error flag clear command. 0: No operation. The read value is always 0. 1: Clears the data consistency error flag (CSIHnSTR0.CSIHnDCE).
2	—	Reserved When read, the value after reset is read. When writing to these bits, write the value after reset.
1	CSIHnPEC	Controls the parity error flag clear command. 0: No operation. The read value is always 0. 1: Clears the parity error flag (CSIHnSTR0.CSIHnPE).
0	CSIHnOVEC	Controls the overrun error flag clear command. 0: No operation. The read value is always 0. 1: Clears the overrun error flag (CSIHnSTR0.CSIHnOVE).

CAUTION

When setting this register, see **Table 18.34, Notes on Setting Registers**.

18.3.7 CSIHnCFGx — CSIHn Configuration Register x (x = 0 to 5)

These eight registers configure the prescaler, parity, data length, recessive configuration for broadcasting, serial data direction, clock phase and data phase, idle enforcement configuration, idle time, hold time, inter-data time, and setup for each chip select signal, CSIHnCSSx.

Slave mode

In slave mode, the transmission protocol setting of the CSIHnCFG0 register is effective.

- CSIHnPS0[1:0]: parity usage
- CSIHnDLS0[3:0]: data length selection
- CSIHnDIR0: data direction
- CSIHnCKP0, CSIHnDAP0: clock phase and data phase

In slave mode, set all bits other than above in the CSIHnCFG0 register, and the CSIHnCFG1 to CSIHnCFG5 registers to 0.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	CSIHnBRSSx [1:0]		CSIHnPSx[1:0]		CSIHnDLSx[3:0]				—	—	—	—	CSIHn RCBx	CSIHn DIRx	CSIHn CKPx	CSIHn DAPx
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

CAUTION

Rewrite is possible only when CSIHnCTL0.CSIHnPWR = 0 (for write access with the same value, rewrite is possible when CSIHnCTL0.CSIHnPWR = 1).

Table 18.21 CSIHnCFGx Register Contents (1/4)

Bit Position	Bit Name	Function																				
31, 30	CSIHnBRSSx[1:0]	These bits select the baud rate setting register (CSIHnBRSy).																				
		<table border="1"> <thead> <tr> <th>CSIHnBRSSx1</th> <th>CSIHnBRSSx0</th> <th>Baud Rate Setting Register Selection</th> </tr> </thead> <tbody> <tr> <td>0</td> <td>0</td> <td>The transfer clock frequency is set according to the CSIHnBRS0 setting.</td> </tr> <tr> <td>0</td> <td>1</td> <td>The transfer clock frequency is set according to the CSIHnBRS1 setting.</td> </tr> <tr> <td>1</td> <td>0</td> <td>The transfer clock frequency is set according to the CSIHnBRS2 setting.</td> </tr> <tr> <td>1</td> <td>1</td> <td>The transfer clock frequency is set according to the CSIHnBRS3 setting.</td> </tr> </tbody> </table>	CSIHnBRSSx1	CSIHnBRSSx0	Baud Rate Setting Register Selection	0	0	The transfer clock frequency is set according to the CSIHnBRS0 setting.	0	1	The transfer clock frequency is set according to the CSIHnBRS1 setting.	1	0	The transfer clock frequency is set according to the CSIHnBRS2 setting.	1	1	The transfer clock frequency is set according to the CSIHnBRS3 setting.					
		CSIHnBRSSx1	CSIHnBRSSx0	Baud Rate Setting Register Selection																		
		0	0	The transfer clock frequency is set according to the CSIHnBRS0 setting.																		
		0	1	The transfer clock frequency is set according to the CSIHnBRS1 setting.																		
		1	0	The transfer clock frequency is set according to the CSIHnBRS2 setting.																		
		1	1	The transfer clock frequency is set according to the CSIHnBRS3 setting.																		
		The maximum value for setting the transfer clock frequency, in accordance with the CSIHnCTL2.CSIHnPRS[2:0] setting, must be as follows:																				
		Master mode: PCLK/8																				
		Slave mode: PCLK/20																				
29, 28	CSIHnPSx[1:0]	Selects the parity for transmitting or receiving chip select signal x.																				
		<table border="1"> <thead> <tr> <th>CSIHnPSx1</th> <th>CSIHnPSx0</th> <th>Transmission</th> <th>Reception</th> </tr> </thead> <tbody> <tr> <td>0</td> <td>0</td> <td>Does not transmit any parity bit.</td> <td>Does not wait for reception of the parity bit.</td> </tr> <tr> <td>0</td> <td>1</td> <td>Adds a parity bit fixed to 0.</td> <td>Waits for reception of the parity bit but does not evaluate it.</td> </tr> <tr> <td>1</td> <td>0</td> <td>Adds an odd parity bit.</td> <td>Waits for the odd parity bit.</td> </tr> <tr> <td>1</td> <td>1</td> <td>Adds an even parity bit.</td> <td>Waits for the even parity bit.</td> </tr> </tbody> </table>	CSIHnPSx1	CSIHnPSx0	Transmission	Reception	0	0	Does not transmit any parity bit.	Does not wait for reception of the parity bit.	0	1	Adds a parity bit fixed to 0.	Waits for reception of the parity bit but does not evaluate it.	1	0	Adds an odd parity bit.	Waits for the odd parity bit.	1	1	Adds an even parity bit.	Waits for the even parity bit.
		CSIHnPSx1	CSIHnPSx0	Transmission	Reception																	
		0	0	Does not transmit any parity bit.	Does not wait for reception of the parity bit.																	
		0	1	Adds a parity bit fixed to 0.	Waits for reception of the parity bit but does not evaluate it.																	
		1	0	Adds an odd parity bit.	Waits for the odd parity bit.																	
1	1	Adds an even parity bit.	Waits for the even parity bit.																			
Selects the data length for chip select signal x.																						
<table border="1"> <thead> <tr> <th>CSIHnDLSx[3:0]</th> <th>Data Length</th> </tr> </thead> <tbody> <tr> <td>0000_B</td> <td>16 bits</td> </tr> <tr> <td>0001_B</td> <td>1 bit</td> </tr> <tr> <td>0010_B</td> <td>2 bits</td> </tr> <tr> <td>...</td> <td>...</td> </tr> <tr> <td>1111_B</td> <td>15 bits</td> </tr> </tbody> </table>		CSIHnDLSx[3:0]	Data Length	0000 _B	16 bits	0001 _B	1 bit	0010 _B	2 bits	1111 _B	15 bits									
CSIHnDLSx[3:0]	Data Length																					
0000 _B	16 bits																					
0001 _B	1 bit																					
0010 _B	2 bits																					
...	...																					
1111 _B	15 bits																					
CAUTION: When CSIHnTX0W.CSIHnEDL = 1, the setting of this bit has no effect.																						
When CSIHnTX0W.CSIHnEDL = 0 (the data length is 16 bits), the setting of this bit is valid. Setting "1 bit" is only enabled if the previous transmit data was 16 bits with CSIHnEDL = 1.																						
23 to 20	—	Reserved When read, the value after reset is read. When writing to these bits, write the value after reset.																				
19	CSIHnRCBx	Selects the recessive configuration for broadcasting for chip select signal x. 0: Dominant (higher priority) 1: Recessive (lower priority) For details, see Section 18.5.3.1, Configuration Registers .																				
18	CSIHnDIRx	Selects the serial data direction of chip select signal x. 0: Data is transmitted/received with MSB first. 1: Data is transmitted/received with LSB first. For details, see Section 18.5.8, Serial Data Direction Selection .

CAUTION

When setting this register, see **Table 18.34, Notes on Setting Registers**.

18.3.8 CSIHnTX0W — CSIHn Transmit Data Register 0 for Word Access

This register stores transmission data. In addition, it specifies the communication interrupt request, the end-of-job, the extended data length, and the chip select activation.

CAUTION

When CSIH0CTL0.CSIH0TXE = CSIH0CTL0.CSIH0RXE = 0 in direct access mode, write access to this register is prohibited.

Value after reset: X0XX XXXX_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	CSIHn EOJ	CSIHn EDL	—	—	—	—	—	—	—	CSIHn CS5	CSIHn CS4	CSIHn CS3	CSIHn CS2	CSIHn CS1	CSIHn CS0
Value after reset	0	—	—	0	0	0	0	0	—	—	—	—	—	—	—	—
R/W	R	R/W	R/W	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	CSIHnTX[15:0]															
Value after reset	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 18.22 CSIHnTX0W Register Contents (1/2)

Bit Position	Bit name	Function
31	—	Reserved When read, the value after reset is read. When writing to these bits, write the value after reset.
30	CSIHnEOJ	Specifies the end of a job. 0: Indicates that it is not end-of-job data. The job continues. 1: Indicates end-of-job data. CAUTION: This bit is only valid when job mode is enabled (CSIHnCTL1.CSIHnJE = 1). This bit must be set to 0 in slave mode.
29	CSIHnEDL	Specifies whether the associated data requires the extended data length (EDL) option. 0: Normal operation 1: Enables the extended data length. The associated data is transmitted as a 16-bit packet. No inter-data time or idle time will be inserted after the data is transmitted. If CSIHnCTL1.CSIHnEDLE = 1 and CSIHnTX0W.CSIHnEDL = 1, the subsequent data must have the same CS selection. If CS is modified for the subsequent data, the correct operation is not assured. CAUTION: This bit is only available if CSIHnCTL1.CSIHnEDLE = 1.
28 to 24	—	Reserved When read, the value after reset is read. When writing to these bits, write the value after reset.
23, 22	—	Reserved When read, the value returned is undefined. The write value should be 1.

Table 18.22 CSIHnTX0W Register Contents (2/2)

Bit Position	Bit name	Function
21 to 16	CSIHnCSx (x =5 to 0)	<p>Activates one or more chip select signals.</p> <p>0: Activates chip select signals x for the associated transmission.</p> <p>1: Deactivates chip select signals x for the associated transmission.</p> <p>Setting bits 23 to 16 = FF_H is prohibited.</p> <p>CAUTION: If several chip select signals are enabled for broadcasting, the configuration of one with CSIHnCFGx.CSIHnRCBx = 0 (dominant) is used. In this case, all dominant chip select signals must be set to precisely the same value.</p> <p>In slave mode, set the bits 23 to 16 are FE_H.</p>
15 to 0	CSIHnTX[15:0]	Stores the transmission data.

CAUTION

When setting this register, see **Table 18.34, Notes on Setting Registers.**

18.3.9 CSIHnTX0H — CSIHn Transmit Data Register 0 for Half Word Access

This register stores the transmission data. This register is the same as bits 15 to 0 of register CSIHnTX0W.

The settings specified by the upper 16 bits of CSIHnTX0W are applied to the transmission. Set transmit data to CSIHnTX0W before using this register because the value of CSIHnTX0W is undefined after reset.

CAUTION

When CSIH0CTL0.CSIH0TXE = CSIH0CTL0.CSIH0RXE = 0 in direct access mode, write access to this register is prohibited.

Table 18.23 CSIHnTX0H Register Contents

Bit Position	Bit name	Function
15 to 0	CSIHnTX[15:0]	Stores the transmission data.

CAUTION

When setting this register, see **Table 18.34, Notes on Setting Registers**.

18.3.10 CSIHnRX0W — CSIHn Receive Data Register 0 for Word Access

This register stores the received data.

CAUTION

This register can be read while CSIHnCTL0.CSIHnPWR = 1.

This register is initialized when CSIHnCTL0.CSIHnPWR changes from 0 to 1 or from 1 to 0.

Value after reset: 0XXX XXXX_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Value after reset	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 18.24 CSIHnRX0W Register Contents

Bit Position	Bit name	Function
31 to 26	—	Reserved When read, the value after reset is read.
25	CSIHnRPE	Indicates whether a reception data parity error was detected. 0: No parity error was detected on the associated reception data. 1: A parity error was detected on the associated reception data.
24	CSIHnTDCE	Indicates whether a transmission data consistency error was detected. 0: No consistency error was detected on the associated transmission data. 1: A consistency error was detected on the associated transmission data.
23 to 22	—	Reserved When read, the value returned is undefined.
21 to 16	CSIHnCSx (x = 5 to 0)	Indicates which chip select signal was activated. 0: Chip select signal x was activated for the associated reception. 1: Chip select signal x was deactivated for the associated reception.
15 to 0	CSIHnRX[15:0]	Stores the received data.

NOTE

Read this register at least one serial clock cycle before an interrupt is generated.

CAUTION

When setting this register, see **Table 18.34, Notes on Setting Registers**.

18.3.11 CSIHnRX0H — CSIHn Receive Data Register 0 for Half Word Access

This register stores the received data. This register is the same as bits 15 to 0 of register CSIHnRX0W.

CAUTION

This register can be read while CSIHnCTL0.CSIHnPWR = 1.

This register is initialized when CSIHnCTL0.CSIHnPWR changes from 0 to 1 or from 1 to 0.

Value after reset: Undefined

Table 18.25 CSIHnRX0H Register Contents

Bit Position	Bit name	Function
15 to 0	CSIHnRX[15:0]	Stores the received data.

CAUTION

When setting this register, see **Table 18.34, Notes on Setting Registers**.

18.3.12 CSIHnBRSy — CSIHn Baud Rate Setting Register y (y = 0 to 3)

This register sets the transfer clock frequency for each chip select signal.

With CSIHnCFG0 to 5.CSIHnBRSSx[1:0] bits, one of the four types of transfer clock frequency settings can be selected for each chip select signal. For details of transfer clock frequency setting, see **Section 18.5.5, Transmission Clock Selection**.

Value after reset: 0000_H

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

R/W	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 18.26 CSIHnBRSy Register Contents

Bit Position	Bit Name	Function
15 to 12	—	Reserved When read, the value after reset is read. When writing to these bits, write the value after reset.
11 to 0	CSIHnBRS[11:0]	0: BRG stopped 1: PCLK / ($2^\alpha \times 1 \times 2$) 2: PCLK / ($2^\alpha \times 2 \times 2$) 3: PCLK / ($2^\alpha \times 3 \times 2$) 4: PCLK / ($2^\alpha \times 4 \times 2$) . . . 4095: PCLK / ($2^\alpha \times 4095 \times 2$)

α is the value of CSIHnCTL2.CSIHnPRS[2:0].

CAUTION

When setting this register, see **Table 18.34, Notes on Setting Registers**.

18.3.13 CSIHnEIE — CSIHn Interrupt Control Register

This register controls enabling or disabling the interrupt of CSIH.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

R/W	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W

Table 18.27 CSIHnEIE Register Contents

Bit Position	Bit Name	Function
31 to 4	—	Reserved When read, the value after reset is read.
3	CSIHnEJE	This bit enables or disables the INTCSIHTIJC interrupt. 0: Disable the INTCSIHTIJC interrupt. 1: Enable the INTCSIHTIJC interrupt.
2	CSIHnEIEE	This bit enables or disables the INTCSIHTIRE interrupt. 0: Disable the INTCSIHTIRE interrupt. 1: Enable the INTCSIHTIRE interrupt.
1	CSIHnEIRE	This bit enables or disables the INTCSIHTIR interrupt. 0: Disable the INTCSIHTIR interrupt. 1: Enable the INTCSIHTIR interrupt.
0	CSIHnEICE	This bit enables or disables the INTCSIHTIC interrupt. 0: Disable the INTCSIHTIC interrupt. 1: Enable the INTCSIHTIC interrupt.

CAUTIONS

- Even when the extended communication function is disabled (CSIHnECTL0.CSIHnEEN = 0), enabling or disabling the interrupt of CSIH is effective. When all interrupts of CSIH are used, specify settings to enable all interrupt outputs (CSIHnEIE[3:0] = 1111_B).
- Specify settings to enable or disable interrupt output while communication is not performed. If the settings are specified during communication, the interrupt output operation is not guaranteed.

18.3.14 CSIHnECTL0 — CSIHn Extended Communication Control Register 0

This register is used to control the operation of the extended communication function.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 18.30 CSIHnETXDAm Register Contents

Bit Position	Bit Name	Function
31 to 0	CSIHnETXDAm[31:0]	These bits retain the data transmitted by the extended communication function.

CAUTION

Access to this register must be done in the same bit mode as the transfer data size.

When the communication data size is 8 bits, access to this register must be 8-bit access.

When the communication data size is 16 bits, access to this register must be 16-bit access.

When the communication data size is 32 bits, access to this register must be 32-bit access.

18.3.17 CSIHnERXDAm — CSIHn Extended Communication Receive Data Register m (m = 0 to 15)

This register is used to control the operation of the extended communication function.

Value after reset: 0000 0000_H

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	CSIHnERXDAm[31:16]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	CSIHnERXDAm[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 18.31 CSIHnERXDAm Register Contents

Bit Position	Bit Name	Function
31 to 0	CSIHnERXDAm[31:0]	These bits retain the data received by the extended communication function.

CAUTIONS

- Access to this register must be done in the same bit mode as the transfer data size.
When the communication data size is 8 bits, access to this register must be 8-bit access.
When the communication data size is 16 bits, access to this register must be 16-bit access.
When the communication data size is 32 bits, access to this register must be 32-bit access.
- When transfer completion interrupt "INTCSIHTIJC" occurs, these registers (reception data) must be read only once.

18.3.18 CSIHnESTT — CSIHn Extended Communication Stop Trigger Register

This register is used to control the operation of the extended communication function.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	CSIHn ESTRG
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Table 18.32 CSIHnESTT Register Contents

Bit Position	Bit Name	Function
31 to 1	—	Reserved When read, the value after reset is read.
0	CSIHnESTRG	This bit stops the extended communication of CSIHn. Writing 1 to this bit stops the communication. Writing 0 to this bit is ignored. The value read from this bit is always 0.

For details about the stop trigger register, see **Section 18.5.14.2, Extended Communication Stop Function**.

18.3.19 CSIHnESTF — CSIHn Extended Communication Status Register

This register is used to control the operation of the extended communication function.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	CSIHnE TSF	—	—	CSIHnETCF[4:0]				
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 18.33 CSIHnESTF Register Contents

Bit Position	Bit Name	Function
31 to 8	—	Reserved When read, the value after reset is read.
7	CSIHnETSF	This bit is a flag that indicates the status of the extended communication. 0: Extended communication stopped 1: Extended communication in progress This bit is cleared to 0 when CSIHnECTL0.CSIHnEEN changes from 1 to 0.
6 to 5	—	Reserved When read, the value after reset is read.
4 to 0	CSIHnETCF[4:0]	These bits are the flags to indicate the transfer count in extended communication. Flags that indicate the remaining number of 32-bit communications: 0: 0 communications remaining 1: 1 communication remaining 2: 2 communications remaining 3: 3 communications remaining 4: 4 communications remaining 5: 5 communications remaining 6: 6 communications remaining 7: 7 communications remaining 8: 8 communications remaining 9: 9 communications remaining 10: 10 communications remaining 11: 11 communications remaining 12: 12 communications remaining 13: 13 communications remaining 14: 14 communications remaining 15: 15 communications remaining 16: 16 communications remaining This bit is cleared to 0000 _B when CSIHnECTL0.CSIHnEEN changes from 1 to 0.

18.3.20 List of Cautions

Table 18.34 Notes on Setting Registers (1/2)

Register Name	Bit Name	Cautions
CSIHnCTL0	CSIHnPWR	If this bit is cleared during communication, ongoing communication is aborted. After the communication is aborted, it is necessary to restart the communication.
CSIHnCTL0	CSIHnTXE CSIHnRXE	Do not modify any of these bits while CSIHnCTL0.CSIHnPWR = 0. (These bits can be modified at the same time as the CSIHnCTL0.CSIHnPWR bit.) Do not modify these bits while CSIHnSTR0.CSIHnTSF = 1, because the specified operation is not guaranteed if ongoing communication is aborted.
CSIHnCTL0	CSIHnJOBE	Do not modify this bit while CSIHnCTL0.CSIHnPWR = 0. This bit is only valid when CSIHnCTL1.CSIHnJE = 1. Setting this bit is prohibited in slave mode.
CSIHnCTL0	CSIHnMBS	Do not modify this bit while CSIHnCTL0.CSIHnPWR = 0. (This bit can be modified at the same time as the CSIHnCTL0.CSIHnPWR bit.) Modification of this bit is only permitted while CSIHnSTR0.CSIHnTSF = 0.
CSIHnCTL1	CSIHnCKR	Modification of this bit is only permitted while CSIHnCTL0.CSIHnPWR = 0. When CS is not used, use this bit instead of CSIHnCFGx.CSIHnCKPx and set CSIHnCFGx.CSIHnCKPx to 0. This bit must be used in slave mode.
CSIHnCTL1	CSIHnSLIT CSIHnCSL[5:0] CSIHnEDLE CSIHnDCS CSIHnCSRI CSIHnHSE	Modification of these bits is only permitted while CSIHnCTL0.CSIHnPWR = 0.
CSIHnCTL1	CSIHnJE CSIHnLBM	Modification of these bits is only permitted while CSIHnCTL0.CSIHnPWR = 0. Setting of these bits are prohibited in slave mode.
CSIHnCTL1	CSIHnSSE	Modification of this bit is only permitted while CSIHnCTL0.CSIHnPWR = 0. Setting this bit to 1 is prohibited in master mode.
CSIHnCTL1	CSIHnSIT	Modification of this bit is only permitted while CSIHnCTL0.CSIHnPWR = 0. This bit is only valid in master mode. In slave mode, no delay is generated.
CSIHnCTL2	CSIHnPRS[2:0]	Modification of these bits are only permitted while CSIHnCTL0.CSIHnPWR = 0. Setting of the maximum transfer clock frequency is as follows. Master mode: 10.0 MHz (however, it must be equal to or lower than PCLK/8) Slave mode: 4.0 MHz (however, it must be equal to or lower than PCLK/20)
CSIHnSTR0	CSIHnTSF	Writing to this bit is prohibited, and only reading is permitted.
CSIHnSTR0	CSIHnDCE CSIHnPE CSIHnOVE	These bits are initialized when CSIHnCTL0.CSIHnPWR = 0 → 1 or CSIHnCTL0.CSIHnPWR = 1 → 0. Writing to these bits are prohibited, and only reading is permitted.
CSIHnCFGx x = 0 to 5	CSIHnBRSSx[1:0] CSIHnRCBx CSIHnDLx CSIHnDx[2:0] CSIHnHDx[3:0] CSIHnNx[3:0] CSIHnSPx[3:0]	Modification of these bits are only permitted while CSIHnCTL0.CSIHnPWR = 0. These bits must be set to 0 in slave mode.
CSIHnCFGx x = 0 to 5	CSIHnPStx[1:0] CSIHnDLSx[3:0] CSIHnDIRx CSIHnDAPx	Modification of these bits are only permitted while CSIHnCTL0.CSIHnPWR = 0. In slave mode, the CSIHnCFG0 setting is used for the configuration. Therefore, all the bits in CSIHnCFG1 to CSIHnCFG5 must be set to 0.
CSIHnCFGx x = 0 to 5	CSIHnCKPx	Modification of these bits are only permitted while CSIHnCTL0.CSIHnPWR = 0. Set these bits to 0 as CSIHnCTL1.CSIHnCKR must be used in slave mode. If CS is not used, use the CSIHnCTL1.CSIHnCKR bit instead of this bit, and clear these bits to 0.

Table 18.34 Notes on Setting Registers (2/2)

Register Name	Bit Name	Cautions
CSIHnTX0W	CSIHnEOJ	This bit is only valid when CSIHnCTL1.CSIHnJE = 1. While CSIHnCTL1.CSIHnJE = 0, values of this bit is ignored even if 1 is read. Set this bit to 0 in slave mode.
CSIHnTX0W	CSIHnEDL	This bit is only valid when CSIHnCTL1.CSIHnEDLE = 1. While CSIHnCTL1.CSIHnEDLE = 0, the value of this bit is ignored even if 1 is read.
CSIHnTX0W	CSIHnCS[5:0]	In master mode, setting bits 23 to 16 = "FF _H " is prohibited. In slave mode, set these bits to "FE _H ".
CSIHnTX0W CSIHnTX0H		While CSIHnCTL0.CSIHnTXE = CSIHnCTL0.CSIHnRXE = 0, writing to these bits are prohibited in direct access mode.
CSIHnRX0W CSIHnRX0H		These bits are initialized when CSIHnCTL0.CSIHnPWR = 0 → 1 or CSIHnCTL0.CSIHnPWR = 1 → 0.
CSIHnBRSy y = 0 to 3		Modification of these bits is only permitted while CSIHnCTL0.CSIHnPWR = 0. The maximum baud rates are determined in combination with the setting of the CSIHnCTL2.PRS[2:0] bits and are as follows. Master mode: PCLK/8 Slave mode: PCLK/20

Table 18.35 Precautions on Extended Communication Function

Item	Description																																				
Restriction on the use of extended communication function	<p>When the extended communication function (by setting the CSIHnECTL0.CSIHnEEN bit to 1) is enabled, specify the following settings for CSIH:</p> <table border="1"> <thead> <tr> <th>Name of Register Bit</th> <th>Setting</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>CSIHnCTL0.CSIHnMBS</td> <td>1</td> <td>Set the access mode to the direct access mode.</td> </tr> <tr> <td>CSIHnCTL1.CSIHnEDLE</td> <td>* right column</td> <td>Communication data size 8 bits or 16 bits: 0 Communication data size 32 bits: 1</td> </tr> <tr> <td>CSIHnCTL1.CSIHnSLIT</td> <td>1</td> <td>Set the timing of INTCSIHTIC interrupt output during direct access to the timing of transmit data transfer to the shift register.</td> </tr> <tr> <td>CSIHnCTL1.CSIHnSIT</td> <td>0</td> <td>Cancel the delay of half a communication clock cycle in interrupt output.</td> </tr> <tr> <td>CSIHnCTL1.CSIHnJE</td> <td>0</td> <td>Disable the job mode.</td> </tr> <tr> <td>CSIHnCFGx.CSIHnDLSx[3:0] *x: 0 to 5</td> <td>* right column</td> <td>Communication data size 8bit: 8 Communication data size 16bit or 32bit: 0</td> </tr> <tr> <td>CSIHnCFGx.CSIHnDIRx *x: 0 to 5</td> <td>0</td> <td>Fix the serial data direction of CSIH to 0 (MSB). Caution of error occurrence	<p>When using the extended communication function, CSIH cannot determine the data bit of the communication data in which the parity check error and the data consistency check error occur.</p>																																				
Access to the CSIH register during communication using the extended communication function	<p>Continuous access to the CSIH registers is prohibited during CSI communication using the extended communication function.</p>																																				

18.4 Interrupt Sources

CSIH can generate the following interrupt requests:

- INTCSIHTIC (communication status interrupt)
- INTCSIHTIR (reception status interrupt)
- INTCSIHTIRE (communication error interrupt)
- INTCSIHTIJC (job completion interrupt)

18.4.1 Overview

The communication error interrupt INTCSIHTIRE is generated when an error is detected. The generation of the other interrupts depends on the memory mode, the job mode, and – in case of the job completion interrupt INTCSIHTIJC – also the operating mode.

The job completion interrupt INTCSIHTIJC is only generated when job mode is enabled (CSIHnCTL1.CSIHnJE = 1). It is not available in slave mode.

All of the interrupt requests are controlled by the CSIHnEIE register.

To enable each of the interrupt request must be set to 1 each bit of the CSIHnEIE register.

The following table gives an overview.

Table 18.36 Interrupt Generation

Memory Mode	Interrupt	Interrupt Source	
		Job Mode Disabled CSIHnCTL1.CSIHnJE = 0	Job Mode Enabled CSIHnCTL1.CSIHnJE = 1
Direct access	INTCSIHTIC	One data transfer	One data transfer except the state of job abort*1
	INTCSIHTIR	Data received and CSIHnCTL0.CSIHnRXE = 1	Data received and CSIHnCTL0.CSIHnRXE = 1
	INTCSIHTIRE	Error detected	Error detected
	INTCSIHTIJC*2	Not applicable	Job abort*1

Note 1. Job abort condition: CSIHnTX0W.CSIHnEOJ = 1 and CSIHnCTL0.CSIHnJOBE = 1

Note 2. INTCSIHTIJC is not available in slave mode.

18.4.2 Interrupt Delay

In master mode, all interrupts generated by the master can be delayed by half a cycle of the transmission clock, CSIHTSCK. This is not possible in slave mode.

The delay is specified by setting `CSIHnCTL1.CSIHnSIT = 1`. (The setting of the `CSIHnSIT` bit is invalid in slave mode.)

The following example illustrates the interrupt delay function, assuming a setting of `CSIHnCTL1.CSIHnSIT = 1` (interrupt delay enabled), `CSIHnCFGx.CSIHnCKPx = 0`, `CSIHnCFGx.CSIHnDAPx = 0` (clock phase and data phase), and `CSIHnCFGx.CSIHnDLSx[3:0] = 1000B` (data length 8 bits).

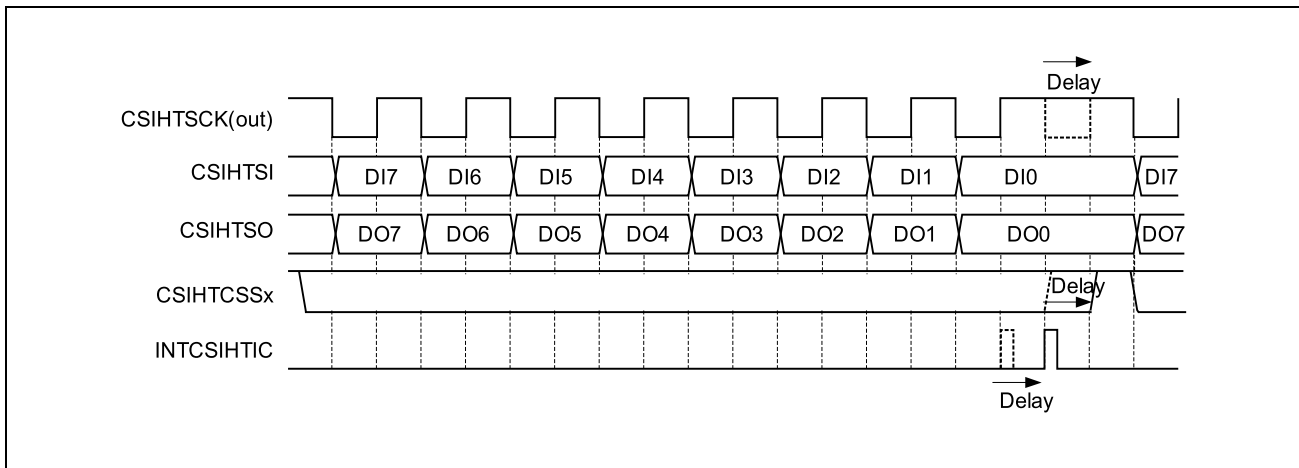

Figure 18.2 Interrupt Delay Function (`CSIHnCTL1.CSIHnSIT = 1`)

Setting `CSIHnCTL1.CSIHnSIT = 1` adds a half cycle delay to the transmission clock. This also delays the end of the present chip select signal (`CSIHTCSSx`).

18.4.3 INTCSIHTIC (Communication Status Interrupt)

Depending on the job mode, this interrupt is generated according to the conditions shown in the following table.

Table 18.37 INTCSIHTIC Interrupt Generation

Memory Mode	Cause of Interrupt	
	Job Mode Disabled CSIHnCTL1.CSIHnJE = 0	Job Mode Enabled CSIHnCTL1.CSIHnJE = 1
Direct access	Generated after every data transfer.	Generated after every data transfer, except when the communication was aborted.

18.4.3.1 INTCSIHTIC in Direct Access Mode

The examples below show the INTCSIHTIC behavior in direct access mode.

The examples assume:

- Master mode
- Direct access mode
- No interrupt delay (CSIHnCTL1.CSIHnSIT = 0)
- Normal clock phase and data phase
(CSIHnCFGx.CSIHnCKPx = 0, CSIHnCFGx.CSIHnDAPx = 0)
- Data length 8 bits (CSIHnCFGx.CSIHnDLSx[3:0] = 1000_B)
- Normal INTCSIHTIC interrupt timing (CSIHnCTL1.CSIHnSLIT = 0)
- Enable the INTCSIHTIC (CSIHnEIE.CSIHnEICE = 1)

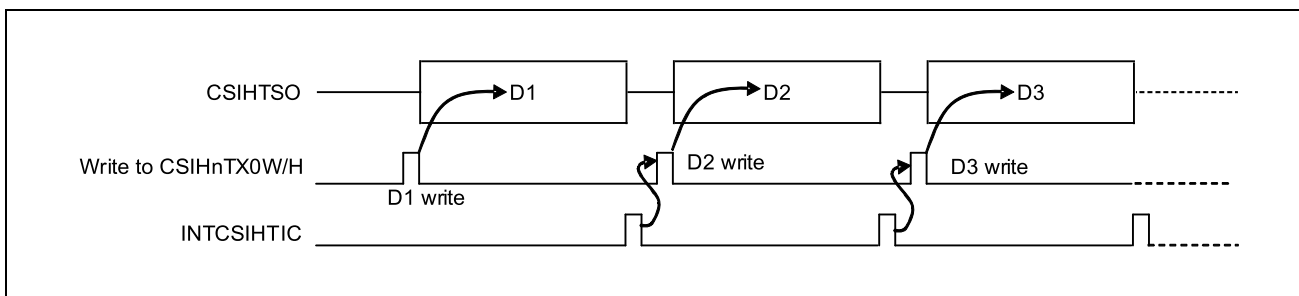

Figure 18.3 Generation of INTCSIHTIC after Transfer (CSIHnCTL1.CSIHnSLIT = 0)

If job mode is enabled (CSIHnCTL1.CSIHnJE = 1) and a job ends because data is sent with CSIHnTX0W.CSIHnEOJ = 1 and communication stop is requested (CSIHnCTL0.CSIHnJOB = 1), then INTCSIHTIC is replaced by the job completion interrupt INTCSIHTIJC.

INTCSIHTIC can also be set up to occur as soon as the CSIHnTX0W/H register becomes empty and available for storing the next data. This is specified by setting CSIHnCTL1.CSIHnSLIT = 1.

The effect is illustrated in the figure below.

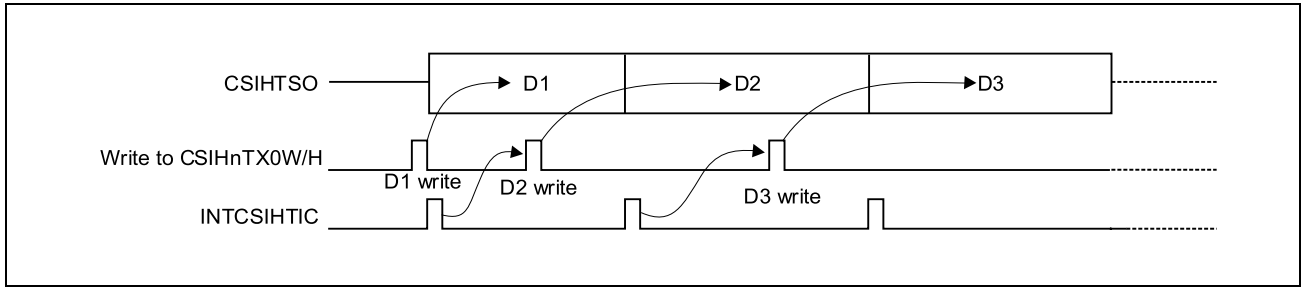

Figure 18.4 Immediate Generation of INTCSIHTIC (CSIHnCTL1.CSIHnSLIT = 1)

Thus, the new data can be written in advance.

NOTE

This mode allows faster data transfer but is only available in direct access mode.

18.4.3.2 INTCSIHTIC in Job Mode

The example below shows the INTCSIHTIC behavior in job mode.

The example assumes:

- Master mode
- Job mode enabled (CSIHnCTL1.CSIHnJE = 1)
- No interrupt delay (CSIHnCTL1.CSIHnSIT = 0)
- Normal clock phase and data phase
(CSIHnCFGx.CSIHnCKPx = 0, CSIHnCFGx.CSIHnDAPx = 0)
- Data length 8 bits (CSIHnCFGx.CSIHnDLSx[3:0] = 1000_B)
- Normal INTCSIHTIC interrupt timing (CSIHnCTL1.CSIHnSLIT = 0)
- Enable the INTCSIHTIC (CSIHnEIE.CSIHnEICE = 1)

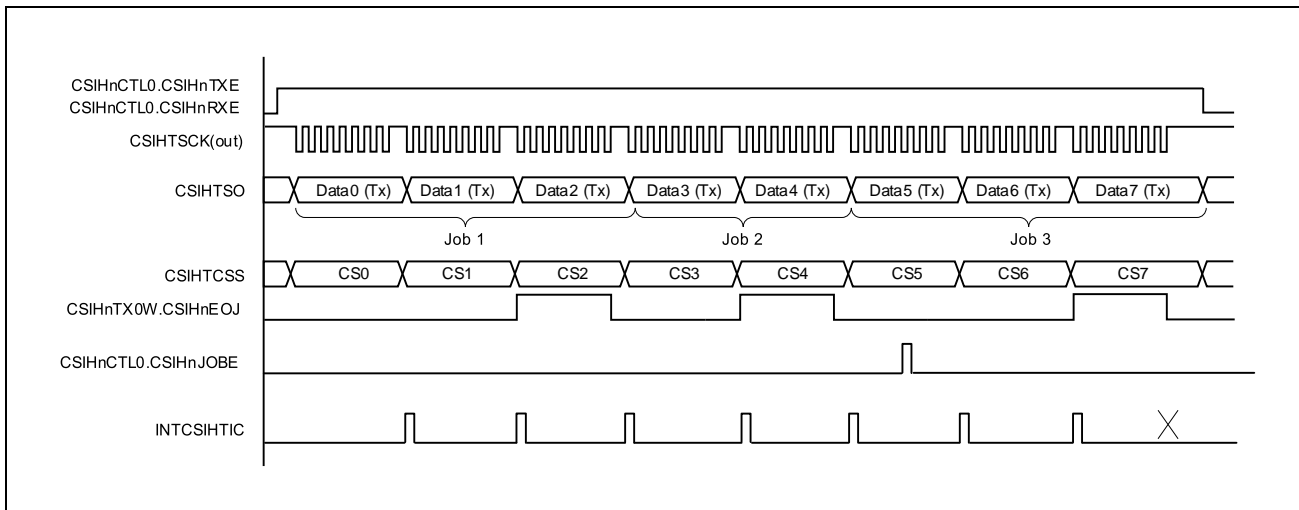

Figure 18.5 Generation of INTCSIHTIC in Job Mode

The rules for generating INTCSIHTIC in job mode are shown in the following table.

Table 18.38 Generation of INTCSIHTIC in Job Mode

CSIHnTX0W.CSIHnEIOJ	INTCSIHTIC
0	Generated
1	CSIHnCTL0.CSIHnJOBE = 0: Generated CSIHnCTL0.CSIHnJOBE = 1: Not generated, replaced by interrupt INTCSIHTIC

18.4.4 INTCSIHTIR (Reception Status Interrupt)

This interrupt is generated according to the conditions below.

Table 18.39 INTCSIHTIR Interrupt Generation

Memory Mode	Cause of Interrupt	
	Job Mode Disabled CSIHnCTL1.CSIHnJE = 0	Job Mode Enabled CSIHnCTL1.CSIHnJE = 1
Direct access	Generated after every data transfer.	

18.4.4.1 INTCSIHTIR in Direct Access Mode

The example below shows the INTCSIHTIR behavior in direct access mode.

The example below assumes:

- Master mode
- Direct access mode
- No interrupt delay (CSIHnCTL1.CSIHnSIT = 0)
- Normal clock phase and data phase
(CSIHnCFGx.CSIHnCKPx = 0, CSIHnCFGx.CSIHnDAPx = 0)
- Data length 8 bits (CSIHnCFGx.CSIHnDLSx[3:0] = 1000_B)
- Enable the INTCSIHTIR (CSIHnEIE.CSIHnEIRE = 1)

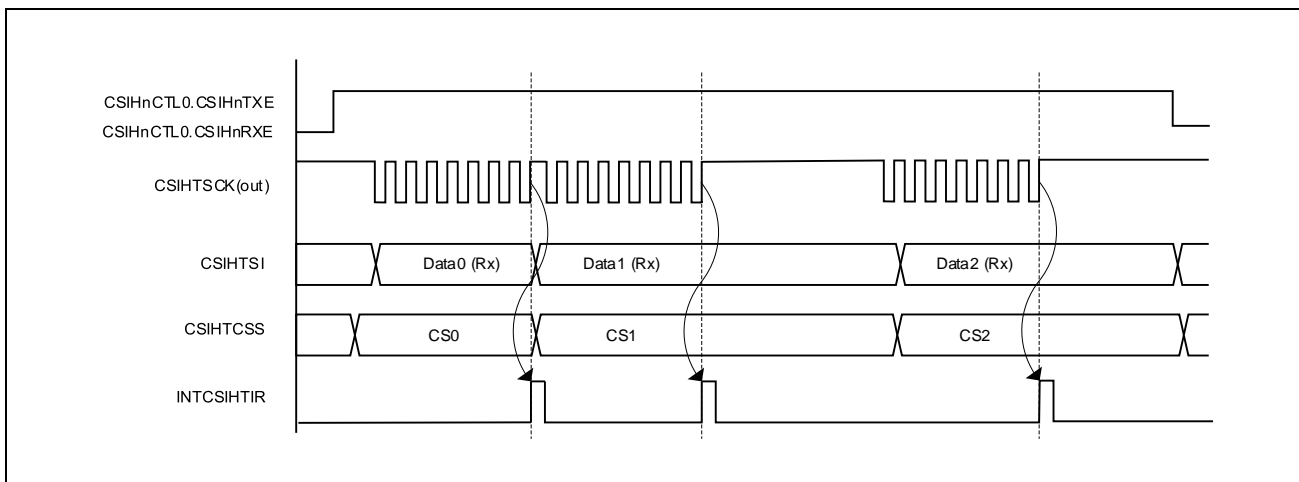

Figure 18.6 Generation of INTCSIHTIR in Direct Access Mode

18.4.5 INTCSIHTIRE (Communication Error Interrupt)

This interrupt is generated whenever an error is detected.

For details about interrupt generation timing, see **Section 18.5.11, Error Detection**.

Table 18.40 Data Error Types

Error Type	Communication Status after Error Interrupt	Note
Parity error	Communication continues even if an interrupt is generated.	—
Data consistency error	Communication continues even if an interrupt is generated.	—
Overrun error	Communication continues even if an interrupt is generated.	This error interrupt is only generated when CSIHnCTL1.CSIHnHSE = 0 (without handshake) in slave mode.

The type of error that caused the generation of INTCSIHTIRE is flagged in register CSIHnSTR0.

Additionally a parity error flag and a data consistency error flag are attached to the received data in CSIHnRX0W.

For details about the various error types, see **Section 18.5.11, Error Detection**.

18.4.6 INTCSIHTIJC (Job Completion Interrupt)

This interrupt supports the handling of jobs. For details, see **Section 18.5.3.3, Job Concept**. This interrupt is only available in master mode.

Job mode is enabled by setting $CSIHnCTL1.CSIHnJE = 1$. When $CSIHnCTL1.CSIHnJE = 0$, INTCSIHTIJC is not generated.

this interrupt is generated according to the condition shown in the following table.

Table 18.41 INTCSIHTIJC Interrupt Generation

Memory Mode	Job Mode Disabled $CSIHnCTL1.CSIHnJE = 0$	Job Mode Enabled $CSIHnCTL1.CSIHnJE = 1$
Direct access	Not applicable	Indicates that the communication stopped at the end of a job after a job abort* ¹ was triggered.

Note 1. Job abort condition: $CSIHnTX0W.CSIHnEOJ = 1$ and $CSIHnCTL0.CSIHnJOBE = 1$

18.5 Operation

18.5.1 Operating Modes (Master/Slave)

Whether CSIH operates in, the master or slave mode determines the source of the serial clock.

18.5.1.1 Master Mode

In master mode, the serial transmission clock is generated by the internal baud rate generator (BRG) and supplied to the slave(s) via CSIHTSCK signal.

Master mode is enabled by setting `CSIHnCTL2.CSIHnPRS[2:0]` to values other than `111B`. In master mode, the BRG frequency can be specified by setting the `CSIHnCTL2.CSIHnPRS[2:0]` bits in combination with the `CSIHnBRSy.CSIHnBRS[11:0]` bits.

(1) Chip select signals

In master mode, one or more chip select signals can be used. If several slaves are connected to the master, the chip select signals can be used to select one or more slaves. Only the selected slave is then enabled for communication.

The communication protocol as well as additional parameters are stored separately for each chip select signal. This makes it possible to adapt the data transfer individually to the requirements of each slave. For details, see **Section 18.5.3, Chip Selection (CS) Features**.

(2) Clock defaults

The default level of CSIHTSCK depends on the clock inversion function bit of the CSIHTSCK, and is high when `CSIHnCTL1.CSIHnCKR = 0` and is low when `CSIHnCTL1.CSIHnCKR = 1`.

The example below shows the communication in master mode for 8-bit data, `CSIHnCTL1.CSIHnCKR = 0`, `CSIHnCFGx.CSIHnCKPx = 0`, `CSIHnCFGx.CSIHnDAPx = 0`, and MSB first.

Figure 18.7 Transmission/Reception in Master Mode

18.5.1.2 Slave Mode

In slave mode, another device is the communication master and supplies the transmission clock. Normal transmit/receive operation is started as soon as a clock signal is detected.

Slave mode is selected by setting the CSIHnCTL2.CSIHnPRS[2:0] bits to 111_B.

In slave mode, the transmission protocol setting by the CSIHnCFG0 registers are enabled (setting of the CSIHnCFG1-CSIHnCFG7 register is disabled).

- CSIHnPSx[1:0]: parity usage
- CSIHnDLsx[3:0]: data length selection
- CSIHnDIRx: data direction
- CSIHnCKPx, CSIHnDAPx: clock phase and data phase

NOTE

When using slave mode, disable the baud rate generator (BRG) by setting the CSIHnBRSy.CSIHnBRS[11:0] bits to 000_H.

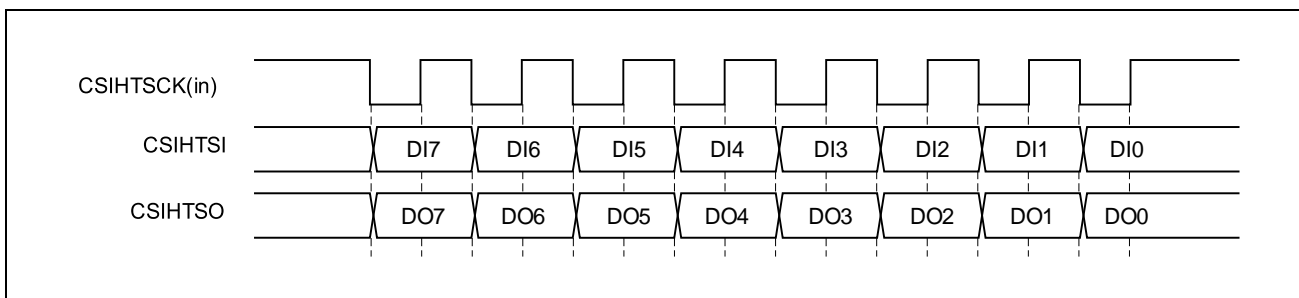

Figure 18.8 Transmission/Reception in Slave Mode

18.5.2 Master/Slave Connections

18.5.2.1 One Master and One Slave

The following figure illustrates the connections between one master and one slave.

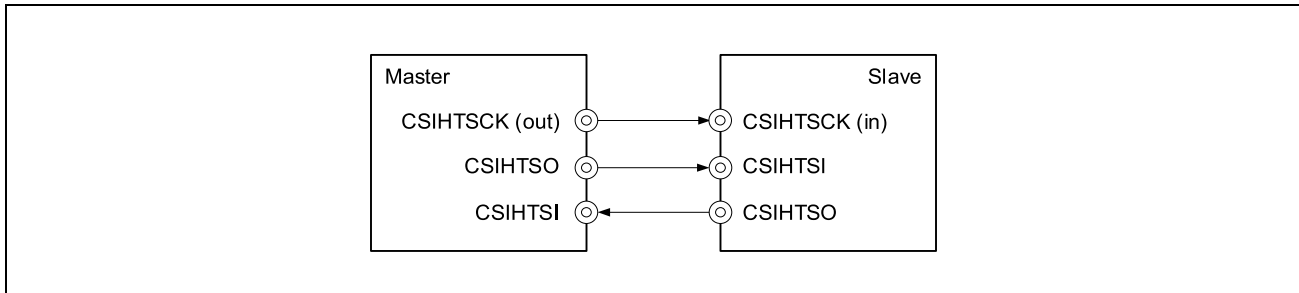

Figure 18.9 Direct Master/Slave Connection

18.5.2.2 One Master and Multiple Slaves

The following figure illustrates the connections between one master and multiple slaves. In this example, the master supplies one chip select (CS) signal to each of the slaves. This signal is connected to the slave select input $\overline{\text{CSIH TSSI}}$ of the slave.

The $\overline{\text{CSIH TSSI}}$ signal can be enabled/disabled by using the $\text{CSIHnCTL1.CSIHnSSE}$ bit.

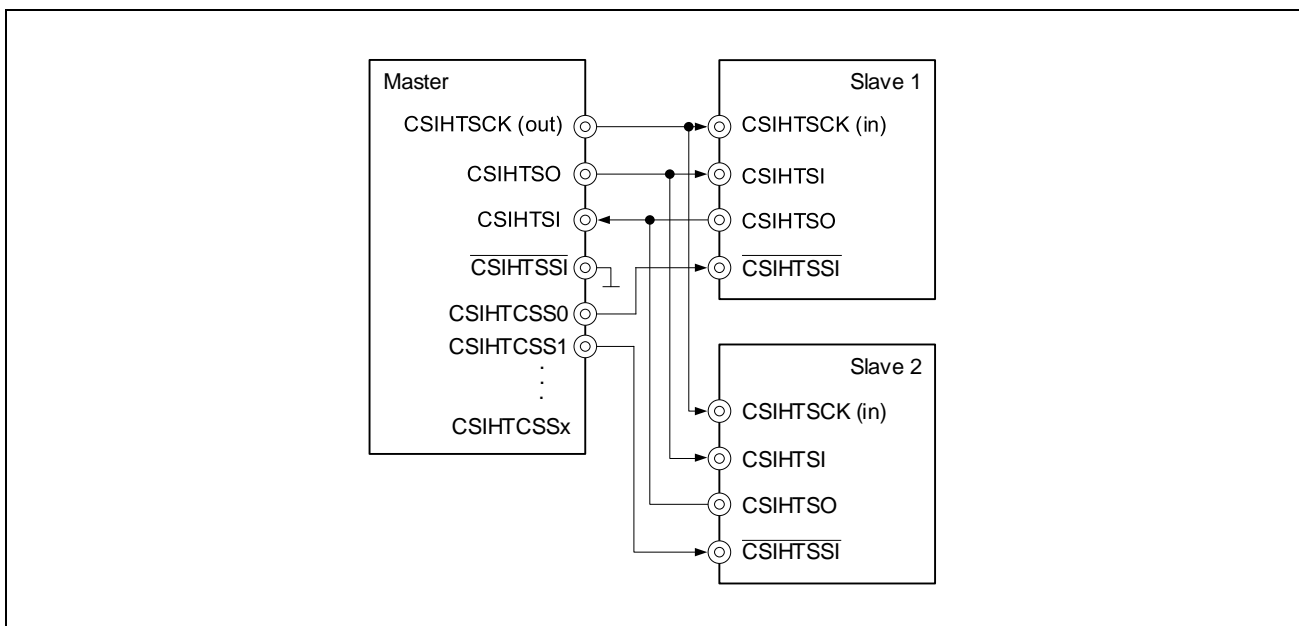

Figure 18.10 Connections between One Master and Multiple Slaves

By default, the chip select level is active low. That means, a slave is selected (enabled) as a CSIH slave when its $\overline{\text{CSIH TSSI}}$ signal is low level. However, to adapt the CS to other devices, the output level of each chip select signal can also be programmed to be active high.

If a slave is not selected, it will neither receive nor transmit data. In addition, when transmit-only mode or transmit/receive mode is set ($\text{CSIHnCTL0.CSIHnTXE} = 1$), the CSIH TSO output of the slaves that are not selected is disabled and set to input mode in order to avoid interference with the output of the selected slave.

18.5.3 Chip Selection (CS) Features

The chip select signal, CSIHnCSSx can be used by the master to select one or more slaves for communication.

18.5.3.1 Configuration Registers

The parameters for each chip select signal CSIHnCSSx are defined in the corresponding configuration register CSIHnCFGx. The parameters include the communication protocol and additional CS parameters.

The communication protocol specifies:

- Data length: The number of bits to be sent or received.
(CSIHnCFGx.CSIHnDLSx[3:0])
- Transfer direction: MSB or LSB first.
(CSIHnCFGx.CSIHnDIRx)
- Parity usage: Odd, even, 0 parity or none.
(CSIHnCFGx.CSIHnPSx[1:0])
- Clock phase and data phase.
(CSIHnCFGx.CSIHnCKPx, CSIHnCFGx.CSIHnDAPx)

Additional parameters for each chip select signal that are only available in master mode are:

- Individual selection of the baud rate generator prescaler for each chip select signal
(CSIHnCFGx.CSIHnBRSSx[1:0])
- Chip select priority: Categorizes chip select signals into “dominant” and “recessive”. The priority applies if two or more chip select signals with different configurations are simultaneously activated for message broadcasting. In this case, the configuration specified for dominant chip select signals is used. (CSIHnCFGx.CSIHnRCBx)

The principle is also called “Recessive Configuration for Broadcasting” (RCB).

CAUTION

When specifying multiple chip select signals as dominant, be sure to configure the same settings for all dominant signals.

- Chip select timing:
 - Setup time Tsetup: The time from when the CS signal becomes active to the start of data output.
(CSIHnCFGx.CSIHnSPx[3:0])
 - Inter-data time Tinter: The time between one data and the next data while the same CS signal is active.
(CSIHnCFGx.CSIHnINx[3:0])
 - Hold time Thold: The time during which the CS signal remains active until CS is switched.
(CSIHnCFGx.CSIHnHDx [3:0])
 - Idle time Tidle: Inactive time after terminating a CS signal or after every data transfer to the same CSx.
(CSIHnCFGx.CSIHnIDx[2:0])

The CS timings of the setup time, the inter-data time, the hold time, and the idle time are illustrated in the figure below. When CSIHnCFGx.CSIHnIDLx bit is set to 1, IDLE time is inserted for every transfer regardless of CS signal.

Figure 18.11 provides an example of when the default active low setting is specified for the CSIHnCSS1 and CSIHnCSS2 signals (CSIHnCTL1.CSIHnCSL1 bit = 0, CSIHnCTL1.CSIHnCSL2 bit = 0). The active level can be specified individually for each CS.

Figure 18.11 Chip Select Timings

Note that each CS signal can have a different value for the setup time, inter-data time, hold time, and idle time.

A particular chip select signal is activated by setting the appropriate bit in the transmission register CSIHnTX0W.CSIHnCSx.

CSIHnRX0W.CSIHnCSx in the reception register indicates the chip select signal associated with the received data.

18.5.3.2 CS Example

The following figure shows an example of two consecutive data transmissions.

The first communication uses CS0 to communicate with one slave. The second enables CS0 and CS1 to broadcast a message to two slaves. The priority of CS0 is set to “recessive: low priority” and the priority of CS1 to “dominant: high priority”. Consequently, the second communication is conducted using the CS1 settings, which are set as dominant.

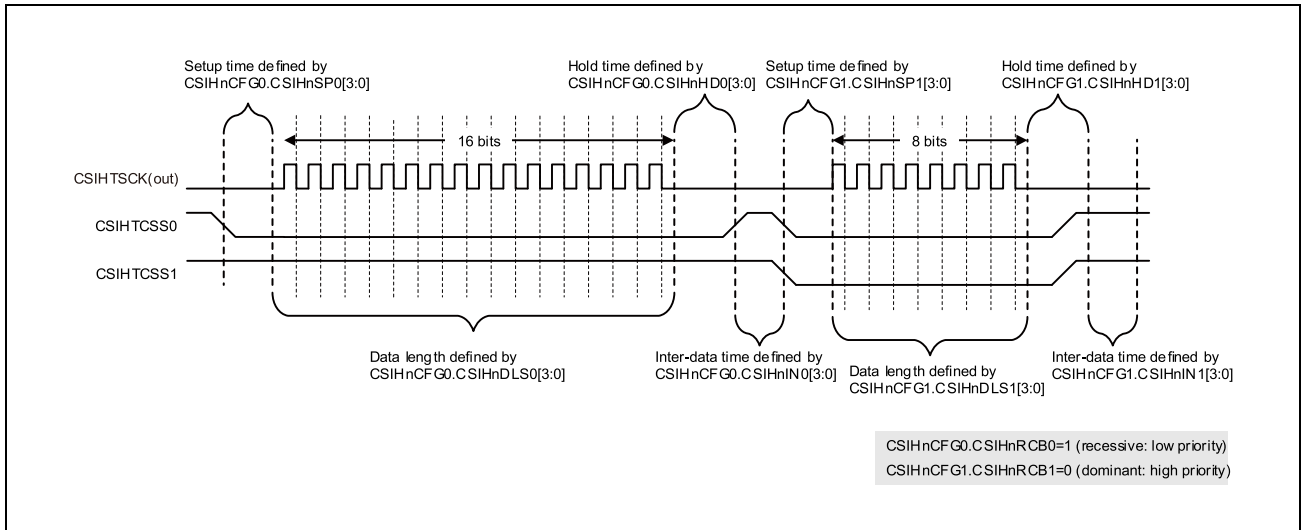

Figure 18.12 Chip Select and RCB Example

18.5.3.3 Job Concept

In CSIH, a job consists of the number of data targeted for transfer.

Job Mode Enable

The job mode can only be enabled in master mode. The job mode is enabled and disabled by CSIHnCTL1.CSIHnJE, while the CSIH is disabled by CSIHnCTL0.CSIHnPWR = 0.

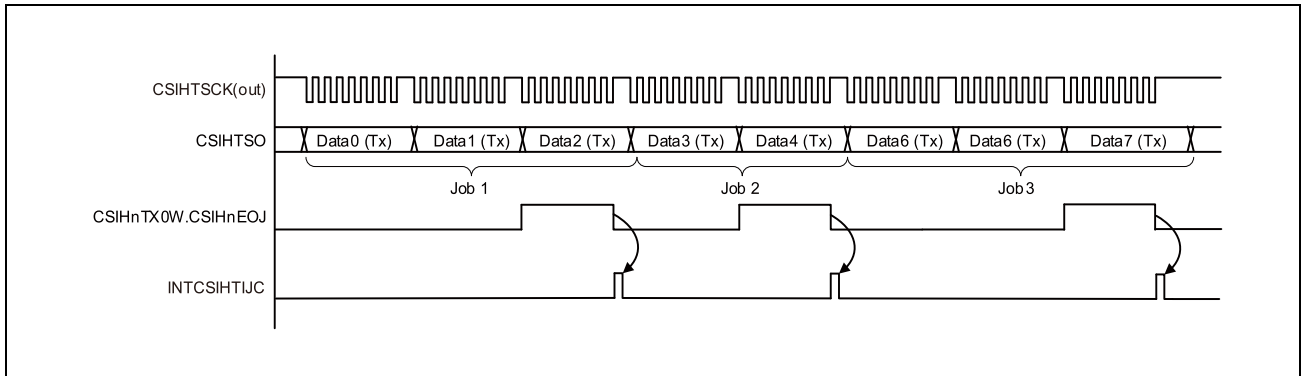

Figure 18.13 Job Examples

A job ends by transmitting data with CSIHnTX0W.CSIHnEOJ = 1.

Communication can be specified to stop when a job is finished. This is done by setting CSIHnCTL0.CSIHnJOB. When CSIHnJOB is set, the communication continues until the data for which the CSIHnEOJ bit is set is transmitted. After this data is sent, the communication is stopped and the job completion interrupt INTCSIHnIJC is generated.

18.5.4 Details of Chip Select Timing

18.5.4.1 Changing the Clock Phase

The serial clock level specified by `CSIHnCFGx.CSIHnCKPx` can be changed while communication is stopped. The minimum value of an idle time is one transmission clock (`CSIHTSCK(out)`) cycle.

If the idle time is set to 0.5 transmission clock cycles (in `CSIHnCFGx.CSIHnIDx[2:0]`) and two consecutive data is sent with different `CSIHnCFGx.CSIHnCKPx` configuration, the idle time is automatically extended to one `CSIHTSCK(out)` cycle.

Figure 18.14 Clock Phase Timing with $PCLK/8$, $T_{hold0} = T_{setup1} = 0.5CSIHTSCK$, $T_{idle0} = 0.5CSIHTSCK$, `CSIHnCFG0.CSIHnCKP0 = 0 (CSIHTCSS0) → CSIHnCFG1.CSIHnCKP1 = 1 (CSIHTCSS1)`

Figure 18.15 Clock Phase Timing with $PCLK/8$, $T_{hold0} = T_{setup1} = 0.5CSIHTSCK$, $T_{idle0} = 1CSIHTSCK$, `CSIHnCFG0.CSIHnCKP0 = 0 (CSIHTCSS0) → CSIHnCFG1.CSIHnCKP1 = 1 (CSIHTCSS1)`

Figure 18.16 Clock Phase Timing with $PCLK/8$, $T_{hold0} = T_{setup1} = 0.5CSIHTSCK$, $T_{idle0} = 0.5CSIHTSCK$, $CSIHnCFG0.CSIHnCKP0 = 0$ (CSIHTCSS0) → $CSIHnCFG2.CSIHnCKP2 = 0$ (CSIHTCSS2)

18.5.4.2 Changing the Data Phase

The CSIHnCFGx.CSIHnDAPx bit defines the phase of the data bits relative to the clock.

The relation between the setting of the CSIHnCFGx.CSIHnDAPx bit and the hold and setup periods is as follows:

Hold time is the period from the last edge of the serial clock (CSIHTSCK) until the signals on CSIHTCSS[5:0] change to the inactive level.

Setup time is the period from when the signals on CSIHTCSS[5:0] change to the active level to when the transmission data (CSIHTSO) is output.

Therefore, there is a gap of 0.5 CSIHTSCK cycles until the edge of the serial clock signal (CSIHTSCK) is output according to the CSIHnCFGx.CSIHnDAPx setting.

Figure 18.17 Data Phase Timing with CSIHnCFG1.CSIHnCKP1 = 0, CSIHnCFG1.CSIHnDAP1 = 0 and CSIHnCFG2.CSIHnCKP2 = 0, CSIHnCFG2.CSIHnDAP2 = 0

Figure 18.18 Data Phase Timing with CSIHnCFG1.CSIHnCKP1 = 1, CSIHnCFG1.CSIHnDAP1 = 0 and CSIHnCFG2.CSIHnCKP2 = 0, CSIHnCFG2.CSIHnDAP2 = 1

18.5.5 Transmission Clock Selection

In master mode, the transfer clock frequency is selectable using the following bits:

- CSIHnCTL2.CSIHnPRS[2:0]
- CSIHnBRSy.CSIHnBRS[11:0]
- CSIHnCFGx.CSIHnBRSSx[1:0]

The transfer clock frequency of transmission clock CSIHTSCK is determined by the setting of the CSIHnCTL2.CSIHnPRS[2:0] bits and the setting of the CSIHnBRSy.CSIHnBRS[11:0] bits, but any one of CSIHnBRS3 to CSIHnBRS0 can be selected for each chip select signal by using the CSIHnCFGx.CSIHnBRSSx[1:0] bits.

The following figure shows a block diagram of the baud rate generator.

Figure 18.19 Baud Rate Generator Block Diagram

By setting CSIHnBRSy.CSIHnBRS[11:0] to 000_H, the baud rate generator is disabled and all CSIHTSCK are stopped.

18.5.5.1 Transfer Clock Frequency Calculation

The transfer clock frequency in master mode is calculated as:

$$\text{Transfer clock frequency (CSIHTSCK)} = \text{PCLK} / (\text{division ratio of PCLK}) = \text{PCLK} / (2^\alpha \times k \times 2),$$

where:

$$\alpha = \text{CSIHnCTL2.CSIHnPRS}[2:0] = 0 \text{ to } 6$$

$$k = \text{CSIHnBRS0.CSIHnBRS}[11:0] = 1 \text{ to } 4095 \text{ (when CSIHnCFGx.CSIHnBRSSx}[1:0] = 00_{\text{B}})$$

$$\text{CSIHnBRS1.CSIHnBRS}[11:0] = 1 \text{ to } 4095 \text{ (when CSIHnCFGx.CSIHnBRSSx}[1:0] = 01_{\text{B}})$$

$$\text{CSIHnBRS2.CSIHnBRS}[11:0] = 1 \text{ to } 4095 \text{ (when CSIHnCFGx.CSIHnBRSSx}[1:0] = 10_{\text{B}})$$

$$\text{CSIHnBRS3.CSIHnBRS}[11:0] = 1 \text{ to } 4095 \text{ (when CSIHnCFGx.CSIHnBRSSx}[1:0] = 11_{\text{B}})$$

18.5.5.2 Transfer Clock Frequency Upper and Lower Limits

When setting the transfer clock frequency, please note the following.

- The minimum transfer clock frequency in master mode and slave mode is PCLK/524160.
- The maximum transfer clock frequency is as follows:
 - In master mode: 10.0 MHz (however, it must be up to PCLK/8)
 - In slave mode: 4.0 MHz (however, it must be up to PCLK/20)

18.5.6 Data Transfer Modes

18.5.6.1 Transmit-Only Mode

Setting CSIHnCTL0.CSIHnTXE = 1 and CSIHnCTL0.CSIHnRXE = 0 puts the CSIH in transmit-only mode.

- In case of direct access mode, transmission starts when transmit data is written to the CSIHnTX0W or CSIHnTX0H register.

18.5.6.2 Receive-Only Mode

Setting CSIHnCTL0.CSIHnTXE = 0 and CSIHnCTL0.CSIHnRXE = 1 puts the CSIH in receive-only mode.

- In case of direct access mode, reception starts when dummy data is written to the CSIHnTX0W or CSIHnTX0H register.

In slave mode, reception starts as soon as the CSIHTSCK transmission clock is received from the master. It is not necessary to write data to the CSIHnTX0W or CSIHnTX0H register of the slave.

18.5.6.3 Transmit/Receive Mode

Setting CSIHnCTL0.CSIHnTXE = 1 and CSIHnCTL0.CSIHnRXE = 1 puts the CSIH in transmit/receive mode.

- In case of direct access mode, communication starts when transmit data is written to the CSIHnTX0W or CSIHnTX0H register.

18.5.6.4 Summary

The following table summarizes this section. It shows how data transfer is started in the various memory, operating, and transfer modes.

Table 18.42 Start of Data Transfer

Operating Mode		Transfer Mode	
		Transmit-Only Transmit/Receive	Receive-Only
Direct access	Master	Writing to the CSIHnTX0W register or the CSIHnTX0H register	Writing to the CSIHnTX0W register or the CSIHnTX0H register
	Slave	Clock reception from master	Incoming clock from master

18.5.7 Data Length Selection

18.5.7.1 Data Length from 2 to 16 Bits

The length of a data packet is selectable for each chip select signal from 2 to 16 bits using $\text{CSIHnCFGx.CSIHnDLSx}[3:0]$. The examples below show the communication with MSB first ($\text{CSIHnCFGx.CSIHnDIRx} = 0$).

Data length = 16 bits ($\text{CSIHnCFGx.CSIHnDLSx}[3:0] = 0000_{\text{B}}$):

Figure 18.20 16 Bit Data Length, MSB First

Data length = 14 bits ($\text{CSIHnCFGx.CSIHnDLSx}[3:0] = 1110_{\text{B}}$):

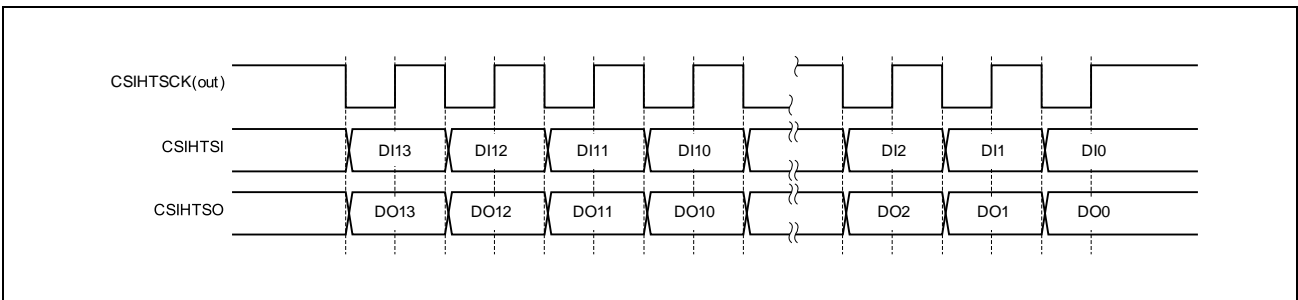

Figure 18.21 14 Bit Data Length, MSB First

18.5.7.2 Data Length Greater than 16 Bits

If the data to be sent/received exceeds 16 bits, the extended data length (EDL) function can be used.

EDL function is enabled by setting the `CSIHnCTL1.CSIHnEDLE` bit to 1.

EDL function works as follows:

- The data has to be broken into 16-bit blocks plus remainder. For example, data of 42 bits would be broken into two 16-bit blocks plus 10 bits.
- The bit length of the remainder is set as “data length” in `CSIHnCFGx.CSIHnDLSx[3:0]`.
- For transmitting the 16-bit blocks, `CSIHnTX0W.CSIHnEDL` must be set to 1. In this case, the data written to `CSIHnTX0W` is sent as a 16-bit data length regardless of the `CSIHnCFGx.CSIHnDLSx[3:0]` bit setting.
- The transfer is complete after a block with the specified data length (the remainder of data specified with `CSIHnTX0W.CSIHnEDL = 0`) has been sent.

Example

Example of transmitting 40-bit data (123456789A_H) to CS0:

40 bits are split into two blocks of 16-bit blocks and 8 bits.

- Initialize to `CSIHnCFG0.CSIHnDLS0[3:0] = 8`.
- To transmit 123456789A_H with MSB first, write the following sequence to `CSIHnTX0W`:
 - 20FE 1234_H (`CSIHnTX0W.CSIHnEDL = 1`)
 - 20FE 5678_H (`CSIHnTX0W.CSIHnEDL = 1`)
 - 00FE 009A_H (`CSIHnTX0W.CSIHnEDL = 0`)

The following figure illustrates the timing.

Figure 18.22 EDL Timing Diagram

NOTES

1. 1-bit data length is allowed only when using the EDL mode.
 2. If parity is enabled, the parity bit is added after the last bit.
 3. When data is sent using extended data length (EDL) function, use the same chip select signal.
 4. Example for configuring the data direction:
 - Data to be sent: 123456_H
 - MSB first:
 - Set CSIHnCFGx.CSIHnDIRx = 0
 - Write CSIHnTX0W = 20FE 1234_H (EDL bit = 1)
 - Write CSIHnTX0W = 00FE 0056_H (EDL bit = 0)
 - LSB first:
 - Set CSIHnCFGx.CSIHnDIRx = 1
 - Write CSIHnTX0W = 20FE 3456_H (EDL bit = 1)
 - Write CSIHnTX0W = 00FE 0012_H (EDL bit = 0)
 5. Operation is not guaranteed if CSIHnTX0W.CSIHnEOJ and CSIHnTX0W.CSIHnEDL are simultaneously set to "1" while CSIHnCTL1.CSIHnJE = 1 and CSIHnCTL1.CSIHnEDLE = 1.
 6. EDL mode cannot be used in receive-only mode of slave mode.
(CSIHnCTL2.CSIHnPRS[2:0] = 111_B, CSIHnCTL0.CSIHnTXE = 0, CSIHnCTL0.CSIHnRXE = 1)
-

18.5.8 Serial Data Direction Selection

The serial data direction is selectable for each chip select signal using the CSIHnDIRx bit in the CSIHnCFGx register.

The examples below show communication for a data length of 8 bits (CSIHnCFGx.CSIHnDLSx[3:0] = 1000_B).

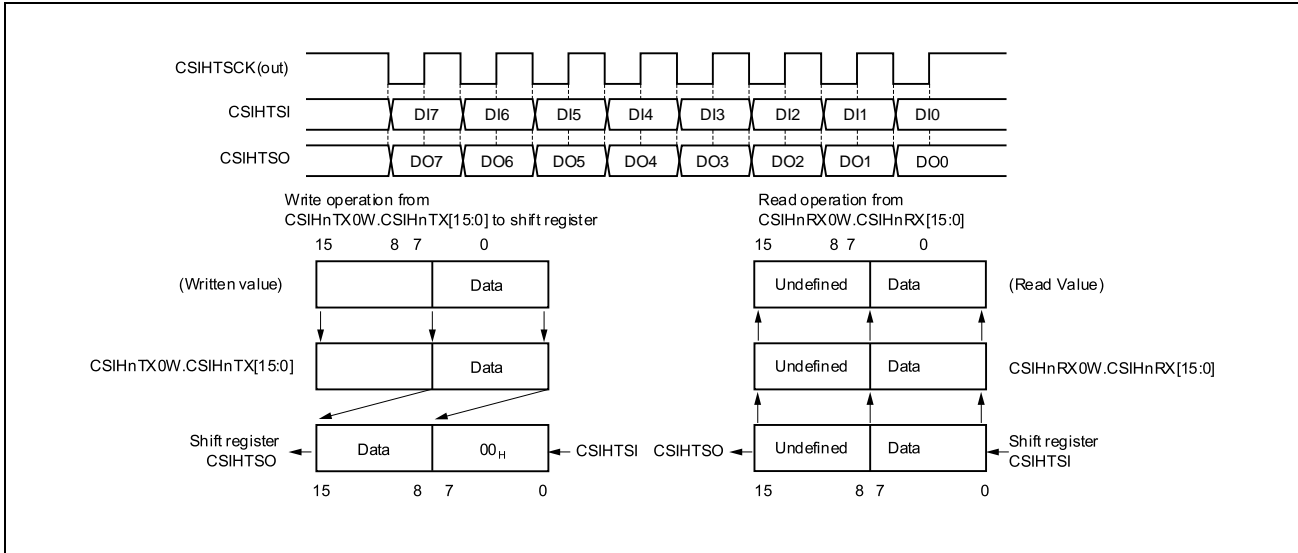

Figure 18.23 Serial Data Direction Select Function - MSB First (CSIHnDIRx = 0)

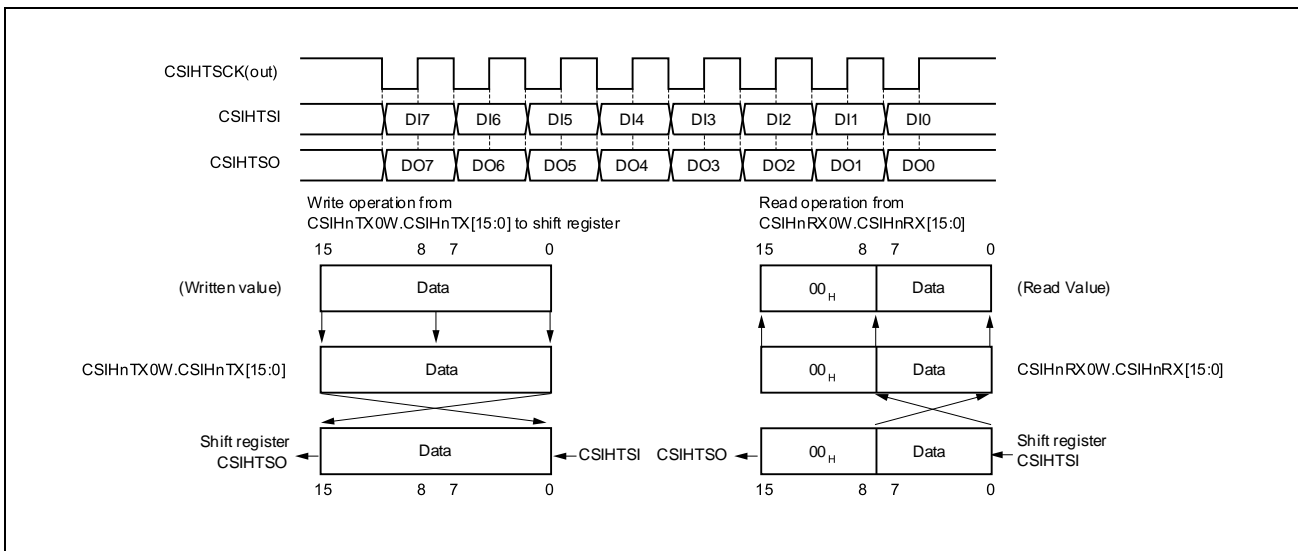

Figure 18.24 Serial Data Direction Select Function - LSB First (CSIHnDIRx = 1)

18.5.9 Slave Select (SS) Function

The Slave Select (SS) function enables communication between one master and multiple slaves.

In master mode, the master device outputs the slave select signal ($\overline{\text{CSIHTCSSx}}$) to a slave. Communication by a device in slave mode is enabled when the slave input select signal ($\overline{\text{CSIHTSSI}}$) is at the low level.

See the **Section 18.5.2, Master/Slave Connections**, for examples of connections using the SS function.

18.5.9.1 Communication Timing Using SS Function

The following figure illustrates the communication signal and timings using the SS function.

In slave mode, the data transfer configuration is determined by the CSIHnCFG0 register.

Figure 18.25 Transmission/Reception Timing of Communication Using SS Function

- (1) CSIH enters slave mode by setting $\text{CSIHnCTL2.CSIHnPRS}[2:0] = 111_{\text{B}}$. $\text{CSIHnCFG0.CSIHnCKP0}$ and $\text{CSIHnCFG0.CSIHnDAP0}$ are 0.
- (2) The data length is 8 bits ($\text{CSIHnCFG0.CSIHnDLS0}[3:0] = 1000_{\text{B}}$). The data direction is MSB first ($\text{CSIHnCFG0.CSIHnDIR0} = 0$).
- (3) The transmit/receive mode is set ($\text{CSIHnCTL0.CSIHnTXE} = 1$, $\text{CSIHnCTL0.CSIHnRXE} = 1$, and $\text{CSIHnCTL0.CSIHnPWR} = 1$). Communication start is permitted.
- (4) The transfer status flag $\text{CSIHnSTR0.CSIHnTSF}$ is automatically set when transfer data is written to the CSIHnTX0W or CSIHnTX0H transmission register during direct access mode.
- (5) As long as signal $\overline{\text{CSIHTSSI}}$ is at the high level, transmission/reception is not started, even if an external transmission clock CSIHTSCK is input. Input to CSIHTSI is ignored.
- (6) $\overline{\text{CSIHTSSI}}$ falling to low level indicates that CSIHTSO is enabled and ready for transmission.
- (7) As soon as the external clock signal CSIHTSCK is detected, the slave transmits data to CSIHTSO and simultaneously captures data from CSIHTSI .
- (8) Interrupt INTCSIHTIR indicates that the reception is complete. The CSIHnRX0W/H register can be read.

18.5.9.2 CSIHTSSO Operation

CSIHnPWR	CSIHnTXE	CSIHnRXE	CSIHnSSE	CSIHTSSO
0	—	—	—	H
1	—	—	0	H
	0		1	H
	1		1	Reversed value of $\overline{\text{CSIHTSSI}}$ level

The CSIHTSSO pin is a signal to control the I/O function of the chip's SO pin when using the SS function.

The CSIHTSO pin is enabled when the CSIHTSSO pin is "High" (the chip's SO pin is being driven).

The CSIHTSO pin is disabled when the CSIHTSSO pin is "Low" (the chip's SO pin is not being driven).

Figure 18.26 Operation of CSIHTSSO

CAUTION

If $\overline{\text{CSIHTSSI}}$ pin is changed during communication (CSIHnSTR0.CSIHnTSF = 1), current communication is not guaranteed.

18.5.10 Handshake Function

CSIH features a handshake function to synchronize the master and the slave devices. This function can be enabled/disabled by the CSIHnCTL1.CSIHnHSE bit. For handshake, the signals CSIHTRYI and CSIHTRYO are used. The busy timing depends on the data phase selection bit CSIHnCFGx.CSIHnDAPx.

18.5.10.1 Slave Mode

If CSIHnCTL1.CSIHnHSE = 1, a low-level CSIHTRYO signal is output when the slave becomes busy. This can happen in two cases:

1. When the next data to be sent is not ready:

When the slave is in transmit-only mode or transmit/receive mode (CSIHnCTL0.CSIHnTXE = 1) and is in the states listed below, the CSIHTRYO outputs the busy state (low level).

Table 18.43 Memory Mode and Slave Transfer State

Memory Mode	Slave Transfer State
Direct access mode	When there is no more data to be sent

2. When receive register is full:

When slave is set in receive-only mode or transmit/receive mode (CSIHnCTL0.CSIHnRXE = 1), and new data cannot be copied from a shift register to CSIHnRX0W/H because the previously received data is still in the CSIHnRX0W/H register (CSIHnRX0W/H is full).

When CSIHnCTL0.CSIHnRXE is 1 and is in any of the following states, CSIHTRYO outputs busy state (low level).

Table 18.44 Memory Mode and Slave Reception State

Memory Mode	Slave Reception State
Direct access mode	When CSIHnRX0W or CSIHnRX0H is full

The following examples assume an eight-bit data length.

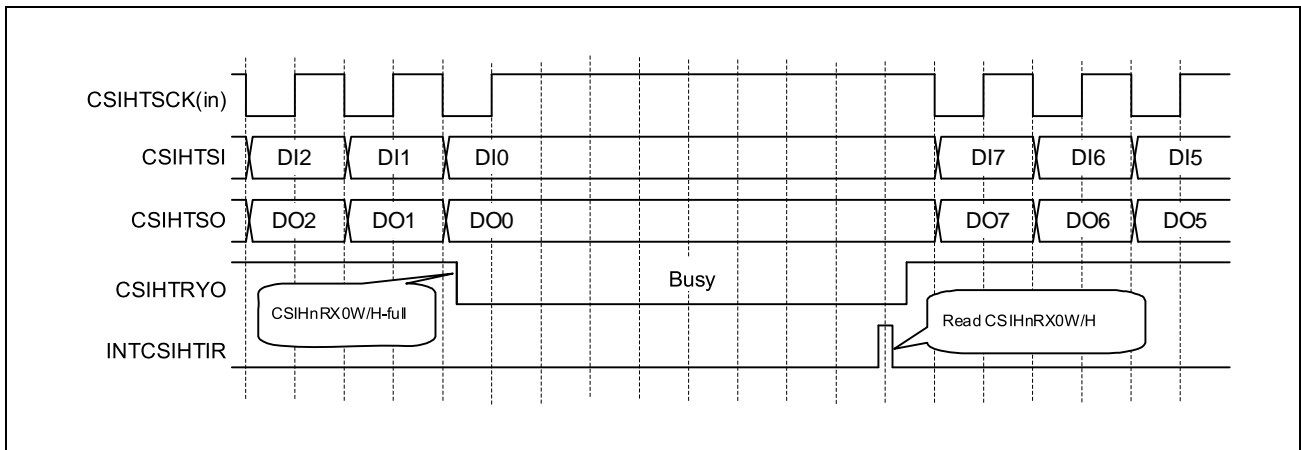

Figure 18.27 Busy Signal from the Slave (Direct Access Mode; CSIHnCFGx.CSIHnDAPx = 0)

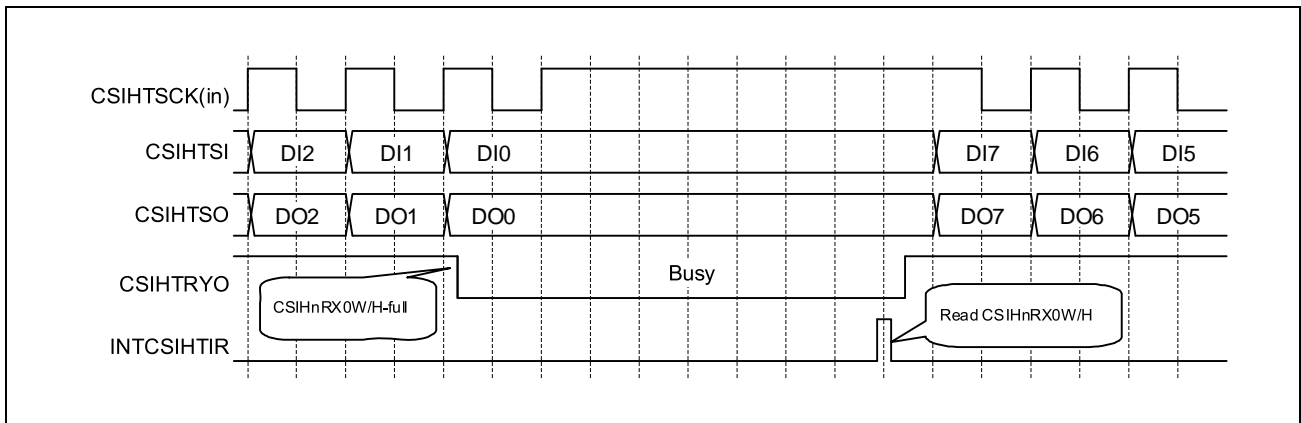

Figure 18.28 Busy Signal from the Slave (Direct Access Mode; CSIHnCFGx.CSIHnDAPx = 1)

18.5.10.2 Master Mode

When the master detects $CSIHTRYI = 0$ while $CSIHnCTL1.CSIHnHSE = 1$, the subsequent transfers are put on hold, and the master goes into wait status. It suspends the $CSIHTSCK$ clock.

