39.3.2 List of Registers for the FIFO Macro

Table 39.12 lists the registers and memory addresses of the FIFO macro. 8, 16, or 32-bit write access to all registers is possible. 32-bit read access to all registers is possible.

Table 39.12 List of the Control Registers for the FIFO Macro

Module Name	Register Name	Symbol	Address	Access Size	Access Protect
DFE FIFO	Buffer A Common Control Register	DFBFACCTL	< DFE_FIFO_base > + 0000 _H	8, 16, 32	—
DFE FIFO	Buffer A Control Register (FCH0)	DFBFACTLCH0	< DFE_FIFO_base > + 0010 _H	8, 16, 32	—
DFE FIFO	Buffer A Control Register (FCH1)	DFBFACTLCH1	< DFE_FIFO_base > + 0014 _H	8, 16, 32	—
DFE FIFO	Buffer A Control Register (FCH2)	DFBFACTLCH2	< DFE_FIFO_base > + 0018 _H	8, 16, 32	—
DFE FIFO	Buffer A Control Register (FCH3)	DFBFACTLCH3	< DFE_FIFO_base > + 001C _H	8, 16, 32	—
DFE FIFO	Buffer A Control Register (FCH4)	DFBFACTLCH4	< DFE_FIFO_base > + 0020 _H	8, 16, 32	—
DFE FIFO	Buffer A Control Register (FCH5)	DFBFACTLCH5	< DFE_FIFO_base > + 0024 _H	8, 16, 32	—
DFE FIFO	Buffer A Control Register (FCH6)	DFBFACTLCH6	< DFE_FIFO_base > + 0028 _H	8, 16, 32	—

39.3.3 DFEjCTLACHn — Control Register A n (n = 0 to 15 for DFE0, n = 0 to 3 for DFE1)

This register is used to execute filter processing, control interrupt requests, and set channel tag and cascade tag for each channel.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Note: While the setting of DFEjCTLACHn.EN or DFEjSTCHn.VALID is 1, writing to CATAG, CAEN, TAG, CMD, FMT, IEP, IEE, IEC, IEO, CNSL, CNSLE and AIME is prohibited.

Table 39.13 DFEjCTLACHn Register Contents (1/3)

Bit Position	Bit Name	Function										
31	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.										
30 to 26	CATAG	Tag Value (Cascade Tag) for Reentering the Filter Result (Cascade Input) 00000 _B to 11111 _B : Output data of the accumulation circuit is reentered (cascaded) during execution (CAEN = 10 _B or 11 _B). A channel tag value (DFEjCTLACHn.TAG) is specified. When cascading is off (CAEN = 00 _B or 01 _B), all CATAG settings are ignored.										
25, 24	CAEN	Cascade Enable 00 _B : Cascade is disabled. Output data of the accumulation circuit is written to the output data register. 01 _B : Setting prohibited 10 _B : Cascade is enabled. Output data of the accumulation circuit is written to the output data register. 11 _B : Cascade is enabled. Output data of the accumulation circuit is not written to the output data register.										
23 to 21	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.										
20 to 16	TAG	Channel Tag 00000 _B to 11111 _B : The following four types of filtering process are enabled when the TAG for this channel and the tags to be filtered are set to the same value and a request is issued:										
		<table border="1"> <thead> <tr> <th>Objects of Filtering Process</th> <th>TAG Settings</th> </tr> </thead> <tbody> <tr> <td>AD input data</td> <td>Same value as the tag value [3:0] for AD*1</td> </tr> <tr> <td>Software input data</td> <td>Same value as DFEjDI.TAG [4:0]</td> </tr> <tr> <td>Cascading input on other channels</td> <td>Same value as DFEjCTLACHn.CATAG [4:0]</td> </tr> <tr> <td>Cascading input on the subtraction channel</td> <td>Same value as DFEjSUBCTLACHnCATAG [4:0]</td> </tr> </tbody> </table>	Objects of Filtering Process	TAG Settings	AD input data	Same value as the tag value [3:0] for AD*1	Software input data	Same value as DFEjDI.TAG [4:0]	Cascading input on other channels	Same value as DFEjCTLACHn.CATAG [4:0]	Cascading input on the subtraction channel	Same value as DFEjSUBCTLACHnCATAG [4:0]
Objects of Filtering Process	TAG Settings											
AD input data	Same value as the tag value [3:0] for AD*1											
Software input data	Same value as DFEjDI.TAG [4:0]											
Cascading input on other channels	Same value as DFEjCTLACHn.CATAG [4:0]											
Cascading input on the subtraction channel	Same value as DFEjSUBCTLACHnCATAG [4:0]											
		Note 1. Set the TAG [4] to 0, to correspond to the AD TAG value.										

Table 39.13 DFEjCTLACHn Register Contents (2/3)

Bit Position	Bit Name	Function
15 to 12	CMD	Filter Processing Select 0000 _B : FIR 8TAP 0001 _B : FIR 16TAP 0010 _B : FIR 24TAP 0011 _B : FIR 32TAP 0100 _B : Setting prohibited 0101 _B : Setting prohibited 0110 _B : Setting prohibited 0111 _B : FIR 64TAP*1 1000 _B : IIR secondary biquad 1 stage 1001 _B : IIR secondary biquad 2 stages 1010 _B : IIR secondary biquad 3 stages 1011 _B to 1100 _B : Setting prohibited 1101 _B : IIR secondary biquad 2 stages with a gain adjustment function 1110 _B : IIR secondary biquad 3 stages with a gain adjustment function 1111 _B : Setting prohibited Note 1. FIR64TAP can be selected only on even-numbered channels. If FIR64TAP is selected on an even-numbered channel n, the use of the next odd-numbered channel n + 1 is prohibited.
11 to 9	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
8	FMT	FIR Input Data Format Select 0: Input data format = 16-bit fixed-point decimal number (value after a reset) 1: Input data format = 16-bit integer To execute accumulation processing or floating-point processing, specify 16-bit fixed-point.
7	IEP	PH End Interrupt Request Enable 0: Disables interrupt requests at the end of PH. (Value after a reset) 1: Enables interrupt requests at the end of PH. CAUTION: Enabled when PH and comparison are used simultaneously (DFEjTLBCHn.PRC5B = 11 _B).
6	IEE	Error Interrupt Request Enable 0: An error interrupt request is disabled: Value after a reset. 1: An error interrupt request is enabled.
5	IEC	Condition Match Interrupt Request Enable 0: A peak-hold end interrupt request is disabled when peak-hold operation is specified: value after a reset. When comparison calculation is specified, an interrupt request when the comparison calculation result is true is disabled: Value after a reset. 1: A peak-hold end interrupt request is enabled when peak-hold operation is specified. When a comparison calculation is specified, an interrupt request when the comparison calculation result is true is enabled.
4	IEO	Output Data Interrupt Request Enable 0: An output data interrupt when the result of calculation is written to the output data register (and the intermediate values output register) is disabled: value after a reset. 1: An output data interrupt when the result of calculation is written to the output data register (and the intermediate values output register) is enabled.

Table 39.13 DFEjCTLACHn Register Contents (3/3)

Bit Position	Bit Name	Function
3	CNSL	Condition Match Interrupt 0/1 Function Selection 0: Value after a reset INT_DFE_CND0: Selects a comparison match interrupt request. INT_DFE_CND1: Selects a PH end interrupt request. 1: INT_DFE_CND0: Selects a PH end interrupt request. INT_DFE_CND1: Selects a comparison match interrupt request. CAUTION: Enabled when PH and comparison are used simultaneously (DFEjCTLBCHn.PRC SB = 11 _B).
2	CNSLE	CNSL Enable 0: CNSL bit settings disabled. (Value after a reset) When PH and comparison are used simultaneously (DFEjCTLBCHn.PRC SB = 11 _B), the following functions are enabled: INT_DFE_CND0: Comparison match interrupt request INT_DFE_CND1: PH end interrupt request 1: CNSL bit settings enabled. Note: When either PH or comparison is specified (DFEjTLBCHn.PRC SB = 01 _B , 10 _B), INT_DFE_CND0/1 act as the following functions: INT_DFE_CND0: Comparison match interrupt request INT_DFE_CND1: No functions CAUTION: Enabled when PH and comparison are used simultaneously (DFEjCTLBCHn.PRC SB = 11 _B).
1	AIME	Automatic Initialization Enable 0: Automatic initialization function disabled. (Value after a reset) 1: Automatic initialization function enabled.
0	EN	Channel Enable 0: Channel disabled No processing is executed for this channel: Value after a reset. 1: Channel enabled Processing is executed for this channel.

When the automatic initialization function is enabled (DFEjCTLACHn.AIME = 1), on this channel the automatic initialization flag is enabled upon the rise of this bit (0 → 1).

Even when the automatic initialization function is disabled (DFEjCTLACHn.AIME = 0), the rise of this bit (0 → 1) is detected, and the automatic initialization flag is also enabled when AIME = 1 and EN = 1 are written simultaneously.

When the filtering request that is input is enabled after the automatic initialization flag is enabled, automatic initialization is executed during the pertinent filtering process.

CAUTION

If FIR64TAP is selected on an even-numbered channel n, it is prohibited to set the EN bit to 1 on the next odd-numbered channel n + 1 (even if the bit is set to 1, no trigger input will be accepted).

39.3.4 DFEjCTLBCHn — Control Register B n (n = 0 to 15 for DFE0, n = 0 to 3 for DFE1)

This register is used to set floating-point conversion, absolute value conversion, accumulation/decimation processing, and peak-hold/comparison processing.

All the bits can be set on even-numbered channels. However, the DFEjCTLBCHn.HOFS bit is not implemented on odd-numbered channels since those channels do not have an intermediate value output register.

Value after reset: 0101 0000_H

Calculation of "equal to (==)" for the comparison target register selected by DFEjCTLBCHn.SELB1 and peak-hold circuit input data is performed: Value after a reset. 001_B: "Equal to or less than (≤)" is selected. Calculation of "equal to or less than (≤)" for the comparison target register selected by DFEjCTLBCHn.SELB1 and peak-hold circuit input data is performed. 010_B: "Equal to or more than (≥)" is selected. Calculation of "equal to or more than (≥)" for the comparison target register selected by DFEjCTLBCHn.SELB1 and peak-hold circuit input data is performed. 011_B: "Less than (<)" is selected. Calculation of "less than (<)" for the comparison target register selected by DFEjCTLBCHn.SELB1 and peak-hold circuit input data is performed. 100_B: "More than (>)" is selected. Calculation of "more than (>)" for the comparison target register selected by DFEjCTLBCHn.SELB1 and peak-hold circuit input data is performed. 101_B to 111_B: Setting prohibited</p>

Table 39.14 DFEjCTLBCHn Register Contents (4/5)

Bit Position	Bit Name	Function
11, 10	SELB1	<p>Comparison Target Register Select</p> <p>When comparison is specified exclusively (DFEjCTLBCHn.PRCSB = 2b10) or when PH and comparison are used simultaneously (DFEjCTLBCHn.PRCSB = 2b11) and DFEjCTLBCHn.CPCS = 0.</p> <p>00_B: DFEjCPA register value is selected for the comparison calculation target value. 01_B: DFEjCPB register value is selected for the comparison calculation target value. 10_B: DFEjCPC register value is selected for the comparison calculation target value. 11_B: DFEjCPD register value is selected for the comparison calculation target value.</p> <p>Enabled when PH and comparison are used simultaneously (DFEjCTLBCHn.PRCSB = 2b11) and DFEjCTLBCHn.CPCS = 1</p> <p>00_B: The following value is selected for the comparison operation [Peak-Hold Result Register (DFEjPHCHn) + Comparison Offset Value Setting Register (DFEjCPOFSTn)]: Value after a reset. 01_B- 11_B: Setting prohibited.</p> <p>Note: Comparison offset value α is selected by Comparison offset value α Select (DFEjCTLBCHn.OFSL).</p>
9, 8	PRCSB	<p>Peak-Hold Circuit Processing Select</p> <p>00_B: Neither peak-hold processing nor comparison calculation processing is executed. 01_B: Peak-hold processing is executed. 10_B: Comparison calculation processing is executed. 11_B: Peak-Hold and comparison are executed simultaneously</p>
7	HOFS	<p>Intermediate Values Output Register Floating-Point Conversion</p> <p>0: Floating-point conversion for DFEjHOHCH and DFEjHOLCH is not executed: Value after a reset. 1: Floating-point conversion for DFEjMOHCH and DFEjMOLCH is executed. The setting of this bit is effective while DFEjCTLBCHn.PRCSC = 0. Fixed-point format is converted to floating-point (IEEE754). This bit must not be set to 1 if the setting of DFEjCTLACHn.FMT = 1 (integer mode) and DFEjCTLBCHn.PRCSC = 1 (output data register floating-point converted) when FIR is selected.</p> <p>Note: This bit is not implemented on odd-numbered channels.</p>
6	PICS	<p>Peak-Hold Index Register Control Select (not supported by channels 10 to 15)</p> <p>0: Peak-hold index updating mode (value after a reset) Following the completion of peak-hold processing, the peak-hold index register is cleared before the start of a next round of peak-hold processing. 1: Peak-hold index-retention mode After the completion of peak-hold processing, the peak-hold index register retains its value until it is read (clearing of the index register proceeds when the next round of peak-hold processing is started).</p>
5, 4	SELA	<p>Accumulation/Decimation Count Register Select</p> <p>00_B: DFEjACA value is selected for the accumulation/decimation count. 01_B: DFEjACB value is selected for the accumulation/decimation count. 10_B: DFEjACC value is selected for the accumulation/decimation count. 11_B: DFEjACD value is selected for the accumulation/decimation count.</p>

Table 39.14 DFEjCTLBCHn Register Contents (5/5)

Bit Position	Bit Name	Function
3	PFMT	<p>PH Result Register Floating-Point Conversion Execution</p> <p>0: Does not execute floating-point conversion on DFEjPHCH. 1: Executes floating-point conversion on DFEjPHCH. Converts the fixed-point format (S.31/S9.22) to the floating-point format (IEEE754). When FIR is selected and DFEjCTLACHn.FMT = 1 (integer mode), it is prohibited to set PFMT to 1.</p> <p>CAUTION: Enabled when PH is specified (DFEjCTLBCHn.PRC SB = 01_B or 11_B).</p>
2	ABS	<p>Absolute Value Calculation</p> <p>0: Absolute value calculation for the filter result is not performed. 1: Absolute value calculation for the filter result is performed.</p>
1, 0	PRCSA	<p>Accumulation Circuit Processing Select</p> <p>00_B: Neither accumulation processing nor decimation processing is executed. 01_B: Accumulation processing is executed. 10_B: Decimation processing is executed. 11_B: Setting prohibited.</p>

39.3.5 DFEjDOCHn — Output Data Register n (n = 0 to 15 for DFE0, n = 0 to 3 for DFE1)

This register is used to store the calculation results for each channel after DFE processing has been completed.

Value after reset: 0000 0000_H

Table 39.15 DFEjDOCHn Register Contents

Bit Position	Bit Name	Function
31 to 0	DO	Output Data These bits show the DFE processing calculation results.

Figure 39.4 Format of Output Data Register Value

39.3.6 DFEjPHCHn — Peak-Hold Result Register n (n = 0 to 15 for DFE0, n = 0 to 3 for DFE1)

This register is used to store the peak-hold processing result value.

Value after reset: 8000 0000_H

Table 39.16 DFEjPHCHn Register Contents

Bit Position	Bit Name	Function
31 to 0	PH	Peak-Hold Result Data These bits show the peak-hold processing calculation results.

Figure 39.5 Format of Peak-Hold Result Register Value

39.3.7 DFEjPHINDCHn — Peak-Hold Index Register n (n = 0 to 15 for DFE0, n = 0 to 3 for DFE1)

These registers hold the number of rounds of peak-hold processing that have occurred when the peak-hold result register is updated.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 39.17 DFEjPHINDCHn Register Contents (1/2)

Bit Position	Bit Name	Function
31 to 16	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
15	PHIOW	Peak-Hold Index Overwrite Flag 0: PHIND has not been overwritten: Value after a reset. This flag becomes 0 when 1 is written to DFEjCLRSTCHn.CLRPHIOW. 1: PHIND has been overwritten in peak-hold index updating mode. This flag is valid in peak-hold index updating mode. It is always 0 in peak-hold index retention mode.
14	PHIOF	Peak-Hold Index Overflow Flag 0: The number of rounds of peak-hold processing has not overflowed (≤ 16383 times): Value after a reset. • If the peak-hold initialization flag is raised in peak-hold index updating mode, peak-hold processing clears it to 0. • In peak-hold index-retention mode, the peak-hold initialization flag is raised after the peak-hold index register is read, and processing of the first value for peak-hold processing clears it to 0. 1: The number of rounds of peak-hold processing has overflowed (> 16383 times). The number of rounds of peak-hold processing is counted from the time of input to the peak-hold initialization flag to the time of input to the peak-hold end flag.

Table 39.17 DFEjPHINDCHn Register Contents (2/2)

Bit Position	Bit Name	Function
13 to 0	PHIND	<p>Peak-Hold Index</p> <p>0_H: Value after a reset</p> <ul style="list-style-type: none"> In peak-hold index-updating mode: Indicates that the first condition for peak-hold updating is not satisfied when the peak-hold initialization flag has been raised. In peak-hold index-retention mode: Indicates that the first condition for peak-hold updating is not satisfied when the peak-hold initialization flag has been raised after the peak-hold index register has been read. <p>1_H: Indicates that the value for the first input to the peak-hold circuit has been written to the peak-hold result register.</p> <p>2_H: Indicates that the value for the second input to the peak-hold circuit has been written to the peak-hold result register.</p> <p>:</p> <p>3FFF_H: Indicates that the value for the 16383rd input to the peak-hold circuit has been written to the peak-hold result register.</p> <p>When the condition for peak-hold updating has been satisfied and the value is stored in the peak-hold result register, the DFEjPHIND register captures the number of values to which peak-hold processing has been applied (the value of the peak-hold counter within the digital filter).</p> <p>After the value of PHIOF becomes "1" when the number of rounds of peak-hold processing reaches and exceeds 16384, operation of the peak-hold counter continues and PHIND continues to be updated.</p>

39.3.8 DFEjSTCHn — Status Register n (n = 0 to 15, for DFE0, n = 0 to 3 for DFE1)

This register is used to indicate channel status.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 39.18 DFEjSTCHn Register Contents (1/4)

Bit Position	Bit Name	Function
31 to 19	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
18 to 16	PH23ST	<p>PH23 Processing Status</p> <p>000_B: This indicates that PH23 function is in an invalid state (value after a reset). When 0 is written to DFEjPH23CCTL0.PEN, PH23ST whose target channel of DFEjPH23CCTL0.CHS is set to 000_B. PH23ST[2:0] is set to 000_B, when the filter processing is executed after the auto initialization flag which is PH23 processing target channel is valid.</p> <p>001_B: This indicates that PH1 processing is in a valid state. This indicates that PH2 processing is in an invalid state. This indicates that PH3 processing is in an invalid state. PH23ST[2:0] is set to 001_B, when the filter processing whose PH1 initialization flag is valid is executed.</p> <p>010_B: This indicates that PH1 processing is in a finished state. This indicates that PH2 processing is in a running state. This indicates that PH3 processing is in an invalid state. PH23ST[2:0] is set to 010_B, when the comparison calculation result of PH1 is true.</p> <p>011_B: This indicates that PH1 processing is in a finished state. This indicates that PH2 processing is in a finished state. This indicates that PH3 processing is in a running state. PH23ST[2:0] is set to 011_B, when the comparison calculation result of PH2 is true.</p> <p>100_B: This indicates that PH1 processing is in a finished state. This indicates that PH2 processing is in a finished state. This indicates that PH3 processing is in a finished state. PH23ST[2:0] is set to 100_B, when the comparison calculation result of PH3 is true.</p> <p>101_B to 111_B: Other than above: Setting prohibited.</p> <p>CAUTION: The PH23ST is enabled only when the PH23 function is enabled (DFEjPH23CCTL0.PEN = 1 and DFEjPH23CCTL0.CHS is set to the target channel)</p>

Table 39.18 DFEjSTCHn Register Contents (2/4)

Bit Position	Bit Name	Function
15 to 13	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
12	VALID	Input Data Register Valid 0: Input data register value is invalid. This indicates that there is no data to be processed: Value after a reset. 1: Input data register value is valid. This bit is set to 1 when data to be processed is input to the input data register, and is cleared to 0 when the data has been processed in the accumulation circuit.
11	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
10	PHE	Peak-Hold End 0: Value after a reset This indicates that the peak-hold end flag is invalid. This is set to 0 when PHE = 1 and DFEjCLRSTCHn.CLRPHE is written to 1. 1: This indicates that the peak-hold end flag was valid and the filter processing was finished. This is set to 1 when PHE = 0 and the filter processing for the peak-hold is finished. CAUTION: Enabled when PH and comparison are used simultaneously (DFEjCTLBCHn.PRCBSB = 11 _B).
9	CND	Condition Match When peak-hold operation is specified exclusively (DFEjCTLBCHn.PRCBSB = 01 _B) 0: Value after a reset This indicates that the peak-hold end flag is invalid. This is set to 0 when CND = 1 and DFEjCLRSTCHn.CLRCND is written to 1. 1: This indicates that that the peak-hold end flag was valid and the filter processing was finished. This is set to 1 when CND = 0 and the filter processing for the peak-hold was finished. Note: When PH and comparison are used simultaneously (DFEjCTLBCHn.PRCBSB = 11 _B), the PHE bit performs this function. When comparison is specified exclusively (DFEjCTLBCHn.PRCBSB = 10 _B) or when PH and comparison are used simultaneously (DFEjCTLBCHn.PRCBSB = 11 _B) 0: Value after a reset This indicates that the condition of a comparison calculation does not match. This is set to 0 when CND = 1 and DFEjCLRSTCHn.CLRCND is written to 1. 1: This indicates that the condition of a comparison calculation is a match. This is set to 1 when CND = 0 and the comparison calculation result is true.

3	MSKMER	Multiplication Error Bit (DFEjSTCHn.MER) Mask 0: The multiplication error bit (DFEjSTCHn.MER) is not masked: Value after a reset. 1: The multiplication error bit (DFEjSTCHn.MER) is masked.
2	MSKGER	Guard Error Bit (DFEjSTCHn.GER) Mask 0: The guard error bit (DFEjSTCHn.GER) is not masked: Value after a reset. 1: The guard error bit (DFEjSTCHn.GER) is masked.
1	MSKDOOW	Output Data Overwrite Error Bit (DFEjSTCHn.DOOW) Mask 0: The output data overwrite error bit (DFEjSTCHn.DOOW) is not masked: Value after a reset. 1: The output data overwrite error bit (DFEjSTCHn.DOOW) is masked.
0	MSKDIOW	Input Data Overwrite Error Bit (DFEjSTCHn.DIOW) Mask 0: The input data overwrite error bit (DFEjSTCHn.DIOW) is not masked: Value after a reset. 1: The input data overwrite error bit (DFEjSTCHn.DIOW) is masked.

39.3.11 DFEjTRGCHn — Trigger Setting Register n (n = 0 to 15 for DFE0, n = 0 to 3 for DFE1)

This register is used to set the generation of trigger flags by using software triggers or timer triggers. It is prohibited to set both the initialization flag and end flag as a software trigger for the peak-hold processing. Furthermore, it is prohibited to set both the initialization flag and the disable flag as a software trigger for the accumulation/decimation processing. Any operation under prohibited settings is not guaranteed.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

39.3.13 DFEjTRHCHn — Trigger History Register n (n = 0 to 15 for DFE0, n = 0 to 3 for DFE1)

This register is used to monitor the execution history of software triggers, timer triggers, and trigger flags.

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	PMITS	PMETS	PITS	PETS	MITS	METS	FITS
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R

Table 39.23 DFEjTRHCHn Register Contents (1/2)

Bit Position	Bit Name	Function
7	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
6	PMITS	Peak-Hold Mask Start flag trigger History 0: Value after a reset The peak-hold mask start flag trigger is not present. This bit is cleared to 0 when execution of the peak-hold mask start flag has been completed while PMITS = 1. This bit is also cleared to 0 if DFEjCTLACHn.EN is set to 0 and there is no input data which is undergoing DFE processing. 1: This bit is set to 1 when a peak-hold mask start flag trigger occurs.
5	PMETS	Peak-Hold Mask End flag trigger History 0: Value after a reset The peak-hold mask end flag trigger is not present. This bit is cleared to 0 when execution of the peak-hold mask end flag has been completed while PMETS = 1. This bit is also cleared to 0 if DFEjCTLACHn.EN is set to 0 and there is no input data which is undergoing DFE processing. 1: This bit is set to 1 when a peak-hold mask end flag trigger occurs.
4	PITS	Peak-Hold Initialization Flag Trigger History 0: Peak-hold initialization flag trigger is not present: Value after a reset. This bit is cleared to 0 when execution of the peak-hold initialization flag has been completed while PITS = 1. This bit is also cleared to 0 if EN in DFEjCTLACHn is set to 0 and there is no input data which is undergoing DFE processing. 1: This bit is set to 1 when a peak-hold initialization flag trigger occurs.
3	PETS	Peak-Hold End Flag Trigger History 0: Peak-hold end flag trigger is not present: Value after a reset. This bit is cleared to 0 when execution of the peak-hold end flag has been completed while PETS = 1. This bit is also cleared to 0 if EN in DFEjCTLACHn is set to 0 and there is no input data which is undergoing DFE processing. 1: This bit is set to 1 when a peak-hold end flag trigger occurs.
2	MITS	Accumulation/Decimation Initialization Flag Trigger History 0: Accumulation/decimation initialization flag trigger is not present: value after a reset. This bit is cleared to 0 when execution of the accumulation/decimation initialization flag has been completed while MITS = 1. This bit is also cleared to 0 if EN in DFEjCTLACHn is set to 0 and there is no input data which is in DFE processing. 1: This bit is set to 1 when an accumulation/decimation initialization flag trigger occurs.

Table 39.23 DFEjTRHCHn Register Contents (2/2)

Bit Position	Bit Name	Function
1	METS	<p>Accumulation/Decimation Disable Flag Trigger History</p> <p>0: Accumulation/decimation disable flag trigger is not present: Value after a reset. This bit is cleared to 0 when execution of the accumulation/decimation disable flag has been completed while METS = 1. This bit is also cleared to 0 if EN in DFEjCTLACHn is set to 0 and there is no input data which is undergoing DFE processing.</p> <p>1: This bit is set to 1 when an accumulation/decimation disable flag trigger occurs.</p>
0	FITS	<p>Filter Initialization Flag Trigger History</p> <p>0: Filter initialization flag trigger is not present: Value after a reset. This bit is cleared to 0 when execution of the filter initialization flag has been completed while FITS = 1. This bit is also cleared to 0 if EN in DFEjCTLACHn is set to 0 and there is no input data which is undergoing DFE processing.</p> <p>1: This bit is set to 1 when a filter initialization flag trigger occurs.</p>

39.3.14 DFEjCPA to DFEjCPD — Comparison Value Setting Register

These registers are used to set a comparison calculation target value when comparison calculation is specified.

Value after reset: 0000 0000_H

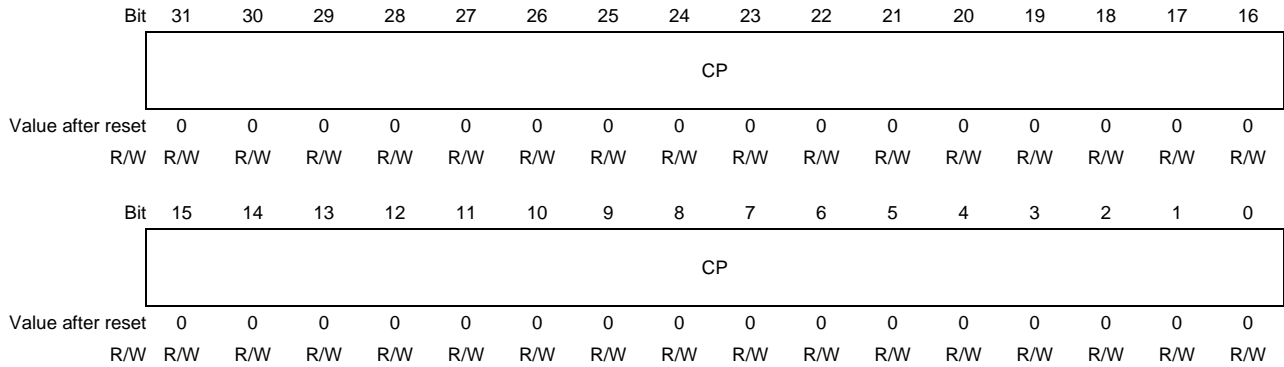

Table 39.24 DFEjCPA to DFEjCPD Register Contents

Bit Position	Bit Name	Function
31 to 0	CP	Comparison Value These bits set the comparison value when comparison calculation is specified.

The data format of the comparison value setting registers is as follows.

Figure 39.6 Data Format of Comparison Value Setting Registers

39.3.15 DFEjPHIA to DFEjPHID — Peak-Hold Initial Value Setting Register

These registers are used to set the initial peak-hold value when peak-hold calculation is specified.

Value after reset: 8000 0000_H

Table 39.25 DFEjPHIA to DFEjPHID Register Contents

Bit Position	Bit Name	Function
31 to 0	PHI	Initial Peak-Hold Value These bits set the initial peak-hold value when Peak-hold calculation is specified. Initial value: Negative minimum value (8000 0000 _H)

The data format of the peak-hold initial value setting registers is as follows.

Figure 39.7 Data Format of Peak-Hold Initial Value Setting Registers

39.3.16 DFEjACA to DFEjACD — Accumulation/Decimation Count Setting Register

These registers are used to set accumulation count or decimation count when accumulation/decimation is specified. A value of 0 to 511 can be set in these registers.

Value after reset: 0000_H

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	AC								
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
	R/W	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 39.26 DFEjACA to DFEjACD Register Contents

Bit Position	Bit Name	Function
15 to 9	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
8 to 0	AC	<p>In the case of accumulation (DFEjCTLACHn.PRCSA = 01_B) Accumulation Count Setting Register</p> <p>000_H: Accumulation processing is not performed*1: Value after a reset. 001_H: Accumulation is performed once. Two filter processing results are added and output from the accumulation circuit. 002_H: Accumulation is performed twice. Three filter processing results are added and output from the accumulation circuit. : 1FF_H: Accumulation is performed 511 times. 512 filter processing results are added and output from the accumulation circuit.</p> <p>In the case of decimation (DFEjCTLACHn.PRCSA = 10_B) Decimation Count Setting Register</p> <p>000_H: Decimation processing is not performed: Value after a reset. 001_H: Decimation is performed once. Filter processing results are output once every two filter processing results. 002_H: Decimation is performed twice. Filter processing results are output once every three filter processing results. : 1FF_H: Decimation is performed 511 times. Filter processing results are output once every 512 filter processing results.</p>

Note 1. However, since arithmetic right shift is executed during accumulation, the format of data that is input to the accumulation circuit is (S.31) data format to (S9.22) data format.

39.3.17 DFEjDI — Software Input Data Register

This register is used to input data to process (software input) from the CPU or DMA to the DFE through the peripheral bus. A write access to this register activates the DFE.

Write access to the TAG[4:0] and DI[15:0] bits should be made at the same time.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	TAG				
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 39.27 DFEjDI Register Contents

Bit Position	Bit Name	Function
31 to 21	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
20 to 16	TAG	Software Input Tag 00 _H to 1F _H : Set the same value as the channel tag (DFEjCTLACHn.TAG) to be allocated.
15 to 0	DI	Software Input Data Data to be filtered is set with the input data format of the channel to be allocated. The fixed-point (S.31) format or the integer format is applicable. Set data to be filtered with the data format of the channel to be allocated. (If DFEjCTLACHn.FMT = 0 while FIR is selected, set data in fixed-point format; if DFEjCTLACHn.FMT = 1, set data to the integer format. While IIR is selected, the fixed-point format is fixed.)

39.3.18 DFEJTRG — Software Trigger Register

This register is used to generate a software trigger by writing a value to this register from the CPU or DMA through the peripheral bus.

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	TRGA
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R/W

Table 39.28 DFEJTRG Register Contents

Bit Position	Bit Name	Function
7 to 1	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
0	TRGA	Software Trigger Generation 0: No software trigger is generated. 1: A software trigger is generated. Writing 1 to this bit generates a software trigger. This bit is always read as 0.

39.3.19 DFEjST — DFE Status Register

This register is used to indicate the DFE status. This register consists of a logical OR of each VALID bit and each error bit in DFEjSTCHn. The CPU application may use this register to monitor error channels when the DFE outputs an error interrupt request.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Note 1. DFE0 only. DFE1 is the reserved.

Table 39.29 DFEjST Register Contents

Bit Position	Bit Name	Function
2xn+1 to 2xn	CHnS	Channel n Status 00 _B : Input data register disabled with no errors: Value after a reset 01 _B : Input data register disabled with an error 10 _B : Input data register enabled with no errors 11 _B : Input data register enabled with an error

39.3.20 DFEjEST — DFE Error Status Register

This register indicates the error status on the DFE subtraction channel and the capture channel. The register is intended for an application where the CPU uses the register to monitor the error-generating channel when the DFE issues an error interrupt request.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 39.30 DFEjEST Register Contents

Bit Position	Bit Name	Function
31 to 19	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
18 to 16	CPnS	Capture Channel-n Status 0: There are no capture errors. Value after a reset Capture channel-n has no error. 1: Capture channel-n has an error.
15 to 3	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
2 to 0	SBnS	Subtraction Channel-n Status 0: There are no subtraction errors. Value after a reset Subtraction Channel-n has no error. 1: Subtraction Channel-n has an error.

39.3.21 DFEjPMITRG0 — Peak-Hold Mask-Start/End Timer Trigger Select Register 0

This register selects which of the 20 timer trigger compare interfaces--compare signals A0/B0 to A19/B19 in the timer--to use for peak-hold mask start/end timer triggers 0 to 3.

Timer triggers 4 and 5 are set using the peak-hold mask start/end timer trigger select register 1 (DFEjPMITRG1).

Value after reset: 0000 0000_H

Table 39.38 DFEjFITRG1 Register Contents

Bit Position	Bit Name	Function
31 to 13	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
12 to 8	FITMTRG5	Filter Initialization Timer Trigger 5 0000 _B : Uses compare A0 of the Timer for the filter initialization flag timer trigger 5: Value after a reset. 00001 _B : Uses compare A1 of the Timer for the filter initialization flag timer trigger 5 00010 _B : Uses compare A2 of the Timer for the filter initialization flag timer trigger 5 : 10011 _B : Uses compare A19 of the Timer for the filter initialization flag timer trigger 5. 10100 _B to 11111 _B : Setting prohibited.
7 to 5	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
4 to 0	FITMTRG4	Filter Initialization Timer Trigger 4 0000 _B : Uses compare A0 of the Timer for the filter initialization flag timer trigger 4: Value after a reset. 00001 _B : Uses compare A1 of the Timer for the filter initialization flag timer trigger 4 00010 _B : Uses compare A2 of the Timer for the filter initialization flag timer trigger 4 : 10011 _B : Uses compare A19 of the Timer for the filter initialization flag timer trigger 4. 10100 _B to 11111 _B : Setting prohibited.

39.3.29 DFEjPHUPDCn — Peak-Hold Update Notification Setting Register n (n = 0 to 3)

These registers are used to set a peak-hold result register update notification during peak-hold processing. One of the channels 0 to 15 for DFE0, channels 0 to 3 for DFE1, or PH2/PH3 processing can be independently selected with DFEjPHUPDC0-3. The set update notification is output to the Timer.

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	PHUPDCH				—	PH23SL	PH23E	OEPH UPD
Value after reset	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R	R/W	R/W	R/W

Table 39.39 DFEjPHUPDCn Register Contents

Bit Position	Bit Name	Function
7 to 4	PHUPDCH	Peak-Hold Result Register Update Notification Channel Select 0 _H : Notify that the peak-hold result register has been updated on channel 0: Value after a reset. 1 _H : Notify that the peak-hold result register has been updated on channel 1. 2 _H : Notify that the peak-hold result register has been updated on channel 2. : C _H : Notify that the peak-hold result register has been updated on channel 12. D _H : Notify that the peak-hold result register has been updated on channel 13. E _H : Notify that the peak-hold result register has been updated on channel 14. F _H : Notify that the peak-hold result register has been updated on channel 15. Note: DFE1 is prohibited from 4 _H to F _H .
3	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
2	PH23SL	PH2/PH3 Result Register Update Notification Select 0: Value after a reset Notify when the PH2 result register has been updated. 1: Notify when the PH3 result register has been updated. Note: This bit is enabled when the PH23 function is used. This bit is disabled in other cases.
1	PH23E	PH2/PH3 Result Register Update Notification Select Enable 0: Value after a reset It is not a notification target that PH2/PH3 result register has been updated. It is a notification target that peak-hold result register n (n = 0 to 15 for DFE0, n = 0 to 3 for DFE1) has been updated. 1: It is a notification target that PH2/PH3 result register has been updated. It is not a notification target that peak-hold result register n (n = 0 to 15 for DFE0, n = 0 to 3 for DFE1) has been updated. Note: This bit is enabled when the PH23 function is used. This bit is disabled in other cases.
0	OEPHUPD	Peak-Hold Result Register Update Notification Enable 0 _B : Notification of peak-hold result register update in the selected channel is disabled: Value after a reset. 1 _B : Notification of peak-hold result register update in the selected channel is enabled.

39.3.30 DFEjHOLCHn — Intermediate Value Output Register L n (n = even channels)

While FIR operation is selected, these registers hold intermediate values for digital filter processing for the corresponding channels.

The output intermediate values are the results of calculations prior to saturation processing.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 39.43 DFEjGAINCHn Register Contents

Bit Position	Bit Name	Function
31 to 16	GAIN3	Gain 3 Coefficient Data GAIN3 setting bits are used for IIR secondary biquad 3-stage with a gain adjustment function.
15 to 0	GAIN2	Gain 2 Coefficient Data GAIN2 setting bits are used for IIR secondary biquad 2/3-stage with a gain adjustment function.

The data format of the IIR filter gain setting registers is as follows.

Figure 39.9 Data Format of IIR Filter Gain Setting Registers

39.3.34 DFEjCPOFSTn — Comparison Offset Value Setting Register n (n = 0 to 2)

This register is used to set the comparison offset value α .

Value after reset: 0000 0000_H

Table 39.44 DFEjCPOFSTn Register Contents

Bit Position	Bit Name	Function
31 to 0	CPOFST	Comparison Offset Value* ¹ These bits set the comparison offset value α .

Note 1. If the Comparison offset value is used, set it in a data format that is the same as the filter operation results. For details on the format of filter operation results, see **Section 39.5.8**.

When the comparison function is used, assign a negative number (2's complement) to the comparison offset value to make the comparison value equal to [Peak-Hold Result Register (DFEjPHCHn) – Comparison Offset Value Setting Register (DFEjCPOFSTn)].

The data format of the Comparison Offset Value Setting Register is as follows.

Figure 39.10 The Data Format of Comparison Offset Value Setting Register

39.3.35 DFEjPH23CCTL0 — Peak-Hold 23 Common Control Register 0

This register is used when the PH23 function is selected. The settings common to PH23 functions are specified using this register.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	CHS			PFMT	—	—	PEN	
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R	R	R/W

Note: When the target channel of the peak-hold 23 is being executed (DFEjPH23CCTL0.PEN = 1), it is prohibited to write to any bit other than the PEN bit.

Table 39.45 DFEjPH23CCTL0 Register Contents

Bit Position	Bit Name	Function
31 to 8	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
7 to 4	CHS	Peak-Hold 23 Function Target Channel Select 0 _H : Value after a reset Channel 0 is the target of the peak-hold-23 function when the peak-hold processing is executed. 1 _H : Channel 1 is the target of the peak-hold-23 function when the peak-hold processing is executed. 2 _H : Channel 2 is the target of the peak-hold-23 function when the peak-hold processing is executed. ... F _H : Channel 15 is the target of peak-hold-23 function when the peak-hold processing of the channel is executed. Note: DFE1 is prohibited from 4 _H to F _H .
3	PFMT	Peak-Hold 23 Result Register Floating-Point Conversion 0: Value after a reset Floating-point conversion for neither DFPH20 nor DFPH30 is executed. 1: Floating-point conversion for both DFPH20 and DFPH30 is executed. Fixed-point format (S.31/S9.22) is converted to floating-point (IEEE754). This bit must not be set to 1 if the setting of DFEjCTLACHn.FMT = 1 (integer mode) while FIR operation is selected.
2, 1	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
0	PEN	Peak-Hold 23 Function Enable 0: Value after a reset The peak-hold 23 function is disabled. The peak-hold 23 function is not used. 1: The peak-hold 23 function is enabled. The peak-hold 23 function can be used.

Note: When 0 is written to DFEjPH23CCTL0.PEN, DFEjSTCHn.PH23ST of the channel set by DFEjPH23CCTL0.CHS is set to 0000_B.

39.3.36 DFEjPH2CTL0 — Peak-Hold 2 Control Register 0

This register is used when the peak-hold 23 function is selected. Any setting related to PH2 processing is specified using this register.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 39.50 DFEjPH2IND0 Register Contents (1/2)

Bit Position	Bit Name	Function
31 to 16	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
15	PH2IOW	0: Value after a reset PH2IND has not been overwritten: Value after a reset. This flag becomes 0 when 1 is written to DFEjCLRSTCHn.CLRPHIOW. 1: PH2IND has been overwritten in peak-hold index updating mode. CAUTION: Enabled when the peak-hold 23 function is used, and disabled in all other cases. Peak-Hold 2 Index Overwrite Flag This flag is valid in peak-hold index updating mode. It is always 0 in peak-hold index retention mode.
14	PH2IOF	0: Value after a reset The number of rounds of peak-hold processing has not overflowed (≤ 16383 times). <ul style="list-style-type: none"> • If the peak-hold initialization flag is raised in peak-hold index updating mode, peak-hold processing clears PH2IOF to 0. • In peak-hold index-retention mode, the peak-hold initialization flag is raised after the peak-hold 2 index register 0 is read, and processing of the first value for peak-hold processing clears PH2IOF to 0. 1: The number of rounds of peak hold processing has overflowed (> 16383 times). CAUTION: Enabled when the peak-hold 23 function is used, and disabled in all other cases. Peak-Hold 2 Index Overflow Flag The number of rounds of peak-hold processing is counted from the time of input to the peak-hold initialization flag to the time of input to the peak-hold end flag.

Table 39.50 DFEjPH2IND0 Register Contents (2/2)

Bit Position	Bit Name	Function
13 to 0	PH2IND	<p>Peak-Hold 2 Index</p> <p>0000_H: Value after a reset</p> <ul style="list-style-type: none"> • In peak-hold index-updating mode: Indicates that the first condition for peak-hold updating is not satisfied when the peak-hold initialization flag has been raised. • In peak-hold index-retention mode: Indicates that the first condition for peak-hold updating is not satisfied when the peak-hold initialization flag has been raised after the peak-hold 2 index register 0 has been read. <p>0001_H: Indicates that the value for the first input to the peak-hold circuit has been written to the peak-hold 2 results register</p> <p>0002_H: Indicates that the value for the second input to the peak-hold circuit has been written to the peak-hold 2 results register</p> <p>.....</p> <p>3FFF_H: Indicates that the value for the 16383rd input to the peak-hold circuit has been written to the peak-hold 2 results register.</p> <p>CAUTION: When the peak-hold 23 function is used and the condition for updating peak-hold has been satisfied and the value is stored in the peak-hold 2 results register, the PH2IND register captures the number of values to which peak-hold 2 processing has been applied (the value of the peak-hold counter within the digital filter). After the value of PH2IOF becomes “1” when the number of rounds of peak-hold processing reaches and exceeds 16384, operation of the peak-hold counter continues and PH2IND continues to be updated.</p>

39.3.41 DFEjPH3IND0 — Peak-Hold 3 Index Register 0

When the peak-hold 23 function is used and the peak-hold 3 result register is updated, this register holds for the peak-hold processing count.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit Position	Bit Name	Function
13 to 0	PH3IND	<p>Peak-Hold 3 Index</p> <p>0000_H: Value after a reset</p> <ul style="list-style-type: none"> • In peak-hold index-updating mode: Indicates that the first condition for peak-hold updating is not satisfied when the peak-hold initialization flag has been raised. • In peak-hold index-retention mode: Indicates that the first condition for peak-hold updating is not satisfied when the peak-hold initialization flag has been raised after the peak-hold 3 index register 0 has been read. <p>0001_H: Indicates that the value for the first input to the peak-hold circuit has been written to the peak-hold 3 results register</p> <p>0002_H: Indicates that the value for the second input to the peak-hold circuit has been written to the peak-hold 3 results register</p> <p>...: ...</p> <p>3FFF_H: Indicates that the value for the 16383th input to the peak-hold circuit has been written to the peak-hold 3 results register.</p> <p>CAUTION: When the peak-hold 23 function is used and the condition for updating peak-hold has been satisfied and the value is stored in the peak-hold 3 results register, the PH3IND register captures the number of values to which peak-hold 3 processing has been applied (the value of the peak-hold counter within the digital filter). After the value of PH3IOF becomes “1” when the number of rounds of peak-hold processing reaches and exceeds 16384, operation of the peak-hold counter continues and PH3IND continues to be updated.</p>

39.3.42 DFEjSUBCTLCHn — Subtraction Control Register n (n = 0 to 2)

This register is used when the subtraction function is selected. Set each subtraction channel.

Assign the same data format to both the subtrahend and minuend channels.

It is prohibited that the subtrahend and minuend channels have different data formats.

$$[\text{Subtraction output data}] = \text{Filter results of minuend channel} - \text{Filter results of subtrahend channel}$$

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	
	—	CATAG					CAEN		—	—	—	—	—	—	—	—	—

Note: When the target channel of the subtrahend or minuend is being executed (DFEjCTLACHn.EN = 1), it is prohibited to write any bit other than the DFEjSUBCTLCHn.SEN.

Table 39.52 DFEjSUBCTLCHn Register Contents (1/2)

Bit Position	Bit Name	Function
31	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
30 to 26	CATAG	Tag Value for Reentering Subtraction Result (cascading tag) 00 _H to 1F _H : Subtraction result data of the subtraction circuit is reentered (cascaded) during execution of cascade. A channel tag value (DFEjCTLACHn.TAG) is specified.
25, 24	CAEN	Cascade Enable 00 _B : Value after a reset Cascade is disabled. Subtraction result data of the subtraction circuit is written to the output data register. 01 _B : Setting prohibited 10 _B : Cascade is enabled. Subtraction result data of the subtraction circuit is written to the output data register together with cascade. 11 _B : Cascade is enabled. Subtraction result data of the subtraction circuit is not written to the output data register together with cascade.
23 to 12	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
11 to 8	MINCH	Minuend Channel Select 0 _H : Channel 0 is set to the minuend channel. Value after a reset 1 _H : Channel 1 is set to the minuend channel. 2 _H : Channel 2 is set to the minuend channel. ... F _H : Channel 15 is set to the minuend channel. Note: DFE1 is prohibited from 4 _H to F _H . CAUTION: It is prohibited to set the same channel to both MINCH and SUBCH.

Table 39.52 DFEjSUBCTLCHn Register Contents (2/2)

Bit Position	Bit Name	Function
7 to 4	SUBCH	<p>Subtrahend Channel Select</p> <p>0_H: Channel 0 is set to the subtrahend channel. Value after a reset</p> <p>1_H: Channel 1 is set to the subtrahend channel.</p> <p>2_H: Channel 2 is set to the subtrahend channel.</p> <p>...</p> <p>F_H: Channel 15 is set to the minuend channel.</p> <p>Note: DFE1 is prohibited from 4_H to F_H.</p> <p>CAUTION: It is prohibited to set the same channel to both MINCH and SUBCH.</p>
3	SFMT	<p>Subtraction Result Register n Floating-Point Conversion</p> <p>0: Floating-point conversion for DFEjSUBDOCHn is not executed. Value after a reset</p> <p>1: Floating-point conversion for DFEjSUBDOCHn is executed.</p> <p>Floating-point conversion for both DFPH20 and DFPH30 is executed.</p> <p>Fixed-point format (S.31/S9.22) is converted to floating-point (IEEE754).</p> <p>This bit must not be set to 1 if the setting of DFEjCTLACHn.FMT = 1 (integer mode) while FIR operation is selected for both the subtrahend and minuend channels.</p>
2	SIEE	<p>Subtraction Error Interrupt Request Enable</p> <p>0: A subtraction error interrupt request is disabled. Value after a reset</p> <p>1: A subtraction error interrupt request is enabled.</p>
1	SIEO	<p>Subtraction Output Data Interrupt Request Enable</p> <p>0: A subtraction output data interrupt is disabled when the result of subtraction is written to the subtraction output data register. Value after a reset</p> <p>1: A subtraction error interrupt request is enabled.</p> <p>A subtraction output data interrupt is enabled when the result of subtraction is written to the subtraction output data register.</p>
0	SEN	<p>Subtraction Channel Enable</p> <p>0: Subtraction Channel disabled.</p> <p>No subtraction processing is executed in this channel. Value after a reset</p> <p>1: Subtraction Channel enabled.</p> <p>The subtraction processing is executed in this channel.</p>

The subtraction processing of the target subtraction channel is stopped by writing 0 to DFEjSUBCTLCHn.SEN.

39.3.43 DFEjSUBDOCHn — Subtraction Result Register n (n = 0 to 2)

This register stores operation results after the completion of subtraction operations for each subtraction channel.

Value after reset: 0000 0000_H

Table 39.53 DFEjSUBDOCHn Register Contents

Bit Position	Bit Name	Function
31 to 0	SDO	Subtraction Output Data Results of subtraction

The data format for the subtraction result data register is shown below.

Figure 39.11 The Data Format for the Subtraction Result Data Register

39.3.44 DFEjSUBSTCHn — Subtraction Status Register n (n = 0 to 2)

This register indicates the status of subtraction channels.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	SDOEN	MINF	SUBF	SCER	—	—	SGER	SDOOW	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 39.54 DFEjSUBSTCHn Register Contents (1/2)

Bit Position	Bit Name	Function
31 to 9	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
8	SDOEN	Subtraction Output Data Register Valid 0: Indicates that the value of the subtraction output data register is invalid. While SDOEN = 1, writing 1 to DFEjSUBCLRSTCHn.CLRSDOEN clears SDOEN to 0. While SDOEN = 1, reading the DFEjSUBDOCHn register clears this bit to 0. Value after a reset 1: Indicates that the value of the subtraction output data register is valid. This bit is set to 1 when the DFE stores the subtraction results in the subtraction output data register.
7	MINF	Minuend Channel Data Input Enable 0: Value after a reset Indicates that no filtering result data has been input on the minuend channel. When MINF = 1 and SUBF = 0, the DFE performs subtraction upon completion of the filtering of the subtrahend channel. Storing subtraction result data in the subtraction result register clears MINF to 0. 1: Indicates that filtering result data has been input on the minuend channel. When SUBF = 0, completion of the filtering of the minuend channel sets MINF to 1.
6	SUBF	Subtrahend Channel Data Input Enabling Bit 0: value after a reset Indicates that no filtering result data has been input on the subtrahend channel. When SUBF = 1 and MINF = 0, the DFE performs subtraction upon completion of the filtering of the minuend channel. Storing subtraction result data in the subtraction result register clears SUBF to 0. 1: Indicates that filtering result data has been input on the subtrahend channel. When MINF = 0, completion of the filtering of the subtrahend channel sets SUBF to 1
5	SCER	Subtraction Circuit Cascade Rounding Error 0: No cascade rounding error is present: value after a reset. When SCER = 1, writing 1 to DFEjSUBCLRSTCHn.CLRSCER clears SCER to 0. 1: A cascade rounding error occurred in the subtraction output data. When DFEjSUBCTLCHn.CAEN = 10 _B or 11 _B , this bit is set to 1 if an overflow occurs when the 32-bit subtraction circuit output data is rounded to 16-bit data. When DFEjSUBCTLCHn.CAEN = 00 _B , this bit is set to 1 if the subtraction result is judged as a cascade rounding overflow will be occurred.
4 to 3	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.

Table 39.54 DFEjSUBSTCHn Register Contents (2/2)

Bit Position	Bit Name	Function
2	SGER	<p>Subtraction Guard Error</p> <p>0: Value after a reset No Subtraction guard error is present. When SGER = 1, writing 1 to DFEjSUBCLRSTCHn.CLRSGER clears SGER to 0.</p> <p>1: A Subtraction guard error is present. This bit is set to 1 if an overflow occurs when the subtraction result is rounded to 32 bits in the filter circuit.</p>
1	SDOOW	<p>Subtraction Result Register Overwrite Error</p> <p>0: Value after a reset No subtraction result register overwrite error is present. When SDOOW = 1, writing 1 to DFEjSUBCLRSTCHn.CLRSDOOW clears SDOOW to 0.</p> <p>1: A subtraction result register overwrite error occurred. When SDOEN = 1, storing subtraction output data in the subtraction result register sets SDOOW to 1.</p>
0	—	<p>Reserved</p> <p>When read, the value after reset is returned. When writing, write the value after reset.</p>

39.3.45 DFEjSUBCLRSTCHn — Subtraction Clear Status Register n (n = 0 to 2)

This register is used to clear the subtraction status register. Writing 1 to clearing bits clears the corresponding DFEjSUBSTCHn bits to 0.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 39.56 DFEjSUBERMCHn Register Contents

Bit Position	Bit Name	Function
31 to 6	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
5	MSKSCER	Subtraction Circuit Cascade Rounding Error Bit Mask 0: DFEjSUBSTCHn.SCER is not masked: Value after a reset. 1: DFEjSUBSTCHn.SCER is masked. Note: When the subtraction circuit is enabled (DFEjSUBCTLCHn.SEN = 1) and the cascade function is disabled (DFEjSUBCTLCHn.CAEN = 00 _B), set this bit to 1.
4 to 3	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
2	MSKSGER	Subtraction Guard Error Bit Mask 0: DFEjSUBSTCHn.SGER is not masked: value after a reset. 1: DFEjSUBSTCHn.SGER is masked.
1	MSKSDOOW	Subtraction Output Data Register Overwrite Error Bit Mask 0: DFEjSUBSTCHn.SDOOW is not masked: Value after a reset. 1: DFEjSUBSTCHn.SDOOW is masked.
0	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.

39.3.47 DFEjSUBTRGCHn — Subtraction Trigger Setting Register n (n = 0 to 2)

This register is used to generate a trigger flag for subtraction channels n, using software and timer triggers. It is prohibited to set both the initialization and ending flags to a software trigger for subtraction processing. If prohibited settings are specified, the integrity of ensuing operations cannot be guaranteed.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 39.57 DFEjSUBTRGCHn Register Contents (1/2)

Bit Position	Bit Name	Function
31 to 16	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
15, 14	SBFE	Subtraction End Flag Trigger Setting 00 _B : Value after a reset Subtraction end flag is not generated. 01 _B : Subtraction end flag is generated by a timer trigger. 10 _B : Subtraction end flag is generated by a software trigger. 11 _B : Setting prohibited CAUTION: It is prohibited to set both the subtraction start flag and the subtraction end flag to a software trigger. (It is prohibited to set DFEjSUBTRGCHn.SBFE = 10 _B and DFEjSUBTRGCHn.SBE = 10 _B). When the subtraction end flag is generated by a timer trigger (DFEjSUBTRGCHn.SBFE = 01 _B), the subtraction end flag is automatically selected from among compare signals B0 to B19 from the timer. Whichever signal corresponds to (has the same number as) the timer trigger (one of compare signals A0 to A19) selected by the subtraction start flag and subtraction end flag timer trigger select bits (DFEjSUBTRGCHn.SBT) is selected.
13 to 8	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
7, 6	SBE	Subtraction Start Flag Trigger Setting 00 _B : Value after a reset Subtraction start flag is not generated. 01 _B : Subtraction start flag is generated by a timer trigger. 10 _B : Subtraction start flag is generated by a software trigger. 11 _B : Setting prohibited
5 to 2	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.

Table 39.57 DFEjSUBTRGCHn Register Contents (2/2)

Bit Position	Bit Name	Function
1, 0	SBT	<p>Subtraction Start Flag and Subtraction End Flag Timer Trigger Select</p> <p>00_B: Value after a reset Timer trigger 0 is selected for generating the subtraction start flag and subtraction end flag.</p> <p>01_B: Timer trigger 1 is selected for generating the subtraction start flag and subtraction end flag.</p> <p>10_B: Timer trigger 2 is selected for generating the subtraction start flag and subtraction end flag.</p> <p>11_B: Setting prohibited</p> <p>CAUTION: This bit is enabled when the subtraction start flag trigger setting bits (DFEjSUBTRGCHn.SBE) are 01_B. Timer triggers 0 to 2 are selected using DFEjSUBTRG0. SUBTMTRG0 to SUBTMTRG2.</p>

39.3.48 DFEjSUBTRHCHn — Subtraction Trigger History Register n (n = 0 to 2)

This register is used to monitor the execution history of software triggers, timer triggers, and trigger flags related to subtraction processing.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 39.58 DFEjSUBTRHCHn Register Contents

Bit Position	Bit Name	Function
31 to 2	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
1	SITS	Subtraction Start Flag Trigger History 0: Value after a reset A subtraction start flag trigger has not been generated. When SITS = 1, this bit becomes 0 upon completion of the execution of the subtraction start flag. This bit also becomes 0 if DFEjSUBCTLCHn.SBEN is set to 0 and subtraction processing is not being performed on a subtraction channel n. 1: This bit becomes 1 when the subtraction start flag trigger is generated.
0	SETS	Subtraction End Flag Trigger History 0: Value after a reset A subtraction end flag trigger has not been generated. When SETS = 1, this bit becomes 0 upon completion of the execution of the subtraction end flag. This bit becomes 0 if DFEjSUBCTLCHn.SBEN is set to 0 and subtraction processing is not being performed on a subtraction channel n. 1: This bit becomes 1 when the subtraction end flag trigger is generated.

39.3.49 DFEjSUBTRG0 — Subtraction Start/End Timer Trigger Select Register 0

This register selects which of the 20 timer trigger compare interfaces--compare signals A0/B0 to A19/B19 in the timer--to use for subtraction start/end timer triggers 0 to 2.

Value after reset: 0000 0000_H

	—	—	—	—	—	—	—	—	CAPCH			—	CIEE	—	CEN	
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R	R/W	R	R/W

Note: While the setting of DFEjCAPCTLCHn.CEN is 1, writing to CAPCH and CIEE is prohibited.

Table 39.60 DFEjCAPCTLCHn Register Contents

Bit Position	Bit Name	Function
31 to 8	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
7 to 4	CAPCH	Capture-Target Channel Select 0 _H : Channel 0 is set to the capture channel. Value after a reset 1 _H : Channel 1 is set to the capture channel 2 _H : Channel 2 is set to the capture channel ... F _H : Channel 15 is set to the capture channel Note: DFE1 is prohibited from 4 _H to F _H .
3	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
2	CIEE	Capture Error Interrupt Request Enable 0: Value after a reset A capture error interrupt request is disabled. 1: A capture error interrupt request is enabled.
1	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
0	CEN	Capture Channel Enable 0: Value after a reset Capture channel disabled. No capture processing is executed in this channel. 1: Capture channel enabled. The Capture processing is executed in this channel.

39.3.51 DFEjCAPDOCHn — Capture Result Register n (n = 0 to 2)

This register stores the output data register value on the capture-target channel. If the data is read with floating-point conversion format, set the output data register (DFEjDOCHn) of the capture-target channel to floating-point conversion format.

Value after reset: 0000 0000_H

Table 39.61 DFEjCAPDOCHn Register Contents

Bit Position	Bit Name	Function
31 to 0	CDO	Capture Output Data Stores the output data register value on the capture-target channel.

The data format of the capture result data register is shown below.

Figure 39.12 The Data Format of the Capture Result Data Register

39.3.52 DFEjCAPSTCHn — Capture Status Register n (n = 0 to 2)

This register indicates the status of the capture channel.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	CDOEN	—	—	—	—	—	—	CDOOW	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 39.62 DFEjCAPSTCHn Register Contents

Bit Position	Bit Name	Function
31 to 9	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
8	CDOEN	Capture Output Data Register Valid 0: Value after a reset Indicates that the value of the capture output data register is invalid. While CDOEN = 1, writing 1 to DFEjCAPCLRSTCHn.CLRCDOEN clears this bit to 0. While CDOEN = 1, reading the DFEjCAPDOCHn register clears this bit to 0. 1: Indicates that the value of the capture output data register is valid. This bit is set to 1 when the DFE stores the capture results in the capture output data register.
7 to 2	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
1	CDOOW	Capture Result Register Overwrite Error 0: value after a reset No capture result register overwrite error. When CDOOW = 1, writing 1 to DFEjCAPCLRSTCHn.CLRCDOOW clears CDOOW to 0. 1: A capture result register overwrite error occurred. When CDOEN = 1, storing capture data in the capture result register sets CDOOW to 1
0	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.

39.3.53 DFEjCAPCLRSTCHn — Capture Clear Status Register n (n = 0 to 2)

This register is used to clear the capture status register. Writing 1 to these bits clears the corresponding DFEjCAPSTCHn bits to 0.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R

Table 39.64 DFEjCAPERMCHn Register Contents

Bit Position	Bit Name	Function
31 to 2	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
1	MSKCDOOW	Capture Result Data Register Overwrite Error Bit Mask 0: DFEjCAPSTCHn.CDOOW is not masked: Value after a reset. 1: DFEjCAPSTCHn.CDOOW is masked.
0	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.

39.3.55 DFBFACCTL — Buffer A Common Control Register

This is a FIFO macro register. Common settings on buffer A processing are specified using this register.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	AUNE	AIEE	AIEO	AEN
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W

Note: When DFBFACCTL.AEN is 1, writing to AUNE, AIEE and AIEO is prohibited.

Table 39.65 DFBFACCTL Register Contents

Bit Position	Bit Name	Function
31 to 4	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
3	AUNE	Buffer A Data Update Flag Enable 0: Value after a reset. The buffer A data update flag (DFBFADDOCHn.AUN) is not used. For data format, see the buffer A output register. 1: The buffer A data update flag (DFBFADDOCHn.AUN) is used. For data format, see the buffer A output register.
2	AIEE	Buffer A Error Interrupt Request Enable 0: Value after a reset Buffer A error interrupt request is disabled. 1: Buffer A error interrupt request is enabled.
1	AIEO	Buffer A Output Data Interrupt Request Enable 0: Value after a reset Buffer A output data interrupt is disabled when output data from the selected DFE channel is written to the buffer A output data register. 1: Buffer A output data interrupt is enabled when output data from the selected DFE channel is written to the buffer A output data register.
0	AEN	Buffer A Enable 0: Value after a reset Buffer A is disabled. No Buffer A processing is executed. 1: The Buffer A processing is executed.

39.3.56 DFBFACTLCHn — Buffer A Control Register n (n = 0 to 7)

This is a FIFO macro register. Settings for each buffer A channel are specified using this register.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	BFACH				—	—	—	—	ADSL	—	—	CHEN
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R/W	R/W	R/W	R/W	R	R	R	R	R/W	R	R	R/W

Note: When DFBFACCTL.AEN is 1, writing to BFACH, ADSL and CHEN is prohibited.

Table 39.66 DFBFACTLCHn Register Contents

Bit Position	Bit Name	Function
31 to 12	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
11 to 8	BFACH	Buffer A Capture-target Channel Select 0 _H : Channel 0 is set to the buffer A capture-target channel. Value after a reset 1 _H : Channel 1 is set to the buffer A capture-target channel 2 _H : Channel 2 is set to the buffer A capture-target channel ... F _H : Channel 15 is set to the buffer A capture-target channel Note: DFE1 is prohibited from 4 _H to F _H .
7 to 4	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
3	ADSL	Buffer A DFE Select 0: Buffer A channel n is selected from DFE0. 1: Buffer A channel n is selected from DFE1.
2, 1	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
0	CHEN	Buffer A Channel n Enable 0: Value after a reset Buffer A channel n disabled When CHEN = 0, buffer A channel n data is not stored in FIFO. 1: Buffer A channel n enabled When CHEN = 0, buffer A channel n data is stored in FIFO.

39.3.57 DFBFADOCHn — Buffer A Output Register n (n = 0 to 7)

This register is a buffer A output data register that holds the output data from the capture-target channel.

A FIFO data format accords with the data format of capture-target channel.

If the data is read with floating-point conversion format, set the output data register (DFEjDOCHn) of the capture-target channel to floating-point conversion format.

- When DFBFACCTL.AUNE = 0:

Value after reset: 0000 0000_H

When DFBFACCTL.AUNE is set to 0, after clear is valid by DFBFACLR.CLRA, the clear value is 0000 0000_H.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 39.70 DFBFACST Register Contents

Bit Position	Bit Name	Function
31 to 24	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
23 to 16	EMPA _n	FIFO Channel n Empty Status 0: Indicates that some data remains on FIFO channel n. When EMPA _n = 1, storing data in the FIFO clears this bit to 0. 1: Value after a reset Indicates that FIFO channel n is empty. When EMPA _n = 0 and when 1 _B is written in DFBFACLR.CLRA, EMPA _n for all FIFO channels are set to 1 _B .
15 to 8	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
7 to 0	OVFA _n	FIFO Channel n FIFO Overflow Error 0: Value after a reset Indicates no FIFO overflow occurred on FIFO channel n. When OVFA _n = 1 and when 1 _B is written in DFBFACLR.CLRA, OVFA _n for all FIFO channels are set to 0. 1: Indicates a FIFO overflow occurred on FIFO channel n. When the FIFO channel n is full and when new data is stored on FIFO channel n, OVFA _n is set to 1 _B .

39.3.60 DFBFBCTL — Buffer B Control Register

This is a FIFO macro register. Settings for buffer B processing are specified using this register.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	BFBCH				—	—	—	—	BDSL	BIEE	BIEO	BEN
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R/W	R/W	R/W	R/W	R	R	R	R	R/W	R/W	R/W	R/W

Note: When DFBFBCTL.BEN is 1, writing to BFBCH, BDSL, BIEE, and BIEO is prohibited.

Table 39.71 DFBFBCTL Register Contents

Bit Position	Bit Name	Function
31 to 12	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
11 to 8	BFBCH	Buffer B Capture-target channel Select 0 _H : Channel 0 is set to the buffer B capture-target channel. Value after a reset 1 _H : Channel 1 is set to the buffer B capture-target channel 2 _H : Channel 2 is set to the buffer B capture-target channel ... F _H : Channel 15 is set to the buffer B capture-target channel Note: DFE1 is prohibited from 4 _H to F _H .
7 to 4	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
3	BDSL	Buffer B DFE Select 0: Buffer B channel n is selected from DFE0. 1: Buffer B channel n is selected from DFE1.
2	BIEE	Buffer B Error Interrupt Request Enable 0: Value after a reset Buffer B error interrupt request is disabled. 1: Buffer B error interrupt request is enabled.
1	BIEO	Buffer B Output Data Interrupt Request Enable 0: Value after a reset Buffer B output data interrupt is disabled when output data from the selected DFE channel is written to the buffer B output data register. 1: Buffer B output data interrupt is enabled when output data from the selected DFE channel is written to the buffer B output data register.
0	BEN	Buffer B Enable 0: Value after a reset Buffer B is disabled. No Buffer B processing is executed. 1: Buffer B is enabled. Buffer B processing is executed.

39.3.61 DFBFBDO — Buffer B Output Register

This register is a buffer B output data register that holds the output data from the capture-target channel.

The FIFO data format accords with the data format of the capture-target channel.

If the data is read with floating-point conversion format, set the output data register (DFEjDOCHn) of the capture-target channel to floating-point conversion format.

Value after reset: 0000 0000_H

Table 39.72 DFBFBDO Register Contents

Bit Position	Bit Name	Function
31 to 0	BDO	FIFO Storage Data The value of the output data register which was stored in an 8-stage FIFO is stored in these bits.

The data that is stored in BDO [31:0] is the output data (DFEjDOCHn.DO[31:0]).

The data format of the buffer B output register is shown below.

Figure 39.15 The Data Format of Buffer B Output Register

39.3.62 DFBFBCLR — Buffer B Clear Register

This register clears the buffer B.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	—	—	—	—	—	—	—	—	—	—	—	—	—	—	EMPB	OVFB
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 39.74 DFBFBST Register Contents

Bit Position	Bit Name	Function
31 to 2	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
1	EMPB	FIFO Channel n Empty Status 0: Indicates that some data remains on FIFO channel n. When EMPB = 1, storing data in the FIFO clears this bit to 0. 1: Value after a reset Indicates that FIFO channel n is empty. When EMPB = 0 and when 1 _B is written in DFBFBCLR.CLRB, EMPB is set to 1 _B .
0	OVFB	FIFO B Overflow Error 0: Value after a reset Indicates no FIFO overflow occurred. When OVFB = 1 and when 1 _B is written in DFBFBCLR.CLRB, OVFB is set to 0. 1: Indicates A FIFO overflow occurred. When FIFO B is full and when new data is stored in FIFO B, OVFB is set to 1 _B .

39.4 Operation

39.4.1 Overview of Operation

39.4.1.1 DFE Macro

The DFE imports output data from the Cyclic-ADC, Delta-Sigma ADC or the SAR-ADC (referred to as AD hereafter) and performs filter (FIR or IIR) processing, accumulation/decimation processing, subtraction processing, peak-hold/comparison calculation processing, or floating-point conversion processing for the output data.

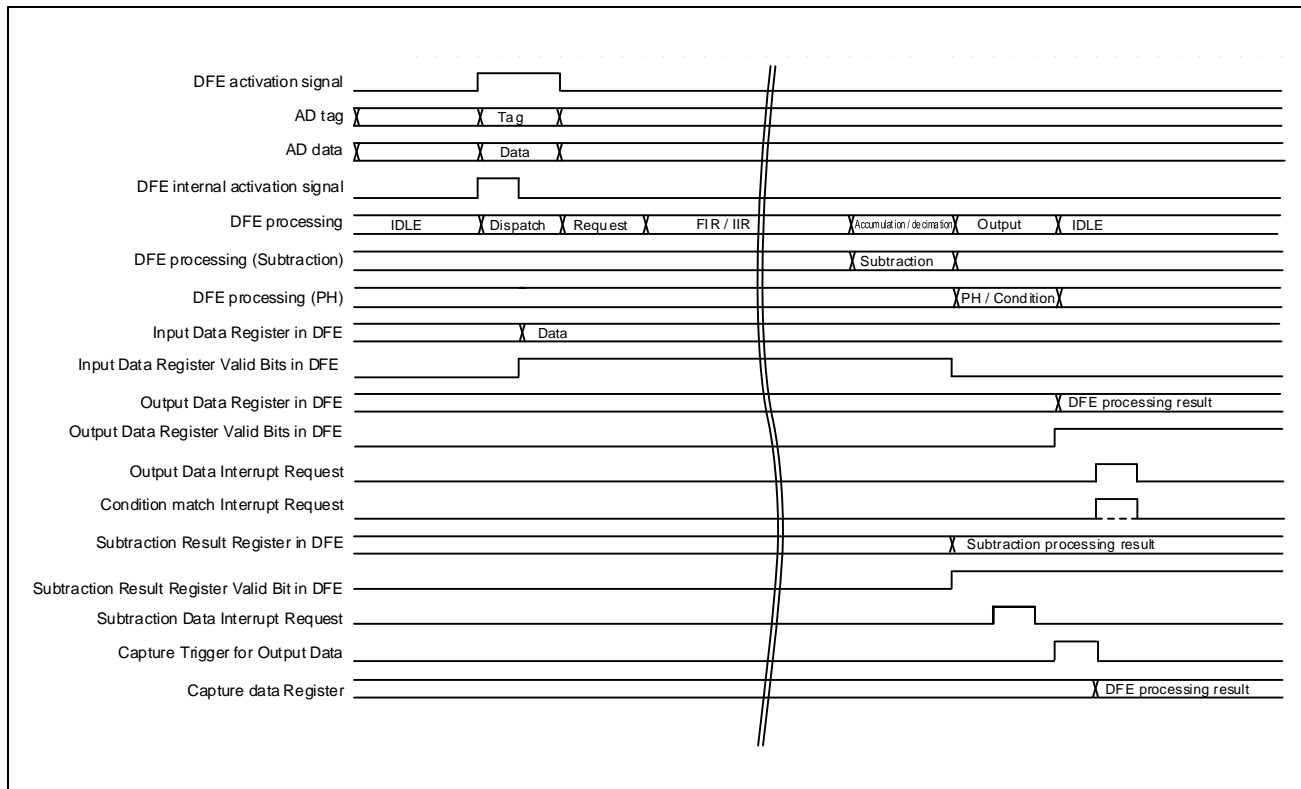

Figure 39.16 Overview of Operation

- The AD inputs the DFE activation signal, AD tag, and AD conversion data (AD data) to the DFE. The DFE imports the AD data in the internal input data register to execute dispatch processing, request processing, FIR/IIR processing, accumulation/decimation processing, subtraction processing, output processing, or peak-hold/comparison processing, and then stores the DFE processing result in the output data register.
- Dispatch processing:
The DFE stores data in the input data register of the relevant channel by using the AD tag from the AD and DFE's control register values. Before data is stored, the input data register is enabled.
- Request processing:
The DFE arbitrates FIR/IIR processing target data from the input data register of 16 channels and inputs the filter processing target data to the FIR/IIR processing.
- FIR/IIR processing (filter processing):
The DFE performs FIR or IIR filter calculation. Coefficient data and intermediate values in the filter calculation are stored in the memory.
- Subtraction processing:
The DFE executes subtraction on the results of a FIR/IIR between two different channels. After the subtraction, the

DFE stores the results in the subtraction result register. When storing the results, the subtraction result register is enabled, and the macro executes a subtraction data interrupt request.

- Accumulation/decimation processing:

The DFE executes accumulation processing or decimation processing for the FIR or IIR processing result. After the accumulation/decimation processing has been completed, the input data register is disabled.

- Output processing:

The DFE stores the accumulation/decimation processing result in the output data register of the relevant channel. Before the result is stored, the output data register is enabled and an output data interrupt request is issued.

- Peak-Hold/comparison processing:

The DFE executes Peak-Hold and/or comparison processing on the results of accumulation/decimation processing. If the Peak-Hold processing is selected, the macro issues a condition match interrupt request when the Peak-Hold end trigger is enabled. If comparison processing is selected, the DFE executes a condition match interrupt request when the result of the comparison operation is TRUE. If Peak-Hold processing and comparison processing are executed simultaneously, in the Peak-Hold processing the macro issues a Peak-Hold end interrupt request; in the comparison processing, the macro issues a condition match interrupt request when the result of the comparison operation is TRUE.

- Capture processing:

If an output data capture trigger is input to the output data register, the macro stores the value of the output data register in the capture result register.

39.4.1.2 FIFO Macro

The FIFO macro selects a DFE macro output data register and stores the data in the FIFO. The FIFO macro selects the required channel from the DFE0 and DFE1, and stores the data in the FIFO.

The macro operates differently between buffer A processing and buffer B processing.

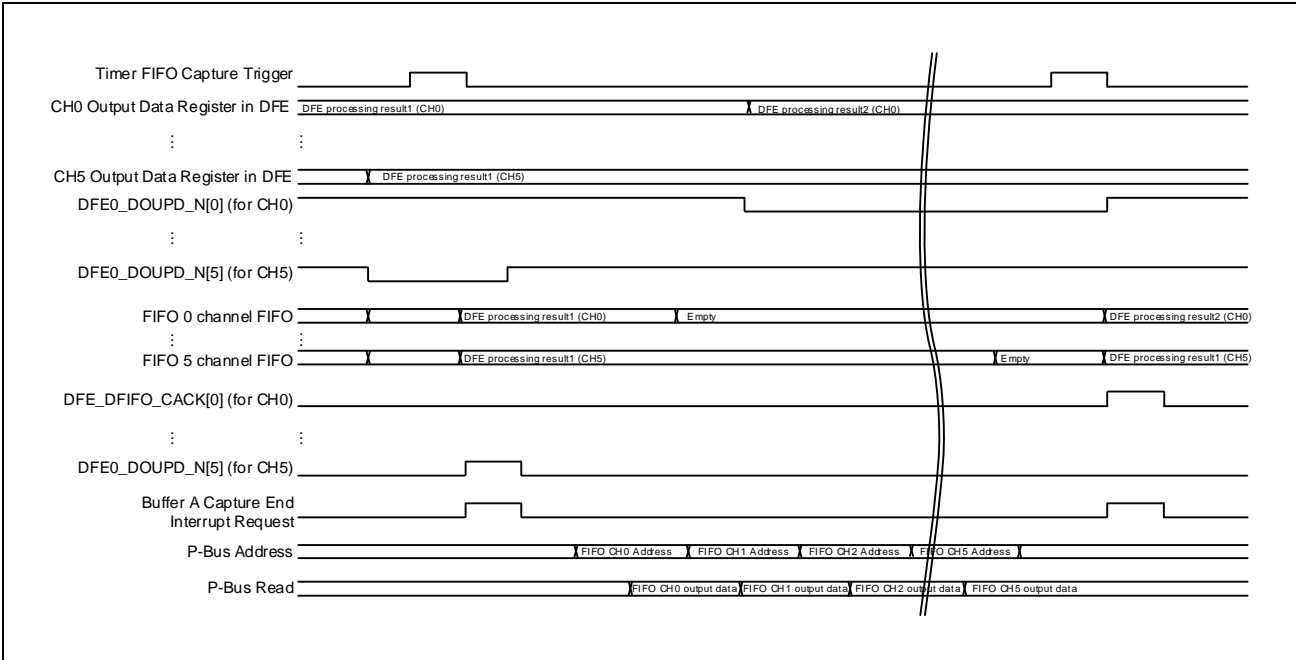

Figure 39.17 Overview of FIFO Macro Operation (buffer A processing)

- Buffer A processing:

The macro stores, in batch, data in the FIFO channel which was enabled by the FIFO capture trigger that was output from the timer. When storing data in the FIFO, the macro issues a buffer A capture end interrupt request. After reading all FIFO channels in which data is stored, the macro issues a buffer A capture end interrupt request if data is stored in the FIFO again. When not reading all FIFO channels in which data is stored, the macro will not issue a buffer A capture end interrupt request even if data is stored in the FIFO again.

Figure 39.18 Overview of FIFO Macro Operation (buffer B processing)

- Buffer B processing:

Each time the value of the DFE output data register is updated, the macro stores the value of the output data register of a selected channel in one FIFO. Repeating this operation until the values from four output data registers have been stored in the FIFO, the macro issues a buffer B capture end interrupt request.

After reading all four data items the macro issues a buffer B capture end interrupt request if four data items are stored in the FIFO again.

When not reading all four stored data items, the macro will not issue a buffer B capture end interrupt request even if four data items are stored in the FIFO again.

39.4.2 Operating Procedures

39.4.2.1 Channel Start Procedure

The procedure to start the DFE channel is shown below.

Figure 39.19 Channel Starting Procedure

The channel start setup process of the DFE is different for the first time versus the subsequent times.

Please refer to step (2) in **Figure 39.19** for the first time setup process. Please refer to step (1) in **Figure 39.19** for the restart process.

- (1) For the restart setup process, set the DFE to stop according to **Section 39.4.2.2, Channel Stop Procedure**.
- (2) For the first time setup process, set the registers as shown in **Figure 39.19**. For the restart process, set the registers as shown in **Figure 39.19** as necessary.
 - For the coefficient memory and data memory, set values in the channel area to be used via the peripheral bus. For the coefficient memory address assignment, see **Section 39.5.3, Section 39.5.4, and Section 39.5.9**. For the data memory address assignment, see **Section 39.5.3, Section 39.5.5, and Section 39.5.9**.
- (*) When selecting an IIR with the gain adjustment function, set the gain coefficient in the IIR filter gain setting register (DFEjGAINCHn).
 - Set control register B (DFEjCTLBCHn) for accumulation/decimation and PH/comparison operation.
 - If DFEjCTLBCHn.DISA = 0, after writing DFEjCTLACHn.EN = 1 in step (13), the macro starts the accumulation/decimation processing on the first input data.
 - If DFEjCTLBCHn.DISB = 0, after writing DFEjCTLACHn.EN = 1 in step (13), the macro starts the peak-hold processing on the first input data.
- (3) Set the registers according to the specific functions to be used, in any order.
- (4) When the accumulation circuit is used, set the accumulation /decimation count setting registers (DFEjACA to DFEjACD).
- (5) When the Peak-Hold circuit is used, set the following registers as necessary:

Peak-Hold Initial Value Setting Registers	DFEjPHIA to DFEjPHID
Comparison Value Setting Registers	DFEjCPA to DFEjCPD
Peak-Hold Update Notification Setting Register	DFEjPHUPDCn

When using the PH23 function, set the following registers:

Peak-Hold 23 Common Control Register 0	DFEjPH23CCTL
Peak-Hold 2 Control Register 0	DFEjPH2CTL
Peak-Hold 3 Control Register 0	DFEjPH3CTL
Comparison Offset Value Setting Register	DFEjCPOFSTn

- (6) When using the subtraction circuit, set the subtraction control registers (DFEjSUBCTLCHn).
- (7) When using the capture circuit, set the capture control registers (DFEjCAPCTLCHn).

- (8) When using a trigger flag, the trigger setting register and the timer trigger setting register need to be set. Set the timer trigger setting registers for the pertinent trigger flag functions according to the specific functions to be used.

Trigger Setting Register	DfEjTRGCHn
Timer Trigger Setting Register	DfEjTMTRGCHn
Software Trigger Register	DfEjTRG
Peak-Hold Initialization/End Timer Trigger Select Register	DfEjPITRG
Peak-Hold Initialization/End Timer Trigger Select Register1	DfEjPITRG1
Accumulation/Decimation Initialization/Prohibition Timer Trigger Select Register	DfEjMITRG
Accumulation/Decimation Initialization/Prohibition Timer Trigger Select Register1	DfEjMITRG1
Filter Initialization Timer Trigger Select Register	DfEjFITRG
Filter Initialization Timer Trigger Select Register 1	DfEjFITRG1
Peak-Hold Mask-Start/End Timer Trigger Select Register 0	DfEjPMITRG0
Peak-Hold Mask-Start/End Timer Trigger Select Register 1	DfEjPMITRG1
Subtraction Trigger Setting Register	DfEjSUBTRGCHn
Subtraction Start/End Timer Trigger Select Register 0	DfEjSUBTRG0

- (9) When the buffer A circuit is used, set the buffer A common control register (DFBFACCTL) and the buffer A control registers (DFBFACTLCHn).
- (10) When the buffer A circuit is used, after the Buffer A circuit is set in step (9), initialize the buffer A circuit by the buffer A clear register (DFBFACLR).
- (11) When the buffer B circuit is used, set the buffer B control registers (DFBFBCTL).
- (12) When the buffer B circuit is used, after the Buffer B circuit is set in step (11), initialize the buffer B circuit by the buffer B clear register (DFBFBCLR).
- (13) When all settings have been completed, use control register A (DfEjCTLACHn) to set filter processing, enable writing to the interrupt request output, enable the channel, and set other necessary parameters. Setting the enable bit (DfEjCTLACHn.EN) for the channel to be used to 1 enables the filter processing on that channel.
- (14) When an activation trigger is input from the AD, the macro starts the filter processing on the input data from the AD.

39.4.2.2 Channel Stop Procedure

The procedure to stop the DFE channel is shown below.

Once the registers have been set and filter processing has started, execute the channel stop procedure as follows. Set the registers according to **Section 39.4.2.1, Channel Start Procedure**.

When the registers of the Buffer A circuit have been set and the filter processing has started, execute the channel stop procedure for all channels selected by the FIFO channels as follows. Set the registers according to **Section 39.4.2.1, Channel Start Procedure**.

When the registers of the Buffer B circuit have been set and the filter processing has started, execute the channel stop procedure for the target channel as follows. Set the registers according to **Section 39.4.2.1, Channel Start Procedure**.

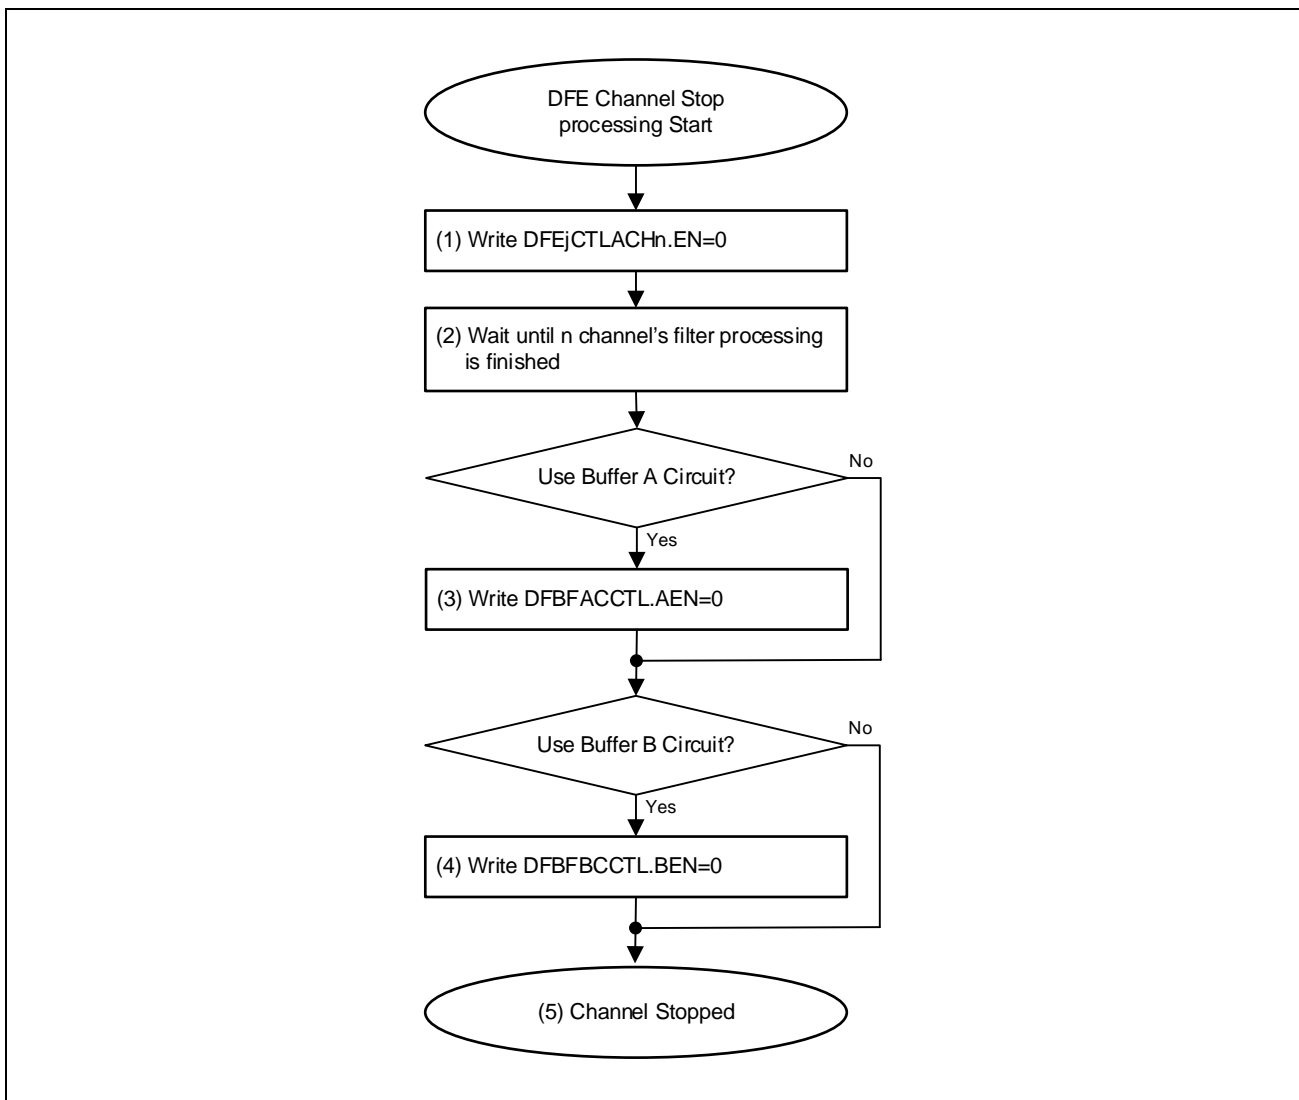

Figure 39.20 Channel Stop Procedure

(1) Clear the enabling bit (DFEjCTLACHn.EN) for the channel to be stopped.

(2) Wait until the processing on the stopped channel terminates.

When the buffer A circuit is used, after all channels which are target to FIFO channels have stopped, set the Buffer A Enable (DFBFACCTL.AEN) to 0. By setting DFBFACCTL.AEN = 0, the Buffer A circuit is stopped.

- (3) When the buffer B circuit is used, after the target channel of Buffer B has stopped, set the Buffer B Enable (DFBFBCTL.BEN) to 0. By setting DFBFBCTL.BEN = 0, Buffer B circuit is stopped.
- (4) The text below describes the operations that occur during the stopping of channel processing:
 - Writing 0 to the enable bit (DFEjCTLACHn.EN) suppresses any subsequent processing of input data and input triggers.
 - Any data that was input before 0 was written to the enable bit (DFEjCTLACHn.EN) continues to be processed after 0 is written.
 - After writing 0 to the enable bit (DFEjCTLACHn.EN), use DFEjSTCHn.VALID to confirm the termination of processing after 0 is written.
 - Any trigger that was input before 0 is written to the enable bit (DFEjCTLACHn.EN) is disabled if there is no data to be processed.

After the channel is stopped, clear the status bits for that channel, for the subtraction channel, and for the capture channel as necessary.

39.4.2.3 Error Processing Procedure

(1) DFE Macro

The DFE operating procedure for an error is shown below.

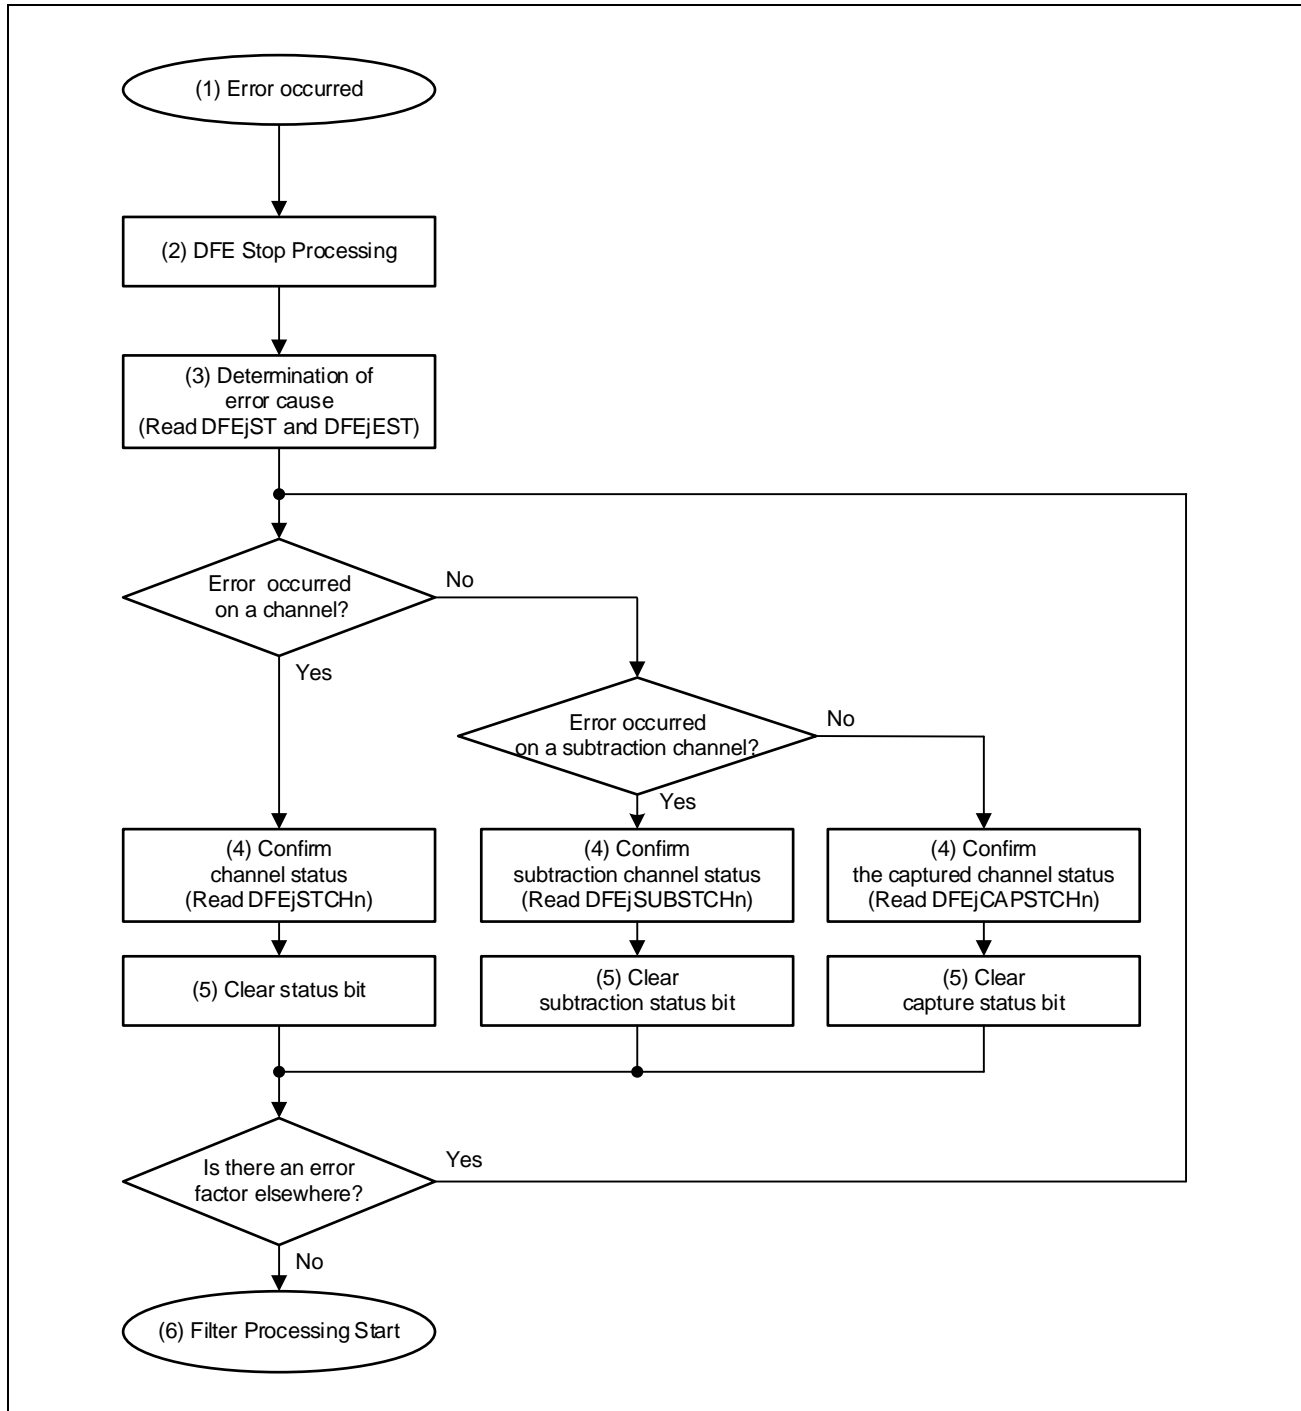

Figure 39.21 DFE Macro Operating Procedure for an Error

- (1) If an error occurs during the processing, the DFE macro issues an interrupt request.
Possible sources of errors include (1) channels, (2) subtraction channels, and (3) capture channels. For each of these sources, error interrupts and error sources can be masked by the following registers.

Classification	Error Interrupt Mask	Error Source Mask
Channel	DFEjCTLACHn.IEE	DFEjERMCHn
Subtraction channel	DFEjSUBCTLCHn.SIEE	DFEjSUBERMCHn
Capture channel	DFEjCAPCTLCHn.CIEE	DFEjCAPERMCHn

- (2) The macro performs DFE stop processing according to the channel stop processing flow of events.
- (3) The macro identifies the channel, the subtraction channel or the capture channel on which error occurred.
By reading the DFEjEST register, the channel on which error occurred can be identified.
By reading the DFEjEST register, the subtraction channel or the capture channel on which error occurred can be identified.
- (4) The error sources can be identified by checking the status register for the channel, subtraction channel, or capture channel on which the error occurred.
(If an error occurred on channel 0, for example, the macro reads DFEjSTCH0.)
- (5) When an error source is identified, the macro writes to the clear status bits corresponding to the error status, and clears the error bits.
(Note) If an error status is not cleared, and if the error status recurs, no error interrupt will be issued.
- (6) The macro starts filter processing according to the channel start processing flow of events.

(2) FIFO Macro

The FIFO macro operating procedure for an error is shown below.

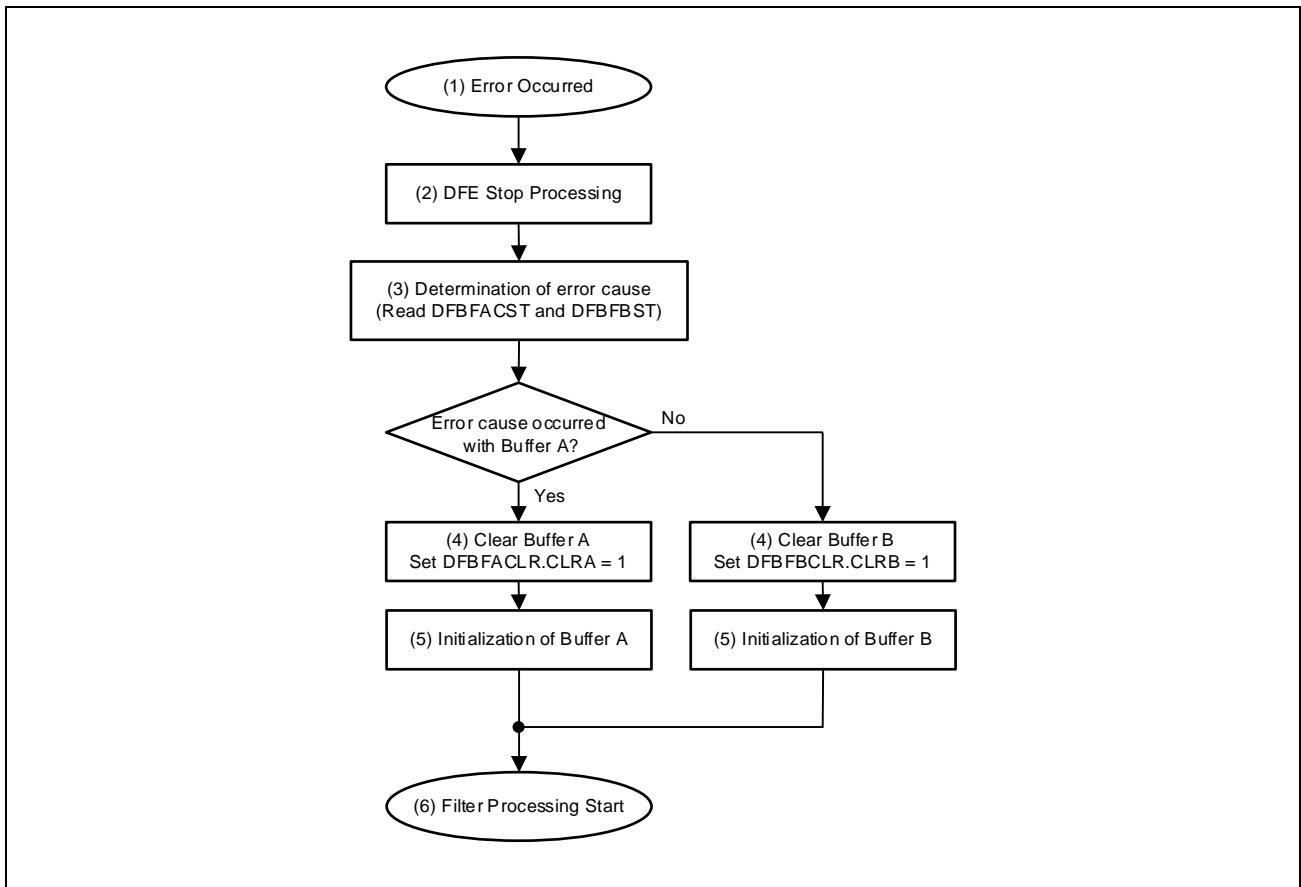

Figure 39.22 FIFO Macro Operating Procedure for an Error

- (1) If an error occurs during processing, the FIFO macro issues an interrupt request.

Possible sources of errors include buffer A and buffer B.

For each of these sources, error interrupt request outputs can be controlled by the following registers.

Classification	Mask Bit of Error Interrupt Request
Buffer A processing	DFBFACCTL.AIEE
Buffer B processing	DFBFBCTL.BIEE

- (2) The macro performs DFE stop processing according to the channel stop processing flow of events.
- (3) The macro identifies the source of the error as buffer A or B.
By reading the DFBFACST register, the macro can identify the FIFO channel on which the buffer A error occurred. By reading the DFBFBST register, the macro can determine that the error occurred in buffer B.
- (5) When an error source is identified, the macro writes to the clearing register, and initializes buffer A or B.
- (6) The macro starts filter processing according to the channel start processing flow of events.

(3) About register rewrite

When an R/W register is written, the bit value is reflected in the DFE processor immediately. When each function is executed, and when an R/W register is changed, the value of an operation result and the status are not guaranteed. Therefore, when an R/W register is changed, it is necessary to stop each function.

Rewrite the following registers when the target channel is stopped (DFEjCTLACHn.EN=0 & DFEjSTCHn.VALID=0).

Register Name	Remarks
DFEjCTLACHn	All bits except EN
DFEjCTLBCHn	All bits
DFEjTRGCHn	All bits
DFEjTMTRGCHn	All bits
DFEjERMCHn	All bits
DFEjPHUPDCn	All bits
DFEjGAINCHn	All bits

Rewrite the following registers when the target channel of the Peak-Hold 23 function is stopped (DFEjCTLACHn.EN=0 & DFEjSTCHn.VALID=0).

Register Name	Remarks
DFEjPH23CCTL0	All bits except PEN
DFEjPH2CTL0	All bits
DFEjPH3CTL0	All bits

Rewrite the following registers when the target channel of the subtraction function is stopped (DFEjCTLACHn.EN=0 & DFEjSTCHn.VALID=0).

Register Name	Remarks
DFEjSUBCTLCHn	All bits except SEN
DFEjSUBTRGCHn	All bits
DFEjSUBERMCHn	All bits

Rewrite the following registers when the capture function is stopped (DFEjCAPCTLCHn.CEN=0).

Register Name	Remarks
DFEjCAPCTLCHn	All bits except CEN
DFEjCAPERMCHn	All bits

Rewrite the following registers when the Buffer A circuit is stopped (DFBFACCTL.AEN=0).

Register Name	Remarks
DFBFACCTL	All bits except AEN
DFBFACTLCHn	All bits

Rewrite the following register when the Buffer B circuit is stopped (DFBFBCTL.BEN=0).

Register Name	Remarks
DFBFBCTL	All bits except BEN

When the following registers are used by multiple channels, rewrite these registers when these channels are stopped (DFEjCTLACHn.EN=0 & DFEjSTCHn.VALID=0).

Register Name	Remarks
DFEjCPA - DFEjCPD	All bits
DFEjPHIA - DFEjPHID	All bits
DFEjACA - DFEjACD	All bits

Rewrite the following registers when the channels which use timer trigger n are stopped (DFEjCTLACHn.EN=0 & DFEjSTCHn.VALID=0).

Register Name	Remarks
DFEjPITRG	All bits
DFEjPITRG1	All bits
DFEjPMITRG0	All bits
DFEjMITRG	All bits
DFEjMITRG1	All bits
DFEjFITRG	All bits
DFEjFITRG1	All bits

Rewrite the following register when the target channel of the subtraction function which use timer trigger n are stopped (DFEjCTLACHn.EN=0 & DFEjSTCHn.VALID=0).

Register Name	Remarks
DFEjSUBTRG0	All bits

39.5 Details

39.5.1 Data Flow

39.5.1.1 DFE Macro

Figure 39.23 shows the data flow and the block diagram of the DFE.

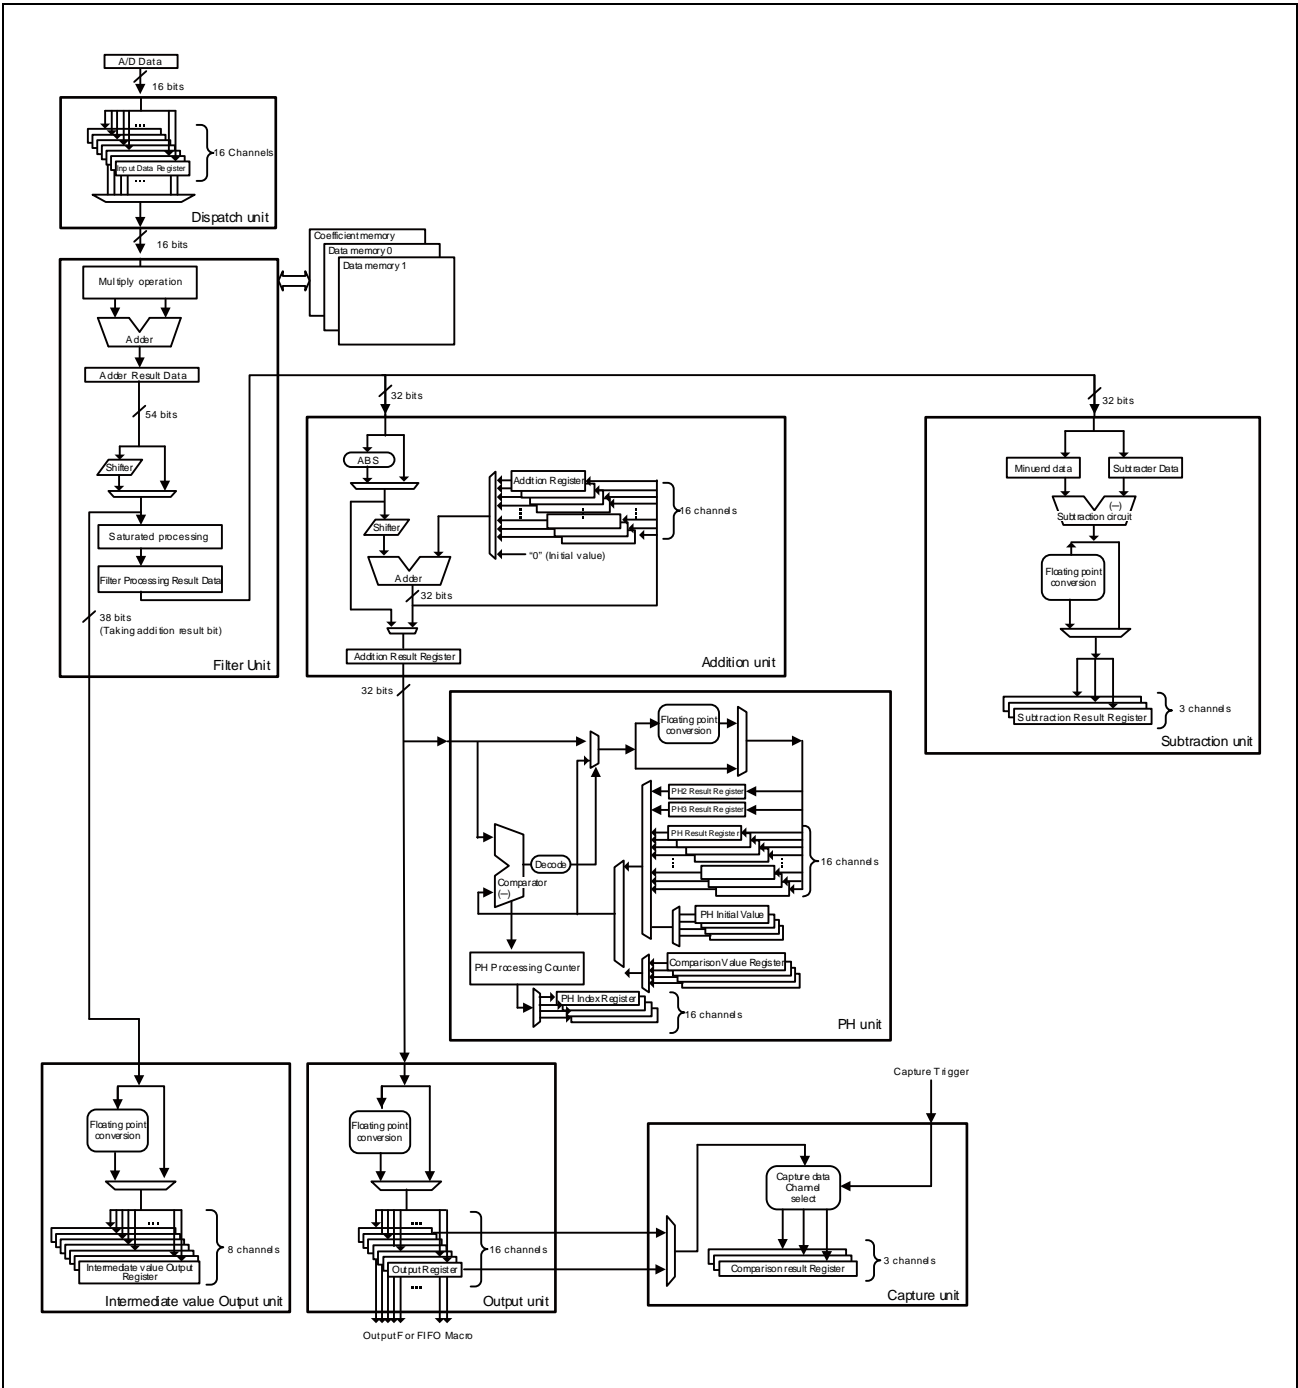

Figure 39.23 Data Flow of the DFE Macro

39.5.1.2 FIFO Macro

The data flow and the block diagram of the FIFO macro is shown below.

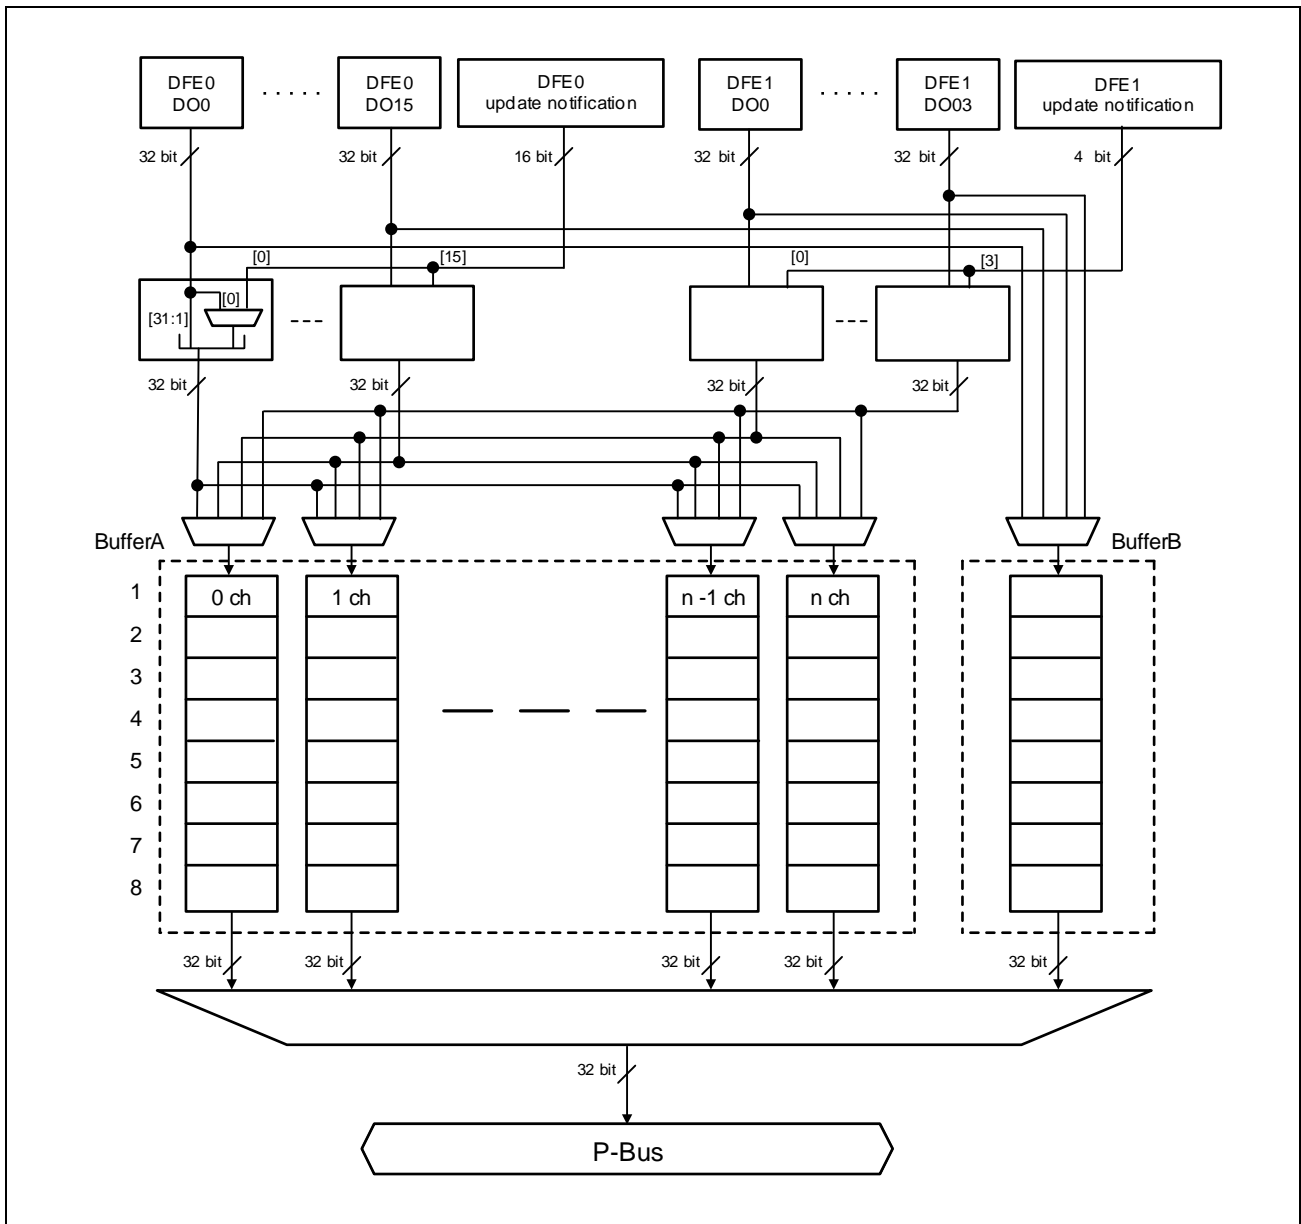

Figure 39.24 Data Flow of the FIFO Macro

39.5.2 Address Map

39.5.2.1 DFE Macro

Figure 39.25 shows an address map of the DFE.

Figure 39.25 Memory Map of the DFE Macro

39.5.2.2 FIFO Macro

An address map of FIFO macro is shown below.

Figure 39.26 Register Map of the FIFO Macro

39.5.3 Memory

Coefficients required for filter processing are stored in coefficient memory (CMEM). Data memory holds the input values for the FIR, and the initial and intermediate values for the IIR. Each channel has its own area. When the FIR 64-TAP is selected on an even-numbered channel (n), the coefficient memory is allocated as shown in the left part of the figure below. Although data memory areas are available to the next odd-numbered channel (n + 1), coefficient memory areas are not available; therefore, use of the next odd-numbered channel (n + 1) is prohibited.

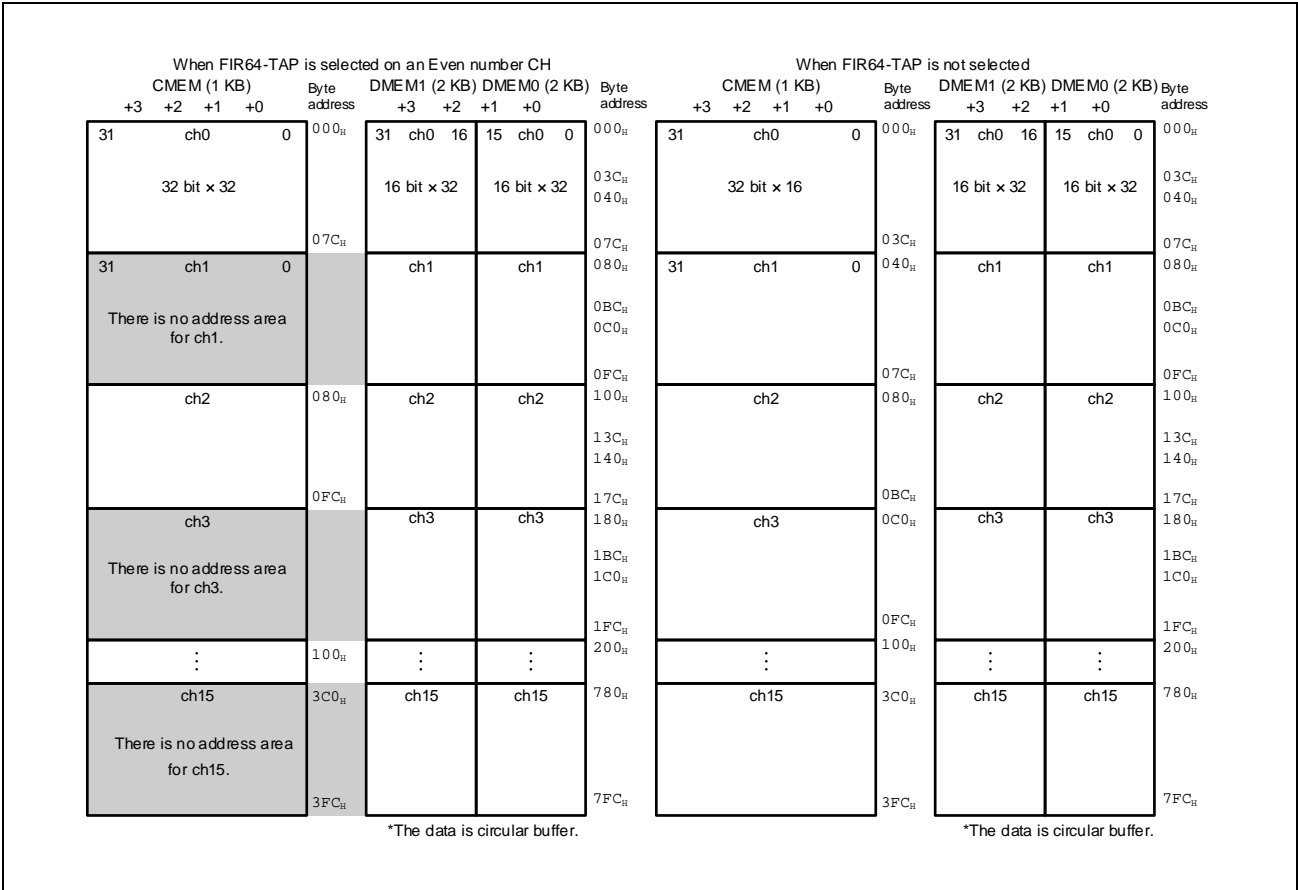

Figure 39.27 Usage of Memory (with and without the Selection of a 64-Tap FIR Filter)

39.5.4 Format of Coefficient Memory

Figure 39.28 shows the data format of the coefficient memory.

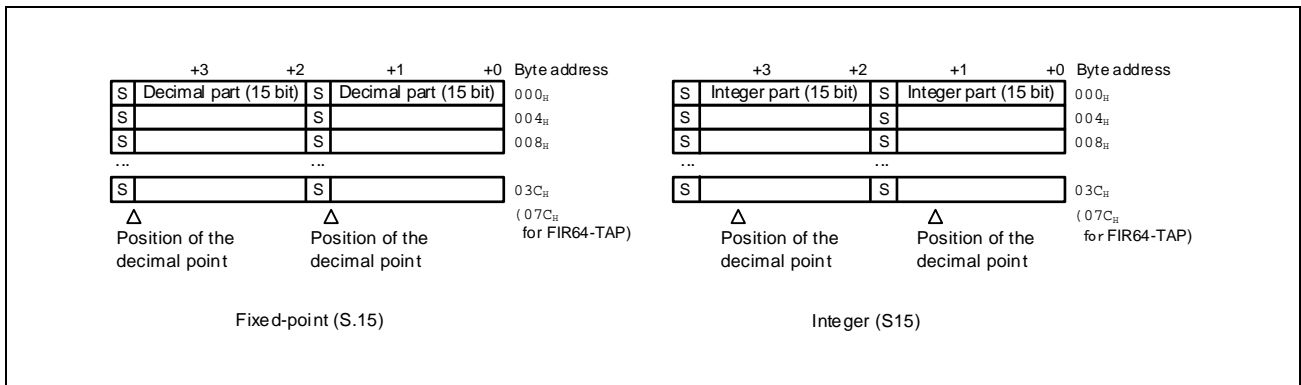

Figure 39.28 Decimal Point Positions in the Coefficient Memory (when the FIR is selected)

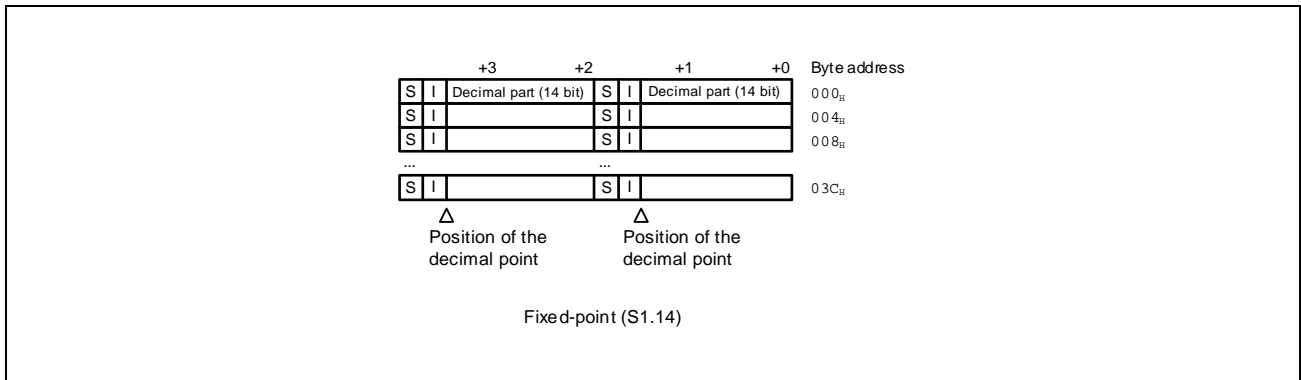

Figure 39.29 Decimal Point Positions in the Coefficient Memory (when the IIR is selected)

39.5.5 Format of Data Memory

Figure 39.30 shows decimal point positions of data in the data memory.

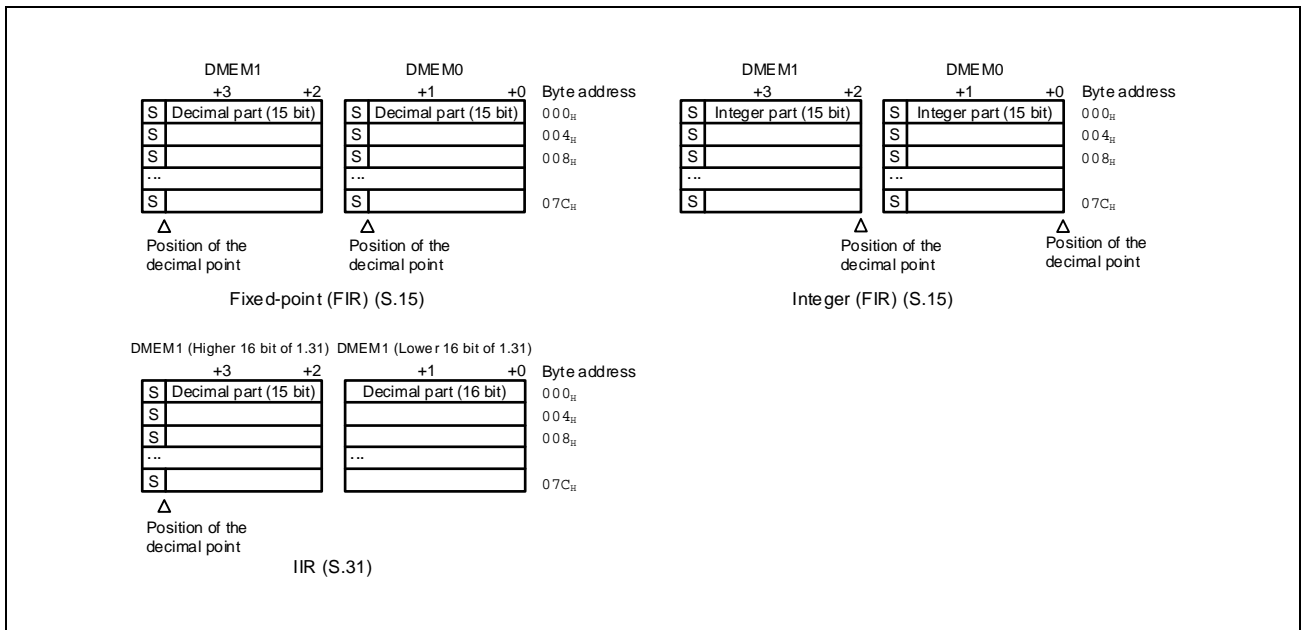

Figure 39.30 Decimal Point Positions in the Data Memory

39.5.6 Setting Control Registers

39.5.6.1 FIR (Fixed-Point)

The following table shows combinations of calculations and cascades that are selectable in the control register A (DFEjCTLACHn) and the control register B (DFEjCTLBCHn) when the FIR and fixed-point format are specified in the control register A. Don't use the cascade function in channels for which accumulation is selected.

Table 39.75 FIR (Fixed-Point)

Input Format	Filter	Accumulation or Decimation	Peak-Hold or Comparison	Floating-Point Conversion	Execution (Result)	Cascade (Output)*1	
Fixed-point (S1.15)	FIR	Accumulation	Peak-hold	Conversion specified	OK (floating-point)	NG	
				Conversion not specified	OK (S9.22)	NG	
				Comparison	Conversion specified	OK (floating-point)	NG
					Conversion not specified	OK (S9.22)	NG
				Not specified	Conversion specified	OK (floating-point)	NG
					Conversion not specified	OK (S9.22)	NG
			Decimation	Peak-hold	Conversion specified	OK (floating-point)	OK (S.15)
					Conversion not specified	OK (S.31)	OK (S.15)
				Comparison	Conversion specified	OK (floating-point)	OK (S.15)
					Conversion not specified	OK (S.31)	OK (S.15)
				Not specified	Conversion specified	OK (floating-point)	OK (S.15)
					Conversion not specified	OK (S.31)	OK (S.15)
		Not specified	Peak-hold	Conversion specified	OK (floating-point)	OK (S.15)	
				Conversion not specified	OK (S.31)	OK (S.15)	
			Comparison	Conversion specified	OK (floating-point)	OK (S.15)	
				Conversion not specified	OK (S.31)	OK (S.15)	
			Not specified	Conversion specified	OK (floating-point)	OK (S.15)	
				Conversion not specified	OK (S.31)	OK (S.15)	

Note 1. This setting is prohibited for NG combinations. For OK combinations, set fixed-point as the input data format of the cascade destination channels.

