19.6 Basic Operation

19.6.1 Master/Slave Mode Operation

19.6.1.1 Master Mode Operation

The master mode is enabled by setting MSPInCTL1.MSPInMSSEL to 0.

In the master mode, all channels can be used.

The serial communication clock frequency and the active chip select can be specified individually for each channels.

The serial communication clock(MSPInSCK) is generated by the internal baud rate generator and the frequency division of MSPInSCK is set by MSPInCFGm3.MSPInPRCSm[1:0] and MSPInCFGm3.MSPInCDIVm[4:0].

One or more chip select signals can be selected MSPInSSELm.MSPInCSRm[7:0].

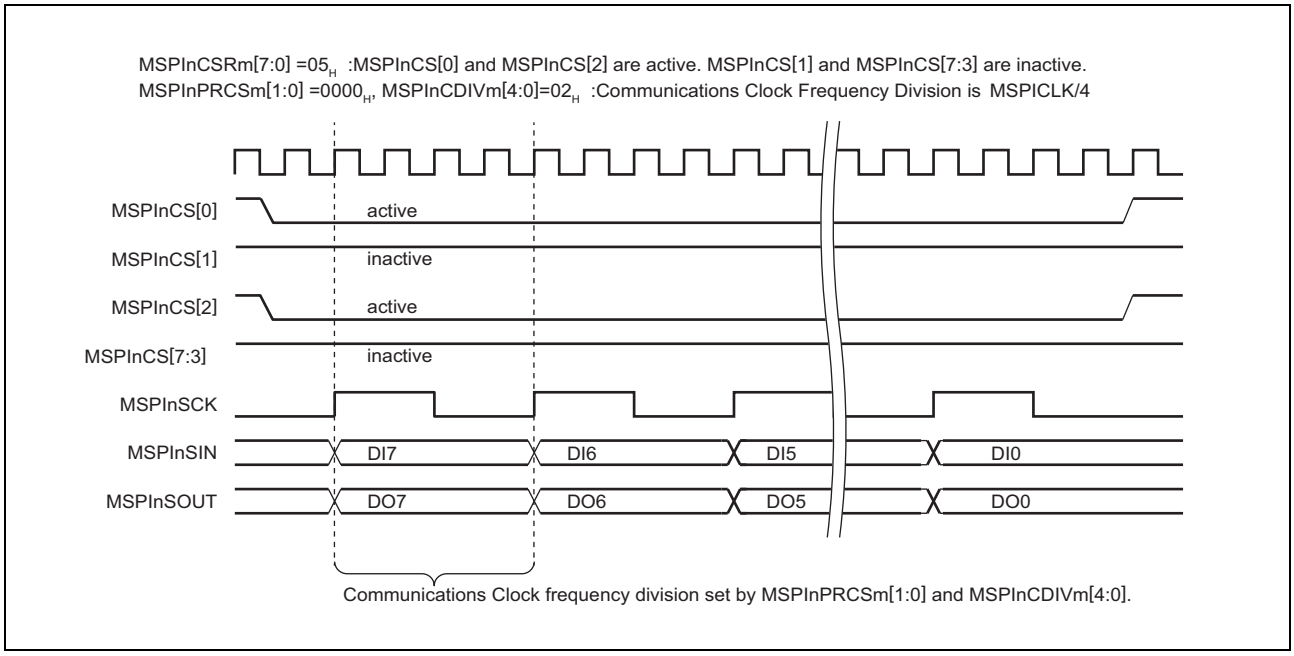

Figure 19.4 Communication in the Master mode

19.6.1.2 Slave Mode Operation

The slave mode is enabled by setting MSPInCTL1.MSPInMSSEL to 1.

In the slave mode, another device fact as the communication master and this supplies the serial communication clock(MSPInSCKI).

In the slave mode, the slave select signal(MSPInCSI) can be enabled/disabled by MSPInCTL1.MSInCSIE.

When MSPInCSI is disabled (MSPInCSIE = 0), normal transmit/receive operation is started as soon as the MSPInSCKI is detected.

When MSPInCSI is enabled (MSPInCSIE = 1), normal transmit/receive operation is started as soon as the MSPInSCKI is detected with the MSPInCSI in an active state.

In the slave mode, only channel 0 can be used.

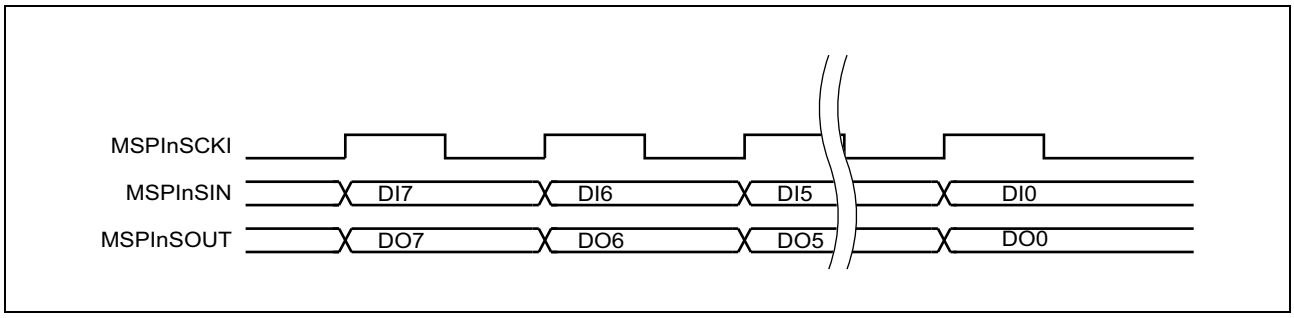

Figure 19.5 Communication in the Slave Mode (MSPInCSIE = 0)

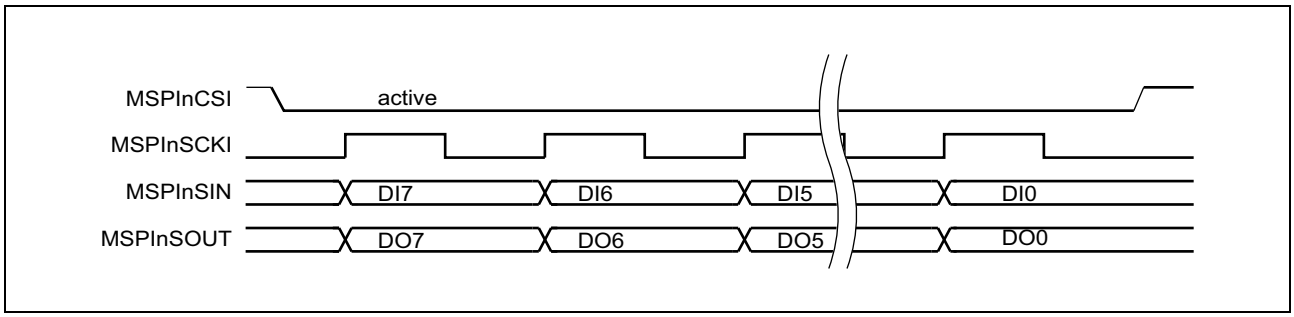

Figure 19.6 Communication in the Slave Mode (MSPInCSIE = 1)

19.6.2 Frame Length and Frame Count

Communication of MSPIn is executed by a preset frame length and frame count.

The frame length is set by MSPInCFGm2.MSPInFLENm[7:0], and the frame count is set by MSPInCFSETm.

The formats of frame length and frame count are shown in the figure below.

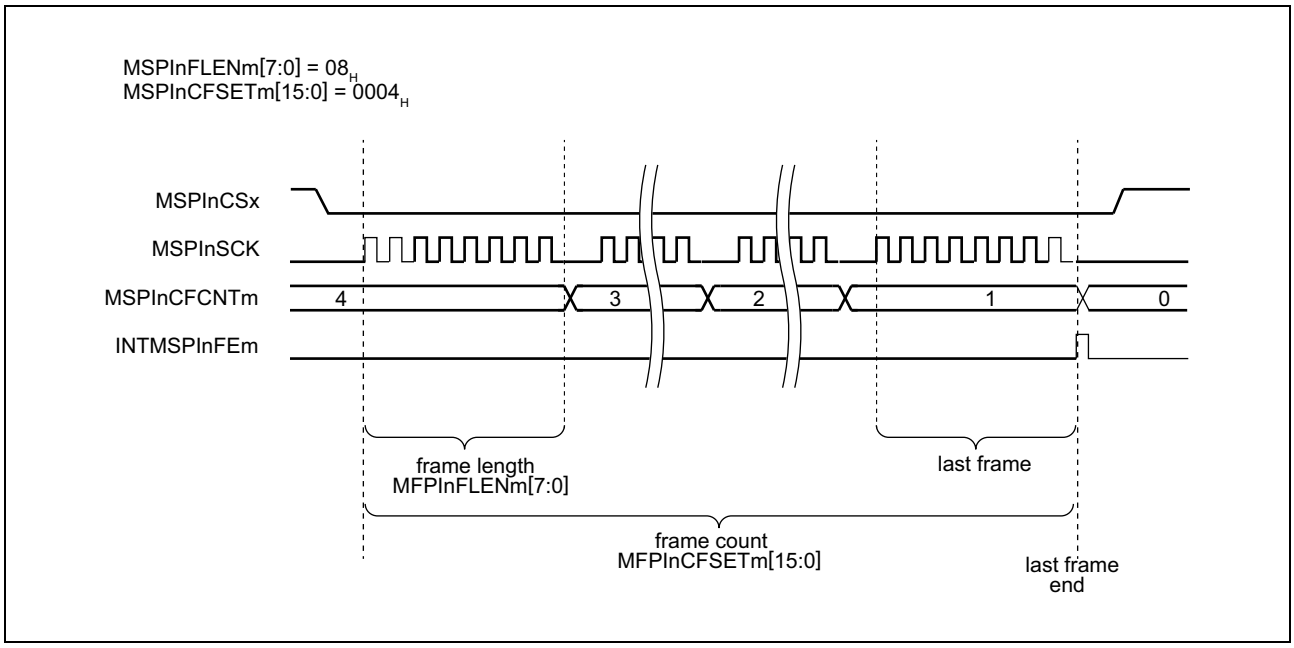

Figure 19.7 Formats of Frame Length and Frame Count

19.6.3 Chip Select Signal Function

19.6.3.1 Active or Inactive Settings of Chip Select Signal

In the master mode, MSPI can communicate with one or more slaves can be performed by using the chip select signals (MSPInCS[7:0]).

The active or inactive state of MSPInCS[7:0] is controlled by MSPInCSRm[7:0] bits.

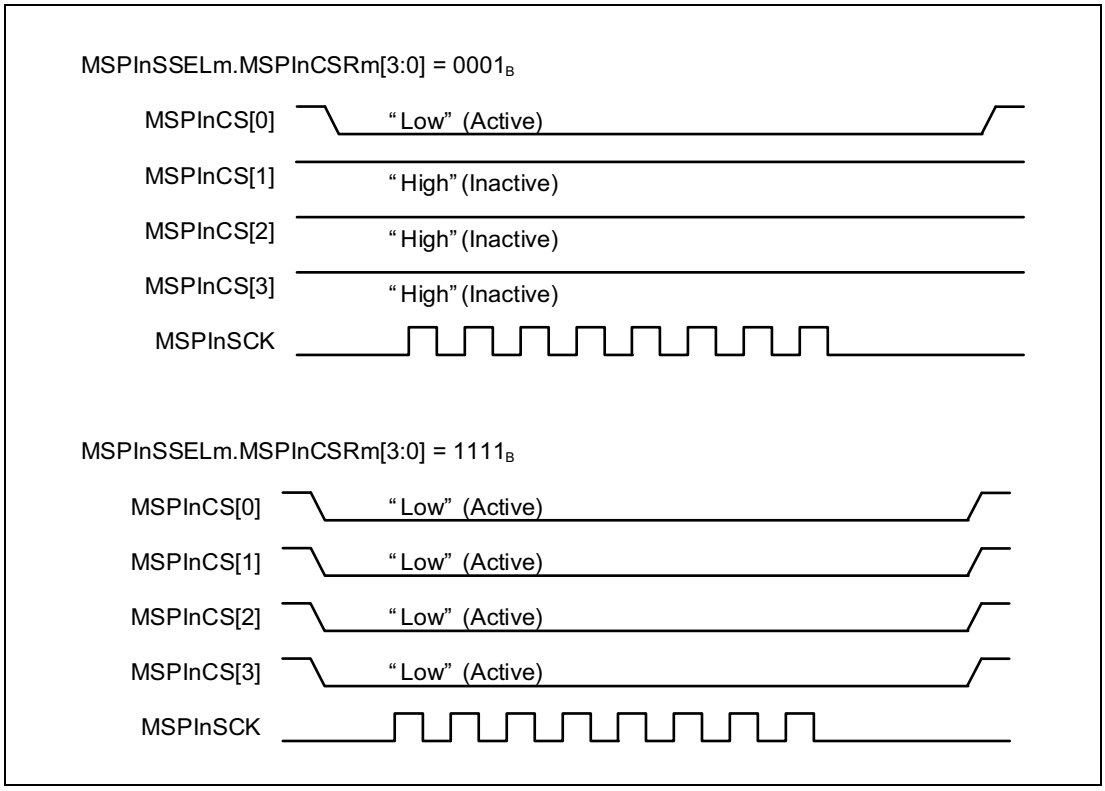

Figure 19.8 Chip Select Signal Control by MSPInCSRm Setting

CAUTION

If MSPInCSRm of multiple channels are the exact same, following parameters have to be set the same value.

- **MSPInCPOLm: Setting of MSPInSCK clock polarity**
- **MSPInCPHAm Data Phase: Setting of MSPInSCK clock phase**
- **MSPInDIRm: Setting of communication direction**
- **MSPInFIDLm: Setting of forced idle insertion.**
- **MSPInSAFCMm: Setting of Safe-SPI protocol format**
- **MSPInSAFSm: Setting of Safe-SPI protocol format**
- **MSPInSAFEm: Enable of Safe-SPI protocol function**
- **MSPInPSm[1:0]: Setting of parity check format**
- **MSPInDECHKm: Enable of parity check**
- **MSPInFLENm[7:0]: Setting of communication frame length**
- **MSPInPRCSm[1:0]: Setting of MSPInSCK baud rate**
- **MSPInCDIVm[4:0]: Setting of MSPInSCK baud rate**
- **MSPInSEUPm[11:0]: Setting of setup time**
- **MSPInHOLDm[11:0]: Setting of hold time**
- **MSPInIDLEm[11:0]: Setting of idle time**
- **MSPInINDAm[11:0]: Setting of inter-data time**

19.6.3.2 Active Output Level Settings of Chip Select Signal

The active or inactive level of MSPInCS[7:0] is set by MSPInCSP [7:0] bits.

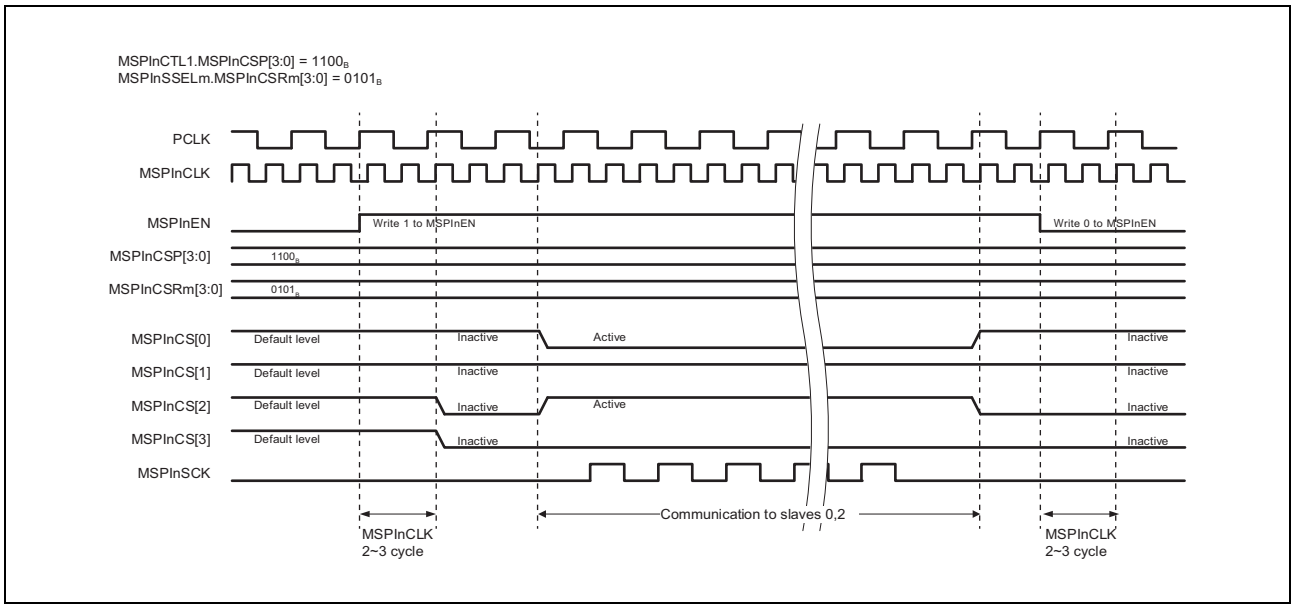

Figure 19.9 Chip Select Signal Control by MSPInCSP[7:0] Setting

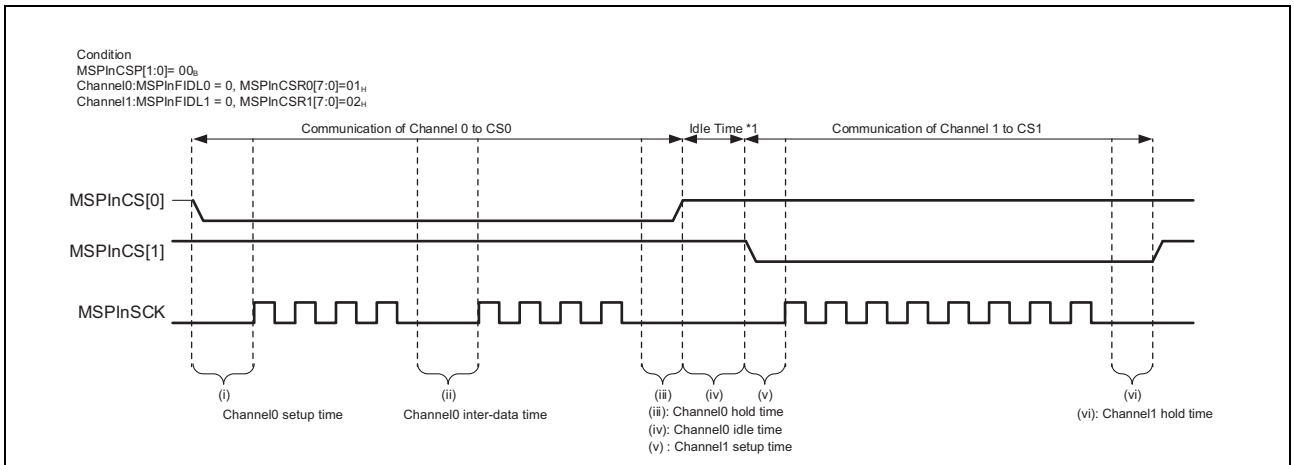
19.6.3.3 Setup/Hold/Idle/Inter-Data Time Settings of Chip Select Signal

The setup time, the hold time, the idle time, and the inter-data time of MSPInCS can be set independently for each channel by MSPInSEUPm, MSPInHOLDm, MSPInIDLEm, and MSPInINDAm, respectively.

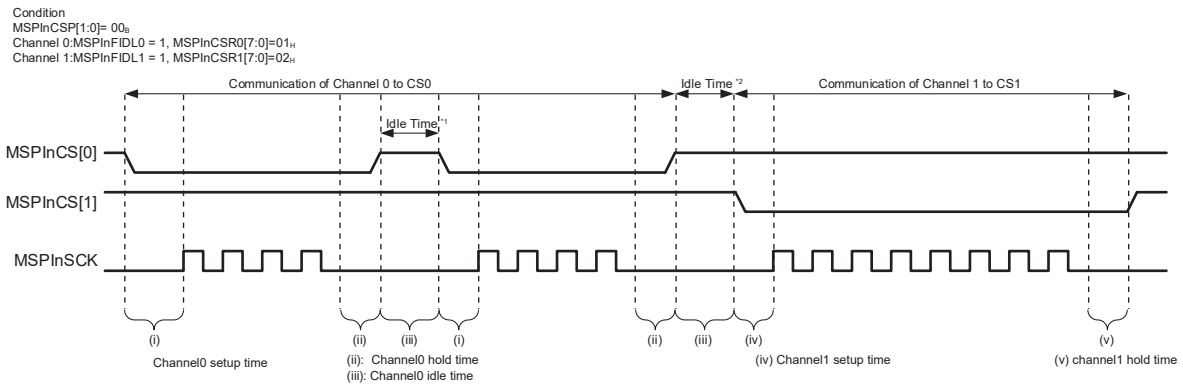
And an idle time can be inserted between two consecutive communications by setting MSPInFIDLm to 1.



(i): Channel0 setup time = MSPInSEUP0[11:0] x MSPInCLK
(ii): Channel0 inter-date time = MSPInINDA0[11:0] x MSPInCLK
(iii): Channel0 hold time = MSPInHOLD0 x MSPInCLK
(iv): Channel0 idle time = MSPInIDLE0 x MSPInCLK
(v): Channel1 setup time = MSPInSEUP1[11:0] x MSPInCLK
(vi): Channel1 hold time = MSPInHOLD1[11:0] x MSPInCLK

Note1. This idle time is inserted because the CS signal has changed(from CS0 to CS1).

Figure 19.10 Chip Select Signal Control by MSPInCSRm Setting (MSPInFIDLm = 0)



(i): Channel0 setup time = MSPInSEUP0[11:0] x MSPInCLK
(ii): Channel0 hold time = MSPInHOLD0[11:0] x MSPInCLK
(iii): Channel0 idle time = MSPInIDLE0 x MSPInCLK
(iv): Channel1 setup time = MSPInSEUP1[11:0] x MSPInCLK
(v): Channel1 hold time = MSPInHOLD1[11:0] x MSPInCLK

Note 1. This idle time is inserted because the MSPInFIDL0 is 1.
Note 2. This idle time is inserted because the CS signal has changed(from CS0 to CS1).

Figure 19.11 Chip Select Signal Control by MSPInCSRm Setting(MSPInFIDLm=1)

19.6.3.4 Level of chip select signal after last frame end

The level of MSPInCS[7:0] after the last frame end can be set independently for each channel by MSPInCSRIm.

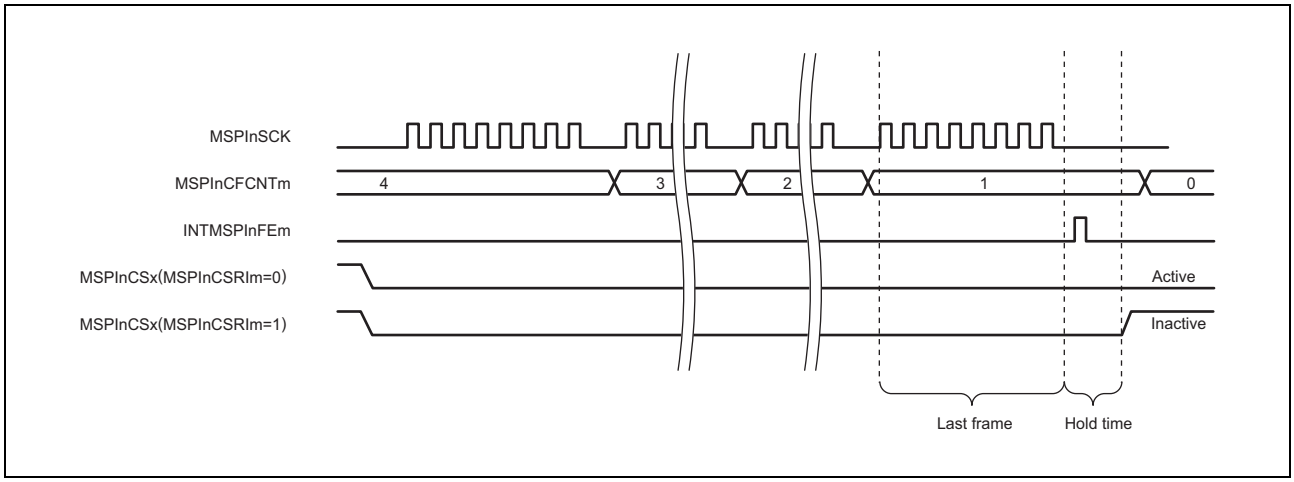


Figure 19.12 Level of Chip Select Signal After Last Frame End

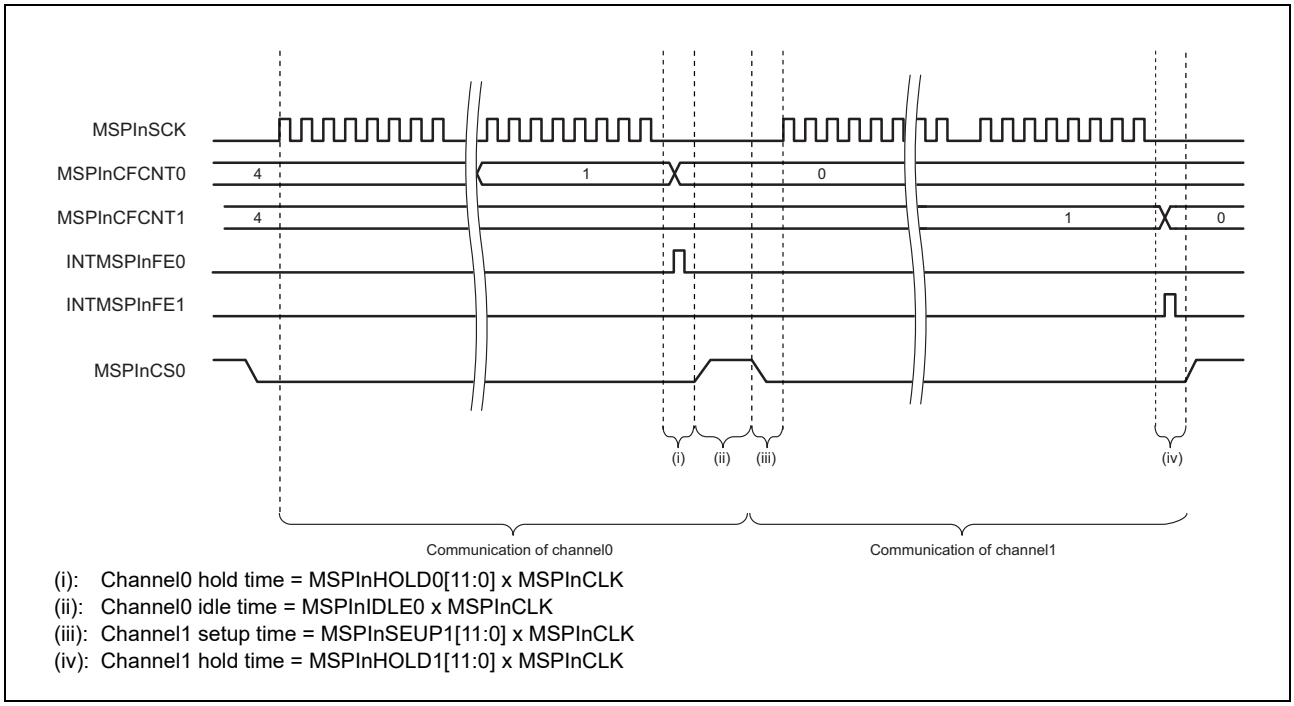
NOTE

When MSPInFCCEm is 1 in the direct memory mode, even if MSPInCSRIm is 1, the MSPInCS signal holds the active level after the last frame.

Even if communication of other channels continues while the same CS signal active settings, the CS signal becomes the inactive level when MSPInCSRIm is set to 1.



(i): Channel0 hold time = MSPInHOLD0[11:0] x MSPInCLK
(ii): Channel0 idle time = MSPInIDLE0 x MSPInCLK
(iii): Channel1 setup time = MSPInSEUP1[11:0] x MSPInCLK
(iv): Channel1 hold time = MSPInHOLD1[11:0] x MSPInCLK

Figure 19.13 End of Last Frame and Continuous Communication of Other Channels (MSPInCSRIm=1)

19.6.3.5 CS Level Control of the Idle Time in the Direct Memory Mode

The level of the CS signal in idle time can be controlled with MSPInCFGm1.MSPInICLSm.

When the MSPInICLSm is set to 1, the CS signal in the idle time keeps the active level.

This function can be used only in the transmission or transmission/reception setting of Direct memory mode.

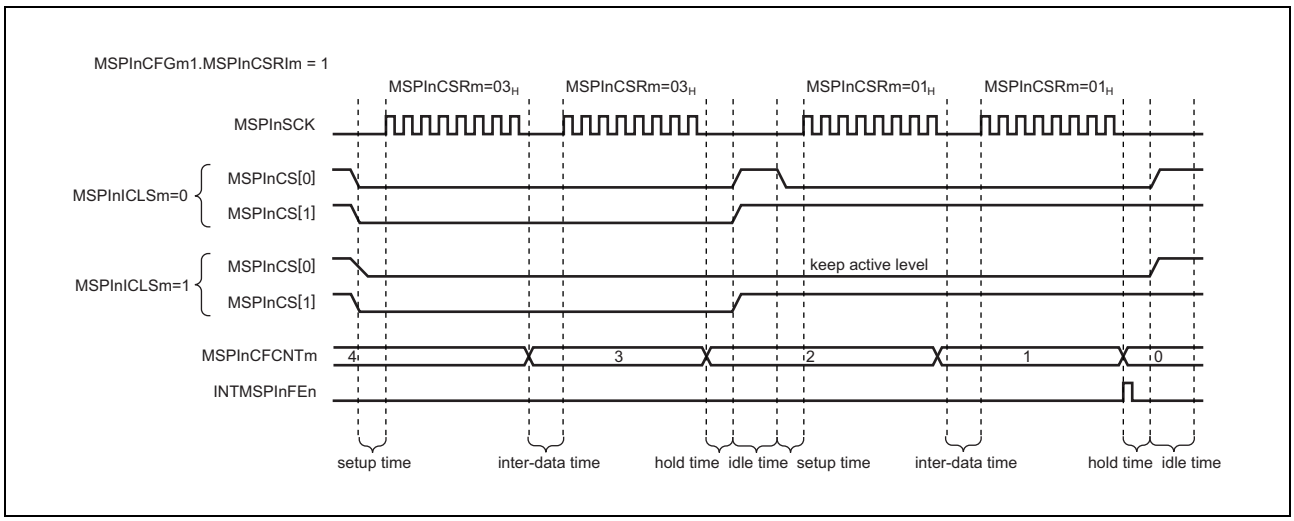


Figure 19.14 CS Level Control of MSPInICLSm (MSPInFIDLm = 0)

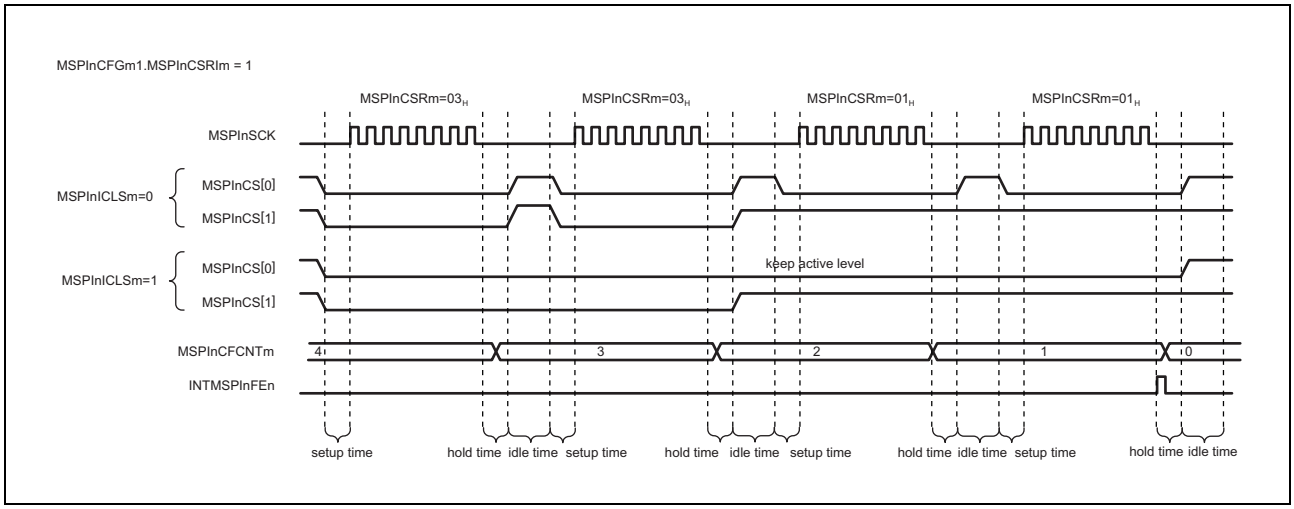

Figure 19.15 CS Level Control of MSPInICLSm (MSPInFIDLm = 1)

CAUTION

When MSPInICLSm = 1, MSPInCSRIm must be set to 1.

19.6.4 Clock Polarity and Data Phase

19.6.4.1 Clock default level, Clock polarity, Data phase and sampling point in the master mode

In the master mode, the default level of MSPInSCK can be set by MSPInCTL1.MSPInCKR, and the clock phase and data phase can be set independently for each channel by MSPInCFGm1. MSPInCPOLm and MSPInCFGm1.MSPInCPHAm, respectively.

The sampling point can be set by MSPInCTL1.MSPInSAMP.

Table 19.55 Clock Polarity and Data Phase Selection in the Master Mode(MSPInCKR = 0)

MSPInCKR	MSPInCPOLm	MSPInCPHAm	
0	0	0	0	0	1	0	1	0	0	1	1	
Note: (b) Polarity change by MSPInCPOLm:
When MSPInSCK switches polarity, MSPInCS activates after 2 clock of MSPInCLK
(i) Reception data sampling point for MSPInSAMP = 0
(ii) Reception data sampling point for MSPInSAMP = 1

Table 19.56 Clock Polarity and Data Phase Selection in the Master Mode(MSPInCKR = 1)

MSPInCKR	MSPInCPOLm	MSPInCPHAm	
1	0	0	1	0	1	1	1	0	1	1	1	
Note: (a) Polarity change by MSPInCKR: When MSPInEN is set to 1, MSPInSCK switches polarity after 2-3 clocks of MSPInCLK.
(b) Polarity change by MSPInCPOLm :When MSPInSCK switches polarity, MSPInCS activates after 3 clock of MSPInCLK.
(i) Reception data sampling point for MSPInSAMP = 0
(ii) Reception data sampling point for MSPInSAMP = 1

19.6.4.2 Clock Default Level and Data Phase in the Slave Mode

In the slave mode, the default level and clock phase of MSPInSCKI can be set by MSPInCTL1.MSPInCKR. And the data phase can be set by MSPInCFG01.MSPInCPHA0.

Set MSPInCFG01.MSPInCPOL0 to 0 and set MSPInCTL1.MSPInSAMP to 0 in the slave mode (MSPInCTL1.MSPInMSSEL = 1).

Table 19.57 Clock Polarity and Data Phase Selection in the Slave Mode

MSPInCKR	MSPInCPHA0	
0	0	0	1	1	0	1	1	
Note: (i) Reception data sampling point in slave mode

19.6.4.3 Changing the Clock Phase

The polarity of the MSPInSCK can be set for each channel by the MSPInCFGm1.MSPInCPOLm.

When the idle time is set to 5 or less and two consecutive data packets are sent with different MSPInCFGm1.MSPInCPOLm configuration, the idle time is automatically extended to six period of MSPInCLK.

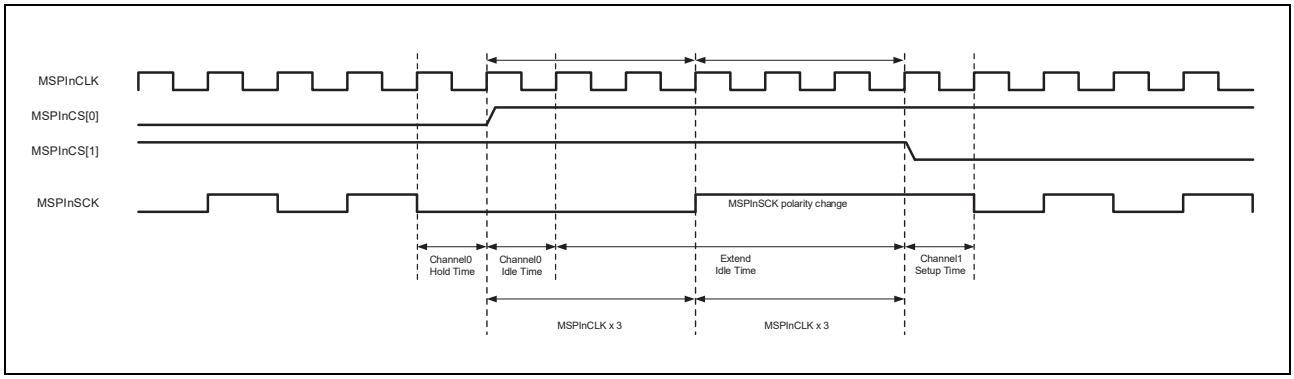

Figure 19.16 Change of the Clock Phase timing (idle time is set to 5 or less)

When the idle time is set to 6 or more and two consecutive data packets are sent with different MSPInCFGm1.MSPInCPOLm configuration, it changes the clock polarity of MSPInCLK three cycles before setup time.

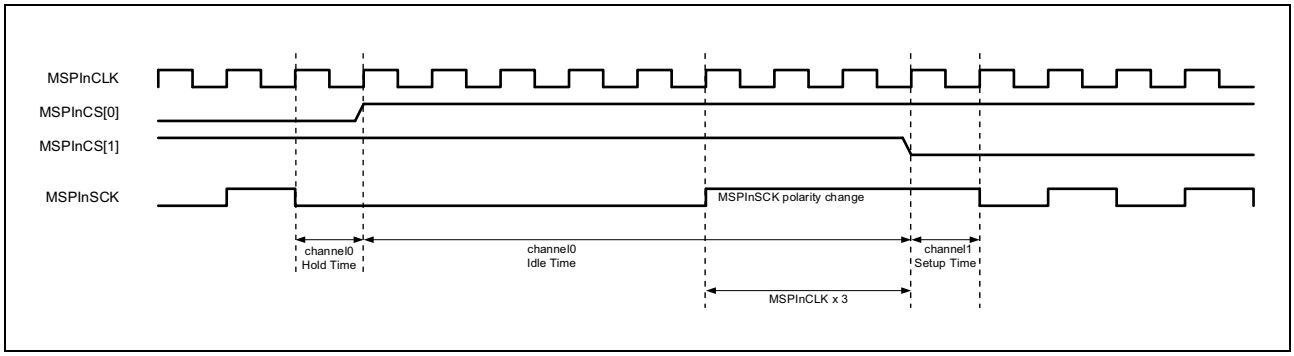

Figure 19.17 Change of the Clock Phase (idle time is set to 6 or more)

19.6.4.4 Clock Output During Communication Stop

When all channels communication ends, MSPI communication stops and MSPInCSx are inactive level (MSPInCSRIm=1), MSPInSCK returns the default level set by MSPInCTL1.MSPInCKR.

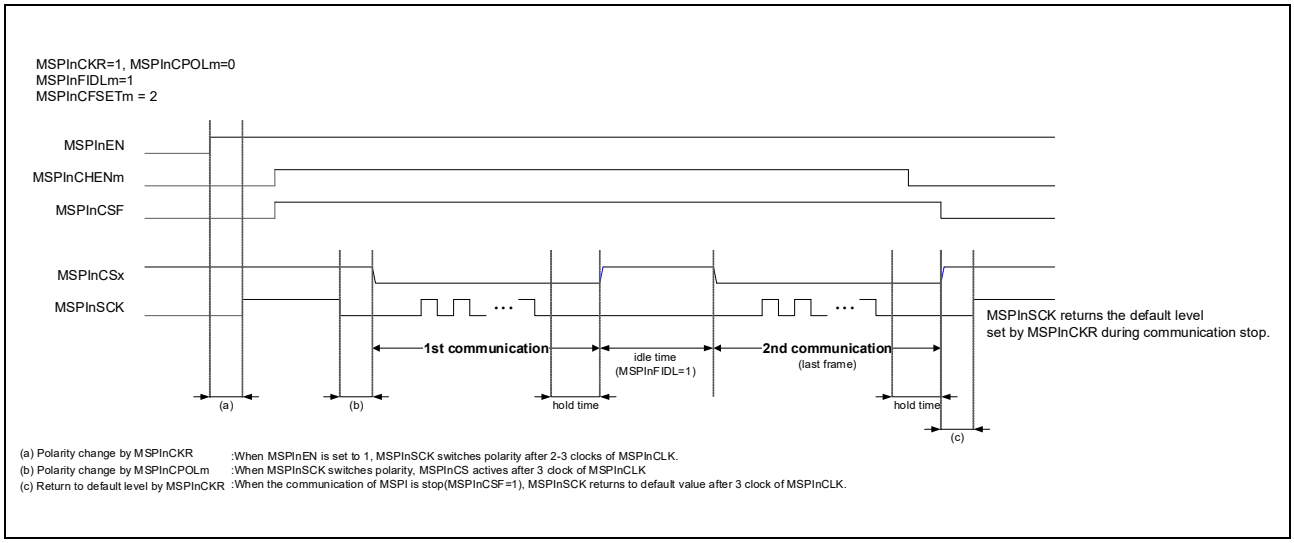

Figure 19.18 Clock Output During Communication Stop

19.6.5 SOUT Default Level and Idle Time Level

The default level and idle time level of MSPInSOUT can be set by MSPInCTL1.MSPInSOLS[1:0].

When MSPInEN is set to 1, MSPInSOUT becomes the inactive level set by MSPInSOLS[1].

The MSPInSOUT is held at the same level or becomes inactive level after communication is completed. This operation is set by the MSPInSOLS[0].

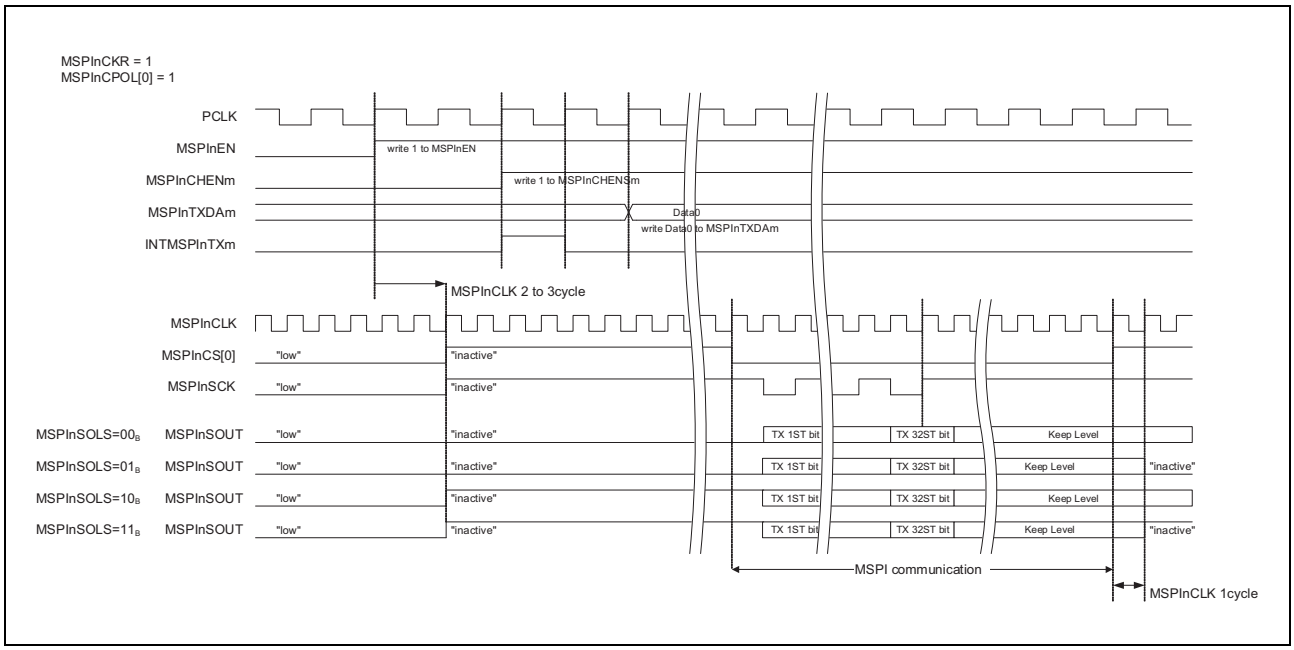

Figure 19.19 SOUT Operation

19.6.6 Serial Data Direction Selection

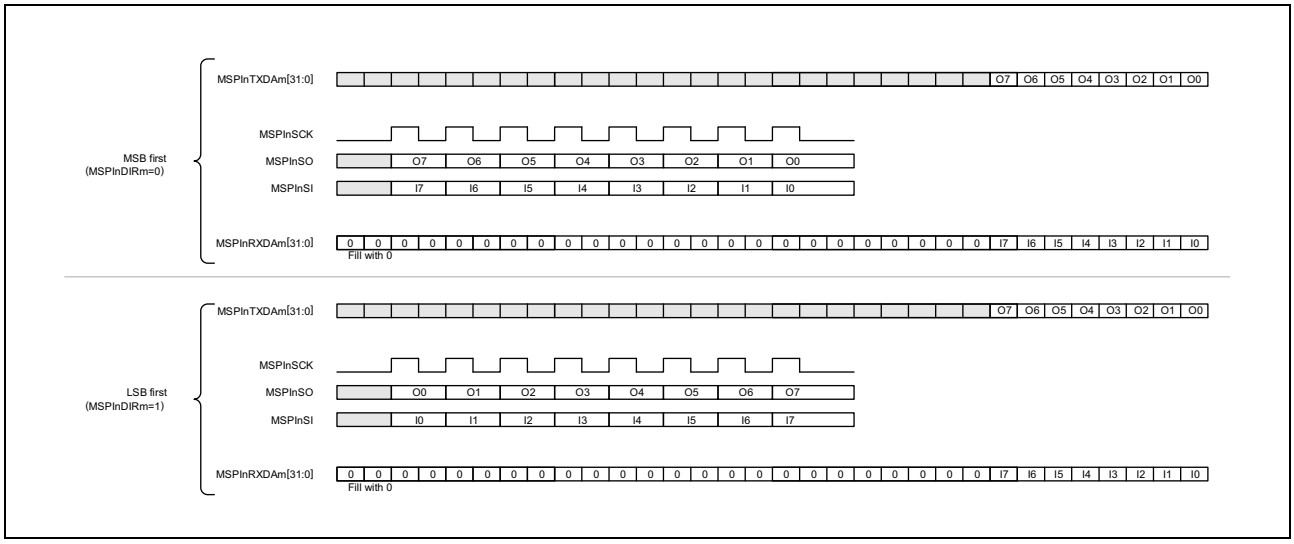

Figure 19.20 Serial Data Direction Select Function for 8-bit Communication

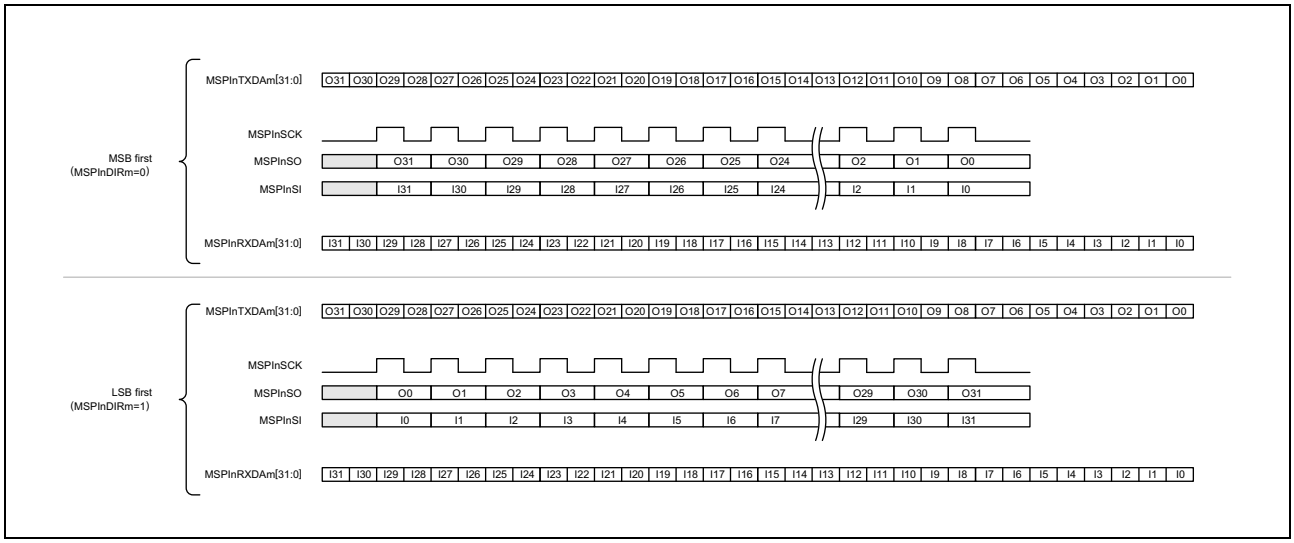

Figure 19.21 Serial Data Direction Select Function for 32-bit Communication

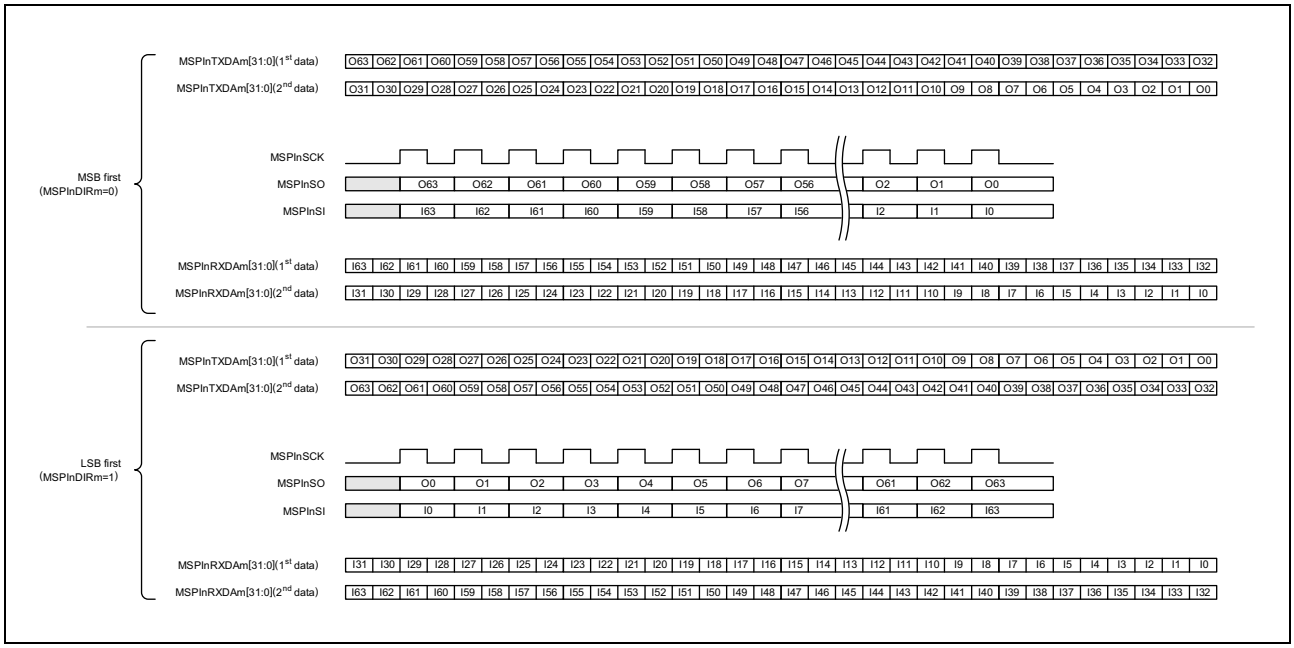

Figure 19.22 Serial Data Direction Select Function for the 64-bit Communication

NOTE

In the MSB communication of 33 bits or more, transmission data must be written from the upper address, and reception data has been read from the upper address.

19.6.7 Channel Priority Control

The priority level can be set independently for each channel by MSPInCFGm0.MSPInPRIOm[2:0]. The channel priority levels can be set from 0 to 7, with 0 the highest and 7 the lowest level.

If the priority settings of several channels are the same, the lowest interrupt channel number has priority.

MSPI has a shift register for communication and a reserve buffer for burst CSI/SPI communication.

The priority of the channel is judged at the timing when the reserve buffer can accept the request of the channel.

The following figure explains the timing of priority judgement when MSPI executes communication using channels 0, 1, 2, 3 in master mode/direct memory mode/transfer only.

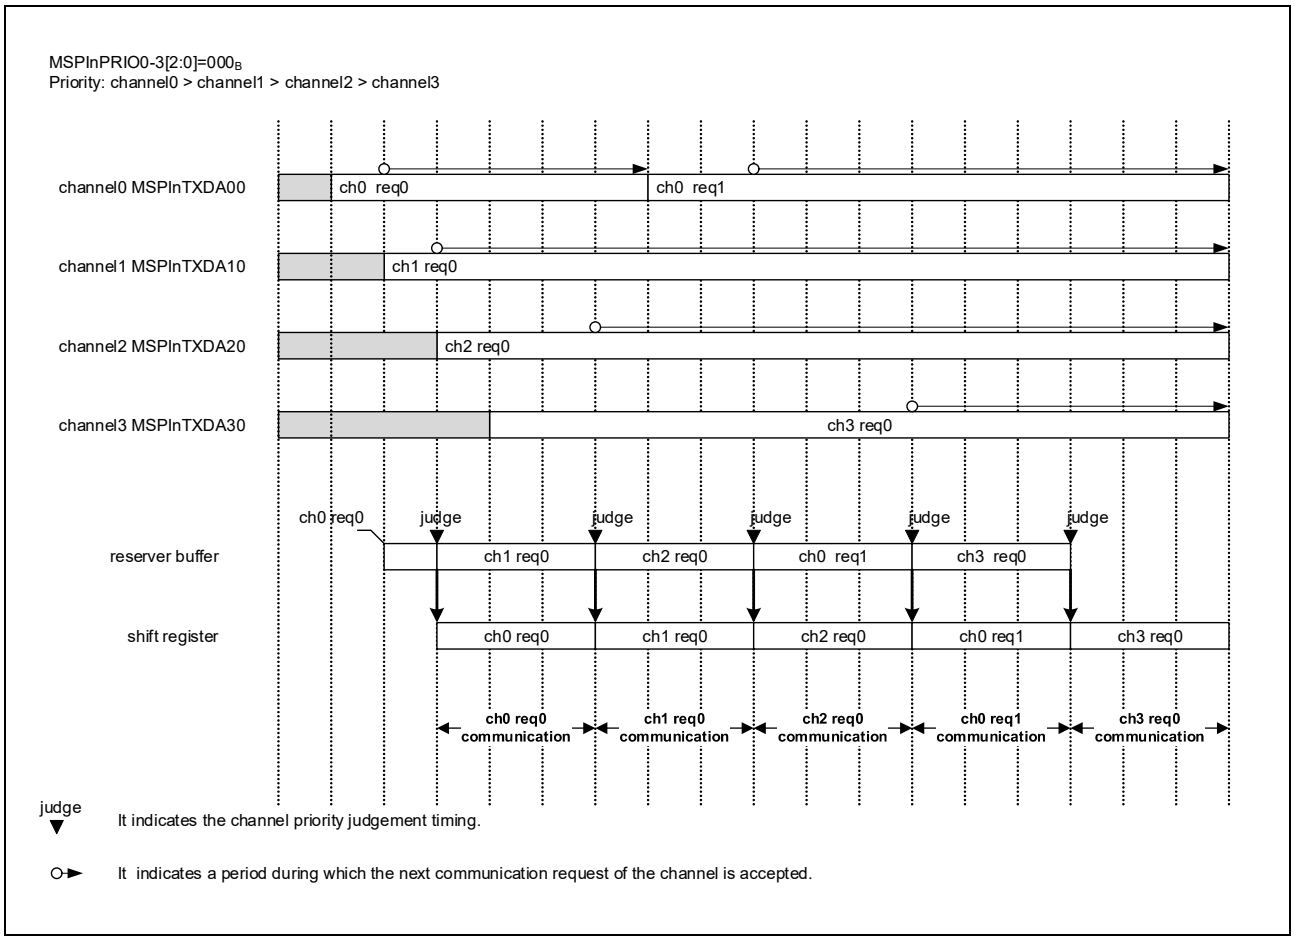

Figure 19.23 Timing Diagram of the Channel Priority Judgement

19.6.7.1 Channel lock function

The channel lock function can be used independently for each channel by MSPInCFGm0.MSPInLOCKm.

If the channel lock function is set, it is possible to reject interrupts of other channels from the acceptance of the first communication frame until the frame counter ends.

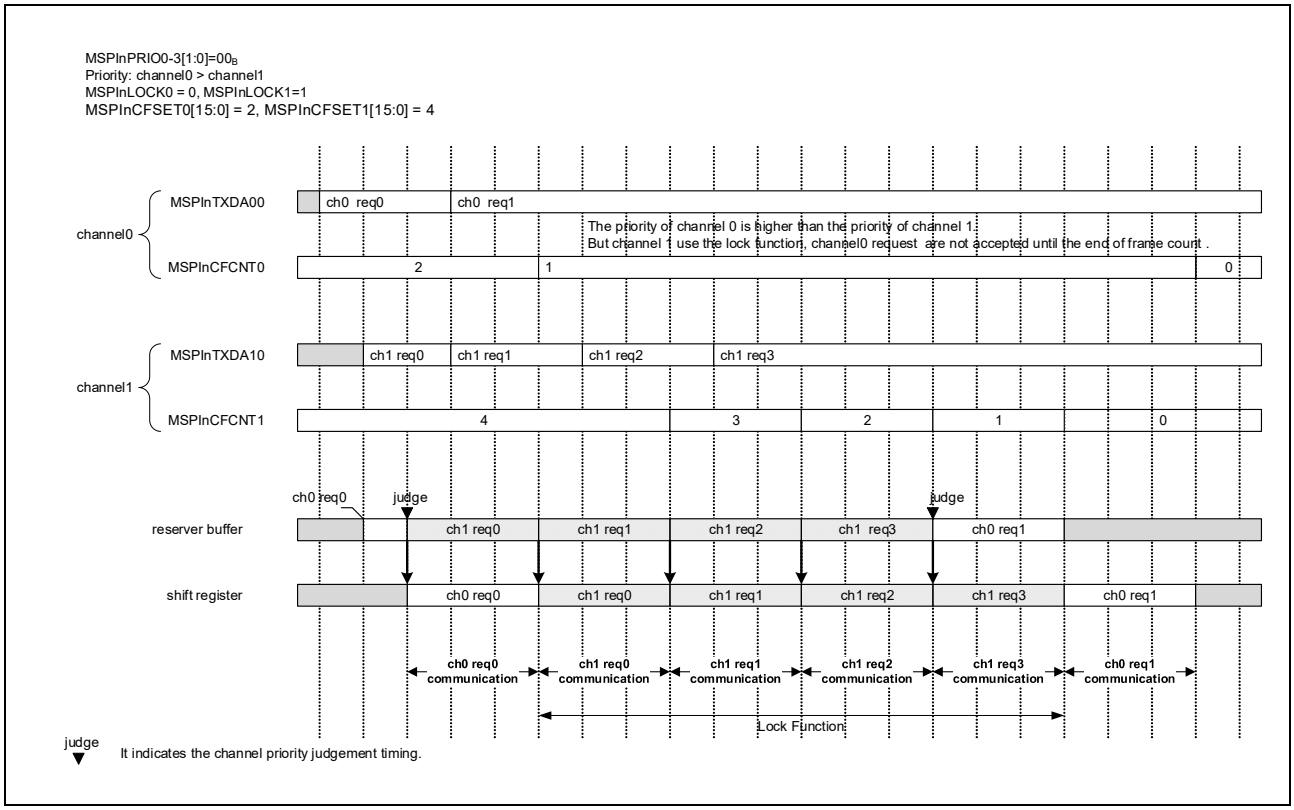

Figure 19.24 Timing Diagram of the Channel Priority Judgement in the Channel Lock Function

19.6.7.2 Job Enable Function in the Direct Memory Mode

The Job Enable function can be used independently for each channel by MSPInSSELm.MSPInJOBENm in the direct memory mode.

If MSPInJOBENm is set to 1, it is possible to reject interrupts from other channels until the MSPInJOBENm is cleared to 0.

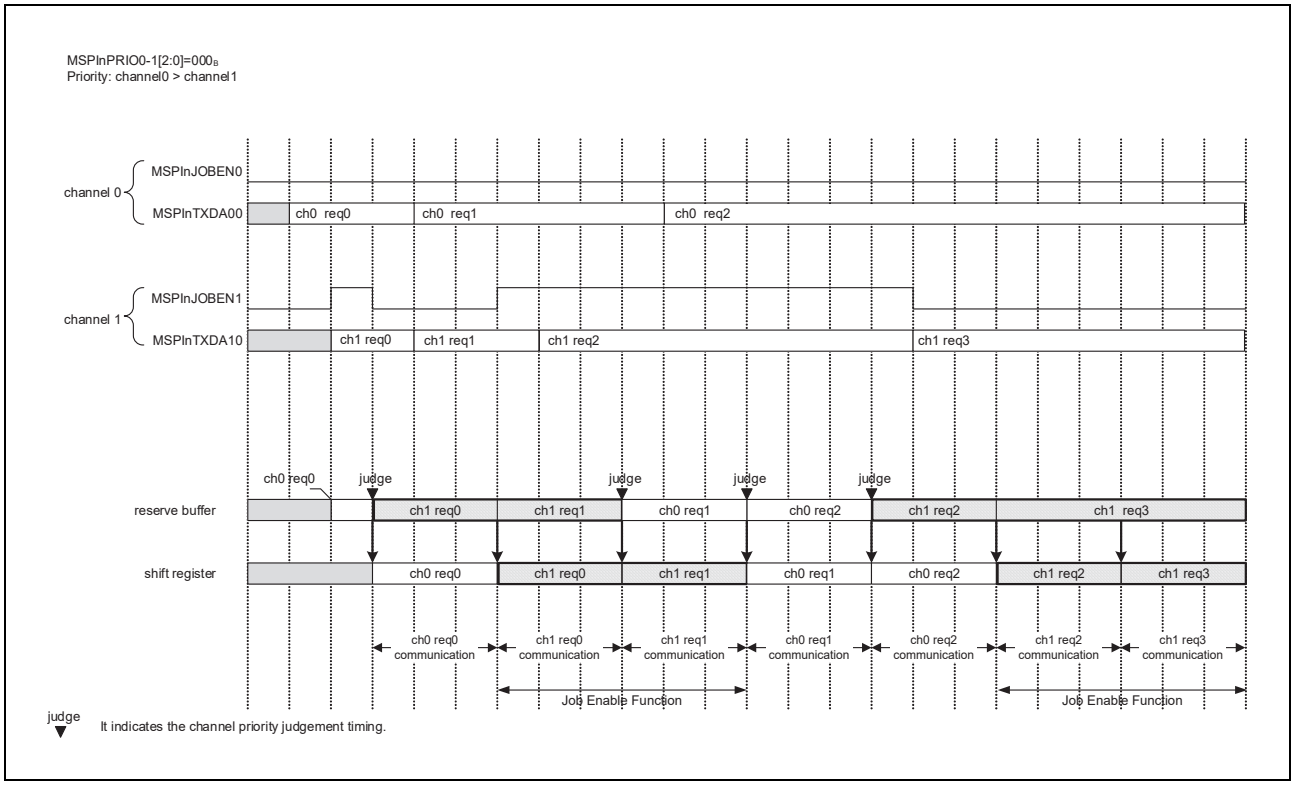

Figure 19.25 Timing Diagram of the Channel Priority Judgement in the Job Enable Function

NOTE

Even if MSPInJOBENm is set to 1 in the last frame data, MSPInJOBENm setting is ignored.

19.6.8 Error Detection

MSPI can detect 6 error types.

1. Parity error
2. CRC error
3. Data consistency error
4. Over-write error
5. Over-read error
6. Overrun error

Check for parity error and data consistency error can be enabled/disabled individually.

The table below shows the error types that can be detected in each mode for transmission/reception operation.

NOTE

The CRC check can use only in Safe-SPI protocol function.(see **Section 19.6.11**)

Table 19.58 Error Detection in Each Memory Mode for Transmission/Reception Operation

Error type	Direct Memory Mode			Fixed Buffer Memory Mode			Fixed FIFO Memory Mode		
	TX/RX*1	TX*2	RX*3	TX/RX*1	TX*2	RX*3	TX/RX*1	TX*2	RX*3
Parity	Detected	Not detected	Detected	Detected	Not detected	Detected	Detected	Not detected	Detected
CRC	Detected	Not detect	Detected	Detected	Not detected	Detected	Detected	Not detected	Detected
Data consistency	Detected	Detected	Not detected	Detected	Detected	Not detected	Detected	Detected	Not detected
Over-write	Not detected	Not detected	Not detected	Not detected	Not detected	Not detected	Detected	Detected	Not detected
Over-read	Not detected	Not detected	Not detected	Not detected	Not detected	Not detected	Detected	Not detected	Detected
Overrun*4	Detected	Not detected	Detected	Not detected	Not detected	Not detected	Detected	Not detected	Detected

Note 1. TX/RX: Transmission/Reception(MSPInTXEm=1 and MSPInRXEm=1)
Note 2. TX: Transmission only (MSPInTXEm=1 and MSPInRXEm=0)
Note 3. RX: Reception only (MSPInTXEm=0 and MSPInRXEm=1)
Note 4. The Overrun error occurs in the slave mode. It does not occur in the master mode.

19.6.8.1 Parity check

The parity check is enabled by setting MSPInCFGm1.MSPInDECHKm to 01_B. The parity type (odd or even) is specified by MSPInCFGm1.MSPInPSm. When parity check is enabled, the 1 bit of the parity bit is added in the communication.

If reception is enabled (MSPInCFGm0.MSPInRXEm =1) and the parity check is enabled (MSPInCFGm1.MSPInDECHKm = 01_B), the parity bit is checked after the communication completion.

When a parity check error occurs, the MSPInPEm flag is set to 1 and INTMSPInERR becomes active.

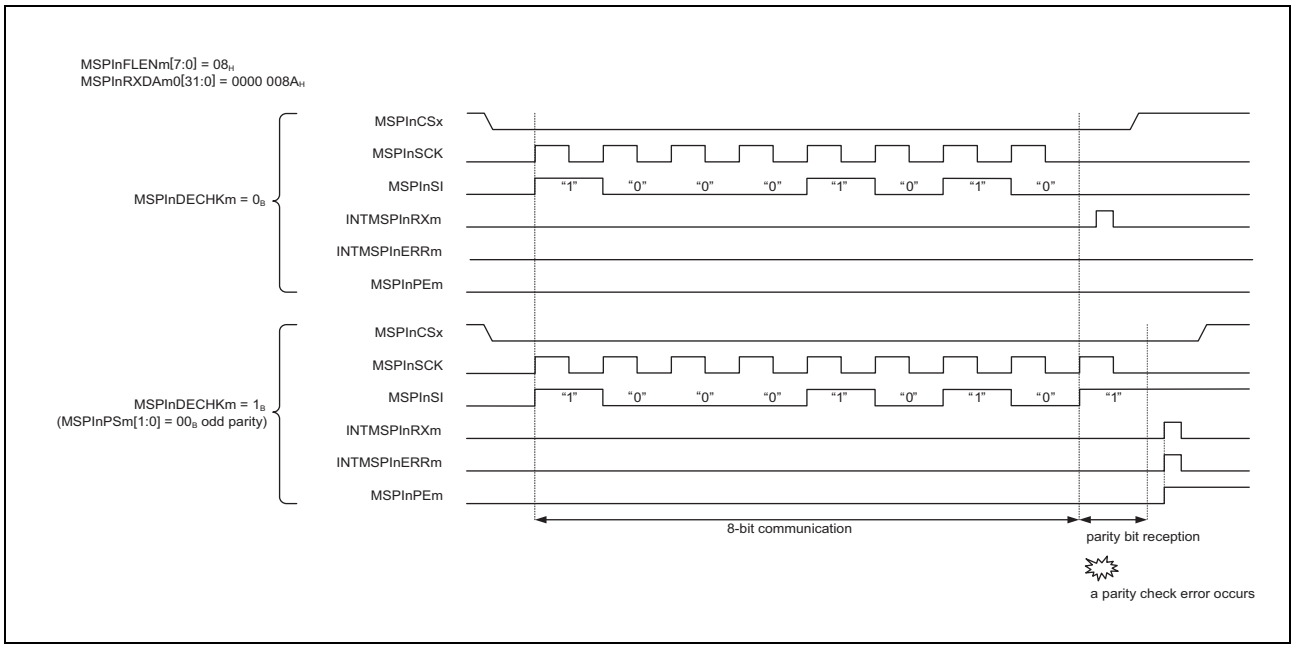

Figure 19.26 Timing Diagram of the Parity Check in the Reception

If transmission is enabled (MSPInCFGm0.MSPInTXEm = 1) and parity check is enabled(MSPInCFGm1.MSPInDECHKm = 01_B), the parity bit is added at the end of the communication frame.

When the transmission only operation is set (MSPInTXEm = 1, MSPInRXEm = 0), a parity check error never occurs.

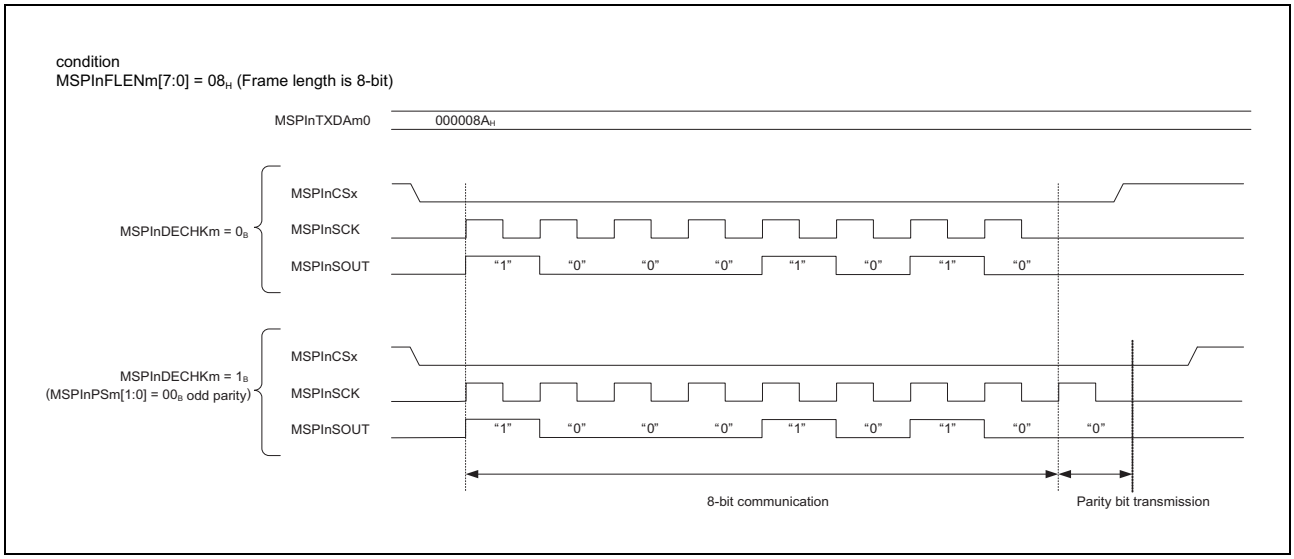

Figure 19.27 Timing Diagram of the Parity Check in the Transmission

19.6.8.2 Data Consistency Check

The data consistency check is enabled by setting MSPInCTL2.MSPInDCS to 1. It is not active if data transmission is disabled (MSPInCFGm0.MSPInTXEm = 0).

When the data consistency check is enabled, MSPIn compares the level of the transmission data (MSPInSOUT) and the physical level of the transmission pin (MSPInDCSI) at the reception sampling point.

When a data consistency check error occurs, the MSPInDCEm flag is set to 1 and INTMSPInERR becomes active at communication completion. The data consistency check error detection is common to all channels. When MSPInCTL2.MSPInDCS is set to 1, it is valid for all transmission setting channels.

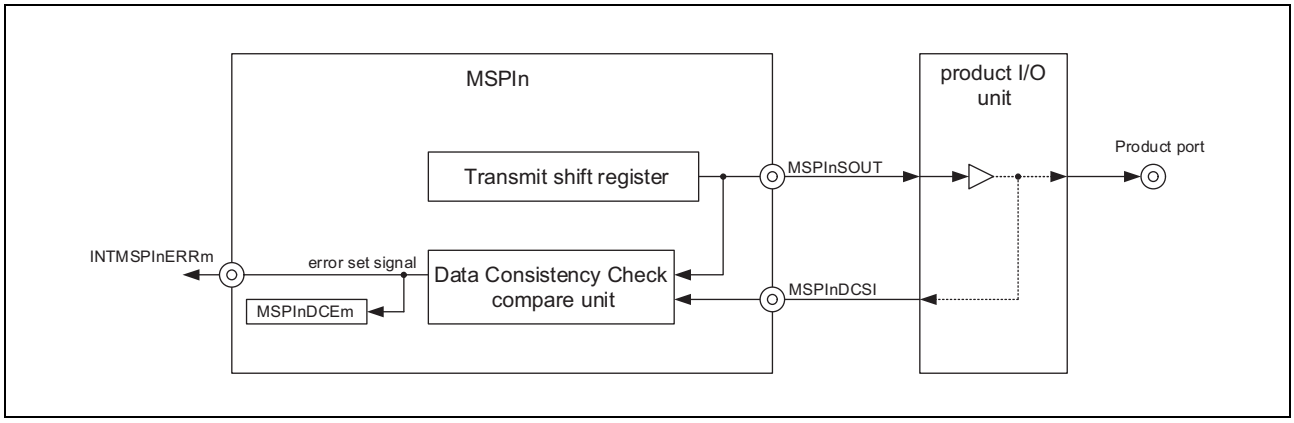

Figure 19.28 Functional Bock Diagram of the Data Consistency Check

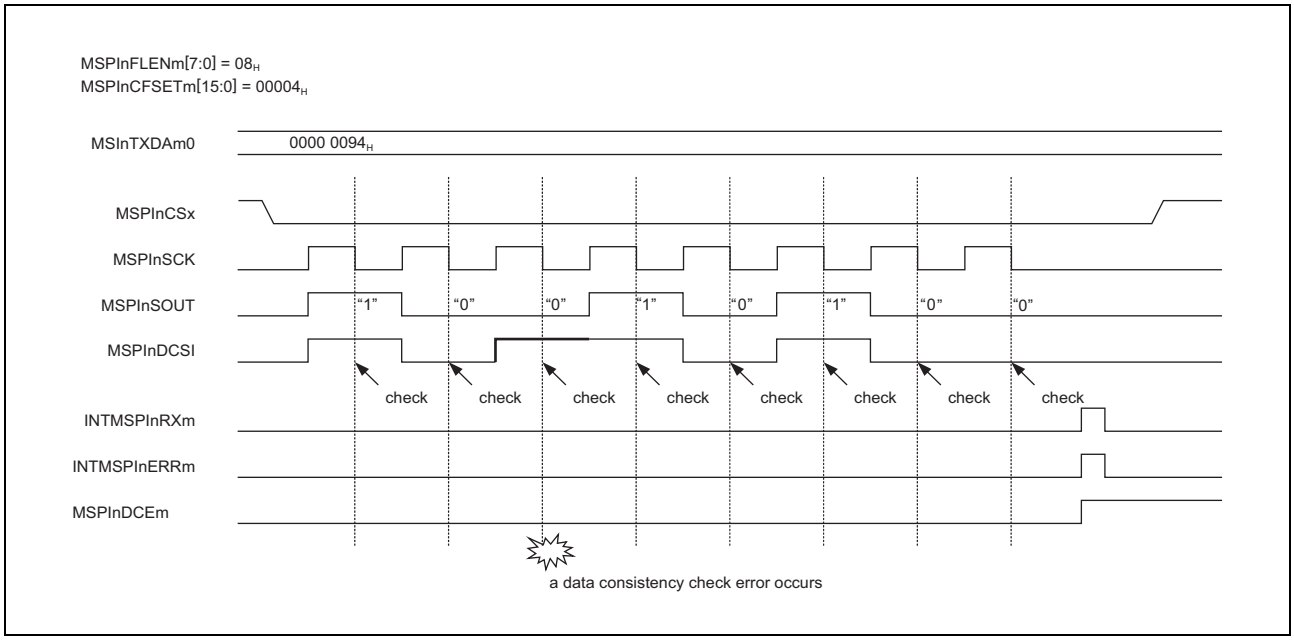

Figure 19.29 Timing Diagram of the Data Consistency Check

CAUTION

This function is not supported with LVDS mode.

19.6.8.3 Over-write/Over-read Error

An over-write and over-read errors may occur in the fixed FIFO memory mode and they never occur in the direct memory mode or fixed buffer memory mode.

An over-write error occurs when transmission data is written to the MSPInTXDAm0 register while the FIFO buffer is full.

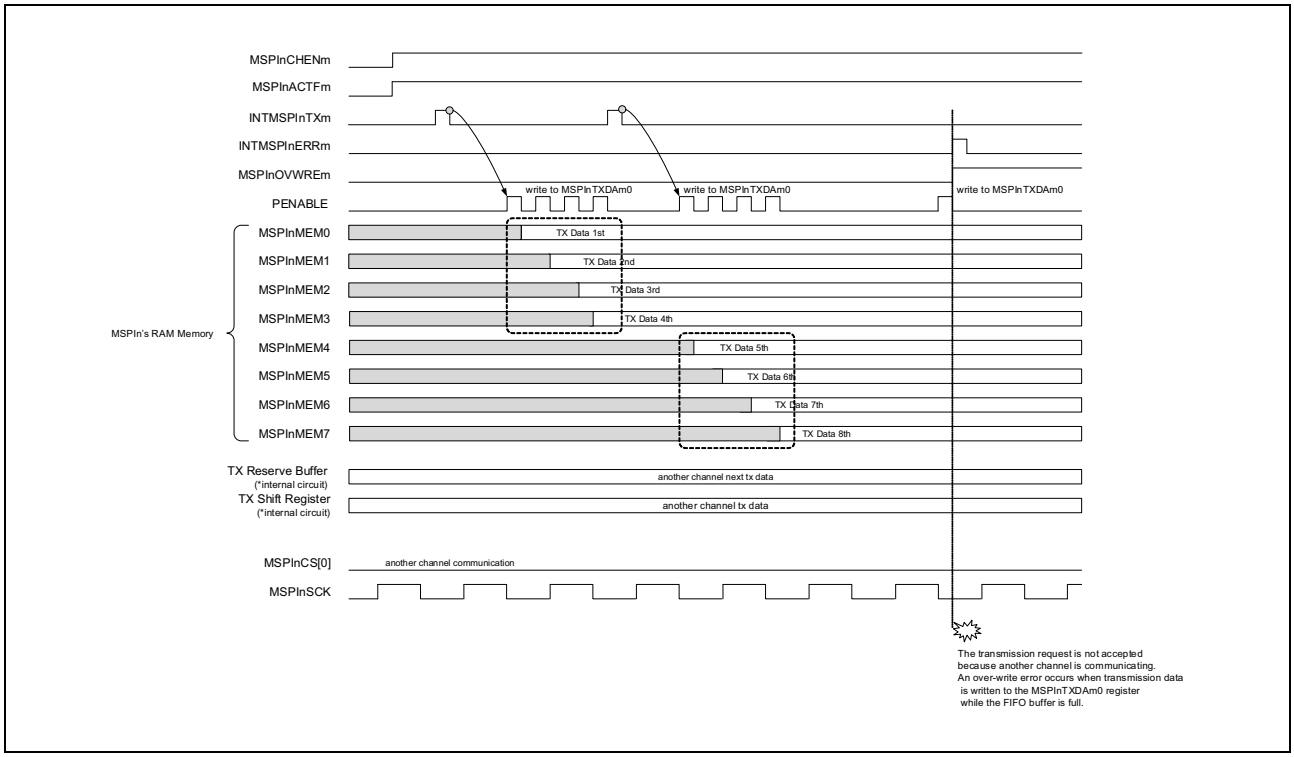

Figure 19.30 Timing Diagram of Over-write Error

An over-read error occurs when MSPInRXDAm0 register is read while the FIFO buffer is empty.

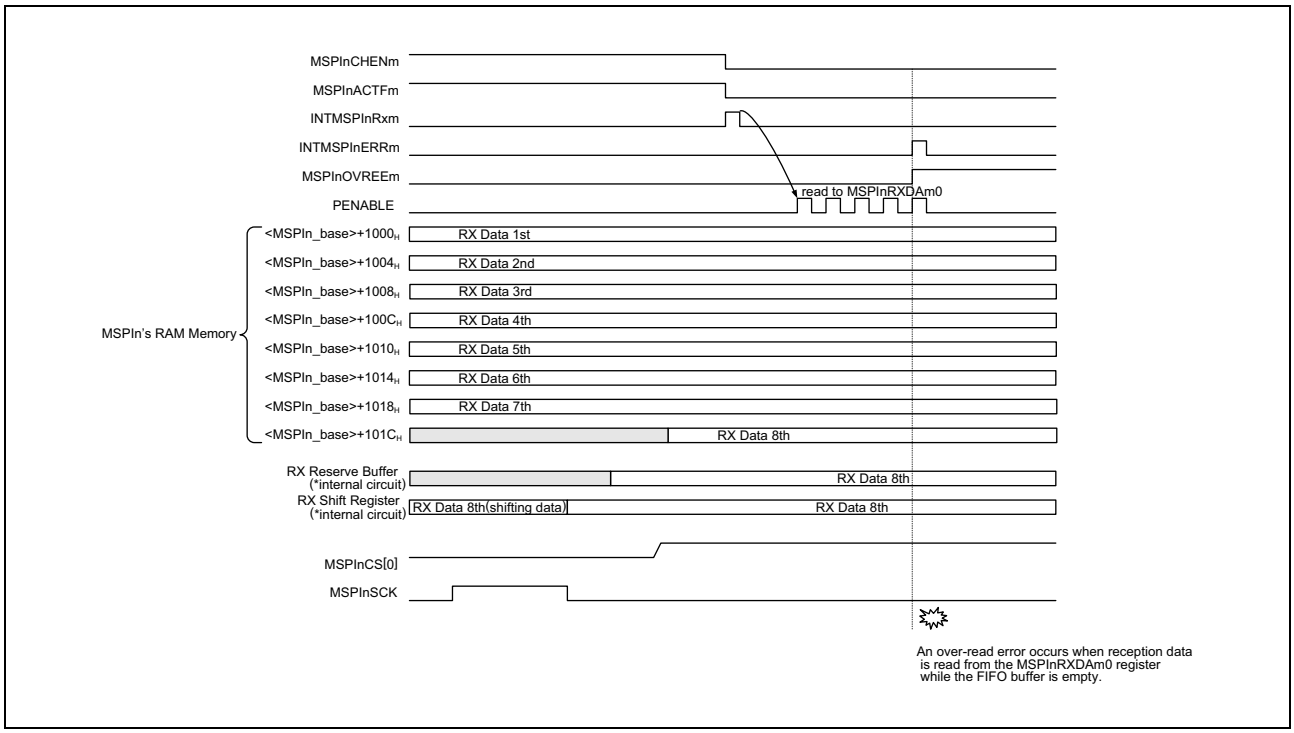

Figure 19.31 Timing Diagram of Over-read Error

19.6.8.4 Overrun Error Check

An overrun error can occur in the slave mode/direct memory mode and slave mode/fixed FIFO memory mode, and cannot occur in the fixed buffer memory mode.

The overrun error is not detected if data reception is disabled (MSPInCFGm0.MSPInRXEm = 0).

In the slave mode/direct memory mode and the slave mode/fixed FIFO memory mode, this error occurs when newly received data cannot be transferred from the shift register(internal reserve buffer) to the receive data register MSPInRXDAm0.

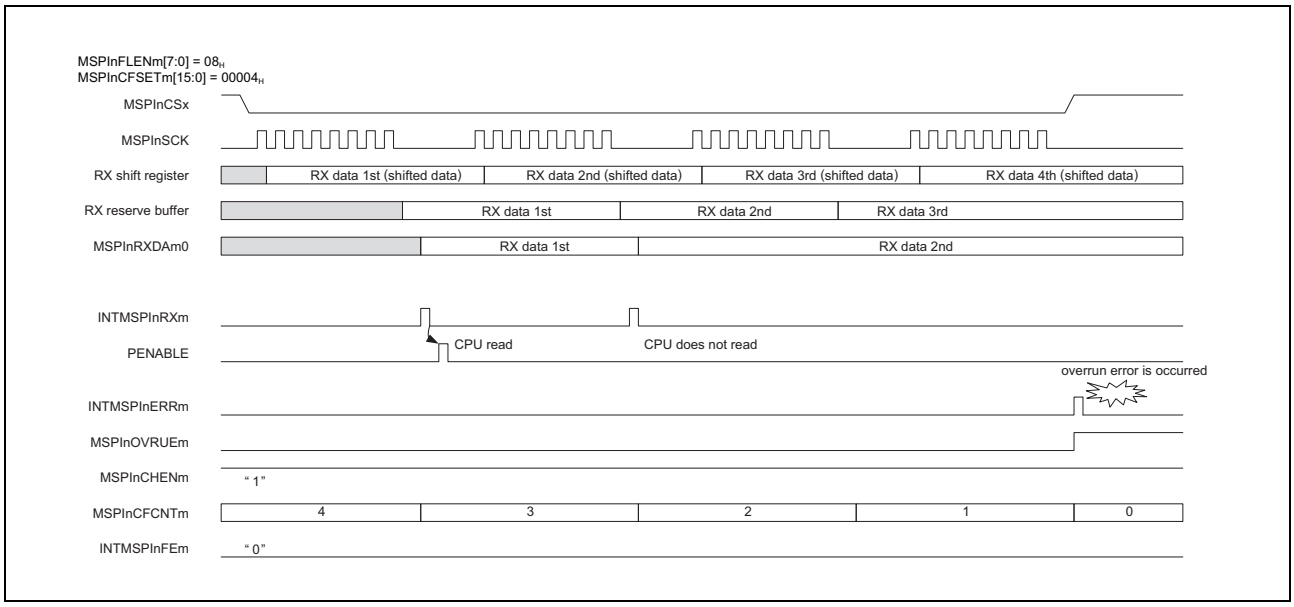

Figure 19.32 Timing Diagram of the Overrun Error

When an overrun error occurs, set MSPInEN = 0, and read received data as necessary.

If reading receive data, follow the procedure below.

Direct memory mode: Read MSPInRXDAm0 until MSPInRXRQFm = 0.

Fixed FIFO memory mode:Check the value of MSPInFIRXNm[7:0] and read the unread reception data.

NOTE

In the master mode, communication is stopped until the reception register MSPInRXDAm0 is read.

19.6.9 Communication Stop or IP Initialize

19.6.9.1 Communication Stop by the Clear Trigger

The channel operation can be stopped in synchronization with communication by using the channel enable clear trigger bit (MSPInCSTCm.MSPInCHENCm).

When the channel is stopped by the MSPInCSTCm.MSPInCHENCm, the communication held in the internal reserve-buffer is executed and then MSPInCHENm is cleared.

Therefore if channel is stopped by the MSPInCHENCm bit, when the current communication or the next communication stops, MSPInCHENm is cleared to 0.(If the channel is not communicating or communication of the channel is not held in the reserve buffer, MSPInCHENm is immediately cleared to 0.)

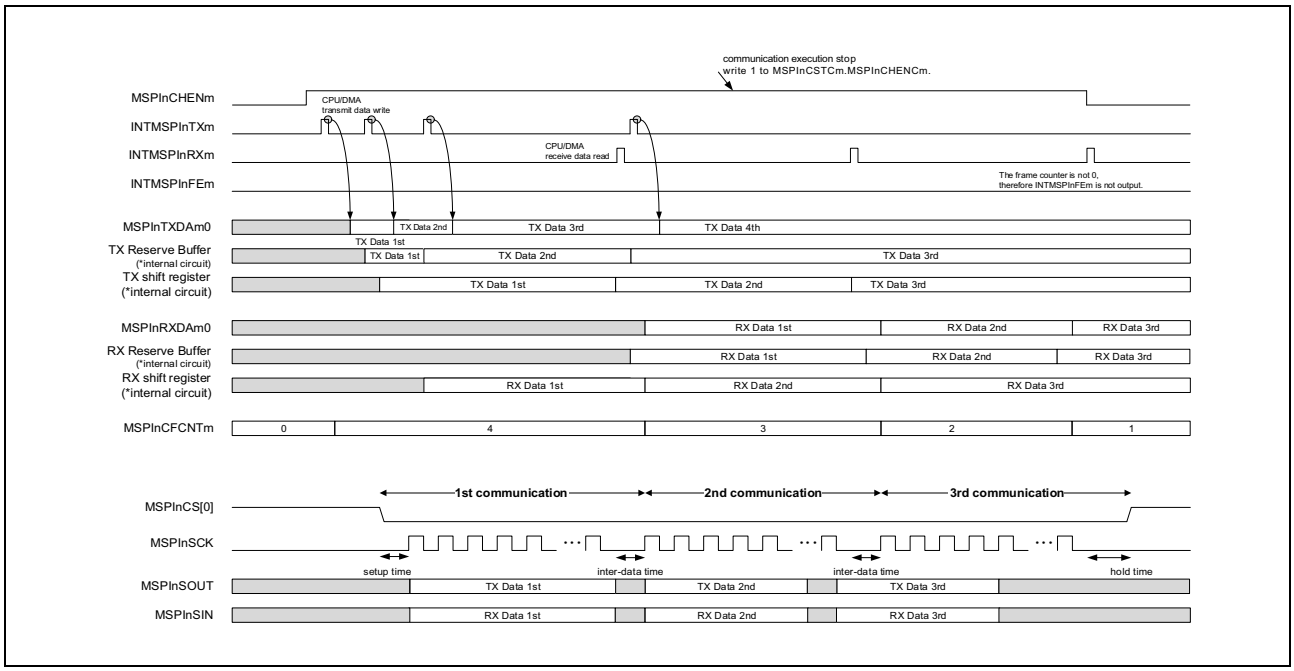

Figure 19.33 Communication Stop by the MSPInCHENCm

NOTE

If MSPInCFGm1.MSPInCSRIm is 1, MSPInCS becomes the inactive level, when the all channels are stopped.

If MSPInCFGm1.MSPInCSRIm is 0, MSPInCS keeps the active level, when the all channels are stopped.

If 1 is written to MSPInCHENCm in the Job Enable function, The communication is continued until the Job Enable function ends, and after receiving the last frame of the Job Enable function, MSPInCHENm is cleared to 0.

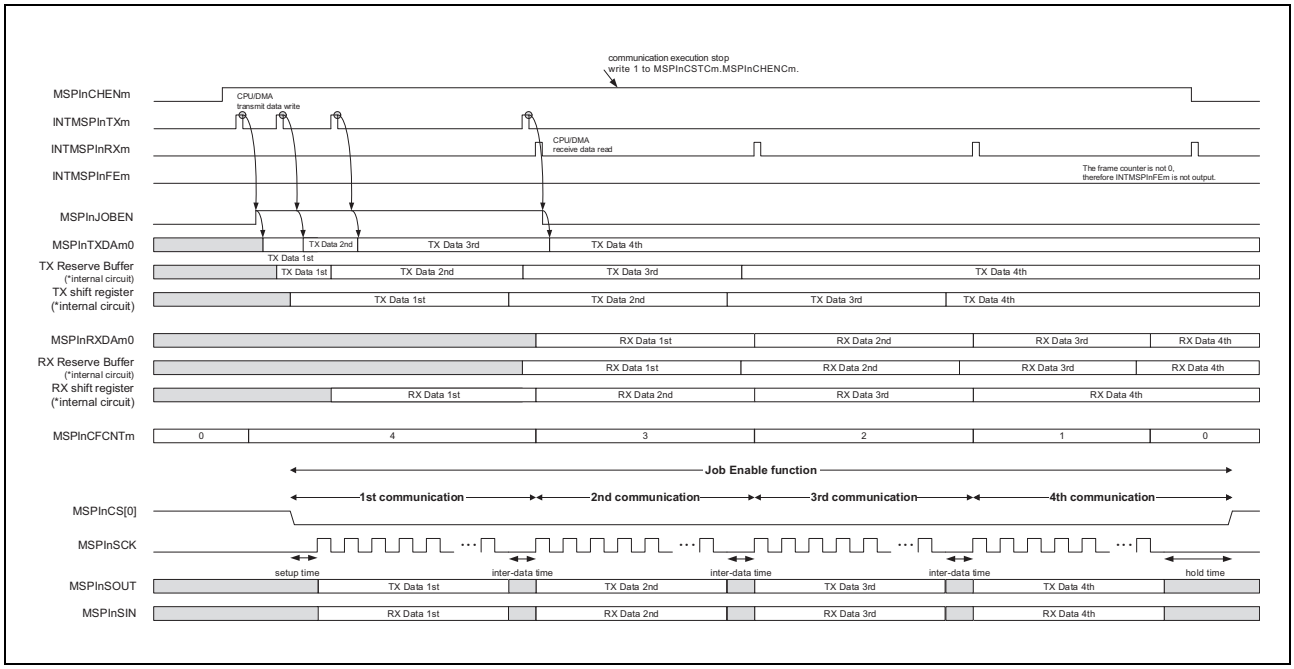

Figure 19.34 Communication Stop by the MSPInCHENCm in Job Enable Function of Direct Memory Mode

To stop communication by using MSPInCSTCm.MSPInCHENCm, follow the procedure below.

(1) Master mode

Direct Memory Mode:

1. Write MSPInCSTCm.MSPInCHENCm to 1.
2. Wait until MSPInCSTRm.MSPInCHENm becomes 0.
   *The remaining frame transmission data and job transmission data must be written.
   If MSPInCSTRm.MSPInRXRQFm is set to 1(INTMSPInRX is output), read the received data.

Fixed buffer memory mode:

1. Write MSPInCSTCm.MSPInCHENCm to 1.
2. Wait until MSPInCSTRm.MSPInCHENm becomes 0.
3. Read received data as necessary.

Fixed FIFO memory mode:

1. Check the value of MSPInCSTRm.MSPInRXRQFm flag and read received data until MSPInCSTRm.MSPInRXRQFm flag becomes 0.
2. Write MSPInCSTCm.MSPInCHENCm to 1.
   *Write MSPInCSTCm.MSPInCHENCm to 1 within one communication frame after Software executes "1".
3. Wait until MSPInCSTRm.MSPInCHENm becomes 0.
   *The remaining frame transmission data must be written.

(2) Slave mode

Direct Memory Mode:

1. Write MSPInCSTCm.MSPInCHENCm to 1.
2. Wait until MSPInCSTRm.MSPInCHENm becomes 0.
   *The remaining frame transmission data must be written.
   If MSPInCSTRm.MSPInRXRQFm is set to 1(INTMSPInRX is output), read the received data.
3. Write MSPInCTL0.MSPInEN to 0.(Initialize IP)

Fixed buffer memory mode:

1. Write MSPInCSTCm.MSPInCHENCm to 1.
2. Wait until MSPInCSTRm.MSPInCHENm becomes 0.
3. Read received data as necessary.
4. Write MSPInCTL0.MSPInEN to 0.(Initialize IP)

Fixed FIFO memory mode:

1. Check the value of MSPInCSTRm.MSPInRXRQFm flag and read received data until MSPInCSTRm.MSPInRXRQFm flag becomes 0.
2. Write MSPInCSTCm.MSPInCHENCm to 1.
   *Write MSPInCSTCm.MSPInCHENCm to 1 within one communication frame after Software executes "1".
3. Wait until MSPInCSTRm.MSPInCHENm becomes 0.
4. Write MSPInCTL0.MSPInEN to 0.(Initialize IP)

Table 19.59 List of Bits Initialized when MSPInCHENm is Cleared from 1 to 0

Bit name	Initialization value
MSPInCSTRm.MSPInTXRQFm	0
MSPInCSTRm.MSPInACTFm	0

MSPInFRERSTm.MSPInCEFSTm	0
MSPInFRERSTm.MSPInPEFSTm	0

19.6.9.2 IP initialize by the IP enable

All channel operation can be stopped immediately by using the IP enable bit (MSPInCTL0.MSPInEN).

When MSPInEN is cleared to 0, the MSPInCSTRm.MSPInCHENm bit is cleared to 0, and the communication stops immediately.

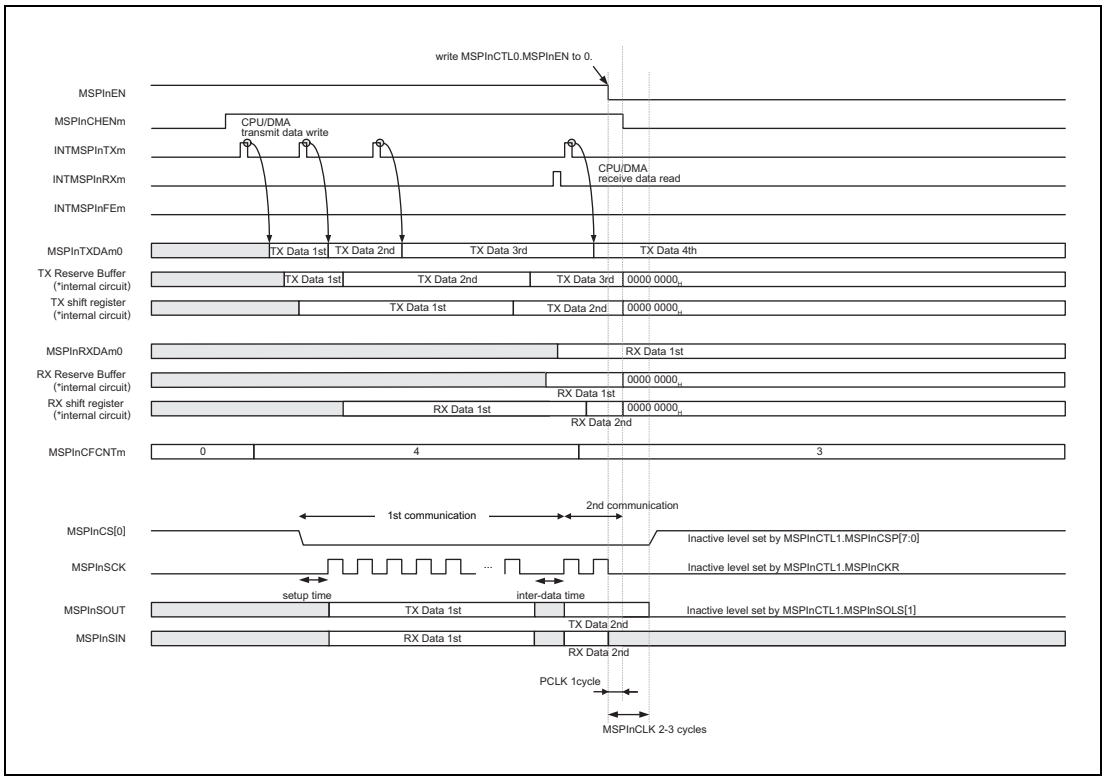

Figure 19.35 IP Initialize by the MSPInEN

NOTE

If MSPInCFGm1.MSPInCSRIm is 1, MSPInCS becomes the inactive level, when the channel is stopped.

Table 19.61 List of Ports or Bits Initialized when MSPInEN is Cleared from 1 to 0

19.6.10 Loop-back mode

Loop-back mode is a special mode for self-test. This mode is only available in the master mode.

In Loop-back mode, MSPInSCK, MSPInCS[7:0] and MSPInSOUT are fixed to the inactive level. The transmit and receive signals are internally connected, as shown in the figures below.

In the self-test of the Loop-back mode, it performs transmission/reception and It checks whether the received data is the same as the transmitted data.

Table 19.63 Port Output Level in Loop-Back Mode

Port Name	Output level
MSPInSCK	Inactive(inactive level set by MSPInCKR)
MSPInCS[7:0]	Inactive(inactive level set by MSPInCSP[7:0])
MSPInSOUT	Inactive(inactive level set by MSPInSOLS[1])

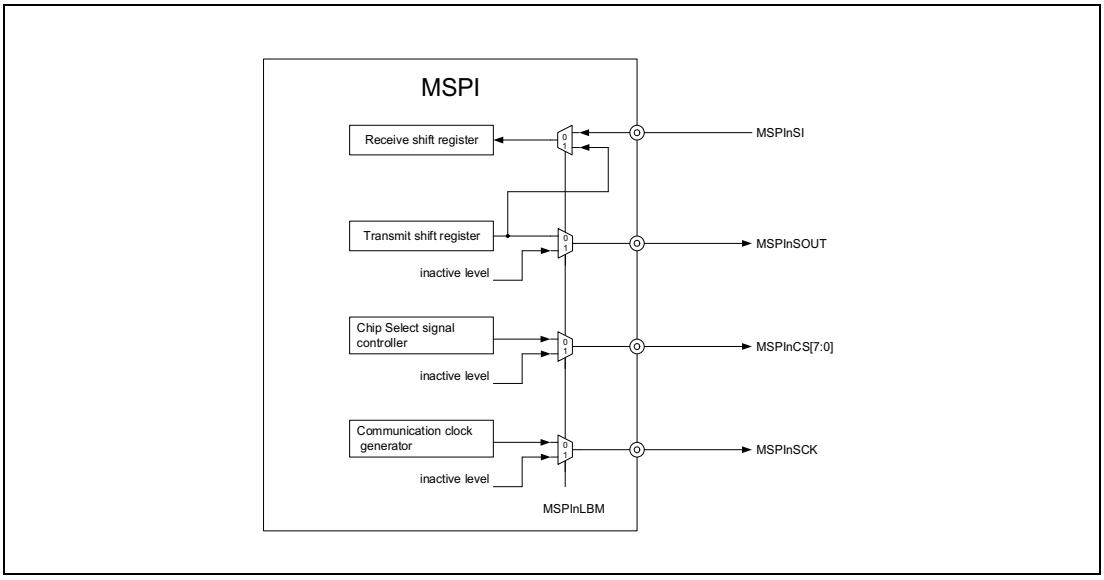

Figure 19.36 Transmission/reception in the Master-direct Memory Mode

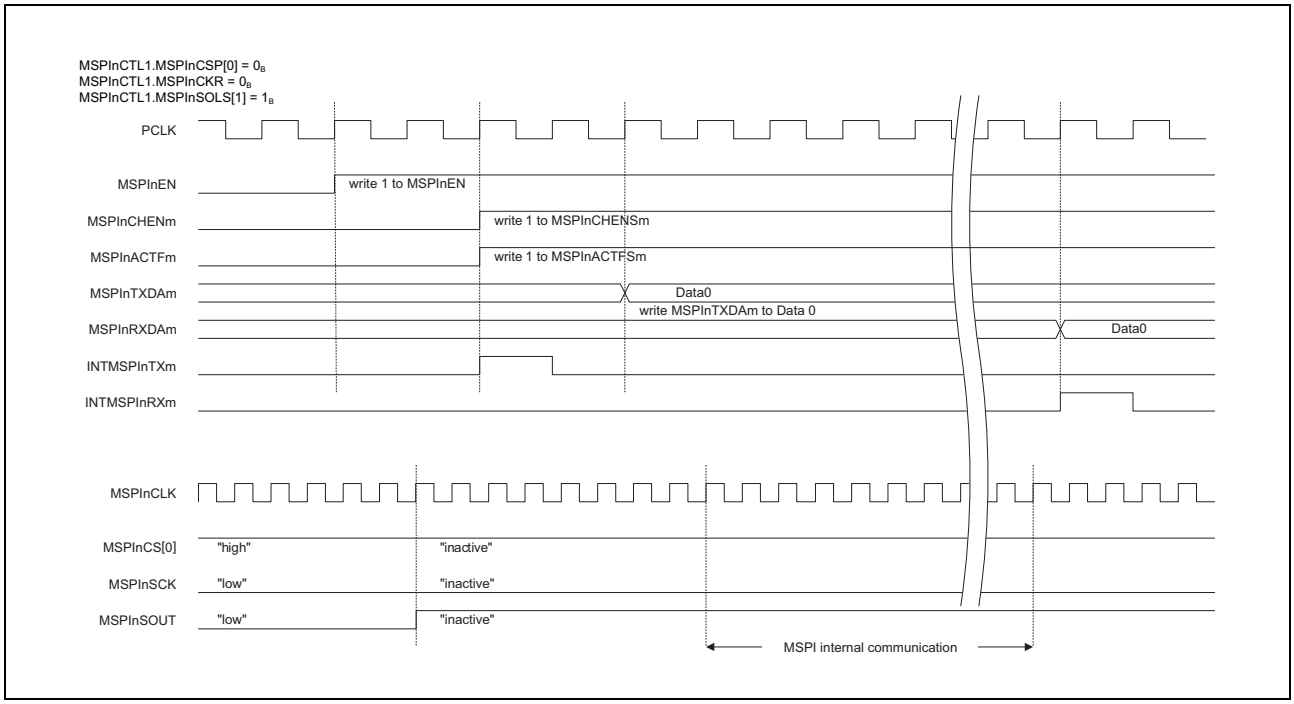

Figure 19.37 Communication of Loop-back Mode in Master Direct Memory Mode

19.6.11 Safe-SPI Protocol Function

In the master mode, MSPI can operates the Safe-SPI protocol function by setting MSPInCFGm1.MSPInSAFEm to 1.

Safe-SPI protocol has two frame formats, in-frame and out-of-frame.

When MSPInCFGm1.MSPInSAFS is 0, MSPI operates in in-frame format. When MSPInCFGm1.MSPInSAFS is 1, MSPI operates in out-of-frame format.

When using the Safe-SPI protocol function, The following configuration must be set.

- Transmission/Reception
- Frame length: 32 bits
- Communication direction : MSB
- The parity check is invalid

CAUTION

The CRC error always occurs when MSPI operates Loop-Back mode in Safe-SPI protocol function.

19.6.11.1 Safe-SPI protocol function in in-frame format

In transmission of in-frame format, MSPI calculates CRC using 31 to 5 bits of setting data, and transmits the CRC code in 4 to 2 bits of the communication transmission data.

In reception of in-frame MSPI internally calculates CRC using 26 to 3 bits of reception data, and compares bit 2 to 0 with internally calculated CRC.

If the comparison result is different, MSPI outputs an INTMSPInERR and sets the MSPInCEm flag.

CRC protection

For the in-frame format a 3 bit CRC with the polynomial 0x5 (x3 + x1 + x0) is used with a start value of 111_B and a target value of 000_B.

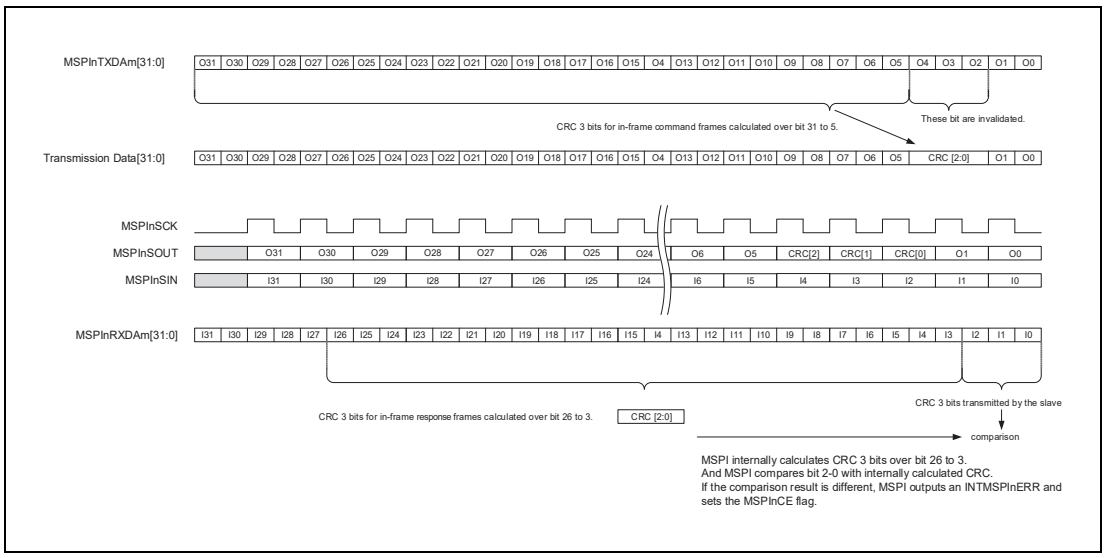

Figure 19.38 MSPI communication of Safe-SPI protocol in in-frame format

19.6.11.2 Safe-SPI protocol function in out-of-frame format

In transmission of out-of-frame format, MSPI calculates CRC using 31 to 3 bit of setting data, and transmits the CRC code in 2 to 0 bits of the communication transmission data.

In reception of out-of-frame MSPI internally calculates CRC using 31 to 3 bits of reception data, and compares bit 2 to 0 with internally calculated CRC.

If the comparison result is different, MSPI outputs an INTMSPInERR and sets the MSPInCE flag.

CRC protection

For the out-of-frame format a 3bit CRC with the polynomial 0x5 (x3 + x1 + x0) is used with a start value of 101_B and a target value of 000_B.

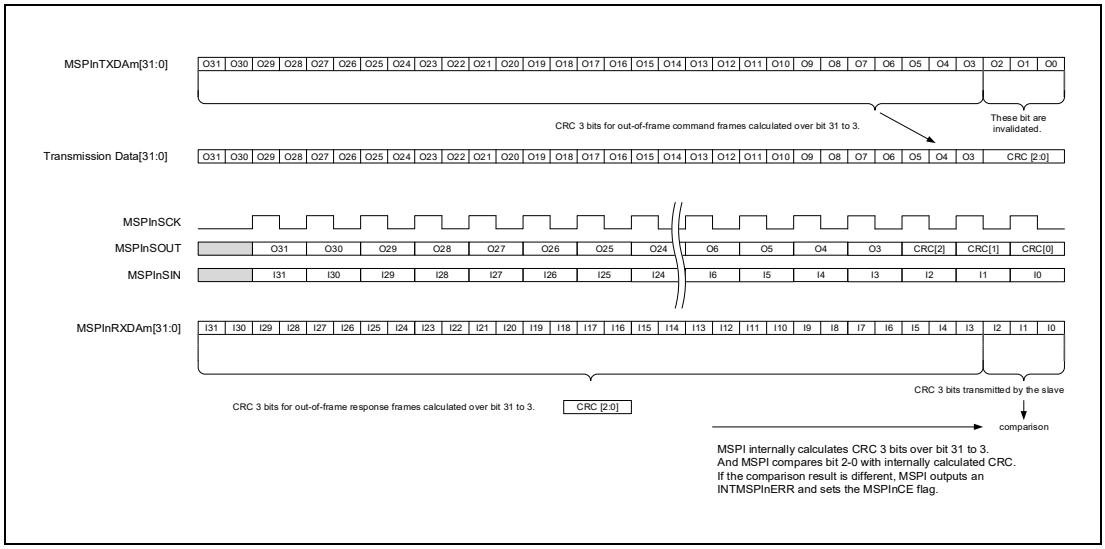

Figure 19.39 MSPI communication of Safe-SPI protocol in out-of-frame format

19.6.11.3 The CRC error mask function in Safe-SPI protocol function

In the out-of-frame format, the slave may not be able to send valid data and CRC on the first communication. Therefore, MSPI may detect a CRC error.

It is possible to mask the CRC error the first frame using the MSPInSAFCMm bit function.

When the MSPInSAFCMm =1, it does not check the CRC error of the first frame(MSPInCFSETm[15:0] = MSPInCFCNTm[15:0])

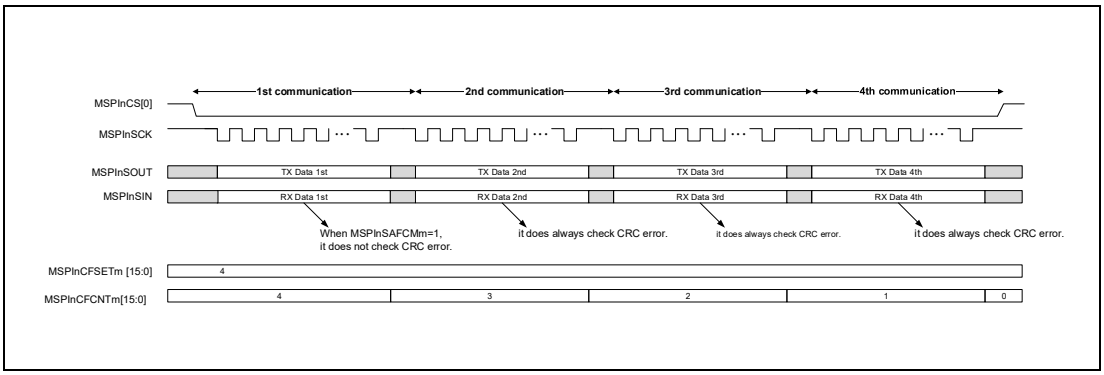

Figure 19.40 The MSPInSAFCMm bit function

NOTE

When the MSPInSAFCMm is set to 1, the CRC error of the first frame is masked in both in-frame format and out-of-frame format.

19.7 Memory Modes

The MSPI has a configurable RAM that can be used for buffered I/O.

The MSPI RAM is shared by each channel. Each channel has a register that sets the RAM area to be used.

The MSPI has three memory modes, and MSPI's RAM is used in two memory modes.

The memory modes can be set for each channels.

The MSPI RAM can be directly accessed by CPU/DMA.

19.7.1 Direct Memory Mode

In direct access memory mode, the channel does not use RAM, communication is using the MSPInTXDAm0 register for transmit data and the MSPInRXDAm0 register for receive data.

Interrupts are output for each transmission and reception, and communication is controlled by CPU/DMA.

19.7.1.1 Operation

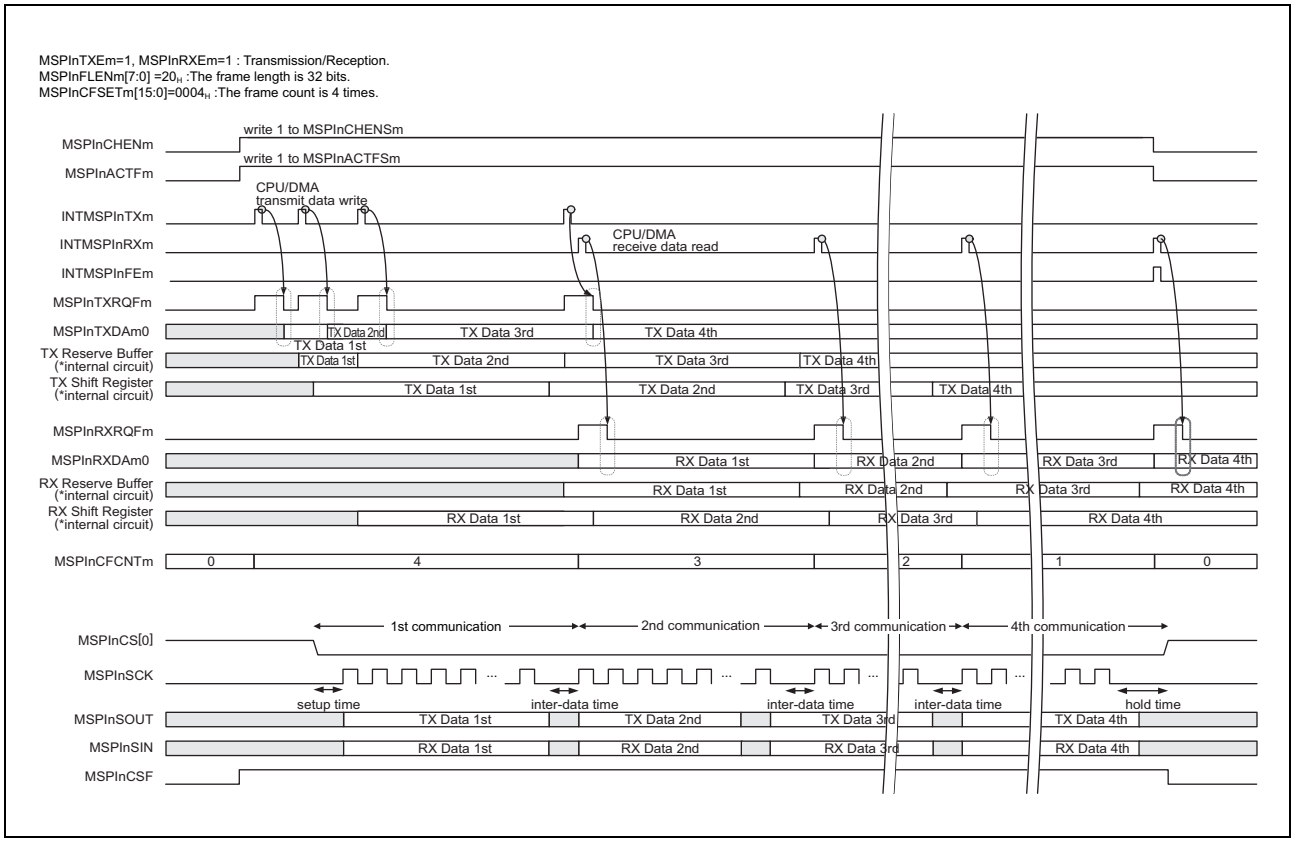

Figure 19.41 Transmission/Reception in the Master-Direct Memory Mode

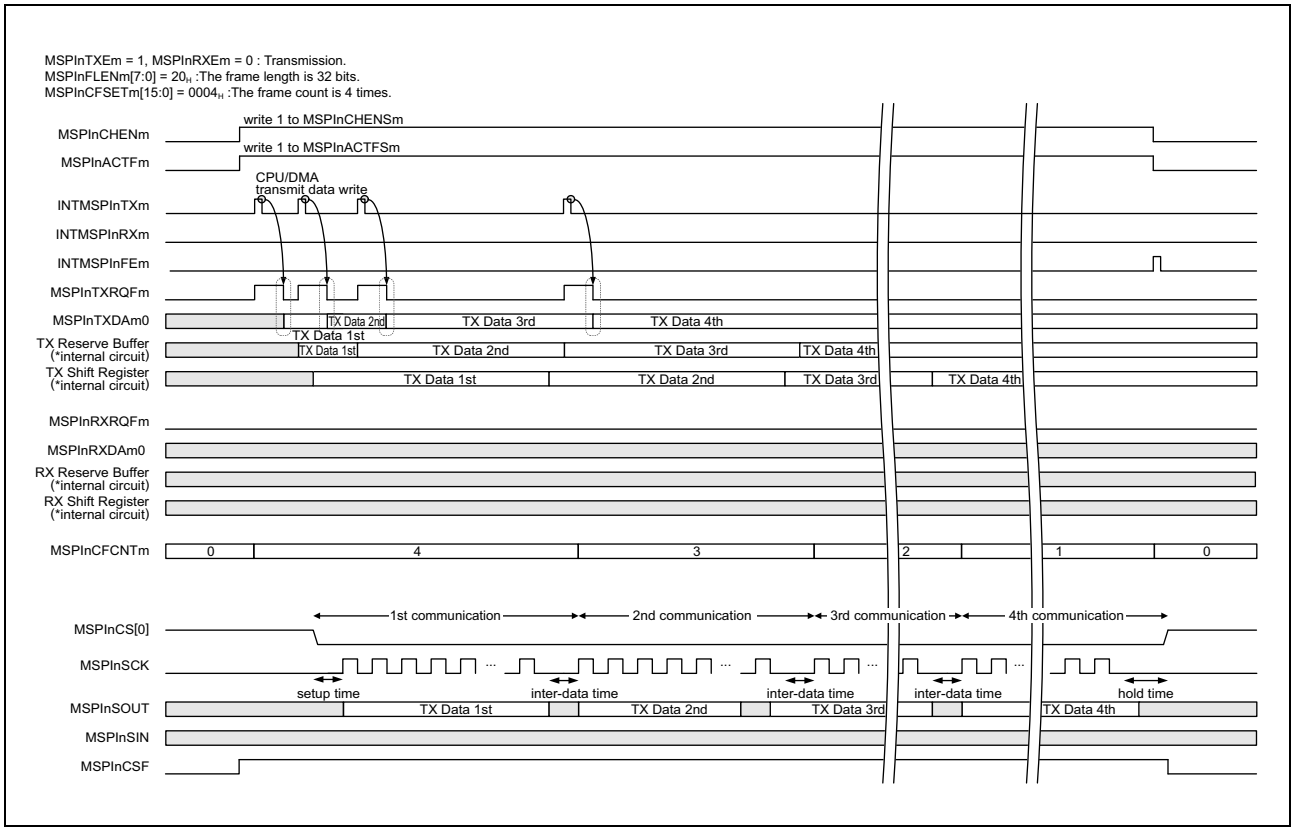

Figure 19.42 Transmission in the Master-Direct Memory Mode

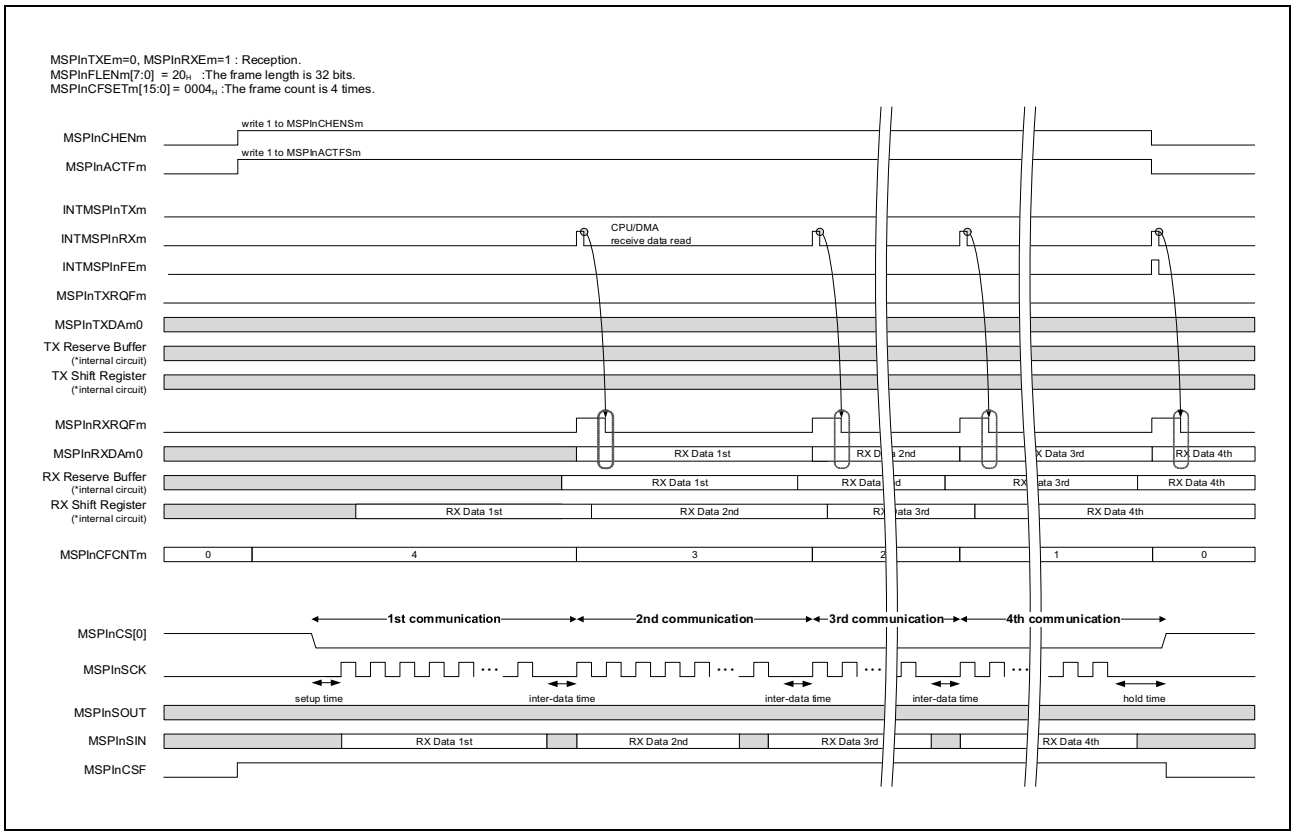

Figure 19.43 Reception in the Master-Direct Memory Mode

When it executes communication of 33 bits or more in the direct mode, an interrupt is output in units of 32 bits.

For each INTMSPInTX interrupt output, write MSPInTXDAm0 to transmission data. And for each INTMSPInRX interrupt output, read reception data of MSPInRXDAm0.

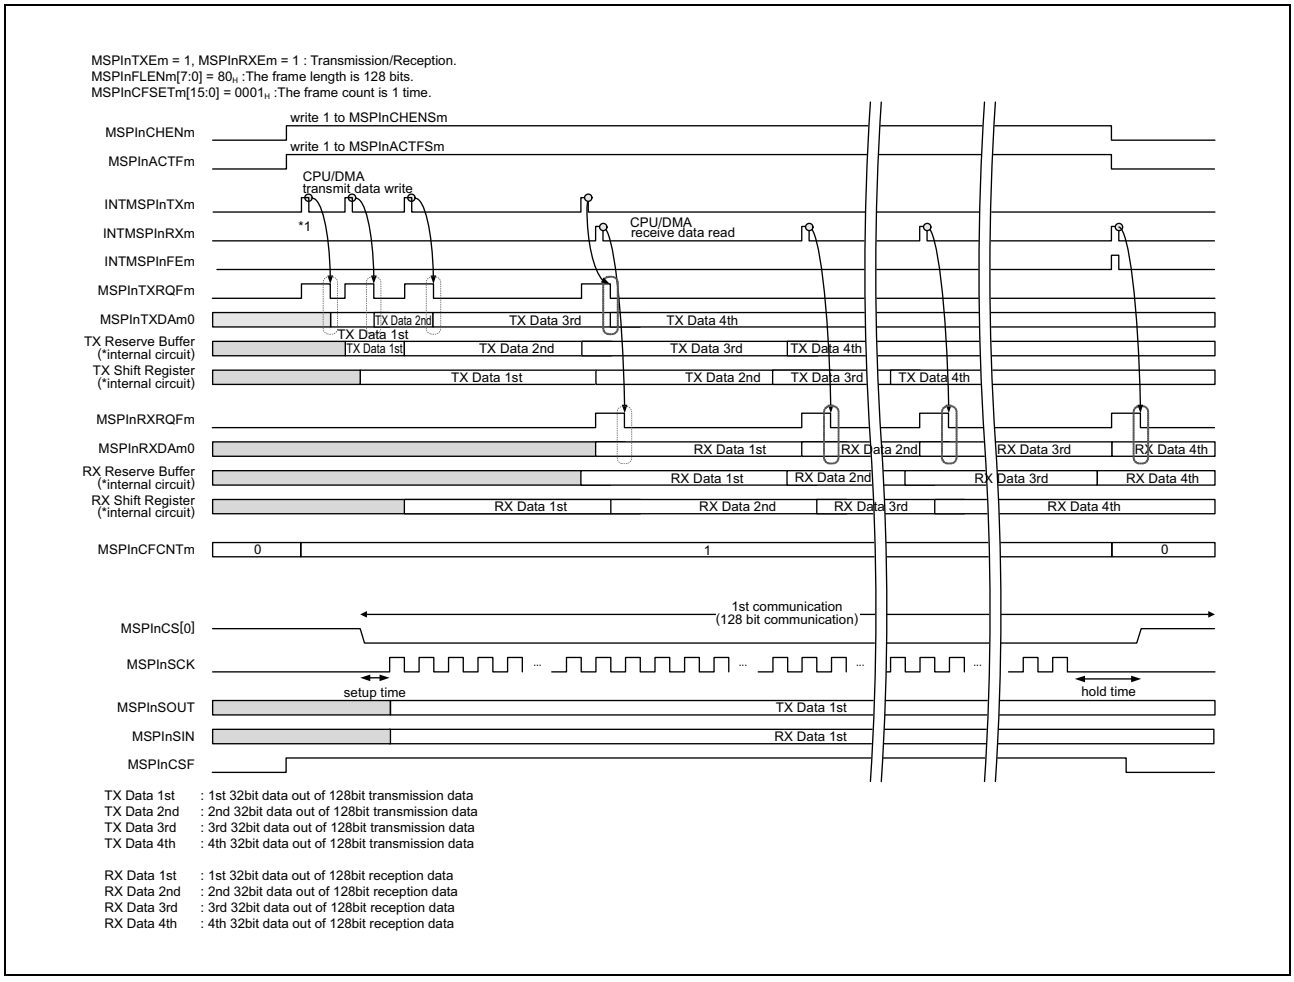

Figure 19.44 Transmission/Reception in the Master-Direct Memory Mode (The Frame Length is 128 bits)

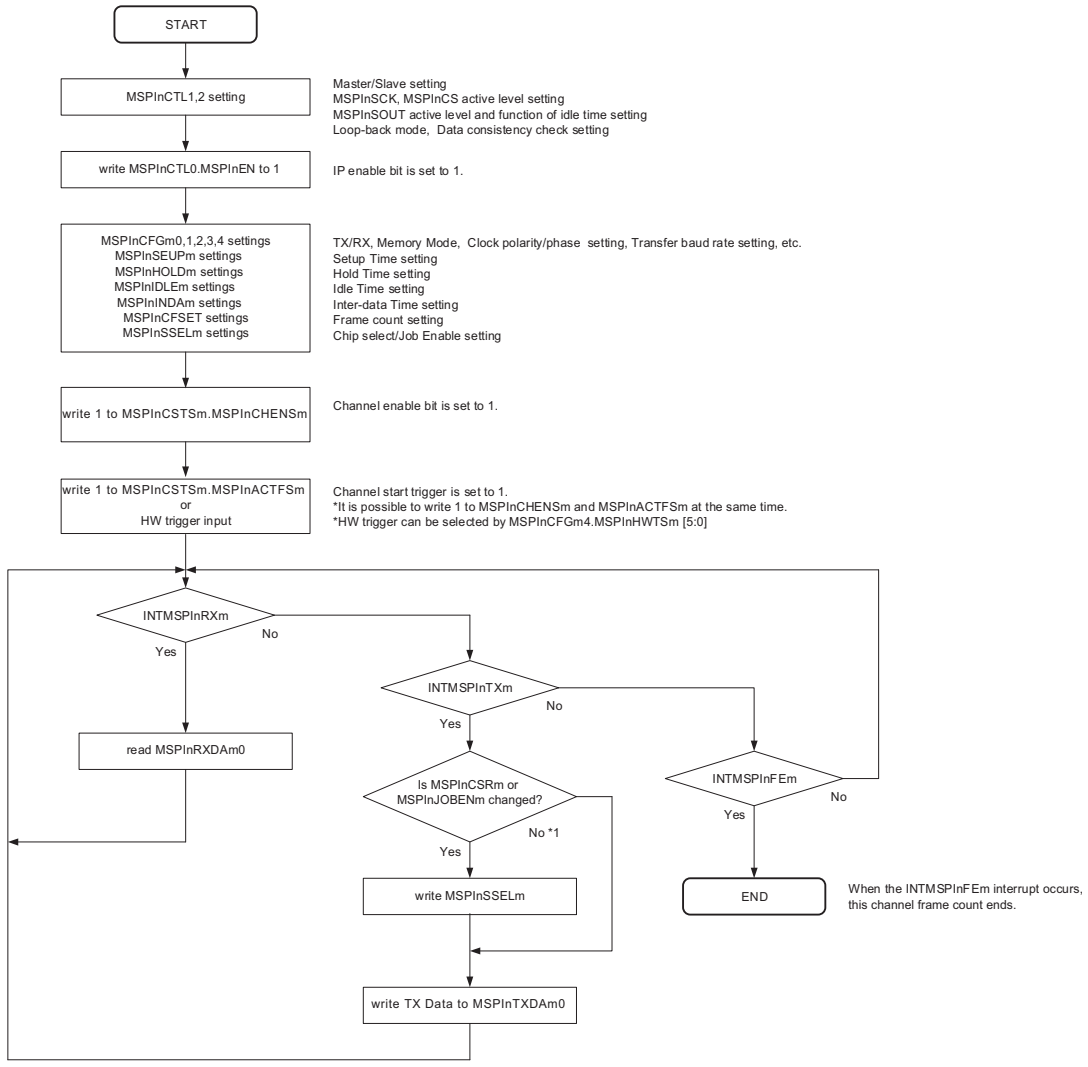
CAUTION

For the MSPInCS [7:0] and MSPInJOBENm settings, the setting value when the first data of the frame is written becomes effective (*1 in the Figure).

19.7.1.2 Operating Procedure

Follow the procedure of this chapter to operate in direct memory mode.

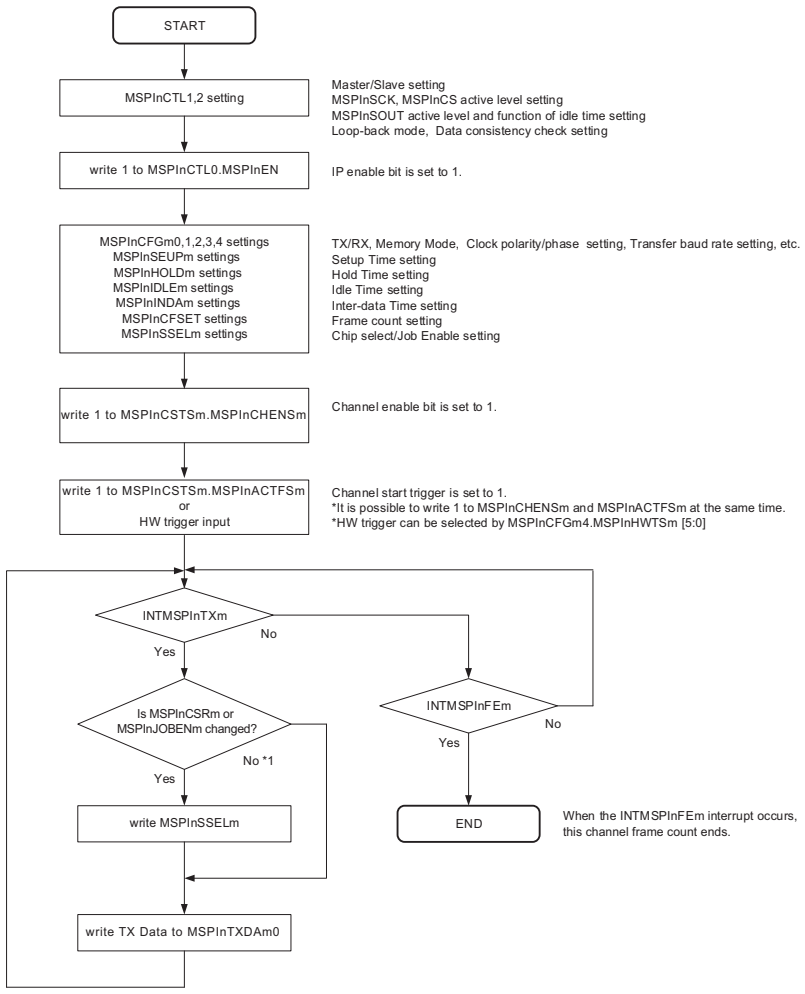
In the direct memory mode, interrupts are output at every communication frame, and communication data is controlled by CPU/DMA.



Note 1. If MSPInCSRm or MSPInJOBENm are not changed, the same value can be written in MSPInSSELm.

Note: Set MSPInJOBENm of the last frame to 0.

Figure 19.45 Master Transmission/Reception Operating Procedure in Direct Memory Mode



Note 1. If MSPInCSRm or MSPInJOBENm are not changed, the same value can be written in MSPInSSELm.

Note: Set MSPInJOBENm of the last frame to 0.

Note 1. In slave mode, communication is controlled by Channel 0.

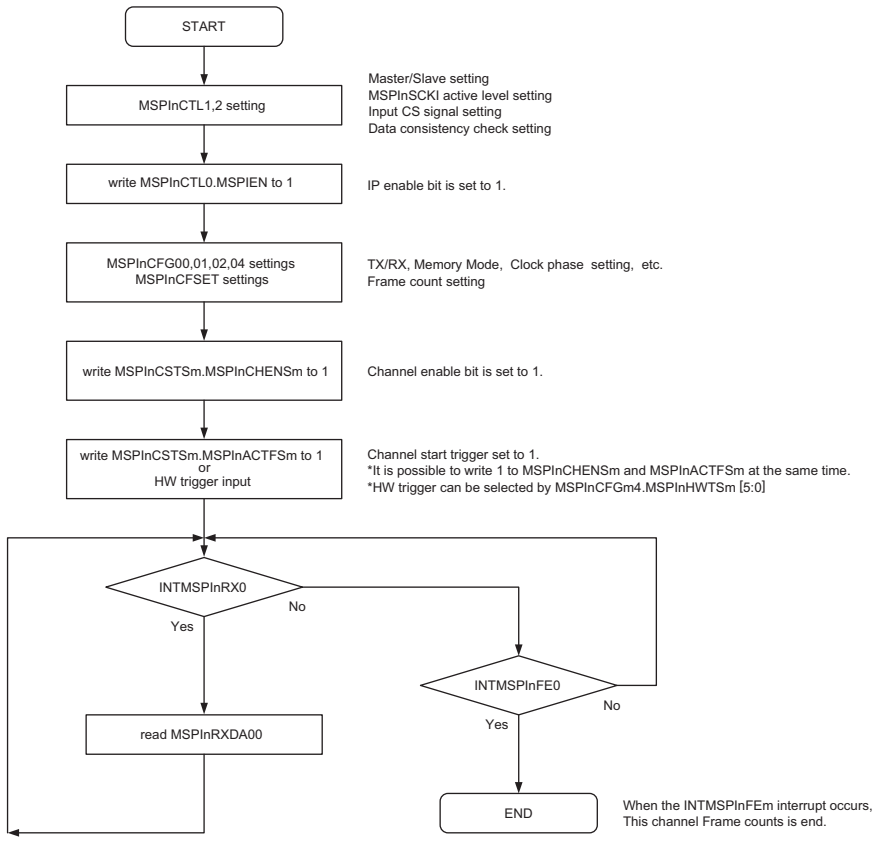
Figure 19.49 Slave Transmission Operating Procedure in the Direct Memory Mode



Note 1. In slave mode, communication is controlled by Channel 0.

Figure 19.50 Slave Reception Operating Procedure in Direct Memory Mode

19.7.2 Fixed Buffer Memory Mode

In the fixed buffer memory mode, the channels use MSPI RAM. Data directly written in the MSPI RAM is used as transmission data, and the received data is stored in the MSPI RAM.

All transmission data must be written before starting communication. All receive data must be read after all communications are completed.

19.7.2.1 Operation

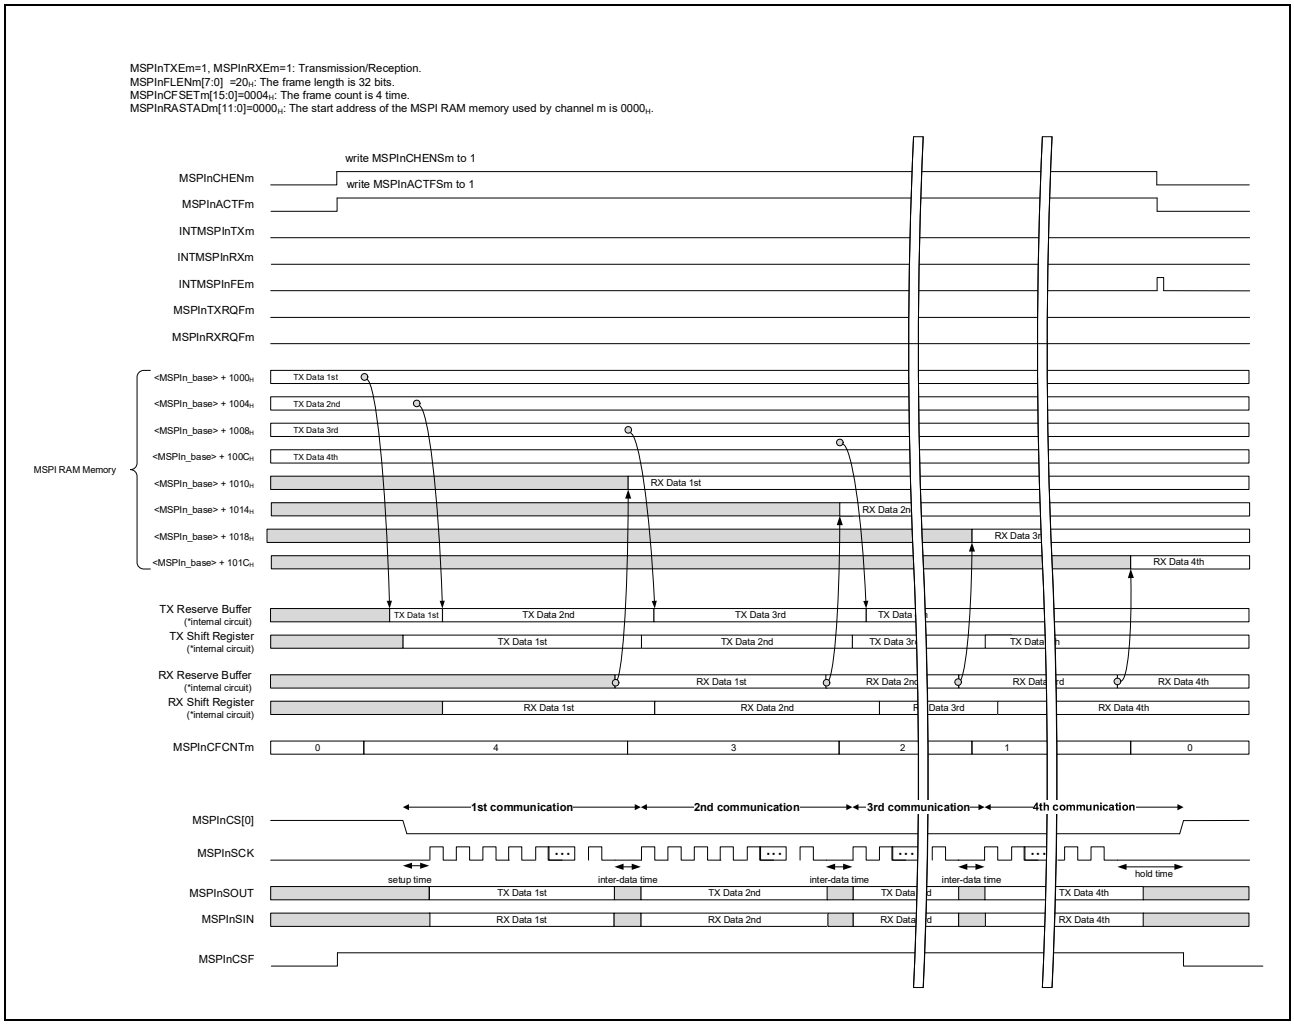


Figure 19.51 Master Transmission/Reception in the Fixed Buffer Memory Mode

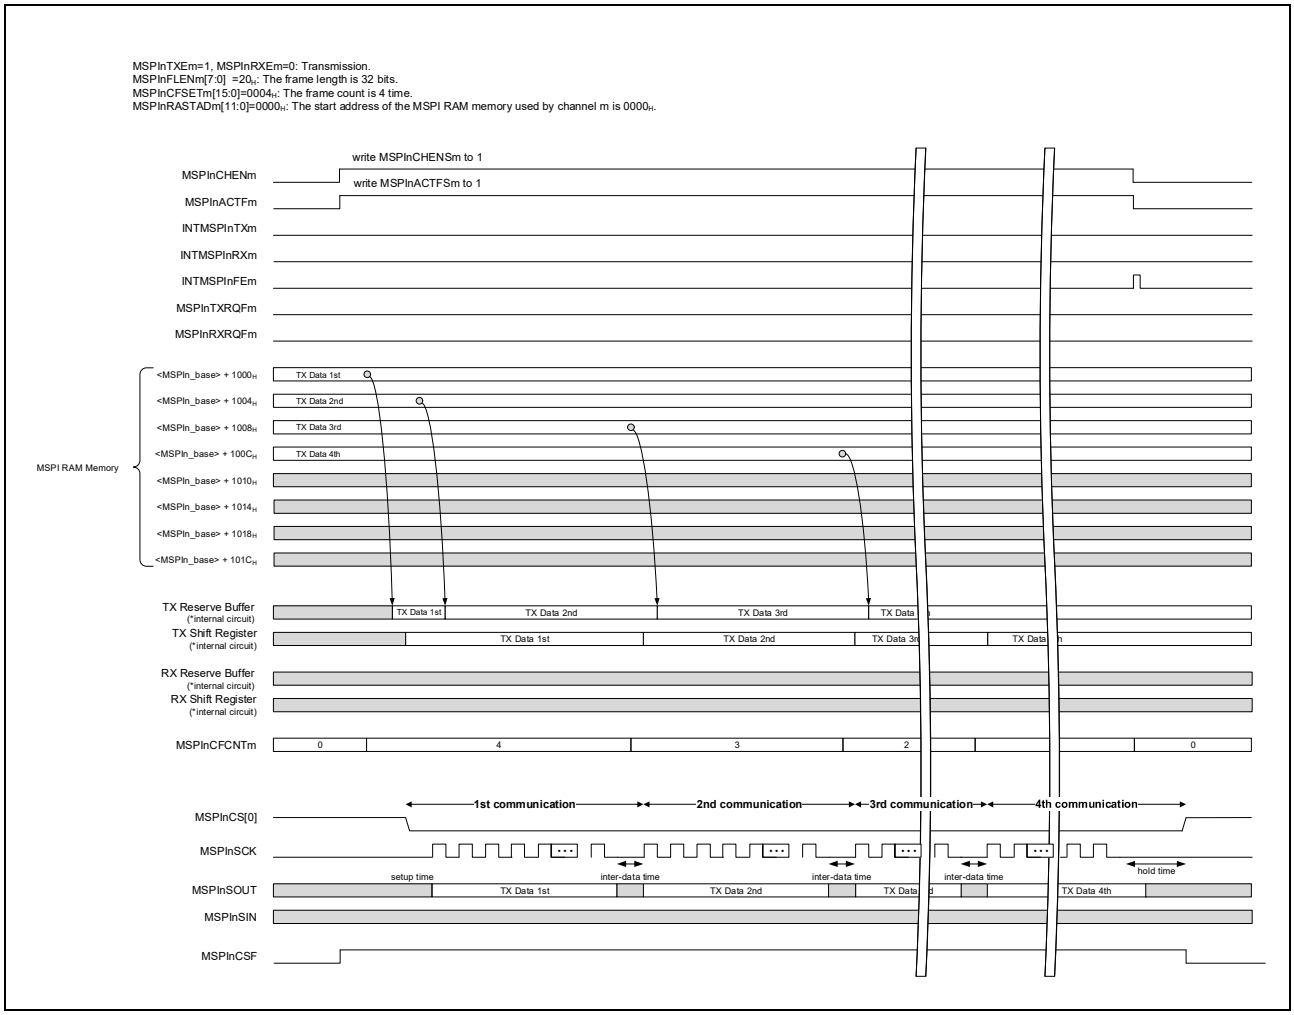

Figure 19.52 Master Transmission in the Fixed Buffer Memory Mode

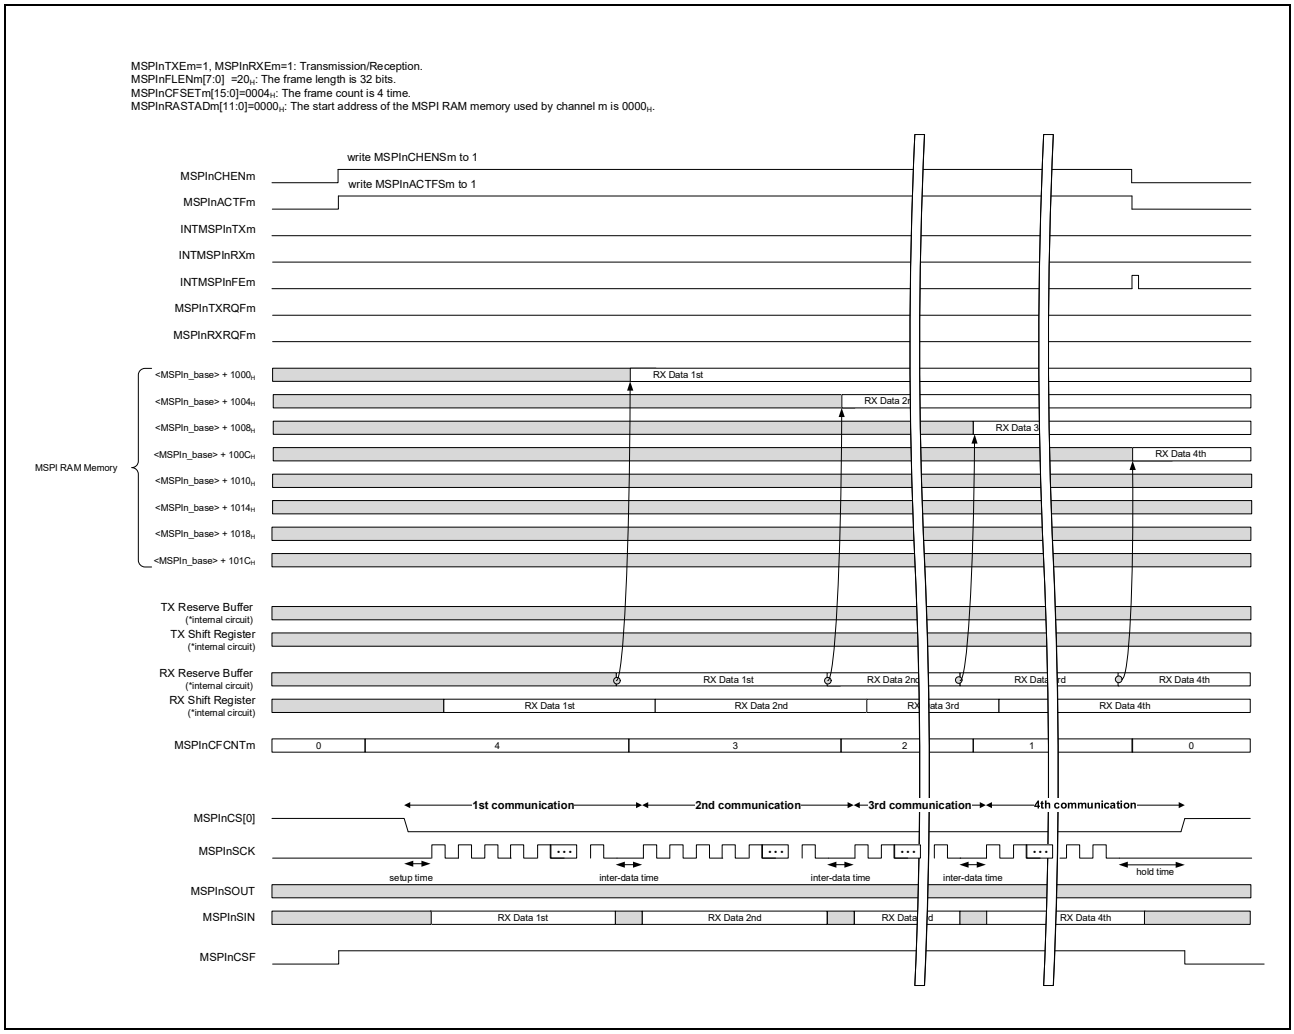

Figure 19.53 Master Reception in the Fixed Buffer Memory Mode

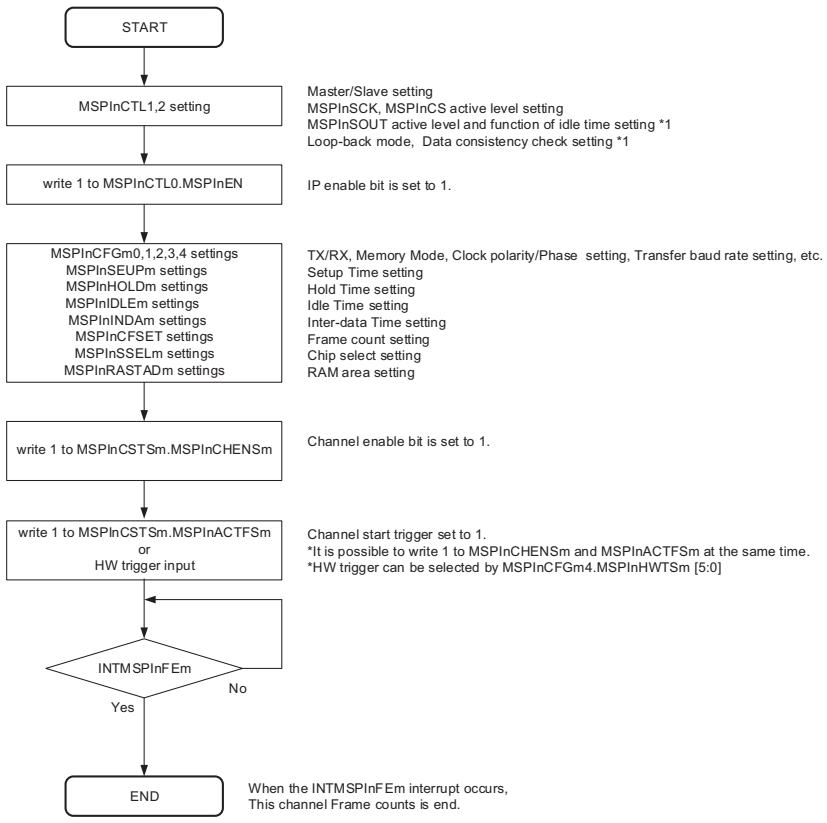
19.7.2.2 Operating Procedure

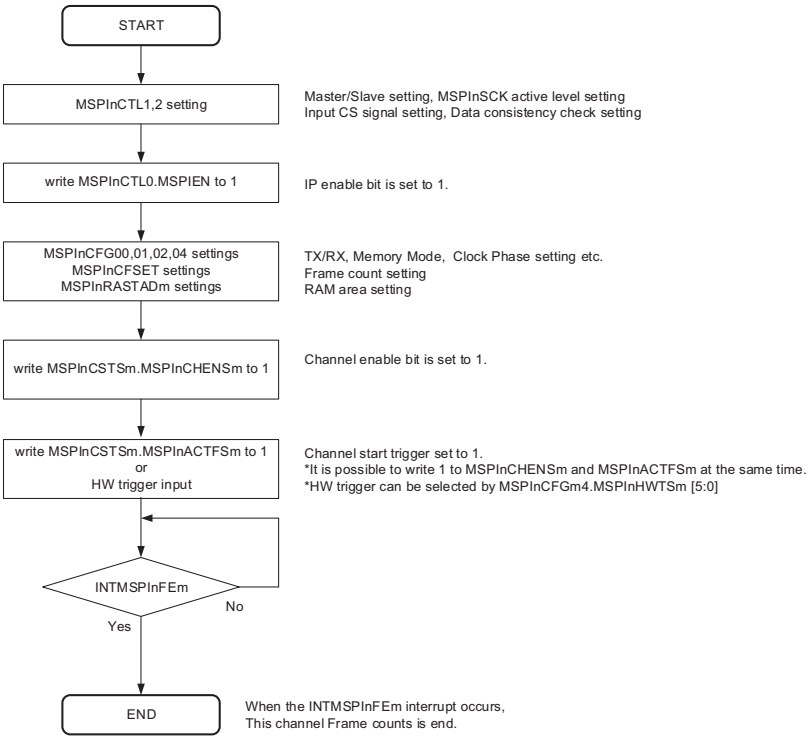
Follow the procedure of this chapter to operate in fixed buffer memory mode.

In the fixed buffer memory mode, an interrupt is output when the Frame count of the communication ends.



Note 1. All transmission data must be written before starting communication, and receive data must be read after all communications are completed.

Figure 19.54 Master Transmission/Reception or Transmission or Reception Operating Procedure in the Fixed Buffer Memory Mode



Note 1. All transmission data must be written before starting communication, and receive data must be read after all communications are completed.

Figure 19.55 Slave Transmission/Reception or Transmission or Reception Operating Procedure in the Fixed Buffer Memory Mode

19.7.2.3 RAM Area

MSPI has its own MSPI RAM, and transmission memory and a reception memory are provided respectively. The MSPI RAM is shared by each channel.

In the fixed buffer memory mode, the RAM area to be used is determined by MSPInCFGm0.MSPInTXEm, MSPInCFGm0.MSPInRXEm, MSPInCFGm2.MSPInFLENm[7:0], MSPInCFSETm and MSPInRASTADm.

Do not configure RAM area exceed the range which is defined in **Table 19.19, Areas of MSPI RAM**.

Table 19.64 Setting Registers of MSPI RAM in the Fixed Buffer Memory Mode

Register Name	Setting
MSPInTXEm	Transmission setting
MSPInRXEm	Reception setting

<MSPIn_base> + 1020_H	Not used by Channel m.
<MSPIn_base> + 1021_H	Not used by Channel m.

*When MSPInTXEm is 0, the channel does not reserve memory for transmission.

19.7.3 Fixed FIFO memory mode

In the fixed FIFO memory mode, the channels use MSPI RAM.

Transmission data written from CPU/DMA to the MSPInTXDAm0 register is automatically stored in MSPI RAM. The reception data is automatically stored in the MSPI RAM, and the CPU/DMA can read received data using MSPInRXDAm0.

A transmission interrupt is output when the buffers of half the number of FIFO stages set by MSPInSIZEm[1:0] become empty, and a reception interrupt is output when the buffers of half the number of FIFO stages set by MSPInSIZEm [1: 0] are filled with receive data.

19.7.3.1 Operation

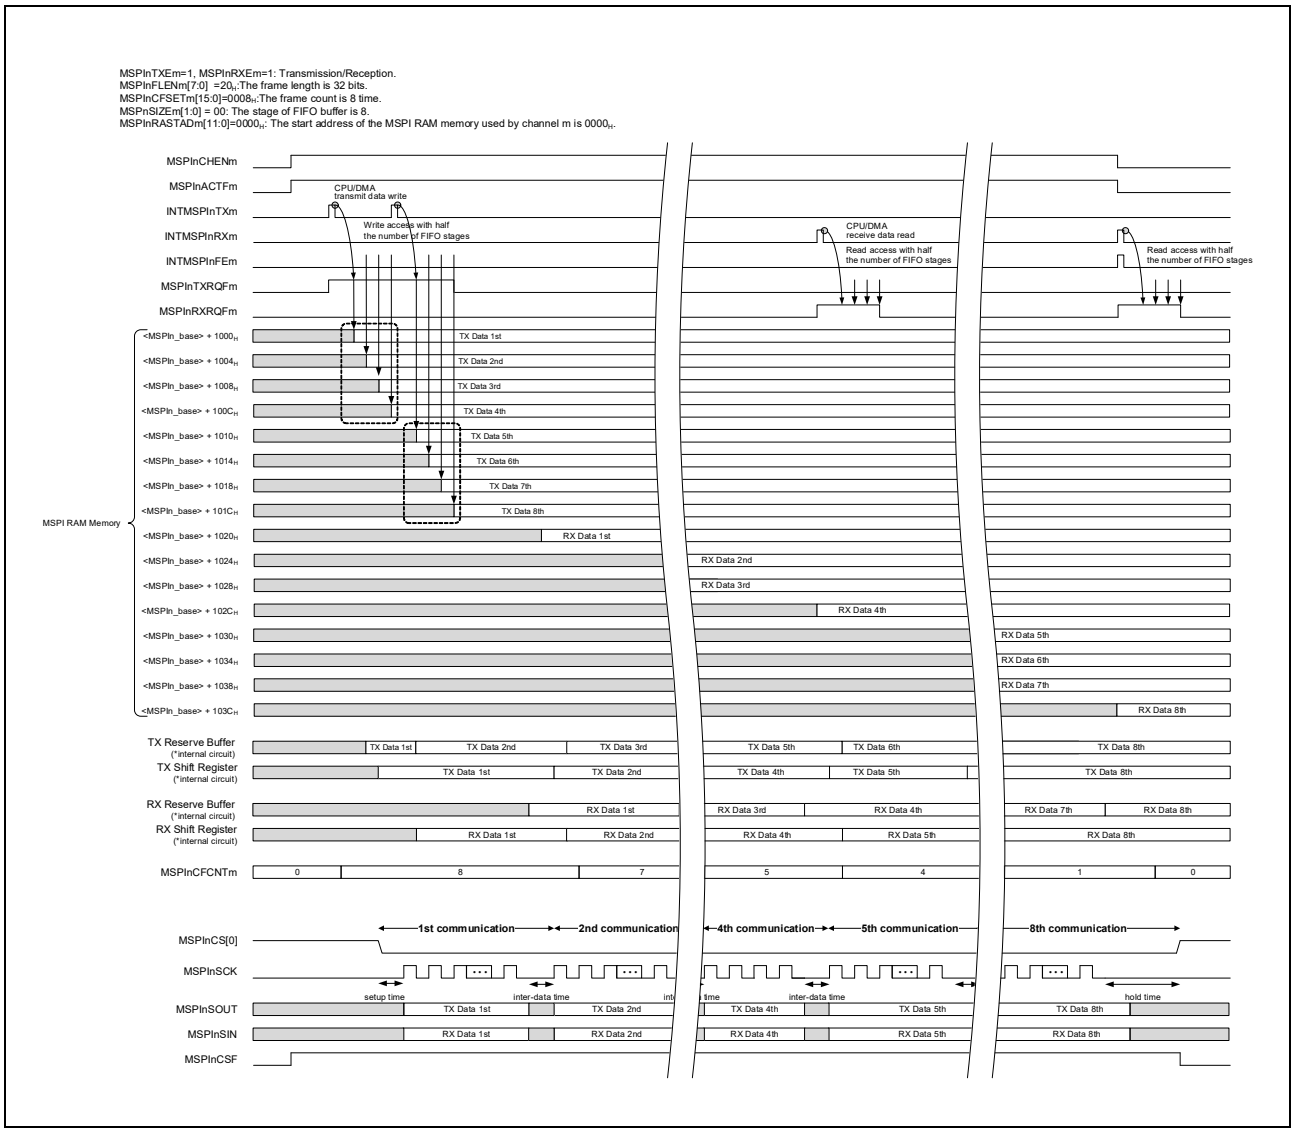

Figure 19.56 Master Transmission/Reception in the Fixed FIFO Memory Mode

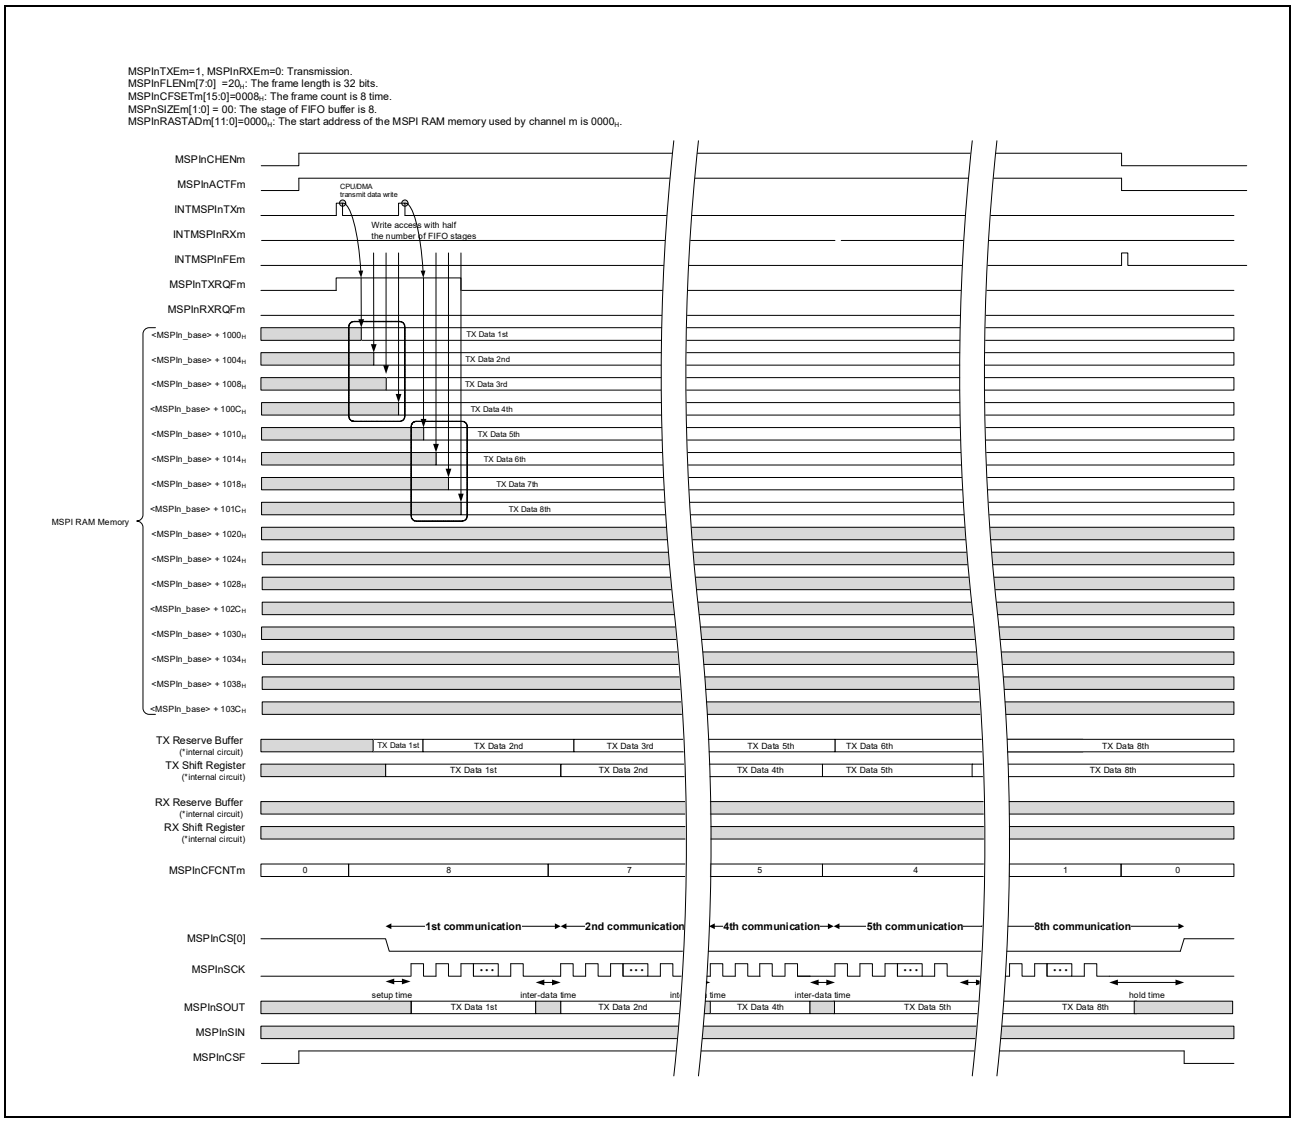

Figure 19.57 Master Transmission in the Fixed FIFO Memory Mode

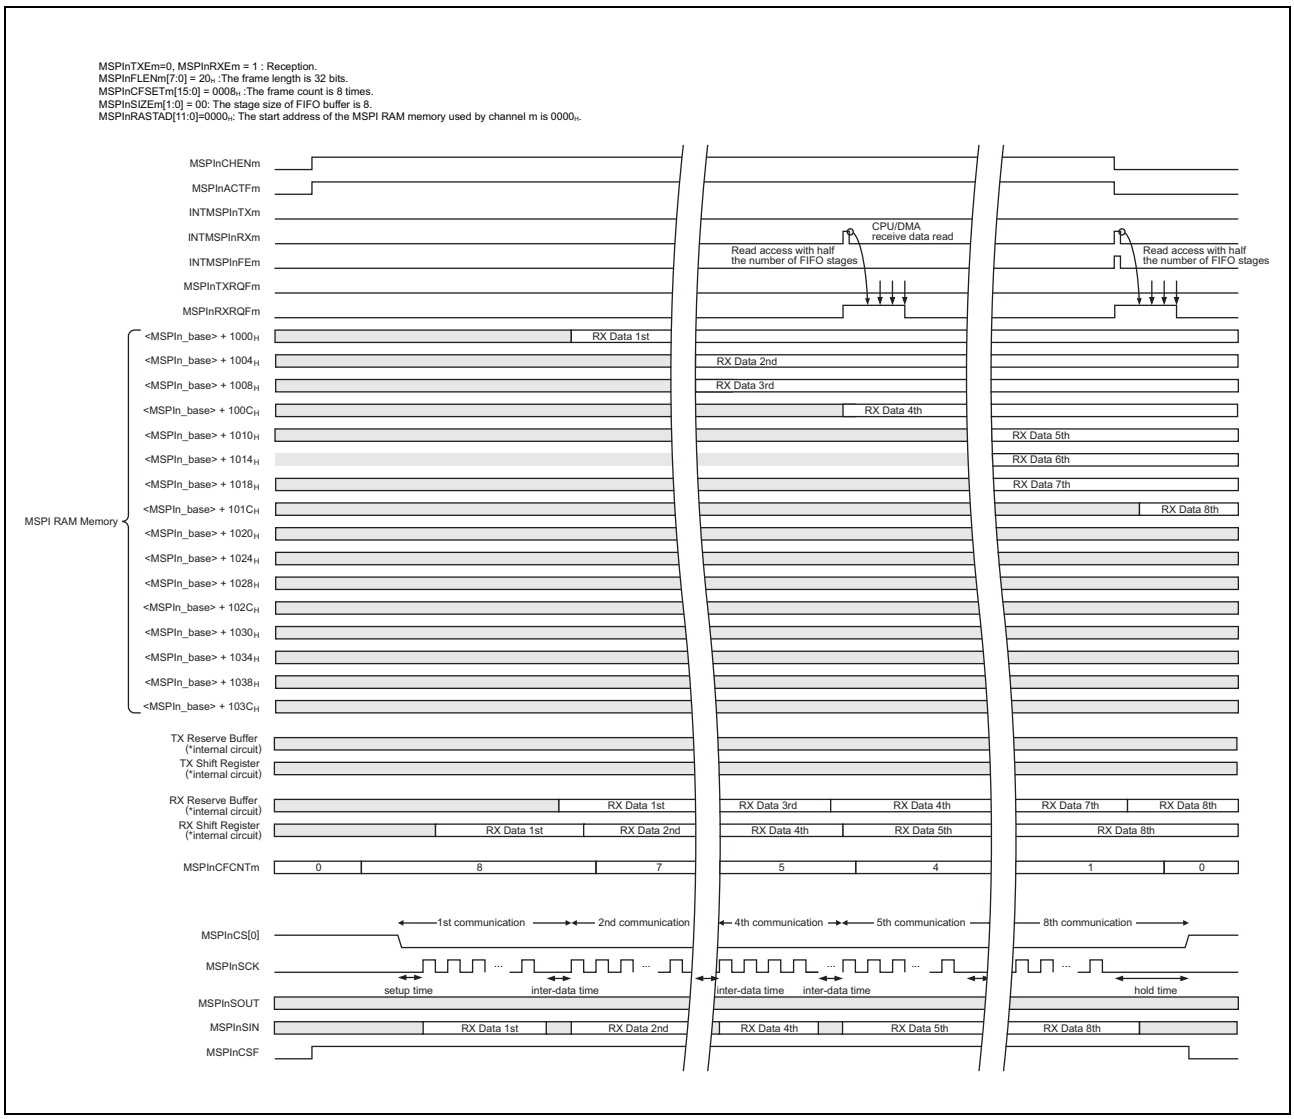

Figure 19.58 Master Reception in the Fixed FIFO Memory Mode

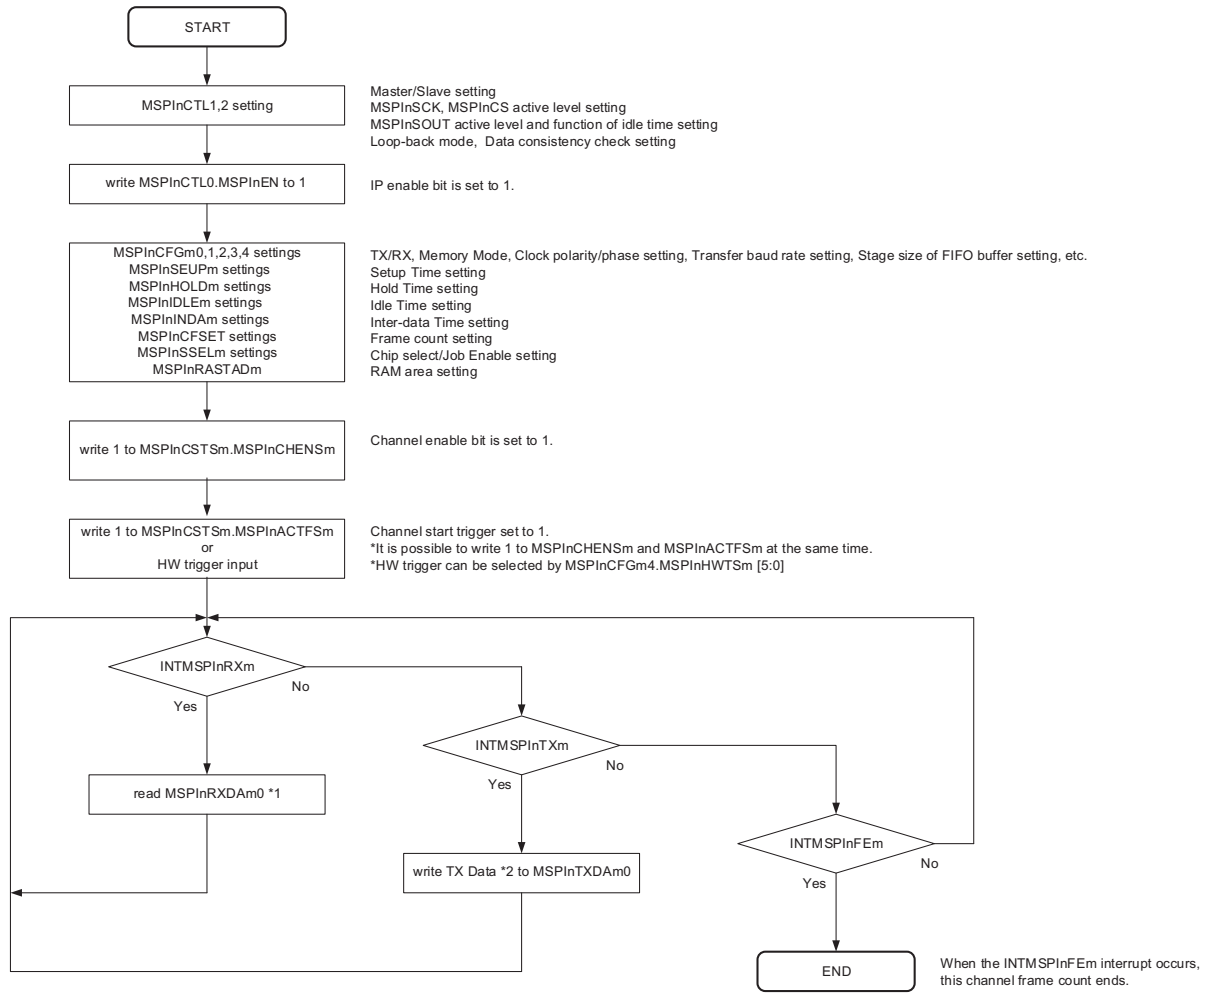
19.7.3.2 Operating Procedure

Follow the procedure of this chapter to operate in fixed FIFO memory mode.

In the fixed FIFO memory mode, an interrupt is output when a communication request that is half of the set buffer size is accepted.



Note 1. It is necessary to read half the size of FIFO stage set by MSPInCFGm4.MSPInSIZEm [1:0]
Note 2. It is necessary to write half the size of FIFO stage set by MSPInCFGm4.MSPInSIZEm [1:0]

Figure 19.64 Slave Reception Operating Procedure in Fixed FIFO Memory Mode

19.7.3.3 RAM Area

MSPI IP has its own MSPI RAM, and transmission memory and a reception memory are provided respectively. The MSPI RAM is shared by each channel.

In the fixed FIFO memory mode, the RAM area to be used is determined by MSPInCFGm0.MSPInTXEm, MSPInCFGm0.MSPInRXEm, MSPInCFGm2.MSPInFLENm[7:0], MSPInCFGm4.MSPInSIZEm[1:0] and MSPInRASTADm.

Do not configure RAM area exceed the range which is defined in **Table 19.19, Areas of MSPI RAM**.

Table 19.65 Setting Registers of MSPI RAM in the Fixed FIFO Memory Mode

Register Name	Setting
MSPInTXEm	Transmission setting
MSPInRXEm	Reception setting
MSPInFLENm[7:0]	Frame length setting
MSPInSIZEm[1:0]	FIFO stage size setting
MSPInRASTADm	MSPI RAM start address setting

[Example 1]

MSPInTXEm, MSPInRXEm = 11

MSPInFLENm[7:0] = 20_H

19.8.1 Issue #1: Misjudgment of Overrun

19.8.1.1 Phenomenon

Unexpected behaviors occur under certain conditions as follows:

(1) Issue #1-(1)

If there is the case that the reception data buffer would be full*1 when MSPInCFGm0.MSPInRXEm = 1 at master mode and direct memory mode, an extra reception interrupt is generated. The flags of MSPInRXDAm0.MSPInRXDAm0[31:0] and MSPInCSTRm.MSPInRXRQFm are influenced by this issue.

(2) Issue #1-(2)

If there is the case that the reception data buffer would be full*1 when MSPInCFGm0.MSPInRXEm = 1 and MSPInCFGm0.MSPInFCCEm = 0 at master mode and direct memory mode, the necessary reception interrupt is not generated at the frame end. The flags of MSPInRXDAm0.MSPInRXDAm0[31:0] and MSPInCSTRm.MSPInRXRQFm are influenced by this issue.

(3) Issue #1-(3)

If the number of reception frames is larger than the number of FIFOs when MSPInCFGm0.MSPInRXEm = 1 at master mode and fixed FIFO memory mode, the reception interrupt is generated before reception completion. The flags of MSPInRXDAm0.MSPInRXDAm0[31:0], MSPInCSTRm.MSPInFIRXNm[7:0] and MSPInRXRQFm are influenced by this issue.

(4) Issue #1-(4)

If there is the case that reception data buffer would be full*1 when MSPInCFGm0.MSPInRXEm = 1 at slave mode and direct memory mode, an over run error cannot be detected. Additionally, if the number of reception frame is larger than the number of FIFO when MSPInCFGm0.MSPInRXEm = 1 at slave mode and fixed FIFO memory mode, an over run error cannot be detected. The flags of MSPInRXDAm0.MSPInRXDAm0[31:0], MSPInCSTRm.MSPInFIRXNm[7:0], MSPInRXRQFm, MSPInACTFm, MSPInCHENm, MSPInCFCNTm.MSPInCFCNTm[15:0], MSPInCESTm.MSPInOVREEm and MSPInOVRUEm are influenced by this issue.

Note 1. It means that after the reception completion interrupt of the 1st data, CPU does not read the following 2 data until their reception is completed. (Refer to **Section 19.6.8.4, Overrun Error Check**.)

19.8.1.2 Workaround

Issue #1-(1) to (4) can be avoided by the following workarounds.

(1) Issue #1-(1) to (3)

These issues occur by a conflict between the reception completion and reception data read when the reception buffer is full at master mode. Therefore, it is necessary to control the reception buffer so that it does not become full. Generally, data is written by INTMSPInTX, but it should be used only for the first 2 data. For the third and later data, write the transmission data by INTMSPInRX after the reception data read. (Refer to **Figure 19.65**.) The reception buffer can be controlled so that it does not become full by controlling the transmission clock. Therefore, these issues can be avoided by this workaround.

(2) Issue #1-(4)

This issue occurs by a conflict between the reception completion and reception data read when the reception buffer is full at slave mode. Therefore, it is necessary to control the reception buffer so that it does not become full. Read the reception data within the transmission time for the next frame data*1 after INTMSPInRX occurs. The reception buffer can be controlled so that it does not become full by this workaround and this issue can be avoided.

Note 1. “Transmission time for the next frame data” means the following.

Direct memory mode:

The transmission time for the frame length defined by MSPInCFGm2.MSPInFLENm[7:0]. But in case of a setting larger than 32bit, since both transmission times for 32bit and for fraction bits are generated, “transmission time for the next frame data” means the transmission time for the fraction bits.

Fixed FIFO memory mode:

The time for storing data which is the half of the located FIFO memory size.

The circuit will be revised for issue #1-(1) to (4).

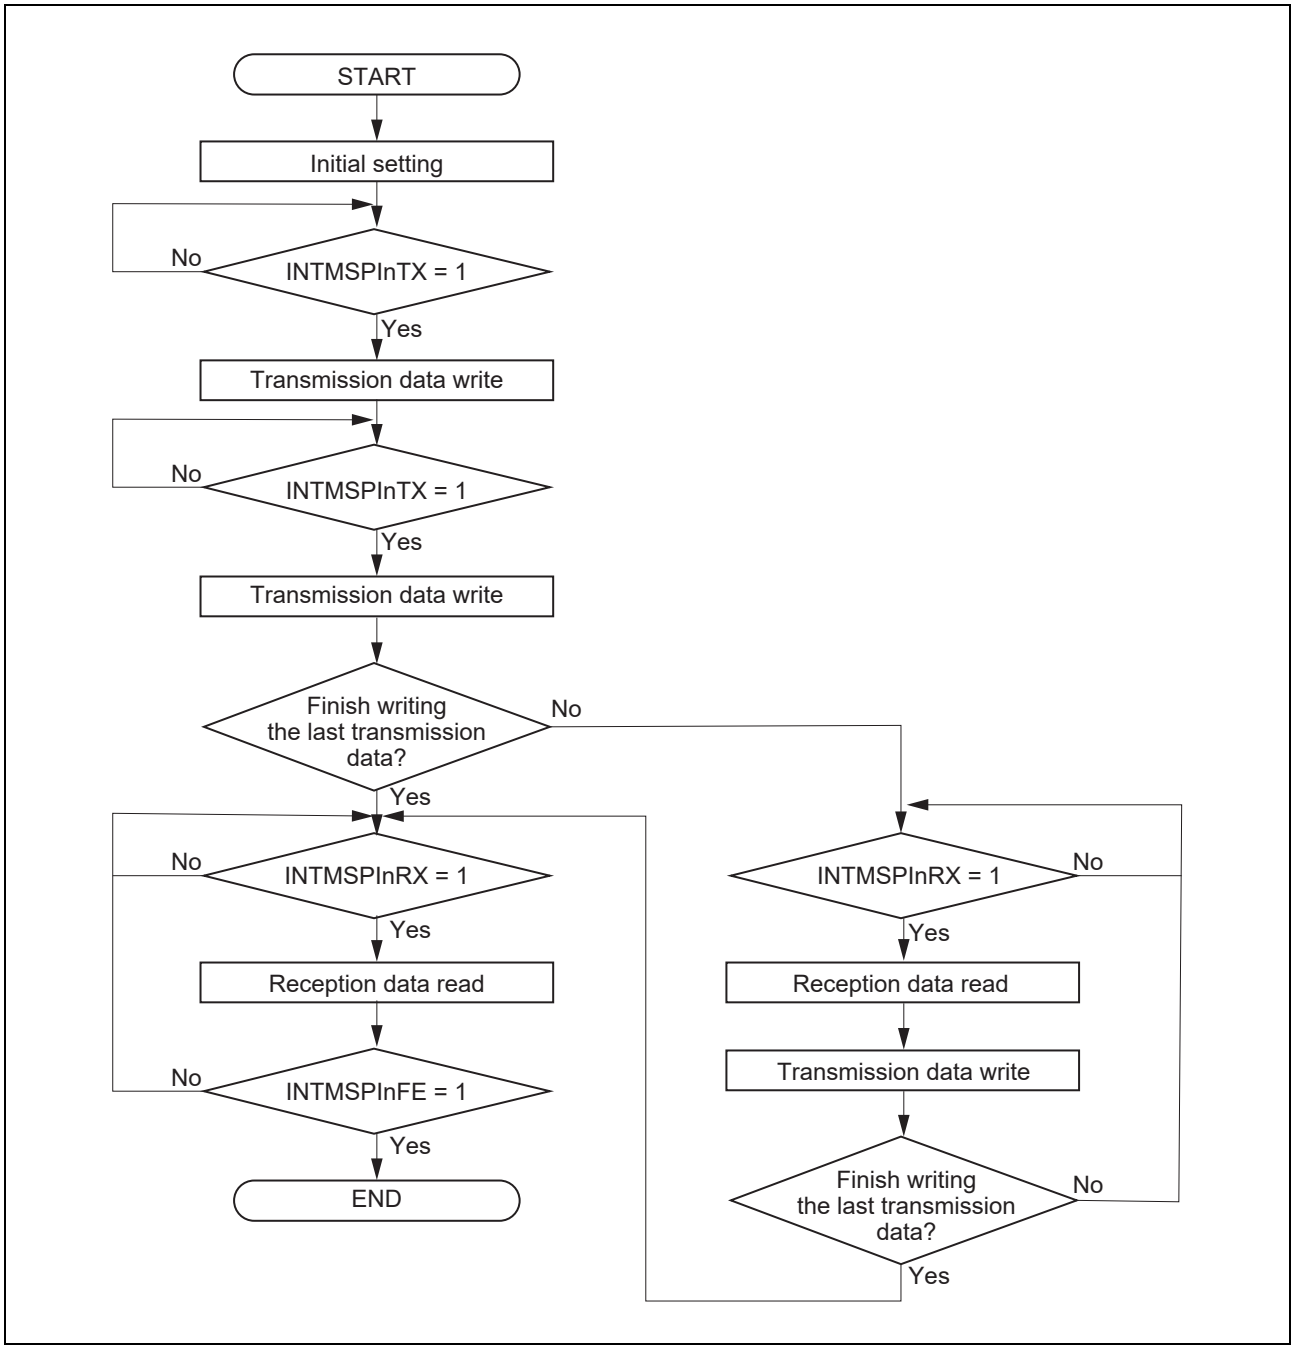

Figure 19.65 Workaround for issue #1-(1) to (3)

Refer to following figures.