The $CSIHTRYI$ level is checked at each half clock cycle of $CSIHTSCK$.

Figure 18.29 Master's Reaction to $CSIHTRYI$ ($CSIHnCFGx.CSIHnDAPx = 0$)

The $CSIHTRYI$ signal must be pulled down by the slave before the next transfer starts. If this is done while data transfer is in progress, the serial clock from the master is suspended after the transfer is complete.

The master resumes the communication as soon as $CSIHTRYI$ becomes high (the slave is "ready").

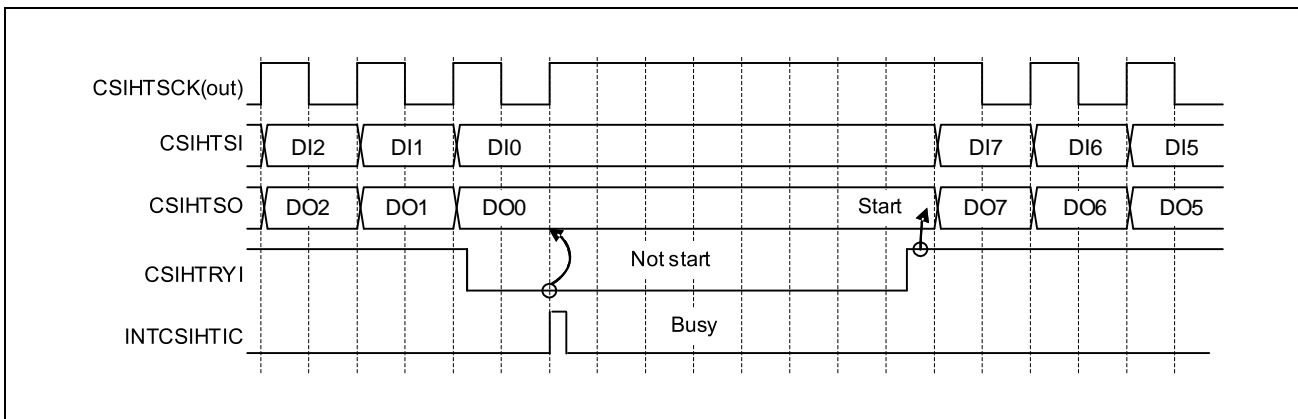

Figure 18.30 Master's Reaction on $CSIHTRYI$ ($CSIHnCFGx.CSIHnDAPx = 1$)

CAUTIONS

1. If multiple slaves are connected, the master must only detect the $CSIHTRYI$ signal of the slave it has selected for communication.
2. Even when the $CSIHTRYI$ pin of the master detects a $CSIHTRYO$ signal from the slave during data transfer, the communication is not put on hold but continues until the data transfer is completed.

18.5.11 Error Detection

CSIH can detect five error types:

- Data consistency error (transmission data)
- Parity error (received data)
- Overrun error (received data)

Check for parity, data consistency can be enabled/disabled individually.

If any of these errors is detected, the interrupt request INTCSIHTIRE is generated and the corresponding flags are set.

18.5.11.1 Data Consistency Check

The purpose of the data consistency check is to ensure that the data physically sent as output signal is identical to the original data that was copied to the shift register.

The data consistency check can be enabled/disabled by the CSIHnCTL1.CSIHnDCS bit (when checking data consistency, make sure that PIPn.PIPn_m = 1 and PIBn.PIBn_m = 0). It will not be enabled if data transmission is disabled (CSIHnCTL0.CSIHTXE = 0).

When the data consistency check is active, the data transferred from CSIHnTX0W or CSIHnTX0H to the shift register is copied to a separate register. In addition, the physical levels of CSIHnTX0 are read back via the CSIHnTX0DCS signal into the corresponding shift register.

After completion of the transmission, the sent data is compared with the original transmission data.

Mismatch is considered as a data consistency error and:

- Interrupt INTCSIHTIRE is generated.
- The CSIHnSTR0.CSIHTDCE bit is set.

Additionally, CSIHnRX0W.CSIHTDCE of data that contains the error is set.

The data consistency check function is illustrated in the following block diagram.

Figure 18.31 Block Diagram of Data Consistency Check Function

18.5.11.2 Parity Check

CSIH can append a parity bit to the last data bit (even if extended data length is used).

The use and type of parity is specified in `CSIHnCFGx.CSIHnPSx[1:0]`.

Parity check is enabled if `CSIHnCFGx.CSIHnPSx[1] = 1`.

The parity bit is checked after a reception is complete. If a parity error occurs, the following happen::

- Interrupt `INTCSIHTIRE` is generated.
- The `CSIHnSTR0.CSIHnPE` bit is set.

Additionally, `CSIHnRX0W.CSIHnRPE` of data that contains the error is set.

The figure below shows an example.

- Data length is 8 bits.
- The data to be transmitted is `05H` and `35H`.
- Data direction is LSB first.
- Parity type is odd.

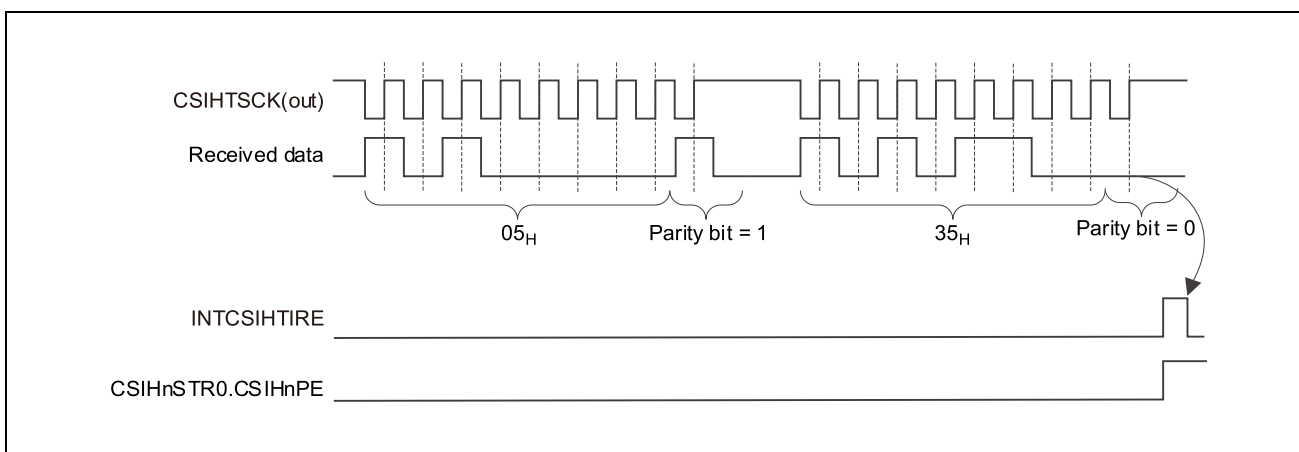

Figure 18.32 Parity Check Example

The parity bit of the first data is 1. There is no parity error, because the total number of ones (including the parity bit) is odd.

The parity bit of the second data is 0. This is detected as a parity error, because the total number of ones (including the parity bit) is even.

If the EDL (extended data length) function is used, the parity bit is added after the last bit of the data.

18.5.11.3 Overrun Error

An overrun error may occur in direct access mode. The overrun error does not occur if data reception is disabled (CSIHnCTL0.CSIHnRXE = 0).

There are one conditions for overrun errors.

Condition for Errors 1

- In slave mode, when CSHnCTL1.CSIHnHSE = 0 (handshake function disabled):
 - In direct access mode, when reception is completed while the previously received data is remains in the CSHnRX0W/H register.

(1) Direct Access

In direct access modes, this error occurs when newly received data cannot be transferred from the shift register to the reception register CSHnRX0W/H. This happens when CSHnRX0W/H was not read and therefore contains previously received data.

The following figure illustrates the overrun error detection function.

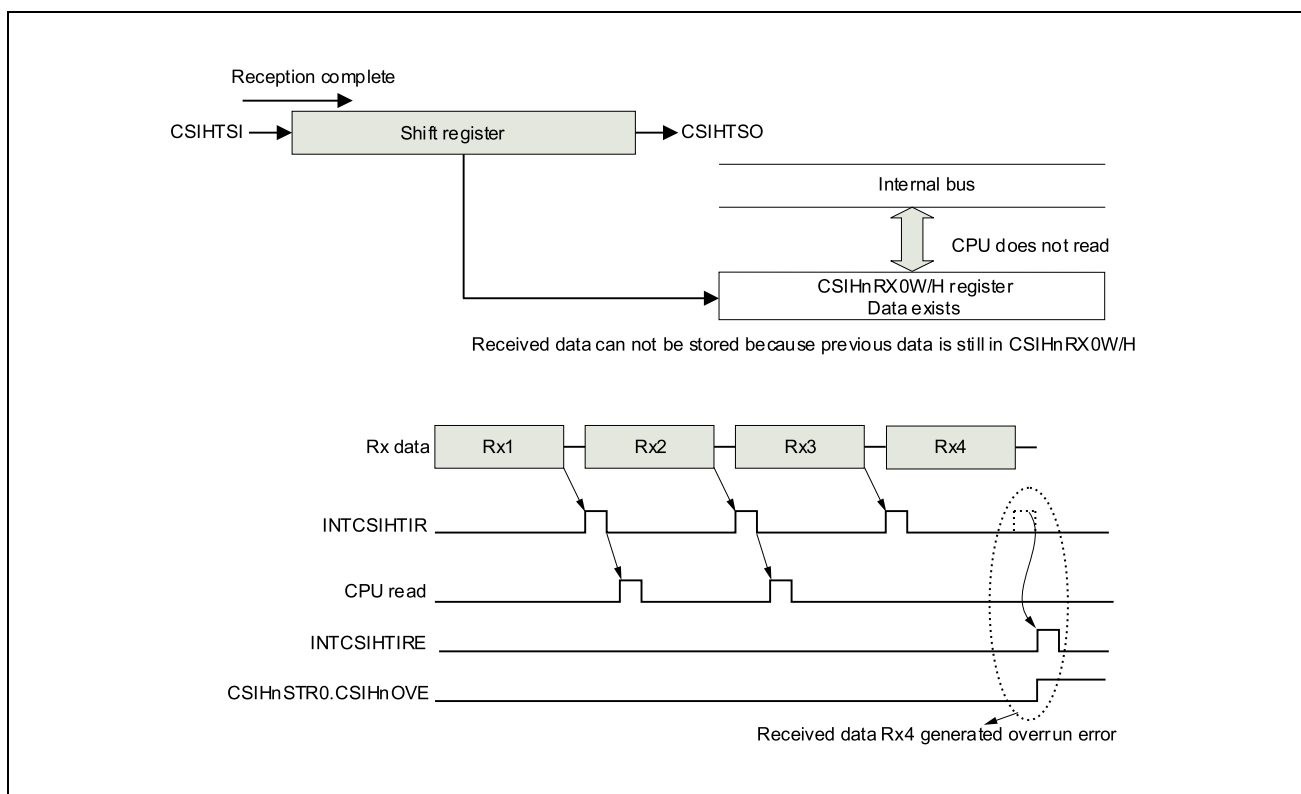

Figure 18.33 Overrun Error Detection in Direct Access Modes

NOTE

An overrun error can be avoided in slave mode by using handshake function. When handshake is used in slave mode, the receiver (slave) signals to the transmitter (master) that it is busy. The transmitter then waits until the receiver reads its reception register and becomes ready again.

18.5.12 Loop-Back Mode

Loop-back mode is a special mode for self-test. This feature is only available in master mode.

When this mode is active (CSIHnCTL1.CSIHnLBM = 1), CSIHnCSSx is fixed to the inactive level (the active level is defined by the CSIHnCTL1.CSIH0CSLx value). The transmit and receive signals are internally connected, as shown in the figures below. The signals CSIHnTSCk, CSIHnTSO, CSIHnTSI, and CSIHnCSSx are disconnected from the ports. In addition, the CSIHnTSO output level is fixed to low, and CSIHnTSCk is set to reset level (High) regardless of the value of the CSIHnCFGx.CSIHnCKPx. The rest of CSIH works as in normal operation.

In order to test CSIH, put it in loop-back mode and carry out normal transfer operations. Then check that the received data is the same as the transmitted data. Any connected device remains unaffected by the loop-back test.

Table 18.45 Pin Output Level in Loop-Back Mode

Pin Name	Output level
CSIHnTSCk(out)	High level
CSIHnCSS[5:0]	Inactive level
CSIHnTSO	Low level (not dependent on the previous value)
Interrupt	Normal function
CSIHnTRYO	Normal function (Low level)

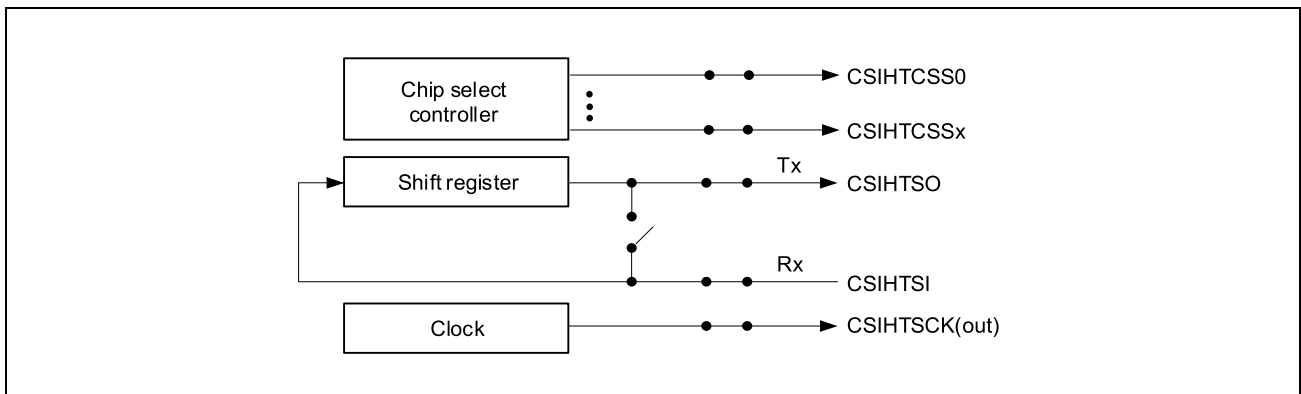

Figure 18.34 Normal Operation

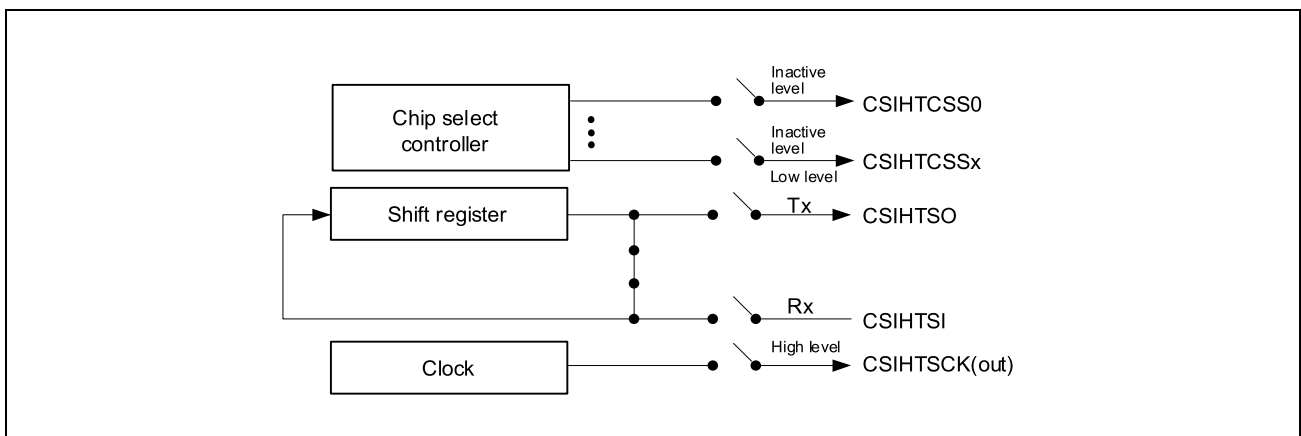

Figure 18.35 Loop-Back Mode Operation

18.5.13 Enforced Chip Select Idle Setting

It is possible to insert an idle state between two consecutive data transfers by setting $CSIHnCFGx.CSIHnIDLx$.

1. When $CSIHnCFGx.CSIHnIDLx = 0$
 If the next $CSIHTCSSx$ is the same as the previous one, an idle state is not inserted and an inter-data time is inserted.
 If the next $CSIHTCSSx$ is different from the previous one, an idle state is inserted.
2. When $CSIHnCFGx.CSIHnIDLx = 1$
 An idle state is always inserted even if a next $CSIHTCSSx$ is not different from the previous one.

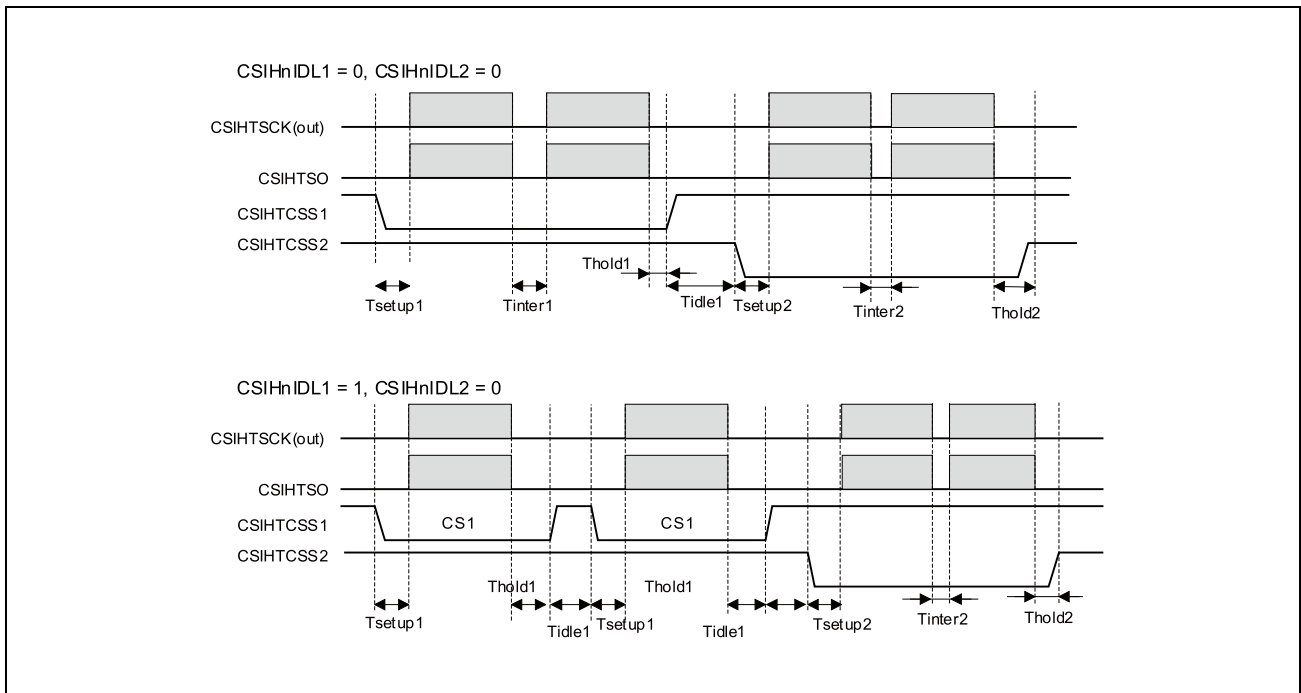

Figure 18.36 Enforced Chip Select Setting Idle Example

18.5.14 Extended Communication Function

CSIH has an extended communication function that can perform 8-bit, 16-bit, or 32-bit CSI (SPI) communication by using up to 16 stages of extended communication data registers.

When the CSIHnECTL0.CSIHnEEN bit is set to 1, the extended communication function is enabled and can perform extended communication based on a specified data size. A data transfer direction can be specified (LSB-first or MSB-first), and the extended communication can be stopped.

When the CSIHnECTL0.CSIHnEEN bit is 0, the extended communication function is disabled and CSIH operates in the same way as the original function.

18.5.14.1 Data Transfer Direction Selection Function

CSIH enables the selection of the data transfer direction by using the CSIHnECTL1.CSIHnEDIR bit when the extended communication function is enabled.

The figures listed in the following table show the data transfer operations with MSB-first transfer or LSB-first transfer selected as the data transfer direction.

Table 18.46 Selection of Data Transfer Direction

Figure No.	Content	Register Setting	
		CSIHnECTL1.CSIHnEDS[1:0]	CSIHnECTRL1.CSIHnEDIR
Figure 18.37	Data size of 32 bits, MSB-first transfer	10 _B	0
Figure 18.38	Data size of 32 bits, LSB-first transfer	10 _B	1
Figure 18.39	Data size of 8 or 16 bits, MSB-first transfer	00 _B or 01 _B	0
Figure 18.40	Data size of 8 or 16 bits, LSB-first transfer	00 _B or 01 _B	1

NOTE

To select the transfer direction when the extended communication function is enabled, use the CSIHnECTL1.CSIHnEDIR bit for the extended communication function, and set the CSIHnCFGx.CSIHnDIRx bit (which is used to select the transfer direction for communication by CSIH) to 0 (MSB-first). If a transfer direction is selected for both the extended communication function and CSIH, the actual transfer direction is not guaranteed.

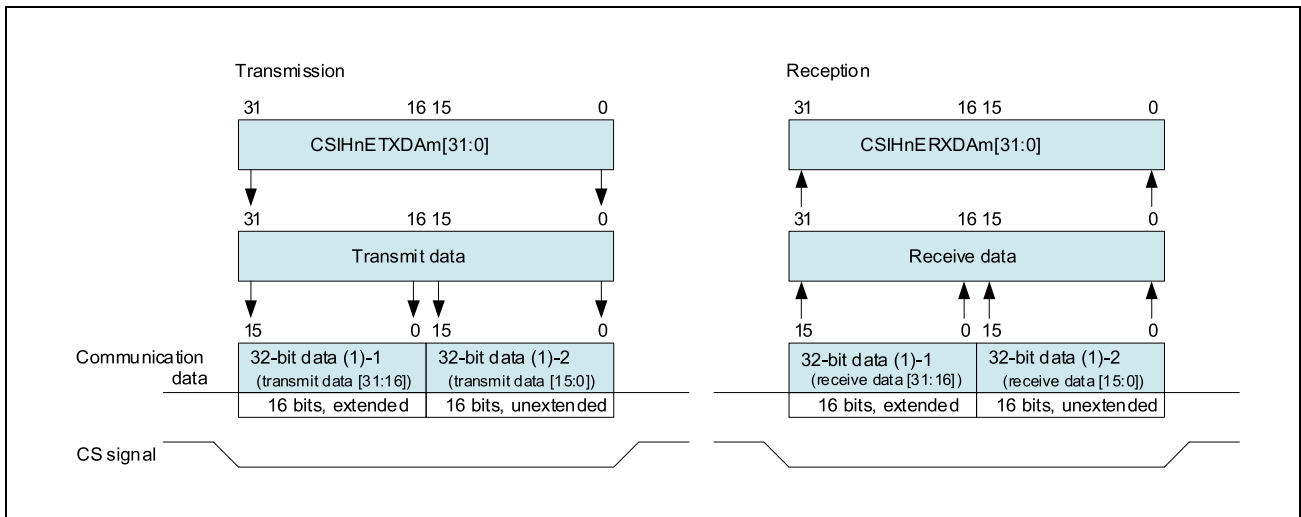

Figure 18.37 Operations with Data Size Set to 32 Bits and Transfer Direction Set to MSB-First

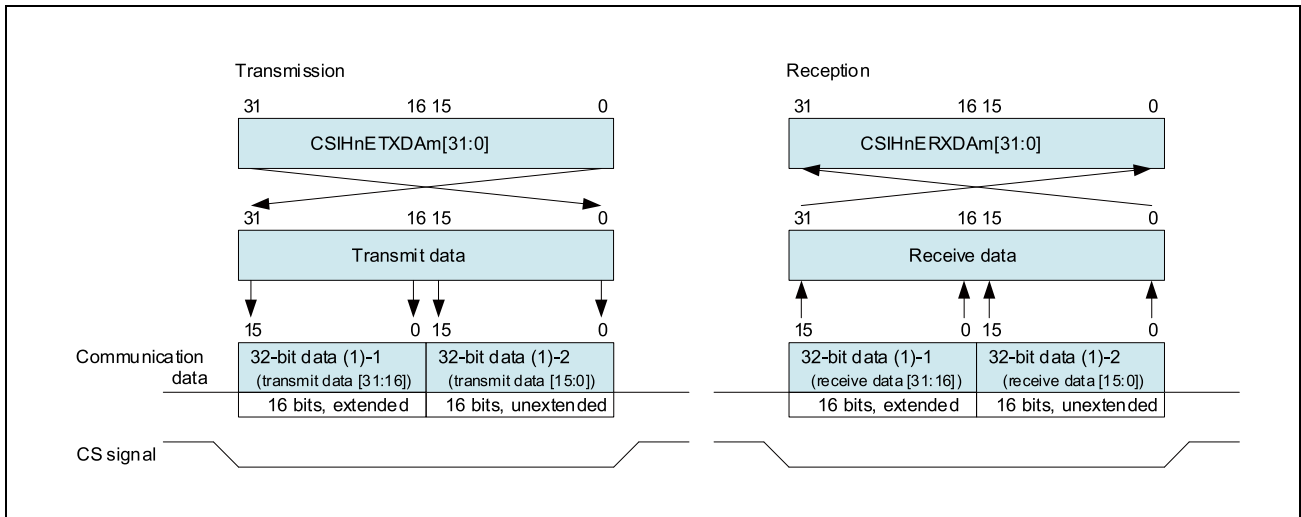

Figure 18.38 Operations with Data Size Set to 32 Bits and Transfer Direction Set to LSB-First

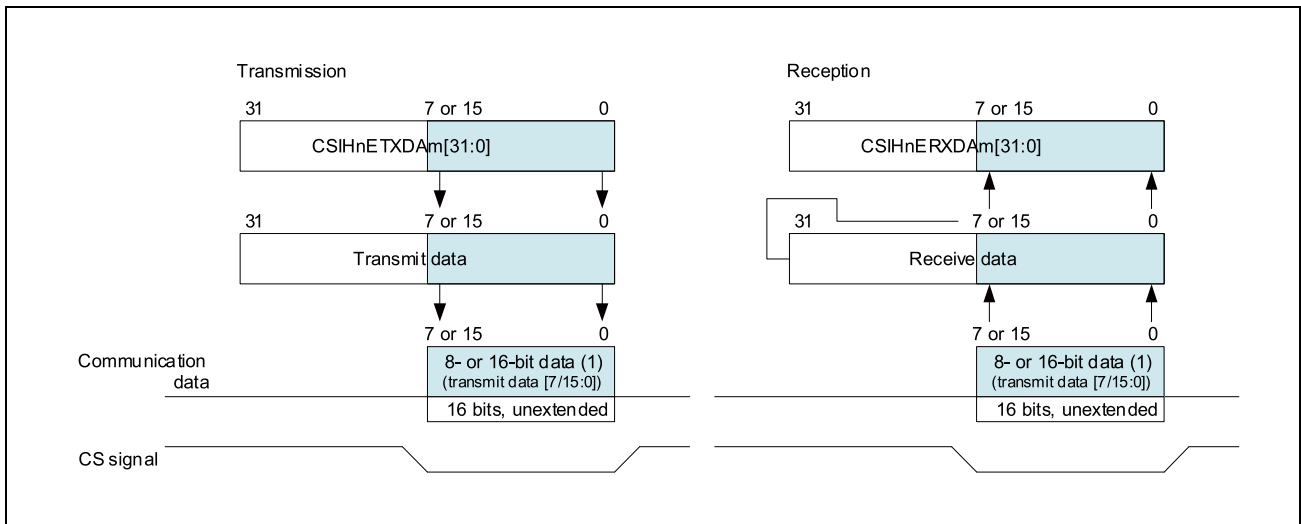

Figure 18.39 Operations with Data Size Set to 8 or 16 Bits and Transfer Direction Set to MSB-First

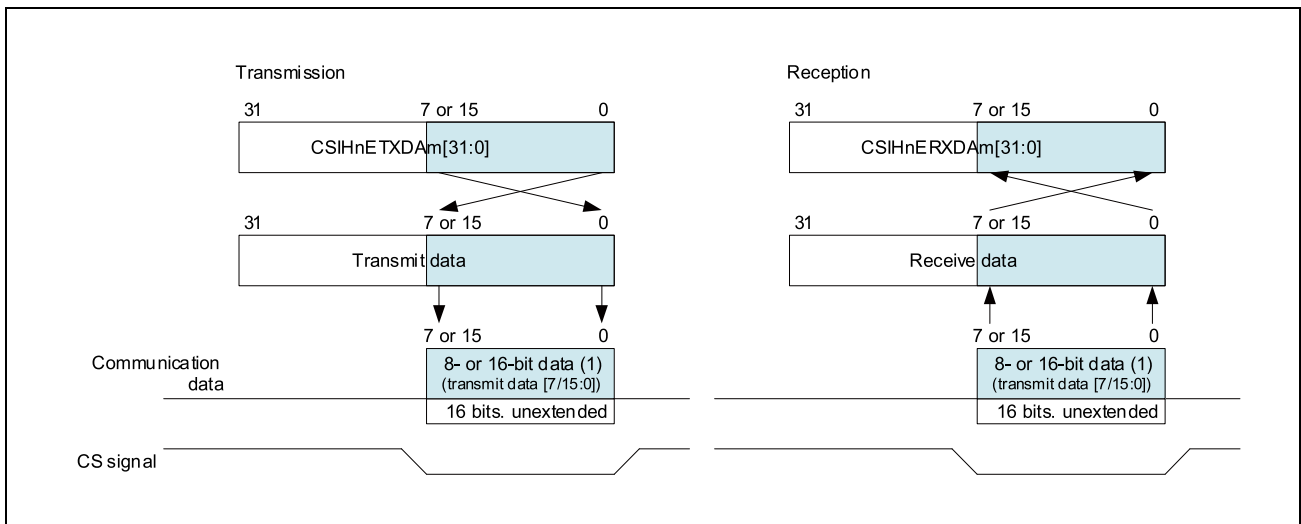

Figure 18.40 Operations with Data Size Set to 8 or 16 Bits and Transfer Direction Set to LSB-First

18.5.14.2 Extended Communication Stop Function

CSIH enables the stopping of extended communication by using the stop trigger bit (CSIHnESTT.CSIHnESTRG).

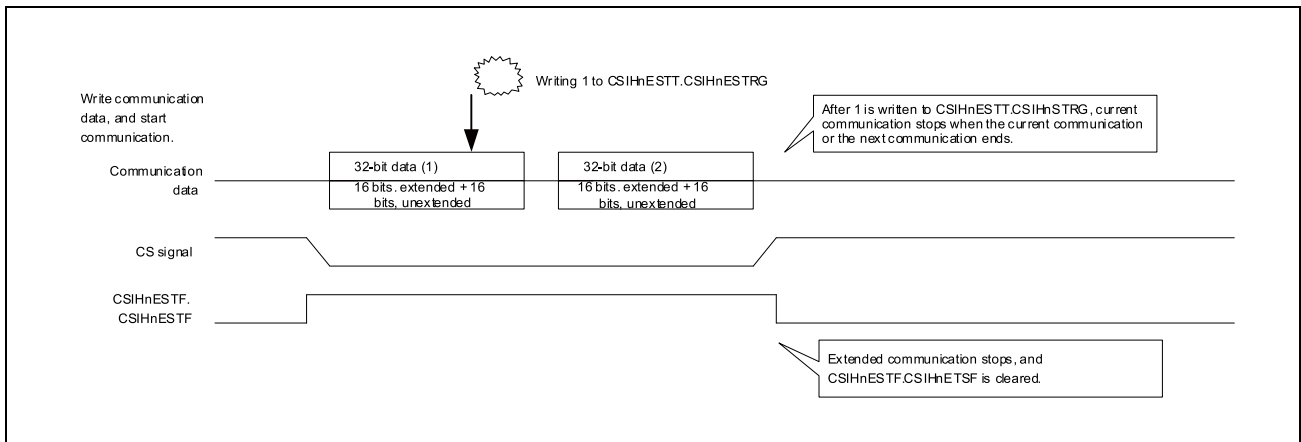

Figure 18.41 Stopping Extended Communication

- When communication is stopped, the CSIHnESTF.CSIHnETCF[4:0] bits indicate the remaining number of data transfers.
- Stopped communication cannot be resumed. Therefore, to complete the communication, perform the operating procedure to start the communication.

18.5.14.3 Extended Communication Status

CSIH enables checking of the status of extended communication. The CSIHnESTF.CSIHnETSF bit indicates whether communication is in progress or stopped, and the CSIHnESTF.CSIHnETCF[4:0] bits indicate the remaining number of communications.

The figures below show examples of communication status according to the condition of communication.

Table 18.47 Examples of Communication Status

Figure No.	Content	Register Transmit/Receive Mode Setting		Register Setting	
		CSIHnTXE	CSIHnRXE	CSIHnECTL1. CSIHnEDS[1:0]	CSIHnECTL1. CSIHnETC[3:0]

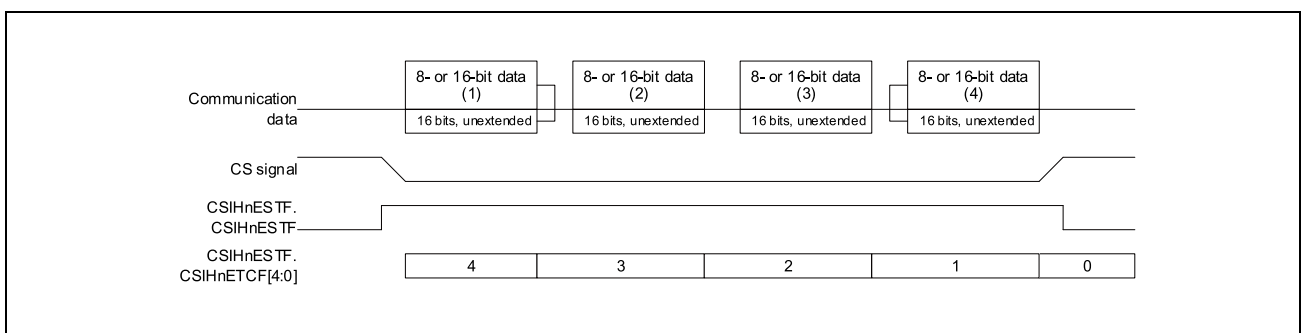

Figure 18.43 Receive-only or Transmit/Receive Mode Status of Communication with Data Size Set to 8 or 16 Bits and Transfer Count Set to 4

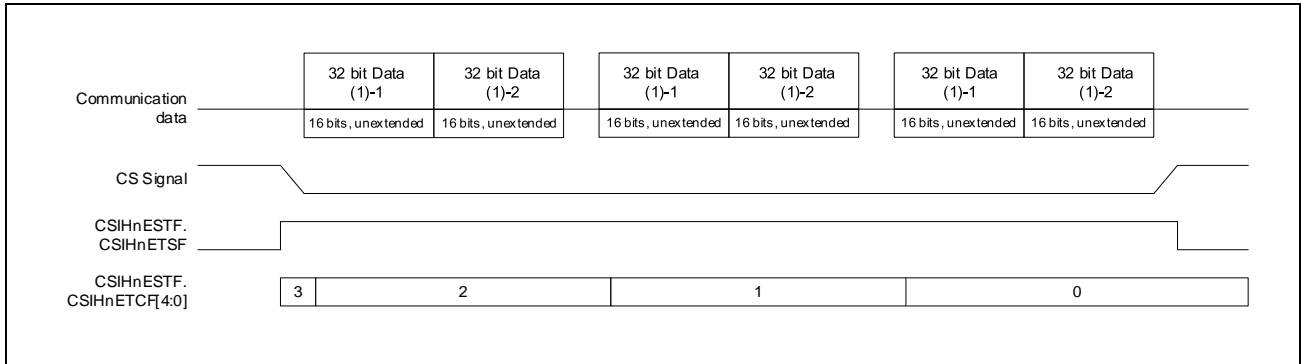

Figure 18.44 Transmit-only Mode Status of Communication with Data Size Set to 32 Bits and Transfer Count Set to 3

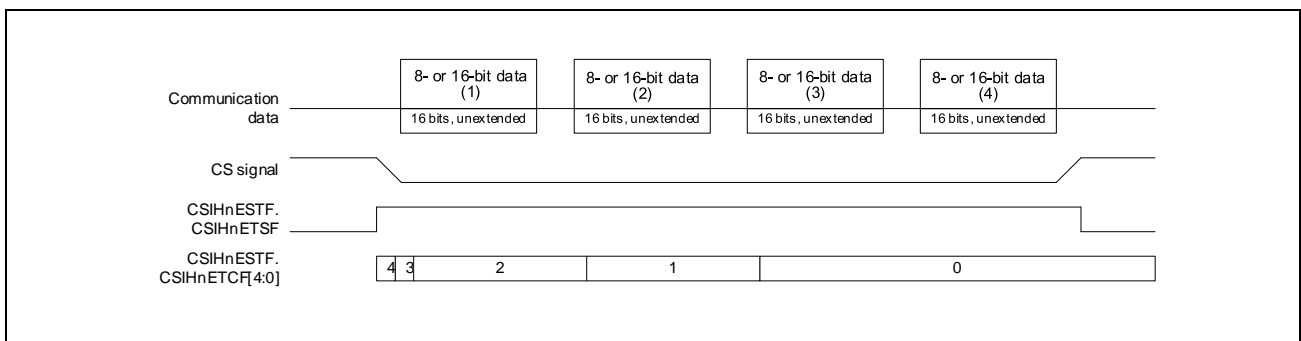

Figure 18.45 Transmit-only Mode Status of Communication with Data Size Set to 8 or 16 Bits and Transfer Count Set to 4

18.5.14.4 Extended Interrupt Control Function

When the extended communication function is enabled, the INTCSIHTIRE interrupt signal from CSIH is output without change. The INTCSIHTIC interrupt and INTCSIHTIR interrupt signals are output after they are fixed to the 0 level by the extended communication function. The INTCSIHTIJC interrupt signal is output only once when the specified number of communications ends.

The following figure shows the interrupt output for the extended communication with transfer count set to 2 (CSIHnECTL1.CSIHnETC[3:0] = 0001_B).

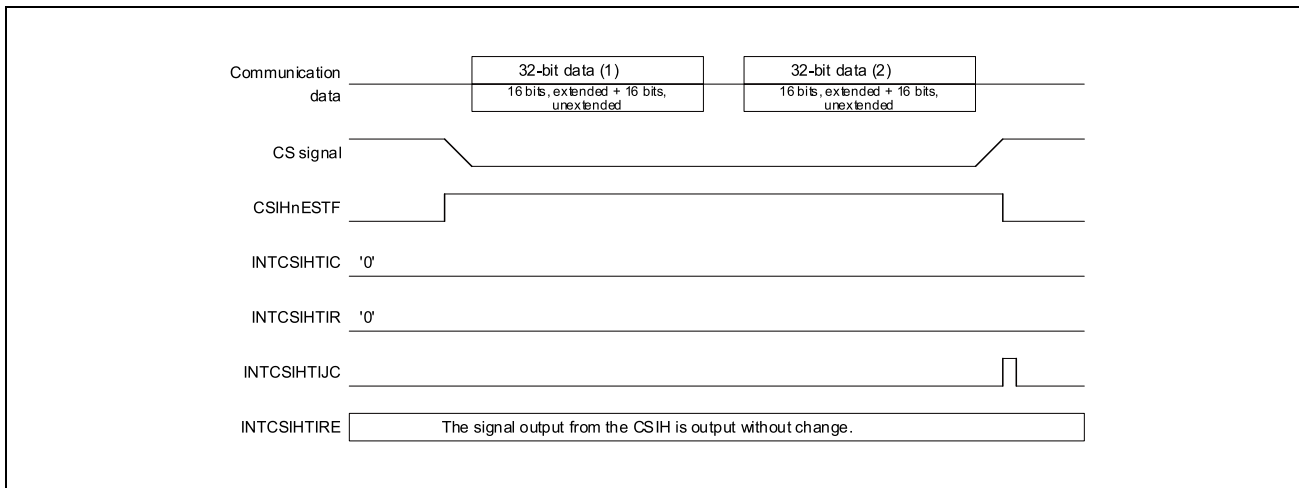

Figure 18.46 Interrupts Output with the Extended Communication Function Enabled

NOTE

When extended communication is stopped halfway by using the stop trigger bit (CSIHnESTT.CSIHnESTRG), the INTCSIHTIJC interrupt is not output. To determine whether the communication is in progress or stopped, check the extended communication status flag (CSIHnESTF.CSIHnETSF).

Note that it can be specified whether to enable individual interrupt outputs by using the CSIHnECTL0.CSIHnEIJE, CSIHnECTL0.CSIHnEIEE, CSIHnECTL0.CSIHnEIRE, and CSIHnECTL0.CSIH0EICE bits. When the output of an interrupt is disabled, the corresponding interrupt request is set to the Low level.

18.6 Operating Procedures

18.6.1 Procedures in Direct Access Mode

Two examples for a master are provided, one with job mode disabled, and the other with job mode enabled.

18.6.1.1 Transmit/Receive in Master Mode when Job Mode Is Disabled

The procedures below are based on the assumption that:

- The transmission data length is 8 bits (CSIHnCFGx.CSIHnDLSx[3:0] = 1000_B).
- Transmission direction is MSB first (CSIHnCFGx.CSIHnDIRx = 0).
- Normal clock phase and data phase (CSIHnCFGx.CSIHnCKPx = 0, CSIHnCFGx.CSIHnDAPx = 0)
- No interrupt delay (CSIHnCTL1.CSIHnSIT = 0)
- Job mode is disabled (CSIHnCTL1.CSIHnJE = 0).
- Normal INTCSIHTIC interrupt timing (CSIHnCTL1.CSIHnSLIT = 0)
- Direct access mode (CSIHnCTL0.CSIHnMBS = 1)

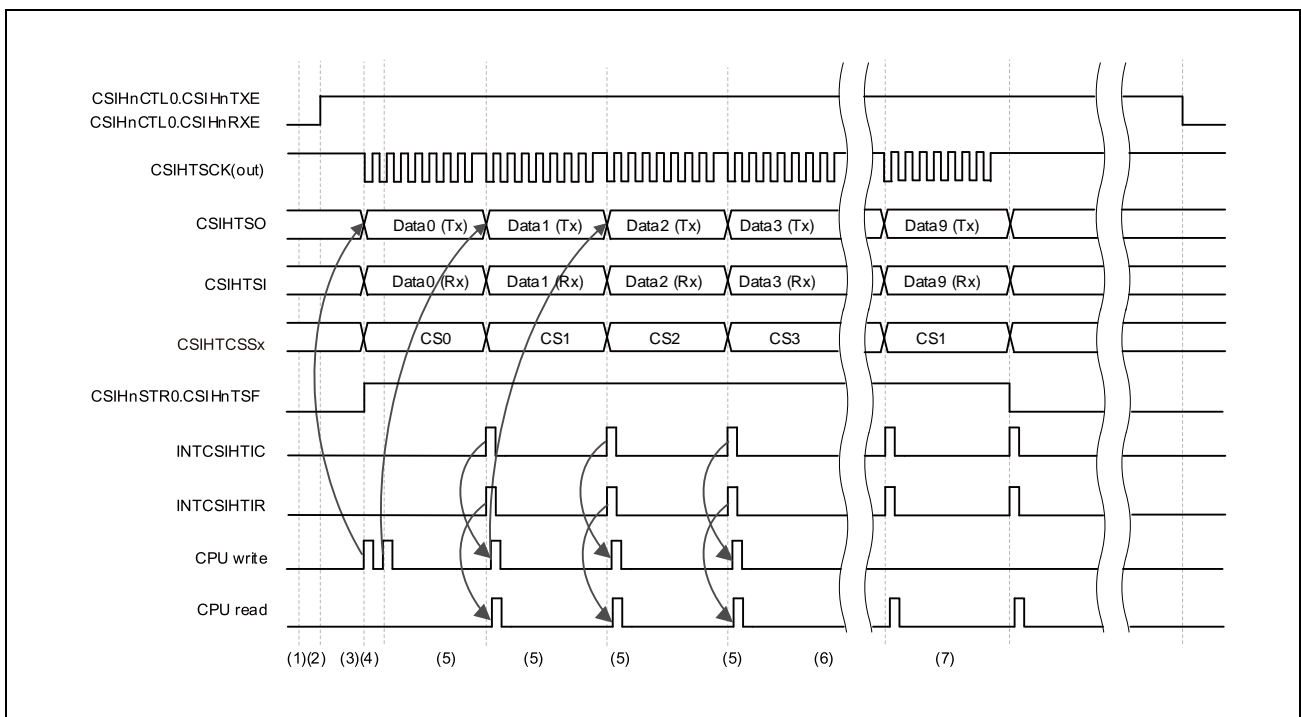

Figure 18.47 Master in Direct Access Mode, CSIHnCTL1.CSIHnJE = 0

Procedure:

1. Configure the communication protocol in the CSIHnCFGx register. This example uses chip select signals CSIHnCSS0 to CSIHnCSS3.
Specify the transfer mode and job mode by setting the corresponding bits in registers CSIHnCTL1 and CSIHnCTL2.
2. In the CSIHnCTL0 register, set CSIHnPWR = 1 (enables the clock), CSIHnTXE = 1 (permits transmission), CSIHnRXE = 1 (permits reception), and CSIHnMBS = 1 (selects direct access mode).
3. Write the first data to be sent to the transmission register CSIHnTX0W. Within the same write operation, activate CS0. Transmission starts automatically when the first data becomes available.
4. Write the second data to CSIHnTX0W. If required, change the CS to address a different device. Writing the second data immediately after the first one avoids unnecessary delays between the data.
5. After data transmission/reception, the interrupts INTCSIHTIC and INTCSIHTIR are generated:
 - INTCSIHTIC indicates that the next data can be written to CSIHnTX0W.
 - INTCSIHTIR indicates that the reception register CSIHnRX0W must be read.
6. No more write action is required after completion of data 8. Data 9 (the last data) has been written in advance. However, reception register CSIHnRX0W must be read after completion of writing data 8 and 9.
7. Finally, clear CSIHnCTL0.CSIHnTXE and CSIHnCTL0.CSIHnRXE to prohibit the transmit/receive operation. When no communication is conducted, set CSIHnCTL0.CSIHnPWR to 0 to minimize power consumption of CSIHn.

18.6.1.2 Transmit/Receive in Master Mode when Job Mode is Enabled

The procedure below is based on the assumption that:

- The transmission data length is 8 bits (CSIHnCFGx.CSIHnDLSx[3:0] = 1000_B).
- Transmission direction is MSB first (CSIHnCFGx.CSIHnDIRx = 0).
- Normal clock phase and data phase (CSIHnCFGx.CSIHnCKPx = 0, CSIHnCFGx.CSIHnDAPx = 0)
- No interrupt delay (CSIHnCTL1.CSIHnSIT = 0)
- Job mode is enabled (CSIHnCTL1.CSIHnJE = 1).
- Normal INTCSIHnTIC interrupt timing (CSIHnCTL1.CSIHnSLIT = 0)
- Direct access mode (CSIHnCTL0.CSIHnMBS = 1)
- Two jobs, each transmitting three data.

Figure 18.48 Master in Direct Access Mode, CSIHnCTL1.CSIHnJE = 1

Procedure:

1. Configure the communication protocol in the CSIHnCFGx register. This example uses chip select signals CS1 and CS2.
Specify the transfer mode and job mode by setting the corresponding bits in registers CSIHnCTL1 and CSIHnCTL2.
2. In the CSIHnCTL0 register, set CSIHnPWR = 1 (enables the clock), CSIHnTXE = 1 (permits transmission), CSIHnRXE = 1 (permits the reception), and CSIHnMBS = 1 (selects direct access mode).
3. Write the first data to be sent to the transmission register CSIHnTX0W. Transmission starts automatically when the first data becomes available.
The CSIHnSTR0.CSIHnTSF flag indicates that communication is in progress.
4. Write the second data to CSIHnTX0W. Writing the second data immediately after the first one avoids unnecessary delays between the data.
5. After every data transmission/reception, the interrupt requests INTCSIHTIC and INTCSIHTIR are generated.
 - INTCSIHTIC indicates that the next data can be written to CSIHnTX0W.
 - INTCSIHTIR indicates that the reception register CSIHnRX0W must be read.
6. Setting CSIHnTX0W.CSIHnEOJ = 1 indicates that the last data of the current job is sent. After that, the next job may begin.
7. By setting CSIHnCTL0.CSIHnJOB2 = 1, communication is forced to stop at the end of the current job (JOB2).
8. After the forced stop of communication, the interrupt request INTCSIHTIC is replaced by INTCSIHTIJC.
INTCSIHTIR is generated as usual.
The interrupt request INTCSIHTIJC indicates that the communication was forcibly stopped at the end of the current job.
The interrupt request INTCSIHTIC is not generated. Additionally, the transmission data available in the CSIHnTX0W register is not sent.
9. Finally, clear CSIHnCTL0.CSIHnTXE and CSIHnCTL0.CSIHnRXE to prohibit the transmit/receive operation.
When no communication is conducted, set CSIHnCTL0.CSIHnPWR to 0 to minimize power consumption of the CSIHn.
To start another transmission without stopping communication, perform steps 3 and later.

18.6.2 Procedures in Extended Communication Function Mode

The extended communication function of CSIH performs CSI (SPI) communication by using the registers dedicated to extended communication. It is possible to select a communication data size from 8, 16, and 32 bits by using the CSIHnECTL1.CSIH0EDS[1:0] bits. Also, it is possible to specify the number of extended communications in the range of 1 to 16 by using the CSIHnECTL1.CSIH0ETC[3:0] bits.

The following describes the operating procedure to use the extended communication function.

NOTE

When the extended communication function is enabled, do not write data to the transmit data registers (CSIHnTX0W[31:0] and CSIHnTX0H[15:0]) of CSIH. If data is written to any of these registers, the content of the communication using the extended communication function is not guaranteed.

Table 18.48 Procedure to Perform Communication Using the Extended Communication Function

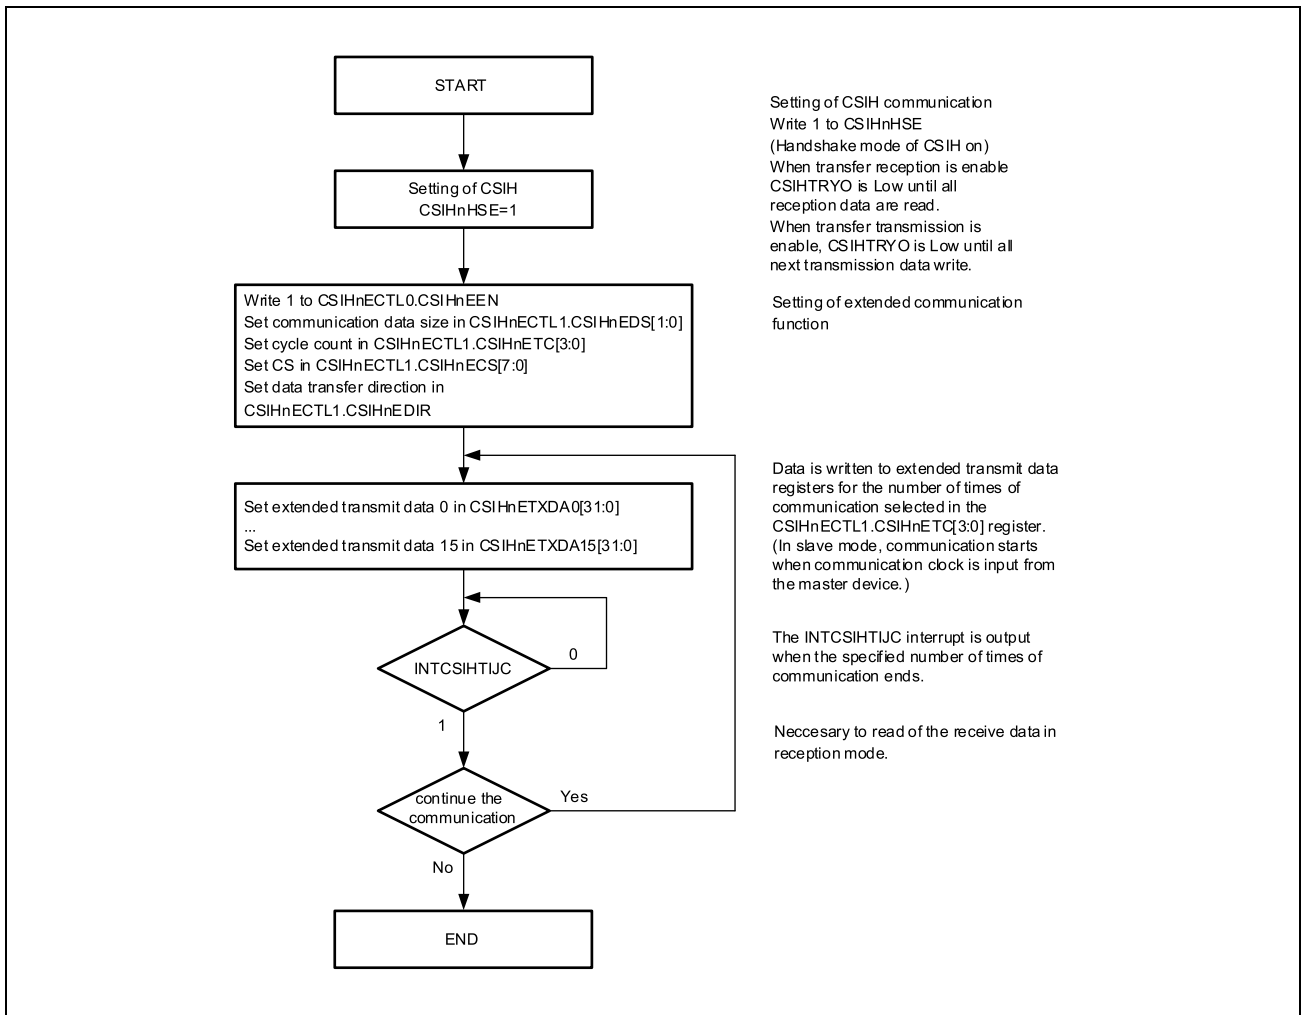

Figure 18.53 Transmission or Transmission/Reception in Slave Mode (more than 17 times)

18.6.2.1 Trigger to Start Extended Communication

For transmission or transmission/reception, CSIH starts communication when the last communication data to be transmitted is written. (In slave mode, CSIH starts communication when the communication clock is input from the master mode after the last data is written).

As examples, **Table 18.49** lists the transfer start timings for the 8-bit, 16-bit, or 32-bit communication with the data transfer count set to 16, and **Table 18.50** lists the transfer start timings for the 8-bit, 16-bit, or 32-bit communication with the data transfer count set to 4.

Table 18.49 Timings When CSIH Starts Transfer (Transfer Count: 16)

Address	Transmit Data Array	Register Name	
<CSIHn_base> + 110C _H	8-bit transmit data 0_0	CSIHnETXDA0

<CSIHn_base> + 1110 _H	8-bit transmit data 1_0	CSIHnETXDA1	
<CSIHn_base> + 1111 _H	8-bit transmit data 1_1		
<CSIHn_base> + 1112 _H	8-bit transmit data 1_2		
<CSIHn_base> + 1113 _H	8-bit transmit data 1_3		-> For the communication of "16 bits x 4" data, transfer starts when the data (<CSIHn_base> + 1113 _H) shown on the left is written.
<CSIHn_base> + 1114 _H	8-bit transmit data 2_0	CSIHnETXDA2	
<CSIHn_base> + 1115 _H	8-bit transmit data 2_1		
<CSIHn_base> + 1116 _H	8-bit transmit data 2_2		
<CSIHn_base> + 1117 _H	8-bit transmit data 2_3		
<CSIHn_base> + 1118 _H	8-bit transmit data 3_0	CSIHnETXDA3	
<CSIHn_base> + 1119 _H	8-bit transmit data 3_1		
<CSIHn_base> + 111A _H	8-bit transmit data 3_2		
<CSIHn_base> + 111B _H	8-bit transmit data 3_3		-> For the communication of "32 bits x 4" data, transfer starts when the data (<CSIHn_base> + 111B _H) shown on the left is written.
.	.	.	
.	.	.	
.	.	.	
<CSIHn_base> + 1128 _H	8-bit transmit data 7_0	CSIHnETXDA7	
<CSIHn_base> + 1129 _H	8-bit transmit data 7_1		
<CSIHn_base> + 112A _H	8-bit transmit data 7_2		
<CSIHn_base> + 112B _H	8-bit transmit data 7_3		
.	.	.	
.	.	.	
.	.	.	
<CSIHn_base> + 1148 _H	8-bit transmit data 15_0	CSIHnETXDA15	
<CSIHn_base> + 1149 _H	8-bit transmit data 15_1		
<CSIHn_base> + 114A _H	8-bit transmit data 15_2		
<CSIHn_base> + 114B _H	8-bit transmit data 15_3		

The CSIHnETXDA0-15[31:0] registers can be accessed in units of 8, 16, or 32 bits.

For the communication of “8 bits x 4” data described above, transfer is started by an 8-bit access to the address “<CSIHn_base> + 110F_H,” 16-bit access to the address “<CSIHn_base> + 110E_H,” or 32-bit access to the address “<CSIHn_base> + 110C_H.”

NOTE

For transmission or transmission/reception, CSIH starts communication when the last transmit data is written (to the extended transmit data register that has the highest address [among the “CSIHnETXDA0-15[31:0] registers] based on the specified transfer count). Therefore, the last transmit data must always be written at the end of writing. If the last transmit data is not written at the end of writing, values previously set in the CSIHnETXDA0-15[31:0] registers might be transmitted. Because transmission by CSI communication conflicts with writing of transmit data, it is not guaranteed which of previously set data and newly written data will be transmitted.

18.6.2.2 Storage Address of Received Data in Extended Communication

The storage address of the received data is determined by the communication data size.

Table 18.51 lists the storage address for the 8-bit, 16-bit, or 32-bit transfer reception data.

Table 18.51 Storage Address of Reception Data

Address	Register Name	Data Size 8 bits	Data Size 16 bits	Data Size 32 bits
<CSIHn_base> + 1150 _H	CSIHnERXDA0	Reception data1	Reception data 1	Reception data 1

Section 19 Serial Communication Interface 3 (SCI3)

19.1 Features of SCI3

19.1.1 Units and Channels

This product contains the serial communication interface for the number of channels shown below.

Table 19.1 Number of Channels (For E2x-FCC2 Series)

Product Name	RH850/E2x-FCC2 series	
	468 Pins	373 Pins
Number of Channels	4	4
Name	SCI3n (n = 0 to 3)	

Meaning of “n”

In this section, each channel of the serial communication interface 3 is identified by “n” (“n” is channel numbers.). For example, a serial mode register is written as SCI3nSMR.

19.1.2 Register Base Address

The base addresses <SCI3n_base> of each SCI3 are listed in **Table 19.2**.

Table 19.2 Register Base Address

SCI3n Channel	SCI3n_base Address	Bus Group
<SCI30_base>	FFD9 0000 _H	Peripheral Group 2L
<SCI31_base>	FFD9 1000 _H	Peripheral Group 2L
<SCI32_base>	FFD9 2000 _H	Peripheral Group 2L
<SCI33_base>	FFD9 3000 _H	Peripheral Group 2L

19.1.3 Clock Supply

Clock supply by and to SCI3 is listed in the following table.

Table 19.3 Clock Supply

Unit Name	Unit Clock Name	Supply Clock Name
SCI3n	PCLK	CLK_LSB

19.1.4 Interrupt Requests

Table 19.4 Interrupt Requests

19.1.6 External Input / Output Signals

The SCI3 has the input / output pins listed in **Table 19.6**.

Table 19.6 Pin Configuration

Unit Signal Name	Outline	Alternative Port Pin Signal
SCI30		
SCI0SCK	SCI30 serial clock input / output	SCI0SCK
SCI0RxD	SCI30 receive data input	SCI0RxD
SCI0TxD	SCI30 transmit data output	SCI0TxD
SCI31		
SCI1SCK	SCI31 serial clock input / output	SCI1SCK
SCI1RxD	SCI31 receive data input	SCI1RxD
SCI1TxD	SCI31 transmit data output	SCI1TxD
SCI32		
SCI2SCK	SCI32 serial clock input / output	SCI2SCK
SCI2RxD	SCI32 receive data input	SCI2RxD
SCI2TxD	SCI32 transmit data output	SCI2TxD
SCI33		
SCI3SCK	SCI33 serial clock input / output	SCI3SCK
SCI3RxD	SCI33 receive data input	SCI3RxD
SCI3TxD	SCI33 transmit data output	SCI3TxD

CAUTION

This AC specification is only applied to the specific pin groups. For details, refer to Appendix file "Limited_conditions_for_AC_specification.xlsx".

19.2 Overview

19.2.1 Functional Overview

The serial communication interface 3 (SCI3: Serial Communication Interface 3) can handle two methods of serial communications: asynchronous and clock synchronous serial communications. Asynchronous serial data communications can be carried out with standard asynchronous communication LSIs such as Universal Asynchronous Receiver / Transmitter (UART) or Asynchronous Communication Interface Adapter (ACIA). Asynchronous mode is equipped with a serial communications function between multiple processors (multi-processor communications function).

SCI3 has following features:

- The serial data communication mode can be configured for asynchronous communications or clock synchronous communications.
- Full-duplex communications are available. The independent transmitter unit and receiver unit allow simultaneous transmission and reception. Both the transmitter and the receiver have a double-buffered structure, enabling continuous data transmission and reception.
- An arbitrary bit rate is selectable with the on-chip baud rate generator. An external clock is also selectable as a transmission/reception clock source.
- LSB-first or MSB-first transfer is selectable (except for asynchronous 7-bit data).
- Interrupt sources: 4 types consisting of transmit-end, transmit-data-empty, receive-data-full, and receive-error. Transmit-data-empty and receive-data-full interrupt sources can activate the sDMA or DTS.
- Module standby can be set for each channel (for details of module standby, see **Section 16, Standby Controller**).
- The bit rate modulation function can reduce errors averagely (even in a high bit rate) by correcting the output of the on-chip baud rate generator (except for the maximum speed in clock synchronous mode).
- The pin level of serial input data can be checked.

19.2.2 Serial Communication Modes

Asynchronous mode

- Data length: 7 bits or 8 bits selectable
- Stop bit length: 1 bit or 2 bits selectable
- Parity: Even parity, odd parity, or none selectable
- Receive error detection: Parity error, overrun error, and framing error
- Break detection: A break can be detected by reading a register when a framing error occurs.

Clock synchronous mode

- Data length: 8 bits
- Receive error detection: Overrun error

19.2.3 Block Diagram

Figure 19.1 SCI3 Block Diagram

19.3 Registers

19.3.1 List of Registers

SCI3n register addresses are given as offsets from the base address <SCI3n_base>.

The SCI3 has the registers listed in **Table 19.7**. Some registers have limitations in read / write by the CPU.

Table 19.7 List of Registers

Module Name	Register Name	Symbol	Address	Access Size	Access Protection
SCI3n	Receive Shift Register	SCI3nRSR	—	—	—
	Serial Mode Register	SCI3nSMR	<SCI3n_base> + 0000 _H	8	—
	Bit Rate Register / Modulation Duty Register	SCI3nBRR / SCI3nMDDR	<SCI3n_base> + 0004 _H	8	—
	Serial Control Register	SCI3nSCR	<SCI3n_base> + 0008 _H	8	—
	Transmit Data Register	SCI3nTDR	<SCI3n_base> + 000C _H	8	—
	Transmit Shift Register	SCI3nTSR	—	—	—
	Serial Status Register	SCI3nSSR	<SCI3n_base> + 0010 _H	8	—
	Receive Data Register	SCI3nRDR	<SCI3n_base> + 0014 _H	8	—
	Serial Transfer Format Register	SCI3nSCMR	<SCI3n_base> + 0018 _H	8	—
	Serial Extended Mode Register	SCI3nSEMR	<SCI3n_base> + 001C _H	8	—

CAUTION

- SCI3nBRR and SCI3nMDDR are allocated to the same address (relative address 4). The SCI3nMDDRS bit in SCI3nSEMR is used to switch these registers.
- Relative addresses $4k + 1$, $4k + 2$, and $4k + 3$ ($k = 0$ to 7) are reserved areas. These areas are always read as 0. Writing is invalid.

19.3.2 SCI3nRSR — Receive Shift Register

SCI3nRSR is a shift register which is used to receive serial data input from the SCIInRxD pin and convert it to parallel data. When one frame of data has been received, it is automatically transferred to SCI3nRDR. SCI3nRSR cannot be directly accessed by the CPU.

19.3.3 SCI3nRDR — Receive Data Register

SCI3nRDR is an 8-bit register to store receive data. The value of SCI3nRDR after a reset is 00_H. When one frame of data has been received, it is transferred from SCI3nRSR to this register allowing SCI3nRSR to receive the next data. SCI3nRSR and SCI3nRDR function as a double-buffer in this way, allowing continuous receive operations. Be sure to check that the RDRF flag in SCI3nSSR is set to 1 before reading SCI3nRDR. SCI3nRDR cannot be written from the CPU.

When the data length is 7 bits, received data is stored in bits 0 to 6. Bit 7 is fixed to 0.

At this time, the fixed value of bit 7 is not affected by the SINV bit in the SCI3nSCMR register.

19.3.4 SCI3nTDR — Transmit Data Register

SCI3nTDR is an 8-bit register to store transmit data. The value of SCI3nTDR after a reset is FF_H. When SCI3nTSR empty is detected, the transmit data written to SCI3nTDR is transferred to SCI3nTSR and transmission starts. The double-buffered structure of SCI3nTDR and SCI3nTSR allows continuous serial transmission. If the next transmit data has been written to SCI3nTDR when one frame of data is sent, the transmit data is transferred to SCI3nTSR to continue transmission. SCI3nTDR can always be read and written by the CPU. Be sure to check that the TDRE flag in SCI3nSSR is set to 1 before writing transmit data to SCI3nTDR.

19.3.5 SCI3nTSR — Transmit Shift Register

SCI3nTSR is a shift register to transmit serial data. To perform serial data transmission, transmit data written to SCI3nTDR is automatically transferred SCI3nTSR, and is then sent to the SCIInTxD pin. SCI3nTSR cannot be directly accessed by the CPU.

19.3.6 SCI3nSMR — Serial Mode Register

SCI3nSMR is a register used to select the transfer format and the clock source for the on-chip baud rate generator.

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	CM	CHR	PE	PM	STOP	MP	CKS[1:0]	
Value after reset	0	0	0	0	0	0	0	0
R/W	R/W*1	R/W*1	R/W*1	R/W*1	R/W*1	R/W*1	R/W*1	R/W*1

Note 1. Writable only when TE = RE = 0.

Table 19.8 SCI3nSMR Register Contents

Bit Position	Bit Name	Function
7	CM	Communication Mode 0: Asynchronous mode 1: Clock synchronous mode
6	CHR	Character Length (Valid only in asynchronous mode) 0: Selects 8 bits as the data length. 1: Selects 7 bits as the data length. It is fixed to LSB-first and the MSB (bit 7) in SCI3nTDR is not sent in transmission. In clock synchronous mode, the data length is fixed to 8 bits.
5	PE	Parity Enable (Valid only in asynchronous mode) When this bit is set to 1, a parity bit is added to transmit data and the parity bit is checked in reception. Regardless of the setting of this bit, no parity bit is added or checked in the multi-processor format.
4	PM	Parity Mode (Valid only when PE = 1 in asynchronous mode) 0: Selects even parity. 1: Selects odd parity. When even parity is set, parity bit is added so that the total number of 1 bits in the transmit/receive character plus the parity bit is even. Similarly, when odd parity is set, parity bit is added so that the total number of 1 bits in the transmit / receive character plus the parity bit is odd.
3	STOP	Stop Bit Length (Valid only in asynchronous mode) 0: 1 stop bit for transmission 1: 2 stop bits for transmission In reception, only the first stop bit is checked regardless of the setting of this bit. If the second stop bit is 0, it is treated as the start bit of the next transmission frame.
2	MP	Multi-Processor Mode (Valid only in asynchronous mode) When this bit is set to 1, the multi-processor communication function is enabled. In multi-processor mode, settings of the PE and PM bits are invalid.
1, 0	CKS[1:0]	Clock Select 1, 0 These bits select the clock source for the on-chip baud rate generator. 00: PCLK clock (m = 0) 01: PCLK / 4 clock (m = 1) 10: PCLK / 16 clock (m = 2) 11: PCLK / 64 clock (m = 3) For the relation between the setting of these bits and the baud rate, see Section 19.3.11, SCI3nBRR — Bit Rate Register . The character m is the decimal notation of the value of m in Section 19.3.11, SCI3nBRR — Bit Rate Register .

19.3.7 SCI3nSCR — Serial Control Register

SCI3nSCR is a register used for the transmission / reception control, interrupt control, and transmission/reception clock source selection listed below. For interrupt requests, see **Section 19.8, Interrupt Sources**.

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	TIE	RIE	TE	RE	MPIE	TEIE	CKE[1:0]	
Value after reset	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W*1	R/W*1	R/W	R/W	R/W*2	R/W*2

Note 1. While the CM bit in SCI3nSMR is 1, a value of 1 can be written only when TE = 0 and RE = 0. After the TE or RE bit is set to 1, only 0 can be written to TE and RE. While the CM bit in SCI3nSMR is 0, writing is enabled at any timing.

Note 2. Writable only when TE = 0 and RE = 0. Also, writable at the same time when TE = 0 and RE = 0 are written.

Table 19.9 SCI3nSCR Register Contents (1/2)

Bit Position	Bit Name	Function
7	TIE	Transmit Interrupt Enable When this bit is set to 1, TXI interrupt request is enabled. TXI interrupt request can be cancelled by reading 1 from the TDRE flag and then clearing the flag to 0, or clearing the TIE bit.
6	RIE	Receive Interrupt Enable When this bit is set to 1, RXI and ERI interrupt requests are enabled. RXI and ERI interrupt requests can be cancelled by reading 1 from the RDRF, FER, PER, or ORER flag and then clearing the flag to 0, or clearing the RIE bit.
5	TE	Transmit Enable When this bit is set to 1, transmission is enabled. In this state, serial transmission is started by writing transmit data to SCI3nTDR and clearing the TDRE flag in SCI3nSSR to 0. Be sure to configure SCI3nSMR before setting the TE bit to 1 to determine the transmission format. When this bit is set to 0 to disable transmission, the TDRE flag in SCI3nSSR is fixed to 1.
4	RE	Receive Enable When this bit is set to 1, reception is enabled. In this state, serial reception is started by detecting a start bit in asynchronous mode or the input of synchronous clock in clock synchronous mode. Be sure to configure SCI3nSMR before setting the RE bit to 1 to determine the reception format. Even if reception is disabled by clearing this bit, the RDRF, FER, PER, and ORER flags are not affected and the previous value is retained.
3	MPIE	Multiprocessor Interrupt Enable (Valid only when MP in SCI3nSMR = 1 in asynchronous mode) When this bit is set to 1 and the data with the multi-processor bit set to 0 is received, the data is not read and setting the RDRF, FER, and ORER flags in SCI3nSSR to 1 is disabled. When the data with the multi-processor bit set to 1 is received, this bit is automatically cleared to 0, and normal reception is resumed. For details, see Section 19.5, Multi-Processor Communication Function . When the receive data includes MPB = 0 in SCI3nSSR, the receive data is not transferred from SCI3nRSR to SCI3nRDR, a receive error is not detected, and setting the RDRF, FER, and ORER flags in SCI3nSSR to 1 is disabled. When the receive data includes MPB = 1 in SCI3nSSR, the MPB bit in SCI3nSSR is set to 1, the MPIE bit is automatically cleared to 0, the RXI and ERI interrupt requests are enabled (if the RIE bit in SCI3nSCR is set to 1), and setting the FER and ORER flags to 1 is enabled.

Table 19.9 SCI3nSCR Register Contents (2/2)

Bit Position	Bit Name	Function
2	TEIE	Transmit End Interrupt Enable When this bit is set to 1, TEI interrupt request is enabled. TEI interrupt request can be cancelled by reading 1 from the TDRE flag and then clearing the flag to 0 to clear the TEND flag to 0, or clearing the TEIE bit.
1, 0	CKE[1:0]	Clock Enable 1, 0 These bits select the clock source and the SCInSCK pin function. For asynchronous mode 00: On-chip baud rate generator (The SCInSCK pin functions as an input / output port.) 01: On-chip baud rate generator (The clock with the same frequency as the bit rate is output from the SCInSCK pin.) 1X: Setting prohibited For clock synchronous mode 0X: Internal clock (The SCInSCK pin functions as a clock output pin.) 1X: External clock (The SCInSCK pin functions as a clock input pin.)

Note: X: Don't care

NOTE

When writing to any bit other than the MPIE bit of this register, use a store instruction such that the value of the MPIE bit becomes 0.

Note that when using a bit-manipulation instruction for writing to this register, the read-modify-write operation may inadvertently set the MPIE bit to 1.

19.3.8 SCI3nSSR — Serial Status Register

SCI3nSSR consists of SCI3 status flags and multi-processor transmit/receive bits.

The TDRE, RDRF, ORER, PER, and FER flags can be cleared only.

Value after reset: 84_H

Bit	7	6	5	4	3	2	1	0
	TDRE	RDRF	ORER	FER	PER	TEND	MPB	MPBT
Value after reset	1	0	0	0	0	1	0	0
R/W	R/W*1	R/W*1	R/W*1	R/W*1	R/W*1	R	R	R/W

Note 1. Only 0 can be written to clear the flag.

Table 19.10 SCI3nSSR Register Contents (1/2)

Bit Position	Bit Name	Function
7	TDRE	Transmit Data Register Empty Indicates whether or not transmit data exists in SCI3nTDR. [Setting conditions] <ul style="list-style-type: none"> When the TE bit in SCI3nSCR is 0 When the data in SCI3nTDR has been transferred to SCI3nTSR so that new data can be written to SCI3nTDR [Clearing condition] <ul style="list-style-type: none"> Writing 0 to TDRE after reading TDRE = 1 When transmit data is written to TDR while TE = 1
6	RDRF	Receive Data Register Full Indicates whether or not receive data exists in SCI3nRDR [Setting condition] <ul style="list-style-type: none"> When reception finishes successfully and the receive data is transferred from SCI3nRSR to SCI3nRDR [Clearing conditions] <ul style="list-style-type: none"> Writing 0 to RDRF after reading RDRF = 1 When data is read from SCI3nRDR Even when the RE bit in SCI3nSCR is cleared, the RDRF flag is not affected and the previous value is retained. Note that completing the reception of the next data with the RDRF flag set to 1 will cause an overrun error, resulting in the loss of the receive data.
5	ORER	Overrun Error Indicates that an overrun error has occurred during reception and the reception ended abnormally. [Setting condition] <ul style="list-style-type: none"> When the next data is received while RDRF = 1 In SCI3nRDR, data received prior to the overrun error is retained, but data received after the overrun error occurrence is lost. When the ORER flag is set to 1, subsequent serial reception cannot be continued. In clock synchronous mode, serial transmission also cannot be continued. [Clearing condition] <ul style="list-style-type: none"> Writing 0 to ORER after reading ORER = 1 Even when the RE bit in SCI3nSCR is cleared, the ORER flag is not affected and the previous value is retained.

Table 19.10 SCI3nSSR Register Contents (2/2)

Bit Position	Bit Name	Function
4	FER	<p>Framing Error</p> <p>Indicates that a framing error has occurred during reception in asynchronous mode and the reception ended abnormally.</p> <p>[Setting condition]</p> <ul style="list-style-type: none"> When the stop bit is 0 In 2-stop-bit mode, only whether the first stop bit is 1 is checked but the second stop bit is not checked. Although the receive data that existed when a framing error has occurred is transferred to SCI3nRDR, the RDRF flag is not set. In addition, while the FER flag is set to 1, the subsequent receive data is not transferred to SCI3nRDR. <p>[Clearing condition]</p> <ul style="list-style-type: none"> Writing 0 to FER after reading FER = 1 Even when the RE bit in SCI3nSCR is cleared to 0, the FER flag is not affected and the previous value is retained.
3	PER	<p>Parity Error</p> <p>Indicates that a parity error has occurred during reception in asynchronous mode and the reception ended abnormally.</p> <p>[Setting condition]</p> <ul style="list-style-type: none"> When a parity error is detected during reception Although the receive data that existed when a parity error has occurred is transferred to SCI3nRDR, the RDRF flag is not set. In addition, while the PER flag is set to 1, the subsequent receive data is not transferred to SCI3nRDR. <p>[Clearing condition]</p> <ul style="list-style-type: none"> Writing 0 to PER after reading PER = 1 Even when the RE bit in SCI3nSCR is cleared to 0, the PER flag is not affected and the previous value is retained.
2	TEND	<p>Transmit End</p> <p>[Setting conditions]</p> <ul style="list-style-type: none"> When the TE bit in SCI3nSCR is 0 When the TDRE flag is 1 while the last bit of a transmit character is being transmitted <p>[Clearing condition]</p> <ul style="list-style-type: none"> Writing 0 to the TDRE flag after reading TDRE = 1 When transmit data is written to SCI3nTDR while TE = 1
1	MPB	<p>Multi-Processor Bit</p> <p>Holds the value of the multi-processor bit in the receive frame.</p>
0	MPBT	<p>Multi-Processor Bit Transfer</p> <p>Sets the value of the multi-processor bit to be added to the transmit frame.</p>

19.3.9 SCI3nSCMR — Serial Transfer Format Register

SCI3nSCMR is a register to select transfer format which can be commonly configured for both asynchronous mode and clock synchronous mode.

Value after reset: F2_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	SDIR	SINV	—	—
Value after reset	1	1	1	1	0	0	1	0
R/W	R	R	R	R	R/W*1	R/W*1	R	R

Note 1. Writable only when TE = 0 and RE = 0.

Table 19.11 SCI3nSCMR Register Contents

Bit Position	Bit Name	Function
7 to 4	—	Reserved These bits are always read as 1. When writing, write the value after reset.
3	SDIR	Serial Data Transfer Direction (Valid in asynchronous mode and clock synchronous mode) This bit is used to select the direction of serial / parallel conversion. 0: Transfer with LSB-first 1: Transfer with MSB-first This bit is valid only when the transfer format is 8-bit data. For 7-bit data, LSB-first transfer is used.
2	SINV	Serial Data Invert (Valid in asynchronous mode and clock synchronous mode) This bit is used to invert the transfer data logic level. The SINV bit does not affect the logic level of the parity bit. To invert the parity bit, invert the PM bit in SCI3nSMR. 0: SCI3nTDR data is transmitted as it is, and receive data is stored in SCI3nRDR as it is. 1: SCI3nTDR data is inverted and transmitted, and receive data is inverted and stored in SCI3nRDR.
1	—	Reserved These bits are always read as 1. When writing, write the value after reset.
0	—	Reserved These bits are always read as 0. When writing, write the value after reset.

19.3.10 SCI3nSEMR — Serial Extended Mode Register

SCI3nSEMR is a register to select a 1-bit period.

Value after reset: 04_H

Bit	7	6	5	4	3	2	1	0
	BRME	MDDRS	—	—	ABCS	RXDMON	—	—
Value after reset	0	0	0	0	0	1	0	0
R/W	R/W*1	R/W*1	R	R	R/W*1	R	R	R

Note 1. Writable only when TE = 0 and RE = 0.

Table 19.12 SCI3nSEMR Register Contents

Bit Position	Bit Name	Function
7	BRME	Bit Rate Modulation Enable When this bit is set to 1, the bit rate modulation function is enabled.
6	MDDRS	Modulation Duty Register Select This bit is used to select an accessible register. 0: SCI3nBRR is accessible. 1: SCI3nMDDR is accessible.
5, 4	—	Reserved These bits are always read as 0. When writing, write the value after reset.
3	ABCS	Asynchronous Reference Clock Select (Valid only in asynchronous mode) This bit is used to select the reference clock for 1-bit period. 0: Operates on the reference clock with a frequency of 16 times the transfer rate. 1: Operates on the reference clock with a frequency of 8 times the transfer rate (double-speed operation).
2	RXDMON	Serial Input Data Monitor This bit indicates the SCInRxD pin state. 0: SCInRxD pin state is low level. 1: SCInRxD pin state is high level.
1, 0	—	Reserved These bits are always read as 0. When writing, write the value after reset.

19.3.11 SCI3nBRR — Bit Rate Register

SCI3nBRR is an 8-bit register to adjust the bit rate. Since each SCI3 channel has an independent baud rate generator, different bit rates can be set for each channel. **Table 19.14** shows the relationship between the setting (N) in SCI3nBRR and the bit rate (B) in normal asynchronous mode, clock synchronous mode. SCI3nBRR is allocated at the same address as SCI3nMDDR and is selected when MDDRS in SCI3nSEMR is 0. This register is writable only when TE = 0 and RE = 0.

Value after reset: FF_H

Table 19.13 SCI3nBRR Register Contents

Bit Position	Bit Name	Function
7 to 0	BRR	Baud rate generator setting (0 ≤ N ≤ 255)

Table 19.14 Relationship between Setting N in SCI3nBRR and Bit Rate B

Mode	ABCS Setting	Bit Rate	Mean Error
Asynchronous	0	$B = \frac{\phi \times 10^6}{64 \times 2^{2m-1} \times (N + 1)}$	$\text{Error (\%)} = \left\{ \frac{\phi \times 10^6}{B \times 64 \times 2^{2m-1} \times (N + 1)} - 1 \right\} \times 100$
	1	$B = \frac{\phi \times 10^6}{32 \times 2^{2m-1} \times (N + 1)}$	$\text{Error (\%)} = \left\{ \frac{\phi \times 10^6}{B \times 32 \times 2^{2m-1} \times (N + 1)} - 1 \right\} \times 100$
Clock synchronous	—	$B = \frac{\phi \times 10^6}{8 \times 2^{2m-1} \times (N + 1)}$	—

Note: B: Bit rate (bit/s)

N: SCI3nBRR setting for baud rate generator (0 ≤ N ≤ 255)

ϕ: Operating frequency PCLK (MHz)

m: Determined by the SCI3nSMR setting as shown in the following table.