39.5.6.2 FIR (Integer)

The following table shows combinations of calculations and cascades that are selectable in the control register A (DFEjCTLACHn) and the control register B (DFEjCTLBCHn) when the FIR and integer format are specified in the control register A. When integer is specified, only the FIR filter processing can be executed. Do not specify floating-point conversion.

Table 39.76 FIR (Integer)

Input Format	Filter	Accumulation or Decimation	Peak-Hold or Comparison	Floating-Point Conversion	Execution (Result)* ¹	Cascade (Output)* ²	
Integer (S15)	FIR	Accumulation	Peak-hold	Conversion specified	NG	NG	
				Conversion not specified	NG	NG	
				Comparison	Conversion specified	NG	NG
					Conversion not specified	NG	NG
				Not specified	Conversion specified	NG	NG
					Conversion not specified	NG	NG
			Decimation	Peak-hold	Conversion specified	NG	OK (S15)
					Conversion not specified	OK (S31)	OK (S15)
				Comparison	Conversion specified	NG	OK (S15)
					Conversion not specified	OK (S31)	OK (S15)
				Not specified	Conversion specified	NG	OK (S15)
					Conversion not specified	OK (S31)	OK (S15)
		Not specified	Peak-hold	Conversion specified	NG	OK (S15)	
				Conversion not specified	OK (S31)	OK (S15)	
				Comparison	Conversion specified	NG	OK (S15)
					Conversion not specified	OK (S31)	OK (S15)
			Not specified	Conversion specified	NG	OK (S15)	
				Conversion not specified	OK (S31)	OK (S15)	

Note 1. The setting is prohibited for NG combinations.

Note 2. The setting is prohibited for NG combinations. For OK combinations, set integer as the input data format of the cascade destination channels.

39.5.6.3 IIR (Fixed-Point)

The following table shows combinations of calculations and cascades that are selectable in the control register A (DFEjCTLACHn) and the control register B (DFEjCTLBCHn) when the IIR is specified in the control register A. When the IIR is specified, only fixed-point format filter processing can be executed. When accumulation is specified, specification of the cascade function is prohibited.

Table 39.77 IIR

Input Format	Filter	Accumulation or Decimation	Peak-Hold or Comparison	Floating-Point Conversion	Execution (Result)	Cascade (Output)*1
Fixed-point (S.15)	IIR	Accumulation	Peak-hold	Conversion specified	OK (floating-point)	NG
				Conversion not specified	OK (S9.22)	NG
			Comparison	Conversion specified	OK (floating-point)	NG
				Conversion not specified	OK (S9.22)	NG
			Not specified	Conversion specified	OK (floating-point)	NG
				Conversion not specified	OK (S9.22)	NG
		Decimation	Peak-hold	Conversion specified	OK (floating-point)	OK (S.15)
				Conversion not specified	OK (S.31)	OK (S.15)
			Comparison	Conversion specified	OK (floating-point)	OK (S.15)
				Conversion not specified	OK (S.31)	OK (S.15)
			Not specified	Conversion specified	OK (floating-point)	OK (S.15)
				Conversion not specified	OK (S.31)	OK (S.15)
		Not specified	Peak-hold	Conversion specified	OK (floating-point)	OK (S.15)
				Conversion not specified	OK (S.31)	OK (S.15)
			Comparison	Conversion specified	OK (floating-point)	OK (S.15)
				Conversion not specified	OK (S.31)	OK (S.15)
			Not specified	Conversion specified	OK (floating-point)	OK (S.15)
				Conversion not specified	OK (S.31)	OK (S.15)

Note 1. The setting is prohibited for NG combinations. For OK combinations, set fixed-point as the input data format of the cascade destination channels.

39.5.7 Trigger Control

39.5.7.1 Timer Trigger Input

The digital filter uses compare An (n = 0 to 19) and compare Bn (n = 0 to 19), for a total of 40 signals as timer triggers through the synchronizer.

To compare An, five timer trigger flags (accumulation/decimation initialization flag, PH initialization flag, PH mask start flag, filter initialization flag, and subtraction starting flag) can be assigned.

To compare Bn, four timer trigger flags (accumulation/decimation disable flag, PH end flag, PH mask end flag, and subtraction end flag) are paired with the timer trigger functions selected for compare An are automatically assigned.

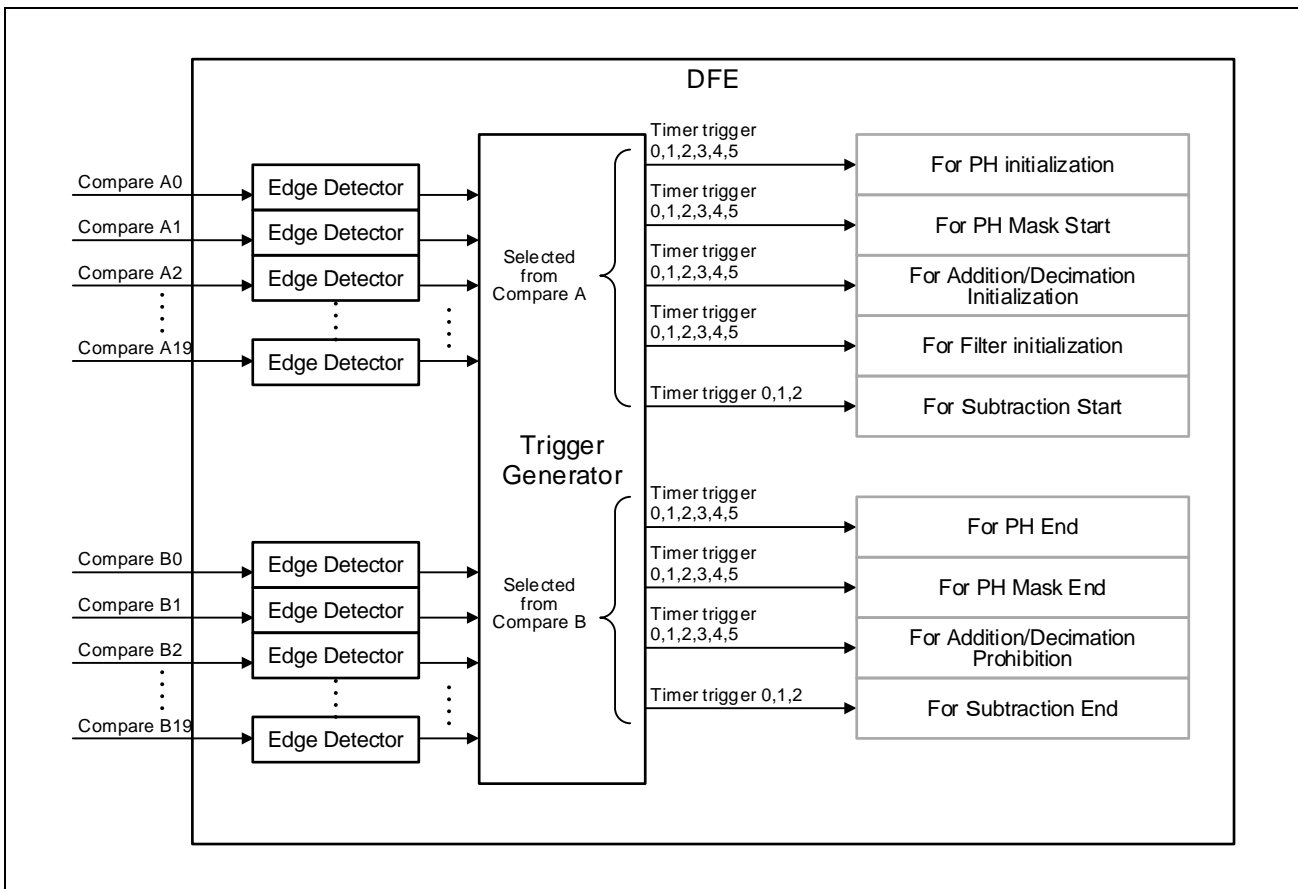

Figure 39.31 Timer Trigger Input

To compare B_n, the signal with the same number as the compare A_n selected for each flag is automatically assigned as the timer trigger for the corresponding trigger flag.

The table below shows the relationships between the trigger flags assigned to compare A_n and compare B_n, and the number of timer triggers available for each trigger flag.

Flag Corresponding to Compare A _n	Flag Corresponding to Compare B _n	Number of Selectable Timer Triggers
Accumulation/decimation initialization flag	Accumulation/decimation disable flag	6 (Timer Trigger 0-5)
Peak-Hold initialization flag	Peak-Hold end flag	6 (Timer Trigger 0-5)
Peak-Hold mask start flag	Peak-Hold mask end flag	6 (Timer Trigger 0-5)
Filter initialization flag	—	6 (Timer Trigger 0-5)
Subtraction start flag	Subtraction end flag	3 (Timer Trigger 0-2)

Compare B_n signals with the same number as the compare A_n signals that are selected for the accumulation/decimation initialization flag are automatically allocated to the accumulation/decimation disable flag timer triggers.

(1) Setting of Accumulation/Decimation Initialization/Disable Flag

For the accumulation/decimation initialization flag and accumulation/decimation disable flag, use of timer triggers 0 to 5 or timer triggers 0 to 3 is enabled with the settings shown below. It is recommended to use timer triggers in the mode where timer triggers 0 to 5 can be used.

(A) Settings for the Mode Where Timer Triggers 0 to 5 are Used

Bit Name	Setting	Description
DFEJTRGCHn.AFE	01 _B	Assigns the accumulation/decimation disabling flag to a timer flag.
DFEJTRGCHn.AE	11 _B	Selects the mode where timer triggers 0 to 5 are used.
DFEJTMTRGCHn.AT	000 _B to 101 _B	Selects a timer trigger to be used from timer triggers 0 to 5.
DFEjMITRG.MITMTRG _n (n = 0,1,2,3)	00000 _B to 10011 _B	Selects a compare A _n to be assigned to timer trigger n. (Set timer triggers 0 to 3.)
DFEjMITRG1.MITMTRG _n (n = 4,5)	00000 _B to 10011 _B	Selects a compare A _n to be assigned to timer trigger n. (Sets timer triggers 4 and 5.)

(B) Settings for the Mode Where Timer Triggers 0 to 3 are Used

Bit Name	Setting	Description
DFEJTRGCHn.AFE	01 _B	Assigns the accumulation/decimation disabling flag to a timer flag.
DFEJTRGCHn.AE	01 _B	Selects the mode where timer triggers 0 to 3 are used.
DFEJTRGCHn.AT	00 _B to 11 _B	Selects a timer trigger to be used from timer triggers 0 to 3.
DFEjMITRG.MITMTRG _n (n = 0,1,2,3)	00000 _B to 10011 _B	Selects a compare A _n to be assigned to timer trigger n.

(2) Setting of Peak-Hold Initialization/End Flag

For the Peak-Hold initialization flag and Peak-Hold end flag, use of timer triggers 0 to 5 or timer triggers 0 to 3 is enabled with the settings shown below. It is recommended to use timer triggers in the mode where timer triggers 0 to 5 can be used.

(A) Settings for the Mode Where Timer Triggers 0 to 5 are Used

Bit Name	Setting	Description
DfEjTRGCHn.PFE	01 _B	Assigns the Peak-Hold end flag to a timer flag.
DfEjTRGCHn.PE	11 _B	Selects the mode where timer triggers 0 to 5 are used.
DfEjTMTRGCHn.PT	000 _B to 101 _B	Selects a timer trigger to be used from timer triggers 0 to 5.
DfEjPITRG.PITMTRGn (n = 0,1,2,3)	00000 _B to 10011 _B	Selects a compare An to be assigned to timer trigger n.
DfEjPITRG1.PITMTRGn (n = 4,5)	00000 _B to 10011 _B	(Sets timer triggers 0 to 3.)

(B) Settings for the Mode Where Timer Triggers 0 to 3 are Used

Bit Name	Setting	Description
DfEjTRGCHn.PFE	01 _B	Assigns the Peak-Hold end flag to a timer flag.
DfEjTRGCHn.PE	01 _B	Selects the mode where timer triggers 0 to 3 are used.
DfEjTRGCHn.PT	00 _B to 11 _B	Selects a timer trigger to be used from timer triggers 0 to 3.
DfEjPITRG.PITMTRGn (n = 0,1,2,3)	00000 _B to 10011 _B	Selects a compare An to be assigned to timer trigger n. (Sets timer triggers 0 to 3.)

(3) Setting of Filter Initialization Flag

For the filter initialization flag, use of timer triggers 0 to 5 or timer triggers 0 to 3 is enabled with the settings shown below. It is recommended to use timer triggers in the mode where timer triggers 0 to 5 can be used.

(A) Settings for the Mode Where Timer Triggers 0 to 5 are Used

Bit Name	Setting	Description
DfEjTRGCHn.FE	11 _B	Selects the mode where timer triggers 0 to 5 are used.
DfEjTMTRGCHn.FT	000 _B to 101 _B	Selects a timer trigger to be used from timer triggers 0 to 5.
DfEjFITRG.FITMTRGn (n = 0,1,2,3)	00000 _B to 10011 _B	Selects a compare An to be assigned to timer trigger n. (Sets timer triggers 0 to 3.)
DfEjFITRG1.FITMTRGn (n = 4,5)	00000 _B to 10011 _B	Selects a compare An to be assigned to timer trigger n. (Sets timer triggers 4 and 5.)

(B) Settings for the Mode Where Timer Triggers 0 to 3 are Used

Bit Name	Setting	Description
DfEjTRGCHn.FE	01 _B	Selects the mode where timer triggers 0 to 3 are used.
DfEjTRGCHn.FT	00 _B to 11 _B	Selects a timer trigger to be used from timer triggers 0 to 3.
DfEjFITRG.FITMTRGn (n = 0,1,2,3)	00000 _B to 10011 _B	Selects a compare An to be assigned to timer trigger n. (Sets timer triggers 0 to 3.)

(4) Setting of Peak-Hold Mask Start/End Flag

For the Peak-Hold mask start flag and Peak-Hold mask end flag, use of timer triggers 0 to 5 is enabled with the settings shown below.

Bit Name	Setting	Description
DFEjTRGCHn.PMFE	01 _B	Assigns the PH mask ending flag to a timer flag.
DFEjTRGCHn.PME	01 _B	Selects the mode where timer triggers are used.
DFEjTMTRGCHn.PMT	000 _B to 101 _B	Selects a timer trigger to be used from timer triggers 0 to 5.
DFEjPMITRG0.PMITMTRGn (n = 0,1,2,3)	00000 _B to 10011 _B	Selects a compare An to be assigned to timer trigger n. (Sets timer triggers 0 to 3.)
DFEjPMITRG1.PMITMTRGn (n = 4,5)	00000 _B to 1001 _B	Selects a compare An to be assigned to timer trigger n. (Sets timer triggers 4 and 5.)

(5) Setting of Subtraction Start/End Flag

For the subtraction start flag and subtraction end flag, use of timer triggers 0 to 2 is enabled with the settings shown below.

Bit Name	Setting	Description
DFEjSUBTRGCHn.SBFE	01 _B	Assigns the subtraction end flag to a timer flag.
DFEjSUBTRGCHn.SBE	01 _B	Selects the mode where timer triggers are used.
DFEjSUBTRGCHn.SBT	00 _B to 10 _B	Selects a timer trigger to be used from timer triggers 0 to 2.
DFEjSUBTRG0.SUBTMTRGn (n = 0,1,2)	00000 _B to 1001 _B	Selects a compare An to be assigned to timer trigger n. (Sets timer triggers 0 to 2.)

39.5.7.2 Trigger Flag Functions

When the channel enable bit (DFEjCTRLACHn.EN) is 1, the DFE can generate flags of the following ten functions for each channel by using software triggers, timer triggers that are allocated to the trigger functions, and the trigger setting register (DFEjTRGCHn). (These flags are referred to as trigger flags hereafter.)

The accumulation/decimation processing is set with DFEjCTLBCHn.PRCSA, and the peak-hold processing is set with DFEjCTLBCHn.PRC SB.

Subtraction is set with DFEjSUBCTLCHn.SEN.

Whether accumulation/decimation processing is currently disabled or enabled can be read from DFEjCTLBn.DISA. Similarly, whether peak-hold processing is currently disabled or enabled can be read from DFEjCTLBn.DISB.

Both DFEjCTLBn.DISA and DFEjCTLBn.DISB can be set before the DFE starts processing (channel is disabled (DFEjCTRLACHn.EN = 0) and there is no data to be processed (DFEjSTCHn.VALID = 0)).

For details, see **Section 39.3.4, DFEjCTLBCHn — Control Register B n (n = 0 to 15 for DFE0, n = 0 to 3 for DFE1)**.

Table 39.78 Trigger Flags (1/2)

Flag Name	Description
Accumulation/decimation initialization flag	When the accumulation/decimation initialization flag is enabled by timer triggers or software triggers specified for each channel while accumulation/decimation processing is in progress or in the enabled or disabled state, the DFE initializes the counter of the accumulation circuit and executes accumulation/decimation processing for the subsequent input data.
Accumulation/decimation disable flag	When the accumulation/decimation disable flag is enabled by timer triggers or software triggers specified for each channel while accumulation/decimation processing is in progress or in the enabled state, the DFE disables accumulation/decimation processing for the subsequent input data. To enable accumulation/decimation processing again, enable the accumulation/decimation initialization flag.
Peak-hold initialization flag	When the peak-hold initialization flag is enabled by timer triggers or software triggers specified for each channel while peak-hold processing is in progress or in the enabled or disabled state, the DFE compares the next input data with the peak-hold initialization register value, not with the peak-hold processing result as before, and after that the DFE compares the subsequent data with the peak-hold processing result.
Peak-hold end flag	When the peak-hold end flag is enabled by timer triggers or software triggers specified for each channel while peak-hold processing is in progress or in the enabled state, the DFE disables peak-hold processing for the subsequent input data. The peak-hold end interrupt can be output when the peak-hold end flag is enabled. To enable peak-hold processing again, enable the peak-hold initialization flag.
Filter initialization flag	When the filter initialization flag is enabled by timer triggers or software triggers specified for each channel, the DFE initializes the filter processing address pointer and executes FIR/IIR processing from the initial value.

CAUTION

When timer triggers are used for the accumulation/decimation disable flag or peak-hold end flag, timer triggers 0 to 5 are automatically allocated as described in **Section 39.5.7.1, Timer Trigger Input**.

Table 39.78 Trigger Flags (2/2)

Flag Name	Description
Peak-Hold mask start flag	In any of the states where Peak-Hold processing is in progress, processing is enabled, or processing is disabled, if the Peak-Hold mask starting flag is enabled by the timer trigger or software trigger input set for each channel, Peak-Hold processing is halted on the subsequent input data. To restart Peak-Hold processing, enable the Peak-Hold mask end flag.
Peak-Hold mask end flag	In any of the states where Peak-Hold processing is in progress, processing is enabled, or processing is disabled, if the Peak-Hold mask ending flag is enabled by the timer trigger or software trigger input set for each channel, Peak-Hold processing is restarted on the subsequent input data.
Subtraction start flag	If the subtraction start flag is enabled by the timer trigger or software trigger input set for each channel, subtraction is initialized and started on the subsequent input data.
Subtraction end flag	If the subtraction end flag is enabled by the timer trigger or software trigger input set for each channel, subtraction is disabled on the subsequent input data. To enable subtraction again, enable the subtraction starting flag.
Automatic initialization flag	<p>If the automatic initialization flag is enabled by writing the channel enable bit (0 → 1), the processing below is executed on the subsequent input data.</p> <ul style="list-style-type: none"> • The target register is initialized when filtering process is started. • After the address pointer for filtering process is initialized, FIR/IIR processing is executed from the initial values (same as the function of the filter initialization flag). • The counter of the accumulation circuit is initialized. • Peak-Hold processing can be started from the state where the input data is compared to the value of the Peak-Hold initial value setting register.

CAUTION

If timer triggers are used for the Peak-Hold mask end flag and subtraction end flag, timer triggers are automatically assigned, as described in **Section 39.5.7.1, Timer Trigger Input**.

Timer triggers and software triggers can be allocated to trigger flags for each channel.

However, the timer triggers for the accumulation/decimation disable flag, Peak-Hold end flag, and Peak-Hold mask end flag are automatically assigned. Detailed operations of each trigger flag are described in the descriptions of the accumulation circuit, Peak-Hold circuit, and filtering circuit.

Table 39.79 Example of Trigger Flag Settings

	Accumulation/ Decimation Initialization Flag	Accumulation/ Decimation/ Disable Flag	Peak-Hold Initialization Flag	Peak-Hold Disable Flag	Filter Initialization Flag	Peak-Hold Mask Start Flag	Peak-Hold Mask End Flag
Channel 0	Timer trigger 0 (compare A0)	Compare B0 is automatically allocated according to the timer trigger selection.	None	None	Timer trigger 3	None	None
Channel 1	None	None	Timer trigger 2 (compare A9)	Compare B9 is automatically allocated according to the timer trigger selection.	Software trigger	Timer trigger 4 (compare A15)	Compare B15 is automatically allocated according to the timer trigger selection
...
Channel 9	Timer trigger 3 (compare A5)	Compare B5 is automatically allocated according to the timer trigger selection.	None	None	None
Channel 10	Timer trigger 1	Software trigger	None	None	Timer trigger 0	None	None
...
Channel 15	None	None	Timer trigger 4 (compare A4)	Compare B4 is automatically allocated according to the timer trigger selection	None	None	None

Timer triggers and software triggers can be assigned to trigger flags for each subtraction channel. However, the timer triggers for the subtraction end flag are automatically assigned. Detailed operations of the trigger flags are described in the descriptions of the subtraction circuit.

Table 39.80 Example of Subtraction Trigger Flag Settings

	Subtraction Starting Flag	Subtraction Ending Flag
0SCH	Timer trigger 0 (compare A16)	Compare B16 is automatically assigned when a timer trigger is selected.
1SCH	Timer trigger 1 (compare A17)	Compare B17 is automatically assigned when a timer trigger is selected.
2SCH	Timer trigger 2 (compare A18)	Software trigger

Trigger flags are valid for data that is input after a software trigger or timer trigger is generated.

If timer trigger 0 is set for the accumulation initialization flag in channel 0, for example, accumulation processing is initialized for the first input data in channel 0 after a timer trigger is generated.

To process the same data on multiple channels, the trigger flag settings should be the same to keep consistency in the processed data.

For example, when data input from AD0 is specified for channels 0 and 1 and the accumulation initialization flag is used, the same accumulation initialization flag timer trigger should be set for both channels 0 and 1.

Figure 39.32 Example of Trigger Flag Operation

39.5.7.3 Trigger Flag Functions and Processing

The accumulation circuit is set with DFEjCTLBCHn.PRCSA.

The Peak-Hold circuit is set with DFEjCTLBCHn.PRCSB and DFEjPH23CTL0.PEN.

Table 39.81 shows the register settings for the accumulation circuit and Peak-Hold circuit, and the relationships between the output data and interrupts according to the combinations of the trigger flag functions.

Table 39.81 Trigger Flag Functions and Processing

Accumulation Circuit		PH Circuit		Input Data Processing after Trigger Flag is Enabled					
Register Settings	Trigger Flag Functions	Register Settings	Trigger Flag Functions	Output Data Write	Output Data Interrupt	Condition Match Interrupt	Peak-Hold End Interrupt	Peak-Hold Update Notification	
PRCSA = 00 _B (Neither accumulation nor decimation executed)	Both accumulation/decimation initialization flag and disable flag disabled	PH/comparison disabled	Both PH initialization flag and disable flag disabled	Provided	Not provided*2	Not provided	Not provided	Not provided	
		Comparison executed exclusively		Provided	Not provided*2	Provided	Not provided	Not provided	
		PH executed exclusively	PH enabled	Provided	Not provided*2	Not provided	Not provided	Not provided	Provided
			PH ended	Provided	Not provided*2	Not provided*1	Not provided	Not provided	Not provided
		PH and comparison executed simultaneously	PH enabled	Provided	Not provided*2	Provided	Not provided	Not provided	Provided
			PH ended	Provided	Not provided*2	Provided	Provided	Not provided	Not provided
		PH23 executed	PH enabled	Provided	Not provided*2	Provided	Not provided	Not provided	Provided
PH ended	Provided		Not provided*2	Not provided	Provided	Not provided	Not provided		
PRCSA = 01 _B or 10 _B (Either accumulation or decimation executed)	Accumulation/decimation enabled	PH/comparison disabled	Both PH initialization flag and disable flag disabled	Provided	Provided	Not provided	Not provided	Not provided	
		Comparison executed exclusively		Provided	Provided	Provided	Not provided	Not provided	
		PH executed exclusively	PH enabled	Provided	Provided	Not provided	Not provided	Not provided	Provided
			PH ended	Provided	Provided	Not provided*1	Not provided	Not provided	Not provided
		PH and comparison executed simultaneously	PH enabled	Provided	Provided	Provided	Not provided	Not provided	Provided
			PH ended	Provided	Provided	Provided	Provided	Not provided	Not provided
		PH23 executed	PH enabled	Provided	Provided	Provided	Not provided	Not provided	Provided
PH ended	Provided		Provided	Not provided	Provided	Not provided	Not provided		
PRCSA = 01 _B or 10 _B (Either accumulation or decimation executed)	Accumulation/decimation disabled	PH/comparison disabled	Both PH initialization flag and disable flag disabled	Not provided	Not provided	Not provided	Not provided	Not provided	
		Comparison executed exclusively		Not provided	Not provided	Not provided	Not provided	Not provided	
		PH executed exclusively		Not provided	Not provided	Not provided	Not provided	Not provided	
		PH and comparison executed simultaneously		Not provided	Not provided	Not provided	Not provided	Not provided	
		PH23 executed		Not provided	Not provided	Not provided	Not provided	Not provided	

Note 1. The interrupt is output when the peak-hold end flag is enabled.

Note 2. Refer to the Output Circuit Register.

When accumulation/decimation processing and peak-hold/comparison processing are used in the same channel with the accumulation/decimation count specified, peak-hold processing is executed on each specified count.

If accumulation/decimation processing is disabled by the trigger flag function, peak-hold/comparison processing is not executed, either. Do not input software triggers or timer triggers for the trigger flag function for peak-hold initialization, peak-hold end trigger flag, peak-hold mask start or peak-hold mask end trigger flag functions to a channel with accumulation/decimation processing disabled.

39.5.7.4 Automatic Initialization of the Channel

When the automatic initialization enable bit (DFEjCTLACHn.AIME) is 1, automatic initialization of the channels is available. When the channel enable bit (DFEjCTLACHn.EN) is modified from 0 to 1, the automatic initialization flag of the channel is enabled.

The automatic initialization flag of the channel is also enabled when 1 is simultaneously written to the automatic initialization enable bit and the channel enable bit.

When the automatic initialization flag of the channel is enabled, the address pointer of the filtering process of the next input data is initialized, and then FIR/IIR processing with initialization is executed.

Also, the registers are initialized simultaneously with the filtering process, and after the filtering process, the accumulation circuit and PH circuit are returned to the initial state. But the accumulation circuit and the peak-hold circuit is not set valid by the automatic initialization flag.

The registers below are initialized.

Register Name		Function
Output data register	DFEjDOCHn	Cleared when the channel processing is started.
Intermediate values output registers L	DFEjHOLCHn	Same as above
Intermediate values output registers H	DFEjHOHCHn	Same as above
Intermediate values output mirror registers L	DFEjHOLMCHn	Same as above
Peak-Hold result register	DFEjPHCHn	Same as above
Peak-Hold index register	DFEjPHINDCHn	Same as above
Status register Status Register PH23 processing status	DFEjSTCHn.PH23ST	Same as above
Peak-Hold 2 Result Register 0*1	DFEjPH20	Same as above
Peak-Hold 3 Result Register 0*1	DFEjPH30	Same as above
Peak-Hold 2 index register*1	DFEjPH2IND0	Same as above
Peak-Hold 3 index register*1	DFEjPH3IND0	Same as above

Note 1. Cleared when the PH23 function is enabled (DFEjPH23CTL0.PEN = 1) and the PH23 function is enabled for the pertinent channel (the pertinent channel number is set with DFEjPH23CTL0.CHS).

When the channel enable bit (DFEjCTLACHn.EN) is modified from 0 to 1, the automatic initialization flag of the channel is enabled. When the automatic initialization flag of the channel is enabled and processing of the next channel is started, FIR or IIR processing with initialization is executed.

Also, the pertinent registers are initialized simultaneously with the start of the filtering process.

After the filtering process, the accumulator and counter for accumulation in the accumulation circuit are initialized even if accumulation/decimation processing is disabled.

After the accumulation process, the Peak-Hold counter in the PH circuit is initialized even if the PH processing has been finished. Also, the PH circuit retains the state in which comparison is possible between the data that was input to the PH circuit during the PH processing and the value of the PH initial value register.

After that, in the PH processing of the subsequent filtering process after PH processing is enabled, the data that was input to the PH circuit is compared to the value of the PH initial value register. Subsequently, in PH processing, the data that was input to the PH circuit is compared to the value of the PH result register.

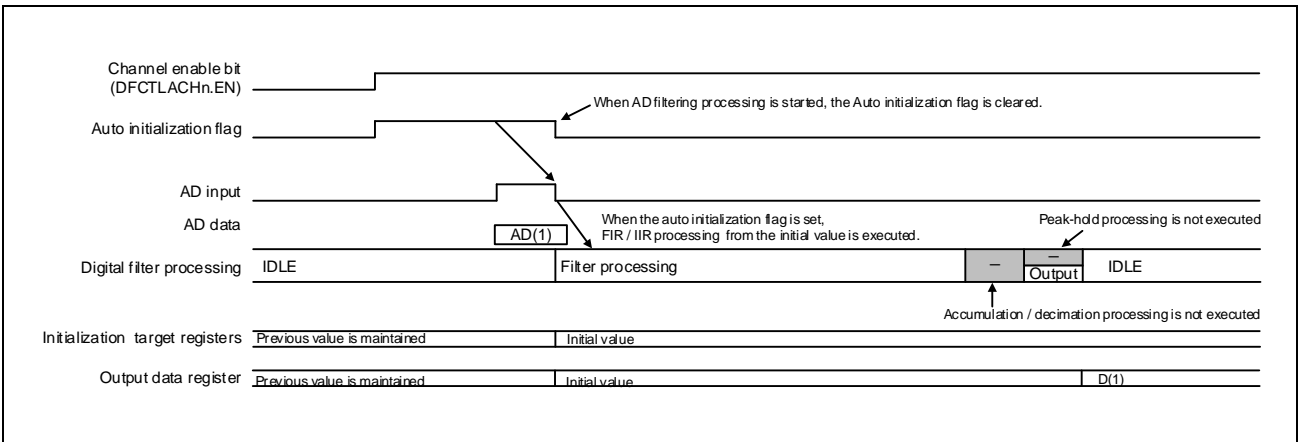

Figure 39.33 Operations of the Channel Automatic Initialization Flag

After the automatic initialization flag of the channel is enabled, the automatic initialization flag is maintained until the filtering process of the channel is requested. However, the automatic initialization flag is cleared if the channel enable bit becomes 0. If 1 is written again to the channel enable bit with the automatic initialization enable bit (DFEjCTLACHn.AIME) being 1, the automatic initialization flag is enabled.

Figure 39.34 Clear Channel Automatic Initialization Flag

39.5.8 Input Data Control

This macro accepts the input of the data listed in the table below.

Table 39.82 Classification of Input Data

Classification	Input Data
AD input	SAR-AD
	Delta-Sigma AD
	Cyclic-AD
Cascade Input	Filter Result Data
	Subtraction Result Data
Software Input	Software Input Data (DFEjDI.DI)

39.5.8.1 AD Input

The digital filter compares the TAG value (called the channel tag hereafter) set in the TAG bits in DFEjCTLACHn for each channel and the TAG input from the AD, and executes processing in the channel that has the matched tag value. This function allows single piece of AD data to be input to processing on multiple channels.

39.5.8.2 Cascade Input

The digital filter has a cascade input function to input the filter processing result or Subtraction result again.

When the filter processing result is input, this cascade input function rounds the 32-bit accumulation circuit output data to 16-bit data, and then executes filter processing again.

When the Subtraction result is input, this cascade input function rounds the 32-bit subtraction circuit output data to 16-bit data, and then executes filter processing again.

In integer mode, when the accumulation circuit output data or subtraction circuit output data is a positive value and the 16 high-order bits contain a valid value, the output data is rounded to a 16-bit positive maximum value (7FFF_H). When the accumulation circuit output data or subtraction circuit output data is a negative value and the 16 high-order bits contain a valid value, the output data is rounded to a 16-bit negative minimum value (8000_H). If rounding of both positive and negative values occurs, the cascade rounding error flag is set to 1.

In fixed-point mode, the accumulation circuit output data or subtraction circuit output data is added to 0000 8000_H and rounding is executed. As a result of this addition, if an overflow occurs in 32-bit positive value, the added data is rounded to a positive maximum value (7FFF_H) and the cascade rounding error flag is set.

The CAEN bits in the DFEjCTLACHn or DFEjSUBCTLCHn control registers can enable or disable the cascade input function and enable or disable the output data register mask function.

Table 39.83 CAEN Flag Function

CAEN Bits	Description
00 _B	Cascade input is disabled. Calculation results are written to the output data register: Value after a reset.
01 _B	Setting prohibited
10 _B	Cascade input is enabled. Calculation results are written to the output data register.
11 _B	Cascade input is enabled. Calculation results are not written to the output data register.

(1) Cascade Input of Filter Processing Results

When a cascade input is enabled, the cascade input destination channel is specified by using the cascade tag value for (cascade tag hereafter). The cascade tag is set by the CATAG bits in DFEjCTLACHn. The DFE compares the cascade tag with the channel tag, and executes cascade input filter processing on the channel where the tags matched. The following figures show operations when the cascade input is enabled.

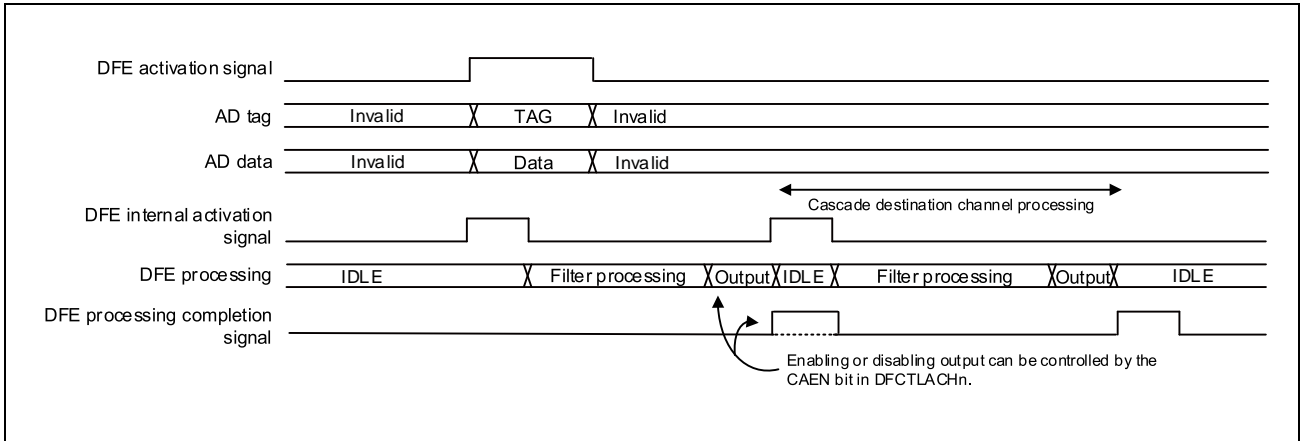

Figure 39.35 Cascade Input Processing (Normal Processing)

When a cascade input is enabled and decimation is specified, a decimation result becomes the cascade input data. When the decimation count is set to 4, for example, the data after filter processing of the fourth AD input becomes the cascade input data.

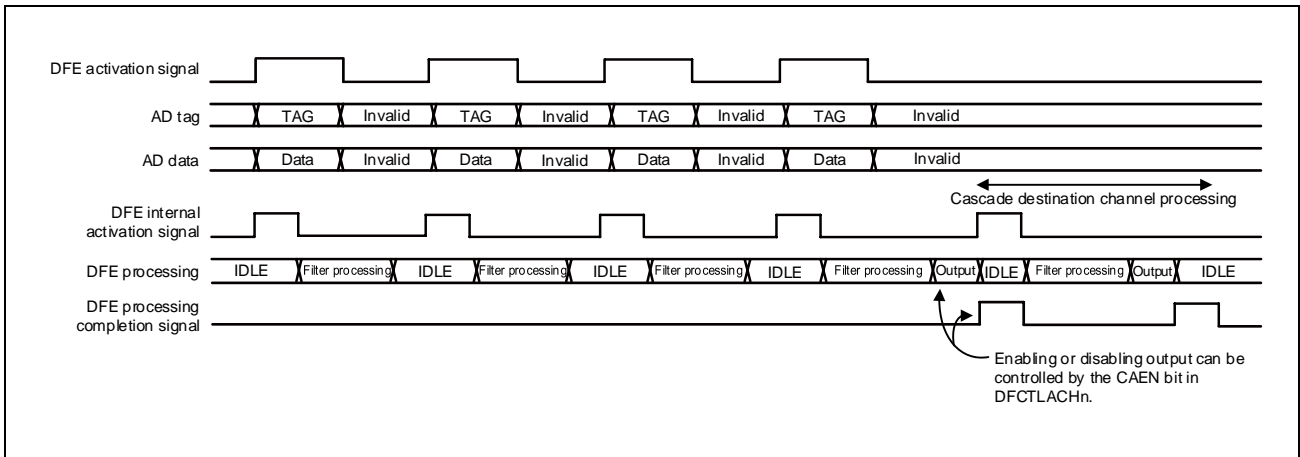

Figure 39.36 Cascade Input Processing (Decimation: 4 Times)

(2) Cascade Input of Subtraction Results

When the cascade input is enabled, a cascade tag is used for the subtraction channel to specify a cascade input destination channel. The cascade tag for subtraction channels is specified with the DFEjSUBCTLCHn.CATAG. The DFE, comparing the cascade tag for the subtraction channel with the channel tag, performs filtering on the cascade input on a matching channel. The text below describes the operation that occurs when the cascade input is enabled.

The cascade input on the results of the subtraction operation is used for each filtering process on the subtrahend channel and the minuend channel, regardless of the specified number of accumulation/decimation operations.

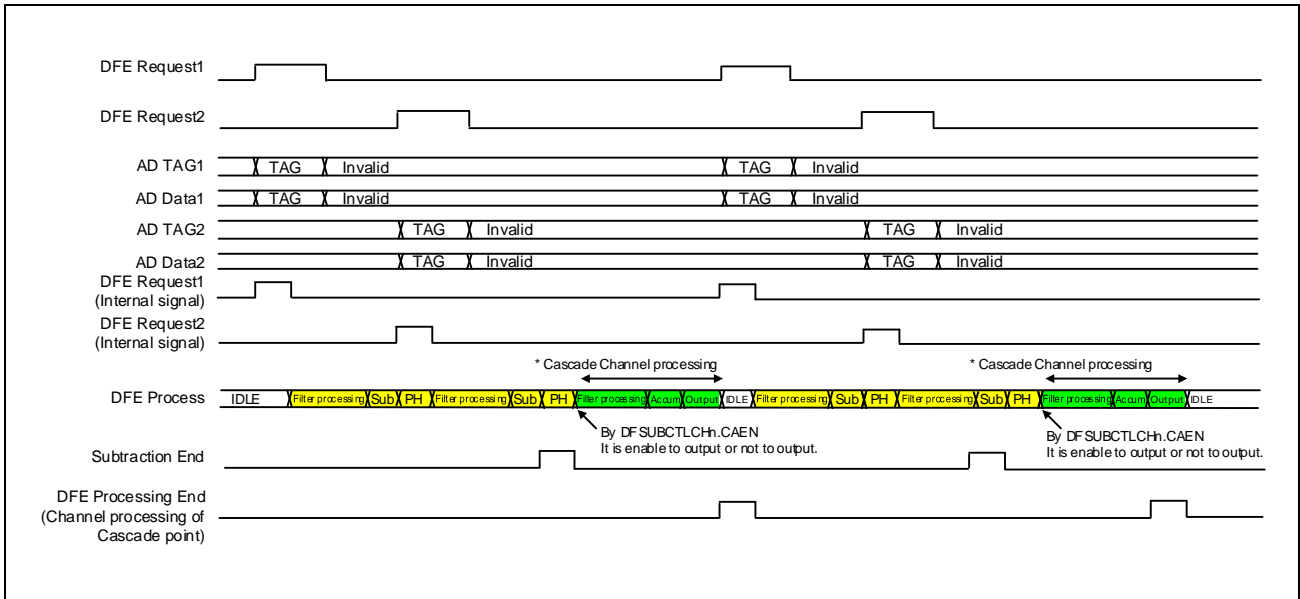

Figure 39.37 Cascading Input Processing on a Subtraction Channel

39.5.8.3 Software Input

The DFE has a function to input DFE processing target data through the peripheral bus by using the CPU or DMA. (This function is referred to as software input function hereafter.) DFE processing can be started by writing filter processing target data and a tag value to the software input data register (DI) from the peripheral bus.

39.5.8.4 Dispatch

A channel to be processed is selected by an activation signals of an AD input (Delta-Sigma AD , SAR-AD and Cyclic-AD), a cascade input, or a software input and the channel tag, and then the data to be processed is stored in the input data register of each channel. This processing is called dispatch.

After the data to be processed is stored in the input data register, the input data register is enabled until the accumulation circuit processing is completed. If new data is stored in the same channel while the input data register is enabled, the data is overwritten and causes an input data overwrite error (DIOW).

Figure 39.38 Input Data Overwrite (DIOW) Error

When the input data register of each channel is enabled, filter processing target data is arbitrated. The highest priority is given to the processing for channel 0, the second highest priority is given to the processing for channel 1, and the lowest priority is given to the processing for channel 11 in the DFE0, for channel 3 in the DFE1. The input data register value of arbitrated channels is input to the filtering circuit where FIR/IIR processing is applied to the input data register value according to the control register value.

If the same data is set for multiple channels, processing is also executed for all of the specified channels in the channel priority order. If the trigger flag function is enabled, it is not applied until the next input data processing.

For example, if the same input data is set for multiple channels, accumulation processing is set, and the same accumulation/decimation disable trigger is set for all the channels, accumulation is not disabled until the next input data processing if there are any channels for which accumulation processing has not been performed when the disable trigger is input.

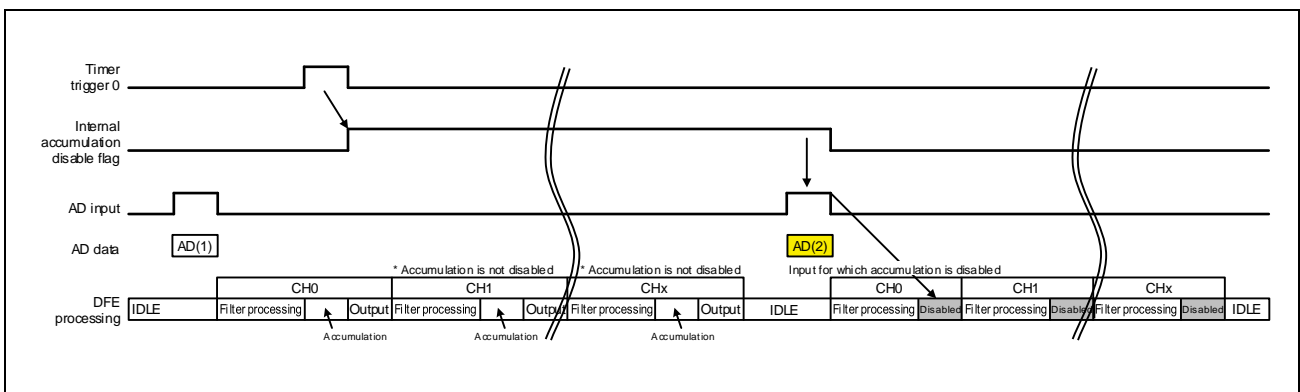

Figure 39.39 Processing when the Same Input Data is Set for Multiple Channels

39.5.9 Filtering Circuit

The filter circuit accepts requests for a single channel selected by the dispatch circuit from among channels 0 to 11 in the DFE0, channel 0 to 3 in the DFE1. When the FIR 64TAP is used on an even-numbered channel, although requests from the channel are accepted, no requests from the next odd-numbered channel are accepted. Once a request is accepted, the selected type of filtering (FIR or IIR) starts. Another request cannot be accepted during execution of filter processing. Upon completion of processing in the accumulation circuit, the DFE accepts a new request. Coefficients required for filtering are stored in the coefficient memory and input data to be used for FIR processing and intermediate data to be used for IIR processing are stored in the data memory. These memory areas are allocated for each channel.

39.5.9.1 FIR (8, 16, 24, 32 Taps)

Figure 39.40 shows the FIR filter configuration.

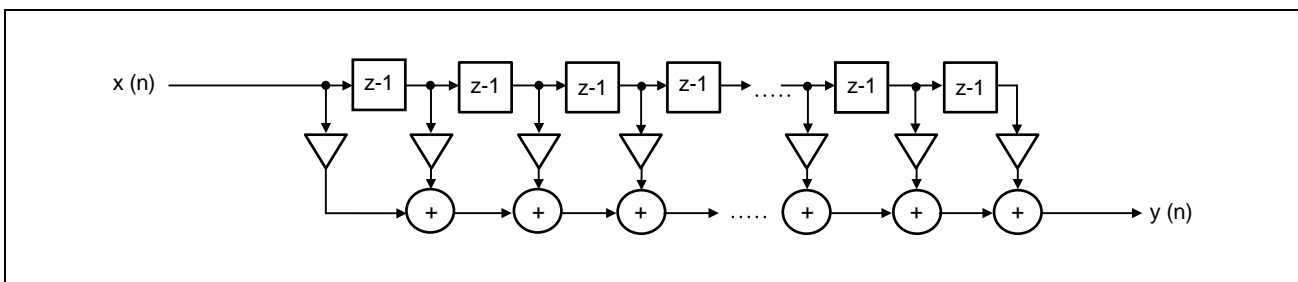

Figure 39.40 FIR Filter Configuration

Before starting FIR filter processing, set values in the coefficient memory and data memory buffer area.

For example, in the case of a 32-tap FIR filter, set value from C[0] to C[31] in coefficient memory and set 0000_H to circular buffer area (= ring buffer area) in data memory.

Figure 39.41 FIR Memory (FIR 32 TAP)

Figure 39.41 shows the access area of coefficient and data memory in the case of a 32-tap FIR.

When 8-tap/16-tap/24-tap FIR filters is selected, the access area of coefficient memory and data memory is same as 32-tap FIR.

When the filter processing initialization flag indicates “enabled”, DFE writes 0000_H in circular buffer area for the number of taps before filter processing starts. For example, when 32-tap FIR filter is selected, after DFE writes 0000_H in circular buffer area from D[0] to D[31], FIR processing is executed.

39.5.9.2 FIR (64 Taps)

When 64-tap FIR filter is selected, set values in the coefficient memory, and data memory buffer area as in 8-tap/16-tap/24-tap/32-tap FIR filter, before filter processing is executed.

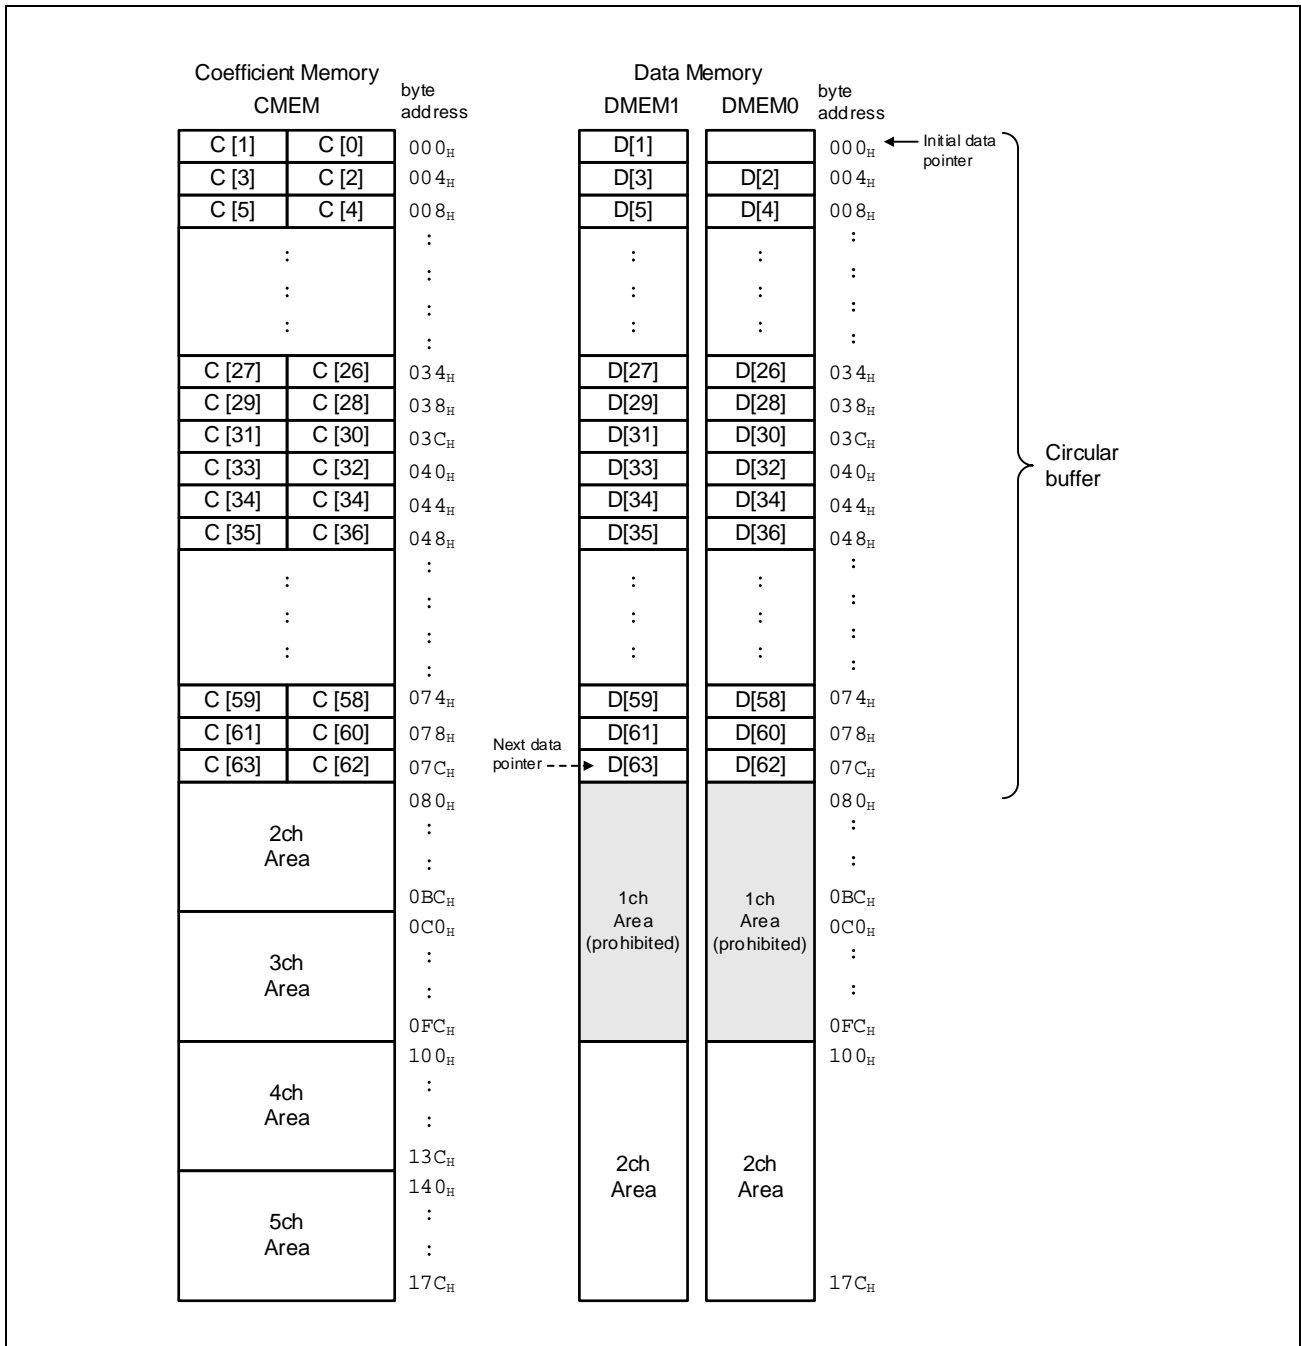

Figure 39.42 FIR Memory (when a 64-Tap FIR Filter is selected)

Figure 39.42 shows the access area in coefficient memory and data memory in the case of a 64-tap FIR. 64-tap FIR can be selected in only even number channels. When the filter processing initialization flag indicates “enabled”, DFE writes 0000_H in circular buffer area from D[0] to D[63] before filter processing is executed.

39.5.9.3 One-Stage IIR

Figure 39.43 shows the configuration of a one-stage IIR filter.

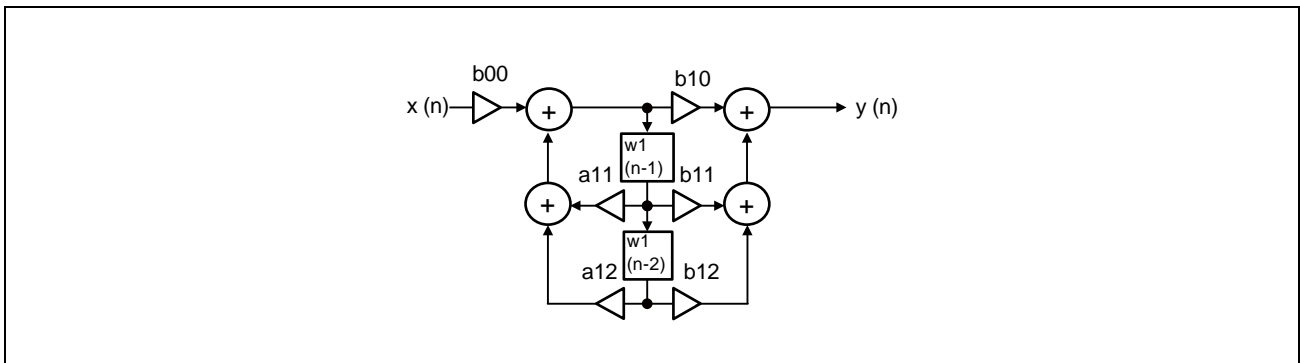

Figure 39.43 Configuration of a One-Stage IIR Filter

Before starting IIR filter processing, set values in the coefficient memory and data memory buffer area. Set the intermediate value in circular buffer area of the data memory. And set the initial value in initial value buffer area of the data memory.

Figure 39.44 Memory Usage for a One-Stage IIR Filter

Figure 39.44 shows the access area in coefficient memory and data memory in the case of a one-stage IIR.

When the filter processing initialization flag indicates “enabled”, DFE initializes data pointer of the circular buffer area to “0”. And DFE writes the data of initial value buffer to the target circular buffer before filter processing is executed.

39.5.9.4 Two-Stage IIR

Figure 39.45 shows the configuration of a two-stage IIR filter.

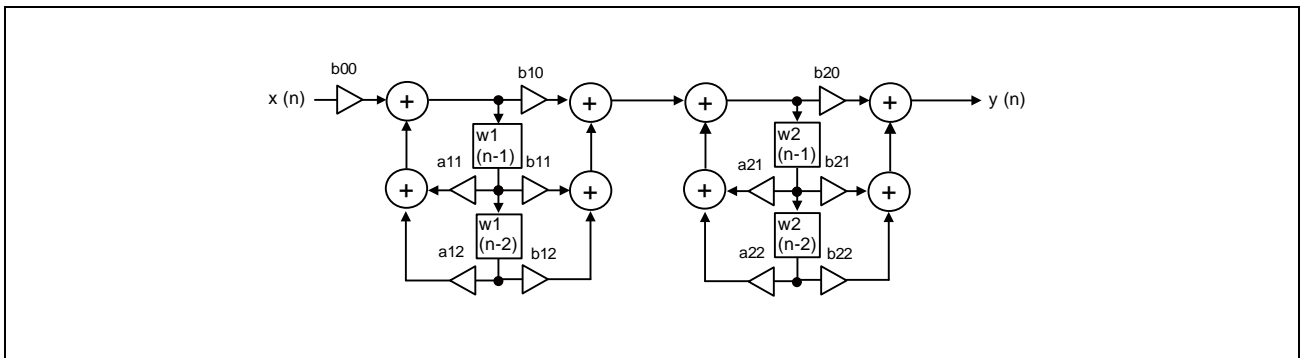

Figure 39.45 Configuration of a Two-Stage IIR Filter

The figure below shows an IIR filter configuration of a second-order 2-stage biquad IIR with a gain adjustment function.

The second-order 2-stage biquad IIR with a gain adjustment function can be used when $DFEjCTLACHn.CMD = 1101_B$. The value of GAIN2 can be set in the IIR filter gain setting register (DFEjGAINCHn).

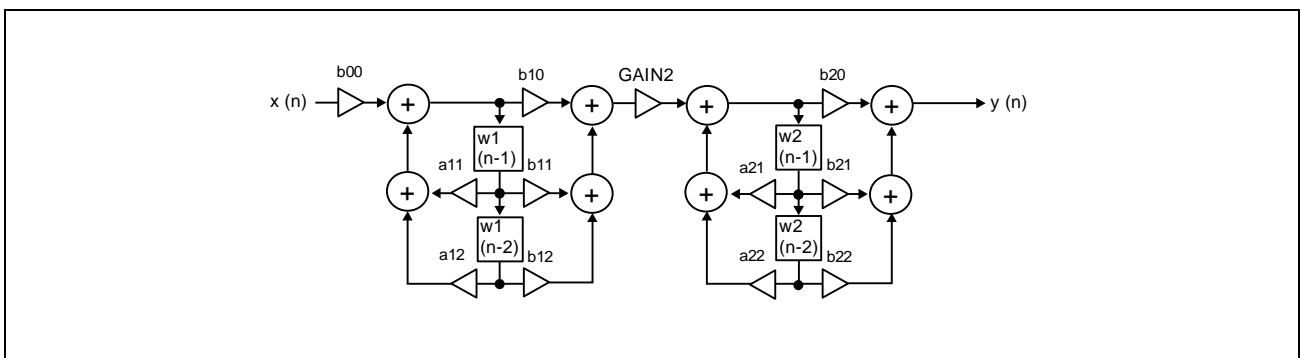

Figure 39.46 Configuration of a Two-Stage IIR Filter with Gain Adjustment Function

Before starting IIR filter processing, set values in IIR Filter Gain Setting Register (DFEjGAINCHn), the coefficient memory and data memory buffer area. Set the intermediate value in circular buffer area of the data memory. And set the initial value in initial value buffer area of the data memory.

Figure 39.47 Memory Usage for a Two-Stage IIR Filter

Figure 39.47 shows the access area in the coefficient memory and data memory in the case of a two-stage IIR.

When the filter processing initialization flag indicates “enabled”, DFE initializes data pointer of the circular buffer area to “0”. And DFE writes data of initial value buffer to the target circular buffer before filter processing is executed.

39.5.9.5 Three-Stage IIR

Figure 39.48 shows the configuration of a three-stage IIR filter.

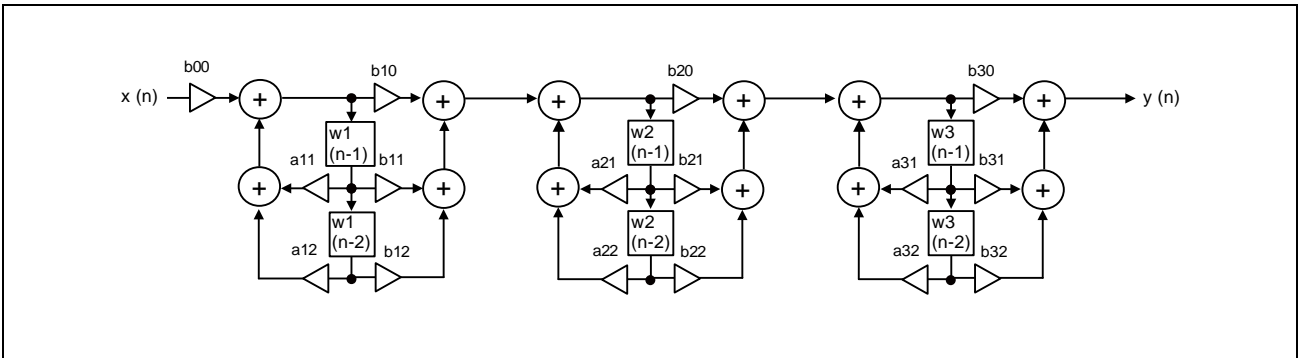

Figure 39.48 Configuration of a Three-Stage IIR Filter

The figure below shows an IIR filter configuration of a second-order 3-stage biquad IIR with a gain adjustment function. The second-order 3-stage biquad IIR with a gain adjustment function can be used when $DFEjCTLACHn.CMD = 1110_B$. The values of GAIN2 and GAIN3 can be set in the IIR filter gain setting register (DFEjGAINCHn).

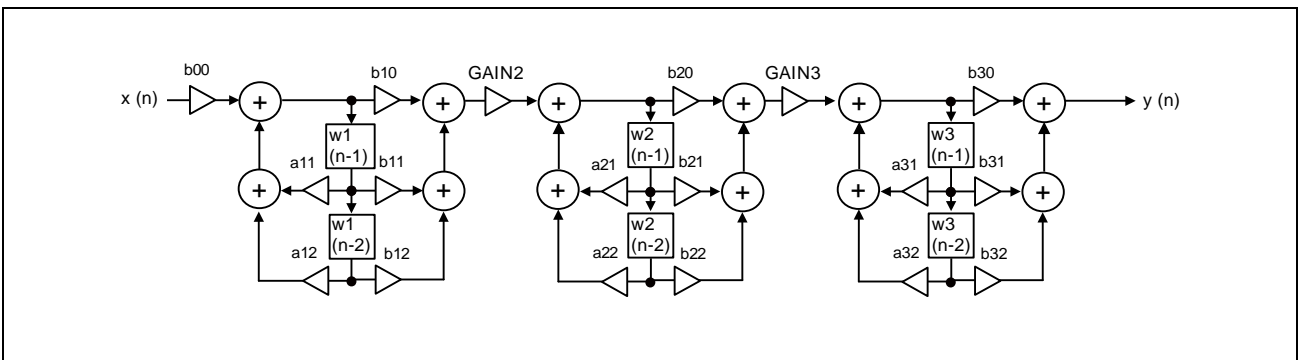

Figure 39.49 Configuration of a Three-Stage IIR with Gain Adjustment Function

Before starting IIR filter processing, set values in IIR Filter Gain Setting Register (DFEjGAINCHn), the coefficient memory and data memory buffer area. Set the intermediate value in circular buffer area of the data memory. And set the initial value in initial value buffer area of the data memory.

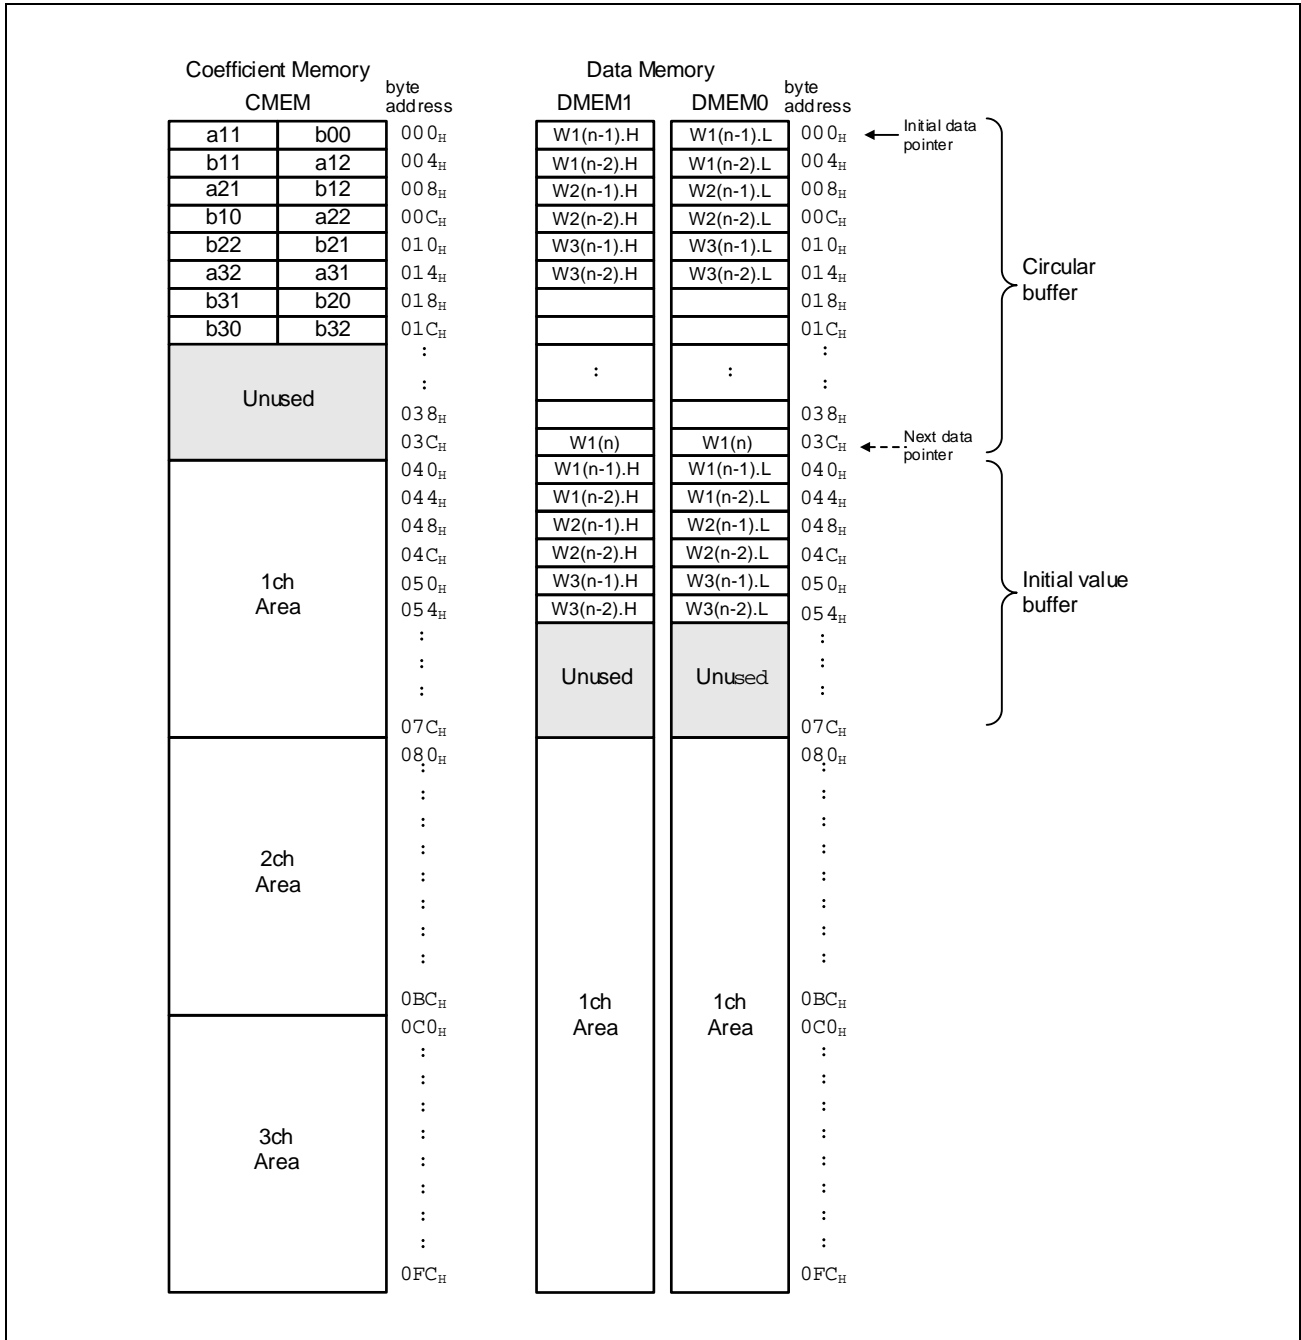

Figure 39.50 Memory Usage for a Three-Stage IIR Filter

Figure 39.50 shows the access area in the coefficient memory and data memory in the case of a three-stage IIR.

When the filter processing initialization flag indicates “enabled”, DFE initializes data pointer of the circular buffer area to “0”. And DFE writes data of initial value buffer to the target circular buffer before filter processing is executed.

39.5.9.6 Errors in the Filtering Circuit

If multiplication of $8000_{\text{H}} \times 8000_{\text{H}}$ is performed by the multiplier, a multiplication error occurs and the multiplication error flag is set to 1.

To prevent an overflow in the multiplication result processing, 3 input adder (54bit) is composed to multiplication data area (48bit) and guard bit area (6bit). To round 54bit of multiplication result to 32bit, DFE accumulates $00\ 0000\ 0000\ 4000_{\text{H}}$ (when IIR 2.14 is selected, $00\ 0000\ 0000\ 2000_{\text{H}}$) to multiplication result (54bit). When guard bits contain a valid value after the rounding operation, the error flag is set to 1. This error is called guard bit error.

When the rounded multiplication result is larger than the 32-bit positive maximum value ($7\text{FFF}\ \text{FFFF}_{\text{H}}$), the result is rounded to $7\text{FFF}\ \text{FFFF}_{\text{H}}$ (saturation processing). When the rounded multiplication result is smaller than the 32-bit negative minimum value ($8000\ 0000_{\text{H}}$), the result is rounded to $8000\ 0000_{\text{H}}$ (saturation processing).

39.5.10 Accumulation Circuit

The accumulation circuit has a function to execute absolute value conversion, accumulation processing, or decimation processing for the filter processing result data that is output from the filtering circuit. The accumulation circuit then outputs the processing result data to the output circuit and/or the peak-hold circuit. When the cascade function is used, the accumulation circuit sends the accumulation circuit output data to the dispatch circuit.

39.5.10.1 Absolute Value Calculation

The filter processing result data that is output from the filtering circuit is converted to an absolute value. When the ABS bit in DFEjCTLBCHn is 1, absolute value conversion is executed. When the ABS bit is 0, absolute value conversion is not executed. If the filter processing result data that is output from the filtering circuit is $8000\ 0000_{\text{H}}$, an absolute value error is generated. The absolute value conversion result when this occurs is $7\text{FFF}\ \text{FFFF}_{\text{H}}$.

Absolute value conversion can be performed even if the PRCSA bit is set to 00_{B} in DFEjCTLBCHn . Accumulation/decimation processing is performed on the absolute value of conversion result.

39.5.10.2 Summary of Accumulation Processing

In accumulation processing, the filter processing result data that is input to the accumulation circuit is arithmetically shifted to the right (9 bits), and then this filter processing result data is added to the filter processing result data that has been input for each channel.

The data format after the accumulation processing is (10.22). Accumulation processing can be executed up to 511 times. After processing for the specified accumulation count has been completed, accumulation processing is executed again.

When the PRCSA bits in DFEjCTLBCHn are 01_{B} , accumulation processing is executed. Specify the accumulation processing count with the SELA bits in DFEjCTLBCHn by selecting one of the four accumulation/decimation count setting registers (ACA to ACD).

39.5.10.3 Operation of Accumulation Processing

The operation of accumulation processing is explained using an example when $ACA = 000_H$, $ACB = 001_H$, $ACC = 002_H$, and $DFEjCTLBCHn.PRCSA = 01_B$.

When the SELA bits in $DFEjCTLBCHn$ are 00_B , ACA is selected and accumulation processing is executed with an accumulation count value of 0.

The 9-bit arithmetical right-shift result data (DADD (1)) from the filter processing result data (D (1)) is written to the output data register and an output data interrupt request is issued.

In accumulation processing with an accumulation count value of 0, one-time filter processing result is right shifted 9-bits arithmetically without addition processing and an interrupt request is issued. This processing is repeated continuously.

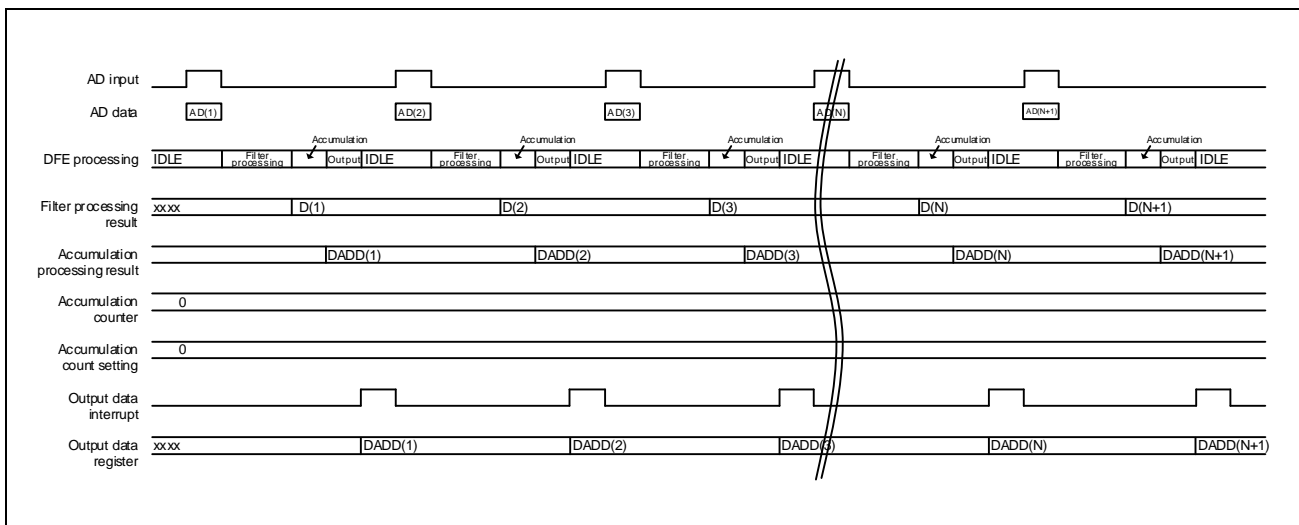

Figure 39.51 Accumulation Processing (Count Value = 0)

When the SELA bits in $DFEjCTLBCHn$ are 01_B , the ACB register is selected and accumulation processing is executed with a set accumulation count value of 1.

When the filter processing result data (D (1)) is input to the accumulation circuit, the 9-bit arithmetical right-shift result data (DADD (1)) from the filter processing result data (D (1)) is written to the accumulator. After that, when the filter processing result data (D (2)) is input to the accumulation circuit, the filter processing result data (D (2)) is right shifted (9 bits) arithmetically (DADD (2)) and this data is added to the accumulator value (DADD (1)). The results of the addition (DADD (1) + DADD (2)) are written to the output data register. After this writing has been completed, an output data interrupt request is issued.

When the accumulation count is set to 1, a 9-bit arithmetical right shift is made for two filter processing results and these results are added, and then an interrupt request is issued once. This processing is repeated continuously.

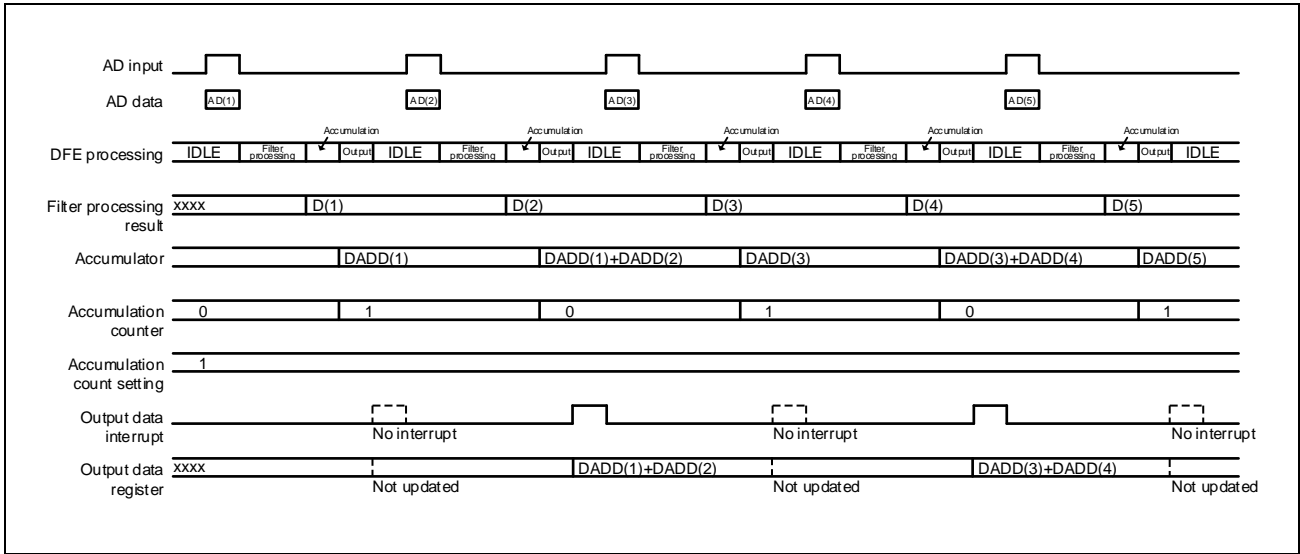

Figure 39.52 Accumulation Processing (Count Value = 1)

When the SELA bits in DFEjCTLBCHn are 10B, the ACC register is selected and accumulation processing is executed with a set accumulation count value of 2.

When the filter processing result data (D (1)) is input to the accumulation circuit, the 9-bit arithmetical right-shift result data (DADD (1)) from the filter processing result data (D (1)) is written to the accumulator. After that, when the filter processing result data (D (2)) is input to the accumulation circuit, the filter processing result data (D (2)) is right shifted (9 bits) arithmetically (DADD (2)) and this data is added to the accumulator value (DADD (1)). The results of the addition (DADD (1) + DADD (2)) are written to the accumulator again. Next, when the filter processing result data (D (3)) is input to the accumulation circuit, the filter processing result data (D (3)) is right shifted (9 bits) arithmetically (DADD (3)) and this data is added to the accumulator value (DADD (1) + DADD (2)). The results of the addition (DADD (1) + DADD (2) + DADD (3)) are written to the output data register. After this writing has been completed, an output data interrupt request is issued.

When the accumulation count is set to 2, a 9-bit arithmetical right shift is made for three filter process results and these results are added, and then an interrupt request is issued once. This processing is repeated continuously.

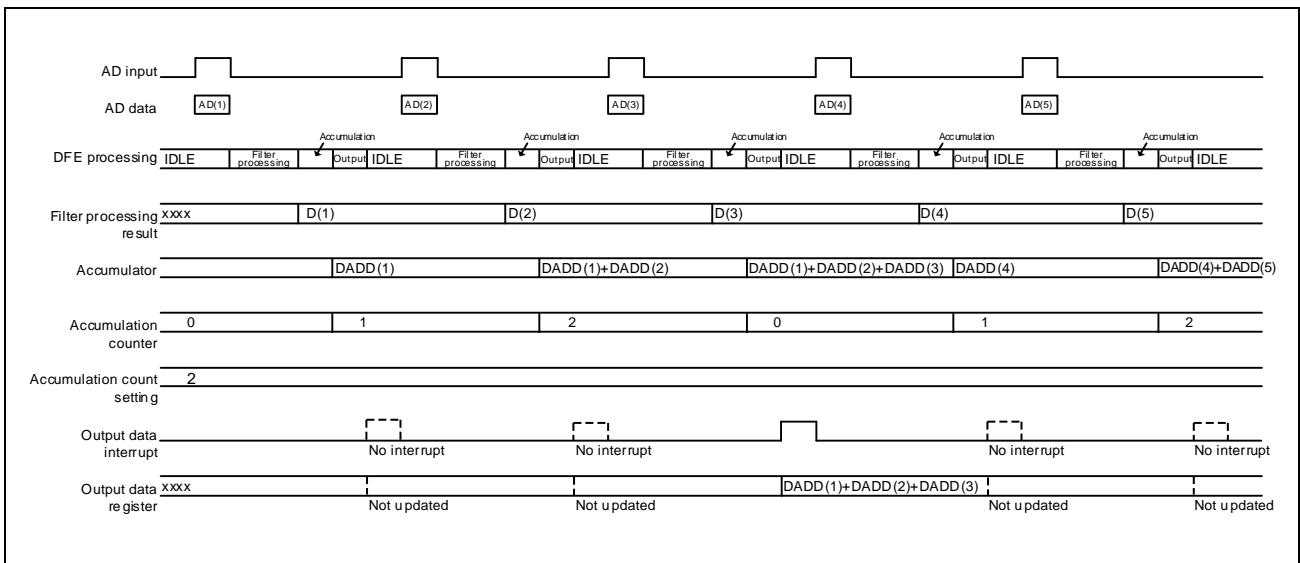

Figure 39.53 Accumulation Processing (Set Count Value = 2)

39.5.10.4 Operation of Accumulation Processing (with Trigger Flag)

The following describes operation of accumulation processing when the accumulation initialization flag and the accumulation disable flag are enabled. Alternate between input to the accumulation initialization and accumulation disable flags. Operations for accumulation processing are not guaranteed in case of consecutive input to either flag.

When the accumulation initialization flag is enabled by a timer trigger or a software trigger while accumulation is specified (PRCSA = 01_B in DFEjCTLBCHn), the accumulation counter is initialized and accumulation processing is executed on the first data from the target channel that immediately follows.

When the accumulation initialization flag is enabled and the accumulation count is set to 2, for example, and data (D (3)) is input to the accumulation circuit for the third time, the 9-bit arithmetical right-shift (DADD (3)) from the third data (D (3)) is written to the accumulator. The accumulation result value (DADD (1) + DADD (2)) is overwritten.

The data (D (4)) that is input to the accumulation circuit is added to the data (D (5)) that is input to the accumulation circuit. Three accumulation results ((DADD (3) + DADD (4) + DADD (5))) are written to the output data register after the accumulation initialization flag is enabled, and an output data interrupt request is issued.

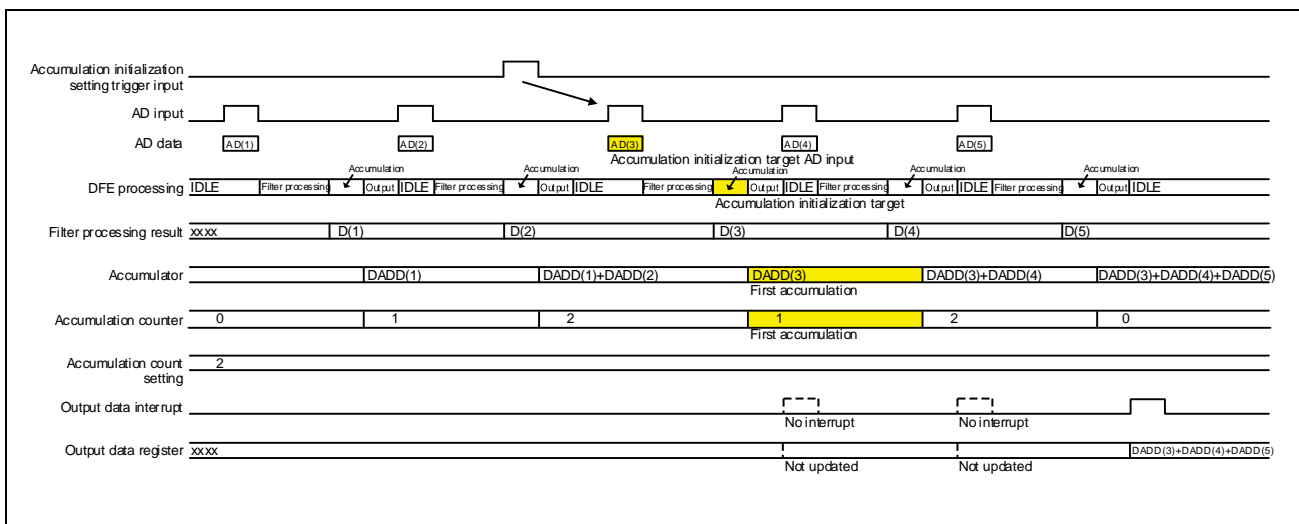

Figure 39.54 Accumulation Processing (with the Initialization Flag Enabled)

When the accumulation disable flag is enabled by a timer trigger or a software trigger while accumulation is specified (PRCSA = 01_B in DFEjCTLBCHn), the DFE's accumulation processing of the target channel that immediately follows is not executed and the internal accumulation disable flag is asserted. No accumulation is performed in the subsequent processing.

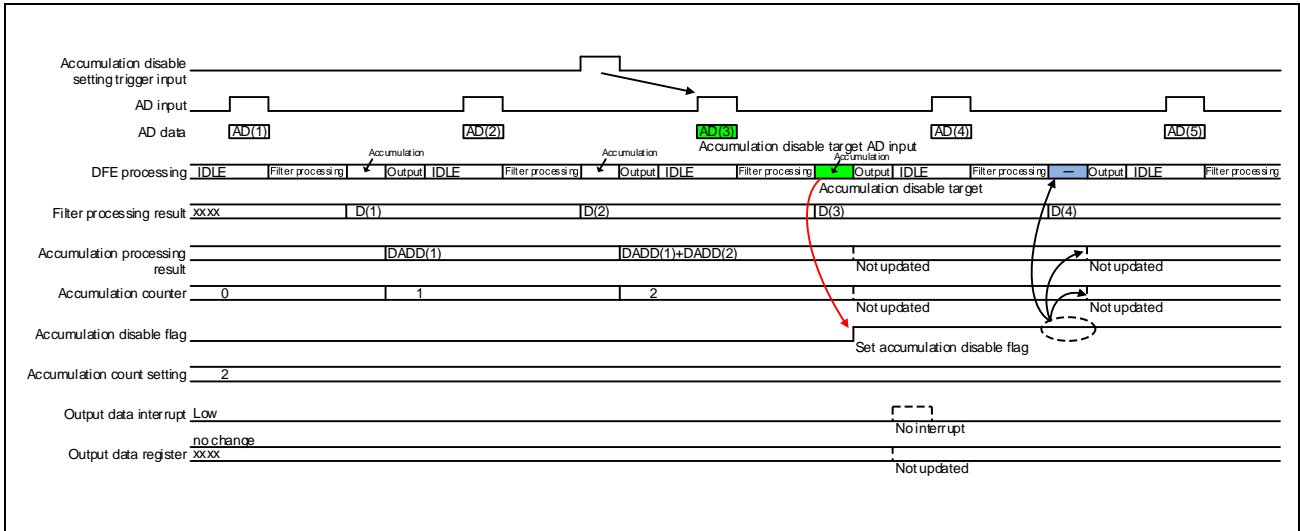

Figure 39.55 Accumulation Processing (with the Accumulation Disable Flag Enabled)

To execute accumulation processing again while the accumulation disable flag is asserted, enable the accumulation initialization flag.

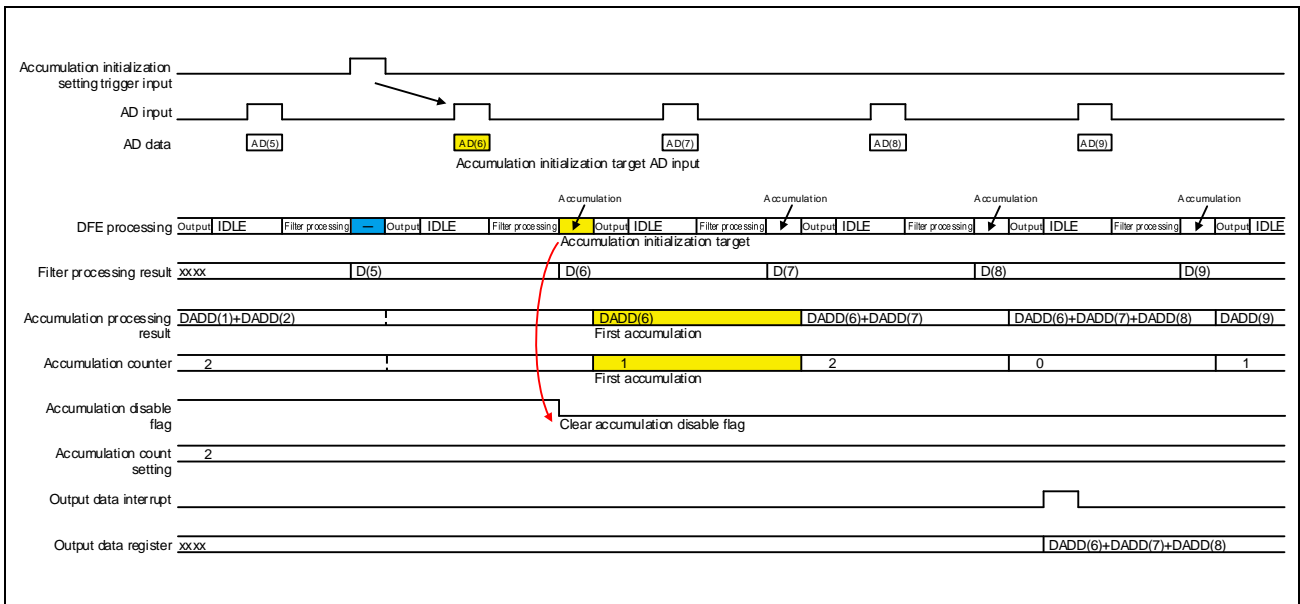

Figure 39.56 Accumulation Processing (Disable to Enable)

39.5.10.5 Summary of Decimation Processing

In the decimation processing, filter processing result data that is input to the accumulation circuit is decimated. The decimation processing count can be set to up to 511. (Data is output once every 512 times.) After processing for the specified decimation count has been completed, decimation processing is executed again.

When the PRCSA bits in DFEjCTLBCHn are 10_B, decimation processing is executed. Specify the decimation processing count by setting the SELA bits in DFEjCTLBCHn to one of the four accumulation/decimation count setting registers (ACA to ACD).

39.5.10.6 Operation for Decimation Processing

The operation for decimation processing is explained using an example when ACA = 0_H, ACB = 1_H, ACC = 2_H, and the PRCSA bits in DFEjCTLBCHn = 10_B.

When the SELA bits in DFEjCTLBCHn are set to 00_B, ACA is selected and decimation processing is executed with a decimation count value of 0.

In decimation processing with a decimation count value of 0, the filter processing result is output as it was input and an interrupt request is issued. This processing is repeated continuously.

Figure 39.57 Decimation Processing (Count Value = 0)

When the SELA bits in DFEjCTLBCHn are set to 01_B, the ACB register is selected and decimation processing is executed with a decimation count value of 1.

When the filter processing result data (D (1)) is input to the accumulation circuit, the decimation counter is incremented. At this time, the accumulation circuit does not output the input filter processing result data (D (1)) to the output circuit because the decimation counter value differs from the specified decimation count value.

When the filter processing result data (D (2)) is input in to the accumulation circuit, the accumulation circuit outputs the input filter processing result data (D (2)) to the output circuit because the decimation counter value is equal to the specified decimation count value. The output circuit writes the data (D (2)) that is input from the accumulation circuit to the output data register and issues an output data interrupt request.

When the decimation count is set to 1, an interrupt request is issued once every two filter processing cycles. This processing is repeated continuously.

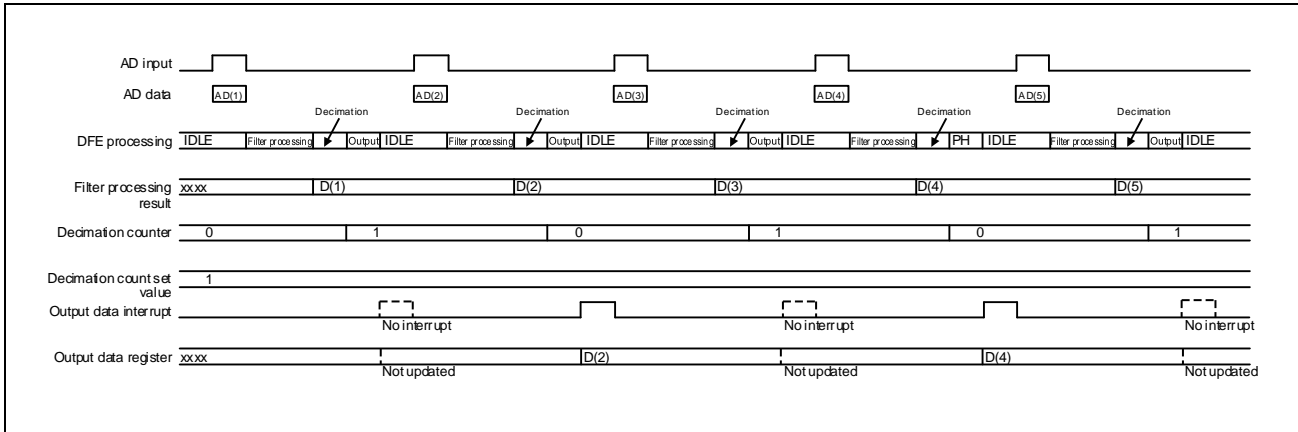

Figure 39.58 Decimation Processing (Count Value = 1)

When the SELA bits in DFEjCTLBCHn are set to 10_B, the ACC register is selected and decimation processing is executed with a set decimation count value of 2.

When the filter processing result data (D (1)) is input to the accumulation circuit, the decimation counter is incremented. At this time, the accumulation circuit does not output the input filter processing result data (D (1)) to the output circuit because the decimation counter value differs from the specified decimation count value.

Then, when the filter processing result data (D (2)) is input to the accumulation circuit, the decimation counter is incremented. At this time, the accumulation circuit does not output the input filter processing result data (D (2)) to the output circuit because the decimation counter value differs from the specified decimation count value.

When the filter processing result data (D (3)) is input to the accumulation circuit, the accumulation circuit outputs the input filter processing result data (D (3)) to the output circuit because the decimation counter value is equal to the set decimation count value. The output circuit writes the data (D (3)) that is input from the accumulation circuit to the output data register and issues an output data interrupt request.

When the decimation count is set to 2, an interrupt request is issued once for every three filter processing cycles. This processing is repeated continuously.

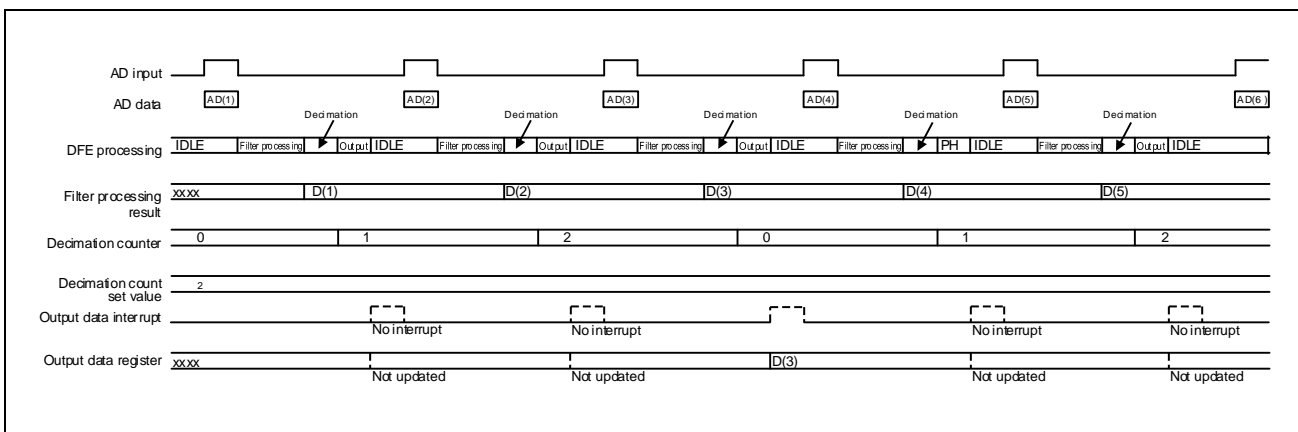

Figure 39.59 Decimation Processing (Count Value = 2)

39.5.10.7 Operation of Decimation Processing (with Trigger Flag)

The following describes the operation of decimation processing when the decimation initialization flag and the decimation disable flag are enabled. Alternate between input to the decimation initialization and decimation disable flags. Operations for decimation processing are not guaranteed in case of consecutive input to either flag. When the decimation initialization flag is enabled by a timer trigger or a software trigger while decimation is specified (PRCSA = 10_B in DFEjCTLBCHn), the decimation counter is initialized and decimation processing is executed on the first data of the target channel that immediately follows.

When the decimation initialization flag is enabled and the decimation count is set to 2, for example, when data (D (3)) is input to the accumulation circuit for the third time, the third data (D (3)) is not output from the accumulation circuit, but is processed as the first input data. Subsequently, the accumulation circuit does not output data (D (4)) that is input to the accumulation circuit, but does output data (D (5)) to the output circuit that is input to the accumulation circuit.

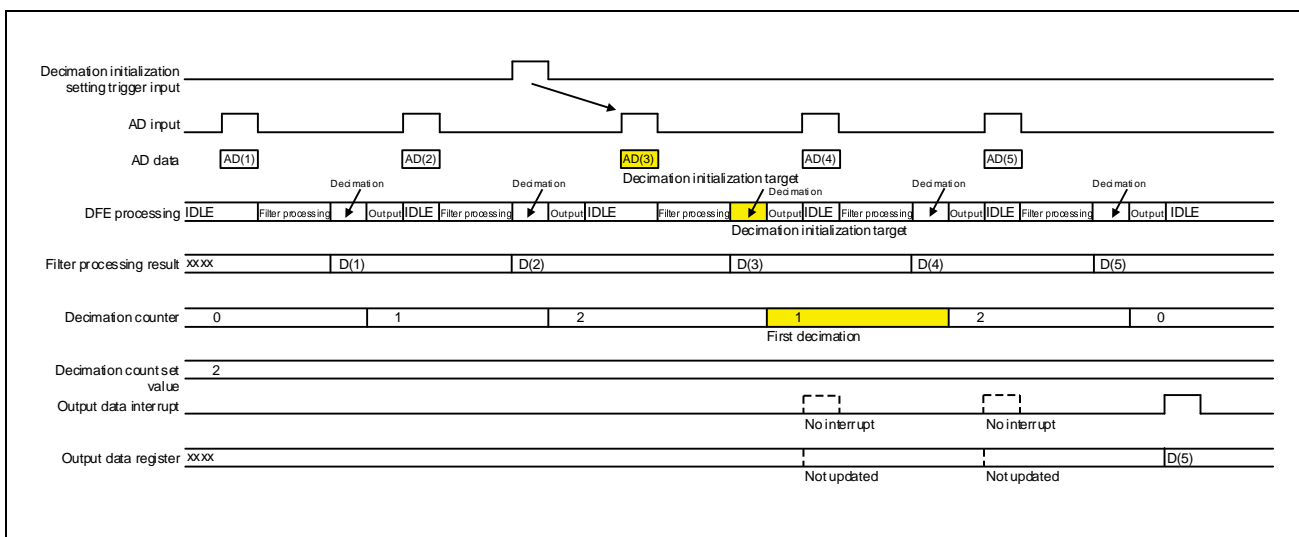

Figure 39.60 Decimation Processing (with the Initialization Flag Enabled)

When decimation is specified (PRCSA = 10_B in DFEjCTLBCHn) and the decimation disable flag is enabled, the internal decimation disable flag is asserted. In the subsequent processing, the decimation counter is disabled. While decimation is disabled, no output data interrupt request is issued.

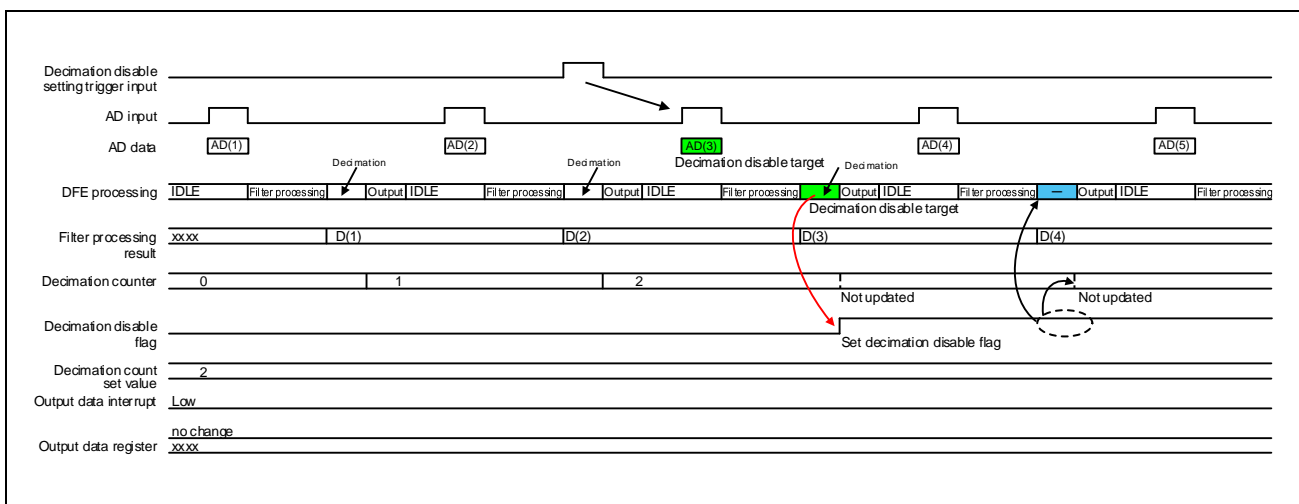

Figure 39.61 Decimation Processing (with the Decimation Disable Flag Enabled)

To execute the decimation processing again while the internal decimation disable flag is asserted, enable the decimation initialization flag.

Figure 39.62 Decimation Processing (Disable to Enable)

39.5.11 Subtraction Circuit

After the end of processing by the filtering circuit, the subtraction circuit performs subtraction processing by using the filtering process result data for any two channels. After subtraction processing, the subtraction result data is stored in the subtraction result register. A subtraction data interrupt request is issued, when the subtraction result data has been stored. A subtraction error interrupt request is also issued, if an error has occurred in the subtraction circuit.

If the cascade function is specified to the subtraction channel, the subtraction circuit output data is input to the dispatch circuit.

The minuend channel and the subtrahend channel must not be set to the same channel.

Use the same format as the filtering process result for the minuend channel and the subtrahend channel. Subtraction processing of the filter processing result of different formats is prohibited. In this case, the data will not be guaranteed.

Subtraction is irrelevant to the specification of accumulation/decimation. Be aware that subtraction among accumulation results (S9.22) is not possible if the input data is in a fixed-point format.

The format of the input data uniquely determines the format of the subtraction result.

When the input data is in the fixed-point (S.15) format, the subtraction result is in the S.31 format.

When the input data is in the integer (S.15) format, the subtraction result is in the S31 format.

Filtering Process Result Format	Floating-point conversion	Execution (Result)	Cascade (Output)
S.31 (Fixed-Point)	Conversion specified	OK (floating-point)	OK (S.15)
	Conversion not specified	OK (S.31)	OK (S.15)
S31 (Integer)	Conversion specified	NO*1	OK (S15)
	Conversion not specified	OK (S31)	OK (S15)

Note 1. Setting is prohibited for NO combinations.

39.5.11.1 Summary of the Subtraction Circuit

If subtraction is specified (DFEjSUBCTLCHn.SEN = 1), after the end of processing by the filtering circuit, subtraction processing is executed on the basis of the filtering process results for the channels set with the minuend channel selection bit (DFEjSUBCTLCHn.MINCH, hereafter called MINCH) and the subtrahend channel selection bit (DFEjSUBCTLCHn.SUBCH, hereafter called SUBCH).

The subtraction result is stored in the subtraction result data register (DFEjSUBDOCHn.SDO, hereafter called SDO).

If 1 is set to the subtraction data interrupt request enabling bit (DFEjSUBCTLCHn.SIEO), the subtraction data interrupt request is issued when the data is stored in the subtraction result data register.

In subtraction processing, three error flags are used.

- (1) "Subtraction result register overwrite error (DFEjSUBSTCHn.SDOOW)" that detects overwrite of the subtraction result data.
- (2) "Subtraction circuit cascading rounding error (DFEjSUBSTCHn.SCER)" that detects an overflow that occurs when 32-bit data is rounded to 16-bit data, and when the subtraction result data is used for cascade processing.
- (3) "Subtraction guard error (DFEjSUBSTCHn.SGER)" that detects an overflow of the subtraction result data.

If one of these errors occurs, the error interrupt request resulting from the subtraction circuit is issued.

The conceptual image of the subtraction circuit is shown below.

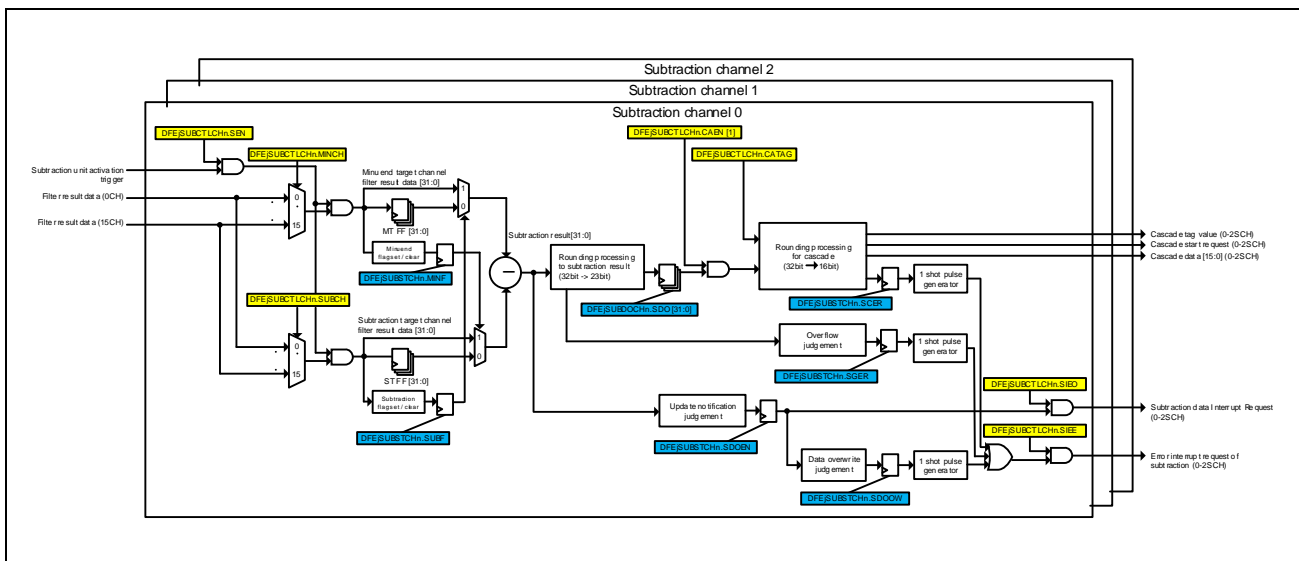

Figure 39.63 Configuration of Subtraction Circuit

39.5.11.2 Operation of the Subtraction Circuit

(1) Operation when Filtering Processing for Minuend Channel Is Executed Earlier

When the filtering process result for the channel set as a minuend is output, the filtering process result is held in the internal FF for storing minuend filtering result (hereafter called MTFF), and the minuend channel data input enabling bit (DFEjSUBSTCHn.MINF, hereafter called MINF) is set to 1. When the filtering process result for the channel set with SUBCH is output after 1 is set to MINF, the subtraction circuit performs subtraction processing of the data stored in MTFF and the filtering process result of the channel set with SUBCH, and stores the subtraction result in SDO. It also clears MTFF to ALL0, and clears MINF to 0. If subtraction is specified, this operation is executed repeatedly.

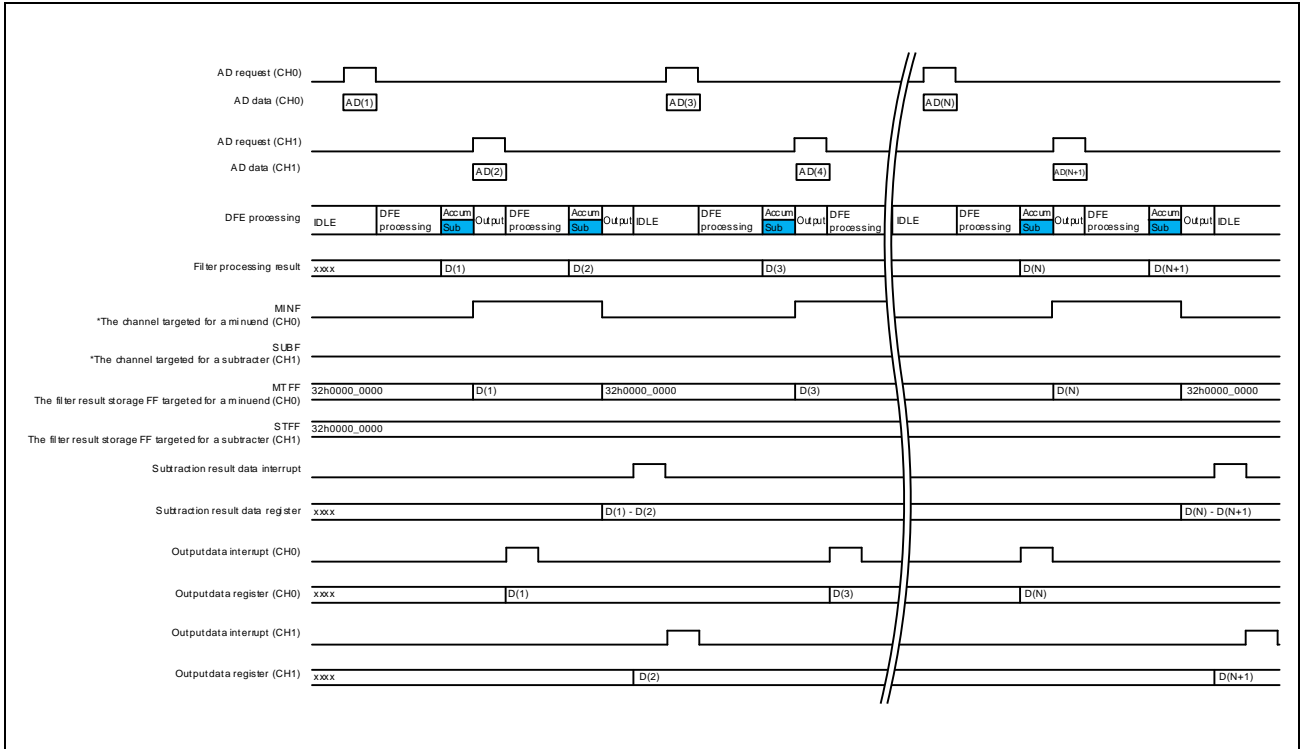

Figure 39.64 Subtraction Processing (When Processing for a Minuend Channel Is Executed Earlier)

(2) Operation when Filtering Processing for Subtrahend Channel is Executed Earlier

When the filtering process result for the channel set as a subtrahend is output, the filtering process result is held in the internal FF for storing subtrahend filtering result (hereafter called STFF), and the subtrahend channel data input enabling bit (DFEjSUBSTCHn.SUBF, hereafter called SUBF) is set to 1. When the filtering process result for the channel set with MINCH is output after 1 is set to SUBF, the subtraction circuit performs subtraction processing of the data stored in STFF and the filtering process result of the channel set with MINCH, and stores the subtraction result in SDO. It also clears STFF to ALL0, and clears SUBF to 0. If subtraction is specified, this operation is executed repeatedly.

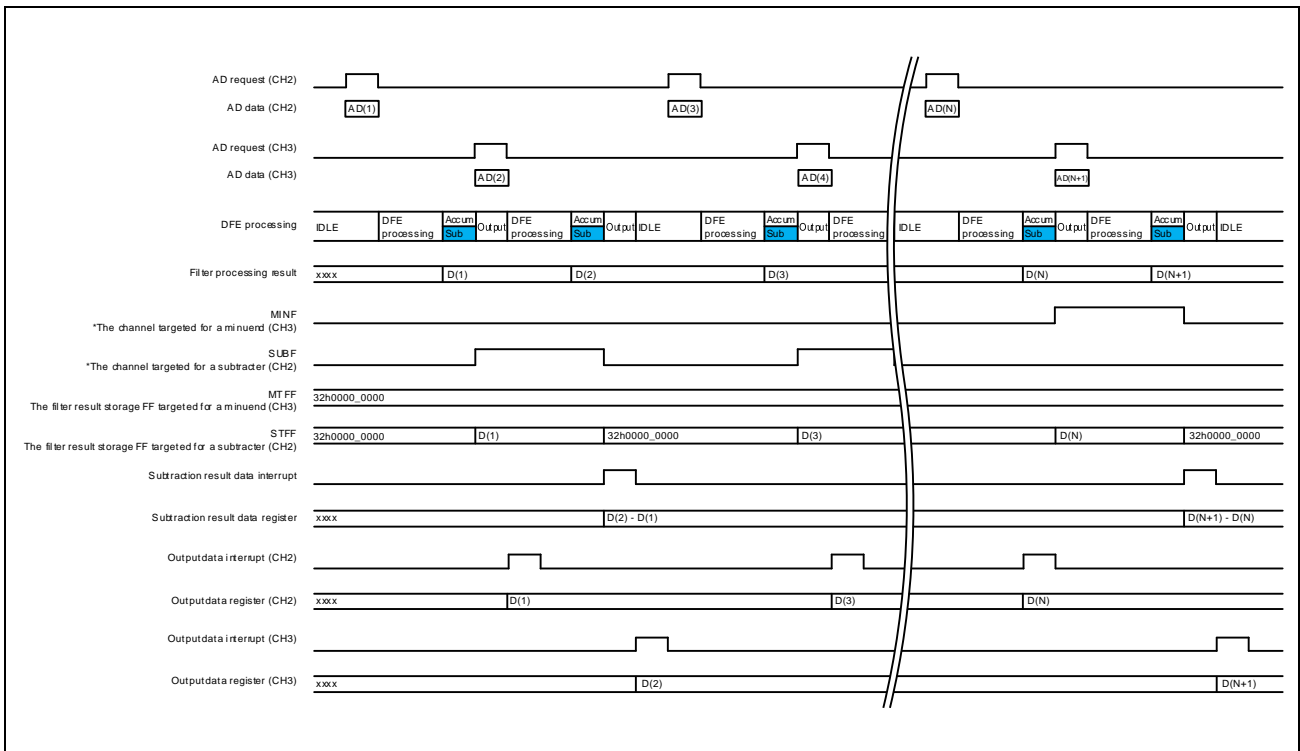

Figure 39.65 Subtraction Processing (when Processing for a Subtrahend Channel is Executed Earlier)

(3) Operation when Filtering Processing Order of Subtrahend and Minuend Channels is Not Constant

The subtraction circuit can perform subtraction processing regardless of the filter input order of the specified MINCH and SUBCH. The following example shows the operation for MINCH = channel 5 and SUBCH = channel 4.

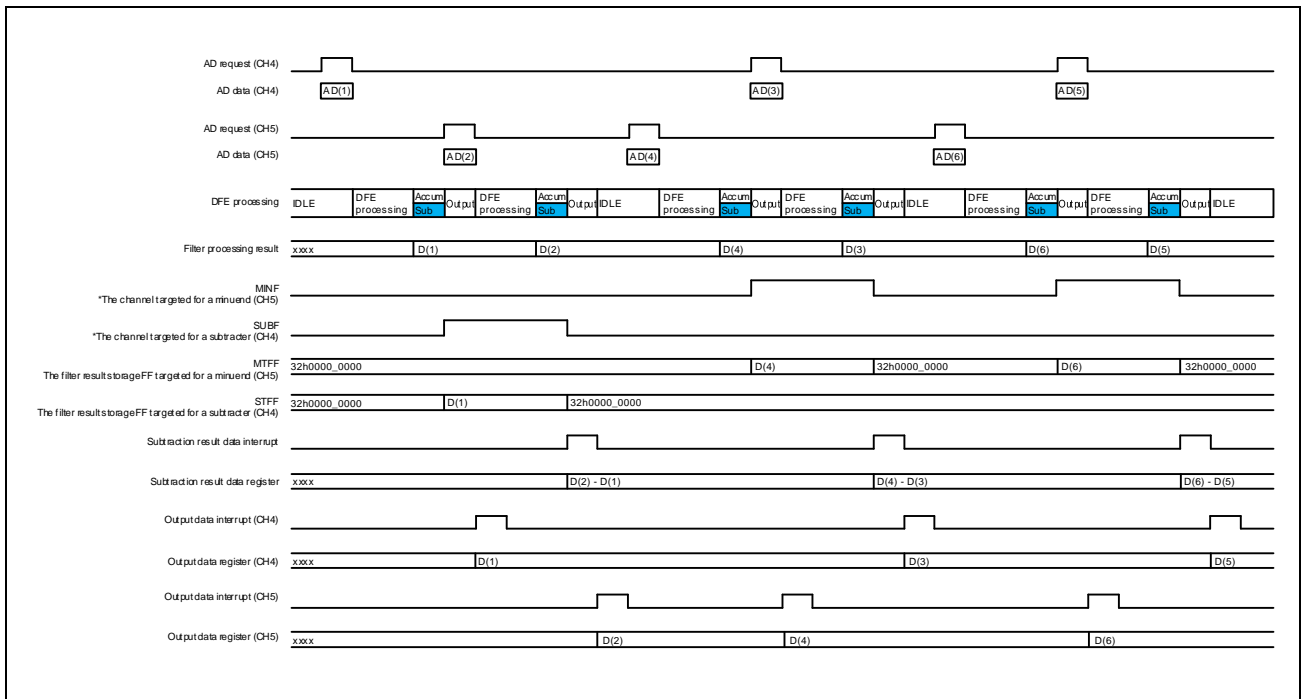

Figure 39.66 Subtraction Processing (when Order of Processing for Subtrahend/Minuend Channels is Not Constant)

(4) Operation when Filtering Processing for One Channel is Executed Continuously

When one channel set as a subtrahend or a minuend is processed continuously, the latest filtering process result is held in STFF or MTFF. When one channel is processed continuously, SUBF or MINF keeps holding 1.

After that, subtraction processing is executed on the basis of the latest filtering process result for both the minuend channel and the subtrahend channel.

Figure 39.67 Subtraction Processing (when Processing for a Subtrahend Channel is Executed Continuously)

(5) Operation when Filtering Processing for Only One Channel is Executed and Finished

When one channel set as a subtrahend or a minuend is processed continuously and the other does not undergo filtering process, SUBF or MINF keeps holding 1.

Even if a subtraction ending flag is enabled and then subtraction processing ends, STFF, MTFF, SUBF, and MINF keep holding the value.

Figure 39.68 Subtraction Processing (when Processing for Only a Subtrahend Channel is Executed and Finished)

39.5.11.3 Operation of Subtraction Circuit (with Subtraction Start Trigger)

To use subtraction processing, it is necessary to start filtering process after enabling the subtraction starting flag when subtraction is specified. Input the subtraction starting trigger by using a timer trigger or a software trigger, and enable the subtraction starting flag.

If the subtraction starting trigger is not input, subtraction processing is not executed during filter processing.

The subtraction circuit performs initialization during subtraction processing for subtrahend or minuend channel just after the subtraction starting flag is enabled. Specifically, the circuit initializes STFF or MTFF, which hold the filtering process result, subtrahend flag SUBF, and minuend flag MINF, and executes subtraction processing using the values as the initial data of subtraction processing.

In the following example, subtraction processing is not executed in filtering process of AD data AD (1) of CH6 and AD data AD (2) of CH7. The subtraction starting flag is enabled in filtering process of AD data AD (3) of CH6 after the subtraction starting trigger is input, and subtraction processing starts.

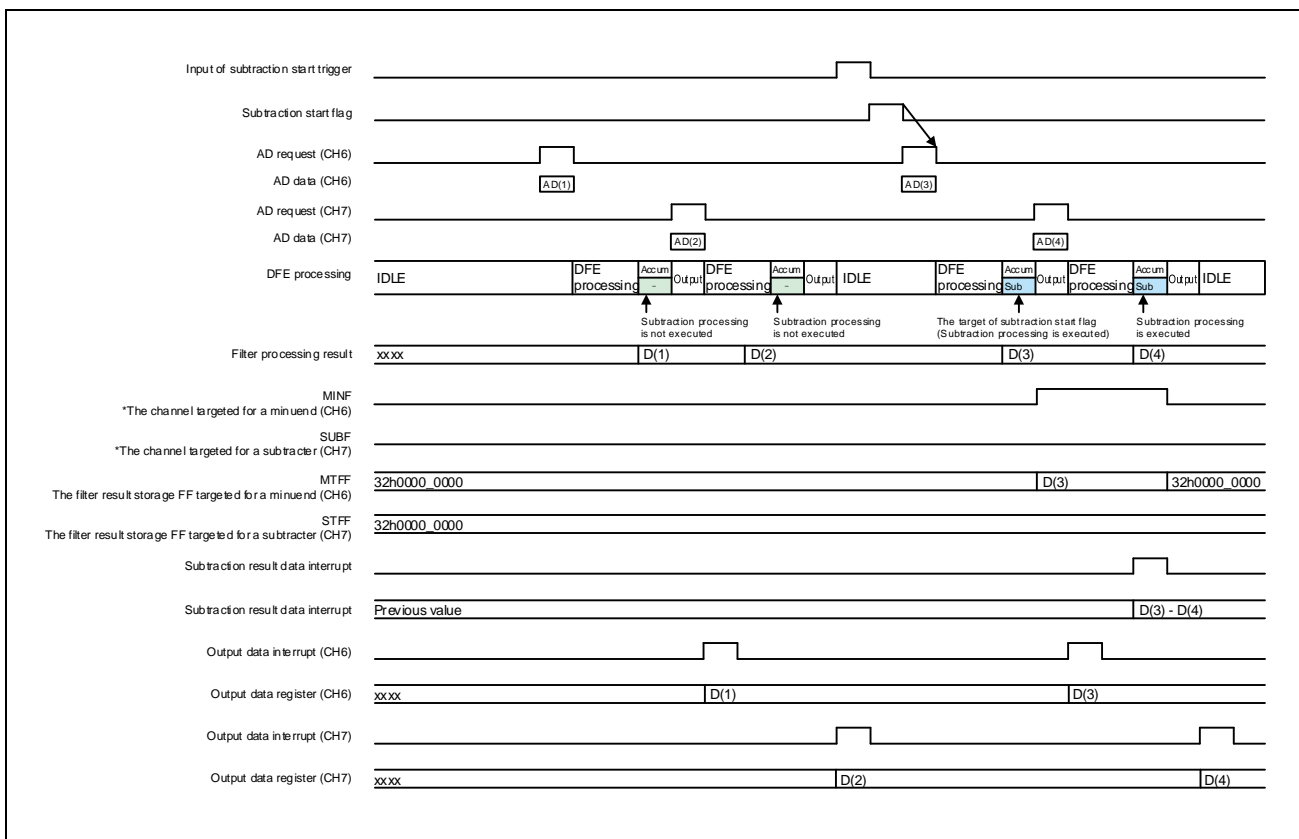

Figure 39.69 Subtraction Processing (Operation when Subtraction Starting Flag is enabled)

39.5.11.4 Operation of Subtraction Circuit (with Subtraction End Trigger)

To stop subtraction processing when subtraction is specified, it is necessary to start filtering process after enabling the subtraction ending flag. Input the subtraction ending trigger by using a timer trigger or a software trigger, and enable the subtraction ending flag.

Subtraction processing stops at the subtrahend or minuend channel just after the subtraction ending flag is enabled. After it stops, STFF, MTFF, which hold the filtering process result, subtrahend flag SUBF, and minuend flag MINF keep holding the value.

The following example shows the case where the subtraction ending trigger is input during filtering process of AD data AD (3) of CH6. The subtraction ending flag is enabled in filtering process of the AD data AD (4) of CH7, and subtraction processing of AD (4) is not executed.

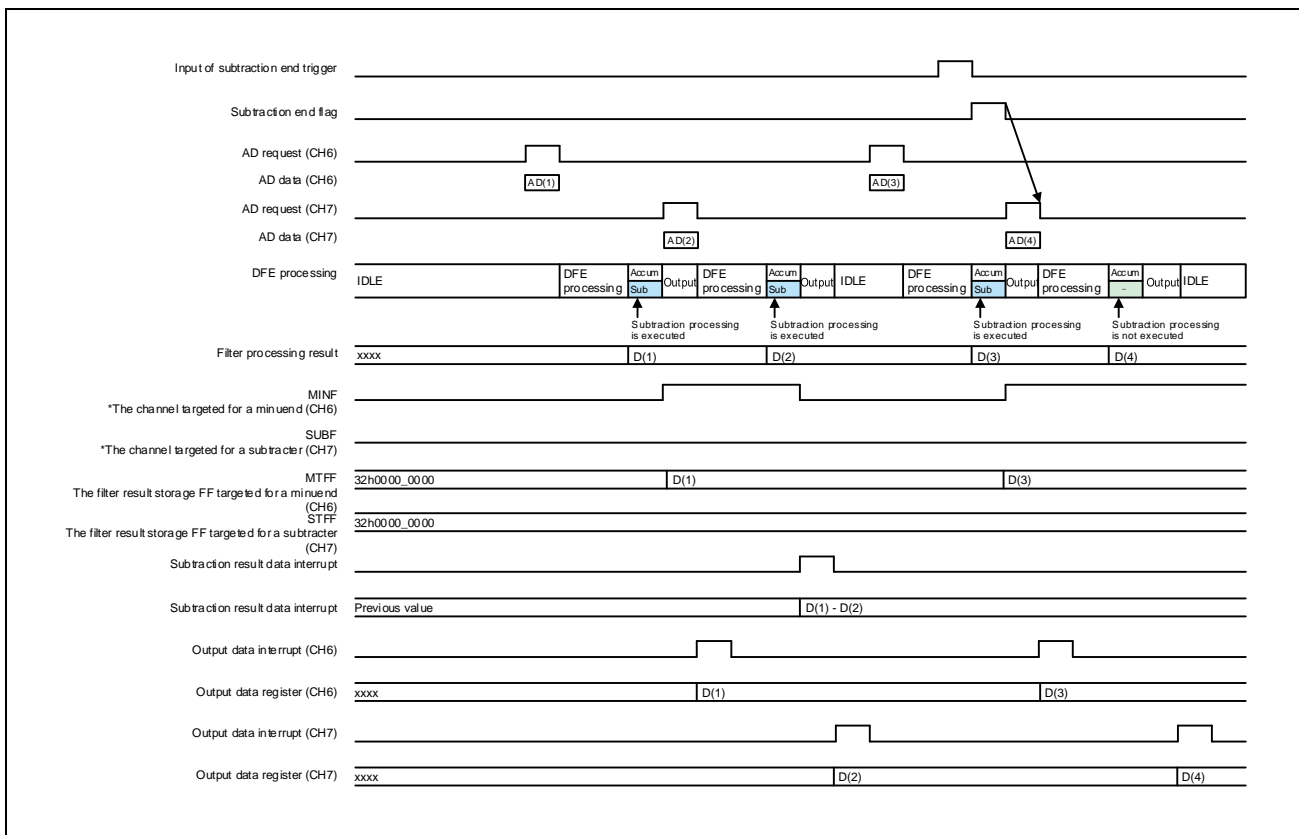

Figure 39.70 Subtraction Processing (Operation when Subtraction Ending Flag is enabled)

39.5.11.5 Operation of Subtraction Circuit (Stop by DFEjSUBCTLCHn.SEN)

By writing 0 to the subtraction channel enabling bit (DFEjSUBCTLCHn.SEN), it is possible to stop subtraction processing for the target of subtraction channel.