Figure 19.45, Master Transmission/Reception Operating Procedure in Direct Memory Mode

Figure 19.46, Master Transmission Operating Procedure in the Direct Memory Mode

Figure 19.59, Master Transmission/Reception Operating Procedure in the Fixed FIFO Memory Mode

Figure 19.61, Master Reception Operating Procedure in Fixed FIFO Memory Mode

19.8.2 Issue #2: Misalignment of Bit at Slave Transmission

19.8.2.1 Phenomenon

When MSPInCFGm0.MSPInTXEm = 1, MSPInCFGm1.MSPInCPHAm = 0 and MSPInCFGm0.MSPInFCCEm = 0, the next transmission data after communication completion is misaligned.

19.8.2.2 Workaround

Issue #2 can be avoided by one of the following workarounds.

(1) Workaround 1

Set MSPInCFGm1.MSPInCPHAm = 1.

(2) Workaround 2

Set MSPInCFGm0.MSPInFCCEm = 1.
This workaround is available only at direct memory mode.
The transmission frame is not counted by MSPI in case of this workaround. Therefore, it is necessary to be counted by DMA etc.

(3) Workaround 3

At each transmission completion, after setting MSPInCTL0.MSPInEN = 0 set MSPInCTL0.MSPInEN = 1 again, before use it.

Section 20 Serial Communication Interface 3 (SCI3)

The serial communication interface 3 (SCI3: Serial Communication Interface 3) can handle two methods of serial communications: asynchronous and clock synchronous serial communications. Asynchronous serial data communications can be carried out with standard asynchronous communication LSIs such as Universal Asynchronous Receiver/Transmitter (UART) or Asynchronous Communication Interface Adapter (ACIA). Asynchronous mode is equipped with a serial communications function between multiple processors (multi-processor communications function).

20.1 Features SCI3 for RH850/U2A-EVA

20.1.1 Number of Units and Channels

This microcontroller has the following number of SCI3 units.

Each unit has one channel SCI3. “Number of channels” is used with the same meaning as “number of units” in this section.

Table 20.1 Number of Units

Product Name	RH850/ U2A-EVA (516 pins)	RH850/ U2A16 (516 pins)	RH850/ U2A16 (373 pins)	RH850/ U2A16 (292 pins)	RH850/ U2A8 (373 pins)	RH850/ U2A8 (292 pins)	RH850/ U2A6 (292 pins)	RH850/ U2A6 (176 pins)	RH850/ U2A6 (156 pins)	RH850/ U2A6 (144 pins)
Number of Units	3 (n = 0 to 2)	3 (n = 0 to 2)	3 (n = 0 to 2)	3 (n = 0 to 2)	3 (n = 0 to 2)	3 (n = 0 to 2)	—	—	—	—
Name	SCI3n									

Table 20.2 Unit Configurations and Channels

Unit Name SCI3n	Channels per Unit	RH850/ U2A-EVA (516 pins)	RH850/ U2A16 (516 pins)	RH850/ U2A16 (373 pins)	RH850/ U2A16 (292 pins)	RH850/ U2A8 (373 pins)	RH850/ U2A8 (292 pins)	RH850/ U2A6 (292 pins)	RH850/ U2A6 (176 pins)	RH850/ U2A6 (156 pins)	RH850/ U2A6 (144 pins)

SCI31	1	√	√	√	√	√	√	—	—	—	—
SCI32	1	√	√	√	√	√	√	—	—	—	—

Note: The channel name is the same as the unit name.

Table 20.3 Indices

Index	Description
n	Throughout this section, the individual SCI3 units are identified by the index “n” (n = 0 to 2): for example, SCI3nSMR is the serial mode register.

20.1.2 Register Base Addresses

SCI3 base addresses are listed in the following table.

SCI3 register addresses are given as offsets from these base addresses.

Table 20.4 Register Base Addresses

Base Address Name	Base Address	Bus Group
<SCI30_base>	FFD3 1000_H	P-Bus Group 3
<SCI31_base>	FFD3 2000_H	P-Bus Group 3
<SCI32_base>	FFD3 3000_H	P-Bus Group 3

20.1.3 Clock Supply

Clock supply by and to SCI3 is listed in the following table.

Table 20.5 Clock Supply

Unit Name	Unit Clock Name	Supply Clock Name
SCI3n	PCLK	High-speed peripheral clock CLK_HSB

20.1.4 Interrupt Requests and Error Notification

SCI3 interrupt requests are listed in the following table.

Table 20.6 Interrupt and DMA/DTS Requests

Unit Interrupt Signal	Description	Interrupt Number	DMA Trigger Number	DTS Trigger Number
SCI30				
INTSCI30ERI	Receive error	348	—	—
INTSCI30RXI	Receive data full	349	Group0-140	Group3-10
INTSCI30TXI	Transmit data empty	350	Group0-141	Group3-11
INTSCI30TEI	End of transmission	351	—	—
SCI31				
INTSCI31ERI	Receive error	352	—	—
INTSCI31RXI	Receive data full	353	Group0-142	Group3-12
INTSCI31TXI	Transmit data empty	354	Group0-143	Group3-13
INTSCI31TEI	End of transmission	355	—	—
SCI32				
INTSCI32ERI	Receive error	356	—	—
INTSCI32RXI	Receive data full	357	Group0-144	Group3-14
INTSCI32TXI	Transmit data empty	358	Group0-145	Group3-15
INTSCI32TEI	End of transmission	359	—	—

This module have no error notifications.

20.1.5 Reset Sources

For details, refer to **Section 9, Reset Controller**.

Table 20.7 Reset Sources

Unit Name	Register Name	Reset Condition						
		Power On Reset	System Reset 1	System Reset 2	Application Reset	DeepSTOP Reset	Module Reset	JTAG Reset
SCI3n	All registers	√	√	√	√	√	√	—

20.1.6 External Input/Output Signals

External input/output signals of SCI3 are listed below.

Table 20.8 External Input/Output Signals

Unit Signal Name	I/O	Description	Alternative Port Pin Signal
SCI30			
SCI0SCK	I	SCI30 serial clock input	SCI30SCK
	O	SCI30 serial clock output	SCI30SCK
SCI0RxD	I	SCI30 data input signal	SCI30RXD
SCI0TxD	O	SCI30 data output signal	SCI30TXD
SCI31			
SCI1SCK	I	SCI31 serial clock input	SCI31SCK
	O	SCI31 serial clock output	SCI31SCK
SCI1RxD	I	SCI31 data input signal	SCI31RXD
SCI1TxD	O	SCI31 data output signal	SCI31TXD
SCI32			
SCI2SCK	I	SCI32 serial clock input	SCI32SCK
	O	SCI32 serial clock output	SCI32SCK
SCI2RxD	I	SCI32 data input signal	SCI32RXD
SCI2TxD	O	SCI32 data output signal	SCI32TXD

20.1.7 Combination of Pins and Ports

Combinations of SCI3 pins and ports are listed in the following table.

Table 20.9 Combinations of Pins and Ports

Function	Pin Name	Port Name
SCI30	SCI30RXD	P6_2
	SCI30TXD	P6_3
	SCI30SCK	P6_4
SCI31	SCI31RXD	P6_5
	SCI31TXD	P6_6
	SCI31SCK	P6_7
SCI32	SCI32RXD	P20_0
	SCI32TXD	P20_1
	SCI32SCK	P20_3

20.2 Overview

- The serial data communication mode can be configured for asynchronous communications or clock synchronous communications.
- Full-duplex communications are available. The independent transmitter unit and receiver unit allow simultaneous transmission and reception. Both the transmitter and the receiver have a double-buffered structure, enabling continuous data transmission and reception.
- An arbitrary bit rate is selectable with the on-chip baud rate generator. An external clock is also selectable as a transmission/reception clock source.
- LSB-first or MSB-first transfer is selectable (except for asynchronous 7-bit data.)
- Interrupt sources: 4 types consisting of transmit-end, transmit-data-empty, receive-data-full, and receive-error. Transmit-data-empty and receive-data-full interrupt sources can activate the DMAC.
- Module standby can be set for each channel (for details of module standby, see **Section 15, Standby Controller (STBC)**).
- The bit rate modulation function can reduce errors averagely (even in a high bit rate) by correcting the output of the on-chip baud rate generator (except for the maximum speed in clock synchronous mode).
- The pin level of serial input data can be checked.

20.2.1 Serial Communication Modes

Asynchronous mode

- Data length: 7 bits, 8 bits or 16 bits selectable
- Stop bit length: 1 bit or 2 bits selectable
- Parity: Even parity, odd parity, or none selectable
- Receive error detection: Parity error, overrun error, and framing error
- Break detection: A break can be detected by reading a register when a framing error occurs

Clock synchronous mode

- Data length: 8 bits or 16 bits
- Receive error detection: Overrun error

20.2.2 Block Diagram

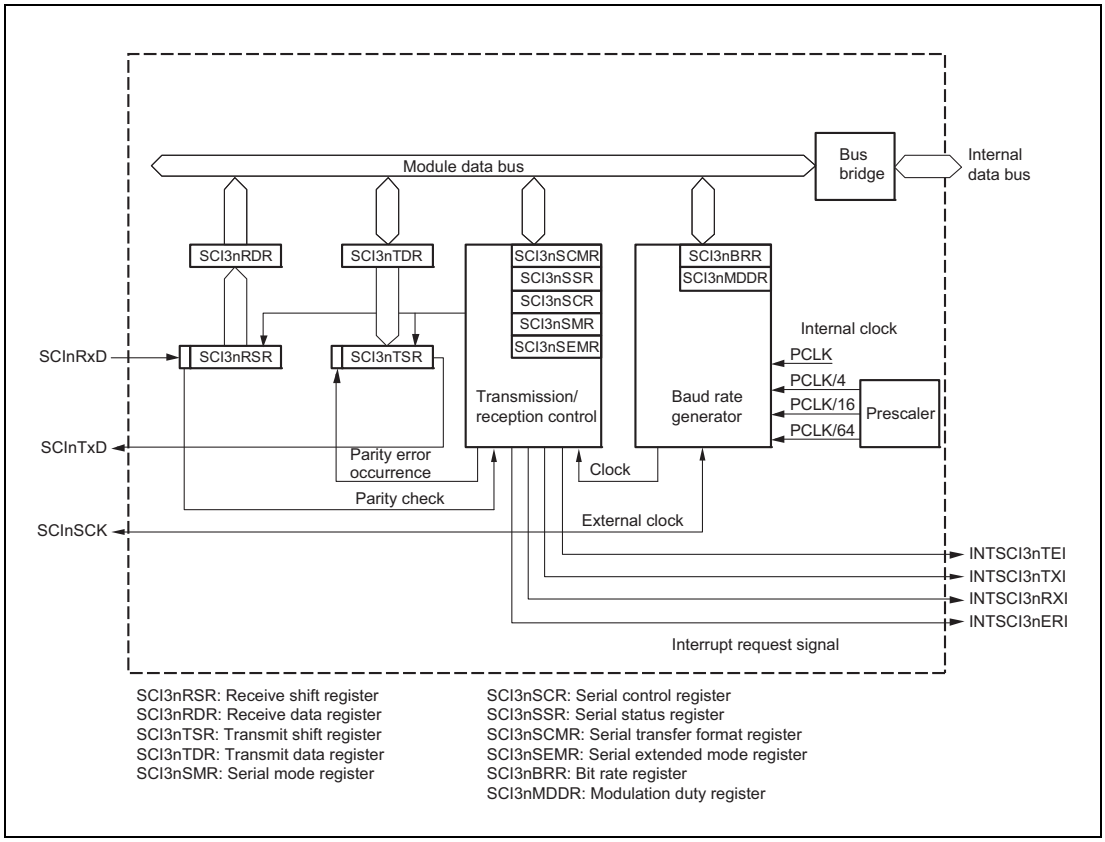

Figure 20.1 Block Diagram

20.3 Registers

20.3.1 List of Registers

The SCI3 has the following registers. Some registers have limitations in read/write by the CPU.
For <SCI3n_base>, refer to **Section 20.1.2, Register Base Addresses**.

CAUTION

SCI3nBRR and SCI3nMDDR are allocated to the same address (relative address 4). The MDDRS bit in SCI3nSEMR is used to switch these registers.

Table 20.10 List of Registers

Register Name	Symbol*1	Value after Reset	Address	Access Protection	
				PBG	Other
Receive shift register	SCI3nRSR	—	—	—	—
Serial mode register	SCI3nSMR	00_H	<SCI3n_base> + 0000_H	*2	—
Bit rate register / Modulation duty register	SCI3nBRR/ SCI3nMDDR	FF_H	<SCI3n_base> + 0004_H	*2	—
Serial control register	SCI3nSCR	00_H	<SCI3n_base> + 0008_H	*2	—
Transmit data register	SCI3nTDR	$FFFF_H$	<SCI3n_base> + $000C_H$	*2	—
Transmit shift register	SCI3nTSR	—	—	—	—
Serial status register	SCI3nSSR	84_H	<SCI3n_base> + 0010_H	*2	—
Receive data register	SCI3nRDR	0000_H	<SCI3n_base> + 0014_H	*2	—
Serial transfer format register	SCI3nSCMR	$F2_H$	<SCI3n_base> + 0018_H	*2	—
Serial extended mode register	SCI3nSEMR	04_H	<SCI3n_base> + $001C_H$	*2	—

Note 1. n = 0 to 2
Note 2. n = 0: PBG30#9
n = 1: PBG30#10
n = 2: PBG30#11

Relative addresses 4k + 1, 4k + 2, and 4k + 3 (k = 0 to 7) are reserved areas. These areas are always read as 0. Writing is invalid.

20.3.2 SCI3nRSR — Receive Shift Register

SCI3nRSR is a shift register which is used to receive serial data input from the SCInRxD pin and convert it to parallel data. When one frame of data has been received, it is automatically transferred to SCI3nRDR. SCI3nRSR cannot be directly accessed by the CPU.

20.3.3 SCI3nRDR — Receive Data Register

SCI3nRDR is an 16-bit register to store receive data. The value of SCI3nRDR after a reset is 0000_H. When one frame of data has been received, it is transferred from SCI3nRSR to this register allowing SCI3nRSR to receive the next data. SCI3nRSR and SCI3nRDR function as a double-buffer, allowing continuous receive operations. Be sure to check that the RDRF flag in SCI3nSSR is set to 1 before reading SCI3nRDR. SCI3nRDR cannot be written from the CPU.

When the data length is 7 bits, receive data is stored in bits 6 to 0 and bit 7 is fixed to 0 regardless of the SINV bit in SCI3nSCMR. When the data length is 8 bits, the received data are stored in bits 7 to 0.

20.3.4 SCI3nTDR — Transmit Data Register

SCI3nTDR is an 16-bit register to store transmit data. The value of SCI3nTDR after a reset is $FFFF_H$.

When SCI3nTSR empty is detected, the transmit data written to SCI3nTDR is transferred to SCI3nTSR and transmission starts. The double-buffered structure of SCI3nTDR and SCI3nTSR allows continuous serial transmission. If the next transmit data has been written to SCI3nTDR when one frame of data is sent, the transmit data is transferred to SCI3nTSR to continue transmission. SCI3nTDR can always be read and written by the CPU. Be sure to check that the TDRE flag in SCI3nSSR is set to 1 before writing transmit data to SCI3nTDR.

Write to bits 0 to 7, if you select the 8-bit data length. Write to bits 0 to 7 at the end when you write the transmit data to SCI3nTDR with setting 16-bit data length and dividing into bytes state of TE = 1.

20.3.5 SCI3nTSR — Transmit Shift Register

SCI3nTSR is a shift register to transmit serial data. To perform serial data transmission, transmit data written to SCI3nTDR is automatically transferred SCI3nTSR, and is then sent to the SCInTxD pin. SCI3nTSR cannot be directly accessed by the CPU.

20.3.6 SCI3nSMR — Serial Mode Register

SCI3nSMR is a register used to select the communication format and the clock source for the on-chip baud rate generator.

Access: This register can be read or written in 8-bit units.

Address: <SCI3n_base> + 0000_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	CM	CHR	PE	PM	STOP	MP	CKS1	CKS0
Value after reset	0	0	0	0	0	0	0	0
R/W	R/W*1	R/W*1	R/W*1	R/W*1	R/W*1	R/W*1	R/W*1	R/W*1

Note 1. Writable only when TE = RE = 0.

Table 20.11 SCI3nSMR Register Contents (1/2)

Bit Position	Bit Name	Function
7	CM	Communication Mode 0: Asynchronous mode 1: Clock synchronous mode
6	CHR	Character Length (Valid only in asynchronous mode) This bit is used in combination with CHR1 bit in SCI3nSCMR. CHR1 CHR 0 0: Selects 16 bits as the data length. 0 1: Reserved 1 0: Selects 8 bits as the data length. 1 1: Selects 7 bits as the data length. LSB-first is fixed and the MSB (bit 7) in SCI3nTDR is not transmitted in transmission. Data length of clocked synchronous mode is selected by CHR1 bit in SCI3nSCMR.
5	PE	Parity Enable (Valid only in asynchronous mode) When this bit is set to 1, a parity bit is added to transmit data and the parity bit is checked in reception. Regardless of the setting of this bit, no parity bit is added or checked in the multi-processor format.
4	PM	Parity Mode (Valid only when PE = 1 in asynchronous mode) 0: Selects even parity. 1: Selects odd parity. When even parity is set, parity bit is added so that the total number of 1-bits in the transmit/receive character plus the parity bit is even. Similarly, when odd parity is set, parity bit is added so that the total number of 1-bits in the transmit/receive character plus the parity bit is odd.
3	STOP	Stop Bit Length (Valid only in asynchronous mode) 0: 1 stop bit for transmission 1: 2 stop bits for transmission In reception, only the first stop bit is checked regardless of the setting of this bit. If the second stop bit is 0, it is treated as the start bit of the next transmission frame.
2	MP	Multi-Processor Mode (Valid only in asynchronous mode and CHR1 bit in SCI3nSCMR is 1) When this bit is set to 1, the multi-processor communication function is enabled. The PE and PM bits settings are invalid in multi-processor mode.

Table 20.11 SCI3nSMR Register Contents (2/2)

Bit Position	Bit Name	Function
1, 0	CKS1, CKS0	Clock Select 1, 0 These bits select the clock source for the on-chip baud rate generator. 00: PCLK clock (α = 0) 01: PCLK/4 clock (α = 1) 10: PCLK/16 clock (α = 2) 11: PCLK/64 clock (α = 3) For the relation between the setting of these bits and the baud rate, see **Section 20.3.11, SCI3nBRR — Bit Rate Register**. The character α is the decimal notation of the value of α in **Section 20.3.11, SCI3nBRR — Bit Rate Register**.

20.3.7 SCI3nSCR — Serial Control Register

SCI3nSCR is a register used for the transmission/reception control, interrupt control, and transmission/reception clock source selection listed below. For interrupt requests, see **Section 20.4.5, Interrupt Sources**.

Access: This register can be read or written in 8-bit units.

Address: <SCI3n_base> + 0008_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	TIE	RIE	TE	RE	MPIE	TEIE	CKE1	CKE0
Value after reset	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W*1	R/W*1	R/W	R/W	R/W*2	R/W*2

Note 1. While the CM bit in SCI3nSMR is 1, a value of 1 can be written only when TE = 0 and RE = 0. After the TE or RE bit is set to 1, only 0 can be written to TE and RE. While the CM bit in SCI3nSMR is 0, writing is enabled at any timing.

Note 2. Writable only when TE = 0 and RE = 0. Also, writable at the same time when TE = 0 and RE = 0 are written.

Table 20.12 SCI3nSCR Register Contents (1/2)

Bit Position	Bit Name	Function
7	TIE	Transmit Interrupt Enable When this bit is set to 1, INTSCI3nTXI interrupt request is enabled. INTSCI3nTXI interrupt request can be cancelled by reading 1 from the TDRE flag and then clearing the flag to 0, or clearing the TIE bit.
6	RIE	Receive Interrupt Enable When this bit is set to 1, INTSCI3nRXI and INTSCI3nERI interrupt requests are enabled. INTSCI3nRXI and INTSCI3nERI interrupt requests can be cancelled by reading 1 from the RDRF, FER, PER, or ORER flag and then clearing the flag to 0, or clearing the RIE bit.
5	TE	Transmit Enable When this bit is set to 1, transmission is enabled. In this state, serial transmission is started by writing transmit data to SCI3nTDR and clearing the TDRE flag in SCI3nSSR to 0. Be sure to configure SCI3nSMR before setting the TE bit to 1 to determine the transmission format. When this bit is set to 0 to disable transmission, the TDRE flag in SCI3nSSR is fixed to 1.
4	RE	Receive Enable When this bit is set to 1, reception is enabled. In this state, serial reception is started by detecting a start bit in asynchronous mode or the input of synchronous clock in clock synchronous mode. Be sure to configure SCI3nSMR before setting the RE bit to 1 to determine the reception format. Even if reception is disabled by clearing this bit, the RDRF, FER, PER, or ORER flags are not affected and the previous value is retained.

Table 20.12 SCI3nSCR Register Contents (2/2)

Bit Position	Bit Name	Function
3	MPIE	Multiprocessor Interrupt Enable (Valid only when MP in SCI3nSMR = 1 in asynchronous mode) When this bit is set to 1 and the data with the multi-processor bit set to 0 is received, the data is not read and setting the RDRF, FER, and ORER flags in SCI3nSSR to 1 is disabled. When the data with the multi-processor bit set to 1 is received, this bit is automatically cleared to 0, and normal reception is resumed. For details, see **Section 20.4.2, Multi-Processor Communication Function**. When the receive data includes MPB = 0 in SCI3nSSR, the receive data is not transferred from SCI3nRSR to SCI3nRDR, a receive error is not detected, and setting the RDRF, FER, and ORER flags in SCI3nSSR to 1 is disabled. When the receive data includes MPB = 1 in SCI3nSSR, the MPB bit in SCI3nSSR is set to 1, the MPIE bit is automatically cleared to 0, the INTSCI3nRXI and INTSCI3nERI interrupt requests are enabled (if the RIE bit in SCI3nSCR is set to 1), and setting the FER and ORER flags to 1 is enabled.
2	TEIE	Transmit End Interrupt Enable When this bit is set to 1, INTSCI3nTEI interrupt request is enabled. INTSCI3nTEI interrupt request can be cancelled by reading 1 from the TDRE flag and then clearing the flag to 0 to clear the TEND flag to 0, or clearing the TEIE bit.
1, 0	CKE1, CKE0	Clock Enable 1, 0 These bits select the clock source and the SCInSCK pin function. For asynchronous mode 00: On-chip baud rate generator (The SCInSCK pin functions as an input/output port.) 01: On-chip baud rate generator (The clock with the same frequency as the bit rate is output from the SCInSCK pin.) 1X: Setting prohibited For clock synchronous mode 0X: Internal clock (The SCInSCK pin functions as a clock output pin.) 1X: External clock (The SCInSCK pin functions as a clock input pin.)

Note: X: Don’t care

Note: When writing to any bit other than the MPIE bit of this register, use a store instruction such that the value of the MPIE bit becomes 0.
Note that when using a bit-manipulation instruction for writing to this register, the read-modify-write operation may inadvertently set the MPIE bit to 1.

20.3.8 SCI3nSSR — Serial Status Register

SCI3nSSR consists of SCI3 status flags and multi-processor transmit/receive bits.
The TDRE, RDRF, ORER, PER, and FER flags can be cleared only.

Access: This register can be read or written in 8-bit units.

Address: <SCI3n_base> + 0010_H

Value after reset: 84_H

Bit	7	6	5	4	3	2	1	0
	TDRE	RDRF	ORER	FER	PER	TEND	MPB	MPBT
Value after reset	1	0	0	0	0	1	0	0
R/W	R/(W)*1	R/(W)*1	R/(W)*1	R/(W)*1	R/(W)*1	R	R	R/W

Note 1. Only 0 can be written to clear the flag.

Table 20.13 SCI3nSSR Register Contents (1/2)

Bit Position	Bit Name	Function
7	TDRE	Transmit Data Register Empty Indicates whether or not transmit data exists in SCI3nTDR. [Setting conditions] • When the TE bit in SCI3nSCR is 0 • When the data in SCI3nTDR has been transferred to SCI3nTSR so that new data can be written to SCI3nTDR [Clearing condition] • Writing 0 to TDRE after reading TDRE = 1 • When transmit data is written to SCI3nTDR while TE = 1
6	RDRF	Receive Data Register Full Indicates whether or not receive data exists in SCI3nRDR [Setting condition] • When reception finishes successfully and the receive data is transferred from SCI3nRSR to SCI3nRDR [Clearing conditions] • Writing 0 to RDRF after reading RDRF = 1 • When data is read from SCI3nRDR Even when the RE bit in SCI3nSCR is cleared, the RDRF flag is not affected and the previous value is retained. • Note that completing the reception of the next data with the RDRF flag set to 1 will cause an overrun error, resulting in the loss of the receive data.
5	ORER	Overrun Error Indicates that an overrun error has occurred during reception and the reception ended abnormally. [Setting condition] • When the next data is received while RDRF = 1 In SCI3nRDR, data received prior to the overrun error is retained, but data received after the overrun error occurrence is lost. When the ORER flag is set to 1, subsequent serial reception cannot be continued. In clock synchronous mode, serial transmission also cannot be continued. [Clearing condition] • Writing 0 to ORER after reading ORER = 1 Even when the RE bit in SCI3nSCR is cleared, the ORER flag is not affected and the previous value is retained.

Table 20.13 SCI3nSSR Register Contents (2/2)

Bit Position	Bit Name	Function
4	FER	Framing Error Indicates that a framing error has occurred during reception in asynchronous mode and the reception ended abnormally. [Setting condition] • When the stop bit is 0 In 2-stop-bit mode, only whether the first stop bit is 1 is checked but the second stop bit is not checked. Although the receive data that existed when a framing error has occurred is transferred to SCI3nRDR, the RDRF flag is not set. In addition, while the FER flag is set to 1, the subsequent receive data is not transferred to SCI3nRDR. [Clearing condition] • Writing 0 to FER after reading FER = 1 Even when the RE bit in SCI3nSCR is cleared to 0, the FER flag is not affected and the previous value is retained.
3	PER	Parity Error Indicates that a parity error has occurred during reception in asynchronous mode and the reception ended abnormally. [Setting condition] • Although the receive data that existed when a parity error has occurred is transferred to SCI3nRDR, the RDRF flag is not set. In addition, while the PER flag is set to 1, the subsequent receive data is not transferred to SCI3nRDR. [Clearing condition] • Writing 0 to PER after reading PER = 1 Even when the RE bit in SCI3nSCR is cleared to 0, the PER flag is not affected and the previous value is retained.
2	TEND	Transmit End Indicates that a transmission is completed. [Setting conditions] • When the TE bit in SCI3nSCR is 0 • When the TDRE flag is 1 while the last bit of a transmit character is being transmitted [Clearing condition] • Writing 0 to the TDRE flag after reading TDRE = 1 • When transmit data is written to SCI3nTDR while TE = 1
1	MPB	Multi-processor Bit Holds the value of the multi-processor bit in the receive frame.
0	MPBT	Multi-processor Bit Transfer Sets the value of the multi-processor bit to be added to the transmit frame.

20.3.9 SCI3nSCMR — Serial Transfer Format Register

SCI3nSCMR is a register to select the communication format which can be commonly configured for both asynchronous mode and clock synchronous mode.

Access: This register can be read or written in 8-bit units.

Address: <SCI3n_base> + 0018_H

Value after reset: $F2_H$

Bit	7	6	5	4	3	2	1	0
	—	—	—	CHR1	SDIR	SINV	ASTLS	—
Value after reset	1	1	1	1	0	0	1	0
R/W	R	R	R	R/W*1	R/W*1	R/W*1	R/W*1	R

Note 1. Writable only when TE = 0 and RE = 0.

Table 20.14 SCI3nSCMR Register Contents

Bit Position	Bit Name	Function
7 to 5	Reserved	When read, the value after reset is read. When writing, write the value after reset.
4	CHR1	Character Length 1 (Valid in asynchronous mode and clocked synchronous mode) • Asynchronous mode CHR1 is used in combination with CHR bit in SCI3nSMR. Refer to the **Section 20.3.6, SCI3nSMR — Serial Mode Register** value. • Clocked synchronous mode 1: Selects 8 bits as the data length 0: Selects 16 bits as the data length
3	SDIR	Serial Data Transfer Direction (Valid in asynchronous mode and clock synchronous mode) This bit is used to select the direction of serial/parallel conversion. 0: Transfer with LSB-first 1: Transfer with MSB-first This bit is valid only when the transfer format is 8-bit and 16-bit data. For 7-bit data, LSB-first transfer is used.
2	SINV	Serial Data Invert (Valid in asynchronous mode and clock synchronous mode) This bit is used to invert the transfer data logic level. The SINV bit does not affect the logic level of the parity bit. To invert the parity bit, invert the PM bit in SCI3nSMR. 0: SCI3nTDR data is transmitted as it is, and receive data is stored in SCI3nRDR as it is. 1: SCI3nTDR data is inverted and transmitted, and receive data is inverted and stored in SCI3nRDR.
1	ASTLS	Asynchronous Mode Start Bit Level Detection Select (Valid only in asynchronous mode) 0: Falling edge of RxD pin input 1: Low level of RxD pin input
0	Reserved	When read, the value after reset is read. When writing, write the value after reset.

20.3.10 SCI3nSEMR — Serial Extended Mode Register

SCI3nSEMR is a register to select a 1-bit period.

Access: This register can be read or written in 8-bit units.

Address: <SCI3n_base> + $001C_H$

Value after reset: 04_H

Bit	7	6	5	4	3	2	1	0
	BRME	MDDRS	—	BGDM	ABCS	RXDMON	—	—
Value after reset	0	0	0	0	0	1	0	0
R/W	R/W*1	R/W*1	R	R/W*1	R/W*1	R	R	R

Note 1. Writable only when TE = 0 and RE = 0.

Table 20.15 SCI3nSEMR Register Contents

Bit Position	Bit Name	Function
7	BRME	Bit Rate Modulation Enable When this bit is set to 1, the bit rate modulation function is enabled.
6	MDDRS	Modulation Duty Register Select This bit is used to select an accessible register. 0: SCI3nBRR is accessible. 1: SCI3nMDDR is accessible.
5	Reserved	When read, the value after reset is read. When writing, write the value after reset.
4	BGDM	Baud Rate Generator Double-Speed Mode Select (Valid only when asynchronous mode and CKE1 bit in SCI3nSCR is 0) This bit selects output clock period of baud rate generator. 0: Output clock is normal frequency from baud rate generator 1: Output clock is twice frequency from baud rate generator (Double speed operation)
3	ABCS	Asynchronous Reference Clock Select (Valid only in asynchronous mode) This bit is used to select the reference clock for 1-bit period. 0: Operates on the reference clock with a frequency of 16 times the transfer rate. 1: Operates on the reference clock with a frequency of 8 times the transfer rate (double-speed operation).
2	RXDMON	Serial Input Data Monitor This bit indicates the SCInRxD pin state. 0: SCInRxD pin state is low level. 1: SCInRxD pin state is high level.
1, 0	Reserved	When read, the value after reset is read. When writing, write the value after reset.

20.3.11 SCI3nBRR — Bit Rate Register

SCI3nBRR is an 8-bit register to adjust the bit rate. Since each SCI3 channel has an independent baud rate generator, different bit rates can be set for each channel. **Table 20.17** shows the relationship between the setting (N) in SCI3nBRR and the bit rate (B) in normal asynchronous mode, clock synchronous mode . The value of SCI3nBRR after reset is FF_H. SCI3nBRR is allocated at the same address as SCI3nMDDR and is selected when MDDRS in SCI3nSEMR is 0. This register is writable only when TE = 0 and RE = 0.

Access: This register can be read or written in 8-bit units.

Address: <SCI3n_base> + 0004_H

Value after reset: FF_H

Bit	7	6	5	4	3	2	1	0
	BRR							
Value after reset	1	1	1	1	1	1	1	1
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 20.16 SCI3nBRR Register Contents

Bit Position	Bit Name	Function
7 to 0	BRR	Baud rate generator setting (0 ≤ N ≤ 255)

Table 20.17 Relationship between Setting N in SCI3nBRR and Bit Rate B

	SEMR Setting			
Mode	ABCS bit	BGDM bit	Bit Rate	Mean Error
Asynchronous	0	0	$B = \frac{PCLK \times 10^6}{64 \times 2^{2\alpha-1} \times (N+1)}$	$Error(\%) = \left\{\frac{PCLK \times 10^6}{B \times 64 \times 2^{2\alpha-1} \times (N+1)} - 1\right\} \times 100$
	0	1	$B = \frac{PCLK \times 10^6}{32 \times 2^{2\alpha-1} \times (N+1)}$	$Error(\%) = \left\{\frac{PCLK \times 10^6}{B \times 32 \times 2^{2\alpha-1} \times (N+1)} - 1\right\} \times 100$
	1	0		
	1	1	$B = \frac{PCLK \times 10^6}{16 \times 2^{2\alpha-1} \times (N+1)}$	$Error(\%) = \left\{\frac{PCLK \times 10^6}{B \times 16 \times 2^{2\alpha-1} \times (N+1)} - 1\right\} \times 100$
Clock synchronous	—		$B = \frac{PCLK \times 10^6}{8 \times 2^{2\alpha-1} \times (N+1)}$	—

Note: B: Bit rate (bps)
N: SCI3nBRR setting value for baud rate generator (0 ≤ N ≤ 255)
PCLK: Operating frequency (MHz)
α: Determined by the SCI3nSMR setting value as shown in the following table.

SCI3nSMR Setting Value		
CKS1	CKS0	α
0	0	0
0	1	1
1	0	2
1	1	3

Table 20.18 lists sample N settings of the SCI3nBRR register in asynchronous mode. **Table 20.19** shows the maximum configurable bit rates.

20.3.12 SCI3nMDDR — Modulation Duty Register

SCI3nMDDR is a register to correct the bit rate adjusted by SCI3nBRR. The value of SCI3nMDDR after a reset is FF_H. When the BRME bit in SCI3nSEMR is set to 1, the bit rate generated by the on-chip baud rate generator is corrected to SCI3nMDDR/256 on average. **Table 20.23** shows the relationship between the SCI3nMDDR setting and the bit rate B. SCI3nMDDR is allocated at the same address as SCI3nBRR and is selected when MDDRS in SCI3nSEMR is 1. This register is writable only when TE = 0 and RE = 0. Bit 7 is fixed to 1.

Access: This register can be read or written in 8-bit units.

Address: <SCI3n_base> + 0004_H

Value after reset: FF_H

Bit	7	6	5	4	3	2	1	0
	MDDR							
Value after reset	1	1	1	1	1	1	1	1
R/W	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W

20.4 Operation

20.4.1 Operation in Asynchronous Mode

Figure 20.2 shows the general format for asynchronous serial communications. One frame consists of a start bit (low level), transmit/receive data, a parity bit, and stop bits (high level). In asynchronous serial communications, the communication line is usually held in the mark state (high level). The SCI3 monitors the communication line, and when the SCI3 detects the space state (low level), it recognizes a start bit and starts serial communications. Inside the SCI3, the transmitter and the receiver are independent, enabling full-duplex communications. Both the transmitter and the receiver have a double-buffered structure so that data can be read or written during transmission or reception, enabling continuous data transmission and reception.

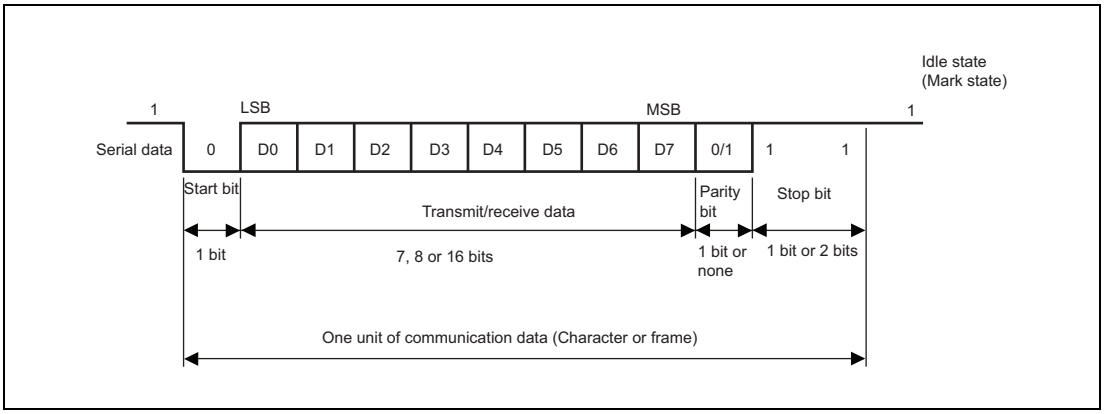

Figure 20.2 Data Format in Asynchronous Serial Communications (Example with 8-Bit Data, Parity, Two Stop Bits)

20.4.1.1 Transmission/Reception Format

Table 20.24 lists the transmission/reception formats that can be configured in asynchronous mode. Any of 16 transmission/reception formats can be selected according to the SCI3nSMR setting. For details of the multi-processor bit, see **Section 20.4.2, Multi-Processor Communication Function**.

Table 20.24 Serial Transmission/Reception Formats (Asynchronous Mode) (1/2)

SCI3nSCMR Setting	SCI3nSMR Setting				Serial Transmission/Reception Format and Frame Length

Note: S: Start bit
STOP: Stop bit
P: Parity bit
MPB: Multi-processor bit

20.4.1.2 Receive Data Sampling Timing and Reception Margin

In asynchronous mode, the SCI3 operates on a reference clock with a frequency of 16 times (8 times when ABCS bit in SCI3nSEMR = 1) the bit rate. In reception, the SCI3 samples the falling edge of the beginning of the start bit (low level) using the reference clock and performs internal synchronization.

As shown in **Figure 20.3**, data is latched at the middle of each bit by sampling receive data at the rising edge of the eighth pulse (fourth pulse when ABCS bit in SCI3nSEMR = 1) of the reference clock.

Thus the reception margin in asynchronous mode is determined by formula (1) below.

$$M = \left| \left(0.5 - \frac{1}{2N}\right) - (L - 0.5)F - \frac{|D - 0.5|}{N}(1 + F) \right| \times 100[\%] \ldots \text{formula(1)}$$

M: Reception margin
N: Ratio of bit rate to clock (N = 16 when ABCS in SCI3nSEMR = 0, N = 8 when ABCS = 1)
D: Duty cycle of clock (D = 0.5 to 1.0)
L: Frame length (L = 9 to 20)
F: Absolute value of clock frequency deviation

Assuming that F (absolute value of clock frequency deviation) = 0, D (duty cycle of clock) = 0.5, and N = 16 in formula (1), the reception margin is obtained by the formula below.

$$M = \left\{0.5 - \frac{1}{(2 \times 16)}\right\} \times 100[\%] = 46.875\%$$

However, this is only the calculated value, and a margin of 20% to 30% should be allowed in system design.

When the bit rate modulation function is used, the reference clock frequency is corrected on average.

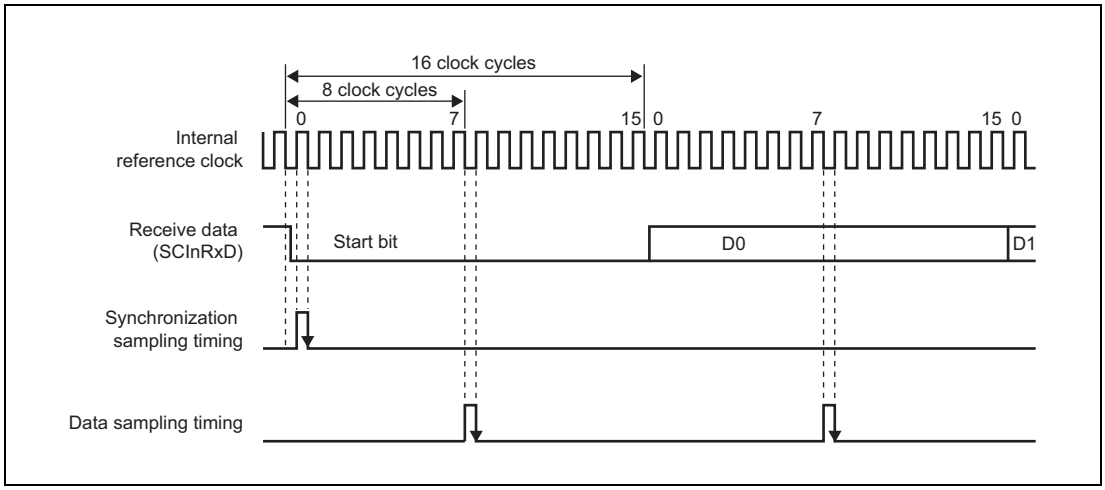

Figure 20.3 Receive Data Sampling Timing in Asynchronous Mode (when ABCS bit in SCI3nSEMR = 0)

20.4.1.3 Clock

An internal clock generated by the on-chip baud rate generator can be selected as the SCI3's transmission/reception clock according to the settings of the CM bit in SCI3nSMR and the CKE1 and CKE0 bits in SCI3nSCR. When the SCI3 is operated on an internal clock, the clock can be output from the SCInSCK pin.

For details of clock synchronous mode, see **Section 20.4.3, Operation in Clock Synchronous Mode**.

In asynchronous mode, the frequency of the clock output is equal to the bit rate and the phase is such that the rising edge of the clock comes at the center of the transmit data, as shown in **Figure 20.4**.

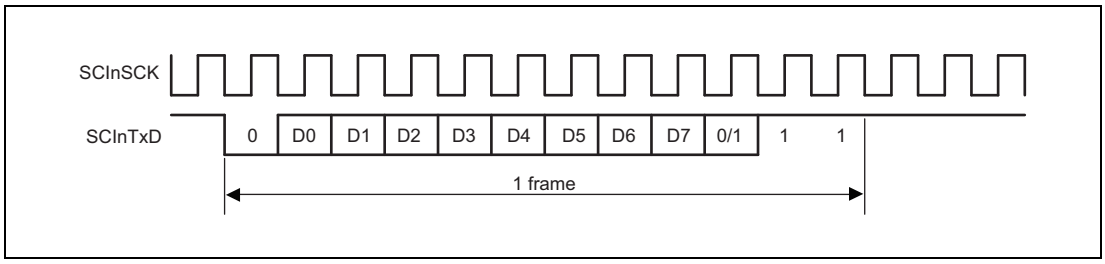

Figure 20.4 Phase Relationship between Output Clock and Transmit Data (Asynchronous Mode)

20.4.1.4 Double-Speed Operation

In addition to the operation described in **Section 20.4.1.3, Clock**, double-speed operation is enabled by the setting of the ABCS bit in SCI3nSEMR.

In double-speed operation, the same operation on a clock with a frequency of 16 times the bit rate in normal operation can be conducted on a clock with a frequency of 8 times the bit rate, meaning that the SCI3 operates on a double transfer rate using the same reference clock.

In addition, the basic clock cycle is halved if BGDM bit in SCI3nSEMR is set to 1, therefore SCI3 operates at a bit rate twice as fast as when BGDM bit is set to 0.

Double-speed operation by the ABCS bit and double-speed operation by the BGDM bit can be used in combination when CKE1 bit in SCR is set to 0 and on-chip baud rate generator is selected. By setting the ABCS bit = 1 and BGDM bit = 1, SCI3 operates at a bit rate four times faster than when ABCS bit = 0 and BGDM bit = 0 .

20.4.1.5 SCI3 Initialization (Asynchronous Mode)

Before transmitting and receiving data, clear the TE and RE bits in SCI3nSCR and then initialize the SCI3 according to the sample flowchart in **Figure 20.5**. Before changing the operating mode or transfer format, be sure to clear the TE and RE bits to 0. Note that clearing the TE bit to 0 sets the TDRE flag to 1, but clearing the RE bit to 0 initializes neither the RDRF, PER, FER, and ORER flags nor SCI3nRDR.

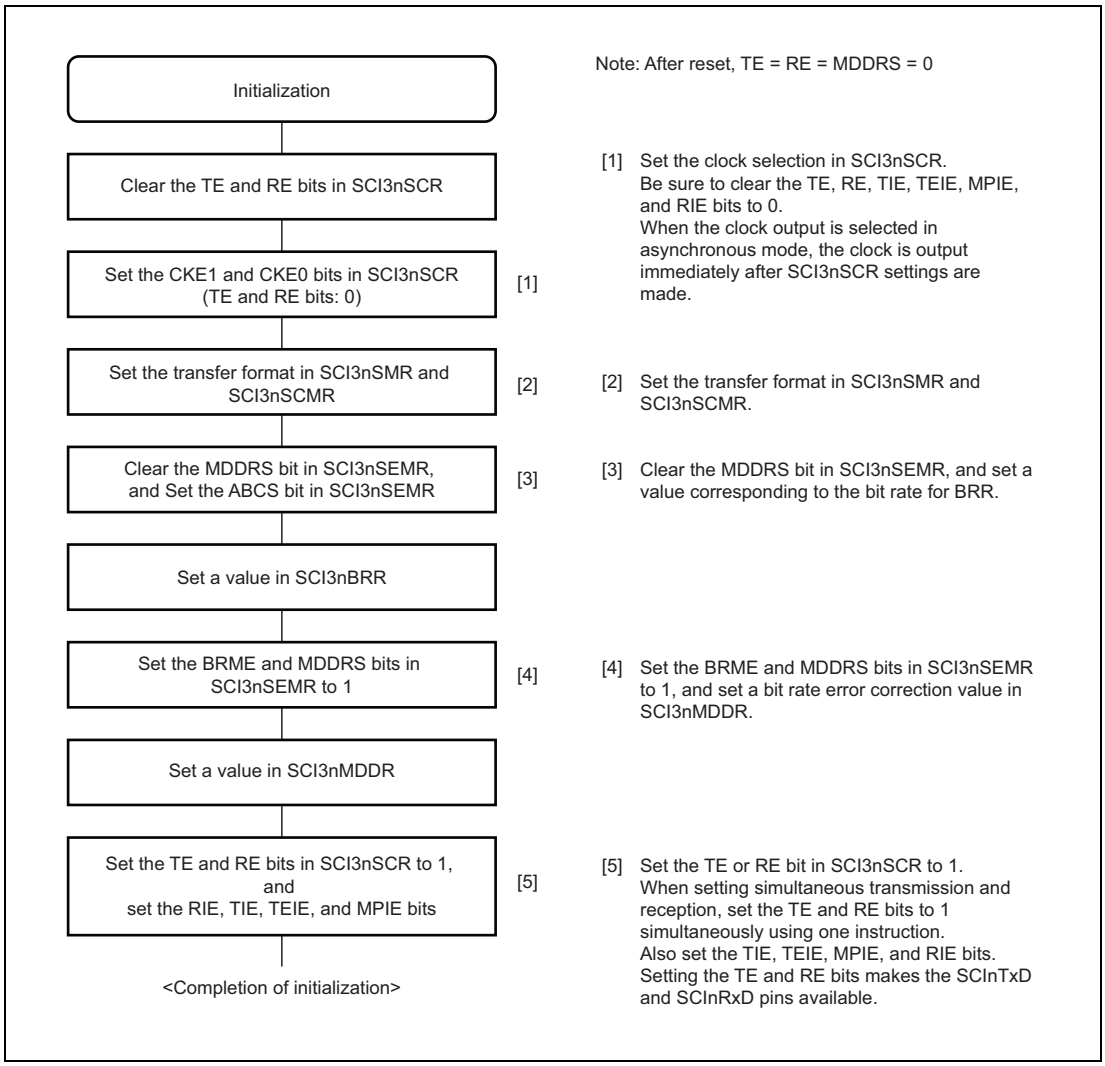

Figure 20.5 Sample Flowchart for SCI3 Initialization

20.4.1.6 Serial Data Transmission (Asynchronous Mode)

Figure 20.6 shows an example of operation for data transmission in asynchronous mode. In data transmission, the SCI3 operates as described below.

1. When transmit data is written to SCI3nTDR, the TDRE flag is automatically cleared to 0. The SCI3 monitors the TDRE flag in SCI3nSSR. When the flag is cleared, the SCI3 recognizes that data has been written to SCI3nTDR and transfers data from SCI3nTDR to SCI3nTSR. When writing transmit data to SCI3nTDR at a trigger of INTSCI3nTXI interrupt request, set the TIE bit to 1 and then set the TE bit to 1 or set both TIE and TE bits simultaneously with one instruction to generate a INTSCI3nTXI interrupt request for starting data transfer.
2. Transmission starts after data is transferred from SCI3nTDR to SCI3nTSR and the TDRE flag is set to 1. If the TIE bit in SCI3nSCR is set to 1 at this time, a INTSCI3nTXI interrupt request is generated. Continuous transmission is enabled by writing the next transmit data to SCI3nTDR in this INTSCI3nTXI interrupt processing routine before transmission of the previously transferred data is completed. When an INTSCI3nTEI interrupt request is used, the TIE bit is cleared to 0 after the last transmit data has been written to SCI3nTDR, and the TEIE bit is set to 1.
3. Data is sent from the SCInTxD pin in the following order: start bit, transmit data, parity bit or multi-processor bit (may be omitted depending on the format), and stop bit.
4. The TDRE flag is checked when the stop bit is output.
5. When the TDRE flag is 0, the next transmit data is transferred from SCI3nTDR to SCI3nTSR. After the stop bit has been sent, transmission of the next frame starts.
6. When the TDRE flag is 1, the TEND flag in SCI3nSSR is set to 1, the stop bit is sent, and then 1 is output to enter the mark state. If the TEIE bit in SCI3nSCR is set to 1 at this time, a INTSCI3nTEI interrupt request is generated.

Figure 20.7 shows a sample flowchart for data transmission. **Figure 20.8** shows a sample flowchart for stopping the SCI3 after data transmission.

Note about the operation when transmission is enabled in asynchronous mode:

When the setting of the TE bit is changed from 0 to 1, a high level (preamble) is output for one frame. If transmit data is written to SCI3nTDR while the preamble is being output, that data will be transferred from SCI3nTDR to SCI3nTSR after preamble output is complete.

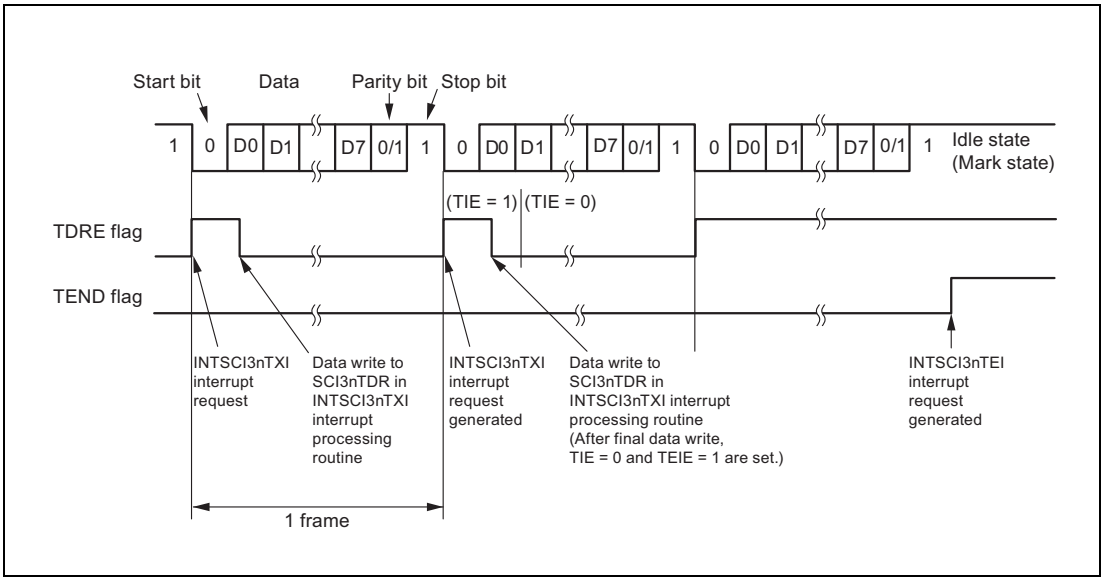

Figure 20.6 Example of Operation for Transmission in Asynchronous Mode (Example with 8-Bit Data, Parity, One Stop Bit)

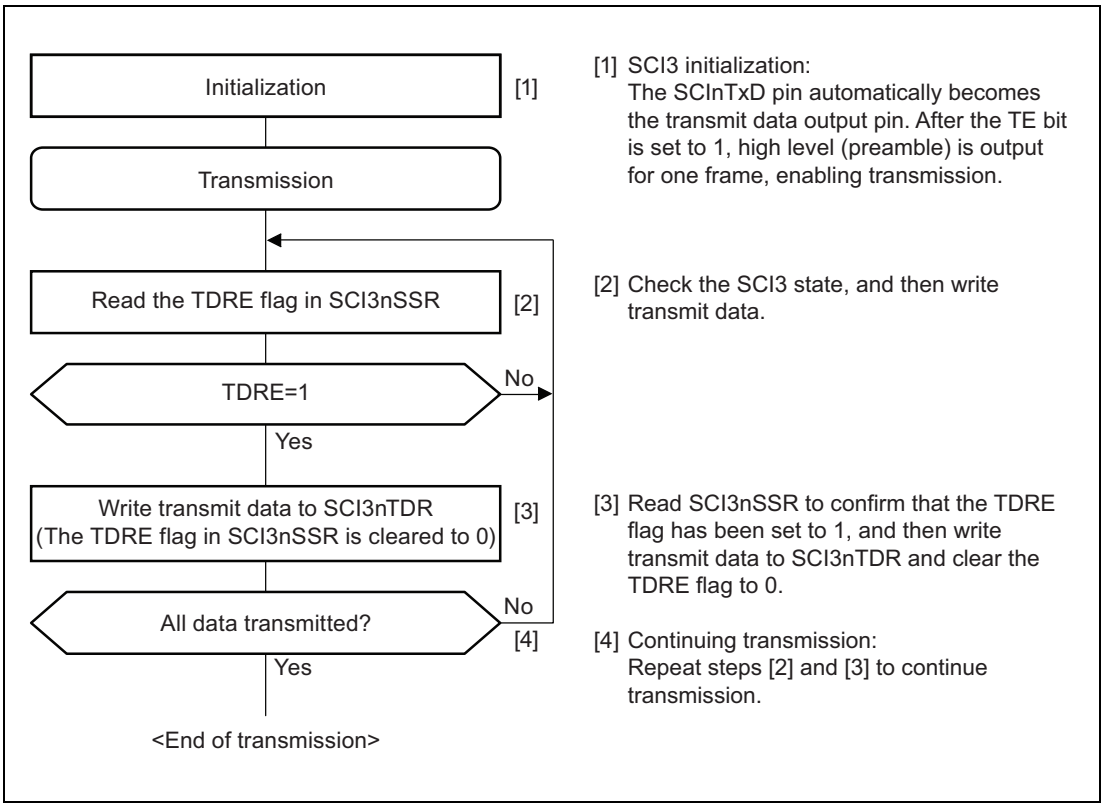

Figure 20.7 Example of Serial Transmission Flowchart

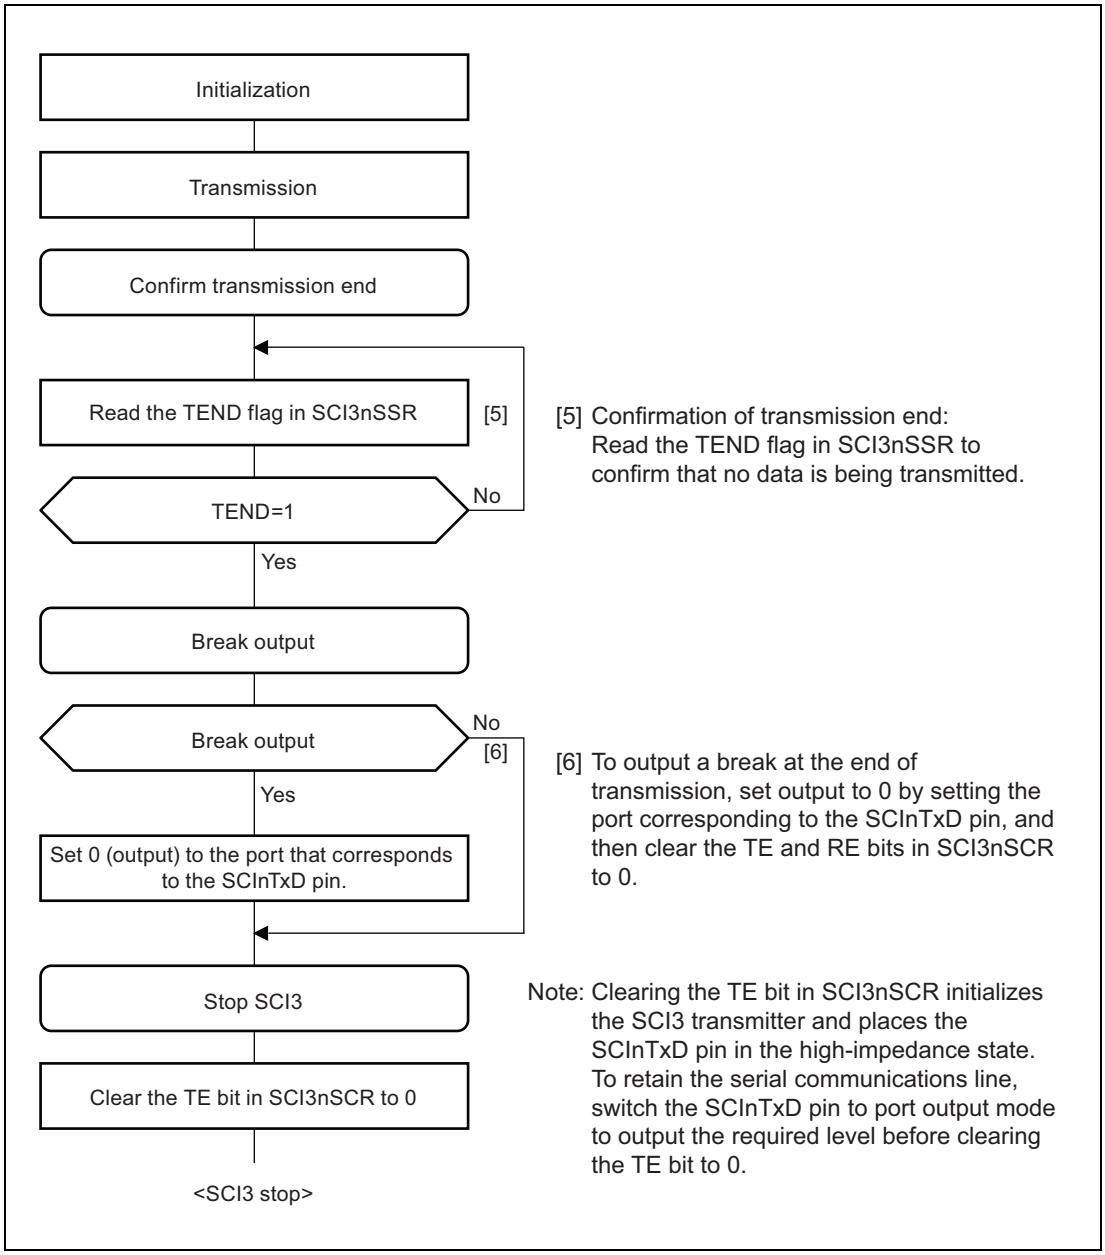

Figure 20.8 Example Flowchart for Stopping the SCI3 after Serial Transmission

20.4.1.7 Serial Data Reception (Asynchronous Mode)

Figure 20.9 shows an example of the operation for data reception in asynchronous mode. In data reception, the SCI3 operates as described below.

1. SCI3 monitors the communications line and upon detection of a start bit, it performs internal synchronization, stores receive data in SCI3nRSR, and checks the parity bit and the stop bit.
2. When an overrun error occurs (the next data has been received with the RDRF flag in SCI3nSSR set to 1), the ORER flag in SCI3nSSR is set to 1. If the RIE bit in SCI3nSCR is set to 1 at this time, an INTSCI3nERI interrupt request is generated. Receive data is not transferred to SCI3nRDR. The RDRF flag retains the state of being set to 1.
3. When a parity error is detected, the PER flag in SCI3nSSR is set to 1 and receive data is transferred to SCI3nRDR. If the RIE bit in SCI3nSCR is set to 1 at this time, an INTSCI3nERI interrupt request is generated.
4. When a framing error (when the stop bit is 0) is detected, the FER flag in SCI3nSSR is set to 1 and receive data is transferred to SCI3nRDR. If the RIE bit in SCI3nSCR is set to 1 at this time, an INTSCI3nERI interrupt request is generated.
5. When reception finishes successfully, the RDRF flag in SCI3nSSR is set to 1 and receive data is transferred to SCI3nRDR. If the RIE bit in SCI3nSCR is set to 1 at this time, an INTSCI3nRXI interrupt request is generated. Continuous reception is enabled by reading the receive data transferred to SCI3nRDR in this INTSCI3nRXI interrupt processing routine before reception of the next receive data is completed. Reading SCI3nRDR automatically clears the RDRF flag to 0.

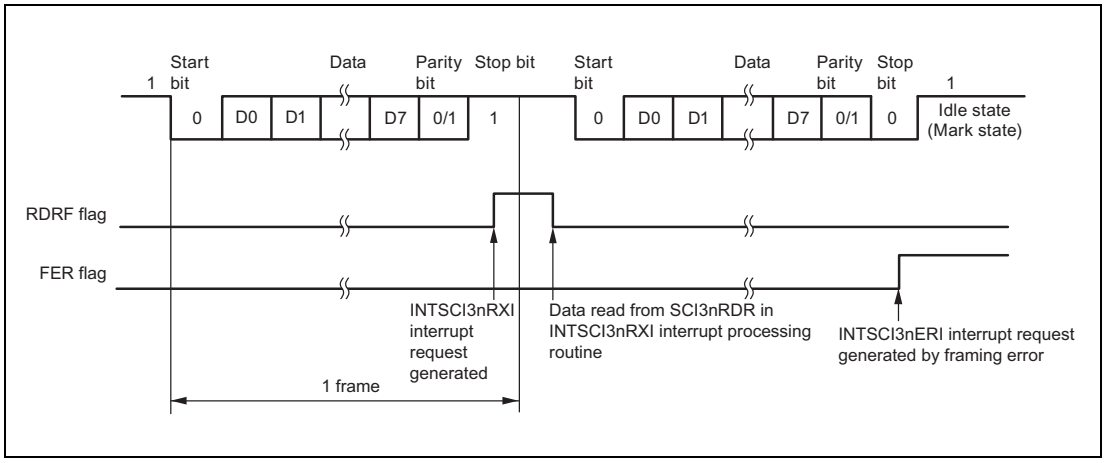

Figure 20.9 Example of Operation for Reception in Asynchronous Mode (Example with 8-Bit Data, Parity, One Stop Bit)

Table 20.25 lists the states of the SCI3nSSR status flags and receive data handling when a receive error is detected. When a receive error is detected, the RDRF flag retains the status before receiving the data. Subsequent data reception is disabled while a receive error flag is set to 1. Accordingly, clear the ORER, FER, PER, and RDRF flags before continuing data reception. **Figure 20.10** shows a sample flowchart for data reception.

Table 20.25 SCI3nSSR Status Flags and Receive Data Handling

SCI3nSSR Status Flags					
RDRF*1	ORER	FER	PER	Receive Data	Receive Status
1	0	0	0	Transferred to SCI3nRDR	Successful reception
0	0	1	0	Transferred to SCI3nRDR	Framing error
0	0	0	1	Transferred to SCI3nRDR	Parity error
0	0	1	1	Transferred to SCI3nRDR	Framing error + parity error
1*	1	0	0	Lost	Overrun error
1*	1	1	0	Lost	Overrun error + framing error
1*	1	0	1	Lost	Overrun error + parity error
1*	1	1	1	Lost	Overrun error + framing error + parity error

Note 1. In the case of an overrun error, the RDRF flag retains the state before the data reception.

Note: "+" indicates that two or more receive statuses occur simultaneously in a single reception operation.

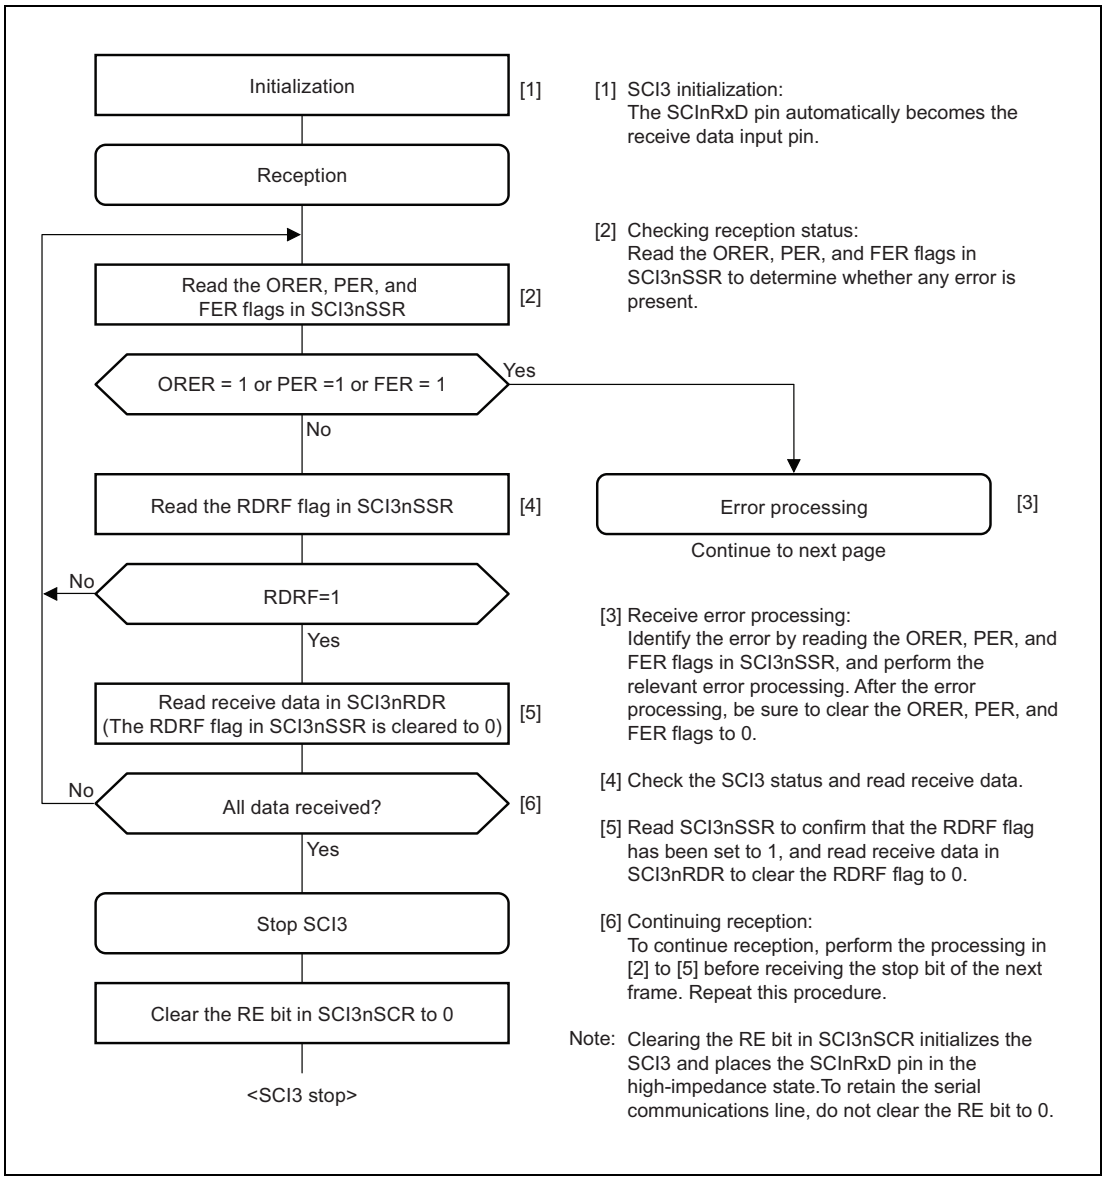

Figure 20.10 Example of Serial Reception Flowchart (1)

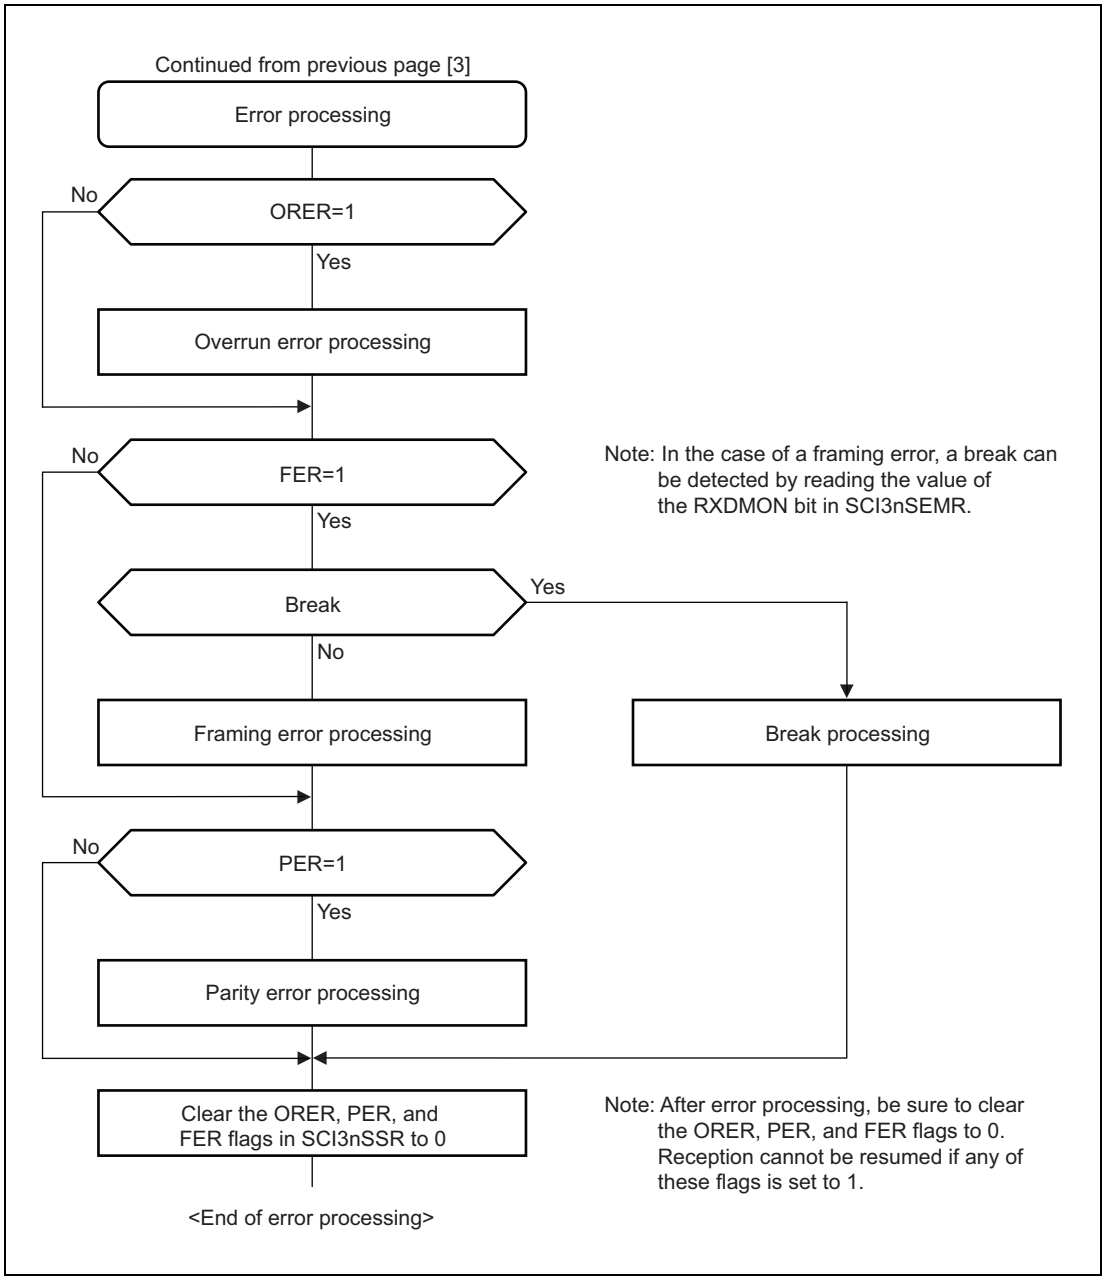

Figure 20.11 Example of Serial Reception Flowchart (2)

20.4.2 Multi-Processor Communication Function

20.4.2.1 Overview and Sample Connection

Using the multi-processor communication function allows data transmission and reception by sharing a communication line between multiple processors by using asynchronous serial communication in which the multi-processor bit is added. In multi-processor communication, a unique ID code is allocated to each receiving station. Serial communication cycles consist of an ID transmission cycle to specify the receiving station and a data transmission cycle to transmit data to the specified receiving station. The multi-processor bit is used to distinguish the ID transmission cycle from the data transmission cycle. When the multi-processor bit is set to 1, it indicates the ID transmission cycle. When the multi-processor bit is set to 0, it indicates the data transmission cycle. **Figure 20.12** shows an example of communication between processors by using the multi-processor format. First, a transmitting station sends communication data in which the multi-processor bit (= 1) is added to the ID code of the receiving station. Next, the transmitting station sends communication data in which the multi-processor bit (= 0) is added to the transmit data. Upon receiving the communication data in which the multi-processor bit is set to 1, the receiving station compares the received ID with the ID of the receiving station itself. When these IDs match, the receiving station receives communication data that is subsequently transmitted. If these IDs do not match, the receiving station skips communication data until it receives communication data in which the multi-processor bit is set to 1.

To support this function, the SCI3 provides the MPIE bit in SCI3nSCR. When the MPIE bit is set to 1, transfer of receive data from SCI3nRSR to SCI3nRDR, detection of a receive error, and setting the RDRF, FER, and ORER flags in SCI3nSSR are disabled until data in which the multi-processor bit is set to 1 is received. Upon receiving a character in which the multi-processor bit is set to 1, the MPB bit in SCI3nSSR is set to 1 and the MPIE bit is automatically cleared to 0, thus returning to a normal reception operation. When the RIE bit in SCI3nSCR is set to 1 at this time, an INTSCI3nRXI interrupt request is generated. While the MPIE bit is cleared to 0, reception operation is conducted regardless of the multi-processor bit value. The multi-processor bit is stored in the MPB bit in SCI3nSSR.

When the multi-processor format is specified, specification of the parity bit is disabled. Apart from this, there is no difference from the operation in the normal asynchronous mode. A clock that is used for multi-processor communications is also the same as the clock used in the normal asynchronous mode.

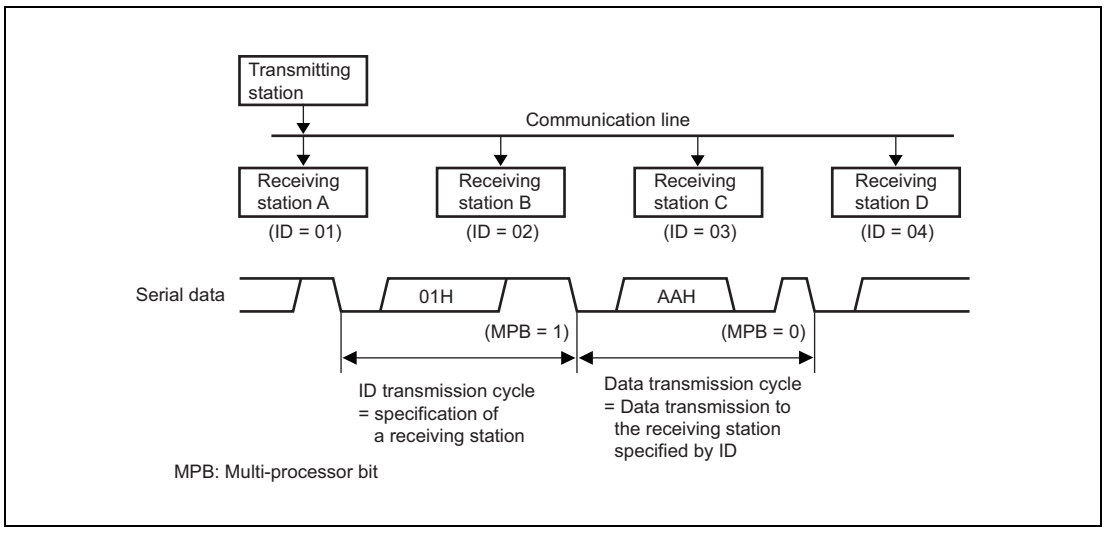

Figure 20.12 Example of Communication Using the Multi-Processor Format (Example of Transmission of Data AA_H to Receiving Station A)

20.4.2.2 Multi-Processor Serial Data Transmission

Figure 20.13 shows a sample flowchart of multi-processor data processing. In the ID transmission cycle, send the ID with the MPBT bit in SCI3nSSR set to 1. In the data transmission cycle, send data with the MPBT bit in SCI3nSSR cleared to 0. Other operations are the same as operations in asynchronous mode.

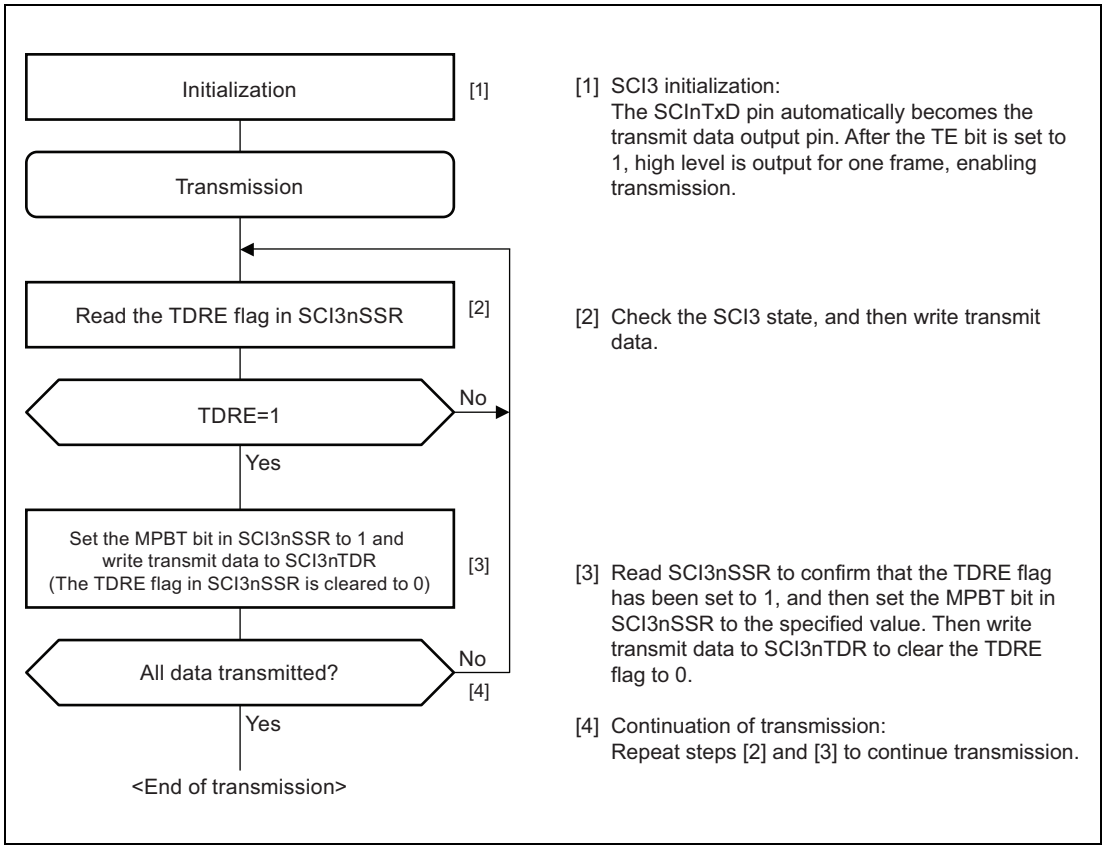

Figure 20.13 Example of Multi-Processor Serial Transmission Flowchart

20.4.2.3 Multi-Processor Serial Data Reception

Figure 20.15 shows a sample flowchart of multi-processor data reception. When the MPIE bit in SCI3nSCR is set to 1, reading the communication data is skipped until communication data in which the multi-processor bit is set to 1 is received. When communication data in which the multi-processor bit is set to 1 is received, the receive data is transferred to SCI3nRDR. At this time, an INTSCI3nRXI interrupt request is generated. Other operations are the same as operations in asynchronous mode. **Figure 20.14** shows an example of operation for reception.

CAUTION

Do not write data to SCI3nSCR when communication data in which the multi-processor bit is set to 1 is received. The MPIE bit may not become the desired state.

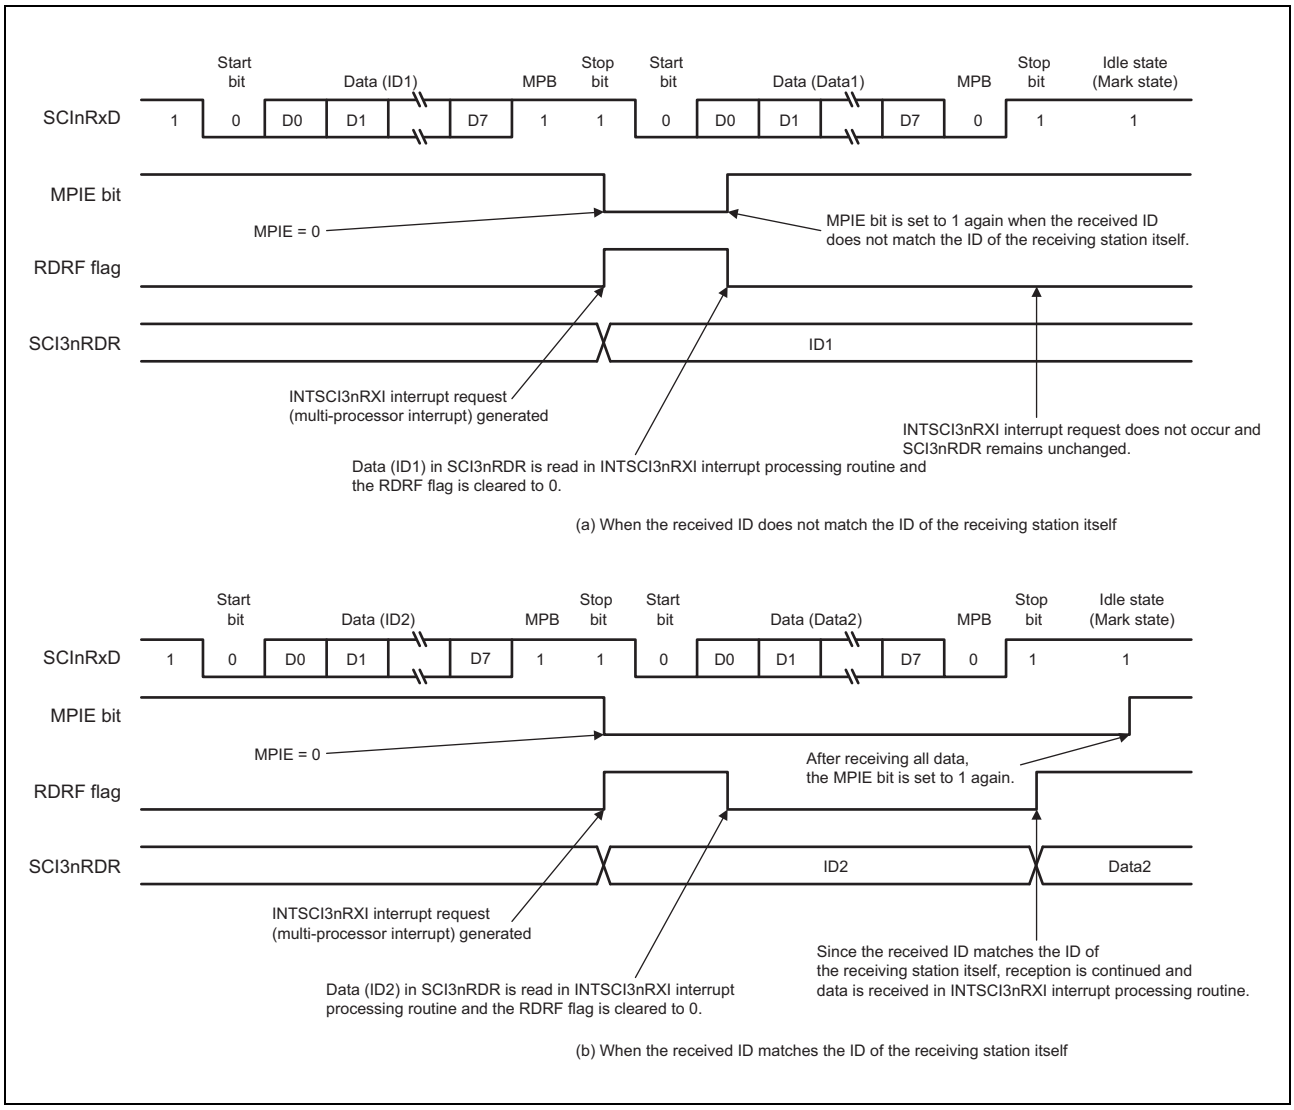

Figure 20.14 Example of SCI3 Reception (8-Bit Data, Multi-Processor Bit, One Stop Bit)

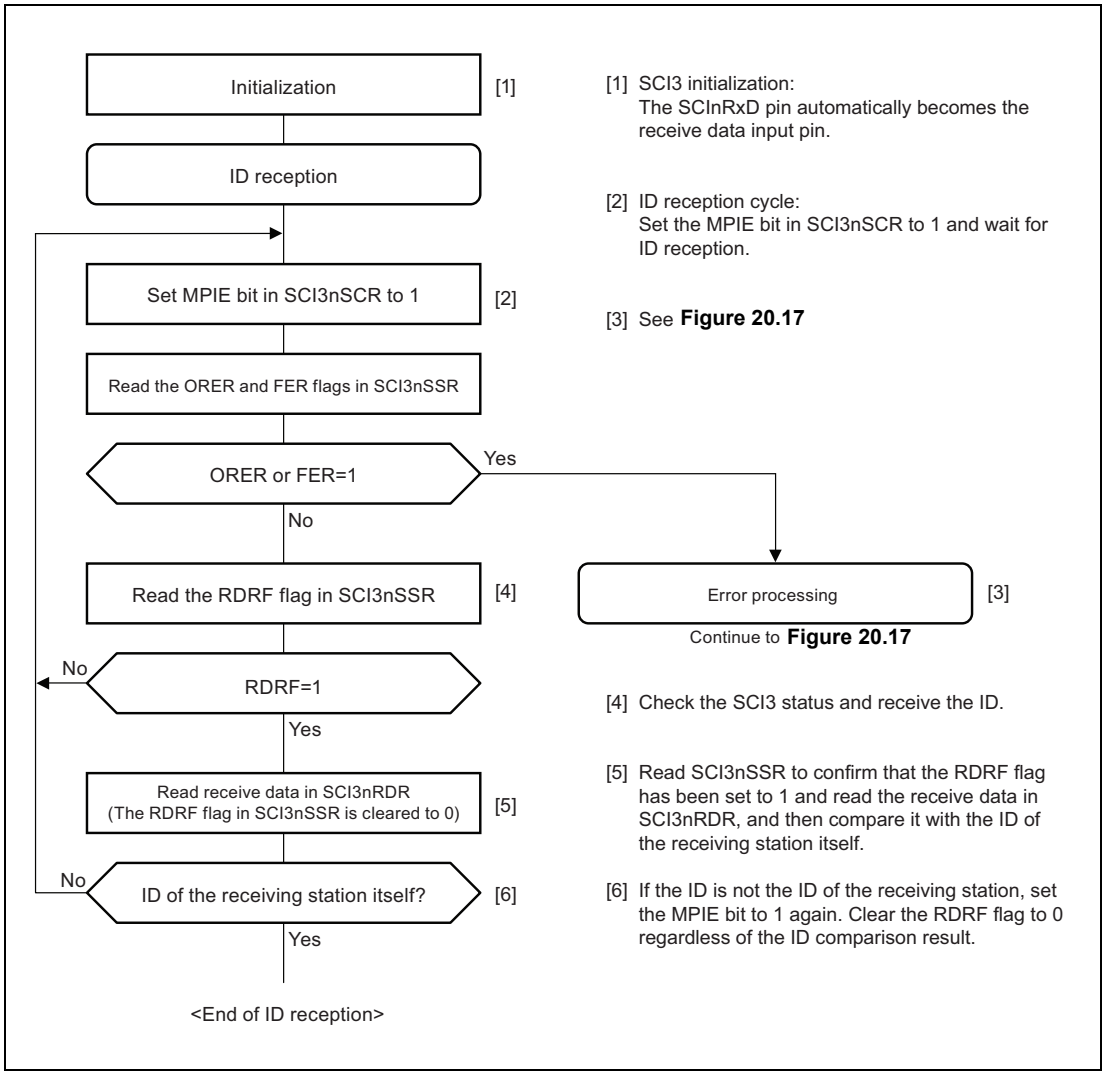

Figure 20.15 Example of Multi-Processor Serial Reception Flowchart (1)

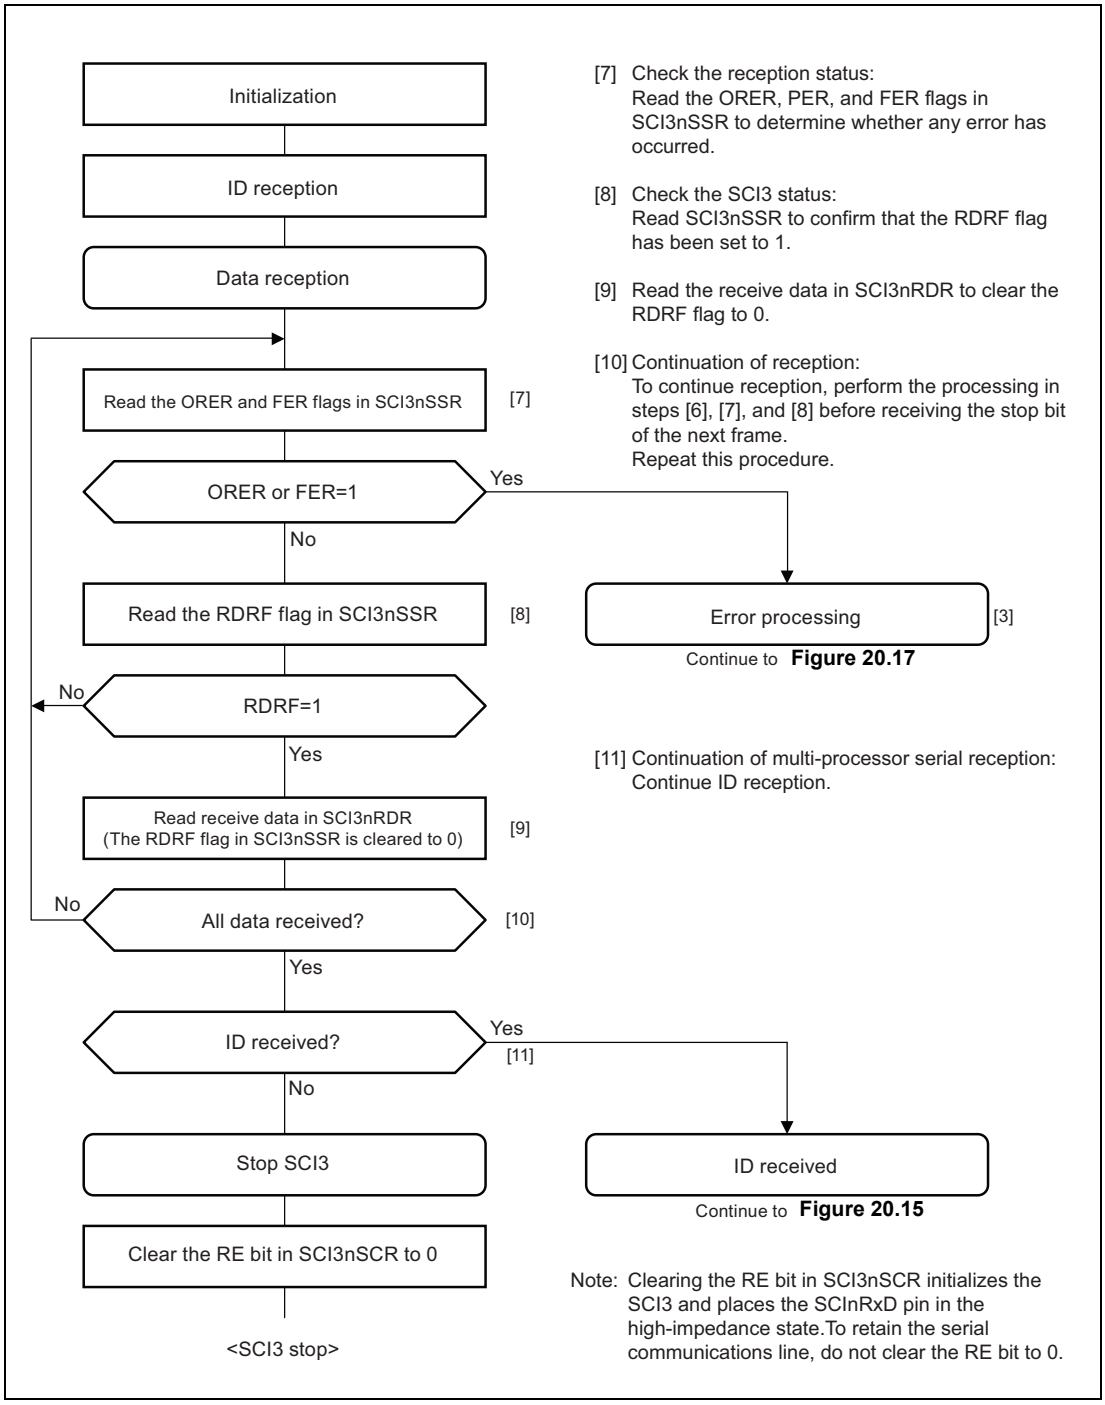

Figure 20.16 Example of Multi-Processor Serial Reception Flowchart (2)

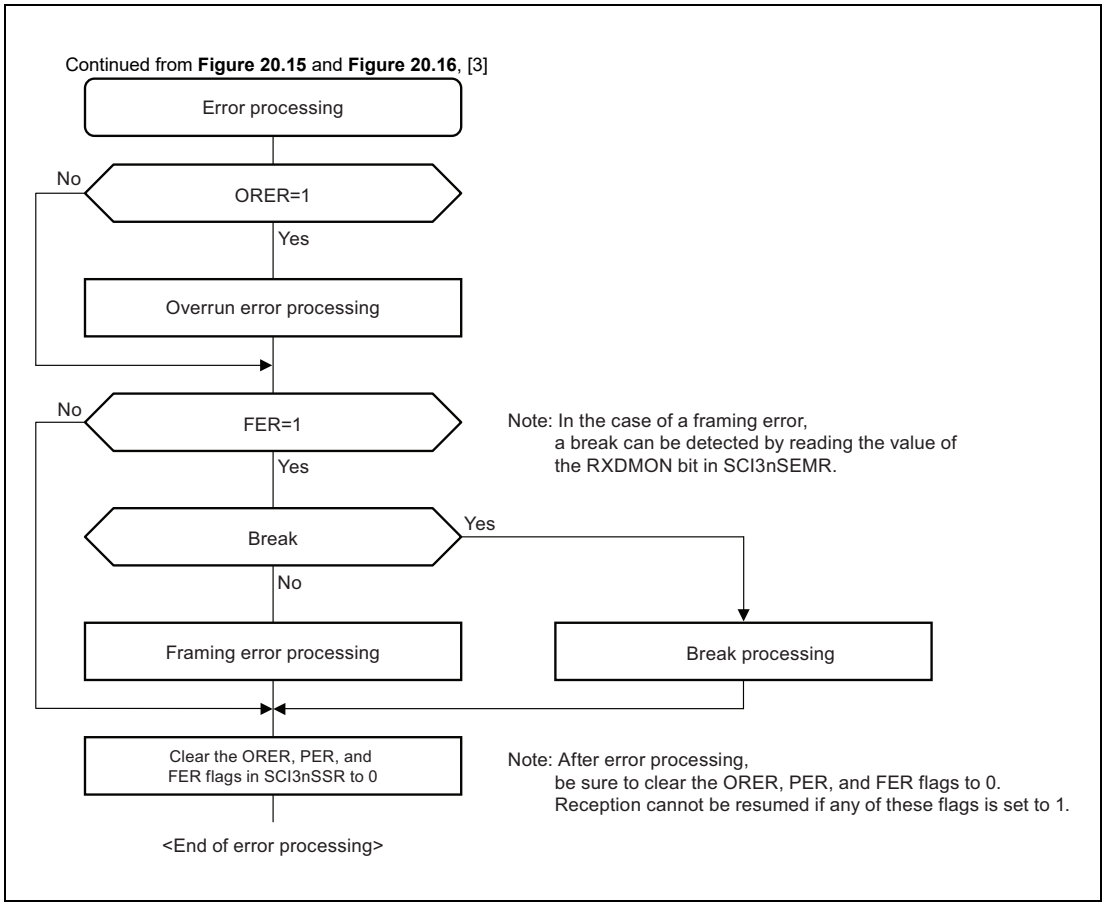

Figure 20.17 Example of Multi-Processor Serial Reception Flowchart (3)

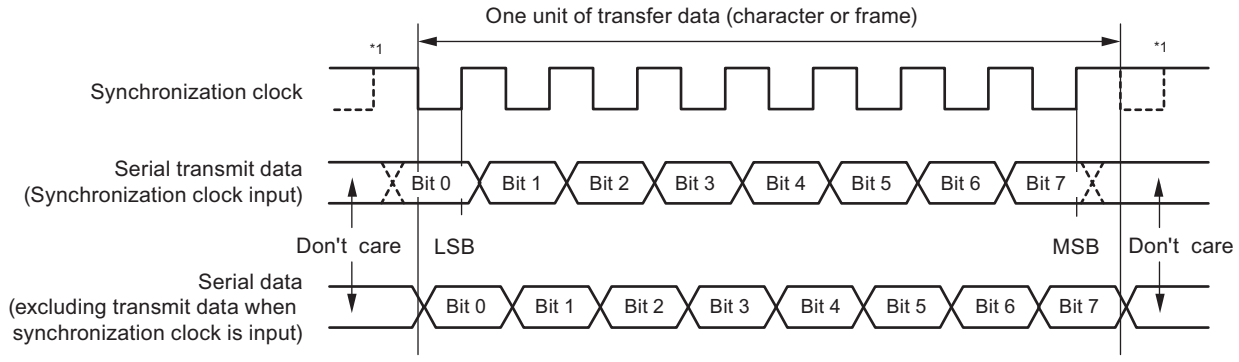
20.4.3 Operation in Clock Synchronous Mode

Figure 20.18 shows the data format for clock synchronous serial data communication. In clock synchronous mode, data is transmitted or received in synchronization with clock pulses. One character in transfer data consists of 8- or 16-bit data. In data transmission with the synchronization clock output, the SCI3 outputs data from one falling edge to the next falling edge of the synchronization clock. In data transmission with the synchronization clock input, the SCI3 outputs the first data (bit 0) after starting transfer immediately after clearing the TDRE bit in SCI3nSSR to 0, and then outputs the next bit data after 2 to 3 PCLK clock cycles from the rising edge of the synchronization clock. In data reception, the SCI3 receives data in synchronization with the rising edge of the synchronization clock. After 8- or 16-bit data is output, the communication line holds the last-bit output state. In clock synchronous mode, neither parity bit nor multi-processor bit can be added. The transmitter and the receiver are independent in the SCI3, enabling full-duplex communication by using a common clock. Both the transmitter and the receiver have a double-buffered structure so that the next transmit data can be written during transmission or the previous receive data can be read during reception, enabling continuous data transfer.



Note 1: Holds a high level except during continuous transmission/reception.

Figure 20.18 Data Format in Clock Synchronous Mode (LSB-First)

20.4.3.1 Clock

An internal clock generated by the on-chip baud rate generator or an external synchronous clock that is input from the SCInSCK pin can be selected by the setting of the CKE1 and CKE0 bits in SCI3nSCR. When operating the SCI3 on the internal clock, a synchronous clock is output from the SCInSCK pin. Eight or sixteen pulses of the synchronous clock are output during transfer of one character, and the clock is held high while no data is transferred.

20.4.3.2 SCI3 Initialization (Clock Synchronous Mode)

Before transmitting and receiving data, clear the TE and RE bits in SCI3nSCR to 0 and then initialize the SCI3 according to the sample flowchart in **Figure 20.19**. To switch the operation between transmission, reception, and transmission/reception, clear the TE and RE bits to 0 and then set these bits to the desired value. Before changing the transfer format, be sure to clear the TE and RE bits to 0. Note that clearing the TE bit to 0 sets the TDRE flag to 1, but clearing the RE bit to 0 initializes neither the RDRF, PER, FER, and ORER flags nor SCI3nRDR.

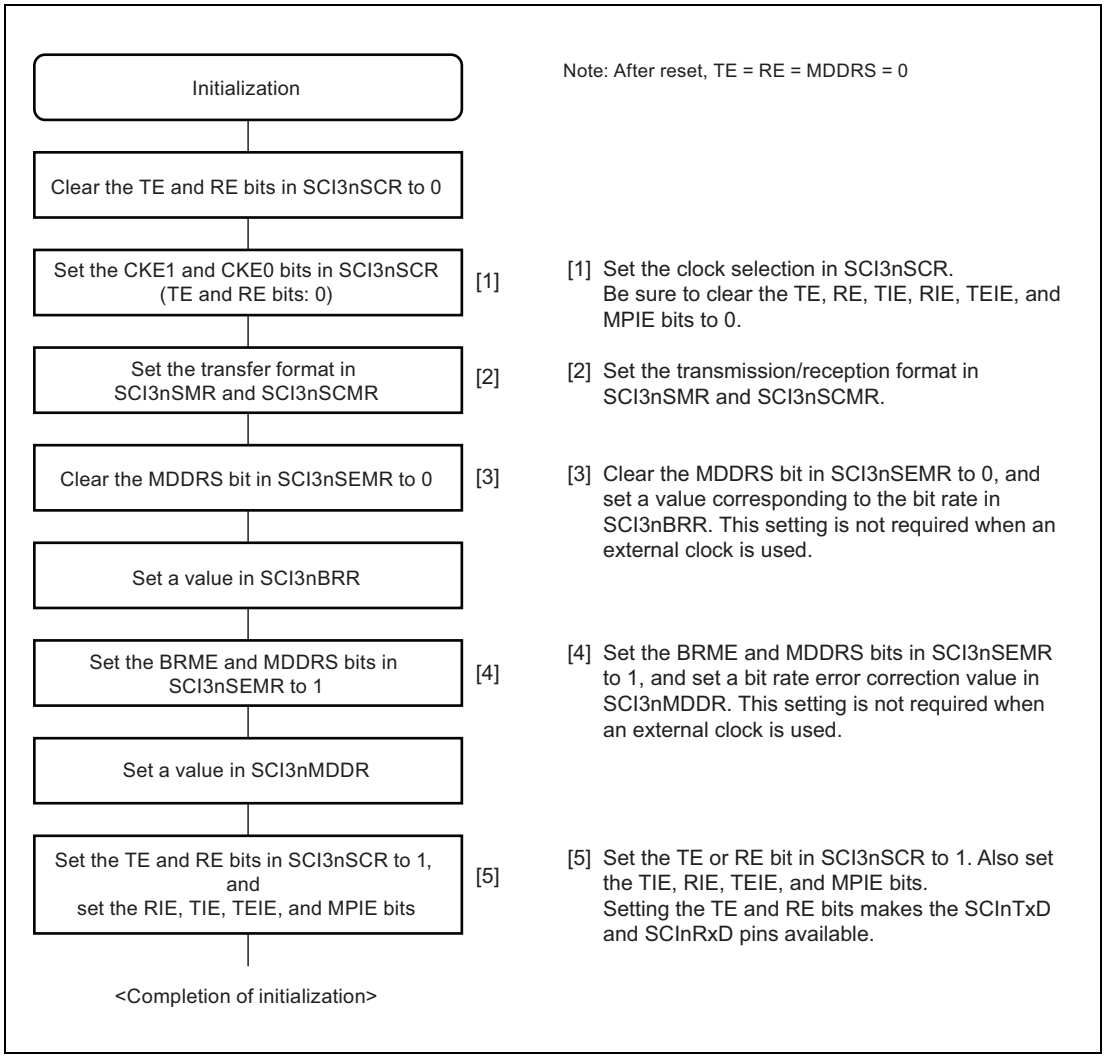


Figure 20.19 Example of SCI3 Initialization Flowchart

20.4.3.3 Serial Data Transmission (Clock Synchronous Mode)

Figure 20.20 shows an example of the operation for serial transmission in clock synchronous mode. In serial data transmission, the SCI3 operates as described below.

1. When transmit data is written to SCI3nTDR, the TDRE flag is automatically cleared to 0. The SCI3 monitors the TDRE flag in SCI3nSSR. When the flag is cleared, the SCI3 recognizes that data has been written to SCI3nTDR and transfers data from SCI3nTDR to SCI3nTSR, starting output of the first bit when the synchronization clock is input. To write transmit data to SCI3nTDR at a trigger of INTSCI3nTXI interrupt request, set the TIE bit to 1 and then set the TE bit to 1 or set both TIE and TE bits simultaneously with one instruction to generate a INTSCI3nTXI interrupt request for starting data transfer.
2. Transmission starts after data is transferred from SCI3nTDR to SCI3nTSR, and the TDRE flag is set to 1. When the TIE bit in SCI3nSCR is set to 1 at this time, a INTSCI3nTXI interrupt request is generated. Continuous transmission is enabled by writing the next transmit data to SCI3nTDR in this INTSCI3nTXI interrupt processing routine before the transmission of the previously transferred data is completed. When a INTSCI3nTEI interrupt request is used, the TIE bit is cleared to 0 after the last transmit data has been written to SCI3nTDR, and the TEIE bit is set to 1.
3. 8-bit or 16-bit data is output from the SCInTxD pin in synchronization with the output clock (when clock output mode has been specified) or in synchronization with the input clock (when external clock has been specified).
4. The SCI3 checks the TDRE flag when the last bit is output.
5. When the TDRE flag is 0, the next transmit data is transferred from SCI3nTDR to SCI3nTSR, and serial transmission of the next frame starts.
6. When the TDRE flag is 1, the TEND flag in SCI3nSSR is set to 1 and the SCInTxD pin retains the output state of the last bit. If the TEIE bit in SCI3nSCR is set to 1 at this time, a INTSCI3nTEI interrupt request is generated. The SCInSCK pin is held high.

Figure 20.21 shows a sample flowchart of serial data transmission. Also, **Figure 20.22** shows a sample flowchart for stopping the SCI3 after data transmission. Transmission will not start even if the TDRE flag is cleared while a receive error flag (ORER) is set to 1. Be sure to clear the receive error flags to 0 before starting transmission. Note that clearing the RE bit to 0 does not clear the receive error flags.

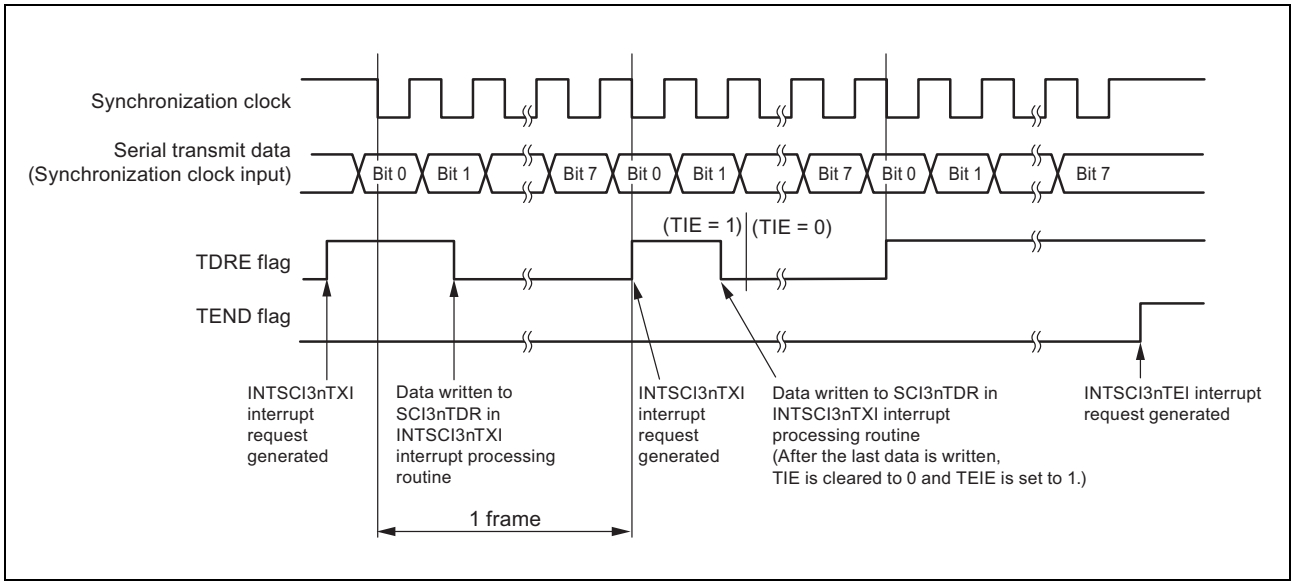

Figure 20.20 Example of Operation for Transmission in Clock Synchronous Mode

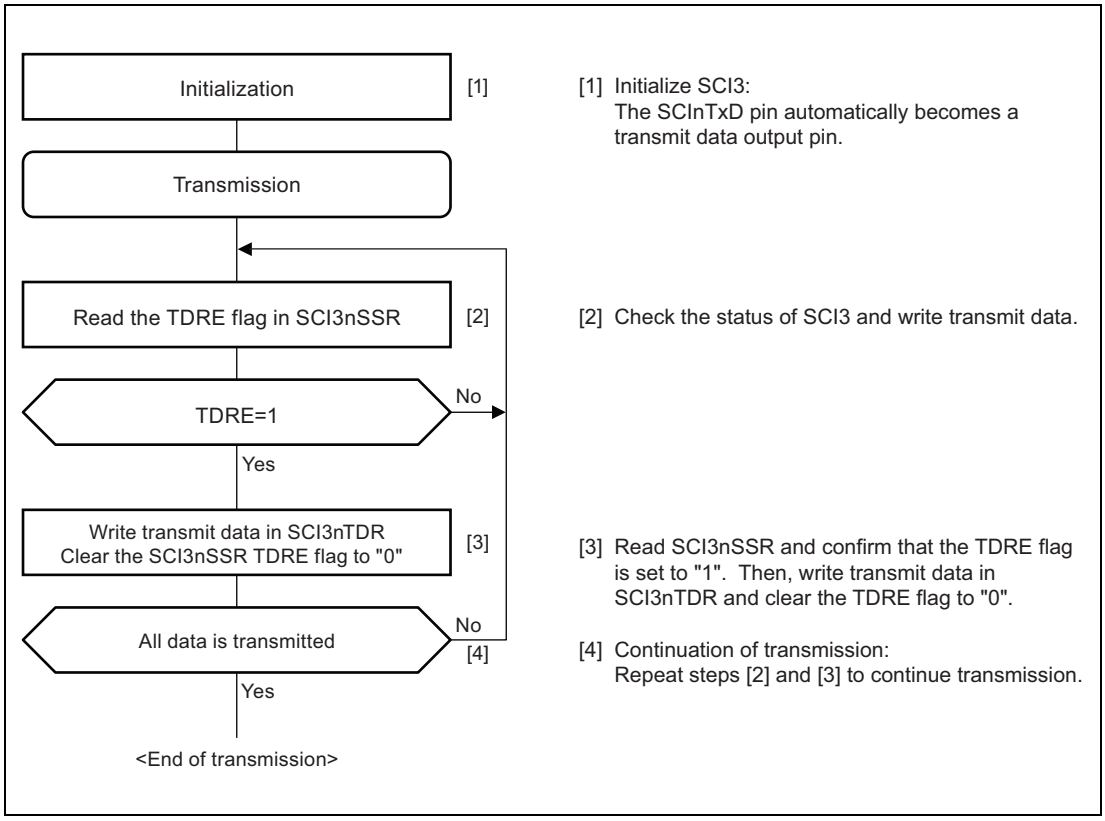

Figure 20.21 Example of Serial Transmission Flowchart

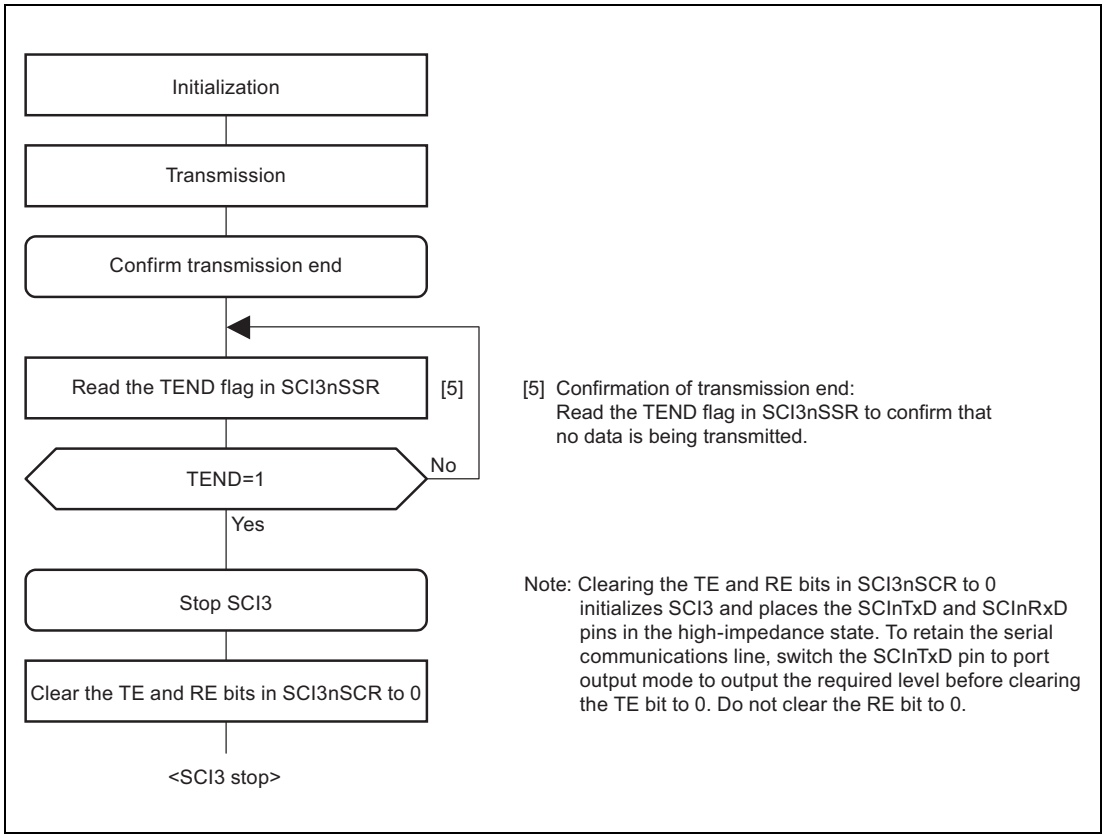

Figure 20.22 Example Flowchart for Stopping the SCI3 after Serial Transmission

20.4.3.4 Serial Data Reception (Clock Synchronous Mode)

Figure 20.23 shows an example of SCI3 operation for serial reception in clock synchronous mode. In serial data reception, the SCI3 operates as described below.

1. The SCI3 performs internal initialization and starts receiving data in synchronization with a synchronization clock input or output, and stores receive data in SCI3nRSR.
2. When an overrun error occurs (the reception of the next data is completed with the RDRF flag in SCI3nSSR set to 1), the ORER flag in SCI3nSSR is set to 1. If the RIE bit in SCI3nSCR is set to 1 at this time, an INTSCI3nERI interrupt request is generated. Receive data is not transferred to SCI3nRDR. The RDRF flag retains the state of being set to 1.
3. When data has been successfully received, the RDRF flag in SCI3nSSR is set to 1 and the receive data is transferred to SCI3nRDR. When the RIE bit in SCI3nSCR is set to 1 at this time, an INTSCI3nRXI interrupt request is generated. Continuous reception is enabled by reading the receive data transferred to SCI3nRDR in this INTSCI3nRXI interrupt processing routine before reception of the next data is completed. Reading SCI3nRDR automatically clears the RDRF flag to 0.

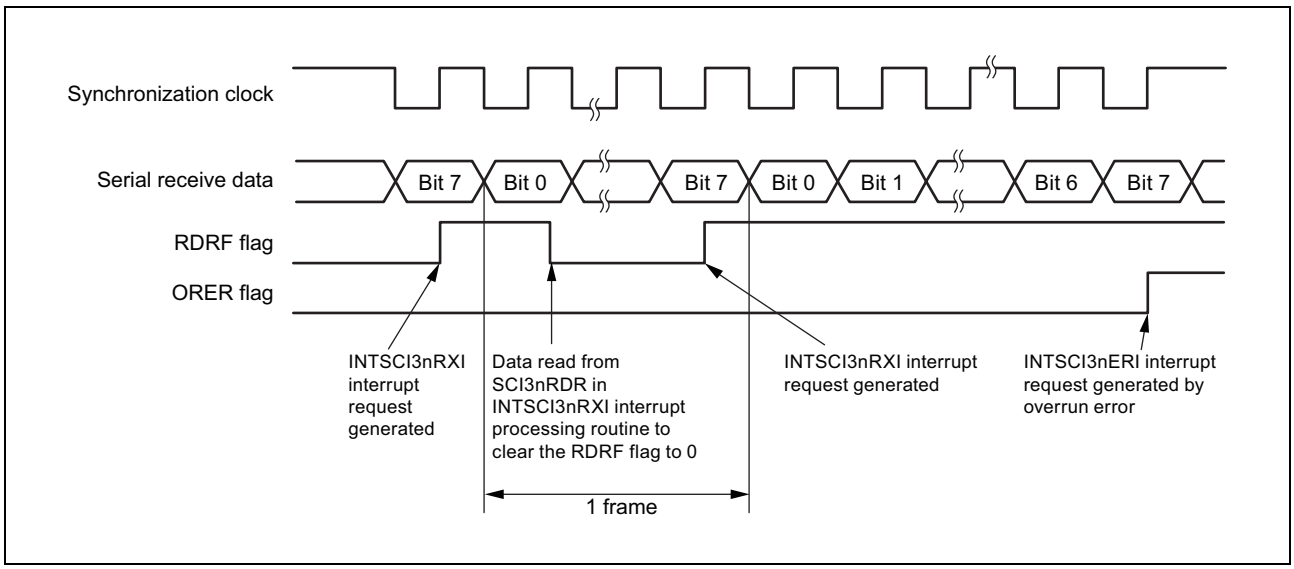

Figure 20.23 Example of SCI3 Operation for Reception

Subsequent transmission and reception are disabled with a receive error flag set to 1. Therefore, be sure to clear the ORER, FER, PER, and RDRF flags to 0 before continuing reception. **Figure 20.24** shows an example of flowchart for data reception.

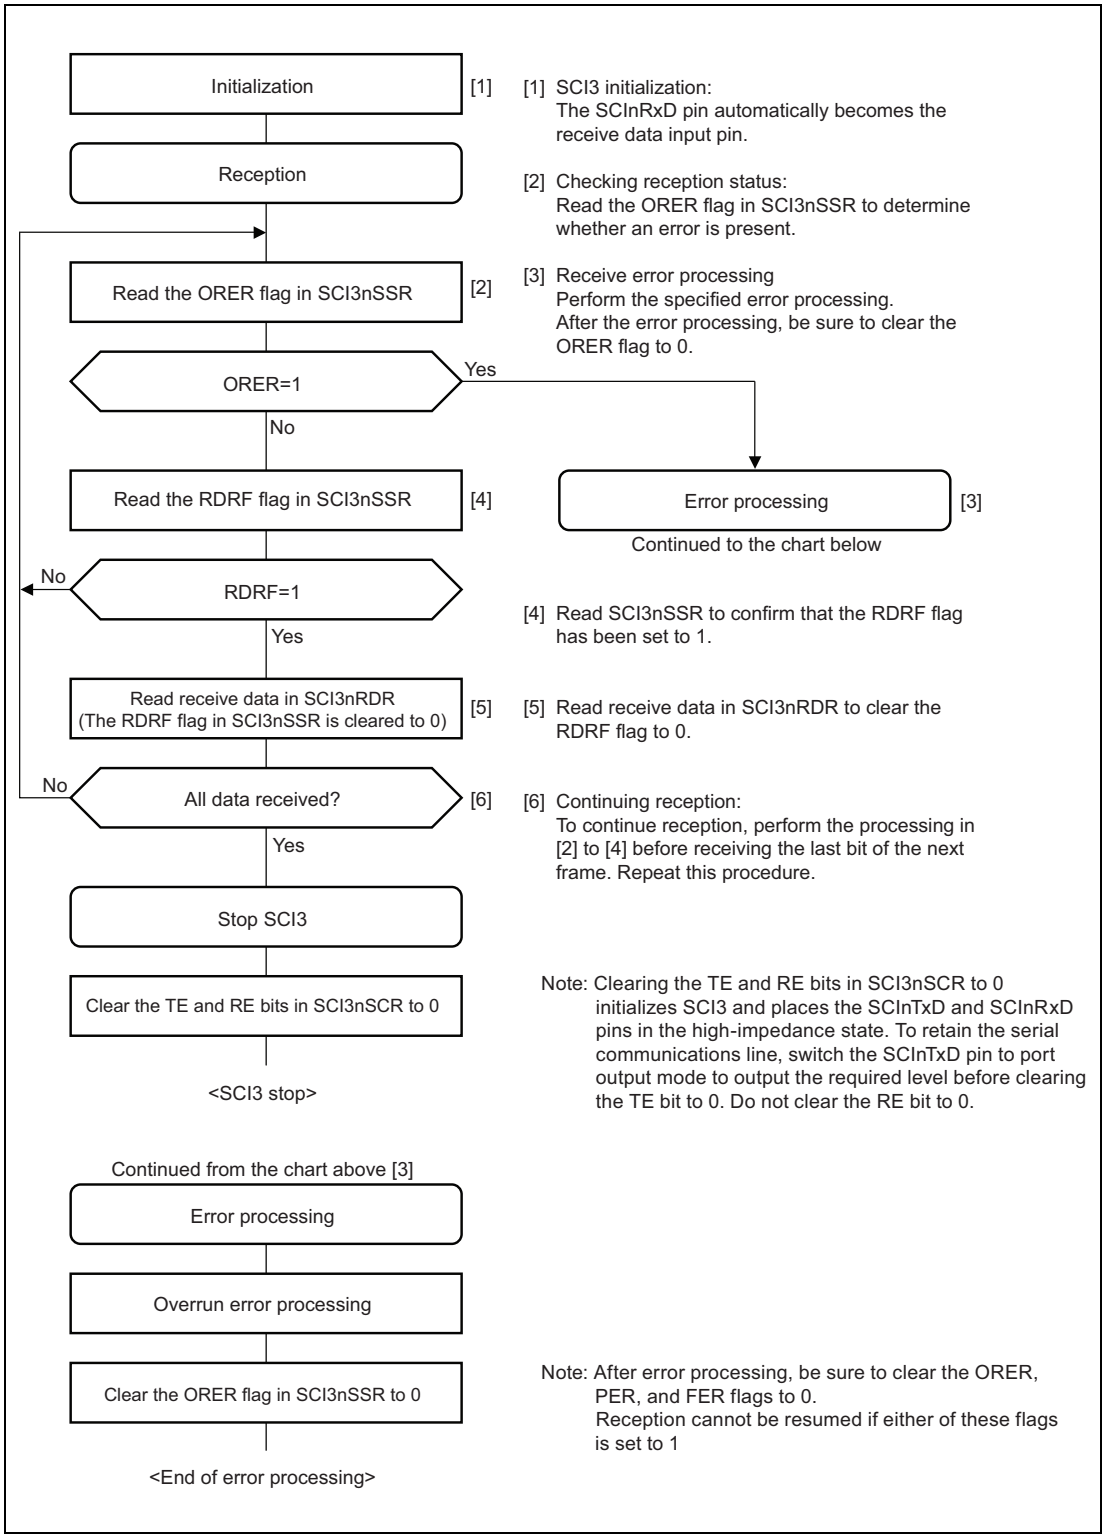

Figure 20.24 Example of Serial Reception Flowchart

20.4.3.5 Simultaneous Serial Data Transmission and Reception (Clock Synchronous Mode)

Figure 20.25 shows a sample flowchart for simultaneous data transmit and receive operations. After the SCI3 is initialized, perform the following procedure for simultaneous data transmit and receive operations.

1. To switch from transmit mode to simultaneous transmit and receive mode, check that the SCI3 has finished transmission and the TDRE and TEND flags are set to 1. Then clear the TE bit to 0 and then set the TE and RE bits to 1 with a single instruction.
2. To switch from receive mode to simultaneous transmit and receive mode, check that the SCI3 has finished reception and clear the RE bit to 0. Then check that the RDRF and error flags (ORER, FER, and PER) are cleared to 0 and then set the TE and RE bits to 1 with a single instruction.

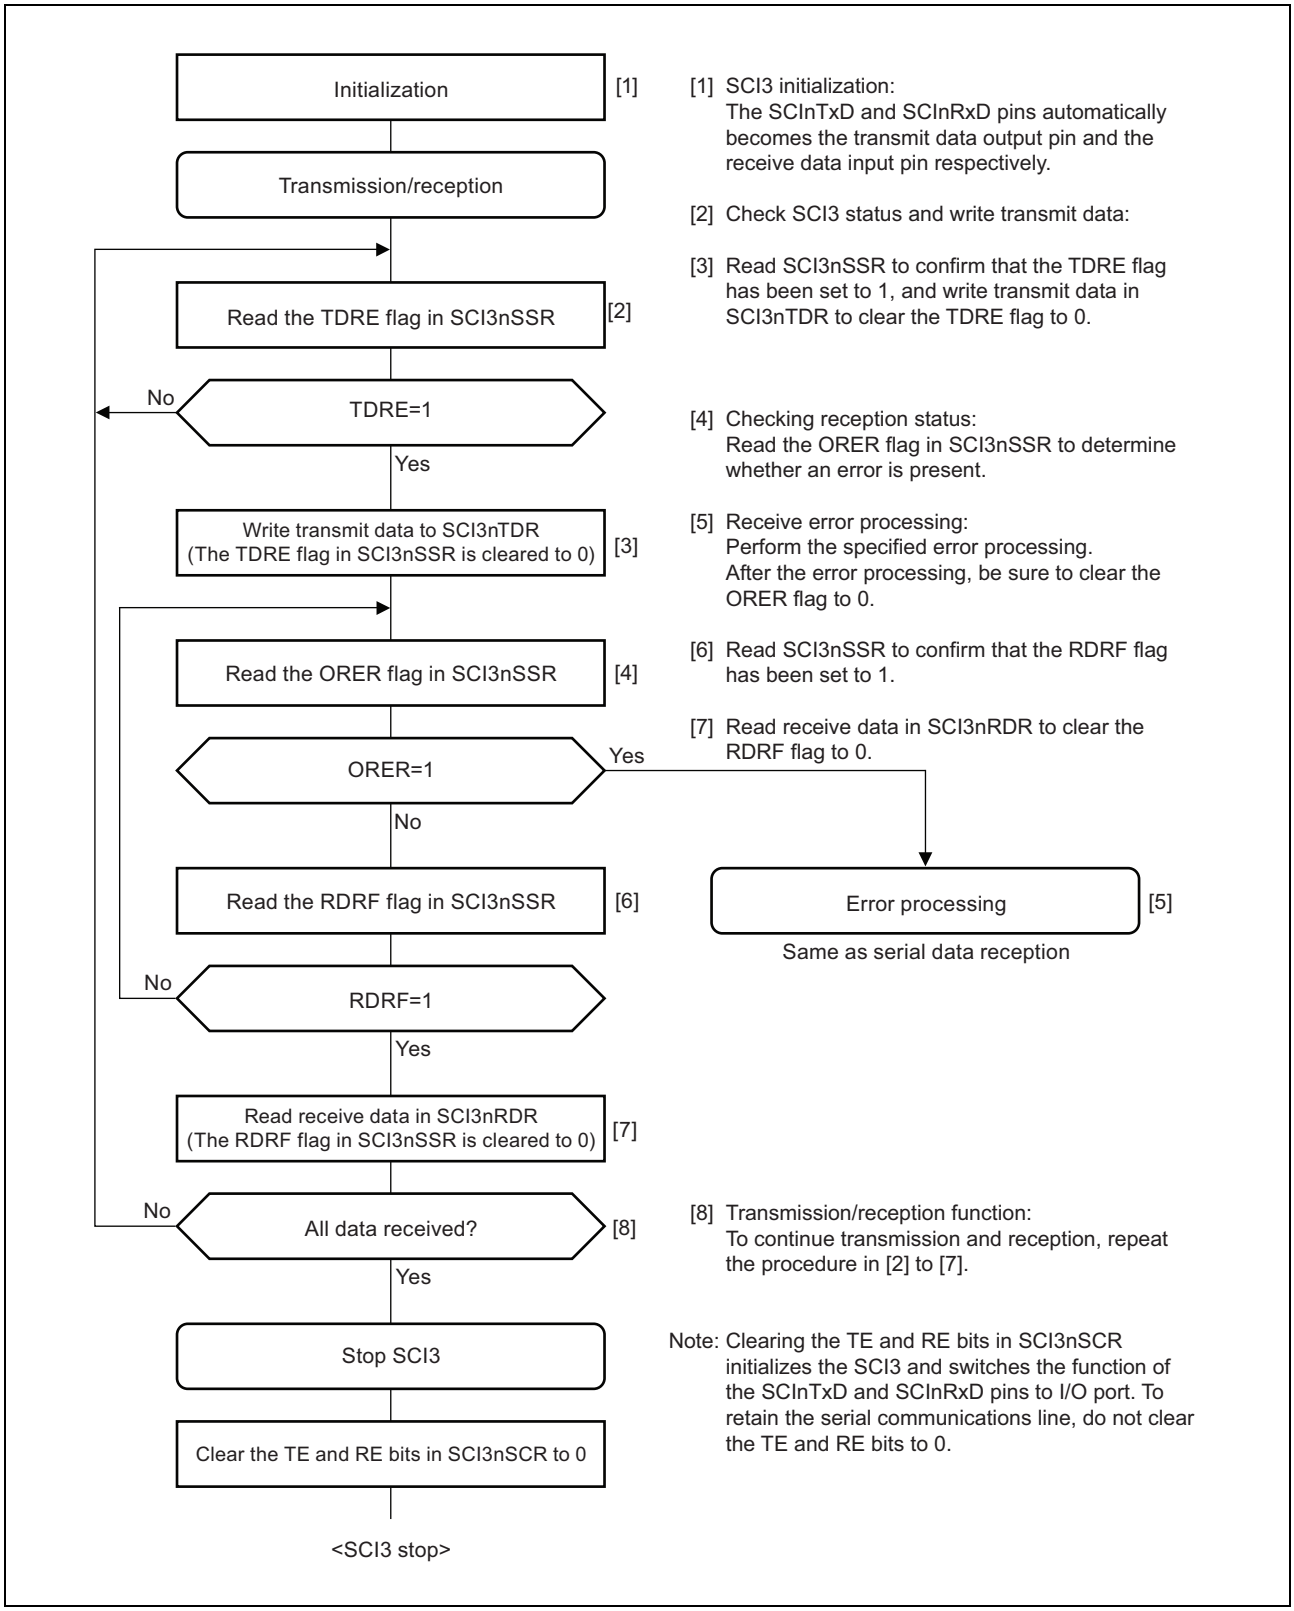

Figure 20.25 Example of Simultaneous Serial Transmission and Reception Flowchart

20.4.4 Bit Rate Modulation Function

The bit rate modulation function corrects a bit rate by averagely enabling the internal clocks specified by the CKS1 and CKS0 bits in SCI3nSMR for the number specified by SCI3nMDDR out of 256 clocks.

Figure 20.26 shows an example of asynchronous mode in which PCLK clock is selected with the CKS1 and CKS0 bits, SCI3nBRR is set to 0, and SCI3nMDDR is set to 160. In this example, the reference clock cycle is corrected to 256/160 on average and the bit rate is corrected to 160/256. Note that the pulse widths of the internal reference clock expand or contract for the amount of the selected internal clocks because there is a deviation in the enabling of the internal clocks.

Do not use this function with the maximum speed settings (CKS1 and CKS0 bits = 0 in SCI3nSMR, CKE1 bit = 0 in SCI3nSCR, and SCI3nBRR = 0) for clock synchronous mode.

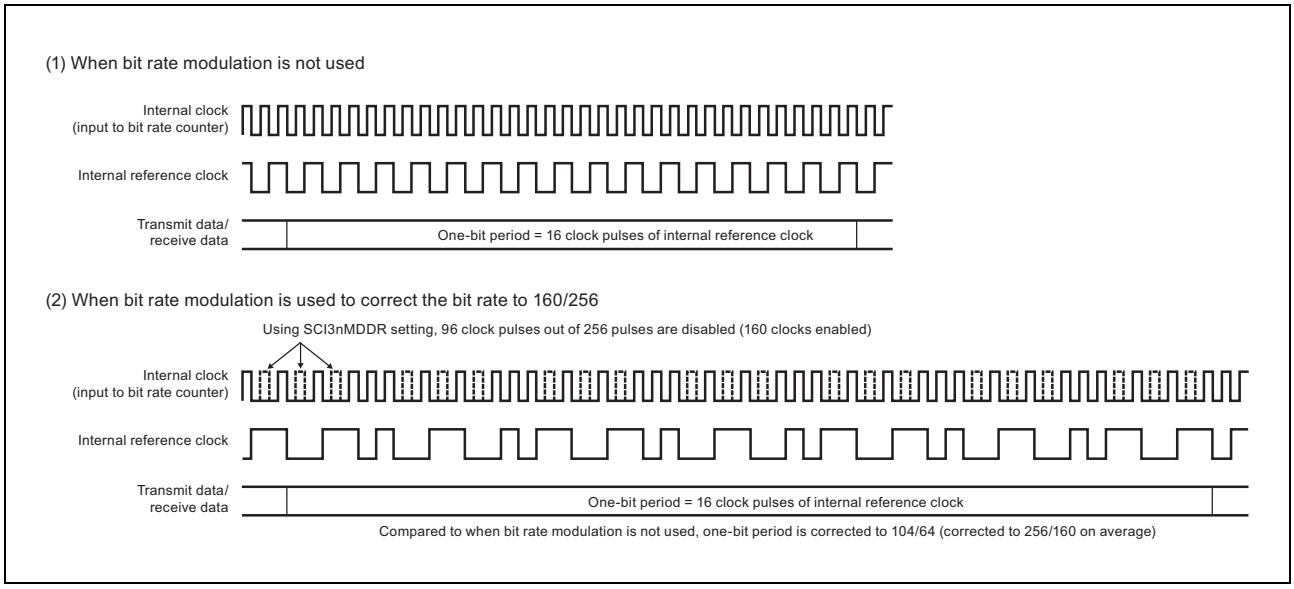

Figure 20.26 Example of Internal Reference Clock when the Bit Rate Modulation Function is Used

20.4.5 Interrupt Sources

20.4.5.1 The Normal Mode of SCI

Table 20.26 lists interrupt sources. Each interrupt source outputs an individual interrupt request signal. These interrupt sources can be enabled independently with the enable bit in SCI3nSCR.

An INTSCI3nTXI interrupt request is generated when the TDRE flag in SCI3nSSR is set to 1. An INTSCI3nTEI interrupt request is generated when the TEND flag in SCI3nSSR is set to 1. An INTSCI3nTXI interrupt request can activate the DMAC to handle data transfer. The TDRE flag is automatically cleared to 0 when data is transferred using the DMAC.

CAUTION

The TDRE flag and the TEND flag cannot be cleared to 0 when the TE bit in SCI3nSCR is 0. Since the TEND flag is the level interrupt request flag of the TEI interrupt, do not set the TEIE bit of SCI3nSCR to 1 when the TE bit is 0.

An INTSCI3nRXI interrupt request is generated when the RDRF flag in SCI3nSSR is set to 1. An INTSCI3nERI interrupt is generated when any of the ORER, PER, and FER flags in SCI3nSSR is set to 1. An INTSCI3nRXI interrupt request can activate the DMAC to handle data transfer. The RDRF flag is automatically cleared to 0 when data is transferred using the DMAC.

A INTSCI3nTEI interrupt request is generated when the TEND flag is set to 1 with the TEIE bit set to 1.

CAUTION

If an INTSCI3nTEI interrupt request and an INTSCI3nTXI interrupt request are generated at the same time, the INTSCI3nTXI interrupt request is accepted first. Note that clearing the TDRE flag to 0 at this time in the INTSCI3nTXI interrupt processing routine also clears the TEND flag to 0 automatically, disabling the branch to the INTSCI3nTEI interrupt processing routine.

Table 20.26 SCI3 Interrupt Sources

Name	Interrupt Source	Interrupt Flag	DMAC Activation	DTS Activation
INTSCI3nERI	Receive error	ORER, FER, PER	Not possible	Not possible
INTSCI3nRXI	Receive data full	RDRF	Possible	Possible
INTSCI3nTXI	Transmit data empty	TDRE	Possible	Possible
INTSCI3nTEI	Transmit end	TEND	Not possible	Not possible

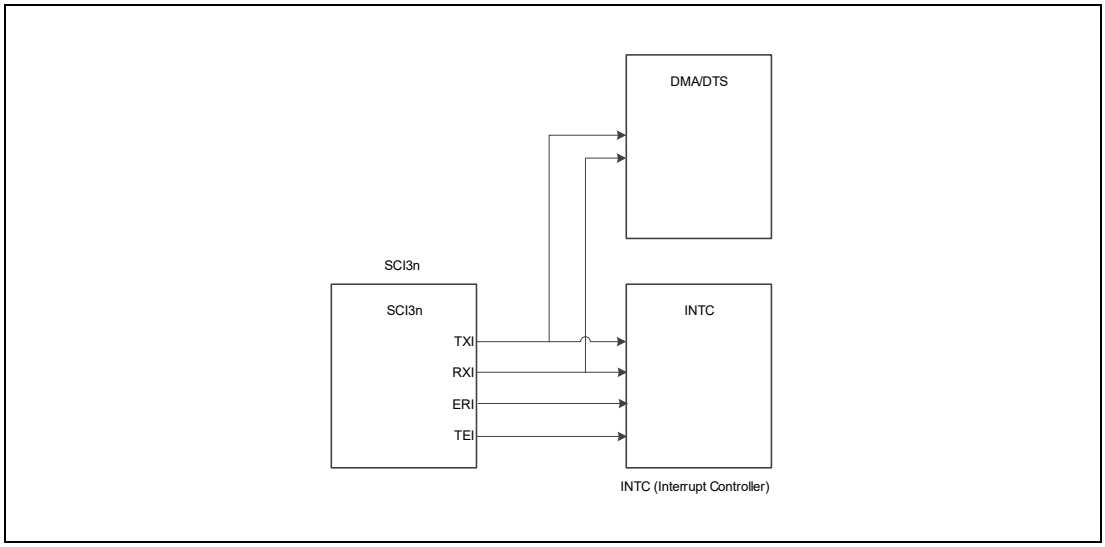

Figure 20.27 Relationship between the SCI3 Interrupt Signals, Interrupt Controller (INTC) and DMA/DTS

20.5 Notes on Use

20.5.1 Break Detection and Processing

A break can be detected by reading the RXDMON bit in SCI3nSEMR when detecting a framing error. Since all inputs from the SCInRxD pin are 0 in the break state, the FER flag is set to 1 and the PER flag may also be set to 1. When ASTLS bit in SCI3nSCMR is set to 1, the SCI3 continues data reception even after it receives a break. For this reason, note that the FER flag is set to 1 again even after the FER flag is cleared to 0. After the break is completed, hold the SCInRxD pin input High level for at least one frame period to avoid bit shift between the transmitter and receiver. On the other hand, when the ASTLS bit in SCI3nSCMR is 0, the FER flag is set to 1 and then the reception operation is stopped in the state of waiting for the start bit detection of the next frame. At this time, if the FER flag is cleared to 0, the FER flag is held at 0 during break. After the input from the SCInRxD pin becomes 1 and the break is completed, the start of the start bit is detected at the first trailing edge of the SCInRxD pin input, and reception operation is started.

20.5.2 Mark State and Break Output

While the TE bit is 0 (transmission/reception disabled), the SCInTxD pin can output any level by switching the SCInTxD pin to a general output port. This allows the SCInTxD pin to enter the mark state or to output a break during data transmission. When the TE bit is cleared to 0, the transmitter unit is initialized regardless of the current transmission state.

20.5.3 Receive Error Flags and Transmit Operations in Clock Synchronous Mode

During the clock synchronous simultaneous data transmit/receive operation, transmission cannot be started when a receive error flag (ORER) is set to 1, even if the TDRE flag is cleared to 0. Be sure to clear the receive error flags to 0 before starting transmission. Note that the receive error flags cannot be cleared to 0 even by clearing the RE bit to 0.

20.5.4 Relationship between Writing to SCI3nTDR and the TDRE Flag

The TDRE flag in SCI3nSSR is a status flag indicating that transmit data in SCI3nTDR has been transferred to SCI3nTSR. The TDRE flag is set to 1 when the SCI3 transfers data from SCI3nTDR to SCI3nTSR.

Data can be written to SCI3nTDR regardless of the status of the TDRE flag. However, writing new data to SCI3nTDR while the TDRE flag is 0 will cause the data stored in SCI3nTDR to be lost because it has not been transferred to SCI3nTSR. Therefore, make sure to check that the TDRE flag is set to 1 before writing transmit data to SCI3nTDR.

20.5.5 Restrictions on Using an External Clock for Transmission in Clock Synchronous Mode

When using an external synchronization clock, clear the TDRE flag to 0 and then input a transmission clock (See **Figure 20.28**). Also in continuous transmission mode, clear the TDRE flag to 0 and then input a transmission clock for the next frame.

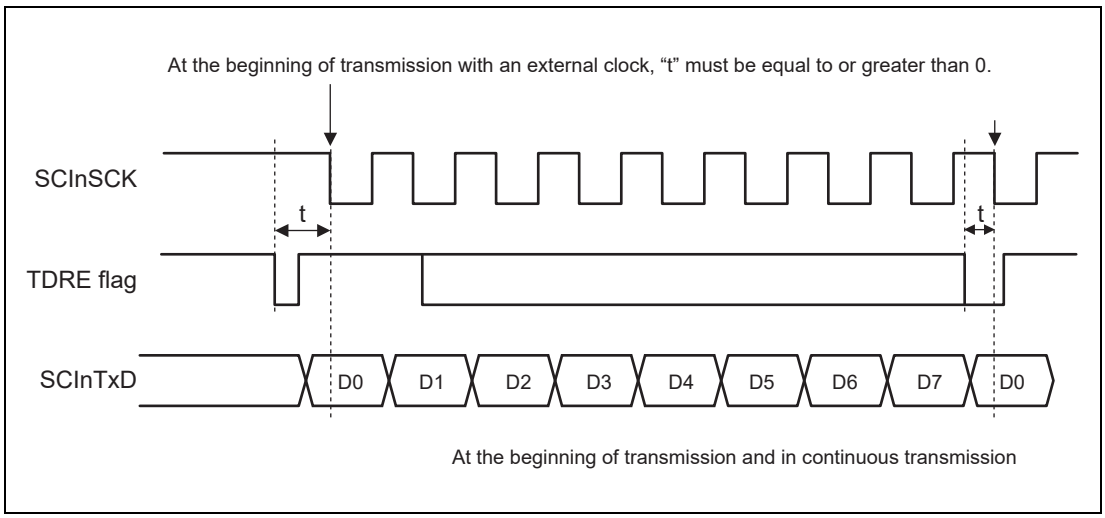

Figure 20.28 Restrictions on Using an External Clock for Transmission in Clock Synchronous Mode

20.5.6 External Clock Input in Clock Synchronous Mode

For the external clock SCInSCK input in clock synchronous mode, see **Section 55.3.11, SCI3 Timing**.

Section 21 LIN/UART Interface (RLIN3)

This section contains a generic description of the LIN/UART interface (RLIN3).

The first part of this section describes all RH850/U2A-EVA specific properties, such as the number of units, register base addresses, etc. The remainder of the section describes the functions and registers of RLIN3.

21.1 Features RLIN3 for RH850/U2A-EVA

21.1.1 Number of Units and Channels

This microcontroller has the following number of RLIN3 units.

Each RLIN3 unit has a single channel interface. “Number of channels” therefore has the same meaning as “number of units” in this section.

Table 21.1 Number of Units

Product Name	RH850/ U2A-EVA (516 pins)	RH850/ U2A16 (516 pins)	RH850/ U2A16 (373 pins)	RH850/ U2A16 (292 pins)	RH850/ U2A8 (373 pins)	RH850/ U2A8 (292 pins)	RH850/ U2A6 (292 pins)	RH850/ U2A6 (176 pins)	RH850/ U2A6 (156 pins)	RH850/ U2A6 (144 pins)
Number of Units	24 (n = 0 to 23)	24 (n = 0 to 23)	24 (n = 0 to 23)	12 (n = 0 to 11)	24 (n = 0 to 23)	12 (n = 0 to 11)	12 (n = 0 to 11)	12 (n = 0 to 11)	8 (n = 0, 3 to 5, 8 to 11)	10 (n = 0, 2 to 5, 7 to 11)
Name	RLIN3n

Note: The channel names are same as those of the corresponding units.

Table 21.3 Indices

Index	Description
n	Throughout this section, the individual RLIN3 units are identified by the index “n” (n = 0 to 23); for example, RLN3nLCUC is the LIN control register.
b	Throughout this section, the individual transmit/receive data buffers of RLIN3n are identified by the index “b” (b = 1 to 8); for example, RLN3nLDBRb is the data buffer register.

The following lists the index value corresponding to each product.

Table 21.4 Index Correspondence of Each Product

Index Corresponding to Product
All products
b = 1 to 8

21.1.2 Register Base Addresses

RLIN3 base addresses are listed in the following table.

RLIN3 register addresses are given as offsets from the base addresses.

Table 21.5 Register Base Addresses

Base Address Name	Base Address	Bus Group
<RLIN30_base>	FFD2 8000$_H$	P-Bus Group 3
<RLIN31_base>	FFC7 C000$_H$	P-Bus Group 5
<RLIN32_base>	FFD2 8200$_H$	P-Bus Group 3
<RLIN33_base>	FFC7 C080$_H$	P-Bus Group 5
<RLIN34_base>	FFD2 8400$_H$	P-Bus Group 3
<RLIN35_base>	FFC7 C100$_H$	P-Bus Group 5
<RLIN36_base>	FFD2 8600$_H$	P-Bus Group 3
<RLIN37_base>	FFC7 C180$_H$	P-Bus Group 5
<RLIN38_base>	FFD2 8800$_H$	P-Bus Group 3
<RLIN39_base>	FFC7 C200$_H$	P-Bus Group 5
<RLIN310_base>	FFD2 8A00$_H$	P-Bus Group 3
<RLIN311_base>	FFC7 C280$_H$	P-Bus Group 5
<RLIN312_base>	FFD2 8C00$_H$	P-Bus Group 3
<RLIN313_base>	FFC7 C300$_H$	P-Bus Group 5
<RLIN314_base>	FFD2 8E00$_H$	P-Bus Group 3
<RLIN315_base>	FFC7 C380$_H$	P-Bus Group 5
<RLIN316_base>	FFD2 9000$_H$	P-Bus Group 3
<RLIN317_base>	FFC7 C400$_H$	P-Bus Group 5
<RLIN318_base>	FFD2 9200$_H$	P-Bus Group 3
<RLIN319_base>	FFC7 C480$_H$	P-Bus Group 5
<RLIN320_base>	FFD2 9400$_H$	P-Bus Group 3
<RLIN321_base>	FFC7 C500$_H$	P-Bus Group 5
<RLIN322_base>	FFD2 9600$_H$	P-Bus Group 3
<RLIN323_base>	FFC7 C580$_H$	P-Bus Group 5

21.1.3 Clock Supply

The RLIN3 clock supply is shown in the following table.

Table 21.6 Clock Supply

Unit Name	Unit Clock Name	Supply Clock Name
RLIN3n	LIN communication clock sources	CLK_RLIN
	Register access clock	CLK_HSB

21.1.4 Interrupt Requests and Error Notifications

RLIN3 interrupt requests are listed in the following table.

Table 21.7 Interrupt and DMA/DTS Requests (1/3)

Unit Interrupt Signal	Description	Interrupt Number	DMA Trigger Number	DTS Trigger Number	Wake up
RLIN30					
INTRLIN3n (n = 0)	RLIN30 interrupt	416	—	—	√
INTRLIN3nUR0 (n = 0)	RLIN30 transmit interrupt	417	Group0-61	Group0-50	—
INTRLIN3nUR1 (n = 0)	RLIN30 receive completion interrupt	418	Group0-62	Group0-51	—
INTRLIN3nUR2 (n = 0)	RLIN30 status interrupt	419	—	—	—
RLIN31					
INTRLIN3n (n = 1)	RLIN31 interrupt	420	—	—	√
INTRLIN3nUR0 (n = 1)	RLIN31 transmit interrupt	421	Group0-63	Group0-52	—
INTRLIN3nUR1 (n = 1)	RLIN31 receive completion interrupt	422	Group0-64	Group0-53	—
INTRLIN3nUR2 (n = 1)	RLIN31 status interrupt	423	—	—	—
RLIN32					
INTRLIN3n (n = 2)	RLIN32 interrupt	424	—	—	√
INTRLIN3nUR0 (n = 2)	RLIN32 transmit interrupt	425	Group0-65	Group0-54	—
INTRLIN3nUR1 (n = 2)	RLIN32 receive completion interrupt	426	Group0-66	Group0-55	—
INTRLIN3nUR2 (n = 2)	RLIN32 status interrupt	427	—	—	—
RLIN33					
INTRLIN3n (n = 3)	RLIN33 interrupt	428	—	—	√
INTRLIN3nUR0 (n = 3)	RLIN33 transmit interrupt	429	Group0-67	Group0-56	—
INTRLIN3nUR1 (n = 3)	RLIN33 receive completion interrupt	430	Group0-68	Group0-57	—
INTRLIN3nUR2 (n = 3)	RLIN33 status interrupt	431	—	—	—
RLIN34					
INTRLIN3n (n = 4)	RLIN34 interrupt	432	—	—	√
INTRLIN3nUR0 (n = 4)	RLIN34 transmit interrupt	433	Group0-69	Group0-58	—
INTRLIN3nUR1 (n = 4)	RLIN34 receive completion interrupt	434	Group0-70	Group0-59	—
INTRLIN3nUR2 (n = 4)	RLIN34 status interrupt	435	—	—	—
RLIN35					
INTRLIN3n (n = 5)	RLIN35 interrupt	436	—	—	√
INTRLIN3nUR0 (n = 5)	RLIN35 transmit interrupt	437	Group0-71	Group0-60	—
INTRLIN3nUR1 (n = 5)	RLIN35 receive completion interrupt	438	Group0-72	Group0-61	—
INTRLIN3nUR2 (n = 5)	RLIN35 status interrupt	439	—	—	—
RLIN36					
INTRLIN3n (n = 6)	RLIN36 interrupt	440	—	—	√
INTRLIN3nUR0 (n = 6)	RLIN36 transmit interrupt	441	Group0-73	Group0-62	—
INTRLIN3nUR1 (n = 6)	RLIN36 receive completion interrupt	442	Group0-74	Group0-63	—
INTRLIN3nUR2 (n = 6)	RLIN36 status interrupt	443	—	—	—
RLIN37					
INTRLIN3n (n = 7)	RLIN37 interrupt	444	—	—	√
INTRLIN3nUR0 (n = 7)	RLIN37 transmit interrupt	445	Group0-75	Group0-64	—
INTRLIN3nUR1 (n = 7)	RLIN37 receive completion interrupt	446	Group0-76	Group0-65	—
INTRLIN3nUR2 (n = 7)	RLIN37 status interrupt	447	—	—	—

Table 21.7 Interrupt and DMA/DTS Requests (2/3)

Unit Interrupt Signal	Description	Interrupt Number	DMA Trigger Number	DTS Trigger Number	Wake up
RLIN38					
INTRLIN3n (n = 8)	RLIN38 interrupt	448	—	—	√
INTRLIN3nUR0 (n = 8)	RLIN38 transmit interrupt	449	Group0-77	Group0-66	—
INTRLIN3nUR1 (n = 8)	RLIN38 receive completion interrupt	450	Group0-78	Group0-67	—
INTRLIN3nUR2 (n = 8)	RLIN38 status interrupt	451	—	—	—
RLIN39					
INTRLIN3n (n = 9)	RLIN39 interrupt	452	—	—	√
INTRLIN3nUR0 (n = 9)	RLIN39 transmit interrupt	453	Group0-79	Group0-68	—
INTRLIN3nUR1 (n = 9)	RLIN39 receive completion interrupt	454	Group0-80	Group0-69	—
INTRLIN3nUR2 (n = 9)	RLIN39 status interrupt	455	—	—	—
RLIN310					
INTRLIN3n (n = 10)	RLIN310 interrupt	456	—	—	√
INTRLIN3nUR0 (n = 10)	RLIN310 transmit interrupt	457	Group0-81	Group0-70	—
INTRLIN3nUR1 (n = 10)	RLIN310 receive completion interrupt	458	Group0-82	Group0-71	—
INTRLIN3nUR2 (n = 10)	RLIN310 status interrupt	459	—	—	—
RLIN311					
INTRLIN3n (n = 11)	RLIN311 interrupt	460	—	—	√
INTRLIN3nUR0 (n = 11)	RLIN311 transmit interrupt	461	Group0-83	Group0-72	—
INTRLIN3nUR1 (n = 11)	RLIN311 receive completion interrupt	462	Group0-84	Group0-73	—
INTRLIN3nUR2 (n = 11)	RLIN311 status interrupt	463	—	—	—
RLIN312					
INTRLIN3n (n = 12)	RLIN312 interrupt	464	—	—	√
INTRLIN3nUR0 (n = 12)	RLIN312 transmit interrupt	465	Group0-85	Group0-74	—
INTRLIN3nUR1 (n = 12)	RLIN312 receive completion interrupt	466	Group0-86	Group0-75	—
INTRLIN3nUR2 (n = 12)	RLIN312 status interrupt	467	—	—	—
RLIN313					
INTRLIN3n (n = 13)	RLIN313 interrupt	468	—	—	√
INTRLIN3nUR0 (n = 13)	RLIN313 transmit interrupt	469	Group0-87	Group0-76	—
INTRLIN3nUR1 (n = 13)	RLIN313 receive completion interrupt	470	Group0-88	Group0-77	—
INTRLIN3nUR2 (n = 13)	RLIN313 status interrupt	471	—	—	—
RLIN314					
INTRLIN3n (n = 14)	RLIN314 interrupt	472	—	—	√
INTRLIN3nUR0 (n = 14)	RLIN314 transmit interrupt	473	Group0-89	Group0-78	—
INTRLIN3nUR1 (n = 14)	RLIN314 receive completion interrupt	474	Group0-90	Group0-79	—
INTRLIN3nUR2 (n = 14)	RLIN314 status interrupt	475	—	—	—
RLIN315					
INTRLIN3n (n = 15)	RLIN315 interrupt	476	—	—	√
INTRLIN3nUR0 (n = 15)	RLIN315 transmit interrupt	477	Group0-91	Group0-80	—
INTRLIN3nUR1 (n = 15)	RLIN315 receive completion interrupt	478	Group0-92	Group0-81	—
INTRLIN3nUR2 (n = 15)	RLIN315 status interrupt	479	—	—	—
RLIN316					
INTRLIN3n (n = 16)	RLIN316 interrupt	480	—	—	√
INTRLIN3nUR0 (n = 16)	RLIN316 transmit interrupt	481	Group0-93	Group0-82	—

Table 21.7 Interrupt and DMA/DTS Requests (3/3)

Unit Interrupt Signal	Description	Interrupt Number	DMA Trigger Number	DTS Trigger Number	Wake up
INTRLIN3nUR1 (n = 16)	RLIN316 receive completion interrupt	482	Group0-94	Group0-83	—
INTRLIN3nUR2 (n = 16)	RLIN316 status interrupt	483	—	—	—
RLIN317					
INTRLIN3n (n = 17)	RLIN317 interrupt	484	—	—	√
INTRLIN3nUR0 (n = 17)	RLIN317 transmit interrupt	485	Group0-95	Group0-84	—
INTRLIN3nUR1 (n = 17)	RLIN317 receive completion interrupt	486	Group0-96	Group0-85	—
INTRLIN3nUR2 (n = 17)	RLIN317 status interrupt	487	—	—	—
RLIN318					
INTRLIN3n (n = 18)	RLIN318 interrupt	488	—	—	√
INTRLIN3nUR0 (n = 18)	RLIN318 transmit interrupt	489	Group0-97	Group0-86	—
INTRLIN3nUR1 (n = 18)	RLIN318 receive completion interrupt	490	Group0-98	Group0-87	—
INTRLIN3nUR2 (n = 18)	RLIN318 status interrupt	491	—	—	—
RLIN319					
INTRLIN3n (n = 19)	RLIN319 interrupt	492	—	—	√
INTRLIN3nUR0 (n = 19)	RLIN319 transmit interrupt	493	Group0-99	Group0-88	—
INTRLIN3nUR1 (n = 19)	RLIN319 receive completion interrupt	494	Group0-100	Group0-89	—
INTRLIN3nUR2 (n = 19)	RLIN319 status interrupt	495	—	—	—
RLIN320					
INTRLIN3n (n = 20)	RLIN320 interrupt	496	—	—	√
INTRLIN3nUR0 (n = 20)	RLIN320 transmit interrupt	497	Group0-101	Group0-90	—
INTRLIN3nUR1 (n = 20)	RLIN320 receive completion interrupt	498	Group0-102	Group0-91	—
INTRLIN3nUR2 (n = 20)	RLIN320 status interrupt	499	—	—	—
RLIN321					
INTRLIN3n (n = 21)	RLIN321 interrupt	500	—	—	√
INTRLIN3nUR0 (n = 21)	RLIN321 transmit interrupt	501	Group0-103	Group0-92	—
INTRLIN3nUR1 (n = 21)	RLIN321 receive completion interrupt	502	Group0-104	Group0-93	—
INTRLIN3nUR2 (n = 21)	RLIN321 status interrupt	503	—	—	—
RLIN322					
INTRLIN3n (n = 22)	RLIN322 interrupt	504	—	—	√
INTRLIN3nUR0 (n = 22)	RLIN322 transmit interrupt	505	Group0-105	Group0-94	—
INTRLIN3nUR1 (n = 22)	RLIN322 receive completion interrupt	506	Group0-106	Group0-95	—
INTRLIN3nUR2 (n = 22)	RLIN322 status interrupt	507	—	—	—
RLIN323					
INTRLIN3n (n = 23)	RLIN323 interrupt	508	—	—	√
INTRLIN3nUR0 (n = 23)	RLIN323 transmit interrupt	509	Group0-107	Group0-96	—
INTRLIN3nUR1 (n = 23)	RLIN323 receive completion interrupt	510	Group0-108	Group0-97	—
INTRLIN3nUR2 (n = 23)	RLIN323 status interrupt	511	—	—	—

This module has no error notifications.

21.1.5 Reset Sources

RLIN3 reset sources are listed in the following table. RLIN3 is initialized by these reset sources.

Table 21.8 Reset Sources

Unit Name	Register Name	Reset Condition						
		Power On Reset	System Reset 1	System Reset 2	Application Reset	DeepSTOP Reset	Module Reset	JTAG Reset
RLIN3n	All registers	√	√	√	√	√	√	—

21.1.6 External Input/output Signals

External input/output signals of RLIN3 are listed below.

Table 21.9 External Input/Output Signals

Unit Signal Name	Description	Alternative Port Pin Signal
RLIN3n		
RLIN3nRX (n = 0 to 23)	RLIN3n receive data input	RLIN3nRX
RLIN3nTX (n = 0 to 23)	RLIN3n transmit data output	RLIN3nTX

21.2 Overview

21.2.1 Functional Overview

The LIN/UART interface is a hardware LIN communication controller that supports LIN Specification Package Revision 1.3, 2.0, 2.1, 2.2, and SAE J2602, and automatically performs frame communication and error determination.

The LIN/UART interface is provided with UART mode and can also be used as a UART.

The appropriate mode should be used for the LIN/UART interface according to the application: LIN master, LIN slave, or UART.

LIN master

- LIN reset mode
- LIN mode (LIN master mode)
  - LIN wake-up mode
  - LIN operation mode
- LIN self-test mode

LIN slave

- LIN reset mode
- LIN mode (LIN slave mode [auto baud rate] or LIN slave mode [fixed baud rate])
  - LIN wake-up mode
  - LIN operation mode
- LIN self-test mode

UART

- LIN reset mode
- UART mode

Table 21.10 shows the LIN/UART interface specifications.

Table 21.10 LIN/UART Interface Specifications (1/3)

Item		Specifications	
	Channel count	Up to 24 channels	
LIN communication function	Protocol	LIN Specification Package Revision 1.3, 2.0, 2.1, 2.2, and SAE J2602	
	Variable frame structure	Master	• Break transmission width: 13 to 28 Tbits • Break delimiter transmission width: 1 to 4 Tbits • Transmission inter-byte space width (header): 0 to 7 Tbits (space between Sync field and ID field)*1 • Transmission response space width: 0 to 7 Tbits*1 • Transmission inter-byte space width: 0 to 3 Tbits (space between data bytes in response area) • Transmission wake-up width: 1 to 16 Tbits
		Slave	• Break reception width : 9.5 or 10.5 Tbits [for fixed baud rate] : 10 or 11 Tbits [for auto baud rate] • Transmission response space width: 0 to 7 Tbits • Transmission inter-byte space width: 0 to 3 Tbits (space between data bytes in response area) • Transmission wake-up width: 1 to 16 Tbits
	Checksum	• Automatic operation for both transmission and reception • Classic or enhanced selectable (for each frame)	
	Response field data byte count	Variable from 0 to 8 bytes Multi-byte (9 or more bytes) response transmission and reception also possible	
	Frame communication modes	Master	• Mode in which header transmission and response transmission/reception are started with a single transmission start request • Mode in which header transmission and response transmission are started with separate transmission start requests (frame separate mode)
		Slave	• Mode in which header is automatically received with fixed baud rate • Mode in which header is automatically received with the baud rate set according to the sync field measurement result of the sync field and break field detected
	Wake-up transmission and reception	LIN wake-up mode provided • Wake-up transmission (1 to 16 Tbits) • Wake-up reception Low-level width of input signals measured	
	Status	Master	• Successful frame/wake-up transmission • Successful header transmission • Successful frame/wake-up reception*2 • Successful data 1 reception • Error detection • Operation mode (LIN reset mode, LIN wake-up mode, LIN operation mode, LIN self-test mode)
		Slave	• Successful response/wake-up transmission • Successful response/wake-up reception*2 • Successful header reception • Break field reception • Sync field reception • Successful data 1 reception • Error detection • Operation mode (LIN reset mode, LIN wake-up mode, LIN operation mode, LIN self-test mode)

Table 21.10 LIN/UART Interface Specifications (2/3)

Item		Specifications	
LIN communication function	Error status	Master	• Bit error • Checksum error • Frame timeout error/response timeout error • Physical bus error • Framing error • Response preparation error
		Slave	• Bit error • Checksum error • Frame timeout error/response timeout error • Sync field error • ID parity error • Framing error • Response preparation error
	Baud rate selection	Baud rates conforming to the LIN specifications generated using baud rate generator	
	Test mode	Self-test mode for user evaluation	
	Interrupt function	Master	• Successful header/frame/wake-up transmission • Successful frame/wake-up reception*2 • Error detection
		Slave	• Successful response/wake-up transmission • Successful Header/response/wake-up reception*2 • Error detection
UART communication function	Data buffer	• Transmission data buffer/transmission data buffer for wait (exclusively for transmission; data length of 1. Character length of 7, 8, and 9 bits supported) • UART buffer (exclusively for transmission; variable data length from 1 to 9. Character length of 7 and 8 bits supported) • Reception data buffer (exclusively for reception; data length of 1. Character length of 7, 8, and 9 bits supported)	
	Data format	Character length: 7 or 8 bits Length of 9 bits supported by using the expansion bit.	
		Transmission stop bit: 1 or 2 bits	
		Parity function: odd, even, 0, or none	
		LSB- or MSB-first transfer selectable	
		Reverse input/output of transmission/reception data possible	
	Status	• Transmission status • Reception status • Successful UART buffer transmission • Error detection • Expansion bit detection • ID match • Reset mode status	
	Error status	• Bit error • Framing error • Parity error • Overrun error	
	Baud rate selection	With the built-in baud rate generator, any baud rate can be set.	
	When a certain expansion bit is at the expected level, the data received can be compared to the 8-bit data preset in the register.		

Table 21.10 LIN/UART Interface Specifications (3/3)

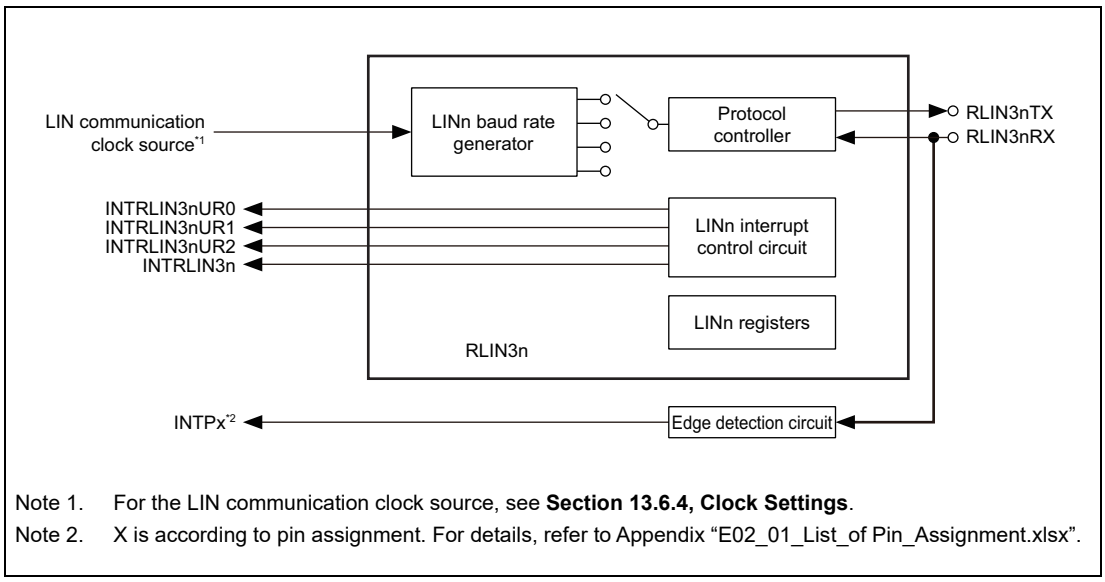
Item		Specifications
UART communication function	Reception of the stop bit is guaranteed (start of transmission can be delayed when start of transmission is attempted during reception of the stop bit).	
	Interrupt function	• Transmission start/complete • Reception complete • Status/error detection

Note 1. Since the same register is used for setting, the inter-byte space (header) = response space.

Note 2. For wake-up reception, the input signal low-level width count is indicated.

21.2.2 Block Diagram

Figure 21.1 shows a block diagram of the LIN/UART interface.



Note 1. For the LIN communication clock source, see **Section 13.6.4, Clock Settings**.
Note 2. X is according to pin assignment. For details, refer to Appendix “E02_01_List_of Pin_Assignment.xlsx”.

Figure 21.1 LIN/UART Interface Block Diagram

21.2.3 Terms used in block diagram

- RLIN3nTX, RLIN3nRX: LIN/UART interface I/O pins
- LINn baud rate generator: Generates the LIN/UART interface communication clock.
- LINn registers: LIN/UART interface registers
- LINn interrupt control circuit: Controls interrupt requests generated by the LIN/UART interface

21.3 Registers

21.3.1 List of Registers

RLIN3 registers are listed in the following table.

For details about <RLIN3n_base>, see **Section 21.1.2, Register Base Addresses**.

Table 21.11 List of Registers (1/2)

Module Name	Register Name	Symbol	Address	LIN Master	LIN Slave	UART	Access Protection	
							PBG	Other
RLN3n	LIN wake-up baud rate select register	RLN3nLWBR	<RLIN3n_base> + 01_H	√	√	√	*1	—
RLN3n	LIN / UART baud rate prescaler 01 register	RLN3nLBRP01	<RLIN3n_base> + 02_H	—	√	√	*1	—
RLN3n	LIN / UART baud rate prescaler 0 register	RLN3nLBRP0	<RLIN3n_base> + 02_H	√	√	√	*1	—
RLN3n	LIN / UART baud rate prescaler 1 register	RLN3nLBRP1	<RLIN3n_base> + 03_H	√	√	√	*1	—
RLN3n	LIN self-test control register	RLN3nLSTC	<RLIN3n_base> + 04_H	√	√	—	*1	—
RLN3n	LIN / UART mode register	RLN3nLMD	<RLIN3n_base> + 08_H	√	√	√	*1	—
RLN3n	LIN break field configuration register/ UART configuration register	RLN3nLBFC	<RLIN3n_base> + 09_H	√	√	√	*1	—
RLN3n	LIN / UART space configuration register	RLN3nLSC	<RLIN3n_base> + $0A_H$	√	√	√	*1	—
RLN3n	LIN wake-up configuration register	RLN3nLWUP	<RLIN3n_base> + $0B_H$	√	√	—	*1	—
RLN3n	LIN interrupt enable register	RLN3nLIE	<RLIN3n_base> + $0C_H$	√	√	—	*1	—
RLN3n	LIN / UART error detection enable register	RLN3nLEDE	<RLIN3n_base> + $0D_H$	√	√	√	*1	—
RLN3n	LIN / UART control register	RLN3nLCUC	<RLIN3n_base> + $0E_H$	√	√	√	*1	—
RLN3n	LIN / UART transmission control register	RLN3nLTRC	<RLIN3n_base> + 10_H	√	√	√	*1	—

21.3.2 LIN Master Related Registers

21.3.2.1 RLN3nLWBR — LIN Wake-Up Baud Rate Select Register

Access: This register can be read or written in 8-bit units.

Address: <RLIN3n_base> + 01_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	NSPB[3:0]				LPRS[2:0]			LWBR0
Value after reset	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 21.12 RLN3nLWBR Register Contents

Bit Position	Bit Name	Function
7 to 4	NSPB[3:0]	These bits configure the value for number of samples in 1 Bit time period. 0000: 16 samples per bit 1111: 16 samples per bit Others: Prohibited
3 to 1	LPRS[2:0]	Prescaler Clock Select b3 b1 0 0 0: 1/1 0 0 1: 1/2 0 1 0: 1/4 0 1 1: 1/8 1 0 0: 1/16 1 0 1: 1/32 1 1 0: 1/64 1 1 1: 1/128
0	LWBR0	Wake-up Baud Rate Select 0: In LIN wake-up mode, the clock specified in the LCKS bit of the RLN3nLMD register is used. (LIN1.3) 1: In LIN wake-up mode, the clock fa is used regardless of the setting in the LCKS bit of the RLN3nLMD register. (LIN2.x)

Configure the RLN3nLWBR register when the OMM0 bit in the RLN3nLMST register is 0_B (LIN reset mode).

NSPB[3:0] Bits (Bit Sampling Count Select)

These bits select the number of sampling in one Tbit (reciprocal of the baud rate).
In LIN master mode (LIN/UART mode select bits in LIN mode register = 00_B), set these bits to 0000_B or 1111_B (16 samplings).

LPRS[2:0] Bits (Prescaler Clock Select)

These bits select the frequency division ratio for the prescaler.
The LIN communication clock source is divided by this prescaler.

LWBR0 Bit (Wake-up Baud Rate Select)

When LIN Specification Package Revision 1.3 is used, set the LWBR0 bit in the RLN3nLWBR register to 0. This allows an input signal with a low-level width of 2.5 Tbits or more to be measured.
When LIN Specification Package Revision 2.x is used, set the LWBR0 bit to 1. Setting the LWBR0 bit to 1 selects fa as the LIN system clock (fLIN) during LIN wake-up mode regardless of the setting of the RLN3nLMD.LCKS bit (the LCKS bit is not changed). This allows an input signal with a low-level width of 2.5 Tbits or more to be measured.

Setting the baud rate to 19200 bps while fa is selected allows an input signal with a low-level width of 130 us or longer to be detected in the LIN wake-up mode regardless of the setting of the RLN3nLMD.LCKS bit.

21.3.2.2 RLN3nLBRP0 — LIN Baud Rate Prescaler 0 Register

Access: This register can be read or written in 8-bit units.

Address: <RLIN3n_base> + 02_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	LBRP0[7:0]							
Value after reset	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 21.13 RLN3nLBRP0 Register Contents

Bit Position	Bit Name	Function
7 to 0	LBRP0[7:0]	Assuming that the value set in this register is N (0 to 255), the baud rate prescaler divides the frequency of the prescaler clock by N + 1. Setting range: 00_H to FF_H

Configure the RLN3nLBRP0 register when the OMM0 bit in the RLN3nLMST register is 0_B (LIN reset mode).

The value set in this register is used to control the frequency of baud rate clock sources fa, fb, and fc.

Assuming that the value set in this register is N, baud rate prescaler 0 divides the frequency of the clock that is selected by the LPRS bits (prescaler clock select bits) by N + 1.

21.3.2.3 RLN3nLBRP1 — LIN Baud Rate Prescaler 1 Register

Access: This register can be read or written in 8-bit units.

Address: <RLIN3n_base> + 03_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	LBRP1[7:0]							
Value after reset	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 21.14 RLN3nLBRP1 Register Contents

Bit Position	Bit Name	Function
7 to 0	LBRP1[7:0]	Assuming that the value set in this register is M (0 to 255), the baud rate prescaler divides the frequency of the prescaler clock by M + 1. Setting range: 00_H to FF_H

Set the RLN3nLBRP1 register when the OMM0 bit in the RLN3nLMST register is 0_B (LIN reset mode).

The value set in this register is used to control the frequency of baud rate clock source fd.

Assuming that the value set in this register is M, baud rate prescaler 1 divides the frequency of the clock that is selected by the LPRS bits (prescaler clock select bits) by M+1.

21.3.2.4 RLN3nLSTC — LIN Self-Test Control Register

Access: This register can be read or written in 8-bit units.

Address: <RLIN3n_base> + 04_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	LSTME[6:1]						LSTM
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 21.15 RLN3nLSTC Register Contents

Bit Position	Bit Name	Function
7	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
6 to 1	LSTME	The test mode key values for configuring the RLIN3 module in Test mode.
0	LSTM	LIN Self-Test Mode 0: The module is not in LIN self-test mode. 1: The module is in LIN self-test mode.

The RLN3nLSTC register cancels protection of LIN self-test mode.

Configure the RLN3nLSTC register when the OMM0 bit in the RLN3nLMST register is 0_B (LIN reset mode).

Writing $A7_H$, 58_H, and 01_H successively to the RLN3nLSTC register places the module into LIN self-test mode.

When successive writing is completed and the mode is changed to LIN self-test mode, the LSTM bit is set to 1.

Do not write any other value during successive writing.

For making transition to LIN self-test mode, see **Section 21.4.6, LIN Self-Test Mode**.

When read, bits 6 to 1 return "000000_B", and bit 7 returns an undefined value.

LSTM Bit (LIN Self-Test Mode)

When transition to LIN self-test mode is completed, the LSTM bit is set to 1.
For exiting LIN self-test mode, see **Section 21.4.6, LIN Self-Test Mode**.
Writing 1 to this bit does not affect the value of the RLN3nLSTC register if it is not a part of successive writing of $A7_H$, 58_H, and 01_H.

LSTME Bit (Self test mode entry key bits)

Users are expected to write the Test mode Key sequence values to these bits. Refer to **Section 21.4.6, LIN Self-Test Mode** for details how to enter the Test mode Key.

21.3.2.5 RLN3nLMD — LIN Mode Register

Access: This register can be read or written in 8-bit units.

Address: <RLIN3n_base>+ 08_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	LRDNFS	LIOS	LCKS[1:0]		LMD[1:0]	
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R/W	R/W	R/W	R/W	R/W	R/W

Table 21.16 RLN3nLMD Register Contents

Bit Position	Bit Name	Function
7, 6	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
5	LRDNFS	LIN Reception Data Noise Filter Disable 0: The noise filter is enabled. 1: The noise filter is disabled.
4	LIOS	LIN Interrupt Output Select 0: RLIN3n interrupt is used. 1: RLIN3n transmission interrupt, RLIN3n successful reception interrupt, and RLIN3n status interrupt are used.
3, 2	LCKS[1:0]	LIN System Clock Select b3 b2 0 0: fa (Clock generated by baud rate prescaler 0) 0 1: fb (1/2 clock generated by baud rate prescaler 0) 1 0: fc (1/8 clock generated by baud rate prescaler 0) 1 1: fd (1/2 clock generated by baud rate prescaler 1)
1, 0	LMD[1:0]	LIN/UART Mode Select b1 b0 0 0: LIN master mode

Configure the RLN3nLMD register when the OMM0 bit in the RLN3nLMST register is 0_B (LIN reset mode).

LRDNFS Bit (LIN Reception Data Noise Filter Disable)

The LRDNFS bit enables or disables the noise filter when receiving data.
With 0 set, the noise filter is enabled when receiving data.
With 1 set, the noise filter is disabled when receiving data.

LIOS Bit (LIN Interrupt Output Select)

The LIOS bit selects the number of interrupt outputs from the LIN/UART interface.
With 0 set, the RLIN3 interrupt is generated from the LIN/UART interface.
With 1 set, the RLIN3n transmission interrupt, RLIN3n successful reception interrupt, and RLIN3n status interrupt are generated from the LIN/UART interface.
For each interrupt source, see **Section 21.4.1, Interrupt Sources**.

LCKS[1:0] Bits (LIN System Clock Select)

The LCKS bits select the clock to be input to the protocol controller.
With 00_B set, the protocol controller is provided with fa (clock generated by baud rate prescaler 0).
With 01_B set, the protocol controller is provided with fb (1/2 clock generated by baud rate prescaler 0).
With 10_B set, the protocol controller is provided with fc (1/8 clock generated by baud rate prescaler 0).
With 11_B set, the protocol controller is provided with fd (1/2 clock generated by baud rate prescaler 1).

When 1_B is set in the LWBR0 bit in the RLN3nLWBR register (LIN 2.x), and the RLN3nLMST register is 01_H (LIN wake-up mode), the protocol controller is supplied with fa regardless of the setting of this bit (the LCKS bit is not changed).

LMD[1:0] Bits (LIN/UART Mode Select)

The LMD bits select the LIN/UART interface mode.
To use the LIN/UART interface as an LIN master, set these bits to 00_B.

21.3.2.6 RLN3nLBFC — LIN Break Field Configuration Register

Access: This register can be read or written in 8-bit units.

Address: <RLIN3n_base> + 09_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	BDT[1:0]		BLT[3:0]			
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R/W	R/W	R/W	R/W	R/W	R/W

Table 21.17 RLN3nLBFC Register Contents

Bit Position	Bit Name	Function
7, 6	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
5, 4	BDT[1:0]	Transmission Break Delimiter (High Level) Width Select b5 b4 0 0: 1 Tbit 0 1: 2 Tbits 1 0: 3 Tbits 1 1: 4 Tbits
3 to 0	BLT[3:0]	Transmission Break (Low Level) Width Select b3 b0 0 0 0 0: 13 Tbits 0 0 0 1: 14 Tbits 0 0 1 0: 15 Tbits : 1 1 1 0: 27 Tbits 1 1 1 1: 28 Tbits

Set the RLN3nLBFC register when the OMM0 bit in the RLN3nLMST register is 0_B (LIN reset mode).

Some combinations of the set values result in the length of a frame exceeding the timeout time. Set the appropriate values in this register.

BDT[1:0] Bits (Transmission Break Delimiter (High Level) Width Select)

The BDT bits set the break delimiter (high level) width of transmission frame header.
1 Tbit to 4 Tbits can be set.

BLT[3:0] Bits (Transmission Break (Low Level) Width Select)

The BLT bits set the break (low level) width of transmission frame header.
13 Tbits to 28 Tbits can be set.

21.3.2.7 RLN3nLSC — LIN Space Configuration Register

Access: This register can be read or written in 8-bit units.

Address: <RLIN3n_base>+ $0A_H$

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	IBS[1:0]		—	IBHS[2:0]		
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R/W	R/W	R	R/W	R/W	R/W

Table 21.18 RLN3nLSC Register Contents

Bit Position	Bit Name	Function
7, 6	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
5, 4	IBS[1:0]	Inter-Byte Space Select b5 b4 0 0: 0 Tbit 0 1: 1 Tbit 1 0: 2 Tbits 1 1: 3 Tbits
3	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
2 to 0	IBHS[2:0]	Inter-Byte Space (Header)/Response Space Select b2 b0 0 0 0: 0 Tbit 0 0 1: 1 Tbit 0 1 0: 2 Tbits 0 1 1: 3 Tbits 1 0 0: 4 Tbits 1 0 1: 5 Tbits 1 1 0: 6 Tbits 1 1 1: 7 Tbits

Set the RLN3nLSC register when the OMM0 bit in the RLN3nLMST register is 0_B (LIN reset mode).

Some combinations of the set values result in the length of a frame or a response exceeding the timeout time. Set the appropriate values in this register.

IBS[1:0] Bits (Inter-Byte Space Select)

The IBS bits set the width of the inter-byte space of the transmission frame response field.
0 Tbit to 3 Tbits can be set.
These bits are enabled only during response transmission; these are disabled during response reception.

IBHS[2:0] Bits (Inter-Byte Space (Header)/Response Space Select)

The IBHS bits set the width of the inter-byte space (header) of the transmission frame header field and the response space.
0 Tbit to 7 Tbits can be set.
The response space setting is enabled only during response transmission; setting is disabled during response reception.
The inter-byte space (header) is equal to the response space.

21.3.2.8 RLN3nLWUP — LIN Wake-Up Configuration Register

Access: This register can be read or written in 8-bit units.

Address: <RLIN3n_base>+ $0B_H$

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	WUTL[3:0]				—	—	—	—
Value after reset	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R	R	R	R

Table 21.19 RLN3nLWUP Register Contents

Bit Position	Bit Name	Function
7 to 4	WUTL[3:0]	Wake-up Transmission Low Level Width Select b7 b4 0 0 0 0: 1 Tbit 0 0 0 1: 2 Tbits 0 0 1 0: 3 Tbits 0 0 1 1: 4 Tbits : 1 1 0 0: 13 Tbits 1 1 0 1: 14 Tbits 1 1 1 0: 15 Tbits 1 1 1 1: 16 Tbits
3 to 0	Reserved	When read, the value after reset is returned. When writing, write the value after reset.

Set the RLN3nLWUP register when the OMM0 bit in the RLN3nLMST register is 0_B (LIN reset mode).

WUTL[3:0] Bits (Wake-up Transmission Low Level Width Select)

The WUTL bits set the low level width of the wake-up signal transmission.
1 Tbit to 16 Tbits can be set.

With 1 is set in the LWBR0 bit in the RLN3nLWBR register (LIN 2.x), fa is selected as the LIN system clock (fLIN) regardless of the setting of the RLN3nLMD.LCKS bit (the LCKS bit is not changed).

21.3.2.9 RLN3nLIE — LIN Interrupt Enable Register

Access: This register can be read or written in 8-bit units.

Address: <RLIN3n_base> + $0C_H$

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	SHIE	ERRIE	FRCIE	FTCIE
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R/W	R/W	R/W	R/W

Table 21.20 RLN3nLIE Register Contents

Bit Position	Bit Name	Function
7 to 4	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
3	SHIE	Successful Header Transmission Interrupt Request Enable 0: Disables successful header transmission interrupt request. 1: Enables successful header transmission interrupt request.
2	ERRIE	Error Detection Interrupt Request Enable 0: Disables error detection interrupt request. 1: Enables error detection interrupt request.
1	FRCIE	Successful Frame/Wake-up Reception Interrupt Request Enable 0: Disables successful frame/wake-up reception interrupt request. 1: Enables successful frame/wake-up reception interrupt request.
0	FTCIE	Successful Frame/Wake-up Transmission Interrupt Request Enable 0: Disables successful frame/wake-up transmission interrupt request. 1: Enables successful frame/wake-up transmission interrupt request.

Set the RLN3nLIE register when the OMM0 bit in the RLN3nLMST register is 0_B (LIN reset mode).

SHIE Bit (Successful Header Transmission Interrupt Request Enable)

The SHIE bit enables or disables interrupt requests upon successful transmission of a header.
With 0 set, the interrupt request for RLIN3n transmission is not generated when the HTRC flag in the RLN3nLST register is set to 1.
With 1 set, the interrupt request for RLIN3n transmission is generated when the HTRC flag in the RLN3nLST register is set to 1.