SCI3nSMR Setting		m
CKS1	CKS0	
0	0	0
0	1	1
1	0	2
1	1	3

Table 19.15 lists sample N settings of the SCI3nBRR register in asynchronous mode. **Table 19.16** shows the maximum configurable bit rates.

Table 19.15 Examples of BRR Settings for Bit Rates (Asynchronous Mode)

Bit Rate (bit/s)	Operating Frequency $\phi = 40$ (MHz)							
	SCI3nSEMR.ABCS = 0				SCI3nSEMR.ABCS = 1			
	m	N	Actual Bit Rate (bit/s)	Error (%)	m	N	Actual Bit Rate (bit/s)	Error (%)
110	3	177	109.73	-0.25	—	—	—	—
150	3	129	150.24	0.16	3	255	152.59	1.73
300	3	64	300.48	0.16	3	129	300.48	0.16
600	2	129	600.96	0.16	3	64	600.96	0.16
1200	2	64	1201.92	0.16	2	129	1201.92	0.16
2400	1	129	2403.85	0.16	2	64	2403.85	0.16
4800	1	64	4807.69	0.16	1	129	4807.69	0.16
9600	0	129	9615.38	0.16	1	64	9615.38	0.16
19200	0	64	19230.77	0.16	0	129	19230.77	0.16
31250	0	39	31250.00	0.00	0	79	31250.00	0.00
38400	0	32	37878.79	-1.36	0	64	38461.54	0.16

Table 19.16 Maximum Bit Rate (Asynchronous Mode)

ϕ (MHz)	Setting			Maximum Bit Rate (bit/s)
	SCI3nSEMR.ABCS Setting	m	N	
40	0	0	0	1250000
	1	0	0	2500000

Table 19.17 lists sample N settings of the SCI3nBRR register in clock synchronous mode.

Table 19.18 shows the maximum configurable bit rates.

Table 19.17 Examples of Bit Rate Settings for Clock Synchronous Mode

Bit Rate (bit/s)	Operating Frequency $\phi = 40$ (MHz)		
	m	N	Actual Bit Rate (bit/s)
1 k	3	155	1001.60
2.5 k	2	249	2500.00
5 k	2	124	5000.00
10 k	1	249	10000.00
25 k	1	99	25000.00
50 k	1	49	50000.00
100 k	0	99	100000.00
250 k	0	39	250000.00
500 k	0	19	500000.00
1 M	0	9	1000000.00
2 M	0	4	2000000.00
2.5 M	0	3	2500000.00
5 M	0	1	5000000.00

Table 19.18 Maximum Bit Rate when Internal Clock is Output (Clock Synchronous Mode)

ϕ (MHz)	m	N	Maximum Bit Rate (bit/s)
40	0	1	5000000.00

19.3.12 SCI3nMDDR — Modulation Duty Register

SCI3nMDDR is a register to correct the bit rate adjusted by SCI3nBRR. The value of SCI3nMDDR after a reset is FF_H. When the BRME bit in SCI3nSEMR is set to 1, the bit rate generated by the on-chip baud rate generator is corrected to SCI3nMDDR / 256 on average. **Table 19.20** shows the relationship between the SCI3nMDDR setting and the bit rate B. SCI3nMDDR is allocated at the same address as SCI3nBRR and is selected when MDDRS in SCI3nSEMR is 1. This register is writable only when TE = 0 and RE = 0. Bit 7 is fixed to 1.

Value after reset: FF_H

Bit	7	6	5	4	3	2	1	0
	MDDR							
Value after reset	1	1	1	1	1	1	1	1
R/W	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 19.19 SCI3nMDDR Register Contents

Bit Position	Bit Name	Function
7 to 0	MDDR	Baud rate generator setting value (128 ≤ MDDR ≤ 255)

Table 19.20 Relationship between SCI3nMDDR Setting and Bit Rate B when Bit Rate Modulation Function Is Used

Mode	ABCS Setting	Bit Rate	Mean Error
Asynchronous	0	$B = \frac{\phi \times 10^6}{64 \times 2^{2m-1} \times (256 / \text{MDDR}) \times (N + 1)}$	$\text{Error (\%)} = \left\{ \frac{\phi \times 10^6}{B \times 64 \times 2^{2m-1} \times (256 / \text{MDDR}) \times (N + 1)} - 1 \right\} \times 100$
	1	$B = \frac{\phi \times 10^6}{32 \times 2^{2m-1} \times (256 / \text{MDDR}) \times (N + 1)}$	$\text{Error (\%)} = \left\{ \frac{\phi \times 10^6}{B \times 32 \times 2^{2m-1} \times (256 / \text{MDDR}) \times (N + 1)} - 1 \right\} \times 100$
Clock synchronous	—	$B = \frac{\phi \times 10^6}{8 \times 2^{2m-1} \times (256 / \text{MDDR}) \times (N + 1)}$	—

Note: B: Bit rate (bit/s)

N: SCI3nBRR setting of baud rate generator (0 ≤ N ≤ 255)

φ: Operating frequency PCLK (MHz)

m: See **Table 19.14**.

MDDR: SCI3nMDDR setting (128 ≤ MDDR ≤ 255)

19.4 Operation in Asynchronous Mode

Figure 19.2 shows the general format for asynchronous serial communications. One frame consists of a start bit (low level), transmit/receive data, a parity bit, and stop bits (high level). In asynchronous serial communications, the communication line is usually held in the mark state (high level). The SCI3 monitors the communication line, and when the SCI3 detects the space state (low level), it recognizes a start bit and starts serial communications. Inside the SCI3, the transmitter and the receiver are independent, enabling full-duplex communications. Both the transmitter and the receiver have a double-buffered structure so that data can be read or written during transmission or reception, enabling continuous data transmission and reception.

Figure 19.2 Data Format in Asynchronous Serial Communications (Example with 8-Bit Data, Parity, Two Stop Bits)

19.4.1 Transmission / Reception Format

Table 19.21 lists the transmission/reception formats that can be configured in asynchronous mode. Any of 12 transmission / reception formats can be selected according to the SCI3nSMR setting. For details of the multi-processor bit, see **Section 19.5, Multi-Processor Communication Function**.

Table 19.21 Serial Transmission / Reception Formats (Asynchronous Mode)

SMR Setting				Serial Transmission/Reception Format and Frame Length												
CHR	PE	MP	STOP	1	2	3	4	5	6	7	8	9	10	11	12	
0	0	0	0	S	8-bit data								STOP			
0	0	0	1	S	8-bit data								STOP	STOP		
0	1	0	0	S	8-bit data								P	STOP		
0	1	0	1	S	8-bit data								P	STOP	STOP	
1	0	0	0	S	7-bit data							STOP				
1	0	0	1	S	7-bit data							STOP	STOP			
1	1	0	0	S	7-bit data							P	STOP			
1	1	0	1	S	7-bit data							P	STOP	STOP		
0	—	1	0	S	8-bit data								MPB	STOP		
0	—	1	1	S	8-bit data								MPB	STOP	STOP	
1	—	1	0	S	7-bit data							MPB	STOP			
1	—	1	1	S	7-bit data							MPB	STOP	STOP		

Note: S: Start bit; STOP: Stop bit; P: Parity bit; MPB: Multi-processor bit

19.4.2 Receive Data Sampling Timing and Reception Margin

In asynchronous mode, the SCI3 operates on a reference clock with a frequency of 16 times (8 times for the double-speed mode) the bit rate. In reception, the SCI3 samples the beginning of the start bit (low level) using the reference clock and performs internal synchronization. As shown in **Figure 19.3**, data is latched at the middle of each bit by sampling receive data at the rising edge of the eighth pulse (fourth pulse for the double-speed mode) of the reference clock.

Thus the reception margin in asynchronous mode is determined by formula (1) below.

$$M = \left| \left(0.5 - \frac{1}{2N} \right) - (L - 0.5)F - \frac{|D - 0.5|}{N} (1 + F) \right| \times 100\% \quad \dots \text{formula (1)}$$

M: Reception margin

N: Ratio of bit rate to clock (N = 16 when ABCS in SCI3nSEMR = 0, N = 8 when ABCS in SCI3nSEMR = 1)

D: Duty cycle of clock (D = 0.5 to 1.0)

L: Frame length (L = 9 to 12)

F: Absolute value of clock frequency deviation

Assuming that F (absolute value of clock frequency deviation) = 0, D (duty cycle of clock) = 0.5, and N = 16 in formula (1), the reception margin is obtained by the formula below.

$$M = \left\{ 0.5 - \frac{1}{(2 \times 16)} \right\} \times 100\% = 46.875\%$$

However, this is only the calculated value, and a margin of 20% to 30% should be allowed in system design.

When the bit rate modulation function is used, the reference clock frequency is corrected on average.

Figure 19.3 Receive Data Sampling Timing in Asynchronous Mode

19.4.3 Clock

An internal clock generated by the on-chip baud rate generator can be set as the SCI3's transmission / reception clock according to the settings of the CM bit in SCI3nSMR and the CKE1 and CKE0 bits in SCI3nSCR. When the SCI3 is operated on an internal clock, the clock can be output from the SCInSCK pin. For details of clock synchronous mode, see **Section 19.6, Operation in Clock Synchronous Mode**.

In asynchronous mode, the frequency of the clock output is equal to the bit rate and the phase is such that the rising edge of the clock comes at the center of the transmit data, as shown in **Figure 19.4**.

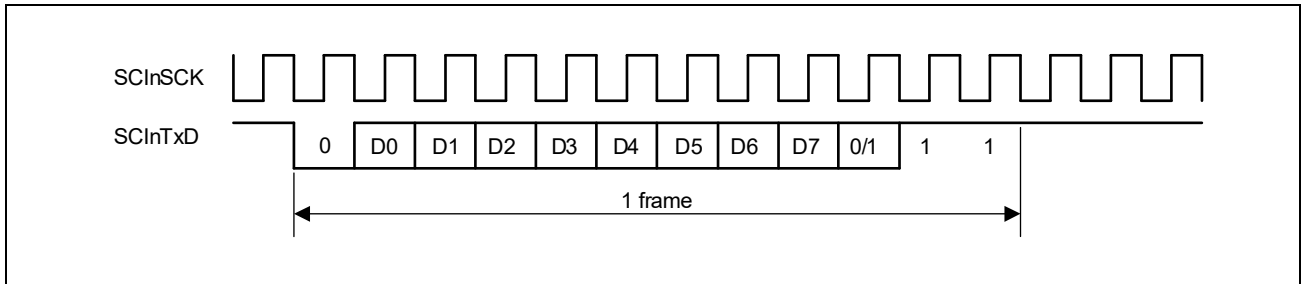

Figure 19.4 Phase Relationship between Output Clock and Transmit Data (Asynchronous Mode)

19.4.4 Double-Speed Operation

In addition to the operation described in **Section 19.4.3, Clock**, double-speed operation is enabled by the setting of the ABCS bit in SCI3nSEMR. In double-speed operation, the same operation on a clock with a frequency of 16 times the bit rate in normal operation can be conducted on a clock with a frequency of 8 times the bit rate, meaning that the SCI3 operates on a double transfer rate using the same reference clock.

Double-speed operation can be configured with either an internal clock generated by the on-chip baud rate generator.

19.4.5 SCI3 Initialization (Asynchronous Mode)

Before transmitting and receiving data, clear the TE and RE bits in SCI3nSCR and then initialize the SCI3 according to the sample flowchart in **Figure 19.5**. Before changing the operating mode or transfer format, be sure to clear the TE and RE bits to 0. Note that clearing the TE bit to 0 sets the TDRE flag to 1, but clearing the RE bit to 0 initializes neither the RDRF, PER, FER, and ORER flags nor SCI3nRDR.

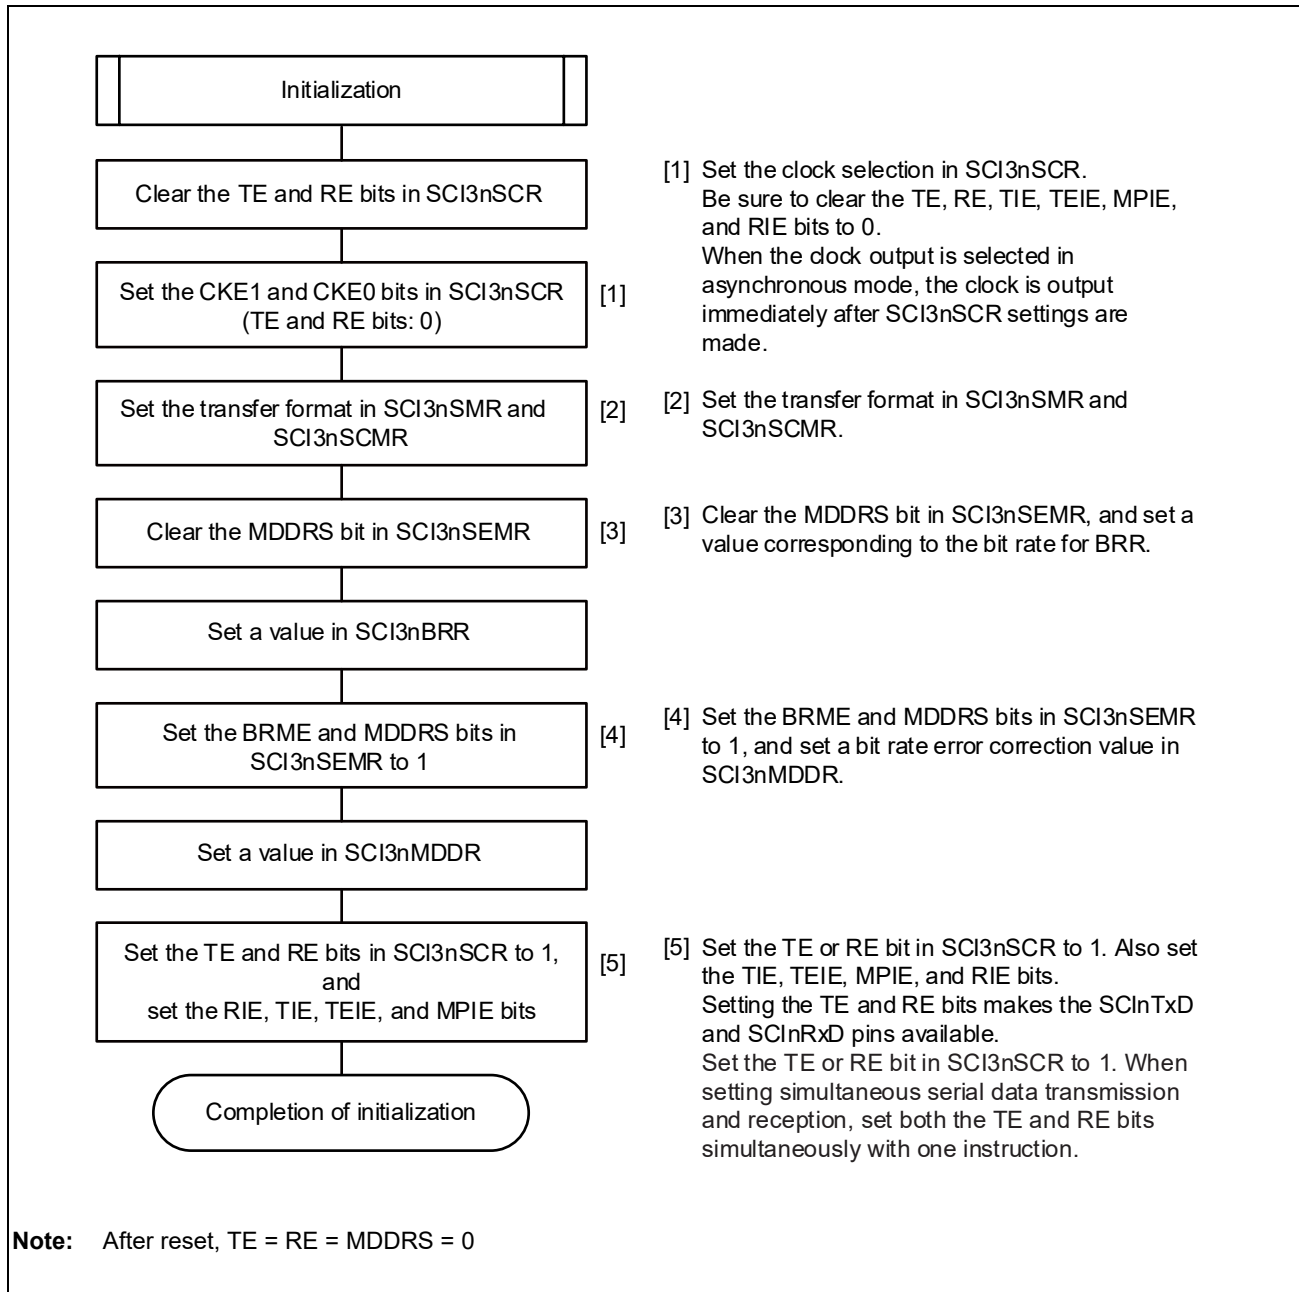

Figure 19.5 Sample Flowchart for SCI3 Initialization

19.4.6 Serial Data Transmission (Asynchronous Mode)

Figure 19.6 shows an example of operation for data transmission in asynchronous mode. In data transmission, the SCI3 operates as described below.

1. When the TE bit is set to 1, the High level (Preamble) for one frame is output.
2. When writing transmit data to SCI3nTDR at a trigger of TXI interrupt request, set the TIE bit to 1 and then set the TE bit to 1 or set both TIE and TE bits simultaneously with one instruction to generate a TXI interrupt request for starting data transfer. Set the TIE bit to 0 when a TXI interrupt request is not used.
3. When transmit data is written to SCI3nTDR, the TDRE flag is automatically cleared to 0. The SCI3 monitors the TDRE flag in SCI3nSSR. When the flag is cleared, the SCI3 recognizes that data has been written to SCI3nTDR and transfers data from SCI3nTDR to SCI3nTSR. When transmit data is written to SCI3nTDR while Preamble is output, the transmit data is transferred from SCI3nTDR to SCI3nTSR after Preamble is output.
4. Transmission starts after data is transferred from SCI3nTDR to SCI3nTSR and the TDRE flag is set to 1. If the TIE bit in SCI3nSCR is set to 1 at this time, a TXI interrupt request is generated.
5. Continuous transmission is enabled by writing the next transmit data to SCI3nTDR in this TXI interrupt processing routine before transmission of the previously transferred data is completed. When an TEI interrupt request is used, the TIE bit is cleared to 0 after the last transmit data has been written to SCI3nTDR, and the TEIE bit is set to 1.
6. Data is sent from the SCInTxD pin in the following order: start bit, transmit data, parity bit or multi-processor bit (may be omitted depending on the format), and stop bit.
7. The TDRE flag is checked when the stop bit is output.
8. When the TDRE flag is 0, the next transmit data is transferred from SCI3nTDR to SCI3nTSR, and re-performs transmission from the procedure No.4.
9. When the TDRE flag is 1, the TEND flag in SCI3nSSR is set to 1, the stop bit is sent, and then 1 is output to enter the mark state. If the TEIE bit in SCI3nSCR is set to 1 at this time, a TEI interrupt request is generated.

Figure 19.8 shows a sample flowchart for data transmission. **Figure 19.9** shows a sample flowchart for stopping the SCI3 after data transmission.

It is unnecessary to clear the TE bit to 0 as long as communication format change, bit rate change, or transmission interruption are not required. Note that communication efficiency may be decreased by Preamble operation when the TE bit is set from 0 to 1 in each transmission.

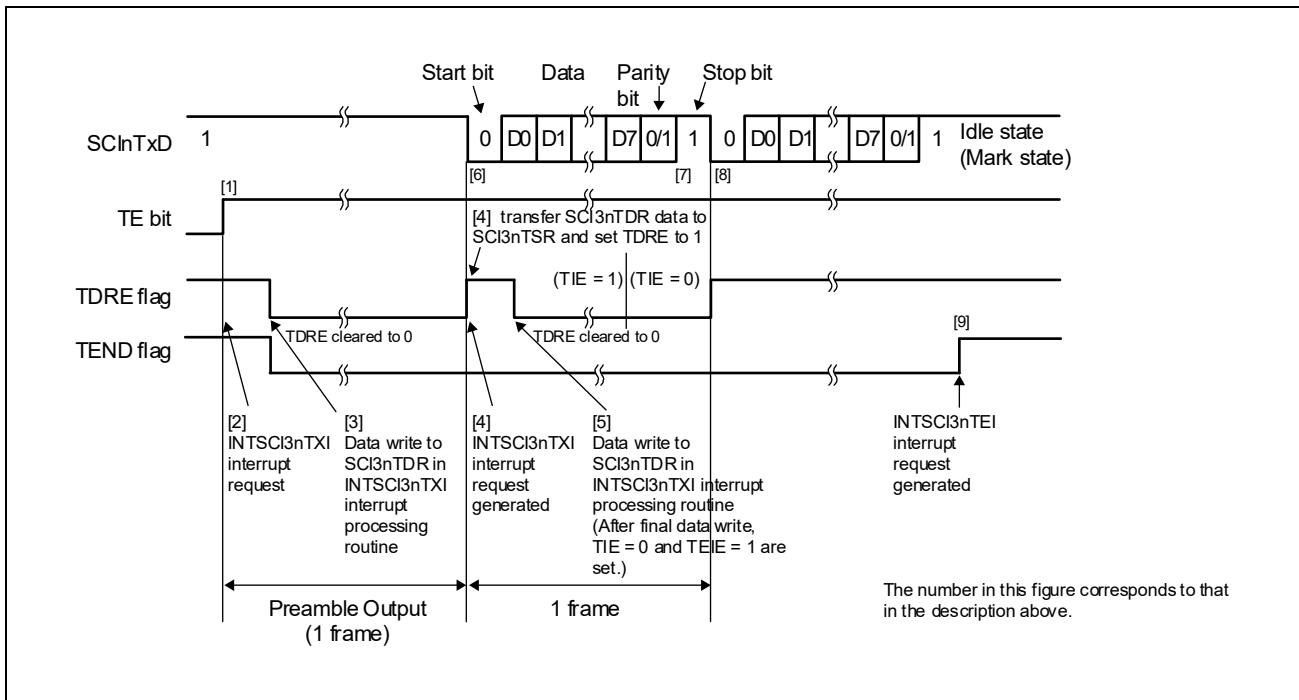

Figure 19.6 Example of Operation for Transmission in Asynchronous Mode (Example with 8-Bit Data, Parity, One Stop Bit)

CAUTION

Do not clear the TDRE flag by writing SCI3nSSR register while the TE bit is set to 1. If the TDRE flag is cleared by register operation before writing data to SCI3nTDR, the register value of SCI3nTDR is transferred to SCI3nTSR at the next transmission start timing and its data value is transmitted. Thus, unintended data may be transferred.

The purpose of Preamble output:

When the TE bit is changed from 0 to 1, the High level (Preamble) for one frame is output so that SCI3 can communicate normally after the transmission is aborted and resumed as follows. Even if the receiver becomes uncertain due to the transmission abortion by the transmitter, the resumed transmission starts after the period of one frame, and the receiver can detect the start bit of the next frame.

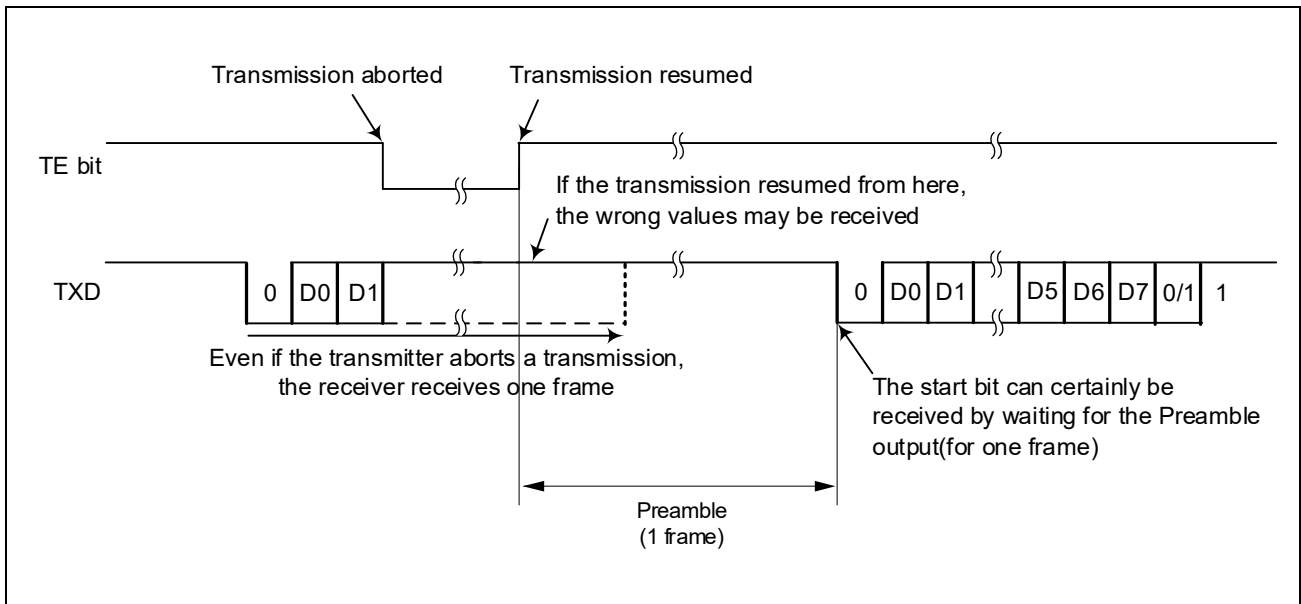

Figure 19.7 Example of Preamble Output

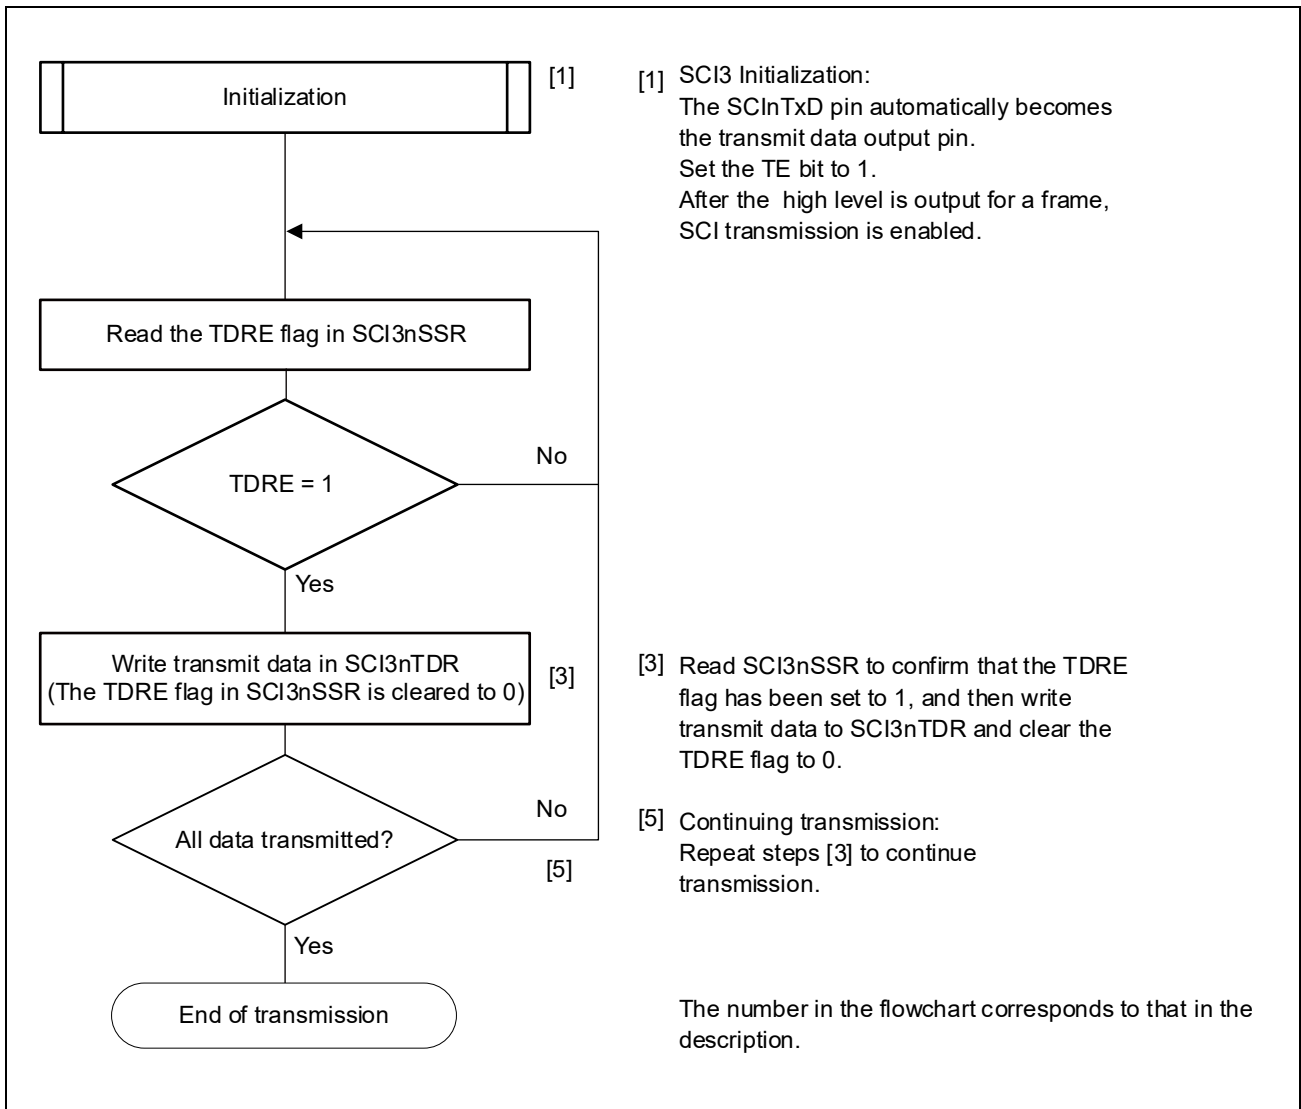

Figure 19.8 Example of Serial Transmission Flowchart

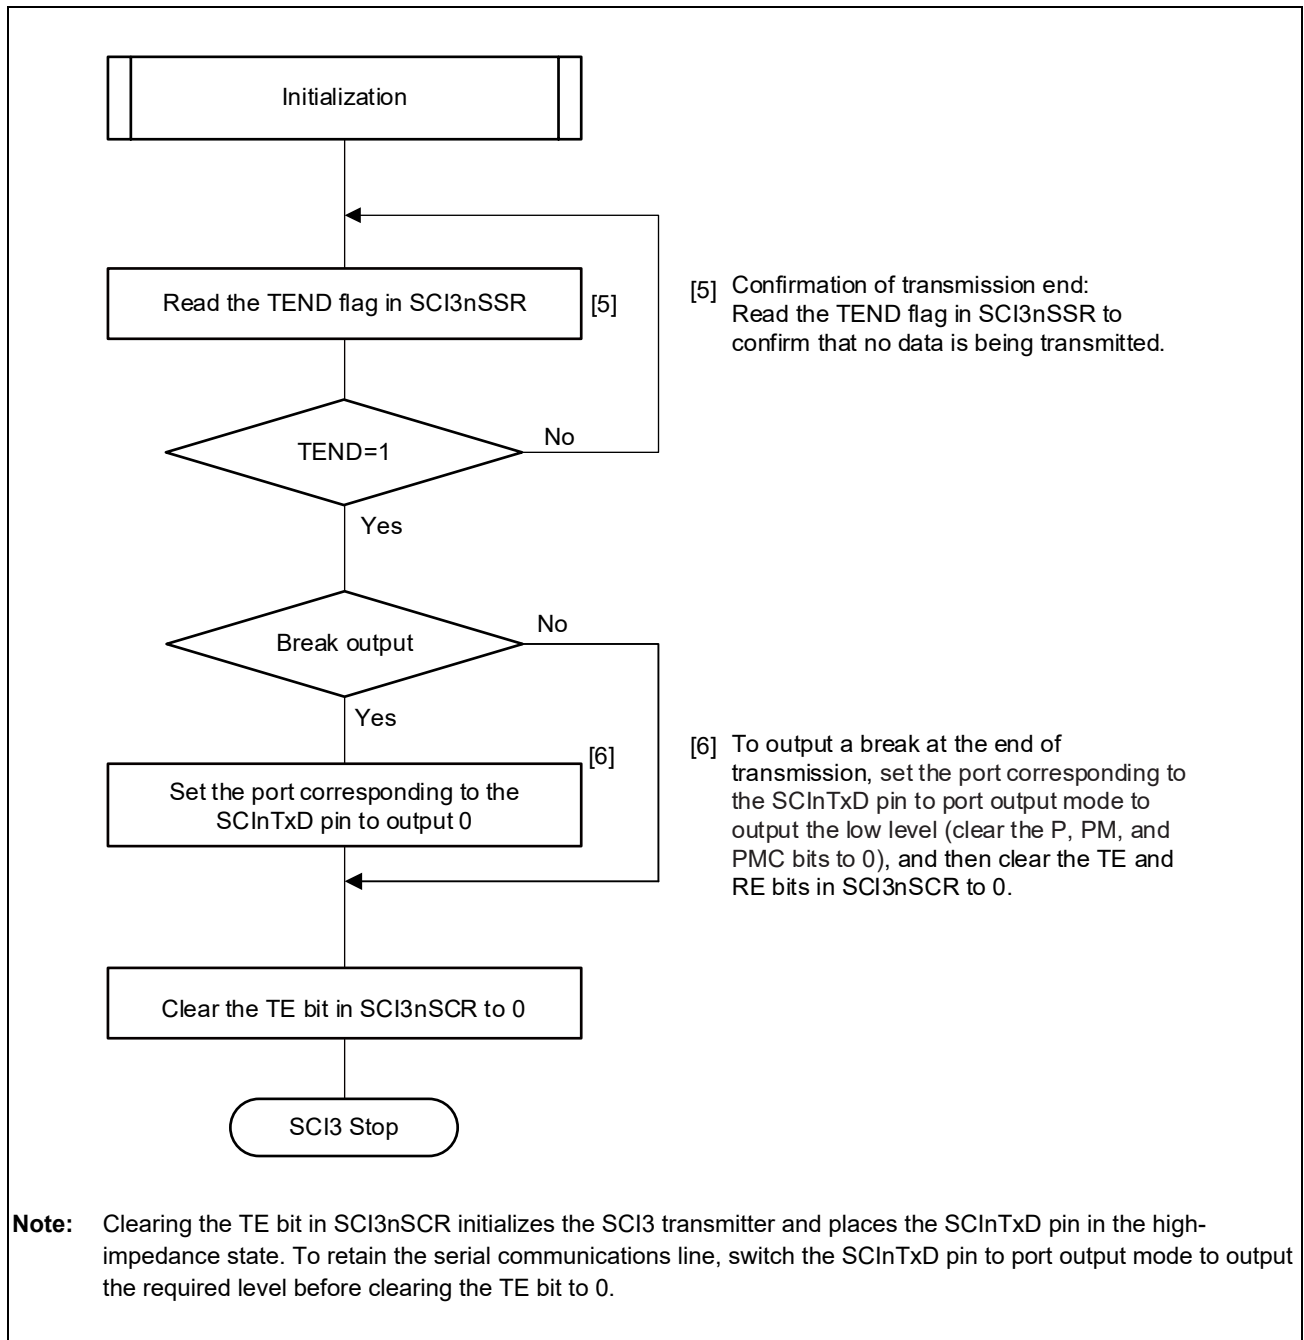

Figure 19.9 Example Flowchart for Stopping the SCI3 after Serial Transmission

19.4.7 Serial Data Reception (Asynchronous Mode)

Figure 19.10 shows an example of the operation for data reception in asynchronous mode. In data reception, the SCI3 operates as described below.

1. SCI3 monitors the communications line and upon detection of a start bit, it performs internal synchronization, stores receive data in SCI3nRSR, and checks the parity bit and the stop bit.
2. When an overrun error occurs (the next data has been received with the RDRF flag in SCI3nSSR set to 1), the ORER flag in SCI3nSSR is set to 1. If the RIE bit in SCI3nSCR is set to 1 at this time, an ERI interrupt request is generated. Receive data is not transferred to SCI3nRDR. The RDRF flag retains the state of being set to 1.
3. When a parity error is detected, the PER flag in SCI3nSSR is set to 1 and receive data is transferred to RDR. If the RIE bit in SCI3nSCR is set to 1 at this time, an ERI interrupt request is generated.
4. When a framing error (when the stop bit is 0) is detected, the FER flag in SCI3nSSR is set to 1 and receive data is transferred to SCI3nRDR. If the RIE bit in SCI3nSCR is set to 1 at this time, an ERI interrupt request is generated.
5. When reception finishes successfully, the RDRF flag in SCI3nSSR is set to 1 and receive data is transferred to SCI3nRDR. If the RIE bit in SCI3nSCR is set to 1 at this time, an RXI interrupt request is generated. Continuous reception is enabled by reading the receive data transferred to SCI3nRDR in this RXI interrupt processing routine before reception of the next receive data is completed. Reading the SCI3nRDR automatically clears the RDRF flag to 0.

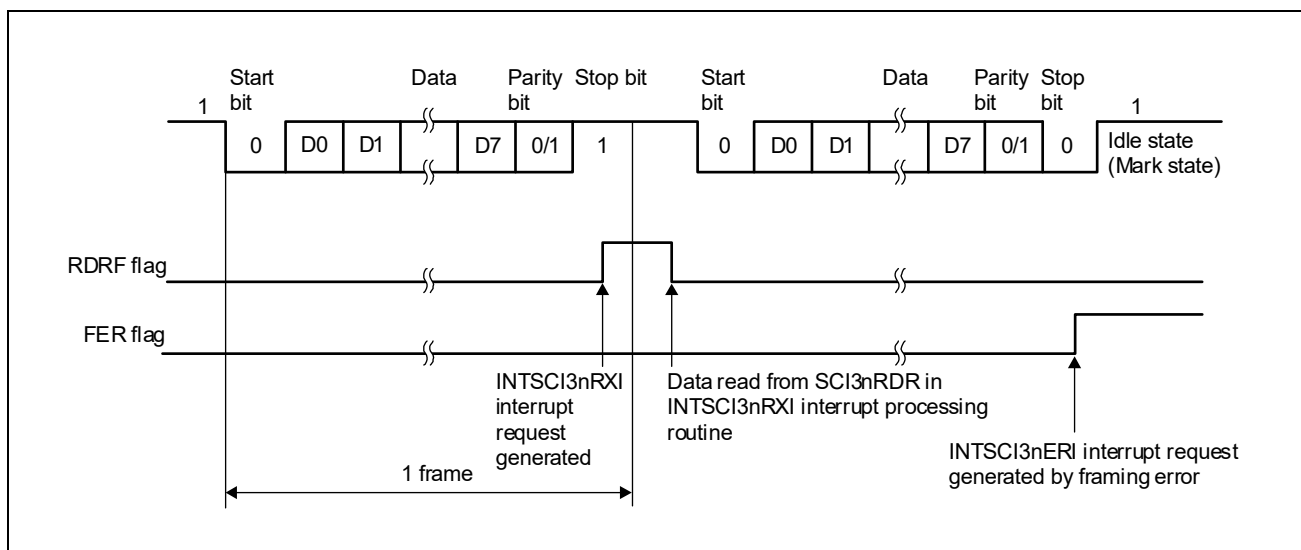

Figure 19.10 Example of Operation for Reception in Asynchronous Mode (Example with 8-Bit Data, Parity, One Stop Bit)

Table 19.22 lists the states of the SCI3nSSR status flags and receive data handling when a receive error is detected. When a receive error is detected, the RDRF flag retains the status before receiving the data. Subsequent data reception is disabled while a receive error flag is set to 1. Accordingly, clear the ORER, FER, PER, and RDRF flags before continuing data reception. **Figure 19.11** or **Figure 19.12** shows sample flowchart for data reception.

Table 19.22 SCI3nSSR Status Flags and Receive Data Handling

SCI3nSSR Status Flags				Receive Data	Receive Status
RDRF*1	ORER	FER	PER		
1	0	0	0	Transferred to SCI3nRDR	Successful reception
0	0	1	0	Transferred to SCI3nRDR	Framing error
0	0	0	1	Transferred to SCI3nRDR	Parity error
0	0	1	1	Transferred to SCI3nRDR	Framing error + parity error
1*1	1	0	0	Lost	Overrun error
1*1	1	1	0	Lost	Overrun error + framing error
1*1	1	0	1	Lost	Overrun error + parity error
1*1	1	1	1	Lost	Overrun error + framing error + parity error

Note: "+" indicates that two or more receive statuses occur simultaneously in a single reception operation.

Note 1. In the case of an overrun error, the RDRF flag retains the state before the data reception.

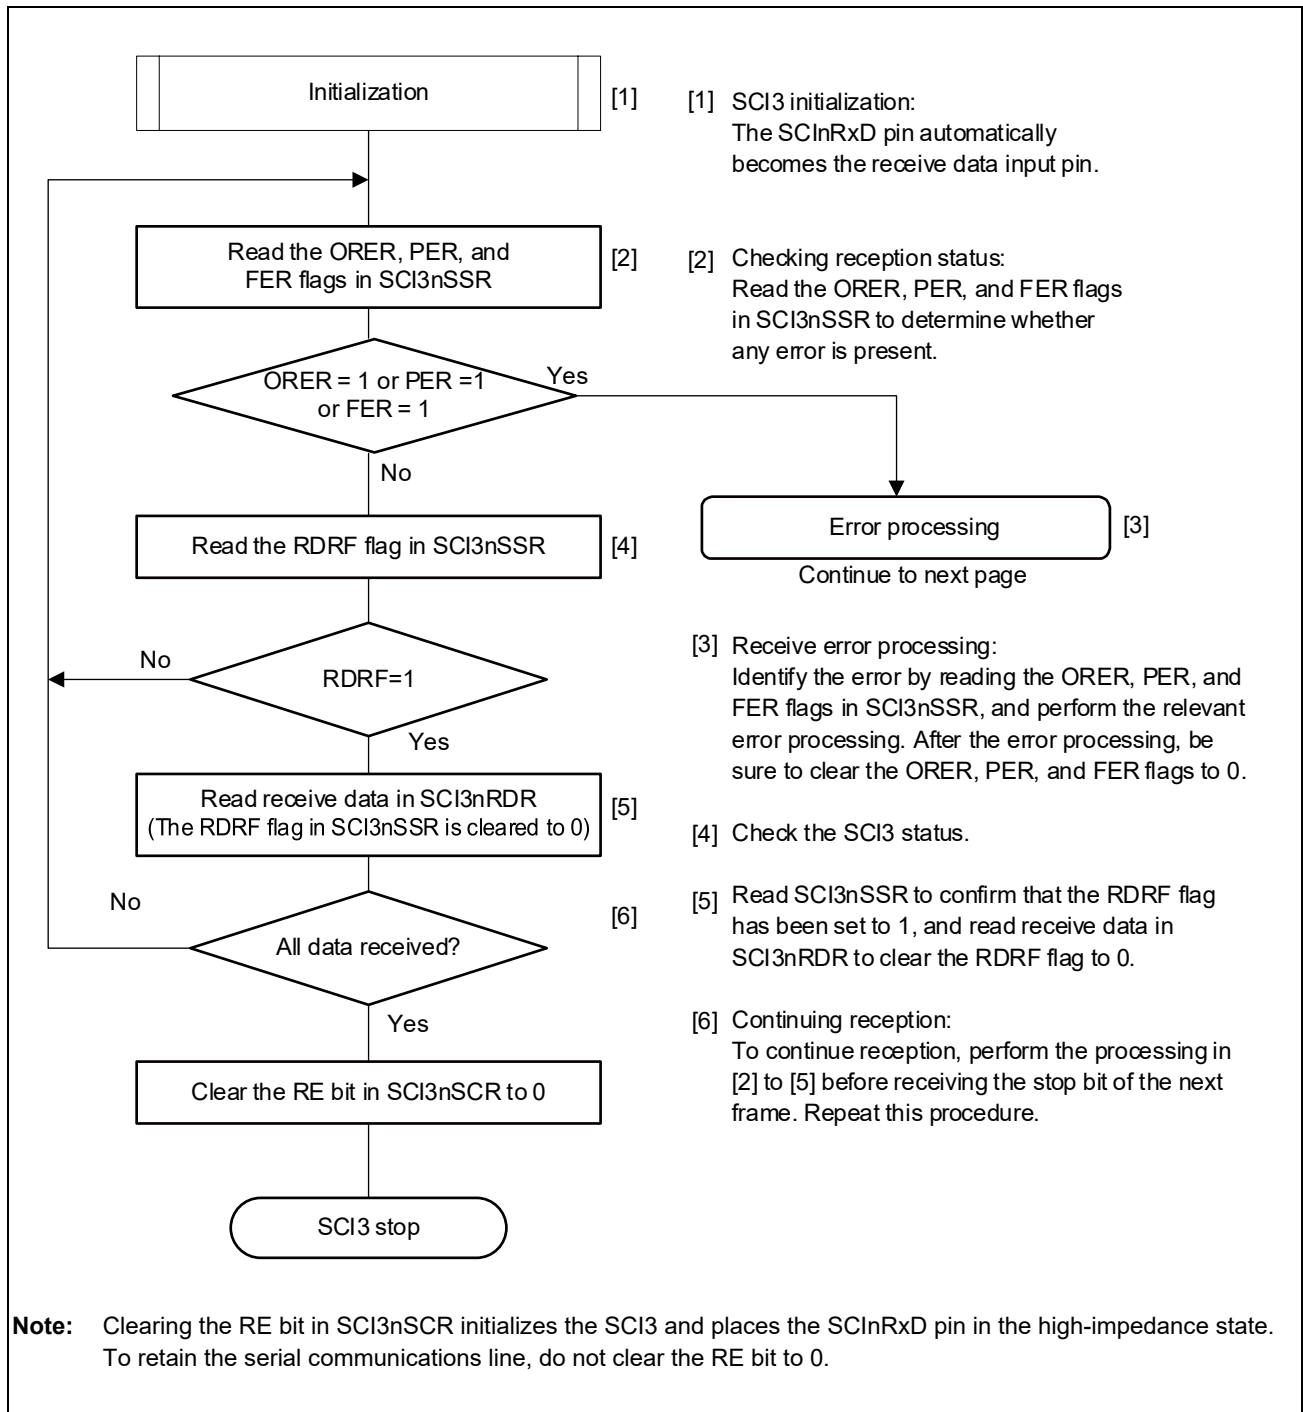

Figure 19.11 Example of Serial Reception Flowchart (1)

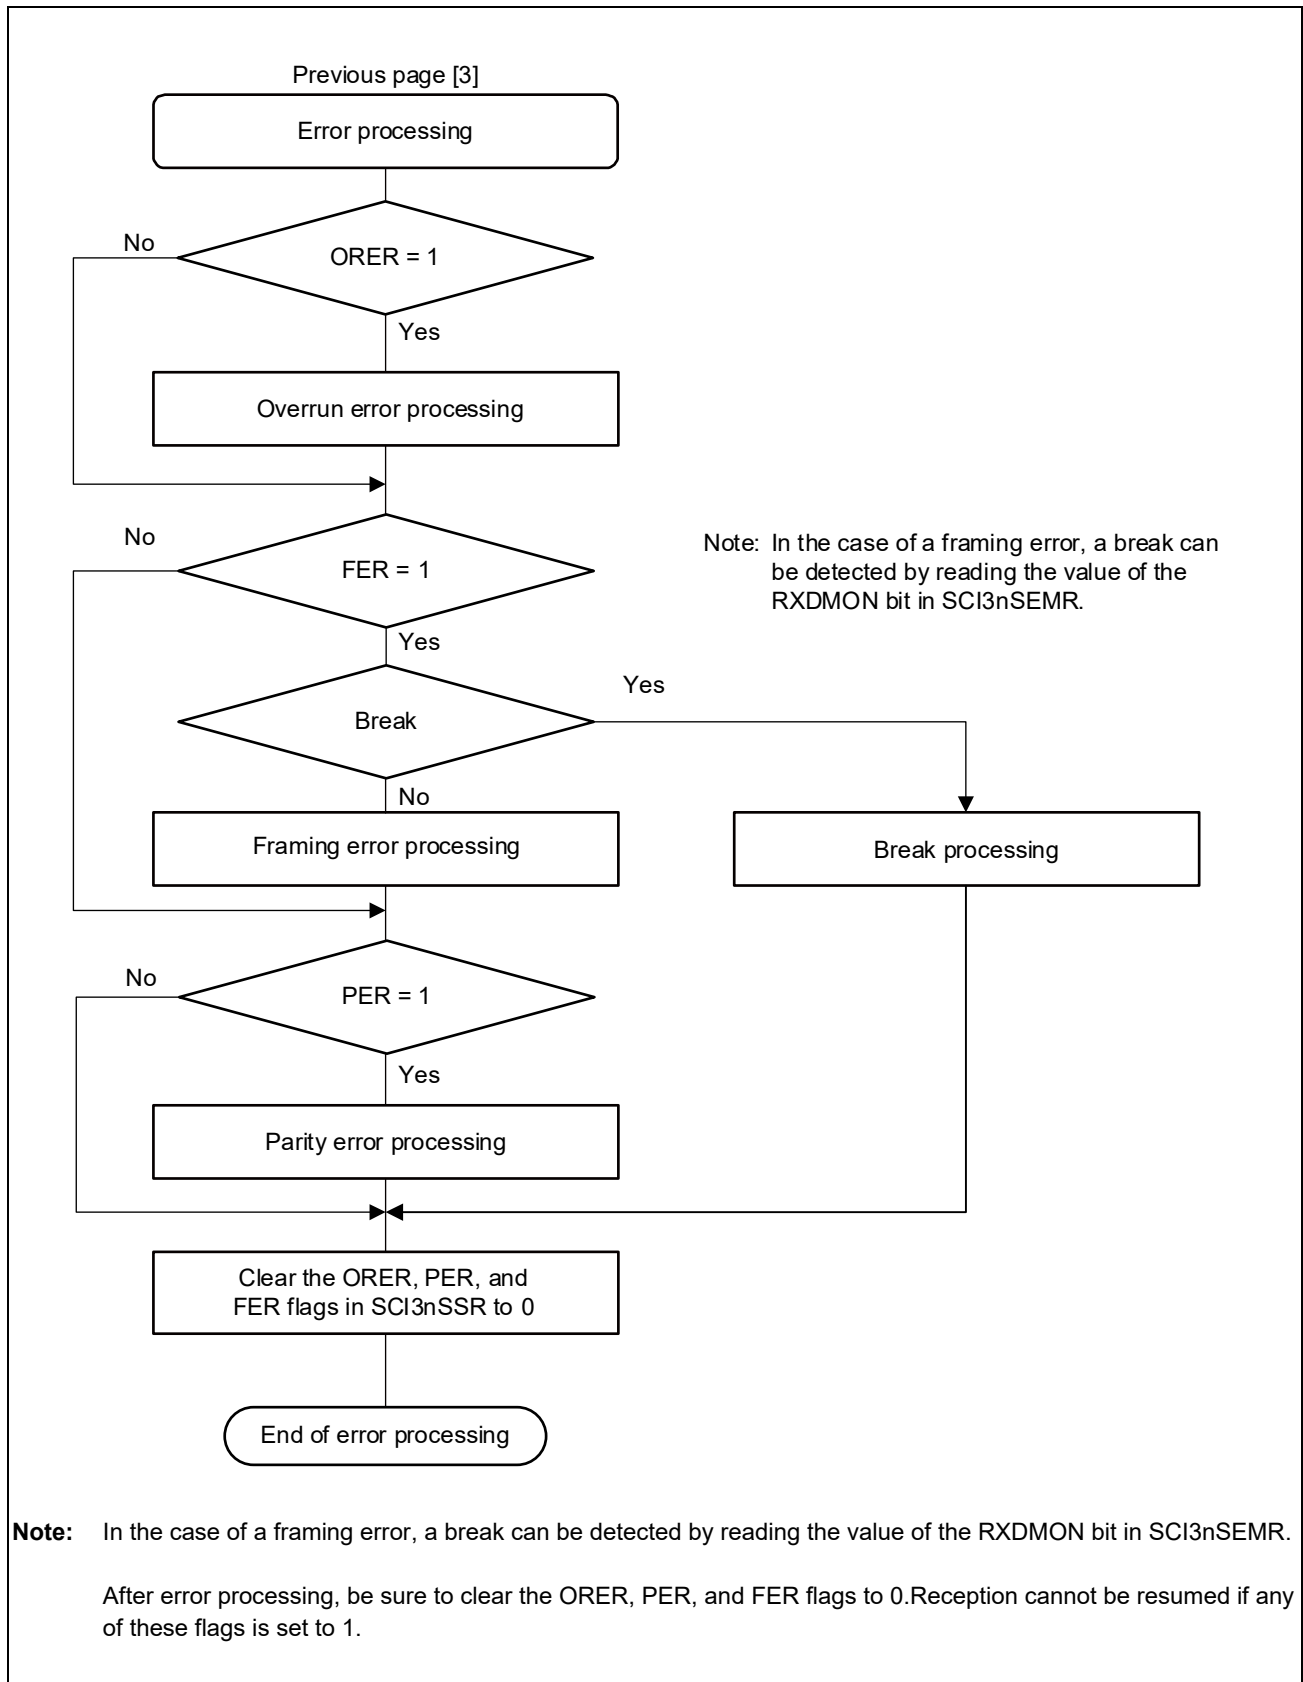

Figure 19.12 Example of Serial Reception Flowchart (2)

19.5 Multi-Processor Communication Function

19.5.1 Overview and Sample Connection

Using the multi-processor communication function allows data transmission and reception by sharing a communication line between multiple processors by using asynchronous serial communication in which the multi-processor bit is added. In multi-processor communication, a unique ID code is allocated to each receiving station. Serial communication cycles consist of an ID transmission cycle to specify the receiving station and a data transmission cycle to transmit data to the specified receiving station. The multi-processor bit is used to distinguish the ID transmission cycle from the data transmission cycle. When the multi-processor bit is set to 1, it indicates the ID transmission cycle. When the multi-processor bit is set to 0, it indicates the data transmission cycle. **Figure 19.13** shows an example of communication between processors by using the multi-processor format. First, a transmitting station sends communication data in which the multi-processor bit (= 1) is added to the ID code of the receiving station. Next, the transmitting station sends communication data in which the multi-processor bit (= 0) is added to the transmit data. Upon receiving the communication data in which the multi-processor bit is set to 1, the receiving station compares the received ID with the ID of the receiving station itself. When these IDs match, the receiving station receives communication data that is subsequently transmitted. If these IDs do not match, the receiving station skips communication data until it receives communication data in which the multi-processor bit is set to 1.

To support this function, the SCI3 provides the MPIE bit in SCI3nSCR. When the MPIE bit is set to 1, transfer of receive data from SCI3nRSR to SCI3nRDR, detection of a receive error, and setting the RDRF, FER, and ORER flags in SCI3nSSR are disabled until data in which the multi-processor bit is set to 1 is received. Upon receiving a character in which the multi-processor bit is set to 1, the MPB bit in SCI3nSSR is set to 1 and the MPIE bit is automatically cleared to 0, thus returning to a normal reception operation. When the RIE bit in SCI3nSCR is set to 1 at this time, an RXI interrupt request is generated. While the MPIE bit is cleared to 0, reception operation is conducted regardless of the multi-processor bit value. The multi-processor bit is stored in the MPB bit in SCI3nSSR.

When the multi-processor format is specified, specification of the parity bit is disabled. Apart from this, there is no difference from the operation in the normal asynchronous mode. A clock that is used for multi-processor communications is also the same as the clock used in the normal asynchronous mode.

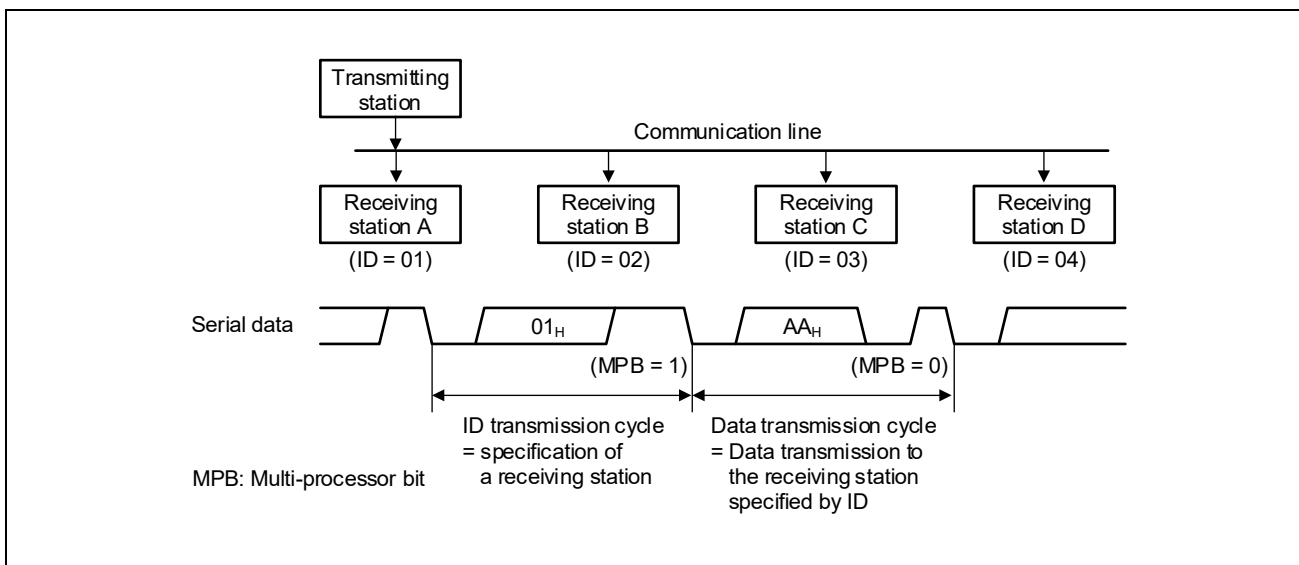

Figure 19.13 Example of Communication Using the Multi-Processor Format (Example of Transmission of Data AA_H to Receiving Station A)

19.5.2 Multi-Processor Serial Data Transmission

Figure 19.14 shows a sample flowchart of multi-processor data processing. In the ID transmission cycle, send the ID with the MPBT bit in SCI3nSSR set to 1. In the data transmission cycle, send data with the MPBT bit in SCI3nSSR cleared to 0. Other operations are the same as operations in asynchronous mode.

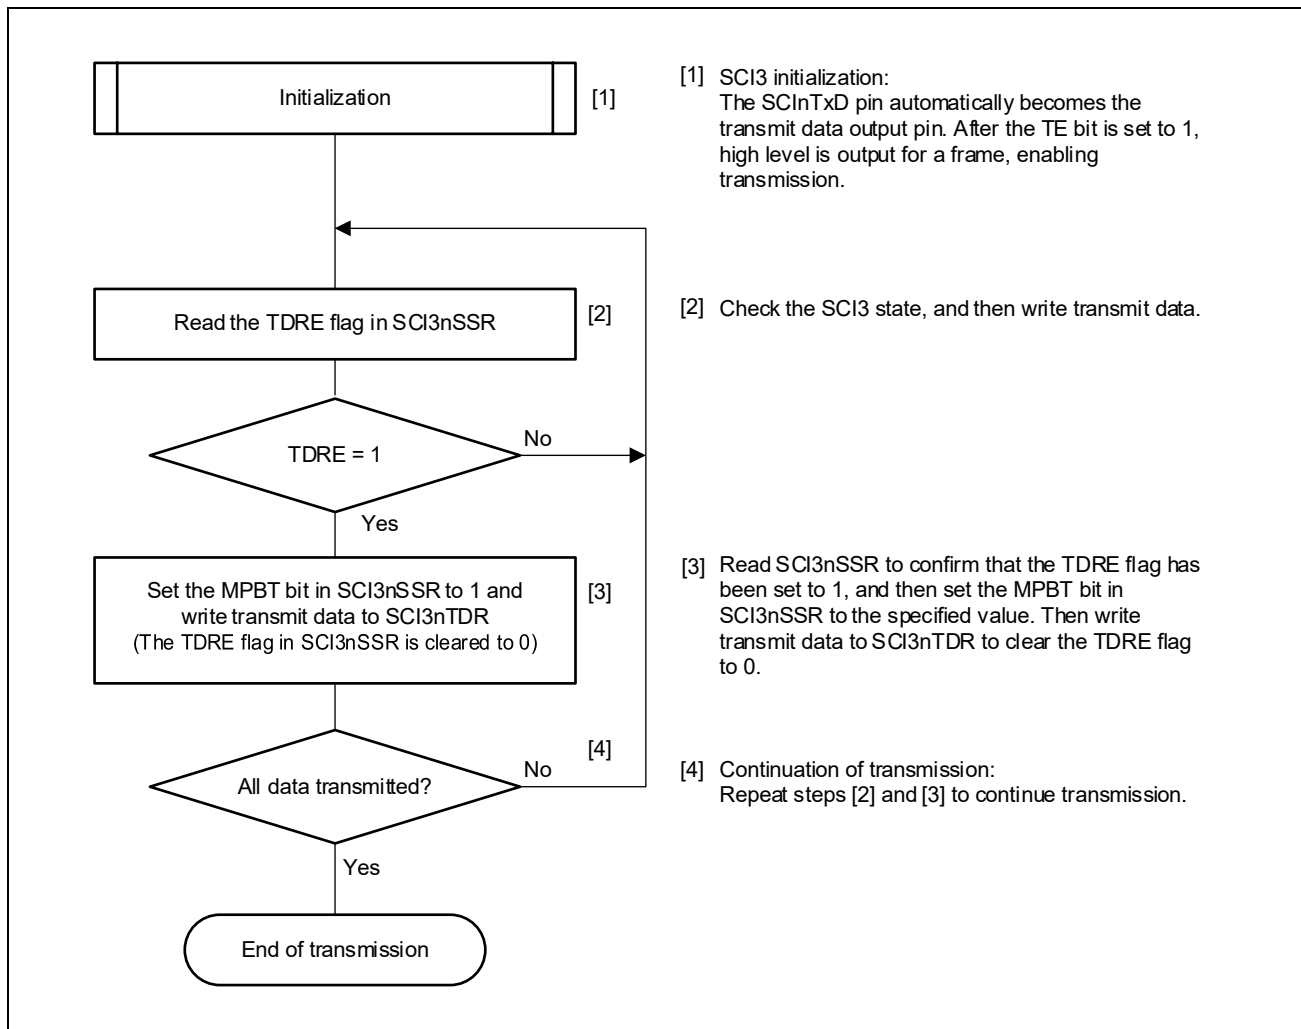

Figure 19.14 Example of Multi-Processor Serial Transmission Flowchart

19.5.3 Multi-Processor Serial Data Reception

Figure 19.16 to Figure 19.18 shows sample flowcharts of multi-processor data reception. When the MPIE bit in SCI3nSCR is set to 1, reading the communication data is skipped until communication data in which the multi-processor bit is set to 1 is received. When communication data in which the multi-processor bit is set to 1 is received, the receive data is transferred to SCI3nRDR. At this time, an RXI interrupt request is generated. Other operations are the same as operations in asynchronous mode. Figure 19.15 shows an example of operation for reception.

CAUTION

Do not write data to SCI3nSCR when communication data in which the multi-processor bit is set to 1 is received. The MPIE bit may not become the desired state.

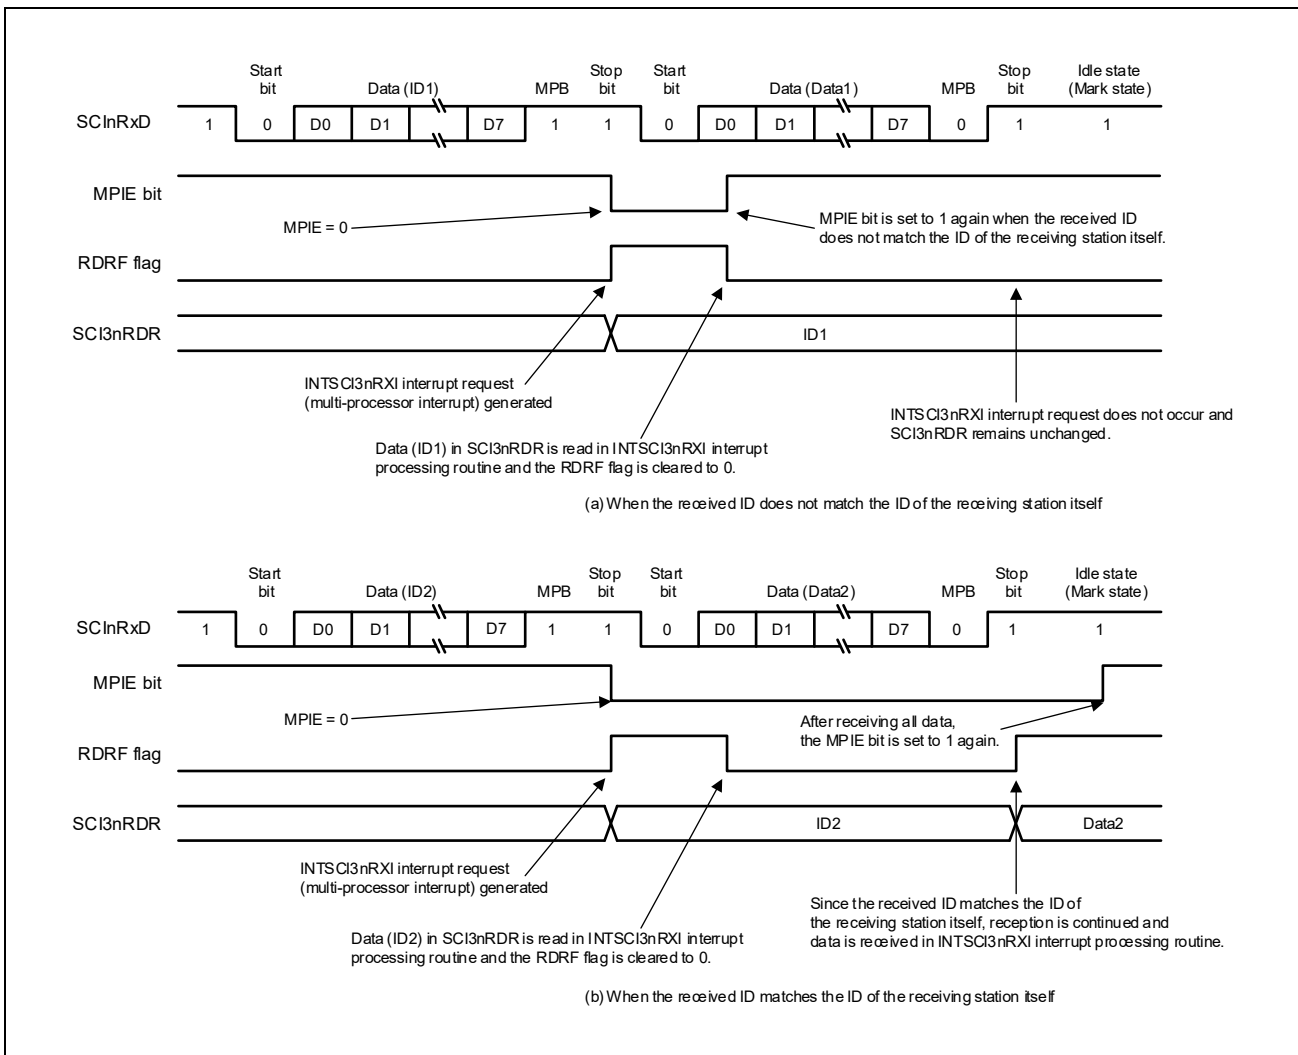

Figure 19.15 Example of SCI3 Reception (8-Bit Data, Multi-Processor Bit, One Stop Bit)

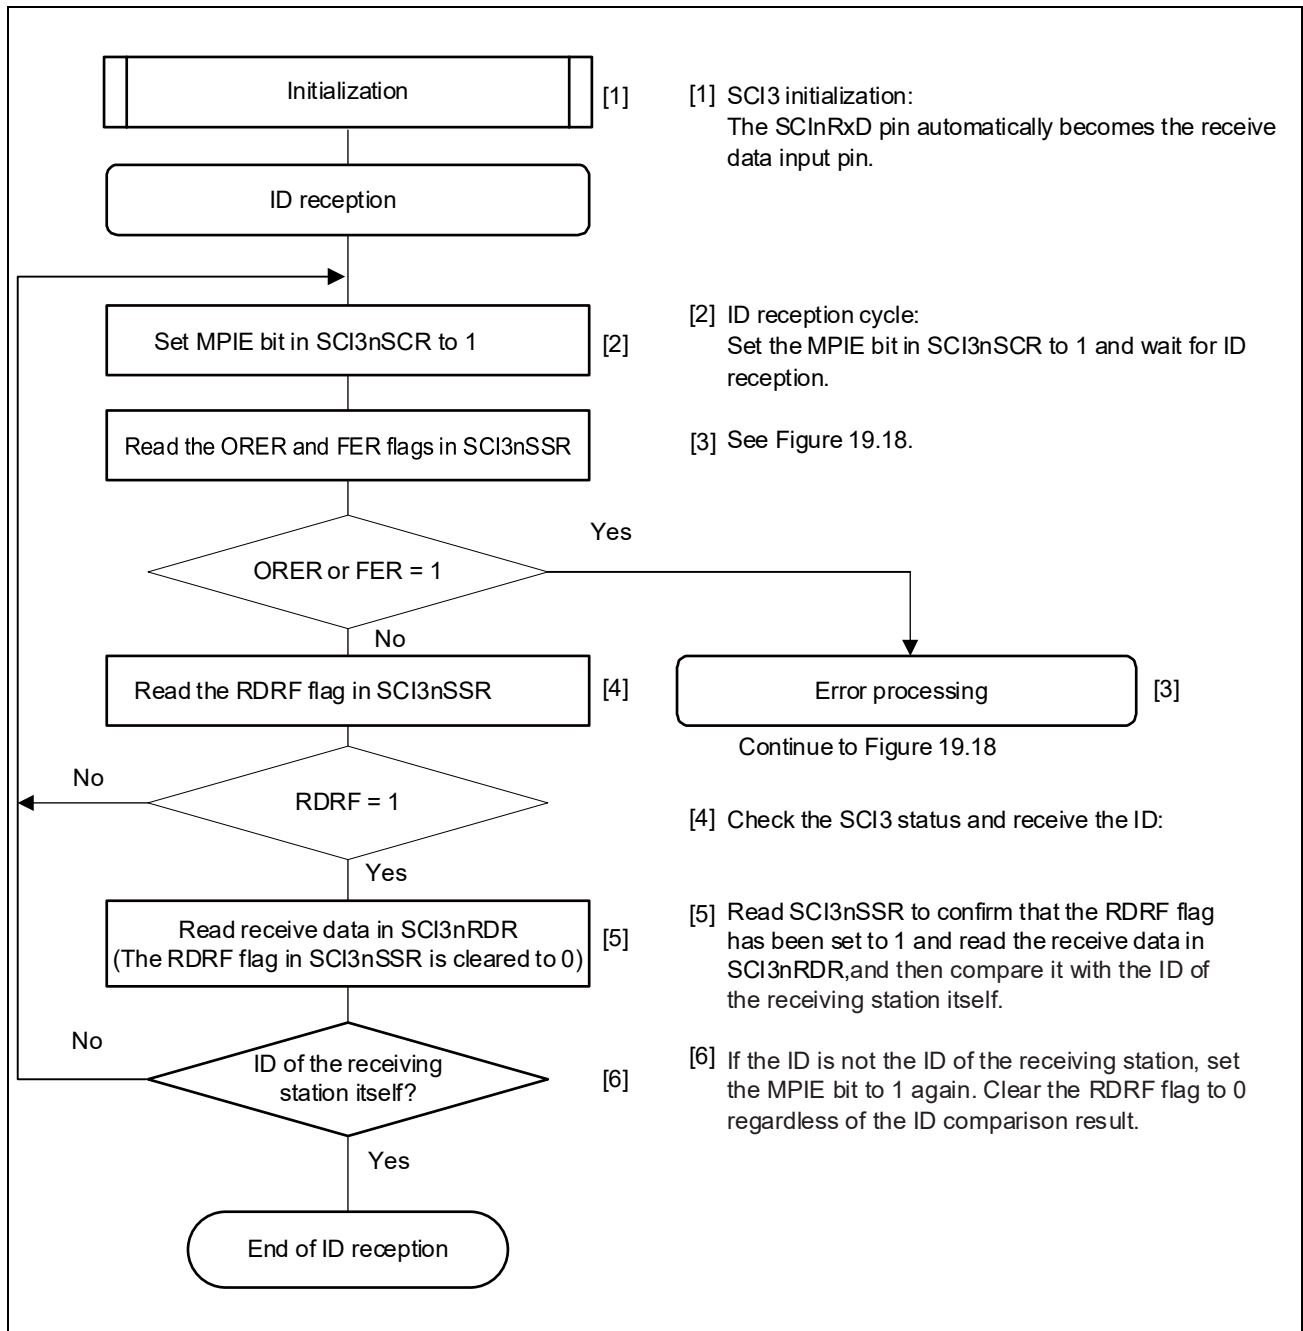

Figure 19.16 Example of Multi-Processor Serial Reception Flowchart (1)

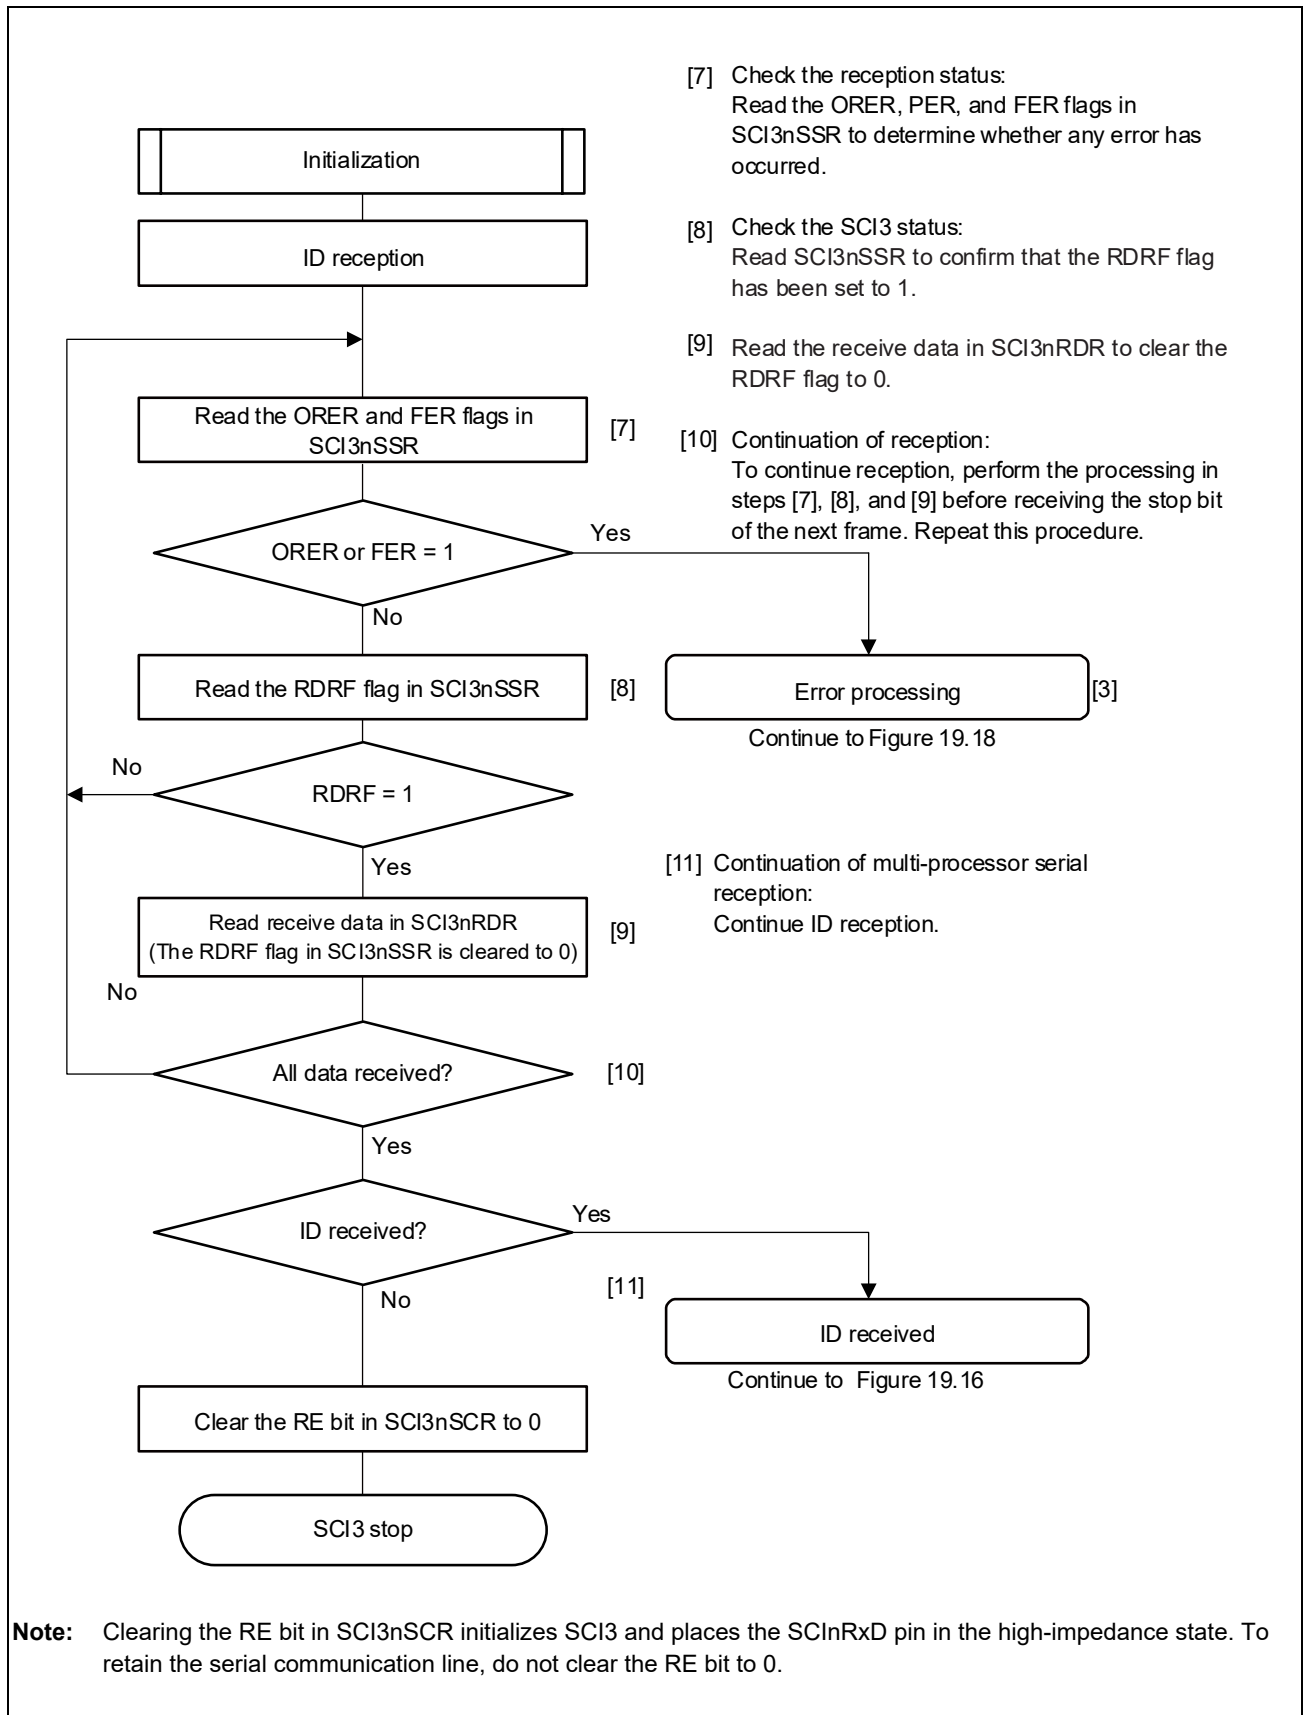

Figure 19.17 Example of Multi-Processor Serial Reception Flowchart (2)

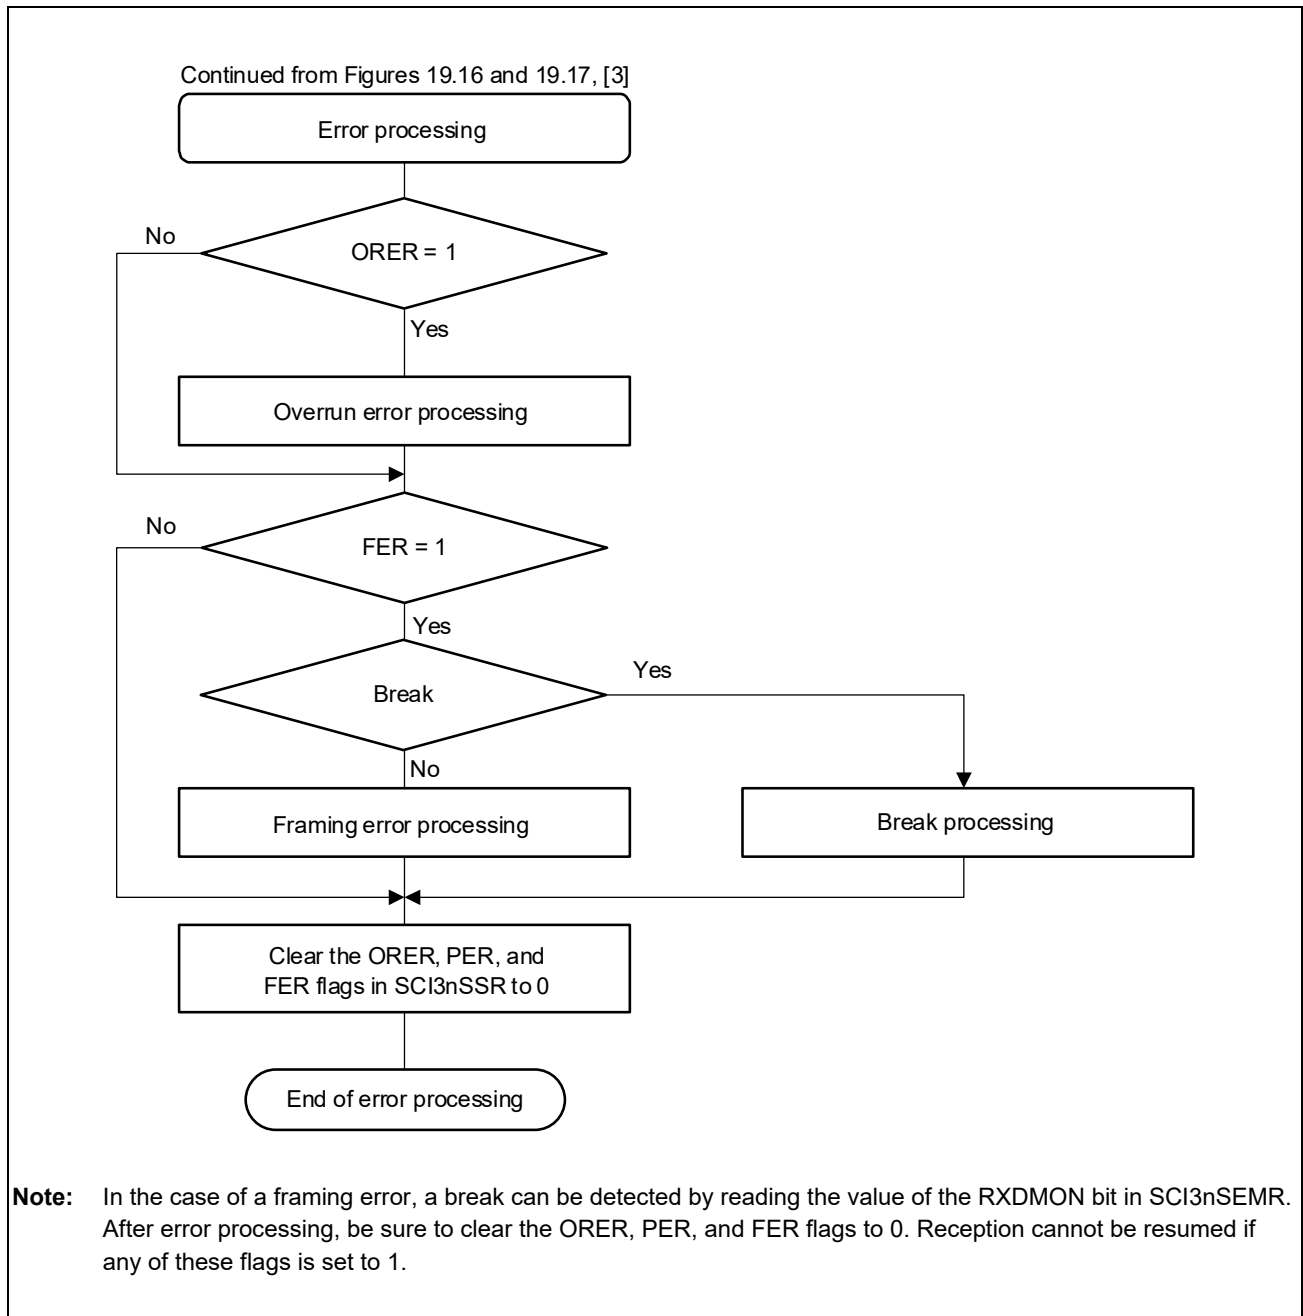

Figure 19.18 Example of Multi-Processor Serial Reception Flowchart (3)

19.6 Operation in Clock Synchronous Mode

Figure 19.19 shows the data format for clock synchronous serial data communication. In clock synchronous mode, data is transmitted or received in synchronization with clock pulses. One character in transfer data consists of 8-bit data. In data transmission with the synchronization clock output, the SCI3 outputs data from one falling edge to the next falling edge of the synchronization clock. In data transmission with the synchronization clock input, the SCI3 outputs the first data (bit 0) after starting transfer immediately after clearing the TDRE bit in SCI3nSSR to 0, and then outputs the next bit data after 2 to 3 ϕ clock cycles from the falling edge of the synchronization clock. In data reception, the SCI3 receives data in synchronization with the rising edge of the synchronization clock. After 8-bit data is output, the communication line holds the last-bit output state. In clock synchronous mode, neither parity bit nor multi-processor bit can be added. The transmitter and the receiver are independent in the SCI3, enabling full-duplex communication by using a common clock. Both the transmitter and the receiver have a double-buffered structure so that the next transmit data can be written during transmission or the previous receive data can be read during reception, enabling continuous data transfer.