Before 0 is written to the subtraction channel enabling bit, subtraction processing is executed for the channel that has accepted an activation request or the channel undergoing filtering process. After 0 is written to the subtraction channel enabling bit, even if activation request of minuend/subtrahend channel has accepted, subtraction processing is not executed in this subtraction channel. The subtraction start/end flags which have been kept are discarded from this subtraction channel.

When subtraction processing in this subtraction channel is restarted, set the bit (DFEjSUBCTLCHn.SEN) to 1. The subtraction processing starts from filter processing after 1 is set to the subtraction channel enabling bit.

Figure 39.71 Subtraction Processing (Subtraction Processing Stopped by Clearing Subtraction Channel Enabling Bit (1/2))

In the following example, since the activation request for AD data AD (2) of CH7 is already accepted when 0 is written to the subtraction channel enabling bit, subtraction processing for this subtraction channel will be stopped after subtraction processing of AD (2) is executed.

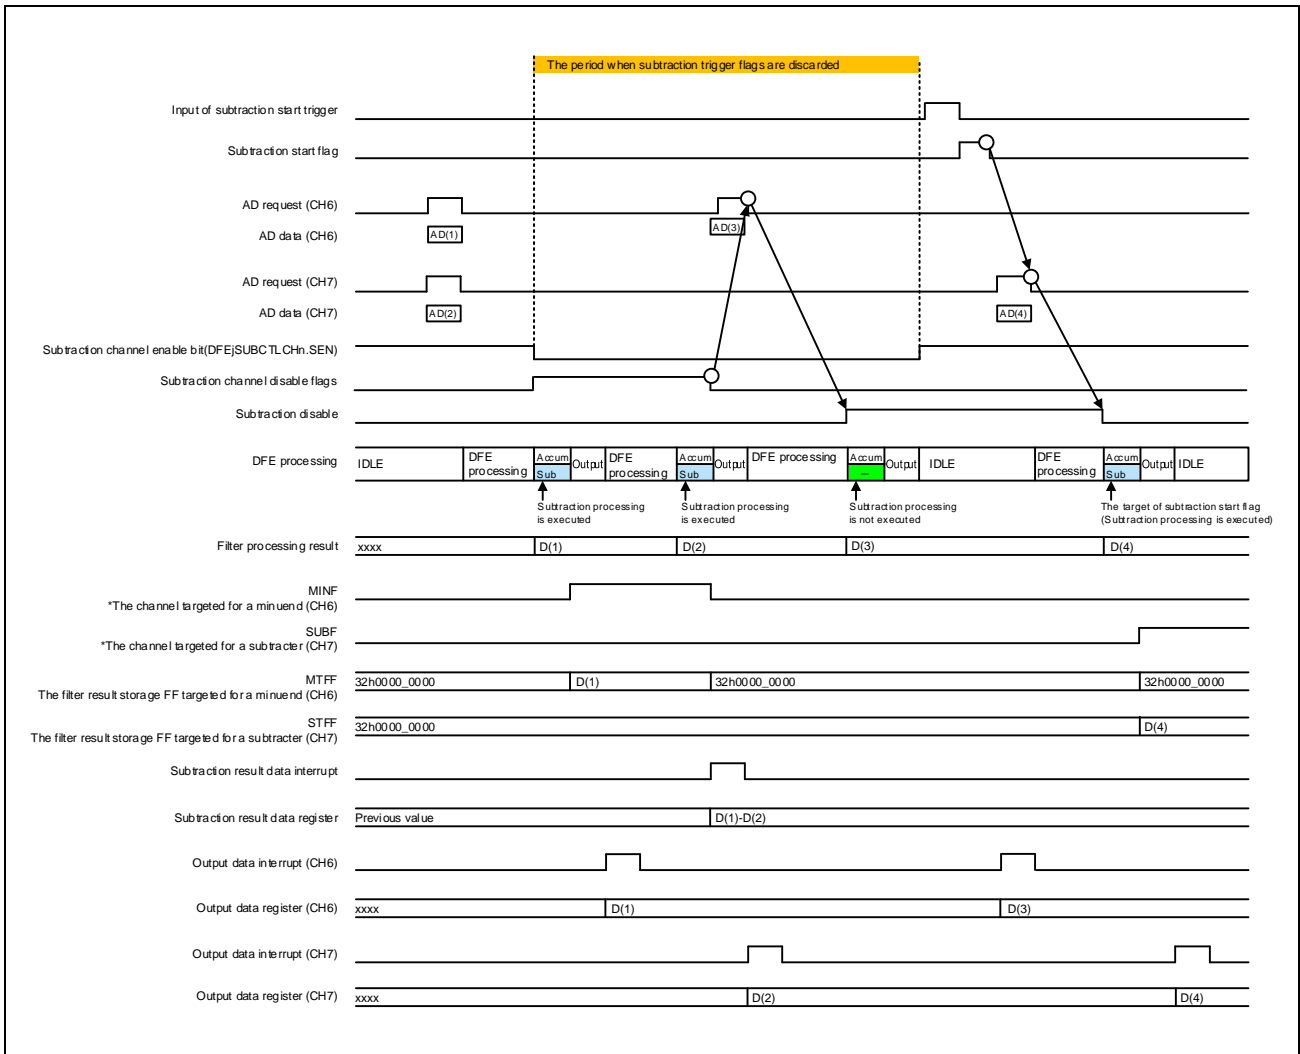

Figure 39.71 Subtraction Processing (Subtraction Processing Stopped by Clearing Subtraction Channel Enabling Bit (2/2))

39.5.12 Peak-Hold Circuit

The peak-hold circuit executes peak-hold processing and comparison processing for data from the accumulation circuit outputs.

According to the setting of DFEjCTLBCHn.PRC SB in the table below, three types of processing can be selected for the peak-hold circuit: (1) Only peak-hold processing executed, (2) Only comparison processing executed, or (3) Both peak-hold processing and comparison processing executed.

If DFEjCTLBCHn.PRC SB = 11_B and DFEjPH23CCTL0.PEN = 1 at the same time, the peak-hold 23 function, which is an extended function for PH processing, can be selected.

Peak-hold Circuit Setting	DFEjCTLBCHn.PRC SB	DFEjPH23CCTL0.PEN
Peak-hold processing and comparison processing prohibited	00 _B	—
Only peak-hold executed	01 _B	—
Only comparison executed	10 _B	—
Both peak-hold processing and comparison processing executed	11 _B	0
Peak-hold 23 function executed	11 _B	1*1

Note 1. To enable the peak-hold 23 function, it is necessary to set the target channel in DFEjPH23CCTL0.CHS.

The peak-hold circuit executes peak-hold processing or comparison processing for data that is output from the accumulation circuit. When the accumulation/decimation count is specified, peak-hold processing is executed on each specified count.

In peak-hold processing, peak-hold results are written to the peak-hold result register. A condition match interrupt is generated at the end of peak-hold processing. In comparison processing, accumulation circuit output data is compared with the values of the comparison target register. When the comparison result is true, a condition match interrupt is generated.

39.5.12.1 Summary of Peak-Hold Processing

In peak-hold processing, the upper peak or the lower peak can be selected by the peak-hold peak selection bit (DFEjCTLBCHn.PHPS).

When the upper peak is selected, data that is input to the peak-hold circuit is compared with the data that has been input to the peak-hold circuit for each channel, and the larger value is written to the peak-hold result register as a peak-hold result.

When the lower peak is selected, data that is input to the peak-hold circuit is compared with the data that has been input to the peak-hold circuit for each channel, and the smaller value is written to the peak-hold result register as a peak-hold result.

The initial peak-hold value can be selected by using the SELB2 bits in DFEjCTLBCHn. The peak-hold circuit executes peak-hold processing from the time the peak-hold initialization flag is valid until the peak-hold end flag is valid. The peak-hold circuit does not execute peak-hold processing from the time the peak-hold end flag is valid until the peak-hold initialization flag is valid. The peak-hold index register indicates how much data has been stored in the peak-hold result register since the start of peak-hold processing.

39.5.12.2 Operation of Peak-Hold Processing

Peak-hold processing proceeds when $DFEjCTLBCHn.PRCsB = 01_B$ (specifying peak-hold operation).

Peak-hold processing starts from the next input of data following the peak-hold initialization flag becoming valid.

Peak-hold processing ends from the next input of data following the peak-hold end flag becoming valid. After this, the peak-hold initialization flag must again become valid for peak-hold processing to be restarted.

Alternate between input to the peak-hold initialized and end flags. Operations for peak-hold processing are not guaranteed in case of consecutive input to either flag.

Values input to the peak-hold circuit are compared with the peak-hold initialization register or the peak-hold result register. The condition for updating the peak-hold value when (1) the upper peak is selected or (2) the lower peak is selected is shown below. When the condition is satisfied, the value input to the peak-hold circuit is stored in the peak-hold result register.

Notifications for peak-hold updating are issued according to the settings of the peak-hold updated notification setting register.

Peak	Function	Number Times of PH	Issue Condition
Upper peaks	PH update notification	First time*1	PH circuit input data*2 > The value of the peak-hold initial value setting register*3
		After the first time	PH circuit input data*2 > The value of the DFEjPHCHn*4
Lower peaks	PH update notification	First time*1	PH circuit input data*2 < The value of the peak-hold initial value setting register*3
		After the first time	PH circuit input data*2 < The value of the DFEjPHCHn*4

Note 1. The first time means when filter processing is executed after PH initialization flag is valid.

Note 2. PH input data is the output data of the filter circuit or accumulation/decimation circuit.

Note 3. The register means one of the DFEjPHIA-DFEjPHID registers.

Note 4. These values are compared in either fixed-point format or integer format regardless of the DFEjCTLBCHn.PFMT bit setting.

When the next value is input after the peak-hold initialization flag is valid, and when the value does not satisfy the condition for updating the peak-hold value, the value of the peak-hold initialization register is stored in the peak-hold result register, and the notification of peak-hold updating is not issued.

Peak	Function	Number Times of PH	Update Condition	Stored Data in DFEjPHCHn
Upper peaks	Peak-Hold Result register	First time* ¹	PH circuit input data* ² > The value of the peak-hold initial value setting register* ³	PH circuit input data
			PH circuit input data* ² ≤ The value of the peak-hold initial value setting register* ³	The value of the peak-hold initial value setting register* ³
		After the first time	PH circuit input data* ² > The value of the DFEjPHCHn* ⁴	PH circuit input data
			PH circuit input data* ² ≤ The value of the DFEjPHCHn* ⁴	Holds the value of DFEjPHCHn
Lower peaks	Peak-Hold Result register	First time* ¹	PH circuit input data* ² < The value of the peak-hold initial value setting register* ³	PH circuit input data
			PH circuit input data* ² ≥ The value of the peak-hold initial value setting register* ³	The value of the peak-hold initial value setting register* ³
		After the first time	PH circuit input data* ² < The value of the DFEjPHCHn* ⁴	PH circuit input data
			PH circuit input data* ² ≥ The value of the DFEjPHCHn* ⁴	Holds the value of DFEjPHCHn

Note 1. The first time means when filter processing is executed after PH initialization flag is valid.

Note 2. PH input data is the output data of the filter circuit or accumulation/decimation circuit.

Note 3. The register means one of the DFEjPHIA-DFEjPHID registers.

Note 4. These values are compared in either fixed-point format or integer format regardless of the DFEjCTLBCHn.PFMT bit setting.

39.5.12.3 Operation of Peak-Hold Processing (Trigger Flag is Enabled)

Operations for peak-hold initialization are shown below.

The execution for the peak-hold processing of values from the given ADC starts once the peak-hold initialization flag becomes valid.

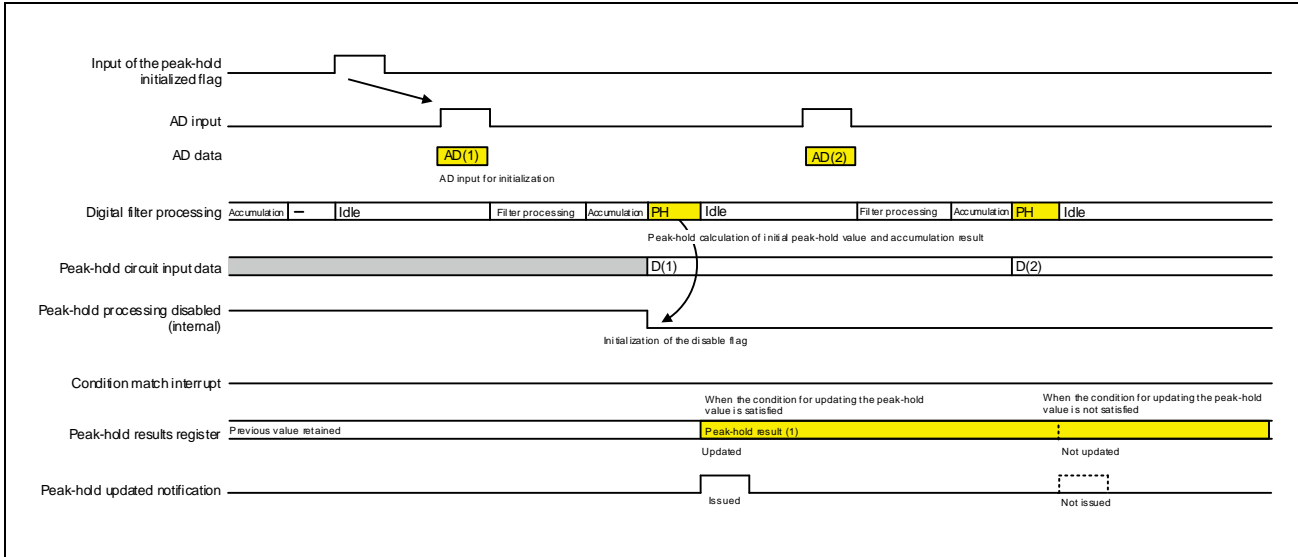

Figure 39.72 Operations for Peak-Hold Initialization

Operations for ending peak-hold are shown below. The execution for the peak-hold processing of values from the given ADC does not start when the peak-hold end flag becomes valid.

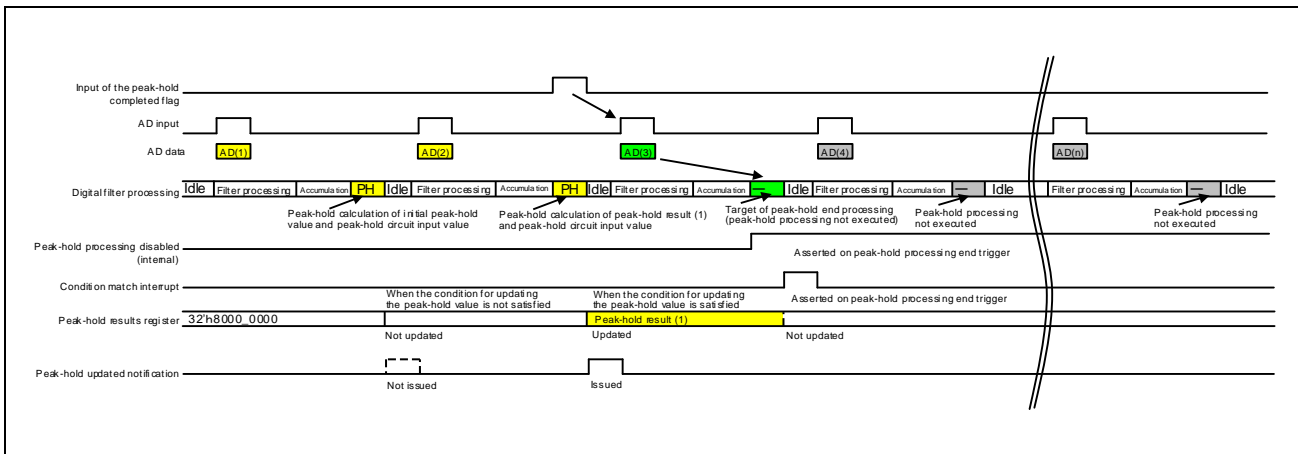

Figure 39.73 Operations for Ending Peak-Hold Processing

The effective range of peak-hold initialization/end flags in each mode of peak-hold circuit is explained below.

The peak-hold processing is always affected by these flags.

The comparison processing is not affected by these flags except for the peak-hold 23 mode. Comparison is performed without being affected by these flags for all modes except peak-hold 23.

For the peak-hold stop status in peak-hold 23 mode, neither the peak-hold processing nor the comparison processing is executed.

Peak-Hold Circuit Setting	Peak-Hold Initialization/End Flag	
	Peak-Hold Processing	Comparison Processing
Peak-hold processing and comparison processing prohibited	—	—
Only peak-hold executed	Valid	—
Only comparison executed	—	Invalid
Both peak-hold processing and comparison processing executed	Valid	Invalid
Peak-hold 23 function executed	Valid	Valid

The effective range of Peak-Hold Processing Disable bit (DFEjCTLBCHn.DISB) in each mode of peak-hold circuit is explained below.

The peak-hold processing is always affected by this bit.

The comparison processing is not affected by this bit except for the peak-hold 23 mode. Comparison is performed without being affected by this bit for all modes except peak-hold 23.

For the peak-hold stop status by this bit in peak-hold 23 mode, neither the peak-hold processing nor the comparison processing is executed.

Peak-Hold Circuit Setting	Start/Stop by DISB	
	Peak-Hold Processing	Comparison Processing
Peak-hold processing and comparison processing prohibited	—	—
Only peak-hold executed	Valid	—
Only comparison executed	—	Invalid
Both peak-hold processing and comparison processing executed	Valid	Invalid
Peak-hold 23 function executed	Valid	Valid

39.5.12.4 Operation of Peak-Hold Mask Processing (Trigger Flag is Enable)

The peak-hold mask start/end operation is described below. If the timer trigger set as the peak-hold mask start flag is input, it is held inside the DFE as the peak-hold mask start flag. In the next filtering process, the peak-hold mask start flag is enabled and peak-hold processing stops. Be aware that, during peak-hold mask, peak-hold processing is stopped but the internal peak-hold counter works without stopping.

If the timer trigger set as the peak-hold mask end flag is input, it is held inside the DFE as the peak-hold mask end flag. When peak-hold processing in the next filtering process is executed, the peak-hold mask end flag is enabled and peak-hold processing resumes.

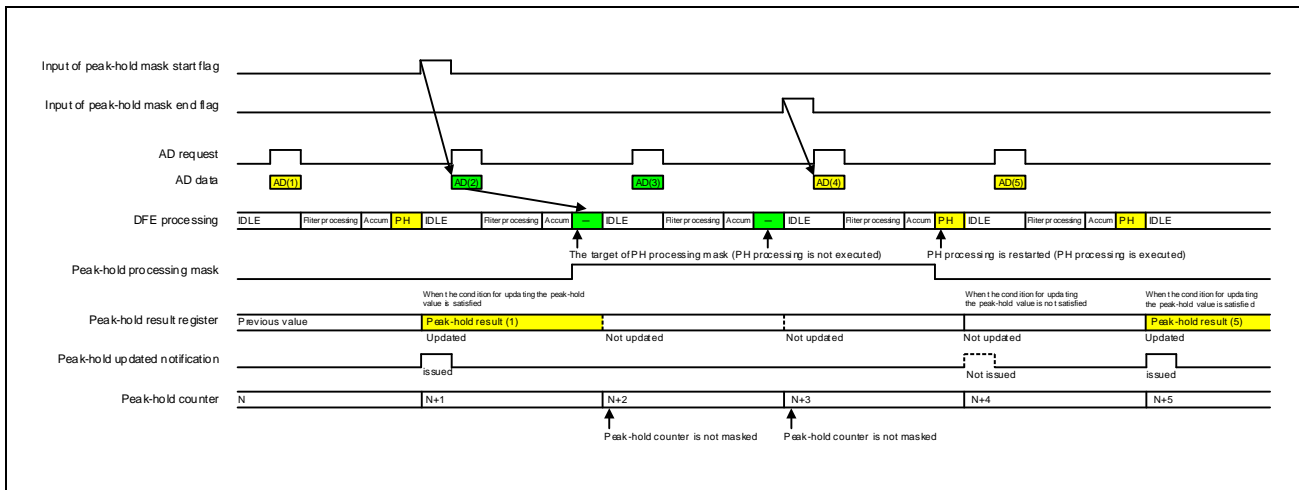

Figure 39.74 Peak-hold Masking Operation

To mask peak-hold processing for a specified period from the start of peak-hold processing, make the settings as follows. Before the filter processing where the peak-hold initialization flag is enabled is started, input the timer trigger set as the peak-hold mask start flag. At this time, both the peak-hold initialization flag and the peak-hold mask start flag are held inside the DFE. When filter processing is started with the peak-hold initialization flag and the peak-hold mask start flag held, peak-hold processing is not executed but remains stopped. Then, the peak-hold counter counts it but the peak-hold index register is hold previous value.

To resume peak-hold processing, enable the peak-hold mask end flag. The peak-hold initialization flag is enabled when the filter processing with the peak-hold mask end flag enabled is executed. Therefore, peak-hold processing is executed from this filter processing, and the value of peak-hold circuit input data and the value of peak-hold initial value register are compared with each other. Then, the peak-hold counter is updated, too.

In both examples (1) and (2) below, the peak-hold processing can be masked from the start of peak-hold processing.

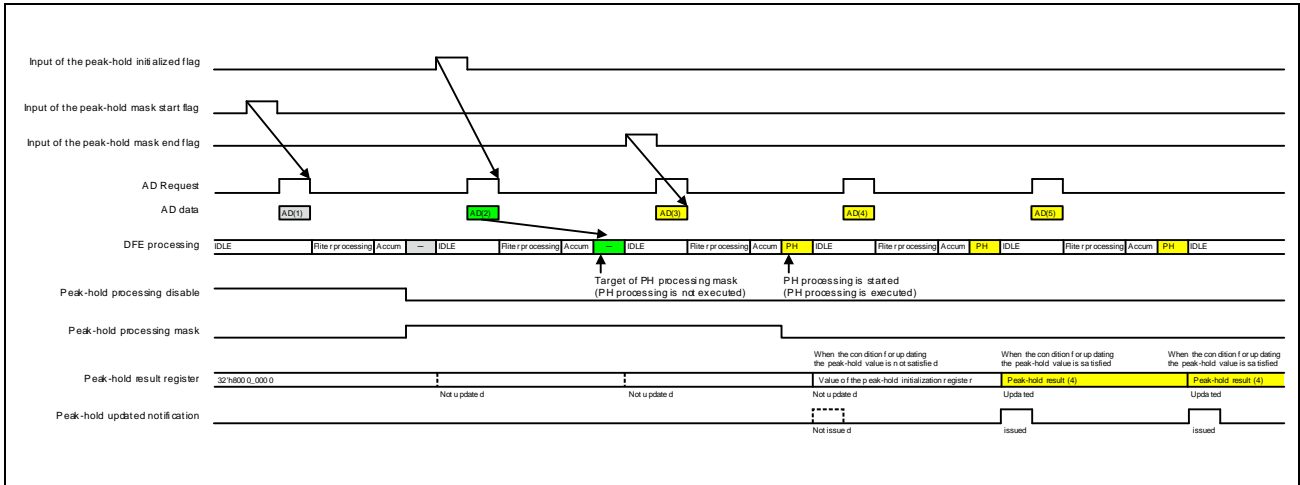

Figure 39.75 Peak-Hold Mask Processing for Specified Period from Start of Peak-Hold Processing (1/2)

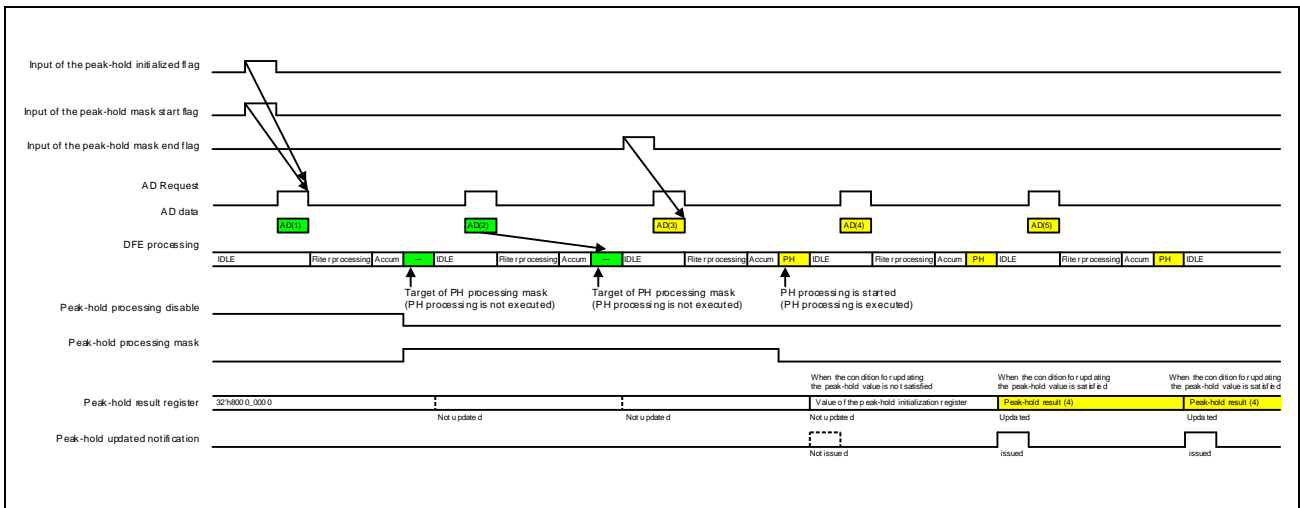

Figure 39.75 Peak-Hold Mask Processing for Specified Period from Start of Peak-Hold Processing (2/2)

The effective range of peak-hold mask start/end flags in each mode of peak-hold circuit is explained below.

The peak-hold processing is always affected by these flags.

Comparison is performed without being affected by these flags for all modes except peak-hold 23.

For the peak-hold mask status in peak-hold 23 mode, neither the peak-hold processing nor the comparison processing is executed.

Peak-Hold Circuit Setting	Peak-Hold Mask Start/End Flag	
	Peak-Hold Processing	Comparison Processing
Peak-hold processing and comparison processing prohibited	—	—
Only peak-hold executed	Valid	—
Only comparison executed	—	Invalid
Both peak-hold processing and comparison processing executed	Valid	Invalid
Peak-hold 23 function executed	Valid	Valid

39.5.12.5 Operation of Comparison Processing

In comparison processing, the peak-hold circuit input data is compared with the values of comparison target registers (CPA to CPD) for each channel. When the comparison result is true, the CND flag (condition match flag) is asserted and a condition match interrupt request is issued. Comparison processing is not affected by trigger flags except for the peak-hold 23 mode.

The following comparison calculations can be performed.

Comparison	Description
Equal to (=)	"Equal to (=)" calculation is performed between the peak-hold circuit input data and the value selected for comparison. When the comparison result is "equal to", it is true.
Equal to or less than (\leq)	"Equal to or less than (\leq)" calculation is performed between the peak-hold circuit input data and the value selected for comparison. When the comparison result is "equal to or less than", it is true.
Equal to or more than (\geq)	"Equal to or more than (\geq)" calculation is performed between the peak-hold circuit input data and the value selected for comparison. When the comparison result is "equal to or more than", it is true.
Less than (<)	"Less than (<)" calculation is performed between the peak-hold circuit input data and the value selected for comparison. When the comparison result is "less than", it is true.
More than (>)	"More than (>)" calculation is performed between the peak-hold circuit input data and the value selected for comparison. When the comparison result is "more than", it is true.

Once the comparison calculation result is true and the condition match bit (CND in DFEjSTCHn) is set to 1, the condition match bit remains 1 even if the subsequent comparison calculation result is false. Use the clear status register to clear the condition match bit to 0.

39.5.12.6 Operation of the Peak-Hold Index Register

When peak-hold processing is enabled (by setting DFEjCTLBCHn.PRCsB to 01_B), the peak-hold counter in the digital filter is cleared after the first round of peak-hold processing following input of the peak-hold initialization flag. After that, the peak-hold counter is incremented every time a value is peak-hold processed (whether or not it satisfies the condition for updating the peak-hold value).

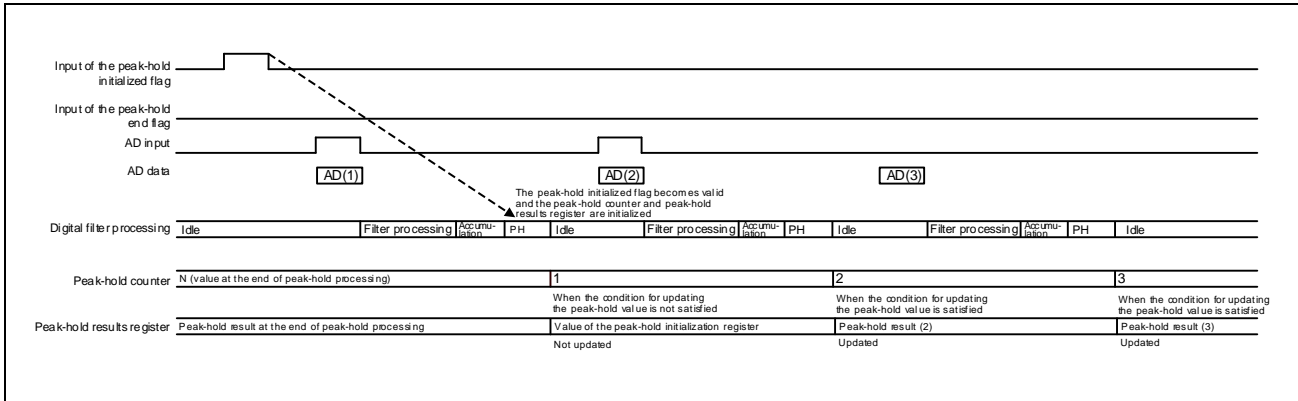

Figure 39.76 Operation of the Peak-Hold Counter at the Start of Peak-Hold Processing

Input of the peak-hold end flag leads to the end of peak-hold processing following input of the next value for peak-hold processing. If the peak-hold end flag becomes valid, the peak-hold counter and results register retain their previous values but do not update in response to data from the ADC. The values are retained until the peak-hold initialization flag becomes valid again.

Figure 39.77 Operation of the Peak-Hold Counter at the End of Peak-Hold Processing

If the peak-hold update condition is satisfied, updating the peak-hold result register stores the peak-hold counter value to the PHIND bits of the peak-hold index register when the peak-hold counter is incremented.

Figure 39.78 Peak-Hold Counter and Peak-Hold Index Register

When 16384 rounds of peak-hold processing are completed, the PHIOF bit in the peak-hold index register is set to 1. At this time, the value of the peak-hold counter becomes 0. Since the value of the peak-hold counter is stored in the PHIND bits when the input value satisfies the condition for updating the peak-hold value, the value of the PHIND bits becomes 0 if the condition is satisfied, but the previous value is retained if it is not.

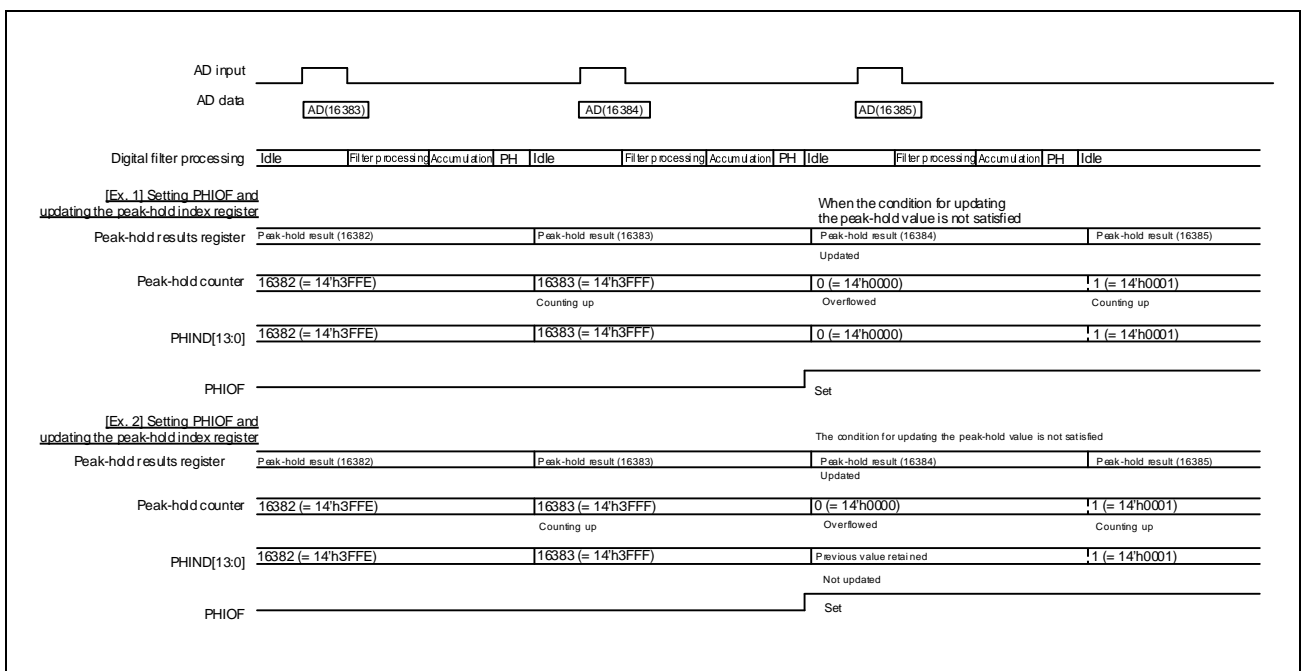

Figure 39.79 Setting of the Peak-Hold Index Overflow Bit

39.5.12.7 Reading of the Peak-Hold Index Register and Operation

Read the peak-hold index register between the end of peak-hold processing and the next time it starts (i.e. while peak-hold processing is disabled).

Operation of the peak-hold index register differs according to whether or not it is read.

Operations in peak-hold index updating and peak-hold retention modes also differ if the peak-hold index register is not read.

(1) When the Register is Read while Peak-Hold Processing is Disabled

The following applies whether the mode is peak-hold index updating or peak-hold index retention.

The PHIND and PHIOF bits are cleared when the first value for peak-hold processing is handled after peak-hold processing starts. The value of the PHIOW bit does not change.

The value of the peak-hold counter becomes 1, as does the value of the PHIND bits.

The peak-hold result register is not affected by whether reading or not reading peak-hold index register. Refer to **Section 39.5.12.2.** for the details.

Figure 39.80 Operation of the Peak-Hold Index Register when it is Read

(2) When the Register is Not Read while Peak-Hold Processing is Disabled

- Peak-hold index update mode (DFEjCTLBCHn.PICS = 0):

The PHIND and PHIOF bits are cleared when the first value for peak-hold processing is handled after peak-hold processing starts and the PHIOW bit is set.

The value of the peak-hold counter becomes 1, as does the value of the PHIND bits.

To clear the PHIOW bit, write 1 to DFEjCLRSTCHn.CLRPHIOW.

Figure 39.81 Operation of the Peak-Hold Index Register When It is Not Read (in Updating Mode)

- Peak-hold index retention mode (DFEjCTLBCHn.PICS = 1):

The values of the PHIND and PHIOF bits are retained the next time peak-hold processing starts. The value of PHIOW does not change.

If the register is read following the next and subsequent times peak-hold processing is ended, starting peak-hold processing again leads to clearing of the PHIND and PHIOF bits (refer to **(1) When the Register is Read while Peak-Hold Processing is Disabled**).

Figure 39.82 Operation of the Peak-Hold Index Register when it is Not Read (in Retention Mode)

39.5.12.8 Operation When Both Peak-Hold Processing and Comparison Processing Are Executed

When the peak-hold circuit processing select bit (DFEjCTLBCHn.PRC SB) is 11_B and the peak-hold 23 function enable bit (DFEjPH23CCTL0.PEN) is 0, peak-hold processing and comparison processing can be executed simultaneously.

In this mode, comparison processing is always executed. Peak-hold processing has a valid processing period based on the peak-hold initialization and end flags, and a peak-hold stop period based on the peak-hold mask start and end flags.

In peak-hold processing, the peak-hold end interrupt request is issued in the filter processing where the peak-hold end flag is enabled.

In comparison processing, the condition match interrupt request is issued when the comparison condition is true.

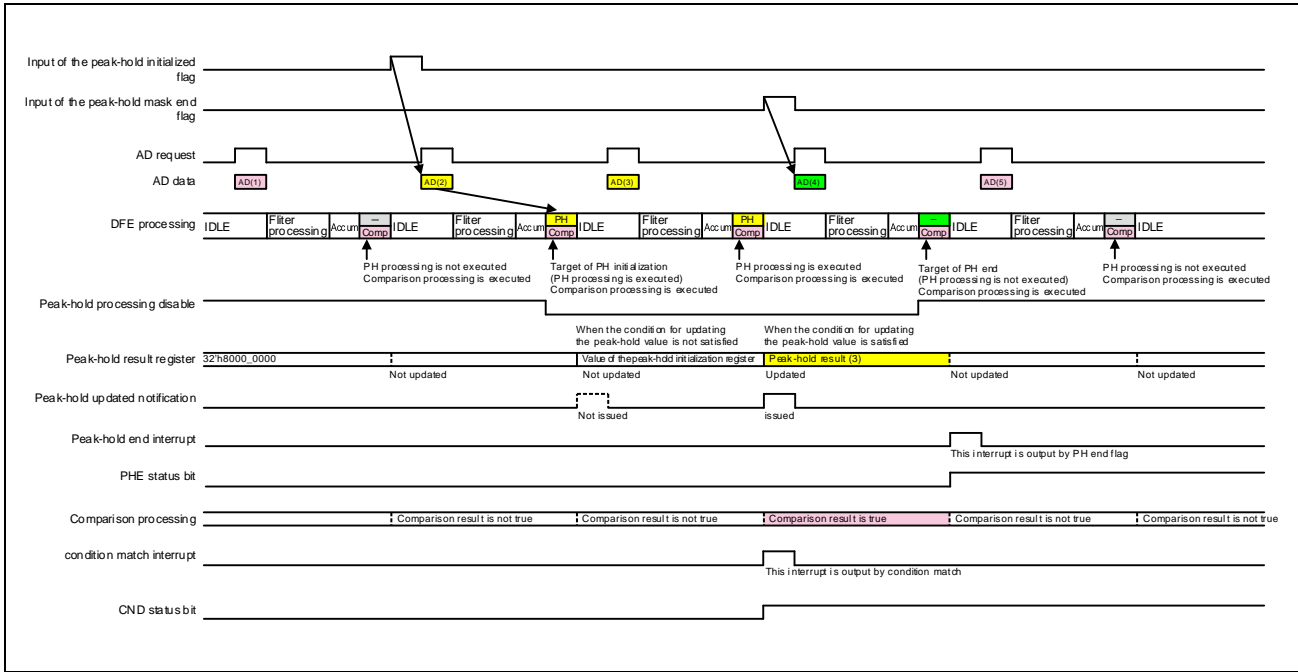

Figure 39.83 Operation when Peak-Hold Processing and Comparison Processing Are Executed Simultaneously (Peak-Hold Initialization/End Flag Enabled)

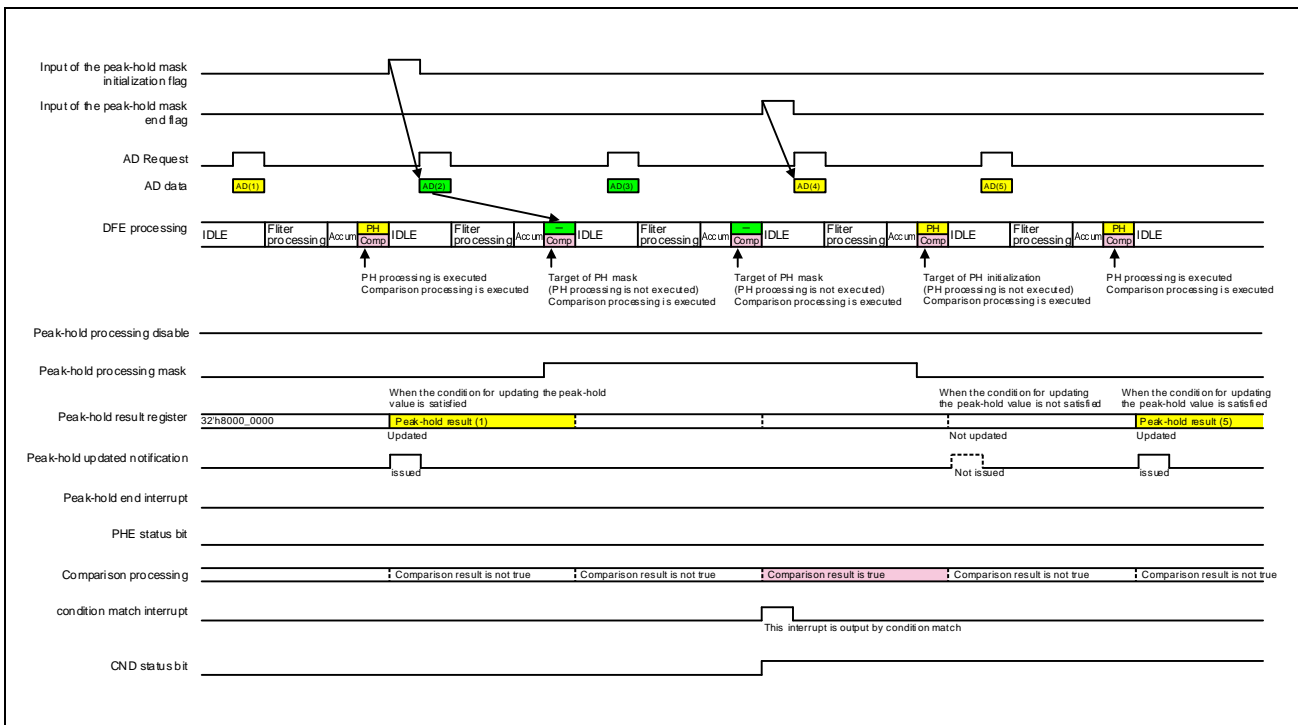

Figure 39.84 Operation when Peak-Hold Processing and Comparison Processing Are Executed Simultaneously (Peak-Hold Mask Start/End Flag Enabled)

39.5.12.9 Summary of Peak-Hold-23 Processing

The peak-hold-23 function is an extended function for peak-hold processing. The peak-hold-23 function allows you to detect the three peak points of the filtering process result.

Peak-hold processing is executed for the channel targeted for the peak-hold-23 function. Transitions from peak-hold-1 processing to peak-hold-2 processing and from peak-hold-2 processing to peak-hold-3 processing are realized in comparison processing. In this way, it is possible to hold the three peak-hold results by switching between peak-hold-1 processing, peak-hold-2 processing, and peak-hold-3 processing.

Table 39.84 Overview of Each Processing of Peak-Hold-23 Function

Category	Peak-hold Processing	Comparison Processing
Peak-hold-1 processing	<ul style="list-style-type: none"> The upper/lower peak is detected. The peak value is held in the peak-hold result register. When the peak is detected, the notification of Peak-hold updates can be output. 	<ul style="list-style-type: none"> When the comparison computation result for peak-hold-1 processing is true, the transition to peak-hold-2 processing occurs. The condition match interrupt is not output.
Peak-hold-2 processing	<ul style="list-style-type: none"> The upper/lower peak is detected. The peak value is held in the peak-hold-2 result register 0. When the peak is detected, the notification of peak-hold updates can be output. 	<ul style="list-style-type: none"> When the comparison computation result for peak-hold-2 processing is true, the transition to peak-hold-3 processing occurs. The condition match interrupt is not output.
Peak-hold-3 processing	<ul style="list-style-type: none"> The upper/lower peak is detected. The peak value is held in the peak-hold-3 result register 0. When the peak is detected, the notification of peak-hold updates can be output. 	<ul style="list-style-type: none"> When the comparison computation result for peak-hold-3 processing is true, the condition match interrupt is output, and peak-hold processing and comparison processing stop.

39.5.12.10 Operation of Peak-Hold-23 Function

With the settings described in **Section 39.5.12.14**, for the target channel, the peak-hold-23 function becomes available in peak-hold processing.

Peak-hold processing is executed by each of peak-hold-1 processes, peak-hold-2 processes, and peak-hold-3 processes using the data input to the peak-hold circuit. When the comparison computation result is true in each peak-hold processing, the transitions to peak-hold-2 and peak-hold-3 processing occur.

The status of the peak-hold-23 function can be checked by the peak-hold-23 function status bits (DFEjSTCHn.PH23ST).

Peak-hold-1 processing starts first for the filter processing where the peak-hold initialization flag has been enabled. When the condition for PH updates is matched during peak-hold-1 processing, the data input to the peak-hold circuit is stored in the peak-hold result register of the channel, and the notification of updates is issued. When the comparison computation result for peak-hold-1 processing is true, the transition to peak-hold-2 processing occurs in the next filtering process.

During peak-hold-2 processing, as with peak-hold-1 processing, the peak value is stored in the peak-hold-2 result register 0, and the notification of updates is issued. When the comparison condition for peak-hold-2 processing is true, the transition to peak-hold-3 processing occurs in the next filtering process.

During peak-hold-3 processing, as with peak-hold-1 processing, the peak value is stored in the peak-hold-3 result register 0, and the notification of updates is issued. When the comparison condition for peak-hold-3 processing is true, the condition match interrupt request is issued, and both peak-hold processing and comparison processing stop in the next filter process.

During the stop period, peak-hold processing and comparison processing are not executed. The peak-hold end interrupt request is issued in the filter process where the peak-hold end flag has been enabled, and the operation of the peak-hold-23 function ends.

When the peak-hold initialization flag is enabled again, peak-hold-1 processing starts in that filter process. Then, this operation is repeated. Operation of the peak-hold-23 function is shown below.

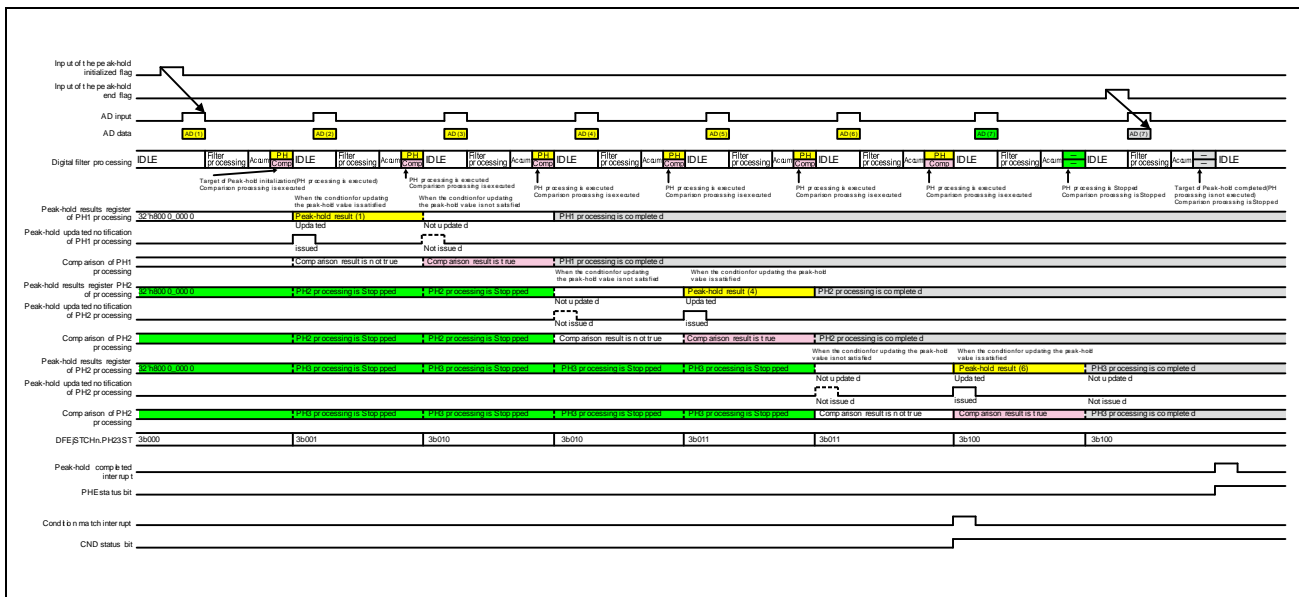

Figure 39.85 Operation of the Peak-Hold-23 Function

(1) Settings of Peak-Hold-23 Function

With the following settings, the peak-hold-23 function can be used for the target channel.

Category	Register Bit Name	Value	Remarks
Setting mode	DFEjPH23CCTL0.PEN	1	Peak-hold-23 Function is enabled.
	DFEjPH23CCTL0.CHS	Channel number	The target channel of peak-hold-23 function is selected.

(2) Settings and Operation of Peak-Hold-1 Processing

(a) Settings

The register settings required for peak-hold-1 processing are shown below.

To make the settings for peak-hold processing, it is necessary to select the upper or lower peak and the initial values of peak-hold processing.

To make the settings for comparison processing, it is necessary to select the comparison computation, the comparison offset value setting register, and the comparison offset value.

Make sure that the data format of the comparison offset value α is the same as the format of the filter processing result. By setting the comparison offset value with a two's complement, it is possible to execute the comparison computation with a comparison target value as "Value of peak-hold result register $n - \alpha$ ". The setting of the comparison offset value α is the same as that for peak-hold-2 processing and peak-hold-3 processing.

Category	Register Bit Name	Value	Remarks
Setting mode	DFEjCTLBCHn.PRC SB	11 _B	Indispensable setting
Peak-hold processing	DFEjCTLBCHn.PHPS	x	Selects the upper or lower peak.
	DFEjCTLBCHn.PHSLB2	xxx _B	Selects the PH initial value register.
Comparison processing	DFEjCTLBCHn.CPCS	1	Indispensable setting
	DFEjCTLBCHn.SELB1	00 _B	Selects the value of PH result register $n + \alpha$.
	DFEjCTLBCHn.SELB2	xxx _B	Selects the comparison computation.
	DFEjCTLBCHn.OFSL	xx _B	Selects the comparison offset value setting register to use.
	DFEjCPOFSTn.CPOFST	xxxx xxx _H	Sets the comparison offset value; two's complement when $-\alpha$ is set.

(b) Operation

In peak-hold processing for the peak-hold-1 process, the notification of peak-hold updates is issued and the data input to the peak-hold circuit is stored in the peak-hold result register. Conditions for peak-hold updates of peak-hold-1 process are as follows.

Peak	Function	Number Times of PH	Issue Condition
Upper peaks	PH update notification	First time* ¹	PH circuit input data* ² > The value of the peak-hold initial value setting register* ³
		After the first time	PH circuit input data* ² > The value of the DFEjPHCHn* ⁴
Lower peaks	PH update notification	First time* ¹	PH circuit input data* ² < The value of the peak-hold initial value setting register* ³
		After the first time	PH circuit input data* ² < The value of the DFEjPHCHn* ⁴

Peak	Function	Number Times of PH	Update Condition	Stored Data in DFEjPHCHn
Upper peaks	Peak-Hold Result register	First time* ¹	PH circuit input data* ² > The value of the peak-hold initial value setting register* ³	PH circuit input data
			PH circuit input data* ² ≤ The value of the peak-hold initial value setting register* ³	The value of the peak-hold initial value setting register* ³
		After the first time	PH circuit input data* ² > The value of the DFEjPHCHn* ⁴	PH circuit input data
			PH circuit input data* ² ≤ The value of the DFEjPHCHn* ⁴	Holds the value of DFEjPHCHn
Lower peaks	Peak-Hold Result register	First time* ¹	PH circuit input data* ² < The value of the peak-hold initial value setting register* ³	PH circuit input data
			PH circuit input data* ² ≥ The value of the peak-hold initial value setting register* ³	The value of the peak-hold initial value setting register* ³
		After the first time	PH circuit input data* ² < The value of the DFEjPHCHn* ⁴	PH circuit input data
			PH circuit input data* ² ≥ The value of the DFEjPHCHn* ⁴	Holds the value of DFEjPHCHn

Note 1. The first time means when filter processing is executed after PH initialization flag is valid.

Note 2. PH input data is the output data of the filter circuit or accumulation/decimation circuit.

Note 3. The register means one of the DFEjPHIA-DFEjPHID registers.

Note 4. These values are compared in either fixed-point format or integer format regardless of the DFEjCTLBCHn.PFMT bit setting.

- Comparison processing of peak-hold-1 processing is used as the condition for the transition to peak-hold-2 processing. In comparison processing, the following comparison computation is performed. In the following comparison processing, a “less-than operation (<)” is selected as an example.

Comparison processing of peak-hold-1	Value of input data to peak-hold circuit < value of peak-hold result register n + α.
--------------------------------------	--

(3) Settings and Operation of Peak-Hold-2 Processing

(a) Settings

The register settings required for peak-hold-2 processing are shown below.

To make the settings for peak-hold processing, it is necessary to select the upper or lower peak and the initial values of peak-hold processing.

To make the settings for comparison processing, it is necessary to select the comparison computation, the comparison offset value setting register, and the comparison offset value.

Category	Register Bit Name	Value	Remarks
Peak-hold processing	DFEjPH2CTL0.PHPS	x	Selects the upper or lower peak.
	DFEjPH2CTL0.PH2SLB2	xxx _B	Selects the PH initial value register.
Comparison processing	DFEjPH2CTL0.CN2SLB2	xxx _B	Selects the comparison computation.
	DFEjPH2CTL0.OFSL	xx _B	Selects the comparison offset value setting register to use.
	DFEjCPOFSTn.CPOFST	xxxx xxx _H	Sets the comparison offset value; two's complement when -α is set.

(b) Operation

In peak-hold processing of peak-hold-2 process, the notification of peak-hold updates is issued and the data input to the peak-hold circuit is stored in the peak-hold-2 result register 0. Conditions for peak-hold updates of peak-hold-2 process are as follows.

Peak	Function	Number Times of PH	Issue Condition
Upper peaks	PH update notification	The first time of transition to PH2 processing	PH circuit input data* ¹ > The value of the peak-hold initial value setting register* ²
		After the first time	PH circuit input data* ¹ > The value of the DFEjPH20* ³
Lower peaks	PH update notification	The first time of transition to PH2 processing	PH circuit input data* ¹ < The value of the peak-hold initial value setting register* ²
		After the first time	PH circuit input data* ¹ < The value of the DFEjPH20* ³

Peak	Function	Number Times of PH	Update Condition	Stored Data in DFEjPH20
Upper peaks	Peak-Hold Result register	The first time of transition to PH2 processing	PH circuit input data* ¹ > The value of the peak-hold initial value setting register* ⁴	PH circuit input data
			PH circuit input data* ¹ ≤ The value of the peak-hold initial value setting register* ⁴	The value of the peak-hold initial value setting register* ⁴
		After the first time	PH circuit input data* ¹ > The value of the DFEjPH20* ³	PH circuit input data
			PH circuit input data* ¹ ≤ The value of the DFEjPH20* ³	Holds the value of DFEjPH20
Lower peaks	Peak-Hold Result register	The first time of transition to PH2 processing	PH circuit input data* ¹ < The value of the peak-hold initial value setting register* ⁴	PH circuit input data
			PH circuit input data* ¹ ≥ The value of the peak-hold initial value setting register* ⁴	The value of the peak-hold initial value setting register* ⁴
		After the first time	PH circuit input data* ¹ < The value of the DFEjPH20* ³	PH circuit input data
			PH circuit input data* ¹ ≥ The value of the DFEjPH20* ³	Holds the value of DFEjPH20

Note 1. PH input data is the output data of the filter circuit or accumulation/decimation circuit.

Note 2. The register means one of the DFEjPHIA-DFEjPHID registers.

Note 3. These values are compared in either fixed-point format or integer format regardless of the DFEjPH23CCTL0.PFMT bit setting.

Note 4. For detail of the peak-hold initial value setting, refer to Note of DFEjPH2CTL0.PH2SLB2 in **Section 39.3.36, DFEjPH2CTL0 — Peak-Hold 2 Control Register 0**.

- Comparison processing of peak-hold-2 process is used as the condition for the transition to peak-hold-3 processing. In comparison processing, the following comparison computation is performed. In the following comparison processing, a “greater-than operation (>)” is selected as an example.

Comparison processing of peak-hold-2	value of input data to peak-hold circuit > value of peak-hold-2 result register 0 + α.
--------------------------------------	--

(4) Settings and Operation of Peak-Hold-3 Processing

(a) Settings

The register settings required for peak-hold-3 processing are shown below.

To make the settings for peak-hold processing, it is necessary to select the upper or lower peak and the initial values of peak-hold processing.

To make the settings for comparison processing, it is necessary to select the comparison computation, the comparison offset value setting register, and the comparison offset value.

Category	Register Bit Name	Value	Remarks
Peak-hold processing	DFEjPH3CTL0.PHPS	x	Selects the upper or lower peak.
	DFEjPH3CTL0.PH3SLB2	xxx _B	Selects the PH initial value register.
Comparison processing	DFEjPH3CTL0.CN3SLB2	xxx _B	Selects the comparison computation.
	DFEjPH3CTL0.OFSL	xx _B	Selects the comparison offset value setting register to use.
	DFEjCPOFSTn.CPOFST	xxxx xxx _H	Sets the comparison offset value; two's complement when $-\alpha$ is set.

(b) Operation

In peak-hold processing of peak-hold-3 process, the notification of peak-hold updates are issued and the data input to the peak-hold circuit is stored in the peak-hold-3 result register 0. Conditions for peak-hold updates of peak-hold-3 process are as follows.

Peak	Function	Number Times of PH	Issue Condition
Upper peaks	PH update notification	The first time of transition to PH3 processing	PH circuit input data* ¹ > The value of the peak-hold initial value setting register* ²
		After the first time	PH circuit input data* ¹ > The value of the DFEjPH30* ³
Lower peaks	PH update notification	The first time of transition to PH3 processing	PH circuit input data* ¹ < The value of the peak-hold initial value setting register* ²
		After the first time	PH circuit input data* ¹ < The value of the DFEjPH30* ³

Peak	Function	Number Times of PH	Update Condition	Stored Data in DFEjPH30
Upper peaks	Peak-Hold Result register	The first time of transition to PH3 processing	PH circuit input data* ¹ > The value of the peak-hold initial value setting register* ⁴	PH circuit input data
			PH circuit input data* ¹ ≤ The value of the peak-hold initial value setting register* ⁴	The value of the peak-hold initial value setting register* ⁴
		After the first time	PH circuit input data* ¹ > The value of the DFEjPH30* ³	PH circuit input data
			PH circuit input data* ¹ ≤ The value of the DFEjPH30* ³	Holds the value of DFEjPH30
Lower peaks	Peak-Hold Result register	The first time of transition to PH3 processing	PH circuit input data* ¹ < The value of the peak-hold initial value setting register* ⁴	PH circuit input data
			PH circuit input data* ¹ ≥ The value of the peak-hold initial value setting register* ⁴	The value of the peak-hold initial value setting register* ⁴
		After the first time	PH circuit input data* ¹ < The value of the DFEjPH30* ³	PH circuit input data
			PH circuit input data* ¹ ≥ The value of the DFEjPH30* ³	Holds the value of DFEjPH30

Note 1. PH input data is the output data of the filter circuit or accumulation/decimation circuit.

Note 2. The register means one of the DFEjPHIA-DFEjPHID registers.

Note 3. These values are compared in either fixed-point format or integer format regardless of the DFEjPH23CCTL0.PFMT bit setting.

Note 4. For detail of the peak-hold initial value setting, refer to Note of DFEjPH3CTL0.PH3SLB2 in **Section 39.3.37, DFEjPH3CTL0 — Peak-Hold 3 Control Register 0.**

- Comparison processing of peak-hold-3 process is used as the condition for ending peak-hold-3 processing. In comparison processing, the following comparison computation is performed. In the following comparison processing, a “less-than operation (<)” is selected as an example.

In peak-hold-3 processing, the condition match interrupt request is issued when the comparison computation result is true. In the subsequent filter processing, both peak-hold processing and comparison processing stop.

The peak-hold end interrupt request is issued in the filter process where the peak-hold end flag has been enabled, and the operation of the peak-hold-23 function for that channel ends.

Comparison processing of peak-hold-3	value of input data to peak-hold circuit < value of peak-hold-3 result register 0 + α.
--------------------------------------	--

39.5.12.11 Operation of the Peak-Hold Index Register When Peak-Hold-23 is Enabled

When the peak-hold-23 function is used, the peak-hold count value is stored in each peak-hold index register for each peak-hold process. The operations of the peak-hold-2 index register 0 (DFEjPH2IND0) and the peak-hold-3 index register 0 (DFEjPH3IND0) are the same as those of the peak-hold index register (DFEjPHINDCHn) of the channel targeted for the peak-hold-23 function.

Category	Target Register	Remarks
Peak-hold 1 processing	DFEjPHINDCHn	This register operates only during peak-hold-1 processing. It holds the value and stops when the transition to peak-hold-2 processing occurs.
Peak-hold 2 processing	DFEjPH2IND0	This register operates only during peak-hold-2 processing. It holds the value and stops when the transition to peak-hold-3 processing occurs.
Peak-hold 3 processing	DFEjPH3IND0	This register operates only during peak-hold-3 processing. It holds the value and stops when peak-hold-3 processing ends.

Figure 39.86 Operation of Peak-Hold Index Register when Peak-Hold-23 Function is used

39.5.12.12 Status of Peak-Hold-23 Function

The condition match interrupt request is issued when the comparison computation result is true in peak-hold-3 processing. The peak-hold end interrupt request is issued when the filter processing where a peak-hold end flag that is enabled is executed.

The status of the peak-hold 23 function can be checked by reading the peak-hold 23 function status bit (DFEjSTCHn.PH23ST). For details, see **Section 39.3.8, DFEjSTCHn — Status Register n (n = 0 to 15, for DFE0, n = 0 to 3 for DFE1)**.

When enabling the peak-hold initialization flag again, clear the status bit to 000_B in advance if the status bit indicates neither 000_B nor 100_B.

39.5.12.13 Operation of Peak-Hold-23 Function (Trigger Flag is enable)

The peak-hold-23 function is affected by the function of peak-hold mask because this is an extended function for peak-hold processing. After the peak-hold mask start flag was set valid, the peak-hold-23 processing is kept stopped until the peak-hold mask end flag is set valid.

And the peak-hold-23 function is affected by the auto initialization flag. After the auto initialization flag which is the peak-hold 23 processing target channel was valid, target registers of the auto initialization are initialized (Target registers are DFEjSTCHn.PH23ST, DFEjPHCHn, DFEjPHINDCHn, DFEjPH20, DFEjPH2IND0, DFEjPH30 and DFEjPH3IND0) .

Then, when the peak-hold processing is invalid, the PH23ST bit is set 000_B. After that, when peak-hold processing is valid, the PH23ST bit is set 001_B.

When the auto initialization flag which is the peak-hold 23 processing target channel is valid, and when the peak-hold initialization flag is valid and when the peak-hold mask start flag is valid, target registers of the auto initialization are initialized. The PH23ST bit keeps 000_B until the peak-hold mask is set invalid.

After the peak-hold mask is set invalid, PH23ST bit is set 001_B and the peak-hold 1 processing is started.

39.5.12.14 Setting Example of Peak-Hold-23 Function

The peak-hold-23 function is used to detect the three peak points of the filtering process result for the channel. The following two cases are assumed.

- (1) To Detect the Three Peak Points Starting from the Rising Edge
- (2) To Detect the Three Peak Points Starting from the Falling Edge

The following paragraphs describe how to make the settings for each of the two cases.

(1) To Detect the Three Peak Points Starting from the Rising Edge

This paragraph exemplifies how to set the peak-hold-23 function when you detect the three peak points of filter output values starting from the rising edge.

For the channel targeted for the peak-hold 23 function, make the settings as shown in the example below.

Table 39.85 Setting Example of Peak Detect Starting from the Rising Edge

	Category	Register Bit Name	Value	Remarks
Peak-hold-23 common setting	Mode setting	DFEjPH23CCTL0.PEN	1	
		DFEjPH23CCTL0.CHS	Channel number	Channel targeted for peak-hold-23
	Initial value setting	DFEjPHIA.PHI	8000 0000 _H	Negative minimum
		DFEjPHIB.PHI	7FFF FFFF _H	Positive maximum
Peak-hold-1 processing	Mode setting	DFEjCTLBCHn.PRCSB	11 _B	Indispensable setting
	Peak-hold processing	DFEjCTLBCHn.PHPS	0	Upper peak
		DFEjCTLBCHn.PHSLB2	000 _B	Selects DFEjPHIA.
	Comparison processing	DFEjCTLBCHn.CPCS	1	Indispensable setting
		DFEjCTLBCHn.SELB1	00 _B	Selects the value of peak-hold result register n + α.
		DFEjCTLBCHn.SELB2	001 _B	Less than or equal (≤)
		DFEjCTLBCHn.OFSL	00 _B	Selects DFEjCPOFST0.
DFEjCPOFST0.CPOFST	Value of α1	Two's complement		
Peak-hold-2 processing	Peak-hold processing	DFEjPH2CTL0.PHPS	1	Lower peak
		DFEjPH2CTL0.PH2SLB2	001 _B	Selects DFEjPHIB.
	Comparison processing	DFEjPH2CTL0.CN2SLB2	010 _B	Greater than or equal (≥)
		DFEjPH2CTL0.OFSL	01 _B	Selects DFEjCPOFST1.
DFEjCPOFST1.CPOFST	Value of α2			
Peak-hold-3 processing	Peak-hold processing	DFEjPH3CTL0.PHPS	0	Upper peak
		DFEjPH3CTL0.PH3SLB2	000 _B	DFEjPHIA selected
	Comparison processing	DFEjPH3CTL0.CN3SLB2	001 _B	Less than or equal (≤)
		DFEjPH3CTL0.OFSL	10 _B	Selects DFEjCPOFST2.
DFEjCPOFST2.CPOFST	Value of α3	Two's complement		

(2) To Detect the Three Peak Points Starting from the Falling Edge

This paragraph exemplifies how to set the peak-hold-23 function when you detect the three peak points of filter output values starting from the rising edge.

For the channel targeted for the peak-hold 23 function, make the settings as shown in the example below.

Table 39.86 Setting Example of Peak Detect Starting from the Falling Edge

	Category	Register Bit Name	Value	Remarks
Peak-hold-23 common setting	Mode setting	DFEjPH23CCTL0.PEN	1	
		DFEjPH23CCTL0.CHS	Channel number	Channel targeted for peak-hold-23
	Initial value setting	DFEjPHIA.PHI	7FFF FFFF _H	Positive maximum
		DFEjPHIB.PHI	8000 0000 _H	Negative minimum
Peak-hold-1 processing	Mode setting	DFEjCTLBCHn.PRC5B	11 _B	Indispensable setting
	Peak-hold processing	DFEjCTLBCHn.PHPS	1	Lower peak
		DFEjCTLBCHn.PHSLB2	000 _B	Selects DFEjPHIA.
	Comparison processing	DFEjCTLBCHn.CPCS	1	Indispensable setting
		DFEjCTLBCHn.SELB1	00 _B	Selects the value of peak-hold result register n + α .
		DFEjCTLBCHn.SELB2	010 _B	Greater than or equal (\geq)
		DFEjCTLBCHn.OFSL	00 _B	Selects DFEjCPOFST0.

		DFEjPH3CTL0.OFSL	10 _B	Selects DFEjCPOFST2.
DFEjCPOFST2.CPOFST	Value of α 3			

39.5.13 Output Circuit

39.5.13.1 Floating-Point Conversion Circuit

This circuit executes IEEE754 floating-point conversion of (S.31) format data that is input to the output circuit and (S9.22) format data after accumulation. Setting the PRCSA bit of the control register B (DFEjCTLBCHn) to 1 converts data to be stored in the output data register to the floating-point format.

39.5.13.2 Output Register Circuit

The output register circuit has 32-bit registers for each channel. Input calculation result data or floating-point conversion results are stored in the output register (DFEjDOCHn.DO[31:0]) for each channel.

When the results of calculation with DFEjCTLBCHn.PRCSA = 01_B (accumulation) or DFEjCTLBCHn.PRCSA = 10_B (decimation) are written to an output register, the DOEN bit in DFEjSTCHn is set and an interrupt request is generated. When filter processing is executed with DFEjCTLBCHn.PRCSA = 00_B, the filtering results are stored in an output register but the DOEN bit is not set and no interrupt is output.

To execute filter processing without accumulation/decimation and output an interrupt, set the PRCSA bit in DFEjCTLBCHn to 10_B (decimation) and set the decimation count to 0.

The DOEN flag in DFEjSTCHn is automatically cleared to 0 by reading the output register. If another calculation result is written to the output data register with the DOEN flag in DFEjSTCHn set to 1, the value in the output data register is overwritten. At this time, the DOOW bit in DFEjSTCHn is set to 1.

The DOEN bit in DFEjSTCHn is cleared to 0 by reading DFEjDOCHn (output data register) from the peripheral bus or setting the CLRDOOW bit in DFEjCLRSTCHn to 1.

39.5.13.3 Floating Point Conversion Circuits for the Intermediate Value Output Registers L and H

An intermediate value circuit produces 38-bit values, which can be processed by floating-point conversion to conform with the IEEE 754 standard in the case of even number channels. If the value of the HOFSA bit in control register B (DFEjCTLBCHn) is 1, the contents of the given intermediate value output register L/H pair are converted from 38- to 32-bit floating-point format. Only even number channels have intermediate value output register L/H.

39.5.13.4 Intermediate Value Output Register Circuits

The intermediate values output register circuits for even number channels include 38-bit registers. They are in service when FIR filtering is selected. Values from the results of calculation to which rounding has not been applied or the results of floating-point conversion are stored in the respective intermediate values output registers L and H.

The values become fixed point if 0 has been written to the HOFSA bit in control register B (DFEjCTLBCHn). In this case, for each 38-bit value, the six higher-order bits from 2 to 7 (guard bits) are stored in DFEjHOHCHn, and the highest-order bit (the sign bit) and 31 lower-order bits (the fractional part) are stored in DFEjHOLCHn.

If 1 has been written to the HOFSA bit, the values are floating-point converted and the 32-bit values thus produced are stored in the given DFEjHOLCHn register. The value of the corresponding DFEjHOHCHn register is fixed to 0.

The timing for updating of the intermediate value register is the same as that for the corresponding output registers.

The intermediate value output registers become invalid if IIR filtering is selected, and their values are fixed to 0.

39.5.14 Capture Circuit

The capture circuit stores the filter results stored in the output circuit in the capture result register in response to a capture trigger generated by the timer.

Filtering results for a maximum of three channels can be stored from the DFE channel.

The data format for the capture result register conforms to the data format for the output data register for a selected channel.

39.5.14.1 Summary of Capture Circuit

Capture trigger input from the timer is enabled when a capture-object channel is selected using a capture-object channel selection bit (DFEjCAPCTLCHn.CAPCH) and when 1 is written to the capture channel enabling bit (DFEjCAPCTLCHn.CEN).

In response to a capture trigger from the timer, the capture circuit stores a value of the output data register (DFEjDOCHn) in the corresponding capture result register (DFEjCAPDOCHn).

39.5.15 Buffer A Circuit

Buffer A is a 32-bit data buffer which is comprised of 8-stage FIFO × 6 channels.

By response to a FIFO capture trigger from the timer, the circuit stores a maximum of the circuit stores a maximum of six values in the output data register on the selected channel in the FIFO--DFE0 or DFE1--in response to a FIFO capture trigger generated by the timer.

The stored data can be read using the P-bus interface.

The circuit issues the buffer A capture end interrupt request indicating the completion of storing of data in the FIFO. For further details, see **Section 39.5.27.2(1), Buffer A Capture End Interrupt Request**.

If an overflow error occurs in the FIFO, the circuit issues an error interrupt request of buffer A.

39.5.15.1 Summary of Buffer A Circuit

The buffer A circuit is enabled by buffer A enable bit, and capture triggers from the timer are enabled.

The storage of data items in each FIFO channel is enabled by the buffer A channel n enable bits. For each of the FIFO channels, either DFE0 or DFE1 is selected by DFE select bits, and the channel number for the output data register is selected by capture-object channel select bits.

Register Bit Name	Remarks
DFBFACCTL.AEN	Enables or disables the buffer A circuit.
DFBFACCTL.AUNE	Enables or disables the capture result register update flag.
DFBFACTLCHn.ADSL	Selects DFE0 or DFE1.
DFBFACTLCHn.BFACH	Selects a channel.
DFBFACTLCHn.CHEN	Enables or disables the FIFO channel.
DFBFACTLCHn.CLRA	Initializes the buffer A circuit.

The data format for the buffer A result register conforms to the data format for the output data register for a selected channel. By using the buffer A data update flag enable bit, it is possible to assign a buffer A update flag to the LSB of the buffer A result register to indicate that the output data register has been updated. For further details, see **Section 39.3.57, DFBFADOCHn — Buffer A Output Register n (n = 0 to 7)**.

Figure 39.87 Buffer A Result Register Data Format Selection

In response to a FIFO capture trigger from the timer, the macro stores in batch the values of the DFE macro output data register in the enabled FIFO.

Figure 39.88 Operation of the Buffer A Circuit

39.5.15.2 Operation of Output Data Register Enable Flag and Buffer A Data Update Flag

When the buffer A circuit is selected, the output data register enable flags (DFEjSTCHn.DOEN) on the selected FIFO channels are cleared if data is stored in the FIFO.

When the value of updated output data is stored in the FIFO, the FIFO channel returns the FIFO capture ACK to the DFE macro; the DFE macro clears the DOEN bit on the pertinent channel to 0.

In this case, the buffer A data update flag (DFBFADOCHn.AUN) becomes 0.

Storing the same data, not updated, in the FIFO sets the buffer A data update flag to 1.

Figure 39.89 Operation of Output Data Register Enable Flag and Buffer A Data Update Flag

39.5.15.3 Initialization of the Buffer A Circuit

By means of the buffer A clear bit (DFBFACLR.CLRA), it is possible to initialize all FIFO channels. In this case, any invalid FIFO channels (DFBFACTLCHn.CHEN = 0) are also initialized.

For details, see **Section 39.3.58, DFBFACLR — Buffer A Clear Register**.

39.5.15.4 Overwriting of FIFO When There is an Overflow

When there is an overflow in a FIFO, no data is overwritten in the FIFO, which rule applies to all FIFOs in the FIFO macro (FIFO channel FIFO and buffer B circuit FIFO). In such a case, any data to store is discarded

Also, when an overflow occurs, the overflow error bit is set to 1. In the waveforms shown below, if an overflow occurs on FIFO channel 0 in the buffer A circuit, the FIFO overflow error bit (DFBFACST.OVFA0) is set to 1.

Figure 39.90 Overwrite Operation during FIFO Overflow

39.5.16 Buffer B Circuit

Buffer B is a 32-bit data buffer comprised of an 8-stage FIFO \times 1 channel.

When the value of the output data register on either a selected DFE0 or DFE1 channel is updated, the circuit stores the output data register value on the selected channel in one FIFO.

The stored data can be read by the P-bus interface.

The circuit issues the buffer B capture end interrupt request indicating the completion of storing of data in the FIFO. For further details, see **Section 39.5.27.2(2), Buffer B Capture End Interrupt Request**.

If an overflow error occurs in the buffer B FIFO, the circuit issues a buffer B interrupt request.

39.5.16.1 Summary of Buffer B Circuit

The buffer B circuit is enabled by buffer B enable bit. The circuit stores data in the FIFO when data of the target channel is updated.

Either DFE0 or DFE1 is selected by DFE select bits, and the channel number for the output data register is selected by capture-object channel select bits.

Register Bit Name	Remarks
DFBFBCTL.BEN	Enables or disables the buffer B circuit.
DFBFBCTL.BDSL	Selects DFE0 or DFE1.
DFBFBCTL.BFBCH	Selects a channel.
DFBFBCLR.CLRB	Initializes the buffer B circuit.

The data format for the buffer B result register conforms to the data format for the output data register for a selected channel. The circuit stores the output data register value in the FIFO when the output data of the target channel is updated.

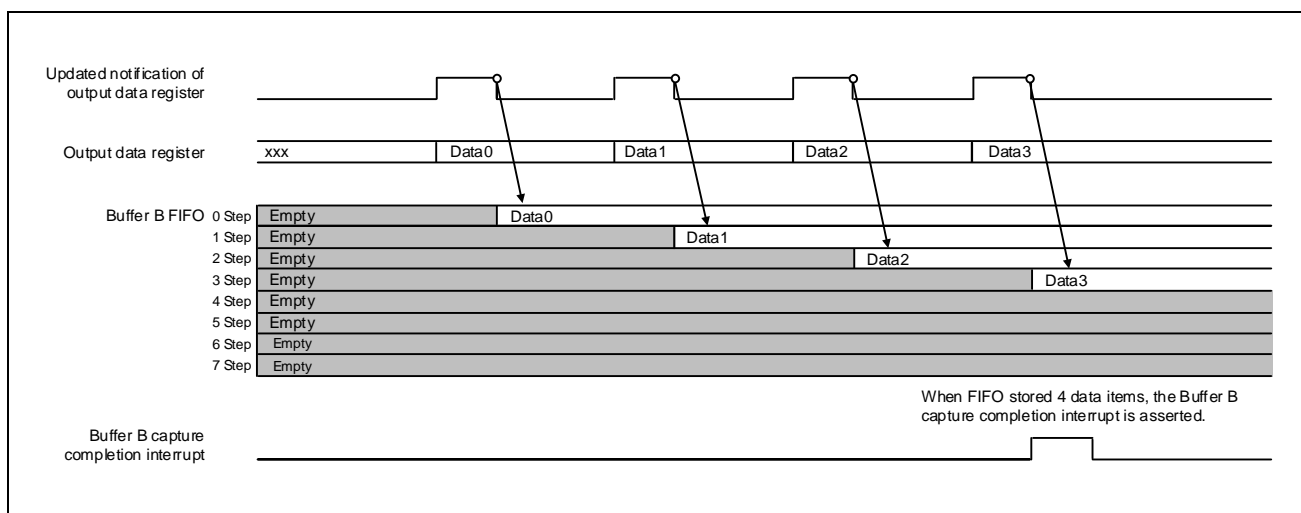

Figure 39.91 Operation of Buffer B Circuit

39.5.16.2 Operation of Output Data Register Enable Flag

When the buffer B circuit is selected, the output data register enable flag (DFEjSTCHn.DOEN) on the selected channel is cleared when data is stored in the buffer B FIFO.

At this time, the buffer B circuit returns the FIFO capture ACK to the DFE macro, and the DFE macro clears the DOEN bit of the target channel to 0.

Figure 39.92 Clear Operation of Output Data Register Enabling Flag

39.5.16.3 Initialization for Buffer B Circuit

By means of buffer B clear bit (DFBFBCLR.CLRB), it is possible to initialize the buffer B circuit. For details, see **Section 39.3.62, DFBFBCLR — Buffer B Clear Register**.

39.5.17 Status Register

The DFE has a status register for each channel. The status register indicates the status shown below. Each flag except PH23ST and VALID can be cleared by using the corresponding clear status register. Only the DOEN flag can be automatically cleared by reading the output data register and the intermediate value output register L/H in addition to the clear status register.

Table 39.87 Status Register

Name	Description
PH23ST	<p>Peak-Hold-23 Processing Status</p> <p>When 0 is written to DFEjPH23CCTL0.PEN, PH23ST whose target channel is DFEjPH23CCTL0.CHS is set to 000_B. PH23ST[2:0] is set to 000_B, when the filter processing is executed after the auto initialization flag which is PH23 processing target channel is valid.</p> <p>PH23ST[2:0] is set to 001_B, when the filter processing whose peak-hold-1 initialization flag is valid is executed.</p> <p>PH23ST[2:0] is set to 010_B, when the comparison calculation result of peak-hold-1 is true.</p> <p>PH23ST[2:0] is set to 011_B, when the comparison calculation result of peak-hold-2 is true.</p> <p>PH23ST[2:0] is set to 100_B, when the comparison calculation result of peak-hold-3 is true.</p>
VALID	<p>Input Data Register Valid</p> <p>This bit is set to 1 when the input data register contains a valid value.</p> <p>This bit is cleared to 0 by a reset or at completion of accumulation/decimation processing.</p>
PHE	<p>Peak-Hold End</p> <p>When peak-hold and comparison are used simultaneously (DFEjCTLBCHn.PRCsb = 11_B), and when the filter processing whose peak-hold end flag is valid is executed, this bit is set to 1.</p> <p>When peak-hold and comparison are not used simultaneously (DFEjCTLBCHn.PRCsb ≠ 11_B), this bit is disabled (fixed 0).</p>
CND	<p>Condition Match</p> <p>When peak-hold is used (DFEjCTLBCHn.PRCsb = 01_B), and when the filter processing whose peak-hold end flag is valid is executed, this bit is set to 1.</p> <p>When comparison is used (DFEjCTLBCHn.PRCsb = 10_B) or peak-hold and comparison are used simultaneously (DFEjCTLBCHn.PRCsb = 11_B), and when the comparison calculation result is true, This bit is set to 1.</p>
DOEN	<p>Output Data Register Enable</p> <p>Conditions for setting and clearing this flag are described later.</p>
DIOW	<p>Input Data Overwrite Error</p> <p>This bit is set to 1 when the input data register is overwritten during processing for the relevant channel. This bit is also set to 1 when the input data register for the process is overwritten by other input data with the same tag.</p>
DOOW	<p>Output Data Overwrite Error</p> <p>This bit is set to 1 when another calculation result is written while the output data register contains valid data.</p>
MER	<p>Multiplication Error</p> <p>This bit is set to 1 when calculation 8000_H × 8000_H is performed in the filtering circuit.</p>
GER	<p>Guard Error</p> <p>This bit is set to 1 when a rounding error (48 bits to 32 bits) occurs in the filtering circuit.</p>
CER	<p>Cascade Rounding Error</p> <p>This bit is set to 1 when a rounding error (32 bits to 16 bits) occurs during execution of cascade input.</p>
AER	<p>Absolute Value Error</p> <p>This bit is set to 1 when absolute value calculation of 8000 0000_H is performed during absolute value calculation in the accumulation circuit.</p>

39.5.17.1 Conditions for Setting and Clearing the DOEN Flag

The DOEN flag indicates whether values stored in output registers are valid. The flag is valid when settings are for accumulation or decimation. Its value stays unchanged as 0 for any other settings.

When even number channel is in use as an IIR filter, the output data register and intermediate value output registers (including the intermediate value output mirror register L) are all in the scope of operations.

When even number channel is in use as an IIR filter, although the values of the intermediate value output registers are fixed to 0, reading a register still leads to clearing of the DOEN flag. Accordingly, since only the output register is in scope for an IIR filter, reading of the intermediate value output registers (including the intermediate values output mirror register L) is prohibited.

Odd number channels do not have intermediate value output registers, so only the output data registers are in the scope of operations, regardless of the selected type of filter.

Conditions for setting and clearing of the DOEN flag differ with the channel, selected filter type, and selection or non-selection of floating point conversion for the intermediate values output registers. The conditions are summarized in the tables below.

Conditions for setting of and the timing of storage in the DFEjDOCHn, DFEjHOLCHn (or DFEjHOLMCHn), and DFEjHOHCHn bits do not vary.

In some case there are multiple conditions for clearing. In this case, the overall condition is the logical OR of the multiple conditions.

Table 39.88 Conditions for Setting and Clearing DOEN

Case 1: Even number channel with IIR filtering selected on an Odd number channel	
DOEN Setting Condition	DOEN Clearing Conditions
The result of filter calculations are stored in DFEjDOCHn	1 is written to DFEjCLRSTCHn.CLRDOEN
	DFEjDOCHn is read
	The data of target channels being stored in FIFO by Buffer A Circuit or Buffer B Circuit
Case 2: Even number channel with FIR filtering selected, and floating-point conversion of intermediate value is not selected	
DOEN Setting Condition	DOEN Clearing Conditions
The result of filter calculations are stored in DFEjDOCHn, DFEjHOLCHn, and DFEjHOHCHn	1 is written to DFEjCLRSTCHn.CLRDOEN
	DFEjDOCHn is read
	Both DFEjHOLCHn (or DFEjHOLMCHn) and DFEjHOHCHn is read (the order of reading does not create a problem)
	The data of target channels being stored in FIFO by Buffer A Circuit or Buffer B Circuit
Case 3: Even number channel with FIR filtering selected, and floating-point conversion of intermediate value is selected	
DOEN Setting Condition	DOEN Clearing Conditions
The result of filter calculations are stored in DFEjDOCHn and DFEjHOLCHn	1 is written to DFEjCLRSTCHn.CLRDOEN
	DFEjDOCHn is read
	DFEjHOLCHn (or DFEjHOLMCHn) is read
	The data of target channels being stored in FIFO by Buffer A Circuit or Buffer B Circuit

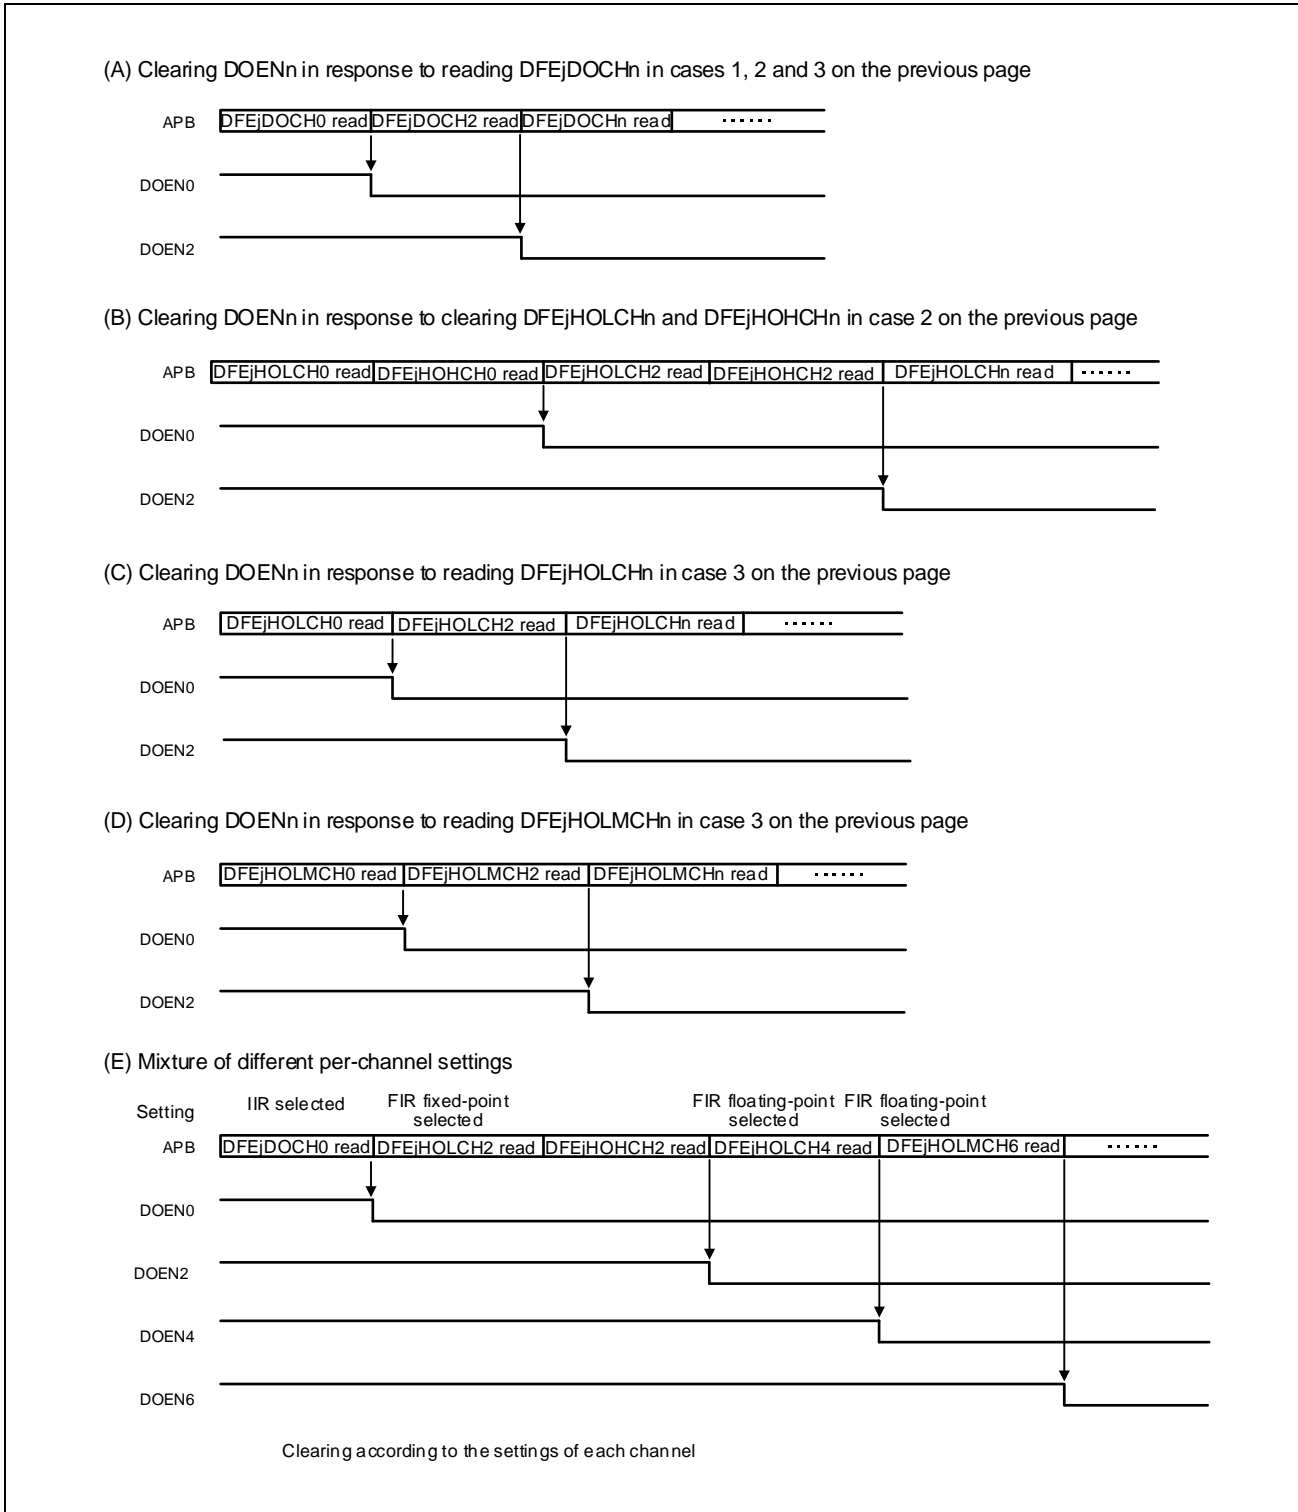

Figure 39.93 Operations for Clearing the DOEN Flag

39.5.18 Error Mask Registers

Functions of error mask registers are shown below. Masked error factors are excluded from error interrupt request conditions.

When the multiplication error mask flag is set to 1 in channel 0, for example, the multiplication error flag is not set to 1 even if a multiplication error occurs in channel 0. No error interrupt request is output in this case.

Table 39.89 Error Mask Registers

Flag	Description
MSKDIOW	Input data error (DIOW) mask bit
MSKDOOW	Output data error (DOOW) mask bit
MSKMER	Multiplication error (MER) mask bit
MSKGER	Guard error (GER) mask bit
MSKAER	Absolute value error (AER) mask bit
MSKCER	Cascade rounding error (CER) mask bit

39.5.19 Subtraction Status Register

For each subtraction channel, there is a subtraction status register. The subtraction status register indicates the status information described below. With the exception of the SUBF and MINF flags, flags are cleared through the use of the corresponding clear status register. In cases exclusively for the SDOEN flag, the flag is cleared automatically when the subtraction result register is read, in addition to the operation of the clear status register.

Table 39.90 Subtraction Status Register

Name	Description
SUBF	Subtrahend Channel Data Input Enable When MINF = 0, completion of the filtering of the subtrahend channel sets SUBF to 1. When SUBF = 1 and MINF = 0, performs subtraction upon completion of the filtering of the minuend channel. Storing subtraction result data in the subtraction result register clears SUBF to 0.
MINF	Minuend Channel Data Input Enable When SUBF = 0, completion of the filtering of the minuend channel sets MINF to 1. When MINF = 1 and SUBF = 0, MINF performs subtraction upon completion of the filtering of the subtrahend channel. Storing subtraction result data in the subtraction result register clears MINF to 0.
SDOEN	Subtraction Output Data Register Valid This bit is set to 1 when the DFE stores the subtraction results in the subtraction output data register. While SDOEN = 1, reading the DFEjSUBDOCHn register clears this bit to 0.
SDOOW	Subtraction Result Register Overwrite Error When SDOEN = 1, storing subtraction output data in the subtraction result register sets SDOOW to 1.
SCER	Subtraction Circuit Cascade Rounding Error When a cascade rounding error occurs in subtraction output data, this bit is set to 1.
SGER	Subtraction Guard Error When an overflow error of subtraction result, this bit is set to 1.

39.5.20 Subtraction Error Mask Registers

The following shows the functions of the subtraction error mask register. Any masked error events are excluded from the error interrupt request conditions.

For example, if the subtraction circuit cascade rounding error mask flag is set on subtraction channel 0, no subtraction circuit cascade rounding error will be set even when a subtraction circuit cascade rounding error condition arises on subtraction channel 0. Also, no error interrupt requests will be issued.

Table 39.91 Subtraction Error Mask Register

Name	Description
MSKSDOOW	Subtraction Result Register Overwrite Error (SDOOW) Mask
MSKSCER	Subtraction Circuit Cascade Rounding Error (SCER) Mask
MSKSGER	Subtraction Guard Error (SGER) Mask

39.5.21 Capture Status Register

For each capture channel, there is a capture status register. The capture status register indicates the status information described below. Flags are cleared through the use of the corresponding capture clear status register.

Table 39.92 Capture Status Register

Name	Description
CDOEN	Capture Output Data Register Valid This bit is set to 1 when the DFE stores the capture results in the capture output data register. While CDOEN = 1, reading the DFEjCAPDOCHn register clears this bit to 0.
CDOOW	Capture Result Register Overwrite Error When CDOEN = 1, storing capture data in the capture result register sets CDOOW to 1.

Note: Even if a capture process is executed, the DOEN for the capture-target of output data register is not cleared.

39.5.22 Capture Error Mask Register

The following shows the functions of the capture error mask register. Any masked error events are excluded from the error interrupt request conditions.

For example, if the capture result register overwrite error mask flag is set on capture channel 0, no capture result register overwrite error will be set even when a capture result register overwrite error condition arises on capture channel 0. Also, no error interrupt requests will be issued.

Table 39.93 Capture Error Mask Register

Name	Description
MSKCDOOW	Capture Result Register Overwrite Error (CDOOW) Mask

39.5.23 Buffer A Status Register

The buffer A status register is provided. The status register indicates the status information described below.

Table 39.94 Buffer A Status Register

Name	Description
EMPA _n	FIFO channel-n empty bit Indicates that no data is stored in the FIFO. The bit is cleared to 0 when data is stored in the FIFO. The bit is set to 1 when all remaining data in the FIFO is read. The bit is set to 1 when 1 is written in DFBFACLR.CLRA. EMPA _n of FIFO channel which is never used indicates 1.
OVFA _n	FIFO channel n FIFO overflow error bit Indicates that a FIFO overflow has occurred. The bit is set to 1 when new data is stored when the FIFO is full. The bit is cleared to 0 when 1 is written in DFBFACLR.CLRA. OVFA _n of FIFO channel which is never used indicates 0.

39.5.24 Buffer A Clear Register

Writing 1 to the buffer A clear bit of the buffer A clear register clears the status bits for all FIFO channels and any internal status (FIFO pointer values for buffer A), and resets them to their initial values.

39.5.25 Buffer B Status Register

The buffer B status register is provided. The status register indicates the status information described below.

Table 39.95 Buffer B Status Register

Name	Description
EMPB	Empty bit Indicates that not data is stored in the FIFO. The bit is cleared to 0 when data is stored in the FIFO. The bit is set to 1 when all remaining data in the FIFO is read. The bit is set to 1 when 1 is written in DFBFBCLR.CLRB. The bit indicates 1 when Buffer B is never used.
OVFB	FIFO overflow error bit Indicates that a FIFO overflow has occurred. The bit is set to 1 when new data is stored when the FIFO is full. The bit is cleared to 0 when 1 is written in DFBFBCLR.CLRB. The bit indicates 0 when Buffer B is never used.

39.5.26 Buffer B Clear Register

Writing 1 to the buffer B clear bit of the buffer B clear register clears the status bits and any internal status (FIFO pointer values for buffer B), and resets them to their initial values.

39.5.27 Interrupt Requests

39.5.27.1 DFE Macro

DFE macro has the interrupt request of the following list.

Table 39.96 List of Interrupt Request for the DFE Macro

Interrupt Request Function	Number	Remarks
Output Data Interrupt Request	DFE0: 16 DFE1: 4	Can be issued to each channel
Condition Match Interrupt Request 0	DFE0: 16 DFE1: 4	Can be issued to each channel
Condition Match Interrupt Request 1	DFE0: 4 DFE1: 4	Can be issued to CH0-CH3 channel
Subtraction Data Interrupt Request	DFE0: 3 DFE1: 3	Can be issued to each subtraction channel
Error Interrupt Request	DFE0: 1 DFE1: 1	Can be issued for all error sources commonly.

(1) Output Data Interrupt Requests

When a calculation result with $DFEjCTLBCHn.PRCSA = 01_B$ (accumulation) or $DFEjCTLBCHn.PRCSA = 10_B$ (decimation) is written to an output register, an output data interrupt request is output. (When the PRCSA is 00_B , a calculation result is stored in an output data register but no interrupt is output.)

Interrupt requests corresponding to each channel can be output.

Interrupt request output can be controlled by using the IEO bit in the control register A.

The relationship between the $DFEjSTCHn.DOEN$ bit and an output data interrupt request in addition to the relationship between the $DFEjSTCHn.DOEN$ flag and an output data interrupt request are shown below. For operation of the $DFEjSTCHn.DOEN$ bit, see **Section 39.5.17.1, Conditions for Setting and Clearing the DOEN Flag**.

If the DOEN flag has been cleared to 0, an output data interrupt is generated when the result of calculation is stored in the output data register again.

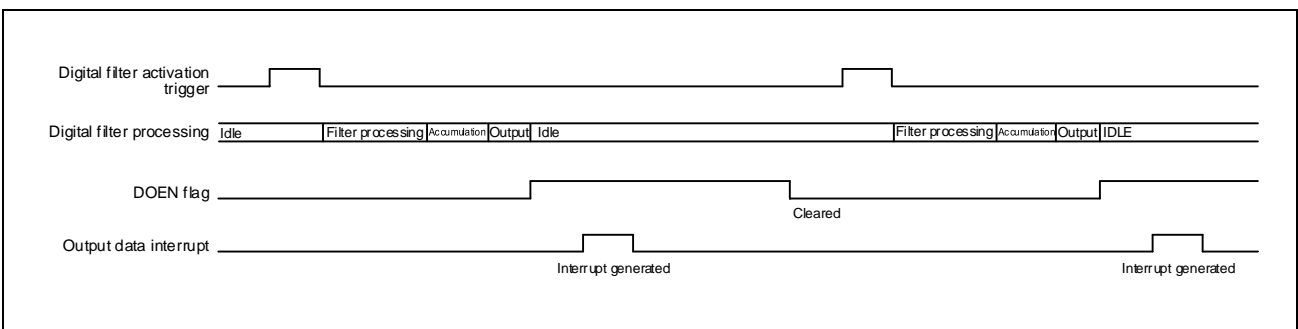

Figure 39.94 Relationship between the DOEN Bit and an Interrupt

When the DOEN bit in $DFEjSTCHn$ is not cleared by the software, an output data interrupt request is not output even if data is rewritten to the output data register. If the output data register value is overwritten, the DOOW bit in $DFEjSTCHn$ is set to 1.

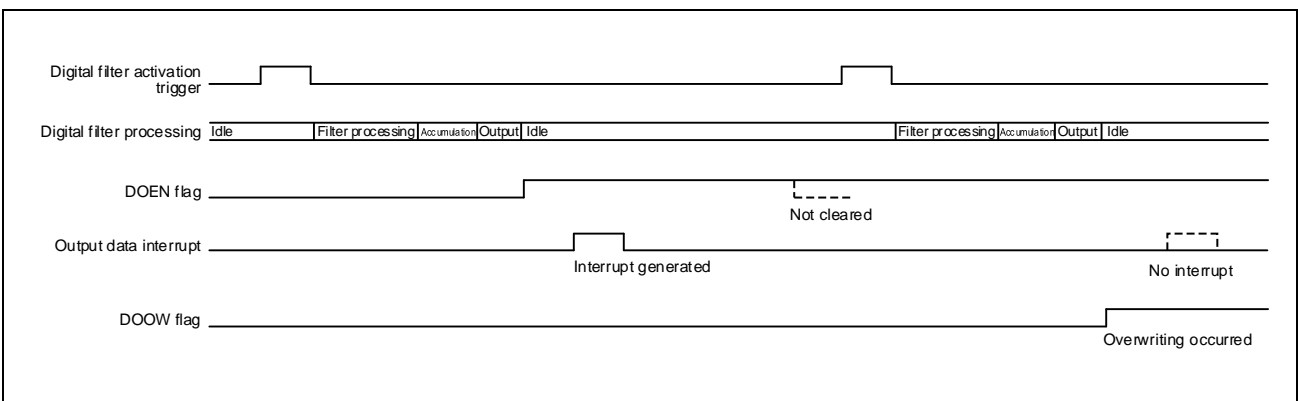

Figure 39.95 Relationship between the DOEN and DOOW Bits and an Interrupt

(2) Condition Match Interrupt Request

When the peak-hold end trigger flag is enabled during peak-hold processing, a condition match interrupt request indicating completion of peak-hold processing is output. When comparison calculation result is true during comparison calculation, a condition match interrupt request is output.

Interrupt request output can be controlled by using the IEC flag in the control register A.

There are two types of condition match interrupt requests: INTDFEjCND0 and INTDFEjCND01. The interrupt source (either DFEjSTCHn.CND or DFEjSTCHn.PHE) can be selected individually for each of these requests. As shown below, interrupt sources that can be assigned vary based on the peak-hold circuit settings (combination of DFEjCTLBCHn.PRCSB and DFEjPH23CCTL0.PEN). INTDFEjCND0 is given to all channels, and INTDFEjCND1 is given to channel 0 to 3. See **Table 39.97**.

Table 39.97 Correspondence between Condition Match Interrupt Requests and Interrupt Sources (1)

Peak-Hold Circuit Settings	PRCSB	PEN	INTDFEjCND0	INTDFEjCND1
Neither peak-hold processing nor comparison calculation processing is executed.	00 _B	—	No function	No function
Peak-hold processing is executed	01 _B	—	CND (peak-hold ended)	No function
Comparison processing is executed.	10 _B	—	CND (condition matched)	No function
Peak-Hold and comparison simultaneously	11 _B	0	*See Table 39.98 .	
Peak-hold-23 is executed.	11 _B	1		

When simultaneous execution of peak-hold processing and comparison processing is selected, or when the peak-hold-23 function is selected, by setting the DFEjCTLACHn.CNSLE and the DFEjCTLACHn.CNSL as shown below, the interrupt source (either DFEjSTCHn.CND or DFEjSTCHn.PHE) to assign to the INTDFEjCND0/1 can be changed.

Table 39.98 Correspondence between Condition Match Interrupt Requests and Interrupt Sources (2)

Peak-Hold Circuit Settings	CNSLE	CNSL	INTDFEjCND0	INTDFEjCND1
Peak-hold and comparison simultaneously	0	—	CND (condition matched)	PHE (peak-hold ended)
	1	0	CND (condition matched)	PHE (peak-hold ended)
		1	PHE (peak-hold ended)	CND (condition matched)
Peak-hold-23 is executed.	0	—	CND (condition matched)	PHE (peak-hold ended)
	1	0	CND (condition matched)	PHE (peak-hold ended)
		1	PHE (peak-hold ended)	CND (condition matched)

Please note that no condition match interrupt request is output after a condition match interrupt request is issued, unless the pertinent interrupt source status is cleared (see **Figure 39.96, item (2)**).

The condition match bit (DFEjSTCHn.CND) is cleared when 1 is written to DFEjCLRSTCHn.CLRCND. Also, peak-hold end bit (DFEjSETCHn.PHE) is cleared when 1 is written to DFEjCLRSTCHn.CLRPHE.

For the condition match interrupt request based on a DFEjSTCHn.CND source, output of an interrupt request can be controlled by means of DFEjCTLACHn.IEC. Also, for the condition match interrupt request based on DFEjSTCHn.PHE, output of an interrupt request can be controlled by means of DFEjCTLACHn.IEP.

Figure 39.96 shows the relationship between the CND bit in the status register (DFEjSTCHn (n = 0 to 11 for DFE0, n = 0 to 3 for DFE1)) and condition match interrupt request. When the peak-hold end flag is enabled, a condition match interrupt request is issued at the same time.

The DISB bit (peak-hold processing disable bit) in DFEjCTLBCHn disables peak-hold processing in the same way as the peak-hold end flag is enabled, but does not output a condition match interrupt. In addition, even if a peak-hold end trigger is input with peak-hold processing, no condition match interrupt is output.

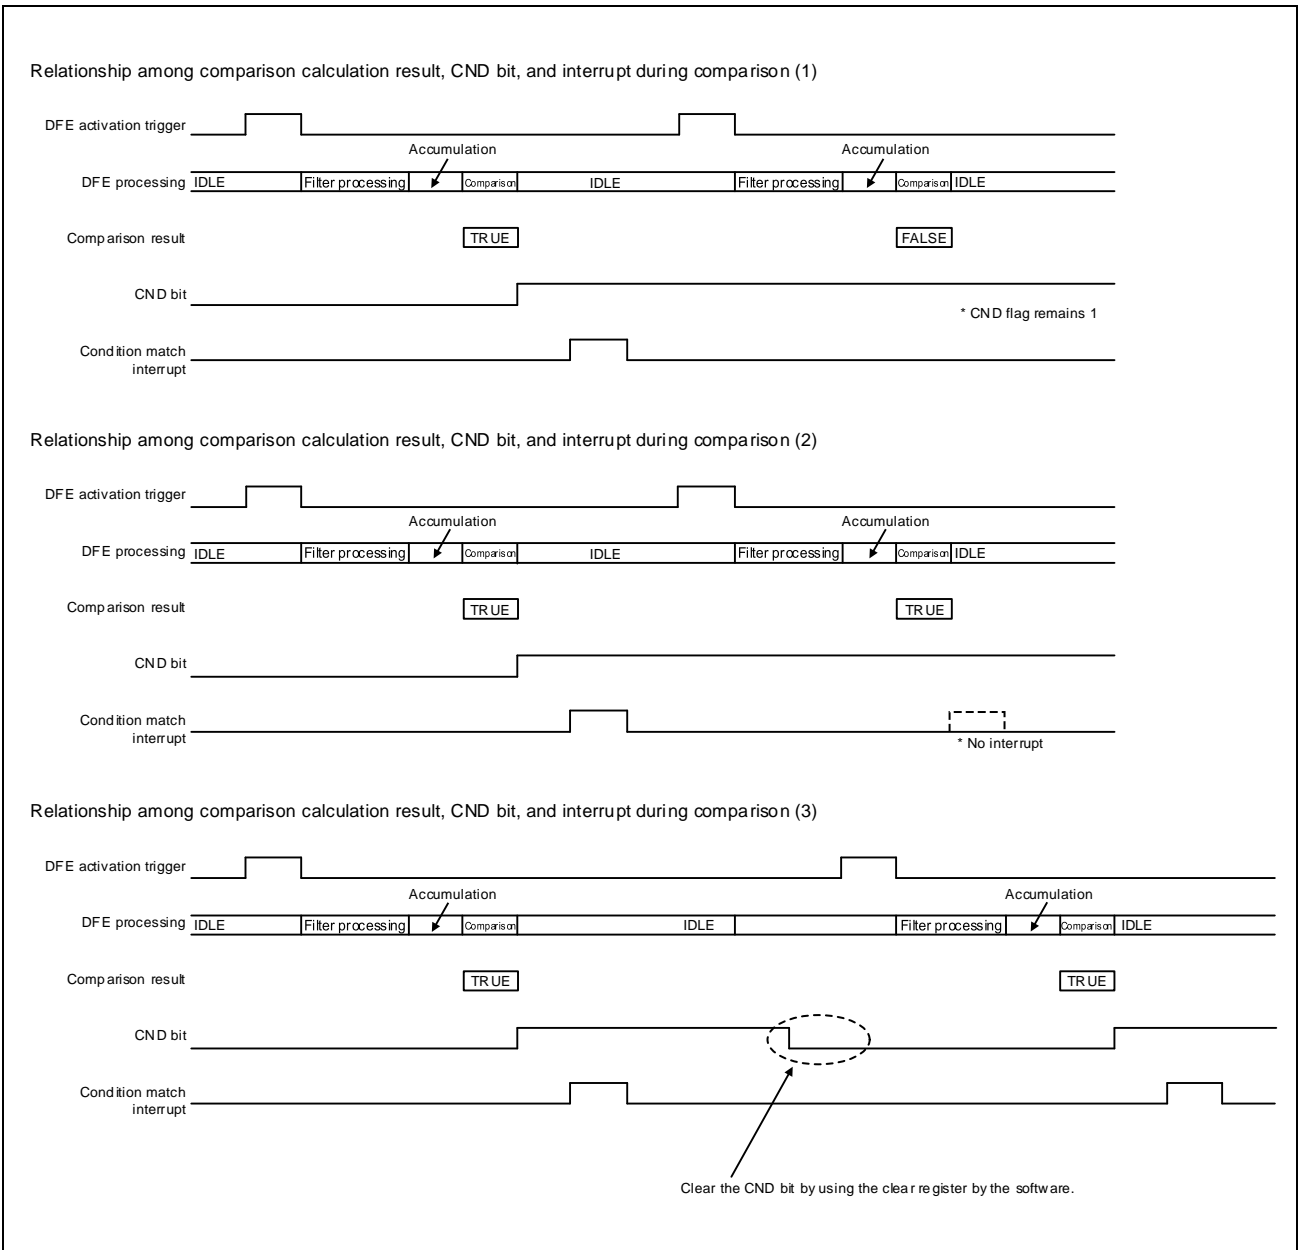

Figure 39.96 Relationship between CND Bit and Condition Match Interrupt Request

(3) Subtraction Data Interrupt Request

Upon storing subtraction results in the subtraction result register, the subtraction circuit issues the subtraction data interrupt request.

The interrupt requests can be issued for corresponding subtraction channels, and by using the DFEjSUBCTLCHn.SIEO bits, each interrupt request output can be controlled.

The figure below shows the relationship between the DFEjSUBSTCHn.SDOEN flags and the subtraction data interrupt requests.

Clearing the SDOEN flag to 0 and storing the subtraction results again in the subtraction result register issues a subtraction data interrupt request.

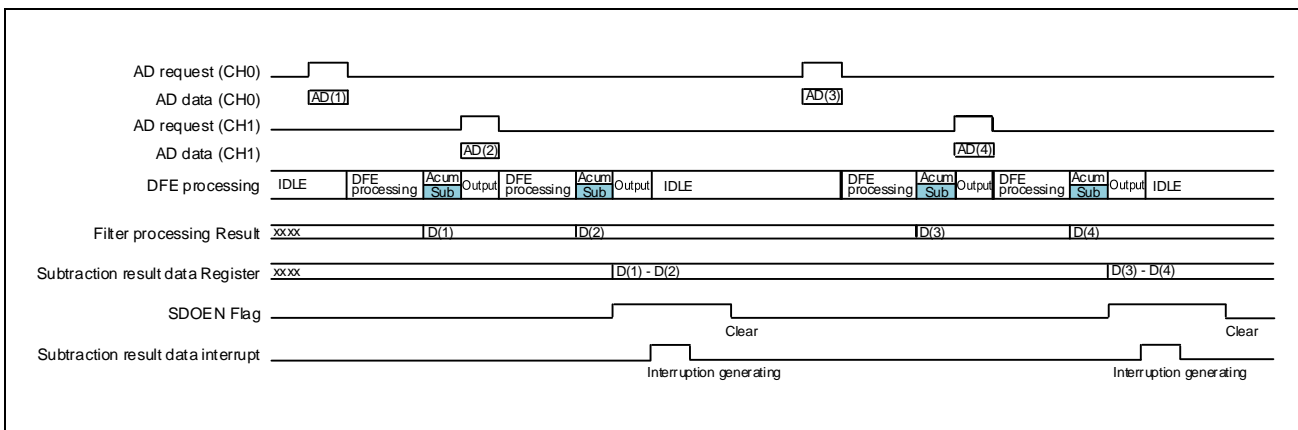

Figure 39.97 Relationship between SDOEN and Subtraction Data Interrupt Request

If the DFEjSUBSTCHn.SDOEN flag is not cleared to 0, no subtraction data interrupt request is issued even when the subtraction results are stored again in the subtraction result register. In this case, because the subtraction result register is overwritten, the DFEjSUBSTCHn.SDOOW flag is set to 1.

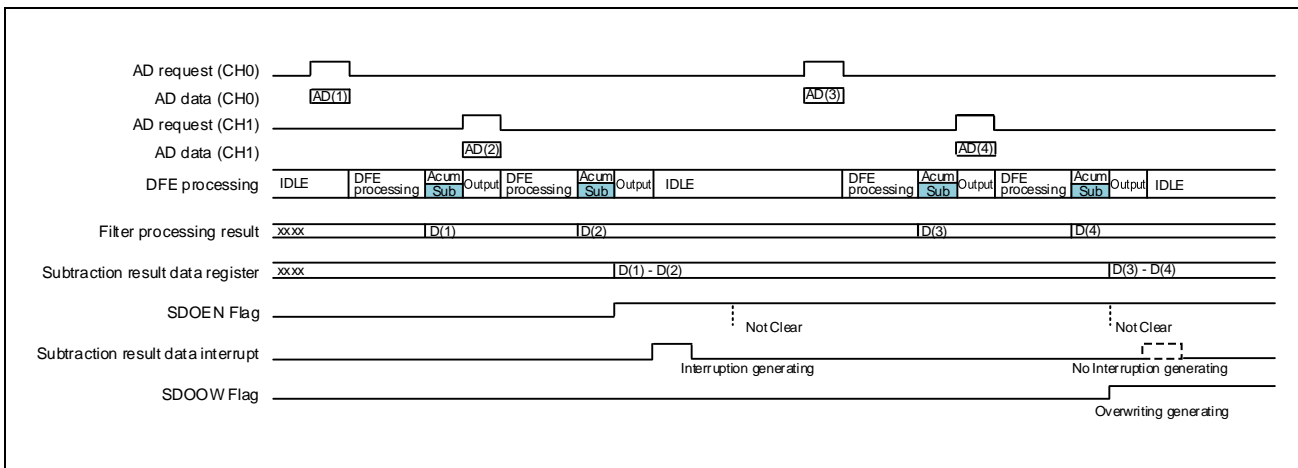

Figure 39.98 Relationship Between SDOEN, SDOOW and Subtraction Data Interrupt Request

(4) Capture Data Overwrite Error

Having stored the value of the output data register in the capture result register, the capture circuit sets DFEjCAPSTCHn.CDOEN to 1; it does not issue an interrupt request that indicates the storage of data in the capture result register.

If the DFEjCAPSTCHn.CDOEN flag is not cleared to 0, storing capture data again in the capture result register causes the overwriting of the capture result register; consequently, the DFEjCAPSTCHn.CDOOW flag is set to 1, enabling an error interrupt to be issued.

For further details on error interrupts, see **Section 39.5.27.1(5)**.

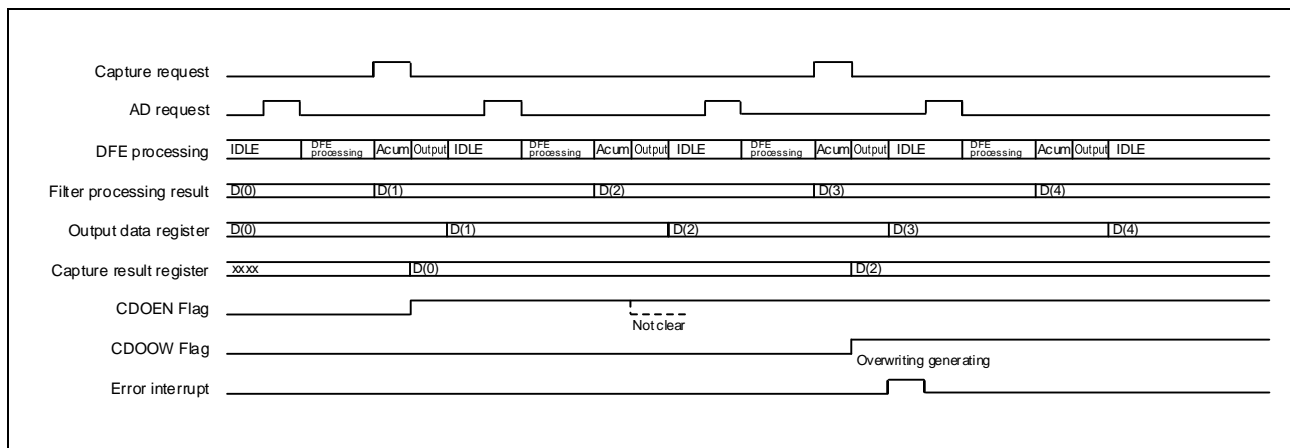

Figure 39.99 Relationship Between CDOEN, CDOOW and Error Interrupt Request

(5) Error Interrupt Requests

Error interrupt request is composed of the 'OR' for the error sources on all channels, all subtraction channels, and all capture channels. All the DFE macro error sources can be summarized as follows.

Error interrupt request output can be controlled by channel, by subtraction channel, and by capture channel. For the meanings of error sources, see **Section 39.5.17** to **Section 39.5.22**.

Table 39.99 Summary of DFE Macro Error Factors

Category	Error Status Bit	Remarks
Channel	DFEjSTCHn.DIOW	Input Data Overwrite Error
	DFEjSTCHn.DOOW	Output Data Overwrite Error
	DFEjSTCHn.MER	Multiplication Error
	DFEjSTCHn.GER	Guard Error
	DFEjSTCHn.CER	Cascade Rounding Error
	DFEjSTCHn.AER	Absolute Value Error
Subtraction Channel	DFEjSUBSTCHn.SDOOW	Subtraction Result Register Overwrite Error
	DFEjSUBSTCHn.SCER	Subtraction Circuit Cascade Rounding Error
	DFEjSUBSTCHn.SGER	Subtraction Guard Error
Capture Channel	DFEjCAPSTCHn.CDOOW	Capture Result Register Overwrite Error

For example, in the case of error interrupt requests for channel 0 to channel 7 are enabled and error interrupt requests for channel 8 to channel 11 are masked, if an error occurs in any channel from 0 to 7, an error interrupt request is output. However, if an error occurs in any channel from 8 to 11 in this state, no error interrupt request is output.

Since error interrupts are composed of the OR of error sources, if an error interrupt request has already been issued, no error interrupts are issued when a new error source occurs. After an error interrupt request is issued, if an error bit occurs again after the error bit is cleared using the clear register, an error interrupt request is issued.

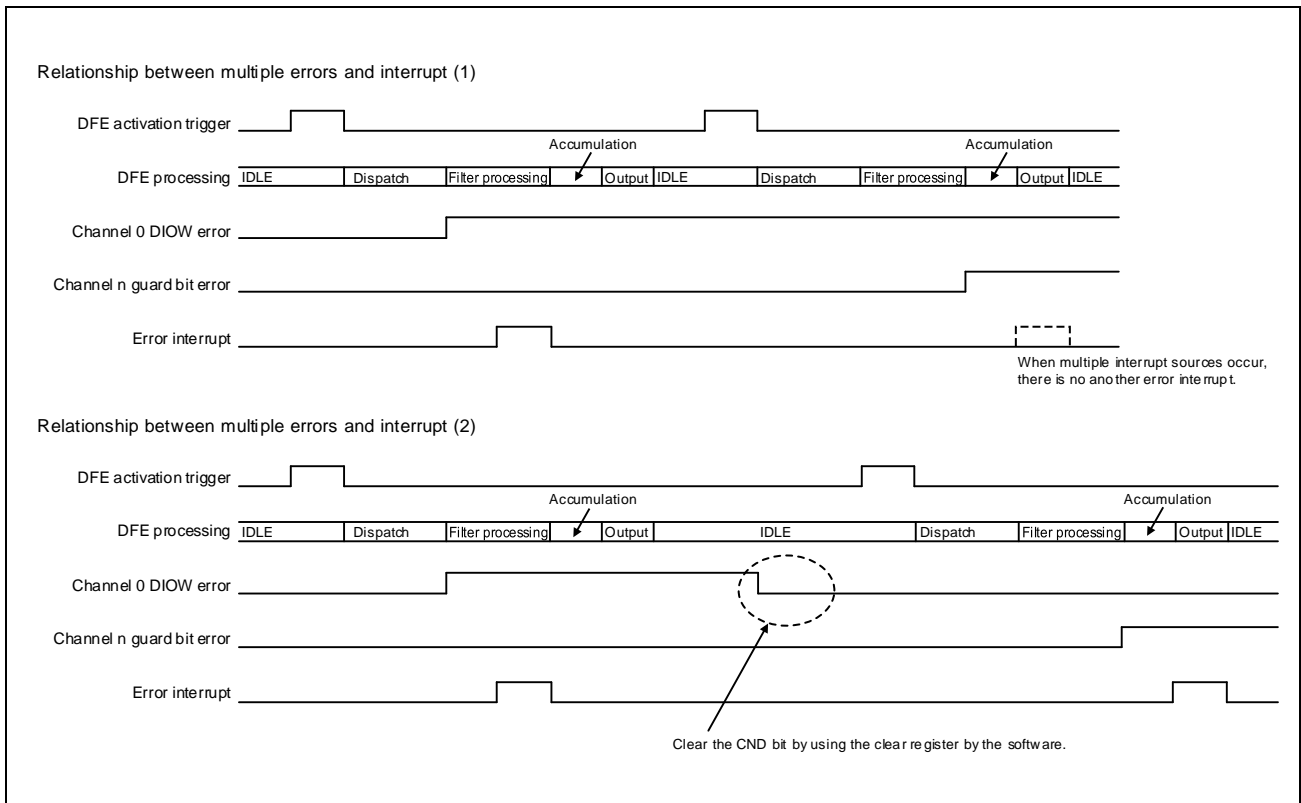

Figure 39.100 Relationship between Error Bit and Error Interrupt

39.5.27.2 FIFO Macro

FIFO macro has the interrupt request in the following list.

Table 39.100 List of Interrupt Request of FIFO Macro

Interrupt Request Function	Number	Remarks
Buffer A capture end interrupt request	1	Can be issued to all FIFO channels commonly
Buffer B capture end interrupt request	1	Can be issued to buffer B simple substance
FIFO Error Interrupt Request	1	Can be issued to all error sources commonly

(1) Buffer A Capture End Interrupt Request

The output of the buffer A capture end interrupt request can be controlled by setting the AIEO bit of the buffer A common control register (DFBFACCTL) to 1.

When the FIFO data, which is the object of reading in the buffer A output data register (DFBFADOCHn) is updated, the buffer A capture end interrupt request is issued.

If data is stored in the FIFO in the FIFO empty state, for example, the buffer A capture end interrupt request is issued. Also, the buffer A capture end interrupt request is issued when all buffer A output data registers are read on the enabled FIFO channels when multiple data items are stored on each of the FIFO channels.

To issue a buffer A capture end interrupt request again, read all data from the enabled FIFO channels. No buffer A capture end interrupt request will be issued if all of the data is not read on the enabled FIFO channels.

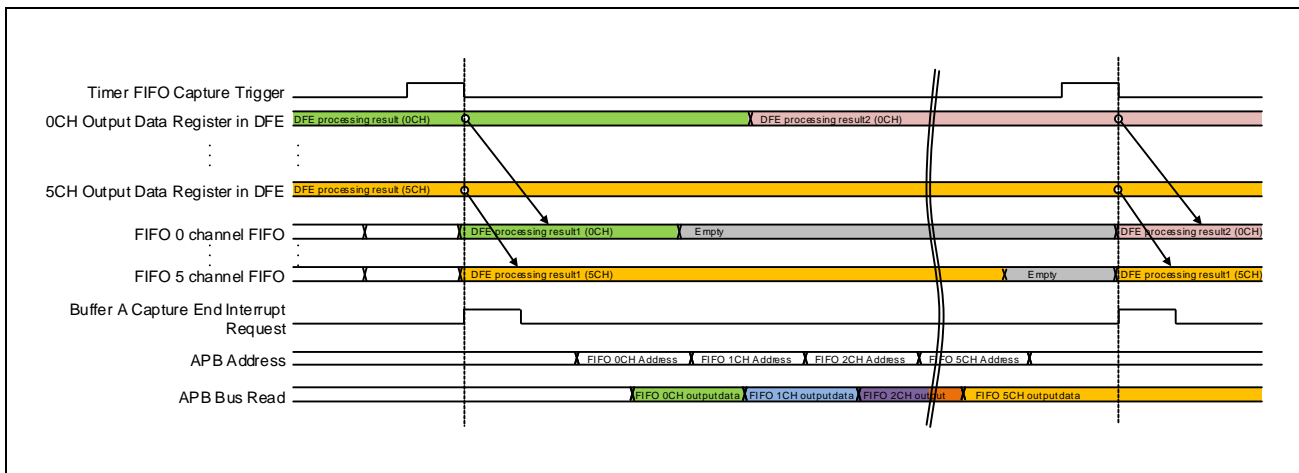

Figure 39.101 FIFO Macro Buffer A Capture End Interrupt Requests

(2) Buffer B Capture End Interrupt Request

The output of the buffer B capture end interrupt request can be controlled by setting the BIEO bit of the buffer B control register (DFBFBCTL) to 1.