ERRIE Bit (Error Detection Interrupt Request Enable)

The ERRIE bit enables or disables an interrupt request upon detection of an error.
With 0 set, the interrupt request for RLIN3n status is not generated when the ERR flag in the RLN3nLST register is set to 1.
With 1 set, the interrupt request for RLIN3n status is generated when the ERR flag in the RLN3nLST register is set to 1.
Occurrence factors are bit errors, physical bus errors, frame/response timeout errors, framing errors, checksum errors, and response preparation errors.
Detection of the bit error, physical bus error, frame/response timeout error, and framing error can be enabled or disabled using the RLN3nLEDE register.

FRCIE Bit (Successful Frame/Wake-up Reception Interrupt Request Enable)

The FRCIE bit enables or disables an interrupt request upon successful reception of a frame or a wake-up signal (input signal low-level width count).

With 0 set, the interrupt request for successful RLIN3n reception is not generated when the FRC flag in the RLN3nLST register is set to 1.
With 1 set, the interrupt request for successful RLIN3n reception is generated when the FRC flag in the RLN3nLST register is set to 1.

FTCIE Bit (Successful Frame/Wake-up Transmission Interrupt Request Enable)

The FTCIE bit enables or disables an interrupt request upon successful transmission of a frame or a wake-up signal.
With 0 set, the interrupt request for RLIN3n transmission is not generated when the FTC flag in the RLN3nLST register is set to 1.
With 1 set, the interrupt request for RLIN3n transmission is generated when the FTC flag in the RLN3nLST register is set to 1.

21.3.2.10 RLN3nLEDE —LIN Error Detection Enable Register

Access: This register can be read or written in 8-bit units.

Address: <RLIN3n_base> + $0D_H$

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	LTES	—	—	—	FERE	FTERE	PBERE	BERE
Value after reset	0	0	0	0	0	0	0	0
R/W	R/W	R	R	R	R/W	R/W	R/W	R/W

Table 21.21 RLN3nLEDE Register Contents

Bit Position	Bit Name	Function
7	LTES	Timeout Error Select 0: Frame timeout error 1: Response timeout error
6 to 4	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
3	FERE	Framing Error Detection Enable*1 0: Disables framing error detection. 1: Enables framing error detection.
2	FTERE	Timeout Error Detection Enable 0: Disables frame/response timeout error detection. 1: Enables frame/response timeout error detection.
1	PBERE	Physical Bus Error Detection Enable 0: Disables physical bus error detection. 1: Enables physical bus error detection.
0	BERE	Bit Error Detection Enable *1 0: Disables bit error detection. 1: Enables bit error detection.

Note 1. Set FERE bit and BERE bit to 1.

Set the RLN3nLEDE register when the OMM0 bit in the RLN3nLMST register is 0_B (LIN reset mode)

LTES Bit (Timeout Error Select)

The LTES bit selects the timeout function to be used.
With 0 set, the timeout function is used for frame timeout.
With 1 set, the timeout function is used for response timeout.
For details on the timeout error, see **Section 21.4.4.7, Error Status**.

FERE Bit (Framing Error Detection Enable)

The FERE bit enables or disables detection of the framing error.
With 0 set, the framing error is not detected.
With 1 set, the framing error is detected.
Set this bit to 1. The detection result of the framing error is indicated in the FER flag in the RLN3nLEST register.
For details on the framing error, see **Section 21.4.4.7, Error Status**.

FTERE Bit (Timeout Error Detection Enable)

The FTERE bit enables or disables detection of the frame timeout error or the response timeout error.
With 0 set, the frame timeout error or response timeout error is not detected.
With 1 set, the frame timeout error or response timeout error is detected.

When this bit is set to 1, the detection result is indicated in the FTER flag in the RLN3nLEST register.
With the LTES bit, either the frame timeout error or response timeout error can be selected.
Do not use the timeout error if response data of 9 bytes or more is to be transmitted or received.
For details on the timeout error, see **Section 21.4.4.7, Error Status**.

If RLIN3 transitions to LIN reset mode by clearing RLN3nLCUC.OM0 to 0 when the timeout function is used (RLN3nLEDE.FTERE = 1), users should take the procedure shown in **Figure 21.4**.

PBERE Bit (Physical Bus Error Detection Enable)

The PBERE bit enables or disables detection of the physical bus error.
With 0 set, the physical bus error is not detected.
With 1 set, the physical bus error is detected.
When this bit is set to 1, the detection result is indicated in the PBER flag in the RLN3nLEST register.
For details on the physical bus error, see **Section 21.4.4.7, Error Status**.

BERE Bit (Bit Error Detection Enable)

The BERE bit enables or disables detection of the bit error.
With 0 set, the bit error is not detected.
With 1 set, the bit error is detected.
Set this bit to 1. The detection result of the bit error is indicated in the BER flag in the RLN3nLEST register.
For details on the bit error, see **Section 21.4.4.7, Error Status**.

21.3.2.11 RLN3nLCUC — LIN Control Register

Access: This register can be read or written in 8-bit units.

Address: <RLIN3n_base> + $0E_H$

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	OM1	OM0
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R/W	R/W

Table 21.22 RLN3nLCUC Register Contents

Bit Position	Bit Name	Function
7 to 2	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
1	OM1	LIN Mode Select 0: LIN wake-up mode. 1: LIN operation mode.
0	OM0	LIN Reset 0: LIN reset mode. 1: LIN reset mode is canceled.

Set the RLN3nLCUC register to 01_H to transition to LIN wake-up mode or to 03_H to transition to LIN operation mode after exiting LIN reset mode.

In LIN self-test mode, set the RLN3nLCUC register to 03_H after a transition to LIN self-test mode is completed.

After a value is written to this register, confirm that the value written is actually indicated in the RLN3nLMST register before writing another value.

OM1 Bit (LIN Mode Select)

The OM1 bit selects the specific operation mode (either LIN wake-up mode or LIN operation mode) after canceling LIN reset mode.
With 0 set, LIN wake-up mode.
With 1 set, LIN operation mode.
This bit is valid only when the OMM0 bit in the RLN3nLMST register is 1.
Writing a value to this bit is disabled while the FTS bit in the RLN3nLTRC register is 1.

OM0 Bit (LIN Reset)

The OM0 bit selects either causing a transition to LIN reset mode or canceling LIN reset mode.
With 0 set, LIN reset mode.
With 1 set, LIN reset mode is canceled.

If RLIN3 transitions to LIN reset mode by clearing RLN3nLCUC.OM0 to 0 when the timeout function is used (RLN3nLEDE.FTERE = 1), users should take the procedure shown in **Figure 21.4**.

21.3.2.12 RLN3nLTRC — LIN Transmission Control Register

Access: This register can be read or written in 8-bit units.

Address: <RLIN3n_base> + 10_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	RTS	FTS
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R/W	R/W

Table 21.23 RLN3nLTRC Register Contents

Bit Position	Bit Name	Function
7 to 2	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
1	RTS	Response Transmission/Reception Start 0: Response transmission/reception is stopped in frame separate mode. 1: Response transmission/reception is started in frame separate mode.
0	FTS	Frame Transmission/Wake-up Transmission /Reception Start 0: Frame Transmission/wake-up transmission/reception is stopped. 1: Frame Transmission/wake-up transmission reception is started.

RTS Bit (Response Transmission/Reception Start)

Set the RTS bit to 1 in frame separate mode after header transmission is started (FTS bit is 1) and response transmission data is ready. Once set, this bit is automatically cleared to 0 upon completion of frame communication (including error detection) or transition to LIN reset mode.
Only 1 can be written to this bit; 0 cannot be written.
To write 1 to this bit, write 02_H to the RLN3nLTRC register using the store instruction.
Writing a value to this bit is disabled when the OMM0 bit in the RLN3nLMST register is 0_B (LIN reset mode).
Writing a value to this bit is disabled when the FTS bit is 0 (frame transmission or wake-up transmission/reception is halted).
When response data of 9 bytes or more is to be transmitted or received, set this bit to 1 each time a data group (variable from 0 to 8 bytes) is transmitted or received. Once set, this bit is automatically cleared to 0 at the end of data group communication or transition to LIN reset mode.

FTS Bit (Frame Transmission/Wake-up Transmission/Reception Start)

Set the FTS bit to 1 to start frame transmission and reception.
Also set this bit to 1 to allow wake-up transmission and reception (input signal low-level width count).
Only 1 can be written to this bit; 0 cannot be written.
Writing a value to this bit is disabled when the OMM0 bit in the RLN3nLMST register is 0_B (LIN reset mode).

This bit is set to 0 upon completion of frame or wake-up communication (including error detection) and transition to LIN reset mode.

21.3.2.13 RLN3nLMST — LIN Mode Status Register

Access: This register is a read-only register that can be read in 8-bit units.

Address: <RLIN3n_base> + 11_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	OMM1	OMM0
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R

Table 21.24 RLN3nLMST Register Contents

Bit Position	Bit Name	Function
7 to 2	Reserved	When read, the value after reset is returned.
1	OMM1	LIN Mode Status Monitor 0: LIN wake-up mode. 1: LIN operation mode.
0	OMM0	LIN Reset Status Monitor 0: LIN reset mode. 1: Not in LIN reset mode.

OMM1 Bit (LIN Mode Status Monitor)

The OMM1 bit indicates the current operating mode.

OMM0 Bit (LIN Reset Status Monitor)

The OMM0 bit indicates the current operating mode.

21.3.2.14 RLN3nLST — LIN Status Register

Access: This register can be read or written in 8-bit units.

Address: <RLIN3n_base> + 12_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	HTRC	D1RC	—	—	ERR	—	FRC	FTC
Value after reset	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R	R	R	R	R/W	R/W

Table 21.25 RLN3nLST Register Contents

Bit Position	Bit Name	Function
7	HTRC	Successful Header Transmission Flag 0: Header transmission has not been completed. 1: Header transmission has been completed.
6	D1RC	Successful Data 1 Reception Flag 0: Data 1 reception has not been completed. 1: Data 1 reception has been completed.
5, 4	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
3	ERR	Error Detection Flag 0: No error has been detected. 1: Error has been detected.
2	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
1	FRC	Successful Frame/Wake-up Reception Flag 0: Frame or wake-up reception has not been completed. 1: Frame or wake-up reception has been completed.
0	FTC	Successful Frame/Wake-up Transmission Flag 0: Frame or wake-up transmission has not been completed. 1: Frame or wake-up transmission has been completed.

The RLN3nLST register is automatically cleared to 00_H upon transition to LIN reset mode and start of the next communication (when the FTS bit of the RLN3nLTRC register is 1).

In LIN reset mode, this register cannot be written to. In LIN reset mode, the register retains 00_H.

To clear the specific bits in the register, write 0 to the bits to be cleared and write 1 to the other bits using the store instruction.

HTRC Flag (Successful Header Transmission Flag)

Only 0 can be written to the HTRC flag; when 1 is written, the bit retains the value it had before 1 is written.
The HTRC flag is set to 1 upon completion of header transmission. Here, an interrupt request for RLN3n transmission is generated if the SHIE bit in the RLN3nLIE register is 1 (interrupt is enabled).
To clear the bit to 0 before the next communication is started (when the FTS bit of the RLN3nLTRC register is 1), write 0 to the bit while in LIN operation mode.

D1RC Flag (Successful Data 1 Reception Flag)

Only 0 can be written to the D1RC flag; when 1 is written, the bit retains the value that has been retained before 1 is written.
The D1RC flag is set to 1 upon completion of data 1 reception. Here, an interrupt request is not

generated. To clear the bit to 0 before the next communication (when the FTS bit of the RLN3nLTRC register is 1), write 0 to the bit in LIN operation mode.
When response data of 9 bytes or more is to be received, this bit is set to 1 each time data 1 of a data group (variable from 0 to 8 bytes) is received. Write 0 before starting reception of the next data group.

ERR Flag (Error Detection Flag)

The ERR flag is set to 1 upon detection of an error (when at least one of the flags of the RLN3nLEST register is set to 1). Here, an interrupt request for RLN3n status is generated if the ERRIE bit in the RLN3nLIE register is 1 (interrupt is enabled). To clear the bit to 0 before the next communication (when the FTS bit of the RLN3nLTRC register is 1), write 0 to the RPER, CSER, FER, FTER, PBER, and BER flags in the RLN3nLEST register in LIN operation mode or LIN wake-up mode. This clears the ERR flag to 0.

FRC Flag (Successful Frame/Wake-up Reception Flag)

Only 0 can be written to the FRC flag; when 1 is written, the bit retains the value that has been retained before 1 is written.
The FRC flag is set to 1 upon completion of frame or wake-up reception. Here, an interrupt request for RLN3n reception complete is generated if the FRCIE bit in the RLN3nLIE register is 1 (interrupt is enabled). To clear the bit to 0 before the next communication (when the FTS bit of the RLN3nLTRC register is 1), write 0 to the bit in LIN operation mode or LIN wake-up mode.
When response data of 9 bytes or more is to be received, this bit is set to 1 each time a data group (variable from 0 to 8 bytes) is received. Write 0 before starting reception of the next data group.

FTC Flag (Successful Frame/Wake-up Transmission Flag)

Only 0 can be written to the FTC flag; when 1 is written, the bit retains the value that has been retained before 1 is written.
The FTC flag is set to 1 upon completion of frame or wake-up transmission. Here, an interrupt request for RLN3n transmission is generated if the FTCIE bit in the RLN3nLIE register is 1 (interrupt is enabled). To clear the bit to 0 before the next communication (when the FTS bit of the RLN3nLTRC register is 1), write 0 to the bit in LIN operation mode or LIN wake-up mode.
When response data of 9 bytes or more is to be transmitted, this bit is set to 1 each time a data group (variable from 0 to 8 bytes) is transmitted. Write 0 before starting transmission of the next data group.

21.3.2.15 RLN3nLEST — LIN Error Status Register

Access: This register can be read or written in 8-bit units.

Address: <RLIN3n_base> + 13_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	RPER	—	CSER	—	FER	FTER	PBER	BER
Value after reset	0	0	0	0	0	0	0	0
R/W	R/W	R	R/W	R	R/W	R/W	R/W	R/W

Table 21.26 RLN3nLEST Register Contents

Bit Position	Bit Name	Function
7	RPER	Response Preparation Error Flag 0: Response preparation error has not been detected. 1: Response preparation error has been detected.
6	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
5	CSER	Checksum Error Flag 0: Checksum error has not been detected. 1: Checksum error has been detected.
4	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
3	FER	Framing Error Flag 0: Framing error has not been detected. 1: Framing error has been detected.
2	FTER	Timeout Error Flag 0: Frame/response timeout error has not been detected. 1: Frame/response timeout error has been detected.
1	PBER	Physical Bus Error Flag 0: Physical bus error has not been detected. 1: Physical bus error has been detected.
0	BER	Bit Error Flag 0: Bit error has not been detected. 1: Bit error has been detected.

The RLN3nLEST register is automatically cleared to 00_H upon transition to LIN reset mode and start of the next communication (when the FTS bit of the RLN3nLTRC register is 1).

In LIN reset mode, this register cannot be written to. In LIN reset mode, the register retains 00_H.

When the FTS bit in the RLN3nLTRC register is 1 (frame transmission or wake-up transmission/ reception is started), do not write a value to this register.

To clear the specific bits in the register, write 0 to the bits to be cleared and write 1 to the other bits using the store instruction.

RPER Flag (Response Preparation Error Flag)

Only 0 can be written to the RPER flag; when 1 is written, the bit retains the value that has been retained before 1 is written.
The RPER flag is set to 1 upon response preparation error detection. To clear the bit to 0 before the next communication (when the FTS bit of the RLN3nLTRC register is 1), write 0 to the bit in LIN operation mode.

CSER Flag (Checksum Error Flag)

Only 0 can be written to the CSER flag; when 1 is written, the bit retains the value that has been retained before 1 is written.
The CSER flag is set to 1 upon checksum error detection. To clear the bit to 0 before the next communication (when the FTS bit of the RLN3nLTRC register is 1), write 0 to the bit in LIN operation mode.

FER Flag (Framing Error Flag)

Only 0 can be written to the FER flag; when 1 is written, the bit retains the value that has been retained before 1 is written.
When the value of the FERE bit of the RLN3nLEDE register is 1 (framing error detection enabled), the FER flag is set to 1 upon framing error detection. To clear the bit to 0 before the next communication (when the FTS bit of the RLN3nLTRC register is 1), write 0 to the bit in LIN operation mode.

FTER Flag (Timeout Error Flag)

Only 0 can be written to the FTER flag; when 1 is written, the bit retains the value that has been retained before 1 is written.
When the FTERE bit of the RLN3nLEDE register is 1 (frame/response timeout error detection enabled), the FTER flag is set to 1 upon frame timeout error or response timeout error detection. To clear the bit to 0 before the next communication (when the FTS bit of the RLN3nLTRC register is 1), write 0 to the bit in LIN operation mode.

PBER Flag (Physical Bus Error Flag)

Only 0 can be written to the PBER flag; when 1 is written, the bit retains the value that has been retained before 1 is written.
When the PBERE bit of the RLN3nLEDE register is 1 (physical bus error detection enabled), the PBER flag is set to 1 upon physical bus error detection. To clear the bit to 0 before the next communication (when the FTS bit of the RLN3nLTRC register is 1), write 0 to the bit in LIN operation mode or LIN wake-up mode.

BER Flag (Bit Error Flag)

Only 0 can be written to the BER flag; when 1 is written, the bit retains the value that has been retained before 1 is written.
When the BERE bit of the RLN3nLEDE register is 1 (bit error detection enabled), the BER flag is set to 1 upon bit error detection. To clear the bit to 0 before the next communication (when the FTS bit of the RLN3nLTRC register is 1), write 0 to the bit in LIN operation mode or LIN wake-up mode.

21.3.2.16 RLN3nLDFC — LIN Data Field Configuration Register

Access: This register can be read or written in 8-bit units.

Address: <RLIN3n_base> + 14_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	LSS	FSM	CSM	RFT	RFDL[3:0]			
Value after reset	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 21.27 RLN3nLDFC Register Contents

Bit Position	Bit Name	Function
7	LSS	Transmission/Reception Continuation Select 0: The data group to be transmitted/received next is the last one. 1: The data group to be transmitted/received next is not the last one. (Checksum is not included.)
6	FSM	Frame Separate Mode Select 0: Frame separate mode is not set. 1: Frame separate mode is set.
5	CSM	Checksum Select 0: Classic checksum 1: Enhanced checksum
4	RFT	Response Field Communication Direction Select 0: Reception 1: Transmission
3 to 0	RFDL[3:0]	Response Field Length Select b3 b0 0 0 0 0: 0 byte (+ checksum) 0 0 0 1: 1 byte (+ checksum) 0 0 1 0: 2 bytes (+ checksum) : 0 1 1 1: 7 bytes (+ checksum) 1 0 0 0: 8 bytes (+ checksum) Settings other than the above are prohibited.

LSS Bit (Transmission/Reception Continuation Select)

The LSS bit indicates that the data group to be transmitted or received next is not the last data group when response data of 9 bytes or more is to be transmitted or received.
With 0 set, data and checksum are transmitted or received because the next data group to be transmitted or received is the last one.
With 1 set, only data is transmitted or received, and the checksum is not included because the next data group to be transmitted or received is not the last one.
Set the LSS bit only when the FSM bit is 1 (frame separate mode) and response data of 9 bytes or more is to be transmitted or received.

Set the LSS bit only when the RTS bit in the RLN3nLTRC is 0 (response transmit/receive is stopped).

FSM Bit (Frame Separate Mode Select)

The FSM bit sets the response communication mode.
With 0 set, frame separate mode is not selected. In this case, after header transmission is started (the FTS bit in the RLN3nLTRC register is 1), response is transmitted/received without setting the RTS bit in the RLN3nLTRC register.

With 1 set, frame separate mode is selected. If the RTS bit of the RLN3nLTRC register is set to 1 during header transmission, response transmission is executed after header transmission is completed.

For response reception which is 8 bytes or less (the RFT bit is 0), set the FSM bit to 0.
When causing a transition to LIN self-test mode, set this bit to 0 before transition.
For details on frame separate mode, see **Section 21.4.4.4(1), Transmission of LIN Frames**.
Set this bit when the FTS bit in the RLN3nLTRC register is 0 (frame transmission or wake-up transmission/reception is halted).
When response data of 9 bytes or more is to be transmitted or received, set the FSM bit to 1.

CSM Bit (Checksum Select)

The CSM bit sets the checksum mode.
With 0 set, classic checksum mode is selected.
With 1 set, enhanced checksum mode is selected.
When the timeout error is used (the FTERE bit in the RLN3nLEDE register is 1), the specific timeout time depends on the setting of this bit. For details on the bit error, see **Section 21.4.4.7, Error Status**.
Set this bit when the FTS bit in the RLN3nLTRC register is 0 (frame transmission or wake-up transmission/reception is halted).
When response data of 9 bytes or more is to be transmitted or received, do not change the CSM bit setting after the first data group through the last data group.
During communication of response data of 9 bytes or more, only the last data group (the LSS bit is 0) includes the checksum, and no other groups (the LSS bit is 1) include the checksum.

RFT Bit (Response Field Communication Direction Select)

The RFT bit sets the direction of the response field/wake-up signal communication.
With 0 set, reception is performed in the response field. In LIN wake-up mode, wake-up reception is performed (input signal low-level width count).
With 1 set, transmission is performed in the response field. In LIN wake-up mode, wake-up transmission is performed.
Set this bit when the FTS bit in the RLN3nLTRC register is 0 (frame transmission or wake-up transmission/reception is halted).
When response data of 9 bytes or more is to be transmitted or received, do not change the RFT bit setting after the first data group through the last data group.

RFDL[3:0] Bits (Response Field Length Select)

The RFDL bits set the length of the response field data.
The data length can be 0 to 8 bytes excluding the checksum size.
To transmit response data with the FSM bit set to 0 (not frame separate mode), set the RFDL bits before header transmission (the FTS bit in the RLN3nLTRC register is 0).
To transmit response data with the FSM bit set to 1 (frame separate mode), set the RFDL bits before response transmission (the RTS bit in the RLN3nLTRC register is 0).
To receive response data, set the RFDL bits before header transmission (the FTS bit in the RLN3nLTRC register is 0).
When response data of 9 bytes or more is to be transmitted or received, set the RFDL bits before data group transmission/reception (RTS bit in the RLN3nLTRC register is 0).
Only the last data group (the LSS bit is 0) includes the checksum, and no other groups (the LSS bit is 1) include the checksum.

21.3.2.17 RLN3nLIDB — LIN ID Buffer Register

Access: This register can be read or written in 8-bit units.

Address: <RLIN3n_base> + 15_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	IDP1	IDP0	ID[5:0]					
Value after reset	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 21.28 RLN3nLIDB Register Contents

Bit Position	Bit Name	Function
7	IDP1	Parity Setting (P1) Sets the parity bits (P1) to be transmitted in the ID field.
6	IDP0	Parity Setting (P0) Sets the parity bits (P0) to be transmitted in the ID field.
5 to 0	ID[5:0]	ID Setting Sets the 6-bit ID value to be transmitted in the ID field.

Set the RLN3nLIDB register when the FTS bit in the RLN3nLTRC register is 0 (frame transmission or wake-up transmission/reception is halted).

In LIN self-test mode, this register operates as described below.

Write the value to be transmitted before communication. After completion of frame transmission/ reception (after loopback), the reversed value of the received value can be read.

For details about the LIN self-test mode, see **Section 21.4.6, LIN Self-Test Mode**.

IDP[1:0] Bits (Parity Setting)

The IDP bits set the parity bits (P0 and P1) to be transmitted in the ID field of the LIN frame. IDP0 is for P0 and IDP1 is for P1.

Since parity is not automatically calculated, set the calculation result. Note that if the erroneous result is set, it is transmitted as is.

ID[5:0] Bits (ID Setting)

The ID bits set the 6-bit ID value to be transmitted in the ID field of the LIN frame.

21.3.2.18 RLN3nLCBR — LIN Checksum Buffer Register

Access: This register is a read-only register that can be read in 8-bit units. In LIN self-test mode, this register can be read or written in 8-bit units.

Address: <RLIN3n_base> + 16_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	CKSM[7:0]							
Value after reset	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 21.29 RLN3nLCBR Register Contents

Bit Position	Bit Name	Function
7 to 0	CKSM[7:0]	Holds the checksum data transmitted or received.

In LIN mode, this register operates as follows:

- When the RFT bit in the RLN3nLDFC register is 1 (transmission):
  The value transmitted can be read from the register. Read the value after transmission is completed.
  Writing to this register is invalid.
- When the RFT bit in the RLN3nLDFC register is 0 (reception):
  The value received can be read from the register. Read the value after reception is completed.
  Writing to this register is invalid.

When response data of 9 bytes or more is to be transmitted or received, the checksum is appended only to the last data group; this register is not updated for other data groups.

In LIN self-test mode, this register operates as follows:

- When the RFT bit in the RLN3nLDFC register is 1 (transmission):
  After completion of the frame transmission (after loopback), the reversed value of the received value can be read.
- When the RFT bit in the RLN3nLDFC register is 0 (reception):
  Write the value to be received before communication. After completion of frame transmission/reception (after loopback), the reversed value of the received value can be read.

For details about the LIN self-test mode, see **Section 21.4.6, LIN Self-Test Mode**.

Set the this register when the FTS bit in the RLN3nLTRC register is 0 (frame transmission or wake-up transmission/reception is halted).

21.3.2.19 RLN3nLDBRb — LIN Data Buffer b Register (b = 1 to 8)

Access: This register can be read or written in 8-bit units.

Address: RLN3nLDBR1: <RLIN3n_base> + 18_H
RLN3nLDBR2: <RLIN3n_base> + 19_H
RLN3nLDBR3: <RLIN3n_base> + $1A_H$
RLN3nLDBR4: <RLIN3n_base> + $1B_H$
RLN3nLDBR5: <RLIN3n_base> + $1C_H$
RLN3nLDBR6: <RLIN3n_base> + $1D_H$
RLN3nLDBR7: <RLIN3n_base> + $1E_H$
RLN3nLDBR8: <RLIN3n_base> + $1F_H$

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	LDB[7:0]							
Value after reset	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 21.30 RLN3nLDBRb Register Contents

Bit Position	Bit Name	Function
7 to 0	LDB[7:0]	Sets the data to be transmitted or reads the received data. Setting range: 00_H to FF_H

- For response transmission:
  These registers set the data to be transmitted in the response field.
  Use these registers with the following settings.
  - RFT in RLN3nLDFC register is 1 (transmission)
  - FSM in RLN3nLDFC register is 0 (not frame separate mode)
  - FTS in RLN3nLTRC register is 0 (frame transmission or wake-up transmission/reception is halted)

  or
  - RFT in RLN3nLDFC register is 1 (transmission)
  - FSM in RLN3nLDFC register is 1 (frame separate mode)
  - RTS in RLN3nLTRC register is 0 (response transmission/reception is halted)
- For response reception:
  These registers hold the data received in the response field.
  The received data is overwritten. If an error is detected, the data up to the byte in which the error was detected are stored in the register.
  Do not read these registers when the FTS bit is 1 (frame transmission or wake-up transmission/reception is started)
- For transmission of response data of 9 bytes or more:
  Use these registers with the following settings.
  - RFT in RLN3nLDFC register is 1 (transmission)
  - FSM in RLN3nLDFC register is 1 (frame separate mode)
  - RTS in RLN3nLTRC register is 0 (response transmission/reception is halted)
- For reception of response data of 9 bytes or more:
  Do not read these registers when the RTS bit is 1 (response transmission/reception is started).

In LIN self-test mode, these registers operate as described below.

Write the value to be transmitted before communication. After completion of frame transmission/ reception (after loopback), the reversed value of the received value can be read.

For details about the LIN self-test mode, see **Section 21.4.6, LIN Self-Test Mode**.

21.3.3 LIN Slave Related Registers

21.3.3.1 RLN3nLWBR — LIN Wake-Up Baud Rate Select Register

Access: This register can be read or written in 8-bit units.

Address: <RLIN3n_base> + 01_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	NSPB[3:0]				LPRS[2:0]			—
Value after reset	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R

Table 21.31 RLN3nLWBR Register Contents

Bit Position	Bit Name	Function
7 to 4	NSPB[3:0]	Bit Sampling Count Select b7 b4 0 0 0 0: 16 samplings 0 0 1 1: 4 samplings 0 1 1 1: 8 samplings 1 1 1 1: 16 samplings Settings other than the above are prohibited.
3 to 1	LPRS[2:0]	Prescaler Clock Select b3 b1 0 0 0: 1/1 0 0 1: 1/2 0 1 0: 1/4 0 1 1: 1/8 1 0 0: 1/16 1 0 1: 1/32 1 1 0: 1/64 1 1 1: 1/128
0	Reserved	When read, the value after reset is returned. When writing, write the value after reset.

Set the RLN3nLWBR register when the OMM0 bit in the RLN3nLMST register is 0_B (LIN reset mode).

NSPB[3:0] Bits (Bit Sampling Count Select)

The NSPB bits select the number of sampling in one Tbit (reciprocal of the baud rate).
When the communication is performed in LIN slave mode (fixed baud rate) (LMD[1:0] bits in the RLN3nLMD register = 11_B), set these bits to "0000_B" or "1111_B" (16 samplings).
When the LIN frame communication is performed in LIN slave mode (auto baud rate) (LMD[1:0] bits in the RLN3nLMD register = 10_B), set these bits to "0011_B" (4 samplings) or "0111_B" (8 samplings).

LPRS[2:0] Bits (Prescaler Clock Select)

The LPRS bits select the frequency division ratio for the prescaler. The LIN communication clock source is divided by this prescaler.

In LIN slave mode (auto baud rate) (LMD[1:0] bits in the RLN3nLMD register = 10_B), set these bits so that the prescaler clock becomes as follows according to the target baud rate.

[Target baud rate]	[Prescaler clock]
1 kbps to 20 kbps	: 4MHz*1
1 kbps to 2.4 kbps (excluding 2.4 kbps)	: 4MHz
2.4 kbps to 20 kbps	: 8 MHz to 12 MHz

Note 1. Use the clock with NSPB bits set to "0011_B" (four samplings).

21.3.3.2 RLN3nLBRP01 — LIN Baud Rate Prescaler 01 Register

Access: RLN3nLBRP01 can be read or written in 16-bit units.
RLN3nLBRP0 can be read or written in 8-bit units.
RLN3nLBRP1 can be read or written in 8-bit units.

Address: RLN3nLBRP01: <RLIN3n_base> + 02_H
RLN3nLBRP0: <RLIN3n_base> + 02_H
RLN3nLBRP1: <RLIN3n_base> + 03_H

Value after reset: 0000_H

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	BRP[15:0]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 21.32 RLN3nLBRP01 Register Contents

Bit Position	Bit Name	Function
15 to 0	BRP[15:0]	Assuming that the value set in this register is L (0 to 65535), the baud rate prescaler divides the frequency of the prescaler clock by L + 1. Setting range: 0000_H to $FFFF_H$

Set the RLN3nLBRP01 register when the OMM0 bit in the RLN3nLMST register is 0_B (LIN reset mode).

Assuming that the value set in this register is L, the baud rate prescaler divides the frequency of the clock that is selected by the LPRS bits (prescaler clock select bits) in the RLN3nLWBR register by L + 1.

The RLN3nLBRP01 register can be accessed in 8-bit units by registers RLN3nLBRP0 and RLN3nLBRP1.

NOTE

In LIN slave mode [auto baud rate], the system automatically sets the result of baud rate correction to the RLN3nLBRP01 register on successful reception of the sync field.

21.3.3.3 RLN3nLSTC — LIN Self-Test Control Register

Access: This register can be read or written in 8-bit units.

Address: <RLIN3n_base> + 04_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	LSTME[6:1]						LSTM
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 21.33 RLN3nLSTC Register Contents

Bit Position	Bit Name	Function
7	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
6 to 1	LSTME	The test mode key values for configuring the RLIN3 module in Test mode.
0	LSTM	LIN Self-Test Mode 0: LIN self test mode is not set. 1: LIN self test mode is set.

The RLN3nLSTC register cancels protection of LIN self-test mode.

Configure the RLN3nLSTC register when the OMM0 bit in the RLN3nLMST register is 0_B (LIN reset mode).

Writing $A7_H$, 58_H, and 01_H successively to the RLN3nLSTC register places the module into LIN self-test mode.

When successive writing is completed thus placing LIN self-test mode to be entered, the LSTM bit is set to 1.

Do not write any other value during successive writing.

For making transition to LIN self-test mode, see **Section 21.4.6, LIN Self-Test Mode**.

When reading bits 6 to 1, they return "000000_B", and reading bit 7, it returns an undefined value.

LSTM Bit (LIN Self-Test Mode)

When transition to LIN self-test mode is completed, the LSTM bit is set to 1.
For exiting LIN self-test mode, see **Section 21.4.6, LIN Self-Test Mode**.
Writing 1 to this bit does not affect the value of the RLN3nLSTC register if it is not a part of successive writing of $A7_H$, 58_H, and 01_H.

LSTME Bit (Self test mode entry key bits)

Users are expected to write the Test mode Key sequence values to these bits. Refer to **Section 21.4.6, LIN Self-Test Mode** for details how to enter the Test mode Key.

21.3.3.4 RLN3nLMD — LIN Mode Register

Access: This register can be read or written in 8-bit units.

Address: <RLIN3n_base> + 08_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	LRDNFS	LIOS	—	—	LMD[1:0]	
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R/W	R/W	R	R	R/W	R/W

Table 21.34 RLN3nLMD Register Contents

Bit Position	Bit Name	Function
7, 6	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
5	LRDNFS	LIN Reception Data Noise Filter Disable 0: The noise filter is enabled. 1: The noise filter is disabled.
4	LIOS	LIN Interrupt Output Select 0: RLIN3 interrupt is used. 1: RLIN3n transmission interrupt, RLIN3n successful reception interrupt, and RLIN3n status interrupt are used.
3, 2	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
1, 0	LMD[1:0]	LIN/UART Mode Select b1 b0 1 0: LIN slave mode with auto baud rate 1 1: LIN slave mode with fixed baud rate

Set the RLN3nLMD register when the OMM0 bit in the RLN3nLMST register is 0_B (LIN reset mode).

LRDNFS Bit (LIN Reception Data Noise Filter Disable)

The LRDNFS bit enables or disables the noise filter when receiving data.
With 0 set, the noise filter is enabled when receiving data.
With 1 set, the noise filter is disabled when receiving data.

LIOS Bit (LIN Interrupt Output Select)

The LIOS bit selects the number of interrupt outputs from the LIN/UART interface.
With 0 set, the RLIN3 interrupt is generated from the LIN/UART interface.
With 1 set, the RLIN3n transmission interrupt, RLIN3n successful reception interrupt, and RLIN3n reception status interrupt are generated from the LIN/UART interface.
For each interrupt source, see **Section 21.4.1, Interrupt Sources**.

LMD[1:0] Bits (LIN/UART Mode Select)

The LMD bits select the LIN/UART interface mode.
To use this module as an LIN slave, set these bits to "10_B" (auto baud rate) or "11_B" (fixed baud rate).

21.3.3.5 RLN3nLBFC — LIN Break Field Configuration Register

Access: This register can be read or written in 8-bit units.

Address: <RLIN3n_base> + 09_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	LBLT
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R/W

Table 21.35 RLN3nLBFC Register Contents

Bit Position	Bit Name	Function
7 to 1	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
0	LBLT	Reception Break (Low-Level) Detection Width Setting 0: A break (low-level) is detected in 9.5 or 10 Tbits 1: A break (low-level) is detected in 10.5 or 11 Tbits

Set the RLN3nLBFC register when the OMM0 bit in the RLN3nLMST register is 0_B (LIN reset mode).

LBLT Bit (Reception Break (Low-Level) Detection Width Setting)

- When RLN3nLMD.LMD is "10_B" (LIN slave mode (auto baud rate))
  - 0: Low-level width of 10 Tbits or longer is detected.
  - 1: Low-level width of 11 Tbits or longer is detected.
- When RLN3nLMD.LMD is "11_B" (LIN slave mode (fixed baud rate))
  - 0: Low-level width of 9.5 Tbits or longer is detected.
  - 1: Low-level width of 10.5 Tbits or longer is detected.

21.3.3.6 RLN3nLSC — LIN Space Configuration Register

Access: This register can be read or written in 8-bit units.

Address: <RLIN3n_base> + $0A_H$

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	IBS[1:0]		—	IBHS[2:0]		
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R/W	R/W	R	R/W	R/W	R/W

Table 21.36 RLN3nLSC Register Contents

Bit Position	Bit Name	Function
7, 6	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
5, 4	IBS[1:0]	Inter-Byte Space Select b5 b4 0 0: 0 Tbit 0 1: 1 Tbit 1 0: 2 Tbits 1 1: 3 Tbits
3	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
2 to 0	IBHS[2:0]	Response Space Setting b2 b0 0 0 0: 0 Tbit 0 0 1: 1 Tbit 0 1 0: 2 Tbits 0 1 1: 3 Tbits 1 0 0: 4 Tbits 1 0 1: 5 Tbits 1 1 0: 6 Tbits 1 1 1: 7 Tbits

Set the RLN3nLSC register when the OMM0 bit in the RLN3nLMST register is 0_B (LIN reset mode).

This register is enabled only for response transmission, and disabled for response reception.

Some combinations of the setting values result in the length of a frame or a response exceeding the timeout time. Set the appropriate values in this register.

IBS[1:0] Bits (Inter-Byte Space Select)

The IBS bits set the width of the inter-byte space of the response transmission.
0 Tbit to 3 Tbits can be set.

IBHS[2:0] Bits (Inter-Byte Space (Header)/Response Space Select)

The IBHS bits set the transmission width of the response space.
0 Tbit to 7 Tbits can be set.

21.3.3.7 RLN3nLWUP — LIN Wake-Up Configuration Register

Access: This register can be read or written in 8-bit units.

Address: <RLIN3n_base> + $0B_H$

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	WUTL[3:0]				—	—	—	—
Value after reset	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R	R	R	R

Table 21.37 RLN3nLWUP Register Contents

Bit Position	Bit Name	Function
7 to 4	WUTL[3:0]	Wake-up Transmission Low level Width Select b7 b4 0 0 0 0: 1 Tbit 0 0 0 1: 2 Tbits 0 0 1 0: 3 Tbits 0 0 1 1: 4 Tbits : 1 1 0 0: 13 Tbits 1 1 0 1: 14 Tbits 1 1 1 0: 15 Tbits 1 1 1 1: 16 Tbits
3 to 0	Reserved	When read, the value after reset is returned. When writing, write the value after reset.

Set the RLN3nLWUP register when the OMM0 bit in the RLN3nLMST register is 0_B (LIN reset mode).

WUTL[3:0] Bits (Wake-up Transmission Low Level Width Select)

The WUTL bits set the low-level width of the wake-up frame transmission.
1 Tbit to 16 Tbits can be set.

21.3.3.8 RLN3nLIE — LIN Interrupt Enable Register

Access: This register can be read or written in 8-bit units.

Address: <RLIN3n_base> + $0C_H$

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	SHIE	ERRIE	FRCIE	FTCIE
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R/W	R/W	R/W	R/W

Table 21.38 RLN3nLIE Register Contents

Bit Position	Bit Name	Function
7 to 4	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
3	SHIE	Successful Header Reception Interrupt Request Enable 0: Disables successful header reception interrupt request. 1: Enables successful header reception interrupt request.
2	ERRIE	Error Detection Interrupt Request Enable 0: Disables error detection interrupt request. 1: Enables error detection interrupt request.
1	FRCIE	Successful Response/Wake-up Reception Interrupt Request Enable 0: Disables successful Response/wake-up reception interrupt request. 1: Enables successful Response/wake-up reception interrupt request.
0	FTCIE	Successful Response/Wake-up Transmission Interrupt Request Enable 0: Disables successful Response/wake-up transmission interrupt request. 1: Enables successful Response/wake-up transmission interrupt request.

Set the RLN3nLIE register when the OMM0 bit in the RLN3nLMST register is 0_B (LIN reset mode).

SHIE Bit (Successful Header Reception Interrupt Request Enable)

The SHIE bit enables or disables an interrupt request upon successful reception of a header.
With 0 set, the interrupt request for RLIN3n reception complete is not generated when the HTRC flag in the RLN3nLST register is set to 1.
With 1 set, the interrupt request for RLIN3n reception complete is generated when the HTRC flag in the RLN3nLST register is set to 1.

ERRIE Bit (Error Detection Interrupt Request Enable)

The ERRIE bit enables or disables an interrupt request upon detection of an error.
With 0 set, the interrupt request for RLIN3n status is not generated when the ERR flag in the RLN3nLST register is set to 1.
With 1 set, the interrupt request for RLIN3n status is generated when the ERR flag in the RLN3nLST register is set to 1.
Error types that are interrupt sources are the bit error, frame/response timeout error, framing error, sync filed error, ID parity error, checksum error, and response preparation error.
Detection of the bit error, frame/response timeout error, sync filed error, ID parity error, and framing error can be enabled or disabled using the RLN3nLEDE register.

FRCIE Bit (Successful Response/Wake-up Reception Interrupt Request Enable)

The FRCIE bit enables or disables an interrupt request upon successful reception of a response or a wake-up frame (input signal low-level width count).

With 0 set, the interrupt request for successful RLIN3n reception is not generated when the FRC flag in the RLN3nLST register is set to 1.
With 1 set, the interrupt request for successful RLIN3n reception is generated when the FRC flag in the RLN3nLST register is set to 1.

FTCIE Bit (Successful Response/Wake-up Transmission Interrupt Request Enable)

The FTCIE bit enables or disables an interrupt request upon successful transmission of a response or a wake-up frame.
With 0 set, the interrupt request for successful RLIN3n transmission is not generated when the FTC flag in the RLN3nLST register is set to 1.
With 1 set, the interrupt request for successful RLIN3n transmission is generated when the FTC flag in the RLN3nLST register is set to 1.

21.3.3.9 RLN3nLEDE — LIN Error Detection Enable Register

Access: This register can be read or written in 8-bit units.

Address: <RLIN3n_base> + $0D_H$

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	LTES	IPERE	—	SFERE	FERE	TERE	—	BERE
Value after reset	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R	R/W	R/W	R/W	R	R/W

Table 21.39 RLN3nLEDE Register Contents

Bit Position	Bit Name	Function
7	LTES	Timeout Error Select 0: Frame timeout error 1: Response timeout error
6	IPERE	ID Parity Error Detection Enable 0: Disables ID Parity error detection. 1: Enables ID Parity error detection.
5	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
4	SFERE	Sync Field Error Detection Enable 0: Disables Sync Field error detection. 1: Enables Sync Field error detection.
3	FERE	Framing Error Detection Enable*1 0: Disables framing error detection. 1: Enables framing error detection.
2	TERE	Timeout Error Detection Enable 0: Disables frame/response timeout error detection. 1: Enables frame/response timeout error detection.
1	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
0	BERE	Bit Error Detection Enable*1 0: Disables bit error detection. 1: Enables bit error detection.

Note 1. Set FERE bit and BERE bit to 1.

Set the RLN3nLEDE register when the OMM0 bit in the RLN3nLMST register is 0_B (LIN reset mode).

LTES Bit (Timeout Error Select)

The LTES bit selects the timeout function to be used.
With 0 set, the timeout function operates as frame timeout.
With 1 set, the timeout function operates as response timeout.
For details on the timeout error, see **Section 21.4.4.7, Error Status**.

IPERE Bit (ID Parity Error Detection Enable)

This bit enables or disables detection of the ID parity error.
With 0 set, the ID parity error is not detected.
With 1 set, the ID parity error is detected.
When this bit is set to 1, the detection result is reflected in the IPER flag in the RLN3nLEST register.
For details on the ID parity error, see **Section 21.4.4.7, Error Status**.

SFERE Bit (Sync Field Error Detection Enable)

This bit enables or disables detection of the sync field error.
With 0 set, the sync field error is not detected.
With 1 set, the sync field error is detected.
Regardless of the setting of this bit, when a sync field error is detected, this module waits for the next header.
When this bit is set to 1, the detection result is reflected in the SFER flag in the RLN3nLEST register.
For details on the sync filed error, see **Section 21.4.4.7, Error Status**.

FERE Bit (Framing Error Detection Enable)

The FERE bit enables or disables detection of the framing error.
With 0 set, the framing error is not detected.
With 1 set, the framing error is detected.
Set this bit to 1. The detection result of the framing error is indicated in the FER flag in the RLN3nLEST register.
For details on the framing error, see **Section 21.4.4.7, Error Status**.

TERE Bit (Timeout Error Detection Enable)

The TERE bit enables or disables detection of the frame timeout error or the response timeout error.
With 0 set, the frame timeout error or response timeout error is not detected.
With 1 set, the frame timeout error or response timeout error is detected.
When this bit is set to 1, the detection result is reflected in the TER flag in the RLN3nLEST register.
With the LTES bit, either the frame timeout error or response timeout error can be selected.
The timeout error should not be used in LIN slave mode [auto baud rate] (when the LMD[1:0] bits in the RLN3nLMD register are "10_B").
Do not use the timeout error if response data of 9 bytes or more is to be transmitted or received.
For details on the timeout error, see **Section 21.4.4.7, Error Status**.

If RLIN3 transitions to LIN reset mode by clearing RLN3nLCUC.OM0 to 0 when the timeout function is used (RLN3nLEDE.TERE = 1), users should take the procedure shown in **Figure 21.4**.

BERE Bit (Bit Error Detection Enable)

The BERE bit enables or disables detection of the bit error.
With 0 set, the bit error is not detected.
With 1 set, the bit error is detected.
Set this bit to 1. The detection result of the bit error is indicated in the BER flag in the RLN3nLEST register.
For details on the bit error, see **Section 21.4.4.7, Error Status**.

21.3.3.10 RLN3nLCUC — LIN Control Register

Access: This register can be read or written in 8-bit units.

Address: <RLIN3n_base> + $0E_H$

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	OM1	OM0
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R/W	R/W

Table 21.40 RLN3nLCUC Register Contents

Bit Position	Bit Name	Function
7 to 2	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
1	OM1	LIN Mode Select 0: LIN wake-up mode. 1: LIN operation mode.
0	OM0	LIN Reset 0: LIN reset mode. 1: LIN reset mode is canceled.

Set the RLN3nLCUC register to 01_H to transition to LIN wake-up mode or to 03_H to transition to LIN operation mode after exiting LIN reset mode.

In LIN self-test mode, set the RLN3nLCUC register to 03_H after a transition to LIN self-test mode is completed.

After a value is written to this register, confirm that the value written is actually indicated in the RLN3nLMST register before writing another value.

OM1 Bit (LIN Mode Select)

The OM1 bit selects the specific LIN operation mode (either LIN wake-up mode or LIN operation mode) after canceling LIN reset mode.
With 0 set, LIN/UART interface enters LIN wake-up mode.
With 1 set, LIN/UART interface enters LIN operation mode.
This bit is valid only when the OMM0 bit in the RLN3nLMST register is 1.
Writing a value to this bit is disabled while the FTS bit in the RLN3nLTRC register is 1.

OM0 Bit (LIN Reset)

The OM0 bit selects either causing a transition to LIN reset mode or canceling LIN reset mode.
With 0 set, LIN/UART interface enters LIN reset mode.
With 1 set, LIN reset mode of LIN/UART interface is canceled.

If RLIN3 transitions to LIN reset mode by clearing RLN3nLCUC.OM0 to 0 when the timeout function is used (RLN3nLEDE.TERE = 1), users should take the procedure shown in **Figure 21.4**.

21.3.3.11 RLN3nLTRC — LIN Transmission Control Register

Access: This register can be read or written in 8-bit units.

Address: <RLIN3n_base> + 10_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	LNRR	RTS	FTS
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R/W	R/W	R/W

Table 21.41 RLN3nLTRC Register Contents

Bit Position	Bit Name	Function
7 to 3	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
2	LNRR	No LIN Response Request 0: Response for the reception ID 1: No response for the reception ID
1	RTS	Response Transmission/Reception Start 0: Response transmission/reception is stopped. 1: Response transmission/reception is started.
0	FTS	LIN Communication Start 0: Header reception/wake-up transmission/reception is stopped. 1: Header reception/wake-up transmission/reception is started.

LNRR Bit (No LIN Response Request)

Set this bit to 1 if no response is to be transmitted/received after receiving the header and checking the received ID.
Once set, this bit is automatically cleared to 0 upon detection of new sync field or transition to LIN reset mode.
Only 1 can be written to this bit; 0 cannot be written.
To write 1 to this bit, write 04_H using the store instruction.
Do not set this bit and the RTS bit to 1 simultaneously.
Writing a value to this bit is disabled when the OMM0 bit of the RLN3nLMST register is 0_B (LIN reset mode).
Writing a value to this bit is disabled when the FTS bit is 0 (header reception or wake-up transmission/reception is halted).
When response data of 9 bytes or more is to be transmitted or received, use this bit only after the completion of the header. (Do not use this bit for the second or later data group.)

RTS Bit (Response Transmission/Reception Start)

Set this bit to 1 to start response transmission or reception after receiving the header and checking the received ID.
Once set, this bit is automatically cleared to 0 upon completion of response transmission or reception (including error detection) or transition to LIN reset mode.
Only 1 can be written to this bit; 0 cannot be written.
To write 1 to this bit, write 02_H to the RLN3nLTRC register using the store instruction.
Do not set this bit and the LNRR bit to 1 simultaneously
Writing a value to this bit is disabled when the OMM0 bit of the RLN3nLMST register is 0_B (LIN reset mode).

Writing a value to this bit is disabled when the FTS bit is 0 (header reception or wake-up transmission/reception is halted).
When response data of 9 bytes or more is to be transmitted or received, set this bit to 1 each time a data group (variable from 0 to 8 bytes) is transmitted or received. Once set, this bit is automatically cleared to 0 upon completion of data group transmission/reception or transition to LIN reset mode.

FTS Bit (LIN Communication Start)

Set this bit to 1 to start header reception or wake-up transmission/reception.
Only 1 can be written to this bit; 0 cannot be written.
Writing a value to this bit is disabled when the OMM0 bit of the RLN3nLMST register is 0_B (LIN reset mode).

This bit is set to 0 upon completion of wake-up communication and transition to LIN reset mode.

21.3.3.12 RLN3nLMST — LIN Mode Status Register

Access: This register is a read-only register that can be read in 8-bit units.

Address: <RLIN3n_base> +11_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	OMM1	OMM0
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R

Table 21.42 RLN3nLMST Register Contents

Bit Position	Bit Name	Function
7 to 2	Reserved	When read, the value after reset is returned.
1	OMM1	LIN Mode Status Monitor 0: LIN wake-up mode. 1: LIN operation mode.
0	OMM0	LIN Reset Status Monitor 0: LIN reset mode. 1: Not in LIN reset mode.

OMM1 Bit (LIN Mode Status Monitor)

The OMM1 bit indicates the current operating mode.

OMM0 Bit (LIN Reset Status Monitor)

The OMM0 bit indicates the current operating mode.

21.3.3.13 RLN3nLST — LIN Status Register

Access: This register can be read or written in 8-bit units.

Address: <RLIN3n_base> + 12_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	HTRC	D1RC	—	—	ERR	—	FRC	FTC
Value after reset	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R	R	R	R	R/W	R/W

Table 21.43 RLN3nLST Register Contents

Bit Position	Bit Name	Function
7	HTRC	Successful Header Reception Flag 0: Header reception has not been completed. 1: Header reception has been completed.
6	D1RC	Successful Data 1 Reception Flag 0: Data 1 reception has not been completed. 1: Data 1 reception has been completed.
5, 4	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
3	ERR	Error Detection Flag 0: No error has been detected. 1: Error has been detected.
2	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
1	FRC	Successful Response/Wake-up Reception Flag 0: Response or wake-up reception has not been completed. 1: Response or wake-up reception has been completed.
0	FTC	Successful Response/Wake-up Transmission Flag 0: Response or wake-up transmission has not been completed. 1: Response or wake-up transmission has been completed.

The RLN3nLST register is automatically cleared to 00_H upon transition to LIN reset mode.

In LIN reset mode, writing a value to this register is disabled. In LIN reset mode, the register retains 00_H.

To clear the specific bits in the register, write 0 to the bits to be cleared and write 1 to the other bits using the store instruction.

HTRC Flag (Successful Header Reception Flag)

Only 0 can be written to the HTRC flag; when 1 is written, the bit retains the value before 1 is written. The HTRC flag is set to 1 upon completion of header reception. Here, an interrupt request for RLIN3n successful reception is generated if the SHIE bit in the RLN3nLIE register is 1 (interrupt is enabled). However, if header reception is completed while this bit is 1, an interrupt is not generated. To clear this bit to 0, write 0 to the bit.
To detect a new header in the response field upon completion of header reception, clear this bit after it is set to 1.

D1RC Flag (Successful Data 1 Reception Flag)

Only 0 can be written to the D1RC flag; when 1 is written, the bit retains the value that has been retained before 1 is written.

The D1RC flag is set to 1 upon completion of data 1 reception. Here, an interrupt request is not generated. Write 0 to clear this bit.
When response data of 9 bytes or more is to be received, this bit is set to 1 each time data 1 of a data group (variable from 0 to 8 bytes) is received. Write 0 before starting reception of the next data group.

ERR Flag (Error Detection Flag)

The ERR flag is set to 1 upon detection of an error (when at least one of the flags of the RLN3nLEST register is set to 1). Here, an interrupt request for RLIN3n status is generated if the ERRIE bit in the RLN3nLIE register is 1 (interrupt is enabled). However, if an error is detected while this bit is 1, an interrupt is not generated. To clear the ERR flag to 0, write 0 to the RPER, IPER, CSER, SFER, FER, TER, and BER flags in the RLN3nLEST register. This clears the ERR flag to 0.

FRC Flag (Successful Response/Wake-up Reception Flag)

Only 0 can be written to the FRC flag; when 1 is written, the bit retains the value that has been retained before 1 is written.
The FRC flag is set to 1 upon completion of response or wake-up reception. Here, an interrupt request for successful RLIN3n reception is generated if the FRCIE bit in the RLN3nLIE register is 1 (interrupt is enabled). However, if response reception or wake-up reception is completed while this bit is 1, an interrupt is not generated. Write 0 to clear this bit.
When response data of 9 bytes or more is to be received, this bit is set to 1 each time a data group (variable from 0 to 8 bytes) is received. Write 0 before starting reception of the next data group.

FTC Flag (Successful Response/Wake-up Transmission Flag)

Only 0 can be written to the FTC flag; when 1 is written, the bit retains the value that has been retained before 1 is written.
The FTC flag is set to 1 upon completion of response or wake-up transmission. Here, an interrupt request for RLIN3n transmission is generated if the FTCIE bit in the RLN3nLIE register is 1 (interrupt is enabled). However, if response transmission or wake-up transmission is completed while this bit is 1, an interrupt is not generated. Write 0 to clear this bit.
When response data of 9 bytes or more is to be transmitted, this bit is set to 1 each time a data group (variable from 0 to 8 bytes) is transmitted. Write 0 before starting transmission of the next data group.

21.3.3.14 RLN3nLEST — LIN Error Status Register

Access: This register can be read or written in 8-bit units.

Address: <RLIN3n_base> + 13_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	RPER	IPER	CSER	SFER	FER	TER	—	BER
Value after reset	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R/W

Table 21.44 RLN3nLEST Register Contents

Bit Position	Bit Name	Function
7	RPER	Response Preparation Error Flag 0: Response preparation error has not been detected. 1: Response preparation error has been detected.
6	IPER	ID Parity Error Flag 0: ID parity error has not been detected. 1: ID parity error has been detected.
5	CSER	Checksum Error Flag 0: Checksum error has not been detected. 1: Checksum error has been detected.
4	SFER	Sync Field Error Flag 0: Sync field error has not been detected. 1: Sync field error has been detected.
3	FER	Framing Error Flag 0: Framing error has not been detected. 1: Framing error has been detected.
2	TER	Timeout Error Flag 0: Frame/response timeout error has not been detected. 1: Frame/response timeout error has been detected.
1	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
0	BER	Bit Error Flag 0: Bit error has not been detected. 1: Bit error has been detected.

The RLN3nLEST register is automatically cleared to 00_H upon transition to LIN reset mode.

In LIN reset mode, this register cannot be written to. In LIN reset mode, the register retains 00_H.

To clear the specific bits in the register, write 0 to the bits to be cleared and write 1 to the other bits using the store instruction.

RPER Flag (Response Preparation Error Flag)

Only 0 can be written to the RPER flag; when 1 is written, the bit retains the value that has been retained before 1 is written.

The RPER flag is set to 1 upon response preparation error detection. Write 0 to clear this bit.

IPER Flag (ID Parity Error Flag)

Only 0 can be written to this flag; when 1 is written, the bit retains the value that has been retained before 1 is written.

When the IPERE bit of the RLN3nLEDE register is 1 (ID parity error detection enabled), this bit is set to 1 upon ID parity error detection. Write 0 to clear this bit.

CSER Flag (Checksum Error Flag)

Only 0 can be written to the CSER flag; when 1 is written, the bit retains the value that has been retained before 1 is written.
The CSER flag is set to 1 upon checksum error detection. Write 0 to clear this bit.

SFER Flag (Sync Field Error Flag)

Only 0 can be written to this flag; when 1 is written, the bit retains the value that has been retained before 1 is written.
When the SFERE bit of the RLN3nLEDE register is 1 (sync field error detection enabled), this bit is set to 1 upon sync field error detection. Write 0 to clear this bit.

FER Flag (Framing Error Flag)

Only 0 can be written to the FER flag; when 1 is written, the bit retains the value that has been retained before 1 is written.
When the FERE bit of the RLN3nLEDE register is 1 (framing error detection enabled), the FER flag is set to 1 upon framing error detection. Write 0 to clear this bit.

TER Flag (Timeout Error Flag)

Only 0 can be written to the TER flag; when 1 is written, the bit retains the value that has been retained before 1 is written.
When the TERE bit of the RLN3nLEDE register is 1 (frame/response timeout error detection enabled), this flag is set to 1 upon frame timeout error or response timeout error detection. Write 0 to clear this bit.

BER Flag (Bit Error Flag)

Only 0 can be written to the BER flag; when 1 is written, the bit retains the value that has been retained before 1 is written.
When the BERE bit of the RLN3nLEDE register is 1 (bit error detection enabled), the BER flag is set to 1 upon bit error detection. Write 0 to clear this bit.

21.3.3.15 RLN3nLDFC — LIN Data Field Configuration Register

Access: This register can be read or written in 8-bit units.

Address: <RLIN3n_base> + 14_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	LSS	—	LCS	RCDS	RFDL[3:0]			
Value after reset	0	0	0	0	0	0	0	0
R/W	R/W	R	R/W	R/W	R/W	R/W	R/W	R/W

Table 21.45 RLN3nLDFC Register Contents

Bit Position	Bit Name	Function
7	LSS	Transmission/Reception Continuation Select 0: The data group to be transmitted/received next is the last one. 1: The data group to be transmitted/received next is not the last one. (Data transmission/reception continues without waiting for reception of the next header.)
6	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
5	LCS	Checksum Select 0: Classic checksum mode 1: Enhanced checksum mode
4	RCDS	Response Field Communication Direction Select 0: Reception 1: Transmission
3 to 0	RFDL[3:0]	Response Field Length Select b3 b0 0 0 0 0: 0 byte (+ checksum) 0 0 0 1: 1 byte (+ checksum) 0 0 1 0: 2 bytes (+ checksum) : 0 1 1 1: 7 bytes (+ checksum) 1 0 0 0: 8 bytes (+ checksum) Settings other than the above are prohibited.

LSS Bit (Transmission/Reception Continuation Select)

The LSS bit indicates that the data group to be transmitted or received next is not the last data group when response data of 9 bytes or more is to be transmitted or received. With 0 set, data and checksum are transmitted or received because the next data group to be transmitted or received is the last one. With 1 set, only data is transmitted or received, and the checksum is not included because the next data group to be transmitted or received is not the last one.
When multi-byte response transmission/reception function is not used, set this bit to “0”.
Set this bit when the RTS bit is 0 (response transmission/reception stopped).

LCS Bit (Checksum Select)

The LCS bit sets the checksum mode.
With 0 set, classic checksum mode is selected.
With 1 set, enhanced checksum mode is selected.
When the timeout error is used (the TERE bit in the RLN3nLEDE register is 1), the specific timeout time depends on the setting of this bit. For details on the bit error, see **Section 21.4.4.7, Error Status**.
When the length of the response field data is 0 bytes (the RFDL bit is 0), do not set this bit to “1”

(enhanced).
When response data of 9 bytes or more is to be transmitted or received, do not change the LCS bit setting after the first data group through the last data group.
During transmission or reception of response data of 9 bytes or more, only the last data group (the LSS bit is 0) includes the checksum, and no other groups (the LSS bit is 1) include the checksum.
Set this bit when the RTS bit is 0 (response transmission/reception stopped).

RCDS Bit (Response Field Communication Direction Select)

This bit selects the direction of the response field/wake-up signal communication.
With 0 set, reception is performed in the response field. In LIN wake-up mode, wake-up reception is performed (input signal low-level width count).
With 1 set, transmission is performed in the response field. In LIN wake-up mode, wake-up transmission is performed.
Set this bit when the RTS bit in the RLN3nLTRC register is 0 in LIN operation mode (response transmission/reception stopped) or when the FTS bit is 0 in LIN wake-up mode (header reception or wake-up transmission/reception stopped).
When response data of 9 bytes or more is to be transmitted or received, do not change this bit setting after the first data group through the last data group.

RFDL[3:0] Bits (Response Field Length Select)

The RFDL bits set the length of the response field data.
The data length can be 0 to 8 bytes excluding the checksum size.
Set these bits when the RTS bit in the RLN3nLTRC register is 0 (response transmission/reception stopped).
When response data of 9 bytes or more is to be transmitted or received, only the last data group (the LSS bit is 0) includes the checksum, and no other groups (the LSS bit in the RLN3nLDFC register is 1) include the checksum.

21.3.3.16 RLN3nLIDB — LIN ID Buffer Register

Access: This register can be read or written in 8-bit units.

Address: <RLIN3n_base> + 15_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	IDP1	IDP0	ID[5:0]					
Value after reset	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 21.46 RLN3nLIDB Register Contents

Bit Position	Bit Name	Function
7, 6	IDP[1:0]	Parity Setting Stores the parity bits (P0 and P1) received in the ID field.
5 to 0	ID[5:0]	ID Setting Stores the 6-bit ID value received in the ID field.

The value in the RLN3nLIDB register is enabled after the completion of header reception. In LIN mode (LIN operation mode, LIN wake-up mode), writing to this register is disabled.

In LIN self-test mode, the operation is as follows.

Write the value to be transmitted before communication. After completion of frame transmission/ reception (after loopback), the reversed value of the received value can be read.

For details about the LIN self-test mode, see **Section 21.4.6, LIN Self-Test Mode**.

IDP[1:0] Bits (Parity Setting)

The IDP bits store the parity bits (P0 and P1) received in the ID field of the LIN frame. IDP0 is for P0 and IDP1 is for P1.

When the IPERE bit in the RLN3nLEDE register is 1 (ID parity detection enabled), the received value and the value calculated internally are checked. If they do not match, IPER (ID parity error flag) is set.

ID[5:0] Bits (ID Setting)

The ID bits store the 6-bit ID value received in the ID field of the LIN frame.

21.3.3.17 RLN3nLCBR — LIN Checksum Buffer Register

Access: This register is a read-only register that can be read in 8-bit units. However, in LIN self-test mode, this register can be read and written in 8-bit units.

Address: <RLIN3n_base> + 16_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	CKSM[7:0]							
Value after reset	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 21.47 RLN3nLCBR Register Contents

Bit Position	Bit Name	Function
7 to 0	CKSM[7:0]	Holds the transmitted or received checksum data.

In LIN operation mode, this register operates as follows:

- When the RCDS bit in the RLN3nLDFC register is 1 (transmission):
  The value transmitted can be read from the register. Read the value after transmission is completed.
  Writing to this register is invalid.
- When the RCDS bit in the RLN3nLDFC register is 0 (reception):
  The value received can be read from the register. Read the value after reception is completed.
  Writing to this register is invalid.

When response data of 9 bytes or more is to be transmitted or received, the checksum is appended only to the last data group; this register is not updated for the other data groups.

In LIN self-test mode, this register operates as follows:

- When the RCDS bit in the RLN3nLDFC register is 1 (transmission):
  After completion of the frame transmission (after loopback), the reversed value of the received value can be read.
- When the RCDS bit in the RLN3nLDFC register is 0 (reception):
  Write the value to be received before communication. After completion of frame transmission/reception (after loopback), the reversed value of the received value can be read.

For details about the LIN self-test mode, see **Section 21.4.6, LIN Self-Test Mode**.

Set the RLN3nLCBR register when the FTS bit in the RLN3nLTRC register is 0 (frame transmission or wake-up transmission/reception is halted).

21.3.3.18 RLN3nLDBRb — LIN Data Buffer b Register (b = 1 to 8)

Access: This register can be read or written in 8-bit units.

Address: RLN3nLDBR1: <RLIN3n_base> + 18_H
RLN3nLDBR2: <RLIN3n_base> + 19_H
RLN3nLDBR3: <RLIN3n_base> + $1A_H$
RLN3nLDBR4: <RLIN3n_base> + $1B_H$
RLN3nLDBR5: <RLIN3n_base> + $1C_H$
RLN3nLDBR6: <RLIN3n_base> + $1D_H$
RLN3nLDBR7: <RLIN3n_base> + $1E_H$
RLN3nLDBR8: <RLIN3n_base> + $1F_H$

Value after reset: 00_H

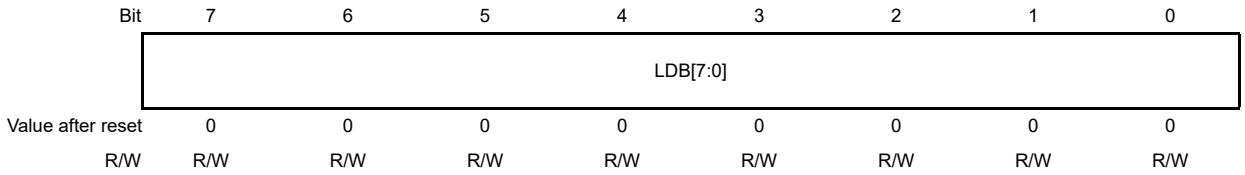

Table 21.48 RLN3nLDBRb Register Contents

Bit Position	Bit Name	Function
7 to 0	LDB[7:0]	Sets the data to be transmitted or holds the received data. Setting range: 00_H to FF_H

- For response transmission:
  The RLN3nLDBRb registers set the data to be transmitted in the response field.
  Set these registers when the RTS bit in the RLN3nLTRC register is 0 (response transmission/reception is halted).
- For response reception:
  The RLN3nLDBRb registers hold the data received in the response field.
  The received data is overwritten. If an error is detected, the data up to the byte in which the error was detected are stored in the register.
  Do not read these registers when the RTS bit is 1 (response transmission/reception is started)

In LIN self-test mode, the operation is as follows.

Write the value to be transmitted before communication. After completion of frame transmission/reception (after loopback), the reversed value of the received value can be read.

For details about the LIN self-test mode, see **Section 21.4.6, LIN Self-Test Mode**.

21.3.3.19 RLN3nLBSS — LIN Slave Break/Sync Field Status Register

Access: This register can be read or written in 8-bit units.

Address: <RLIN3n_base> + 30_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	SYCC	BRKC
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R/W	R/W

Table 21.49 RLN3nLBSS Register Contents

Bit Position	Bit Name	Function
7 to 2	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
1	SYCC	LIN Sync Field Reception Flag 0: LIN Sync Field Rx not completed 1: LIN Sync Field Rx completed successfully
0	BRKC	LIN Break Field Reception Flag 0: LIN Break Field Rx not completed 1: LIN Break Field Rx completed successfully

The RLN3nLBSS register is automatically cleared to 00_H upon transition to LIN reset mode.

In LIN reset mode, this register cannot be written to. In LIN reset mode, the register retains 00_H.

To clear the specific bits in the register, write 0 to the bits to be cleared and write 1 to the other bits using the store instruction.

BRKC Bit (LIN Break Field Reception Flag)

Only 0 can be written to the BRKC Bit; when 1 is written, the bit retains the value that has been retained before 1 is written.

Users can not write to this bit if the OMM0 bit in the RLN3nLMST register is 0_B (LIN reset mode).

This bit is cleared by writing “0” to it.

The BRKC bit is cleared when RLIN3 module is transitioning to the reset mode.

This bit is set when Break field is successfully reception in LIN Slave mode.

Users should use this bit only for the re-transmission of a wake-up signal. (Refer to **Section 21.4.4.9, Wake-up Processing for Retransmission in LIN Slave Mode**)

SYCC Bit (LIN Sync Field Reception Flag)

Only 0 can be written to the SYCC Bit; when 1 is written, the bit retains the value that has been retained before 1 is written.

Users can not write to this bit if the OMM0 bit in the RLN3nLMST register is 0_B (LIN reset mode).

This bit is cleared by writing “0” to it.

The SYCC bit is cleared when RLIN3 module is transitioning to the reset mode.

This bit is set when Sync field is successfully reception in LIN Slave mode.

Users should use this bit only for the re-transmission of a wake-up signal. (Refer to **Section 21.4.4.9, Wake-up Processing for Retransmission in LIN Slave Mode**)

21.3.3.20 RLN3nLRSS — LIN Slave Response Space Status Register

Access: This register is a read-only register that can be read in 8-bit units.

Address: <RLIN3n_base> + 34_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	RSDD
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R

Table 21.50 RLN3nLRSS Register Contents

Bit Position	Bit Name	Function
7 to 1	Reserved	When read, the value after reset is returned.
0	RSDD	Response Space Dominant Detection Flag 0: No dominant detected. 1: Dominant detected.

RSDD Bit (Response Space Dominant Detection Flag)

Users can not write to this bit.

This bit is valid only for LIN response transmission in LIN slave mode.

This bit is invalid when a bit error is occurred in the transmission of the response space.

This bit is cleared when Sync field is received.

This bit is cleared when RLIN3 module is transitioning to the reset mode.

This bit is set when a dominant level of 0.5 Tbit or more is detected from the completion of the header reception (the stop bit of the ID field) to the start of transmission*1 in LIN slave mode, the operation is continued.

Note 1. When RLN3nLSC.IBHS = 0_H, it is the transmission of the start bit of the 1st Data byte.
When RLN3nLSC.IBHS = 1 to 7_H, it is the transmission of the response space.

21.3.4 UART Related Registers

21.3.4.1 RLN3nLWBR — UART Wake-Up Baud Rate Select Register

Access: This register can be read or written in 8-bit units.

Address: <RLIN3n_base> + 01_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	NSPB[3:0]				LPRS[2:0]			—
Value after reset	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R

Table 21.51 RLN3nLWBR Register Contents

Bit Position	Bit Name	Function
7 to 4	NSPB[3:0]	Bit Sampling Count Select b7 b4 0 0 0 0: 16 samplings 0 1 0 1: 6 samplings 0 1 1 0: 7 samplings 0 1 1 1: 8 samplings 1 0 0 0: 9 samplings 1 0 0 1: 10 samplings 1 0 1 0: 11 samplings 1 0 1 1: 12 samplings 1 1 0 0: 13 samplings 1 1 0 1: 14 samplings 1 1 1 0: 15 samplings 1 1 1 1: 16 samplings Settings other than the above are prohibited.
3 to 1	LPRS[2:0]	Prescaler Clock Select b3 b1 0 0 0: 1/1 0 0 1: 1/2 0 1 0: 1/4 0 1 1: 1/8 1 0 0: 1/16 1 0 1: 1/32 1 1 0: 1/64 1 1 1: 1/128
0	Reserved	When read, the value after reset is returned. When writing, write the value after reset.

Set the RLN3nLWBR register when the OMM0 bit in the RLN3nLMST register is 0_B (LIN reset mode).

NSPB[3:0] Bits (Bit Sampling Count Select)

The NSPB bits select the number of sampling in one Tbit (reciprocal of the baud rate).
In UART mode, it is possible to set the NSPB bits from 6 samplings to 16 samplings.

LPRS[2:0] Bits (Prescaler Clock Select)

The LPRS bits select the frequency division ratio for the prescaler.
The LIN communication clock source is divided by this prescaler.

21.3.4.2 RLN3nLBRP01 — UART Baud Rate Prescaler 01 Register

Access: RLN3nLBRP01 register can be read or written in 16-bit units.
RLN3nLBRP0 register can be read or written in 8-bit units.
RLN3nLBRP1 register can be read or written in 8-bit units.

Address: RLN3nLBRP01: <RLIN3n_base> + 02_H
RLN3nLBRP0: <RLIN3n_base> + 02_H
RLN3nLBRP1: <RLIN3n_base> + 03_H

Value after reset: 0000_H

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	BRP[15:0]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 21.52 RLN3nLBRP01 Register Contents

Bit Position	Bit Name	Function
15 to 0	BRP[15:0]	Assuming that the value set in this register is L (0 to 65535), the baud rate prescaler divides the frequency of the prescaler clock by L + 1. Setting range: 0000_H to $FFFF_H$

Set the RLN3nLBRP01 register when the OMM0 bit in the RLN3nLMST register is 0_B (LIN reset mode).

Assuming that the value set in this register is L, the baud rate prescaler divides the frequency of the clock that is selected by the LPRS bits (prescaler clock select bits) in the RLN3nLWBR register by L + 1.

The RLN3nLBRP01 register can be accessed in 8-bit units by the registers RLN3nLBRP0 and RLN3nLBRP1.

21.3.4.3 RLN3nLMD — UART Mode Register

Access: This register can be read or written in 8-bit units.

Address: <RLIN3n_base> + 08_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	LRDNFS	—	—	—	LMD[1:0]	
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R/W	R	R	R	R/W	R/W

Table 21.53 RLN3nLMD Register Contents

Bit Position	Bit Name	Function
7, 6	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
5	LRDNFS	UART Reception Data Noise Filter Disable 0: The noise filter is enabled. 1: The noise filter is disabled.
4 to 2	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
1, 0	LMD[1:0]	LIN/UART Mode Select b1 b0 0 1: UART mode

Set the RLN3nLMD register when the OMM0 bit in the RLN3nLMST register is 0_B (LIN reset mode).

LRDNFS Bit (UART Reception Data Noise Filter Disable)

The LRDNFS bit enables or disables the noise filter when receiving data.
With 0 set, the noise filter is enabled when receiving data.
With 1 set, the noise filter is disabled when receiving data.

LMD[1:0] Bits (LIN/UART Mode Select)

The LMD bits select the LIN/UART interface mode.
To use the LIN/UART interface as an UART, set these bits to 01_B.

21.3.4.4 RLN3nLBFC — UART Configuration Register

Access: This register can be read or written in 8-bit units.

Address: <RLIN3n_base> + 09_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	UTPS	URPS	UPS[1:0]		USBLS	UBOS	UBLS
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 21.54 RLN3nLBFC Register Contents

Bit Position	Bit Name	Function
7	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
6	UTPS	UART Output Polarity Switch 0: Transmit data normal output 1: Transmit data with inverted output
5	URPS	UART Input Polarity Switch 0: Reception data normal input 1: Reception data inverted input
4, 3	UPS[1:0]	UART Parity Select 00: Parity disabled 01: Even parity 10: 0 Parity 11: Odd parity
2	USBLS	UART Stop Bit length Select 0: Stop bit: 1 bit 1: Stop bit: 2 bits
1	UBOS	UART Transfer Format Order Select 0: LSB First 1: MSB First
0	UBLS	UART Character Length Select 0: UART 8 bits communication 1: UART 7 bits communication

Set the RLN3nLBFC register when the OMM0 bit in the RLN3nLMST register is 0_B (LIN reset mode).

UTPS Bit (UART Output Polarity Switch)

Sets the output polarity for UART communication.
With 0 set, transmit data is output without inversion.
With 1 set, inverted transmit data is output.
The setting of this bit is valid for all the bits of the UART frame.
In half-duplex communication, this setting should match the setting of URPS bit.

URPS Bit (UART Input Polarity Switch)

Sets the input polarity for UART communication.
With 0 set, receive data is input without inversion.
With 1 set, receive data is input with inversion.
The setting of this bit is valid for all the bits of the UART frame.
In half-duplex communication, this setting should match the setting of UTPS bit.
When setting this bit to “1” and expansion bit reception ((with expansion bit comparison) or (with data comparison)) is performed, set the inverse of the expected value to the UEBDL bit in the

RLN3nLUOR1 register and RLN3nLIDB register to enable comparison of the inverted values of the received values.

UPS[1:0] Bits (UART Parity Select)

Sets the UART parity.

- When these bits are set to "00_B", data is transmitted/received without the parity.

  [Transmission]

  A parity bit is not added to transmit data.

  [Reception]

  Data is received without parity processing. Therefore, a parity error does not occur.

- When these bits are set to "01_B", data is transmitted/received with the even parity.

  [Transmission]

  If the number of 1s in transmit data is odd, "1" is added to the parity bit. If the number of 1s in transmit data is even, "0" is added to the parity bit.

  [Reception]

  If the number of 1s in receive data including the parity bit is odd, a parity error occurs.

- When these bits are set to "10_B", data is transmitted/received with 0 parity.

  [Transmission]

  Regardless of the number of 1s in transmit data, "0" is added to the parity bit.

  [Reception]

  The value of the parity bit is not judged. Therefore, no parity error occurs.

- When these bits are set to "11_B", data is transmitted/received with the odd parity.

  [Transmission]

  If the number of 1s in transmit data is odd, "0" is added to the parity bit. If the number of 1s in transmit data is even, "1" is added to the parity bit.

  [Reception]

  If the number of 1s in receive data including the parity bit is even, a parity error occurs.

USBLS Bit (UART Stop Bit Length Select)

Sets the stop bit length of data for UART communication.
With 0 set, stop bit length of 1 bit is selected.
With 1 set, stop bit length of 2 bits is selected.

UBOS Bit (UART Transfer Format Select)

Sets the bit order of data for UART communication.
With 0 set, LSB first is selected.
With 1 set, MSB first is selected.

UBLS Bit (UART Character Length Select)

Sets the character length of one frame for UART communication.
With 0 set, the character length is 8 bits.
With 1 set, the character length is 7 bits.
When the character length of one frame is 9 bits (the UEBE bit in the RLN3nLUOR1 register is 1), the setting of this bit is invalid.

21.3.4.5 RLN3nLSC — UART Space Configuration Register

Access: This register can be read or written in 8-bit units.

Address: <RLIN3n_base> + $0A_H$

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	IBS[1:0]		—	—	—	—
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R/W	R/W	R	R	R	R

Table 21.55 RLN3nLSC Register Contents

Bit Position	Bit Name	Function
7, 6	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
5, 4	IBS[1:0]	Inter-Byte Space Select b5 b4 0 0: 0 Tbit 0 1: 1 Tbit 1 0: 2 Tbits 1 1: 3 Tbits
3 to 0	Reserved	When read, the value after reset is returned. When writing, write the value after reset.

Set the RLN3nLSC register when the OMM0 bit in the RLN3nLMST register is 0_B (LIN reset mode).

IBS[1:0] Bits (Inter-Byte Space Select)

The IBS bits set the width of the space between the UART frames when transmitting data from the UART buffer. 0 to 3 Tbits can be set.
Set IBS[1:0] bits to "00_B" when UART buffer is not used.

When data is transferred from the UART transmission data register (RLN3nLUTDR) and the UART wait transmission data register (RLN3nLUWTDR), the setting of these bits is ignored. Set these bits to "00_B".

21.3.4.6 RLN3nLEDE —UART Error Detection Enable Register

Access: This register can be read or written in 8-bit units.

Address: <RLIN3n_base> + $0D_H$

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	FERE	OERE	—	BERE
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R/W	R/W	R	R/W

Table 21.56 RLN3nLEDE Register Contents

Bit Position	Bit Name	Function
7 to 4	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
3	FERE	Framing Error Detection Enable 0: Disables framing error detection. 1: Enables framing error detection.
2	OERE	Overrun Error Detection Enable 0: Disables overrun error detection. 1: Enables overrun error detection.
1	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
0	BERE	Bit Error Detection Enable 0: Disables bit error detection. 1: Enables bit error detection.

Set the RLN3nLEDE register when the OMM0 bit in the RLN3nLMST register is 0_B (LIN reset mode).

FERE Bit (Framing Error Detection Enable)

The FERE bit enables or disables detection of the framing error.
With 0 set, the framing error is not detected.
With 1 set, the framing error is detected.
When this bit is set to 1, the detection result is indicated in the FER flag in the RLN3nLEST register.
For details on the framing error, see **Section 21.4.5.5, Error Status**.

OERE Bit (Overrun Error Detection Enable)

This bit enables or disables detection of the overrun error.
With 0 set, the overrun error is not detected.
With 1 set, the overrun error is detected.
When this bit is set to 1, the detection result is reflected in the OER flag in the RLN3nLEST register.
For details on the overrun error, see **Section 21.4.5.5, Error Status**.

BERE Bit (Bit Error Detection Enable)

The BERE bit enables or disables detection of the bit error.
With 0 set, the bit error is not detected.
With 1 set, the bit error is detected.
When this bit is set to 1, the detection result is indicated in the BER flag in the RLN3nLEST register.
In full-duplex communication, do not set this bit to “1”.
Do not set this register when the NSPB bits in the RLN3nLWBR register are 0101_B (6 samplings) and the LRDNFS bit in the RLN3nLMD register is 0 (noise filtering is enabled).

For details on the bit error, see **Section 21.4.5.5, Error Status**.

21.3.4.7 RLN3nLCUC — UART Control Register

Access: This register can be read or written in 8-bit units.

Address: <RLIN3n_base> + $0E_H$

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	OM0
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R/W

Table 21.57 RLN3nLCUC Register Contents

Bit Position	Bit Name	Function
7 to 1	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
0	OM0	LIN Reset 0: LIN reset mode. 1: LIN reset mode is canceled.

After a value is written to this register, confirm that the value written is actually indicated in the RLN3nLMST register before writing another value.

OM0 Bit (LIN Reset)

The OM0 bit selects either causing a transition to reset mode or canceling reset mode.
With 0 set, reset mode.
With 1 set, reset mode is canceled.

21.3.4.8 RLN3nLTRC — UART Transmission Control Register

Access: This register can be read or written in 8-bit units.

Address: <RLIN3n_base> + 10_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	RTS	—
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R/W	R

Table 21.58 RLN3nLTRC Register Contents

Bit Position	Bit Name	Function
7 to 2	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
1	RTS	UART Buffer Transmission Start 0: UART Buffer transmission is stopped. 1: UART Buffer transmission is started.
0	Reserved	When read, the value after reset is returned. When writing, write the value after reset.

RTS Bit (UART Buffer Transmission Start)

When transmitting data from the UART buffer, set this bit to “1”.
Only 1 can be written to this bit; 0 cannot be written.
Write to this bit when the UTOE bit in the RLN3nLUOER register is 1 (transmission enabled) and the UTS bit in the RLN3nLST register is 0 (transmission is not in progress).
Once set, regardless of errors, this bit is automatically cleared to 0 upon completion of the number of data transmission specified by the MDL bit in the RLN3nLDFC register. Moreover, this bit is automatically cleared to 0 upon transition to reset mode.
Writing a value to this bit is disabled when the OMM0 bit of the RLN3nLMST register is 0_B (LIN reset mode).
When writing 1 to this bit while the UTSW bit in the RLN3nLDFC register is 1 (when UART buffer transmission is requested, the start of transmission is delayed until the stop bit of reception data is completed), write only during the reception of stop bit.

21.3.4.9 RLN3nLMST — UART Mode Status Register

Access: This register is a read-only register that can be read in 8-bit units.

Address: <RLIN3n_base> + 11_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	OMM0
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R

Table 21.59 RLN3nLMST Register Contents

Bit Position	Bit Name	Function
7 to 1	Reserved	When read, the value after reset is returned.
0	OMM0	LIN Reset Status Monitor 0: LIN reset mode. 1: Not in LIN reset mode.

OMM0 Bit (LIN Reset Status Monitor)

The OMM0 bit indicates the current operating mode.

21.3.4.10 RLN3nLST — UART Status Register

Access: This register can be read or written in 8-bit units.

Address: <RLIN3n_base> + 12_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	URS	UTS	ERR	—	—	FTC
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R/W

Table 21.60 RLN3nLST Register Contents

Bit Position	Bit Name	Function
7, 6	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
5	URS	Reception Status Flag 0: Reception is stopped. 1: Reception is started.
4	UTS	Transmission Status Flag 0: Transmission is stopped. 1: Transmission is started.
3	ERR	Error Detection Flag 0: No error has been detected. 1: Error has been detected.
2, 1	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
0	FTC	Successful UART Buffer Transmission Flag 0: UART buffer transmission has not been completed. 1: UART buffer transmission has been completed.

The RLN3nLST register is automatically cleared to "00_H" upon transition to LIN reset mode. In LIN reset mode, this register cannot be written to. In LIN reset mode, the register retains "00_H". To clear the specific bits in the register, write 0 to the bits to be cleared and write 1 to the other bits using the store instruction.

URS Flag (Reception Status Flag)

At the start of the reception, this flag is set to 1.
The reception is started under the following condition.

- When the start bit is detected

At the end of reception, this flag is cleared to 0. While reception is stopped, this flag retains 0.
The reception is ended under the following conditions.

- Sampling point of the first bit of the stop bits

UTS Flag (Transmission Status Flag)

At the start of the transmission, this flag is set to 1. During the transmission, this flag retains 1.
The transmission is started under the following conditions.

- When transmission data is set to the RLN3nLUTDR or RLN3nLUWTDR register
- When the RTS bit in the RLN3nLTRC register is set to 1

This flag is cleared to 0 at the end of transmission.
The transmission is ended under the following conditions.

- When transmission of data set in the RLN3nLUTDR or RLN3nLUWTDR register is completed and next data is not set
- When transmission from UART buffer is completed (when the RTS bit in the RLN3nLTRC register is cleared to 0)

ERR Flag (Error Detection Flag)

This flag is set to 1 upon detection of an error, detection of an expansion bit, or upon ID matching (when at least one of the flags of the RLN3nLEST register is 1). At this time, an interrupt request for RLIN3n status is generated. However, when this bit is 1, an interrupt is not generated upon detection of an error, detection of an expansion bit, or upon ID matching. To clear the bit to 0, write 0 to the UPER, IDMT, EXBT, FER, OER, and BER flags in the RLN3nLEST register.

FTC Flag (Successful UART Buffer Transmission Flag)

Only 0 can be written to the FTC flag; when 1 is written, the bit retains the value that it was before 1 was written.
Regardless of errors, this bit is set to 1 upon completion of transmission of the number of data specified by the MDL bit in the RLN3nLDFC register from the UART buffer. At this time, an interrupt request for RLIN3n transmission is generated. Write 0 to clear this flag.

21.3.4.11 RLN3nLEST — UART Error Status Register

Access: This register can be read or written in 8-bit units.

Address: <RLIN3n_base> + 13_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	UPER	IDMT	EXBT	FER	OER	—	BER
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R/W	R/W	R/W	R/W	R/W	R	R/W

Table 21.61 RLN3nLEST Register Contents

Bit Position	Bit Name	Function
7	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
6	UPER	Parity Error Flag 0: Parity error has not been detected. 1: Parity error has been detected.
5	IDMT	ID Match Flag 0: The receive data does not match the ID value. 1: The receive data matches the ID value.
4	EXBT	Expansion Bit Detection Flag 0: Expansion bit has not been detected. 1: Expansion bit has been detected.
3	FER	Framing Error Flag 0: Framing error has not been detected. 1: Framing error has been detected.
2	OER	Overrun Error Flag 0: Overrun error has not been detected. 1: Overrun error has been detected.
1	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
0	BER	Bit Error Flag 0: Bit error has not been detected. 1: Bit error has been detected.

The RLN3nLEST register is automatically cleared to 00_H upon transition to LIN reset mode. In LIN reset mode, this register cannot be written to, and the value of 00_H is retained. To clear certain bits in this register, write 0 to those bits, and write 1 to the bits not to be cleared by using the store instruction.

UPER Flag (Parity Error Flag)

Only 0 can be written to this flag; when 1 is written, the bit retains the value it had before 1 is written. This flag is set to 1 upon parity error detection. Write 0 to clear this flag.

IDMT Flag (ID Match Flag)

Only 0 can be written to this flag; when 1 is written, the bit retains the value it had before 1 is written.

The IDMT flag is set to 1 when all the following conditions are met:

- The UEBE bit in the RLN3nLUOR1 register is 1 (expansion bit enabled)
- The UECD bit in the RLN3nLUOR1 register is 0 (expansion bit comparison enabled)
- The UEBDCE bit in the RLN3nLUOR1 register is 1 (expansion bit/data comparison enabled)

– The received expansion bit and the value of the UEBDL bit of the RLN3nLUOR1 register match.
– The 8-bit receive data excluding the expansion bit and the value of the RLN3nLIDB register match.

Write 0 to clear this flag.

EXBT Flag (Expansion Bit Detection Flag)

Only 0 can be written to this flag; when 1 is written, the bit retains the value it had before 1 is written.
When the UEBE bit in the RLN3nLUOR1 register is 1 (expansion bit enable), if the received expansion bit matches with the UEBDL bit in the RLN3nLUOR1 register, this flag is set to 1.
Write 0 to clear this flag.

FER Flag (Framing Error Flag)

Only 0 can be written to this flag; when 1 is written, the bit retains the value it had before 1 is written.
The FER flag is set to 1 upon framing error detection while the FERE bit of the RLN3nLEDE register is 1 (framing error detection enabled).
Write 0 to clear this flag.

OER Flag (Overrun Error Flag)

Only 0 can be written to this flag; when 1 is written, the bit retains the value it had before 1 is written.
The OER flag is set to 1 upon overrun error detection while the OERE bit of the RLN3nLEDE register is 1 (overrun error detection enabled).
Write 0 to clear this flag.

BER Flag (Bit Error Flag)

Only 0 can be written to the BER flag; when 1 is written, the bit retains the value it had before 1 is written.
The BER flag is set to 1 when the transmitted data and the data monitored by the receive pin do not match while the BERE bit of the RLN3nLEDE register is 1 (bit error detection enabled).
Write 0 to clear this flag.

21.3.4.12 RLN3nLDFC — UART Data Field Configuration Register

Access: This register can be read or written in 8-bit units.

Address: <RLIN3n_base> + 14_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	UTSW	—	MDL[3:0]			
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R/W	R	R/W	R/W	R/W	R/W

Table 21.62 RLN3nLDFC Register Contents

Bit Position	Bit Name	Function
7, 6	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
5	UTSW	Transmission Start Wait 0: When UART buffer transmission is requested, transmission is started immediately. 1: When UART buffer transmission is requested, transmission is not started until reception of the stop bit is completed.
4	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
3 to 0	MDL[3:0]	UART Buffer Data Length Select b3 b0 0 0 0 0: 9 data 0 0 0 1: 1 data 0 0 1 0: 2 data 0 0 1 1: 3 data 0 1 0 0: 4 data 0 1 0 1: 5 data 0 1 1 0: 6 data 0 1 1 1: 7 data 1 0 0 0: 8 data 1 0 0 1: 9 data Settings other than the above are prohibited.

UTSW Bit (Transmission Start Wait)

This bit controls the transmission start timing of UART buffer.
With 0 set, transmission is started as soon as the start of UART buffer transmission is requested.
With 1 set, transmission is started after the completion of the stop bit reception.
Note that the wait time is only 1 bit even if the stop bit length is set to 2 bits with the USBLS bit in the RLN3nLBFC register.
This bit is enabled when the RTS bit in the RLN3nLTRC register is set to 1. In addition, writing a value to this bit is disabled when the RTS bit is 1 (UART buffer transmission started).
Set this bit to 1 only to switch from reception to transmission in half-duplex communication.

MDL[3:0] Bits (UART Buffer Data Length Select)

These bits specify the data length of the UART buffer.
Writing a value to these bits is disabled when the RTS bit in the RLN3nLTRC register is 1 (UART buffer transmission started).

21.3.4.13 RLN3nLIDB — UART ID Buffer Register

Access: This register can be read or written in 8-bit units.

Address: <RLIN3n_base> + 15_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	ID[7:0]							
Value after reset	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 21.63 RLN3nLIDB Register Contents

Bit Position	Bit Name	Function
7 to 0	ID[7:0]	ID value that is referred for the expansion bit data comparison is set

ID Bits (ID)

When the UEBE bit in the RLN3nLUOR1 register is set to 1 (expansion bit enabled), the UECD bit is set to 0 (expansion bit comparison enabled), and the UEBDCE bit is set to 1 (data comparison after expansion bit is detected), set the value to be compared with the received data. Write to the RLN3nLIDB register when the URS bit in the RLN3nLST register is 0 (receive operation is not in progress).

21.3.4.14 RLN3nLUDB0 — UART Data Buffer 0 Register

Access: This register can be read or written in 8-bit units.

Address: <RLIN3n_base> + 17_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	UDB[7:0]							
Value after reset	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 21.64 RLN3nLUDB0 Register Contents

Bit Position	Bit Name	Function
7 to 0	UDB[7:0]	Sets the data to be transmitted. Setting range: 00_H to FF_H

When transmitting 9-byte data from the UART buffer (the RLN3nLDFC.MDL bit is "0_H" or "9_H"), set the first data to be transmitted.

Write to the RLN3nLUDB0 register when the RTS bit of the RLN3nLTRC register is 0 (UART buffer transmission stopped).

Table 21.65, Bit Arrangement of the RLN3nLUDB0 Register According to Each Communication Format, shows the bit arrangement according to the settings for communication format.

For details about the UART buffer, see **Section 21.4.5.1(2), UART Buffer Transmission**.

Table 21.65 Bit Arrangement of the RLN3nLUDB0 Register According to Each Communication Format

	RLN3nLUDB0							
	b7	b6	b5	b4	b3	b2	b1	b0
7-bit; LSB first	—*1	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	Bit 0
7-bit; MSB first	—*1	Bit 0	Bit 1	Bit 2	Bit 3	Bit 4	Bit 5	Bit 6
8-bit; LSB first	Bit 7	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	Bit 0
8-bit; MSB first	Bit 0	Bit 1	Bit 2	Bit 3	Bit 4	Bit 5	Bit 6	Bit 7

Note 1. In the case of 7-bit data length, write the value after reset.

21.3.4.15 RLN3nLDBRb — UART Data Buffer b Register (b = 1 to 8)

Access: This register can be read or written in 8-bit units.

Address: RLN3nLDBR1: <RLIN3n_base> + 18_H
RLN3nLDBR2: <RLIN3n_base> + 19_H
RLN3nLDBR3: <RLIN3n_base> + $1A_H$
RLN3nLDBR4: <RLIN3n_base> + $1B_H$
RLN3nLDBR5: <RLIN3n_base> + $1C_H$
RLN3nLDBR6: <RLIN3n_base> + $1D_H$
RLN3nLDBR7: <RLIN3n_base> + $1E_H$
RLN3nLDBR8: <RLIN3n_base> + $1F_H$

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	LDB[7:0]							
Value after reset	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 21.66 RLN3nLDBRb Register Contents

Bit Position	Bit Name	Function
7 to 0	LDB[7:0]	Sets the data to be transmitted. Setting range: 00_H to FF_H

This register specifies the data transmitted from the UART buffer.

Write to these registers when the RTS bit of the RLN3nLTRC register is 0 (UART buffer transmission stopped).

Table 21.67, Bit Arrangement of the RLN3nLDBRb Register According to Each Communication Format, shows the bit arrangement according to the set communication format.

For details about the UART buffer, see **Section 21.4.5.1(2), UART Buffer Transmission**.

Table 21.67 Bit Arrangement of the RLN3nLDBRb Register According to Each Communication Format

	RLN3nLDBRb							
	b7	b6	b5	b4	b3	b2	b1	b0
7-bit; LSB first	—*1	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	Bit 0
7-bit; MSB first	—*1	Bit 0	Bit 1	Bit 2	Bit 3	Bit 4	Bit 5	Bit 6
8-bit; LSB first	Bit 7	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	Bit 0
8-bit; MSB first	Bit 0	Bit 1	Bit 2	Bit 3	Bit 4	Bit 5	Bit 6	Bit 7

Note 1. In the case of 7-bit data length, write the value after reset.

21.3.4.16 RLN3nLUOER — UART Operation Enable Register

Access: This register can be read or written in 8-bit units.

Address: <RLIN3n_base> + 20_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	UROE	UTOE
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R/W	R/W

Table 21.68 RLN3nLUOER Register Contents

Bit Position	Bit Name	Function
7 to 2	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
1	UROE	Reception Enable 0: Disables reception. 1: Enables reception.
0	UTOE	Transmission Enable 0: Disables transmission. 1: Enables transmission.

The RLN3nLUOER register is automatically cleared to 00_H upon transition to LIN reset mode.
In LIN reset mode, this register cannot be written to.
In LIN reset mode, the register retains 00_H.

UROE Bit (Reception Enable)

The UROE bit enables or disables reception.
With 0 set, reception is disabled.
With 1 set, reception is enabled.
Do not clear this bit during reception. If the communication is suspended during reception, set the OM0 bit in the RLN3nLCUC register to 0 (LIN reset mode) to transition to the LIN reset mode. However, the transmit operation is also suspended at this time.

Do not set this bit to 1 when data transmission from the UART buffer is in progress.

UTOE Bit (Transmission Enable)

The UTOE bit enables or disables transmission.
With 0 set, transmission is disabled.
With 1 set, transmission is enabled.
Do not clear this bit during transmission. If the communication is suspended during transmission, set the OM0 bit in the RLN3nLCUC register to 0 (LIN reset mode) to transition to the LIN reset mode. However, the receive operation is also suspended at this time.

21.3.4.17 RLN3nLUOR1 — UART Option Register 1

Access: This register can be read or written in 8-bit units.

Address: <RLIN3n_base> + 21_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	UECD	UTIGTS	UEBDCE	UEBDL	UEBE
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R/W	R/W	R/W	R/W	R/W

Table 21.69 RLN3nLUOR1 Register Contents

Bit Position	Bit Name	Function
7 to 5	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
4	UECD	Expansion Bit Comparison Disable 0: Enables expansion bit comparison. 1: Disables expansion bit comparison.
3	UTIGTS	Transmission Interrupt Generation Timing Select 0: Transmission interrupt is generated at the start of transmission. 1: Transmission interrupt is generated at the completion of transmission.
2	UEBDCE	Expansion Bit Data Comparison Enable 0: Disables data comparison after an expansion bit is detected. 1: Enables data comparison after an expansion bit is detected.
1	UEBDL	Expansion Bit Detection Level Select 0: Selects expansion bit value 0 as the expansion bit detection level. 1: Selects expansion bit value 1 as the expansion bit detection level.
0	UEBE	Expansion Bit Enable 0: Disables expansion bit operation. 1: Enables expansion bit operation.

UECD Bit (Expansion Bit Comparison Disable)

The UECD bit enables or disables comparison between the received expansion bit and the UEBDL bit value when the UEBE bit is 1 (expansion bit operation is enabled).
With 0 set, comparison between the received expansion bit and the UEBDL bit value is enabled when the expansion bit is received.
With 1 set, comparison between the received expansion bit and the UEBDL bit value is disabled when the expansion bit is received.
Set this bit when the OMM0 bit of the RLN3nLMST register is 0_B (LIN reset mode).
Do not set this bit to 1 when the UART buffer is used.
Do not set this bit to 1 when the UEBDCE bit is 1 (data comparison after expansion bit is detected).

UTIGTS Bit (Transmission Interrupt Generation Timing Select)

The UTIGTS bit sets the generation timing of the transmission interrupt.
With 0 set, the transmission interrupt is generated at the start of transmission.
With 1 set, the transmission interrupt is generated at the completion of transmission.
When transmission from the UART buffer is performed with 0 set, the transmission interrupt is generated only at the start of the transmission of the last data of the data length set with the MDL bits in the RLN3nLDFC register.
When transmission from the UART buffer is performed with 1 set, the transmission interrupt is

generated only at the completion of the transmission of the last data of the data length set with the MDL bits in the RLN3nLDFC register.

UEBDCE Bit (Expansion Bit Data Comparison Enable)

After an expansion bit is detected, this bit enables or disables the comparison between the 8-bit receive data excluding the expansion bit and the value of the RLN3nLIDB register.
With 0 set, when the level selected by the UEBDL bit is detected as an expansion bit, the comparison between the received value in the RLN3nLURDR register and the value of the RLN3nLIDB register is disabled.
With 1 set, when the level selected by the UEBDL bit is detected as an expansion bit, the comparison between the received value in the RLN3nLURDR register and the value of the RLN3nLIDB register is enabled.
Set this bit when the OMM0 bit of the RLN3nLMST register is 0_B (LIN reset mode).
Do not set this bit to 1 when the UEBE bit is 0 (expansion bit operation disabled).
Do not set this bit to 1 when the UECD bit is 1 (expansion bit comparison disabled).
Do not set this bit to 1 when the UART buffer is used.

UEBDL Bit (Expansion Bit Detection Level Select)

The UEBDL bit sets the level to be detected as the expansion bit when the UEBE bit is 1 (expansion bit operation is enabled) and the UECD bit is 0 (comparison of the expansion bit is enabled).
With 0 set, expansion bit value 0 is the level to be detected as the expansion bit.
With 1 set, expansion bit value 1 is the level to be detected as the expansion bit.
Set this bit when the OMM0 bit of the RLN3nLMST register is 0_B (LIN reset mode).
Do not set this bit to 1 when the UART buffer is used.

UEBE Bit (Expansion Bit Enable Bit)

The UEBE bit enables or disables expansion bit operation.
With 0 set, expansion bit operation is disabled.
With 1 set, expansion bit operation is enabled.
Set this bit when the OMM0 bit of the RLN3nLMST register is 0_B (LIN reset mode).
Do not set this bit to 1 when the UART buffer is used.

21.3.4.18 RLN3nLUTDR — UART Transmission Data Register

Access: RLN3nLUTDR register can be read or written in 16-bit units.
RLN3nLUTDRL register can be read or written in 8-bit units.
RLN3nLUTDRH register can be read or written in 8-bit units.

Address: RLN3nLUTDR: <RLIN3n_base> + 24_H
RLN3nLUTDRL: <RLIN3n_base> + 24_H
RLN3nLUTDRH: <RLIN3n_base> + 25_H

Value after reset: 0000_H

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	UTD[8:0]								
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 21.70 RLN3nLUTDR Register Contents

Bit Position	Bit Name	Function
15 to 9	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
8 to 0	UTD[8:0]	Sets the data to be transmitted. Setting range: 000_H to $1FF_H$

The RLN3nLUTDR register sets the data to be transmitted from the transmit data register.

Writing data to this register with the UTOE bit in the RLN3nLUOER register set to 1 starts transmission.

This register can be accessed in 8 bits.

In 9-bit communication mode, do not attempt 8-bit access.

Do not write data to this register when data transmission from the UART buffer is in progress.

Also, do not write data to this register when a transmission request is being generated due to write access to the RLN3nLUWTDR register.

When transmitting data continuously, do not set another piece of transmission data in this register before the generation of transmission interrupt.

The table below shows the bit arrangement according to the set communication format.

Table 21.71 Bit Arrangement of the RLN3nLUTDR Register According to Each Communication Format

	RLN3nLUTDR								
	b8	b7	b6	b5	b4	b3	b2	b1	b0
7-bit; LSB first	—*1	—*1	Bit6	Bit5	Bit4	Bit3	Bit2	Bit1	Bit0
7-bit; MSB first	—*1	—*1	Bit0	Bit1	Bit2	Bit3	Bit4	Bit5	Bit6
8-bit; LSB first	—*1	Bit7	Bit6	Bit5	Bit4	Bit3	Bit2	Bit1	Bit0
8-bit; MSB first	—*1	Bit0	Bit1	Bit2	Bit3	Bit4	Bit5	Bit6	Bit7
9-bit; LSB first	Bit8	Bit7	Bit6	Bit5	Bit4	Bit3	Bit2	Bit1	Bit0
9-bit; MSB first	Bit0	Bit1	Bit2	Bit3	Bit4	Bit5	Bit6	Bit7	Bit8

Note 1. In the case of 7-bit or 8-bit data length, write the value after reset.

21.3.4.19 RLN3nLURDR — UART Reception Data Register

Access: RLN3nLURDR register is a read-only register that can be read in 16-bit units.
RLN3nLURDRL register is a read-only register that can be read in 8-bit units.
RLN3nLURDRH register is a read-only register that can be read in 8-bit units.

Address: RLN3nLURDR: <RLIN3n_base> + 26_H
RLN3nLURDRL: <RLIN3n_base> + 26_H
RLN3nLURDRH: <RLIN3n_base> + 27_H

Value after reset: 0000_H

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	URD [8:0]								
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 21.72 RLN3nLURDR Register Contents

Bit Position	Bit Name	Function
15 to 9	Reserved	When read, the value after reset is returned.
8 to 0	URD [8:0]	Stores the received data Setting range: 000_H to $1FF_H$

The RLN3nLURDR allows the reception data to be read from the receive data register.

When the UROE bit in the RLN3nLUOER register is 1, the reception data is stored in this register and can be read out.

This register is updated when the stop bit of the receive data is received.

This register is also updated when an error is caused by the parity or stop bit.

However, the value of this register is not updated upon occurrence of an overrun error when the OERE bit of the RLN3nLEDE register is 1 (overrun error detection enabled). The value of this register is updated upon occurrence of an overrun error when the OERE bit is 0 (overrun error detection disabled).

Read this register upon occurrence of a receive error (overrun error, framing error, parity error) when the OERE bit of the RLN3nLEDE register is 1 (overrun error detection enabled). If the next data is received without reading this register, an overrun error occurs.

This register can be accessed in 8 bits.

However, during expansion bit use (UEBE bit of the RLN3nLUOR1 register is 1 (expansion bit operation enabled), do not attempt 8-bit access.

The table below shows the bit arrangement according to the set communication format.

Table 21.73 Bit Arrangement of the RLN3nLURDR Register According to Each Communication Format

	RLN3nLURDR								
	b8	**b7**	**b6**	**b5**	**b4**	**b3**	**b2**	**b1**	**b0**

Table 21.74 RLN3nLUWTDR Register Contents

Bit Position	Bit Name	Function
15 to 9	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
8 to 0	UWTD[8:0]	Sets the data to be transmitted from the wait transmit data register after waiting for the stop bit reception to be completed. Setting range: 000_H to $1FF_H$

The RLN3nLUWTDR register sets the data to be transmitted from the UART wait transmit data register.

Writing data to this register with the UTOE bit in the RLN3nLUOER register set to 1 starts transmission.

Use this register only to switch from reception to transmission in half-duplex communication.

The user should write to this register only while the stop bit is being received.

Note that the wait time is only 1 bit even if the stop bit length is set to 2 bits with the USBLS bit in the RLN3nLBFC register.

When this register is read, the RLN3nLUTDR register value is actually read.

In 9-bit communication mode, do not attempt 8-bit access.

Do not write data to this register when data transmission from the UART buffer is in progress.

The table below shows the bit arrangement according to the set communication format.

Table 21.75 Bit Arrangement of the RLN3nLUWTDR Register According to Each Communication Format

	RLN3nLUWTDR								
	b8	b7	b6	b5	b4	b3	b2	b1	b0
7-bit; LSB first	—*1	—*1	Bit6	Bit5	Bit4	Bit3	Bit2	Bit1	Bit0
7-bit; MSB first	—*1	—*1	Bit0	Bit1	Bit2	Bit3	Bit4	Bit5	Bit6
8-bit; LSB first	—*1	Bit7	Bit6	Bit5	Bit4	Bit3	Bit2	Bit1	Bit0
8-bit; MSB first	—*1	Bit0	Bit1	Bit2	Bit3	Bit4	Bit5	Bit6	Bit7
9-bit; LSB first	Bit8	Bit7	Bit6	Bit5	Bit4	Bit3	Bit2	Bit1	Bit0
9-bit; MSB first	Bit0	Bit1	Bit2	Bit3	Bit4	Bit5	Bit6	Bit7	Bit8

Note 1. In the case of 7-bit or 8-bit data length, write the value after reset.

21.4 Operation

21.4.1 Interrupt Sources

The LIN/UART interface generates four types of interrupt requests.

- RLIN3n transmission interrupt
- RLIN3n successful reception interrupt
- RLIN3n status interrupt
- RLIN3n interrupt

Setting the LIOS bit in the RLN3nLMD register to 0 allows to perform logical OR operation on all of the interrupt sources, outputting the interrupt request from the RLIN3n interrupt.

Setting the LIOS bit in the RLN3nLMD register to 1 allows to output the RLIN3n transmission interrupt, RLIN3n successful reception interrupt, or RLIN3n status interrupt depending on the interrupt source.

Table 21.76 lists the sources for each interrupt.

Table 21.76 Interrupt Sources

		LIOS bit in RLN3nLMD register is 0	LIOS bit in RLN3nLMD register is 1*1		
		RLIN3n Interrupt	RLIN3n Transmission Interrupt	RLIN3n Successful Reception Interrupt	RLIN3n Status Interrupt
LIN mode	LIN master mode	• Successful frame transmission • Successful frame reception • Successful wake-up transmission • Successful wake-up reception • Successful header transmission • Bit error • Physical bus error • Frame/response timeout error • Framing error • Checksum error • Response preparation error	• Successful frame transmission • Successful wake-up transmission • Successful header transmission	• Successful response reception • Successful wake-up reception	• Bit error • Physical bus error • Frame/response timeout error • Framing error • Checksum error • Response preparation error
	LIN slave mode	• Successful response transmission • Successful response reception • Successful wake-up transmission • Successful wake-up reception • Successful header reception • Bit error • Frame/response timeout error • Framing error • Sync field error • Checksum error • ID parity error • Response preparation error	• Successful response transmission • Successful wake-up transmission	• Successful response reception • Successful wake-up reception • Successful header reception	• Bit error • Frame/response timeout error • Framing error • Sync field error • Checksum error • ID parity error • Response preparation error
UART mode		—	• Transmission start/ successful transmission	• Successful reception • Expansion bit mismatch	• Bit error • Overrun error • Framing error • Expansion bit match • ID match • Parity error

Note 1. The LIOS bit setting is valid in LIN Mode. In UART mode, setting the LIOS bit is not required.

In LIN mode, each interrupt request is output when the corresponding bit in the RLN3nLIE register is 1 (interrupt is enabled) and the corresponding flag in the RLN3nLST register is 1.

21.4.2 Modes

The LIN/UART interface provides the following four modes, depending upon the specific function to be performed:

- LIN reset mode
- LIN mode
  - LIN master mode
  - LIN slave mode [auto baud rate]
  - LIN slave mode [fixed baud rate]
- UART mode
- LIN self-test mode

Figure 21.2 shows mode transitions. **Table 21.77** describes mode transition conditions. **Table 21.78** lists operations available in each mode.

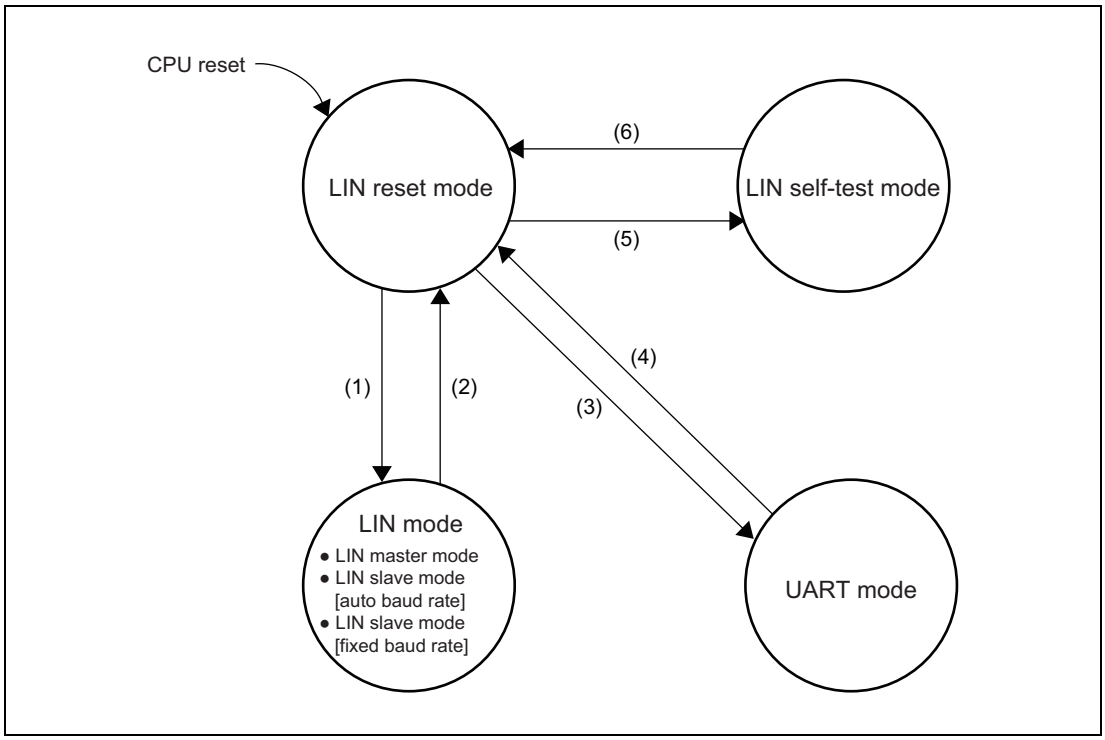

Figure 21.2 Mode Transitions

Table 21.77 Transition Condition of Each Mode

	Mode Transition			Transition Condition
(1)	LIN reset mode	→	LIN mode	
			• LIN master mode	• LMD bits in RLN3nLMD register = 00_B and OM1 and OM0 bits in RLN3nLCUC register = 01_B or 11_B
			• LIN slave mode [auto baud rate]	• LMD bits in RLN3nLMD register = 10_B and OM1 and OM0 bits in RLN3nLCUC register = 01_B or 11_B
			• LIN slave mode [fixed baud rate]	• LMD bits in RLN3nLMD register = 11_B and OM1 and OM0 bits of RLN3nLCUC register = 01_B or 11_B
(2)	LIN mode	→	LIN reset mode	OM0 bit in RLN3nLCUC register = 0_B
(3)	LIN reset mode	→	UART mode	LMD bits in RLN3nLMD register = 01_B and OM0 bit in RLN3nLCUC register = 1_B
(4)	UART mode	→	LIN reset mode	OM0 bit in RLN3nLCUC register = 0_B
(5)	LIN reset mode	→	LIN self-test mode	See **Section 21.4.6, LIN Self-Test Mode**.
(6)	LIN self-test mode	→	LIN reset mode	See **Section 21.4.6, LIN Self-Test Mode**.

Table 21.78 Operations Available in Each Mode

LIN Mode			
LIN Master Mode	**LIN Slave Mode [auto baud rate] LIN Slave Mode [fixed baud rate]**	**UART Mode**	**LIN Self-Test Mode**
Header transmission Response transmission Response reception Wake-up transmission Wake-up reception Error detection	Header reception Response transmission Response reception Wake-up transmission Wake-up reception Error detection	UART transmission UART reception Error detection	Self test

Whether mode has transitioned to LIN reset mode, the LIN mode, or the UART mode can be verified by reading the LMD bits in the RLN3nLMD register and the OMM0 bit in the RLN3nLMST register.

For a description of the LIN self-test mode, see **Section 21.4.6, LIN Self-Test Mode**.

21.4.3 LIN Reset Mode

Setting the OM0 bit in the RLN3nLCUC register to 0 (LIN reset mode) causes a transition to LIN reset mode. The change to LIN reset mode can be verified by determining that the OMM0 bit in the RLN3nLMST register has been set to 0 (LIN reset mode). In this mode, the LIN communication and the UART communication functions are halted.

From LIN reset mode, transitions to LIN mode, UART mode, and LIN self-test mode can be made.

When the mode changes to LIN reset mode, the following registers are initialized to their reset values, and as long as LIN reset mode is in effect, they retain their initial values.

- RLN3nLTRC register
- RLN3nLST register
- RLN3nLEST register
- RLN3nLUOER register

The following registers retain their previous values even when a transition to LIN reset mode is made:

- RLN3nLWBR register
- RLN3nLBRP0 register
- RLN3nLBRP1 register
- RLN3nLMD register
- RLN3nLBFC register
- RLN3nLSC register
- RLN3nLWUP register
- RLN3nLIE register
- RLN3nLEDE register
- RLN3nLDFC register
- RLN3nLIDB register
- RLN3nLCBR register
- RLN3nLUDB0 register
- RLN3nLDBRb register (b = 1 to 8)
- RLN3nLUOR1 register
- RLN3nLUTDR register
- RLN3nLURDR register
- RLN3nLUWTDR register

21.4.4 LIN Mode

LIN mode can operate in the following submodes: LIN master mode, LIN slave mode [auto baud rate], and LIN slave mode [fixed baud rate].

In LIN master mode, the following operations can be performed: header transmission, response transmission, response reception, wake-up transmission, wake-up reception, and error detection. In LIN reset mode, setting the LMD bits in the RLN3nLMD register to 00_B (LIN master mode) and the OM1 and OM0 bits in the RLN3nLCUC register to either 01_B or 11_B sets LIN master mode, turning the OMM1 and OMM0 bits in the RLN3nLMST register to either 01_B to 11_B.

In LIN slave mode [auto baud rate] and LIN slave mode [fixed baud rate], header reception, response transmission, response reception, wake-up transmission, wake-up reception, and error detection can be performed.

The LIN slave mode [auto baud rate] allows automatic detection of the break field and the sync field, and sets a baud rate based on the results of measurement of a sync field. The baud rate can be set to 1 kbps to 20 kbps.

Set the LPRS[2:0] bits in the RLN3nLWBR register so that the prescaler clock (with the frequency of the LIN communication clock source divided by the prescaler) becomes as follows according to the target baud rate.

[Target baud rate]	[Prescaler clock]
1 kbps to 20 kbps	: 4MHz*1
1 kbps to 2.4 kbps (excluding 2.4 kbps)	: 4MHz
2.4 kbps to 20 kbps	: 8 MHz to 12 MHz

Note 1. Use the clock with NSPB[3:0] bits in the RLN3nLWBR register set to "0011_B" (four samplings).

LIN slave mode [fixed baud rate] allows automatic detection of the break field, sync field, and ID field at a baud rate that is set in advance by the baud rate generator.

In LIN reset mode, setting the LMD bits in the RLN3nLMD register to 10_B (LIN slave mode [auto baud rate]) and setting the OM1 and OM0 bits in the RLN3nLCUC register to 01_B or 11_B sets LIN slave mode [auto baud rate]; and setting the LMD bits in the RLN3nLMD register to 11_B (LIN slave mode [fixed baud rate]), and setting the OM1 and OM0 bits in the RLN3nLCUC register to 01_B or 11_B sets LIN slave mode [fixed baud rate], turning the OMM1 and OMM0 bits in the RLN3nLMST register to 01_B or 11_B.

When changing a submode to another submode within LIN mode, a transition to LIN reset mode should first be made and change the LMD bits in the RLN3nLMD register.

The LIN mode provides the following two operation modes:

- LIN operation mode
- LIN wake-up mode

Figure 21.3 shows the transition of operation modes. **Table 21.79** describes the transition conditions of operation modes.

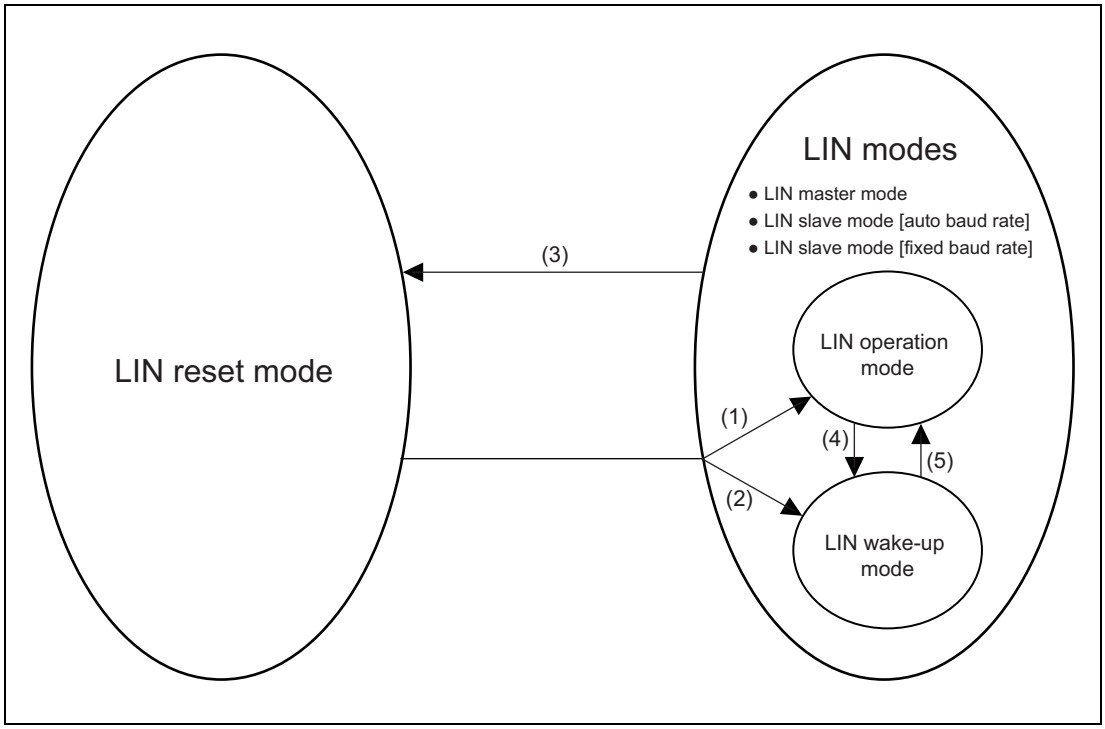

Figure 21.3 Transition of Operation Modes

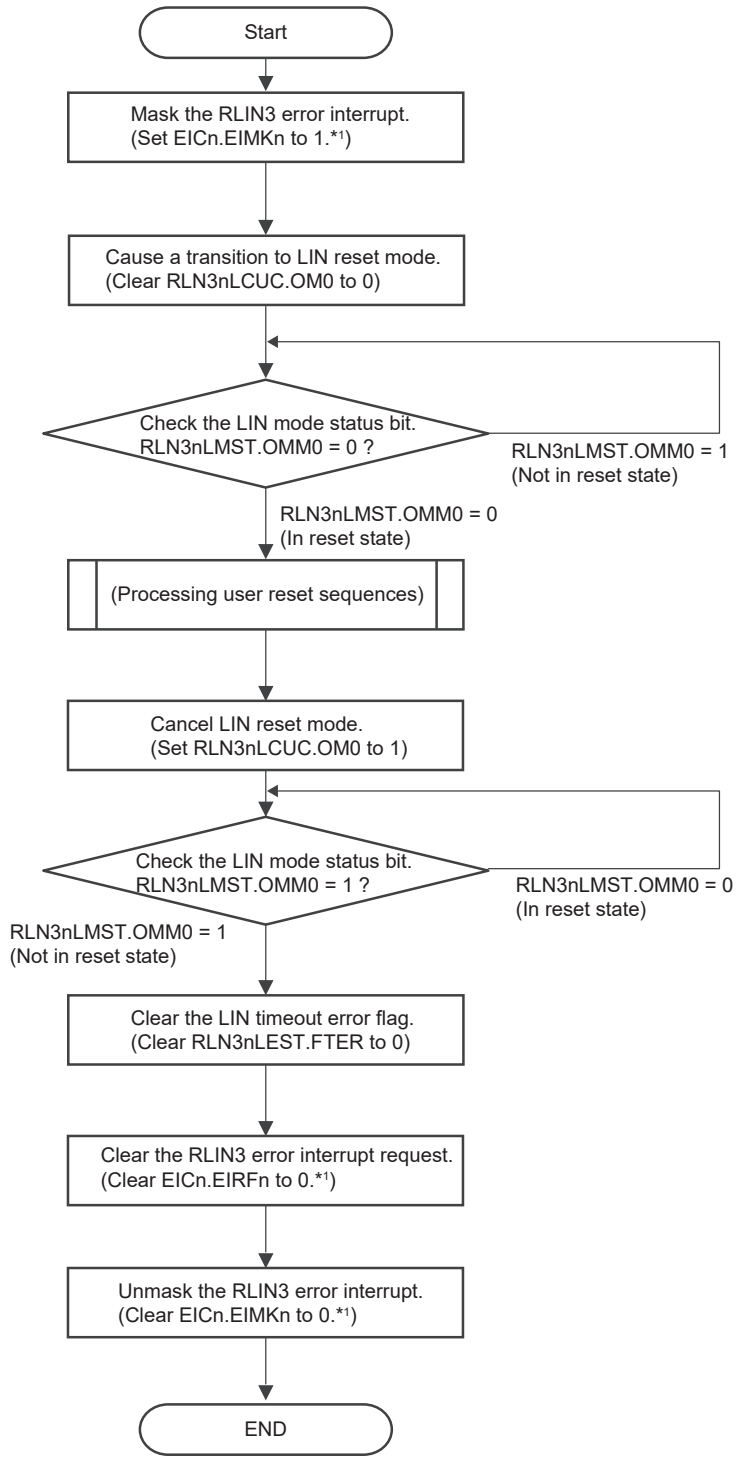
Table 21.79 Transition Condition for Operation Mode

	Operation Mode Transition			Transition Condition
(1)	LIN reset mode	→	LIN mode • LIN operation mode	LMD bits in RLN3nLMD register = 00_B or 10_B or 11_B and OM1 and OM0 bits in RLN3nLCUC register = 11_B
(2)	LIN reset mode	→	LIN mode • LIN wake-up mode	LMD bits in RLN3nLMD register = 00_B or 10_B or 11_B and OM1 and OM0 bits in RLN3nLCUC register = 01_B
(3) *2	LIN mode • LIN operation mode • LIN wake-up mode	→	LIN reset mode	OM0 bit in RLN3nLCUC register = 0_B
(4) *1	LIN mode • LIN operation mode	→	LIN mode • LIN wake-up mode	OM1 and OM0 bits in RLN3nLCUC register = 01_B
(5) *1	LIN mode • LIN wake-up mode	→	LIN mode • LIN operation mode	OM1 and OM0 bits in RLN3nLCUC register = 11_B

Note 1. Transition between LIN operation mode and LIN wake-up mode cannot be made when communication is in progress (when the FTS bit in the RLN3nLTRC register is 1).

Note 2. In LIN mode, if RLIN3 transitions to LIN reset mode by clearing RLN3nLCUC.OM0 to 0 when the timeout function is used (RLN3nLEDE.FTERE = 1 or RLN3nLEDE.TERE = 1), users should take the procedure shown in **Figure 21.4**. The procedure is to protect a RLIN3 error interrupt and clear a RLIN3 error interrupt request.



Note 1. This “n” value means interrupt number. See **Section 21.1.4, Interrupt Requests and Error Notifications** and confirm interrupt numbers of RLIN3n interrupt or RLIN3n status interrupt (n = 0 to 23) in **Table 21.7** in accordance with the value of RLN3nLMD.LIOS. For EICn, refer to **Section 6, Interrupts**.

Figure 21.4 LIN reset sequence by clearing RLN3nLCUC.OM0 to 0 when the timeout function is used

(1) LIN Operation Mode

In LIN operation mode, frame processing (header transmission, header reception, response transmission, response reception, and error detection) can be performed.

During a transition from LIN reset mode to LIN mode, setting the OM1 and OM0 bits in the RLN3nLCUC register to 11_B changes the mode to LIN operation mode, changing the OMM1 and OMM0 bits in the RLN3nLMST register to 11_B. Communication settings should be performed after the OMM1 and OMM0 bits have become 11_B.

(2) LIN Wake-up Mode

In LIN wake-up mode, wake-up signal processing (wake-up transmission, wake-up reception, and error detection) can be performed.

During a transition from LIN reset mode to LIN mode, setting the OM1 and OM0 bits in the RLN3nLCUC register to 01_B changes the mode to LIN wake-up mode, changing the OMM1 and OMM0 bits in the RLN3nLMST register to 01_B. Communication settings should be performed after the OMM1 and OMM0 bits have become 01_B.

21.4.4.1 LIN Master Mode

(1) Header Transmission

Figure 21.5 shows the operation of the LIN/UART interface (LIN master mode) in header transmission. **Table 21.80** describes the processing in header transmission.

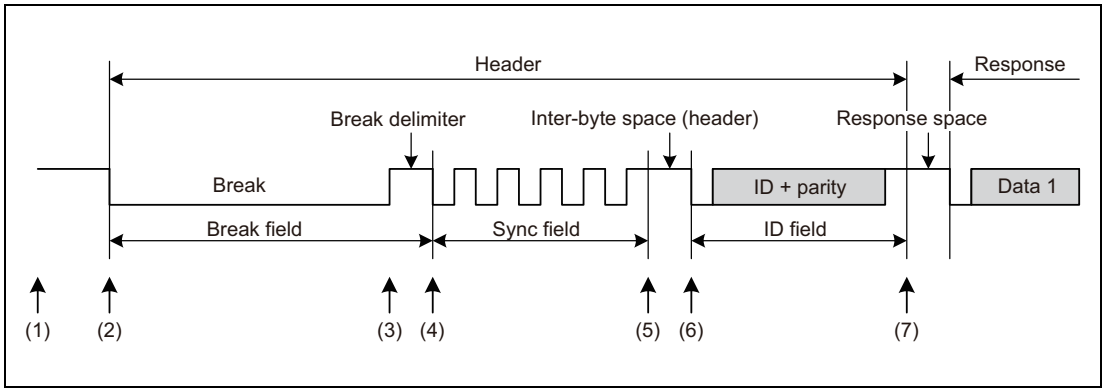


Figure 21.5 Operation in Header Transmission

Table 21.80 Processing in Header Transmission

	Software Processing	LIN/UART Interface Processing
(1)	• Sets a baud rate • Sets noise filter ON/OFF • Enables interrupt • Enables error detection • Sets frame configuration parameters • Changes the LIN/UART interface to the LIN master mode: LIN operation mode • Sets information on the frame to be transmitted (ID, parity, data length, response direction, checksum method, and transmission data)	Waits for the setting of the FTS bit in the RLN3nLTRC register by software (idle)
(2)	Sets the FTS bit in the RLN3nLTRC register to 1 (frame transmission or wake-up transmission/reception started)	Transmits a break.
(3)	Waits for an interrupt request	Transmits a break delimiter.
(4)		Transmits a sync field (55_H).
(5)		Transmits an inter-byte space (header).
(6)		Transmits an ID field.
(7)		Sets a successful header transmission flag.

NOTE

For information about error detection conditions, see **Section 21.4.4.7, Error Status**.

(2) Response Transmission

Figure 21.6 shows the operation of the LIN/UART interface (LIN master mode) in response transmission. **Table 21.81** describes the processing in response transmission.

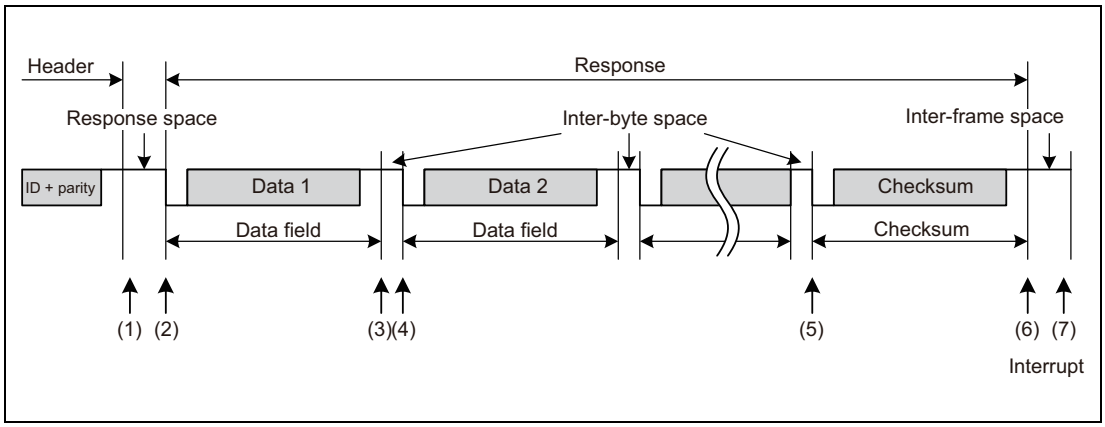

Figure 21.6 Operation in Response Transmission

Table 21.81 Processing in Response Transmission

	Software Processing	LIN/UART Interface Processing
(1)	[When in frame separate mode] • Sets the RTS bit in the RLN3nLTRC register to 1 (response transmission/ reception started) [When not in frame separate mode] • Waits for an interrupt request	[When in frame separate mode] • Waits for the setting of the RTS bit in the RLN3nLTRC register to 1 by software. • When the bit is set to 1, sends a response space. [When not in frame separate mode] • Sends a response space.
(2)	Waits for an interrupt request	Transmits data 1.
(3)		Transmits an inter-byte space.
(4)		• Transmits data 2. • Transmits an inter-byte space • Transmits data 3. • Transmits an inter-byte space (Repeats as many times as the data length specified in bits RFDL[3:0] in the RLN3nLDFC register). : :
(5)		Transmits the checksum.
(6)		• Sets a successful frame/wake-up transmission flag. • Sets the FTS bit in the RLN3nLTRC register to 0 (frame transmission or wake-up transmission/reception stopped) [When in frame separate mode] • Sets the RTS bit in the RLN3nLTRC register to 0 (response transmission/reception is halted).
(7)	• Processing after communication Checks the RLN3nLST register, and clears flags.	Idle

NOTE

For information about error detection conditions, see **Section 21.4.4.7, Error Status**.

(3) Response Reception

Figure 21.7 shows the operation of the LIN/UART interface (LIN master mode) in response reception. **Table 21.82** describes the processing in response reception.

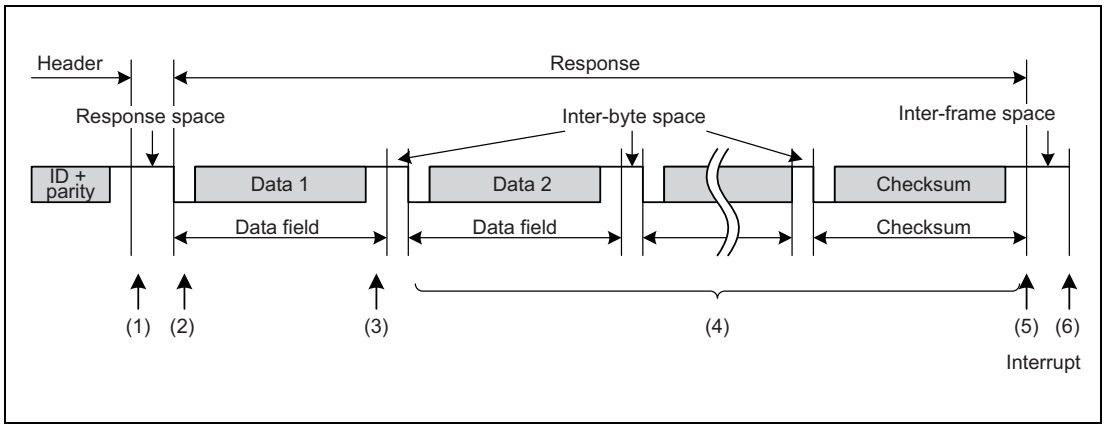

Figure 21.7 Operation in Response Reception

Table 21.82 Processing in Response Reception

	Software Processing	LIN/UART Interface Processing
(1)	Waits for an interrupt request (no processing)	Waits for detection of a start bit.
(2)		Receives data 1 when the start bit is detected.
(3)		Sets the successful data 1 reception flag.
(4)		• Receives data 2 when the start bit is detected. • Receives data 3 when the start bit is detected. Repeats as many times as the data length specified in bits RFDL[3:0] in the RLN3nLDFC register). : : • Receives the checksum when the start bit is detected.
(5)		• Determines the checksum. • Sets the successful frame/wake-up reception flag. • Sets the FTS bit in the RLN3nLTRC register to 0 (frame transmission or wake-up transmission/reception stopped).
(6)	• Processing after communication Reads the received data. Checks the RLN3nLST register, and clears flags.	Idle

NOTE

For information about error detection, see **Section 21.4.4.7, Error Status**.

21.4.4.2 LIN Slave Mode

(1) Header Reception

Figure 21.8 shows the operation of the LIN/UART interface (LIN slave mode) in header reception.
Table 21.83 provides processing in header reception.

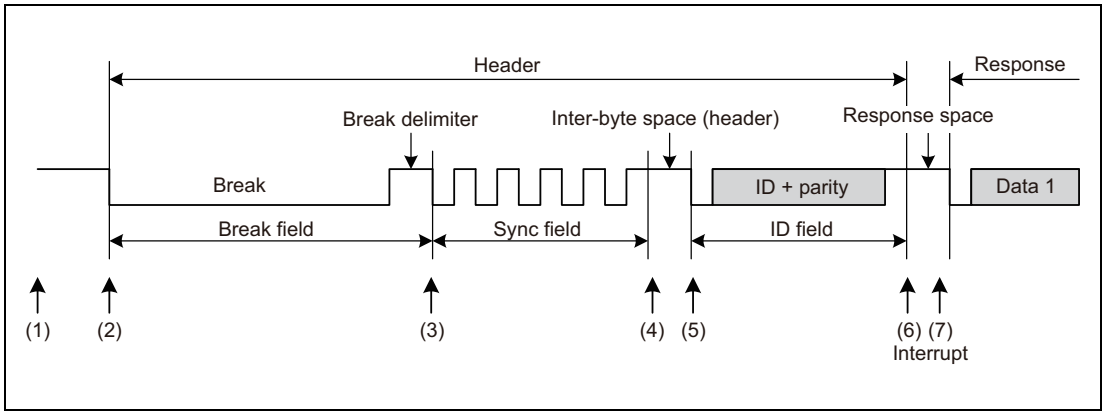

Figure 21.8 Operation in Header Reception

Table 21.83 Processing in Header Reception

	Software Processing	LIN/UART Interface Processing
(1)	• Sets a baud rate • Sets noise filter ON/OFF • Enables interrupt • Enables error detection • Sets frame configuration parameters • Changes the LIN/UART interface to the LIN slave mode: LIN operation mode • Sets the FTS bit in the RLN3nLTRC register to 1 (header reception or wake-up transmission/ reception started)	Waits for the setting of the FTS bit in the RLN3nLTRC register by software.
(2)	Waits for an interrupt request.	Waits for detection of break field
(3)		Detects a break field. (LIN slave mode [fixed baud rate]). For details about the break field detection timing in the case of LIN slave mode [auto baud rate], see [Auto Baud Rate Correction Function].)
(4)		• Detects a sync field (55_H) • Sets the baud rate generator (in the case of LIN slave mode [auto baud rate]) • Clears the no-response request bit (LNRR bit).
(5)		• Receives an ID field. • Checks an ID parity bit
(6)		Sets a header reception complete flag.
(7)	• Checks the RLN3nLST register, and clears flags. • Checks the RLN3nLIDB register, and prepares a response.	• Completes a header reception process. • Waits for a response request.

NOTE

The LIN/UART interface allows reception of break fields during frame transmission/reception. In that case, a framing error, bit error or other error may be detected at the stop bit position of the frame before the break field is received, and a status interrupt may occur as a result. However, reception of a new header (the following Sync field and ID field) continues regardless of whether an error occurred. For information about error detection conditions, see **Section 21.4.4.7, Error Status**.

[Auto Baud Rate Correction Function]

In LIN slave mode [auto baud rate], the system always measures the low-level widths that are received. If the first "Low level" width is 10 times (if the BLT bit of the RLN3nLBFC register is "0") or 11 times (if the BLT bit of the RLN3nLBFC register is "1") or greater than the bit width calculated from the average of the starting 2 bits (the period of the consecutive falling edges from the beginning of the sync field) of the sync field, the system concludes that the detection of break field was successful, the system verifies that the data in the sync field is 55_H. If the data in the sync field is indeed 55_H and the system judges that sync field reception was successful, the system automatically sets the baud rate correction result to the RLN3nLBRP01 register.

If data is received up to the ID field without error, a successful header reception interrupt is generated at the stop bit position.

On the other hand, if the data in the sync field is not 55_H and the system judges that sync field reception failed, the system sets the sync field error flag and an error interrupt is generated. In that case, baud rate correction is not performed and the LIN/UART interface waits for the detection of the next break field (low level).

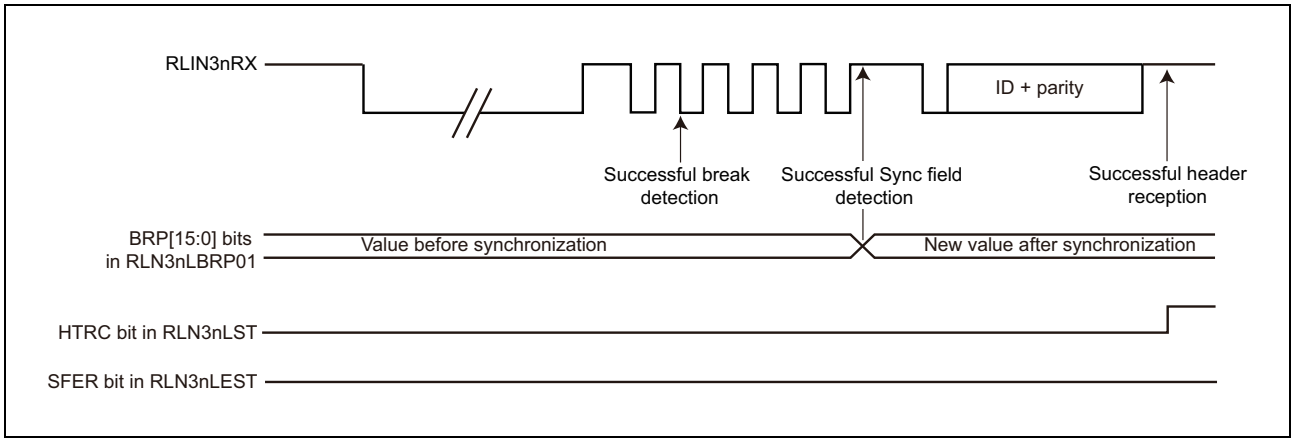

Figure 21.9 Header Reception in LIN Slave Mode [Auto Baud Rate] (in Normal Operation)

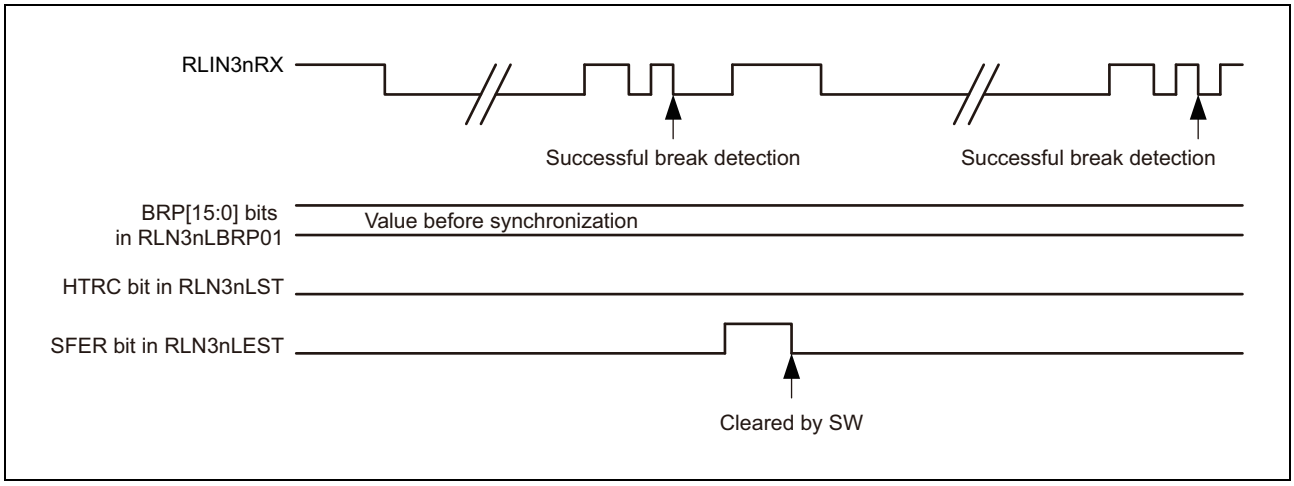

Figure 21.10 Header Reception in LIN Slave Mode [Auto Baud Rate] (Sync Field Error)

(2) Response Transmission

Figure 21.11 shows the operation of the LIN/UART interface (LIN slave mode) in response transmission. **Table 21.84** describes the processing in response transmission.

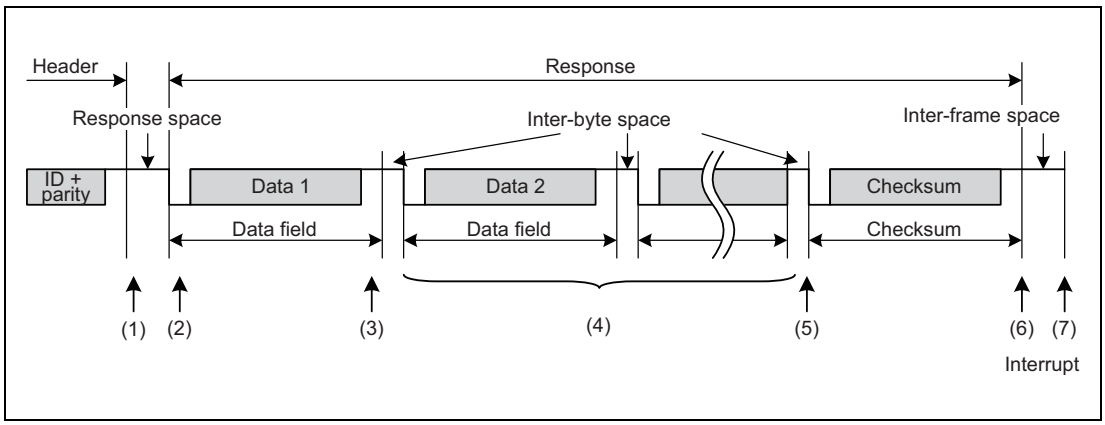

Figure 21.11 Operation in Response Transmission

Table 21.84 Processing in Response Transmission (1/2)

	Software Processing	LIN/UART Interface Processing
(1)	• Sets the RLN3nLDFC register. • Sets the RLN3nLDBRb registers.(b = 1 to 8) • Sets the RTS bit in the RLN3nLTRC register to 1 (response transmission/ reception started)	• Waits for the setting of the RTS or LNRR bit of the RLN3nLTRC register by software • Transmits the response space after the RTS bit of the RLN3nLTRC register is set to 1

Table 21.84 Processing in Response Transmission (2/2)

	Software Processing	LIN/UART Interface Processing
(2)	Waits for an interrupt request.	Transmits data 1.
(3)		Transmits the inter-byte space.
(4)		• Transmits data 2. • Transmits an inter-byte space • Transmits data 3. • Transmits an inter-byte space (Repeats as many times as the data length specified in bits RFDL[3:0] in the RLN3nLDFC register). : :
(5)		Transmits the checksum.
(6)		• Sets the successful response/wake-up transmission flag. • Sets the RTS bit in the RLN3nLTRC register to 0 (response transmission/reception stopped).
(7)	• Processing after communication Checks the RLN3nLST, RLIN3nLRSS registers, and clears flags.	• Completes the response transmission process. • Waits for a new break.

NOTE

- For information about error detection, see **Section 21.4.4.7, Error Status**.
- The LIN/UART interface allows reception of break fields during frame transmission/reception. In that case, a framing error, bit error or other error may be detected at the stop bit position of the frame before the break field is received, and a status interrupt may occur as a result. However, reception of a new header (the following Sync field and ID field) continues regardless of whether an error occurred.

(3) Response Reception

Figure 21.12 shows the operation of the LIN/UART interface (LIN slave mode) in response reception. **Table 21.85** describes the processing in response reception.

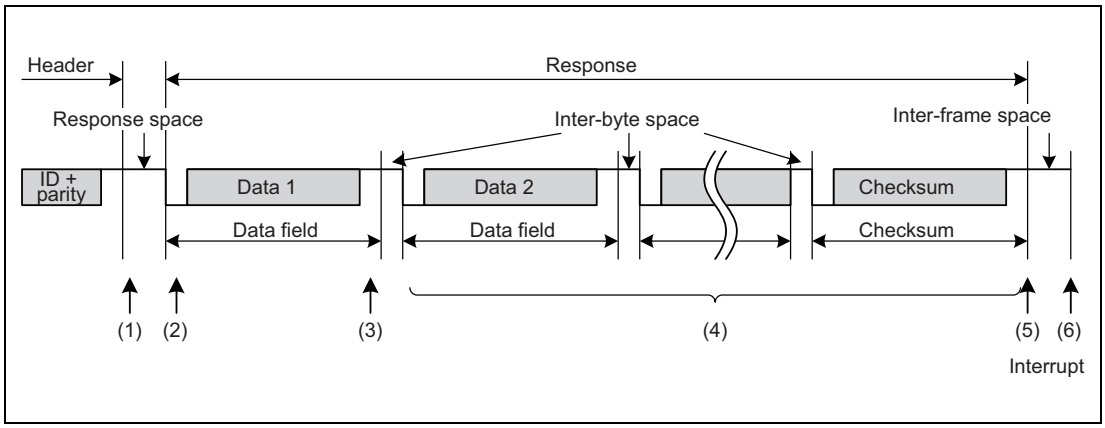

Figure 21.12 Operation in Response Reception

Table 21.85 Processing in Response Reception

	Software Processing	LIN/UART Interface Processing
(1)	• Sets the RLN3nLDFC register. • Sets the response transmission/ reception start bit (RTS bit) to 1.	• Waits for the setting by software of the response transmission/ reception start bit (RTS bit) or the no-response request bit (LNRR bit). • Waits for detection of the start bit.
(2)	Waits for an interrupt request.	Receives data 1 when the start bit is detected.
(3)		Sets the successful data 1 reception flag.
(4)		• Receives data 2 when the start bit is detected. • Receives data 3 when the start bit is detected. Repeats as many times as the data length specified in bits RFDL[3:0] in the RLN3nLDFC register). : : • Receives the checksum when the start bit is detected.
(5)		• Determines the checksum. • Sets a successful response/wake-up reception flag or error flag. • Sets the RTS bit in the RLN3nLTRC register to 0 (response transmission/reception stopped).
(6)	• Processing after communication Reads the received data. Checks the RLN3nLST register, and clears flags.	• Completes the response process. • Waits for a new break.

NOTE

- For information about error detection conditions, see **Section 21.4.4.7, Error Status**.
- The LIN/UART interface allows reception of break fields during frame transmission/reception. In that case, a framing error, bit error or other error may be detected at the stop bit position of the frame before the break field is received, and a status interrupt may occur as a result. However, reception of a new header (the following Sync field and ID field) continues regardless of whether an error occurred.

(4) No-response Request

Figure 21.13 shows the operation of the LIN/UART interface (LIN slave mode) when no response is requested. **Table 21.86** shows the processing that occurs when no response is requested.

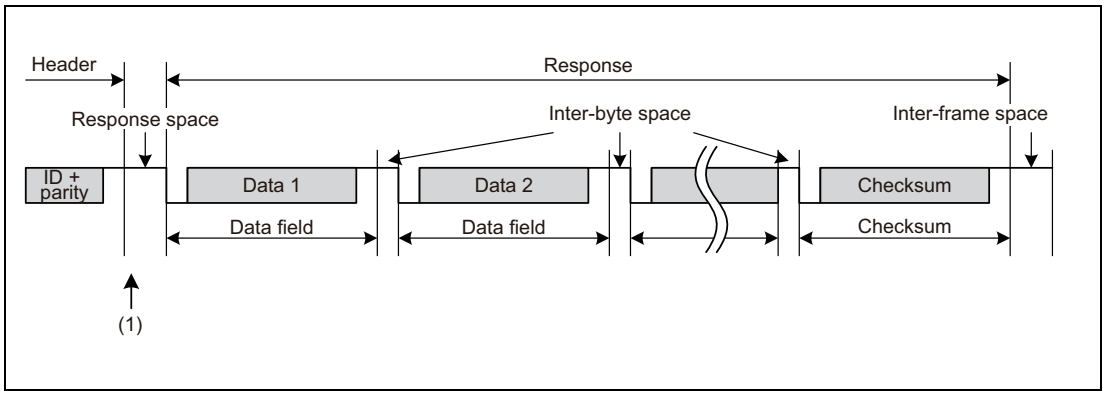

Figure 21.13 Operation when No Response is Requested

Table 21.86 Processing when No Response is Requested

	Software Processing	LIN/UART Interface Processing
(1)	• Sets the no-response request bit (LNRR bit) to 1.	• Waits for setting of the no-response request bit (LNRR bit) by software • Completes the frame reception process • Waits for a new break

21.4.4.3 Data Transmission/Reception

(1) Data Transmission

One bit of data is transmitted per 1 Tbit.

The data that is transmitted returns to the reception data input pin via the LIN transceiver. The received data and the transmitted data are compared bit by bit, and the results are stored in the BER flag in the RLN3nLEST register (see **Section 21.4.4.7, Error Status**).

In LIN master mode and LIN slave mode [fixed baud rate], 1 Tbit is generated to be 16/fLIN, and thus the sampling point for received data is at the 13th clock cycle (81.25% position).

In LIN slave mode [auto baud rate], if 1 Tbit is generated to be 4/fLIN, the sampling point for received data is at the third clock cycle (75% position). If 1 Tbit is generated to be 8/fLIN, the sampling point for received data is at the 7th clock cycle (87.5% position).

Figure 21.14 shows an example of data transmission timing.

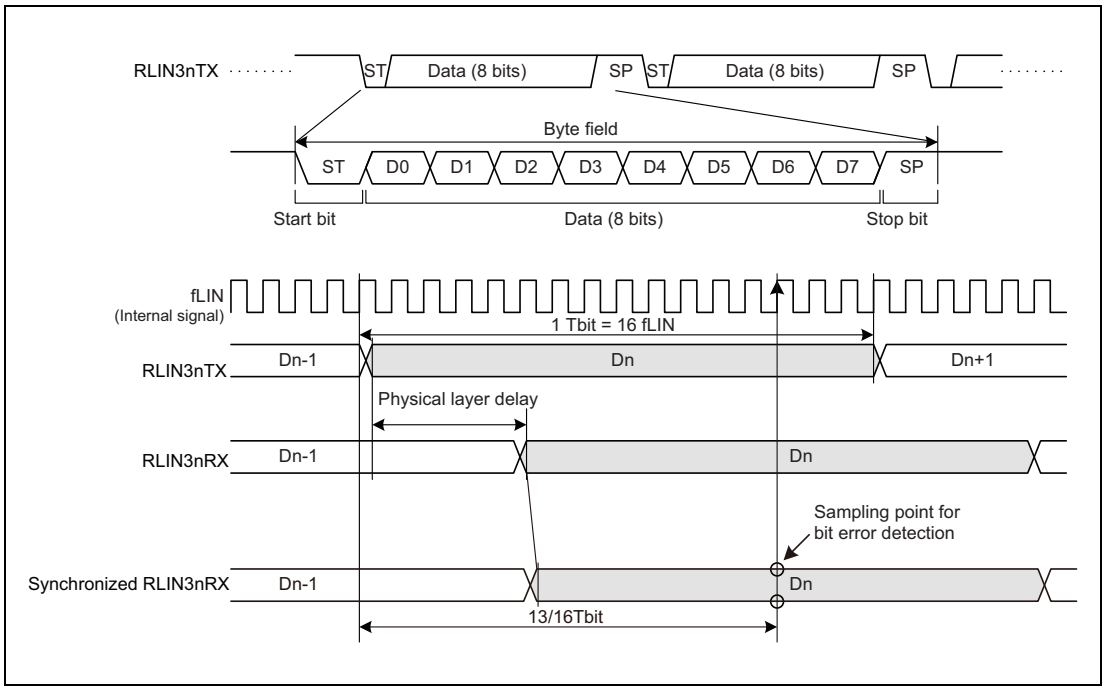

Figure 21.14 Example of Data Transmission Timing (LIN Master Mode, LIN Slave Mode [Fixed Baud Rate])

(2) Data Reception

Data reception is performed by using the synchronized RLIN3nRX signal (an internal signal) that is the input from the RLIN3nRX pin synchronized with prescaler clock.

The byte field is synchronized at the falling edge of the start bit for the synchronized RLIN3nRX signal. After the falling edge is detected, sampling is performed again 0.5 Tbit later, and the falling edge is recognized as a start bit if the synchronized RLIN3nRX signal is low level. The falling edge is not recognized as a start bit if the RLIN3nRX signal after the reset is de-asserted is fixed to low level or if a high level is detected on re-sampling.

After the start bit is detected, the system samples 1 bit per Tbit.

The LIN/UART interface has a noise filter function for reception data. If the LRDNFS bit in the RLN3nLMD register is 0, the LIN/UART interface uses a noise filter, and the value determined by a 3-sampling majority rule on prescaler clocks is used as the sampling value. If the LRDNFS bit in the RLN3nLMD register is 1, the LIN/UART interface does not use a noise filter, and the value of the synchronized RLIN3nRX value at the sampling position is used as the sampling value.

Figure 21.15 shows an example of data reception timing.

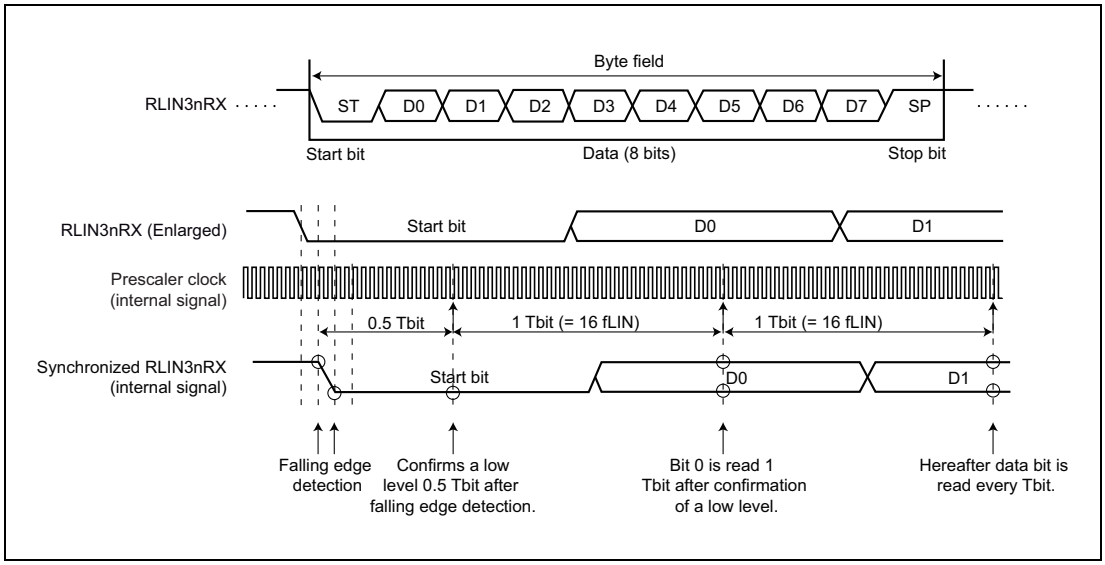

Figure 21.15 Example of Data Reception Timing (LIN Master Mode, LIN Slave Mode [Fixed Baud Rate])

21.4.4.4 Transmission/Reception Data Buffering

This section explains the buffer processing that takes place when the LIN/UART interface sends or receives data continuously.

(1) Transmission of LIN Frames

For an 8-byte transmission, the contents stored in registers RLN3nLDBR1 to RLN3nLDBR8 are sequentially transmitted to data areas 1 to 8 of the LIN frame. In the case of a 4-bytes transmission, the contents stored in registers RLN3nLDBR1 to RLN3nLDBR4 are transmitted to data areas 1 to 4 of the LIN frame, but the contents of registers RLN3nLDBR5 to RLN3nLDBR8 are not transmitted. The transmitted checksum data is stored in the RLN3nLCBR register.

Figure 21.16 shows the LIN transmission processing and the required buffers.

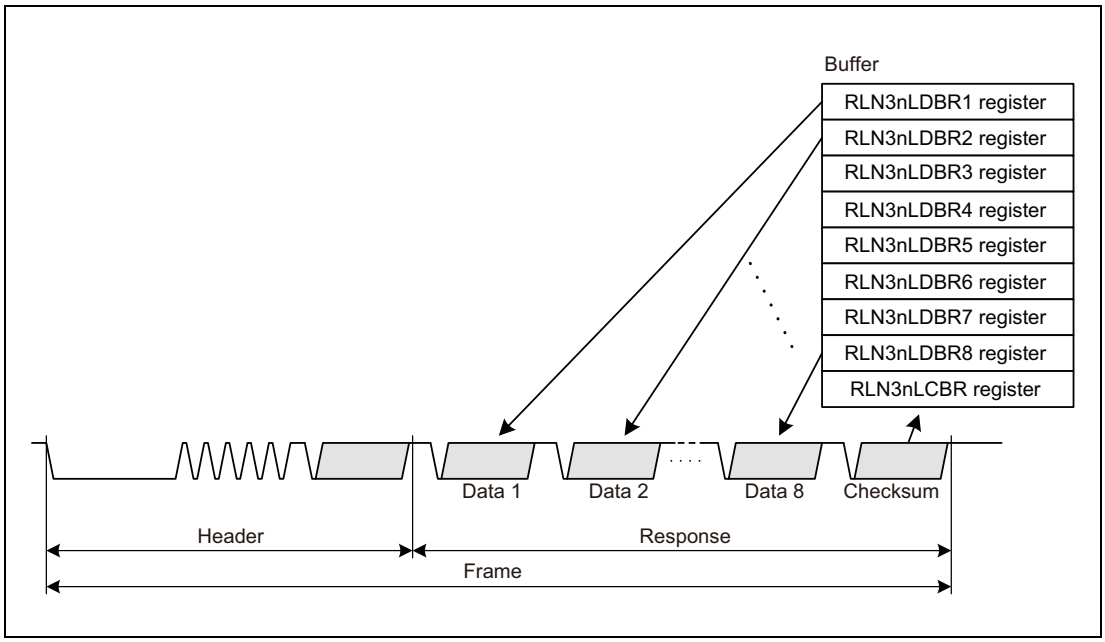

Figure 21.16 LIN Transmission Processing and Required Buffer

[Frame Separate Mode]

Setting the FSM bit in the RLN3nLDFC register to 1 turns on the frame separate mode.

In frame separate mode, a header and a response are transmitted when prompted by separate transmission start requests.

When the transmission of a header is finished, the HTRC flag in the RLN3nLST register is set to 1 (successful header transmission).

Use frame separate mode when transmitting or receiving response data of 9 bytes or more in LIN master mode.

(2) Reception of LIN Frames

For an 8-byte reception, the contents of data areas 1 to 8 of the LIN frame are stored in registers RLN3nLDBR1 to RLN3nLDBR8, respectively, upon reception of a stop bit. In the case of a 4-byte reception, the contents of data areas 1 to 4 of the LIN frame are stored in registers RLN3nLDBR1 to RLN3nLDBR4, respectively; no data is stored in registers RLN3nLDBR5 to RLN3nLDBR8. Also, the received checksum data is stored in the RLN3nLCBR register.

Figure 21.17 shows the LIN reception processing and the required buffers.

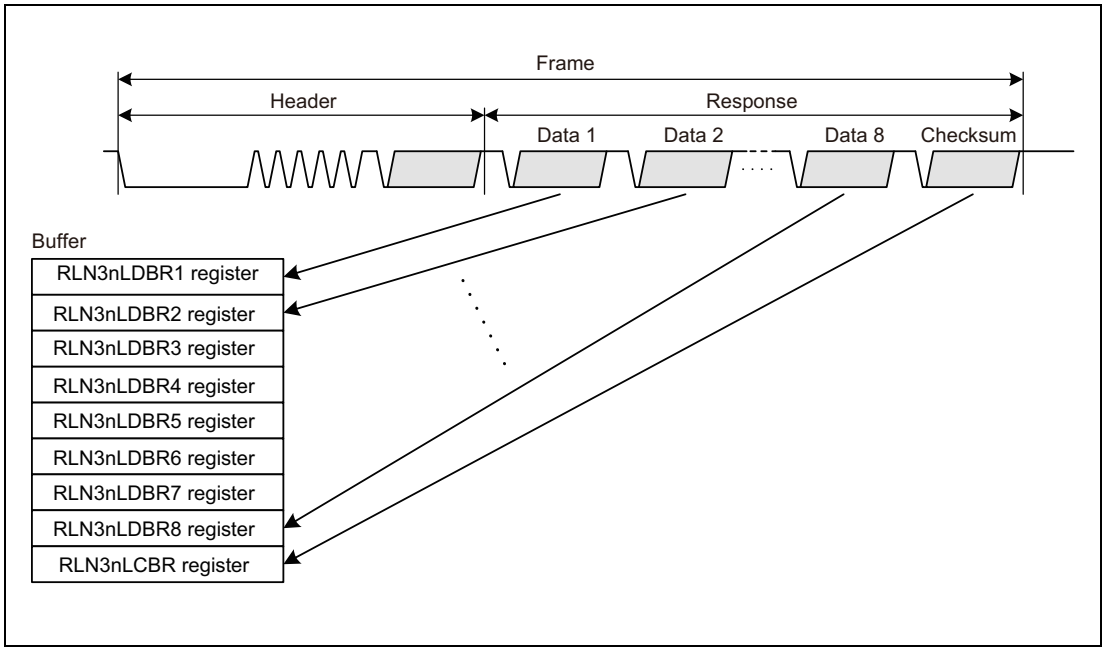

Figure 21.17 LIN Reception Processing and Required Buffer

[Reception of Data 1]

When the reception of the first byte of data is finished, the D1RC flag in the RLN3nLST register is set to 1 (successful data 1 reception).

(3) Multi-Byte Response Transmission/Reception Function

Normally in LIN communications, a response is 9 bytes or less including a checksum field; however, responses of 10 bytes or more can also be transmitted and received.

In such a case, the bit error, framing error, response preparation error detection, and auto checksum functions are enabled.

If the data length is longer than 8 bytes, the LSS bit in RLN3nLDFC register should be set to 1 (indicating that the next data group to be transmitted or received is not the last data group) in the first data group (variable from 0 to 8 bytes) before transmitting or receiving the data group. After the transmission or reception, the user should determine whether the next data group is the last data group. If it is the last data group, the LSS bit in the RLN3nLDFC register should be set to 0 (indicating that the next data group to be transmitted or received is the last data group), and a checksum should be appended to the last data group.

By changing the RFDL bit in RLN3nLDFC register settings when the RTS bit in RLN3nLTRC register is 0, the user can change the data length for each data group.

When performing multi-byte response transmission/reception in LIN master mode, set the FSM bit in RLN3nLDFC register to 1 (frame separate mode).

NOTE

In LIN slave mode, the LIN/UART interface can detect a new break field during the transmission or reception of a response.

21.4.4.5 Wake-up Transmission/Reception

The wake-up transmission/reception can be used in LIN wake-up mode.

(1) Wake-up Transmission

In LIN wake-up mode, setting the RFT bit in the RLN3nLDFC register to 1 (LIN master mode: response transmission), or setting the RCDS bit in the RLN3nLDFC register to 1 (LIN slave mode: response transmission), and then the FTS bit in the RLN3nLTRC register to 1 (frame transmission, header reception or wake-up transmission/reception started) causes a wake-up signal to be output from the output pin. The low width of the wake-up signal should be set using the WUTL[3:0] bits in the RLN3nLWUP register.

However, if the LWBR0 bit of the RLN3nLWBR register in LIN master mode is 1 (LIN2.x), the LIN system clock (fLIN) becomes low level width at fa regardless of the setting of the LCKS bit of the RLN3nLMD register. By setting the WUTL[3:0] bits of the RLN3nLWUP register to 0100_B (5 Tbits), 260 µs low width can be output in LIN wake-up mode regardless of the setting of the LCKS bit of the RLN3nLMD register.

If a wake-up low-level width is output without any bit error, the FTC flag in the RLN3nLST register is set to 1 (successful frame response or wake-up transmission); when the FTCIE bit in the RLN3nLIE register is 1 (successful frame response/wakeup transmission interrupt enabled), an interrupt request for RLIN3n transmission is generated.

If RLN3nLEDE.BERE is set and a bit error is detected, wake-up transmission is canceled and the BER flag in the RLN3nLEST register is set to 1 (bit error detection).
When RLN3nLEDE.PBERE is set in LIN master mode, set RLN3nLEST.PBER flag to 1 (physical bus error detection) at the same time of a bit error.

Figure 21.18 shows the wake-up transmission timing.

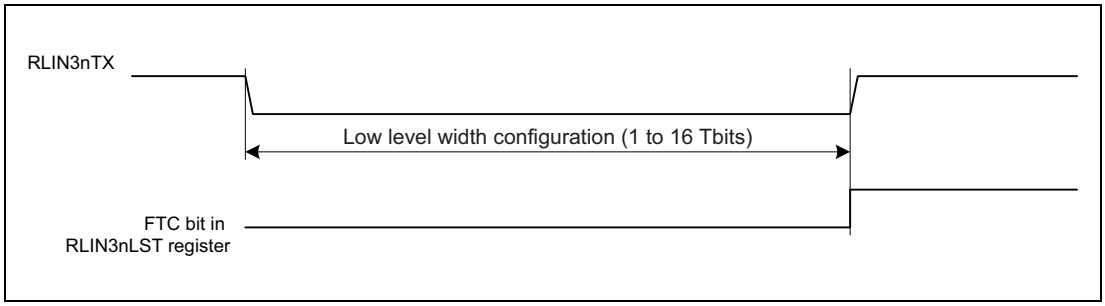

Figure 21.18 Wake-up Transmission Timing

For wake-up retransmission in LIN slave mode, refer to **Section 21.4.4.9, Wake-up Processing for Retransmission in LIN Slave Mode**.

(2) Wake-up Reception

To detect a wake-up signal, use the input signal low-level width count function. The input signal low level width count function measures the low level width of the input signal to the RLIN3nRX pin, using the same sampling point as data reception. This allows the 2.5-Tbit or longer low-level width of the input signal of fLIN to be measured.

In LIN master mode, by setting the LWBR0 bit in the RLN3nLWBR register, operation can be executed without changing the baud rate generator setting when switching between LIN operation mode and LIN wake-up mode.

When LIN Specification Package Revision 1.3 is used, set the LWBR0 bit in the RLN3nLWBR register to 0. When LIN Specification Package Revision 2.x is used, set the LWBR0 bit to 1. Setting the LWBR0 bit to 1 sets the LIN system clock (fLIN) to fa regardless of the setting of the LCKS bit in the RLN3nLMD register. (The LCKS bit is not changed). By setting the baud rate to 19200bps while fa is selected, an input signal with a low-level width of 130 us or longer can be measured in LIN wake-up mode regardless of the setting of the LCKS bit in the RLN3nLMD register.

When using the wake-up reception function, in LIN wake-up mode set the RFT bit in the RLN3nLDFC register to 0 (LIN master mode: response reception), or the RCDS bit in the RLN3nLDFC register to 0 (LIN slave mode: response reception), and then set the FTS bit in the RLN3nLTRC register to 1 (frame transmission (header reception) or wake-up transmission/reception started).

When the low level width to be measured is reached, the FRC flag in the RLN3nLST register is set to 1 (successful frame response/wake-up reception). If the FRCIE bit in the RLN3nLIE register is 1 (successful frame response or wake-up reception interrupt enabled), an interrupt request for successful RLIN3n reception is generated.

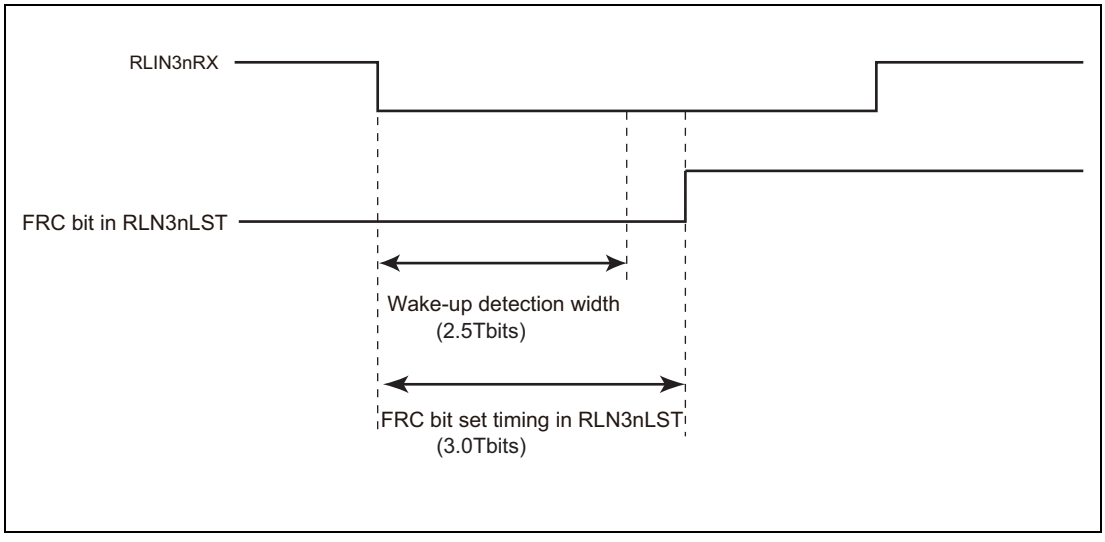

Figure 21.19 Input Signal Low level Count Function

(3) Wakeup Collision

If the master node and the slave node transmit wakeup signals simultaneously, a collision will occur on the LIN bus, though a collision of wakeup signals is not detected by the LIN/UART interface.

21.4.4.6 Status

In LIN mode operation, the LIN/UART interface can detect seven types of statuses.

The four statuses, successful frame/wake-up transmission, successful frame/wake-up reception, error detection, and successful header transmission/reception, can generate interrupt requests.

Table 21.87 shows the types of statuses available in LIN master mode. **Table 21.88** lists the types of statuses available in LIN slave mode [auto baud rate] and in LIN slave mode [fixed baud rate].

Table 21.87 Types of Statuses in LIN Master Mode

Status	Status Set Condition	Status Clear Condition	Operation Mode Capable of Status Detection	Corresponding Bit	Interrupt
Reset	After the OM0 bit in the RLN3nLCUC register is set to not-LIN-reset-mode, if actually the LIN/UART interface is cleared from LIN reset mode.	After the OM0 bit in the RLN3nLCUC register is set to LIN reset mode, if actually the LIN/UART interface enters LIN reset mode.	All modes	OMM0 bit in RLN3nLMST register	—
Operation mode	After the OM1 bit in the RLN3nLCUC register is set to LIN operation mode, if actually the LIN/UART interface enters LIN operation mode.	After the OM1 bit in the RLN3nLCUC register is set to LIN wake-up mode, if actually the LIN/UART interface enters LIN wake-up mode.	• LIN operation mode • LIN wake-up mode	OMM1 bit in RLN3nLMST register	—
Frame/wake-up transmission end	When a frame (header transmission + response transmission), a wake-up signal, or a data group is transmitted successfully.	• When another communication is started (When the FTS bit in the RLN3nLTRC register is set) • When cleared by software • After transition to LIN reset mode	• LIN operation mode • LIN wake-up mode	FTC flag in RLN3nLST register	√
Frame/wake-up reception end	When a frame (header transmission + response reception), a wake-up signal, or a data group is received successfully.	• When another communication is started (When the FTS bit in the RLN3nLTRC register is set) • When cleared by software • After transition to LIN reset mode	• LIN operation mode • LIN wake-up mode	FRC flag in RLN3nLST register	√
Error detection	If any of the RPER flag, CSER flag, FER flag, FTER flag, PBER flag, and BER flag in the RLN3nLEST register is set to 1 (error detected).	• When another communication is started (When the FTS bit in the RLN3nLTRC register is set) • When cleared by software*1 • After transition to LIN reset mode	• LIN operation mode • LIN wake-up mode	ERR flag in RLN3nLST register	√
Data 1 reception end	The RFT bit in the RLN3nLDFC register is 0 (reception) and the first byte of the response field or the first byte of each data group is received successfully.*2	• When another communication is started (When the FTS bit in the RLN3nLTRC register is set) • When cleared by software • After transition to LIN reset mode	LIN operation mode	D1RC flag in RLN3nLST register	—
Header transmission end	When a header field is transmitted successfully.	• When another communication is started (When the FTS bit in the RLN3nLTRC register is set) • When cleared by software • After transition to LIN reset mode	LIN operation mode	HTRC flag in RLN3nLST register	√

Note 1. In LIN wake-up mode or LIN operation mode, the ERR flag in the RLN3nLST register is cleared to 0 by writing 0 to the RPER flag, CSER flag, FER flag, FTER flag, PBER flag, or BER flag in the RLN3nLEST register.

Note 2. Not detected when the RFDL [3:0] bits in the RLN3nLDFC register are 0000_B (0-byte + checksum).

Table 21.88 Types of Statuses in LIN Slave Mode

Status	Status Set Condition	Status Clear Condition	Operation Mode Capable of Status Detection	Corresponding Bit	Interrupt
Reset	After the OM0 bit in the RLN3nLCUC register is set to not-LIN–reset-mode, if actually the LIN/UART interface is cleared from LIN reset mode.	After the OM0 bit of the RLN3nLCUC register is set to LIN reset mode, if actually the LIN/UART interface enters LIN reset mode.	All modes	OMM0 bit in RLN3nLMST register	—
Operation mode	After the OM1 bit in the RLN3nLCUC register is set to LIN operation mode, if actually the LIN/UART interface enters LIN operation mode.	• After the OM1 bit in the RLN3nLCUC register is set to LIN wake-up mode, if actually the LIN/UART interface enters LIN wake-up mode.	• LIN operation mode • LIN wake-up mode	OMM1 bit in RLN3nLMST register	—
Response/ wake-up transmission end	When a response field, a wake-up signal, or a data group is transmitted successfully.	• When cleared by software • Transition to LIN reset mode	• LIN operation mode • LIN wake-up mode	FTC flag in RLN3nLST register	√
Response/ wake-up reception end	When a response field, a wake-up signal, or a data group is received successfully.	• When cleared by software • Transition to LIN reset mode	• LIN operation mode • LIN wake-up mode	FRC flag in RLN3nLST register	√
Error detection	If any of the RPER flag, IPER flag, CSER flag, SFER flag, FER flag, TER flag, and BER flag in the RLN3nLEST register is set to 1 (error detected).	• When cleared by software*1 • Transition to LIN reset mode	• LIN operation mode • LIN wake-up mode	ERR flag in RLN3nLST register	√
Data 1 reception end	The RCDS bit in the RLN3nLDFC register is 0 (reception) and the first byte of the response field or the first byte for each data group is received successfully.*2	• When cleared by software • Transition to LIN reset mode	LIN operation mode	D1RC flag in RLN3nLST register	—
Header reception end	When a header field is received successfully.	• When cleared by software • Transition to LIN reset mode	LIN operation mode	HTRC flag in RLN3nLST register	√
Break field reception	When break field is received successfully	• When cleared by software • Transition to LIN reset mode	LIN wake-up mode	BRKC flag in RLN3nLBSS register	—
Sync field reception	When sync field is received successfully	• When cleared by software • Transition to LIN reset mode	LIN wake-up mode	SYCC flag in RLN3nLBSS register	—
Response space dominant detection	When a dominant level of 0.5 Tbit or more is detected from the completion of the header reception to the start of transmission	• When received a sync field • Transition to LIN reset mode	LIN operation mode	RSDD flag in RLN3nLRSS register	—

Note 1. In LIN wake-up mode or LIN operation mode, the ERR flag in the RLN3nLST register is cleared to 0 by writing 0 to the RPER flag, IPER flag, CSER flag, SFER flag, FER flag, TER flag, or BER flag in the RLN3nLEST register.

Note 2. Not detected when the RFDL [3:0] bits in the RLN3nLDFC register are 0000_B (0-byte + checksum).

21.4.4.7 Error Status

(1) LIN Master Mode

(a) Types of Error Statuses

The LIN/UART interface can detect six types of error statuses in LIN master mode. The condition of these error statuses can be verified by checking the corresponding bits in the RLN3nLEST register.

All error statuses are interrupt factors.

Table 21.89 shows the types of error statuses.

Table 21.89 Types of Error Statuses in LIN Master Mode

Status	Error Detection Condition	Operation Mode Capable of Error Detection	Communication	Enable/ Disable Detection	Corresponding Bit
Bit error	The transmitted data and the data on the LIN bus monitored by the receive pin do not match *1*2	• LIN operation mode • LIN wake-up mode	Cancel	Enabled	BER flag in RLN3nLEST register
Physical bus error	• LIN bus detected a high level when sending a break • LIN bus detected a low level when sending a break delimiter • LIN bus detected a high level when sending a wake-up	• LIN operation mode • LIN wake-up mode	Cancel	Enabled	PBER flag in RLN3nLEST register
Timeout error	A frame or response transmission/reception is not completed within a given time*3,*4	LIN operation mode	Cancel	Enabled	FTER flag in RLN3nLEST register
Framing error	In response field reception, a stop bit of each data byte is low level	LIN operation mode	Cancel	Enabled	FER flag in RLN3nLEST register
Checksum error	In response field reception, the result of checksum indicates an error	LIN operation mode	—	Disabled	CSER flag in RLN3nLEST register
Response preparation error	One of the following conditions occurs in frame separate mode during a multi-byte response reception: • After header transmission is complete, the first byte of receive data is received before a response transmission/reception request is set. • After the previous data group reception is complete, the first byte of receive data is received before a transmission/reception request for the next data group is set.	LIN operation mode	Cancel	Disabled	RPER flag in RLN3nLEST register

Note 1. If a bit error is detected, processing is stopped after a stop bit is sent. If a bit error is detected in a non-data area, such as an inter-byte space, the transmission is suspended immediately after the bit which had the error is sent. If a bit error is detected during the transmission of a wake-up, the transmission of the wake-up is canceled after the error-causing bit is sent.

Note 2. In a multi-byte response transmission, bit errors are also detected between data groups.

Note 3. The timeout time depends on the response field data length (the RFDL [3:0] bits in the RLN3nLDFC register) and the checksum selection (the CSM bit in the RLN3nLDFC register), and can be calculated from the following formula.
When the FSM bit in the RLN3nLDFC register is 1 (frame separation mode), the timeout time is that for eight bytes until the RTS bit of the RLN3nLTRC register is set. Once the RTS bit is set, the timeout time is re-set to the time based on the response field data length (the RFDL[3:0] bits in the RLN3nLDFC register).

Note 4. If RLIN3 transitions to LIN reset mode by clearing RLN3nLCUC.OM0 to 0 when the timeout function is used (RLN3nLEDE.FTERE = 1), users should take the procedure shown in **Figure 21.4**.

[Frame timeout]
When classic checksum is selected (when the CSM bit in RLN3nLDFC is 0): Timeout time = 49 + (number of data bytes + 1) × 14 [Tbit]
When enhanced checksum is selected (when the CSM bit in RLN3nLDFC is 1): Timeout time = 48 + (number of data bytes + 1) × 14 [Tbit]
The aforementioned timeout time is a time longer than the TFRAME_MAX of LIN Specification Package Revision 1.3 when classic checksum is selected, or the TFRAME_MAX of LIN Specification Package Revision 2.x when enhanced checksum is selected.
[Response timeout]
Timeout time = (number of data bytes + 1) × 14 [Tbit]

When an error is detected, the timeout error detection function stops.

The error status is cleared when the next communication is started (when the FTS bit in the RLN3nLTRC register is set) when it is cleared by software, or at a transition to LIN reset mode.

(b) Target Time Area for LIN Error Detection

Figure 21.20 shows the time domain in which the LIN/UART interface in LIN master mode performs monitoring for error detection.

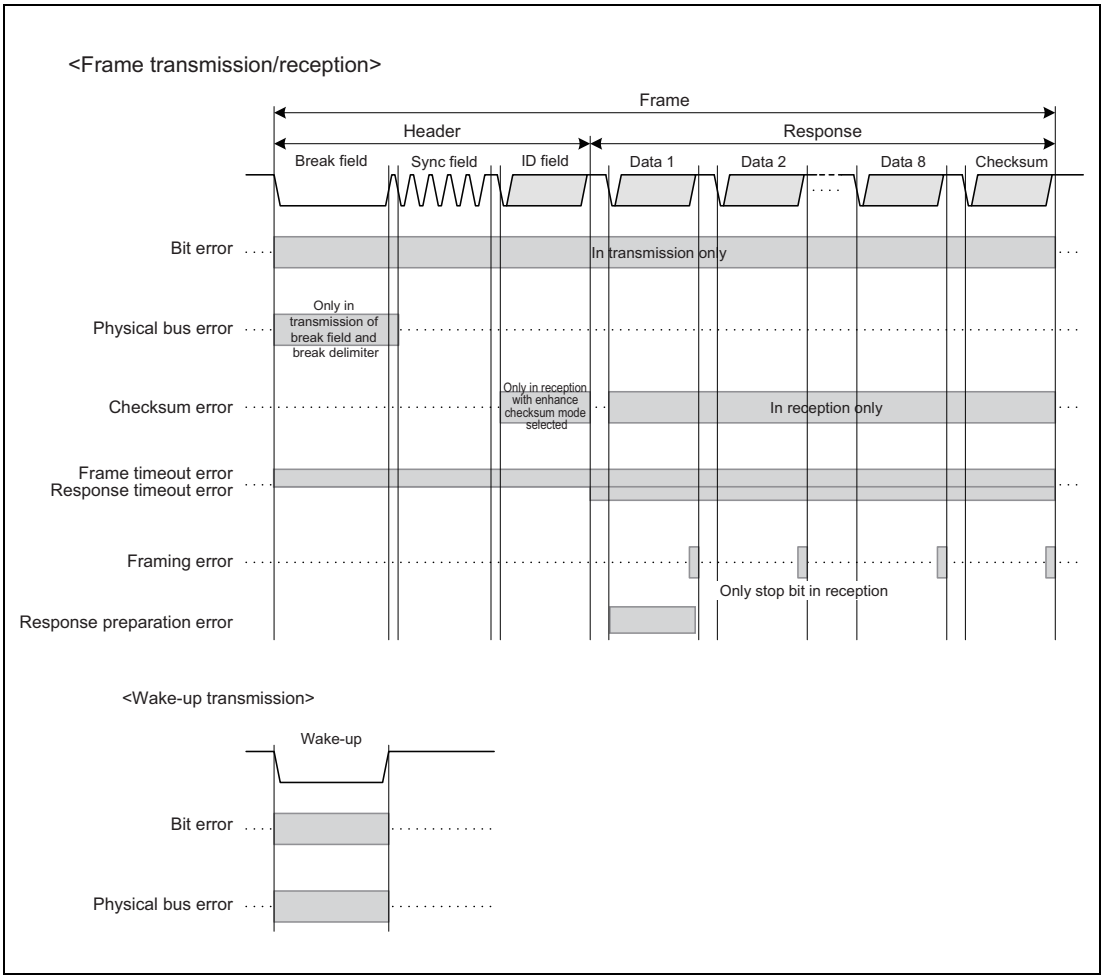

Figure 21.20 Target Time Area for LIN Error Detection (LIN Master Mode)

(2) LIN Slave Mode

(a) Types of Error Statuses

The LIN/UART interface can detect seven types of error statuses in LIN slave mode [auto baud rate] or in LIN slave mode [fixed baud rate]. These error statuses can be verified by checking the corresponding bits in the RLN3nLEST register.