Figure 19.19 Data Format in Clock Synchronous Mode (LSB-First)

19.6.1 Clock

An internal clock generated by the on-chip baud rate generator or an external synchronous clock that is input from the SCInSCK pin can be selected by the setting of the CKE1 and CKE0 bits in SCI3nSCR. When operating the SCI3 on the internal clock, a synchronous clock is output from the SCInSCK pin. Eight pulses of the synchronous clock are output during transfer of one character, and the clock is held high while no data is transferred.

19.6.2 SCI3 Initialization (Clock Synchronous Mode)

Before transmitting and receiving data, clear the TE and RE bits in SCI3nSCR to 0 and then initialize the SCI3 according to the sample flowchart in **Figure 19.20**. To switch the operation between transmission, reception, and transmission / reception, clear the TE and RE bits to 0 and then set these bits to the desired value. Before changing the transfer format, be sure to clear the TE and RE bits to 0. Note that clearing the TE bit to 0 sets the TDRE flag to 1, but clearing the RE bit to 0 initializes neither the RDRF, PER, FER, and ORER flags nor SCI3nRDR.

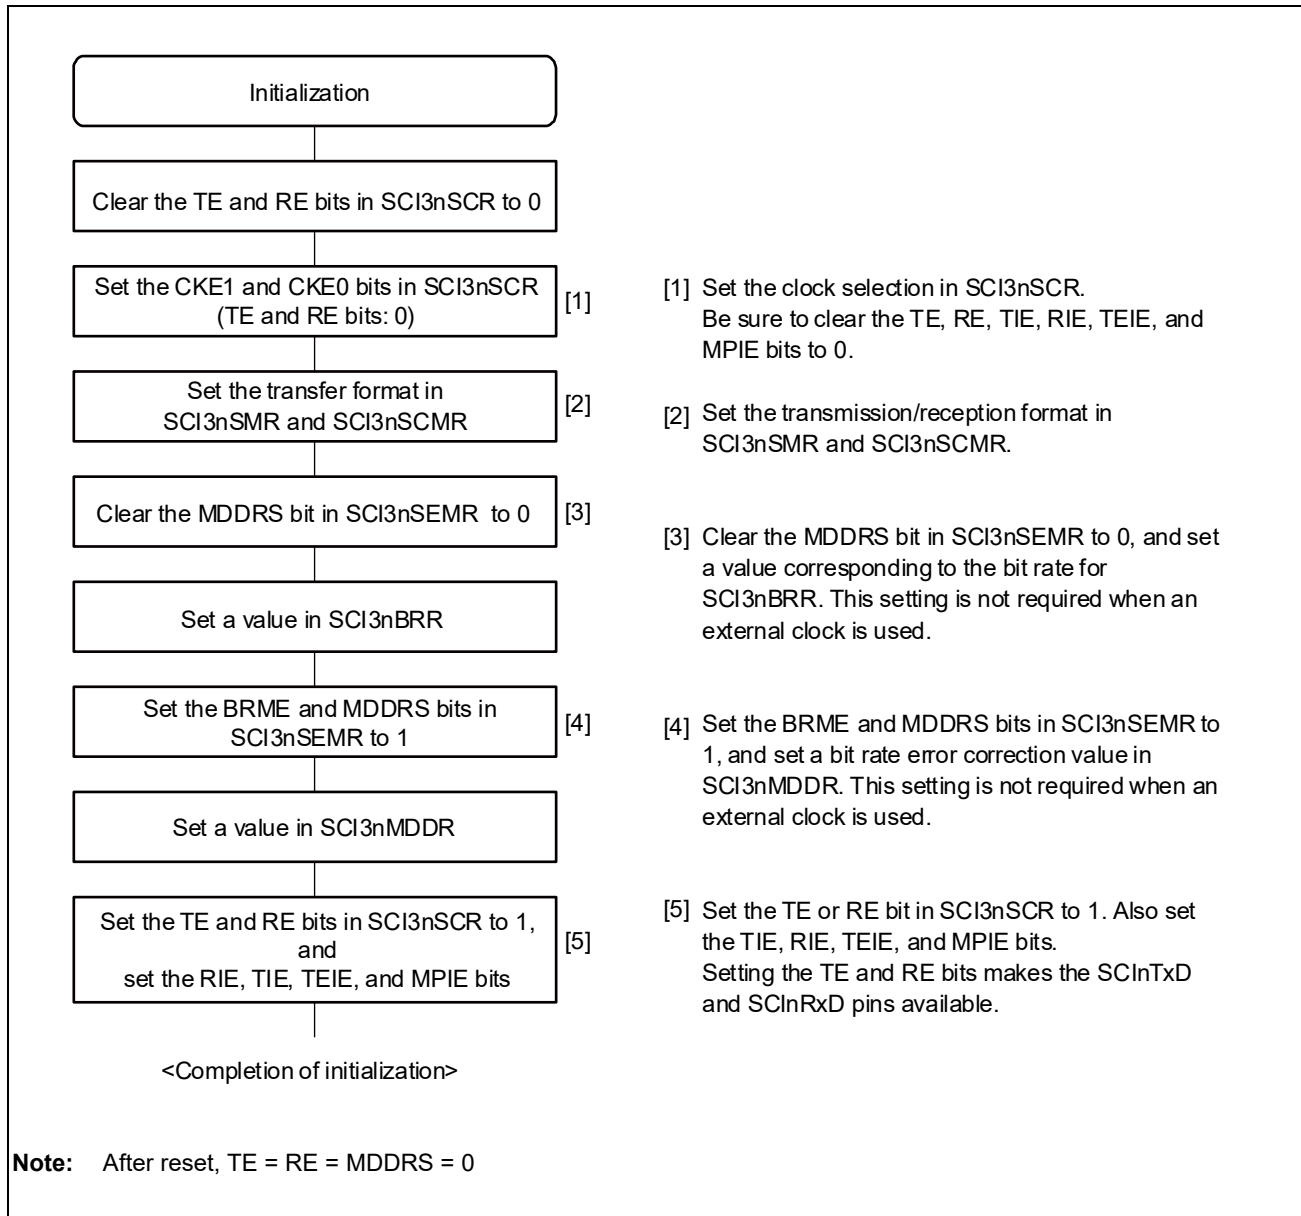

Figure 19.20 Example of SCI3 Initialization Flowchart

19.6.3 Serial Data Transmission (Clock Synchronous Mode)

Figure 19.21 shows an example of the operation for serial transmission in clock synchronous mode. In serial data transmission, the SCI3 operates as described below.

1. When transmit data is written to SCI3nTDR, the TDRE flag is automatically cleared to 0. The SCI3 monitors the TDRE flag in SCI3nSSR. When the flag is cleared, the SCI3 recognizes that data has been written to SCI3nTDR and transfers data from SCI3nTDR to SCI3nTSR, starting output of the first bit when the synchronization clock is input. To write transmit data to SCI3nTDR at a trigger of TXI interrupt request, set the TIE bit to 1 and then set the TE bit to 1 or set both TIE and TE bits simultaneously with one instruction to generate a TXI interrupt request for starting data transfer.
2. Transmission starts after data is transferred from SCI3nTDR to SCI3nTSR, and the TDRE flag is set to 1. When the TIE bit in SCI3nSCR is set to 1 at this time, a TXI interrupt request is generated. Continuous transmission is enabled by writing the next transmit data to SCI3nTDR in this TXI interrupt processing routine before the transmission of the previously transferred data is completed. When a TEI interrupt request is used, the TIE bit is cleared to 0 after the last transmit data has been written to SCI3nTDR, and the TEIE bit is set to 1.
3. 8-bit data is output from the SCInTxD pin in synchronization with the output clock (when clock output mode has been specified) or in synchronization with the input clock (when external clock has been specified).
4. The SCI3 checks the TDRE flag when the last bit is output.
5. When the TDRE flag is 0, the next transmit data is transferred from SCI3nTDR to SCI3nTSR, and serial transmission of the next frame starts.
6. When the TDRE flag is 1, the TEND flag in SCI3nSSR is set to 1 and the SCInTxD pin retains the output state of the last bit. If the TEIE bit in SCI3nSCR is set to 1 at this time, a TEI interrupt request is generated. The SCInSCK pin is held high.

Figure 19.22 shows a sample flowchart of serial data transmission. Also, **Figure 19.23** shows a sample flowchart for stopping the SCI3 after data transmission. Transmission will not start even if the TDRE flag is cleared while a receive error flag (ORER) is set to 1. Be sure to clear the receive error flags to 0 before starting transmission. Note that clearing the RE bit to 0 does not clear the receive error flags.

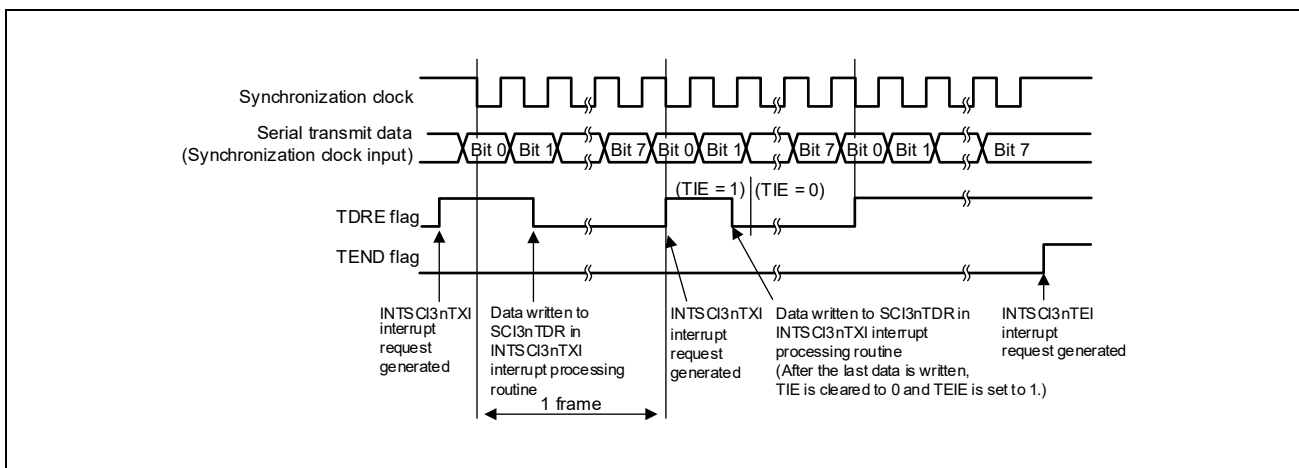

Figure 19.21 Example of Operation for Transmission in Clock Synchronous Mode

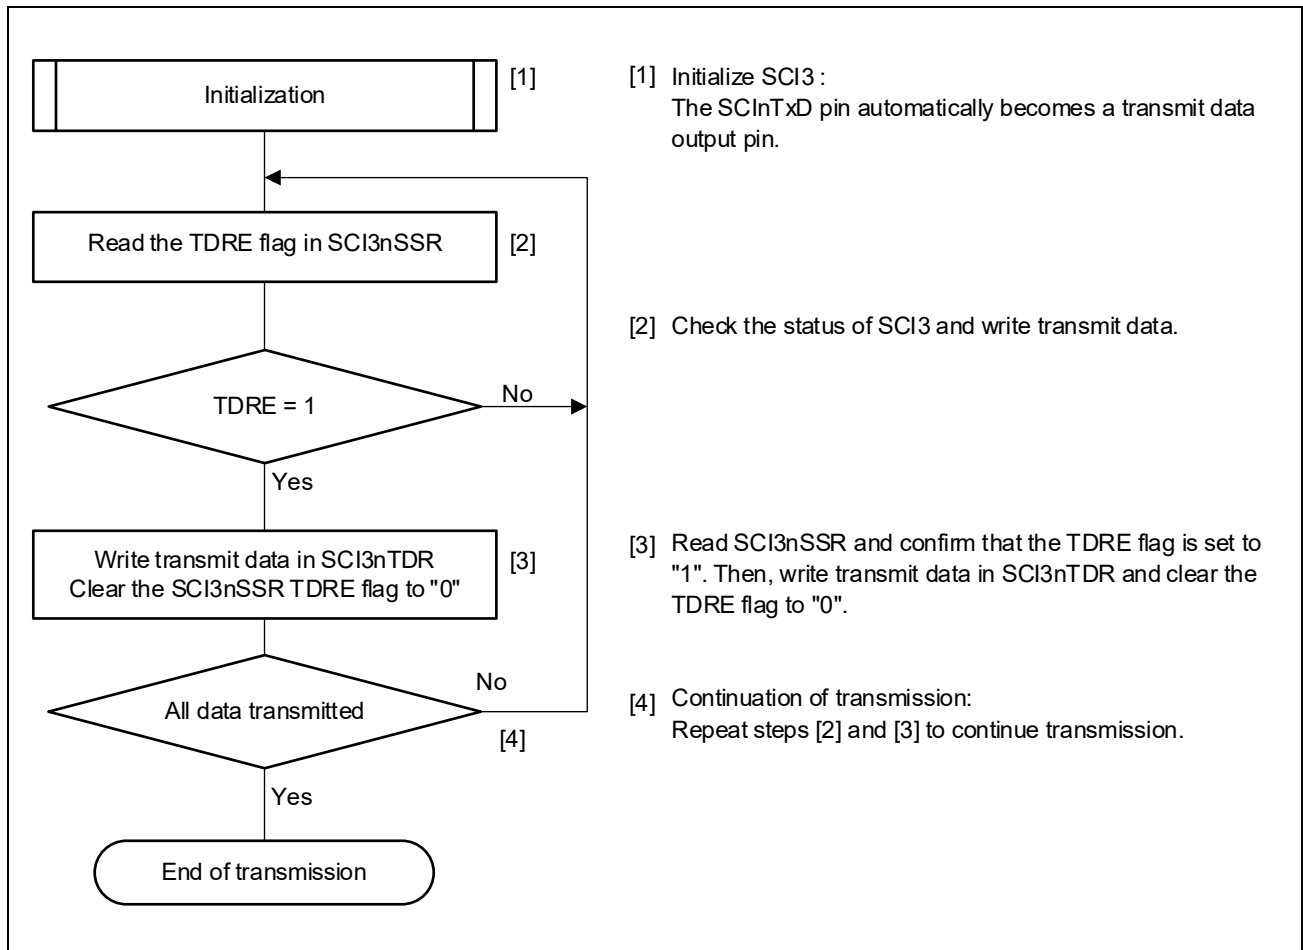

Figure 19.22 Example of Serial Transmission Flowchart

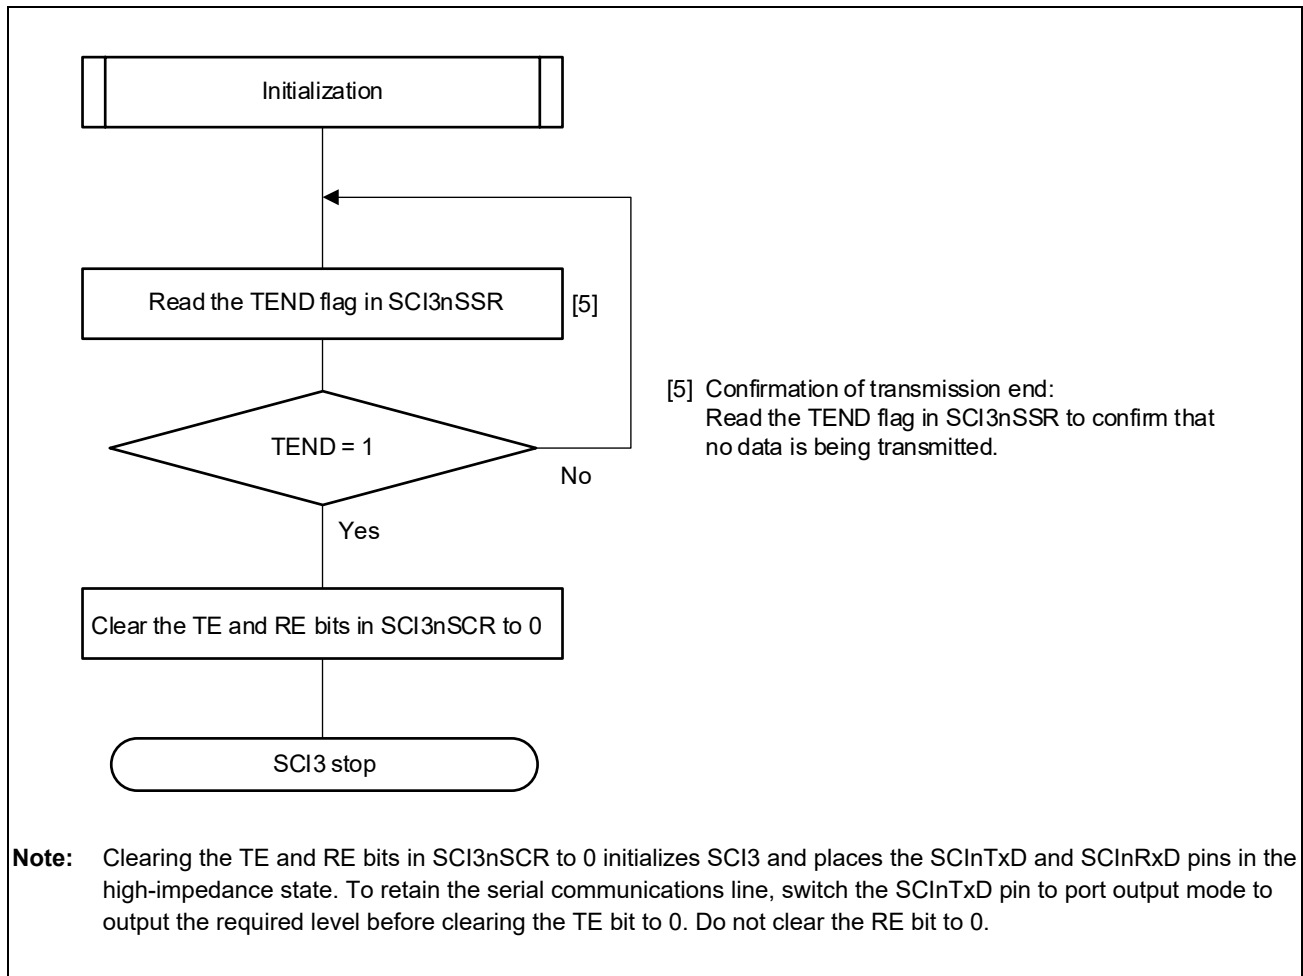

Figure 19.23 Example Flowchart for Stopping the SCI3 after Serial Transmission

19.6.4 Serial Data Reception (Clock Synchronous Mode)

Figure 19.24 shows an example of SCI3 operation for serial reception in clock synchronous mode. In serial data reception, the SCI3 operates as described below.

1. The SCI3 performs internal initialization and starts receiving data in synchronization with a synchronization clock input or output, and stores receive data in SCI3nRSR.
2. When an overrun error occurs (the reception of the next data is completed with the RDRF flag in SCI3nSSR set to 1), the ORER flag in SCI3nSSR is set to 1. If the RIE bit in SCI3nSCR is set to 1 at this time, an ERI interrupt request is generated. Receive data is not transferred to SCI3nRDR. The RDRF flag retains the state of being set to 1.
3. When data has been successfully received, the RDRF flag in SCI3nSSR is set to 1 and the receive data is transferred to SCI3nRDR. When the RIE bit in SCI3nSCR is set to 1 at this time, an RXI interrupt request is generated. Continuous reception is enabled by reading the receive data transferred to SCI3nRDR in this RXI interrupt processing routine before reception of the next data is completed. Reading SCI3nRDR automatically clears the RDRF flag to 0.

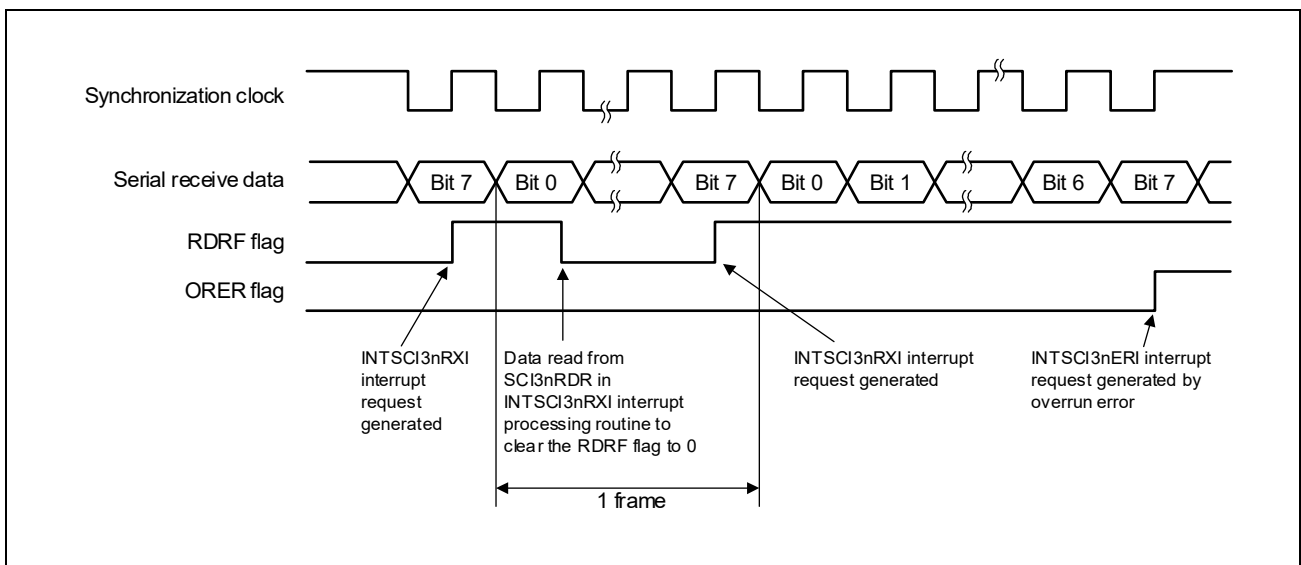

Figure 19.24 Example of SCI3 Operation for Reception

Subsequent transmission and reception are disabled with a receive error flag set to 1. Therefore, be sure to clear the ORER, FER, PER, and RDRF flags before continuing reception. **Figure 19.25** shows an example of flowchart for data reception.

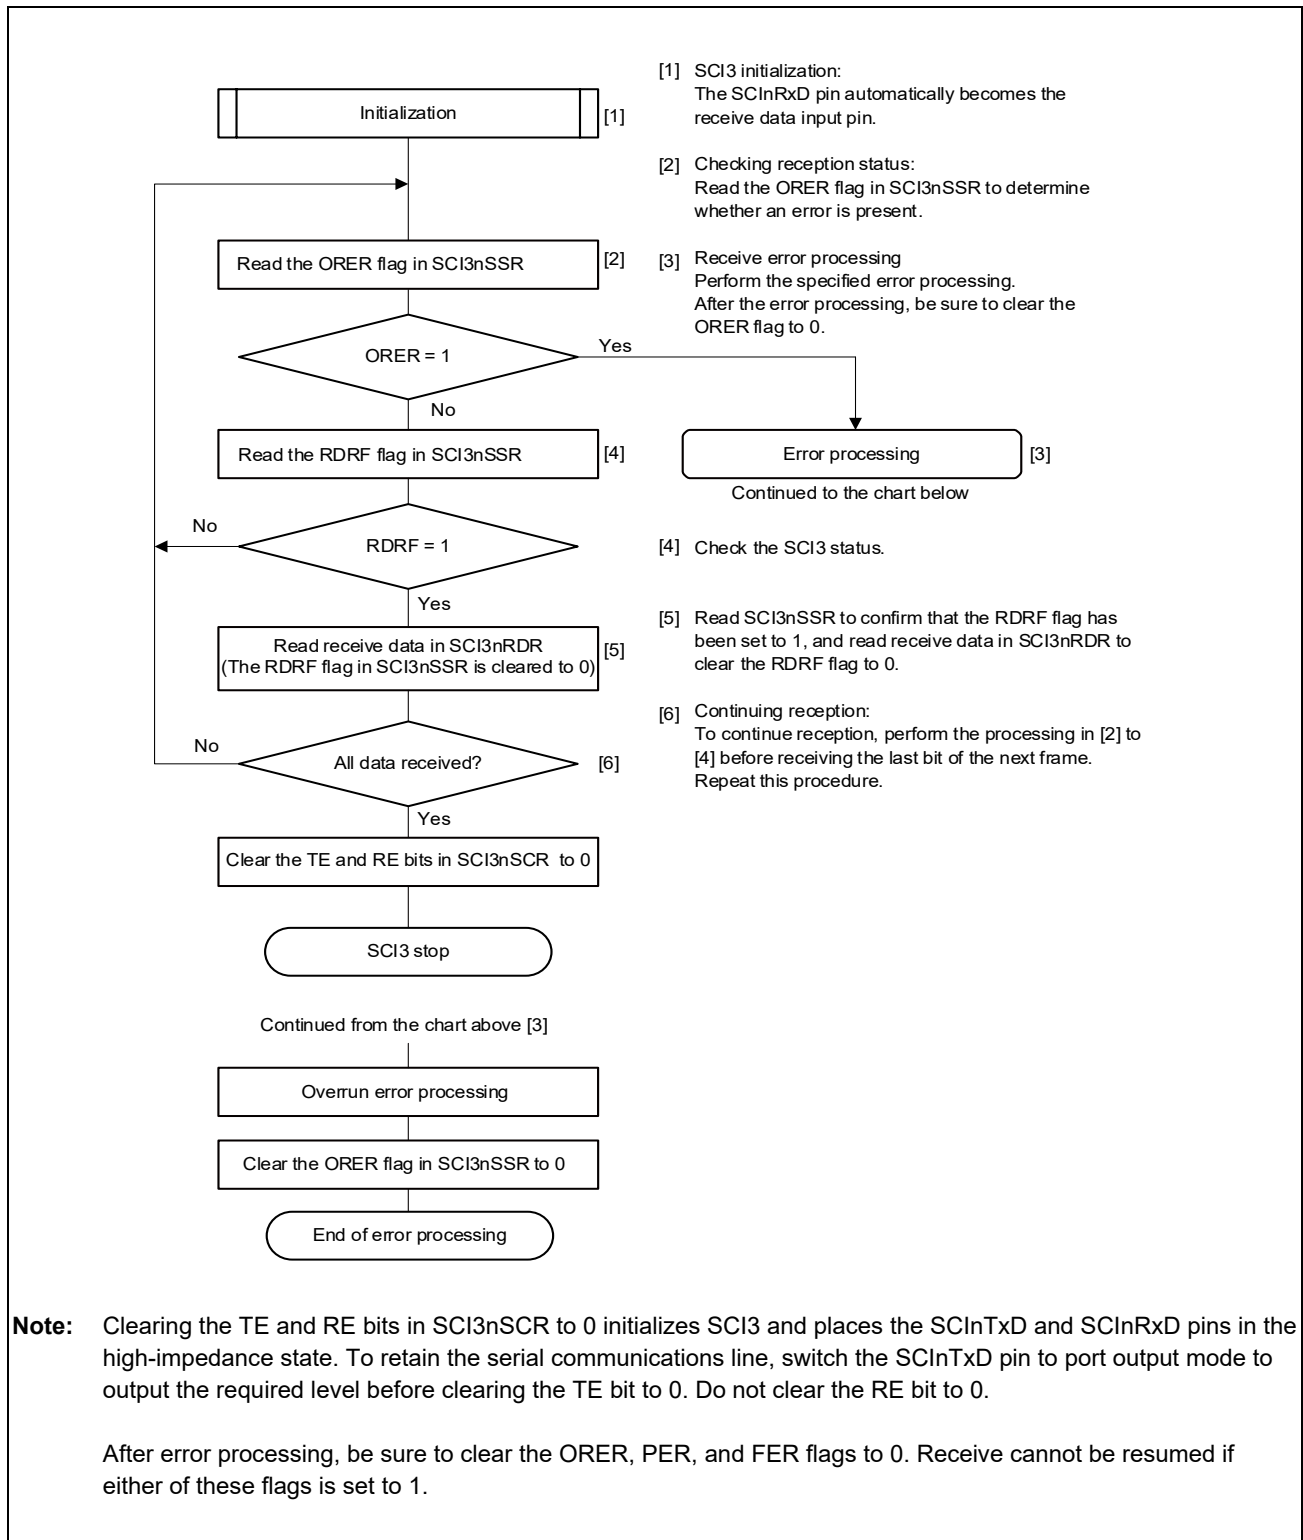

Figure 19.25 Example of Serial Reception Flowchart

19.6.5 Simultaneous Serial Data Transmission and Reception (Clock Synchronous Mode)

Figure 19.26 shows a sample flowchart for simultaneous data transmit and receive operations. After the SCI3 is initialized, perform the following procedure for simultaneous data transmit and receive operations.

1. To switch from transmit mode to simultaneous transmit and receive mode, check that the SCI3 has finished transmission and the TDRE and TEND flags are set to 1. Then clear the TE bit to 0 and then set the TE and RE bits to 1 with a single instruction.
2. To switch from receive mode to simultaneous transmit and receive mode, check that the SCI3 has finished reception and clear the RE bit to 0. Then check that the RDRF and error flags (ORER, FER, and PER) are cleared to 0 and then set the TE and RE bits to 1 with a single instruction.

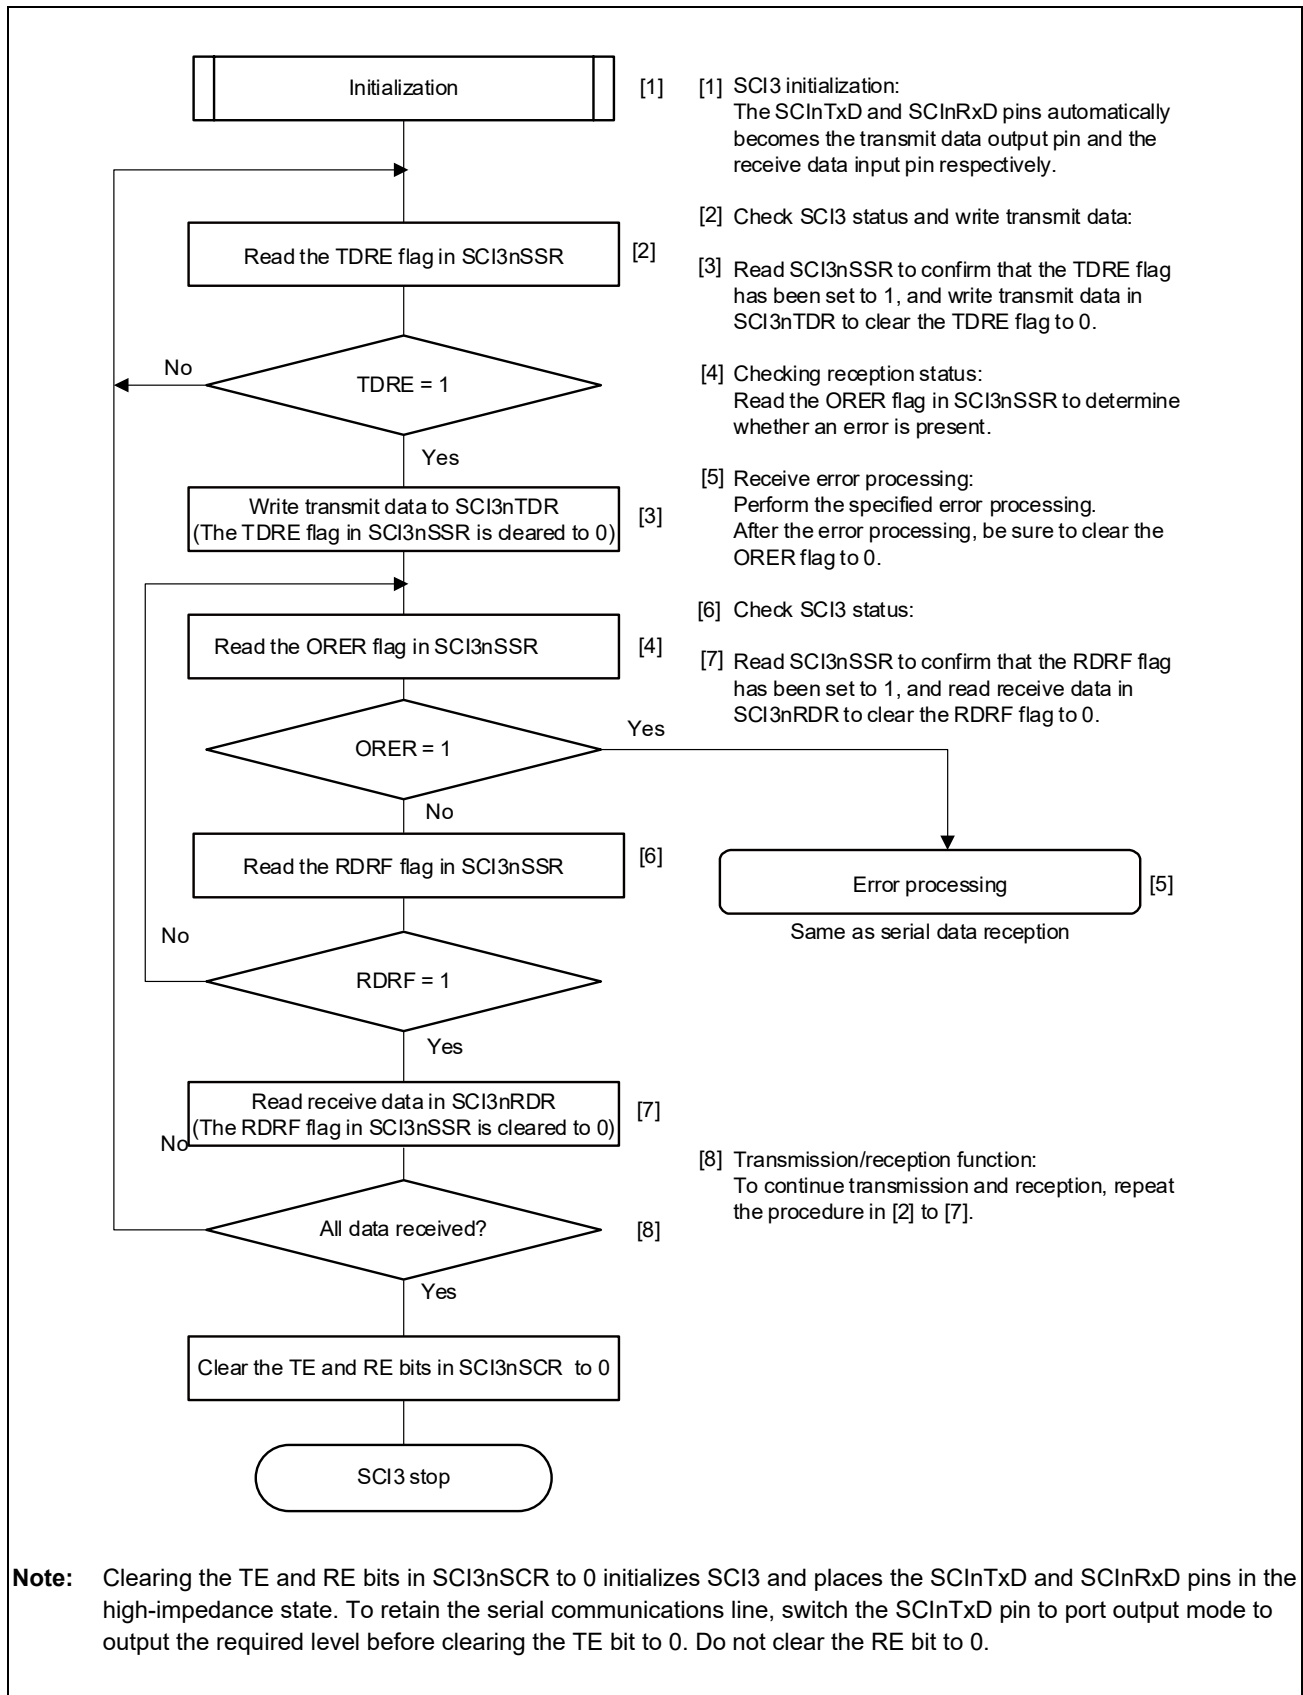

Figure 19.26 Example of Simultaneous Serial Transmission and Reception Flowchart

19.7 Bit Rate Modulation Function

The bit rate modulation function corrects a bit rate by averagely enabling the internal clocks specified by the CKS1 and CKS0 bits in SCI3nSMR for the number specified by SCI3nMDDR out of 256 clocks.

Figure 19.27 shows an example of asynchronous mode in which ϕ clock is selected with the CKS1 and CKS0 bits, SCI3nBRR is set to 0, and SCI3nMDDR is set to 160. In this example, the reference clock cycle is corrected to $256/160$ on average and the bit rate is corrected to $160 / 256$. Note that the pulse widths of the internal reference clock expand or contract for the amount of the selected internal clocks because there is a deviation in the enabling of the internal clocks.

Do not use this function with the maximum speed settings (CKS1 and CKS0 bits = 0 in SCI3nSMR, CKE1 bit = 0 in SCI3nSCR, and SCI3nBRR = 0) for clock synchronous mode.

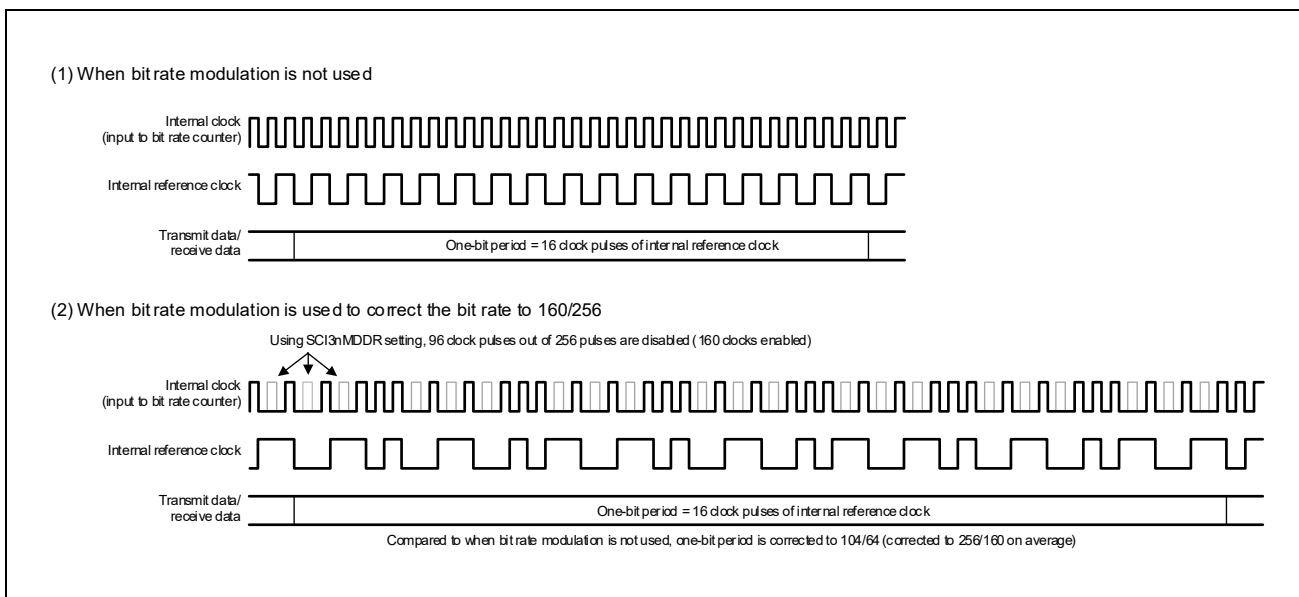

Figure 19.27 Example of Internal Reference Clock when the Bit Rate Modulation Function is Used

19.8 Interrupt Sources

Table 19.23 lists interrupt sources. Each interrupt source outputs an individual interrupt request signal. These interrupt sources can be enabled independently with the enable bit in SCI3nSCR.

A TXI interrupt request is generated when the TDRE flag in SCI3nSSR is set to 1.

A TEI interrupt request is generated when the TEND flag in SCI3nSSR is set to 1.

A TXI interrupt request can activate the DMA to handle data transfer. The TDRE flag is automatically cleared to 0 when data is transferred using the DMA.

CAUTION

The TDRE flag and TEND flag cannot be cleared to 0 when the TE bit in SCI3nSCR is 0. Do not set the TEIE bit in SCI3nSCR to 1 when the TE bit is set to 0 because the TEND flag is a level interrupt request flag of TEI interrupt.

An RXI interrupt request is generated when the RDRF flag in SCI3nSSR is set to 1.

An ERI interrupt is generated when any of the ORER, PER, and FER flags in SCI3nSSR is set to 1.

An RXI interrupt request can activate the DMA to handle data transfer. The RDRF flag is automatically cleared to 0 when data is transferred using the DMA.

A TEI interrupt request is generated when the TEND flag is set to 1 with the TEIE bit set to 1.

CAUTION

If a TEI interrupt request and a TXI interrupt request are generated at the same time, the TXI interrupt request is accepted first. Note that clearing the TDRE flag to 0 at this time in the TXI interrupt processing routine also clears the TEND flag to 0 automatically, disabling the branch to the TEI interrupt processing routine.

Table 19.23 SCI3 Interrupt Sources

Name	Interrupt Source	Interrupt Flag	sDMA / DTS Activation
ERI / TEI	Receive error / Transmit end	ORER, FER, PER / TEND	Not possible
RXI	Receive data full	RDRF	Possible
TXI	Transmit data empty	TDRE	Possible

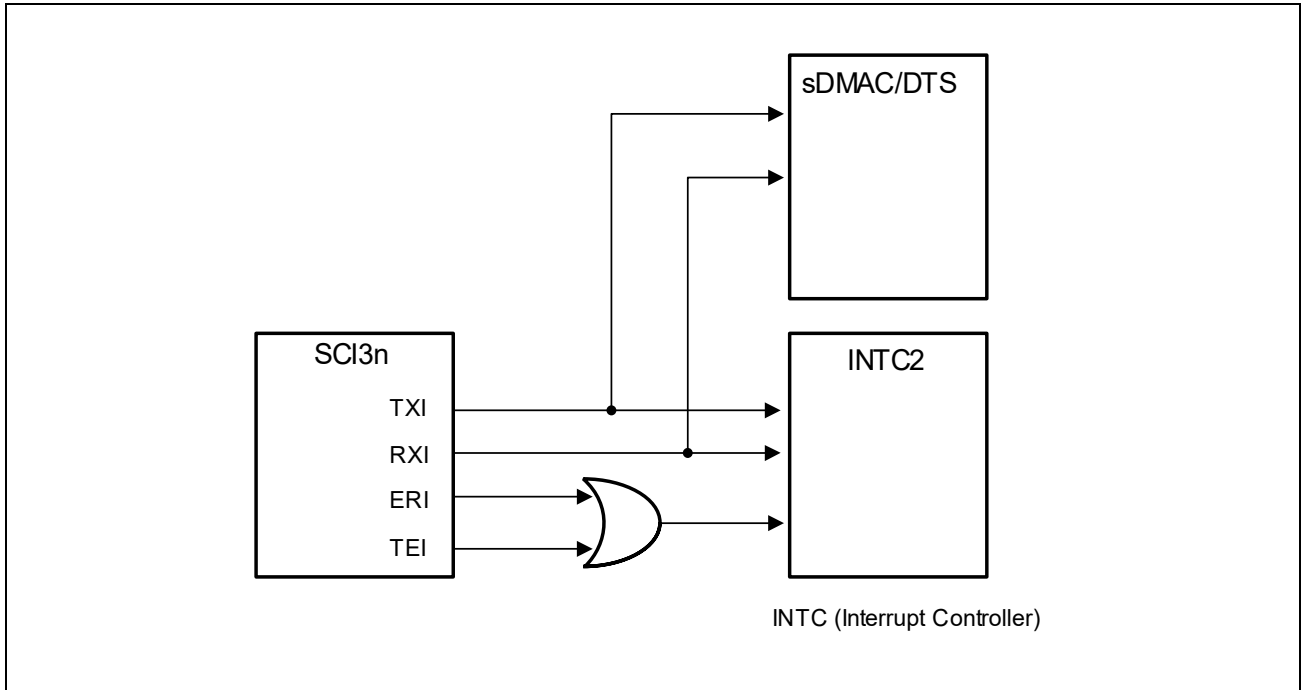

Figure 19.28 Relationship between the SCI3 Interrupt Signals, Interrupt Controller (INTC) and sDMAC / DTS

19.9 Usage Notes

19.9.1 Break Detection and Processing

A break can be detected by reading the RXDMON bit in SCI3nSEMR when detecting a framing error. Since all inputs from the SCInRxD pin are 0 in the break state, the FER flag is set to 1 and the PER flag may also be set to 1. The SCI3 continues data reception even after it receives a break. For this reason, note that FER flag is set to 1 again even after the FER flag is cleared to 0.

19.9.2 Mark State and Production of Breaks

While the TE bit is 0 (transmission/reception disabled), the SCInTxD pin can output any level by switching the SCInTxD pin to a general output port. This allows the SCInTxD pin to be in mark state or break output during data transmission.

19.9.3 Receive Error Flags and Transmit Operations in Clock Synchronous Mode

During the clock synchronous simultaneous data transmit / receive operation, transmission cannot be started when a receive error flag (ORER) is set to 1, even if the TDRE flag is cleared to 0. Be sure to clear the receive error flags to 0 before starting transmission. Note that the receive error flags cannot be cleared to 0 even by clearing the RE bit to 0.

19.9.4 Relationship between Writing to SCI3nTDR and the TDRE Flag

The TDRE flag in SCI3nSSR is a status flag indicating that transmit data in SCI3nTDR has been transferred to SCI3nTSR. The TDRE flag is set to 1 when the SCI3 transfers data from SCI3nTDR to SCI3nTSR.

Data can be written to SCI3nTDR regardless of the status of the TDRE flag. However, writing new data to SCI3nTDR while the TDRE flag is 0 will cause the data stored in SCI3nTDR to be lost because it has not been transferred to SCI3nTSR. Therefore, make sure to check that the TDRE flag is set to 1 before writing transmit data to SCI3nTDR.

19.9.5 Restrictions on Using an External Clock for Transmission in Clock Synchronous Mode

When using an external synchronization clock, clear the TDRE flag to 0 and then input a transmission clock (**Figure 19.29**). Also in continuous transmission mode, clear the TDRE flag to 0 and then input a transmission clock for the next frame.

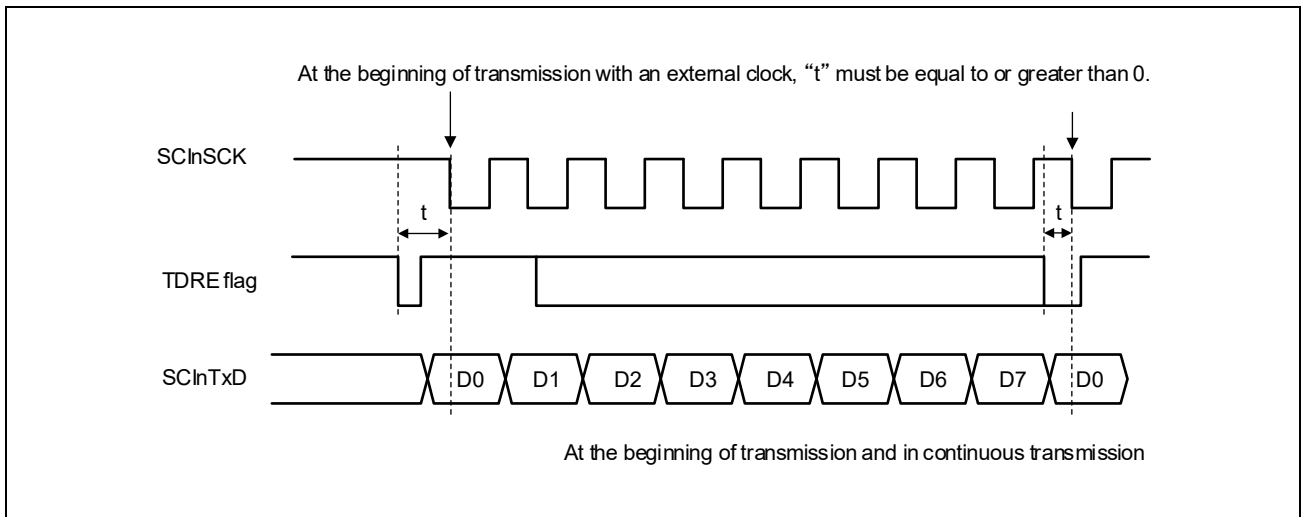

Figure 19.29 Restrictions on Using an External Clock for Transmission in Clock Synchronous Mode

19.9.6 External Clock Input in Clock Synchronous Mode

In clock synchronous mode, set at least two cycles of the external SCInSCK clock input for the widths at both high and low levels, and at least six cycles as the period.

Section 20 LIN/UART Interface (RLIN3)

This section contains a generic description of the LIN/UART interface (RLIN3).

The first part of this section describes all this product specific properties, such as the number of units, register base addresses, etc.

The remainder of the section describes the functions and registers of RLIN3.

20.1 Features of RLIN3

20.1.1 Units and Channels

This microcontroller has the following number of RLIN3 units.

Each RLIN3 unit has one channel interface. “Number of channels” is used with the same meaning as “number of units” in this section.

Table 20.1 Number of Channels (For E2x-FCC2)

Product Name	RH850/E2x-FCC2	
	468 Pins	373 Pins
Number of Channels	8	6
Name	RLIN3n (n = 0 to 7)	RLIN3n (n = 0 to 5)

Table 20.2 Number of Channels (For E2UH)

Product Name	RH850/E2UH	
	468 Pins	373 Pins
Number of Channels	8	
Name	RLIN3n (n = 0 to 7)	

Table 20.3 Number of Channels (For E2H)

Product Name	RH850/E2H	
	468 Pins	373 Pins
Number of Channels	6	
Name	RLIN3n (n = 0 to 5)	

Note: The channel names are same as those of the corresponding units.

Table 20.4 Indices

Index	Meaning
n	Throughout this section, the individual RLIN3 units are identified by the index “n” (“n” is channel numbers.); for example, the LIN control register of RLIN3n is described as RLIN3nLCUC.
b	Throughout this section, the individual transmit/receive data buffers of RLIN3n are identified by the index “b” (b = 1 to 8); for example, the data buffer register of the index “b” is described as RLIN3nLDBRb.

20.1.2 Register Base Addresses

RLIN3 base addresses are listed in the following table.

RLIN3 register addresses are given as offsets from the base addresses.

Table 20.5 Register Base Addresses

Base Address Name	Base Address	Bus Group
<RLIN30_base>	FFD2 0000H	Peripheral Group 3
<RLIN31_base>	FFD2 0040H	Peripheral Group 3
<RLIN32_base>	FFD2 0080H	Peripheral Group 3
<RLIN33_base>	FFD2 00C0H	Peripheral Group 3
<RLIN34_base>	FFD2 0100H	Peripheral Group 3
<RLIN35_base>	FFD2 0140H	Peripheral Group 3
<RLIN36_base>	FFD2 0180H	Peripheral Group 3
<RLIN37_base>	FFD2 01C0H	Peripheral Group 3

20.1.3 Clock Supply

The RLIN3 clock supply is shown in the following table.

Table 20.6 Clock Supply

Unit Name	Unit Clock Name	Supply Clock Name
RLIN3n	LIN communication clock source	CLK_LSB
	Register access clock	CLK_HSB

20.1.4 Interrupt Requests

RLIN3 interrupt requests are listed in the following table.

Table 20.7 Interrupt Requests (1/2)

Interrupt symbol name	Unit Interrupt Signal	Outline	Interrupt Number	sDMA Trigger Number	DTS Trigger Number
RLIN30					
INTRLIN30UR0	INTRLIN3nUR0 (n = 0)	RLIN30 transmit interrupt	404	group0-153	group1-61
INTRLIN30UR1	INTRLIN3nUR1 (n = 0)	RLIN30 receive completion interrupt	405	group0-154	group1-62
INTRLIN30UR2	INTRLIN3nUR2 (n = 0)	RLIN30 status interrupt	406	—	—
RLIN31					
INTRLIN31UR0	INTRLIN3nUR0 (n = 1)	RLIN31 transmit interrupt	407	group0-155	group1-63
INTRLIN31UR1	INTRLIN3nUR1 (n = 1)	RLIN31 receive completion interrupt	408	group0-156	group1-64
INTRLIN31UR2	INTRLIN3nUR2 (n = 1)	RLIN31 status interrupt	409	—	—
RLIN32					
INTRLIN32UR0	INTRLIN3nUR0 (n = 2)	RLIN32 transmit interrupt	410	group0-157	group1-65
INTRLIN32UR1	INTRLIN3nUR1 (n = 2)	RLIN32 receive completion interrupt	411	group0-158	group1-66
INTRLIN32UR2	INTRLIN3nUR2 (n = 2)	RLIN32 status interrupt	412	—	—
RLIN33					
INTRLIN33UR0	INTRLIN3nUR0 (n = 3)	RLIN33 transmit interrupt	413	group0-159	group1-67
INTRLIN33UR1	INTRLIN3nUR1 (n = 3)	RLIN33 receive completion interrupt	414	group0-160	group1-68
INTRLIN33UR2	INTRLIN3nUR2 (n = 3)	RLIN33 status interrupt	415	—	—
RLIN34					
INTRLIN34UR0	INTRLIN3nUR0 (n = 4)	RLIN34 transmit interrupt	416	group0-161	group1-69
INTRLIN34UR1	INTRLIN3nUR1 (n = 4)	RLIN34 receive completion interrupt	417	group0-162	group1-70
INTRLIN34UR2	INTRLIN3nUR2 (n = 4)	RLIN34 status interrupt	418	—	—
RLIN35					
INTRLIN35UR0	INTRLIN3nUR0 (n = 5)	RLIN35 transmit interrupt	419	group0-163	group1-71
INTRLIN35UR1	INTRLIN3nUR1 (n = 5)	RLIN35 receive completion interrupt	420	group0-164	group1-72
INTRLIN35UR2	INTRLIN3nUR2 (n = 5)	RLIN35 status interrupt	421	—	—

Table 20.7 Interrupt Requests (2/2)

Interrupt symbol name	Unit Interrupt Signal	Outline	Interrupt Number	sDMA Trigger Number	DTS Trigger Number
RLIN36					
INTRLIN36UR0	INTRLIN3nUR0 (n = 6)	RLIN36 transmit interrupt	588	group0-239	group1-0
INTRLIN36UR1	INTRLIN3nUR1 (n = 6)	RLIN36 receive completion interrupt	589	group0-240	group1-1
INTRLIN36UR2	INTRLIN3nUR2 (n = 6)	RLIN36 status interrupt	590	—	—
RLIN37					
INTRLIN37UR0	INTRLIN3nUR0 (n = 7)	RLIN37 transmit interrupt	591	group0-241	group1-2
INTRLIN37UR1	INTRLIN3nUR1 (n = 7)	RLIN37 receive completion interrupt	592	group0-242	group1-3
INTRLIN37UR2	INTRLIN3nUR2 (n = 7)	RLIN37 status interrupt	593	—	—

20.1.5 Reset Sources

RLIN3 reset sources are listed in the following table. RLIN3 is initialized by these reset sources.

Table 20.8 Reset Sources

Unit Name	Register Name	Reset Condition					
		Power Up Reset	System Reset 1	System Reset 2	Application Reset	Module Reset	JTAG Reset
RLIN3n	All registers	✓	✓	✓	✓	—	—

20.1.6 External Input/Output Signals

External input/output signals of RLIN3 are listed below.

Table 20.9 External Input/Output Signals

Unit Signal Name	Description	Alternative Port Pin Signal
RLIN30		
RLIN3nRX (n = 0)	RLIN30 receive data input	LRX0
RLIN3nTX (n = 0)	RLIN30 transmit data output	LTX0
RLIN31		
RLIN3nRX (n = 1)	RLIN31 receive data input	LRX1
RLIN3nTX (n = 1)	RLIN31 transmit data output	LTX1
RLIN32		
RLIN3nRX (n = 2)	RLIN32 receive data input	LRX2
RLIN3nTX (n = 2)	RLIN32 transmit data output	LTX2
RLIN33		
RLIN3nRX (n = 3)	RLIN33 receive data input	LRX3
RLIN3nTX (n = 3)	RLIN33 transmit data output	LTX3
RLIN34		
RLIN3nRX (n = 4)	RLIN34 receive data input	LRX4
RLIN3nTX (n = 4)	RLIN34 transmit data output	LTX4
RLIN35		
RLIN3nRX (n = 5)	RLIN35 receive data input	LRX5
RLIN3nTX (n = 5)	RLIN35 transmit data output	LTX5
RLIN36		
RLIN3nRX (n = 6)	RLIN36 receive data input	LRX6
RLIN3nTX (n = 6)	RLIN36 transmit data output	LTX6
RLIN37		
RLIN3nRX (n = 7)	RLIN37 receive data input	LRX7
RLIN3nTX (n = 7)	RLIN37 transmit data output	LTX7

CAUTION

This AC specification is only applied to the specific pin groups. For details, please refer to Appendix file "Limited_conditions_for_AC_specification.xlsx".

20.2 Overview

20.2.1 Functional Overview

The LIN/UART interface is a hardware LIN communication controller that supports LIN Specification Package Revision 1.3, 2.0, 2.1, 2.2, and SAE J2602, and automatically performs frame communication and error determination.

The LIN/UART interface is provided with UART mode and can also be used as a UART.

The appropriate mode should be used for the LIN/UART interface according to the application: LIN master, LIN slave or UART.

LIN master

- LIN reset mode
- LIN mode (LIN master mode)
 - LIN wake-up mode
 - LIN operation mode
- LIN Self-Test mode

LIN slave

- LIN reset mode
- LIN mode (LIN slave mode [auto baud rate] or LIN slave mode [fixed baud rate])
 - LIN wake-up mode
 - LIN operation mode
- LIN Self-Test mode

UART

- LIN reset mode
- UART mode

Table 20.10 shows the LIN/UART interface specifications.

Table 20.10 LIN/UART Interface Specifications (1/3)

Item	Specifications	
LIN communication function	Protocol	LIN Specification Package Revision 1.3, 2.0, 2.1, 2.2, and SAE J2602
	Variable frame structure	Master <ul style="list-style-type: none"> • Break transmission width: 13 to 28 Tbits • Break delimiter transmission width: 1 to 4 Tbits • Transmission inter-byte space width (header): 0 to 7 Tbits (space between Sync field and ID field)*1 • Transmission response space width: 0 to 7 Tbits*1 • Transmission inter-byte space width: 0 to 3 Tbits (space between data bytes in response area) • Transmission wake-up width: 1 to 16 Tbits
		Slave <ul style="list-style-type: none"> • Break reception width: 9.5 or 10.5 Tbits [for fixed baud rate] : 10 or 11 Tbits [for auto baud rate] • Transmission response space width: 0 to 7 Tbits • Transmission inter-byte space width: 0 to 3 Tbits (space between data bytes in response area) • Transmission wake-up width: 1 to 16 Tbits
	Checksum	<ul style="list-style-type: none"> • Automatic operation for both transmission and reception • Classic or enhanced selectable (for each frame)
	Response field data byte count	Variable from 0 to 8 bytes Multi-byte (9 or more bytes) response transmission and reception also possible
	Frame communication modes	Master <ul style="list-style-type: none"> • Mode in which header transmission and response transmission/reception are started with a single transmission start request • Mode in which header transmission and response transmission are started with separate transmission start requests(frame separate mode)
Slave <ul style="list-style-type: none"> • Mode in which header is automatically received with fixed baud rate • Mode in which header is automatically received with the baud rate set according to the sync field measurement result of the sync field and break field detected 		
Wake-up transmission and reception	LIN wake-up mode provided <ul style="list-style-type: none"> • Wake-up transmission (1 to 16 Tbits) • Wake-up reception Low-level width of input signals measured 	
LIN communication function	Status	Master <ul style="list-style-type: none"> • Successful frame/wake-up transmission • Successful header transmission • Successful frame/wake-up reception*2 • Successful data 1 reception • Error detection • Operation mode (LIN reset mode, LIN wake-up mode, LIN operation mode, LIN Self-Test mode)
		Slave <ul style="list-style-type: none"> • Successful response/wake-up transmission • Successful response/wake-up reception*2 • Successful header reception • Successful data 1 reception • Error detection • Operation mode (LIN reset mode, LIN wake-up mode, LIN operation mode, LIN Self-Test mode)

Table 20.10 LIN/UART Interface Specifications (2/3)

Item	Specifications		
LIN communication function	Error status	Master <ul style="list-style-type: none"> • Bit error • Checksum error • Frame timeout error/response timeout error • Physical bus error • Framing error • Response preparation error 	
		Slave <ul style="list-style-type: none"> • Bit error • Checksum error • Frame timeout error/response timeout error • Sync field error • ID parity error • Framing error • Response preparation error 	
	Baud rate selection	Baud rates conforming to the LIN specifications generated using baud rate generator	
	Test mode	Self-Test mode for user evaluation	
	Interrupt function	Master <ul style="list-style-type: none"> • Successful header/frame/wake-up transmission • Successful frame/wake-up reception*2 • Error detection 	
Slave <ul style="list-style-type: none"> • Successful response/wake-up transmission • Successful header/response/wake-up reception*2 • Error detection 			
UART communication function	Data buffer	<ul style="list-style-type: none"> • Transmission data buffer/transmission data buffer for wait (exclusively for transmission; data length of 1. Character length of 7, 8, and 9 bits supported) • UART buffer (exclusively for transmission; variable data length from 1 to 9. Character length of 7 and 8 bits supported) • Reception data buffer (exclusively for reception; data length of 1. Character length of 7, 8, and 9 bits supported) 	
	Data format	Character length: 7 or 8 bits	
		Length of 9 bits supported by using the expansion bit.	
		Transmission stop bit: 1 or 2 bits	
		Parity function: odd, even, 0, or none	
		LSB- or MSB-first transfer selectable	
	Reverse input/output of transmission/reception data possible		
Status	<ul style="list-style-type: none"> • Transmission status • Reception status • Successful UART buffer transmission • Error detection • Expansion bit detection • ID match • Reset mode status 		
Error status	<ul style="list-style-type: none"> • Bit error • Framing error • Parity error • Overrun error 		
Baud rate selection	With the built-in baud rate generator, any baud rate can be set.		

Table 20.10 LIN/UART Interface Specifications (3/3)

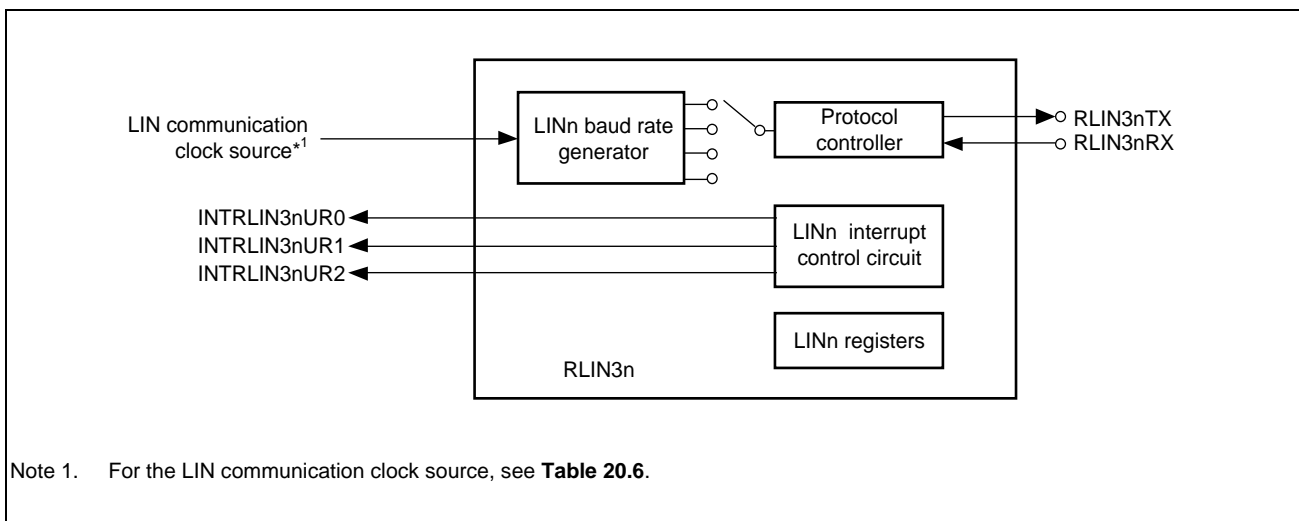

Item	Specifications
UART communication function	When a certain expansion bit is at the expected level, the data received can be compared to the 8-bit data preset in the register. Reception of the stop bit is guaranteed (start of transmission can be delayed when start of transmission is attempted during reception of the stop bit).
Interrupt function	<ul style="list-style-type: none"> • Transmission start/complete • Reception complete • Status/error detection

Note 1. Since the same register is used for setting, the inter-byte space (header) = response space.

Note 2. For wake-up reception, the input signal low-level width count is indicated.

20.2.2 Block Diagram

Figure 20.1 shows a block diagram of the LIN/UART interface.

Note 1. For the LIN communication clock source, see Table 20.6.

Figure 20.1 LIN/UART Interface Block Diagram

20.2.3 Terms Used in Block Diagram

- RLIN3nTX, RLIN3nRX: LIN/UART interface I/O pins
- LINn baud rate generator: Generates the LIN/UART interface communication clock.
- LINn registers: LIN/UART interface registers
- LINn interrupt control circuit: Controls interrupt requests generated by the LIN/UART interface

20.3 Registers

20.3.1 List of Registers

RLIN3 registers are listed in the following table.

For details about <RLIN3n_base>, see **Section 20.1.2, Register Base Addresses**.

Table 20.11 List of Registers

Module Name	Register Name	Symbol	Address	LIN Master	LIN Slave	UART	Access	Access Protection
RLN3n	LIN / UART Wake-Up Baud Rate Select Register	RLN3nLWBR	<RLIN3n_base> + 01 _H	✓	✓	✓	8	—
RLN3n	LIN / UART Baud Rate Prescaler 01 Register	RLN3nLBRP01	<RLIN3n_base> + 02 _H	—	✓	✓	16	—
RLN3n	LIN / UART Baud Rate Prescaler 0 Register	RLN3nLBRP0	<RLIN3n_base> + 02 _H	✓	✓	✓	8	—
RLN3n	LIN / UART Baud Rate Prescaler 1 Register	RLN3nLBRP1	<RLIN3n_base> + 03 _H	✓	✓	✓	8	—
RLN3n	LIN Self-Test Control Register	RLN3nLSTC	<RLIN3n_base> + 04 _H	✓	✓	—	8	—
RLN3n	LIN / UART Mode Register	RLN3nLMD	<RLIN3n_base> + 08 _H	✓	✓	✓	8	—
RLN3n	LIN Break Field Configuration Register/ UART Configuration Register	RLN3nLBFC	<RLIN3n_base> + 09 _H	✓	✓	✓	8	—
RLN3n	LIN / UART Space Configuration Register	RLN3nLSC	<RLIN3n_base> + 0A _H	✓	✓	✓	8	—
RLN3n	LIN Wake-Up Configuration Register	RLN3nLWUP	<RLIN3n_base> + 0B _H	✓	✓	—	8	—
RLN3n	LIN Interrupt Enable Register	RLN3nLIE	<RLIN3n_base> + 0C _H	✓	✓	—	8	—
RLN3n	LIN / UART Error Detection Enable Register	RLN3nLEDE	<RLIN3n_base> + 0D _H	✓	✓	✓	8	—
RLN3n	LIN / UART Control Register	RLN3nLCUC	<RLIN3n_base> + 0E _H	✓	✓	✓	8	—
RLN3n	LIN / UART Transmission Control Register	RLN3nLTRC	<RLIN3n_base> + 10 _H	✓	✓	✓	8	—
RLN3n	LIN / UART Mode Status Register	RLN3nLMST	<RLIN3n_base> + 11 _H	✓	✓	✓	8	—
RLN3n	LIN / UART Status Register	RLN3nLST	<RLIN3n_base> + 12 _H	✓	✓	✓	8	—
RLN3n	LIN / UART Error Status Register	RLN3nLEST	<RLIN3n_base> + 13 _H	✓	✓	✓	8	—
RLN3n	LIN / UART Data Field Configuration Register	RLN3nLDFC	<RLIN3n_base> + 14 _H	✓	✓	✓	8	—
RLN3n	LIN / UART ID Buffer Register	RLN3nLIDB	<RLIN3n_base> + 15 _H	✓	✓	✓	8	—
RLN3n	LIN Checksum Buffer Register	RLN3nLCBR	<RLIN3n_base> + 16 _H	✓	✓	—	8	—
RLN3n	UART Data Buffer 0 Register	RLN3nLUDB0	<RLIN3n_base> + 17 _H	—	—	✓	8	—
RLN3n	LIN / UART Data Buffer 1 Register	RLN3nLDBR1	<RLIN3n_base> + 18 _H	✓	✓	✓	8	—
RLN3n	LIN / UART Data Buffer 2 Register	RLN3nLDBR2	<RLIN3n_base> + 19 _H	✓	✓	✓	8	—
RLN3n	LIN / UART Data Buffer 3 Register	RLN3nLDBR3	<RLIN3n_base> + 1A _H	✓	✓	✓	8	—
RLN3n	LIN / UART Data Buffer 4 Register	RLN3nLDBR4	<RLIN3n_base> + 1B _H	✓	✓	✓	8	—
RLN3n	LIN / UART Data Buffer 5 Register	RLN3nLDBR5	<RLIN3n_base> + 1C _H	✓	✓	✓	8	—
RLN3n	LIN / UART Data Buffer 6 Register	RLN3nLDBR6	<RLIN3n_base> + 1D _H	✓	✓	✓	8	—
RLN3n	LIN / UART Data Buffer 7 Register	RLN3nLDBR7	<RLIN3n_base> + 1E _H	✓	✓	✓	8	—
RLN3n	LIN / UART Data Buffer 8 Register	RLN3nLDBR8	<RLIN3n_base> + 1F _H	✓	✓	✓	8	—
RLN3n	UART Operation Enable Register	RLN3nLUOER	<RLIN3n_base> + 20 _H	—	—	✓	8	—
RLN3n	UART Option Register 1	RLN3nLUOR1	<RLIN3n_base> + 21 _H	—	—	✓	8	—
RLN3n	UART Transmission Data Register	RLN3nLUTDR	<RLIN3n_base> + 24 _H	—	—	✓	16	—
RLN3n	UART Transmission Data Register L	RLN3nLUTDRL	<RLIN3n_base> + 24 _H	—	—	✓	8	—
RLN3n	UART Transmission Data Register H	RLN3nLUTDRH	<RLIN3n_base> + 25 _H	—	—	✓	8	—
RLN3n	UART Reception Data Register	RLN3nLURDR	<RLIN3n_base> + 26 _H	—	—	✓	16	—
RLN3n	UART Reception Data Register L	RLN3nLURDRL	<RLIN3n_base> + 26 _H	—	—	✓	8	—
RLN3n	UART Reception Data Register H	RLN3nLURDRH	<RLIN3n_base> + 27 _H	—	—	✓	8	—
RLN3n	UART Wait Transmission Data Register	RLN3nLUWTD	<RLIN3n_base> + 28 _H	—	—	✓	16	—
RLN3n	UART Wait Transmission Data Register L	RLN3nLUWTDRL	<RLIN3n_base> + 28 _H	—	—	✓	8	—
RLN3n	UART Wait Transmission Data Register H	RLN3nLUWTDH	<RLIN3n_base> + 29 _H	—	—	✓	8	—

Note: ✓: Used, —: Not used

When writing to an unused register, write the value after reset.

20.3.2 LIN Master Related Registers

20.3.2.1 RLN3nLWBR — LIN Wake-Up Baud Rate Select Register

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	NSPB[3:0]				LPRS[2:0]			LWBR0
Value after reset	0	0	0	0	0	0	0	0
	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 20.12 RLN3nLWBR Register Contents

Bit Position	Bit Name	Function
7 to 4	NSPB[3:0]	Bit Sampling Count Select b7 b4 0 0 0 0: 16 samplings Settings other than the above are prohibited.
3 to 1	LPRS[2:0]	Prescaler Clock Select b3 b1 0 0 0: 1/1 0 0 1: 1/2 0 1 0: 1/4 0 1 1: 1/8 1 0 0: 1/16 1 0 1: 1/32 1 1 0: 1/64 1 1 1: 1/128
0	LWBR0	Wake-up Baud Rate Select 0: In LIN wake-up mode, the clock specified in the LCKS bit of the RLN3nLMD register is used. (LIN1.3) 1: In LIN wake-up mode, the clock fa is used regardless of the setting in the LCKS bit of the RLN3nLMD register. (LIN2.x)

Configure the RLN3nLWBR register when the OMM0 bit in the RLN3nLMST register is 0_B (in LIN reset mode).

NSPB[3:0] Bits (Bit Sampling Count Select)

These bits select the number of sampling in one Tbit (reciprocal of the baud rate).

In LIN master mode (LIN/UART mode select bits in LIN mode register = 00_B), set these bits to 0000_B (16 sampling).

LPRS[2:0] Bits (Prescaler Clock Select)

These bits select the frequency division ratio for the prescaler.

The LIN communication clock source is divided by this prescaler.

LWBR0 Bit (Wake-up Baud Rate Select)

When LIN Specification Package Revision 1.3 is used, set the LWBR0 bit in the RLN3nLWBR register to 0. This allows an input signal with a low-level width of 2.5 Tbits or more to be measured.

When LIN Specification Package Revision 2.x is used, set the LWBR0 bit to 1. Setting the LWBR0 bit to 1 selects fa as the LIN system clock (fLIN) during LIN wake-up mode regardless of the setting of the RLN3nLMD.LCKS bit (the LCKS bit is not changed). This allows an input signal with a low-level width of 2.5 Tbits or more to be measured.

Setting the baud rate to 19200 bps while fa is selected allows an input signal with a low-level width of 130 us or longer to be detected in the LIN wake-up mode regardless of the setting of the RLN3nLMD.LCKS bit.

20.3.2.2 RLN3nLBRP0 — LIN Baud Rate Prescaler 0 Register

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	LBRP0[7:0]							
Value after reset	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 20.13 RLN3nLBRP0 Register Contents

Bit Position	Bit Name	Function
7 to 0	LBRP0[7:0]	Assuming that the value set in this register is N (0 to 255), the baud rate prescaler divides the frequency of the prescaler clock by N + 1. Setting range: 00 _H to FF _H

Configure the RLN3nLBRP0 register when the OMM0 bit in the RLN3nLMST register is 0_B (in LIN reset mode).

The value set in this register is used to control the frequency of baud rate clock sources fa, fb, and fc.

Assuming that the value set in this register is N, baud rate prescaler 0 divides the frequency of the clock that is selected by the LPRS bits (prescaler clock select bits) by N + 1.

Registers RLN3nLBRP0 and RLN3nLBRP1 can be accessed as RLN3nLBRP01 in 16-bit units.

20.3.2.3 RLN3nLBRP1 — LIN Baud Rate Prescaler 1 Register

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	LBRP1[7:0]							
Value after reset	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 20.14 RLN3nLBRP1 Register Contents

Bit Position	Bit Name	Function
7 to 0	LBRP1[7:0]	Assuming that the value set in this register is M (0 to 255), the baud rate prescaler divides the frequency of the prescaler clock by M + 1. Setting range: 00 _H to FF _H

Set the RLN3nLBRP1 register when the OMM0 bit in the RLN3nLMST register is 0_B (in LIN reset mode).

The value set in this register is used to control the frequency of baud rate clock source f_d .

Assuming that the value set in this register is M, baud rate prescaler 1 divides the frequency of the clock that is selected by the LPRS bits (prescaler clock select bits) by M+1.

Registers RLN3nLBRP0 and RLN3nLBRP1 can be accessed as RLN3nLBRP01 in 16-bit units.

20.3.2.4 RLN3nLSTC — LIN Self-Test Control Register

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	LSTM
Value after reset	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 20.15 RLN3nLSTC Register Contents

Bit Position	Bit Name	Function
7 to 0	—	LIN Self-Test Mode Entry In writing to this bit, write value is meaningful only when A7H, 58H, and 01H are written successively to this register in LIN Self-Test mode. In other cases, write value is ignored.
0	LSTM	LIN Self-Test Mode 0: The module is not in LIN Self-Test mode. 1: The module is in LIN Self-Test mode.

The RLN3nLSTC register cancels protection of LIN Self-Test mode.

Set the RLN3nLSTC register when the OMM0 bit in the RLN3nLMST register is 0_B (in LIN reset mode).

Writing A7H, 58H, and 01H successively to the RLN3nLSTC register places the module into LIN Self-Test mode.

When successive writing is completed and the mode is changed to LIN self-test mode, the LSTM bit is set to 1.

Do not write any other value during successive writing. For making transition to LIN Self-Test mode, see **Section 20.5.5, LIN Self-Test Mode**.

When read, bits 6 to 1 return “000 000_B”, and bit 7 returns an undefined value.

LSTM Bit (LIN Self-Test Mode)

When transition to LIN Self-Test mode is completed, the LSTM bit is set to 1.

For exiting LIN Self-Test mode, see **Section 20.5.5, LIN Self-Test Mode**.

Writing 1 to this bit does not affect the value of the RLN3nLSTC register if it is not a part of successive writing of A7H, 58H, and 01H.

20.3.2.5 RLN3nLMD — LIN Mode Register

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	LRDNFS	LIOS	LCKS[1:0]		LMD[1:0]	
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R/W	R/W	R/W	R/W	R/W	R/W

Table 20.16 RLN3nLMD Register Contents

Bit Position	Bit Name	Function															
7, 6	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.															
5	LRDNFS	LIN Reception Data Noise Filter Disable 0: The noise filter is enabled. 1: The noise filter is disabled.															
4	LIOS	LIN Interrupt Output Select 0: Not supported, setting is prohibited. 1: RLIN3n transmission interrupt, RLIN3n successful reception interrupt, and RLIN3n status interrupt are used.															
3, 2	LCKS[1:0]	LIN System Clock Select <table border="0"> <tr> <td>b3</td> <td>b2</td> <td></td> </tr> <tr> <td>0</td> <td>0:</td> <td>fa (Clock generated by baud rate prescaler 0)</td> </tr> <tr> <td>0</td> <td>1:</td> <td>fb (1/2 clock generated by baud rate prescaler 0)</td> </tr> <tr> <td>1</td> <td>0:</td> <td>fc (1/8 clock generated by baud rate prescaler 0)</td> </tr> <tr> <td>1</td> <td>1:</td> <td>fd (1/2 clock generated by baud rate prescaler 1)</td> </tr> </table>	b3	b2		0	0:	fa (Clock generated by baud rate prescaler 0)	0	1:	fb (1/2 clock generated by baud rate prescaler 0)	1	0:	fc (1/8 clock generated by baud rate prescaler 0)	1	1:	fd (1/2 clock generated by baud rate prescaler 1)
b3	b2																
0	0:	fa (Clock generated by baud rate prescaler 0)															
0	1:	fb (1/2 clock generated by baud rate prescaler 0)															
1	0:	fc (1/8 clock generated by baud rate prescaler 0)															
1	1:	fd (1/2 clock generated by baud rate prescaler 1)															
1, 0	LMD[1:0]	LIN/UART Mode Select <table border="0"> <tr> <td>b1</td> <td>b0</td> <td></td> </tr> <tr> <td>0</td> <td>0:</td> <td>LIN master mode</td> </tr> </table>	b1	b0		0	0:	LIN master mode									
b1	b0																
0	0:	LIN master mode															

Set the RLN3nLMD register when the OMM0 bit in the RLN3nLMST register is 0_B (in LIN reset mode)

LRDNFS Bit (LIN Reception Data Noise Filtering Disable)

The LRDNFS bit enables or disables the noise filter when receiving data.

With 0 set, the noise filter is enabled when receiving data.

With 1 set, the noise filter is disabled when receiving data.

LIOS Bit (LIN Interrupt Output Select)

The LIOS bit selects the number of interrupt outputs from the LIN/UART interface.

With 0 set, Not supported, setting is prohibited.

With 1 set, the RLIN3n transmission interrupt, RLIN3n successful reception interrupt, and RLIN3n status interrupt are generated from the LIN/UART interface.

For each interrupt source, see **Section 20.4, Interrupt Sources**.