When data is stored in the buffer B four times, the buffer B capture end interrupt request is issued. To issue a buffer B capture end interrupt request again, read all the four data items. Otherwise, no buffer B capture end request will be issued even if four data items are stored in the buffer B again.

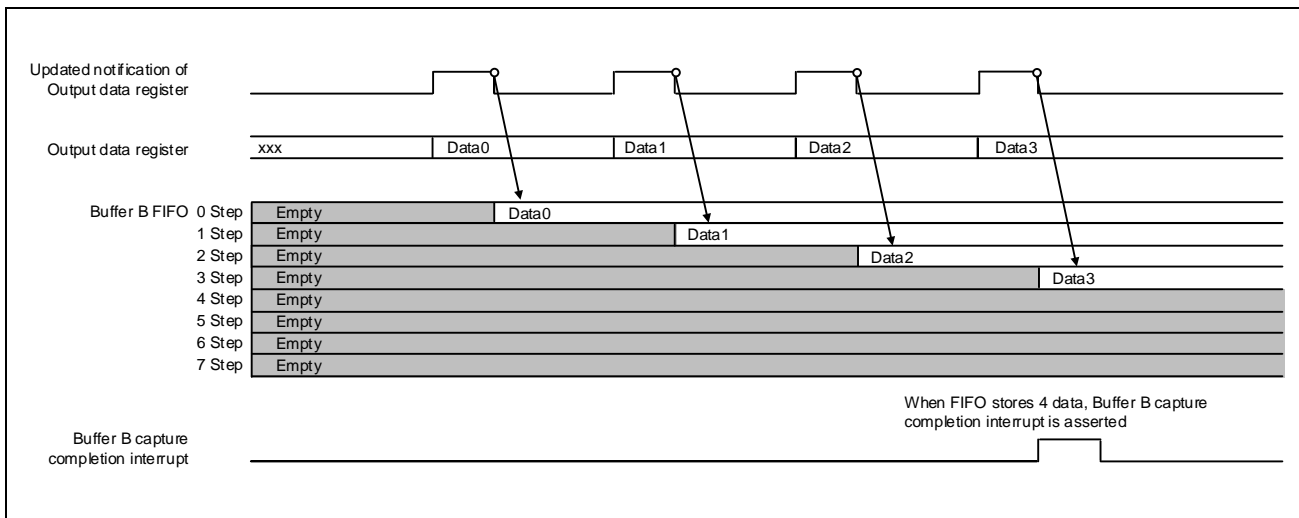

Figure 39.102 FIFO Macro Buffer B Capture End Interrupt Requests

(3) Error Interrupt Request

The error interrupt request of the FIFO macro indicates that an overflow was detected in the FIFO.

The error interrupt request is the OR of a buffer A FIFO channel overflow error and a buffer B overflow error.

Table 39.101 Summary of FIFO Macro Error Factors

Category	Error Status Bit	Remarks
Buffer A Circuit	DFBFACST.OVFAn (n = 0, 1, ..., 7)	FIFO Over Flow Error in Buffer A
Buffer B Circuit	DFBFBST.OVFB	FIFO Over Flow Error in Buffer B

The output of the FIFO macro error interrupt request can be controlled by setting the AIEE bit of the buffer A common control register (DFBFACCTL) to 1. The FIFO macro error interrupt request is issued if a FIFO overflow error occurs on a FIFO channel.

The output of the FIFO macro error interrupt request can be controlled by setting the BIEE bit of the buffer B control register (DFBFBCTL) to 1. The FIFO macro error interrupt request is issued if a FIFO overflow error occurs in the buffer B FIFO.

The FIFO macro error interrupt request is composed of the OR of error sources. Consequently, if an error interrupt request is issued once and then an error occurs due to another source, no new error interrupts will be issued.

39.6 Notes and Restrictions

39.6.1 Processing Time

39.6.1.1 Processing Time for One Channel

The digital filter executes a one-time FIR or IIR processing at a maximum of 0.7 μs . When there is no memory access competition. If memory access competition occurs, the processing time is a maximum of 1.2 μs .

39.6.1.2 Termination Processing Time

When the EN bit in DFEjCTLACHn is set to 0, the digital filter executes processing for all the input data that has been accepted and terminates processing. The maximum processing time up to the termination is obtained by “the number of channels for which input data has been accepted (number of channels for which processing has not been done) \times processing time”. For example, if five channels have not been processed, the termination processing time is a maximum of 3.5 μs .

39.6.2 DFE Activation Input Interval

An interval of DFE activation signal inputs should be a minimum of 0.7 μs if there is no memory access competition or a minimum of 1.2 μs if memory competition occurs.

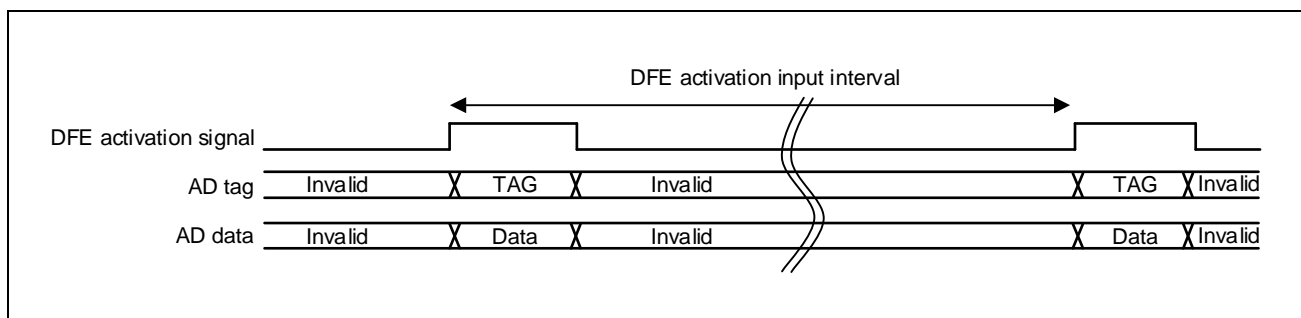

Figure 39.103 DFE Activation Input Interval (AD Input)

39.6.2.1 DFE Processing Time

The following two tables list the DFE processing time, i.e. the cycle from the input of a startup trigger from the AD until the next startup trigger on the same channel is accepted.

Table 39.102 Processing Time of FIR and IIR (with no initialization)

		Cycle
FIR (normal case)	8TAP	22 cycle
	16TAP	26 cycle
	24TAP	30 cycle
	32TAP	34 cycle
	64TAP	50 cycle
IIR (normal case)	Secondary biquad 1 stage	28 cycle
	Secondary biquad 2 stages	36 cycle
	Secondary biquad 3 stages	44 cycle
IIR (with gain adjustment function)	Secondary biquad 2 stages	42 cycle
	Secondary biquad 3 stages	56 cycle

Table 39.103 Processing Time of FIR and IIR (with Initialization)

		Time
FIR (with initialization)	8TAP	28 cycle
	16TAP	36 cycle
	24TAP	44 cycle
	32TAP	52 cycle
	64TAP	84 cycle
IIR (with initialization)	Secondary biquad 1 stage	38 cycle
	Secondary biquad 2 stages	54 cycle
	Secondary biquad 3 stages	70 cycle
IIR (with gain adjustment function)	Secondary biquad 2 stages	60 cycle
	Secondary biquad 3 stages	82 cycle

When the coefficient memory or data memory is accessed by the CPU during the DFE processing period, the access increases the total time for processing. Specifically, it takes more time per access.

39.6.3 Trigger Input

The following figure shows an example for an input of timer triggers 0 to 3 and a software trigger. When timer trigger 0 is used, for example, it is assumed that the DFE activation signal is input once or more times and timer trigger 0 is input again after the trigger flag function is enabled by the timer trigger 0 input.

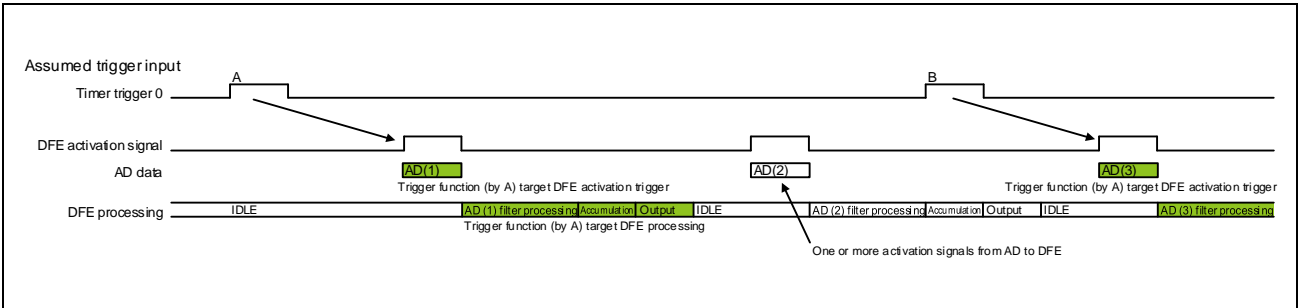

Figure 39.104 Example of Trigger Input

Input of a trigger from a timer or from software leads to setting of the corresponding trigger flag and the start of digital filter processing, but repeating input of the same trigger is prohibited.

In the example below, the trigger function by B is not enabled in some cases.

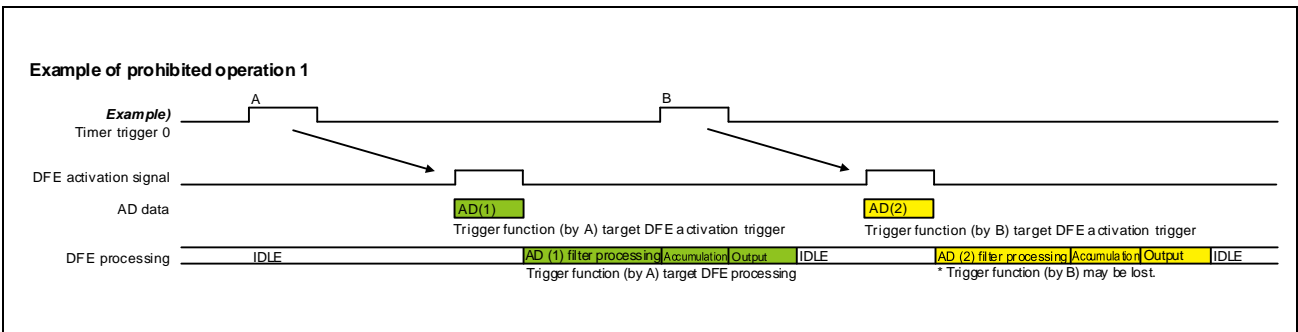

Figure 39.105 Operation When the Same Trigger is Prohibited 1

Before a timer trigger or a software trigger is input and the DFE activation signal is input, the same timer trigger or software trigger must not be input again. An example is shown below. In this case, two consecutive triggers are input at A and B, but are only effective as a single trigger from AD (2).

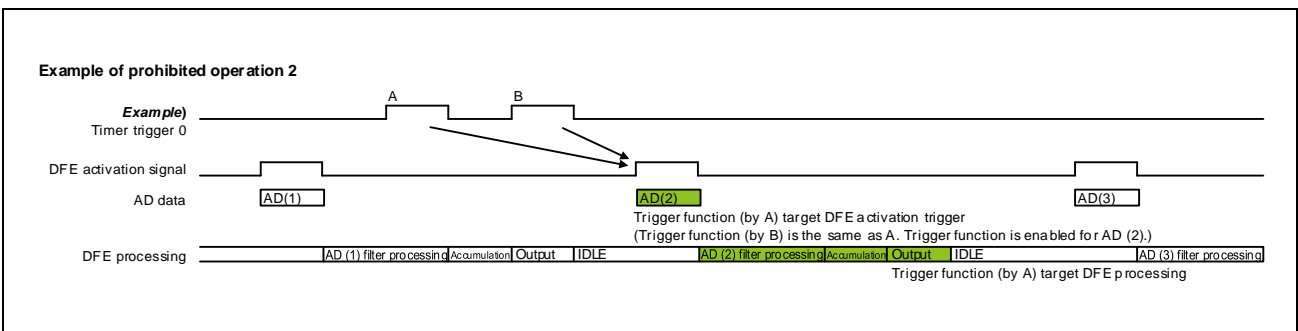

Figure 39.106 Operation When the Same Trigger is Prohibited 2

39.6.4 Channel Tag and AD Tag

If a tag value (AD tag) that the AD inputs to the digital filter and a tag value (channel tag) that the software sets for the digital filter are different, correct processing is disabled. For example, the AD inputs an AD tag value of 0001_B to the digital filter and there is no channel with a digital filter's channel tag value 00001_B, the DFE does not execute filter processing.

39.6.5 Input Data Format and Calculation Restrictions

Restrictions on available calculations are provided for the digital filter. For details, see **Section 39.5.6, Setting Control Registers**.

39.6.6 Restrictions on Cascade Processing

Cascade processing is a function to round 32-bit accumulation circuit output data or 32-bit subtraction circuit output data to 16-bit data to be input as data of other channels. The following restrictions are provided for cascade processing. Observe these restrictions together with the descriptions in **Section 39.5.6, Setting Control Registers**.

1. When cascade is enabled, do not set the same value for cascade tag and channel tag on the same channel. Assign a channel that is different from the channel for which cascade is specified as a cascade destination channel. If the same tag value is set, the filter processing result is input to the same channel again and calculation is repeated.
2. When cascade is enabled, the data format of cascade enabled channels must be the same as the data format of cascade destination channels. For example, when the fixed-point input format is specified for cascade enabled channels, the fixed-point input format is also specified for cascade destination channels.
3. Cascade input can be enabled for up to 15 channels on 16 channels. If cascade input is enabled for all channels, calculation is repeated for filter calculation results that are input in cascade.
4. The CAEN bits in the control register A (DFEjCTLACHn) must not be set to 01_B.
5. When peak-hold processing and comparison processing are enable, peak-hold processing and comparison processing are executed for 32-bit data.
6. No floating-point conversion result can be a cascade input.
7. When enabling the cascade function of two or more channels and selecting a single cascade destination channel, pay attention to the priority of channels. Specify cascade channels so that higher priority is given to cascade destination channels than cascade enabled channels. To enable the cascade function of channel 1 and channel 2 and select the same cascade destination for channel 1 and channel 2, for example, specify channel 0 as a cascade destination channel.
8. When enabling the cascade function of channel n and the cascade function of subtraction channel 0-2 selecting a single cascade destination channel, it is possible to be output the filter result and subtraction result at the same time. At this time, these are processed in the following priority. Low priority cascade input is not executed to cascade processing. And the cascade input is discarded.
 Cascade input of channel n > Cascade input of subtraction channel 0 > Cascade input of subtraction channel 1 > Cascade input of subtraction channel 2
9. When the subtraction circuit is enabled, the cascade rounding error is always judged with the subtraction results even if its cascade function is not used. Depending on the result of this judgement, the subtraction circuit cascade rounding error may be occurred. In this case, set the error mask bit (DFEjSUBERMCHn.MSKSCER) to 1.

39.6.7 Operation when the Given Channel is Disabled

39.6.7.1 Channel Enable Bits and Invalidation

While the channel enable bit (DFEjCTRLACHn.EN) is set to 0, filter processing is not activated even if the AD tag value that is input from the AD is equal to the channel tag value.

In addition, timer trigger input of the trigger flag function specified for the channel and software trigger input are not accepted.

When the channel enable bit (DFEjCTRLACHn.EN) is set to 0 from 1, the data to be processed that was input before this bit was set to 0 is processed.

At this time, if a trigger for the trigger flag function is input before the channel enable bit is set to 0, the trigger flag function is enabled for the data to be processed.

When the channel enable bit (DFEjCTRLACHn.EN) is 1, input trigger for the trigger flag function is held until AD data is input and the trigger flag function is enabled for the data to be processed (trigger held).

After the channel enable bit (DFEjCTRLACHn.EN) is set to 0 from 1, the held trigger is cleared if there is no data to be processed.

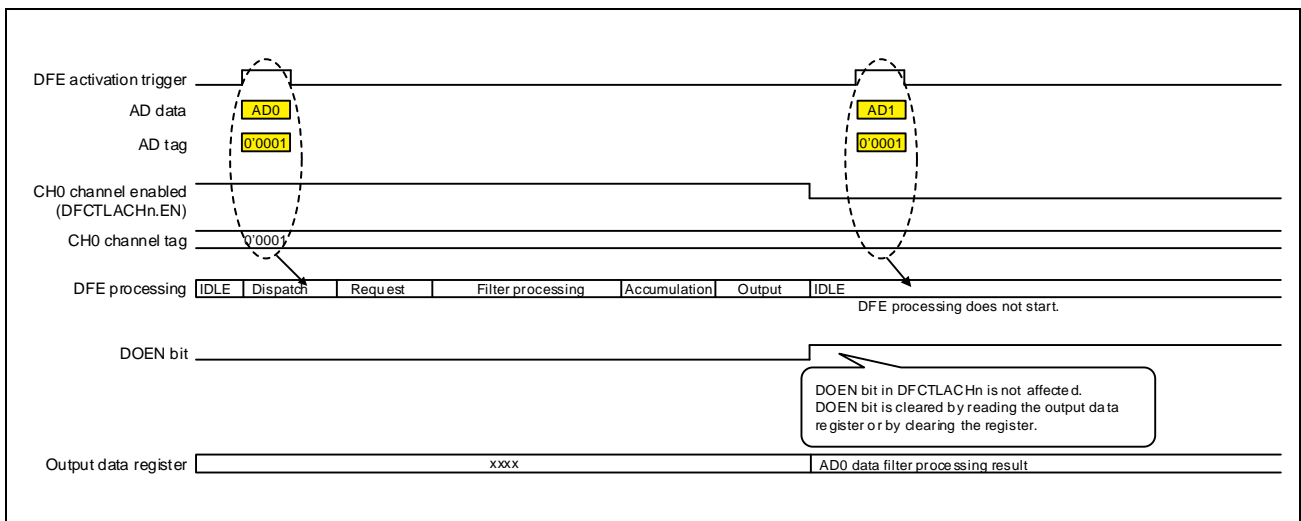

Figure 39.107 EN Bit and DOEN Bit

Even if the channel enable bit (EN in DFEjCTRLACHn) is cleared to 0, the status register is not cleared. Clear the status register with the software as necessary.

If the channel enable bit is set to 1 from 0 to restart the DFE processing:

- Accumulation/decimation counter starts at 0 in the same way as the first DFE processing after a reset.
- Comparison with the initial value register value is performed during the first peak-hold processing, and comparison with the peak-hold result register value is performed during the subsequent processing.

39.6.8 Restrictions on FIR 64TAP

If FIR64TAP is selected on an even-numbered channel (n) (DFEjCTRLACHn.CMD = 0111_B), no triggers or requests are accepted and are nullified on the next odd-numbered channel (n + 1).

39.6.9 Restrictions on Memory Access

8-bit or 16-bit write access to the coefficient memory is prohibited. Write data to the coefficient memory in 32 bits.

8 bit write access to data memory 0 and 1 is prohibited.

Upper/lower 16-bit write access to data memory 0 and 1 is enabled.

32-bit write access in batch to data memory 0 and 1 is enabled.

If a prohibited access is made, data may become corrupt. In the case of the coefficient memory, word data (32 bits) including a byte-write address may become corrupt. In the case of data memory 0 and data memory 1, half-word data (16 bits) including a byte-write address may become corrupt.

39.6.10 Restrictions on Trigger Setting Registers

A software trigger must not be specified for the accumulation/decimation initialization flag and the accumulation/decimation disable flag setting. Operations with prohibited settings are not guaranteed.

A software trigger must not be specified for the peak-hold initialization flag and the peak-hold end flag setting. Operations with prohibited settings are not guaranteed.

A software trigger must not be specified for the peak-hold mask start flag and the peak-hold mask end flag setting. Operation with prohibited setting is not guaranteed.

A software trigger must not be specified for the subtraction start flag and the subtraction end flag setting. Operation with prohibited setting is not guaranteed.

39.6.11 Setting of Peak-Hold Processing Disable Bit and Accumulation/Decimation Processing Disable Bit

When the EN bit in DFEjCTLACHn and VALID bit in DFEjSTCHn are both 0, the DISB bit (peak-hold processing disable bit) in DFEjCTLBCHn and DISA bit (accumulation/decimation processing disable bit) in DFEjCTLBCHn can be set by software.

When the PRCSB bit in DFEjCTLBCHn is set to 01_B (for peak-hold processing) or 11_B (for peak-hold processing and comparison processing simultaneously), peak-hold processing becomes invalid by writing 1 to the DISB bit in DFEjCTLBCHn. When the PRCSA bit is set to 01_B (for accumulation processing) or 10_B (for decimation processing), accumulation/decimation processing becomes invalid by writing 1 to the DISA bit in DFEjCTLBCHn.

39.6.12 Controlling Control Registers A and B

Set control registers A (DFEjCTLACHn) and B (DFEjCTLBCHn) in advance of trigger input. Setting control registers A and B is prohibited during digital filter operations while the value of the DFEjSTCHn.VALID or DFEjCTLACHn.EN1 bit is 1. If this is done, operations for digital filtering are not guaranteed.

Furthermore, as well as the above restrictions, writing to the intermediate value output register floating point conversion bit (DFEjCTLBCHn.HOFS) is prohibited while the value of the output data register enable bit (DFEjSTCHn.DOEN) is 1. Again, operations for digital filtering are not guaranteed if this is done.

39.6.13 Controlling the Peak-Hold Index Registers

A peak-hold index register retains its value even if the given channel is disabled (the DFEjCTRLACHn.EN bit is 0).

When Peak-hold circuit is set to peak-hold processing mode (DFEjCTLBCHn.PRCBSB = 2b01), read a peak-hold index register, when the value of the condition matching bit (DFEjSTCHn.CND) is set to 1 after the value of the input data valid bit (DFEjSTCHn.VALID) has been 0. When Peak-hold circuit is set to peak-hold and comparison simultaneously mode (DFEjCTLBCHn.PRCBSB = 2b11), read a peak-hold index register, when the value of the peak-hold end bit (DFEjSTCHn.PHE) has been 1 after the value of the input data valid bit (DFEjSTCHn.VALID) is set to 0.

39.6.14 Restrictions on the Intermediate Value Output Registers

Reading the intermediate value output registers (including the intermediate value output mirror register L) is prohibited for channels in use as IIR filters.

39.6.15 Restrictions on Subtraction Circuit

It is prohibited to set a minuend channel and a subtrahend channel to the same channel.

Use the same format for the filter results of the minuend and subtrahend channels.

It is prohibited to perform subtraction between the filter results with the different formats. In this case, data integrity is not guaranteed.

39.6.16 Restrictions on Buffer A Circuit

39.6.16.1 Restrictions on FIFO Channels In Use

Use it for ascending order from FIFO channel 0 consecutively by all means, when valid FIFO channels are less than the max FIFO channels which buffer A circuit has.

For example, set FIFO channel 0, 1, 2, and 3 to valid when 4 FIFO channels are used. It is prohibited to set the following settings.

- Setting FIFO channel 2, 3, 4, and 5 to valid (When not using FIFO channel 0)
- Setting FIFO channel 0, 2, 3, and 5 to valid (When not using FIFO channel in ascending order consecutively)

39.6.16.2 Notes about Read Registers

The output condition of buffer A capture interrupt request is the reading of the Buffer A output registers of all FIFO channels which are set to valid (DFBFACTLCHn.CHEN = 1).

Reading invalid FIFO channels is not included in the output condition for the interrupt request. The read value varies when according to the setting of DFBFACCTL.AUNE when reading invalid FIFO channels.

- The read value is as follows when output data of invalid FIFO channels is read.

When DFBFACCTL.AUNE is set to 0, read value is 32h00000000.

When DFBFACCTL.AUNE is set to 1, read value is 32h00000001.

- When valid FIFO channels are set to invalid, Set buffer A circuit is cleared once (Refer to **Section 39.4.2.1**). So the read value is as follows.

When DFBFACCTL.AUNE is set to 0, read value is 32h00000000.

When DFBFACCTL.AUNE is set to 1, read value is 32h00000001.

39.6.16.3 Notes about Buffer A Capture Interrupt Request

After an overflow error (DFBFACST.OVFAn (n = 0, 1, ..., 7)) has occurred on any of the FIFO channels, the buffer A capture interrupt request is not output even if the data of valid FIFO channels (DFBFACTLCHn.CHEN = 1) is read.

When an overflow error has occurred, clear buffer A circuit by using Buffer A clear bit (DFBFACLR.CLRA).

39.6.17 Restrictions on Buffer B Circuit

39.6.17.1 Notes Concerning the Buffer B Capture Interrupt Request

After an overflow error (DFBFBST.OVFB) has occurred, the buffer B capture interrupt request is not output even if FIFO data is read 4 times. When an overflow error has occurred, clear buffer B circuit by using Buffer B clear bit (DFBFBCLR.CLRB).

39.6.17.2 Restrictions on Buffer B Circuit when both Buffer A and Buffer B are in Use

When both Buffer A and Buffer B are used, it is prohibited to set same DFE and same DFE channel for Buffer A and Buffer B. For example, when 10CH of DFE0 is selected for FIFO channel 0 of Buffer A, it is prohibited to select 10CH of DFE0 for buffer B.

39.6.18 Note on Using Automatic Channel Initialization

Observe the following when using automatic channel initialization when restarting a channel:

- (1) Set the registers according to the channel start procedure described in **Section 39.4.2.1**.
- (2) If the channel is subject to capture by the buffer A circuit or buffer B circuit, set the registers according to the channel start procedure described in **Section 39.4.2.1**.

If either of the above are not observed, the following problems occur:

- Buffer A circuit:

If the DFBACLR.CLRA bit is not cleared after the buffer A circuit is stopped, the FIFO includes a mixture of the following data because a capture trigger is issued from the timer at the optionally set timing:

1. The filter results from before automatic channel initialization was enabled
2. Data that was cleared by automatic channel initialization
3. The filter results from after automatic channel initialization was enabled

This makes it impossible to judge the point from which data is valid.

- Buffer B circuit:

If the DFBACLR.CLRB bit is not cleared after the buffer B circuit is stopped, the FIFO includes a mixture of the following data because the data in the buffer B circuit is captured after the filter results of the target channel are output:

1. The filter results from before automatic channel initialization was enabled
2. The filter results from after automatic channel initialization was enabled

This makes it impossible to judge the point from which data is valid.

39.6.19 Restrictions on Using Peak-Hold Mask Function

When using the peak-hold mask function, be sure to disable the peak-hold mask function while peak-hold processing is enabled. Specifically, be sure to disable the peak-hold mask function by enabling the peak-hold mask end trigger flag before enabling the peak-hold end trigger flag.

39.6.20 Restrictions on Using Peak-Hold Function

When processing A and B below in the peak-hold circuit in parallel, allocate processing A to DFE_i and processing B to DFE_j. (where $i \neq j$)

When processing A and B in parallel in one DFE unit, use two DFE channels for processing A instead of one channel. Execute PH processing on one channel and comparison processing on the other channel.

- A) Both peak-hold processing and comparison processing simultaneously
- B) Peak-Hold-23 function

Section 40 Functional Safety

40.1 Overview

This section describes the intended safety mechanisms provided to detect the MCU failures with a short detection time. Here, the failures include both the recoverable transient failures such as soft errors of a memory and the unrecoverable permanent failures.

This MCU was developed to meet the requirements for a Safety Element out of Context (SEooC) as described in the ISO26262. In a SEooC development, safety requirements of target device (component) are assumed from market requirements by component manufacturers, and then the device is developed according to these assumed requirements. As this application is targeted for powertrain applications, some special considerations are already included to minimize gaps with powertrain requirements, however this should not restrict use with other applications. If Renesas assumptions are not enough to achieve system safety requirements derived from safety goals, the system safety requirements need to be modified. Contact our sale office for the details regarding the development process and safety organization.

The following lists the intended safety mechanisms provided by this product.

Note 1. The suitability of the safety mechanisms referenced in this chapter will finally be judged during the safety analysis and safety assessment of the MCU. Therefore, the safety documentation shall always be considered as additional requirements for the system or software derived from the results of the safety analysis.

ECC and EDC

Detect failures of memory and data transfer paths; correct failures.

Lockstep

Detects failures of the CPU and DTS with a short detection time.

Memory Protection

Detects erroneous access to the memory and peripheral circuits to protect the data in these elements against erroneous access.

BIST

Detects failures of the failure detection function itself.

MISG

Monitors write access to a specific address by the CPU, generates the signatures based on the written data, and automatically compares the generated signatures with each other.

Error Control Module (ECM)

Monitors various failure detection states in the MCU and defines the operation to be carried out when a failure occurs reaction.

Voltage Monitor

Monitors power supply voltage to detect over and under voltage.

Clock Monitor

Monitors the clock operation to detect abnormal operation.

Data CRC

Generates CRC to verify the data streams protected by CRC.

40.2 Reset Sources

Register reset conditions are shown in **Table 40.1**.

Table 40.1 Reset sources

Register Name	Reset Source					
	Power Up Reset	System Reset 1	System Reset 2	Application Reset	Module Reset	JTAG Reset
Functional Safety related registers* ¹ (ECC and EDC, Hardware Redundancy, Memory Protection, and MISG)	✓	✓	✓	✓	—	—

Note 1. Except for BIST registers. For details about BIST register reset conditions, see **Section 40.6.2.3, Reset of Registers**. For details about register reset conditions of Voltage Monitor, Clock Monitor, ECM, and Data CRC Function, see **Section 12, Power Supply Voltage Monitor**, **Section 14, Clock Monitor**, **Section 41, Error Control Module (ECM)**, and **Section 42, Data CRC Function B (DCRB)**.

40.3 ECC and EDC

40.3.1 Overview

40.3.1.1 ECC

This product incorporates ECC for the following memories. The ECC enables detection and correction of errors of the data retained in memory. The ECC also enables detection and correction of errors produced between the ECC encoder and memory; and memory and ECC decoder.

Table 40.2 ECC Overview

Applicable Memory	Applicable Data Width [bits]	Operation upon Error Detection				Failure Insertion
		Detection/Correction	Notice to ECM	Error Status	Address Capture	
Code flash	256	SEC-DED	Possible*2	Possible*2	Possible*2	Possible
Data flash	32	SEC-DED	Possible	Possible	Possible	Possible
Local RAM (all CPU cores)	32	SEC-DED	Possible	Possible	Possible	Possible
Cluster RAM	32	SEC-DED	Possible	Possible	Possible	Possible
Instruction cache (data)	64	SED-DED	Possible	Possible	Possible	Possible
Instruction cache (tag)	32	SED-DED	Possible	Possible	Possible	Possible
RAM for DTS	32	SEC-DED	Possible	Possible	Possible	Possible
RAM for sDMAC (Descriptor)	32	SEC-DED	Possible	Possible	Possible	Possible
RAM for sDMAC (Data Transfer)	64	SEC-DED	Possible	Possible	Possible	Possible
Peripheral RAM (32 bits)	32	SEC-DED	Possible	Possible*1	Possible*1	Possible*1
Peripheral RAM (16 bits)	16	SEC-DED	Possible	Possible	Possible	Possible
Data transfer path (data)	32/128	SEC-DED	Possible	Possible	N/A	Possible
Data transfer path (address)	32	SED-DED	Possible	Possible	N/A	Possible

Note 1. Except for Ethernet RAM.

Note 2. When an error except ECC 1-bit error correction occurs in instruction fetch at the time of cache miss or cache invalid, ECM error sources may not be notified and error status / error address registers may not be updated. For details, see **Section 3, CPU System**.

Detection/Correction

SEC-DED: 1-bit errors can be detected and corrected, and 2-bit errors can only be detected.

SED-DED: 1-bit errors and 2-bit errors can only be detected.

Notice to ECM

A detected error can be reported to the ECM.

Error Status

The status of a detected error is retained.

Address Capture

The address of a detected error is retained.

Failure Insertion

An ECC error can be intentionally generated to enable software test of the ECC decoder operation.

40.3.1.2 Address Parity

This product incorporates address parity for the following types of memory. The address parity enables detection of errors during address decoding. It also enables detection of errors produced at addresses between the parity encoder and memory.

Table 40.3 Address Parity Overview

Applicable Memory	Parity Bit	Notice to ECM	Error Status	Address Capture	Failure Insertion
Code flash	1 bit	Possible* ¹	Possible* ¹	Possible* ¹	Possible

Note 1. When an error occurs in instruction fetch at the time of cache miss or cache invalid, ECM error sources may not be notified and error status / error address registers may not be updated. For details, see **Section 3, CPU System**.

40.3.1.3 Address Feedback

This product incorporates an address feedback function for the following types of memory. The address feedback function enables detection of address errors inside memory module itself.

Table 40.4 Address Feedback Overview

Applicable Memory	Notice to ECM	Error Status	Address Capture	Failure Insertion
Local RAM (all CPU cores)	Possible	Possible	Possible	Possible
Cluster RAM	Possible	Possible	Possible	Possible
Instruction cache (data/tag)	Possible	Possible	Possible	Possible
RAM for DTS	Possible	Possible	Possible	Possible

40.3.2 Key Code Protection for ECC Control Registers

40.3.2.1 Overview

The product incorporates key code register to protect ECC control registers from unintended access.

40.3.2.2 List of Registers

Table 40.5 List of Registers

Module Name	Register Name	Symbol	Address	Access	Access Protection
ECCKC (Peripheral Group0)	ECC Control Key Code Protection Register	KCPROT	FFFB 2800 _H	32	

40.3.2.3 KCPROT — ECC Control Key Code Protection Register

This register is used for protection against writing to the ECC control registers due to program malfunction and the like.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	KCPROT[31:16]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	KCPROT[15:1]															KCE
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W	R/W

Table 40.6 KCPROT Register Contents

Bit Position	Bit Name	Function
31 to 1	KCPROT[31:1]	Enable or disable modification of the KCE bit. The written value is not retained. These bits are always read as 0.*1
0	KCE	Key Code Enable bit*2 0: Disable write access to protected registers 1: Enable write access to protected registers

Note 1. Write A5A5A500_H to this register to disable writing protected registers.
Write A5A5A501_H to this register to enable writing protected registers.

Note 2. Unlocking this protection is one of necessary conditions to enable writing the protected registers. It is also necessary to unlock security protection driven by the ICUM when ICUM function is active. For details, see RH850/E2x-FCC2 ICUMD User's Manual: Hardware Section 9.

40.3.3 Code Flash ECC and Address Parity

40.3.3.1 Overview

The code flash ECC is summarized in the table below.

Table 40.7 Code Flash ECC

Item	Description
ECC error detection and correction	<p>ECC error detection and correction can be either enabled or disabled. When enabled, either of the following settings can be selected.</p> <ul style="list-style-type: none"> ECC error detection and correction are carried out (2-bit error detection, and 1-bit error detection and correction are carried out). ECC error detection is carried out (2-bit error detection and 1-bit error detection are carried out). <p>When disabled, neither error detection nor correction is carried out.</p> <p>In the initial state, this function is enabled; 1-bit error detection and correction and 2-bit error detection are carried out.</p>
Address parity	<p>Address parity check can be either enabled or disabled. When enabled, Address parity is checked during address decoding. When disabled, no address parity check is carried out. In the initial state, this function is enabled.</p>
Error notification	<p>The occurrence of an ECC error or a parity error is reported to the Error Control Module.</p> <p>ECC Error:</p> <ul style="list-style-type: none"> Error notification can be either enabled or disabled upon detection of an ECC 2-bit error. Error notification can be either enabled or disabled upon detection of an ECC 1-bit error. <p>In the initial state, error notification is enabled upon detection of an ECC 2-bit error, and error notification is enabled upon detection of an ECC 1-bit error.</p> <p>Address Parity Error:</p> <ul style="list-style-type: none"> Error notification can be either enabled or disabled upon detection of an address parity error. <p>In the initial state, error notification is enabled upon detection of an address parity error.</p> <p>Overflow Error:</p> <ul style="list-style-type: none"> Error notification can be either enabled or disabled upon detection of an address buffer overflow error for ECC 1-bit error. <p>In the initial state, error notification is enabled upon detection of an address buffer overflow error.</p> <p>An ECC 2-bit error, an ECC 1-bit error, an address parity error, and an overflow error are handled as individual sources in ECM.</p> <p>An ECC 1-bit error signal is only issued to the ECM if the ECC 1-bit error address is not yet stored in the error address buffer.</p>
Error status	<p>A status register is provided that indicates the statuses of ECC 2-bit error detection, ECC 1-bit error detection, and address parity error detection. If an error occurs while no error status is set, the corresponding status is set.</p> <p>The error status can be cleared using the clear register.</p>
Address capture	<p>The address is captured when an ECC 2-bit error, an ECC 1-bit error, or an address parity error is detected. The error status serves as the enable bit of the capture address. Address buffers are updated if the error status is cleared.</p> <p>Multi-stage address buffers are provided for an ECC 1-bit error. ECC 1-bit error: Four stages ECC 2-bit error, address parity error shared: One stage</p>
Self-diagnosis	<p>The ROM data and the ECC and address parity bits in Code Flash can be read directly. Self-diagnosis of ECC and address parity is possible by reading data from ECC test area.</p>

40.3.3.2 Register Base Address

Base addresses of safety modules are listed in the following table. Each register address is given as an offset from the base addresses.

Table 40.8 Register Base Addresses

Base Address Name	Base Address	Bus Group
<ECCCNT_CFP_PE0CL0_base>	FFC4 8000 _H	Peripheral Group 0
<ECCCNT_CFP_PE1CL0_base>	FFC4 8080 _H	Peripheral Group 0
<ECCCNT_CFP_PE2CL1_base>	FFC4 8100 _H	Peripheral Group 0
<ECCCNT_CFP_PE3CL1_base>	FFC4 8180 _H	Peripheral Group 0
<ECCCNT_CFP_PE4CL2_base> ^{*1}	FFC4 8200 _H	Peripheral Group 0
<ECCCNT_CFP_PE5CL2_base> ^{*1}	FFC4 8280 _H	Peripheral Group 0
<ECCCNT_CFCCL0_base>	FFC4 8800 _H	Peripheral Group 0
<ECCCNT_CFCCL1_base>	FFC4 8880 _H	Peripheral Group 0
<ECCCNT_CFCCL2_base> ^{*1}	FFC4 8900 _H	Peripheral Group 0
<ECCCNT_CFS_base>	FFC4 8A00 _H	Peripheral Group 0
<MECCCAP_CFL_base>	FFC5 2400 _H	Peripheral Group 0

Note 1. This function is not implemented in E2H.

40.3.3.3 List of Registers

Table 40.9 List of Registers

Module Name	Register Name	Symbol	Address	Access	Access Protection
ECCCNT_CFP_PEn CL0 (n = 0, 1)	ECC Control Register	CFPECCCTL	<ECCCNT_CFP_PEnCL0_base> + 00H	8, 16, 32	KCPROT
ECCCNT_CFP_PEn CL1 (n = 2, 3)	ECC Control Register	CFPECCCTL	<ECCCNT_CFP_PEnCL1_base> + 00H	8, 16, 32	KCPROT
ECCCNT_CFP_PEn CL2 (n = 4, 5)*1	ECC Control Register	CFPECCCTL	<ECCCNT_CFP_PEnCL2_base> + 00H	8, 16, 32	KCPROT
ECCCNT_CFCCL0	ECC Control Register	CFCECCCTL	<ECCCNT_CFCCL0_base> + 00H	8, 16, 32	KCPROT
ECCCNT_CFCCL1	ECC Control Register	CFCECCCTL	<ECCCNT_CFCCL1_base> + 00H	8, 16, 32	KCPROT
ECCCNT_CFCCL2 *1	ECC Control Register	CFCECCCTL	<ECCCNT_CFCCL2_base> + 00H	8, 16, 32	KCPROT
ECCCNT_CFS	ECC Control Register	CFSECCCTL	<ECCCNT_CFS_base> + 00H	8, 16, 32	KCPROT
MECCCAP_CFL	Error Notification Control Register	CF_ERRINT	<MECCCAP_CFL_base> + 00H	8, 16, 32	KCPROT
	1-bit Error Status Clear Register	CF_SSTCLR	<MECCCAP_CFL_base> + 10H	8, 16, 32	
	Fatal Error Status Clear Register	CF_DSTCLR	<MECCCAP_CFL_base> + 14H	8, 16, 32	
	1-bit Error Overflow Status Clear Register	CF_OVFCLR	<MECCCAP_CFL_base> + 18H	8, 16, 32	
	1-bit Error Status Register	CF_SERSTR	<MECCCAP_CFL_base> + 20H	8, 16, 32	
	Fatal Error Status Register	CF_DERSTR	<MECCCAP_CFL_base> + 24H	8, 16, 32	
	1-bit Error Overflow Status Register	CF_OVFSTR	<MECCCAP_CFL_base> + 28H	8, 16, 32	
	1-bit Error Location Information Register	CF_SERINF	<MECCCAP_CFL_base> + 30H	32	
	1st 1-bit Error Address Register	CF_00SEADR	<MECCCAP_CFL_base> + 70H	32	
	2nd 1-bit Error Address Register	CF_01SEADR	<MECCCAP_CFL_base> + 74H	32	
	3rd 1-bit Error Address Register	CF_02SEADR	<MECCCAP_CFL_base> + 78H	32	
	4th 1-bit Error Address Register	CF_03SEADR	<MECCCAP_CFL_base> + 7CH	32	
	1st Fatal Error Address Register	CF_00DEADR	<MECCCAP_CFL_base> + F0H	32	

Note 1. This function is not implemented in E2H.

40.3.3.4 CFPECCCTL — ECC Control Register

This register controls ECC error detection/correction and 1-bit error correction for read data from Code Flash to PE.

This register is protected by the KCPROT register. When KCPROT.KCE = 0, it cannot be written. It can be written only when KCPROT.KCE = 1.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit Position	Bit Name	Function
31 to 2	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
1	SECDIS	ECC 1-bit error correction disable bit When using ECC error detection/correction (ECCDIS = 0), this bit sets 1-bit error correction to enable/disable. 0: Correction is enabled when 1-bit error is detected 1: Correction is disabled when 1-bit error is detected
0	ECCDIS	ECC disable bit Sets ECC error detection/correction to enable/disable. 0: ECC error detection/correction is enabled 1: ECC error detection/correction is disabled.

40.3.3.5 CFCECCCTL — ECC Control Register

This register controls address parity error detection, ECC error detection/correction and 1-bit error correction for read data from Code Flash.

This register is protected by the KCPROT register. When KCPROT.KCE = 0, it cannot be written. It can be written only when KCPROT.KCE = 1.

Value after reset: 0000 0000_H

Bit Position	Bit Name	Function
31 to 3	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
2	APEDIS	Address parity error disable bit Enables/disables address parity error detection. 0: Address parity error detection is enabled 1: Address parity error detection is disabled
1	SECDIS	ECC 1-bit error correction enable bit Enables/disables 1-bit error correction when using ECC error detection/correction (ECCDIS = 0). 0: Corrects when 1-bit error is detected 1: Does not correct when 1-bit error is detected
0	ECCDIS	ECC disable bit Enables/disables ECC error detection/correction. 0: ECC error detection/correction is enabled 1: ECC error detection/correction is disabled

40.3.3.6 CFSECCCTL — ECC Control Register

This register controls ECC error detection/correction and 1-bit error correction for read data to SAXI2FAXI bridge.

This register is protected by the KCPROT register. When KCPROT.KCE = 0, it cannot be written. It can be written only when KCPROT.KCE = 1.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 40.12 CFSECCCTL Register Contents

Bit Position	Bit Name	Function
31 to 2	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
1	SECDIS	ECC 1-bit error correction enable bit Enables/disables 1-bit error correction when using ECC error detection/correction (ECCDIS = 0). 0: Correct when 1-bit error is detected 1: Do not correct when 1-bit error is detected
0	ECCDIS	ECC disable bit Enables/disables ECC error detection/correction. 0: ECC error detection/correction is enabled 1: ECC error detection/correction is disabled

40.3.3.7 CF_ERRINT — Error Notification Control Register

This register controls whether error information is reported to the ECM when an address parity error, ECC error and/or overflow error has occurred.

This register is protected by the KCPROT register. When KCPROT.KCE = 0, it cannot be written. It can be written only when KCPROT.KCE = 1.

Value after reset: 0000 0087_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 40.16 CF_OVFCLR Register Contents

Bit Position	Bit Name	Function
31 to 2	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
1	SERROVFCLR1	Writing 1 to this bit clears SERROVF1 in CF_OVFSTR.
0	SERROVFCLR0	Writing 1 to this bit clears SERROVF0 in CF_OVFSTR.

40.3.3.11 CF_SERSTR — 1-bit Error Status Register

This register indicates whether an ECC 1-bit error has occurred. The location and address of the error that is detected is stored in CF_nSEADR register when SEDFn flag is set. The SEDFn flag is set only when a unique ECC 1-bit error, which is different from previous errors stored in 1-bit error address registers, is detected while the SEDFn is “0”. If the newly detected error has the same address with errors already stored, this flag is not set.

This register can be cleared by SSTCLRn in CF_SSTCLR register.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 40.17 CF_SERSTR Register Contents

Bit Position	Bit Name	Function
31 to 4	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
3	SEDF03	Indicates that an ECC 1-bit error was detected and error address is stored in CF_03SEADR register.
2	SEDF02	Indicates that an ECC 1-bit error was detected and error address is stored in CF_02SEADR register.
1	SEDF01	Indicates that an ECC 1-bit error was detected and error address is stored in CF_01SEADR register.
0	SEDF00	Indicates that an ECC 1-bit error was detected and error address is stored in CF_00SEADR register.

40.3.3.12 CF_DERSTR — Fatal Error Status Register

This register indicates whether an address parity error and/or an ECC 2-bit error has occurred. The location and address of the error that is detected are stored in CF_00DEADR register when APEF00 and/or DEDF00 flags are set. The APEF00 and/or DEDF00 flag is set only when an address parity error and/or an ECC 2-bit error is detected while all the flags are “0”. Multiple flags are set only when multiple errors occur due to one error cause.

This register can be cleared by DSTCLR00 in CF_DSTCLR register.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 40.18 CF_DERSTR Register Contents

Bit Position	Bit Name	Function
31 to 3	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
2	APEF00	Indicates that an address parity error was detected.
1	DED00	Indicates that an ECC 2-bit error was detected.
0	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.

40.3.3.13 CF_OVFSTR — 1-bit Error Overflow Status Register

This register indicates whether an overflow of the address buffer or working memory has occurred.

SERROVF0 flag is set when a unique ECC 1-bit error that differs from previous errors in error address is detected when the address buffer is fully used. If the newly detected error has the same address with errors already stored, this flag is not set.

On the other hand, SERROVF1 flag is set when the number of times an ECC 1-bit error occurs at the same time regardless of the same occurrence address exceed the size of internal buffer.

SERROVF0 and SERROVF1 flags can be cleared by SERROVFCLR0 and SERROVFCLR1 in CF_OVFCLR register respectively.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Table 40.19 CF_OVFSTR Register Contents

Bit Position	Bit Name	Function
31 to 2	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
1	SERROVF1	Indicates that ECC 1-bit error s over working memory were detected simultaneously.
0	SERROVF0	Indicates that a unique ECC 1-bit error was detected when all ECC 1bit error flags in CF_SERSTR are set.

40.3.3.14 CF_SERINF — 1-bit Error Location Information Register

This register is used to indicate summary of locations where ECC 1-bit errors stored in CF_SERSTR register were detected.

This register is updated whenever CF_SERSTR register is updated.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	SEDLIN F16

R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 40.20 CF_SERINF Register Contents

Bit Position	Bit Name	Function
31 to 17	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
16	SEDLINF16	Indicates that an ECC 1-bit error was detected in read data from Code Flash to SAXI2FAXI.
15 to 12	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
11	SEDLINF11	Indicates that an ECC 1-bit error was detected in read data loaded from Code Flash to PE5*1.
10	SEDLINF10	Indicates that an ECC 1-bit error was detected in read data fetched from Code Flash to PE5*1.
9	SEDLINF09	Indicates that an ECC 1-bit error was detected in read data loaded from Code Flash to PE4*1.
8	SEDLINF08	Indicates that an ECC 1-bit error was detected in read data fetched from Code Flash to PE4*1.
7	SEDLINF07	Indicates that an ECC 1-bit error was detected in read data loaded from Code Flash to PE3.
6	SEDLINF06	Indicates that an ECC 1-bit error was detected in read data fetched from Code Flash to PE3.
5	SEDLINF05	Indicates that an ECC 1-bit error was detected in read data loaded from Code Flash to PE2.
4	SEDLINF04	Indicates that an ECC 1-bit error was detected in read data fetched from Code Flash to PE2.
3	SEDLINF03	Indicates that an ECC 1-bit error was detected in read data loaded from Code Flash to PE1.
2	SEDLINF02	Indicates that an ECC 1-bit error was detected in read data fetched from Code Flash to PE1.
1	SEDLINF01	Indicates that an ECC 1-bit error was detected in read data loaded from Code Flash to PE0.
0	SEDLINF00	Indicates that an ECC 1-bit error was detected in read data fetched from Code Flash to PE0.

Note 1. This function is not implemented in E2H.

40.3.3.15 CF_nSEADR — n-th 1-bit Error Address Register (n = 00 to 03)

This register is used to hold the address and the location of the error when the SEDFn flag is not set and an ECC 1-bit error is detected.

This register can only be cleared by reset.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	SEDL[4:0]					—	SEADR0[25:16]									
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	SEADR0[15:2]														—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 40.21 CF_nSEADR Register Contents

Bit Position	Bit Name	Function
31 to 27	SEDL[4:0]	Indicates where this error was detected.
26	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
25 to 2	SEADR0[25:2]	Indicates at which address this error was detected.
1, 0	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.

NOTE

SEADR0 indicates the address right-shifted by 2 bits rather than the actual address, so it is necessary for users to multiply it by 4 to get address at which the error was detected.

Please refer to the following table to confirm the detailed information which each SEDL indicates.

Table 40.22 SEDL information

SEDL[4:0]	Indicated information
31 to 17	Reserved
16	Indicates an ECC 1-bit error is detected in loading data from Code Flash by any master except PEs.
15 to 12	Reserved
11	Indicates an ECC 1-bit error is detected in loading data from Code Flash by PE5*1 master.
10	Indicates an ECC 1-bit error is detected in fetching instructions from Code Flash by PE5*1 master.
9	Indicates an ECC 1-bit error is detected in loading data from Code Flash by PE4*1 master.
8	Indicates an ECC 1-bit error is detected in fetching instructions from Code Flash by PE4*1 master.
7	Indicates an ECC 1-bit error is detected in loading data from Code Flash by PE3 master.
6	Indicates an ECC 1-bit error is detected in fetching instructions from Code Flash by PE3 master.
5	Indicates an ECC 1-bit error is detected in loading data from Code Flash by PE2 master.
4	Indicates an ECC 1-bit error is detected in fetching instructions from Code Flash by PE2 master.
3	Indicates an ECC 1-bit error is detected in loading data from Code Flash by PE1 master.
2	Indicates an ECC 1-bit error is detected in fetching instructions from Code Flash by PE1 master.
1	Indicates an ECC 1-bit error is detected in loading data from Code Flash by PE0 master.
0	Indicates an ECC 1-bit error is detected in fetching instructions from Code Flash by PE0 master.

Note 1. This function is not implemented in E2H.

40.3.3.16 CF_00DEADR — 1st Fatal Error Address Register

This register is used to hold the address and the location of the error when neither APEF00 nor DEDF00 flag is set and an address parity error and/or ECC 2-bit error was detected.

This register can only be cleared by reset.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 40.23 CF_00DEADR Register Contents

Bit Position	Bit Name	Function
31 to 27	DEDL[4:0]	Indicates where this error was detected.
26	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
25 to 2	DEADR0[25:2]	Indicates at which address this error was detected.
1, 0	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.

NOTE

DEADR0 indicates the address right-shifted by 2 bits rather than the actual address, so it is necessary for users to multiply it by 4 to get address at which the error was detected.

Please refer to the following table to confirm the detailed information which each DEDL indicates.

Table 40.24 DEDL Information

DEDL[4:0]	Indicated information
31 to 17	Reserved
16	Indicates a fatal error is detected in loading data from Code Flash by any master except PEs.
15 to 12	Reserved
11	Indicates a fatal error is detected in loading data from Code Flash by PE5*1 master.
10	Indicates a fatal error is detected in fetching instructions from Code Flash by PE5*1 master.
9	Indicates a fatal error is detected in loading data from Code Flash by PE4*1 master.
8	Indicates a fatal error is detected in fetching instructions from Code Flash by PE4*1 master.
7	Indicates a fatal error is detected in loading data from Code Flash by PE3 master.
6	Indicates a fatal error is detected in fetching instructions from Code Flash by PE3 master.
5	Indicates a fatal error is detected in loading data from Code Flash by PE2 master.
4	Indicates a fatal error is detected in fetching instructions from Code Flash by PE2 master.
3	Indicates a fatal error is detected in loading data from Code Flash by PE1 master.
2	Indicates a fatal error is detected in fetching instructions from Code Flash by PE1 master.
1	Indicates a fatal error is detected in loading data from Code Flash by PE0 master.
0	Indicates a fatal error is detected in fetching instructions from Code Flash by PE0 master.

Note 1. This function is not implemented in E2H.

40.3.3.17 Test Function

(1) Reading Code Flash

- (a) Set the ECCDIS bit in the CFPECCCTL register to 1 to disable ECC error detection and correction.
- (b) When ECCDIS=1, neither error detection nor correction proceeds when the code flash is read; the data output from the code flash is read unchanged.

How to exit this test mode:

- (a) Set the ECCDIS bit in the CFPECCCTL register to 0 to enable ECC error detection and correction.

(2) Reading the ECC and address parity bits

- (a) When the Blank check area of Code Flash is read, the ECC and address parity bits of the corresponding address are read. The bit assignment is as follows:

Table 40.25 Bit assignment of read data when the Blank check area of Code Flash is read

Bit Position	Function
255 to 16	Always 0
15	Blank Flag
14 to 11	Always 0
10	Address parity bit
9 to 0	ECC bits

(3) Self-diagnosis of ECC and address parity check function

Self-diagnosis of the ECC decoder and address parity checker for the access ports is possible by reading data from ECC test area.

For details about the ECC test area, refer to *RH850/E2x Safety Application Note*.

40.3.4 Data Flash ECC

40.3.4.1 Overview

The data flash ECC is summarized in the table below.

Table 40.26 Data Flash ECC

Item	Description
ECC error detection and correction	<p>ECC error detection and correction can be either enabled or disabled.</p> <p>When enabled, either of the following settings can be selected.</p> <ul style="list-style-type: none"> • ECC error detection and correction are carried out (2-bit error detection, and 1-bit error detection and correction are carried out). • ECC error detection is carried out (2-bit error detection and 1-bit error detection are carried out). <p>When disabled, neither error detection nor correction is carried out.</p> <p>In the initial state, this function is enabled; 1-bit error detection and correction, and 2-bit error detection are carried out.</p>
Error notification	<p>Upon occurrence of an ECC error, it is notified to the Error Control Module.</p> <p>ECC Error:</p> <ul style="list-style-type: none"> • Error notification can be either enabled or disabled upon detection of a 2-bit ECC error. • Error notification can be either enabled or disabled upon detection of a 1-bit ECC error. <p>In the initial state, error notification is enabled upon detection of an ECC 2-bit error, and error notification is enabled upon detection of an ECC 1-bit error.</p> <p>An ECC 2-bit error, an ECC 1-bit error and an overflow error are handled as individual sources in ECM.</p>
Error status	<p>A status register is provided that indicates the statuses of ECC 2-bit error detection and ECC 1-bit error detection. If an error occurs while no error status is set, the corresponding status is set.</p> <p>The error status can be cleared using the clear register.</p>
Address capture	<p>The address is captured when an ECC 2-bit error or an ECC 1-bit error is detected. The error status serves as the enable bit of the capture address.</p> <p>If an ECC error occurs while no error status is set, the address at which the associated error has occurred is captured.</p>
Self-diagnosis	<p>The ROM data and the ECC bits in Data Flash can be read directly.</p> <p>Desired values can be written to the data and the ECC bits in Data Flash.</p>

40.3.4.2 List of Registers

Table 40.27 List of Registers

Module Name	Register Name	Symbol	Address	Access	Access Protection
ECCDF (Peripheral Group1)	Data Flash ECC Control Register	DFECCCTL	FFC6 2C00 _H	16, 32	DFKCPROT
	Data Flash Error Status Register	DFERSTR	FFC6 2C04 _H	32	
	Data Flash Error Status Clear Register	DFERSTC	FFC6 2C08 _H	8, 16, 32

Table 40.28 DFECCTL Register Contents

Bit Position	Bit Name	Function
31 to 2	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
1	SECDIS	ECC 1-bit error correction disable bit When using ECC error detection/correction (ECCDIS = 0), this bit sets 1-bit error correction to enable/disable. 0: Correction is enabled when 1-bit error is detected. 1: Correction is disabled when 1-bit error is detected.
0	ECCDIS	ECC disable bit Sets ECC error detection/correction to enable/disable. 0: ECC error detection/correction is enabled. 1: ECC error detection/correction is disabled.

40.3.4.4 DFERSTR — Data Flash Error Status Register

DFERSTR monitors occurrence of errors.

The SEDF bit is set if an ECC 1-bit error is detected while ECC error detection/correction is enabled (ECCDIS = 0), and the DEDF bit is set if an ECC 2-bit error is detected.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 40.29 DFERSTR Register Contents

Bit Position	Bit Name	Function
31 to 2	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
1	DEDF	ECC 2-Bit Error Monitor Flag 0: An ECC 2-bit error is not generated. 1: An ECC 2-bit error is generated. Clearing condition: ERRCLR bit is set in Data Flash error status clear register. Setting condition: ECC 2-bit error is generated.
0	SEDF	ECC 1-bit error Monitor Flag 0: An ECC 1-bit error is not generated. 1: An ECC 1-bit error is generated. Clearing condition: ERRCLR bit is set in Data Flash error status clear register. Setting condition: ECC 1-bit error is generated with both SEDF and DEDF being 0.

40.3.4.5 DFERSTC — Data Flash Error Status Clear Register

DFERSTC clears the error flags in the Data Flash error status register. DFERSTC is a write-only register and is always read as 0.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	W

Table 40.32 DFOVFSTC Register Contents

Bit Position	Bit Name	Function
31 to 1	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
0	ERROVFCLR	Error Overflow Flag Clear 0: No effect (Setting the ERROVFCLR bit to 0 does not affect the flag in DFOVFSTR.) 1: The ERROVF flag in the DFOVFSTR register is cleared.

40.3.4.8 DFERRINT — Data Flash Error Notification Control Register

DFERRINT enables or disables generation of the error notification signal upon detection of an ECC 2-bit error or an ECC 1-bit error.

DFERRINT register is protected by DFKCPROT register.

Value after reset: 0000 0007_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1	1
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W

Table 40.33 DFERRINT Register Contents

Bit Position	Bit Name	Function
31 to 3	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
2	EOVFIE	ECC Error Address Overflow Notification Control Enables or disables generation of the error notification signal upon detection of an address buffer overflow error. 0: Error address overflow report disabled 1: Error address overflow report enabled
1	DEDIE	ECC 2-bit error Notification Control Enables or disables generation of the error notification signal upon detection of a 2-bit error when ECC error detection/correction is enabled (ECCDIS = 0). 0: Disables notification of the ECC 2-bit error. 1: Enables notification of the ECC 2-bit error.
0	SEDIE	ECC 1-bit error Notification Control Enables or disables generation of the error notification signal upon detection of a 1-bit error when ECC error detection/correction is enabled (ECCDIS = 0). 0: Disables notification of the ECC 1-bit error. 1: Enables notification of the ECC 1-bit error.

40.3.4.9 DFEADR — Data Flash 1st Error Address Register

DFEADR holds the address if the following occur:

- An ECC 1-bit error occurs when DFERSTR.SEDF = 0 and DFERSTR.DEDF = 0
- An ECC 2-bit error occurs when DFERSTR.DEDF = 0

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	DFEADR[20:16]

R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 40.34 DFEADR Register Contents

Bit Position	Bit Name	Function
31 to 21	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
20 to 2	DFEADR[20:2]	ECC Error Address DFEADR is a read-only field to monitor the address at which an ECC error has occurred. This register holds an internal address. Convert it to the actual address by adding the data flash base address described in Section 4 Address MAP.
1, 0	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.

40.3.4.10 DFTSTCTL — Data Flash Test Control Register

DFTSTCTL is used for ECC testing.

The data of the ECC bit can be read after setting the ECC test mode (ECCTST = 1).

DFTSTCTL register is protected by DFKCPROT register.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	ECC TST
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Table 40.35 DFTSTCTL Register Contents

Bit Position	Bit Name	Function
31 to 1	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
0	ECCTST	ECC Test By setting ECC test mode bit to "1" (ECCTST = 1), CPU can read ECC bit.

40.3.4.11 DFKCPROT — Data Flash ECC Key Code Protection Register

DFKCPROT is used for access protection of other Data Flash ECC registers.

Protected registers:

DFECCCTL

DFERRINT

DFTSTCTL

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	KCPCROT[31:16]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	KCPCROT[15:1]															KCE
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W	R/W

Table 40.36 DFKCPROT Register Contents

Bit Position	Bit Name	Function
31 to 1	KCPCROT[31:1]	Enable or disable modification of the KCE bit. The written value is not retained. These bits are always read as 0.* ¹
0	KCE	Key Code Enable bit* ² 0: Disable write access to protected registers 1: Enable write access to protected registers

Note 1. Write A5A5A500_H to this register to disable writing protected registers.

Write A5A5A501_H to this register to enable writing protected registers.

Note 2. Unlocking this protection is one of necessary conditions to enable writing the protected registers. It is also necessary to unlock security protection driven by the ICUM when ICUM function is active. For details, see RH850/E2x-FCC2 ICUMD User's Manual: Hardware Section 9.

40.3.4.12 Test Function

Data in the ROM and the ECC bits can be read by setting the data flash test control register (DFTSTCTL).

(1) Reading the ROM data

- (a) Set the ECCDIS bit in the data flash ECC control register to 1 to disable ECC error detection and correction.
- (b) When ECCDIS = 1, neither error detection nor correction proceeds when the data flash is read; the data output from the data flash is read unchanged.

How to exit this test mode:

- (a) Set the ECCDIS bit in the data flash ECC control register to 0 to enable ECC error detection and correction.

(2) Reading the ECC bits

- (a) Set the ECCDIS bit in the data flash ECC control register to 1 to disable ECC error detection and correction.
- (b) Set the ECCTST bit in the data flash test control register to 1 to set test mode.
- (c) When the data flash is read, the 7 lower-order bits of read data are read as ECC data.

How to exit this test mode:

- (a) Set the ECCDIS bit in the data flash ECC control register to 0 to enable ECC error detection and correction.
- (b) Set the ECCTST bit in the data flash test control register to 0 to set normal mode.

(3) Self-diagnosis of ECC check function

Self-diagnosis of the ECC decoder is possible by writing incorrect data to the data flash memory beforehand (fault injection) and then reading this data. A 1- or 2-bit ECC error fault can be injected by generating correct ECC bits once and inverting only the appropriate bits. For details on programming of the data flash, refer to *the RH850/E2x-FCC2 Flash Memory User's Manual: Hardware Interface*.

40.3.5 Local RAM ECC and Address Feedback

40.3.5.1 Overview

Local RAM ECC is summarized in the table below.

Table 40.37 Local RAM ECC

Item	Description
ECC error detection and correction	<p>ECC error detection and correction can be either enabled or disabled.</p> <p>When enabled, either of the following settings can be selected:</p> <ul style="list-style-type: none"> • ECC error detection and correction are carried out (2-bit error detection, and 1-bit error detection and correction are carried out). • ECC error detection is carried out (2-bit error detection and 1-bit error detection are carried out). <p>When disabled, neither error detection nor correction is carried out.</p> <p>In the initial state, this function is enabled; 1-bit error detection and correction, and 2-bit error detection are carried out.</p>
Address feedback	<p>Address feedback check can be either enabled or disabled.</p> <p>When enabled, Address feedback error detection is carried out.</p> <p>When disabled, no error detection is carried out.</p> <p>In the initial state, this function is enabled.</p>
Error notification	<p>The occurrence of an ECC error or an address feedback error is reported to the Error Control Module.</p> <p>ECC Error:</p> <ul style="list-style-type: none"> • Error notification can be either enabled or disabled upon detection of an ECC 2-bit error. • Error notification can be either enabled or disabled upon detection of an ECC 1-bit error. <p>In the initial state, error notification is enabled upon detection of an ECC 2-bit error, and error notification is enabled upon detection of an ECC 1-bit error.</p> <p>Address Feedback Error:</p> <ul style="list-style-type: none"> • Error notification can be either enabled or disabled upon detection of an address feedback error. <p>In the initial state, error notification is enabled upon detection of an address feedback error.</p> <p>Overflow Error:</p> <ul style="list-style-type: none"> • Error notification can be either enabled or disabled upon detection of an address buffer overflow error for ECC 1-bit error. <p>In the initial state, error notification is enabled upon detection of an address buffer overflow error. The error notification signal is output with an address feedback error handled as one source. An ECC 2-bit error, an ECC 1-bit error and an overflow error are handled as individual sources in ECM. An ECC 1-bit error signal is only issued to the ECM, if the ECC 1-bit error address is not yet stored in the error address buffer.</p>
Error status	<p>A status register is provided that indicates the statuses of ECC 2-bit error detection, ECC 1-bit error detection, and address feedback error detection. If an error occurs while no error status is set, the corresponding status is set. The error status can be cleared using the clear register.</p>
Address capture	<p>The address is captured when an ECC 2-bit error, an ECC 1-bit error, or an address feedback error is detected. The error status serves as the enable bit of the address that is captured.</p> <p>Address buffers are updated if the error status is cleared.</p> <p>Multi-stage address buffers are provided for an ECC 1-bit error.</p> <p>ECC 1-bit error: Eight stages (for each CPU)</p> <p>ECC 2-bit error and address feedback error: One stage (for each CPU)</p>
Self-diagnosis	<p>Desired values can be written to the RAM data and the ECC bits.</p> <p>The RAM data can be read directly and the ECC bits can be read via Read Buffer Register in ECC Test Mode.</p> <p>Moreover, the error injection to an address feedback checker is possible by setting AFINV.</p>

ECC of Local RAM is provided for each 32 bits of data and each 32-bit data is called bank 0 to 3. The relationship between addresses and bank numbers are as follows.

Table 40.38 Relationship between addresses and bank numbers

4 lower-order bits of address (Hexadecimal Notation)	F _H to C _H	B _H to 8 _H	7 _H to 4 _H	3 _H to 0 _H
Bank number	Bank 3	Bank 2	Bank 1	Bank 0

40.3.5.2 Register Base Address

Base addresses of safety modules are listed in the following table. Each register address is given as offsets from the base addresses.

Table 40.39 Register Base Addresses

Base Address Name	Base Address	Bus Group
<ECCCNT_LR_PE0CL0_base>	FFC4 9800 _H	Peripheral Group 0
<ECCCNT_LR_PE1CL0_base>	FFC4 9880 _H	Peripheral Group 0
<ECCCNT_LR_PE2CL1_base>	FFC4 9900 _H	Peripheral Group 0
<ECCCNT_LR_PE3CL1_base>	FFC4 9980 _H	Peripheral Group 0
<ECCCNT_LR_PE4CL2_base>*1	FFC4 9A00 _H	Peripheral Group 0
<ECCCNT_LR_PE5CL2_base>*1	FFC4 9A80 _H	Peripheral Group 0
<MECCCAP_LR_PE0CL0_base>	FFC5 0000 _H	Peripheral Group 0
<MECCCAP_LR_PE1CL0_base>	FFC5 0100 _H	Peripheral Group 0
<MECCCAP_LR_PE2CL1_base>	FFC5 0200 _H	Peripheral Group 0
<MECCCAP_LR_PE3CL1_base>	FFC5 0300 _H	Peripheral Group 0
<MECCCAP_LR_PE4CL2_base>*1	FFC5 0400 _H	Peripheral Group 0
<MECCCAP_LR_PE5CL2_base>*1	FFC5 0500 _H	Peripheral Group 0
<MECCCAP_LRA_base>	FFC5 0800 _H	Peripheral Group 0

Note 1. This function is not implemented in E2H.

40.3.5.3 List of Registers

Table 40.40 List of Registers (1/3)

Module Name	Register Name	Symbol	Address	Access	Access Protection
ECCCNT_LR_PEnC L0 (n = 0, 1)	ECC Control Register	LRECCCTL	<ECCCNT_LR_PEnCL0_base> + 00 _H	8, 16, 32	KCPROT

	1-bit Error Status Register	LR1_SERSTR	<MECCCAP_LRA_base> + 20H	8, 16, 32	
	Fatal Error Status Register	LR1_DERSTR	<MECCCAP_LRA_base> + 24H	8, 16, 32	
	1-bit Error Overflow Status Register	LR1_OVFSTR	<MECCCAP_LRA_base> + 28H	8, 16, 32	
	1-bit Error Location Information Register	LR1_SERINF	<MECCCAP_LRA_base> + 30H	32	
	1st 1-bit Error Address Register	LR1_00SEADR	<MECCCAP_LRA_base> + 70H	32	
	2nd 1-bit Error Address Register	LR1_01SEADR	<MECCCAP_LRA_base> + 74H	32	
	3rd 1-bit Error Address Register	LR1_02SEADR	<MECCCAP_LRA_base> + 78H	32	
	4th 1-bit Error Address Register	LR1_03SEADR	<MECCCAP_LRA_base> + 7CH	32	
	5th 1-bit Error Address Register	LR1_04SEADR	<MECCCAP_LRA_base> + 80H	32	
	6th 1-bit Error Address Register	LR1_05SEADR	<MECCCAP_LRA_base> + 84H	32	
	7th 1-bit Error Address Register	LR1_06SEADR	<MECCCAP_LRA_base> + 88H	32	
	8th 1-bit Error Address Register	LR1_07SEADR	<MECCCAP_LRA_base> + 8CH	32	
	1st fatal Error Address Register	LR1_00DEADR	<MECCCAP_LRA_base> + F0H	32	

Note 1. This function is not implemented in E2H.

40.3.5.4 LRECCCTL — ECC Control Register

This register controls ECC error detection/correction and 1-bit error correction for read data from Local RAM and address feedback error detection for request address to Local RAM.

This register is protected by the KCPROT register. When KCPROT.KCE = 0, it cannot be written. It can be written only when KCPROT.KCE = 1.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	AFE DIS	—	SEC DIS	ECC DIS

R/W	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R	R/W	R/W

Table 40.41 LRECCCTL Register Contents

Bit Position	Bit Name	Function
31 to 4	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
3	AFEDIS	Address feedback error disable bit Sets address feedback error detection to enable/disable. 0: Address feedback error detection is enabled 1: Address feedback error detection is disabled
2	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
1	SECDIS	ECC 1-bit error correction enable bit When using ECC error detection/correction (ECCDIS = 0), this bit sets 1-bit error correction to enable/disable. 0: Correct when 1-bit error is detected 1: Do not correct when 1-bit error is detected
0	ECCDIS	ECC disable bit Sets ECC error detection/correction to enable/disable. 0: ECC error detection/correction is enabled 1: ECC error detection/correction is disabled

40.3.5.5 LRECCTSTCTL — ECC Test Control Register

ECC test (self-diagnostics) register. After setting the ECC test mode (ECCTST = 1), either data field or ECC field of Local RAM can be written separately.

This register is protected by the KCPROT register. When KCPROT.KCE = 0, it cannot be written. It can be written only when KCPROT.KCE = 1.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W

Table 40.42 LRECCTSTCTL Register Contents

Bit Position	Bit Name	Function
31 to 2	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
1	ECCTST	Sets the write mode to Local RAM. 0: Normal mode 1: Test mode Either data field or ECC field can be written according to the DATSEL setting in test mode.
0	DATSEL	Sets the field to write data when ECCTST = 1. 0: Data field only 1: ECC field only

40.3.5.6 LRAFINV — Address Feedback Test Control Register

This register is used to inject errors into the feedback address from Local RAM for self-diagnosis. Feedback address XOR-ed with AFINV can be input to address feedback checker.

This register is protected by the KCPROT register. When KCPROT.KCE = 0, it cannot be written. It can be written only when KCPROT.KCE = 1.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	AFINV[20:16]				
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R	R

Table 40.43 LRAFINV Register Contents

Bit Position	Bit Name	Function
31 to 21	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
20 to 4	AFINV[20:4]	Specifies bit pattern to inject errors into feedback address.
3 to 0	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.

40.3.5.7 LRTDATBFECF — ECC Read Buffer Register

This register is used to hold ECC field read from Local RAM for self-diagnosis. ECC field in requested address can be stored this register while reading from Local RAM where ECCTST = 1.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	BFEC3[6:0]						—	BFEC2[6:0]

Table 40.44 LRTDATBFECF Register Contents

Bit Position	Bit Name	Function
31	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
30 to 24	BFEC3[6:0]	ECC field read from the address that is requested in Local RAM bank 3
23	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
22 to 16	BFEC2[6:0]	ECC field read from the address that is requested in Local RAM bank 2
15	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
14 to 8	BFEC1[6:0]	ECC field read from the address that is requested in Local RAM bank 1
7	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
6 to 0	BFEC0[6:0]	ECC field read from the address that is requested in Local RAM bank 0

40.3.5.8 LR0_ERRINT — Error Notification Control Register

This register controls whether error information is reported to ECM, when address feedback error, ECC error and/or overflow error has occurred.

This register is protected by the KCPROT register. When KCPROT.KCE = 0, it cannot be written. It can be written only when KCPROT.KCE = 1.

Value after reset: 0000 008B_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Table 40.45 LR0_ERRINT Register Contents

Bit Position	Bit Name	Function
31 to 8	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
7	SEOVFIE	Controls error reports when overflow error occurs. 0: Overflow error report disabled 1: Overflow error report enabled
6 to 4	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
3	AFEIE	Controls error reports when address feedback error is detected. 0: Address feedback error report disabled 1: Address feedback error report enabled
2	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
1	DEDIE	Controls error reports when ECC 2-bit error is detected. 0: ECC 2-bit error report disabled 1: ECC 2-bit error report enabled
0	SEDIE	Controls error reports when ECC 1-bit error is detected. 0: ECC 1-bit error report disabled 1: ECC 1-bit error report enabled

40.3.5.9 LR0_SSTCLR — 1-bit Error Status Clear Register

This register is used to clear error flags in LR0_SERSTR. This is a write only register and read value is always “0”.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	W	W	W	W	W	W	W	W

Table 40.46 LR0_SSTCLR Register Contents

Bit Position	Bit Name	Function
31 to 8	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
7	SSTCLR07	Writing 1 to this bit clears SEDF07 in LR0_SERSTR.
6	SSTCLR06	Writing 1 to this bit clears SEDF06 in LR0_SERSTR.
5	SSTCLR05	Writing 1 to this bit clears SEDF05 in LR0_SERSTR.
4	SSTCLR04	Writing 1 to this bit clears SEDF04 in LR0_SERSTR.
3	SSTCLR03	Writing 1 to this bit clears SEDF03 in LR0_SERSTR.
2	SSTCLR02	Writing 1 to this bit clears SEDF02 in LR0_SERSTR.
1	SSTCLR01	Writing 1 to this bit clears SEDF01 in LR0_SERSTR.
0	SSTCLR00	Writing 1 to this bit clears SEDF00 in LR0_SERSTR.

40.3.5.10 LR0_DSTCLR — Fatal Error Status Clear Register

This register is used to clear error flags in LR0_DERSTR. This is write only register and read value is always “0”.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 40.47 LR0_DSTCLR Register Contents

Bit Position	Bit Name	Function
31 to 1	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
0	DSTCLR00	Writing 1 to this bit clears AFEF00 and DEDF00 in LR0_DERSTR.

40.3.5.11 LR0_OVFCLR — 1-bit Error Overflow Status Clear Register

This register is used to clear error overflow flags in LR0_OVFSTR. This is write only register and read value is always “0”.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	SERR OVF CLR1	SERR OVF CLR0
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	W	W

Table 40.48 LR0_OVFCLR Register Contents

Bit Position	Bit Name	Function
31 to 2	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
1	SERROVFCLR1	Writing 1 to this bit clears SERROVF1 in LR0_OVFSTR.
0	SERROVFCLR0	Writing 1 to this bit clears SERROVF0 in LR0_OVFSTR.

40.3.5.12 LR0_SERSTR — 1-bit Error Status Register

This register indicates whether an ECC 1-bit error has occurred. The location and address of the error that is detected are stored in LR0_nSEADR register when SEDFn flag is set. The SEDFn flag is set only when a unique ECC 1-bit error, which is different from previous errors stored in 1-bit error address registers, is detected while the SEDFn is “0”. If the newly detected error has the same address with errors already stored, this flag is not set.

This register can be cleared by SSTCLRn in LR0_SSTCLR register.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 40.49 LR0_SERSTR Register Contents

Bit Position	Bit Name	Function
31 to 8	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
7	SEDF07	Indicates that an ECC 1-bit error was detected and error address is stored in LR0_07SEADR register.
6	SEDF06	Indicates that an ECC 1-bit error was detected and error address is stored in LR0_06SEADR register.
5	SEDF05	Indicates that an ECC 1-bit error was detected and error address is stored in LR0_05SEADR register.
4	SEDF04	Indicates that an ECC 1-bit error was detected and error address is stored in LR0_04SEADR register.
3	SEDF03	Indicates that an ECC 1-bit error was detected and error address is stored in LR0_03SEADR register.
2	SEDF02	Indicates that an ECC 1-bit error was detected and error address is stored in LR0_02SEADR register.
1	SEDF01	Indicates that an ECC 1-bit error was detected and error address is stored in LR0_01SEADR register.
0	SEDF00	Indicates that an ECC 1-bit error was detected and error address is stored in LR0_00SEADR register.

40.3.5.13 LR0_DERSTR — Fatal Error Status Register

This register indicates whether an address feedback error and/or an ECC 2-bit error has occurred. The location and address of the error that is detected are stored in LR0_00DEADR register when AFEF00 and/or DEDF00 flag are set. The AFEF00 and/or DEDF00 flag is set only when an address feedback error and/or an ECC 2-bit error is detected while all the flags are “0”. Multiple flags are set only when multiple errors occur due to one error cause.

This register can be cleared by DSTCLR00 in LR0_DSTCLR register.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 40.50 LR0_DERSTR Register Contents

Bit Position	Bit Name	Function
31 to 4	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
3	AFEF00	Indicates that an address feedback error was detected.
2	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
1	DEDF00	Indicates that an ECC 2-bit error was detected.
0	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.

40.3.5.14 LR0_OVFSTR — 1-bit Error Overflow Status Register

This register indicates whether overflow of address buffer or working memory has occurred.

SERROVF0 flag is set when a unique ECC 1-bit error that differs from previous errors in error address, is detected when the address buffer is fully used. If the newly detected error has the same address with errors already stored, this flag is not set.

On the other hand, SERROVF1 flag is set when the number of times an ECC 1-bit error occurs at the same time regardless of the same occurrence address exceed the size of internal buffer.

SERROVF0 and SERROVF1 flags can be cleared by SERROVFCLR0 and SERROVFCLR1 in LR0_OVFCLR register respectively.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit Position	Bit Name	Function
31 to 2	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
1	SERROVF1	Indicates that more ECC 1-bit errors than the working memory were detected simultaneously.
0	SERROVF0	Indicates that a unique ECC 1-bit error was detected when all ECC 1bit error flags in LR0_SERSTR are set.

40.3.5.15 LR0_SERINF — 1-bit Error Location Information Register

This register is used to indicate summary of locations where ECC 1-bit errors stored in LR0_SERSTR register were detected.

This register is updated whenever LR0_SERSTR register is updated.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 40.52 LR0_SERINF Register Contents

Bit Position	Bit Name	Function
31 to 5	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
4	SEDLINF04	Indicates that an ECC 1-bit error was detected in bank 3 of Local RAM.
3	SEDLINF03	Indicates that an ECC 1-bit error was detected in bank 2 of Local RAM.
2	SEDLINF02	Indicates that an ECC 1-bit error was detected in bank 1 of Local RAM.
1	SEDLINF01	Indicates that an ECC 1-bit error was detected in bank 0 of Local RAM.
0	SEDLINF00	Indicates that an ECC 1-bit error was detected in read data loaded from its own Local RAM speculatively.

40.3.5.16 LR0_nSEADR — n-th 1-bit Error Address Register (n = 00 to 07)

This register is used to hold the address and the location of the error when the SEDFn flag is not set and an ECC 1-bit error is detected.

This register can only be cleared by reset.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 40.53 LR0_nSEADR Register Contents

Bit Position	Bit Name	Function
31 to 27	SEDL[4:0]	Indicates where this error was detected.
26 to 16	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
15 to 2	SEADR0[15:2]	Indicates at which address this error was detected.
1, 0	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.

Please refer to the following table to confirm the detailed information which each SEDL indicates.

Table 40.54 SEDL information

SEDL[4:0]	Indicated information
31 to 5	Reserved
4	Indicates an ECC 1-bit error is detected in storing data to or fetching instructions from bank 3 of Local RAM.
3	Indicates an ECC 1-bit error is detected in storing data to or fetching instructions from bank 2 of Local RAM.
2	Indicates an ECC 1-bit error is detected in storing data to or fetching instructions from bank 1 of Local RAM.
1	Indicates an ECC 1-bit error is detected in storing data to or fetching instructions from bank 0 of Local RAM.
0	Indicates an ECC 1-bit error is detected in loading data from its own Local RAM.

40.3.5.17 LR0_00DEADR — 1st Fatal Error Address Register

This register is used to hold the address and the location of the error when neither AFEF00 nor DEDF00 flag is set and an address feedback error and/or ECC 2-bit error was detected.

This register can only be cleared by reset.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 40.55 LR0_00DEADR Register Contents

Bit Position	Bit Name	Function
31 to 27	DEDL[4:0]	Indicates where this error was detected.
26 to 16	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
15 to 2	DEADR0[15:2]	Indicates at which address this error was detected.
1, 0	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.

Please refer to the following table to confirm the detailed information which each DEDL indicates.

Table 40.56 DEDL Information

DEDL[4:0]	Indicated information
31 to 5	Reserved
4	Indicates a fatal error is detected in storing data to or fetching instructions from bank 3 of Local RAM.
3	Indicates a fatal error is detected in storing data to or fetching instructions from bank 2 of Local RAM.
2	Indicates a fatal error is detected in storing data to or fetching instructions from bank 1 of Local RAM.
1	Indicates a fatal error is detected in storing data to or fetching instructions from bank 0 of Local RAM.
0	Indicates a fatal error is detected in loading data from its own Local RAM.

40.3.5.18 LR1_ERRINT — Error Notification Control Register

This register controls whether error information is reported to ECM when an ECC error and/or overflow error occurs.

This register is protected by the KCPROT register. When KCPROT.KCE = 0, it cannot be written. It can be written only when KCPROT.KCE = 1.

Value after reset: 0000 0083_H

Table 40.60 LR1_OVFCLR Register Contents

Bit Position	Bit Name	Function
31 to 2	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
1	SERROVFCLR1	Writing 1 to this bit clears SERROVF1 in LR1_OVFSTR.
0	SERROVFCLR0	Writing 1 to this bit clears SERROVF0 in LR1_OVFSTR.

40.3.5.22 LR1_SERSTR — 1-bit Error Status Register

This register indicates whether ECC 1-bit error has occurred. The location and address of the error that is detected are stored in LR1_nSEADR register when SEDFn flag is set. The SEDFn flag is set only when a unique ECC 1-bit error, which is different from previous errors stored in 1-bit error address registers, is detected while the SEDFn is “0”. If the newly detected error has the same address with errors already stored, this flag is not set.

This register can be cleared by SSTCLRn in LR1_SSTCLR register.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 40.61 LR1_SERSTR Register Contents

Bit Position	Bit Name	Function
31 to 8	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
7	SEDF07	Indicates that an ECC 1-bit error was detected and error address is stored in LR1_07SEADR register.
6	SEDF06	Indicates that an ECC 1-bit error was detected and error address is stored in LR1_06SEADR register.
5	SEDF05	Indicates that an ECC 1-bit error was detected and error address is stored in LR1_05SEADR register.
4	SEDF04	Indicates that an ECC 1-bit error was detected and error address is stored in LR1_04SEADR register.
3	SEDF03	Indicates that an ECC 1-bit error was detected and error address is stored in LR1_03SEADR register.
2	SEDF02	Indicates that an ECC 1-bit error was detected and error address is stored in LR1_02SEADR register.
1	SEDF01	Indicates that an ECC 1-bit error was detected and error address is stored in LR1_01SEADR register.
0	SEDF00	Indicates that an ECC 1-bit error r was detected and error address is stored in LR1_00SEADR register.

40.3.5.23 LR1_DERSTR — Fatal Error Status Register

This register indicates whether an ECC 2-bit error has occurred. The location and address of the error that is detected are stored in LR1_00DEADR register when DEDF00 flag is set. The DEDF00 flag is set only when an ECC 2-bit error is detected while the DEDF00 is “0”.

This register can be cleared by DSTCLR00 in LR1_DSTCLR register.

Value after reset: 0000 0000_H

Bit Position	Bit Name	Function
31 to 2	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
1	DEDF00	Indicates that an ECC 2-bit error was detected.
0	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.

40.3.5.24 LR1_OVFSTR — 1-bit Error Overflow Status Register

This register indicates whether overflow of address buffer or working memory has occurred.

SERROVF0 flag is set when a unique ECC 1-bit error that differs from previous errors in error address, is detected when the address buffer is fully used. If the newly detected error has the same address with errors already stored, this flag is not set.

On the other hand, SERROVF1 flag is set when the number of times an ECC 1-bit error occurs at the same time regardless of the same occurrence address exceed the size of internal buffer.

SERROVF0 and SERROVF1 flags can be cleared by SERROVFCLR0 and SERROVFCLR1 in LR1_OVFCLR register respectively.

Value after reset: 0000 0000_H

Bit Position	Bit Name	Function
31 to 6	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
5	SEDLINF05	Indicates that an ECC 1-bit error was detected in read data to PE5*1 loaded from the other PE's Local RAM speculatively.
4	SEDLINF04	Indicates that an ECC 1-bit error was detected in read data to PE4*1 loaded from the other PE's Local RAM speculatively.
3	SEDLINF03	Indicates that an ECC 1-bit error was detected in read data to PE3 loaded from the other PE's Local RAM speculatively.
2	SEDLINF02	Indicates that an ECC 1-bit error was detected in read data to PE2 loaded from the other PE's Local RAM speculatively.
1	SEDLINF01	Indicates that an ECC 1-bit error was detected in read data to PE1 loaded from the other PE's Local RAM speculatively.
0	SEDLINF00	Indicates that an ECC 1-bit error was detected in read data to PE0 loaded from the other PE's Local RAM speculatively.

Note 1. This function is not implemented in E2H.

40.3.5.26 LR1_nSEADR — n-th 1-bit Error Address Register (n = 00 to 07)

This register is used to hold the address and the location of the error when SEDFn flag is not set and an ECC 1-bit error is detected.

This register can only be cleared by reset.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 40.65 LR1_nSEADR Register Contents

Bit Position	Bit Name	Function
31 to 27	SEDL[4:0]	Indicates where this error was detected.
26 to 24	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
23 to 2	SEADR0[23:2]	Indicates at which address this error was detected.
1, 0	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.

Please refer to the following table to confirm the detailed information which each SEDL indicates.

Table 40.66 SEDL information

SEDL[4:0]	Indicated information
31 to 6	Reserved
5	Indicates an ECC 1-bit error is detected in loading data from the other PE's Local RAM by PE5*1 master.
4	Indicates an ECC 1-bit error is detected in loading data from the other PE's Local RAM by PE4*1 master.
3	Indicates an ECC 1-bit error is detected in loading data from the other PE's Local RAM by PE3 master.
2	Indicates an ECC 1-bit error is detected in loading data from the other PE's Local RAM by PE2 master.
1	Indicates an ECC 1-bit error is detected in loading data from the other PE's Local RAM by PE1 master.
0	Indicates an ECC 1-bit error is detected in loading data from the other PE's Local RAM by PE0 master.

Note 1. This function is not implemented in E2H.

40.3.5.27 LR1_00DEADR — 1st Fatal Error Address Register

This register is used to hold the address and the location of the error when DEDF00 flag is not set and an ECC 2-bit error is detected.

This register can only be cleared by reset.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 40.67 LR1_00DEADR Register Contents

Bit Position	Bit Name	Function
31 to 27	DEDL[4:0]	Indicates where this error was detected.
26 to 24	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
23 to 2	DEADR0[23:2]	Indicates at which address this error was detected.
1, 0	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.

Please refer to the following table to confirm the detailed information which each DEDL indicates.

Table 40.68 DEDL Information

DEDL[4:0]	Indicated information
31 to 6	Reserved
5	Indicates a fatal error is detected in loading data from the other PE's Local RAM by PE5 ^{*1} master.
4	Indicates a fatal error is detected in loading data from the other PE's Local RAM by PE4 ^{*1} master.
3	Indicates a fatal error is detected in loading data from the other PE's Local RAM by PE3 master.
2	Indicates a fatal error is detected in loading data from the other PE's Local RAM by PE2 master.
1	Indicates a fatal error is detected in loading data from the other PE's Local RAM by PE1 master.
0	Indicates a fatal error is detected in loading data from the other PE's Local RAM by PE0 master.

Note 1. This function is not implemented in E2H.

40.3.5.28 Test Function

Through appropriate register settings, desired values can be written as RAM data and to the ECC bits. Also, data in the RAM and the ECC bits can all be read.

(1) Writing RAM data

- (a) Set the ECCTST bit in the ECC Test Control Register to 1 to set test mode.
- (b) Set the corresponding DATSEL bit in the ECC Test Control Register to 0 to select RAM data for access when writing.
- (c) When data is written to the Local RAM, only the RAM data can be modified without updating the ECC bits.

How to exit this test mode:

- (a) Set the ECCTST bit in the ECC Test Control Register to 0 to disable test mode (normal mode).

(2) Reading RAM data

- (a) Set the ECCDIS bit in the ECC Control Register to 1 to disable ECC error detection and correction.
- (b) Read the Local RAM. Since neither error detection nor correction proceeds when the Local RAM is read, the RAM data is read unchanged.

How to exit this test mode:

- (a) Set the ECCDIS bit in the ECC Control Register to 0 to enable ECC error detection and correction.

(3) Writing to the ECC bits

- (a) Set the ECCTST bit in the ECC Test Control Register to 1 to set test mode.
- (b) Set the corresponding DATSEL bit in the ECC Test Control Register to 1 to select the ECC bits for access when writing.
- (c) When data is written to the Local RAM, only the ECC bits can be modified without updating the RAM data. At that time, bits[6:0] are written to the ECC bits.

How to exit this test mode:

- (a) Set the ECCTST bit in the ECC Test Control Register to 0 to disable test mode (normal mode).

(4) Reading the ECC bits

- (a) Set the ECCTST bit in the ECC Test Control Register to 1 to set test mode.
- (b) When the Local RAM is read, the ECC bits are stored in the word corresponding to local RAM ECC read buffer register.

How to exit this test mode:

- (a) Set the ECCTST bit in the ECC Test Control Register to 0 to disable test mode (normal mode).

(5) Self-diagnosis of the ECC check function

Desired values can be written to the RAM data, ECC bits by the procedure described in (1) or (3) above. Therefore, a fault can be injected by, for example, inverting appropriate bits of the RAM data and/or ECC bits. After that, self-diagnosis of the ECC decoder is possible by reading the Local RAM in normal mode and checking the result of error correction or detection.

(6) Self-diagnosis of the address feedback check function

Self-diagnosis is enabled by following procedure below.

- (a) Set the desired bit(s) of AFINV[20:4] in the Address Feedback Test Control Register to 1 to set test mode.
- (b) When the Local RAM is read or written, address feedback error occurs because feedback address XOR-ed with AFINV can be input to address feedback checker.

How to exit this test mode:

- (a) Set the AFINV[20:4] bits in the Address Feedback Test Control Register all to 0 to disable test mode (normal mode).

40.3.6 Cluster RAM ECC and Address Feedback

40.3.6.1 Overview

The Cluster RAM ECC is summarized in the table below.

The ECC protection described below takes into consideration all possible Cluster RAM accesses from PE, H-Bus, System Bus and read access for read-modify-write processing unit of 8-bit and 16-bit data.

Table 40.69 Cluster RAM ECC

Item	Description
ECC error detection and correction	<p>ECC error detection and correction can be either enabled or disabled.</p> <p>When enabled, either of the following settings can be selected.</p> <ul style="list-style-type: none"> • ECC error detection and correction are carried out (2-bit error detection, and 1-bit error detection and correction are carried out). • ECC error detection is carried out (2-bit error detection and 1-bit error detection are carried out). <p>When disabled, neither error detection nor correction is carried out.</p> <p>In the initial state, the ECC function is enabled; 1-bit error detection and correction, and 2-bit error detection are carried out.</p>
Address feedback	<p>Address feedback check can be either enabled or disabled.</p> <p>When enabled, Address feedback error detection is carried out.</p> <p>When disabled, no error detection is carried out.</p> <p>In the initial state, this function is enabled.</p>
Error notification	<p>The occurrence of an ECC error or an address feedback error is reported to the Error Control Module.</p> <p>ECC Error:</p> <ul style="list-style-type: none"> • Error notification can be either enabled or disabled upon detection of an ECC 2-bit error. • Error notification can be either enabled or disabled upon detection of an ECC 1-bit error. <p>In the initial state, error notification is enabled upon detection of an ECC 2-bit error, and error notification is enabled upon detection of an ECC 1-bit error.</p> <p>Address Feedback Error:</p> <ul style="list-style-type: none"> • Error notification can be either enabled or disabled upon detection of an address feedback error. <p>In the initial state, error notification is enabled upon detection of an address feedback error.</p> <p>Overflow Error:</p> <ul style="list-style-type: none"> • Error notification can be either enabled or disabled upon detection of an address buffer overflow error for ECC 1-bit error. <p>In the initial state, error notification is enabled upon detection of an address buffer overflow error. The error notification signal is output with an address feedback error handled as one source. An ECC 2-bit error, an ECC 1-bit error and an overflow error are handled as individual sources in ECM. An ECC 1-bit error signal is only issued to the ECM if the ECC 1-bit error address is not yet stored in the error address buffer.</p>
Error status	<p>A status register is provided that indicates the statuses of ECC 2-bit error detection, ECC 1-bit error detection, and address feedback error detection. If an error occurs while no error status is set, the corresponding status is set.</p> <p>The error status can be cleared using the clear register.</p>
Address capture	<p>The address is captured when an ECC 2-bit error, an ECC 1-bit error, or an address feedback error is detected. The error status serves as the enable bit of the address that is captured. Address buffers are updated if the error status is cleared.</p> <p>Multi-stage address buffers are provided for a 1-bit data error.</p> <ul style="list-style-type: none"> • ECC 1-bit error: Eight stages • ECC 2-bit error and address feedback error shared: One stage
Self-diagnosis	<p>Desired values can be written to the RAM data and the ECC bits.</p> <p>The RAM data can be read directly and the ECC bits can be read via Read Buffer Register in ECC Test Mode.</p> <p>Moreover, the error injection to an address feedback checker is possible by setting AFINV.</p>

ECC of Cluster RAM is provided for each 32 bits of data and each 32-bit data is called bank 0 to 3. The relationship between addresses and bank numbers are as follows.

Table 40.70 Relationship between addresses and bank numbers

4 lower-order bits of address (Hexadecimal Notation)	F _H to C _H	B _H to 8 _H	7 _H to 4 _H	3 _H to 0 _H
Bank number	Bank 3	Bank 2	Bank 1	Bank 0

40.3.6.2 Register Base Address

Base addresses of safety modules are listed in the following table. Each register address is given as offsets from the base addresses.

Table 40.71 Register Base Addresses

Base Address Name	Base Address	Bus Group
<ECCCNT_CRCCL0_base>	FFC4 9C00 _H	Peripheral Group 0
<ECCCNT_CRCCL1_base>	FFC4 9C80 _H	Peripheral Group 0
<ECCCNT_CRCCL2_base>*1	FFC4 9D00 _H	Peripheral Group 0
<ECCCNT_CRA_base>	FFC4 9E00 _H	Peripheral Group 0
<MECCCAP_CRAM_base>	FFC5 2000 _H	Peripheral Group 0

Note 1. This function is not implemented in E2H.

40.3.6.3 List of Registers

Table 40.72 List of Registers

Module Name	Register Name	Symbol	Address	Access	Access Protection
ECCCNT_CRCCLn (n = 0-2)	Address Feedback Control Register	CRCAFCTL	<ECCCNT_CRCCLn_base> + 00 _H	8, 16, 32	KCPROT

	1-bit Error Status Register	CR_SERSTR	<MECCCAP_CRAM_base> + 20 _H	8, 16, 32	
	Fatal Error Status Register	CR_DERSTR	<MECCCAP_CRAM_base> + 24 _H	8, 16, 32	
	1-bit Error Overflow Status Register	CR_OVFSTR	<MECCCAP_CRAM_base> + 28 _H	8, 16, 32	
	1-bit Error Location Information Register	CR_SERINF	<MECCCAP_CRAM_base> + 30 _H	32	
	1st 1-bit Error Address Register	CR_00SEADR	<MECCCAP_CRAM_base> + 70 _H	32	
	2nd 1-bit Error Address Register	CR_01SEADR	<MECCCAP_CRAM_base> + 74 _H	32	
	3rd 1-bit Error Address Register	CR_02SEADR	<MECCCAP_CRAM_base> + 78 _H	32	
	4th 1-bit Error Address Register	CR_03SEADR	<MECCCAP_CRAM_base> + 7C _H	32	
	5th 1-bit Error Address Register	CR_04SEADR	<MECCCAP_CRAM_base> + 80 _H	32	
	6th 1-bit Error Address Register	CR_05SEADR	<MECCCAP_CRAM_base> + 84 _H	32	
	7th 1-bit Error Address Register	CR_06SEADR	<MECCCAP_CRAM_base> + 88 _H	32	
	8th 1-bit Error Address Register	CR_07SEADR	<MECCCAP_CRAM_base> + 8C _H	32	
	1st Fatal Error Address Register	CR_00DEADR	<MECCCAP_CRAM_base> + F0 _H	32	

40.3.6.4 CRCAFCTL — Address Feedback Control Register

This register controls address feedback error detection for the address that is requested to Cluster RAM.

This register is protected by the KCPROT register. When KCPROT.KCE = 0, it cannot be written. It can be written only when KCPROT.KCE = 1.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 40.73 CRCAFCTL Register Contents

Bit Position	Bit Name	Function
31 to 4	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
3	AFEDIS	Address feedback error disable bit Sets address feedback error detection to enable/disable. 0: Address feedback error detection is enabled 1: Address feedback error detection is disabled
2 to 0	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.

40.3.6.5 CRCECCTSTCTL — ECC Test Control Register

ECC test (self-diagnostics) register. After setting the ECC test mode (ECCTST = 1), either data field or ECC field of Cluster RAM can be written separately.

This register is protected by the KCPROT register. When KCPROT.KCE = 0, it cannot be written. It can be written only when KCPROT.KCE = 1.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Table 40.74 CRCECCTSTCTL Register Contents

Bit Position	Bit Name	Function
31 to 2	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
1	ECCTST	Selects the write mode to Cluster RAM. 0: Normal mode 1: Test mode Either data field or ECC field can be written according to DATSEL setting in test mode.
0	DATSEL	Selects field to write data when ECCTST = 1. 0: Data field only 1: ECC field only

40.3.6.6 CRCAFINV — Address Feedback Test Control Register

This register is used to inject errors into the feedback address from Cluster RAM for self-diagnosis. Feedback address XOR-ed with AFINV can be input to address feedback checker.

This register is protected by the KCPROT register. When KCPROT.KCE = 0, it cannot be written. It can be written only when KCPROT.KCE = 1.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 40.75 CRCAFINV Register Contents

Bit Position	Bit Name	Function
31 to 20	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
19 to 4*1	AFINV[19:4]	Specifies bit pattern to inject errors into feedback address.
3 to 0	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.

Note 1. AFINV[19] is valid for Cluster2 only.

40.3.6.7 CRCTDATBFECF — ECC Read Buffer Register

This register is used to hold ECC field read from Cluster RAM for self-diagnosis. ECC field in the address that is requested can be stored in this register while reading from Cluster RAM where ECCTST = 1.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit Position	Bit Name	Function
31	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
30 to 24	BFEC3[6:0]	ECC field read from requested address in Cluster RAM bank 3
23	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
22 to 16	BFEC2[6:0]	ECC field read from requested address in Cluster RAM bank 2
15	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
14 to 8	BFEC1[6:0]	ECC field read from requested address in Cluster RAM bank 1
7	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
6 to 0	BFEC0[6:0]	ECC field read from requested address in Cluster RAM bank 0

40.3.6.8 CRAECCCTL — ECC Control Register

This register controls ECC error detection/correction and 1-bit error correction for data read from Cluster RAM.

This register is protected by the KCPROT register. When KCPROT.KCE = 0, it cannot be written. It can be written only when KCPROT.KCE = 1.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 40.77 CRAECCCTL Register Contents

Bit Position	Bit Name	Function
31 to 2	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
1	SECDIS	ECC 1-bit error correction enable bit When using ECC error detection/correction (ECCDIS = 0), this bit sets 1-bit error correction to enable/disable. 0: Correct when 1-bit error is detected 1: Do not correct when 1-bit error is detected
0	ECCDIS	ECC disable bit Sets ECC error detection/correction to enable/disable. 0: ECC error detection/correction is enabled 1: ECC error detection/correction is disabled

40.3.6.9 CR_ERRINT — Error Notification Control Register

This register controls whether error information is reported to ECM, when address feedback error, ECC error and/or overflow error occurs.

This register is protected by the KCPROT register. When KCPROT.KCE = 0, it cannot be written. It can be written only when KCPROT.KCE = 1.

Value after reset: 0000 008B_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 40.81 CR_OVFCLR Register Contents

Bit Position	Bit Name	Function
31 to 2	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
1	SERROVFCLR1	Writing 1 to this bit clears SERROVF1 in CR_OVFSTR.
0	SERROVFCLR0	Writing 1 to this bit clears SERROVF0 in CR_OVFSTR.

40.3.6.13 CR_SERSTR — 1-bit Error Status Register

This register indicates whether ECC 1-bit error has occurred. The location and address of the error that is detected are stored in CR_nSEADR register when SEDFn flag is set. The SEDFn flag is set only when a unique ECC 1-bit error, which is different from previous errors stored in 1-bit error address registers, is detected while the SEDFn is “0”. If the newly detected error has the same address with errors already stored, this flag is not set.

This register can be cleared by SSTCLRn in CR_SSTCLR register.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

	—	—	—	—	—	—	—	—	SEDF07	SEDF06	SEDF05	SEDF04	SEDF03	SEDF02	SEDF01	SEDF00
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 40.82 CR_SERSTR Register Contents

Bit Position	Bit Name	Function
31 to 8	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
7	SEDF07	Indicates that an ECC 1-bit error was detected and error address is stored in CR_07SEADR register.
6	SEDF06	Indicates that an ECC 1-bit error was detected and error address is stored in CR_06SEADR register.
5	SEDF05	Indicates that an ECC 1-bit error was detected and error address is stored in CR_05SEADR register.
4	SEDF04	Indicates that an ECC 1-bit error was detected and error address is stored in CR_04SEADR register.
3	SEDF03	Indicates that an ECC 1-bit error was detected and error address is stored in CR_03SEADR register.
2	SEDF02	Indicates that an ECC 1-bit error was detected and error address is stored in CR_02SEADR register.
1	SEDF01	Indicates that an ECC 1-bit error was detected and error address is stored in CR_01SEADR register.
0	SEDF00	Indicates that an ECC 1-bit error was detected and error address is stored in CR_00SEADR register.

40.3.6.14 CR_DERSTR — Fatal Error Status Register

This register indicates whether an address feedback error and/or an ECC 2-bit error has occurred. The location and address of the error that is detected are stored in CR_00DEADR register when AFEF00 and/or DEDF00 flags are set. The AFEF00 and/or DEDF00 flag is set only when an address feedback error and/or an ECC 2-bit error is detected while all the flags are “0”. Multiple flags are set only when multiple errors occur due to one error cause.

This register can be cleared by DSTCLR00 in CR_DSTCLR register.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

	—	—	—	—	—	—	—	—	—	—	—	—	AFEF00	—	DEDF00	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 40.83 CR_DERSTR Register Contents

Bit Position	Bit Name	Function
31 to 4	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
3	AFEF00	Indicates that an address feedback error was detected.
2	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
1	DEDF00	Indicates that an ECC 2-bit error was detected.
0	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.

40.3.6.15 CR_OVFSTR — 1-bit Error Overflow Status Register

This register indicates whether overflow of address buffer or working memory has occurred.

SERROVF0 flag is set when a unique ECC 1-bit error that differs from previous errors in error address is detected when the address buffer is fully used. If the newly detected error has the same address as errors already stored, this flag is not set.

On the other hand, SERROVF1 flag is set when the number of times an ECC 1-bit error occurs at the same time regardless of the same occurrence address exceed the size of internal buffer.

SERROVF0 and SERROVF1 flags can be cleared by SERROVFCLR0 and SERROVFCLR1 in CR_OVFCLR register.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

	—	—	—	—	—	—	—	—	—	—	—	—	—	—	SERR OVF1	SERR OVF0
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 40.84 CR_OVFSTR Register Contents

Bit Position	Bit Name	Function
31 to 2	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
1	SERROVF1	Indicates that more ECC 1-bit errors than working memory were detected simultaneously.
0	SERROVF0	Indicates that a unique ECC 1-bit error was detected when all ECC 1bit error flags in CR_SERSTR are set.

40.3.6.16 CR_SERINF — 1-bit Error Location Information Register

This register is used to indicate summary of locations where ECC 1-bit errors stored in CR_SERSTR register were detected.

This register is updated whenever CR_SERSTR register is updated.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 40.85 CR_SERINF Register Contents (1/2)

Bit Position	Bit Name	Function
31 to 22	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
21	SEDLINF21	Indicates that an ECC 1-bit error was detected in upper address of Cluster RAM for cluster 2*1 during the RMW operation.
20	SEDLINF20	Indicates that an ECC 1-bit error was detected in lower address of Cluster RAM for cluster 2*1 during the RMW operation.
19	SEDLINF19	Indicates that an ECC 1-bit error was detected in upper address of Cluster RAM for cluster 1 during the RMW operation.
18	SEDLINF18	Indicates that an ECC 1-bit error was detected in lower address of Cluster RAM for cluster 1 during the RMW operation.
17	SEDLINF17	Indicates that an ECC 1-bit error was detected in upper address of Cluster RAM for cluster 0 during the RMW operation.
16	SEDLINF16	Indicates that an ECC 1-bit error was detected in lower address of Cluster RAM for cluster 0 during the RMW operation.
15, 14	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
13	SEDLINF13	Indicates that an ECC 1-bit error was detected in the data read from upper address of Cluster RAM to SAXI2MBI for cluster 2*1.
12	SEDLINF12	Indicates that an ECC 1-bit error was detected in the data read from lower address of Cluster RAM to SAXI2MBI for cluster 2*1.
11	SEDLINF11	Indicates that an ECC 1-bit error was detected in the data read from upper address of Cluster RAM to SAXI2MBI for cluster 1.
10	SEDLINF10	Indicates that an ECC 1-bit error was detected in the data read from lower address of Cluster RAM to SAXI2MBI for cluster 1.
9	SEDLINF09	Indicates that an ECC 1-bit error was detected in the data read from upper address of Cluster RAM to SAXI2MBI for cluster 0.
8	SEDLINF08	Indicates that an ECC 1-bit error was detected in the data read from lower address of Cluster RAM to SAXI2MBI for cluster 0.
7, 6	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
5	SEDLINF05	Indicates that an ECC 1-bit error was detected in the data read from Cluster RAM to PE5*1.

Table 40.85 CR_SERINF Register Contents (2/2)

Bit Position	Bit Name	Function
4	SEDLINF04	Indicates that an ECC 1-bit error was detected in the data read from Cluster RAM to PE4*1.
3	SEDLINF03	Indicates that an ECC 1-bit error was detected in the data read from Cluster RAM to PE3.
2	SEDLINF02	Indicates that an ECC 1-bit error was detected in the data read from Cluster RAM to PE2.
1	SEDLINF01	Indicates that an ECC 1-bit error was detected in the data read from Cluster RAM to PE1.
0	SEDLINF00	Indicates that an ECC 1-bit error was detected in the data read from Cluster RAM to PE0.

Note 1. This function is not implemented in E2H.

40.3.6.17 CR_nSEADR — n-th 1-bit Error Address Register (n = 00 to 07)

This register is used to hold the address and the location of the error when SEDFn flag is not set and an ECC 1-bit error is detected.

This register can only be cleared by reset.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 40.86 CR_nSEADR Register Contents

Bit Position	Bit Name	Function
31 to 27	SEDL[4:0]	Indicates where this error was detected.
26 to 21	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
20 to 2	SEADR0[20:2]	Indicates at which address this error was detected.
1, 0	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.

Please refer to the following table to confirm the detailed information which each SEDL indicates.

Table 40.87 SEDL information

SEDL[4:0]	Indicated information
31 to 22	Reserved
21	Indicates an ECC 1-bit error is detected in the following operation to bank 1 or 3 of Cluster RAM in cluster 2*1: Storing sub-word data by any master. CAXI operation by any PE master.
20	Indicates an ECC 1-bit error is detected in the following operation to bank 0 or 2 of Cluster RAM in cluster 2*1: Storing sub-word data by any master. CAXI operation by any PE master.
19	Indicates an ECC 1-bit error is detected in the following operation to bank 1 or 3 of Cluster RAM in cluster 1: Storing sub-word data by any master. CAXI operation by any PE master.
18	Indicates an ECC 1-bit error is detected in the following operation to bank 0 or 2 of Cluster RAM in cluster 1: Storing sub-word data by any master. CAXI operation by any PE master.
17	Indicates an ECC 1-bit error is detected in the following operation to bank 1 or 3 of Cluster RAM in cluster 0: Storing sub-word data by any master. CAXI operation by any PE master.
16	Indicates an ECC 1-bit error is detected in the following operation to bank 0 or 2 of Cluster RAM in cluster 0: Storing sub-word data by any master. CAXI operation by any PE master.
15 to 14	Reserved
13	Indicates an ECC 1-bit error is detected in the following operation to bank 1 or 3 of Cluster RAM in cluster 2*1: Loading data by any master except PEs. Fetching instructions by any PE master.
12	Indicates an ECC 1-bit error is detected in the following operation to bank 0 or 2 of Cluster RAM in cluster 2*1: Loading data by any master except PEs. Fetching instructions by any PE master.
11	Indicates an ECC 1-bit error is detected in the following operation to bank 1 or 3 of Cluster RAM in cluster 1: Loading data by any master except PEs. Fetching instructions by any PE master.
10	Indicates an ECC 1-bit error is detected in the following operation to bank 0 or 2 of Cluster RAM in cluster 1: Loading data by any master except PEs. Fetching instructions by any PE master.
9	Indicates an ECC 1-bit error is detected in the following operation to bank 1 or 3 of Cluster RAM in cluster 0: Loading data by any master except PEs. Fetching instructions by any PE master.
8	Indicates an ECC 1-bit error is detected in the following operation to bank 0 or 2 of Cluster RAM in cluster 0: Loading data by any master except PEs. Fetching instructions by any PE master.
7, 6	Reserved
5	Indicates an ECC 1-bit error is detected in loading data from Cluster RAMs by PE5*1 master.
4	Indicates an ECC 1-bit error is detected in loading data from Cluster RAMs by PE4*1 master.
3	Indicates an ECC 1-bit error is detected in loading data from Cluster RAMs by PE3 master.
2	Indicates an ECC 1-bit error is detected in loading data from Cluster RAMs by PE2 master.
1	Indicates an ECC 1-bit error is detected in loading data from Cluster RAMs by PE1 master.
0	Indicates an ECC 1-bit error is detected in loading data from Cluster RAMs by PE0 master.

Note 1. This function is not implemented in E2H.

40.3.6.18 CR_00DEADR — 1st Fatal Error Address Register

This register is used to hold the address and the location of the error when neither AFEF00 nor DEDF00 flag is set and an address feedback error and/or ECC 2-bit error was detected.

This register can only be cleared by reset.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 40.88 CR_00DEADR Register Contents

Bit Position	Bit Name	Function
31 to 27	DEDL[4:0]	Indicates where this error was detected.
26 to 21	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
20 to 2	DEADR0[20:2]	Indicates at which address this error was detected.
1, 0	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.

Please refer to the following table to confirm the detailed information which each DEDL indicates.

Table 40.89 DEDL Information

DEDL[4:0]	Indicated information
31 to 22	Reserved
21	Indicates a fatal error is detected in the following operation to bank 1 or 3 of Cluster RAM in cluster 2*1: Storing sub-word data by any master. CAXI operation by any PE master.
20	Indicates a fatal error is detected in the following operation to bank 0 or 2 of Cluster RAM in cluster 2*1: Storing sub-word data by any master. CAXI operation by any PE master.
19	Indicates a fatal error is detected in the following operation to bank 1 or 3 of Cluster RAM in cluster 1: Storing sub-word data by any master. CAXI operation by any PE master.
18	Indicates a fatal error is detected in the following operation to bank 0 or 2 of Cluster RAM in cluster 1: Storing sub-word data by any master. CAXI operation by any PE master.
17	Indicates a fatal error is detected in the following operation to bank 1 or 3 of Cluster RAM in cluster 0: Storing sub-word data by any master. CAXI operation by any PE master.
16	Indicates a fatal error is detected in the following operation to bank 0 or 2 of Cluster RAM in cluster 0: Storing sub-word data by any master. CAXI operation by any PE master.
15 to 14	Reserved
13	Indicates a fatal error is detected in the following operation to bank 1 or 3 of Cluster RAM in cluster 2*1: Loading data by any master except PEs. Fetching instructions by any PE master.
12	Indicates a fatal error is detected in the following operation to bank 0 or 2 of Cluster RAM in cluster 2*1: Loading data by any master except PEs. Fetching instructions by any PE master.
11	Indicates a fatal error is detected in the following operation to bank 1 or 3 of Cluster RAM in cluster 1: Loading data by any master except PEs. Fetching instructions by any PE master.
10	Indicates a fatal error is detected in the following operation to bank 0 or 2 of Cluster RAM in cluster 1: Loading data by any master except PEs. Fetching instructions by any PE master.
9	Indicates a fatal error is detected in the following operation to bank 1 or 3 of Cluster RAM in cluster 0: Loading data by any master except PEs. Fetching instructions by any PE master.
8	Indicates a fatal error is detected in the following operation to bank 0 or 2 of Cluster RAM in cluster 0: Loading data by any master except PEs. Fetching instructions by any PE master.
7, 6	Reserved
5	Indicates a fatal error is detected in loading data from Cluster RAMs by PE5*1 master.
4	Indicates a fatal error is detected in loading data from Cluster RAMs by PE4*1 master.
3	Indicates a fatal error is detected in loading data from Cluster RAMs by PE3 master.
2	Indicates a fatal error is detected in loading data from Cluster RAMs by PE2 master.
1	Indicates a fatal error is detected in loading data from Cluster RAMs by PE1 master.
0	Indicates a fatal error is detected in loading data from Cluster RAMs by PE0 master.

Note 1. This function is not implemented in E2H.

40.3.6.19 Test Function

(1) Writing RAM data

- (a) Set the ECCTST bit in the ECC Test Control Register to 1 to set test mode.
- (b) Set the corresponding DATSEL bit in the ECC Test Control Register to 0 to select RAM data for access when writing.
- (c) When data is written to the cluster RAM, the RAM data is modified without updating the ECC bits.

How to exit this test mode:

- (a) Set the ECCTST bit in the ECC Test Control Register to 0 to disable test mode (normal mode).

(2) Reading RAM data

- (a) Set the ECCDIS bit in the ECC Control Register to 1 to disable ECC error detection and correction.
- (b) Read the Cluster RAM. Since neither error detection nor correction proceeds when the Cluster RAM is read, the RAM data is read unchanged.

How to exit this test mode:

- (a) Set the ECCDIS bit in the ECC Control Register to 0 to enable ECC error detection and correction.

(3) Writing to the ECC bits

- (a) Set the ECCTST bit in the ECC Test Control Register to 1 to set test mode.
- (b) Set the corresponding DATSEL bit in the ECC Test Control Register to 1 to select the ECC bits for access when writing.
- (c) When data is written to the Cluster RAM, the ECC bits are modified without updating the RAM data. At that time, bits[6:0] are respectively written to the ECC bits.

How to exit this test mode:

- (a) Set the ECCTST bit in the ECC Test Control Register to 0 to disable test mode (normal mode).

(4) Reading the ECC bits

- (a) Set the ECCTST bit in the ECC Test Control Register to 1 to set test mode.
- (b) When the Cluster RAM is read, the ECC bits are stored in the word corresponding to cluster RAM ECC read buffer register.

How to exit this test mode:

- (a) Set the ECCTST bit in the ECC Test Control Register to 0 to disable test mode (normal mode).

(5) Self-diagnosis of the ECC check function

Desired values can be written to the RAM data, ECC bits by using the procedure described in (1) or (3) above. Therefore, a fault can be injected by, for example, inverting appropriate bits of the RAM data and/or ECC bits. After that, self-diagnosis of the ECC decoder is possible by reading the Cluster RAM in normal mode and checking the result of error correction or detection.

(6) Self-diagnosis of the address feedback check function

Self-diagnosis is enabled by following procedure below.

- (a) Set the desired bit(s) of AFINV in the Address Feedback Test Control Register to 1 to set test mode.
- (b) When the Cluster RAM is read or written, address feedback error occurs because feedback address XOR-ed with AFINV can be input to address feedback checker.

How to exit this test mode:

- (a) Set the AFINV bits in the Address Feedback Test Control Register all to 0 to disable test mode (normal mode).

40.3.7 Instruction Cache EDC and Address Feedback

40.3.7.1 Overview

The instruction cache EDC is summarized in the table below.

Table 40.90 Instruction Cache EDC

Item	Description
ECC error detection	<p>ECC error detection can be either enabled or disabled.</p> <p>When enabled, the following settings can be selected:</p> <ul style="list-style-type: none"> • ECC error detection is carried out (2-bit error detection and 1-bit error detection are carried out). <p>When disabled, error detection is not carried out.</p> <p>In the initial state, the ECC function is enabled; 1-bit error detection, and 2-bit error detection are carried out.</p>
Address feedback	<p>Address feedback check can be either enabled or disabled.</p> <p>When enabled, Address feedback error detection is carried out.</p> <p>When disabled, no error detection is carried out.</p> <p>In the initial state, this function is enabled.</p>
Error notification	<p>The occurrence of an ECC error or an address feedback error is reported to the Error Control Module.</p> <p>ECC Error:</p> <ul style="list-style-type: none"> • Error notification can be either enabled or disabled upon detection of an ECC 2-bit error. • Error notification can be either enabled or disabled upon detection of an ECC 1-bit error. <p>In the initial state, notification of both an ECC 2-bit error and an ECC 1-bit error is disabled.</p> <p>Address Feedback Error:</p> <ul style="list-style-type: none"> • Error notification can be either enabled or disabled upon detection of an address feedback error. <p>In the initial state, error notification is disabled upon detection of an address feedback error.</p> <p>The error notification signal is output with an ECC 2-bit error and an ECC 1-bit error handled as one source. An address feedback error is handled as individual source.</p> <p>An ECC error signal is only issued to the ECM if the ECC error address is not yet stored in the error address buffer.</p>
Error status	<p>A status register is provided that indicates the statuses of ECC 2-bit error detection, ECC 1-bit error detection and address feedback error detection. If an error occurs while no error status is set, the corresponding status is set.</p> <p>The error status can be cleared using the clear register.</p>
Address capture	<p>The address is captured when an ECC 2-bit error, an ECC 1-bit error or an address feedback error is detected. The error status serves as the enable bit of the captured address.</p> <p>If an ECC error occurs while no error status is set, the address at which the associated error occurred is captured.</p>
Self-diagnosis	<p>A cache instruction is used to write the desired values as RAM data and to the ECC bits.</p> <p>Similarly, data in the RAM and the ECC bits can be read directly.</p> <p>Since cache instructions go through the same encoding or decoding path as a normal cache fill or instruction fetch, errors can be both inserted and confirmed simply by using a cache instruction.</p> <p>Errors can also be injected into an address feedback checker by setting AFINV.</p>

40.3.7.2 Register Base Address

Base addresses of safety modules are listed in the following table. Each register address is given as an offset from the base addresses.

Table 40.91 Register Base Addresses

Base Address Name	Base Address	Bus Group
<ECCCNT_IT_PE0CL0_base>	FFC4 9000 _H	Peripheral Group 0
<ECCCNT_IT_PE1CL0_base>	FFC4 9080 _H	Peripheral Group 0
<ECCCNT_IT_PE2CL1_base>	FFC4 9100 _H	Peripheral Group 0
<ECCCNT_IT_PE3CL1_base>	FFC4 9180 _H	Peripheral Group 0
<ECCCNT_IT_PE4CL2_base>*1	FFC4 9200 _H	Peripheral Group 0
<ECCCNT_IT_PE5CL2_base>*1	FFC4 9280 _H	Peripheral Group 0
<ECCCNT_ID_PE0CL0_base>	FFC4 9400 _H	Peripheral Group 0
<ECCCNT_ID_PE1CL0_base>	FFC4 9480 _H	Peripheral Group 0
<ECCCNT_ID_PE2CL1_base>	FFC4 9500 _H	Peripheral Group 0
<ECCCNT_ID_PE3CL1_base>	FFC4 9580 _H	Peripheral Group 0
<ECCCNT_ID_PE4CL2_base>*1	FFC4 9600 _H	Peripheral Group 0
<ECCCNT_ID_PE5CL2_base>*1	FFC4 9680 _H	Peripheral Group 0
<MECCCAP_IT_PE0CL0_base>	FFC5 1000 _H	Peripheral Group 0
<MECCCAP_IT_PE1CL0_base>	FFC5 1100 _H	Peripheral Group 0
<MECCCAP_IT_PE2CL1_base>	FFC5 1200 _H	Peripheral Group 0
<MECCCAP_IT_PE3CL1_base>	FFC5 1300 _H	Peripheral Group 0
<MECCCAP_IT_PE4CL2_base>*1	FFC5 1400 _H	Peripheral Group 0
<MECCCAP_IT_PE5CL2_base>*1	FFC5 1500 _H	Peripheral Group 0
<MECCCAP_ID_PE0CL0_base>	FFC5 1800 _H	Peripheral Group 0
<MECCCAP_ID_PE1CL0_base>	FFC5 1900 _H	Peripheral Group 0
<MECCCAP_ID_PE2CL1_base>	FFC5 1A00 _H	Peripheral Group 0
<MECCCAP_ID_PE3CL1_base>	FFC5 1B00 _H	Peripheral Group 0
<MECCCAP_ID_PE4CL2_base>*1	FFC5 1C00 _H	Peripheral Group 0
<MECCCAP_ID_PE5CL2_base>*1	FFC5 1D00 _H	Peripheral Group 0

Note 1. This function is not implemented in E2H.

40.3.7.3 List of Registers

Table 40.92 List of Registers (1/2)

Module Name	Register Name	Symbol	Address	Access	Access Protection
ECCCNT_IT_PEnCL0 (n = 0, 1)	ECC Control Register	ITECCCTL	<ECCCNT_IT_PEnCL0_base> + 00 _H	8, 16, 32	KCPROT

	1st Fatal Error Address Register	ID_00DEADR	<MECCCAP_ID_PEnCL2_base> + F0 _H	32	

Note 1. This function is not implemented in E2H.

40.3.7.4 ITECCCTL — ECC Control Register

This register controls ECC error detection for data read from cache tag RAM and address feedback error detection for the address that is requested to cache tag RAM.

This register is protected by the KCPROT register. When KCPROT.KCE = 0, it cannot be written. It can be written only when KCPROT.KCE = 1.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Table 40.93 ITECCCTL Register Contents

Bit Position	Bit Name	Function
31 to 4	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
3	AFEDIS	Address feedback error disable bit Sets the address feedback error detection to enable/disable. 0: Address feedback error detection is enabled 1: Address feedback error detection is disabled
2, 1	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
0	ECCDIS	ECC disable bit Sets the ECC error detection to enable/disable. 0: ECC error detection is enabled 1: ECC error detection is disabled

40.3.7.5 ITAFINV — Address Feedback Test Control Register

This register is used to inject errors into the feedback address from cache tag RAM for self-diagnosis. Feedback address XOR-ed with AFINV can be input to address feedback checker.

This register is protected by the KCPROT register. When KCPROT.KCE = 0, it cannot be written. It can be written only when KCPROT.KCE = 1.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 40.95 IDECCCTL Register Contents

Bit Position	Bit Name	Function
31 to 4	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
3	AFEDIS	Address feedback error disable bit Sets the address feedback error detection to enable/disable. 0: Address feedback error detection is enabled 1: Address feedback error detection is disabled
2, 1	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
0	ECCDIS	ECC disable bit Sets the ECC error detection to enable/disable. 0: ECC error detection is enabled 1: ECC error detection is disabled

40.3.7.7 IDAFINV — Address Feedback Test Control Register

This register is used to inject errors into the feedback address from the cache data RAM for self-diagnosis. Feedback address XOR-ed with AFINV can be input to address feedback checker.

This register is protected by the KCPROT register. When KCPROT.KCE = 0, it cannot be written. It can be written only when KCPROT.KCE = 1.

Value after reset: 0000 0000_H

Table 40.96 IDAFINV Register Contents

Bit Position	Bit Name	Function
31 to 13	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
12 to 3	AFINV[12:3]	Specifies bit pattern to inject errors into feedback address.
2 to 0	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.

40.3.7.8 IT_ERRINT — Error Notification Control Register

This register controls whether error information is reported to ECM when an address feedback error, ECC error and/or overflow error occurs.

This register is protected by the KCPROT register. When KCPROT.KCE = 0, it cannot be written. It can be written only when KCPROT.KCE = 1.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 40.100 IT_OVFCLR Register Contents

Bit Position	Bit Name	Function
31 to 2	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
1	SERROVFCLR1	Writing 1 to this bit clears SERROVF1 in IT_OVFSTR.
0	SERROVFCLR0	Writing 1 to this bit clears SERROVF0 in IT_OVFSTR.

40.3.7.12 IT_SERSTR — 1-bit Error Status Register

This register indicates whether ECC 1-bit error has occurred. The location and address of the error that is detected are stored in IT_00SEADR register when SEDF00 flag is set. The SEDF00 flag is set only when an ECC 1-bit error is detected while the SEDF00 is “0”.