Table 21.90 shows the types of error statuses.

Table 21.90 Types of Error Statuses in LIN Slave Mode

Status	Error Detection Condition	Operation Mode Capable of Error Detection	Communication	Enable/ Disable Detection	Corresponding Bit
Bit error	The transmitted data and the data on the LIN bus monitored by the receive pin do not match*1 *2	• LIN operation mode • LIN wake-up mode	Cancel	Enabled	BER flag in RLN3nLEST register
Timeout error	A frame or response transmission/reception is not completed within a given time*3, *6	LIN operation mode	Cancel	Enabled	TER flag in RLN3nLEST register
Framing error	In frame reception, a stop bit of each data byte is low level	LIN operation mode	Cancel	Enabled	FER flag in RLN3nLEST register
Sync field error	If the width of the break low level is greater than the width set by the LBLT bit in the RLN3nLBFC register and the sync field is not 55_H	LIN operation mode	Cancel	Enabled*4	SFER flag in RLN3nLEST register
Checksum error	In response field reception, the result of checksum indicates an error	LIN operation mode	—*5	Disabled	CSER flag in RLN3nLEST register
ID parity error	If the received ID parity bit does not match the value that is automatically calculated by the LIN/ UART interface	LIN operation mode	Cancel	Enabled	IPER flag in RLN3nLEST register
Response preparation error	• After the reception of a header, response preparation is not completed in time before the first byte of reception data is received. • In multi-byte response reception, the reception preparation for the next data group is not completed in time before the first byte of the next data group reception data is received.	LIN operation mode	Cancel	Disabled	RPER flag in RLN3nLEST register

Note 1. If a bit error is detected, processing is stopped after a stop bit is sent. If a bit error is detected in a non-data area, such as an inter-byte space, the transmission is suspended immediately after the bit which had the error is sent. If a bit error is detected during the transmission of a wake-up, the transmission of the wake-up is canceled after the error-causing bit is sent.

Note 2. In a multi-byte response transmission, bit errors are also detected between data groups.

Note 3. The timeout time depends on the response field data length (the RFDL [3:0] bits in the RLN3nLDFC register) and the checksum selection (the LCS bit in the RLN3nLDFC register), and this can be calculated according to the following formula. The timeout period until the RTS or LNRR bit of the RLN3nLTRC register is set is 8 data bytes. When the RTS bit is set, the timeout time is reset to the time based on the response field data length (RFDL[3:0] bits of the RLN3nLDFC register). When the LNRR bit is set, the timeout function stops.

[Frame timeout]
When classic checksum is selected (when the CSM bit in RLN3nLDFC is 0): Timeout time = 49 + (number of data bytes + 1) × 14 [Tbit]
When enhanced checksum is selected (when the CSM bit in RLN3nLDFC is 1): Timeout time = 48 + (number of data bytes + 1) × 14 [Tbit]

The aforementioned timeout time is a time longer than the TFRAME_MAX of LIN Specification Package Revision 1.3 when classic is selected, or the TFRAME_MAX of LIN Specification Package Revision 2.x when enhanced is selected.

[Response timeout]
Timeout time = (number of data bytes + 1) × 14 [Tbit]
When an error is detected, timeout error detection function stops.

Note 4. Only reflection of the result to the SFER flag can be enabled/disabled. Error detection cannot be enabled/disabled.

Note 5. Checksum judgment is performed upon completion of response frame reception. In case of an error, the successful reception flag is not set to 1.

Note 6. If RLIN3 transitions to LIN reset mode by clearing RLN3nLCUC.OM0 to 0 when the timeout function is used (RLN3nLEDE.TERE = 1), users should take the procedure shown in **Figure 21.4**.

The error status is cleared by software or at a transition to LIN reset mode.

(b) Target Time Area for LIN Error Detection

Figure 21.21 shows the time domain in which the LIN/UART interface in slave mode performs monitoring for error detection.

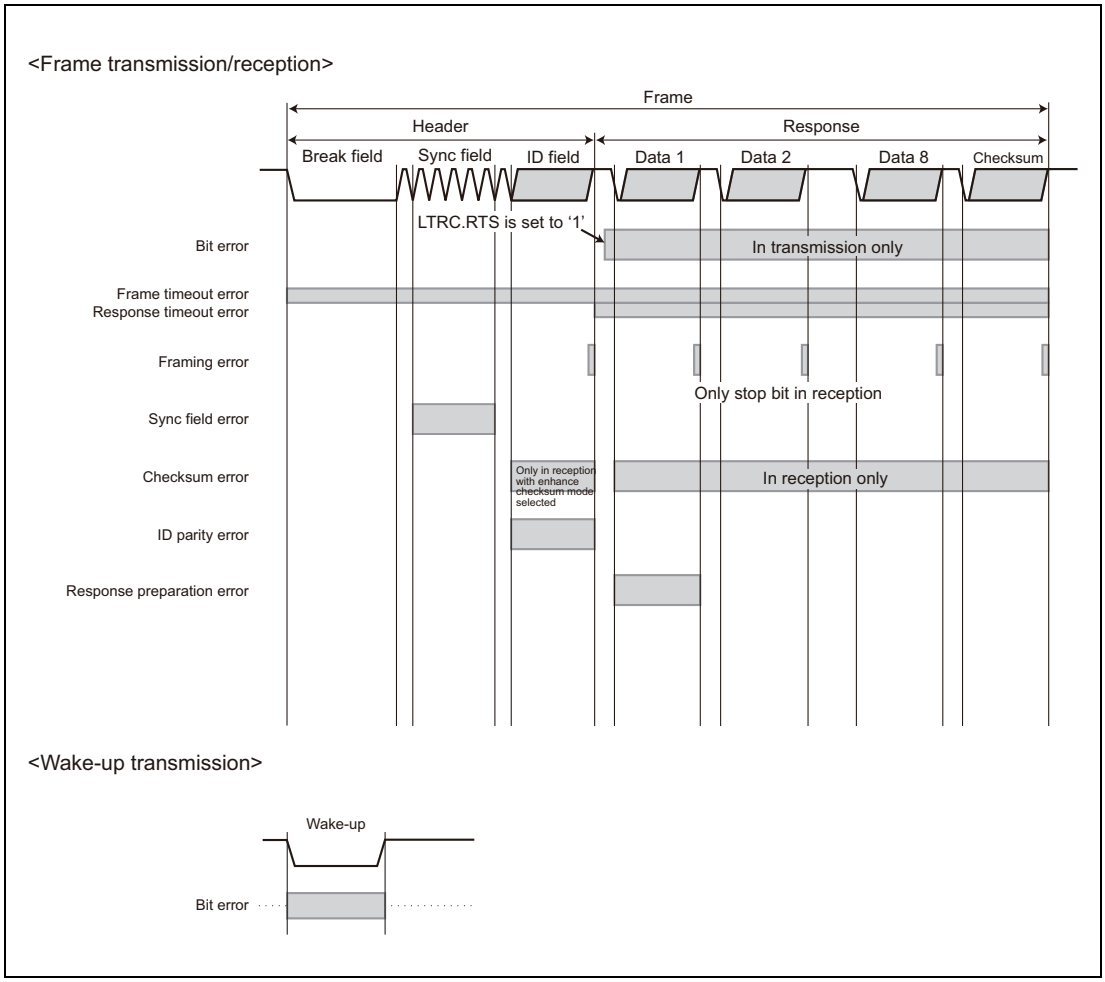

Figure 21.21 Target Time Area for LIN Error Detection (LIN Slave Mode)

21.4.4.8 Conflicts of Error Status

The table below shows the condition of error status bits that occurs at the end of single frame in LIN Master Mode.

The combination not listed in the table, condition does not occur.

Table 21.91 Conflicts of Error Status (LIN Master Mode)

Number of Conflict	kinds of Errors

21.4.4.9 Wake-up Processing for Retransmission in LIN Slave Mode

The figure below illustrates flow of the wake-up processing in LIN slave mode.

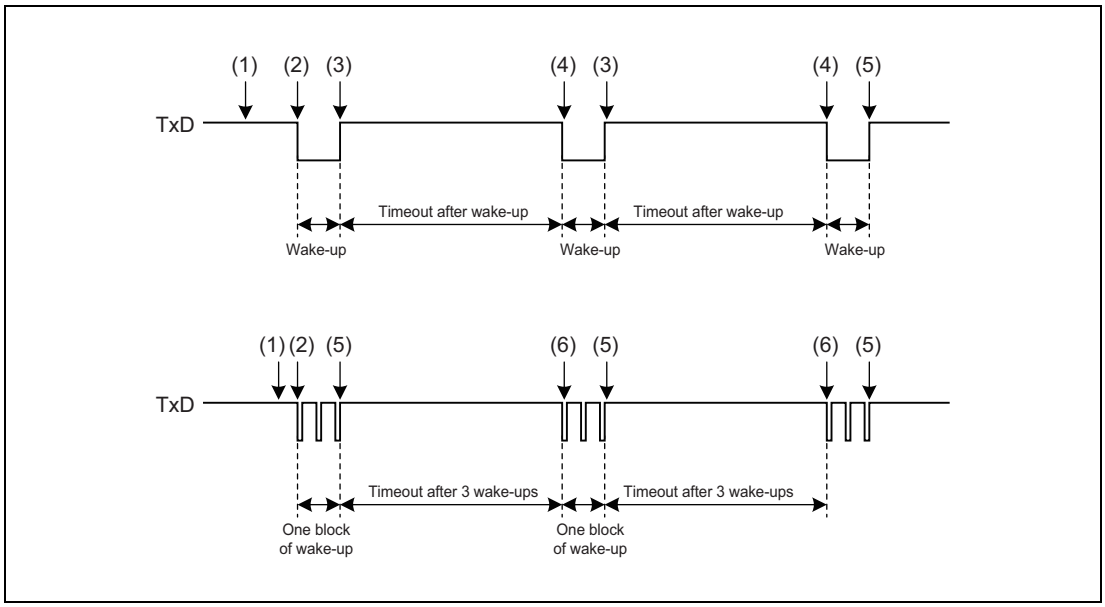

Figure 21.22 The Wake-up Processing with Retransmission in LIN Slave Mode

(1) LIN Break Field Reception flag and LIN Sync Field Reception flag are cleared by writing “0” to them.

(2) Transmitting a wake-up signal.

(3) Wait for wake-up signal transmission complete. When the wake-up transmission is aborted, LIN controller handles the error. When the wake-up transmission is successful, a timer for “timeout after wake-up” is started.

(4) When a master node does not transmit a header (the LIN Break Field Reception flag or the LIN Sync Field Reception flag is not set) within the time specified by LIN standard, a SW driver should retransmit a wake-up signal.

(5) When three wake-up transmissions are completed, a timer for “timeout after 3 wake-ups” is started.

(6) When a master node does not transmit a header (the LIN Break Field Reception flag or the LIN Sync Field Reception flag is not set) within the time specified (after three wake-up signals) by LIN standard, a SW driver should retransmit a wake-up signal.

21.4.4.10 Detail of Response Space Dominant Detection

Flow of operation on response space dominant detection is illustrated below.

The detection period of the Response Space Dominant Detection Flag is (2) to (4) in the figure below.

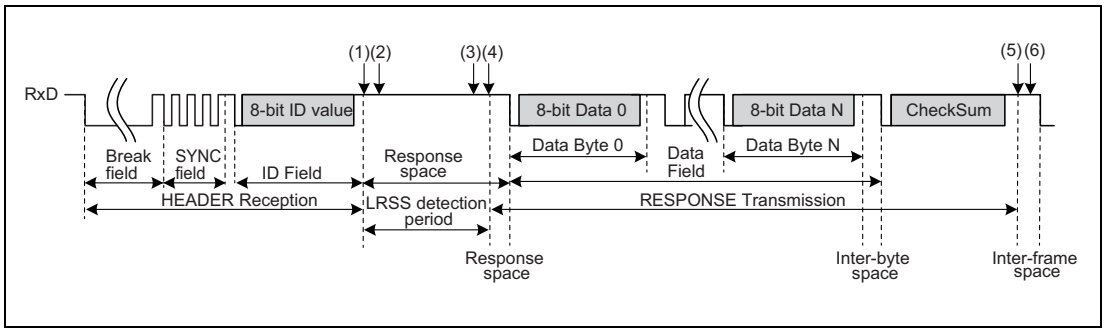

Figure 21.23 Flow of Operation of the LIN Controller on Response Space Dominant Detection

(1) Output LIN Header Reception flag.

(2) Header Reception process completed and SW drivers should read the received ID to check if Response preparation is required.

(3) Check the LIN Response Space Dominant Detection flag and set Response Transmission or Reception start bit or the LIN No Response request bit to “1”.

(4) When Response Transmission or Reception start bit is set and response Transmission is selected, LIN Controller transmits Response Space.

(5) Output Frame Transmission complete flag. The Response Transmission or Reception start bit is cleared by HW.

(6) LIN Response Transmission is completed and SW drivers should read the Response Space Dominant Detection Flag to check status of response transmission.

The figure below illustrates a flow of response transmission in LIN slave mode.

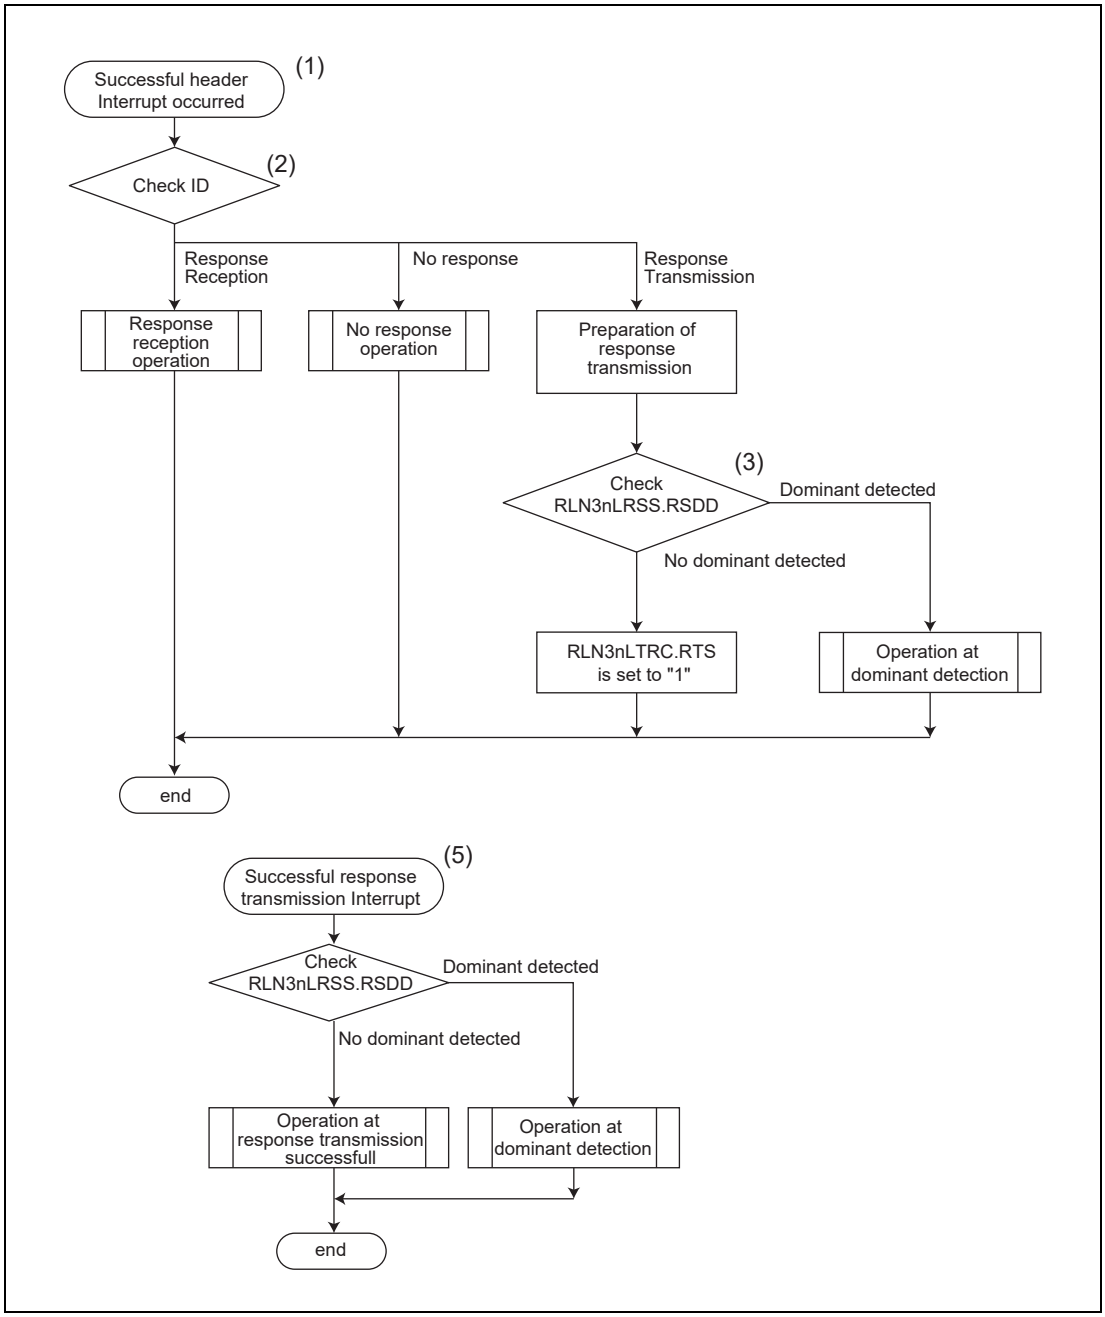

Figure 21.24 Flow of Response Transmission in LIN Slave Mode

21.4.5 UART Mode

In LIN reset mode, setting the LMD bits in the RLN3nLMD register to 01_B (UART mode) and the OM0 bit in the RLN3nLCUC register to 1 changes the mode to UART mode, turning the OMM0 bit in the RLN3nLMST register to 1.

21.4.5.1 Transmission

Figure 21.25 shows LIN/UART interface (in UART mode) transmission operations; **Table 21.93** shows LIN/UART interface (in UART mode) transmission processing.

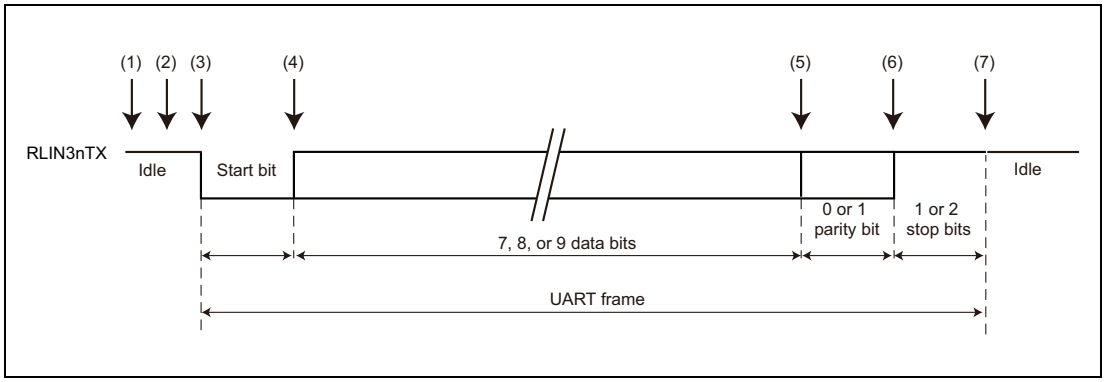

Figure 21.25 LIN/UART Interface (in UART Mode) Transmission Operation

Table 21.93 LIN/UART Interface (UART Mode) Transmission Processing (1/2)

	Software Processing	LIN/UART Interface Processing
(1)	• Sets a baud rate. • Sets noise filter ON/OFF. • Enables error detection. • Sets data format. • Sets an interrupt generation timing. • Clears the LIN/UART interface from LIN reset mode. • Sets the transmit enable bit (UTOE bit) to 1.	• Waits for a transmission trigger (RLN3nLUTDR register) by software.
(2)	• Sets the transmit data to the UART transmit data register (RLN3nLUTDR) or UART wait transmit data register (RLN3nLUWTDR).	• Sets the transmit status flag.
(3)	• Waits an interrupt request. [When the UTIGTS bit is 0 (a transmission interrupt request is generated upon start of transmission)] • When transmitting data continuously, sets another piece of transmission data in the UART transmit data register (RLN3nLUTDR register), waits for the generation of an interrupt request.	• Transmits a start bit (for switching between transmission and reception in half duplex communication, transmits a start bit after receiving 1 stop bit. For details about this function, see **Section 21.4.5.1(4), Transmission Start Wait Function**. [When the UTIGTS bit is 0 (a transmission interrupt request is generated upon start of transmission)] • Outputs a transmission interrupt.
(4)		Transmits the data set in the UART (for wait) transmit data register.
(5)		Transmits a parity bit when parity is used.
(6)		Transmits 1 or 2 stop bits.

Table 21.93 LIN/UART Interface (UART Mode) Transmission Processing (2/2)

	Software Processing	LIN/UART Interface Processing
(7)	[When the UTIGTS bit is 0 (a transmission interrupt request is generated upon start of transmission)] • If another item of transmission data is set, goes to step (3). [When the UTIGTS bit is 1 (a transmission interrupt is generated upon end of transmission)] • When transmitting data continuously, goes to step (2).	[When the UTIGTS bit is 0 (a transmission interrupt request is generated upon start of transmission)] • If another piece of transmission data is set, goes to step (3). • If another piece of transmission data is not set, clears the transmit status flag. [When the UTIGTS bit is 1 (a transmission interrupt is generated upon end of transmission)] • Generates RLIN3n transmission interrupt request. • Clears the transmission status flag.

(1) Continuous Transmission

The LIN/UART interface (in UART mode) can transmit multiple sets of data continuously by using the RLN3nLUTDR register. **Figure 21.26** shows an operation example where the transmission interrupt generation timing is the start of transmission and an operation example where the transmission interrupt generation timing is the end of transmission.

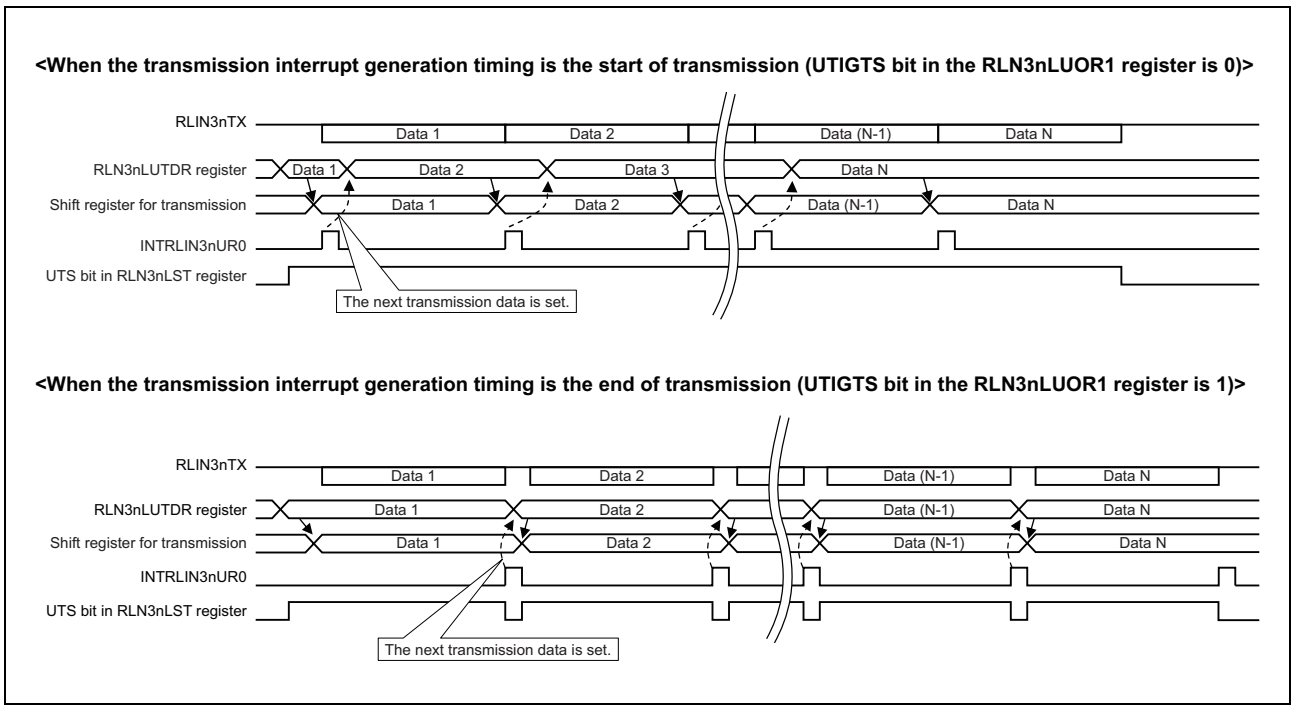

Figure 21.26 Operation Example of LIN/UART Interface (UART Mode) Continuous Transmission

An interrupt can be generated at the end of a transmission by changing the UTIGTS bit in the RLN3nLUOR1 register from 0 to 1 after the start of transmission of final data, provided that the transmission interrupt generation timing is the start of transmission and the end of transmission of final data needs to be known.

(2) UART Buffer Transmission

The LIN/UART interface (in UART mode) has a maximum of nine bytes of UART buffers, and thus it is capable of performing continuous transmissions through the use of UART buffers.

Figure 21.27 shows the UART buffer transmission operation of the LIN/UART interface (in UART mode). **Table 21.94** describes the UART buffer transmission processing.

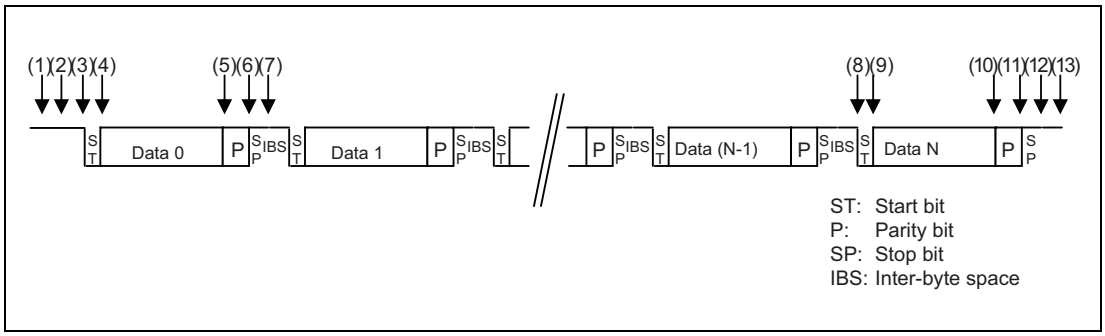

Figure 21.27 UART Buffer Transmission of LIN/UART Interface (in UART Mode)

Table 21.94 UART Buffer Transmission Processing of LIN/UART Interface (in UART Mode) (1/2)

	Software Processing	LIN/UART Interface Processing
(1)	• Sets a baud rate • Sets noise filter ON/OFF • Enables error detection • Sets data format • Sets an interrupt generation timing to the end of transmission. • Clears the LIN/UART interface from LIN reset mode. • Sets the transmit enable bit (UTOE bit) to 1	• Waits for a transmission trigger (RTS bit) by software
(2)	• Sets the UART buffer data length and whether the system must wait for the start of transmission. • Sets the transmission data in the UART data 0 buffer register (RLN3nLUDB0) and the LIN data buffer b register (RLN3nLDBRb). (b =1 to 8) • Sets the UART buffer transmission start bit (RTS).	• Sets the transmit status flag.
(3)	Waits for an interrupt request.	Transmits a start bit. (When switching from reception to transmission during half-duplex communication, transmits the start bit upon completion of the stop bit for reception. For details about this function, see **Section 21.4.5.1(4), Transmission Start Wait Function**.)
(4)		Transmits the data set in the UART data buffer 0 register (RLN3nLUDB0) and the LIN/UART data buffer b register (RLN3nLDBRb).
(5)		Transmits a parity bit when parity is used.
(6)		Transmits 1 or 2 stop bits (When the number of data set in UART buffer data length select bits is 1, proceeds to (12).)
(7)		Transmits an inter-byte space (idle).
		Repeats steps (3) to (7) until number of data set in the UART buffer data length select bits -1 is reached.

Table 21.94 UART Buffer Transmission Processing of LIN/UART Interface (in UART Mode) (2/2)

	Software Processing	LIN/UART Interface Processing
(8)		Transmits a start bit.
(9)		Transmits the data set in the LIN/UART data buffer b register (RLN3nLDBRb).
(10)		Transmits a parity bit when parity is used.
(11)		Transmits 1 or 2 stop bits.
(12)		• Sets the successful buffer transmission flag. • Clears the UART buffer transmit start bit (RTS). • A transmission interrupt request signal. • Clears the transmission status flag.
(13)	• Checks the RLN3nLST register, and clears flags • In the case of continuous data transmission, goes to step (2).	

(a) UART Buffer Transmission

For a 9-byte transmission, the contents stored in the RLN3nLUDB0 and RLN3nLDBR1 to RLN3nLDBR8 registers are transmitted to data areas 0 to 8. The RLN3nLUDB0 register is used only if 9-byte transmission is set. In other cases, the RLN3nLDBR1 to RLN3nLDBR8 registers are selected depending upon the length of data involved. For a 4-byte transmission, the contents stored in the RLN3nLDBR1 to RLN3nLDBR4 registers are transmitted to data areas 1 to 4, but the contents of the RLN3nLDBR5 to RLN3nLDBR8 registers are not transmitted. An RLIN3n transmission interrupt is generated after the number of data specified in the MDL [3:0] bits of the RLN3nLDFC register is transmitted. The spaces between transmission data items can be set in the IBS bit in the RLN3nLSC register.

Figure 21.28 shows a 9-byte UART buffer and the transmission processing.

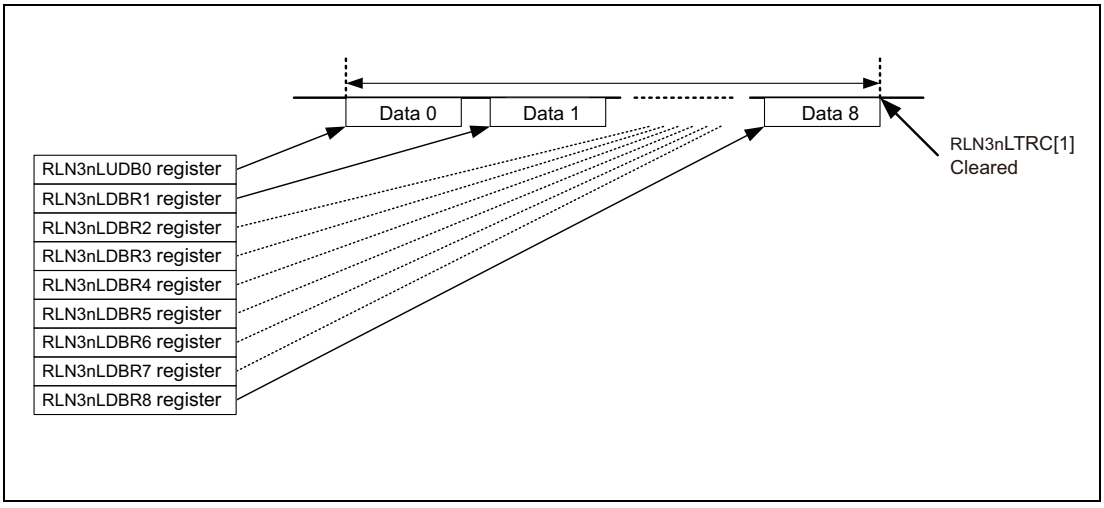

Figure 21.28 UART Buffer and Transmission Processing (for 9-Byte Transmission)

(3) Data Transmission

One bit of data is transmitted per Tbit.

In half-duplex communication, if the BERE bit in the RLN3nLEDE register is 1 (bit error detection enabled), the transmission data and the input pin level are compared bit by bit during data transmission, and the results are stored in the BER flag in the RLN3nLEST register (see **Section 21.4.5.5, Error Status**). The timing at which the input pin is sampled during data transmission can vary depending upon the settings of the LPRS[2:0] and NSPB[3:0] bits in the RLN3nLWBR register.

The bit error detection timing in UART mode is shown in **Table 21.95**.

Table 21.95 Error Detection Timing in UART Mode

Sampling Count Per Bit	Bit Error Detection Timing
6 samples	3rd clock cycle + 1 prescaler clock
7 samples	4th clock cycle + 1 prescaler clock
8 samples	4th clock cycle + 1 prescaler clock
9 samples	5th clock cycle + 1 prescaler clock
10 samples	5th clock cycle + 1 prescaler clock
11 samples	6th clock cycle + 1 prescaler clock
12 samples	6th clock cycle + 1 prescaler clock
13 samples	7th clock cycle + 1 prescaler clock
14 samples	7th clock cycle + 1 prescaler clock
15 samples	8th clock cycle + 1 prescaler clock
16 samples	8th clock cycle + 1 prescaler clock

Example of Data Transmission Timing (when 1 Tbit = 16 samplings) is shown in **Figure 21.29**

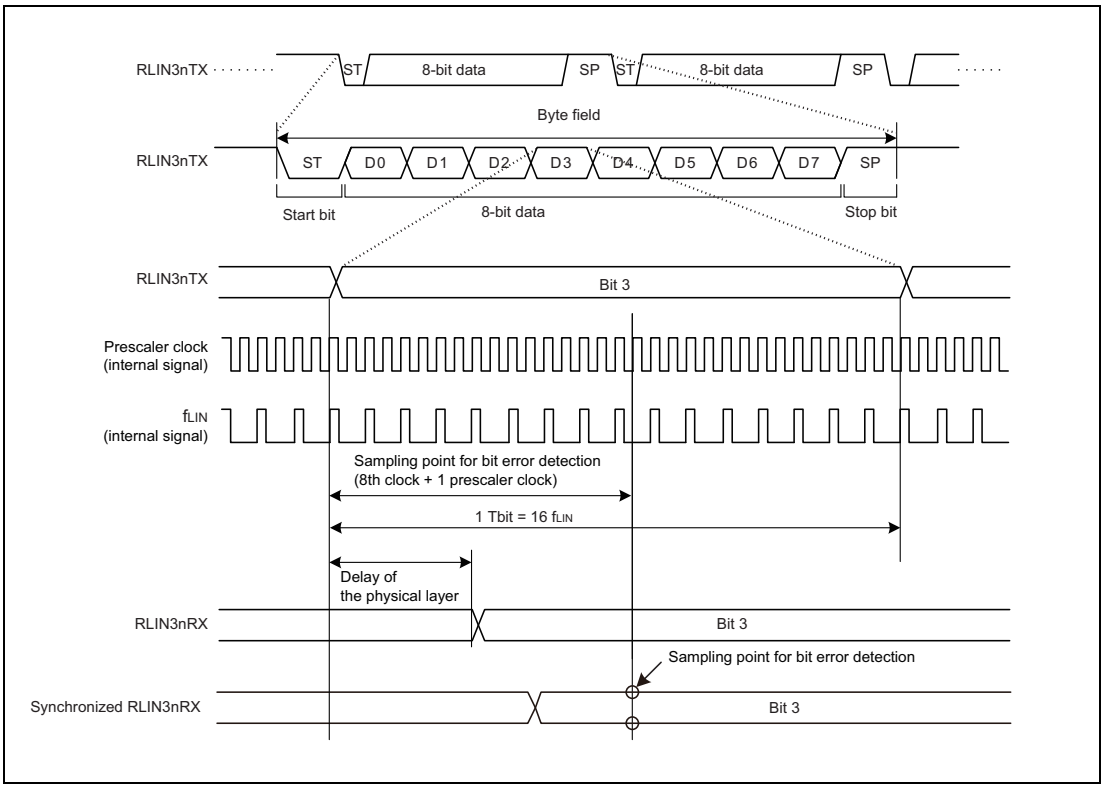

Figure 21.29 Example of Data Transmission Timing (When 1 Tbit = 16 samplings)

(4) Transmission Start Wait Function

For performing half-duplex communication, the LIN/UART interface (in UART mode) has the function of securing the reception stop bit length when switching from reception to transmission.

If it is desired to delay the start of transmission until the stop bits for the reception are completed, set data in the RLN3nLUWTDR register, which is used only for the wait function, instead of setting transmission data in the RLN3nLUTDR register as a start-of-transmission request. When transmitting from the UART buffer, set 1 (UART buffer transmission started) in the RTS bit in the RLN3nLTRC register with 1 set in the UTSW bit in the RLN3nLDFC register.

In such a case, the LIN/UART interface delays the start of transmission until the stop bits of reception data are completed.

Note that even if the UART stop bit length selection bit (USBLS) in RLN3nLBFC register is 1 (stop bits = 2 bits), there is only a 1-bit delay.

Figure 21.30 shows the operation of transmission wait function.

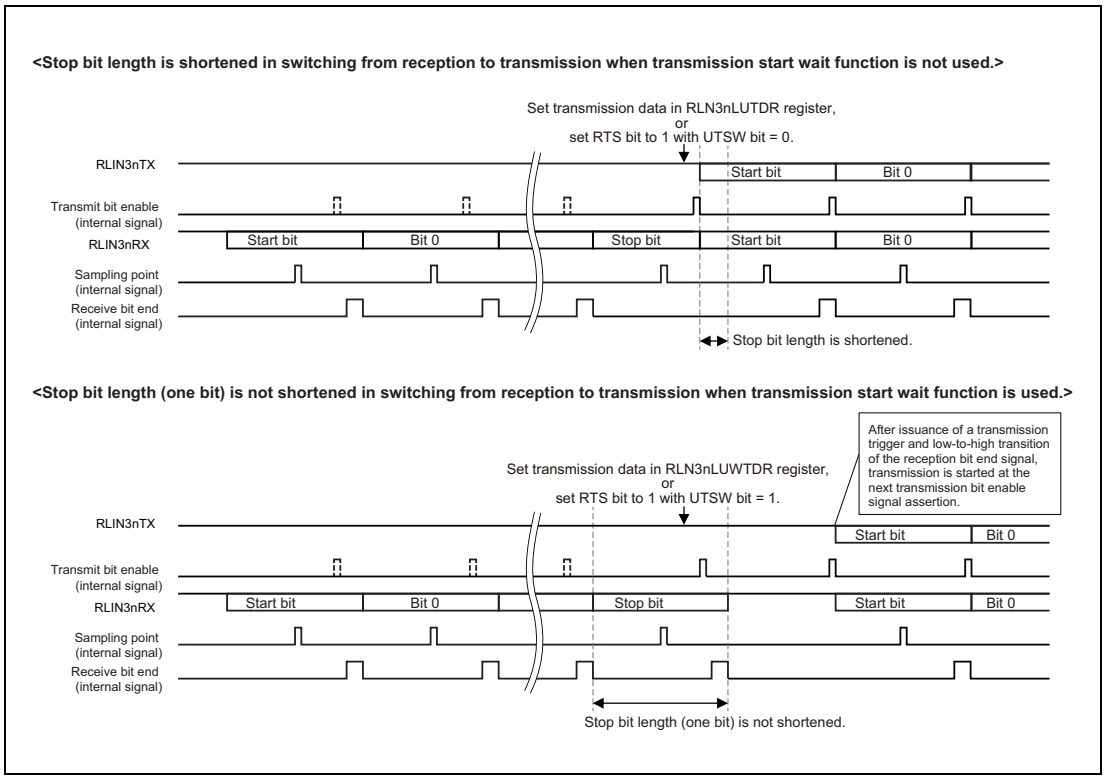

Figure 21.30 Case When Transmit Data Is Set While Stop Bits Are Being Received

21.4.5.2 Reception

Figure 21.31 shows the LIN/UART interface (in UART mode) reception operation. **Table 21.96** shows the LIN/UART interface (in UART mode) reception processing.

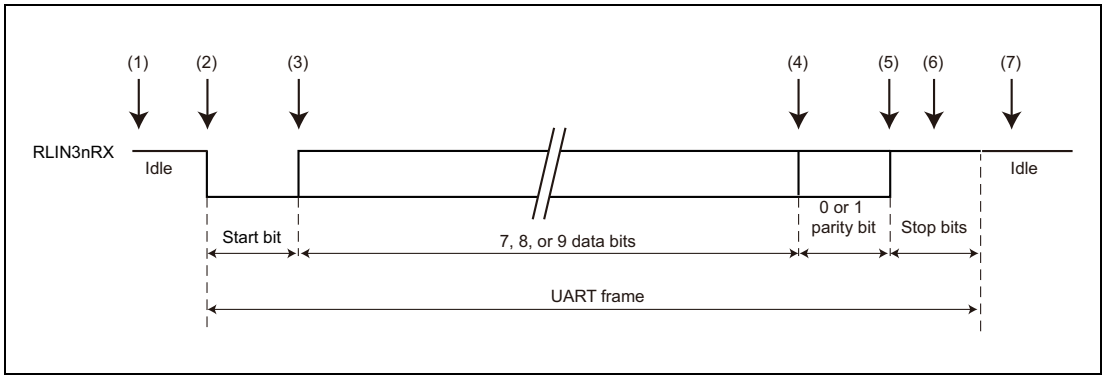

Figure 21.31 LIN/UART Interface (in UART Mode) Reception Operation

Table 21.96 LIN/UART Interface (in UART Mode) Reception Processing

	Software Processing	LIN/UART Interface Processing
(1)	• Sets a baud rate. • Sets noise filter ON/OFF. • Enables error detection. • Sets data format. • Clears the LIN/UART interface from LIN reset mode. • Sets the receive enable bit (UROE bit) to 1.	• Waits for the reception to be enabled by software. • Waits for detection of a start bit.
(2)	Waits for an interrupt request.	• Waits for a falling edge from the reception pin, and detects a start bit. • Sets the reception status flag.
(3)		Receives data.
(4)		Receives a parity bit when parity is used.
(5)		Receives only 1 stop bit.
(6)		• Generates a successful RLIN3n reception interrupt request. • Clears the reception status flag.
(7)	Checks the RLN3nLST register, and clears flags	Waits for a falling edge from the reception pin.

(1) Data Reception

Data reception is performed by using the synchronized RLIN3nRX (an internal signal) that is the input from the RLIN3nRX pin synchronized with the prescaler clock.

The byte field is synchronized at the falling edge of the start bit for the synchronized RLIN3nRX signal. After the falling edge is detected, resampling is performed 0.5 Tbits later when the number of sampling per 1 Tbit is even and {(the number of sampling + 1) / 2} / (the number of sampling) Tbits later when the number is odd. If the synchronized RLIN3nRX signal is low level, the bit is recognized as a start bit. The bit is not recognized as a start bit if the RLIN3nRX signal after the reset is de-asserted is fixed to low level or if a high level is detected during the resampling.

After the start bit is detected, 1 bit is sampled per Tbit.

However, when the BERE bit in the RLN3nLEDE register is 1, the sampling point is the same as the bit error detection timing.

The LIN/UART interface has a noise filtering function for received data. If the LRDNFS bit in the RLN3nLMD register is 0, the noise filter is used. For a sampling value, the value determined by a 3-samplings majority rule by the prescaler clock is used. If the LRDNFS bit in the RLN3nLMD register is 1, the noise filter is not used. In this case, for a sampling value, the synchronized RLIN3nRX value at the sampling position is used as is.

Figure 21.32 shows an example of data reception timing.

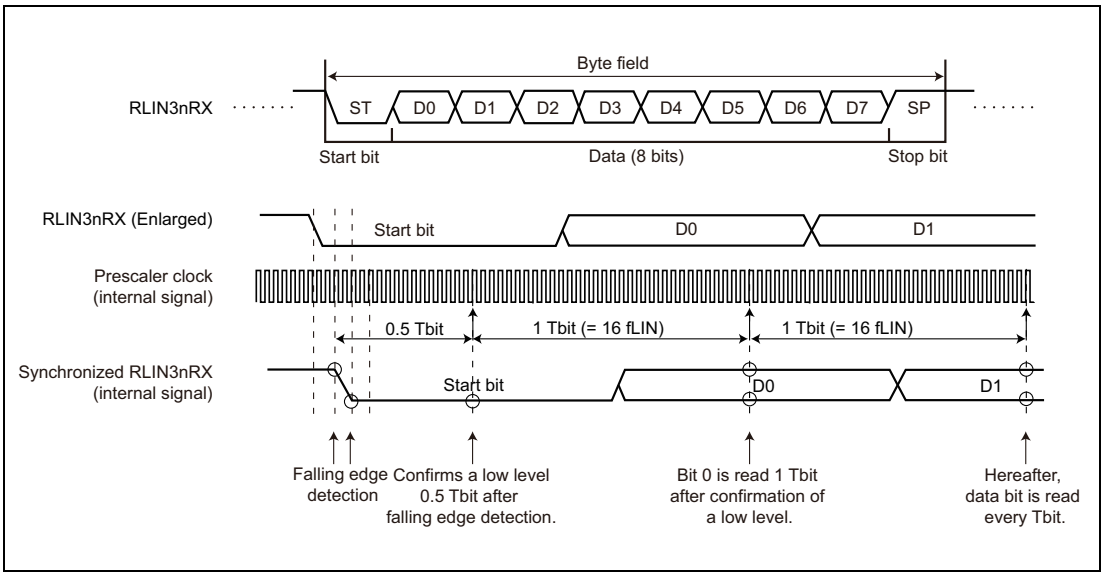

Figure 21.32 Example of Data Reception Timing (When Sampling Count is 16 in 1 Tbit)

21.4.5.3 Expansion Bits

The LIN/UART interface (in UART mode) can transmit and receive 9-bit long data by setting the UEBE bit in the RLN3nLUOR1 register to 1.

(1) Expansion Bit Transmission

The LIN/UART interface (in UART mode) can transmit 9-bit long data when the expansion bit enable bit (UEBE) in the UART option register 1 (RLN3nLUOR1) is 1 and by writing the 9-bit data to either the UART transmission data register (RLN3nLUTDR) or the UART wait transmission data register (RLN3nLUWTDR).

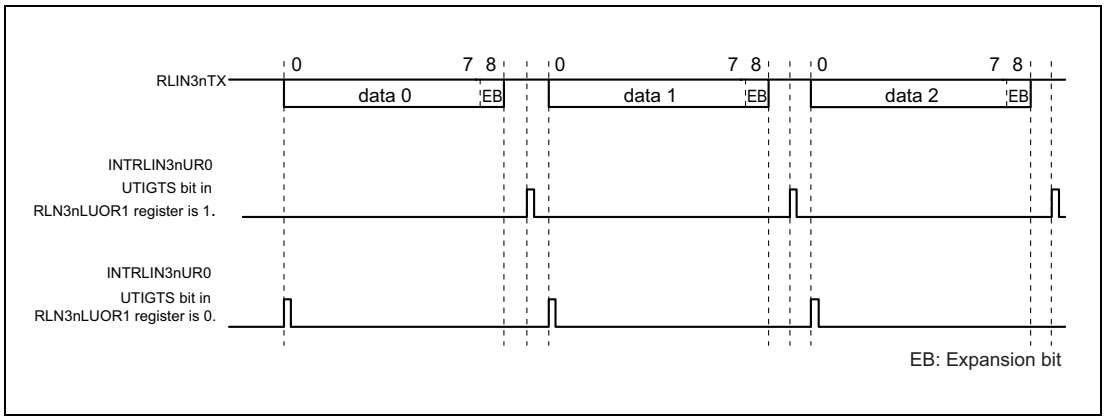

Figure 21.33 Transmission Example When Expansion Bit is Enabled (LSB First)

(2) Expansion Bit Reception

With the LIN/UART interface (in UART mode), 9-bit data can always be received without requiring a comparison of expansion bits, provided that the expansion bit enable bit (UEBE) in the UART option register 1 (RLN3nLUOR1) is 1, the expansion bit comparison disable bit (UECD) is 1, and the expansion bit data comparison enable bit (UEBDCE) is 0. Irrespective of the particular setting of the expansion bit detection level selection bit (UEBDL) in the UART option register 1 (RLN3nLUOR1), a successful RLIN3n reception interrupt is generated when 9-bit data is received.

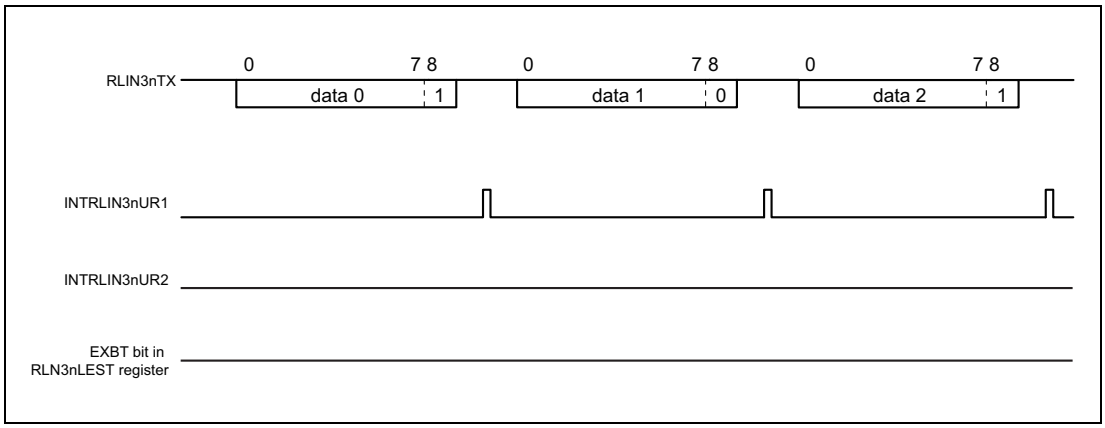

Figure 21.34 Expansion Bit Reception Example (LSB First)

(3) Expansion Bit Reception (with Expansion Bit Comparison)

The LIN/UART interface (in UART mode) can compare received expansion bits and the UEBDL bits when the expansion bit enable bit (UEBE) in the UART option register 1 (RLN3nLUOR1) is 1, the expansion bit comparison disable bit (UECD) is 0 and the expansion bit/data comparison enable bit (UEBDCE) is 0.

If the level that was set in the expansion bit detection level selection bit (UEBDL) is detected, an RLIN3n status interrupt request is generated upon completion of data reception, and the expansion bit detection flag (EXBT) in the LIN error status register (RLN3nLEST) is set. If the reversed value of an expansion bit detection level is detected, successful RLIN3n reception interrupt request is generated. In either case, the received data is stored in the UART reception data register (RLN3nLURDR), unless there was an overrun error.

Figure 21.35 shows an example when the expansion bit detection level selection bit (UEBDL) is set to 0.

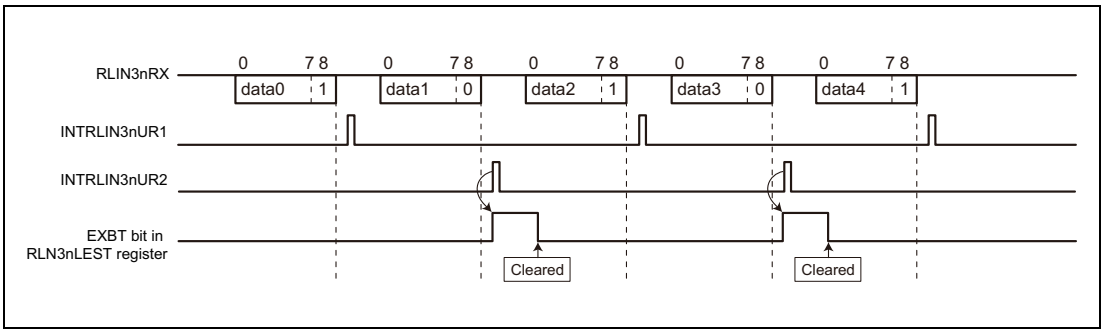

Figure 21.35 Expansion Bit Reception Example (with Expansion Bit Comparison) (LSB First, UEBDL = 0)

NOTE

- If a reception error (parity error, framing error, or overrun error) occurs in received data 0, 2, or 4 (if a reversed value of an expansion bit detection level is detected), an RLIN3n status interrupt is generated, and the error flag is updated. In this case, a successful RLIN3n reception interrupt is not generated.
- If a reception error (parity error, framing error, or overrun error) occurs in received data 1 or 3 (if an expansion bit detection level is detected), an RLIN3n status interrupt is generated, and the error flag is updated. If the overrun error occurs, the expansion bit detection flag (EXBT) is also set.

(4) Expansion Bit Reception (with Data Comparison)

If the expansion bit enable bit (UEBE) in the UART option register 1 (RLN3nLUOR1) is 1, the expansion bit comparison disable bit (UECD) is 0 and the expansion bit/data comparison enable bit (UEBDCE) is 1, and if the level that was set by the expansion bit detection level selection bit (UEBDL) is detected, the LIN/UART interface (in UART mode) compares the 8 bits, excluding the expansion bit in the received data, with the a pre-set RLN3nLIDB register value.

If the result of the comparison is a match, the LIN/UART interface performs the following operations:

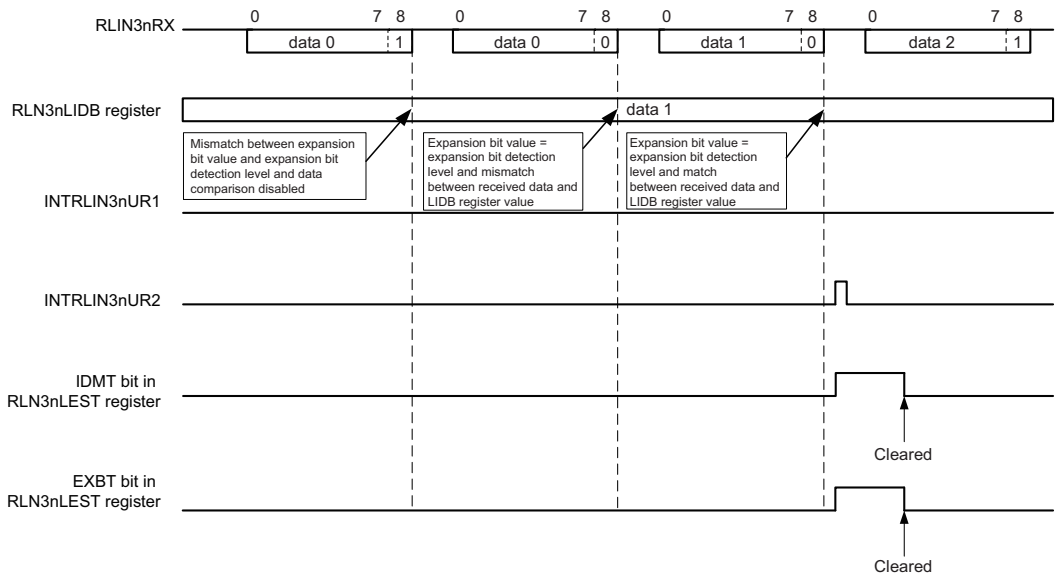
- Generates an RLIN3n status interrupt
- Sets an expansion bit detection flag (EXBT)
- Sets an ID match flag (IDMT)
- Stores the received data in the UART reception data register (RLN3nLURDR)

Even when the result of the comparison is a match, successful RLIN3n reception interrupt is not generated.

If the result of the comparison is not a match, no successful RLIN3n reception interrupt or RLIN3n status interrupt is generated, and the EXBT and IDMT flags are not set to 1. The received data is not stored in the UART reception data register (RLN3nLURDR).

When changing the UEBDCE bit to 0, make the change before the reception of another set of data is finished.

Figure 21.36 shows an example when the expansion bit detection level selection bit (UEBDL) is set to 0.



Note: If a reception error (parity error, framing error, or overrun error) occurs, an RLIN3n status interrupt is generated, and the error flag is updated. If the overrun error occurs and the result of comparison is a match, the EXBT and IDMT are also set to 1.

Figure 21.36 Expansion Bit Reception Example (with Data Comparison) (LSB First, UEBDL = 0)

21.4.5.4 Status

In UART mode, the LIN/UART interface can detect five types of statuses.

Two statuses, successful UART buffer transmission and error detection, can generate interrupt requests.

Table 21.97 shows the types of statuses available in UART mode.

Table 21.97 Types of Statuses in UART Mode

Status	Status Set Condition	Status Clear Condition	Corresponding Bit	Interrupt
Reset	After the OM0 bit in the RLN3nLCUC register is set to not-LIN-reset-mode, if actually the LIN/UART interface is cleared from LIN reset mode.	After the OM0 bit in the RLN3nLCUC register is set to LIN reset mode, if actually the LIN/UART interface enters LIN reset mode.	OMM0 bit in RLN3nLMST register	—
Successful UART buffer transmission	• When the UTIGTS bit in the RLN3nLUOR1 register is 0 (transmission interrupt request is generated upon start of transmission), the transmission of the last data of the data length set by the MDL bit in the RLN3nLDFC register is started. • When the UTIGTS bit in the RLN3nLUOR1 register is 1 (transmission interrupt request is generated upon end of transmission), the transmission of the data length set by the MDL bit in the RLN3nLDFC register is ended.	• When cleared by software • After transition to LIN reset mode	FTC flag in RLN3nLST register	√
Error detection	If any of the UPER flag, IDMT flag, EXBT flag, FER flag, OER flag, and BER flag in the RLN3nLEST register is set to 1 (error detected).	• When cleared by software*1 • After transition to LIN reset mode	ERR flag in RLN3nLST register	√
Transmission status	• When data is written to the RLN3nLUTDR or RLN3nLUWTDR register. • When 1 is written to the RTS bit in the RLN3nLTRC register.	• When the transmission of the data specified in the RLN3nLUTDR or RLN3nLUWTDR register is completed, but the next transmission data is not specified. • When the transmission of the data in the UART buffer is completed and the RTS bit in the RLN3nLTRC register is cleared. • After transition to LIN reset mode	UTS flag in RLN3nLST register	—
Reception status	• When a start bit is detected.	• When a sampling point for stop bits is detected • After transition to LIN reset mode	URS flag in RLN3nLST register	—

Note 1. Writing a 0 to the UPER, IDMT, EXBT, FER, OER, and BER flags in the RLN3nLEST register when the LIN reset mode is being canceled sets the ERR flag in the RLN3nLST register to 0.

21.4.5.5 Error Status

Types of Error Statuses

In UART mode, the LIN/UART interface can detect four types of errors and two types of statuses. The condition of these statuses can be verified by using the corresponding bits in the RLN3nLEST register.

Table 21.98 shows available status types.

Table 21.98 Types of Statuses in UART Mode

Status	Error Detection Condition	Communication	Enable/ Disable Detection	Corresponding Bit
Bit error	The transmitted data and the data monitored on the receive pin do not match*1	Continues until the transmission of the set transmission data is finished.	Enabled	BER flag in RLN3nLEST register
Overrun error	After received data is stored in the RLN3nLURDR register, another data item is received before the data is read. (In this case, no data is stored in the RLN3nLURDR register).	— (Reception is finished by the time this error is detected)	Enabled	OER flag in RLN3nLEST register
Framing error	When the first stop bit is low level in the reception processing.	— (Reception is finished by the time this error is detected)	Enabled	FER flag in RLN3nLEST register
Parity error	The received parity value fails to match the parity value calculated from the received data	Continues until the data reception is finished.	Disabled *2	UPER flag in RLN3nLEST register
Expansion bit detection	The value of the received expansion bit matches the value of the UEBDL bit in the RLN3nLUOR1 register.	—	Enabled	EXBT flag in RLN3nLEST register
ID match detection	The value of the received expansion bit matches the value of the UEBDL bit in the RLN3nLUOR1 register and the 8-bit receive data excluding the expansion bit matches the value of the RLN3nLIDB register.	—	Enabled	IDMT flag in RLN3nLEST register

Note 1. In the case of transmission from the UART buffer, bit errors are detected even in the space between UART frames (inter-byte space).

Note 2. Setting the UPS[1:0] bits in the RLN3nLBFC register to 10_B (0 parity) disables the checking of parity bit values. In this case, no parity error is generated.

The error status is cleared by software or at a transition to LIN reset mode.

21.4.5.6 Conflicts of Error Status

The table below shows the condition of error status bits that occurs at the end of single frame in UART Mode.

The combination not listed in the table, condition does not occur.

Table 21.99 Conflicts of Error Status (UART Mode)

Number of Conflict	kinds of Errors					
	BER	OER	FER	EXBT	IDMT	UPER
1	1	0	0	0	0	0
	0	1	0	0	0	0
	0	0	1	0	0	0
	0	0	0	1	0	0
	0	0	0	0	0	1
2	1	1	0	0	0	0
	1	0	1	0	0	0
	1	0	0	1	0	0
	1	0	0	0	0	1
	0	1	1	0	0	0
	0	1	0	1	0	0
	0	1	0	0	0	1
	0	0	1	0	0	1
	0	0	0	1	1	0
3	1	1	1	0	0	0
	1	1	0	1	0	0
	1	1	0	0	0	1
	1	0	1	0	0	1
	1	0	0	1	1	0
	0	1	1	0	0	1
	0	1	0	1	1	0
4	1	1	0	1	1	0
	1	1	1	0	0	1
5	—	—	—	—	—	—
6	—	—	—	—	—	—

Note: 1: set error
0: no error

21.4.6 LIN Self-Test Mode

The LIN/UART interface provides a LIN self-test mode.

When the LIN/UART interface enters the LIN self-test mode, RLIN3nTX and RLIN3nRX are disconnected from external pins and RLIN3nTX and RLIN3nRX are connected to the LIN/UART interface internally. Therefore, the frame transmitted from RLIN3nTX is looped back to RLIN3nRX. The LIN self-test mode can perform tests exclusively in LIN mode.

The self-test can be performed in the following four modes:

- LIN master self-test mode (transmission): Header transmission and response transmission
- LIN master self-test mode (reception): Header transmission and response reception
- LIN slave self-test mode (transmission): Header reception and response transmission
- LIN slave self-test mode (reception): Header reception and response reception

In LIN self-test mode, operation is performed at the fastest baud rate, regardless of the setting of the baud rate generator.

Regardless of the setting of the baud rate related registers, the baud rate setting is the LIN communication clock source/16 [bps].
(The NSPB bits in the RLN3nLWBR register should be set to 0000_B or 1111_B.)
(The LPRS bits in the RLN3nLWBR register should be set to 000_B.)

In addition, in LIN self-test mode, the following functions are not supported.

- LIN wake-up mode
- Frame separate mode
- Multi-byte response transmission/reception
- LIN slave mode (Auto baud rate)
- Frame/response timeout error

Do not use these functions.

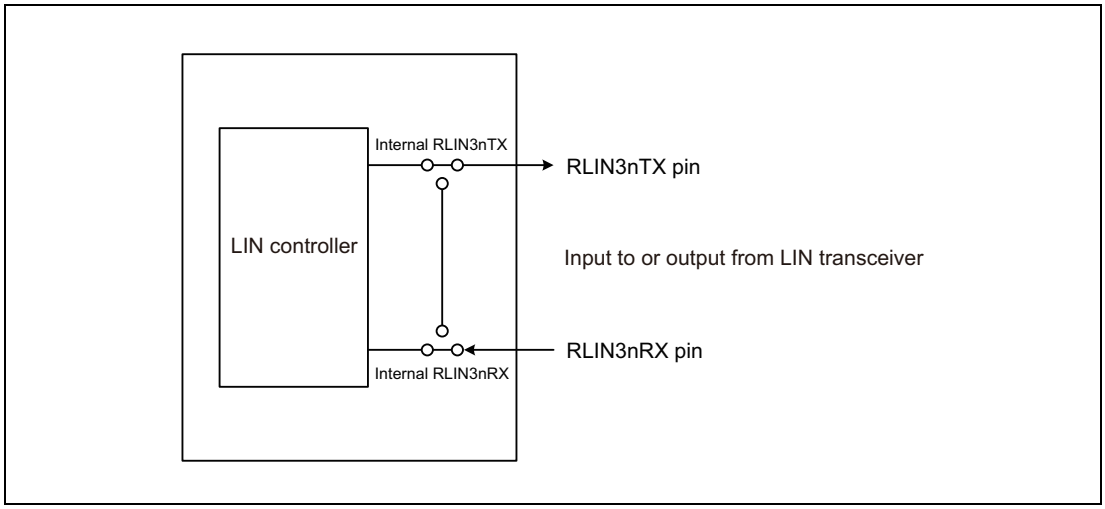


Figure 21.37 Connection in LIN Reset Mode, LIN Mode, and UART Mode

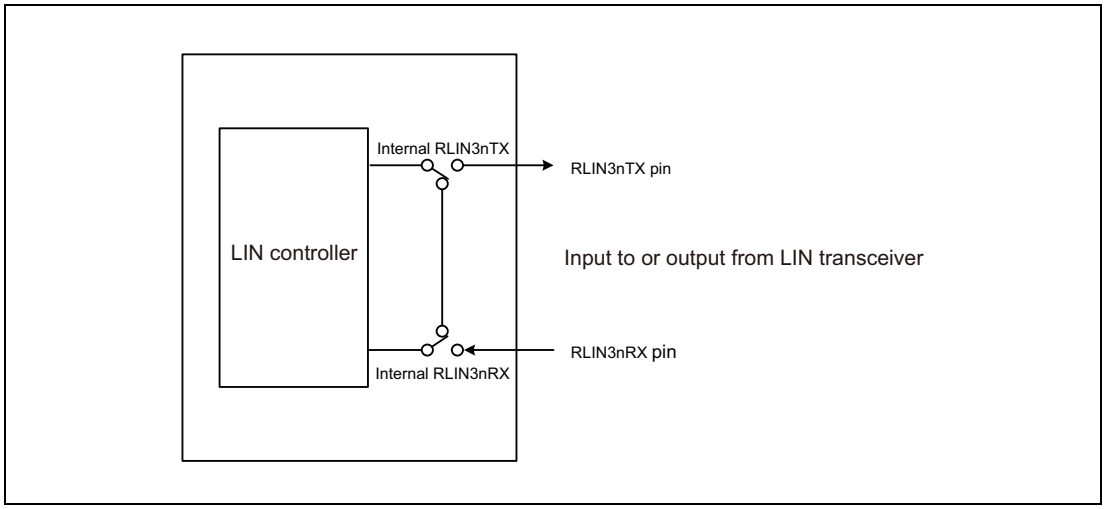

Figure 21.38 Connection in LIN Self-Test Mode

21.4.6.1 Transitioning to LIN Self-Test Mode

Writing to the RLN3nLSTC register makes a transition to the LIN self-test mode.
The LSTM bit in the RLN3nLSTC register set to 1 indicates that the mode has transitioned to the LIN self-test mode.

To transition to LIN self-test mode, be sure to execute a specific sequence. In that sequence, information must be written three times consecutively to the LIN self-test control register as shown below:

- Transition to LIN reset mode
  Set the OM0 bit in the RLN3nLCUC register to 0 (LIN reset mode).
  Read the OMM0 bit in the RLN3nLMST register; verify that it is 0 (LIN reset mode).
- Select a LIN mode
  LMD bits in RLN3nLMD = 00_B (LIN master mode) or 11_B (LIN slave mode [fixed baud rate])
- 1st write: RLN3nLSTC register = 1010 0111_B ($A7_H$)
- 2nd write: RLN3nLSTC register = 0101 1000_B (58_H)
- 3rd write: RLN3nLSTC register = 0000 0001_B (01_H)
- Verify the transition to LIN self-test mode
  Read the LSTM bit in the RLN3nLSTC register; verify that it is 1 (LIN self-test mode).

If the key of the first write ($A7_H$) is written twice by mistake, the transition to LIN self-test mode is canceled. The above sequence should be retried from the step of first write. In addition, if a write to another LIN-related register is performed during transition to LIN self-test mode (three consecutive write operations to the RLN3nLSTC register), the transition is also canceled.

21.4.6.2 Transmission in LIN Master Self-Test Mode

To execute a self-test on LIN master transmission, perform the procedure below:

- Set the baud rate, noise filter, and interrupt output related registers.
  RLN3nLWBR register = 0000 $000x_B$
  RLN3nLBRP0 register = xxxx $xxxx_B$*1
  RLN3nLBRP1 register = xxxx $xxxx_B$*1
  RLN3nLMD register = 00xx $xx00_B$*1
- Set the interrupt enable and error enable related registers.
  RLN3nLIE register = 0000 $xxxx_B$*2
  RLN3nLEDE register = x000 $x0xx_B$
- Set the break field and space related registers.
  RLN3nLBFC register = 00xx $xxxx_B$
  RLN3nLSC register = 00xx $0xxx_B$
- Release from the LIN reset mode.
  Write 11_B to the OM1 and OM0 bits in the RLN3nLCUC register, and check that the OMM1 and OMM0 bits in the RLN3nLMST register are 11_B.
- Set the transmit frame related registers.
  RLN3nLDFC register = 00x1 $xxxx_B$
  RLN3nLIDB register = xxxx $xxxx_B$
  RLN3nLDRB1 to RLN3nLDRB8 registers = xxxx $xxxx_B$
- Header transmission → response transmission started
  Set the FTS bit in the RLN3nLTRC register to 1 (frame transmission or wake-up transmission/ reception started).
  The LIN master self-test mode (transmission) is executed. In this mode, interrupt is generated, and status and error status are also updated. The checksum is automatically calculated by the LIN/ UART interface. To suspend the LIN master self-test mode (transmission) being executed, write 0 (LIN reset mode) to the OM0 bit in the RLN3nLCUC register for transition to LIN reset mode.
- When the transmission is completed, the reversed value of the looped-back frame data is stored in the RLN3nLIDB, RLN3nLDBRb (b = 1 to 8), and RLN3nLCBR registers (the data is stored as a reversed value because the transmitted value should be compared with the looped-back value). Then, the FTS bit in the RLN3nLTRC register is cleared.
- If the transmission fails to complete due to an error, the corresponding error flag is set and the FTS bit in the RLN3nLTRC register is cleared.

Note: x: Arbitrary value can be specified.

Note 1. The following register settings are not reflected to the operation of the LIN self-test mode. The RLN3nLBRP0 register, the RLN3nLBRP1 register and the LCKS bit in the RLN3nLMD register. Therefore, those settings are not necessary.

Note 2. If necessary, set the related registers described in **Section 6, Interrupts**.

Note 3. When the successful header transmission interrupt and the successful frame transmission interrupt are used in the same interrupt processing, if the software processing of the successful header transmission interrupt is not completed before the generation of the successful frame transmission interrupt, the SHIE bit in the RLN3nLIE register should not be set to 1 (successful header transmission interrupt enabled). The time required from the setting of the successful header transmission flag to the setting of the successful frame/wake-up transmission flag is calculated by the following formula.

10 × (number of data bytes + 1) [Tbit]

1 Tbit = 1/frequency of LIN communication clock source × 16

21.4.6.3 Reception in LIN Master Self-Test Mode

To execute a self-test on LIN master reception, perform the procedure below:

- Set the baud rate, noise filter, and interrupt output related registers.
  RLN3nLWBR register = 0000 $000x_B$
  RLN3nLBRP0 register = xxxx $xxxx_B$*1
  RLN3nLBRP1 register = xxxx $xxxx_B$*1
  RLN3nLMD register = 00xx $xx00_B$*1
- Set the interrupt enable and error enable related registers.
  RLN3nLIE register = 0000 $xxxx_B$*2
  RLN3nLEDE register = x000 $x0xx_B$
- Set the break field and space related registers.
  RLN3nLBFC register = 00xx $xxxx_B$
  RLN3nLSC register = 00xx $0xxx_B$*1
- Release from the LIN reset mode.
  Write 11_B to the OM1 and OM0 bits in the RLN3nLCUC register, and check that the OMM1 and OMM0 bits in the RLN3nLMST register are 11_B.
- Set the reception frame related registers.
  RLN3nLDFC register = 00x0 $xxxx_B$
  RLN3nLIDB register = xxxx $xxxx_B$
  RLN3nLDRB1 to RLN3nLDRB8 registers = xxxx $xxxx_B$
  RLN3nLCBR register = xxxx $xxxx_B$
  Since the checksum value to be transmitted is not automatically calculated, users must calculate it and set it to the RLN3nLCBR register. A checksum test can be performed by setting an incorrect checksum value here.
- Header transmission → response reception started
  Set the FTS bit in the RLN3nLTRC register to 1 (frame transmission or wake-up transmission/ reception started).
  The LIN master self-test mode (reception) is executed. In this mode, interrupt is generated, and status and error status are also updated. To suspend the LIN master self-test mode (reception) being executed, write 0 (LIN reset mode) to the OM0 bit in the RLN3nLCUC register for transition to LIN reset mode.
- When the reception is completed, the reversed value of the looped-back frame data is stored in the RLN3nLIDB, RLN3nLDBRb (b = 1 to 8), and RLN3nLCBR registers (the data is stored as a reversed value because the set value should be compared with the looped-back value). Then, the FTS bit in the RLN3nLTRC register is cleared.
- If the reception fails to complete due to an error, the corresponding error flag is set and the FTS bit in the RLN3nLTRC register is cleared.

Note: x: Arbitrary value can be specified.

Note 1. The following register settings are not reflected to the operation of the LIN self-test mode. The RLN3nLBRP0 register, the RLN3nLBRP1 register, the LCKS bit in the RLN3nLMD register, and the IBS bit in the RLN3nLSC register. Therefore, those settings are not necessary.

Note 2. If necessary, set the related registers described in **Section 6, Interrupts**.

Note 3. When the successful header transmission interrupt and the successful frame reception interrupt are used in the same interrupt processing, if the software processing of the successful header transmission interrupt is not completed before the generation of the successful frame reception interrupt, the SHIE bit in the RLN3nLIE register should not be set to 1 (successful header transmission interrupt enabled).

The time required from the setting of the successful header transmission flag to the setting of the successful frame/wake-up reception flag is calculated by the following formula.

10 × (number of data bytes + 1) [Tbit]

1 Tbit = 1/frequency of LIN communication clock source × 16

21.4.6.4 Transmission in LIN Slave Self-Test Mode

To execute a self-test on LIN slave transmission, perform the procedure below:

- Set the baud rate, noise filter, and interrupt output related registers.
  RLN3nLWBR register = $0000\ 0000_B$
  RLN3nLBRP0 register = $xxxx\ xxxx_B$*1
  RLN3nLBRP1 register = $xxxx\ xxxx_B$*1
  RLN3nLMD register = $00x\ x0011_B$
- Set the interrupt enable and error enable related registers.
  RLN3nLIE register = $0000\ xxxx_B$*2
  RLN3nLEDE register = $xx0x\ x00x_B$
- Set the break field and space related registers.
  RLN3nLBFC register = $0000\ 000x_B$*3
  RLN3nLSC register = $00xx\ 0001_B$
- Release from the LIN reset mode.
  Write 11_B to the OM1 and OM0 bits in the RLN3nLCUC register, and check that the OMM1 and OMM0 bits in the RLN3nLMST register are 11_B.
- Set the transmit frame related registers.
  RLN3nLDFC register = $00x1\ xxxx_B$
  RLN3nLIDB register = $xxxx\ xxxx_B$
  RLN3nLDBR1 to RLN3nLDBR8 registers = $xxxx\ xxxx_B$
- Header reception → response transmission started
  Set the FTS bit in the RLN3nLTRC register to 1 (header reception or wake-up transmission/ reception started).
  (The header reception and the response transmission are executed in this order, without manipulating the RTS bit in the RLN3nLTRC register.)
  The LIN slave self-test mode (transmission) is executed. In this mode, interrupt is generated, and status and error status are also updated.
  The checksum is automatically calculated by the LIN/UART interface. To suspend the LIN slave self-test mode (transmission) being executed, write 0 (LIN reset mode) to the OM0 bit in the RLN3nLCUC register for transition to LIN reset mode.
- When the transmission is completed, the reversed value of the looped-back frame data is stored in the RLN3nLIDB, RLN3nLDBRb (b = 1 to 8), and RLN3nLCBR registers (the data is stored as a reversed value because the transmitted value should be compared with the looped-back value). Then, the FTS bit in the RLN3nLTRC register is cleared.
- If the transmission fails to complete due to an error, the corresponding error flag is set and the FTS bit in the RLN3nLTRC register is cleared.

Note: x: Arbitrary value can be specified.

Note 1. The following register settings are not reflected to the operation of the LIN self-test mode. The RLN3nLBRP0 register, and the RLN3nLBRP1 register. Therefore, those settings are not necessary.

Note 2. If necessary, set the related registers described in **Section 6, Interrupts**

Note 3. According to the setting of this register, 9.5-Tbit or 10.5-Tbit width break is output from the internal RLIN3nTX.

Note 4. When the successful header reception interrupt and the successful response transmission interrupt are used in the same interrupt processing, if the software processing of the successful header reception interrupt is not completed before the generation of the successful response transmission interrupt, the SHIE bit in the RLN3nLIE register should not be set to 1 (successful header reception interrupt enabled).
The time required from the setting of the successful header reception flag to the setting of the successful response/wake-up transmission flag is calculated by using the following formula.

10 × (number of data bytes + 1) [Tbit]

1 Tbit = 1/frequency of LIN communication clock source × 16

21.4.6.5 Reception in LIN Slave Self-Test Mode

To execute a self-test on LIN slave reception, perform the procedure below:

- Set the baud rate, noise filter, and interrupt output related registers.
  RLN3nLWBR register = $0000\ 0000_B$
  RLN3nLBRP0 register = $xxxx\ xxxx_B$*1
  RLN3nLBRP1 register = $xxxx\ xxxx_B$*1
  RLN3nLMD register = $00xx\ 0011_B$
- Set the interrupt enable and error enable related registers.
  RLN3nLIE register = $0000\ xxxx_B$*2
  RLN3nLEDE register = $xx0x\ x00x_B$
- Set the break field and space related registers.
  RLN3nLBFC register = $0000\ 000x_B$*3
  RLN3nLSC register = $00xx\ 0001_B$*1
- Release from the LIN reset mode.
  Write 11_B to the OM1 and OM0 bits in the RLN3nLCUC register, and check that the OMM1 and OMM0 bits in the RLN3nLMST register are 11_B.
- Set the reception frame related registers.
  RLN3nLDFC register = $00x0\ xxxx_B$
  RLN3nLIDB register = $xxxx\ xxxx_B$
  RLN3nLDBR1 to RLN3nLDBR8 registers = $xxxx\ xxxx_B$
  RLN3nLCBR register = $xxxx\ xxxx_B$
  Since the checksum value to be transmitted is not automatically calculated, users must calculate it and set it to the RLN3nLCBR register. A checksum test can be performed by setting an incorrect checksum value here.
- Header reception → response reception started
  Set the FTS bit in the RLN3nLTRC register to 1 (header reception or wake-up transmission/ reception started).
  (Without any setting of the RTS bit in the RLN3nLTRC register, the header reception and the response reception are executed in this order.)
  The LIN slave self-test mode (reception) is executed. In this mode, interrupt is generated, and status and error status are also updated. To suspend the LIN slave self-test mode (reception) being executed, write 0 (LIN reset mode) to the OM0 bit in the RLN3nLCUC register for transition to LIN reset mode.
- When the reception is completed, the reversed value of the looped-back frame data is stored in the RLN3nLIDB, RLN3nLDBRb (b = 1 to 8), and RLN3nLCBR registers (the data is stored as a reversed value because the set value should be compared with the looped-back value). Then, the FTS bit in the RLN3nLTRC register is cleared.
- If the reception fails to complete due to an error, the corresponding error flag is set and the FTS bit in the RLN3nLTRC register is cleared.

Note: x: Arbitrary value can be specified.

Note 1. The following register settings are not reflected to the operation of the LIN self-test mode.
The RLN3nLBRP0 register, the RLN3nLBRP1 register, and the IBS bit in the RLN3nLSC register.
Therefore, those settings are not necessary.

Note 2. If necessary, set the related registers described in **Section 6, Interrupts**.

Note 3. According to the setting of this register, 9.5-Tbit or 10.5-Tbit width break is output from the internal RLIN3nTX.

Note 4. When the successful header reception interrupt and the successful response reception interrupt are used in the same interrupt processing, if the software processing of the successful header reception interrupt is not completed before the generation of the successful response reception interrupt, the SHIE bit in the RLN3nLIE register should not be set to 1 (successful header reception interrupt enabled).
The time required from the setting of the successful header reception flag to the setting of the successful response/wake-up reception flag is calculated by the following formula.

10 × (number of data bytes + 1) [Tbit]

1 Tbit = 1/frequency of LIN communication clock source × 16

21.4.6.6 Terminating LIN Self-Test Mode

To terminate LIN self-test mode, perform the procedure below:

- Write 0 (LIN reset mode) to the OM0 bit in the RLN3nLCUC register.
  If the OMM1 and OMM0 bits in the RLN3nLMST register are not 11_B, write 11_B to the OM1 and OM0 bits in the RLN3nLCUC register. After confirming that the OMM1 and OMM0 bits in the RLN3nLMST register are set to 11_B, transition to LIN reset mode.
- Verify the cancelation of LIN self-test mode.
  Read the LSTM bit in the RLN3nLSTC register; confirm that it is 0 (not in LIN self-test mode).
- Verify the transition to LIN reset mode.
  Read the OMM0 bit in the RLN3nLMST register; verify that it is 0 (LIN reset mode).

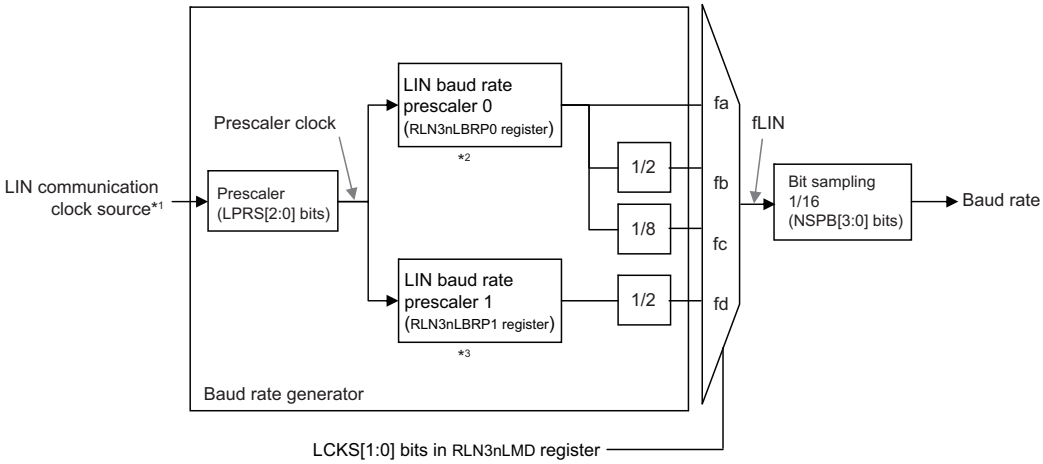
21.4.7 Baud Rate Generator

The prescaler clock is obtained by frequency-dividing the LIN communication clock source by the prescaler, and the LIN system clock (fLIN) is obtained by frequency-dividing the prescaler clock by the baud rate generator. The clock obtained by frequency-dividing the LIN system clock (fLIN) by the number of samplings is the baud rate. The reciprocal of this baud rate is called the bit time (Tbit).

The LIN/UART interface has two types of baud rate generators. The baud rate generator to be used is switched according to the mode.

21.4.7.1 LIN Master Mode

Figure 21.39 shows a block diagram of baud rate generation in LIN master mode.



Note 1. For the LIN communication clock source, see **Section 13.6.4, Clock Settings**.
Note 2. When the value in RLN3nLBRP0 register is N (N = 0 to 255), the clock frequency is divided by N + 1.
Note 3. When the value in RLN3nLBRP1 register is M (M = 0 to 255), the clock frequency is divided by M + 1.

Figure 21.39 Block Diagram of Baud Rate Generation in LIN Master Mode

By setting the RLN3nLBRP0 register so that fa is 307200 Hz (= 19200 × 16), the resulting system clock frequencies are fa = 19200 × 16, fb = 9600 × 16, and fc = 2400 × 16. These system clock frequencies are divided by 16 in the bit timing generator, enabling bit rates of 19200 bps, 9600 bps and 2400 bps, to be generated. Also, by setting the RLN3nLBRP1 register so that fd is 166672 Hz (= 10417 × 16), the resulting system clock frequency is fd = 10417 × 16. This system clock frequency is divided by 16 in the bit timing generator, enabling 10417 bps to be generated.

The formula for calculating the baud rate is described below.

Baud rate of LIN master

= {Frequency of LIN communication clock source} × (RLN3nLWBR.LPRS[2:0] selection clock)
÷ (RLN3nLBRP0+ 1) ÷ 16 [bps] (When fa is selected for f_{LIN})

= {Frequency of LIN communication clock source} × (RLN3nLWBR.LPRS[2:0] selection clock)
÷ (RLN3nLBRP0 + 1) ÷ 2 ÷ 16 [bps] (When fb is selected for f_{LIN})

= {Frequency of LIN communication clock source} × (RLN3nLWBR.LPRS[2:0] selection clock)

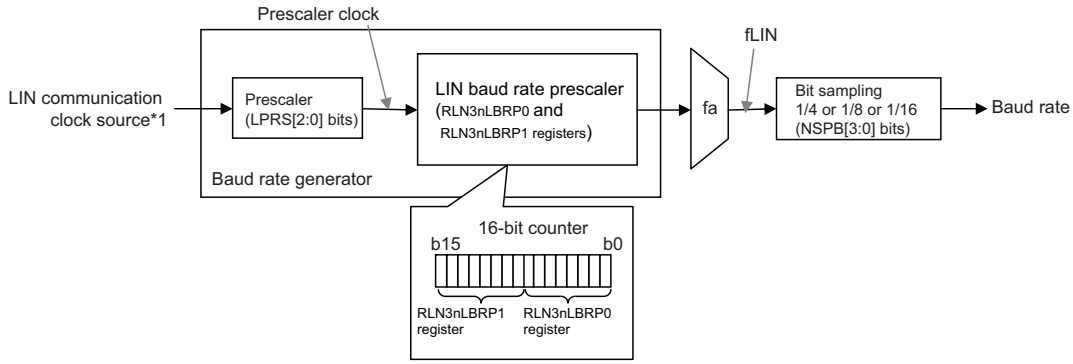
÷ (RLN3nLBRP0 + 1) ÷ 8 ÷ 16 [bps] (When fc is selected for f_{LIN})

= {Frequency of LIN communication clock source} × (RLN3nLWBR.LPRS[2:0] selection clock)

÷ (RLN3nLBRP1 + 1) ÷ 2 ÷ 16 [bps] (When fd is selected for f_{LIN})

21.4.7.2 LIN Slave Mode

Figure 21.40 shows a block diagram of baud rate generation in LIN slave mode.



Note 1. For the LIN communication clock source, see **Section 13.6.4, Clock Settings**.

Figure 21.40 Block Diagram of Baud Rate Generation in LIN Slave Mode

In LIN slave mode (auto baud rate), the baud rate can be set to 1 kbps to 20 kbps. Set the prescaler clock as follows according to the target baud rate:

[Target baud rate]	[Prescaler clock]
1 kbps to 20 kbps	: 4MHz *1
1 kbps to 2.4 kbps (excluding 2.4 kbps)	: 4MHz
2.4 kbps to 20 kbps	: 8 MHz to 12 MHz

Note 1. Use the clock with NSPB[3:0] bits in the RLN3nLWBR register set to "0011_B" (four samplings).

The formula for baud rate is described below.
Baud rate of LIN slave

= {Frequency of LIN communication clock source} × (RLN3nLWBR.LPRS[2:0] selection clock)

÷ (RLN3nLBRP01 + 1) ÷ 16 [bps] ([Fixed baud rate])

= {Frequency of LIN communication clock source} × (RLN3nLWBR.LPRS[2:0] selection clock)

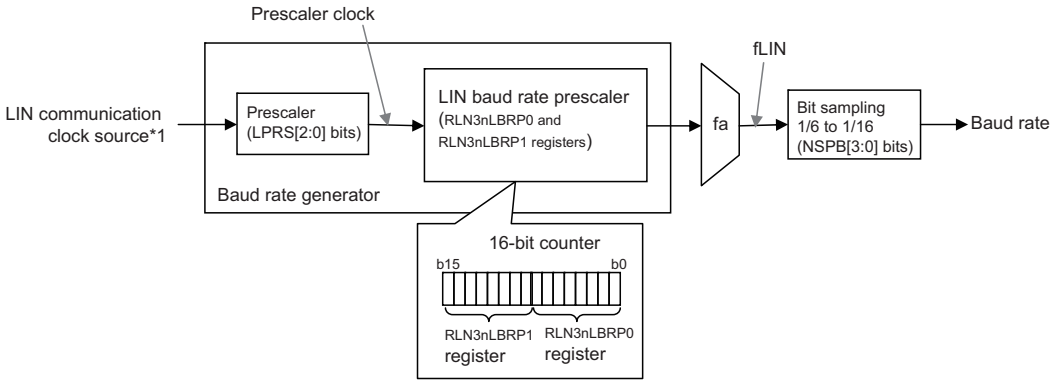
÷ (RLN3nLBRP01 + 1) ÷ 4 or 8 [bps] ([Auto baud rate])

NOTE

For a LIN slave with fixed baud rate, set the NSPB[3:0] bits to "0000_B" (16 samples) or "1111_B" (16 samples). For a LIN slave with auto baud rate, set the NSPB[3:0] bits to "0011_B" (4 samples) or "0100_B" (8 samples).

21.4.7.3 UART Mode

Figure 21.41 shows a block diagram of baud rate generation in UART mode.



Note 1. For the LIN communication clock source, see **Section 13.6.4, Clock Settings**.

Figure 21.41 Block Diagram of Baud Rate Generation in UART Mode

UART baud rate is calculated with the following formula:

UART baud rate
= {LIN communication clock source frequency} × (RLN3nLWBR.LPRS[2:0] selection clock) ÷ (RLN3nLBRP01 + 1) ÷ {RLN3nLWBR.NSPB[3:0] selection count} [bps]

21.4.8 Noise Filter

The LIN/UART interface has a noise filter for reducing erroneous receiving of data due to noise. By setting the LRDNFS bit in the RLN3nLMD register to 0 (use the noise filter), the noise filter is enabled. The noise filter samples the level of the synchronized RLIN3nRX with the prescaler clock, and outputs the sampling value determined by a 3-samplings majority rule. The value of each bit of the receive data is determined based on the noise filter output.

Figure 21.42 shows the configuration of the noise filter, **Figure 21.43** shows an example of a noise filter circuit, and **Figure 21.44** shows the determination of the received data when the noise filter is used.

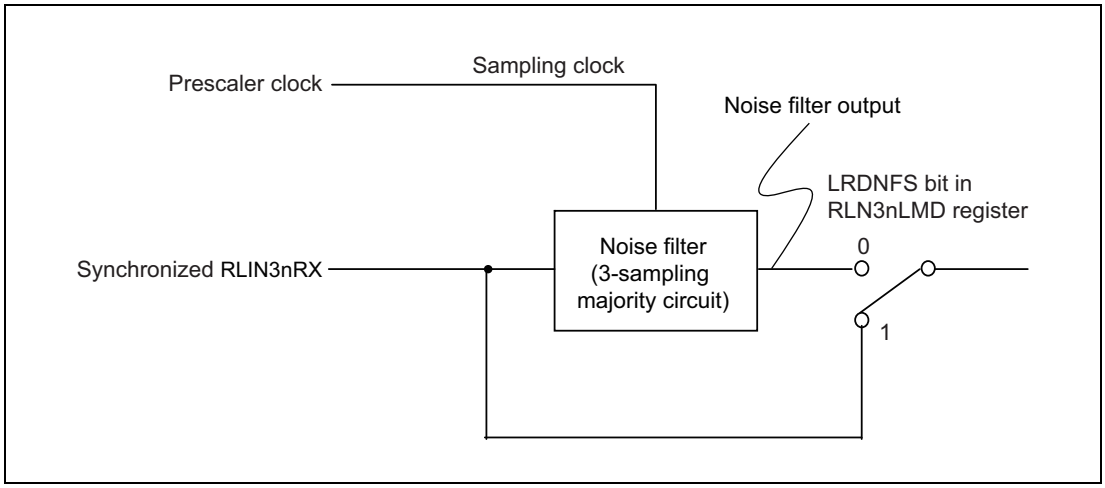


Figure 21.42 Configuration of Noise Filter

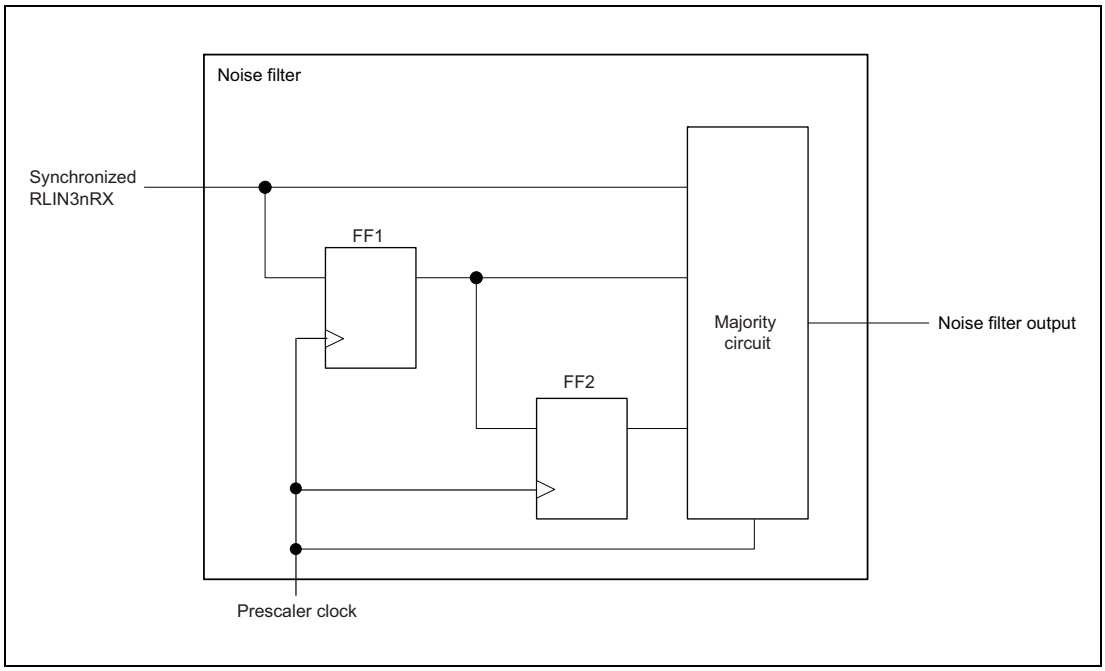

Figure 21.43 Example of Noise Filter Circuit

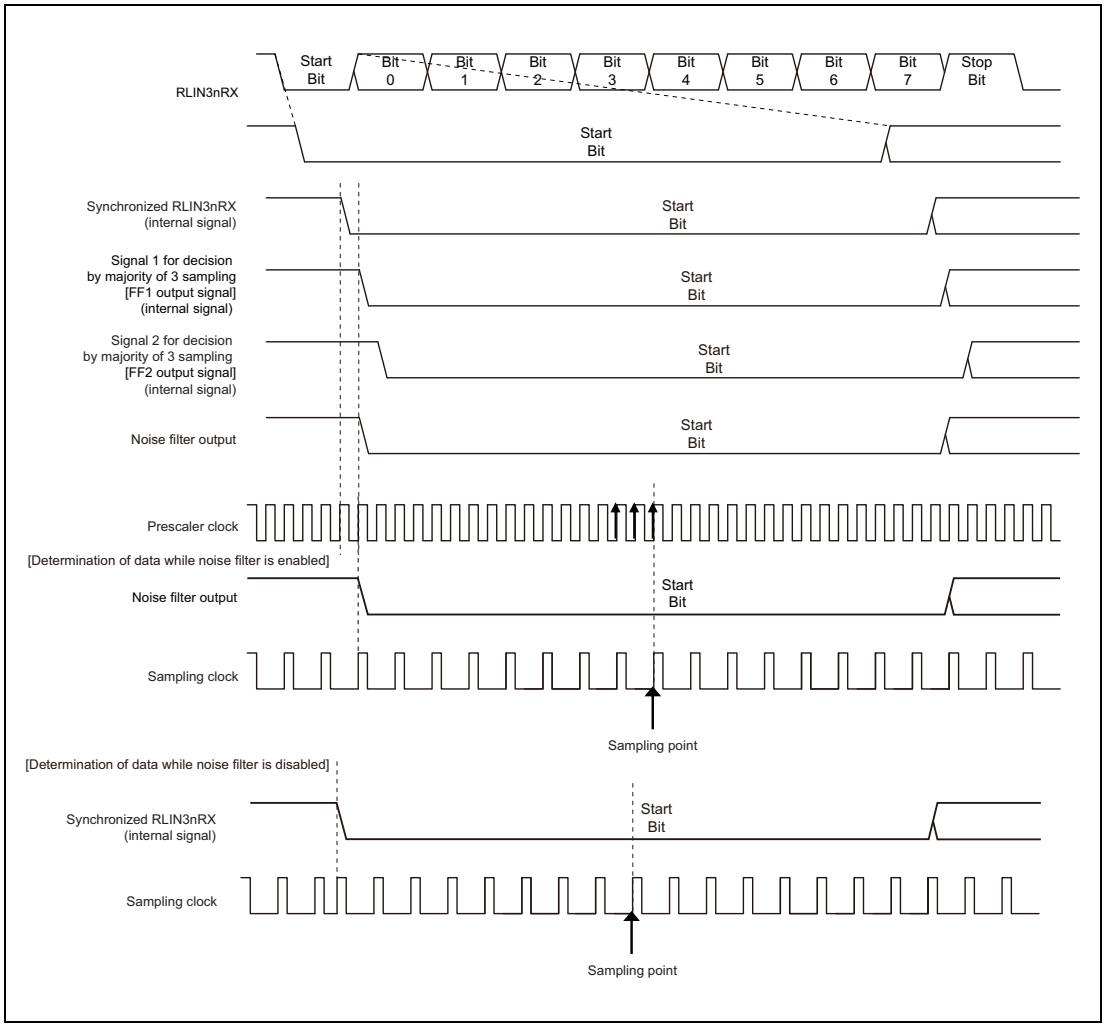

Figure 21.44 Determination of Received Data when Noise Filter is Used

21.5 Notes on Use

21.5.1 Note on LIN Master mode

If in frame separate mode (RLN3nLDFC.FSM=1) the start of the response transmission (Writing 1 to RLN3nLTRC.RTS) coincides with an error*1 occurrence, the response transmission will not be started.

Additionally, after receiving the header of next frame, unexpected data may be sent on the response transmission, even though "1" is not written to RLN3nLTRC.RTS. In case of an error occurrence, re-initialize the LIN/UART module (RLIN3) by transiting to LIN reset mode.

Note 1. Bit error, Physical bus error, Frame/Response timeout error, Framing error, Response preparation error.

21.5.2 Note on LIN Slave mode (Fixed baud rate)

If the low-level width, set by Reception Break (Low-Level) Detection Width Setting bit (RLN3nLBFC.LBLT), is detected during the response transmission (RLN3nLDFC.RCDS=1 and RLN3nLTRC.RTS=1), the response transmission will be interrupted and the RLIN3nTX pin will keep the same status as at the low-level width detection.

If in LIN Slave mode with fixed baud rate, set RLN3nLEDE.BERE=1 (Bit error detection is enable) and RLN3nLSC.IBHS [2:0] = 001_B to 111_B (Except 0 Tbit as response space).

If the Response Space Setting with 0 Tbit (RLN3nLSC.IBHS [2:0] = 000_B), set RLN3nLEDE.BERE=1 and RLN3nLEDE.TERE=1 (Timeout error detection is enable). And transit to LIN reset mode after a timeout error occurrence to initialize the LIN/UART module (RLIN3).

21.5.3 Note on LIN Slave mode (Auto baud rate)

If the conditions (1.) and (2.) are met subsequently, the header might not be received due to false recognition of the ID field. However, the next header will be received correctly.

1. The falling edge is detected from the sampling point of the Stop-bit and Response/Inter-Byte-Space which Bit error is occurred to the end of its bit.
2. The falling edge of the start bit of the ID field is detected from the sampling point of the sync field of the next reception to the end of its bit.

Section 22 I2C Bus Interface (RIIC)

This section contains a generic description of the I2C Bus Interface (RIIC).

The first part of this section describes all RH850/U2A-EVA specific properties, such as the number of units, register base addresses, etc. The remainder of the section describes the functions and registers of RIIC.

22.1 Features RIIC for RH850/U2A-EVA

22.1.1 Number of Units and Channels

This microcontroller has the following number of RIIC units.

Each RIIC unit has one channel interface. “Number of channels” is used with the same meaning as “number of units” in this section.

Table 22.1 Number of Units

Product Name	RH850/ U2A-EVA (516 pins)	RH850/ U2A16 (516 pins)	RH850/ U2A16 (373 pins)	RH850/ U2A16 (292 pins)	RH850/ U2A8 (373 pins)	RH850/ U2A8 (292 pins)	RH850/ U2A6 (292 pins)	RH850/ U2A6 (176 pins)	RH850/ U2A6 (156 pins)	RH850/ U2A6 (144 pins)
Number of Units	2 (n = 0 to 1)	2 (n = 0 to 1)	2 (n = 0 to 1)	2 (n = 0 to 1)	2 (n = 0 to 1)	2 (n = 0 to 1)	2 (n = 0 to 1)	2 (n = 0 to 1)	2 (n = 0 to 1)	1 (n = 0)
Name	RIICn									

Table 22.2 Index

Index	Description
n	Throughout this section, the individual RIIC units are identified by the index “n” (n = 0 to 1): for example, RIICnCR1 is the I2C bus control register 1.

22.1.2 Register Base Addresses

RIICn base addresses are listed in the following table.

RIICn register addresses are given as offsets from the base address.

Table 22.3 Register Base Addresses

Base Address Name	Base Address	Bus Group
<RIIC0_base>	FFF2 2000_H	P-Bus Group 7
<RIIC1_base>	FFF2 3000_H	P-Bus Group 7

22.1.3 Clock Supply

The RIICn clock supply is shown in the following table.

Table 22.4 Clock Supply

Unit Name	Unit Clock Name	Supply Clock Name	Description
RIICn	PCLK*1	CLK_LSB	Bus clock

Note 1. Set PCLK to a value that is less than 1/2 the SCL clock (high level width).
For information about SCL clock, refer to **Table 22.7, External Input/Output Signals**.
For details of clock supply, see **Section 13, Clock Controller**.

22.1.4 Interrupt Requests and Error Notifications

RIICn interrupt requests are listed in the following table.

Table 22.5 Interrupt and DMA/DTS Requests

Unit Interrupt Signal	Description	Interrupt Number	DMA Trigger Number	DTS Trigger Number
RIIC0				
INTRIIC0EE	RIIC communication error/event generation interrupt	685	—	—
INTRIIC0RI	RIIC receive end interrupt	686	Group0-150	Group0-122
INTRIIC0TI	RIIC transmit data empty interrupt	687	Group0-151	Group0-123
INTRIIC0TEI	RIIC transmit end interrupt	688	—	—
RIIC1				
INTRIIC1EE	RIIC communication error/event generation interrupt	689	—	—
INTRIIC1RI	RIIC receive end interrupt	690	Group0-152	Group0-124
INTRIIC1TI	RIIC transmit data empty interrupt	691	Group0-153	Group0-125
INTRIIC1TEI	RIIC transmit end interrupt	692	—	—

This module has no error notifications.

22.1.5 Reset Sources

RIICn reset sources are listed in the following table. RIICn is initialized by these reset sources.

Table 22.6 Reset Sources

Unit Name	Register Name	Reset Condition						
		Power On Reset	System Reset 1	System Reset 2	Application Reset	DeepSTOP Reset	Module Reset	JTAG Reset
RIICn	All registers	√	√	√	√	√	√	—

For details of reset source, see **Section 9, Reset Controller**.

22.1.6 External Input/Output Signals

External input/output signals of RIIC are listed below.

Table 22.7 External Input/Output Signals

Unit Signal Name	Description	Alternative Port Pin Signal Name
RIIC0		
RIIC0SCL	Serial clock I/O pin	RIIC0SCL
RIIC0SDA	Serial data I/O pin	RIIC0SDA
RIIC1		
RIIC1SCL	Serial clock I/O pin	RIIC1SCL
RIIC1SDA	Serial data I/O pin	RIIC1SDA

When using these ports, the PBDCn register for the corresponding port and the corresponding bit in the PODCn register must be set to 1.

For details about PBDCn/PODCn registers, refer to **Section 2.5, Port Register Description**.

22.2 Overview

22.2.1 Functional Overview

Communications format

- I2C bus format
- Master mode or slave mode selectable
- Automatic securing of the various set-up times, hold times, and bus-free times according to the specified transfer rate.

Transfer rate

Up to 400 kbps

SCL clock

- For master operation, the duty cycle of the SCL clock is selectable in the following range:
  - 0% < Duty < 100%

Issuing and detecting conditions

Start, restart, and stop conditions are automatically generated. Start conditions (including restart conditions) and stop conditions are detectable.

Slave address

- Up to three slave-address settings can be made.
- Seven- and ten-bit address formats are supported (along with the use of both at once).
- General call addresses and device ID addresses are detectable.

Acknowledgement

- For transmission, the acknowledge bit is automatically loaded
  - Transfer of the next data for transmission can be automatically suspended on detection of a not-acknowledge bit.
- For reception, the acknowledge bit is automatically transmitted
  - If a wait between the eighth and ninth clock cycles has been selected, software control of the value in the acknowledge field in response to the received value is possible.

Wait function

- In reception, the following periods of waiting can be obtained by holding the clock signal (SCL) at the low level:
  - Waiting between the eighth and ninth clock cycles
  - Waiting between the ninth clock cycle and the first clock cycle of the next transfer (WAIT function)

SDA output delay function

Timing of the output of transmitted data, including the acknowledge bit, can be delayed.

Arbitration

- For multi-master operation
  - Operation to synchronize the SCL (clock) signal in cases of conflict with the SCL signal from another master is possible.
  - When issuing the start condition would create a conflict on the bus, loss of arbitration is detected by testing for non-matching between the internal signal for the SDA line and the level on the SDA line.
  - In master operation, loss of arbitration is detected by testing for non-matching of internal and line levels for transmit data.
- Loss of arbitration due to detection of the start condition while the bus is busy can be detected (to prevent the issuing of double start conditions).
- Loss of arbitration in transfer of a not-acknowledge bit due to the internal signal for the SDA line and the level on the SDA line not matching can be detected.
- Loss of arbitration due to non-matching of internal and line levels for data can be detected in slave transmission.

Timeout function

The internal time-out function is capable of detecting long-interval stop of the SCL (clock signal).

Noise removal

The interface incorporates digital noise filters for both the SCL and SDA signals, and the width for noise cancellation by the filters is adjustable by software.

Interrupt sources

- Four sources:
  - Error in transfer or occurrence of events (detection of arbitration loss, NACK, time-out, a start condition including a restart condition, or a stop condition)
  - Reception complete (including matching with a slave address)
  - Transmit-data-empty (including matching with a slave address)
  - Transmission complete

22.2.2 Block Diagram

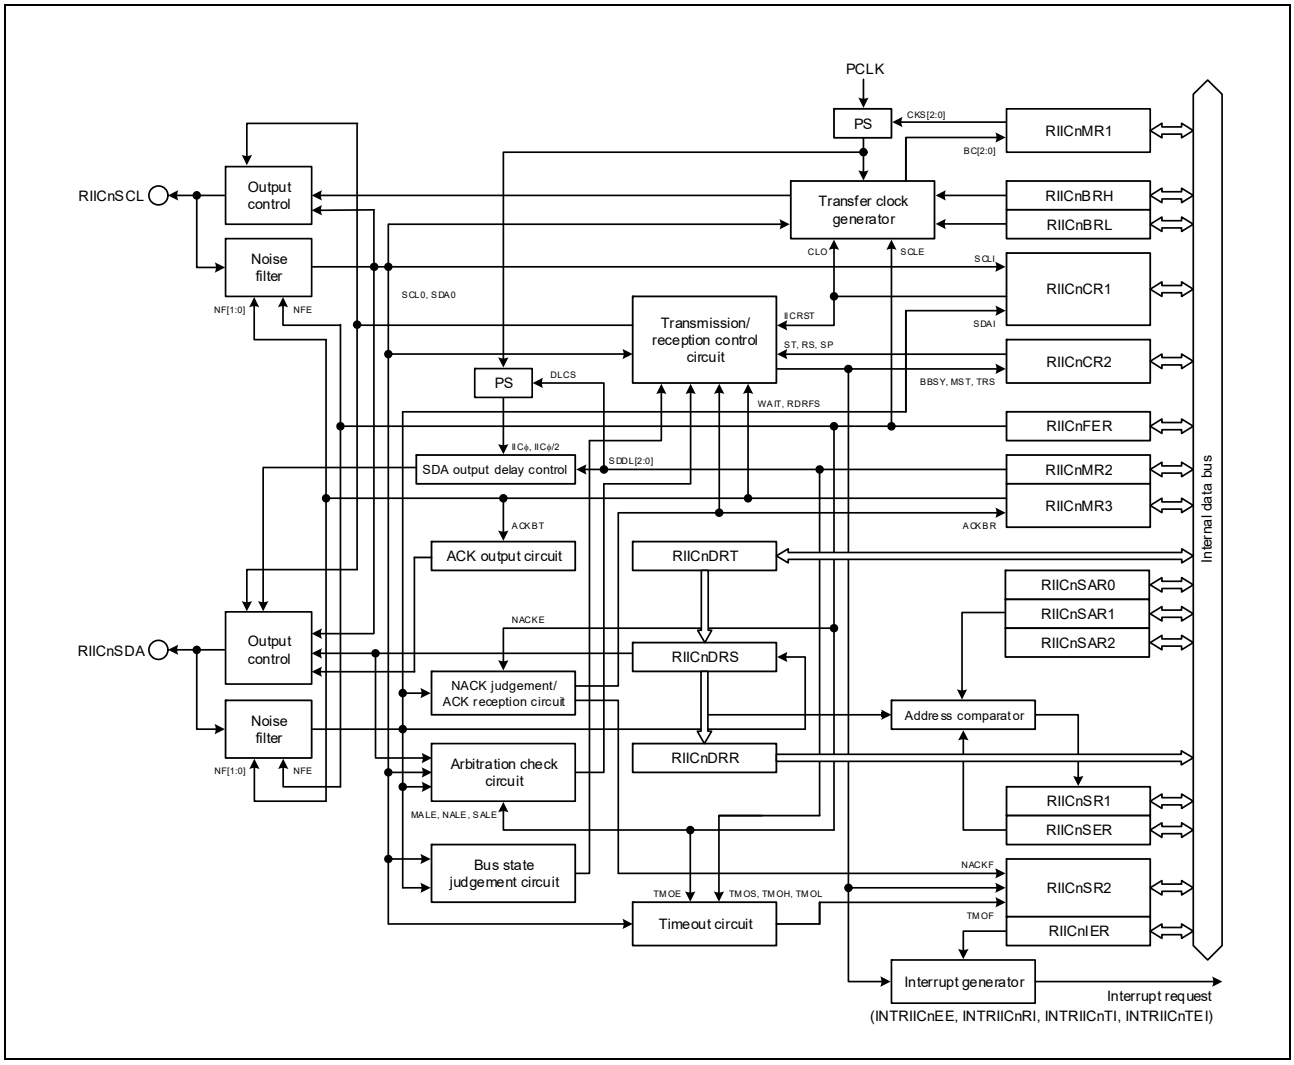

Figure 22.1 Block Diagram of RIIC

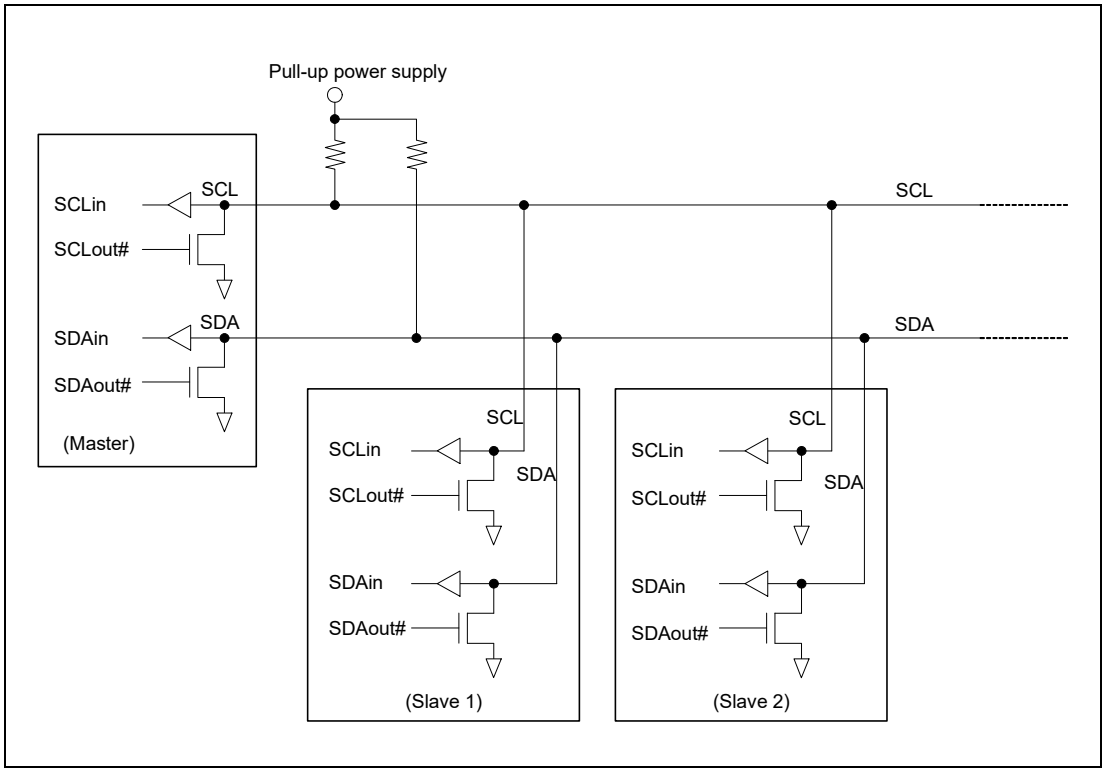

Figure 22.2 Example of Connections to the External Circuit by the I/O Pins (I2C Bus Configuration Example)

22.3 Registers

22.3.1 List of Registers

RIIC registers are listed in the table below.

For details about <RIICn_base>, see **Section 22.1.2, Register Base Addresses**.

Table 22.8 List of Registers

Unit Name	Register Name	Symbol	Address	Access Size	Access Protection	
					PBG	Other
RIICn	I2C Bus Control Register 1	RIICnCR1	<RIICn_base> + 0000_H	8, 16, 32	*1	—
RIICn	I2C Bus Control Register 2	RIICnCR2	<RIICn_base> + 0004_H	8, 16, 32	*1	—
RIICn	I2C Bus Mode Register 1	RIICnMR1	<RIICn_base> + 0008_H	8, 16, 32	*1	—
RIICn	I2C Bus Mode Register 2	RIICnMR2	<RIICn_base> + $000C_H$	8, 16, 32	*1	—
RIICn	I2C Bus Mode Register 3	RIICnMR3	<RIICn_base> + 0010_H	8, 16, 32	*1	—
RIICn	I2C Bus Function Enable Register	RIICnFER	<RIICn_base> + 0014_H	8, 16, 32	*1	—
RIICn	I2C Bus Status Enable Register	RIICnSER	<RIICn_base> + 0018_H	8, 16, 32	*1	—
RIICn	I2C Bus Interrupt Enable Register	RIICnIER	<RIICn_base> + $001C_H$	8, 16, 32	*1	—
RIICn	I2C Bus Status Register 1	RIICnSR1	<RIICn_base> + 0020_H	8, 16, 32	*1	—
RIICn	I2C Bus Status Register 2	RIICnSR2	<RIICn_base> + 0024_H	8, 16, 32	*1	—
RIICn	I2C Slave Address Register 0	RIICnSAR0	<RIICn_base> + 0028_H	8, 16, 32	*1	—
RIICn	I2C Slave Address Register 1	RIICnSAR1	<RIICn_base> + $002C_H$	8, 16, 32	*1	—
RIICn	I2C Slave Address Register 2	RIICnSAR2	<RIICn_base> + 0030_H	8, 16, 32	*1	—
RIICn	I2C Bus Bit Rate Low-Level Register	RIICnBRL	<RIICn_base> + 0034_H	8, 16, 32	*1	—
RIICn	I2C Bus Bit Rate High-Level Register	RIICnBRH	<RIICn_base> + 0038_H	8, 16, 32	*1	—
RIICn	I2C Bus Transmit Data Register	RIICnDRT	<RIICn_base> + $003C_H$	8, 16, 32	*1	—
RIICn	I2C Bus Receive Data Register	RIICnDRR	<RIICn_base> + 0040_H	8, 16, 32	*1	—
RIICn	I2C Bus Shift Register	RIICnDRS	—	—	—	—

Note 1. n = 0: PBG70#3
n = 1: PBG70#4

22.3.2 RIICnCR1 — I2C Bus Control Register 1

Access: RIICnCR1 register can be read or written in 32-bit units.
RIICnCR1L and RIICnCR1H registers can be read or written in 16-bit units.
RIICnCR1LL, RIICnCR1LH, RIICnCR1HL, and RIICnCR1HH registers can be read or written in 8-bit units.

Address: RIICnCR1: <RIICn_base> + 0000_H

RIICnCR1L: <RIICn_base> + 0000_H, RIICnCR1H: <RIICn_base> + 0002_H

RIICnCR1LL: <RIICn_base> + 0000_H, RIICnCR1LH: <RIICn_base> + 0001_H,
RIICnCR1HL: <RIICn_base> + 0002_H, RIICnCR1HH: <RIICn_base> + 0003_H

Value after reset: 0000 $001F_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	ICE	IICRST	CLO	SOWP	SCLO	SDAO	SCLI	SDAI
Value after reset	0	0	0	0	0	0	0	0	0	0	0	1	1	1	1	1
R/W	R	R	R	R	R	R	R	R	R/W	R/W	R/W	W	R/W	R/W	R	R

Table 22.9 RIICnCR1 Register Contents (1/2)

Bit Position	Bit Name	Function
31 to 8	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
7	ICE	I2C Bus Interface Enable 0: Disabled (the RIICnSCL and RIICnSDA pins are not driven). 1: Enabled (the RIICnSCL and RIICnSDA pins are driven). (This bit selects an RIIC reset or internal reset in combination with the IICRST bit.)
6	IICRST	I2C Bus Internal Reset 0: Clears the RIIC reset or internal reset. 1: Initiates the RIIC reset or internal reset. (Clears the bit counter and the SCL/SDA output latch)
5	CLO	Extra SCL Clock Cycle Output 0: Does not output an extra SCL clock cycle (default). 1: Outputs an extra SCL clock cycle. (This bit is cleared automatically after one clock cycle is output.)
4	SOWP	SCLO/SDAO Write Protect 0: SCLO and SDAO bits can be written. 1: SCLO and SDAO bits are protected. (When read, 1 is returned.)
3	SCLO	SCL Output Control/Monitor • Read: 0: The RIIC has driven the RIICnSCL pin low. 1: The RIICnSCL pin has been released. • Write: 0: The RIIC drives the RIICnSCL pin low. 1: Releases the RIICnSCL pin.

Table 22.9 RIICnCR1 Register Contents (2/2)

Bit Position	Bit Name	Function
2	SDAO	SDA Output Control/Monitor • Read: 0: The RIIC has driven the RIICnSDA pin low. 1: The RIICnSDA pin has been released. • Write: 0: The RIIC drives the RIICnSDA pin low. 1: Releases the RIICnSDA pin.
1	SCLI	SCL Line Monitor 0: RIICnSCL line is low. 1: RIICnSCL line is high.
0	SDAI	SDA Line Monitor 0: RIICnSDA line is low. 1: RIICnSDA line is high.

SDAO Bit (SDA Output Control/Monitor) and SCLO Bit (SCL Output Control/Monitor)

These bits are used to directly control the RIICnSDA and RIICnSCL signals output from the RIIC.

When writing to these bits, also write 0 to the SOWP bit.

The result of setting these bits is input to the RIIC via the input buffer. When slave mode is selected, a start condition may be detected and the bus may be released depending on the bit settings.

Do not rewrite these bits during a start condition, stop condition, restart condition, or during transmission or reception. Operation after rewriting in the periods mentioned above is not guaranteed.

When reading these bits, the state of signals output from the RIIC is returned.

CLO Bit (Extra SCL Clock Cycle Output)

This bit is used to output an extra SCL clock cycle for debugging or error processing.

Normally, set the bit to 0. Setting the bit to 1 in a normal communication state causes a communication error.

For details on this function, see **Section 22.4.10.2, Extra SCL Clock Cycle Output Function**.

IICRST Bit (I2C Bus Internal Reset)

This bit is used to reset the internal states of the RIIC.

Setting this bit to 1 initiates an RIIC reset or internal reset.

Whether an RIIC reset or internal reset is initiated is determined according to the combination with the ICE bit. **Table 22.10** lists the types of RIIC reset.

The RIIC reset resets all registers (except ICE and IICRST) including the RIICnCR2.BBSY flag and internal states of the RIIC, and the internal reset resets the bit counter (RIICnMR1.BC[2:0] bits), the I2C bus shift register (RIICnDRS), and the I2C bus status registers (RIICnSR1 and RIICnSR2) as well as the internal states of the RIIC. For the reset conditions for each register, see **Section 22.4.11, Reset Function of RIIC**.

An internal reset initiated with the IICRST bit set to 1 during operation (with the ICE bit set to 1) resets the internal states of the RIIC without initializing the port settings and the control and setting registers of the RIIC when the bus or RIIC hangs up due to a communication error, etc.

If the RIIC hangs up in a low level output state, resetting the internal states cancels the low level output state and releases the bus with the RIICnSCL pin and RIICnSDA pin at a high impedance.

CAUTION

If an internal reset is initiated using the IICRST bit for a bus hang-up occurred during communication with the master device in slave mode, the states may become different between the slave device and the master device (due to the difference in the bit counter information). For this reason, do not initiate an internal reset in slave mode, but instead initiate restoration processing from the master device. If an internal reset is necessary because the RIIC hangs up with the SCL line in a low level output state in slave mode, initiate an internal reset and then issue a restart condition from the master device or resume communication from the start condition issuance after issuing a stop condition. If communication is restarted by initiating a reset solely in the slave device without issuing a start condition or restart condition from the master device, synchronization will be lost because the master and slave devices operate asynchronously.

Table 22.10 RIIC Resets

IICRST	ICE	State	Specifications
1	0	RIIC reset	Resets all registers (except ICE and IICRST) and internal states of the RIIC.
	1	Internal reset	Reset the RIICnMR1.BC[2:0] bits, and the RIICnSR1, RIICnSR2, RIICnDRS registers and the internal states of the RIIC.

ICE Bit (I2C Bus Interface Enable)

The ICE bit selects driving or non-driving of the RIICnSCL and RIICnSDA pins. Moreover, this bit can perform two types of reset in combination with the IICRST bit. For the types of reset, see **Table 22.10, RIIC Resets**.

Set the ICE bit to 1 when using RIIC. Setting the ICE bit to 1 selects driving of the RIICnSCL and RIICnSDA pins.

Set the ICE bit to 0 when RIIC is not to be used. Clearing the ICE bit to 0 stops driving of the RIICnSCL and RIICnSDA pins.

CAUTION

Though the output from RIICnSDA or RIICnSCL is disabled while the ICE bit is 0, the input to RIICnSDA or RIICnSCL is enabled. The RIICnSCL and RIICnSDA pin functions should not be assigned to the RIIC. If assigned, it causes the slave addresses to be compared.

22.3.3 RIICnCR2 — I2C Bus Control Register 2

Access: RIICnCR2 register can be read or written in 32-bit units.
RIICnCR2L and RIICnCR2H registers can be read or written in 16-bit units.
RIICnCR2LL, RIICnCR2LH, RIICnCR2HL, and RIICnCR2HH registers can be read or written in 8-bit units.

Address: RIICnCR2: <RIICn_base> + 0004_H

RIICnCR2L: <RIICn_base> + 0004_H, RIICnCR2H: <RIICn_base> + 0006_H

RIICnCR2LL: <RIICn_base> + 0004_H, RIICnCR2LH: <RIICn_base> + 0005_H,
RIICnCR2HL: <RIICn_base> + 0006_H, RIICnCR2HH: <RIICn_base> + 0007_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 22.11 RIICnCR2 Register Contents

Bit Position	Bit Name	Function
31 to 8	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
7	BBSY	Bus Busy Detection Flag 0: The I2C bus is released (the bus is free). 1: The I2C bus is occupied (the bus is busy).
6	MST*1	Master/Slave Mode 0: Slave mode 1: Master mode
5	TRS*1	Transmit/Receive Mode 0: Receive mode 1: Transmit mode
4	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
3	SP	Stop Condition Issuance Request 0: Does not request to issue a stop condition. 1: Requests to issue a stop condition.
2	RS	Restart Condition Issuance Request 0: Does not request to issue a restart condition. 1: Requests to issue a restart condition.
1	ST	Start Condition Issuance Request 0: Does not request to issue a start condition. 1: Requests to issue a start condition.
0	Reserved	When read, the value after reset is returned. When writing, write the value after reset.

Note 1. When the RIICnMR1.MTWP bit is set to 1, the MST and TRS bits can be written to.

ST Bit (Start Condition Issuance Request)

This bit is used to request transition to master mode and issuance of a start condition.

When this bit is set to 1 to request to issue a start condition, a start condition is issued when the BBSY flag is set to 0 (bus free).

For details on the start condition issuance, see **Section 22.4.9, Start Condition/Restart Condition/Stop Condition Issuing Function**.

[Setting condition]

When 1 is written to the ST bit

[Clearing conditions]

- When 0 is written to the ST bit
- When a start condition has been issued
- When the RIICnSR2.AL (arbitration-lost) flag is set to 1
- When 1 is written to the RIICnCR1.IICRST bit to apply an RIIC reset or an internal reset

CAUTION

Set the ST bit to 1 (start condition issuance request) when the BBSY flag is set to 0 (bus free).
Note that arbitration may be lost as the start condition issuance error if the ST bit is set to 1 (start condition issuance request) when the BBSY flag is set to 1 (bus busy).

RS Bit (Restart Condition Issuance Request)

This bit is used to request that a restart condition be issued in master mode.

When this bit is set to 1 to request to issue a restart condition, a restart condition is issued when the BBSY flag is set to 1 (bus busy) and the MST bit is set to 1 (master mode).

For details on the restart condition issuance, see **Section 22.4.9, Start Condition/Restart Condition/Stop Condition Issuing Function**.

[Setting condition]

When 1 is written to the RS bit with the RIICnCR2.BBSY flag set to 1

[Clearing conditions]

- When 0 is written to the RS bit
- When a restart condition has been issued or a start condition is detected
- When a stop condition is detected
- When the RIICnCR2.AL (arbitration-lost) flag is set to 1
- When 1 is written to the RIICnCR1.IICRST bit to apply an RIIC reset or an internal reset

CAUTIONS

1. Do not set the RS bit to 1 while issuing a stop condition.
2. It is commended to issue a restart condition in master transmit mode. If the RS bit is set to 1 (restart condition issuance request) in mode other than master mode, the restart condition is not issued in this mode but the RS bit remains set. If the operating mode changes to master mode with the bit not being cleared, the restart condition may be issued.

SP Bit (Stop Condition Issuance Request)

This bit is used to request that a stop condition be issued in master mode.

When this bit is set to 1 to request to issue a stop condition, a stop condition is issued when the BBSY flag is set to 1 (bus busy) and the MST bit is set to 1 (master mode).

For details on the stop condition issuance, see **Section 22.4.9, Start Condition/Restart Condition/Stop Condition Issuing Function**.

[Setting condition]

When 1 is written to the SP bit with both the RIICnCR2.BBSY flag and the RIICnCR2.MST bit set to 1

[Clearing conditions]

- When 0 is written to the SP bit
- When a stop condition has been issued or a stop condition is detected
- When the RIICnSR2.AL (arbitration-lost) flag is set to 1
- When a start condition and a restart condition are detected
- When 1 is written to the RIICnCR1.IICRST bit to apply an RIIC reset or an internal reset

CAUTIONS

1. Writing to the SP bit is not possible while the setting of the BBSY flag is 0 (bus free).
2. Do not set the SP bit to 1 while a restart condition is being issued.

TRS Bit (Transmit/Receive Mode)

This bit indicates transmit or receive mode.

The RIIC is in receive mode when the TRS bit is set to 0 and is in transmit mode when the bit is set to 1. Combination of this bit and the MST bit indicates the operating mode of the RIIC.

The value of the TRS bit is automatically changed to the value for transmission mode or reception mode (1 or 0) by the following conditions.

[Setting conditions]

- When a start condition is issued normally according to the start condition issuance request (when a start condition is detected with the ST bit set to 1)
- When the address received in slave mode matches the address enabled in RIICnSER, with the R/W# bit set to 1
- When 1 is written to the TRS bit with the RIICnMR1.MTWP bit set to 1

[Clearing conditions]

- When a stop condition is detected
- The RIICnSR2.AL (arbitration-lost) flag being set to 1
- In master mode, reception of a slave address to which an R/W# bit with the value 1 is appended
- In slave transmit mode, a restart condition is detected (a restart condition is detected with RIICnCR2.BBSY = 1 and RIICnCR2.MST = 0)
- When 0 is written to the TRS bit with the RIICnMR1.MTWP bit set to 1
- When 1 is written to the RIICnCR1.IICRST bit to apply an RIIC reset or an internal reset

MST Bit (Master/Slave Mode)

This bit indicates master or slave mode.

The RIIC is in slave mode when the MST bit is set to 0 and is in master mode when the bit is set to 1. Combination of this bit and the TRS bit indicates the operating mode of the RIIC.

The value of the MST bit is automatically changed to the value for master mode or slave mode (1 or 0) by the following conditions.

[Setting conditions]

- When a start condition is issued normally according to the start condition issuance request (when a start condition is detected with the ST bit set to 1)
- When 1 is written to the MST bit with the RIICnMR1.MTWP bit set to 1

[Clearing conditions]

- When a stop condition is detected
- When the RIICnSR2.AL (arbitration-lost) flag is set to 1
- When 0 is written to the MST bit with the RIICnMR1.MTWP bit set to 1
- When 1 is written to the RIICnCR1.IICRST bit to apply an RIIC reset or an internal reset

BBSY Flag (Bus Busy Detection)

The BBSY flag indicates whether the I2C bus is occupied (bus busy) or released (bus free).

This bit is set to 1 when the SDA line changes from high to low under the condition of SCL = high, assuming that a start condition has been issued.

When the SDA line changes from low to high under the condition of SCL = high, this bit is cleared to 0 after the bus free time (specified in RIICnBRL) start condition is not detected, assuming that a stop condition has been issued.

[Setting condition]

When a start condition is detected

[Clearing conditions]

- When the bus free time (specified in RIICnBRL) start condition is not detected after detecting a stop condition
- When 1 is written to the RIICnCR1.IICRST bit with the RIICnCR1.ICE bit set to 0 (RIIC reset)

CAUTIONS

- When an internal reset is applied while the bus is free after detection of a stop condition, the setting of the BBSY flag is 0 while the bus is free following de-assertion of the internal reset signal.
- When an internal reset is applied while the bus is not free, the BBSY flag is not cleared.

22.3.4 RIICnMR1 — I2C Bus Mode Register 1

Access: RIICnMR1 register can be read or written in 32-bit units.
RIICnMR1L and RIICnMR1H registers can be read or written in 16-bit units.
RIICnMR1LL, RIICnMR1LH, RIICnMR1HL, and RIICnMR1HH registers can be read or written in 8-bit units.

Address: RIICnMR1: <RIICn_base> + 0008_H

RIICnMR1L: <RIICn_base> + 0008_H, RIICnMR1H: <RIICn_base> + $000A_H$

RIICnMR1LL: <RIICn_base> + 0008_H, RIICnMR1LH: <RIICn_base> + 0009_H,
RIICnMR1HL: <RIICn_base> + $000A_H$, RIICnMR1HH: <RIICn_base> + $000B_H$

Value after reset: 0000 0008_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 22.12 RIICnMR1 Register Contents

Bit Position	Bit Name	Function
31 to 8	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
7	MTWP	MST/TRS Write Protect 0: Disables writing to the RIICnCR2.MST and TRS bits. 1: Enables writing to the RIICnCR2.MST and TRS bits.
6 to 4	CKS[2:0]	Internal Reference Clock Selection (IICϕ) b6 b4 0 0 0: PCLK/1 clock 0 0 1: PCLK/2 clock 0 1 0: PCLK/4 clock 0 1 1: PCLK/8 clock 1 0 0: PCLK/16 clock 1 0 1: PCLK/32 clock 1 1 0: PCLK/64 clock 1 1 1: PCLK/128 clock
3	BCWP*1	BC Write Protect 0: Enables a value to be written in the BC[2:0] bits. (This bit is read as 1.) 1: Protects the BC[2:0] bits.
2 to 0	BC[2:0]	Bit Counter b2 b0 0 0 0: 9 bits 0 0 1: 2 bits 0 1 0: 3 bits 0 1 1: 4 bits 1 0 0: 5 bits 1 0 1: 6 bits 1 1 0: 7 bits 1 1 1: 8 bits

Note 1. When rewriting the BC[2:0] bits, write 0 to the BCWP bit simultaneously.

BC[2:0] Bits (Bit Counter)

These bits function as a counter that indicates the number of bits remaining to be transferred at the detection of a rising edge on the SCL line. Although these bits are writable and readable, it is not necessary to access these bits under normal conditions.

To write to these bits, specify the number of bits to be transferred plus one (data is transferred with an additional acknowledge bit) between transferred frames. When setting any value other than 000_B, set the value while the SCL line is at a low level.

[Clearing conditions]

- When 1 is written to the RIICnCR1.IICRST bit to apply a RIIC reset or an internal reset is initiated.
- Data transfer including the acknowledge bit being completed.
- A start condition including a restart condition being detected.

22.3.5 RIICnMR2 — I2C Bus Mode Register 2

Access: RIICnMR2 register can be read or written in 32-bit units.
RIICnMR2L and RIICnMR2H registers can be read or written in 16-bit units.
RIICnMR2LL, RIICnMR2LH, RIICnMR2HL, and RIICnMR2HH registers can be read or written in 8-bit units.

Address: RIICnMR2: <RIICn_base> + $000C_H$

RIICnMR2L: <RIICn_base> + $000C_H$, RIICnMR2H: <RIICn_base> + $000E_H$

RIICnMR2LL: <RIICn_base> + $000C_H$, RIICnMR2LH: <RIICn_base> + $000D_H$,
RIICnMR2HL: <RIICn_base> + $000E_H$, RIICnMR2HH: <RIICn_base> + $000F_H$

Value after reset: $0000\ 0006_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 22.13 RIICnMR2 Register Contents (1/2)

Bit Position	Bit Name	Function
31 to 8	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
7	DLCS	SDA Output Delay Clock Source Selection 0: The internal reference clock (IICϕ) is selected as the clock source of the SDA output delay counter. 1: The internal reference clock divided by 2 (IICϕ/2) is selected as the clock source of the SDA output delay counter.*1
6 to 4	SDDL[2:0]	SDA Output Delay Counter • When RIICnMR2.DLCS = 0 (IICϕ) b6 b4 0 0 0: No output delay 0 0 1: 1 IICϕ cycle 0 1 0: 2 IICϕ cycles 0 1 1: 3 IICϕ cycles 1 0 0: 4 IICϕ cycles 1 0 1: 5 IICϕ cycles 1 1 0: 6 IICϕ cycles 1 1 1: 7 IICϕ cycles • When RIICnMR2.DLCS = 1 (IICϕ/2) b6 b4 0 0 0: No output delay 0 0 1: 1 or 2 IICϕ cycles 0 1 0: 3 or 4 IICϕ cycles 0 1 1: 5 or 6 IICϕ cycles 1 0 0: 7 or 8 IICϕ cycles 1 0 1: 9 or 10 IICϕ cycles 1 1 0: 11 or 12 IICϕ cycles 1 1 1: 13 or 14 IICϕ cycles
3	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
2	TMOH	Timeout H Count Control 0: Disables counting while the SCL line is at a high level. 1: Enables counting while the SCL line is at a high level.

Table 22.13 RIICnMR2 Register Contents (2/2)

Bit Position	Bit Name	Function
1	TMOL	Timeout L Count Control 0: Disables counting while the SCL line is at a low level. 1: Enables counting while the SCL line is at a low level.
0	TMOS	Timeout Detection Time Selection 0: Long mode is selected. 1: Short mode is selected.

Note 1. The setting DLCS = 1 (IICϕ/2) only becomes valid when SCL is at the low level. When SCL is at the high level, the setting DLCS = 1 becomes invalid and the clock source becomes the internal reference clock (IICϕ).

TMOS Bit (Timeout Detection Time Selection)

This bit is used to select long mode or short mode for the timeout detection time when the timeout function is enabled (RIICnFER.TMOE bit = 1). When this bit is set to 0, long mode is selected. When this bit is set to 1, short mode is selected. In long mode, the timeout detection internal counter functions as a 16 bit-counter. In short mode, the counter functions as a 14 bit-counter. While the SCL line is in the state that enables this counter as specified by bits TMOH and TMOL, the counter counts up in synchronization with the internal reference clock (IICϕ) as a count source.

For details on the timeout function, see **Section 22.4.10.1, Timeout Function**.

TMOL Bit (Timeout L Count Control)

This bit is used to enable or disable the internal counter of the timeout function to count up while the SCL line is held low when the timeout function is enabled (RIICnFER.TMOE bit = 1).

TMOH Bit (Timeout H Count Control)

This bit is used to enable or disable the internal counter of the timeout function to count up while the SCL line is held high when the timeout function is enabled (RIICnFER.TMOE bit = 1).

SDDL[2:0] Bits (SDA Output Delay Setup Counter)

The SDA output can be delayed by the SDDL[2:0] setting. This counter works with the clock source selected by the DLCS bit. The setting of this function can be used for all types of SDA output, including the transmission of the acknowledge bit.

For details on this function, see **Section 22.4.4, Facility for Delaying SDA Output**.

CAUTION

Set the SDA output delay time to meet the I2C bus standard (within the data enable time/acknowledge enable time*1). Note that, if a value outside the standard is set, communication with communication devices may malfunction or it may seemingly become a start condition or stop condition depending on the bus state.

Note 1. Data enable time/acknowledge enable time
3,450 ns (up to 100 kbps: standard mode [Sm])
900 ns (up to 400 kbps: fast mode [Fm])

22.3.6 RIICnMR3 — I2C Bus Mode Register 3

Access: RIICnMR3 register can be read or written in 32-bit units.
RIICnMR3L and RIICnMR3H registers can be read or written in 16-bit units.
RIICnMR3LL, RIICnMR3LH, RIICnMR3HL, and RIICnMR3HH registers can be read or written in 8-bit units.

Address: RIICnMR3: <RIICn_base> + 0010_H

RIICnMR3L: <RIICn_base> + 0010_H, RIICnMR3H: <RIICn_base> + 0012_H

RIICnMR3LL: <RIICn_base> + 0010_H, RIICnMR3LH: <RIICn_base> + 0011_H,
RIICnMR3HL: <RIICn_base> + 0012_H, RIICnMR3HH: <RIICn_base> + 0013_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	WAIT	RDRFS	ACKWP	ACKBT	ACKBR	NF[1:0]	
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R	R/W	R/W

Table 22.14 RIICnMR3 Register Contents

Bit Position	Bit Name	Function
31 to 7	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
6	WAIT*2	WAIT 0: No WAIT (The period between ninth clock cycle and first clock cycle is not held low.) 1: WAIT (The period between ninth clock cycle and first clock cycle is held low.) Low-hold is released by reading RIICnDRR.
5	RDRFS*2	RDRF Flag Set Timing Selection 0: The RDRF flag is set at the rising edge of the ninth SCL clock cycle. (The SCL line is not held low at the falling edge of the eighth clock cycle.) 1: The RDRF flag is set at the rising edge of the eighth SCL clock cycle. (The SCL line is held low at the falling edge of the eighth clock cycle.) Low-hold is released by writing a value to the ACKBT bit.
4	ACKWP*1	ACKBT Write Protect 0: Modification of the ACKBT bit is disabled. 1: Modification of the ACKBT bit is enabled.
3	ACKBT*1	Transmit Acknowledge 0: A 0 is sent as the acknowledge bit (ACK transmission). 1: A 1 is sent as the acknowledge bit (NACK transmission).
2	ACKBR	Receive Acknowledge 0: A 0 is received as the acknowledge bit (ACK reception). 1: A 1 is received as the acknowledge bit (NACK reception).
1, 0	NF[1:0]	Digital noise Filter Stage Selection b1 b0 0 0: Noise of up to one IICϕ cycle is filtered out (single-stage filter). 0 1: Noise of up to two IICϕ cycles is filtered out (2-stage filter). 1 0: Noise of up to three IICϕ cycles is filtered out (3-stage filter). 1 1: Noise of up to four IICϕ cycles is filtered out (4-stage filter).

Note 1. If it is attempted to write 1 to both ACKWP and ACKBT bits, the ACKBT bit cannot be set to 1.

Note 2. The WAIT and RDRFS bits are valid only in receive mode (invalid in transmit mode).

NF[1:0] Bits (Digital Noise Filter Stage Selection)

These bits are used to select the number of stages of the digital noise filter.

CAUTION

Set the noise range to be filtered out by the noise filter within a range less than the SCL line high-level period or low-level period. If the noise range is set to a value of (SCL clock width: high-level period or low-level period, whichever is shorter) - [1.5 internal reference clock synchronized (IICϕ) cycles] or more, the SCL clock is regarded as noise by the noise filter function of the RIIC, which may prevent the RIIC from operating normally.

ACKBR Bit (Receive Acknowledge)

This bit is used to store the acknowledge bit information received from the receive device in transmit mode.

[Setting condition]

When 1 is received as the acknowledge bit with the RIICnCR2.TRS bit set to 1

[Clearing conditions]

- When 0 is received as the acknowledge bit with the RIICnCR2.TRS bit set to 1
- When 1 is written to the RIICnCR1.IICRST bit while the RIICnCR1.ICE bit is 0 (RIIC reset)

ACKBT Bit (Transmit Acknowledge)

This bit is used to set the bit to be sent at the acknowledge timing in receive mode.

[Setting condition]

When 1 is written to this bit with the ACKWP bit set to 1

[Clearing conditions]

- When 0 is written to this bit after ACKBT reading while the ACKWP bit is set to 1
- When a stop condition is detected
- When 1 is written to the RIICnCR1.IICRST bit while the RIICnCR1.ICE bit is 0 (RIIC reset)

CAUTION

The ACKBT bit must be written to while the ACKWP bit is 1. If the ACKBT bit is written to with the ACKWP bit cleared to 0, writing to the ACKBT bit is disabled.

ACKWP Bit (ACKBT Write Protect)

This bit is used to control the modification of the ACKBT bit.

RDRFS Bit (RDRF Flag Set Timing Selection)

This bit is used to select the RDRF flag set timing in receive mode and also to select whether to hold the SCL line low at the falling edge of the eighth SCL clock cycle.

When the RDRFS bit is 0, the SCL line is not held low at the falling edge of the eighth SCL clock cycle, and the RDRF flag is set to 1 at the rising edge of the ninth SCL clock cycle.

When the RDRFS bit is 1, the RDRF flag is set to 1 at the rising edge of the eighth SCL clock cycle and the SCL line is held low at the falling edge of the eighth SCL clock cycle. The low-hold of the SCL line is released by writing a value to the ACKBT bit.

After data is received with this setting, the SCL line is automatically held low before the acknowledge bit is sent. This enables processing to send ACK (ACKBT = 0) or NACK (ACKBT = 1) according to receive data.

WAIT Bit (WAIT)

This bit is used to control whether to hold the period between the ninth SCL clock cycle and the first SCL clock cycle low until the receive data buffer (RIICnDRR) is completely read each time single-byte data is received in receive mode.

When the WAIT bit is 0, the receive operation is continued without holding the period between the ninth and the first SCL clock cycle low. When both the RDRFS and WAIT bits are 0, continuous receive operation is enabled with the double buffer.

When the WAIT bit is 1, the SCL line is held low from the falling edge of the ninth clock cycle until the RIICnDRR value is read each time single-byte data is received. This enables receive operation in byte units.

CAUTION

When the value of the WAIT bit is cleared to 0, be sure to read the RIICnDRR beforehand.

22.3.7 RIICnFER — I2C Bus Function Enable Register

Access: RIICnFER register can be read or written in 32-bit units.
RIICnFERL and RIICnFERH registers can be read or written in 16-bit units.
RIICnFERLL, RIICnFERLH, RIICnFERHL, and RIICnFERHH registers can be read or written in 8-bit units.

Address: RIICnFER: <RIICn_base> + 0014_H

RIICnFERL: <RIICn_base> + 0014_H, RIICnFERH: <RIICn_base> + 0016_H

RIICnFERLL: <RIICn_base> + 0014_H, RIICnFERLH: <RIICn_base> + 0015_H,
RIICnFERHL: <RIICn_base> + 0016_H, RIICnFERHH: <RIICn_base> + 0017_H

Value after reset: $0000\ 0072_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Table 22.15 RIICnFER Register Contents

Bit Position	Bit Name	Function
31 to 7	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
6	SCLE	SCL Synchronous Circuit Enable 0: No SCL synchronous circuit is used. 1: An SCL synchronous circuit is used.
5	NFE	Digital Noise Filter Circuit Enable 0: No digital noise filter circuit is used. 1: A digital noise filter circuit is used.
4	NACKE	NACK Reception Transfer Suspension Enable 0: Transfer operation is not suspended during NACK reception (transfer suspension disabled). 1: Transfer operation is suspended during NACK reception (transfer suspension enabled).
3	SALE	Slave Arbitration-Lost Detection Enable 0: Slave arbitration-lost detection is disabled. 1: Slave arbitration-lost detection is enabled.
2	NALE	NACK Transmission Arbitration-Lost Detection Enable 0: NACK transmission arbitration-lost detection is disabled. 1: NACK transmission arbitration-lost detection is enabled.
1	MALE	Master Arbitration-Lost Detection Enable 0: Master arbitration-lost detection is disabled. (Disables the arbitration-lost detection function and does not clear the RIICnCR2.MST and TRS bits automatically when arbitration is lost.) 1: Master arbitration-lost detection is enabled. (Enables the arbitration-lost detection function and clears the RIICnCR2.MST and TRS bits automatically when arbitration is lost.) If 1 is written to the ST bit while the BBSY flag is 1 in slave transmit mode, the TRS bit is not cleared.
0	TMOE	Timeout Function Enable 0: The timeout function is disabled. 1: The timeout function is enabled.

TMOE Bit (Timeout Function Enable)

This bit is used to enable or disable the timeout function.

For details on the timeout function, see **Section 22.4.10.1, Timeout Function**.

MALE Bit (Master Arbitration-Lost Detection Enable)

This bit is used to select enabling or disabling of the arbitration-lost detection function. Normally, set this bit to 1.

NALE Bit (NACK Transmission Arbitration-Lost Detection Enable)

This bit is used to specify whether the detection of ACK during transmission of NACK in reception (such as when slaves with the same address are present on the bus and each is transmitting different data, or when two or more masters select the same slave device simultaneously with different numbers of bytes for reception) is judged to represent a loss in arbitration.

SALE Bit (Slave Arbitration-Lost Detection Enable)

This bit is used to specify whether to cause arbitration to be lost when a value different from the value being transmitted is detected on the bus in slave transmit mode (such as when slaves with the same address exist on the bus or when a mismatch with the transmit data occurs due to noise).

NACKE Bit (NACK Reception Transfer Suspension Enable)

This bit is used to specify whether to continue or discontinue the transfer operation when NACK is received in transmit mode. Normally, set this bit to 1.

When NACK is received with the NACKE bit set to 1, the next transfer operation is suspended.

When the NACKE bit is 0, the next transfer operation is continued regardless of the received acknowledge content.

SCLE Bit (SCL Synchronous Circuit Enable)

This bit is used to specify whether to synchronize the SCL clock with a rising or falling edge on the SCL line. Normally, set this bit to 1.

When the SCLE bit is cleared to 0 (SCL synchronous circuit not used), the RIIC does not synchronize the SCL clock with the SCL input clock. In this setting, the RIIC outputs the SCL clock with the transfer rate set in RIICnBRH and RIICnBRL regardless of the SCL line state. For this reason, if the bus load of the I2C bus line is much larger than the specification value or if the SCL clock output overlaps in multiple masters, the short-cycle SCL clock that does not meet the specification may be output. When no SCL synchronous circuit is used, it also affects the issuance of a start condition, restart condition, and stop condition, and the continuous output of extra SCL clock cycles.

This bit must not be cleared to 0 except for checking the output of the transfer rate.

22.3.8 RIICnSER — I2C Bus Status Enable Register

Access: RIICnSER register can be read or written in 32-bit units.
RIICnSERL and RIICnSERH registers can be read or written in 16-bit units.
RIICnSERLL, RIICnSERLH, RIICnSERHL, and RIICnSERHH registers can be read or written in 8-bit units.

Address: RIICnSER: <RIICn_base> + 0018_H

RIICnSERL: <RIICn_base> + 0018_H, RIICnSERH: <RIICn_base> + $001A_H$

RIICnSERLL: <RIICn_base> + 0018_H, RIICnSERLH: <RIICn_base> + 0019_H,
RIICnSERHL: <RIICn_base> + $001A_H$, RIICnSERHH: <RIICn_base> + $001B_H$

Value after reset: $0000\ 0009_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

R/W	R	R	R	R	R	R	R	R	R	R	R/W	R	R/W	R/W	R/W	R/W

Table 22.16 RIICnSER Register Contents

Bit Position	Bit Name	Function
31 to 6	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
5	DIDE	Device-ID Address Detection Enable 0: Device-ID address detection is disabled. 1: Device-ID address detection is enabled.
4	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
3	GCE	General Call Address Enable 0: General call address detection is disabled. 1: General call address detection is enabled.
2	SAR2	Slave Address Register 2 Enable 0: Slave address in RIICnSAR2 is disabled. 1: Slave address in RIICnSAR2 is enabled.
1	SAR1	Slave Address Register 1 Enable 0: Slave address in RIICnSAR1 is disabled. 1: Slave address in RIICnSAR1 is enabled.
0	SAR0	Slave Address Register 0 Enable 0: Slave address in RIICnSAR0 is disabled. 1: Slave address in RIICnSAR0 is enabled.

SARy Bit (Slave Address Register y Enable) (y = 0 to 2)

This bit is used to enable or disable the slave address set in RIICnSARy.

When this bit is set to 1, the slave address set in RIICnSARy is enabled and is compared with the received slave address.

When this bit is cleared to 0, the slave address set in RIICnSARy is disabled and is ignored even if it matches the received slave address.

GCE Bit (General Call Address Enable)

This bit is used to specify whether to ignore the general call address ($0000\ 000_B$ + 0 [W]: All 0) when it is received.

When this bit is set to 1, if the received slave address matches the general call address, the RIIC recognizes the received slave address as the general call address independently of the slave addresses set in RIICnSARy (y = 0 to 2) and performs data receive operation.

When this bit is cleared to 0, the received slave address is ignored even if it matches the general call address.

DIDE Bit (Device-ID Address Detection Enable)

This bit is used to specify whether to recognize and execute the Device-ID address when a device ID ($1111\ 100_B$) is received in the first frame after a start condition or restart condition is detected.

When this bit is set to 1, if the received first frame matches the device ID, the RIIC recognizes that the Device-ID address has been received. When the following R/W# bit is 0 [W], the RIIC recognizes the second and the following frames as slave addresses and continues the receive operation.

When this bit is cleared to 0, the RIIC ignores the received first frame even if it matches the device ID address and recognizes the first frame as a normal slave address.

For details on the device-ID address detection, see **Section 22.4.6.3, Device-ID Address Detection**.

22.3.9 RIICnIER — I2C Bus Interrupt Enable Register

Access: RIICnIER register can be read or written in 32-bit units.
RIICnIERL and RIICnIERH registers can be read or written in 16-bit units.
RIICnIERLL, RIICnIERLH, RIICnIERHL, and RIICnIERHH registers can be read or written in 8-bit units.

Address: RIICnIER: <RIICn_base> + $001C_H$

RIICnIERL: <RIICn_base> + $001C_H$, RIICnIERH: <RIICn_base> + $001E_H$

RIICnIERLL: <RIICn_base> + $001C_H$, RIICnIERLH: <RIICn_base> + $001D_H$,
RIICnIERHL: <RIICn_base> + $001E_H$, RIICnIERHH: <RIICn_base> + $001F_H$

Value after reset: $0000\ 0000_H$

Table 22.17 RIICnIER Register Contents

Bit Position	Bit Name	Function
31 to 8	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
7	TIE	Transmit Data Empty Interrupt Enable 0: Transmit data empty interrupt request (INTRIICnTI) is disabled. 1: Transmit data empty interrupt request (INTRIICnTI) is enabled.
6	TEIE	Transmit End Interrupt Enable 0: Transmit end interrupt request (INTRIICnTEI) is disabled. 1: Transmit end interrupt request (INTRIICnTEI) is enabled.
5	RIE	Receive Complete Interrupt Enable 0: Receive complete interrupt request (INTRIICnRI) is disabled. 1: Receive complete interrupt request (INTRIICnRI) is enabled.
4	NAKIE	NACK Reception Interrupt Enable 0: NACK reception interrupt request (NAKI) is disabled. 1: NACK reception interrupt request (NAKI) is enabled.
3	SPIE	Stop Condition Detection Interrupt Enable 0: Stop condition detection interrupt request (SPI) is disabled. 1: Stop condition detection interrupt request (SPI) is enabled.
2	STIE	Start Condition Detection Interrupt Enable 0: Start condition detection interrupt request (STI) is disabled. 1: Start condition detection interrupt request (STI) is enabled.
1	ALIE	Arbitration-Lost Interrupt Enable 0: Arbitration-lost interrupt request (ALI) is disabled. 1: Arbitration-lost interrupt request (ALI) is enabled.
0	TMOIE	Timeout Interrupt Enable 0: Timeout interrupt request (TMOI) is disabled. 1: Timeout interrupt request (TMOI) is enabled.

TMOIE Bit (Timeout Interrupt Enable)

This bit is used to enable or disable timeout interrupt requests (TMOI) when the RIICnSR2.TMOF flag is set to 1. A TMOI interrupt request is canceled by clearing the TMOF flag or the TMOIE bit to 0.

ALIE Bit (Arbitration-Lost Interrupt Enable)

This bit is used to enable or disable arbitration-lost interrupt requests (ALI) when the RIICnSR2.AL flag is set to 1. An ALI interrupt request is canceled by clearing the AL flag or the ALIE bit to 0.

STIE Bit (Start Condition Detection Interrupt Enable)

This bit is used to enable or disable start condition detection interrupt requests (STI) when the RIICnSR2.START flag is set to 1. An STI interrupt request is canceled by clearing the START flag or the STIE bit to 0.

SPIE Bit (Stop Condition Detection Interrupt Enable)

This bit is used to enable or disable stop condition detection interrupt requests (SPI) when the RIICnSR2.STOP flag is set to 1. An SPI interrupt request is canceled by clearing the STOP flag or the SPIE bit to 0.

NAKIE Bit (NACK Reception Interrupt Enable)

This bit is used to enable or disable NACK reception interrupt requests (NAKI) when the RIICnSR2.NACKF flag is set to 1. An NAKI interrupt request is canceled by clearing the NACKF flag or the NAKIE bit to 0.

RIE Bit (Receive Complete Interrupt Enable)

This bit is used to enable or disable receive complete interrupt requests (INTRIICnRI) when the RIICnSR2.RDRF flag is set to 1.

TEIE Bit (Transmit End Interrupt Enable)

This bit is used to enable or disable transmit end interrupts (INTRIICnTEI) when the RIICnSR2.TEND flag is set to 1. An INTRIICnTEI interrupt request is canceled by clearing the TEND flag or the TEIE bit to 0.

TIE Bit (Transmit Data Empty Interrupt Enable)

This bit is used to enable or disable transmit data empty interrupts (INTRIICnTI) when the RIICnSR2.TDRE flag is set to 1.

22.3.10 RIICnSR1 — I2C Bus Status Register 1

Access: RIICnSR1 register can be read or written in 32-bit units.
RIICnSR1L and RIICnSR1H registers can be read or written in 16-bit units.
RIICnSR1LL, RIICnSR1LH, RIICnSR1HL, and RIICnSR1HH registers can be read or written in 8-bit units.

Address: RIICnSR1: <RIICn_base> + 0020_H

RIICnSR1L: <RIICn_base> + 0020_H, RIICnSR1H: <RIICn_base> + 0022_H

RIICnSR1LL: <RIICn_base> + 0020_H, RIICnSR1LH: <RIICn_base> + 0021_H,
RIICnSR1HL: <RIICn_base> + 0022_H, RIICnSR1HH: <RIICn_base> + 0023_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 22.18 RIICnSR1 Register Contents

Bit Position	Bit Name	Function
31 to 6	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
5	DID	Device-ID Address Detection Flag 0: Device-ID address is not detected. 1: Device-ID address is detected.
4	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
3	GCA	General Call Address Detection Flag 0: General call address is not detected. 1: General call address is detected.
2	AAS2	Slave Address 2 Detection Flag 0: Slave address 2 is not detected. 1: Slave address 2 is detected.
1	AAS1	Slave Address 1 Detection Flag 0: Slave address 1 is not detected. 1: Slave address 1 is detected.
0	AAS0	Slave Address 0 Detection Flag 0: Slave address 0 is not detected. 1: Slave address 0 is detected.

AASy Flag (Slave Address y Detection) (y = 0 to 2)

[Setting conditions]

<For 7-bit address format: RIICnSARy.FSy = 0>

When the received slave address matches the RIICnSARy.SVA[7:1] value with the RIICnSER.SARy bit set to 1 (slave address y detection enabled)
This flag is set to 1 at the rising edge of the ninth SCL clock cycle in the frame.

<For 10-bit address format: RIICnSARy.FSy = 1>

When the received slave address matches a value of (1111 0_B + RIICnSARy.SVA[9:8]) and the following address matches the RIICnSARy.SVA[7:0] value with the RIICnSER.SARy bit set to 1 (slave address y detection enabled)
This flag is set to 1 at the rising edge of the ninth SCL clock cycle in the frame.

[Clearing conditions]

- When 0 is written to the AASy bit after reading AASy = 1
- When a stop condition is detected
- When 1 is written to the RIICnCR1.IICRST bit to apply an RIIC reset or an internal reset

<For 7-bit address format: RIICnSARy.FSy = 0>

- When the received slave address does not match the RIICnSARy.SVA[7:1] value with the RIICnSER.SARy bit set to 1 (slave address y detection enabled)
  This flag is cleared to 0 at the rising edge of the ninth SCL clock cycle in the frame.

<For 10-bit address format: RIICnSARy.FSy = 1>

- When the received slave address does not match a value of (1111 0_B + RIICnSARy.SVA[9:8]) with the RIICnSER.SARy bit set to 1 (slave address y detection enabled)
  This flag is cleared to 0 at the rising edge of the ninth SCL clock cycle in the frame.
- When the received slave address matches a value of (1111 0_B + RIICnSARy.SVA[9:8]) and the following address does not match the RIICnSARy.SVA[7:0] value with the RIICnSER.SARy bit set to 1 (slave address y detection enabled)
  This flag is cleared to 0 at the rising edge of the ninth SCL clock cycle in the frame.

GCA Flag (General Call Address Detection)

[Setting condition]

- When the received slave address matches the general call address (0000 000_B + 0 [W]) with the RIICnSER.GCE bit set to 1 (general call address detection enabled)
  This flag is set to 1 at the rising edge of the ninth SCL clock cycle in the frame.

[Clearing conditions]

- When 0 is written to the GCA bit after reading GCA = 1
- When a stop condition is detected
- When the received slave address does not match the general call address (0000 000_B + 0 [W]) with the RIICnSER.GCE bit set to 1 (general call address detection enabled)
  This flag is cleared to 0 at the rising edge of the ninth SCL clock cycle in the frame.
- When 1 is written to the RIICnCR1.IICRST bit to apply an RIIC reset or an internal reset

DID Flag (Device-ID Address Detection)

[Setting condition]

- When the first frame received immediately after a start condition or restart condition is detected matches a value of (device ID ($1111\ 100_B$) + 0 [W]) with the RIICnSER.DIDE bit set to 1 (Device-ID address detection enabled). This flag is set to 1 at the rising edge of the ninth SCL clock cycle in the frame.
- When a restart condition is detected after a match with the device ID address and the device ID address ($1111\ 100_B$) plus 1[R] has matched while the setting of the RIICnSER.DIDE bit is 1 (device ID address detection enabled). This flag is set to 1 at the rising edge of the ninth SCL clock cycle in the frame.

[Clearing conditions]

- When 0 is written to the DID bit after reading DID = 1
- When a stop condition is detected
- When the first frame received immediately after a start condition or restart condition is detected does not match a value of (device ID ($1111\ 100_B$)) with the RIICnSER.DIDE bit set to 1 (Device-ID address detection enabled)
  This flag is cleared to 0 at the rising edge of the ninth SCL clock cycle in the frame.
- When the first frame received immediately after a start condition or restart condition is detected matches a value of (device ID ($1111\ 100_B$) + 0 [W]) and the second frame does not match any of slave addresses 0 to 2 with the RIICnSER.DIDE bit set to 1 (Device-ID address detection enabled)
  This flag is cleared to 0 at the rising edge of the ninth SCL clock cycle in the frame.
- When 1 is written to the RIICnCR1.IICRST bit to apply an RIIC reset or an internal reset

22.3.11 RIICnSR2 — I2C Bus Status Register 2

Access: RIICnSR2 register can be read or written in 32-bit units.
RIICnSR2L and RIICnSR2H registers can be read or written in 16-bit units.
RIICnSR2LL, RIICnSR2LH, RIICnSR2HL, and RIICnSR2HH registers can be read or written in 8-bit units.

Address: RIICnSR2: <RIICn_base> + 0024_H

RIICnSR2L: <RIICn_base> + 0024_H, RIICnSR2H: <RIICn_base> + 0026_H

RIICnSR2LL: <RIICn_base> + 0024_H, RIICnSR2LH: <RIICn_base> + 0025_H,
RIICnSR2HL: <RIICn_base> + 0026_H, RIICnSR2HH: <RIICn_base> + 0027_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Note 1. Only 0 can be written to this bit.

Table 22.19 RIICnSR2 Register Contents

Bit Position	Bit Name	Function
31 to 8	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
7	TDRE	Transmit Data Empty Flag 0: RIICnDRT contains transmit data. 1: RIICnDRT contains no transmit data.
6	TEND	Transmit End Flag 0: Data is being transmitted. 1: Data has been transmitted.
5	RDRF	Receive Complete Flag 0: RIICnDRR contains no receive data. 1: RIICnDRR contains receive data.
4	NACKF	NACK Detection Flag 0: NACK is not detected. 1: NACK is detected.
3	STOP	Stop Condition Detection Flag 0: Stop condition is not detected. 1: Stop condition is detected.
2	START	Start Condition Detection Flag 0: Start condition is not detected. 1: Start condition is detected.
1	AL	Arbitration-Lost Flag 0: Arbitration is not lost. 1: Arbitration is lost.
0	TMOF	Timeout Detection Flag 0: Timeout is not detected. 1: Timeout is detected.

TMOF Flag (Timeout Detection)

This flag is set to 1 when the RIIC recognizes timeout after the SCL line state remains unchanged for a certain period.

[Setting condition]

The timeout function is enabled when the RIICnFER.TMOE bit is 1. It detects an abnormal bus state that the SCL line is stuck low or high during the following conditions:

- The bus is busy (the RIICnCR2.BBSY flag is 1) in master mode (the RIICnCR2.MST bit is 1).
- The RIIC's own slave address matches (the RIICnSR1 register is not 00_H) and the bus is busy (the RIICnCR2.BBSY bit is 1) in slave mode (the RIICnCR2.MST bit is 0).
- The bus is free (the RIICnCR2.BBSY flag is 0) while generation of a start condition is requested (the RIICnCR2.ST bit is 1).

[Clearing conditions]

- When 0 is written to the TMOF bit after reading TMOF = 1
- When 1 is written to the RIICnCR1.IICRST bit to apply an RIIC reset or an internal reset

AL Flag (Arbitration-Lost)

This flag shows that bus mastership has been lost (loss in arbitration) due to a bus conflict or some other reason when a start condition is issued or an address and data are transmitted. The RIIC monitors the level on the SDA line during transmission and, if the level on the line does not match the value of the bit being output, sets the value of the AL bit to 1 to indicate that the bus is occupied by another device.

The RIIC can also set the flag to indicate the detection of loss of arbitration during NACK transmission in receive mode or during data transmission in slave mode.

[Setting conditions]

<When master arbitration-lost detection is enabled: RIICnFER.MALE = 1>

- When the internal SDA output state does not match the SDA line level at the rising edge of SCL clock except for the ACK period during data (including slave address) transmission in master transmit mode (when the SDA line is driven low while the internal SDA output is at a high level (the SDA pin is in the high-impedance state))
- When a start condition is detected while the RIICnCR2.ST bit is 1 (start condition issuance request) or the internal SDA output state does not match the SDA line level
- When the RIICnCR2.ST bit is set to 1 (start condition issuance request) with the RIICnCR2.BBSY flag set to 1.

<When NACK arbitration-lost detection is enabled: RIICnFER.NALE = 1>

When the internal SDA output state does not match the SDA line level at the rising edge of SCL clock in the ACK period during NACK transmission in receive mode

<When slave arbitration-lost detection is enabled: RIICnFER.SALE = 1>

When the internal SDA output state does not match the SDA line level at the rising edge of SCL clock except for the ACK period during data transmission in slave transmit mode

[Clearing conditions]

- When 0 is written to the AL bit after reading AL = 1

- When 1 is written to the RIICnCR1.IICRST bit to apply an RIIC reset or an internal reset

Table 22.20 Relationship between Arbitration-Lost Generation Sources and Arbitration-Lost Enable Functions

RIICnFER			RIICnSR2		
MALE	NALE	SALE	AL	Error	Arbitration-Lost Generation Source
1	—	—	1	Start condition issuance error	When internal SDA output state does not match SDA line level when a start condition is detected while the RIICnCR2.ST bit is 1
					When RIICnCR2.ST is set to 1 with RIICnCR2.BBSY set to 1
			1	Transmit data mismatch	When transmit data (including slave address) does not match the bus state in master transmit mode
—	1	—	1	NACK transmission mismatch	When ACK is detected during transmission of NACK in master receive mode or slave receive mode
—	—	1	1	Transmit data mismatch	When transmit data does not match the bus state in slave transmit mode

—: Don't care

START Flag (Start Condition Detection)

[Setting condition]

When a start condition (or a restart condition) is detected

[Clearing conditions]

- When 0 is written to the START bit after reading START = 1
- When a stop condition is detected
- When 1 is written to the RIICnCR1.IICRST bit to apply an RIIC reset or an internal reset

STOP Flag (Stop Condition Detection)

[Setting condition]

When a stop condition is detected

[Clearing conditions]

- When 0 is written to the STOP bit after reading STOP = 1
- When 1 is written to the RIICnCR1.IICRST bit to apply an RIIC reset or an internal reset

NACKF Flag (NACK Detection)

[Setting condition]

When acknowledge is not received (NACK is received) from the receive device in transmit mode with the RIICnFER.NACKE bit set to 1 (transfer suspension enabled)

[Clearing conditions]

- When 0 is written to the NACKF bit after reading NACKF = 1
- When 1 is written to the RIICnCR1.IICRST bit to apply an RIIC reset or an internal reset

CAUTION

When the NACKF flag is set to 1, the RIIC suspends data transmission/reception. Writing to RIICnDRT in transmit mode or reading from RIICnDRR in receive mode with the NACKF flag set to 1 does not enable data transmit/receive operation. To restart data transmission/reception, clear the NACKF flag to 0.

RDRF Flag (Receive Complete)

[Setting conditions]

- When receive data has been transferred from RIICnDRS to RIICnDRR
  At the rising edge of the eighth or ninth SCL clock cycle (selected by the RIICnMR3.RDRFS bit)
- When the received slave address matches the address enabled in RIICnSER after a start condition (or a restart condition) is detected with the RIICnCR2.TRS bit cleared to 0
- In master mode, transition to master reception while the R/W# bit appended to the slave address is set to 1

[Clearing conditions]

- When 0 is written to the RDRF bit after reading RDRF = 1
- When data is read from RIICnDRR
- When 1 is written to the RIICnCR1.IICRST bit to apply an RIIC reset or an internal reset

TEND Flag (Transmit End)

[Setting condition]

At the rising edge of the ninth SCL clock cycle while the TDRE flag is 1

[Clearing conditions]

- When 0 is written to the TEND bit after reading TEND = 1
- When data is written to RIICnDRT
- When a stop condition is detected
- When 1 is written to the RIICnCR1.IICRST bit to apply an RIIC reset or an internal reset

TDRE Flag (Transmit Data Empty)

[Setting conditions]

- When data has been transferred from RIICnDRT to RIICnDRS and RIICnDRT becomes empty
- When the RIICnCR2.TRS bit is set to 1
  - When the RIICnCR2.MST bit is set to 1 after a start condition is detected
  - When 1 is written to the RIICnCR2.TRS bit while the RIICnMR1.MTWP bit is 1
- When the received slave address matches the address enabled in RIICnSER after a start condition including a restart condition is detected with the RIICnCR2.TRS bit set to 1

[Clearing conditions]

- When data is written to RIICnDRT
- When the RIICnCR2.TRS bit is cleared to 0
  - When a stop condition is detected
  - When the RIIC enters receive mode from transmit mode
  - When 0 is written to the RIICnCR2.TRS bit while the RIICnMR1.MTWP bit is 1
- When 1 is written to the RIICnCR1.IICRST bit to apply an RIIC reset or an internal reset

CAUTION

When the NACKF flag is set to 1 while the RIICnFER.NACKE bit is 1, the RIIC suspends data transmission/reception. Here, if the TDRE flag is 0 (next transmit data has been written), data is not transferred to the RIICnDRS register and the data of RIICnDRT register is retained, and the TDRE flag is not set to 1.

22.3.12 RIICnSARy — I2C Slave Address Register y (y = 0 to 2)

Access: RIICnSARy register can be read or written in 32-bit units.
RIICnSARyL and RIICnSARyH registers can be read or written in 16-bit units.
RIICnSARyLL, RIICnSARyLH, RIICnSARyHL, and RIICnSARyHH registers can be read or written in 8-bit units.

Address: RIICnSAR0: <RIICn_base> + 0028_H

RIICnSAR0L: <RIICn_base> + 0028_H, RIICnSAR0H: <RIICn_base> + $002A_H$

RIICnSAR0LL: <RIICn_base> + 0028_H, RIICnSAR0LH: <RIICn_base> + 0029_H,
RIICnSAR0HL: <RIICn_base> + $002A_H$, RIICnSAR0HH: <RIICn_base> + $002B_H$

RIICnSAR1: <RIICn_base> + $002C_H$

RIICnSAR1L: <RIICn_base> + $002C_H$, RIICnSAR1H: <RIICn_base> + $002E_H$

RIICnSAR1LL: <RIICn_base> + $002C_H$, RIICnSAR1LH: <RIICn_base> + $002D_H$,
RIICnSAR1HL: <RIICn_base> + $002E_H$, RIICnSAR1HH: <RIICn_base> + $002F_H$

RIICnSAR2: <RIICn_base> + 0030_H

RIICnSAR2L: <RIICn_base> + 0030_H, RIICnSAR2H: <RIICn_base> + 0032_H

RIICnSAR2LL: <RIICn_base> + 0030_H, RIICnSAR2LH: <RIICn_base> + 0031_H,
RIICnSAR2HL: <RIICn_base> + 0032_H, RIICnSAR2HH: <RIICn_base> + 0033_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

R/W	R/W	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 22.21 RIICnSARy Register Contents

Bit Position	Bit Name	Function
31 to 16	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
15	FSy	7-Bit/10-Bit Address Format Selection 0: The 7-bit address format is selected. 1: The 10-bit address format is selected.
14 to 10	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
9 to 1	SVA[9:1]	7-Bit Address/10-Bit Address Upper Bits A slave address is set. • When the FSy bit is 0 (7-bit address format), the SVA[7:1] bits are valid and form a 7-bit slave address. • When the FSy bit is 1 (10-bit address format), SVA[9:1] bits form a 10-bit slave address (combined with the SVA0 bit).
0	SVA0	10-Bit Address LSB The least significant bit (LSB) of a 10-bit slave address is set. • When the FSy bit is 0 (7-bit address format), this bit is invalid. • When the FSy bit is 1 (10-bit address format), this bit is a 10-bit slave address (combined with the SVA[9:1] bits).

SVA0 Bit (10-Bit Address LSB)

When the 10-bit address format is selected (RIICnSARy.FSy = 1), this bit functions as the LSB of a 10-bit address and forms a 10-bit address in combination with the SVA[9:1] bits.

When the RIICnSER.SARy bit is set to 1 (RIICnSARy enabled) and the RIICnSARy.FSy bit is 1, this bit is valid. While the RIICnSARy.FSy bit or SARy bit is 0, the setting of this bit is ignored.

SVA[9:1] Bits (7-Bit Address/10-Bit Address Upper Bits)

When the 7-bit address format is selected (RIICnSARy.FSy = 0), these bits function as a 7-bit address. When the 10-bit address format is selected (RIICnSARy.FSy = 1), these bits function as a 10-bit address in combination with the SVA0 bit.

While the RIICnSER.SARy bit is 0, the setting of these bits is ignored.

FSy Bit (7-Bit/10-Bit Address Format Selection)

This bit is used to select 7-bit address or 10-bit address for slave address y (in RIICnSARy).

When the RIICnSER.SARy bit is set to 1 (RIICnSARy enabled) and the RIICnSARy.FSy bit is 0, the 7-bit address format is selected for slave address y, the RIICnSARy.SVA[7:1] setting is valid, and the settings of the SVA[9:8] bits and the RIICnSARy.SVA0 bit are ignored.

When the RIICnSER.SARy bit is set to 1 (RIICnSARy enabled) and the RIICnSARy.FSy bit is 1, the 10-bit address format is selected for slave address y and the settings of the SVA[9:1] bits and the SVA0 bit are valid.

While the RIICnSER.SARy bit is 0 (RIICnSARy disabled), the setting of the RIICnSARy.FSy bit is invalid.

22.3.13 RIICnBRL — I2C Bus Bit Rate Low-Level Register

Access: RIICnBRL register can be read or written in 32-bit units.
RIICnBRLL and RIICnBRLH registers can be read or written in 16-bit units.
RIICnBRLLL, RIICnBRLLH, RIICnBRLHL, and RIICnBRLHH registers can be read or written in 8-bit units.

Address: RIICnBRL: <RIICn_base> + 0034_H

RIICnBRLL: <RIICn_base> + 0034_H, RIICnBRLH: <RIICn_base> + 0036_H

RIICnBRLLL: <RIICn_base> + 0034_H, RIICnBRLLH: <RIICn_base> + 0035_H,
RIICnBRLHL: <RIICn_base> + 0036_H, RIICnBRLHH: <RIICn_base> + 0037_H

Value after reset: 0000 $00FF_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R/W	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W

Table 22.22 RIICnBRL Register Contents

Bit Position	Bit Name	Function
31 to 5	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
4 to 0	BRL[4:0]	Bit Rate Low-Level Period Low-level period of SCL clock

The RIICnBRL register is a 5-bit register that is used to set the width at low level for the SCL clock.

It also works to generate the data setup time for automatic SCL low-hold operation (see **Section 22.4.7, Automatic Low-Hold Function for SCL**); when the RIIC is used only in slave mode, this register needs to be set to a value longer than the data setup time*1.

RIICnBRL counts the low-level period with the internal reference clock source (IICϕ) specified by the RIICnMR1.CKS[2:0] bits.

Note 1. Data setup time (tSU: DAT)
250 ns (up to 100 kbps: standard mode [Sm])
100 ns (up to 400 kbps: fast mode [Fm])

22.3.14 RIICnBRH — I2C Bus Bit Rate High-Level Register

Access: RIICnBRH register can be read or written in 32-bit units.
RIICnBRHL and RIICnBRHH registers can be read or written in 16-bit units.
RIICnBRHLL, RIICnBRHLH, RIICnBRHHL, and RIICnBRHHH registers can be read or written in 8-bit units.

Address: RIICnBRH: <RIICn_base> + 0038_H

RIICnBRHL: <RIICn_base> + 0038_H, RIICnBRHH: <RIICn_base> + $003A_H$

RIICnBRHLL: <RIICn_base> + 0038_H, RIICnBRHLH: <RIICn_base> + 0039_H,
RIICnBRHHL: <RIICn_base> + $003A_H$, RIICnBRHHH:<RIICn_base> + $003B_H$

Value after reset: 0000 $00FF_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

	—	—	—	—	—	—	—	—	—	—	—	BRH[4:0]				
Value after reset	0	0	0	0	0	0	0	0	1	1	1	1	1	1	1	1
R/W	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W

Table 22.23 RIICnBRH Register Contents

Bit Position	Bit Name	Function
31 to 5	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
4 to 0	BRH[4:0]	Bit Rate High-Level Period High-level period of SCL clock

RIICnBRH is a 5-bit register to set the high-level period of SCL clock. RIICnBRH is valid in master mode. If the RIIC is used only in slave mode, this register need not to set the high-level period.

RIICnBRH counts the high-level period with the internal reference clock source (IICϕ) specified by the RIICnMR1.CKS[2:0] bits.

The I2C transfer rate and the SCL clock duty are calculated using the following expression.

(1) When RIICnFER.SCLE = 0
Transfer rate = 1 / {[(RIICnBRH+1) + (RIICnBRL+1)] / IICφ*1 + tr + tf}
Duty cycle = {tr+[(RIICnBRH+1)/ IICφ]}/{ tr + tf + [(RIICnBRH+1) + (RIICnBRL+1)]/IICφ}

(2) When RIICnFER.SCLE=1, RIICnFER.NFE=0, IICφ = PCLK
Transfer rate = 1 / {[(RIICnBRH+3) + (RIICnBRL+3)] / IICφ*1 + tr + tf}
Duty cycle = {tr +[(RIICnBRH+3)/ IICφ]}/{ tr + tf + [(RIICnBRH+3) + (RIICnBRL+3)]/IICφ}

(3) When RIICnFER.SCLE=1, RIICnFER.NFE=1, IICφ = PCLK
Transfer rate =1 / {[(RIICnBRH+3+nf) + (RIICnBRL+3+nf)] / IICφ*1 + tr + tf}
Duty cycle = {tr +[(RIICnBRH+3+nf)/ IICφ]}/{ tr + tf + [(RIICnBRH+3+nf) + (RIICnBRL+3+nf)]/ IICφ}

(4) RIICnFER.SCLE=1, RIICnFER.NFE=0, IICφ < PCLK
Transfer rate =1 / {[(RIICnBRH+2) + (RIICnBRL+2)] / IICφ*1+ tr + tf}
Duty cycle = {tr +[(RIICnBRH+2)/ IICφ]}/{ tr + tf + [(RIICnBRH+2) + (RIICnBRL+2)]/IICφ}

(5) When RIICnFER.SCLE=1, RIICnFER.NFE=1, IICφ < PCLK
Transfer rate =1 / {[(RIICnBRH+2+nf) + (RIICnBRL+2+nf)] / IICφ*1+ tr + tf}
Duty cycle = {tr +[(RIICnBRH+2+nf)/ IICφ]}/{ tr + tf + [(RIICnBRH+2+nf) + (RIICnBRL+2+nf)]/ IICφ}

tf: SCL line falling time [ns]*2
tr: SCL line rising time [ns]*2
nf: Digital noise filter stage
Duty cycle: 0% < Duty < 100%

Note 1. As for IICφ, see CKS[2:0] in **Section 22.3.4, RIICnMR1 — I2C Bus Mode Register 1**.

Note 2. The SCL line rising time [tr] and SCL line falling time [tf] depend on the total bus line capacitance [Cb] and the pull-up resistor [Rp]. For details, see the I2C bus standard from NXP Semiconductors.

Table 22.24 lists examples of the RIICnBRH and RIICnBRL register settings when the SCL synchronization circuit is not used.

Table 22.24 Examples of RIICnBRH/RIICnBRL Settings for Transfer Rate

Transfer Rate (kbps)	PCLK Frequency (MHz)														
	8					10					12.5

CAUTION

CBRH/ICBRL settings in these tables are calculated using the following values:
SCL line rising time (tr): 100 kbps or less, [Sm]: 1000 ns, 400 kbps or less, [Fm]: 300 ns
SCL line falling time (tf): 400 kbps or less, [Sm/Fm]: 300 ns
For the specified values of SCL line rising time (tr) and SCL line falling time (tf), see the I2C bus standard from NXP Semiconductors.

22.3.15 RIICnDRT — I2C Bus Transmit Data Register

Access: RIICnDRT register can be read or written in 32-bit units.
RIICnDRTL and RIICnDRTH registers can be read or written in 16-bit units.
RIICnDRTLL, RIICnDRTLH, RIICnDRTHL, and RIICnDRTHH registers can be read or written in 8-bit units.

Address: RIICnDRT: <RIICn_base> + $003C_H$

RIICnDRTL: <RIICn_base> + $003C_H$, RIICnDRTH: <RIICn_base> + $003E_H$

RIICnDRTLL: <RIICn_base> + $003C_H$, RIICnDRTLH: <RIICn_base> + $003D_H$,
RIICnDRTHL: <RIICn_base> + $003E_H$, RIICnDRTHH: <RIICn_base> + $003F_H$

Value after reset: $0000\ 00FF_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	DRT[7:0]							
Value after reset	0	0	0	0	0	0	0	0	1	1	1	1	1	1	1	1
R/W	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

When RIICnDRT detects a space in the I2C bus shift register (RIICnDRS), it transfers the transmit data that has been written to RIICnDRT to RIICnDRS and starts transmitting data in transmit mode.

The double-buffer structure of RIICnDRT and RIICnDRS allows continuous transmit operation if the next transmit data has been written to RIICnDRT while the RIICnDRS data is being transmitted.

RIICnDRT can always be read and written. Write transmit data to RIICnDRT once when a transmit data empty interrupt (INTRIICnTI) request is generated. When writing to bit 31 to 8, write the value after reset.

22.3.16 RIICnDRR — I2C Bus Receive Data Register

Access: RIICnDRR register is a read-only register that can be read in 32-bit units.
RIICnDRRL and RIICnDRRH registers are the read-only registers that can be read in 16-bit units.
RIICnDRRLL, RIICnDRRLH, RIICnDRRHL, and RIICnDRRHH registers are the read-only registers that can be read in 8-bit units.

Address: RIICnDRR: <RIICn_base> + 0040_H

RIICnDRRL: <RIICn_base> + 0040_H, RIICnDRRH: <RIICn_base> + 0042_H

RIICnDRRLL: <RIICn_base> + 0040_H, RIICnDRRLH: <RIICn_base> + 0041_H,
RIICnDRRHL: <RIICn_base> + 0042_H, RIICnDRRHH: <RIICn_base> + 0043_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	DRR[7:0]							
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

When 1 byte of data has been received, the received data is transferred from the I2C bus shift register (RIICnDRS) to RIICnDRR to enable the next data to be received.

The double-buffer structure of RIICnDRS and RIICnDRR allows continuous receive operation if the received data has been read from RIICnDRR while RIICnDRS is receiving data.

RIICnDRR cannot be written. Read data from RIICnDRR once when a receive complete interrupt (INTRIICnRI) request is generated.

If RIIC receives the next receive data before the current data is read from RIICnDRR (while the RIICnSR2.RDRF flag is 1), the RIIC automatically holds the SCL clock low one cycle before the RDRF flag is set to 1 next.

22.3.17 RIICnDRS — I2C Bus Shift Register

Access: This register is not accessible.

Address: —

Value after reset: 0000 00FF$_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	DRS[7:0]							
Value after reset	0	0	0	0	0	0	0	0	1	1	1	1	1	1	1	1
R/W	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

RIICnDRS is a shift register to transmit and receive data.

During transmission, transmit data is transferred from RIICnDRT to RIICnDRS and is sent from the SDA pin. During reception, data is transferred from RIICnDRS to RIICnDRR after 1 byte of data has been received.

RIICnDRS cannot be accessed directly.

22.4 Operation

22.4.1 Interrupt Sources

The RIIC issues four types of interrupt request: transfer error or event generation (arbitration-lost detection, NACK detection, timeout detection, start condition detection, and stop condition detection), receive end, transmit data empty, and transmit end.

Table 22.25 lists details of the several interrupt requests. The receive complete and transmit data empty interrupt request are both capable of launching data transfer by the DMAC.