The LIOS bit must always be set when using LIN mode operation, in order to enable the interrupt generation by the RLIN3 module. For UART mode, this bit is not relevant.

LCKS[1:0] Bits (LIN System Clock Select)

The LCKS bits select the clock to be input to the protocol controller.

With 00_B set, the protocol controller is provided with fa (clock generated by baud rate prescaler 0).

With 01_B set, the protocol controller is provided with fb (1/2 clock generated by baud rate prescaler 0).

With 10_B set, the protocol controller is provided with fc (1/8 clock generated by baud rate prescaler 0).

With 11_B set, the protocol controller is provided with fd (1/2 clock generated by baud rate prescaler 1).

When 1_B is set in the LWBR0 bit in the RLN3nLWBR register (LIN 2.x), and the RLN3nLMST register is 01_H (in LIN wake-up mode), the protocol controller is supplied with fa regardless of the setting of this bit (the LCKS bit is not changed).

LMD[1:0] Bits (LIN/UART Mode Select)

The LMD bits select the LIN/UART interface mode.

To use the LIN/UART interface as an LIN master, set these bits to 00_B.

20.3.2.6 RLN3nLBFC — LIN Break Field Configuration Register

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	BDT[1:0]		BLT[3:0]			
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R/W	R/W	R/W	R/W	R/W	R/W

Table 20.17 RLN3nLBFC Register Contents

Bit Position	Bit Name	Function																					
7, 6	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.

0	0	0: 13 Tbits																					
0	0	1: 14 Tbits																					
0	0	1: 15 Tbits																					
		:																					
1	1	1: 27 Tbits																					
1	1	1: 28 Tbits																					

Set the RLN3nLBFC register when the OMM0 bit in the RLN3nLMST register is 0_B (in LIN reset mode).

Some combinations of the set values result in the length of a frame exceeding the timeout time. Set the appropriate values in this register.

BDT[1:0] Bits (Transmission Break Delimiter (High Level) Width Select)

The BDT bits set the break delimiter (high level) width of transmission frame header. 1 Tbit to 4 Tbits can be set.

BLT[3:0] Bits (Transmission Break (Low Level) Width Select)

The BLT bits set the break (low level) width of transmission frame header. 13 Tbits to 28 Tbits can be set.

20.3.2.7 RLN3nLSC — LIN Space Configuration Register

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	IBS[1:0]		—	IBHS[2:0]		
Value after reset	0	0	0	0	0	0	0	0

1	0	1: 5 Tbits																											
1	1	0: 6 Tbits																											
1	1	1: 7 Tbits																											

Set the RLN3nLSC register when the OMM0 bit in the RLN3nLMST register is 0_B (in LIN reset mode).

Some combinations of the set values result in the length of a frame or a response exceeding the timeout time. Set the appropriate values in this register.

IBS[1:0] Bits (Inter-Byte Space Select)

The IBS bits set the width of the inter-byte space of the transmission frame response field.

0 Tbit to 3 Tbits can be set.

These bits are enabled only during response transmission; these are disabled during response reception.

IBHS[2:0] Bits (Inter-Byte Space (Header)/Response Space Select)

The IBHS bits set the width of the response space before response transmission.

0 Tbit to 7 Tbits can be set.

The response space setting is enabled only during response transmission; setting is disabled during response reception.

The inter-byte space (header) is equal to the response space.

20.3.2.8 RLN3nLWUP — LIN Wake-Up Configuration Register

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	WUTL[3:0]				—	—	—	—
Value after reset	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R	R	R	R

Table 20.19 RLN3nLWUP Register Contents

Bit Position	Bit Name	Function
7 to 4	WUTL[3:0]	Wake-up Transmission Low Level Width Select b7 b4 0 0 0 0: 1 Tbit 0 0 0 1: 2 Tbits 0 0 1 0: 3 Tbits 0 0 1 1: 4 Tbits : 1 1 0 0: 13 Tbits 1 1 0 1: 14 Tbits 1 1 1 0: 15 Tbits 1 1 1 1: 16 Tbits
3 to 0	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.

Set the RLN3nLWUP register when the OMM0 bit in the RLN3nLMST register is 0_B (in LIN reset mode).

WUTL[3:0] Bits (Wake-up Transmission Low Level Width Select)

The WUTL bits set the low level width of the wake-up signal transmission.

1 Tbit to 16 Tbits can be set.

With 1 is set in the LWBR0 bit in the RLN3nLWBR register (LIN 2.x), fa is selected as the LIN system clock (fLIN) regardless of the setting of the RLN3nLMD.LCKS bit (the LCKS bit is not changed).

20.3.2.9 RLN3nLIE — LIN Interrupt Enable Register

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	SHIE	ERRIE	FRCIE	FTCIE
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R/W	R/W	R/W	R/W

Table 20.20 RLN3nLIE Register Contents

Bit Position	Bit Name	Function
7 to 4	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
3	SHIE	Successful Header Transmission Interrupt Enable 0: Disables successful header transmission interrupt request. 1: Enables successful header transmission interrupt request.
2	ERRIE	Error Detection Interrupt Enable 0: Disables error detection interrupt request. 1: Enables error detection interrupt request.
1	FRCIE	Successful Frame/Wake-up Reception Interrupt Enable 0: Disables successful frame/wake-up reception interrupt request. 1: Enables successful frame/wake-up reception interrupt request.
0	FTCIE	Successful Frame/Wake-up Transmission Interrupt Enable 0: Disables successful frame/wake-up transmission interrupt request. 1: Enables successful frame/wake-up transmission interrupt request.

Set the RLN3nLIE register when the OMM0 bit in the RLN3nLMST register is 0_B (in LIN reset mode).

SHIE Bit (Successful Header Transmission Interrupt Enable)

The SHIE bit enables or disables interrupt requests upon successful transmission of a header.

With 0 set, the interrupt request for RLIN3n transmission is not generated when the HTRC flag in the RLN3nLST register is set to 1.

With 1 set, the interrupt request for RLIN3n transmission is generated when the HTRC flag in the RLN3nLST register is set to 1.

ERRIE Bit (Error Detection Interrupt Enable)

The ERRIE bit enables or disables an interrupt request upon detection of an error.

With 0 set, the interrupt request for RLIN3n status is not generated when the ERR flag in the RLN3nLST register is set to 1.

With 1 set, the interrupt request for RLIN3n status is generated when the ERR flag in the RLN3nLST register is set to 1.

Occurrence factors are bit errors, physical bus errors, frame/response timeout errors, framing errors, checksum errors, and response preparation errors.

Detection of the bit error, physical bus error, frame/response timeout error, and framing error can be enabled or disabled using the RLN3nLEDE register.

FRCIE Bit (Successful Frame/Wake-up Reception Interrupt Enable)

The FRCIE bit enables or disables an interrupt request upon successful reception of a frame or a wake-up signal (input signal low-level width count).

With 0 set, the interrupt request for successful RLIN3n reception is not generated when the FRC flag in the RLN3nLST register is set to 1.

With 1 set, the interrupt request for successful RLIN3n reception is generated when the FRC flag in the RLN3nLST register is set to 1.

FTCIE Bit (Successful Frame/Wake-up Transmission Interrupt Enable)

The FTCIE bit enables or disables an interrupt request upon successful transmission of a frame or a wake-up signal.

With 0 set, the interrupt request for RLIN3n transmission is not generated when the FTC flag in the RLN3nLST register is set to 1.

With 1 set, the interrupt request for RLIN3n transmission is generated when the FTC flag in the RLN3nLST register is set to 1.

20.3.2.10 RLN3nLEDE —LIN Error Detection Enable Register

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	LTES	—	—	—	FERE	FTERE	PBERE	BERE
Value after reset	0	0	0	0	0	0	0	0
R/W	R/W	R	R	R	R/W	R/W	R/W	R/W

Table 20.21 RLN3nLEDE Register Contents

Bit Position	Bit Name	Function
7	LTES	Timeout Error Select 0: Frame timeout error 1: Response timeout error
6 to 4	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
3	FERE	Framing Error Detection Enable 0: Disables framing error detection. 1: Enables framing error detection.
2	FTERE	Timeout Error Detection Enable 0: Disables frame/response timeout error detection. 1: Enables frame/response timeout error detection.
1	PBERE	Physical Bus Error Detection Enable 0: Disables physical bus error detection. 1: Enables physical bus error detection.
0	BERE	Bit Error Detection Enable 0: Disables bit error detection. 1: Enables bit error detection.

Set the RLN3nLEDE register when the OMM0 bit in the RLN3nLMST register is 0_B (in LIN reset mode)

LTES Bit (Timeout Error Select)

The LTES bit selects the timeout function to be used.

With 0 set, the timeout function is used for frame timeout.

With 1 set, the timeout function is used for response timeout.

For details on the timeout error, see **Section 20.5.3.7, Error Status**.

FERE Bit (Framing Error Detection Enable)

The FERE bit enables or disables detection of the framing error.

With 0 set, the framing error is not detected.

With 1 set, the framing error is detected.

When this bit is set to 1, the detection result is indicated in the FER flag in the RLN3nLEST register.

For details on the framing error, see **Section 20.5.3.7, Error Status**.

FTERE Bit (Timeout Error Detection Enable)

The FTERE bit enables or disables detection of the frame timeout error or the response timeout error.

With 0 set, the frame timeout error or response timeout error is not detected.

With 1 set, the frame timeout error or response timeout error is detected.

When this bit is set to 1, the detection result is indicated in the FTER flag in the RLN3nLEST register.
With the LTES bit, either the frame timeout error or response timeout error can be selected.

Do not use the timeout error if response data of 9 bytes or more is to be transmitted or received.
For details on the timeout error, see **Section 20.5.3.7, Error Status**.

Timeout error should be disabled for data group communication.

PBERE Bit (Physical Bus Error Detection Enable)

The PBERE bit enables or disables detection of the physical bus error.

With 0 set, the physical bus error is not detected.

With 1 set, the physical bus error is detected.

When this bit is set to 1, the detection result is indicated in the PBER flag in the RLN3nLEST register.

For details on the physical bus error, see **Section 20.5.3.7, Error Status**.

BERE Bit (Bit Error Detection Enable)

The BERE bit enables or disables detection of the bit error.

With 0 set, the bit error is not detected.

With 1 set, the bit error is detected.

When this bit is set to 1, the detection result is indicated in the BER flag in the RLN3nLEST register.

For details on the bit error, see **Section 20.5.3.7, Error Status**.

20.3.2.11 RLN3nLCUC — LIN Control Register

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	OM1	OM0
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R/W	R/W

Table 20.22 RLN3nLCUC Register Contents

Bit Position	Bit Name	Function
7 to 2	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
1	OM1	LIN Mode Select 0: LIN wake-up mode. 1: LIN operation mode.
0	OM0	LIN Reset 0: LIN reset mode. 1: LIN reset mode is canceled.

Set the RLN3nLCUC register to 01_H to transition to LIN wake-up or to 03_H to transition to LIN operation mode after exiting LIN reset mode.

In LIN Self-Test mode, set the RLN3nLCUC register to 03_H after a transition to LIN Self-Test mode is completed.

After a value is written to this register, confirm that the value written is actually indicated in the RLN3nLMST register before writing another value.

OM1 Bit (LIN Mode Select)

The OM1 bit selects the specific operation mode (either LIN wake-up mode or LIN operation mode) after canceling LIN reset mode.

With 0 set, LIN wake-up mode.

With 1 set, LIN operation mode.

This bit is valid only when the OMM0 bit in the RLN3nLMST register is 1.

Writing a value to this bit is disabled while the FTS bit in the RLN3nLTRC register is 1.

OM0 Bit (LIN Reset)

The OM0 bit selects either causing a transition to LIN reset mode or canceling LIN reset mode.

With 0 set, LIN reset mode is caused.

With 1 set, LIN reset mode is canceled.

20.3.2.12 RLN3nLTRC — LIN Transmission Control Register

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	RTS	FTS
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R/W	R/W

Table 20.23 RLN3nLTRC Register Contents

Bit Position	Bit Name	Function
7 to 2	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
1	RTS	Response Transmission/Reception Start 0: Response transmission/reception is stopped in frame separate mode. 1: Response transmission/reception is started in frame separate mode.
0	FTS	Frame Transmission/Wake-up Transmission /Reception Start 0: Frame Transmission/wake-up transmission/reception is stopped. 1: Frame Transmission/wake-up transmission reception is started.

RTS Bit (Response Transmission/Reception Start)

Set the RTS bit to 1 in frame separate mode after header transmission is started (FTS bit is 1) and response transmission data is ready. Once set, this bit is automatically cleared to 0 upon completion of frame communication (including error detection) or transition to LIN reset mode.

Only 1 can be written to this bit; 0 cannot be written.

To write 1 to this bit, write 02_H to the RLN3nLTRC register using the store instruction.

Writing a value to this bit is disabled when the OMM0 bit in the RLN3nLMST register is 0_B (in LIN reset mode).

Writing a value to this bit is disabled when the FTS bit is 0 (frame transmission or wake-up transmission/reception is halted).

When response data of 9 bytes or more is to be transmitted or received, set this bit to 1 each time a data group (variable from 0 to 8 bytes) is transmitted or received. Once set, this bit is automatically cleared to 0 at the end of data group communication or transition to LIN reset mode.

FTS Bit (Frame Transmission/Wake-up Transmission/Reception Start)

Set the FTS bit to 1 to start frame transmission and reception.

Also set this bit to 1 to allow wake-up transmission and reception (input signal low-level width count).

Only 1 can be written to this bit; 0 cannot be written.

Writing a value to this bit is disabled when the OMM0 bit in the RLN3nLMST register is 0_B (in LIN reset mode).

This bit is set to 0 upon completion of frame or wake-up communication (including error detection) and transition to LIN reset mode.

20.3.2.13 RLN3nLMST — LIN Mode Status Register

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	OMM1	OMM0
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R

Table 20.24 RLN3nLMST Register Contents

Bit Position	Bit Name	Function
7 to 2	—	Reserved When read, the value after reset is returned. Writing is ignored.
1	OMM1	LIN Mode Status Monitor 0: LIN wake-up mode. 1: LIN operation mode.
0	OMM0	LIN Reset Status Monitor 0: LIN reset mode. 1: Not in LIN reset mode.

OMM1 Bit (LIN Mode Status Monitor)

The OMM1 bit indicates the current operating mode.

OMM0 Bit (LIN Reset Status Monitor)

The OMM0 bit indicates the current operating mode.

It takes 3 peripheral clock cycles + 4 communication clock cycles, until the OMM0 bit in the RLN3nLMST register reflects the OMM0 bit setting in the RLN3nLCUC register.

20.3.2.14 RLN3nLST — LIN Status Register

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	HTRC	D1RC	—	—	ERR	—	FRC	FTC
Value after reset	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R	R	R	R	R/W	R/W

Table 20.25 RLN3nLST Register Contents

Bit Position	Bit Name	Function
7	HTRC	Successful Header Transmission Flag 0: Header transmission has not been completed. 1: Header transmission has been completed.
6	D1RC	Successful Data 1 Reception Flag 0: Data 1 reception has not been completed. 1: Data 1 reception has been completed.
5, 4	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
3	ERR	Error Detection Flag 0: No error has been detected. 1: Error has been detected.
2	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
1	FRC	Successful Frame/Wake-up Reception Flag 0: Frame or wake-up reception has not been completed. 1: Frame or wake-up reception has been completed.
0	FTC	Successful Frame/Wake-up Transmission Flag 0: Frame or wake-up transmission has not been completed. 1: Frame or wake-up transmission has been completed.

The RLN3nLST register is automatically cleared to 00_H upon transition to LIN reset mode and start of the next communication (when the FTS bit of the RLN3nLTRC register is 1).

In LIN reset mode, this register cannot be written to. In LIN reset mode, the register retains 00_H.

To clear the specific bits in the register, write 0 to the bits to be cleared and write 1 to the other bits using the store instruction.

HTRC Flag (Successful Header Transmission Flag)

Only 0 can be written to the HTRC flag; when 1 is written, the bit retains the value that has been retained before 1 is written.

The HTRC flag is set to 1 upon completion of header transmission. Here, an interrupt is generated if the SHIE bit in the RLN3nLIE register is 1 (interrupt is enabled). This bit is cleared automatically when LTRC.FTS is set.

D1RC Flag (Successful Data 1 Reception Flag)

Only 0 can be written to the D1RC flag; when 1 is written, the bit retains the value that has been retained before 1 is written.

The D1RC flag is set to 1 upon completion of data 1 reception. Here, an interrupt request is not generated.

To clear the bit to 0 before the next communication (when the FTS bit of the RLN3nLTRC register is 1), write 0 to the bit in LIN operation mode.

When response data of 9 bytes or more is to be received, this bit is set to 1 each time data 1 of a data group (variable from 0 to 8 bytes) is received. Write 0 before starting reception of the next data group.

ERR Flag (Error Detection Flag)

The ERR flag is set to 1 upon detection of an error (when at least one of the flags of the RLN3nLEST register is set to 1). Here, an interrupt request for RLN3n status is generated if the ERRIE bit in the RLN3nLIE register is 1 (interrupt is enabled). To clear the bit to 0 before the next communication (when the FTS bit of the RLN3nLTRC register is 1), write 0 to the RPER, CSER, FER, FTER, PBER, and BER flags in the RLN3nLEST register in LIN operation mode or LIN wake-up mode. This clears the ERR flag to 0.

FRC Flag (Successful Frame/Wake-up Reception Flag)

Only 0 can be written to the FRC flag; when 1 is written, the bit retains the value that has been retained before 1 is written.

The FRC flag is set to 1 upon completion of frame or wake-up reception. Here, an interrupt request for RLN3n reception complete is generated if the FRCIE bit in the RLN3nLIE register is 1 (interrupt is enabled). To clear the bit to 0 before the next communication (when the FTS bit of the RLN3nLTRC register is 1), write 0 to the bit in LIN operation mode or LIN wake-up mode.

When response data of 9 bytes or more is to be received, this bit is set to 1 each time a data group (variable from 0 to 8 bytes) is received. Write 0 before starting reception of the next data group.

FTC Flag (Successful Frame/Wake-up Transmission Flag)

Only 0 can be written to the FTC flag; when 1 is written, the bit retains the value that has been retained before 1 is written.

The FTC flag is set to 1 upon completion of frame or wake-up transmission. Here, an interrupt request for RLN3n transmission is generated if the FTCIE bit in the RLN3nLIE register is 1 (interrupt is enabled). To clear the bit to 0 before the next communication (when the FTS bit of the RLN3nLTRC register is 1), write 0 to the bit in LIN operation mode or LIN wake-up mode.

When response data of 9 bytes or more is to be transmitted, this bit is set to 1 each time a data group (variable from 0 to 8 bytes) is transmitted. Write 0 before starting transmission of the next data group.

20.3.2.15 RLN3nLEST — LIN Error Status Register

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	RPER	—	CSER	—	FER	FTER	PBER	BER
Value after reset	0	0	0	0	0	0	0	0
R/W	R/W	R	R/W	R	R/W	R/W	R/W	R/W

Table 20.26 RLN3nLEST Register Contents

Bit Position	Bit Name	Function
7	RPER	Response Preparation Error Flag 0: Response preparation error has not been detected. 1: Response preparation error has been detected.
6	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
5	CSER	Checksum Error Flag 0: Checksum error has not been detected. 1: Checksum error has been detected.
4	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
3	FER	Framing Error Flag 0: Framing error has not been detected. 1: Framing error has been detected.
2	FTER	Timeout Error Flag 0: Frame/response timeout error has not been detected. 1: Frame/response timeout error has been detected.
1	PBER	Physical Bus Error Flag 0: Physical bus error has not been detected. 1: Physical bus error has been detected.
0	BER	Bit Error Flag 0: Bit error has not been detected. 1: Bit error has been detected.

The RLN3nLEST register is automatically cleared to 00_H upon transition to LIN reset mode and start of the next communication (when the FTS bit of the RLN3nLTRC register is 1).

In LIN reset mode, this register cannot be written to. In LIN reset mode, the register retains 00_H.

When the FTS bit in the RLN3nLTRC register is 1 (frame transmission or wake-up transmission/reception is started), do not write a value to this register.

To clear the specific bits in the register, write 0 to the bits to be cleared and write 1 to the other bits using the store instruction.

RPER Flag (Response Preparation Error Flag)

Only 0 can be written to the RPER flag; when 1 is written, the bit retains the value that has been retained before 1 is written.

The RPER flag is set to 1 upon response preparation error detection. This happens, if response preparation was not completed before the first byte of a response has been received.

This bit is cleared automatically when LTRC.FTS is set.

CSER Flag (Checksum Error Flag)

Only 0 can be written to the CSER flag; when 1 is written, the bit retains the value that has been retained before 1 is written.

The CSER flag is set to 1 upon checksum error detection.

This bit is cleared automatically when LTRC.FTS is set.

FER Flag (Framing Error Flag)

Only 0 can be written to the FER flag; when 1 is written, the bit retains the value that has been retained before 1 is written.

When the value of the FERE bit of the RLN3nLEDE register is 1 (framing error detection enabled), the FER flag is set to 1 upon framing error detection. This bit is cleared automatically when LTRC.FTS is set.

FTER Flag (Timeout Error Flag)

Only 0 can be written to the FTER flag; when 1 is written, the bit retains the value that has been retained before 1 is written.

When the FTERE bit of the RLN3nLEDE register is 1 (frame/response timeout error detection enabled), the FTER flag is set to 1 upon frame timeout error or response timeout error detection. This bit is cleared automatically when LTRC.FTS is set.

PBER Flag (Physical Bus Error Flag)

Only 0 can be written to the PBER flag; when 1 is written, the bit retains the value that has been retained before 1 is written.

When the PBERE bit of the RLN3nLEDE register is 1 (physical bus error detection enabled), the PBER flag is set to 1 upon physical bus error detection. This bit is cleared automatically when LTRC.FTS is set.

BER Flag (Bit Error Flag)

Only 0 can be written to the BER flag; when 1 is written, the bit retains the value that has been retained before 1 is written.

When the BERE bit of the RLN3nLEDE register is 1 (bit error detection enabled), the BER flag is set to 1 upon bit error detection. This bit is cleared automatically when LTRC.FTS is set.

20.3.2.16 RLN3nLDFC — LIN Data Field Configuration Register

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	LSS	FSM	CSM	RFT	RFDL[3:0]			
Value after reset	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 20.27 RLN3nLDFC Register Contents

Bit Position	Bit Name	Function
7	LSS	Transmission/Reception Continuation Select 0: The data group to be transmitted/received next is the last one. 1: The data group to be transmitted/received next is not the last one. (Checksum is not included.)
6	FSM	Frame Separate Mode Select 0: Frame separate mode is not set. 1: Frame separate mode is set.
5	CSM	Checksum Select 0: Classic checksum 1: Enhanced checksum
4	RFT	Response Field Communication Direction Select 0: Reception 1: Transmission
3 to 0	RFDL[3:0]	Response Field Length Select b3 b0 0 0 0 0: 0 byte (+ checksum) 0 0 0 1: 1 byte (+ checksum) 0 0 1 0: 2 bytes (+ checksum) : 0 1 1 1: 7 bytes (+ checksum) 1 0 0 0: 8 bytes (+ checksum) 1 0 0 1: 8 bytes (+ checksum) 1 0 1 0: 8 bytes (+ checksum) : 1 1 1 1: 8 bytes (+ checksum)

LSS Bit (Transmission/Reception Continuation Select)

The LSS bit indicates that the data group to be transmitted or received next is not the last data group when response data of 9 bytes or more is to be transmitted or received.

With 0 set, data and checksum are transmitted or received because the next data group to be transmitted or received is the last one.

With 1 set, only data is transmitted or received, and the checksum is not included because the next data group to be transmitted or received is not the last one.

Set the LSS bit only when the FSM bit is 1 (frame separate mode) and response data of 9 bytes or more is to be transmitted or received.

Set the LSS bit only when the RTS bit in the RLN3nLTRC is 0 (response transmit/receive is stopped).

FSM Bit (Frame Separate Mode Select)

The FSM bit sets the response communication mode.

With 0 set, frame separate mode is not selected. In this case, after header transmission is started (the FTS bit in the

RLN3nLTRC register is 1), response is transmitted/received without setting the RTS bit in the RLN3nLTRC register. With 1 set, frame separate mode is selected. If the RTS bit of the RLN3nLTRC register is set to 1 during header transmission, response transmission is executed after header transmission is completed.

For response reception which is 8 bytes or less (the RFT bit is 0), set the FSM bit to 0.

When causing a transition to LIN Self-Test mode, set this bit to 0 before transition.

For details on frame separate mode, see **Section 20.5.3.4(1), Transmission of LIN Frames**.

Set this bit when the FTS bit in the RLN3nLTRC register is 0 (frame transmission or wake-up transmission/reception is halted).

When response data of 9 bytes or more is to be transmitted or received, set the FSM bit to 1.

CSM Bit (Checksum Select)

The CSM bit sets the checksum mode.

With 0 set, classic checksum mode is selected.

With 1 set, enhanced checksum mode is selected.

When the timeout error is used (the FTERE bit in the RLN3nLEDE register is 1), the specific timeout time depends on the setting of this bit. For details on the bit error, see **Section 20.5.3.7, Error Status**.

Set this bit when the FTS bit in the RLN3nLTRC register is 0 (frame transmission or wake-up transmission/reception is halted).

When response data of 9 bytes or more is to be transmitted or received, do not change the CSM bit setting after the first data group through the last data group.

During communication of response data of 9 bytes or more, only the last data group (the LSS bit is 0) includes the checksum, and no other groups (the LSS bit is 1) include the checksum.

RFT Bit (Response Field Communication Direction Select)

The RFT bit sets the direction of the response field/wake-up signal communication.

With 0 set, reception is performed in the response field. In LIN wake-up mode, wake-up reception is performed (input signal low-level width count).

With 1 set, transmission is performed in the response field. In LIN wake-up mode, wake-up transmission is performed.

Set this bit when the FTS bit in the RLN3nLTRC register is 0 (frame transmission or wake-up transmission/reception is halted).

When response data of 9 bytes or more is to be transmitted or received, do not change the RFT bit setting after the first data group through the last data group.

RFDL[3:0] Bits (Response Field Length Select)

The RFDL bits set the length of the response field data.

The data length can be 0 to 8 bytes excluding the checksum size.

To transmit response data with the FSM bit set to 0 (not frame separate mode), set the RFDL bits before header transmission (the FTS bit in the RLN3nLTRC register is 0).

To transmit response data with the FSM bit set to 1 (frame separate mode), set the RFDL bits before response transmission (the RTS bit in the RLN3nLTRC register is 0).

To receive response data, set the RFDL bits before header transmission (the FTS bit in the RLN3nLTRC register is 0).

When response data of 9 bytes or more is to be transmitted or received, set the RFDL bits before data group transmission/reception (RTS bit in the RLN3nLTRC register is 0).

Only the last data group (the LSS bit is 0) includes the checksum, and no other groups (the LSS bit is 1) include the checksum.

20.3.2.17 RLN3nLIDB — LIN ID Buffer Register

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	IDP1	IDP0	ID[5:0]					
Value after reset	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 20.28 RLN3nLIDB Register Contents

Bit Position	Bit Name	Function
7	IDP1	Parity Setting (P1) Sets the parity bits (P1) to be transmitted in the ID field.
6	IDP0	Parity Setting (P0) Sets the parity bits (P0) to be transmitted in the ID field.
5 to 0	ID[5:0]	ID Setting Sets the 6-bit ID value to be transmitted in the ID field.

Set the RLN3nLIDB register when the FTS bit in the RLN3nLTRC register is 0 (frame transmission or wake-up transmission/reception is halted).

In LIN Self-Test mode, this register operates as described below.

Write the value to be transmitted before communication. After completion of frame transmission/reception (after loopback), the reversed value of the received value can be read.

For details about the LIN Self-Test mode, see **Section 20.5.5, LIN Self-Test Mode**.

IDP[1:0] Bits (Parity Setting)

The IDP bits set the parity bits (P0 and P1) to be transmitted in the ID field of the LIN frame. IDP0 is for P0 and IDP1 for P1.

Since parity is not automatically calculated, set the calculation result. Note that if the erroneous result is set, it is transmitted as is.

ID[5:0] Bits (ID Setting)

The ID bits set the 6-bit ID value to be transmitted in the ID field of the LIN frame.

20.3.2.18 RLN3nLCBR — LIN Checksum Buffer Register

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	CKSM[7:0]							
Value after reset	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 20.29 RLN3nLCBR Register Contents

Bit Position	Bit Name	Function
7 to 0	CKSM[7:0]	Holds the checksum data transmitted or received.

In LIN mode, this register operates as follows:

- When the RFT bit in the RLN3nLDFC register is 1 (transmission):
The value transmitted can be read from the register. Read the value after transmission is completed.
Writing to this register is invalid.
- When the RFT bit in the RLN3nLDFC register is 0 (reception):
The value received can be read from the register. Read the value after reception is completed.
Writing to this register is invalid.

In LIN Self-Test mode, this register operates as follows:

- When the RFT bit in the RLN3nLDFC register is 1 (transmission):
After completion of the frame transmission (after loopback), the reversed value of the received value can be read.
- When the RFT bit in the RLN3nLDFC register is 0 (reception):
Write the value to be received before communication. After completion of frame transmission/reception (after loopback), the reversed value of the received value can be read.

For details about the LIN Self-Test mode, see **Section 20.5.5, LIN Self-Test Mode**.

Set this register when the FTS bit in the RLN3nLTRC register is 0 (frame transmission or wake-up transmission/reception is halted).

When response data of 9 bytes or more is to be transmitted or received, the checksum is appended only to the last data group; this register is not updated for other data groups.

20.3.2.19 RLN3nLDBRb — LIN Data Buffer b Register (b = 1 to 8)

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	LDB[7:0]							
Value after reset	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 20.30 RLN3nLDBRb Register Contents

Bit Position	Bit Name	Function
7 to 0	LDB[7:0]	Sets the data to be transmitted or reads the received data. Setting range: 00 _H to FF _H

- For response transmission:

These registers set the data to be transmitted in the response field.
Use these registers with the following settings.

 - RFT in RLN3nLDFC register is 1 (transmission)
 - FSM in RLN3nLDFC register is 0 (not frame separate mode)
 - FTS in RLN3nLTRC register is 0 (frame transmission or wake-up transmission/reception is halted)

or

 - RFT in RLN3nLDFC register is 1 (transmission)
 - FSM in RLN3nLDFC register is 1 (frame separate mode)
 - RTS in RLN3nLTRC register is 0 (response transmission/reception is halted)
- For response reception:

These registers hold the data received in the response field.
The received data is overwritten. If an error is detected, the data up to the byte in which the error was detected are stored in the register.
Do not read these registers when the FTS bit is 1 (frame transmission or wake-up transmission/reception is started)
- For transmission of response data of 9 bytes or more:

Use these registers with the following settings.

 - RFT in RLN3nLDFC register is 1 (transmission)
 - FSM in RLN3nLDFC register is 1 (frame separate mode)
 - RTS in RLN3nLTRC register is 0 (response transmission/reception is halted)
- For reception of response data of 9 bytes or more:

Do not read these registers when the RTS bit is 1 (response transmission/reception is started).

In LIN Self-Test mode, these registers operate as described below.

Write the value to be transmitted before communication. After completion of frame transmission/reception (after loopback), the reversed value of the received value can be read.

For details about the LIN Self-Test mode, see **Section 20.5.5, LIN Self-Test Mode**.

20.3.3 LIN Slave Related Registers

20.3.3.1 RLN3nLWBR — LIN Wake-Up Baud Rate Select Register

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	NSPB[3:0]				LPRS[2:0]			—
Value after reset	0	0	0	0	0	0	0	0
	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R

Table 20.31 RLN3nLWBR Register Contents

Bit Position	Bit Name	Function
7 to 4	NSPB[3:0]	Bit Sampling Count Select b7 b4 0 0 0 0: 16 sampling 0 0 1 1: 4 sampling 0 1 1 1: 8 sampling Settings other than the above are prohibited.
3 to 1	LPRS[2:0]	Prescaler Clock Select b3 b1 0 0 0: 1/1 0 0 1: 1/2 0 1 0: 1/4 0 1 1: 1/8 1 0 0: 1/16 1 0 1: 1/32 1 1 0: 1/64 1 1 1: 1/128
0	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.

Set the RLN3nLWBR register when the OMM0 bit in the RLN3nLMST register is 0_B (in LIN reset mode).

NSPB[3:0] Bits (Bit Sampling Count Select)

The NSPB bits select the number of sampling in one Tbit (reciprocal of the baud rate).

When the communication is performed in LIN slave mode (fixed baud rate) (LMD[1:0] bits in the RLN3nLMD register = 11_B), set these bits to “0000_B (16 sampling).

When the communication is performed in LIN slave mode (auto baud rate) (LMD[1:0] bits in the RLN3nLMD register = 10_B), set these bits to “0011_B” (4 sampling) or “0111_B” (8 sampling).

LPRS[2:0] Bits (Prescaler Clock Select)

The LPRS bits select the frequency division ratio for the prescaler. The LIN communication clock source is divided by this prescaler.

In LIN slave mode (auto baud rate) (LMD[1:0] bits in the RLN3nLMD register = 10_B), set these bits so that the prescaler clock becomes as follows according to the target baud rate.

[Target baud rate]	[Prescaler clock]
1 kbps to 20 kbps:	4 MHz* ¹
1 kbps to 2.4 kbps (excluding 2.4 kbps):	4 MHz
2.4 kbps to 20 kbps:	8 MHz to 12 MHz

Note 1. Use the clock with NSPB bits set to "0011_B" (four samplings).

20.3.3.2 RLN3nLBRP01 — LIN Baud Rate Prescaler 01 Register

Value after reset: 0000_H

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	BRP[15:0]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 20.32 RLN3nLBRP01 Register Contents

Bit Position	Bit Name	Function
15 to 0	BRP[15:0]	Assuming that the value set in this register is L (0 to 65535), the baud rate prescaler divides the frequency of the prescaler clock by L + 1. Setting range: 0000 _H to FFFF _H

Set the RLN3nLBRP01 register when the OMM0 bit in the RLN3nLMST register is 0_B (in LIN reset mode).

Assuming that the value set in this register is L, the baud rate prescaler divides the frequency of the clock that is selected by the LPRS bits (prescaler clock select bits) in the RLN3nLWBR register by L + 1.

The RLN3nLBRP01 register can be accessed in 8-bit units by registers RLN3nLBRP0 and RLN3nLBRP1.

20.3.3.3 RLN3nLSTC — LIN Self-Test Control Register

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	LSTM
Value after reset	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 20.33 RLN3nLSTC Register Contents

Bit Position	Bit Name	Function
7 to 0	—	LIN Self-Test Mode Entry In writing to this bit, the write value is meaningful only when A7 _H , 58 _H , and 01 _H are written successively to this register in LIN Self-Test mode. In other cases, the write value is ignored.
0	LSTM	LIN Self-Test Mode 0: LIN Self-Test mode is not set. 1: LIN Self-Test mode is set.

The RLN3nLSTC register cancels protection of LIN Self-Test mode.

Set the RLN3nLSTC register when the OMM0 bit in the RLN3nLMST register is 0_B (in LIN reset mode).

Writing A7_H, 58_H, and 01_H successively to the RLN3nLSTC register places the module into LIN Self-Test mode.

When successive writing is completed thus placing LIN Self-Test mode to be entered, the LSTM bit is set to 1.

Do not write any other value during successive writing.

For making transition to LIN Self-Test mode, see **Section 20.5.5, LIN Self-Test Mode**.

When reading bits 6 to 1, they return “000000_B”, and reading bit 7, it returns an undefined value.

LSTM Bits (LIN Self-Test Mode)

When transition to LIN Self-Test mode is completed, the LSTM bit is set to 1.

For exiting LIN Self-Test mode, see **Section 20.5.5, LIN Self-Test Mode**.

Writing 1 to this bit does not affect the value of the RLN3nLSTC register if it is not a part of successive writing of A7_H, 58_H, and 01_H.

20.3.3.4 RLN3nLMD — LIN Mode Register

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	LRDNFS	LIOS	—	—	LMD[1:0]	
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R/W	R/W	R	R	R/W	R/W

Table 20.34 RLN3nLMD Register Contents

Bit Position	Bit Name	Function
7, 6	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
5	LRDNFS	LIN Reception Data Noise Filtering Disable 0: The noise filter is enabled. 1: The noise filter is disabled.
4	LIOS	LIN Interrupt Output Select 0: Not supported, setting is prohibited. 1: RLIN3n transmission interrupt, RLIN3n successful reception interrupt, and RLIN3n status interrupt are used.
3, 2	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
1, 0	LMD[1:0]	LIN/UART Mode Select b1 b0 1 0: LIN slave mode with auto baud rate 1 1: LIN slave mode with fixed baud rate

Set the RLN3nLMD register when the OMM0 bit in the RLN3nLMST register is 0_B (LIN reset mode).

LRDNFS Bit (LIN Reception Data Noise Filter Disable)

The LRDNFS bit enables or disables the noise filter when receiving data.

With 0 set, the noise filter is enabled when receiving data.

With 1 set, the noise filter is disabled when receiving data.

LIOS Bit (LIN Interrupt Output Select)

The LIOS bit selects the number of interrupt outputs from the LIN/UART interface.

With 0 set, not supported, setting is prohibited.

With 1 set, the RLIN3n transmission interrupt, RLIN3n successful reception interrupt, and RLIN3n reception status interrupt are generated from the LIN/UART interface.

For each interrupt source, see **Section 20.4, Interrupt Sources**.

The LIOS bit must always be set when using LIN mode operation, in order to enable the interrupt generation by the RLIN3n module. For UART mode, this bit is not relevant.

LMD[1:0] Bits (LIN/UART Mode Select)

The LMD bits select the LIN/UART interface mode.

To use this module as an LIN slave, set these bits to “10_B” (auto baud rate) or “11_B” (fixed baud rate).

20.3.3.5 RLN3nLBFC — LIN Break Field Configuration Register

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	LBLT
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R/W

Table 20.35 RLN3nLBFC Register Contents

Bit Position	Bit Name	Function
7 to 1	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
0	LBLT	Reception Break (Low-Level) Detection Width Setting 0: A break (low-level) is detected in 9.5 or 10 Tbits 1: A break (low-level) is detected in 10.5 or 11 Tbits

Set the RLN3nLBFC register when the OMM0 bit in the RLN3nLMST register is 0_B (LIN reset mode).

LBLT Bit (Reception Break (Low-Level) Detection Width Setting)

- When RLN3nLMD.LMD is “10_B” (in LIN slave mode (auto baud rate))
 - 0: Low-level width of 10 Tbits or longer is detected.
 - 1: Low-level width of 11 Tbits or longer is detected.
- When RLN3nLMD.LMD is “11_B” (in LIN slave mode (fixed baud rate))
 - 0: Low-level width of 9.5 Tbits or longer is detected.
 - 1: Low-level width of 10.5 Tbits or longer is detected.

20.3.3.6 RLN3nLSC — LIN Space Configuration Register

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	IBS[1:0]		—	IBHS[2:0]		
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R/W	R/W	R	R/W	R/W	R/W

Table 20.36 RLN3nLSC Register Contents

Bit Position	Bit Name	Function																																				
7, 6	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.

0	0	1	1 Tbit																																			
0	1	0	2 Tbits																																			
0	1	1	3 Tbits																																			
1	0	0	4 Tbits																																			
1	0	1	5 Tbits																																			
1	1	0	6 Tbits																																			
1	1	1	7 Tbits																																			

Set the RLN3nLSC register when the OMM0 bit in the RLN3nLMST register is 0_B (LIN reset mode).

This register is enabled only for response transmission, and disabled for response reception.

Some combinations of the setting values result in the length of a frame or a response exceeding the timeout time. Set the appropriate values in this register.

IBS[1:0] Bits (Inter-Byte Space Select)

The IBS bits set the width of the inter-byte space of the response transmission.
0 Tbit to 3 Tbits can be set.

IBHS[2:0] Bits (Inter-Byte Space (Header)/Response Space Select)

These bits set the transmission width of the response space.
0 Tbit to 7 Tbits can be set.

20.3.3.7 RLN3nLWUP — LIN Wake-Up Configuration Register

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	WUTL[3:0]				—	—	—	—
Value after reset	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R	R	R	R

Table 20.37 RLN3nLWUP Register Contents

Bit Position	Bit Name	Function
7 to 4	WUTL[3:0]	Wake-up Transmission Low level Width Select b7 b4 0 0 0 0: 1 Tbit 0 0 0 1: 2 Tbits 0 0 1 0: 3 Tbits 0 0 1 1: 4 Tbits : 1 1 0 0: 13 Tbits 1 1 0 1: 14 Tbits 1 1 1 0: 15 Tbits 1 1 1 1: 16 Tbits
3 to 0	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.

Set the RLN3nLWUP register when the OMM0 bit in the RLN3nLMST register is 0_B (in LIN reset mode).

WUTL[3:0] Bits (Wake-up Transmission Low Level Width Select)

The WUTL bits set the low-level width of the wake-up frame transmission.

1 Tbit to 16 Tbits can be set.

20.3.3.8 RLN3nLIE — LIN Interrupt Enable Register

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	SHIE	ERRIE	FRCIE	FTCIE
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R/W	R/W	R/W	R/W

Table 20.38 RLN3nLIE Register Contents

Bit Position	Bit Name	Function
7 to 4	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
3	SHIE	Successful Header Reception Interrupt Enable 0: Disables successful header reception interrupt request. 1: Enables successful header reception interrupt request.
2	ERRIE	Error Detection Interrupt Enable 0: Disables error detection interrupt request. 1: Enables error detection interrupt request.
1	FRCIE	Successful Response/Wake-up Reception Interrupt Enable 0: Disables successful Response/wake-up reception interrupt request. 1: Enables successful Response/wake-up reception interrupt request.
0	FTCIE	Successful Response/Wake-up Transmission Interrupt Enable 0: Disables successful Response/wake-up transmission interrupt request. 1: Enables successful Response/wake-up transmission interrupt request.

Set the RLN3nLIE register when the OMM0 bit in the RLN3nLMST register is 0_B (in LIN reset mode).

SHIE Bit (Successful Header Reception Interrupt Enable)

The SHIE bit enables or disables an interrupt request upon successful reception of a header.

With 0 set, the interrupt request for RLIN3n reception complete is not generated when the HTRC flag in the RLN3nLST register is set to 1.

With 1 set, the interrupt request for RLIN3n reception complete is generated when the HTRC flag in the RLN3nLST register is set to 1.

ERRIE Bit (Error Detection Interrupt Enable)

The ERRIE bit enables or disables an interrupt request upon detection of an error.

With 0 set, the interrupt request for RLIN3n status is not generated when the ERR flag in the RLN3nLST register is set to 1.

With 1 set, the interrupt request for RLIN3n status is generated when the ERR flag in the RLN3nLST register is set to 1.

Error types that are interrupt sources are the bit error, frame/response timeout error, framing error, sync filed error, ID parity error, checksum error, and response preparation error.

Detection of the bit error, frame/response timeout error, sync filed error, ID parity error, and framing error can be enabled or disabled using the RLN3nLEDE register.

FRCIE Bit (Successful Response/Wake-up Reception Interrupt Enable)

The FRCIE bit enables or disables an interrupt request upon successful reception of a response or a wake-up frame (input signal low-level width count).

With 0 set, the interrupt is not generated when the FTC flag in the RLIN3nLST register is set to 1.

With 1 set, the interrupt is generated when the FTC flag in the RLIN3nLST register is set to 1.

FTCIE Bit (Successful Response/Wake-up Transmission Interrupt Enable)

The FTCIE bit enables or disables an interrupt request upon successful transmission of a response or a wake-up frame.

With 0 set, the interrupt request for successful RLIN3n transmission is not generated when the FTC flag in the RLIN3nLST register is set to 1.

With 1 set, the interrupt request for successful RLIN3n transmission is generated when the FTC flag in the RLIN3nLST register is set to 1.

20.3.3.9 RLN3nLEDE — LIN Error Detection Enable Register

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	LTES	IPERE	—	SFERE	FERE	TERE	—	BERE
Value after reset	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R	R/W	R/W	R/W	R	R/W

Table 20.39 RLN3nLEDE Register Contents

Bit Position	Bit Name	Function
7	LTES	Timeout Error Select 0: Frame timeout error 1: Response timeout error
6	IPERE	ID Parity Error Detection Enable 0: Disables ID Parity error detection. 1: Enables ID Parity error detection.
5	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
4	SFERE	Sync Field Error Detection Enable 0: Disables Sync Field error detection. 1: Enables Sync Field error detection.
3	FERE	Framing Error Detection Enable 0: Disables framing error detection. 1: Enables framing error detection.
2	TERE	Timeout Error Detection Enable 0: Disables frame/response timeout error detection. 1: Enables frame/response timeout error detection.
1	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
0	BERE	Bit Error Detection Enable 0: Disables bit error detection. 1: Enables bit error detection.

Set the RLN3nLEDE register when the OMM0 bit in the RLN3nLMST register is 0_B (in LIN reset mode).

LTES Bit (Timeout Error Select)

The LTES bit selects the timeout function to be used.

With 0 set, the timeout function operates as frame timeout.

With 1 set, the timeout function operates as response timeout.

For details on the timeout error, see **Section 20.5.3.7, Error Status**.

IPERE Bit (ID Parity Error Detection Enable)

This bit enables or disables detection of the ID parity error.

With 0 set, the ID parity error is not detected.

With 1 set, the ID parity error is detected.

When this bit is set to 1, the detection result is reflected in the IPER flag in the RLN3nLEST register.

For details on the ID parity error, see **Section 20.5.3.7, Error Status**.

SFERE Bit (Sync Field Error Detection Enable)

This bit enables or disables detection of the sync field error.

With 0 set, the sync field error is not detected.

With 1 set, the sync field error is detected.

Regardless of the setting of this bit, when a sync field error is detected, this module waits for the next header.

When this bit is set to 1, the detection result is reflected in the SFER flag in the RLN3nLEST register.

For details on the sync field error, see **Section 20.5.3.7, Error Status**.

FERE Bit (Framing Error Detection Enable)

The FERE bit enables or disables detection of the framing error.

With 0 set, the framing error is not detected.

With 1 set, the framing error is detected.

Set this bit to 1. The detection result is indicated in the FER flag in the RLN3nLEST register.

For details on the framing error, see **Section 20.5.3.7, Error Status**.

TERE Bit (Timeout Error Detection Enable)

The TERE bit enables or disables detection of the frame timeout error or the response timeout error.

With 0 set, the frame timeout error or response timeout error is not detected.

With 1 set, the frame timeout error or response timeout error is detected.

When this bit is set to 1, the detection result is reflected in the TER flag in the RLN3nLEST register.

With the LTES bit, either the frame timeout error or response timeout error can be selected.

The timeout error should not be used in LIN slave mode [auto baud rate] (when the LMD[1:0] bits in the RLN3nLMD register are "10_B").

Do not use the timeout error if response data of 9 bytes or more is to be transmitted or received.

For details on the timeout error, see **Section 20.5.3.7, Error Status**.

BERE Bit (Bit Error Detection Enable)

The BERE bit enables or disables detection of the bit error.

With 0 set, the bit error is not detected.

With 1 set, the bit error is detected.

When this bit is set to 1, the detection result is reflected in the BER flag in the RLN3nLEST register.

For details on the bit error, see **Section 20.5.3.7, Error Status**.

20.3.3.10 RLN3nLCUC — LIN Control Register

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	OM1	OM0
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R/W	R/W

Table 20.40 RLN3nLCUC Register Contents

Bit Position	Bit Name	Function
7 to 2	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
1	OM1	LIN Mode Select 0: LIN wake-up mode. 1: LIN operation mode.
0	OM0	LIN Reset 0: LIN reset mode. 1: LIN reset mode is canceled.

Set the RLN3nLCUC register to 01_H to transition to LIN wake-up mode or to 03_H to transition to LIN operation mode after exiting LIN reset mode.

In LIN Self-Test mode, set the RLN3nLCUC register to 03_H after a transition to LIN Self-Test mode is completed.

After a value is written to this register, confirm that the value written is actually indicated in the RLN3nLMST register before writing another value.

OM1 Bit (LIN Mode Select)

The OM1 bit selects the specific LIN operation mode (either LIN wake-up mode or LIN operation mode) after canceling LIN reset mode.

With 0 set, LIN wake-up mode is caused.

With 1 set, LIN operation mode is caused.

This bit is valid only when the OMM0 bit in the RLN3nLMST register is 1.

Writing a value to this bit is disabled while the FTS bit in the RLN3nLTRC register is 1.

OM0 Bit (LIN Reset)

The OM0 bit selects either causing a transition to LIN reset mode or canceling LIN reset mode.

With 0 set, LIN reset mode.

With 1 set, LIN reset mode is canceled.

It takes 3 peripheral clock cycles + 4 communication clock cycles, until the OMM0 bit in the RLN3nLMST register reflects the OM0 bit setting in the RLN3nLCUC register.

20.3.3.11 RLN3nLTRC — LIN Transmission Control Register

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	LNRR	RTS	FTS
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R/W	R/W	R/W

Table 20.41 RLN3nLTRC Register Contents

Bit Position	Bit Name	Function
7 to 3	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
2	LNRR	No LIN Response Request 0: Response for the reception ID 1: No response for the reception ID
1	RTS	Response Transmission/Reception Start 0: Response transmission/reception is stopped. 1: Response transmission/reception is started.
0	FTS	LIN Communication Start 0: Header reception/wake-up transmission/reception is stopped. 1: Header reception/wake-up transmission reception is started.

LNRR Bit (No LIN Response Request)

Set this bit to 1 if no response is to be transmitted/received after receiving the header and checking the received ID. Once set, this bit is automatically cleared to 0 upon detection of new sync field or transition to LIN reset mode.

Only 1 can be written to this bit; 0 cannot be written.

To write 1 to this bit, write 04_H using the store instruction.

Do not set this bit and the RTS bit to 1 simultaneously.

Writing a value to this bit is disabled when the OMM0 bit of the RLN3nLMST register is 0_B (in LIN reset mode).

Writing a value to this bit is disabled when the FTS bit is 0 (header reception or wake-up transmission/reception is halted).

RTS Bit (Response Transmission/Reception Start)

Set this bit to 1 to start response transmission or reception after receiving the header and checking the received ID.

Once set, this bit is automatically cleared to 0 upon completion of response transmission or reception (including error detection) or transition to LIN reset mode.

Only 1 can be written to this bit; 0 cannot be written.

To write 1 to this bit, write 02_H to the RLN3nLTRC register using the store instruction.

Do not set this bit and the LNRR bit to 1 simultaneously

Writing a value to this bit is disabled when the OMM0 bit of the RLN3nLMST register is 0_B (in LIN reset mode).

Writing a value to this bit is disabled when the FTS bit is 0 (header reception or wake-up transmission/reception is halted).

When response data of 9 bytes or more is to be transmitted or received, set this bit to 1 each time a data group (variable from 0 to 8 bytes) is transmitted or received. Once set, this bit is automatically cleared to 0 upon completion of data group transmission/reception or transition to LIN reset mode.

FTS Bit (LIN Communication Start)

Set this bit to 1 to start header reception or wake-up transmission/reception.

Only 1 can be written to this bit; 0 cannot be written.

Writing a value to this bit is disabled when the OMM0 bit of the RLN3nLMST register is 0_B (in LIN reset mode).

This bit is set to 0 upon completion of wake-up communication and transition to LIN reset mode.

20.3.3.12 RLN3nLMST — LIN Mode Status Register

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	OMM1	OMM0
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R

Table 20.42 RLN3nLMST Register Contents

Bit Position	Bit Name	Function
7 to 2	—	Reserved When read, the value after reset is returned.
1	OMM1	LIN Mode Status Monitor 0: LIN wake-up mode. 1: LIN operation mode.
0	OMM0	LIN Reset Status Monitor 0: LIN reset mode. 1: The module is not in LIN reset mode.

OMM1 Bit (LIN Mode Status Monitor)

The OMM1 bit indicates the current operating mode.

OMM0 Bit (LIN Reset Status Monitor)

The OMM0 bit indicates the current operating mode.

It takes 3 peripheral clock cycles + 4 communication clock cycles, until the OMM0 bit in the RLN3nLMST register reflects the OMM0 bit setting in the RLN3nLCUC register.

20.3.3.13 RLN3nLST — LIN Status Register

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	HTRC	D1RC	—	—	ERR	—	FRC	FTC
Value after reset	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R	R	R	R	R/W	R/W

Table 20.43 RLN3nLST Register Contents

Bit Position	Bit Name	Function
7	HTRC	Successful Header Reception Flag 0: Header reception has not been completed. 1: Header reception has been completed.
6	D1RC	Successful Data 1 Reception Flag 0: Data 1 reception has not been completed. 1: Data 1 reception has been completed.
5, 4	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
3	ERR	Error Detection Flag 0: No error has been detected. 1: Error has been detected.
2	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
1	FRC	Successful Response/Wake-up Reception Flag 0: Response or wake-up reception has not been completed. 1: Response or wake-up reception has been completed.
0	FTC	Successful Response/Wake-up Transmission Flag 0: Response or wake-up transmission has not been completed. 1: Response or wake-up transmission has been completed.

The RLN3nLST register is automatically cleared to 00_H upon transition to LIN reset mode and start of the next communication (when the FTS bit of the RLN3nLTRC register is 1).

In LIN reset mode, writing a value to this register is disabled. In LIN reset mode, the register retains 00_H.

To clear the specific bits in the register, write 0 to the bits to be cleared and write 1 to the other bits using the store instruction.

HTRC Flag (Successful Header Reception Flag)

Only 0 can be written to the HTRC flag; when 1 is written, the bit retains the value before 1 is written.

The HTRC flag is set to 1 upon completion of header transmission. Here, an interrupt is generated if the SHIE bit in the RLN3nLIE register is 1 (interrupt is enabled). This bit is cleared automatically when LTRC.FTS is set.

D1RC Flag (Successful Data 1 Reception Flag)

Only 0 can be written to the D1RC flag; when 1 is written, the bit retains the value that has been retained before 1 is written.

The D1RC flag is set to 1 upon completion of data 1 reception. Here, an interrupt request is not generated. Write 0 to clear this bit.

When response data of 9 bytes or more is to be received, this bit is set to 1 each time data 1 of a data group (variable from 0 to 8 bytes) is received. Write 0 before starting reception of the next data group.

ERR Flag (Error Detection Flag)

The ERR flag is set to 1 upon detection of an error (when at least one of the flags of the RLIN3nLEST register is set to 1). Here, an interrupt request for RLIN3n status is generated if the ERRIE bit in the RLIN3nLIE register is 1 (interrupt is enabled). However, if an error is detected while this bit is 1, an interrupt is not generated. To clear the ERR flag to 0, write 0 to the RPER, IPER, CSER, SFER, FER, TER, and BER flags in the RLIN3nLEST register. This clears the ERR flag to 0.

FRC Flag (Successful Response/Wake-up Reception Flag)

Only 0 can be written to the FRC flag; when 1 is written, the bit retains the value that has been retained before 1 is written.

The FRC flag is set to 1 upon completion of response or wake-up reception. Here, an interrupt request for successful RLIN3n reception is generated if the FRCIE bit in the RLIN3nLIE register is 1 (interrupt is enabled). This bit is cleared automatically when LTRC.FTS is set.

When response data of 9 bytes or more is to be received, this bit is set to 1 each time a data group (variable from 0 to 8 bytes) is received. Write 0 before starting reception of the next data group.

FTC Flag (Successful Response/Wake-up Transmission Flag)

Only 0 can be written to the FTC flag; when 1 is written, the bit retains the value that has been retained before 1 is written.

The FTC flag is set to 1 upon completion of frame or wake-up transmission. Here, an interrupt request for RLIN3n transmission is generated if the FTCIE bit in the RLIN3nLIE register is 1 (interrupt is enabled). This bit is cleared automatically when LTRC.FTS is set.

When response data of 9 bytes or more is to be transmitted, this bit is set to 1 each time a data group (variable from 0 to 8 bytes) is transmitted. Write 0 before starting transmission of the next data group.

20.3.3.14 RLN3nLEST — LIN Error Status Register

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	RPER	IPER	CSER	SFER	FER	TER	—	BER
Value after reset	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R/W

Table 20.44 RLN3nLEST Register Contents

Bit Position	Bit Name	Function
7	RPER	Response Preparation Error Flag 0: Response preparation error has not been detected. 1: Response preparation error has been detected.
6	IPER	ID Parity Error Flag 0: ID parity error has not been detected. 1: ID parity error has been detected.
5	CSER	Checksum Error Flag 0: Checksum error has not been detected. 1: Checksum error has been detected.
4	SFER	Sync Field Error Flag 0: Sync field error has not been detected. 1: Sync field error has been detected.
3	FER	Framing Error Flag 0: Framing error has not been detected. 1: Framing error has been detected.
2	TER	Timeout Error Flag 0: Frame/response timeout error has not been detected. 1: Frame/response timeout error has been detected.
1	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
0	BER	Bit Error Flag 0: Bit error has not been detected. 1: Bit error has been detected.

The RLN3nLEST register is automatically cleared to 00_H upon transition to LIN reset mode.

In LIN reset mode, this register cannot be written to. In LIN reset mode, the register retains 00_H.

To clear the specific bits in the register, write 0 to the bits to be cleared and write 1 to the other bits using the store instruction.

RPER Flag (Response Preparation Error Flag)

Only 0 can be written to the RPER flag; when 1 is written, the bit retains the value that has been retained before 1 is written.

The RPER flag is set to 1 when response preparation is not completed before reception of the first byte of response is completed. Write 0 to clear this bit.

IPER Flag (ID Parity Error Flag)

Only 0 can be written to this flag; when 1 is written, the bit retains the value that has been retained before 1 is written. When the IPERE bit of the RLIN3nLEDE register is 1 (ID parity error detection enabled), this bit is set to 1 upon ID parity error detection. Write 0 to clear this bit.

CSER Flag (Checksum Error Flag)

Only 0 can be written to the CSER flag; when 1 is written, the bit retains the value that has been retained before 1 is written.

The CSER flag is set to 1 when the received checksum value during response reception does not match the internally calculated checksum value. Write 0 to clear this bit.

SFER Flag (Sync Field Error Flag)

Only 0 can be written to this flag; when 1 is written, the bit retains the value that has been retained before 1 is written.

This bit is set to 1 if the sync field is not detected as “55H” and the break low width is more than or equal to the configured break low width. Write 0 to clear this bit.

FER Flag (Framing Error Flag)

Only 0 can be written to the FER flag; when 1 is written, the bit retains the value that has been retained before 1 is written.

The FER flag is set to 1 when a ‘0’ value is sampled as STOP bit during reception and the corresponding error detection is enabled. Write 0 to clear this bit.

TER Flag (Timeout Error Flag)

Only 0 can be written to the TER flag; when 1 is written, the bit retains the value that has been retained before 1 is written.

This flag is set to 1 when the internal timeout counter (frame or response timeout) reaches the error threshold value (calculated automatically) and the corresponding error detection is enabled. Write 0 to clear this bit.

BER Flag (Bit Error Flag)

Only 0 can be written to the BER flag; when 1 is written, the bit retains the value that has been retained before 1 is written.

The BER flag is set to 1 when the sampled bit value does not match the transmitted bit value during transmission and the corresponding error detection is enabled. Write 0 to clear this bit.

20.3.3.15 RLN3nLDFC — LIN Data Field Configuration Register

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	LSS	—	LCS	RCDS	RFDL[3:0]			
Value after reset	0	0	0	0	0	0	0	0
R/W	R/W	R	R/W	R/W	R/W	R/W	R/W	R/W

Table 20.45 RLN3nLDFC Register Contents

Bit Position	Bit Name	Function
7	LSS	Transmission/Reception Continuation Select 0: The data group to be transmitted/received next is the last one. 1: The data group to be transmitted/received next is not the last one. (Data transmission/reception continues without waiting for reception of the next header.)
6	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
5	LCS	Checksum Select 0: Classic checksum mode 1: Enhanced checksum mode
4	RCDS	Response Field Communication Direction Select 0: Reception 1: Transmission
3 to 0	RFDL[3:0]	Response Field Length Select b3 b0 0 0 0 0: 0 byte (+ checksum) 0 0 0 1: 1 byte (+ checksum) 0 0 1 0: 2 bytes (+ checksum) : 0 1 1 1: 7 bytes (+ checksum) 1 0 0 0: 8 bytes (+ checksum) 1 0 0 1: 8 bytes (+ checksum) 1 0 1 0: 8 bytes (+ checksum) : 1 1 1 1: 8 bytes (+ checksum)

LSS Bit (Transmission/Reception Continuation Select)

The LSS bit indicates that the data group to be transmitted or received next is not the last data group when response data of 9 bytes or more is to be transmitted or received. With 0 set, data and checksum are transmitted or received because the next data group to be transmitted or received is the last one.

With 1 set, only data is transmitted or received, and the checksum is not included because the next data group to be transmitted or received is not the last one.

During LIN communication, do not set “1” to this bit.

Set this bit when the RTS bit is 0(response transmission/reception stopped).

LCS Bit (Checksum Select)

The LCS bit sets the checksum mode.

With 0 set, classic checksum mode is selected.

With 1 set, enhanced checksum mode is selected.

When the timeout error is used (the TERE bit in the RLN3nLEDE register is 1), the specific timeout time depends on

the setting of this bit. For details on the bit error, see **Section 20.5.3.7, Error Status**.

When the length of the response field data is 0 bytes (the RFDL bit is 0), do not set this bit to “1” (enhanced).

When response data of 9 bytes or more is to be transmitted or received, do not change the LCS bit setting after the first data group through the last data group.

During transmission or reception of response data of 9 bytes or more, only the last data group (the LSS bit is 0) includes the checksum, and no other groups (the LSS bit is 1) include the checksum.

When response data of 9 bytes or more is to be transmitted or received, set the FSM bit to 1.

Set this bit when the RTS bit is 0 (response transmission/reception stopped).

RCDS Bit (Response Field Communication Direction Select)

This bit selects the direction of the response field/wake-up signal communication.

With 0 set, reception is performed in the response field. In LIN wake-up mode, wake-up reception is performed (input signal low-level width count).

With 1 set, transmission is performed in the response field. In LIN wake-up mode, wake-up transmission is performed.

Set this bit when the RTS bit in the RLN3nLTRC register is 0 in LIN operation mode (response transmission/reception stopped) or when the FTS bit is 0 in LIN wake-up mode (header reception or wake-up transmission/reception stopped).

When response data of 9 bytes or more is to be transmitted or received, do not change this bit setting after the first data group through the last data group.

RFDL[3:0] Bits (Response Field Length Select)

The RFDL bits set the length of the response field data.

The data length can be 0 to 8 bytes excluding the checksum size.

Set these bits when the RTS bit in the RLN3nLTRC register is 0 (response transmission/reception stopped).

When response data of 9 bytes or more is to be transmitted or received, only the last data group (the LSS bit is 0) includes the checksum, and no other groups (the LSS bit in the RLN3nLDFC register is 1) include the checksum.

20.3.3.16 RLN3nLIDB — LIN ID Buffer Register

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	IDP1	IDP0	ID[5:0]					
Value after reset	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 20.46 RLN3nLIDB Register Contents

Bit Position	Bit Name	Function
7, 6	IDP[1:0]	Parity Setting Stores the parity bits (P0 and P1) to be received in the ID field.
5 to 0	ID[5:0]	ID Setting Stores the 6-bit ID value received in the ID field.

The value in the RLN3nLIDB register is enabled after the completion of header reception. In LIN mode (LIN operation mode, LIN wake-up mode), writing to this register is disabled.

In LIN Self-Test mode, the operation is as follows.

Write the value to be transmitted before communication. After completion of frame transmission/reception (after loopback), the reversed value of the received value can be read.

For details about the LIN Self-Test mode, see **Section 20.5.5, LIN Self-Test Mode**.

IDP[1:0] Bits (Parity Setting)

The IDP bits store the parity bits (P0 and P1) received in the ID field of the LIN frame. IDP0 is for P0 and IDP1 is for P1.

When the IPERE bit in the RLN3nLEDE register is 1 (ID parity detection enabled), the received value and the value calculated internally are checked. If they do not match, IPER (ID parity error flag) is set.

ID[5:0] Bits (ID Setting)

The ID bits store the 6-bit ID value received in the ID field of the LIN frame.

20.3.3.17 RLN3nLCBR — LIN Checksum Buffer Register

Table 20.47 RLN3nLCBR Register Contents

Bit Position	Bit Name	Function
7 to 0	CKSM[7:0]	Holds the transmitted or received checksum data.

In LIN operation mode, this register operates as follows:

- When the RCDS bit in the RLN3nLDFC register is 1 (transmission):
The value transmitted can be read from the register. Read the value after transmission is completed.
Writing to this register is invalid.
- When the RCDS bit in the RLN3nLDFC register is 0 (reception):
The value received can be read from the register. Read the value after reception is completed.
Writing to this register is invalid.

When response data of 9 bytes or more is to be transmitted or received, the checksum is appended only to the last data group; this register is not updated for the other data groups.

In LIN Self-Test mode, this register operates as follows:

- When the RCDS bit in the RLN3nLDFC register is 1 (transmission):
After completion of the frame transmission (after loopback), the reversed value of the received value can be read.
- When the RCDS bit in the RLN3nLDFC register is 0 (reception):
Write the value to be received before communication. After completion of frame transmission/reception (after loopback), the reversed value of the received value can be read.

For details about the LIN Self-Test mode, see **Section 20.5.5, LIN Self-Test Mode**.

Set the RLN3nLCBR register when the FTS bit in the RLN3nLTRC register is 0 (frame transmission or wake-up transmission/reception is halted).

20.3.3.18 RLN3nLDBRb — LIN Data Buffer b Register (b = 1 to 8)

Table 20.48 RLN3nLDBRb Register Contents

Bit Position	Bit Name	Function
7 to 0	LDB[7:0]	Sets the data to be transmitted or holds the received data. Setting range: 00 _H to FF _H

- For response transmission:
The RLN3nLDBRb registers set the data to be transmitted in the response field.
Set these registers when the RTS bit in the RLN3nLTRC register is 0 (response transmission/reception is halted).
- For response reception:
The RLN3nLDBRb registers hold the data received in the response field.
The received data is overwritten. If an error is detected, the data up to the byte in which the error was detected are stored in the register.
Do not read these registers when the RTS bit is 1 (response transmission/reception is started)

In LIN Self-Test mode, the operation is as follows.

Write the value to be transmitted before communication. After completion of frame transmission/reception (after loopback), the reversed value of the received value can be read.

For details about the LIN Self-Test mode, see **Section 20.5.5, LIN Self-Test Mode**.

20.3.4 UART Related Registers

20.3.4.1 RLN3nLWBR — UART Wake-Up Baud Rate Select Register

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	NSPB[3:0]				LPRS[2:0]			—
Value after reset	0	0	0	0	0	0	0	0
	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R

Table 20.49 RLN3nLWBR Register Contents

Bit Position	Bit Name	Function
7 to 4	NSPB[3:0]	Bit Sampling Count Select b7 b4 0 1 0 1: 6 sampling 0 1 1 0: 7 sampling 0 1 1 1: 8 sampling 1 0 0 0: 9 sampling 1 0 0 1: 10 sampling 1 0 1 0: 11 sampling 1 0 1 1: 12 sampling 1 1 0 0: 13 sampling 1 1 0 1: 14 sampling 1 1 1 0: 15 sampling 1 1 1 1: 16 sampling Settings other than the above are prohibited.
3 to 1	LPRS[2:0]	Prescaler Clock Select b3 b1 0 0 0: 1/1 0 0 1: 1/2 0 1 0: 1/4 0 1 1: 1/8 1 0 0: 1/16 1 0 1: 1/32 1 1 0: 1/64 1 1 1: 1/128
0	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.

Set the LN3nLWBR register when the OMM0 bit in the RLN3nLMST register is 0_B (in LIN reset mode).

NSPB[3:0] Bits (Bit Sampling Count Select)

The NSPB bits select the number of sampling in one Tbit (reciprocal of the baud rate).

In UART mode, it is possible to set the NSPB bits from 6 sampling to 16 sampling.

LPRS[2:0] Bits (Prescaler Clock Select)

The LPRS bits select the frequency division ratio for the prescaler.

The LIN communication clock source is divided by this prescaler.

20.3.4.2 RLN3nLBRP01 — UART Baud Rate Prescaler 01 Register

Value after reset: 0000_H

Table 20.50 RLN3nLBRP01 Register Contents

Bit Position	Bit Name	Function
15 to 0	BRP [15:0]	Assuming that the value set in this register is L (0 to 65535), the baud rate prescaler divides the frequency of the prescaler clock by L + 1. Setting range: 0000 _H to FFFF _H

Assuming that the value set in this register is L, the baud rate prescaler divides the frequency of the clock that is selected by the LPRS bits (prescaler clock select bits) in the RLN3nLWBR register by L + 1.

The RLN3nLBRP01 register can be accessed in 8-bit units by the registers RLN3nLBRP0 and RLN3nLBRP1.

20.3.4.3 RLN3nLMD — UART Mode Register

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	LRDNFS	—	—	—	LMD[1:0]	
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R/W	R	R	R	R/W	R/W

Table 20.51 RLN3nLMD Register Contents

Bit Position	Bit Name	Function
7, 6	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
5	LRDNFS	UART Reception Data Noise Filtering Disable 0: The noise filter is enabled. 1: The noise filter is disabled.
4 to 2	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
1, 0	LMD[1:0]	LIN/UART Mode Select b1 b0 0 1: UART mode

Set the RLN3nLMD register when the OMM0 bit in the RLN3nLMST register is 0_B (in LIN reset mode).

LRDNFS Bit (UART Reception Data Noise Filter Disable)

The LRDNFS bit enables or disables the noise filter when receiving data.

With 0 set, the noise filter is enabled when receiving data.

With 1 set, the noise filter is disabled when receiving data.

LMD[1:0] Bits (LIN/UART Mode Select)

The LMD bits select the LIN/UART interface mode.

To use the LIN/UART interface as an UART, set these bits to 01_B.

20.3.4.4 RLN3nLBFC — UART Configuration Register

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	UTPS	URPS	UPS[1:0]		USBLS	UBOS	UBLS
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 20.52 RLN3nLBFC Register Contents

Bit Position	Bit Name	Function
7	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
6	UTPS	UART Output Polarity Switch 0: Transmit data normal output 1: Transmit data inverted output
5	URPS	UART Input Polarity Switch 0: Reception data normal output 1: Reception data inverted output
4, 3	UPS[1:0]	UART Parity Select 00: Parity disabled 01: Even parity 10: 0 parity 11: Odd parity
2	USBLS	UART Stop Bit length Select 0: Stop bit: 1 bit 1: Stop bit: 2 bits
1	UBOS	UART Transfer Format Order Select 0: LSB first 1: MSB first
0	UBLS	UART Character Length Select 0: UART 8 bits communication 1: UART 7 bits communication

Set the RLN3nLBFC register when the OMM0 bit in the RLN3nLMST register is 0_B (LIN reset mode).

UTPS Bit (UART Output Polarity Switch)

Sets the output polarity for UART communication.

With 0 set, transmit data is output without inversion.

With 1 set, inverted transmit data is output.

The setting of this bit is valid for all the bits of the UART frame.

In half-duplex communication, this setting should match the setting of URPS bit.

URPS Bit (UART Input Polarity Switch)

Sets the input polarity for UART communication.

With 0 set, receive data is input without inversion.

With 1 set, receive data is input with inversion.

The setting of this bit is valid for all the bits of the UART frame.

In half-duplex communication, this setting should match the setting of UTPS bit.

UPS[1:0] Bits (UART Parity Select)

Sets the UART parity.

- When these bits are set to “00_B”, data is transmitted/received without the parity.

[Transmission]

A parity bit is not added to transmit data.

[Reception]

Data is received without parity processing. Therefore, a parity error does not occur.

- When these bits are set to “01_B”, data is transmitted/received with the even parity.

[Transmission]

If the number of 1s in transmit data is odd, “1” is added to the parity bit. If the number of 1s in transmit data is even, “0” is added to the parity bit.

[Reception]

If the number of 1s in receive data including the parity bit is odd, a parity error occurs.

- When these bits are set to “10_B”, data is transmitted/received with 0 parity.

[Transmission]

Regardless of the number of 1s in transmit data, “0” is added to the parity bit.

[Reception]

The value of the parity bit is not judged. Therefore, no parity error occurs.

- When these bits are set to “11_B”, data is transmitted/received with the odd parity.

[Transmission]

If the number of 1s in transmit data is odd, “0” is added to the parity bit. If the number of 1s in transmit data is even, “1” is added to the parity bit.

[Reception]

If the number of 1s in receive data including the parity bit is even, a parity error occurs.

USBLS Bit (UART Stop Bit Length Select)

Sets the stop bit length of data for UART communication.

With 0 set, stop bit length of 1 bit is selected.

With 1 set, stop bit length of 2 bits is selected.

UBOS Bit (UART Transfer Format Select)

Sets the bit order of data for UART communication.

With 0 set, LSB first is selected.

With 1 set, MSB first is selected.

UBLS Bit (UART Character Length Select)

Sets the character length of one frame for UART communication.

With 0 set, the character length is 8 bits.

With 1 set, the character length is 7 bits.

When the character length of one frame is 9 bits (the UEBE bit in the RLIN3nLUOR1 register is 1), the setting of this bit is invalid.

20.3.4.5 RLN3nLSC — UART Space Configuration Register

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	IBS[1:0]		—	—	—	—
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R/W	R/W	R	R	R	R

Table 20.53 RLN3nLSC Register Contents

Bit Position	Bit Name	Function															
7, 6	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.															
5, 4	IBS[1:0]	Inter-Byte Space Select <table border="0"> <tr> <td>b5</td> <td>b4</td> <td></td> </tr> <tr> <td>0</td> <td>0</td> <td>0 Tbit</td> </tr> <tr> <td>0</td> <td>1</td> <td>1 Tbit</td> </tr> <tr> <td>1</td> <td>0</td> <td>2 Tbits</td> </tr> <tr> <td>1</td> <td>1</td> <td>3 Tbits</td> </tr> </table>	b5	b4		0	0	0 Tbit	0	1	1 Tbit	1	0	2 Tbits	1	1	3 Tbits
b5	b4																
0	0	0 Tbit															
0	1	1 Tbit															
1	0	2 Tbits															
1	1	3 Tbits															
3 to 0	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.															

Set the RLN3nLSC register when the OMM0 bit in the RLN3nLMST register is 0_B (in LIN reset mode).

IBS[1:0] Bits (Inter-Byte Space Select)

The IBS bits set the width of the inter-byte space during multi-byte UART transmission.
0 to 3 Tbits can be set.

20.3.4.6 RLN3nLEDE —UART Error Detection Enable Register

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	FERE	OERE	—	BERE
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R/W	R/W	R	R/W

Table 20.54 RLN3nLEDE Register Contents

Bit Position	Bit Name	Function
7 to 4	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
3	FERE	Framing Error Detection Enable 0: Disables framing error detection. 1: Enables framing error detection.
2	OERE	Overrun Error Detection Enable 0: Disables overrun error detection. 1: Enables overrun error detection.
1	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
0	BERE	Bit Error Detection Enable 0: Disables bit error detection. 1: Enables bit error detection.

Set the RLN3nLEDE register when the OMM0 bit in the RLN3nLMST register is 0_B (in LIN reset mode).

FERE Bit (Framing Error Detection Enable)

The FERE bit enables or disables detection of the framing error.

With 0 set, the framing error is not detected.

With 1 set, the framing error is detected.

When this bit is set to 1, the detection result is indicated in the FER flag in the RLN3nLEST register.

For details on the framing error, see **Section 20.5.4.5, Error Status**.

OERE Bit (Overrun Error Detection Enable)

This bit enables or disables detection of the overrun error.

With 0 set, the overrun error is not detected.

With 1 set, the overrun error is detected.

When this bit is set to 1, the detection result is reflected in the OER flag in the RLN3nLEST register.

For details on the overrun error, see **Section 20.5.4.5, Error Status**.

BERE Bit (Bit Error Detection Enable)

The BERE bit enables or disables detection of the bit error.

With 0 set, the bit error is not detected.

With 1 set, the bit error is detected.

When this bit is set to 1, the detection result is indicated in the BER flag in the RLN3nLEST register.

In full-duplex communication, do not set this bit to “1”.

Do not set this register when the NSPB bits in the RLN3nLWBR register are 0101_B (6 samplings) and the LRDNFS bit

in the RLN3nLMD register is 0 (noise filtering is enabled).
For details on the bit error, see **Section 20.5.4.5, Error Status**.

20.3.4.7 RLN3nLCUC — UART Control Register

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	OM0
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R/W

Table 20.55 RLN3nLCUC Register Contents

Bit Position	Bit Name	Function
7 to 1	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
0	OM0	LIN Reset 0: LIN reset mode. 1: LIN reset mode is canceled.

After a value is written to this register, confirm that the value written is actually indicated in the RLN3nLMST register before writing another value.

OM0 Bit (LIN Reset)

The OM0 bit selects either causing a transition to reset mode or canceling reset mode.

With 0 set, reset mode.

With 1 set, reset mode is canceled.

It takes 3 peripheral clock cycles + 4 communication clock cycles, until the OMM0 bit in the RLN3nLMST register reflects the OM0 bit setting in the RLN3nLCUC register.

20.3.4.8 RLN3nLTRC — UART Transmission Control Register

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	RTS	—
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R/W	R

Table 20.56 RLN3nLTRC Register Contents

Bit Position	Bit Name	Function
7 to 2	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
1	RTS	UART Buffer Transmission Start 0: UART Buffer transmission is stopped. 1: UART Buffer transmission is started.
0	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.

RTS Bit (UART Buffer Transmission Start)

When transmitting data from the UART buffer, set this bit to “1”.

Only 1 can be written to this bit; 0 cannot be written.

Write to this bit when the UTOE bit in the RLN3nLUOER register is 1 (transmission enabled) and the UTS bit in the RLN3nLST register is 0 (transmission is not in progress).

Once set, regardless of errors, this bit is automatically cleared to 0 upon completion of the number of data transmission specified by the MDL bit in the RLN3nLDFC register. Moreover, this bit is automatically cleared to 0 upon transition to reset mode.

Writing a value to this bit is disabled when the OMM0 bit of the RLN3nLMST register is 0_B (in LIN reset mode).

When writing 1 to this bit while the UTSW bit in the RLN3nLDFC register is 1 (when UART buffer transmission is requested, the start of transmission is delayed until the stop bit of reception data is completed), write only during the reception of stop bit.

20.3.4.9 RLN3nLMST — UART Mode Status Register

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	OMM0
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R

Table 20.57 RLN3nLMST Register Contents

Bit Position	Bit Name	Function
7 to 1	—	Reserved When read, the value after reset is returned.
0	OMM0	LIN Reset Status Monitor 0: LIN reset mode. 1: Not in LIN reset mode.

OMM0 Bit (LIN Reset Status Monitor)

The OMM0 bit indicates the current operating mode.

It takes 3 peripheral clock cycles + 4 communication clock cycles, until the OMM0 bit in the RLN3nLMST register reflects the OM0 bit setting in the RLN3nLCUC register.

20.3.4.10 RLN3nLST — UART Status Register

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	URS	UTS	ERR	—	—	FTC
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R/W

Table 20.58 RLN3nLST Register Contents

Bit Position	Bit Name	Function
7, 6	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
5	URS	UART Reception Status Flag 0: Reception is not operated. 1: Reception is operated.
4	UTS	UART Transmission Status Flag 0: Transmission is not operated. 1: Transmission is operated.
3	ERR	Error Detection Flag 0: No error has been detected. 1: Error has been detected.
2, 1	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
0	FTC	Successful UART Buffer Transmission Flag 0: UART buffer transmission has not been completed. 1: UART buffer transmission has been completed.

The RLN3nLST register is automatically cleared to “00_H” upon transition to LIN reset mode. In LIN reset mode, this register cannot be written to. In LIN reset mode, the register retains “00_H”. To clear the specific bits in the register, write 0 to the bits to be cleared and write 1 to the other bits using the store instruction.

URS Flag (UART Reception Status Flag)

At the start of the reception, this flag is set to 1.

The reception is started under the following condition.

- When the start bit is detected

At the end of reception, this flag is cleared to 0. While reception is stopped, this flag retains 0.

The reception is ended under the following condition.

- Sampling point of the first bit of the stop bits

UTS Flag (UART Transmission Status Flag)

At the start of the transmission, this flag is set to 1. During the transmission, this flag retains 1.

The transmission is started under the following conditions.

- When transmission data is set to the RLN3nLUTDR or RLN3nLUWTDR register
- When the RTS bit in the RLN3nLTRC register is set to 1

This flag is cleared to 0 at the end of transmission.

The transmission is ended under the following conditions.

- When transmission of data set in the RLN3nLUTDR or RLN3nLUWTDR register is completed and next data is not set
- When the UART buffer transmission is completed (when the RTS bit in the RLN3nLTRC register is cleared to 0)
- When transmission operation enable bit UTOE in register LUOER is cleared.

ERR Flag (Error Detection Flag)

This flag is set to 1 upon detection of an error, detection of an expansion bit, or upon ID matching (when at least one of the flags of the RLN3nLEST register is 1). At this time, an interrupt request for RLIN3n status is generated. However, when this bit is 1, an interrupt is not generated upon detection of an error, detection of an expansion bit, or upon ID matching. To clear the bit to 0, write 0 to the UPER, IDMT, EXBT, FER, OER, and BER flags in the RLN3nLEST register.

FTC Flag (Successful UART Buffer Transmission Flag)

Only 0 can be written to the FTC flag; when 1 is written, the bit retains the value that it was before 1 was written. Regardless of errors, this bit is set to 1 upon completion of transmission of the number of data specified by the MDL bit in the RLN3nLDFC register from the UART buffer. At this time, an interrupt request for RLIN3n transmission is generated. Write 0 to clear this flag.

20.3.4.11 RLN3nLEST — UART Error Status Register

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	UPER	IDMT	EXBT	FER	OER	—	BER
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R/W	R/W	R/W	R/W	R/W	R	R/W

Table 20.59 RLN3nLEST Register Contents

Bit Position	Bit Name	Function
7	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
6	UPER	Parity Error Flag 0: Parity error has not been detected. 1: Parity error has been detected.
5	IDMT	ID Matching Flag 0: The receive data does not match with the ID value. 1: The receive data matches with the ID value.
4	EXBT	Expanded Bit Detection Flag 0: Expanded bit has not been detected. 1: Expanded bit has been detected.
3	FER	Framing Error Flag 0: Framing error has not been detected. 1: Framing error has been detected.
2	OER	Overrun Error Flag 0: Overrun error has not been detected. 1: Overrun error has been detected.
1	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
0	BER	Bit Error Flag 0: Bit error has not been detected. 1: Bit error has been detected.

The RLN3nLEST register is automatically cleared to 00_H upon transition to LIN reset mode. In LIN reset mode, this register cannot be written to, and the value of 00_H is held. To clear certain bits in this register, write 0 to those bits, and write 1 to the bits not to be cleared by using the store instruction.

UPER Flag (Parity Error Flag)

Only 0 can be written to this flag; when 1 is written, the bit retains the value that it was before 1 was written. This flag is set to 1 upon parity error detection. Write 0 to clear this flag.

IDMT Flag (ID Matching Flag)

Only 0 can be written to this flag; when 1 is written, the bit retains the value that it was before 1 was written. The IDMT flag becomes 1 when all the following conditions are met:

- The UEBE bit in the RLN3nLUOR1 register is 1 (expansion bit enabled)
- The UECD bit in the RLN3nLUOR1 register is 0 (expansion bit comparison enabled)

- The UEBDCE bit in the RLN3nLUOR1 register is 1 (data comparison after expansion bit is detected)
 - The received expansion bit and the value of the UEBDL bit of the RLN3nLUOR1 register match.
 - The value of the value of the 8-bit of the received data excluding the expansion bit and the value of the RLN3nLIDB register match.