This register can be cleared by SSTCLR00 in IT_SSTCLR register.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 40.101 IT_SERSTR Register Contents

Bit Position	Bit Name	Function
31 to 1	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
0	SEDF00	Indicates that an ECC 1-bit error was detected.

40.3.7.13 IT_DERSTR — Fatal Error Status Register

This register indicates whether an address feedback error and/or an ECC 2-bit error has occurred. The location and address of the error that is detected are stored in IT_00DEADR register when AFEF00 and/or DEDF00 flags are set. The AFEF00 and/or DEDF00 flag is set only when an address feedback error and/or an ECC 2-bit error is detected while all the flags are “0”. Multiple flags are set only when multiple errors occur due to one error cause.

This register can be cleared by DSTCLR00 in IT_DSTCLR register.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	—	—	—	—	—	—	—	—	—	—	—	—	AFEF00	—	DEDF00	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 40.102 IT_DERSTR Register Contents

Bit Position	Bit Name	Function
31 to 4	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
3	AFEF00	Indicates that an address feedback error was detected.
2	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
1	DEDF00	Indicates that an ECC 2-bit error was detected.
0	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.

40.3.7.14 IT_OVFSTR — 1-bit Error Overflow Status Register

This register indicates whether overflow of address buffer or working memory has occurred.

SERROVF0 flag is set when a unique ECC 1-bit error that differs from previous errors in error address is detected when the address buffer is fully used. If the newly detected error has the same address as errors already stored, this flag is not set.

On the other hand, SERROVF1 flag is set when the number of times an ECC 1-bit error occurs at the same time regardless of the same occurrence address exceed the size of internal buffer.

SERROVF0 and SERROVF1 flags can be cleared by SERROVFCLR0 and SERROVFCLR1 in IT_OVFCLR register.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Table 40.103 IT_OVFSTR Register Contents

Bit Position	Bit Name	Function
31 to 2	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
1	SERROVF1	Indicates that more ECC 1-bit errors than working memory were detected simultaneously.
0	SERROVF0	Indicates that a unique ECC 1-bit error was detected when SEDF00 was already set.

40.3.7.15 IT_SERINF — 1-bit Error Location Information Register

This register is used to indicate summary of locations where ECC 1-bit errors stored in IT_SERSTR register were detected.

This is up-to-date whenever IT_SERSTR register is updated.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 40.104 IT_SERINF Register Contents

Bit Position	Bit Name	Function
31 to 4	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
3	SEDLINF03	Indicates that an ECC 1-bit error was detected in way 3 of cache tag RAM.
2	SEDLINF02	Indicates that an ECC 1-bit error was detected in way 2 of cache tag RAM.
1	SEDLINF01	Indicates that an ECC 1-bit error was detected in way 1 of cache tag RAM.
0	SEDLINF00	Indicates that an ECC 1-bit error was detected in way 0 of cache tag RAM.

40.3.7.16 IT_00SEADR — 1st 1-bit Error Address Register

This register is used to hold the address and the location of the error when SEDF00 flag is not set and an ECC 1-bit error is detected.

This register can only be cleared by reset.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 40.105 IT_00SEADR Register Contents

Bit Position	Bit Name	Function
31 to 27	SEDL[4:0]	Indicates where this error was detected.
26 to 13	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
12 to 5	SEADR0[12:5]	Indicates at which address this error was detected.
4 to 0	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.

Please refer to the following table to confirm the detailed information which each SEDL indicates.

Table 40.106 SEDL information

SEDL[4:0]	Indicated information
31 to 4	Reserved
3	Indicates an ECC 1-bit error is detected in storing data to or loading data from way 3 of cache tag RAM.
2	Indicates an ECC 1-bit error is detected in storing data to or loading data from way 2 of cache tag RAM.
1	Indicates an ECC 1-bit error is detected in storing data to or loading data from way 1 of cache tag RAM.
0	Indicates an ECC 1-bit error is detected in storing data to or loading data from way 0 of cache tag RAM.

40.3.7.17 IT_00DEADR — 1st Fatal Error Address Register

This register is used to hold the address and the location of the error when neither AFEF00 nor DEDF00 flag is set and an address feedback error and/or ECC 2-bit error is detected.

This register can only be cleared by reset.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 40.107 IT_00DEADR Register Contents

Bit Position	Bit Name	Function
31 to 27	DEDL[4:0]	Indicates where this error was detected.
26 to 13	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
12 to 5	DEADR0[12:5]	Indicates at which address this error was detected.
4 to 0	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.

Please refer to the following table to confirm the detailed information which each DEDL indicates.

Table 40.108 DEDL Information

DEDL[4:0]	Indicated information
31 to 4	Reserved
3	Indicates a fatal error is detected in storing data to or loading data from way 3 of cache tag RAM.
2	Indicates a fatal error is detected in storing data to or loading data from way 2 of cache tag RAM.
1	Indicates a fatal error is detected in storing data to or loading data from way 1 of cache tag RAM.
0	Indicates a fatal error is detected in storing data to or loading data from way 0 of cache tag RAM.

40.3.7.18 ID_ERRINT — Error Notification Control Register

This register controls whether error information is reported to the ECM when address feedback error, ECC error and/or overflow error occurs.

This register is protected by the KCPROT register. When KCPROT.KCE = 0, it cannot be written. It can be written only when KCPROT.KCE = 1.

Value after reset: 0000 0000_H

Table 40.112 ID_OVFCLR Register Contents

Bit Position	Bit Name	Function
31 to 2	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
1	SERROVFCLR1	Writing 1 to this bit clears SERROVF1 in ID_OVFSTR.
0	SERROVFCLR0	Writing 1 to this bit clears SERROVF0 in ID_OVFSTR.

40.3.7.22 ID_SERSTR — 1-bit Error Status Register

This register indicates whether ECC 1-bit error has occurred. The location and address of the error that is detected are stored in ID_00SEADR register when SEDF00 flag is set. The SEDF00 flag is set only when an ECC 1-bit error is detected while the SEDF00 is “0”.

This register can be cleared by SSTCLR00 in ID_SSTCLR register.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Table 40.113 ID_SERSTR Register Contents

Bit Position	Bit Name	Function
31 to 1	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
0	SEDF00	Indicates an ECC 1-bit error is detected.

40.3.7.23 ID_DERSTR — Fatal Error Status Register

This register indicates whether an address feedback error and/or an ECC 2-bit error has occurred. The location and address of the error that is detected are stored in ID_00DEADR register when AFEF00 and/or DEDF00 flags are set. The AFEF00 and/or DEDF00 flag is set only when an address feedback error and/or an ECC 2-bit error is detected while all the flags are “0”. Multiple flags are set only when multiple errors occur due to one error cause.

This register can be cleared by DSTCLR00 in ID_DSTCLR register.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Table 40.114 ID_DERSTR Register Contents

Bit Position	Bit Name	Function
31 to 4	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
3	AFEF00	Indicates that address feedback error was detected.
2	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
1	DEDF00	Indicates that an ECC 2-bit error was detected.
0	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.

40.3.7.24 ID_OVFSTR — 1-bit Error Overflow Status Register

This register indicates whether overflow of address buffer or working memory has occurred.

SERROVF0 flag is set when a unique ECC 1-bit error that differs from previous errors in error address is detected when the address buffer is fully used. If the newly detected error has the same address as errors already stored, this flag is not set.

On the other hand, SERROVF1 flag is set when the number of times an ECC 1-bit error occurs at the same time regardless of the same occurrence address exceed the size of internal buffer.

SERROVF0 and SERROVF1 flags can be cleared by SERROVFCLR0 and SERROVFCLR1 in ID_OVFCLR register respectively.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Table 40.115 ID_OVFSTR Register Contents

Bit Position	Bit Name	Function
31 to 2	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
1	SERROVF1	Indicates that more ECC 1-bit errors than working memory were detected simultaneously.
0	SERROVF0	Indicates that a unique ECC 1-bit error was detected when SEDF00 was already set.

40.3.7.25 ID_SERINF — 1-bit Error Location Information Register

This register is used to indicate summary of locations where ECC 1-bit errors stored in ID_SERSTR register were detected.

This is up-to-date whenever ID_SERSTR register is updated.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit Position	Bit Name	Function
31 to 4	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
3	SEDLINF03	Indicates that an ECC 1-bit error was detected in way 3 of the cache data RAM.
2	SEDLINF02	Indicates that an ECC 1-bit error was detected in way 2 of the cache data RAM.
1	SEDLINF01	Indicates that an ECC 1-bit error was detected in way 1 of the cache data RAM.
0	SEDLINF00	Indicates that an ECC 1-bit error was detected in way 0 of the cache data RAM.

40.3.7.26 ID_00SEADR — 1st 1-bit Error Address Register

This register is used to hold the address and the location of the error when SEDF00 flag is not set and an ECC 1-bit error is detected.

This register can only be cleared by reset.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 40.117 ID_00SEADR Register Contents

Bit Position	Bit Name	Function
31 to 27	SEDL[4:0]	Indicates where this error was detected.
26 to 13	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
12 to 3	SEADR0[12:3]	Indicates at which address this error was detected.
2 to 0	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.

Please refer to the following table to confirm the detailed information which each SEDL indicates.

Table 40.118 SEDL information

SEDL[4:0]	Indicated information
31 to 4	Reserved
3	Indicates an ECC 1-bit error is detected in storing data to or loading data from way 3 of cache data RAM.
2	Indicates an ECC 1-bit error is detected in storing data to or loading data from way 2 of cache data RAM.
1	Indicates an ECC 1-bit error is detected in storing data to or loading data from way 1 of cache data RAM.
0	Indicates an ECC 1-bit error is detected in storing data to or loading data from way 0 of cache data RAM.

40.3.7.27 ID_00DEADR — 1st Fatal Error Address Register

This register is used to hold the address and the location of the error when neither AFEF00 nor DEDF00 flag is set and an address feedback error and/or ECC 2-bit error is detected.

This register can only be cleared by reset.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 40.119 ID_00DEADR Register Contents

Bit Position	Bit Name	Function
31 to 27	DEDL[4:0]	Indicates where this error was detected.
26 to 13	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
12 to 3	DEADR0[12:3]	Indicates at which address this error was detected.
2 to 0	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.

Please refer to the following table to confirm the detailed information which each DEDL indicates.

Table 40.120 DEDL Information

DEDL[4:0]	Indicated information
31 to 4	Reserved
3	Indicates a fatal error is detected in storing data to or loading data from way 3 of cache data RAM.
2	Indicates a fatal error is detected in storing data to or loading data from way 2 of cache data RAM.
1	Indicates a fatal error is detected in storing data to or loading data from way 1 of cache data RAM.
0	Indicates a fatal error is detected in storing data to or loading data from way 0 of cache data RAM.

40.3.7.28 Test Function

A cache instruction is used to write the desired values as RAM data and to the ECC bits, and read data in the RAM and the ECC bits directly.

Since cache instructions go through the same encoding or decoding path as a normal cache fill or instruction fetch, errors can be both inserted and confirmed simply by using a cache instruction.

For details, refer to *the RH850G4MH User's Manual: Software*.

40.3.8 sDMAC/DTS RAM ECC and Address Feedback

40.3.8.1 Overview

sDMAC RAM ECC is summarized in the table below.

Table 40.121 sDMAC RAM ECC

Item	Description
ECC error detection and correction	<p>ECC error detection and correction can be either enabled or disabled.</p> <p>When enabled, either of the following settings can be selected:</p> <ul style="list-style-type: none"> • ECC error detection and correction are carried out (2-bit error detection, and 1-bit error detection and correction are carried out). • ECC error detection is carried out (2-bit error detection and 1-bit error detection are carried out). <p>When disabled, neither error detection nor correction is carried out.</p> <p>In the initial state, the ECC function is enabled; 1-bit error detection and correction, and 2-bit error detection are carried out.</p>
Error notification	<p>The occurrence of an ECC error is reported to the Error Control Module.</p> <p>ECC Error:</p> <ul style="list-style-type: none"> • Error notification can be either enabled or disabled upon detection of an ECC 2-bit error. • Error notification can be either enabled or disabled upon detection of an ECC 1-bit error. <p>In the initial state, notification of both a 2-bit error and a 1-bit error is enabled.</p> <p>Overflow Error:</p> <ul style="list-style-type: none"> • Error notification can be either enabled or disabled upon detection of an address buffer overflow error for ECC 1-bit error. <p>In the initial state, error notification is enabled upon detection of an address buffer overflow error.</p> <p>An ECC 2-bit error, an ECC 1-bit error and an overflow error are handled as individual sources. An ECC 1-bit error signal is only issued to the ECM if the ECC 1-bit error address is not yet stored in the error address buffer.</p>
Error status	<p>A status register is provided that indicates the statuses of ECC 2-bit error detection and ECC 1-bit error detection. If an error occurs while no error status is set, the corresponding status is set. The error status can be cleared using the clear register.</p>
Address capture	<p>The address is captured when an ECC 2-bit error or an ECC 1-bit error is detected. The error status serves as the enable bit of the captured address.</p> <p>ECC 1-bit error: One stage ECC 2-bit error: One stage</p>
Self-diagnosis	<p>Desired values can be written to the RAM data and the ECC bits in sDMAC RAM in ECC Test Mode.</p> <p>The RAM data and the ECC bits in sDMAC RAM can be also read via Read Buffer Registers in this mode.</p>

DTS RAM ECC is summarized in the table below.

Table 40.122 DTS RAM ECC

Item	Description
ECC error detection and correction	<p>ECC error detection and correction can be either enabled or disabled.</p> <p>When enabled, either of the following settings can be selected.</p> <ul style="list-style-type: none"> • ECC error detection and correction are carried out (2-bit error detection, 1-bit error detection and correction are carried out). • ECC error detection is carried out (2-bit error detection and 1-bit error detection are carried out). <p>When disabled, neither error detection nor correction is carried out.</p> <p>In the initial state, the ECC function is enabled; 1-bit error detection and correction, and 2-bit error detection are carried out.</p>
Address feedback	<p>Address feedback check can be either enabled or disabled.</p> <p>When enabled, Address feedback error detection is carried out.</p> <p>When disabled, no error detection is carried out.</p> <p>In the initial state, this function is enabled.</p>
Error notification	<p>The occurrence of an ECC error or an address feedback error is reported to the Error Control Module.</p> <p>ECC Error:</p> <ul style="list-style-type: none"> • Error notification can be either enabled or disabled upon detection of an ECC 2-bit error. • Error notification can be either enabled or disabled upon detection of an ECC 1-bit error. <p>In the initial state, notification of both a 2-bit error and a 1-bit error is enabled.</p> <p>Address Feedback Error:</p> <ul style="list-style-type: none"> • Error notification can be either enabled or disabled upon detection of an address feedback error. <p>In the initial state, error notification is enabled upon detection of an address feedback error.</p> <p>Overflow Error:</p> <ul style="list-style-type: none"> • Error notification can be either enabled or disabled upon detection of an address buffer overflow error for ECC 1-bit error. <p>In the initial state, error notification is enabled upon detection of an address buffer overflow error.</p> <p>The error notification signal is output with an ECC 2-bit error and an address feedback error handled as one source, and an ECC 1-bit error and an overflow error are handled as individual sources. An ECC 1-bit error signal is only issued to the ECM, if the ECC 1-bit error address is not yet stored in the error address buffer.</p>
Error status	<p>A status register is provided that indicates the statuses of ECC 2-bit error detection, ECC 1-bit error detection, and address feedback error detection. If an error occurs while no error status is set, the corresponding status is set. The error status can be cleared using the clear register.</p>
Address capture	<p>The address is captured when an ECC 2-bit error, an ECC 1-bit error, or an address feedback error is detected. The error status serves as the enable bit of the capture address.</p> <p>ECC 1-bit error: One stage</p> <p>ECC 2-bit error and address feedback error: One stage</p>
Self-diagnosis	<p>Desired values can be written to the RAM data and the ECC bits in DTS RAM in ECC Test Mode.</p> <p>The RAM data and the ECC bits in DTS RAM can be also read via Read Buffer Registers in this mode.</p> <p>Moreover, the error injection to an address feedback checker is possible by setting AFINV.</p>

40.3.8.2 Register Base Address

Base addresses of safety modules are listed in the following table. Each register address is given as offset from the base addresses.

Table 40.123 Register Base Addresses

Base Address Name	Base Address	Bus Group
<ECCCNT_DTS_base>	FFC4 A000 _H	Peripheral Group 0
<ECCCNT_DMDE0_base>	FFC4 A400 _H	Peripheral Group 0
<ECCCNT_DMDA0_base>	FFC4 A480 _H	Peripheral Group 0
<ECCCNT_DMDE1_base>	FFC4 A500 _H	Peripheral Group 0
<ECCCNT_DMDA1_base>	FFC4 A580 _H	Peripheral Group 0
<MECCCAP_DTS_base>	FFC5 2600 _H	Peripheral Group 0
<MECCCAP_DMDE0_base>	FFC5 2800 _H	Peripheral Group 0
<MECCCAP_DMDA0_base>	FFC5 2900 _H	Peripheral Group 0
<MECCCAP_DMDE1_base>	FFC5 2A00 _H	Peripheral Group 0
<MECCCAP_DMDA1_base>	FFC5 2B00 _H	Peripheral Group 0

40.3.8.3 List of Registers

Table 40.124 List of Registers (1/2)

Module Name	Register Name	Symbol	Address	Access	Access Protection
ECCCNT_DTS	ECC Control Register	DRECCCTL	<ECCCNT_DTS_base> + 00 _H	8, 16, 32	KCPROT

Note: The initial characters of DTS/sDMAC register symbols indicates the followings.

DR: DTS RAM

DE: Descriptor RAM of sDMAC

DA: Data RAM of sDMAC

40.3.8.4 DRECCCTL — ECC Control Register

This register controls ECC error detection/correction and 1-bit error correction for data read from DTS RAM and address feedback error detection for the address that is requested to DTS RAM.

This register is protected by the KCPROT register. When KCPROT.KCE = 0, it cannot be written. It can be written only when KCPROT.KCE = 1.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 40.125 DRECCCTL Register Contents

Bit Position	Bit Name	Function
31 to 4	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
3	AFEDIS	Address feedback error disable bit Sets the address feedback error detection to enable/disable. 0: Address feedback error detection is enabled 1: Address feedback error detection is disabled
2	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
1	SECDIS	ECC 1-bit error correction enable bit When using ECC error detection/correction (ECCDIS = 0), this bit sets 1-bit error correction to enable/disable. 0: Correct when 1-bit error is detected 1: Do not correct when 1-bit error is detected
0	ECCDIS	ECC disable bit Sets the ECC error detection/correction to enable/disable. 0: ECC error detection/correction is enabled 1: ECC error detection/correction is disabled

40.3.8.5 DRECCTSTCTL — ECC Test Control Register

ECC test (self-diagnostics) register. After setting the ECC test mode (ECCTST = 1), arbitrary data value can be written to data field and ECC field of DTS RAM.

This register is protected by the KCPROT register. When KCPROT.KCE = 0, it cannot be written. It can be written only when KCPROT.KCE = 1.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Table 40.126 DRECCTSTCTL Register Contents

Bit Position	Bit Name	Function
31 to 2	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
1	ECCTST	Selects input data for DTS RAM. 0: Normal mode 1: Test mode The values of DRECCTSTDIN0 and DRECCTSTEIN registers are written to data and ECC fields of DTS RAM when writing in test mode.
0	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.

40.3.8.6 DRAFINV — Address Feedback Test Control Register

This register is used to inject errors into the feedback address from DTS RAM for self-diagnosis. Feedback address XOR-ed with AFINV can be input to address feedback checker.

This register is protected by the KCPROT register. When KCPROT.KCE = 0, it cannot be written. It can be written only when KCPROT.KCE = 1.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 40.127 DRAFINV Register Contents

Bit Position	Bit Name	Function
31 to 12	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
11 to 2	AFINV[11:2]	Specifies bit pattern to inject errors into feedback address.
1, 0	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.

40.3.8.7 DRECCTSTDIN0 — Test Data Input Register

This register is used to inject errors into data field of DTS RAM for self-diagnosis. The values of DRECCTSTDIN0 and DRECCTSTEIN registers are written to the requested address when write operation to DTS RAM occurs in test mode.

This register is protected by the KCPROT register. When KCPROT.KCE = 0, it cannot be written. It can be written only when KCPROT.KCE = 1.

Value after reset: 0000 0000_H

Table 40.128 DRECCTSTDIN0 Register Contents

Bit Position	Bit Name	Function
31 to 0	DATA[31:0]	Specify the test data for DTS RAM. The data is provided to data field of DTS RAM when ECCTST = 1.

40.3.8.8 DRECCTSTEIN — Test ECC Input Register

This register is used to inject errors into ECC field of DTS RAM for self-diagnosis. The values of DRECCTSTDIN0 and DRECCTSTEIN registers are written to the requested address when write operation to DTS RAM occurs in test mode.

This register is protected by the KCPROT register. When KCPROT.KCE = 0, it cannot be written. It can be written only when KCPROT.KCE = 1.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 40.139 DAECCTSTCTL Register Contents

Bit Position	Bit Name	Function
31 to 2	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
1	ECCTST	Selects input data for Data RAM of sDMAC. 0: Normal mode 1: Test mode The values of DAECCTSTDIN0, DAECCTSTDIN1 and DAECCTSTEIN registers are written to data and ECC field for Data RAM of sDMAC when buffering transfer data in test mode.
0	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.

40.3.8.19 DAECCTSTDIN0 — Test Lower Data Input Register

This register is used to inject errors into lower data field of Data RAM of sDMAC for self-diagnosis. The values of DAECCTSTDIN0, DAECCTSTDIN1 and DAECCTSTEIN registers are written to the requested address when write operation to Data RAM occurs in test mode.

This register is protected by the KCPROT register. When KCPROT.KCE = 0, it cannot be written. It can be written only when KCPROT.KCE = 1.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

7 to 0	BFEC0[7:0]	ECC field read from the requested address in Data RAM

40.3.8.25 DR_ERRINT — Error Notification Control Register

This register controls whether error information is reported to ECM, when address feedback error, ECC error and/or overflow error occurs.

This register is protected by the KCPROT register. When KCPROT.KCE = 0, it cannot be written. It can be written only when KCPROT.KCE = 1.

Value after reset: 0000 008B_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 40.149 DR_OVFCLR Register Contents

Bit Position	Bit Name	Function
31 to 2	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
1	SERROVFCLR1	Writing 1 to this bit clears SERROVF1 in DR_OVFSTR.
0	SERROVFCLR0	Writing 1 to this bit clears SERROVF0 in DR_OVFSTR.

40.3.8.29 DR_SERSTR — 1-bit Error Status Register

This register indicates whether ECC 1-bit error has occurred. The location and address of the error that is detected are stored in DR_00SEADR register when SEDF00 flag is set. The SEDF00 flag is set only when an ECC 1-bit error is detected while the SEDF00 is “0”.

This register can be cleared by SSTCLR00 in DR_SSTCLR register.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 40.150 DR_SERSTR Register Contents

Bit Position	Bit Name	Function
31 to 1	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
0	SEDF00	Indicates that ECC 1-bit error was detected.

40.3.8.30 DR_DERSTR — Fatal Error Status Register

This register indicates whether an address feedback error and/or an ECC 2-bit error has occurred. The location and address of the error that is detected are stored in DR_00DEADR register when AFEF00 and/or DEDF00 flags are set. The AFEF00 and/or DEDF00 flag is set only when an address feedback error and/or an ECC 2-bit error is detected while all the flags are “0”. Multiple flags are set only when multiple errors occur due to one error cause.

This register can be cleared by DSTCLR00 in DR_DSTCLR register.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 40.151 DR_DERSTR Register Contents

Bit Position	Bit Name	Function
31 to 4	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
3	AFEF00	Indicates that address feedback error was detected.
2	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
1	DEDF00	Indicates that ECC 2-bit error was detected.
0	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.

40.3.8.31 DR_OVFSTR — 1-bit Error Overflow Status Register

This register indicates whether overflow of address buffer or working memory has occurred.

SERROVF0 flag is set when a unique ECC 1-bit error that differs from previous errors in error address is detected when the address buffer is fully used. If the newly detected error has the same address as errors already stored, this flag is not set.

On the other hand, SERROVF1 flag is set when the number of times an ECC 1-bit error occurs at the same time regardless of the same occurrence address exceed the size of internal buffer.

SERROVF0 and SERROVF1 flag can be cleared by SERROVFCLR0 and SERROVFCLR1 in DR_OVFCLR register respectively.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Table 40.152 DR_OVFSTR Register Contents

Bit Position	Bit Name	Function
31 to 2	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
1	SERROVF1	Indicates that more ECC 1-bit errors than working memory were detected simultaneously.
0	SERROVF0	Indicates that a unique ECC error was detected when SEDF00 was already set.

40.3.8.32 DR_SERINF — 1-bit Error Location Information Register

This register is used to indicate summary of locations where ECC 1-bit errors stored in DR_SERSTR register were detected.

This register is updated whenever DR_SERSTR register is updated.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 40.154 DR_00SEADR Register Contents

Bit Position	Bit Name	Function
31 to 27	SEDL[4:0]	Indicates where this error was detected.
26 to 12	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
11 to 2	SEADR0[11:2]	Indicates at which address this error was detected.
1, 0	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.

Table 40.155 SEDL Information

Values	Function
31 to 1	These values are reserved.
0	Indicates an ECC 1bit error is detected in storing data to or loading data from DTS RAM.

40.3.8.34 DR_00DEADR — 1st Fatal Error Address Register

This register is used to hold the address and the location of the error when neither AFEF00 nor DEDF00 flag is set and an address feedback error and/or ECC 2-bit error is detected.

This register can only be cleared by reset.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 40.156 DR_00DEADR Register Contents

Bit Position	Bit Name	Function
31 to 27	DEDL[4:0]	Indicates where this error was detected.
26 to 12	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
11 to 2	DEADR0[11:2]	Indicates at which address this error was detected.
1, 0	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.

Please refer to the following table to confirm the detailed information which each DEDL indicates.

Table 40.157 DEDL Information

Values	Function
31 to 1	These values are reserved.
0	Indicates a fatal error is detected in storing data to or loading data from DTS RAM.

40.3.8.35 DE_ERRINT — Error Notification Control Register

This register controls whether error information is reported to ECM, when ECC error and/or overflow error occurs.

This register is protected by the KCPROT register. When KCPROT.KCE = 0, it cannot be written. It can be written only when KCPROT.KCE = 1.

Value after reset: 0000 0083_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 40.161 DE_OVFCLR Register Contents

Bit Position	Bit Name	Function
31 to 2	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
1	SERROVFCLR1	Writing 1 to this bit clears SERROVF1 in DE_OVFSTR.
0	SERROVFCLR0	Writing 1 to this bit clears SERROVF0 in DE_OVFSTR.

40.3.8.39 DE_SERSTR — 1-bit Error Status Register

This register indicates whether ECC 1-bit error has occurred. The location and address of the error that is detected are stored in DE_00SEADR register when SEDF00 flag is set. The SEDF00 flag is set only when an ECC 1-bit error is detected while the SEDF00 is “0”.

This register can be cleared by SSTCLR00 in DE_SSTCLR register.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 40.162 DE_SERSTR Register Contents

Bit Position	Bit Name	Function
31 to 1	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
0	SEDF00	Indicates that ECC 1-bit error was detected.

40.3.8.40 DE_DERSTR — Fatal Error Status Register

This register indicates whether ECC 2-bit error has occurred. The location and the address of the error that is detected are stored in DE_00DEADR register when DEDF00 flag is set. The DEDF00 flag is set only when an ECC 2-bit error is detected while the DEDF00 is “0”.

This register can be cleared by DSTCLR00 in DE_DSTCLR register.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 40.163 DE_DERSTR Register Contents

Bit Position	Bit Name	Function
31 to 2	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
1	DEDF00	Indicates that ECC 2-bit error was detected.
0	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.

40.3.8.41 DE_OVFSTR — 1-bit Error Overflow Status Register

This register indicates whether overflow of address buffer or working memory has occurred.

SERROVF0 flag is set when a unique ECC 1-bit error that differs from previous errors in error address is detected when the address buffer is fully used. If the newly detected error has the same address as errors already stored, this flag is not set.

On the other hand, SERROVF1 flag is set when the number of times an ECC 1-bit error occurs at the same time regardless of the same occurrence address exceed the size of internal buffer.

SERROVF0 and SERROVF1 flags can be cleared by SERROVFCLR0 and SERROVFCLR1 in DE_OVFCLR register.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

	—	—	—	—	—	—	—	—	—	—	—	—	—	—	SERR OVF1	SERR OVF0
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 40.164 DE_OVFSTR Register Contents

Bit Position	Bit Name	Function
31 to 2	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
1	SERROVF1	Indicates that more ECC 1-bit errors than working memory were detected simultaneously.
0	SERROVF0	Indicates that a unique ECC 1-bit error was detected when SEDF00 was already set.

40.3.8.42 DE_SERINF — 1-bit Error Location Information Register

This register is used to indicate summary of locations where ECC 1-bit errors stored in DE_SERSTR register were detected.

This register is updated whenever DE_SERSTR register is updated.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Table 40.173 DA_OVFCLR Register Contents

Bit Position	Bit Name	Function
31 to 2	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
1	SERROVFCLR1	Writing 1 to this bit clears SERROVF1 in DA_OVFSTR.
0	SERROVFCLR0	Writing 1 to this bit clears SERROVF0 in DA_OVFSTR.

40.3.8.49 DA_SERSTR — 1-bit Error Status Register

This register indicates whether ECC 1-bit error has occurred. The location and address of the error that is detected are stored in DA_00SEADR register when SEDF00 flag is set. The SEDF00 flag is set only when an ECC 1-bit error is detected while the SEDF00 is “0”.

This register can be cleared by SSTCLR00 in DA_SSTCLR register.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Table 40.174 DA_SERSTR Register Contents

Bit Position	Bit Name	Function
31 to 1	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
0	SEDF00	Indicates that ECC 1-bit error was detected.

40.3.8.50 DA_DERSTR — Fatal Error Status Register

This register indicates whether ECC 2-bit error has occurred. The location and address of the error that is detected are stored in DA_00DEADR register when DEDF00 flag is set. The DEDF00 flag is set only when an ECC 2-bit error is detected while the DEDF00 is “0”.

This register can be cleared by DSTCLR00 in DA_DSTCLR register.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 40.175 DA_DERSTR Register Contents

Bit Position	Bit Name	Function
31 to 2	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
1	DEDF00	Indicates that ECC 2-bit error was detected.
0	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.

40.3.8.51 DA_OVFSTR — 1-bit Error Overflow Status Register

This register indicates whether overflow of address buffer or working memory has occurred.

SERROVF0 flag is set when a unique ECC 1-bit error that differs from previous errors in error address is detected when the address buffer is fully used. If the newly detected error has the same address as errors already stored, this flag is not set.

On the other hand, SERROVF1 flag is set when the number of times an ECC 1-bit error occurs at the same time regardless of the same occurrence address exceed the size of internal buffer.

SERROVF0 and SERROVF1 flag can be cleared by SERROVFCLR0 and SERROVFCLR1 in DA_OVFCLR register respectively.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 40.176 DA_OVFSTR Register Contents

Bit Position	Bit Name	Function
31 to 2	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
1	SERROVF1	Indicates that more ECC 1-bit errors than the working memory were detected simultaneously.
0	SERROVF0	Indicates that a unique ECC 1-bit error was detected when SEDF00 was already set.

40.3.8.52 DA_SERINF — 1-bit Error Location Information Register

This register is used to indicate summary of locations where ECC 1-bit errors stored in DA_SERSTR register were detected.

This register is updated whenever DA_SERSTR register is updated.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 40.180 DA_00DEADR Register Contents

Bit Position	Bit Name	Function
31 to 27	DEDL[4:0]	Indicates where this error was detected.
26 to 11	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
10 to 3	DEADR0[10:3]	Indicates at which address this error was detected.
2 to 0	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.

Please refer to the following table to confirm the detailed information which each DEDL indicates.

Table 40.181 DEDL Information

Values	Function
31 to 1	These values are reserved.
0	Indicates a fatal error is detected in storing data to or loading data from Data RAM of sDMAC.

40.3.8.55 Test Function

(1) DTS RAM ECC

The ECC of the DTS RAM can be tested by using the following procedure:

1. Make sure that the RAM address to be tested is not modified by any ongoing DTS transfer. It is recommended to disable DTS entirely.
2. Write data to any DTS RAM address.
3. Write 0x02 to the DTS RAM ECC Test Control Register (DRECCTSTCTL). Enable ECC Test Mode and encode ECC from write data.
4. Read data from the same DTS RAM address.
5. Check Data and ECC field by using the Data Read Buffer Register (DRTDATBFDATAF0) and ECC Read Buffer Register (DRTDATBFECCECF).
6. Restore DTS RAM data and ECC with 1-bit or 2-bit errors by using the Test Data Input Register (DRECCTSTDIN0) or the Test ECC Input Register (DRECCTSTEIN).
7. Write data to the same DTS RAM address.
8. Write 0x00 to the DTS RAM ECC Test Control Register (DRECCTSTCTL). Then, Read data from the same DTS RAM address and check if ECC error occurs.

(2) sDMAC Descriptor RAM ECC

The ECC of the sDMAC Descriptor RAM can be tested by using the following procedure:

1. Make sure that the RAM address to be tested is not modified by any ongoing sDMAC transfer. It is recommended to disable sDMAC entirely.
2. Write data to any sDMAC Descriptor RAM address.
3. Write 0x02 to the sDMAC Descriptor RAM ECC Test Control Register (DEECCTSTCTL). Enable ECC Test Mode and encode ECC from write data.
4. Read data from the same sDMAC Descriptor RAM address.
5. Check Data and ECC field by using the Data Read Buffer Register (DETDATBFDATAF0) and ECC Read Buffer Register (DETDATBFECCECF).
6. Restore sDMAC Descriptor RAM data and ECC with 1-bit or 2-bit errors by using the Test Data Input Register (DEECCTSTDIN0) or the Test ECC Input Register (DEECCTSTEIN).
7. Write data to the same sDMAC Descriptor RAM address.
8. Write 0x00 to the sDMAC Descriptor RAM ECC Test Control Register (DEECCTSTCTL). Then, Read data from the same sDMAC Descriptor RAM address and check if ECC error occurs.

(3) sDMAC Data RAM ECC

The ECC of the sDMAC Data RAM can be tested by using ECC calculation of ERRGEN. For details, see **Section 40.3.12.8, Usage of ERRGEN**.

40.3.9 ECC for Peripheral RAM (32 Bits)

40.3.9.1 Overview

This is an ECC module for the RAM of the following peripheral modules:

RS-CAN-FD, FlexRay, Ethernet, GTM and DFE

(1) RS-CAN-FD, FlexRay, GTM and DFE

Error Detection and Correction

Seven-bit ECC data is appended to the 32-bit RAM data.

This ECC module provides 2-bit ECC error detection and 1-bit ECC error detection and correction.

Table 40.182 RS-CANFD, FlexRay, GTM and DFE RAM ECC

Item	Description
ECC error detection and correction	<p>ECC error detection and correction can be either enabled or disabled. When enabled, either of the following settings can be selected.</p> <ul style="list-style-type: none"> • ECC error detection and correction are carried out (2-bit error detection, and 1-bit error detection and correction are carried out). • ECC error detection is carried out (2-bit error detection and 1-bit error detection are carried out). <p>When disabled, neither error detection nor correction is carried out.</p> <p>In the initial state, this function is enabled; 2-bit error detection, and 1-bit error detection and correction are carried out.</p>
Error notification	<p>Upon occurrence of an ECC error, it is notified to the Error Control Module.</p> <p>ECC Error:</p> <ul style="list-style-type: none"> • Error notification can be either enabled or disabled upon detection of an ECC 2-bit error. • Error notification can be either enabled or disabled upon detection of an ECC 1-bit error. <p>In the initial state, error notification is enabled upon detection of an ECC 2-bit error, and error notification is disabled upon detection of an ECC 1-bit error.</p> <p>An ECC 2-bit error and an ECC 1-bit error are handled as individual source in ECM. All overflow errors of each peripheral module (RS-CANFD, FlexRay, GTM and DFE) are notified to ECM as one factor.</p> <p>An ECC error signal is only issued to the ECM, if the ECC error address is not yet stored in the error address buffer.</p>
Error status	<p>A status register is provided, which indicates the statuses of ECC 2-bit error detection and ECC 1-bit error detection. A one-stage buffer is provided for 2-bit error and 1-bit error.</p> <p>The error status can be cleared using the clear register.</p>
Address capture	<p>The address is captured when an ECC 2-bit error or an ECC 1-bit error is detected.</p> <p>The error status serves as the enable bit of the capture address. Address buffer is updated if the error status is cleared.</p> <p>One-stage address buffer is provided for an ECC 2-bit error and an ECC 1-bit error.</p>
Self-diagnosis	<ul style="list-style-type: none"> • By setting the test mode, register values can be used as the data to be output to the RAM. When a peripheral module writes to the RAM, the E710TED.ECEDB[31:0] bit value can be written to the RAM data section, and the E710TRC.ECERDB[6:0] bit value can be written to the ECC redundant bit section. • By setting the test mode, the ECC redundant bit section can be latched when RAM data is read, and the value can be confirmed. • By setting the test mode, the ECC redundant bit (encoding circuit) and syndrome code (decoding circuit), which are generated from the input data, can be confirmed.

(2) Ethernet

Error Detection and Correction

Seven-bit ECC data is appended to the 32-bit RAM data.

This ECC module provides 2-bit ECC error detection and 1-bit ECC error detection and correction.

Table 40.183 Ethernet RAM ECC

Item	Description
ECC error detection and correction	<p>ECC error detection can not be disabled. ECC error correction can be either enabled or disabled. Either of the following settings can be selected.</p> <ul style="list-style-type: none"> • ECC error detection and correction are carried out (2-bit error detection, and 1-bit error detection and correction are carried out). • ECC error detection is carried out (2-bit error detection and 1-bit error detection are carried out). <p>In the initial state, this function is enabled; 2-bit error detection, and 1-bit error detection and correction are carried out.</p>
Error notification	<p>Upon occurrence of an ECC error, it is notified to the Error Control Module.</p> <p>ECC Error:</p> <ul style="list-style-type: none"> • Error notification can not be disabled upon detection of an ECC 2-bit error. • Error notification can not be disabled upon detection of an ECC 1-bit error.
Error Status	None
Address Capture	None
Self-diagnosis	None

40.3.9.2 List of Registers

(1) List of ECC Modules

The RAMs of the multiple peripheral functions are provided with the ECC modules. The following table shows the peripheral functions provided with the ECC modules, the corresponding ECC module names, and base addresses of the ECC modules.

Table 40.184 List of ECC Modules (1/2)

Peripheral Functions		ECC Module Names and Register Base Address	
		Module Name	Base Address <base_addr>
RS-CAN-FD0 (Peripheral Group3)	Message buffer RAM (MB RAM)	E7RC01	FFC7 0000 _H
	Acceptance filter list RAM (AFL RAM)	E7RC02	FFC7 0020 _H
RS-CAN-FD1*1 (Peripheral Group3)	Message buffer RAM (MB RAM)	E7RC11	FFC7 0040 _H
	Acceptance filter list RAM (AFL RAM)	E7RC12	FFC7 0060 _H
FlexRay0 (Peripheral Group9)	Message RAM (MRAM)	E7FR00	FF05 0000 _H
	Temporary buffer (TBF A)	E7FR01	FF05 0020 _H
	Temporary buffer (TBF B)	E7FR02	FF05 0040 _H
FlexRay1*1 (Peripheral Group9)	Message RAM (MRAM)	E7FR10	FF05 0060 _H
	Temporary buffer (TBF A)	E7FR11	FF05 0080 _H
	Temporary buffer (TBF B)	E7FR12	FF05 00A0 _H
GTM (Peripheral Group2H)	MCS0_RAM0	E7GT00	FFDE 4000 _H
	MCS0_RAM1	E7GT01	FFDE 4100 _H
	MCS1_RAM0	E7GT10	FFDE 4200 _H
	MCS1_RAM1	E7GT11	FFDE 4300 _H
	MCS2_RAM0	E7GT20	FFDE 4400 _H
	MCS2_RAM1	E7GT21	FFDE 4500 _H
	MCS3_RAM0	E7GT30	FFDE 4600 _H
	MCS3_RAM1	E7GT31	FFDE 4700 _H
	MCS4_RAM0	E7GT40	FFDE 4800 _H
	MCS4_RAM1	E7GT41	FFDE 4900 _H
	MCS5_RAM0	E7GT50	FFDE 4A00 _H
	MCS5_RAM1	E7GT51	FFDE 4B00 _H
	MCS6_RAM0	E7GT60	FFDE 4C00 _H
	MCS6_RAM1	E7GT61	FFDE 4D00 _H
	MCS7_RAM0	E7GT170	FFDE 4E00 _H
	MCS7_RAM1	E7GT171	FFDE 4F00 _H
	MCS8_RAM0	E7GT180	FFDE 5000 _H
	MCS8_RAM1	E7GT181	FFDE 5100 _H
	MCS9_RAM0	E7GT190	FFDE 5200 _H
	MCS9_RAM1	E7GT191	FFDE 5300 _H
DFE0 (Peripheral Group5)	FIFO0_RAM	E7GT70	FFDE 5800 _H
	FIFO1_RAM	E7GT71	FFDE 5900 _H
	DPLL_RAM1A	E7GT80	FFDE 5A00 _H
	DPLL_RAM1B (include PLL_RAM1C)	E7GT81	FFDE 5B00 _H
	DPLL_RAM2	E7GT82	FFDE 5C00 _H
	Coefficient memory (CMEM)	E7DF00	FFC7 8000 _H

Table 40.184 List of ECC Modules (2/2)

Peripheral Functions		ECC Module Names and Register Base Address	
		Module Name	Base Address <base_addr>
DFE1 (Peripheral Group5)	Coefficient memory (CMEM)	E7DF10	FFC7 8060 _H
Ethernet (Peripheral Group9)	Transmit/Receive buffer	EETC	FF06 0000 _H

Note 1. This function is not implemented in E2H.

(2) List of Registers

Each ECC module has the registers shown in the following table.

Table 40.185 List of Registers

Register Name	Symbol	Address	Access	Access Protection
ECC Control Register	E710CTL* ¹	<base_addr> + 00 _H	8, 16	
ECC Test Mode Control Register	E710TMC* ¹	<base_addr> + 04 _H	8, 16	
ECC Redundant Bit Data Control Test Register	E710TRC* ¹	<base_addr> + 08 _H	32	
ECC Encoder and Decoder Data Test Register	E710TED* ¹	<base_addr> + 0C _H	32	
ECC Error Address Register	E710EAD* ¹	<base_addr> + 10 _H	32	
Ethernet TX RAM ECC Control Register	ETCTXECCCTL	FF06 0000 _H	8, 16, 32	
Ethernet RX RAM ECC Control Register	ETCRXECCCTL	FF06 0004 _H	8, 16, 32	

Note 1. This function is not implemented in Ethernet.

(3) Register Map

Table 40.186 Register Map

Symbol	31	24	23	16	15	8	7	0	Address
E710CTL	— (00 _H)		— (00 _H)		ECCTL[15:8]		ECCTL[7:0]		00 _H
E710TMC	— (00 _H)		— (00 _H)		ECTMC[15:8]		ECTMC[7:0]		04 _H
E710TRC	ECSYND[7:0]		ECHORD[7:0]		ECECRD[7:0]		ECERDB[7:0]		08 _H
E710TED	ECEDB[31:24]		ECEDB[23:16]		ECEDB[15:8]		ECEDB[7:0]		0C _H
E710EAD	ECEAD[31:24]		ECEAD[23:16]		ECEAD[15:8]		ECEAD[7:0]		10 _H

40.3.9.3 E710CTL — ECC Control Register

E710CTL controls the status and modes of the ECC modules.

E710CTL can be read and written to using the 16-bit or 8-bit manipulation instruction.

Value after reset: Undefined

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	EMCA[1:0]	—	—	—	ECOVFF	ECER2C	ECER1C	—	ECTHM	—	EC1ECP	EC2EDIC	EC1EDIC	ECER2F	ECER1F	ECEMF
Value after reset	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	Undefined
	R/W	R/W*	R/W*	R	R	R	R/W*	R/W*	R	R/W	R	R/W	R/W	R/W	R	R

Note 1. This bit is always read as 0.

Table 40.187 E710CTL Register Contents (1/2)

Bit Position	Bit Name	Function
15, 14	EMCA[1:0]	Sets Access Control 1 and 0 to ECC Mode Select Bit These bits enable or disable writing to bit 7. The read value is always 0.
13, 12	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
11	ECOVFF	Error Overflow Detection Flag This flag is set when an error of any source other than the same error address occurs while the error flag (ECER2F or ECER1F) is set. One of the following clears this flag: <ul style="list-style-type: none"> • An internal or external reset • When ECC function is disabled (ECTHM = 1) • Writing 1 to ECER2C and ECER1C
10	ECER2C	2-Bit ECC Error Detection Flag Clear Clears the bit 2 (ECER2F) status flag. The read value is always 0, and writing 0 to ECER2C does not change the state. If writing 1 to ECER2C conflicts with the condition for setting bit 2, the former takes priority. Writing 1 to ECER2C while ECER2F is set clears ECER2F.
9	ECER1C	1-Bit ECC Error Detection Flag Clear Clears the bit 1 (ECER1F) status flag. The read value is always 0, and writing 0 to ECER1C does not change the internal state. If writing 1 to ECER1C conflicts with the condition for setting bit 1, the former takes priority. Writing 1 to ECER1C while ECER1F is set clears ECER1F.
8	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
7	ECTHM	ECC Function Disable Select Selects the ECC decoding operation. Write access to ECTHM is enabled when the value of bits 15 and 14 is 01 _B . Therefore, only the 16-bit manipulation instruction is valid. Setting ECTHM to 1 disables error detection and bit correction. Here, if the data to be output to the peripheral module contains an error, the data is output without bit correction. Setting ECTHM to 1 has no effect on the encoder side. <ul style="list-style-type: none"> 0: Enable ECC detection and correction. 1: Disable ECC detection and correction.
6	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.

Table 40.187 E710CTL Register Contents (2/2)

Bit Position	Bit Name	Function
5	EC1ECP	<p>1-Bit ECC Error Correction Enable</p> <p>0: Enable 1-bit error correction upon error detection.</p> <p>1: Disable 1-bit error correction upon error detection.</p>
4	EC2EDIC	<p>2-Bit ECC Error Detection Notification Enable</p> <p>0: When a 2-bit error is detected, the ECM is not notified of the error.</p> <p>1: When a 2-bit error is detected, the ECM is notified of the error.</p>
3	EC1EDIC	<p>1-Bit ECC Error Detection Notification Enable</p> <p>0: When a 1-bit error is detected, the ECM is not notified of the error.</p> <p>1: When a 1-bit error is detected, the ECM is notified of the error.</p>
2	ECER2F	<p>2-Bit ECC Error Detection Flag</p> <p>Indicates that errors have been detected at two bits in bits 0 to 38 of the data read from the RAM during RAM read access while error detection is enabled.</p> <p>This bit is a read only flag.</p> <p>0: A 2-bit error has not occurred since this bit was cleared.</p> <p>1: A 2-bit error has occurred.</p> <p>Clearing conditions</p> <p>(1) Reset is applied.</p> <p>(2) 1 is written to ECER2C.</p> <p>(3) ECC function is disabled (ECTHM = 1)</p>
1	ECER1F	<p>1-Bit ECC Error Detection and Correction Flag</p> <p>Indicates that an error has been detected at one bit in bits 0 to 38 of the data read from the RAM during RAM read access while error detection is enabled. Setting this bit generates no interrupt signal.</p> <p>This bit is a read only flag.</p> <p>0: A 1-bit error has not occurred.</p> <p>1: A 1-bit error has occurred.</p> <p>Clearing conditions</p> <p>(1) Reset is applied.</p> <p>(2) 1 is written to ECER1C.</p> <p>(3) ECC function is disabled (ECTHM = 1)</p>
0	ECEMF	<p>ECC Error Message Flag</p> <p>Indicates that the current read data contains an error.</p> <p>ECEMF is updated every time RAM data is read. Since the RAM value after reset is undefined, if this bit is read before the RAM is initialized, this bit might be set, indicating an error. Therefore, the ECEMF value after reset is undefined.</p> <p>0: The current RAM data contains no bit errors.</p> <p>1: The current RAM data contains bit errors.</p> <p>Clearing conditions</p> <p>(1) ECC function is disabled (ECTHM = 1)</p> <p>(2) Decoding circuit input data contains no 1-bit errors.</p> <p>ECEMF remains set as long as RAM data containing a bit error is output with error detection being enabled.</p>

40.3.9.4 E710TMC — ECC Test Mode Control Register

E710TMC is a 16-bit register used to switch the mode to test mode and control the mode.

E710TMC can be read and written to using the 16-bit or 8-bit manipulation instruction.

Value after reset: 0000_H

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	ETMA[1:0]		—	—	—	—	—	—	ECTMCE	—	—	ECTRRS	ECREOS	ECENS	ECDCS	ECREIS
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W*	R/W*	R	R	R	R	R	R	R/W	R	R	R/W	R/W	R/W	R/W	R/W

Note 1. This bit is always read as 0.

Table 40.188 E710TMC Register Contents (1/2)

Bit Position	Bit Name	Function
15, 14	ETMA[1:0]	Access Control 1 and 0 to ECC Test Mode Control Enable Bit These bits enable or disable writing to bit 7. The read value is always 0.
13 to 8	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
7	ECTMCE	ECC Test Mode Control Enable ECTMCE enables or disables access to the test registers and test control bits. Write access to ECTMCE is enabled when the value of bits 15 and 14 is 10 _B . 0: Disable access to the test registers and test control bits. 1: Enable access to the test registers and test control bits.
6, 5	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
4	ECTRRS	ECC RAM Read Test Mode Control Enable ECTRRS enables the read status of RAM to be generated by reading the E710TED register, and also allows the RAM output data to be read out when the E710TRC:ECERDB[7:0] bits and the E710TED register are read. Write access to ECTRRS is enabled only when ECTMCE is 1 (can be set simultaneously). ECTRRS is cleared by writing 0 to ECTMCE (can be cleared synchronously). 0: Disable generation of RAM read status for testing when E710TED is read. 1: Enable generation of RAM read status for testing when E710TED is read. When E710TRC:ECERDB[7:0] and E710TED are read, the values of the RAM output data pin are read out.
3	ECREOS	ECC Redundant Bit Output Data Select ECREOS selects either the ECC encoder output data or the ECERDB register value to be output as the ECC redundant bit output. Write access to ECREOS is enabled only when ECTMCE is 1 (can be set simultaneously). ECREOS is cleared by writing 0 to ECTMCE (can be cleared synchronously). 0: Allow encoding result to be output as the ECC redundant bit output. 1: Allow the E710TRC:ECERDB[6:0] value to be output as the ECC redundant bit output.
2	ECENS	ECC Encoder Input Select ECENS selects either the data value from the peripheral module or the internal test register value (E710TED:ECEDB[31:0]) as the input signal to be encoded. Write access to ECENS is enabled only when ECTMCE is 1 (can be set simultaneously). ECENS is cleared by writing 0 to ECTMCE (can be cleared synchronously). 0: Allow the RAM write data from the peripheral module to be input as the ECC encoder input data. 1: Allow the E710TED:ECEDB[31:0] value to be input as the ECC encoder input data.

Table 40.188 E710TMC Register Contents (2/2)

Bit Position	Bit Name	Function
1	ECDCS	<p>ECC Decoder Input Select</p> <p>ECDCS selects either the lower 32-bit data value from the RAM or the internal test register value (E710TED:ECEDB[31:0]) as the lower 32-bit data of the input signal to be decoded. Write access to ECDCS is enabled only when ECTMCE is 1 (can be set simultaneously). ECDCS is cleared by writing 0 to ECTMCE (can be cleared synchronously).</p> <p>0: Allow the lower 32-bit RAM output data to be input to the data area (32 lower-order bits) to the decoder.</p> <p>1: Allow the E710TED:ECEDB[31:0] value to be input to the data area to the decoder.</p>
0	ECREIS	<p>ECC Redundant Bit Input Data Select</p> <p>ECREIS selects either the upper 7-bit data value from the RAM (redundant bit area) or the internal test register value (E710TRC:ECERDB[6:0]) as the upper 7-bit data of the input signal to be decoded. Write access to ECREIS is enabled only when ECTMCE is 1 (can be set simultaneously). ECREIS is cleared by writing 0 to ECTMCE (can be cleared synchronously).</p> <p>0: Allow the upper 7-bit RAM output data to be input to the ECC redundant bit area to the decoder.</p> <p>1: Allow the E710TRC:ECERDB[6:0] value to be input to the ECC redundant bit area to the decoder.</p>

40.3.9.5 E710TED — ECC Encoder and Decoder Data Test Register

E710TED is a 32-bit data test register for ECC encoding and decoding.

When ECTMCE = 1, E710TED can be read and written to using the 32-bit manipulation instruction.

When ECTMCE = 0, E710TED is always read as 0.

In test mode, the E710TED value can be used as the data input to the encoding circuit and decoding circuit.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
ECEDB[31:16]																
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ECEDB[15:0]																
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

NOTE

Changing ECTMCE from 1 to 0 resets E710TED synchronously.

When E710TMC:ECENS = 1, the ECEDB value is input to the encoding circuit and supplied to the RAM.

When E710TMC:ECDCS = 1, the ECEDB value is input as bits 31 to 0 of the data input to the decoding circuit.

When E710TMC:ECTRRS = 1, reading ECEDB returns the RAM output data instead of the data written to ECEDB.

40.3.9.6 E710TRC — ECC Redundant Bit Data Control Test Register

E710TRC is a 32-bit test register consisting of four fields (ECSYND, ECHORD, ECECRD, and ECRODM) corresponding to the ECC redundant bit area. Each field can be accessed as the 8-bit register with the same name. For details of each field, refer to the descriptions of these four registers.

When ECTMCE = 0, E710TRC is always read as 0.

When ECTMCE = 1, E710TRC can be read using the 32-bit manipulation instruction.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	ECSYND								ECHORD							
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	ECECRD								ECERDB							
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W

NOTE

Changing ECTMCE from 1 to 0 resets E710TRC synchronously.

40.3.9.7 ECSYND — ECC Decoder Syndrome Data Register

ECSYND is a read-only register used to confirm the syndrome code generated by the decoding circuit in test mode (ECTMCE = 1).

Write access to ECSYND is ignored.

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	SYND[6:0]						
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R

When read, the ECSYND bits return the value of the syndrome code (SYND[6:0]) generated based on the data input to the decoding circuit.

The ECSYND bits are not holding circuits; the register value changes as the input signal changes.

ECSYND is valid only when ECTMCE = 1, and is always read as 00_H when ECTMCE = 0.

Bit 7 is reserved. When read, the value after reset is returned. When writing, write the value after reset.

40.3.9.8 ECHORD — ECC 7-Bit Redundant Data Holding Test Register

ECHORD holds the 7-bit ECC redundant area (upper 7-bit RAM data) that cannot be confirmed by the peripheral module when the peripheral module accesses the RAM for reading in test mode (ECTMCE = 1).

Value after reset: 00H

Bit	7	6	5	4	3	2	1	0
	—	HORD[6:0]						
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R

The ECHORD bits are loaded with the upper 7-bit RAM output data at the next rising edge of the operating clock signal after the peripheral module accesses the RAM for reading data in test mode (ECTMCE = 1).

The ECHORD bits are also loaded with the data on the input pins EC7TERI38 to EC7TERI32 at the next operating clock pulse when the ECEDB[15:0] register is read while E710TMC:ECTRRS = 1.

ECHORD is valid only when ECTMCE = 1, and is always read as 00H when ECTMCE = 0.

Bit 7 is reserved. When read, the value after reset is returned. When writing, write the value after reset.

40.3.9.9 ECECRD — ECC Encoder Test Register

ECECRD is a read-only register used to read the 7-bit redundant section generated by the encoding circuit in test mode (ECTMCE = 1).

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	ECECRD[6:0]						
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R

ECECRD is used to confirm the redundant bits generated by the input data from the peripheral module. Here, the data that is read is the result of encoding (ECC[6:0]), not the output value.

ECECRD is valid only when ECTMCE = 1, and is always read as 00_H when ECTMCE = 0.

Bit 7 is reserved. When read, the value after reset is returned. When writing, write the value after reset.

40.3.9.10 ECERDB — ECC Redundant Bit Input and Output Substitution Buffer Register

ECERDB is a buffer register for the data that substitutes for the input and output data for the 7-bit ECC redundant data area in test mode (ECTMCE = 1).

ECERDB can be read and written to in ECC test mode (ECTMCE = 1).

When ECREOS = 1, the ECERDB value, instead of the seven redundant bits generated by the encoding circuit, is output to the pin and supplied to the RAM.

When ECREIS = 1, the ECERDB value, instead of the upper seven data bits to be input to the decoding circuit, is handled by the decoding circuit.

When ECTRRS = 1, reading ECERDB returns the signal value supplied to RAM instead of the data written to ECERDB.

Bit 7 is reserved. When read, the value after reset is returned. When writing, write the value after reset.

40.3.9.11 E710EAD — ECC Error Address Register

E710EAD is a read-only register used to hold the address at which an ECC error has occurred.

If an ECC error is detected while ECC error detection is enabled, the RAM address is latched using the detection signal as a trigger, and the address is stored in E710EAD as the address at which the ECC error occurred.

The address is stored upon detection of the first ECC error while no error status is set. However, if a 1-bit error is followed by a 2-bit error, the address of the latter is stored. The address can be calculated by adding the base address.

Only one address can be held in E710EAD.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
ECEAD[31:16]																
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ECEAD[15:0]																
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

40.3.9.12 ETCTXECCCTL— Ethernet TX RAM ECC Control Register

This register controls 1-bit ECC error correction for data read from Ethernet TX RAM.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	EC1ECP	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R/W	R	R	R	R	R

Table 40.189 ETCTXECCCTL Register Contents

Bit Position	Bit Name	Function
31 to 6	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
5	EC1ECP	1-Bit ECC Error Correction Enable 0: Enable 1-bit error correction upon error detection. 1: Disable 1-bit error correction upon error detection.
4 to 0	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.

40.3.9.13 ETCRXECCCTL— Ethernet RX RAM ECC Control Register

This register controls 1-bit ECC error correction for data read from Ethernet RX RAM.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

R/W	R	R	R	R	R	R	R	R	R	R	R/W	R	R	R	R	R

Table 40.190 ETCRXECCCTL Register Contents

Bit Position	Bit Name	Function
31 to 6	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
5	EC1ECP	1-Bit ECC Error Correction Enable 0: Enable 1-bit error correction upon error detection. 1: Disable 1-bit error correction upon error detection.
4 to 0	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.

40.3.9.14 Notification to ECM

Detection of errors in two bits can be set for this module and the ECM is notified of detected errors.

- 1-bit Error Notification

While EC1EDIC is set to 1_B, when an error is detected in one bit from among bits 0 to 38 of data read from RAM, the ECM is notified of the 1-bit error. When ECER1F or ECER2F is already set, however, the ECM will not be notified of the error.

- 2-bit Error Notification

While EC2EDIC is set to 1_B, when an error is detected in two bits from among bits 0 to 38 of data read from RAM, the ECM is notified of the 2-bit error. When ECER2F is already set, however, the ECM will not be notified of the error.

40.3.9.15 Test Function

(1) Writing RAM Data

Write data to the peripheral RAM. However, the ECC corresponding to the written data will be written to the ECC bits simultaneously. In order to write a specified value to the ECC bits, use the ECC test mode described in **(3)** below.

(2) Reading RAM Data

- Set the ECTHM bit in the E710CTL register to 1 to disable ECC error detection and correction.
- Read the peripheral RAM. Since neither error detection nor correction proceeds when the peripheral RAM is read, the RAM data is read unchanged.

How to exit this test mode:

- Set the ECTHM bit in the E710CTL register to 0 to enable ECC error detection and correction.

(3) Writing to the ECC Bits

- Set the ECTMCE bit in the E710TMC register to 1 to set ECC test mode.
- Write the value to be written to the ECC bits to E710TRC.ECERDB[6:0].
- Set the ECREOS bit in the E710TMC register to 1 to select writing of the value of the E710TRC.ECERDB[6:0] bits to the ECC bits.
- When data is written to the peripheral RAM, the value in the E710TRC.ECERDB[6:0] bits will be written to the ECC bits.

How to exit this test mode:

- Set the ECTMCE bit in the E710TMC register to 0 to set normal mode.

(4) Reading the ECC Bits

- Set the ECTMCE bit in the E710TMC register to 1 to set ECC test mode.
- When data in the peripheral RAM is read, the ECC bits are stored in the E710TRC.ECHORD[6:0] bits.

How to exit this test mode:

- Set the ECTMCE bit in the E710TMC register to 0 to set normal mode.

40.3.10 ECC for Peripheral RAM (16 Bits)

40.3.10.1 Overview

This is an ECC module for the RAM of the following peripheral module:

DFE

Error Detection and Correction

Six-bit ECC data is appended to the 16-bit RAM data.

This ECC module provides 2-bit ECC error detection and 1-bit ECC error detection and correction.

Table 40.191 DFE RAM ECC

Item	Description
ECC error detection and correction	<p>ECC error detection and correction can be either enabled or disabled. When enabled, either of the following settings can be selected.</p> <ul style="list-style-type: none"> • ECC error detection and correction are carried out (2-bit error detection, and 1-bit error detection and correction are carried out). • ECC error detection is carried out (2-bit error detection and 1-bit error detection are carried out). <p>When disabled, neither error detection nor correction is carried out. In the initial state, this function is enabled; 2-bit error detection, and 1-bit error detection and correction are carried out.</p>
Error notification	<p>Upon occurrence of an ECC error, it is notified to the Error Control Module.</p> <p>ECC Error:</p> <ul style="list-style-type: none"> • Error notification can be either enabled or disabled upon detection of an ECC 2-bit error. • Error notification can be either enabled or disabled upon detection of an ECC 1-bit error. <p>In the initial state, error notification is enabled upon detection of an ECC 2-bit error, and error notification is disabled upon detection of an ECC 1-bit error.</p> <p>An ECC 2-bit error and an ECC 1-bit error are handled as individual source in ECM. All overflow errors of each peripheral module (RS-CANFD, FlexRay, GTM and DFE) are notified to ECM as one factor. An ECC error signal is only issued to the ECM, if the ECC error address is not yet stored in the error address buffer.</p>
Error status	<p>A status register is provided, which indicates the statuses of ECC 2-bit error detection and ECC 1-bit error detection. A one-stage buffer is provided for 2-bit error and 1-bit error. The error status can be cleared using the clear register.</p>
Address capture	<p>The address is captured when an ECC 2-bit error or an ECC 1-bit error is detected. The error status serves as the enable bit of the capture address. Address buffer is updated if the error status is cleared.</p> <p>One-stage address buffer is provided for an ECC 2-bit error and an ECC 1-bit error.</p>
Self-diagnosis	<ul style="list-style-type: none"> • By setting the test mode, register values can be used as the data to be output to the RAM. When a peripheral module writes to the RAM, the E610TED.ECEDB[15:0] bit value can be written to the RAM data section, and the E610TED.ERDB[5:0] bit value can be written to the ECC redundant bit section. • By setting the test mode, the ECC redundant bit section can be latched when RAM data is read, and the value can be confirmed. • By setting the test mode, the ECC redundant bit (encoding circuit) and syndrome code (decoding circuit), which are generated from the input data, can be confirmed.

40.3.10.2 List of Registers

(1) List of ECC Modules

The RAMs of the multiple peripheral functions are provided with the ECC modules. The following table shows the peripheral functions provided with the ECC modules, the corresponding ECC module names, and base addresses of the ECC modules.

Table 40.192 List of ECC modules

Peripheral Functions		ECC Module Names and Register Base Addresses	
		Module Name	Base Address <base_addr>
DFE0 (Peripheral Group5)	Data memory (DMEM0)	E6DF00	FFC7 8020 _H
	Data memory (DMEM1)	E6DF01	FFC7 8040 _H
DFE1 (Peripheral Group5)	Data memory (DMEM0)	E6DF10	FFC7 8080 _H
	Data memory (DMEM1)	E6DF11	FFC7 80A0 _H

(2) List of Registers

Each ECC module has the registers shown in the following table.

Table 40.193 List of Registers

Register Name	Symbol	Address	Access	Access Protection
ECC Control Register	E610CTL	<base_addr> + 00 _H	8, 16	
ECC Test Mode Control Register	E610TMC	<base_addr> + 04 _H	8, 16	
ECC Redundant Bit Data Control Test Register	E610TRC	<base_addr> + 08 _H	32	
ECC Encoder and Decoder Data Test Register	E610TED	<base_addr> + 0C _H	32	
ECC Error Address Register	E610EAD	<base_addr> + 10 _H	32	

(3) Register Map

Table 40.194 Register Map

Symbol	31	24	23	16	15	8	7	0	Address
E610CTL	— (00 _H)		— (00 _H)		ECCTL[15:8]		ECCTL[7:0]		00 _H
E610TMC	— (00 _H)		— (00 _H)		ECTMC[15:8]		ECTMC[7:0]		04 _H
E610TRC	ECSYND[7:0]		ECHORD[7:0]		ECECRD[7:0]		ECRODM[7:0]		08 _H
E610TED	ECEDB[31:24]		ECEDB[23:16]		ECRIDM[15:8]		ECERDB[7:0]		0C _H

40.3.10.3 E610CTL — ECC Control Register

E610CTL controls the status and modes of the ECC modules.

E610CTL can be read and written to using the 16-bit or 8-bit manipulation instruction.

Value after reset: Undefined

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
	EMCA[1:0]	—	—	—	ECOVFF	ECER2C	ECER1C	—	ECTHM	—	EC1ECP	EC2EDIC	EC1EDIC	ECER2F	ECER1F	ECEMF	
Value after reset	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	Undefined	
	R/W	R/W*	R/W*	R	R	R	R/W*	R/W*	R	R/W	R	R/W	R/W	R/W	R	R	R

Note 1. This bit is always read as 0.

Table 40.195 E610CTL Register Contents (1/2)

Bit Position	Bit Name	Function
15, 14	EMCA[1:0]	Access Control 1 and 0 to ECC Mode Select Bit These bits enable or disable writing to bit 7. The read value is always 0.
13, 12	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
11	ECOVFF	Error Overflow Detection Flag This flag is set when an error of any source other than the same error address occurs while the error flag (ECER2F or ECER1F) is set. This flag is cleared by an internal or external reset, by disabling ECC function (ECTHM = 1), or by writing 1 to ECER2C and ECER1C.
10	ECER2C	2-Bit ECC Error Detection Flag Clear Clears the bit 2 (ECER2F) status flag. The read value is always 0, and writing 0 to ECER2C does not change the state. If writing 1 to ECER2C conflicts with the condition for setting bit 2, the former takes priority. Writing 1 to ECER2C while ECER2F is set clears ECER2F.
9	ECER1C	1-Bit ECC Error Detection And Correction Accumulated Flag Clear Clears the bit 1 (ECER1F) status flag. The read value is always 0, and writing 0 to ECER1C does not change the state. If writing 1 to ECER1C conflicts with the condition for setting bit 1, the former takes priority. Writing 1 to ECER1C while ECER1F is set clears ECER1F.
8	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
7	ECTHM	ECC Function Disable Selection Selects the ECC decoding operation. Write access to ECTHM is enabled when the value of bits 15 and 14 is 01 _B . Therefore, only the 16-bit manipulation instruction is valid. Setting ECTHM to 1 disables error detection and bit correction. Here, if the data to be output to the peripheral module contains an error, the data is output without bit correction. Setting ECTHM to 1 has no effect on the encoder side. 0: Enable ECC detection and correction 1: Disable ECC detection and correction. Has no effect on the encoder side.
6	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
5	EC1ECP	1-Bit ECC Error Correction Enable 0: Enable 1-bit error correction upon error detection. 1: Disable 1-bit error correction upon error detection.

Table 40.195 E610CTL Register Contents (2/2)

Bit Position	Bit Name	Function
4	EC2EDIC	<p>2-Bit ECC Error Detection Notification Enable</p> <p>0: When a 2-bit error is detected, the ECM is not notified of the error. 1: When a 2-bit error is detected, the ECM is notified of the error.</p>
3	EC1EDIC	<p>1-Bit ECC Error Detection Notification Enable</p> <p>0: When a 1-bit error is detected, the ECM is not notified of the error. 1: When a 1-bit error is detected, the ECM is notified of the error.</p>
2	ECER2F	<p>2-Bit ECC Error Detection Flag</p> <p>Indicates that errors have been detected at two bits in bits 0 to 21 of the data read from the RAM during RAM read access while error detection is enabled.</p> <p>This bit is a read only flag.</p> <p>0: A 2-bit error has not occurred since this bit was cleared. 1: A 2-bit error has occurred.</p> <p>Clearing conditions</p> <p>(1) Reset is applied. (2) 1 is written to ECER2C. (3) ECC function is disabled (ECTHM = 1).</p>
1	ECER1F	<p>1-Bit ECC Error Detection And Correction Flag</p> <p>Indicates that an error has been detected at one bit in bits 0 to 21 of the data read from the RAM during RAM read access while error detection is enabled. Setting this bit generates no interrupt signal.</p> <p>This bit is a read only flag.</p> <p>0: A 1-bit error has not occurred since this bit was cleared. 1: A 1-bit error has occurred.</p> <p>Clearing conditions</p> <p>(1) Reset is applied. (2) 1 is written to ECER1C. (3) ECC function is disabled.</p>
0	ECEMF	<p>ECC Error Message Flag</p> <p>Indicates that the current read data contains an error.</p> <p>ECEMF is updated every time RAM data is read. Since the RAM value after reset is undefined, if this bit is read before the RAM is initialized, this bit might be set, indicating an error. Therefore, the ECEMF value after reset is undefined.</p> <p>0: The current RAM data contains no bit errors. 1: The current RAM data contains bit errors.</p> <p>Clearing conditions</p> <p>(1) ECC function is disabled. (2) Decoding circuit input data contains no 1-bit errors.</p> <p>ECEMF remains set as long as RAM data containing a bit error is output with error detection being enabled.</p>

40.3.10.4 E610TMC — ECC Test Mode Control Register

E610TMC is a 16-bit register used to switch the mode to test mode and control the mode.

E610TMC can be read and written to using the 16-bit or 8-bit manipulation instruction.

Value after reset: 0000H

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	ETMA[1:0]		—	—	—	—	—	—	ECTMCE	—	—	ECTRRS	ECREOS	ECENS	ECDCS	ECREIS
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W*	R/W*	R	R	R	R	R	R	R/W	R	R	R/W	R/W	R/W	R/W	R/W

Note 1. This bit is always read as 0.

Table 40.196 E610TMC Register Contents (1/2)

Bit Position	Bit Name	Function
15, 14	ETMA[1:0]	Sets Access Control 1 and 0 to ECC Test Mode Control Enable Bit These bits enable or disable writing to bit 7. The read value is always 0.
13 to 8	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
7	ECTMCE	ECC Test Mode Control Enable ECTMCE enables or disables access to the test registers and test control bits. Write access to ECTMCE is enabled when the value of bits 15 and 14 is 10 _B . 0: Disable access to the test registers and test control bits. 1: Enable access to the test registers and test control bits.
6, 5	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
4	ECTRRS	ECC RAM Read Test Mode Control Enable ECTRRS enables the read status of RAM to be generated by reading the E610TED register, and also allows the RAM output data to be read out when the E610TED:ECEDB[15:0] and E610TED:ECRIDM[7:0] are read. Write access to ECTRRS is enabled only when ECTMCE is 1 (can be set simultaneously). ECTRRS is cleared by writing 0 to ECTMCE (can be cleared synchronously). 0: Disable generation of RAM read status for testing when E610TED is read. 1: Enable generation of RAM read status for testing when E610TED is read. When E610TED:ECEDB[15:0] and E610TED:ECRIDM[7:0] are read, the values of the RAM output data pin are read out.
3	ECREOS	ECC Redundant Bit Output Data Select ECREOS selects either the ECC encoder output data or the ECERDB register value to be output as the ECC redundant bit output. Write access to ECREOS is enabled only when ECTMCE is 1 (can be set simultaneously). ECREOS is cleared by writing 0 to ECTMCE (can be cleared synchronously). 0: Allow encoding results to be output as the ECC redundant bit output. 1: Allow the E610TED:ECERDB[5:0] value to be output as the ECC redundant bit output.
2	ECENS	ECC Encoder Input Select ECENS selects either the data value from the peripheral module or the internal test register value (E610TED: ECEDB[15:0]) as the input signal to be encoded. Write access to ECENS is enabled only when ECTMCE is 1 (can be set simultaneously). ECENS is cleared by writing 0 to ECTMCE (can be cleared synchronously). 0: Allow the RAM write data from the peripheral module to be input as the ECC encoder input data. 1: Allow the E610TED:ECEDB[15:0] value to be input as the ECC encoder input data.

Table 40.196 E610TMC Register Contents (2/2)

Bit Position	Bit Name	Function
1	ECDCS	<p>ECC Decoder Input Select</p> <p>ECDCS selects either the lower 16-bit data value from the RAM or the internal test register value (E610TED:ECEDB[15:0]) as the lower 32-bit data of the input signal to be decoded. Write access to ECDCS is enabled only when ECTMCE is 1 (can be set simultaneously). ECDCS is cleared by writing 0 to ECTMCE (can be cleared synchronously).</p> <p>0: Allow the lower 16-bit RAM output data to be input to the data area (lower 16 bits) to the decoder.</p> <p>1: Allow the E610TED:ECEDB[15:0] value to be input to the data area to the decoder.</p>
0	ECREIS	<p>ECC Redundant Bit Input Data Select</p> <p>ECREIS selects either the upper 6-bit data value from the RAM (redundant bit area) or the internal test register value (E610TED:ECERDB[5:0]) as the upper 6-bit data of the input signal to be decoded. Write access to ECREIS is enabled only when ECTMCE is 1 (can be set simultaneously). ECREIS is cleared by writing 0 to ECTMCE (can be cleared synchronously).</p> <p>0: Allow the upper 6-bit RAM output data to be input to the ECC redundant bit area to the decoder.</p> <p>1: Allow the E610TED:ECERDB[5:0] value to be input to the ECC redundant bit area to the decoder.</p>

40.3.10.5 E610TED — ECC Encoder and Decoder Data Test Register

E610TED is a 32-bit test register consisting of three fields (ECEDB, ECRIDM, and ECERDB) corresponding to the ECC data area and redundant bit area. Each field can be accessed as the register with the same name. For details of each field, refer to the descriptions of these three registers.

When ECTMCE = 1, E610TED can be read and written to using the 32-bit manipulation instruction.

When ECTMCE = 0, E610TED is always read as 0.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
ECEDB																
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ECRIDM								ECERDB								
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W

NOTE

Changing ECTMCE from 1 to 0 resets E610TED synchronously.

40.3.10.6 ECEDB — ECC Encoder and Decoder Data Input and Output Substitution Buffer Register

ECEDB is a 16-bit data buffer register for ECC encoding and decoding.

ECEDB can be read and written to in test mode (ECTMCE = 1).

When ECTMCE = 1, the ECEDB value can be used as the data input to the encoding circuit and decoding circuit.

When E610TMC:ECENS = 1, the ECEDB value is input to the encoding circuit and supplied to the RAM.

When E610TMC:ECDCS = 1, the ECEDB value is input as the 15th to 0th bits of the input data to the decoding circuit.

When E610TMC:ECTRRS = 1, reading ECEDB returns the RAM output data instead of the data written to ECEDB.

40.3.10.7 ECRIDM — ECC Redundant Bit Input Data Monitoring Register

ECRIDM is a read-only register used to monitor the upper 6-bit data (redundant bit area) value from the RAM in test mode (ECTMCE = 1) when E610TMC:ECTRRS = 1. With ECRIDM, the RAM output data can be confirmed easily.

When ECTRRS = 0, ECRIDM is always read as 0.

Bit 7 and 6 are reserved. When read, the value after reset is returned. When writing, write the value after reset.

40.3.10.8 ECERDB — ECC Redundant Bit Input and Output Substitution Buffer Register

ECERDB is a buffer register for the data that substitutes for the input and output data for the 6-bit ECC redundant data area in test mode (ECTMCE = 1).

ECERDB can be read and written to in test mode (ECTMCE = 1).

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	ERDB[5:0]					
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R/W	R/W	R/W	R/W	R/W	R/W

When ECREOS = 1, the ECERDB value, instead of the six redundant bits generated by the encoding circuit, is output to the ECC redundant bit output pin and supplied to the RAM.

When ECREIS = 1, the ECERDB value, instead of the upper six data bits to be input to the decoding circuit, is handled by the decoding circuit.

Bit 7 and 6 are reserved. When read, the value after reset is returned. When writing, write the value after reset.

40.3.10.9 E610TRC — ECC Redundant Bit Data Control Test Register

E610TRC is a 32-bit test register consisting of four fields (ECSYND, ECHORD, ECECRD, and ECRODM) corresponding to the ECC redundant bit area. Each field can be accessed as the 8-bit register with the same name. For details of each field, refer to the descriptions of these four registers.

When ECTMCE = 0, E610TRC is always read as 0.

When ECTMCE = 1, E610TRC can be read using the 32-bit manipulation instruction.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	ECSYND								ECHORD							
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	ECECRD								ECRODM							
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

40.3.10.10 ECSYND — ECC Decoder Syndrome Data Register

ECSYND is a read-only register used to confirm the syndrome code generated by the decoding circuit in test mode (ECTMCE = 1).

Write access to ECSYND is ignored.

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	SYND[5:0]					
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R

When read, the ECSYND bits return the value of the syndrome code (SYND[5:0]) generated based on the data input to the decoding circuit.

The ECSYND bits are not holding circuits; the register value changes as the input signal changes.

ECSYND is valid only when ECTMCE = 1, and is always read as 00_H when ECTMCE = 0.

Bit 7 and 6 are reserved. When read, the value after reset is returned. When writing, write the value after reset.

40.3.10.11 ECHORD — ECC 6-Bit Redundant Data Holding Test Register

ECHORD holds the 6-bit ECC redundant area (upper 6-bit RAM data) that cannot be confirmed by the peripheral module when the peripheral module accesses the RAM for reading in test mode (ECTMCE = 1).

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	HORD[5:0]					
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R

The ECHORD bits are loaded with the upper 6-bit RAM output data at the next rising edge of the operating clock signal after the peripheral module accesses the RAM for reading data in test mode (ECTMCE = 1).

The ECHORD bits are also loaded with the data on the input pins at the next operating clock pulse when the ECEDB[15:0] register is read while E610TMC:ECTRRS = 1.

ECHORD is valid only when ECTMCE = 1, and is always read as 00_H when ECTMCE = 0.

Bit 7 and 6 are reserved. When read, the value after reset is returned. When writing, write the value after reset.

40.3.10.12 ECECRD — ECC Encoder Test Register

ECECRD is a read-only register used to read the 6-bit redundant section generated by the encoding circuit in test mode (ECTMCE = 1).

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	ECRD[5:0]					
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R

ECECRD is used to confirm the redundant bits generated by the input data from the peripheral module. Here, the data that is read is the result of encoding (ECC[5:0]), not the value output from the ECC redundant bits.

ECECRD is valid only when ECTMCE = 1, and is always read as 00_H when ECTMCE = 0.

Bit 7 and 6 are reserved. When read, the value after reset is returned. When writing, write the value after reset.

40.3.10.13 ECRODM — ECC Redundant Bit Output Data Monitoring Register

ECRODM is a read-only register used to monitor the value of the ECC redundant bit output pin in test mode (ECTMCE = 1).

With ECRODM, the upper 6-bit output data to the RAM can be confirmed easily.

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	RODM[5:0]					
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R

ECRODM is valid only when ECTMCE = 1, and is always read as 00_H when ECTMCE = 0.

Bit 7 and 6 are reserved. When read, the value after reset is returned. When writing, write the value after reset.

40.3.10.14 E610EAD — ECC Error Address Register

E610EAD is a read-only register used to hold the address at which an ECC error has occurred.

If an ECC error is detected while ECC error detection is enabled, the RAM address is latched using the detection signal as a trigger, and the address is stored in E610EAD as the address at which the ECC error occurred.

The address is stored upon detection of the first ECC error while no error status is set. However, if a 1-bit error is followed by a 2-bit error, the address of the latter is stored. The address can be calculated by adding the base address.

Only one address can be held in E610EAD.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
E610EAD[31:16]																
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
E610EAD[15:0]																
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

40.3.10.15 Notification to ECM

Detection of errors in two bits can be set for this module and the ECM is notified of detected errors.

- 1-bit Error Notification

While EC1EDIC is set to 1_B, when an error is detected in one bit from among bits 0 to 21 of data read from RAM, the ECM is notified of the 1-bit error. When ECER1F or ECER2F is already set, however, the ECM will not be notified of the error.

- 2-bit Error Notification

While EC2EDIC is set to 1_B, when an error is detected in two bits from among bits 0 to 21 of data read from RAM, the ECM is notified of the 2-bit error. When ECER2F is already set, however, the ECM will not be notified of the error.

40.3.10.16 Test Function

(1) Writing RAM Data

Write data to the peripheral RAM. However, the ECC corresponding to the written data will be written to the ECC bits simultaneously. In order to write a specified value to the ECC bits, use the ECC test mode described in **(3)** below.

(2) Reading RAM Data

- Set the ECTHM bit in the E610CTL register to 1 to disable ECC error detection and correction.
- Read the peripheral RAM. Since neither error detection nor correction proceed when the peripheral RAM is read, the RAM data is read unchanged.

How to exit this test mode:

- Set the ECTHM bit in the E610CTL register to 0 to enable ECC error detection and correction.

(3) Writing to the ECC Bits

- Set the ECTMCE bit in the E610TMC register to 1 to set ECC test mode.
- Write the value to be written to the ECC bits to E610TED.ECERDB[5:0].
- Set the ECREOS bit in the E610TMC register to 1 to select writing of the value of the E610TED.ECERDB[5:0] bits to the ECC bits.
- When data is written to the peripheral RAM, the value in the E610TED.ECERDB[5:0] bits will be written to the ECC bits.

How to exit this test mode:

- Set the ECTMCE bit in the E610TMC register to 0 to set normal mode.

(4) Reading the ECC Bits

- Set the ECTMCE bit in the E610TMC register to 1 to set ECC test mode.
- When data in the peripheral RAM is read, the ECC bits are stored in the E610TRC.ECHORD[5:0] bits.

How to exit this test mode:

- Set the ECTMCE bit in the E610TMC register to 0 to set normal mode.

40.3.11 Safety Mechanism on Data Transfer Path

40.3.11.1 Overview

This product provides a function that protects the transaction data and the addresses on each bus. This function applies to Cluster RAM Bus, Local FLASH Bus, Global FLASH Bus, Inter-processor element Bus, Inter-cluster Bus, System Bus, Peripheral Bus and High speed Bus.

ECC protection on bus is summarized in the table below.

Table 40.197 ECC protection on Bus

Item	Description
Data ECC error detection and correction	<p>ECC error detection and correction on data bus between master and slave can be either enabled or disabled.</p> <p>When enabled, either of the following settings can be selected:</p> <ul style="list-style-type: none"> • ECC error detection and correction are carried out (2-bit error detection, 1-bit error detection and correction are carried out). • ECC error detection is carried out (2-bit error detection and 1-bit error detection are carried out). <p>When disabled, neither error detection nor correction is carried out.</p> <p>In the initial state, the ECC function is enabled; 1-bit error detection and correction, and 2-bit error detection are carried out.</p>
Address ECC error detection	<p>ECC error detection on address bus between master and slave can be either enabled or disabled.</p> <p>In the initial state, 1-bit error detection and 2-bit error detection are carried out.</p>
Error notification	<p>The occurrence of a Data ECC error or an Address EDC error is reported to the Error Control Module.</p> <p>Data ECC Error:</p> <ul style="list-style-type: none"> • Error notification can be either enabled or disabled upon detection of an ECC 2-bit error. • Error notification can be either enabled or disabled upon detection of an ECC 1-bit error. <p>In the initial state, error notification is enabled upon detection of an ECC 2-bit and ECC 1-bit error.</p> <p>Address EDC Error:</p> <ul style="list-style-type: none"> • Error notification can be either enabled or disabled upon detection of an ECC 2-bit error. • Error notification can be either enabled or disabled upon detection of an ECC 1-bit error. <p>In the initial state, error notification is enabled upon detection of an ECC 2-bit and ECC 1-bit error.</p> <p>The error notification signal is output with an Address ECC 2-bit error, an Address ECC 1-bit error handled as one source, and a Data ECC 2-bit error and a Data ECC 1-bit error are handled as individual sources.</p>
Error status	<p>A status register is provided that indicates the status of Data ECC 2-bit error detection, Data ECC 1-bit error detection, Address ECC 2-bit error detection, and Address ECC 1-bit error detection. If an error occurs while no error status is set, the corresponding status is set. The error status can be cleared using the clear register.</p>
Self-diagnosis	<p>ERRGEN is available for self-diagnosis of ECC decoder of data transfer path.</p>

40.3.11.2 Register Base Address

Base addresses of safety modules are listed in the following table. Each register address is given as an offset from the base addresses.

Table 40.198 Register Base Addresses (1/3)

Base Address Name	Base Address	Bus Group
<ECCCNT_A_CCIB0CL0_base>	FFC4 B000 _H	Peripheral Group 0
<ECCCNT_A_CCIB1CL0_base>	FFC4 B080 _H	Peripheral Group 0
<ECCCNT_A_CCIB0CL1_base>	FFC4 B200 _H	Peripheral Group 0
<ECCCNT_A_CCIB1CL1_base>	FFC4 B280 _H	Peripheral Group 0
<ECCCNT_A_CCIB0CL2_base>*1	FFC4 B400 _H	Peripheral Group 0
<ECCCNT_A_CCIB1CL2_base>*1	FFC4 B480 _H	Peripheral Group 0
<ECCCNT_SA_PE0CL0_base>	FFC4 C000 _H	Peripheral Group 0
<ECCCNT_A_GCFU0ICL0_base>	FFC4 C080 _H	Peripheral Group 0
<ECCCNT_A_GCFU0DCL0_base>	FFC4 C100 _H	Peripheral Group 0

- Note 1. For an access by using a master except for PE, the path from Global FLASH Bus to Code Flash is covered.
- Note 2. For an access by using a master except for PE, the path from a master to Global FLASH Bus is covered.
- Note 3. An access by specific instructions (CLR1, NOT1, SET1, and CAXI) is targeted. For details, see *the RH850G4MH User's Manual: Software*.
- Note 4. Instruction fetch access from PEn to PEn's Local RAM is covered. (n = 0 to 5: n = 4 to 5 is not implemented in E2H)
- Note 5. Instruction fetch access from PEn to Cluster RAM is covered.
- Note 6. Data access from PEn to Cluster RAM and PEn's Local RAM is not covered. (n = 0 to 5: n = 4 to 5 is not implemented in E2H)
- Note 7. This function is not implemented in E2H.
- Note 8. This function is implemented in E2x-FCC2 only.

40.3.11.4 BUSAECCCTL — ECC Control Register

This register controls ECC error detection for requested address.

This register is protected by the Key Code Protection Register. For details whether this register is protected by either KCPROT or APECKCPROT, see **Table 40.199, List of Registers**.

This register can be written only when KCE = 1.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Table 40.201 BUSAECCCTL Register Contents

Bit Position	Bit Name	Function
31 to 1	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
0	ECCDIS	Address ECC disable bit Sets ECC error detection to enable/disable. 0: ECC error detection is enabled 1: ECC error detection is disabled

40.3.11.5 BUSAECCTSTCTL — ECC Test Control Register

ECC test (self-diagnostics) register. After setting the ECC test mode (ECCTST = 1), arbitrary data value can be input to ECC decoder.

This register is protected by the Key Code Protection Register. For details whether this register is protected by either KCPROT or APECKCROT, see **Table 40.199, List of Registers**.

This register can be written only when KCE = 1.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 40.202 BUSAECCTSTCTL Register Contents

Bit Position	Bit Name	Function
31 to 2	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
1	ECCTST	Selects input data for the address ECC decoder. 0: Normal mode 1: Test mode The values of BUSAECCTSTDINO and BUSAECCTSTEIN registers are provided to data and ECC fields of the ECC decoder in test mode.
0	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.

40.3.11.6 BUSAECCTSTDIN0 — Test Data Input Register

This register is used to inject errors into data field of ECC decoder for self-diagnosis. The values of BUSAECCTSTDIN0 and BUSAECCTSTEIN registers are input to data and ECC field of the target ECC decoder in test mode.

This register is protected by the Key Code Protection Register. For details whether this register is protected by either KCPROT or APECKCPROT, see **Table 40.199, List of Registers**.

This register can be written only when KCE = 1.

Value after reset: 0000 0000_H

Table 40.203 BUSAECCTSTDIN0 Register Contents

Bit Position	Bit Name	Function
31 to 0	DATA[31:0]	Specify test data for the data ECC decoder. The data is provided to data field of the ECC decoder when ECCTST = 1.

40.3.11.7 BUSAECCTSTEIN — Test ECC Input Register

This register is used to inject errors into ECC field of ECC decoder for self-diagnosis. The values of BUSAECCTSTDIN0 and BUSAECCTSTEIN registers are input to data and ECC field of the target ECC decoder in test mode.

This register is protected by the Key Code Protection Register. For details whether this register is protected by either KCPROT or APECKCPROT, see **Table 40.199, List of Registers**.

This register can be written only when KCE = 1.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 40.204 BUSAECCTSTEIN Register Contents

Bit Position	Bit Name	Function
31 to 7	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
6 to 0	ECC[6:0]	Specify test data for ECC decoder. The data is provided to ECC field of the ECC decoder when ECCTST = 1.

40.3.11.8 BUSDVCECCCTL — ECC Control Register

This register controls ECC error detection/correction and 1-bit error correction.

This register is protected by the Key Code Protection Register. For details whether this register is protected by either KCPROT or APECKCPROT, see **Table 40.199, List of Registers**.

This register can be written only when KCE = 1.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W

Table 40.205 BUSDVCECCCTL Register Contents

Bit Position	Bit Name	Function
31 to 2	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
1	SECDIS	Data ECC error correction enable bit When using ECC error detection/correction (ECCDIS = 0), this bit sets 1-bit error correction to enable/disable. 0: Correct when 1-bit error is detected 1: Do not correct when a 1-bit error is detected
0	ECCDIS	Data ECC disable bit Sets ECC error detection/correction to enable/disable. 0: ECC error detection/correction is enabled 1: ECC error detection/correction is disabled

40.3.11.9 BUSDVCECCTSTCTL — ECC Test Control Register

ECC test (self-diagnostics) register. After setting the ECC test mode (ECCTST = 1), arbitrary data value can be input to ECC decoder.

This register is protected by the Key Code Protection Register. For details whether this register is protected by either KCPROT or APECKCPROT, see **Table 40.199, List of Registers**.

This register can be written only when KCE = 1.

Value after reset: 0000 0000_H

R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W

Table 40.206 BUSDVCECCTSTCTL Register Contents

Bit Position	Bit Name	Function
31 to 2	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
1	ECCTST	Selects input data for the data ECC decoder. 0: Normal mode 1: Test mode The values of BUSDVCECCTSTDIN0 and BUSDVCECCTSTEIN registers are provided to data and ECC fields of one of the ECC decoders along with DATSEL setting in test mode.
0	DATSEL	Selects ECC decoder to replace input data when ECCTST = 1. 0: ECC decoder for lower data 1: ECC decoder for upper data

40.3.11.10 BUSDVCECCTSTDIN0 — Test Data Input Register

This register is used to inject errors into data field of ECC decoder for self-diagnosis. The values of BUSDVCECCTSTDIN0 and BUSDVCECCTSTEIN registers are input to data and ECC field of the target ECC decoder in test mode.

This register is protected by the Key Code Protection Register. For details whether this register is protected by either KCPROT or APECKCPROT, see **Table 40.199, List of Registers**.

This register can be written only when KCE = 1.

Value after reset: 0000 0000_H

Table 40.209 BUSDEMECCCTL Register Contents

Bit Position	Bit Name	Function
31 to 2	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
1	SECDIS	Data ECC 1-bit error correction enable bit When using ECC error detection/correction (ECCDIS = 0), this bit sets 1-bit error correction to enable/disable. 0: Correct when 1-bit error is detected 1: Do not correct when 1-bit error is detected
0	ECCDIS	Data ECC disable bit Sets ECC error detection/correction to enable/disable. 0: ECC error detection/correction is enabled 1: ECC error detection/correction is disabled

40.3.11.13 BUSDEMECCTSTCTL — ECC Test Control Register

ECC test (self-diagnostics) register. After ECC test mode (ECCTST = 1) setting, arbitrary data value can be input to ECC decoder.

This register is protected by the KCPROT register. When KCPROT.KCE = 0, it cannot be written. It can be written only when KCPROT.KCE = 1.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 40.210 BUSDEMECCTSTCTL Register Contents

Bit Position	Bit Name	Function
31 to 2	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
1	ECCTST	Selects input data for the data ECC decoder. 0: Normal mode 1: Test mode The values of BUSDEMECCTSTDIN0 and BUSDEMECCTSTEIN registers are provided to data and ECC field of one of the ECC decoders along with DATSEL setting in test mode.
0	DATSEL	Selects ECC decoder to replace input data under ECCTST = 1. 0: ECC decoder for lower data 1: ECC decoder for upper data

40.3.11.14 BUSDEMECCTSTDIN0 — Test Data Input Register

This register is used to inject errors into data field of ECC decoder for self-diagnosis. The values of BUSDEMECCTSTDIN0 and BUSDEMECCTSTEIN registers are input to data and ECC field of the target ECC decoder in test mode.

This register is protected by the KCPROT register. When KCPROT.KCE = 0, it cannot be written. It can be written only when KCPROT.KCE = 1.

Value after reset: 0000 0000_H

2	DSSTCLR02	Writing 1 to this bit clears DSEDF02 in LR_BUSDSESTR.
1	DSSTCLR01	Writing 1 to this bit clears DSEDF01 in LR_BUSDSESTR.
0	DSSTCLR00	Writing 1 to this bit clears DSEDF00 in LR_BUSDSESTR.

Note 1. This function is not implemented in E2H.

40.3.11.26 LR_BUSDDSTCLR — Data 2-bit Error Status Clear Register

This register is used to clear error flags in LR_BUSDDERSTR. This is write only register and read value is always “0”.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Table 40.223 LR_BUSDDSTCLR Register Contents

Bit Position	Bit Name	Function
31 to 6	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
5	DDSTCLR05* ¹	Writing 1 to this bit clears DDEDF05 in LR_BUSDDERSTR.
4	DDSTCLR04* ¹	Writing 1 to this bit clears DDEDF04 in LR_BUSDDERSTR.
3	DDSTCLR03	Writing 1 to this bit clears DDEDF03 in LR_BUSDDERSTR.
2	DDSTCLR02	Writing 1 to this bit clears DDEDF02 in LR_BUSDDERSTR.
1	DDSTCLR01	Writing 1 to this bit clears DDEDF01 in LR_BUSDDERSTR.
0	DDSTCLR00	Writing 1 to this bit clears DDEDF00 in LR_BUSDDERSTR.

Note 1. This function is not implemented in E2H.

40.3.11.27 LR_BUSASERSTR — Address 1-bit Error Status Register

This register indicates that an address ECC 1-bit error has occurred in a path related to Local RAMs. When a new error occurs, status flag corresponding to the error is set if the flag has been cleared. If multiple errors are detected at the same time, flags of the detected errors are all set.

This register can be cleared by LR_BUSASSTCLR register.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 40.224 LR_BUSASERSTR Register Contents

Bit Position	Bit Name	Function
31 to 19	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
18	ASEDF18*1	Indicates that an address ECC 1-bit error was detected in request address to AXI2VCI bridge in cluster 2.
17	ASEDF17	Indicates that an address ECC 1-bit error was detected in request address to AXI2VCI bridge in cluster 1.
16	ASEDF16	Indicates that an address ECC 1-bit error was detected in request address to AXI2VCI bridge in cluster 0.
15 to 6	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
5	ASEDF05*1	Indicates that an address ECC 1-bit error was detected in request address to PE5.
4	ASEDF04*1	Indicates that an address ECC 1-bit error was detected in request address to PE4.
3	ASEDF03	Indicates that an address ECC 1-bit error was detected in request address to PE3.
2	ASEDF02	Indicates that an address ECC 1-bit error was detected in request address to PE2.
1	ASEDF01	Indicates that an address ECC 1-bit error was detected in request address to PE1.
0	ASEDF00	Indicates that an address ECC 1-bit error was detected in request address to PE0.

Note 1. This function is not implemented in E2H.

40.3.11.28 LR_BUSADERSTR — Address 2-bit Error Status Register

This register indicates that an address ECC 2-bit error has occurred in a path related to Local RAMs. When a new error occurs, status flag corresponding to the error is set if the flag has been cleared. If multiple errors are detected at the same time, the flags of the detected errors are all set.

This register can be cleared by LR_BUSADSTCLR register.

Value after reset: 0000 0000_H

Table 40.225 LR_BUSADERSTR Register Contents

Bit Position	Bit Name	Function
31 to 19	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
18	ADEDF18*1	Indicates that an address ECC 2-bit error was detected in request address to AXI2VCI bridge in cluster 2.
17	ADEDF17	Indicates that an address ECC 2-bit error was detected in request address to AXI2VCI bridge in cluster 1.
16	ADEDF16	Indicates that an address ECC 2-bit error was detected in request address to AXI2VCI bridge in cluster 0.
15 to 6	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
5	ADEDF05*1	Indicates that an address ECC 2-bit error was detected in request address to PE5.
4	ADEDF04*1	Indicates that an address ECC 2-bit error was detected in request address to PE4.
3	ADEDF03	Indicates that an address ECC 2-bit error was detected in request address to PE3.
2	ADEDF02	Indicates that an address ECC 2-bit error was detected in request address to PE2.
1	ADEDF01	Indicates that an address ECC 2-bit error was detected in request address to PE1.
0	ADEDF00	Indicates that an address ECC 2-bit error was detected in request address to PE0.

Note 1. This function is not implemented in E2H.

40.3.11.29 LR_BUSDSESTR — Data 1-bit Error Status Register

This register indicates that a data ECC 1-bit error has occurred in a path related to Local RAMs. When a new error occurs, status flag corresponding to the error is set if the flag has been cleared. If multiple errors are detected at the same time, the flags of the detected errors are all set.

This register can be cleared by LR_BUSDSSTCLR register.

Value after reset: 0000 0000_H

Table 40.227 LR_BUSDDERSTR Register Contents

Bit Position	Bit Name	Function
31 to 6	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
5	DDED F05 ^{*1}	Indicates that a data ECC 2-bit error has been detected in write data to PE5.
4	DDED F04 ^{*1}	Indicates that a data ECC 2-bit error has been detected in write data to PE4.
3	DDED F03	Indicates that a data ECC 2-bit error has been detected in write data to PE3.
2	DDED F02	Indicates that a data ECC 2-bit error has been detected in write data to PE2.
1	DDED F01	Indicates that a data ECC 2-bit error has been detected in write data to PE1.
0	DDED F00	Indicates that a data ECC 2-bit error has been detected in write data to PE0.

Note 1. This function is not implemented in E2H.

40.3.11.31 CR_BUSERRINT — Error Notification Control Register

This register controls whether error information is reported to ECM, when address/data ECC 2-bit error and address/data ECC 1-bit error are detected.

This register is protected by the KCPROT register. When KCPROT.KCE = 0, it cannot be written. It can be written only when KCPROT.KCE = 1.

Value after reset: 0000 000F_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Note 1. This function is not implemented in E2H.

40.3.11.36 CR_BUSASERSTR — Address 1-bit Error Status Register

This register indicates that an address ECC 1-bit error has occurred in a path related to Cluster RAMs. When a new error occurs, status flag corresponding to the error is set if the flag has been cleared. If multiple errors are detected at the same time, the flags of the detected errors are all set.

This register can be cleared by CR_BUSASSTCLR register.

Value after reset: 0000 0000_H

Table 40.233 CR_BUSASERSTR Register Contents (1/2)

Bit Position	Bit Name	Function
31 to 27	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
26	ASEDF26*1	Indicates that an address ECC 1-bit error was detected in request address to SAXI2MBI bridge for cluster 2.
25	ASEDF25	Indicates that an address ECC 1-bit error was detected in request address to SAXI2MBI bridge for cluster 1.
24	ASEDF24	Indicates that an address ECC 1-bit error was detected in request address to SAXI2MBI bridge for cluster 0.
23 to 11	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
10	ASEDF10*1	Indicates that an address ECC 1-bit error was detected in request address to Cluster RAM in cluster 2 from outside.
9	ASEDF09*1	Indicates that an address ECC 1-bit error was detected in request address from PE5 to Cluster RAM in cluster 2.
8	ASEDF08*1	Indicates that an address ECC 1-bit error was detected in request address from PE4 to Cluster RAM in cluster 2.
7	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
6	ASEDF06	Indicates that an address ECC 1-bit error was detected in request address to Cluster RAM in cluster 1 from outside.
5	ASEDF05	Indicates that an address ECC 1-bit error was detected in request address from PE3 to Cluster RAM in cluster 1.
4	ASEDF04	Indicates that an address ECC 1-bit error was detected in request address from PE2 to Cluster RAM in cluster 1.
3	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
2	ASEDF02	Indicates that an address ECC 1-bit error was detected in request address to Cluster RAM in cluster 0 from outside.
1	ASEDF01	Indicates that an address ECC 1-bit error was detected in request address from PE1 to Cluster RAM in cluster 0.

Table 40.233 CR_BUSASERSTR Register Contents (2/2)

Bit Position	Bit Name	Function
0	ASEDF00	Indicates that an address ECC 1-bit error was detected in request address from PE0 to Cluster RAM in cluster 0.

Note 1. This function is not implemented in E2H.

40.3.11.37 CR_BUSADERSTR — Address 2-bit Error Status Register

This register indicates that an address ECC 2-bit error has occurred in a path related to Cluster RAMs. When a new error occurs, status flag corresponding to the error is set if the flag has been cleared. If multiple errors are detected at the same time, the flags of the detected errors are all set.

This register can be cleared by CR_BUSADSTCLR register.

Value after reset: 0000 0000_H

Bit Position	Bit Name	Function
31 to 27	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
26	ADEDF26* ¹	Indicates that an address ECC 2-bit error was detected in request address to SAXI2MBI bridge for cluster 2.
25	ADEDF25	Indicates that an address ECC 2-bit error was detected in request address to SAXI2MBI bridge for cluster 1.
24	ADEDF24	Indicates that an address ECC 2-bit error was detected in request address to SAXI2MBI bridge for cluster 0.
23 to 11	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
10	ADEDF10* ¹	Indicates that an address ECC 2-bit error was detected in request address to Cluster RAM in cluster 2 from outside.
9	ADEDF09* ¹	Indicates that an address ECC 2-bit error was detected in request address from PE5 to Cluster RAM in cluster 2.
8	ADEDF08* ¹	Indicates that an address ECC 2-bit error was detected in request address from PE4 to Cluster RAM in cluster 2.
7	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
6	ADEDF06	Indicates that an address ECC 2-bit error was detected in request address to Cluster RAM in cluster 1 from outside.
5	ADEDF05	Indicates that an address ECC 2-bit error was detected in request address from PE3 to Cluster RAM in cluster 1.
4	ADEDF04	Indicates that an address ECC 2-bit error was detected in request address from PE2 to Cluster RAM in cluster 1.
3	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
2	ADEDF02	Indicates that an address ECC 2-bit error was detected in request address to Cluster RAM in cluster 0 from outside.
1	ADEDF01	Indicates that an address ECC 2-bit error was detected in request address from PE1 to Cluster RAM in cluster 0.

Table 40.234 CR_BUSADERSTR Register Contents (2/2)

Bit Position	Bit Name	Function
0	ADEDF00	Indicates that an address ECC 2-bit error was detected in request address from PE0 to Cluster RAM in cluster 0.

Note 1. This function is not implemented in E2H.

40.3.11.38 CR_BUSDSESTR — Data 1-bit Error Status Register

This register indicates that a data ECC 1-bit error has occurred in a path related to Cluster RAMs. When a new error occurs, status flag corresponding to the error is set if the flag has been cleared. If multiple errors are detected at the same time, the flags of the detected errors are all set.

This register can be cleared by CR_BUSDSSTCLR register.

Bit Position	Bit Name	Function
31 to 11	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
10	DDED _{F10} ^{*1}	Indicates that a data ECC 2-bit error was detected in write data to Cluster RAM in cluster 2 from outside.
9	DDED _{F09} ^{*1}	Indicates that a data ECC 2-bit error was detected in write data from PE5 to Cluster RAM in cluster 2.
8	DDED _{F08} ^{*1}	Indicates that a data ECC 2-bit error was detected in write data from PE4 to Cluster RAM in cluster 2.
7	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
6	DDED _{F06}	Indicates that a data ECC 2-bit error was detected in write data to Cluster RAM in cluster 1 from outside.
5	DDED _{F05}	Indicates that a data ECC 2-bit error was detected in write data from PE3 to Cluster RAM in cluster 1.
4	DDED _{F04}	Indicates that a data ECC 2-bit error was detected in write data from PE2 to Cluster RAM in cluster 1.
3	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
2	DDED _{F02}	Indicates that a data ECC 2-bit error was detected in write data to Cluster RAM in cluster 0 from outside.
1	DDED _{F01}	Indicates that a data ECC 2-bit error was detected in write data from PE1 to Cluster RAM in cluster 0.
0	DDED _{F00}	Indicates that a data ECC 2-bit error was detected in write data from PE0 to Cluster RAM in cluster 0.

Note 1. This function is not implemented in E2H.

40.3.11.40 CF_BUSERRINT — Error Notification Control Register

This register controls whether error information is reported to ECM, when address ECC 2-bit error and address ECC 1-bit error are detected.

This register is protected by the KCPROT register. When KCPROT.KCE = 0, it cannot be written. It can be written only when KCPROT.KCE = 1.

Value after reset: 0000 000CH

9	ADEDF09*1	Indicates that an address ECC 2-bit error was detected in request address to Code Flash bank F in cluster 2.
8	ADEDF08*1	Indicates that an address ECC 2-bit error was detected in request address to Code Flash bank E in cluster 2.
7 to 6	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
5	ADEDF05	Indicates that an address ECC 2-bit error was detected in request address to Code Flash bank D in cluster 1.
4	ADEDF04	Indicates that an address ECC 2-bit error was detected in request address to Code Flash bank C in cluster 1.
3 to 2	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
1	ADEDF01	Indicates that an address ECC 2-bit error was detected in request address to Code Flash bank B in cluster 0.
0	ADEDF00	Indicates that an address ECC 2-bit error was detected in request address to Code Flash bank A in cluster 0.

Note 1. This function is not implemented in E2H.

40.3.11.45 PH_BUSERRINT — Error Notification Control Register

This register controls whether error information is reported to ECM, when address/data ECC 2-bit error and address/data ECC 1-bit error are detected.

This register is protected by the KCPROT register. When KCPROT.KCE = 0, it cannot be written. It can be written only when KCPROT.KCE = 1.

Value after reset: 0000 000F_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 40.246 PH_BUSDDSTCLR Register Contents

Bit Position	Bit Name	Function
31 to 26	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
25	DDSTCLR25	Writing 1 to this bit clears DDED25 in PH_BUSDDERSTR.
24 to 20	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
19	DDSTCLR19	Writing 1 to this bit clears DDED19 in PH_BUSDDERSTR.
18	DDSTCLR18	Writing 1 to this bit clears DDED18 in PH_BUSDDERSTR.
17	DDSTCLR17	Writing 1 to this bit clears DDED17 in PH_BUSDDERSTR.
16	DDSTCLR16	Writing 1 to this bit clears DDED16 in PH_BUSDDERSTR.
15 to 14	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
13	DDSTCLR13*1	Writing 1 to this bit clears DDED13 in PH_BUSDDERSTR.
12	DDSTCLR12*1	Writing 1 to this bit clears DDED12 in PH_BUSDDERSTR.
11	DDSTCLR11	Writing 1 to this bit clears DDED11 in PH_BUSDDERSTR.
10	DDSTCLR10	Writing 1 to this bit clears DDED10 in PH_BUSDDERSTR.
9	DDSTCLR09	Writing 1 to this bit clears DDED09 in PH_BUSDDERSTR.
8	DDSTCLR08	Writing 1 to this bit clears DDED08 in PH_BUSDDERSTR.
7 to 6	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
5	DDSTCLR05*1	Writing 1 to this bit clears DDED05 in PH_BUSDDERSTR.
4	DDSTCLR04*1	Writing 1 to this bit clears DDED04 in PH_BUSDDERSTR.
3	DDSTCLR03	Writing 1 to this bit clears DDED03 in PH_BUSDDERSTR.
2	DDSTCLR02	Writing 1 to this bit clears DDED02 in PH_BUSDDERSTR.
1	DDSTCLR01	Writing 1 to this bit clears DDED01 in PH_BUSDDERSTR.
0	DDSTCLR00	Writing 1 to this bit clears DDED00 in PH_BUSDDERSTR.

Note 1. This function is not implemented in E2H.

40.3.11.50 PH_BUSASERSTR — Address 1-bit Error Status Register

This register indicates that an address ECC 1-bit error has occurred in a path related to peripherals. When a new error occurs, status flag corresponding to the error is set if the flag has been cleared. If multiple errors are detected at the same time, the errors that are detected are all set.

This register can be cleared by PH_BUSASSTCLR register.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 40.247 PH_BUSASERSTR Register Contents

Bit Position	Bit Name	Function
31 to 26	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
25	ASEDF25	Indicates that an address ECC 1-bit error was detected in request address to VC12APB bridge for peripheral group 0.
24 to 21	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
20	ASEDF20	Indicates that an address ECC 1-bit error was detected in request address to AXI2PVC1 bridge.
19	ASEDF19	Indicates that an address ECC 1-bit error was detected in request address to MEV.
18	ASEDF18	Indicates that an address ECC 1-bit error was detected in request address to IPIR.
17	ASEDF17	Indicates that an address ECC 1-bit error was detected in request address to BarrierSync.
16	ASEDF16	Indicates that an address ECC 1-bit error was detected in request address to TPTM.
15 to 0	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.

40.3.11.51 PH_BUSADERSTR — Address 2-bit Error Status Register

This register indicates that an address ECC 2-bit error has occurred in a path related to peripherals. When a new error occurs, status flag corresponding to the error is set if the flag has been cleared. If multiple errors are detected at the same time, the errors that are detected are all set.

This register can be cleared by PH_BUSADSTCLR register.

Value after reset: 0000 0000_H

Table 40.249 PH_BUSDSESTR Register Contents

Bit Position	Bit Name	Function
31 to 26	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
25	DSEDF25	Indicates that a data ECC 1-bit error was detected in write data to VCI2APB bridge for peripheral group 0.
24 to 20	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
19	DSEDF19	Indicates that a data ECC 1-bit error was detected in write data to MEV.
18	DSEDF18	Indicates that a data ECC 1-bit error was detected in write data to IPIR.
17	DSEDF17	Indicates that a data ECC 1-bit error was detected in write data to BarrierSync.
16	DSEDF16	Indicates that a data ECC 1-bit error was detected in write data to TPTM.
15 to 14	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
13	DSEDF13*1	Indicates that a data ECC 1-bit error was detected in read data to VCI2AXI bridge in cluster 2.
12	DSEDF12*1	Indicates that a data ECC 1-bit error was detected in write data to VCI2AXI bridge in cluster 2.
11	DSEDF11	Indicates that a data ECC 1-bit error was detected in read data to VCI2AXI bridge in cluster 1.
10	DSEDF10	Indicates that a data ECC 1-bit error was detected in write data to VCI2AXI bridge in cluster 1.
9	DSEDF09	Indicates that a data ECC 1-bit error was detected in read data to VCI2AXI bridge in cluster 0.
8	DSEDF08	Indicates that a data ECC 1-bit error was detected in write data to VCI2AXI bridge in cluster 0.
7 to 6	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
5	DSEDF05*1	Indicates that a data ECC 1-bit error was detected in read data to PE5 from peripherals.
4	DSEDF04*1	Indicates that a data ECC 1-bit error was detected in read data to PE4 from peripherals.
3	DSEDF03	Indicates that a data ECC 1-bit error was detected in read data to PE3 from peripherals.
2	DSEDF02	Indicates that a data ECC 1-bit error was detected in read data to PE2 from peripherals.
1	DSEDF01	Indicates that a data ECC 1-bit error was detected in read data to PE1 from peripherals.
0	DSEDF00	Indicates that a data ECC 1-bit error was detected in read data to PE0 from peripherals.

Note 1. This function is not implemented in E2H.

40.3.11.53 PH_BUSDDERSTR — Data 2-bit Error Status Register

This register indicates that a data ECC 2-bit error has occurred in a path related to peripherals. When a new error occurs, status flag corresponding to the error is set if the flag has been cleared. If multiple errors are detected at the same time, the errors that are detected are all set.

This register can be cleared by PH_BUSDDSTCLR register.

Bit Position	Bit Name	Function
31 to 26	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
25	DDED _F 25	Indicates that a data ECC 2-bit error was detected in write data to VCI2APB bridge for peripheral group 0.
24 to 20	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
19	DDED _F 19	Indicates that a data ECC 2-bit error was detected in write data to MEV.
18	DDED _F 18	Indicates that a data ECC 2-bit error was detected in write data to IPIR.
17	DDED _F 17	Indicates that a data ECC 2-bit error was detected in write data to BarrierSync.
16	DDED _F 16	Indicates that a data ECC 2-bit error was detected in write data to TPTM.
15 to 14	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
13	DDED _F 13 ^{*1}	Indicates that a data ECC 2-bit error was detected in read data to VCI2AXI bridge in cluster 2.
12	DDED _F 12 ^{*1}	Indicates that a data ECC 2-bit error was detected in write data to VCI2AXI bridge in cluster 2.
11	DDED _F 11	Indicates that a data ECC 2-bit error was detected in read data to VCI2AXI bridge in cluster 1.
10	DDED _F 10	Indicates that a data ECC 2-bit error was detected in write data to VCI2AXI bridge in cluster 1.
9	DDED _F 09	Indicates that a data ECC 2-bit error was detected in read data to VCI2AXI bridge in cluster 0.
8	DDED _F 08	Indicates that a data ECC 2-bit error was detected in write data to VCI2AXI bridge in cluster 0.
7 to 6	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
5	DDED _F 05 ^{*1}	Indicates that a data ECC 2-bit error was detected in read data to PE5 from peripherals.
4	DDED _F 04 ^{*1}	Indicates that a data ECC 2-bit error was detected in read data to PE4 from peripherals.
3	DDED _F 03	Indicates that a data ECC 2-bit error was detected in read data to PE3 from peripherals.
2	DDED _F 02	Indicates that a data ECC 2-bit error was detected in read data to PE2 from peripherals.
1	DDED _F 01	Indicates that a data ECC 2-bit error was detected in read data to PE1 from peripherals.
0	DDED _F 00	Indicates that a data ECC 2-bit error was detected in read data to PE0 from peripherals.

Note 1. This function is not implemented in E2H.

40.3.11.54 DM_BUSERRINT — Error Notification Control Register

This register controls whether error information is reported to ECM, when data ECC 2-bit error and data ECC 1-bit error are detected.

This register is protected by the KCPROT register. When KCPROT.KCE = 0, it cannot be written. It can be written only when KCPROT.KCE = 1.

Value after reset: 0000 0003_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit Position	Bit Name	Function
31 to 9	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
8	DDSTCLR08	Writing 1 to this bit clears DDEDF08 in DM_BUSDDERSTR.
7 to 4	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
3	DDSTCLR03	Writing 1 to this bit clears DDEDF03 in DM_BUSDDERSTR.
2	DDSTCLR02	Writing 1 to this bit clears DDEDF02 in DM_BUSDDERSTR.
1	DDSTCLR01	Writing 1 to this bit clears DDEDF01 in DM_BUSDDERSTR.
0	DDSTCLR00	Writing 1 to this bit clears DDEDF00 in DM_BUSDDERSTR.

40.3.11.57 DM_BUSDSESTR — Data 1-bit Error Status Register

This register indicates that a data ECC 1-bit error has occurred in a path related to DMA/DTS. When a new error occurs, status flag corresponding to the error is set if the flag has been cleared. If multiple errors are detected at the same time, the errors that are detected are all set.

This register can be cleared by DM_BUSDSTCLR register.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit Position	Bit Name	Function
31 to 9	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
8	DDED F08	Indicates that a data ECC 2-bit error was detected in read data to DTS.
7 to 4	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
3	DDED F03	Indicates that a data ECC 2-bit error was detected in internal buffer of sDMAC 1.
2	DDED F02	Indicates that a data ECC 2-bit error was detected in read data to sDMAC 1.
1	DDED F01	Indicates that a data ECC 2-bit error was detected in internal buffer of sDMAC 0.
0	DDED F00	Indicates that a data ECC 2-bit error was detected in read data to sDMAC 0.

40.3.11.59 EM_BUSERRINT — Error Notification Control Register

This register controls whether error information is reported to ECM, when address/data ECC 2-bit error and address/data ECC 1-bit error are detected.

This register is protected by the KCPROT register. When KCPROT.KCE = 0, it cannot be written. It can be written only when KCPROT.KCE = 1.

Value after reset: 0000 000F_H

Bit Position	Bit Name	Function
31 to 18	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
17	DDSTCLR17	Writing 1 to this bit clears DDED17 in EM_BUSDDERSTR.
16 to 0	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.

40.3.11.64 EM_BUSASERSTR — Address 1-bit Error Status Register

This register indicates that an address ECC 1-bit error has occurred in a path related to emulation. When a new error occurs, status flag corresponding to the error is set if the flag has been cleared. If multiple errors are detected at the same time, the errors that are detected are all set.

This register can be cleared by EM_BUSASSTCLR register.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 40.261 EM_BUSASERSTR Register Contents (1/2)

Bit Position	Bit Name	Function
31 to 18	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
17	ASEDF17	Indicates that an address ECC 1-bit error was detected in request address to FAXI2SAXI bridge.
16	ASEDF16	Indicates that an address ECC 1-bit error was detected in request address to the remap module from a SAXI master.
15 to 12	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
11	ASEDF11*1	Indicates that an address ECC 1-bit error was detected in request address to the remap module for data read from PE5.
10	ASEDF10*1	Indicates that an address ECC 1-bit error was detected in request address to the remap module for instruction fetch from PE5.
9	ASEDF09*1	Indicates that an address ECC 1-bit error was detected in request address to the remap module for data read from PE4.
8	ASEDF08*1	Indicates that an address ECC 1-bit error was detected in request address to the remap module for instruction fetch from PE4.
7	ASEDF07	Indicates that an address ECC 1-bit error was detected in request address to the remap module for data read from PE3.
6	ASEDF06	Indicates that an address ECC 1-bit error was detected in request address to the remap module for instruction fetch from PE3.
5	ASEDF05	Indicates that an address ECC 1-bit error was detected in request address to the remap module for data read from PE2.
4	ASEDF04	Indicates that an address ECC 1-bit error was detected in request address to the remap module for instruction fetch from PE2.
3	ASEDF03	Indicates that an address ECC 1-bit error was detected in request address to the remap module for data read from PE1.
2	ASEDF02	Indicates that an address ECC 1-bit error was detected in request address to the remap module for instruction fetch from PE1.
1	ASEDF01	Indicates that an address ECC 1-bit error was detected in request address to the remap module for data read from PE0.

Table 40.261 EM_BUSASERSTR Register Contents (2/2)

Bit Position	Bit Name	Function
0	ASEDF00	Indicates that an address ECC 1-bit error was detected in request address to the remap module for instruction fetch from PE0.

Note 1. This function is not implemented in E2H.

40.3.11.65 EM_BUSADERSTR — Address 2-bit Error Status Register

This register indicates that an address ECC 2-bit error has occurred in a path related to emulation. When a new error occurs, status flag corresponding to the error is set if the flag has been cleared. If multiple errors are detected at the same time, the errors that are detected are all set.

This register can be cleared by EM_BUSADSTCLR register.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 40.262 EM_BUSADERSTR Register Contents (1/2)

Bit Position	Bit Name	Function
31 to 18	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
17	AEDDF17	Indicates that an address ECC 2-bit error was detected in request address to FAXI2SAXI bridge.
16	AEDDF16	Indicates that an address ECC 2-bit error was detected in request address to the remap module from a SAXI master.
15 to 12	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
11	AEDDF11* ¹	Indicates that an address ECC 2-bit error was detected in request address to the remap module for data read from PE5.
10	AEDDF10* ¹	Indicates that an address ECC 2-bit error was detected in request address to remap module for instruction fetch from PE5.
9	AEDDF09* ¹	Indicates that an address ECC 2-bit error was detected in request address to the remap module for data read from PE4.
8	AEDDF08* ¹	Indicates that an address ECC 2-bit error was detected in request address to remap module for instruction fetch from PE4.
7	AEDDF07	Indicates that an address ECC 2-bit error was detected in request address to the remap module for data read from PE3.
6	AEDDF06	Indicates that an address ECC 2-bit error was detected in request address to remap module for instruction fetch from PE3.
5	AEDDF05	Indicates that an address ECC 2-bit error was detected in request address to the remap module for data read from PE2.
4	AEDDF04	Indicates that an address ECC 2-bit error was detected in request address to remap module for instruction fetch from PE2.
3	AEDDF03	Indicates that an address ECC 2-bit error was detected in request address to the remap module for data read from PE1.
2	AEDDF02	Indicates that an address ECC 2-bit error was detected in request address to remap module for instruction fetch from PE1.
1	AEDDF01	Indicates that an address ECC 2-bit error was detected in request address to remap module for data read from PE0.

Table 40.262 EM_BUSADERSTR Register Contents (2/2)

Bit Position	Bit Name	Function
0	ADEDF00	Indicates that an address ECC 2-bit error was detected in request address to remap module for instruction fetch from PE0.

Note 1. This function is not implemented in E2H.

40.3.11.66 EM_BUSDSERSTR — Data 1-bit Error Status Register

This register indicates that a data ECC 1-bit error has occurred in a path related to emulation. When a new error occurs, status flag corresponding to the error is set if the flag has been cleared. If multiple errors are detected at the same time, the errors that are detected are all set.

This register can be cleared by EM_BUSDSSTCLR register.

Value after reset: 0000 0000_H

Table 40.265 APECKCPROT Register Contents

Bit Position	Bit Name	Function
31 to 1	KCPROT[31:1]	Enable or disable modification of the KCE bit. The written value is not retained. These bits are always read as 0.*1
0	KCE	Key Code Enable bit*2 0: Disable write access to protected registers 1: Enable write access to protected registers

Note 1. Write A5A5A500_H to this register to disable writing protected registers.
Write A5A5A501_H to this register to enable writing protected registers.

Note 2. Unlocking this protection is one of necessary conditions to enable writing the protected registers. It is also necessary to unlock security protection driven by the ICUM when ICUM function is active. For details, see *the RH850/E2x-FCC2 ICUMD User's Manual: Hardware, Section 9*.

The security protection covers the following modules:

ECCCNT_A_V2An (n = 1, 6, 9)

ECCCNT_D_V2AnW (n = 1, 6, 9)

BECCAP_V2An (n = 1, 6, 9)

40.3.11.69 PHC_BUSERRINT — Error Notification Control Register

This register controls whether error information is reported to ECM, when address/data ECC 2-bit error and address/data ECC 1-bit error are detected.

This register is protected by the PBnECC.APECKCPROT register. When PBnECC.APECKCPROT.KCE = 0, it cannot be written. It can be written only when PBnECC.APECKCPROT.KCE = 1.

Note: For BECCCAP_V2An of peripheral group2, PB2HECC.APECKCPROT controls access protection.

Value after reset: 0000 000F_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit Position	Bit Name	Function
31 to 1	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
0	DDED00	Indicates that a data ECC 2-bit error was detected in write data to VCI2APB bridge for peripheral group n.

40.3.11.78 HBECECCCTL — ECC Control Register

This register controls the ECC error detection/correction and 1-bit error correction.

This register is protected by the key-code protection register. When KCE = 0, it cannot be written. It can be written only when KCE = 1.

Value after reset: 0000 0008_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 40.275 HBECECCCTL Register Contents

Bit Position	Bit Name	Function
31 to 3	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
2	AECCDIS	Address ECC disable bit (for H-Bus slave) Sets address ECC error detection/to enable/disable. 0: Address ECC error detection/is enabled 1: Address ECC error detection/is disabled For H-Bus master, when writing, write the value after reset because this bit is reserved.
1	SECDIS	ECC 1-bit error correction enable bit When using ECC error detection/correction (ECCDIS = 0), this bit sets 1-bit error correction to enable/disable. 0: Correct when 1-bit error is detected 1: Do not correct when 1-bit error is detected
0	ECCDIS	ECC disable bit Sets ECC error detection/correction to enable/disable. 0: ECC error detection/correction is enabled 1: ECC error detection/correction is disabled

40.3.11.79 HBECERRINT — Error Notification Control Register

This register controls whether error information is reported to ECM, when address/data ECC 2-bit error, address/data ECC 1-bit error are detected.

This register is protected by the key-code protection register. When KCE = 0, it cannot be written. It can be written only when KCE = 1.

Value after reset: 0000 0033_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 40.276 HBECERRINT Register Contents

Bit Position	Bit Name	Function
31 to 6	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
5	ADEDIE	Controls error reports when address ECC 2-bit error is detected (for H-Bus slave). 0: Address ECC 2-bit error report disabled 1: Address ECC 2-bit error report enabled For H-Bus master, when writing, write the value after reset because this bit is reserved.
4	ASEDIE	Controls error reports when address ECC 1-bit error is detected (for H-Bus slave). 0: Address ECC 1-bit error report disabled 1: Address ECC 1-bit error report enabled For H-Bus master, when writing, write the value after reset because this bit is reserved.
3, 2	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
1	DEDIE	Controls error reports when data ECC 2-bit error is detected. 0: Data ECC 2-bit error report disabled 1: Data ECC 2-bit error report enabled
0	SEDIE	Controls error reports when data ECC 1-bit error is detected. 0: Data ECC 1-bit error report disabled 1: Data ECC 1-bit error report enabled

40.3.11.80 HBECSTCLR — Error Status Clear Register

This register is used to clear error flag in HBEC1STERSTR. This is write only register and read value is always “0”.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	W

Table 40.277 HBECSTCLR Register Contents

Bit Position	Bit Name	Function
31 to 1	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
0	STCLR0	Writing 1 to this bit clears AECDEDF0/AECSEDF0/DEDF0/SEDF0 in HBEC1STERSTR.

40.3.11.81 HBEC1STERSTR — Error Status Register

This register indicates whether error has occurred. When all error flags are “0” and a new error occurs, error status flag is set.

If address ECC 1-bit error or data ECC 1-bit error are set and the new error is address ECC 2-bit error or data ECC 2-bit error, the new error is set (does not clear the previous error flag).