Table 22.25 Interrupt Sources

Symbol	Interrupt Source	Interrupt Flag	DMACA Launching	Interrupt Condition
INTRIICnTI	Transmit Data Empty	TDRE	Possible	TDRE = 1 and TIE = 1
INTRIICnTEI	Transmit End	TEND	Not possible	TEND = 1 and TEIE = 1
INTRIICnRI	Receive End	RDRF	Possible	RDRF = 1 and RIE = 1
INTRIICnEE	Transfer Error/ Event Generation	AL	Not possible	AL = 1 and ALIE = 1
		NACKF		NACKF = 1 and NAKIE = 1
		TMOF		TMOF = 1 and TMOIE = 1
		START		START = 1 and STIE = 1
		STOP		STOP = 1 and SPIE = 1

Clear or mask the each flag during interrupt handling.

CAUTIONS

1. **There is a latency (delay) between the execution of a write instruction for a peripheral module by the CPU and actual writing to the module. Thus, when an interrupt flag has been cleared or masked, read the relevant flag again to check whether clearing or masking has been completed, and then return from interrupt processing. Returning from interrupt processing without checking that writing to the module has been completed creates a possibility of repeated processing of the same interrupt.**
2. **Since INTRIICnTI is an edge-detected interrupt, it does not require clearing. Furthermore, the RIICnSR2.TDRE flag (a condition for INTRIICnTI) is automatically cleared to 0 when data for transmission are written to RIICnDRT or a stop condition is detected (RIICnSR2.STOP flag = 1).**
3. **Since INTRIICnRI is an edge-detected interrupt, it does not require clearing. Furthermore, the RIICnSR2.RDRF flag (a condition for INTRIICnRI) is automatically cleared to 0 when data are read from RIICnDRR.**
4. **When using the INTRIICnTEI interrupt, clear the RIICnSR2.TEND flag in the INTRIICnTEI interrupt processing.**
   Note that the RIICnSR2.TEND flag is automatically cleared to 0 when data for transmission are written to RIICnDRT or a stop condition is detected (RIICnSR2.STOP flag = 1).
5. **Even when using the INTRIICnEE interrupt, clear the RIICnSR2.NACKF flag after detecting the stop condition (RIICnSR2.STOP flag = 1) as shown in Figure 22.6, Example of Master Transmission Flowchart, Figure 22.10, Example of Master**

Reception Flowchart (7-Bit Address Format, 1 or 2 Bytes), Figure 22.11, Example of Master Reception Flowchart (7-Bit Address Format, 3 Bytes or More), and Figure 22.15, Example of Slave Transmission Flowchart. If the RIICnSR2.NACKF flag is cleared before detecting the STOP condition, the automatic low-hold function for SCL (Section 22.4.7.1, Function to Prevent Wrong Transmission of Transmit Data) may be enabled.

22.4.2 I2C Operation

22.4.2.1 Communication Data Format

The I2C bus format consists of 8-bit data and 1-bit acknowledge. The frame following a start condition or restart condition is an address frame used to specify a slave device with which the master device communicates. The specified slave is valid until a new slave is specified or a stop condition is issued.

Figure 22.3 shows the I2C bus format, and **Figure 22.4** shows the I2C bus timing.

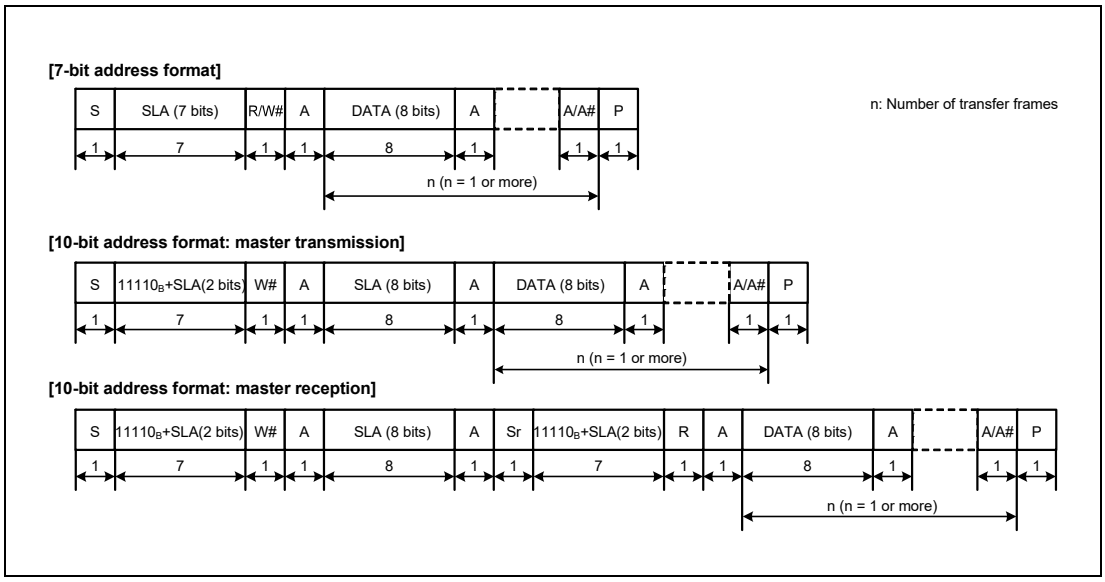

Figure 22.3 I2C Bus Format

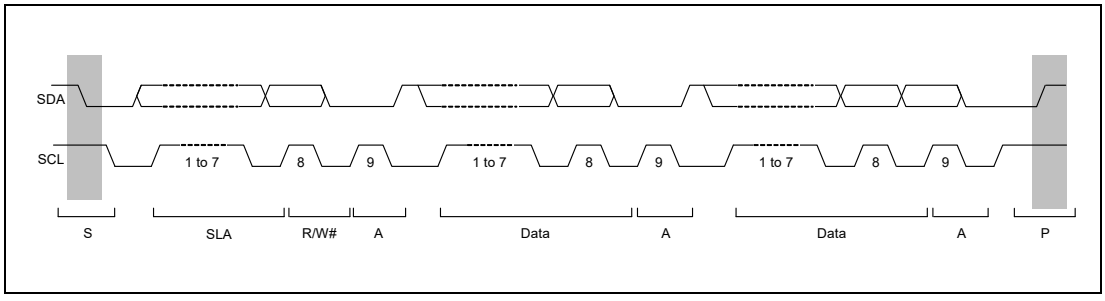

Figure 22.4 I2C Bus Timing (SLA = 7 Bits)

S: Start condition. The master device drives the SDA line low from high level while the SCL line is at a high level.

SLA: Slave address, by which the master device selects a slave device.

R/W#: Indicates the direction of data transfer: from the slave device to the master device when R/W is 1, or from the master device to the slave device when R/W is 0.

A: Acknowledge. The receive device drives the SDA line low. (In master transmit mode, the slave device returns acknowledge. In master receive mode, the master device returns acknowledge.)

A#: Not-acknowledge. The receiving device has not returned a response or is not present so the SDA line has remained at the high level.

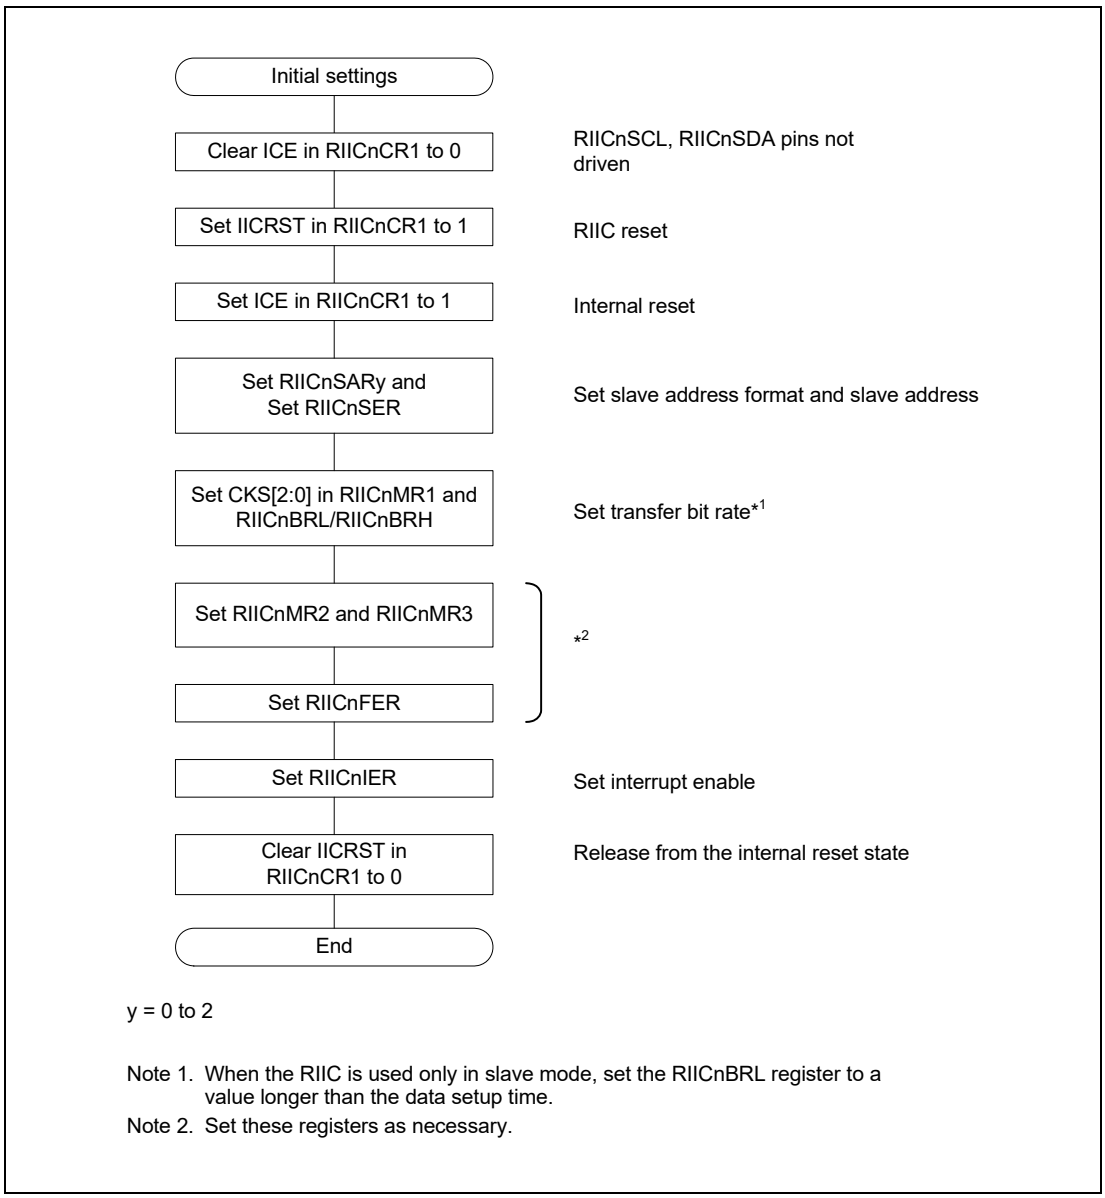
Sr: Restart condition. The master device drives the SDA line low from the high level after the setup time has elapsed with the SCL line at the high level.

DATA: Transmitted or received data

P: Stop condition. The master device drives the SDA line high from low level while the SCL line is at a high level.

22.4.2.2 Initial Settings

Before starting data transmission and reception, initialize the RIIC according to the procedure in **Figure 22.5**. Make initial settings for the RIIC once when starting the RIIC.



Note 1. When the RIIC is used only in slave mode, set the RIICnBRL register to a value longer than the data setup time.

Note 2. Set these registers as necessary.

Figure 22.5 Example of RIIC Initialization Flowchart

22.4.2.3 Master Transmit Operation

In master transmit operation, the RIIC outputs the SCL (clock) and transmitted data signals as the master device, and the slave device returns acknowledgements. **Figure 22.6** shows an example of usage of master transmission and **Figure 22.7** to **Figure 22.9** show the timing of operations in master transmission.

The following describes the procedure and operations for master transmission.

(1) Set the RIICnCR1.IICRST bit 1 to 1 (RIIC reset) and then set the RIICnCR1.ICE bit to 1 (internal reset) with the RIICnCR1.ICE bit cleared to 0 (RIICnSCL and RIICnSDA pins not driven). This initializes the internal state and the various flags of RIICnSR1. After that, set registers RIICnSARy, RIICnSER, RIICnMR1, RIICnBRH, and RIICnBRL (y = 0 to 2), and set the other registers as necessary (for initial settings of the RIIC, see **Figure 22.5**). When the necessary register settings have been completed, set the RIICnCR1.IICRST bit to 0 (for release from the reset state). This step is not necessary if initialization of the RIIC has already been completed.

(2) Read the RIICnCR2.BBSY flag to check that the bus is open, and then set the RIICnCR2.ST bit to 1 (start condition issuance request). Upon receiving the request, the RIIC issues a start condition. At the same time, the BBSY flag and the RIICnSR2.START flag are automatically set to 1 and the ST bit is automatically cleared to 0. At this time, if the start condition is detected and the internal levels for the SDA output state and the levels on the SDA line have matched while the ST bit is 1, the RIIC recognizes that issuing of the start condition as requested by the ST bit has been successfully completed, and the RIICnCR2.MST and TRS bits are automatically set to 1, placing the RIIC in master transmit mode. The RIICnSR2.TDRE flag is also automatically set to 1 in response to setting of the TRS and MST bits to 1.

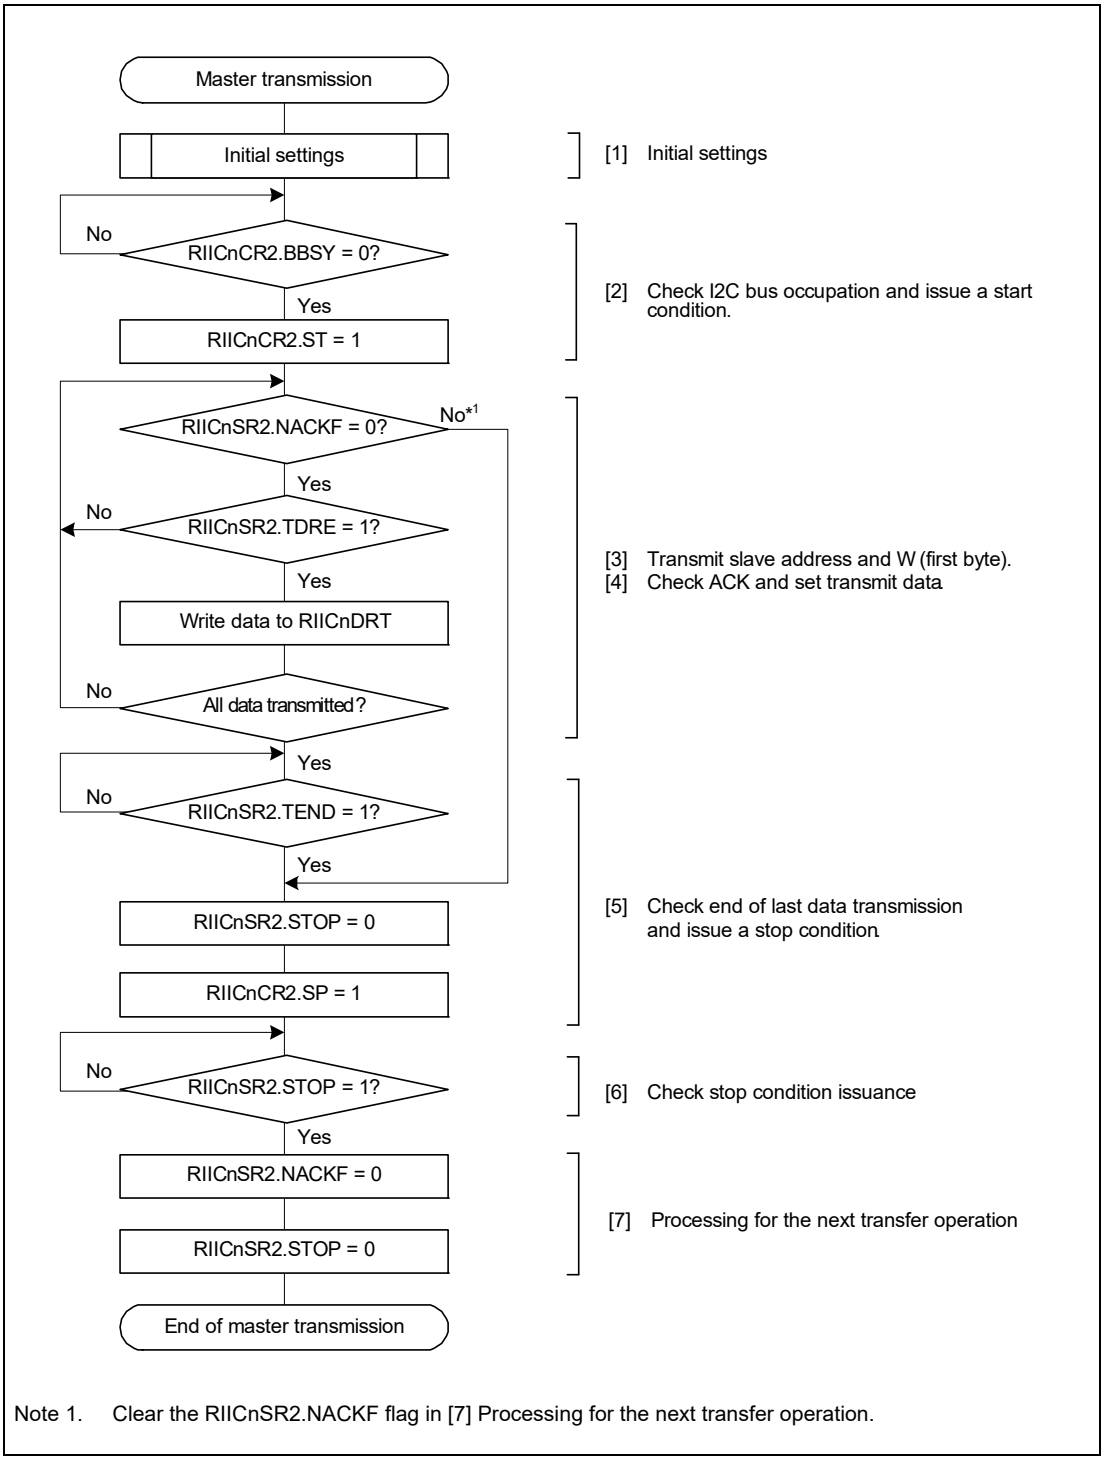
(3) Check that the RIICnSR2.TDRE flag is 1, and then write the value for transmission (the slave address and the R/W# bit) to RIICnDRT. Once the data for transmission are written to RIICnDRT, the TDRE flag is automatically cleared to 0, the data are transferred from RIICnDRT to RIICnDRS, and the TDRE flag is again set to 1. After the slave address including the R/W# bit has been transmitted, the value of the TRS bit is automatically updated to select master transmit or master receive mode in accord with the value of the transmitted R/W# bit. If the value of the R/W# bit was 0, the RIIC continues in master transmit mode.
Since the RIICnSR2.NACKF flag being 1 at this time indicates that the slave address has not been recognized or there was an error in communications, write 1 to the RIICnCR2.SP bit to issue a stop condition.
For data transmission with an address in the 10-bit format, start by writing 1111 0_B, the two higher-order bits of the slave address, and W# to RIICnDRT as the first address transmission. Then, as the second address transmission, write the eight lower-order bits of the slave address to RIICnDRT.

(4) After confirming that the RIICnSR2.TDRE flag is 1, write the data for transmission to the RIICnDRT register. The RIIC automatically holds the SCL line low until the data for transmission are ready or a stop condition is issued.

(5) After all bytes of data for transmission have been written to the RIICnDRT register, wait until the value of the RIICnSR2.TEND flag returns to 1, and then set the RIICnCR2.SP bit to 1 (stop condition issuance request). Upon receiving a stop condition issuance request, the RIIC issues the stop condition.

(6) Upon detecting the stop condition, the RIIC automatically clears the RIICnCR2.MST and TRS bits to 00_B and enters slave receive mode. Furthermore, it automatically clears the RIICnSR2.TDRE and TEND flags to 0, and sets the RIICnSR2.STOP flag in to 1.

(7) After checking that the RIICnSR2.STOP flag is 1, clear the RIICnSR2.NACKF and STOP flags to 0 for the next transfer operation.



Note 1. Clear the RIICnSR2.NACKF flag in [7] Processing for the next transfer operation.

Figure 22.6 Example of Master Transmission Flowchart

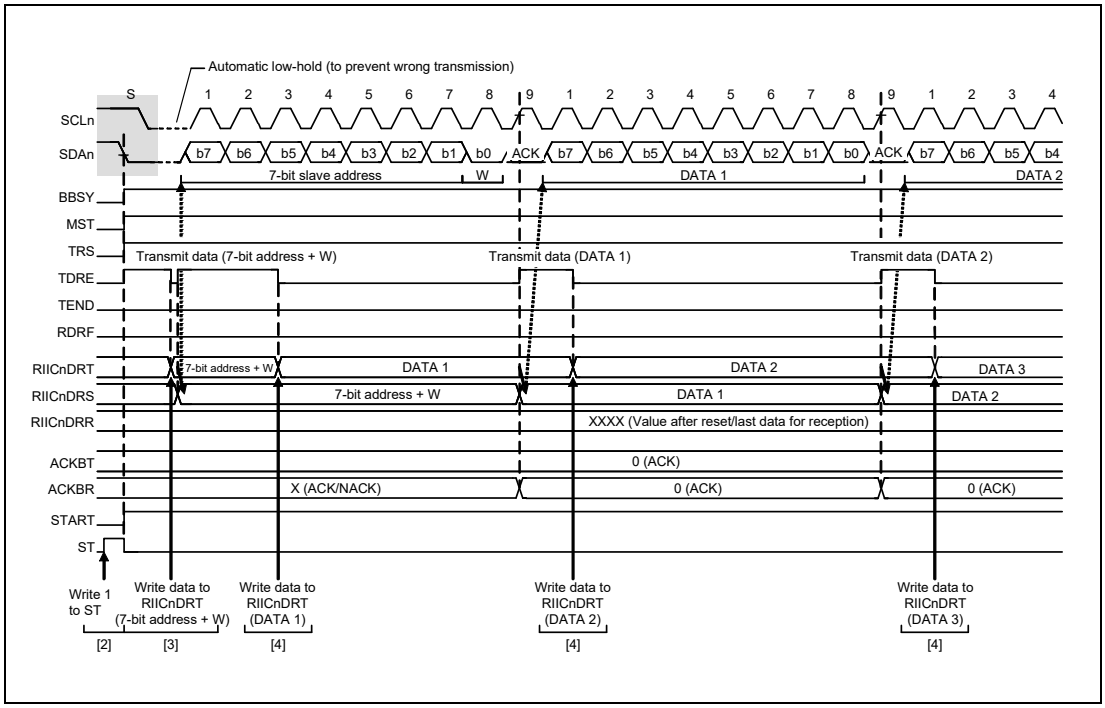


Figure 22.7 Master Transmit Operation Timing (1) (7-Bit Address Format)

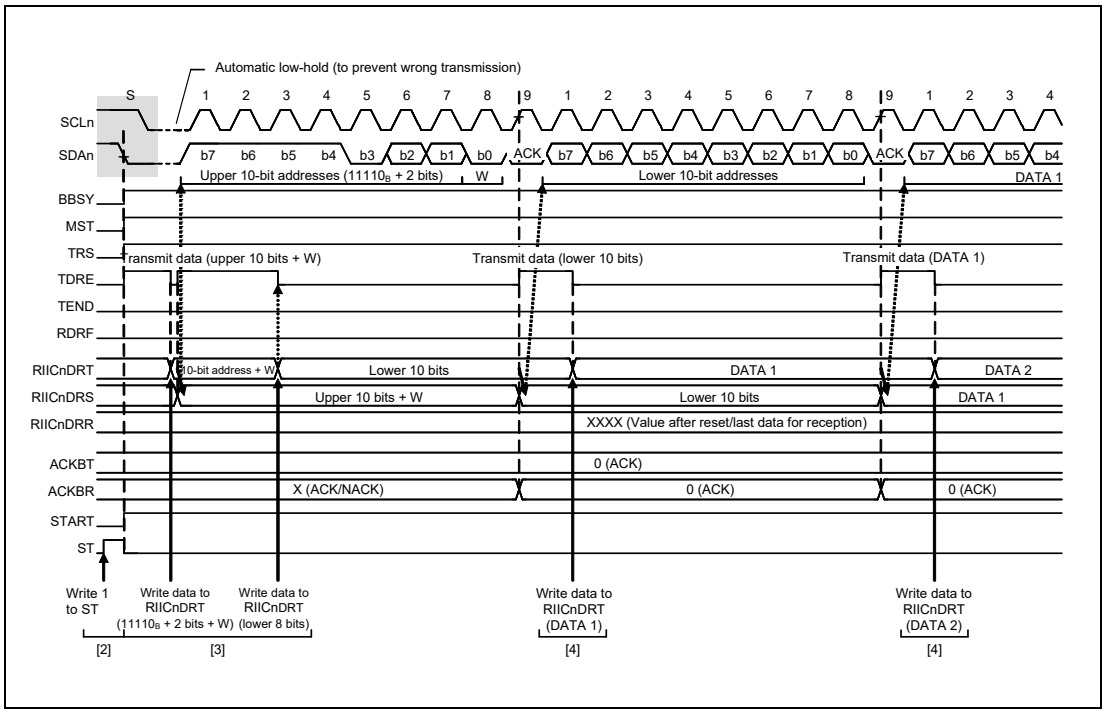

Figure 22.8 Master Transmit Operation Timing (2) (10-Bit Address Format)

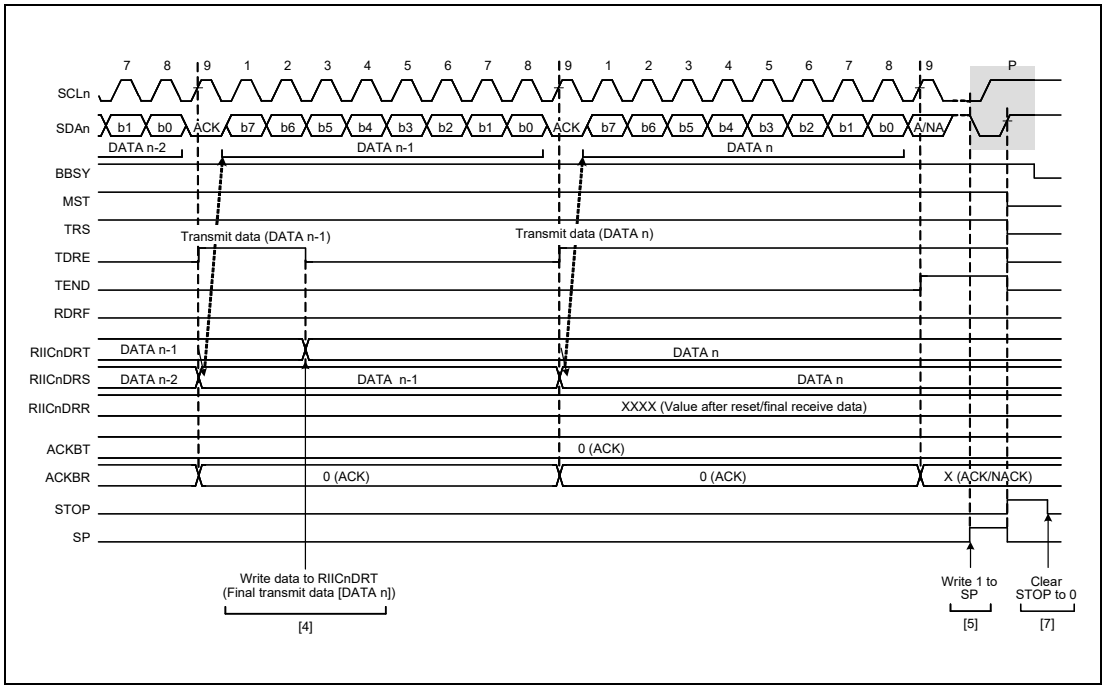

Figure 22.9 Master Transmit Operation Timing (3)

22.4.2.4 Master Receive Operation

In master receive operation, the RIIC as a master device outputs the SCL (clock) signal, receives data from the slave device, and returns acknowledgements. Since the RIIC must start by sending a slave address to the corresponding slave device, this part of the procedure is performed in master transmit mode, but the subsequent steps are in master receive mode.

Figure 22.10 shows an example of master reception flowchart (7-bit address format, 1 or 2 bytes), **Figure 22.11** shows an example of master reception flowchart (7-bit address format, 3 bytes or more), and **Figure 22.12** to **Figure 22.14** show the timing of operations in master reception.

The following describes the procedure and operations for master reception.

(1) Set the RIICnCR1.IICRST bit to 1 (RIIC reset) and then set the RIICnCR1.ICE bit to 1 (internal reset) with the RIICnCR1.ICE bit cleared to 0 (RIICnSCL and RIICnSDA pins not driven). This initializes the internal state and the various flags of RIICnSR1. After that, set registers RIICnSARy, RIICnSER, RIICnMR1, RIICnBRH, and RIICnBRL (y = 0 to 2), and set the other registers as necessary (for initial settings of the RIIC, see **Figure 22.5**). When the necessary register settings have been completed, set the RIICnCR1.IICRST bit to 0 (for release from the reset state). This step is not necessary if initialization of the RIIC has already been completed.

(2) Read the RIICnCR2.BBSY flag to check that the bus is open, and then set the RIICnCR2.ST bit to 1 (start condition issuance request). Upon receiving the request, the RIIC issues a start condition. When the RIIC detects the start condition, the BBSY flag and the RIICnSR2.START flag are automatically set to 1 and the ST bit is automatically cleared to 0. At this time, if the start condition is detected and the levels for the SDA output and the levels on the SDA line have matched while the ST bit is 1, the RIIC recognizes that issuing of the start condition as requested by the ST bit has been successfully completed, and the RIICnCR2.MST and TRS bits are automatically set to 1, placing the RIIC in master transmit mode. The RIICnSR2.TDRE flag is also automatically set to 1 in response to setting of the TRS bit to 1.

(3) Check that the RIICnSR2.TDRE flag is 1, and then write the value for transmission (the slave address and value of the R/W# bit) to RIICnDRT. Once the data for transmission are written to RIICnDRT, the TDRE flag is automatically cleared to 0, the data are transferred from RIICnDRT to RIICnDRS, and the TDRE flag is again set to 1. After the slave address including the R/W# bit has been transmitted, the value of the RIICnCR2.TRS bit is automatically updated to select transmit or receive mode in accord with the value of the transmitted R/W# bit. If the value of the R/W# bit was 1, the RIICnCR2.TRS bit is cleared to 0 on the rising edge of the ninth cycle of SCL (the clock signal), placing the RIIC in master receive mode. At this time, the TDRE flag is automatically cleared to 0 and the RIICnSR2.RDRF flag is automatically set to 1.
Since the RIICnSR2.NACKF flag being 1 at this time indicates that the slave address has not been recognized or there was an error in communications, write 1 to the RIICnCR2.SP bit to issue a stop condition.
For master reception from a device with a 10-bit address, start by using master transmission to transmit the two higher-order bits of the slave address and then the eight lower-order bits of the slave address, and issue a restart condition following generation of the transmission end interrupt (or after TEND = 1) (For details about the operation timing, see **Figure 22.13**). After that, transmitting 1111 0_B plus the two higher-order bits of the slave address, and the R bit places the RIIC in master receive mode.

(4) Dummy read RIICnDRR after confirming that the RIICnSR2.RDRF flag is 1; this makes the RIIC start output of the SCL (clock) signal and start data reception.

(5) After 1 byte of data has been received, the RIICnSR2.RDRF flag is set to 1 on the rising edge of the eighth or ninth cycle of SCL clock (the clock signal) as selected by the RIICnMR3.RDRFS bit. Reading out RIICnDRR at this time will produce the received data, and the RDRF flag is automatically cleared to 0 at the same time. Furthermore, the value of the acknowledgement field received during the ninth cycle of SCL clock is returned as the value set in the RIICnMR3.ACKBT bit. Furthermore, if the next byte to be received is the next to last byte, set the RIICnMR3.WAIT bit to 1 (for wait insertion) before reading the RIICnDRR (containing the second byte from last). As well as enabling NACK output even in the case of delays in processing to set the RIICnMR3.ACKBT bit to 1 (NACK) in step (6), due to other interrupts, etc., this fixes the SCL line to the low level on the rising edge of the ninth clock cycle in reception of the last byte, so the state is such that issuing a stop condition is possible.

(6) When the RIICnMR3.RDRFS bit is 0 and the slave device must be notified that it is to end transfer for data reception after transfer of the next (final) byte, set the RIICnMR3.ACKBT bit to 1 (NACK).

(7) After reading out the byte before last from the RIICnDRR register, if the value of the RIICnSR2.RDRF flag is confirmed to be 1, write 1 to the RIICnCR2.SP bit (stop condition issuance request) and then read the last byte from RIICnDRR. When RIICnDRR is read, the RIIC is released from the wait state and issues the stop condition after low-level output in the ninth clock cycle is completed or the SCL line is released from the low-hold state.

(8) Upon detecting the stop condition, the RIIC automatically clears the RIICnCR2.MST and TRS bits to 00_B and enters slave receive mode. Furthermore, detection of the stop condition leads to setting of the RIICnSR2.STOP flag to 1.

(9) After checking that the RIICnSR2.STOP flag is 1, clear the RIICnSR2.NACKF and STOP flags to 0 for the next transfer operation.

22.4.2.5 Slave Transmit Operation

In slave transmit operation, the master device outputs the SCL (clock) signal, the RIIC transmits data as a slave device, and the master device returns acknowledgements.

Figure 22.5 shows an example of usage of slave transmission and **Figure 22.16** and **Figure 22.17** show the timing of operations in slave transmission.

The following describes the procedure and operations for slave transmission.

(1) Follow the procedure in **Figure 22.5** to make initial settings for the RIIC. This step is not necessary if initialization of the RIIC has already been completed. After initial settings, the RIIC automatically sets the BBSY and RIICnSR2.START flags to 1 and automatically clears the ST bit to 0 on detection of a start condition.

(2) After receiving a matching slave address, the RIIC sets one of the corresponding bits RIICnSR1.GCA, and AASy (y = 0 to 2) to 1 on the rising edge of the ninth cycle of SCL clock (the clock signal) and returns the value set in the RIICnMR3.ACKBT bit to the acknowledge bit on the ninth cycle of SCL clock. If the value of the R/W# bit that was also received at this time is 1, the RIIC automatically places itself in slave transmit mode by setting both the RIICnCR2.TRS bit and the RIICnSR2.TDRE flag to 1.

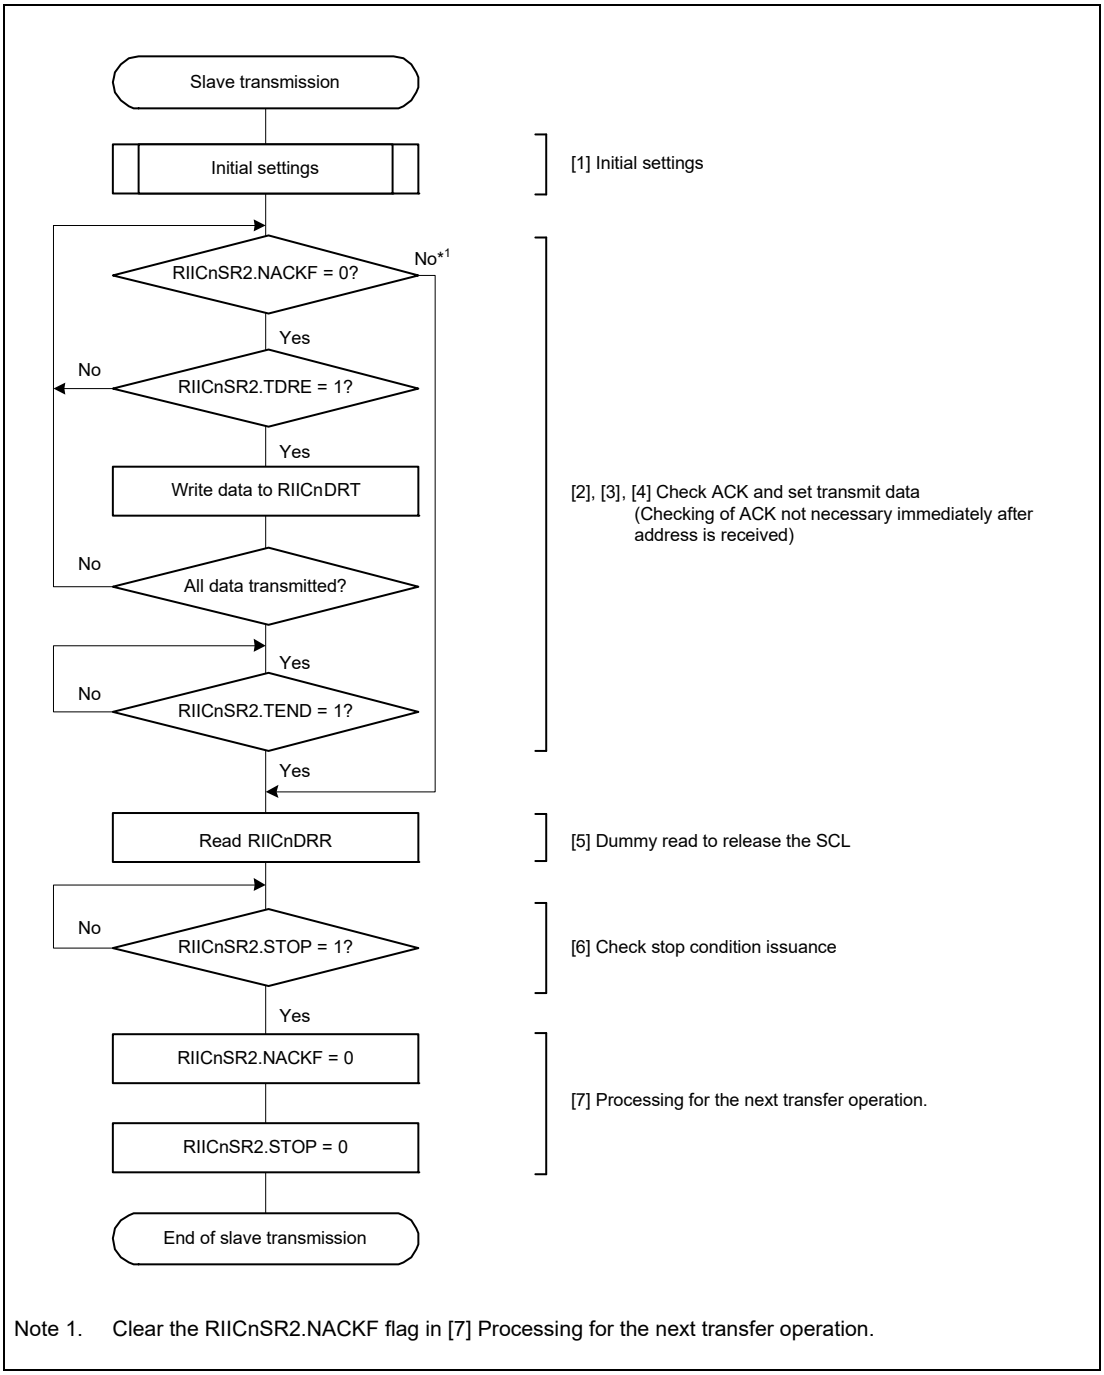
(3) After the RIICnSR2.TDRE flag is confirmed to be 1, write the data for transmission to the RIICnDRT register. At this time, if the RIIC receives no acknowledge from the master device (receives an NACK signal) while the RIICnFER.NACKE bit is 1, the RIIC suspends transfer of the next data.

(4) Wait until the RIICnSR2.TEND flag is set to 1 while the RIICnSR2.TDRE flag is 1, after the RIICnSR2.NACKF flag is set to 1 or the last byte for transmission is written to the RIICnDRT register. When the RIICnSR2.NACKF flag or the TEND flag is 1, the RIIC drives the SCL line low on the ninth falling edge of SCL clock.

(5) When the RIICnSR2.NACKF flag or the RIICnSR2.TEND flag is 1, dummy read RIICnDRR to complete the processing. This releases the SCL line.

(6) Upon detecting the stop condition, the RIIC automatically clears bits RIICnSR1.GCA, and AASy (y = 0 to 2), flags RIICnSR2.TDRE and TEND, and the RIICnCR2.TRS bit to 0, and enters slave receive mode. Furthermore, it automatically sets the RIICnSR2.STOP flag to 1.

(7) After checking that the RIICnSR2.STOP flag is 1, clear the RIICnSR2.NACKF and STOP flags to 0 for the next transfer operation.



Note 1. Clear the RIICnSR2.NACKF flag in [7] Processing for the next transfer operation.

Figure 22.15 Example of Slave Transmission Flowchart

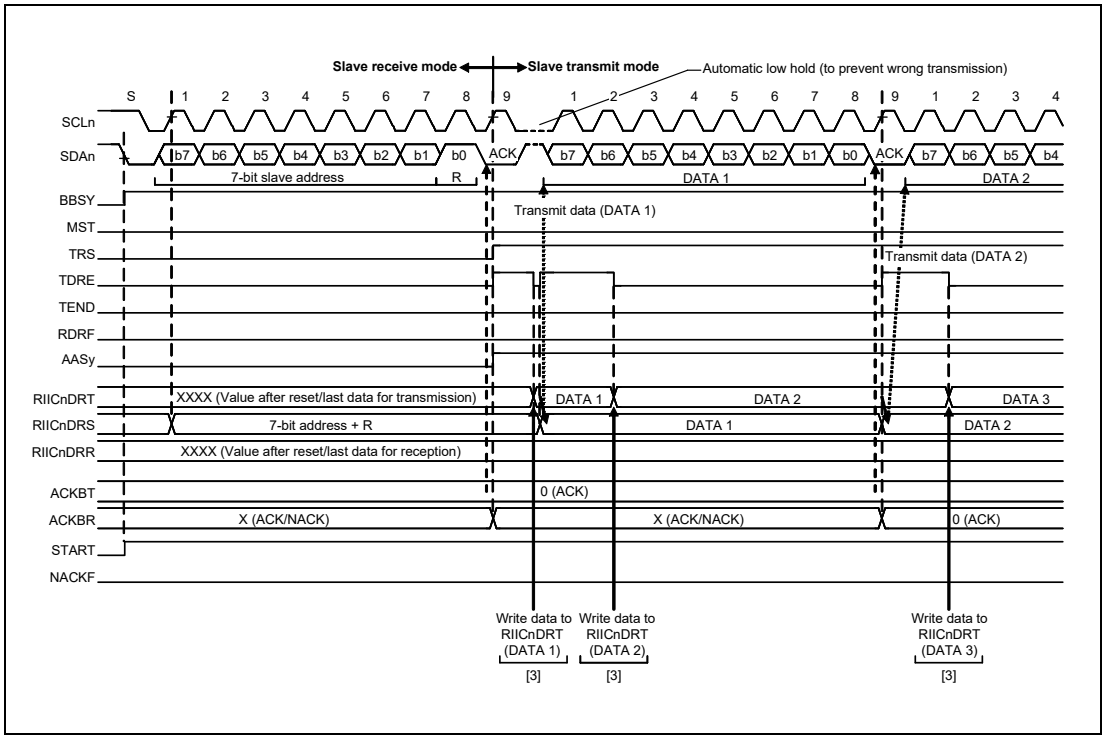


Figure 22.16 Slave Transmit Operation Timing (1) (7-Bit Address Format)

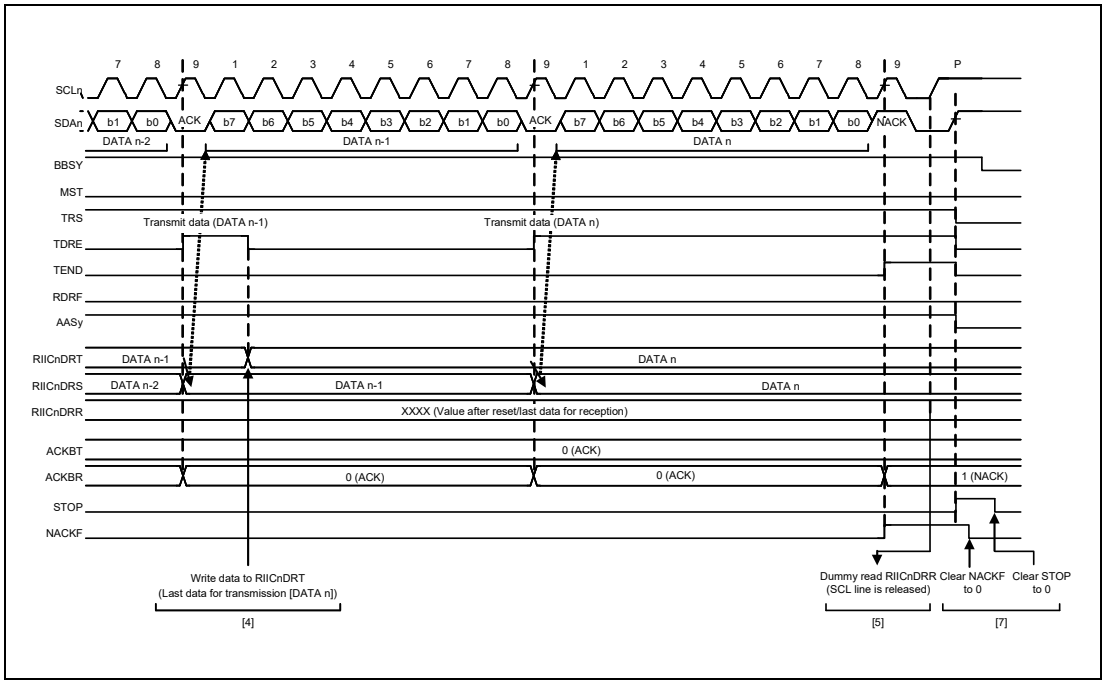

Figure 22.17 Slave Transmit Operation Timing (2)

22.4.2.6 Slave Receive Operation

In slave receive operation, the master device outputs the SCL clock and transmit data, and the RIIC returns acknowledgements as a slave device.

Figure 22.18 shows an example of usage of slave reception and **Figure 22.19** and **Figure 22.20** show the timing of operations in slave reception.

The following describes the procedure and operations for slave reception.

(1) Follow the procedure in **Figure 22.5** to make initial settings for the RIIC. This step is not necessary if initialization of the RIIC has already been completed. After initial settings, the RIIC automatically sets the BBSY and RIICnSR2.START flags to 1 and automatically clears the ST bit to 0 on detection of a start condition.

(2) After receiving a matching slave address, the RIIC sets one of the corresponding bits RIICnSR1.GCA, and AASy (y = 0 to 2) to 1 on the rising edge of the ninth cycle of SCL clock (the clock signal) and returns the value set in the RIICnMR3.ACKBT bit to the acknowledge bit on the ninth cycle of SCL clock. If the value of the R/W# bit that was also received at this time is 0, the RIIC continues to place itself in slave receive mode and sets the RIICnSR2.RDRF flag to 1.

(3) After the RIICnSR2.STOP flag is confirmed to be 0 and the RIICnSR2.RDRF flag to be 1, dummy read RIICnDRR as the first read operation (the dummy value consists of the slave address and R/W# bit when the 7-bit address format is selected, or the lower eight bits when the 10-bit address format is selected).

(4) When RIICnDRR is read, the RIIC automatically clears the RIICnSR2.RDRF flag to 0. If reading of RIICnDRR is delayed and a next byte is received while the RDRF flag is still set to 1, the RIIC holds the SCL line low from one SCL cycle before the timing with which RDRF should be set. In this case, reading RIICnDRR releases the SCL line from being held at the low level.
When the RIICnSR2.STOP flag is 1 and the RIICnSR2.RDRF flag is also 1, read RIICnDRR until all the data is completely received.

(5) Upon detecting the stop condition, the RIIC automatically clears bits RIICnSR1.GCA, and AASy (y = 0 to 2) to 0. Furthermore, it automatically sets the RIICnSR2.STOP flag to 1.

(6) After checking that the RIICnSR2.STOP flag is 1, clear the RIICnSR2.STOP flag to 0 for the next transfer operation.

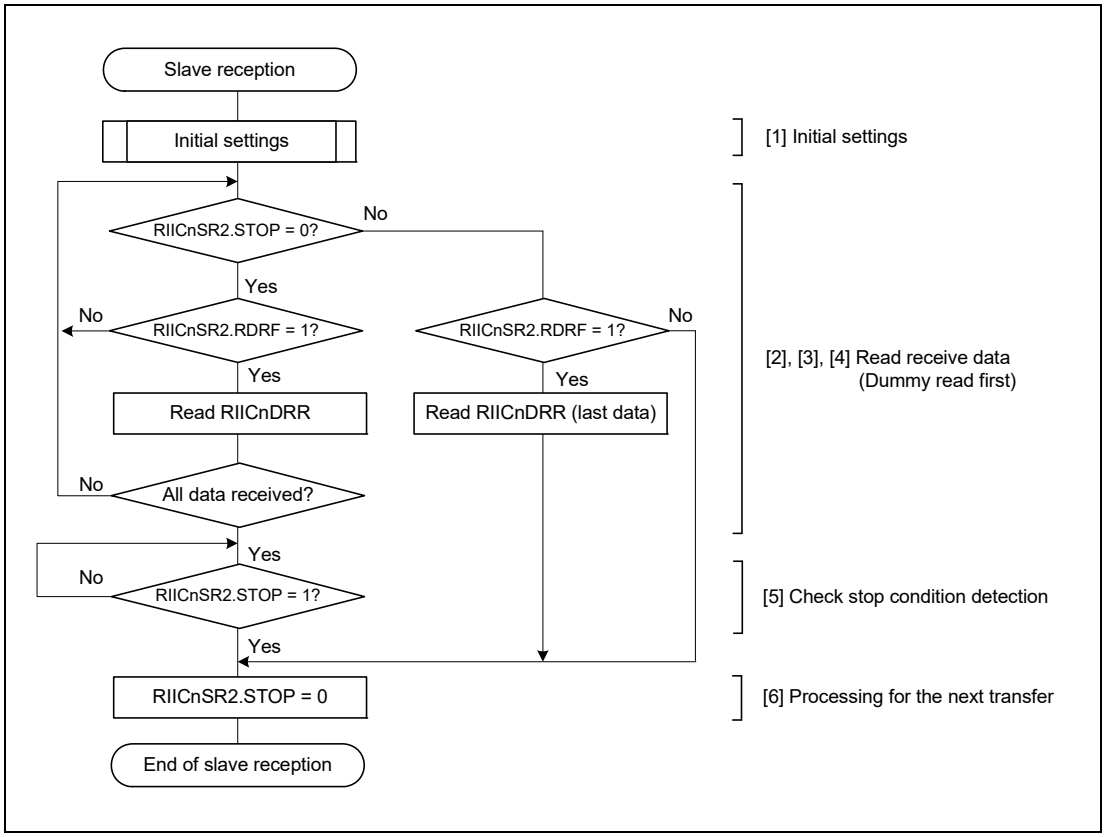

Figure 22.18 Example of Slave Reception Flowchart

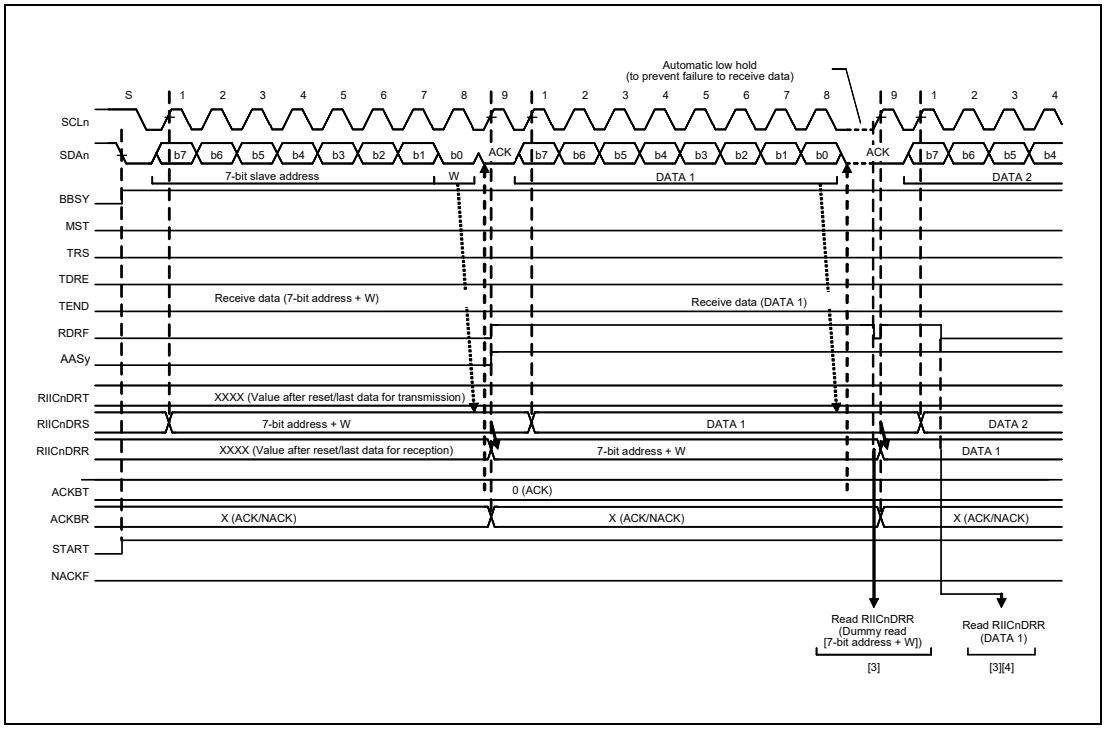

Figure 22.19 Slave Receive Operation Timing (1) (7-Bit Address Format, when RDRFS = 0)

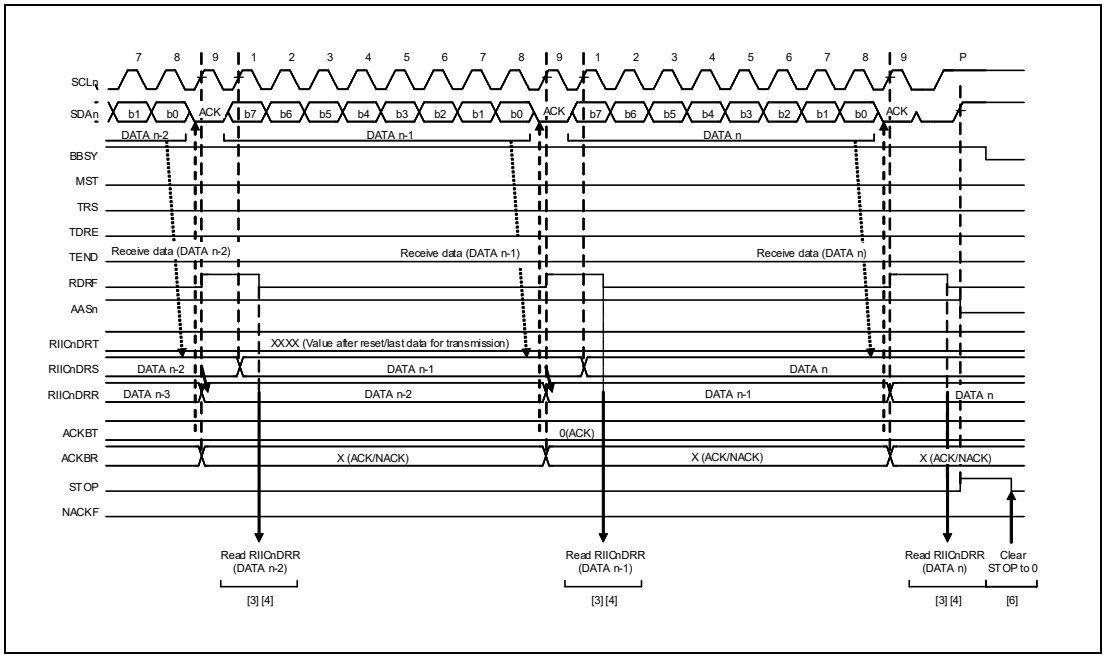

Figure 22.20 Slave Receive Operation Timing (2) (when RDRFS = 0)

22.4.3 SCL Synchronization Circuit

In generation of the SCL (clock) signal, the RIIC starts counting out the value for width at high level specified in RIICnBRH when it detects a rising edge on the SCL line and drives the SCL line low once counting of the width at high level is complete. When the RIIC detects the falling edge of the SCL line, it starts counting out the width at low level period specified in RIICnBRL, and then stops driving the SCL line (releases the line) once counting of the width at low level is complete. The SCL (clock) signal is thus generated.

If multiple master devices are connected to the I2C bus, a collision of SCL signals may arise due to contention with another master device. In such cases, the master devices have to synchronize their SCL signals. Since this synchronization of SCL signals must be bit by bit, the RIIC is equipped with a facility (the SCL synchronization circuit) to obtain bit-by-bit synchronization of the SCL clock signals by monitoring the SCL line during communication.

When the RIIC has detected a rising edge on the SCL line and thus started counting out the width at high level specified in RIICnBRH, and the level on the SCL line falls because an SCL signal is being generated by another master device, the RIIC stops counting when it detects the falling edge, drives the level on the SCL line low, and starts counting out the width at low level specified in RIICnBRL. When the RIIC finishes counting out the width at low level, it stops driving the SCL line to the low level (i.e. releases the line). At this time, if the width at low level of the SCL clock signal from the other master device is longer than the width at low level set in the RIIC, the width at low level of the SCL signal will be extended. Once the width at low level for the other master device has ended, the SCL signal rises because the SCL line has been released. That is, in cases of contention of SCL signals from more than one master, the width at high level of the SCL signal is synchronized with that of the clock having the narrower width, and the width at low level of the SCL signal is synchronized with that of the clock having the broader width. However, such synchronization of the SCL signal is only enabled when the RIICnFER.SCLE bit is set to 1.

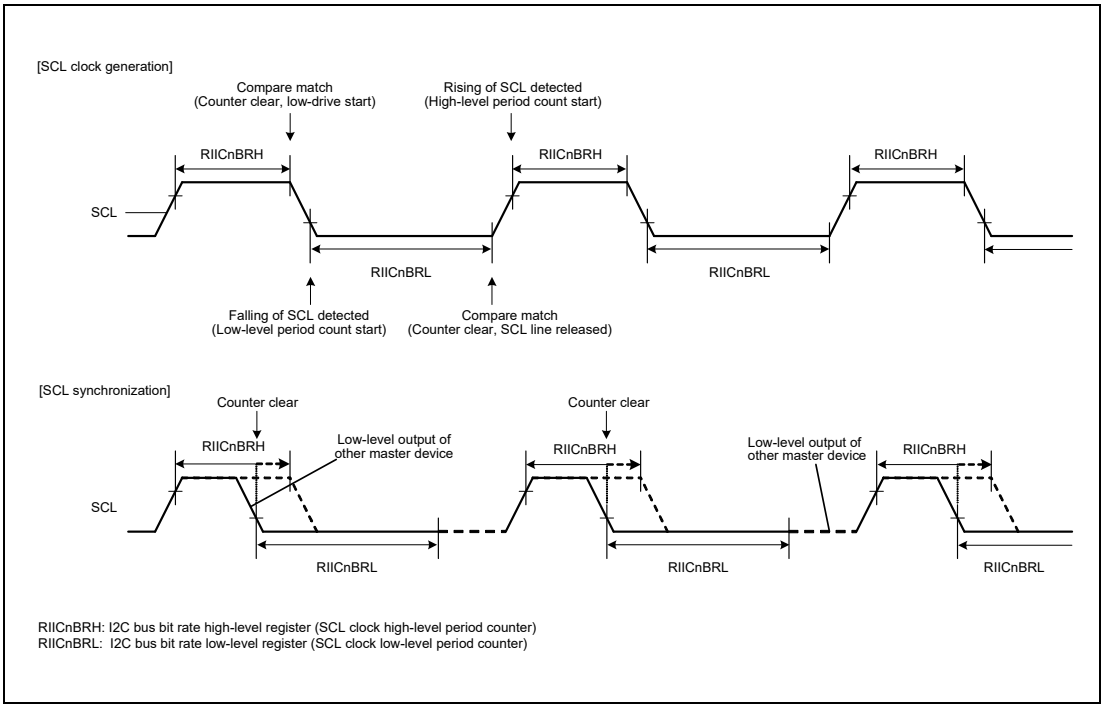

Figure 22.21 Generation and Synchronization of the SCL Signal from the RIIC

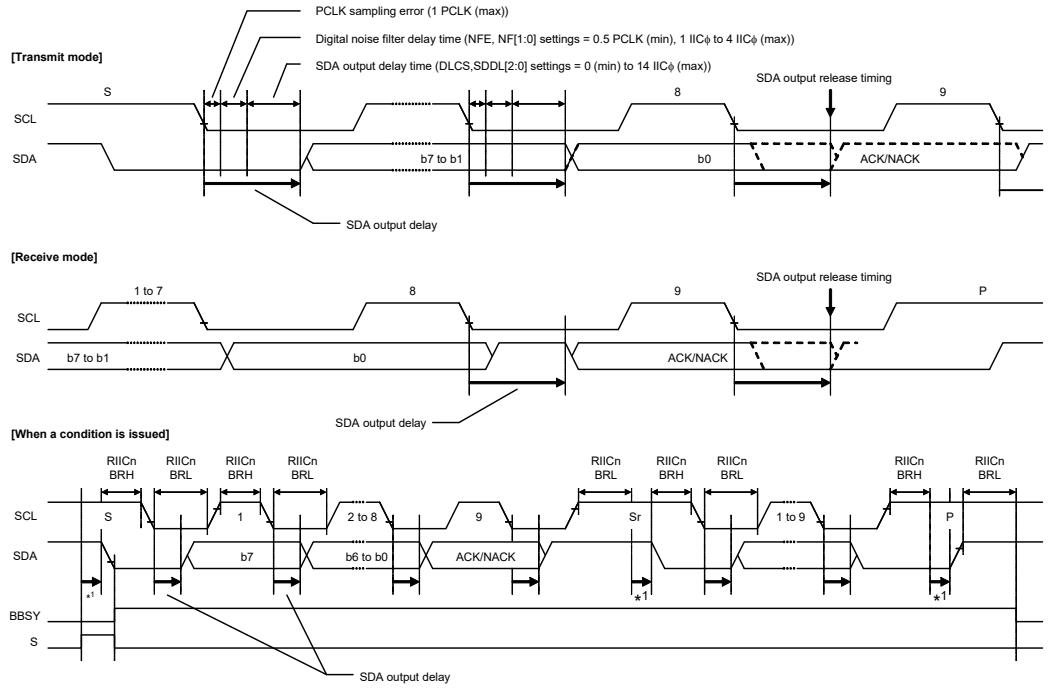
22.4.4 Facility for Delaying SDA Output

The RIIC module incorporates a facility for delaying output on the SDA line. The delay can be applied to all output (issuing of the start, restart, and stop conditions, data, and the ACK and NACK signals) on the SDA line.

With the SDA output delay facility, SDA output is delayed from detection of a falling edge of the SCL signal to ensure that the SDA signal is output within the interval over which the SCL (clock) signal is at the low level. Doing this leads to usage with the aim of preventing erroneous operation of communications devices.

The output delay facility is enabled by setting the RIICnMR2.SDDL[2:0] bits to any value other than 000_B, and disabled by setting the same bits to 000_B.

While the SDA output delay facility is enabled (i.e. while the SDDL[2:0] bits are set to any value other than 000_B), the RIICnMR2.DLCS bit selects the clock source for counting by the SDA output delay counter as the internal base clock (IICϕ) for the RIIC module or as a clock signal derived by dividing the frequency of the internal base clock by two (IICϕ/2). The counter counts the number of cycles set in the SDDL[2:0] bits. After counting of the set number of cycles of delay is completed, the RIIC module places the required output (start, restart, or stop condition, data, or an ACK or NACK signal) on the SDA line.



Note 1. The output delay facility is set by the SDDL[2:0] bits when a start (S), restart (Sr), or stop (P) condition is issued.

Figure 22.22 SDA Output Delay Facility

22.4.5 Digital Noise-Filter Circuits

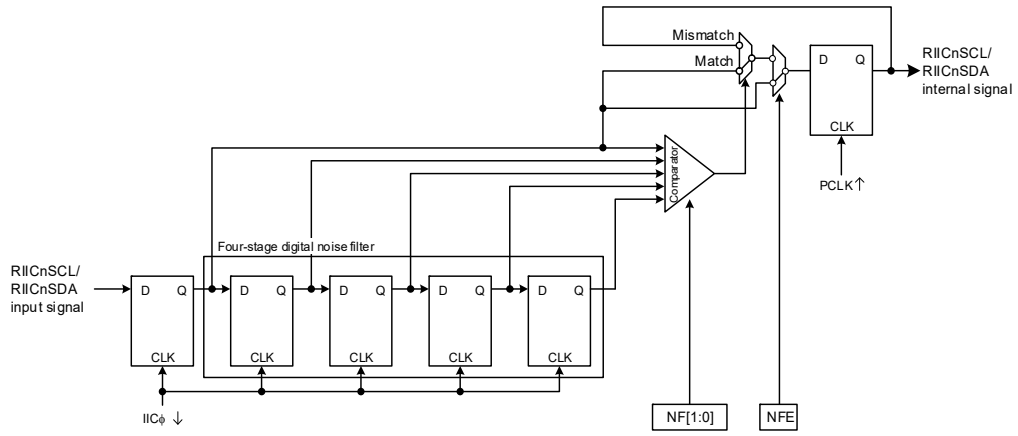
The states of the RIICnSCL and RIICnSDA pins are conveyed to the internal circuitry through the digital noise-filter circuit. **Figure 22.23** is a block diagram of the digital noise-filter circuit.

The on-chip digital noise-filter circuit of the RIIC consists of four flip-flop circuit stages connected in series and a match-detection circuit.

The number of effective stages in the digital noise filter is selected by the RIICnMR3.NF[1:0] bits. The selected number of effective stages determines the noise-filtering capability as a period from one to four IICϕ cycles.

The input signal to the RIICnSCL pin (or RIICnSDA pin) is sampled on falling edges of the IICϕ signal. When the input signal level matches the output level of the number of effective flip-flop circuit stages as selected by the RIICnMR3.NF[1:0] bits, the signal level is conveyed as an internal signal. If the signal levels do not match, the previous value is retained.

If the ratio between the frequency of the internal operating clock (PCLK) and the transfer rate is small, the characteristics of the digital noise filter may lead to the elimination of needed signals as noise. In such cases, it is possible to disable the digital noise-filter circuit (by clearing the RIICnFER.NFE bit to 0).



Note: NFE is Noise filter enable bit. (**22.3.7, RIICnFER — I2C Bus Function Enable Register**)
NF[1:0]: Digital noise filter stage selection bit

Figure 22.23 Block Diagram of Digital Noise Filter Circuit

22.4.6 Address Match Detection

The RIIC can set three unique slave addresses in addition to the general call address and device ID address, and also can set 7-bit or 10-bit slave addresses.

22.4.6.1 Slave-Address Match Detection

The RIIC can set three unique slave addresses, and has a slave address detection function for each unique slave address. When the RIICnSER.SARy bit (y = 0 to 2) is set to 1, the slave addresses set in RIICnSARy (y = 0 to 2) can be detected.

When the RIIC detects a match of the set slave address, the corresponding RIICnSR1.AASy flag (y = 0 to 2) is set to 1 at the rising edge of the ninth SCL clock cycle and returns the value set in the RIICnMR3.ACKBT bit to the acknowledge bit on the ninth cycle of SCL clock. The RIICnSR2.RDRF flag or the RIICnSR2.TDRE flag is set to 1 by the following R/W# bit. This causes a receive complete interrupt (INTRIICnRI) or transmit data empty interrupt (INTRIICnTI) to be generated. The AASy flag is used to identify which slave address has been specified.

Figure 22.24 to **Figure 22.26** show the AASy flag set timing in three cases.

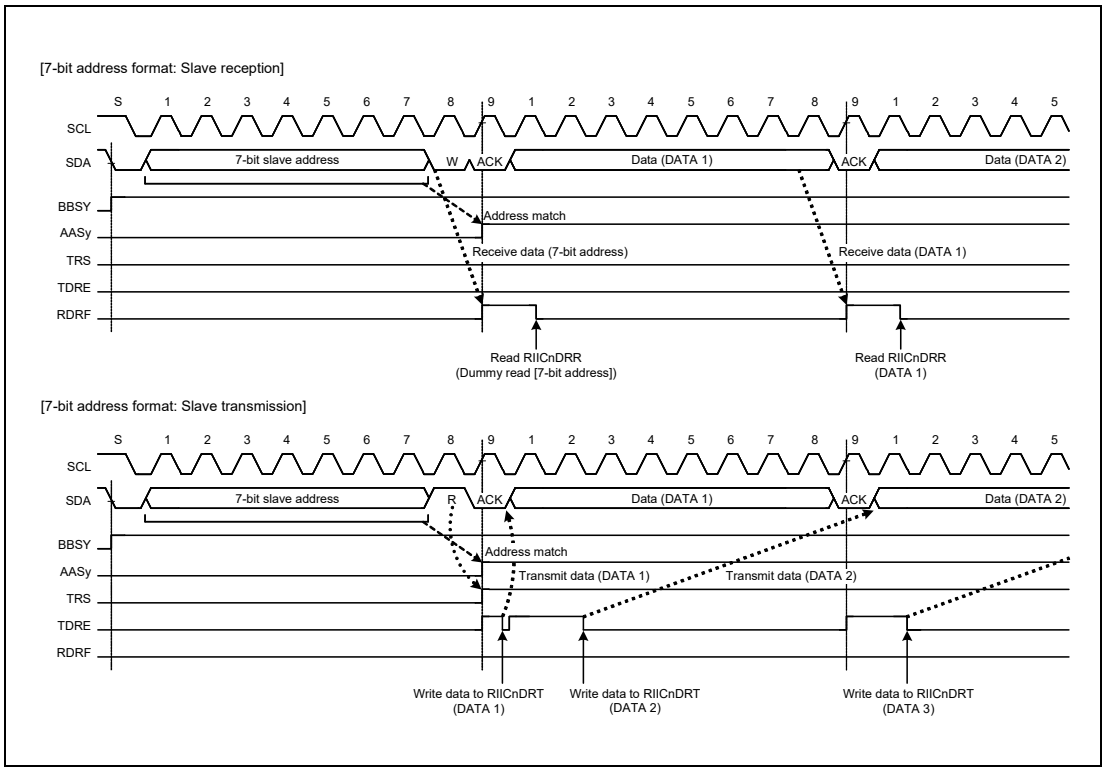


Figure 22.24 AASy Flag Set Timing with 7-Bit Address Format Selected

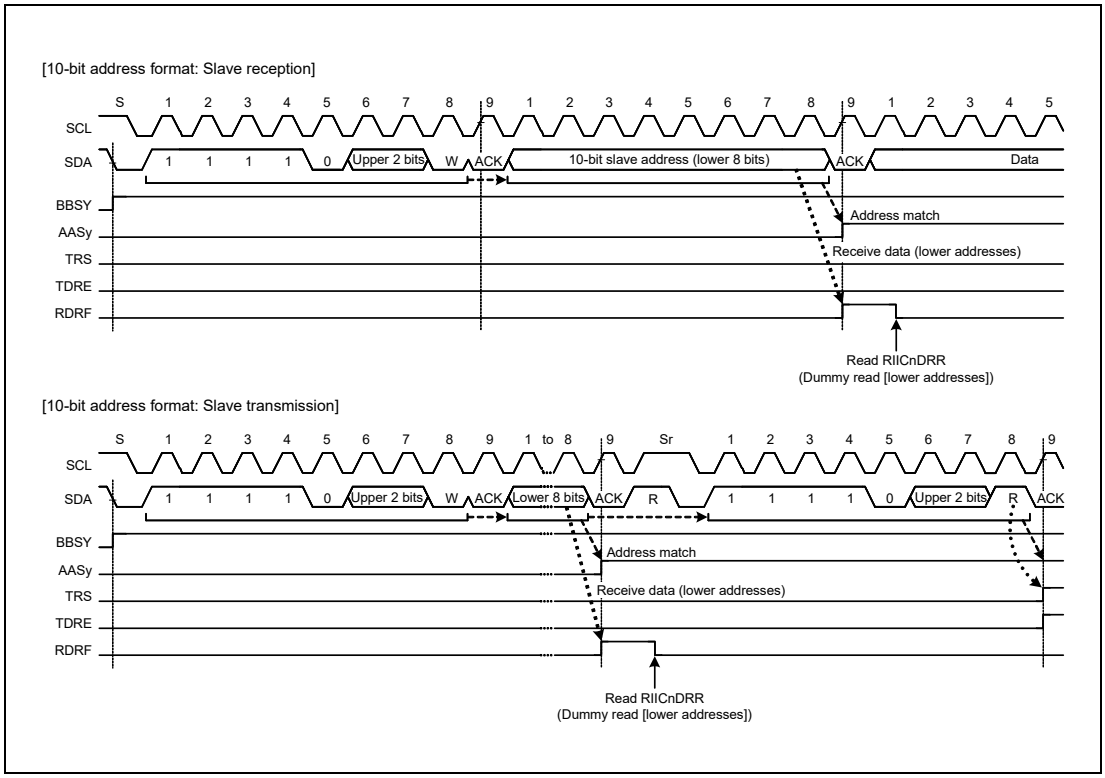

Figure 22.25 AASy Flag Set Timing with 10-Bit Address Format Selected

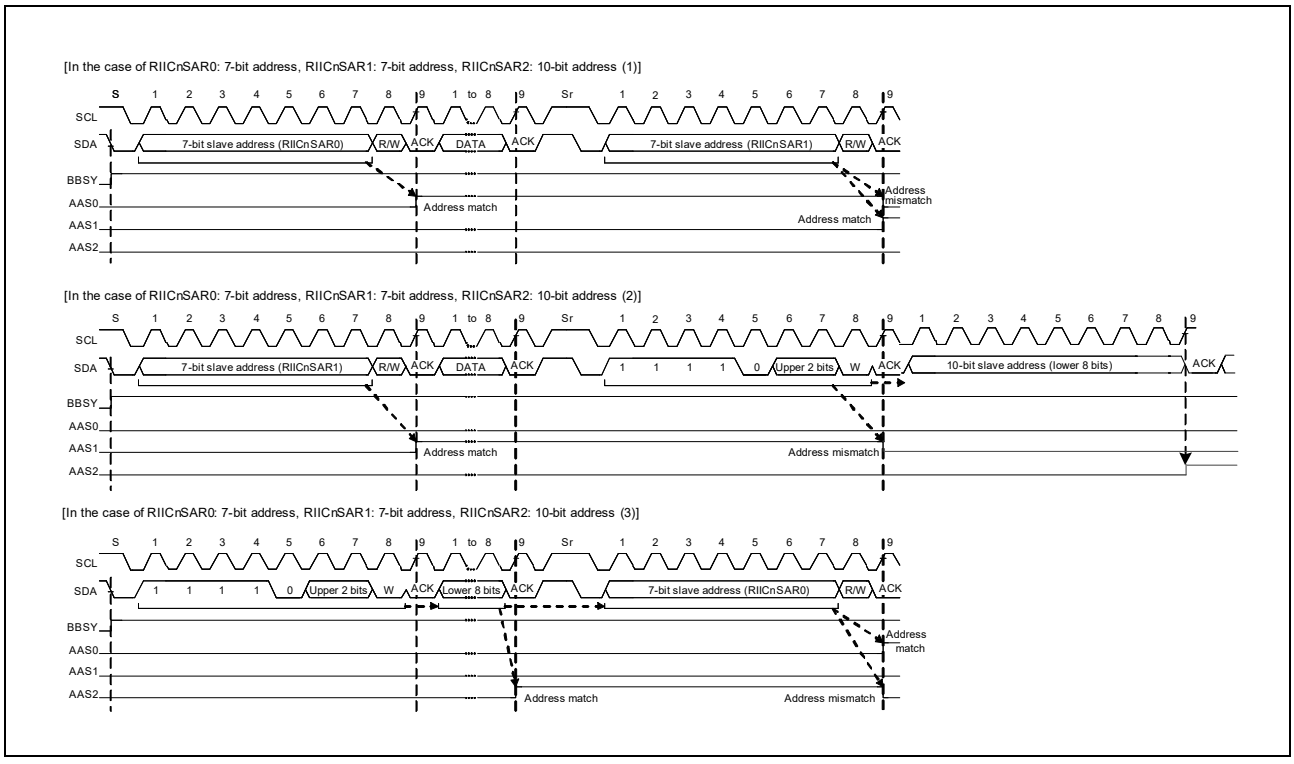

Figure 22.26 AASy Flag Set/Clear Timing with 7-Bit/10-Bit Address Formats Mixed

22.4.6.2 Detection of the General Call Address

The RIIC has a facility for detecting the general call address (0000 000_B + 0 [W]). This is enabled by setting the RIICnSER.GCE bit to 1.

If the address received after a start or restart condition is issued is 0000 000_B + 1[R] (start byte), the RIIC recognizes this as the address of a slave device with an “all-zero” address but not as the general call address.

When the RIIC detects the general call address, both the RIICnSR1.GCA flag and the RIICnSR2.RDRF flag are set to 1 on the rising edge of the ninth cycle of SCL clock. This leads to the generation of a receive complete interrupt (INTRIICnRI). The value of the GCA flag can be confirmed to recognize that the general call address has been transmitted.

Operation after detection of the general call address is the same as normal slave receive operation.

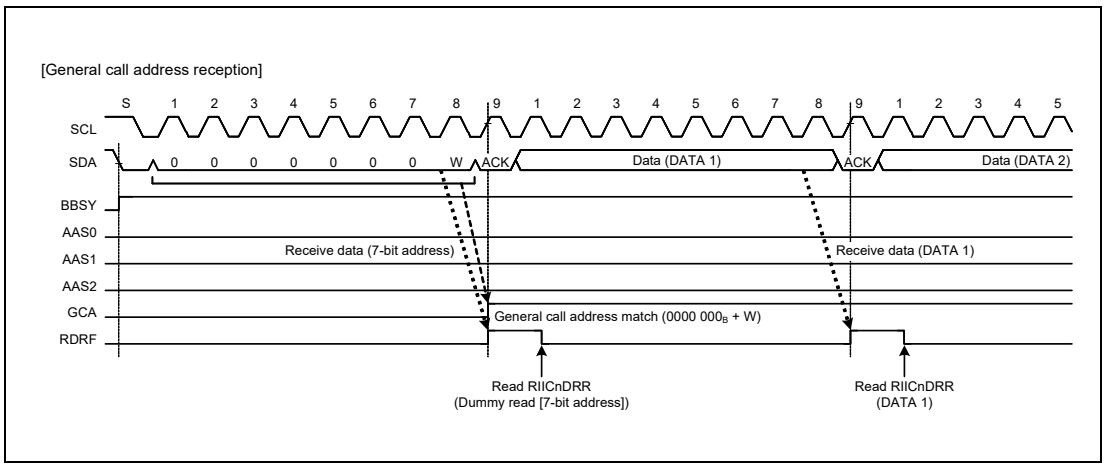

Figure 22.27 Timing of GCA Flag Setting during Reception of General Call Address

22.4.6.3 Device-ID Address Detection

The RIIC module has a facility for detecting device-ID addresses conforming with the I2C bus specification (Rev. 03). When the RIIC receives 1111 100_B as the first byte after a start condition or restart condition was issued with the RIICnSER.DIDE bit set to 1, the RIIC recognizes the address as a device ID, sets the RIICnSR1.DID flag to 1 on the rising edge of the ninth SCL clock cycle when the following R/W# bit is 0, and then compares the second and subsequent bytes with its own slave address. If the address matches the value in the slave address register, the RIIC sets the corresponding RIICnSR1.AASy flag (y = 0 to 2) to 1.

After that, when the first byte received after a start or restart condition is issued matches the device ID address (1111 100_B) again and the following R/W# bit is 1, the RIIC does not compare the second and subsequent bytes and sets the RIICnSR2.TDRE flag to 1.

In the device-ID address detection function, the RIIC clears the DID flag to 0 if a match with the RIIC's own slave address is not obtained or a match with the device ID address is not obtained after a match with the RIIC's own slave address and the detection of a restart condition. If the first byte after detection of a start or restart condition matches the device ID address (1111 100_B) and the R/W# bit is 0, the RIIC sets the DID flag to 1 and compares the second and subsequent bytes with the RIIC's slave address. If the R/W# bit is 1, the DID flag holds the previous value and the RIIC does not compare the second and subsequent bytes. Therefore, the reception of a device-ID address can be checked by reading the DID flag after confirming that TDRE = 1.

Furthermore, prepare the device-ID fields (three bytes: 12 bits indicating the manufacturer + 9 bits identifying the part + 3 bits indicating the revision) that must be sent to the host after reception of a continuous device-ID field as normal data for transmission. For details, see I2C Bus Standard from NXP Semiconductors.

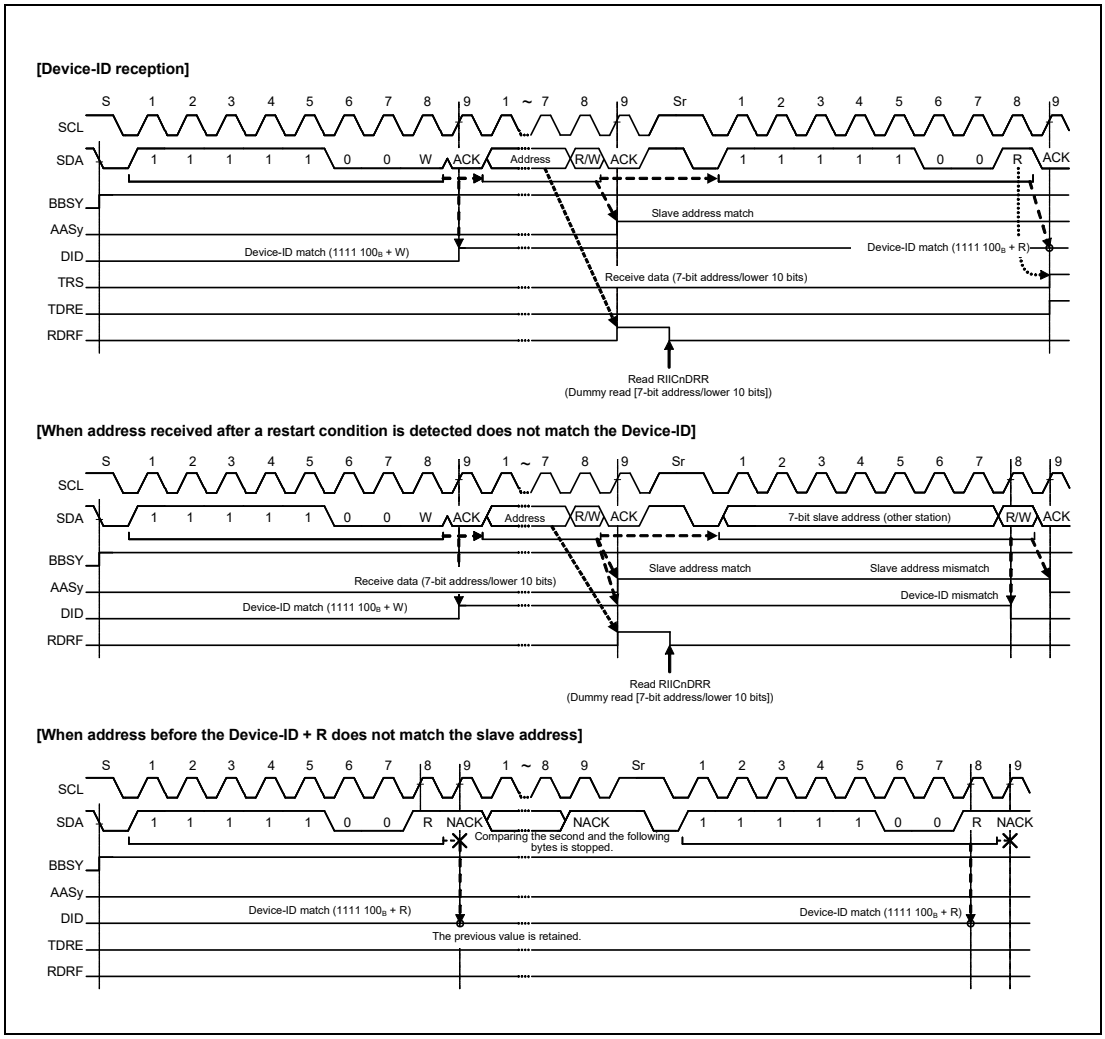

Figure 22.28 AASy/DID Flag Set/Clear Timing during Reception of Device-ID

22.4.7 Automatic Low-Hold Function for SCL

22.4.7.1 Function to Prevent Wrong Transmission of Transmit Data

To prevent the unintended transmission of erroneous data, this low-hold period is extended until data for transmission have been written. In addition, the RIIC holds the SCL line low over the period until a stop condition is issued and also over the period until the RIICnDRR register is dummy read.

<Master transmit mode>

- Low-level interval after a start condition or restart condition is issued
- Low-level interval between the ninth clock cycle of one transfer and the first clock cycle of the next
- Low-level interval from the ninth clock cycle until a stop condition is issued

<Slave transmit mode>

- Low-level interval between the ninth clock cycle of one transfer and the first clock cycle of the next
- Low-level interval from the ninth clock cycle and the RIICnDRR register is dummy read

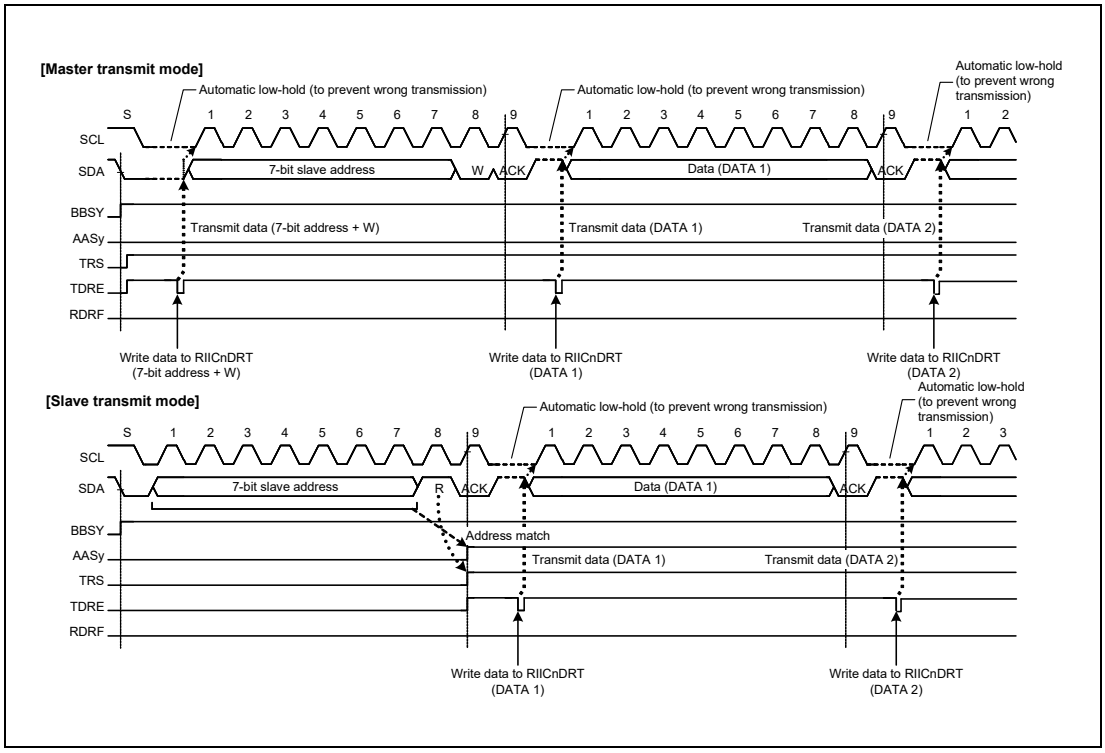

Figure 22.29 Automatic Low-Hold Operation in Transmit Mode

22.4.7.2 NACK Reception Transfer Suspension Function

The RIIC has a function to suspend transfer operation when NACK is received in transmit mode (RIICnCR2.TRS bit = 1). This function is enabled when the RIICnFER.NACKE bit is set to 1 (transfer suspension enabled). If the next transmit data has already been written (RIICnSR2.TDRE flag = 0) when NACK is received, next data transmission at the falling edge of the ninth SCL clock cycle is automatically suspended. This prevents the SDA line output level from being held low when the MSB of the next transmit data is 0.

If the transfer operation is suspended by this function (RIICnSR2.NACKF flag = 1), transmit operation and receive operation are discontinued. To restore transmit/receive operation, be sure to clear the NACKF flag to 0. In master transmit mode, clear the NACKF flag to 0 after issue a restart condition or NACKF flag to 0 after issue a stop condition, and then issue a start condition again.

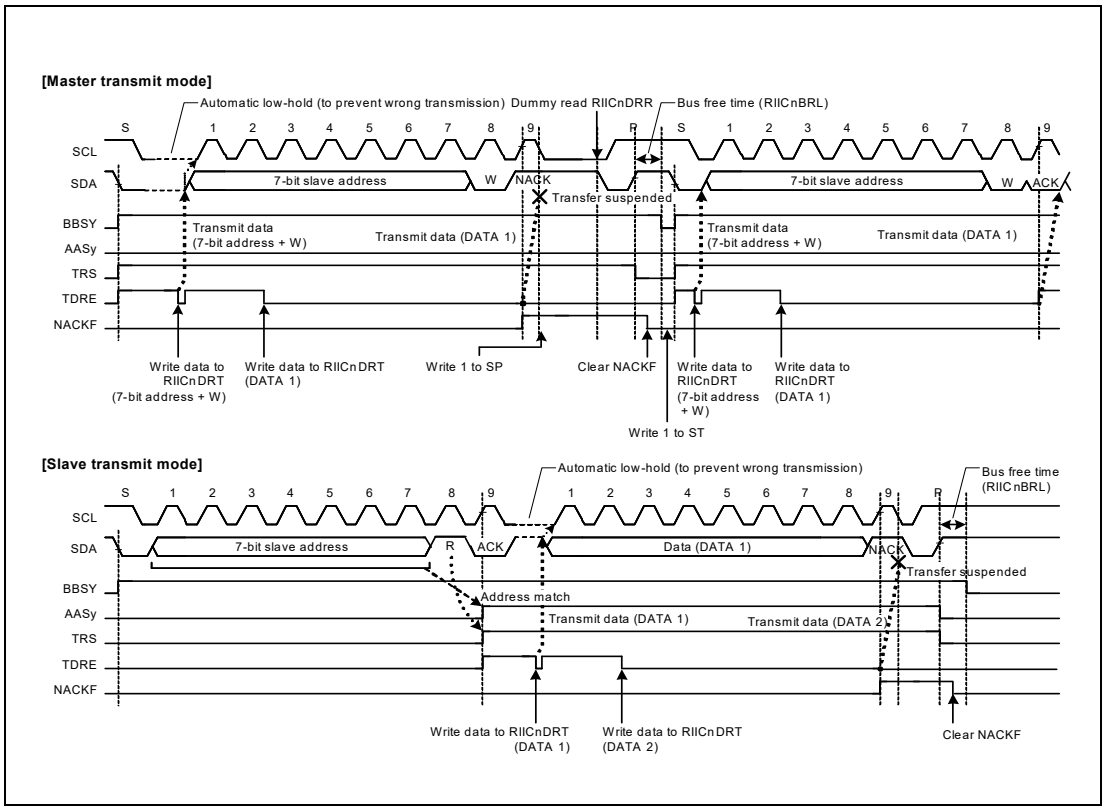

Figure 22.30 Suspension of Data Transfer when NACK is Received (NACKE = 1)

22.4.7.3 Function to Prevent Failure to Receive Data

If response processing is delayed when receive data (RIICnDRR) read is delayed for a period of one transfer frame or more with receive complete (RIICnSR2.RDRF flag = 1) in receive mode (RIICnCR2.TRS = 0), the RIIC holds the SCL line low automatically immediately before the next data is received to prevent failure to receive data.

This function to prevent failure to receive data using the automatic low-hold function is also enabled even if the read processing of the final receive data is delayed and, in the meantime, the RIIC's own slave address is designated after a stop condition is issued. This function does not disturb other communication because the RIIC does not hold the SCL line low when a mismatch with its own slave address occurs after a stop condition is issued.

Sections in which the SCL line is held low can be selected with a combination of the RIICnMR3.WAIT and RDRFS bits.

(1) One-Byte Receive Operation and Automatic Low-Hold Function Using the WAIT Bit

When the RIICnMR3.WAIT bit is set to 1, the RIIC performs one-byte receive operation using the WAIT bit function.
Furthermore, when the RIICnMR3.RDRFS bit is 0, the RIIC automatically sends the RIICnMR3.ACKBT bit value for the acknowledge bit in the period from the falling edge of the eighth SCL clock cycle to the falling edge of the ninth SCL clock cycle, and automatically holds the SCL line low at the falling edge of the ninth SCL clock cycle using the WAIT bit function. This low-hold is released by reading data from RIICnDRR, which enables bytewise receive operation.

The WAIT bit function is enabled for receive frames after a match with the RIIC's own slave address (including the general call address and device ID address) is obtained in master receive mode or slave receive mode.

(2) One-Byte Receive Operation (ACK/NACK Transmission Control) and Automatic Low-Hold Function Using the RDRFS Bit

When the RIICnMR3.RDRFS bit is set to 1, the RIIC performs one-byte receive operation using the RDRFS bit function.
When the RIICnSR2.RDRFS bit is set to 1, the RDRF flag (receive complete) in RIICnSR2 is set to 1 at the rising edge of the eighth SCL clock cycle, and the SCL line is automatically held low at the falling edge of the eighth SCL clock cycle. This low-hold is released by writing a value to the RIICnMR3.ACKBT bit, but cannot be released by reading data from RIICnDRR, which enables receive operation by the ACK/NACK transmission control according to the data received in byte units.

The RDRFS bit function is enabled for receive frames after a match with the RIIC's own slave address (including the general call address and device ID address) is obtained in master receive mode or slave receive mode.

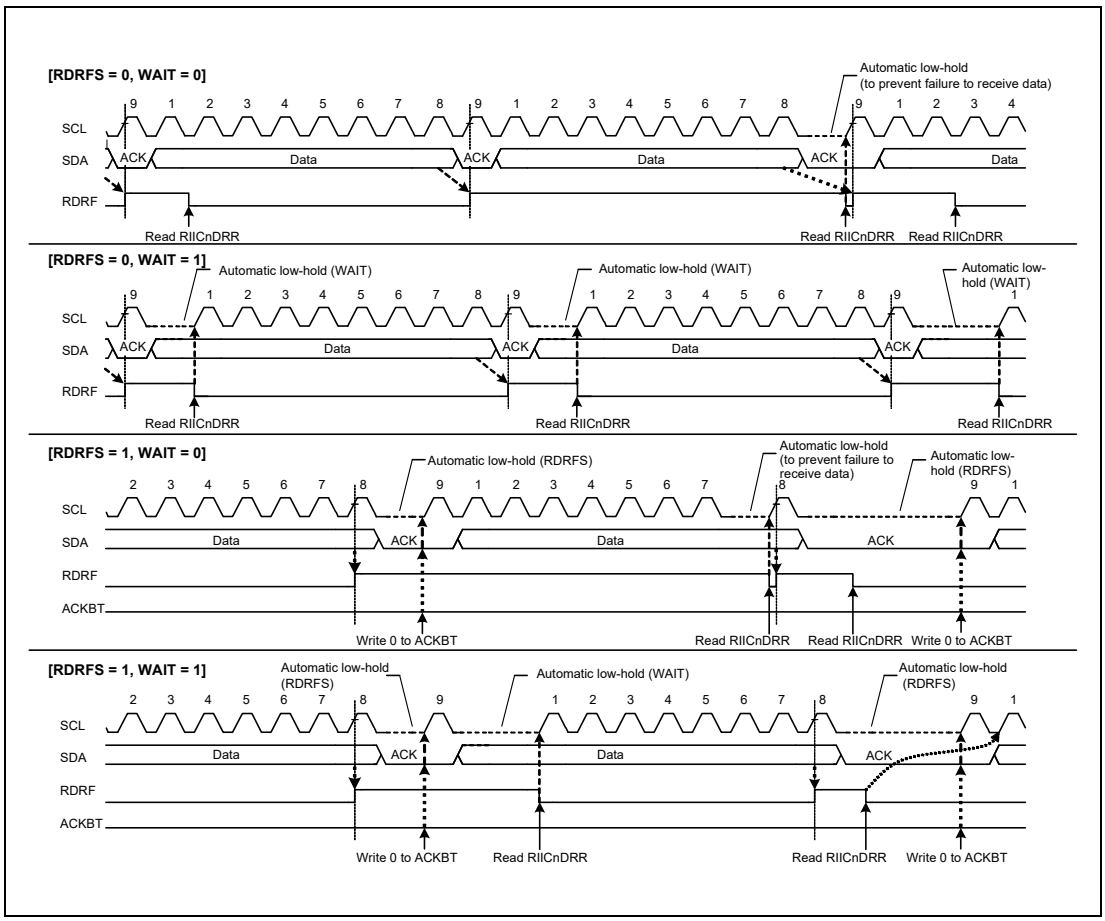

Figure 22.31 Automatic Low-Hold Operation in Receive Mode (Using RDRFS and WAIT Bits)

22.4.8 Arbitration-Lost Detection Functions

In addition to the normal arbitration-lost detection function defined by the I2C bus standard, the RIIC has functions to prevent double-issue of a start condition, to detect arbitration-lost during transmission of NACK, and to detect arbitration-lost in slave transmit mode.

22.4.8.1 Master Arbitration-Lost Detection (MALE Bit)

The RIIC drives the SDA line low to issue a start condition. However, if the SDA line has already been driven low by another master device issuing a start condition, the RIIC considers this a loss in arbitration, so priority is given to transfer by the other master device. Similarly, if the RIICnCR2.ST bit is set to 1 while the bus is busy (RIICnCR2.BBSY flag = 1), the RIIC considers itself to have lost in arbitration, so priority is given to transfer by the other master device and no start condition is generated.

When a start condition is issued successfully, if the data for transmission including the address bits (i.e. the internal SDA output level) and the level on the SDA line do not match (the high output as the internal SDA output; i.e. the SDA pin is in the high-impedance state, and the low level is detected on the SDA line), the RIIC loses in arbitration.

After a loss in arbitration of mastership, the RIIC immediately enters slave receive mode. If a slave address (including the general call address) matches its own address at this time, the RIIC continues in slave operation.

A loss in arbitration of mastership is detected when the following conditions are met while the RIICnFER.MALE bit is 1 (master arbitration-lost detection enabled).

[Master arbitration-lost conditions]

- Non-matching of the internal level for output on SDA and the level on the SDA line after a start condition was issued by setting the RIICnCR2.ST bit to 1 while the RIICnCR2.BBSY flag was cleared to 0 (erroneous issuing of a start condition)
- Setting of the RIICnCR2.ST bit to 1 (start condition double-issue error) while the RIICnCR2.BBSY flag is set to 1
- When the transmit data excluding acknowledge (internal SDA output level) does not match the level on the SDA line in master transmit mode (RIICnCR2.MST and TRS bits = 11_B)

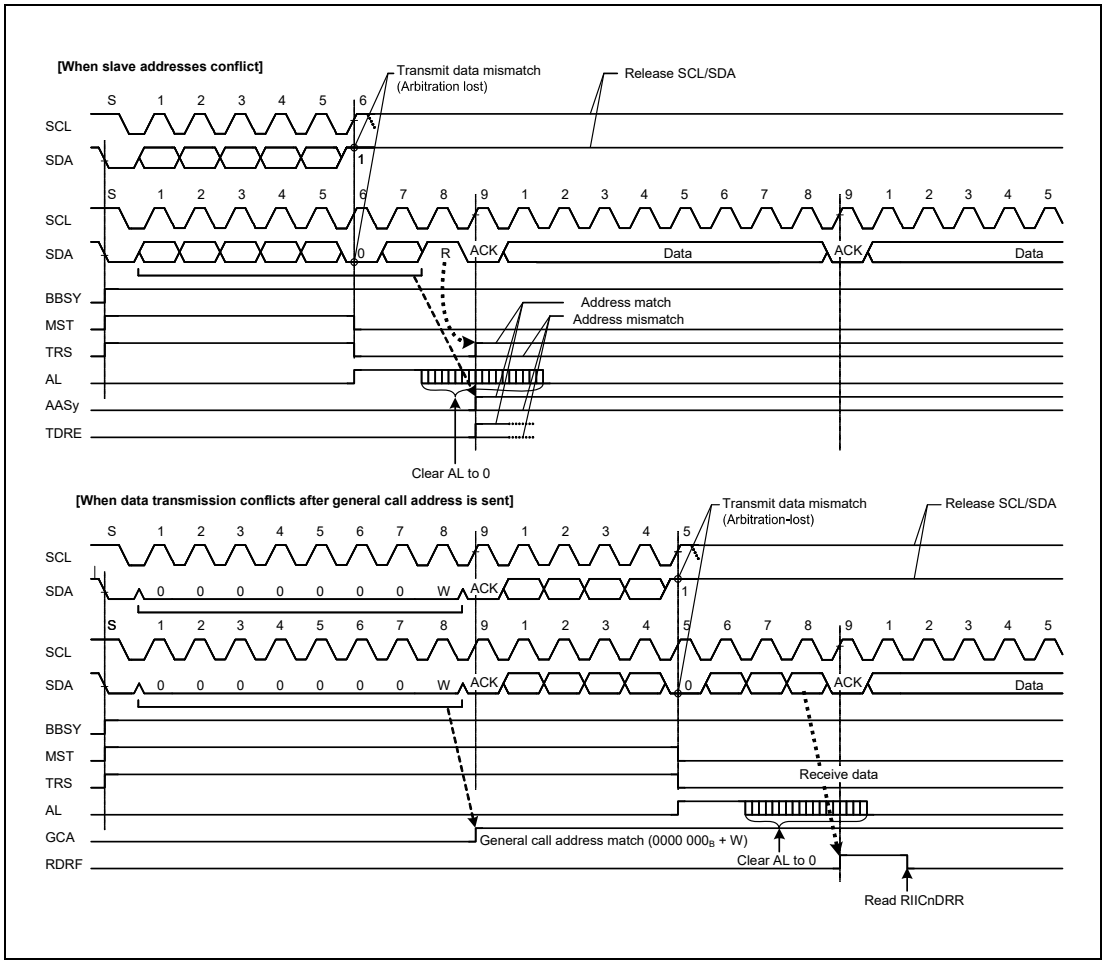

Figure 22.32 Examples of Master Arbitration-Lost Detection (MALE = 1)

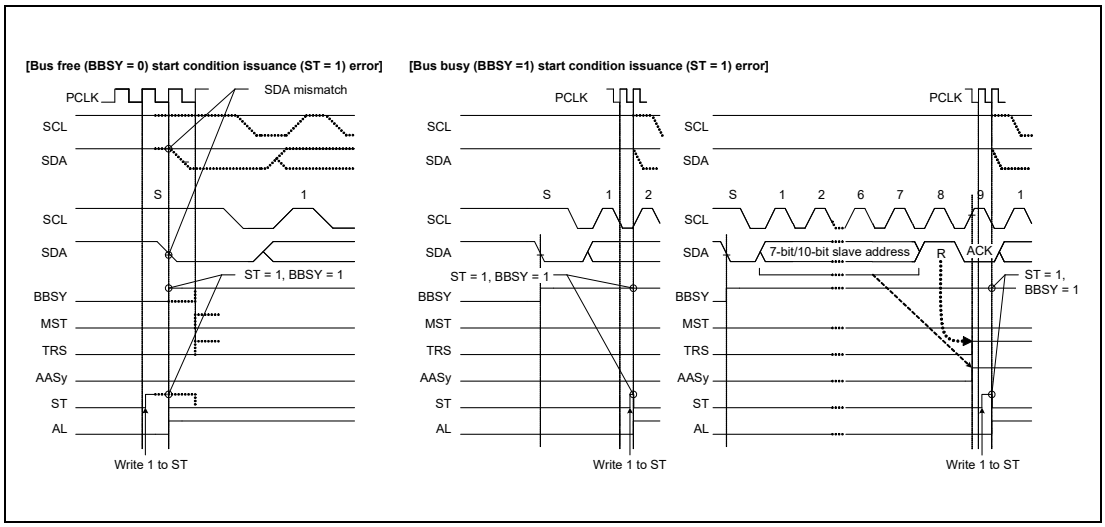

Figure 22.33 Arbitration-Lost when a Start Condition is Issued (MALE = 1)

The TRS bit is not cleared if 1 is written to the ST bit while the BBSY flag is 1 in slave transmit mode.

22.4.8.2 Function to Detect Loss of Arbitration during NACK Transmission (NALE Bit)

The RIIC has a function to cause arbitration to be lost if the internal SDA output level does not match the level on the SDA line (the high output as the internal SDA output; i.e. the SDA pin is in the high-impedance state, and the low level is detected on the SDA line) during transmission of NACK in receive mode. Arbitration is lost due to a conflict of NACK transmission and ACK transmission when two or more master devices receive data from the same slave device simultaneously in a multi-master system. Such conflict occurs when multiple master devices send/receive the same information through a single slave device. **Figure 22.34** shows an example of arbitration-lost detection during transmission of NACK.

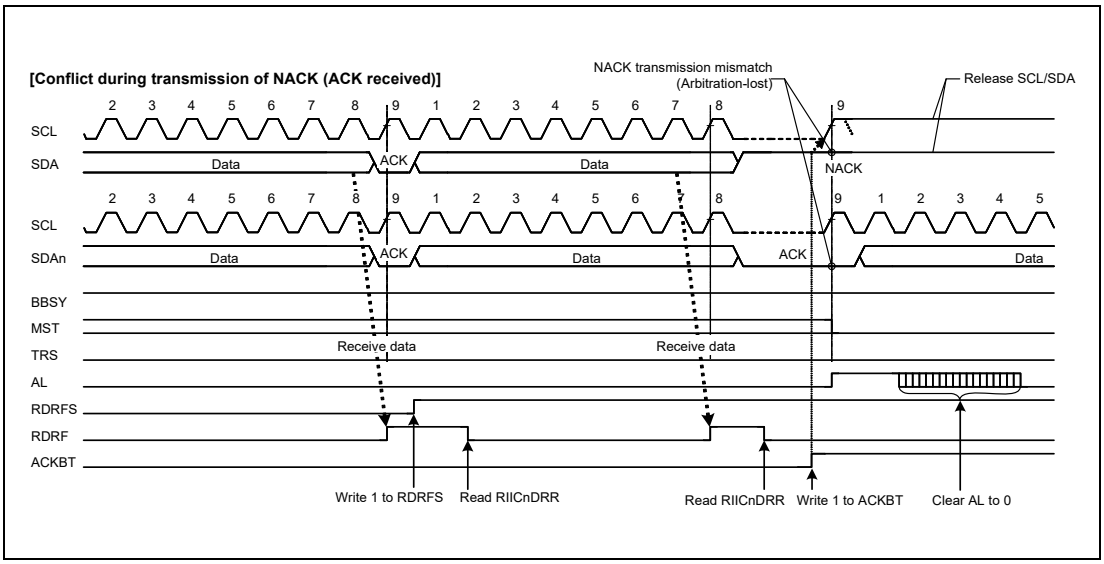

Figure 22.34 Example of Arbitration-Lost Detection during Transmission of NACK (NALE = 1)

The following explains arbitration-lost detection using an example where two master devices (master A and master B) and a single slave device are connected through the bus. In this example, master A receives two bytes of data from the slave device, and master B receives four bytes of data from the slave device.

If master A and master B access the slave device simultaneously, because the slave address is identical, arbitration is not lost in both master A and master B during access to the slave device. Therefore, both master A and master B recognize that they have obtained the bus mastership and operate as such. Here, master A sends NACK when it has received two final bytes of data from the slave device. Meanwhile, master B sends ACK because it has not received necessary four bytes of data. At this time, the NACK transmission from master A and the ACK transmission from master B conflict. In general, if a conflict like this occurs, master A cannot detect ACK transmitted by master B and issues a stop condition.

Therefore, the issuance of the stop condition conflicts with the SCL clock output of master B, which disturbs communication.

When the RIIC receives ACK during transmission of NACK, it detects a defeat in conflict with other master devices and causes arbitration to be lost.

If arbitration is lost during transmission of NACK, the RIIC enters slave receive mode. This prevents a stop condition from being issued, preventing a communication failure on the bus.

The RIIC detects arbitration-lost during transmission of NACK when the following condition is met with the RIICnFER.NALE bit set to 1 (arbitration-lost detection during NACK transmission enabled).

[Condition for arbitration-lost during NACK transmission]

When the internal SDA output level does not match the SDA line (ACK is received) during transmission of NACK (RIICnMR3.ACKBT bit = 1)

22.4.8.3 Slave Arbitration-Lost Detection (SALE Bit)

The RIIC has a function to cause arbitration to be lost if the data for transmission (i.e. the internal SDA output level) and the level on the SDA line do not match (the high output as the internal SDA output; i.e. the SDA pin is in the high impedance state, and the low level is detected on the SDA line) in slave transmit mode.

When it loses slave arbitration, the RIIC enters slave receive mode.

The RIIC detects slave arbitration-lost when the following condition is met with the RIICnFER.SALE bit set to 1 (slave arbitration-lost detection enabled).

[Condition for slave arbitration-lost]

When transmit data excluding acknowledge (internal SDA output level) does not match the SDA line in slave transmit mode (RIICnCR2.MST and TRS bits = 01_B)

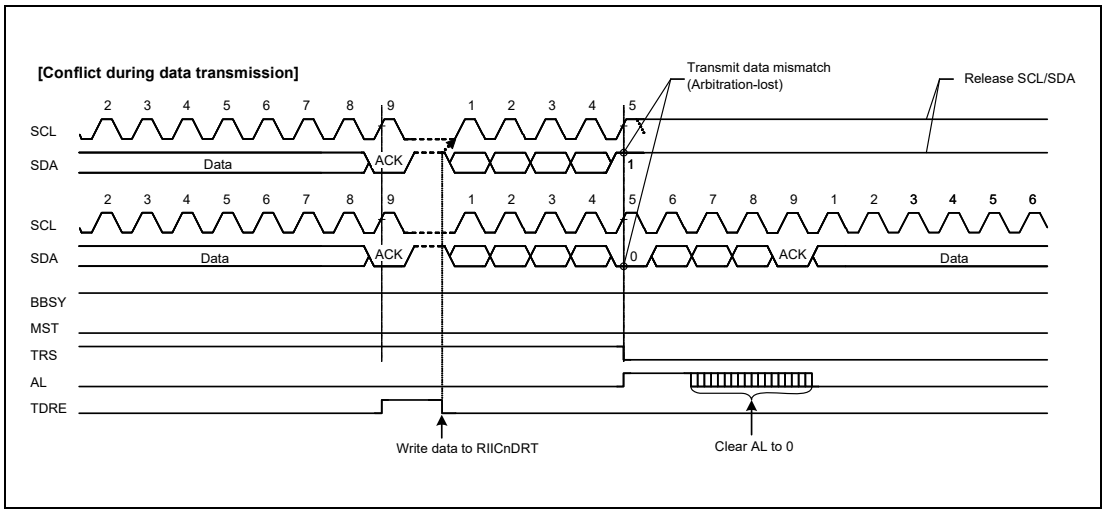

Figure 22.35 Example of Slave Arbitration-Lost Detection (SALE = 1)

22.4.9 Start Condition/Restart Condition/Stop Condition Issuing Function

22.4.9.1 Issuing a Start Condition

The RIIC issues a start condition when the RIICnCR2.ST bit is set to 1.

When the ST bit is set to 1, a start condition issuance request is made and the RIIC issues a start condition when the RIICnCR2.BBSY flag is 0 (bus free). When a start condition is issued normally, the RIIC automatically shifts to the master transmit mode.

A start condition is issued in the following sequence.

[Start condition issuance]

- Drive the SDA line low (high level to low level).
- Ensure the time set in RIICnBRH and the start condition hold time.
- Drive the SCL line low (high level to low level).
- Detect low level of the SCL line and ensure the low-level period of SCL line set in RIICnBRL.

22.4.9.2 Issuing a Restart Condition

The RIIC issues a restart condition when the RIICnCR2.RS bit is set to 1.

When the RS bit is set to 1, a restart condition issuance request is made even during communication and the RIIC issues a restart condition when the RIICnCR2.BBSY flag is 1 (bus busy) and the RIICnCR2.MST bit is 1 (master mode).

(To detect the issuance of a restart condition, clear the RIICnSR2.START flag before a restart condition is issued.)

A restart condition is issued in the following sequence.

[Restart condition issuance]

- Release the SDA line.
- Ensure the low-level period of SCL line set in RIICnBRL.
- Release the SCL line (low level to high level).
- Detect a high level of the SCL line and ensure the time set in RIICnBRL and the restart condition setup time.
- Drive the SDA line low (high level to low level).
- Ensure the time set in RIICnBRH and the restart condition hold time.
- Drive the SCL line low (high level to low level).
- Detect a low level of the SCL line and ensure the low-level period of SCL line set in RIICnBRL.

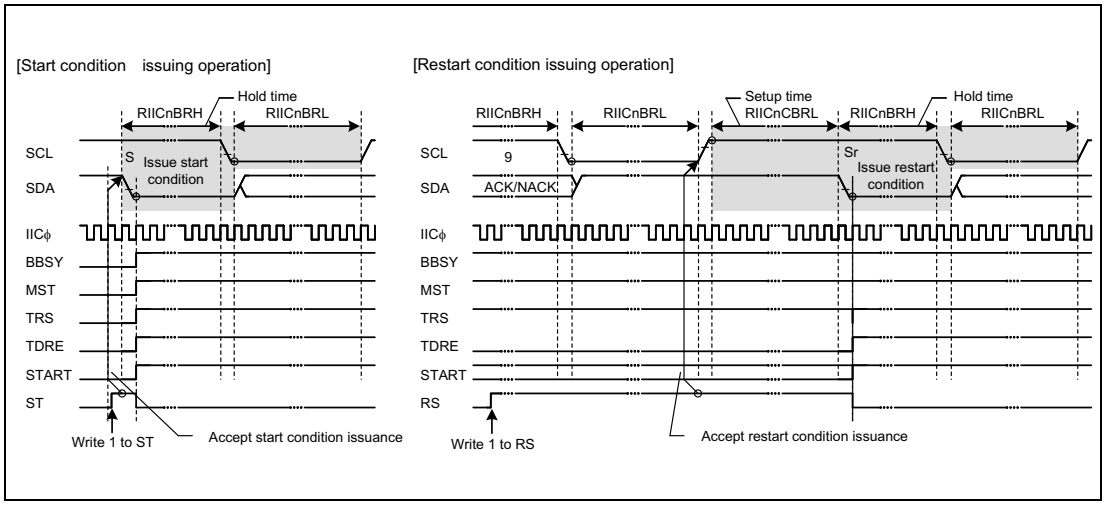

Figure 22.36 Start Condition/Restart Condition Issue Timing (ST and RS Bits)

22.4.9.3 Issuing a Stop Condition

The RIIC issues a stop condition when the RIICnCR2.SP bit is set to 1.

When the SP bit is set to 1, a stop condition issuance request is made and the RIIC issues a stop condition when the RIICnCR2.BBSY flag is 1 (bus busy) and the RIICnCR2.MST bit is 1 (master mode).

A stop condition is issued in the following sequence.

[Stop condition issuance]

- Drive the SDA line low (high level to low level).
- Ensure the low-level period of SCL line set in RIICnBRL.
- Release the SCL line (low level to high level).
- Detect a high level of the SCL line and ensure the time set in RIICnBRH and the stop condition setup time.
- Release the SDA line (low level to high level).
- Ensure the time set in RIICnBRL and the bus free time.
- Clear the BBSY flag to 0 (to release the bus mastership).

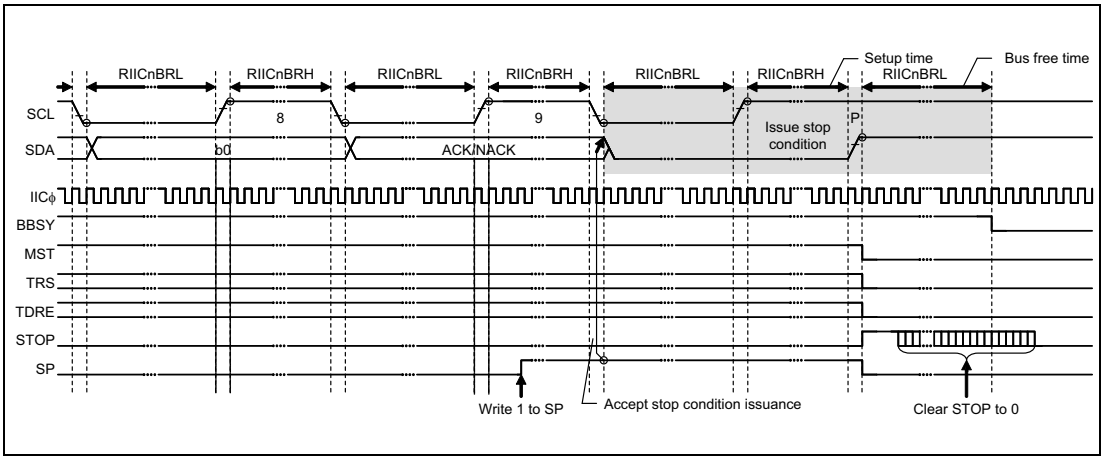

Figure 22.37 Stop Condition Issue Timing (SP Bit)

22.4.10 Bus Hanging

If the clock signals from the master and slave devices go out of synchronization due to noise or other factors, the I2C bus might hang with a fixed level on the SCL line and/or SDA line.

As measures against the bus hanging, the RIIC has a timeout function to detect hanging by monitoring the SCL line, a function for the output of an extra SCL clock cycle to release the bus from a hung state due to clock signals being out of synchronization, and the RIIC/internal reset function.

By checking the RIICnCR1.SCLO, SDAO, SCLI, and SDAI bits, it is possible to see whether the RIIC or its partner in communications is placing the low level on the SCL or SDA lines.

22.4.10.1 Timeout Function

The RIIC has the timeout function to detect an abnormality that the SCL line is held for a certain period of time. The RIIC can detect an abnormal bus state by monitoring that the SCL line is held low or high for a predetermined time.

The timeout function monitors the SCL line state and counts the low-level period or high-level period using the internal counter. The timeout function resets the internal counter each time the SCL line changes (rising or falling), but continues to count unless the SCL line changes. If the internal counter overflows due to no SCL line change, the RIIC can detect the timeout and report the bus abnormality.

The internal counter is cleared when one of the conditions is met.

(1) When RIICnMR2.TMOH=0, and RIICnMR2.TMOL=1:
The internal counter is cleared by SCL rising

(2) When RIICnMR2.TMOH=1, and RIICnMR2.TMOL=0:
The internal counter is cleared by SCL falling

(3) When RIICnMR2.TMOH=RIICnMR2.TMOL=1:
The internal counter is cleared by SCL rising or falling

This timeout function is enabled when the RIICnFER.TMOE bit is 1. It detects an abnormal bus state that the SCL line is stuck low or high during the following conditions:

- The bus is busy (RIICnCR2.BBSY flag is 1) in master mode (RIICnCR2.MST bit is 1).
- The RIIC's own slave address matches (RIICnSR1 register is not 00_H) and the bus is busy (RIICnCR2.BBSY flag is 1) in slave mode (RIICnCR2.MST bit is 0).
- The bus is free (RIICnCR2.BBSY flag is 0) while generation of a START condition is requested (RIICnCR2.ST bit is 1).

The internal counter of the timeout function works using the internal reference clock (IICϕ) set by the RIICnMR1.CKS[2:0] bits as a count source. It functions as a 16-bit counter when long mode is selected (RIICnMR2.TMOS bit = 0) or a 14-bit counter when short mode is selected (TMOS bit = 1).

The SCL line level (low/high or both levels) during which this counter is activated can be selected by the setting of the RIICnMR2.TMOH and TMOL bits. If both TMOL and TMOH bits are cleared to 0, the internal counter does not work.

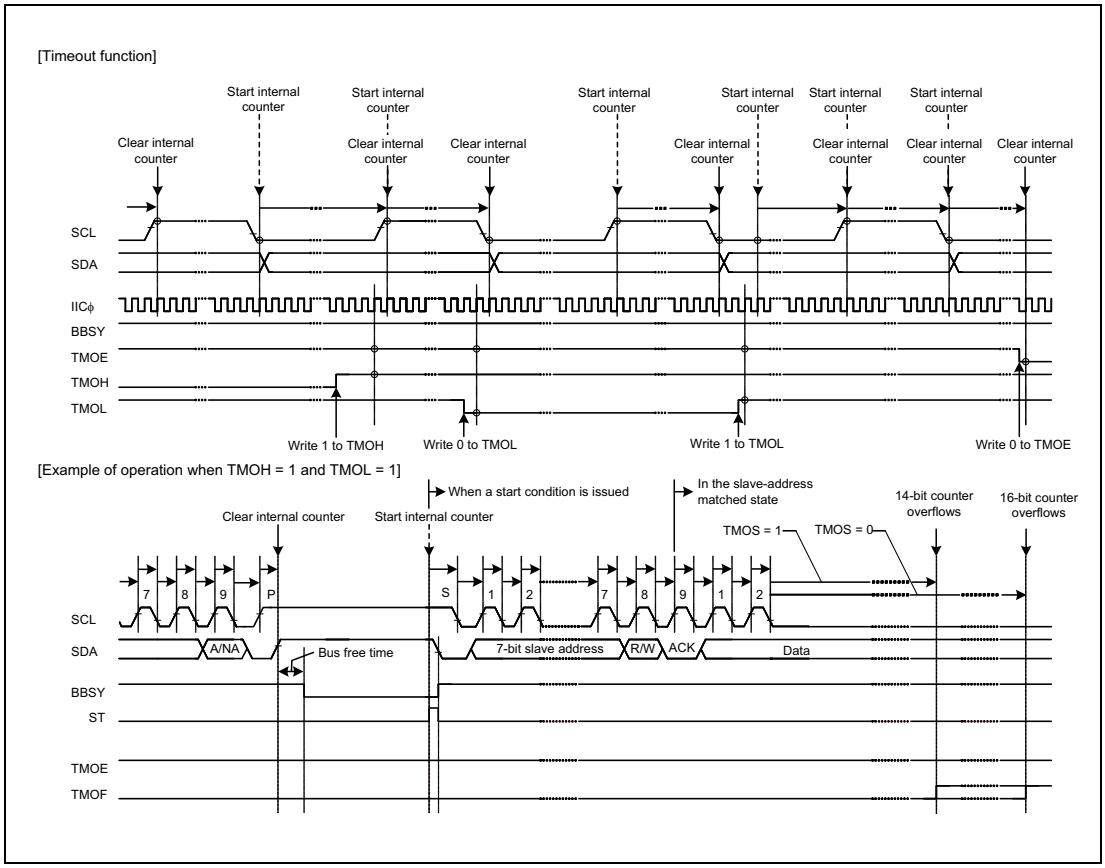

Figure 22.38 Timeout Function (TMOE, TMOS, TMOH, and TMOL Bits)

22.4.10.2 Extra SCL Clock Cycle Output Function

In master mode, the RIIC module has a facility for the output of extra SCL (clock) cycles to release the SDA line of the slave device from being held at the low level due to the master being out of synchronization with the slave device.

This function is mainly used in master mode to release the SDA line of the slave device from the state of being fixed to the low level by including extra cycles of SCL output from the RIIC with single cycles of the SCL (clock) signal as the unit in the case of a bus error where the RIIC cannot issue a stop condition because the slave device is holding the SDA line at the low level. Do not use this facility in normal situations. Using it when communications are proceeding correctly will lead to malfunctions.

When the RIICnCR1.CLO bit is set to 1 in master mode, a single cycle of the SCL clock at the frequency corresponding to the transfer rate settings (settings of the RIICnMR1.CKS[2:0] bits, and of the RIICnBRH and RIICnBRL registers) is output as an extra clock cycle. After output of this single cycle of the SCL clock, the CLO bit is automatically cleared to 0. Therefore, further extra clock cycles can be output consecutively by the software program writing 1 to the CLO bit after having read CLO = 0.

When the RIIC module is in master mode and the slave device is holding the SDA line at the low level because synchronization with the slave device has been lost due to the effects of noise, etc., the output of a stop condition is not possible. The facility for output of an extra cycle of the SCL (clock) signal can be used to output extra cycles of SCL one by one to make the slave device release the SDA line from being held at the low level, thus recovering the bus from an unusable state. Release of the SDA line by the slave device can be monitored by reading the RIICnCR1.SDAI bit. After confirming release of the SDA line by the slave device, complete communications by reissuing the stop condition.

Use this facility with the RIICnFER.MALE bit (master arbitration-lost detection disabled) cleared to 0. If the MALE bit is set to 1 (master arbitration-lost detection enabled), arbitration can be lost when the value of the RIICnCR1.SDAO bit does not match the state of the SDA line, so do not use this function.

[Additional output conditions for the SCL clock]

- In master mode and when the bus is free
- In master mode and the SCL line is not held low (the bus is busy)

Figure 22.39 shows the operation timing of the extra SCL clock cycle output function (CLO bit).

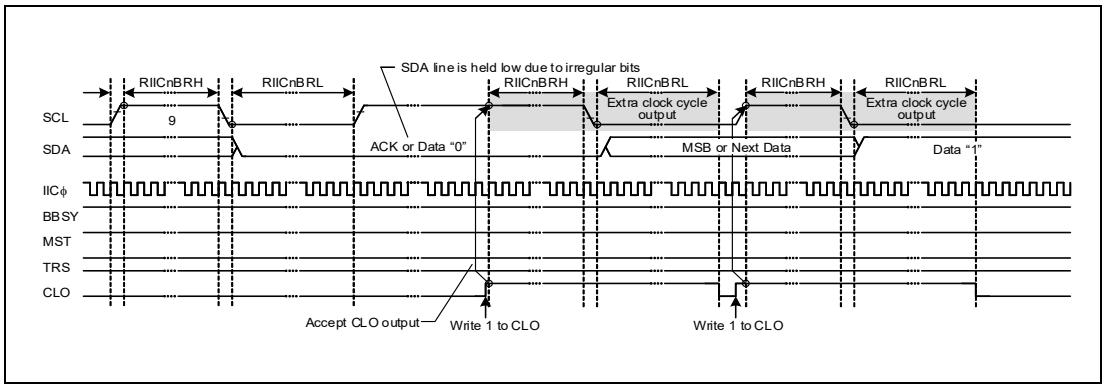

Figure 22.39 Extra SCL Clock Cycle Output Function (CLO Bit)

22.4.10.3 RIIC Reset and Internal Reset

The RIIC module incorporates a function for resetting itself. There are two types of reset. One is referred to as an RIIC reset; this initializes all registers including the RIICnCR2.BBSY flag. The other is referred to as an internal reset; this releases the RIIC from the slave-address matched state and initializes the internal counter while retaining other settings.

After issuing a reset, be sure to clear the RIICnCR1.IICRST bit to 0.

Both types of reset are effective for release from bus-hung states since both restore the output state of the SCL and SDA pins to the high impedance state.

Issuing a reset during slave operation may lead to a loss of synchronization between the master device clock and the slave device clock, so avoid this where possible. Note that monitoring of the bus state, such as for the presence of a start condition, is not possible during an RIIC reset (RIICnCR1.ICE and IICRST bits = 01_B).

For a detailed description of the RIIC and internal resets, see **Section 22.4.11, Reset Function of RIIC**.

22.4.11 Reset Function of RIIC

The RIIC has RIIC reset, and internal reset functions. In addition RIIC is cleared by ISORES. **Table 22.26** lists the scope of each reset and reset conditions.

Table 22.26 RIIC Reset Functions (1/2)

Note 1. When an internal reset is applied while the bus is free after detection of a stop condition, the setting of the BBSY flag is 0 while the bus is free following de-assertion of the internal reset signal.
When an internal reset is applied while the bus is not free, the BBSY flag is not cleared.

Section 23 CANFD Interface (RS-CANFD)

This section contains a generic description of the CANFD Interface (RS-CANFD).

The first part of this section describes all RH850/U2A-EVA specific properties, such as the number of units, register base addresses, etc. The remainder of the section describes the functions and registers of RS-CANFD.

23.1 Features RS-CANFD for RH850/U2A-EVA

23.1.1 Number of Units and Channels

This microcontroller has the following number of RS-CANFD units.

Table 23.1 Number of Units and Channels

Product Name	RH850/ U2A-EVA (516 pins)	RH850/ U2A16 (516 pins)	RH850/ U2A16 (373 pins)	RH850/ U2A16 (292 pins)	RH850/ U2A8 (373 pins)	RH850/ U2A8 (292 pins)	RH850/ U2A6 (292 pins)	RH850/ U2A6 (176 pins)	RH850/ U2A6 (156 pins)	RH850/ U2A6 (144 pins)
Number of Units	2 (n = 0, 1)	2 (n = 0, 1)	2 (n = 0, 1)	2 (n = 0, 1)	2 (n = 0, 1)	2 (n = 0, 1)	2 (n = 0, 1)	2 (n = 0, 1)	2 (n = 0, 1)	2 (n = 0, 1)

The individual products have the CANFD Interface Channels listed below.

Table 23.2 Unit Configurations and Channels

Unit Name	Channel Name	RH850/ U2A-EVA (516 pins)	RH850/ U2A16 (516 pins)	RH850/ U2A16 (373 pins)	RH850/ U2A16 (292 pins)	RH850/ U2A8 (373 pins)	RH850/ U2A8 (292 pins)	RH850/ U2A6 (292 pins)	RH850/ U2A6 (176 pins)	RH850/ U2A6 (156 pins)	RH850/ U2A6 (144 pins)
RSCFD0	CAN0	√	√	√	√	√	√	√	√	√	√
	CAN1	√	√	√	√	√	√	√	√	√	√
	CAN2	√	√	√	√	√	√	√			√
	CAN3	√	√	√	√	√	√	√	√		
	CAN4	√	√	√	√	√	√	√	√	√	√
	CAN5	√	√	√	√	√	√	√	√		
	CAN6	√	√	√	√	√	√	√	√	√	√
	CAN7	√	√	√	√	√	√	√	√		√
RSCFD1	CAN8	√	√	√	√	√	√	√	√	√	√
	CAN9	√	√	√	√	√	√	√	√	√	
	CAN10	√	√	√	√	√	√	√	√	√	
	CAN11	√	√	√	√	√	√	√	√	√	
	CAN12	√	√	√	√	√	√				
	CAN13	√	√	√	√	√	√				
	CAN14	√	√	√	√	√	√				
	CAN15	√	√	√	√	√	√				

Table 23.3 Indices (1/2)

Index	Description
n	Throughout this section, the individual RS-CANFD units are generically indicated by the index “n”; for example, RSCFDnCFDGCTR is the global control register of the RSCFDn unit.
m	Throughout this section, the individual channels of RS-CANFD units are generically indicated by the index “m”; for example, RSCFDnCFDCmSTS is the channel m status register.
w	The individual channels of both RSCFD0 and RSCFD1 units are generically indicated by the index “w”; for example, CANwRX is receive data input.
j	The individual registers associated with receive rule table are generically indicated by the index “j”; for example, RSCFDnCFDGAFLIDj is the receive rule ID register.
k	The individual transmit/receive FIFO buffers are generically indicated by the index “k”; for example, RSCFDnCFDCFCCk is the transmit/receive FIFO buffer configuration/control register.
x	The individual receive FIFO buffers are generically identified by the index “x”; for example, RSCFDnCFDRFSTSx is the receive FIFO buffer status register.
d	Data field registers of receive buffers, transmit buffers,transmit/receive FIFO buffers, and receive FIFO buffers are identified by the index “d”. For example, the receive message buffer data field register is described as RSCFDnCFDRMDFd.
p	The individual transmit buffers are generically indicated by the index “p”; for example, RSCFDnCFDTMCp is the transmit buffer control register.
b	Message buffer component index of receive message buffer, receive FIFO, transmit/receive FIFO, transmit message buffer are identified by “b”. For example, the receive message buffer component register is described as RSCFDnCFDRMBCPbm.
q	Number of data byte of data field register are identified by “q”.
r	The individual RAM tests for CAN are generically indicated by the index “r”; for example, RSCFDnCFDRPGACCr is the RAM test page access register.
y	The transmit message buffer transmission are generically indicated by index “y”; for example, RSCFDnCFDTMTRSTSy is the transmit message buffer transmission request status register.
v	A global register which setting for 02 channels indicated by the index “v”; for example, RSCFDnCFDGAFLCFGv is the global AFL configuration register.
s	A global register which setting for 04 channels indicated by the index “s”; for example, RSCFDnCFDGTINTSTSs is the global transmit interrupt status register.

Table 23.3 Indices (2/2)

Index	Description
o	When a global register setting for 04 channels, the channel number indicated by the index “o”; for example, RSCFDnCFDGTINTSTSs.CFOTIFo is the Transmit/Receive FIFO One Frame Transmission Interrupt Flag Channel (o + s * 4).
t	The receive message buffer new data are generically indicated by index "t"; for example, RSCFDnCFDRMNDt is the receive message buffer new data register.
u	The New Data Flag status for the corresponding RX Message Buffer is indicated by index "u"; for example RSCFDnCFDRMNDt.RMNSu is the the NewData Flag status for the corresponding RX Message Buffer.
c	The Message Buffer Component Register index is indicated by index "c"; for example, in register RSCFDnCFDRMBCPbm.Rc, "c" is RX Message Buffer Component Register index.

Note 1. The functions and descriptions of registers in this section are for the RS-CANFDs that has 8 channels (m = 0 to 7). When referring to information with indices, regard the index values as the ones corresponding to the target product.

Note 2. In some figure or table, this section use acronyms: CH, Ch, Ch instead of "channel".

The following table lists the values of indices for individual products.

Table 23.4 Indices for Individual Products

Index Correspondence of Each Product																
	RH850/ U2A-EVA (516 pins)	**RH850/ U2A16 (516 pins)**	**RH850/ U2A16 (373 pins)**	**RH850/ U2A16 (292 pins)**	**RH850/ U2A8 (373 pins)**	**RH850/ U2A8 (292 pins)**	**RH850/ U2A6 (292 pins)**		**RH850/ U2A6 (176 pins)**		**RH850/ U2A6 (156 pins)**		**RH850/ U2A6 (144 pins)**	
n	n = 0, 1						n = 0	n = 1	n = 0	n = 1	n = 0	n = 1	n = 0	n = 1
m	m = 0 to 7						m = 0 to 7	m = 0 to 3	m = 0, 1, 3 to 7	m = 0 to 3	m = 0, 1, 4, 6	m = 0 to 3	m = 0 to 2, 4, 6, 7	m = 0
w	w = 0 to 15						w = 0 to 7	w = 8 to 11	w = 0, 1, 3 to 7	w = 8 to 11	w = 0, 1, 4, 6	w = 8 to 11	w = 0 to 2, 4, 6, 7	w = 8
j	j = 0 to 15						j = 0 to 15	j = 0 to 15	j = 0 to 15	j = 0 to 15	j = 0 to 15	j = 0 to 15	j = 0 to 15	j = 0 to 15
k	k = 0 to 23						k = 0 to 23	k = 0 to 11	k = 0 to 5, 9 to 23	k = 0 to 11	k = 0 to 5, 12 to 14, 18 to 20	k = 0 to 11	k = 0 to 8, 12 to 14, 18 to 23	k = 0 to 2
x	x = 0 to 7						x = 0 to 7	x = 0 to 7	x = 0 to 7	x = 0 to 7	x = 0 to 7	x = 0 to 7	x = 0 to 7	x = 0 to 7
d	d = 0 to 15						d = 0 to 15	d = 0 to 15	d = 0 to 15	d = 0 to 15	d = 0 to 15	d = 0 to 15	d = 0 to 15	d = 0 to 15
p	p = 0 to 511						p = 64*m to 64*m + 15, 64*m + 32 to 64*m + 47							
b	Refer to **Table 23.106, Message Buffer Component Register Start Addresses**													
q	q = 4						q = 4	q = 4	q = 4	q = 4	q = 4	q = 4	q = 4	q = 4
r	r = 0 to 63						r = 0 to 63	r = 0 to 63	r = 0 to 63	r = 0 to 63	r = 0 to 63	r = 0 to 63	r = 0 to 63	r = 0 to 63
y	y = 0 to 15						y = 0 to 15	y = 0 to 7	y = 0, 1, 2, 3, 6 to 15	y = 0 to 7	y = 0 to 3, 8, 9, 12, 13	y = 0 to 7	y = 0 to 5, 8, 9, 12 to 15	y = 0, 1
v	v = 0 to 3						v = 0 to 3	v = 0 to 1	v = 0 to 3	v = 0 to 1	v = 0, 2, 3	v = 0 to 1	v = 0 to 3	v = 0
s	s = 0 to 1						s = 0 to 1	s = 0	s = 0 to 1	s = 0	s = 0 to 1	s = 0	s = 0 to 1	s = 0
o	o = 0 to 3						o = 0 to 3	o = 0 to 3	o = 0 to 3	o = 0 to 3	o = 0 to 2	o = 0 to 3	o = 0 to 3	o = 0
t	t = 0 to 3						t = 0 to 3	t = 0 to 1	t = 0 to 3	t = 0 to 1	t = 0, 2, 3	t = 0 to 1	t = 0 to 3	t = 0
u	u = 0 to 127						u = 0 to 127	u = 0 to 63	u = 0 to 31, 48 to 127	u = 0 to 63	u = 0 to 31, 64 to 79, 96 to 111	u = 0 to 63	u = 0 to 47, 64 to 79, 96 to 127	u = 0 to 15
c	c = 0 to 18						c = 0 to 18	c = 0 to 18	c = 0 to 18	c = 0 to 18	c = 0 to 18	c = 0 to 18	c = 0 to 18	c = 0 to 18

23.1.2 Register Base Addresses

RSCFDn base addresses are listed in the following table.

RSCFDn register addresses are given as offsets from the base addresses in general.

Table 23.5 Register Base Addresses

Base Address Name	Base Address	Bus Group
<RSCFD0_base>	FFF5 0000_H	P-Bus Group 8
<RSCFD1_base>	FFD0 0000_H	P-Bus Group 3

23.1.3 Clock Supply

The RSCFDn clock supply is shown in the following table.

Table 23.6 Clock Supply

Unit Name	Clock for the Unit	Supply Clock Name
RSCFDn	clk_xincan	RS-CANFD clock CLK_RCANOSC
	clkc	High-speed peripheral clock CLK_HSB
	pclk	High-speed peripheral clock CLK_HSB
	ramclk	Peripheral ultra high speed clock CLK_UHSB

The operating frequency of the RSCFDn depends on the transfer rate and the number of channels in use. **Table 23.7** shows the range of the frequency.

Table 23.7 Range of Operating Frequency Depending on the Transfer Rate and the Number of Channels in Use

Condition		Range of Operating Frequency			
Transfer Rate	No. of Channels in Use	pclk	clk_xincan*1	clkc*1	ramclk
(Transfer Rate) ≤ 2Mbps	Max. 8 ch	80 MHz (fixed)	Max. 40 MHz	Max. 80 MHz	160 MHz (fixed)
2Mbps<(Transfer Rate) ≤ 5Mbps	Max. 8 ch	80 MHz (fixed)	(do not select)	Max. 80 MHz	160 MHz (fixed)
5Mbps<(Transfer Rate) ≤ 8Mbps	Max. 6 ch	80 MHz (fixed)	(do not select)	80 MHz	160 MHz (fixed)

Note 1. Setting the DCS bit in the RSCFDnCFDGCFG register enables to select either clk_xincan or clkc.

23.1.4 Interrupt Requests and Error Notifications

The RSCFDn interrupt requests are listed in the following table.

Table 23.8 Interrupt Requests (1/2)

Unit Interrupt Signal		Description	Interrupt Number
RSCFD0			
INTRCANGERR0		CAN global error interrupt	296
INTRCANGRECC0		CAN receive FIFO interrupt	297
CAN0	INTRCAN0ERR	CAN0 error interrupt	298
	INTRCAN0REC	CAN0 transmit/receive FIFO receive completion interrupt	299
	INTRCAN0TRX	CAN0 transmit interrupt	300
CAN1	INTRCAN1ERR	CAN1 error interrupt	301
	INTRCAN1REC	CAN1 transmit/receive FIFO receive completion interrupt	302
	INTRCAN1TRX	CAN1 transmit interrupt	303
CAN2	INTRCAN2ERR	CAN2 error interrupt	304
	INTRCAN2REC	CAN2 transmit/receive FIFO receive completion interrupt	305
	INTRCAN2TRX	CAN2 transmit interrupt	306
CAN3	INTRCAN3ERR	CAN3 error interrupt	307
	INTRCAN3REC	CAN3 transmit/receive FIFO receive completion interrupt	308
	INTRCAN3TRX	CAN3 transmit interrupt	309
CAN4	INTRCAN4ERR	CAN4 error interrupt	310
	INTRCAN4REC	CAN4 transmit/receive FIFO receive completion interrupt	311
	INTRCAN4TRX	CAN4 transmit interrupt	312
CAN5	INTRCAN5ERR	CAN5 error interrupt	313
	INTRCAN5REC	CAN5 transmit/receive FIFO receive completion interrupt	314
	INTRCAN5TRX	CAN5 transmit interrupt	315
CAN6	INTRCAN6ERR	CAN6 error interrupt	316
	INTRCAN6REC	CAN6 transmit/receive FIFO receive completion interrupt	317
	INTRCAN6TRX	CAN6 transmit interrupt	318
CAN7	INTRCAN7ERR	CAN7 error interrupt	319
	INTRCAN7REC	CAN7 transmit/receive FIFO receive completion interrupt	320
	INTRCAN7TRX	CAN7 transmit interrupt	321
RSCFD1			
INTRCANGERR1		CAN global error interrupt	322
INTRCANGRECC1		CAN receive FIFO interrupt	323
CAN8	INTRCAN8ERR	CAN8 error interrupt	324
	INTRCAN8REC	CAN8 transmit/receive FIFO receive completion interrupt	325
	INTRCAN8TRX	CAN8 transmit interrupt	326
CAN9	INTRCAN9ERR	CAN9 error interrupt	327
	INTRCAN9REC	CAN9 transmit/receive FIFO receive completion interrupt	328
	INTRCAN9TRX	CAN9 transmit interrupt	329
CAN10	INTRCAN10ERR	CAN10 error interrupt	330
	INTRCAN10REC	CAN10 transmit/receive FIFO receive completion interrupt	331
	INTRCAN10TRX	CAN10 transmit interrupt	332

Table 23.8 Interrupt Requests (2/2)

Unit Interrupt Signal		Description	Interrupt Number
CAN11	INTRCAN11ERR	CAN11 error interrupt	333
	INTRCAN11REC	CAN11 transmit/receive FIFO receive completion interrupt	334
	INTRCAN11TRX	CAN11 transmit interrupt	335
CAN12	INTRCAN12ERR	CAN12 error interrupt	336
	INTRCAN12REC	CAN12 transmit/receive FIFO receive completion interrupt	337
	INTRCAN12TRX	CAN12 transmit interrupt	338
CAN13	INTRCAN13ERR	CAN13 error interrupt	339
	INTRCAN13REC	CAN13 transmit/receive FIFO receive completion interrupt	340
	INTRCAN13TRX	CAN13 transmit interrupt	341
CAN14	INTRCAN14ERR	CAN14 error interrupt	342
	INTRCAN14REC	CAN14 transmit/receive FIFO receive completion interrupt	343
	INTRCAN14TRX	CAN14 transmit interrupt	344
CAN15	INTRCAN15ERR	CAN15 error interrupt	345
	INTRCAN15REC	CAN15 transmit/receive FIFO receive completion interrupt	346
	INTRCAN15TRX	CAN15 transmit interrupt	347

Table 23.9 sDMA/DTS Requests (1/2)

Interrupt symbol name	Unit Interrupt Signal	Description	sDMA Trigger Number	DTS Trigger Number
INTRCANRFDREQ15	can_rf_dmareq[7]	Receive FIFO DMA request 15	Group0 - 60	Group0 - 49
INTRCANRFDREQ14	can_rf_dmareq[6]	Receive FIFO DMA request 14	Group0 - 59	Group0 - 48
INTRCANRFDREQ13	can_rf_dmareq[5]	Receive FIFO DMA request 13	Group0 - 58	Group0 - 47
INTRCANRFDREQ12	can_rf_dmareq[4]	Receive FIFO DMA request 12	Group0 - 57	Group0 - 46
INTRCANRFDREQ11	can_rf_dmareq[3]	Receive FIFO DMA request 11	Group0 - 56	Group0 - 45
INTRCANRFDREQ10	can_rf_dmareq[2]	Receive FIFO DMA request 10	Group0 - 55	Group0 - 44
INTRCANRFDREQ9	can_rf_dmareq[1]	Receive FIFO DMA request 9	Group0 - 54	Group0 - 43
INTRCANRFDREQ8	can_rf_dmareq[0]	Receive FIFO DMA request 8	Group0 - 53	Group0 - 42
INTRCANRFDREQ7	can_rf_dmareq[7]	Receive FIFO DMA request 7	Group0 - 52	Group0 - 41
INTRCANRFDREQ6	can_rf_dmareq[6]	Receive FIFO DMA request 6	Group0 - 51	Group0 - 40
INTRCANRFDREQ5	can_rf_dmareq[5]	Receive FIFO DMA request 5	Group0 - 50	Group0 - 39
INTRCANRFDREQ4	can_rf_dmareq[4]	Receive FIFO DMA request 4	Group0 - 49	Group0 - 38
INTRCANRFDREQ3	can_rf_dmareq[3]	Receive FIFO DMA request 3	Group0 - 48	Group0 - 37
INTRCANRFDREQ2	can_rf_dmareq[2]	Receive FIFO DMA request 2	Group0 - 47	Group0 - 36
INTRCANRFDREQ1	can_rf_dmareq[1]	Receive FIFO DMA request 1	Group0 - 46	Group0 - 35
INTRCANRFDREQ0	can_rf_dmareq[0]	Receive FIFO DMA request 0	Group0 - 45	Group0 - 34
INTRCANCFDREQ15	can_cf_dmareq[7]	Common FIFO DMA request 15	Group0 - 44	Group0 - 33
INTRCANCFDREQ14	can_cf_dmareq[6]	Common FIFO DMA request 14	Group0 - 43	Group0 - 32
INTRCANCFDREQ13	can_cf_dmareq[5]	Common FIFO DMA request 13	Group0 - 42	Group0 - 31
INTRCANCFDREQ12	can_cf_dmareq[4]	Common FIFO DMA request 12	Group0 - 41	Group0 - 30
INTRCANCFDREQ11	can_cf_dmareq[3]	Common FIFO DMA request 11	Group0 - 40	Group0 - 29
INTRCANCFDREQ10	can_cf_dmareq[2]	Common FIFO DMA request 10	Group0 - 39	Group0 - 28
INTRCANCFDREQ9	can_cf_dmareq[1]	Common FIFO DMA request 9	Group0 - 38	Group0 - 27
INTRCANCFDREQ8	can_cf_dmareq[0]	Common FIFO DMA request 8	Group0 - 37	Group0 - 26

Table 23.9 sDMA/DTS Requests (2/2)

Interrupt symbol name	Unit Interrupt Signal	Description	sDMA Trigger Number	DTS Trigger Number
INTRCANCFDREQ7	can_cf_dmareq[7]	Common FIFO DMA request 7	Group0 - 36	Group0 - 25
INTRCANCFDREQ6	can_cf_dmareq[6]	Common FIFO DMA request 6	Group0 - 35	Group0 - 24
INTRCANCFDREQ5	can_cf_dmareq[5]	Common FIFO DMA request 5	Group0 - 34	Group0 - 23
INTRCANCFDREQ4	can_cf_dmareq[4]	Common FIFO DMA request 4	Group0 - 33	Group0 - 22
INTRCANCFDREQ3	can_cf_dmareq[3]	Common FIFO DMA request 3	Group0 - 32	Group0 - 21
INTRCANCFDREQ2	can_cf_dmareq[2]	Common FIFO DMA request 2	Group0 - 31	Group0 - 20
INTRCANCFDREQ1	can_cf_dmareq[1]	Common FIFO DMA request 1	Group0 - 30	Group0 - 19
INTRCANCFDREQ0	can_cf_dmareq[0]	Common FIFO DMA request 0	Group0 - 29	Group0 - 18

NOTE

For selecting the DMA requests, see **Section 7.1.5, sDMAC Transfer Requests**.

For selecting the DTS requests, see **Section 8.1.5, DTS Transfer Requests**.

This module has no error notifications.

23.1.5 Reset Sources

Table 23.10 Reset Sources

Unit Name	Register Name	Reset Condition						
		Power On Reset	System Reset 1	System Reset 2	Application Reset	DeepSTOP Reset	Module Reset	JTAG Reset
RSCFDn	All registers	√	√	√	√	√	√	—

23.1.6 External Input/Output Signals

External input/output signals of RSCFDn are listed below.

Table 23.11 External Input/Output Signals

Unit Signal Name	Description	Alternative Port Pin Signal
RSCFD0		
CANwRX (w = 0 to 7)	CANw receive data input	CANwRX (w = 0 to 7)
CANwTX (w = 0 to 7)	CANw transmit data output	CANwTX (w = 0 to 7)
RSCFD1		
CANwRX (w = 8 to 15)	CANw receive data input	CANwRX (w = 8 to 15)
CANwTX (w = 8 to 15)	CANw transmit data output	CANwTX (w = 8 to 15)

23.2 Overview

23.2.1 Functional Overview

Table 23.12 shows the RS-CANFD module specifications. **Figure 23.1** shows the RS-CANFD module block diagram.

Table 23.12 RS-CANFD Module Specifications (1/3)

Item	Specification
Protocol	ISO 11898-1 (2015) compliant Using frames is selectable by switching interface modes.
Communication speed	Classical CAN mode: • Maximum 1 Mbps $\text{Communication speed (CANm bit time clock)} = \frac{1}{\text{CANm bit time}}$ CANm bit time = CANmTq × Tq count per bit $\text{CANmTq} = \frac{\text{(NBRP[9:0] bits in the RSCFDnCFDCmNCFG register + 1)}}{\text{fCAN}}$ fCAN: Frequency of CAN clock (selected by the DCS bit in the RSCFDnCFDGCFG register) CANFD mode: • Nominal bit rate: max.1 Mbps, data bit rate: max. 8 Mbps $\text{Transmission rate (CANm nominal bit time clock)} = \frac{1}{\text{CANm nominal bit time}}$ $\text{Transmission rate (CANm data bit time clock)} = \frac{1}{\text{CANm data bit time}}$ CANm nominal bit time = CANmTq(N) × Tq count per nominal bit CANm data bit time = CANmTq(D) × Tq count per data bit $\text{CANmTq(N)} = \frac{\text{(NBRP[9:0] bits in the RSCFDnCFDCmNCFG register + 1)}}{\text{fCAN}}$ $\text{CANmTq(D)} = \frac{\text{(DBRP[7:0] bits in the RSCFDnCFDCmDCFG register + 1)}}{\text{fCAN}}$ fCAN: Frequency of CAN clock (selected by the DCS bit in the RSCFDnCFDGCFG register) n = 0, 1 m = 0 to 7 Tq: Time quantum
Buffer	(Number of TXMB + Number of RXMB) x (Number of Channel) in total when 64 byte data payload. • Individual buffers: (Number of TXMB) x (Number of Channel) buffers. Transmit buffer: (Number of TXMB) buffers per channel. Transmit queue: Four queue per channel (shared with the transmit buffer; up to (Number of TXMB) buffers allocatable) • Shared buffers: (Number of RXMB) x (Number of Channel), shared among all the CAN channels in a unit. Receive buffer: 0 to 16 buffers for one channel Receive FIFO buffer: 8 FIFO buffers (up to 128 buffers allocatable to each) Transmit/Receive FIFO buffer: 3 FIFO buffers per channel (up to 128 buffers allocatable to each) • ECC included
Reception function	• Receives data frames and remote frames. • Selects ID format (standard ID, extended ID, or both IDs) to be received. • Sets interrupt enable/disable for each FIFO. • Mirror function (reception of message transmitted from message the own CAN node) • Timestamp function (to record message reception time as a 16-bit timer value)

Table 23.12 RS-CANFD Module Specifications (2/3)

Item	Specification
Reception filter function	• Selects receive messages according to: (Number of AFL entry) x (Number of Channel) receive rules. • Sets the number of receive rules (U2A-EVA, U2A16, U2A8: maximum is 384; U2A6: maximum is 255) for each channel. • Acceptance filter processing: Sets ID and mask for each receive rule. • DLC filter processing: Enables DLC filter check for each acceptance rule.
Receive message transfer function	• Routing function Transfers receive messages to arbitrary destinations (can be transferred to up to 8 buffers) Transfer destination: Receive buffer, receive FIFO buffer, transmit/receive FIFO buffer, and/or transmit queue. • Label addition function (Pointer / Pointer field) Stores label information together with a message in a receive buffer, FIFO buffer, and transmit queue.
Transmission function	• Transmits data frames and remote frames. • Selects ID format (standard ID, extended ID, or both IDs) to be transmitted. • Sets interrupt enable/disable for each transmit buffer, transmit/receive FIFO buffer, and transmit queue. • Selects ID priority transmission or transmit buffer number priority transmission. • Transmit request can be aborted (possible to confirm with a flag) • One-shot transmission function
Interval transmission function	Transmit messages at configurable intervals (transmit mode or gateway mode of transmit/receive FIFO buffers)
Transmit queue function	Transmits all stored messages according to the ID priority.
Transmit history function	Stores the history information of transmission-completed messages. Adds timestamp (recording message transmission time as a 16-bit timer value) to the history information.
Gateway function	Transmits a received message automatically.
Bus off recovery mode selection	Selects the method for returning from bus off state. • ISO 11898-1 (2015) compliant • Automatic entry to channel halt mode at bus-off entry • Automatic entry to channel halt mode at bus-off end • Transition to channel halt mode by program request • Transition to the error-active state by program request (forcible return from bus-off state)
Error status monitoring	• Monitors CAN protocol errors (stuff error, form error, ACK error, CRC error, bit error, ACK delimiter error, and bus lock). • Detects error status transitions (error warning, error passive, bus off entry, and bus off recovery) • Reads the error counter. • Monitors DLC errors.
Interrupt source	[Number of units] x 2 + [Number of channels] x 3 sources in total • Global Interrupts (4 sources) – Receive FIFO interrupt for unit 0/1 – Global error interrupt for unit 0/1 • Channel interrupts (3 sources/channel) – CANm transmit interrupt – CANm transmit/receive FIFO receive complete interrupt (in receive mode, gateway mode) – CANm error interrupt

Table 23.12 RS-CANFD Module Specifications (3/3)

Item	Specification
CAN stop mode	Reduces power consumption by stopping clock supply to the RS-CANFD module.
CAN clock source	Selects the clkc or the clk_xincan. As for the range of operating frequency, see **Table 23.7**.
Test function	Test function for user evaluation • Listen-only mode • Self-test mode 0 (external loopback) • Self-test mode 1 (internal loopback) • Restricted operation mode • RAM test (read/write test) • Internal CAN Bus Communication Test Mode [CRC error test enabled]

23.2.2 Interface Modes

The RS-CANFD has two interface modes.

- Classical CAN mode: Handles only classical CAN frames.
- CANFD mode: Handles classical CAN frames and CANFD frames.

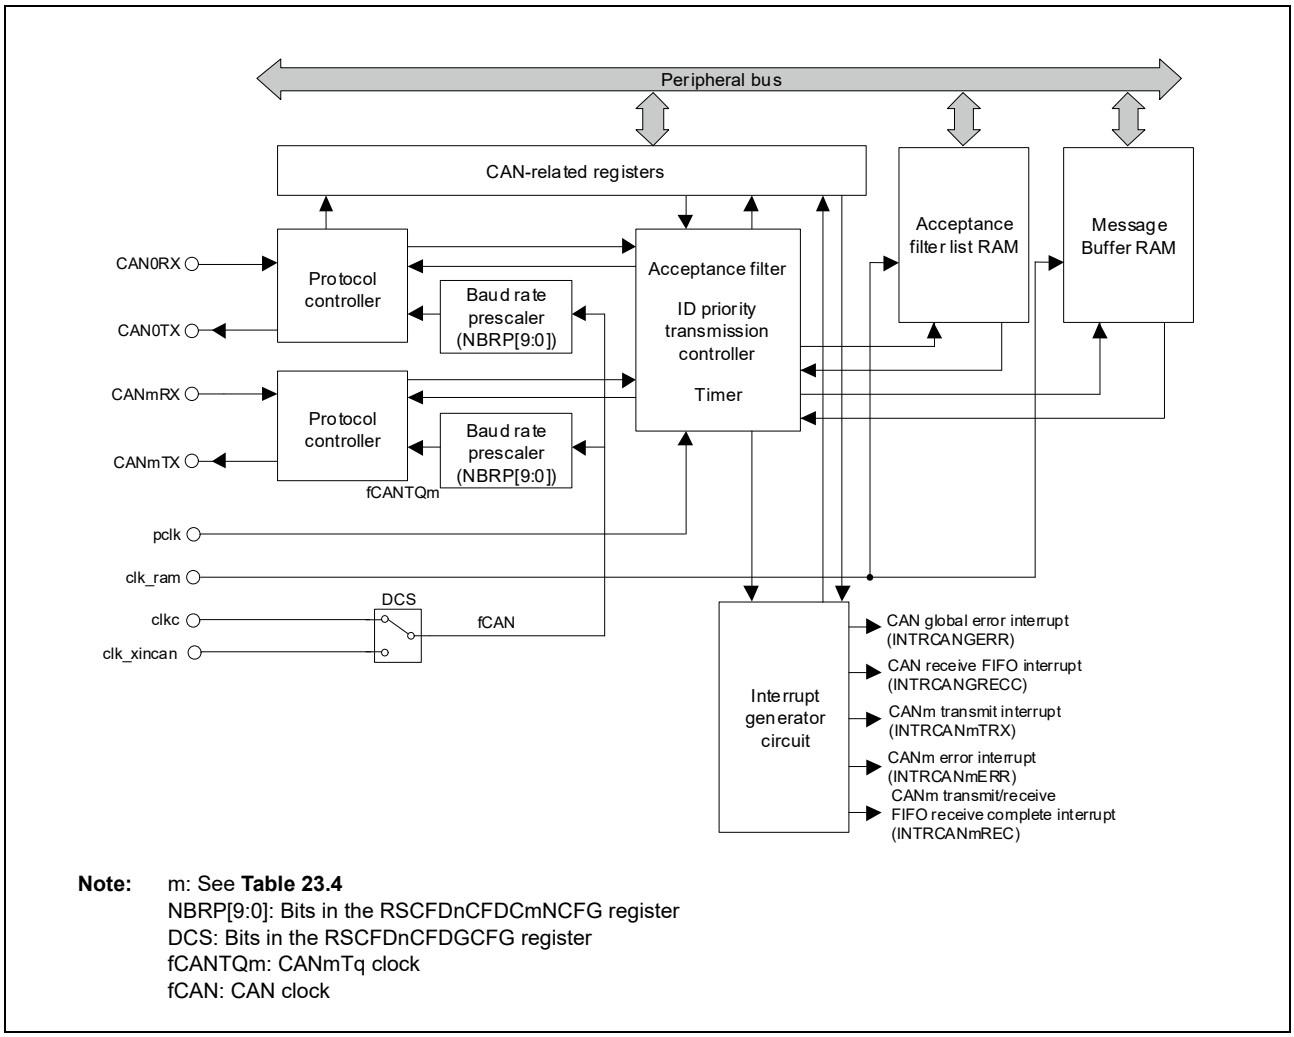
Interface modes are switched by the FDOE bit and CLOE bit in the RSCFDnCFDCmFDCFG register.

23.2.3 CANFD Protocol

This product supports CANFD according to the ISO 11898-1 (2015) protocol that specifies the new CRC field including stuff counters.

23.2.4 Block Diagram

In CANFD mode, different clock signals are input to the baud rate prescaler and the protocol controller respectively. See **Section 23.5.1.3, Baud Rate**.



Note: m: See **Table 23.4**
NBRP[9:0]: Bits in the RSCFDnCFDCmNCFG register
DCS: Bits in the RSCFDnCFDGCFG register
fCANTQm: CANmTq clock
fCAN: CAN clock

Figure 23.1 RS-CANFD Module Block Diagram

Tx/Rx:

Input/Output pins of the CAN module

Protocol controller:

Handles CAN protocol processing such as bus arbitration, bit timing at transmission and reception, stuffing, error handling, etc.

Acceptance filter list RAM:

This RAM is used to store the message acceptance filtering entries for all channels. Each acceptance filter entry has an individual ID, data length code, data field, message pointer for upper layer application usage and message direction pointer. The AFLRAM is divided in two parts to accelerate the AFL access process.

Message Buffer RAM:

This RAM is used to store messages after reception or for transmission using a normal Message Buffer or a FIFO. Each message entry has an individual ID, data length code, data field, message pointer for upper layer application usage and a time stamp.

Acceptance filter:

Performs filtering of received messages. The entries in the Acceptance filter list RAM are used for the filtering process.

Timer:

Two timers

- Reception Timestamp function
- Transmission separation time for FIFO Buffers

Interrupt generator:

Generates several types of global and channel interrupts

CAN SFRs:

Register associated with CAN. Refer to **Section 23.3**.

23.3 Registers

This section describes all registers of RS-CANFD.

23.3.1 List of Registers

The 'Value after Reset' shown in the table for the RAM area, consisting of RSCFDnCFDGAFLIDj, RSCFDnCFDGAFLMj, RSCFDnCFDGAFLP0j, RSCFDnCFDGAFLP1j, RSCFDnCFDRMBCPb, RSCFDnCFDRFMBCPb, RSCFDnCFDCFMBCPb, RSCFDnCFDTMBCPb, RSCFDnCFDTHLACC0m, RSCFDnCFDTHLACC1m and RSCFDnCFDRPGACCr is True, after, initialization after HW Reset. Refer to **Section 23.5.2, CAN Module Configuration after H/W Reset** for details of the initialization process.

Also for the RAM area, if a write access with a size of 8 or 16 bits is done then the RS-CANFD module does a read modify write access to the RAM location, because the RAM requires a 32-bit access via the ECC module.

In case of single bit error the correct data will be written back.

In case of multiple bit errors unknown data will be written back.

Note: The RAM area is initialized after HW reset, refer **Section 23.5.2, CAN Module Configuration after H/W Reset**.

Users should not access the space where the register is not assigned.

The read data from the space where the register is not assigned is unknown.

RSCFD registers are listed in the table below.
For details about <RSCFDn_base>, see **Section 23.1.2, Register Base Addresses**.

Table 23.13 Registers (1/4)

Register Name	Symbol	Address	Access Size	Access Protection	
				PBG	Other
Channel m Nominal Bit Rate Configuration Register	RSCFDnCFDCmNCFG	<RSCFDn_base> + 0000_H + m×0010_H	8, 16, 32	*1	—
Channel m Control Register	RSCFDnCFDCmCTR	<RSCFDn_base> + 0004_H + m×0010_H	8, 16, 32	*1	—
Channel m Status Register	RSCFDnCFDCmSTS	<RSCFDn_base> + 0008_H + m×0010_H	8, 16, 32	*1	—
Channel m Error Flag Register	RSCFDnCFDCmERFL	<RSCFDn_base> + $000C_H$ + m×0010_H	8, 16, 32	*1	—
Global Configuration Register	RSCFDnCFDGCFG	<RSCFDn_base> + 0084_H	8, 16, 32	*2	—
Global Control Register	RSCFDnCFDGCTR	<RSCFDn_base> + 0088_H	8, 16, 32	*2	—
Global Status Register	RSCFDnCFDGSTS	<RSCFDn_base> + $008C_H$	8, 16, 32	*2	—
Global Error Flag Register	RSCFDnCFDGERFL	<RSCFDn_base> + 0090_H	8, 16, 32	*2	—
Global Timestamp Counter Register	RSCFDnCFDGTSC	<RSCFDn_base> + 0094_H	16, 32	*2	—
Global Acceptance Filter List Entry Control Register	RSCFDnCFDGAFLECTR	<RSCFDn_base> + 0098_H	8, 16, 32	*2	—
Global Acceptance Filter List Configuration Register v	RSCFDnCFDGAFLCFGv	<RSCFDn_base> + $009C_H$ + v×0004_H	8, 16, 32	*2	—
Receive Message Buffer Number Register	RSCFDnCFDRMNB	<RSCFDn_base> + $00AC_H$	8, 16, 32	*2	—
Receive Message Buffer New Data Register t	RSCFDnCFDRMNDt	<RSCFDn_base> + $00B0_H$ + t×0004_H	8, 16, 32	*2	—
Receive FIFO Configuration / Control Register x	RSCFDnCFDRFCCx	<RSCFDn_base> + $00C0_H$ + x×0004_H	8, 16, 32	*2	—
Receive FIFO Status Register x	RSCFDnCFDRFSTSx	<RSCFDn_base> + $00E0_H$ + x×0004_H	8, 16, 32	*2	—
Receive FIFO Pointer Control Register x	RSCFDnCFDRFPCTRx	<RSCFDn_base> + 0100_H + x×0004_H	8, 16, 32	*2	—
Transmit/Receive FIFO Configuration / Control Register k	RSCFDnCFDCFCCk	<RSCFDn_base> + 0120_H + k×0004_H	8, 16, 32	*1	—
Transmit/Receive FIFO Configuration / Control Enhancement Register k	RSCFDnCFDCFCCEk	<RSCFDn_base> + 0180_H + k×0004_H	8, 16, 32	*1	—
Transmit/Receive FIFO Status Register k	RSCFDnCFDCFSTSk	<RSCFDn_base> + $01E0_H$ + k×0004_H	8, 16, 32	*1	—

Table 23.13 Registers (2/4)

Register Name	Symbol	Address	Access Size	Access Protection	
				PBG	Other
Transmit/Receive FIFO Pointer Control Register k	RSCFDnCFDCFPCTRk	<RSCFDn_base> + 0240_H + k×0004_H	8, 16, 32	*1	—
FIFO Empty Status Register	RSCFDnCFDFESTS	<RSCFDn_base> + $02A0_H$	8, 16, 32	*2	—
FIFO Full Status Register	RSCFDnCFDFFSTS	<RSCFDn_base> + $02A4_H$	8, 16, 32	*2	—
FIFO Message Lost Status Register	RSCFDnCFDFMSTS	<RSCFDn_base> + $02A8_H$	8, 16, 32	*2	—
Receive FIFO Interrupt Flag Status Register	RSCFDnCFDRFISTS	<RSCFDn_base> + $02AC_H$	8, 16, 32	*2	—
Transmit/Receive FIFO Receive Interrupt Flag Status Register	RSCFDnCFDCFRISTS	<RSCFDn_base> + $02B0_H$	8, 16, 32	*2	—
Transmit/Receive FIFO Transmit Interrupt Flag Status Register	RSCFDnCFDCFTISTS	<RSCFDn_base> + $02B4_H$	8, 16, 32	*2	—
Transmit/Receive FIFO One Frame Receive Interrupt Flag Status Register	RSCFDnCFDCFOFRISTS	<RSCFDn_base> + $02B8_H$	8, 16, 32	*2	—
Transmit/Receive FIFO One Frame Transmit Interrupt Flag Status Register	RSCFDnCFDCFOFTISTS	<RSCFDn_base> + $02BC_H$	8, 16, 32	*2	—
Transmit/Receive FIFO Message Over Write Status Register	RSCFDnCFDCFMOWSTS	<RSCFDn_base> + $02C0_H$	8, 16, 32	*2	—
FIFO FDC Level Full Status Register	RSCFDnCFDFFFSTS	<RSCFDn_base> + $02C4_H$	8, 16, 32	*2	—
Transmit Message Buffer Control Register p	RSCFDnCFDTMCp	<RSCFDn_base> + $02D0_H$ + p×0001_H	8	*1	—
Transmit Message Buffer Status Register p	RSCFDnCFDTMSTSp	<RSCFDn_base> + $07D0_H$ + p×0001_H	8	*1	—
Transmit Message Buffer Transmission Request Status Register y	RSCFDnCFDTMTRSTSy	<RSCFDn_base> + $0CD0_H$ + y×0004_H	8, 16, 32	*1	—
Transmit Message Buffer Transmission Abort Request Status Register y	RSCFDnCFDTMTARSTSy	<RSCFDn_base> + $0D70_H$ + y×0004_H	8, 16, 32	*1	—
Transmit Message Buffer Transmission Completion Status Register y	RSCFDnCFDTMTCSTSy	<RSCFDn_base> + $0E10_H$ + y×0004_H	8, 16, 32	*1	—
Transmit Message Buffer Transmission Abort Status Register y	RSCFDnCFDTMTASTSy	<RSCFDn_base> + $0EB0_H$ + y×0004_H	8, 16, 32	*1	—
Transmit Message Buffer Interrupt Enable Configuration Register y	RSCFDnCFDTMIECy	<RSCFDn_base> + $0F50_H$ + y×0004_H	8, 16, 32	*1	—
Transmit Queue Configuration / Control Register 0 m	RSCFDnCFDTXQCC0m	<RSCFDn_base> + 1000_H + m×0004_H	8, 16, 32	*1	—
Transmit Queue Status Register 0 m	RSCFDnCFDTXQSTS0m	<RSCFDn_base> + 1020_H + m×0004_H	8, 16, 32	*1	—
Transmit Queue Pointer Control Register 0 m	RSCFDnCFDTXQPCTR0m	<RSCFDn_base> + 1040_H + m×0004_H	8, 16, 32	*1	—
Transmit Queue Configuration / Control Register 1 m	RSCFDnCFDTXQCC1m	<RSCFDn_base> + 1060_H + m×0004_H	8, 16, 32	*1	—
Transmit Queue Status Register 1 m	RSCFDnCFDTXQSTS1m	<RSCFDn_base> + 1080_H + m×0004_H	8, 16, 32	*1	—
Transmit Queue Pointer Control Register 1 m	RSCFDnCFDTXQPCTR1m	<RSCFDn_base> + $10A0_H$ + m×0004_H	8, 16, 32	*1	—
Transmit Queue Configuration / Control Register 2 m	RSCFDnCFDTXQCC2m	<RSCFDn_base> + $10C0_H$ + m×0004_H	8, 16, 32	*1	—
Transmit Queue Status Register 2 m	RSCFDnCFDTXQSTS2m	<RSCFDn_base> + $10E0_H$ + m×0004_H	8, 16, 32	*1	—
Transmit Queue Pointer Control Register 2 m	RSCFDnCFDTXQPCTR2m	<RSCFDn_base> + 1100_H + m×0004_H	8, 16, 32	*1	—
Transmit Queue Configuration / Control Register 3 m	RSCFDnCFDTXQCC3m	<RSCFDn_base> + 1120_H + m×0004_H	8, 16, 32	*1	—
Transmit Queue Status Register 3 m	RSCFDnCFDTXQSTS3m	<RSCFDn_base> + 1140_H + m×0004_H	8, 16, 32	*1	—
Transmit Queue Pointer Control Register 3 m	RSCFDnCFDTXQPCTR3m	<RSCFDn_base> + 1160_H + m×0004_H	8, 16, 32	*1	—
Transmit Queue Empty Status Register	RSCFDnCFDTXQESTS	<RSCFDn_base> + 1180_H	8, 16, 32	*2	—
Transmit Queue Full Interrupt Status Register	RSCFDnCFDTXQFISTS	<RSCFDn_base> + 1184_H	8, 16, 32	*2	—
Transmit Queue Message Lost Status Register	RSCFDnCFDTXQMSTS	<RSCFDn_base> + 1188_H	8, 16, 32	*2	—
Transmit Queue Message Overwrite Status Register	RSCFDnCFDTXQOWSTS	<RSCFDn_base> + $118C_H$	8, 16, 32	*2	—
Transmit Queue Interrupt Status Register	RSCFDnCFDTXQISTS	<RSCFDn_base> + 1190_H	8, 16, 32	*2	—
Transmit Queue One Frame Transmit Interrupt Status Register	RSCFDnCFDTXQOFTISTS	<RSCFDn_base> + 1194_H	8, 16, 32	*2	—

Table 23.13 Registers (3/4)

Register Name	Symbol	Address	Access Size	Access Protection

23.3.2 Details of Channel-Related Registers

23.3.2.1 RSCFDnCFDCmNCFG — Channel m Nominal Bit Rate Configuration Register

Access: RSCFDnCFDCmNCFG register can be read or written in 32-bit units
RSCFDnCFDCmNCFGL, RSCFDnCFDCmNCFGH register can be read or written in 16-bit units
RSCFDnCFDCmNCFGLL, RSCFDnCFDCmNCFGLH, RSCFDnCFDCmNCFGHL,
RSCFDnCFDCmNCFGHH register can be read or written in 8-bit units

Address: RSCFDnCFDCmNCFG: <RSCFDn_base> + 0000_H + (10_H × m)

RSCFDnCFDCmNCFGL: <RSCFDn_base> + 0000_H + (10_H × m),
RSCFDnCFDCmNCFGH: <RSCFDn_base> + 0002_H + (10_H × m)

RSCFDnCFDCmNCFGLL: <RSCFDn_base> + 0000_H + (10_H × m),
RSCFDnCFDCmNCFGLH: <RSCFDn_base> + 0001_H + (10_H × m),
RSCFDnCFDCmNCFGHL: <RSCFDn_base> + 0002_H + (10_H × m),
RSCFDnCFDCmNCFGHH: <RSCFDn_base> + 0003_H + (10_H × m)

Table 23.14 RSCFDnCFDCmNCFG Register Contents

Bit Position	Bit Name	Function
31 to 25	NTSEG2[6:0]	Time Segment 2 0000000: Setting prohibited 0000001: 2 Tq : : 1111110: 127 Tq 1111111: 128 Tq
24 to 17	NTSEG1[7:0]	Time Segment 1 00000000: Setting prohibited 00000001: 2 Tq : : 11111110: 255 Tq 11111111: 256 Tq
16 to 10	NSJW[6:0]	Nominal Bit Rate Resynchronization Jump Width Control 0000000: 1 Tq 0000001: 2 Tq : : 1111110: 127 Tq 1111111: 128 Tq
9 to 0	NBRP[9:0]	Channel Nominal Baud Rate Prescaler Nominal Baud Rate Prescaler division ratio

This register is used to configure the transmission / reception nominal Baud Rate parameters of the channels.

RSCFDnCFDCmNCFG.NTSEG2[6:0]

Timing Segment 2.

These bits are used to set the segment TSEG2 to compensate for edges on the CAN Bus with a negative phase error.

This bit cannot be written in CH_COMMUNICATION or CH_STOP mode.

Users should write to these bits, only when the RS-CANFD channel is in CH_RESET or CH_HALT mode.

Users should configure a Tq value, only between 2 and 128 inclusive.

RSCFDnCFDCmNCFG.NTSEG1[7:0]

Timing Segment 1.

These bits are used to set the segment TSEG1 to compensate for edges on the CAN Bus with a positive phase error.

It also contains the propagation segment.

This bit cannot be written in CH_COMMUNICATION or CH_STOP mode.

Users should write to these bits, only when the RS-CANFD channel is in CH_RESET or CH_HALT mode.

Users should configure a Tq value, only between 2 and 256 inclusive. See **Section 23.5.1.2** for more details.

RSCFDnCFDCmNCFG.NSJW[6:0]

Resynchronization Jump Width.

These bits set the synchronization jump width. A value from 1 to 128 time quanta can be set.

This bit cannot be written in CH_COMMUNICATION or CH_STOP mode.

Users should write to these bits, only when the RS-CANFD channel is in CH_RESET or CH_HALT mode.

RSCFDnCFDCmNCFG.NBRP[9:0]

Channel Nominal Baud Rate Prescaler.

These bits are used to define the peripheral bus clock periods contained in a Time Quantum.

This bit cannot be written in CH_COMMUNICATION or CH_STOP mode.

Users should write to these bits, only when the RS-CANFD channel is in CH_RESET or CH_HALT mode.

23.3.2.2 RSCFDnCFDCmCTR — Channel m Control Register

Access: RSCFDnCFDCmCTR register can be read or written in 32-bit units
RSCFDnCFDCmCTRL, RSCFDnCFDCmCTRH register can be read or written in 16-bit units
RSCFDnCFDCmCTRLL, RSCFDnCFDCmCTRLH, RSCFDnCFDCmCTRHL, RSCFDnCFDCmCTRHH register can be read or written in 8-bit units

Address: RSCFDnCFDCmCTR: <RSCFDn_base> + 0004_H + (10_H × m)

RSCFDnCFDCmCTRL: <RSCFDn_base> + 0004_H + (10_H × m),
RSCFDnCFDCmCTRH: <RSCFDn_base> + 0006_H + (10_H × m)

RSCFDnCFDCmCTRLL: <RSCFDn_base> + 0004_H + (10_H × m),
RSCFDnCFDCmCTRLH: <RSCFDn_base> + 0005_H + (10_H × m),
RSCFDnCFDCmCTRHL: <RSCFDn_base> + 0006_H + (10_H × m),
RSCFDnCFDCmCTRHH: <RSCFDn_base> + 0007_H + (10_H × m)

Value after reset: $0000\ 0005_H$

9	EWIE	Error Warning Interrupt Enable 0: Error Warning Interrupt disabled 1: Error Warning Interrupt enabled
8	BEIE	Bus Error Interrupt Enable 0: Bus Error Interrupt disabled 1: Bus Error Interrupt enabled
7 to 4	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
3	RTBO	Return from Bus-Off 0: Channel is not forced to return from Bus-Off 1: Channel is forced to return from Bus-Off
2	CSLPR	Channel Stop Request 0: Channel Stop Request disabled 1: Channel Stop Request enabled
1, 0	CHMDC[1:0]	Channel Mode Control 00: Channel Communication Mode request 01: Channel Reset request 10: Channel Halt request 11: Keep current value

Each Channel control register is used to control the modes of the related channel. It is used to enable generation of interrupts if errors are detected on the CAN bus connected to this channel. It is also used to configure the channel in test mode.

RSCFDnCFDCmCTR.ROM

Restricted Operation Mode.

The Restricted Operation Mode is enabled if RSCFDnCFDCmCTR.ROM and RSCFDnCFDCmCTR.CTME are both 1_B.

This bit cannot be set in CH_STOP mode.

Users should write to this bit only when the related RS-CANFD channel is in CH_HALT mode.

This mode should only be used in Basic Test mode RSCFDnCFDCmCTR.CTMS(1:0) = 00_B.

This bit is cleared automatically when the related RS-CANFD channel is in CH_RESET mode.

Users should not set to this bit when Classical only mode.

RSCFDnCFDCmCTR.CRCT

CRC Error Test.

This bit is used to check the internal CRC generator logic of the protocol controller.
It inverts the first bit (ID bit) of the CAN message data stream being received, so that the internal generated CRC result will not match the received CRC value of the frame. Users should refer to the bit stuffing rule when using this feature, as there is the possibility of receiving a stuff error (due to the inversion) rather than a CRC error.

The internal generated CRC value is always observed in the following registers:
RSCFDnCFDCmERFL.CRCREG (classical CAN frames)
RSCFDnCFDCmFDCRC.CRCREG (CANFD frames)

There are some limitations when using this bit:

- It is not possible to use this feature with CAN nodes connected to the MCU externally, only with nodes connected to the Internal CAN Bus communication can be used.
- One CAN node will send a reference message and the receiver node(s) can invert one bit of incoming bit stream
- Note, the transmitter and receiver mode are sharing the same CRC generator, therefore, it is not necessary to consider the modes separately when testing this limitation.
- The CRC Error Test Mode is enabled if RSCFDnCFDCmCTR.CRCT (new control signal which is inverting the first bit of the bit stream) and RSCFDnCFDCmCTR.CTME are both 1_B.

This bit cannot be set in CH_STOP mode.

Users can write to this bit only when the related RS-CANFD channel is in CH_HALT mode.

This bit is cleared automatically when the related RS-CANFD channel is in CH_RESET mode.

RSCFDnCFDCmCTR.CTMS[1:0]

Channel Test Mode Select

The RSCFDnCFDCmCTR.CTMS bits are used to select the required test mode.

These bits cannot be set in CH_STOP or CH_RESET mode.

Users should write to these bits only when the related RS-CANFD channel is in CH_HALT mode.

The field is cleared automatically when the related RS-CANFD channel moves to CH_RESET mode.

RSCFDnCFDCmCTR.CTME

Channel Test Mode Enable.

This bit is set to enable the channel test modes.

Users can only write to this bit when the related RS-CANFD channel is in CH_HALT mode

This bit cannot be set in CH_STOP mode.

The bit is cleared automatically when the related RS-CANFD channel transits to CH_RESET mode.

RSCFDnCFDCmCTR.ERRD

Channel Error Display.

This bit controls the display mode of the error flag bits (bits [14:8]) in the Channel Error Flag Register

(RSCFDnCFDCmERFL).
If the RSCFDnCFDCmCTR.ERRD bit is 0_B and more than one error occurs at the same time, then the error flag bits will set for all the errors that occurred at the same time. No further errors are flagged until RSCFDnCFDCmERFL[14:8] is cleared.

This bit cannot be set in CH_STOP mode.

Users should write to this bit only when the related RS-CANFD channel is in CH_RESET or CH_HALT mode.

RSCFDnCFDCmCTR.BOM[1:0]

Channel Bus-Off Mode.

These bits control the timing of the recovery from Bus-Off mode of the RS-CANFD Channel.

This bit cannot be set in CH_STOP mode.

Users should write to this bit only when the related RS-CANFD channel is in CH_RESET mode.

RSCFDnCFDCmCTR.TDCVFIE

Transceiver Delay Compensation Violation Interrupt enable.

An error interrupt is generated, when the RSCFDnCFDCmCTR.TDCVFIE bit is 1_B and the RSCFDnCFDCmFDSTS.TDCVF

bit belonging to the corresponding CAN channel is 1_B.

This bit cannot be set in CH_STOP mode.

Users should write to this bit only when the related RS-CANFD channel is in CH_RESET mode.

Users should not set to this bit when Classical only mode.

RSCFDnCFDCmCTR.SOCOIE

Successful Occurrence Counter Overflow Interrupt enable.

An error interrupt is generated, when the RSCFDnCFDCmCTR.SOCOIE bit is 1_B and the RSCFDnCFDCmFDSTS.SOCO bit belonging to the corresponding CAN channel is 1_B.

This bit cannot be set in CH_STOP mode.

Users should write to this bit only when the related RS-CANFD channel is in CH_RESET mode.

RSCFDnCFDCmCTR.EOCOIE

Error occurrence counter overflow Interrupt enable.

An error interrupt is generated, when the RSCFDnCFDCmCTR.EOCOIE bit is 1_B and the RSCFDnCFDCmFDSTS.EOCO bit

belonging to the corresponding CAN channel is 1_B.

This bit cannot be set in CH_STOP mode.

Users should write to this bit only when the related RS-CANFD channel is in CH_RESET mode.

RSCFDnCFDCmCTR.TAIE

Transmission abort Interrupt Enable.

An interrupt is generated, when the RSCFDnCFDCmCTR.TAIE bit is 1_B and a transmission is successfully aborted from a TX MB belonging to the corresponding CAN channel.

This bit cannot be set in CH_STOP mode.

Users should write to this bit only when the related RS-CANFD channel is in CH_RESET mode.

RSCFDnCFDCmCTR.ALIE

Arbitration Lost Interrupt Enable.

An error interrupt is generated, when the RSCFDnCFDCmCTR.ALIE bit and the RSCFDnCFDCmERFL.ALF are both 1_B.

This bit cannot be set in CH_STOP mode.

Users should write to this bit only when the related RS-CANFD channel is in CH_RESET mode.

RSCFDnCFDCmCTR.BLIE

Bus Lock Interrupt Enable.

An error interrupt is generated, when the RSCFDnCFDCmCTR.BLIE bit and the RSCFDnCFDCmERFL.BLF are both 1_B.

This bit cannot be set in CH_STOP mode.

Users should write to this bit only when the related RS-CANFD channel is in CH_RESET mode.

RSCFDnCFDCmCTR.OLIE

Overload Interrupt Enable.

An error interrupt is generated, when the RSCFDnCFDCmCTR.OLIE bit and the RSCFDnCFDCmERFL.OVLF are both 1_B.

This bit cannot be set in CH_STOP mode.

Users should write to this bit only when the related RS-CANFD channel is in CH_RESET mode.

RSCFDnCFDCmCTR.BORIE

Bus-Off Recovery Interrupt Enable.

An error interrupt is generated, when the RSCFDnCFDCmCTR.BORIE bit and the RSCFDnCFDCmERFL.BORF are both 1_B.

This bit cannot be set in CH_STOP mode.

Users should write to this bit only when the related RS-CANFD channel is in CH_RESET mode.

RSCFDnCFDCmCTR.BOEIE

Bus-Off Entry Interrupt Enable.

An error interrupt is generated, when the RSCFDnCFDCmCTR.BOEIE bit and the RSCFDnCFDCmERFL.BOEF are both 1_B.

This bit cannot be set in CH_STOP mode.

Users should write to this bit only when the related RS-CANFD channel is in CH_RESET mode.

RSCFDnCFDCmCTR.EPIE

Error Passive Interrupt Enable.

An error interrupt is generated, when the RSCFDnCFDCmCTR.EPIE bit and the RSCFDnCFDCmERFL.EPF are both 1_B.

This bit cannot be set in CH_STOP mode.

Users should write to this bit only when the related RS-CANFD channel is in CH_RESET mode.

RSCFDnCFDCmCTR.EWIE

Error Warning Interrupt Enable.

An error interrupt is generated, when the RSCFDnCFDCmCTR.EWIE bit and the RSCFDnCFDCmERFL.EWF are both 1_B.

This bit cannot be set in CH_STOP mode.

Users should write to this bit only when the related RS-CANFD channel is in CH_RESET mode.

RSCFDnCFDCmCTR.BEIE

Bus Error Interrupt Enable.

An error interrupt is generated, when the RSCFDnCFDCmCTR.BEIE bit and the RSCFDnCFDCmERFL.BEF are both 1_B.