Write 0 to clear this flag.

EXBT Flag (Expansion Bit Detection Flag)

Only 0 can be written to this flag; when 1 is written, the bit retains the value that it was before 1 was written.

When the UEBE bit in the RLN3nLUOR1 register is 1 (expansion bit enable), if the received expansion bit matches the UEBDL bit in the RLN3nLUOR1 register, this flag is set to 1.

Write 0 to clear this flag.

FER Flag (Framing Error Flag)

Only 0 can be written to this flag; when 1 is written, the bit retains the value it was before 1 was written.

The FER flag is set to 1 upon framing error detection while the FERE bit of the RLN3nLEDE register is 1 (framing error detection enabled). Write 0 to clear this flag.

Framing error is detected always on the first stop bit, regardless of the stop bit amount setting.

OER Flag (Overrun Error Flag)

Only 0 can be written to this flag; when 1 is written, the bit retains the value Write 0 to clear this flag.

The OER flag is set to 1 upon overrun error detection while the OERE bit of the RLN3nLEDE register is 1 (overrun error detection enabled). Write 0 to clear this flag.

BER Flag (Bit Error Flag)

Only 0 can be written to this flag; when 1 is written, the bit retains the value that it was before 1 was written.

The BER flag is set to 1 when the transmitted data and the data monitored by the receive pin do not match while the BERE bit of the RLN3nLEDE register is 1 (bit error detection enabled).

Write 0 to clear this flag.

20.3.4.12 RLN3nLDFC — UART Data Field Configuration Register

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	UTSW	—	MDL[3:0]			
Value after reset	0	0	0	0	0	0	0	0

		: :																																										
1 1 1 1		: 9 bytes																																										

UTSW Bit (UART Transmission Start Wait)

This bit controls the start timing of UART buffer transmission.

With 0 set, transmission is started as soon as the start of UART buffer transmission is requested.

With 1 set, transmission is started after the completion of the stop bit reception.

Note that the wait time is only 1 bit even if the stop bit length is set to 2 bits with the USBLS bit in the RLN3nLBFC register.

This bit is enabled when the RTS bit in the RLN3nLTRC register is set to 1. In addition, writing a value to this bit is disabled when the RTS bit is 1 (UART buffer transmission started).

Set this bit to 1 only to switch from reception to transmission in half-duplex communication.

MDL[3:0] Bits (UART Buffer Data Length Select)

These bits specify the data length of the UART buffer.

Writing a value to these bits is disabled when the RTS bit in the RLN3nLTRC register is 1 (UART buffer transmission started).

20.3.4.13 RLN3nLIDB — UART ID Buffer Register

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	ID[7:0]							
Value after reset	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 20.61 RLN3nLIDB Register Contents

Bit Position	Bit Name	Function
7 to 0	ID[7:0]	ID value that is referred for the expansion bit data comparison is set

ID Bits (ID)

When the UEBE bit in the RLN3nLUOR1 register is set to 1 (expansion bit enabled), the UECD bit is set to 0 (expansion bit comparison enabled), and the UEBDCE bit is set to 1 (data comparison after expansion bit is detected), set the value to be compared with the received data. Write to the RLN3nLIDB register when the URS bit in the RLN3nLST register is 0 (receive operation is not in progress).

20.3.4.14 RLN3nLUDB0 — UART Data Buffer 0 Register

Value after reset: 00_H

Table 20.62 RLN3nLUDB0 Register Contents

Bit Position	Bit Name	Function
7 to 0	UDB[7:0]	Value of UART transmission data

When transmitting 9-byte data from the UART buffer transmission (the RLN3nLDFC.MDL bit is 0_H or 9_H), set the first data to be transmitted.

Write to the RLN3nLUDB0 register when the RTS bit of the RLN3nLTRC register is 0 (UART buffer transmission stopped).

Table 20.63 shows the bit arrangement according to the settings for communication format.

For details about the UART buffer transmission, see **Section 20.5.4.1(2) UART Buffer Transmission**.

Table 20.63 Bit Arrangement of the RLN3nLUDB0 Register According to Each Communication Format

	RLN3nLUDB0							
	b7	b6	b5	b4	b3	b2	b1	b0
7-bit; LSB first	—	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	Bit 0

20.3.4.15 RLN3nLDBRb — UART Data Buffer b Register (b = 1 to 8)

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	LDB[7:0]							
Value after reset	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 20.64 RLN3nLDBRb Register Contents

Bit Position	Bit Name	Function
7 to 0	LDB[7:0]	Value of UART transmission data

This register specifies the data transmitted from the UART buffer.

Write to these registers when the RTS bit of the RLN3nLTRC register is 0 (UART buffer transmission stopped).

Table 20.65 shows the bit arrangement according to the set communication format.

For details about the UART buffer transmission, see **Section 20.5.4.1(2) UART Buffer Transmission**.

Table 20.65 Bit Arrangement of the RLN3nLDBRb Register According to Each Communication Format

	RLN3nLDBRb							
	b7	b6	b5	b4	b3	b2	b1	b0
7-bit; LSB first	—	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	Bit 0
7-bit; MSB first	—	Bit 0	Bit 1	Bit 2	Bit 3	Bit 4	Bit 5	Bit 6
8-bit; LSB first	Bit 7	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	Bit 0

20.3.4.16 RLN3nLUOER — UART Operation Enable Register

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	UROE	UTOE
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R/W	R/W

Table 20.66 RLN3nLUOER Register Contents

Bit Position	Bit Name	Function
7 to 2	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
1	UROE	UART Reception Enable 0: Disables reception. 1: Enables reception.
0	UTOE	UART Transmission Enable 0: Disables transmission. 1: Enables transmission.

The RLN3nLUOER register is automatically cleared to 00_H upon transition to LIN reset mode.

In LIN reset mode, this register cannot be written to.

In LIN reset mode, the register retains 00_H.

UROE Bit (UART Reception Enable)

The UROE bit enables or disables reception.

With 0 set, reception is disabled.

With 1 set, reception is enabled.

Do not clear this bit during reception. If the communication is suspended during reception, set the OM0 bit in the RLN3nLCUC register to 0 (in LIN reset mode) to transition to the LIN reset mode. However, the transmit operation is also suspended at this time.

Do not set this bit to 1 when data transmission from the UART buffer is in progress.

UTOE Bit (UART Transmission Enable)

The UTOE bit enables or disables transmission.

With 0 set, transmission is disabled.

With 1 set, transmission is enabled.

Do not clear this bit during transmission. If the communication is suspended during transmission, set the OM0 bit in the RLN3nLCUC register to 0 (in LIN reset mode) to transition to the LIN reset mode. However, the receive operation is also suspended at this time.

20.3.4.17 RLN3nLUOR1 — UART Option Register 1

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	UECD	UTIGTS	UEBDCE	UEBDL	UEBE
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R/W	R/W	R/W	R/W	R/W

Table 20.67 RLN3nLUOR1 Register Contents

Bit Position	Bit Name	Function
7 to 5	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
4	UECD	UART Expansion Bit Comparison Disable 0: Enables expansion bit comparison. 1: Disables expansion bit comparison.
3	UTIGTS	UART Transmission Interrupt Generation Timing Select 0: Transmission interrupt is generated at the start of transmission. 1: Transmission interrupt is generated at the completion of transmission.
2	UEBDCE	UART Expansion Bit Data Comparison Enable 0: Disables data comparison after an expansion bit is detected. 1: Enables data comparison after an expansion bit is detected.
1	UEBDL	UART Expansion Bit Detection Level Select 0: Selects expansion bit value 0 as the expansion bit detection level. 1: Selects expansion bit value 1 as the expansion bit detection level.
0	UEBE	UART Expansion Bit Enable 0: Disables expansion bit operation. 1: Enables expansion bit operation.

UECD Bit (Expansion Bit Comparison Disable)

The UECD bit enables or disables comparison between the received expansion bit and the UEBDL bit value when the UEBE bit is 1 (expansion bit operation is enabled).

With 0 set, comparison between the received expansion bit and the UEBDL bit value is enabled when the expansion bit is received.

With 1 set, comparison between the received expansion bit and the UEBDL bit value is disabled when the expansion bit is received.

Set this bit when the OMM0 bit of the RLN3nLMST register is 0_B (in LIN reset mode).

Do not set this bit to 1 when the UART buffer is used.

Do not set this bit to 1 when the UEBDCE bit is 1 (data comparison after expansion bit is detected).

UTIGTS Bit (Transmission Interrupt Generation Timing Select)

The UTIGTS bit sets the generation timing of the transmission interrupt.

With 0 set, the transmission interrupt is generated at the start of transmission.

With 1 set, the transmission interrupt is generated at the completion of transmission.

When transmission from the UART buffer is performed with 0 set, the transmission interrupt is generated only at the start of the transmission of the last data of the data length set with the MDL bits in the RLN3nLDFC register.

When transmission from the UART buffer is performed with 1 set, the transmission interrupt is generated only at the completion of the transmission of the last data of the data length set with the MDL bits in the RLN3nLDFC register.

UEBDCE Bit (Expansion Bit Data Comparison Enable)

After an expansion bit is detected, this bit enables or disables the comparison between the 8-bit receive data excluding the expansion bit and the value of the RLN3nLIDB register.

With 0 set, when the level selected by the UEBDL bit is detected as an expansion bit, the comparison between the received value in the RLN3nLURDR register and the value of the RLN3nLIDB register is disabled.

With 1 set, when the level selected by the UEBDL bit is detected as an expansion bit, the comparison between the received value in the RLN3nLURDR register and the value of the RLN3nLIDB register is enabled.

Set this bit when the OMM0 bit of the RLN3nLMST register is 0_B (in LIN reset mode).

Do not set this bit to 1 when the UEBE bit is 0 (expansion bit operation disabled).

Do not set this bit to 1 when the UECD bit is 1 (expansion bit comparison disabled).

Do not set this bit to 1 when the UART buffer is used.

UEBDL Bit (Expansion Bit Detection Level Select)

The UEBDL bit sets the level to be detected as the expansion bit when the UEBE bit is 1 (expansion bit operation is enabled) and the UECD bit is 0 (comparison of the expansion bit is enabled).

With 0 set, expansion bit value 0 is the level to be detected as the expansion bit.

With 1 set, expansion bit value 1 is the level to be detected as the expansion bit.

Set this bit when the OMM0 bit of the RLN3nLMST register is 0_B (in LIN reset mode).

Do not set this bit to 1 when the UART buffer is used.

UEBE Bit (Expansion Bit Enable Bit)

The UEBE bit enables or disables expansion bit operation.

With 0 set, expansion bit operation is disabled.

With 1 set, expansion bit operation is enabled.

Set this bit when the OMM0 bit of the RLN3nLMST register is 0_B (in LIN reset mode).

Do not set this bit to 1 when the UART buffer is used.

20.3.4.18 RLN3nLUTDR — UART Transmission Data Register

Value after reset: 0000_H

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	UTD[8:0]								
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 20.68 RLN3nLUTDR Register Contents

Bit Position	Bit Name	Function
15 to 9	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
8 to 0	UTD[8:0]	Value of UART transmission data. Setting range: 000 _H to 1FF _H

The RLN3nLUTDR register sets the data to be transmitted from the transmit data register.

Writing data to this register with the UTOE bit in the RLN3nLUOER register set to 1 starts transmission.

This register can be accessed in 8 bits.

In 9-bit communication mode, do not attempt 8-bit access.

Do not write data to this register when data transmission from the UART buffer is in progress.

Also, do not write data to this register when a transmission request is being generated due to write access to the RLN3nLUWTDR register.

When transmitting data continuously, do not set another piece of transmission data in this register before the generation of transmission interrupt.

The table below shows the bit arrangement according to the set communication format.

Table 20.69 Bit Arrangement of the RLN3nLUTDR Register According to Each Communication Format

	RLN3nLUTDR								
	b8	b7	b6	b5	b4	b3	b2	b1	b0
7-bit; LSB first	—	—	Bit6	Bit5	Bit4	Bit3	Bit2	Bit1	Bit0
7-bit; MSB first	—	—	Bit0	Bit1	Bit2	Bit3	Bit4	Bit5	Bit6
8-bit; LSB first	—	Bit7	Bit6	Bit5	Bit4	Bit3	Bit2	Bit1	Bit0
8-bit; MSB first	—	Bit0	Bit1	Bit2	Bit3	Bit4	Bit5	Bit6	Bit7
9-bit; LSB first	Bit8	Bit7	Bit6	Bit5	Bit4	Bit3	Bit2	Bit1	Bit0
9-bit; MSB first	Bit0	Bit1	Bit2	Bit3	Bit4	Bit5	Bit6	Bit7	Bit8

20.3.4.19 RLN3nLURDR — UART Reception Data Register

Value after reset: 0000_H

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	URD [8:0]								
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 20.70 RLN3nLURDR Register Contents

Bit Position	Bit Name	Function
15 to 9	—	Reserved When read, the value after reset is returned.
8 to 0	URD [8:0]	Value of UART reception data. Setting range: 000 _H to 1FF _H

The RLN3nLURDR allows the reception data to be read from the receive data register.

When the UROE bit in the RLN3nLUOER register is 1, the reception data is stored in this register and can be read out.

This register is updated when the stop bit of the receive data is received.

This register is also updated when an error is caused by the parity or stop bit.

However, the value of this register is not updated upon occurrence of an overrun error when the OERE bit of the RLN3nLEDE register is 1 (overrun error detection enabled). The value of this register is updated upon occurrence of an overrun error when the OERE bit is 0 (overrun error detection disabled).

Read this register upon occurrence of a receive error (overrun error, framing error, parity error) when the OERE bit of the RLN3nLEDE register is 1 (overrun error detection enabled). If the next data is received without reading this register, an overrun error occurs.

This register can be accessed in 8 bits.

However, during expansion bit use (UEBE bit of the RLN3nLUOR1 register is 1 (expansion bit operation enabled), do not attempt 8-bit access.

The table below shows the bit arrangement according to the set communication format.

Table 20.71 Bit Arrangement of the RLN3nLURDR Register According to Each Communication Format

	RLN3nLURDR									
	b8	b7	b6	b5	b4	b3	b2	b1	b0

R/W	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 20.72 RLN3nLUWTDR Register Contents

Bit Position	Bit Name	Function
15 to 9	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
8 to 0	UWTD[8:0]	Sets the data to be transmitted from the wait transmit data register after waiting for the stop bit reception to be completed. Setting range: 000 _H to 1FF _H

The RLN3nLUWTDR register sets the data to be transmitted from the UART wait transmit data register.

Writing data to this register with the UTOE bit in the RLN3nLUOER register set to 1 starts transmission.

Use this register only to switch from reception to transmission in half-duplex communication.

The user should write to this register only while the stop bit is being received.

Note that the wait time is only 1 bit even if the stop bit length is set to 2 bits with the USBLS bit in the RLN3nLBFC register.

When this register is read, the RLN3nLUTDR register value is actually read.

In 9-bit communication mode, do not attempt 8-bit access.

Do not write data to this register when data transmission from the UART buffer is in progress.

The table below shows the bit arrangement according to the set communication format.

Table 20.73 Bit Arrangement of the RLN3nLUWTDR Register According to Each Communication Format

	RLN3nLUWTDR								
	b8	b7	b6	b5	b4	b3	b2	b1	b0

20.4 Interrupt Sources

The LIN/UART interface generates three types of interrupt requests.

- RLIN3n successful transmission interrupt
- RLIN3n successful reception interrupt
- RLIN3n status interrupt

Setting the LIOS bit in the RLIN3nLMD register to 1 allows to output the RLIN3n transmission interrupt, RLIN3n successful reception interrupt, or RLIN3n status interrupt depending on the interrupt source.

Table 20.74 lists the sources for each interrupt.

Table 20.74 Interrupt Sources

		LIOS bit in RLIN3nLMD register is 1*1		
		RLIN3n Transmission Interrupt	RLIN3n Reception Interrupt	RLIN3n Status Interrupt
LIN mode	LIN master mode	<ul style="list-style-type: none"> • Successful frame transmission • Successful wake-up transmission • Successful header transmission 	<ul style="list-style-type: none"> • Successful response reception • Successful wake-up reception 	<ul style="list-style-type: none"> • Bit error • Physical bus error • Frame/response timeout error • Framing error • Checksum error • Response preparation error
	LIN slave mode	<ul style="list-style-type: none"> • Successful response transmission • Successful wake-up transmission 	<ul style="list-style-type: none"> • Successful response reception • Successful wake-up reception • Successful header reception 	<ul style="list-style-type: none"> • Bit error • Frame/response timeout error • Framing error • Sync field error • Checksum error • ID parity error • Response preparation error
UART mode		<ul style="list-style-type: none"> • Transmission start/successful transmission 	<ul style="list-style-type: none"> • Successful reception • Expansion bit mismatch 	<ul style="list-style-type: none"> • Bit error • Overrun error • Framing error • Expansion bit detection • ID match • Parity error

Note 1. The LIOS bit setting is valid in LIN Mode. In UART mode, setting the LIOS bit is not required.

In LIN mode, each interrupt request is output when the corresponding bit in the RLIN3nLIE register is 1 (interrupt is enabled) and the corresponding flag in the RLIN3nLST register is 1.

20.5 Operation

20.5.1 Modes

The LIN/UART interface provides the following four modes, depending upon the specific function to be performed:

- LIN reset mode
- LIN mode
 - LIN master mode
 - LIN slave mode [auto baud rate]
 - LIN slave mode [fixed baud rate]
- UART mode
- LIN Self-Test mode

Figure 20.2 shows mode transitions. **Table 20.75** describes mode transition conditions. **Table 20.76** lists operations available in each mode.

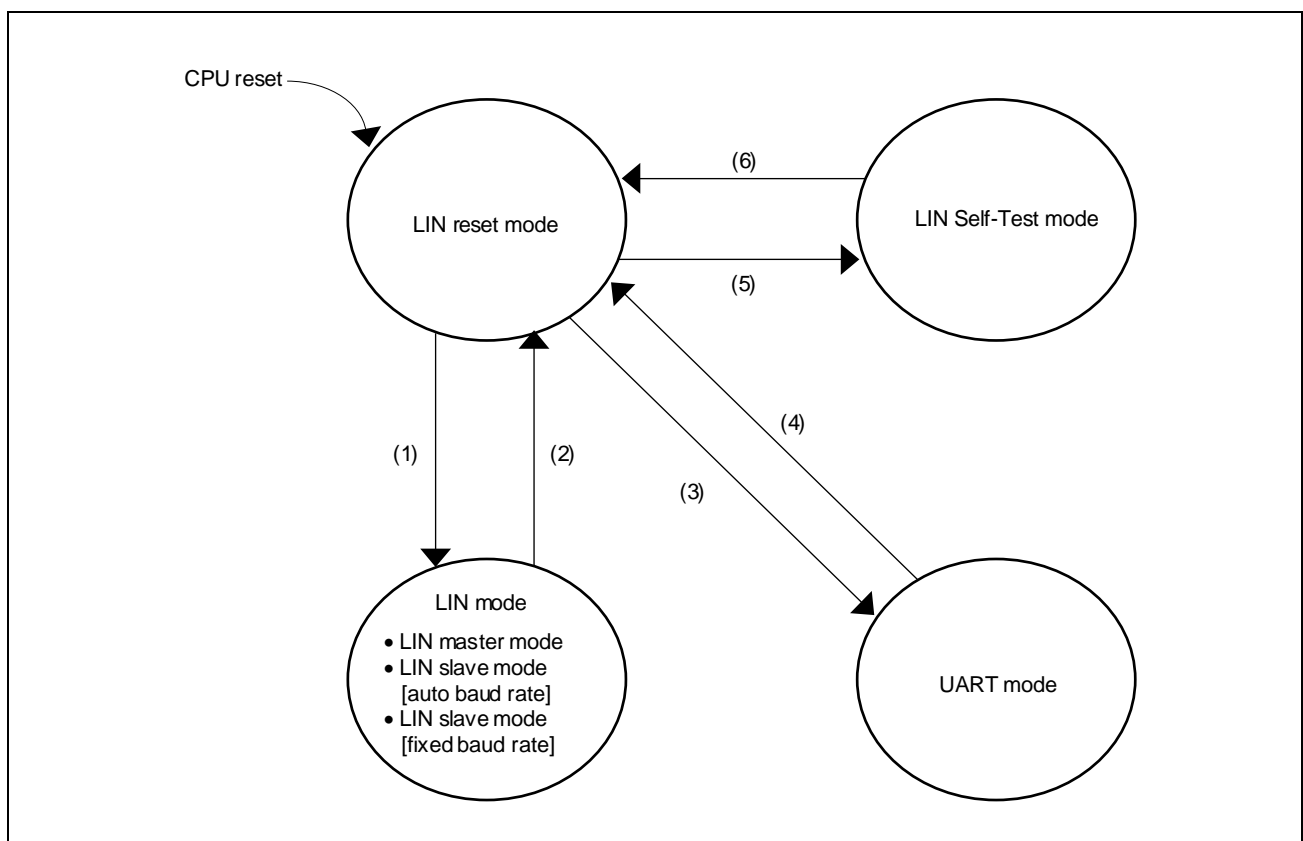

Figure 20.2 Mode Transitions

Table 20.75 Transition Condition of Each Mode

Mode Transition		Transition Condition
(1)	LIN reset mode → LIN mode <ul style="list-style-type: none"> • LIN master mode • LIN slave mode [auto baud rate] • LIN slave mode [fixed baud rate] 	<ul style="list-style-type: none"> • LMD bits in RLN3nLMD register = 00_B and OM1 and OM0 bits in RLN3nLCUC register = 01_B or 11_B • LMD bits in RLN3nLMD register = 10_B and OM1 and OM0 bits in RLN3nLCUC register = 01_B or 11_B • LMD bits in RLN3nLMD register = 11_B and OM1 and OM0 bits of RLN3nLCUC register = 01_B or 11_B
(2)	LIN mode → LIN reset mode	OM0 bit in RLN3nLCUC register = 0 _B
(3)	LIN reset mode → UART mode	LMD bits in RLN3nLMD register = 01 _B and OM0 bit in RLN3nLCUC register = 1 _B
(4)	UART mode → LIN reset mode	OM0 bit in RLN3nLCUC register = 0 _B
(5)	LIN reset mode → LIN Self-Test mode	See Section 20.5.5, LIN Self-Test Mode.
(6)	LIN Self-Test mode → LIN reset mode	See Section 20.5.5, LIN Self-Test Mode.

Table 20.76 Operations Available in Each Mode

LIN Mode		UART Mode	LIN Self-Test Mode
LIN Master Mode	LIN Slave Mode [auto baud rate] LIN Slave Mode [fixed baud rate]		
Header transmission	Header reception	UART transmission	Self test
Response transmission	Response transmission	UART reception	
Response reception	Response reception	Error detection	
Wake-up transmission	Wake-up transmission		
Wake-up reception	Wake-up reception		
Error detection	Error detection		

Whether mode has transitioned to LIN reset mode, the LIN mode, or the UART mode can be verified by reading the LMD bits in the RLN3nLMD register and the OMM0 bit in the RLN3nLMST register.

For a description of the LIN Self-Test mode, see **Section 20.5.5, LIN Self-Test Mode.**

20.5.2 LIN Reset Mode

Setting the OM0 bit in the RLN3nLCUC register to 0 (in LIN reset mode) causes a transition to LIN reset mode. The change to LIN reset mode can be verified by determining that the OMM0 bit in the RLN3nLMST register has been set to 0 (in LIN reset mode). In this mode, the LIN communication and the UART communication functions are halted.

From LIN reset mode, transitions to LIN mode, UART mode, and LIN Self-Test mode can be made.

When the mode changes to LIN reset mode, the following registers are initialized to their reset values, and as long as LIN reset mode is in effect, they retain their initial values.

- RLN3nLSTC register
- RLN3nLTRC register
- RLN3nLST register
- RLN3nLEST register
- RLN3nLUOER register

The following registers retain their previous values even when a transition to LIN reset mode is made:

- RLN3nLWBR register
- RLN3nLBRP0 register
- RLN3nLBRP1 register
- RLN3nLMD register
- RLN3nLBFC register
- RLN3nLSC register
- RLN3nLWUP register
- RLN3nLIE register
- RLN3nLEDE register
- RLN3nLDFC register
- RLN3nLIDB register
- RLN3nLCBR register
- RLN3nLUDB0 register
- RLN3nLDBRb register (b = 1 to 8)
- RLN3nLUOR1 register
- RLN3nLUTDR register
- RLN3nLURDR register
- RLN3nLUWTDR register

20.5.3 LIN Mode

LIN mode can operate in the following submodes:

LIN master mode, LIN slave mode [auto baud rate], and LIN slave mode [fixed baud rate].

In LIN master mode, the following operations can be performed: header transmission, response transmission, response reception, wake-up transmission, wake-up reception, and error detection. In LIN reset mode, setting the LMD bits in the RLN3nLMD register to 00_B (in LIN master mode) and the OM1 and OM0 bits in the RLN3nLCUC register to either 01_B or 11_B sets LIN master mode, turning the OMM1 and OMM0 bits in the RLN3nLMST register to either 01_B to 11_B.

In LIN slave mode [auto baud rate] and LIN slave mode [fixed baud rate], header reception, response transmission, response reception, wake-up transmission, wake-up reception, and error detection can be performed.

The LIN slave mode [auto baud rate] allows automatic detection of the break field and the sync field, and sets a baud rate based on the results of measurement of a sync field. The baud rate can be set to 1 kbps to 20 kbps.

Set the LPRS[2:0] bits in the RLN3nLWBR register so that the prescaler clock (with the frequency of the LIN communication clock source divided by the prescaler) becomes as follows according to the target baud rate.

[Target baud rate]	[Prescaler clock]
1 kbps to 20 kbps:	4 MHz* ¹
1 kbps to 2.4 kbps (excluding 2.4 kbps):	4 MHz
2.4 kbps to 20 kbps:	8 MHz to 12 MHz

Note 1. Use the clock with NSPB[3:0] bits in the RLN3nLWBR register set to "0011_B" (four samplings).

LIN slave mode [fixed baud rate] allows automatic detection of the break field, sync field, and ID field at a baud rate that is set in advance by the baud rate generator.

In LIN reset mode, setting the LMD bits in the RLN3nLMD register to 10_B (in LIN slave mode [auto baud rate]) and setting the OM1 and OM0 bits in the RLN3nLCUC register to 01_B or 11_B sets LIN slave mode [auto baud rate]; and setting the LMD bits in the RLN3nLMD register to 11_B (in LIN slave mode [fixed baud rate]), and setting the OM1 and OM0 bits in the RLN3nLCUC register to 01_B or 11_B sets LIN slave mode [fixed baud rate], turning the OMM1 and OMM0 bits in the RLN3nLMST register to 01_B or 11_B.

When changing a submode to another submode within LIN mode, a transition to LIN reset mode should first be made and change the LMD bits in the RLN3nLMD register.

The LIN mode provides the following two operation modes:

- LIN operation mode
- LIN wake-up mode

Figure 20.3 shows the transition of operation modes. **Table 20.77** describes the transition conditions of operation modes.

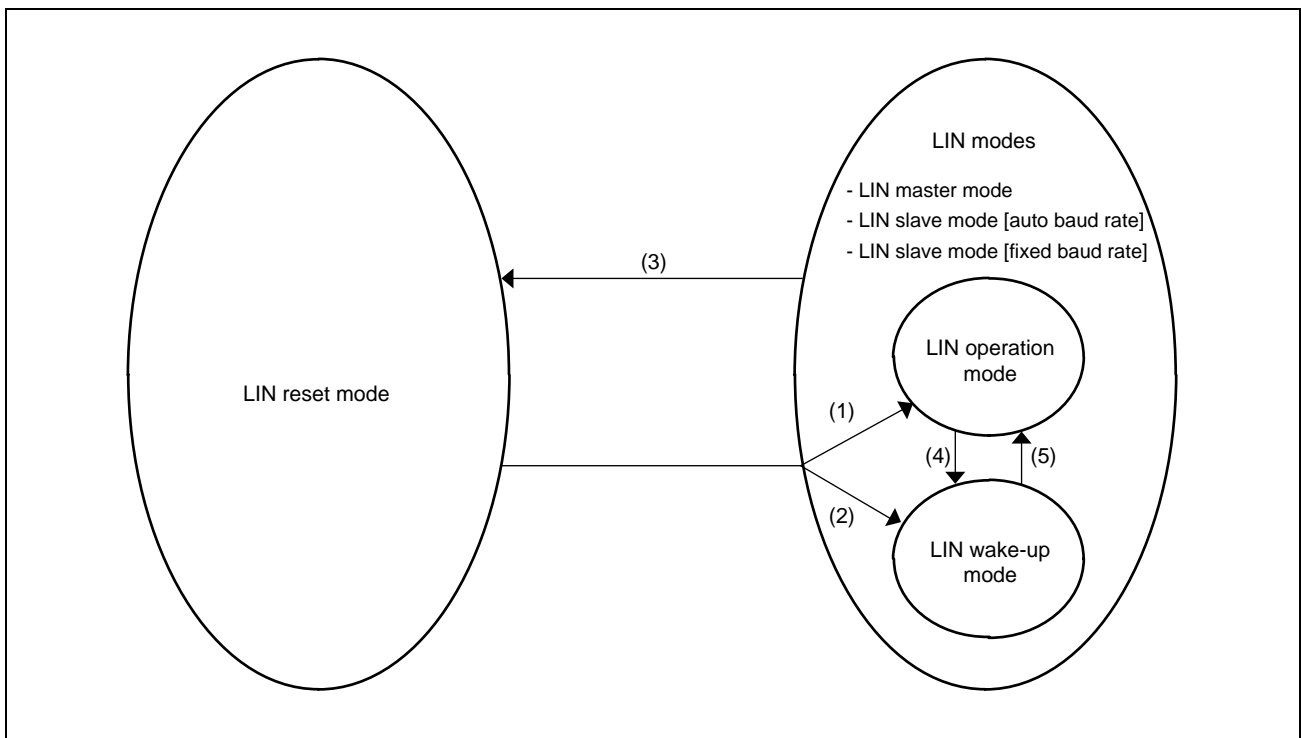

Figure 20.3 Transition of Operation Modes

Table 20.77 Transition Condition for Operation Mode

Operation Mode Transition		Transition Condition
(1)	LIN reset mode → LIN mode • LIN operation mode	LMD bits in RLN3nLMD register = 00 _B or 10 _B or 11 _B and OM1 and OM0 bits in RLN3nLCUC register = 11 _B
(2)	LIN reset mode → LIN mode • LIN wake-up mode	LMD bits in RLN3nLMD register = 00 _B or 10 _B or 11 _B and OM1 and OM0 bits in RLN3nLCUC register = 01 _B
(3)	LIN mode • LIN operation mode • LIN wake-up mode → LIN reset mode	OM0 bit in RLN3nLCUC register = 0 _B
(4)	LIN mode *1 • LIN operation mode → LIN mode • LIN wake-up mode	OM1 and OM0 bits in RLN3nLCUC register = 01 _B
(5)	LIN mode *1 • LIN wake-up mode → LIN mode • LIN operation mode	OM1 and OM0 bits in RLN3nLCUC register = 11 _B

Note 1. Transition between LIN operation mode and LIN wake-up mode cannot be made when communication is in progress (when the FTS bit in the RLN3nLTRC register is 1).

(1) LIN Operation Mode

In LIN operation mode, frame processing (header transmission, header reception, response transmission, response reception, and error detection) can be performed.

During a transition from LIN reset mode to LIN mode, setting the OM1 and OM0 bits in the RLN3nLCUC register to 11_B changes the mode to LIN operation mode, changing the OMM1 and OMM0 bits in the RLN3nLMST register to 11_B. Communication settings should be performed after the OMM1 and OMM0 bits have become 11_B.

(2) LIN Wake-up Mode

In LIN wake-up mode, wake-up signal processing (wake-up transmission, wake-up reception, and error detection) can be performed.

During a transition from LIN reset mode to LIN mode, setting the OM1 and OM0 bits in the RLN3nLCUC register to 01_B changes the mode to LIN wake-up mode, changing the OMM1 and OMM0 bits in the RLN3nLMST register to 01_B. Communication settings should be performed after the OMM1 and OMM0 bits have become 01_B.

20.5.3.1 LIN Master Mode

(1) Header Transmission

Figure 20.4 shows the operation of the LIN/UART interface (LIN master mode) in header transmission.

Table 20.78 describes the processing in header transmission.

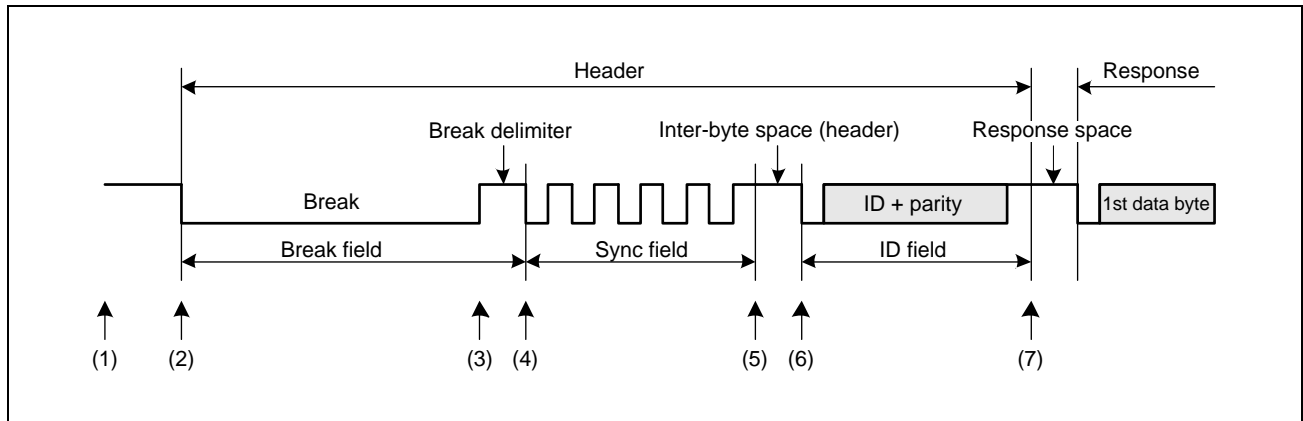

Figure 20.4 Operation in Header Transmission

Table 20.78 Processing in Header Transmission

	Software Processing	LIN/UART Interface Processing
(1)	<ul style="list-style-type: none"> • Sets a baud rate • Sets noise filter ON/OFF • Enables interrupt • Enables error detection • Sets frame configuration parameters • Changes the LIN/UART interface to the LIN master mode: LIN operation mode • Sets information on the frame to be transmitted (ID, parity, data length, response direction, checksum method, and transmission data) 	Waits for the setting of the FTS bit in the RLN3nLTRC register by software (idle)
(2)	Sets the FTS bit in the RLN3nLTRC register to 1 (frame transmission or wake-up transmission/reception started)	Transmits a break.
(3)	Waits for an interrupt request	Transmits a break delimiter.
(4)		Transmits a sync field (55 _H).
(5)		Transmits an inter-byte space (header).
(6)		Transmits an ID field.
(7)		Sets a successful header transmission flag.

NOTE

For information about error detection conditions, see **Section 20.5.3.7, Error Status**.

(2) Response Transmission

Figure 20.5 shows the operation of the LIN/UART interface (LIN master mode) in response transmission. **Table 20.79** describes the processing in response transmission.

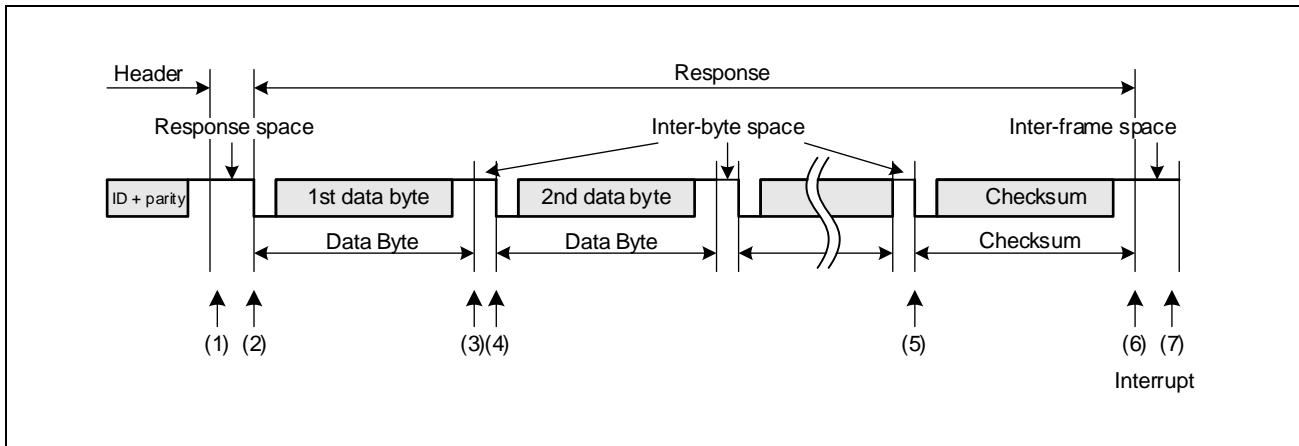

Figure 20.5 Operation in Response Transmission

Table 20.79 Processing in Response Transmission

NOTE

For information about error detection conditions, see **Section 20.5.3.7, Error Status**.

20.5.3.2 LIN Slave Mode

(1) Header Reception

Figure 20.7 shows the operation of the LIN/UART interface (LIN slave mode) in header reception.

Table 20.81 describes the processing in header reception.

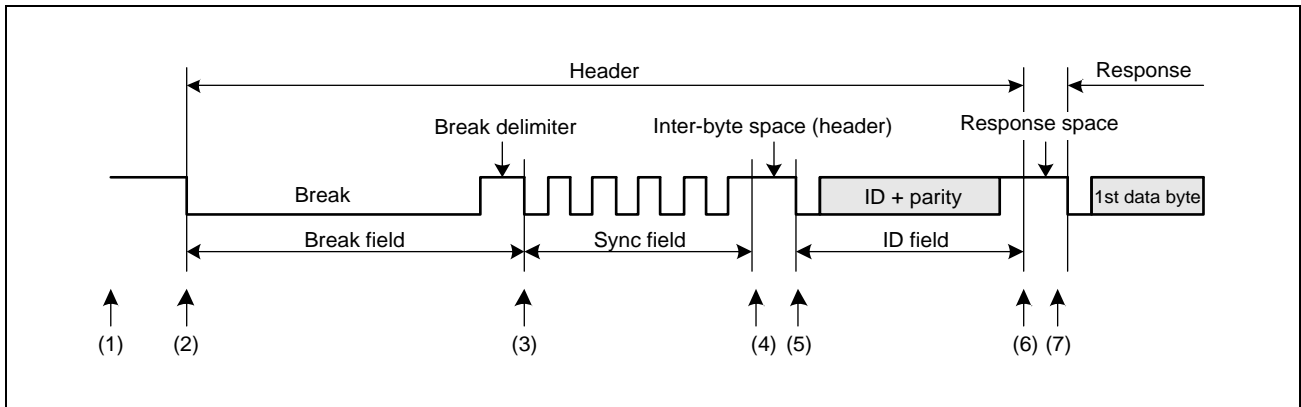

Figure 20.7 Operation in Header Reception

Table 20.81 Processing in Header Reception

Software Processing	LIN/UART Interface Processing
(1) <ul style="list-style-type: none"> • Sets a baud rate • Sets noise filter ON/OFF • Enables interrupt • Enables error detection • Sets frame configuration parameters • Changes the LIN/UART interface to the LIN slave mode: LIN operation mode • Sets the FTS bit in the RLN3nLTRC register to 1 (header reception or wake-up transmission/reception started) 	Waits for the setting of the FTS bit in the RLN3nLTRC register by software.
(2) Waits for an interrupt request.	Waits for detection of break field
(3)	Detects a break field. (LIN slave mode [fixed baud rate]). For details about the break field detection timing in the case of LIN slave mode [auto baud rate], see [Auto Baud Rate Correction Function].)
(4)	<ul style="list-style-type: none"> • Detects a sync field (55μs) • Set the baud rate generator (in the case of LIN slave mode [auto baud rate]) • Clears the no-response request bit (LNRR bit).
(5)	<ul style="list-style-type: none"> • Receives an ID field. • Checks an ID parity bit
(6)	Sets a header reception complete flag.
(7) <ul style="list-style-type: none"> • Checks the RLN3nLST register, and clears flags. • Checks the RLN3nLIDB register, and prepares a response. 	<ul style="list-style-type: none"> • Completes a header reception process. • Waits for a response request.

NOTE

The LIN/UART interface allows reception of break fields during frame transmission/reception. In that case, a framing error, bit error or other error may be detected at the stop bit position of the frame before the break field is received, and a status interrupt may occur as a result. However, reception of a new header (the following Sync field and ID field) continues regardless of whether an error occurred. For information about error detection conditions, see **Section 20.5.3.7, Error Status**.

[Auto Baud Rate Correction Function]

In LIN slave mode [auto baud rate], the system always measures the low-level widths that are received. If the first “Low level” width is 10 times (if the BLT bit of the RLIN3nLBFC register is “0”) or 11 times (if the BLT bit of the RLIN3nLBFC register is “1”) or greater than the bit width calculated from the average of the starting 2 bits (the period of the consecutive falling edges from the beginning of the sync field) of the sync field, the system concludes that the detection of break field was successful, the system verifies that the data in the sync field is 55_H. If the data in the sync field is indeed 55_H and the system judges that sync field reception was successful, the system automatically sets the baud rate correction result to the RLIN3nLBRP01 register.

If data is received up to the ID field without error, a successful header reception interrupt is generated at the stop bit position.

On the other hand, if the data in the sync field is not 55_H and the system judges that sync field reception failed, the system sets the sync field error flag and an error interrupt is generated. In that case, baud rate correction is not performed and the LIN/UART interface waits for the detection of the next break field (low level).

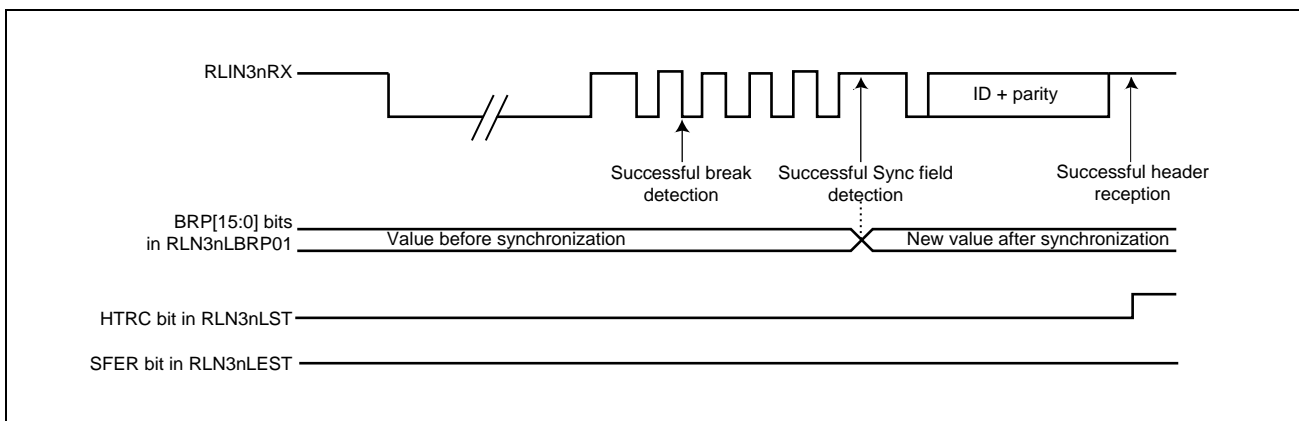

Figure 20.8 Header Reception in LIN Slave Mode [Auto Baud Rate] (in Normal Operation)

Figure 20.9 Header Reception in LIN Slave Mode [Auto Baud Rate] (Sync Field Error)

(2) Response Transmission

Figure 20.10 shows the operation of the LIN/UART interface (LIN slave mode) in response transmission. **Table 20.82** describes the processing in response transmission.

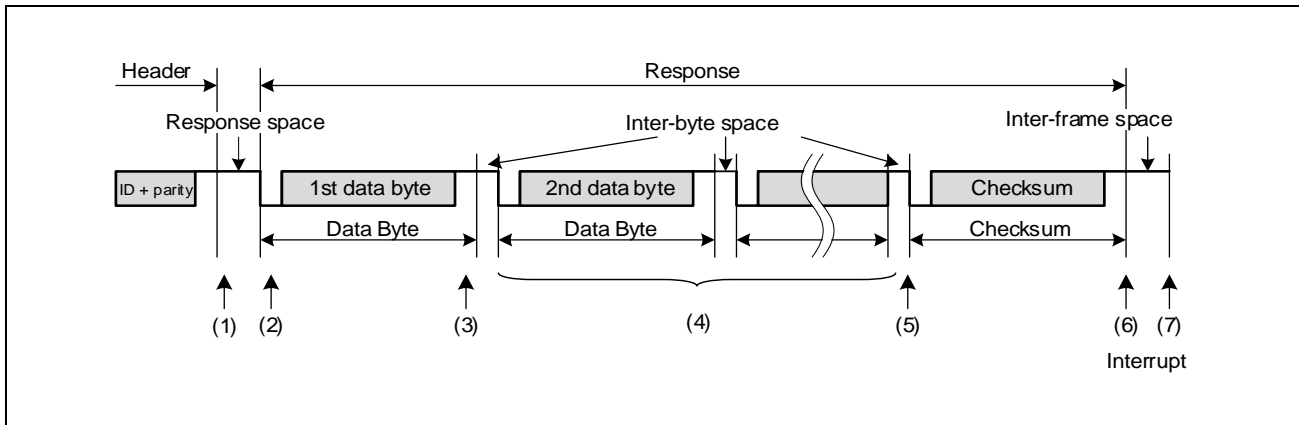

Figure 20.10 Operation in Response Transmission

Table 20.82 Processing in Response Transmission

Software Processing	LIN/UART Interface Processing
(1) <ul style="list-style-type: none"> Sets the RLN3nLDFC register. Sets the RLN3nLDBRb registers. NOTE

- For information about error detection conditions, see **Section 20.5.3.7, Error Status**.
 - The LIN/UART interface allows reception of break fields during frame transmission/reception. In that case, a framing error, bit error or other error may be detected at the stop bit position of the frame before the break field is received, and a status interrupt may occur as a result. However, reception of a new header (the following Sync field and ID field) continues regardless of whether an error occurred.
-

(4) No-response Request

Figure 20.12 shows the operation of the LIN/UART interface (LIN slave mode) when no response is requested. **Table 20.84** shows the processing that occurs when no response is requested.

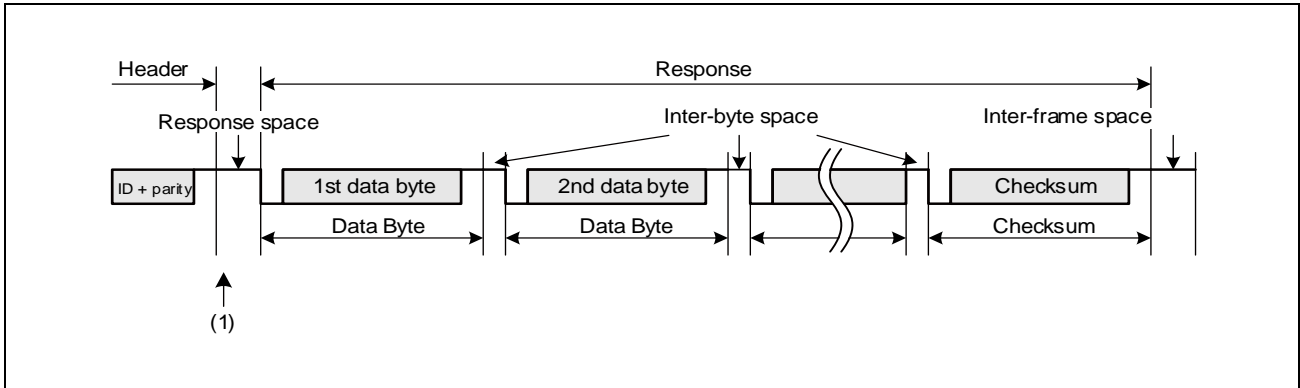

Figure 20.12 Operation when No Response is Requested

Table 20.84 Processing when No Response is Requested

Software Processing	LIN/UART Interface Processing
(1) <ul style="list-style-type: none"> • Sets the no-response request bit (LNRR bit) to 1. 	<ul style="list-style-type: none"> • Waits for setting of the no-response request bit (LNRR bit) by software • Completes the frame reception process • Waits for a new break

20.5.3.3 Data Transmission/Reception

(1) Data Transmission

One bit of data is transmitted per 1 Tbit.

The data that is transmitted returns to the reception data input pin via the LIN transceiver. The received data and the transmitted data are compared bit by bit, and the results are stored in the BER flag in the RLIN3nLEST register (see **Section 20.5.3.7, Error Status.**).

In LIN master mode and LIN slave mode [fixed baud rate], 1 Tbit is generated to be $16f_{LIN}$, and thus the sampling point for received data are at the 13th clock cycle (81.25% position).

In LIN slave mode [auto baud rate], if 1 Tbit is generated to be $4f_{LIN}$, the sampling point for received data is at the third clock cycle (75% position). If 1 Tbit is generated to be $8f_{LIN}$, the sampling point for received data is at the 7th clock cycle (87.5% position).

Figure 20.13 shows an example of data transmission timing.

Figure 20.13 Example of Data Transmission Timing (LIN Master Mode, LIN Slave Mode [Fixed Baud Rate])

(2) Data Reception

Data reception is performed by using the synchronized RLIN3nRX signal (an internal signal) that is the input from the RLIN3nRX pin synchronized with prescaler clock.

The data byte is synchronized at the falling edge of the start bit for the synchronized RLIN3nRX signal. After the falling edge is detected, sampling is performed again 0.5 Tbit later, and the falling edge is recognized as a start bit if the synchronized RLIN3nRX signal is low level. The falling edge is not recognized as a start bit if the RLIN3nRX signal after the reset is de-asserted is fixed to low level or if a high level is detected on re-sampling.

After the start bit is detected, the system samples 1 bit per Tbit.

The LIN/UART interface has a noise filter function for reception data. If the LRDNFS bit in the RLIN3nLMD register is 0, the LIN/UART interface uses a noise filter, and the value determined by a 3-sampling majority rule on prescaler clocks is used as the sampling value. If the LRDNFS bit in the RLIN3nLMD register is 1, the LIN/UART interface does not use a noise filter, and the value of the synchronized RLIN3nRX value at the sampling position is used as the sampling value.

Figure 20.14 shows an example of data reception timing.

Figure 20.14 Example of Data Reception Timing (LIN Master Mode, LIN Slave Mode [Fixed Baud Rate])

20.5.3.4 Transmission/Reception Data Buffering

This section explains the buffer processing that takes place when the LIN/UART interface sends or receives data continuously.

(1) Transmission of LIN Frames

For an 8-byte transmission, the contents stored in registers RLN3nLDBR1 to RLN3nLDBR8 are sequentially transmitted to data areas 1 to 8 of the LIN frame. In the case of a 4-byte transmission, the contents stored in registers RLN3nLDBR1 to RLN3nLDBR4 are transmitted to data areas 1 to 4 of the LIN frame, but the contents of registers RLN3nLDBR5 to RLN3nLDBR8 are not transmitted. The transmitted checksum data is stored in the RLN3nLCBR register.

Figure 20.15 shows the LIN transmission processing and the required buffers.

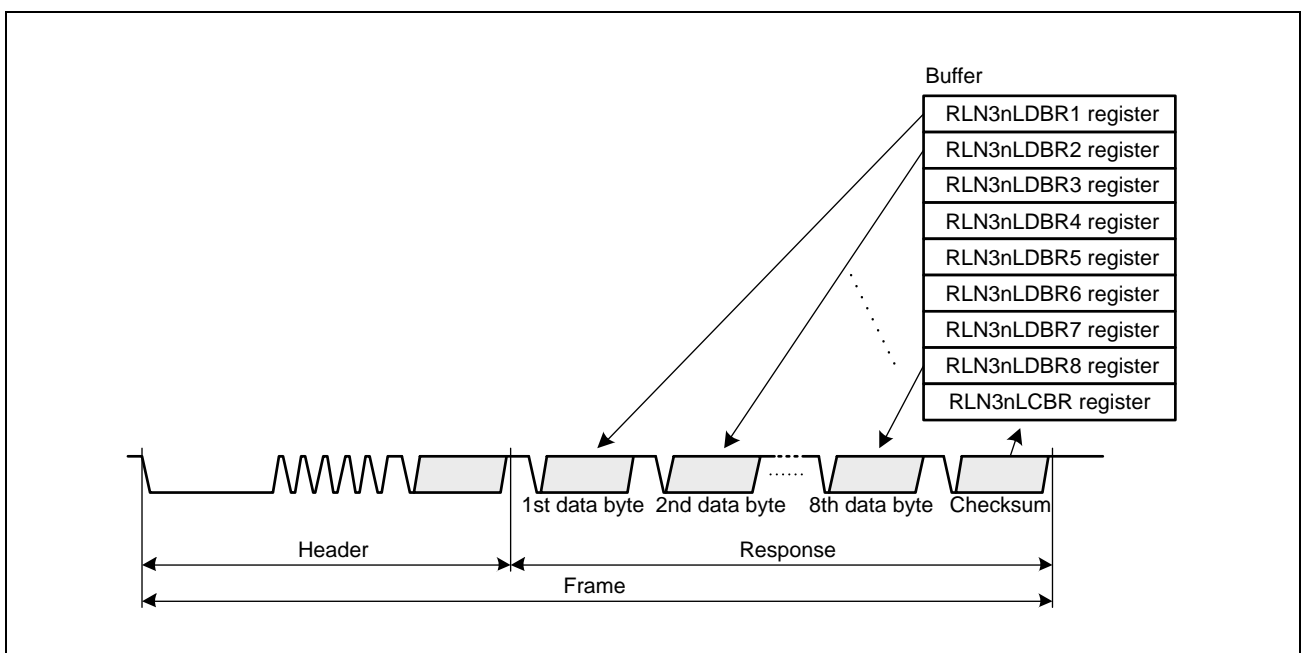

Figure 20.15 LIN Transmission Processing and Required Buffer

[Frame separate mode]

Setting the FSM bit in the RLN3nLDFC register to 1 turns on the frame separate mode.

In frame separate mode, a header and a response are transmitted when prompted by separate transmission start requests.

When the transmission of a header is finished, the HTRC flag in the RLN3nLST register is set to 1 (successful header transmission).

Use frame separate mode when transmitting or receiving response data of 9 bytes or more in LIN master mode.

(2) Reception of LIN Frames

For an 8-byte reception, the contents of data areas 1 to 8 of the LIN frame are stored in registers RLN3nLDBR1 to RLN3nLDBR8, respectively, upon reception of a stop bit. In the case of a 4-byte reception, the contents of data areas 1 to 4 of the LIN frame are stored in registers RLN3nLDBR1 to RLN3nLDBR4, respectively; no data is stored in registers RLN3nLDBR5 to RLN3nLDBR8. Also, the received checksum data is stored in the RLN3nLCBR register.

Figure 20.16 shows the LIN reception processing and the required buffers.

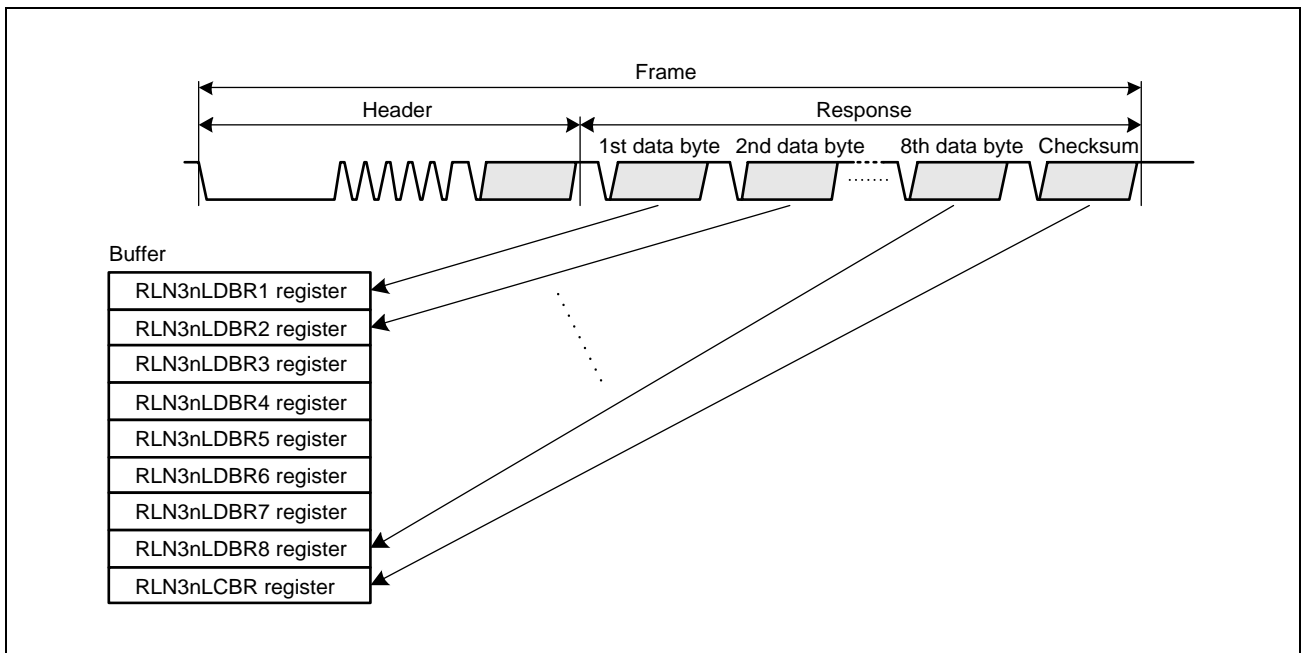

Figure 20.16 LIN Reception Processing and Required Buffer

[Reception of 1st Data Byte]

When the reception of the first byte of data is finished, the DIRC flag in the RLN3nLST register is set to 1 (successful data 1 reception).

(3) Multi-Byte Response Transmission/Reception Function

Normally in LIN communications, a response is 9 bytes or less including a checksum field; however, responses of 10 bytes or more can also be transmitted and received.

In such a case, the bit error, framing error, response preparation error detection, and auto checksum functions are enabled.

If the data length is longer than 8 bytes, the LSS bit in RLN3nLDFC register should be set to 1 (indicating that the next data group to be transmitted or received is not the last data group) in the first data group (variable from 0 to 8 bytes) before transmitting or receiving the data group. After the transmission or reception, the user should determine whether the next data group is the last data group.

If it is the last data group, the LSS bit in the RLN3nLDFC register should be set to 0 (indicating that the next data group to be transmitted or received is the last data group), and a checksum should be appended to the last data group.

By changing the RFDL bit in RLN3nLDFC register settings when the RTS bit in RLN3nLTRC register is 0, the user can change the data length for each data group.

When performing multi-byte response transmission/reception in LIN master mode, set the FSM bit in RLN3nLDFC register to 1 (frame separate mode).

NOTE

In LIN slave mode, the LIN/UART interface can detect a new break field during the transmission or reception of a response.

20.5.3.5 Wake-up Transmission/Reception

The wake-up transmission/reception can be used in LIN wake-up mode.

(1) Wake-up Transmission

In LIN wake-up mode, setting the RFT bit in the RLIN3nLDFC register to 1 (in LIN master mode: response transmission), or setting the RCDS bit in the RLIN3nLDFC register to 1 (in LIN slave mode: response transmission), and then the FTS bit in the RLIN3nLTRC register to 1 (frame transmission, header reception or wake-up transmission/reception started) causes a wake-up signal to be output from the output pin. The low width of the wake-up signal should be set using the WUTL[3:0] bits in the RLIN3nLWUP register.

However, if the LWBR0 bit of the RLIN3nLWBR register in LIN master mode is 1 (LIN2.x), the LIN system clock (fLIN) becomes low level width at fa regardless of the setting of the LCKS bit of the RLIN3nLMD register. By setting the WUTL[3:0] bits of the RLIN3nLWUP register to 0100_B (5 Tbits), 260 μs low width can be output in LIN wake-up mode regardless of the setting of the LCKS bit of the RLIN3nLMD register.

If a wake-up low-level width is output without any bit error, the FTC flag in the RLIN3nLST register is set to 1 (successful frame response or wake-up transmission); when the FTCIE bit in the RLIN3nLIE register is 1 (successful frame response/wakeup transmission interrupt enabled), an interrupt request for RLIN3n transmission is generated.

If RLIN3nLEDE.BERE is set and a bit error is detected, wake-up transmission is canceled and the BER flag in the RLIN3nLEST register is set to 1 (bit error detection).

When RLIN3nLEDE.PBERE is set in LIN master mode, set RLIN3nLEST.PBER flag to 1 (physical bus error detection) at the same time of a bit error.

Figure 20.17 shows the wake-up transmission timing.

Figure 20.17 Wake-up Transmission Timing

(2) Wake-up Reception

To detect a wake-up signal, use the input signal low-level width count function. The input signal low level width count function measures the low level width of the input signal to the RLIN3nRX pin, using the same sampling point as data reception. This allows the 2.5-Tbit or longer low-level width of the input signal of fLIN to be measured.

In LIN master mode, by setting the LWBR0 bit in the RLN3nLWBR register, operation can be executed without changing the baud rate generator setting when switching between LIN operation mode and LIN wake-up mode.

When LIN Specification Package Revision 1.3 is used, set the LWBR0 bit in the RLN3nLWBR register to 0. When LIN Specification Package Revision 2.x is used, set the LWBR0 bit to 1. Setting the LWBR0 bit to 1 sets the LIN system clock (fLIN) to fa regardless of the setting of the LCKS bit in the RLN3nLMD register. (The LCKS bit is not changed). By setting the baud rate to 19200bps while fa is selected, an input signal with a low-level width of 130 us or longer can be measured in LIN wake-up mode regardless of the setting of the LCKS bit in the RLN3nLMD register.

When using the wake-up reception function, in LIN wake-up mode set the RFT bit in the RLN3nLDFC register to 0 (LIN master mode: response reception), or the RCDS bit in the RLN3nLDFC register to 0 (in LIN slave mode: response reception), and then set the FTS bit in the RLN3nLTRC register to 1 (frame transmission (header reception) or wake-up transmission/reception started).

When the low level width to be measured is reached, the FRC flag in the RLN3nLST register is set to 1 (successful frame response/wake-up reception). If the FRCIE bit in the RLN3nLIE register is 1 (successful frame response or wake-up reception interrupt enabled), an interrupt request for successful RLIN3n reception is generated.

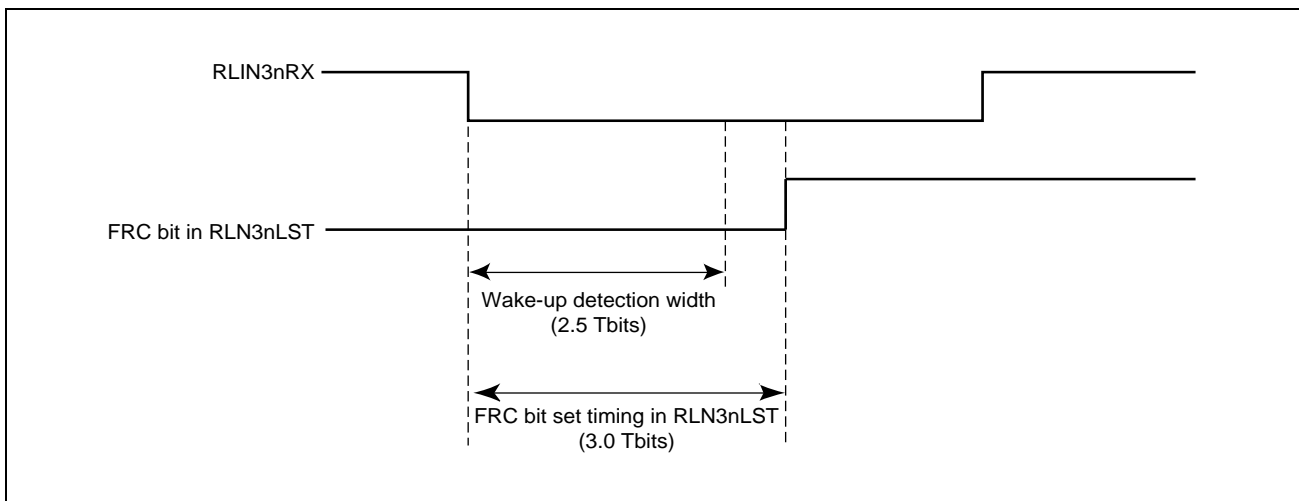

Figure 20.18 Input Signal Low Level Count Function

(3) Wakeup Collision

If the master node and the slave node transmit wakeup signals simultaneously, a collision will occur on the LIN bus, though a collision of wakeup signals is not detected by the LIN/UART interface.

20.5.3.6 Status

In LIN mode operation, the LIN/UART interface can detect seven types of statuses.

The four statuses, successful frame/wake-up transmission, successful frame/wake-up reception, error detection, and successful header transmission/reception, can generate interrupt requests.

Table 20.85 shows the types of statuses available in LIN master mode. **Table 20.86** lists the types of statuses available in LIN slave mode [auto baud rate] and in LIN slave mode [fixed baud rate].

Table 20.85 Types of Statuses in LIN Master Mode

Status	Status Set Condition	Status Clear Condition	Operation Mode Capable of Status Detection	Corresponding Bit	Interrupt
Reset	After the OM0 bit in the RLN3nLCUC register is set to not-LIN-reset-mode, if actually the LIN/UART interface is cleared from LIN reset mode.	After the OM0 bit in the RLN3nLCUC register is set to LIN reset mode, if actually the LIN/UART interface enters LIN reset mode.	All modes	OMM0 bit in RLN3nLMST register	—
Operation mode	After the OM1 bit in the RLN3nLCUC register is set to LIN operation mode, if actually the LIN/UART interface enters LIN operation mode.	After the OM1 bit in the RLN3nLCUC register is set to LIN wake-up mode, if actually the LIN/UART interface enters LIN wake-up mode.	<ul style="list-style-type: none"> • LIN operation mode • LIN wake-up mode 	OMM1 bit in RLN3nLMST register	—
Frame/wake-up transmission end	When a frame (header transmission + response transmission), a wake-up signal, or a data group is transmitted successfully.	<ul style="list-style-type: none"> • When another communication is started (When the FTS bit in the RLN3nLTRC register is set) • When cleared by software • After transition to LIN reset mode 	<ul style="list-style-type: none"> • LIN operation mode • LIN wake-up mode 	FTC flag in RLN3nLST register	✓

Error detection	If any of the RPER flag, IPER flag, CSER flag, SFER flag, FER flag, TER flag, and BER flag in the RLN3nLEST register is set to 1 (error detected).	<ul style="list-style-type: none"> When cleared by software*1 Transition to LIN reset mode 	<ul style="list-style-type: none"> LIN operation mode LIN wake-up mode 	ERR flag in RLN3nLST register	✓
1st data byte reception end	The RCDS bit in the RLN3nLDFC register is 0 (reception) and the first byte of the response field or the first byte for each data group is received successfully.*2	<ul style="list-style-type: none"> When cleared by software Transition to LIN reset mode 	LIN operation mode	D1RC flag in RLN3nLST register	—
Header reception end	When a header field is received successfully.	<ul style="list-style-type: none"> When cleared by software Transition to LIN reset mode 	LIN operation mode	HTRC flag in RLN3nLST register	✓

Note 1. In LIN wake-up mode or LIN operation mode, the ERR flag in the RLN3nLST register is cleared to 0 by writing 0 to the RPER flag, IPER flag, CSER flag, SFER flag, FER flag, TER flag, or BER flag in the RLN3nLEST register.

Note 2. Not detected when the RFDL [3:0] bits in the RLN3nLDFC register are 0000_B (0-byte + checksum).

20.5.3.7 Error Status

(1) LIN Master Mode

(a) Types of Error Statuses

The LIN/UART interface can detect six types of error statuses in LIN master mode. The condition of these error statuses can be verified by checking the corresponding bits in the RLIN3nLEST register.

All error statuses are interrupt factors.

Table 20.87 shows the types of error statuses.

Table 20.87 Types of Error Statuses in LIN Master Mode

Status	Error Detection Condition	Operation Mode Capable of Error Detection	Communication	Enable/Disable Detection	Corresponding Bit
Bit error	The transmitted data and the data on the LIN bus monitored by the receive pin do not match <small>*1,*2</small>	<ul style="list-style-type: none"> LIN operation mode LIN wake-up mode 	Cancel	Enabled	BER flag in RLIN3nLEST register
Physical bus error	<ul style="list-style-type: none"> LIN bus detected a high level when sending a break LIN bus detected a low level when sending a break delimiter LIN bus detected a high level when sending a wake-up 	<ul style="list-style-type: none"> LIN operation mode LIN wake-up mode 	Cancel	Enabled	PBER flag in RLIN3nLEST register
Timeout error	A frame or response transmission/reception is not completed within a given time ^{*3}	LIN operation mode	Cancel	Enabled	FTER flag in RLIN3nLEST register
Framing error	In response field reception, a stop bit of each data byte is low level	LIN operation mode	Cancel	Enabled	FER flag in RLIN3nLEST register
Checksum error	In response field reception, the result of checksum indicates an error	LIN operation mode	—	Disabled	CSEF flag in RLIN3nLEST register
Response preparation error	<p>One of the following conditions occurs in frame separate mode during a multi-byte response reception:</p> <ul style="list-style-type: none"> After header transmission is complete, the first byte of receive data is received before a response transmission/reception request is set. After the previous data group reception is complete, the first byte of receive data is received before a transmission/reception request for the next data group is set. 	LIN operation mode	Cancel	Disabled	RPER flag in RLIN3nLEST register

Note 1. If a bit error is detected, processing is stopped after a stop bit is sent. If a bit error is detected in a non-data area, such as an inter-byte space, the transmission is suspended immediately after the bit which had the error is sent. If a bit error is detected during the transmission of a wake-up, the transmission of the wake-up is canceled after the error-causing bit is sent.

Note 2. In a multi-byte response transmission, bit errors are also detected between data groups.

Note 3. The timeout time depends on the response field data length (the RFDL [3:0] bits in the RLIN3nLDFC register) and the checksum selection (the CSM bit in the RLIN3nLDFC register), and can be calculated from the following formula. When the FSM bit in the RLIN3nLDFC registers is 1 (frame separation mode), the timeout time is that for eight bytes until the RTS bit of the RLIN3nLTRC register is set. Once the RTS bit is set, the timeout time is re-set to the time based on the response field data length (the RFDL[3:0] bits in the RLIN3nLDFC register).

[Frame timeout]

When classic is selected (when the CSM bit in RLIN3nLDFC is 0): Timeout time = 49 + (number of data bytes + 1) × 14 [Tbit]

When enhanced is selected (when the CSM bit in RLIN3nLDFC is 1): Timeout time = 48 + (number of data bytes + 1) × 14 [Tbit]

The aforementioned timeout time is a time longer than the TFRAME_MAX of LIN Specification Package Revision 1.3 when classic is selected, or the TFRAME_MAX of LIN Specification Package Revision 2.x when enhanced is selected.

[Response timeout]

$$\text{Timeout time} = (\text{number of data bytes} + 1) \times 14 \text{ [Tbit]}$$

When an error is detected, the timeout error detection function stops.

The error status is cleared when the next communication is started (when the FTS bit in the RLIN3nLTRC register is set), by software, or at a transition to LIN reset mode.

(b) Target Time Area for LIN Error Detection

Figure 20.19 shows the time domain in which the LIN/UART interface in LIN master mode performs monitoring for error detection.

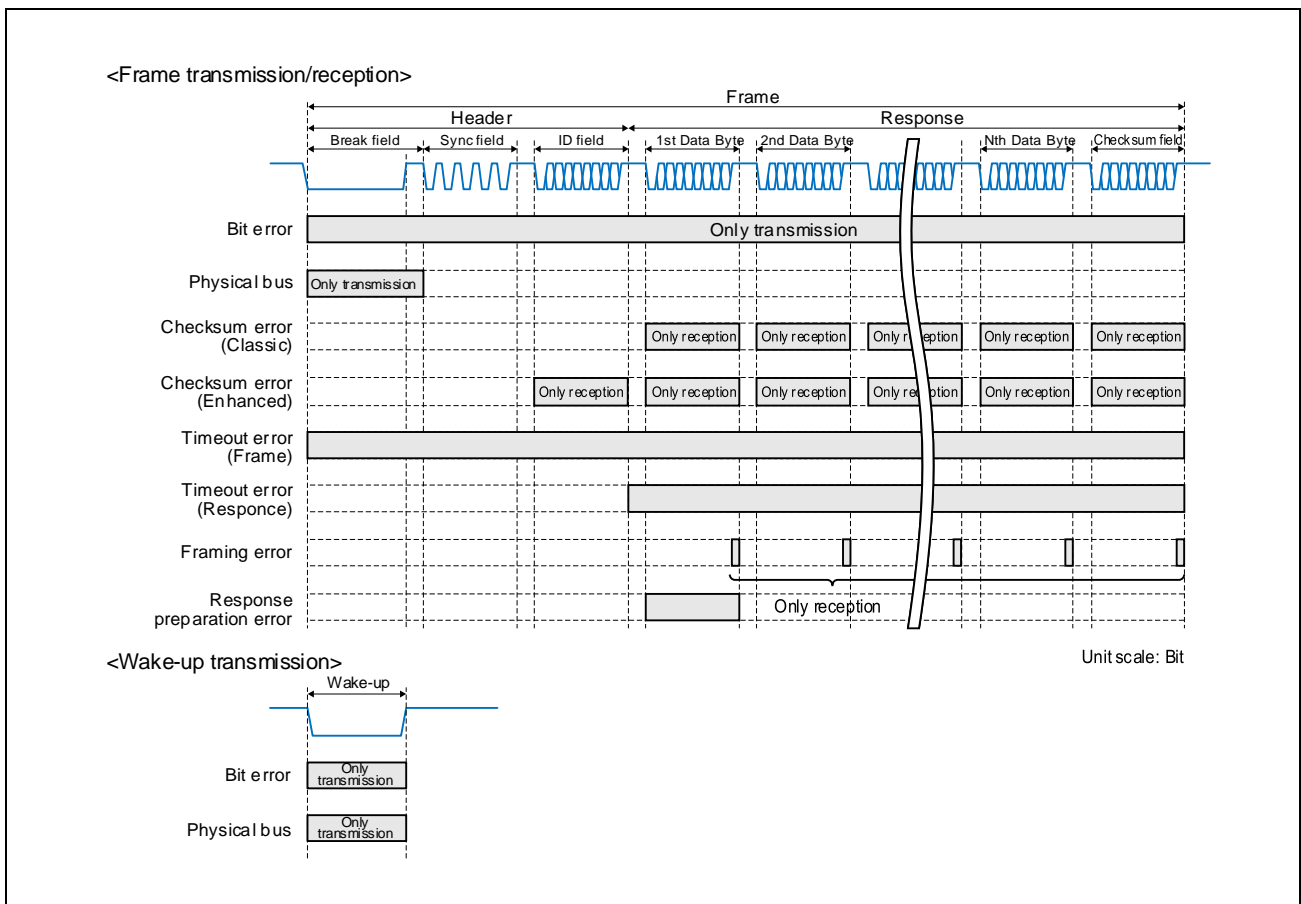

Figure 20.19 Target Time Area for LIN Error Detection (LIN Master Mode)

(2) LIN Slave Mode

(a) Types of Error Statuses

The LIN/UART interface can detect seven types of error statuses in LIN slave mode [auto baud rate] or in LIN slave mode [fixed baud rate]. These error statuses can be verified by checking the corresponding bits in the RLN3nLEST register.

Table 20.88 shows the types of error statuses.

Table 20.88 Types of Error Statuses in LIN Slave Mode

Status	Error Detection Condition	Operation Mode Capable of Error Detection	Communication	Enable/Disable Detection	Corresponding Bit
Bit error	The transmitted data and the data on the LIN bus monitored by the receive pin do not match ^{*1*2}	<ul style="list-style-type: none"> • LIN operation mode • LIN wake-up mode 	Cancel	Enabled	BER flag in RLN3nLEST register
Timeout error	A frame or response transmission/reception is not completed within a given time ^{*3}	LIN operation mode	Cancel	Enabled	TER flag in RLN3nLEST register
Framing error	In frame reception, a stop bit of each data byte is low level	LIN operation mode	Cancel	Enabled	FER flag in RLN3nLEST register
Sync field error	If the width of the break low level is greater than the width set by the LBLT bit in the RLN3nLBFC register and the sync field is not 55 _H	LIN operation mode	Cancel	Enabled ^{*4}	SFER flag in RLN3nLEST register
Checksum error	In response field reception, the result of checksum indicates an error	LIN operation mode	— ^{*5}	Disabled	CSEF flag in RLN3nLEST register
ID parity error	If the received ID parity bit does not match the value that is automatically calculated by the LIN/UART interface	LIN operation mode	Cancel	Enabled	IPER flag in RLN3nLEST register
Response preparation error	<ul style="list-style-type: none"> • After the reception of a header, response preparation is not completed in time before the first byte of reception data is received • In multi-byte response reception, the reception preparation for the next data group is not completed in time before the first byte of the next data group reception data is received. 	LIN operation mode	Cancel	Disabled	RPER flag in RLN3nLEST register

Note 1. If a bit error is detected, processing is stopped after a stop bit is sent. If a bit error is detected in a non-data area, such as an inter-byte space, the transmission is suspended immediately after the bit which had the error is sent. If a bit error is detected during the transmission of a wake-up, the transmission of the wake-up is canceled after the error-causing bit is sent.

Note 2. In a multi-byte response transmission, bit errors are also detected between data groups.

Note 3. The timeout time depends on the response field data length (the RFDL [3:0] bits in the RLN3nLDFC register) and the checksum selection (the LCS bit in the RLN3nLDFC register), and this can be calculated according to the following formula. The timeout period until the RTS or LNRR bit of the RLN3nLTRC register is set is 8 data bytes. When the RTS bit is set, the timeout time is reset to the time based on the response field data length (RFDL[3:0] bits of the RLN3nLDFC register). When the LNRR bit is set, the timeout function stops.

[Frame timeout]

When classic is selected (when the LCS bit in RLN3nLDFC is 0): Timeout time = 49 + (number of data bytes + 1) × 14 [Tbit]

When enhance is selected (when the LCS bit in RLN3nLDFC is 1): Timeout time = 48 + (number of data bytes + 1) × 14 [Tbit]

The aforementioned timeout time is a time longer than the TFRAME_MAX of LIN Specification Package Revision 1.3 when classic is selected, or the TFRAME_MAX of LIN Specification Package Revision 2.x when enhanced is selected.

[Response timeout]

Timeout time = (number of data bytes + 1) × 14 [Tbit]

When an error is detected, timeout error detection function stops.

Note 4. Only reflection of the result to the SFER flag can be enabled/disabled. Error detection cannot be enabled/disabled.

Note 5. Checksum judgment is performed upon completion of response frame reception. In case of an error, the successful reception flag is not set to 1.

The error status is cleared by software or at a transition to LIN reset mode.

(b) Target Time Area for LIN Error Detection

Figure 20.20 shows the time domain in which the LIN/UART interface in slave mode performs monitoring for error detection.

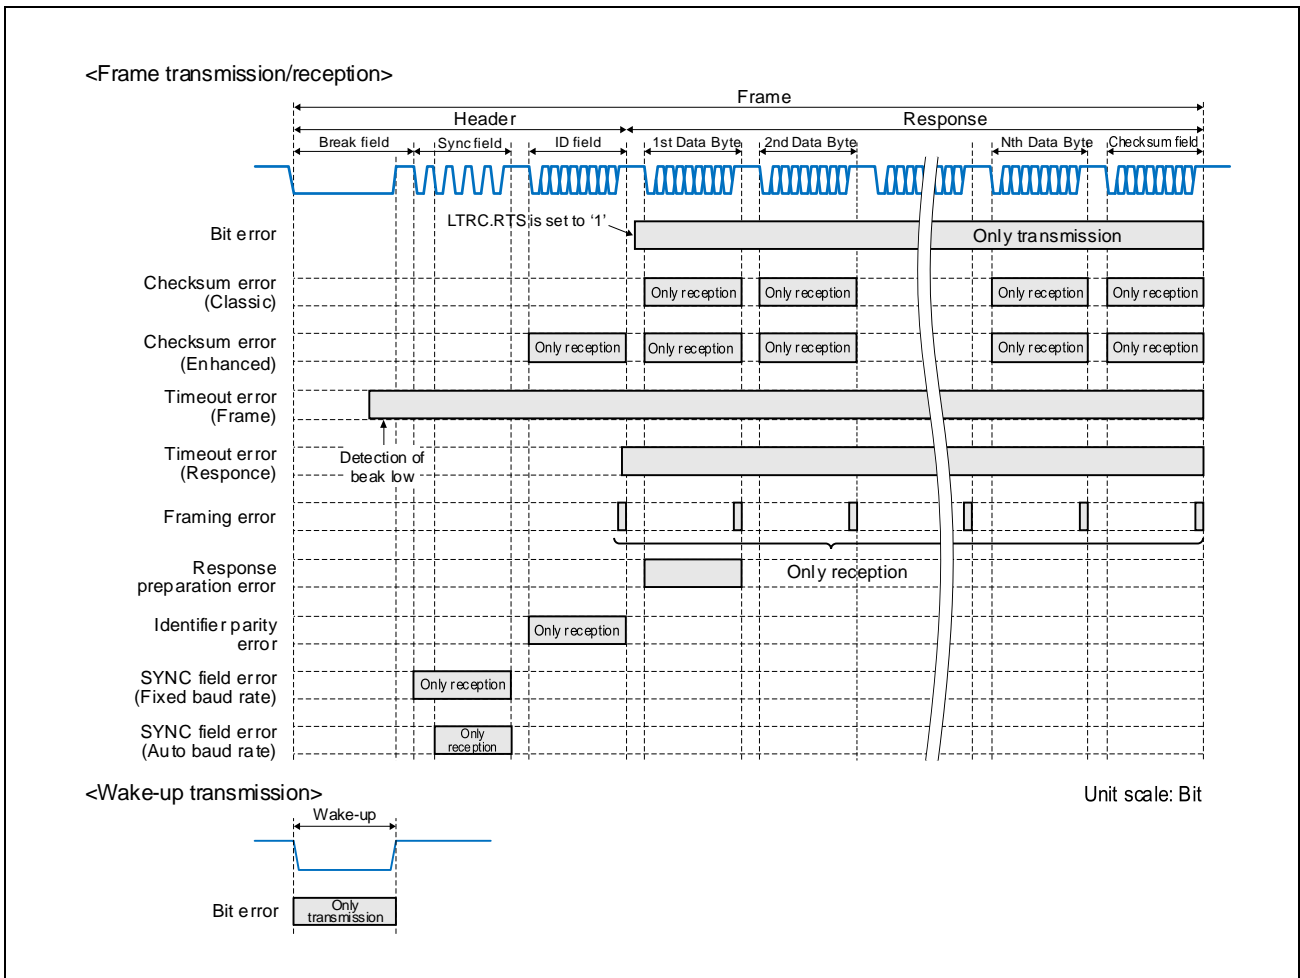

Figure 20.20 Target Time Area for LIN Error Detection (LIN Slave Mode)

20.5.4 UART Mode

In LIN reset mode, setting the LMD bits in the RLN3nLMD register to 01_B (UART mode) and the OM0 bit in the RLN3nLCUC register to 1 changes the mode to UART mode, turning the OMM0 bit in the RLN3nLMST register to 1.