If multiple causes of errors are detected, the errors that are detected are all set (e.g. if data ECC 2-bit error and address ECC 2-bit error are detected at the same access, DEDF0 and AECDEDF0 are both set.).

This register can be cleared by STCLR0 in HBECSTCLR register.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 40.278 HBEC1STERSTR Register Contents

Bit Position	Bit Name	Function
31 to 8	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
7	AECDEDF0	Indicates address ECC 2-bit error was detected (for H-Bus slave). This is set when address ECC 2-bit error is detected when AECDEDF0 and DEDFO are all “0”. For H-Bus master, when read, the value after reset is returned because this bit is reserved.
6	AECSEDF0	Indicates address ECC 1-bit error was detected (for H-Bus slave). This is set when address ECC 1-bit error is detected when all error flags are “0”. For H-Bus master, when read, the value after reset is returned because this bit is reserved.
5 to 2	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
1	DEDFO	Indicates data ECC 2-bit error was detected. This is set when data ECC 2-bit error is detected when AECDEDF0 and DEDFO are all “0”.
0	SEDF0	Indicates data ECC 1-bit error was detected. This is set when data ECC 1-bit error is detected when all error flags are “0”.

40.3.11.82 HBECTSTCTL — ECC Test Control Register

ECC test (self-diagnostics) register. After ECC test mode (ECCTST = 1) setting, arbitrary data value can be input to ECC decoder of H-Bus slave. For H-Bus master, keep the value after reset because this register is reserved.

This register is protected by the key-code protection register. When KCE = 0, it cannot be written. It can be written only when KCE = 1.

When accessing any registers in the same peripheral group, ECCTST is cleared to 0.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 40.279 HBECTSTCTL Register Contents

Bit Position	Bit Name	Function
31 to 2	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
1	ECCTST	Selects input data for the address ECC decoder. 0:Normal mode 1:Test mode The values of HBECTSTDIN0 and HBECTSTEIN registers are provided to data and ECC field of the ECC decoder respectively when accessing any registers in the same peripheral group in test mode. This bit is always read as 0.
0	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.

40.3.11.83 HBECTSTDIN0 — Test Data Input Register

This register is used to inject errors into data field of ECC decoder for self-diagnosis. The values of HBECTSTDIN0 and HBECTSTEIN registers are input to data and ECC field of the target ECC decoder in test mode.

This register is protected by the key-code protection register. When KCE = 0, it cannot be written. It can be written only when KCE = 1.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 40.282 HBECKCPROT Register Contents

Bit Position	Bit Name	Function
31 to 1	KCPROT[31:1]	Enable or disable modification of the KCE bit. The written value is not retained. These bits are always read as 0.*1
0	KCE	Key Code Enable bit 0: Disable write access to protected registers 1: Enable write access to protected registers

Note 1. Write A5A5A500_H to this register to disable writing protected registers.
Write A5A5A501_H to this register to enable writing protected registers.

40.3.11.86 Test Function

ECC on the write data, the read data and the address are checked by the each ECC decoder. Each ECC decoder has a self-diagnosis function that uses ERRGEN module.

For details, refer to **Section 40.3.12.8, Usage of ERRGEN.**

40.3.12 Error Injection for ECC Function

40.3.12.1 Overview

ERRGEN is a utility module for self-diagnosis tests of ECC decoders. ERRGEN can be used to generate a data pairs and ECC including errors in any bit. ERRGEN has the following features.

Table 40.283 Error Injection for ECC Function

Item	Description
ECC calculation	Provides the correct 7-bit and 8-bit ECC value of arbitrary data.
Error injection	<p>Injects various errors into read data include ECC field.</p> <ul style="list-style-type: none"> • Error injection is only into the 32-bit data and 7-bit ECC fields. • No function to inject errors into 64-bit data and 8-bit ECC fields directly but ECC calculation register is available.
Register set	A set of registers in odd and even words respectively used to inject errors to 64-bit bus consisting of 2 sets of 32-bit data and 7-bit ECC are implemented, and also a register for users to calculate 8-bit ECC field.

40.3.12.2 List of Registers

Table 40.284 List of Registers

Module Name	Register Name	Symbol	Address	Access	Access Protection
ERRGEN (Peripheral Group0)	Error Data Register	EGDATORGn (n = 0-1)	FFC5 8400 _H + n × 04 _H	8, 16, 32	
	7-bit ECC Calculation Register	EGECCCALn (n = 0-1)	FFC5 8408 _H + n × 04 _H	8, 16, 32	
	Error Injection Register	EGDATINVn (n = 0-1)	FFC5 8410 _H + n × 04 _H	8, 16, 32	
	Error Injection Register	EGECCINVn (n = 0-1)	FFC5 8418 _H + n × 04 _H	8, 16, 32	
	8-bit ECC Calculation Register	EGECC8CAL	FFC5 8420 _H	8, 16, 32	

40.3.12.3 EGDATORGn — Error Data Register

This register is used to set original data before the error injection and to obtain the modified data containing injected errors according to the settings of EGDATINVn and EGECCINVn. The read data is the value of this register XOR-ed with EGDATINVn and the read value of ECC is EGECCCALn XOR-ed with EGECCINVn when reading this register.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 40.285 EGDATORGn Register Contents

Bit Position	Bit Name	Function
31 to 0	DATORG[31:0]	Write data before injecting errors and read data after errors are injected

40.3.12.4 EGECCALn — 7-bit ECC Calculation Register

This register is used to obtain a 7-bit ECC value for the arbitrary value written to EGDATORGn. This ECC value is then injected into an ECC decoder on the address channel. ECC value calculated from EGDATORGn can be read when reading this register. The value of this register is updated simultaneously when EGDATORGn is updated.

Value after reset: 0000 0003_H

6 to 0	ECCINV[6:0]	Bit pattern to invert ECC value of EGDATORGn when reading EGDATORGn

40.3.12.7 EGECC8CAL — 8-bit ECC Calculation Register

This register is used to obtain an ECC values for the arbitrary values written to EGDATORG0 and EGDATORG1. These ECC values are then injected into ECC decoders on Data RAM of sDMAC. ECC values calculated from {EGDATORG1, EGDATORG0} can be read when reading this register. The value of this register is updated simultaneously when either EGDATORG0 or EGDATORG1 is updated.

Value after reset: 0000 0003_H

Bit Position	Bit Name	Function
31 to 8	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
7 to 0	ECC8CAL[7:0]	Read ECC values calculated from {EGDATORG1,EGDATORG0}

40.3.12.8 Usage of ERRGEN

(1) Error Injection into Read Data Channel

ERRGEN can be used to run self-diagnosis tests for ECC decoders of some bus masters on read data channel. Self-diagnosis tests for an ECC decoder on read data channel are made in the following way.

1. Write arbitrary data to EGDATORG0 and EGDATORG1.
2. Set any 1 or 2 bits among EGDATINV0, EGDATINV1, EGECCINV0 and EGECCINV1 to 1.
3. Read EGDATORG0 and EGDATORG1 at the same time in double word access from a target bus master.
4. Check ECC error notification asserted from the bus master.

(2) Error Injection into Write Data Channel

ERRGEN can be used to run self-diagnosis tests for ECC decoders of some bus slaves on write data channel. Self-diagnosis tests for an ECC decoder on write data channel are made in the following way.

1. Write arbitrary data to EGDATORG0 and EGDATORG1.
2. Set any 1 or 2 bits among EGDATINV0, EGDATINV1, EGECCINV0 and EGECCINV1 to 1.
3. Make DTS transfer data from EGDATORG0 and EGDATORG1 to a target bus slave in 64-bit mode.
4. Check ECC error notification asserted from the bus slave.

(3) Error Injection into Address Channel

This case uses a different feature of ERRGEN, which can calculate ECC value of data. It is necessary for users to know correct ECC value for any data to inject various errors into ECC decoders of bus slaves on address channel. Self-diagnosis tests for an ECC decoder on address channel are made in the following way.

1. Write arbitrary data to EGDATORGn.
2. Read EGECCCALn to obtain correct ECC value of the data.
3. Invert any 1 or 2 bits among the data and the ECC value.
4. Set the modified data and ECC value to related registers*¹ of the Address EDC decoder and enable its test function.
5. Read data from a target bus slave including the ECC decoder.
6. Check ECC error notification asserted from the ECC decoder.

(4) Error Injection into Data RAM of sDMAC

ERRGEN can also calculate ECC value of 64-bit data. It is necessary for users to learn correct ECC value for any data to inject various errors into ECC decoders on Data RAM of sDMAC. Self-diagnosis tests for an ECC decoder on Data RAM of sDMAC are made in the following way.

1. Write arbitrary data to EGDATORG0 and EGDATORG1.
2. Read EGECC8CAL to obtain correct ECC value of the data.
3. Invert any 1 or 2 bits among the data and the ECC value.
4. Set the modified data and ECC value to related registers*² of the sDMAC Data RAM ECC module and enable its test function.
5. Make sDMAC including the ECC decoder transfer data from anywhere to anywhere.

6. Check ECC error notification asserted from the ECC decoder.

Note 1: For details, refer to **Section 40.3.11, Safety Mechanism on Data Transfer Path.**

Note 2: For details, refer to **Section 40.3.8, sDMAC/DTS RAM ECC and Address Feedback.**

40.4 Hardware Redundancy

40.4.1 Overview

This product implements the CPU0/1/4/5 and DTS with the lockstep function to quickly detect failures without software interaction. The CPU0/1/4/5 and DTS execute the function using two different cores; that is, a master core and checker core, and constantly compare the execution results of the two cores. When the results do not match, an error is reported to the ECM. The comparison targets of the CPU's bus outputs are own Local RAM, Cluster RAM, Inter-processor element Bus, Local FLASH Bus, and the tag RAM and data RAM of Instruction cache.

The lockstep function of the CPU0/1/4/5 and DTS features of failure insertion, through which errors can be intentionally triggered and thus self-diagnosis of the lockstep operation is possible. For details on CPU0/1/4/5's failure insertion, refer to **Section 3, CPU System**.

Following table shows redundant structure implemented in this product.

Table 40.290 Redundant Blocks

Block Name	Features	Comparator Error Injection
CPU0, CPU1, CPU4*1, CPU5*1 (G4MHPE)	Dual lock step with 2-cycle delay and inverted input for comparator	Yes
DTS	Dual lock step with 2-cycle delay and inverted input for comparator	Yes

Note 1. This function is not implemented in E2H.

40.4.2 List of Registers

Table 40.291 List of Registers

Module Name	Register Name	Symbol	Address	Access	Access Protection
DTS_COMPC (Peripheral Group0)	Error Injection Control Register	DTS_COMP_CNTRL	FFC5 8200 _H	32	Self

40.4.3 DTS_COMP_CNTRL — Error Injection Control Register

This register can control the output signals on the checker side of the DTS. A DTS comparison error can be generated by setting this register.

Writing to this register should be executed with PROT[31:30] = 01_B.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	PROT[31:30]		DTSCMPERR[29:16]													
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	W	W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	DTSCMPERR[15:0]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 40.292 DTS_COMP_CNTRL Register Contents

Bit Position	Bit Name	Function
31 to 30	PROT[31:30]	Protection Bit 01: Writing is enabled Other: Writing is disabled These bits are always read as 0.
29 to 0	DTSCMPERR[29:0]	A DMA comparison error can be generated by writing 111111_11111011_11111111_11111111 to DTSCMPERR together with the PROT bit. Clear all these bits to 0 if there is no need to generate this error.

40.4.4 Usage Note

Reading a register with a value that is undefined after a reset without initializing the register may lead to a CPU comparison error. Accordingly, such registers must be initialized with the desired settings. Even if the branch instruction and the subsequent instruction is issued in parallel, the CPU comparison error might be occurred by undefined register after the reset. It should be applied as specified below until the register which refer by subsequent instruction is initialized in case of branching in the preceding instruction.

- Insert the SYNCI instruction or the RIE instruction following the branch instruction. (It has to be added by assembler language. When C language is used, it could be optimized.)
- Applicable branch instructions: Bcond except BR, JARL, JMP

40.5 Memory Protection

40.5.1 Overview

This product incorporates the memory protection/guard functions to prevent erroneous access to data in the memory and control registers of the peripheral modules. **Figure 40.1** shows the overall memory protection architecture. Each programmable core (bus master) has a Memory Protection Unit (MPU) that defines the software access protection. In addition, each resource (bus slave) has a guard that controls the access by any bus master, including ones that do not have an MPU such as the DMA.

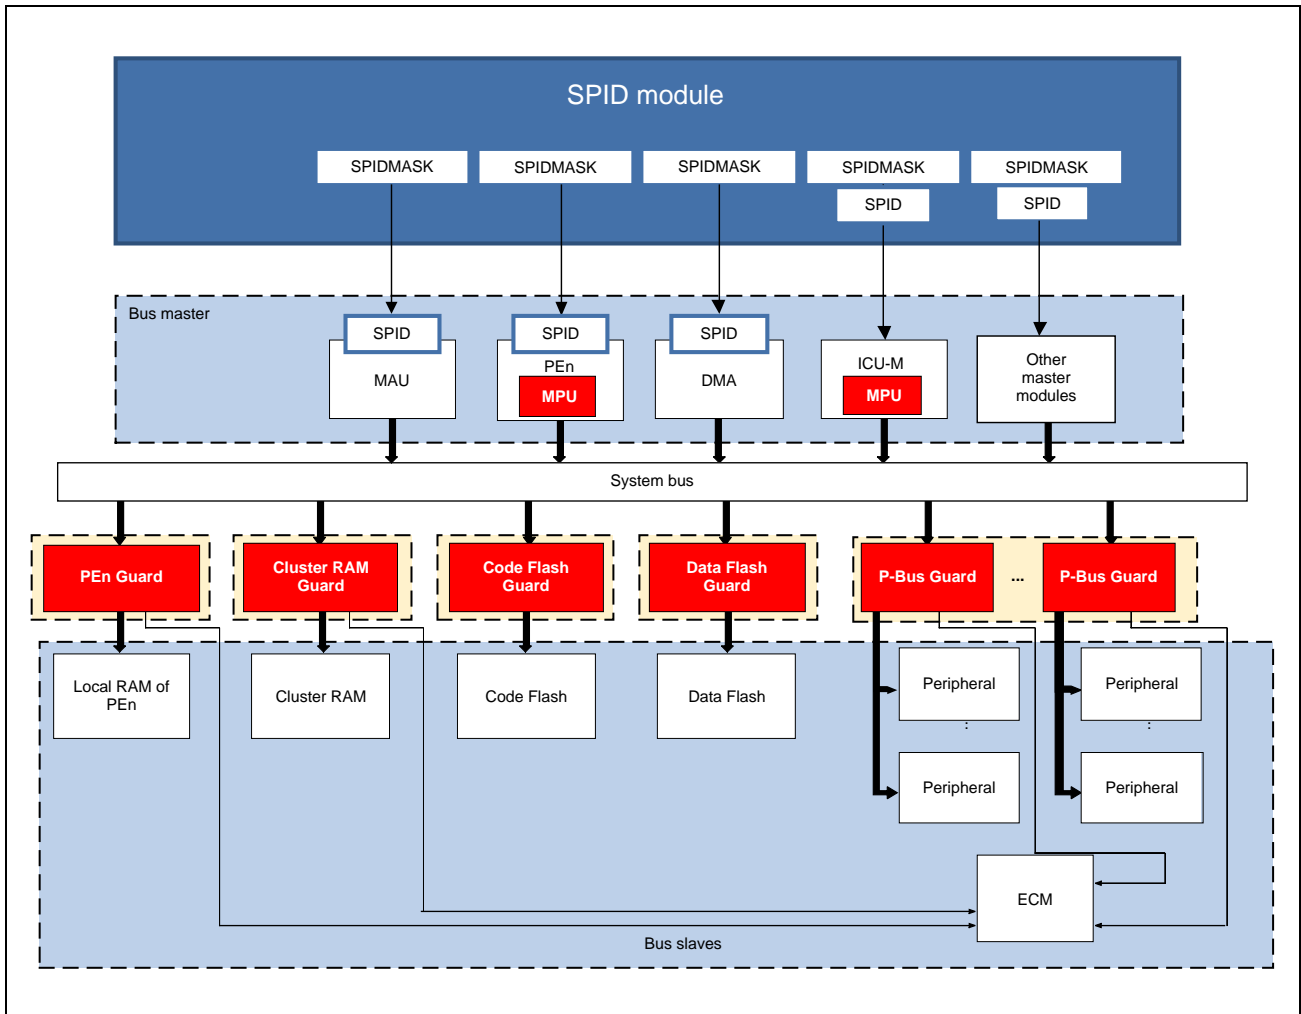

Figure 40.1 Memory Protection Architecture

Note: For details of Code Flash Guard and Data Flash Guard, See *RH850/E2x-FCC2 ICUMD User's Manual: Hardware*.

• MPU

All CPU cores and ICU-M protect the memory against unintended access from the CPU cores and ICU-M themselves. Requests to access addresses that are prohibited by the MPU are never issued by the CPU cores or ICU-M. For details, refer to **Section 3, CPU System** and *the RH850ICUMD User's Manual: Hardware*.

• Slave Guard

A specific memory is protected against unintended access from any bus master. Slave guard includes the following guard types. The details of each type are given in the following sections.

– PEG

Local RAM and INTC1 are protected against unintended access except from the CPU incorporating the Local RAM and INTC1 themselves. For example, access from the CPU0 to Local RAM in the CPU0 is not rejected by the PEG.

For details, refer to **Section 40.5.3, PEG**.

– CRG

Cluster RAM is protected against unintended access.

– Peripheral Guard

The control registers in the peripheral circuits and memory are protected against unintended access.

Peripheral Guard includes INTC2 Guard, DTS Guard, sDMAC Guard, IBG, HBG and PBG.

For details, refer to **Section 40.5.5, INTC2 Guard** to **Section 40.5.10, HBG**.

For this purpose, each bus access contains the following context information that identifies the bus master in addition to access address.

Table 40.293 Identifiers for Memory Protection

Identifier	Function
UM	Indicates the operating mode of the CPU or ICU-M when the CPU core accesses an address. 0: Supervisor mode 1: User mode When DTS or sDMAC or MAU ¹ accesses an address, this identifier indicates the value set in each dedicated register. When the other masters accesses an address, the value of this identifier is always 0.
SEC	Indicates the access mode of the ICU-M when ICU-M accesses an address. 0: Non-secure 1: Secure When the other master accesses an address, the value of this identifier is always 0.
DBG	Indicates the access mode of the debug modules when the debug module accesses an address. 0: Normal mode 1: Debug mode When the other master accesses an address, the value of this identifier is always 0.
SPID	Indicates the system protection identifier SPID that is assigned by the system register when the CPU core or ICU-M or DTS/sDMAC accesses an address. When DTS or sDMAC or MAU ¹ accesses an address, this identifier indicates the value set in each dedicated register. When the other masters accesses an address, this identifier indicates the value set in SPID module. See Section 40.5.2, SPID for details.
WRITE	Indicates the access type of bus master. 0: Read access 1: Write access

Note 1. MAU is one of the debug functions to read and write the memory and registers.

40.5.2 SPID

40.5.2.1 Overview

SPID (System Protection identifier) indicates an identifier of the software task. The value of SPID for CPU cores, DTS/sDMAC and MAU*³ can be set individually in each configuration register. For the other masters, it can be set in SPID module.

SPID module supervises all SPIDs except for some bus masters which have own configuration register. These SPID registers present in SPID module are configurable by software. In addition, the SPID module also supervises SPIDs which all bus masters use through SPID mask registers.

SPID mask registers can be locked by SPID mask lock registers for security purposes. Once SPID mask lock register locks a SPID mask register, it can be cleared by Power Up Reset, System Reset1, System Reset2, and Application Reset.

Table 40.294 shows the initial values of SPID for each bus master.

Table 40.294 Initial Value and Register Location of SPID

Initial value of SPID	Bus master	Register location
0	CPU0	CPU0
1	CPU1	CPU1
2	CPU2	CPU2
3	CPU3	CPU3
4	CPU4* ²	CPU4
5	CPU5* ²	CPU5
6 to 18	Reserved	—
19	RHSIF0	SPID module
20	Reserved	—
21	HSSPI0	SPID module
22	FlexRay1* ²	SPID module
23	FlexRay0	SPID module
24	Ethernet	SPID module
25	Reserved	—
26	ICU-M	SPID module
27	sDMAC1	sDMAC1
28	sDMAC0	sDMAC0
29	DTS* ¹	DTS
30	Reserved	—
31	MAU	MAU

Note 1. Initial value of SPID for DTS is stored in DTS RAM. Therefore, it is undefined after reset and it becomes 0 after RAM initialization. Please refer to **Section 10.3.6**, about RAM initialization in detail.

Note 2. This function is not implemented in E2H.

Note 3. MAU is one of the debug functions to read and write the memory and registers.

Features of SPID:

- SPID of each bus master is configurable by software with high flexibility according to user's system.
- It is possible to assign one SPID to one bus master or assign one SPID to several bus masters.
- It is possible to limit SPID that each bus master uses by SPIDMASK register. Moreover this configuration can be locked.
- The lock function above prevents unauthorized use of SPID for security purpose.

Table 40.295 shows a case which eight SPIDs are allocated only to CPU0 and other SPIDs are allocated to each remained bus master. **Table 40.296** shows a case which some SPIDs are allocated to each CPU and some peripheral bus masters use one same SPID.

The system integrator should define the SPID assignment according to the system.

Table 40.295 Example of SPID setting (Several SPIDs are allocated only to CPU0)

SPID value	Bus master	Lock/Unlock
0	CPU0	Unlocked
1	CPU1	Locked
2	CPU2	Locked
3	CPU3	Locked
4	CPU4*1	Locked
5	CPU5*1	Locked
6 to 12	CPU0	Unlocked
13 to 18	Reserved	—
19	RHSIF0	Locked
20	Reserved	—
21	HSSPI0	Locked
22	FlexRay1*1	Locked
23	FlexRay0	Locked
24	Ethernet	Locked
25	Reserved	—
26	ICU-M	Locked
27	sDMAC1	Locked
28	sDMAC0	Locked
29	DTS	Locked
30	Reserved	—
31	MAU	Locked

Note 1. This function is not implemented in E2H.

Table 40.296 Example of SPID setting (Several SPIDs are allocated to each CPU)

SPID value	Bus master	Lock/Unlock
0	CPU0	Unlocked
1	CPU1	Unlocked
2	CPU2	Unlocked
3	CPU3	Unlocked
4	CPU4*1	Unlocked
5	CPU5*1	Unlocked
6 to 12	CPU0	Unlocked
13 to 19	CPU1	Unlocked
20	CPU2	Unlocked
21	CPU3	Unlocked
22	CPU4	Unlocked
23	CPU5	Unlocked
24	RHSIF0/HSSPI0/FlexRay1*1/FlexRay0/Ethernet	Locked
25	Reserved	—
26	ICU-M	Locked
27	sDMAC1	Locked
28	sDMAC0	Locked
29	DTS	Locked
30	Reserved	—
31	MAU	Locked

Note 1. This function is not implemented in E2H.

40.5.2.2 List of Registers

Table 40.297 List of SPID Registers (1/2)

Module Name	Register Name	Symbol	Address	Access	Access Protection
SPIDCTL (Peripheral Group9)	Reserved	—	FF0A 8000 _H to FF0A 804B _H	—

Note 1. This function is not implemented in E2H.

40.5.2.3 BMnSPID — BusMaster n SPID Register

This register is used to set the SPID of each bus master.

Value after reset: 0000 00XX_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	SPID[4:0]				
Value after reset	0	0	0	0	0	0	0	0	0	0	0	(defined for each bus master)				
R/W	R	R	R	R	R	R	R	R	R	R	R	R/W				

Note 1. See **Section 40.5.2.1, Overview** for the initial value of each SPID.

Table 40.298 BMnSPID Register Contents

Bit Position	Bit Name	Function
31 to 5	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
4 to 0	SPID[4:0]	SPID for each bus master.

40.5.2.4 BMnSPIDMSK — BusMaster n SPID Mask Register

This register is used to set the SPID that each bus-master can use.

This register is protected by key-code register.

Value after reset: FFFF FFFF_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SPIDMSK[31:16]																
Value after reset	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

Value after reset	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 40.299 BMnSPIDMSK Register Contents

Bit Position	Bit Name	Function
31 to 0	SPIDMSK[31:0]	Set inhibition of SPID value which that each bus master can use. Each bit corresponds to a single SPID value. 0: The bus-master cannot use this SPID. Setting of this SPID is inhibited. 1: The bus-master can use this SPID. Setting of this SPID is not inhibited.

40.5.2.5 BMnSPIDMSKLOCK — BusMaster n SPID Mask Lock Register

This register is used to set write-mask to each BMnSPIDMSK.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	LOCK
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Table 40.300 BMnSPIDMSKLOCK Register Contents

Bit Position	Bit Name	Function
31 to 1	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
0	LOCK	Lock of register 0: Register (BMnSPIDMSK) can be re-written 1: Any further write to the register (BMnSPIDMSK) is ignored. LOCK can be cleared by Power Up Reset, System Reset1, System Reset2, and Application Reset.

40.5.2.6 SPIDKCPROT — SPID Key Code Protect Register

This register is used to set the key-code lock or unlock of BMnSPIDMSK.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	KCPROT[31:16]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 40.301 SPIDKCPROT Register Contents

Bit Position	Bit Name	Function
31 to 1	KCPROT[31:1]	Enable or disable modification of the KCE bit. The written value is not retained. These bits are always read as 0.* ¹
0	KCE	Key Code Enable bit 0: Disable write access to protected registers 1: Enable write access to protected registers

Note 1. Write A5A5A500_H to this register to disable writing protected registers.
Write A5A5A501_H to this register to enable writing protected registers.

40.5.2.7 Usage

SPID is used for one of the identifiers of the memory protection/guard functions. SPID setting procedure is as follows.

1. Set the SPID key code protection register (SPIDKCPROT) to enable writing to SPID registers.
2. Set the SPID mask register (BMnSPIDMSK) to define the SPID values that the bus master can set according to system FFI.
3. Set the SPID mask lock register (BMnSPIDMSKLOCK) to prohibit changing the SPID mask register setting for security purposes.
4. Set the value allowed by the SPID mask register (BMnSPIDMSK) to the SPID register (BMnSPID) for the next time the bus master is accessed.
5. Set the SPID key code protection register (SPIDKCPROT) to disable writing to SPID registers.
6. Configure the memory protection/guard settings to prevent erroneous access identified by SPID and other Identifiers.

40.5.3 PEG

40.5.3.1 Overview

Each PE has a guard that controls the access to the Local RAM and INTC1 from other bus masters. Access by bus masters can be controlled via their bus context for four regions through this PE Guard (PEG). Bus masters can only access the Local RAM area and INTC1 register area if permission is granted. PEG can prevent read*¹ and write accesses against which the Local RAM area and INTC1 register area should be protected. If PEG detects illegal access, guard error is reported to ECM.

If the guard enable bit (GEN) of all PEGPROT_m registers is disabled, all masters can access to both the Local RAM area and INTC1 registers.

If the guard enable bit (GEN) of either PEGPROT_m registers is enabled, an access to Local RAM area and INTC1 registers is limited according to that setting.

Note 1. including fetch access.

40.5.3.2 Register Base Address

Base addresses of safety modules are listed in the following table. Each register address is given as an offset from the base addresses.

Table 40.302 Register Base Addresses

Base Address Name	Base Address	Bus Group
<GUARD_PE0CL0_base>	FFC6 C00 _H	Peripheral Group 0
<GUARD_PE1CL0_base>	FFC6 C100 _H	Peripheral Group 0
<GUARD_PE2CL1_base>	FFC6 C200 _H	Peripheral Group 0
<GUARD_PE3CL1_base>	FFC6 C300 _H	Peripheral Group 0
<GUARD_PE4CL2_base>* ¹	FFC6 C400 _H	Peripheral Group 0
<GUARD_PE5CL2_base>* ¹	FFC6 C500 _H	Peripheral Group 0
<PEGCAP_M_PE0CL0_base>	FFC6 C800 _H	Peripheral Group 0
<PEGCAP_S_PE0CL0_base>	FFC6 C810 _H	Peripheral Group 0

Note 1. This function is not implemented in E2H.

40.5.3.3 List of Registers

Table 40.303 List of Registers

Module Name	Register Name	Symbol	Address	Access	Access Protection
GUARD_PEnCL0 (n = 0, 1) *1	Key Code Protection Register	PEGKCPROT	<GUARD_PEnCL0_base> + 00 _H	32	
	Channel Protection Control Register	PEGPROTm (m = 0 to 3)	<GUARD_PEnCL0_base> + 40 _H + m × 10 _H	8, 16, 32	PEGKCPROT
	Channel SPID Setting Register	PEGSPIDm (m = 0 to 3)	<GUARD_PEnCL0_base> + 44 _H + m × 10 _H	8, 16, 32	PEGKCPROT
	Channel Base Address Setting Register	PEGBADm (m = 0 to 3)	<GUARD_PEnCL0_base> + 48 _H + m × 10 _H	32	PEGKCPROT
	Channel Valid Bit Setting Register	PEGADVm (m = 0 to 3)	<GUARD_PEnCL0_base> + 4C _H + m × 10 _H	32	PEGKCPROT
GUARD_PEnCL1 (n = 2, 3) *1	Key Code Protection Register	PEGKCPROT	<GUARD_PEnCL1_base> + 00 _H	32	
	Channel Protection Control Register	PEGPROTm (m = 0 to 3)	<GUARD_PEnCL1_base> + 40 _H + m × 10 _H	8, 16, 32	PEGKCPROT
	Channel SPID Setting Register	PEGSPIDm (m = 0 to 3)	<GUARD_PEnCL1_base> + 44 _H + m × 10 _H	8, 16, 32	PEGKCPROT
	Channel Base Address Setting Register	PEGBADm (m = 0 to 3)	<GUARD_PEnCL1_base> + 48 _H + m × 10 _H	32	PEGKCPROT
	Channel Valid Bit Setting Register	PEGADVm (m = 0 to 3)	<GUARD_PEnCL1_base> + 4C _H + m × 10 _H	32	PEGKCPROT
GUARD_PEnCL2 (n = 4, 5) *1+2	Key Code Protection Register	PEGKCPROT	<GUARD_PEnCL2_base> + 00 _H	32	
	Channel Protection Control Register	PEGPROTm (m = 0 to 3)	<GUARD_PEnCL2_base> + 40 _H + m × 10 _H	8, 16, 32	PEGKCPROT
	Channel SPID Setting Register	PEGSPIDm (m = 0 to 3)	<GUARD_PEnCL2_base> + 44 _H + m × 10 _H	8, 16, 32	PEGKCPROT
	Channel Base Address Setting Register	PEGBADm (m = 0 to 3)	<GUARD_PEnCL2_base> + 48 _H + m × 10 _H	32	PEGKCPROT
	Channel Valid Bit Setting Register	PEGADVm (m = 0 to 3)	<GUARD_PEnCL2_base> + 4C _H + m × 10 _H	32	PEGKCPROT
PEGCAP_M_PEnCL0 (n = 0, 1)	Guard Error Clear Register	PEGERRCLR	<PEGCAP_M_PEnCL0_base> + 00 _H	8, 16, 32	
	Guard Error Status Register	PEGERRSTAT	<PEGCAP_M_PEnCL0_base> + 04 _H	8, 32	
	Guard Error Address Register	PEGERRADDR	<PEGCAP_M_PEnCL0_base> + 08 _H	32	
	Guard Error Access Information Register	PEGERRTYPE	<PEGCAP_M_PEnCL0_base> + 0C _H	16, 32	
PEGCAP_S_PEnCL0 (n = 0, 1)	Guard Error Clear Register	PEGERRCLR	<PEGCAP_S_PEnCL0_base> + 00 _H	8, 16, 32	
	Guard Error Status Register	PEGERRSTAT	<PEGCAP_S_PEnCL0_base> + 04 _H	8, 32	
	Guard Error Address Register	PEGERRADDR	<PEGCAP_S_PEnCL0_base> + 08 _H	32	
	Guard Error Access Information Register	PEGERRTYPE	<PEGCAP_S_PEnCL0_base> + 0C _H	16, 32	
PEGCAP_M_PEnCL1 (n = 2, 3)	Guard Error Clear Register	PEGERRCLR	<PEGCAP_M_PEnCL1_base> + 00 _H	8, 16, 32	
	Guard Error Status Register	PEGERRSTAT	<PEGCAP_M_PEnCL1_base> + 04 _H	8, 32	
	Guard Error Address Register	PEGERRADDR	<PEGCAP_M_PEnCL1_base> + 08 _H	32	
	Guard Error Access Information Register	PEGERRTYPE	<PEGCAP_M_PEnCL1_base> + 0C _H	16, 32	
PEGCAP_S_PEnCL1 (n = 2, 3)	Guard Error Clear Register	PEGERRCLR	<PEGCAP_S_PEnCL1_base> + 00 _H	8, 16, 32	
	Guard Error Status Register	PEGERRSTAT	<PEGCAP_S_PEnCL1_base> + 04 _H	8, 32	
	Guard Error Address Register	PEGERRADDR	<PEGCAP_S_PEnCL1_base> + 08 _H	32	
	Guard Error Access Information Register	PEGERRTYPE	<PEGCAP_S_PEnCL1_base> + 0C _H	16, 32	
PEGCAP_M_PEnCL2 (n = 4, 5) *2	Guard Error Clear Register	PEGERRCLR	<PEGCAP_M_PEnCL2_base> + 00 _H	8, 16, 32	
	Guard Error Status Register	PEGERRSTAT	<PEGCAP_M_PEnCL2_base> + 04 _H	8, 32	
	Guard Error Address Register	PEGERRADDR	<PEGCAP_M_PEnCL2_base> + 08 _H	32	
	Guard Error Access Information Register	PEGERRTYPE	<PEGCAP_M_PEnCL2_base> + 0C _H	16, 32	
PEGCAP_S_PEnCL2 (n = 4, 5) *2	Guard Error Clear Register	PEGERRCLR	<PEGCAP_S_PEnCL2_base> + 00 _H	8, 16, 32	
	Guard Error Status Register	PEGERRSTAT	<PEGCAP_S_PEnCL2_base> + 04 _H	8, 32	
	Guard Error Address Register	PEGERRADDR	<PEGCAP_S_PEnCL2_base> + 08 _H	32	
	Guard Error Access Information Register	PEGERRTYPE	<PEGCAP_S_PEnCL2_base> + 0C _H	16, 32	

Note 1. It is necessary to give read permission even when fetching instructions from its own Local RAM.

Note 2. This function is not implemented in E2H.

40.5.3.4 PEGKCPROT — Key Code Protection Register

This register is used to unlock/lock key protection of the PE guard register.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	KCPROT[31:16]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	KCPROT[15:1]															KCE
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W	R/W

Table 40.304 PEGKCPROT Register Contents

Bit Position	Bit Name	Function
31 to 1	KCPROT[31:1]	Enable or disable modification of the KCE bit. The written value is not retained. These bits are always read as 0.*1
0	KCE	Key Code Enable bit 0: Disable write access to protected registers 1: Enable write access to protected registers

Note 1. Write A5A5A500_H to this register to disable writing protected registers.
Write A5A5A501_H to this register to enable writing protected registers.

40.5.3.5 PEGPROTm — Channel Protection Control Register

Specifies the PE resource access to be protected against. Access prohibited by any of the identifiers is blocked as unauthorized access. This register is used to specify the settings other than SPID.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Table 40.305 PEGPROTm Register Contents

Bit Position	Bit Name	Function
31 to 9	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
8	GEN	Enables/disables guard setting 0: Disables the guard setting 1: Enables the guard setting
7	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
6	DBG	R/W enable setting for debug master 0: Depends on other enable/disable settings 1: Enables R/W
5	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
4	UM	R/W disable setting in user mode 0: R/W disabled 1: R/W depends on other enable/disable settings
3, 2	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
1	WG	Write Global Enable 0: During write, PEGSPIDm is used as a judgment condition. 1: During write, PEGSPIDm is not used as a judgment condition.
0	RG	Read Global Enable 0: During read, PEGSPIDm is used as the judgment condition. 1: During read, PEGSPIDm is not used as a judgment condition.

40.5.3.6 PEGSPIDm — Channel SPID Setting Register

Specifies the PE resource access to be protected against. Access prohibited by any of the identifiers is blocked as unauthorized access. This register is used to specify the SPID settings.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 40.306 PEGSPIDm Register Contents

Bit Position	Bit Name	Function
31 to 0	SPID[31:0]	<p>R/W enable setting based on SPID</p> <p>PEGSPIDm is a list of bits each representing one SPID value. Multiple SPID values are enabled simultaneously by setting multiple bits.</p> <p>For example, setting PEGSPIDm to 0101_B enables access to areas SPID = 0 and SPID = 2.</p> <p>0: Reading/writing the area with SPID = m depends on the RG and WG bit setting</p> <p>1: Enables reading/writing the area with SPID = m</p>

40.5.3.7 PEGBADm — Channel Base Address Setting Register

This register is used to define area m when the setting of PEGPROTm and PEGSPIDm is valid. PEGBADm specifies base address of area m and PEGADVm specifies valid bits of PEGBADm.

Value after reset: FC00 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	BAD[25:16]

R/W	R/W	R/W	R/W	R/W	R	R	R	R	R	R	R	R	R	R	R	R

Table 40.307 PEGBADm Register Contents

Bit Position	Bit Name	Function
31 to 26	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
25 to 12	BAD[25:12]	Base address
11 to 0	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.

40.5.3.8 PEGADV_m — Channel Valid Bit Setting Register

This register is used to define area *m* when the setting of PEGPROT_m and PEGSPID_m is valid. PEGBAD_m specifies base address of area *m* and PEGADV_m specifies valid bits of PEGBAD_m.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	ADV[25:16]									
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	ADV[15:12]				—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R	R	R	R	R	R	R	R	R	R	R	R

Table 40.308 PEGADV_m Register Contents

Bit Position	Bit Name	Function
31 to 26	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
25 to 12	ADV[25:12]	Valid bits of PEGBAD _m When an ADV bit is 1, the address of each access will be compared with the corresponding BAD bit of PEGBAD _m . When all ADV bits are set to 1, 4 KB (the minimum unit) is targeted for protection based on the address specified by PEGBAD _m . When all ADV bits are set to 0, the target of protection is the entire Local RAM.
11 to 0	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.

Example: When PEGBAD_m[25:12] is set to 1C00_H and PEGADV_m[25:12] is set to 3FFE_H, PE guard protection area *m* is FDC0 0000_H to FDC0 0FFF_H and FDC0 1000_H to FDC0 1FFF_H.

Commentary: When PEGBAD_m[25:12] is set to 1C00_H, the base address is FDC0 0000_H and the configurable range of bits is enclosed in [] as shown below.

1111 11[01 1100 0000 0000] 0000 0000 0000

F D C 0 0 0 0 0

When PEGADV_m[25:12] is 3FFE_H, bits set to 0 in that range and the 12 lower-order bits are ignored, so we have

1111 11[01 1100 0000 000X] XXXX XXXX XXXX

which means that the 4 KB ranges (a total of 8 KB) from

F D C 0 0 0 0 0 to

F D C 0 0 F F F,

and

F D C 0 1 0 0 0 to

F D C 0 1 F F F

will be protected.

40.5.3.9 PEGERRCLR — Guard Error Clear Register

This register is used to clear the PEGERRSTAT register. The PEGERRSTAT.OVF and/or PEGERRSTAT.ERR bits are cleared immediately after writing this register. 0 is always returned when reading this register.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	CLRO	CLRE
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	W	W

Table 40.309 PEGERRCLR Register Contents

Bit Position	Bit Name	Function
31 to 2	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
1	CLRO	Clears the PEGERRSTAT.OVF bit
0	CLRE	Clears the PEGERRSTAT.ERR bit

40.5.3.10 PEGERRSTAT — Guard Error Status Register

This register is used to notify users whether guard errors occurred. The ERR bit is set when a guard error is reported by an error detection module, etc. The OVF bit is set when a guard error is reported again when the ERR bit is already set. This register is not writable and is cleared when writing the PEGERRCLR register. See **Section 40.5.3.9, PEGERRCLR — Guard Error Clear Register.**

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 40.310 PEGERRSTAT Register Contents

Bit Position	Bit Name	Function
31 to 2	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
1	OVF	Overflow status flag
0	ERR	Error status flag

40.5.3.11 PEGERRADDR — Guard Error Address Register

This register is used to get an access address when a guard error is occurred. Error address is stored in this register only when PEGERRSTAT.ERR bit is not set.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	ADDR[31:16]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 40.312 PEGERRTYPE Register Contents

Bit Position	Bit Name	Function
31 to 14	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
13	SEC	Access attribute of SEC to the target slave when a guard error has occurred
12	DBG	Access attribute of DBG to the target slave when a guard error has occurred
11	UM	Access attribute of UM to the target slave when a guard error has occurred
10 to 6	SPID[4:0]	Access attribute of SPID to the target slave when a guard error has occurred
5 to 1	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
0	WRITE	Access type of read or write to the target slave when a guard error has occurred

40.5.4 CRG

40.5.4.1 Overview

The Cluster RAM is protected by a memory guard. Access to the Cluster RAM can be controlled via the bus context for eight regions by this Cluster RAM Guard (CRG). Bus masters can only access the Cluster RAM area if permission is granted. CRG can prevent read*¹ and write accesses against which the Cluster RAM area should be protected. If CRG detects illegal access, guard error notification is signaled to ECM.

If the guard enable bit (GEN) of all CRGPROTm registers is disabled, all masters can access to the Cluster RAM area.

If the guard enable bit (GEN) of either CRGPROTm registers is enabled, an access to Cluster RAM area is limited according to that setting.

Note 1. including fetch access.

40.5.4.2 Register Base Address

Base addresses of safety modules are listed in the following table. Each register address is given as offsets from the base addresses.

Table 40.313 Register Base Addresses

Base Address Name	Base Address	Bus Group
<GUARD_CRAMCL0_base>	FFC6 D000 _H	Peripheral Group 0
<GUARD_CRAMCL1_base>	FFC6 D100 _H	Peripheral Group 0
<GUARD_CRAMCL2_base>* ¹	FFC6 D200 _H	Peripheral Group 0
<CRGCAP_PE0CL0_base>	FFC6 D800 _H	Peripheral Group 0

<CRGCAP_SX2MBLCL2_base>* ¹	FFC6 D9B0 _H	Peripheral Group 0

Note 1. This function is not implemented in E2H.

40.5.4.3 List of Registers

Table 40.314 List of Registers

Module Name	Register Name	Symbol	Address	Access	Access Protection
GUARD_CRAMCLn (n = 0-2) *2	Key Code Protection Register	CRGKCPROT	<GUARD_CRAMCLn_base> + 00H	32	
	Channel Protection Control Register	CRGPROTm (m = 0-7)	<GUARD_CRAMCLn_base> + 10H + m × 10H	8, 16, 32	CRGKCPROT
	Channel SPID Setting Register	CRGSPIDm (m = 0-7)	<GUARD_CRAMCLn_base> + 14H + m × 10H	8, 16, 32	CRGKCPROT
	Channel Base Address Setting Register	CRGBADm (m = 0-7)	<GUARD_CRAMCLn_base> + 18H + m × 10H	8, 16, 32	CRGKCPROT
	Channel Valid Bit Setting Register	CRGADVm (m = 0-7)	<GUARD_CRAMCLn_base> + 1CH + m × 10H	8, 16, 32	CRGKCPROT
CRGCAP_PEnCL0 (n = 0, 1)	Guard Error Clear Register	CRGERRCLR	<CRGCAP_PEnCL0_base> + 00H	8, 16, 32	
	Guard Error Status Register	CRGERRSTAT	<CRGCAP_PEnCL0_base> + 04H	8, 32	
	Guard Error Address Register	CRGERRADDR	<CRGCAP_PEnCL0_base> + 08H	32	
	Guard Error Access Information Register	CRGERRTYPE	<CRGCAP_PEnCL0_base> + 0CH	16, 32	
CRGCAP_PEnCL1 (n = 2, 3)	Guard Error Clear Register	CRGERRCLR	<CRGCAP_PEnCL1_base> + 00H	8, 16, 32	
	Guard Error Status Register	CRGERRSTAT	<CRGCAP_PEnCL1_base> + 04H	8, 32	
	Guard Error Address Register	CRGERRADDR	<CRGCAP_PEnCL1_base> + 08H	32	
	Guard Error Access Information Register	CRGERRTYPE	<CRGCAP_PEnCL1_base> + 0CH	16, 32	
CRGCAP_PEnCL2 (n = 4, 5) *1	Guard Error Clear Register	CRGERRCLR	<CRGCAP_PEnCL2_base> + 00H	8, 16, 32	
	Guard Error Status Register	CRGERRSTAT	<CRGCAP_PEnCL2_base> + 04H	8, 32	
	Guard Error Address Register	CRGERRADDR	<CRGCAP_PEnCL2_base> + 08H	32	
	Guard Error Access Information Register	CRGERRTYPE	<CRGCAP_PEnCL2_base> + 0CH	16, 32	
CRGCAP_CRAMHCLn (n = 0-2) *2	Guard Error Clear Register	CRGERRCLR	<CRGCAP_CRAMHCLn_base> + 00H	8, 16, 32	
	Guard Error Status Register	CRGERRSTAT	<CRGCAP_CRAMHCLn_base> + 04H	8, 32	
	Guard Error Address Register	CRGERRADDR	<CRGCAP_CRAMHCLn_base> + 08H	32	
	Guard Error Access Information Register	CRGERRTYPE	<CRGCAP_CRAMHCLn_base> + 0CH	16, 32	
CRGCAP_CRAMLCLn (n = 0-2) *2	Guard Error Clear Register	CRGERRCLR	<CRGCAP_CRAMLCLn_base> + 00H	8, 16, 32	
	Guard Error Status Register	CRGERRSTAT	<CRGCAP_CRAMLCLn_base> + 04H	8, 32	
	Guard Error Address Register	CRGERRADDR	<CRGCAP_CRAMLCLn_base> + 08H	32	
	Guard Error Access Information Register	CRGERRTYPE	<CRGCAP_CRAMLCLn_base> + 0CH	16, 32	
CRGCAP_SX2MBHCLn (n = 0-2) *2	Guard Error Clear Register	CRGERRCLR	<CRGCAP_SX2MBHCLn_base> + 00H	8, 16, 32	
	Guard Error Status Register	CRGERRSTAT	<CRGCAP_SX2MBHCLn_base> + 04H	8, 32	
	Guard Error Address Register	CRGERRADDR	<CRGCAP_SX2MBHCLn_base> + 08H	32	
	Guard Error Access Information Register	CRGERRTYPE	<CRGCAP_SX2MBHCLn_base> + 0CH	16, 32	
CRGCAP_SX2MBLCLn (n = 0-2) *2	Guard Error Clear Register	CRGERRCLR	<CRGCAP_SX2MBLCLn_base> + 00H	8, 16, 32	
	Guard Error Status Register	CRGERRSTAT	<CRGCAP_SX2MBLCLn_base> + 04H	8, 32	
	Guard Error Address Register	CRGERRADDR	<CRGCAP_SX2MBLCLn_base> + 08H	32	
	Guard Error Access Information Register	CRGERRTYPE	<CRGCAP_SX2MBLCLn_base> + 0CH	16, 32	

Note 1. This function is not implemented in E2H.

Note 2. "n = 2" is not implemented in E2H.

40.5.4.4 CRGKCPROT — Key Code Protection Register

This register is used to unlock/lock key protection of the Cluster RAM guard register.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	KCPROT[31:16]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	KCPROT[15:1]															KCE
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W	R/W

Table 40.315 CRGKCPROT Register Contents

Bit Position	Bit Name	Function
31 to 1	KCPROT[31:1]	Enable or disable modification of the KCE bit. The written value is not retained. These bits are always read as 0.* ¹
0	KCE	Key Code Enable bit 0: Disable write access to protected registers 1: Enable write access to protected registers

Note 1. Write A5A5A500_H to this register to disable writing protected registers.
Write A5A5A501_H to this register to enable writing protected registers.

40.5.4.5 CRGPROTm — Channel Protection Control Register

Specifies the Cluster RAM access to be protected against. Access prohibited by any of the identifiers is blocked as unauthorized access. This register is used to specify the settings other than SPID.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

R/W	R	R	R	R	R	R	R	R/W	R	R/W	R	R/W	R	R	R/W	R/W

Table 40.316 CRGPROTm Register Contents

Bit Position	Bit Name	Function
31 to 9	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
8	GEN	Enables/disables guard setting 0: Disables the guard setting 1: Enables the guard setting
7	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
6	DBG	R/W enable setting for debug master 0: Depends on other enable/disable settings 1: Enables R/W
5	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
4	UM	R/W disable setting in user mode 0: R/W disabled 1: R/W depends on other enable/disable settings
3, 2	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
1	WG	Write Global Enable 0: During write, CRGSPIDm is used as a judgment condition. 1: During write, CRGSPIDm is not used as a judgment condition.
0	RG	Read Global Enable 0: During read, CRGSPIDm is used as the judgment condition. 1: During read, CRGSPIDm is not used as a judgment condition.

40.5.4.6 CRGSPIDm — Channel SPID Setting Register

Specifies the Cluster RAM access to be protected against. Access prohibited by any of the identifiers is blocked as unauthorized access. This register is used to specify the SPID settings.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	SPID[31:16]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	SPID[15:0]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 40.317 CRGSPIDm Register Contents

Bit Position	Bit Name	Function
31 to 0	SPID[31:0]	<p>R/W enable setting based on SPID</p> <p>CRGSPIDm is a list of bits each representing one SPID value. Multiple SPID values are enabled simultaneously by setting multiple bits.</p> <p>For example, setting CRGSPIDm to 0101_B enables access to areas with SPID = 0 and SPID = 2.</p> <p>0: Reading/writing the area with SPID = m depends on the RG and WG bit setting</p> <p>1: Enables reading/writing the area with SPID = m</p>

40.5.4.7 CRGBADm — Channel Base Address Setting Register

This register is used to define area m when the setting of CRGPROTm and CRGSPIDm is valid. CRGBADm specifies base address of area m and CRGADVm specifies valid bits of CRGBADm.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	BAD[19:16]			
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	BAD[15:8]								—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R	R	R	R	R	R

Table 40.318 CRGBADm Register Contents

Bit Position	Bit Name	Function
31 to 20	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
19 to 8*1	BAD[19:8]	Base address
7 to 0	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.

Note 1. BAD[19] is valid for Cluster2 only.

40.5.4.8 CRGADV_m — Channel Valid Bit Setting Register

This register is used to define area *m* when the setting of CRGPROT_m and CRGSPID_m is valid. CRGBAD_m specifies base address of area *m* and CRGADV_m specifies valid bits of CRGBAD_m

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	ADV[19:16]			
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	ADV[15:8]								—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R	R	R	R	R	R	R

Table 40.319 CRGADV_m Register Contents

Bit Position	Bit Name	Function
31 to 20	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
19 to 8 ^{*1}	ADV[19:8]	Valid bits of CRGBAD _m When an ADV bit is 1, the address of each access will be compared with the corresponding BAD bit of CRGBAD _m . When all ADV bits are set to 1, 256 bytes (the minimum unit) are targeted for protection based on the address specified by CRGBAD _m . When all ADV bits are set to 0, the target of protection is the whole of the entire Cluster RAM.
7 to 0	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.

Note 1. ADV[19] is valid for Cluster2 only.

Example: When CRGBAD_m[19:8] is set to 000_H and CRGADV_m[19:8] is set to 7EF_H, Cluster RAM guard protection area *m* is FE00 0000_H to FE00 00FF_H and FE00 1000_H to FE00 10FF_H.

Commentary: When CRGBAD_m[19:8] is set to 000_H, the base address is FE00 0000_H and the configurable range of bits is enclosed in [] as shown below.

```
1111 1110 0000 0[000 0000 0000] 0000 0000
F E 0 0 0 0 0 0
```

When CRGADV_m[19:8] is 7EF_H, bits set to 0 in that range and the 8 lower-order bits are ignored, so we have

```
1111 1110 0000 0[000 000X 0000] XXXX XXXX
```

which means that the 256-byte ranges (a total of 512 bytes) from

```
F E 0 0 0 0 0 0
```

```
F E 0 0 0 0 F F,
```

and

```
F E 0 0 1 0 0 0
```

```
F E 0 0 1 0 F F
```

will be protected.

40.5.4.9 CRGERRCLR — Guard Error Clear Register

This register is used to clear the CRGERRSTAT register. The CRGERRSTAT.OVF and/or CRGERRSTAT.ERR bits are cleared immediately after writing this register. Response data is always 0 when reading this register.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	CLRO	CLRE
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	W	W

Table 40.320 CRGERRCLR Register Contents

Bit Position	Bit Name	Function
31 to 2	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
1	CLRO	Clears the CRGERRSTAT.OVF bit
0	CLRE	Clears the CRGERRSTAT.ERR bit

40.5.4.10 CRGERRSTAT — Guard Error Status Register

This register is used to notify users whether guard errors occurred. The ERR bit is set when a guard error is reported by an error detection module, etc. The OVF bit is set when a guard error is reported again when the ERR bit is already set. This register is not writable and is cleared when writing the CRGERRCLR register. See **Section 40.5.4.9, CRGERRCLR — Guard Error Clear Register**.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Table 40.323 CRGERRTYPE Register Contents

Bit Position	Bit Name	Function
31 to 14	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
13	SEC	Access attribute of SEC to the target slave when a guard error has occurred
12	DBG	Access attribute of DBG to the target slave when a guard error has occurred
11	UM	Access attribute of UM to the target slave when a guard error has occurred
10 to 6	SPID[4:0]	Access attribute of SPID to the target slave when a guard error has occurred
5 to 1	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
0	WRITE	Access type of read or write to the target slave when a guard error has occurred

40.5.5 INTC2 Guard

40.5.5.1 Overview

INTC2 guard is one of the slave guards used to control the access to INTC2 registers. INTC2 guard can protect respectively the read and write access against INTC2 registers of each channel. If INTC2 guard detects illegal access, guard error notification is signaled to ECM.

40.5.5.2 List of Registers

Table 40.324 List of Registers

Module Name	Register Name	Symbol	Address	Access	Access Protection
GUARD_INTC2 (Peripheral Group0)	Key Code Protection Register	INTC2GKCPROT	FFC6 4000 _H	32	
	Guard Error Clear Register	INTC2GERRCLR	FFC6 4004 _H	8, 32	
	Guard Error Status Register	INTC2GERRSTAT	FFC6 4008 _H	8, 32	
	Guard Error Address Register	INTC2GERRADDR	FFC6 400C _H	32	
	Guard Error Access Information Register	INTC2GERRTYPE	FFC6 4010 _H	16, 32	
	SPID Setting Register	INTC2GMPIDn (n = 0-7)	FFC6 4040 _H + n × 04 _H	8, 32	INTC2GKCPROT
	INTC2 Protection Control Register	INTC2GPROT_GR	FFC6 40F0 _H	32	INTC2GKCPROT
	Channel Protection Control Register	INTC2GPROT_m (m = 032-695)	FFC6 4100 _H + m × 04 _H	32	INTC2GKCPROT

Table 40.325 Target Register of Protection Control Register

Symbol	Target Register
INTC2GPROT_m (m = 032 to 695)	EICn (n = 32 to 695)
INTC2GPROT_GR	IMRn (n = 1 to 21), EIBDn (n = 32 to 695)

40.5.5.3 INTC2GERRCLR — Guard Error Clear Register

This register is used to clear the INTC2GERRSTAT register. The INTC2GERRSTAT.OVF and/or INTC2GERRSTAT.ERR bits are cleared immediately after writing this register. Response data is always 0 when reading this register.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

1	CLRO	Clears the INTC2GERRSTAT.OVF bit
0	CLRE	Clears the INTC2GERRSTAT.ERR bit

40.5.5.4 INTC2GERRSTAT — Guard Error Status Register

This register is used to notify users whether guard errors occurred. The ERR bit is set when a guard error is reported by an error detection module, etc. The OVF bit is set when a guard error is reported again when the ERR bit is already set. This register is not writable and is cleared when writing the INTC2GERRCLR register. See **Section 40.5.5.3, INTC2GERRCLR — Guard Error Clear Register.**

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 40.330 INTC2GKCPROT Register Contents

Bit Position	Bit Name	Function
31 to 1	KCPROT[31:1]	Enable or disable modification of the KCE bit. The written value is not retained. These bits are always read as 0.*1
0	KCE	Key Code Enable bit 0: Disable write access to protected registers 1: Enable write access to protected registers

Note 1. Write A5A5A500_H to this register to disable writing protected registers.
Write A5A5A501_H to this register to enable writing protected registers.

40.5.5.8 INTC2GMPIDn — SPID Setting Register

INTC2GMPIDn are used to specify a set of SPIDs, which are referred by INTC2GPROT_m/GR registers. Access protection can be controlled by combination of INTC2GMPIDn registers and INTC2GPROT_m/GR register. For example, masters with SPID=1 or SPID=7 can access to global registers when setting INTC2GPROT_GR.MPID=00000101_B, INTC2GMPID0.SPID=01_H and INTC2GMPID2.SPID=07_H.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 40.332 INTC2GPROT_m/GR Register Contents

Bit Position	Bit Name	Function
31 to 24	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
23 to 16	MPID[7:0]	R/W enable setting based on MPID MPID is a list of bits each representing one MPID value. Multiple MPID values are enabled simultaneously by setting multiple bits. For example, setting MPID to 0101 _B enables access to areas MPID = 0 and MPID = 2. 0: Reading/writing the area with MPID = m depends on the RG and WG bit setting 1: Enables reading/writing the area with MPID = m
15 to 9	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
8	GEN	Enables/disables guard setting 0: Disables the guard setting 1: Enables the guard setting
7	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
6	DBG	R/W enable setting for debug master 0: Depends on other enable/disable settings 1: Enables R/W
5	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
4	UM	R/W disable setting in user mode 0: R/W disabled 1: R/W depends on other enable/disable settings
3, 2	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
1	WG	Write Global Enable 0: During write, MPID is used as a judgment condition. 1: During write, MPID is not used as a judgment condition.
0	RG	Read Global Enable 0: During read, MPID is used as the judgment condition. 1: During read, MPID is not used as a judgment condition.

40.5.6 DTS Guard

40.5.6.1 Overview

DTS guard is one of the slave guards used to control the access to the registers for DTS transfer. DTS guard can prevent read and write access to the DTS registers of each channel. If DTS guard detects illegal access, guard error notification is signaled to ECM.

40.5.6.2 List of Registers

Table 40.333 List of Registers

Module Name	Register Name	Symbol	Address	Access	Access Protection
GUARD_DTS (Peripheral Group0)	Key Code Protection Register	DTSGKCPROT	FFC6 8000 _H	32	
	Guard Error Clear Register	DTSGERRCLR	FFC6 8004 _H	8, 32	
	Guard Error Status Register	DTSGERRSTAT	FFC6 8008 _H	8, 32	
	Guard Error Address Register	DTSGERRADDR	FFC6 800C _H	32	
	Guard Error Access Information Register	DTSGERRTYPE	FFC6 8010 _H	16, 32	
	SPID Setting Register	DTSGMPIDn (n = 0-7)	FFC6 8040 _H + n × 04 _H	8, 32	DTSGKCPROT
	DTS Protection Control Register	DTSGPROT_GR	FFC6 80F0 _H	32	DTSGKCPROT
	Channel Protection Control Register	DTSGPROT_m (m = 000-127)	FFC6 8100 _H + m × 04 _H	32	DTSGKCPROT

Table 40.334 Target Register of Protection Control Register

Symbol	Target Register
DTSGPROT_GR	DTSCTL1, DTSCTL2, DTSSTS, DTSER, DTSPR0, DTSPR1, DTSPR2, DTSPR3, DTSPR4, DTSPR5, DTSPR6, DTSPR7, DTSnnnCM(nnn = 000 to 127)
DTSGPROT_m (m = 000 to 127)	DTSAAnnn, DTDAnnn, DTTcnnn, DTTCTnnn, DTRSAAnnn, DTRDAAnnn, DTRTCnnn, DTTCCnnn, DTFSLnnn, DTFSTnnn, DTFSSnnn, DTFSCnnn (nnn = 000 to 127)

40.5.6.3 DTSGERRCLR — Guard Error Clear Register

This register is used to clear the DTSGERRSTAT register. The DTSGERRSTAT.OVF and/or DTSGERRSTAT.ERR bits are cleared immediately after writing this register. Response data is always 0 when reading this register.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 40.341 DTSGPROT_m/GR Register Contents

Bit Position	Bit Name	Function
31 to 24	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
23 to 16	MPID[7:0]	R/W enable setting based on MPID MPID is a list of bits each representing one MPID value. Multiple MPID values are enabled simultaneously by setting multiple bits. For example, setting MPID to 0101 _B enables access to areas with MPID = 0 and MPID = 2. 0: Reading/writing the area with MPID = m depends on the RG and WG bit setting 1: Enables reading/writing the area with MPID = m
15 to 9	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
8	GEN	Enables/disables guard setting 0: Disables the guard setting 1: Enables the guard setting
7	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
6	DBG	R/W enable setting for debug master 0: Depends on other enable/disable settings 1: Enables R/W
5	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
4	UM	R/W disable setting in user mode 0: R/W disabled 1: R/W depends on other enable/disable settings
3, 2	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
1	WG	Write Global Enable 0: During write, MPID is used as a judgment condition. 1: During write, MPID is not used as a judgment condition.
0	RG	Read Global Enable 0: During read, MPID is used as the judgment condition. 1: During read, MPID is not used as a judgment condition.

40.5.7 sDMAC Guard

40.5.7.1 Overview

sDMAC guard is one of the slave guards used to control the access to the registers for sDMAC transfer. sDMAC guard can prevent read and write access to the sDMAC registers of each channel. If sDMAC guard detects illegal access, guard error notification is signaled to ECM.

40.5.7.2 Register Base Address

Base addresses of safety modules are listed in the following table. Each register address is given as offsets from the base addresses.

Table 40.342 Register Base Addresses

Base Address Name	Base Address	Bus Group
<GUARD_DMACH_base>	FFC6 9000 _H	Peripheral Group 0
<GUARD_DMACH1_base>	FFC6 9400 _H	Peripheral Group 0

40.5.7.3 List of Registers

Table 40.343 List of Registers

Module Name	Register Name	Symbol	Address	Access	Access Protection
GUARD_DMACH (j = 0, 1)	Key Code Protection Register	DMAGKCPROT	<GUARD_DMACH_base> + 00 _H	32	
	Guard Error Clear Register	DMAGERRCLR	<GUARD_DMACH_base> + 04 _H	8, 16, 32	
	Guard Error Status Register	DMAGERRSTAT	<GUARD_DMACH_base> + 08 _H	8, 32	
	Guard Error Address Register	DMAGERRADDR	<GUARD_DMACH_base> + 0C _H	32	
	Guard Error Access Information Register	DMAGERRTYPE	<GUARD_DMACH_base> + 10 _H	16, 32	
	SPID Setting Register	DMAGMPIDn (n = 0-7)	<GUARD_DMACH_base> + 40 _H + n × 04 _H	8, 16, 32	DMAGKCPROT
	DMA Protection Control Register	DMAGPROT_GR	<GUARD_DMACH_base> + F0 _H	8, 16, 32	DMAGKCPROT
	DMA Descriptor Protection Control Register	DMAGPROT_DP	<GUARD_DMACH_base> + F4 _H	8, 16, 32	DMAGKCPROT
Channel Protection Control Register	DMAGPROT_m (m = 000-015)	<GUARD_DMACH_base> + 100 _H + m × 04 _H	8, 16, 32	DMAGKCPROT	

Table 40.344 Target Register of Protection Control Register

Symbol	Target Register
DMAGPROT_GR	sDMAC global registers
DMAGPROT_DP	Descriptor RAM
DMAGPROT_m (m = 000 to 015)	sDMAC channel registers

40.5.7.4 DMAGERRCLR — Guard Error Clear Register

This register is used to clear the DMAGERRSTAT register. The DMAGERRSTAT.OVF and/or DMAGERRSTAT.ERR bits are cleared immediately after writing this register. Response data is always 0 when reading this register.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	W	W

Table 40.345 DMAGERRCLR Register Contents

Bit Position	Bit Name	Function
31 to 2	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
1	CLRO	Clears the DMAGERRSTAT.OVF bit
0	CLRE	Clears the DMAGERRSTAT.ERR bit

40.5.7.5 DMAGERRSTAT — Guard Error Status Register

This register is used to notify users whether guard errors occurred. The ERR bit is set when a guard error is reported by an error detection module, etc. The OVF bit is set when a guard error is reported again when the ERR bit is already set. This register is not writable and is cleared when writing the DMAGERRCLR register. See **Section 40.5.7.4, DMAGERRCLR — Guard Error Clear Register.**

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 40.348 DMAGERRTYPE Register Contents

Bit Position	Bit Name	Function
31 to 14	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
13	SEC	Access attribute of SEC to the target slave when a guard error has occurred
12	DBG	Access attribute of DBG to the target slave when a guard error has occurred
11	UM	Access attribute of UM to the target slave when a guard error has occurred
10 to 6	SPID[4:0]	Access attribute of SPID to the target slave when a guard error has occurred
5 to 1	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
0	WRITE	Access type of read or write to the target slave when a guard error has occurred

40.5.7.8 DMAGKCPROT — Key Code Protection Register

This register is used for protection against writing to the channel/DMA/DMA descriptor protection control registers due to program malfunction and the like.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	KCPROT[31:16]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

R/W	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W	R/W

Table 40.349 DMAGKCPROT Register Contents

Bit Position	Bit Name	Function
31 to 1	KCPROT[31:1]	Enable or disable modification of the KCE bit. The written value is not retained. These bits are always read as 0.*1
0	KCE	Key Code Enable bit 0: Disable write access to protected registers 1: Enable write access to protected registers

Note 1. Write A5A5A500_H to this register to disable writing protected registers.
Write A5A5A501_H to this register to enable writing protected registers.

40.5.7.9 DMAGMPIDn — SPID Setting Register

DMAGMPIDn are used to specify a set of SPIDs, which are referred by DMAGPROT_m/GR/DP registers. Access protection can be controlled by combination of DMAGMPIDn registers and DMAGPROT_m/GR/DP register. For example, masters with SPID=1 or SPID=7 can access to global registers when setting DMAGPROT_GR.MPID=00000101_B, DMAGMPID0.SPID=01_H and DMAGMPID2.SPID=07_H.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 40.351 DMAGPROT_m/GR/DP Register Contents

Bit Position	Bit Name	Function
31 to 24	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
23 to 16	MPID[7:0]	R/W enable setting based on MPID MPID is a list of bits each representing one MPID value. Multiple MPID values are enabled simultaneously by setting multiple bits. For example, setting MPID to 0101 _B enables access to areas with MPID = 0 and MPID = 2. 0: Reading/writing the area with MPID = m depends on the RG and WG bit setting 1: Enables reading/writing the area with MPID = m
15 to 9	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
8	GEN	Enables/disables guard setting 0: Disables the guard setting 1: Enables the guard setting
7	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
6	DBG	R/W enable setting for debug master 0: Depends on other enable/disable settings 1: Enables R/W
5	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
4	UM	R/W disable setting in user mode 0: R/W disabled 1: R/W depends on other enable/disable settings
3, 2	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
1	WG	Write Global Enable 0: During write, MPID is used as a judgment condition. 1: During write, MPID is not used as a judgment condition.
0	RG	Read Global Enable 0: During read, MPID is used as the judgment condition. 1: During read, MPID is not used as a judgment condition.

40.5.8 IBG

40.5.8.1 Overview

IPIR, MEV, BarrierSync and TPTM connect to Inter-cluster Bus (I-Bus). I-Bus Guard (IBG) is one of the slave guards used to control the access to these I-Bus modules. IBG can prevent read and write access to the registers of each module. If IBG detects illegal access, guard error notification is signaled to ECM.

40.5.8.2 Register Base Address

Base addresses of safety modules are listed in the following table. Each register address is given as offsets from the base addresses.

Table 40.352 Register Base Addresses

Base Address Name	Base Address	Bus Group
<GUARD_IPIR_base>	FFC6 A200 _H	Peripheral Group 0
<GUARD_MEV_base>	FFC6 A400 _H	Peripheral Group 0
<GUARD_BARR_base>	FFC6 A000 _H	Peripheral Group 0
<GUARD_TPTM_base>	FFC6 A600 _H	Peripheral Group 0

40.5.8.3 List of Registers

Table 40.353 List of Registers (1/2)

Module Name	Register Name	Symbol	Address	Access	Access Protection
GUARD_IPIR	Guard Error Clear Register	IPIGERRCLR	<GUARD_IPIR_base> + 00 _H	8, 32	
	Guard Error Status Register	IPIGERRSTAT	<GUARD_IPIR_base> + 04 _H	8, 32	
	Guard Error Address Register	IPIGERRADDR	<GUARD_IPIR_base> + 08 _H	32	
	Guard Error Access Information Register	IPIGERRTYPE	<GUARD_IPIR_base> + 0C _H	16, 32	
	Key Code Protection Register	IPIGKCPROT	<GUARD_IPIR_base> + 10 _H	32	
	Channel Protection Control Register	IPIGPROT0_n (n = 0-3)	<GUARD_IPIR_base> + 80 _H + n × 08 _H	8, 16, 32	IPIGKCPROT
	Channel SPID Setting Register	IPIGPROT1_n (n = 0-3)	<GUARD_IPIR_base> + 84 _H + n × 08 _H	8, 16, 32	IPIGKCPROT

	Guard Error Status Register	MEGERRSTAT	<GUARD_MEV_base> + 04 _H	8, 32	
	Guard Error Address Register	MEGERRADDR	<GUARD_MEV_base> + 08 _H	32	
	Guard Error Access Information Register	MEGERRTYPE	<GUARD_MEV_base> + 0C _H	16, 32	
	Key Code Protection Register	MEGKCPROT	<GUARD_MEV_base> + 10 _H	32	
	Channel Protection Control Register	MEGPROT0_n (n = 0-7)	<GUARD_MEV_base> + 80 _H + n × 08 _H	8, 16, 32	MEGKCPROT
	Channel SPID Setting Register	MEGPROT1_n (n = 0-7)	<GUARD_MEV_base> + 84 _H + n × 08 _H	8, 16, 32	MEGKCPROT
GUARD_BARR	Guard Error Clear Register	BRGERRCLR	<GUARD_BARR_base> + 00 _H	8, 32	
	Guard Error Status Register	BRGERRSTAT	<GUARD_BARR_base> + 04 _H	8, 32	
	Guard Error Address Register	BRGERRADDR	<GUARD_BARR_base> + 08 _H	32	

Table 40.353 List of Registers (2/2)

Module Name	Register Name	Symbol	Address	Access	Access Protection
GUARD_BARR	Guard Error Access Information Register	BRGERRTYPE	<GUARD_BARR_base> + 0C _H	16, 32	
	Key Code Protection Register	BRGKCPROT	<GUARD_BARR_base> + 10 _H	32	
	Channel Protection Control Register	BRGPROT0_n (n = 0-15)	<GUARD_BARR_base> + 80 _H + n × 08 _H	8, 16, 32	BRGKCPROT
	Channel SPID Setting Register	BRGPROT1_n (n = 0-15)	<GUARD_BARR_base> + 84 _H + n × 08 _H	8, 16, 32	BRGKCPROT
	Common Protection Control Register	BRGPROT0_16	<GUARD_BARR_base> + 100 _H	8, 16, 32	BRGKCPROT
	Common SPID Setting Register	BRGPROT1_16	<GUARD_BARR_base> + 104 _H	8, 16, 32	BRGKCPROT
GUARD_TPTM	Guard Error Clear Register	TPTGERRCLR	<GUARD_TPTM_base> + 00 _H	8, 32	
	Guard Error Status Register	TPTGERRSTAT	<GUARD_TPTM_base> + 04 _H	8, 32	
	Guard Error Address Register	TPTGERRADDR	<GUARD_TPTM_base> + 08 _H	32	
	Guard Error Access Information Register	TPTGERRTYPE	<GUARD_TPTM_base> + 0C _H	16, 32	
	Key Code Protection Register	TPTGKCPROT	<GUARD_TPTM_base> + 10 _H	32	
	Channel Protection Control Register	TPTGPROT0_n (n = 0 - 5)* ¹	<GUARD_TPTM_base> + 80 _H + n × 08 _H	8, 16, 32	TPTGKCPROT
	Channel SPID Setting Register	TPTGPROT1_n (n = 0 - 5)* ¹	<GUARD_TPTM_base> + 84 _H + n × 08 _H	8, 16, 32	TPTGKCPROT

Note 1. n = 4 to 5 is not implemented in E2H.

Table 40.354 Target Register of Protection Control Register

Related Function	Symbol	Target Register
IPIR	IPIGPROT0_n (n = 0 to 3)	IPInENS, IPInFLGS, IPInFCLRS, IPInREQS, IPInRCLRS * ¹
	IPIGPROT0_4	IPInENm, IPInFLGm, IPInFCLRm, IPInREQm, IPInRCLRm * ¹
MEV	MEGPROT0_n (n = 0 to 7)	G0MEV(4n) to G0MEV(4n+3) (n = 0 to 7)
BARR	BRGPROT0_n (n = 0 to 15)	BRnINIT, BRnEN, BRnCHKS, BRnSYNCS * ²
	BRGPROT0_16	BRnCHKm, BRnSYNCm * ²
TPTM	TPTGPROT0_n (n = 0 to 5)* ⁵	TPTMnIRUN, TPTMnIRRUN, TPTMnIStP, TPTMnIStR, TPTMnIIEEN, TPTMnIUStR, TPTMnIDIV, TPTMnFRUN, TPTMnFRUN, TPTMnFStP, TPTMnFStR, TPTMnFDIV, TPTMnICNT0, TPTMnILD0, TPTMnICNT1, TPTMnILD1, TPTMnICNT2, TPTMnILD2, TPTMnICNT3, TPTMnILD3, TPTMnFCNT * ^{3*4}

Note 1. n = 0 to 3: n is the channel number of IPIR. m = 0 to 5: m is PE number. m = 4 to 5 is not implemented in E2H.

Note 2. n = 0 to 15: n is the channel number of Barrier-Synchronization. m = 0 to 5: m is PE number. m = 4 to 5 is not implemented in E2H.

Note 3. n = 0 to 5: n is PE number. n = 4 to 5 is not implemented in E2H.

Note 4. TPTM Self region registers are protected according to TPTGPROT0_n setting.

Note 5. n = 4 to 5 is not implemented in E2H.

40.5.8.4 IPIGERRCLR — Guard Error Clear Register

This register is used to clear the IPIGERRSTAT register. The IPIGERRSTAT.OVF and/or IPIGERRSTAT.ERR bits are cleared immediately after writing this register. Response data is always 0 when reading this register.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	—	—	—	—	—	—	—	—	—	—	—	—	—	—	CLRO	CLRE
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	W	W

Table 40.355 IPIGERRCLR Register Contents

Bit Position	Bit Name	Function
31 to 2	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
1	CLRO	Clears the IPIGERRSTAT.OVF bit
0	CLRE	Clears the IPIGERRSTAT.ERR bit

40.5.8.5 IPIGERRSTAT — Guard Error Status Register

This register is used to notify users whether guard errors occurred. The ERR bit is set when a guard error is reported by an error detection module, etc. The OVF bit is set when a guard error is reported again when the ERR bit is already set. This register is not writable and is cleared when writing the IPIGERRCLR register. See **Section 40.5.8.4, IPIGERRCLR — Guard Error Clear Register.**

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 40.369 BRGERRCLR Register Contents

Bit Position	Bit Name	Function
31 to 2	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
1	CLRO	Clears the BRGERRSTAT.OVF bit
0	CLRE	Clears the BRGERRSTAT.ERR bit

40.5.8.19 BRGERRSTAT — Guard Error Status Register

This register is used to notify users whether guard errors occurred. The ERR bit is set when a guard error is reported by an error detection module, etc. The OVF bit is set when a guard error is reported again when the ERR bit is already set. This register is not writable and is cleared when writing the BRGERRCLR register. See **Section 40.5.8.18, BRGERRCLR — Guard Error Clear Register.**

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Multiple SPID values are enabled simultaneously by setting multiple bits.</p> <p>For example, setting TPTGPROT1_n to 0101_B enables access to areas with SPID = 0 and SPID = 2.</p> <p>0: Reading/writing the area with SPID = m depends on the RG and WG bit setting</p> <p>1: Enables reading/writing the area with SPID = m</p>

40.5.9 PBG

40.5.9.1 Overview

The PBG module is divided into several PBG groups, each of which is provided with a maximum of 16 protection channels. A single PBG channel can designate the access against which a single peripheral circuit should be protected. Each PBG group can hold the information of the access that has been rejected.

The following table lists the peripheral circuits to be protected, the corresponding PBG group names, and the PBG channel numbers.

Table 40.383 List of Peripheral Circuit Modules to be Protected (1/6)

PBG Group	PBG Channel Number	Module to be Protected
PBG00	0	ECC modules of Peripheral Group 0 (Group A) *4
	1	ECC modules of Peripheral Group 0 (Group B) *5
	3	MISG
	4	PFSYSTEM
	5	GCFU
PBG10	0	ECC module of Data Flash
	1	ECC modules of Peripheral Group 1
PBG2L0	0	SCI30
	1	SCI31
	2	SCI32
	3	SCI33
	4	RHSB XBAR0
	5	RHSB XBAR1
	6	ECC modules of Peripheral Group 2L
	7	OSTM0
	8	OSTM1
	9	OSTM2
	10	OSTM3
	11	OSTM4
	12	OSTM5 *2
	13	OSTM6 *2
	14	RHSB XBAR2
15	RHSB XBAR3 *2	
PBG2L1	0	WDTB0
	1	WDTB1
	2	WDTB2
	3	WDTB3
	4	WDTB4 *2
	5	WDTB5 *2

Note 1. The port group registers are divided into the following two groups and controlled separately.

Group A: Registers except PCR_n_m/JPCR_n_m registers (see **Section 2.4.1, Table 2.11**)

Group B: PCR_n_m/JPCR_n_m

Note 2. This function is not implemented in E2H.

Note 3. For details of the target registers, RH850/E2x-FCC2 Flash Memory User's Manual: Hardware Interface section 4.2 Registers Related to Write and Erase Protection of Flash Memory.

- Note 4. This PBG channel protects the registers related to the following modules:
ECCCNT_* (except for ECCCNT_A_V2An(n = 1 to 9), and ECCCNT_D_V2AnW(n = 1 to 9))
DTS_COMPC
- Note 5. This PBG channel protects the registers related to the following modules:
MECCCAP_*
BECCCAP_* (except for BECCCAP_V2An(n = 1 to 9))

40.5.9.2 Register Base Address

Base addresses of safety modules are listed in the following table. Each register address is given as offsets from the base addresses.

Table 40.384 Register Base Addresses

Base Address Name	Base Address	Bus Group
<PBG00_base>	FFC6 B000 _H	Peripheral Group 0
<PBG10_base>	FFC6 3000 _H	Peripheral Group 1
<PBG2L0_base>	FFDA 0800 _H	Peripheral Group 2L
<PBG2L1_base>	FFDA 0900 _H	Peripheral Group 2L
<PBG2H0_base>	FFDE 1000 _H	Peripheral Group 2H
<PBG2H1_base>	FFDE 1100 _H	Peripheral Group 2H
<PBG30_base>	FFC7 2B00 _H	Peripheral Group 3
<PBG31_base>	FFC7 2C00 _H	Peripheral Group 3
<PBG40_base>	FFC7 5300 _H	Peripheral Group 4
<PBG50_base>	FFC7 B000 _H	Peripheral Group 5
<PBG60_base>	FFC8 1000 _H	Peripheral Group 6
<PBG61_base>	FFC8 1100 _H	Peripheral Group 6
<PBG62_base>	FFC8 1200 _H	Peripheral Group 6
<PBG63_base>	FFC8 1300 _H	Peripheral Group 6
<PBG64_base>	FFC8 1400 _H	Peripheral Group 6
<PBG65_base>	FFC8 1500 _H	Peripheral Group 6
<PBG66_base>	FFC8 1600 _H	Peripheral Group 6
<PBG68_base>	FFC8 1800 _H	Peripheral Group 6
<PBG69_base>	FFC8 1900 _H	Peripheral Group 6
<PBG70_base>	FFF4 9000 _H	Peripheral Group 7
<PBG80_base>	FFF5 9000 _H	Peripheral Group 8
<PBG90_base>	FF0A 1300 _H	Peripheral Group 9

40.5.9.3 List of Registers

Table 40.385 List of Registers

Module Name	Register Name	Symbol	Address	Access	Access Protection
PBGn (n = 00, 10, 2L0, 2L1, 2H0, 2H1, 30, 31, 40, 50, 60-66, 68, 69, 70, 80,90)	Guard Error Clear Register	PBGERRCLR	<PBGn_base> + 00 _H	8, 16, 32	
	Guard Error Status Register	PBGERRSTAT	<PBGn_base> + 04 _H	8, 32	
	Guard Error Address Register	PBGERRADDR	<PBGn_base> + 08 _H	32	
	Guard Error Access Information Register	PBGERRTYPE	<PBGn_base> + 0C _H	16, 32	
	Key Code Protection Register	PBGKCPROT	<PBGn_base> + 10 _H	32	
	Channel Protection Control Register	PBGPROT0_m (m = 0-15)*1	<PBGn_base> + 80 _H + m × 08 _H	8, 16, 32	PBGKCPROT
Channel SPID Setting Register	PBGPROT1_m (m = 0-15)*1	<PBGn_base> + 84 _H + m × 08 _H	8, 16, 32	PBGKCPROT	

Note 1. "m" of PBGPROT0_m and PBGPROT1_m indicates the number of PBG channel. Each channel number is different from each other then please refer to **Section 40.5.9.1, Overview**.

40.5.9.4 PBGERRCLR —Guard Error Clear Register

This register is used to clear the PBGERRSTAT register. The PBGERRSTAT.OVF and/or PBGERRSTAT.ERR bits are cleared immediately after writing this register. Response data is always 0 when reading this register.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	W	W

Table 40.386 PBGERRCLR Register Contents

Bit Position	Bit Name	Function
31 to 2	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
1	CLRO	Clears the PBGERRSTAT.OVF bit
0	CLRE	Clears the PBGERRSTAT.ERR bit

40.5.9.5 PBGERRSTAT — Guard Error Status Register

This register is used to notify users whether guard errors occurred. The ERR bit is set when a guard error is notified by an error detection module, etc. The OVF bit is set when a guard error is notified again when the ERR bit is already set. This register is not writable and is cleared when writing the PBGERRCLR register. See **Section 40.5.9.4, PBGERRCLR —Guard Error Clear Register.**

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Table 40.387 PBGERRSTAT Register Contents

Bit Position	Bit Name	Function
31 to 2	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
1	OVF	Overflow status flag
0	ERR	Error status flag

40.5.9.6 PBGERRADDR — Guard Error Address Register

This register is used to get an access address when a guard error is occurred. Error address is stored in this register only when PBGERRSTAT.ERR bit is not set.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	ADDR[31:16]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	ADDR[15:0]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 40.388 PBGERRADDR Register Contents

Bit Position	Bit Name	Function
31 to 0	ADDR[31:0]	Access address to the target slave when a guard error has occurred

40.5.9.7 PBGERRTYPE — Guard Error Access Information Register

This register is used to get an access attributes when a guard error is occurred. Error information is stored in this register only when PBGERRSTAT.ERR bit is not set.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	SEC	DBG	UM	SPID[4:0]				—	—	—	—	—	—	WRITE
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 40.389 PBGERRTYPE Register Contents

Bit Position	Bit Name	Function
31 to 14	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
13	SEC	Access attribute of SEC to the target slave when a guard error has occurred
12	DBG	Access attribute of DBG to the target slave when a guard error has occurred
11	UM	Access attribute of UM to the target slave when a guard error has occurred
10 to 6	SPID[4:0]	Access attribute of SPID to the target slave when a guard error has occurred
5 to 1	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
0	WRITE	Access type of read or write to the target slave when a guard error has occurred

40.5.9.8 PBGKCPROT — Key Code Protection Register

This register is used to unlock/lock key protection of the P-bus guard register.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	KCPROT[31:16]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	KCPROT[15:1]															KCE
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W	R/W

Table 40.390 PBGKCPROT Register Contents

Bit Position	Bit Name	Function
31 to 1	KCPROT[31:1]	Enable or disable modification of the KCE bit. The written value is not retained. These bits are always read as 0.* ¹
0	KCE	Key Code Enable bit 0: Disable write access to protected registers 1: Enable write access to protected registers

Note 1. Write A5A5A500_H to this register to disable writing protected registers.
Write A5A5A501_H to this register to enable writing protected registers.

40.5.9.9 PBGPROT0_m — Channel Protection Control Register

Specifies the P-Bus peripheral access to be protected against. Access prohibited by any of the identifiers is blocked as unauthorized access. This register is used to specify the settings other than SPID.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	GEN	—	DBG	—	UM	—	—	WG	RG
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R/W	R	R/W	R	R/W	R	R	R/W	R/W

Table 40.391 PBGPROT0_m Register Contents

Bit Position	Bit Name	Function
31 to 9	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
8	GEN	Enables/disables guard setting 0: Disables the guard setting 1: Enables the guard setting
7	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
6	DBG	R/W enable setting for debug master 0: Depends on other enable/disable settings 1: Enables R/W
5	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
4	UM	R/W disable setting in user mode 0: R/W disabled 1: R/W depends on other enable/disable settings
3, 2	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
1	WG	Write Global Enable 0: During write, PBGPROT1_m is used as a judgment condition. 1: During write, PBGPROT1_m is not used as a judgment condition.
0	RG	Read Global Enable 0: During read, PBGPROT1_m is used as the judgment condition. 1: During read, PBGPROT1_m is not used as a judgment condition.

Note: An access by specific instructions (CLR1, NOT1, SET1 and CAXI) is protected by PBG if either reading or writing is disabled.

40.5.9.10 PBGPROT1_m — Channel SPID Setting Register

Specifies the P-Bus peripheral access to be protected against. Access prohibited by any of the identifiers is blocked as unauthorized access. This register is used to specify the SPID setting.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	SPID[31:16]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	SPID[15:0]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 40.392 PBGPROT1_m Register Contents

Bit Position	Bit Name	Function
31 to 0	SPID[31:0]	<p>R/W enable setting based on SPID</p> <p>PBGPROT1_m is a list of bits each representing one SPID value. Multiple SPID values are enabled simultaneously by setting multiple bits.</p> <p>For example, setting PBGPROT1_m to 0101_B enables access to areas with SPID = 0 and SPID = 2.</p> <p>0: Reading/writing the area with SPID = m depends on the RG and WG bit setting</p> <p>1: Enables reading/writing the area with SPID = m</p>

40.5.10 HBG

40.5.10.1 Overview

HBG can prevent read and write access against which a peripheral circuit on H-Bus should be protected. If HBG detects illegal access, guard error notification is signaled to ECM.

The following table lists the peripheral circuits to be protected and the corresponding HBG names.

Table 40.393 List of Peripheral Circuit Module to be Protected

HBG	Module to be Protected
HBG91	RHSIF0
HBG93	FlexRay0
HBG94 *1	FlexRay1
HBG95	Ethernet
HBG98	External Bus Controller

Note 1. This function is not implemented in E2H.

40.5.10.2 Register Base Address

Base addresses of safety modules are listed in the following table. Each register address is given as offsets from the base addresses.

Table 40.394 Register Base Addresses

Base Address Name	Base Address	Bus Group
<HBG91_base>	FF0D 0300 _H	Peripheral Group 9
<HBG93_base>	FF0D 0000 _H	Peripheral Group 9
<HBG94_base>*1	FF0D 0100 _H	Peripheral Group 9
<HBG95_base>	FF0D 0200 _H	Peripheral Group 9
<HBG98_base>	FF0D 0500 _H	Peripheral Group 9

Note 1. This function is not implemented in E2H.

40.5.10.3 List of Registers

Table 40.395 List of Registers

Module Name	Register Name	Symbol	Address	Access	Access Protection
HBGn (n = 91, 93, 94*1, 95, 98)	Guard Error Clear Register	HBGERRCLR	<HBGn_base> + 00 _H	8, 16, 32	
	Guard Error Status Register	HBGERRSTAT	<HBGn_base> + 04 _H	8, 16, 32	
	Guard Error Address Register	HBGERRADDR	<HBGn_base> + 08 _H	32	
	Guard Error Access Information Register	HBGERRTYPE	<HBGn_base> + 0C _H	16, 32	
	Key Code Protection Register	HBGKCPROT	<HBGn_base> + 10 _H	32	
	Channel Protection Control Register	HBGPROT0	<HBGn_base> + 80 _H	8, 16, 32	HBGKCPROT
	Channel SPID Setting Register	HBGPROT1	<HBGn_base> + 84 _H	8, 16, 32	HBGKCPROT

Note 1. This function is not implemented in E2H.

40.5.10.4 HBGERRCLR — Guard Error Clear Register

This register is used to clear the HBGERRSTAT register. The HBGERRSTAT.OVF and/or HBGERRSTAT.ERR bits are cleared immediately after writing this register. Response data is always 0 when reading this register.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	CLRO	CLRE
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	W	W

Table 40.396 HBGERRCLR Register Contents

Bit Position	Bit Name	Function
31 to 2	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
1	CLRO	Clears the HBGERRSTAT.OVF bit
0	CLRE	Clears the HBGERRSTAT.ERR bit

40.5.10.5 HBGERRSTAT — Guard Error Status Register

This register is used to notify users whether guard errors occurred. The ERR bit is set when a guard error is reported by an error detection module, etc. The OVF bit is set when a guard error is reported again when the ERR bit is already set. This register is not writable and is cleared when writing the HBGERRCLR register. See **Section 40.5.10.4, HBGERRCLR — Guard Error Clear Register**.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Table 40.397 HBGERRSTAT Register Contents

Bit Position	Bit Name	Function
31 to 2	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
1	OVF	Overflow status flag
0	ERR	Error status flag

40.5.10.6 HBGERRADDR — Guard Error Address Register

This register is used to get an access address when a guard error is occurred. Error address is stored in this register only when HBGERRSTAT.ERR bit is not set.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	ADDR[31:16]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	ADDR[15:0]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 40.398 HBGERRADDR Register Contents

Bit Position	Bit Name	Function
31 to 0	ADDR[31:0]	Access address to the target slave when a guard error has occurred

40.5.10.7 HBGERRTYPE — Guard Error Access Information Register

This register is used to get an access attributes when a guard error is occurred. Error information is stored in this register only when HBGERRSTAT.ERR bit is not set.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 40.399 HBGERRTYPE Register Contents

Bit Position	Bit Name	Function
31 to 14	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
13	SEC	Access attribute of SEC to the target slave when a guard error has occurred
12	DBG	Access attribute of DBG to the target slave when a guard error has occurred
11	UM	Access attribute of UM to the target slave when a guard error has occurred
10 to 6	SPID[4:0]	Access attribute of SPID to the target slave when a guard error has occurred
5 to 1	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
0	WRITE	Access type of read or write to the target slave when a guard error has occurred

40.5.10.8 HBGKCPROT — Key Code Protection Register

This register is used for protection against writing to the channel protection control registers due to program malfunction and the like.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	KCPROT[31:16]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	KCPROT[15:1]															KCE
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W	R/W

Table 40.400 HBGKCPROT Register Contents

Bit Position	Bit Name	Function
31 to 1	KCPROT[31:1]	Enable or disable modification of the KCE bit. The written value is not retained. These bits are always read as 0.*1
0	KCE	Key Code Enable bit 0: Disable write access to protected registers 1: Enable write access to protected registers

Note 1. Write A5A5A500_H to this register to disable writing protected registers.
Write A5A5A501_H to this register to enable writing protected registers.

40.5.10.9 HBGPROT0 — Channel Protection Control Register

Specifies the H-Bus peripheral access to be protected against. Access prohibited by any of the identifiers is blocked as unauthorized access. This register is used to specify the settings other than SPID.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	GEN	—	DBG	—	UM	—	—	WG	RG
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R/W	R	R/W	R	R/W	R	R	R/W	R/W

Table 40.401 HBGPROT0 Register Contents

Bit Position	Bit Name	Function
31 to 9	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
8	GEN	Enables/disables guard setting 0: Disables the guard setting 1: Enables the guard setting
7	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
6	DBG	R/W enable setting for debug master 0: Depends on other enable/disable settings 1: Enables R/W
5	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
4	UM	R/W disable setting in user mode 0: R/W disabled 1: R/W depends on other enable/disable settings
3, 2	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
1	WG	Write Global Enable 0: During write, HBGPROT1_n is used as a judgment condition. 1: During write, HBGPROT1_n is not used as a judgment condition.
0	RG	Read Global Enable 0: During read, HBGPROT1_n is used as the judgment condition. 1: During read, HBGPROT1_n is not used as a judgment condition.

40.5.10.10 HBGPROT1 — Channel SPID Setting Register

Specifies the H-Bus peripheral access to be protected against. Access prohibited by any of the identifiers is blocked as unauthorized access. This register is used to specify the SPID setting.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	SPID[31:16]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	SPID[15:0]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 40.402 HBGPROT1 Register Contents

Bit Position	Bit Name	Function
31 to 0	SPID[31:0]	<p>R/W enable setting based on SPID</p> <p>HBGPROT1_n is a list of bits each representing one SPID value. Multiple SPID values are enabled simultaneously by setting multiple bits.</p> <p>For example, setting HBGPROT1_n to 0101_B enables access to areas with SPID = 0 and SPID = 2.</p> <p>0: Reading/writing the area with SPID = m depends on the RG and WG bit setting</p> <p>1: Enables reading/writing the area with SPID = m</p>

40.6 BIST

40.6.1 Overview

This product incorporates Built-In-Self-Test (BIST) function to detect failures of the safety mechanism itself. The BIST consists of Logic BIST (LBIST) and Memory BIST (MBIST). LBIST is considered as the effective hardware safety mechanism to measure latent faults which can reduce software load for error injection tests. LBIST covers over 90% of the safety mechanisms for LFM. The BIST is executed during the reset sequence of System Reset 1 and System Reset 2 before the CPU starts operation. BIST execution results can be identified by the BIST result register (BSEQ0ST). In addition, by setting System Reset 2 before shutdown, BIST can be performed during the reset sequence in accordance with the setting of the BSEQ0CTL register. When running BIST, the scenario can be selected in accordance with the setting of the BSEQ0SEL register. For LBIST and MBIST, either a power-up BIST using System Reset 1 (set by using flash option byte 3) or a shutdown BIST using System Reset 2 (set by the BSEQ0SEL register) can be selected.

40.6.2 Registers

40.6.2.1 Register Protection

Write protected registers are protected from inadvertent write access due to erroneous program execution, etc. Write protected registers can be written by releasing the protection of RESKCPROT. For details of RESKCPROT, see **Section 10.2.16, RESKCPROT — Reset Controller Register Key Code Protection Register**.

40.6.2.2 List of Registers

Table 40.403 List of Registers

Module Name	Register Name	Symbol	Address	Access	Access Protection
BIST (Peripheral Group6)	Logic BIST Reference Value Register 1	LBISTREF1	FF70 E100 _H	32	
	Logic BIST Reference Value Register 2	LBISTREF2	FF70 E104 _H	32

Table 40.407 MBISTREF1 Register Contents

Bit Position	Bit Name	Function
31 to 20	—	Reserved When reading, the value after reset is read. When writing, write the value after reset.
19 to 0	MBISTREF1[19:0]	Reference signature value (expected signature value)

Note 1. Value after reset depends on BIST execution condition. For details about BIST execution condition, see **Section 40.6.3.1, BIST Execution Condition.**

BIST is skipped: 000A A55A_H

BIST is executed: BIST reference value

40.6.2.7 LBISTSIG1 — Logic BIST Signature Value Register 1

This register indicates the signature value of the Logic BIST. This register is automatically updated by the BIST result signature after BIST execution.

The user compares the reference signature of LBISTREF1 against the resulting signature LBISTSIG1. The Logic BIST is passed if these are equal.

Value after reset: BIST result *1

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	LBISTSIG1[19:16]

Table 40.408 LBISTSIG1 Register Contents

Bit Position	Bit Name	Function
31 to 20	—	Reserved When reading, the value after reset is read. When writing, write the value after reset.
19 to 0	LBISTSIG1[19:0]	Logic BIST1 result signature value

Note 1. Value after reset depends on BIST execution condition. For details about BIST execution condition, see **Section 40.6.3.1, BIST Execution Condition.**

BIST is skipped:	0005 A5A5 _H
BIST is executed without LBIST:	LBISTREF1
BIST is executed with LBIST:	BIST result

40.6.2.8 LBISTSIG2 — Logic BIST Signature Value Register 2

This register indicates the signature value of the Logic BIST. This register is automatically updated by the BIST result signature after BIST execution.

The user shall compare the reference signature of LBISTREF2 against the resulting signature LBISTSIG2. The Logic BIST is passed if these are equal.

Value after reset: BIST result *1

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	LBISTSIG2[19:16]

Table 40.409 LBISTSIG2 Register Contents

Bit Position	Bit Name	Function
31 to 20	—	Reserved When reading, the value after reset is read. When writing, write the value after reset.
19 to 0	LBISTSIG2[19:0]	Logic BIST2 result signature value

Note 1. Value after reset depends on BIST execution condition. For details about BIST execution condition, see **Section 40.6.3.1, BIST Execution Condition.**

BIST is skipped: 000A 5A5A_H

BIST is executed without LBIST: LBISTREF2

BIST is executed with LBIST: BIST result

40.6.2.9 MBISTSIG1 — Memory BIST Signature Value Register 1

This register indicates the signature value of the Memory BIST. This register is automatically updated by the BIST result signature after BIST execution.

The user shall compare the reference signature of MBISTREF1 against the resulting signature MBISTSIG1. The Memory BIST is passed if these are equal.

Value after reset: BIST result *1

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	MBISTSIG1[19:16]

R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 40.427 BISTST Register Contents

Bit Position	Bit Name	Function
31 to 3	—	Reserved When reading, the value after reset is read. When writing, write the value after reset.
2	MBIST1ST	Memory BIST result 0: MBIST1 passed successfully 1: MBIST1 has detected an error
1	LBIST2ST	Logic BIST (Reset toggle check) result 0: LBIST2 passed successfully 1: LBIST2 has detected an error
0	LBIST1ST	Logic BIST (Data toggle check) result 0: LBIST1 passed successfully 1: LBIST1 has detected an error

Note 1. Value after reset depends on BIST execution condition. For details about BIST execution condition, see **Section 40.6.3.1, BIST Execution Condition.**

BIST is skipped: 0000 000F_H

BIST is executed:

MBIST1ST value:

without MBIST: 0

with MBIST: BIST result

LBIST1ST, LBIST2ST value:

without LBIST: 0

with LBIST: BIST result

40.6.2.20 BSEQ0SEL — BIST Scenario Select Register

This register is used to select the execution scenario of BIST at the next System Reset 2 occurrence.

Value after reset: 0000 0030_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 40.428 BSEQ0SEL Register Contents

Bit Position	Bit Name	Function
31 to 16	—	Reserved When reading, the value after reset is read. When writing, write the value after reset.
15	PARAMSEL	Selects BIST parameters (HWLBISTSEL[1:0], HWTESTSET[1:0]) of BIST which will be executed during next System Reset 2 triggered by software reset. 0: Parameters specified by Flash option byte*1. (default) 1: Parameters specified by BSEQ0SEL registers.
14 to 6	—	Reserved When reading, the value after reset is read. When writing, write the value after reset.
5 to 4	HWTESTSET[1:0]	BIST selection 00 _B : Prohibited 01 _B : LBIST ONLY 10 _B : MBIST ONLY 11 _B : LBIST AND MBIST For BIST, four operation settings can be selected by combining HWTESTSET[1:0] and HWLBISTSEL[1:0]. Refer to Table 40.429, BIST scenario use case.
3 to 2	—	Reserved When reading, the value after reset is read. When writing, write the value after reset.
1, 0	HWLBISTSEL[1:0]	BIST scenario selection 00 _B : BIST scenario 1 01 _B : BIST scenario 2 10 _B : BIST scenario 3 11 _B : BIST scenario 4 For BIST, four operation settings can be selected by combining HWTESTSET[1:0] and HWLBISTSEL[1:0]. Refer to Table 40.429, BIST scenario use case.

Note 1. For details, see **Section 43, Flash Memory.**

Table 40.429 BIST scenario use case

HwLBISTSEL [1:0]* ¹	HwTESTSET [1:0]* ¹	Function	Run time* ²	Target ASIL* ³
00	10	MBIST Execution	5 ms (MBIST 5ms)	—
01	11	LBIST and MBIST Execution	10 ms (LBIST 5 ms, MBIST 5 ms)	ASIL B
10	01	LBIST Execution	15 ms (LBIST 15 ms)	ASIL D
11	11	LBIST and MBIST Execution	20 ms (LBIST 15 ms, MBIST 5 ms)	ASIL D

Note 1. Settings other than above are prohibited.

Note 2. Run time is calculated by the typical frequency of the Internal OSC. For details, see *the RH850/E2x-FCC2 Electrical Characteristics, User's Manual: Hardware*.

Note 3. ISO26262 compliance for LFM by LBIST.

40.6.2.21 BSEQ0CTL — BIST Skip Control Register

This register is used to control the BIST execution at the next System Reset 2 occurrence.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W

Table 40.430 BSEQ0CTL Register Contents

Bit Position	Bit Name	Function
31 to 2	—	Reserved When reading, the value after reset is read. When writing, write the value after reset.
1	HWBISTSEL	Selects flash option byte value or register value for the BIST execution setting. 0: BIST is executed according to Flash Option Byte* ¹ value. 1: BIST is executed according to HWBISTEXE value.
0	HWBISTEXE	This bit selects if BIST is skipped or not at the next system reset 2. 0: BIST is skipped at the next system reset 2 1: BIST is executed at the next system reset 2

Note 1. For details, see **Section 43, Flash Memory**.

40.6.3 Functions

40.6.3.1 BIST Execution Condition

The BIST is executed during reset sequence of System Reset 1 and System Reset 2. The following tables explain the conditions of BIST execution.

Table 40.431 BIST Execution during System Reset 1

Conditions			BIST Execution during Reset Sequence
Reset Category	TRST pin	HWBIST (Flash option*1)	
System Reset 1	High	1	BIST not executed. *2
		0	BIST is skipped. *3
	Low	1	BIST is executed. *4
		0	BIST is skipped. *3

Note 1. For details, See **Section 43, Flash Memory**.

Note 2. Reset is released after the expiration of the selected BIST scenario time.

Note 3. Reset is released without waiting for the selected BIST scenario time.

Note 4. Reset is released after BIST has finished. BIST is executed with preset parameters. For details, See **Section 43, Flash Memory**.

Table 40.432 BIST Execution during System Reset 2 (ECM, SWDTA, Software Reset)

Reset Category	TRST pin	HWBISTSEL (Register)	
System Reset 2	High	0	HWBIST (Flash option*1) Value 1: BIST is not executed.*2 0: BIST is skipped.*3
		1	BSEQOCTL register HWBISTEXE Value 1: BIST is not executed.*2 0: BIST is skipped.*3
	Low	0	HWBIST (Flash option*1) Value 1: BIST is executed.*4 0: BIST is skipped.*3
		1	BSEQOCTL register HWBISTEXE Value 1: BIST is executed. 0: BIST is skipped.*3

Note 1. For details, See **Section 43, Flash Memory**.

Note 2. Reset is released after the expiration of the selected BIST scenario time.

Note 3. Reset is released without waiting for the selected BIST scenario time.

Note 4. Reset is released after BIST has finished. BIST is executed with preset parameters. For details, See **Section 43, Flash Memory**.

40.6.3.2 BIST Result Confirmation

After the BIST execution, read and compare the following register values to confirm whether the BIST execution completed normally without failure.

- BSEQ0ST = 0000 0002_H
- BSEQ0STB = 0000 0001_H
- LBISTSIG1 = LBISTREF1
- LBISTSIG2 = LBISTREF2
- MBISTSIG1 = MBISTREF1
- BISTST = 0000 0000_H

40.6.4 Operation

By setting System Reset 2 before shutdown, BIST can be performed during the reset sequence in accordance with the setting of the BSEQ0CTL register. When running BIST, the scenario can be selected in accordance with the setting of the BSEQ0SEL register. For LBIST and MBIST, either a power-up BIST using System Reset 1 (set by using flash option byte 3) or a shutdown BIST using System Reset 2 (set by the BSEQ0SEL register) can be selected.

Table 40.433 BIST Scenario Select Condition

RESET	Source	BIST Scenario Select
System Reset 1	External Reset, Standby Reset, VMON reset	Flash option byte*1
System Reset 2	ECM reset, SWDTA reset, Software reset	BSEQ0SEL register (PARAMSEL = 1)

Note 1. For details, See **Section 43, Flash Memory**.

40.7 MISG

40.7.1 Overview

This MCU incorporates multi-input signature generators (MISG) for self-diagnosis by the CPUs.

The table below shows the overview of the MISG specifications.

Table 40.434 Specification Overview

Item	Description
Signature generation units	This MCU incorporates the signature generation unit for each CPU core. MISG extracts necessary information from CPU trace and inputs it to the signature generation units in write monitoring mode.
Generating polynomials	Two types of polynomials are available to generate a 32-bit signature. <ul style="list-style-type: none"> MISR1: $G(x) = x^{32} + x^{26} + x^{23} + x^{22} + x^{16} + x^{12} + x^{11} + x^{10} + x^8 + x^7 + x^5 + x^4 + x^2 + x + 1$ MISR2: $G(x) = x^{32} + x^{22} + x^2 + x + 1$
Signature generation	Signature generation can be enabled or disabled. <ul style="list-style-type: none"> Signature generation in MISR1 can be enabled or disabled. Signature generation in MISR2 can be enabled or disabled. <p>The following two conditions can be selected as conditions for signature generation:</p> <ul style="list-style-type: none"> Writing to the register A signature is generated by writing to the MISR calculation data register (MISRCDR_*). Monitoring write access A signature is generated if writing to the address area specified for monitoring occurs when writing by using the CPU that is being monitored. The address area is specified by the monitoring area base address register and the monitoring area address mask register.
Automatic signature comparison	Two signature generation units are selected for comparison of signatures. Each signature generation unit has a data counter, and comparison proceeds when the values of the data counters in the MISGs selected as the target for comparison match. Moreover, MISG stops the generation of signature and the count of the data counters when the values of the data counters in the MISGs match the values of MISR compare data counter register (MISRCMPDCNT), and comparison also proceeds after both the counters that are the target for comparison match stop. The data counter counts the number of write accesses to the MISRCDR_* register or the address area being monitored.
Error notification	When signatures are compared and do not match, the ECM is notified of an error. Enabling or disabling of error notification to the ECM can be selected. An interrupt request is not issued directly to the INTC.

Note 1. "*" in MISRCDR_*, MISR1_*, and MISR2_* indicates PEm. (m = 0 to 5: m = 4 to 5 is not implemented in E2H.)

40.7.2 Block Diagram

40.7.2.1 MISG

Figure 40.2 shows a block diagram of the MISG. The MISG consists of the signature generation unit and the signature comparison unit.

Using write monitoring mode as the signature generation condition (**Section 40.7.3.1(2), Write Monitoring Mode**) is only possible between the corresponding signature generation unit and the CPU. Therefore, each signature generation unit is given a name corresponding to the CPU number (MISG_PE0, MISG_PE1). MISG_PEm can monitor write access by CPU_m. (m = 0 to 5: m = 4 to 5 is not implemented in E2H.)

When register write mode is the signature generation condition, there is no correspondence between a CPU and the signature generation unit. Any CPU can generate a signature in any signature generation unit.

Figure 40.2 MISG Block Diagram (Multi Core)

40.7.2.2 Signature Generation

Figure 40.3 shows the flow of data in signature generation. MISR1 and MISR2 consist of two 32-bit signature generation units (MISR1_*, MISR2_*).

MISR2_* can generate a signature from 32-bits of data being written by the CPU being monitored, or from data being written to MISRCDR_*. Signature generation units stop the signature generation based on a signal from signature compare unit triggered by automatic signature comparison.

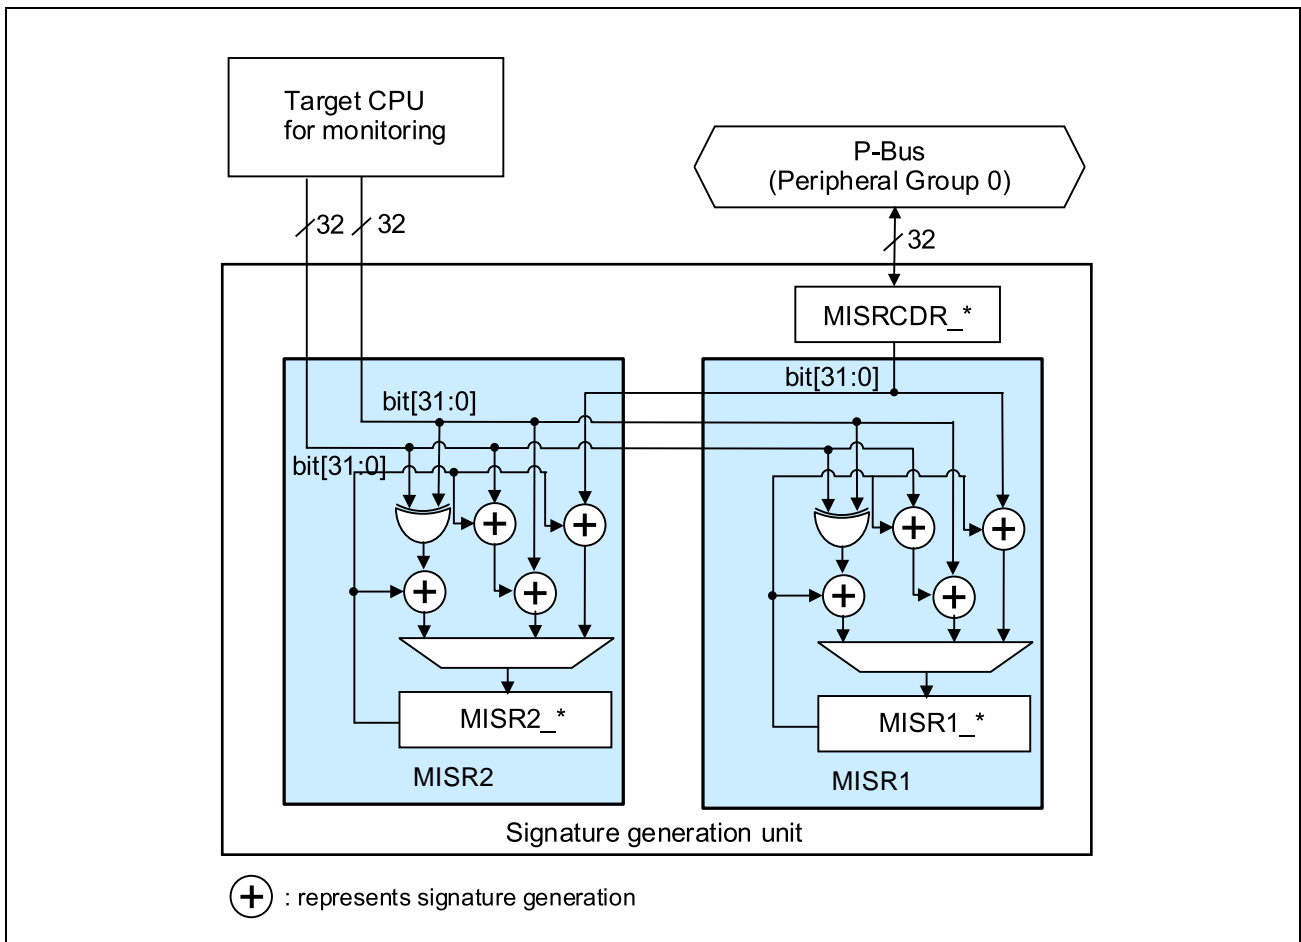

Figure 40.3 Signature Generation Units

Figure 40.4 shows the block diagram of signature generation in MISR1_* and the polynomials.

Figure 40.4 Block Diagram of Signature Generation in MISR1_*

Figure 40.5 shows the block diagram of signature generation in MISR2_* and the polynomials.

Figure 40.5 Block Diagram of Signature Generation in MISR2_*

40.7.2.3 Signature Compare Unit

The signature compare unit consists of the signature generation selector part, counter compare part and signature compare part. The signature generation selector part can select the input signals to the signature compare part and the counter compare part from all implemented signature generation units. Furthermore, the signature generation selector part inputs the stop signal for signature generation and the control signal for count up generated by the counter compare part.

Figure 40.6 Block Diagram of MSD

40.7.3 Functional Specifications

40.7.3.1 Conditions for Signature Generation

The conditions for signature generation in MISR1 and MISR2 can be selected by the setting the MISR control register (MISRCR_*).

Note 1. “*” in MISRCR_* indicates PEm. (m = 0 to 5: m = 4 to 5 is not implemented in E2H.)

Signature generation conditions for MISRi (i = 1, 2)

Table 40.435 Signature Generation Conditions for MISRi

MISRCR. MISRiEN	MISRCR. MISEiCND	Signature Generation Conditions
0	—	MISRi does not generate a signature.
1	0	Register write mode Writing to the MISRCDR_* register leads to MISRi generating a signature.
1	1	Write monitoring mode MISRi generates a signature after the corresponding CPU writes to an address specified for monitoring.

(1) Register Write Mode

Writing to the MISR calculation data register (MISRCDR_*) while MISR1 is in register write mode leads to the generation of a 32-bit signature in MISR1 from the value held in the multi-input signature register 1 (MISR1_*) and the data written to MISRCDR_*, and the result is retained in MISR1_*. Similarly, a 32-bit signature is generated in MISR2 from the value held in the multi-input signature register 2 (MISR2_*) and the data written to MISRCDR_*, and the result is retained in MISR2_*.

Writing to MISRCDR_* can proceed in 8-, 16-, or 32-bit units, and bits to which a value is not written are treated as 0. For example, writing to the 16 lower-order bits of MISRCDR_* leads to the generation of a signature with the 16 higher-order bits of write data treated as 0. Similarly, writing to the 16 higher-order bits of MISRCDR_* leads to the generation of a signature with the 16 lower-order bits of write data treated as 0.

MISR1 and MISR2 do not identify the bus master that writes to the MISRCDR_*. Writing by any bus master, whether a CPU, DMAC, or debugging master, produces a signature.

Note 1. “*” in MISRCDR_*, MISR1_*, and MISR2_* indicates PEm. (m = 0 to 5: m = 4 to 5 is not implemented in E2H.)

(2) Write Monitoring Mode

When the CPU writes to an address area specified for monitoring while MISR1 is in write-monitoring mode, MISR1 generates compressed 32-bit signatures from the value in MISR1_* and 32-bit data being written by the CPU, and generates signatures from the 32-bit compressed data and the value that is again held in MISR1_*. The generated signatures are stored in MISR1_*. Similarly, when the CPU writes to an address area specified for monitoring while MISR2 is in write-monitoring mode, MISR2 generates compressed 32-bit signatures from the value in MISR2_* and 32-bit data being written by the CPU, and generates signatures from the 32-bit compressed data and the value that is again held in MISR2_*. The generated signatures are stored in MISR2_*.

The address area specified for monitoring for signature generation is set by the MISR monitoring base address register (MISRBASEADR) and the MISR monitoring address mask register (MISRADRMASK). If the CPU write address is within the address area specified for monitoring, a signature is generated.

Write monitoring mode monitors write access by the corresponding CPU in 8-, 16-, 32-, or 64-bit units. When writing proceeds in 8-, or 16-bit units, remaining bits to which a value is not written are treated as 0, and 32-bit data is always input to MISR1 or MISR2. Write data is allocated to the lower-order side regardless of the destination address. For example, when 16 bits are written to an address of the form $4N + 2$, the 16 bits are allocated to the lower-order side and a signature is generated with the 16 higher-order bits treated as 0.

In case of 64-bit write access, the data is split into two 32-bit data, that is, lower word and upper word, and then they are used to generate a signature in lower to upper order.

The CPU write access destinations that can be monitored by MISR1 and MISR2 are as follows:

Local RAM, Cluster RAM, Peripheral module connected to System bus, I-Bus or P-Bus

Furthermore, CPU instructions which MISR1 and MISR2 can monitor are:

ST.B, ST.H, ST.W, ST.DW

SST.B, SST_H, SST_W

PREPARE, PUSHHP (Following restriction exists.)

The restrictions described below apply to the given store operations.

- (1) Instructions that cause the CPU to write data in response to a slave request: Store operations such as CLR1, NOT1, SET1, CAXI, and STC.W are not subject to monitoring.
- (2) Instructions for saving units of data larger than 64 bits on the stack (PREPARE and PUSHSP): signature values between the masters may not match when the instruction is suspended because of an interrupt. Therefore, the area to be used with the instructions must not be subject to monitoring or steps must be taken to make sure that the operation is not suspended due to an interrupt.
- (3) STV.DW, STV.QW, STV.W, STVZ.H4 (FXU store operation) and CACHE, PREFI are not subject to monitoring.
- (4) Register bank function: signature values can be uncertain when context switch occurs. Therefore, the area to be used by the evacuations needs to be out of monitoring.

Write monitoring mode can only be implemented between the specified signature generation unit and the corresponding CPU.

In this product, the following monitoring operations are possible:

- Monitoring of CPU_m write access by signature generation unit m (m = 0 to 5: m = 4 to 5 is not implemented in E2H.)

Note 1. “*” in MISR1_* and MISR2_* indicates PEm. (m = 0 to 5: m = 4 to 5 is not implemented in E2H.)

40.7.3.2 Automatic Signature Comparison

The signature compare part is enabled by MISR1CMPENn bit and MISR2CMPENn bit of the comparator control register (MISRCMPCTL) and it compares signatures selected from two signature generation units by the MISR compare data select register (MISRCMPDSEL) corresponding to the signature compare part. Each signature generation unit contains the data counter and the comparison is done when the count values of the data counters contained in the signature generation unit which are selected as the target for comparison match each other. Moreover, MISG stops the generation of signature and the count of the data counters when the values of the data counters in the MISGs match the values of MISR compare data counter register (MISRCMPDCNT) and comparison is also done after both counters that are the target for comparison match stop.

40.7.3.3 Data Counter

The MISR data counter register (MISRDCNT_*) counts the number of write accesses to MISRCDR_* or to the address range specified by BASEADR and ADRMSK. When the CNTSTA bit = 1 and the CNTTRG bit = 0 in the data counter control register (MISRDCNTCTL), MISRDCNT_* counts the number of write accesses to MISRCDR_*. When the CNTSTA bit = 1 and the CNTTRG bit = 1 in MISRDCNTCTL, MISRDCNT_* counts the number of write accesses by the corresponding CPU to the address range specified by MISRBASEADR and MISRADRMSK.

MISRDCNT_* can count the number of times either MISR1 or MISR2 or both MISR1 and MISR2 generate signatures by setting the trigger for counting up by MISRDCNT_* as the signature generation condition in MISR1 or MISR2. Note, however, that if the signature generation conditions for MISR1 and MISR2 and the trigger for counting up by the data counter are not consistent, the value of MISRDCNT_* and the signature generation count will not match.

The MISR data counter register (MISRDCNT_*) stops the count base on a signal from the signature compare part triggered by the automatic signature compare function.

CAUTIONS

1. When the MISR1EN and MISR2EN bits in the MISRCR register are both 0, counting by MISRDCNTCTL is not incremented even if writing to MISRCDR and the address range specified by MISRBASEADR and MISRADRMSK proceeds.
2. A double word access is treated as two single word accesses and MISRDCNT_* register counts two in write monitoring mode. Signature generation unit (MISG) uses only lower word and stops just in the stop count specified by MISRCMPDCNTn register in case a double word access occurs when MISRDCNT_* = MISRCMPDCNTn – 1.

Note 1. “*” in MISRDCNT_* and MISRCDR_* indicates PE_m. (m = 0 to 5: m = 4 to 5 is not implemented in E2H.)

40.7.3.4 Error Notification

When the CMPERREN bit in the error notification control register (MISRERRCTL) is set to 1, the ECM is notified of a MISR compare error (MISR_ERR) when signatures are compared and do not match. At the same time, the error flag in the compare error status register is set. Moreover, MISR compare error is being notified during compare mismatch of signatures. See **Section 40.7.5.3, Recommended Clear Flow of Error Flag** regarding error flag clear.

There is no generation of interrupt request to INTC.

40.7.4 Register Specifications

40.7.4.1 Register Map

The table below lists the registers of the signature generation units.

Registers with symbols ending in “_PEm” are those of signature generation unit m (MISG_PEm). (m = 0 to 5)

Note that the endings of the register symbols (“_PEm”) are omitted if signature generation unit m does not require identification.

$$\text{MISG_PEm_base} = \text{FFFB } 0000_{\text{H}} + m \times 40_{\text{H}} \quad (m = 0 \text{ to } 5)$$

$$\text{MSD_base} = \text{FFFB } 0200_{\text{H}}$$

Note 1. m = 4 to 5 is not implemented in E2H.

Table 40.436 List of Registers

Module Name	Register Name	Symbol	Address	Access	Access Protection
MISG_PEm (m = 0-5) (Peripheral Group0)	Multi Input Signature Register 1	MISR1	<MISG_PEm_base> + 00 _H	32	
	Multi Input Signature Register 2	MISR2	<MISG_PEm_base> + 08 _H	32	
	Calculation Data Register	MISRCDR	<MISG_PEm_base> + 10 _H	8, 16, 32	
	Control Register	MISRCR	<MISG_PEm_base> + 18 _H	8

	Compare Data Select Register 0	MISRCMPDSEL0	<MSD_base> + 10 _H	8	
	Compare Data Select Register 1	MISRCMPDSEL1	<MSD_base> + 14 _H	8	
	Compare Data Select Register 2	MISRCMPDSEL2	<MSD_base> + 18 _H	8	
	Compare Data Counter Register 0	MISRCMPDCNT0	<MSD_base> + 20 _H	16	
	Compare Data Counter Register 1	MISRCMPDCNT1	<MSD_base> + 24 _H	16	
	Compare Data Counter Register 2	MISRCMPDCNT2	<MSD_base> + 28 _H	16	

40.7.4.2 MISR1 — Multi Input Signature Register 1

The Multi-input signature register 1 is a 32-bit readable/writable register.

Once the signature generation condition is met, this register generates a new signature each time the condition is met and retains the generated value. For the conditions for signature generation, see **Section 40.7.3.1, Conditions for Signature Generation**.

Signatures are generated by using the following polynomial:

$$G(x) = x^{32} + x^{26} + x^{23} + x^{22} + x^{16} + x^{12} + x^{11} + x^{10} + x^8 + x^7 + x^5 + x^4 + x^2 + x + 1$$

Value after reset: 0000 0000_H

31 to 0	MISR2[31:0]	Multi Input signature register 2

40.7.4.4 MISRCR — Calculation Data Register

The MISR calculation data register is a 32-bit write-only register.

When signature generation in register write mode is selected, a signature is generated in MISR1 or MISR2 by writing to this register. Data written to this register is the data input to the multi-input signature register 1 (MISR1_*) or the multi-input signature register 2 (MISR2_*). For the conditions for signature generation, see **Section 40.7.3.1, Conditions for Signature Generation**.

This register can be written in 8-, 16-, or 32-bit units. When writing proceeds in 8- or 16-bit units, remaining bits to which a value is not written are treated as 0, and 32-bit data is always input to MISR1_* or MISR2_*.

Value after reset: 0000 0000_H

Table 40.439 MISRCR Register Contents

Bit Position	Bit Name	Function
31 to 0	MISRCR[31:0]	Calculation data to MISR1 or MISR2 New signatures are generated by the CPU writing to this register. The signature generating condition is as follows: MISRCR.MISR1EN = 1 and MISRCR.MISR1CND = 0 or MISRCR.MISR2EN = 1 and MISRCR.MISR2CND = 0

40.7.4.5 MISRCR — Control Register

MISR control register is an 8-bit readable/writable register.

The MISR1EN and MISR2EN bits are used to enable signature generation in MISR1 and MISR2. When the MISR1EN or MISR2EN bit is 1, MISR1 or MISR2 generates a signature and retains the generated value. When the MISR1EN or MISR2EN bit is 0, MISR1 or MISR2 does not generate signatures and the values of these registers are not updated.

When the MISR1EN or MISR2EN bit is 1, the MISR1CND or MISR2CND bit selects the signal generation condition for MISR1 or MISR2. Setting the MISR1CND or MISR2CND bit to 0 selects signature generation by MISR1 or MISR2 in register write mode, so writing to MISRCDR_* leads to signature generation. Setting the MISR1CND or MISR2CND bit to 1 selects signature generation by MISR1 or MISR2 in write monitoring mode. Writing by the CPU to the address range specified by the MISRBASEADR and MISRADRMSK registers leads to signature generation. For the conditions for signature generation, see **Section 40.7.3.1, Conditions for Signature Generation**.

MISR1EN bit and MISR2EN bit are cleared by the signal from the signature compare part of the signature compare unit in automatic signature comparison. The clear timing is the next edge of the bus clock after the counter value set by the MISR data counter register (MISRDCNT_*) and the MISR compare data counter register (MISRCMPDCNT). After the clear, it is possible to set again the MISR1EN or MISR2EN in a state that the MISRDCNT_* matches MISRCMPDCNT however neither the signature nor the counter value is updated.

2	MISR1CND	Controls the signature generation condition when MISR1EN is "1" 0: Writing to MISRCDR 1: Writing to the address range specified by BASEADR and ADRMSK
1	MISR2EN	MISR2 enable bit 0: Do not generate the MISR2 signature 1: Generate the MISR2 signature by writing to MISRCDR and by writing to the address range specified BASEADR and ADRMSK
0	MISR1EN	MISR1 enable bit 0: Do not generate the MISR1 signature 1: Generate the MISR1 signature by writing to MISRCDR and by writing to the address range specified BASEADR and ADRMSK

40.7.4.6 MISRBASEADR — Monitoring Base Address Register

MISRBASEADR specifies the CPU write access area to be monitored by MISG when signature generation in write monitoring mode is selected. In combination with the setting of the monitoring area mask address register, this register specifies the address range of the monitoring area. For the conditions for signature generation, see **Section 40.7.3.1, Conditions for Signature Generation**.

For the mechanism to judge access to the monitoring area, see **Section 40.7.4.7, MISRADRMSK — Monitoring Address Mask Register**.

40.7.4.7 MISRADRMSK — Monitoring Address Mask Register

MISRADRMSK specifies the CPU write access area to be monitored by MISG when signature generation in write monitoring mode is selected. In combination with the setting of the monitoring area base address register, this register specifies the address range of the monitoring area. For the conditions for signature generation, see **Section 40.7.3.1, Conditions for Signature Generation**.

40.7.4.8 MISRDCNTCTL — Data Counter Control Register

The MISR data counter control register is an 8-bit readable/writable register.

This register controls operation of the MISR data counter register. If the event selected by the CNTTRG bit occurs while the CNTSTA bit is 1, the data counter is incremented. For operation of the data counter, see **Section 40.7.3.3, Data Counter**.