This bit cannot be set in CH_STOP mode.

Users should write to this bit only when the related RS-CANFD channel is in CH_RESET mode.

RSCFDnCFDCmCTR.RTBO

Return from Bus-Off.

When the protocol controller of the CAN channel enters Bus-Off state, users can force it to recover from Bus-Off state by setting the RSCFDnCFDCmCTR.RTBO bit in the Channel Control Register to 1_B.
The error state changes from Bus-Off state to integrating with a maximum delay of 1 CAN Bit time.

If the RSCFDnCFDCmCTR.RTBO bit is set to 1_B, the REC and TEC registers are initialized and the Bus-Off status bit (Channel Bus-off Status, RSCFDnCFDCmSTS .BOSTS) is set to 0_B.

The other registers are not initialized by this command. Even if RSCFDnCFDCmCTR.BORIE is set, a Bus-Off recovery interrupt is not generated by this recovery from the Bus-Off state.

This bit cannot be set in CH_STOP mode.
Setting this bit in any state (other than Bus-Off) will have no effect and the bit will be cleared immediately.

Read value is always 0.

Return from Bus-Off command should be used only when RSCFDnCFDCmCTR.BOM is set to 00_B.
Users should only write to this bit when the related RS-CANFD channel is in CH_COMMUNICATION mode.

This bit is automatically cleared once set by the System SW.

RSCFDnCFDCmCTR.CSLPR

Channel Stop Request.

A Stop Mode request is generated for the corresponding CAN channel, when the RSCFDnCFDCmCTR.CSLPR bit is 1_B.
A request to exit Stop Mode is generated for the corresponding CAN channel, when the RSCFDnCFDCmCTR.CSLPR bit is 0_B.

Users can only write to this bit when the related RS-CANFD channel is in CH_RESET or CH_STOP mode.

RSCFDnCFDCmCTR.CHMDC[1:0]

Channel Mode Control.

RSCFDnCFDCmCTR.CHMDC bits can be used to configure the modes of the CAN channel.
CAN mode transitions are described in more details in **Section 23.4.2**

Setting RSCFDnCFDCmCTR.CHMDC to 11_B by the CPU has no effect.
When the RS-CANFD module is in GL_TEST mode, these bits can only be set to 10_B or 01_B.
This bit cannot be set in CH_STOP mode.

RSCFDnCFDCmCTR.CHMDC can change automatically in case of transition to Halt mode due to RSCFDnCFDCmCTR.BOM settings.
If CPU write access to RSCFDnCFDCmCTR.CHMDC happens at the same time when the CAN channel is about to enter Halt Mode (at the start of Bus-Off when RSCFDnCFDCmCTR.BOM=01_B, or at the end of Bus-Off when RSCFDnCFDCmCTR.BOM =10_B), then the CPU write access will have the highest priority.

The CAN channel changes the value of RSCFDnCFDCmCTR.CHMDC within the Channel Control Register for the above cases only if the RSCFDnCFDCmCTR.CHMDC value is 00_B (Communication Mode).

23.3.2.3 RSCFDnCFDCmSTS — Channel m Status Register

Access: RSCFDnCFDCmSTS register can be read or written in 32-bit units
RSCFDnCFDCmSTS L, RSCFDnCFDCmSTS H register can be read or written in 16-bit units
RSCFDnCFDCmSTS LL, RSCFDnCFDCmSTS LH, RSCFDnCFDCmSTS HL, RSCFDnCFDCmSTS HH register can be read or written in 8-bit units

Address: RSCFDnCFDCmSTS : <RSCFDn_base> + 0008_H + (10_H × m)

RSCFDnCFDCmSTS L: <RSCFDn_base> + 0008_H + (10_H × m),
RSCFDnCFDCmSTS H: <RSCFDn_base> + $000A_H$ + (10_H × m)

RSCFDnCFDCmSTS LL: <RSCFDn_base> + 0008_H + (10_H × m),
RSCFDnCFDCmSTS LH: <RSCFDn_base> + 0009_H + (10_H × m),
RSCFDnCFDCmSTS HL: <RSCFDn_base> + $000A_H$ + (10_H × m),
RSCFDnCFDCmSTS HH: <RSCFDn_base> + $000B_H$ + (10_H × m)

Value after reset: $0000\ 0005_H$

Table 23.16 RSCFDnCFDCmSTS Register Contents (1/2)

Bit Position	Bit Name	Function
31 to 24	TEC[7:0]	Transmission Error Count This register increments or decrements the counter value according to error status of the CAN channel during Transmission.
23 to 16	REC[7:0]	Reception Error Count This register increments or decrements the counter value according to error status of the CAN channel during Reception.
15 to 9	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
8	ESIF	Error State Indication Flag 0: No CANFD message has been received with the ESI flag was set 1: At least 1 CANFD message was received where the ESI flag was set
7	COMSTS	Channel Communication Status 0: Channel is not ready for communication 1: Channel is ready for communication
6	RECSTS	Channel Receive Status 0: Channel is not receiving 1: Channel is receiving
5	TRMSTS	Channel Transmit Status 0: Channel is not transmitting 1: Channel is transmitting
4	BOSTS	Channel Bus-Off Status 0: Channel not in Bus-Off state 1: Channel in Bus-Off state
3	EPSTS	Channel Error Passive Status 0: Channel not in Error Passive state. 1: Channel in Error Passive state.
2	CSLPSTS	Channel STOP Status 0: Channel not in Stop Mode 1: Channel in Stop Mode

Table 23.16 RSCFDnCFDCmSTS Register Contents (2/2)

Bit Position	Bit Name	Function
1	CHLTSTS	Channel HALT Status 0: Channel not in Halt Mode 1: Channel in Halt Mode
0	CRSTSTS	Channel RESET Status 0: Channel not in Reset Mode 1: Channel in Reset Mode

Each Channel Status Register shows the mode, Error and TX / RX status of the related channel together with its Reception and Transmission Error Count values.

RSCFDnCFDCmSTS .TEC[7:0]

Transmission Error Count

The value of TEC error counter is displayed.

Users should only write to these bits when in Test Mode and RS-CANFD channel is in CH_HALT mode.

These bits are cleared automatically when RS-CANFD module is in GL_RESET or CAN channel is in CH_RESET mode.

RSCFDnCFDCmSTS .REC[7:0]

Reception Error Count

The value of the REC error counter is displayed.

The value in Bus-Off state is indeterminate.

These bits are cleared automatically when RS-CANFD module enters GL_RESET or CAN channel is in CH_RESET mode.

RSCFDnCFDCmSTS .ESIF

Error State Indication Flag

This flag is set when the ESI bit was sampled recessive for a reception CAN message without any error.
Note that in case of Loopback or Mirror Mode the self transmitted messages are considered as reception messages.

If the set from the CAN channel occurs simultaneously with the clear by the write access, then the bit is set.

The bit is cleared by writing 0_B to it.
This bit is cleared automatically when the related CAN channel is in Reset.

Users can only write to this bit when the related RS-CANFD channel is in CH_HALT or CH_COMMUNICATION mode.

Do not use bit clear instruction for clearing this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Then the other bits remain set to 1_B.

RSCFDnCFDCmSTS .COMSTS

Channel Communication Status

Indicates if the related CAN channel is ready for communication.

This bit is set automatically when the related CAN channel is ready to perform communication following the detection of eleven consecutive recessive bits after leaving the Reset or Halt mode.

This bit is cleared automatically when the related CAN channel is in Reset or Halt Mode.

NOTE

This bit is 1_B during Bus-Off status.

RSCFDnCFDCmSTS .RECSTS

Channel Receive Status

Indicates if the related CAN channel is receiving a message.

This bit is set automatically when the related CAN channel is operating as a receiver node.

This bit is cleared automatically when the related CAN channel is in the bus-idle state or starts operating as a transmitter node.

RSCFDnCFDCmSTS .TRMSTS

Channel Transmit Status

Indicates if the related CAN channel is transmitting a message.

This bit is set automatically when the related CAN channel is operating as a transmitter node or is in the Bus-Off state.

This bit is cleared automatically when the related CAN channel is in the bus-idle state or starts operating as a receiver node.

RSCFDnCFDCmSTS .BOSTS

Channel Bus-Off Status

Indicates if the related CAN channel has entered the error Bus-Off state.

This bit is set automatically when the value of the related CAN Transmission Error Count Register exceeds 255 and the related CAN channel is in the Bus-Off state (CAN Transmission Error Count Register > 255).

This bit is cleared automatically when the related CAN channel exits the Bus-Off state.

RSCFDnCFDCmSTS .EPSTS

Channel Error Passive Status.

Indicates if the related CAN channel has entered the error passive state.

This bit is set automatically when the value of the CAN Transmission or Reception Counter Register exceeds the value of 127.

This bit is cleared automatically when the related CAN channel exits the Error Passive state or enters Reset Mode.

RSCFDnCFDCmSTS .CSLPSTS

Channel STOP Status.

Indicates if the related CAN channel is in Stop Mode.

This bit is set automatically when the related CAN channel enters Stop Mode.

This bit is cleared automatically when the related CAN channel exits Stop Mode.

RSCFDnCFDCmSTS .CHLTSTS

Channel HALT Status.

Indicates if the related CAN channel is in Halt mode.

This bit is set automatically when the related CAN channel enters Halt Mode.

This bit is cleared automatically when the related CAN channel exits Halt Mode.

RSCFDnCFDCmSTS .CRSTSTS

Channel RESET Status.

Indicates if the related CAN channel is in Reset mode.

This bit is set automatically when the related CAN channel enters Channel Reset Mode. If the mode is changed from Reset Mode to Stop Mode, RSCFDnCFDCmSTS.CRSTSTS remains set to 1_B.

This bit is cleared automatically when the related CAN channel exits the Channel Reset Mode, except when changing to Stop Mode.

23.3.2.4 RSCFDnCFDCmERFL — Channel m Error Flag Register

Access: RSCFDnCFDCmERFL register can be read or written in 32-bit units
RSCFDnCFDCmERFLL, RSCFDnCFDCmERFLH register can be read or written in 16-bit units
RSCFDnCFDCmERFLLL, RSCFDnCFDCmERFLLH, RSCFDnCFDCmERFLHL, RSCFDnCFDCmERFLHH register can be read or written in 8-bit units

Address: RSCFDnCFDCmERFL: <RSCFDn_base> + $000C_H$ + (10_H × m)

RSCFDnCFDCmERFLL: <RSCFDn_base> + $000C_H$ + (10_H × m),
RSCFDnCFDCmERFLH: <RSCFDn_base> + $000E_H$ + (10_H × m)

RSCFDnCFDCmERFLLL: <RSCFDn_base> + $000C_H$ + (10_H × m),
RSCFDnCFDCmERFLLH: <RSCFDn_base> + $000D_H$ + (10_H × m),
RSCFDnCFDCmERFLHL: <RSCFDn_base> + $000E_H$ + (10_H × m),
RSCFDnCFDCmERFLHH: <RSCFDn_base> + $000F_H$ + (10_H × m)

Value after reset: $0000\ 0000_H$

8	SERR	Stuff Error 0: Channel stuff Error not detected 1: Channel stuff Error detected

Table 23.17 RSCFDnCFDCmERFL Register Contents (2/2)

Bit Position	Bit Name	Function
7	ALF	Arbitration Lost Flag 0: Channel Arbitration Lost not detected 1: Channel Arbitration Lost detected
6	BLF	Bus Lock Flag 0: Channel Bus Lock not detected 1: Channel Bus Lock detected
5	OVLF	Overload Flag 0: Channel Overload not detected 1: Channel Overload detected
4	BORF	Bus-Off Recovery Flag 0: Channel Bus-Off Recovery not detected 1: Channel Bus-Off Recovery detected
3	BOEF	Bus-Off Entry Flag 0: Channel Bus-Off Entry not detected 1: Channel Bus-Off Entry detected
2	EPF	Error Passive Flag 0: Channel Error Passive not detected 1: Channel Error Passive detected
1	EWF	Error Warning Flag 0: Channel Error Warning not detected 1: Channel Error Warning detected
0	BEF	Bus Error Flag 0: Channel Bus Error not detected 1: Channel Bus Error detected

Each Channel Error Flag register shows the status of various error conditions detectable regardless of the setting of the related CAN channel Error Interrupt Enable Register. It also shows the status of the various bus errors detectable by the CAN channel. Refer to the CAN specification (ISO 11898-1 (2015)) to check when each error condition can occur.

For this register, when only a single bit is to be cleared by the program, do not use bit clear instruction – use the MOV instruction to ensure that only the specified bit is cleared. Then the other bits remain set to 1.

An example in assembler language for clearing the RSCFDnCFDCmERFL.BEF bit:

```
mov.b #0Feh, RSCFDnCFDCmERFL ;
```

RSCFDnCFDCmERFL.CRCREG[14:0]

CRC Register value.

The calculated CRC value can be read from these bits, only when RSCFDnCFDCmCTR.CTME is 1_B for the channel.

If RSCFDnCFDCmCTR.CTME bit is 0_B, then these bits are always read as 0.

These bits show the CAN2.0 CRC value calculated by the RS-CANFD channel logic if the CTME bit is enabled.

The RSCFDnCFDCmERFL.CRCREG value is updated in the 1st bit of CRC field of the CAN Frame (reception as well as transmission).

These bits are cleared automatically when the related channel is in CH_RESET mode.

RSCFDnCFDCmERFL.ADERR

Acknowledge Delimiter Error.

Indicates a detection of a Acknowledge Delimiter bit error.

This bit can only be cleared by writing 0_B to it when it is 1_B.
This bit can only be set by RS-CANFD module logic.
Writing 1_B has no influence on the bit value.

For clearing this bit, the following sequence should be used:
1. Clear the corresponding flag bit
2. Read if the flag bit is cleared
3. If yes, continue, else, go back to step 1.

This bit is set automatically when a form error is detected during the Acknowledge Delimiter state of frame transmission.
If RSCFDnCFDCmCTR.ERRD bit is 1_B, then this bit will be set if the set and clear conditions occur at the same time for this bit.

The bit is cleared by writing 0_B to it.
It is cleared automatically when the related RS-CANFD channel is in CH_RESET mode.
If RSCFDnCFDCmCTR.ERRD bit is 0_B and the set and clear conditions occur at the same time for this bit, it will be cleared if a bit at RSCFDnCFDCmERFL[14:8] is already set and it will be set if RSCFDnCFDCmERFL[14:8] is 00_H.

Users can only write to this bit when the related RS-CANFD channel is in CH_HALT or CH_COMMUNICATION mode.

RSCFDnCFDCmERFL.B0ERR

Bit 0 Error.

Indicates a detection of a Dominant bit error.

This bit can only be cleared by writing 0_B to it when it is 1_B.
This bit can only be set by RS-CANFD module logic.
Writing 1_B has no influence on the bit value.

For clearing this bit, the following sequence should be used:

1. Clear the corresponding flag bit
2. Read if the flag bit is cleared
3. If yes, continue, else, go back to step 1.

This bit is set automatically when a Dominant bit error (expected dominant bit, sampled as recessive bit) is detected.
If RSCFDnCFDCmCTR.ERRD bit is 1_B, then this bit will be set if the set and clear conditions occur at the same time for this bit.

The bit is cleared by writing 0_B to it.
It is cleared automatically when the related RS-CANFD channel is in CH_RESET mode.
If RSCFDnCFDCmCTR.ERRD bit is 0_B and the set and clear conditions occur at the same time for this bit, it will be cleared if a bit at RSCFDnCFDCmERFL[14:8] is already set and it will be set if RSCFDnCFDCmERFL[14:8] is 00_H.

Users can only write to this bit when the related RS-CANFD channel is in CH_HALT or CH_COMMUNICATION mode.

RSCFDnCFDCmERFL.B1ERR

Bit 1 Error.

Indicates a detection of a Recessive bit error.

This bit can only be cleared by writing 0_B to it when it is 1_B.
This bit can only be set by RS-CANFD module logic.
Writing 1_B has no influence on the bit value.

For clearing this bit, the following sequence should be used:
1. Clear the corresponding flag bit
2. Read if the flag bit is cleared
3. If yes, continue, else, go back to step 1.

This bit is set automatically when a Recessive bit error (expected recessive bit, sampled as dominant bit) is detected.
If RSCFDnCFDCmCTR.ERRD bit is 1_B, then this bit will be set if the set and clear conditions occur at the same time for this bit.

The bit is cleared by writing 0_B to it.
It is cleared automatically when the related RS-CANFD channel is in CH_RESET mode.
If RSCFDnCFDCmCTR.ERRD bit is 0_B and the set and clear conditions occur at the same time for this bit, it will be cleared if a bit at RSCFDnCFDCmERFL[14:8] is already set and it will be set if RSCFDnCFDCmERFL[14:8] is 00_H.

Users can only write to this bit when the related RS-CANFD channel is in CH_HALT or CH_COMMUNICATION mode.

RSCFDnCFDCmERFL.CERR

CRC Error.

Indicates a detection of a CAN CRC Error.

This bit can only be cleared by writing 0 to it when it is 1_B.
This bit can only be set by RS-CANFD module logic.
Writing 1_B has no influence on the bit value.

For clearing this bit, the following sequence should be used:

1. Clear the corresponding flag bit
2. Read if the flag bit is cleared
3. If yes, continue, else, go back to step 1.

This bit is set automatically when a CRC error is detected.
If RSCFDnCFDCmCTR.ERRD bit is 1_B, then this bit will be set if the set and clear conditions occur at the same time for this bit.

The bit is cleared by writing 0_B to it.
It is cleared automatically when the related RS-CANFD channel is in CH_RESET mode.
If RSCFDnCFDCmCTR.ERRD bit is 0_B and the set and clear conditions occur at the same time for this bit, it will be cleared if a bit at RSCFDnCFDCmERFL[14:8] is already set and it will be set if RSCFDnCFDCmERFL[14:8] is 00_H.

Users can only write to this bit when the related RS-CANFD channel is in CH_HALT or CH_COMMUNICATION mode.

RSCFDnCFDCmERFL.AERR

Acknowledge Error

Indicates a detection of a CAN Acknowledge Error.

This bit can only be cleared by writing 0_B to it when it is 1_B.
This bit can only be set by RS-CANFD module logic.
Writing 1_B has no influence on the bit value.

For clearing this bit, the following sequence should be used:

1. Clear the corresponding flag bit
2. Read if the flag bit is cleared
3. If yes, continue, else, go back to step 1.

This bit is set automatically when an Acknowledge error is detected.
If RSCFDnCFDCmCTR.ERRD bit is 1_B, then this bit will be set if the set and clear conditions occur at the same time for this bit.

The bit is cleared by writing 0_B to it.
It is cleared automatically when the related RS-CANFD channel is in CH_RESET mode.
If RSCFDnCFDCmCTR.ERRD bit is 0_B and the set and clear conditions occur at the same time for this bit, it will be cleared if a bit at RSCFDnCFDCmERFL[14:8] is already set and it will be set if RSCFDnCFDCmERFL[14:8] is 00_H.

Users can only write to this bit when the related RS-CANFD channel is in CH_HALT or CH_COMMUNICATION mode.

RSCFDnCFDCmERFL.FERR

Form Error

Indicates a detection of a CAN Form Error.

This bit can only be cleared by writing 0_B to it when it is 1_B.
This bit can only be set by RS-CANFD module logic.
Writing 1_B has no influence on the bit value.

For clearing this bit, the following sequence should be used:
1. Clear the corresponding flag bit
2. Read if the flag bit is cleared
3. If yes, continue, else, go back to step 1.

This bit is set automatically when a Form error is detected.
If RSCFDnCFDCmCTR.ERRD bit is 1_B, then this bit will be set if the set and clear conditions occur at the same time for this bit.

The bit is cleared by writing 0_B to it.
It is cleared automatically when the related RS-CANFD channel is in CH_RESET mode.
If RSCFDnCFDCmCTR.ERRD bit is 0_B and the set and clear conditions occur at the same time for this bit, it will be cleared if a bit at RSCFDnCFDCmERFL[14:8] is already set and it will be set if RSCFDnCFDCmERFL[14:8] is 00_H.

Users can only write to this bit when the related RS-CANFD channel is in CH_HALT or CH_COMMUNICATION mode.

RSCFDnCFDCmERFL.SERR

Stuff Error

Indicates a detection of a CAN Stuff Error.

This bit can only be cleared by writing 0_B to it when it is 1_B.
This bit can only be set by RS-CANFD module logic.
Writing 1_B has no influence on the bit value.

For clearing this bit, the following sequence should be used:
1. Clear the corresponding flag bit
2. Read if the flag bit is cleared
3. If yes, continue, else, go back to step 1.

This bit is set automatically when a Stuff error is detected.
If RSCFDnCFDCmCTR.ERRD bit is 1_B, then this bit will be set if the set and clear conditions occur at the same time for this bit.

The bit is cleared by writing 0_B to it.
It is cleared automatically when the related RS-CANFD channel is in CH_RESET mode.
If RSCFDnCFDCmCTR.ERRD bit is 0_B and the set and clear conditions occur at the same time for this bit, it will be cleared if a bit at RSCFDnCFDCmERFL[14:8] is already set and it will be set if RSCFDnCFDCmERFL[14:8] is 00_H.

Users can only write to this bit when the related RS-CANFD channel is in CH_HALT or CH_COMMUNICATION mode.

RSCFDnCFDCmERFL.ALF

Arbitration Lost Flag

Indicates a detection of a CAN channel Bus Arbitration Lost condition.

This bit can only be cleared by writing 0_B to it when it is 1_B.
This bit can only be set by RS-CANFD module logic.
Writing 1_B has no influence on the bit value.

The bit is set automatically when an arbitration lost condition is detected on the CAN bus while the CAN channel is in Communication Mode.
If the set condition occurs simultaneously with the clear condition, the bit is set.

The bit is cleared by writing 0_B to it.
It is cleared automatically when the related RS-CANFD channel is in CH_RESET mode.

Users can only write to this bit when the related RS-CANFD channel is in CH_HALT or CH_COMMUNICATION mode.

RSCFDnCFDCmERFL.BLF

Bus Lock Flag

Indicates a detection of a CAN channel Bus Lock condition.

This bit can only be cleared by writing 0_B to it when it is 1_B.
This bit can only be set by RS-CANFD module logic.
Writing 1_B has no influence on the bit value.

The bit is set automatically when 32 consecutive dominant bits are detected on the CAN bus while the CAN channel is in Communication Mode.
If the set condition occurs simultaneously with the clear condition, the bit is set.

The bit is cleared by writing 0_B to it.
It is cleared automatically when the related RS-CANFD channel is in CH_RESET mode.

Users can only write to this bit when the related RS-CANFD channel is in CH_HALT or CH_COMMUNICATION mode.

RSCFDnCFDCmERFL.OVLF

Overload Flag

Indicates a detection of a CAN channel Overload State.

This bit can only be cleared by writing 0_B to it when it is 1_B.
This bit can only be set by RS-CANFD module logic.
Writing 1_B has no influence on the bit value.

The bit is set automatically when an overload condition is detected.
If the set condition occurs simultaneously with the clear condition, the bit is set.

The bit is cleared by writing 0_B to it.
It is cleared automatically when the related RS-CANFD channel is in CH_RESET mode.

Users can only write to this bit when the related RS-CANFD channel is in CH_HALT or CH_COMMUNICATION mode.

RSCFDnCFDCmERFL.BORF

Bus-Off Recovery Flag

Indicates a detection of a CAN channel Bus-Off Recovery State

This bit can only be cleared by writing 0_B to it when it is 1_B.
This bit can only be set by RS-CANFD module logic.
Writing 1_B has no influence on the bit value.

The bit is set automatically if CAN channel recovers from Bus-Off state in the following conditions:

- When RSCFDnCFDCmCTR.BOM is 00_B and normal recovery (11 consecutive recessive bits X 128 times detected) occurs.
- When RSCFDnCFDCmCTR.BOM is 10_B and normal recovery (11 consecutive recessive bits X 128 times detected) occurs.
- When RSCFDnCFDCmCTR.BOM is 11_B and normal recovery (11 consecutive recessive bits X 128 times detected) occurs.

The bit is not set if CAN channel recovers from Bus-Off state in the following conditions:

- When CAN Reset Mode is requested
- When RSCFDnCFDCmCTR.RTBO is instructed (the CAN channel returns to error active)
- When RSCFDnCFDCmCTR.BOM is 01_B
- When RSCFDnCFDCmCTR.BOM is 11_B and a Halt Request is asserted before the CAN channel reaches the end of the Bus-Off State.

The bit is cleared by writing 0 to it.
It is cleared automatically when the related RS-CANFD channel is in CH_RESET mode.

If the set condition occurs simultaneously with the clear condition, the bit is set.

Users can only write to this bit when the related RS-CANFD channel is in CH_HALT or CH_COMMUNICATION mode.

RSCFDnCFDCmERFL.BOEF

Bus-Off Entry Flag

Indicates a detection of a CAN channel Bus-Off Entry State.

This bit can only be cleared by writing 0_B to it when it is 1_B.
This bit can only be set by RS-CANFD module logic.
Writing 1_B has no influence on the bit value.

The bit is set automatically when the CAN error state enters the Bus-Off State.

The bit is cleared by writing 0_B to it.
It is cleared automatically when the related RS-CANFD channel is in CH_RESET mode.

If the set condition occurs simultaneously with the clear condition, the bit is set.

Users can only write to this bit when the related RS-CANFD channel is in CH_HALT or CH_COMMUNICATION mode.

RSCFDnCFDCmERFL.EPF

Error Passive Flag

Indicates a detection of a CAN channel Error Passive State.

This bit can only be cleared by writing 0_B to it when it is 1_B.
This bit can only be set by RS-CANFD module logic.
Writing 1_B has no influence on the bit value.

The bit is set automatically when the CAN error state becomes Error Passive State.
The setting of this bit only occurs when the TEC or REC initially exceed 127. Hence if the TEC or REC remain > 127 and the RSCFDnCFDCmERFL.EPF bit is cleared by the system SW, it will not be set again until both the TEC and REC go below 128 and either TEC or REC cross over again from a value ≤ 127 to a value > 127.
If the set condition occurs simultaneously with the clear condition, the bit is set.

The bit is cleared by writing 0_B to it.
It is cleared automatically when the related RS-CANFD channel is in CH_RESET mode.

Users can only write to this bit when the related RS-CANFD channel is in CH_HALT or CH_COMMUNICATION mode.

RSCFDnCFDCmERFL.EWF

Error Warning Flag

This bit indicates if an Error Warning condition has been detected for the CAN channel.

This bit can only be cleared by writing 0_B to it when it is 1_B.
This bit can only be set by RS-CANFD module logic.
Writing 1_B has no influence on the bit value.

The bit is set automatically when either TEC or REC exceeds 95.
The setting of this bit only occurs when the TEC or REC initially exceed 95. Hence if the TEC or REC remain > 95 and the EWF bit is cleared by the system SW, it will not be set again until both the TEC and REC go below 96 and either TEC or REC cross over again from a value ≤ 95 to a value > 95.
If the set condition occurs simultaneously with the clear condition, the bit is set.

The bit is cleared by writing 0_B to it.
It is cleared automatically when the related RS-CANFD channel is in CH_RESET mode.

Users can only write to this bit when the related RS-CANFD channel is in CH_HALT or CH_COMMUNICATION mode.

RSCFDnCFDCmERFL.BEF

Bus Error Flag

Indicates a detection of a CAN channel Bus error state, flagged by the bits [14:8] in this register.

This bit can only be cleared by writing 0_B to it when it is 1_B.
This bit can only be set by RS-CANFD module logic.
Writing 1_B has no influence on the bit value.

The bit is set automatically when a Bus Error is detected.

If the set from the CAN channel occurs simultaneously with the clear by the write access, then the bit is set.

The bit is cleared by writing 0_B to it.
It is cleared automatically when the related RS-CANFD channel is in CH_RESET mode.

Users can only write to this bit when the related RS-CANFD channel is in CH_HALT or CH_COMMUNICATION mode.

23.3.2.5 RSCFDnCFDCmDCFG — Channel m Data Bit Rate Configuration Register

Access: RSCFDnCFDCmDCFG register can be read or written in 32-bit units
RSCFDnCFDCmDCFGL, RSCFDnCFDCmDCFGH register can be read or written in 16-bit units
RSCFDnCFDCmDCFGLL, RSCFDnCFDCmDCFGLH, RSCFDnCFDCmDCFGHL,
RSCFDnCFDCmDCFGHH register can be read or written in 8-bit units

Address: RSCFDnCFDCmDCFG: <RSCFDn_base> + 1400_H + (20_H × m)

RSCFDnCFDCmDCFGL: <RSCFDn_base> + 1400_H + (20_H × m),
RSCFDnCFDCmDCFGH: <RSCFDn_base> + 1402_H + (20_H × m)

RSCFDnCFDCmDCFGLL: <RSCFDn_base> + 1400_H + (20_H × m),
RSCFDnCFDCmDCFGLH: <RSCFDn_base> + 1401_H + (20_H × m),
RSCFDnCFDCmDCFGHL: <RSCFDn_base> + 1402_H + (20_H × m),
RSCFDnCFDCmDCFGHH: <RSCFDn_base> + 1403_H + (20_H × m)

7 to 0	DBRP[7:0]	Channel Data Rate Prescaler Data Rate Prescaler division ratio

This register is used to configure the transmission/reception Data Baud Rate parameters of the channels.

The channel of Classical CAN only mode does not have to perform the configuration of this register.

RSCFDnCFDCmDCFG.DSJW[3:0]

Resynchronization Jump Width.

These bits set the synchronization jump width. A value from 1 to 16 time quanta can be set.

This bit cannot be written in CH_COMMUNICATION or CH_STOP mode.

Users should write to these bits, only when the RS-CANFD channel is in CH_RESET or CH_HALT mode.

RSCFDnCFDCmDCFG.DTSEG2[3:0]

Timing Segment 2.

These bits are used to set the segment TSEG2 to compensate for edges on the CAN Bus with a negative phase error.

Any value from 2 to 16 time quanta can be written to these bits.

This bit cannot be written in CH_COMMUNICATION or CH_STOP mode.

Users should write to these bits, only when the RS-CANFD channel is in CH_RESET or CH_HALT mode.
Users should not write any other value to these bits.

RSCFDnCFDCmDCFG.DTSEG1[4:0]

Timing Segment 1.

These bits are used to set the segment TSEG1 to compensate for edges on the CAN Bus with a positive phase error.
It also contains the propagation segment.

Any value from 2 to 32 time quanta can be configured.

This bit cannot be written in CH_COMMUNICATION or CH_STOP mode.

Users should write to these bits, only when the RS-CANFD channel is in CH_RESET or CH_HALT mode.
Users should not write any other value to these bits. See **Section 23.5.1.2** for more details.

RSCFDnCFDCmDCFG.DBRP[7:0]

Channel Data Baud Rate Prescaler.

These bits are used to define the peripheral bus clock periods contained in a Time Quantum.

This bit cannot be written in CH_COMMUNICATION or CH_STOP mode.

Users should write to these bits, only when the RS-CANFD channel is in CH_RESET or CH_HALT mode.

23.3.2.6 RSCFDnCFDCmFDCFG — Channel m CANFD Configuration Register

Access: RSCFDnCFDCmFDCFG register can be read or written in 32-bit units
RSCFDnCFDCmFDCFGL, RSCFDnCFDCmFDCFGH register can be read or written in 16-bit units
RSCFDnCFDCmFDCFGLL, RSCFDnCFDCmFDCFGLH, RSCFDnCFDCmFDCFGHL,
RSCFDnCFDCmFDCFGHH register can be read or written in 8-bit units

Address: RSCFDnCFDCmFDCFG: <RSCFDn_base> + 1404_H + (20_H × m)

RSCFDnCFDCmFDCFGL: <RSCFDn_base> + 1404_H + (20_H × m),
RSCFDnCFDCmFDCFGH: <RSCFDn_base> + 1406_H + (20_H × m)

RSCFDnCFDCmFDCFGLL: <RSCFDn_base> + 1404_H + (20_H × m),
RSCFDnCFDCmFDCFGLH: <RSCFDn_base> + 1405_H + (20_H × m),
RSCFDnCFDCmFDCFGHL: <RSCFDn_base> + 1406_H + (20_H × m),
RSCFDnCFDCmFDCFGHH: <RSCFDn_base> + 1407_H + (20_H × m)

Value after reset: $0000\ 0000_H$

15 to 11	Reserved	When read, the value after reset is returned. When writing, write the value after reset.

Table 23.19 RSCFDnCFDCmFDCFG Register Contents (2/2)

Bit Position	Bit Name	Function
10	ESIC	Error State Indication Configuration 0: The ESI bit in the frame will be representing the Error state of the node itself 1: The ESI bit in the frame will be representing the Error state of message buffer if the node itself is not in error passive. If the node is in Error Passive then the ESI bit will be driven by the node itself
9	TDCE	Transceiver Delay Compensation Enable 0: Transceiver Delay Compensation Disabled 1: Transceiver Delay Compensation Enabled
8	TDCOC	Transceiver Delay Compensation Offset Configuration 0: Measured + offset 1: offset only
7 to 3	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
2 to 0	EOCCFG[2:0]	Error Occurrence Counter Configuration 000: All Transmitter or Receiver CAN Frames 001: All Transmitter CAN Frames 010: All Receiver CAN Frames 011: Setting prohibited 100: Only Transmitter or Receiver CANFD Data-Phase (fast bits) 101: Only Transmitter CANFD Data-Phase (fast bits) 110: Only Receiver CANFD Data-Phase (fast bits) 111: Setting prohibited

The Channel m CANFD Configuration Register is used to configure which communication direction (transmitter and/or receiver) errors will be counted.

RSCFDnCFDCmFDCFG.CLOE

Classical CAN only enable.

This bits enables the Classical CAN only mode. If this bit is 1_B, then the protocol controller can only send Classical Frames and will react with a Form or CRC error on FD frames.

User should not set RSCFDnCFDCmFDCFG.CLOE and RSCFDnCFDCmFDCFG.FDOE simultaneously.

RSCFDnCFDCmFDCFG.CLOE	RSCFDnCFDCmFDCFG.FDOE	channel mode
0	0	CANFD mode
0	1	CANFD only mode
1	0	Classical CAN only mode
1	1	Reserved

This bit cannot be written in CH_COMMUNICATION, CH_HALT and CH_STOP mode.
Users should only write to these bits when the RS-CANFD channel is in CH_RESET mode.

RSCFDnCFDCmFDCFG.REFE

RX edge filter enable.

This bits enables the RX edge filter during the IDLE detection (bus integration). When it is enabled then 2 consecutive dominant TQ required to detect a synchronization edge.

This bit cannot be written in CH_COMMUNICATION, CH_HALT and CH_STOP mode.

Users should not set to this bit when Classical only mode.

RSCFDnCFDCmFDCFG.FDOE

CANFD only enable.

This bits enables the reception and transmission of CANFD only frames. If enabled then communication in Classical CAN frame format is disabled. Transmission of classical CAN frames is not possible, the FDF bit of the message buffer is don't care (RSCFDnCFDCFFDCSTS.CFFDF / RSCFDnCFDTMFDCTR.TMFDF). If messages with classical CAN frame format is received then the protocol controller will treated them as invalid frames and response with error frames.

In case a Classical CAN frame is configured for transmitting, the FDF bit is sent as recessive, so a CANFD frame is sent. If the DLC is configured bigger than 8 the remaining data bytes are padded with CCh.

User should not set RSCFDnCFDCmFDCFG.FDOE and RSCFDnCFDCmFDCFG.CLOE simultaneously.

This bit cannot be written in CH_COMMUNICATION, CH_HALT and CH_STOP mode.

RSCFDnCFDCmFDCFG.GWBRS

Gateway BRS configuration bit.

When the bit RSCFDnCFDCmFDCFG.GWEN is set to 1_B then the BRS bit of the transmitting GW frame will be replaced by the value of RSCFDnCFDCmFDCFG.GWBRS.

In classical CAN frames the BRS bit has no meaning

This bit cannot be written in CH_COMMUNICATION or CH_STOP mode.

Users should only write to these bits when the RS-CANFD channel is in CH_RESET mode.

Users should not set to this bit when Classical only mode.

RSCFDnCFDCmFDCFG.GWFDF

Gateway FDF configuration bit.

When the bit RSCFDnCFDCmFDCFG.GWEN is set to 1_B then the FDF bit of the transmitting GW frame will be replaced by the value of RSCFDnCFDCmFDCFG.GWFDF.

This bit cannot be written in CH_COMMUNICATION or CH_STOP mode.

Users should only write to these bits when the RS-CANFD channel is in CH_RESET mode.

Users should not set to this bit when Classical only mode.

RSCFDnCFDCmFDCFG.GWEN

CAN2.0, CANFD <> CAN2.0, CANFD Multi Gateway Enable

When this bit is enabled then a multi gateway is enabled. Message received on one node can be routed to another node by using the Transmit/Receive FIFO when they are configured as GW FIFO (RSCFDnCFDCFCCk.CFM = 10_B).

Moreover, when TX Queue is set as GW mode, the message received on one node can be stored in TX Queue, and it can be sent to another node.

The FDF and BRS bit of the routed message can be changed by the configuration value of the RSCFDnCFDCmFDCFG.GWFDF and RSCFDnCFDCmFDCFG.GWBRS.

By this the transmitted value of these bits can be replaced.

Example :

RSCFDnCFDCmFDCFG.GWEN = 1 on channel y

RSCFDnCFDCmFDCFG.GWFDF = 1

If a Classical CAN frame is received on channel x and routed to a GW FIFO or TX Queue of channel y. Then this CAN frame is sent on Channel y as a CANFD frame, due to the RSCFDnCFDCmFDCFG.GWFDF bit.

The table below shows how the message information is changed depending on received and configured data.

Routed CAN frame	Routed Received DLC	CAN BRS	Configured RSCFDnCFDCmFDCFG.GWFDF bit	GW message DLC	GW message BRS Bit	GW message frame type
CAN2.0	≤ 8	N/A	1	≤ 8	Based on configuration RSCFDnCFDCmFDCFG.GWBRS	FD
CAN2.0	> 8	N/A	1	= 8	Based on configuration RSCFDnCFDCmFDCFG.GWBRS	FD
FD	≤ 8	?	1	≤ 8	Based on configuration RSCFDnCFDCmFDCFG.GWBRS	FD
FD	> 8	?	1	> 8	Based on configuration RSCFDnCFDCmFDCFG.GWBRS	FD
CAN2.0	≤ 8	N/A	0	≤ 8	N/A	CAN2.0
CAN2.0	> 8	N/A	0	> 8	N/A	CAN2.0
FD	≤ 8	?	0	≤ 8	N/A	CAN2.0
FD	> 8	?	0	= 8	N/A	CAN2.0

Note this Gateway is limited to 8 byte data payload for different frame type. If routing and target frame type is same then the DLC value is untouched.

In case the source frame was a CANFD with more than 8 data byte, then on classical destination node the Data payload is cut down to 8 byte. Only 8 bytes of top data performs GW transmission, and the remaining byte cancels it.

In case the source frame was a CLASSICAL with a DLC value > 8, then on CANFD destination node the DLC value itself is changed to 8.

NOTE

Other transmission buffer than the GW-FIFO are not affected by this feature.

Remote frames should not be routed via the Gateway, when RSCFDnCFDCmFDCFG.GWEN is set.

When a destination node is RSCFDnCFDCmFDCFG.FDOE=1, set RSCFDnCFDCmFDCFG.GWEN=1 and RSCFDnCFDCmFDCFG.GWFDF=1.

When a destination node is RSCFDnCFDCmFDCFG.CLOE=1, set RSCFDnCFDCmFDCFG.GWEN=1 and RSCFDnCFDCmFDCFG.GWFDF=0.

This bit cannot be written in CH_COMMUNICATION or CH_STOP mode.

Users should only write to these bits when the RS-CANFD channel is in CH_RESET mode.

RSCFDnCFDCmFDCFG.TDCO[7:0]

Transceiver Delay Compensation Offset

These bits set the secondary sample point offset. How this value is used, depends on the RSCFDnCFDCmFDCFG.TDCOC setting.

If RSCFDnCFDCmFDCFG.TDCOC = 0_B, the Transceiver Delay Compensation result is equal to the Trv_Delay (measured delay) + the value in RSCFDnCFDCmFDCFG.TDCO, rounded down to the nearest integer number of time quanta. Otherwise, the Transceiver Delay Compensation result is equal to the value in RSCFDnCFDCmFDCFG.TDCO. Refer to **Section 23.5.1.5** for details on how RSCFDnCFDCmFDCFG.TDCO is used.

The actual offset value is interpreted as TDCO + 1. E.g if 4 is set in TDCO, the offset is 5 clock cycle.

Clock cycle is 1 cycle of CAN channel DLL clock.

This bit cannot be written in CH_COMMUNICATION or CH_STOP mode.

Users should write to these bits, only when the RS-CANFD channel is in CH_RESET or CH_HALT mode.

Users should not set to this bit when Classical only mode.

RSCFDnCFDCmFDCFG.ESIC

Error State Indication Configuration

Bus controllers to be used as CAN to CAN gateways shall support that in every forwarded CANFD message the ESI flag is not changed to reflect the status of the gateway/bridge/router but instead the ESI flag is sent as it was in the original message.

This Error State Indication Configuration, controls the sending of either the own ESI flag information or the message ESI flag information (RSCFDnCFDCFFDCSTS.CFESI or RSCFDnCFDTMFDCTR.TMESI)

This bit cannot be written in CH_COMMUNICATION or CH_STOP mode.

Users should only write to these bits when the RS-CANFD channel is in CH_RESET or CH_HALT mode.

Users should not set to this bit when Classical only mode.

RSCFDnCFDCmFDCFG.TDCE

Transceiver Delay Compensation Enable

This bit enables the Transceiver Delay Compensation for the RS-CANFD channel.

This bit cannot be written in CH_COMMUNICATION or CH_STOP mode.

Users should only write to these bits when the RS-CANFD channel is in CH_RESET or CH_HALT mode.

Users should not set to this bit when Classical only mode.

RSCFDnCFDCmFDCFG.TDCOC

Transceiver Delay Compensation Offset Configuration

This bit selects which offset is used when defining the position of the secondary sample point (SSP) for the RS-CANFD channel. If the bit is set to 0_B then the position of the SSP is the measured Transceiver delay plus the fixed offset. If the bit is 1_B then the position of the SSP is defined only by the offset.

This bit cannot be written in CH_COMMUNICATION or CH_STOP mode.

Users should only write to these bits when the RS-CANFD channel is in CH_RESET or CH_HALT mode.

Users should not set to this bit when Classical only mode.

RSCFDnCFDCmFDCFG.EOCCFG[2:0]

Error Occurrence Counter Configuration

These bits select which type of CAN frame configuration and direction, protocol errors are counted in.

This bit cannot be written in CH_COMMUNICATION or CH_STOP mode.

Users should only write to these bits when the RS-CANFD channel is in CH_RESET or CH_HALT mode.

23.3.2.7 RSCFDnCFDCmFDCTR — Channel m CANFD Control Register

Access: RSCFDnCFDCmFDCTR register can be read or written in 32-bit units
RSCFDnCFDCmFDCTRL, RSCFDnCFDCmFDCTRH register can be read or written in 16-bit units
RSCFDnCFDCmFDCTRLL, RSCFDnCFDCmFDCTRLH, RSCFDnCFDCmFDCTRHL,
RSCFDnCFDCmFDCTRHH register can be read or written in 8-bit units

Address: RSCFDnCFDCmFDCTR: <RSCFDn_base> + 1408_H + (20_H × m)

RSCFDnCFDCmFDCTRL: <RSCFDn_base> + 1408_H + (20_H × m),
RSCFDnCFDCmFDCTRH: <RSCFDn_base> + $140A_H$ + (20_H × m)

RSCFDnCFDCmFDCTRLL: <RSCFDn_base> + 1408_H + (20_H × m),
RSCFDnCFDCmFDCTRLH: <RSCFDn_base> + 1409_H + (20_H × m),
RSCFDnCFDCmFDCTRHL: <RSCFDn_base> + $140A_H$ + (20_H × m),
RSCFDnCFDCmFDCTRHH: <RSCFDn_base> + $140B_H$ + (20_H × m)

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 23.20 RSCFDnCFDCmFDCTR Register Contents

Bit Position	Bit Name	Function
31 to 2	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
1	SOCCLR	Successful Occurrence Counter Clear 0: No Successful Occurrence Counter clear 1: Clear Successful Occurrence Counter
0	EOCCLR	Error Occurrence Counter Clear 0: No Error Occurrence Counter clear 1: Clear Error Occurrence Counter

The Channel m CANFD Control Register is used to control the error and successful occurrence counters.

RSCFDnCFDCmFDCTR.SOCCLR

Successful Occurrence Counter Clear.

This bit is used to clear the Successful Occurrence Counter.

This bit cannot be set in CH_STOP mode or CH_RESET.

Read value is always 0.

This bit is cleared automatically by the RS-CANFD logic.

This bit is cleared automatically when the related RS-CANFD channel is in CH_RESET mode.

RSCFDnCFDCmFDCTR.EOCCLR

Error Occurrence Counter Clear.

This bit is used to clear the error occurrence counter.

This bit cannot be set in CH_STOP mode or CH_RESET.

Read value is always 0.

This bit is cleared automatically by the RS-CANFD logic.

This bit is cleared automatically when the related RS-CANFD channel is in CH_RESET mode.

23.3.2.8 RSCFDnCFDCmFDSTS — Channel m CANFD Status Register

Access: RSCFDnCFDCmFDSTS register can be read or written in 32-bit units
RSCFDnCFDCmFDSTSL, RSCFDnCFDCmFDSTSH register can be read or written in 16-bit units
RSCFDnCFDCmFDSTSLL, RSCFDnCFDCmFDSTSLH, RSCFDnCFDCmFDSTSHL,
RSCFDnCFDCmFDSTSHH register can be read or written in 8-bit units

Address: RSCFDnCFDCmFDSTS: <RSCFDn_base> + $140C_H$ + (20_H × m)

RSCFDnCFDCmFDSTSL: <RSCFDn_base> + $140C_H$ + (20_H × m),
RSCFDnCFDCmFDSTSH: <RSCFDn_base> + $140E_H$ + (20_H × m)

RSCFDnCFDCmFDSTSLL: <RSCFDn_base> + $140C_H$ + (20_H × m),
RSCFDnCFDCmFDSTSLH: <RSCFDn_base> + $140D_H$ + (20_H × m),
RSCFDnCFDCmFDSTSHL: <RSCFDn_base> + $140E_H$ + (20_H × m),
RSCFDnCFDCmFDSTSHH: <RSCFDn_base> + $140F_H$ + (20_H × m)

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	SOC[7:0]								EOC[7:0]

Table 23.21 RSCFDnCFDCmFDSTS Register Contents

Bit Position	Bit Name	Function
31 to 24	SOC[7:0]	Successful occurrence counter register These bits show the successful occurrence counter value.
23 to 16	EOC[7:0]	Error occurrence counter register These bits show the error occurrence counter value.
15	TDCVF	Transmitter Delay Compensation Violation Flag 0: Transmitter Delay Compensation Violation has not occurred 1: Transmitter Delay Compensation Violation has occurred
14 to 10	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
9	SOCO	Successful occurrence counter overflow 0: Successful occurrence counter has not overflowed 1: Successful occurrence counter has overflowed
8	EOCO	Error occurrence counter overflow 0: Error occurrence counter has not overflowed 1: Error occurrence counter has overflowed
7 to 0	TDCR[7:0]	Transmitter Delay Compensation Result Transmitter delay compensation result

The Channel m CANFD Status Register indicates the transceiver compensation delay result and its related FIFO message lost status.

RSCFDnCFDCmFDSTS.SOC[7:0]

Successful occurrence counter register

These bits are set only by RS-CANFD module logic.

Writing any value has no influence on these bits.

These bits are updated (incremented) when the occurrence of any error-free messages on the bus is detected. Any means (received or transmitted). When the counter reaches the value of FF_H then updating is stopped.

Note in case of Loopback mode the counter would be incremented twice.

These bits are cleared by writing 1_B to RSCFDnCFDCmFDCTR.SOCCLR
These bits are cleared automatically when the related RS-CANFD channel is in CH_RESET mode.

RSCFDnCFDCmFDSTS.EOC[7:0]

Error occurrence counter register

This counter is used together with the RSCFDnCFDCmFDSTS.SOC counter to support an option for host-controlled fall-back to payload bit rate identical to arbitration bit rate when messages utilizing reduced payload bit length experience significantly higher error rates compared to other messages.

This higher error rate can be detected depending on the configuration of the RSCFDnCFDCmFDCFG.EOCCFG

These bits are set only by RS-CANFD module logic.

Writing any value has no influence on these bits.

These bits are updated (incremented) when an error occurs, according to the configuration of the RSCFDnCFDCmFDCFG.EOCCFG bits. When the counter reaches the value of FF_H then updating is stopped.

These bits are cleared by writing 1_B to RSCFDnCFDCmFDCTR.EOCCLR
These bits are cleared automatically when the related RS-CANFD channel is in CH_RESET mode.

RSCFDnCFDCmFDSTS.TDCVF

Transceiver Delay Compensation Violation Flag

The RS-CANFD module is capturing internally the transmitted data bit by a Bit.
This data is compared against the received CAN-Bus level which is delayed by the Transceiver loop delay.
The Transceiver delay has some variation depending on physical parameters like temperature. The result flag RSCFDnCFDCmFDSTS.TDCR will be updated by every message. Hence temporary max. delay violation could be missed. This bit is capturing this violation.

Writing 1_B has no influence on the bit value.

This bit is set automatically when the Transceiver Delay Compensation is greater than the max. delay compensation (6 data bit times – 2clk_dlc) and the internal Bit is overrun.

This bit is cleared by writing a 0_B to it.

This bit is cleared automatically when the related RS-CANFD channel is in CH_RESET mode.

Users can only write to this bit when the related RS-CANFD channel is in CH_HALT or CH_COMMUNICATION mode.

Do not use bit clear instruction for clearing this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Then the other bits remain set to 1_B.

RSCFDnCFDCmFDSTS.SOCO

Successful occurrence counter overflow

Indicates if the related CAN channel successful occurrence counter has overflowed.

Writing 1_B has no influence on the bit value.

This bit is set automatically when RSCFDnCFDCmFDSTS.SOC is FF_H and, successful message reception or successful message transmission occurs.

This bit is cleared by writing a 0_B to it.

This bit is cleared automatically when the related RS-CANFD channel is in CH_RESET mode.

Users can only write to this bit when the related RS-CANFD channel is in CH_HALT or CH_COMMUNICATION mode.

Do not use bit clear instruction for clearing this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Then the other bits remain set to 1_B.

RSCFDnCFDCmFDSTS.EOCO

Error occurrence counter overflow

Indicates if the related CAN channel error occurrence counter has overflowed.

Writing 1_B has no influence on the bit value.

This bit is set automatically when RSCFDnCFDCmFDSTS.EOC is FF_H and a CAN bus error is detected based on the configuration defined in RSCFDnCFDCmFDCFG.EOCCFG.

This bit is cleared by writing a 0_B to it.

This bit is cleared automatically when the related RS-CANFD channel is in CH_RESET mode.

Users can only write to this bit when the related RS-CANFD channel is in CH_HALT or CH_COMMUNICATION mode.

Do not use bit clear instruction for clearing this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Then the other bits remain set to 1_B.

RSCFDnCFDCmFDSTS.TDCR[7:0]

Transceiver Delay Compensation Result

The measured delay is a multiple of the CAN channel DLL clock.

This result depends on the RSCFDnCFDCmFDCFG.TDCOC configuration and the offset value in RSCFDnCFDCmFDCFG.TDCO. Refer to **Section 23.5.1.5** for details on how this value is derived.

These bits are set when the transceiver delay has been measured.

These bits are updated at the falling edge between FDF and res bit if RSCFDnCFDCmFDCFG.TDCOC = 0_B and the transceiver delay compensation is enabled (RSCFDnCFDCmFDCFG.TDCE = 1_B).

These bits are cleared automatically when the related RS-CANFD channel is in CH_RESET mode.

23.3.2.9 RSCFDnCFDCmFDCRC — Channel m CANFD CRC Register

Access: RSCFDnCFDCmFDCRC register is a read-only register that can be read in 32-bit units
RSCFDnCFDCmFDCRCL, RSCFDnCFDCmFDCRCH register is a read-only register that can be read in 16-bit units
RSCFDnCFDCmFDCRCLL, RSCFDnCFDCmFDCRCLH, RSCFDnCFDCmFDCRCHL, RSCFDnCFDCmFDCRCHH register is a read-only register that can be read in 8-bit units

Address: RSCFDnCFDCmFDCRC: <RSCFDn_base> + 1410_H + (20_H × m)

RSCFDnCFDCmFDCRCL: <RSCFDn_base> + 1410_H + (20_H × m),
RSCFDnCFDCmFDCRCH: <RSCFDn_base> + 1412_H + (20_H × m)

RSCFDnCFDCmFDCRCLL: <RSCFDn_base> + 1410_H + (20_H × m),
RSCFDnCFDCmFDCRCLH: <RSCFDn_base> + 1411_H + (20_H × m),
RSCFDnCFDCmFDCRCHL: <RSCFDn_base> + 1412_H + (20_H × m),
RSCFDnCFDCmFDCRCHH: <RSCFDn_base> + 1413_H + (20_H × m)

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	SCNT[3:0]				—	—	—	CRCREG[20:16]				
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	CRCREG[15:0]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 23.22 RSCFDnCFDCmFDCRC Register Contents

Bit Position	Bit Name	Function
31 to 28	Reserved	When read, the value after reset is returned.
27 to 24	SCNT[3:0]	Stuff bit count These bits show the stuff bit count (mod 8) for the CANFD frame.
23 to 21	Reserved	When read, the value after reset is returned.
20 to 0	CRCREG[20:0]	CRC Register value These bits show the CRC value calculated for the CANFD Frame.

The CRC Register holds the CRC value calculated for the CANFD Frame

RSCFDnCFDCmFDCRC.SCNT[3:0]

Stuff bit count

These bits show the Stuff Count value of the CANFD frame. It shows the number of inserted stuff bits (modulo 8, Gray-coded) for a CANFD frame if the RSCFDnCFDCmCTR.CTME bit is enabled on RSCFDnCFDCmFDCRC.SCNT[3:1]. And the corresponding Parity bit to this counter value on RSCFDnCFDCmFDCRC.SCNT[0].

If RSCFDnCFDCmCTR.CTME bit is 0_B, then these bits are always read as 0.

The RSCFDnCFDCmFDCRC.SCNT value is updated in the 1st bit of CRC field of the CANFD Frame (reception as well as transmission).

These bits are cleared automatically when the related RS-CANFD channel is in CH_RESET mode.

RSCFDnCFDCmFDCRC.CRCREG[20:0]

CRC Register value

The calculated CRC value can be read from these bits, only when RSCFDnCFDCmCTR.CTME is 1_B for the

channel.

If RSCFDnCFDCmCTR.CTME bit is 0_B, then these bits are always read as 0.

If CRC_17 (17 bit CRC) is used, then bits [20:17] are always read as 0.

These bits show the CRC value calculated by the RS-CANFD channel logic if the RSCFDnCFDCmCTR.CTME bit is enabled.

The RSCFDnCFDCmFDCRC.CRCREG value is updated in the 1st bit of CRC field of the CANFD Frame (reception as well as transmission).

These bits are cleared automatically when the related RS-CANFD channel is in CH_RESET mode.

23.3.3 Details of Global-Related Registers

23.3.3.1 RSCFDnCFDGCFG — Global Configuration Register

Access: RSCFDnCFDGCFG register can be read or written in 32-bit units
RSCFDnCFDGCFGL, RSCFDnCFDGCFGH register can be read or written in 16-bit units
RSCFDnCFDGCFGLL, RSCFDnCFDGCFGLH, RSCFDnCFDGCFGHL, RSCFDnCFDGCFGHH register can be read or written in 8-bit units

Address: RSCFDnCFDGCFG: <RSCFDn_base> + 0084_H

RSCFDnCFDGCFGL: <RSCFDn_base> + 0084_H, RSCFDnCFDGCFGH: <RSCFDn_base> + 0086_H

4	DCS	Data Link Controller Clock Select 0: Internal clean clock 1: External Clock source connected to clk_xincan pin

Table 23.23 RSCFDnCFDGCFG Register Contents (2/2)

Bit Position	Bit Name	Function
3	MME	Mirror Mode Enable 0: Mirror Mode disabled 1: Mirror Mode enabled
2	DRE	DLC Replacement Enable 0: DLC replacement disabled 1: DLC replacement enabled
1	DCE	DLC Check Enable 0: DLC check disabled 1: DLC check enabled
0	TPRI	Transmission Priority 0: ID Priority 1: Message Buffer Number Priority

The Global Configuration Register is used to select the transmission priority to be used for all the TX Message Buffers and the clock source for the CAN protocol engine of all CAN channels. It is also used to select the source for the timestamp clock and to configure the frequency for the timestamp clock and interval timer reference clock.

RSCFDnCFDGCFG.ITRCP[15:0]

Interval Timer Reference Clock Prescaler.

These bits allow the definition of a reference clock for the FIFO interval timer source clock.

When the RSCFDnCFDGCFG.ITRCP[15:0] bits are 0000_H, then the timer is disabled.

Users cannot write to this bit in GL_STOP mode.

Users should only write to this bit when RS-CANFD module is in GL_RESET mode.

RSCFDnCFDGCFG.TSBTCS[2:0]

Timestamp Bit Time Channel Select.

These bits allow the selection of the Bit Time clock of a particular channel for the Timestamp counter.

Users cannot write to this bit in GL_STOP mode.

Users should only write to this bit when RS-CANFD module is in GL_RESET mode.

RSCFDnCFDGCFG.TSSS

Timestamp Source Select.

This bit allows the selection of the clock source for the Timestamp counter.

Users cannot write to this bit in GL_STOP mode.

Users should only write to this bit when RS-CANFD module is in GL_RESET mode.

Users should not write 1_B when CANFD communication will be used.

Note bit time clock could be variable depending on the nominal and data rate bit configuration.

RSCFDnCFDGCFG.TSP[3:0]

Timestamp Prescaler.

The value configured in these bits defines the period of the clock source used for the Timestamp counter.

Users cannot write to this bit in GL_STOP mode.

Users should only write to this bit when RS-CANFD module is in GL_RESET mode.

RSCFDnCFDGCFG.CMPOC

CANFD message Payload overflow configuration.

The received message payload is always compared with the available message payload size in the Message Buffer. This bit controls the message payload acceptance mechanism in the case when the received payload is higher than the Message Buffer payload size RSCFDnCFDRMNB.RMPLS, RSCFDnCFDRFCCx.RFPLS, RSCFDnCFDCFCCk.CFPLS.

Users cannot write to this bit in GL_STOP & GL_OPERATING mode.

Users should only write to this bit when RS-CANFD module is in GL_RESET mode.

When this bit is set and payload overflow occurs, DLC value is stored in a RXMB or FIFO without changing.

RSCFDnCFDGCFG.DCS

Data Link Controller Clock Select.

This bit selects the clock source for the CAN communications. Internal clean clock has a smaller clock jitter than the Peripheral clock (pclk).

Users cannot write to this bit in GL_STOP & GL_OPERATING mode.

Users should only write to this bit when RS-CANFD module is in GL_RESET mode.

RSCFDnCFDGCFG.MME

Mirror Mode Enable.

This bit enables the Mirror Mode for all CAN channels.

Users cannot write to this bit in GL_STOP mode.

Users should only write to this bit when RS-CANFD module is in GL_RESET mode.

RSCFDnCFDGCFG.DRE

DLC Replacement Enable.

If this bit is 1_B and RSCFDnCFDGCFG.DCE is 1_B, then RS-CANFD will store the configured value (RSCFDnCFDGAFLP0j.GAFLDLC) of DLC in the destination RX Message Buffer or FIFO buffer if the DLC check passes. Otherwise the DLC value in the destination RX Message Buffer or FIFO buffer is unchanged.

Users cannot write to this bit in GL_STOP mode.

Users should only write to this bit when RS-CANFD module is in GL_RESET mode.

RSCFDnCFDGCFG.DCE

DLC Check Enable.

This bit enables the DLC check for all CAN channels.

Users cannot write to this bit in GL_STOP mode.

Users should only write to this bit when RS-CANFD module is in GL_RESET mode.

RSCFDnCFDGCFG.TPRI

Transmission Priority.

This bit selects the transmission priority for all CAN channels.

Users cannot write to this bit in GL_STOP mode.

Message Buffer Number Priority should not be used together with TX Queue transmission.

Users should only write to this bit when RS-CANFD module is in GL_RESET mode.

23.3.3.2 RSCFDnCFDGCTR — Global Control Register

Access: RSCFDnCFDGCTR register can be read or written in 32-bit units
RSCFDnCFDGCTRL, RSCFDnCFDGCTRH register can be read or written in 16-bit units
RSCFDnCFDGCTRLL, RSCFDnCFDGCTRLH, RSCFDnCFDGCTRHL, RSCFDnCFDGCTRHH register can be read or written in 8-bit units

Address: RSCFDnCFDGCTR: <RSCFDn_base> + 0088_H

RSCFDnCFDGCTRL: <RSCFDn_base> + 0088_H, RSCFDnCFDGCTRH: <RSCFDn_base> + $008A_H$

RSCFDnCFDGCTRLL: <RSCFDn_base> + 0088_H, RSCFDnCFDGCTRLH: <RSCFDn_base> + 0089_H,
RSCFDnCFDGCTRHL: <RSCFDn_base> + $008A_H$, RSCFDnCFDGCTRHH: <RSCFDn_base> + $008B_H$

Value after reset: $0000\ 0005_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 23.24 RSCFDnCFDGCTR Register Contents (1/2)

Bit Position	Bit Name	Function
31 to 17	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
16	TSRST	Timestamp Reset 0: Timestamp not reset 1: Timestamp reset
15	MOWEIE	GW FIFO Message overwrite Error Interrupt Enable 0: GW FIFO Message overwrite Error Interrupt Disabled 1: GW FIFO Message overwrite Error Interrupt Enabled
14	QMEIE	TXQ Message lost Error Interrupt Enable 0: TXQ Message Lost Error Interrupt Disabled 1: TXQ Message Lost Error Interrupt Enabled
13	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
12	QOWEIE	TXQ Message overwrite Error Interrupt Enable 0: TXQ Message overwrite Error Interrupt Disabled 1: TXQ Message overwrite Error Interrupt Enabled
11	CMPOFIE	CANFD message payload overflow Flag Interrupt enable 0: CANFD message payload overflow Flag Interrupt Disabled 1: CANFD message payload overflow Flag Interrupt Enabled
10	THLEIE	TX History List Entry Lost Interrupt Enable 0: TX History List Entry Lost Interrupt Disabled 1: TX History List Entry Lost Interrupt Enabled
9	MEIE	Message lost Error Interrupt Enable 0: Message Lost Error Interrupt Disabled 1: Message Lost Error Interrupt Enabled
8	DEIE	DLC check Interrupt Enable 0: DLC check Interrupt Disabled 1: DLC check Interrupt Enabled
7 to 3	Reserved	When read, the value after reset is returned. When writing, write the value after reset.

Table 23.24 RSCFDnCFDGCTR Register Contents (2/2)

Bit Position	Bit Name	Function
2	GSLPR	Global Stop Request 0: Global Stop Request Disabled 1: Global Stop Request Enabled
1, 0	GMDC[1:0]	Global Mode Control 00: Global Operating Mode Request 01: Global Reset Mode Request 10: Global Test Mode Request 11: Keep Current Value

The Global Control Register is used to control the global mode of the RS-CANFD module and to control the timestamp function. It is also used to enable and disable the global error interrupts

RSCFDnCFDGCTR.TSRST

Timestamp Reset.

When this bit is 1_B, the Global Timestamp Register is reset to 0000_H.

Users cannot write to this bit when the RS-CANFD module is in GL_STOP mode.

Users should not write to this bit when the RS-CANFD module is in GL_RESET mode.

Read value is always 0.

This bit is cleared automatically by the RS-CANFD logic.

RSCFDnCFDGCTR.MOWEIE

GW FIFO Message overwrite Error Interrupt Enable.

If this bit is 1_B, then an Interrupt will be generated when GW mode and GW FIFO Message over write condition occurs.

Users cannot write to this bit when the RS-CANFD module is in GL_STOP mode.

RSCFDnCFDGCTR.QMEIE

TXQ Message lost Error Interrupt Enable.

If this bit is 1_B, then an Interrupt will be generated when a TXQ Message Lost condition occurs

Users cannot write to this bit when the RS-CANFD module is in GL_STOP mode.

RSCFDnCFDGCTR.QOWEIE

TXQ Message overwrite Error Interrupt Enable.

If this bit is 1_B, then an Interrupt will be generated when TXQ Message overwrite condition occurs.

Users cannot write to this bit when the RS-CANFD module is in GL_STOP mode.

RSCFDnCFDGCTR.CMPOFIE

CANFD message payload overflow Flag Interrupt enable.

If this bit is 1_B, then an Interrupt will be generated when a CANFD message payload overflow condition occurs.

Users cannot write to this bit when the RS-CANFD module is in GL_STOP mode.

RSCFDnCFDGCTR.THLEIE

TX History List Entry Lost Interrupt Enable.

If this bit is 1_B, then an Interrupt will be generated when a TX History List Entry Lost condition occurs.

Users cannot write to this bit when the RS-CANFD module is in GL_STOP mode.

RSCFDnCFDGCTR.MEIE

Message lost Error Interrupt Enable.

If this bit is 1_B, then an Interrupt will be generated when a Message Lost condition occurs.

Users cannot write to this bit when the RS-CANFD module is in GL_STOP mode.

RSCFDnCFDGCTR.DEIE

DLC check Interrupt Enable

If this bit is 1_B, then an interrupt will be generated when a DLC error is detected in received frames.

Users cannot write to this bit when the RS-CANFD module is in GL_STOP mode.

RSCFDnCFDGCTR.GSLPR

Global Stop Request

This bit globally selects the Stop request for RS-CANFD module including all CAN channels (Channel Stop request is set automatically for all channels).

Users can only write to this bit when RS-CANFD module is in GL_RESET or GL_STOP mode.

RSCFDnCFDGCTR.GMDC[1:0]

Global Mode Control

RSCFDnCFDGCTR.GMDC bits can be used to configure the modes for the RS-CANFD module.

Additionally, if RSCFDnCFDGCTR.GSLPR is 1_B when the RS-CANFD module is in Reset Mode, then the RS-CANFD module transits to Global Stop Mode.

Setting RSCFDnCFDGCTR.GMDC to 11_B has no effect. Mode transition is described in detail later in **Section 23.4.1**.

Users cannot write to this bit when the RS-CANFD module is in GL_STOP mode.

23.3.3.3 RSCFDnCFDGSTS — Global Status Register

Access: RSCFDnCFDGSTS register is a read-only register that can be read in 32-bit units
RSCFDnCFDGSTSL, RSCFDnCFDGSTSH register is a read-only register that can be read in 16-bit units
RSCFDnCFDGSTSLL, RSCFDnCFDGSTSLH, RSCFDnCFDGSTSHL, RSCFDnCFDGSTSHH register is a read-only register that can be read in 8-bit units

Address: RSCFDnCFDGSTS: <RSCFDn_base> + $008C_H$

RSCFDnCFDGSTSL: <RSCFDn_base> + $008C_H$, RSCFDnCFDGSTSH: <RSCFDn_base> + $008E_H$

RSCFDnCFDGSTSLL: <RSCFDn_base> + $008C_H$, RSCFDnCFDGSTSLH: <RSCFDn_base> + $008D_H$,
RSCFDnCFDGSTSHL: <RSCFDn_base> + $008E_H$, RSCFDnCFDGSTSHH: <RSCFDn_base> + $008F_H$

Value after reset: $0000\ 000D_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	GRAMINIT	GSLPSTS	GHLTSTS	GRSTSTS
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	1	1	0	1
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 23.25 RSCFDnCFDGSTS Register Contents

Bit Position	Bit Name	Function
31 to 4	Reserved	When read, the value after reset is returned.
3	GRAMINIT	Global RAM Initialization 0: RAM initialization is finished 1: RAM initialization ongoing
2	GSLPSTS	Global Stop Status 0: Not in Stop Mode 1: In Stop Mode
1	GHLTSTS	Global Test Status 0: Not in Test Mode 1: In Test Mode
0	GRSTSTS	Global Reset Status 0: Not in Reset Mode 1: In Reset Mode

The Global Status Register indicates the global status of the RS-CANFD module.

RSCFDnCFDGSTS.GRAMINIT

Global RAM Initialization.

Indicates the Global RS-CANFD Module RAM initialization state.

This bit is set automatically when the RS-CANFD module enters Global Stop Mode after HW Reset.

This bit is cleared automatically when the RS-CANFD module has finished the RAM initialization.

This bit is cleared when the test_mode input port is set to 1_B.

RSCFDnCFDGSTS.GSLPSTS

Global Stop Status.

Indicates the Global RS-CANFD Module Stop mode.

This bit is set automatically when the RS-CANFD module enters Global Stop Mode.

This bit is cleared automatically when the RS-CANFD module exits the Stop Mode.

RSCFDnCFDGSTS.GHLTSTS

Global Test Status.

Indicates the Global RS-CANFD Module Test mode.

This bit is set automatically when the RS-CANFD module enters Global Test Mode.

This bit is cleared automatically when the RS-CANFD module exits the Test Mode.

RSCFDnCFDGSTS.GRSTSTS

Global Reset Status.

Indicates the Global RS-CANFD Module Reset mode.

This bit is set automatically when the RS-CANFD module enters Global Reset Mode. When the mode is changed from Global Reset Mode to Global Stop Mode, RSCFDnCFDGSTS.GRSTSTS remains set.

This bit is cleared automatically when the RS-CANFD module exits the Global Reset Mode.

23.3.3.4 RSCFDnCFDGERFL — Global Error Flag Register

Access: RSCFDnCFDGERFL register can be read or written in 32-bit units
RSCFDnCFDGERFLL, RSCFDnCFDGERFLH register can be read or written in 16-bit units
RSCFDnCFDGERFLLL, RSCFDnCFDGERFLLH, RSCFDnCFDGERFLHL, RSCFDnCFDGERFLHH register can be read or written in 8-bit units

Address: RSCFDnCFDGERFL: <RSCFDn_base> + 0090_H

RSCFDnCFDGERFLL: <RSCFDn_base> + 0090_H, RSCFDnCFDGERFLH: <RSCFDn_base> + 0092_H

RSCFDnCFDGERFLLL: <RSCFDn_base> + 0090_H, RSCFDnCFDGERFLLH: <RSCFDn_base> + 0091_H, RSCFDnCFDGERFLHL: <RSCFDn_base> + 0092_H, RSCFDnCFDGERFLHH: <RSCFDn_base> + 0093_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	EEF7	EEF6	EEF5	EEF4	EEF3	EEF2	EEF1	EEF0
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

	—	—	—	—	—	—	—	—	MOWES	QMES	—	QOWES	CMPOF	THLES	MES	DEF
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R	R	R/W

Table 23.26 RSCFDnCFDGERFL Register Contents (1/2)

Bit Position	Bit Name	Function
31 to 24	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
23	EEF7	ECC Error Flag for Channel 7 0: ECC error not detected during TX-SCAN 1: ECC error detected during TX-SCAN
22	EEF6	ECC Error Flag for Channel 6 0: ECC error not detected during TX-SCAN 1: ECC error detected during TX-SCAN
21	EEF5	ECC Error Flag for Channel 5 0: ECC error not detected during TX-SCAN 1: ECC error detected during TX-SCAN
20	EEF4	ECC Error Flag for Channel 4 0: ECC error not detected during TX-SCAN 1: ECC error detected during TX-SCAN
19	EEF3	ECC Error Flag for Channel 3 0: ECC error not detected during TX-SCAN 1: ECC error detected during TX-SCAN
18	EEF2	ECC Error Flag for Channel 2 0: ECC error not detected during TX-SCAN 1: ECC error detected during TX-SCAN
17	EEF1	ECC Error Flag for Channel 1 0: ECC error not detected during TX-SCAN 1: ECC error detected during TX-SCAN
16	EEF0	ECC Error Flag for Channel 0 0: ECC error not detected during TX-SCAN 1: ECC error detected during TX-SCAN
15 to 8	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
7	MOWES	Message overwrite Error Status 0: Message overwrite Error not detected 1: Message overwrite Error detected

Table 23.26 RSCFDnCFDGERFL Register Contents (2/2)

Bit Position	Bit Name	Function
6	QMES	TXQ Message Lost Error Status 0: TXQ Message lost Error not detected 1: TXQ Message lost Error detected
5	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
4	QOWES	TXQ Message overwrite Error Status 0: TXQ Message overwrite Error not detected 1: TXQ Message overwrite Error detected
3	CMPOF	CANFD Message payload overflow Flag 0: CANFD message payload overflow not detected 1: CANFD message payload overflow detected
2	THLES	TX History List Entry Lost Error Status 0: TX History List Entry Lost Error not detected 1: TX History List Entry Lost Error detected
1	MES	Message Lost Error Status 0: Message lost Error not detected 1: Message lost Error detected
0	DEF	DLC Error Flag 0: DLC Error not detected 1: DLC Error detected

The Global Error Flag register indicates the detection of global errors.

RSCFDnCFDGERFL.EEFm

ECC Error Flag for Channel m.

Users cannot write to this bit when the RS-CANFD module is in GL_STOP or GL_RESET mode.

Writing 1_B has no influence on the bit values.

Do not use bit clear instruction for clearing this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Then the other bits remain set to 1_B.

The bit is cleared by writing 0_B to it.
This bit will be cleared automatically in GL_RESET mode.

RSCFDnCFDGERFL.MOWES

Message overwrite Error Status.

This bit is set automatically when GW mode and Transmit/Receive FIFO Message overwrite Error is detected.

This bit is cleared automatically when all Transmit/Receive FIFO Message overwrite flags are cleared.

This bit will be cleared automatically in GL_RESET mode.

RSCFDnCFDGERFL.QMES

TXQ Message lost Error Status.

This bit is set automatically when TXQ Message lost Error is detected.

This bit is cleared automatically when all TXQ Message lost flags are cleared.

This bit will be cleared automatically in GL_RESET mode.

RSCFDnCFDGERFL.QOWES

TXQ Message overwrite Error Status.

This bit is set automatically when TXQ Message overwrite Error is detected.

This bit is cleared automatically when all TXQ Message overwrite flags are cleared.

This bit will be cleared automatically in GL_RESET mode.

RSCFDnCFDGERFL.CMPOF

CANFD message payload overflow Flag.

If this bit is set then a payload overflow has happened on at least one channel.

Users cannot write to this bit when the RS-CANFD module is in GL_STOP or GL_RESET mode. Writing 1_B has no influence on the bit values.

This bit is set automatically when a CANFD message payload overflow is detected on at least one channel.

The bit is cleared by writing 0_B to it.
Do not use bit clear instruction for clearing this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Then the other bits remain set to 1_B.

This bit will be cleared automatically in GL_RESET mode.

RSCFDnCFDGERFL.THLES

TX History List Entry Lost Error Status.

This bit is set automatically when a TX History List Entry Lost Error is detected.

This bit is cleared automatically when all TX History List Entry Lost flags are cleared.
This bit will be cleared automatically in GL_RESET mode.

RSCFDnCFDGERFL.MES

Message Lost Error Status.

This bit is set automatically when a FIFO Message Lost Error is detected.

This bit is cleared automatically when all FIFO Message Lost flags are cleared.
This bit will be cleared automatically in GL_RESET mode.

RSCFDnCFDGERFL.DEF

DLC Error Flag.

Users cannot write to this bit when the RS-CANFD module is in GL_STOP or GL_RESET mode. Writing 1_B has no influence on the bit values.

Do not use bit clear instruction for clearing this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Then the other bits remain set to 1_B.

This bit is set automatically when a DLC Error is detected in a received frame.

The bit is cleared by writing 0_B to it.
This bit will be cleared automatically in GL_RESET mode.

23.3.3.5 RSCFDnCFDGTSC — Global Timestamp Counter Register

Access: RSCFDnCFDGTSC register is a read-only register that can be read in 32-bit units.
RSCFDnCFDGTSCL, RSCFDnCFDGTSCH register is a read-only register that can be read in 16-bit units.

Address: RSCFDnCFDGTSC: <RSCFDn_base> + 0094_H

RSCFDnCFDGTSCL: <RSCFDn_base> + 0094_H, RSCFDnCFDGTSCH: <RSCFDn_base> + 0096_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TS[15:0]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 23.27 RSCFDnCFDGTSC Register Contents

Bit Position	Bit Name	Function
31 to 16	Reserved	When read, the value after reset is returned.
15 to 0	TS[15:0]	Timestamp Value

The Timestamp counter register stores the Timestamp based on the selected configuration.

RSCFDnCFDGTSC.TS[15:0]

Timestamp Value.

The proper incrementing of the Time Stamp counter cannot be guaranteed when moving to Halt state.

The Timestamp value is stored in this register based on the configuration of TSSS, TSBTCS and TSP.

Users cannot write to these bits when the RS-CANFD module is in GL_RESET or GL_STOP mode.

These bits will be cleared automatically in GL_RESET mode.

23.3.3.6 RSCFDnCFDGTINTSTSs — Global Transmit Interrupt Status Register s

Access: RSCFDnCFDGTINTSTSs register is a read-only register that can be read in 32-bit units
RSCFDnCFDGTINTSTSsL, RSCFDnCFDGTINTSTSsH register is a read-only register that can be read in 16-bit units
RSCFDnCFDGTINTSTSsLL, RSCFDnCFDGTINTSTSsLH, RSCFDnCFDGTINTSTSsHL, RSCFDnCFDGTINTSTSsHH register is a read-only register that can be read in 8-bit units

Address: RSCFDnCFDGTINTSTSs: <RSCFDn_base> + 1300_H + (4_H × s)

RSCFDnCFDGTINTSTSsL: <RSCFDn_base> + 1300_H + (4_H × s),
RSCFDnCFDGTINTSTSsH: <RSCFDn_base> + 1300_H + (4_H × s)

RSCFDnCFDGTINTSTSsLL: <RSCFDn_base> + 1300_H + (4_H × s),
RSCFDnCFDGTINTSTSsLH: <RSCFDn_base> + 1300_H + (4_H × s),
RSCFDnCFDGTINTSTSsHL: <RSCFDn_base> + 1300_H + (4_H × s),
RSCFDnCFDGTINTSTSsHH: <RSCFDn_base> + 1300_H + (4_H × s)

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	CFOTIF3	TQOFIF3	THIF3	CFTIF3	TQIF3	TAIF3	TSIF3	—	CFOTIF2	TQOFIF2	THIF2	CFTIF2	TQIF2	TAIF2	TSIF2
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

2	TQIF0	TX Queue Interrupt Flag Channel (0 + (s * 4)) 0: Channel m TX Queue Interrupt flag not set 1: Channel m TX Queue Interrupt flag set
1	TAIF0	TX Abort Interrupt Flag Channel (0 + (s * 4)) 0: Channel m TX abort Interrupt flag not set 1: Channel m TX abort Interrupt flag set
0	TSIF0	TX Successful Interrupt Flag Channel (0 + (s * 4)) 0: Channel m TX Successful completion Interrupt flag not set 1: Channel m TX Successful completion Interrupt flag set

(s) can be calculated from the desired Interrupt Channel (m) status flags using the formula s = floor(m / 4)

Byte position can be calculated using the formula (m – (s * 4))

e.g. for Interrupt Channel 7 Status Flags we have:

m = 7, s = floor(7 / 4) = 1 and Byte position = (7 – (1 * 4)) = 3

Therefore, Users should read the Byte 3 (4^{th} Byte) of RSCFDnCFDGTINTSTS1.

RSCFDnCFDGTINTSTSs.CFOTIFo

Transmit/Receive FIFO One Frame Transmission Interrupt Flag Channel (o + (s * 4))

RSCFDnCFDGTINTSTSs.CFOTIFo Bit (Transmit/Receive FIFO One Frame Transmission Interrupt flag Channel m)

This bit is set automatically when the related Transmit/Receive FIFO One Frame Transmission Interrupt Flag (RSCFDnCFDCFSTSk.CFOFTXIF) is set when the Interrupt is enabled.

This bit is cleared automatically when related Transmit/Receive FIFO One Frame Transmission Interrupt Flag (RSCFDnCFDCFSTSk.CFOFTXIF) is cleared or the Interrupt enable is disabled.
This bit will be cleared automatically in GL_RESET mode or CH_RESET mode.

RSCFDnCFDGTINTSTSs.TQOFIFo

TX Queue One Frame Transmission Interrupt Flag Channel (o + (s * 4))

RSCFDnCFDGTINTSTSs.TQOFIFo Bit (TX Queue One Frame Transmission Interrupt Flag Channel m)

This bit is set automatically when the related TX Queue One Frame TX Interrupt flag of the related channel is set when the Interrupt is enabled.

This bit is cleared automatically when related TX Queue One Frame TX Interrupt flag is cleared or the

Interrupt enable is disabled.
This bit will be cleared automatically in GL_RESET mode or CH_RESET mode.

RSCFDnCFDGTINTSTSs.THIFo

TX History List Interrupt Channel (o + (s * 4))

RSCFDnCFDGTINTSTSs.THIFo Bit (TX History List Interrupt flag Channel m)

This bit is set automatically when the related TX History List Interrupt Flag (RSCFDnCFDTHLSTSm.THLIF) is set when the Interrupt is enabled.

This bit is cleared automatically when related TX History List Interrupt Flag (RSCFDnCFDTHLSTSm.THLIF) is cleared or the Interrupt enable is disabled.
This bit will be cleared automatically in GL_RESET mode or CH_RESET mode.

RSCFDnCFDGTINTSTSs.CFTIFo

Transmit/Receive FIFO TX/GW Mode Interrupt Flag Channel (o + (s * 4))

RSCFDnCFDGTINTSTSs.CFTIFo Bit (Transmit/Receive FIFO in TX/GW mode Interrupt flag Channel m)

This bit is set automatically when the related Common TX/GW FIFO Interrupt Flag (RSCFDnCFDCFSTSk.CFTXIF) is set when the Interrupt is enabled.

This bit is cleared automatically when related Common TX/GW FIFO Interrupt Flag is cleared or the Interrupt enable is disabled.
This bit will be cleared automatically in GL_RESET mode or CH_RESET mode.

RSCFDnCFDGTINTSTSs.TQIFo

TX Queue Interrupt Flag Channel (o + (s * 4))

RSCFDnCFDGTINTSTSs.TQIFo Bit (TX Queue Interrupt Flag Channel m)

This bit is set automatically when the related TX Queue Interrupt flag of the related channel is set when the Interrupt is enabled.

This bit is cleared automatically when related TX Queue Interrupt flag is cleared or the Interrupt enable is disabled.
This bit will be cleared automatically in GL_RESET mode or CH_RESET mode.

RSCFDnCFDGTINTSTSs.TAIFo

TX Abort Interrupt Flag Channel (o + (s * 4))

RSCFDnCFDGTINTSTSs.TAIFo Bit (TX Abort Interrupt Flag Channel m)

This bit is set automatically when abort Successful flag of the related channel is set when the Interrupt is enabled.

This bit is cleared automatically when the related TX MB Result status bits are cleared or the Interrupt enable is disabled.
This bit will be cleared automatically in GL_RESET mode or CH_RESET mode.

RSCFDnCFDGTINTSTSs.TSIFo

TX Successful Interrupt Flag Channel (o + (s * 4))

RSCFDnCFDGTINTSTSs.TSIFo Bit (TX Successful Completion Interrupt Flag Channel m)

This bit is set automatically when the Transmission Successful flag of the related channel is set when the Interrupt is enabled.

This bit is cleared automatically when related TX MB Result status bits are cleared or the Interrupt enable is disabled.
This bit will be cleared automatically in GL_RESET mode or CH_RESET mode.

23.3.3.7 RSCFDnCFDGRINTSTSm — Global Receive Interrupt Status Register m

Access: RSCFDnCFDGRINTSTSm register is a read-only register that can be read in 32-bit units
RSCFDnCFDGRINTSTSmL, RSCFDnCFDGRINTSTSmH register is a read-only register that can be read in 16-bit units
RSCFDnCFDGRINTSTSmLL, RSCFDnCFDGRINTSTSmLH, RSCFDnCFDGRINTSTSmHL, RSCFDnCFDGRINTSTSmHH register is a read-only register that can be read in 8-bit units

Address: RSCFDnCFDGRINTSTSm: <RSCFDn_base> + 1350_H + (04_H × m)

RSCFDnCFDGRINTSTSmL: <RSCFDn_base> + 1350_H + (04_H × m),
RSCFDnCFDGRINTSTSmH: <RSCFDn_base> + 1352_H + (04_H × m)

RSCFDnCFDGRINTSTSmLL: <RSCFDn_base> + 1350_H + (04_H × m),
RSCFDnCFDGRINTSTSmLH: <RSCFDn_base> + 1351_H + (04_H × m),
RSCFDnCFDGRINTSTSmHL: <RSCFDn_base> + 1352_H + (04_H × m),
RSCFDnCFDGRINTSTSmHH: <RSCFDn_base> + 1353_H + (04_H × m)

Value after reset: $0000\ 0000_H$

Table 23.29 RSCFDnCFDGRINTSTSm Register Contents (1/2)

Bit Position	Bit Name	Function
31	Reserved	When read, the value after reset is returned.
30 to 28	CFOFRIF[2:0]	Transmit/Receive FIFO One Frame RX Interrupt Flag Channel m 0: Corresponding Transmit/Receive FIFO One Frame RX interrupt flag is not set 1: Corresponding Transmit/Receive FIFO One Frame RX interrupt flag is set
27	Reserved	When read, the value after reset is returned.
26 to 24	CFRFIF[2:0]	Transmit/Receive FIFO FDC level Full Interrupt Flag Channel m 0: Corresponding Transmit/Receive FIFO Full interrupt flag is not set 1: Corresponding Transmit/Receive FIFO Full interrupt flag is set
23 to 19	Reserved	When read, the value after reset is returned.
18 to 16	CFRIF[2:0]	Transmit/Receive FIFO RX Interrupt Flag Channel m 0: Corresponding Transmit/Receive FIFO RX interrupt flag is not set 1: Corresponding Transmit/Receive FIFO RX interrupt flag is set
15, 14	Reserved	When read, the value after reset is returned.
13, 12	BQOFRIF[1:0]	Borrowed TXQ One Frame RX Interrupt Flag Channel m 0: Corresponding TXQ One Frame RX interrupt flag is not set 1: Corresponding TXQ One Frame RX interrupt flag is set
11	Reserved	When read, the value after reset is returned.
10 to 8	QOFRIF[2:0]	TXQ One Frame RX Interrupt Flag Channel m 0: Corresponding TXQ One Frame RX interrupt flag is not set 1: Corresponding TXQ One Frame RX interrupt flag is set
7, 6	Reserved	When read, the value after reset is returned.
5, 4	BQFIF[1:0]	Borrowed TXQ Full Interrupt Flag Channel m 0: Corresponding TXQ Full interrupt flag is not set 1: Corresponding TXQ Full interrupt flag is set
3	Reserved	When read, the value after reset is returned.

Table 23.29 RSCFDnCFDGRINTSTSm Register Contents (2/2)

Bit Position	Bit Name	Function
2 to 0	QFIF[2:0]	TXQ Full Interrupt Flag Channel m 0: Corresponding TXQ Full interrupt flag is not set 1: Corresponding TXQ Full interrupt flag is set

RSCFDnCFDGRINTSTSm.CFOFRIF[2:0]

Transmit/Receive FIFO One Frame RX Interrupt Flag Channel m.

This bit is set automatically when the Transmit/Receive FIFO One Frame RX Interrupt flag of the related channel is set when the Interrupt is enabled.
This bit is cleared automatically when related Transmit/Receive FIFO RX Result status bits are cleared or the Interrupt enable is disabled.
This bit will be cleared automatically in GL_RESET mode or CH_RESET mode.

RSCFDnCFDGRINTSTSm.CFRFIF[2:0]

Transmit/Receive FIFO FDC level full Interrupt Flag Channel m.

This bit is set automatically when the Transmit/Receive FIFO Full Interrupt flag of the related channel is set when the Interrupt is enabled.
This bit is cleared automatically when related Transmit/Receive FIFO RX Result status bits are cleared or the Interrupt enable is disabled.
This bit will be cleared automatically in GL_RESET mode or CH_RESET mode.

RSCFDnCFDGRINTSTSm.CFRIF[2:0]

Transmit/Receive FIFO RX Interrupt Flag Channel m.

This bit is set automatically when the Transmit/Receive FIFO RX Interrupt flag of the related channel is set when the Interrupt is enabled.
This bit is cleared automatically when related Transmit/Receive FIFO RX Result status bits are cleared or the Interrupt enable is disabled.
This bit will be cleared automatically in GL_RESET mode or CH_RESET mode.

RSCFDnCFDGRINTSTSm.BQOFRIF[1:0]

Borrowed TXQ One Frame RX Interrupt Flag Channel m.

This bit is set, when a Flexible transmission buffer assignment function is used and borrowed TXQ receives one frame. Operation is the same as RSCFDnCFDGRINTSTSm.QOFRIF.

This bit of the channel which lends TXMB is a reserve bit.

RSCFDnCFDGRINTSTSm.QOFRIF[2:0]

TXQ One Frame RX Interrupt Flag Channel m.

This bit is set automatically when the TXQ One Frame RX Interrupt flag of the related channel is set when the Interrupt is enabled.
This bit is cleared automatically when related TXQ Result status bits are cleared or the Interrupt enable is disabled.
This bit will be cleared automatically in GL_RESET mode or CH_RESET mode.

RSCFDnCFDGRINTSTSm.BQFIF[1:0]

Borrowed TXQ Full Interrupt Flag Channel m.

This bit is set, when a Flexible transmission buffer assignment function is used and borrowed TXQ is in full status. Operation is the same as RSCFDnCFDGRINTSTSm.QFIF.

This bit of the channel which lends TXMB is a reserve bit.

RSCFDnCFDGRINTSTSm.QFIF[2:0]

TXQ Full Interrupt Flag Channel m.

This bit is set automatically when the TXQ Full Interrupt flag of the related channel is set when the Interrupt is enabled.

This bit is cleared automatically when related TXQ Result status bits are cleared or the Interrupt enable is disabled.

This bit will be cleared automatically in GL_RESET mode or CH_RESET mode.

23.3.3.8 RSCFDnCFDGFDCFG — Global FD Configuration Register

Access: RSCFDnCFDGFDCFG register can be read or written in 32-bit units
RSCFDnCFDGFDCFGL, RSCFDnCFDGFDCFGH register can be read or written in 16-bit units
RSCFDnCFDGFDCFGLL, RSCFDnCFDGFDCFGLH, RSCFDnCFDGFDCFGHL, RSCFDnCFDGFDCFGHH register can be read or written in 8-bit units

Address: RSCFDnCFDGFDCFG: <RSCFDn_base> + 1314_H

RSCFDnCFDGFDCFGL: <RSCFDn_base> + 1314_H,
RSCFDnCFDGFDCFGH: <RSCFDn_base> + 1316_H

RSCFDnCFDGFDCFGLL: <RSCFDn_base> + 1314_H,
RSCFDnCFDGFDCFGLH: <RSCFDn_base> + 1315_H,
RSCFDnCFDGFDCFGHL: <RSCFDn_base> + 1316_H,
RSCFDnCFDGFDCFGHH: <RSCFDn_base> + 1317_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R/W	R/W	R	R	R	R	R	R	R	R/W

Table 23.30 RSCFDnCFDGFDCFG Register Contents

Bit Position	Bit Name	Function
31 to 10	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
9, 8	TSCCFG	Timestamp capture configuration 00: Timestamp capture at the sample point of SOF (start of frame). 01: Timestamp capture at frame valid indication. 10: Timestamp capture at the sample point of RES bit 11: Setting prohibited
7 to 1	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
0	RPED	RES bit Protocol exception disable 0: Protocol exception event detection enabled. 1: Protocol exception event detection disabled.

RSCFDnCFDGFDCFG.TSCCFG

Timestamp capture configuration.

These bits configure the different capture points of the timestamp; for transmission and reception. When RSCFDnCFDGFDCFG.TSCCFG[1:0] = 10_B then the timestamp capture is done for CANFD frames at RES bit and for Classical frames at the start of frame.

Users can set these bits only when RS-CANFD module is in GL_RESET mode.

RSCFDnCFDGFDCFG.RPED

RES bit Protocol exception state disable.

This bit configures the protocol exception event handling according to ISO 11898-1 (2015). When this bit is enabled then the protocol exception event detection is disabled, and the protocol controller will transmit an error frame when the protocol exception event is detected (RES-bit is sampled recessive).

Users can set this bit only when RS-CANFD module is in GL_RESET mode.

23.3.3.9 RSCFDnCFDGRSTC — Global Reset Control Register

Access: RSCFDnCFDGRSTC register can be read or written in 32-bit units
RSCFDnCFDGRSTCL, RSCFDnCFDGRSTCH register can be read or written in 16-bit units

Address: RSCFDnCFDGRSTC: <RSCFDn_base> + 1380_H

RSCFDnCFDGRSTCL: <RSCFDn_base> + 1380_H,
RSCFDnCFDGRSTCH: <RSCFDn_base> + 1382_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	KEY[7:0]								—	—	—	—	—	—	—	SRST
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	W	W	W	W	W	W	W	W	R	R	R	R	R	R	R	R/W

Table 23.31 RSCFDnCFDGRSTC Register Contents

Bit Position	Bit Name	Function
31 to 16	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
15 to 8	KEY[7:0]	Key code These bits control the right or wrong of rewriting of a SRST bit.
7 to 1	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
0	SRST	Software reset 0: Normal state. 1: Software reset state.

RSCFDnCFDGRSTC.KEY[7:0]

KEY code.

When $C4_H$ is written in these bits, the write of a RSCFDnCFDGRSTC.SRST bit becomes available.

Read value from these bits is always 00_H.

Users should write a CFDGRSTC.SRST bit and the CFDGRSTC.KEY bit simultaneously.

RSCFDnCFDGRSTC.SRST

Software Reset

When this bit is set, RS-CANFD module will be in the same state as hardware reset.

When reset of IP is required, users should write 1 to this bit. Then user should write 0 to this bit.

When this bit is cleared, a RS-CANFD module is in GL_STOP mode.

When this bit is cleared, the RAM initialization sequence does not operate. The configuration of RAM is performed by software.

RAM is not initialized when software reset is performed during the initialization of RAM.

Software needs to perform the initialization of RAM.

23.3.3.10 RSCFDnCFDGFCMC — Global Flexible CAN mode Configuration Register

Access: RSCFDnCFDGFCMC register can be read or written in 32-bit units
RSCFDnCFDGFCMCL, RSCFDnCFDGFCMCH register can be read or written in 16-bit units
RSCFDnCFDGFCMCLL, RSCFDnCFDGFCMCLH, RSCFDnCFDGFCMCHL, RSCFDnCFDGFCMCHH register can be read or written in 8-bit units

Address: RSCFDnCFDGFCMC: <RSCFDn_base> + 1384_H

RSCFDnCFDGFCMCL: <RSCFDn_base> + 1384_H,
RSCFDnCFDGFCMCH: <RSCFDn_base> + 1386_H

RSCFDnCFDGFCMCLL: <RSCFDn_base> + 1384_H,
RSCFDnCFDGFCMCLH: <RSCFDn_base> + 1385_H,
RSCFDnCFDGFCMCHL: <RSCFDn_base> + 1386_H,
RSCFDnCFDGFCMCHH: <RSCFDn_base> + 1387_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	FLXC3	FLXC2	FLXC1	FLXC0
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W

Table 23.32 RSCFDnCFDGFCMC Register Contents

Bit Position	Bit Name	Function
31 to 4	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
3	FLXC3	Flexible CAN mode between Channel 7 and Channel 6 0: Normal mode. 1: Flexible CAN mode.
2	FLXC2	Flexible CAN mode between Channel 5 and Channel 4 0: Normal mode. 1: Flexible CAN mode.
1	FLXC1	Flexible CAN mode between Channel 3 and Channel 2 0: Normal mode. 1: Flexible CAN mode.
0	FLXC0	Flexible CAN mode between Channel 0 and Channel 1 0: Normal mode. 1: Flexible CAN mode.

Flexible transmission buffer assignment configured in RSCFDnCFDGFTBAC register and Flexible CAN mode configured in RSCFDnCFDGFCMC register should not be used simultaneously.

RSCFDnCFDGFCMC.FLXC3

Flexible CAN mode between Channel 6 and Channel 7.

When this bit is set, Channel 6 and Channel 7 of a RS-CANFD module are Flexible CAN mode.

Channel 7 uses TX/RX terminal of Channel 6. The TX/RX terminal of Channel 7 can not use.

Users can only write to this bit when RS-CANFD module is in GL_RESET mode.

RSCFDnCFDGFCMC.FLXC2

Flexible CAN mode between Channel 4 and Channel 5.

When this bit is set, Channel 4 and Channel 5 of a RS-CANFD module are Flexible CAN mode.

Channel 5 uses TX/RX terminal of Channel 4. The TX/RX terminal of Channel 5 can not use.

Users can only write to this bit when RS-CANFD module is in GL_RESET mode.

RSCFDnCFDGFCMC.FLXC1

Flexible CAN mode between Channel 2 and Channel 3.

When this bit is set, Channel 2 and Channel 3 of a RS-CANFD module are Flexible CAN mode.

Channel 3 uses TX/RX terminal of Channel 2. The TX/RX terminal of Channel 3 can not use.

Users can only write to this bit when RS-CANFD module is in GL_RESET mode.

RSCFDnCFDGFCMC.FLXC0

Flexible CAN mode between Channel 0 and Channel 1.

When this bit is set, Channel 0 and Channel 1 of a RS-CANFD module are Flexible CAN mode.

Channel 1 uses TX/RX terminal of Channel 0. The TX/RX terminal of Channel 1 can not use.

Users can only write to this bit when RS-CANFD module is in GL_RESET mode.

23.3.3.11 RSCFDnCFDGFTBAC — Global Flexible transmission buffer assignment Configuration Register

Access: RSCFDnCFDGFTBAC register can be read or written in 32-bit units
RSCFDnCFDGFTBACL, RSCFDnCFDGFTBACH register can be read or written in 16-bit units
RSCFDnCFDGFTBACLL, RSCFDnCFDGFTBACLH, RSCFDnCFDGFTBACHL, RSCFDnCFDGFTBACHH register can be read or written in 8-bit units

Address: RSCFDnCFDGFTBAC: <RSCFDn_base> + $138C_H$

RSCFDnCFDGFTBACL: <RSCFDn_base> + $138C_H$,
RSCFDnCFDGFTBACH: <RSCFDn_base> + $138F_H$

RSCFDnCFDGFTBACLL: <RSCFDn_base> + $138C_H$,
RSCFDnCFDGFTBACLH: <RSCFDn_base> + $138D_H$,
RSCFDnCFDGFTBACHL: <RSCFDn_base> + $138E_H$,
RSCFDnCFDGFTBACHH: <RSCFDn_base> + $138F_H$

Value after reset: $0000\ 0000_H$

Table 23.33 RSCFDnCFDGFTBAC Register Contents (1/2)

Bit Position	Bit Name	Function
31 to 28	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
27 to 24	FLXMB3[3:0]	Flexible transmission buffer assignment between Channel 6 and Channel 7 0000: 0 0001: 4 0010: 8 0011: 12 0100: 16 0101: 20 0110: 24 0111: 28 1000: 32 Other than the above: Setting prohibited By setting these bits the even channel can use the configured number of TX mailboxes of the odd channel.
23 to 20	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
19 to 16	FLXMB2[3:0]	Flexible transmission buffer assignment between Channel 4 and Channel 5 0000: 0 0001: 4 0010: 8 0011: 12 0100: 16 0101: 20 0110: 24 0111: 28 1000: 32 Other than the above: Setting prohibited By setting these bits the even channel can use the configured number of TX mailboxes of the odd channel.

Table 23.33 RSCFDnCFDGFTBAC Register Contents (2/2)

Bit Position	Bit Name	Function
15 to 12	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
11 to 8	FLXMB1[3:0]	Flexible transmission buffer assignment between Channel 2 and Channel 3 0000: 0 0001: 4 0010: 8 0011: 12 0100: 16 0101: 20 0110: 24 0111: 28 1000: 32 Other than the above: Setting prohibited By setting these bits the even channel can use the configured number of TX mailboxes of the odd channel.
7 to 4	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
3 to 0	FLXMB0[3:0]	Flexible transmission buffer assignment between Channel 0 and Channel 1 0000: 0 0001: 4 0010: 8 0011: 12 0100: 16 0101: 20 0110: 24 0111: 28 1000: 32 Other than the above: Setting prohibited By setting these bits the even channel can use the configured number of TX mailboxes of the odd channel.

RSCFDnCFDGFTBAC.FLXMBv[3:0]

Flexible transmission buffer assignment between Channel m-1 and Channel m.

Channel m-1 can use the number TXMB of Channel m from 0 to 32 [for U2A-EVA, U2A16, U2A8] and 16 [for U2A6] by the configuration of these bits.

Users can only write to this bit when RS-CANFD module is in GL_RESET mode.

Flexible transmission buffer assignment configured in RSCFDnCFDGFTBAC register and Flexible CAN mode configured in RSCFDnCFDGFCMC register should not be used simultaneously. (m =1, 3, 5, 7)

23.3.4 Details of Acceptance Filter List-Related Registers

23.3.4.1 RSCFDnCFDGAFLECTR — Global Acceptance Filter List Entry Control Register

Access: RSCFDnCFDGAFLECTR register can be read or written in 32-bit units
RSCFDnCFDGAFLECTRL, RSCFDnCFDGAFLECTRH register can be read or written in 16-bit units
RSCFDnCFDGAFLECTRLL, RSCFDnCFDGAFLECTRLH, RSCFDnCFDGAFLECTRHL,
RSCFDnCFDGAFLECTRHH register can be read or written in 8-bit units

Address: RSCFDnCFDGAFLECTR: <RSCFDn_base> + 0098_H

RSCFDnCFDGAFLECTRL: <RSCFDn_base> + 0098_H, RSCFDnCFDGAFLECTRH: <RSCFDn_base> + $009A_H$

RSCFDnCFDGAFLECTRLL: <RSCFDn_base> + 0098_H, RSCFDnCFDGAFLECTRLH: <RSCFDn_base> + 0099_H,
RSCFDnCFDGAFLECTRHL: <RSCFDn_base> + $009A_H$, RSCFDnCFDGAFLECTRHH: <RSCFDn_base> + $009B_H$

Value after reset: $0000\ 0000_H$

Table 23.34 RSCFDnCFDGAFLECTR Register Contents

Bit Position	Bit Name	Function
31 to 9	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
8	AFLDAE	Acceptance Filter List Data Access Enable 0: Acceptance Filter List Data access disabled 1: Acceptance Filter List Data access enabled
7	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
6 to 0	AFLPN[6:0]	Acceptance Filter List Page Number Selected an Acceptance Filter List Page

This register is used to select the Global Acceptance Filter List page for reading or writing entries into the Global Acceptance Filter List.

RSCFDnCFDGAFLECTR.AFLDAE

Acceptance Filter List Data Access Enable.

This bit prevents Acceptance Filter List write access if cleared after configuration of the Acceptance Filter List.
Users can read data from Acceptance Filter List independent of the status of this bit.

Users cannot write to this bit when RS-CANFD module is in GL_STOP mode.

This bit should be set to enable write access to Acceptance Filter List.

RSCFDnCFDGAFLECTR.AFLPN[6:0]

Acceptance Filter List Page Number

These bits select the Page Number to access the desired RAM area of the Acceptance Filter List. One Acceptance Filter List page consists of 16 Acceptance Filter List entries.

Read/Write accesses to the Acceptance Filter List can only be performed via a fixed window.

Users cannot write to this bit when RS-CANFD module is in GL_STOP mode.

Users should enter, only the values between 0 and 95 ($5F_H$) inclusive.

23.3.4.2 RSCFDnCFDGAFLCFGv — Global Acceptance Filter List Configuration Register v

Access: RSCFDnCFDGAFLCFGv register can be read or written in 32-bit units
RSCFDnCFDGAFLCFGvL, RSCFDnCFDGAFLCFGvH register can be read or written in 16-bit units
RSCFDnCFDGAFLCFGvLL, RSCFDnCFDGAFLCFGvLH, RSCFDnCFDGAFLCFGvHL,
RSCFDnCFDGAFLCFGvHH register can be read or written in 8-bit units

Address: RSCFDnCFDGAFLCFGv: <RSCFDn_base> + $009C_H$ + (04_H × v),

RSCFDnCFDGAFLCFGvL: <RSCFDn_base> + $009C_H$ + (04_H × v), RSCFDnCFDGAFLCFGvH: <RSCFDn_base> + $009E_H$ + (04_H × v),

RSCFDnCFDGAFLCFGvLL: <RSCFDn_base> + $009C_H$ + (04_H × v), RSCFDnCFDGAFLCFGvLH: <RSCFDn_base> + $009D_H$ + (04_H × v), RSCFDnCFDGAFLCFGvHL: <RSCFDn_base> + $009E_H$ + (04_H × v), RSCFDnCFDGAFLCFGvHH: <RSCFDn_base> + $009F_H$ + (04_H × v)

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	RNC(0 + v*2) [8:0]								
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	RNC(1 + v*2) [8:0]								
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 23.35 RSCFDnCFDGAFLCFGv Register Contents

Bit Position	Bit Name	Function
31 to 25	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
24 to 16	RNC(0 + v*2) [8:0]	Rule Number for Channel (0 +v*2)
15 to 9	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
8 to 0	RNC(1 + v*2) [8:0]	Rule Number for Channel (1 +v*2)

Below is an example to calculate index for U2A16:

(no_of_channels = no_of_RNs = 8)

(no_of_RNs_per_RSCFDnCFDGAFLCFG = 2)

(no_of_RSCFDnCFDGAFLCFGs = ceil(no_of_RNs / no_of_RNs_per_RSCFDnCFDGAFLCFG) = ceil(8 / 2) = 4)

v = [0...no_of_RSCFDnCFDGAFLCFGs-1]

(v) can be calculated from the desired Channel (m) Rule Number using the formula v = floor (m / 2)

Word position can be calculated using the formula: (1 – m) + (v * 2)

e.g. for Channel 7 Rule Number we have:
m = 7, v = floor(7/2) = 3 and Word position = ((1 – 7) + (3 * 2)) = 0
Therefore, Users should read the Word 0 (First Word of RSCFDnCFDGAFLCFG3.

This register is used to define the number of Acceptance Filter List Entries (called “Rules”) applicable for channels 0 to 7 in the Acceptance Filter List.
The total number of available entries in the Acceptance Filter List is 192 * (m+1) (e.g. 1536 for 8 CAN channels). However, the filters can be allocated flexibly to the different channels depending on

requirements as long as both of the following conditions are satisfied:
the maximum number of Acceptance Filter per channel is 384 and the total number of rules defined for all channels is not exceeding the number of available entries in the Acceptance Filter List.

RSCFDnCFDGAFLCFGv.RNC(0 + v*2) [8:0]

Rule Number for Channel (0 + v*2)

These bits define the number of rules in the Acceptance Filter List for channel (0 + v*2).

Users can only write to this bit when RS-CANFD module is in GL_RESET mode.

RSCFDnCFDGAFLCFGv.RNC(1 + v*2) [8:0]

Rule Number for Channel (1 + v*2)

These bits define the number of rules in the Acceptance Filter List for channel (1 + v*2).

Users can only write to this bit when RS-CANFD module is in GL_RESET mode.

23.3.4.3 RSCFDnCFDGAFLIDj — Global Acceptance Filter List ID Register j

Access: RSCFDnCFDGAFLIDj register can be read or written in 32-bit units
RSCFDnCFDGAFLIDjL, RSCFDnCFDGAFLIDjH register can be read or written in 16-bit units
RSCFDnCFDGAFLIDjLL, RSCFDnCFDGAFLIDjLH, RSCFDnCFDGAFLIDjHL, RSCFDnCFDGAFLIDjHH register can be read or written in 8-bit units

Address: RSCFDnCFDGAFLIDj: <RSCFDn_base> + 1800_H + (10_H × j)

RSCFDnCFDGAFLIDjL: <RSCFDn_base> + 1800_H + (10_H × j),
RSCFDnCFDGAFLIDjH: <RSCFDn_base> + 1802_H + (10_H × j)

RSCFDnCFDGAFLIDjLL: <RSCFDn_base> + 1800_H + (10_H × j),
RSCFDnCFDGAFLIDjLH: <RSCFDn_base> + 1801_H + (10_H × j),
RSCFDnCFDGAFLIDjHL: <RSCFDn_base> + 1802_H + (10_H × j),
RSCFDnCFDGAFLIDjHH: <RSCFDn_base> + 1803_H + (10_H × j)

Value after reset: $0000\ 0000_H$

Table 23.36 RSCFDnCFDGAFLIDj Register Contents

Bit Position	Bit Name	Function
31	GAFLIDE	Global Acceptance Filter List Entry IDE Field 0: Standard Identifier of Rule entry ID is valid for acceptance filtering 1: Extended Identifier of Rule entry ID is valid for acceptance filtering
30	GAFLRTR	Global Acceptance Filter List Entry RTR Field 0: Data Frame 1: Remote Frame
29	GAFLLB	Global Acceptance Filter List Entry Loopback Configuration 0: Global Acceptance Filter List entry ID for acceptance filtering has attribute 'RX' 1: Global Acceptance Filter List entry ID for acceptance filtering has attribute 'TX'
28 to 0	GAFLID[28:0]	Global Acceptance Filter List Entry ID Field ID part of the Global Acceptance Filter List entry

These registers are used to configure the ID field of the Rule Entries in the Global Acceptance Filter List.

RSCFDnCFDGAFLIDj.GAFLIDE

Global Acceptance Filter List Entry IDE Field

This bit allows the configuration of the ID format (Standard ID or Extended ID) for each of the Global Acceptance Filter List entry. For each Rule entry of the related CAN channel the Acceptance filter process compares this bit against the IDE bit of the received CAN message.

Users cannot write to these bits when RSCFDnCFDGAFLECTR.AFLDAE bit is 0_B.

Users should only write to these bits when the related RS-CANFD channel is in CH_RESET or CH_HALT mode.

RSCFDnCFDGAFLIDj.GAFLRTR

Global Acceptance Filter List Entry RTR Field

This bit allows the configuration of the specified frame format (Data Frame or Remote Frame) for each Global Acceptance Filter List entry. For each Rule entry in a CAN channel the Acceptance filter process compares this bit against the RTR bit of the received CAN message.

Users cannot write to these bits when RSCFDnCFDGAFLECTR.AFLDAE bit is 0_B.

Users should only write to these bits when the related RS-CANFD channel is in CH_RESET or CH_HALT mode.

RSCFDnCFDGAFLIDj.GAFLLB

Global Acceptance Filter List Entry Loopback Configuration

This bit selects if the Global Acceptance Filter List entry gets the attribute ‘RX’ or ‘TX’. This attribute decides about the validity of the entry in the mirror mode case, loopback test mode case and during standard (nonloopback) reception. See **Table 23.145** for detailed description of the validity of the Global Acceptance Filter List entry depending on transmitter/receiver case, type of loopback mode and RX/TX attribute.

Users cannot write to these bits when RSCFDnCFDGAFLECTR.AFLDAE bit is 0_B.

Users should only write to these bits when the related RS-CANFD channel is in CH_RESET or CH_HALT mode.

RSCFDnCFDGAFLIDj.GAFLID[28:0]

Global Acceptance Filter List Entry ID Field

These bits represent the CAN Identifier (ID) field of each of the Global Acceptance Filter List entry. Acceptance filter process compares this field against the ID of a received CAN message.

For alignment of these bits in standard and extended frame format, see **Section 23.4.3**.

Users cannot write to these bits when RSCFDnCFDGAFLECTR.AFLDAE bit is 0_B.

Users should only write to these bits when the related RS-CANFD channel is in CH_RESET or CH_HALT mode.

23.3.4.4 RSCFDnCFDGAFLMj — Global Acceptance Filter List Mask Register j

Access: RSCFDnCFDGAFLMj register can be read or written in 32-bit units
RSCFDnCFDGAFLMjL, RSCFDnCFDGAFLMjH register can be read or written in 16-bit units
RSCFDnCFDGAFLMjLL, RSCFDnCFDGAFLMjLH, RSCFDnCFDGAFLMjHL, RSCFDnCFDGAFLMjHH register can be read or written in 8-bit units

Address: RSCFDnCFDGAFLMj: <RSCFDn_base> + 1804_H + (10_H × j)

RSCFDnCFDGAFLMjL: <RSCFDn_base> + 1804_H + (10_H × j),
RSCFDnCFDGAFLMjH: <RSCFDn_base> + 1806_H + (10_H × j)

RSCFDnCFDGAFLMjLL: <RSCFDn_base> + 1804_H + (10_H × j),
RSCFDnCFDGAFLMjLH: <RSCFDn_base> + 1805_H + (10_H × j),
RSCFDnCFDGAFLMjHL: <RSCFDn_base> + 1806_H + (10_H × j),
RSCFDnCFDGAFLMjHH: <RSCFDn_base> + 1807_H + (10_H × j)

Value after reset: $0000\ 0000_H$

Bit Position	Bit Name	Function
31	GAFLIDEM	Global Acceptance Filter List IDE Mask 0: IDE bit is not considered for ID matching 1: IDE bit is considered for ID matching
30	GAFLRTRM	Global Acceptance Filter List Entry RTR Mask 0: RTR bit is not considered for ID matching 1: RTR bit is considered for ID matching
29	GAFLIFL1	Global Acceptance Filter List Information Label 1 Global Acceptance Filter List Information Label bit 1
28 to 0	GAFLIDM[28:0]	Global Acceptance Filter List ID Mask Field Global Acceptance Filter List Mask field bits for ID field bits

The Global Rule Mask entry registers are used to configure the Mask field of each Rule Entries in the Global Acceptance Filter List.

RSCFDnCFDGAFLMj.GAFLIDEM

Global Acceptance Filter List IDE Mask

This bit allows the configuration of the IDE mask bit for each Global Acceptance Filter List entry.
When IDE mask bit is 0_B, then the ID comparison depends upon the received IDE bit.
If received IDE bit is 0_B, then STD-ID comparison takes place.
If received IDE bit is 1_B, then EXT-ID comparison takes place.

Users cannot write to these bits when RSCFDnCFDGAFLECTR.AFLDAE bit is 0_B.

Users should only write to these bits when the related RS-CANFD channel is in CH_RESET or CH_HALT mode.

RSCFDnCFDGAFLMj.GAFLRTRM

Global Acceptance Filter List Entry RTR Mask

This bit allows the configuration of the RTR mask bit for each Global Acceptance Filter List entry.

Users cannot write to these bits when RSCFDnCFDGAFLECTR.AFLDAE bit is 0_B.

Users should only write to these bits when the related RS-CANFD channel is in CH_RESET or CH_HALT mode.

RSCFDnCFDGAFLMj.GAFLIFL1

Global Acceptance Filter List Information Label 1

These bits allow the configuration of a 2-bit Information label that will be attached to a received message accepted by the related Global Acceptance Filter List entry. This bit is a MSB bit of an information label.

Users cannot write to these bits when RSCFDnCFDGAFLECTR.AFLDAE bit is 0_B.

Users should only write to these bits when the related RS-CANFD channel is in CH_RESET or CH_HALT mode.

This bit is stored in Information Label Field [1] (RSCFDnCFDRMFDSTS.RMIFL [1], RSCFDnCFDRFFDSTS.RFIFL [1], RSCFDnCFDCFFDCSTS.CFIFL [1]) of the storage location of an incoming message.

This bit is stored in RSCFDnCFDTHLACC1m.TIFL [1] when RSCFDnCFDTHLCCm.THLDGE=1 is set up using GW function.

RSCFDnCFDGAFLMj.GAFLIDM[28:0]

Global Acceptance Filter List ID Mask Field

These bits are the filter mask bits for the related bits in the CAN Identifier field of each Global Acceptance Filter List entry.

0_B	Corresponding STD-ID / EXT-ID bit is not considered for ID matching
1_B	Corresponding STD-ID / EXT-ID bit is considered for ID matching

Users cannot write to these bits when RSCFDnCFDGAFLECTR.AFLDAE bit is 0_B.

Users should only write to these bits when the related RS-CANFD channel is in CH_RESET or CH_HALT mode.

23.3.4.5 RSCFDnCFDGAFLP0j — Global Acceptance Filter List Pointer 0 Register j

Access: RSCFDnCFDGAFLP0j register can be read or written in 32-bit units
RSCFDnCFDGAFLP0jL, RSCFDnCFDGAFLP0jH register can be read or written in 16-bit units
RSCFDnCFDGAFLP0jLL, RSCFDnCFDGAFLP0jLH, RSCFDnCFDGAFLP0jHL, RSCFDnCFDGAFLP0jHH register can be read or written in 8-bit units

Address: RSCFDnCFDGAFLP0j: <RSCFDn_base> + 1808_H + (10_H × j)

Bit Position	Bit Name	Function
31 to 16	GAFLPTR[15:0]	Global Acceptance Filter List Pointer Field Global Acceptance Filter List Pointer
15	GAFLRMV	Global Acceptance Filter List RX Message Buffer Valid 0: Global Acceptance Filter List Single Message Buffer Direction Pointer is invalid 1: Global Acceptance Filter List Single Message Buffer Direction Pointer is valid
14 to 8	GAFLRMDP[6:0]	Global Acceptance Filter List RX Message Buffer Direction Pointer RX Message Buffer number for storage of received messages
7	GAFLIFL0	Global Acceptance Filter List Information Label 0 Global Acceptance Filter List Information Label bit 0
6	GAFLSRD2	Global Acceptance Filter List Select Routing destination 2 0: Routing target is CFIFO2 1: Routing target is TX Queue 2 instead of CFIFO2
5	GAFLSRD1	Global Acceptance Filter List Select Routing destination 1 0: Routing target is CFIFO1 1: Routing target is TX Queue 1 instead of CFIFO1
4	GAFLSRD0	Global Acceptance Filter List Select Routing destination 0 0: Routing target is CFIFO0 1: Routing target is TX Queue 0 instead of CFIFO0
3 to 0	GAFLDLC[3:0]	Global Acceptance Filter List DLC Field Minimum no. of Data Bytes in a Data Frame required for its acceptance

The Global Acceptance Filter List Pointer 0 registers are used to configure the DLC, SW Pointer, Single Message Buffer select and Message Buffer direction pointer for each Rule Entry in the Global Acceptance Filter List.

RSCFDnCFDGAFLP0j.GAFLPTR[15:0]

Global Acceptance Filter List Pointer Field

These bits allow the configuration of a 16-bit pointer that will be attached to a received message accepted by the related Global Acceptance Filter List entry. The Pointer will be added during message storage in the Message Buffer area and can be used by the application as support function. The pointer information could be used for example to support PDU Identifier allocation for the received message in AUTOSAR systems.

Users cannot write to these bits when RSCFDnCFDGAFLECTR.AFLDAE bit is 0_B.

Users should only write to these bits when the related RS-CANFD channel is in CH_RESET or CH_HALT mode.

RSCFDnCFDGAFLP0j.GAFLRMV

Global Acceptance Filter List RX Message Buffer Valid

This bit allows the enabling/disabling of a single reception Message Buffer as the target for a received message that is passing the acceptance check of the related Global Acceptance Filter List entry.

Users cannot write to these bits when RSCFDnCFDGAFLECTR.AFLDAE bit is 0_B.

Users should only write to these bits when the related RS-CANFD channel is in CH_RESET or CH_HALT mode.

RSCFDnCFDGAFLP0j.GAFLRMDP[6:0]

Global Acceptance Filter List RX Message Buffer Direction Pointer

These bits allow the configuration of a single reception Message Buffer as the destination target for a received message that is passing the acceptance check of the related Global Acceptance Filter List entry.
The value entered is the single destination Message Buffer number.

Users cannot write to these bits when RSCFDnCFDGAFLECTR.AFLDAE bit is 0_B.

Users should only write to these bits when the related RS-CANFD channel is in CH_RESET or CH_HALT mode.
RSCFDnCFDRMNB.NRXMB[7:0] is the value entered in the RX Message Buffer Number Register to configure the number of RX Message Buffers. The value to be entered in RSCFDnCFDGAFLP0j.GAFLRMDP[6:0] bits should only be between 0_H and (RSCFDnCFDRMNB.NRXMB[7:0] - 1_H).
If RSCFDnCFDRMNB.NRXMB[7:0] = 0_H, then the GAFLRMV bit should be configured as 0_B.

RSCFDnCFDGAFLP0j.GAFLIFL0

Global Acceptance Filter List Information Label 0

These bits allow the configuration of a 2-bit Information label that will be attached to a received message accepted by the related Global Acceptance Filter List entry. This bit is a LSB bit of an information label.

Users cannot write to these bits when RSCFDnCFDGAFLECTR.AFLDAE bit is 0_B.

Users should only write to the bit when the related RS-CANFD channel is in CH_RESET or CH_HALT mode.

This bit is stored in Information Label Field[0] (RSCFDnCFDRMFDSTS.RMIFL[0], RSCFDnCFDRFFDSTS.RFIFL[0], RSCFDnCFDCFFDCSTS.CFIFL[0]) of the storage location of an incoming message.

This bit is stored in RSCFDnCFDTHLACC1m.TIFL[0] when RSCFDnCFDTHLCCm.THLDGE=1 is set up using GW function.

RSCFDnCFDGAFLP0j.GAFLSRD2

Global Acceptance Filter List Select Routing destination 2

This bit changes a copy destination to CFIFO2 or TXQ2 by routing.

If this bit is set as 1, the preset value of RSCFDnCFDGAFLP1j.GAFLFDP will choose TX Queue.

If this bit is cleared to 0, the preset value of RSCFDnCFDGAFLP1j.GAFLFDP will choose Transmit/ Receive FIFO.

Users cannot write to these bits when RSCFDnCFDGAFLECTR.AFLDAE bit is 0_B.

Users should only write to the bit when the related RS-CANFD channel is in CH_RESET or CH_HALT mode.

RSCFDnCFDGAFLP0j.GAFLSRD1

Global Acceptance Filter List Select Routing destination 1

This bit changes a copy destination to CFIFO1 or TXQ1 by routing.

If this bit is set as 1, the preset value of RSCFDnCFDGAFLP1j.GAFLFDP will choose TX Queue.

If this bit is cleared to 0, the preset value of RSCFDnCFDGAFLP1j.GAFLFDP will choose Transmit/ Receive FIFO.

Users cannot write to these bits when RSCFDnCFDGAFLECTR.AFLDAE bit is 0_B.

Users should only write to the bit when the related RS-CANFD channel is in CH_RESET or CH_HALT mode.

RSCFDnCFDGAFLP0j.GAFLSRD0

Global Acceptance Filter List Select Routing destination 0

This bit changes a copy destination to CFIFO0 or TXQ0 by routing.

If this bit is set as 1, the preset value of RSCFDnCFDGAFLP1j.GAFLFDP will choose TX Queue.

If this bit is cleared to 0, the preset value of RSCFDnCFDGAFLP1j.GAFLFDP will choose Transmit/ Receive FIFO.

Users cannot write to these bits when RSCFDnCFDGAFLECTR.AFLDAE bit is 0_B.

Users should only write to the bit when the related RS-CANFD channel is in CH_RESET or CH_HALT mode.

RSCFDnCFDGAFLP0j.GAFLDLC[3:0]

Global Acceptance Filter List DLC Field.

These bits allow the configuration of the minimum DLC (Data Length Code) value for a message to be accepted by the related Global Acceptance Filter List entry (automatic DLC filter function). DLC filter process is only passed if the DLC value of the message accepted by a Global Acceptance Filter List entry is equal or higher than the DLC value configured for this related Global Acceptance Filter List entry. Automatic DLC filter function is disabled for the corresponding Rule Entry when this field is set to 0_H.

Following binary values can be configured:

Format	DLC[3]	DLC[2]	DLC[1]	DLC[0]	Description
CAN and CANFD	0	0	0	0	DLC of received message = 0 or more (DLC Filter check is disabled)
CAN and CANFD	0	0	0	1	DLC of received message = 1 or more
CAN and CANFD	0	0	1	0	DLC of received message = 2 or more
CAN and CANFD	0	0	1	1	DLC of received message = 3 or more
CAN and CANFD	0	1	0	0	DLC of received message = 4 or more
CAN and CANFD	0	1	0	1	DLC of received message = 5 or more
CAN and CANFD	0	1	1	0	DLC of received message = 6 or more
CAN and CANFD	0	1	1	1	DLC of received message = 7 or more
CAN	1	x	x	x	DLC of received message = 8 or more
CANFD	1	0	0	0	DLC of received message = 8 or more
CANFD	1	0	0	1	DLC of received message = 12 or more
CANFD	1	0	1	0	DLC of received message = 16 or more
CANFD	1	0	1	1	DLC of received message = 20 or more
CANFD	1	1	0	0	DLC of received message = 24 or more
CANFD	1	1	0	1	DLC of received message = 32 or more
CANFD	1	1	1	0	DLC of received message = 48 or more
CANFD	1	1	1	1	DLC of received message = 64

Users cannot write to these bits when RSCFDnCFDGAFLECTR.AFLDAE bit is 0_B.

Users should only write to these bits when the related RS-CANFD channel is in CH_RESET or CH_HALT mode.

23.3.4.6 RSCFDnCFDGAFLP1j — Global Acceptance Filter List Pointer 1 Register j

Access: RSCFDnCFDGAFLP1j register can be read or written in 32-bit units
RSCFDnCFDGAFLP1jL, RSCFDnCFDGAFLP1jH register can be read or written in 16-bit units
RSCFDnCFDGAFLP1jLL, RSCFDnCFDGAFLP1jLH, RSCFDnCFDGAFLP1jHL, RSCFDnCFDGAFLP1jHH register can be read or written in 8-bit units

Address: RSCFDnCFDGAFLP1j: <RSCFDn_base> + $180C_H$ + (10_H × j)

RSCFDnCFDGAFLP1jL: <RSCFDn_base> +$180C_H$ + (10_H × j),
RSCFDnCFDGAFLP1jH: <RSCFDn_base> + $180E_H$ + (10_H × j)

RSCFDnCFDGAFLP1jLL: <RSCFDn_base> + $180C_H$ + (10_H × j),
RSCFDnCFDGAFLP1jLH: <RSCFDn_base> + $180D_H$ + (10_H × j),
RSCFDnCFDGAFLP1jHL: <RSCFDn_base> + $180E_H$ + (10_H × j),
RSCFDnCFDGAFLP1jHH: <RSCFDn_base> + $180F_H$ + (10_H × j)

Value after reset: $0000\ 0000_H$

Table 23.39 RSCFDnCFDGAFLP1j Register Contents

Bit Position	Bit Name	Function
31 to 0	GAFLFDP[31:0]	Global Acceptance Filter List FIFO Direction Pointer (GAFLFDP[((m+1)*3+7):0]) FIFO direction pointer bits for received message storage

The Global Acceptance Filter List Pointer 1 registers are used to configure the FIFO direction pointer fields in each Rule Entry of the Global Acceptance Filter List.

RSCFDnCFDGAFLP1j.GAFLFDP[31:0]

Global Acceptance Filter List FIFO Direction Pointer (GAFLFDP[((m+1)*3+7):0])

These bits allow the configuration of FIFO Buffers as the target for a received message passing the acceptance check of the related Global Acceptance Filter List entry. Each bit of the RSCFDnCFDGAFLP1j.GAFLFDP[31:0] is configuring a dedicated FIFO:

Bit	Value (Binary)	Function
31	0	Disable Transmit/Receive FIFO 23 and Channel 7 TX Queue 2 as target for reception
	1	GAFLSRD2=0:Enable Transmit/Receive FIFO 23 as target for reception GAFLSRD2=1:Enable Channel 7 TX Queue 2 as target for reception
30	0	Disable Transmit/Receive FIFO 22 and Channel 7 TX Queue 1 as target for reception
	1	GAFLSRD1=0:Enable Transmit/Receive FIFO 22 as target for reception GAFLSRD1=1:Enable Channel 7 TX Queue 1 as target for reception
29	0	Disable Transmit/Receive FIFO 21 and Channel 7 TX Queue 0 as target for reception
	1	GAFLSRD0=0:Enable Transmit/Receive FIFO 21 as target for reception GAFLSRD0=1:Enable Channel 7 TX Queue 0 as target for reception

Bit	Value (Binary)	Function
28	0	Disable Transmit/Receive FIFO 20 and Channel 6 TX Queue 2 as target for reception
	1	GAFLSRD2=0:Enable Transmit/Receive FIFO 20 as target for reception GAFLSRD2=1:Enable Channel 6 TX Queue 2 as target for reception
27	0	Disable Transmit/Receive FIFO 19 and Channel 6 TX Queue 1 as target for reception
	1	GAFLSRD1=0:Enable Transmit/Receive FIFO 19 as target for reception GAFLSRD1=1:Enable Channel 6 TX Queue 1 as target for reception
26	0	Disable Transmit/Receive FIFO 18 and Channel 6 TX Queue 0 as target for reception
	1	GAFLSRD0=0:Enable Transmit/Receive FIFO 18 as target for reception GAFLSRD0=1:Enable Channel 6 TX Queue 0 as target for reception
25	0	Disable Transmit/Receive FIFO 17 and Channel 5 TX Queue 2 as target for reception

	1	GAFLSRD1=0:Enable Transmit/Receive FIFO 10 as target for reception GAFLSRD1=1:Enable Channel 3 TX Queue 1 as target for reception
17	0	Disable Transmit/Receive FIFO 9 and Channel 3 TX Queue 0 as target for reception
	1	GAFLSRD0=0:Enable Transmit/Receive FIFO 9 as target for reception GAFLSRD0=1:Enable Channel 3 TX Queue 0 as target for reception
16	0	Disable Transmit/Receive FIFO 8 and Channel 2 TX Queue 2 as target for reception
	1	GAFLSRD2=0:Enable Transmit/Receive FIFO 8 as target for reception GAFLSRD2=1:Enable Channel 2 TX Queue 2 as target for reception

Bit	Value (Binary)	Function
15	0	Disable Transmit/Receive FIFO 7 and Channel 2 TX Queue 1 as target for reception
	1	GAFLSRD1=0:Enable Transmit/Receive FIFO 7 as target for reception GAFLSRD1=1:Enable Channel 2 TX Queue 1 as target for reception
14	0	Disable Transmit/Receive FIFO 6 and Channel 2 TX Queue 0 as target for reception
	1	GAFLSRD0=0:Enable Transmit/Receive FIFO 6 as target for reception GAFLSRD0=1:Enable Channel 2 TX Queue 0 as target for reception
13	0	Disable Transmit/Receive FIFO 5 and Channel 1 TX Queue 2 as target for reception
	1	GAFLSRD2=0:Enable Transmit/Receive FIFO 5 as target for reception GAFLSRD2=1:Enable Channel 1 TX Queue 2 as target for reception
12	0	Disable Transmit/Receive FIFO 4 and Channel 1 TX Queue 1 as target for reception
	1	GAFLSRD1=0:Enable Transmit/Receive FIFO 4 as target for reception GAFLSRD1=1:Enable Channel 1 TX Queue 1 as target for reception
11	0	Disable Transmit/Receive FIFO 3 and Channel 1 TX Queue 0 as target for reception
	1	GAFLSRD0=0:Enable Transmit/Receive FIFO 3 as target for reception GAFLSRD0=1:Enable Channel 1 TX Queue 0 as target for reception
10	0	Disable Transmit/Receive FIFO 2 and Channel 0 TX Queue 2 as target for reception
	1	GAFLSRD2=0:Enable Transmit/Receive FIFO 2 as target for reception GAFLSRD2=1:Enable Channel 0 TX Queue 2 as target for reception
9	0	Disable Transmit/Receive FIFO 1 and Channel 0 TX Queue 1 as target for reception
	1	GAFLSRD1=0:Enable Transmit/Receive FIFO 1 as target for reception GAFLSRD1=1:Enable Channel 0 TX Queue 1 as target for reception
8	0	Disable Transmit/Receive FIFO 0 and Channel 0 TX Queue 0 as target for reception
	1	GAFLSRD0=0:Enable Transmit/Receive FIFO 0 as target for reception GAFLSRD0=1:Enable Channel 0 TX Queue 0 as target for reception
7	0	Disable RX FIFO 7 as target for reception
	1	Enable RX FIFO 7 as target for reception
6	0	Disable RX FIFO 6 as target for reception
	1	Enable RX FIFO 6 as target for reception
5	0	Disable RX FIFO 5 as target for reception
	1	Enable RX FIFO 5 as target for reception
4	0	Disable RX FIFO 4 as target for reception
	1	Enable RX FIFO 4 as target for reception
3	0	Disable RX FIFO 3 as target for reception
	1	Enable RX FIFO 3 as target for reception
2	0	Disable RX FIFO 2 as target for reception
	1	Enable RX FIFO 2 as target for reception
1	0	Disable RX FIFO 1 as target for reception
	1	Enable RX FIFO 1 as target for reception
0	0	Disable RX FIFO 0 as target for reception
	1	Enable RX FIFO 0 as target for reception

Users cannot write to these bits when RSCFDnCFDGAFLECTR.AFLDAE bit is 0_B.
For storage in Transmit/Receive FIFO, target for reception can only be those Transmit/Receive FIFO Buffers that are configured as RX FIFO or GW FIFO.

For storage in TX Queue, when these TX Queue buffers of a target are in GW mode, it can do.

Users should only write to these bits when the related RS-CANFD channel is in CH_RESET or CH_HALT mode.
Users should only configure up to 8 destination FIFO Buffers or 7 destination FIFO Buffers plus one RX Message Buffer or 8 destination TX Queue Buffers or 7 destination TX Queue Buffers plus one RX Message Buffer.

Or a setup of a maximum of 8 destinations in all is possible at FIFO buffer and TX Queue buffer.

23.3.5 Details of Receive Buffer-Related Registers

23.3.5.1 RSCFDnCFDRMNB — Receive Message Buffer Number Register

Access: RSCFDnCFDRMNB register can be read or written in 32-bit units
RSCFDnCFDRMNBL, RSCFDnCFDRMNBH register can be read or written in 16-bit units
RSCFDnCFDRMNBLL, RSCFDnCFDRMNBLH, RSCFDnCFDRMNBHL, RSCFDnCFDRMNBHH register can be read or written in 8-bit units

Address: RSCFDnCFDRMNB: <RSCFDn_base> + $00AC_H$

RSCFDnCFDRMNBL: <RSCFDn_base> + $00AC_H$, RSCFDnCFDRMNBH: <RSCFDn_base> + $00AE_H$

RSCFDnCFDRMNBLL: <RSCFDn_base> + $00AC_H$, RSCFDnCFDRMNBLH: <RSCFDn_base> + $00AD_H$,
RSCFDnCFDRMNBHL: <RSCFDn_base> + $00AE_H$, RSCFDnCFDRMNBHH: <RSCFDn_base> + $00AF_H$

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

R/W	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 23.40 RSCFDnCFDRMNB Register Contents

Bit Position	Bit Name	Function
31 to 11	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
10 to 8	RMPLS[2:0]	Reception Message Buffer Payload Data Size 000: 8 bytes 001: 12 bytes 010: 16 bytes 011: 20 bytes 100: 24 bytes 101: 32 bytes 110: 48 bytes 111: 64 bytes
7 to 0	NRXMB[7:0]	Number of RX Message Buffers Used to define the number of RX Message Buffer

The RX Message Buffer Number register is used to configure the total number of RX Message Buffers allocated to all channels.

RSCFDnCFDRMNB.RMPLS[2:0]

Reception Message Buffer Payload Data Size.

These bits are used to configure the message buffer payload data size.

Users can only write to these bits when RS-CANFD module is in GL_RESET modes.

RSCFDnCFDRMNB.NRXMB[7:0]

Number of RX Message Buffers.

These bits are used to configure the number of RX Message Buffers.

Users can only write to these bits when RS-CANFD module is in GL_RESET modes.

Users should enter, only the values between 0 and ((m+1)*16) inclusive, with 0_H indicating that, no RX Message Buffer is allocated.

23.3.5.2 RSCFDnCFDRMNDt — Receive Message Buffer New Data Register t

Access: RSCFDnCFDRMNDt register can be read or written in 32-bit units
RSCFDnCFDRMNDtL, RSCFDnCFDRMNDtH register can be read or written in 16-bit units
RSCFDnCFDRMNDtLL, RSCFDnCFDRMNDtLH, RSCFDnCFDRMNDtHL, RSCFDnCFDRMNDtHH register can be read or written in 8-bit units

Address: RSCFDnCFDRMNDt: <RSCFDn_base> + $00B0_H$ + (04_H × t)

RSCFDnCFDRMNDtL: <RSCFDn_base> + $00B0_H$ + (04_H × t),
RSCFDnCFDRMNDtH: <RSCFDn_base> + $00B2_H$ + (04_H × t)

RSCFDnCFDRMNDtLL: <RSCFDn_base> + $00B0_H$ + (04_H × t),
RSCFDnCFDRMNDtLH: <RSCFDn_base> + $00B1_H$ + (04_H × t),
RSCFDnCFDRMNDtHL: <RSCFDn_base> + $00B2_H$ + (04_H × t),
RSCFDnCFDRMNDtHH: <RSCFDn_base> + $00B3_H$ + (04_H × t)

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	RMNSu[31:16]

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	RMNSu[15:0]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 23.41 RSCFDnCFDRMNDt Register Contents

Bit Position	Bit Name	Function
31 to 0	RMNSu[31:0]	RX Message Buffer New Data Status 0: New Data not stored in corresponding RX Message Buffer 1: New Data stored in corresponding RX Message Buffer

The RX Message Buffer New Data status register bits show the New Data storage status of the RX Message Buffers.

RSCFDnCFDRMNDt.RMNSu[31:0]

RX Message Buffer New Data Status

These bits show the NewData Flag status for the corresponding RX Message Buffer. RMNS bit 0 corresponds to RX Message Buffer 0 and so on.

Below is an example to calculate index for U2A16:
(no_of_channels = 8)
(no_of_RSCFDnCFDRMBCPs_per_channel = No. of RX Message Buffer Components per Channel = 16)
(no_of_RSCFDnCFDRMBCPs = No. of RX Message Buffer Components = no_of_channels*no_of_RSCFDnCFDRMBCPs_per_channel = 8 * 16 = 128)
(no_of_bits_per_register = 32)
(no_of_RSCFDnCFDRMNDs = No. of RSCFDnCFDRMND Register = no_of_RSCFDnCFDRMBCPs/no_of_bits_per_register = 128 / 32 = 4)
(t = [0...no_of_RSCFDnCFDRMNDs-1])
(u = [t*32...(no_of_RSCFDnCFDRMBCPs – ((no_of_RSCFDnCFDRMNDs – 1 – t) * 32) – 1)])
(t) can be calculated from the desired NewData status flag (u) using the formula t = floor(u / 32)
Bit position can be calculated using the formula (u – (t * 32))
e.g. for NewData Status Flag 47 we have:

u = 47, t = floor(47 / 32) = 1 and bit position = (47 – (1 * 32)) = 15
Therefore, Users should read the bit 15 of RSCFDnCFDRMND1.
Users cannot write to these bits when RS-CANFD module is in GL_RESET or GL_STOP mode.
Writing 1_B has no influence on the bit values.

This bit cannot be cleared when message storage in the corresponding RX Message Buffer is in progress.

Do not use bit clear instruction for clearing these bits. Use the MOV instruction to ensure that only the specified bit is cleared. Then the other bits remain set to 1_B.

The field is set automatically when storage of a new message starts in the corresponding RX Message Buffer.

The duration of message storage time is 6 peripheral clock (pclk) cycles for RSCFDnCFDRMNB.RMPLS = 000_B (max 8 byte payload).

For RSCFDnCFDRMNB.RMPLS > 000_B it is 6 + 1 for each four byte (max 20 peripheral clock (pclk) cycles for 64 byte).

This bit is cleared by writing a 0_B to it.

This bit is cleared automatically when RS-CANFD module enters GL_RESET mode.

23.3.6 Details of Receive FIFO Buffer-Related Registers

23.3.6.1 RSCFDnCFDRFCCx — Receive FIFO Configuration / Control Register x

Access: RSCFDnCFDRFCCx register can be read or written in 32-bit units
RSCFDnCFDRFCCxL, RSCFDnCFDRFCCxH register can be read or written in 16-bit units
RSCFDnCFDRFCCxLL, RSCFDnCFDRFCCxLH, RSCFDnCFDRFCCxHL, RSCFDnCFDRFCCxHH register can be read or written in 8-bit units

Address: RSCFDnCFDRFCCx: <RSCFDn_base> + $00C0_H$ + (04_H × x)

RSCFDnCFDRFCCxL: <RSCFDn_base> + $00C0_H$ + (04_H × x),

1	RFIE	RX FIFO Interrupt Enable 0: FIFO Interrupt generation disabled 1: FIFO Interrupt generation enabled
0	RFE	RX FIFO Enable 0: FIFO disabled 1: FIFO enabled

The RX FIFO Configuration / Control registers are used to configure and control the 8 RX FIFOs.

(x = RX FIFO index = [0…no_of_RFIFOs-1])

(no_of_RFIFOs = No. of RX FIFOs = 8)

RSCFDnCFDRFCCx.RFFIE

RX FIFO Full Interrupt Enable

This bit enables generation of the RXFIFO Full Interrupt when it is set.

Users cannot write to the bit when the RS-CANFD module is in GL_STOP mode.

The following contents are imagined as how to use interruption.

1. Interruption output in number of arbitrary stages (RSCFDnCFDRFCCx.RFIGCV)

2. Interruption output in FIFO full state

Management of the receiving data of FIFO can be performed by these notices of interruption.

RSCFDnCFDRFCCx.RFIGCV[2:0]

RX FIFO Interrupt Generation Counter Value

These bits select the counter value of the FIFO for generation of FIFO Interrupt. These values represent fractions of the FIFO depth for which Interrupt is generated.

Users cannot write to these bits when the RS-CANFD module is in GL_STOP mode.

The setting of these bits should be synchronized with the RSCFDnCFDRFCCx.RFDC bits. Refer to **Section 23.7.2.1(5), FIFO Interrupt Configuration** for detailed information.
Users should only write to these bits when RS-CANFD module is in GL_RESET mode.

RSCFDnCFDRFCCx.RFIM

RX FIFO Interrupt Mode

This bit selects the Interrupt generation condition for the FIFO.

Users cannot write to this bit when the RS-CANFD module is in GL_STOP mode.

Users should only write to this bit when RS-CANFD module is in GL_RESET mode.

RSCFDnCFDRFCCx.RFDC[2:0]

RX FIFO Depth Configuration

These bits select the depth of the FIFO in terms of number of Messages. If the FIFO depth is configured to 0 Messages then the FIFO cannot be used.

Users can only write to these bits when RS-CANFD module is in GL_RESET mode.

RSCFDnCFDRFCCx.RFPLS[2:0]

Rx FIFO Payload Data Size configuration

These bits define the message data payload allocation in the RAM.
This is the max. number of Bytes which can be received by this FIFO.
Refer to **Section 23.7.2.1(4), FIFO Payload Size Configuration** for details.

Users can only write to these bits when RS-CANFD module is in GL_RESET mode.

RSCFDnCFDRFCCx.RFIE

RX FIFO Interrupt Enable

This bit enables generation of the FIFO Interrupt when it is set.

Users cannot write to this bit when RS-CANFD module is in GL_STOP mode.

RSCFDnCFDRFCCx.RFE

RX FIFO Enable

This bit enables the FIFO when it is set. If this bit is cleared, the RX FIFO will be cleared and is empty.

Users can only write to this bit when RS-CANFD module is in GL_TEST or GL_OPERATING modes.

This bit can only be set if the configured FIFO depth is greater than 0_H (RSCFDnCFDRFCCx.RFDC > 000_B).

The RSCFDnCFDRFCCd.RFE bit should be set by a separate write access to the RSCFDnCFDRFCCd register, after all the other bits of the RSCFDnCFDRFCCd register have been set.

This bit is cleared automatically when RS-CANFD module enters GL_RESET mode.

23.3.6.2 RSCFDnCFDRFSTSx — Receive FIFO Status Register x

Access: RSCFDnCFDRFSTSx register can be read or written in 32-bit units
RSCFDnCFDRFSTSxL, RSCFDnCFDRFSTSxH register can be read or written in 16-bit units
RSCFDnCFDRFSTSxLL, RSCFDnCFDRFSTSxLH, RSCFDnCFDRFSTSxHL, RSCFDnCFDRFSTSxHH register can be read or written in 8-bit units

Address: RSCFDnCFDRFSTSx: <RSCFDn_base> + $00E0_H$ + (04_H × x)

RSCFDnCFDRFSTSxL: <RSCFDn_base> + $00E0_H$ + (04_H × x),
RSCFDnCFDRFSTSxH: <RSCFDn_base> + $00E2_H$ + (04_H × x)

RSCFDnCFDRFSTSxLL: <RSCFDn_base> + $00E0_H$ + (04_H × x),
RSCFDnCFDRFSTSxLH: <RSCFDn_base> + $00E1_H$ + (04_H × x),
RSCFDnCFDRFSTSxHL: <RSCFDn_base> + $00E2_H$ + (04_H × x),
RSCFDnCFDRFSTSxHH: <RSCFDn_base> + $00E3_H$ + (04_H × x)

Value after reset: $0000\ 0001_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R	R

Table 23.43 RSCFDnCFDRFSTSx Register Contents

Bit Position	Bit Name	Function
31 to 17	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
16	RFFIF	RX FIFO Full Interrupt Flag 0: FIFO Full interrupt condition not satisfied 1: FIFO Full interrupt condition satisfied
15 to 8	RFMC[7:0]	RX FIFO Message Counter Number of Messages stored in FIFO
7 to 4	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
3	RFIF	RX FIFO Interrupt Flag 0: FIFO Interrupt condition not satisfied 1: FIFO Interrupt condition satisfied
2	RFMLT	RX FIFO Message Lost 0: NO Message Lost in FIFO 1: FIFO Message Lost
1	RFFLL	RX FIFO Full 0: FIFO Not Full 1: FIFO Full
0	RFEMP	RX FIFO Empty 0: FIFO Not Empty 1: FIFO Empty

The FIFO status registers show the status of the messages stored in corresponding FIFO Buffers.

(x = RX FIFO index = [0…no_of_RFIFOs-1])

(no_of_RFIFOs = No. of RX FIFOs = 8)

RSCFDnCFDRFSTSx.RFFIF

RX FIFO Full Interrupt Flag.

This bit will not be cleared automatically if the RX FIFO Buffer is disabled.

Users can only write to this bit when RS-CANFD module is in GL_TEST or GL_OPERATING modes.

Writing 1_B has no influence on the bit values.

Do not use bit clear instruction for clearing this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Then the other bits remain set to 1_B.

This bit is set automatically when the Interrupt condition is satisfied.

If the set from the CAN channel occurs simultaneously with the clear by the write access, then the bit is set.

The bit is cleared by writing 0_B to it.

The bit is cleared when RS-CANFD module enters GL_RESET mode.

RSCFDnCFDRFSTSx.RFMC[7:0]

RX FIFO Message Count.

These bits indicate the number of CAN messages stored in the RX FIFO that can be read by the CPU.

These bits are cleared automatically when the FIFO is disabled.

These bits are cleared automatically when RS-CANFD module enters GL_RESET mode.

RSCFDnCFDRFSTSx.RFIF

RX FIFO Interrupt Flag.

This bit will not be cleared automatically if the RX FIFO Buffer is disabled.

Users can only write to this bit when RS-CANFD module is in GL_TEST or GL_OPERATING modes.
Writing 1_B has no influence on the bit values.

Do not use bit clear instruction for clearing this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Then the other bits remain set to 1_B.

This bit is set automatically when the configured Interrupt condition is satisfied.

If the set from the CAN channel occurs simultaneously with the clear by the write access, then the bit is set.

The bit is cleared by writing 0_B to it.
The bit is cleared when RS-CANFD module enters GL_RESET mode.

RSCFDnCFDRFSTSx.RFMLT

RX FIFO Message Lost.

Users can only write to this bit when RS-CANFD module is in GL_TEST or GL_OPERATING modes.

Writing 1_B has no influence on the bit values.

Do not use bit clear instruction for clearing this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Then the other bits remain set to 1_B.

This bit is set automatically whenever a message is lost due to attempted storage when the FIFO is already full.
If the set from the CAN channel occurs simultaneously with the clear by the write access, then the bit is set.

The bit is cleared by writing 0_B to it.
The bit is cleared when RS-CANFD module enters GL_RESET mode.

RSCFDnCFDRFSTSx.RFFLL

RX FIFO Full.

This bit is set automatically when number of CAN messages stored in the FIFO matches the configured FIFO depth.

This bit is cleared automatically when the number of CAN messages stored in the FIFO is less than the configured FIFO depth.
This bit is cleared automatically when RX FIFO is disabled by setting the RSCFDnCFDRFCCx.RFE bit to 0_B.
This bit is cleared automatically when RS-CANFD module enters GL_RESET mode.

RSCFDnCFDRFSTSx.RFEMP

RX FIFO Empty.

This bit is set automatically when RSCFDnCFDRFSTSx.RFMC is 0_H.
This bit is set automatically when RX FIFO is disabled by setting the RSCFDnCFDRFCCx.RFE bit to 0_B.
This bit is set automatically when RS-CANFD module enters GL_RESET mode.

This bit is cleared automatically when the first message is stored in the RX FIFO Buffer.

23.3.6.3 RSCFDnCFDRFPCTRx — Receive FIFO Pointer Control Register x

Access: RSCFDnCFDRFPCTRx register is a write-only register that can be written in 32-bit units
RSCFDnCFDRFPCTRxL, RSCFDnCFDRFPCTRxH register is a write-only register that can be written in 16-bit units
RSCFDnCFDRFPCTRxLL, RSCFDnCFDRFPCTRxLH, RSCFDnCFDRFPCTRxHL,
RSCFDnCFDRFPCTRxHH register is a write-only register that can be written in 8-bit units

Address: RSCFDnCFDRFPCTRx: <RSCFDn_base> + 0100_H + (04_H × x)

RSCFDnCFDRFPCTRxL: <RSCFDn_base> + 0100_H + (04_H × x),
RSCFDnCFDRFPCTRxH: <RSCFDn_base> + 0101_H + (04_H × x)

RSCFDnCFDRFPCTRxLL: <RSCFDn_base> + 100_H + (04_H × x),
RSCFDnCFDRFPCTRxLH: <RSCFDn_base> + 0101_H + (04_H × x),
RSCFDnCFDRFPCTRxHL: <RSCFDn_base> + 0102_H + (04_H × x),
RSCFDnCFDRFPCTRxHH: <RSCFDn_base> + 0103_H + (04_H × x)

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	RFPC[7:0]							
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	W	W	W	W	W	W	W	W

Table 23.44 RSCFDnCFDRFPCTRx Register Contents

Bit Position	Bit Name	Function
31 to 8	Reserved	When writing, write the value after reset.
7 to 0	RFPC[7:0]	RX FIFO Pointer Control Increments read pointer of the corresponding RX FIFO Buffers

These registers can be used to increment the Read Pointer of the corresponding RX FIFO Buffers.

(x = RX FIFO index = [0…no_of_RFIFOs-1])

(no_of_RFIFOs = No. of RX FIFOs = 8)

RSCFDnCFDRFPCTRx.RFPC[7:0]

RX FIFO Pointer Control

When the value FF_H is written to these bits, then the Pointer of the corresponding RX FIFO Buffer is moved to the next FIFO entry.

Read value from these bits is always 0_H.
Users can only write to these bits when RS-CANFD module is in GL_TEST or GL_OPERATING modes.

Users should only write FF_H to these registers when the corresponding RX FIFO is enabled and not empty.

Users should not write to the FIFO control registers when DMA is enabled.

23.3.7 Details of Transmit/Receive FIFO Buffer Related Registers

23.3.7.1 RSCFDnCFDCFCCk — Transmit/Receive FIFO Configuration/Control Register k

Access: RSCFDnCFDCFCCk register can be read or written in 32-bit units
RSCFDnCFDCFCCkL, RSCFDnCFDCFCCkH register can be read or written in 16-bit units
RSCFDnCFDCFCCkLL, RSCFDnCFDCFCCkLH, RSCFDnCFDCFCCkHL, RSCFDnCFDCFCCkHH register can be read or written in 8-bit units

Address: RSCFDnCFDCFCCk: <RSCFDn_base> + 0120_H + (04_H × k)

RSCFDnCFDCFCCkL: <RSCFDn_base> + 0120_H + (04_H × k),
RSCFDnCFDCFCCkH: <RSCFDn_base> + 0122_H + (04_H × k)

RSCFDnCFDCFCCkLL: <RSCFDn_base> + 0120_H + (04_H × k),
RSCFDnCFDCFCCkLH: <RSCFDn_base> + 0121_H + (04_H × k),
RSCFDnCFDCFCCkHL: <RSCFDn_base> + 0122_H + (04_H × k),

Table 23.45 RSCFDnCFDCFCCk Register Contents (2/2)

Bit Position	Bit Name	Function
12	CFIM	Transmit/Receive FIFO Interrupt Mode 0: RX FIFO Mode: RX Interrupt generated when Transmit/Receive FIFO counter reaches CFIGCV value from a lower value; TX FIFO Mode: TX Interrupt generated when Transmit/Receive FIFO transmits the last message successfully; GW FIFO Mode: For RX interrupt flag: Interrupt generated when FIFO counter increments and reaches the value configured in CFIGCV; For TX interrupt flag: Interrupt generated when FIFO transmits the last message successfully; 1: RX FIFO Mode: RX Interrupt generated at the end of every received message storage; TX FIFO Mode: Interrupt generated for every successfully transmitted message; GW FIFO Mode: For RX interrupt flag: Interrupt generated when a message is stored in the FIFO; For TX interrupt flag: Interrupt generated when a message is successfully transmitted from the FIFO;
11	CFITR	Transmit/Receive FIFO Interval Timer Resolution 0: Reference Clock Period x1 1: Reference Clock Period x10
10	CFITSS	Transmit/Receive FIFO Interval Timer Source Select 0: Reference Clock (x1 / x10 period) 1: Bit Time Clock of related channel (FIFO is linked to fixed channel)
9, 8	CFM[1:0]	Transmit/Receive FIFO Mode 00: RX FIFO Mode 01: TX FIFO Mode 10: CAN – CAN GW FIFO Mode 11: Setting prohibited
7	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
6 to 4	CFPLS[2:0]	Transmit/Receive FIFO Payload Data size configuration 000: 8 bytes 001: 12 bytes 010: 16 bytes 011: 20 bytes 100: 24 bytes 101: 32 bytes 110: 48 bytes 111: 64 bytes
3	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
2	CFTXIE	Transmit/Receive FIFO TX Interrupt Enable 0: FIFO Interrupt generation disabled for Frame TX 1: FIFO Interrupt generation enabled for Frame TX
1	CFRXIE	Transmit/Receive FIFO RX Interrupt Enable 0: FIFO Interrupt generation disabled for Frame RX 1: FIFO Interrupt generation enabled for Frame RX
0	CFE	Transmit/Receive FIFO Enable 0: FIFO disabled 1: FIFO enabled

The Transmit/Receive FIFO Configuration / Control registers are used to configure the Transmit/ Receive FIFOs.
Below is an example to calculate index for U2A16:
(no_of_channels = 8)
(no_of_CFIFOs_per_channel = No. of Transmit/Receive FIFOs per Channel = 3)
Where the total number of CFIFOs = no_of_CFIFOs = no_of_CFIFOs_per_channel * no_of_channels = 3 * 8
= 24 as shown in **Figure 23.27**
(k = Transmit/Receive FIFO index = [0 .. no_of_CFIFOs -1])

RSCFDnCFDCFCCk.CFITT[7:0]

Transmit/Receive FIFO Interval Transmission Time.

These bits select the delay in the start of transmission for all messages transmitted from this FIFO when configured in TX or GW mode. The delay is a multiple of the basic Interval Timer Clock Source period (Reference Clock x1, Reference Clock x10 or Bit Time Clock of the related CAN channel).

Users cannot write to this bit when the RS-CANFD module is in GL_STOP mode.

Users should not write to this bit when the RSCFDnCFDCFCCk.CFE bit is set to 1_B.
For RSCFDnCFDGCFG.ITRCP[15:0] = 0_H these bits should only be set to 0_H.

RSCFDnCFDCFCCk.CFDC[2:0]

Transmit/Receive FIFO Depth Configuration.

These bits select the depth of the Transmit/Receive FIFO in terms of number of Messages. If the FIFO depth is configured to 0 Messages then the FIFO cannot be used.

Users can only write to this bit when RS-CANFD module is in GL_RESET mode.

RSCFDnCFDCFCCk.CFTML[4:0]

Transmit/Receive FIFO TX Message Buffer Link.

These bits select the normal transmit Message Buffer position where the TX or GW FIFO is linked to, for transmission scanning.

Users cannot write to these bits in GL_OPERATING & GL_STOP modes.

Users should only write to this bit when RS-CANFD module is in GL_RESET mode.

RSCFDnCFDCFCCk.CFIGCV[2:0]

Transmit/Receive FIFO Interrupt Generation Counter Value.

These bits select the message counter value for the generation of the FIFO Interrupt. These values represent fractions of the FIFO depth at which Interrupt is to be generated.

Users cannot write to these bits when the RS-CANFD module is in GL_STOP mode.

The setting of these bits should be synchronized with the RSCFDnCFDCFCCk.CFDC bits. Refer to **Section 23.7.2.1(5), FIFO Interrupt Configuration** for detailed information.
Users should only write to this bit when RS-CANFD module is in GL_RESET mode.

RSCFDnCFDCFCCk.CFIM

Transmit/Receive FIFO Interrupt Mode.

This bit selects the Interrupt generation condition for the FIFO.

Users cannot write to this bit in GL_STOP mode.

Users should only write to this bit when RS-CANFD module is in GL_RESET mode.

RSCFDnCFDCFCCk.CFITR

Transmit/Receive FIFO Interval Timer Resolution.

This bit selects the resolution of the Reference Clock for the Interval Transmission Timer (Peripheral Clock is the source for the Reference Clock).

Users cannot write to this bit when the RS-CANFD module is in GL_STOP mode.

Users should not write to this bit when the RSCFDnCFDCFCCk.CFE bit is set to 1_B.

RSCFDnCFDCFCCk.CFITSS

Transmit/Receive FIFO Interval Timer Source Select.

This bit selects the basic clock source for the Interval Transmission Timer.

Users cannot write to this bit when the RS-CANFD module is in GL_STOP mode.

Users should not write to this bit when the RSCFDnCFDCFCCk.CFE bit is set to 1_B.

Users should not write 1_B when CANFD communication will be used.
Note bit time clock could be variable depending on the nominal and data rate bit configuration.

RSCFDnCFDCFCCk.CFM[1:0]

Transmit/Receive FIFO Mode.

These bits select the Mode of the FIFO. When HW Reset is active, all the Transmit/Receive FIFO Buffers will be configured in RX FIFO mode.

Users cannot write to these bits in GL_OPERATING & GL_STOP modes.

Users should not configure these bits to 11_B.
Users should only write to this bit when RS-CANFD module is in GL_RESET mode.

RSCFDnCFDCFCCk.CFPLS[2:0]

Transmit/Receive FIFO Payload Data size configuration.

These bits define the message data payload allocation in the RAM.
This is the max. number of Bytes which can be received or transmitted by this FIFO.
Refer to **Section 23.7** for details.

Users can only write to this bit when RS-CANFD module is in GL_RESET mode.

RSCFDnCFDCFCCk.CFTXIE

Transmit/Receive FIFO TX Interrupt Enable.

This bit enables the generation of the Transmit/Receive FIFO Interrupt when the Interrupt flag is set after transmission of a frame from the corresponding FIFO.

Users cannot write to this bit when the RS-CANFD module is in GL_STOP mode.

RSCFDnCFDCFCCk.CFRXIE

Transmit/Receive FIFO RX Interrupt Enable.

This bit enables generation of the FIFO Interrupt when the Interrupt flag is set after reception of a frame in the corresponding FIFO.

Users cannot write to this bit when the RS-CANFD module is in GL_STOP mode.

RSCFDnCFDCFCCk.CFE

Transmit/Receive FIFO Enable.

This bit enables the FIFO when it is set.
FIFO is disabled when this bit is cleared.
This bit can also be used, by clearing it, to abort transmission from Transmit/Receive FIFO when configured in TX Mode or GW Mode.
This bit can also be used, by clearing it, to stop reception into the Transmit/Receive FIFO in RX mode.

Users can only write to this bit when RS-CANFD module is in GL_TEST or GL_OPERATING modes and the related RS-CANFD channel is not in CH_RESET mode for FIFOs configured as TX or GW FIFO.
This bit can only be set if the configured FIFO depth is greater than 0_H (RSCFDnCFDCFCCk.CFDC > 000_B).

The RSCFDnCFDCFCCk.CFE bit should be set by a separate write access to the RSCFDnCFDCFCCk register, after all the other bits of the RSCFDnCFDCFCCk register have been set.

This bit is cleared automatically when RS-CANFD module enters GL_RESET mode.
This bit is cleared automatically when the related channel enters CH_RESET mode if the FIFO is configured in TX or GW mode.

23.3.7.2 RSCFDnCFDCFCCEk — Transmit/Receive FIFO Configuration / Control Enhancement Register

Access: RSCFDnCFDCFCCEk register can be read or written in 32-bit units
RSCFDnCFDCFCCEkL, RSCFDnCFDCFCCEkH register can be read or written in 16-bit units
RSCFDnCFDCFCCEkLL, RSCFDnCFDCFCCEkLH, RSCFDnCFDCFCCEkHL, RSCFDnCFDCFCCEkHH register can be read or written in 8-bit units

Address: RSCFDnCFDCFCCEk: <RSCFDn_base> + 0180_H + (04_H × k)

RSCFDnCFDCFCCEkL: <RSCFDn_base> + 0180_H + (04_H × k),
RSCFDnCFDCFCCEkH: <RSCFDn_base> + 0182_H + (04_H × k)

RSCFDnCFDCFCCEkLL: <RSCFDn_base> + 0180_H + (04_H × k),
RSCFDnCFDCFCCEkLH: <RSCFDn_base> + 0181_H + (04_H × k),
RSCFDnCFDCFCCEkHL: <RSCFDn_base> + 0182_H + (04_H × k),
RSCFDnCFDCFCCEkHH: <RSCFDn_base> + 0183_H + (04_H × k)

Value after reset: $0000\ 0000_H$

Table 23.46 RSCFDnCFDCFCCEk Register Contents

Bit Position	Bit Name	Function
31 to 17	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
16	CFBME	Transmit/Receive FIFO Buffering Mode Enable 0: Transmission from Transmit/Receive FIFO 1: Transmission halt from Transmit/Receive FIFO
15 to 9	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
8	CFMOWM	Transmit/Receive FIFO message overwrite mode 0: Message discarded mode 1: Message overwrite mode
7 to 3	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
2	CFOFTXIE	Transmit/Receive FIFO One Frame Transmission Interrupt Enable 0: One Frame TX Interrupt generation disabled 1: One Frame TX Interrupt generation enabled
1	CFOFRXIE	Transmit/Receive FIFO One Frame Reception Interrupt Enable 0: One Frame RX Interrupt generation disabled 1: One Frame RX Interrupt generation enabled
0	CFFIE	Transmit/Receive FIFO Full interrupt Enable 0: FIFO Interrupt generation disabled 1: FIFO Interrupt generation enabled

The Transmit/Receive FIFO Configuration / Control Enhancement registers are used to configure the transmit/receive FIFOs.
Below is an example to calculate index for U2A16:
(no_of_channels = 8)
(no_of_CFIFOs_per_channel = No. of Transmit/Receive FIFOs per Channel = 3)

Where the total number of CFIFOs = no_of_CFIFOs = no_of_CFIFOs_per_channel * no_of_channels
= 3 * 8
= 24 as shown in **Figure 23.27**
(k = Transmit/Receive FIFO index = [0 .. no_of_CFIFOs -1])

RSCFDnCFDCFCCEk.CFBME

Transmit/Receive FIFO Buffering Mode Enable

When this bit is 0, messages are transmitted from FIFO.
When this bit is 1, messages are not transmitted from FIFO.
Users cannot write to this bit when the RS-CANFD module is in GL_STOP mode.
Users should not write 1 from 0 for this bit when the RSCFDnCFDCFCCk.CFE bit is 1_B.

RSCFDnCFDCFCCEk.CFMOWM

Transmit/Receive FIFO message overwrite mode

A receiving message is discarded, when this bit is 0 and FIFO is full.
A receiving message is overwritten, when this bit is 1 and FIFO is full.
Users cannot write to this bit when the RS-CANFD module is in GL_STOP mode.
Users should only write 1 to this bit when the Transmit/Receive FIFO is in GW mode.
Users should not write change for this bit when the RSCFDnCFDCFCCk.CFE bit is 1_B.

RSCFDnCFDCFCCEk.CFOFTXIE

Transmit/Receive FIFO One Frame Transmission Interrupt Enable

This bit enables generation of the One Frame Transmission Interrupt when the Interrupt flag is set after transmission of a frame in the corresponding FIFO.
Users cannot write to this bit when the RS-CANFD module is in GL_STOP mode.

RSCFDnCFDCFCCEk.CFOFRXIE

Transmit/Receive FIFO One Frame Reception Interrupt Enable

This bit enables generation of the One Frame Reception Interrupt when the Interrupt flag is set after reception of a frame in the corresponding FIFO.
Users cannot write to this bit when the RS-CANFD module is in GL_STOP mode.

RSCFDnCFDCFCCEk.CFFIE

Transmit/Receive FIFO Full interrupt Enable

This bit enables generation of the FIFO full Interrupt when the Interrupt flag is set after reception of a frame in the corresponding FIFO.
Users cannot write to this bit when the RS-CANFD module is in GL_STOP mode.

The following contents are imagined as how to use interruption.

1. Interruption output in number of arbitrary stages (RSCFDnCFDCFCCk.CFIGCV)

2. Interruption output in FIFO full state

Management of the receiving data of FIFO can be performed by these notices of interruption.

23.3.7.3 RSCFDnCFDCFSTSk — Transmit/Receive FIFO Status Register k

Access: RSCFDnCFDCFSTSk register can be read or written in 32-bit units
RSCFDnCFDCFSTSkL, RSCFDnCFDCFSTSkH register can be read or written in 16-bit units
RSCFDnCFDCFSTSkLL, RSCFDnCFDCFSTSkLH, RSCFDnCFDCFSTSkHL, RSCFDnCFDCFSTSkHH register can be read or written in 8-bit units

Address: RSCFDnCFDCFSTSk: <RSCFDn_base> + $01E0_H$ + (04_H × k)

RSCFDnCFDCFSTSkL: <RSCFDn_base> + $01E0_H$ + (04_H × k),
RSCFDnCFDCFSTSkH: <RSCFDn_base> + $01E2_H$ + (04_H × k)

RSCFDnCFDCFSTSkLL: <RSCFDn_base> + $01E0_H$ + (04_H × k),
RSCFDnCFDCFSTSkLH: <RSCFDn_base> + $01E1_H$ + (04_H × k),
RSCFDnCFDCFSTSkHL: <RSCFDn_base> + $01E2_H$ + (04_H × k),
RSCFDnCFDCFSTSkHH: <RSCFDn_base> + $01E3_H$ + (04_H × k)

Value after reset: $0000\ 0001_H$

Table 23.47 RSCFDnCFDCFSTSk Register Contents (1/2)

Bit Position	Bit Name	Function
31 to 25	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
24	CFMOW	Transmit/Receive FIFO message overwrite 0: No Message overwrite occurred in FIFO 1: Message overwrite occurred in FIFO
23 to 19	Reserved	These bits are read as the value after reset. When writing, write the value after reset.
18	CFOFTXIF	Transmit/Receive FIFO One Frame Transmission Every FIFO transmits a frame, a corresponding interrupt is set.
17	CFOFRXIF	Transmit/Receive FIFO One Frame Reception Every FIFO receives a frame, a corresponding interrupt is set.
16	CFFIF	Transmit/Receive FIFO Full Interrupt Flag 0: Interrupt condition not satisfied for FIFO Full interrupt 1: Interrupt condition satisfied for FIFO Full interrupt
15 to 8	CFMC[7:0]	Transmit/Receive FIFO Message Count No. of Messages stored in FIFO
7 to 5	Reserved	These bits are read as the value after reset. When writing, write the value after reset.
4	CFTXIF	Transmit/Receive TX FIFO Interrupt Flag 0: FIFO Interrupt condition not satisfied after Frame Transmission 1: FIFO Interrupt condition satisfied after Frame Transmission
3	CFRXIF	Transmit/Receive RX FIFO Interrupt Flag 0: FIFO Interrupt condition not satisfied after Frame Reception 1: FIFO Interrupt condition satisfied after Frame Reception
2	CFMLT	Transmit/Receive FIFO Message Lost 0: No Message lost in FIFO 1: FIFO Message Lost

Table 23.47 RSCFDnCFDCFSTSk Register Contents (2/2)

Bit Position	Bit Name	Function
1	CFFLL	Transmit/Receive FIFO Full 0: FIFO Not Full 1: FIFO Full
0	CFEMP	Transmit/Receive FIFO Empty 0: FIFO Not Empty 1: FIFO Empty

The FIFO status registers show the status of the messages stored in corresponding FIFO Buffers.
Below is an example to calculate index for U2A16:
(no_of_channels = 8)
(no_of_CFIFOs_per_channel = No. of Transmit/Receive FIFOs per Channel = 3)
Where the total number of CFIFOs = no_of_CFIFOs = no_of_CFIFOs_per_channel * no_of_channels
= 3 * 8
= 24 as shown in **Figure 23.27**
(k = Transmit/Receive FIFO index = [0 .. no_of_CFIFOs -1])

RSCFDnCFDCFSTSk.CFMOW

Transmit/Receive FIFO Message overwrite.

Users can only write to this bit when RS-CANFD module is in GL_TEST or GL_OPERATING mode and the related RS-CANFD channel is not in CH_RESET mode for FIFOs configured as TX or GW FIFO.
Writing 1_B has no influence on the bit values.
Do not use bit clear instruction for clearing this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Then the other bits remain set to 1_B.
This bit is set automatically whenever a message is overwrite storage of a new message when RSCFDnCFDCFCCEk.CFMOWM=1 and FIFO is already full in GW mode.
If the set from the CAN channel occurs simultaneously with the clear by the write access, then the bit is set.
The bit is cleared by writing 0_B to it.
The bit is cleared when RS-CANFD module enters GL_RESET mode.
The bit is cleared when the related channel enters CH_RESET mode if the FIFO is configured in TX or GW mode.

RSCFDnCFDCFSTSk.CFOFTXIF

Transmit/Receive FIFO One Frame Transmission Interrupt Flag.

This bit will not be cleared automatically if the Transmit/Receive FIFO Buffer is disabled.
Users can only write to this bit when RS-CANFD module is in GL_TEST or GL_OPERATING mode and the related RS-CANFD channel is not in CH_RESET mode for FIFOs configured as TX or GW FIFO.
Writing 1_B has no influence on the bit values.
Do not use bit clear instruction for clearing this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Then the other bits remain set to 1_B.
This bit is set automatically when the One Frame Transmission Interrupt condition is satisfied for transmit/receive FIFO Buffers configured in GW mode or TX mode.
If the set from the CAN channel occurs simultaneously with the clear by the write access, then the bit is set.
The bit is cleared by writing 0_B to it.
The bit is cleared when RS-CANFD module enters GL_RESET mode.
The bit is cleared when the related channel enters CH_RESET mode if the FIFO is configured in TX or GW mode.
This bit is not influenced by the value of RSCFDnCFDCFCCk.CFIM.

RSCFDnCFDCFSTSk.CFOFRXIF

Transmit/Receive FIFO One Frame Reception Interrupt Flag.

This bit will not be cleared automatically if the Transmit/Receive FIFO Buffer is disabled.
Users can only write to this bit when RS-CANFD module is in GL_TEST or GL_OPERATING mode and the related RS-CANFD channel is not in CH_RESET mode for FIFOs configured as TX or GW FIFO.
Writing 1_B has no influence on the bit values.
Do not use bit clear instruction for clearing this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Then the other bits remain set to 1_B.
This bit is set automatically when the One Frame Reception Interrupt condition is satisfied for Transmit/Receive FIFO Buffers when configured in GW mode or RX mode.
If the set from the CAN channel occurs simultaneously with the clear by the write access, then the bit is set.
The bit is cleared by writing 0_B to it.
The bit is cleared when RS-CANFD module enters GL_RESET mode.
The bit is cleared when the related channel enters CH_RESET mode if the FIFO is configured in TX or GW mode.
This bit is not influenced by the value of RSCFDnCFDCFCCk.CFIM.

RSCFDnCFDCFSTSk.CFFIF

Transmit/Receive FIFO Full Interrupt Flag.

This bit will not be cleared automatically if the Transmit/Receive FIFO Buffer is disabled.
Users can only write to this bit when RS-CANFD module is in GL_TEST or GL_OPERATING mode and the related RS-CANFD channel is not in CH_RESET mode for FIFOs configured as TX or GW FIFO.
Writing 1_B has no influence on the bit values.
Do not use bit clear instruction for clearing this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Then the other bits remain set to 1_B.
This bit is set automatically when the FIFO full Interrupt condition is satisfied for Transmit/Receive FIFO Buffers when configured in GW mode or RX mode.
If the set from the CAN channel occurs simultaneously with the clear by the write access, then the bit is set.
The bit is cleared by writing 0_B to it.
The bit is cleared when RS-CANFD module enters GL_RESET mode.
The bit is cleared when the related channel enters CH_RESET mode if the FIFO is configured in TX or GW mode.

RSCFDnCFDCFSTSk.CFMC[7:0]

Transmit/Receive FIFO Message Count.

These bits indicate the following:
Number of CAN messages stored by the CPU in the FIFO configured in TX Mode pending for transmission.
Number of CAN messages stored in the FIFO Buffer configured in RX Mode by RS-CANFD to be read by the CPU.
Number of CAN messages stored by the RS-CANFD in the GW FIFO pending for transmission.
These bits are cleared automatically when the FIFO is disabled.
These bits are cleared automatically when RS-CANFD module enters GL_RESET mode.
These bits are cleared automatically when the related channel enters CH_RESET mode if the FIFO is configured in TX or GW mode.

RSCFDnCFDCFSTSk.CFTXIF

Transmit/Receive TX FIFO Interrupt Flag.

This bit will not be cleared automatically if the Transmit/Receive FIFO Buffer is disabled.

Users can only write to this bit when RS-CANFD module is in GL_TEST or GL_OPERATING mode and the related RS-CANFD channel is not in CH_RESET mode for FIFOs configured as TX or GW FIFO.
Writing 1_B has no influence on the bit values.

Do not use bit clear instruction for clearing this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Then the other bits remain set to 1_B.

This bit is set automatically when the configured Interrupt condition is satisfied for Transmit/Receive FIFO Buffers configured in GW mode or TX mode.

The bit is cleared by writing 0_B to it.
The bit is cleared when RS-CANFD module enters GL_RESET mode.
The bit is cleared when the related channel enters CH_RESET mode if the FIFO is configured in TX or GW mode.

RSCFDnCFDCFSTSk.CFRXIF

Transmit/Receive RX FIFO Interrupt Flag.

This bit will not be cleared automatically if the Transmit/Receive FIFO Buffer is disabled.

Users can only write to this bit when RS-CANFD module is in GL_TEST or GL_OPERATING mode and the related RS-CANFD channel is not in CH_RESET mode for FIFOs configured as TX or GW FIFO.
Writing 1_B has no influence on the bit values.

Do not use bit clear instruction for clearing this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Then the other bits remain set to 1_B.

This bit is set automatically when the configured Interrupt condition is satisfied for Transmit/Receive FIFO Buffers when configured in GW mode or RX mode.

The bit is cleared by writing 0_B to it.
The bit is cleared when RS-CANFD module enters GL_RESET mode.
The bit is cleared when the related channel enters CH_RESET mode if the FIFO is configured in GW mode.

RSCFDnCFDCFSTSk.CFMLT

Transmit/Receive FIFO Message Lost.

Users can only write to this bit when RS-CANFD module is in GL_TEST or GL_OPERATING mode and the related RS-CANFD channel is not in CH_RESET mode for FIFOs configured as TX or GW FIFO.
Writing 1_B has no influence on the bit values.

Do not use bit clear instruction for clearing this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Then the other bits remain set to 1_B.

This bit is set automatically whenever a message is lost due to attempted storage of a new message when FIFO is already full in RX or GW mode.
If the set from the CAN channel occurs simultaneously with the clear by the write access, then the bit is set.

The bit is cleared by writing 0_B to it.
The bit is cleared when RS-CANFD module enters GL_RESET mode.
The bit is cleared when the related channel enters CH_RESET mode if the FIFO is configured in TX or GW mode.

RSCFDnCFDCFSTSk.CFFLL

Transmit/Receive FIFO Full.

This bit is set automatically when the number of CAN messages stored in the FIFO matches the configured FIFO depth.

This bit is cleared automatically when the number of CAN messages stored in the FIFO is less than the configured FIFO depth.
This bit is cleared automatically when the FIFO is disabled by setting the CFE bit to 0_B.
This bit is cleared automatically when RS-CANFD module enters GL_RESET.
This bit is cleared automatically when RS-CANFD module enters CH_RESET when FIFO is configured in TX or GW Mode.

RSCFDnCFDCFSTSk.CFEMP

Transmit/Receive FIFO Empty.

This bit is set automatically when the CPU has read all messages from the FIFO configured in RX mode.
This bit is set automatically when all messages have been transmitted from the FIFO configured in TX or GW Mode.
This bit is set automatically when FIFO is disabled by setting the CFE bit to 0_B.
This bit is set automatically when RS-CANFD module enters GL_RESET mode.
This bit is set automatically when RS-CANFD module enters CH_RESET when FIFO configured in TX Mode or GW Mode.
This bit is cleared automatically when the first reception message is stored in the FIFO when configured in RX Mode.
This bit is cleared automatically when the first message to be transmitted is stored in the FIFO when configured in TX or GW Mode.

23.3.7.4 RSCFDnCFDCFPCTRk — Transmit/Receive FIFO Pointer Control Register k

Access: RSCFDnCFDCFPCTRk register is a write-only register that can be written in 32-bit units
RSCFDnCFDCFPCTRkL, RSCFDnCFDCFPCTRkH register is a write-only register that can be written in 16-bit units
RSCFDnCFDCFPCTRkLL, RSCFDnCFDCFPCTRkLH, RSCFDnCFDCFPCTRkHL, RSCFDnCFDCFPCTRkHH register is a write-only register that can be written in 8-bit units

Address: RSCFDnCFDCFPCTRk: <RSCFDn_base> + 0240_H + (04_H × k)

RSCFDnCFDCFPCTRkL: <RSCFDn_base> + 0240_H + (04_H × k),
RSCFDnCFDCFPCTRkH: <RSCFDn_base> + 0242_H + (04_H × k)

RSCFDnCFDCFPCTRkLL: <RSCFDn_base> + 0240_H + (04_H × k),
RSCFDnCFDCFPCTRkLH: <RSCFDn_base> + 0241_H + (04_H × k),
RSCFDnCFDCFPCTRkHL: <RSCFDn_base> + 0242_H + (04_H × k),
RSCFDnCFDCFPCTRkHH: <RSCFDn_base> + 0243_H + (04_H × k)

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Table 23.48 RSCFDnCFDCFPCTRk Register Contents

Bit Position	Bit Name	Function
31 to 8	Reserved	When writing, write the value after reset.
7 to 0	CFPC[7:0]	Transmit/Receive FIFO Pointer Control Increments read or write pointer of the corresponding Transmit/Receive FIFO Buffers depending upon the mode configuration

These registers can be used to increment the Read or Write Pointer of the corresponding Transmit/ Receive FIFO.
Below is an example to calculate index for U2A16:
(no_of_channels = 8)
(no_of_CFIFOs_per_channel = No. of Transmit/Receive FIFOs per Channel = 3)
Where the total number of CFIFOs = no_of_CFIFOs = no_of_CFIFOs_per_channel * no_of_channels
= 3 * 8
= 24 as shown in **Figure 23.27**
(k = Transmit/Receive FIFO index = [0 .. no_of_CFIFOs -1])

RSCFDnCFDCFPCTRk.CFPC[7:0]

Transmit/Receive FIFO Pointer Control

When the value FF_H is written into these bits, then the Read Pointer of the corresponding Transmit/Receive FIFO Buffer, when configured in RX mode, or the Write Pointer of the corresponding Transmit/Receive FIFO Buffer, when configured in TX mode, moves to the next FIFO entry.

Read value from these bits is always 0_H.
Users can only write to these bits when RS-CANFD module is in GL_TEST or GL_OPERATING modes.

Users should only write FF_H to this register when the Transmit/Receive FIFO is enabled and is not empty if configured in RX mode.
Users should only write FF_H to this register when the Transmit/Receive FIFO is enabled and is not full if configured in TX mode.
Users should only write FF_H to this register when the Transmit/Receive FIFO is enabled and is not configured in GW mode.

Users should not write to the FIFO control registers when DMA is enabled.

23.3.8 Details of FIFO Status-Related Registers

23.3.8.1 RSCFDnCFDFESTS — FIFO Empty Status Register

Access: RSCFDnCFDFESTS register is a read-only register that can be read in 32-bit units
RSCFDnCFDFESTSL, RSCFDnCFDFESTSH register is a read-only register that can be read in 16-bit units
RSCFDnCFDFESTSLL, RSCFDnCFDFESTSLH, RSCFDnCFDFESTSHL, RSCFDnCFDFESTSHH register is a read-only register that can be read in 8-bit units

Address: RSCFDnCFDFESTS: <RSCFDn_base> + $02A0_H$

RSCFDnCFDFESTSL: <RSCFDn_base> + $02A0_H$, RSCFDnCFDFESTSH: <RSCFDn_base> + $02A2_H$

RSCFDnCFDFESTSLL: <RSCFDn_base> + $02A0_H$, RSCFDnCFDFESTSLH: <RSCFDn_base> + $02A1_H$,
RSCFDnCFDFESTSHL: <RSCFDn_base> + $02A2_H$, RSCFDnCFDFESTSHH: <RSCFDn_base> + $02A3_H$

Value after reset: FFFF $FFFF_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 23.49 RSCFDnCFDFESTS Register Contents

Bit Position	Bit Name	Function
31 to 8	CFkEMP[23:0]	Transmit/Receive FIFO Empty Status 0: Corresponding FIFO not Empty 1: Corresponding FIFO Empty
7 to 0	RFxEMP[7:0]	RX FIFO Empty Status 0: Corresponding FIFO not Empty 1: Corresponding FIFO Empty

The FIFO Empty status register bits show the status of the Empty bits of the FIFO Buffers.

RSCFDnCFDFESTS.CFkEMP[23:0]

Transmit/Receive FIFO Empty Status

This bit is set when the RS-CANFD module enters GL_RESET mode.
Each bit is set automatically when the corresponding bit is set in the Transmit/Receive FIFO Status Register.

Each bit is cleared automatically when the corresponding bit is cleared in the Transmit/Receive FIFO Status Register.

RSCFDnCFDFESTS.RFxEMP[7:0]

RX FIFO Empty Status

This bit is set when the RS-CANFD module enters GL_RESET mode.
Each bit is set automatically when the corresponding bit is set in the RX FIFO Status Register.

Each bit is cleared automatically when the corresponding bit is cleared in the RX FIFO Status Register.

23.3.8.2 RSCFDnCFDFFSTS — FIFO Full Status Register

Access: RSCFDnCFDFFSTS register is a read-only register that can be read in 32-bit units
RSCFDnCFDFFSTSL, RSCFDnCFDFFSTSH register is a read-only register that can be read in 16-bit units
RSCFDnCFDFFSTSLL, RSCFDnCFDFFSTSLH, RSCFDnCFDFFSTSHL, RSCFDnCFDFFSTSHH register is a read-only register that can be read in 8-bit units

Address: RSCFDnCFDFFSTS: <RSCFDn_base> + $02A4_H$

RSCFDnCFDFFSTSL: <RSCFDn_base> + $02A4_H$, RSCFDnCFDFFSTSH: <RSCFDn_base> + $02A6_H$

RSCFDnCFDFFSTSLL: <RSCFDn_base> + $02A4_H$, RSCFDnCFDFFSTSLH: <RSCFDn_base> + $02A5_H$,

Table 23.50 RSCFDnCFDFFSTS Register Contents

Bit Position	Bit Name	Function
31 to 8	CFkFLL[23:0]	Transmit/Receive FIFO Full Status 0: Corresponding FIFO not Full 1: Corresponding FIFO Full
7 to 0	RFxFLL[7:0]	RX FIFO Full Status 0: Corresponding FIFO not Full 1: Corresponding FIFO Full

The FIFO Full status register bits show the status of the Full bits of the FIFO Buffers.

RSCFDnCFDFFSTS.CFkFLL[23:0]

Transmit/Receive FIFO Full Status

Each bit is set automatically when the corresponding bit is set in the Transmit/Receive FIFO Status Register.

Each bit is cleared automatically when the corresponding bit is cleared in the Transmit/Receive FIFO Status Register.
This bit is cleared when RS-CANFD module enters GL_RESET mode.

RSCFDnCFDFFSTS.RFxFLL[7:0]

RX FIFO Full Status

Each bit is set automatically when the corresponding bit is set in the RX FIFO Status Register.

Each bit is cleared automatically when the corresponding bit is cleared in the RX FIFO Status Register.
This bit is cleared when RS-CANFD module enters GL_RESET mode.