20.5.4.1 Transmission

Figure 20.21 shows LIN/UART interface (in UART mode) transmission operations;

Table 20.89 shows LIN/UART interface (in UART mode) transmission processing.

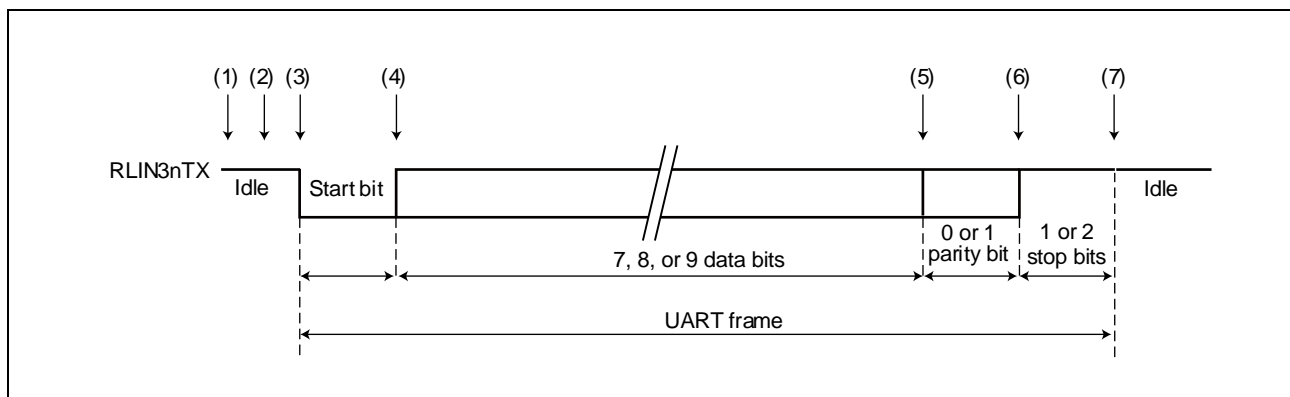

Figure 20.21 LIN/UART Interface (in UART Mode) Transmission Operation

Table 20.89 LIN/UART Interface (UART Mode) Transmission Processing (2/2)

Software Processing	LIN/UART Interface Processing
<p>(7) [When the UTIGTS bit is 0 (a transmission interrupt request is generated upon start of transmission)]</p> <ul style="list-style-type: none"> • If another item of transmission data is set, goes to step (3). <p>[When the UTIGTS bit is 1 (a transmission interrupt is generated upon end of transmission)]</p> <ul style="list-style-type: none"> • When transmitting data continuously, goes to step (2). 	<p>[When the UTIGTS bit is 0 (a transmission interrupt request is generated upon start of transmission)]</p> <ul style="list-style-type: none"> • If another piece of transmission data is set, goes to step (3). • If another piece of transmission data is not set, clears the transmit status flag. <p>[When the UTIGTS bit is 1 (a transmission interrupt is generated upon end of transmission)]</p> <ul style="list-style-type: none"> • Generates RLIN3n transmission interrupt request. • Clears the transmission status flag.

(1) Continuous Transmission

The LIN/UART interface (in UART mode) can transmit multiple sets of data continuously by using the RLN3nLUTDR register. **Figure 20.22** shows an operation example where the transmission interrupt generation timing is the start of transmission and an operation example where the transmission interrupt generation timing is the end of transmission.

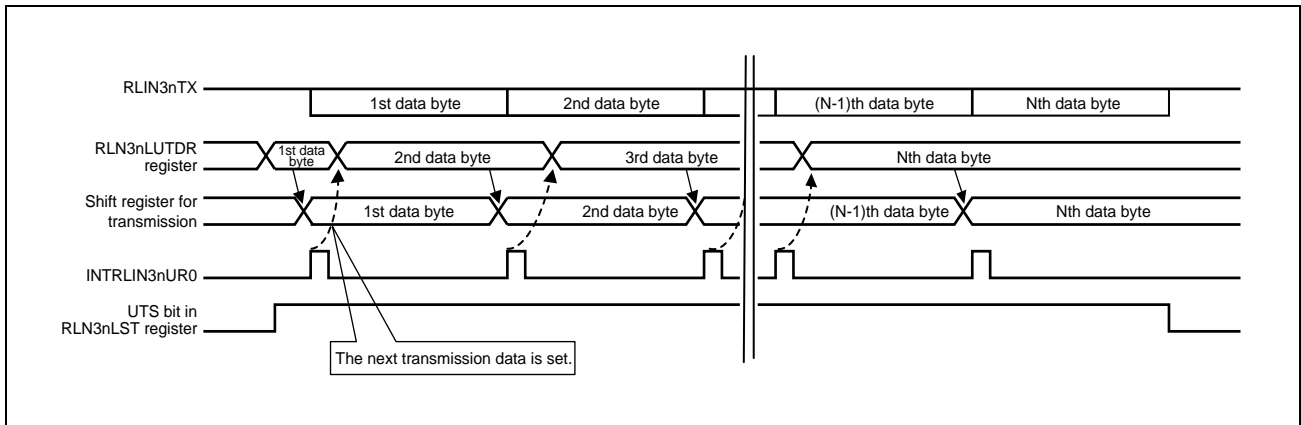

Figure 20.22 Operation Example of LIN/UART Interface (UART Mode) Continuous Transmission

An interrupt can be generated at the end of a transmission by changing the UTIGTS bit in the RLN3nLUOR1 register from 0 to 1 after the start of transmission of final data, provided that the transmission interrupt generation timing is the start of transmission and the end of transmission of final data needs to be known.

(2) UART Buffer Transmission

The LIN/UART interface (in UART mode) has a maximum of nine bytes of UART buffers, and thus it is capable of performing continuous transmissions through the use of UART buffers.

Figure 20.23 shows the UART buffer transmission operation of the LIN/UART interface (in UART mode).

Table 20.90 describes the UART buffer data transmission processing.

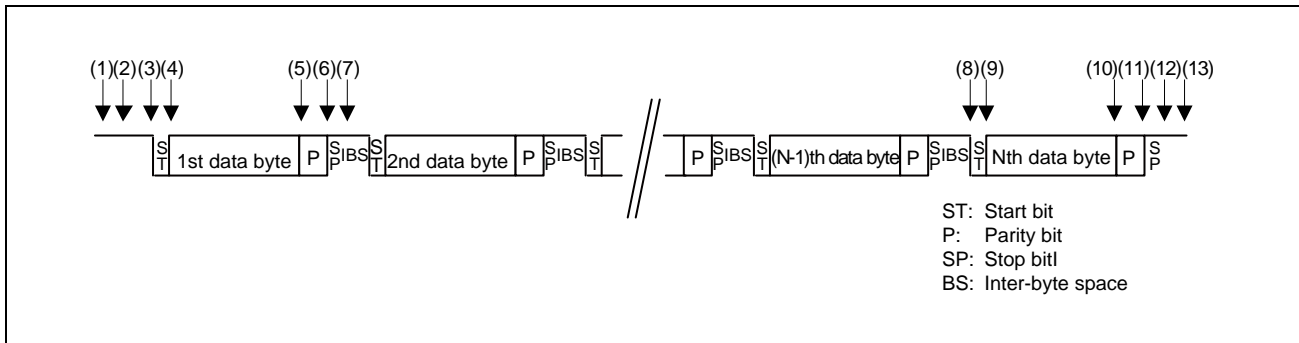

Figure 20.23 UART Buffer Transmission of LIN/UART Interface (in UART Mode)

Table 20.90 UART Buffer Transmission Processing of LIN/UART Interface (in UART Mode) (2/2)

Software Processing	LIN/UART Interface Processing
(7) Waits for an interrupt request.	Transmits an inter-byte space (idle). Repeats steps (3) to (7) until frame count –1 that was set in the UART buffer data length select bits is reached.
(8)	Transmits a start bit.
(9)	Transmits the data set in the LIN/UART data buffer b register (RLN3nLDBRb).
(10)	Transmits a parity bit when parity is used.
(11)	Transmits 1 or 2 stop bits.
(12)	<ul style="list-style-type: none"> • Sets the successful buffer transmission flag. • Clears the UART Buffer Transmission Start bit (RTS). • A transmission interrupt request signal. • Clears the transmission status flag.
(13) <ul style="list-style-type: none"> • Checks the RLN3nLST register, and clears flags • In the case of continuous data transmission, goes to step (2). 	

(a) UART Buffer Transmission

For a 9-byte transmission, the contents stored in the RLN3nLUDB0 and RLN3nLDBR1 to RLN3nLDBR8 registers are transmitted to data areas 1 to 9. The RLN3nLUDB0 register is used only if 9-byte transmission is set. In other cases, the RLN3nLDBR1 to RLN3nLDBR8 registers are selected depending upon the length of data involved. For a 4-byte transmission, the contents stored in the RLN3nLDBR1 to RLN3nLDBR4 registers are transmitted to data areas 1 to 4, but the contents of the RLN3nLDBR5 to RLN3nLDBR8 registers are not transmitted. An RLIN3n transmission interrupt is generated after the number of data specified in the MDL [3:0] bits of the RLN3nLDFC register is transmitted. The spaces between transmission data items can be set in the IBS bit in the RLN3nLSC register.

Figure 20.24 shows a UART buffer and the transmission processing.

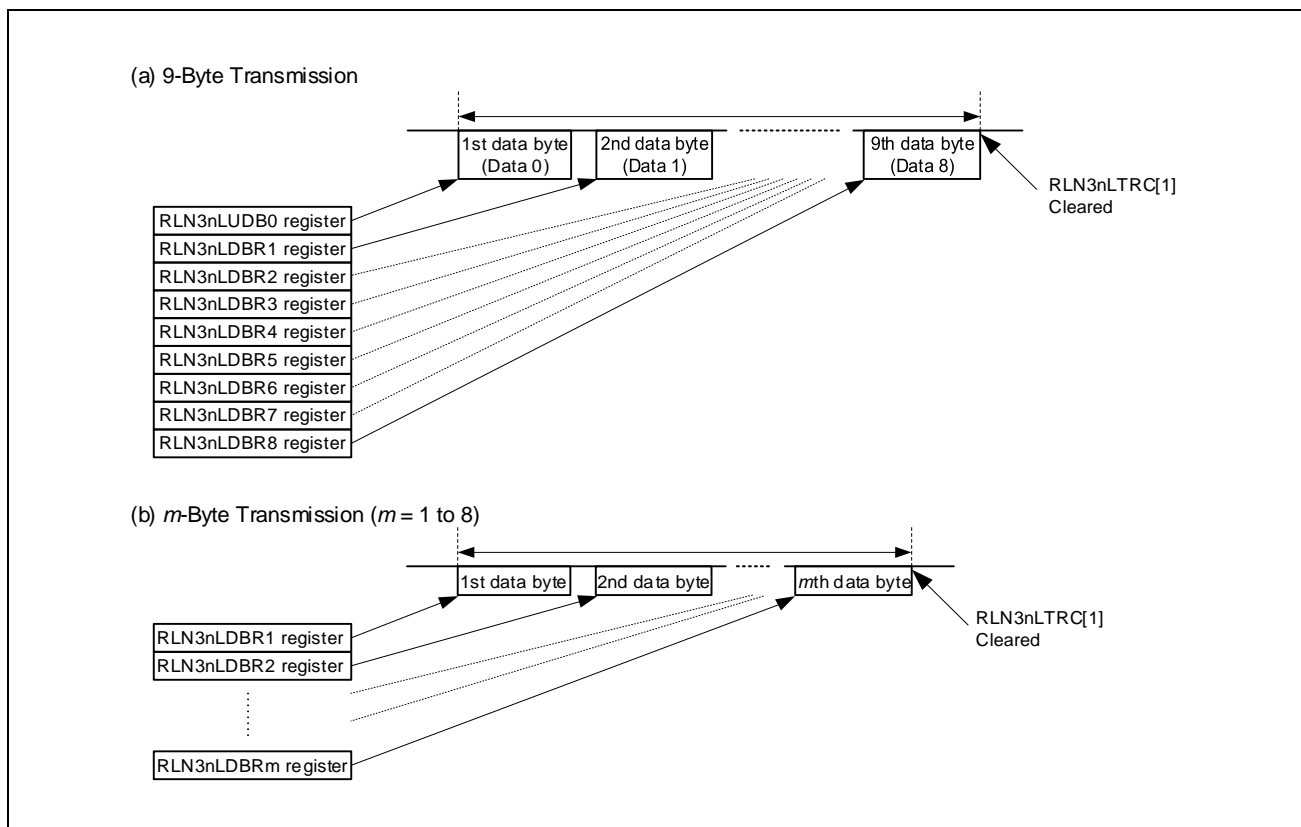

Figure 20.24 UART Buffer and Transmission Processing

(3) Data Transmission

One bit of data is transmitted per Tbit.

In half-duplex communication, if the BERE bit in the RLN3nLEDE register is 1 (bit error detection enabled), the transmission data and the input pin level are compared bit by bit during data transmission, and the results are stored in the BER flag in the RLN3nLEST register (see **Section 20.5.4.5, Error Status**). The timing at which the input pin is sampled during data transmission can vary depending upon the settings of the LPRS[2:0] and NSPB[3:0] bits in the RLN3nLWBR register.

The bit error detection timing in UART mode is shown in **Table 20.91**.

Table 20.91 Error Detection Timing in UART Mode

Sampling Count Per Bit	Bit Error Detection Timing
6 samples	3rd clock cycle + 1 prescaler clock
7 samples	4th clock cycle + 1 prescaler clock
8 samples	4th clock cycle + 1 prescaler clock
9 samples	5th clock cycle + 1 prescaler clock
10 samples	5th clock cycle + 1 prescaler clock
11 samples	6th clock cycle + 1 prescaler clock
12 samples	6th clock cycle + 1 prescaler clock
13 samples	7th clock cycle + 1 prescaler clock
14 samples	7th clock cycle + 1 prescaler clock
15 samples	8th clock cycle + 1 prescaler clock
16 samples	8th clock cycle + 1 prescaler clock

Example of Data Transmission Timing (when 1 Tbit = 16 Sampling) is shown in **Figure 20.25**.

Figure 20.25 Example of Data Transmission Timing (When 1 Tbit = 16 Sampling)

(4) Transmission Start Wait Function

For performing half-duplex communication, the LIN/UART interface (in UART mode) has the function of securing the reception stop bit length when switching from reception to transmission.

If it is desired to delay the start of transmission until the stop bits for the reception are completed, set data in the RLIN3nLUWTDR register, which is used only for the wait function, instead of setting transmission data in the RLIN3nLUTDR register as a start-of-transmission request. When transmitting from the UART buffer, set 1 (UART buffer transmission started) in the RTS bit in the RLIN3nLTRC register with 1 set in the UTSW bit in the RLIN3nLDFC register. In such a case, the LIN/UART interface delays the start of transmission until the stop bits of reception data are completed.

It should be noted that even if the UART stop bit length selection bit (USBLS) in RLIN3nBLFC register is 1 (stop bits = 2 bits), delay is made only for 1 bits.

Figure 20.26 shows the operation of transmission wait function.

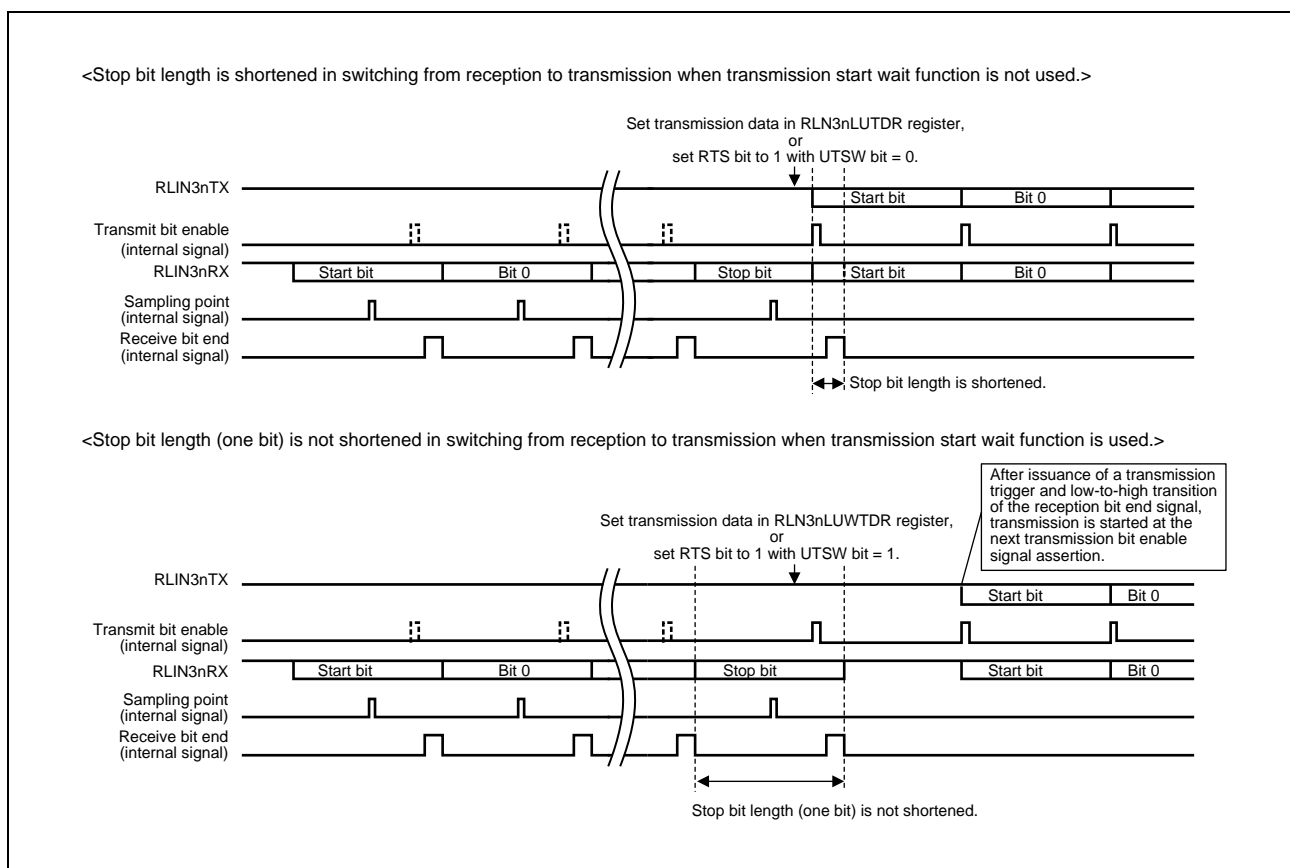

Figure 20.26 Case When Transmit Data Is Set While Stop Bits Are Being Received

20.5.4.2 Reception

Figure 20.27 shows the LIN/UART interface (in UART mode) reception operation. Table 20.92 shows the LIN/UART interface (in UART mode) reception processing.

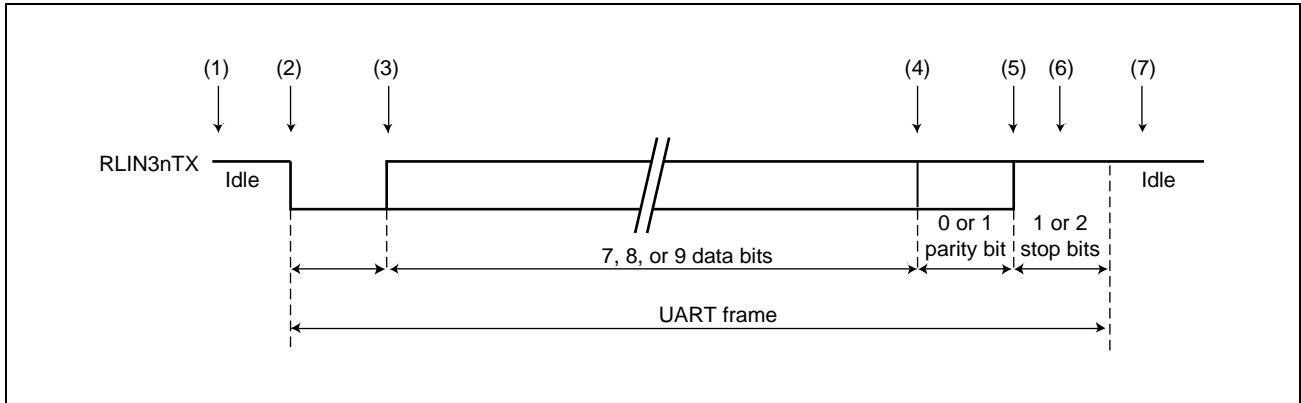

Figure 20.27 LIN/UART Interface (in UART Mode) Reception Operation

Table 20.92 LIN/UART Interface (in UART Mode) Reception Processing

Software Processing	LIN/UART Interface Processing
(1) <ul style="list-style-type: none"> • Sets a baud rate. • Sets noise filter ON/OFF. • Enables error detection. • Sets data format. • Clears the LIN/UART interface from LIN reset mode. • Sets the receive enable bit (UROE bit) to 1. 	<ul style="list-style-type: none"> • Waits for the reception to be enabled by software. • Waits for detection of a start bit.
(2) Waits for an interrupt request.	<ul style="list-style-type: none"> • Waits for a falling edge from the reception pin, and detects a start bit. • Sets the reception status flag.
(3)	Receives data.
(4)	Receives a parity bit when parity is used.
(5)	Receives only 1 stop bit.
(6)	<ul style="list-style-type: none"> • Generates a successful RLIN3n reception interrupt request. • Clears the reception status flag.
(7) Checks the RLIN3nLST register, and clears flags	Waits for a falling edge from the reception pin.

(1) Data Reception

Data reception is performed by using the synchronized RLIN3nRX (an internal signal) that is the input from the RLIN3nRX pin synchronized with the prescaler clock.

The Data Byte is synchronized at the falling edge of the start bit for the synchronized RLIN3nRX signal. After the falling edge is detected, resampling is performed 0.5 Tbits later when the number of sampling per 1 Tbit is even and $\{(the\ number\ of\ sampling + 1) / 2\} / (the\ number\ of\ sampling)$ Tbits later when the number is odd. If the synchronized RLIN3nRX signal is low level, the bit is recognized as a start bit. The bit is not recognized as a start bit if the RLIN3nRX signal after the reset is de-asserted is fixed to low level or if a high level is detected during the resampling.

After the start bit is detected, 1 bit is sampled per Tbit.

However, when the BERE bit in the RLN3nLEDE register is 1, the sampling point is the same as the bit error detection timing.

The LIN/UART interface has a noise filtering function for received data. If the LRDNFS bit in the RLN3nLMD register is 0, the noise filter is used. For a sampling value, the value determined by a 3-samplings majority rule by the prescaler clock is used. If the LRDNFS bit in the RLN3nLMD register is 1, the noise filter is not used. In this case, for a sampling value, the synchronized RLIN3nRX value at the sampling position is used as is.

Figure 20.28 shows an example of data reception timing.

Figure 20.28 Example of Data Reception Timing (When Sampling Count is 16 in 1 Tbit)

20.5.4.3 Expansion Bits

The LIN/UART interface (in UART mode) can transmit and receive 9-bit long data by setting the UEBE bit in the RLN3nLUOR1 register to 1.

(1) Expansion Bit Transmission

The LIN/UART interface (in UART mode) can transmit 9-bit long data when the expansion bit enable bit (UEBE) in the UART option register 1 (RLN3nLUOR1) is 1 and by writing the 9-bit data to either the UART transmission data register (RLN3nLUTDR) or the UART wait transmission data register (RLN3nLUWTDR).

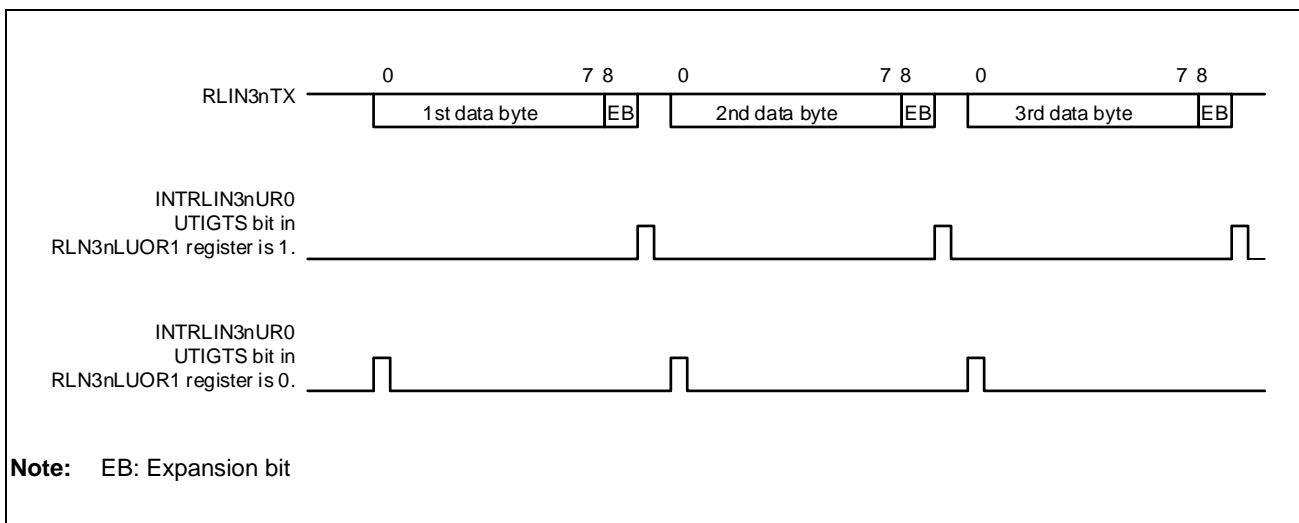

Figure 20.29 Transmission Example When Expansion Bit is Enabled (LSB First)

(2) Expansion Bit Reception

With the LIN/UART interface (in UART mode), 9-bit data can always be received without requiring a comparison of expansion bits, provided that the expansion bit enable bit (UEBE) in the UART option register 1 (RLN3nLUOR1) is 1, the expansion bit comparison disable bit (UECD) is 1, and the expansion bit data comparison enable bit (UEBDCE) is 0. Irrespective of the particular setting of the expansion bit detection level selection bit (UEBDL) in the UART option register 1 (RLN3nLUOR1), a successful RLIN3n reception interrupt is generated when 9-bit data is received.

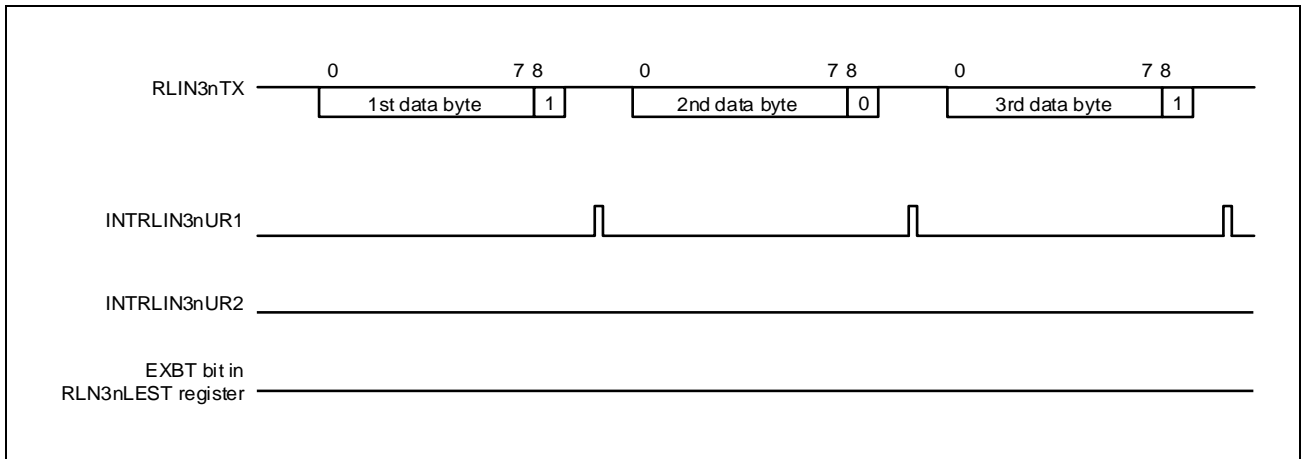

Figure 20.30 Expansion Bit Reception Example (LSB First)

(3) Expansion Bit Reception (with Expansion Bit Comparison)

The LIN/UART interface (in UART mode) can compare received expansion bits and the UEBDL bits when the expansion bit enable bit (UEBE) in the UART option register 1 (RLN3nLUOR1) is 1, the expansion bit comparison disable bit (UECD) is 0 and the expansion bit/data comparison enable bit (UEBDCE) is 0.

If the level that was set in the expansion bit detection level selection bit (UEBDL) is detected, an RLIN3n status interrupt request is generated upon completion of data reception, and the expansion bit detection flag (EXBT) in the LIN error status register (RLN3nLEST) is set. If the reversed value of an expansion bit detection level is detected, successful RLIN3n reception interrupt request is generated. In either case, the received data is stored in the UART reception data register (RLN3nLURDR), unless there was an overrun error.

Figure 20.31 shows an example when the expansion bit detection level selection bit (UEBDL) is set to 0.

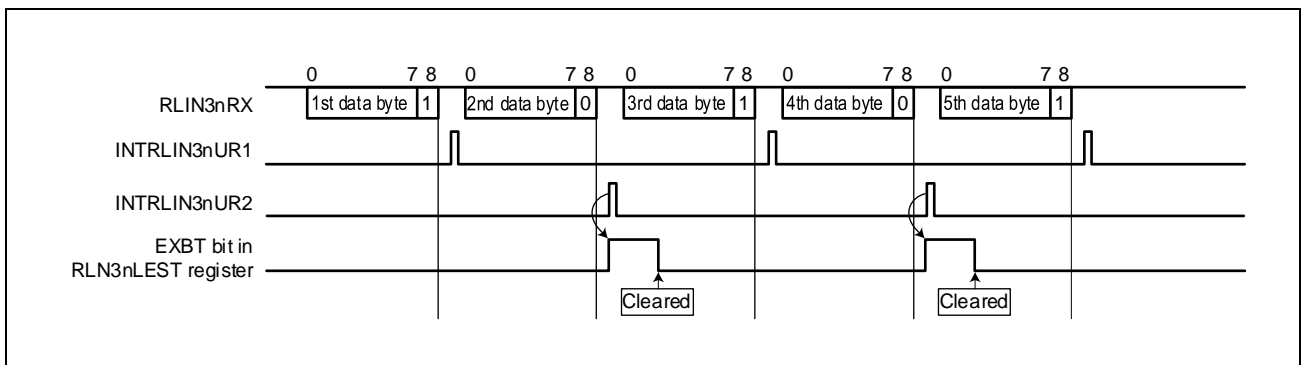

Figure 20.31 Expansion Bit Reception Example (with Expansion Bit Comparison) (LSB First, UEBDL = 0)

NOTE

- If a reception error (parity error, framing error, or overrun error) occurs in received data 0, 2, or 4 (if a reversed value of an expansion bit detection level is detected), an RLIN3n status interrupt is generated, and the error flag is updated. In this case, a successful RLIN3n reception interrupt is not generated.
- If a reception error (parity error, framing error, or overrun error) occurs in received data 1 or 3 (if an expansion bit detection level is detected), an RLIN3n status interrupt is generated, and the error flag is updated. If the overrun error occurs, the expansion bit detection flag (EXBT) is also set.

(4) Expansion Bit Reception (with Data Comparison)

If the expansion bit enable bit (UEBE) in the UART option register 1 (RLN3nLUOR1) is 1, the expansion bit comparison disable bit (UECD) is 0 and the expansion bit/data comparison enable bit (UEBDCE) is 1, and if the level that was set by the expansion bit detection level selection bit (UEBDL) is detected, the LIN/UART interface (in UART mode) compares the 8 bits, excluding the expansion bit in the received data, with the a pre-set RLN3nLIDB register value.

If the result of the comparison is a match, the LIN/UART interface performs the following operations:

- Generates an RLIN3n status interrupt
- Sets an expansion bit detection flag (EXBT)
- Sets an ID match flag (IDMT)
- Stores the received data in the UART reception data register (RLN3nLURDR)

Even when the result of the comparison is a match, successful RLIN3n reception interrupt is not generated.

If the result of the comparison is not a match, no successful RLIN3n reception interrupt or RLIN3n status interrupt is generated, and the EXBT and IDMT flags are not set to 1. The received data is not stored in the UART reception data register (RLN3nLURDR).

When changing the UEBDCE bit to 0, make the change before the reception of another set of data is finished.

Figure 20.32 shows an example when the expansion bit detection level selection bit (UEBDL) is set to 0.

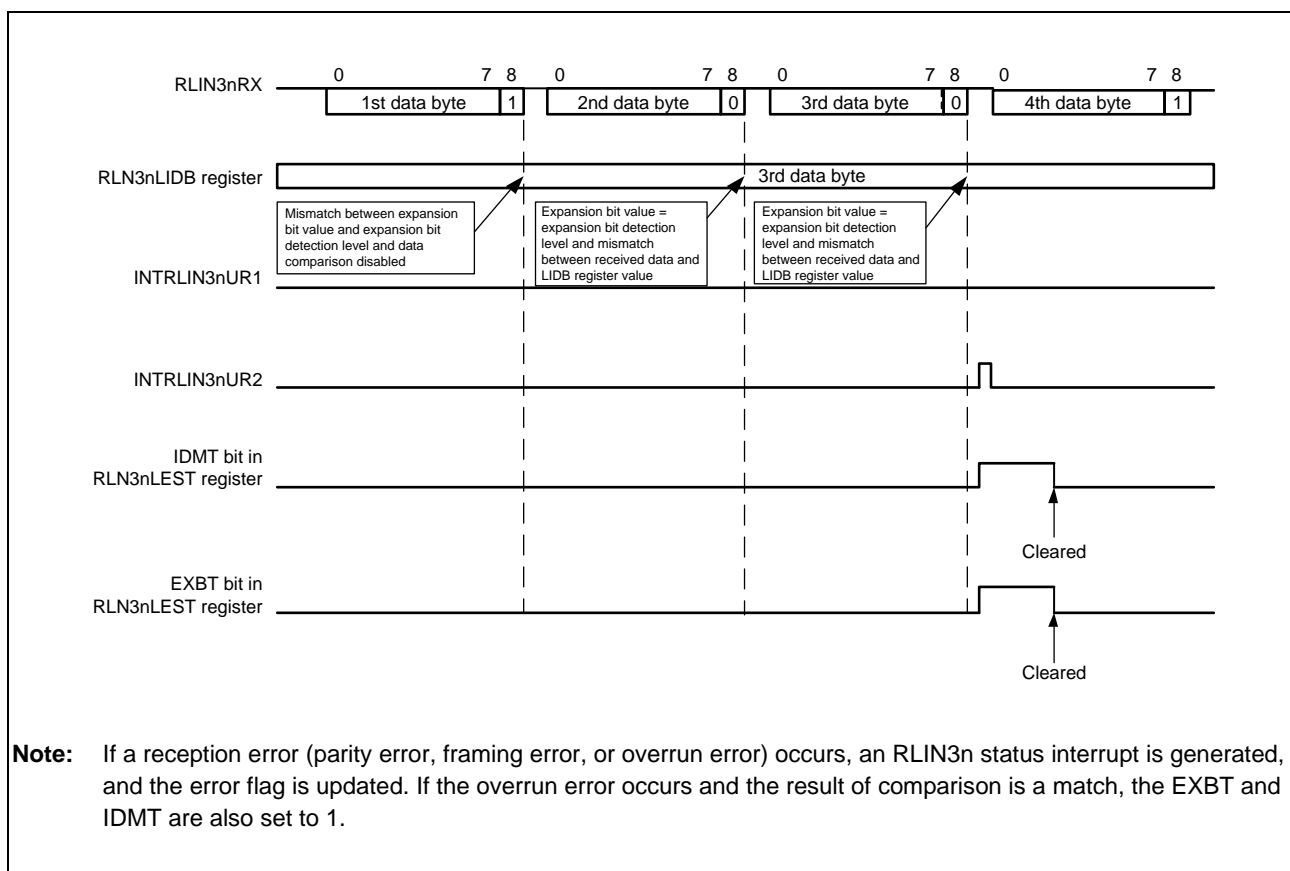

Figure 20.32 Expansion Bit Reception Example (with Data Comparison) (LSB First, UEBDL = 0)

20.5.4.4 Status

In UART mode, the LIN/UART interface can detect five types of statuses.

Two statuses, successful UART buffer transmission and error detection, can generate interrupt requests.

Table 20.93 shows the types of statuses available in UART mode.

Table 20.93 Types of Statuses in UART Mode

Status	Status Set Condition	Status Clear Condition	Corresponding Bit	Interrupt
Reset	After the OM0 bit in the RLN3nLCUC register is set to not-LIN-reset-mode, if actually the LIN/UART interface is cleared from LIN reset mode.	After the OM0 bit in the RLN3nLCUC register is set to LIN reset mode, if actually the LIN/UART interface enters LIN reset mode.	OMM0 bit in RLN3nLMST register	—
Successful UART buffer transmission	<ul style="list-style-type: none"> When the transmission is finished of data equal to the length set in the MDL bits in the RLN3nLDFC register. When the UTIGTS bit in the RLN3nLUOR1 register is 0 (transmission interrupt request is generated upon start of transmission), the transmission of the last data of the data length set by the MDL bit in the RLN3nLDFC register is started. When the UTIGTS bit in the RLN3nLUOR1 register is 1 (transmission interrupt request is generated upon end of transmission), the transmission of the data length set by the MDL bit in the RLN3nLDFC register is ended. 	<ul style="list-style-type: none"> When cleared by software Transition to LIN reset mode 	FTC flag in RLN3nLST register	✓
Error detection	If any of the UPER flag, IDMT flag, EXBT flag, FER flag, OER flag, and BER flag in the RLN3nLEST register is set to 1 (error detected).	<ul style="list-style-type: none"> When cleared by software*1 Transition to LIN reset mode 	ERR flag in RLN3nLST register	✓
Transmission status	<ul style="list-style-type: none"> When data is written to the RLN3nLUTDR or RLN3nLUWTDRC register. When 1 is written to the RTS bit in the RLN3nLTRC register. 	<ul style="list-style-type: none"> The transmission of the data set in the RLN3nLUTDR or RLN3nLUWTDRC register is complete, but another transmission data item is not set The transmission of the data in the UART buffer is complete, and the RTS bit in the RLN3nLTRC register is cleared Transition to LIN reset mode 	UTS flag in RLN3nLST register	—
Reception status	<ul style="list-style-type: none"> When a start bit is detected. 	<ul style="list-style-type: none"> When a sampling point for stop bits is detected Transition to LIN reset mode 	URS flag in RLN3nLST register	—

Note: Writing a 0 to the UPER, IDMT, EXBT, FER, OER, and BER flags in the RLN3nLEST register when the LIN reset mode is being canceled sets the ERR flag in the RLN3nLST register to 0.

20.5.4.5 Error Status

Types of Error Statuses

In UART mode, the LIN/UART interface can detect four types of errors and two types of statuses. The condition of these statuses can be verified by using the corresponding bits in the RLN3nLEST register.

Table 20.94 shows available status types.

Table 20.94 Types of Statuses in UART Mode

Status	Error Detection Condition	Communication	Enable/Disable Detection	Corresponding Bit
Bit error	The transmitted data and the data monitored on the receive pin do not match*1	Continues until the transmission of the set transmission data is finished.	Enabled	BER flag in RLN3nLEST register
Overrun error	After received data is stored in the RLN3nLURDR register, another data item is received before the data is read. (In this case, no data is stored in the RLN3nLURDR register).	— (Reception is finished by the time this error is detected)	Enabled	OER flag in RLN3nLEST register
Framing error	When the first stop bit is low level in the reception processing.	— (Reception is finished by the time this error is detected)	Enabled	FER flag in RLN3nLEST register
Parity error	The received parity value fails to match the parity value calculated from the received data	Continues until the data reception is finished.	Disabled*2	UPER flag in RLN3nLEST register
Expansion bit detection	The value of the received expansion bit matches the value of the UEBDL bit in the RLN3nLUOR1 register.	—	Enabled	EXBT flag in RLN3nLEST register
ID match detection	The value of the received expansion bit matches the value of the UEBDL bit in the RLN3nLUOR1 register and the 8-bit receive data excluding the expansion bit matches the value of the RLN3nLIDB register.	—	Enabled	IDMT flag in RLN3nLEST register

Note 1. In the case of transmission from the UART buffer, bit errors are detected even in the space between UART frames (inter-byte space).

Note 2. Setting the UPS[1:0] bits in the RLN3nLBFC register to 10_B (0 parity) disables the checking of parity bit values. In this case, no parity error is generated.

The error status is cleared by software or at a transition to LIN reset mode.

20.5.5 LIN Self-Test Mode

The LIN/UART interface provides a LIN Self-Test mode.

When the LIN/UART interface enters the LIN Self-Test mode, RLIN3nTX and RLIN3nRX are disconnected from external pins and RLIN3nTX and RLIN3nRX are connected to the LIN/UART interface internally. Therefore, the frame transmitted from RLIN3nTX is looped back to RLIN3nRX. The LIN Self-Test mode can perform tests exclusively in LIN mode.

The Self-Test can be performed in the following four modes:

- LIN master Self-Test mode (transmission): Header transmission and response transmission
- LIN master Self-Test mode (reception): Header transmission and response reception
- LIN slave Self-Test mode (transmission): Header reception and response transmission
- LIN slave Self-Test mode (reception): Header reception and response reception

In LIN Self-Test mode, operation is performed at the fastest baud rate, regardless of the setting of the baud rate generator.

Regardless of the setting of the baud rate related registers, the baud rate setting is the LIN communication clock source/16 [bps]. (The NSPB bits in the RLN3nLWBR register should be set to 0000_B or 1111_B.)

(The LPRS bits in the RLN3nLWBR register should be set to 000_B.)

In addition, in LIN Self-Test mode, the following functions are not supported.

- LIN wake-up mode
- Frame separate mode
- Multi-byte response transmission/reception
- LIN slave mode (Auto baud rate)
- Frame/response timeout error

Do not use these functions.

Figure 20.33 Connection in LIN Reset Mode, LIN Mode, and UART Mode

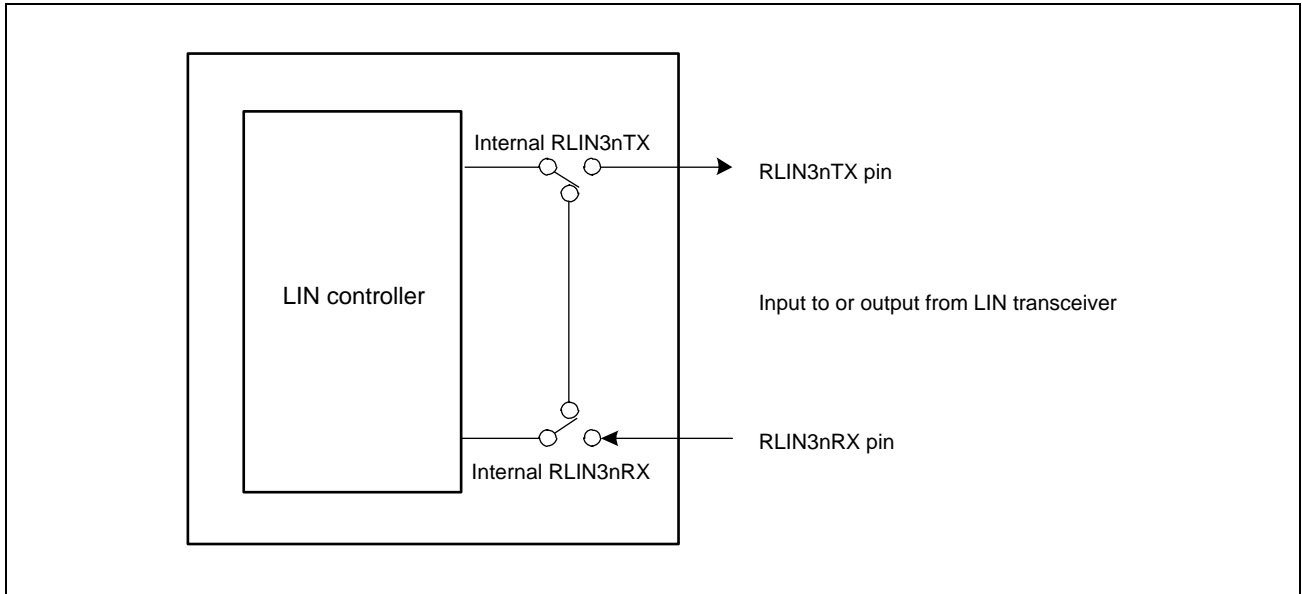

Figure 20.34 Connection in LIN Self-Test Mode

20.5.5.1 Transitioning to LIN Self-Test Mode

Writing to the RLN3nLSTC register makes a transition to the LIN Self-Test mode.

The LSTM bit in the RLN3nLSTC register set to 1 indicates that the mode has transitioned to the LIN Self-Test mode.

To transition to LIN Self-Test mode, be sure to execute a specific sequence. In that sequence, information must be written three times consecutively to the LIN Self-Test control register as shown below:

- Transition to LIN reset mode
 - Set the OM0 bit in the RLN3nLCUC register to 0 (in LIN reset mode).
 - Read the OMM0 bit in the RLN3nLMST register; verify that it is 0 (in LIN reset mode).
- Select a LIN mode
 - LMD bits in RLN3nLMD = 00_B (in LIN master mode) or 11_B (in LIN slave mode [fixed baud rate])
- 1st write: RLN3nLSTC register = 1010 0111_B (A7_H)
- 2nd write: RLN3nLSTC register = 0101 1000_B (58_H)
- 3rd write: RLN3nLSTC register = 0000 0001_B (01_H)
- Verify the transition to LIN Self-Test mode
 - Read the LSTM bit in the RLN3nLSTC register; verify that it is 1 (in LIN Self-Test mode).

If the key of the first write (A7_H) is written twice by mistake, the transition to LIN Self-Test mode is canceled. The above sequence should be retried from the step of first write. In addition, if a write to another LIN-related register is performed during transition to LIN Self-Test mode (three consecutive write operations to the RLN3nLSTC register), the transition is also canceled.

20.5.5.2 Transmission in LIN Master Self-Test Mode

To execute a Self-Test on LIN master transmission, perform the procedure below:

- Set the baud rate, noise filter, and interrupt output related registers.

RLN3nLWBR register = 0000 000x_B

RLN3nLBRP0 register = xxxx xxxxB*¹

RLN3nLBRP1 register = xxxx xxxxB*¹

RLN3nLMD register = 00xx xx00_B*¹

- Set the interrupt enable and error enable related registers.

RLN3nLIE register = 0000 xxxxB*²

RLN3nLEDE register = x000 x0xx_B

- Set the break field and space related registers.

RLN3nLBFC register = 00xx xxxxB

RLN3nLSC register = 00xx 0xxx_B

- Release from the LIN reset mode.

Write 11_B to the OM1 and OM0 bits in the RLN3nLCUC register, and check that the OMM1 and OMM0 bits in the RLN3nLMST register are 11_B.

- Set the transmit frame related registers.

RLN3nLDFC register = 00x1 xxxxB

RLN3nLIDB register = xxxx xxxxB

RLN3nLDRB1 to RLN3nLDRB8 registers = xxxx xxxxB

- Header transmission → response transmission started

Set the FTS bit in the RLN3nLTRC register to 1 (frame transmission or wake-up transmission/reception started).

The LIN master Self-Test mode (transmission) is executed. In this mode, interrupt is generated, and status and error status are also updated. The checksum is automatically calculated by the LIN/UART interface. To suspend the LIN master Self-Test mode (transmission) being executed, write 0 (in LIN reset mode) to the OM0 bit in the RLN3nLCUC register for transition to LIN reset mode.

- When the transmission is completed, the reversed value of the looped-back frame data is stored in the RLN3nLIDB, RLN3nLDBRb (b = 1 to 8), and RLN3nLCBR registers (the data is stored as a reversed value because the transmitted value should be compared with the looped-back value). Then, the FTS bit in the RLN3nLTRC register is cleared.
- If the transmission fails to complete due to an error, the corresponding error flag is set and the FTS bit in the RLN3nLTRC register is cleared.

Note: x: Arbitrary value can be specified.

Note 1. The following register settings are not reflected to the operation of the LIN Self-Test mode. The RLN3nLBRP0 register, the RLN3nLBRP1 register and the LCKS bit in the RLN3nLMD register. Therefore, those settings are not necessary.

Note 2. If necessary, set the related registers described in **Section 6, Interrupts**.

Note 3. When the successful header transmission interrupt and the successful frame transmission interrupt are used in the same interrupt processing, if the software processing of the successful header transmission interrupt is not completed before the generation of the successful frame transmission interrupt, the SHIE bit in the RLN3nLIE register should not be set to 1 (successful header transmission interrupt enabled).
The time required from the setting of the successful header transmission flag to the setting of the successful

frame/wake-up transmission flag is calculated by the following formula.

$$10 \times (\text{number of data bytes} + 1) \text{ [Tbit]}$$

$$1 \text{ Tbit} = 1/\text{frequency of LIN communication clock source} \times 16$$

20.5.5.3 Reception in LIN Master Self-Test Mode

To execute a Self-Test on LIN master reception, perform the procedure below:

- Set the baud rate, noise filter, and interrupt output related registers.

RLN3nLWBR register = 0000 000x_B

RLN3nLBRP0 register = xxxx xxxx_B*¹

RLN3nLBRP1 register = xxxx xxxx_B*¹

RLN3nLMD register = 00xx xx00_B*¹

- Set the interrupt enable and error enable related registers.

RLN3nLIE register = 0000 xxxx_B*²

RLN3nLEDE register = x000 x0xx_B

- Set the break field and space related registers.

RLN3nLBFC register = 00xx xxxx_B

RLN3nLSC register = 00xx 0xxx_B*¹

- Release from the LIN reset mode.

Write 11_B to the OM1 and OM0 bits in the RLN3nLCUC register, and check that the OMM1 and OMM0 bits in the RLN3nLMST register are 11_B.

- Set the reception frame related registers.

RLN3nLDFC register = 00x0 xxxx_B

RLN3nLIDB register = xxxx xxxx_B

RLN3nLDRB1 to RLN3nLDRB8 registers = xxxx xxxx_B

RLN3nLCBR register = xxxx xxxx_B

Since the checksum value to be transmitted is not automatically calculated, users must calculate it and set it to the RLN3nLCBR register. A checksum test can be performed by setting an incorrect checksum value here.

- Header transmission → response reception started

Set the FTS bit in the RLN3nLTRC register to 1 (frame transmission or wake-up transmission/reception started).

The LIN master Self-Test mode (reception) is executed. In this mode, interrupt is generated, and status and error status are also updated. To suspend the LIN master Self-Test mode (reception) being executed, write 0 (in LIN reset mode) to the OM0 bit in the RLN3nLCUC register for transition to LIN reset mode.

- When the reception is completed, the reversed value of the looped-back frame data is stored in the RLN3nLIDB, RLN3nLDBRb (b = 1 to 8), and RLN3nLCBR registers (the data is stored as a reversed value because the set value should be compared with the looped-back value). Then, the FTS bit in the RLN3nLTRC register is cleared.
- If the reception fails to complete due to an error, the corresponding error flag is set and the FTS bit in the RLN3nLTRC register is cleared.

Note: x: Don't care

Note 1. The following register settings are not reflected to the operation of the LIN Self-Test mode. The RLN3nLBRP0 register, the RLN3nLBRP1 register, the LCKS bit in the RLN3nLMD register, and the IBS bit in the RLN3nLSC register. Therefore, those settings are not necessary.

Note 2. If necessary, set the related registers described in **Section 6, Interrupts**.

Note 3. When the successful header transmission interrupt and the successful frame reception interrupt are used in the same interrupt processing, if the software processing of the successful header transmission interrupt is not

completed before the generation of the successful frame reception interrupt, the SHIE bit in the RLIN3nLIE register should not be set to 1 (successful header transmission interrupt enabled).

Note 4. The time required from the setting of the successful header transmission flag to the setting of the successful frame/wake-up reception flag is calculated by the following formula.

$$10 \times (\text{number of data bytes} + 1) \text{ [Tbit]}$$

$$1 \text{ Tbit} = 1/\text{LIN communication clock source} \times 16$$

20.5.5.4 Transmission in LIN Slave Self-Test Mode

To execute a Self-Test on LIN slave transmission, perform the procedure below:

- Set the baud rate, noise filter, and interrupt output related registers.

RLN3nLWBR register = 0000 0000_B

RLN3nLBRP0 register = xxxx xxxx_B*¹

RLN3nLBRP1 register = xxxx xxxx_B*¹

RLN3nLMD register = 00xx 0011_B

- Set the interrupt enable and error enable related registers.

RLN3nLIE register = 0000 xxxx_B*²

RLN3nLEDE register = xx0x x00x_B

- Set the break field and space related registers.

RLN3nLBFC register = 0000 000x_B*³

RLN3nLSC register = 00xx 0001_B

- Release from the LIN reset mode.

Write 11_B to the OM1 and OM0 bits in the RLN3nLCUC register, and check that the OMM1 and OMM0 bits in the RLN3nLMST register are 11_B.

- Set the transmit frame related registers.

RLN3nLDFC register = 00x1 xxxx_B

RLN3nLIDB register = xxxx xxxx_B

RLN3nLDBR1 to RLN3nLDBR8 registers = xxxx xxxx_B

- Header reception → response transmission started

Set the FTS bit in the RLN3nLTRC register to 1 (The header reception and the response transmission are executed in this order, without manipulating the RTS bit in the RLN3nLTRC register.).

The LIN slave Self-Test mode (transmission) is executed. In this mode, interrupt is generated, and status and error status are also updated.

The checksum is automatically calculated by the LIN/UART interface. To suspend the LIN slave Self-Test mode (transmission) being executed, write 0 (in LIN reset mode) to the OM0 bit in the RLN3nLCUC register for transition to LIN reset mode.

- When the transmission is completed, the reversed value of the looped-back frame data is stored in the RLN3nLIDB, RLN3nLDBRb (b = 1 to 8), and RLN3nLCBR registers (the data is stored as a reversed value because the transmitted value should be compared with the looped-back value). Then, the FTS bit in the RLN3nLTRC register is cleared.
- If the transmission fails to complete due to an error, the corresponding error flag is set and the FTS bit in the RLN3nLTRC register is cleared.

Note: x: Arbitrary value can be specified

Note 1. The following register settings are not reflected to the operation of the LIN Self-Test mode. The RLN3nLBRP0 register, and the RLN3nLBRP1 register. Therefore, those settings are not necessary.

Note 2. If necessary, set the related registers described in **Section 6, Interrupts**.

Note 3. According to the setting of this register, 9.5-Tbit or 10.5-Tbit width break is output from the internal RLIN3nTX.

Note 4. When the successful header reception interrupt and the successful response transmission interrupt are used in the same interrupt processing, if the software processing of the successful header reception interrupt is not completed before the generation of the successful response transmission interrupt, the SHIE bit in the

RLN3nLIE register should not be set to 1 (successful header reception interrupt enabled).

The time required from the setting of the successful header reception flag to the setting of the successful response/wake-up transmission flag is calculated by using the following formula.

$$10 \times (\text{number of data bytes} + 1) \text{ [Tbit]}$$

$$1 \text{ Tbit} = 1/\text{frequency of LIN communication clock source} \times 16$$

20.5.5.5 Reception in LIN Slave Self-Test Mode

To execute a Self-Test on LIN slave reception, perform the procedure below:

- Set the baud rate, noise filter, and interrupt output related registers.

RLN3nLWBR register = 0000 0000_B

RLN3nLBRP0 register = xxxx xxxx_B*¹

RLN3nLBRP1 register = xxxx xxxx_B*¹

RLN3nLMD register = 00xx 0011_B

- Set the interrupt enable and error enable related registers.

RLN3nLIE register = 0000 xxxx_B*²

RLN3nLEDE register = xx0x x00x_B

- Set the break field and space related registers.

RLN3nLBFC register = 0000 000x_B*³

RLN3nLSC register = 00xx 0001_B*¹

- Release from the LIN reset mode.

Write 11_B to the OM1 and OM0 bits in the RLN3nLCUC register, and check that the OMM1 and OMM0 bits in the RLN3nLMST register are 11_B.

- Set the reception frame related registers.

RLN3nLDFC register = 00x0 xxxx_B

RLN3nLIDB register = xxxx xxxx_B

RLN3nLDBR1 to RLN3nLDBR8 registers = xxxx xxxx_B

RLN3nCBR register = xxxx xxxx_B

Since the checksum value to be transmitted is not automatically calculated, users must calculate it and set it to the RLN3nLCBR register. A checksum test can be performed by setting an incorrect checksum value here.

- Header reception → response reception started

Set the FTS bit in the RLN3nLTRC register to 1 (header reception or wake-up transmission/reception started).

(Without any setting of the RTS bit in the RLN3nLTRC register, the header reception and the response reception are executed in this order.)

The LIN slave Self-Test mode (reception) is executed. In this mode, interrupt is generated, and status and error status are also updated. To suspend the LIN slave Self-Test mode (reception) being executed, write 0 (in LIN reset mode) to the OM0 bit in the RLN3nLCUC register for transition to LIN reset mode.

- When the reception is completed, the reversed value of the looped-back frame data is stored in the RLN3nLIDB, RLN3nLDBRb (b = 1 to 8), and RLN3nLCBR registers (the data is stored as a reversed value because the set value should be compared with the looped-back value). Then, the FTS bit in the RLN3nLTRC register is cleared.
- If the reception fails to complete due to an error, the corresponding error flag is set and the FTS bit in the RLN3nLTRC register is cleared.

Note: x: Arbitrary value can be specified

Note 1. The following register settings are not reflected to the operation of the LIN Self-Test mode. The RLN3nLBRP0 register, the RLN3nLBRP1 register, and the IBS bit in the RLN3nLSC register. Therefore, those settings are not necessary.

Note 2. If necessary, set the related registers described in **Section 6, Interrupts**.

Note 3. According to the setting of this register, 9.5-Tbit or 10.5-Tbit width break is output from the internal RLIN3nTX.

Note 4. When the successful header reception interrupt and the successful response reception interrupt are used in the same interrupt processing, if the software processing of the successful header reception interrupt is not completed before the generation of the successful response reception interrupt, the SHIE bit in the RLIN3nLIE register should not be set to 1 (successful header reception interrupt enabled).

The time required from the setting of the successful header reception flag to the setting of the successful response/wake-up reception flag is calculated by the following formula.

$$10 \times (\text{number of data bytes} + 1) \text{ [Tbit]}$$

$$1 \text{ Tbit} = 1/\text{frequency of LIN communication clock source} \times 16$$

20.5.5.6 Terminating LIN Self-Test Mode

To terminate LIN Self-Test mode, perform the procedure below:

- Write 0 (in LIN reset mode) to the OM0 bit in the RLN3nLCUC register.

If the OMM1 and OMM0 bits in the RLN3nLMST register are not 11_B, write 11_B to the OM1 and OM0 bits in the RLN3nLCUC register. After confirming that the OMM1 and OMM0 bits in the RLN3nLMST register are set to 11_B, transition to LIN reset mode.

- Verify the cancelation of LIN Self-Test mode.

Read the LSTM bit in the RLN3nLSTC register; confirm that it is 0 (not in LIN Self-Test mode).

- Verify the transition to LIN reset mode.

Read the OMM0 bit in the RLN3nLMST register; verify that it is 0 (in LIN reset mode).

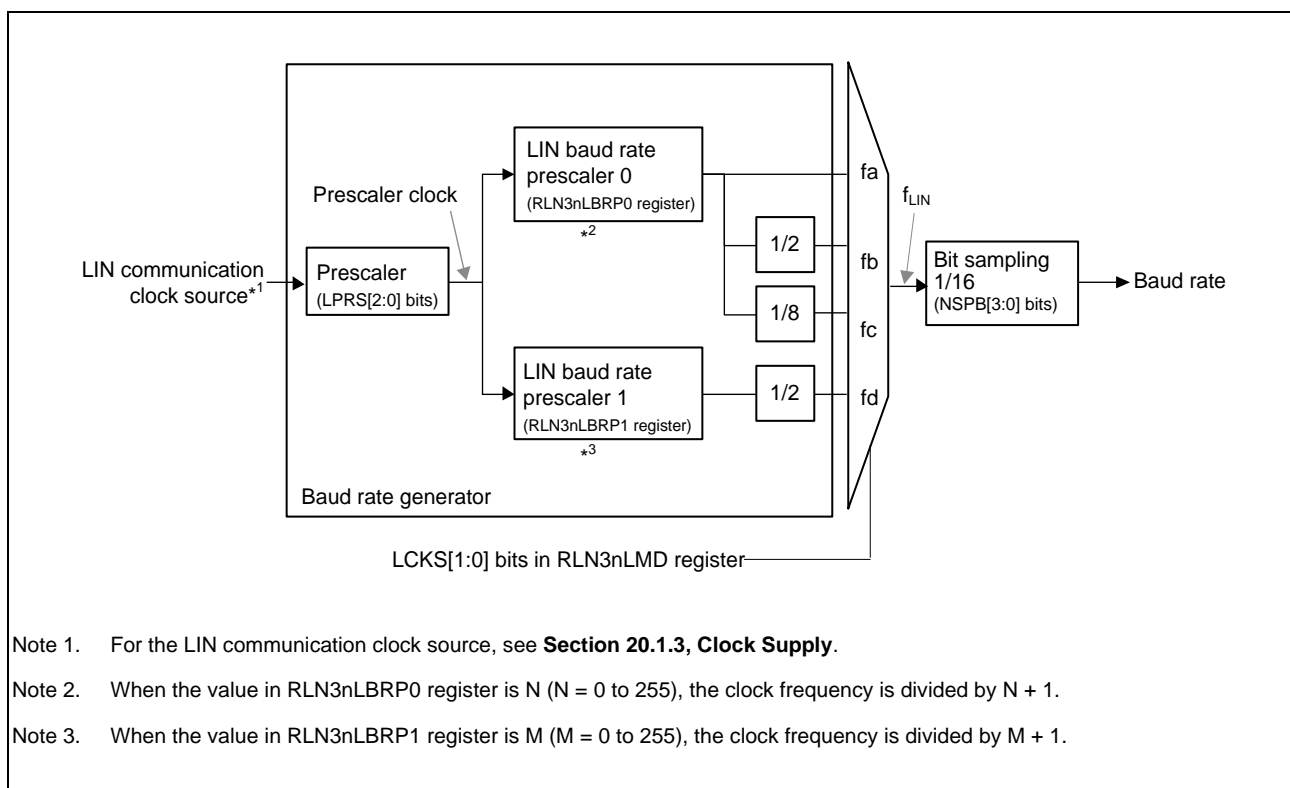

20.5.6 Baud Rate Generator

The prescaler clock is obtained by frequency-dividing the LIN communication clock source by the prescaler, and the LIN system clock (fLIN) is obtained by frequency-dividing the prescaler clock by the baud rate generator. The clock obtained by frequency-dividing the LIN system clock (fLIN) by the number of samplings is the baud rate. The reciprocal of this baud rate is called the bit time (Tbit).

The LIN/UART interface has two types of baud rate generators. The baud rate generator to be used is switched according to the mode.

20.5.6.1 LIN Master Mode

Figure 20.35 shows a block diagram of baud rate generation in LIN master mode.

- Note 1. For the LIN communication clock source, see **Section 20.1.3, Clock Supply**.
- Note 2. When the value in RLN3nLBRP0 register is N (N = 0 to 255), the clock frequency is divided by N + 1.
- Note 3. When the value in RLN3nLBRP1 register is M (M = 0 to 255), the clock frequency is divided by M + 1.

Figure 20.35 Block Diagram of Baud Rate Generation in LIN Master Mode

By setting the RLN3nLBRP0 register so that fa is 307200 Hz (= 19200 × 16), the resulting system clock frequencies are fa = 19200 × 16, fb = 9600 × 16, and fc = 2400 × 16. These system clock frequencies are divided by 16 in the bit timing generator, enabling bit rates of 19200 bps, 9600 bps and 2400 bps, to be generated. Also, by setting the RLN3nLBRP1 register so that fd is 166672 Hz (= 10417 × 16), the resulting system clock frequency is fd = 10417 × 16. This system clock frequency is divided by 16 in the bit timing generator, enabling 10417 bps to be generated.

Table 20.95 shows examples of baud rate (19200, 9600, 2400, and 10417 bps) generation for each LIN communication clock source frequency, and also the corresponding errors.

Table 20.95 Examples of Baud Rate (19200, 10417, 9600, and 2400 bps) Generation in LIN Master Mode

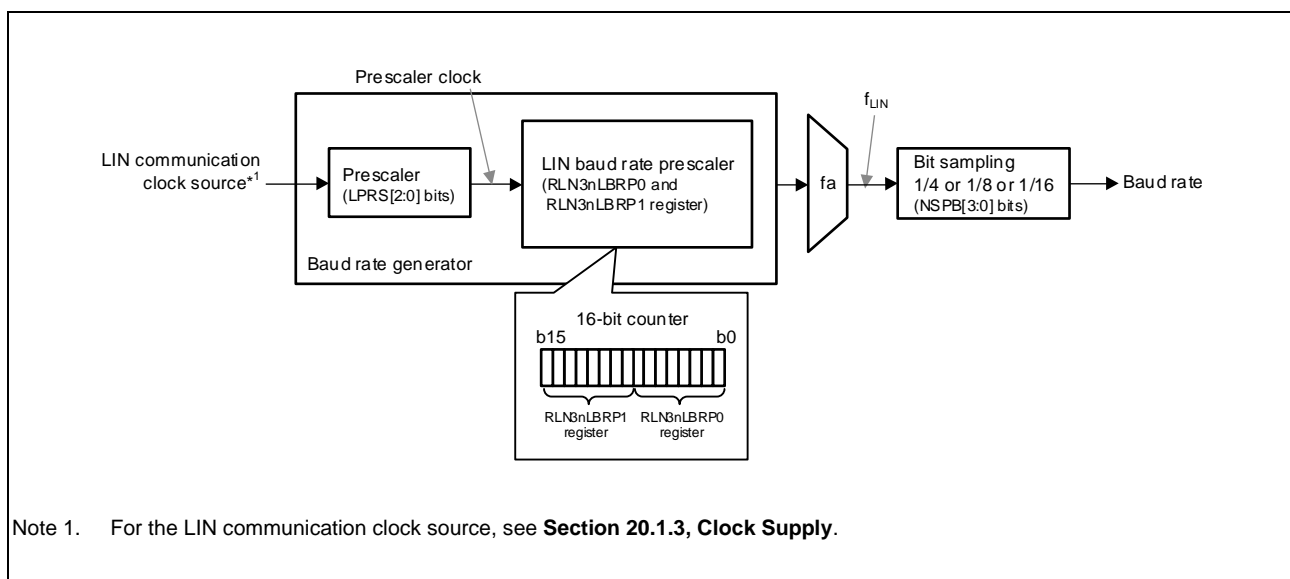

LIN communication clock source	Prescaler	Baud rate generator 0 (MN+1) frequency-divided	Baud rate generator 1 (MN+1) frequency-divided	System Clock	Baud rate	Error
CLK_LSB	1/1	130	—	fa	19230.77	+0.16%
		—	120	fd	10416.67	-0.003%
		130	—	fb	9615.38	+0.16%
		130	—	fc	2403.85	+0.16%

NOTE

Bit sampling count is 16 sampling (RLIN3nLWBR.NSPB[3:0] = 0000_B).

20.5.6.2 LIN Slave Mode

Figure 20.36 shows a block diagram of baud rate generation in LIN slave mode.

Note 1. For the LIN communication clock source, see Section 20.1.3, Clock Supply.

Figure 20.36 Block Diagram of Baud Rate Generation in LIN Slave Mode

Table 20.96 shows examples of baud rate (19200, 10417, 9600, and 2400 bps) generation for each peripheral function clock frequency, and also the corresponding errors.

Table 20.96 Examples of Baud Rate (19200, 10417, 9600, and 2400 bps) Generation in LIN Slave Mode [Fix Baud Rate]

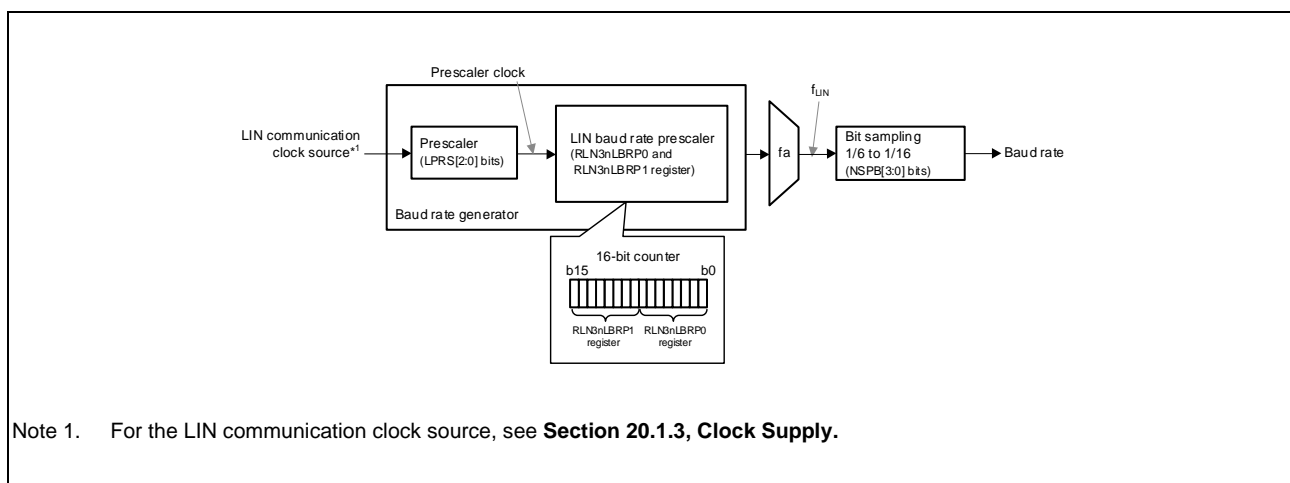

LIN communication clock source	Prescaler	Baud rate generator 01 (MN+1) frequency-divided	Baud rate	Error
CLK_LSB	1/1	130	19230.77	+0.16%
		—	10416.67	-0.003%
		130	9615.38	+0.16%
		130	2403.85	+0.16%

NOTE

The bit sampling count is 16 sampling (RLN3nLWBR.NSPB[3:0] = 0000_B).

20.5.6.3 UART Mode

Figure 20.37 shows a block diagram of baud rate generation in UART mode.

Note 1. For the LIN communication clock source, see Section 20.1.3, Clock Supply.

Figure 20.37 Block Diagram of Baud Rate Generation in UART Mode

UART baud rate is calculated with the following formula:

<UART baud rate>

$$= \{ \text{LIN communication clock source frequency} \} \times (\text{RLN3nLWBR.LPRS}[2:0] \text{ selection clock}) \div (\text{RLN3nLBRP0} + 1) \div \{ \text{RLN3nLWBR.NSPB}[3:0] \text{ selection count} \} \text{ [bps]}$$

Table 20.97 lists the examples of baud rate (6600000, 38400, 31250, 19200, 9600, 4800, 2400 and 1200 bps) generation for each LIN communication clock source frequency, and also the corresponding errors.

Table 20.97 UART Baud Rate Setting Examples (when LIN communication clock source = 40 MHz)

UART Baud Rate (Target Baud Rate)	Prescaler	Baud rate generator 01 (MN+1) frequency-divided	Baud rate	Error
1200 bps	1/2	1042	1199.62	-0.03%
2400 bps	1/2	521	2399.23	-0.03%
4800 bps	1/2	260	4807.69	+0.16%
9600 bps	1/2	130	9615.38	+0.16%
19200 bps	1/2	65	19230.77	+0.16%
31250 bps	1/2	40	31250.00	0.00%
38400 bps	1/2	33	37878.79	-1.36%
6600000 bps	1/1	0	6666666.67	-1.36%

NOTE

The bit sampling count for each baud rate is written below.

- 6.6Mbps: 6 sampling (RLN3nLWBR.NSPB[3:0] = 0101_B)
- other than 6.6Mbps: 16 sampling (RLN3nLWBR.NSPB[3:0] = 1111_B)

20.5.7 Noise Filter

The LIN/UART interface has a noise filter for reducing erroneous receiving of data due to noise. By setting the LRDNFS bit in the RLIN3nLMD register to 0 (use the noise filter), the noise filter is enabled. The noise filter samples the level of the synchronized RLIN3nRX with the prescaler clock, and outputs the sampling value determined by a 3-sampling majority rule. The value of each bit of the receive data is determined based on the noise filter output.

Figure 20.38 shows the configuration of the noise filter, **Figure 20.39** shows an example of a noise filter circuit, and **Figure 20.40** shows the determination of the received data when the noise filter is used.

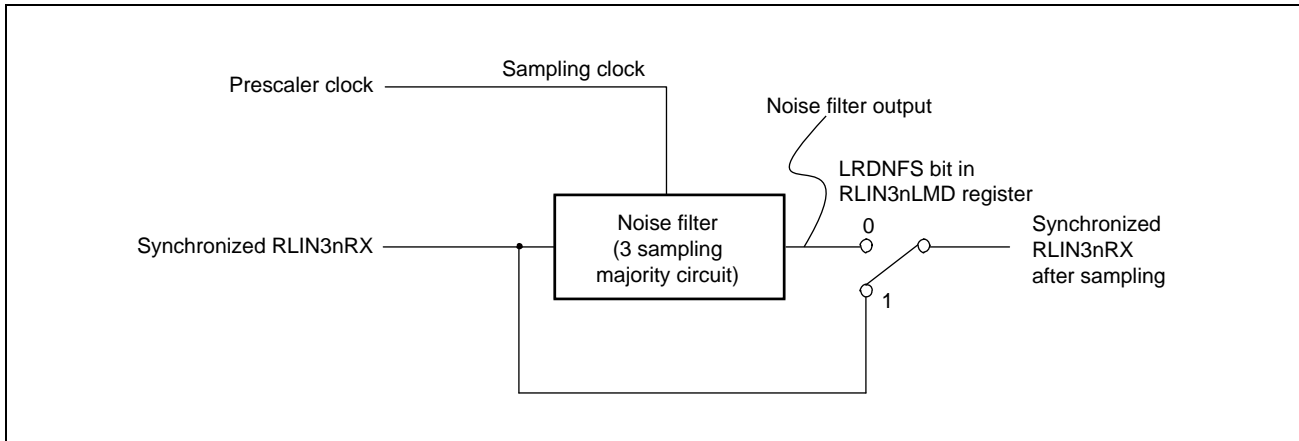

Figure 20.38 Configuration of Noise Filter

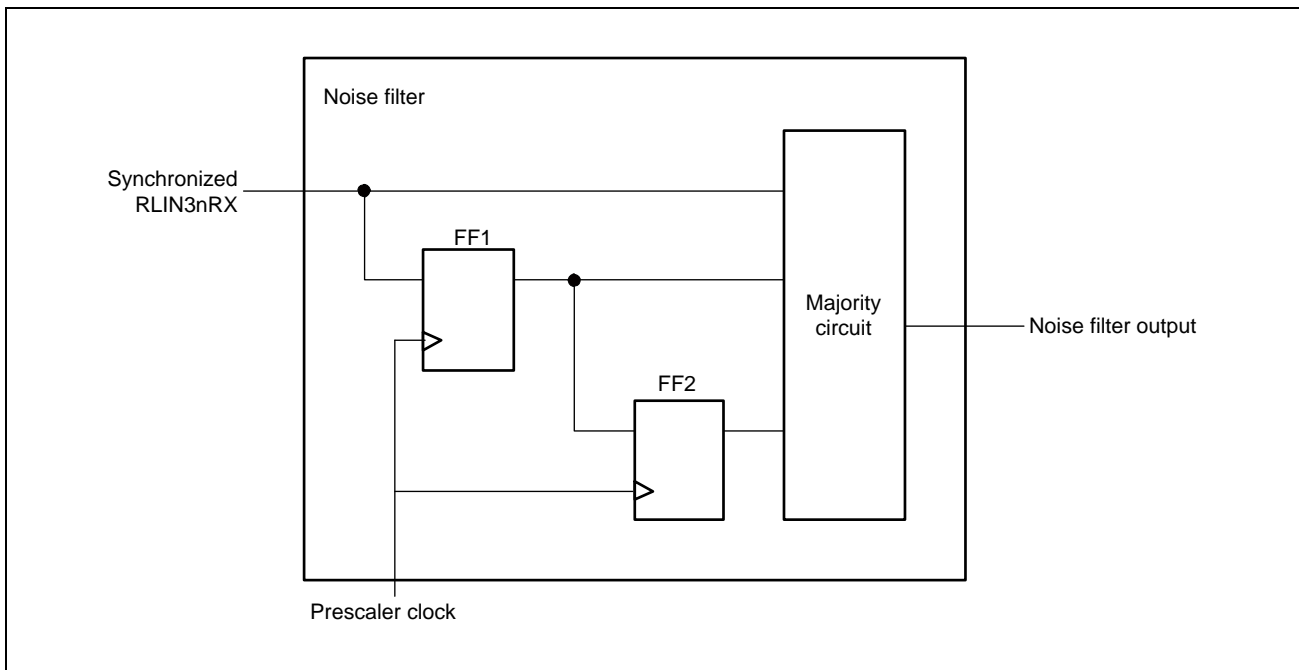

Figure 20.39 Example of Noise Filter Circuit

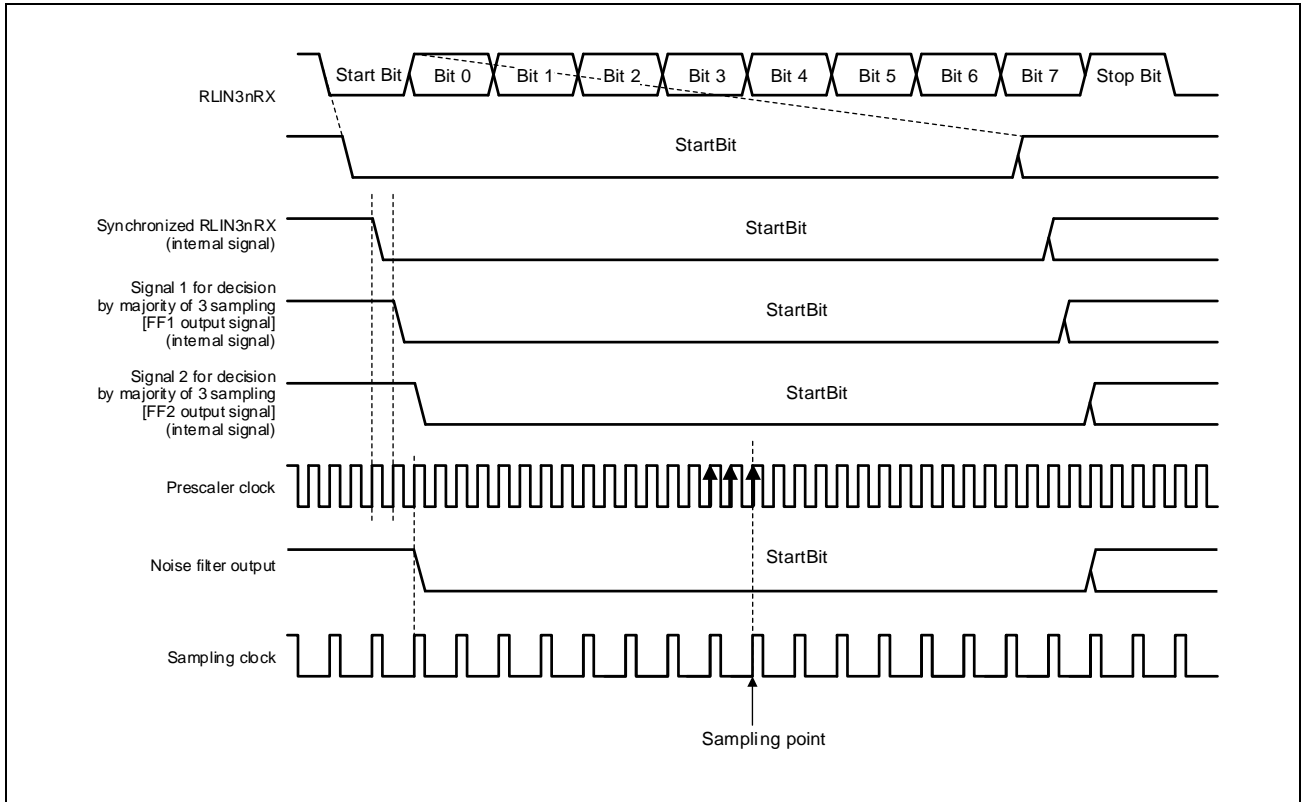

Figure 20.40 Determination of Received Data when Noise Filter is Used

Section 21 CANFD Interface (RS-CANFD)

21.1 Features of RS-CANFD

21.1.1 Units and Channels

This microcontroller has the following number of RS-CANFD units.

Table 21.1 Number of Units (for E2x-FCC2)

Product Name	RH850/E2x-FCC2	
	468 Pins	373 Pins
Number of Units	2	2
Name	RSCFDn (n = 0, 1)	

Table 21.2 Number of Units (for E2UH)

Product Name	RH850/E2UH	
	468 Pins	373 Pins
Number of Units	2	
Name	RSCFDn (n = 0, 1)	

Table 21.3 Number of Units (for E2H)

Product Name	RH850/E2H	
	468 Pins	373 Pins
Number of Units	1	
Name	RSCFDn (n = 0)	

The individual products have the CANFD interface channels listed below.

Table 21.4 Unit Configurations and Channels (for E2x-FCC2)

	CAN2	✓	✓
	CAN3	✓	✓
	CAN4	✓	✓
	CAN5	✓	✓

The RS-CANFD has two interface modes (classical CAN mode and CAN FD mode) and uses different registers for each mode. There are two types of register names RSCANnXXX and RSCFDnCFDXXX (XXX: arbitrary) depending on interface modes. When explaining specifications common to two registers, register names are described as RSCFDn(CFD)XXX.

Table 21.7 Indices

Index	Meaning
n	Throughout this section, the individual RS-CANFD units are generically indicated by the index "n".
m	Throughout this section, the individual channels of RS-CANFD units are generically indicated by the index "m".
j	The individual registers associated with receive rule table are generically indicated by the index "j". j = 0 to 15.
k	The individual transmit/receive FIFO buffers are generically indicated by the index "k". k = 0 to [channel m × 3 + 2];
x	The individual receive FIFO buffers are generically identified by the index "x". x = 0 to 7.
d	Data field registers of transmit/receive FIFO buffers and receive FIFO buffers are identified by "d". classical CAN mode: d = 0 or 1, CAN FD mode: d = 0 to 15.
q	The individual receive buffers are generically indicated by the index "q". q = 0 to [channel m × 16 + 15].
p	The individual transmit buffers are generically indicated by the index "p". p = 0 to [channel m × 16 + 15].
b	Data field registers of receive buffers and transmit buffers are identified by "b". classical CAN mode: b = 0 or 1, CAN FD mode: b = 0 to 4.
r	The individual RAM tests for CAN are generically indicated by the index "r". r = 0 to 63.
y	The registers not covered above are indicated by the letter "y".

Note: When writing a value to bits in the register that are outside of the index range on the product, write the value after reset to these bits.

The following table lists the values of indices for individual products.