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	CNTTRG	CNTSTA
Value after reset	0	0	0	0	0	0	0	0

7 to 2	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
1	CNTTRG	Selects the trigger to count up: 0: Writing to the MISRCRDR 1: Writing to the address range specified by BASEADR and the ADRMSK
0	CNTSTA	Enables the counter when CNTSTA = 1 and MISR1EN = 1 or MISR2EN = 1 0: Stop the data counter 1: Enable the data counter: the count up trigger is selected by CNTTRG

40.7.4.9 MISRDCNT — Data Counter Register

The data counter is a 16-bit readable/writable register.

If the data counter values of two signature generation units selected for comparison match, automatic comparison of the signatures proceeds.

When the CNTTRG bit in the data counter control register is 0, the data counter is incremented by write access to the MISR calculation data register. When the CNTTRG bit in the data control register is 1, the data counter is incremented by write access by the corresponding CPU to the address area specified by the MISRBASEADR and MISRADRMSK registers. For operation of the data counter, see **Section 40.7.3.3, Data Counter**.

Table 40.444 MISRDCNT Register Contents

Bit Position	Bit Name	Function
15 to 0	DCNT[15:0]	The data counter register

40.7.4.10 MISRCMPCTL — Comparator Control Register

MISRCMPCTL is an 8-bit readable/writable register.

This register controls the comparator that compares signatures generated in the signature generation units. For automatic comparison of signatures, see **Section 40.7.3.2, Automatic Signature Comparison**.

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0

6	MISR2CMPEN2	Controls comparator for MISR2 signatures specified by MISRCMPDSEL2 register 0: Do not compare 1: Compare
5	MISR2CMPEN1	Controls comparator for MISR2 signatures specified by MISRCMPDSEL1 register 0: Do not compare 1: Compare
4	MISR2CMPEN0	Controls comparator for MISR2 signatures specified by MISRCMPDSEL0 register 0: Do not compare 1: Compare
3	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
2	MISR1CMPEN2	Controls comparator for MISR1 signatures specified by MISRCMPDSEL2 register 0: Do not compare 1: Compare
1	MISR1CMPEN1	Controls comparator for MISR1 signatures specified by MISRCMPDSEL1 register 0: Do not compare 1: Compare
0	MISR1CMPEN0	Controls comparator for MISR1 signatures specified by MISRCMPDSEL0 register 0: Do not compare 1: Compare

40.7.4.11 MISRCMPERSTR — Compare Error Status Register

The compare error status register is an 8-bit read-only register.

If a mismatch occurs in signature comparison enabled by the comparator control register, the corresponding error flag is set.

The error flag is cleared by writing 1 to the corresponding clear bit in the compare error status clear register. The flag is also cleared by a reset.

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	MISR2ERR2	MISR2ERR1	MISR2ERR0	—	MISR1ERR2	MISR1ERR1	MISR1ERR0
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R

4	MISR2ERR0	Indicates compare errors occurred in MISR2 signatures specified by MISRCMPDSEL0 register 0: Signatures matched 1: Signatures did not match
3	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
2	MISR1ERR2	Indicates compare errors occurred in MISR1 signatures specified by MISRCMPDSEL2 register 0: Signatures matched 1: Signatures did not match
1	MISR1ERR1	Indicates compare errors occurred in MISR1 signatures specified by MISRCMPDSEL1 register 0: Signatures matched 1: Signatures did not match
0	MISR1ERR0	Indicates compare errors occurred in MISR1 signatures specified by MISRCMPDSEL0 register 0: Signatures matched 1: Signatures did not match

40.7.4.12 MISRCMPERRSTC — Compare Error Status Clear Register

The compare error status clear register is an 8-bit write-only register.

When an error flag in the compare error status register is 1, writing 1 to corresponding clear bit clears the error flag. Read the MISR compare error status register and write 1 to the clear bit for the flag that is 1.

See **Section 40.7.5.3, Recommended Clear Flow of Error Flag** regarding error flag clear.

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0

5	MISR2CLR1	MISR2 signature compare error clear bit 1 1: Clear the MISR2ERR1 bit of MISRCMPERSTR register
4	MISR2CLR0	MISR2 signature compare error clear bit 0 1: Clear the MISR2ERR0 bit of MISRCMPERSTR register
3	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
2	MISR1CLR2	MISR1 signature compare error clear bit 2 1: Clear the MISR1ERR2 bit of MISRCMPERSTR register
1	MISR1CLR1	MISR1 signature compare error clear bit 1 1: Clear the MISR1ERR1 bit of MISRCMPERSTR register
0	MISR1CLR0	MISR1 signature compare error clear bit 0 1: Clear the MISR1ERR0 bit of MISRCMPERSTR register

40.7.4.13 MISRERRCTL — Error Notification Control Register

The error notification control register is an 8-bit readable/writable register.

This register enables or disables error notification when signatures are compared by the automatic signature comparison and do not match. For the automatic signature comparison and error notification, see **Section 40.7.3.2, Automatic Signature Comparison** and **Section 40.7.3.4, Error Notification**.

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	CMPPEREN
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R/W

0	CMPPEREN	Comparison error notice permission bit 0: Do not report the error when the signatures do not match 1: Report the error when the signatures do not match

40.7.4.14 MISRCMPDSELn — Compare Data Select Register (n = 0 to 2)

The compare data select register is an 8-bit readable/writable register.

This register selects the input data of signatures to be compared by the automatic signature comparison. For the automatic signature comparison and error notification, see **Section 40.7.3.2, Automatic Signature Comparison** and **Section 40.7.3.4, Error Notification**.

Value after reset: 03_H

Note 1. This function is not implemented in E2H.

NOTE

Signature compare unit supports mutually exclusive use for MISG modules. Do not assign multiple compare parts to the same MISG module. For example, the following setting is prohibited.

MISRCMPDSEL0=000011_B and MISRCMPDSEL1=000101_B.

40.7.4.15 MISRCMPDCNTn — Compare Data Counter Register (n = 0 to 2)

The compare data counter register is a 16-bit readable/writable register.

This register sets the count value that stops the data counter of the signature generation unit in automatic signature comparison. For the automatic signature comparison and error notification, see **Section 40.7.3.2, Automatic Signature Comparison** and **Section 40.7.3.4, Error Notification**.

Value after reset: FFFF_H

Table 40.450 MISRCMPDCNTn Register Contents

Bit Position	Bit Name	Function
15 to 0	CMPDCNT[15:0]	Specify the counter value to stop generating signatures

40.7.5 Usage

40.7.5.1 Usage Example 1

MISG facilitates diagnosis of the self-diagnostic program. By using the MISG to compress intermediate transitions of the self-diagnostic program, the saving and comparison of all intermediate results becomes unnecessary. Results of self diagnosis including intermediate transitions can be judged by comparing the results of compression by the MISG with the expected results after the program ends.

This has the effect of reducing requirements for memory capacity and time for processing comparisons (substitution by CRCs is also possible).

Example of settings (when PEm is running the self-diagnostic program)

The descriptions of MISG registers below applies to the registers of signature generation unit 1 (MISG_PEm), which is for PEm.

- (1) Initialize the multi-input signature register 1 (MISR1) and multi-input signature register 2 (MISR2).
- (2) Set the MISR1CND or MISR2CND bit in the MISR control register (MISRCR) to 1 to select signature generation by MISR1 or MISR2 in write monitoring mode.
- (3) Use the MISR monitoring base address register (MISRBASEADR) and MISR monitoring address mask register (MISRADRMASK) to set the address area for monitoring.
- (4) Set the MISR1EN or MISR2EN bit in the MISR control register to 1 to enable signature generation in MISR1 or MISR2.
- (5) Read the MISR control register (MISRCR) and execute “syncp” instruction to confirm MISR enabled.
- (6) Run the self-diagnostic program on PEm.
- (7) Upon completion of execution of the self-diagnostic program, MISR1 or MISR2 data is compared with the expected value in flash memory.

40.7.5.2 Usage Example 2

Use multiple processors to run the same processing (including the self-diagnostic program) to confirm the correctness of results. Comparing results from different hardware raises reliability.

Example of settings (when PE0 and PE1 are running the same task)

The descriptions of MISG registers below applies to the MISG registers of PE0 and PE1.

- (1) Initialize the multi-input signature register 1 (MISR1), multi-input signature register 2 (MISR2), and data counter register (MISRDCNT).
- (2) Set the MISR1CND or MISR2CND bit in the MISR control register (MISRCR) to 0 to select signature generation by MISR1 or MISR2 in register write mode.
- (3) Set the signature generation unit of PE0 and PE1 as the input of the signature compare part by using the MISR compare data select register (MISRCMPDSEL).
- (4) Set the value of data counter for comparing the signatures by using the MISR compare data counter register (MISRCMPDCNT).
- (5) Set MISR1CMPEN0 or MISR2CMPEN0 in the MISR comparator control register (MISRCMPCTL) to 1 to enable signature comparison by the comparator.

- (6) Set the CMPERREN bit in the MISR error notification control register to 1 to enable error notification to the ECM.
- (7) Set the CNTTRG bit in the MISR data counter control register (MISRDCNTCTL) to 0 to set writing to MISRCDR_* as the trigger for counting up by the data counter. Set the CNTSTA bit to 1 to enable operation of the data counter.
- (8) Set the MISR1EN or MISR2EN bit in the MISR control register to 1 to enable signature generation in MISR1 or MISR2.
- (9) Read the MISR control registers (MISRCR in MISG_PE0 and MISG_PE1) and execute “syncp” instruction to confirm MISR enabled.
- (10) Run the self-diagnostic program on all CPUs.
- (11) The self-diagnostic program stores intermediate results while the program is running in MISRCDR_* of the signature generation units. The signature comparison part stops the signature generation and the counting of data counter when it matches the value of the MISR compare data counter register (MISRCMPDCNT). Signature comparison is then performed when the data counters of both PE0 and PE1 reach the value of the MISR compare data counter register (MISRCMPDCNT).
- (12) Check the comparison status register to see if there were any errors in comparison. See **Section 40.7.5.3, Recommended Clear Flow of Error Flag** regarding error flag clear.

40.7.5.3 Recommended Clear Flow of Error Flag

If the MISR compare error status clear register (MISRCMPERRSTC) clears the MISR compare error status register (MISRCMPERSTR) with signature mismatch and signature comparison enabled, the flag of MISR compare error is set again. Following shows the recommended clear flow of the error flag.

- (1) Set the MISRiCMPENn bit in the MISR comparator control register (MISRCMPCTL) to 0 to disable the comparison.
- (2) Clear the MISR compare error status register (MISRCMPERSTR) by the MISR compare error status clear register (MISRCMPERRSTC).
- (3) Check if the MISR compare error status register (MISRCMPERSTR) is cleared.
- (4) Initialize the multi-input signature register 1 (MISR1), multi-input signature register 2 (MISR2), and data counter register (MISRDCNT).

40.8 ECM

The ECM monitors various failure detection states in this microcontroller, and defines the operation to be carried out upon failure detection. For the details of the ECM, see **Section 41, Error Control Module (ECM)**.

40.9 Voltage Monitor

The Voltage Monitor detects over and under voltage of the voltage domains, E0VCC, VCC and VDD. For the details of the Voltage Monitor, see **Section 12, Power Supply Voltage Monitor**.

40.10 Clock Monitor

The Clock Monitor detects abnormal frequencies of internal clocks related to the safety of the device. For the details of the Clock Monitor, see **Section 14, Clock Monitor**.

40.11 Data CRC Function

The Data CRC Function generates CRC to verify the data streams protected by CRC. For the details of the Data CRC Function, see **Section 42, Data CRC Function B (DCRB)**.

Section 41 Error Control Module (ECM)

41.1 Features

41.1.1 Number of Units and Channels

This microcontroller has the following number of ECM unit.

Table 41.1 Number of Units

Product Name	RH850/E2x-FCC2	
	468 Pins	373 Pins
Number of Units	1	1
Name	ECM	ECM

Table 41.2 Number of Units

Product Name	RH850/E2UH	
	468 Pins	373 Pins
Number of Units	1	1
Name	ECM	ECM

Table 41.3 Number of Units

Product Name	RH850/E2H	
	468 Pins	373 Pins
Number of Units	1	1
Name	ECM	ECM

Table 41.4 Index

Index	Meaning
m	Throughout this section, the individual ECM Master and ECM Checker are identified by the index "m" (m = M, C).

41.1.2 Register Base Address

ECM base addresses are listed in the following table.

ECM register addresses are given as offsets from the base addresses in general.

Table 41.5 Register Base Address

Base Address Name	Base Address	Bus Group
<ECMM_base>	FFCB 0000 _H	Peripheral Group 6
<ECMC_base>	FFCB 1000 _H	Peripheral Group 6
<ECM_base>	FFCB 2000 _H	Peripheral Group 6

41.1.3 Clock Supply

Clock supply by and to ECM is listed in the following table.

Table 41.6 Clock Supply

Unit Name	Unit Clock Name	Clock Supply Name
ECM	PCLK	CLK_LSB
	cntclk* ¹	CLK_WDTICUM

Note 1. cntclk is used for delay timer and clear mask timer logics

41.1.4 Interrupt Requests

ECM interrupt requests are listed in the following table. The interrupt request signal is driven to the high level with a pulse width of one PCLK cycle when the error source status flag of an error source for which interrupt generation is enabled is set.

Table 41.7 Interrupt Requests

Interrupt Symbol Name	Unit Interrupt Signal	Description	Interrupt Number	sDMA Trigger Number	DTS Trigger Number
INTECMMI	INTECMMI	ECM maskable interrupt (EI level)	EIINT8	—	—
INTECMDCLSMI	INTECMDCLSMI* ¹	DCLS error interrupt (EI level)	EIINT9	—	—
FEINT0	INTECMNMI	ECM FE level interrupt (FE level)	FEINT0	—	—

Note 1. Checker core is not implemented for PE2 and PE3.

41.1.5 Reset Sources

ECMM, ECMC and ECM reset sources are listed in the following table. ECMM, ECMC and ECM are initialized by these reset sources.

Table 41.8 Reset Sources

Unit Name	Register Name	Reset Condition							
		Power Up Reset	System Reset1			System Reset2	Application Reset	Module Reset	JTAG Reset
			Standby Reset	External Reset	VMON Reset				
ECM Master Registers									
ECMM	ECM master error set trigger register	✓	✓	✓	✓	✓	✓	—	—
ECMM	ECM master error clear trigger register	✓	✓	✓	✓	✓	✓	—	—

Note: ✓: Register is initialized by reset, —: Register is not initialized by reset, X: Undefined value

(—): When the terminal RESET is asserted during reset sequence including BIST execution by external / internal reset, it will become X.

Note 1. n = 0 to 9

41.1.6 External Input and Output Signals

External Input/output signals of ECM are listed below.

Table 41.9 External Input/Output Signals

Unit Signal Name	Description	Alternative Port Pin Signal
<u>ERROROUT_M</u>	Error output master signal	<u>ERROROUT_M</u>
<u>ERROROUT_C</u>	Error output checker signal	<u>ERROROUT_C</u>
<u>ERRORIN</u>	Error input signal	<u>ERRORIN</u>

41.2 Overview

41.2.1 Specification Overview

ECM (Error Control Module) collects error signals coming from different error sources and monitoring circuits. It also outputs error signals from the error pins ($\overline{\text{ERROROUT_M}}$, $\overline{\text{ERROROUT_C}}$) and generates interrupts and Error Control Module Reset signals. **Table 41.10** shows the specification overview of ECM.

Table 41.10 Specification Overview

Item	Description
Safety processing	<p>ECM can handle the following processing in response to error signal inputs from individual modules.</p> <ul style="list-style-type: none"> • Error flag set • EI level interrupt generation EI level interrupt generation can be controlled (enabled/disabled) for individual errors. • DCLS error interrupt generation DCLS error interrupt generation (EI level) can be controlled (enabled/disabled) for individual errors. Count the DCLS error and error message based on the DCLS error happen times are reported. 2bit status register for counting the DCLS error, the max count is 3. • FE level interrupt generation FE level interrupt generation can be controlled (enabled/disabled) for individual errors. • Internal reset generation System reset 2 or Application reset generation can be controlled (enabled/disabled) for individual errors. • Error pin output Pin output mask can be controlled (enabled/disabled) for individual errors. Output can be toggled in response to a timer input or made at a fixed level.
Error status	<p>ECM incorporates error source status registers, which can be used to confirm the error status from the error flag.</p> <p>The error flags are only cleared by a power up reset or Standby Reset (System reset 1). In case of External reset (System reset1), System reset2, Application reset, Module reset and JTAG reset, the error flags are kept and the reset generation source can be confirmed by reading the status register after reset.</p>
Debug, self-diagnosis	<ul style="list-style-type: none"> • Pseudo errors can be generated for debug and self-diagnosis. The operation during injection of pseudo errors is identical to that for the occurrence of real errors. All configurations for the masking of the error pin output, interrupt, or Error Control Module Reset apply in the same way. • ECM incorporates a loop-back function of the error pin output that is used to diagnose the path to the error output pin. The status of the error output pin is reflected to an internal register and can be confirmed by reading the register.
Timeout function	<p>ECM incorporates a function that generates an error signal output or Error Control Module Reset when the count value of the delay timer matches with the delay timer compare register because the delay timer was not stopped during the interrupt processing after being started simultaneously with the occurrence of an interrupt request.</p>
Port safe state	<p>$\overline{\text{ERROROUTZ}}$ connects to port safe state and ECM can control the state of general purpose I/O to a condition according to user configuration. Configuration state is Hi-Z, Low and High output. For details of function, see Section 2, Pin Function.</p>
Register protection	<p>A write-protection with a key code is implemented to protect registers from illegal write access. For details of function, see Section 41.3.11, ECMKCPROT — ECM Key Code Protection Register.</p>
$\overline{\text{ERROROUT}}$ clear masking	<p>ECM incorporates a function that can mask software clearance of $\overline{\text{ERROROUT}}$ until the counter which is started from error occurrence reaches the value specified in the Error Output Clear Invalidation Configuration register. If another error occurs during time counting, then the time count is reset and restarted from 0.</p>
Others	<p>ECM is duplexed. ECM incorporates the error output pin.</p>

41.2.2 Block Diagram

ECM is redundantly implemented using ECM Master and ECM Checker. See **Figure 41.1** Connection of two ECM and **Figure 41.2** Connection between ECM Master, ECM Checker and peripherals.

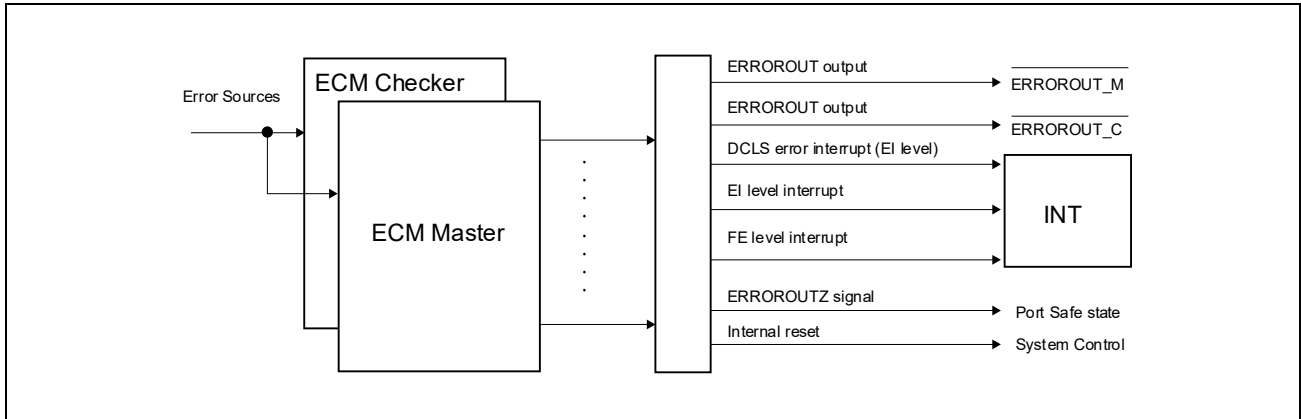

Figure 41.1 Connection of ECM

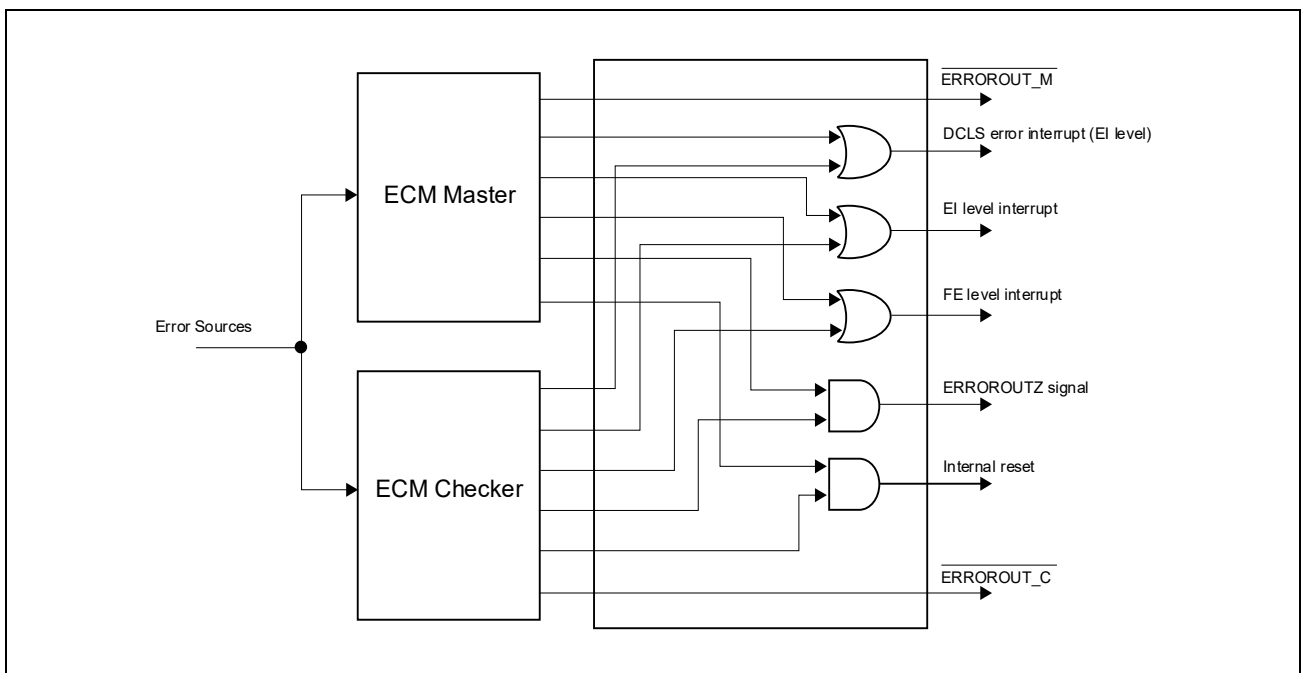

Figure 41.2 Connection between ECM Master, ECM Checker and Peripherals

CAUTION

Pay attention to the difference in output voltage between the $\overline{\text{ERROROUT_M}}$ and $\overline{\text{ERROROUT_C}}$ pins because different power supply systems are used for those pins.

$\overline{\text{ERROROUT_M}}$ pin: SYSVCC (5 V / 3.3 V)

$\overline{\text{ERROROUT_C}}$ pin: E0VCC (5 V) for P01_7, P15_7, P22_5 and P32_3; E1VCC (5 V / 3.3 V) for P11_2; E2VCC (5 V / 3.3 V) for P12_8

41.2.3 Error Input

Table 41.11 shows the inputs to ECM of E2x-FCC2.

Table 41.12 shows the inputs to ECM of E2UH.

Table 41.13 shows the inputs to ECM of E2H.

“—”: not covered, “✓”: covered, gray hatching: its number is reserve bit.

Note 1. The internal reset generation is enabled in the initial state.

Note 2. Please enable DNF for noise elimination if ERRORIN function is used. There is a possibility that ECMmESSTRn for ERRORIN is set. Therefore please set ECMEMKn for ERRORIN before setting DNF and clear ECMESSTCn for ERRORIN after setting DNF. Then please clear ECMEMKn if needed. About DNF setting flow, refer to **Section 2.6.1.2, Peripheral Function DNF**.

Note 3. BUS routing checker can detect an unintended routing on internal bus.

Note 1. The internal reset generation is enabled in the initial state.

Note 2. Please enable DNF for noise elimination if ERRORIN function is used. There is a possibility that ECMmESSTRn for ERRORIN is set. Therefore please set ECMEMKn for ERRORIN before setting DNF and clear ECMESSTCn for ERRORIN after setting DNF. Then please clear ECMEMKn if needed. About DNF setting flow, refer to **Section 2.6.1.2, Peripheral Function DNF**.

Note 3. BUS routing checker can detect an unintended routing on internal bus.

Note 1. The internal reset generation is enabled in the initial state.

Note 2. Please enable DNF for noise elimination if ERRORIN function is used. There is a possibility that ECMESSTRn for ERRORIN is set. Therefore please set ECMEMKn for ERRORIN before setting DNF and clear ECMESSTCn for ERRORIN after setting DNF. Then please clear ECMEMKn if needed. About DNF setting flow, refer to **Section 2.6.1.2, Peripheral Function DNF**.

Note 3. BUS routing checker can detect an unintended routing on internal bus.

41.2.4 Operations for Error Output

After reset release, the $\overline{\text{ERROROUT_M}}$ pin outputs the low (error) level. Follow the procedure described in **Section 41.3.3, ECMmECLR — ECM Master/Checker Error Clear Trigger Register (m = M/C)**, to clear the error before using ECM. As the $\overline{\text{ERROROUT_C}}$ pin is multiplexed with a general-purpose port and other functions, select the $\overline{\text{ERROROUT_C}}$ function before use. For settings, see **Section 2, Pin Function**.

The error output can be configured for two different modes of operation, non-dynamic or dynamic.

The error output is in synchronization with the occurrence of error source conditions and the error level is output as the pin state regardless of the dynamic mode pulse cycle.

ERROROUTZ connects to port safe state and ECM can control the state of general purpose I/O to a condition according to user configuration. For details of function, see **Section 2, Pin Function**. ERROROUTZ can be used as only non-dynamic mode.

Table 41.14 Operation for Error Output

Error Status ECMmSSE	Operating Mode		Error Output		
	ECMEPCFG.ECMSL0 Bit	Operating Mode	Error Output Level*1	ERROROUTZ*1	Error Status
0	0	Non-dynamic	H	H	No error
	1	Dynamic	Toggles (according to timer input)	H	No error
1	0	Non-dynamic	L	L	Error
	1	Dynamic	L	L	Error

Note 1. The level of the error output ($\overline{\text{ERROROUT_M}}$ and $\overline{\text{ERROROUT_C}}$) and ERROROUTZ can be masked by ECMEMKn registers value.

41.2.5 ERROROUT_M and ERROROUT_C Behavior at Reset

Below table explains the behavior of the error output logic and the ERROROUT_M and ERROROUT_C pins at reset. Also the level of the ERROROUT_M and ERROROUT_C signals during and after reset is explained.

Table 41.15 ERROROUT_M Behavior at Reset

Category	Reset Condition					
	Power Up Reset	System Reset 1	System Reset 2	Application Reset	Module Reset	JTAG Reset
<u>ERROROUT_M</u> pin level during reset	Low level	Low level	Level according to error status before reset*1	Level according to error status before reset*1	Level according to error status before reset	Level according to error status before reset
<u>ERROROUT_M</u> pin level after reset	Low level	Low level	Level according to error status before reset*1	Level according to error status before reset*1	Level according to error status before reset	Level according to error status before reset

Note 1. The level of the ERROROUT_M can be changed by clearing ECMEMKn registers at reset. To keep the level, it is necessary to clear the ECMMESSTRn bit which corresponds to ECMEMKn bit of setting which masked error signal output before reset.

Table 41.16 ERROROUT_C Behavior at Reset

Category	Reset Condition					
	Power Up Reset	System Reset 1	System Reset 2	Application Reset	Module Reset	JTAG Reset
<u>ERROROUT_C</u> pin level during reset	Hi-Z	Hi-Z	Hi-Z	Hi-Z	Level according to error status before reset	Level according to error status before reset
<u>ERROROUT_C</u> pin level after reset	Hi-Z	Hi-Z	Hi-Z	Hi-Z	Level according to error status before reset	Level according to error status before reset

41.2.5.1 Dynamic Mode Enable

1. Initialize the related timer OSTM0.
2. Set the error output to high level by setting the ECMmECT (m = M/C) bit in the ECM master/checker error clear trigger register to 1.
3. Set the ECMEPCFG.ECMSL0 bit to 1 for dynamic mode.
4. Start the timer OSTM0.

41.2.5.2 Dynamic Mode Disable

1. Set the error output to low level by setting the ECMmEST bit (m = M/C) in the ECM master/checker error set trigger register to 1.
2. Stop the timer OSTM0.
3. Clear the ECMSL0 bit in the ECM error pulse configuration register to 0 to specify non-dynamic mode.

41.2.6 Loop-Back Function

ECM incorporates a loop-back function that is used to check the path to the error output pin. The output level of the error output pin can be checked with the ECMmSSE311 bit (m = M/C) in the ECM master/checker error source status register 9.

41.2.7 Pseudo Error Generation

ECM incorporates a function that can generate pseudo errors for test or debug purposes. The operation of the ECM during injection of pseudo errors is identical to that for the occurrence of real errors. All configurations for error masks, interrupt, internal reset, or delay timer apply in the same way.

41.2.8 Error Status

The error status is indicated by ECM master/checker error source status registers. The error status is only cleared by writing to ECMESSTCn, power up reset or standby reset. In case of reset except for power up reset and standby reset, the error status is kept and the error that triggered the reset can be confirmed by reading the ECM master/checker error source status registers after reset release.

41.2.9 Register Protection

Write protected registers are protected from inadvertent write access due to erroneous program execution, etc.

By releasing the protection of ECMKCROT, it can be written. For details, see **Section 41.3.11, ECMKCROT — ECM Key Code Protection Register**.

41.2.10 Timeout Function for Interrupt Processing

The delay timer incorporated in ECM can be started simultaneously with the occurrence of an interrupt request. ECM incorporates a function that generates an error signal output or Error Control Module Reset when the count value of the delay timer matches with the value of the delay timer compare register because the delay timer was not stopped during the interrupt processing. The timer counting is not stopped when a break occurs.

The counting of the delay timer always starts from 0. Configure the duration until an Error Control Module Reset or error output is generated with the settings of the delay timer compare register.

In response to the occurrence of a new error source condition with the setting to start the delay timer while the delay timer is operating, the counter value of the delay timer which is currently operating is not reset. Instead, counting by the timer continues.

41.2.11 Masking of “Error Clear Trigger Registers”

The active error output status must be cleared by software via the Error clear trigger registers (ECMMECLR/ECMCECLR). A minimum activation time of the error output is achieved by the Error output clear invalidation counter. This counter is (re)started each time a new error event is triggered at the ECM. It counts up from 0000_H to FFFF_H. Error output clear by software is not possible unless this counter reaches the compare value configured in the ECMEOCCFG register. If Error output clear invalidation counter is still running, Error output clear is masked and Error output clear request by software is ignored.

41.2.12 DCLS Error Interrupt (EI Level) and EI Level Interrupt

This module can generate specific interrupts of DCLS error for each CPU. When DCLS error is occurred in the state of setting the ECMMICFG0, DCLS error interrupt and EI level interrupt are generated. The following figure shows the generation logic of DCLS error interrupt and EI level interrupt from ECM. For each PEn (n = 0, 1), EI level interrupt of CPU_n is generated by EI level interrupt from ECM master, ECM checker and other DCLS error interrupt except self's DCLS error interrupt being OR-ed.

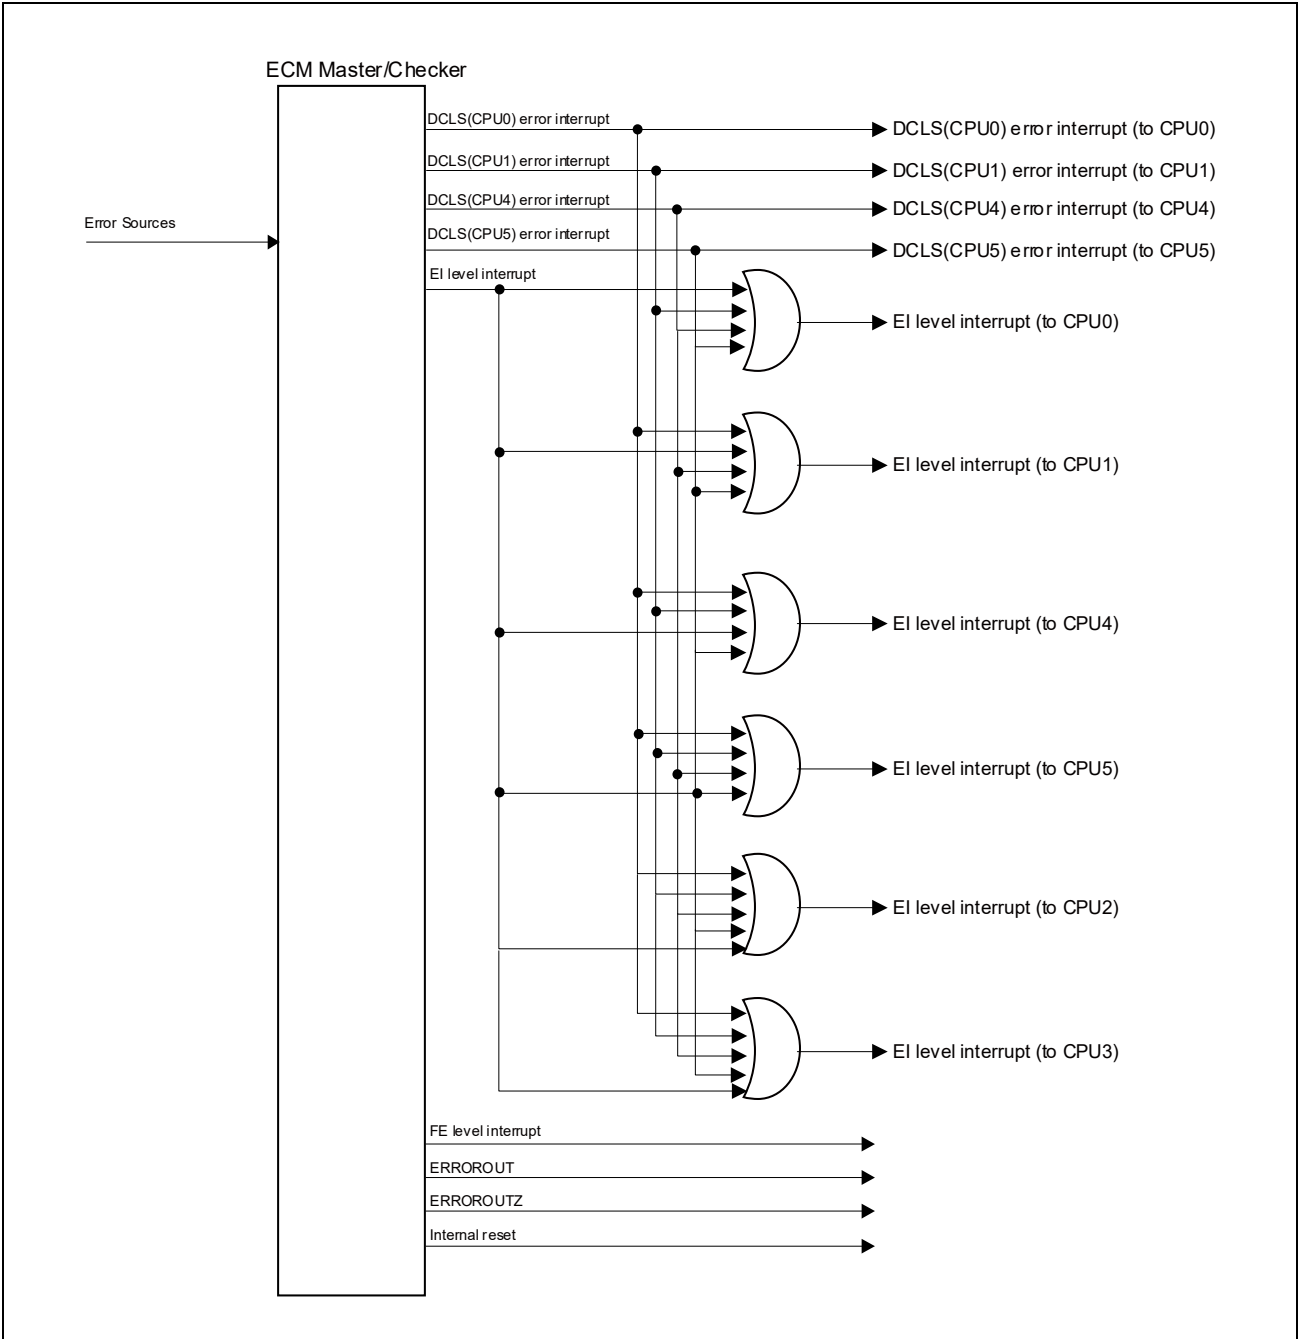

Figure 41.3 DCLS Error Interrupt (EI Level) and EI Level Interrupt for RH850/E2x-FCC2 and E2UH

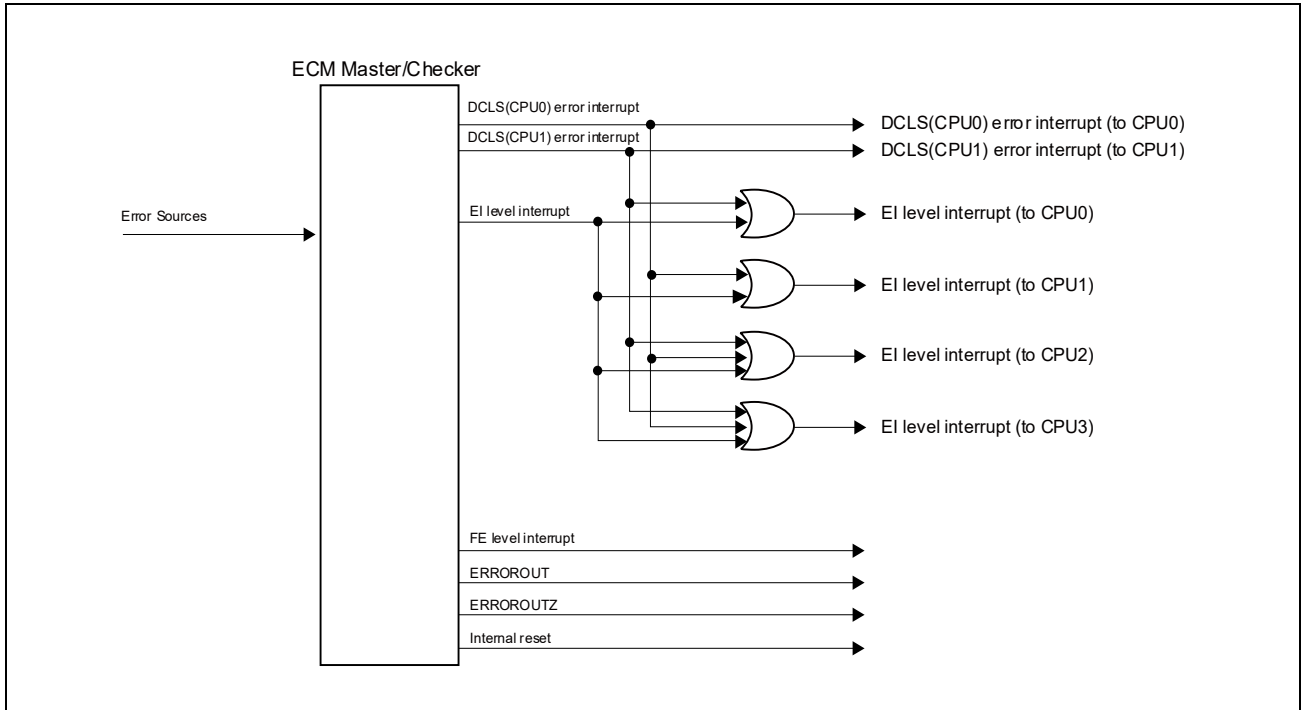

Figure 41.4 DCLS Error Interrupt (EI Level) and EI Level Interrupt for RH850/E2H

41.3 Register Specification

41.3.1 List of Registers

ECM consists of three address areas: ECM master, ECM checker, ECM common.

The following shows the register map of the ECM master and checker registers.

Table 41.17 Address List of ECM Master and Checker Registers

Module Name	Register Name	Symbol	Address	Access	Access Protection
ECM Master Registers <ECMM_base: FFCB 0000 _H >					
ECMM	ECM Master Error Set Trigger Register	ECMMESET	<ECMM_base> + 00 _H	8	ECMKCPROT
ECMM	ECM Master Error Clear Trigger Register	ECMMECLR	<ECMM_base> + 04 _H	8	ECMKCPROT
ECMM	ECM Master Error Source Status Register n ^{*1}	ECMMESSTRn ^{*1}	<ECMM_base> + 08 _H to 2C _H	32	—
ECM Checker Registers <ECMC_base: FFCB 1000 _H >					
ECMC	ECM Checker Error Set Trigger Register	ECMCESET	<ECMC_base> + 00 _H	8	ECMKCPROT
ECMC	ECM Checker Error Clear Trigger Register	ECMCECLR	<ECMC_base> + 04 _H	8	ECMKCPROT
ECMC	ECM Checker Error Source Status Register n ^{*1}	ECMCESSTRn ^{*1}	<ECMC_base> + 08 _H to 2C _H	32	—

Note 1. n = 0 to 9

The following shows the register map of the ECM common registers.

Table 41.18 Address List of ECM Common Registers

Module Name	Register Name	Symbol Name	Address	Access	Access Protection
ECM Common Registers <ECM_base: FFCB 2000 _H >					
ECM	ECM Error Pulse Configuration Register	ECMEPCFG	<ECM_base> + 00 _H	8	ECMKCPROT
ECM	ECM Maskable Interrupt Configuration Register n*1	ECMMICFGn*1	<ECM_base> + 04 _H ~28 _H	32	ECMKCPROT
ECM	ECM FE Level Interrupt Configuration Register n*1	ECNMICFGn*1	<ECM_base> + 2C _H ~50 _H	32	ECMKCPROT
ECM	ECM Internal Reset Configuration Register n*1	ECMIRCFGn*1	<ECM_base> + 54 _H ~78 _H	32	ECMKCPROT
ECM	ECM Error Mask Register n*1	ECMEMKn*1	<ECM_base> + 7C _H ~A0 _H	32	ECMKCPROT
ECM	ECM Error Source Status Clear Trigger Register n*1	ECMESSTCn*1	<ECM_base> + A4 _H ~C8 _H	32	ECMKCPROT
ECM	ECM Key Code Protection Register	ECMKCPROT	<ECM_base> + CC _H	32	—
ECM	ECM Pseudo Error Trigger Register n*1	ECMPEn*1	<ECM_base> + D0 _H to F4 _H	32	ECMKCPROT
ECM	ECM Delay Timer Control Register	ECMDTMCTL	<ECM_base> + F8 _H	8	ECMKCPROT
ECM	ECM Delay Timer Register	ECMDTMR	<ECM_base> + FC _H	16	—
ECM	ECM Delay Timer Compare Register	ECMDTMCMP	<ECM_base> + 100 _H	32	ECMKCPROT
ECM	ECM Maskable Interrupt Delay Timer Configuration Register n*1	ECMMIDTMCFGn*1	<ECM_base> + 104 _H to 128 _H	32	ECMKCPROT
ECM	ECM FE Level Interrupt Delay Timer Configuration Register n*1	ECNMIDTMCFGn*1	<ECM_base> + 12C _H to 150 _H	32	ECMKCPROT
ECM	ECM Error Output Clear Invalidation Configuration Register	ECMEOCCFG	<ECM_base> + 154 _H	32	ECMKCPROT
ECM	ECM Pseudo Error Mask Register	ECMPPEM	<ECM_base> + 158 _H	32	—

Note 1. n = 0 to 9

The register areas of the ECM registers are common to the redundancy area to be implemented. Writes to the common register areas are conducted simultaneously. The common area for ECM master is read by reading access to the common area. The ECM master register and the ECM checker register represent the address areas which can be written separately.

41.3.2 ECMmESET — ECM Master/Checker Error Set Trigger Register (m = M/C)

The ECM Master/Checker Error Set Trigger Register is for setting the error signal from the error pin to the low level. When the ECMmEST bit is set to 1, the error pin outputs the low level. The output cannot be masked. This registers is also the trigger for the port safe state function. When Error signal output is set, each port state will be changed to a condition according to user's setting. Writing to this register is protected by ECMKCPROT. Refer to **Section 41.3.11, ECMKCPROT — ECM Key Code Protection Register** for the details of key code protection. This register is always read as 00_H.

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	ECMmEST
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	W

Table 41.19 ECMmESET Register Contents

Bit Position	Bit Name	Function
7 to 1	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
0	ECMmEST	Error set trigger bit 0: Writing 0 is invalid 1: Sets the output level from the error pin to the active (low) level.

CAUTIONS

Setting or clearing the error output from the $\overline{\text{ERROROUT_M}}$ and $\overline{\text{ERROROUT_C}}$ pin via the ECMmESET or ECMmECLR register will set the ECMmSSE308 bit of the ECMmESSTR9 register (ECM compare error). Therefore, the ECMmESET register has to be set following the sequence below.

1. Set the MSKM bit and MSKC bit of the ECMPPEM register to "masked".
2. Set the ECMmEST bit in the ECMmESET register.
3. Wait until $\overline{\text{ERROROUT_M}}$ and $\overline{\text{ERROROUT_C}}$ become low by checking that the ECMmSSE311 bit of the ECMmESSTR9 register is "0".
4. Set the MSKM bit and MSKC bit of the ECMPPEM register to "not masked".

41.3.3 ECMmECLR — ECM Master/Checker Error Clear Trigger Register (m = M/C)

The ECM Master/Checker Error Clear Trigger Register is for setting the error signal from the error pin to the high level (toggle). When the ECMmECT bit is set to 1, the error pin outputs the high level (toggle) as long as there are no other sources that set the error pin to the low level. This registers is also the trigger for the port safe state function. When Error signal output is cleared, each port state will be changed to a condition according to user's setting. Writing to this register is protected by ECMKCPROT. Refer to **Section 41.3.11, ECMKCPROT — ECM Key Code Protection Register** for the details of key code protection. This register is always read as 00_H.

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	ECMmECT
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	W

Table 41.20 ECMmECLR Register Contents

Bit Position	Bit Name	Function
7 to 1	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
0	ECMmECT	Error clear trigger bit 0: Writing 0 is invalid 1: Sets the output level from the error pin to the inactive (high) level.

CAUTIONS

Clearing of the error pin is only possible if all errors, not masked by ECMEMK registers, are cleared beforehand.

Setting or clearing the error output via the ECMmECLR register will generate an error. Therefore, the following has to be set in advance. The sequence below is executed by either CPU.

1. Set the MSKM bit and MSKC bit of the ECMPEM register to “masked”.
2. Set the ECMmECT bit in the ECMmECLR register.
3. Wait until $\overline{\text{ERROROUT_M}}$ and $\overline{\text{ERROROUT_C}}$ become high by reading ECMmSSE311 bit of ECMmESSTR9 register 5 times. After that, check that the ECMmSSE311 bit of the ECMmESSTR9 register is “1”. If the ECMmSSE311 bit of the ECMmESSTR9 register is not “1”, a new error may have occurred.
4. Set the MSKM bit and MSKC bit of the ECMPEM register to “not masked”.

Note: This procedure is used when the ECMEOCCFG register is not set.

NOTE

If the Error Pin Low Time counter is still running, the Error Output clear function is masked and Error Output clear requests are ignored. Error Output clear function is executed, after the Error Pin Low Time Counter has expired and the Error Output clear register is written.

The configuration flow of port safe state mode must be set after error signal is cleared by the ECMmECLR register. For the configuration flow of port safe state mode setting, see **Section 2.6.2.3, Configuration Flow**.

41.3.4 ECMmESSTR0 to ECMmESSTR9 — ECM Master/Checker Error Source Status Register 0 to 9 (m = M/C)

The ECM Master/Checker Error Source Status Registers 0 to 9 are read-only registers.

This register represents the status of individual internal error sources, and is unrelated to the setting of the error mask.

ECMmSSEs are provided for the each status of individual internal error sources.

ECMmSSE005-ECMmSSE000 are status bits for counting DCLS error from PE5-PE0(except PE2/3)*1. To each DCLS error from each CPU, 2bit expanded status register is prepared for counting the DCLS error. If DCLS error occurs when these bits are “11_B”, these bits keep the values.

Note 1. PE4 and PE5 are not implemented for E2H.

Value after reset: 0000 0000_H

NOTE

Reserved bit

The read value of ECMmSSE bit listed as reserved in **Table 41.11**, **Table 41.12** and **Table 41.13** is undefined. Please mask these values of reserve bit when user confirms ECMmESSTRn.

41.3.5 ECMEPCFG — ECM Error Pulse Configuration Register

The ECM Error Pulse Configuration Register is a read/write register. Writing to this register is protected by ECMKCPROT. Refer to **Section 41.3.11, ECMKCPROT — ECM Key Code Protection Register**, for the details of key code protection.

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	ECMSL0
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R/W

Table 41.24 ECMEPCFG Register Contents

Bit Position	Bit Name	Function
7 to 1	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
0	ECMSL0	Error pin operation configuration bit Error output operation setting for the error pin 0: Non-dynamic mode 1: Dynamic mode

In Dynamic mode the timer output OSTM0 determines the output wave of the $\overline{\text{ERROROUT_M}}$ and $\overline{\text{ERROROUT_C}}$ pin in case of no error.

CAUTION

After setting the dynamic mode, it is recommended not to change to non-dynamic mode again, because this can cause a glitch in the error output.

41.3.6 ECMMICFG0 to ECMMICFG9 — ECM Maskable Interrupt Configuration Register 0 to 9

The ECM Maskable Interrupt Configuration Registers 0 to 9 are used to set the generation of the INTECMMI interrupts (EI level interrupts) and the INTECMDCLSMI interrupts (EI level interrupts) when DCLS error occurs. The generation of EI level interrupts in response to errors can be enabled. Writing to these registers are protected by ECMKCPROT. Refer to **Section 41.3.11, ECMKCPROT — ECM Key Code Protection Register**, for the details of key code protection.

Value after reset: 0000 0000_H

NOTE

Reserved bit

The value of ECMMIE bit listed as reserved for the given error input numbers in **Table 41.11**, **Table 41.12** and **Table 41.13**. When read, the value after reset is returned. When writing, write the value after reset.

41.3.7 ECMNMICFG0 to ECMNMICFG9 — ECM FE Level Interrupt Configuration Register 0 to 9

The ECM FE Level Interrupt Configuration Registers 0 to 9 are used to set the generation of INTECMNMI interrupts (FE level interrupt). Writing to these registers are protected by ECMKCROT. Refer to **Section 41.3.11, ECMKCROT — ECM Key Code Protection Register**, for the details of key code protection.

Value after reset: 0000 0000_H

ECMNMICFG0

NOTE

Reserved bit

The value of ECMIRE bit listed as reserved for the given error input numbers in **Table 41.11**, **Table 41.12** and **Table 41.13**. When read, the value after reset is returned. When writing, write the value after reset.

41.3.9 ECMEMK0 to ECMEMK9 — ECM Error Mask Register 0 to 9

The ECM Error Mask Registers 0 to 9 are used to mask the individual error sources of the error pin output. This registers is also the trigger for the port safe state function. When Error signal output is not masked, each port state will be changed to a condition according to user’s setting. Writing to this register is protected by ECMKCPROT. Refer to **Section 41.3.11, ECMKCPROT — ECM Key Code Protection Register**, for the details of key code protection.

Table 41.36 ECMEMK9 Register Contents

Bit Position	Bit Name	Function
31, 30	—	Reserved When read, the value after reset is returned. When writing, write the value to “1”.
29	ECMEMK309	ECM error output signal mask control bit ECMEMK309 corresponds to delay timer overflow. 0: Error signal output is not masked 1: Error signal output is masked
28 to 27	ECMEMK308 to ECMEMK307	ECM error output signal mask control bit ECMEMK308 to ECMEMK307 correspond to error sources 308 to 307. 0: Error signal output is not masked 1: Error signal output is masked
26	—	Reserved When read, the value after reset is returned. When writing, write the value to “1”.
25 to 0	ECMEMK305 to ECMEMK280	ECM error output signal mask control bit ECMEMK305 to ECMEMK280 correspond to error sources 305 to 280. 0: Error signal output is not masked 1: Error signal output is masked

NOTES

- Error mask specification
If an error flag is set but masked, clearing the mask will set the $\overline{\text{ERROROUT_M}}$, $\overline{\text{ERROROUT_C}}$ and $\overline{\text{ERROROUTZ}}$ to active low level. This happens independently from the time of the error occurrence. In other words, the flag is evaluated statically.
- PE4 and PE5 are not implemented in RH850/E2x-FCC2 for E2H. But the initial value of ECMEMK bit related PE3 and PE4 function is “0”.

41.3.10 ECMESSTC0 to ECMESSTC9 — ECM Error Source Status Clear Trigger Register 0 to 9

The ECM Error Source Status Clear Trigger Registers 0 to 9 are a write-only register and can be written in 32-bit units. These registers are used to clear the individual error source status of the ECM master/checker error source status registers 0 to 9. Both the error status of the ECM master and the ECM checker are cleared simultaneously.

Writing to this register is protected by ECMKCPROT. Refer to **Section 41.3.11, ECMKCPROT — ECM Key Code Protection Register.**

Value after reset: 0000 0000_H

Table 41.40 ECMKCPROT Register Contents

Bit Position	Bit Name	Function
31 to 1	KCPROT[31:1]	Enable or disable modification of the KCE bit. The written value is not retained. These bits are always read as 0.*1
0	KCE	Key Code Enable bit 0: Disable write access to protected registers 1: Enable write access to protected registers

Note 1. Write A5A5A500_H to this register to disable writing protected registers.
Write A5A5A501_H to this register to enable writing protected registers.

41.3.12 ECMPE0 to ECMPE9 — ECM Pseudo Error Trigger Register 0 to 9

The ECM Pseudo Error Trigger Registers 0 to 9 are write-only registers. These registers are used to generate a pseudo error for test purposes. The ECM operation in response to the generation of a pseudo error is identical to that of a real error source. Writing to this register is protected by ECMKCPROT. Refer to **Section 41.3.11, ECMKCPROT — ECM Key Code Protection Register**, for the details of key code protection.

Value after reset: 0000 0000_H

Table 41.43 ECMPE9 Register Contents

Bit Position	Bit Name	Function
31, 30	—	Reserved When writing, write the value after reset.
29	ECMPE309	ECM pseudo error trigger bit ECMPE309 corresponds to delay timer overflow. 0: Pseudo error is not generated. 1: Pseudo error is generated.
28	ECMPE308	ECM pseudo error trigger bit ECMPE308 corresponds to error source 308. 0: Pseudo error is not generated. 1: Pseudo error is generated.
27, 26	—	Reserved When writing, write the value after reset.
25 to 0	ECMPE305 to ECMPE280	ECM pseudo error trigger bit ECMPE305 to ECMPE280 correspond to error sources 305 to 280. 0: Pseudo error is not generated. 1: Pseudo error is generated.

NOTE**Reserved bit**

The value of ECMPE bit listed as reserved for the given error input numbers in **Table 41.11**, **Table 41.12** and **Table 41.13**. When writing, write the value after reset.

41.3.13 ECMDTMCTL — ECM Delay Timer Control Register

The ECM Delay Timer Control Register is a read/write register. This register is used to control the delay timer. Writing to this register is protected by ECMKCPROT. Refer to **Section 41.3.11, ECMKCPROT — ECM Key Code Protection Register**, for the details of key code protection.

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	DTMSTACNTCLK	—	—	DTMSTP	DTMSTA
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	W	R/W

Table 41.44 ECMDTMCTL Register Contents

Bit Position	Bit Name	Function
7 to 5	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
4	DTMSTACNTCLK	Delay timer start confirmation status. 0: Delay timer does not start 1: Delay timer starts.
3, 2	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
1	DTMSTP	Delay timer stop bit By writing "1" to this bit, delay timer is stopped (writing 0 is ignored). Simultaneously, DTMSTA bit will be 0. 0: Delay timer is completed or stop request is not in progress. 1: Stop request for delay timer is in progress.
0	DTMSTA	Delay timer start bit Specifies the operation of the delay timer at the occurrence of an error event. 0: Delay timer does not start 1: Delay timer starts

NOTES

- ECMDTMCTL register can be accessed via P-Bus but delay timer runs with not P-Bus clock but dedicated counter clock.
Therefore, time lag exists between writing of ECMDTMCTL and enabling of delay timer.
DTMSTACNTCLK can be used to confirm whether delay timer is enabled or not. Reconfirm that DTMSTA has been updated by checking DTMSTACNTCLK after writing to DTMSTA.
- ECMDTMCTL register can be written only when (DTMSTA, DTMSTACNTCLK) = (0, 0) or (1, 1).
Confirm the values of DTMSTA and DTMSTACNTCLK before writing to ECMDTMCTL.
- The delay timer needs 3 clocks of cntclk until it stops an overflow certainly.
Please consider to set the sufficient value to ECMDTMCMP[15:0].

41.3.14 ECMDTMR — ECM Delay Timer Register

The ECM Delay Timer Register is a read-only register. The ECM delay timer register is initialized by setting the ECMSTA bit of the ECM delay timer control register from 1 (timer in operation) to 0 (timer stopped).

Value after reset: 0000H

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	ECMDTMR[15:0]

Table 41.45 ECMDTMR Register Contents

Bit Position	Bit Name	Function
15 to 0	ECMDTMR[15:0]	Delay timer counter value.

41.3.15 ECMDTMCMP — ECM Delay Timer Compare Register

The ECM Delay Timer Compare Register is a read/write register. The ECMmESSTR9.ECMmSSE309 bit is set when the value of this register matches with the value of the ECM delay timer register. Writing data to this register has to be conducted while the delay timer is stopped. Writing to this register is protected by ECMKCPROT. Refer to **Section 41.3.11, ECMKCPROT — ECM Key Code Protection Register**, for the details of key code protection.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	CMPW

R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 41.46 ECMDTMCMP Register Contents

Bit Position	Bit Name	Function
31 to 17	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
16	CMPW	Indicates whether a write to the counter clock region of the ECMDTMCMP register setting is in progress 0: Not in progress 1: In progress. While the bit is set, further setting to the ECMDTMCMP is prohibited.
15 to 0	ECMDTMCMP[15:0]	Delay timer compare value

NOTES

- ECMDTMCMP register is set via P-bus, however actual delay timer exists in a different clock domain. When ECMDTMCMP is configured, the value is copied across clock domains to reflect to the delay timer, which takes a certain time. CMPW indicates whether reflecting the new ECMDTMCMP value across clock domains is in progress.
- While CMPW is “1”, further setting to ECMDTMCMP is ignored.
Please confirm CMPW = 0, before writing of ECMDTMCMP.

41.3.16 ECMMIDTMCFG0 to ECMMIDTMCFG9 — ECM Maskable Interrupt Delay Timer Configuration Register 0 to 9

The ECM Maskable Interrupt Delay Timer Configuration Registers 0 to 9 are used to enable/disable the delay timer start caused by EI level interrupts in response to errors. Writing to this register is protected by ECMKCROT. Refer to **Section 41.3.11, ECMKCROT — ECM Key Code Protection Register**, for the details of key code protection.

Value after reset: 0000 0000_H

The value of ECMNMITE bit listed as reserved for the given error input numbers in **Table 41.11**, **Table 41.12** and **Table 41.13**. When read, the value after reset is returned. When writing, write the value after reset.

41.3.18 ECMEOCCFG — ECM Error Output Clear Invalidation Configuration Register

This register is a read/write register and can be written in 32-bit units.

After counter for Error Output clear invalidation exceed the value which is configured to this register, it is possible to clear non-safe status of error output by SW.

Configure to this register only if error output status is safe.

Writing to this register is protected by ECMKCPROT. Refer to **Section 41.3.11, ECMKCPROT — ECM Key Code Protection Register**, for the details of key code protection.

Value after reset: 0000 0000_H.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	EOCI EN	—	—	—	—	—	—	—	—	—	—	—	—	—	—	CMPW

Table 41.53 ECMEOCCFG Register Contents

Bit Position	Bit Name	Function
31	EOCIEN	ERROROUT Clear Invalidation Function Enabled 0: Disabled 1: Enabled
30 to 17	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
16	CMPW	Indicates on execution of ECMEOUTCLRT[15:0] register setting to counter clock domain 0: Not in progress 1: In progress. While the bit is set, further setting to the ECMEOUTCLRT is prohibited.
15 to 0	ECMEOUTCLRT [15:0]	The number of clock cycles after which it is possible to clear error output by SW.

NOTES

- ECMEOCCFG register is set via P-bus, however actual “output clear invalidation counter” exists in a different clock domain. When ECMEOCCFG is configured, the value is copied across clock domains to reflect to the counter, which takes a certain time. CMPW indicates whether the reflection across clock domains is in progress.
- While CMPW is “1”, writing of ECMEOUTCLRT[15:0] is ignored. Please confirm CMPW = 0 before writing of ECMEOUTCLRT[15:0].

41.3.19 ECMPEM — ECM Pseudo Error Mask Register

This register can mask the pseudo error of “ECM compare error” to support self-diagnosis of the binding components for `ERROROUT_M` and `ERROROUT_C` pins.

Value after reset: 0000 0000_H

1	MSKM	0: Pseudo error of “ECM compare error” for ECM master is NOT masked. 1: Pseudo error of “ECM compare error” for ECM master is masked.
0	MSKC	0: Pseudo error of “ECM compare error” for ECM checker is NOT masked. 1: Pseudo error of “ECM compare error” for ECM checker is masked.

Section 42 Data CRC Function B (DCRB)

This section contains a generic description of Data CRC Function B (DCRB). The first part of this section describes the features specific to this product, such as the number of units and register base addresses. The remainder of the section describes the functions and registers of DCRB.

42.1 Features

42.1.1 Number of Units

This microcontroller has the following number of DCRB units.

Table 42.1 Number of Units

Product Name	468 Pins	373 Pins
Number of Units	3	3
Name	DCRBn (n = 0 to 2)	DCRBn (n = 0 to 2)

Note: "n" in this section indicates the unit number of the individual DCRB units.

There are 468 pins in E2xFCC2, E2UH and E2H, and 373 pins in E2xFCC2, E2UH and E2H.

42.1.2 Register Base Addresses

DCRBn base addresses are listed in the following table. DCRBn register addresses are given as offsets from the base addresses in general.

Table 42.2 Register Base Addresses

Base Address Name	Base Address	Peripheral Group
<DCRB0_base>	FFF7 0000 _H	6
<DCRB1_base>	FFF7 1000 _H	6
<DCRB2_base>	FFF7 2000 _H	6

42.1.3 Clock Supply

The clock supply by and to DCRBn is given in the following table.

Table 42.3 Clock Supply

Unit Name	Unit Clock Name	Clock Supply Name
DCRBn	PCLK	CLK_LSB

42.1.4 Interrupt Requests

This module has no interrupt requests.

42.1.5 Reset Sources

The DCRBn reset sources are shown below. DCRBn is initialized by the following reset sources.

Table 42.4 Reset Sources

Unit Name	Register Name	Reset Condition					
		Power Up Reset	System Reset 1	System Reset 2	Application Reset	Module Reset	JTAG Reset
DCRBn	All registers	✓	✓	✓	✓	—	—

42.1.6 External Input/Output Signals

This module has no external input/output signals.

42.2 Overview

42.2.1 Functional Overview

Data CRC Function B can be used to verify or generate CRC protected data streams of arbitrary length and different bit widths.

- Supported CRC polynomials
 - 32-bit Ethernet CRC
04C1 1DB7_H: $X^{32} + X^{26} + X^{23} + X^{22} + X^{16} + X^{12} + X^{11} + X^{10} + X^8 + X^7 + X^5 + X^4 + X^2 + X + 1$
 - 16-bit CCITT CRC
1021_H: $X^{16} + X^{12} + X^5 + 1$
 - 8-bit SAE J1850 CRC
1D_H: $X^8 + X^4 + X^3 + X^2 + 1$
 - 8-bit 0x2F CRC
2F_H: $X^8 + X^5 + X^3 + X^2 + X + 1$
- CRC generation to an arbitrary data block length
- After initialization of the DCRB data register, every write access to the DCRB input register generates a new CRC according to the chosen polynomial and the result is stored in the DCRB data register.

42.2.2 Block Diagram

The following figure shows the block diagram of Data CRC Function B.

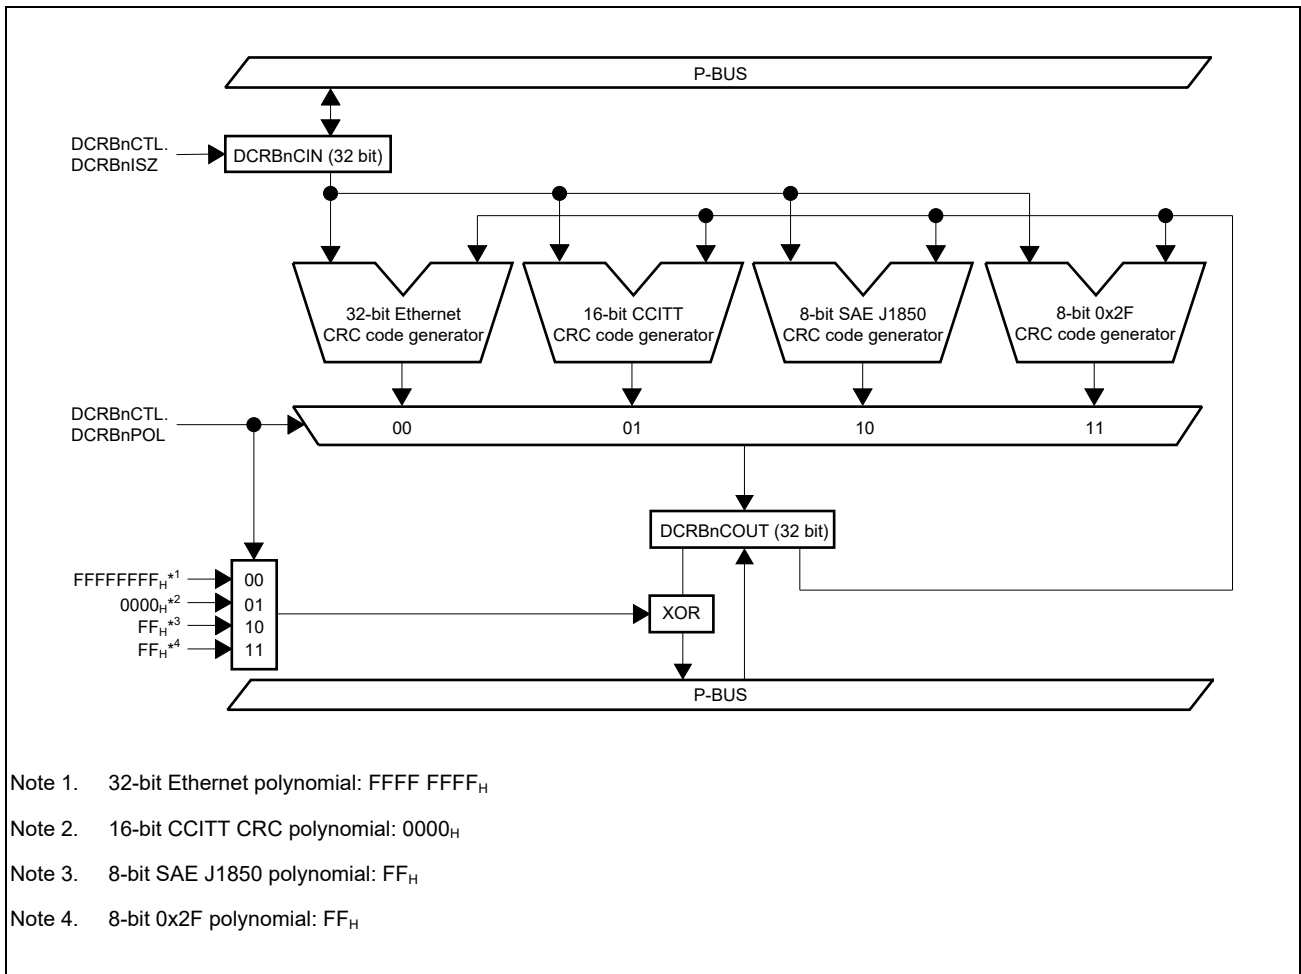

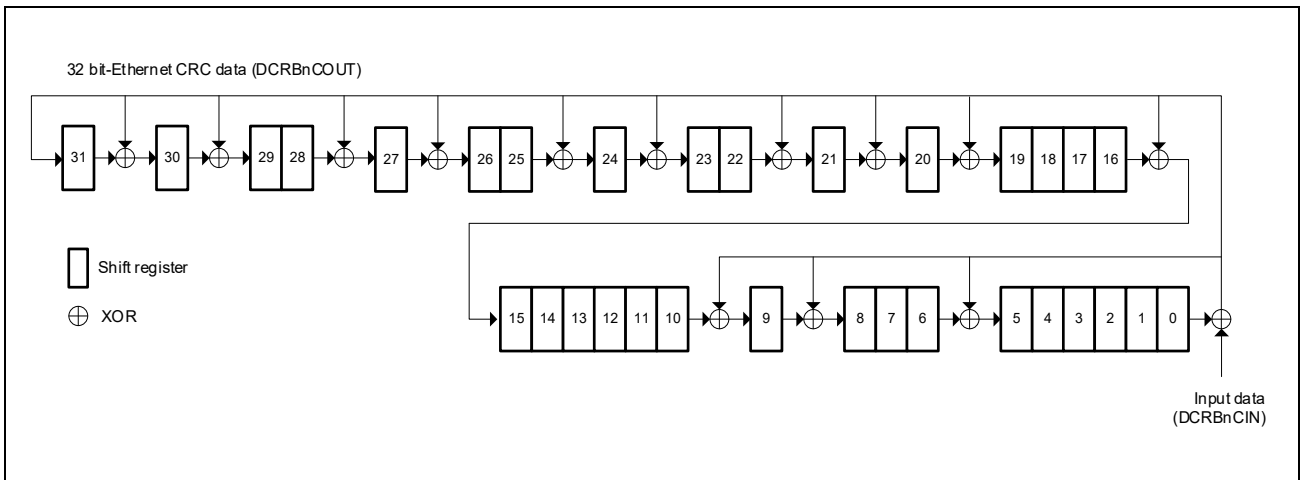

Figure 42.1 Block Diagram of Data CRC Function B

42.2.3 Configuration of CRC Calculation

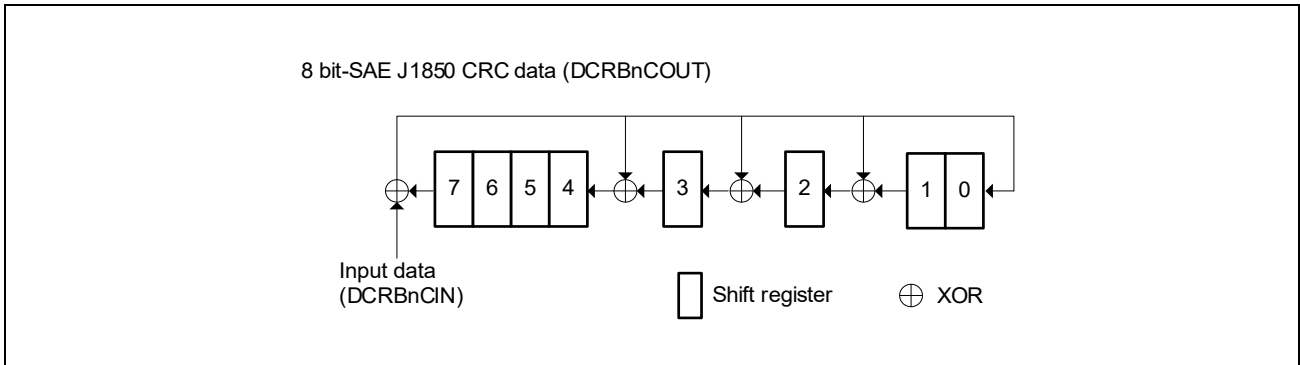

- 32-bit Ethernet

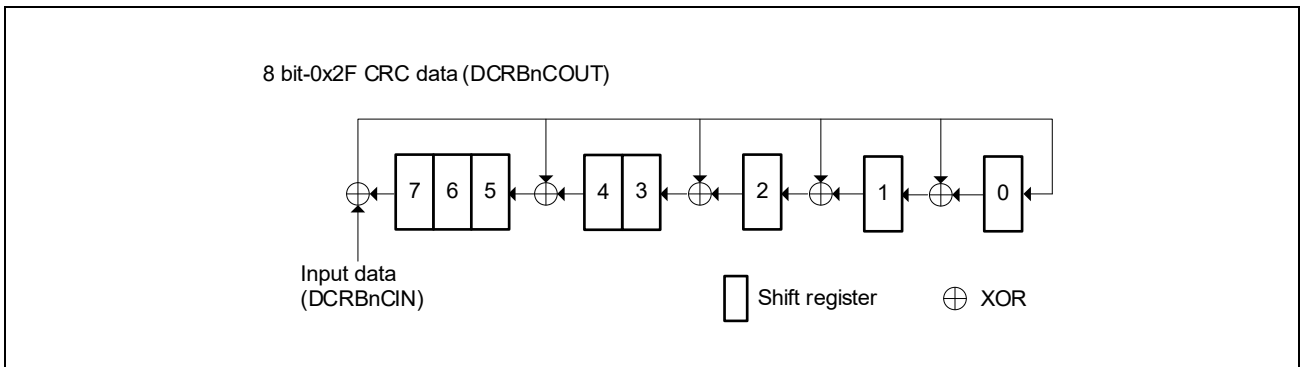

- 16-bit CCITT

- 8-bit SAE J1850

- 8-bit 0x2F

42.3 Registers

42.3.1 List of Registers

Table 42.5 List of Registers

Module Name	Register Name	Symbol	Address	Access	Access Protection
DCRBn	DCRB Input Register	DCRBnCIN	<DCRBn_base> + 00 _H	32	—
	DCRB Data Register	DCRBnCOUT	<DCRBn_base> + 04 _H	32	—
	DCRB Control Register	DCRBnCTL	<DCRBn_base> + 20 _H	8	—

42.3.2 DCRBnCIN — DCRB Input Register

This register holds the input data for CRC calculation. The effective bit width used for CRC calculation must be set by DCRBnCTL.DCRBnISZ[1:0].

When data is written to this register, the CRC code is generated. The CRC calculation is immediately started after the DCRBnCIN register is written. The DCRBnCOUT register must be initialized with the initial value before the first data of the data block is written to the DCRBnCIN register.

The byte order in DCRBnCIN depends on the selected CRC generating function:

- 32-bit Ethernet CRC polynomial generation (DCRBnCTL.DCRBnPOL[1:0] = 00_B)

The byte order is LSB (least significant byte) first. This means that if the CRC input bit width is 8 bits (DCRBnISZ[1:0] = 10_B), the input values are in bits 7 to 0 of the DCRBnCIN register and bit 0 (the LSB) is the first bit of the input data.

- 16-bit CCITT CRC polynomial generation (DCRBnCTL.DCRBnPOL[1:0] = 01_B)

The byte order is MSB (most significant byte) first. This means that if the CRC input bit width is 8 bits (DCRBnISZ[1:0] = 10_B), the input values are in bits 7 to 0 of the DCRBnCIN register and bit 7 (the MSB) is the first bit of the input data.

- 8-bit SAE J1850 CRC polynomial generation (DCRBnCTL.DCRBnPOL[1:0] = 10_B)

The byte order is MSB (most significant byte) first. This means that if the CRC input bit width is 8 bits (DCRBnISZ[1:0] = 10_B), the input values are in bits 7 to 0 of the DCRBnCIN register and bit 7 (the MSB) is the first bit of the input data.

- 8-bit 0x2F CRC polynomial generation (DCRBnCTL.DCRBnPOL[1:0] = 11_B)

The byte order is MSB (most significant byte) first. This means that if the CRC input bit width is 8 bits (DCRBnISZ[1:0] = 10_B), the input values are in bits 7 to 0 of the DCRBnCIN register and bit 7 (the MSB) is the first bit of the input data.

Value after reset:		0000 0000 _H

Table 42.6 DCRBnCIN Register Contents

Bit Position	Bit Name	Function
31 to 0	DCRBnCIN[31:0]	Input data for CRC calculation. The valid bits are: For 32 bit effective bit width: DCRBnCIN[31:0] For 16 bit effective bit width: DCRBnCIN[15:0] For 8 bit effective bit width: DCRBnCIN[7:0]

42.3.3 DCRBnCOUT — DCRB Data Register

This register stores the result of the CRC code generated by the CRC polynomial selected by DCRBnCTL.DCRBnPOL[1:0].

Value after reset: FFFF FFFF_H

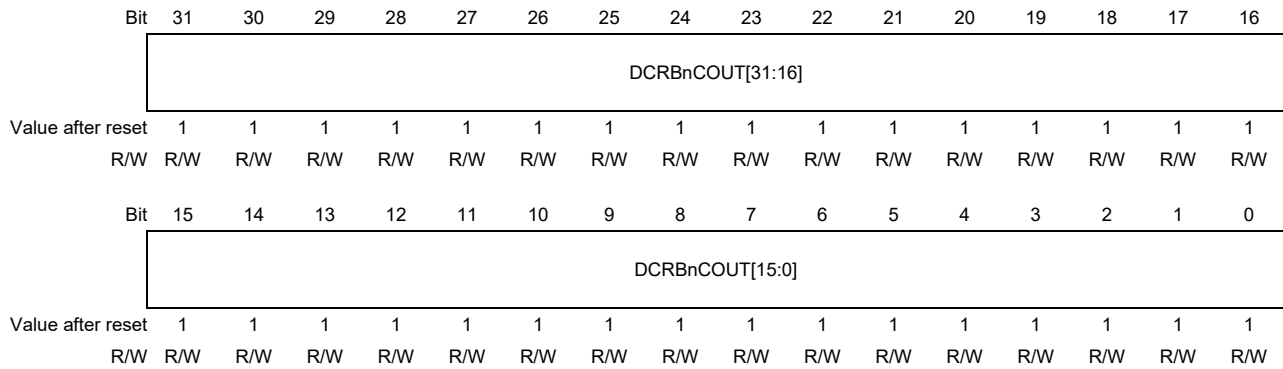

Table 42.7 DCRBnCOUT Register Contents

Bit Position	Bit Name	Function
31 to 0	DCRBnCOUT[31:0]	<p>Result of the CRC code generation.</p> <p>When the 16-bit CCITT polynomial is enabled, bits 15 to 0 show the CRC result. Bits 31 to 16 are undefined.</p> <p>When 8-bit SAE J1850 or 8-bit 0x2F polynomial is enabled, bits 7 to 0 show the CRC result. Bits 31 to 8 are undefined.</p> <p>When reading from this register, the value is XORed by hardware with the value described below for the chosen polynomial.</p> <p>32-bit Ethernet polynomial: FFFF FFFF_H</p> <p>16-bit CCITT CRC polynomial: 0000_H</p> <p>8-bit SAE J1850 polynomial: FF_H</p> <p>8-bit 0x2F polynomial: FF_H</p> <p>Therefore, for the 32-bit Ethernet polynomial, 0000 0000_H is read from this register even in the initial state.</p>

CAUTION

The read value after reset is 0000 0000_H since the 32-bit Ethernet CRC polynomial is selected as the CRC generating function after reset and the value is XORed onto FFFF FFFF_H by hardware.

This register must be initialized with the start value before the first data of the data block is written to the DCRBnCIN register.

42.3.4 DCRBnCTL — DCRB Control Register

This register controls the CRC generation process.

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0

Table 42.8 DCRBnCTL Register Contents

Bit Position	Bit Name	Function
7 to 6	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
5 to 4	DCRBnISZ[1:0]	Specifies the CRC input bit width. 00: 32 bit (DCRBnCIN[31:0]) 01: 16 bit (DCRBnCIN[15:0]) 10: 8 bit (DCRBnCIN[7:0]) 11: Setting prohibited
3 to 2	—	Reserved When read, the value after reset is returned. When writing, write the value after reset.
1 to 0	DCRBnPOL[1:0]	Specifies the CRC generating function. 00: 32-bit Ethernet CRC polynomial generation. The byte order of the DCRBnCIN register is LSB (Least Significant Byte) first. This means that if the CRC input bit width is 8 bits (DCRBnISZ[1:0] = 10 _B), the input values are in bits 7 to 0 of the DCRBnCIN register and bit 0 (the LSB) is the first bit of the input data. The half-word order of the DCRBnCIN register is LSB (Least Significant Byte) first. This means that if the CRC input bit width is 16 bits (DCRBnISZ[1:0] = 10 _B), the input values are in bits 15 to 0 of the DCRBnCIN register and bit 0 (the LSB) is the first bit of the input data. 01: 16-bit CCITT CRC polynomial generation. The byte order of the DCRBnCIN register is MSB (Most Significant Byte) first. This means that if the CRC input bit width is 8 bits (DCRBnISZ[1:0] = 10 _B), the input values are in bits 7 to 0 of the DCRBnCIN register and bit 7 (the MSB) is the first bit of the input data. 10: 8-bit SAE J1850 CRC polynomial generation The byte order of the DCRBnCIN register is MSB (Most Significant Byte) first. This means that if the CRC input bit width is 8 bits (DCRBnISZ[1:0] = 10 _B), the input values are in bits 7 to 0 of the DCRBnCIN register and bit 7 (the MSB) is the first bit of the input data. 11: 8-bit 0x2F CRC polynomial generation The byte order of the DCRBnCIN register is MSB (Most Significant Byte) first. This means that if the CRC input bit width is 8 bits (DCRBnISZ[1:0] = 10 _B), the input values are in bits 7 to 0 of the DCRBnCIN register and bit 7 (the MSB) is the first bit of the input data.

NOTE

After changing the CRC generating function (DCRBnCTL.DCRBnPOL[1:0]), the DCRBnCOUT register must be initialized.

CAUTIONS

- The CRC bit width (DCRBnCTL.DCRBnSZ[1:0]) must be set according to the data block bit width. Switching the CRC bit width is not allowed during processing of a data block (a data block consists of N bytes, half words or words). After the final CRC result is read from the DCRBnCOUT register, the bit width can be changed and the DCRBnCOUT register must be initialized with the initial value.
 - Switching the CRC polynomial (DCRBnCTL.DCRBnPOL[1:0]) is also not allowed during processing of a data block.
-

42.4 Operation

Data CRC Function B generates a CRC (cyclic redundancy check) of arbitrary data block length. The data can be forwarded to the Data CRC Function in 8-, 16- or 32-bit units. The CRC polynomial can either be selected for 32-bit Ethernet, 16-bit CCITT, 8-bit SAE J1850 or 8-bit 0x2F polynomial CRC, and the initial starting value must be set at the DCRBnCOUT register before the first write access to the DCRB input register (DCRBnCIN) is performed.

After the last write access to the DCRBnCIN register is performed, the result can be read out from the DCRBnCOUT register after one clock period.

The flow chart below shows the CRC generation procedure.

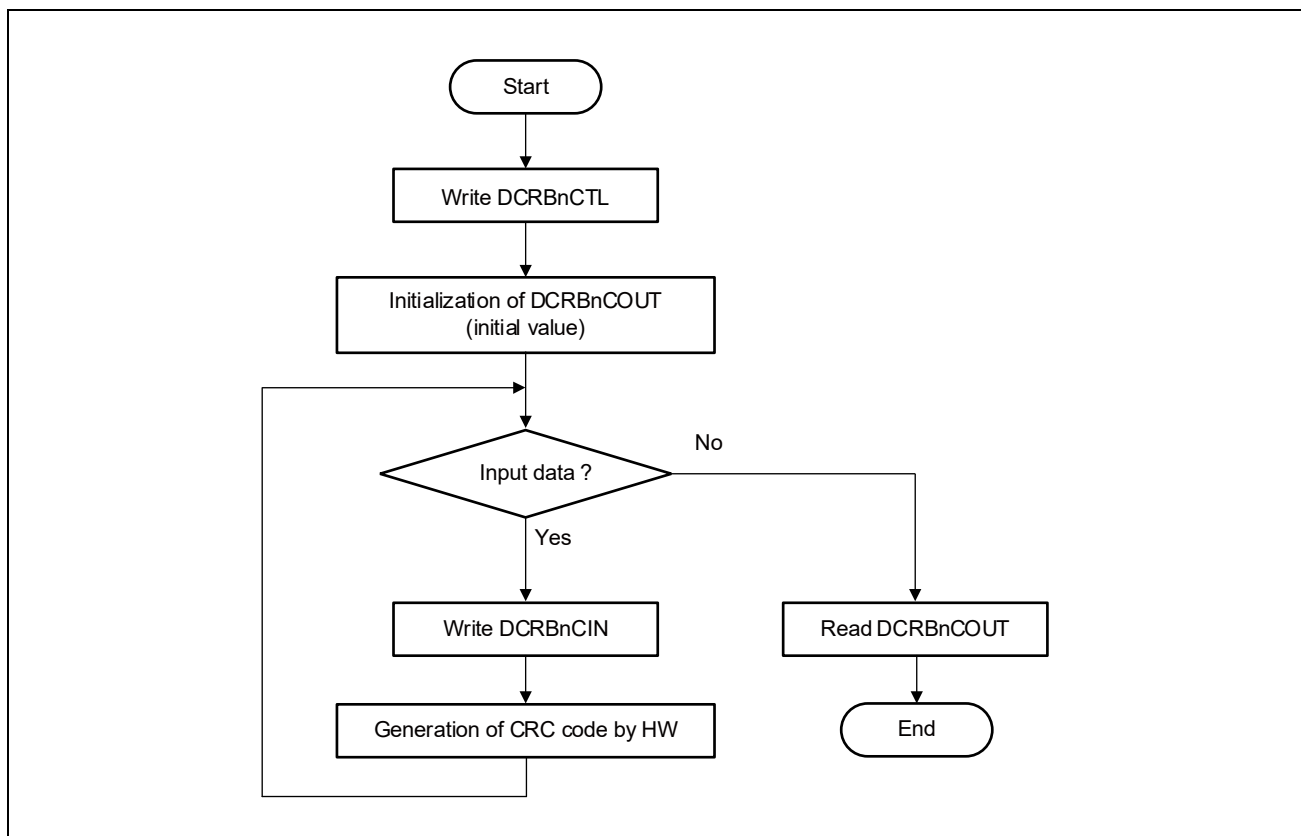

Figure 42.2 Data CRC Function B Flow Diagram

NOTES

- The initial value to be written to DCRBnCOUT can be chosen by the user.
- When reading from register DCRBnCOUT, the value is XORed by hardware with the value specified in the chosen polynomial.
- Generation of CRC code and storage to DCRBnCOUT are done by hardware.
- All registers are accessible by CPU or by CPU-independent read/write access via DMA/DTS. Independent from access of the DCRB via CPU or DMA/DTS the verification of the CRC code (CRC-check result in DCRBnCOUT) has to be performed by SW.

Section 43 Flash Memory

This product incorporates Code Flash Memory and Data Flash Memory.

Product Name	Code Flash Memory		Data Flash Memory	
	User Area	User Boot Area	Data Area	Exclusively for ICUM
RH850/E2x-FCC2 (for E2UH)	16M bytes	64K bytes	256K bytes	64K bytes
RH850/E2x-FCC2 (for E2H)	12M bytes	64K bytes	256K bytes	32K bytes
RH850/E2UH	16M bytes	64K bytes	256K bytes	64K bytes
RH850/E2H	12M bytes	64K bytes	256K bytes	32K bytes

43.1 Features

- Code Flash

- Capacity: Up to 16 MB of User Area and 64 KB of User Boot Area.
- Multi banked configuration in Multi CPU devices.
- Program unit: 512 bytes
- Erase unit: 16 KB for 8 blocks and 64 KB for remaining blocks
- OTP (One Time Programmable) supported for each block.

- Data Flash

- Capacity: Up to 256 KB (dual banked: 128 KB + 128 KB) and Up to 64KB for data area exclusively for ICUM
- Program unit: 4, 8, 16, 32, 64, 128 bytes
DMA can initiate 4 bytes program in multiple time without software overhead. (within one Data Flash Bank *1)
- Erase unit: 4KB x N (N = 1, 2, 3 ...) (within one Data Flash Bank *1)

Note 1. max 4 to 128 KB.

- Extended Data Area

- Capacity: 2 KB
- Program unit: 4, 8, 16, 32, 64, 128 bytes
- Erase unit: 2KB

- Programming method
 - Serial programming: Programming of flash memory by external flash memory programmer through serial interface or CAN/CAN-FD interface.
This Mode uses the program to control flash memory rewriting included in a microcomputer (Boot Firmware). Boot Firmware communicate with external flash memory programmer by a serial interface or CAN/CAN-FD interface.
When using CAN/CAN-FD interface, Boot Firmware receives a user program for flash memory rewriting and starts this.
 - Self programming: Programming of flash memory by a user program written on Code Flash already.
- Support for security functions to protect against illicit tampering and illicit reading with data in flash memory
- Support for protection functions to protect against erroneous programming / erasure of the flash memory
- ECC support for error detection and correction for both Code Flash and Data Flash
 - Reading erased Code Flash results in an ECC error.
 - Reading erased Data Flash results in an ECC error.
- Background Operation (BGO) support
 - Code Flash Read is possible during programming / erasing of Data Flash.
 - Data Flash (except bank Z) Read is possible during programming / erasing of the Code Flash.
 - One bank Code Flash Read is possible during programming / erasing of the other bank of Code Flash.
 - One bank (except bank Z) of Data Flash Read is possible during programming / erasing of the other bank of Data Flash.
- Dual Operation support
 - The bank Data Flash for ICUM programming / erasing is possible during programming / erasing of the other bank of Data Flash.
 - The bank Data Flash for ICUM programming / erasing is possible during programming / erasing of the Code Flash. This operation is supported only in E2UH and E2H.
- Suspend/Resume support for both Code Flash and Data Flash
 - Programming / erasing operation can be suspended. Suspended operation can be resumed.
It can be used for interruption processing received during self- programming.
- The Settings of this product can be configured in Flash Extra area of Flash Memory.
Flash Extra Areas is divided into Configuration Setting Area, Extended data area, Security Setting Area and Block Protection Area.
 - Configuration Setting Area: To store the System Configuration Parameters. (Flash Option Byte, Reset Vector, etc.)
 - Security Setting Area: To store the Security Parameters. (ID Codes, Security Setting flag, etc.)
 - Block Protection Area: To store the Code Flash Protection Settings. (OTP flag, etc.)
 - Extended data area To store any data to use by user software.

- Interrupt Requests

The flash memory supports an interrupt to indicate completion of processing by the flash sequencer.

Table 43.1 Interrupt Requests

Interrupt Name	Description	Interrupt Number	sDMA Trigger Number	DTS Trigger Number
INTFACI0ENDNM	Flash sequencer of code flash and data flash (except bank for ICUM) processing end interrupt	33	—	—
INTFACI1ENDNM	Flash sequencer of the data flash for ICUM processing end interrupt	35	—	—
INTDMAFLO	DMA request of DMA programming for the data flash bank A/B	—	group0-218	group0-124
INTDMAFL1	DMA request of DMA programming for the data flash bank for ICUM	—	group0-219	group0-125

- Blank Check Area for code flash memory

This area is used for checking that User Area or User Boot Area is blank or not. Which area(User or User Boot) to specify is selected by BLCHKSELR register. It can be accessed by 0C000000_H address offset of User Area or 04000000_H address offset of User Boot Area.

- Non-overlay Area for code flash memory

This area is mirror of User Area without remapping. It can be accessed by 04000000_H address offset of User Area. In case that remap setting (For details, refer to *Section 17, Calibration*, in the *RH850/E2x User's Manual: Emulation*) is enabled by CFU or GCFU, the data of corresponding non-secure User Area in Code Flash Memory cannot be read from bus masters via non-secure User Area. On the other hand, the data in Code Flash Memory can be read via this area without being influenced by CFU/GCFU setting.

- Blank Check Area for data flash memory

This area is used for checking that Data Area or Extended Data Area is blank or not. It can be accessed by 00200000_H address offset of Data Area or Extended Data Area.

- OTA(Over-the-Air) update support

Code Flash programming / erasure is possible while executing the user program that is stored in the User Area.

Two types of Code Flash Memory Mapping Mode are supported (Single Map Mode and Double Map Mode). For details, see **Section 43.2.1, Mapping of Code Flash Memory**.

Note that these Code Flash Memory Mapping Modes are supported only in E2UH and E2H. Code Flash Memory Mapping Mode can be selected by Option Bytes setting. For details, refer to **Section 43.11.11, OPBT10 — Option Byte 43 to 40 Bit Arrangement (E2UH/E2H Only)**.

- Single Map Mode

Hardware remapping of User Area read address is supported by GCFU. The details, see **Section 43.14, GCFU**. Two User Boot Area and Product Info Area are effective. The detailed address mapping, see **Figure 43.2**.

- Double Map Mode

Hardware swapping of address map between Code Flash Memory Banks is supported. The Code Flash Memory Banks are mapped into two areas. One is valid area and the other is invalid area. The Banks in valid area and invalid area can be swapped by Option Bytes setting. For details, refer to **Section 43.11.12, OPBT11 — Option Byte 47 to 44 Bit Arrangement (E2UH/E2H Only)**. The user program can be executed from the

banks in valid area while the banks of invalid area are being programmed / erased. Two User Boot Area and Product Info Area are effective. The detailed address mapping, see **Figure 43.3**. Note that the first 8 blocks of User Area Bank A and Bank B are 16KB units. The remaining blocks of User Area are 64KB units.

43.2 Structure of Memory

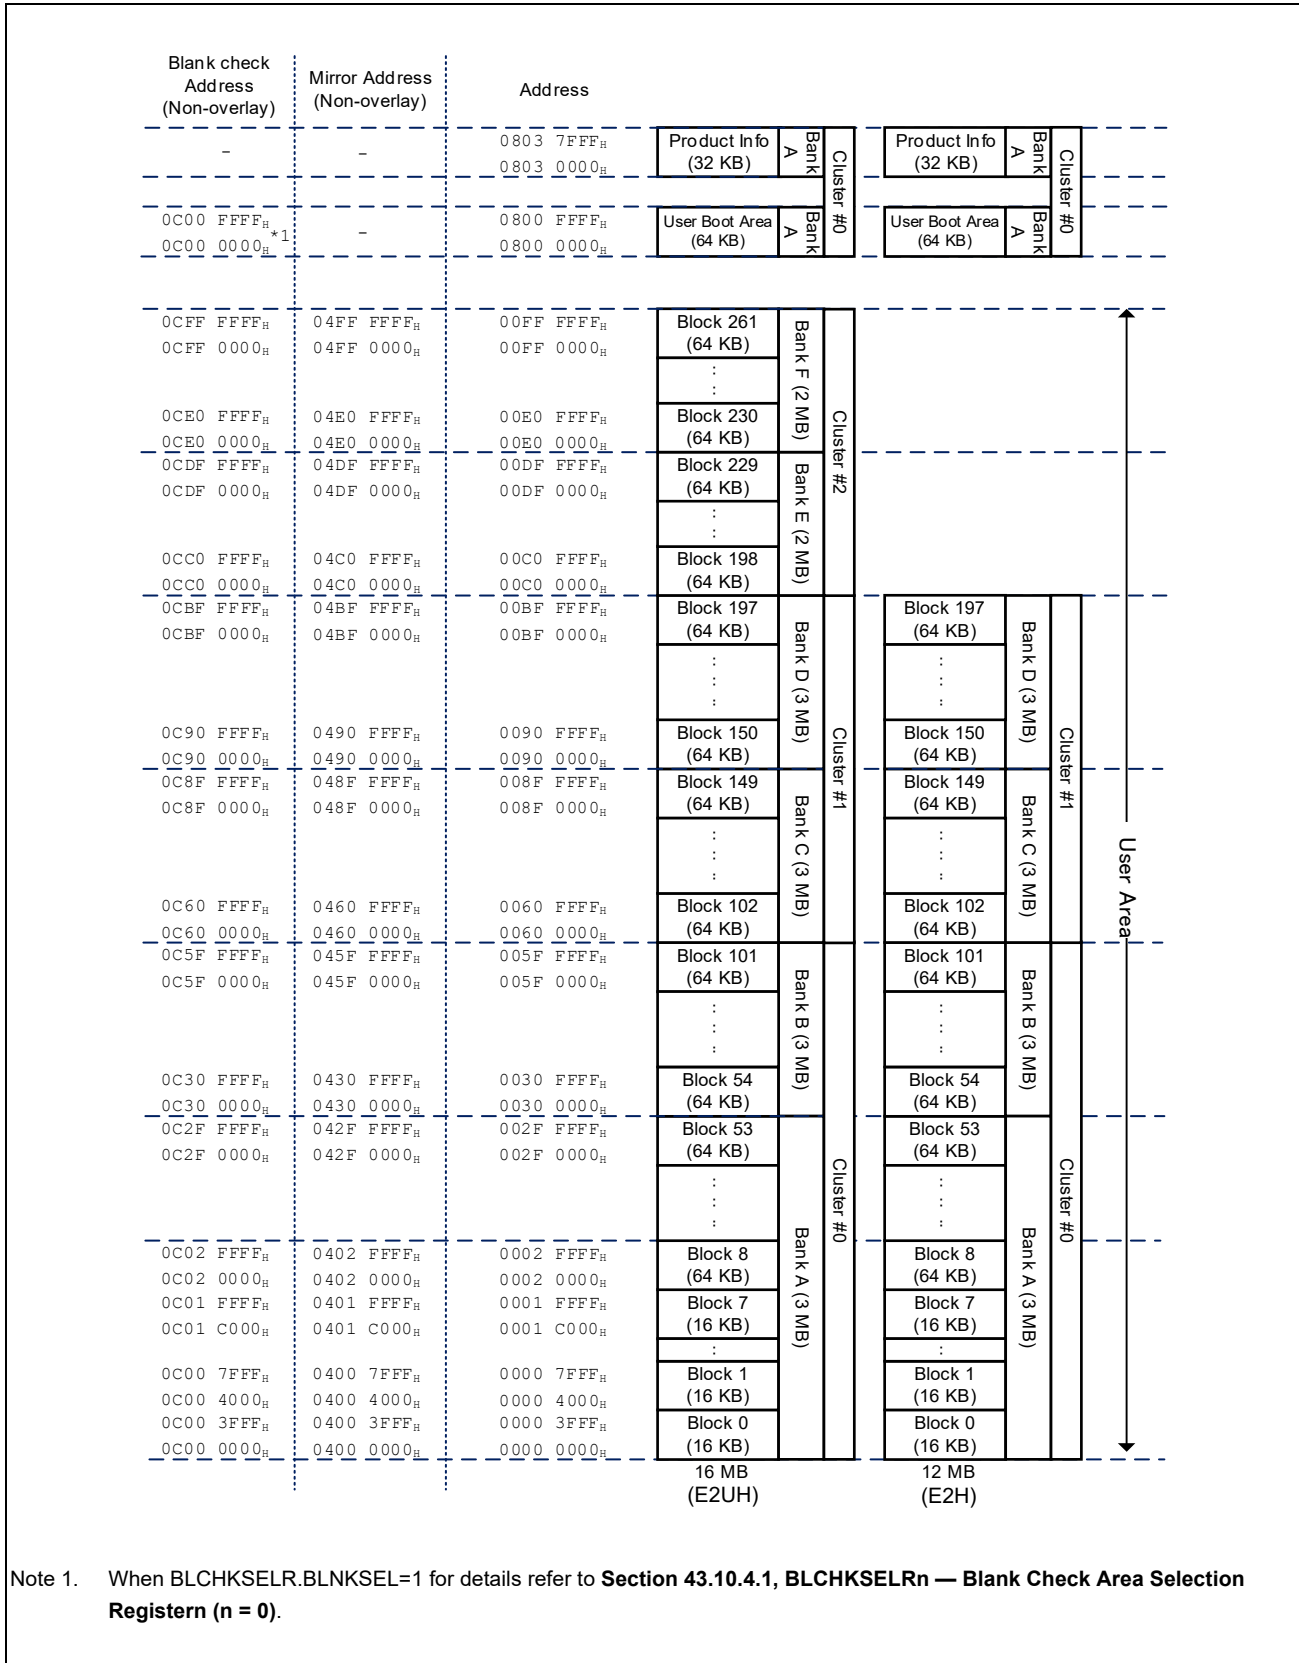

Table 43.2 gives information on all of these areas.

Table 43.2 Area on the Flash Memory

Area	Address	Peripheral Group
User Area (code flash)	See Figure 43.1, Mapping of Code Flash Memory of Each FCC2 Products See Figure 43.2, Mapping of Code Flash Memory in Single Map Mode See Figure 43.3, Mapping of Code Flash Memory in Double Map Mode	—
User Boot Area (code flash)	See Figure 43.1, Mapping of Code Flash Memory of Each FCC2 Products See Figure 43.2, Mapping of Code Flash Memory in Single Map Mode See Figure 43.3, Mapping of Code Flash Memory in Double Map Mode	—
Product Info Area (code flash)	See Figure 43.1, Mapping of Code Flash Memory of Each FCC2 Products See Figure 43.2, Mapping of Code Flash Memory in Single Map Mode See Figure 43.3, Mapping of Code Flash Memory in Double Map Mode	—
Data Area (data flash)	See Figure 43.4, Mapping of Data Flash Memory	1
Security Setting Area (Flash Extra Area)	See Figure 43.5, Mapping of Flash Extra Area	1
Extended Data Area (Flash Extra Area)	See Figure 43.5, Mapping of Flash Extra Area	1
Configuration Setting Area (Flash Extra Area)	See Figure 43.5, Mapping of Flash Extra Area	1
Block Protection Area (Flash Extra Area)	See Figure 43.5, Mapping of Flash Extra Area	1

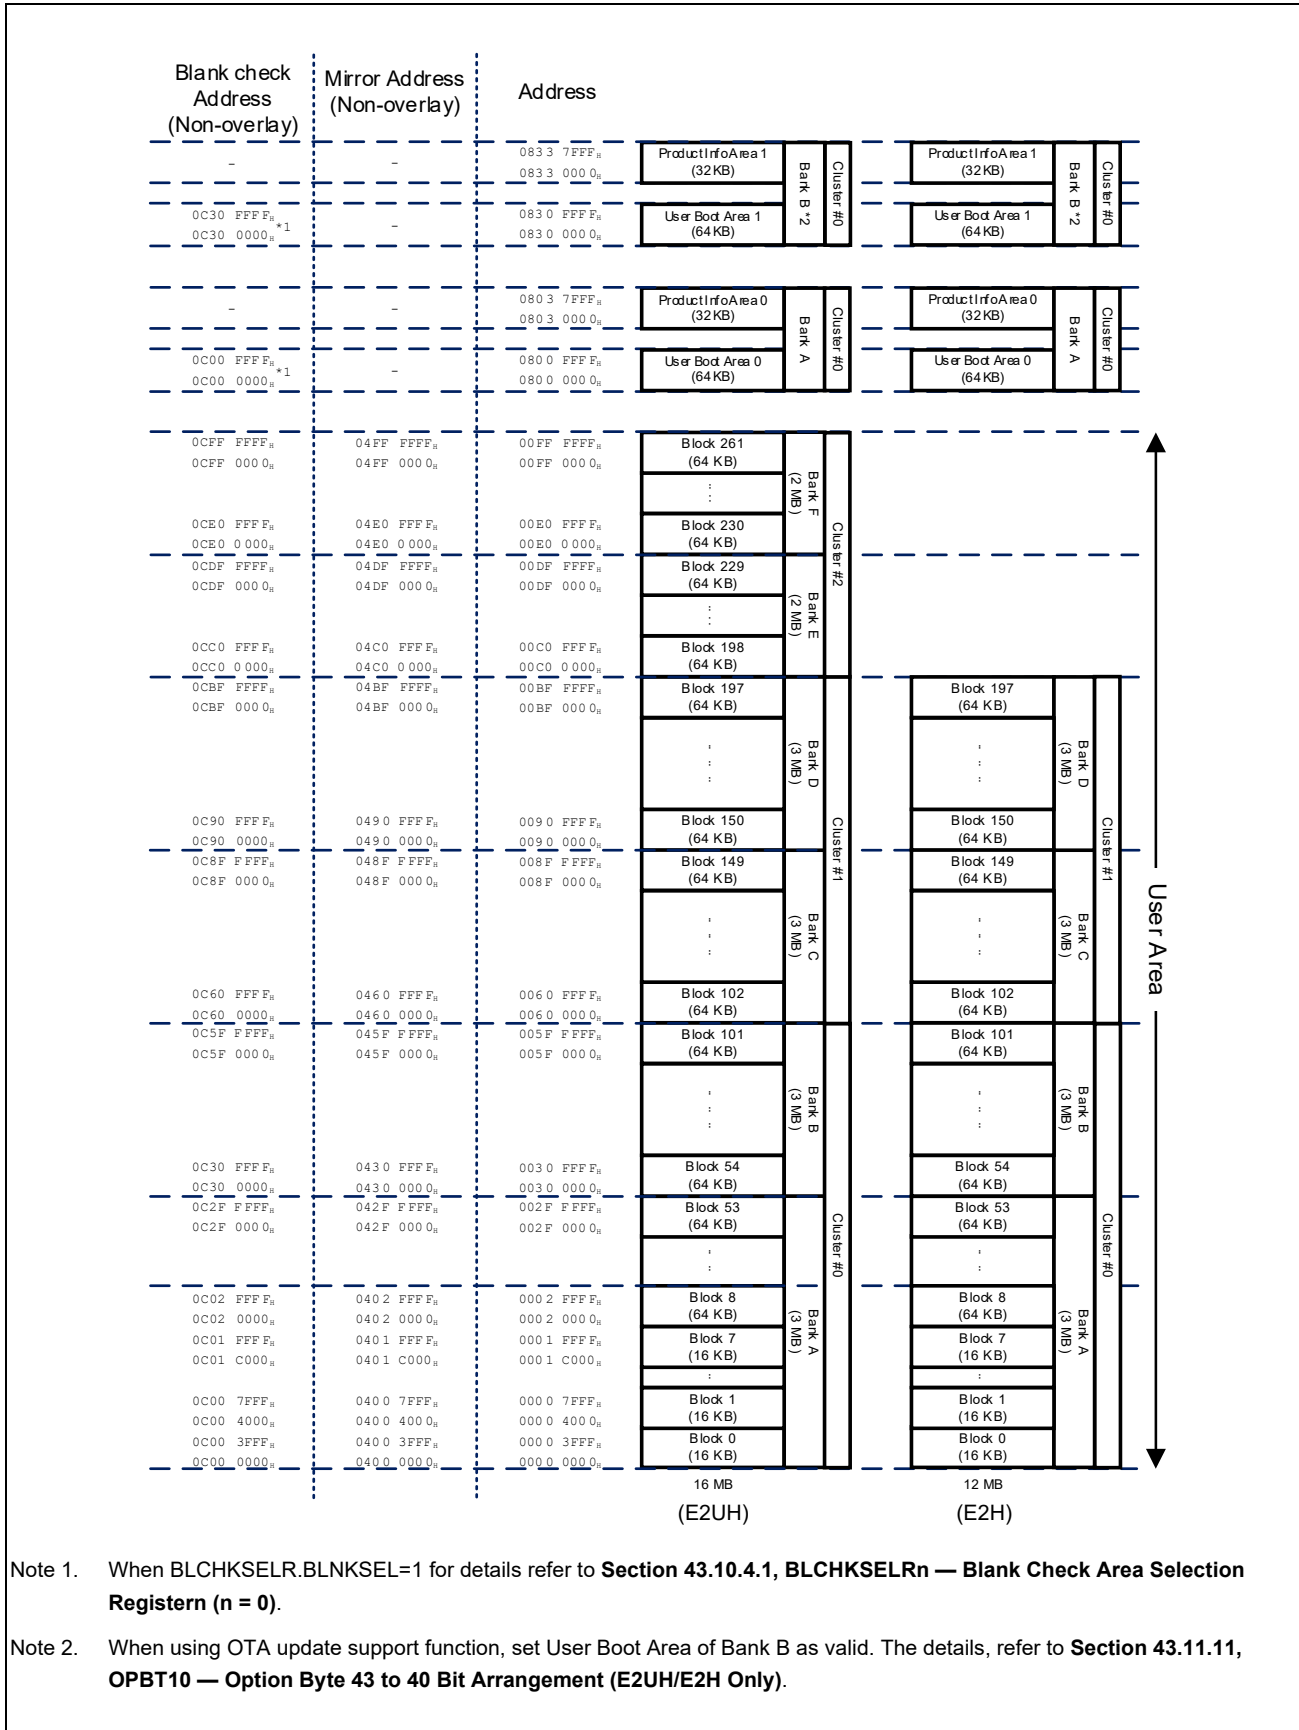

43.2.1 Mapping of Code Flash Memory

Figure 43.1 illustrates the mapping of the code flash memory for the 16-MB (E2x-FCC2 for E2UH) and 12-MB (E2x-FCC2 for E2H) device. **Figure 43.2** illustrates the mapping of the code flash memory for the 16-MB (E2UH) and 12-MB (E2H) device at the Single Map Mode. **Figure 43.3** illustrates the mapping of the code flash memory for the 16-MB (E2UH) and 12-MB (E2H) device at the Double Map Mode. The user area in the code flash memory of this product is divided into 16- and 64-Kbyte blocks, which can be erased individually. A single block of 64-Kbyte user boot area is also incorporated. The user area can be used to store the user program. For details about the access to each bank, see **Section 43.8.2, Parallel Access to the Code Flash Memory**. The user boot area can be used to store a non-rewritable boot program during user program operation, such as a boot program for rewriting code flash memory through a selected user interface. The Product Info Area stores Product information. (See **Section 43.10.3, Registers Related to Product Information**) This area is not rewritable. The BGO condition is same as User Area / User Boot Area of same bank.

Note 1. When BLCHKSELR.BLNKSEL=1 for details refer to Section 43.10.4.1, BLCHKSELRn — Blank Check Area Selection Register (n = 0).

Figure 43.1 Mapping of Code Flash Memory of Each FCC2 Products

- Note 1. When BLCHKSEL.R.BLNKSEL=1 for details refer to Section 43.10.4.1, BLCHKSEL_{Rn} — Blank Check Area Selection Register (n = 0).
- Note 2. When using OTA update support function, set User Boot Area of Bank B as valid. The details, refer to Section 43.11.11, OPBT10 — Option Byte 43 to 40 Bit Arrangement (E2UH/E2H Only).

Figure 43.2 Mapping of Code Flash Memory in Single Map Mode

- Note 1. When BLCHKSEL.R.BLNKSEL=1 for details refer to **Section 43.10.4.1, BLCHKSEL_n — Blank Check Area Selection Register (n = 0)**.
- Note 2. The bank of valid area can be swapped by each cluster with Option Bytes setting for details refer to **Section 43.11.12, OPBT11 — Option Byte 47 to 44 Bit Arrangement (E2UH/E2H Only)**.

Figure 43.3 Mapping of Code Flash Memory in Double Map Mode

Table 43.3, Table 43.4, Table 43.5, and Table 43.6 show Base address of Product Info Area in each Code Flash Memory Map Mode. Note that Code Flash Memory Mapping Modes of Single Map Mode and Double Map Mode are supported only in E2UH and E2H.

43.2.2 Mapping of Data Flash Memory

The data area of the data flash memory in this product is divided into 4K-byte blocks, with each being a unit for erasure.

Figure 43.4 shows data flash memory map.

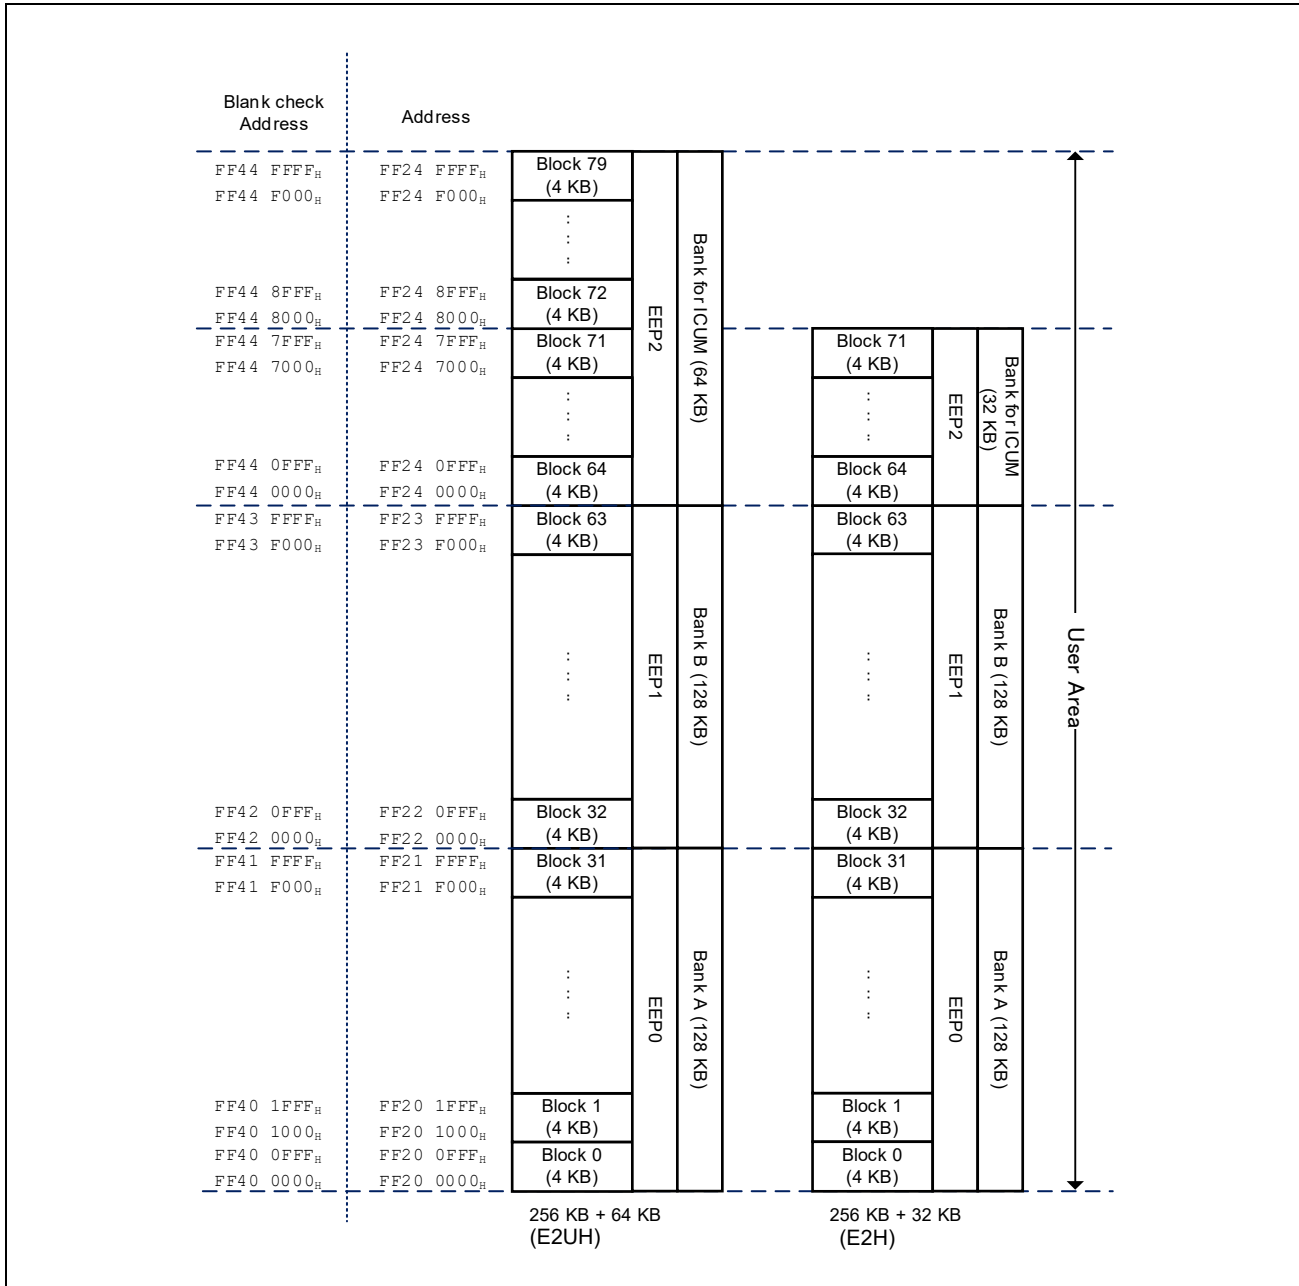

Figure 43.4 Mapping of Data Flash Memory

43.2.3 Mapping of Flash Extra Area

Flash Extra Area in this product has 4 of areas (Configuration Setting Area, Extended Data Area, Security Setting Area and Block Protection Area).

- For Security Setting Area, refer to **Section 44.6, Security Settings Area**.
- For Extended Data Area, refer to **Section 43.13, Extended Data Area**.
- For Configuration Setting Area, refer to **Section 43.11, Configuration Setting Area (Option Bytes, Reset Vector)**.
- For Block Protection Area, refer to **Section 44.5.1, Block Protection Function** and **Section 44.5.2, OTP (One Time Programming) Function**.

Each Extra Area supports the exclusive rewriting command (32-byte rewriting or 4-byte rewriting).

Each Extra Area can be set OTP (One Time Programming) by 4bytes unit.

Figure 43.5 shows Extra Area memory map. This area is placed in the data flash memory.

The condition of BGO, see **Table 43.13, Conditions under which Background Operation is Usable**.

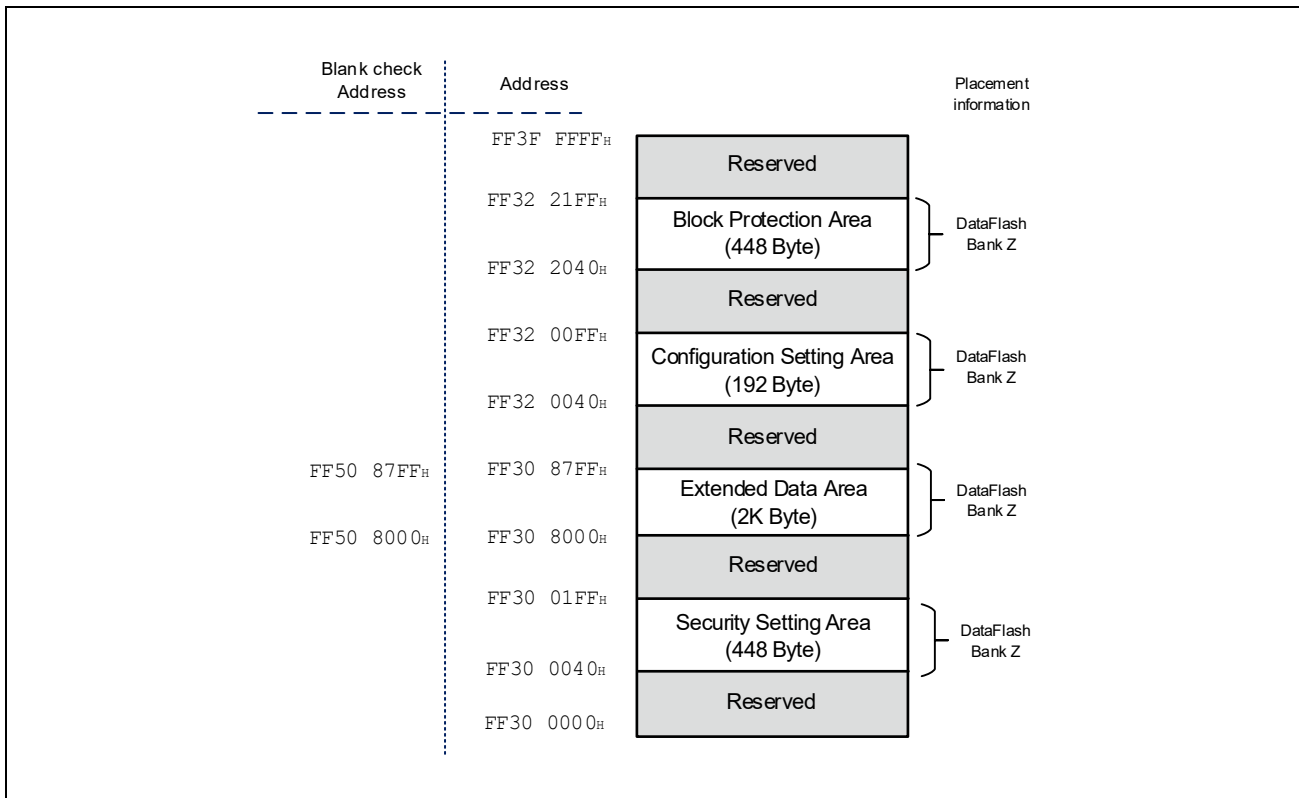

Figure 43.5 Mapping of Flash Extra Area

43.2.4 Examples of the Chip Writing

Set OTP after programming target data, because OTP setting becomes effective without reset.

The figure below is an example of the chip writing.

Figure 43.6 shows the examples of the chip writing.