23.3.8.3 RSCFDnCFDFMSTS — FIFO Message Lost Status Register

Access: RSCFDnCFDFMSTS register is a read-only register that can be read in 32-bit units
RSCFDnCFDFMSTSL, RSCFDnCFDFMSTSH register is a read-only register that can be read in 16-bit units
RSCFDnCFDFMSTSLL, RSCFDnCFDFMSTSLH, RSCFDnCFDFMSTSHL, RSCFDnCFDFMSTSHH register is a read-only register that can be read in 8-bit units

Address: RSCFDnCFDFMSTS: <RSCFDn_base> + $02A8_H$

RSCFDnCFDFMSTSL: <RSCFDn_base> + $02A8_H$, RSCFDnCFDFMSTSH: <RSCFDn_base> + $02AA_H$

RSCFDnCFDFMSTSLL: <RSCFDn_base> + $02A8_H$, RSCFDnCFDFMSTSLH: <RSCFDn_base> + $02A9_H$,
RSCFDnCFDFMSTSHL: <RSCFDn_base> + $02AA_H$, RSCFDnCFDFMSTSHH: <RSCFDn_base> + $02AB_H$

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 23.51 RSCFDnCFDFMSTS Register Contents

Bit Position	Bit Name	Function
31 to 8	CFkMLT[23:0]	Transmit/Receive FIFO Msg Lost Status 0: Transmit/Receive FIFO Msg Lost flag not set 1: Transmit/Receive FIFO Msg Lost flag set
7 to 0	RFxMLT[7:0]	RX FIFO Msg Lost Status 0: Transmit/Receive FIFO Msg Lost flag not set 1: Transmit/Receive FIFO Msg Lost flag set

The FIFO Msg Lost status register bits show the status of the Msg Lost bits of the FIFO Buffers.

RSCFDnCFDFMSTS.CFkMLT[23:0]

Transmit/Receive FIFO Msg Lost Status

This bit is cleared when RS-CANFD module enters GL_RESET mode.
Each bit is set automatically when the corresponding bit is set in the Transmit/Receive FIFO Status Register.

Each bit is cleared automatically when the corresponding bit is cleared in the Transmit/Receive FIFO Status Register.

RSCFDnCFDFMSTS.RFxMLT[7:0]

RX FIFO Msg Lost Status

This bit is cleared when RS-CANFD module enters GL_RESET mode.
Each bit is set automatically when the corresponding bit is set in the RX FIFO Status Register.

Each bit is cleared automatically when the corresponding bit is cleared in the RX FIFO Status Register.

23.3.8.4 RSCFDnCFDRFISTS — Receive FIFO Interrupt Flag Status Register

Access: RSCFDnCFDRFISTS register is a read-only register that can be read in 32-bit units
RSCFDnCFDRFISTSL, RSCFDnCFDRFISTSH register is a read-only register that can be read in 16-bit units
RSCFDnCFDRFISTSLL, RSCFDnCFDRFISTSLH, RSCFDnCFDRFISTSHL, RSCFDnCFDRFISTSHH register is a read-only register that can be read in 8-bit units

Address: RSCFDnCFDRFISTS: <RSCFDn_base> + $02AC_H$

RSCFDnCFDRFISTSL: <RSCFDn_base> + $02AC_H$, RSCFDnCFDRFISTSH: <RSCFDn_base> + $02AE_H$

RSCFDnCFDRFISTSLL: <RSCFDn_base> + $02AC_H$, RSCFDnCFDRFISTSLH: <RSCFDn_base> + $02AD_H$, RSCFDnCFDRFISTSHL: <RSCFDn_base> + $02AE_H$, RSCFDnCFDRFISTSHH: <RSCFDn_base> + $02AF_H$

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 23.52 RSCFDnCFDRFISTS Register Contents

Bit Position	Bit Name	Function
31 to 24	Reserved	When read, the value after reset is returned.
23 to 16	RFxFFLL[7:0]	RX FIFO[x] Interrupt Full Flag Status 0: Corresponding RX FIFO interrupt Full flag not set 1: Corresponding RX FIFO interrupt Full flag set
15 to 8	Reserved	When read, the value after reset is returned.
7 to 0	RFxIF[7:0]	RX FIFO[x] Interrupt Flag Status 0: Corresponding RX FIFO interrupt flag not set 1: Corresponding RX FIFO interrupt flag set

The FIFO Interrupt Flag status register bits show the status of the Interrupt Flag bits of the RX FIFO Buffers.

RSCFDnCFDRFISTS.RFxFFLL[7:0]

RX FIF0[x] Interrupt Full Flag Status

Each bit is set automatically when the corresponding interrupt Full flag bit is set in the RX FIFO Status Register.

This bit is cleared when RS-CANFD module enters GL_RESET mode.
Each bit is cleared automatically when the corresponding interrupt Full flag bit is cleared in the RX FIFO Status Register.

RSCFDnCFDRFISTS.RFxIF[7:0]

RX FIFO[x] Interrupt Flag Status

Each bit is set automatically when the corresponding interrupt flag bit is set in the RX FIFO Status Register.

This bit is cleared when RS-CANFD module enters GL_RESET mode.
Each bit is cleared automatically when the corresponding interrupt flag bit is cleared in the RX FIFO Status Register.

23.3.8.5 RSCFDnCFDCFRISTS — Transmit/Receive FIFO Receive Interrupt Flag Status Register

Access: RSCFDnCFDCFRISTS register is a read-only register that can be read in 32-bit units
RSCFDnCFDCFRISTSL, RSCFDnCFDCFRISTSH register is a read-only register that can be read in 16-bit units
RSCFDnCFDCFRISTSLL, RSCFDnCFDCFRISTSLH, RSCFDnCFDCFRISTSHL, RSCFDnCFDCFRISTSHH register is a read-only register that can be read in 8-bit units

Address: RSCFDnCFDCFRISTS: <RSCFDn_base> + $02B0_H$

RSCFDnCFDCFRISTSL: <RSCFDn_base> + $02B0_H$, RSCFDnCFDCFRISTSH: <RSCFDn_base> + $02B2_H$

RSCFDnCFDCFRISTSLL: <RSCFDn_base> + $02B0_H$, RSCFDnCFDCFRISTSLH: <RSCFDn_base> + $02B1_H$,

Table 23.53 RSCFDnCFDCFRISTS Register Contents

Bit Position	Bit Name	Function
31 to 24	Reserved	When read, the value after reset is returned.
23 to 0	CFkRXIF[23:0]	Transmit/Receive FIFO [k] RX Interrupt Flag Status 0: Corresponding Transmit/Receive FIFO RX interrupt flag is not set 1: Corresponding Transmit/Receive FIFO RX interrupt flag is set

The FIFO Interrupt Flag status register bits show the status of the Interrupt Flag bits of the Transmit/ Receive FIFO Buffers.

RSCFDnCFDCFRISTS.CFkRXIF[23:0]

Transmit/Receive FIFO [k] RX Interrupt Flag Status

Each bit is set automatically when the corresponding RX interrupt flag bit is set in the Transmit/ Receive FIFO Status Register.

This bit is cleared when RS-CANFD module enters GL_RESET mode.
Each bit is cleared automatically when the corresponding RX interrupt flag bit is cleared in the Transmit/Receive FIFO Status Register.

23.3.8.6 RSCFDnCFDCFTISTS — Transmit/Receive FIFO Transmit Interrupt Flag Status Register

Access: RSCFDnCFDCFTISTS register is a read-only register that can be read in 32-bit units
RSCFDnCFDCFTISTSL, RSCFDnCFDCFTISTSH register is a read-only register that can be read in 16-bit units
RSCFDnCFDCFTISTSLL, RSCFDnCFDCFTISTSLH, RSCFDnCFDCFTISTSHL, RSCFDnCFDCFTISTSHH register is a read-only register that can be read in 8-bit units

Address: RSCFDnCFDCFTISTS: <RSCFDn_base> + $02B4_H$

RSCFDnCFDCFTISTSL: <RSCFDn_base> + $02B4_H$, RSCFDnCFDCFTISTSH: <RSCFDn_base> + $02B6_H$

RSCFDnCFDCFTISTSLL: <RSCFDn_base> + $02B4_H$, RSCFDnCFDCFTISTSLH: <RSCFDn_base> + $02B5_H$,

R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 23.54 RSCFDnCFDCFTISTS Register Contents

Bit Position	Bit Name	Function
31 to 24	Reserved	When read, the value after reset is returned.
23 to 0	CFkTXIF[23:0]	Transmit/Receive FIFO [k] TX Interrupt Flag Status 0: Corresponding Transmit/Receive FIFO TX interrupt flag is not set 1: Corresponding Transmit/Receive FIFO TX interrupt flag is set

The FIFO Interrupt Flag status register bits show the status of the Interrupt Flag bits of the Transmit/ Receive FIFO Buffers.

RSCFDnCFDCFTISTS.CFkTXIF[23:0]

Transmit/Receive FIFO [k] TX Interrupt Flag Status

Each bit is set automatically when the corresponding TX interrupt flag bit is set in the Transmit/ Receive FIFO Status Register.

This bit is cleared when RS-CANFD module enters GL_RESET mode.
Each bit is cleared automatically when the corresponding TX interrupt flag bit is cleared in the Transmit/Receive FIFO Status Register.

23.3.8.7 RSCFDnCFDFFFSTS — FIFO FDC level Full Status Register

Access: RSCFDnCFDFFFSTS register is a read-only register that can be read in 32-bit units
RSCFDnCFDFFFSTSL, RSCFDnCFDFFFSTSH register is a read-only register that can be read in 16-bit units
RSCFDnCFDFFFSTSLL, RSCFDnCFDFFFSTSLH, RSCFDnCFDFFFSTSHL, RSCFDnCFDFFFSTSHH register is a read-only register that can be read in 8-bit units

Address: RSCFDnCFDFFFSTS: <RSCFDn_base> + $02C4_H$

RSCFDnCFDFFFSTSL: <RSCFDn_base> + $02C4_H$, RSCFDnCFDFFFSTSH: <RSCFDn_base> + $02C6_H$

RSCFDnCFDFFFSTSLL: <RSCFDn_base> + $02C4_H$, RSCFDnCFDFFFSTSLH: <RSCFDn_base> + $02C5_H$,
RSCFDnCFDFFFSTSHL: <RSCFDn_base> + $02C6_H$, RSCFDnCFDFFFSTSHH: <RSCFDn_base> + $02C7_H$

Value after reset: $0000\ 0000_H$

Table 23.55 RSCFDnCFDFFFSTS Register Contents

Bit Position	Bit Name	Function
31 to 8	CFkFFLL[23:0]	Transmit/Receive FIFO FDC level full Status 0: Corresponding FIFO Full interrupt not set 1: Corresponding FIFO Full interrupt is set
7 to 0	RFxFFLL[7:0]	RX FIFO FDC level full Status 0: Corresponding FIFO Full interrupt not set 1: Corresponding FIFO Full interrupt is set

The FIFO Full status register bits show the status of the Full Interrupt Flag bits of the FIFO Buffers.

RSCFDnCFDFFFSTS.CFkFFLL[23:0]

Transmit/Receive FIFO FDC level Full Status

Each bit is set automatically when the corresponding bit is set in the Transmit/Receive FIFO Status Register.
Each bit is cleared automatically when the corresponding bit is cleared in the Transmit/Receive FIFO Status Register.
This bit is cleared when RS-CANFD module enters GL_RESET mode.

RSCFDnCFDFFFSTS.RFxFFLL[7:0]

RX FIFO FDC level Full Status.

Each bit is set automatically when the corresponding bit is set in the RX FIFO Status Register.
Each bit is cleared automatically when the corresponding bit is cleared in the RX FIFO Status Register.
This bit is cleared when RS-CANFD module enters GL_RESET mode.

23.3.8.8 RSCFDnCFDCFMOWSTS — Transmit/Receive FIFO Message OverWrite Status Register

Access: RSCFDnCFDCFMOWSTS register is a read-only register that can be read in 32-bit units
RSCFDnCFDCFMOWSTSL, RSCFDnCFDCFMOWSTSH register is a read-only register that can be read in 16-bit units
RSCFDnCFDCFMOWSTSLL, RSCFDnCFDCFMOWSTSLH, RSCFDnCFDCFMOWSTSHL, RSCFDnCFDCFMOWSTSHH register is a read-only register that can be read in 8-bit units

Address: RSCFDnCFDCFMOWSTS: <RSCFDn_base> + $02C0_H$

RSCFDnCFDCFMOWSTSL: <RSCFDn_base> + $02C0_H$, RSCFDnCFDCFMOWSTSH: <RSCFDn_base> + $02C2_H$

Table 23.56 RSCFDnCFDCFMOWSTS Register Contents

Bit Position	Bit Name	Function
31 to 24	Reserved	When read, the value after reset is returned.
23 to 0	CFkMOW[23:0]	Transmit/Receive FIFO [k] Message overwrite Status 0: Corresponding FIFO overwrite flag is not set 1: Corresponding FIFO overwrite flag is set

RSCFDnCFDCFMOWSTS.CFkMOW[23:0]

Transmit/Receive FIFO [k] Message OverWrite Status.

This bit is cleared when RS-CANFD module enters GL_RESET mode.
Each bit is set automatically when the corresponding bit is set in the Transmit/Receive FIFO Status Register.
Each bit is cleared automatically when the corresponding bit is cleared in the Transmit/Receive FIFO Status Register.
This register is effective only in GW mode.

23.3.8.9 RSCFDnCFDCFOFRISTS — Transmit/Receive FIFO One Frame Receive Interrupt Flag Status

Access: RSCFDnCFDCFOFRISTS register is a read-only register that can be read in 32-bit units
RSCFDnCFDCFOFRISTSL, RSCFDnCFDCFOFRISTSH register is a read-only register that can be read in 16-bit units
RSCFDnCFDCFOFRISTSLL, RSCFDnCFDCFOFRISTSLH, RSCFDnCFDCFOFRISTSHL, RSCFDnCFDCFOFRISTSHH register is a read-only register that can be read in 8-bit units

Address: RSCFDnCFDCFOFRISTS: <RSCFDn_base> + $02B8_H$

RSCFDnCFDCFOFRISTSL: <RSCFDn_base> + $02B8_H$, RSCFDnCFDCFOFRISTSH: <RSCFDn_base> + $02BA_H$

RSCFDnCFDCFOFRISTSLL: <RSCFDn_base> + $02B8_H$, RSCFDnCFDCFOFRISTSLH: <RSCFDn_base> + $02B9_H$,
RSCFDnCFDCFOFRISTSHL: <RSCFDn_base> + $02BA_H$, RSCFDnCFDCFOFRISTSHH: <RSCFDn_base> + $02BB_H$

Value after reset: $0000\ 0000_H$

Table 23.58 RSCFDnCFDCFOFTISTS Register Contents

Bit Position	Bit Name	Function
31 to 24	Reserved	When read, the value after reset is returned.
23 to 0	CFkOFTXIF [23:0]	Transmit/Receive FIFO [k] One Frame TX Interrupt Flag Status 0: Corresponding Transmit/Receive FIFO One Frame TX interrupt flag is not set 1: Corresponding Transmit/Receive FIFO One Frame TX interrupt flag is set

The FIFO One Frame TX Interrupt Flag status register bits show the status of the Interrupt Flag bits of the Transmit/Receive FIFO Buffers.

RSCFDnCFDCFOFTISTS.CFkOFTXIF[23:0]

Transmit/Receive FIFO [k] One Frame TX Interrupt Flag Status.

Each bit is set automatically when the corresponding One Frame TX interrupt flag bit is set in the Transmit/Receive FIFO Status Register.
This bit is cleared when RS-CANFD module enters GL_RESET mode.
Each bit is cleared automatically when the corresponding One Frame TX interrupt flag bit is cleared in the Transmit/Receive FIFO Status Register.

23.3.9 Details of FIFO DMA-Related Registers

23.3.9.1 RSCFDnCFDCDTCT — DMA Transfer Control Register

Access: RSCFDnCFDCDTCT register can be read or written in 32-bit units
RSCFDnCFDCDTCTL, RSCFDnCFDCDTCTH register can be read or written in 16-bit units
RSCFDnCFDCDTCTLL, RSCFDnCFDCDTCTLH, RSCFDnCFDCDTCTHL, RSCFDnCFDCDTCTHH register can be read or written in 8-bit units

Table 23.59 RSCFDnCFDCDTCT Register Contents (1/2)

Bit Position	Bit Name	Function
31 to 16	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
15	CFDMAE7	DMA Transfer Enable for Transmit/Receive FIFO 0 of channel 7 0: DMA Transfer Request disabled for channel m 1: DMA Transfer Request enabled for channel m
14	CFDMAE6	DMA Transfer Enable for Transmit/Receive FIFO 0 of channel 6 0: DMA Transfer Request disabled for channel m 1: DMA Transfer Request enabled for channel m
13	CFDMAE5	DMA Transfer Enable for Transmit/Receive FIFO 0 of channel 5 0: DMA Transfer Request disabled for channel m 1: DMA Transfer Request enabled for channel m
12	CFDMAE4	DMA Transfer Enable for Transmit/Receive FIFO 0 of channel 4 0: DMA Transfer Request disabled for channel m 1: DMA Transfer Request enabled for channel m
11	CFDMAE3	DMA Transfer Enable for Transmit/Receive FIFO 0 of channel 3 0: DMA Transfer Request disabled for channel m 1: DMA Transfer Request enabled for channel m
10	CFDMAE2	DMA Transfer Enable for Transmit/Receive FIFO 0 of channel 2 0: DMA Transfer Request disabled for channel m 1: DMA Transfer Request enabled for channel m
9	CFDMAE1	DMA Transfer Enable for Transmit/Receive FIFO 0 of channel 1 0: DMA Transfer Request disabled for channel m 1: DMA Transfer Request enabled for channel m
8	CFDMAE0	DMA Transfer Enable for Transmit/Receive FIFO 0 of channel 0 0: DMA Transfer Request disabled for channel m 1: DMA Transfer Request enabled for channel m

Table 23.59 RSCFDnCFDCDTCT Register Contents (2/2)

Bit Position	Bit Name	Function
7	RFDMAE7	DMA Transfer Enable for RXFIFO 7 0: DMA Transfer Request disabled 1: DMA Transfer Request enabled
6	RFDMAE6	DMA Transfer Enable for RXFIFO 6 0: DMA Transfer Request disabled 1: DMA Transfer Request enabled
5	RFDMAE5	DMA Transfer Enable for RXFIFO 5 0: DMA Transfer Request disabled 1: DMA Transfer Request enabled
4	RFDMAE4	DMA Transfer Enable for RXFIFO 4 0: DMA Transfer Request disabled 1: DMA Transfer Request enabled
3	RFDMAE3	DMA Transfer Enable for RXFIFO 3 0: DMA Transfer Request disabled 1: DMA Transfer Request enabled
2	RFDMAE2	DMA Transfer Enable for RXFIFO 2 0: DMA Transfer Request disabled 1: DMA Transfer Request enabled
1	RFDMAE1	DMA Transfer Enable for RXFIFO 1 0: DMA Transfer Request disabled 1: DMA Transfer Request enabled
0	RFDMAE0	DMA Transfer Enable for RXFIFO 0 0: DMA Transfer Request disabled 1: DMA Transfer Request enabled

The DMA Transfer Control Register bits control the start and stop of the DMA transfer operation.

RSCFDnCFDCDTCT.CFDMAEm

DMA Transfer Enable for Transmit/Receive FIFO 0 of channel m.

By this bit only Transmit/Receive FIFO0 can be linked to a DMA channel, to link Transmit/Receive FIFO2 see RSCFDnCFDCDTTCT.CFDMAEm.

Transmit/Receive FIFO1 cannot be linked to a DMA channel.

This bit cannot be set in GL_STOP or GL_RESET mode.

Users should not enable a DMA transfer for a Transmit/Receive FIFO that is configured as TX or GW FIFO.

This bit is cleared when RS-CANFD module enters GL_RESET mode.

RSCFDnCFDCDTCT.RFDMAEe

DMA Transfer Enable for RXFIFO e.

(e = DMA Transfer Enable FIFO index = [0... No. of RX FIFOs-1]) (No. of RX FIFOs = 8)

This bit cannot be set in GL_STOP or GL_RESET mode.

This bit is cleared when RS-CANFD module enters GL_RESET mode.

23.3.9.2 RSCFDnCFDCDTSTS — DMA Transfer Status Register

Access: RSCFDnCFDCDTSTS register is a read-only register that can be read in 32-bit units
RSCFDnCFDCDTSTSL, RSCFDnCFDCDTSTSH register is a read-only register that can be read in 16-bit units
RSCFDnCFDCDTSTSLL, RSCFDnCFDCDTSTSLH, RSCFDnCFDCDTSTSHL, RSCFDnCFDCDTSTSHH register is a read-only register that can be read in 8-bit units

Address: RSCFDnCFDCDTSTS: <RSCFDn_base> + 1334_H

RSCFDnCFDCDTSTSL: <RSCFDn_base> + 1334_H
RSCFDnCFDCDTSTSH: <RSCFDn_base> + 1336_H

RSCFDnCFDCDTSTSLL: <RSCFDn_base> + 1334_H,
RSCFDnCFDCDTSTSLH: <RSCFDn_base> + 1335_H,
RSCFDnCFDCDTSTSHL: <RSCFDn_base> + 1336_H,
RSCFDnCFDCDTSTSHH: <RSCFDn_base> + 1337_H

Value after reset: $0000\ 0000_H$

Table 23.60 RSCFDnCFDCDTSTS Register Contents (1/2)

Bit Position	Bit Name	Function
31 to 16	Reserved	When read, the value after reset is returned.
15	CFDMASTS7	DMA Transfer Status only for Transmit/Receive FIFO 0 of channel 7 0: DMA transfer stopped 1: DMA transfer ongoing
14	CFDMASTS6	DMA Transfer Status only for Transmit/Receive FIFO 0 of channel 6 0: DMA transfer stopped 1: DMA transfer ongoing
13	CFDMASTS5	DMA Transfer Status only for Transmit/Receive FIFO 0 of channel 5 0: DMA transfer stopped 1: DMA transfer ongoing
12	CFDMASTS4	DMA Transfer Status only for Transmit/Receive FIFO 0 of channel 4 0: DMA transfer stopped 1: DMA transfer ongoing
11	CFDMASTS3	DMA Transfer Status only for Transmit/Receive FIFO 0 of channel 3 0: DMA transfer stopped 1: DMA transfer ongoing
10	CFDMASTS2	DMA Transfer Status only for Transmit/Receive FIFO 0 of channel 2 0: DMA transfer stopped 1: DMA transfer ongoing
9	CFDMASTS1	DMA Transfer Status only for Transmit/Receive FIFO 0 of channel 1 0: DMA transfer stopped 1: DMA transfer ongoing
8	CFDMASTS0	DMA Transfer Status only for Transmit/Receive FIFO 0 of channel 0 0: DMA transfer stopped 1: DMA transfer ongoing
7	RFDMASTS7	DMA Transfer Status for RX FIFO 7 0: DMA transfer stopped R 1: DMA transfer ongoing

Table 23.60 RSCFDnCFDCDTSTS Register Contents (2/2)

Bit Position	Bit Name	Function
6	RFDMASTS6	DMA Transfer Status for RX FIFO 6 0: DMA transfer stopped R 1: DMA transfer ongoing
5	RFDMASTS5	DMA Transfer Status for RX FIFO 5 0: DMA transfer stopped R 1: DMA transfer ongoing
4	RFDMASTS4	DMA Transfer Status for RX FIFO 4 0: DMA transfer stopped R 1: DMA transfer ongoing
3	RFDMASTS3	DMA Transfer Status for RX FIFO 3 0: DMA transfer stopped R 1: DMA transfer ongoing
2	RFDMASTS2	DMA Transfer Status for RX FIFO 2 0: DMA transfer stopped R 1: DMA transfer ongoing
1	RFDMASTS1	DMA Transfer Status for RX FIFO 1 0: DMA transfer stopped R 1: DMA transfer ongoing
0	RFDMASTS0	DMA Transfer Status for RX FIFO 0 0: DMA transfer stopped R 1: DMA transfer ongoing

The DMA Transfer Status Register bits show the status of the DMA transfer.

RSCFDnCFDCDTSTS.CFDMASTSm

DMA Transfer Status only for Transmit/Receive FIFO 0 of channel m

Each bit is set automatically when the corresponding DMA enable bit is set and the corresponding DMA FIFO is not empty.

Each bit is cleared automatically when the DMA transfer stops either because the DMA is disabled or the DMA FIFO is empty.
When RSCFDnCFDCDTCT.CFDMAEm is set to 0_B while DMA transfer for the corresponding FIFO is on going, RSCFDnCFDCDTSTS.CFDMASTSm becomes 0_B when the DMA transfer is completed. This bit is cleared when RS-CANFD module enters GL_RESET mode.

RSCFDnCFDCDTSTS.RFDMASTSe

DMA Transfer Status for RX FIFO e

(e = DMA Transfer Enable FIFO index = [0... No. of RX FIFOs-1]) (No. of RX FIFOs = 8)

Each bit is set automatically when the corresponding DMA enable bit is set and the corresponding DMA FIFO is not empty.

Each bit is cleared automatically when the DMA transfer stops either because the DMA is disabled or the DMA FIFO is empty.
When RSCFDnCFDCDTCT.RFDMAEe is set to 0_B while DMA transfer for the corresponding FIFO is on going, RSCFDnCFDCDTSTS.RFDMASTSe becomes 0_B when the DMA transfer is completed. This bit is cleared when RS-CANFD module enters GL_RESET mode.

23.3.9.3 RSCFDnCFDCDTTCT — DMA Transmit Transfer Control Register

Access: RSCFDnCFDCDTTCT register can be read or written in 32-bit units
RSCFDnCFDCDTTCTL, RSCFDnCFDCDTTCTH register can be read or written in 16-bit units
RSCFDnCFDCDTTCTLL, RSCFDnCFDCDTTCTLH, RSCFDnCFDCDTTCTHL,
RSCFDnCFDCDTTCTHHregister can be read or written in 8-bit units

Address: RSCFDnCFDCDTTCT: <RSCFDn_base> + 1340_H

RSCFDnCFDCDTTCTL: <RSCFDn_base> + 1340_H
RSCFDnCFDCDTTCTH: <RSCFDn_base> + 1342_H

RSCFDnCFDCDTTCTLL: <RSCFDn_base> + 1340_H,
RSCFDnCFDCDTTCTLH: <RSCFDn_base> + 1341_H,
RSCFDnCFDCDTTCTHL: <RSCFDn_base> + 1342_H,

8	TQ3DMAE0	DMA TX Transfer Enable for TXQ 3 of channel 0 0: DMA TX Transfer Request disabled 1: DMA TX Transfer Request enabled
7	TQ0DMAE7	DMA TX Transfer Enable for TXQ 0 of channel 7 0: DMA TX Transfer Request disabled 1: DMA TX Transfer Request enabled
6	TQ0DMAE6	DMA TX Transfer Enable for TXQ 0 of channel 6 0: DMA TX Transfer Request disabled 1: DMA TX Transfer Request enabled
5	TQ0DMAE5	DMA TX Transfer Enable for TXQ 0 of channel 5 0: DMA TX Transfer Request disabled 1: DMA TX Transfer Request enabled
4	TQ0DMAE4	DMA TX Transfer Enable for TXQ 0 of channel 4 0: DMA TX Transfer Request disabled 1: DMA TX Transfer Request enabled
3	TQ0DMAE3	DMA TX Transfer Enable for TXQ 0 of channel 3 0: DMA TX Transfer Request disabled 1: DMA TX Transfer Request enabled
2	TQ0DMAE2	DMA TX Transfer Enable for TXQ 0 of channel 2 0: DMA TX Transfer Request disabled 1: DMA TX Transfer Request enabled
1	TQ0DMAE1	DMA TX Transfer Enable for TXQ 0 of channel 1 0: DMA TX Transfer Request disabled 1: DMA TX Transfer Request enabled
0	TQ0DMAE0	DMA TX Transfer Enable for TXQ 0 of channel 0 0: DMA TX Transfer Request disabled 1: DMA TX Transfer Request enabled

The DMA TX Transfer Control Register bits control the start and stop of the DMA transfer operation.

RSCFDnCFDCDTTCT.CFDMAEm

DMA TX Transfer Enable for Transmit/Receive FIFO 2 of channel m.

By this bit only Transmit/Receive FIFO2 can be linked to a DMA channel, to link Transmit/Receive FIFO0 see RSCFDnCFDCDTCT.CFDMAEm.

Transmit/Receive FIFO1 cannot be linked to a DMA channel.

This bit cannot be set in GL_STOP or GL_RESET mode.

Users should not enable a DMA transfer for a Transmit/Receive FIFO that is configured as RX or GW FIFO.

This bit is cleared when RS-CANFD module enters GL_RESET mode.

RSCFDnCFDCDTTCT.TQ3DMAEm

DMA TX Transfer Enable for TXQ 3 of channel m.

This bit cannot be set in GL_STOP or GL_RESET mode.

This bit is cleared when RS-CANFD module enters GL_RESET mode.

RSCFDnCFDCDTTCT.TQ0DMAEm

DMA TX Transfer Enable for TXQ 0 of channel m.

This bit cannot be set in GL_STOP or GL_RESET mode.

This bit is cleared when RS-CANFD module enters GL_RESET mode.

23.3.9.4 RSCFDnCFDCDTTSTS — DMA Transmit Transfer Status Register

Access: RSCFDnCFDCDTTSTS register is a read-only register that can be read in 32-bit units
RSCFDnCFDCDTTSTSL, RSCFDnCFDCDTTSTSH register is a read-only register that can be read in 16-bit units
RSCFDnCFDCDTTSTSLL, RSCFDnCFDCDTTSTSLH, RSCFDnCFDCDTTSTSHL, RSCFDnCFDCDTTSTSHH register is a read-only register that can be read in 8-bit units

Address: RSCFDnCFDCDTTSTS: <RSCFDn_base> + 1344_H

RSCFDnCFDCDTTSTSL: <RSCFDn_base> + 1344_H
RSCFDnCFDCDTTSTSH: <RSCFDn_base> + 1346_H

RSCFDnCFDCDTTSTSLL: <RSCFDn_base> + 1344_H,

21	CFDMASTS5	DMA TX Transfer Status only for Transmit/Receive FIFO 2 of channel 5 0: DMA transfer stopped 1: DMA transfer enable
20	CFDMASTS4	DMA TX Transfer Status only for Transmit/Receive FIFO 2 of channel 4 0: DMA transfer stopped 1: DMA transfer enable
19	CFDMASTS3	DMA TX Transfer Status only for Transmit/Receive FIFO 2 of channel 3 0: DMA transfer stopped 1: DMA transfer enable
18	CFDMASTS2	DMA TX Transfer Status only for Transmit/Receive FIFO 2 of channel 2 0: DMA transfer stopped 1: DMA transfer enable
17	CFDMASTS1	DMA TX Transfer Status only for Transmit/Receive FIFO 2 of channel 1 0: DMA transfer stopped 1: DMA transfer enable
16	CFDMASTS0	DMA TX Transfer Status only for Transmit/Receive FIFO 2 of channel 0 0: DMA transfer stopped 1: DMA transfer enable
15	TQ3DMASTS7	DMA TX Transfer Status for TXQ 3 of channel 7 0: DMA transfer stopped 1: DMA transfer enable

Table 23.62 RSCFDnCFDCDTTSTS Register Contents (2/2)

Bit Position	Bit Name	Function
14	TQ3DMASTS6	DMA TX Transfer Status for TXQ 3 of channel 6 0: DMA transfer stopped 1: DMA transfer enable
13	TQ3DMASTS5	DMA TX Transfer Status for TXQ 3 of channel 5 0: DMA transfer stopped 1: DMA transfer enable
12	TQ3DMASTS4	DMA TX Transfer Status for TXQ 3 of channel 4 0: DMA transfer stopped 1: DMA transfer enable
11	TQ3DMASTS3	DMA TX Transfer Status for TXQ 3 of channel 3 0: DMA transfer stopped 1: DMA transfer enable
10	TQ3DMASTS2	DMA TX Transfer Status for TXQ 3 of channel 2 0: DMA transfer stopped 1: DMA transfer enable
9	TQ3DMASTS1	DMA TX Transfer Status for TXQ 3 of channel 1 0: DMA transfer stopped 1: DMA transfer enable
8	TQ3DMASTS0	DMA TX Transfer Status for TXQ 3 of channel 0 0: DMA transfer stopped 1: DMA transfer enable
7	TQ0DMASTS7	DMA TX Transfer Status for TXQ 0 of channel 7 0: DMA transfer stopped 1: DMA transfer enable
6	TQ0DMASTS6	DMA TX Transfer Status for TXQ 0 of channel 6 0: DMA transfer stopped 1: DMA transfer enable
5	TQ0DMASTS5	DMA TX Transfer Status for TXQ 0 of channel 5 0: DMA transfer stopped 1: DMA transfer enable
4	TQ0DMASTS4	DMA TX Transfer Status for TXQ 0 of channel 4 0: DMA transfer stopped 1: DMA transfer enable
3	TQ0DMASTS3	DMA TX Transfer Status for TXQ 0 of channel 3 0: DMA transfer stopped 1: DMA transfer enable
2	TQ0DMASTS2	DMA TX Transfer Status for TXQ 0 of channel 2 0: DMA transfer stopped 1: DMA transfer enable
1	TQ0DMASTS1	DMA TX Transfer Status for TXQ 0 of channel 1 0: DMA transfer stopped 1: DMA transfer enable
0	TQ0DMASTS0	DMA TX Transfer Status for TXQ 0 of channel 0 0: DMA transfer stopped 1: DMA transfer enable

The DMA Transfer Status Register bits show the status of the DMA transfer.

RSCFDnCFDCDTTSTS.CFDMASTSm

DMA TX Transfer Status only for Transmit/Receive FIFO 2 of channel m.

This bit is set when the RSCFDnCFDCDTTCT.CFDMAEm bit in the corresponding RSCFDnCFDCDTTCT register is set.

This bit is cleared when the RSCFDnCFDCDTTCT.CFDMAEm bit in the corresponding RSCFDnCFDCDTTCT register is cleared.

This bit is cleared when RS-CANFD module enters GL_RESET mode.

RSCFDnCFDCDTTSTS.TQ3DMASTSm

DMA TX Transfer Status for TXQ3 of channel m.

This bit is set when the RSCFDnCFDCDTTCT.TQ3DMAEm bit in the corresponding RSCFDnCFDCDTTCT register is set.

This bit is cleared when the RSCFDnCFDCDTTCT.TQ3DMAEm bit in the corresponding RSCFDnCFDCDTTCT register is cleared.

This bit is cleared when RS-CANFD module enters GL_RESET mode.

RSCFDnCFDCDTTSTS.TQ0DMASTSm

DMA TX Transfer Status for TXQ0 of channel m.

This bit is set when the RSCFDnCFDCDTTCT.TQ0DMAEm bit in the corresponding RSCFDnCFDCDTTCT register is set.

This bit is cleared when the RSCFDnCFDCDTTCT.TQ0DMAEm bit in the corresponding RSCFDnCFDCDTTCT register is cleared.

This bit is cleared when RS-CANFD module enters GL_RESET mode.

23.3.10 Details of Transmit Buffer-Related Registers

23.3.10.1 RSCFDnCFDTMCp — Transmit Message Buffer Control Register p

Access: RSCFDnCFDTMCp register can be read or written in 8-bit units

Address: RSCFDnCFDTMCp: <RSCFDn_base> + $02D0_H$ + (01_H × p)

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	TMOM	TMTAR	TMTR
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R/W	R/W	R/W

Table 23.63 RSCFDnCFDTMCp Register Contents

Bit Position	Bit Name	Function
7 to 3	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
2	TMOM	TX Message Buffer One-shot Mode 0: TX Message Buffer not configured in one-shot mode 1: TX Message Buffer configured in one-shot mode
1	TMTAR	TX Message Buffer Transmission abort Request 0: TX Message Buffer transmission request abort not requested 1: TX Message Buffer transmission request abort requested
0	TMTR	TX Message Buffer Transmission Request 0: TX Message Buffer Transmission not requested 1: TX Message Buffer Transmission requested

The TX Message Buffer Control register configures the TX Message Buffer functions.
Below is an example to calculate index for U2A16:
(no_of_channels = 8)

(no_of_TMBCTRs_per_channel = No. of TX Message Buffer Control Register per Channel = 64)
Where the total number of TMBCTRs = no_of_TMBCTRs = no_of_TMBCTRs_per_channel * no_of_channels = 64 * 8 = 512
(p = TX Message Buffer Control Register index = [0…no_of_TMBCTRs-1])

RSCFDnCFDTMCp.TMOM

TX Message Buffer One-shot Mode.

If this bit is set, then the RS-CANFD module logic will attempt transmission of the message only once. If the transmission is successful, the RSCFDnCFDTMSTSp.TMTRF bits are set to 10_B or 11_B. If it is not successful due to bus error or bus arbitration lost, the transmission is automatically aborted and RSCFDnCFDTMSTSp.TMTRF bits are set to 01_B.
The RSCFDnCFDTMCp.TMOM bit will remain set if the transmission is completed successfully or aborted due to error or loss of arbitration.

Users can only write to this bit when the related RS-CANFD channel is in CH_HALT or CH_COMMUNICATION mode.

Users should set this bit at the same time as RSCFDnCFDTMCp.TMTR bit.
Users should clear this bit by a write access.

If a message has been already requested for transmission, then users should not write to this bit until the message has been successfully transmitted or transmission has been aborted.

This bit will be automatically cleared by the RS-CANFD module logic when the RS-CANFD module enters GL_RESET mode or the related channel enters CH_RESET mode.

RSCFDnCFDTMCp.TMTAR

TX Message Buffer Transmission abort Request.

If this bit is set, then the RS-CANFD module logic will try to abort the transmission of the frame stored in the corresponding Message Buffer.
In most cases, transmission cannot be aborted if the internal scan for transmission is completed and the Message Buffer has already been selected for Transmission. In this case, frame may be transmitted successfully from the Message Buffer. The Message Buffer selection will be released by entering CH_HALT mode.
However, MB selected for transmission can be aborted by Abort request when the CAN node detects a new message on the bus (RX pin) before it can start transmission from the selected MB.

Users can only write to this bit when the related RS-CANFD channel is in CH_HALT or CH_COMMUNICATION mode.
This bit can only be set when the related transmit request (RSCFDnCFDTMCp.TMTR) bit is set.
This bit cannot be cleared by a CPU write access.

Clearing of this bit by RS-CANFD has priority over setting by CPU write access.

This bit is automatically cleared by the RS-CANFD module logic at the end of successful transmission
This bit is automatically cleared by the RS-CANFD module logic at the end of transmission abort
This bit is automatically cleared by the RS-CANFD module logic when there is the detection of CAN bus error or arbitration loss
This bit is automatically cleared by the RS-CANFD module logic when the RS-CANFD module enters GL_RESET mode or the related channel enters CH_RESET mode.

RSCFDnCFDTMCp.TMTR

TX Message Buffer Transmission Request.

If this bit is set, then the RS-CANFD module logic will try to transmit the message stored in the corresponding Message Buffer.

Users can only write to this bit when the related RS-CANFD channel is in CH_HALT or CH_COMMUNICATION mode.
Users cannot set this bit if the corresponding TX Message Buffer is linked to a Transmit/Receive FIFO in TX or GW mode or is a part of TX Queue.
This bit cannot be directly cleared by a CPU write access.
This bit can only be set when Transmission Result Flag bits (RSCFDnCFDTMSTSp.TMTRF) in the RSCFDnCFDTMSTSp register corresponding to the MB are cleared to 00_B.

This bit is automatically cleared by the RS-CANFD module logic at the end of successful transmission.
This bit is automatically cleared by the RS-CANFD module logic at the end of transmission abort, requested by the corresponding RSCFDnCFDTMCp.TMTAR bit.
This bit is automatically cleared by the RS-CANFD module logic when there is the detection of CAN bus error or arbitration loss if RSCFDnCFDTMCp.TMOM bit is set for the Message Buffer.

This bit is automatically cleared by the RS-CANFD module logic when the RS-CANFD module enters GL_RESET mode or the related channel enters CH_RESET mode.

23.3.10.2 RSCFDnCFDTMSTSp — Transmit Message Buffer Status Register p

Access: RSCFDnCFDTMSTSp register can be read or written in 8-bit units

Address: RSCFDnCFDTMSTSp: <RSCFDn_base> + $07D0_H$ + (01_H × p)

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	TMTARM	TMTRM	TMTRF[1:0]		TMTSTS
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R/W	R/W	R

Table 23.64 RSCFDnCFDTMSTSp Register Contents

Bit Position	Bit Name	Function
7 to 5	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
4	TMTARM	TX Message Buffer Transmission abort Request Mirrored 0: TX Message Buffer transmission request abort not requested 1: TX Message Buffer transmission request abort requested
3	TMTRM	TX Message Buffer Transmission Request Mirrored 0: TX Message Buffer Transmission not requested 1: TX Message Buffer Transmission requested
2, 1	TMTRF[1:0]	TX Message Buffer Transmission Result Flag 00: No Result 01: Transmission aborted from the TX MB 10: Transmission successful from the TX MB & Transmission abort was not requested 11: Transmission successful from the TX MB & Transmission abort was requested
0	TMTSTS	TX Message Buffer Transmission Status 0: No transmission ongoing 1: Transmission ongoing

The TX Message Buffer Status Register shows the Transmission and Transmission abort status for the corresponding Message Buffers.
No_of_TMBSTRs_per_channel = No. of TX Message Buffer Status Registers per Channel = 64)
Where the total number of TMBSTRs = no_of_TMBSTRs = no_of_TMBSTRs_per_channel * no_of_channels = 64 * 8 = 512
(p = TX Message Buffer Status Register index = [0…no_of_TMBSTRs-1])

RSCFDnCFDTMSTSp.TMTARM

TX Message Buffer Transmission abort Request Mirrored.

This bit is set when the RSCFDnCFDTMCp.TMTAR bit in the corresponding RSCFDnCFDTMCp register is set.

This bit is cleared when the RSCFDnCFDTMCp.TMTAR bit in the corresponding RSCFDnCFDTMCp register is cleared.

RSCFDnCFDTMSTSp.TMTRM

TX Message Buffer Transmission Request Mirrored.

This bit is set when the RSCFDnCFDTMCp.TMTR bit in the corresponding RSCFDnCFDTMCp register is set.

This bit is cleared when the RSCFDnCFDTMCp.TMTR bit in the corresponding RSCFDnCFDTMCp register is cleared.

RSCFDnCFDTMSTSp.TMTRF[1:0]

TX Message Buffer Transmission Result Flag.

These bits show the result for the corresponding TX MB. The status is as follows:
00: Transmission in progress or has not been requested.
01: Transmission has been aborted from the corresponding TX MB.
10: Transmission was successful from the corresponding TX MB and TMTAR bit was not set for this TX MB.
11: Transmission was successful from the corresponding TX MB. But, TMTAR bit was set for this TX MB.

Users can only write to this bit when the related RS-CANFD channel is in CH_HALT or CH_COMMUNICATION mode.

These bits will be cleared automatically when the RS-CANFD module enters GL_RESET or the related channel enters CH_RESET mode.

RSCFDnCFDTMSTSp.TMTSTS

TX Message Buffer Transmission Status.

This bit is set automatically at the start of the transmission from the corresponding TX Message Buffer.

This bit is cleared automatically when the transmission stops.
This bit is cleared automatically when the RS-CANFD module enters GL_RESET mode.
This bit is cleared automatically when the related channel enters CH_RESET mode.

23.3.10.3 RSCFDnCFDTMIECy — Transmit Message Buffer Interrupt Enable Configuration Register y

Access: RSCFDnCFDTMIECy register can be read or written in 32-bit units
RSCFDnCFDTMIECyL, RSCFDnCFDTMIECyH register can be read or written in 16-bit units
RSCFDnCFDTMIECyLL, RSCFDnCFDTMIECyLH, RSCFDnCFDTMIECyHL, RSCFDnCFDTMIECyHH register can be read or written in 8-bit units

Address: RSCFDnCFDTMIECy: <RSCFDn_base> + $0F50_H$ + (04_H × y)

RSCFDnCFDTMIECyL: <RSCFDn_base> + $0F50_H$ + (04_H × y),
RSCFDnCFDTMIECyH: <RSCFDn_base> + $0F52_H$ + (04_H × y)

RSCFDnCFDTMIECyLL: <RSCFDn_base> + $0F50_H$ + (04_H × y),
RSCFDnCFDTMIECyLH: <RSCFDn_base> + $0F51_H$ + (04_H × y),
RSCFDnCFDTMIECyHL: <RSCFDn_base> + $0F52_H$ + (04_H × Y),
RSCFDnCFDTMIECyHH: <RSCFDn_base> + $0F53_H$ + (04_H × y)

Value after reset: $0000\ 0000_H$

When m=2, y=[4, 5] ymin=4, ymax=5
When m=3, y=[6, 7] ymin=6, ymax=7
When m=4, y=[8, 9] ymin=8, ymax=9
When m=5, y=[10, 11] ymin=10, ymax=11
When m=6, y=[12, 13] ymin=12, ymax=13
When m=7, y=[14, 15] ymin=14, ymax=15

RSCFDnCFDTMIECy.TMIEp[31:0]

TX Message Buffer Interrupt Enable

If this bit is set, then an interrupt will be generated at the end of a successful transmission from the corresponding Message Buffer.

Refer to **Section 23.8** for TX Message Buffer Interrupt specification.

An example in U2A16 for alignment of the bits is as shown in **Table 23.66**.

Table 23.66 Alignment of TMIE bits

Bit position	p = TX Message Buffer Number
m*64-ymin*32	m*64+0
m*64+1-ymin*32	m*64+1
.	.
.	.
m*64+31-ymin*32	m*64+31
m*64+32-ymax*32	m*64+32
m*64+33-ymax*32	m*64+33
.	.
.	.
m*64+62-ymax*32	m*64+62
m*64+63-ymax*32	m*64+63

Users cannot write to this bit when the RS-CANFD module is in GL_STOP mode.

Users should not write to these bits when the related CAN_channel is in CH_STOP mode.

Users should not write to these bits if the corresponding TX Message Buffer is part of a TX Queue.

Users should not write to these bits if the corresponding TX Message Buffer is linked to a Transmit/ Receive FIFO (via RSCFDnCFDCFCCk.CFTML bits)

23.3.11 Details of Transmit Buffer Status-Related Registers

23.3.11.1 RSCFDnCFDTMTRSTSy — Transmit Message Buffer Transmission Request Status Register y

Access: RSCFDnCFDTMTRSTSy register is a read-only register that can be read in 32-bit units
RSCFDnCFDTMTRSTSyL, RSCFDnCFDTMTRSTSyH register is a read-only register that can be read in 16-bit units
RSCFDnCFDTMTRSTSyLL, RSCFDnCFDTMTRSTSyLH, RSCFDnCFDTMTRSTSyHL, RSCFDnCFDTMTRSTSyHH register is a read-only register that can be read in 8-bit units

Address: RSCFDnCFDTMTRSTSy: <RSCFDn_base> + $0CD0_H$ + (04_H × y)

RSCFDnCFDTMTRSTSyL: <RSCFDn_base> + $0CD0_H$ + (04_H × y),
RSCFDnCFDTMTRSTSyH: <RSCFDn_base> + $0CD2_H$ + (04_H × y)

RSCFDnCFDTMTRSTSyLL: <RSCFDn_base> + $0CD0_H$ + (04_H × y),

.	.
m*64+31-ymin*32	m*64+31
m*64+32-ymax*32	m*64+32
m*64+33-ymax*32	m*64+33
.	.
.	.
m*64+62-ymax*32	m*64+62
m*64+63-ymax*32	m*64+63

Each bit is set automatically when the corresponding bit is set in the TX Message Buffer Status Register.

Each bit is cleared automatically when the corresponding bit is cleared in the TX Message Buffer Status Register.
Each bit is cleared automatically when the RS-CANFD module enters GL_RESET or CH_RESET mode.
If a CAN channel enters CH_RESET mode, then the bits related to that channel will be cleared.

23.3.11.4 RSCFDnCFDTMTASTSy — Transmit Message Buffer Transmission Abort Status Register y

Access: RSCFDnCFDTMTASTSy register is a read-only register that can be read in 32-bit units
RSCFDnCFDTMTASTSyL, RSCFDnCFDTMTASTSyH register is a read-only register that can be read in 16-bit units
RSCFDnCFDTMTASTSyLL, RSCFDnCFDTMTASTSyLH, RSCFDnCFDTMTASTSyHL, RSCFDnCFDTMTASTSyHH register is a read-only register that can be read in 8-bit units

Address: RSCFDnCFDTMTASTSy: <RSCFDn_base> + $0EB0_H$ + (04_H × y)

RSCFDnCFDTMTASTSyL: <RSCFDn_base> + $0EB0_H$ + (04_H × y),
RSCFDnCFDTMTASTSyH: <RSCFDn_base> + $0EB2_H$ + (04_H × y)

RSCFDnCFDTMTASTSyLL: <RSCFDn_base> + $0EB0_H$ + (04_H × y),
RSCFDnCFDTMTASTSyLH: <RSCFDn_base> + $0EB1_H$ + (04_H × y),
RSCFDnCFDTMTASTSyHL: <RSCFDn_base> + $0EB2_H$ + (04_H × y),
RSCFDnCFDTMTASTSyHH: <RSCFDn_base> + $0EB3_H$ + (04_H × y)

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	CFDTMTASTSp[31:16]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 23.73 RSCFDnCFDTMTASTSy Register Contents

Bit Position	Bit Name	Function
31 to 0	CFDTMTASTSp [31:0]	TX Message Buffer Transmission abort Status 0: Transmission not aborted for corresponding TX Message Buffer 1: Transmission aborted for corresponding TX Message Buffer

Below is an example to calculate ymin and ymax for U2A16:
(no_of_channels = 8)
(no_of_TXMBs_per_channel = 64)
(no_of_bits_per_register = 32)
(no_of_TXMBs = No. of TX Message Buffers = no_of_channels*no_of_TXMBs_per_channel = 512)
(no_of_CFDTMTASTS = No. of CFDTMTASTS = no_of_TXMBs/no_of_bits_per_register = 512 / 32 = 16)
(y = CFDTMTASTS index = [0...no_of_CFDTMTASTS-1])
y = [0 to 15]
When m=0, y=[0, 1] ymin=0, ymax=1
When m=1, y=[2, 3] ymin=2, ymax=3
When m=2, y=[4, 5] ymin=4, ymax=5
When m=3, y=[6, 7] ymin=6, ymax=7
When m=4, y=[8, 9] ymin=8, ymax=9
When m=5, y=[10, 11] ymin=10, ymax=11
When m=6, y=[12, 13] ymin=12, ymax=13
When m=7, y=[14, 15] ymin=14, ymax=15

RSCFDnCFDTMTASTSy.CFDTMTASTSp[31:0]

TX Message Buffer Transmission abort Status

These bits show the status of the successful transmission abort of the corresponding TX Message Buffer.

An example in U2A16 for alignment of the bits is as shown in **Table 23.74**.

Table 23.74 Alignment of CFDTMTASTS mirror bits

Bit position	p = TX Message Buffer Number
m*64-ymin*32	m*64+0
m*64+1-ymin*32	m*64+1
.	.
.	.
m*64+31-ymin*32	m*64+31
m*64+32-ymax*32	m*64+32
m*64+33-ymax*32	m*64+33
.	.
.	.
m*64+62-ymax*32	m*64+62
m*64+63-ymax*32	m*64+63

Each bit is set automatically when the RSCFDnCFDTMSTSp.TMTRF bits are set to 01_B in the corresponding TX Message Buffer Status Register.

Each bit is cleared automatically when the RSCFDnCFDTMSTSp.TMTRF bits are cleared in the corresponding TX Message Buffer Status Register.
Each bit is cleared automatically when the RS-CANFD module enters GL_RESET or CH_RESET mode.
If a CAN channel enters CH_RESET mode, then the bits related to that channel will be cleared.

23.3.12 Details of Transmit Queue-Related Registers

23.3.12.1 RSCFDnCFDTXQCC0m — Transmit Queue Configuration / Control Register 0 m

Access: RSCFDnCFDTXQCC0m register can be read or written in 32-bit units
RSCFDnCFDTXQCC0mL, RSCFDnCFDTXQCC0mH register can be read or written in 16-bit units
RSCFDnCFDTXQCC0mLL, RSCFDnCFDTXQCC0mLH, RSCFDnCFDTXQCC0mHL,
RSCFDnCFDTXQCC0mHH register can be read or written in 8-bit units

Address: RSCFDnCFDTXQCC0m: <RSCFDn_base> + 1000_H + (04_H × m)

RSCFDnCFDTXQCC0mL: <RSCFDn_base> + 1000_H + (04_H × m),
RSCFDnCFDTXQCC0mH: <RSCFDn_base> + 1002_H + (04_H × m)

RSCFDnCFDTXQCC0mLL: <RSCFDn_base> + 1000_H + (04_H × m),
RSCFDnCFDTXQCC0mLH: <RSCFDn_base> + 1001_H + (04_H × m),
RSCFDnCFDTXQCC0mHL: <RSCFDn_base> + 1002_H + (04_H × m),
RSCFDnCFDTXQCC0mHH: <RSCFDn_base> + 1003_H + (04_H × m)

Value after reset: $0000\ 0000_H$

Table 23.75 RSCFDnCFDTXQCC0m Register Contents (1/2)

Bit Position	Bit Name	Function
31 to 19	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
18	TXQOFTXIE	TXQ One Frame Transmission Interrupt Enable 0: One Frame TX Interrupt generation disabled 1: One Frame TX Interrupt generation enabled
17	TXQOFRXIE	TXQ One Frame Reception Interrupt Enable 0: One Frame RX Interrupt generation disabled 1: One Frame RX Interrupt generation enabled
16	TXQFIE	TXQ Full interrupt Enable 0: TX Queue Full Interrupt generation disabled 1: TX Queue Full Interrupt generation enabled
15 to 13	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
12 to 8	TXQDC[4:0]	TX Queue Depth Configuration 00000: 0 messages 00001: Setting prohibited 00010: 3 messages 00011: 4 messages : 11110: 31 messages 11111: 32 messages
7	TXQIM	TX Queue Interrupt Mode 0: when the last message is successfully transmitted 1: At every successful transmission
6	Reserved	When read, the value after reset is returned. When writing, write the value after reset.

Table 23.75 RSCFDnCFDTXQCC0m Register Contents (2/2)

Bit Position	Bit Name	Function
5	TXQTXIE	TX Queue TX Interrupt Enable 0: TX Queue TX Interrupt disabled 1: TX Queue TX Interrupt enabled
4, 3	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
2	TXQOWE	TX Queue Overwrite Mode Enable 0: TX Queue OW mode disabled 1: TX Queue OW mode enabled
1	TXQGWE	TX Queue Gateway Mode Enable 0: TX Queue GW mode disabled 1: TX Queue GW mode enabled
0	TXQE	TX Queue Enable 0: TX Queue disabled 1: TX Queue enabled

The TX Queue Configuration/Control Register is used to configure the TX Queue transmission.

TXQ0 is composed of TXMB0 to TXMB31 (at the maximum) when TXQE is enabled.

RSCFDnCFDTXQCC0m.TXQOFTXIE

TXQ One Frame Transmission Interrupt Enable.

If this bit is set, then an interrupt will be generated based on the setting of the RSCFDnCFDTXQSTS0m.TXQOFTXIF bit.

Users cannot write to this bit when the RS-CANFD module is in GL_STOP mode.

Users should not write to this bit when the RS-CANFD module is in CH_STOP mode.

RSCFDnCFDTXQCC0m.TXQOFRXIE

TXQ One Frame Reception Interrupt Enable.

If this bit is set, then an interrupt will be generated based on the setting of the RSCFDnCFDTXQSTS0m.TXQOFRXIF bit.

Users cannot write to this bit when the RS-CANFD module is in GL_STOP mode.

Users should not write to this bit when the RS-CANFD module is in CH_STOP mode.

Users should write 1 to this bit only when the Gateway mode (RSCFDnCFDTXQCC0m.TXQGWE=1).

RSCFDnCFDTXQCC0m.TXQFIE

TXQ Full Interrupt Enable.

If this bit is set, then an interrupt will be generated based on the setting of the RSCFDnCFDTXQSTS0m.TXQFIF bit.

Users cannot write to this bit when the RS-CANFD module is in GL_STOP mode.

Users should not write to this bit when the RS-CANFD module is in CH_STOP mode.

Users should write 1 to this bit only when the Gateway mode (RSCFDnCFDTXQCC0m.TXQGWE=1).

RSCFDnCFDTXQCC0m.TXQDC[4:0]

TX Queue Depth Configuration.

These bits select the depth of the transmission queue. The Message Buffer selection starts from MB[0] up to MB[31] depending upon the configured depth.

When users use TXQ1 and TXQ0 simultaneously, the total depth of TXQ1 and TXQ0 should be 32 or less.

Users cannot write to these bits when the RS-CANFD module is in GL_STOP mode.
Users cannot write to these bits when the related RS-CANFD channel is in CH_HALT or CH_COMMUNICATION mode.

Users should not write to these bits when the related RS-CANFD channel is in CH_STOP.

RSCFDnCFDTXQCC0m.TXQIM

TX Queue Interrupt Mode.

This bit selects the Interrupt generation condition for the TX Queue.

Users cannot write to this bit when the RS-CANFD module is in GL_STOP mode.

Users should not write to this bit when the RS-CANFD module is in CH_STOP mode.

Users should not write to this bit when the RS-CANFD module is in CH_HALT or CH_COMMUNICATION mode.

RSCFDnCFDTXQCC0m.TXQTXIE

TX Queue TX Interrupt Enable.

If this bit is set, then an interrupt will be generated based on the setting of the TXQIM bit.

Users cannot write to this bit when the RS-CANFD module is in GL_STOP mode.

Users should not write to this bit when the RS-CANFD module is in CH_STOP mode.

RSCFDnCFDTXQCC0m.TXQOWE

TX Queue Overwrite Mode Enable.

When this bit is set, the TX queue is in TX queue overwrite mode.

An overwrite function is valid when the same ID as ID of the data written in from the gateway or CPU is in TX Queue, e.g. when a frame is received and is stored into the TX queue, if a message with the same ID has been stored in the TX queue, the old message will be overwritten by the new message.

Users cannot write to the bit when the RS-CANFD module is in GL_STOP mode.

Users cannot write to the bit when the related RS-CANFD channel is in CH_HALT or CH_COMMUNICATION mode.

Users should not write to the bit when the related RS-CANFD channel is in CH_STOP.

When users use the function in GW mode, the depth of TXQ (RSCFDnCFDTXQCC0m.TXQDC) should be configured to the value which is the various number of ID which is used in the TX queue plus 3.

Then the function is valid for the standard ID frame and is invalid for the extended ID frame.

Users should not write change for this bit when the RSCFDnCFDTXQCC0m.TXQE bit is 1_B.

RSCFDnCFDTXQCC0m.TXQGWE

TX Queue Gateway Mode Enable.

When this bit is set, the TX queue is in TX queue GW mode.

Users cannot write to the bit when the RS-CANFD module is in GL_STOP mode.

Users cannot write to the bit when the related RS-CANFD channel is in CH_HALT or CH_COMMUNICATION mode.

Users should not write to the bit when the related RS-CANFD channel is in CH_STOP.

When this bit is set, CPU must not access the TX queue.

RSCFDnCFDTXQCC0m.TXQE

TX Queue Enable.

Users cannot write to this bit when the related RS-CANFD channel is in CH_RESET mode.
Users cannot write to this bit when the RS-CANFD module is in GL_STOP mode.
This bit cannot be set if the configured TX Queue depth is 0_H (RSCFDnCFDTXQCC0m.TXQDC = 0_H).
Users cannot write to this bit when the related channel is in CH_STOP mode.

This bit is cleared automatically when the related RS-CANFD channel is in CH_RESET mode.

23.3.12.2 RSCFDnCFDTXQCC1m — Transmit Queue Configuration / Control Register 1 m

Access: RSCFDnCFDTXQCC1m register can be read or written in 32-bit units
RSCFDnCFDTXQCC1mL, RSCFDnCFDTXQCC1mH register can be read or written in 16-bit units
RSCFDnCFDTXQCC1mLL, RSCFDnCFDTXQCC1mLH, RSCFDnCFDTXQCC1mHL,
RSCFDnCFDTXQCC1mHH register can be read or written in 8-bit units

Address: RSCFDnCFDTXQCC1m: <RSCFDn_base> + 1060_H + (04_H × m)

RSCFDnCFDTXQCC1mL: <RSCFDn_base> + 1060_H + (04_H × m),
RSCFDnCFDTXQCC1mH: <RSCFDn_base> + 1062_H + (04_H × m)

RSCFDnCFDTXQCC1mLL: <RSCFDn_base> + 1060_H + (04_H × m),
RSCFDnCFDTXQCC1mLH: <RSCFDn_base> + 1061_H + (04_H × m),
RSCFDnCFDTXQCC1mHL: <RSCFDn_base> + 1062_H + (04_H × m),
RSCFDnCFDTXQCC1mHH: <RSCFDn_base> + 1063_H + (04_H × m)

7	TXQIM	TX Queue Interrupt Mode 0: when the last message is successfully transmitted 1: At every successful transmission
6	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
5	TXQTXIE	TX Queue TX Interrupt Enable 0: TX Queue TX Interrupt disabled 1: TX Queue TX Interrupt enabled

Table 23.76 RSCFDnCFDTXQCC1m Register Contents (2/2)

Bit Position	Bit Name	Function
4, 3	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
2	TXQOWE	TX Queue Overwrite Mode Enable 0: TX Queue OW mode disabled 1: TX Queue OW mode enabled
1	TXQGWE	TX Queue Gateway Mode Enable 0: TX Queue GW mode disabled 1: TX Queue GW mode enabled
0	TXQE	TX Queue Enable 0: TX Queue disabled 1: TX Queue enabled

The TX Queue Configuration / Control Register is used to configure the TX Queue transmission.

TXQ1 is composed of TXMB31 to TXMB0 (at the maximum) when TXQE is enabled.

RSCFDnCFDTXQCC1m.TXQOFTXIE

TXQ One Frame Transmission Interrupt Enable.

If this bit is set, then an interrupt will be generated based on the setting of the RSCFDnCFDTXQSTS1m.TXQOFTXIF bit.

Users cannot write to this bit when the RS-CANFD module is in GL_STOP mode.

Users should not write to this bit when the RS-CANFD module is in CH_STOP mode.

RSCFDnCFDTXQCC1m.TXQOFRXIE

TXQ One Frame Reception Interrupt Enable.

If this bit is set, then an interrupt will be generated based on the setting of the RSCFDnCFDTXQSTS1m.TXQOFRXIF bit.

Users cannot write to this bit when the RS-CANFD module is in GL_STOP mode.

Users should not write to this bit when the RS-CANFD module is in CH_STOP mode.

Users should write 1 to this bit only when the Gateway mode (RSCFDnCFDTXQCC1m.TXQGWE=1).

RSCFDnCFDTXQCC1m.TXQFIE

TXQ Full Interrupt Enable.

If this bit is set, then an interrupt will be generated based on the setting of the RSCFDnCFDTXQSTS1m.TXQFIF bit.

Users cannot write to this bit when the RS-CANFD module is in GL_STOP mode.

Users should not write to this bit when the RS-CANFD module is in CH_STOP mode.

Users should write 1 to this bit only when the Gateway mode (RSCFDnCFDTXQCC1m.TXQGWE=1).

RSCFDnCFDTXQCC1m.TXQDC[4:0]

TX Queue Depth Configuration.

These bits select the depth of the transmission queue. The Message Buffer selection starts from MB[31] down to MB[0] depending upon the configured depth.

When users use TXQ1 and TXQ0 simultaneously, the total depth of TXQ1 and TXQ0 should be 32 or less.
Users cannot write to these bits when the RS-CANFD module is in GL_STOP mode.
Users cannot write to these bits when the related RS-CANFD channel is in CH_HALT or CH_COMMUNICATION mode.

Users should not write to these bits when the related RS-CANFD channel is in CH_STOP.

RSCFDnCFDTXQCC1m.TXQIM

TX Queue Interrupt Mode.

This bit selects the Interrupt generation condition for the TX Queue.

Users cannot write to this bit when the RS-CANFD module is in GL_STOP mode.

Users should not write to this bit when the RS-CANFD module is in CH_STOP mode.

Users should not write to this bit when the RS-CANFD module is in CH_HALT or CH_COMMUNICATION mode.

RSCFDnCFDTXQCC1m.TXQTXIE

TX Queue TX Interrupt Enable.

If this bit is set, then an interrupt will be generated based on the setting of the TXQIM bit.

Users cannot write to this bit when the RS-CANFD module is in GL_STOP mode.

Users should not write to this bit when the RS-CANFD module is in CH_STOP mode.

RSCFDnCFDTXQCC1m.TXQOWE

TX Queue Overwrite Mode Enable.

When this bit is set, the TX queue is in TX queue overwrite mode.

An overwrite function is valid when the same ID as ID of the data written in from the gateway or CPU is in TX Queue, e.g. when a frame is received and is stored into the TX queue, if a message with the same ID has been stored in the TX queue, the old message will be overwritten by the new message.

Users cannot write to the bit when the RS-CANFD module is in GL_STOP mode.

Users cannot write to the bit when the related RS-CANFD channel is in CH_HALT or CH_COMMUNICATION mode.

Users should not write to the bit when the related RS-CANFD channel is in CH_STOP.

When users use the function in GW mode, the depth of TXQ (RSCFDnCFDTXQCC1m.TXQDC) should be configured to the value which is the various number of ID which is used in the TX queue plus 3.

Then the function is valid for the standard ID frame and is invalid for the extended ID frame.

Users should not write change for this bit when the RSCFDnCFDTXQCC1m.TXQE bit is 1_B.

RSCFDnCFDTXQCC1m.TXQGWE

TX Queue Gateway Mode Enable.

When this bit is set, the TX queue is in TX queue GW mode.

Users cannot write to the bit when the RS-CANFD module is in GL_STOP mode.

Users cannot write to the bit when the related RS-CANFD channel is in CH_HALT or CH_COMMUNICATION mode.

Users should not write to the bit when the related RS-CANFD channel is in CH_STOP.

When this bit is set, CPU must not access the TX queue.

RSCFDnCFDTXQCC1m.TXQE

TX Queue Enable.

Users cannot write to this bit when the related RS-CANFD channel is in CH_RESET mode.
Users cannot write to this bit when the RS-CANFD module is in GL_STOP mode.
This bit cannot be set if the configured TX Queue depth is 0_H (RSCFDnCFDTXQCC1m.TXQDC = 0_H).
Users cannot write to this bit when the related channel is in CH_STOP mode.

This bit is cleared automatically when the related RS-CANFD channel is in CH_RESET mode.

23.3.12.3 RSCFDnCFDTXQCC2m — Transmit Queue Configuration / Control Register 2 m

Access: RSCFDnCFDTXQCC2m register can be read or written in 32-bit units
RSCFDnCFDTXQCC2mL, RSCFDnCFDTXQCC2mH register can be read or written in 16-bit units
RSCFDnCFDTXQCC2mLL, RSCFDnCFDTXQCC2mLH, RSCFDnCFDTXQCC2mHL,
RSCFDnCFDTXQCC2mHH register can be read or written in 8-bit units

Table 23.77 RSCFDnCFDTXQCC2m Register Contents (2/2)

Bit Position	Bit Name	Function
4, 3	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
2	TXQOWE	TX Queue Overwrite Mode Enable 0: TX Queue OW mode disabled 1: TX Queue OW mode enabled
1	TXQGWE	TX Queue Gateway Mode Enable 0: TX Queue GW mode disabled 1: TX Queue GW mode enabled
0	TXQE	TX Queue Enable 0: TX Queue disabled 1: TX Queue enabled

The TX Queue Configuration / Control Register is used to configure the TX Queue transmission.

TXQ2 is composed of TXMB32 to TXMB63 (at the maximum) when TXQE is enabled.

RSCFDnCFDTXQCC2m.TXQOFTXIE

TXQ One Frame Transmission Interrupt Enable

If this bit is set, then an interrupt will be generated based on the setting of the RSCFDnCFDTXQSTS2m.TXQOFTXIF bit.

Users cannot write to this bit when the RS-CANFD module is in GL_STOP mode.

Users should not write to this bit when the RS-CANFD module is in CH_STOP mode.

RSCFDnCFDTXQCC2m.TXQOFRXIE

TXQ One Frame Reception Interrupt Enable

If this bit is set, then an interrupt will be generated based on the setting of the RSCFDnCFDTXQSTS2m.TXQOFRXIF bit.

Users cannot write to this bit when the RS-CANFD module is in GL_STOP mode.

Users should not write to this bit when the RS-CANFD module is in CH_STOP mode.

Users should write 1 to this bit only when the Gateway mode (RSCFDnCFDTXQCC2m.TXQGWE=1)

RSCFDnCFDTXQCC2m.TXQFIE

TXQ Full Interrupt Enable

If this bit is set, then an interrupt will be generated based on the setting of the RSCFDnCFDTXQSTS2m.TXQFIF bit.

Users cannot write to this bit when the RS-CANFD module is in GL_STOP mode.

Users should not write to this bit when the RS-CANFD module is in CH_STOP mode.

Users should write 1 to this bit only when the Gateway mode (RSCFDnCFDTXQCC2m.TXQGWE=1)

RSCFDnCFDTXQCC2m.TXQDC[4:0]

TX Queue Depth Configuration

These bits select the depth of the transmission queue. The Message Buffer selection starts from MB[32] up to MB[63] depending upon the configured depth.

When users use TXQ3 and TXQ2 simultaneously, the total depth of TXQ3 and TXQ2 should be 32 or less.
Users cannot write to these bits when the RS-CANFD module is in GL_STOP mode.
Users cannot write to these bits when the related RS-CANFD channel is in CH_HALT or CH_COMMUNICATION mode.

Users should not write to these bits when the related RS-CANFD channel is in CH_STOP.

RSCFDnCFDTXQCC2m.TXQIM

TX Queue Interrupt Mode

This bit selects the Interrupt generation condition for the TX Queue.

Users cannot write to this bit when the RS-CANFD module is in GL_STOP mode.

Users should not write to this bit when the RS-CANFD module is in CH_STOP mode.

Users should not write to this bit when the RS-CANFD module is in CH_HALT or CH_COMMUNICATION mode.

RSCFDnCFDTXQCC2m.TXQTXIE

TX Queue TX Interrupt Enable

If this bit is set, then an interrupt will be generated based on the setting of the TXQIM bit.

Users cannot write to this bit when the RS-CANFD module is in GL_STOP mode.

Users should not write to this bit when the RS-CANFD module is in CH_STOP mode.

RSCFDnCFDTXQCC2m.TXQOWE

TX Queue Overwrite Mode Enable

When this bit is set, the TX queue is in TX queue overwrite mode.

An overwrite function is valid when the same ID as ID of the data written in from the gateway or CPU is in TX Queue, e.g. when a frame is received and is stored into the TX queue, if a message with the same ID has been stored in the TX queue, the old message will be overwritten by the new message.

Users cannot write to the bit when the RS-CANFD module is in GL_STOP mode.

Users cannot write to the bit when the related RS-CANFD channel is in CH_HALT or CH_COMMUNICATION mode.

Users should not write to the bit when the related RS-CANFD channel is in CH_STOP.

When users use the function in GW mode, the depth of TXQ (RSCFDnCFDTXQCC2m.TXQDC) should be configured to the value which is the various number of ID which is used in the TX queue plus 3.

Then the function is valid for the standard ID frame and is invalid for the extended ID frame.

Users should not write change for this bit when the RSCFDnCFDTXQCC2m.TXQE bit is 1_B.

RSCFDnCFDTXQCC2m.TXQGWE

TX Queue Gateway Mode Enable

When this bit is set, the TX queue is in TX queue GW mode.

Users cannot write to the bit when the RS-CANFD module is in GL_STOP mode.

Users cannot write to the bit when the related RS-CANFD channel is in CH_HALT or CH_COMMUNICATION mode.

Users should not write to the bit when the related RS-CANFD channel is in CH_STOP.

When this bit is set, CPU must not access the TX queue.

RSCFDnCFDTXQCC2m.TXQE

TX Queue Enable

Users cannot write to this bit when the related RS-CANFD channel is in CH_RESET mode.
Users cannot write to this bit when the RS-CANFD module is in GL_STOP mode.
This bit cannot be set if the configured TX Queue depth is 0_H (RSCFDnCFDTXQCC2m.TXQDC = 0_H).
Users cannot write to this bit when the related channel is in CH_STOP mode.

This bit is cleared automatically when the related RS-CANFD channel is in CH_RESET mode.

23.3.12.4 RSCFDnCFDTXQCC3m — Transmit Queue Configuration / Control Register 3 m

Access: RSCFDnCFDTXQCC3m register can be read or written in 32-bit units
RSCFDnCFDTXQCC3mL, RSCFDnCFDTXQCCnH register can be read or written in 16-bit units
RSCFDnCFDTXQCC3mLL, RSCFDnCFDTXQCCnLH, RSCFDnCFDTXQCC3mHL,
RSCFDnCFDTXQCC3mHH register can be read or written in 8-bit units

Address: RSCFDnCFDTXQCC3m: <RSCFDn_base> + 1120_H + (04_H × m)

RSCFDnCFDTXQCC3mL: <RSCFDn_base> + 1120_H + (04_H × m),
RSCFDnCFDTXQCC3mH: <RSCFDn_base> + 1122_H + (04_H × m)

RSCFDnCFDTXQCC3mLL: <RSCFDn_base> + 1120_H + (04_H × m),
RSCFDnCFDTXQCC3mLH: <RSCFDn_base> + 1121_H + (04_H × m),
RSCFDnCFDTXQCC3mHL: <RSCFDn_base> + 1122_H + (04_H × m),
RSCFDnCFDTXQCC3mHH: <RSCFDn_base> + 1123_H + (04_H × m)

Value after reset: 0000 0000_H

5	TXQTXIE	TX Queue TX Interrupt Enable 0: TX Queue TX Interrupt disabled 1: TX Queue TX Interrupt enabled
4, 3	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
2	TXQOWE	TX Queue Overwrite Mode Enable 0: TX Queue OW mode disabled 1: TX Queue OW mode enabled

Table 23.78 RSCFDnCFDTXQCC3m Register Contents (2/2)

Bit Position	Bit Name	Function
1	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
0	TXQE	TX Queue Enable 0: TX Queue disabled 1: TX Queue enabled

The TX Queue Configuration / Control Register is used to configure the TX Queue transmission.

TXQ3 is composed of TXMB63 to TXMB32 (at the maximum) when TXQE is enabled.

RSCFDnCFDTXQCC3m.TXQOFTXIE

TXQ One Frame Transmission Interrupt Enable.

If this bit is set, then an interrupt will be generated based on the setting of the RSCFDnCFDTXQSTS3m.TXQOFTXIF bit.

Users cannot write to this bit when the RS-CANFD module is in GL_STOP mode.

Users should not write to this bit when the RS-CANFD module is in CH_STOP mode.

RSCFDnCFDTXQCC3m.TXQDC[4:0]

TX Queue Depth Configuration.

These bits select the depth of the transmission queue. The Message Buffer selection starts from MB[63] down to MB[32] depending upon the configured depth.

When users use TXQ3 and TXQ2 simultaneously, the total depth of TXQ3 and TXQ2 should be 32 or less.
Users cannot write to these bits when the RS-CANFD module is in GL_STOP mode.
Users cannot write to these bits when the related RS-CANFD channel is in CH_HALT or CH_COMMUNICATION mode.

Users should not write to these bits when the related RS-CANFD channel is in CH_STOP.

RSCFDnCFDTXQCC3m.TXQIM

TX Queue Interrupt Mode.

This bit selects the Interrupt generation condition for the TX Queue.

Users cannot write to this bit when the RS-CANFD module is in GL_STOP mode.

Users should not write to this bit when the RS-CANFD module is in CH_STOP mode.

Users should not write to this bit when the RS-CANFD module is in CH_HALT or CH_COMMUNICATION mode.

RSCFDnCFDTXQCC3m.TXQTXIE

TX Queue TX Interrupt Enable.

If this bit is set, then an interrupt will be generated based on the setting of the TXQIM bit.

Users cannot write to this bit when the RS-CANFD module is in GL_STOP mode.

Users should not write to this bit when the RS-CANFD module is in CH_STOP mode.

RSCFDnCFDTXQCC3m.TXQOWE

TX Queue Overwrite Mode Enable.

When this bit is set, the TX queue is in TX queue overwrite mode.

An overwrite function is valid when the same ID as ID of the data written in from CPU is in TX Queue, e.g. when a frame is received and is stored into the TX queue, if a message with the same ID has been stored in the TX queue, the old message will be overwritten by the new message.

Users cannot write to the bit when the RS-CANFD module is in GL_STOP mode.

Users cannot write to the bit when the related RS-CANFD channel is in CH_HALT or CH_COMMUNICATION mode.

Users should not write to the bit when the related RS-CANFD channel is in CH_STOP.

When users use the function, the depth of TXQ (RSCFDnCFDTXQCC3m.TXQDC) should be configured to the value which is the various number of ID which is used in the TX queue plus 3.

Then the function is valid for the standard ID frame and is invalid for the extended ID frame.

Users should not write change for this bit when the RSCFDnCFDTXQCC3m.TXQE bit is set to 1_B.

RSCFDnCFDTXQCC3m.TXQE

TX Queue Enable.

Users cannot write to this bit when the related RS-CANFD channel is in CH_RESET mode.
Users cannot write to this bit when the RS-CANFD module is in GL_STOP mode.
This bit cannot be set if the configured TX Queue depth is 0_H (RSCFDnCFDTXQCC3m.TXQDC = 0_H).
Users cannot write to this bit when the related channel is in CH_STOP mode.

This bit is cleared automatically when the related RS-CANFD channel is in CH_RESET mode.

23.3.12.5 RSCFDnCFDTXQSTS0m — Transmit Queue Status Register 0 m

Access: RSCFDnCFDTXQSTS0m register can be read or written in 32-bit units
RSCFDnCFDTXQSTS0mL, RSCFDnCFDTXQSTSnH register can be read or written in 16-bit units
RSCFDnCFDTXQSTS0mLL, RSCFDnCFDTXQSTS0mLH, RSCFDnCFDTXQSTS0mHL, RSCFDnCFDTXQSTS0mHH register can be read or written in 8-bit units

Address: RSCFDnCFDTXQSTS0m: <RSCFDn_base> + 1020_H + (04_H × m)

RSCFDnCFDTXQSTS0mL: <RSCFDn_base> + 1020_H + (04_H × m),
RSCFDnCFDTXQSTS0mH: <RSCFDn_base> + 1022_H + (04_H × m)

RSCFDnCFDTXQSTS0mLL: <RSCFDn_base> + 1020_H + (04_H × m),
RSCFDnCFDTXQSTS0mLH: <RSCFDn_base> + 1021_H + (04_H × m),
RSCFDnCFDTXQSTS0mHL: <RSCFDn_base> + 1022_H + (04_H × m),
RSCFDnCFDTXQSTS0mHH: <RSCFDn_base> + 1023_H + (04_H × m)

Value after reset: $0000\ 0001_H$

1	TXQFLL	TX Queue Full 0: TX Queue Not Full 1: TX Queue Full

Table 23.79 RSCFDnCFDTXQSTS0m Register Contents (2/2)

Bit Position	Bit Name	Function
0	TXQEMP	TX Queue Empty 0: TX Queue Not Empty 1: TX Queue Empty

The TX Queue status registers show the status of the TX Queue of corresponding CAN Channel.

RSCFDnCFDTXQSTS0m.TXQMOW

TXQ message overwrite.

This bit will not be cleared automatically if the TX Queue is disabled.

Users cannot write to this bit when the related RS-CANFD channel is in CH_STOP or CH_RESET mode.

When stopping TX Queue, this bit should be cleared, after disabling TXQE and checking an empty state of TX Queue.

When RSCFDnCFDTXQCC0m.TXQOWE=1 and Message overwrite occurs in TX queue, this bit is set automatically.

The bit is cleared by writing 0_B to it.

The bit is cleared if the related RS-CANFD channel enters CH_RESET mode.

Do not use bit clear instruction for clearing this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Then the other bits remain set to 1_B.

Writing 1_B has no influence on the bit values.

RSCFDnCFDTXQSTS0m.TXQMLT

TXQ Message Lost.

This bit will not be cleared automatically if the TX Queue is disabled.

Users cannot write to this bit when the related RS-CANFD channel is in CH_STOP or CH_RESET mode.

When stopping TX Queue, this bit should be cleared, after disabling TXQE and checking an empty state of TX Queue.

When Message lost occurs in the Gateway mode of TX queue, this bit is set automatically.

The bit is cleared by writing 0_B to it.

The bit is cleared if the related RS-CANFD channel enters CH_RESET mode.

Do not use bit clear instruction for clearing this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Then the other bits remain set to 1_B.

Writing 1_B has no influence on the bit values.

RSCFDnCFDTXQSTS0m.TXQOFTXIF

TXQ One Frame Transmission Interrupt Flag

This bit will not be cleared automatically if the TX Queue is disabled.

Users cannot write to this bit when the related RS-CANFD channel is in CH_STOP or CH_RESET mode.

When stopping TX Queue, this bit should be cleared, after disabling TXQE and checking an empty state of TX Queue.

When transmission is successful in TX queue, this bit is set automatically.

The bit is cleared by writing 0_B to it.

The bit is cleared if the related RS-CANFD channel enters CH_RESET mode.

Do not use bit clear instruction for clearing this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Then the other bits remain set to 1_B.

Writing 1_B has no influence on the bit values.

RSCFDnCFDTXQSTS0m.TXQOFRXIF

TXQ One Frame Reception Interrupt Flag

This bit will not be cleared automatically if the TX Queue is disabled.

Users cannot write to this bit when the related RS-CANFD channel is in CH_STOP or CH_RESET mode.

When stopping TX Queue, this bit should be cleared, after disabling TXQE and checking an empty state of TX Queue.

When receiving data is stored in TX queue in Gateway mode, this bit is set automatically.

The bit is cleared by writing 0_B to it.

The bit is cleared if the related RS-CANFD channel enters CH_RESET mode.

This function can use only the Gateway mode of TX queue.

Do not use bit clear instruction for clearing this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Then the other bits remain set to 1_B.

Writing 1_B has no influence on the bit values.

RSCFDnCFDTXQSTS0m.TXQFIF

TXQ Full Interrupt Flag

This bit will not be cleared automatically if the TX Queue is disabled.

Users cannot write to this bit when the related RS-CANFD channel is in CH_STOP or CH_RESET mode.

When stopping TX Queue, this bit should be cleared, after disabling TXQE and checking an empty state of TX Queue.

Only when the Gateway mode (RSCFDnCFDTXQCC0m.TXQGWE=1), this bit is set automatically when TX Queue transits to a buffer full status.

The bit is cleared by writing 0_B to it.

The bit is cleared if the related RS-CANFD channel enters CH_RESET mode.

Do not use bit clear instruction for clearing this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Then the other bits remain set to 1_B.

Writing 1_B has no influence on the bit values.

RSCFDnCFDTXQSTS0m.TXQMC[5:0]

TX Queue Message Count

These bits show the number of CAN messages in the TX Queue.

These bits are cleared automatically when the related channel is in CH_RESET mode.

RSCFDnCFDTXQSTS0m.TXQTXIF

TX Queue TX Interrupt Flag

This bit will not be cleared automatically if the TX Queue is disabled.

Users cannot write to this bit when the related RS-CANFD channel is in CH_STOP or CH_RESET mode.

When stopping TX Queue, this bit should be cleared, after disabling TXQE and checking an empty state of TX Queue.

This bit is set automatically when the configured interrupt condition is satisfied for the TX Queue.

The bit is cleared by writing 0_B to it.

The bit is cleared if the related RS-CANFD channel enters CH_RESET mode.

Do not use bit clear instruction for clearing this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Then the other bits remain set to 1_B.

Writing 1_B has no influence on the bit values.

RSCFDnCFDTXQSTS0m.TXQFLL

TX Queue Full

This bit is set automatically when the number of CAN messages stored in the TX Queue matches the configured TX Queue depth.

This bit is cleared automatically when the number of CAN messages stored in the TX Queue is less than the configured TX Queue depth.
This bit is cleared automatically when the related channel enters CH_RESET mode.

RSCFDnCFDTXQSTS0m.TXQEMP

TX Queue Empty

This bit is set automatically when the TX Queue is disabled or no messages are stored in the TX Queue.
This bit is set automatically when the last message is transmitted from the TX Queue.
This bit is set automatically when the related RS-CANFD channel enters CH_RESET mode.
The bit is cleared automatically when the first message to be transmitted is stored in the TX Queue.

23.3.12.6 RSCFDnCFDTXQSTS1m — Transmit Queue Status Register 1 m

Access: RSCFDnCFDTXQSTS1m register can be read or written in 32-bit units
RSCFDnCFDTXQSTS1mL, RSCFDnCFDTXQSTS1mH register can be read or written in 16-bit units
RSCFDnCFDTXQSTS1mLL, RSCFDnCFDTXQSTS1mLH, RSCFDnCFDTXQSTS1mHL,
RSCFDnCFDTXQSTS1mHH register can be read or written in 8-bit units

Address: RSCFDnCFDTXQSTS1m: <RSCFDn_base> + 1080_H + (04_H × m)

RSCFDnCFDTXQSTS1mL: <RSCFDn_base> + 1080_H + (04_H × m),
RSCFDnCFDTXQSTS1mH: <RSCFDn_base> + 1082_H + (04_H × m)

RSCFDnCFDTXQSTS1mLL: <RSCFDn_base> + 1080_H + (04_H × m),
RSCFDnCFDTXQSTS1mLH: <RSCFDn_base> + 1081_H + (04_H × m),

Table 23.80 RSCFDnCFDTXQSTS1m Register Contents (2/2)

Bit Position	Bit Name	Function
0	TXQEMP	TX Queue Empty 0: TX Queue Not Empty 1: TX Queue Empty

The TX Queue status registers show the status of the TX Queue of corresponding CAN Channel.

RSCFDnCFDTXQSTS1m.TXQMOW

TXQ message overwrite.

This bit will not be cleared automatically if the TX Queue is disabled.

Users cannot write to this bit when the related RS-CANFD channel is in CH_STOP or CH_RESET mode.

When stopping TX Queue, this bit should be cleared, after disabling TXQE and checking an empty state of TX Queue.

When RSCFDnCFDTXQCC1m.TXQOWE=1 and Message overwrite occurs in TX queue, this bit is set automatically.

The bit is cleared by writing 0_B to it.

The bit is cleared if the related RS-CANFD channel enters CH_RESET mode.

Do not use bit clear instruction for clearing this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Then the other bits remain set to 1_B.

Writing 1_B has no influence on the bit values.

RSCFDnCFDTXQSTS1m.TXQMLT

TXQ Message Lost.

This bit will not be cleared automatically if the TX Queue is disabled.

Users cannot write to this bit when the related RS-CANFD channel is in CH_STOP or CH_RESET mode.

When stopping TX Queue, this bit should be cleared, after disabling TXQE and checking an empty state of TX Queue.

When Message lost occurs in the Gateway mode of TX queue, this bit is set automatically.

The bit is cleared by writing 0_B to it.

The bit is cleared if the related RS-CANFD channel enters CH_RESET mode.

Do not use bit clear instruction for clearing this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Then the other bits remain set to 1_B.

Writing 1_B has no influence on the bit values.

RSCFDnCFDTXQSTS1m.TXQOFTXIF

TXQ One Frame Transmission Interrupt Flag.

This bit will not be cleared automatically if the TX Queue is disabled.

Users cannot write to this bit when the related RS-CANFD channel is in CH_STOP or CH_RESET mode.

When stopping TX Queue, this bit should be cleared, after disabling TXQE and checking an empty state of TX Queue.

When transmission is successful in TX queue, this bit is set automatically.

The bit is cleared by writing 0_B to it.

The bit is cleared if the related RS-CANFD channel enters CH_RESET mode.

Do not use bit clear instruction for clearing this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Then the other bits remain set to 1_B.

Writing 1_B has no influence on the bit values.

RSCFDnCFDTXQSTS1m.TXQOFRXIF

TXQ One Frame Reception Interrupt Flag

This bit will not be cleared automatically if the TX Queue is disabled.

Users cannot write to this bit when the related RS-CANFD channel is in CH_STOP or CH_RESET mode.

When stopping TX Queue, this bit should be cleared, after disabling TXQE and checking an empty state of TX Queue.

When receiving data is stored in TX queue in Gateway mode, this bit is set automatically.

The bit is cleared by writing 0_B to it.

The bit is cleared if the related RS-CANFD channel enters CH_RESET mode.

This function can use only the Gateway mode of TX queue.

Do not use bit clear instruction for clearing this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Then the other bits remain set to 1_B.

Writing 1_B has no influence on the bit values.

RSCFDnCFDTXQSTS1m.TXQFIF

TXQ Full Interrupt Flag

This bit will not be cleared automatically if the TX Queue is disabled.

Users cannot write to this bit when the related RS-CANFD channel is in CH_STOP or CH_RESET mode.

When stopping TX Queue, this bit should be cleared, after disabling TXQE and checking an empty state of TX Queue.

Only when the Gateway mode (RSCFDnCFDTXQCC0m.TXQGWE=1), this bit is set automatically when TX Queue transits to a buffer full status.

The bit is cleared by writing 0_B to it.

The bit is cleared if the related RS-CANFD channel enters CH_RESET mode.

Do not use bit clear instruction for clearing this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Then the other bits remain set to 1_B.

Writing 1_B has no influence on the bit values.

RSCFDnCFDTXQSTS1m.TXQMC[5:0]

TX Queue Message Count.

These bits show the number of CAN messages in the TX Queue.

These bits are cleared automatically when the related channel is in CH_RESET mode.

RSCFDnCFDTXQSTS1m.TXQTXIF

TX Queue TX Interrupt Flag

This bit will not be cleared automatically if the TX Queue is disabled.

Users cannot write to this bit when the related RS-CANFD channel is in CH_STOP or CH_RESET mode.

When stopping TX Queue, this bit should be cleared, after disabling TXQE and checking an empty state of TX Queue.

This bit is set automatically when the configured interrupt condition is satisfied for the TX Queue.

The bit is cleared by writing 0_B to it.

The bit is cleared if the related RS-CANFD channel enters CH_RESET mode.

Do not use bit clear instruction for clearing this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Then the other bits remain set to 1_B.

Writing 1_B has no influence on the bit values.

RSCFDnCFDTXQSTS1m.TXQFLL

TX Queue Full.

This bit is set automatically when the number of CAN messages stored in the TX Queue matches the configured TX Queue depth.

This bit is cleared automatically when the number of CAN messages stored in the TX Queue is less than the configured TX Queue depth.
This bit is cleared automatically when the related channel enters CH_RESET mode.

RSCFDnCFDTXQSTS1m.TXQEMP

TX Queue Empty.

This bit is set automatically when the TX Queue is disabled or no messages are stored in the TX Queue.
This bit is set automatically when the last message is transmitted from the TX Queue.
This bit is set automatically when the related RS-CANFD channel enters CH_RESET mode.
The bit is cleared automatically when the first message to be transmitted is stored in the TX Queue.

23.3.12.7 RSCFDnCFDTXQSTS2m — Transmit Queue Status Register 2 m

Access: RSCFDnCFDTXQSTS2m register can be read or written in 32-bit units
RSCFDnCFDTXQSTS2mL, RSCFDnCFDTXQSTS2mH register can be read or written in 16-bit units
RSCFDnCFDTXQSTS2mLL, RSCFDnCFDTXQSTS2mLH, RSCFDnCFDTXQSTS2mHL, RSCFDnCFDTXQSTS2mHH register can be read or written in 8-bit units

Address: RSCFDnCFDTXQSTS2m: <RSCFDn_base> + $10E0_H$ + (04_H × m)

RSCFDnCFDTXQSTS2mL: <RSCFDn_base> + $10E0_H$ + (04_H × m),
RSCFDnCFDTXQSTS2mH: <RSCFDn_base> + $10E2_H$ + (04_H × m)

RSCFDnCFDTXQSTS2mLL: <RSCFDn_base> + $10E0_H$ + (04_H × m),
RSCFDnCFDTXQSTS2mLH: <RSCFDn_base> + $10E1_H$ + (04_H × m),
RSCFDnCFDTXQSTS2mHL: <RSCFDn_base> + $10E2_H$ + (04_H × m),
RSCFDnCFDTXQSTS2mHH: <RSCFDn_base> + $10E3_H$ + (04_H × m)

Value after reset: $0000\ 0001_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Note 1. The only effective value for writing to this flag bit is 0, which clears the bit. Otherwise writing to the bit results in retention of its state.

Table 23.81 RSCFDnCFDTXQSTS2m Register Contents (1/2)

Bit Position	Bit Name	Function
31 to 21	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
20	TXQMOW	TXQ message overwrite 0: No Message overwrite in TXQ 1: Message overwrite in TXQ
19	TXQMLT	TXQ Message Lost 0: No Message Lost in TXQ 1: TXQ Message Lost
18	TXQOFTXIF	TXQ One Frame Transmission Interrupt Flag If one frame transmits from TXQ, an interrupt will set.
17	TXQOFRXIF	TXQ One Frame Reception Interrupt Flag If TXQ receives one frame, an interrupt will set.
16	TXQFIF	TXQ Full Interrupt Flag If TXQ will be in full status, an interrupt will set.
15, 14	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
13 to 8	TXQMC	TX Queue Message Count No. of Messages in the TX Queue
7 to 3	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
2	TXQTXIF	TX Queue TX Interrupt Flag 0: TX Queue TX interrupt condition not satisfied after Frame TX 1: TX Queue TX interrupt condition satisfied after Frame TX
1	TXQFLL	TX Queue Full 0: TX Queue Not Full 1: TX Queue Full

Table 23.81 RSCFDnCFDTXQSTS2m Register Contents (2/2)

Bit Position	Bit Name	Function
0	TXQEMP	TX Queue Empty 0: TX Queue Not Empty 1: TX Queue Empty

The TX Queue status registers show the status of the TX Queue of corresponding CAN Channel.

RSCFDnCFDTXQSTS2m.TXQMOW

TXQ message overwrite.

This bit will not be cleared automatically if the TX Queue is disabled.

Users cannot write to this bit when the related RS-CANFD channel is in CH_STOP or CH_RESET mode.

When stopping TX Queue, this bit should be cleared, after disabling TXQE and checking an empty state of TX Queue.

When RSCFDnCFDTXQCC2m.TXQOWE=1 and Message overwrite occurs in TX queue, this bit is set automatically.

The bit is cleared by writing 0_B to it.

The bit is cleared if the related RS-CANFD channel enters CH_RESET mode.

Do not use bit clear instruction for clearing this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Then the other bits remain set to 1_B.

Writing 1_B has no influence on the bit values.

RSCFDnCFDTXQSTS2m.TXQMLT

TXQ Message Lost.

This bit will not be cleared automatically if the TX Queue is disabled.

Users cannot write to this bit when the related RS-CANFD channel is in CH_STOP or CH_RESET mode.

When stopping TX Queue, this bit should be cleared, after disabling TXQE and checking an empty state of TX Queue.

When Message lost occurs in the Gateway mode of TX queue, this bit is set automatically.

The bit is cleared by writing 0_B to it.

The bit is cleared if the related RS-CANFD channel enters CH_RESET mode.

Do not use bit clear instruction for clearing this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Then the other bits remain set to 1_B.

Writing 1_B has no influence on the bit values.

RSCFDnCFDTXQSTS2m.TXQOFTXIF

TXQ One Frame Transmission Interrupt Flag.

This bit will not be cleared automatically if the TX Queue is disabled.

Users cannot write to this bit when the related RS-CANFD channel is in CH_STOP or CH_RESET mode.

When stopping TX Queue, this bit should be cleared, after disabling TXQE and checking an empty state of TX Queue.

When transmission is successful in TX queue, this bit is set automatically.

The bit is cleared by writing 0_B to it.

The bit is cleared if the related RS-CANFD channel enters CH_RESET mode.

Do not use bit clear instruction for clearing this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Then the other bits remain set to 1_B.

Writing 1_B has no influence on the bit values.

RSCFDnCFDTXQSTS2m.TXQOFRXIF

TXQ One Frame Reception Interrupt Flag.

This bit will not be cleared automatically if the TX Queue is disabled.

Users cannot write to this bit when the related RS-CANFD channel is in CH_STOP or CH_RESET mode.

When stopping TX Queue, this bit should be cleared, after disabling TXQE and checking an empty state of TX Queue.

When receiving data is stored in TX queue in Gateway mode, this bit is set automatically.

The bit is cleared by writing 0_B to it.

The bit is cleared if the related RS-CANFD channel enters CH_RESET mode.

This function can use only the Gateway mode of TX queue.

Do not use bit clear instruction for clearing this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Then the other bits remain set to 1_B.

Writing 1_B has no influence on the bit values.

RSCFDnCFDTXQSTS2m.TXQFIF

TXQ Full Interrupt Flag

This bit will not be cleared automatically if the TX Queue is disabled.

Users cannot write to this bit when the related RS-CANFD channel is in CH_STOP or CH_RESET mode.

When stopping TX Queue, this bit should be cleared, after disabling TXQE and checking an empty state of TX Queue.

Only when the Gateway mode (RSCFDnCFDTXQCC0m.TXQGWE=1), this bit is set automatically when TX Queue transits to a buffer full status.

The bit is cleared by writing 0_B to it.

The bit is cleared if the related RS-CANFD channel enters CH_RESET mode.

Do not use bit clear instruction for clearing this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Then the other bits remain set to 1_B.

Writing 1_B has no influence on the bit values.

RSCFDnCFDTXQSTS2m.TXQMC[5:0]

TX Queue Message Count.

These bits show the number of CAN messages in the TX Queue.

These bits are cleared automatically when the related channel is in CH_RESET mode.

RSCFDnCFDTXQSTS2m.TXQTXIF

TX Queue TX Interrupt Flag

This bit will not be cleared automatically if the TX Queue is disabled.

Users cannot write to this bit when the related RS-CANFD channel is in CH_STOP or CH_RESET mode.

When stopping TX Queue, this bit should be cleared, after disabling TXQE and checking an empty state of TX Queue.

This bit is set automatically when the configured interrupt condition is satisfied for the TX Queue.

The bit is cleared by writing 0_B to it.

The bit is cleared if the related RS-CANFD channel enters CH_RESET mode.

Do not use bit clear instruction for clearing this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Then the other bits remain set to 1_B.

Writing 1_B has no influence on the bit values.

RSCFDnCFDTXQSTS2m.TXQFLL

TX Queue Full.

This bit is set automatically when the number of CAN messages stored in the TX Queue matches the configured TX Queue depth.

This bit is cleared automatically when the number of CAN messages stored in the TX Queue is less than the configured TX Queue depth.

This bit is cleared automatically when the related channel enters CH_RESET mode.

RSCFDnCFDTXQSTS2m.TXQEMP

TX Queue Empty.

This bit is set automatically when the TX Queue is disabled or no messages are stored in the TX Queue.

This bit is set automatically when the last message is transmitted from the TX Queue.

This bit is set automatically when the related RS-CANFD channel enters CH_RESET mode.

The bit is cleared automatically when the first message to be transmitted is stored in the TX Queue.

23.3.12.8 RSCFDnCFDTXQSTS3m — Transmit Queue Status Register 3 m

Access: RSCFDnCFDTXQSTS3m register can be read or written in 32-bit units
RSCFDnCFDTXQSTS3mL, RSCFDnCFDTXQSTS3mH register can be read or written in 16-bit units
RSCFDnCFDTXQSTS3mLL, RSCFDnCFDTXQSTS3mLH, RSCFDnCFDTXQSTS3mHL,
RSCFDnCFDTXQSTS3mHH register can be read or written in 8-bit units

Address: RSCFDnCFDTXQSTS3m: <RSCFDn_base> + 1140_H + (04_H × m)

RSCFDnCFDTXQSTS3mL: <RSCFDn_base> + 1140_H + (04_H × m),
RSCFDnCFDTXQSTS3mH: <RSCFDn_base> + 1142_H + (04_H × m)

RSCFDnCFDTXQSTS3mLL: <RSCFDn_base> + 1140_H + (04_H × m),
RSCFDnCFDTXQSTS3mLH: <RSCFDn_base> +1141_H + (04_H × m),

Note 1. The only effective value for writing to this flag bit is 0, which clears the bit. Otherwise writing to the bit results in retention of its state.

Table 23.82 RSCFDnCFDTXQSTS3m Register Contents

Bit Position	Bit Name	Function
31 to 21	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
20	TXQMOW	TXQ message overwrite 0: No Message overwrite in TXQ 1: Message overwrite in TXQ
19	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
18	TXQOFTXIF	TXQ One Frame Transmission Interrupt Flag If one frame transmits from TXQ, an interrupt will set.
17 to 14	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
13 to 8	TXQMC[5:0]	TX Queue Message Count No. of Messages in the TX Queue
7 to 3	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
2	TXQTXIF	TX Queue TX Interrupt Flag 0: TX Queue TX Interrupt condition not satisfied after Frame TX 1: TX Queue TX Interrupt condition satisfied after Frame TX
1	TXQFLL	TX Queue Full 0: TX Queue Not Full 1: TX Queue Full
0	TXQEMP	TX Queue Empty 0: TX Queue Not Empty 1: TX Queue Empty

The TX Queue status registers show the status of the TX Queue of corresponding CAN Channel.

RSCFDnCFDTXQSTS3m.TXQMOW

TXQ message overwrite.

This bit will not be cleared automatically if the TX Queue is disabled.

Users cannot write to this bit when the related RS-CANFD channel is in CH_STOP or CH_RESET mode.

When stopping TX Queue, this bit should be cleared, after disabling TXQE and checking an empty state of TX Queue.

When RSCFDnCFDTXQCC3m.TXQOWE=1 and Message overwrite occurs in TX queue, this bit is set automatically.

The bit is cleared by writing 0_B to it.

The bit is cleared if the related RS-CANFD channel enters CH_RESET mode.

Do not use bit clear instruction for clearing this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Then the other bits remain set to 1_B.

Writing 1_B has no influence on the bit values.

RSCFDnCFDTXQSTS3m.TXQOFTXIF

TXQ One Frame Transmission Interrupt Flag

This bit will not be cleared automatically if the TX Queue is disabled.

Users cannot write to this bit when the related RS-CANFD channel is in CH_STOP or CH_RESET mode.

When stopping TX Queue, this bit should be cleared, after disabling TXQE and checking an empty state of TX Queue.

When transmission is successful in TX queue, this bit is set automatically.

The bit is cleared by writing 0_B to it.

The bit is cleared if the related RS-CANFD channel enters CH_RESET mode.

Do not use bit clear instruction for clearing this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Then the other bits remain set to 1_B.

Writing 1_Bhas no influence on the bit values.

RSCFDnCFDTXQSTS3m.TXQMC[5:0]

TX Queue Message Count.

These bits show the number of CAN messages in the TX Queue.

These bits are cleared automatically when the related channel is in CH_RESET mode.

RSCFDnCFDTXQSTS3m.TXQTXIF

TX Queue TX Interrupt Flag

This bit will not be cleared automatically if the TX Queue is disabled.

Users cannot write to this bit when the related RS-CANFD channel is in CH_STOP or CH_RESET mode.

When stopping TX Queue, this bit should be cleared, after disabling TXQE and checking an empty state of TX Queue.

This bit is set automatically when the configured interrupt condition is satisfied for the TX Queue.

The bit is cleared by writing 0_B to it.

The bit is cleared if the related RS-CANFD channel enters CH_RESET mode.

Do not use bit clear instruction for clearing this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Then the other bits remain set to 1_B.

Writing 1_B has no influence on the bit values.

RSCFDnCFDTXQSTS3m.TXQFLL

TX Queue Full.

This bit is set automatically when the number of CAN messages stored in the TX Queue matches the configured TX Queue depth.

This bit is cleared automatically when the number of CAN messages stored in the TX Queue is less than the configured TX Queue depth.

This bit is cleared automatically when the related channel enters CH_RESET mode.

RSCFDnCFDTXQSTS3m.TXQEMP

TX Queue Empty.

This bit is set automatically when the TX Queue is disabled or no messages are stored in the TX Queue.

This bit is set automatically when the last message is transmitted from the TX Queue.

This bit is set automatically when the related RS-CANFD channel enters CH_RESET mode.

The bit is cleared automatically when the first message to be transmitted is stored in the TX Queue.

23.3.12.9 RSCFDnCFDTXQPCTR0m — Transmit Queue Pointer Control Register 0 m

Access: RSCFDnCFDTXQPCTR0m register is a write-only register that can be written in 32-bit units
RSCFDnCFDTXQPCTR0mL, RSCFDnCFDTXQPCTR0mH register is a write-only register that can be written in 16-bit units
RSCFDnCFDTXQPCTR0mLL, RSCFDnCFDTXQPCTR0mLH, RSCFDnCFDTXQPCTR0mHL, RSCFDnCFDTXQPCTR0mHH register is a write-only register that can be written in 8-bit units

Address: RSCFDnCFDTXQPCTR0m: <RSCFDn_base> + 1040_H + (04_H × m)

RSCFDnCFDTXQPCTR0mL: <RSCFDn_base> + 1040_H + (04_H × m),
RSCFDnCFDTXQPCTR0mH: <RSCFDn_base> + 1042_H + (04_H × m)

RSCFDnCFDTXQPCTR0mLL: <RSCFDn_base> + 1040_H + (04_H × m),
RSCFDnCFDTXQPCTR0mLH: <RSCFDn_base> + 1041_H + (04_H × m),
RSCFDnCFDTXQPCTR0mHL: <RSCFDn_base> + 1042_H + (04_H × m),
RSCFDnCFDTXQPCTR0mHH: <RSCFDn_base> + 1043_H + (04_H × m)

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Table 23.83 RSCFDnCFDTXQPCTR0m Register Contents

Bit Position	Bit Name	Function
31 to 8	Reserved	When writing, write the value after reset.
7 to 0	TXQPC[7:0]	TX Queue Pointer Control Increments the write pointer to the TX Queue buffer in the corresponding channel

These registers can be used to confirm storage of a full message in the corresponding TX Queue Buffers.

RSCFDnCFDTXQPCTR0m.TXQPC [7:0]

TX Queue Pointer Control.

When the value FF_H is written to these bits, then the Write Pointer of the corresponding TX Queue Buffer is updated and a transmit request is initiated for this message.

Read value from these bits is always 0_H.

Users cannot write to these bits when the related RS-CANFD channel is in CH_STOP or CH_RESET mode.

Users should only write FF_H to this register when the corresponding TX Queue is enabled and not full.

Users should only write FF_H to this register when the Transmit/Receive FIFO is enabled and is not configured in GW mode.

Users should not write to the FIFO control registers when DMA is enabled.

23.3.12.10 RSCFDnCFDTXQPCTR1m — Transmit Queue Pointer Control Register 1 m

Access: RSCFDnCFDTXQPCTR1m register is a write-only register that can be written in 32-bit units
RSCFDnCFDTXQPCTR1mL, RSCFDnCFDTXQPCTR1mH register is a write-only register that can be written in 16-bit units

Table 23.85 RSCFDnCFDTXQPCTR2m Register Contents

Bit Position	Bit Name	Function
31 to 8	Reserved	When writing, write the value after reset.
7 to 0	TXQPC[7:0]	TX Queue Pointer Control Increments the write pointer to the TX Queue buffer in the corresponding channel

These registers can be used to confirm storage of a full message in the corresponding TX Queue Buffers.

RSCFDnCFDTXQPCTR2mTXQPC [7:0]

TX Queue Pointer Control.

When the value FF_H is written to these bits, then the Write Pointer of the corresponding TX Queue Buffer is updated and a transmit request is initiated for this message.

Read value from these bits is always 0_H.

Users cannot write to these bits when the related RS-CANFD channel is in CH_STOP or CH_RESET mode.

Users should only write FF_H to this register when the corresponding TX Queue is enabled and not full.

Users should only write FF_H to this register when the Transmit/Receive FIFO is enabled and is not configured in GW mode.

23.3.12.12 RSCFDnCFDTXQPCTR3m — Transmit Queue Pointer Control Register 3 m

Access: RSCFDnCFDTXQPCTR3m register is a write-only register that can be written in 32-bit units
RSCFDnCFDTXQPCTR3mL, RSCFDnCFDTXQPCTR3mH register is a write-only register that can be written in 16-bit units
RSCFDnCFDTXQPCTR3mLL, RSCFDnCFDTXQPCTR3mLH, RSCFDnCFDTXQPCTR3mHL, RSCFDnCFDTXQPCTR3mHH register is a write-only register that can be written in 8-bit units

Address: RSCFDnCFDTXQPCTR3m: <RSCFDn_base> + 1160_H + (04_H × m)

RSCFDnCFDTXQPCTR3mL: <RSCFDn_base> + 1160_H + (04_H × m),
RSCFDnCFDTXQPCTR3mH: <RSCFDn_base> + 1162_H + (04_H × m)

RSCFDnCFDTXQPCTR3mLL: <RSCFDn_base> + 1160_H + (04_H × m),
RSCFDnCFDTXQPCTR3mLH: <RSCFDn_base> + 1161_H + (04_H × m),

Table 23.86 RSCFDnCFDTXQPCTR3m Register Contents

Bit Position	Bit Name	Function
31 to 8	Reserved	When writing, write the value after reset.
7 to 0	TXQPC[7:0]	TX Queue Pointer Control Increments the write pointer to the TX Queue buffer in the corresponding channel

These registers can be used to confirm storage of a full message in the corresponding TX Queue Buffers.

RSCFDnCFDTXQPCTR3m.TXQPC [7:0]

TX Queue Pointer Control.

When the value FF_H is written to these bits, then the Write Pointer of the corresponding TX Queue Buffer is updated and a transmit request is initiated for this message.

Read value from these bits is always 0_H.

Users cannot write to these bits when the related RS-CANFD channel is in CH_STOP or CH_RESET mode.

Users should only write FF_H to this register when the corresponding TX Queue is enabled and not full.

Users should not write to the FIFO control registers when DMA is enabled.

23.3.12.13 RSCFDnCFDTXQESTS — Transmit Queue Empty Status Register

Access: RSCFDnCFDTXQESTS register is a read-only register that can be read in 32-bit units
RSCFDnCFDTXQESTSL, RSCFDnCFDTXQESTSH register is a read-only register that can be read in 16-bit units
RSCFDnCFDTXQESTSLL, RSCFDnCFDTXQESTSLH, RSCFDnCFDTXQESTSHL, RSCFDnCFDTXQESTSHH register is a read-only register that can be read in 8-bit units

Table 23.91 RSCFDnCFDTXQISTS Register Contents

Bit Position	Bit Name	Function
31 to 0	TXQ31ISF to TXQ0ISF	TXQ Interrupt Status Flag 0: TXQ Interrupt flag is not set. 1: TXQ Interrupt flag is set.

The TXQ status register bits show the status of the Interrupt flag bits of the TXQ Buffers.

RSCFDnCFDTXQISTS.TXQ31ISF to TXQ0ISF

TXQ Interrupt Status Flag.

Each bit is set automatically when the corresponding bit is set in the TXQ Status Register.

Each bit is cleared automatically when the corresponding bit is cleared in the TXQ Status Register. This bit is cleared when RS-CANFD module enters GL_RESET mode.

Bit position	Corresponding TXQueue

23.3.13 Details of Transmit History-Related Registers

23.3.13.1 RSCFDnCFDTHLCCm — Transmit History List Configuration/Control Register m

Access: RSCFDnCFDTHLCCm register can be read or written in 32-bit units
RSCFDnCFDTHLCCmL, RSCFDnCFDTHLCCmH register can be read or written in 16-bit units
RSCFDnCFDTHLCCmLL, RSCFDnCFDTHLCCmLH, RSCFDnCFDTHLCCmHL, RSCFDnCFDTHLCCmHH register can be read or written in 8-bit units

Address: RSCFDnCFDTHLCCm: <RSCFDn_base> + 1200_H + (04_H × m)

RSCFDnCFDTHLCCmL: <RSCFDn_base> + 1200_H + (04_H × m),
RSCFDnCFDTHLCCmH: <RSCFDn_base> + 1202_H + (04_H × m)

RSCFDnCFDTHLCCmLL: <RSCFDn_base> + 1200_H + (04_H × m),
RSCFDnCFDTHLCCmLH: <RSCFDn_base> + 1201_H + (04_H × m),
RSCFDnCFDTHLCCmHL: <RSCFDn_base> + 1202_H + (04_H × m),
RSCFDnCFDTHLCCmHH: <RSCFDn_base> + 1203_H + (04_H × m)

Value after reset: $0000\ 0000_H$

Table 23.95 RSCFDnCFDTHLCCm Register Contents

Bit Position	Bit Name	Function
31 to 12	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
11	THLDGE	TX History List Dedicated GW Enable 0: Not dedicate Gateway FIFO + Gateway TX Queue. 1: Dedicate Gateway FIFO + Gateway TX Queue.
10	THLDTE	TX History List Dedicated TX Enable 0: TX FIFO + TX Queue. 1: Flat TX MB + TX FIFO + TX Queue.
9	THLIM	TX History List Interrupt Mode 0: Interrupt generated if TX History List level reaches three-quarters of the TX History List depth. 1: Interrupt generated for every successfully stored entry.
8	THLIE	TX History List Interrupt Enable 0: TX History List Interrupt disabled. 1: TX History List Interrupt enabled.
7 to 1	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
0	THLE	TX History List Enable 0: TX History List disabled. 1: TX History List enabled.

The TX History List Configuration/Control register configures the TX History List functions.

RSCFDnCFDTHLCCm.THLDGE

TX History List Dedicated GW Enable.

This bit selects the conditions for storing an entry in the TX History list after successful transmission.

Users cannot write to this bit when RS-CANFD module is in GL_STOP mode.

Users should not write to this bit when RS-CANFD module is in GL_TEST or GL_OPERATING mode.

RSCFDnCFDTHLCCm.THLDTE

TX History List Dedicated TX Enable.

This bit selects the conditions for storing an entry in the TX History list after successful transmission.

Users cannot write to this bit when RS-CANFD module is in GL_STOP mode.

Users should not write to this bit when RS-CANFD module is in GL_TEST or GL_OPERATING mode.

RSCFDnCFDTHLCCm.THLIM

TX History List Interrupt Mode.

This bit selects the Interrupt generation condition for the FIFO.

Users cannot write to this bit when RS-CANFD module is in GL_STOP mode.

Users should not write to this bit when RS-CANFD module is in GL_TEST or GL_OPERATING mode.

RSCFDnCFDTHLCCm.THLIE

TX History List Interrupt Enable.

This bit enables the generation of the TX History List Interrupt when it is set.

Users cannot write to this bit when RS-CANFD module is in GL_STOP mode.

RSCFDnCFDTHLCCm.THLE

TX History List Enable.

This bit enables the TX History List Buffer when it is set.

Users cannot write to this bit when the related RS-CANFD channel is in CH_RESET or CH_STOP mode.

This bit is cleared automatically when the related RS-CANFD channel is in CH_RESET mode.

23.3.13.2 RSCFDnCFDTHLSTSm — Transmit History List Status Register m

Access: RSCFDnCFDTHLSTSm register can be read or written in 32-bit units
RSCFDnCFDTHLSTSmL, RSCFDnCFDTHLSTSmH register can be read or written in 16-bit units
RSCFDnCFDTHLSTSmLL, RSCFDnCFDTHLSTSmLH, RSCFDnCFDTHLSTSmHL, RSCFDnCFDTHLSTSmHH register can be read or written in 8-bit units

Address: RSCFDnCFDTHLSTSm: <RSCFDn_base> + 1220_H + (04_H × m)

RSCFDnCFDTHLSTSmL: <RSCFDn_base> + 1220_H + (04_H × m),
RSCFDnCFDTHLSTSmH: <RSCFDn_base> + 1222_H + (04_H × m)

RSCFDnCFDTHLSTSmLL: <RSCFDn_base> + 1220_H + (04_H × m),
RSCFDnCFDTHLSTSmLH: <RSCFDn_base> + 1221_H + (04_H × m),
RSCFDnCFDTHLSTSmHL: <RSCFDn_base> + 1222_H + (04_H × m),
RSCFDnCFDTHLSTSmHH: <RSCFDn_base> + 1223_H + (04_H × m)

Value after reset: $0000\ 0001_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Table 23.96 RSCFDnCFDTHLSTSm Register Contents

Bit Position	Bit Name	Function
31 to 14	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
13 to 8	THLMC[5:0]	TX History List Message Count Number of messages stored in TX history list
7 to 4	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
3	THLIF	TX History List Interrupt Flag 0: TX History List Interrupt condition not satisfied. 1: TX History List Interrupt condition satisfied.
2	THLELT	TX History List Entry Lost 0: No Entry Lost in TX History List. 1: TX History List Entry Lost.
1	THLFLL	TX History List Full 0: TX History List Not Full. 1: TX History List Full.
0	THLEMP	TX History List Empty 0: TX History List Not Empty. 1: TX History List Empty.

The TX History List Status register shows the status of the data stored in the TX History List Buffer.

RSCFDnCFDTHLSTSm.THLMC[5:0]

TX History List Message Count.

These bits show the number of transmitted messages stored in the TX History List.

These bits are cleared automatically when the related channel is in CH_RESET mode.

RSCFDnCFDTHLSTSm.THLIF

TX History List Interrupt Flag.

Users can write to this bit only when RS-CANFD module is in CH_HALT or CH_COMMUNICATION modes.

Writing 1 has no influence on the bit values.

Do not use bit clear instruction for clearing this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Then the other bits remain set to 1.

This bit is set when the configured Interrupt condition is satisfied.

The bit is cleared by writing 0 to it.

This bit is automatically cleared in CH_RESET mode.

RSCFDnCFDTHLSTSm.THLELT

TX History List Entry Lost.

Users can write to this bit only when RS-CANFD module is in CH_HALT or CH_COMMUNICATION modes.

Writing 1 has no influence on the bit values.

Do not use bit clear instruction for clearing this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Then the other bits remain set to 1.

This bit is set when a new Entry cannot be stored as the related TX History List Buffer is already full.

This bit is cleared by writing 0 to it.

This bit is automatically cleared in CH_RESET mode.

RSCFDnCFDTHLSTSm.THLFLL

TX History List Full.

Each TX History List can store up to 32 entries (each channel has a dedicated TX History List).

This bit is set automatically when the number of entries in the TX History List Buffer matches the TX History List depth.

This bit is cleared automatically when the number of entries in the TX History List Buffer is less than the TX History List depth.

This bit is cleared automatically when TX History List is disabled.

This bit is cleared automatically when the corresponding CAN channel enters CH_RESET mode.

RSCFDnCFDTHLSTSm.THLEMP

TX History List Empty.

This bit is set automatically when CPU has read all the entries from the TX History List Buffer.

This bit is set automatically when TX History List is disabled.

This bit is set automatically when the corresponding CAN channel enters CH_RESET mode.

This bit is cleared automatically when the first entry is stored to the TX History List.

23.3.13.3 RSCFDnCFDTHLPCTRm — Transmit History List Pointer Control Register

Access: RSCFDnCFDTHLPCTRm register is a write-only register that can be write in 32-bit units
RSCFDnCFDTHLPCTRmL, RSCFDnCFDTHLPCTRmH register is a write-only register that can be write in 16-bit units
RSCFDnCFDTHLPCTRmLL, RSCFDnCFDTHLPCTRmLH, RSCFDnCFDTHLPCTRmHL, RSCFDnCFDTHLPCTRmHH register is a write-only register that can be write in 8-bit units

Address: RSCFDnCFDTHLPCTRm: <RSCFDn_base> + 1240_H + (04_H × m)

RSCFDnCFDTHLPCTRmL: <RSCFDn_base> + 1240_H + (04_H × m),
RSCFDnCFDTHLPCTRmH: <RSCFDn_base> + 1242_H + (04_H × m)

RSCFDnCFDTHLPCTRmLL: <RSCFDn_base> + 1240_H + (04_H × m),
RSCFDnCFDTHLPCTRmLH: <RSCFDn_base> + 1241_H + (04_H × m),
RSCFDnCFDTHLPCTRmHL: <RSCFDn_base> + 1242_H + (04_H × m),
RSCFDnCFDTHLPCTRmHH: <RSCFDn_base> + 1243_H + (04_H × m)

Value after reset: $0000\ 0000_H$

Table 23.97 RSCFDnCFDTHLPCTRm Register Contents

Bit Position	Bit Name	Function
31 to 8	Reserved	When writing, write the value after reset.
7 to 0	THLPC[7:0]	TX History List Pointer Control Increments the write pointer to the TX History List in the corresponding channel.

This register can be used to increment the Read Pointer of the TX History List.

RSCFDnCFDTHLPCTRm.THLPC[7:0]

TX History List Pointer Control.

When FF_H is written to these bits, the Read Pointer of the TX History List is moved to the next TX History List entry address.

Read value from these bits is always 00_H.

Users can write to this bit only when RS-CANFD module is in CH_HALT or CH_COMMUNICATION modes.

Users should only write FF_H to these registers when the corresponding TX History List is enabled and is not empty.

23.3.13.4 RSCFDnCFDTHLACC0m — Channel m Transmit History List Access Register 0

Access: RSCFDnCFDTHLACC0m register is a read-only register that can be read in 32-bit units
RSCFDnCFDTHLACC0mL, RSCFDnCFDTHLACC0mH register is a read-only register that can be read in 16-bit units
RSCFDnCFDTHLACC0mLL, RSCFDnCFDTHLACC0mLH, RSCFDnCFDTHLACC0mHL, RSCFDnCFDTHLACC0mHH register is a read-only register that can be read in 8-bit units

Address: RSCFDnCFDTHLACC0m: <RSCFDn_base> + 8000_H + (08_H × m)

RSCFDnCFDTHLACC0mL: <RSCFDn_base> + 8000_H + (08_H × m),
RSCFDnCFDTHLACC0mH: <RSCFDn_base> + 8002_H + (08_H × m)

RSCFDnCFDTHLACC0mLL: <RSCFDn_base> + 8000_H + (08_H × m),
RSCFDnCFDTHLACC0mLH: <RSCFDn_base> + 8001_H + (08_H × m),
RSCFDnCFDTHLACC0mHL: <RSCFDn_base> + 8002_H + (08_H × m),
RSCFDnCFDTHLACC0mHH: <RSCFDn_base> + 8003_H + (08_H × m)

Value after reset: $0000\ 0000_H$

Table 23.98 RSCFDnCFDTHLACC0m Register Contents

Bit Position	Bit Name	Function
31 to 16	TMTS[15:0]	Transmit Timestamp Transmit Timestamp value for SW drivers.
15	TGW	Transmit Gateway Buffer indication 0: Not transmission from Gateway. 1: Transmission from Gateway.
14 to 10	Reserved	When read, the value after reset is returned.
9 to 3	BN[6:0]	Buffer Number Number of the Message Buffer
2 to 0	BT[2:0]	Buffer Type 001: Flat TX Message Buffer 010: TX FIFO MB Number and GW FIFO MB Number. 100: TX Queue MB Number. Other than the above: Setting prohibited

The TX History List Access register provides access to the entry in the TX History List based on the Read Timestamp value.

RSCFDnCFDTHLACC0m.TMTS[15:0]

Transmit Timestamp.

These bits indicate the Timestamp for use by the SW drivers.

RSCFDnCFDTHLACC0m.TGW

Transmit Gateway Buffer indication.

This bit is automatically set to 1, when transmission is completed in GW mode.

RSCFDnCFDTHLACC0m.BN[6:0]

Buffer Number.

These bits show the Message Buffer from which transmission was successfully completed. If a message from a Transmit/Receive FIFO is transmitted, then these bits show the Message Buffer that is linked to the Transmit/Receive FIFO for transmission.

RSCFDnCFDTHLACC0m.BT[2:0]

Buffer Type.

These bits indicate if the data has been stored following a transmission from a FIFO, a TX Queue or a TX MB.

23.3.13.5 RSCFDnCFDTHLACC1m — Channel m Transmit History List Access Register 1

Access: RSCFDnCFDTHLACC1m register is a read-only register that can be read in 32-bit units
RSCFDnCFDTHLACC1mL, RSCFDnCFDTHLACC1mH register is a read-only register that can be read in 16-bit units
RSCFDnCFDTHLACC1mLL, RSCFDnCFDTHLACC1mLH, RSCFDnCFDTHLACC1mHL, RSCFDnCFDTHLACC1mHH register is a read-only register that can be read in 8-bit units

Address: RSCFDnCFDTHLACC1m: <RSCFDn_base> + 8004_H + (08_H × m)

RSCFDnCFDTHLACC1mL: <RSCFDn_base> + 8004_H + (08_H × m),
RSCFDnCFDTHLACC1mH: <RSCFDn_base> + 8006_H + (08_H × m)

RSCFDnCFDTHLACC1mLL: <RSCFDn_base> + 8004_H + (08_H × m),
RSCFDnCFDTHLACC1mLH: <RSCFDn_base> + 8005_H + (08_H × m),
RSCFDnCFDTHLACC1mHL: <RSCFDn_base> + 8006_H + (08_H × m),
RSCFDnCFDTHLACC1mHH: <RSCFDn_base> + 8007_H + (08_H × m)

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	TIFL[1:0]

	TID[15:0]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 23.99 RSCFDnCFDTHLACC1m Register Contents

Bit Position	Bit Name	Function
31 to 18	Reserved	When read, the value after reset is returned.
17, 16	TIFL[1:0]	Transmit Information Label MB information label or TX FIFO information label or AFL information label is stored for SW drivers.
15 to 0	TID[15:0]	Transmit ID MB reference ID or TX FIFO references ID or AFL pointer field is stored for SW drivers.

The TX History List Access register1 provides access to the entry in the TX History List based on the Read Pointer value.

RSCFDnCFDTHLACC1m.TIFL[1:0]

Transmit Information Label.

These bits indicate the MB information label (RSCFDnCFDTMFDCTR.TMIFL) or the TX FIFO information label (RSCFDnCFDCFFDCSTS.CFIFL) for use by the SW drivers.

In a case of transmission in GW mode, these bits indicate the AFL pointer field (RSCFDnCFDGAFLMj.GAFLIFL1, RSCFDnCFDGAFLP0j.GAFLIFL0) instead of the MB information label (RSCFDnCFDTMFDCTR.TMIFL).

RSCFDnCFDTHLACC1m.TID[15:0]

Transmit ID.

These bits indicate the MB reference ID (RSCFDnCFDTMFDCTR.TMPTR) or the TX FIFO reference ID (RSCFDnCFDCFFDCSTS.CFPTR) for use by the SW drivers.

In a case of transmission in GW mode, these bits indicate the AFL pointer field (RSCFDnCFDGAFLP0j.GAFLPTR) instead of the MB reference ID (RSCFDnCFDTMFDCTR.TMPTR).

23.3.14 Details of Test-Related Registers

23.3.14.1 RSCFDnCFDGTSTCFG — Global Test Configuration Register

Access: RSCFDnCFDGTSTCFG register can be read or written in 32-bit units
RSCFDnCFDGTSTCFGL, RSCFDnCFDGTSTCFGH register can be read or written in 16-bit units
RSCFDnCFDGTSTCFGLL, RSCFDnCFDGTSTCFGLH, RSCFDnCFDGTSTCFGHL,
RSCFDnCFDGTSTCFGHH register can be read or written in 8-bit units

Address: RSCFDnCFDGTSTCFG: <RSCFDn_base> + 1308_H

RSCFDnCFDGTSTCFGL: <RSCFDn_base> + 1308_H,
RSCFDnCFDGTSTCFGH: <RSCFDn_base> + $130A_H$

RSCFDnCFDGTSTCFGLL: <RSCFDn_base> + 1308_H,
RSCFDnCFDGTSTCFGLH: <RSCFDn_base> + 1309_H,
RSCFDnCFDGTSTCFGHL: <RSCFDn_base> + $130A_H$,
RSCFDnCFDGTSTCFGHH: <RSCFDn_base> + $130B_H$

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	RTMPS[9:0]

R/W	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 23.100 RSCFDnCFDGTSTCFG Register Contents

Bit Position	Bit Name	Function
31 to 26	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
25 to 16	RTMPS[9:0]	RAM Test Mode Page Select Select a RAM Test Mode page
15 to 8	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
7 to 0	CmICBCE[7:0]	Channel m Internal CAN Bus Communication Test Mode Enable 0: Channel m internal CAN bus communication disabled. 1: Channel m internal CAN bus communication enabled.

The Global Test Configuration Register is used to configure the CAN channels joining the internal CAN Bus Communication Test Mode and the RAM Test Mode Page.

RSCFDnCFDGTSTCFG.RTMPS[9:0]

RAM Test Mode Page Select.

These bits select the RAM Page mode for CPU read/write access when RS-CANFD module is configured in RAM Test mode.

Refer to **Section 23.11.2.1** for RAM Test Mode Specification.

Users cannot write to these bits when the RS-CANFD module is in GL_RESET or GL_STOP mode.

In U2A-EVA, U2A16, U2A8 users should only enter values from 0 to 95 ($5F_H$) for the AFL RAM and 96 to 868 (364_H) for the MB RAM.

In U2A6 users should only enter values from 0 to 63 ($3F_H$) for the AFL RAM and 64 to 304 (130_H) for the MB RAM for RSCFD0; from 0 to 31 ($1F_H$) for the AFL RAM and 32 to 152 (98_H) for the MB RAM for RSCFD1.

Users should write to this bit only when RS-CANFD module is in GL_TEST mode.

These bits are cleared automatically when the related RS-CANFD channel is in GL_RESET mode.

RSCFDnCFDGTSTCFG.CmICBCE[7:0]

Channel m Internal CAN Bus Communication Test Mode Enable.

If this bit is set and RS-CANFD module is configured in Internal CAN Bus Communication Test Mode, then CAN channel m will participate to the Internal CAN Bus Communication Test Mode operation.

Users cannot write to this bit when the RS-CANFD module is in GL_RESET or GL_STOP mode.

Users should write to this bit only when RS-CANFD module is in GL_TEST mode.

These bits are cleared automatically when the RS-CANFD module is in GL_RESET mode.

23.3.14.2 RSCFDnCFDGTSTCTR — Global Test Control Register

Access: RSCFDnCFDGTSTCTR register can be read or written in 32-bit units
RSCFDnCFDGTSTCTRL, RSCFDnCFDGTSTCTRH register can be read or written in 16-bit units
RSCFDnCFDGTSTCTRLL, RSCFDnCFDGTSTCTRLH, RSCFDnCFDGTSTCTRHL,
RSCFDnCFDGTSTCTRHH register can be read or written in 8-bit units

Address: RSCFDnCFDGTSTCTR: <RSCFDn_base> + $130C_H$

RSCFDnCFDGTSTCTRL: <RSCFDn_base> + $130C_H$,
RSCFDnCFDGTSTCTRH: <RSCFDn_base> + $130E_H$

RSCFDnCFDGTSTCTRLL: <RSCFDn_base> + $130C_H$,
RSCFDnCFDGTSTCTRLH: <RSCFDn_base> + $130D_H$,
RSCFDnCFDGTSTCTRHL: <RSCFDn_base> + $130E_H$,
RSCFDnCFDGTSTCTRHH: <RSCFDn_base> + $130F_H$

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R	R/W

Table 23.101 RSCFDnCFDGTSTCTR Register Contents

Bit Position	Bit Name	Function
31 to 3	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
2	RTME	RAM Test Mode Enable 0: RAM Test Mode disabled. 1: RAM Test Mode enabled.
1	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
0	ICBCTME	Internal CAN Bus Communication Test Mode Enable 0: Internal CAN Bus communication test mode disabled. 1: Internal CAN Bus communication test mode enabled.

The Global Test Control register is used to control the global test modes of the RS-CANFD module.

RSCFDnCFDGTSTCTR.RTME

RAM Test Mode Enable.

If this bit is set, RS-CANFD module is configured in RAM Test Mode. Refer to **Section 23.11.2.1** for RAM Test Mode Specification.

Users can set this bit only when RS-CANFD module is in GL_TEST mode.

Users should clear this bit when RS-CANFD module is in GL_TEST mode.

This bit is cleared automatically when RS-CANFD module enters GL_RESET mode.

RSCFDnCFDGTSTCTR.ICBCTME

Internal CAN Bus Communication Test Mode Enable.

If this bit is set, internal CAN Bus Communication is enabled for the CAN channels that are configured for Internal CAN Bus Communication participation. Refer to **Section 23.11.2.2, Internal CAN Bus Communication Test Mode**.

Users can set this bit only when RS-CANFD module is in GL_TEST mode.

Users should clear this bit when RS-CANFD module is in GL_TEST mode.

This bit is cleared automatically when RS-CANFD module enters GL_RESET mode.

23.3.14.3 RSCFDnCFDGLOCKK — Global Lock Key Register

Access: RSCFDnCFDGLOCKK is a write-only register that can be written in 32-bit units
RSCFDnCFDGLOCKKL, RSCFDnCFDGLOCKKH is a write-only register that can be written in 16-bit units

Address: RSCFDnCFDGLOCKK: <RSCFDn_base> + $131C_H$

RSCFDnCFDGLOCKKL: <RSCFDn_base> + $131C_H$,
RSCFDnCFDGLOCKKH: <RSCFDn_base> + $131E_H$

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	LOCK[15:0]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W

Table 23.102 RSCFDnCFDGLOCKK Register Contents

Bit Position	Bit Name	Function
31 to 16	Reserved	When writing, write the value after reset.
15 to 0	LOCK[15:0]	Lock Key Key bits for unlocking the protection of test modes.

The Global Lock Key register is a write only register that is used to unlock the protection for special test bits.

Refer to **Section 23.11.2** for Lock Key specification.

RSCFDnCFDGLOCKK.LOCK[15:0]

Lock Key.

The Unlock Key sequence must be written in these bits to configure RS-CANFD module in FIFO OTB disable and RAM Test.

Read value from these bits is always 0000_H.

Users can not write to these bits when RS-CANFD module is in GL_STOP or GL_RESET mode.

Users should not write to these bits when RS-CANFD module is in GL_OPERATING mode.

23.3.14.4 RSCFDnCFDRPGACCr — RAM Test Page Access Register r

Access: RSCFDnCFDRPGACCr register can be read or written in 32-bit units
RSCFDnCFDRPGACCrL, RSCFDnCFDRPGACCrH register can be read or written in 16-bit units
RSCFDnCFDRPGACCrLL, RSCFDnCFDRPGACCrLH, RSCFDnCFDRPGACCrHL,
RSCFDnCFDRPGACCrHH register can be read or written in 8-bit units

Address: RSCFDnCFDRPGACCr: <RSCFDn_base> + 8400_H + (04_H × r)

RSCFDnCFDRPGACCrL: <RSCFDn_base> + 8400_H + (04_H × r),
RSCFDnCFDRPGACCrH: <RSCFDn_base> + 8402_H + (04_H × r)

RSCFDnCFDRPGACCrLL: <RSCFDn_base> + 8400_H + (04_H × r),
RSCFDnCFDRPGACCrLH: <RSCFDn_base> + 8401_H + (04_H × r),
RSCFDnCFDRPGACCrHL: <RSCFDn_base> + 8402_H + (04_H × r),
RSCFDnCFDRPGACCrHH: <RSCFDn_base> + 8403_H + (04_H × r)

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 23.103 RSCFDnCFDRPGACCr Register Contents

Bit Position	Bit Name	Function
31 to 0	RDTA[31:0]	RAM Data Test Access RAM Data Bytes

(Average number of entries for 1 channel = no_of_entries = 64)

(r = [0...no_of_entries-1])

RSCFDnCFDRPGACCr.RDTA[31:0]

RAM Data Test Access.

Data can be read from or written into these register bits when RS-CANFD module is configured in RAM Test Mode.

Users can only write to this bit when RS-CANFD module is in GL_TEST mode, and RAM test mode is enabled.

Software data should be read/written in the RAM Test Page Access registers during RAM Test Mode.

23.3.15 Details of BUS Load Counter Register

23.3.15.1 RSCFDnCFDCmBLCT — Channel m Bus load Control Register

Access: RSCFDnCFDCmBLCT register can be read or written in 32-bit units
RSCFDnCFDCmBLCTL, RSCFDnCFDCmBLCTH register can be read or written in 16-bit units
RSCFDnCFDCmBLCTLL, RSCFDnCFDCmBLCTLH, RSCFDnCFDCmBLCTHL, RSCFDnCFDCmBLCTHH register can be read or written in 8-bit units

Address: RSCFDnCFDCmBLCT: <RSCFDn_base> + 1418_H + (20_H × m)

RSCFDnCFDCmBLCTL: <RSCFDn_base> + 1418_H + (20_H × m),
RSCFDnCFDCmBLCTH: <RSCFDn_base> + $141A_H$ + (20_H × m)

RSCFDnCFDCmBLCTLL: <RSCFDn_base> + 1418_H + (20_H × m),
RSCFDnCFDCmBLCTLH: <RSCFDn_base> + 1419_H + (20_H × m),
RSCFDnCFDCmBLCTHL: <RSCFDn_base> + $141A_H$ + (20_H × m),
RSCFDnCFDCmBLCTHH: <RSCFDn_base> + $141B_H$ + (20_H × m)

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

R/W	R	R	R	R	R	R	R	W	R	R	R	R	R	R	R	R/W

Table 23.104 RSCFDnCFDCmBLCT Register Contents

Bit Position	Bit Name	Function
31 to 9	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
8	BLCLD	BUS Load counter load When RSCFDnCFDCmBLCT.BLCLD is set, it is reset after a BUS Load counter value is loaded.
7 to 1	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
0	BLCE	BUS Load counter Enable 0: BUS Load counter disable. 1: BUS Load counter enable.

RSCFDnCFDCmBLCT.BLCLD

BUS Load counter load.

When RSCFDnCFDCmBLCT.BLCLD is set, the BUS Load counter value is loaded to RSCFDnCFDCmBLSTS.BLC and then the BUS Load counter is reset.

Read value is always 0.

RSCFDnCFDCmBLCT.BLCE

BUS Load counter enable.

The enabling signal of a BUS Load counter.

When this bit is 0, BUS Load counter stops. But counter is not clear.

The bit is cleared when the related channel enters CH_RESET mode.

This bit cannot be written in CH_STOP mode.

Write in this bit, after setting up a RSCFDnCFDCmNCFG register.

23.3.15.2 RSCFDnCFDCmBLSTS — Channel m Bus load Status Register

Access: RSCFDnCFDCmBLSTS register is a read-only register that can be read in 32-bit units
RSCFDnCFDCmBLSTSL, RSCFDnCFDCmBLSTSH register is a read-only register that can be read in 16-bit units
RSCFDnCFDCmBLSTSLL, RSCFDnCFDCmBLSTSLH, RSCFDnCFDCmBLSTSHL,
RSCFDnCFDCmBLSTSHH register is a read-only register that can be read in 8-bit units

Address: RSCFDnCFDCmBLSTS: <RSCFDn_base> + $141C_H$ + (20_H × m)

RSCFDnCFDCmBLSTSL: <RSCFDn_base> + $141C_H$ + (20_H × m),
RSCFDnCFDCmBLSTSH: <RSCFDn_base> + $141E_H$ + (20_H × m)

Table 23.105 RSCFDnCFDCmBLSTS Register Contents

Bit Position	Bit Name	Function
31 to 3	BLC[31:3]	BUS Load counter Status
2 to 0	Reserved	When read, the value after reset is returned.

RSCFDnCFDCmBLSTS.BLC[31:3]

BUS Load counter status.

The bus load counter increases by clkc period while CAN bus is in an idle state.

When RSCFDnCFDCmBLCT.BLCLD bit is set, the BUS Load counter value is loaded to BLC bit and then the BUS Load counter is reset.

Bit 2 to Bit 0 is fixed 000_B.

These bits are set only by RS-CANFD module.

Writing any value has no influence on these bits.

23.3.16 Identifier Bits Alignment

Standard Identifier (11 bit) format: ID28 to ID18 is aligned to bit 10 to bit 0.

Extended Identifier (29 bit) format: ID28 to ID0 is aligned to bit 28 to bit 0.

For Standard Identifier format bit 11 to bit 28 should be 0 0000_H.

(1) Bit alignment for Standard Identifier (11 bit) format

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
IDE=0	RTR	—	0	0	0	0	0	0	0	0	0	0	0	0	0

23.3.17 Message Buffer Component Structure

23.3.17.1 Start Addresses

The start address for each of the Message Buffer Components is calculated using the number of related Message Buffer Components and the number of channels.

The start addresses for each register in the Message Buffer Component are depicted in **Table 23.106**.

Table 23.106 Message Buffer Component Register Start Addresses

b = Message Buffer Component Index	MBCP	Register	Regular Start Address*1
[0 .. 15]	RMBCPbm	RMID	2000_H + b*0080_H + m*800_H
		RMPTR	2004_H + b*0080_H + m*800_H
		RMFDSTS	2008_H + b*0080_H + m*800_H
		RMDFd	$200C_H$ + d*0004_H + b*0080_H + m*800_H
[0 .. 7]	RFMBCPb	RFID	6000_H + b*0080_H
		RFPTR	6004_H + b*0080_H
		RFFDSTS	6008_H + b*0080_H
		RFDFd	$600C_H$ + d*0004_H + b*0080_H
[0 .. 2]	CFMBCPbm	CFID	6400_H + b*0080_H + m*180_H
		CFPTR	6404_H + b*0080_H + m*180_H
		CFFDCSTS	6408_H + b*0080_H + m*180_H
		CFDFd	$640C_H$ + d*0004_H + b*0080_H + m*180_H
U2A-EVA, U2A16, U2A8: [0 .. 63] U2A6: [0 .. 15, 31, 32 .. 47, 63]	TMBCPbm	TMID	10000_H + b*0080_H + m*2000_H
		TMPTR	10004_H + b*0080_H + m*2000_H
		TMFDCTR	10008_H + b*0080_H + m*2000_H
		TMDFd	$1000C_H$ + d*0004_H + b*0080_H + m*2000_H

Note 1. Regular Start Address columns are offset address to RS-CANFD base addresses: <RSCFDn_base>.

The message buffer configuration consists of 4 types of message buffer components, namely RX Message Buffer Component (RSCFDnCFDRMBCPbm), RX FIFO Access Message Buffer Component (RSCFDnCFDRFMBCPb), Transmit/Receive FIFO Access Message Buffer Component (RSCFDnCFDCFMBCPbm) and TX Message Buffer Component (RSCFDnCFDTMBCPbm). Where b = the Message Buffer Component index that has a range that varies based on the type of message buffer component. For a summary of this configuration, refer to **Figure 23.27**. For a detailed description of the number of and the different types of message buffers, refer to **Section 23.7**.

As mentioned in **Section 23.4** each message buffer component consists of the following registers: Identifier (ID), Pointer (PTR) and Data Field (DFp) where p = the Data Field register index that has a range that varies based on the type of message buffer component.

Rc is the message buffer component register where c = Message Buffer Component Register index that has a range that varies based on the type of message buffer component.

A description of the registers, their associated bits and their accessibility is shown below the summary and detailed figures of each component.

In each of the figures below, a cell that contains '-' means reserved. Same behavior as the reserved bits for registers in **Section 23.4.2**.

23.3.17.2 RSCFDnCFDRMBCPbm — Receive Message Buffer Component bm

Access: This register is a read-only register that can be read in 32-bit units.

Address: Refer to **Table 23.106**

Value after reset: 0000 0000$_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	Rc[31:16]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	Rc[15:0]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 23.107 RSCFDnCFDRMBCPbm Register Contents

Bit Position	Bit Name	Function
31 to 0	Rc[31:0]	RX Message Buffer Component c Refer to **Table 23.108**, **Table 23.109** and the descriptions that follow for a detailed description of each register and its related bits, contained within this message buffer component.

Below is an example to calculate index for U2A16:

(no_of_channels = 8)

(b = RX Message Buffer Component index = [0…no_of_RSCFDnCFDRMBCPs_per_channel-1])
(no_of_RSCFDnCFDRMBCPs_per_channel = No. of RX Message Buffer Components per Channel = 16)

Where the total number of RSCFDnCFDRMBCPs = no_of_RSCFDnCFDRMBCPs_per_channel * no_of_channels = 16 * 8 = 128

as shown in **Section 23.7, FIFO Buffers & Normal MB Configuration**.

(c = RX Message Buffer Component Register index = [0…no_of_REGs_per_RSCFDnCFDRMBCP-1]).

(no_of_REGs_per_RSCFDnCFDRMBCP = No. of Registers per RX Message Buffer Component =19).

RSCFDnCFDRMBCPbm.Rc[31:0]

RX Message Buffer Component c

The RX Message Buffer Component is made up of the following registers: RSCFDnCFDRMID, RSCFDnCFDRMPTR, RSCFDnCFDRMFDSTS, and RSCFDnCFDRMDFd. Refer to **Table 23.109** for details of how to interpret the structure of this buffer component and how to access the respective registers.

Table 23.108 RX Message Buffer Component Summary

23.3.17.3 RSCFDnCFDRMID — Receive Message Buffer ID Register

Access: This register is a read-only register that can be read in 32-bit units.

Address: Refer to **Table 23.106**

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	RMIDE	RMRTR	—	RMID[28:16]

R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 23.110 RSCFDnCFDRMID Register Contents

Bit Position	Bit Name	Function
31	RMIDE	RX Message Buffer IDE Bit 0_B: STD-ID is stored 1_B: EXT-ID is stored
30	RMRTR	RX Message Buffer RTR 0: Data Frame 1: Remote Frame
29	Reserved	When read, the value after reset is read.
28 to 0	RMID[28:0]	RX Message Buffer ID Field STD-ID / EXT-ID fields

The RX Message Buffer ID register stores the ID field, IDE bit and RTR bit of the received message.

RSCFDnCFDRMID.RMIDE

RX Message Buffer IDE Bit.

This bit shows whether message with Standard Identifier or Extended Identifier was stored in the RX Message Buffer.

RSCFDnCFDRMID.RMRTR

RX Message Buffer RTR Bit.

This bit shows whether a Data Frame or a Remote Frame was stored in the RX Message Buffer.

NOTE

There are no remote frames in CANFD format. In case a CANFD frame was received the register reflects the state of the received value (RRS bit in FD frame format).

RSCFDnCFDRMID.RMID[28:0]

RX Message Buffer ID Field.

These are the bits of the STD-ID / EXT-ID fields of the message stored in the RX Message Buffer. For alignment of these bits in standard and extended frame format, see **Section 23.4.3, Global Mode – Channel Mode transition interactions**.

Refer to **Section 23.3.17.1, Start Addresses** for details of how to interpret the structure of this buffer component.

23.3.17.4 RSCFDnCFDRMPTR — Receive Message Buffer Pointer Register

Access: This register is a read-only register that can be read in 32-bit units.

Address: Refer to **Table 23.106**

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	RMDLC[3:0]				—	—	—	—	—	—	—	—	—	—	—	—

	RMTS[15:0]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 23.111 RSCFDnCFDRMPTR Register Contents

Bit Position	Bit Name	Function
31 to 28	RMDLC[3:0]	RX Message Buffer DLC Field No. of Data Bytes received in a CAN Frame
27 to 16	Reserved	When read, the value after reset is read.
15 to 0	RMTS[15:0]	RX Message Buffer Timestamp Field Timestamp value stored for the message stored in the RX Message Buffer

The RX Message Buffer Pointer register stores the DLC and Timestamp fields for the received message.

RSCFDnCFDRMPTR.RMDLC[3:0]

RX Message Buffer DLC Field.

The number of Data Bytes that were received in the RX Message Buffer is stored in these bits.

Refer to Table 5 in ISO 11898-1 (2015) Specification for details defining the number of Data Bytes that were received.

NOTE

The max. capacity of the buffer belongs to the RSCFDnCFDRMNB.RMPLS.

RSCFDnCFDRMPTR.RMTS[15:0]

RX Message Buffer Timestamp Field

The Timestamp value taken at the capture point as configured by RSCFDnCFDGFDCFG.TSCCFG of the received message is stored in these bits.

23.3.17.5 RSCFDnCFDRMFDSTS — Receive Message Buffer CANFD Status Register

Access: This register is a read-only register that can be read in 32-bit units.

Address: Refer to **Table 23.106**

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	RMPTR[15:0]

Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 23.112 RSCFDnCFDRMFDSTS Register Contents

Bit Position	Bit Name	Function
31 to 16	RMPTR[15:0]	RX Message Buffer Pointer Field RX Message Buffer Pointer
15 to 10	Reserved	When read, the value after reset is read.
9, 8	RMIFL[1:0]	RX Message Buffer Information label Field RX Message Buffer Information Label
7 to 3	Reserved	When read, the value after reset is read.
2	RMFDF	CANFD Format bit 0: Non CANFD frame received 1: CANFD frame received
1	RMBRS	Bit Rate Switch bit 0: CANFD frame received with no bit rate switch 1: CANFD frame received with bit rate switch
0	RMESI	Error State Indicator bit 0: CANFD frame received from error active node 1: CANFD frame received from error passive node

The RX Message Buffer CANFD Status register shows the status of the FDF, BRS and ESI bits, Pointer of the received CANFD frame.

RSCFDnCFDRMFDSTS.RMPTR[15:0]

RX Message Buffer Pointer Field.

The Pointer value from the related Global Acceptance Filter List entry is stored in these bits.

RSCFDnCFDRMFDSTS.RMIFL[1:0]

RX Message Buffer Information label Field.

The Information Label value from the related Global Acceptance Filter List entry is stored in these bits.

RSCFDnCFDRMFDSTS.RMFDF

CANFD Format bit.

This bit is the same value as the FDF bit of the received CANFD frame.

RSCFDnCFDRMFDSTS.RMBRS

Bit Rate Switch bit.

This bit is the same value as the BRS bit of the received CANFD frame.

When the received FDF bit is 0_B, means a CAN2.0 frame is received, 0_B is always stored to this bit.

RSCFDnCFDRMFDSTS.RMESI

Error State Indicator bit.

This bit is the same value as the ESI bit of the received CANFD frame.

When the received FDF bit is 0_B, means a CAN2.0 frame is received, 0_B is always stored to this bit.

23.3.17.6 RSCFDnCFDRMDFd — Receive Message Buffer Data Field d Register

Access: This register is a read-only register that can be read in 32-bit units.

Address: Refer to **Table 23.106**

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	RMDB(d*q) + (q-1)[7:0]								RMDB(d*q) + (q-2)[7:0]							
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	RMDB(d*q) + (q-3)[7:0]								RMDB(d*q) + (q-4)[7:0]							
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 23.113 RSCFDnCFDRMDFd Register Contents

Bit Position	Bit Name	Function
31 to 24	RMDB(d*q) + (q-1) [7:0]	RX Message Buffer Data Byte (d*q) + (q-1)
23 to 16	RMDB(d*q) + (q-2) [7:0]	RX Message Buffer Data Byte (d*q) + (q-2)
15 to 8	RMDB(d*q) + (q-3) [7:0]	RX Message Buffer Data Byte (d*q) + (q-3)
7 to 0	RMDB(d*q) + (q-4) [7:0]	RX Message Buffer Data Byte (d*q) + (q-4)

RSCFDnCFDRMDFd.RMDB(d*q) + (q-1)[7:0]

RX Message Buffer Data Byte (d*q) + (q-1)

Data Byte (d*q) + (q-1) of the Message stored in the RX Message Buffer. Unused Data Bytes will be filled with 0_H.

RSCFDnCFDRMDFd.RMDB(d*q) + (q-2)[7:0]

RX Message Buffer Data Byte (d*q) + (q-2)

Data Byte (d*q) + (q-2) of the Message stored in the RX Message Buffer. Unused Data Bytes will be filled with 0_H.

RSCFDnCFDRMDFd.RMDB(d*q) + (q-3)[7:0]

RX Message Buffer Data Byte (d*q) + (q-3)

Data Byte (d*q) + (q-3) of the Message stored in the RX Message Buffer. Unused Data Bytes will be filled with 0_H.

RSCFDnCFDRMDFd.RMDB(d*q) + (q-4)[7:0]

RX Message Buffer Data Byte (d*q) + (q-4)

Data Byte (d*q) + (q-4) of the Message stored in the RX Message Buffer. Unused Data Bytes will be filled with 0_H.

23.3.17.7 RSCFDnCFDRFMBCPb — Receive FIFO Access Message Buffer Component b

Access: This register is a read-only register that can be read in 32-bit units.

Address: Refer to **Table 23.106**

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	Rc[31:16]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	Rc[15:0]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 23.114 RSCFDnCFDRFMBCPb Register Contents

Bit Position	Bit Name	Function
31 to 0	Rc[31:0]	RX FIFO Access Message Buffer Component c Refer to **Table 23.115**, **Table 23.116** and the descriptions that follow for a detailed description of each register and its related bits, contained within this message buffer component.

Below is an example to calculate index for U2A16:
(no_of_channels = 8)
(b = RX FIFO Access Message Buffer Component index = [0…no_of_RSCFDnCFDRFMBCPs-1])
(no_of_RSCFDnCFDRFMBCPs = No. of RX FIFO Access Message Buffer Components = 8) as shown in **Section 23.7, FIFO Buffers & Normal MB Configuration** (c = RX FIFO Access Message Buffer Component Register index = [0…no_of_REGs_per_RSCFDnCFDRFMBCP-1])
no_of_REGs_per_RSCFDnCFDRFMBCP = No. of Registers per RX FIFO Access Message Buffer Component = 19

RSCFDnCFDRFMBCPb.Rc[31:0]

RX FIFO Access Message Buffer Component c.

The RX FIFO Access Message Buffer Component is made up of the following registers: RSCFDnCFDRFID, RSCFDnCFDRFPTR, RSCFDnCFDRFFDSTS, and RSCFDnCFDRFDFd. Refer to **Table 23.116, RX FIFO Access Message Buffer Component Detailed** for details of how to interpret the structure of this buffer component and how to access the respective registers.

Table 23.115 RX FIFO Access Message Buffer Component Summary

23.3.17.8 RSCFDnCFDRFID — Receive FIFO Access ID Register

Access: This register is a read-only register that can be read in 32-bit units.

Address: Refer to **Table 23.106**

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	RFIDE	RFRTR	—	RFID[28:16]												
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 23.117 RSCFDnCFDRFID Register Contents

Bit Position	Bit Name	Function
31	RFIDE	RX FIFO Buffer IDE Bit 0_B: STD-ID has been received 1_B: EXT-ID has been received
30	RFRTR	RX FIFO Buffer RTR Bit 0_B: Data Frame 1_B: Remote Frame
29	Reserved	When read, the value after reset is read.
28 to 0	RFID[28:0]	RX FIFO Buffer ID Field STD-ID / EXT-ID fields

The RX FIFO Access ID registers stores the ID field, IDE bit and RTR bit of the message.

RSCFDnCFDRFID.RFID[28:0]

RX FIFO Buffer ID Field.

These are the bits of the STD-ID / EXT-ID fields of the message in the FIFO Buffer. For alignment of these bits in standard and extended frame format, see **Section 23.4.3, Global Mode – Channel Mode transition interactions**.

RSCFDnCFDRFID.RFRTR

RX FIFO Buffer RTR Bit.

This bit shows whether a Data Frame or a Remote Frame was stored in the FIFO Buffer.

NOTE

There are no remote frames in CANFD format. In case a CANFD frame was received the register reflects the state of the received value (RRS bit in FD frame format).

RSCFDnCFDRFID.RFIDE

RX FIFO Buffer IDE Bit.

This bit shows whether message with Standard Identifier or Extended Identifier was received in the FIFO Buffer.

23.3.17.9 RSCFDnCFDRFPTR — Receive FIFO Access Pointer Register

Access: This register is a read-only register that can be read in 32-bit units.

Address: Refer to **Table 23.106**

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	RFDLC[3:0]				—	—	—	—	—	—	—	—	—	—	—	—

R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 23.118 RSCFDnCFDRFPTR Register Contents

Bit Position	Bit Name	Function
31 to 28	RFDLC	RX FIFO Buffer DLC Field No. of Data Bytes received in a CAN Frame
27 to 16	Reserved	When read, the value after reset is read.
15 to 0	RFTS	RX FIFO Timestamp Value Timestamp value of the received CAN Frame

The FIFO Access Pointer registers store the DLC & Timestamp fields for the received message.

RSCFDnCFDRFPTR.RFDLC

RX FIFO Buffer DLC Field.

The number of Data Bytes that were received in the RX FIFO Buffer is stored in these bits.

Refer to Table 5 in ISO 11898-1 (2015) Specification for details defining the number of Data Bytes that were received.

RSCFDnCFDRFPTR.RFTS

RX FIFO Timestamp Value.

The Timestamp value taken at the capture point as configured by RSCFDnCFDGFDCFG.TSCCFG of the received message is stored in these bits.

23.3.17.10 RSCFDnCFDRFFDSTS — Receive FIFO Access CANFD Status Register

Access: This register is a read-only register that can be read in 32-bit units.

Address: Refer to **Table 23.106**

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 23.119 RSCFDnCFDRFFDSTS Register Contents

Bit Position	Bit Name	Function
31 to 16	CFDRFPTR [15:0]	RX FIFO Buffer Pointer Field FIFO Buffer Pointer
15 to 10	Reserved	When read, the value after reset is read.
9, 8	RFIFL[1:0]	RX FIFO Buffer Information label Field RX FIFO Buffer Information Label
7 to 3	Reserved	When read, the value after reset is read.
2	RFFDF	CANFD Format bit 0_B: Non CANFD frame received 1_B: CANFD frame received
1	RFBRS	Bit Rate Switch bit 0: CANFD frame received with no bit rate switch 1: CANFD frame received with bit rate switch
0	RFESI	Error State Indicator bit 0: CANFD frame received from error active node 1: CANFD frame received from error passive node

The RX FIFO Access CANFD Status register shows the status of the FDF, BRS and ESI bits, Pointer of the received CANFD frame.

RSCFDnCFDRFFDSTS.CFDRFPTR[15:0]

RX FIFO Buffer Pointer Field

The Pointer value from the related Global Acceptance Filter List entry is stored in these bits.

RSCFDnCFDRFFDSTS.RFIFL[1:0]

RX FIFO Buffer Information Label Field.

The Information label value from the related Global Acceptance Filter List entry is stored in these bits.

RSCFDnCFDRFFDSTS.RFFDF

CANFD Format bit.

This bit is the same value as the FDF bit of the received CANFD frame.

RSCFDnCFDRFFDSTS.RFBRS

Bit Rate Switch bit.

This bit is the same value as the BRS bit of the received CANFD frame.

When the received FDF bit is 0_B, means a CAN2.0 frame is received, 0_B is always stored to this bit.

RSCFDnCFDRFFDSTS.RFESI

Error State Indicator bit.

This bit is the same value as the ESI bit of the received CANFD frame.

When the received FDF bit is 0_B, means a CAN2.0 frame is received, 0_B is always stored to this bit.

23.3.17.11 RSCFDnCFDRFDFd — Receive FIFO Access Data Field d Register

Access: This register is a read-only register that can be read in 32-bit units.

Address: Refer to **Table 23.106**

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	RFDB(d*q) + (q-1)[7:0]								RFDB(d*q) + (q-2)7:0]							
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	RFDB(d*q) + (q-3)[7:0]								RFDB(d*q) + (q-4)[7:0]							
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 23.120 RSCFDnCFDRFDFd Register Contents

Bit Position	Bit Name	Function
31 to 24	RFDB(d*q) + (q-1) [7:0]	FIFO Buffer Data Byte (d*q) + (q-1)
23 to 16	RFDB(d*q) + (q-2) [7:0]	FIFO Buffer Data Byte (d*q) + (q-2)
15 to 8	RFDB(d*q) + (q-3) [7:0]	FIFO Buffer Data Byte (d*q) + (q-3)
7 to 0	RFDB(d*q) + (q-4) [7:0]	FIFO Buffer Data Byte (d*q) + (q-4)

RSCFDnCFDRFDFd.RFDB(d*q) + (q-1)[7:0]

RX FIFO Buffer Data Byte (d*q) + (q-1).

Data Byte (d*q) + (q-1) of the Message present in the FIFO Buffer.

Unused Data Bytes will be filled with 0_H.

RSCFDnCFDRFDFd.RFDB(d*q) + (q-2)[7:0]

RX FIFO Buffer Data Byte (d*q) + (q-2).

Data Byte (d*q) + (q-2) of the Message present in the FIFO Buffer. Unused Data Bytes will be filled with 0_H.

RSCFDnCFDRFDFd.RFDB(d*q) + (q-3)[7:0]

RX FIFO Buffer Data Byte (d*q) + (q-3).

Data Byte (d*q) + (q-3) of the Message present in the FIFO Buffer. Unused Data Bytes will be filled with 0_H.

RSCFDnCFDRFDFd.RFDB(d*q) + (q-4)[7:0]

RX FIFO Buffer Data Byte (d*q) + (q-4).

Data Byte (d*q) + (q-4) of the Message present in the FIFO Buffer.

Unused Data Bytes will be filled with 0_H, according to there configured data payload size RSCFDnCFDRFCCx.RFPLS.

23.3.17.12 RSCFDnCFDCFMBCPbm — Transmit/Receive FIFO Access Message Buffer Component bm

Access: This register is a read-only register that can be read in 32-bit units.

Address: Refer to **Table 23.106**

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	Rc[31:16]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	Rc[15:0]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 23.121 RSCFDnCFDCFMBCPbm Register Contents

Bit Position	Bit Name	Function
31 to 0	Rc[31:0]	Transmit/Receive FIFO Access Message Buffer Component c Refer to **Table 23.122**, **Table 23.123** and the descriptions that follow for a detailed description of each register and its related bits, contained within this message buffer component.

Below is an example to calculate index for U2A16:
(no_of_channels = 8)
(b = Transmit/Receive FIFO Message Buffer Component index = [0…no_of_RSCFDnCFDCFMBCPs_per_channel-1]) (no_of_RSCFDnCFDCFMBCPs_per_channel = No. of Transmit/Receive FIFO Message Buffer Components per Channel = 3) Where the total number of RSCFDnCFDCFMBCPs = no_of_RSCFDnCFDCFMBCPs_per_channel * no_of_channels = 3 * 8 = 24

as shown in **Figure 23.27**

(c = Transmit/Receive FIFO Message Buffer Component Register index = [0…no_of_REGs_per_RSCFDnCFDCFMBCP-1]) no_of_REGs_per_RSCFDnCFDCFMBCP = No. of Register per Transmit/Receive FIFO Message Buffer Component = 19

RSCFDnCFDCFMBCPbm.Rc[31:0]

Transmit/Receive FIFO Access Message Buffer Component c.

The Transmit/Receive FIFO Access Message Buffer Component is made up of the following registers: RSCFDnCFDCFID, RSCFDnCFDCFPTR, CFFDSTS, and RSCFDnCFDCFDFd. Refer to **Table 23.123** for details of how to interpret the structure of this buffer component and how to access the respective registers.

Table 23.124 RSCFDnCFDCFID Register Contents

Bit Position	Bit Name	Function
31	CFIDE	Transmit/Receive FIFO Buffer IDE Bit 0_B: STD-ID will be transmitted or has been received 1_B: EXT-ID will be transmitted or has been received
30	CFRTR	Transmit/Receive FIFO Buffer RTR Bit 0_B: Data Frame 1_B: Remote Frame
29	THLEN	THL Entry enable TX FIFO Mode: 0_B: Entry will not be stored in THL after successful TX. 1_B: Entry will be stored in THL after successful TX. RX FIFO Mode: Reserved, this bit is read as 0
28 to 0	CFID[28:0]	Transmit/Receive FIFO Buffer ID Field STD-ID / EXT-ID fields

The Transmit/Receive FIFO Access ID registers store the ID field, IDE bit and RTR bit of the message.

In TX mode, users can read data from the FIFO, only for the current entry based on the write pointer value, not for the other entries.

RSCFDnCFDCFID.CFIDE

Transmit/Receive FIFO Buffer IDE Bit.

This bit selects whether a message with EXT-ID or STD-ID will be transmitted from or was received in the FIFO Buffer.

In TX mode, users can write and read from FIFO buffers.

In RX mode, users can only read data from FIFO buffers. In GW mode, users cannot write data to the FIFO buffers.

RSCFDnCFDCFID.CFRTR

Transmit/Receive FIFO Buffer RTR Bit.

This bit selects whether a Data Frame or a Remote Frame will be transmitted from or was received in the FIFO Buffer.

NOTE

There are no remote frames in CANFD format. In case a CANFD frame was received (RX mode) the register reflects the state of the received value (RRS bit in FD frame format). In case of CANFD transmission (TX or GW mode RSCFDnCFDCFID.CFFDF = 1_B) the bit is always transmitted dominant (Data Frame).

In TX mode, users can write and read from FIFO buffers.

In RX mode, users can only read data from FIFO buffers. In GW mode, users cannot write data to the FIFO buffers.

RSCFDnCFDCFID.THLEN

THL Entry enable.

This bit controls the storage of an entry corresponding to the transmitted message in the TX History list at the end of a successful transmission.

In TX mode, users can write and read from FIFO buffers.

In RX mode, users can only read data from FIFO buffers.

In GW mode, users cannot write data to the FIFO buffers.

RSCFDnCFDCFID.CFID[28:0]

Transmit/Receive FIFO Buffer ID Field.

These are the bits of the STD-ID / EXT-ID fields of the message in the FIFO Buffer. For alignment of these bits in standard and extended frame format, see **Section 23.4.3, Global Mode – Channel Mode transition interactions**.

In TX mode, users can write and read from FIFO buffers.

In RX mode, users can only read data from FIFO buffers.

In GW mode, users cannot write data to the FIFO buffers.

23.3.17.14 RSCFDnCFDCFPTR — Transmit/Receive FIFO Access Pointer Register

Access: This register can be read or written in 32-bit units.

Address: Refer to **Table 23.106**

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	CFDLC[3:0]				—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 23.125 RSCFDnCFDCFPTR Register Contents

Bit Position	Bit Name	Function
31 to 28	CFDLC[3:0]	Transmit/Receive FIFO Buffer DLC Field No. of Data Bytes received in a CAN Frame, or to be transmitted in a CAN Frame
27 to 16	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
15 to 0	CFTS[15:0]	Transmit/Receive FIFO Timestamp Value Timestamp value of the received CAN Frame (FIFO in RX Mode)

The Transmit/Receive FIFO Access Pointer registers store the DLC and Timestamp fields.

In TX mode, users can read data from the FIFO, only for the current entry based on the write pointer value, not for the other entries.

RSCFDnCFDCFPTR.CFDLC[3:0]

Transmit/Receive FIFO Buffer DLC Field.

The number of Data Bytes that were received in the FIFO Buffer or are to be transmitted, is stored in these bits.

Refer to Table 5 in ISO 11898-1 (2015) Specification for details defining the number of Data Bytes In TX mode, users can write and read from FIFO buffers.

In RX mode, users can only read data from FIFO buffers. In GW mode, users cannot write data to the FIFO buffers.

Users cannot read data for the other entries in the FIFO when configured in TX mode.

RSCFDnCFDCFPTR.CFTS

Transmit/Receive FIFO Timestamp Value.

The Timestamp value taken at the capture point as configured by RSCFDnCFDGFDCFG.TSCCFG of the received message is stored in these bits (if FIFO is configured in RX mode).

In TX mode, users can write and read from FIFO buffers.

In RX mode, users can only read data from FIFO buffers. In GW mode, users cannot write data to the FIFO buffers.

23.3.17.15 RSCFDnCFDCFFDCSTS — Transmit/Receive FIFO Access CANFD Control/ Status Register

Access: This register can be read or written in 32-bit units.

Address: Refer to **Table 23.106**

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

9, 8	CFIFL[1:0]	Transmit/Receive FIFO Buffer Information label Field Transmit/Receive FIFO Buffer Information Label
7 to 3	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
2	CFFDF	CANFD Format bit 0_B: Non CANFD frame received or to transmit 1_B: CANFD frame received or to transmit
1	CFBRS	Bit Rate Switch bit 0_B: CANFD frame received or to transmit with no bit rate switch 1_B: CANFD frame received or to transmit with bit rate switch
0	CFESI	Error State Indicator bit 0_B: CANFD frame received from or to transmit by error active node 1_B: CANFD frame received from or to transmit by error passive node

The Transmit/Receive FIFO Access CANFD Status register shows the status of the FDF, BRS and ESI bits, Pointer of the received CANFD frame or the CANFD frame to transmit.

In TX mode, users can read data from the FIFO, only for the current entry based on the write pointer value, not for the other entries.

RSCFDnCFDCFFDCSTS.CFPTR[15:0]

Transmit/Receive FIFO Buffer Pointer Field

If the Transmit/Receive FIFO is configured in TX Mode, the value programmed in RSCFDnCFDCFFDCSTS.CFPTR[15:0] will be stored together with further message information, to the TX History List after successful transmission of the message.

The Pointer value from the related Global Acceptance Filter List entry is stored in these bits (if FIFO is configured in either RX or GW mode).

In TX mode, users can write and read from FIFO buffers. In RX mode, users can only read data from FIFO buffers. In GW mode, users cannot write data to the FIFO buffers.

RSCFDnCFDCFFDCSTS.CFIFL[1:0]

Transmit/Receive FIFO Buffer Information Label Field

If the Transmit/Receive FIFO is configured in TX Mode, the value programmed in RSCFDnCFDCFFDCSTS.CFIFL[1:0] will be stored together with further message information, to the TX History List after successful transmission of the message.

The Information label value from the related Global Acceptance Filter List entry is stored in these bits (if FIFO is configured in either RX or GW mode).

In TX mode, users can write and read from FIFO buffers. In RX mode, users can only read data from FIFO buffers. In GW mode, users cannot write data to the FIFO buffers.

RSCFDnCFDCFFDCSTS.CFFDF

CANFD Format bit

In TX mode, users can write and read from FIFO buffers.

In RX mode, users can only read data from FIFO buffers. In GW mode, users cannot write data to the FIFO buffers.

In RX or GW mode, this bit is updated with the FDF bit value of the CAN frame when it has been received, indicating whether it is a CAN 2.0 frame (0_B) or a CANFD frame (1_B).

In TX mode, the RS-CANFD module will either transmit a 0_B to indicate a CAN 2.0 frame is to be transmitted or a 1_B to indicate a CANFD frame is to be transmitted.

RSCFDnCFDCFFDCSTS.CFBRS

Bit Rate Switch bit

In TX mode, users can write and read from FIFO buffers.

In RX mode, users can only read data from FIFO buffers. In GW mode, users cannot write data to the FIFO buffers.

In RX or GW mode, this bit is updated with the BRS bit value of the CANFD frame when it has been received, indicating whether there is a bit rate switch (1_B) or not (0_B) on the CANFD frame.

In RX or GW mode 0_B is stored to this bit when the received FDF bit is 0_B, means a CAN 2.0 frame is received.

In TX mode, the RS-CANFD module will either transmit a 0_B to indicate no bit rate switch in the frame to be transmitted or a 1_B to indicate a bit rate switch in the frame to be transmitted.

RSCFDnCFDCFFDCSTS.CFESI

Error State Indicator bit.

In TX mode, users can write and read from FIFO buffers.

In RX mode, users can only read data from FIFO buffers. In GW mode, users cannot write data to the FIFO buffers.

In RX or GW mode, this bit is updated with the ESI bit value of the CANFD frame when it has been received, indicating the error state of the transmitting node.

In RX or GW mode 0_B is stored to this bit when the received FDF bit is 0_B, means a CAN 2.0 frame is received.

In TX mode, if the RS-CANFD module is not in error passive, then this bit equals the write value, else it is don’t care and the bit is transmitted as 1_B on the CAN bus; indicating that this is an error passive node.

23.3.17.16 RSCFDnCFDCFDFd — Transmit/Receive FIFO Access Data Field d Register

Access: This register can be read or written in 32-bit units.

Address: Refer to **Table 23.106**

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	CFDB(d*q) + (q-1)[7:0]								CFDB(d*q) + (q-2)[7:0]							
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	CFDB(d*q) + (q-3)[7:0]								CFDB(d*q) + (q-4)[7:0]							
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 23.127 RSCFDnCFDCFDFd Register Contents

Bit Position	Bit Name	Function
31 to 24	CFDB(d*q) + (q-1) [7:0]	Transmit/Receive FIFO Buffer Data Byte (d*q) + (q-1) FIFO Buffer Data Byte (d*q) + (q-1)
23 to 16	CFDB(d*q) + (q-2) [7:0]	Transmit/Receive FIFO Buffer Data Byte (d*q) + (q-2) FIFO Buffer Data Byte (d*q) + (q-2)
15 to 8	CFDB(d*q) + (q-3) [7:0]	Transmit/Receive FIFO Buffer Data Byte (d*q) + (q-3) FIFO Buffer Data Byte (d*q) + (q-3)
7 to 0	CFDB(d*q) + (q-4) [7:0]	Transmit/Receive FIFO Buffer Data Byte (d*q) + (q-4) FIFO Buffer Data Byte (d*q) + (q-4)

In TX mode, users can read data from the FIFO, only for the current entry based on the write pointer value, not for the other entries.

RSCFDnCFDCFDFd.CFDB(d*q) + (q-1)[7:0]

Transmit/Receive FIFO Buffer Data Byte (d*q) + (q-1).

Data Byte (d*q) + (q-1)of the Message present in the FIFO Buffer. In TX mode, users can write and read from FIFO buffers.

In RX mode, users can only read data from FIFO buffers. In GW mode, users cannot write data to the FIFO buffers.

In RX or GW mode, unused Data Bytes will be filled with 0_H, according to their configured data payload size RSCFDnCFDCFCCk.CFPLS.

RSCFDnCFDCFDFd.CFDB(d*q) + (q-2)[7:0]

Transmit/Receive FIFO Buffer Data Byte (d*q) + (q-2).

Data Byte (d*q) + (q-2) of the Message present in the FIFO Buffer. In TX mode, users can write and read from FIFO buffers.

In RX mode, users can only read data from FIFO buffers. In GW mode, users cannot write data to the FIFO buffers.

In RX or GW mode, unused Data Bytes will be filled with 0_H, according to their configured data payload size RSCFDnCFDCFCCk.CFPLS.

RSCFDnCFDCFDFd.CFDB(d*q) + (q-3)[7:0]

Transmit/Receive FIFO Buffer Data Byte(d*q) + (q-3).

Data Byte (d*q) + (q-3) of the Message present in the FIFO Buffer. In TX mode, users can write and read from FIFO buffers.

In RX mode, users can only read data from FIFO buffers. In GW mode, users cannot write data to the FIFO buffers.

In RX or GW mode, unused Data Bytes will be filled with 0_H, according to their configured data payload size RSCFDnCFDCFCCk.CFPLS.

RSCFDnCFDCFDFd.CFDB(d*q) + (q-4)[7:0]

Transmit/Receive FIFO Buffer Data Byte (d*q) + (q-4).

Data Byte (d*q) + (q-4) of the Message present in the FIFO Buffer. In TX mode, users can write and read from FIFO buffers.

In RX mode, users can only read data from FIFO buffers. In GW mode, users cannot write data to the FIFO buffers.

In RX or GW mode, unused Data Bytes will be filled with 0_H, according to their configured data payload size RSCFDnCFDCFCCk.CFPLS.

23.3.17.17 RSCFDnCFDTMBCPbm — Transmit Message Buffer Component bm

Access: This register is a read-only register that can be read in 32-bit units.

Address: Refer to **Table 23.106**

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	Rc[31:16]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 23.128 RSCFDnCFDTMBCPbm Register Contents

Bit Position	Bit Name	Function
31 to 0	Rc[31:0]	TX Message Buffer Component c Refer to **Table 23.129**, **Table 23.130** and the descriptions that follow for a detailed. description of each register and its related bits, contained within this message buffer component.

Below is an example to calculate index for U2A16:

(no_of_channels = 8)

(b = TX Message Buffer Component index = [0…no_of_RSCFDnCFDTMBCPs_per_channel-1]) (no_of_RSCFDnCFDTMBCPs_per_channel = No. of TX Message Buffer Components per Channel = 64)

Where the total number of RSCFDnCFDTMBCPs= no_of_RSCFDnCFDTMBCPs_per_channel * no_of_channels = 64 * 8 = 512

as shown in **Figure 23.28**.

(c = TX Message Buffer Component Register index = [0…no_of_REGs_per_RSCFDnCFDTMBCP-1]) no_of_REGs_per_RSCFDnCFDTMBCP = No. of Register per TX Message Buffer Component = 19

RSCFDnCFDTMBCPbm.Rc[31:0]

TX Message Buffer Component c.

The TX Message Buffer Component is made up of the following registers: RSCFDnCFDTMID, RSCFDnCFDTMPTR, RSCFDnCFDTMFDCTR, and RSCFDnCFDTMDFd. Refer to **Table 23.129** for details of how to interpret the structure of this buffer component and how to access the respective registers.

Table 23.131 RSCFDnCFDTMID Register Contents

Bit Position	Bit Name	Function
31	TMIDE	TX Message Buffer IDE Bit 0_B: STD-ID will be transmitted 1_B: EXT-ID will be transmitted
30	TMRTR	TMRTR TX Message Buffer RTR Bit 0_B: Data Frame 1_B: Remote Frame
29	THLEN	Tx History List Entry 0_B: Entry not stored in THL after successful TX 1_B: Entry stored in THL after successful TX
28 to 0	TMID[28:0]	TX Message Buffer ID Field STD-ID / EXT-ID fields

Each TX Message Buffer ID register is used to store the ID, IDE, RTR fields and history configuration of the message to be transmitted from the associated buffer.

RSCFDnCFDTMID.TMIDE

TX Message Buffer IDE Bit.

This bit selects whether a message with EXT-ID or STD-ID will be transmitted from this TX Message Buffer. Users should not write to these bits when corresponding channel is in CH_STOP.

RSCFDnCFDTMID.TMRTR

TX Message Buffer RTR Bit.

This bit selects whether a Data Frame or a Remote Frame will be transmitted from this TX Message Buffer.

NOTE

There are no remote frames in CANFD format. In case of CANFD transmission(RSCFDnCFDTMFDCTR.CFFDF = 1_B) the bit is always transmitted dominant (Data Frame).

Users should not write to these bits when corresponding channel is in CH_STOP.

RSCFDnCFDTMID.THLEN

Tx History List Entry.

This bit controls the storage of an entry corresponding to the transmitted message in the TX History list at the end of a successful transmission.

Users should not write to these bits when corresponding channel is in CH_STOP.

RSCFDnCFDTMID.TMID[28:0]

TX Message Buffer ID Field.

These are the bits of the STD-ID / EXT-ID fields of the message stored in this TX MB. For alignment of these bits in standard and extended frame format, see **Section 23.4.3, Global Mode – Channel Mode transition interactions**.

Users should not write to these bits when corresponding channel is in CH_STOP.

23.3.17.19 RSCFDnCFDTMPTR — Transmit Message Buffer Pointer Register

Access: This register can be read or written in 32-bit units.

Address: Refer to **Table 23.106**

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 23.132 RSCFDnCFDTMPTR Register Contents

Bit Position	Bit Name	Function
31 to 28	TMDLC[3:0]	TX Message Buffer DLC Field No. of Data Bytes to be transmitted in a CAN Frame
27 to 0	Reserved	When read, the value after reset is read. When writing, write the value after reset.

Each TX Message Buffer Pointer register is used to store the DLC fields of the message to transmit from the associated buffer.

RSCFDnCFDTMPTR.TMDLC[3:0]

TX Message Buffer DLC Field

These bits select the number of Data Bytes that will be transmitted from this TX Message Buffer if corresponding TMRTR bit is configured as 0_B.

Refer to Table 5 in ISO 11898-1 (2015) Specification for details defining the number of Data Bytes that will be transmitted.

Users should not write to these bits when corresponding channel is in CH_STOP.

23.3.17.20 RSCFDnCFDTMFDCTR — Transmit Message Buffer CANFD Control Register

Access: This register can be read or written in 32-bit units.

Address: Refer to **Table 23.106**

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R/W	R	R	R	R	R	R	R/W	R/W	R	R	R	R	R	R/W	R/W	R/W

Table 23.133 RSCFDnCFDTMFDCTR Register Contents

Bit Position	Bit Name	Function
31 to 16	TMPTR[15:0]	TX Message Buffer Pointer Field TX Message Buffer Pointer
15 to 10	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
9, 8	TMIFL[1:0]	TMIFL TX Message Buffer Information Label Field TX Message Buffer Information Label
7 to 3	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
2	TMFDF	CANFD Format bit 0_B: Non CANFD frame to transmit 1_B: CANFD frame to transmit
1	TMBRS	Bit Rate Switch bit 0_B: CANFD frame to transmit with no bit rate switch 1_B: CANFD frame to transmit with bit rate switch
0	TMESI	Error State Indicator bit 0_B: CANFD frame to transmit by error active node 1_B: CANFD frame to transmit by error passive node

The TX Message Buffer CANFD Control register shows the status of the FDF, BRS and ESI bits and Pointer fields of the CANFD frame to be transmitted.

RSCFDnCFDTMFDCTR.TMPTR[15:0]

TX Message Buffer Pointer Field.

The Pointer value is stored in these bits. It will be copied, together with further message information, in the TX History List after successful transmission of the message.

Users should not write to these bits when corresponding channel is in CH_STOP.

RSCFDnCFDTMFDCTR.TMIFL[1:0]

TX Message Buffer Information label Field.

The Information label value is stored in these bits. It will be copied, together with further message information, in the TX History List after successful transmission of the message.

Users should not write to these bits when corresponding channel is in CH_STOP.

RSCFDnCFDTMFDCTR.TMFDF

CANFD Format bit.

Users should not write to these bits when corresponding channel is in CH_STOP.

RSCFDnCFDTMFDCTR.TMBRS

Bit Rate Switch bit.

Users should not write to these bits when corresponding channel is in CH_STOP.

RSCFDnCFDTMFDCTR.TMESI

Error State Indicator bit.

If the channel is not in error passive, then this bit equals the write value, else it is don't care and the bit is transmitted as 1_B on the CAN bus; indicating that this is an error passive node.

Users should not write to these bits when corresponding channel is in CH_STOP.

23.3.17.21 RSCFDnCFDTMDFd — Transmit Message Buffer Data Field d Register

Access: This register can be read or written in 32-bit units.

Address: Refer to **Table 23.106**

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 23.134 RSCFDnCFDTMDFd Register Contents

Bit Position	Bit Name	Function
31 to 24	TMDB(d*q) + (q-1) [7:0]	TX Message Buffer Data Byte (d*q) + (q-1)
23 to 16	TMDB(d*q) + (q-2) [7:0]	TX Message Buffer Data Byte (d*q) + (q-2)
15 to 8	TMDB(d*q) + (q-3) [7:0]	TX Message Buffer Data Byte (d*q) + (q-3)
7 to 0	TMDB(d*q) + (q-4) [7:0]	TX Message Buffer Data Byte (d*q) + (q-4)

RSCFDnCFDTMDFd.TMDB(d*q) + (q-1)

TX Message Buffer Data Byte (d*q) + (q-1).

Data Byte (d*q) + (q-1) of the Message stored in the TX Message Buffer.

Users should not write to these bits when corresponding channel is in CH_STOP.

RSCFDnCFDTMDFd.TMDB(d*q) + (q-2)

TX Message Buffer Data Byte (d*q) + (q-2).

Data Byte (d*q) + (q-2) of the Message stored in the TX Message Buffer.

Users should not write to these bits when corresponding channel is in CH_STOP.

RSCFDnCFDTMDFd.TMDB(d*q) + (q-3)

TX Message Buffer Data Byte (d*q) + (q-3).

Data Byte (d*q) + (q-3) of the Message stored in the TX Message Buffer.

Users should not write to these bits when corresponding channel is in CH_STOP.

RSCFDnCFDTMDFd.TMDB(d*q) + (q-4)

TX Message Buffer Data Byte (d*q) + (q-4).

Data Byte (d*q) + (q-4) of the Message stored in the TX Message Buffer.

Users should not write to these bits when corresponding channel is in CH_STOP.

23.4 CAN Modes

The RS-CANFD module has four global modes to control entire RS-CANFD module status and four channel modes to control individual channel status. Details of global modes are described in **Section 23.4.1, Global Modes**, and details of channel modes are described in **Section 23.4.2, Channel Modes**.

- Global stop mode: Stops clocks of the entire module to achieve low power consumption.
- Global reset mode: Performs initial settings for the entire module.
- Global test mode: Performs test settings and performs RAM test.
- Global operating mode: Makes the entire module operable.
- Channel stop mode: Stops the channel clock.
- Channel reset mode: Performs initial settings for the channels.
- Channel halt mode: Stops CAN communication and allows channel testing.
- Channel communication mode: Performs CAN communication.

23.4.1 Global Modes

Figure 23.2 shows the transitions of global modes. Refer to **Section 23.4.3.1, Global Mode change timing**.

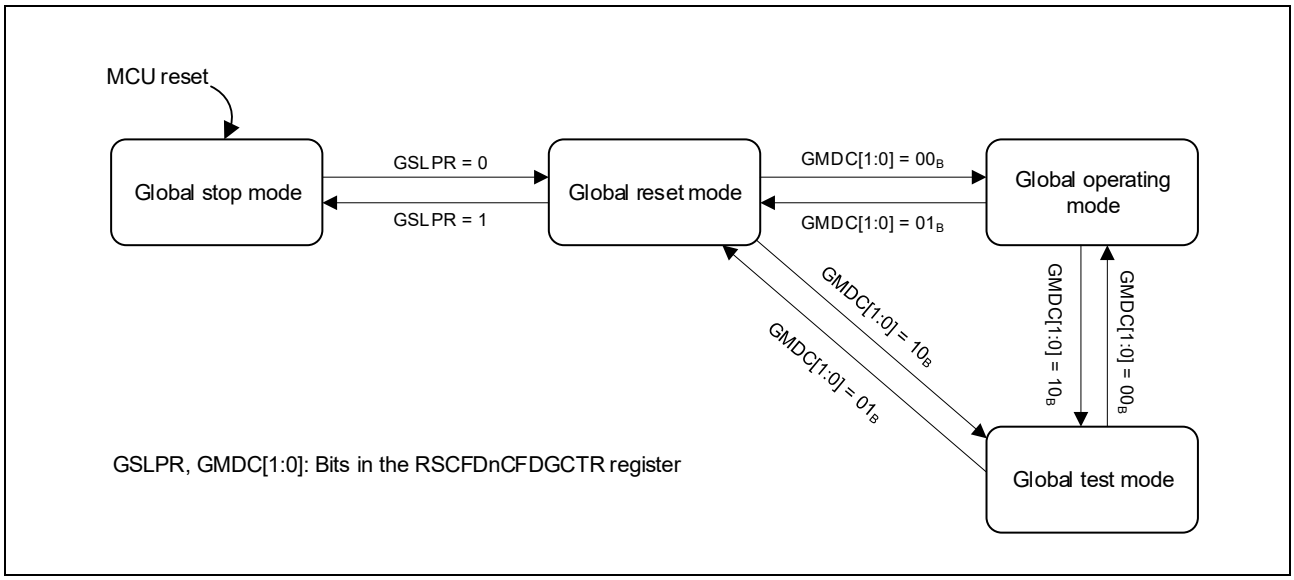

Figure 23.2 Transitions of Global Modes

Table 23.135 Possible CAN channel Modes versus Global Module Modes

Current Global mode \ Target Global mode	Stop	Reset	Test	Operating

23.4.1.1 Global Stop Mode

After the release of the hardware reset or after setting and clearing a RSCFDnCFDGRSTC.SRST bit, the RS-CANFD module automatically enters Global Stop Mode.