Table 21.8 Indices for Individual Products

Indices for Individual Products				
E2x-FCC2		E2UH		E2H
n = 0	n = 1	n = 0	n = 1	n = 0
m = 0 to 5	m = 0 to 3	m = 0 to 5	m = 0 to 3	m = 0 to 5
j = 0 to 15	j = 0 to 15	j = 0 to 15	j = 0 to 15	j = 0 to 15
k = 0 to 17	k = 0 to 11	k = 0 to 17	k = 0 to 11	k = 0 to 17
x = 0 to 7	x = 0 to 7	x = 0 to 7	x = 0 to 7	x = 0 to 7
d = 0, 1* ¹ d = 0 to 15* ²	d = 0, 1* ¹ d = 0 to 15* ²	d = 0, 1* ¹ d = 0 to 15* ²	d = 0, 1* ¹ d = 0 to 15* ²	d = 0, 1* ¹ d = 0 to 15* ²
q = 0 to 95	q = 0 to 63	q = 0 to 95	q = 0 to 63	q = 0 to 95
p = 0 to 95	p = 0 to 63	p = 0 to 95	p = 0 to 63	p = 0 to 95
b = 0, 1* ¹ b = 0 to 4* ²	b = 0, 1* ¹ b = 0 to 4* ²	b = 0, 1* ¹ b = 0 to 4* ²	b = 0, 1* ¹ b = 0 to 4* ²	b = 0, 1* ¹ b = 0 to 4* ²

y = 0 to 2	y = 0 to 1	y = 0 to 2	y = 0 to 1	y = 0 to 2

Note 1. In classical CAN mode

Note 2. In CAN FD mode

21.1.2 Register Base Address

The base addresses of registers in RSCFDn are described in the list below.

All Access to RSCFDn register addresses are given as address offsets to the base address.

Table 21.9 Register Base Address

Base Address Name	Base Address	Bus Group
<RSCFD0_base>	FFD0 0000 _H	Peripheral Group 3
<RSCFD1_base>	FFD0 8000 _H	Peripheral Group 3

21.1.3 Clock Supply

The clocks listed below are supplied to the RSCFDn.

Table 21.10 Clock Supply

Unit Name	Clock for the Unit	Supply Clock Name
RSCFDn	clk_xincan	CLK_MOSC
	clkc	CLK_LSB
	pclk* ¹	CLK_HSB

Note 1. pclk must satisfy the following conditions so that no event of the CAN engine clock is overlooked.

- $pclk \geq 2 \times clkc$
- $pclk \geq 2 \times clk_xincan$

21.1.4 Interrupt Requests

The RSCFDn interrupt requests are listed in the following table.

Table 21.11 Interrupt Requests (for E2x-FCC2)

Interrupt Symbol Name	Unit Interrupt Signal	Outline	Interrupt Number
RSCFD0			
INTRCANGERR0	INTRCANGERR	RSCFD0 global error interrupt	379
INTRCANGRECC0	INTRCANGRECC	RSCFD0 receive FIFO interrupt	380
INTRCAN0ERR	INTRCANmERR (m = 0)	CAN0 error interrupt	381
INTRCAN0REC	INTRCANmREC (m = 0)	CAN0 transmit/receive FIFO receive completion interrupt	382
INTRCAN0TRX	INTRCANmTRX (m = 0)	CAN0 transmit interrupt	383
INTRCAN1ERR	INTRCANmERR (m = 1)	CAN1 error interrupt	384
INTRCAN1REC	INTRCANmREC (m = 1)	CAN1 transmit/receive FIFO receive completion interrupt	385
INTRCAN1TRX	INTRCANmTRX (m = 1)	CAN1 transmit interrupt	386
INTRCAN2ERR	INTRCANmERR (m = 2)	CAN2 error interrupt	387
INTRCAN2REC	INTRCANmREC (m = 2)	CAN2 transmit/receive FIFO receive completion interrupt	388
INTRCAN2TRX	INTRCANmTRX (m = 2)	CAN2 transmit interrupt	389
INTRCAN3ERR	INTRCANmERR (m = 3)	CAN3 error interrupt	390
INTRCAN3REC	INTRCANmREC (m = 3)	CAN3 transmit/receive FIFO receive completion interrupt	391

21.1.5 Reset Sources

RSCFDn reset sources are listed in the following table. RSCFDn is initialized by these reset sources.

Table 21.17 Reset sources

Unit Name	Register Name	Reset Condition					
		Power Up Reset	System Reset 1	System Reset 2	Application Reset	Module Reset	JTAG Reset
RSCFDn	All registers	✓	✓	✓	✓	—	—

21.1.6 External Input/Output Signals

External input/output signals of RSCFDn are listed below.

Table 21.18 External Input/Output Signals

Unit Signal Name	Outline	Alternative Port Pin Signal
RSCFD0		
CANmRX	CANm receive data input	CRXm
CANmTX	CANm transmit data output	CTXm
RSCFD1		
CANmRX	CANm receive data input	CRXm
CANmTX	CANm transmit data output	CTXm

CAUTION

This AC specification is only applied to the specific pin groups. For details, refer to Appendix file "*Limited_conditions_for_AC_specification.xlsx*".

21.2 Overview

21.2.1 Functional Outline

Table 21.19 shows the RS-CANFD module specifications. **Figure 21.1** shows the RS-CANFD module block diagram.

Table 21.19 RS-CANFD Module Specifications (1/3)

Item	Specification
Protocol	ISO11898-1 compliant Using CAN FD frames is selectable by switching interface modes.
Communication speed	<p>Classical CAN mode:</p> <ul style="list-style-type: none"> Up to 1 Mbps $\text{Communication speed (CANm bit time clock)} = \frac{1}{\text{CANm bit time}}$ $\text{CANm bit time} = \text{CANmTq} \times \text{Tq count per bit}$ $\text{CANmTq} = \frac{(\text{BRP}[9:0] \text{ bits in the RSCANnCrMCFG register} + 1)}{f_{\text{CAN}}}$ <p>f_{CAN}: Frequency of CAN clock (selected by the DCS bit in the RSCANnGCFCFG register)</p> <p>CAN FD mode:</p> <ul style="list-style-type: none"> Nominal bit rate: up to 1 Mbps; data bit rate: up to 8 Mbps $\text{Transmission rate (CANm nominal bit time clock)} = \frac{1}{\text{CANm nominal bit time}}$ $\text{Transmission rate (CANm data bit time clock)} = \frac{1}{\text{CANm data bit time}}$ $\text{CANm nominal bit time} = \text{CANmTq(N)} \times \text{Tq count per nominal bit}$ $\text{CANm data bit time} = \text{CANmTq(D)} \times \text{Tq count per data a bit}$ $\text{CANmTq(N)} = \frac{(\text{NBRP}[9:0] \text{ bits in the RSCFDnCFDCmNCFG register} + 1)}{f_{\text{CAN}}}$ $\text{CANmTq(D)} = \frac{(\text{DBRP}[7:0] \text{ bits in the RSCFDnCFDCmDCFCFG register} + 1)}{f_{\text{CAN}}}$ <p>f_{CAN}: Frequency of CAN clock (selected by the DCS bit in the RSCFDnCFDCGFCFG register)</p> <p>m = see Table 21.8 Tq: Time quantum</p>
Buffer	<p>480 buffers ($n = 0$) and 320 buffers ($n = 1$) in total</p> <ul style="list-style-type: none"> Individual buffers: 96 buffers ($n = 0$) (16 buffers \times 6 channels) 64 buffers ($n = 1$) (16 buffers \times 4 channels) Transmit buffer: 16 buffers per channel Transmit queue: Single queue per channel (shared with the transmit buffer; up to 16 buffers allocatable) Shared buffers: 384 buffers ($n = 0$) 256 buffers ($n = 1$) Receive buffer: 0 to 96 buffers ($n = 0$) 0 to 64 buffers ($n = 1$) Receive FIFO buffer: 8 FIFO buffers for all channels (up to 128 buffers allocatable to each) Transmit/receive FIFO buffer: 3 FIFO buffers per channel (up to 128 buffers allocatable to each) ECC protected
Reception function	<ul style="list-style-type: none"> Receives data frames and remote frames. Selects ID format (standard ID, extended ID, or both IDs) to be received. Sets interrupt enable/disable for each FIFO. Mirror function (CAN node receives its own transmitted message.) Timestamp function (to record message reception time as a 16-bit timer value)

Table 21.19 RS-CANFD Module Specifications (2/3)

Item	Specification
Reception filter function	<ul style="list-style-type: none"> • Selects receive messages according to 384 receive rules. (n = 0) • Selects receive messages according to 256 receive rules. (n = 1) • Sets the number of receive rules (0 to 128) for each channel. • Acceptance filter processing: Sets ID and mask for each receive rule. • DLC filter processing: Sets DLC check value for each acceptance rule.
Receive message transfer function	<ul style="list-style-type: none"> • Routing function Transfer receive messages to arbitrary destinations (can be transferred to up to 8 buffers) Transfer destination: Receive buffer, receive FIFO buffer, and/or transmit/receive FIFO buffer • Label addition function Stores label information together with the message in a receive buffer and FIFO buffer.
Transmission function	<ul style="list-style-type: none"> • Transmits data frames and remote frames. • Selects ID format (standard ID, extended ID, or both IDs) to be transmitted. • Sets interrupt enable/disable for each transmit buffer and transmit/receive FIFO buffer. • Selects ID priority transmission or transmit buffer number priority transmission. • Transmit request can be aborted (possible to confirm with a flag) • One-shot transmission function
Interval transmission function	Transmit messages at configurable intervals (transmit mode or gateway mode of transmit/receive FIFO buffers)
Transmit queue function	Transmits all stored messages according to the ID priority.
Transmit history function	Stores the history information of transmitted messages. Adds timestamp (recording message transmission time as a 16-bit timer value) to the history information.
Gateway function	A received message is automatically routed to a different channel.
Bus off recovery mode selection	Selects the method for returning from bus off state. <ul style="list-style-type: none"> • ISO11898-1 compliant • Automatic entry to channel halt mode at bus-off entry • Automatic entry to channel halt mode at bus-off end • Entry to channel halt mode by program request • Transition to the error-active state by program request (forcible return from bus-off)
Error status monitoring	<ul style="list-style-type: none"> • Monitors CAN protocol errors (stuff error, form error, ACK error, CRC error, bit error, ACK delimiter error, and bus dominant lock). • Detects error status transitions (error warning, error passive, bus off entry, and bus off recovery) • Reads the error counter. • Monitors DLC errors.
Interrupt source	20 sources (n = 0) and 14 sources (n = 1) <ul style="list-style-type: none"> • Global Interrupts (2 sources/unit) Receive FIFO interrupt Global error interrupt • Channel interrupts (3 sources/channel) CANm transmit interrupt (m = see Table 21.8) <ul style="list-style-type: none"> – CANm transmit complete interrupt – CANm transmit abort interrupt – CANm transmit/receive FIFO transmit complete interrupt (in transmit mode, gateway mode) – CANm transmit history interrupt – CANm transmit queue interrupt CANm transmit/receive FIFO receive complete interrupt (in receive mode, gateway mode) CANm error interrupt
CAN stop mode	Reduces power consumption by stopping clock supply to the RS-CANFD module.
CAN communication clock	The source is selectable on-chip peripheral clock (clk) or crystal clock (clk_xincan).

Table 21.19 RS-CANFD Module Specifications (3/3)

Item	Specification
Test function	Test function for user evaluation <ul style="list-style-type: none"> • Listen-only mode • Self-test mode 0 (external loopback) • Self-test mode 1 (internal loopback) • Restricted operation mode • RAM test (read/write test) • Inter-channel communication test [CRC error test enabled]

21.2.2 Interface Modes

The RS-CANFD has two interface modes.

- Classical CAN mode: Handles only classical CAN frames.
- CAN FD mode: Handles classical CAN frames and CAN FD frames.

These two modes use different register maps with the same base address. Register maps change by switching interface modes.

Interface modes are switched by the RCMC bit in the RSCFDn(CFD)GRMCFG register.

21.2.3 CAN FD Protocol

This product supports CAN FD according to the ISO 11898-1(2015) protocol.

21.2.4 Block Diagram

Figure 21.1 RS-CANFD Module Block Diagram

In CAN FD mode, different clock signals are input to the baud rate prescaler and the protocol controller respectively. See **Section 21.11.1.3, Communication Speed Setting.**

21.3 Registers (Classical CAN Mode)

21.3.1 List of Registers

The following tables list RS-CANFD registers to be used in classical CAN mode.

For details about <RSCFDn_base>, see **Section 21.1.2, Register Base Address**.

For details about registers initialized in Global reset mode or Channel reset mode, see following.

- **Table 21.190, Registers Initialized in Global Reset Mode or Channel Reset Mode**
- **Table 21.191, Registers Initialized Only in Global Reset Mode**

Table 21.20 List of Registers (1/4)

Module Name	Register Name	Symbol	Address	Access	Access Protection
Interface Mode-Related Registers					
RSCANn	Global Interface Mode Select Register	RSCANnGRMCFG	<RSCFDn_base> + 04FC _H	8,16,32	—
Channel-Related Registers

Table 21.25 RSCANnGRMCFG Register Contents

Bit Position	Bit Name	Function
31 to 1	—	Reserved When read, the value after reset is returned. When writing to these bits, write the value after reset.
0	RCMC	Interface Mode Select 0: Classical CAN mode 1: CAN FD mode

Note 1. The RSCANnGRMCFG register and the RSCFDnCFDGRMCFG register are the same register. Therefore, set either one of the registers.

Modify the RSCANnGRMCFG register only in global reset mode. Before setting other RS-CANFD registers, set this register.

RCMC Bit

Setting this bit to 0 makes classical CAN mode available.

Setting this bit to 1 causes the RS-CANFD module to transition to CAN FD mode.

To switch the RS-CANFD module from CAN FD mode to classical CAN mode, set the values after reset to all respective registers and bits allocated only to the register map in CAN FD mode, and then modify the value of RSCANnGRMCFG register.

21.3.3 Details of Channel-Related Registers

21.3.3.1 RSCANnCmCFG — Channel m Configuration Register

Note: For the value of index "m", see **Table 21.8**.

Table 21.26 RSCANnCmCFG Register Contents (2/2)

Bit Position	Bit Name	Function
19 to 16	TSEG1 [3:0]	Time Segment 1 Control b19 b18 b17 b16 0 0 0 0: Setting is prohibited for channels for CAN communications. 0 0 0 1: Setting is prohibited for channels for CAN communications. 0 0 1 0: Setting is prohibited for channels for CAN communications. 0 0 1 1: 4Tq 0 1 0 0: 5Tq 0 1 0 1: 6Tq 0 1 1 0: 7Tq 0 1 1 1: 8Tq 1 0 0 0: 9Tq 1 0 0 1: 10Tq 1 0 1 0: 11Tq 1 0 1 1: 12Tq 1 1 0 0: 13Tq 1 1 0 1: 14Tq 1 1 1 0: 15 Tq 1 1 1 1: 16 Tq
15 to 10	—	Reserved When read, the value after reset is returned. When writing to these bits, write the value after reset.
9 to 0	BRP [9:0]	Prescaler Division Ratio Setting When these bits are set to P (0 to 1023), the baud rate prescaler divides fCAN by P + 1.

Modify the RSCANnCmCFG register in channel reset mode or channel halt mode. Set this register in channel reset mode before transitioning to channel communication mode or channel halt mode. For a description of the bit timing parameters and settings, see **Section 21.11.1, Initial Settings**.

SJW[1:0] Bits

These bits are used to specify a Tq value for the resynchronization jump width. Allowed values are 1 Tq to 4 Tq, inclusive.

Set a value less than or equal to the value of the TSEG2 bits.

TSEG2[2:0] Bits

These bits are used to specify a Tq value for the length of phase segment 2 (PHASE_SEG2).

Allowed values are 2 Tq to 8 Tq, inclusive.

Set a value smaller than the value of the TSEG1 bits.

TSEG1[3:0] Bits

These bits are used to specify a Tq value for the total length of the propagation segment (PROP_SEG) and phase segment 1 (PHASE_SEG1).

Allowed values are 4 Tq to 16 Tq, inclusive.

BRP[9:0] Bits

The CANmTq clock (fCANTQm) is calculated by dividing the CAN clock (fCAN) by the baud rate prescaler ((BRP[9:0]) + 1). One clock cycle of the CANmTq clock is 1 Time Quantum (Tq).

21.3.3.2 RSCANnCMCTR — Channel m Control Register

Note: For the value of index "m", see **Table 21.8**.

Value after reset: 0000 0005_H

12	BORIE	Bus Off Recovery Interrupt Enable 0: Bus off recovery interrupt is disabled. 1: Bus off recovery interrupt is enabled.
11	BOEIE	Bus Off Entry Interrupt Enable 0: Bus off entry interrupt is disabled. 1: Bus off entry interrupt is enabled.
10	EPIE	Error Passive Interrupt Enable 0: Error passive interrupt is disabled. 1: Error passive interrupt is enabled.
9	EWIE	Error Warning Interrupt Enable 0: Error warning interrupt is disabled. 1: Error warning interrupt is enabled.
8	BEIE	Bus Error Interrupt Enable 0: Bus error interrupt is disabled. 1: Bus error interrupt is enabled.
7 to 4	—	Reserved When read, the value after reset is returned. When writing to these bits, write the value after reset.
3	RTBO	Forcible Return from Bus-off When this bit is set to 1, forcible return from the bus off state is made. This bit is always read as 0.
2	CSLPR	Channel Stop Mode 0: Other than channel stop mode 1: Channel stop mode
1, 0	CHMDC[1:0]	Mode Select b1 b0 0 0: Channel communication mode 0 1: Channel reset mode 1 0: Channel halt mode 1 1: Setting prohibited

CRCT Bit

This bit is used to test the CRC generation circuit in the RS-CANFD module. Setting this bit to 1 inverts the first bit of the ID field when a message is received. With this inversion of bit, the CRC calculation result does not match the normal CRC value of the received frame, which can detect a CRC error (the CERR bit in the RSCANnCMERFL register is 1).

When using this function, note the following.

- This function is available while the CTME bit in the RSCANnCMCTR register is 1 (communication test mode enabled).

- This function cannot communicate with other CAN nodes. Use this function for inter-channel communication test (the CmlCBCE bit in the RSCANnGTSTCFG register is 1).
- Bit inversion in the ID field may cause bit stuffing rule violation. In that case, no CRC error is detected but a stuff error is detected.

Modify this bit only in channel halt mode. This bit is always 0 in channel reset mode.

CTMS[1:0] Bits

These bits are used to select a communication test mode. Modify these bits in channel halt mode only. These bits are set to 0 in channel reset mode.

CTME Bit

Setting this bit to 1 enables communication test mode. Modify this bit in channel halt mode. This bit is set to 0 in channel reset mode.

ERRD Bit

This bit is used to control display mode of bits 14 to 8 in the RSCANnCmERFL register.

When this bit is cleared to 0, if any error is detected while the flags of bits 14 to 8 in the RSCANnCmERFL register are all 0, only the flags of the first error event are set to 1. If two or more errors occur in first error event, all the flags of the detected errors are set to 1.

When this bit is set to 1, all the flags of errors that have occurred are set to 1 regardless of the error occurrence order.

Modify this bit only in channel reset mode or channel halt mode.

BOM[1:0] Bits

These bits are used to select a bus off recovery mode of the RS-CANFD module.

When the BOM[1:0] bits are set to 00_B, return from the bus off state is compliant with the CAN specifications. That is, the RS-CANFD module reenters the CAN communication (error active state) after 11 consecutive recessive bits are detected 128 times. A bus off recovery interrupt request is generated at the time of return from the bus off state. Even if the CHMDC[1:0] bits are set to 10_B (channel halt mode) before recessive bits are detected 128 times, the RS-CANFD module does not transition to channel halt mode until recessive bits are detected 128 times.

When the RS-CANFD module reaches the bus off state when the BOM[1:0] bits are set to 01_B, the CHMDC[1:0] bits in the RSCANnCmCTR register (m = see **Table 21.8**) are set to 10_B and the RS-CANFD module transitions to channel halt mode. No bus off recovery interrupt request is generated at the time of return from the bus off state and the TEC[7:0] and REC[7:0] bits in the RSCANnCmSTS register are cleared to 00_H.

When the RS-CANFD module reaches the bus off state when the BOM[1:0] bits are set to 10_B, the CHMDC[1:0] bits are set to 10_B and the RS-CANFD module transitions to channel halt mode after return from the bus off state (11 consecutive recessive bits are detected 128 times). A bus off recovery interrupt request is generated at the time of return from the bus off state and the TEC[7:0] and REC[7:0] bits are cleared to 00_H.

When the BOM[1:0] bits are set to 11_B and the CHMDC[1:0] bits are set to 10_B while the RS-CANFD module is in the bus off state, the RS-CANFD module transitions to channel halt mode. No bus off recovery interrupt request is generated at the time of return from the bus off state and the TEC[7:0] and REC[7:0] bits are cleared to 00_H. However, if 11 consecutive recessive bits are detected 128 times and the RS-CANFD module has recovered to the error active state from the bus off state before the CHMDC[1:0] bits are set to 10_B, a bus off recovery interrupt request is generated.

When the RS-CANFD module transitions to channel halt mode (at bus off entry when the BOM[1:0] bits are 01_B or at bus off end when the BOM[1:0] bits are 10_B), if the CHMDC[1:0] bits are written by a program at the same time, writing by a program takes precedence. Modify BOM[1:0] bits in channel reset mode.

TAIE Bit

When transmit abort of the transmit buffer is completed with the TAIE bit set to 1, an interrupt request is generated. Modify this bit only in channel reset mode.

ALIE Bit

When the ALF flag in the RSCANnCMERFL register is set to 1 with the ALIE bit set to 1, an error interrupt request is generated. Modify this bit only in channel reset mode.

BLIE Bit

When the BLF flag in the RSCANnCMERFL register is set to 1 with the BLIE bit set to 1, an error interrupt request is generated. Modify this bit only in channel reset mode.

OLIE Bit

When the OVLf flag in the RSCANnCMERFL register is set to 1 with the OLIE bit set to 1, an error interrupt request is generated. Modify this bit only in channel reset mode.

BORIE Bit

When the BORF flag in the RSCANnCMERFL register is set to 1 with the BORIE bit set to 1, an error interrupt request is generated. Modify this bit only in channel reset mode.

BOEIE Bit

When the BOEF flag in the RSCANnCMERFL register is set to 1 with the BOEIE bit set to 1, an error interrupt request is generated. Modify this bit only in channel reset mode.

EPIE Bit

When the EPF flag in the RSCANnCMERFL register is set to 1 with the EPIE bit set to 1, an error interrupt request is generated. Modify this bit only in channel reset mode.

EWIE Bit

When the EWF flag in the RSCANnCMERFL register is set to 1 with the EWIE bit set to 1, an error interrupt request is generated. Modify this bit only in channel reset mode.

BEIE Bit

When the BEF flag in the RSCANnCMERFL register is set to 1 with the BEIE bit set to 1, an error interrupt request is generated. Modify this bit only in channel reset mode.

RTBO Bit

Setting this bit to 1 (forcible return from the bus off state) in the bus off state changes the state forcibly from the bus off state to the error active state. This bit is automatically cleared to 0. Setting this bit to 1 clears the TEC[7:0] and REC[7:0] bits in the RSCANnCMSTS register to 00_H and also clears the BOSTS flag in the RSCANnCMSTS register to 0 (not in bus off state). The other registers remain unchanged. No bus off recovery interrupt request due to return from the bus off state is generated. Use this bit only when the BOM[1:0] bits in the RSCANnCMCTR register are 00_B (ISO11898-1 compliant).

A delay of up to 1 CAN bit time occurs after the RTBO bit is set to 1 until the RS-CANFD module transitions to the error active state. Set this bit to 1 in channel communication mode.

CSLPR Bit

Setting this bit to 1 places the channel in channel stop mode.

Clearing this bit to 0 makes the channel leave from channel stop mode.

Do not rewrite this bit in channel communication mode or in channel halt mode.

CHMDC[1:0] Bits

These bits are used to select a channel mode (channel communication mode, channel reset mode, or channel halt mode). For details, see **Section 21.6.2, Channel Modes**. Setting the CSLPR bit to 1 in channel reset mode allows transition to channel stop mode. Do not set these bits to 11_B. When the RS-CANFD module has transitioned to channel halt mode by the setting of the BOM[1:0] bits, the CHMDC[1:0] bits are automatically set to 10_B.

21.3.3.3 RSCANnCmSTS — Channel m Status Register

Note: For the value of index "m", see **Table 21.8**.

Value after reset: 0000 0005_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 21.28 RSCANnCmSTS Register Contents

Bit Position	Bit Name	Function
31 to 24	TEC [7:0]	The transmit error counter (TEC) can be read.
23 to 16	REC [7:0]	The receive error counter (REC) can be read.
15 to 8	—	Reserved When read, the value after reset is returned. When writing to these bits, write the value after reset.
7	COMSTS	Communication Status Flag 0: Communication is not ready. 1: Communication is ready.
6	RECSTS	Receive Status Flag 0: Bus idle, in transmission, or bus off state 1: In reception
5	TRMSTS	Transmit Status Flag 0: Bus idle or in reception 1: In transmission or bus off state
4	BOSTS	Bus Off Status Flag 0: Not in bus off state 1: In bus off state
3	EPSTS	Error Passive Status Flag 0: Not in error passive state 1: In error passive state
2	CSLPSTS	Channel Stop Status Flag 0: Not in channel stop mode 1: In channel stop mode
1	CHLTSTS	Channel Halt Status Flag 0: Not in channel halt mode 1: In channel halt mode
0	CRSTSTS	Channel Reset Status Flag 0: Not in channel reset mode 1: In channel reset mode

TEC[7:0] Bits

These bits indicate the transmit error counter value. For transmit error counter increment/decrement conditions, see *the CAN specification (ISO11898-1)*.

These bits are cleared to 0 in channel reset mode.

REC[7:0] Bits

These bits indicate the receive error counter value. For receive error counter increment/decrement conditions, see *the CAN specification (ISO11898-1)*.

These bits are cleared to 0 in channel reset mode.

COMSTS Flag

This flag indicates that communication is ready.

This flag is set to 1 when the RS-CANFD module has detected 11 consecutive recessive bits after it has transitioned from channel reset mode or channel halt mode to channel communication mode. This flag is cleared to 0 in channel reset mode or channel halt mode.

RECSTS Flag

This flag is set to 1 when reception has started, and is cleared to 0 when the bus has become idle or transmission has started.

TRMSTS Flag

This flag is set to 1 when transmission has started, and is cleared to 0 when the bus has become idle or reception has started. This flag remains 1 in the bus off state.

BOSTS Flag

This flag is set to 1 when the TEC[7:0] value exceeds 255 and the RS-CANFD module has entered the bus off state (TEC[7:0] value > 255), and is cleared to 0 when the RS-CANFD module has exited the bus off state.

EPSTS Flag

This flag is set to 1 when the TEC[7:0] or REC[7:0] value exceeds 127 and the RS-CANFD module has entered the error passive state ($128 \leq \text{TEC}[7:0] \text{ value} \leq 255$ or $128 \leq \text{REC}[7:0] \text{ value}$), and is cleared to 0 when the RS-CANFD module has exited the error passive state or has entered channel reset mode.

CSLPSTS Flag

This flag is set to 1 when the RS-CANFD module has transitioned to channel stop mode, and is cleared to 0 when the RS-CANFD module has returned from channel stop mode.

CHLTSTS Flag

This flag is set to 1 when the RS-CANFD module has transitioned to channel halt mode, and is cleared to 0 when the RS-CANFD module has exited channel halt mode.

CRSTSTS Flag

This flag is set to 1 when the RS-CANFD module has transitioned to channel reset mode, and is cleared to 0 when the RS-CANFD module has transitioned to channel communication mode or channel halt mode. This flag remains 1 if the RS-CANFD module transitions from channel reset mode to channel stop mode.

21.3.3.4 RSCANnCmERFL — Channel m Error Flag Register

Note: For the value of index "m", see **Table 21.8**.

Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R/W*1	R/W*1	R/W*1	R/W*1	R/W*1	R/W*1	R/W*1	R/W*1	R/W*1	R/W*1	R/W*1	R/W*1	R/W*1	R/W*1	R/W*1

Note 1. The only effective value for writing to this flag bit is 0, which clears the status. Any other writing to the bit results in retention of the status and does not change the value.

Table 21.29 RSCANnCmERFL Register Contents (1/2)

Bit Position	Bit Name	Function
31	—	Reserved When read, the value after reset is returned. When writing to this bit, write the value after reset.
30 to 16	CRCREG[14:0]	CRC Calculation Data A CRC value calculated based on the transmitted message or received message is indicated.
15	—	Reserved When read, the value after reset is returned. When writing to this bit, write the value after reset.
14	ADERR	ACK Delimiter Error Flag 0: No ACK delimiter error is detected. 1: ACK delimiter error is detected.
13	B0ERR	Dominant Bit Error Flag 0: No dominant bit error is detected. 1: Dominant bit error is detected.
12	B1ERR	Recessive Bit Error Flag 0: No recessive bit error is detected. 1: Recessive bit error is detected.
11	CERR	CRC Error Flag 0: No CRC error is detected. 1: CRC error is detected.
10	AERR	ACK Error Flag 0: No ACK error is detected. 1: ACK error is detected.
9	FERR	Form Error Flag 0: No form error is detected. 1: Form error is detected.
8	SERR	Stuff Error Flag 0: No stuff error is detected. 1: Stuff error is detected.
7	ALF	Arbitration Lost Flag 0: No arbitration lost is detected. 1: Arbitration lost is detected.

Table 21.29 RSCANnCmERFL Register Contents (2/2)

Bit Position	Bit Name	Function
6	BLF	Bus Lock Flag 0: No channel bus lock is detected. 1: Channel bus lock is detected.
5	OVLf	Overload Flag 0: No overload is detected. 1: Overload is detected.
4	BORF	Bus Off Recovery Flag 0: No bus off recovery is detected. 1: Bus off recovery is detected.
3	BOEF	Bus Off Entry Flag 0: No bus off entry is detected. 1: Bus off entry is detected.
2	EPF	Error Passive Flag 0: No error passive is detected. 1: Error passive is detected.
1	EWf	Error Warning Flag 0: No error warning is detected. 1: Error warning is detected.
0	BEF	Bus Error Flag 0: No channel bus error is detected. 1: Channel bus error is detected.

See the *CAN specification (ISO11898-1)* for a description of error occurrence conditions. To clear each flag of this register, the program must write 0 to the corresponding bit. These flags cannot be set to 1 by the program. If any of these flags is set to 1 at the same time that the program writes 0 to the flag, the flag is still set to 1. The channel reset mode transition clears all of these flags to 0.

If the ERRD bit in the RSCANnCmCTR register is set to 0 (i.e., only the flags for the first error event are displayed) and an error related to bits 14 to 8 of RSCANnCmERFL is detected, the flag bits are set to 1 by the error event if bits 14 to 8 were all 0 when the error occurred.

CRCREG[14:0] Flags

When the CTME bit in the RSCANnCmCTR register is set to 1 (communication test mode is enabled), the CRC value calculated based on the transmitted or received message can be read. When the CTME bit is set to 0 (communication test mode is disabled), these bits are always read as 0. This bit is always 0 in channel reset mode.

ADERR Flag

This flag is set to 1 when a form error has been detected in the ACK delimiter during transmission.

B0ERR Flag

This flag is set to 1 when a recessive bit has been detected even though a dominant bit was transmitted.

B1ERR Flag

This flag is set to 1 when a dominant bit has been detected even though a recessive bit was transmitted.

CERR Flag

This flag is set to 1 when a CRC error has been detected.

AERR Flag

This flag is set to 1 when an ACK error has been detected.

FERR Flag

This flag is set to 1 when a form error has been detected.

SERR Flag

This flag is set to 1 when a stuff error has been detected.

ALF Flag

This flag is set to 1 when an arbitration-lost has been detected.

BLF Flag

This flag is set to 1 when 32 consecutive dominant bits have been detected on the CAN bus in channel communication mode. After that, detection of bus lock is restarted when either of the following conditions is met.

- A recessive bit is detected after the BLF bit has been modified from 1 to 0.
- The RS-CANFD module transitions to channel reset mode and returns to channel communication mode after the BLF bit has been modified from 1 to 0.

OVLV Flag

This flag is set to 1 when the overload frame transmit condition has been detected when performing reception or transmission.

BORF Flag

This flag is set to 1 when 11 consecutive recessive bits have been detected 128 times and the RS-CANFD module returns from the bus off state. However, this flag is not set to 1 if the RS-CANFD module returns from the bus off state in either of the following cases before 11 consecutive recessive bits are detected 128 times.

- The CHMDC[1:0] bits in the RSCANnCMCTR register are set to 01_B (channel reset mode).
- The RTBO bit in the RSCANnCMCTR register is set to 1 (forcible return from the bus off state).
- The BOM[1:0] bits in the RSCANnCMCTR register are set to 01_B (transition to channel halt mode at bus off entry).
- The CHMDC[1:0] bits in the RSCANnCMCTR register are set to 10_B (channel halt mode) before 11 consecutive recessive bits are detected 128 times with the BOM[1:0] bits set to 11_B (transition to channel halt mode upon a request from the program during bus off).

BOEF Flag

This flag is set to 1 when the state becomes bus off state (TEC[7:0] value > 255). This flag is also set to 1 when the state becomes bus off state with the BOM[1:0] bits in the RSCANnCMCTR register (m = see **Table 21.8**) are set to 01_B (transition to channel halt mode at bus off entry).

EPF Flag

This flag is set to 1 when the error passive state is entered ($(128 \leq \text{TEC}[7:0] \leq 255)$ or $(128 \leq \text{REC}[7:0])$). This flag is set to 1 only when the REC[7:0] or TEC[7:0] value exceeds 127 for the first time. Therefore, if the program writes 0 to this flag with the REC[7:0] or TEC[7:0] value remaining over 127, this bit is not set to 1 until both REC [7:0] and TEC[7:0] values become 127 or less and then either the REC[7:0] or TEC[7:0] value exceeds 127 again.

EFWF Flag

This flag is set to 1 only when the REC[7:0] or TEC[7:0] value exceeds 95 for the first time. Therefore, if the program writes 0 to this flag with the REC[7:0] or TEC[7:0] value remaining over 95, this bit is not set to 1 until both REC [7:0] and TEC[7:0] values become 95 or less and then either the REC[7:0] or TEC[7:0] value exceeds 95 again.

BEF Flag

This flag is set to 1 when any one of the ADERR, BOERR, B1ERR, CERR, AERR, FERR, and SERR flags in the RSCANnCMERFL register is set to 1.

NOTE

To clear the flag of this register to 0, use a store instruction to write "0" to that flag and "1" to the other flags.

21.3.4 Details of Global-Related Registers

21.3.4.1 RSCANnGCFG — Global Configuration Register

Value after reset: 0000 0000_H

6	EEFE	ECC Error Flag Enable 0: The ECC error flag is disabled. 1: The ECC error flag is enabled.
5	—	Reserved When read, the value after reset is returned. When writing to this bit, write the value after reset.
4	DCS	CAN Clock Source Select 0: clkc 1: clk_xincan
3	MME	Mirror Function Enable 0: Mirror function is disabled. 1: Mirror function is enabled.
2	DRE	DLC Replacement Enable 0: DLC replacement is disabled. 1: DLC replacement is enabled.
1	DCE	DLC Check Enable 0: DLC check is disabled. 1: DLC check is enabled.
0	TPRI	Transmit Priority Select 0: ID priority 1: Transmit buffer number priority

Note 1. Set TSBTCS[2:0] to 000_b before select pclk/2 as the timestamp count source.

Note 2. Setting is prohibited in (n = 1).

Modify the RSCANnGCFG register in global reset mode.

ITRCP[15:0] Bits

These bits are used to set a clock source division value of the interval timer for FIFO buffers. For details, see **Section 21.8.3.1, Interval Transmission Function**.

TSBTCS[2:0] Bits

When the TSSS bit is 1, these bits are used to select the channel of the bit time clock that will be the clock source of the timestamp counter.

TSSS Bit

This bit is used to select a clock source of the timestamp counter.

TSP[3:0] Bits

These bits specify the prescaler used to divide the clock source (selected by the TSBTCS[2:0] and TSSS bits) to generate the timestamp counter clock signal.

TMTSCE Bit

Setting this bit to 1 makes it possible to store the timestamp of a transmitted message in the transmit history buffer. The timestamp is stored in TMTS[15:0] bits in the RSCANnTHLACCm register.

EEFE Bit

Setting this bit to 1 sets the EEFm bit in the RSCANnGERFL register to 1 when a 2-bit ECC error is detected during the transmission priority determination. At this time, the message in which a 2-bit ECC error was detected is not transmitted.

DCS Bit

When this bit is set to 0, clk_c is used as the clock source of the CAN clock (fCAN).

When this bit is set to 1, the main clock is used as the clock source of the CAN clock (fCAN).

MME Bit

Setting this bit to 1 makes the mirror function available.

DRE Bit

When the DRE bit is set to 1, the DLC value of the receive rule is stored in the buffer instead of the DLC value of the received message after the DLC value has passed through the DLC filter. In this case, a value of 00_H is stored in the data byte that exceeds the DLC value of the receive rule.

When the DCE bit is set to 1 (DLC check is enabled), the DLC replacement function is available.

DCE Bit

Setting this bit to 1 makes the DLC check function available. Set the GAFLDLC[3:0] bits in the RSCANnGAFLP0_j register to 0000_B before clearing the DCE bit in the RSCANnGCFG register to 0.

TPRI Bit

This bit is used to set the transmit priority.

When this bit is set to 0, ID priority is selected and the transmit priority complies with the CAN bus arbitration rule (ISO11898-1 specifications). When this bit is set to 1, transmit buffer number priority is selected and the lowest-numbered transmit buffer among those specified for transmission takes precedence.

When using the transmit queue, clear this bit to 0.

21.3.4.2 RSCANnGCTR — Global Control Register

Value after reset: 0000 0005_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	TSRST
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0	1
R/W	R	R	R	R	R	R/W	R/W	R/W	R	R	R	R	R	R/W	R/W	R/W

Table 21.31 RSCANnGCTR Register Contents

Bit Position	Bit Name	Function
31 to 17	—	Reserved When read, the value after reset is returned. When writing to these bits, write the value after reset.
16	TSRST	Timestamp Counter Reset Setting the TSRST bit to 1 resets the timestamp counter. This bit is always read as 0.
15 to 11	—	Reserved When read, the value after reset is returned. When writing to these bits, write the value after reset.
10	THLEIE	Transmit History Buffer Overflow Interrupt Enable 0: Transmit history buffer overflow interrupt is disabled. 1: Transmit history buffer overflow interrupt is enabled.
9	MEIE	FIFO Message Lost Interrupt Enable 0: FIFO message lost interrupt is disabled. 1: FIFO message lost interrupt is enabled.
8	DEIE	DLC Error Interrupt Enable 0: DLC error interrupt is disabled. 1: DLC error interrupt is enabled.
7 to 3	—	Reserved When read, the value after reset is returned. When writing to these bits, write the value after reset.
2	GSLPR	Global Stop Mode 0: Other than global stop mode 1: Global stop mode
1, 0	GMDC[1:0]	Global Mode Select b1 b0 0 0: Global operating mode 0 1: Global reset mode 1 0: Global test mode 1 1: Setting prohibited

TSRST Bit

This bit is used to reset the timestamp counter. When this bit is set to 1, the RSCANnGTSC register is cleared to 0000_H.

THLEIE Bit

When the THLEIE bit is set to 1 and the THLES flag in the RSCANnGERFL register is set to 1, an interrupt request is generated. Modify this bit only in global reset mode.

MEIE Bit

When the MEIE bit is set to 1 and the MES flag in the RSCANnGERFL register is set to 1, an interrupt request is generated. Modify this bit only in global reset mode.

DEIE Bit

When the DEIE bit is set to 1 and the DEF flag in the RSCANnGERFL register is set to 1, an interrupt request is generated. Modify this bit only in global reset mode.

GSLPR Bit

Setting this bit to 1 places the RS-CANFD module in global stop mode.

Clearing this bit to 0 releases the RS-CANFD module from global stop mode.

Do not modify this bit from 0 to 1 in global operation mode or global test mode.

GMDC[1:0] Bits

These bits are used to select a mode of the entire RS-CANFD module (global operating mode, global reset mode, or global test mode). For details, see **Section 21.6.1, Global Modes**. Setting the GSLPR bit to 1 in global reset mode makes the RS-CANFD module transition to global stop mode.

21.3.4.3 RSCANnGSTS — Global Status Register

Value after reset: 0000 000D_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	GRAM INIT	GSLPS TS	GHLT TS	GRST TS
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	1	1	0	1
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 21.32 RSCANnGSTS Register Contents

Bit Position	Bit Name	Function
31 to 4	—	Reserved When read, the value after reset is returned. When writing to these bits, write the value after reset.
3	GRAMINIT	CAN RAM Initialization Status Flag 0: CAN RAM initialization is completed. 1: CAN RAM initialization is ongoing.
2	GSLPSTS	Global Stop Status Flag 0: Not in global stop mode 1: In global stop mode
1	GHLTSTS	Global Test Status Flag 0: Not in global test mode 1: In global test mode
0	GRSTSTS	Global Reset Status Flag 0: Not in global reset mode 1: In global reset mode

GRAMINIT Flag

This flag indicates the initialization status of the CAN RAM.

This flag is set to 1 after the MCU has been reset, and is cleared to 0 when CAN RAM initialization is completed.

GSLPSTS Flag

This flag is set to 1 when the RS-CANFD module has transitioned to global stop mode, and is cleared to 0 when the RS-CANFD module has returned from global stop mode.

GHLTSTS Flag

This flag is set to 1 when the RS-CANFD module has transitioned to global test mode, and is cleared to 0 when the RS-CANFD module has exited global test mode.

GRSTSTS Flag

This flag is set to 1 when the RS-CANFD module has transitioned to global reset mode, and is cleared to 0 when the RS-CANFD module has exited global reset mode. This flag remains 1 if the RS-CANFD module has transitioned from global reset mode to global stop mode.

21.3.4.4 RSCANnGERFL — Global Error Flag Register

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	EEF5	EEF4	EEF3	EEF2	EEF1	EEF0
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R/W*1	R/W*1	R/W*1	R/W*1	R/W*1	R/W*1
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	THLES	MES	DEF
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W*1

Note 1. The only effective value for writing to this flag bit is 0, which clears the status. Any other writing to the bit results in retention of the status and does not change the value.

Table 21.33 RSCANnGERFL Register Contents (1/2)

Bit Position	Bit Name	Function
31 to 22	—	Reserved When read, the value after reset is returned. When writing to these bits, write the value after reset.
21	EEF5*1	ECC Error Flag for Unit Channel 5 0: No 2-bit ECC error when deciding transmission priority 1: A 2-bit ECC error when deciding transmission priority
20	EEF4*1	ECC Error Flag for Unit Channel 4 0: No 2-bit ECC error when deciding transmission priority 1: A 2-bit ECC error when deciding transmission priority
19	EEF3	ECC Error Flag for Unit Channel 3 0: No 2-bit ECC error when deciding transmission priority 1: A 2-bit ECC error when deciding transmission priority
18	EEF2	ECC Error Flag for Unit Channel 2 0: No 2-bit ECC error when deciding transmission priority 1: A 2-bit ECC error when deciding transmission priority
17	EEF1	ECC Error Flag for Unit Channel 1 0: No 2-bit ECC error when deciding transmission priority 1: A 2-bit ECC error when deciding transmission priority
16	EEF0	ECC Error Flag for Unit Channel 0 0: No 2-bit ECC error when deciding transmission priority 1: A 2-bit ECC error when deciding transmission priority
15 to 14, 7 to 6, 4 to 3	—	Reserved When read, the value after reset is returned. When writing to these bits, write the value after reset.
13 to 8, 5	—	Reserved When read, the undefined value is returned. When writing these bits, write the value after reset.
2	THLES	Transmit History Buffer Overflow Status Flag 0: No transmit history buffer overflow is present. 1: A transmit history buffer overflow is present.
1	MES	FIFO Message Lost Status Flag 0: No FIFO message lost error is present. 1: A FIFO message lost error is present.

Table 21.33 RSCANnGERFL Register Contents (2/2)

Bit Position	Bit Name	Function
0	DEF	DLC Error Flag 0: No DLC error is present. 1: A DLC error is present.

Note 1. This bit is a reserved bit in (n = 1). When read, the value after reset is returned. When writing to this bit, write the value after reset.

All flags in the RSCANnGERFL register are cleared to 0 in global reset mode.

EEFm Flag

While the EEFE bit in the RSCANnGCFG register is 1, when a 2-bit ECC error is detected during the transmission priority determination of channel m (m = see **Table 21.8**), the EEFm flag is set to 1, disabling message transmission. This flag can be cleared to 0 by writing 0 by the program.

THLES Flag

The THLES flag is set to 1 when any one of the THLELT flags in the RSCANnTHLSTSm register (m = see **Table 21.8**) is set to 1.

This flag is cleared to 0 when the THLELT flags of all channels are set to 0.

MES Flag

The MES flag is set to 1 when any one of the RFMLT flags in the RSCANnRFSTSk register (x = see **Table 21.8**) or the CFMLT flags in the RSCANnCFSTSk register (k = see **Table 21.8**) is set to 1.

This flag is cleared to 0 when all the RFMLT flags and CFMLT flags are set to 0.

DEF Flag

The DEF flag is set to 1 when an error has been detected during the DLC check. This flag can be cleared to 0 by writing 0 by the program.

NOTE

To clear the flag of the register to 0, the program must write 0 to the given flag. When writing 0, use a store instruction to write 0 to the given flag and 1 to the other flags.

21.3.4.5 RSCANnGTSC — Global Timestamp Counter Register

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 21.34 RSCANnGTSC Register Contents

Bit Position	Bit Name	Function
31 to 16	—	Reserved When read, the value after reset is returned.
15 to 0	TS[15:0]	Timestamp value The timestamp counter value can be read. Counter value: 0000 _H to FFFF _H

TS[15:0] Bits

When the TS[15:0] bits are read, the read value shows the timestamp counter (16-bit free-running counter) value at that time. The TS[15:0] value at the time when the SOF of the received message is detected is stored in the receive buffer or the FIFO buffer. The timestamp counter is initialized in global reset mode.

Start timing and stop timing of the timestamp counter depend on the count source.

- When the TSSS bit value in the RSCANnGCFG register is 0 (pclk):
The timestamp counter starts counting when the RS-CANFD module has transitioned to global operating mode. This counter stops counting when the RS-CANFD module has transitioned to global stop mode or global test mode.
- When the TSSS bit value in the RSCANnGCFG register is 1 (CANm bit time clock):
The timestamp counter starts counting when the corresponding channel has transitioned to channel communication mode. This counter stops counting when the corresponding channel has transitioned to channel reset mode or channel halt mode.

21.3.4.6 RSCANnGTINTSTS0 — Global TX Interrupt Status Register 0

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Note 1. The bit is automatically cleared in global reset or channel reset mode.

Table 21.35 RSCANnGTINTSTS0 Register Contents (1/2)

Bit Position	Bit Name	Function
31 to 29	—	Reserved When read, the value after reset is returned. When writing to these bits, write the value after reset.
28	THIF3	Unit Channel 3 Transmit History Interrupt Status Flag 0: Transmit history interrupt is not requested. 1: Transmit history interrupt is requested.
27	CFTIF3	Unit Channel 3 Transmit/receive FIFO Transmit Interrupt Status Flag 0: Transmit/receive FIFO transmit interrupt is not requested. 1: Transmit/receive FIFO transmit interrupt is requested.
26	TQIF3	Unit Channel 3 Transmit Queue Interrupt Status Flag 0: Transmit queue interrupt is not requested. 1: Transmit queue interrupt is requested.
25	TAIF3	Unit Channel 3 Transmit Buffer Abort Interrupt Status Flag 0: Transmit buffer abort interrupt is not requested. 1: Transmit buffer abort interrupt is requested.
24	TSIF3	Unit Channel 3 Transmit Buffer Transmit Complete Interrupt Status Flag 0: Transmit buffer transmit complete interrupt is not requested. 1: Transmit buffer transmit complete interrupt is requested.
23 to 21	—	Reserved When read, the value after reset is returned. When writing to these bits, write the value after reset.
20	THIF2	Unit Channel 2 Transmit History Interrupt Status Flag 0: Transmit history interrupt is not requested. 1: Transmit history interrupt is requested.
19	CFTIF2	Unit Channel 2 Transmit/receive FIFO Transmit Interrupt Status Flag 0: Transmit/receive FIFO transmit interrupt is not requested. 1: Transmit/receive FIFO transmit interrupt is requested.
18	TQIF2	Unit Channel 2 Transmit Queue Interrupt Status Flag 0: Transmit queue interrupt is not requested. 1: Transmit queue interrupt is requested.
17	TAIF2	Unit Channel 2 Transmit Buffer Abort Interrupt Status Flag 0: Transmit buffer abort interrupt is not requested. 1: Transmit buffer abort interrupt is requested.

Table 21.35 RSCANnGTINTSTS0 Register Contents (2/2)

Bit Position	Bit Name	Function
16	TSIF2	Unit Channel 2 Transmit Buffer Transmit Complete Interrupt Status Flag 0: Transmit buffer transmit complete interrupt is not requested. 1: Transmit buffer transmit complete interrupt is requested.
15 to 13	—	Reserved When read, the value after reset is returned. When writing to these bits, write the value after reset.
12	THIF1	Unit Channel 1 Transmit History Interrupt Status Flag 0: Transmit history interrupt is not requested. 1: Transmit history interrupt is requested.
11	CFTIF1	Unit Channel 1 Transmit/receive FIFO Transmit Interrupt Status Flag 0: Transmit/receive FIFO transmit interrupt is not requested. 1: Transmit/receive FIFO transmit interrupt is requested.
10	TQIF1	Unit Channel 1 Transmit Queue Interrupt Status Flag 0: Transmit queue interrupt is not requested. 1: Transmit queue interrupt is requested.
9	TAIF1	Unit Channel 1 Transmit Buffer Abort Interrupt Status Flag 0: Transmit buffer abort interrupt is not requested. 1: Transmit buffer abort interrupt is requested
8	TSIF1	Unit Channel 1 Transmit Buffer Transmit Complete Interrupt Status Flag 0: Transmit buffer transmit complete interrupt is not requested. 1: Transmit buffer transmit complete interrupt is requested.
7 to 5	—	Reserved When read, the value after reset is returned. When writing to these bits, write the value after reset.
4	THIF0	Unit Channel 0 Transmit History Interrupt Status Flag 0: Transmit history interrupt is not requested. 1: Transmit history interrupt is requested.
3	CFTIF0	Unit Channel 0 Transmit/receive FIFO Transmit Interrupt Status Flag 0: Transmit/receive FIFO transmit interrupt is not requested. 1: Transmit/receive FIFO transmit interrupt is requested.
2	TQIF0	Unit Channel 0 Transmit Queue Interrupt Status Flag 0: Transmit queue interrupt is not requested. 1: Transmit queue interrupt is requested.
1	TAIF0	Unit Channel 0 Transmit Buffer Abort Interrupt Status Flag 0: Transmit buffer abort interrupt is not requested. 1: Transmit buffer abort interrupt is requested
0	TSIF0	Unit Channel 0 Transmit Buffer Transmit Complete Interrupt Status Flag 0: Transmit buffer transmit complete interrupt is not requested. 1: Transmit buffer transmit complete interrupt is requested.

TSIFm Bit

When the RSCANnTMIECy.TMIEp bit is set to 1 (transmit buffer interrupt is enabled) and corresponding RSCANnTMSTSp.TMTRF[1:0] flags are set to 10_B (transmission has been completed, without transmit abort request) or 11_B (transmission has been completed, with transmit abort request), the TSIFm bit becomes 1.

The TSIFm flag becomes 0 by setting 00_B to all the TMTRF[1:0] flags which satisfy the condition to lead TSIFm = 1. The TSIFm flag also becomes 0 by setting the TMIEp bit to 0.

TAIFm Bit

When the RSCANnCMCTR.TAIE bit is set to 1 (transmit abort interrupt is enabled) and the RSCANnTMSTSp.TMTRF[1:0] flags are 01_B (transmit abort has been completed), the TAIFm bit becomes 1.

The TAIFm flag becomes 0 by setting 00_B to all the TMTRF[1:0] flags of which transmit abort has been completed.

TQIFm Bit

When the RSCANnTXQCCm.TXQIE bit is set to 1 (transmit queue interrupt is enabled) and the RSCANnTXQSTSm.TXQIF bit is set to 1 (a transmit queue interrupt request is present), the TQIFm bit becomes 1.

When the RSCANnTXQSTSm.TXQIF bit (transmit queue interrupt request) is set to 0, the TQIFm bit becomes 0. The TQIFm flag also becomes 0 by setting the TXQIE bit to 0.

CFTIFm Bit

When the RSCANnCFCCk.CFTXIE bit is set to 1 (transmit/receive FIFO transmit interrupt is enabled) and the RSCANnCFSTSk.CFTXIF bit is set to 1 (a transmit/receive FIFO transmit interrupt request is present), the CFTIFm bit becomes 1.

The CFTIFm bit becomes 0 by setting all the RSCANnCFSTSk.CFTXIF bits to 0. The CFTIFm flag also becomes 0 by setting the CFTXIE bit to 0.

THIFm Bit

When the RSCANnTHLCCm.THLIE bit is set to 1 (transmit history interrupt is enabled) and the RSCANnTHLSTSm.THLIF bit is set to 1 (a transmit history interrupt request is present), the THIFm bit becomes 1.

The THIFm bit becomes 0 by setting the RSCANnTHLSTSm.THLIF bit to 0. The THIFm flag also becomes 0 by setting the THLIE bit to 0.

21.3.4.7 RSCANnGTINTSTS1 — Global TX Interrupt Status Register 1

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

R/W	R	R	R	R*	R*	R*	R*	R*	R	R	R	R*	R*	R*	R*	R*

Note 1. The bit is automatically cleared in global reset or channel reset mode.

Table 21.36 RSCANnGTINTSTS1 Register Contents (1/2)

Bit Position	Bit Name	Function
31 to 13	—	Reserved When read, the value after reset is returned. When writing to these bits, write the value after reset.
12	THIF5*	Unit Channel 5 Transmit History Interrupt Status Flag 0: Transmit history interrupt is not requested. 1: Transmit history interrupt is requested.
11	CFTIF5*	Unit Channel 5 Transmit/receive FIFO Transmit Interrupt Status Flag 0: Transmit/receive FIFO transmit interrupt is not requested. 1: Transmit/receive FIFO transmit interrupt is requested.
10	TQIF5*	Unit Channel 5 Transmit Queue Interrupt Status Flag 0: Transmit queue interrupt is not requested. 1: Transmit queue interrupt is requested.
9	TAIF5*	Unit Channel 5 Transmit Buffer Abort Interrupt Status Flag 0: Transmit buffer abort interrupt is not requested. 1: Transmit buffer abort interrupt is requested.
8	TSIF5*	Unit Channel 5 Transmit Buffer Transmit Complete Interrupt Status Flag 0: Transmit buffer transmit complete interrupt is not requested. 1: Transmit buffer transmit complete interrupt is requested.
7 to 5	—	Reserved When read, the value after reset is returned. When writing to these bits, write the value after reset.
4	THIF4*	Unit Channel 4 Transmit History Interrupt Status Flag 0: Transmit history interrupt is not requested. 1: Transmit history interrupt is requested.
3	CFTIF4*	Unit Channel 4 Transmit/receive FIFO Transmit Interrupt Status Flag 0: Transmit/receive FIFO transmit interrupt is not requested. 1: Transmit/receive FIFO transmit interrupt is requested.
2	TQIF4*	Unit Channel 4 Transmit Queue Interrupt Status Flag 0: Transmit queue interrupt is not requested. 1: Transmit queue interrupt is requested.
1	TAIF4*	Unit Channel 4 Transmit Buffer Abort Interrupt Status Flag 0: Transmit buffer abort interrupt is not requested. 1: Transmit buffer abort interrupt is requested.

Table 21.36 RSCANnGTINTSTS1 Register Contents (2/2)

Bit Position	Bit Name	Function
0	TSIF4*1	Unit Channel 4 Transmit Buffer Transmit Complete Interrupt Status Flag 0: Transmit buffer transmit complete interrupt is not requested. 1: Transmit buffer transmit complete interrupt is requested.

Note 1. This bit is a reserved bit in (n = 1). When read, the value after reset is returned. When writing to this bit, write the value after reset.

TSIFm Bit

When the RSCANnTMIECy.TMIE bit is set to 1 (transmit buffer interrupt is enabled) and corresponding RSCANnTMSTSp.TMTRF[1:0] flags are set to 10_B (transmission has been completed, without transmit abort request) or 11_B (transmission has been completed, with transmit abort request), the TSIFm bit becomes 1.

The TSIFm flag becomes 0 by setting 00_B to all the TMTRF[1:0] flags which satisfy the condition to lead TSIFm = 1. The TSIFm flag also becomes 0 by setting the TMIE bit to 0.

TAIFm Bit

When the RSCANnCmCTR.TAIE bit is set to 1 (transmit abort interrupt is enabled) and the RSCANnTMSTSp.TMTRF[1:0] flags are 01_B (transmit abort has been completed), the TAIFm bit becomes 1.

The TAIFm flag becomes 0 by setting 00_B to all the TMTRF[1:0] flags of which transmit abort has been completed.

TQIFm Bit

When the RSCANnTXQCCm.TXQIE bit is set to 1 (transmit queue interrupt is enabled) and the RSCANnTXQSTSm.TXQIF bit is set to 1 (a transmit queue interrupt request is present), the TQIFm bit becomes 1.

When the RSCANnTXQSTSm.TXQIF bit (transmit queue interrupt request) is set to 0, the TQIFm bit becomes 0. The TQIFm flag also becomes 0 by setting the TXQIE bit to 0.

CFTIFm Bit

When the RSCANnCFCCk.CFTXIE bit is set to 1 (transmit/receive FIFO transmit interrupt is enabled) and the RSCANnCFSTSk.CFTXIF bit is set to 1 (a transmit/receive FIFO transmit interrupt request is present), the CFTIFm bit becomes 1.

The CFTIFm bit becomes 0 by setting all the RSCANnCFSTSk.CFTXIF bits to 0. The CFTIFm flag also becomes 0 by setting the CFTXIE bit to 0.

THIFm Bit

When the RSCANnTHLCCm.THLIE bit is set to 1 (transmit history interrupt is enabled) and the RSCANnTHLSTSm.THLIF bit is set to 1 (a transmit history interrupt request is present), the THIFm bit becomes 1.

The THIFm bit becomes 0 by setting the RSCANnTHLSTSm.THLIF bit to 0. The THIFm flag also becomes 0 by setting the THLIE bit to 0.

21.3.4.8 RSCANnGFDCFG — Global FD Configuration Register

Value after reset: 0000 0000_H

	—	—	—	—	—	—	—	AFL DAE	—	—	—	AFLPN[4:0]				
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R/W	R	R	R	R/W	R/W	R/W	R/W	R/W

Table 21.38 RSCANnGAFLECTR Register Contents

Bit Position	Bit Name	Function
31 to 9	—	Reserved When read, the value after reset is returned. When writing to these bits, write the value after reset.
8	AFLDAE	Receive Rule Table Write Enable 0: Receive rule table write is disabled. 1: Receive rule table write is enabled.
7 to 5	—	Reserved When read, the value after reset is returned. When writing to these bits, write the value after reset.
4 to 0	AFLPN [4:0]	Receive Rule Table Page Number Configuration A page number can be selected from a range of page 0 (00000 _B) to page 23 (10111 _B) (n = 0). A page number can be selected from a range of page 0 (00000 _B) to page 15 (01111 _B) (n = 1).

AFLDAE Bit

Setting this bit to 0 disables data writing to the receive rule table. After data writing to the receive rule table is completed, set this bit to 0 to disable writing to the receive rule table. The receive rule table can be read regardless of the value of this bit.

Set the AFLDAE bit to 1 in global reset mode.

AFLPN[4:0] Bits

These bits are used to set the page number of the receive rule table. Sixteen receive rules can be set per page.

Set these bits to a value within a range of 00000_B to 10111_B (n = 0).

Set these bits to a value within the range of 00000_B to 01111_B (n = 1).

21.3.5.2 RSCANnGAFLCFG0 — Receive Rule Configuration Register 0

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	RNC0[7:0]								RNC1[7:0]							
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 21.39 RSCANnGAFLCFG0 Register Contents

Bit Position	Bit Name	Function
31 to 24	RNC0[7:0]	Number of Rules for Unit Channel 0 The number of rules for channel 0
23 to 16	RNC1[7:0]	Number of Rules for Unit Channel 1 The number of rules for channel 1
15 to 8	RNC2[7:0]	Number of Rules for Unit Channel 2 The number of rules for channel 2
7 to 0	RNC3[7:0]	Number of Rules for Unit Channel 3 The number of rules for channel 3

Modify the RSCANnGAFLCFG0 register in global reset mode.

Up to “64 × (number of channels)” rules can be registered to the receive rule tables in the entire module. The number of receive rules per channel should meet the following conditions.

- The maximum number of rules per channel is 128.
- The total of the number of rules allocated to each channel is not larger than the number of rules permitted to the entire unit.

RNC0[7:0] Bits

These bits are used to set the number of rules to be registered in the unit channel 0 receive rule table.

Set these bits to a value within a range of 00_H to 80_H.

RNC1[7:0] Bits

These bits are used to set the number of rules to be registered in the unit channel 1 receive rule table.

Set these bits to a value within a range of 00_H to 80_H.

RNC2[7:0] Bits

These bits are used to set the number of rules to be registered in the unit channel 2 receive rule table.

Set these bits to a value within a range of 00_H to 80_H.

RNC3[7:0] Bits

These bits are used to set the number of rules to be registered in the unit channel 3 receive rule table.

Set these bits to a value within a range of 00_H to 80_H.

21.3.5.3 RSCANnGAFLCFG1 — Receive Rule Configuration Register 1

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 21.40 RSCANnGAFLCFG1 Register Contents

Bit Position	Bit Name	Function
31 to 24	RNC4[7:0] ^{*1}	Number of Rules for Unit Channel 4 The number of rules for channel 4
23 to 16	RNC5[7:0] ^{*1}	Number of Rules for Unit Channel 5 The number of rules for channel 5
15 to 0	—	Reserved These bits are always read as 0. The write value should always be 0.

Note 1. These bits are a reserved bit in (n = 1). These bits are always read as 0. The write value should always be 0.

Modify the RSCANnGAFLCFG1 register in global reset mode.

Up to “64 × (number of channels)” rules can be registered to the receive rule tables in the entire module. The number of receive rules per channel should meet the following conditions.

- The maximum number of rules per channel is 128.
- The total number of rules allocated to each channel is not larger than the number of rules permitted to the entire unit.

RNC4[7:0] Bits

These bits are used to set the number of rules to be registered in the unit channel 4 receive rule table.

Set these bits to a value within a range of 00_H to 80_H.

RNC5[7:0] Bits

These bits are used to set the number of rules to be registered in the unit channel 5 receive rule table.

Set these bits to a value within a range of 00_H to 80_H.

21.3.5.4 RSCANnGAFLIDj — Receive Rule ID Register j

Note: For the value of index "j", see **Table 21.8**.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	GAFLIDE	GAFLRTR	GAFLLB	GAFLID[28:16]												
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 21.41 RSCANnGAFLIDj Register Contents

Bit Position	Bit Name	Function
31	GAFLIDE	IDE Select 0: Standard ID 1: Extended ID
30	GAFLRTR	RTR Select 0: Data frame 1: Remote frame
29	GAFLLB	Receive Rule Target Message Select 0: When a message transmitted from another CAN node is received 1: When a message transmitted from own node is received
28 to 0	GAFLID[28:0]	ID Setting Set the ID of the receive rule. For the standard ID, set the ID in bits 10 to 0 and set bits 28 to 11 to 0.

Modify the RSCANnGAFLIDj register when the AFLDAE bit in the RSCANnGAFLECTR register is set to 1 (receive rule table write is enabled) in global reset mode.

GAFLIDE Bit

This bit is used to select the ID format (standard ID or extended ID) of the receive rule. This bit is compared with the IDE bit in the received message during the acceptance filter processing.

GAFLRTR Bit

This bit is used to select the frame format (data frame or remote frame) of the receive rule. This bit is compared with the RTR bit in the received message during the acceptance filter processing.

GAFLLB Bit

Setting this bit to 0 causes data processing to be performed using the receive rule when a message transmitted from another CAN node is received.

Setting this bit to 1 when the mirror function is used causes data processing to be performed using the receive rule when a message transmitted from the own CAN node is received.

GAFLID[28:0] Bits

These bits are used to set the ID field of the receive rule. The ID set by these bits is compared with the ID in the received message during the acceptance filter processing.

21.3.5.5 RSCANnGAFLMj — Receive Rule Mask Register j

Note: For the value of index "j", see **Table 21.8**.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	GAFLIDEM	GAFLRTRM	—	GAFLIDM[28:16]

Table 21.42 RSCANnGAFLMj Register Contents

Bit Position	Bit Name	Function
31	GAFLIDEM	IDE Mask 0: The IDE bit is not compared. 1: The IDE bit is compared.
30	GAFLRTRM	RTR Mask 0: The RTR bit is not compared. 1: The RTR bit is compared.
29	—	Reserved When read, the value after reset is returned. When writing to this bit, write the value after reset.
28 to 0	GAFLIDM [28:0]	ID Mask 0: The corresponding ID bit is not compared. 1: The corresponding ID bit is compared.

Modify the RSCANnGAFLMj register when the AFLDAE bit in the RSCANnGAFLECTR register is set to 1 (receive rule table write is enabled) in global reset mode.

GAFLIDEM Bit

When this bit is set to 1, filter processing is performed only for messages of the ID format specified by the GAFLIDE bit in the RSCANnGAFLIDj register.

When this bit is cleared to 0, the IDs of all the receive messages and the specified IDs are regarded as matched.

To set the GAFLIDEM bit to 0, set all the GAFLIDM[28:0] bits to 0 at the same time.

GAFLRTRM Bit

This bit is used to mask the RTR bit of the receive rule.

GAFLIDM[28:0] Bits

These bits are used to mask the corresponding ID bits of the receive rule.

21.3.5.6 RSCANnGAFLP0_j — Receive Rule Pointer 0 Register j

Note: For the value of index "j", see **Table 21.8**.

Value after reset: 0000 0000_H

Table 21.43 RSCANnGAFLP0_j Register Contents

Bit Position	Bit Name	Function
31 to 28	GAFLDLC [3:0]	Receive Rule DLC Set b31 b30 b29 b28 0 0 0 0: DLC check is disabled. 0 0 0 1: 1 data byte 0 0 1 0: 2 data bytes 0 0 1 1: 3 data bytes 0 1 0 0: 4 data bytes 0 1 0 1: 5 data bytes 0 1 1 0: 6 data bytes 0 1 1 1: 7 data bytes 1 X X X: 8 data bytes
27 to 16	GAFLPTR [11:0]	Receive Rule Label Set Set the 12-bit label information.
15	GAFLRMV	Receive Buffer Enable 0: No receive buffer is used. 1: A receive buffer is used.
14 to 8	GAFLRMDP [6:0]	Receive Buffer Number Select Set the receive buffer number to store received messages.
7 to 0	—	Reserved When read, the value after reset is returned. When writing to these bits, write the value after reset.

Modify the RSCANnGAFLP0_j register when the AFLDAE bit in the RSCANnGAFLECTR register is set to 1 (receive rule table write is enabled) in global reset mode.

GAFLDLC[3:0] Bits

These bits are used to set the minimum data length necessary for receiving messages. If the data length of a message that is being filtered is equal to or larger than the value set by the GAFLDLC[3:0] bits, the message passes the DLC check. Setting these bits to 0000_B disables the DLC check function, allowing messages with any data length to pass the DLC check.

GAFLPTR[11:0] Bits

These bits are used to set a 12-bit label to be attached to messages that have passed through the filter. A label is attached when a message is stored in the receive buffer or the FIFO buffer.

GAFLRMV Bit

When this bit is set to 1, received messages that have passed through the filter are stored in the receive buffer selected by the GAFLRMDP[6:0] bits.

GAFLRMDP[6:0] Bits

These bits are used to select the number of a receive buffer that stores received messages having passed through the filter when the GAFLRMV bit is set to 1. Set these bits to a value smaller than the value set by the NRXMB[7:0] bits in the RSCANnRMNB register.

21.3.5.7 RSCANnGAFLP1_j — Receive Rule Pointer 1 Register j

Note: For the value of index "j", see **Table 21.8**.

Value after reset: 0000 0000_H

Table 21.44 RSCANnGAFLP1_j Register Contents

Bit Position	Bit Name	Function
31 to 26	—	Reserved When read, the value after reset is returned. When writing to these bits, write the value after reset.
25 to 8	GAFLFDP[25:8]*1	Transmit/Receive FIFO Buffer k Select (Bit position –8 = target transmit/receive FIFO buffer number k) 0: Transmit/receive FIFO buffer is not selected. 1: Transmit/receive FIFO buffer is selected.
7 to 0	GAFLFDP[7:0]	Receive FIFO Buffer x Select (Bit position = target receive FIFO buffer number x) 0: Receive FIFO buffer is not selected. 1: Receive FIFO buffer is selected.

Note 1. Bit 25 to 20 are reserved bits in (n = 1). When read, the value after reset is returned. When writing to these bits, write the value after reset.

Modify the RSCANnGAFLP1_j register when the AFLDAE bit in the RSCANnGAFLECTR register is set to 1 (receive rule table write is enabled) in global reset mode.

GAFLFDP [25:0] Bits

These bits are used to specify FIFO buffers that store received messages having passed through the filter. Up to eight FIFO buffers can be selected. However, when the GAFLRMV bit in the RSCANnGAFLP0_j register is set to 1 (a receive buffer is used), up to seven FIFO buffers are selectable. Selectable buffers are receive FIFO buffers and the transmit/receive FIFO buffers for which the CFM[1:0] bits in the RSCANnCFCCk register are set to 00_B (receive mode) or 10_B (gateway mode).

21.3.6 Details of Receive Buffer-Related Registers

21.3.6.1 RSCANnRMNB — Receive Buffer Number Register

Value after reset: 0000 0000_H

Table 21.45 RSCANnRMNB Register Contents

Bit Position	Bit Name	Function
31 to 8	—	Reserved When read, the value after reset is returned. When writing to these bits, write the value after reset.
7 to 0	NRXMB [7:0]	Receive Buffer Number Configuration Set the number of receive buffers. Set a value of 0 to 96 (n = 0). Set a value of 0 to 64 (n = 1).

Modify the RSCANnRMNB register in global reset mode.

NRXMB[7:0] Bits

These bits are used to set the total number of receive buffers of the entire RS-CANFD module. The maximum value is “16 × (number of channels)”.

Setting all of these bits 0 makes receive buffers unavailable.

21.3.6.2 RSCANnRMNDy — Receive Buffer New Data Register y

Note: For the value of index "y", see **Table 21.8**.

Value after reset: 0000 0000_H

Table 21.46 RSCANnRMNDy Register Contents

Bit Position	Bit Name	Function
31 to 0	RMNSq	Receive Buffer Receive Complete Flag q (q = y × 32 + 31 to y × 32 + 0) 0: Receive buffer q contains no new message. 1: Receive buffer q contains a new message.

Write 0 to the RSCANnRMNDy register in global operating mode or global test mode.

RMNSq Flags (q = see Table 21.8)

Each flag is set to 1 when a process starts to store a message in the corresponding receive buffer.

To clear these flags to 0, write 0 by the program. Use a store instruction to write "0" to the flag and "1" to other flags.

These bits cannot be set to 0 while a message is being stored. Time for storing a message is 10 pclk clock cycles.

These flags are cleared to 0 in global reset mode.

21.3.6.3 RSCANnRMIDq — Receive Buffer ID Register q

Note: For the value of index "q", see **Table 21.8**.

Value after reset: 0000 0000_H

30	RMRTR	Receive Buffer RTR 0: Data frame 1: Remote frame
29	—	Reserved When read, the value after reset is returned. When writing to these bits, write the value after reset.
28 to 0	RMID [28:0]	Receive Buffer ID Data The standard ID or extended ID of received message can be read. Read bits b10 to b0 for standard ID. Bits b28 to b11 are read as 0.

RMIDE Bit

This bit indicates the ID format (standard ID or extended ID) of the message stored in the receive buffer.

RMRTR Bit

This bit indicates the frame format (data frame or remote frame) of the message stored in the receive buffer.

RMID[28:0] Bits

These bits indicate the ID of the message stored in the receive buffer.

21.3.6.4 RSCANnRMPTRq — Receive Buffer Pointer Register q

Note: For the value of index "q", see **Table 21.8**.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 21.48 RSCANnRMPTRq Register Contents

Bit Position	Bit Name	Function
31 to 28	RMDLC [3:0]	Receive Buffer DLC Data b31 b30 b29 b28 0 0 0 0: No data byte 0 0 0 1: 1 data byte 0 0 1 0: 2 data bytes 0 0 1 1: 3 data bytes 0 1 0 0: 4 data bytes 0 1 0 1: 5 data bytes 0 1 1 0: 6 data bytes 0 1 1 1: 7 data bytes 1 X X X: 8 data bytes
27 to 16	RMPTR [11:0]	Receive Buffer Label Data Label information of the received message can be read.
15 to 0	RMTS [15:0]	Receive Buffer Timestamp Data Timestamp value of the received message can be read.

RMDLC[3:0] Bits

These bits indicate the data length of the message stored in the receive buffer.

RMPTR[11:0] Bits

These bits indicate the label information of the message stored in the receive buffer.

RMTS[15:0] Bits

These bits indicate the timestamp value of the message stored in the receive buffer.

21.3.6.5 RSCANnRMDF0_q — Receive Buffer Data Field 0 Register q

Note: For the value of index "q", see **Table 21.8**.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

12	RFIM	Receive FIFO Interrupt Source Select 0: An interrupt occurs when the condition set by the RFIGCV[2:0] bits is met. 1: An interrupt occurs each time a message has been received.
11	—	Reserved When read, the value after reset is returned. When writing to these bits, write the value after reset.
10 to 8	RFDC [2:0]	Receive FIFO Buffer Depth Configuration b10 b9 b8 0 0 0: 0 messages 0 0 1: 4 messages 0 1 0: 8 messages 0 1 1: 16 messages 1 0 0: 32 messages 1 0 1: 48 messages 1 1 0: 64 messages 1 1 1: 128 messages
7 to 2	—	Reserved When read, the value after reset is returned. When writing to these bits, write the value after reset.

Table 21.51 RSCANnRFCCx Register Contents (2/2)

Bit Position	Bit Name	Function
1	RFIE	Receive FIFO Interrupt Enable 0: Receive FIFO interrupt is disabled. 1: Receive FIFO interrupt is enabled.
0	RFE	Receive FIFO Buffer Enable 0: No receive FIFO buffer is used. 1: Receive FIFO buffers are used.

RFIGCV[2:0] Bits

These bits are used to specify the number of received messages required to generate a receive FIFO interrupt request when the RFIM bit is set to 0 with a fraction for the total number of buffers (the setting of RFDC[2:0]).

When the RFDC[2:0] bits are set to 001_B (4 messages), set the RFIGCV[2:0] bits to 001_B, 011_B, 101_B, or 111_B. Modify these bits in global reset mode.

RFIM Bit

This bit is used to select a FIFO interrupt source. Modify this bit in global reset mode.

RFDC[2:0] Bits

These bits are used to select the number of messages that can be stored in a single receive FIFO buffer. If these bits are set to 000_B, do not use any receive FIFO buffer. Modify these bits in global reset mode.

RFIE Bit

Setting the RFIE bit to 1 enables receive FIFO interrupts. Modify this bit with the RFE bit is set to 0 (no receive FIFO buffer is used).

RFE Bit

Setting the RFE bit to 1 enables the use of receive FIFO buffers. Clearing this bit to 0 sets the RFEMP flag in the RSCANnRFSTs_x register to 1 (the receive FIFO buffer contains no unread message (buffer empty)). Modify this bit in global operating mode or global test mode.

Set this bit to 1 with another instruction after the settings to all bits in the RSCANnRFCC_x register have been done.

This bit is cleared to 0 in global reset mode.

21.3.7.2 RSCANnRFSTx — Receive FIFO Buffer Status Register x

Note: For the value of index "x", see **Table 21.8**.

Value after reset: 0000 0001_H

R/W	R	R	R	R	R	R	R	R	R	R	R	R	R/W*1	R/W*1	R	R

Note 1. The only effective value for writing to this flag bit is 0, which clears the status. Any other writing to the bit results in retention of the status and does not change the value.

Table 21.52 RSCANnRFSTx Register Contents

Bit Position	Bit Name	Function
31 to 16	—	Reserved When read, the value after reset is returned. When writing to these bits, write the value after reset.
15 to 8	RFMC[7:0]	Receive FIFO Unread Message Counter The number of unread messages stored in the receive FIFO buffer is displayed.
7 to 4	—	Reserved When read, the value after reset is returned. When writing to these bits, write the value after reset.
3	RFIF	Receive FIFO Interrupt Request Flag 0: No receive FIFO interrupt request is present. 1: A receive FIFO interrupt request is present.
2	RFMLT	Receive FIFO Message Lost Flag 0: No receive FIFO message is lost. 1: A receive FIFO message is lost.
1	RFFLL	Receive FIFO Buffer Full Status Flag 0: The receive FIFO buffer is not full. 1: The receive FIFO buffer is full.
0	RFEMP	Receive FIFO Buffer Empty Status Flag 0: The receive FIFO buffer contains unread messages. 1: The receive FIFO buffer contains no unread message (buffer empty).

RFMC[7:0] Flags

These flags indicate the number of unread messages in the receive FIFO buffer. These flags become 00_H when the RFE bit in the RSCANnRFCCx register is set to 0.

This flag is 00_H in global reset mode.

RFIF Flag

This flag is set to 1 when the conditions for receive FIFO interrupt request generation set by the RFIGCV[2:0] bits and the RFIM bit in the RSCANnRFCCx register are satisfied. This flag is cleared to 0 in global reset mode or by writing 0 to this flag. Modify this bit in global operating mode or global test mode.

To clear the flags of the register to 0, the program must write 0 to the corresponding flags to be cleared.

When writing 0, using store instruction, set the bit to be set to “0” to “0”, and the bits not to be set to “0” to “1”.

RFMLT Flag

This flag is set to 1 if it is attempted to store a new message when the receive FIFO buffer is full. In this case, the new message is discarded.

This flag is cleared to 0 in global reset mode or by writing 0 to this flag.

Modify this bit in global operating mode or global test mode.

To clear the flag of the register to 0, the program must write 0 to the given flag. When writing 0, use a store instruction to write 0 to the given flag and 1 to the other flags.

RFLL Flag

This flag is set to 1 when the number of messages stored in the receive FIFO buffer matches the FIFO buffer depth set by the RFDC[2:0] bits in the RSCANnRFCCx register.

If the number of messages stored in the receive FIFO buffer becomes smaller than the FIFO buffer depth set by the RFDC[2:0] bits, this flag is cleared to 0. This flag is also cleared to 0 when the RFE bit in the RSCANnRFCCx register is set to 0 (no receive FIFO buffer is used) or in global reset mode.

RFEMP Flag

This flag is set to 1 when all messages in the receive FIFO buffer have been read. This flag is also set to 1 when the RFE bit in the RSCANnRFCCx register is 0 or in global reset mode.

This flag is cleared to 0 when even a single received message is stored in the receive FIFO buffer.

NOTE

To clear the RFMLT or RFIF flag to 0, use a store instruction to write “0” to the given flag and “1” to the other flags. Note that when using a bit-manipulation instruction for writing to this register, the read-modify-write operation may inadvertently clear the flags.

21.3.7.3 RSCANnRFPCTR_x — Receive FIFO Buffer Pointer Control Register x

Note: For the value of index "x", see **Table 21.8**.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	RFPC[7:0]							
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 21.53 RSCANnRFPCTR_x Register Contents

Bit Position	Bit Name	Function
31 to 8	—	Reserved When writing to these bits, write the value after reset.
7 to 0	RFPC [7:0]	Receive FIFO Pointer Control When FF _H is written to these bits, the read pointer moves to the next unread message in the receive FIFO buffer.

RFPC[7:0] Bits

When FF_H is written to the RFPC[7:0] bits, the read pointer moves to the next unread message in the receive FIFO buffer. At this time, the RFMC[7:0] (receive FIFO unread message counter) value in the RSCANnRFSTS_x register is decremented by 1. Read the RSCANnRFID_x, RSCANnRFPTR_x, RSCANnRFDFO_x, and RSCANnRFD1_x registers to read messages in the receive FIFO buffer, and then write FF_H to the RFPC[7:0] bits.

Write FF_H to these bits when the RFE bit in the RSCANnRFCC_x register is set to 1 (receive FIFO buffers are used) and the RFEMP flag in the RSCANnRFSTS_x register is 0 (the receive FIFO buffer contains unread messages).

21.3.7.4 RSCANnRFIDx — Receive FIFO Buffer Access ID Register x

Note: For the value of index "x", see **Table 21.8**.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 21.54 RSCANnRFIDx Register Contents

Bit Position	Bit Name	Function
31	RFIDE	Receive FIFO Buffer IDE 0: Standard ID 1: Extended ID
30	RFRTTR	Receive FIFO Buffer RTR 0: Data frame 1: Remote frame
29	—	Reserved When read, the value after reset is returned.
28 to 0	RFID [28:0]	Receive FIFO Buffer ID Data The standard ID or extended ID of received message can be read. Read bits b10 to b0 for standard ID. Bits b28 to b11 are read as 0.

RFIDE Bit

This bit indicates the ID format (standard ID or extended ID) of the message stored in the receive FIFO buffer.

RFRTTR Bit

This bit indicates the frame format (data frame or remote frame) of the message stored in the receive FIFO buffer.

RFID[28:0] Bits

These bits indicate the ID of the message stored in the receive FIFO buffer.

21.3.7.5 RSCANnRFPTRx — Receive FIFO Buffer Access Pointer Register x

Note: For the value of index "x", see **Table 21.8**.

Value after reset: 0000 0000_H

Table 21.55 RSCANnRFPTRx Register Contents

Bit Position	Bit Name	Function
31 to 28	RFDLC [3:0]	Receive FIFO Buffer DLC Data b31 b30 b29 b28 0 0 0 0: 0 data bytes 0 0 0 1: 1 data byte 0 0 1 0: 2 data bytes 0 0 1 1: 3 data bytes 0 1 0 0: 4 data bytes 0 1 0 1: 5 data bytes 0 1 1 0: 6 data bytes 0 1 1 1: 7 data bytes 1 X X X: 8 data bytes
27 to 16	RFPTR [11:0]	Receive FIFO Buffer Label Data Label information of the received message can be read.
15 to 0	RFTS [15:0]	Receive FIFO Buffer Timestamp Data Timestamp value of the received message can be read.

RFDLC[3:0] Bits

These bits indicate the data length of the message stored in the receive FIFO buffer.

RFPTR[11:0] Bits

These bits indicate the label information of the message stored in the receive FIFO buffer.

RFTS[15:0] Bits

These bits indicate the timestamp value of the message stored in the receive FIFO buffer.

21.3.7.6 RSCANnRFDF0_x — Receive FIFO Buffer Access Data Field 0 Register x

Note: For the value of index "x", see **Table 21.8**.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	RFDB3[7:0]								RFDB2[7:0]

Table 21.56 RSCANnRFDF0_x Register Contents

Bit Position	Bit Name	Function
31 to 24	RFDB3 [7:0]	Receive FIFO Buffer Data Byte 3
23 to 16	RFDB2 [7:0]	Receive FIFO Buffer Data Byte 2
15 to 8	RFDB1 [7:0]	Receive FIFO Buffer Data Byte 1
7 to 0	RFDB0 [7:0]	Receive FIFO Buffer Data Byte 0

Data in the message stored in the receive FIFO buffer can be read.

When the RFDLC[3:0] value in the RSCANnRFPTRx register is smaller than 1000_B, data bytes for which no data is set are read as 00_H.

21.3.7.7 RSCANnRFDF1_x — Receive FIFO Buffer Access Data Field 1 Register x

Note: For the value of index "x", see **Table 21.8**.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