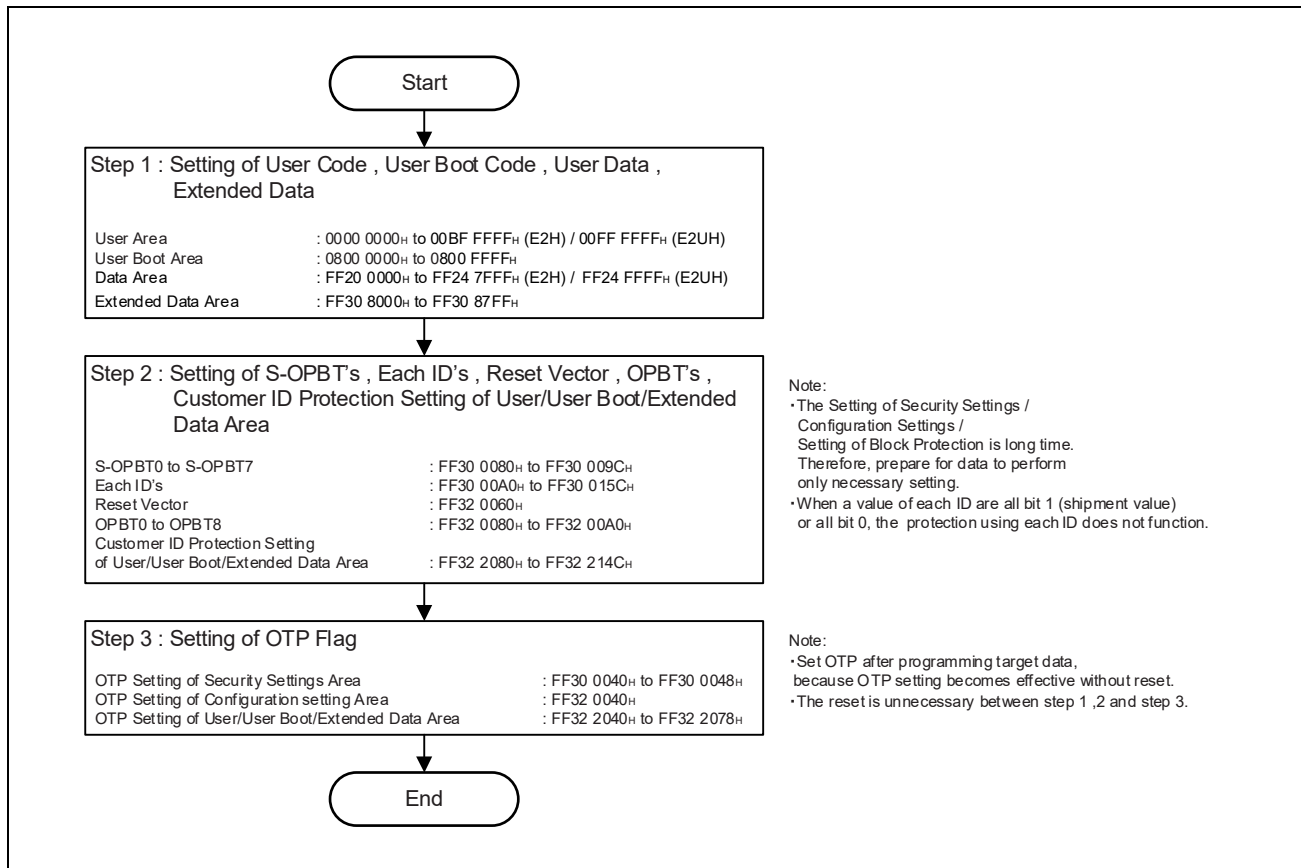

Figure 43.6 Examples of the Chip Writing (E2x-FCC2 for E2UH / E2H) (1/3)

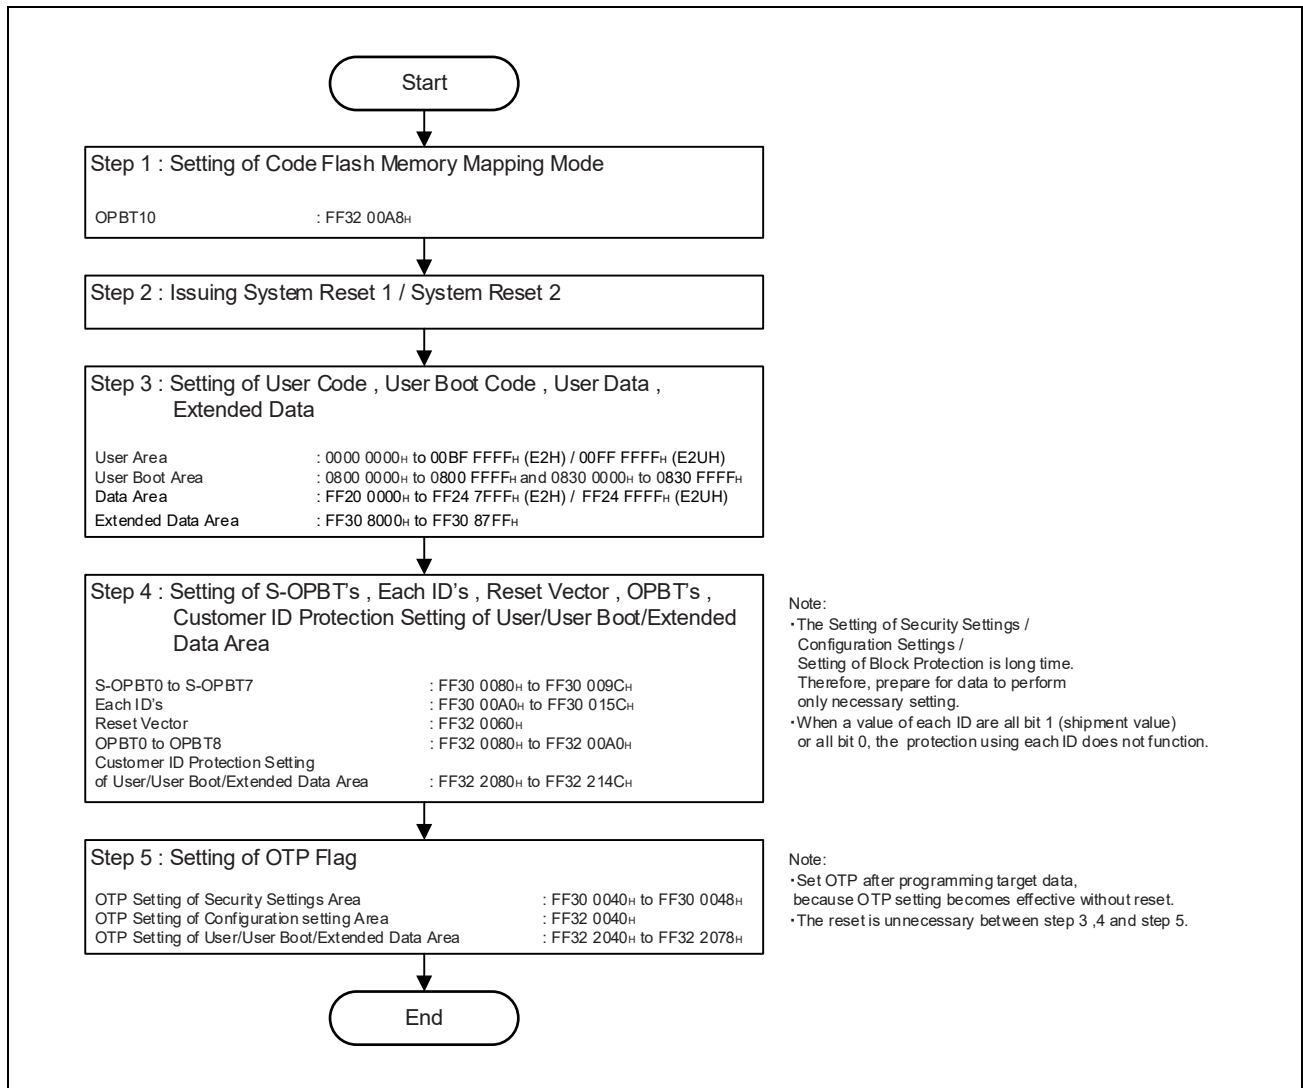

Figure 43.6 Examples of the Chip Writing (E2UH / E2H in Single Map Mode) (2/3)

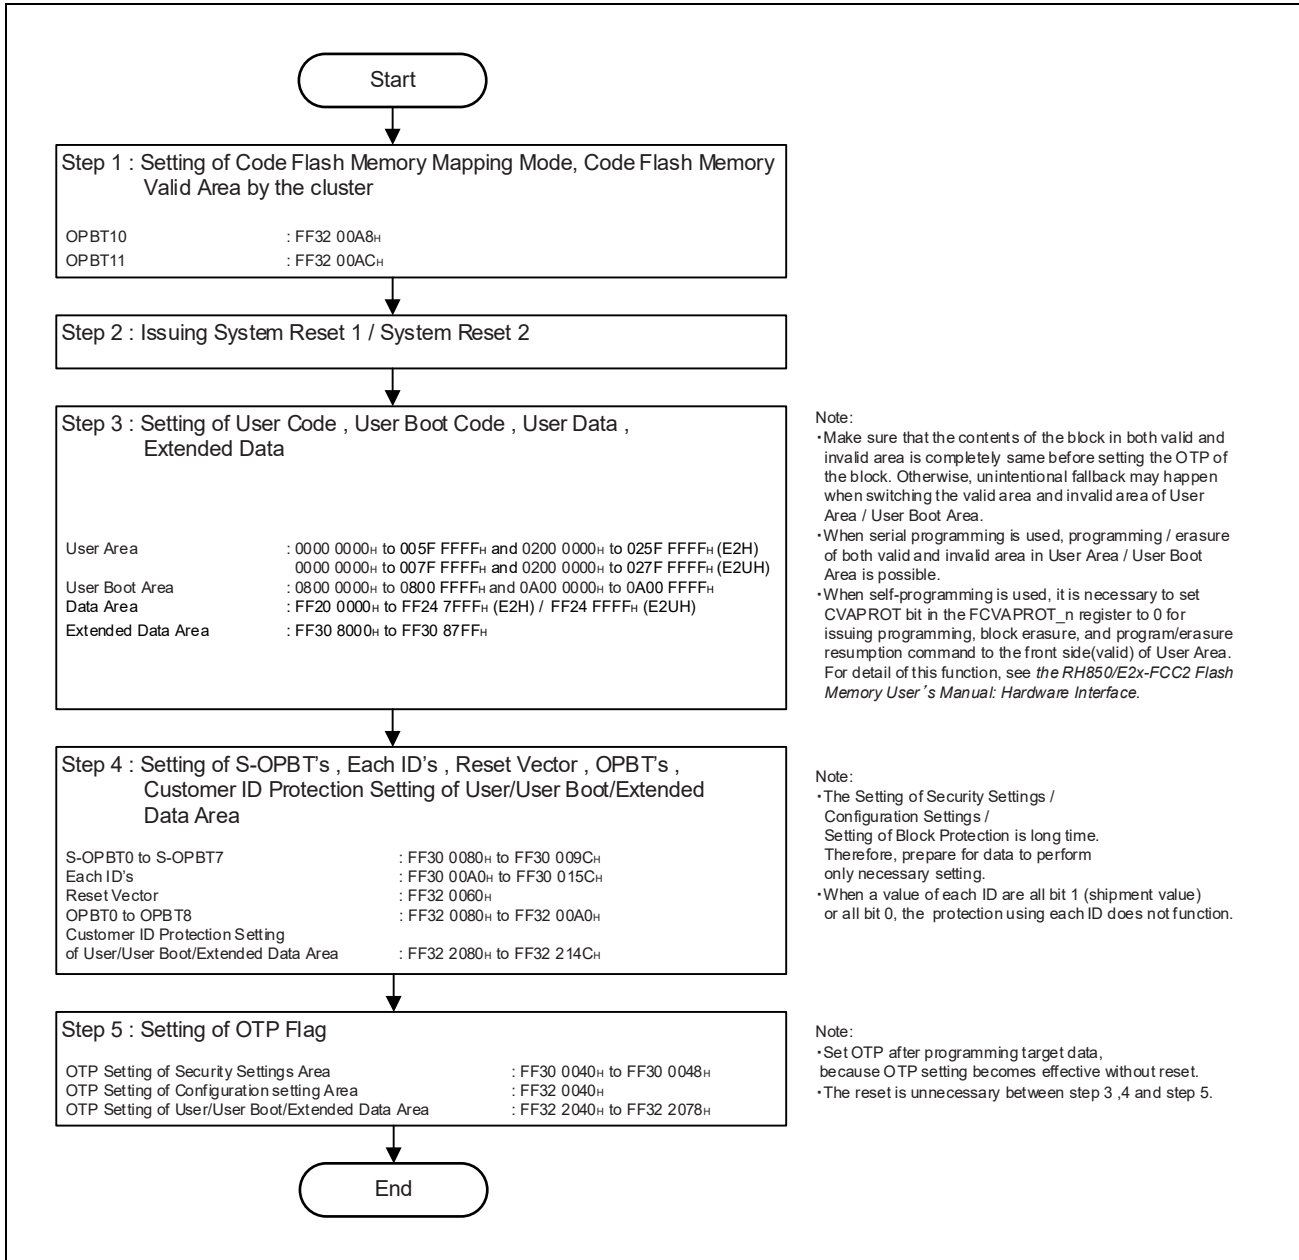

Figure 43.6 Examples of the Chip Writing (E2UH / E2H in Double Map Mode) (3/3)

43.2.5 Examples of User Program Update Procedure in the Field

The figure below is an example of user program update procedure in the field using hardware swapping in Double Map Mode.

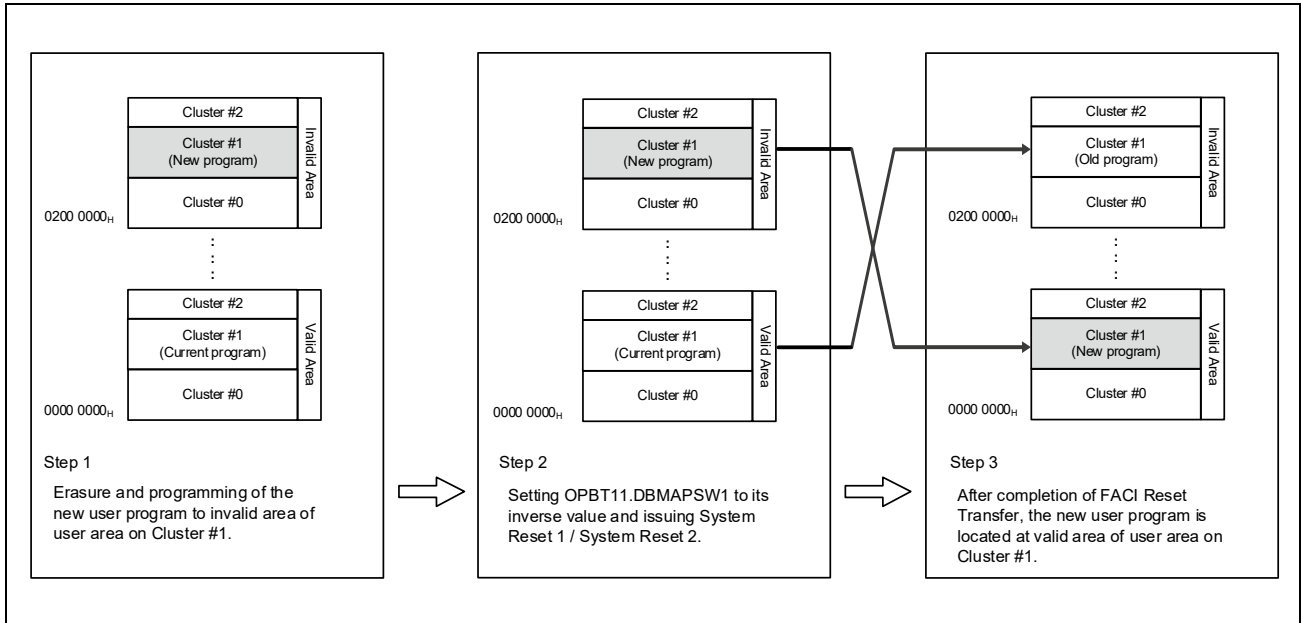

Figure 43.7 Example of User Program Update Procedure in the Field (In case of Update user area on Cluster#1(Bank C/D))

43.3 Operating Modes Associated with Flash Memory

Figure 43.8 is a diagram of the mode transitions associated with the flash memory. For the procedures for setting the modes, refer to Section 5, Operating Modes.

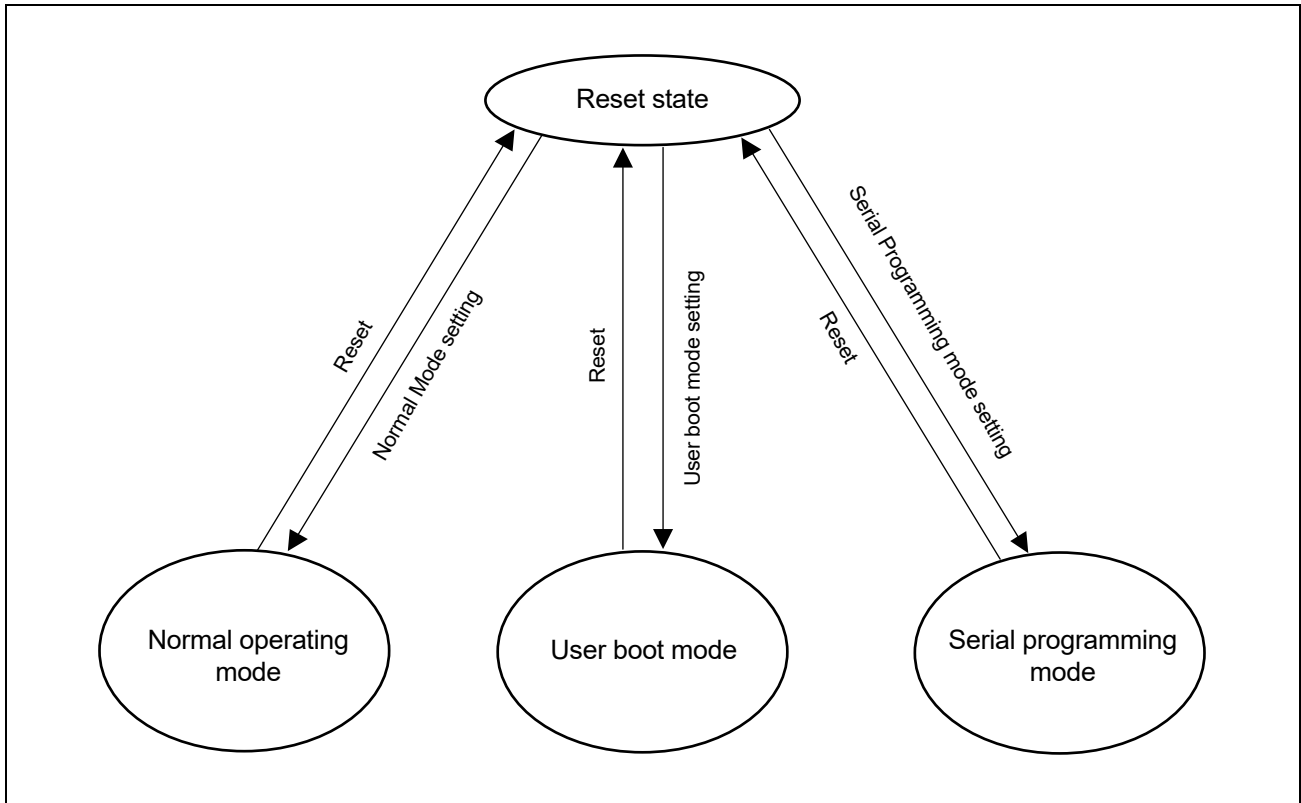

Figure 43.8 Mode Transition Associated with Flash Memory

Table 43.7 shows the flash memory area which is programmable and erasable in each mode and the boot program after reset release.

Table 43.7 Programmable and Erasable Area in Each Mode and the Boot Program after Reset Release

Item	Normal Operating Mode	User Boot Mode	Serial Programming Mode
Programmable and erasable area	<ul style="list-style-type: none"> User area Data area 	<ul style="list-style-type: none"> User area Data area 	<ul style="list-style-type: none"> User area User boot area Data area
Boot program after reset release	Program in user area (Changeable by using the variable reset vector)	Program in user boot area	Boot Firmware program for serial programming

43.4 Functional Overview

The flash memory of this device can be updated via a serial interface by a dedicated flash memory programmer (serial programming), before being mounted on the target system or on a flash adapter system.

When using CAN-FD/CAN interface for a connection with flash memory programmer, it's possible to forward a user program for rewriting to internal RAM and start.

Furthermore, security functions to prohibit updating of the user program written in the flash memory are incorporated, and this can prevent tampering by third parties.

Programming by the user program (self-programming) is suited for applications where the target system program may require updating after deployed to the end user. Protection features for the safe rewriting of the flash memory are also incorporated. Furthermore, interrupt processing during self-programming is supported, so programming can proceed at the same time as external communications, etc., and this allows programming under various conditions.

Table 43.8 gives an overview of the methods of programming and the corresponding operating modes.

Table 43.8 Methods of Programming

Method of Programming	Overview of Functionality	Operating Mode
Serial programming	<p>A dedicated flash-memory programmer allows on-board programming the flash memory after the device is mounted on the target system.</p> <p>A dedicated flash memory programmer and dedicated programming adapter board allow off-board programming of the flash memory, i.e. programming of the device before it is mounted on the target system.</p>	Serial programming mode
Self-programming	<p>The user program that is written to code flash memory in advance by serial programming executing also allows updating the flash memory.</p> <p>When data flash memory is being programmed with self-programming, the BGO function enables instruction fetch and data read from code flash memory. Thus, data flash memory can be programmed by executing a program on code flash memory prepared for flash programming.</p> <p>When code flash memory is being programmed with self-programming, instruction fetch and data read from code flash memory for a bank during the programming are prohibited. This programming needs to be carried out by executing a program prepared for flash programming that has been transferred to the Cluster-RAM or the Local-RAM in advance or a program on a different bank.</p>	Normal operating mode, User boot mode

When executing self-programming, see *the RH850/E2x Flash Memory User's Manual: Hardware Interface* which this product targets.

Table 43.9 lists the functions of the on-chip flash memory. Dedicated flash memory programmer commands enable serial programming, while reading of the on-chip flash memory by interface operation of flash memory or the user program enables self-programming.

Table 43.9 Basic Functions at a Glance

Function	Description in Overview	Level of Support (✓: Supported, x: Not Supported)	
		Serial Programming	Self-Programming
Blank checking	This is used to check a specified block to ensure that writing to it has not already proceeded. Results of reading from code flash memory and data flash memory to which nothing has been written after erasure are not guaranteed, so use blank checking to confirm that writing to memory has not proceeded after erasure.	✓	✓
Block erasure	This is for erasing the contents of a specified block of memory.	✓	✓
Programming	This is for writing to a specified address.	✓	✓
Reading	Data that have been written to the flash memory are read out.	✓	✓
Setting of Security Settings (Setting an ID Codes)	Security Settings (ID codes, Debugger connection prohibited setting, etc.) are set and the security is made effective. An ID setting is made for use in controlling the connection of a dedicated flash memory programmer for serial programming, controlling of the on-chip debugger, and etc. Refer to Section 44, Basic Hardware Protection (BHP) for Security settings.	✓	✓
Setting of Block Protection	A specified block of code flash memory is set for Customer ID Protection Setting and OTP (one-time programming). (OTP can only be set, that is, it is not possible to release a block's OTP setting). Refer to Section 44, Basic Hardware Protection (BHP) for settings.	✓	✓
Setting of Configuration Settings	Configuration Settings (Option bytes, Reset Vector, etc.) are set to change them from the initial values for this product.	✓	✓
CAN-FD/CAN Bootstrap	Transfer user program by CAN-FD/CAN interface to internal RAM, and execute the program.	✓	x

For details on serial programming, refer to *the Renesas Flash Programmer Flash Programming Software User's Manual*.

For details on self-programming, refer to *the RH850/E2x Flash Memory User's Manual: Hardware Interface* which this product targets.

The on-chip flash memory supports various security functions.

Setting of OTP and authentication of the ID code are security functions for use with serial programming and self-programming.

In serial programming, authentication of the ID code, and prohibiting connection of a dedicated flash memory programmer are available for use as security functions.

Table 43.10 lists security functions that are supported by the on-chip flash memory and **Table 43.11** lists Available Operations and Security Settings. Security Settings is established in the Security Setting Area. For Security Settings, refer to **Section 44, Basic Hardware Protection (BHP)**.

Table 43.10 Summary of Security Functions

Function	Description
OTP	OTP can be individually set for each block of the user area and the user boot area of code flash memory. When the OTP setting is made for an area, programming by serial programming and by self programming is prohibited. Once set, the OTP setting cannot be released.
ID authentication	The result of ID authentication can be used to control the connection of a dedicated flash memory programmer for serial programming. The result of ID authentication can also be used to control enabling of code flash memory and data flash memory writing by self-programming.
Prohibition of connection of a dedicated flash memory programmer	The connection of a dedicated flash memory programmer for serial programming is prohibited.

Table 43.11 Available Operations and Security Settings

Function	All Security Settings and Erasure, Programming, and Read Operations (✓: Executable, ×: Not Executable, —: Not Supported)		Point for Caution Regarding the Security Setting	
	Serial Programming	Self Programming	Serial Programming	Self Programming
OTP	<ul style="list-style-type: none"> • Areas for which OTP is set – Block erasure commands: × – Programming commands: × – Read commands: ✓ • Areas for which OTP is not set – Block erasure commands: ✓ – Programming commands: ✓ – Read commands: ✓ 	<ul style="list-style-type: none"> • Areas for which OTP is set – Block erasure: × – Programming: × – Reading: ✓ • Areas for which OTP is not set – Block erasure: ✓ – Programming: ✓ – Reading: ✓ 	The OTP setting cannot be released.	The OTP setting cannot be released.
ID authentication	<ul style="list-style-type: none"> • When the ID codes do not match – Block erasure commands: × – Programming commands: × – Read commands: × • When the ID codes match – Block erasure commands: ✓ – Programming commands: ✓ – Read commands: ✓ 	<ul style="list-style-type: none"> • When the ID codes do not match – Block erasure: ×*1 – Programming: ×*1 – Reading: ✓ • When the ID codes match – Block erasure: ✓ – Programming: ✓ – Reading: ✓ 	Serial programming ID authentication is always in effect.	Customer ID authentication enabled when Customer ID Protection setting bit is set. / DataFlash ID authentication enabled when DPROT bit is set.
Prohibition of the connection of a dedicated flash memory programmer	<ul style="list-style-type: none"> • Block erasure commands: × • Programming commands: × • Read commands: × 	<ul style="list-style-type: none"> • Block erasure: ✓ • Programming: ✓ • Reading: ✓ 	Since execution of the serial programming command is prohibited, initialization of the setting for prohibition is not possible.	If OTP is not set, initialization of the settings prohibited is possible after ID authentication.

Note 1. The block where protection setting was accomplished.

The on-chip flash memory supports various protection functions. **Table 43.12** lists protection functions that are supported by the on-chip flash memory.

Table 43.12 Summary of Protection Functions

Function	Description
User boot protection	Programming or erasure of the user boot area by self programming is prohibited. Programming or erasure of the user boot area by serial programming is available.
Variable reset vector	The protection settings include control of the reset vector. As shown in Figure 43.9 , after programming of a new boot program while leaving the existing boot program in place, changing the reset vector is a safe way to change to the area holding the new boot program. The areas that can be specified by using the reset vector are the user area.
Code Flash Valid area protection	Code Flash Valid area protection is function for front side(valid) of User Area in Double Map Mode. The front side(valid) of User Area can be protected from programming, block erasure, and program/erasure resumption command. Note that this protection function is supported only in E2UH and E2H. For detail of this function, see <i>the RH850/E2x-FCC2 Flash Memory User's Manual: Hardware Interface</i> .

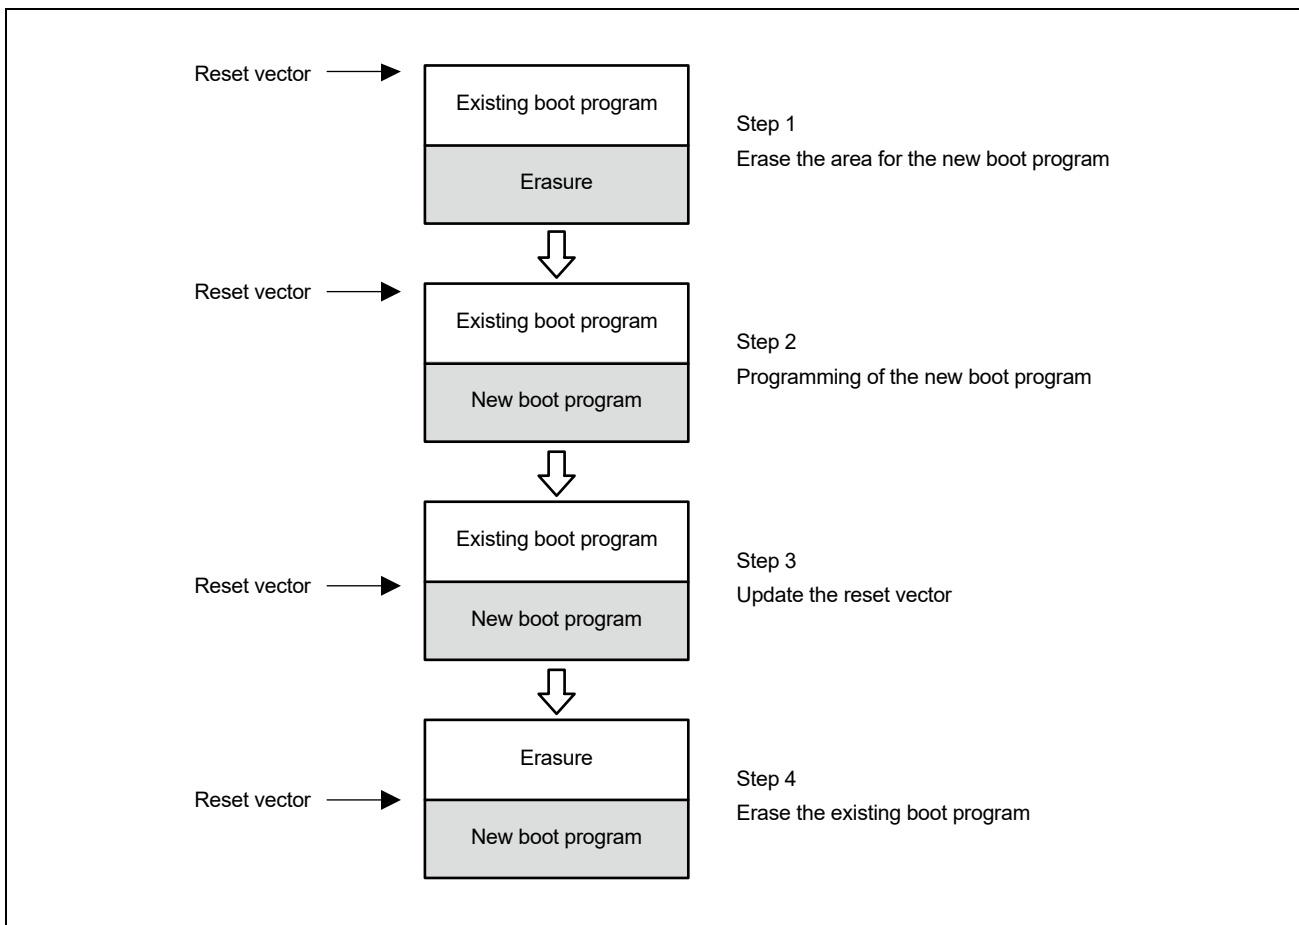

Figure 43.9 Utilizing the Variable Reset Vector Function to Update the Boot Program

43.5 Serial Programming

A dedicated flash memory programmer can be used to handle the flash memory in serial programming mode.

Serial Programming

The microcontroller is mounted on the system board at the time of serial programming. Providing a connector to the board enables handling of the target microcontroller by the flash memory programmer to proceed.

In one example, the recommended environment for programming the flash memory of the microcontroller with data is the Renesas Flash Programmer Flash Programming Software.

NOTE

For details on Renesas Flash Programmer, see *the Renesas Flash Programmer Flash Programming Software User's Manual*.

43.6 Communication Modes

43.6.1 Asynchronous Flash Programming Interface — 2-Wire UART

The double-wire asynchronous serial programming interface, 2-wire UART is connected to the flash memory programmer with the following ports.

- FPDR(TDI): Receive data input
- FPDT(TDO): Transmit data output

43.6.2 Synchronous Flash Programming Interface CSI

The synchronous serial programming interface CSI is connected to the flash memory programmer with the following ports.

- FPDR(TDI): Receive data input
- FPDT(TDO): Transmit data output
- FPCK(TCK): Serial clock input

The flash memory programmer outputs the serial data clock SCK, and the microcontroller operates as a slave.

43.6.3 CAN-FD/CAN Bootstrap

Transfer user program by CAN-FD/CAN interface to internal RAM, and execute the program. (e.g. User customized flash programming software, etc.).

CAN-FD/CAN interface is connected to the flash memory programmer with the following ports.

- CRX: P32_0, Schmitt1 input type
- CTX: P32_1, Push-pull output

Procedure summary of a CAN-FD/CAN bootstrap.

step 1: Select CAN-FD/CAN boot. (Please refer **Section 43.6.4, Selection of Communication Method**)

step 2: Boot Firmware starts, and CAN-FD/CAN communication with external flash memory programmer is established.

step 3: A user program is forwarded from external flash memory programmer to internal RAM of the microcontroller via CAN-FD/CAN interface. Boot Firmware receives a user program for flash memory rewriting and starts this.

step 4: Processing is moved from a Boot Firmware to a forwarded user program. The transfer program can not return to Boot Firmware.

43.6.4 Selection of Communication Method

In this product, communication method can be selected by pulse input to the MD0 pin (up to 5 pulses) after transition to the Serial programming mode. The MD0 pulse is generated by a dedicated flash memory programmer.

Figure 43.10 shows the relation between the number of pulses and communication method.

Figure 43.10 Selection of Communication Method

43.7 Self-Programming

43.7.1 Outline

This product supports programming of the flash memory by user program itself. The code flash and data flash memory can be programmed by using the commands of flash memory application command interface (FACI) for flash memory programming in user's applications. Therefore, update of the user program and programming of constant data fields can be possible.

When the data flash memory is programmed, the background operation facility makes it possible to execute a programming program from the code flash memory to program the data flash memory. Furthermore, the programming program can be copied to the local RAM or the cluster RAM in advance and executed to program the data flash memory.

When the code flash memory is programmed, the background operation facility makes it possible to execute a programming program from the code flash memory of a bank to program the code flash memory of other bank. Furthermore, the programming program can be copied to the local RAM or the cluster RAM in advance and executed to program the code flash memory.

For comprehensive information on flash self-programming, see *the RH850/E2x-FCC2 Flash Memory User's Manual: Hardware Interface* which this product targets.

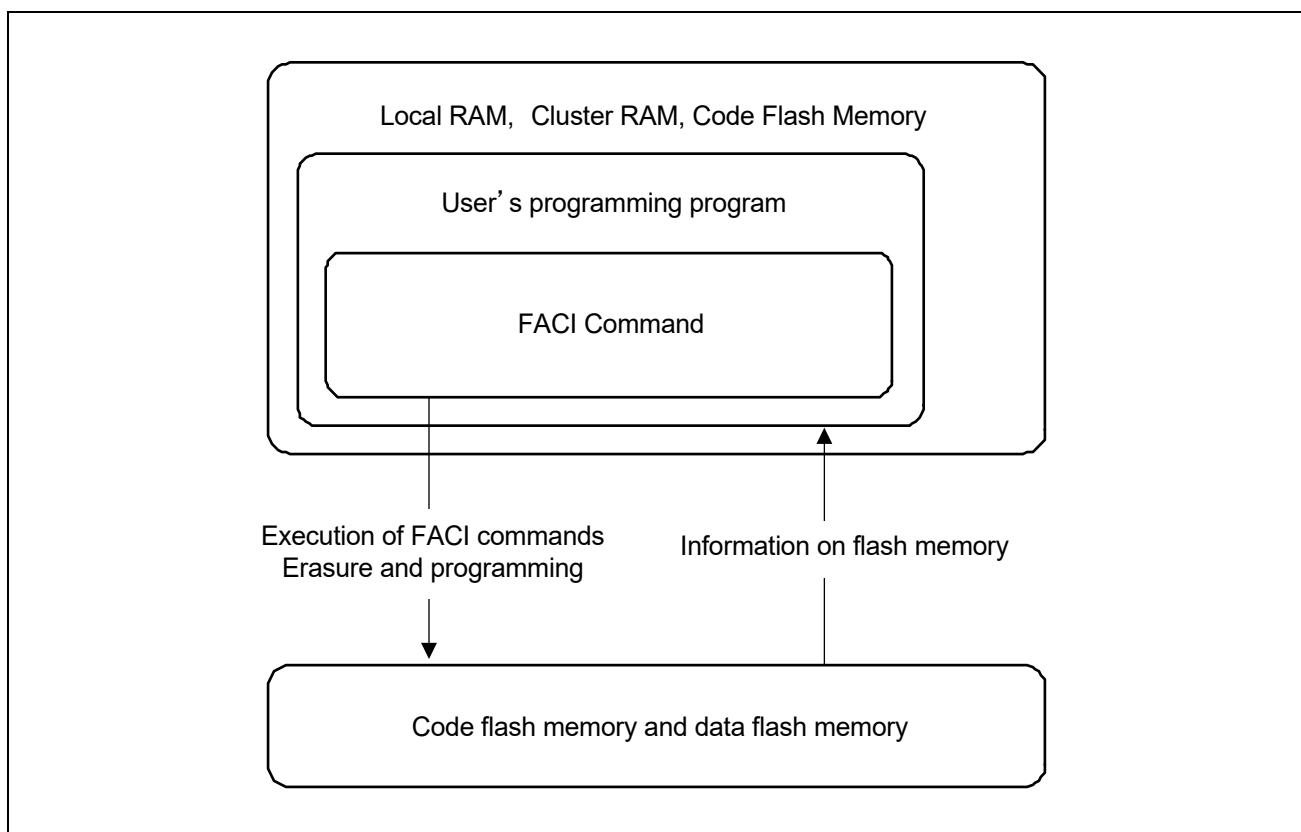

Figure 43.11 Concept of Self-Programming

43.7.2 Background Operation

Background operations can be used when the combination of the flash memory for programming/erasure and the flash memory for reading is any of those listed below.

Table 43.13 Conditions under which Background Operation is Usable

BGO Conditions		Range for Reading					
		Code Flash Bank		Data Flash Bank			
Range for Programming / Erasure		N	M	A	B	Z (Extra)	for ICUM
Code Flash Bank	N	—	Yes	Yes	Yes	—	Yes
	M (M !=N)	Yes	—	Yes	Yes	—	Yes
Data Flash Bank	A	Yes	Yes	—	Yes	—	Yes
	B	Yes	Yes	Yes	—	—	Yes
	Z (Extra)	Yes	Yes	Yes	Yes	—	Yes
	for ICUM	Yes	Yes	Yes	Yes	Yes	—

43.7.3 Dual Operation

Dual operations can be used when the combination of the flash memory for programming/erasure and the flash memory for programming / erasing is any of those listed below.

Table 43.14 Conditions under which Dual Operation is Usable

Dual Operation Conditions		Range for Programming / Erasure					
		Code Flash Bank		Data Flash Bank			
Range for Programming / Erasure		N	M	A	B	Z (Extra)	for ICUM
Code Flash Bank	N	—	—	—	—	—	Yes*1
	M (M !=N)	—	—	—	—	—	Yes*1
Data Flash Bank	A	—	—	—	—	—	Yes
	B	—	—	—	—	—	Yes
	Z (Extra)	—	—	—	—	—	Yes
	for ICUM	Yes*1	Yes*1	Yes	Yes	Yes	—

Note 1. This operation is supported only in E2UH and E2H.

43.8 Reading Flash Memory

43.8.1 Reading Code Flash Memory

Special settings are not required to read code flash memory in normal mode and user boot mode. Data can simply be read out through access to addresses in the code flash memory.

Reading from an area of code flash memory that has been erased but not yet been programmed again (i.e. that is in the non-programmed state) can lead to the detection of an ECC error and generation of the corresponding exception. Furthermore, since the values of data cannot be guaranteed when an ECC error has been generated, use blank checking when you need to confirm that an area is in the non-programmed state. See **Section 40, Functional Safety** for the details on ECC.

43.8.2 Parallel Access to the Code Flash Memory

The code flash memory is multi banked configuration. One bus master may access one bank and another bus master access other bank without a wait for arbitration of contention for the access path. The figure below is an example of parallel access to Bank A and Bank B. In case of parallel access to Bank C and Bank D, also to Bank E and Bank F are same as below.

When multiple bus masters access the same bank access is arbitrated in round-robin fashion.

Figure 43.12 Operation in Access to Banks A and B (Example)

43.8.3 Reading Data Flash Memory

Reading from an area of data flash memory that has been erased but not yet been programmed again (i.e. that is in the non-programmed state) can lead to the detection of an ECC error and reading data are all-bit 1. Use blank checking when you need to confirm that an area is in the non-programmed state.

43.9 Blank Checking Flash Memory

This product has blank check area. This area is a mirror area of the flash memory and can read address parity and ECC field written in flash memory. In addition, blank flag is set if the read object address is blank.

43.9.1 Blank Check Area of Code Flash Memory

Table 43.15 Blank Check Address of Code Flash Memory

Name	Address	Object Address	
		User Code Area*1	User Boot Area/Product Info Area*1
Blank check address of code flash memory	$0C00\ 0000_H + 20_H \times n$	$0000\ 0000_H + 20_H \times n$ to $0000\ 0000_H + 20_H \times n + 1F_H$ $n = 0, 1, 2, \dots, 524287$ for E2x-FCC2(E2UH mode) / E2UH (E2x-FCC2 Compatible Mode) $n = 0, 1, 2, \dots, 393215$ for E2x-FCC2(E2H mode) / E2H (E2x-FCC2 Compatible Mode)	$0800\ 0000_H + 20_H \times n$ to $0800\ 0000_H + 20_H \times n + 1F_H$ $n = 0, 1, 2, \dots, 2047$
Blank check address of code flash memory in Single Map Mode	$0C00\ 0000_H + 20_H \times n$	$0000\ 0000_H + 20_H \times n$ to $0000\ 0000_H + 20_H \times n + 1F_H$ $n = 0, 1, 2, \dots, 524287$ for E2UH $n = 0, 1, 2, \dots, 393215$ for E2H	$0800\ 0000_H + 20_H \times n$ to $0800\ 0000_H + 20_H \times n + 1F_H$ $n = 0, 1, 2, \dots, 2047$ for Bank A $n = 98304 + (0, 1, 2, \dots, 2047)$ for Bank B
Blank check address of code flash memory in Double Map Mode	Valid area: $0C00\ 0000_H + 20_H \times n$ Invalid area: $0E00\ 0000_H + 20_H \times n$	Valid area: $0000\ 0000_H + 20_H \times n$ to $0000\ 0000_H + 20_H \times n + 1F_H$ Invalid area: $0200\ 0000_H + 20_H \times n$ to $0200\ 0000_H + 20_H \times n + 1F_H$ $n = 0, 1, 2, \dots, 262143$ for E2UH $n = 0, 1, 2, \dots, 196607$ for E2H	Valid area: $0800\ 0000_H + 20_H \times n$ to $0800\ 0000_H + 20_H \times n + 1F_H$ Invalid area: $0A00\ 0000_H + 20_H \times n$ to $0A00\ 0000_H + 20_H \times n + 1F_H$ $n = 0, 1, 2, \dots, 2047$

Note 1. The detail of this function, see **Section 43.10.4.1, BLCHKSELrN — Blank Check Area Selection Register (n = 0)**.

Table 43.16 Blank Check of Code Flash Memory Contents

Bit Position	Bit Name	Function
31 to 16	Reserved	When read, all '0' is returned.
15	BF	Blank Flag. 0: the object address is not blank. 1: the object address is blank.
14 to 11	Reserved	When read, all '0' is returned.
10	AP	Address parity bit Address[27] and [24:5] are used for generating an address parity, and generation type is even parity. If object address is blank, AP bit is "1".
9 to 0	ECC[9:0]	ECC bits for Code Flash 256bit data. If object address is blank, all bit of ECC is "1".

43.9.2 Blank Check Area of Data Flash Memory

Table 43.17 Blank Check Address of Data Flash Memory

Name	Address	Object Address
Blank check address of data flash memory	FF40 0000 _H + 4 _H × n	FF20 0000 _H + 4 _H × n to FF20 0000 _H + 4 _H × n + 3 _H n = 0, 1, 2, ..., 81919 for E2x-FCC2(E2UH mode) / E2UH n = 0, 1, 2, ..., 73727 for E2x-FCC2(E2H mode) / E2H
Blank check address of Extended Data Area	FF50 8000 _H + 4 _H × n	FF30 8000 _H + 4 _H × n to FF30 8000 _H + 4 _H × n + 3 _H n = 0, 1, 2, ..., 511

Table 43.18 Blank Check of Data Flash Memory Contents

Bit Position	Bit Name	Function
31 to 16	Reserved	When read, all '0' is returned.
15	BF	Blank Flag. 0: the object address is not blank. 1: the object address is blank.
14 to 7	—	When read, all '0' is returned.
6 to 0	ECC[6:0]	ECC bits for Data Flash 32bit data. If object address is blank, all bit of ECC is "1".

43.10 Description of Registers

43.10.1 Register Base Address

Register base addresses are listed in the following table.

Register addresses are given as offsets from the base addresses in general.

Table 43.19 Register Base Address

Base Address Name	Base Address	Bus Group
<CCIB0_base>	FFFB 0800 _H	Peripheral Group 0
<SCDS_base>	FFCD 0000 _H	Peripheral Group 6
<SYSCTRL_base>	FF70 0000 _H	Peripheral Group 6

43.10.2 Registers Related to Write and Erase Protection of Flash Memory

Table 43.20 shows the list of registers related to write and erase protection of flash memory.

Table 43.20 Registers Related to Write and Erase Protection of Flash Memory

Unit Name	Register Name	Symbol	Address	Access Size
SYSCTRL	FHVE15 Control Register	FHVE15	<SYSCTRL_base> + 3804 _H	32
SYSCTRL	FHVE3 Control Register	FHVE3	<SYSCTRL_base> + 3800 _H	32

Table 43.21 Register Reset Conditions

Symbol	Reset Source

FHVE15	✓	✓	✓	✓	—	—
FHVE3	✓	✓	✓	✓	—	—

43.10.2.1 FHVE15 — FHVE15 Control Register

FHVE15 is a readable / writable register for software protection of flash memory against programming and erasure. Set both the FHVE15 and FHVE3 registers in the programmable and erasable state (0000 0001_H) to program or erase flash memory.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	FHVE 15CNT
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Table 43.22 FHVE15 Register Contents

Bit Position	Bit Name	Function
31 to 1	—	Reserved
0	FHVE15CNT	0: Programming / erasure / DataFlashBlankChecking are disabled. 1: Programming / erasure / DataFlashBlankChecking are enabled.

43.10.2.2 FHVE3 — FHVE3 Control Register

FHVE3 is a readable / writable register for software protection of flash memory against programming and erasure. Set both FHVE15 and FHVE3 in the programmable and erasable state (0000 0001_H) to program or erase flash memory.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	FHVE3 CNT

R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Note 1. This value is dependent on the value in the flash memory which is specified by the user.

Table 43.34 CFSWSTT Register Contents

Bit Position	Bit Name	Function
31 to 3	—	The value after reset is read.
2	DBMAPSW2	Double Map Mode Switching Status of Cluster 2 (no features at E2H) 0: Bank F is mapped in valid area. 1: Bank E is mapped in valid area.
1	DBMAPSW1	Double Map Mode Switching Status of Cluster 1 0: Bank D is mapped in valid area. 1: Bank C is mapped in valid area.
0	DBMAPSW0	Double Map Mode Switching Status of Cluster 0 0: Bank B is mapped in valid area. 1: Bank A is mapped in valid area.

43.11 Configuration Setting Area (Option Bytes, Reset Vector)

The flash memory has the extended Extra area (option bytes) to store data specified by the user for various purposes. Changes in settings such as initial setting of peripheral functions using option bytes become effective after release from the reset state. (Refer to **Section 10.3.4, FACL Reset Transfer**.) OTP setting of Configuration setting Area becomes effective without reset. **Table 43.35** shows option byte setting area. For setting and reading option bytes, see *the Renesas Flash Programmer Flash Programming Software User's Manual*, or *the RH850/E2x-FCC2 Flash Memory User's Manual: Hardware Interface*.

Table 43.35 Setting Area of Reset Vector and Option Bytes

Name	Address	Initial State of Shipped Product*1	Write Protection ID*2	Read Protection ID*3
OTP Setting of Configuration setting Area*4,*6	FF32 0040 _H	FFFF FFFF _H	—	—
Reserved	FF32 0044 _H to FF32 005C _H	FFFF FFFF _H *5	—	—
Reset Vector	FF32 0060 _H	0000 0000 _H	Customer ID	—
Reserved	FF32 0064 _H to FF32 007C _H	FFFF FFFF _H *5	Customer ID	—
Option bytes 3 to 0 (OPBT0)	FF32 0080 _H	3FFF 0010 _H	Customer ID	—
Option bytes 7 to 4 (OPBT1)	FF32 0084 _H	FFFF 0000 _H	Customer ID	—
Option bytes 11 to 8 (OPBT2)	FF32 0088 _H	FFFF FFFF _H	Customer ID	—
Option bytes 15 to 12 (OPBT3)	FF32 008C _H	C1FF FFFF _H (E2UH) F1FF FFFF _H (E2H)	Customer ID	—
Option bytes 19 to 16 (OPBT4)	FF32 0090 _H	FFFF FFFF _H	Customer ID	—
Option bytes 23 to 20 (OPBT5)	FF32 0094 _H	FFFF EFFF _H	Customer ID	—
Option bytes 27 to 24 (OPBT6)	FF32 0098 _H	FFFF FFEB _H	Customer ID	—
Option bytes 31 to 28 (OPBT7)	FF32 009C _H	FFFF 899F _H	Customer ID	—
Option bytes 35 to 32 (OPBT8)	FF32 00A0 _H	7FFF FFFF _H	Customer ID	—
Option bytes 39 to 36 (OPBT9) Reserved	FF32 00A4 _H	FFFF FFF* _H *5	Customer ID	—
Option bytes 43 to 40 (OPBT10)*7	FF32 00A8 _H	FFFF FFFF _H	Customer ID	—
Option bytes 47 to 44 (OPBT11)*7	FF32 00AC _H	FFFF FFFF _H	Customer ID	—
Option bytes 51 to 48 (OPBT12) Reserved	FF32 00B0 _H	6000 0055 _H *5	Customer ID	—
Option bytes 55 to 52 (OPBT13) Reserved	FF32 00B4 _H	6000 0056 _H *5	Customer ID	—
Option bytes 59 to 56 (OPBT14) Reserved	FF32 00B8 _H	F8DC 0101 _H *5	Customer ID	—
Option bytes 63 to 60 (OPBT15) Reserved	FF32 00BC _H	258C 0401 _H *5	Customer ID	—
Reserved	FF32 00C0 _H to FF32 00FC _H	FFFF FFFF _H *5	—	—

Note 1. This is the initial value of the shipped product. The value can be modified.

Note 2. When all bits of Customer ID are all "1" or all "0", the ID authentication is no needed to set.

Note 3. When Sub mode is OCD mode, the Customer ID authentication is needed to read.

Note 4. The detail of this function, see **Section 44, Basic Hardware Protection**.

(**Table 44.13** shows **Mapping of OTP setting for extra Area**.)

Note 5. It is prohibited to change from a read value.

Note 6. Set OTP after programming target data, because OTP setting becomes effective without reset.

Note 7. This Option Bytes is supported only in E2UH and E2H. It is prohibited to change from a read value in E2x-FCC2 because it is reserved.

43.11.1 Reset Vector PE

Customer ID authentication is needed for write this option byte. When all bits of Customer ID are all “1” or all “0”, the ID authentication is no needed to change the setting.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	OPT_RBASE[23:16]

27	VDDFLTEN	VMON configurations for VDD Enable output filter for <u>ERROROUT_M</u> and <u>VMONF</u> .*1 0: Disable output filter for <u>ERROROUT_M</u> and <u>VMONF</u> . 1: Enable output filter for <u>ERROROUT_M</u> and <u>VMONF</u> .										
26	—	Reserved (The setting value should be 1.)										
25	VDDHDE	VMON configurations for VDD VDD High voltage detection enable.*1 0: Disable VDD high voltage detection 1: Enable VDD high voltage detection										
24	VDDLDE	VMON configurations for VDD VDD Low voltage detection enable.*1 0: Disable VDD low voltage detection 1: Enable VDD low voltage detection										

Table 43.41 OPBT4 Contents (2/3)

Bit Position	Bit Name	Function
23, 22	VCCFLTW[1:0]	VMON configurations for VCC Select the minimum filtering width of digital noise filter.*1 (The minimum filtering width is given by the cycle-count of the clock selected by VCCCLKSEL1, 0.)
	VCCFLTW[1:0]	Minimum Filtering Width (Cycle)
	00	20 cycles
	01	13 cycles
	10	8 cycles
	11	3 cycles
21, 20	VCCCLKSEL[1:0]	VMON configurations for VCC Select a clock of the digital noise filter from the following clocks.*1
	VCCCLKSEL[1:0]	Clock of the Digital Filter
	00	CLK_HVIOSC frequency / 256
	01	CLK_HVIOSC frequency / 128
	10	CLK_HVIOSC frequency / 64
	11	CLK_HVIOSC frequency / 32
		CAUTION: The frequency of CLK_HVIOSC is typ. 16 MHz, min. 8 MHz.
19	VCCFLTEN	VMON configurations for VCC Enable output filter for $\overline{\text{ERROROUT_M}}$ and VMONF.*1 0: Disable output filter for $\overline{\text{ERROROUT_M}}$ and VMONF. 1: Enable output filter for $\overline{\text{ERROROUT_M}}$ and VMONF.
18	—	Reserved (The setting value should be 1.)
17	VCCHDE	VMON configurations for VCC VCC High voltage detection enable.*1 0: Disable VCC high voltage detection 1: Enable VCC high voltage detection
16	—	Reserved (The setting value should be 1.)
15, 14	EVCCFLTW[1:0]	VMON configurations for EVCC Select the minimum filtering width of digital noise filter.*1 (The minimum filtering width is given by the cycle-count of the clock selected by EVCCCLKSEL1, 0)
	EVCCFLTW[1:0]	Minimum Filtering Width (Cycle)
	00	20 cycles
	01	13 cycles
	10	8 cycles
	11	3 cycles
13, 12	EVCCCLKSEL[1:0]	VMON configurations for EVCC Select a clock of the digital noise filter from the following clocks.*1
	EVCCCLKSEL[1:0]	Clock of the Digital Filter
	00	CLK_HVIOSC frequency / 256
	01	CLK_HVIOSC frequency / 128
	10	CLK_HVIOSC frequency / 64
	11	CLK_HVIOSC frequency / 32
		CAUTION: The frequency of CLK_HVIOSC is typ. 16 MHz, min 8 MHz.
11	EVCCFLTEN	VMON configurations for EVCC Enable output filter for $\overline{\text{ERROROUT_M}}$ and VMONF.*1 0: Disable output filter for $\overline{\text{ERROROUT_M}}$ and VMONF. 1: Enable output filter for $\overline{\text{ERROROUT_M}}$ and VMONF.
10	—	Reserved (The setting value should be 1.)

Table 43.41 OPBT4 Contents (3/3)

Bit Position	Bit Name	Function
9	EVCCHDE	VMON configurations for EVCC EVCC High voltage detection enable.*1 0: Disable EVCC high voltage detection 1: Enable EVCC high voltage detection
8 to 0	—	Reserved (The setting value should be 1.)

Note 1. For details, see **Section 12.2, Primary Detection of Voltage Monitor (VMON)**.

43.11.7 OPBT5 — Option Byte 23 to 20 Bit Arrangement

Customer ID authentication is needed for write this option byte. When all bits of Customer ID are all “1” or all “0”, the ID authentication is no needed to change the setting.

For details of this OPBT5, see *the RH850/E2x ICUMD User's Manual*.

43.11.8 OPBT6 — Option Byte 27 to 24 Bit Arrangement

Customer ID authentication is needed for write this option byte. When all bits of Customer ID are all “1” or all “0”, the ID authentication is no needed to change the setting.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Note 1. This is the initial value of the shipped product. The value can be modified by setting the option bytes.

Note 2. Only when an FACI command or serial programming (ex. the Renesas Flash Programmer flash programming software) is used, setting (W) is possible.

Table 43.46 OPBT11 Contents

Bit Position	Bit Name	Function
31 to 3	—	Reserved (The setting value should be 1.)
2	DBMAPSW2	Double Map Mode Switching of Cluster 2 (no features at E2H) 0: Bank F is mapped in valid area. 1: Bank E is mapped in valid area. Set the value of valid area at the shipping in E2H.
1	DBMAPSW1	Double Map Mode Switching of Cluster 1 0: Bank D is mapped in valid area. 1: Bank C is mapped in valid area.
0	DBMAPSW0	Double Map Mode Switching of Cluster 0 0: Bank B is mapped in valid area. 1: Bank A is mapped in valid area.

Figure 43.13 Examples of DBMAPSW

43.12 Block Protection Area

The flash memory has the extended Extra area to store a data specified by the user for Code Flash OTP Settings and Code Flash Customer ID Protection Settings. These settings become effective without reset.

The detail of this function, see **Section 44, Basic Hardware Protection**.

Table 43.47 Block Protection Area

Name	Address	Initial State of Shipped Product.*1	Write/Erase Protection ID*2	Read Protection ID*3
OTP Setting of User/User Boot/Extended Data Area*4	FF32 2040 _H to FF32 2078 _H	FFFF FFFF _H	—	—
Reserved	FF32 207C _H	FFFF FFFF _H *6	—	—
Customer ID Protection Setting of User/User Boot/Extended Data Area*5	FF32 2080 _H to FF32 214C _H	FFFF FFFF _H	Customer ID	—
Reserved	FF32 2150 _H to FF32 21FC _H	FFFF FFFF _H *6	—	—

Note 1. This is the initial value of the shipped product. The value can be modified.

Note 2. When all bits of Customer ID are all "1" or all "0", the ID authentication is no needed to set.

Note 3. When Sub mode is OCD mode, the Customer ID authentication is needed to read.

Note 4. The detail of this function, see **Section 44, Basic Hardware Protection**.

Table 44.9, Table 44.10, Table 44.11 shows **Mapping of OTP setting for (User Area and User Boot Area)**.

Note 5. The detail of this function, see **Section 44, Basic Hardware Protection**.

Figure 44.2 Block Protection Function Structure and **Table 44.6, Table 44.7, Table 44.8** shows **Mapping of Block Protection Setting**.

Note 6. It is prohibited to change from a read value.

43.13 Extended Data Area

Extended Data Area is used to store any data to use by user software.

This area is 1 block of the data flash. But, protection specifications are different.

Table 43.48 Extended Data Area

Name	Address	Initial State of Shipped Product.*1	Write/Erase Protection ID*2	Read Protection ID*3
Extended Data Area	FF30 8000 _H to FF30 87FF _H	Erased	Customer ID	—

Note 1. This is the value at the shipping.

Note 2. When all bits of Customer ID are all "1" or all "0", the ID authentication is no needed to set.

Note 3. When Sub mode is OCD mode, the Customer ID authentication is needed to read.

43.14 GCFU

CAUTION

The GCFU is not supported with E2xFCC2. The GCFU mentioned in this chapter is same hardware resource as debug function "Global Calibration Function Unit(GCFU)". So when using GCFU, it should confirm the usage of GCFU for debugging and should be considered to avoid conflict of resources.

Note: For details on debugging, see the user's manual of the debugger used.

43.14.1 Features of GCFU

43.14.1.1 Number of Units and Channels

This product has the following number of GCFU units.

Table 43.49 Number of Units

RH850/E2x-FCC2 *1	
Number of Channels	0
Name	GCFU

Note 1. For details on debugging, see the user's manual of the debugger used.

Table 43.50 Number of Units

RH850/E2UH	
Number of Channels	1
Name	GCFU

Table 43.51 Number of Units

RH850/E2H	
Number of Channels	1
Name	GCFU

43.14.1.2 Register Base Address

Table 43.52 Register Base Address

Base Address Name	Base Address	Bus Group
<GCFU_base>	FFFB 1400 _H	Peripheral Group 0

43.14.1.3 Clock Supply

The clocks supplied to the GCFU are listed in the following table.

Table 43.53 Clock Supply

Unit Name	Unit Clock Name	Supply Clock Name
GCFU	PCLK	CLK_HBUS

43.14.1.4 Interrupt Requests

Interrupt requests is None.

43.14.1.5 Reset Sources

Table 43.54 Reset Sources

Unit Name	Register Name	Reset Condition					
		Power Up Reset	System Reset 1	System Reset 2	Application Reset	Module Reset	JTAG Reset
GCFU	All registers	✓	✓ *1	✓ *1	✓ *1	—	—

Note 1. When debugging tools are used, initialization of the debug registers by system reset may be protected so that debugging can be performed at system reset assertion by debug setting. Protect debugging Registers (Reset mask function).
For details on debugging, see the user's manual of the debugger used.

43.14.2 Overview

43.14.2.1 Functional Overview

The GCFU is a function unit to remap address of flash memory area to another address.

- Number of blocks

This function unit allows setting of up to 32 blocks of independent address conversion information.

- Block size

This function can be set from 8 KB to 1024KB as the size of target blocks.

- Target area

This function can be used to enable or disable mapping for the code flash memory to the desired areas of the code flash memory area (up to 32 block areas). User Area can be set to source address. An address of code flash which is different from a source address of the code flash can be set to a destination address.

NOTE

- The addresses are replaced without distinction made between instruction fetch and data access.
 - The accesses from ICUM is out of address conversion target.
 - The accesses from flash memory application command interface (FACI) for flash memory programming in user's applications is out of address conversion target.
-

- Cache clear request output

Each time the mapping setting is updated, a cache clear request is output for the cache following acquisition of the flash memory bus use right.

As a result, coherency is maintained between the memory contents of the flash memory and cache.

43.14.3 Registers

This section lists function registers (data registers) which control operation of the GCFU.

43.14.3.1 List of Register

GCFU registers are given as offsets from the base address <GCFU_base>.

The GCFU has the registers listed in **Table 43.5**.

Table 43.55 List of Registers (1/2)

Module Name	Register Name	Symbol	Address	Access Size	Access Protection
GCFU	Memory Mapping Enable Register	TM_ME	<GCFU_base> +10 _H	32	—
	Memory Mapping Status Register	TM_MS	<GCFU_base> +14 _H	32	—
	Memory Mapping Size Configuration Register 0	TM_SZC0	<GCFU_base> +30 _H	32	—
	Memory Mapping Size Configuration Register 1	TM_SZC1	<GCFU_base> +34 _H	32	—

43.14.3.2 TM_ME — Memory Mapping Enable Register

The memory mapping enable register is used to control the address conversion function by memory mapping setting.

This register can be read or written in 32-bit units.

NOTES

- Cache clear request is executed by update of mapping enable bit (TMEn) (not including update to the same value (without changing value)) (n = 0 to 31).
- Before updating memory mapping source address register n (TM_MSA_n register) as well as memory mapping destination address register n (TM_MDAn register), be sure to set the corresponding mapping enable bit TMEn to 0 (mapping disabled) (n = 0 to 31).
- Following TM_ME register update, be sure to wait until the read value of the TM_MS register becomes the same as the value set to the TM_ME register (until the mapping setting set to the TM_ME register is actually applied).
- After the mapping enable bit TMEn is updated, the following processing is automatically executed and the mapping setting of each block is actually switched.
 - (1) When the mapping enable bit TMEn (n = 0 to 31) is updated, the GCFU requests the flash memory bus use right from the flash arbiter.
 - (2) After acquiring the flash memory bus use right, the GCFU switches the mapping settings of all blocks.
 - (3) The GCFU requests cache clear (for maintaining data coherency between the flash memory and the cache).
 - (4) The GCFU releases the flash memory bus use right.
- The mapping setting of each block is switched independently of the CPU's instruction execution sequence.

43.14.3.3 TM_MS — Memory Mapping Status Register

The memory mapping status register is used to indicate the mapping state of memory mapping blocks 00 to 31.

This register can only be read in 32-bit units.

NOTE

Following TM_ME register update, be sure to wait until the read value of the TM_MS register becomes the same as the value set to the TM_ME register (until the mapping setting set to the TM_ME register is actually applied).

43.14.3.4 TM_SZC 0 to 3 — Memory Mapping Size Configuration Registers 0 to 3

The memory mapping size configuration registers are used to set the mapping size of memory mapping blocks 00 to 31.

These registers can be read or written in 32-bit units.

NOTES

1. Be sure to set the memory mapping size configuration registers before using.
2. Each entry (blocks 00 to 31) can be mapped only in mapping size alignment units.
3. Setting mapping sizes that exceed the implementation size is prohibited (the operation is not guaranteed).
4. Before updating the memory mapping size configuration registers (TM_SZC0 to 3 registers), be sure to set the corresponding mapping enable bit TME_n to 0 (mapping disabled) (n = 0 to 31).
5. The mapping size setting of each block is switched independently of the CPU's instruction execution sequence.

43.14.3.5 TM_MSA 00 to 31 — Memory Mapping Source Address Registers 00 to 31

Memory mapping source address registers 00 to 31 are used to set the addresses of the flash area.

Any address ranges in the flash area (up to 32 areas) can be set. The address specified with memory mapping source address register n is replaced with the address specified with memory mapping destination address register n (TM_MDAn).

The address range to be mapped can be specified from 8 KB/block to 1024KB/block.

Up to 32 blocks can be specified.

These registers can be read or written in 32-bit units.

NOTES

- Before updating memory mapping source address register n (TM_MSA_n register), be sure to set the corresponding mapping enable bit TM_ME.TME_n to 0 (mapping disabled). (n = 0 to 31)
- Do not overlap mapping setting (source area) of the mapping enabled blocks. The operation is not guaranteed if mapping setting of the mapping enabled blocks are overlapped.

Value after reset: 0000 0000 _H

43.14.3.6 TM_MDA 00 to 31 — Memory Mapping Destination Address Registers 00 to 31

Memory mapping destination address registers 00 to 31 are used to set the addresses.

Any address ranges in the flash area (up to 32 areas) can be set. The address specified with memory mapping source address register n is replaced with the address specified with memory mapping destination address register n (TM_MDA n). The address range to be mapped can be specified from 8 KB/block to 1024 KB/block. Up to 32 blocks can be specified.

These registers can be read or written in 32-bit units.

NOTE

Before updating memory mapping destination address register n (TM_MDA n register), be sure to set the corresponding mapping enable bit TM_ME.TME n to 0 (mapping disabled). ($n = 0$ to 31)

43.14.4 Remap Function

43.14.4.1 Remap Setting Sequence

The remap setting requires that the registers of GCFU be set in the appropriate sequence. During the sequence, do not access source area of the mapping block whose mapping will be changed by the sequence. It is necessary to prepare new data to User Area which will be destination of the remap in advance.

(1) Mapping status checking		
(1-1)	CPU core	Check the mapping setting of block n whose mapping is to be changed with mapping status bit MESn (if "0", go to (3), if "1", go to (2)). (n = 0 to 31)
(2) Mapping disable processing		
(2-1)	CPU core	Set mapping enable bit TMEn of block n to "0" (mapping disabled) (n = 0 to 31).
(2-2)	GCFU*1	Request the flash memory bus use right from GCFU upon updating of the mapping enable register (TM_ME register).
(2-3)	GCFU*1	Following acquisition of the bus use right, switch the memory mapping (to apply the setting of the mapping enable register (TM_ME register)).
(2-4)	GCFU*1	Following acquisition of the bus use right, output the cache clear request signal from GCFU to the Instruction cache and data buffer.
(2-5)	GCFU*1	Following the mapping switch/cache clear request signal output, GCFU releases the flash memory bus use right.
(2-6)*2	CPU core	Check whether the mapping setting has been applied with mapping status bits MESn (if "0", go to (3), if "1", go to (2-6)). (n = 0 to 31)
(3) Remap address Setting		
(3-1)	CPU core	Set mapping size configuration bits MMSZn of the block n (n = 0 to 31).
(3-2)	CPU core	Set source address of User Area to TM_MSAn register of the block n (n = 0 to 31).
(3-3)	CPU core	Set destination address of User Area to TM_MDAn register of the block n (n = 0 to 31).
(4) Mapping enable processing		
(4-1)	CPU core	Set mapping enable bit TMEn of block n for which remap settings have been completed to "1" (mapping enabled) (n = 0 to 31)..
(4-2)	GCFU*1	Request the flash memory bus use right from GCFU upon updating of the mapping enable register (TM_ME register).
(4-3)	GCFU*1	Following acquisition of the bus use right, switch the memory mapping (to apply the setting of the mapping enable register (TM_ME register)).
(4-4)	GCFU*1	Following acquisition of the bus use right, output the cache clear request signal from GCFU to the Instruction cache and data buffer.
(4-5)	GCFU*1	Following the mapping switch/cache clear request signal output, the GCFU releases the flash memory bus use right.
(4-6)*2	CPU core	Check whether the mapping setting has been applied with mapping status bits MESn (if "0", go to (4-6), if "1", end) (n = 0 to 31).

Note 1. This processing is performed by hardware.

Note 2. The appropriate synchronization processing is required. For details, refer to **Section 3.8.1.2, When the Updated Results in the Control Registers and Memories are Reflected in the Instruction Fetch of a Subsequent Instruction.**

43.15 Usage Notes

- (1) Reading areas where programming or erasure was interrupted
When programming or erasure of an area of flash memory is interrupted intentionally or unintentionally, the data stored in the area become undefined. To avoid undefined data that are read out becoming the source of faulty operation, take care not to fetch instructions or read data from areas where programming or erasure was interrupted.
- (2) Reading the code flash memory that has been erased but not yet been programming again
Note that reading from an area of code flash memory that has been erased but not yet been programming again (i.e. that is in the non-programmed state) can lead to the detection of an ECC error and generation of the corresponding exception. Use blank checking when you need to confirm that an area is in the non-programmed state.
- (3) Prohibition of additional writing
Writing to a given area twice is not possible. If you want to update data in an area of flash memory after writing to the area has been completed, erase the area first. (Erasure is unnecessary for rewriting of flash extra area.)
- (4) Resets during programming and erasure
In the case of an external reset during programming and erasure, wait for at least the minimum value of reset pulse width once the operating voltage is within the range stipulated in the electrical characteristics after assertion of the reset signal before releasing the device from the reset state.
- (5) Allocation of vectors for interrupts and other exceptions during programming and erasure
Generation of an interrupt or other exception during programming or erasure may lead to fetching of the vector from the code flash memory. If this does not satisfy the conditions for using background operation, set the address for vector fetching to an address that is not in the code flash memory.
- (6) Checking the areas where programming or erasure was interrupted
If programming or erasure is interrupted intentionally or unintentionally, the programming or erasure state of the flash memory with undefined data cannot be verified or checked. For the area where programming or erasure was interrupted, the blank check function cannot judge whether the area is erased successfully or not. Erase the area again to prove that the corresponding area is completely erased before using.
- (7) Items prohibited during programming / erasure / blank check
Do not perform the following operations while the flash memory is programmed, erased, or checked for blank.
 - Have the operating voltage from the power supply go beyond the allowed range.
 - Update the values of FHVE15 and FHVE3.
 - Change the operating frequency of peripheral clock.
- (8) Flash memory commands prohibited before completion of clock gear-up sequence
Various commands during serial programming and self-programming must be executed after clock gear-up sequence is complete. For details of clock gear-up sequence, see **Section 15, Clock Controller**.

- (9) Securing coherency of instruction cache and data buffer
After the code flash memory is programmed or erased, a reset or instruction cache and data buffer clearing are required to secure coherency of the instruction cache and data buffer. For details of instruction cache and data buffer, see **Section 3, CPU System**.
- (10) Setting of OTP.
Set OTP after programming target data, because OTP setting becomes effective without reset.
Please be careful about Configuration Setting Area and Security Settings Area where OTP setting address is smaller than the address of the target.
OTP setting becomes effective in the first place if programming the target data in the order of OTP setting of Security Settings Area, Security Settings Area, OTP setting of Configuration Setting Area, and Configuration Setting Area. Therefore, the target data of Configuration Setting Area and Security Settings Area cannot be written.
- (11) Reprogramming of User Area after Code Flash Memory Mapping Mode change.
Do not issue reprogramming of User Area without reset after changing the Code Flash Memory Mapping Mode which affects the address mapping of User Area.
MAPMODE in OPBT10 will change Code Flash Memory Mapping Mode after the reset which causes FACI Reset Transfer. For detail of the reset, see **Section 10.3.4, FACI Reset Transfer**.
- (12) Code Flash Memory Mapping Mode change after once it is set.
If Code Flash Memory Mapping Mode is changed by mis-operation, the area which is protected in old mode may be revealed in new mode unintentionally.
MAPMODE in OPBT10 will change Code Flash Memory Mapping Mode.
It is recommended to set OTP for MAPMODE in OPBT10 once the configuration of MAPMODE is set.
- (13) Two User Boot Area for OTA(Over-the-Air) update support function
Code Flash Memory Mapping Mode of Single Map Mode and Double Map Mode have two User Boot Area. These two User Boot Area are arranged in address space. One is located at Bank A and the other is at Bank B. In Double Map Mode, the stored data in two User Boot Area can be swapped with each other by setting of User Area on Cluster 0 (OPBT11.DBMAPSW0). It has no setting to swap only User Boot Area. Therefore, it is necessary to store same data on both sides of User Boot Area in advance when using User Boot Area in Double Map Mode.

Section 44 Basic Hardware Protection (BHP)

To protect the code flash memory, data flash memory and Flash extra area, this product has several Flash protection functions.

The security function that is used by the ID authentication and setting of Flash Option Byte is described in this section. The ID code and the Flash Option Byte that is described in this section are mapped at Security Settings area and Block Protection Settings area.

In the initial state of the product at shipment, the ID code are set by all - 1. These ID should be set at the first programming to Flash Option Byte. For detailed description of the programming to the flash memory, see **Section 43, Flash Memory**.

44.1 Features

ID code

- **Table 44.1** shows the ID code that can be set in this product.

The system requires each ID authentication for programming and reading the ID.

Table 44.1 ID Code

ID Code	Function
OCD ID	Protection for debug connection
Serial Programmer ID	Protection to enter the serial programming mode
RHSIF ID	Protection for RHSIF Link Partner
Customer ID	Protection for Code Flash and Flash extra area
Data Flash ID	Protection for Data Flash
C-TEST ID	Protection to enter the test mode

- The setting and function that related each ID code can select the Flash Option Byte. The system requires each ID authentication to re-programming these Flash Option Byte.

User/User boot/Data area protection by ID authentication

- The system requires 256 bit Customer ID authentication for re-programming to User area by each block.
- The Customer ID authentication is needed to read the User/User boot area when debugger is connected.
- The system requires 256 bit Data Flash ID authentication for re-programming to Data area.
- The Data Flash ID authentication is needed to read the Data area when debugger is connected.

User/User boot area protection by OTP

- User area on code flash supports OTP (One Time Programmable) functionality for each block.
- Flash extra area protection by OTP
- Dedicated configuration area supports OTP functionality for each 4 Byte unit.

44.2 Security Functions in Serial Programming Mode

Two functions are provided as security functions in serial programming mode: ID authentication and prohibition of serial programmer connection. Parallel use of these functions is not allowed.

1. Serial Programmer ID Authentication

The ID codes are checked for authenticity to protect the code flash memory, data flash memory and Flash extra area. Programming, erasure, and reading of the code flash and data flash memory can proceed upon successful ID authentication.

2. Prohibition of Serial Programmer Connection

Issuing commands for programming, erasure, or reading to the code flash memory, data flash memory and Flash extra area can be disabled in serial programming mode.

44.3 Security Functions in Debug Interfaces

This product is capable of restricting connection of the debug interfaces to protect against unauthorized access via the debug interfaces. This feature has two security levels.

- Security level 1:

Debug interface can be used. At this level, the on-chip debugging (OCD) function is protected by using OCD ID authentication. For OCD to be used, it must be unlocked by using OCD ID authentication.

- Security level 2:

At this level, the debug interface cannot be used.

These security levels can be changed by Flash Option Byte (JPDBGIF_EN) in Security Setting area of the flash memory.

When ICUMD is enabled, The C&R authentication is added to security function.

For details, see *the RH850/E2x ICUMD User's Manual*.

44.3.1 Security Levels and State of Restricting the Connection of Debug Interfaces

Table 44.2 show each security level and the corresponding security states and **Figure 44.1** shows the conditions for transitions.

Table 44.2 Security Levels and State of Restricting Connection to the Debug Interfaces

State	Result of OCD ID Authentication	JPDBGIF_EN* ¹	Restriction on Debug Interface Connection
Security level 1	Unlocked	1 _B	No restriction on access via the debug interfaces
	Locked	1 _B	Restriction on access via the debug interfaces is in place.
Security level 2	—	0 _B	Connection to the debug interfaces is prohibited.

Note 1. For a detailed description of the JPDBGIF_EN bits, see **Section 44.6.1, S_OPBT0 — OCD ID Related Option Bytes**.

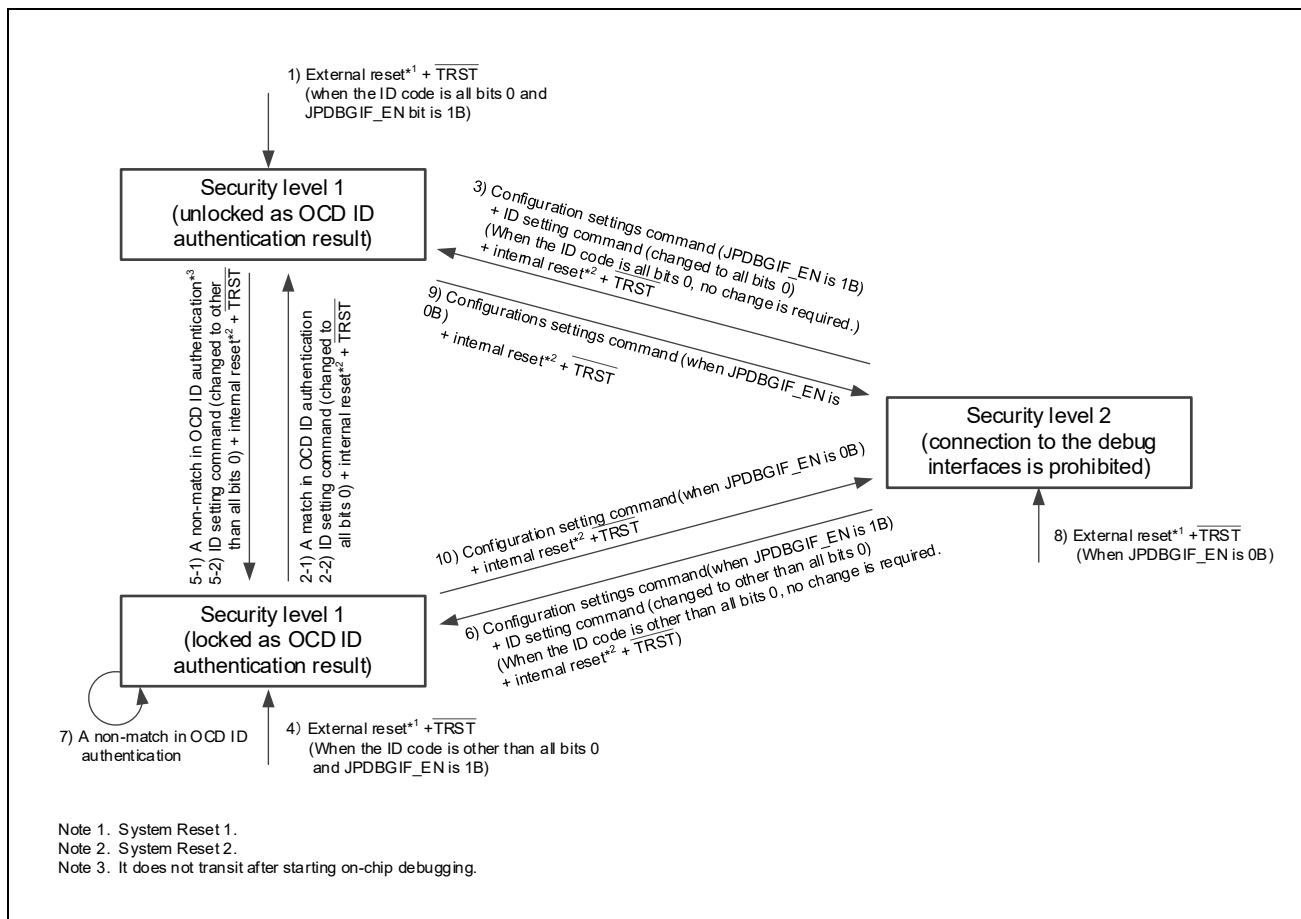

Figure 44.1 Transitions of Security Level

Conditions for transitions to each security level described in **Table 44.2**.

- Conditions for transitions to security level 1 (locked as OCD ID authentication result)

1. Startup in the state of security level 1 (unlocked as OCD ID authentication result)

When an external reset*¹ and a reset by TRST# are applied while the ID code is all 0s and while the value of the JPDBGIF_EN is 1_B, startup proceeds with security level 1 (unlocked as OCD ID authentication result).

2. Transition from security level 1 (locked as OCD ID authentication result) to security level 1 (unlocked as OCD ID authentication result)
 - Transition to security level 1 (unlocked as OCD ID authentication result) follows a match in OCD ID authentication.
 - When an internal reset*² and a reset by TRST# is applied after changing the ID code to “all bits 0”, startup proceeds at security level 1 (unlocked as OCD ID authentication result).
3. Transition from security level 2 to security level 1 (unlocked as OCD ID authentication result)

When an internal reset*² and a reset by TRST# is applied after changing the ID code to “all bits 0” and the value of the JPDBGIF_EN to 1_B, startup proceeds at security level 1 (unlocked as OCD ID authentication result).

 - Conditions for Transitions to Security Level 1 (locked as OCD ID Authentication result)
4. Startup in the state of security level 1 (locked as OCD ID authentication result)

When an external reset*¹ and a reset by TRST# is applied while the ID code is “other than all bits 0” and the value of the JPDBGIF_EN is 1_B, startup proceeds at security level 1 (locked OCD ID authentication result).
5. Transition from security level 1 (unlocked as OCD ID authentication result) to security level 1 (locked as OCD ID authentication result)
 - A transition to security level 1 (locked as OCD ID authentication result) follows a non-match in OCD ID authentication.*³
 - When an internal reset*² and a reset by TRST# is applied after changing the ID code to “other than all bits 0”, startup proceeds at security level 1 (locked as OCD ID authentication result).
6. Transition from security level 2 to security level 1 (locked as OCD ID authentication result)

When an internal reset*² and a reset by TRST# is applied after changing the ID code to “other than all bits 0” and the value of JPDBGIF_EN is 1_B, startup proceeds at security level 1 (locked as OCD ID authentication result).
7. Retaining security level 1 (locked as OCD ID authentication result)

In case of a non-match in OCD ID authentication, security level 1 (failure in OCD ID authentication) remains in place.

 - Transition to security level 2
8. Startup at security level 2

When an external reset*¹ and a reset by TRST# is applied while the value of JPDBGIF_EN is 0_B, startup proceeds at security level 2.
9. Transition from security level 1 (unlocked as OCD ID authentication result) to security level 2

When an internal reset*² and a reset by TRST# is applied after changing the value of the JPDBGIF_EN to 0_B, startup proceeds at security level 2.
10. Transition from security level 1 (locked as OCD ID authentication result) to security level 2

When an internal reset*² and a reset by TRST# is applied after changing the value of the JPDBGIF_EN to 0_B, startup proceeds at security level 2.

Note 1. System Reset 1.

Note 2. System Reset 2.

Note 3. It does not transit after starting on-chip debugging.

44.3.2 The Case of CAN BootStrap Mode

When the system is in CAN BootStrap Mode, debug interface can be used.

When user program is running, the security level depends on the setting of JPDBGIF_EN.

44.4 Security Functions in Connection of RHSIF Link Partner

Three functions are provided as security functions unique to RHSIF ID authentication, and prohibition of RHSIF Link Partner connection.

- RHSIF ID Authentication

ID codes are checked for authenticity to protect RHSIF Link Partner connection.

When ICUMD is enabled, The C&R authentication is added to security function.

For details, see *the RH850/E2x ICUMD User's Manual*.

- Access Window setting

User can set the access area from Link Partner that is configured the access window register. The access window register can not set from Link Partner.

The detail of this function, see **Section 29, Renesas High-Speed Serial I/F (RHSIF)**.

44.5 Code Flash / Data Flash Protection

Protection based on section password operates for non-secure area and doesn't affect the access from ICUMD. The section password is stored in Security settings area for each of code flash, extended data area and data flash (Customer ID and Data Flash ID). User can unlock protection by inputting correct section password by software or external debugging tool.

Inputting target registers for software, see *the RH850/E2x-FCC2 Flash Memory User's Manual: Hardware Interface*.

Customer ID and Data Flash ID, see **Section 44.6.11, CUSTOMERIDn — Customer ID (n = 0 to 7)** and **Section 44.6.12, DATAFLASH IDn — Data Flash ID (n = 0 to 7)**.

The ID authentication for read access can be skipped by setting read protection flag in Security settings area for code and data flash respectively. (CFRPF and DFRPF)

Table 44.3 shows access protection to user area of Code flash memory and extended data area. ID authentication to read access in Normal Operation mode/OCD mode is done via debugger I/F. ID authentication for reading access in serial programming mode is not needed. ID authentication for writing access is always done by SW.

Table 44.4 shows access protection to Data Flash memory. ID authentication to access is same as user area of Code flash memory. But the ID to authenticate becomes Data Flash ID.

Table 44.5 shows access protection to Extra Area (Configuration Setting, Security Setting, Block Protection Area). ID authentication for reading/writing access is done by SW. Protection ID of Configuration Setting Area, see **Section 43.11, Configuration Setting Area (Option Bytes, Reset Vector)**. Protection ID of Security Setting Area, see **Section 44.6, Security Settings Area**. Protection ID of Block Protection Area, see **Section 43.12, Block Protection Area**.

Table 44.3 Access Protection to User Area and Extended Data Area from PEs

Mode	Sub Mode	Access from PEs		Access Via PEs Debug Master	
		Read	Erase/Write	Read	Erase/Write
Normal Operation Mode / User Boot Mode	Self-programming	Don't care	Customer ID authentication by SW	N/A	N/A
	OCD mode	Customer ID authentication by debugger I/F	Customer ID authentication by SW*1	Customer ID authentication by debugger I/F	Customer ID authentication by SW*1
	Except above	Don't care	N/A	N/A	N/A
Serial programming mode	—	Don't care	Don't care	N/A	N/A
	OCD mode (CAN/CAN-FD)	Customer ID authentication by debugger I/F	Don't care	Customer ID authentication by debugger I/F	Don't care

Note: Don't care: there are no access restriction, N/A: not applicable

Note 1. If target ID has been authenticated by debugger I/F, the ID certification by SW is unnecessary.

Table 44.4 Access Protection to Data Flash from PEs

Mode	Sub Mode	Access from PEs		Access Via PEs Debug Master	
		Read	Erase/Write	Read	Erase/Write
Normal Operation Mode / User Boot Mode	Self-programming	Don't care	Data Flash ID authentication by SW	N/A	N/A
	OCD mode	Data Flash ID authentication by debugger I/F	Data Flash ID authentication by SW*1	Data Flash ID authentication by debugger I/F	Data Flash ID authentication by SW*1
	Except above	Don't care	N/A	N/A	N/A
Serial programming mode	—	Don't care	Don't care	N/A	N/A
	OCD mode (CAN/CAN-FD)	Data Flash ID authentication by debugger I/F	Don't care	Data Flash ID authentication by debugger I/F	Don't care

Note: Don't care: there are no access restriction, N/A: not applicable

Note 1. If target ID has been authenticated by debugger I/F, the ID certification by SW is unnecessary.

Table 44.5 Access Protection to Extra Area (Configuration Setting, Security Setting, Block Protection Area) from PEs

Mode	Sub Mode	Access from Pes		Access Via PEs Debug Master	
		Read	Erase/Write	Read	Erase/Write
Normal Operation Mode / User Boot Mode	Self-programming	ID authentication by SW	ID authentication by SW	N/A	N/A
	OCD mode	ID authentication by SW*1	ID authentication by SW*1	ID authentication by SW*1	ID authentication by SW*1
	Except above	ID authentication by SW	N/A	N/A	N/A
Serial programming mode	—	ID authentication by SW	ID authentication by SW	N/A	N/A
	OCD mode (CAN/CAN-FD)	ID authentication by SW*1	ID authentication by SW*1	ID authentication by SW*1	ID authentication by SW*1

Note: Don't care: there are no access restriction, N/A: not applicable

Note 1. If target ID has been authenticated by debugger I/F, the ID certification by SW is unnecessary.

44.5.1 Block Protection Function

- User Area Erase/Write Protection

Code flash can be protected from Erase/Write by Customer ID authentication. This function can be set by 4 bit per Block of code flash. **Figure 44.2** shows an example of Block Protection structure. Once set, the OTP setting cannot be released.

- Data Flash Erase/Write Protection

Data Flash can be protected from Erase/Write by Data Flash ID authentication. This function can be set by DPROT. (see **Section 44.6.5, S_OPBT4 — Data Flash ID Related Option Bytes**)

Note 1. Refer to **Section 43.12, Block Protection Area**.

Note 2. Block Protection setting area of User Block 0-133, User Boot Area for valid area are shared with invalid area.

44.5.2 OTP (One Time Programmable) Function

OTP can be individually set for each block of the user area and the user boot area of code flash memory. When the OTP setting is made for an area (When OTP bit is “0”), programming by serial programming and by self programming is prohibited. Once set, the OTP setting cannot be released.

Table 44.9, Table 44.10, and Table 44.11 shows Mapping of OTP setting for User area and User boot area.

Table 44.9 Mapping of OTP Setting (User Area and User Boot Area)*1

Note 1. Refer to **Section 44.6, Security Settings Area**.

Note 2. Refer to **Section 43.11, Configuration Setting Area**.

44.5.3 Test Mode Entry Protection

Test mode is used to perform production test or failure analysis by Renesas. The authentication scheme to enter the test mode is configurable by Security settings area.

The password can be select from TESTID (that only Renesas uses) or C-TESTID to enter the test mode by Security settings area. For details, see *Section 16.8*, in the *RH850/E2x ICUMD User's Manual*.

44.6 Security Settings Area

The flash memory has the extended Extra area (Option Bytes) to store a data specified by the user for security settings. Changes in settings become effective after release from the reset state. (Refer to **Section 10.3.4, FACL reset transfer.**) OTP Setting of Security Settings Area becomes effective without reset. **Table 44.14** shows Security settings area. For setting and reading option bytes, see *the Renesas Flash Programmer Flash Programming Software User's Manual*, or *the RH850/E2x-FCC2 Flash Memory User's Manual: Hardware Interface*.

Table 44.14 Security Settings Area

Name	Address	Initial State of Shipped Product.*1	Write/Erase Protection ID*3	Read Protection ID*3*7
OTP Setting of Security Settings Area*2*8	FF30 0040 _H to FF30 0048 _H	FFFF FFFF _H	—	—

Serial Programmer ID (SPIDn)	FF30 00C0 _H to FF30 00DC _H	All FFFF FFFF _H	Serial Programmer ID*6	Serial Programmer ID*6
Customer ID (CUSTOMERIDn)	FF30 00E0 _H to FF30 00FC _H	All FFFF FFFF _H	Customer ID	Customer ID
Data Flash ID (DATAFLASH IDn)	FF30 0100 _H to FF30 011C _H	All FFFF FFFF _H	Data Flash ID	Data Flash ID
C-TEST ID (CTESTIDn)	FF30 0120 _H to FF30 013C _H	All FFFF FFFF _H	C-TEST ID	C-TEST ID
RHSIF ID (RHSIFIDn)	FF30 0140 _H to FF30 015C _H	All FFFF FFFF _H	RHSIF ID	RHSIF ID
Reserved	FF30 0160 _H to FF30 01DC _H	FFFF FFFF _H *5	—	—
Reserved*9	FF30 01E0 _H to FF30 01FC _H	*9	*9	*9

Note 1. This is the initial value of the shipped product. The value can be modified.

Note 2. The detail of this function, see **Section 44, Basic Hardware Protection (BHP)**.
(**Table 44.12** shows Mapping of OTP setting for extra Area.)

Note 3. When all bits of Protection ID are "1" or "0", the ID authentication is no needed to set.

Note 4. When CFRPF is set (CFRPF bit is 0).

Note 5. It is prohibited to change from a read value.

Note 6. When the all bits are "1", the ID authentication is needed to connect a flash memory programmer.

Note 7. When Sub mode is OCD mode, the Customer ID authentication is needed to read.

Note 8. Set OTP after programming target data, because OTP setting becomes effective without reset.

Note 9. There are OPBT of ICUMD. For details, see *the RH850/E2x ICUMD User's Manual*.
When ICUMD is unused, please do not write it.

44.6.1 S_OPBT0 — OCD ID Related Option Bytes

OCD ID authentication is needed for write this option byte.

When all bits of OCD ID are “1” or “0”, the ID authentication is no needed to change the setting.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Note 1. This is the initial value of the shipped product. The value can be modified by setting the option bytes.

Note 2. Only when an FACL command or serial programming (ex. the Renesas Flash Programmer flash programming software) is used, setting (W) is possible.

Table 44.20 RHSIF Related Option Bytes Register Contents

Bit Position	Bit Name	Function
31 to 17	—	Reserved (The setting value should be 1.)
16	HSIF_IDAUTH_NEED	RHSIF Link Partner Authentication Setting 0: RHSIF ID authentication for Link Partner access is not needed 1: RHSIF ID authentication for Link Partner access is needed.
15 to 0	—	Reserved (The setting value should be 1.)

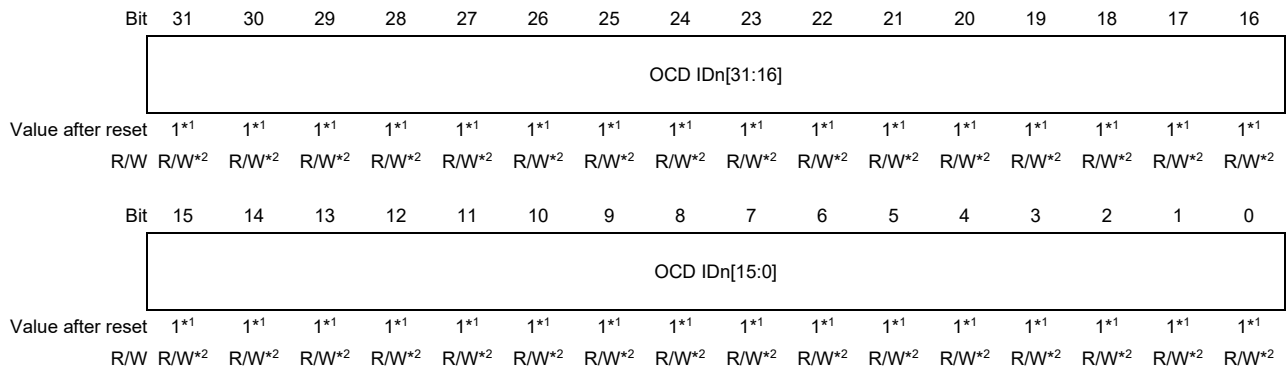

44.6.8 S_OPBT7

For details of this S_OPBT7, see *the RH850/E2x ICUMD User's Manual*.

44.6.9 OCDIDn — OCD ID (n = 0 to 7)

OCD ID authentication is needed for read / write this option byte.

When all bits of OCD ID are “1” or “0”, the ID authentication is no needed to change/read the setting.

Note 1. This is the initial value of the shipped product. The value can be modified by setting the option bytes.

Note 2. Only when an FACL command or serial programming (ex. the Renesas Flash Programmer flash programming software) is used, setting (W) is possible.

Table 44.21 OCD IDn Register Contents

Bit Position	Bit Name	Function
31 to 0	OCD ID	ID Code for debug connection authentication. Bit mapping table is as follows: OCD ID[31:0]: OCDID0[31:0] OCD ID[63:32]: OCDID1[31:0] OCD ID[95:64]: OCDID2[31:0] OCD ID[127:96]: OCDID3[31:0] OCD ID[159:128]: OCDID4[31:0] OCD ID[191:160]: OCDID5[31:0] OCD ID[223:192]: OCDID6[31:0] OCD ID[255:224]: OCDID7[31:0]

44.6.10 SPIDn — Serial Programmer ID (n = 0 to 7)

Serial Programmer ID authentication is needed for read / write this option byte.

When all bits of Serial Programmer ID are “0”, the ID authentication is no needed to change/read the setting.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	Serial Programmer IDn[31:16]

Note 1. This is the initial value of the shipped product. The value can be modified by setting the option bytes.

Note 2. Only when an FACL command or serial programming (ex. the Renesas Flash Programmer flash programming software) is used, setting (W) is possible.

Table 44.22 SPIDn Contents

Bit Position	Bit Name	Function
31 to 0	Serial Programmer ID	ID Code for Serial Programmer authentication. Bit mapping table is as follows: Serial Programmer ID[31:0]: SPID0[31:0] Serial Programmer ID[63:32]: SPID1[31:0] Serial Programmer ID[95:64]: SPID2[31:0] Serial Programmer ID[127:96]: SPID3[31:0] Serial Programmer ID[159:128]: SPID4[31:0] Serial Programmer ID[191:160]: SPID5[31:0] Serial Programmer ID[223:192]: SPID6[31:0] Serial Programmer ID[255:224]: SPID7[31:0]

44.6.11 CUSTOMERIDn — Customer ID (n = 0 to 7)

Customer ID authentication is needed for read / write this option byte.

When all bits of Customer ID are “1” or “0”, the ID authentication is no needed to change/read the setting.

Note 1. This is the initial value of the shipped product. The value can be modified by setting the option bytes.

Note 2. Only when an FACL command or serial programming (ex. the Renesas Flash Programmer flash programming software) is used, setting (W) is possible.

Table 44.23 CUSTOMERIDn Contents

Bit Position	Bit Name	Function
31 to 0	Customer ID	ID Code for Code Flash Protection, Configuration setting and etc. Bit mapping table is as follows: Customer ID[31:0]: CUSTOMERID0[31:0] Customer ID[63:32]: CUSTOMERID1[31:0] Customer ID[95:64]: CUSTOMERID2[31:0] Customer ID[127:96]: CUSTOMERID3[31:0] Customer ID[159:128]: CUSTOMERID4[31:0] Customer ID[191:160]: CUSTOMERID5[31:0] Customer ID[223:192]: CUSTOMERID6[31:0] Customer ID[255:224]: CUSTOMERID7[31:0]

44.6.12 DATAFLASH IDn — Data Flash ID (n = 0 to 7)

Data Flash ID authentication is needed for read / write this option byte.

When all bits of Data Flash ID are “1” or “0”, the ID authentication is no needed to change/read the setting.

Note 1. This is the initial value of the shipped product. The value can be modified by setting the option bytes.

Note 2. Only when an FACL command or serial programming (ex. the Renesas Flash Programmer flash programming software) is used, setting (W) is possible.

Table 44.24 DATAFLASH IDn Register Contents

Bit Position	Bit Name	Function
31 to 0	Data Flash ID	ID Code for Data Flash Protection. Bit mapping table is as follows: Data Flash ID[31:0]: DATAFLASHID0[31:0] Data Flash ID[63:32]: DATAFLASHID1[31:0] Data Flash ID[95:64]: DATAFLASHID2[31:0] Data Flash ID[127:96]: DATAFLASHID3[31:0] Data Flash ID[159:128]: DATAFLASHID4[31:0] Data Flash ID[191:160]: DATAFLASHID5[31:0] Data Flash ID[223:192]: DATAFLASHID6[31:0] Data Flash ID[255:224]: DATAFLASHID7[31:0]

44.6.13 CTESTIDn — C-Test ID (n = 0 to 7)

C-TEST ID authentication is needed for read / write this option byte.

When all bits of C-TEST ID are “1” or “0”, the ID authentication is no needed to change/read the setting.

Note 1. This is the initial value of the shipped product. The value can be modified by setting the option bytes.

Note 2. Only when an FACI command or serial programming (ex. the Renesas Flash Programmer flash programming software) is used, setting (W) is possible.

Table 44.25 CTESTIDn Register Contents

Bit Position	Bit Name	Function
31 to 0	C-TEST ID	ID Code for test mode entry authentication. Bit mapping table is as follows: C-TEST ID[31:0]: CTESTID0[31:0] C-TEST ID[63:32]: CTESTID1[31:0] C-TEST ID[95:64]: CTESTID2[31:0] C-TEST ID[127:96]: CTESTID3[31:0] C-TEST ID[159:128]: CTESTID4[31:0] C-TEST ID[191:160]: CTESTID5[31:0] C-TEST ID[223:192]: CTESTID6[31:0] C-TEST ID[255:224]: CTESTID7[31:0]

44.6.14 RHSIFIDn — RHSIF ID (n = 0 to 7)

RHSIF ID authentication is needed for read / write this setting.

When all bits of RHSIF ID are “1” or “0”, the ID authentication is no needed to change/read the setting.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

	RHSIF IDn[15:0]															
Value after reset	1*1	1*1	1*1	1*1	1*1	1*1	1*1	1*1	1*1	1*1	1*1	1*1	1*1	1*1	1*1	1*1
R/W	R/W*2	R/W*2	R/W*2	R/W*2	R/W*2	R/W*2	R/W*2	R/W*2	R/W*2	R/W*2	R/W*2	R/W*2	R/W*2	R/W*2	R/W*2	R/W*2

Note 1. This is the initial value of the shipped product. The value can be modified by setting the option bytes.

Note 2. Only when an FACI command or serial programming (ex. the Renesas Flash Programmer flash programming software) is used, setting (W) is possible.

Table 44.26 RHSIFIDn Register Contents

Bit Position	Bit Name	Function
31 to 0	RHSIF ID	ID Code for RHSIF Link Partner connection authentication. Bit mapping table is as follows: RHSIF ID[31:0]: HSIFID0[31:0] RHSIF ID[63:32]: HSIFID1[31:0] RHSIF ID[95:64]: HSIFID2[31:0] RHSIF ID[127:96]: HSIFID3[31:0] RHSIF ID[159:128]: HSIFID4[31:0] RHSIF ID[191:160]: HSIFID5[31:0] RHSIF ID[223:192]: HSIFID6[31:0] RHSIF ID[255:224]: HSIFID7[31:0]

44.7 Usage Notes

- (1) OTP setting for Double Map Mode.

The setting for User Block 0-133 of valid area also affects User Block 0-133 of invalid area, the setting for User Boot Area of valid area also affects User Boot Area of invalid area in case of Double Map Mode.

Make sure that the contents of the block in both valid and invalid area is completely same before setting the OTP of the block. Otherwise, unintentional fallback may happen when switching the valid area and invalid area of User Area / User Boot Area.

Section 45 Intelligent Cryptographic Unit/Master (ICUMD)

Please refer to the separate volume about ICUMD (Security function).

Section 46 Secure Watchdog Timer (SWDT)

Please refer to the separate volume about SWDT.

Section 47 Debugging and Calibration

This microcontroller has an on-chip debug function. By using the on-chip debug emulator, programs can be debugged with the microcontroller mounted in the target system.

The debug functions incorporated in this microcontroller conform to IEEE-ISTO 5001™-2003, a Nexus debug interface standard.

Production devices support Nexus Class 1 debug functionality. Emulation devices support Nexus Class 3 debug functionality.

For details of Production devices, see **Section 1.4, Ordering Information, Table 1.1**.

For details of Emulation devices, see **Section 1.4, Ordering Information, Table 1.2**.

CAUTION

The debug functions described in this section are supported by the microcontroller but whether these functions can actually be used depends on the debugger. For details on debugging, see the user's manual of the debugger used.

47.1 Debug Interface

This microcontroller supports the following debug interfaces:

1. Nexus JTAG Interface
2. Low Pin Debug Interface (4-pin) (LPD4)
3. CAN Debug interface - A CAN port can be selected as the debug communication interface by using the 2 pin protocol version of LPD4.
4. In emulation devices, a 1-lane Aurora trace port is provided.
5. Trigger Input / Output pin ($\overline{\text{EVTI}}$ / $\overline{\text{EVTO}}$)

On-chip debugging can be performed by using these debug interfaces.

Table 47.1 Debug Interface Modes

Serial programming mode*1		Normal operating mode/user boot mode*1	Debug ports		Option bytes*3			Register*4	JP0 port usage
2-wire UART/CSI*5	CAN/CAN-FD*5		$\overline{\text{TRST}}$	TDI(JP0_0)*2	DRDY_EN	JPDBGIF_EN	DBG_OV CAN_DISS	DBG_OVCAN_DOC_EN	
1	0	0	x	x	x	x	x	x	Serial programming*7
0	1	0	0	x	x	x	x	x	GPIO*6
0	1	0	1	0	x	0	x	x	GPIO (security level 2*3)*6,*8
0	1	0	1	0	x	1	x	x	LPD4*6,*9
0	1	0	1	1	x	0	x	x	GPIO (security level 2*3)*6,*8
0	1	0	1	1	1	1	x	x	Nexus (with $\overline{\text{DRDY}}$)*6,*9
0	1	0	1	1	0	1	x	x	Nexus (without $\overline{\text{DRDY}}$)*6,*9
0	0	1	0	x	x	x	x	x	GPIO
0	0	1	1	0	x	0	x	x	GPIO (security level 2*3)*6
0	0	1	1	0	x	1	x	0	LPD4*9
0	0	1	1	1	x	0	x	x	JTAG Boundary Scan (security level 2*3)
0	0	1	1	1	1	1	x	0	Nexus (with $\overline{\text{DRDY}}$) & JTAG Boundary Scan*9
0	0	1	1	1	0	1	x	0	Nexus (without $\overline{\text{DRDY}}$) & JTAG Boundary Scan*9
0	0	1	1	x	x	1	0	1	GPIO (Debug Over CAN)

Note: x = don't care

Note 1. For details, see **Section 5, Operating Modes**.

- Note 2. Latch output at rising edge of $\overline{\text{TRST}}$.
- Note 3. For details, see **Section 44, Basic Hardware Protection (BHP)**.
- Note 4. For details, see **Section 47.8.1.5(1), DBOVCANC — Debug Over CAN Control Register**.
- Note 5. For details, see **Section 43, Flash Memory**.
- Note 6. Can be selected externally by using the boot firmware.
- Note 7. The function of the port can be switched between 2-wire UART and CSI by using the boot firmware.
- Note 8. The operation is not guaranteed if a reset is asserted while data is being output. When GPIO is used, $\overline{\text{TRST}}$ must be "0".
- Note 9. When the interface is to be switched, the JP0 port register settings must be their initial values.

47.2 Run Control Functions

(1) Debug functions

- Downloading a user-created program
- Reading and writing the memory and registers
- Running a user-created program starting at any address

(2) On-chip break functions

A maximum of 12 breakpoints can be specified at any execution address. Of the 12 breakpoints, a maximum of four breakpoints can be specified for the data access address.

The following break functions are supported:

- Relay break function: Each CPU can be configured to stop execution when another CPU hits a breakpoint.
- Individual break function: Each CPU can be configured to continue execution when another CPU hits a breakpoint.

CAUTION

Whether the individual break function can be used or not depends on the debugger.

(3) Software break function

Software breakpoints can be specified at any execution address.

(4) Forced break function

Execution of a user-created program can be interrupted forcibly by a debugger.

(5) Peripheral break control

The peripheral break function generates a stop request to the peripheral modules of the microcontroller if the user-created program is stopped, for instance upon a breakpoint hit.

(6) Forced reset function

This device (microcontroller) can be forcibly reset by a debugger.

(7) Reset mask function

A reset factor (external reset, software reset, and ECM reset) can be masked.

(8) Event detection function

Events can be detected based on execution address, data access address, data value, data value range, and sequential execution.

(9) Trigger input interface

This microcontroller incorporates an event trigger input interface to acknowledge external events. It can acknowledge an external event in response to an input from the $\overline{\text{EVTI}}$ pin.

(10) Trigger output interface

An event trigger output interface is included in this microcontroller to notify an external debug device of event detection. Output from the $\overline{\text{EVTO}}$ pin reports detection of an event trigger to the outside. Debug trigger registers control trigger output to an external debug device via a request from the CPU. Up to eight debug trigger registers are supported. Each register supports 32 software triggers.

When $\overline{\text{TRST}} / \overline{\text{LPDRST}}$ is low level, output system reset signal from $\overline{\text{EVTO}}$.

(11) Debug interrupt interface function

Execution of a user program can be forcibly suspended by asserting an input signal on the $\overline{\text{EVTI}}$ pin from the outside.

(12) Multi core debug function

The following multi-core debug functions are supported for each CPU: synchronization functions (including reset, execution, and break), synchronous setting, and simultaneous tracing for multiple cores.

47.3 Calibration Functions

This microcontroller includes emulation RAM as emulation memory for the on-chip flash memory.

(1) Real-time RAM monitoring (RRM)

The memory can be read during program execution. Because this read access uses debug-dedicated DMA, it has minimal effect on program execution.

(2) Dynamic memory modification (DMM)

The memory can be written during program execution. Because this write access uses debug-dedicated DMA, it has minimal effect on program execution.

(3) Emulation RAM (ERAM) - only in emulation devices

For details, see **Section 9, RAM**.

47.4 Trace Control Functions

This microcontroller provides several trace functions including branch PC trace and data trace for each CPU, and DMA data trace.

(1) Trace RAM - only in emulation devices

This microcontroller has 64 KB of trace RAM. The trace information in the trace RAM is accessible via Nexus and LPD4 debug interfaces.

(2) Trace filter RAM - only in emulation devices

- Advanced data trace filtering allows selection of small 4 byte sections of data which can be individually enabled for data trace.
- Trace filter RAM does not have ECC.

(3) Software trace

This function enables the obtaining of user program execution histories, data changes, etc. The software trace information can be output to the trace RAM or via Aurora debug interface.

(4) Software trace

This function enables the obtaining of user program execution histories, data changes, etc. The software trace information can be output via LPD4 debug interfaces.

(5) Trace over reset

Remaining trace data is output after a reset.

(6) Global timestamp information

The global timestamp information is the absolute time from (absolute time 0) when the trace buffer is cleared.

(7) The trace message format in conforms to the Nexus standard.

(8) Windowed instruction trace or data trace

47.5 Performance Measurement Function

This microcontroller provides a two-event interval time difference measurement function to measure the time difference between the points at which two events occur.

(1) Two-event interval time difference measurement function

- Provides a function to measure the time difference (maximum time, minimum time, accumulation time) between two events (measurement start event to measurement stop event).
- Provides a function to measure the number of measurements (the number of measurement stop events) for two-event intervals (measurement start event to measurement stop event).
- Provides a threshold value violation detection function for two-event intervals (measurement start event to measurement stop event).
- Measurement clock: Debugging clock or CPU clock
- Measurement counter: 32-bit counter × 4 channels
- Measurement items: Maximum value, minimum value, accumulation value, measurement count (measurement stop event count)
- Count conditions: Number of debugging clock cycles, measurement count (measurement stop event count); number of CPU clock cycles, instruction execution or other events.
- Measurement limitations: When the interval between the measurement start event and the measurement stop event (from measurement start to measurement stop) or between a measurement stop event and the next measurement start event (from measurement stop to measurement start) is short, it may not be possible to correctly detect the measurement start or measurement stop events due to synchronization processing (from the system clock to the debugging clock).

Note that the required interval for detection depends on the system clock and the debugging clock frequencies.

- Measurement of the cache hit rate
- Measurement of the number of CPU cycles when a pipeline stall has occurred

47.6 Debug Support Function

(1) Hot plug-in function

Debugging can be started in normal operating mode without external reset input.

(2) Security function

To prevent the contents of the flash memory from being read by an unauthorized person, a 256-bit ID code must be written to the microcontroller. If the code the user inputs when starting a debugger does not match the ID code in the microcontroller, the flash memory cannot be accessed.

For details, refer to **Section 44, Basic Hardware Protection (BHP)**.

(3) Halt after reset

The debugger can control the start of CPU0 after internal reset release.

This must be set by using an option byte. For details, see **Section 44, Basic Hardware Protection (BHP)**.

(4) ICUMD debug function

For details, see *the RH850/E2x ICUMD User's Manual*.

(5) GTM debug function

For details, see **Section 33, GTM**.

(6) Device ID function

Device ID (device identification) information can be acquired via the debug interface (Nexus).

(7) Reset output pin

The reset output pin ($\overline{\text{RES_OUT}}$) reflects the state of the internal reset condition.

For details, see **Section 2, Pin Function**.

47.7 Peripheral Break Control

The peripheral break function generates a stop request to the peripheral modules of the microcontroller if the user-created program is stopped, for instance upon a breakpoint hit.

During a peripheral break, the peripheral modules operate as follows:

1. Modules that stop unconditionally regardless of the EPC.SVSTOP setting
WDTB0, WDTB1, WDTB2, WDTB3, WDTB4, WDTB5, SWDT0
2. Modules that stop when EPC.SVSTOP = 1 and EPC_SVSTOPn setting
OSTM0, OSTM1, OSTM2, OSTM3, OSTM4, OSTM5, OSTM6, ENCA0, ENCA1, ATU-V, GTM

47.8 Debugging-Related Registers

47.9 Aurora Trace Interface

47.9.1 Overview

Aurora is lightweight link-layer protocol for communicating over high-speed serial lanes.

Nexus introduces this protocol in IEEE-ISTO 5001-2012 (Nexus standard).

This product supports a simplex TX-only interface. Only one lane is used. Aurora for this product is fully compatible with Nexus standards and Xilinx's Aurora Protocol spec V2.2.

Table 47.7 shows the Aurora reference documents for this product.

Table 47.7 Reference Documents

Reference Document	Document Name	Reference
Aurora 8b / 10b protocol specification V2.2	aurora_8b10b_protocol_spec_sp002.pdf	http://www.xilinx.com/
The Nexus 5001 Forum™ Standard for a Global Embedded Processor Debug Interface V3.0.1	ieee_isto_5001_2012_301_Final.pdf	http://www.nexus5001.org .

47.9.2 Summary of Specifications

Summarized specifications of Aurora for this product are shown below.

The Aurora interface for this product is compliant with IEEE-ISTO 5001-2012 (Nexus standard). Its specifications are also compliant with the Nexus standards.

Table 47.8 Summary of Specifications

Item	Specifications	Note
I/F	1 lane	Simplex Tx only
Protocol specifications	Aurora protocol spec V2.2 compatible	
DC balanced order	8b / 10b	
IO level	AC coupling only	
AC specifications	IEEE-ISTO 5001-2012 compliant	Compliant with Nexus standards
PLL multiplier ratio	20:1	
Baud rate	1.25 Gbps 2.5 Gbps	Reference CLK = 62.5 MHz = 125 MHz
Data format	Streaming	
Back channel	Sideband (JTAG, LPD)	
Flow control	None	
Error detection and correction	None	

47.10 Cautions on Using On-Chip Debugger

(1) Handling of devices used for debugging

Do not install a device that was used for debugging on a mass-produced product. This is because the flash memory will be rewritten during system debugging and thus the write/erase count of flash memory cannot be guaranteed.

(2) This product does not support hot plug out for power off (including removal of the connector) of the debug tool during debug mode. Do not turn off the power of the Nexus tool (including removal of the connector) in debug mode.

(3) When ending on-chip debugging, set the $\overline{\text{TRST}}$ pin and external reset pin to low level.

(4) When a debugger is used, the program written to the microcontroller before the OCD emulator is ready to communicate with the microcontroller is executed from the reset vector. To stop the operation of the program, release the $\overline{\text{TRST}}$ before $\overline{\text{RES_IN}}$.

Section 48 Boundary Scan

This section contains a generic description of the boundary scan.

The first part in this section describes all specific properties of this product, such as the clock supply, reset sources, etc.

The remainder of the section describes the functions and registers of the boundary scan.

48.1 Features of Boundary Scan

48.1.1 Products that Incorporate Boundary Scan

This microcontroller has the JTAG interface and provides the boundary scan function conforming to the IEEE1149.1 standard.

48.1.2 Register Base Address

The JTAG interface has no base address because none of the registers can be accessed by the CPU.

48.1.3 Clock Supply

The boundary scan clock supply is shown in the following table.

Table 48.1 Clock Supply

Unit Name	Unit Clock Name	Supply Clock Name
Boundary scan	TCK	tck

48.1.4 Interrupt Requests

Interrupt request is none.

48.1.5 Reset Sources

The boundary scan reset sources are shown below. Boundary scan is initialized by the following reset sources. For details about register symbols, refer to **Table 48.4**.

Table 48.2 Reset Sources

Unit Name	Register Symbol	Reset Condition					
		Power Up Reset	System Reset 1	System Reset 2	Application Reset	Module Reset	JTAG Reset
Boundary scan	SDIR	—	—	—	—	—	✓
	SDID	—	—	—	—	—	—
	SDBPR	—	—	—	—	—	—
	SDBSR	—	—	—	—	—	—

48.1.6 External Input/Output Signals

External input/output signals of boundary scan are listed below.

Table 48.3 External Input/Output Signals

Unit Signal Name	Description	Alternative Port Pin Signal Name
Boundary scan		
TCK	Serial data input clock signal	TCK
TMS	Mode select input signal	TMS
$\overline{\text{TRST}}$	Reset input signal	$\overline{\text{TRST}}$
TDI	Serial data input signal	TDI
TDO	Serial data output signal	TDO

48.2 Overview

Boundary scan is a test method defined in the IEEE standard 1149.1 that is used to test the connection between the devices mounted on the printed-circuit board. The boundary scan of the RH850/E2x-FCC2 conforms to IEEE Std 1149.1-2001.

48.2.1 Functional Overview

This microcontroller supports the following.

- Five test signals (TCK, TDI, TDO, TMS, and $\overline{\text{TRST}}$)
- TAP controller
- Instruction register
- Bypass register
- Boundary scan register

The JTAG interface has six instructions.

- BYPASS mode
Test mode conforming to the IEEE 1149.1
- EXTEST mode
Test mode conforming to the IEEE 1149.1
- SAMPLE/PRELOAD mode
Test mode conforming to the IEEE 1149.1
- CLAMP mode
Test mode conforming to the IEEE 1149.1
- HIGHZ mode
Test mode conforming to the IEEE 1149.1
- IDCODE mode
Test mode conforming to the IEEE 1149.1

48.2.2 Block Diagram

The following block diagram shows the main components of the boundary scan.

Figure 48.1 Block Diagram of JTAG Interface

48.3 Registers

48.3.1 List of Registers

The boundary scan registers are listed in the following table.

Table 48.4 List of Registers

Module Name	Register Name	Symbol	Address*1	Access	Access Protection
BSCAN	Instruction register	SDIR	—	8	—
	ID register	SDID	—	32	—
	Bypass register	SDBPR	—	1	—
	Boundary scan register	SDBSR	—	*2	—

Note 1. This register can be access by TAP controller.

Note 2. The register is a shift register to control external pins, and thus it can't define access size.

The ID register (SDID) information is listed in the following table.

For the ID register of mass produced products, please to each target specification.

Table 48.5 List of ID Register (SDID) Value

Product Type Name	Description	SDID Value
E2H 400MHz BGA468	R7F702011EABG	183A 3447 _H
E2H 400MHz BGA373	R7F702011EABA	183A 5447 _H
E2UH 400MHz BGA468	R7F702012AEABG	283A 7447 _H
E2UH 400MHz BGA373	R7F702012AEABA	283F 8447 _H
E2x-FCC2 for E2H BGA468	R7F702Z11AEDBG	283B 1447 _H
E2x-FCC2 for E2H BGA373	R7F702Z11AEDBA	283B 2447 _H
E2x-FCC2 for E2UH BGA468	R7F702Z12AEDBG	283B 4447 _H
E2x-FCC2 for E2UH BGA373	R7F702Z12AEDBA	283F 7447 _H

Instructions can be serially transferred from the serial data input pin (TDI) and input to the instruction register (SDIR). The bypass register (SDBPR) is a 1-bit register, to which TDI and TDO are connected in BYPASS mode, CLAMP mode, and HIGHZ mode. The boundary scan register (SDBSR) is connected to TDI and TDO in SAMPLE/PRELOAD mode and EXTEST mode. The ID code register (SDID) is a 32-bit register, from which the ID code is output via TDO in IDCODE mode.

48.3.2 Details of Registers

48.3.2.1 SDIR — Instruction Register

SDIR is an 8-bit register that holds a boundary scan instruction. SDIR is initialized by a low-level input of $\overline{\text{TRST}}$ or in the TAP Test-Logic-Reset state. Operation is not guaranteed when any reserved instruction is set in this register.

Table 48.6 Boundary Scan Instructions

SDIR[7:0]	Description
0000 0000	JTAG EXTEST
0100 0000	JTAG SAMPLE/PRELOAD
1101 0000	JTAG CLAMP
1000 0000	JTAG HIGHZ
0101 0101	JTAG IDCODE (value after reset)
1111 1111	JTAG BYPASS
Other than above	Reserved

48.3.2.2 SDID — ID Register

SDID is a 32-bit register with a device specific ID.

SDID can be read via the JTAG interface pin when the IDCODE instruction is set but cannot be written to.

48.3.2.3 SDBPR — Bypass Register

SDBPR is a 1-bit register to go through the boundary scan register. When SDIR is set to BYPASS mode, CLAMP mode or HIGHZ mode, SDBPR is connected between TDI and TDO. The value after reset is undefined. SDBPR is not initialized by a reset as described in **Section 48.1.5, Reset Sources**.

48.3.2.4 SDBSR — Boundary Scan Register

SDBSR is a shift register located on the PADs for controlling the external I/O pins. When SDIR is set to SAMPLE/PRELOAD or EXTEST mode, SDBSR is connected between TDI and TDO. The value after reset is undefined. SDBSR is not initialized by a reset as described in **Section 48.1.5, Reset Sources**.

48.4 Operation

48.4.1 TAP Controller

The following block diagram shows the TAP controller internal states.

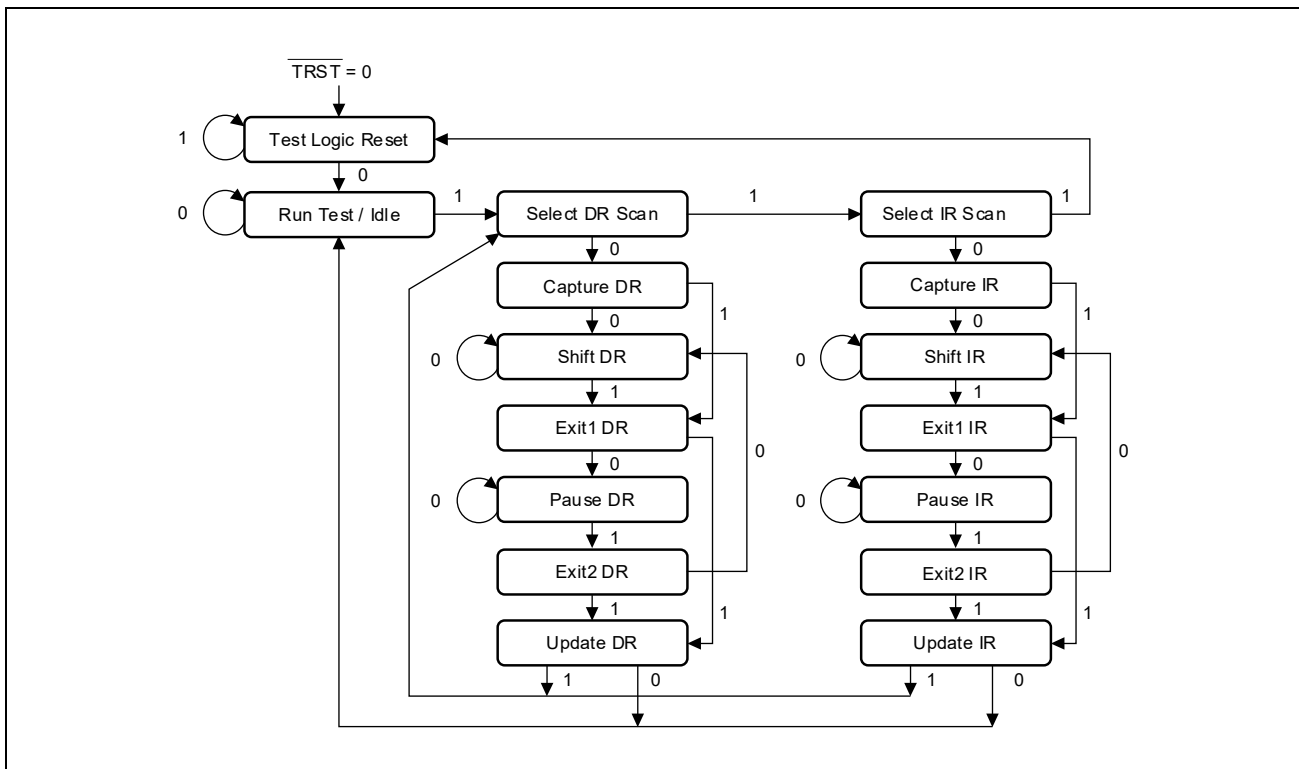

Figure 48.2 TAP Controller Internal States*1

Note 1. Transition is made according to the TMS value at the rising edge of TCK. The TDI value is sampled at the rising edge of TCK and is shifted at the falling edge. TDO is in the high-impedance state in the states other than Shift-DR (DataRegister) and Shift-IR. Asserting $\overline{\text{TRST}}$ causes transition to the test-logic-reset state asynchronously with TCK.

48.4.2 Supported Instructions

48.4.2.1 BYPASS

The BYPASS instruction is a standard instruction indispensable to bypass register operation. This instruction shortens the shift path to achieve high-speed serial data transfer of other devices on the printed-circuit board. During execution of this instruction, the test circuit has no effect on the system circuit.

48.4.2.2 SAMPLE/PRELOAD

The SAMPLE/PRELOAD instruction is used to input the value to the boundary scan register from the internal circuits of this LSI; to output the value from the scan path; and to load data onto the scan path. During execution of this instruction, the level of the input pin of this LSI is sent to the internal circuits as is, and the value of the internal circuits is output to the outside via the output pin as is. Executing this instruction has no effect on the system circuit of this LSI.

The SAMPLE operation allows taking in the snapshots of the value to be transferred to the internal circuits from the input pin or the value to be transferred to the output pin from the internal circuits to the boundary scan register, and allows reading the snapshots from the scan path. Snapshots can be taken in without preventing the normal operation of this LSI.

The PRELOAD operation allows setting the initial value to the parallel output latch of the boundary scan register from the scan path prior to the EXTEST instruction. If the EXTEST instruction is executed without PRELOAD operation, an undefined value is output from the output pin until the first scan sequence is completed (transfer to the output latch) because the parallel output latch value is always output to the output pin by the EXTEST instruction.

48.4.2.3 EXTEST

The EXTEST instruction is used to test the external circuits when this LSI is mounted on the printed circuit board. When this instruction is executed, the output pin is used to output the test data (previously set by the SAMPLE/PRELOAD instruction) from the boundary scan register to the printed-circuit board; whereas the input pin is used to take in the test result from the printed-circuit board to the boundary scan register. When the EXTEST instruction is executed N times for testing, the test data for the Nth execution is scanned in at the (N – 1)th scan-out. If the data is loaded onto the boundary scan register of the output pin in the Capture-DR state of this instruction, it is not used for testing the external circuits (replaced through shift operation).

48.4.2.4 CLAMP

When the CLAMP instruction is selected, the output pin outputs the boundary scan register value that has been previously set by the SAMPLE/PRELOAD instruction. While the CLAMP instruction is selected, the boundary scan register retains the previous state regardless of the TAP controller state. The bypass register is connected between TDI and TDO and operates in the same manner as when the BYPASS instruction is selected.

48.4.2.5 HIGHZ

When the HIGHZ instruction is selected, all the output pins go to the high-impedance state. While the HIGHZ instruction is selected, the boundary scan register retains the previous state regardless of the TAP controller state. The bypass register is connected between TDI and TDO and operates in the same manner as when the BYPASS instruction is selected.

48.4.2.6 IDCODE

The IDCODE instruction sets the JTAG interface pins to IDCODE mode, which is defined by the JTAG standard. When the JTAG interface is initialized (by asserting TRST or placing TAP in the test-logic-reset state), IDCODE mode is set.

48.4.3 Supported Pins

48.4.3.1 Supported Pin Information

There are supported pins related to the JTAG interface as follows.

- General purpose I/O pins.
- External reset output pin.
- Non maskable input pin.
- DRDY pin.

There are restrictions related to the JTAG interface as follows.

- NC pins.
- Power supply and GND pins.
- Reference voltage pins of A/D converters.
- Analog input pins.
- The pin to be connected to a stabilizing capacitor.
- External reset input pin.
- Debug control pins.
- Mode setting pins.
- Crystal pins.
- Error output pin.

The following table shows the list of pins not subjected to boundary scan.

Table 48.7 Pins Not Subjected to Boundary Scan

Type	Pin Name
Reference voltage pins of A/D converters.	ADSVREFH, ADSVREFL, A0VREFH, A1VREFH, A2VREFH, A3VREFH
Analog input pins.*1	ANxxx, CANxxxN, CANxxxP, DSANxxxN, DSANxxxP
The pin to be connected to Capacitor.	ADSVCL, RAMSVCL
External reset input pin.	$\overline{\text{RES_IN}}$
Debug control pins.	CICREFP*2, CICREFN*2, TODP0*2, TODN0*2, TCK, TDI, TDO, TMS, $\overline{\text{TRST}}$, AURES*2
Mode setting pins.	MD0, MD1
Crystal pins.	XTAL, EXTAL
Error output pin.	$\overline{\text{ERROROUT_M}}$

Note 1. See **Section 2.6.6, Dedicated Analog Pin Table** about detail names of analog input pins.

Note 2. The pin is implemented only E2x-FCC2 (for E2UH BGA468, E2UH BGA373) and E2xFCC2 (for E2H BGA468, E2H BGA373).

48.4.3.2 Usage Note

1. Once an instruction is set, it is not modified until another instruction is issued. To issue the same instructions twice in a row, insert an instruction that has no effect on chip operation (such as BYPASS mode) between the instructions.
2. To start the system in boundary scan mode, de-assert $\overline{\text{TRST}}$ while $\overline{\text{RES_IN}}$ is low. Also, be sure to set TMS to low before de-asserting $\overline{\text{TRST}}$. Furthermore, “CPUBTMSK_EN” of OCD ID Related Option Bytes Register bit setting value must be “1” at that time. See **Section 44.6.1, S_OPBT0 — OCD ID Related Option Bytes** about “CPUBTMSK_EN”.
3. For details of boundary scan timing constraint, see *Section 1.3.1, Power ON / OFF Timing*, and *Section 1.3.14, JTAG / NEXUS Timing in the RH850/E2x-FCC2 Electrical Characteristics, User’s Manual: Hardware*.
4. If serial transfer is performed exceeding the number of bits of the register connected between TDI and TDO, the data that is input from TDI is output from TDO as is.
5. If the serial transfer sequence is corrupted, be sure to assert $\overline{\text{TRST}}$. In this case, transfer starts again from the beginning regardless of the point of transfer corruption.
6. Data is output via TDO synchronized with the falling edge of TCK.
7. To facilitate debugging, route $\overline{\text{TRST}}$ on the board in such a way that patterns can be easily cut.
8. No instructions can be accepted in power-off standby mode.
9. When using the boundary scan, the ICUM function must be disable.
10. The switching of NEXUS and boundary scan require the initialize by $\overline{\text{RES_IN}}$ and $\overline{\text{TRST}}$.

Section 49 Electrical Characteristics

Please refer to the separate volume about Electrical Characteristics.

Appendix A List of Registers

Please refer to Appendix file of “List_of_Registers.xlsx”.

Appendix B Package

JEITA Package code	RENESAS code	MASS(TYP.)[g]
P-FBGA373-21x21-0.80	PRBG0373GB-A	1.4