The RS-CANFD module will also enter this mode, when the Global Stop Request bit is set while it is in Global Reset Mode.

This control bit cannot be set in Global Test Mode or Global Operating Mode.

Setting the Global Stop Request bit will set all Channel Stop Request bits and force all channels into the Channel Stop Mode.

Stop Mode is used for power saving purpose. When RS-CANFD module is in Global Stop Mode, only the clock for CPU write access to the Global Stop Mode Request bit is active. All other clocks are stopped and all other functions of the RS-CANFD module are suspended.

Read access from all registers is still possible and all register values are preserved.

After setting Global Stop Request bit, it is necessary to confirm that the Global Stop status has been updated indicating successful transition to Global Stop Mode before the Global Stop Request bit can be cleared again.

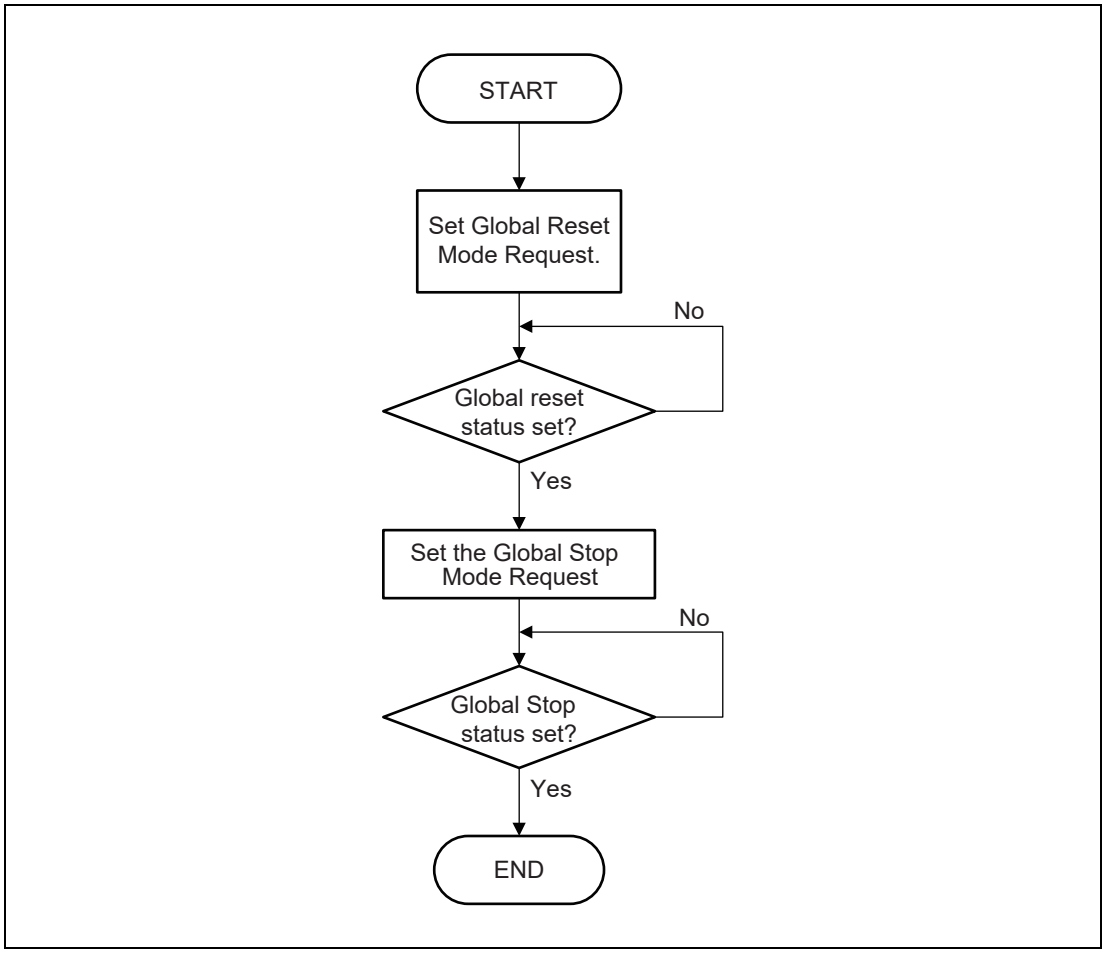

Figure 23.3 Procedure for entering global Stop Mode

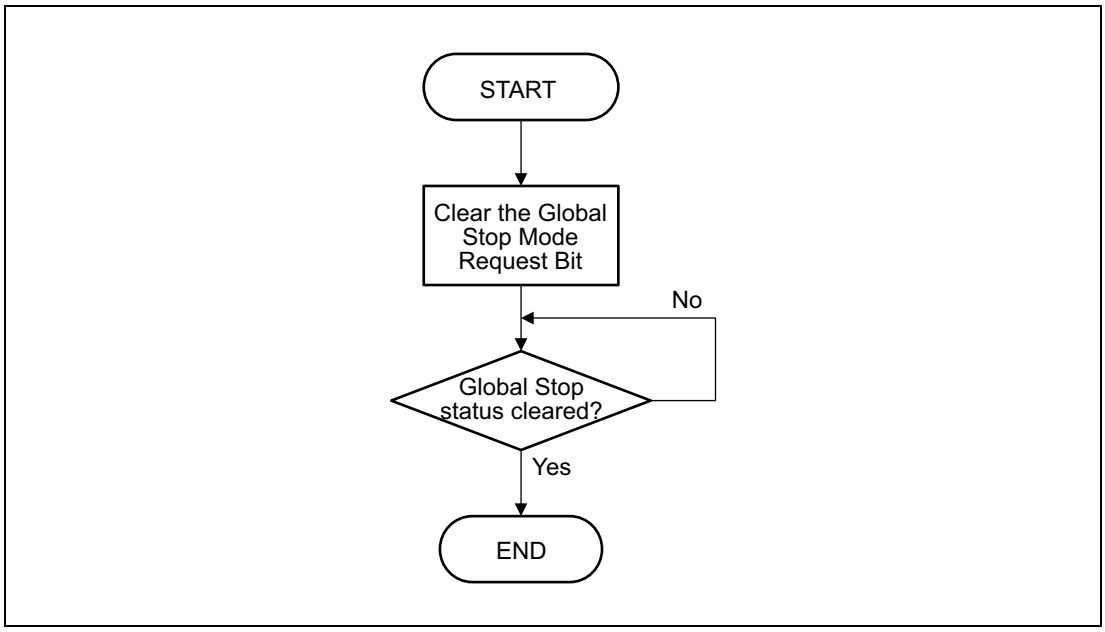

Figure 23.4 Procedure for exiting global Stop Mode

23.4.1.2 Global Reset Mode

The RS-CANFD module enters this mode in the following ways:

Global Mode Control RSCFDnCFDGCTR.GMDC in the Global Control Register is configured for Global Reset Mode while the RS-CANFD module is in Global Test Mode or Global Operating Mode

Global Stop Mode request bit is cleared while RS-CANFD module is in Global Stop Mode

In Global Reset Mode, all RS-CANFD module functions are suspended and all status and flag registers are initialized.

Additionally all FIFOs and all channel TX Queues are disabled and transmission control bits are cleared.

Configuration registers (except the test mode registers) are not initialized in this mode to their MCU Reset values and the RS-CANFD module can be configured.

Refer to **Section 23.4.3, Global Mode – Channel Mode transition interactions** for detailed description of the behavior of all registers when transition to Global Reset Mode is performed.

Setting the global mode to Reset by setting the Global Mode Control bits RSCFDnCFDGCTR.GMDC in the Global Control Register to 01_B will set all Channel Mode Control bits RSCFDnCFDCmCTR.CHMDC in the Channel Control Register to 01_B and force all channels into the Channel Reset Mode.

For channels that are already in Channel Reset Mode or Channel Stop Mode this automatic transition is not performed (RSCFDnCFDCmCTR.CHMDC of related channel already set to 01_B).

After setting Global Mode Control RSCFDnCFDGCTR.GMDC to Reset Mode it is necessary to confirm that the Reset Mode Status RSCFDnCFDGSTS.GRSTSTS in the Global Status Register has been updated indicating successful transition to Global Reset Mode before RSCFDnCFDGCTR.GMDC can be changed again.

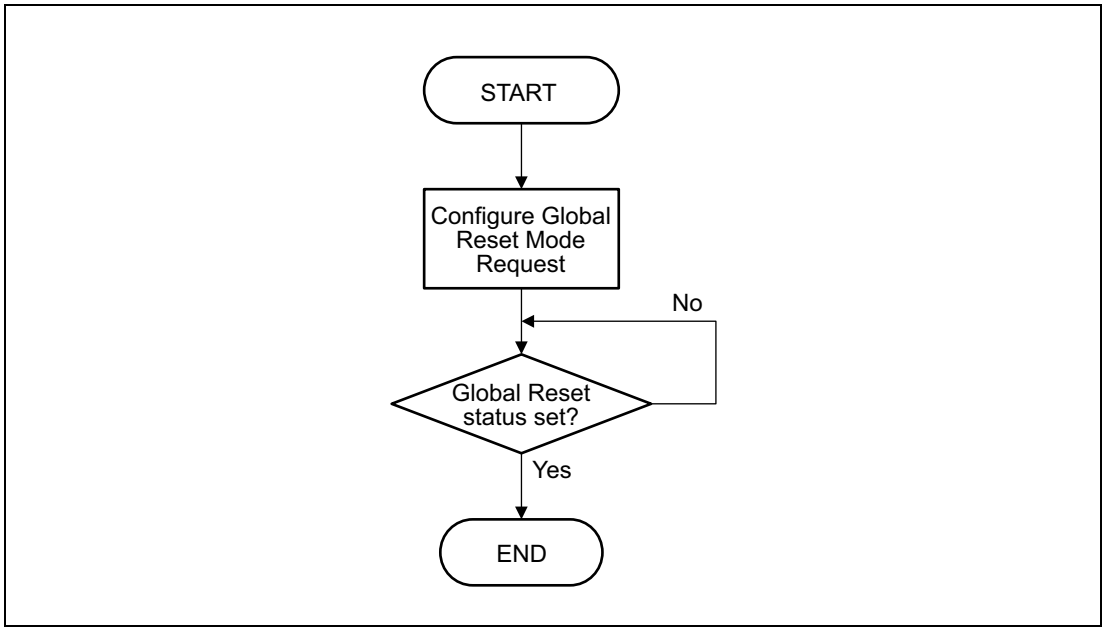

Figure 23.5 Procedure for entering global Reset Mode

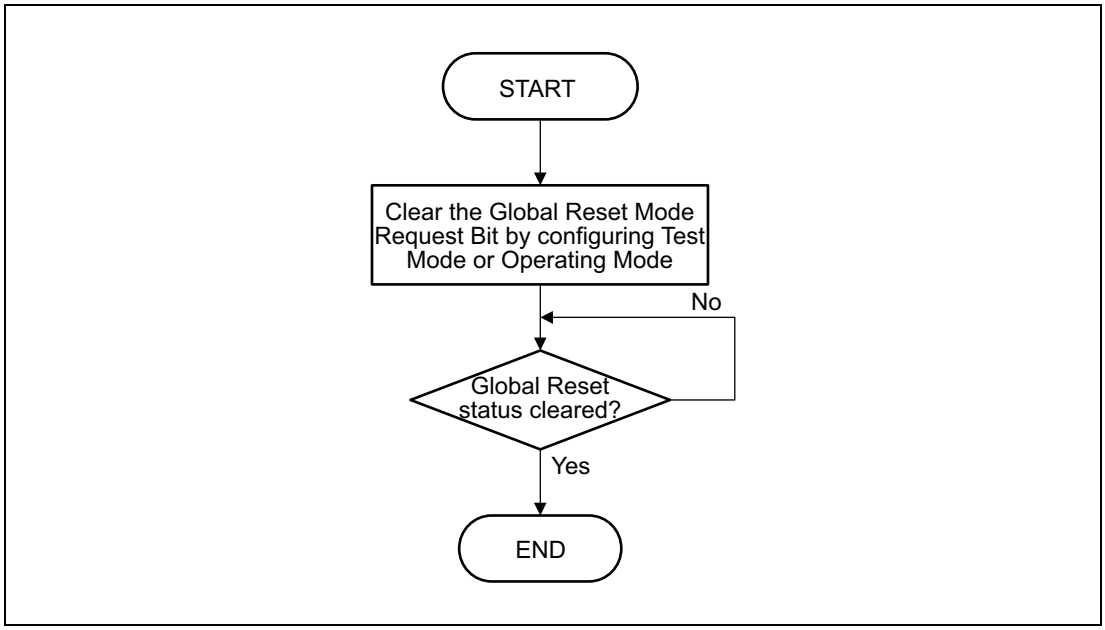

Figure 23.6 Procedure for exiting global Reset Mode

23.4.1.3 Global Test Mode

The RS-CANFD module enters this mode in the following ways:

Global Mode Control RSCFDnCFDGCTR.GMDC in the Global Control Register is configured for Global Test Mode while the RS-CANFD module is in Global Reset Mode

- The channels will be in either Channel Reset Mode or Channel Stop Mode and will remain in this mode

Global Mode Control RSCFDnCFDGCTR.GMDC in the Global Control Register is configured for Global Test Mode while the RS-CANFD module is in Global Operating Mode

- All channels in Channel Reset Mode, Channel Halt Mode or Channel Stop Mode will remain in this mode
- All channels in Channel Communication Mode will transit to Channel Halt Mode
- Global Test Mode Status bit is set when all channels have left Channel Communication Mode

If a transmission or reception is ongoing for a channel the transition to Channel Halt Mode is delayed until the completion of the communication.

Similarly, if a channel is in Bus-Off, the full Bus-Off recovery sequence may be delayed depending on the channel configuration.

In the Global Test Mode, all communications are suspended and RS-CANFD logic will not cause any change to status and flag registers (only when a channel is in the Bus-Off its REC and TEC values are cleared).

Also the test mode configuration and control registers are not initialized in this mode.

The Global Test Mode should be used to configure global module test modes.

Refer to **Section 23.4.3, Global Mode – Channel Mode transition interactions** for a detailed description of the behavior of all registers when transition to Global Test Mode is performed.

Setting the global mode to Test by setting the Global Mode Control bits RSCFDnCFDGCTR.GMDC in the Global Control Register to 10_B will set all Channel Mode Control bits RSCFDnCFDCmCTR.CHMDC in the Channel Control Register to 10_B for the channels that are in Channel Communication Mode and force these channels into the Channel Halt Mode.

For channels that are already in Channel Reset Mode, Channel Halt Mode or Channel Stop Mode this automatic transition is not performed.

Therefore, the Global Test Mode request can be used to shut down all CAN channel communications without loss of messages and disruption on the related CAN Bus (no interruption of reception/ transmission processes on the channels).

After setting Global Mode Control RSCFDnCFDGCTR.GMDC to Test Mode it is necessary to confirm that the Test Mode status RSCFDnCFDGSTS.GHLTSTS in the Global Status Register has been updated indicating successful transition to Global Test Mode. User should not do any other SFR setting until confirming RSCFDnCFDGSTS.GHLTSTS is set.

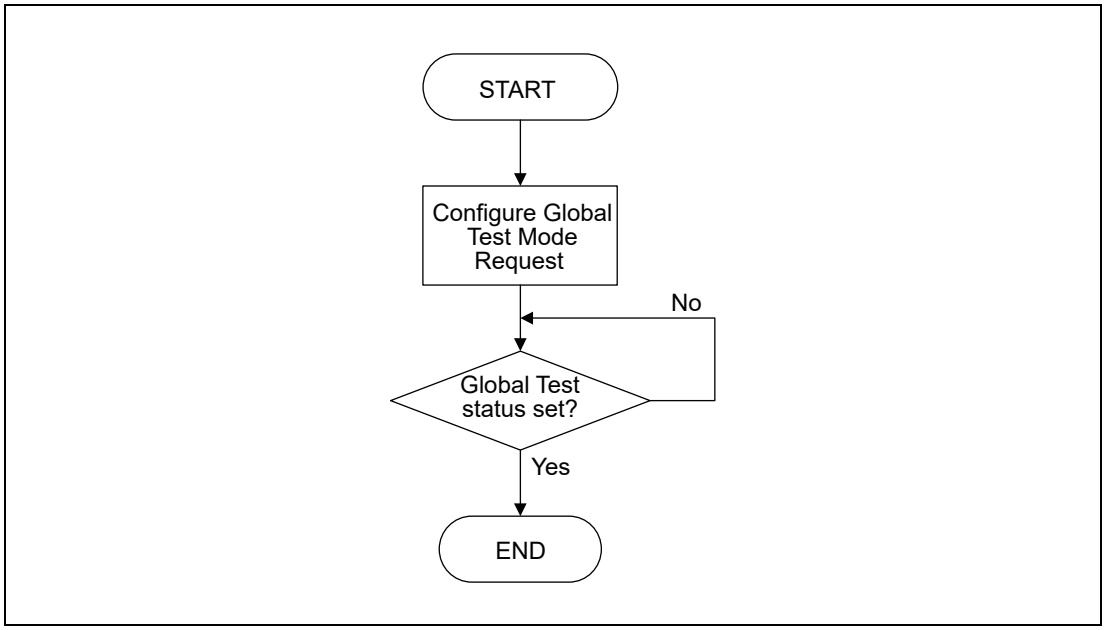

Figure 23.7 Procedure for entering global Test Mode

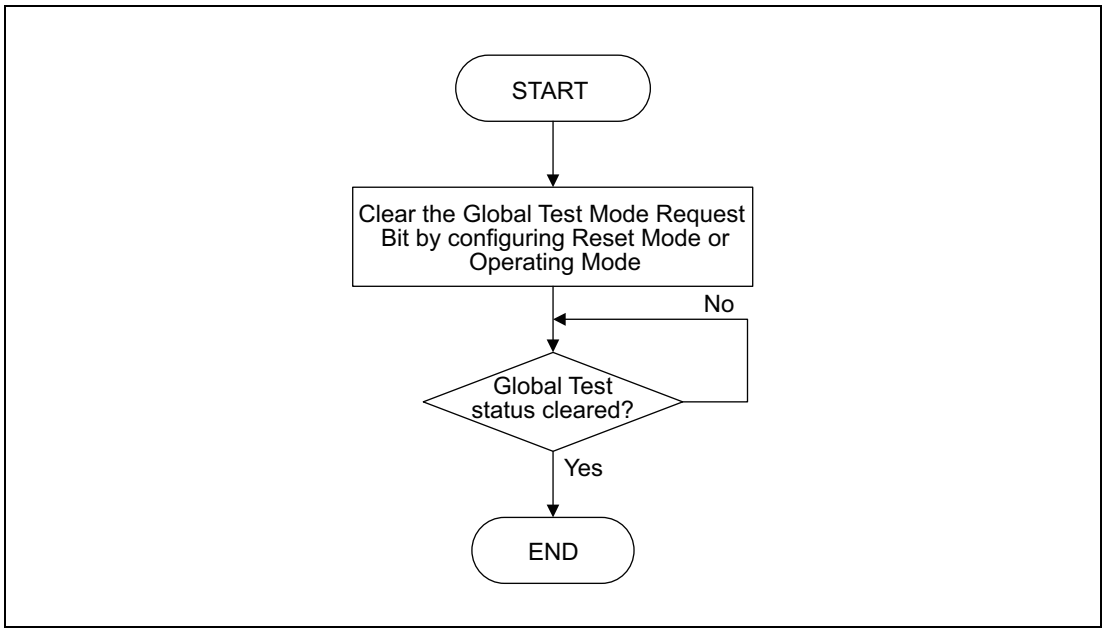

Figure 23.8 Procedure for exiting global Test Mode

23.4.1.4 Global Operating Mode

The RS-CANFD module enters this mode when the Global Mode Configuration bits are set to Global Operating Mode.

CAN channels can only be set to Channel Operation Mode and start CAN communication when RS-CANFD is in Global Operating Mode.

After setting Global Mode Control RSCFDnCFDGCTR.GMDC to Global Operating Mode it is necessary to confirm that the Global Reset Mode status RSCFDnCFDGSTS.GRSTSTS and the Global Test Mode status RSCFDnCFDGSTS.GHLTSTS in the Global Status Register have been cleared indicating successful transition to Global Operating Mode before RSCFDnCFDGCTR.GMDC can be changed again.

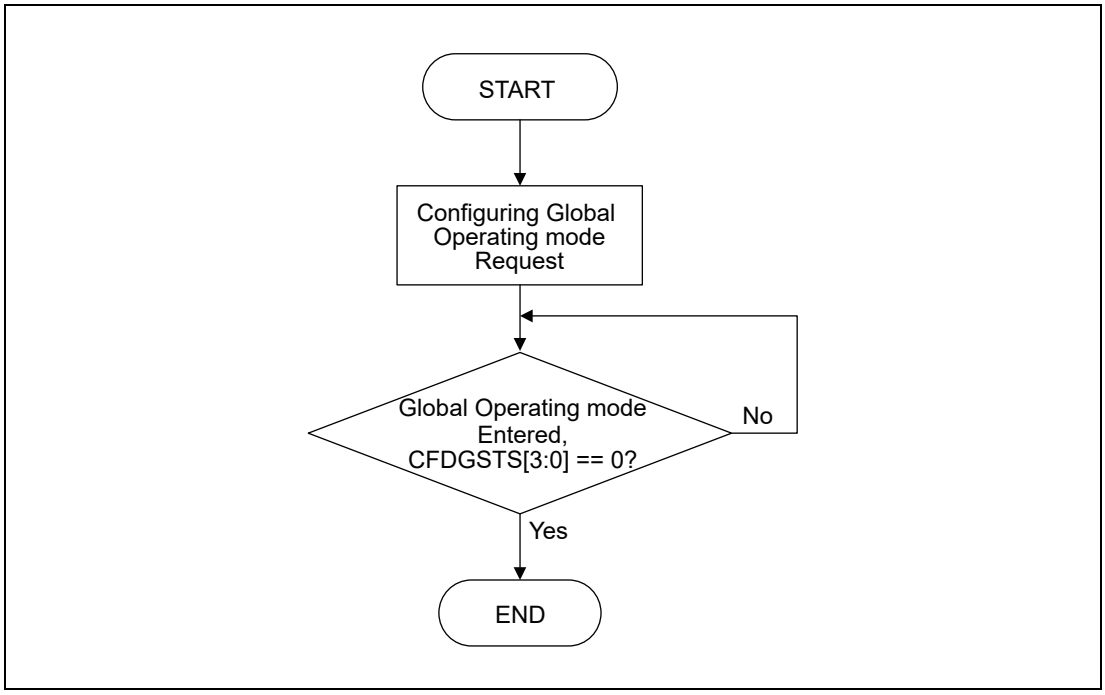

Figure 23.9 Procedure for Entering Global Operating Mode

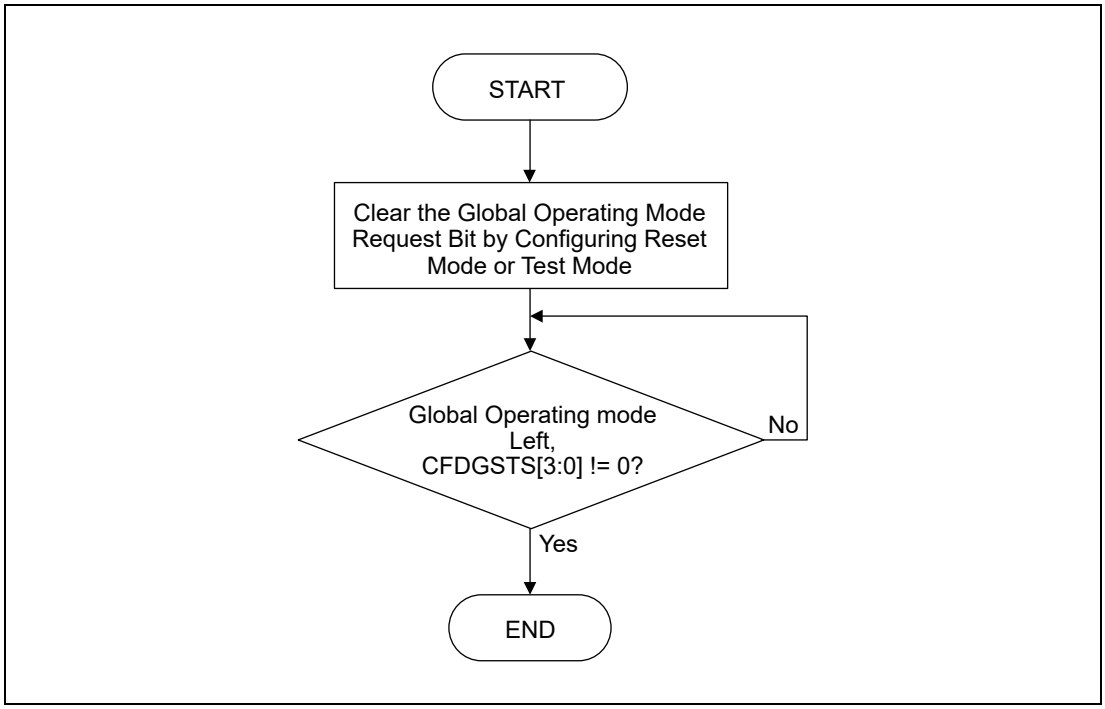

Figure 23.10 Procedure for Exiting Global Operating Mode

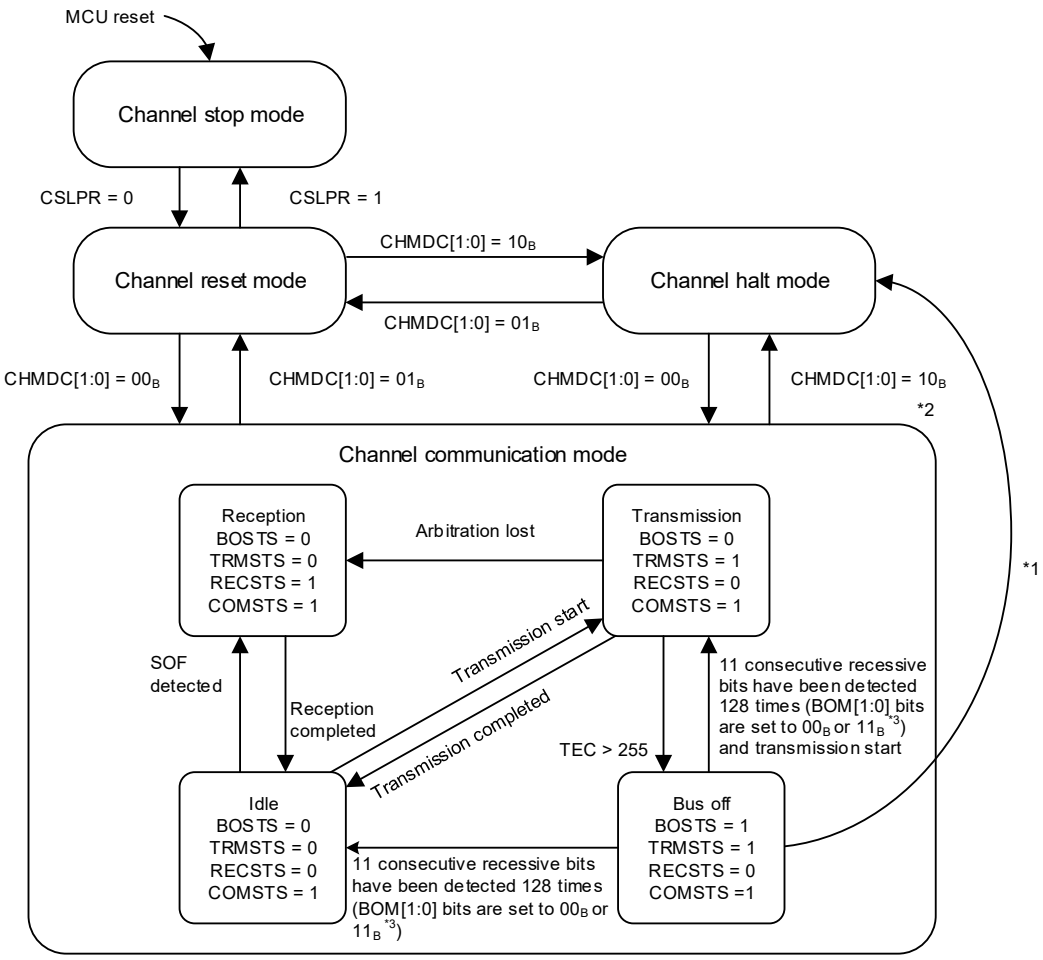
23.4.2 Channel Modes

Figure 23.11 shows a channel mode state transition chart. Refer to **Section 23.4.3.2, Channel Mode change timing**.



Note: CHMDC[1:0], CSLPR, BOM[1:0]: Bits in the RSCFDnCFDCmCTR register (m = 0 to 7)
BOSTS, TRMSTS, RECSTS, COMSTS: Bits in the RSCFDnCFDCmSTS register

Note 1. Timing of transition from bus off state to channel halt mode
- When BOM[1:0] = 01_B: Transition to channel halt mode when TEC exceeds 255
- When BOM[1:0] = 10_B: Transition to channel halt mode when 11 consecutive recessive bits have been detected 128 times
- When BOM[1:0] = 11_B: Transition to channel halt mode when the CHMDC[1:0] bits are set to 10_B

Note 2. While the CAN bus is locked to the dominant level, transition to channel halt mode is not made. In that case, enter channel reset mode

Note 3. When 11 consecutive recessive bits are detected 128 times before the CHMDC[1:0] bits are set to 10_B

Figure 23.11 Channel Mode State Transition Chart

23.4.2.1 CAN Channel Stop Mode

After the release of the hardware reset or after setting and clearing a RSCFDnCFDGRSTC.SRST bit, each CAN channel of the RS-CANFD module automatically enters Channel Stop Mode.

Each CAN channel will also enter this mode, when the related Channel Stop Mode Request bit is set while the CAN channel is in Channel Reset Mode.

This control bit should not be set in Channel Halt Mode or Channel Communication Mode.

Entering the CAN channel Stop Mode instantly stops the clock supplied to the CAN channel unit and thereby reduces power consumption.

After setting Channel Stop Mode request bit it is necessary to confirm that the Channel Stop Mode Status has been updated indicating successful transition to Channel Stop Mode before the Channel Stop Mode request bit can be cleared again.

During Channel Stop Mode, users cannot write to channel related registers. Read operation is still possible.

23.4.2.2 CAN channel Reset Mode

An RS-CANFD CAN channel enters this mode in the following ways:

Channel Mode Control RSCFDnCFDCmCTR.CHMDC in the Channel Control Register is configured for Channel Reset Mode while the related CAN channel is in Channel Halt Mode or Channel Communication Mode

Channel Stop Mode request bit is cleared while the related CAN channel is in Channel Stop Mode

Global Mode Control RSCFDnCFDGCTR.GMDC is set to Global Reset Mode and CAN channel is not in Channel Stop Mode or Channel Reset Mode

In Channel Reset Mode, all CAN channel status and flag registers are initialized.

Additionally all channel related transmission control bits are cleared and the channel related TX Queue is disabled.

Configuration registers (except the Channel Test Mode registers) are not initialized in this mode and the RS-CANFD module CAN channel can be configured for communication.

Refer to **Section 23.4.3, Global Mode – Channel Mode transition interactions** for detailed description of the behavior of all registers when transition to Channel Reset Mode is performed.

After setting Channel Mode Control RSCFDnCFDCmCTR.CHMDC to Channel Reset Mode, it is necessary to confirm that the Reset Mode Status RSCFDnCFDCmSTS .CRSTSTS in the related Channel Status Register has been updated indicating successful transition to Channel Reset Mode before the related RSCFDnCFDCmCTR.CHMDC can be changed again.

Refer to **Table 23.136** below regarding the influence of transition to Channel Reset Mode while CAN communication is ongoing.

23.4.2.3 CAN channel Halt Mode

An RS-CANFD CAN channel enters this mode in the following ways:

Channel Mode Control RSCFDnCFDCmCTR.CHMDC in the Channel Control Register is configured for Channel Halt Mode while the related CAN channel is in Channel Reset Mode or Channel Communication Mode

Global Mode Control RSCFDnCFDGCTR.GMDC is set to Global Test Mode and CAN channel is in Channel Communication Mode

In Channel Halt Mode, all channel CAN communication is suspended but all status and flag registers remain unchanged during Channel Halt Mode entry (except for the Bus-Off case where REC and TEC values are cleared for this channel).

In addition, the channel test mode configuration and control registers are not initialized in this mode.

The Channel Halt Mode should be used to configure channel test modes.

Refer to **Section 23.4.3, Global Mode – Channel Mode transition interactions** for detailed description of the behavior of all registers when transition to Channel Halt Mode is performed.

After setting Channel Mode Control RSCFDnCFDCmCTR.CHMDC to Channel Halt Mode it is necessary to confirm that the Halt Mode status RSCFDnCFDCmSTS .CHLTSTS in the related Channel Status Register has been updated indicating successful transition to Channel Halt Mode before the related RSCFDnCFDCmCTR.CHMDC can be changed again.

Refer to **Table 23.136** regarding the influence of transition to Channel Halt Mode while CAN communication is ongoing.

Table 23.136 Behavior in CAN Reset / Halt Mode

State / Mode	Receiver	Transmitter	Bus-Off
CAN channel Reset Mode (RSCFDnCFDCmCTR.CHMDC= 01_B)	The CAN channel transits to Channel Reset Mode without waiting for the completion of the ongoing reception.*1	The CAN channel transits to Channel Reset Mode without waiting for the completion of the ongoing transmission.*1	The CAN channel transits to Channel Reset Mode without waiting for the completion of the Bus-Off Recovery.
CAN channel Halt Mode (RSCFDnCFDCmCTR.CHMDC= 10_B)	CAN channel transits to Channel Halt Mode at the end of the ongoing reception or error.*2	CAN channel transits to Channel Halt Mode after completion of the ongoing transmission.	When RSCFDnCFDCmCTR.BOM is set to 00_B, a Channel Halt Mode request will be accepted only after the completion of the full Bus-Off Recovery sequence. When RSCFDnCFDCmCTR.BOM is set to 10_B, then, the CAN channel transits automatically to Channel Halt Mode after waiting for the completion of the Bus-Off Recovery. When RSCFDnCFDCmCTR.BOM is set to 01_B, then, the CAN channel transits automatically to Channel Halt Mode without waiting for the completion of the Bus-Off Recovery. When RSCFDnCFDCmCTR.BOM is set to 11_B, the CAN channel transits to Channel Halt Mode as soon as the Channel Halt Mode is requested (without waiting for the completion of the Bus-Off Recovery).

Note 1. If the entry to Channel Reset Mode is required only at the end of an ongoing communication, then Channel Halt Mode can be requested first to prevent interruption of CAN communication by direct transition to Channel Reset Mode. After the CAN channel enters Channel Halt Mode the Channel Reset Mode can be requested.

Note 2. If CAN communication is locked at dominant level after an error flag, Application SW can detect this situation by monitoring the channel related BusLock Flag and resolve lock condition by setting the CAN channel to Channel Reset Mode.

23.4.2.4 CAN Channel Communication Mode

The Channel Communication Mode is activated by setting the RSCFDnCFDCmCTR.CHMDC bits to 00_B. If 11 consecutive recessive bits are detected after entering the CAN Communication Mode, then the RSCFDnCFDCmSTS.COMSTS bit is set and the CAN channel:

Enables channel's communication functions allowing the channel to become an active node on the CAN network

releases the internal fault confinement logic including receive and transmit error counters

At this point, it can start transmission and reception of CAN messages.

Within the CAN channel Communication Mode, the channel may be in four different sub-modes, depending on which type of communication functions are performed (see **Figure 23.12**):

Channel idle: The CAN channel is neither receiving nor transmitting.

Channel receives: The channel is receiving a CAN message sent by another CAN node.

Channel transmits: The channel is transmitting a CAN message.

NOTE

The channel may receive its own message simultaneously when Self Test Mode is enabled.

Channel is in Bus-Off state: The CAN channel is cut-off from CAN Bus communication

After setting Channel Mode Control RSCFDnCFDCmCTR.CHMDC to Communication Mode, it is necessary to confirm that the Channel Reset Mode Status RSCFDnCFDCmSTS.CRSTSTS and the Channel Halt Mode Status RSCFDnCFDCmSTS.CHLTSTS in the Channel Status Register have been updated indicating successful transition to Channel Communication Mode before the related RSCFDnCFDCmCTR.CHMDC can be changed again.

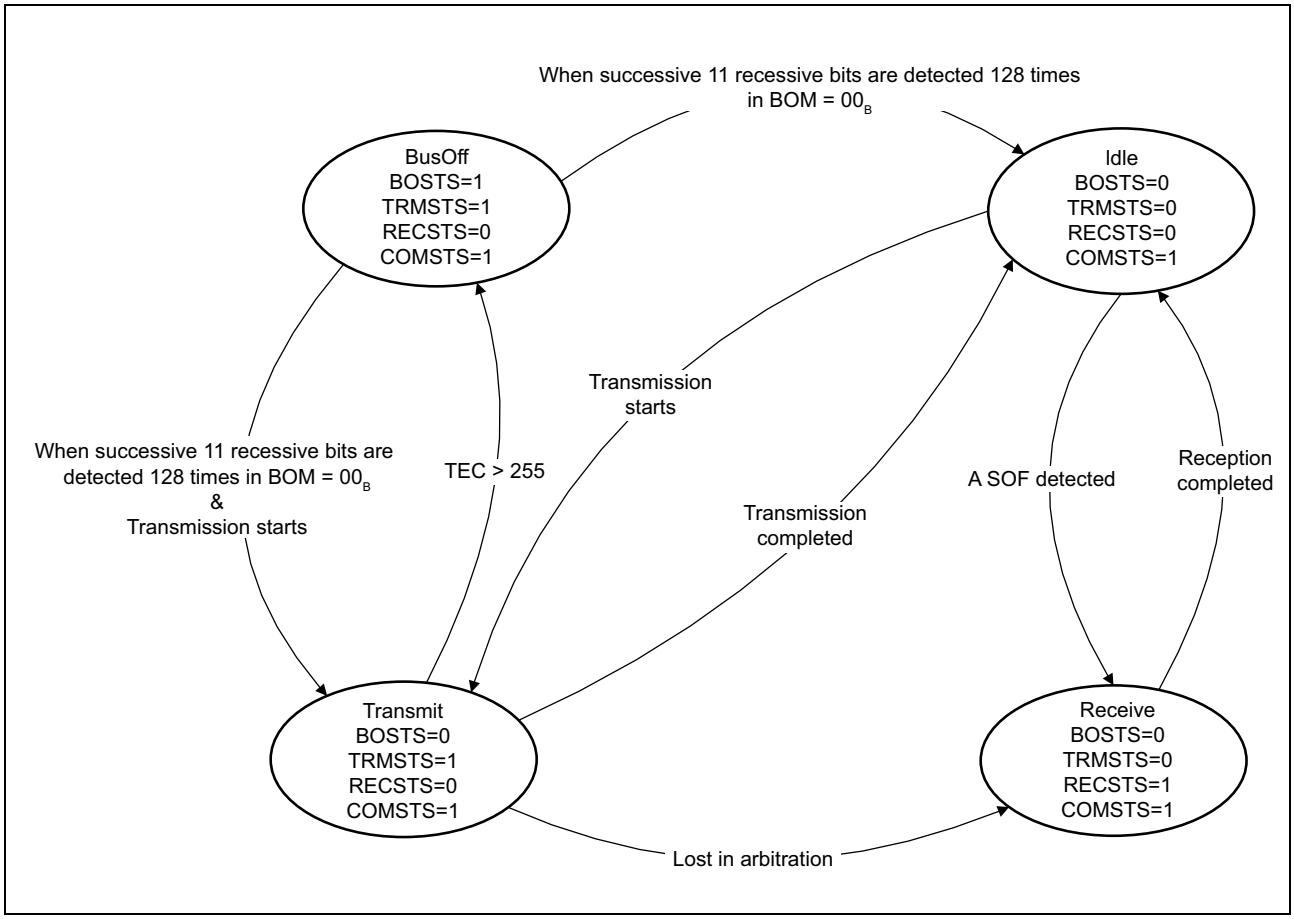


Figure 23.12 Sub-Modes of CAN Channel Communication Mode (only BOM = 00_B)

23.4.2.5 CAN channel Bus-Off State

The CAN channel Bus-Off state is entered according to the fault confinement rules of the CAN specification. Following modes for returning to the CAN channel Communication Mode from the Bus-Off state can be configured:

RSCFDnCFDCmCTR.BOM = 00_B:

Bus-Off recovery is compliant to ISO 11898-1 (2015), namely the CAN channel re-enters CAN communication (Error Active state) after 11 consecutive recessive bits are detected 128 times. TEC and REC counters are initialized to zero. The Bus-Off Recovery Flag RSCFDnCFDCmERFL.BORF is set in this case.

RSCFDnCFDCmCTR.BOM = 01_B:

The CAN channel changes the value of the RSCFDnCFDCmCTR.CHMDC bits within the CAN channel Control Register to 10B and switches immediately to Channel Halt Mode automatically after entering the Bus-Off state. TEC and REC counters are initialized to zero. The Bus-Off Recovery Flag RSCFDnCFDCmERFL.BORF is not set in this case.

RSCFDnCFDCmCTR.BOM = 10_B:

The CAN channel changes the value of the RSCFDnCFDCmCTR.CHMDC bits within the CAN channel Control Register to 10_B as soon as it reaches the Bus-Off state and enters Channel Halt Mode automatically after the CAN channel has completed the Bus-Off recovery sequence (i.e. after 11 consecutive recessive bits are detected 128 times). TEC and REC counters are initialized to zero. The Bus-Off Recovery Flag RSCFDnCFDCmERFL.BORF is set in this case.

RSCFDnCFDCmCTR.BOM = 11_B:

Bus-Off recovery is initiated but CAN channel can enter immediately the Channel Halt Mode when still in Bus-Off state if a request is made to enter Channel Halt Mode.

TEC and REC counters are initialized to zero. In this case, the Bus-Off Recovery Flag RSCFDnCFDCmERFL.BORF is not set and TEC and REC counters are initialized to zero.

Without setting RSCFDnCFDCmCTR.CHMDC [1:0] =10_B and when 11recessive bits is detected 128 times continuously, transition conditions become the same as RSCFDnCFDCmCTR.BOM = 00_B.

Note, however, that if the recovery from Bus-Off occurs normally in this mode (i.e. after waiting for 128 sequences of 11 consecutive recessive bits), and no Halt request has been generated during this period, then the Bus-Off Recovery Flag RSCFDnCFDCmERFL.BORF is set.

In the case where Application SW writes into RSCFDnCFDCmCTR.CHMDC at the same time as the CAN channel is due to enter Halt Mode (at the start of Bus-Off when RSCFDnCFDCmCTR.BOM = 01_B, or at the end of Bus-Off when RSCFDnCFDCmCTR.BOM = 10_B) then the System SW request will have the highest priority.

Note that, in the above cases, the automatic setting of the RSCFDnCFDCmCTR.CHMDC to Channel Halt mode request is performed when the RSCFDnCFDCmCTR.CHMDC value is previously 00_B (Channel Communication Mode).

Additional it is possible to force the CAN channel to recover from the Bus-Off state by setting RSCFDnCFDCmCTR.RTBO to 1_B. The error state changes from Bus-Off state to integrating state

with a maximum delay of 1 CAN Bit time, and the CAN communication becomes possible again after 11 consecutive recessive bits are detected. The Bus-Off Recovery Flag is not set in this case.

TEC and REC counters are initialized to zero.

Before setting RSCFDnCFDCmCTR.RTBO to 1_B, all pending transmissions from TX Message Buffers, TX Queues and/or Transmit/Receive FIFO in TX or GW Mode should be disabled.

The disable of the pending transmission Message Buffer, TX Queue or FIFO must be confirmed by the corresponding acknowledge flags.

For TX Message Buffer these are the Transmission Result Flags (RSCFDnCFDTMSTSp.TMTRF) for the TX Queue it is the TX Queue empty flag (RSCFDnCFDTXQSTSm.TXQEMP) and for the FIFO it is the FIFO empty flag (RSCFDnCFDCFSTSk.CFEMP).

The RSCFDnCFDCmCTR.RTBO bit should be used for Bus-Off recovery only when RSCFDnCFDCmCTR.BOM is set to 00_B.

Setting this bit in any state (other than Bus-Off) will have no effect and the bit will be cleared immediately.

Table 23.137 summarises the setting of Bus-Off Entry Flag RSCFDnCFDCmERFL.BOEF and Bus-Off Recovery Flag RSCFDnCFDCmERFL.BORF for different configurations of RSCFDnCFDCmCTR.BOM.

Table 23.137 Bus-Off entry / recovery flag behavior

BOM	BOEF bit set	BORF bit set
00_B	Always (on entry to Bus-Off)	Always (on exit from Bus-Off)
00_B RSCFDnCFDCmCTR. RTBO set to '1'	Always (on entry to Bus-Off)	Only if normal Bus-Off recovery occurs before System SW sets RSCFDnCFDCmCTR.RTBO to '1'
01_B	Always (on entry to Bus-Off)	Never
10_B	Always (on entry to Bus-Off)	Always (on exit from Bus-Off)
11_B	Always (on entry to Bus-Off)	Only if normal Bus-Off recovery occurs before System SW issues Halt request

To make an efficient SW procedure it is not mandatory to wait for BusOff recovery sequence end.

It is possible to do the transmission re-initialization during the BusOff recovery. To do this following SW-flow is recommended to use, refer to **Figure 23.13**.

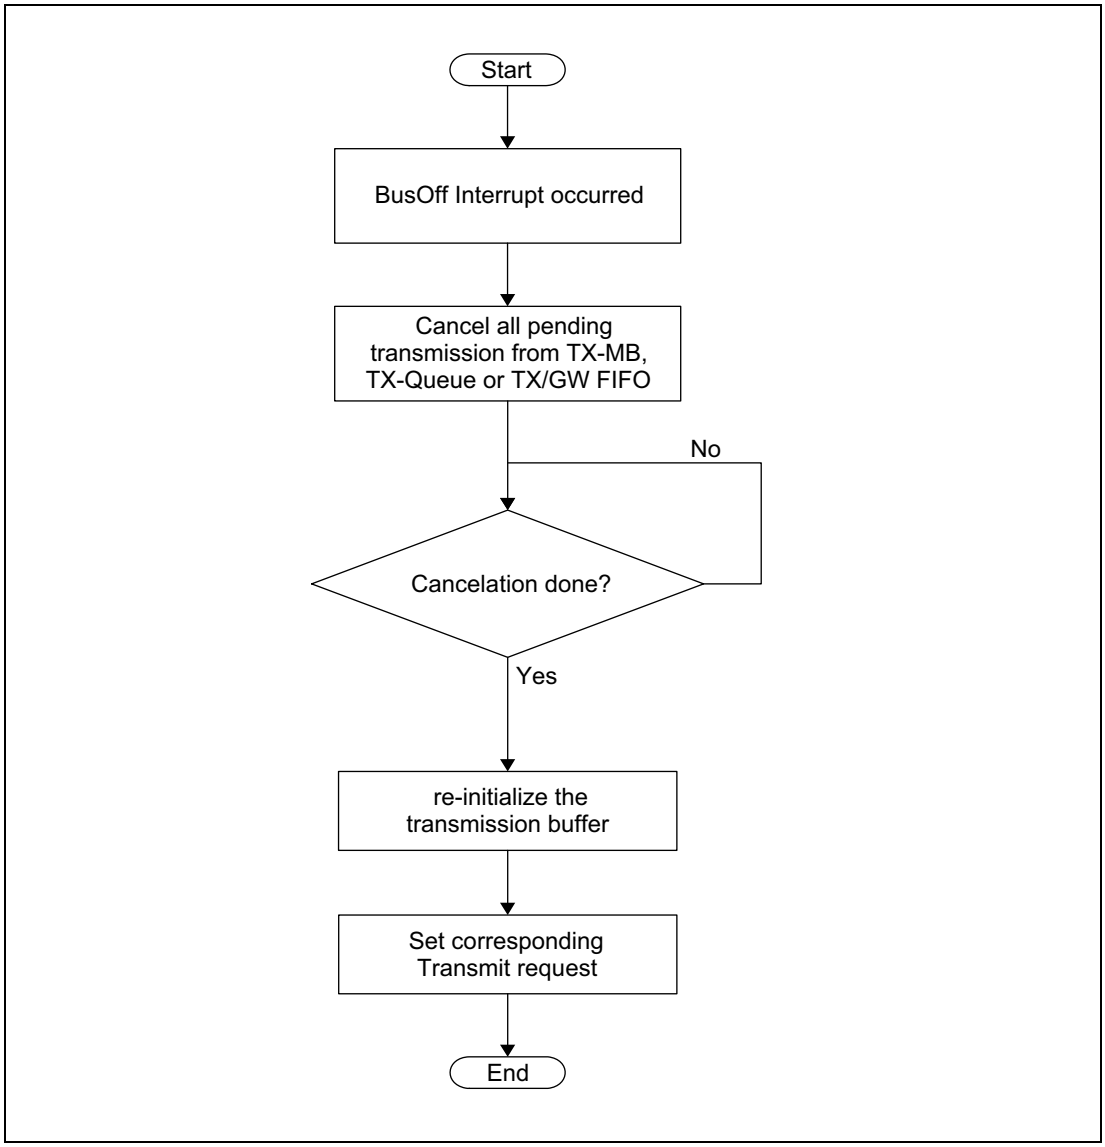

Figure 23.13 Transmission re-initialization during Bus-Off

23.4.3 Global Mode – Channel Mode transition interactions

In the following, the interaction between global mode setting and channel mode setting is summarized:

Changing of Channel Mode Control RSCFDnCFDCmCTR.CHMDC in the Channel Control Register does not have any influence on the Global Mode Control RSCFDnCFDGCTR.GMDC.

Changing of Global Mode Control RSCFDnCFDGCTR.GMDC is influencing the channel mode control in the way described in **Table 23.138**.

Table 23.138 Global – Channel mode transition interaction

Global Mode Change	Channel Mode	Channel Mode Transition Action
Stop → Reset	Stop	channel remains in Stop Mode
Stop → Halt	- (global mode change not possible)	
Stop → Communication	- (global mode change not possible)	
Reset → Stop	Stop	channels remains in Stop Mode
	Reset	channel Stop request bit is set automatically, channel transits to Stop Mode
Reset → Halt	Stop	channel remains in Stop Mode
	Reset	channel remains in Reset Mode
Reset → Communication	Stop	channel remains in Stop Mode
	Reset	channel remains in Reset Mode
Halt → Stop	- (global mode change not possible)	
Halt → Reset	Stop	channel remains in Stop Mode
	Reset	channel remains in Reset Mode
	Halt	channel mode control is set to Reset Mode, channel transits to Reset Mode
Halt → Communication	Stop	channel remains in Stop Mode
	Reset	channel remains in Reset Mode
	Halt	channel remains in Halt Mode
Communication → Stop	- (global mode change not possible)	
Communication → Reset	Stop	channel remains in Stop Mode
	Reset	channel remains in Reset Mode
	Halt	channel mode control is set to Reset Mode, channel transits to Reset Mode
	Communication	channel mode control is set to Reset Mode, channel transits to Reset Mode
Communication → Halt	Stop	channel remains in Stop Mode
	Reset	channel remains in Reset Mode
	Halt	channel remains in Halt Mode
	Communication	channel mode control is set to Halt Mode, channel transits to Halt Mode after communication finished

23.4.3.1 Global Mode change timing

The transition time for the Global mode changes are shown below.

Table 23.139 Global Mode change timing

From	To	max. transition time
GL_STOP	GL_RESET	3 peripheral clock cycle*2
GL_RESET	GL_STOP	3 peripheral clock cycle
GL_RESET	GL_TEST	10 peripheral clock cycle
GL_RESET	GL_OPERATING	10 peripheral clock cycle
GL_TEST	GL_RESET	2 CAN bit times
GL_TEST	GL_OPERATING	3 peripheral clock cycle
GL_OPERATING	GL_RESET	2 CAN bit times
GL_OPERATING	GL_TEST	3 CAN frames*1, *3

Note 1. The given transition time is the time without any errors on the bus. In case of Error condition the transition time could lengthen to an uncalculated result. As well it could also come to stuck condition in case of locked RX lines or continues error conditions.

Note 2. Users should leave GL_STOP mode, only when RSCFDnCFDGSTS.GRAMINIT is cleared.

Note 3. TQ, CAN frame and CAN bits are related to the individual channels, for the max transition time the channel with the lowest Baud Rate has to be used.

23.4.3.2 Channel Mode change timing

The transition time for the Channel mode changes are shown below.

Table 23.140 Channel Mode change timing

From	To	Max. transition time
CH_STOP	CH_RESET	3 peripheral clock cycle
CH_RESET	CH_STOP	3 peripheral clock cycle
CH_RESET	CH_HALT	3 CAN bit times
CH_RESET	CH_COMMUNICATION	4 CAN bit times
CH_HALT	CH_RESET	2 CAN bit times
CH_HALT	CH_COMMUNICATION	4 CAN bit times*3
CH_COMMUNICATION	CH_RESET	2 CAN bit times
CH_COMMUNICATION	CH_HALT	2 CAN frames*1, *2

Note 1. The time specified for this transition does not include the case where channel enters Bus-Off state. In case of Bus-Off the timing depends upon the configuration of the RSCFDnCFDCmCTR.BOM[1:0] bits.

Note 2. The given transition time is the time without any errors on the bus. In case of Error condition the transition time could lengthen to an uncalculated result. As well it could also come to a stuck condition in case of locked RX lines or continues error conditions.

Note 3. In general if the Baudrate prescaler value RSCFDnCFDCmNCFG.NBRP is changed in CH_HALT then the transition time could be deviate from above. As the internal prescaler is a free running down counter to create the TQ clock. And new BRP value will earliest be captured when the counter reached the value zero.

23.4.3.3 Register behavior in global/channel Modes

The following table shows the bit behavior when RS-CANFD module changes state.

Table 23.141 Register behavior in global/channel Modes (1/13)

RS-CANFD SFR feature List						Initial Value (after transition, in the state -> initialized value is kept in the state)

Note: After HW Reset, the RSCFDnCFDGSTS.GRAMINIT is set to indicate that the RS-CANFD module is initializing the RAM.
This bit is cleared automatically when the RAM initialization is completed and will not set again until HW reset is activated.

23.5 Initialization

Before joining CAN communications the following shall be configured:

Clock setting

Bit timing setting (nominal and data rate)

Baud Rate setting (nominal and data rate)

CANFD setting

Acceptance Filter setting (configuration of Global Acceptance Filter List)

Reception-, Transmission- and GW-FIFO setting

CAN Communication Mode setting

23.5.1 Initialization of CAN Clock, Bit Timing and Baud Rate

23.5.1.1 Bit Timing Conditions

The following lines describe the composition of each segment and the limitations that apply to the segment setting.

(1) Each segment setting

SS = Fixed to 1 TQ

TSEG1 = Refer to (RSCFDnCFDCmNCFG) and (RSCFDnCFDCmDCFG)

TSEG2 = Refer to (RSCFDnCFDCmNCFG) and (RSCFDnCFDCmDCFG)

SJW = Refer to (RSCFDnCFDCmNCFG) and (RSCFDnCFDCmDCFG)

SS + TSEG1 + TSEG2 = 5 to 49 TQs for Data Bit Rate and 8 to 385 for Nominal Bit Rate

(2) Limitations on TSEG1, TSEG2 and SJW

TSEG1(N) > TSEG2(N) ≥ SJW(N)

TSEG1(D) ≥ TSEG2(D) ≥ SJW(D)

When only classical frames will be used, the user should configure the bit fields TSEG1 and TSEG2 of RSCFDnCFDCmDCFG to valid values.

Table 23.142 shows an example of how to set the bit timing to achieve required Sample Point settings.

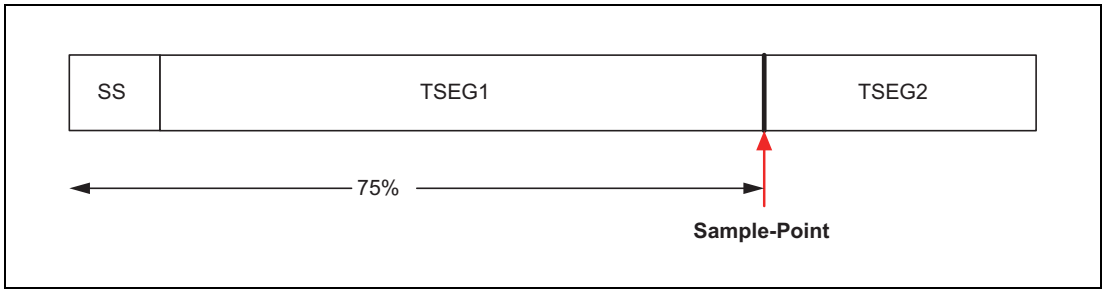
Table 23.142 Bit timing examples (1/2)

1 bit	Set value (TQ)				Sample point*1(%)
	SS	TSEG1	TSEG2	SJW	
5TQ	1	2	2	1	60.00
8TQ	1	4	3	1	62.50
	1	5	2	1	75.00
10TQ	1	6	3	1	70.00
	1	7	2	1	80.00
12TQ	1	8	3	1	75.00
	1	9	2	1	83.33

Table 23.142 Bit timing examples (2/2)

1 bit	Set value (TQ)				Sample point*1(%)
	SS	TSEG1	TSEG2	SJW	
15TQ	1	10	4	1	73.33
	1	11	3	1	80.00
16TQ	1	10	5	1	68.75
	1	11	4	1	75.00
20TQ	1	12	7	1	65.00
	1	13	6	1	70.00
24TQ	1	15	8	1	66.66
	1	16	7	1	70.83
50TQ	1	39	10	4	80.00

Note 1. Sample point (in case of 75%)



23.5.1.2 CAN Bit Timing

In the CAN protocol, each bit in a communication frame is composed of three segments, which can be configured individually for each channel via the related RSCFDnCFDCmNCFG and RSCFDnCFDCmDCFG registers.

Figure 23.14 shows the segment composition of a bit and the sample point in it.

Of these segments, the Time Segment 1 (hereafter TSEG1) and Time Segment 2 (hereafter TSEG2) are used to specify the position of the sample point, so that the timing at which each bit on the CAN Bus is sampled can be altered by changing the values of these segments.

The minimum resolution for this timing is referred to as Time Quantum (hereafter TQ), which is determined by the clock frequency supplied to the CAN channel and the divide-by-N value of the Baud Rate Prescaler (nominal and data rate).

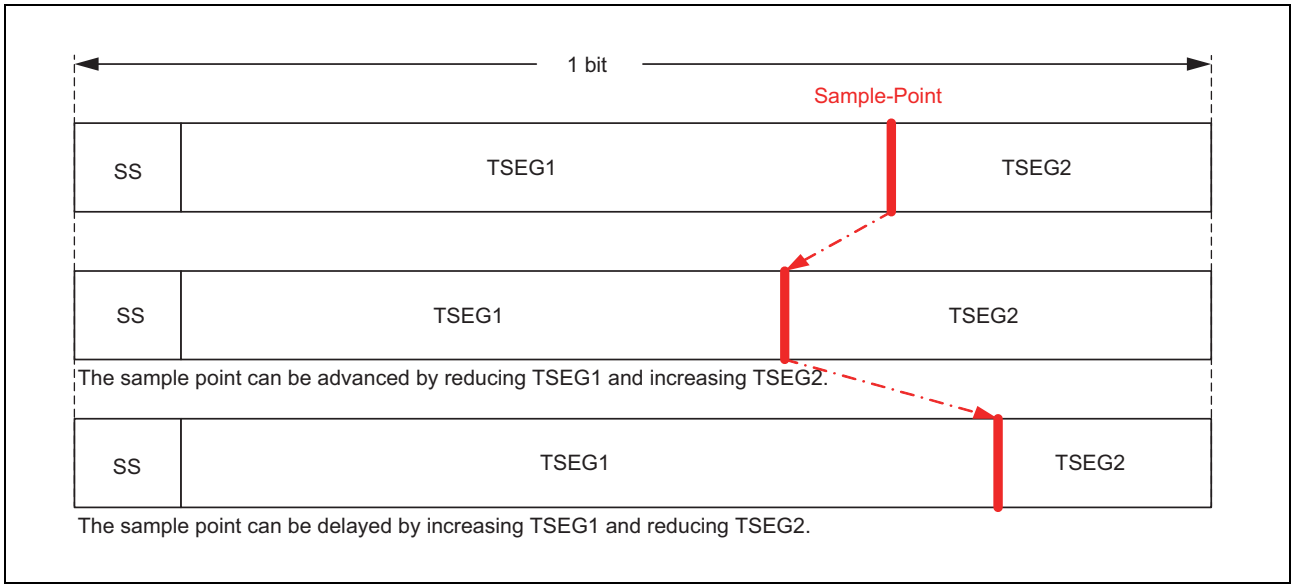


Figure 23.14 Segment composition of a bit and the sample point

1. SS: Synchronization Segment
   This segment is used to synchronize bits by monitoring a recessive-to-dominant edge during the Interframe Space (comprised of Intermission, Suspend Transmission, and Bus Idle; during Bus Idle, all nodes can start transmission)
2. TSEG1: Time Segment 1
   This segment absorbs physical delays on the CAN network. A physical delay on the network is two times the total sum of a bus delay, input comparator delay, and output driver delay. It can be lengthened by SJW.
3. TSEG2: Time Segment 2
   This segment is used to correct a phase error by performing resynchronization. It can be shortened by SJW (While sending or receiving a message, communication frames between some nodes may get out of sync due to a drift in the oscillator frequency or a delay in the transmission path. This is referred to as a phase error).
4. SJW: Resynchronization Jump Width
   This is the maximum width by which bits that have become out of sync due to a phase error may be corrected.
   The above figure reports only one symbolic sample point.

23.5.1.3 Baud Rate

Either the CAN channel system clock (Clean clock) or the External oscillator clock can be selected globally for all CAN channels as CAN communication clock.

The transfer speed is determined by the DLL Clock, the divide-by-N value of the Baud Rate Prescaler, and the number of TQs in one bit.

$$baudrate = \frac{DLL\_Clock}{number\_of\_time\_quanta\_per\_bit) \times (BRP + 1)}$$

Figure 23.15 shows a block diagram of the circuit that generates the CAN channel system clock and **Table 23.144** shows a Baud Rate examples.

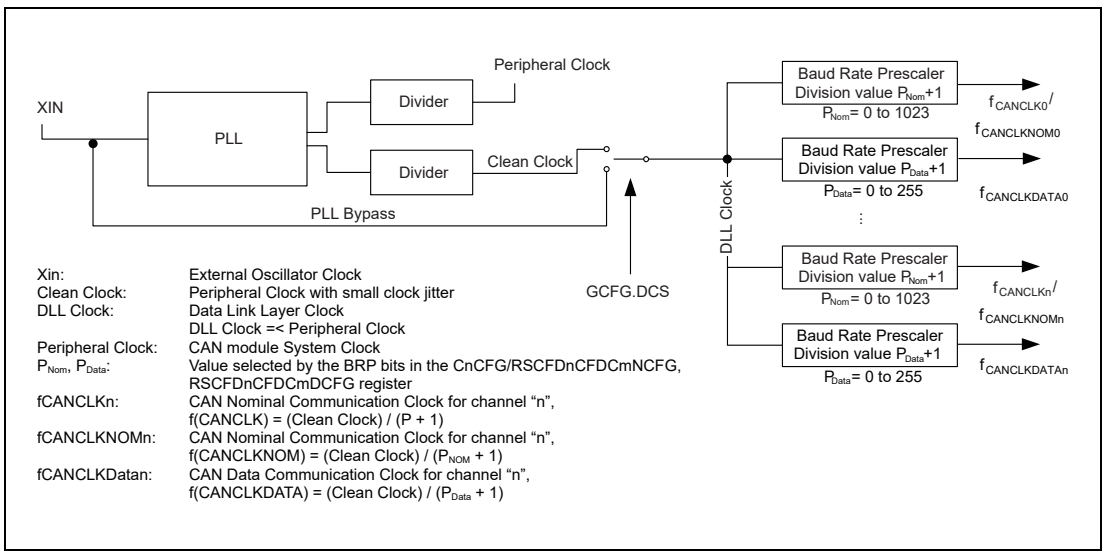

Figure 23.15 Block diagram of the circuit that generates the CAN channel communication clock

Table 23.143 Nominal Baud Rate calculation formula and example CAN communication configurations

Note 1. Baud Rate Prescaler divide-by-N value = P + 1 (P = 0-1023)
P: value selected by the BRP bits in the Channel Configuration Register.

Note 2. Minimum Frequency to achieve max. Nominal Baud Rate of 1Mbps

Note: Shown in ( ) are the Baud Rate Prescaler divide-by-N values

Table 23.144 Baud Rate calculation example for nominal and data bit rate CAN communication configurations

Baud rate	DLL Clock		
	80MHz	40MHz	20MHz
Nominal 1Mbps	80TQ (1)	40TQ (1)	20TQ (1)
Data 8Mbps	10TQ (1)	5TQ (1)	Not possible
Nominal 1Mbps	80TQ (1)	40TQ (1)	20TQ (1)
Data 5Mbps	16TQ (1)	8TQ (1)	Not possible
Nominal 500Kbps	160TQ (1)	80TQ (1)	40TQ (1)
Data 2Mbps	40TQ (1)	20TQ (1)	10TQ (1)

Note 1. Baud Rate Prescaler divide-by-N value = P + 1 (P = 0-1023)
P: value selected by the BRP bits in the Channel Configuration Register.

Note: Shown in ( ) are the Baud Rate Prescaler divide-by-N values

For optimum clock tolerance in networks using the FD frame format, the length of the time quantum should be the same in the nominal bit time and in the data bit time; means RSCFDnCFDCmNCFG.NBRP = RSCFDnCFDCmDCFG.DBRP.

Further if Transceiver Delay Compensation is used then the RSCFDnCFDCmDCFG.DBRP shall not be programmed greater than 1; 1 means divide by 2.

23.5.1.4 Setting of CAN Clock, Bit Timing and Baud Rate

Figure 23.16 shows the procedure for setting the CAN clock and the Baud Rate for each channel.

These settings should be performed during Channel Reset Mode (Configuration Mode) for the CAN channels.

Before going to channel communication state the Baud Rate must be configured, otherwise the mode will not switch correctly.

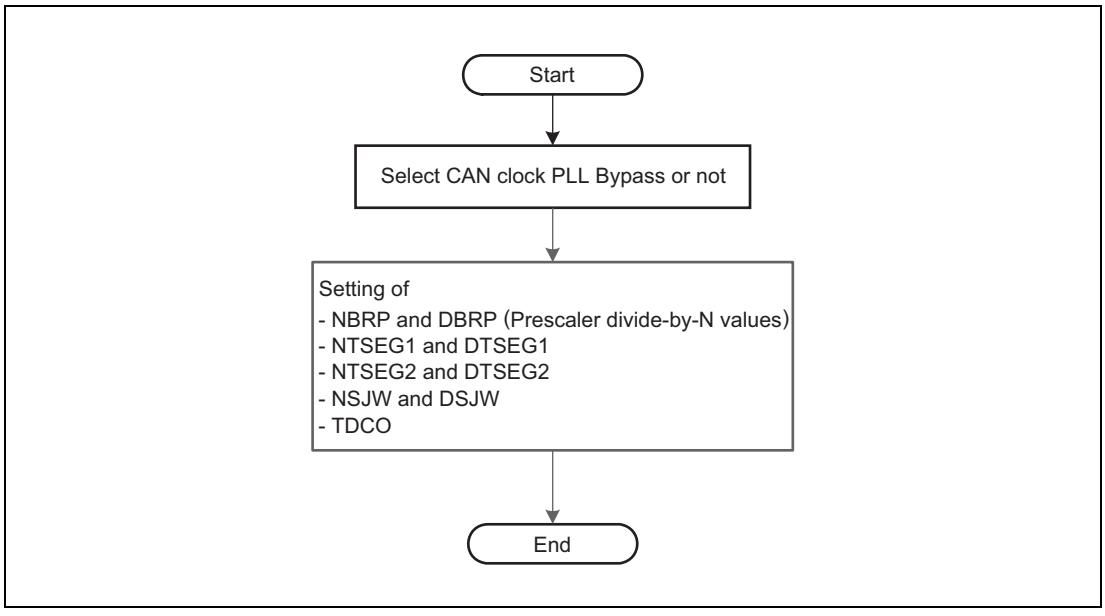

Figure 23.16 Procedure for setting the CAN bit timing and Baud Rate

23.5.1.5 Transmitter delay compensation

In case a high Baud Rate is used such as 5 to 8 Mbps for the Data phase, the Transmitter delay could become greater than TSEG1. In this case the transmitter would always detect a bit-error in the data-phase of the CANFD frame. The TDC compensates the transmitter's inability to receive its own transmitted bit at the sample point of that bit.

There is another symbolic sample point known as the Secondary Sample Point (SSP) that is used only during the Data phase of CANFD frames. This is derived from the Transceiver Delay Compensation Result (RSCFDnCFDCmFDSTS.TDCR) as shown in **Figure 23.17**.

The resolution of the configuration, measured and offset values is based on the CAN channel DLL clock.

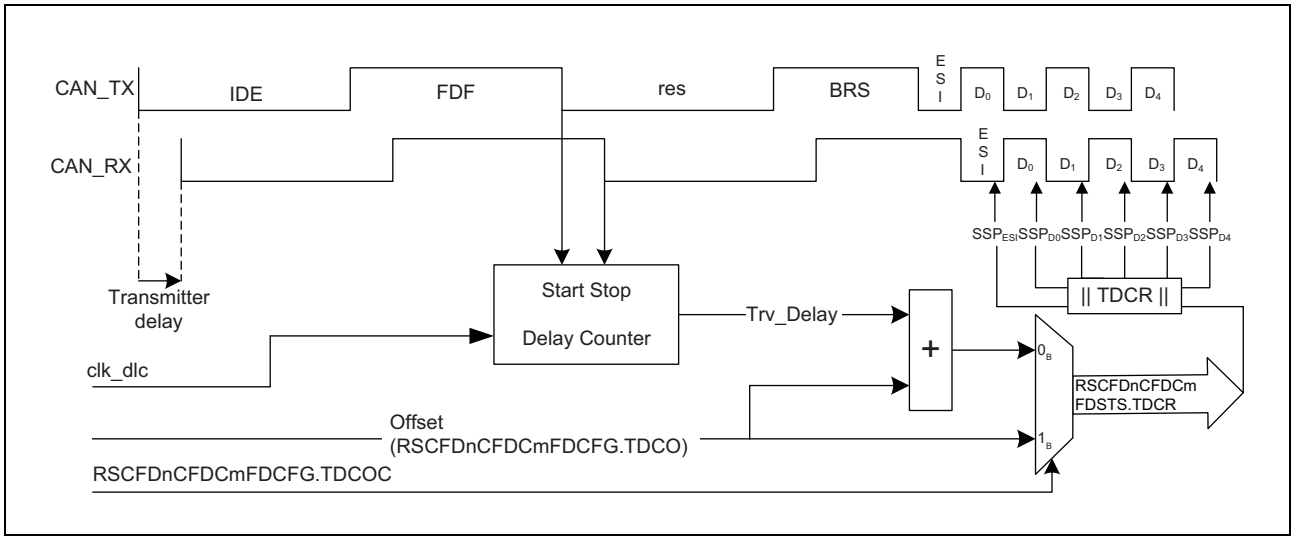

Figure 23.17 Transmitter Delay Compensation

The measured Trv_Delay is based on integer number of clk_dlc clock cycles.The delay is counted up by one for each started clock until the dominant value is seen on CAN_RX. The figure below illustrates the measured result. Trv_Delay counted to maximum 127 with a clk_dlc clock.

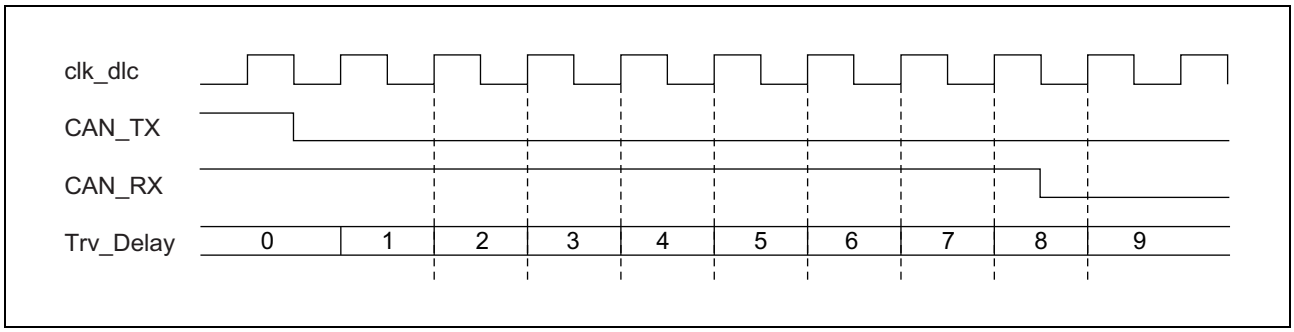

Figure 23.18 Trv_Delay measurement example

The SSP is calculated by taking the result from RSCFDnCFDCmFDSTS.TDCR and rounding the value down to the nearest integer number of data time quanta.

The **Figure 23.19** illustrates the positioning of the secondary sample point. In case the RSCFDnCFDCmFDCFG.TDCOC is equal to 0_B the SSP is equal to the Trv_Delay (measured delay) + RSCFDnCFDCmFDCFG.TDCO, rounded down to the nearest integer number of time quanta. Usually

the TDCO value should have the size of ($SyncSegment_{data}$ + $TSEG1_{data}$) to position the SSP to the theoretical location of a sample point.

If the RSCFDnCFDCmFDCFG.TDCOC is equal to 1_B then the SSP is just defined by the RSCFDnCFDCmFDCFG.TDCO. If the RSCFDnCFDCmDCFG.DBRP > zero then the value will also be rounded down to the nearest integer number of time quanta.

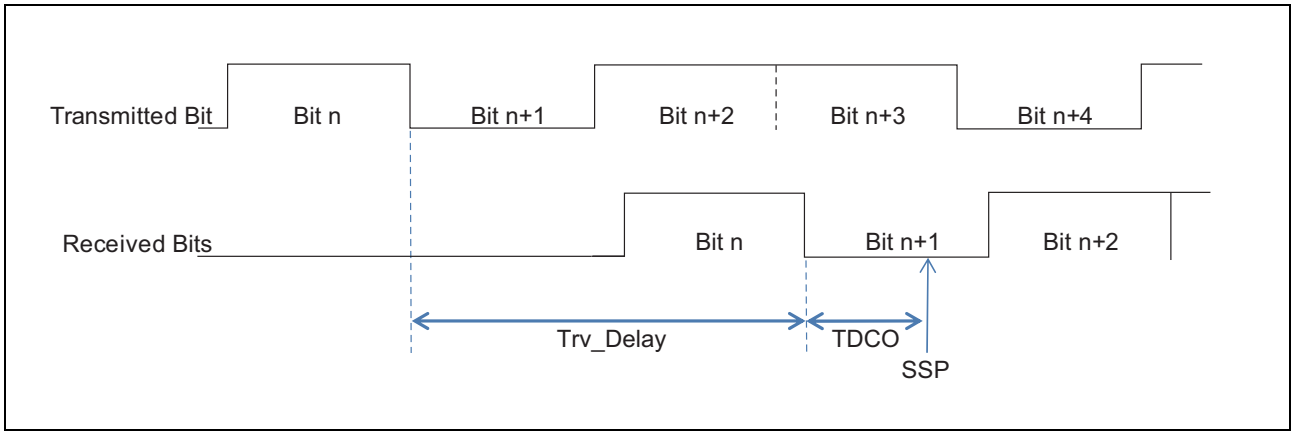

Figure 23.19 Position of the Secondary Sample Point

The maximum delay (Trv_Delay + TDCO) which can be compensated by the RS-CANFD module is (6 data bits – 2clk_dlc).

The ISO 11898-1 (2015) allows the users to set different values for BRP_data and BRP_nom.

If different values are used for RSCFDnCFDCmNCFG.NBRP and RSCFDnCFDCmDCFG.DBRP, then 2 CAN nodes may be out of synchronization at the point when the bit rate changes from nominal bit rate to data bit rate after Sample point of the BRS bit. This condition is shown in **Figure 23.20** below.

The length of the time quantum should be the same in the nominal bit time and in the data bit time; means RSCFDnCFDCmNCFG.NBRP = RSCFDnCFDCmDCFG.DBRP.

Different Bit rates can be achieved by selecting different configuration values for the Time Segments. Note the Nominal Bit rate can be configured from 8 to 385TQs and the Data Bit rate from 5 to 49TQs.

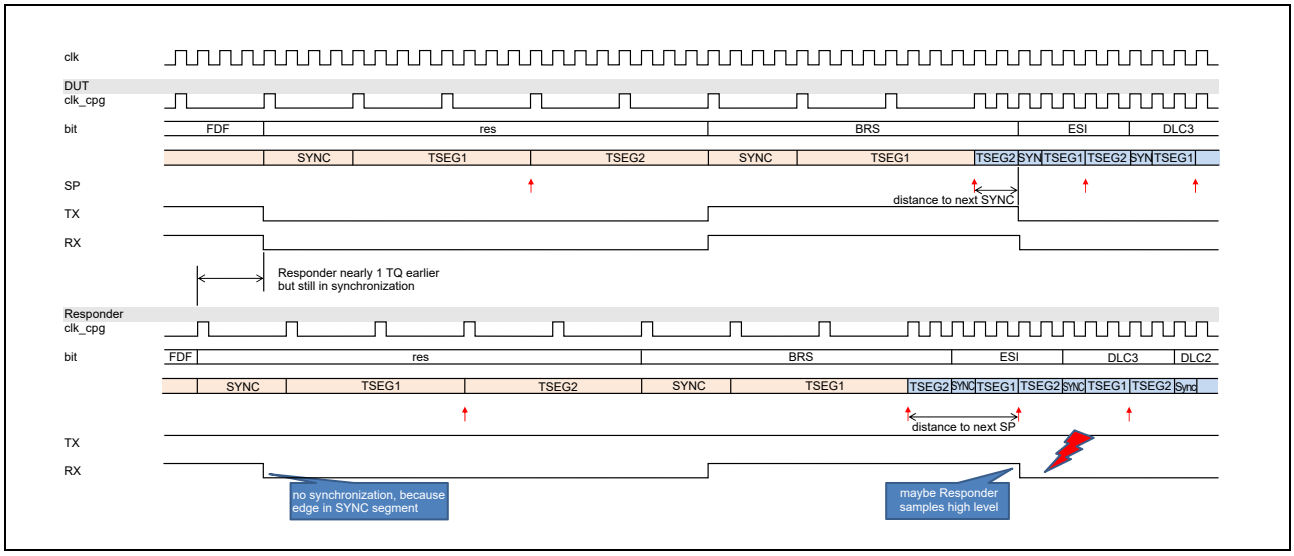

Figure 23.20 Loss of synchronization between 2 CAN nodes

The transmitter delay compensation measurement result is updated at the falling edge from FDF bit to res bit when configured accordingly (RSCFDnCFDCmFDCFG.TDCE = 1_B, RSCFDnCFDCmFDCFG.TDCOC = 0_B)

Figure 23.21 shows the read flow to get the measured transmitter delay compensation result.

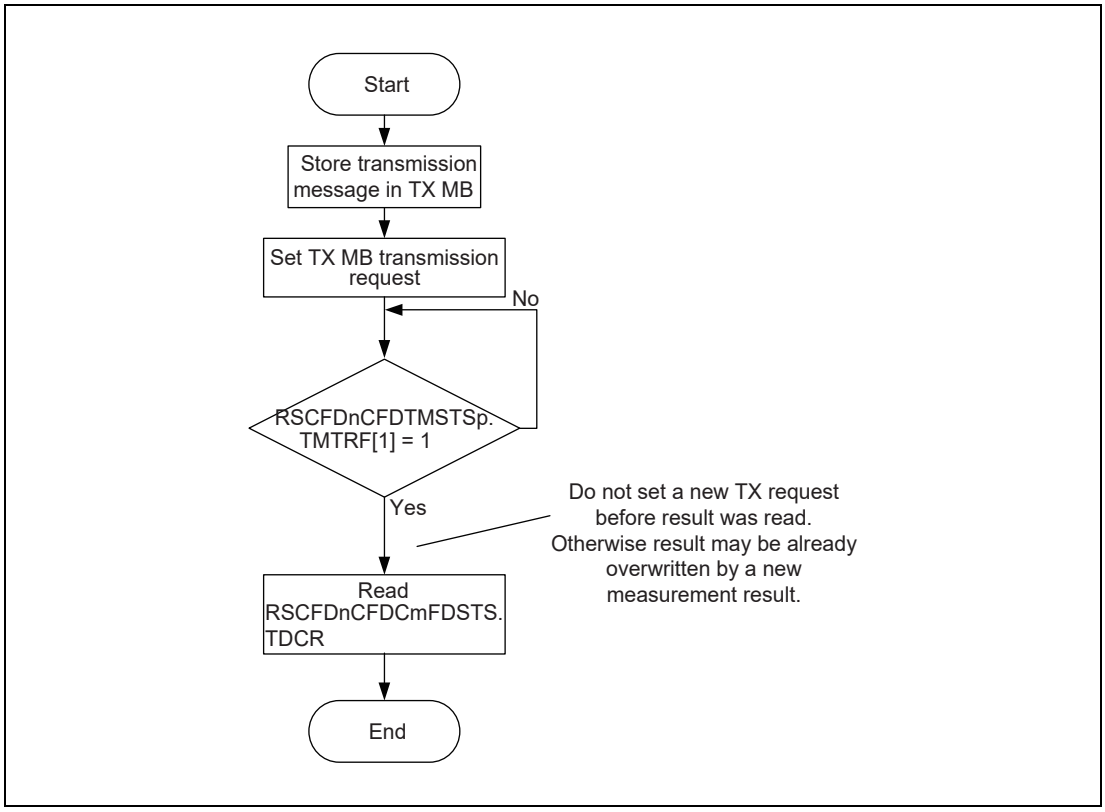

Figure 23.21 TDC result read flow

23.5.2 CAN Module Configuration after H/W Reset

After MCU HW is reset or after setting and clearing a RSCFDnCFDGRSTC.SRST bit, the RS-CANFD module enters Global Stop Mode automatically.

To enable configuration of the RS-CANFD module, the Stop Mode has to be left by clearing the Global Stop Request bit RSCFDnCFDGCTR.GSLPR to 0_B.

After MCU HW reset the module starts the RAM initialization, the RSCFDnCFDGSTS.GRAMINIT bit in the Global Status Register is set automatically indicating that the RS-CANFD logic is initializing the RAM.

After the RAM initialization is completed, this bit is cleared automatically.

The RAM initialization is necessary to avoid setting of false ECC error flag after HW reset due to random data present in the RAM.

The registers of RS-CANFD should not be accessed (in either read or write) until the RAM initialization is complete and the RSCFDnCFDGSTS.GRAMINIT bit is cleared.

Before going to communication mode the Global Acceptance Filter List and message FIFO buffers must be configured. Furthermore each required CAN channel has to be configured (e.g. CAN bit timing)

For this all required CAN channels have to be released from channel Stop Mode and have to be configured for communication in channel Reset Mode (Configuration Mode).

Figure 23.22, Configuration procedure after H/W Reset shows the configuration procedure. For details about each step, refer to **Section 23.6, Acceptance Filtering Function using Global Acceptance Filter List (AFL)**, **Section 23.7, FIFO Buffers & Normal MB Configuration**, **Section 23.8, Interrupts and DMA** and **Section 23.5.1.3, Baud Rate**.

The RS-CANFD module does not perform the RAM initialization sequence after executing SW Reset by setting RSCFDnCFDGRSTC.SRST.

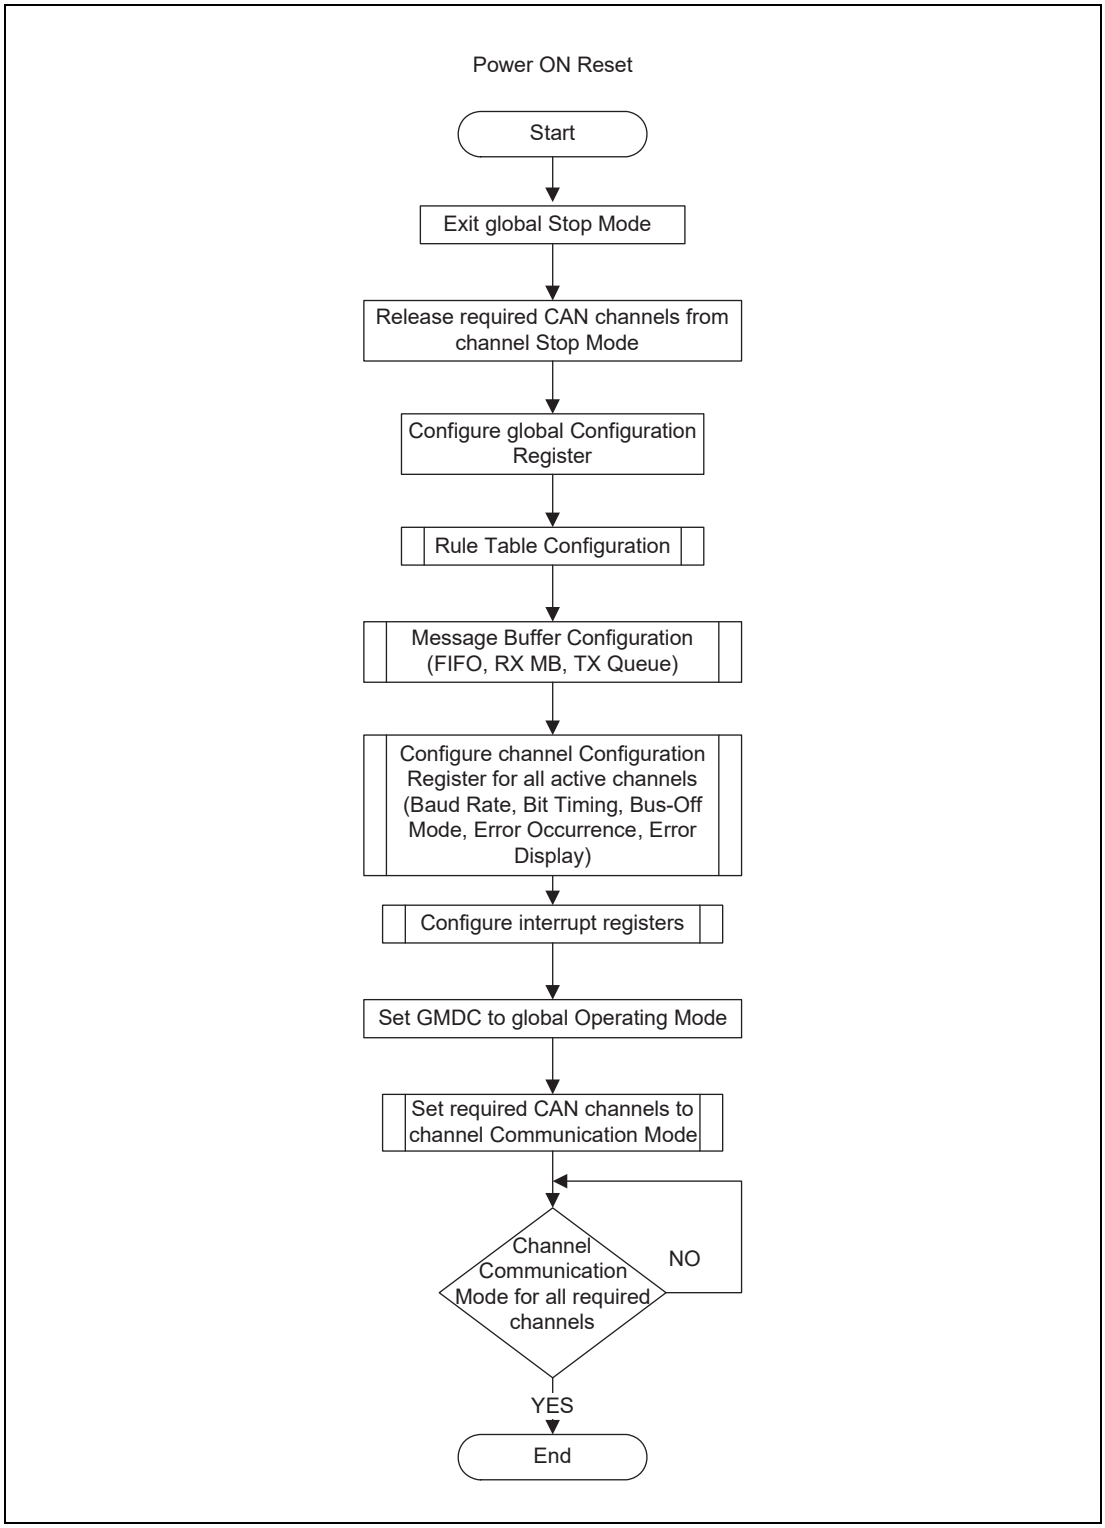

Figure 23.22 Configuration procedure after H/W Reset

23.6 Acceptance Filtering Function using Global Acceptance Filter List (AFL)

23.6.1 Overview

The RS-CANFD module can handle message acceptance filtering for all channels with a global Acceptance Filter List (called AFL). Each element of the AFL defines a filter rule for messages received on a specific channel.

Following actions will be done based on the AFL entries:

- Acceptance filtering based on received CAN Identifier and masking
- DLC filtering based on received DLC value
- Message data payload according to the RSCFDnCFDGCFG.CMPOC bit
- Storage of accepted messages in the Message Buffer objects defined in the related AFL entry
- Attaching a 16 bit pointer to the stored messages defined in the related AFL entry e.g. to support AUTOSAR applications
- Attaching a 2 bit information label to the stored messages defined in the related AFL entry

The RS-CANFD module allows a maximum of (Number of AFL) x (Number of Channel) entries across all channels with a maximum of 384 AFL entries for U2A-EVA, U2A16, U2A8 and 255 AFL entries for U2A6 per single channel in a unit.

During acceptance filtering process, each AFL entry in a channel is checked against the received message by the acceptance filter unit. Check is starting from the lowest AFL entry number for this channel.

AFL search is stopped when a match of the received Identifier with a configured Identifier/Mask combination occurs or when the received Identifier has been compared against all AFL entries defined for the related channel. If no match occurs, then the received message is rejected. No notification is given to the application in this case.

Additionally, an automatic DLC filtering is performed for each accepted message if DLC Check is globally enabled. If the DLC value of the received message is equal to or higher than the configured DLC value in the matching AFL entry, then the DLC check is passed.

If DLC replacement (RSCFDnCFDGCFG.DRE bit) is enabled, DLC value configured in the matching AFL entry is greater than 0000_H and DLC check passes, then the configured value of DLC in the matching AFL entry is stored in the destination RXMB or FIFO Buffer.

If the received value of DLC is greater than the configured DLC value in the matching AFL entry, then the additional Data Bytes received on the CAN Bus are not stored in the destination RXMB or FIFO Buffer. These additional Data Bytes will be stored as 0_H in the destination RXMB or FIFO Buffer.

If DLC replacement is enabled and DLC value of matching AFL entry is 0_H, then the received value of DLC will be stored in the destination RX MB or FIFO Buffer.

If DLC replacement (RSCFDnCFDGCFG.DRE bit) is disabled and DLC check passes, then the received value of DLC on the CAN Bus is stored in the destination RXMB or FIFO Buffer.

If the received value of DLC is greater than the configured DLC value in the matching AFL entry, then the additional Data Bytes received from the CAN Bus are also stored in the destination RXMB or FIFO Buffer.

If DLC value of the received message is less than the configured DLC value in the matching AFL entry, then DLC check fails. In this case, the received message is rejected and it is not stored in any RXMB or FIFO Buffer.

Additionally, DLC check failure will be flagged by the DLC Error Flag in the Global Error Flag Register.

If configured, an error interrupt will also be generated.

The DLC replacement configuration has no impact if the DLC check fails.

If a message has passed both acceptance filtering and DLC filtering, it is stored in a single reception Message Buffer and/or in FIFO buffers configured for reception or gateway function or Tx queue configured for gateway function.

This message storage target information is also defined in the same AFL entry. Users should not set a target at the AFL entry which is not configured.

Each accepted received message could be stored into a maximum of 8 different target destinations (single reception Message Buffer and/or FIFO buffers).

(Programming of more than 8 target destinations is not allowed. In the case more destinations are programmed then internal timing race condition can occur and received message may not be stored to the Message RAM. Correct configuration of the numbers of Target destination is the responsibility of the application)

Further protection mechanism is made for the case when a received message contains more data payload Bytes than possible to store in the target destination (RSCFDnCFDRMNB.RMPLS, RSCFDnCFDRFCCx.RFPLS or RSCFDnCFDCFCCk.CFPLS).

If the RSCFDnCFDGCFG.CMPOC = 0_B then the message is completely rejected and will not be stored in the target destination. In the case of RSCFDnCFDGCFG.CMPOC = 0_B and RX or Transmit/Receive FIFO full and the received message contains more data payload Bytes than possible to store in the target destination (RSCFDnCFDRMNB.RMPLS, RSCFDnCFDRFCCx.RFPLS or RSCFDnCFDCFCCk.CFPLS), the corresponding RSCFDnCFDFMSTS.RFxMLT or RSCFDnCFDFMSTS.CFkMLT will not be set to 1_B respectively.

If the RSCFDnCFDGCFG.CMPOC = 1_B then the received Data Bytes greater than RSCFDnCFDRMNB.RMPLS will be rejected. In the case of RSCFDnCFDGCFG.CMPOC = 1_B and RX or Transmit/Receive FIFO full and the received message contains more data payload Bytes than possible to store in the target destination (RSCFDnCFDRMNB.RMPLS, RSCFDnCFDRFCCx.RFPLS or RSCFDnCFDCFCCk.CFPLS), the corresponding RSCFDnCFDFMSTS.RFxMLT or RSCFDnCFDFMSTS.CFkMLT will be set to 1_B respectively.

Depending on the RSCFDnCFDGCFG.DRE the original received DLC or the DLC value configured at the AFL entry will be stored.

Regardless of RSCFDnCFDGCFG.CMPOC configuration, RSCFDnCFDGERFL.CMPOF will be set to 1_B if payload overflow condition is detected.

The DLC filtering is performed before the payload overflow function. Hence for one reception frame only one flag could be set at the same time RSCFDnCFDGERFL.DEF or RSCFDnCFDGERFL.CMPOF.

23.6.2 Allocation of AFL entries to each CAN channel

The number of AFL entries per channel can be configured using the dedicated field in the related Global Acceptance Filter Configuration Register (see **Figure 23.23**).

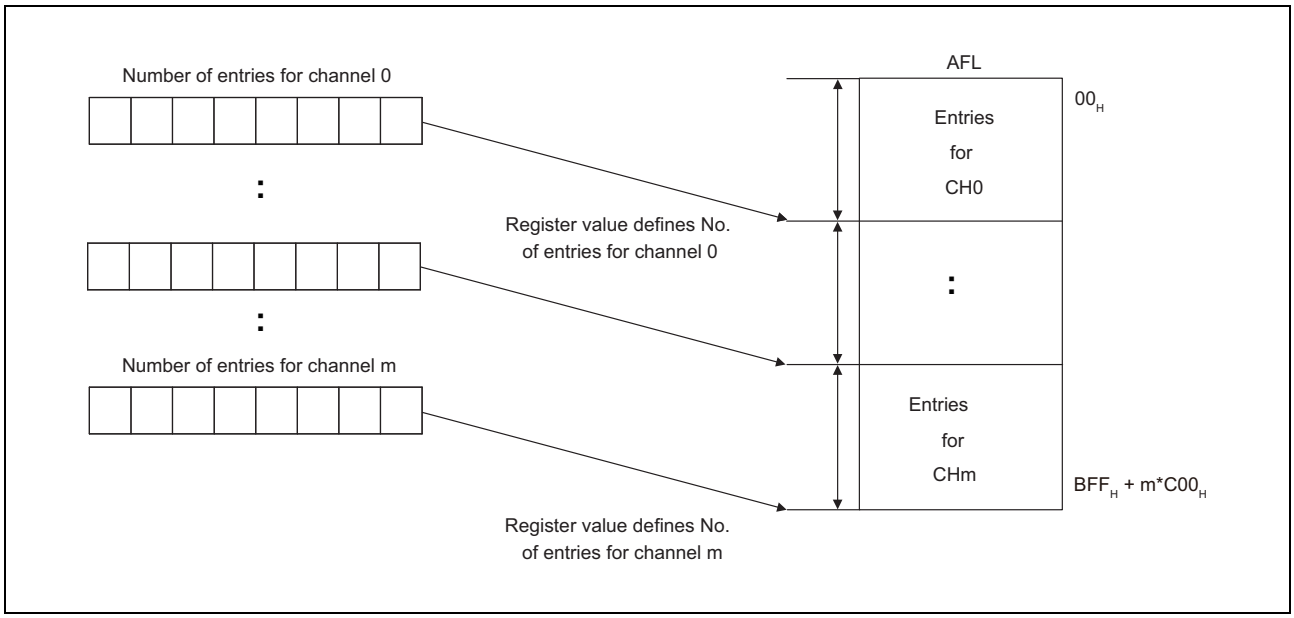

Figure 23.23 Configuration of AFL for each channel

The minimum number of entries for one channel is 0 (no entries defined for the channel), the maximum number of entries for one channel is 384 for U2A-EVA, U2A16, U2A8 and 255 for U2A6. The total number of entries for all channels in a unit should not exceed the maximum limit of (m+1) x (Number of AFL).

All entries are unique for a channel and overlapping or sharing of entries is not supported. Correct configuration of the AFL is the responsibility of the application.

The RS-CANFD module will not flag errors related to the configuration of the AFL.

23.6.3 AFL entry description

Each AFL entry consists of 16 Bytes. The fields in all entries are identical.

Each entry contains the following information for acceptance filtering and DLC filtering:

Identifier (11 bits for Standard Frame Format, 29 bits for Extended Frame Format):

Acceptance filter unit will check Identifier field of received message against Identifier field of each AFL entry (full 29 bit masking of Identifier bits possible, see below).

IDE bit:

Acceptance filter unit will check IDE bit of received message against this bit and selects the relevant part of the Identifier field for acceptance filtering (masking of IDE bit possible, see below).

RTR bit:

Acceptance filter unit will only accept Data Frames (RTR = 0) or Remote Frames (RTR = 1) according to the setting of this bit (masking of RTR bit possible, see below).

Loopback Configuration bit:

This bit can enable/disable the AFL entry depending on the Loopback Configuration or Mirror Mode condition.

Mask for Identifier bits (29 bits):

Each bit in the Identifier Mask can mask the corresponding Identifier bit in the AFL entry during acceptance filtering (**Figure 23.24**).

Mask for IDE bit:

If this Mask bit masks the IDE bit of the AFL entry both Standard Identifier and Extended Identifier format messages can be accepted by this AFL entry. The identifier of the received message is compared against the Standard Identifier part of the AFL entry for Standard Identifier format messages and against the Extended Identifier part of the AFL entry for Extended Identifier format messages.

Mask for RTR bit:

If this Mask bit masks the RTR bit of the AFL entry both frame formats ‘Data Frame’ and ‘Remote Frame’ will be accepted by this AFL entry.

Pointer information (16 bits):

This 16 bit pointer will be attached to a received message accepted by the related AFL entry. The Pointer will be added during message storage in the Message Buffer area and can be used by application as support function. The pointer information could be used for example to support PDU Identifier allocation for the received message in AUTOSAR systems.

Information Label (2 bits):

This 2bit label will be attached to a received message accepted by the related AFL entry. The label will be added during message storage in the Message Buffer area and can be used by application as support function.

DLC value for automatic DLC filtering:

If the DLC value of the received message is equal or higher than the configured DLC value the DLC check is passed.

If the DLC value in this AFL entry is configured to 1’b0 DLC filtering is effectively disabled for this entry (all accepted messages will pass DLC filtering).

Each AFL entry contains the following information for the handling of received messages.

Message Buffer number of one single reception Message Buffer as target for received message storage.

Single reception Message Buffer enable bit to configure the single reception Message Buffer number as valid/invalid as target for received message storage

FIFO direction pointer: each bit of the FIFO direction pointer configures a dedicated FIFO as possible target for a received message.

NOTE

A message received on channel “A” can be routed to Transmit/Receive FIFO Buffer of another channel and if this Transmit/Receive FIFO Buffer is configured in GW mode, then the message stored in this Transmit/Receive FIFO Buffer will be transmitted on that channel since Transmit/Receive FIFO Buffer is associated with channel.

There is no hardware protection against such storage of message. Hence the FIFO direction pointer should be configured carefully.

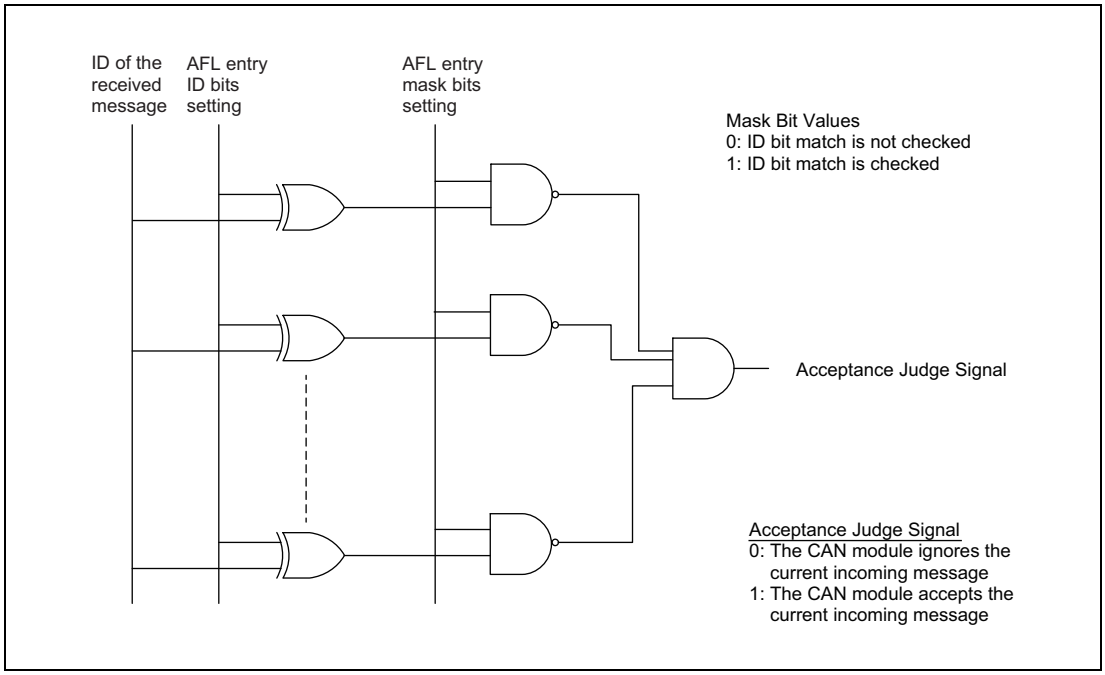

Figure 23.24 Acceptance Function

23.6.4 Entering entries in the AFL

Application SW can enter one full entry into the AFL via following registers:

- Global AFL ID Register: Part 1 of the AFL entry
- Global AFL Mask Register: Part 2 of the AFL entry
- Global AFL Pointer 0 Register: Part 3 of the AFL entry
- Global AFL Pointer 1 Register: Part 4 of the AFL entry

16 sets of these registers form a group of AFL entries. Each group can be accessed via a page mechanism. For the RS-CANFD module, 8-channel version, 96 of these pages exist to allow access to the whole AFL range. The AFL should only be configured in CH_RESET or CH_HALT. Pages are linked to the AFL entries in the following way:

NOTE

In U2A6, the maximum number of page of RSCFD0 is 64, the maximum number of page of RSCFD1 is 32.

The selection of the AFL access page is done using the Global Acceptance Filter List Entry Control Register (RSCFDnCFDGAFLECTR) (**Figure 23.25**). This register has following fields:

- 7 bit to select the AFL Page number
- 1 bit to enable/disable the AFL Data access to prevent unwanted write access to the AFL

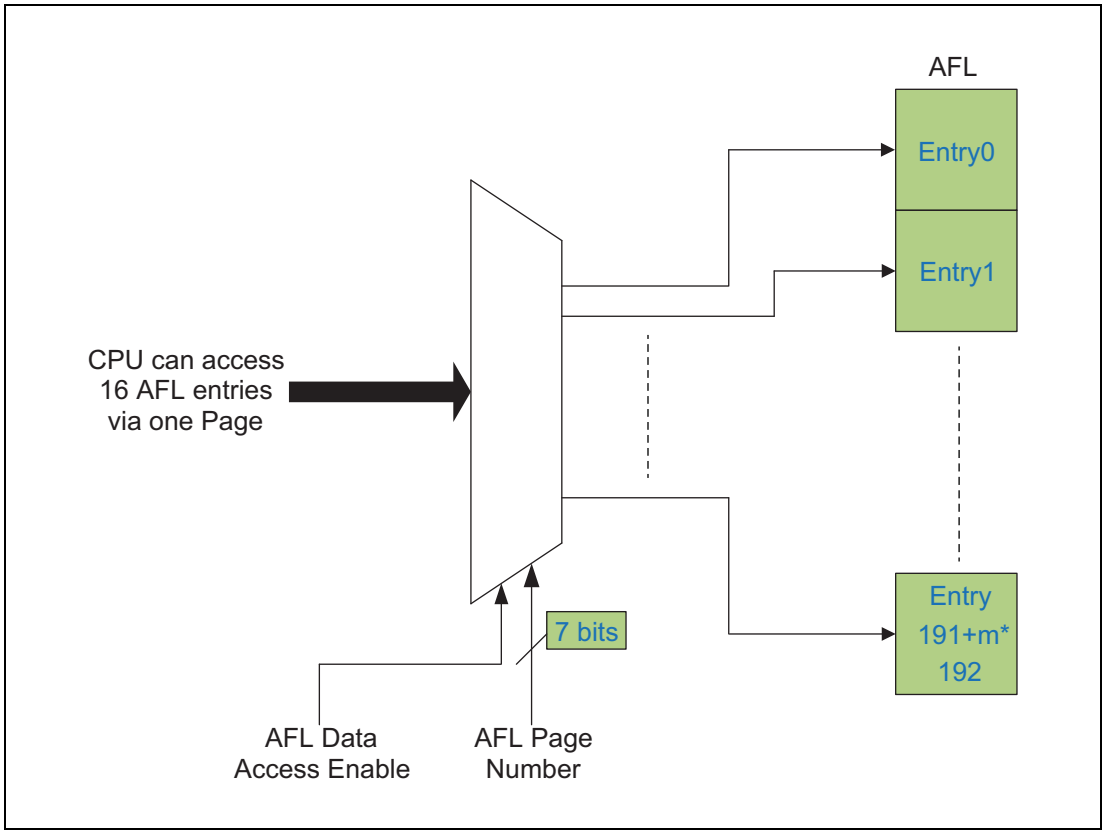

Figure 23.25 AFL page access

Application SW should not write numbers higher than $5F_H$ for the AFL Page number.

The configuration flow shown in **Figure 23.26** should be followed to program the AFL.

After entering all entries in Configuration Mode, locking of the AFL access should be performed to protect unwanted write access to the AFL.

Write protection is active during all global modes if the lock bit is set (GL_RESET, GL_TEST, and GL_OPERATING).

Read access to AFL is still possible during all global modes even if AFL data access is disabled (consistency check of AFL contents possible during runtime).

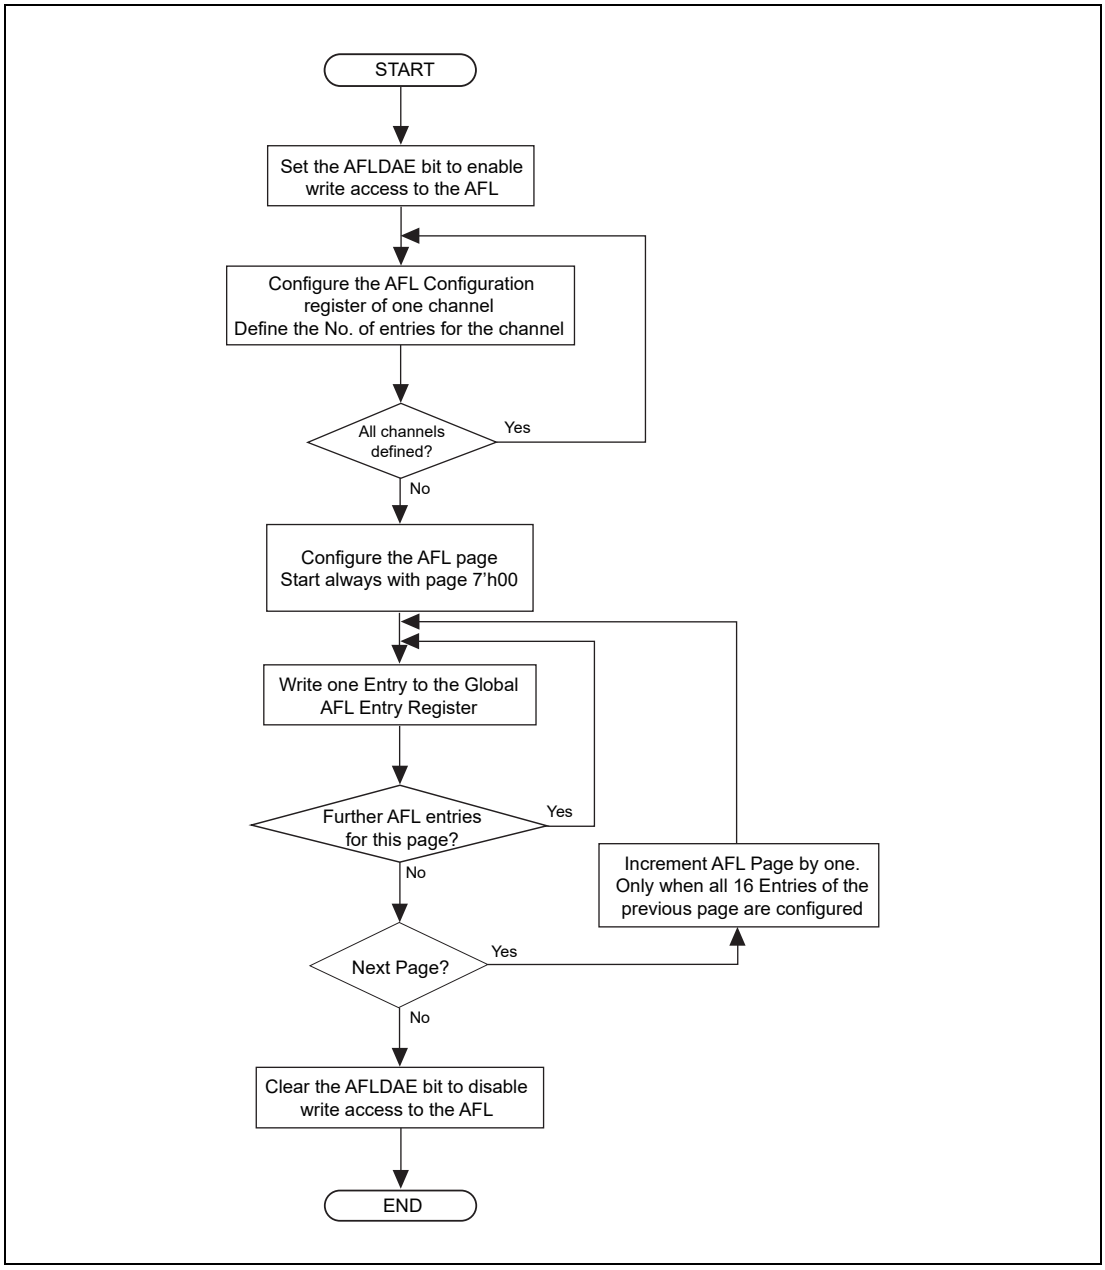

Figure 23.26 AFL configuration flow

23.6.5 Loopback modes

If the Loopback Configuration bit is set, the AFL entry is only valid in loopback test mode (Self test mode 0 or Self test mode 1) or in mirror mode when receiving messages that were transmitted by the respective CAN channel itself.

The AFL entry is not valid for received messages in loopback mode transmitted by other CAN nodes on the bus (the expression ‘valid or invalid’ for the related entry means that this AFL entry ‘will or will not’ be compared against the received message ID respectively).

If the Loopback Configuration bit is 0_B the AFL entry is only valid for

- Received messages transmitted by other CAN nodes on the bus in normal (non-loopback mode) and mirror mode
- Received messages transmitted by other CAN nodes or the CAN channel itself in loopback test mode

The mirror mode can be enabled via the RSCFDnCFDGCFG.MME bit in the Global Configuration Register. If RSCFDnCFDGCFG.MME bit is set, then a successfully Transmitted message can be stored back in an RX MB or FIFO Buffer if a matching Entry is configured in the AFL for that channel.

The Loopback configuration bit in the matching AFL Entry must be set for storing this Frame.

If mirror mode and loopback test mode are configured at the same time the loopback test mode behavior applies.

Table 23.145 shows the behavior of the acceptance filter unit depending on the setting of the related input signals.

Table 23.145 Acceptance filter behavior based on Loopback Configuration setting in AFL entry

Mirror mode enable (MME configuration bit)	Loopback in test mode (Selftest Mode 0 or Selftest Mode 1)	Channel Mode	Loopback configuration bit in AFL Entry	AFL entry
0	0	Receiver	0	valid
			1	invalid
		Transmitter	0	invalid
			1	invalid
	1	Receiver	0	valid
			1	invalid
		Transmitter	0	valid
			1	valid
1	0	Receiver	0	valid
			1	invalid
		Transmitter	0	invalid
			1	valid
	1	Receiver	0	valid
			1	invalid
		Transmitter	0	valid
			1	valid

Note: The expression ‘valid’ or ‘invalid’ for the related entry means that this AFL entry ‘will or will not’ be compared against the received message ID respectively.

23.6.6 IDE Masking

When the GAFLIDEM bit is 0_B in an AFL entry, then the IDE bit configured in the AFL Entry is not considered for ID matching. In this case the decision of ID[10:0] or ID[28:0] matching is based on the received IDE bit.

Consider the following Example:

The ID & Mask fields of an AFL Entry “x” is configured as follows:

RSCFDnCFDGAFLID [x] = $C0553A20_H$ → IDE = 1, RTR = 1, LLB = 0, ID[10:0] = 220_H / ID[28:0] = $0553A20_H$

RSCFDnCFDGAFLMj = $0000FFFF_H$ → IDEM = 0. RTRM = 0, IDM[10:0] = $7FF_H$ / IDM[28:0] = $0000FFFF_H$

The result of comparison of 4 different received Ids with AFL Entry X is described below:

If a frame with IDE = 0_B & ID = 220_H is received, then this is considered as a match.

If a frame with IDE = 0_B & ID = 320_H is received, then this is not a match.

If a frame with IDE = 1_B & ID = $1FFF3A20_H$ is received, then this is considered as a match.

If a frame with IDE = 1_B & ID = 08803220_H is received, then this is not a match.

23.7 FIFO Buffers & Normal MB Configuration

This Section describes the process for configuration of the number of RX Message Buffers, the FIFO Buffers and the Flat TX Message Buffers in the RS-CANFD module. The Message Buffers are mapped as shown in **Figure 23.27** below.

The RX Message Buffers can be accessed via RX Message Buffer Register.

The RX FIFO buffers and the Transmit/Receive FIFO buffers configured in RX mode or TX mode or GW mode can only be accessed via the FIFO Access Register.

If the Transmit/Receive FIFO is configured in TX mode, then users can only write data into the FIFO via FIFO Access registers.

If the Transmit/Receive FIFO is configured in GW mode or RX mode then users can only read data from the FIFO Access Register.

The TX Message Buffers can be accessed via the TX Message Buffer Register.

If users read unused Message Buffer locations, the MB locations are read as unknown values.

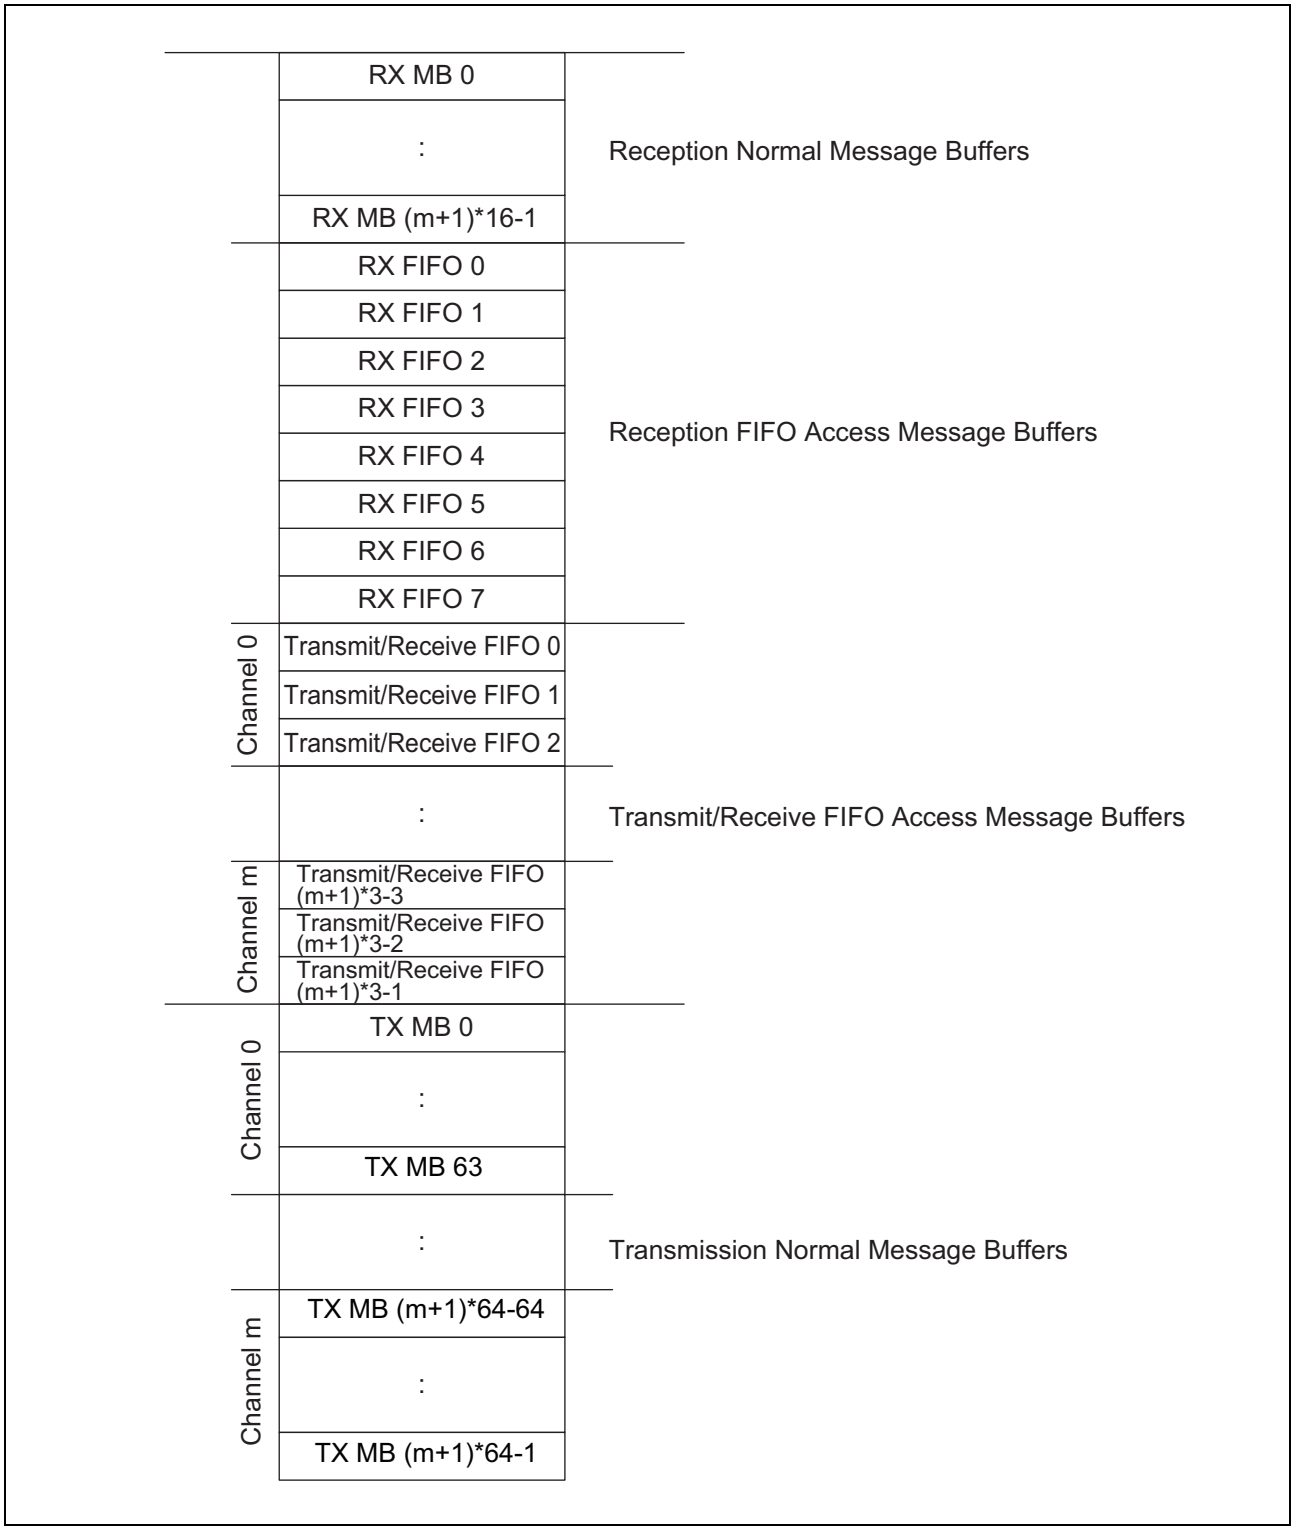

Figure 23.27 Message Buffer Configuration

23.7.1 Normal RX Message Buffers

In RS-CANFD module, the frames received by various channels can be stored in Normal RX Message Buffers based on the configuration of the AFL entries.

Additionally, the number of Normal RX Message Buffers required in the system can be chosen up to a fixed maximum limit.

23.7.1.1 Normal RX Message Buffer configuration

In RS-CANFD module, the number of normal RX Message Buffers can be configured by writing to the RX Message Buffer Number Register.

The limiting values for the configuration of number of Message Buffers are:

Minimum Value = 0_H (no Normal RX MB)

Maximum Value = (16 * No. of CAN channels)

= 80_H (128 Flat RX MBs for 8 channels)

Users should not use values outside these limits.

The AFL entries for routing the received messages to normal RX Message Buffers should be configured to match the requirements of the system.

The AFL entries should also be configured properly. An AFL entry for normal RX Message Buffers should not exceed the number of Message Buffers configured in the RX Message Buffer Number Register.

NOTE

There is no internal check procedure provided in RS-CANFD module against wrong configuration of the AFL.

The data field size of the RX Message Buffer can be configured via the RSCFDnCFDRMNB.RMPLS. The default size is 8 Bytes the max. data payload size is 64 Bytes.

In case the receiving frame exceeds the data field size then the acceptance depends on the configuration of the RSCFDnCFDGCFG.CMPOC (message rejecting or data payload cut).

23.7.2 FIFO Buffers

The RS-CANFD module provides a fixed number of FIFO Buffers to support storage of frames for reception, transmission and gateway functions for various CAN channels.

Number of reception-only FIFO Buffers is fixed to 8.

However, 3 Transmit/Receive FIFO Buffers per channel can be configured for storing messages for transmission or reception or gateway function.

These FIFO Buffers can be enabled or disabled and the size, Interrupt structure and Message Lost mechanism and Message overwrite mechanism of the FIFO Buffers, as well as the location of the TX FIFO or GW FIFO can be configured to match the system requirements.

In case the receiving frame exceeds the data field size then the acceptance depends on the configuration of the RSCFDnCFDGCFG.CMPOC (message rejecting or data payload cut).

23.7.2.1 FIFO Buffers configuration

In RS-CANFD module, the FIFO Buffers can be configured to match the system requirements.

The total number of FIFO Buffers = 8 RX FIFO Buffers + 24 Transmit/Receive FIFO Buffers =32 FIFO Buffers for 8 channels and Message overwrite mechanism

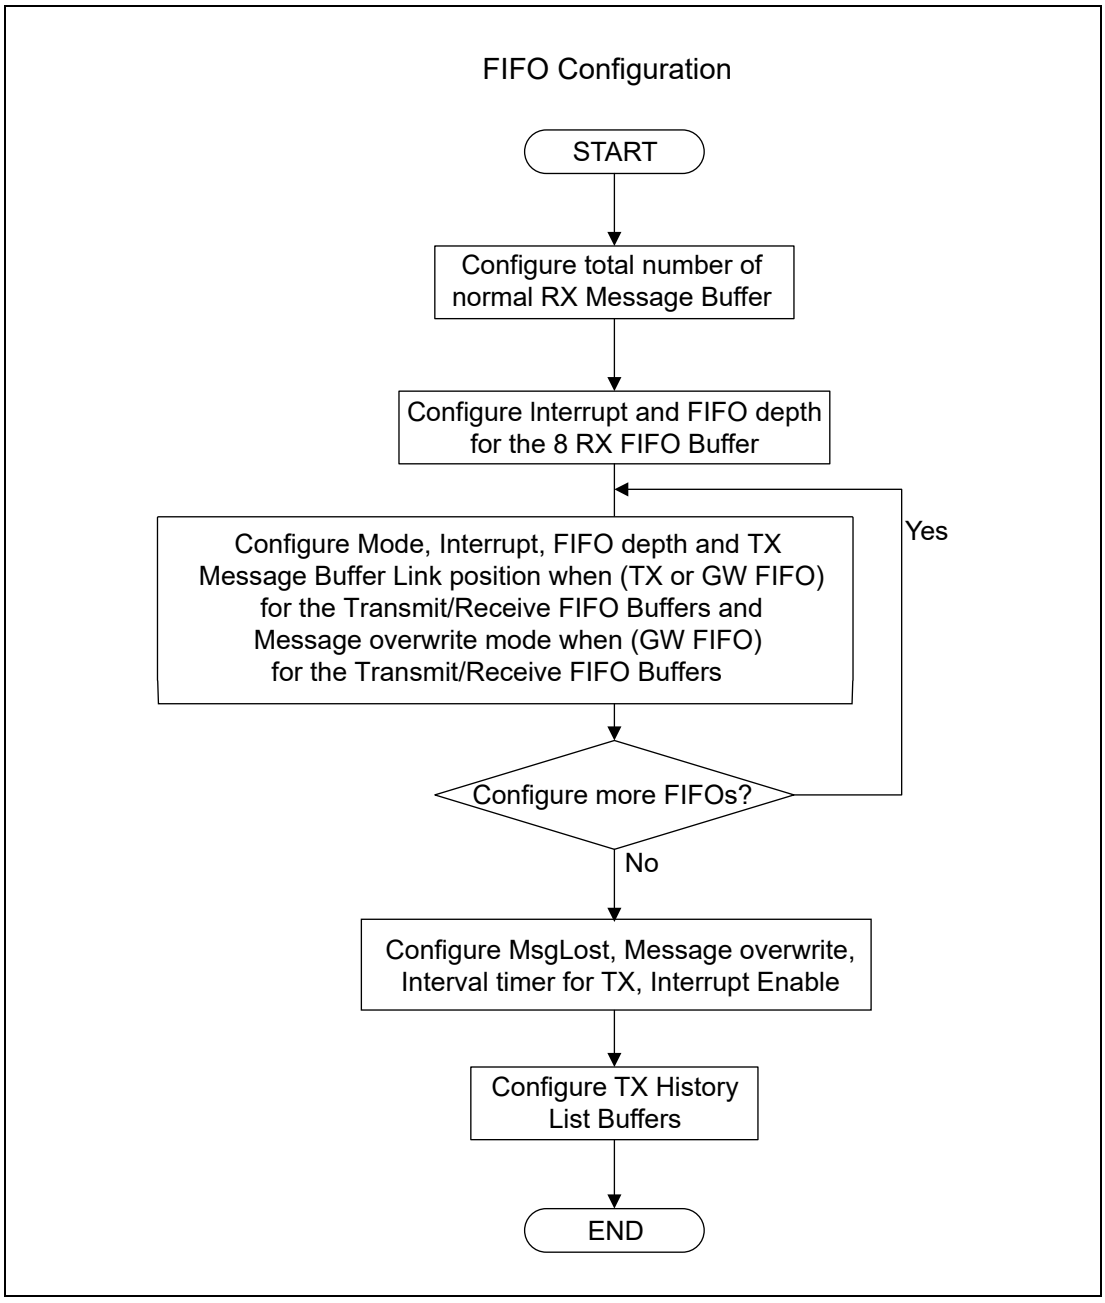

Figure 23.28 FIFO Buffer configuration flow in RS-CANFD module

As shown in **Figure 23.28**, the various FIFO Buffers can be configured by writing to the RX FIFO Configuration/Control Register and the Transmit/Receive FIFO Configuration/Control Register.

For the 8 RX FIFO Buffers, the Interrupts, the FIFO depth and the FIFO payload data size can be configured.

For the Transmit/Receive FIFO Buffers, the mode, Interrupts FIFO depth, the FIFO payload data size and the FIFO TX link position can be configured.

(1) FIFO Mode Configuration of Transmit/Receive FIFO Buffers

The mode of the Transmit/Receive FIFO Buffers can be configured by writing to the RSCFDnCFDCFCCk.CFM[1:0] bits in the Transmit/Receive FIFO Configuration/Control Register. The possible modes of configuration for Transmit/Receive FIFO Buffers are:

00_B: RX mode (default mode after HW Reset)

01_B: TX mode

10_B: GW mode.

11_B: Reserved (Users should not write this value to the Register bits)

Messages can only be read from the RX FIFO Buffers and the Transmit/Receive FIFO Buffers configured in RX Mode.

Messages are stored by the CAN module in these FIFO buffers based on the AFL entries.

Messages can be read and written into the Transmit/Receive FIFO Buffers configured in TX mode. These messages will be transmitted on the appropriate CAN channel.

Messages can only be read from the Transmit/Receive FIFO Buffers configured in GW mode. However, the CPU read access has no impact on the read or write pointers.

The pointers can only be incremented when a new message is stored in the FIFO Buffer and decremented when a message is transmitted on the corresponding CAN channel by the RS-CANFD module.

After HW reset, all the Transmit/Receive FIFO Buffers are configured in RX mode by default. Users should only enable the FIFO Buffers after configuring the Transmit/Receive FIFO Buffers in the required modes.

In GW mode, when a transmit/receive FIFO buffer is trying to receive a new message while the transmit/receive FIFO buffer is already full of data, the oldest data of the buffer will be overwritten with the message received or the message will be discarded. The behavior is determined by setting RSCFDnCFDCFCCEk.CFMOWM bit.

When RSCFDnCFDCFCCEk.CFMOWM=0:

When writing of data is required due to reception of a new message while a transmit/receive FIFO buffer is full of data, the received message will be discarded. And RSCFDnCFDCFSTSk.CFMLT bit is set to 1.

When RSCFDnCFDCFCCEk.CFMOWM=1:

When writing of data is required due to reception of a new message while a transmit/receive FIFO buffer is full of data, the oldest data in the buffer will be overwritten with the received message.

The read pointer of the transmit/receive FIFO buffer simultaneously moves to the next oldest message.

Then, RSCFDnCFDCFSTSk.CFMOW bit is set to 1, which notifies that the oldest message has been overwritten with the received message.

In addition, in a case a CAN bus error or arbitration-lost for the transmitting message occurs in transmit/receive FIFO buffer full, the transmitting message is lost and re-transmission for the message is not performed. Then the read point moves to the next message automatically.

Users should not write change for this bit when the RSCFDnCFDCFCCk.CFE bit is 1_B.

(2) FIFO TX-Message Buffer Link configuration

When the Transmit/Receive FIFO is configured as TX or GW FIFO, then the FIFO Buffer must be linked to a normal TX Message Buffer to participate in the transmission scan of a CAN channel.

The link to a normal TX Message Buffer should be unique i.e. the same TX Message Buffer cannot be shared between 2 or more Transmit/Receive FIFO Buffers.

Users should not write data into a TX Message Buffer that is linked to a Transmit/Receive FIFO buffer.

Also, the TX Message Buffer linked to a Transmit/Receive FIFO buffer should not be a part of the TX Queue.

The TX Message Buffer link of each Transmit/Receive FIFO Buffer can be configured by writing to the RSCFDnCFDCFCCk.CFTML[4:0] bits in the Transmit/Receive FIFO Configuration / Control Register. Available options for TX Message Buffer link configuration are:

00000_B: TX Message Buffer 32

00001_B: TX Message Buffer 33

: :

: :

11110_B: TX Message Buffer 62

11111_B: TX Message Buffer 63

(3) FIFO Depth Configuration

The depth of each FIFO Buffer can be configured by writing to the RSCFDnCFDRFCCx.RFDC[2:0] bits and RSCFDnCFDCFCCk.CFDC[2:0] bits in the RX FIFO Configuration / Control Register and the Transmit/Receive FIFO Configuration / Control Register. The 8 available options for depth configuration are:

000_B: 0 Messages (FIFO Buffer cannot be enabled)

001_B: 4 Messages

010_B: 8 Messages

011_B: 16 Messages

100_B: 32 Messages

101_B: 48 Messages

110_B: 64 Messages

111_B: 128 Messages

The RAM allocation for RX Message Buffers along with FIFO Buffers is limited to (m+1)*256 messages. Configuration of the RX Message Buffers, along with FIFO Buffers, that exceeds this maximum limit should not be done.

RS-CANFD module logic will not check the validity of the configuration.

NOTE

If the FIFO depth of a Transmit/Receive FIFO is 4 messages or more (RSCFDnCFDCFCCk.CFDC[2:0] > 000_B), then the Transmit/Receive FIFO TX Message Buffer link is valid when the FIFO is disabled as well as enabled.

If FIFO depth is 0 messages, then the Transmit/Receive FIFO TX Message Buffer link is not valid when the FIFO is disabled as well as enabled.

(4) FIFO Payload Size Configuration

The data size of each FIFO Buffer can be configured by writing to the RSCFDnCFDRFCCx.RFPLS[2:0] bits and RSCFDnCFDCFCCk.CFPLS[2:0] bits in the RX FIFO Configuration / Control Register and the Transmit/Receive FIFO Configuration / Control Register. The 8 available options for depth configuration are:

000_B: 8 Bytes

001_B: 12 Bytes

010_B: 16 Bytes

011_B: 20 Bytes

100_B: 24 Bytes

101_B: 32 Bytes

110_B: 48 Bytes

111_B: 64 Bytes

The RAM allocation for RX Message Buffers along with FIFO Buffers is limited to (m+1)*256 messages with 64 Data Bytes. Configuration of the RX Message Buffers, along with FIFO Buffers, that exceeds this maximum limit should not be done.

RS-CANFD module logic will not check the validity of the configuration.

(5) FIFO Interrupt Configuration

The Interrupt generation conditions for the FIFO Buffers can be configured by writing to the RSCFDnCFDRFCCx.RFIM and RSCFDnCFDCFCCk.CFIM bit in the RX FIFO Configuration / Control Register and the Transmit/Receive FIFO Configuration / Control Register. The 2 available options are:

0:

RX FIFO Mode: Interrupt generated when Transmit/Receive FIFO counter reaches RSCFDnCFDRFCCx.RFIGCV / RSCFDnCFDCFCCk.CFIGCV value from below values;

TX FIFO Mode: Interrupt generated when Transmit/Receive FIFO transmits last message successfully;

GW FIFO Mode:

Frame RX: Interrupt generated when message counter increments and reaches the Interrupt Threshold value;

Frame TX: Interrupt generated when last message is transmitted successfully from FIFO;

1:

RX FIFO Mode: Interrupt generated at the end of storage of every received message;

TX FIFO Mode: Interrupt generated for every successfully transmitted message;

GW FIFO Mode:

Frame RX: Interrupt generated when message is stored in the FIFO;

Frame TX: Interrupt generated when message is successfully transmitted from the FIFO;

If the interrupt mode bit is 0_B for a RX FIFO, then interrupt is generated based on the configuration of the RSCFDnCFDRFCCx.RFIGCV[2:0] bits.

Similarly, if the interrupt mode bit is 0_B for a Transmit/Receive FIFO configured in RX mode, then interrupt is generated based on the configuration of RSCFDnCFDCFCCk.CFIGCV[2:0] bits.

The 8 available options for configuring the FIFO counter value for generation of an interrupt are:

000: Interrupt generated when FIFO is 1/8th Full

001: Interrupt generated when FIFO is 1/4th Full

010: Interrupt generated when FIFO is 3/8th Full

011: Interrupt generated when FIFO is 1/2 Full

100: Interrupt generated when FIFO is 5/8th Full

101: Interrupt generated when FIFO is 3/4th Full

110: Interrupt generated when FIFO is 7/8th Full

111: Interrupt generated when FIFO is Full

In this case, an interrupt is generated when the Message Count matches the configured value.

However, there are some limitations on the configuration of the RSCFDnCFDRFCCx.RFIGCV[2:0] and RSCFDnCFDCFCCk.CFIGCV[2:0] bits depending upon the FDC[2:0] bits (FIFO Depth Configuration) see **Table 23.146**.

Table 23.146 FIFO Interrupt generation counter vs. FIFO depth configuration

RFDC[2:0] (CFDC[2:0])	RFIGCV[2:0] (CFIGCV[2:0])							
	111	110	101	100	011	010	001	000
000	Don't care (FIFO can not be enabled)							
001	Allowed	Not allowed	Allowed	Not allowed	Allowed	Not allowed	Allowed	Not allowed
010	Allowed							
011	Allowed							
100	Allowed							
101	Allowed							
110	Allowed							
111	Allowed							

Transmit/Receive FIFO can set an interrupt output at the time of the completion of transmitting of one frame, or the completion of reception. Moreover, Transmit/Receive FIFO and RX FIFO can set an interrupt output, when stored to the set-up number (CFDC/RFDC) of FIFO stages

23.7.2.2 FIFO Buffers control

The FIFO Interrupt should be enabled by setting the RSCFDnCFDRFCCx.RFIE bit or RSCFDnCFDRFCCx.RFFIE bits in the RX FIFO Configuration/Control Register and RSCFDnCFDCFCCk.CFRXIE or RSCFDnCFDCFCCk.CFTXIE bits or RSCFDnCFDCFCCEk.CFFIE bits or RSCFDnCFDCFCCEk.CFOFRXIE or RSCFDnCFDCFCCEk.CFOFTXIE in the Transmit/Receive FIFO Configuration/Control Register.

After configuration is complete, each FIFO can be enabled by setting the RSCFDnCFDRFCCx.RFE and RSCFDnCFDCFCCk.CFE bit in the RX FIFO Configuration / Control Register and the Transmit/ Receive FIFO Configuration/Control Register to allow transmission and reception of messages.

In the case of RSCFDnCFDCFCCEk.CFBME = 1, it becomes FIFO buffering mode, send data is stored in Transmit/Receive FIFO, and transmission is stopped. Transmission will be started if it is set as RSCFDnCFDCFCCEk.CFBME = 0.

Users should not write 1 from 0 for this bit when the RSCFDnCFDCFCCk.CFE bit is 1_B.

23.8 Interrupts and DMA

23.8.1 Interrupts

The RS-CANFD module generates several Interrupts.

The interrupt output, which is connected to the Interrupt Controller Unit, can be controlled by the corresponding interrupt enable bit.

The status flag will be set independent from this enable bit.

The channel Transmission Interrupt has an additional Status flag register; these Status bits will only be set when the corresponding interrupt enables are set.

This register supports the identification of the interrupt source for the channel transmission, as this interrupt is driven by several trigger sources.

The Interrupts in the RS-CANFD module can be classified into 2 groups, Global Interrupts and Channel Interrupts:

Global Interrupts:

The RS-CANFD module can generate 2 Global Interrupts:

1. One Global Interrupt for successful reception into the 8 RX FIFO buffers
2. One Global Error Interrupt

Channel Interrupts:

Each channel of the RS-CANFD module can generate 3 Channel Interrupts:

1. Channel Transmission
2. Channel Error Interrupt
3. Successful Reception in a transmit/receive FIFO in RX or GW mode for a channel or Successful Reception in a TXQ

The interrupts are cleared when the corresponding flag bits are cleared or Interrupt enable bits are cleared.

If the set from the RS-CANFD module occurs simultaneously with the clear by the write access, then each flag bit is set. The set condition of the flag bits is prioritized.

Table 23.147 below gives an overview of interrupt sources for the different interrupt outputs.

The Interrupt outputs are Active High.

Table 23.147 Interrupt source overview (1/3)

	Interrupt terminal	Interrupt	Interrupt source	Interrupt clearing
Global Interrupts	can_rxf_int	Successful reception into at least one RX FIFO	Interrupt flag of corresponding RX FIFO for which interrupt is enabled	Clear the interrupt flag of corresponding RX FIFO buffer for which interrupt is enabled
		FIFO full into at least one RX FIFO	FIFO full interrupt flag of corresponding RX FIFO for which interrupt is enabled	Clear the FIFO full interrupt flags of corresponding RX FIFO buffer for which interrupt is enabled
	can_glerr_int	Global Error	Any of the following: • DLC Error Flag • Message Lost Status bit • Message Over Write Status bit • TXQ Message Lost Status bit • TXQ Message Over Write Status bit • TX History Entry Lost Status bit • CANFD Message Payload overflow flag	Clear all of: • DLC Error Flag • Message Lost Flags in all of the FIFO Status Register • Message Overwrite Flags in all of the Transmit/Receive FIFO Status Register • Message Lost Flags in all of the TXQ Status Register • Message Overwrite Flags in all of the TXQ Status Register • TX History List Entry Lost Flag • CANFD Message Payload overflow flag

Table 23.147 Interrupt source overview (2/3)

	Interrupt terminal	Interrupt	Interrupt source	Interrupt clearing
Channel Transmission Interrupts	can_tx_int [m:0]	Channel m successful transmission	Any channel related TX MB Successful flag when Interrupt is enabled NOTE These interrupts are only set for TX Message Buffers that do not belong to an enabled TX Queue and are not pointing to a Transmit/Receive FIFO. Separate interrupts are provided for Transmit/ Receive FIFO buffers & TX Queue	Clear all channel related TX MB Result status bits for which the Interrupt is enabled
		Channel m Abort	Any channel related TX MB Abort flag when Interrupt is enabled NOTE These interrupts are only set for TX Message Buffers that do not belong to an enabled TX Queue and are not pointing to a Transmit/Receive FIFO. Separate interrupts are provided for Transmit/ Receive FIFO buffers & TX Queue	Clear all channel related TX MB Result Status bits for which the Interrupt is enabled globally
		Channel m transmission from TX Queue	Related channel TX Queue Interrupt Flag	Clear related channel TX Queue Interrupt Flag
		Channel m THL Interrupt	Channel m THL Interrupt status flag	Clear the relevant THL Interrupt status flag
		Channel m Transmit/ Receive FIFO TX Interrupt	Interrupt Flag for Transmit/Receive FIFOs in TX or GW mode belonging to the related channel	Clear the interrupt flags of Transmit/Receive FIFOs in TX or GW mode belonging to the related channel
		Channel m Transmit/ Receive FIFO One Frame TX Interrupt	One Frame Transmission Interrupt Flag for Transmit/Receive FIFOs in TX or GW mode belonging to the related channel	Clear the One Frame Transmission interrupt flags of Transmit/Receive FIFOs in TX or GW mode belonging to the related channel
		Channel m TXQ One Frame TX Interrupt	One Frame Transmission Interrupt Flag for TXQs belonging to the related channel	Clear the One Frame Transmission interrupt flags of TXQs belonging to the related channel

Table 23.147 Interrupt source overview (3/3)

	Interrupt terminal	Interrupt	Interrupt source	Interrupt clearing
Channel Transmit/ Receive FIFO RX Interrupt	can_com_frx_int[m:0]	Channel m Transmit/ Receive FIFO RX Interrupt	Interrupt Flag for Transmit/Receive FIFOs in RX or GW mode belonging to the related channel	Clear the interrupt flags of Transmit/Receive FIFOs in RX or GW mode belonging to the related channel
		Channel m Transmit/ Receive FIFO One Frame RX Interrupt	One Frame Reception Interrupt Flag for Transmit/ Receive FIFOs in RX or GW mode belonging to the related channel	Clear the One Frame Reception interrupt flags of Transmit/Receive FIFOs in RX or GW mode belonging to the related channel
		Channel m Transmit/ Receive FIFO Full Interrupt	FIFO Full Interrupt Flag for Transmit/Receive FIFOs in RX or GW mode belonging to the related channel	Clear the FIFO full interrupt flags of Transmit/Receive FIFOs in RX or GW mode belonging to the related channel
		Channel m TXQ One Frame RX Interrupt	One Frame Reception Interrupt Flag for TXQs in GW mode belonging to the related channel	Clear the One Frame Reception interrupt flags of TXQs in GW mode belonging to the related channel
		Channel m TXQ Full Interrupt	TXQ Full Interrupt Flag for TXQs in GW mode belonging to the related channel	Clear the TXQ full interrupt flags of TXQs in GW mode belonging to the related channel
Channel Error Interrupt	can_cherr_int[m:0]	Channel m Error	Any channel related error flag in the Channel Error Flag Register for which Interrupt is enabled in the Channel Error Interrupt Enable Register	Clear all channel related error flags in the Channel Error Flag Register for which Interrupt is enabled in the Channel Error Interrupt Enable Register

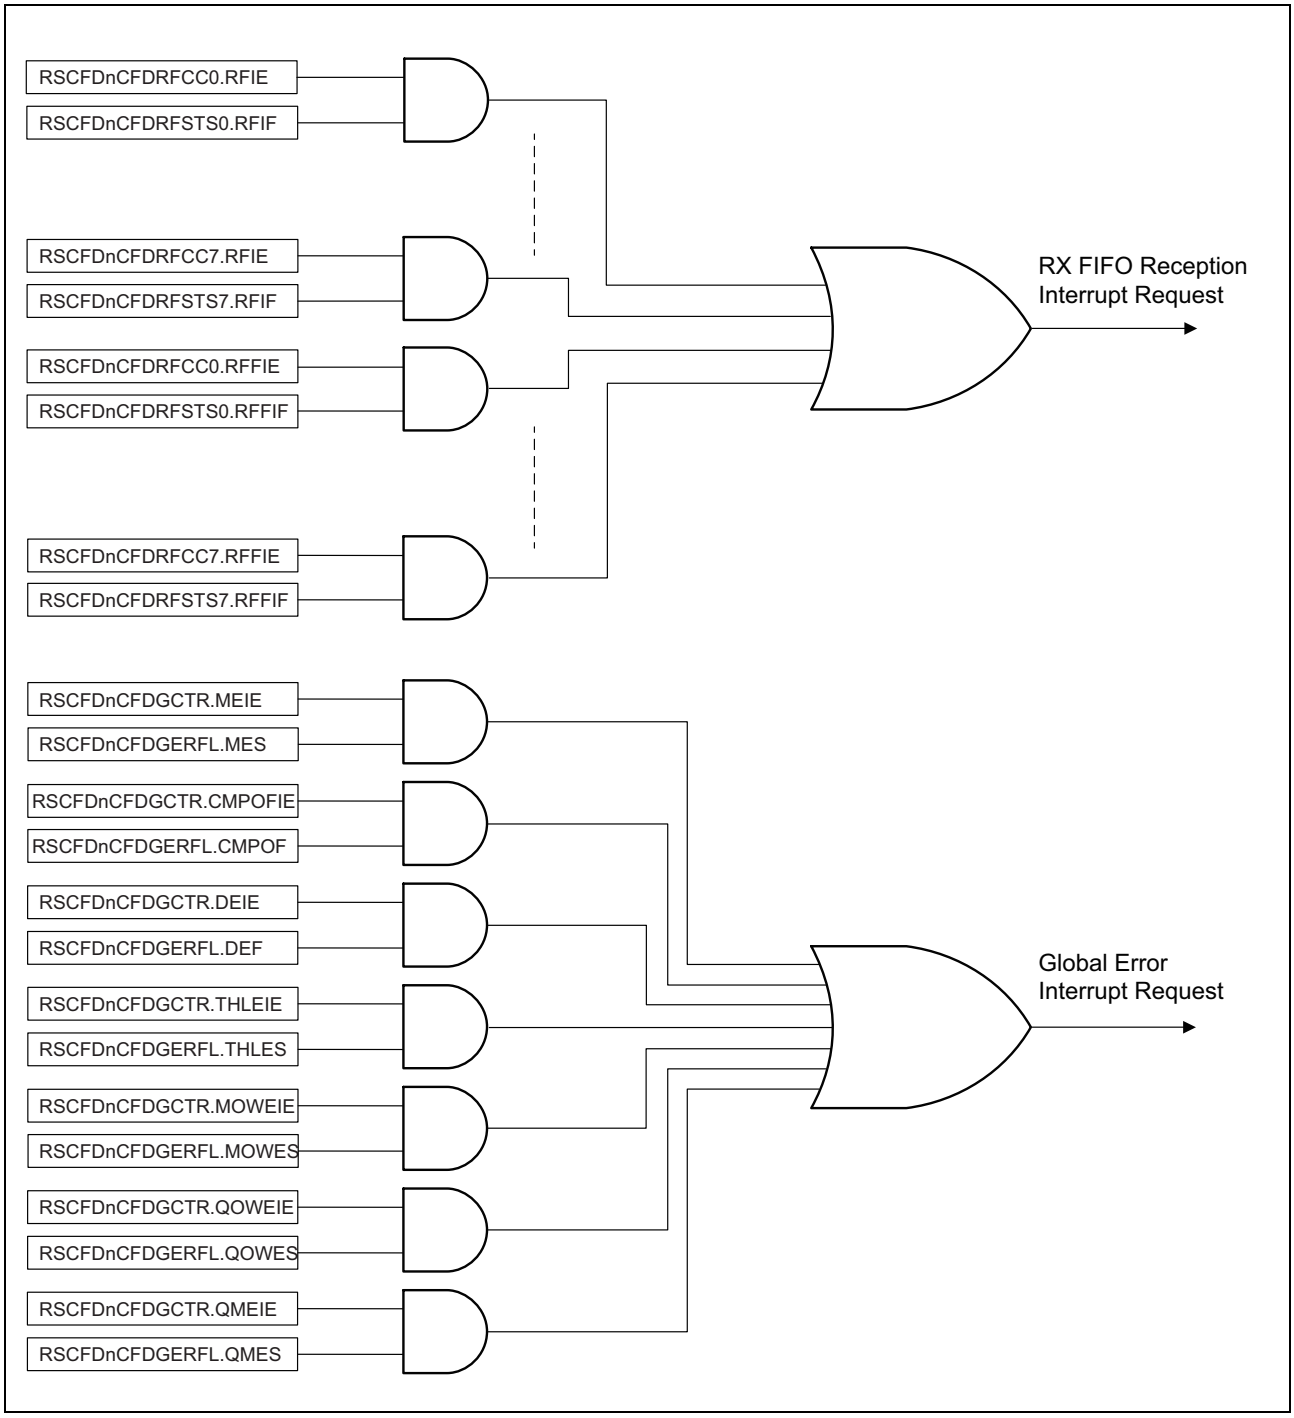

Figure 23.29 Global Interrupt Block Diagram

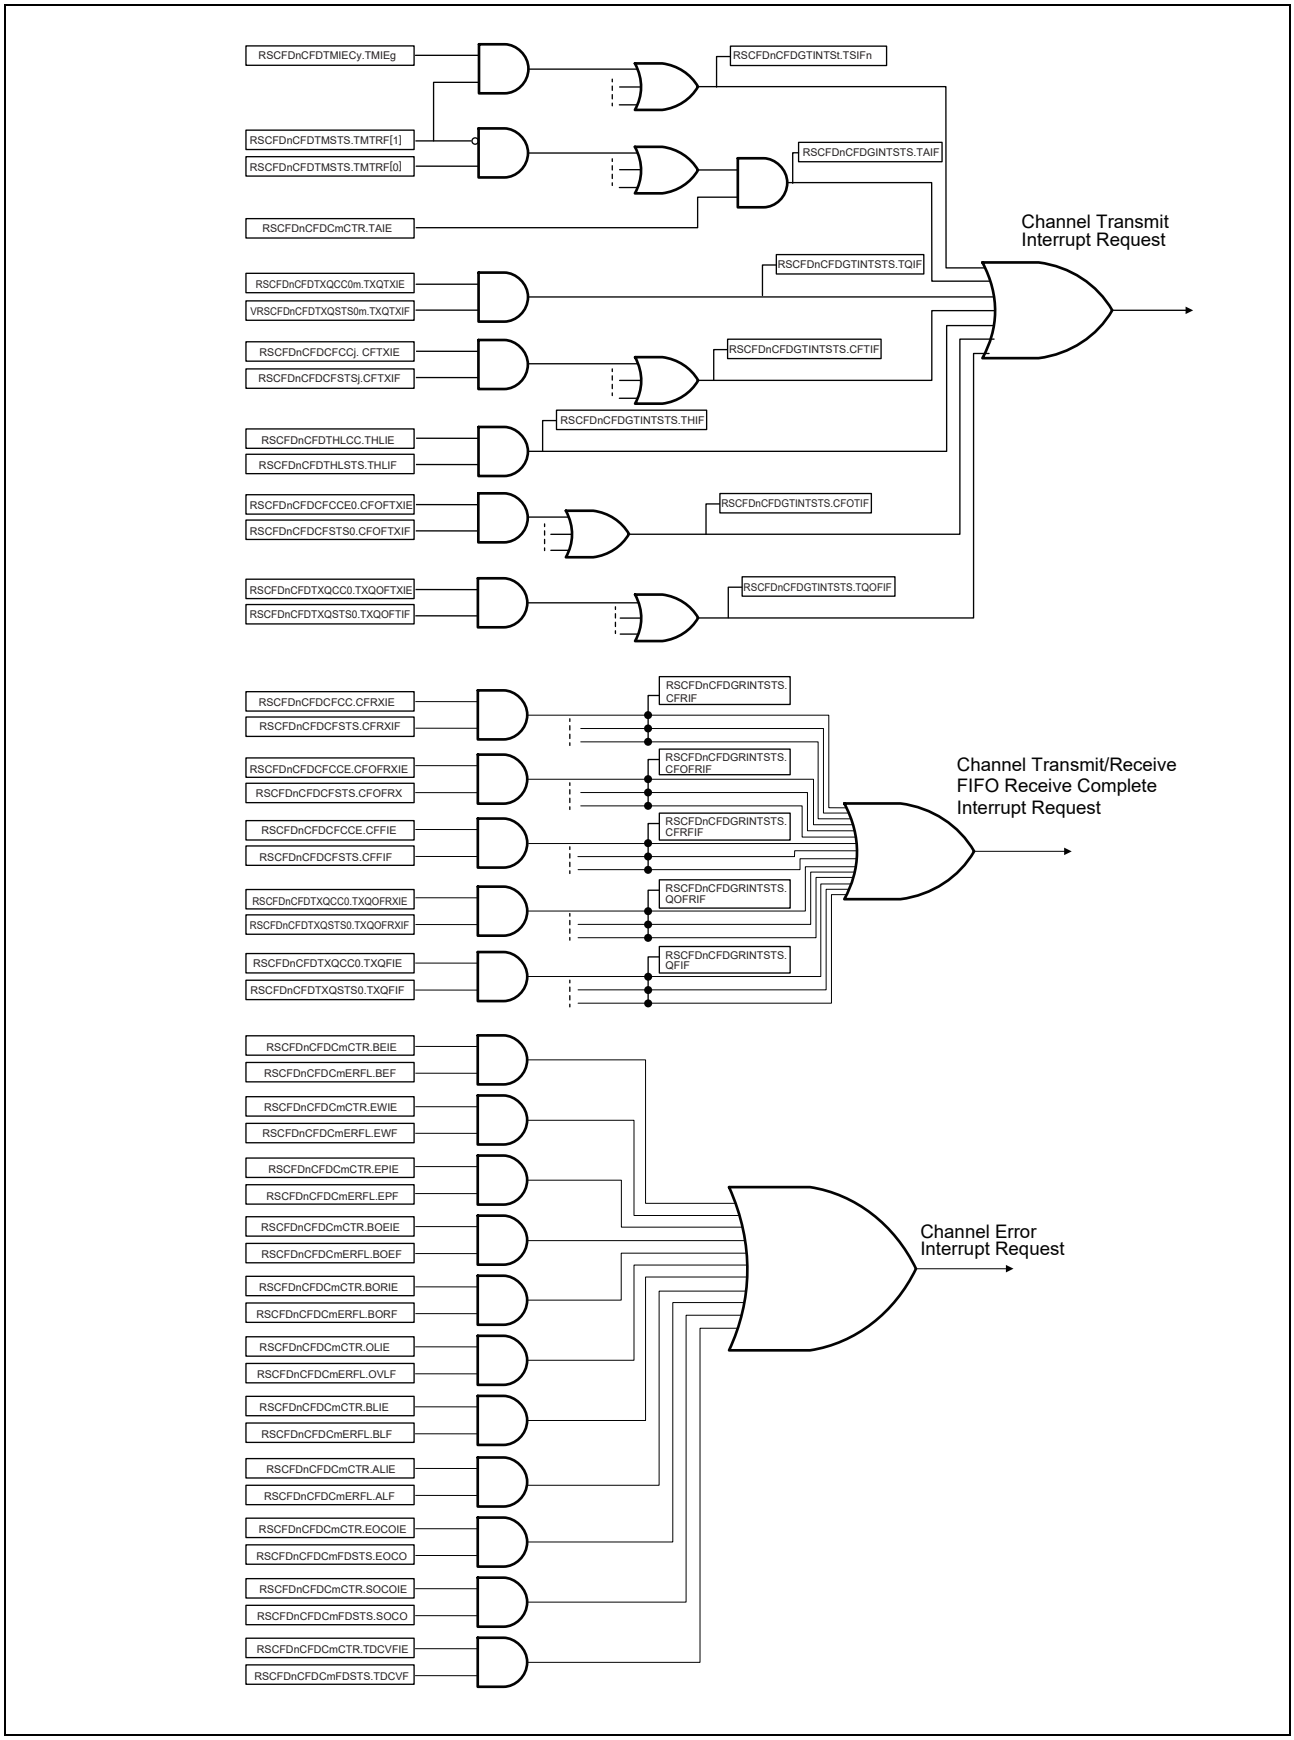

Figure 23.30 Channel Interrupt Block Diagram

23.8.2 DMA Transfer

The RS-CANFD module has some message buffer which can be associated with a DMA channels:

Reception DMA

- 8 RX FIFO Message Buffers
- 8 Transmit/Receive FIFO Message Buffers

Transmission DMA

- 2 x m TXQ Message Buffers (TXQ0, TXQ3)
- m Transmit/Receive FIFO Message Buffers

The figure below illustrates the potential DMA channels.

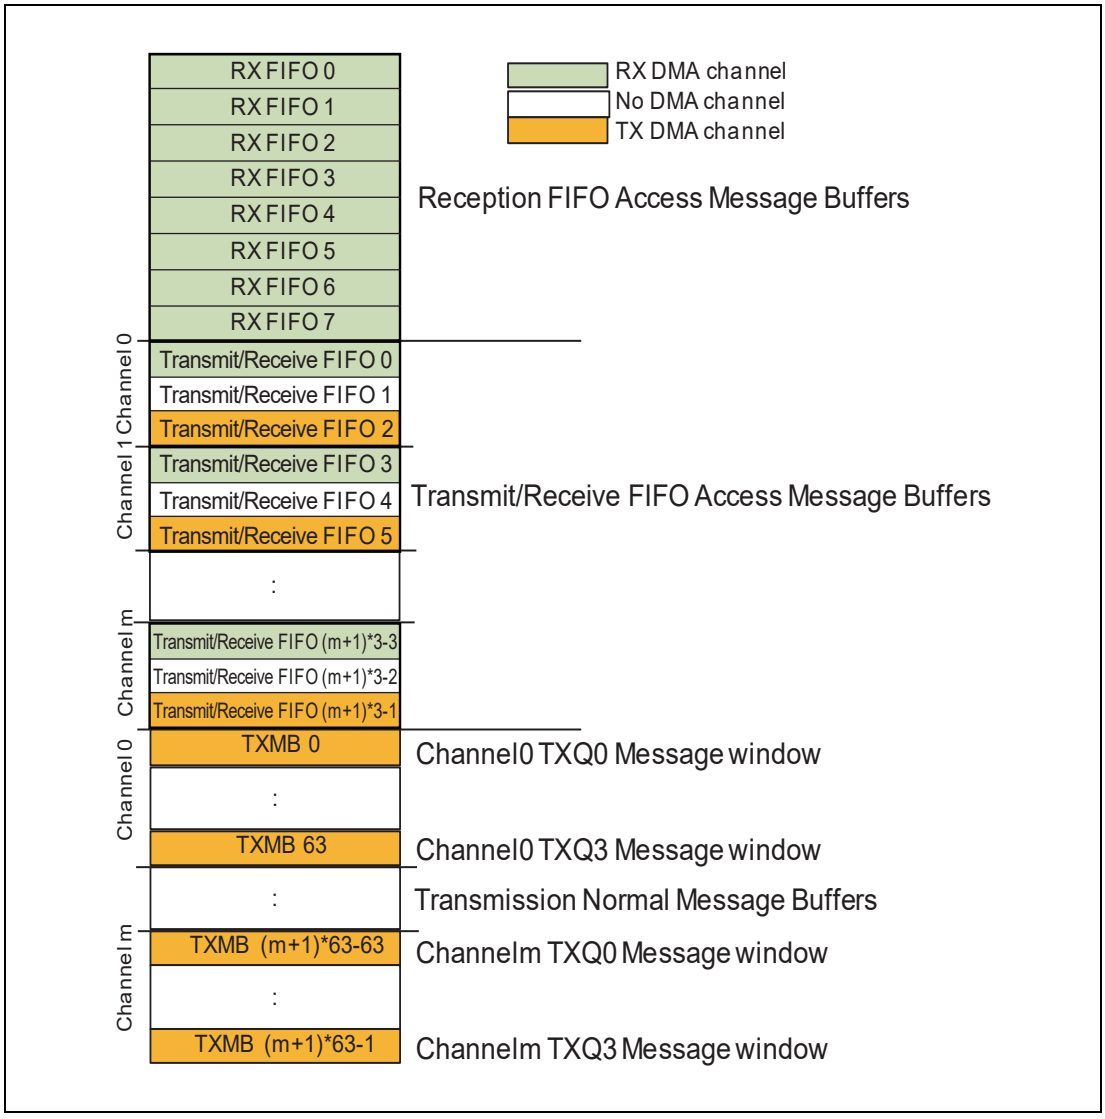

Figure 23.31 Message Buffer connectable to a DMA channel

A DMA channel transfer request will be generated for each FIFO entry to the DMAC when the related RSCFDnCFDCDTCT.RFDMAE or RSCFDnCFDCDTCT.CFDMAE is set to 1_B and the belonging FIFO is not empty.

Reception FIFO Interrupt should be disabled for this particular FIFO (RSCFDnCFDRFCCx.RFIE or RSCFDnCFDCFCCk.CFRXIE).

Users should use the regular start address for the DMA access window address. Refer to the table below.

Table 23.148 DMA channel access window address

b = Message Buffer Component Index	MBCP	Register	d	Regular Start Address m = [0…no_of_channels-1]
[0…no_of_RFMBCPs-1]	RFMBCPb	RFID	x	$6000_H + b\times0080_H$
		RFPTR	x	$6004_H + b\times0080_H$
		RFFDSTS	x	$6008_H + b\times0080_H$
		RFDFd	[0 to 15]	$600C_H + d\times0004_H + b\times0080_H$
[0…no_of_CFMBCPs_per_channel-1]	CFMBCPbm	CFID	x	$6400_H + b\times0080_H + m\times180_H$
		CFPTR	x	$6404_H + b\times0080_H + m\times180_H$
		CFFDCSTS	x	$6408_H + b\times0080_H + m\times180_H$
		RSCFDnCFDFd	[0 to 15]	$640C_H + d\times0004_H + b\times0080_H + m\times180_H$

DMA FIFO pointer decrement will be done automatically with reading the last configured data payload Byte (RSCFDnCFDRFCCx.RFPLS or RSCFDnCFDCFCCk.CFPLS).

Note: The DMA should read the exact length of the configured data payload size (RSCFDnCFDRFCCx.RFPLS or RSCFDnCFDCFCCk.CFPLS), no more, no less.

Users should not write to the FIFO and TXQ control registers when DMA is enabled.

The DMA enable of the particular DMA FIFO (RSCFDnCFDCDTCT.RFDMAE or RSCFDnCFDCDTCT.CFDMAE) can be set at any time, **Figure 23.32, DMA enable flow** is a configuration flow for an initial set-up.

When RSCFDnCFDCDTTCT.TQ0DMAE or RSCFDnCFDCDTTCT.TQ3DMAE or RSCFDnCFDCDTTCT.CFDMAE is set, the messages of the corresponding TXQ or Transmit/Receive FIFO can be handled by DMA controller.
Take the following procedure when the TXQ or the Transmit/Receive FIFO can be handled by DMA controller.

1. CPU checks the TXQ or the Transmit/Receive FIFO is not full.
2. When transmit data can be used, CPU enables DMA to set this data to Transmit/Receive FIFO or TXQ.
   When using Transmit/Receive FIFO, transmit data is write in RSCFDnCFDCFID, RSCFDnCFDCFPTR, RSCFDnCFDCFFDCSTS and RSCFDnCFDTMBCPbm register.
   When using TXQ, transmit data is write in RSCFDnCFDTMID, RSCFDnCFDTMPTR, RSCFDnCFDTMFDCTR and RSCFDnCFDTMDFd register.
3. In a case of the Transmit/Receive FIFO, Transmit/Receive FIFO pointer is incremented automatically when DMA controller writes the last data payload byte configured by RSCFDnCFDCFCCk.CFPLS.
   In the case of TXQ, if the data of 64 data payload is written, a TXQ pointer will increase automatically.
   When payload data is less than 64 byte, dummy data must be written in and 64 data payload size must be done.
   Note only 32-bit write-access can be possible on the DMA message handling.

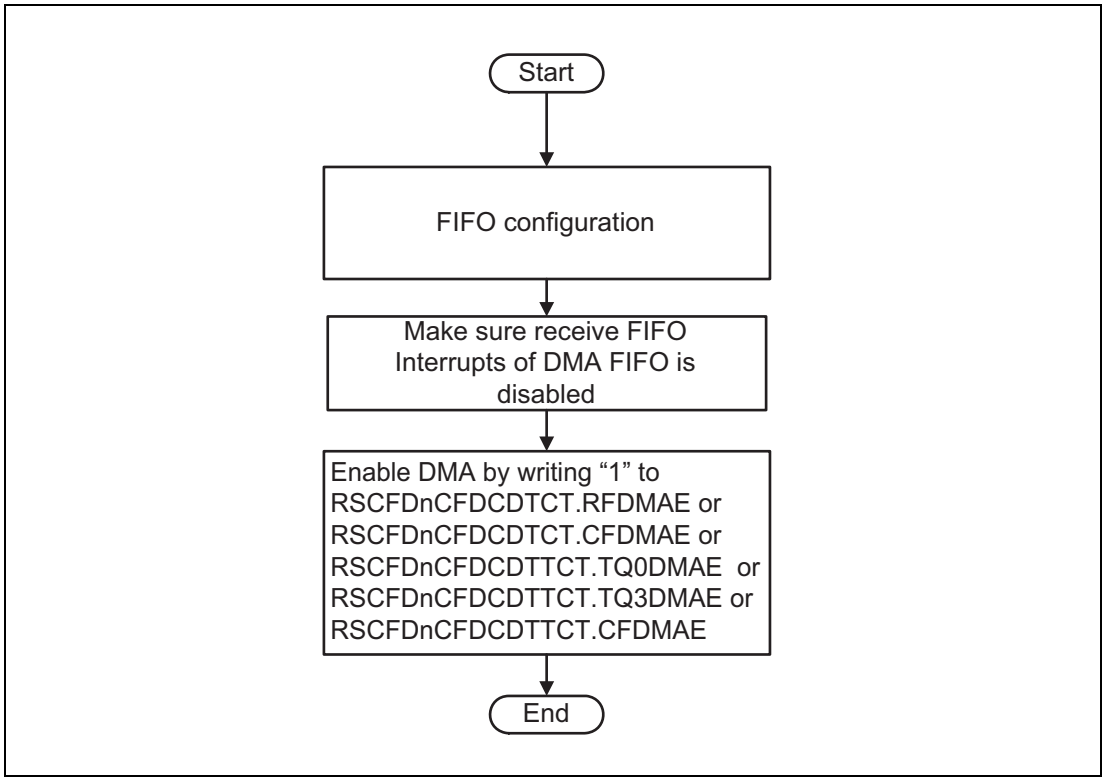

Figure 23.32 DMA enable flow

To disable a DMA transfer requested, disable the particular DMA enable bit (RSCFDnCFDCDTCT.RFDMAE or RSCFDnCFDCDTCT.CFDMAE). If the disable is made during an ongoing transfer then this must be completed first before further action should be taken. The transfer status can be identified by the RSCFDnCFDCDTSTS.RFDMASTS or RSCFDnCFDCDTSTS.CFDMASTS. For reference see the flow below. When the DMA is disabled then consider what to do with the remaining or new incoming messages to this particular reception FIFO’s.

When the FIFO is not disabled then reception to the FIFO will continue.

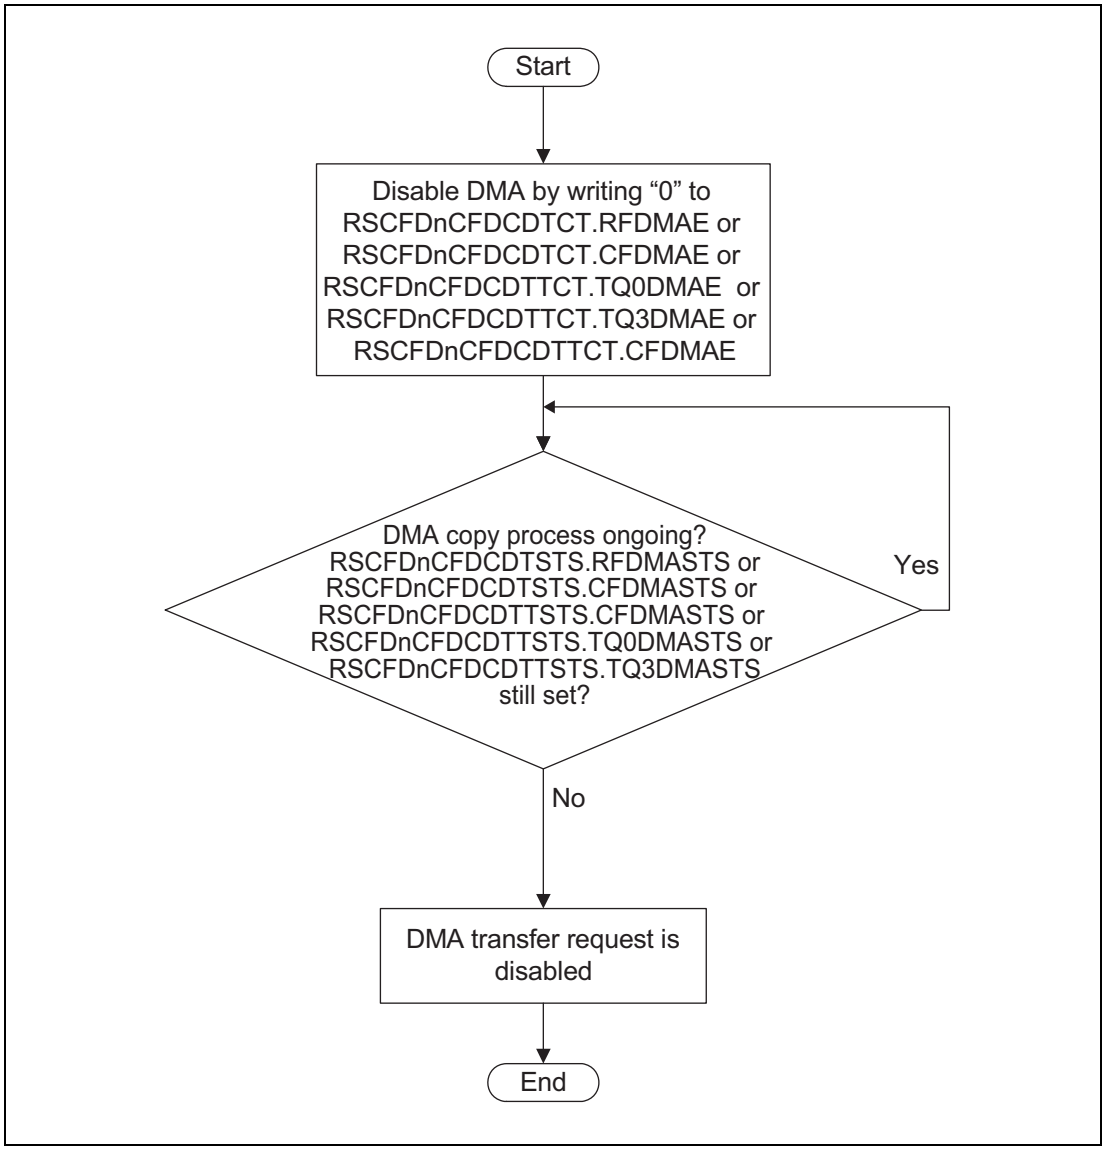

Figure 23.33 DMA disable flow

23.9 Reception and Transmission

23.9.1 Reception

In the RS-CANFD module, CAN messages received on any of the channels, will be stored in RX Message Buffers or in RX FIFO Buffers or Transmit/Receive FIFO Buffers configured in RX Mode or GW Mode depending upon the Acceptance Filter List entries:

- Up to ((m+1)×16) RX Message Buffers can be configured
- 8 RX FIFO Buffers available
- Up to ((m+1)×3) Transmit/Receive FIFO Buffers can be configured in RX mode or GW mode
- Up to ((m+1)×3) TX Queue can be configured in GW mode

23.9.1.1 Message storage in RX Message Buffers

When a message is successfully received and stored in a RX Message Buffer, the corresponding New data Flag is set in the RX Message Buffer New data Register.

The CAN Message can be read from the corresponding RX Message Buffer.

If a new message is stored into a RX Message Buffer before the previous message in this Message Buffer can be read, then the original message is overwritten. There is no mechanism for preventing a new message from overwriting the current message in the RX Message Buffer. If such a loss of messages is not acceptable, then RX FIFO should be used for storing related messages.

NOTES

1. Interrupts are not provided for the RX Message Buffers in the RS-CANFD module and hence the RX Message Buffer New data Register should be accessed periodically to check if a new message has been stored in the RX Message Buffers.
2. Unused Data Bytes will be filled with 0_H depending upon the DLC value.

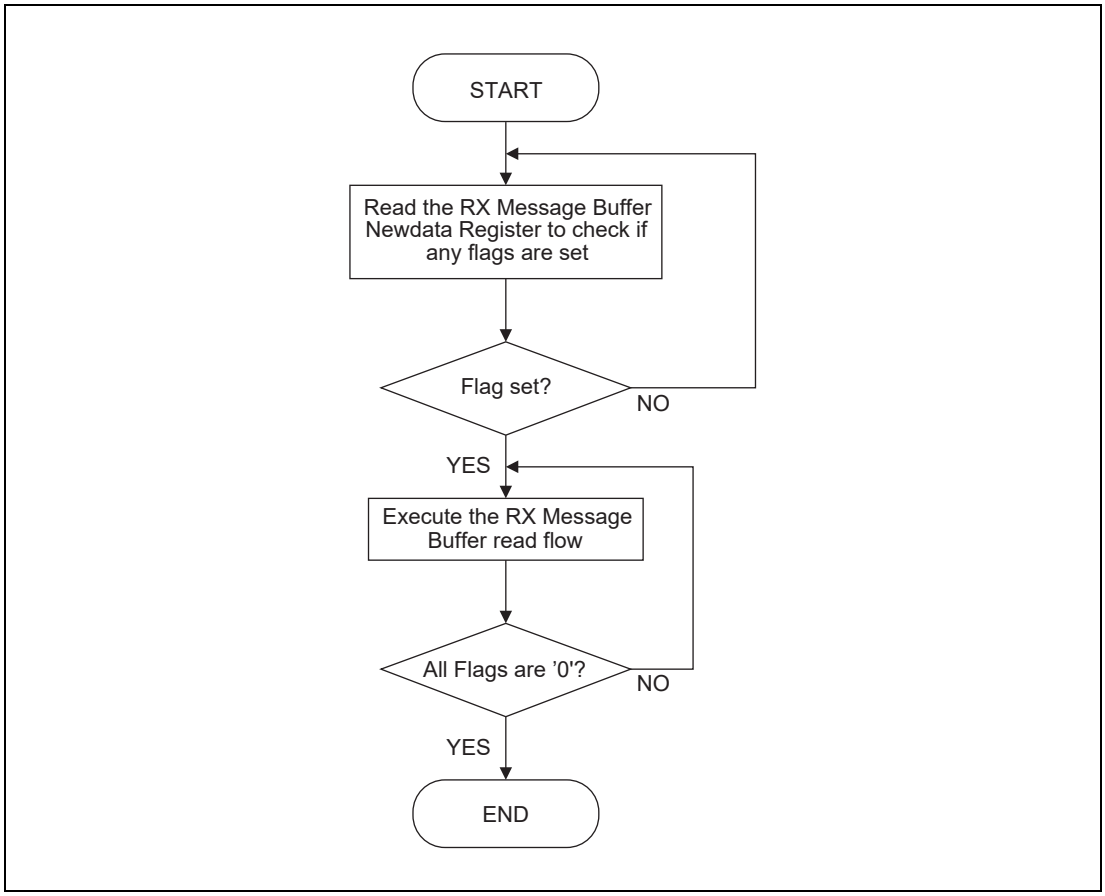

Figure 23.34 RX Message Buffer Message Access Flow

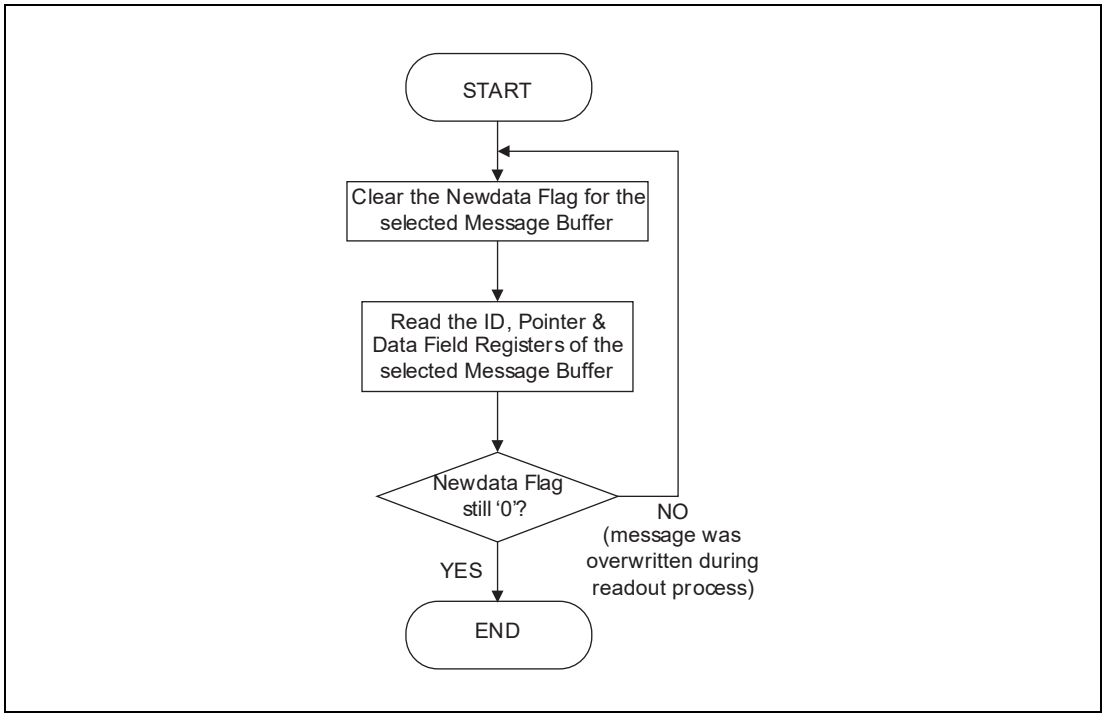

Figure 23.35 RX Message Buffer Read flow

23.9.1.2 Message storage in FIFO Buffers

The AFL entries for routing the received messages to RX FIFO buffers or Transmit/Receive FIFO Buffers configured in RX or GW Mode should be configured based on the requirements of the system.

The RSCFDnCFDGAFLP1j.GAFLFDP[31:0] field in the matching AFL entry selects the FIFO Buffers to which the related reception message will be stored.

When the received message is stored in one or more RX FIFO Buffers or Transmit/Receive FIFO Buffers configured in RX Mode or GW Mode, then the Message counter value is incremented in the corresponding RX FIFO Status Register or Transmit/Receive FIFO Status Register.

Depending upon the configuration of the FIFO Buffers, an Interrupt may also be generated.

The message can be read from the corresponding FIFO access registers.

NOTE

Since many messages can be stored in the FIFO Buffers, reading more than 1 message may be required to read the latest message stored in a FIFO Buffer.

If the Message count value matches the FIFO depth, then the FIFO Full Flag is set.

When the value FF_H is written to the corresponding FIFO Pointer Control Register, then the Message Count is decremented by 1.

Users should only write FF_H to the FIFO Pointer Control register after reading the complete message from the FIFO Access registers of the corresponding FIFO.

When all the messages stored in the FIFO are read, then the FIFO Empty flag is set.

If a new message is stored into the FIFO when the FIFO Message count matches the FIFO Depth (FIFO Full condition), the FIFO Message Lost flag is set and the new message will be lost (no overwrite of already stored messages will take place).

An appropriate value can be configured as warning level to generate an interrupt before the FIFO full condition occurs to avoid loss of a Message due to Overrun condition.

In GW mode, when a transmit/receive FIFO buffer is trying to receive a new message while the transmit/receive FIFO buffer is already full of data, the oldest data of the buffer will be overwritten with the message received or the message will be discarded. The behavior is determined by setting RSCFDnCFDCFCCEk.CFMOWM bit.

When RSCFDnCFDCFCCEk.CFMOWM = 0:

When writing of data is required due to reception of a new message while a transmit/receive FIFO buffer is full of data, the received message will be discarded. And RSCFDnCFDCFSTSk.CFMLT bit is set to 1.

When RSCFDnCFDCFCCEk.CFMOWM = 1:

When writing of data is required due to reception of a new message while a transmit/receive FIFO buffer is full of data, the oldest data in the buffer will be overwritten with the received message. The read pointer of the transmit/receive FIFO buffer simultaneously moves to the next oldest message.
Then, RSCFDnCFDCFSTSk.CFMOW bit is set to 1, which notifies that the oldest message has

been overwritten with the received message.
In addition, in a case a CAN bus error or arbitration-lost for the transmitting message occurs in transmit/receive FIFO buffer full, the transmitting message is lost and re-transmission for the message is not performed. Then the read point moves to the next message automatically.

Users should not write change for this bit when the RSCFDnCFDCFCCk.CFE bit is 1_B.

Transmit/Receive FIFO can set interrupt, when CAN frame reception is completed.

Transmit/Receive FIFO can set interrupt, when FIFO is in full status in RX mode or GW mode.

NOTES

1. The Message Lost can be set only in RX or GW mode by CAN side, the flag will not be set when the CPU side is overloading the FIFO buffers.
2. When RSCFDnCFDGAFLP0j.GAFLSRDi (i = 0 to 2) is set and the RSCFDnCFDTXQCCim.TXQGWE (i = 0 to 2) is also set, a receiving frame is stored in the target TXQ as send data by routing.

The RX FIFO Buffers and the Transmit/Receive FIFO Buffers configured in RX or GW Mode can be disabled at any time by clearing the RSCFDnCFDRFCCx.RFE or RSCFDnCFDCFCCk.CFE bit in the RX FIFO Configuration / Control Register and the Transmit/Receive FIFO Configuration / Control Register.

When the RSCFDnCFDRFCCx.RFE or RSCFDnCFDCFCCk.CFE bit is cleared, then the message read and write pointers of the FIFO are cleared and are no longer active. Hence, all messages in the FIFO Buffers will be lost and no further messages can be stored into the FIFO.

When the RX FIFO Buffers or Transmit/Receive FIFO Buffers configured in RX Mode is assigned as DMA channel then the SW should not access the FIFO Access Register of this FIFO buffer or write FF_H to the FIFO Pointer Control Register (RSCFDnCFDCFPCTRk.CFPC or RSCFDnCFDRFPCTRx.RFPC), because this could lead to unintended FIFO message decrement. The DMA channel will control the FIFO decrement by automatically.

NOTE

If the interrupt flag is set for a FIFO Buffer and then the FIFO is disabled, then the interrupt flag will not be cleared automatically. The interrupt flag should be cleared before disabling the FIFO.

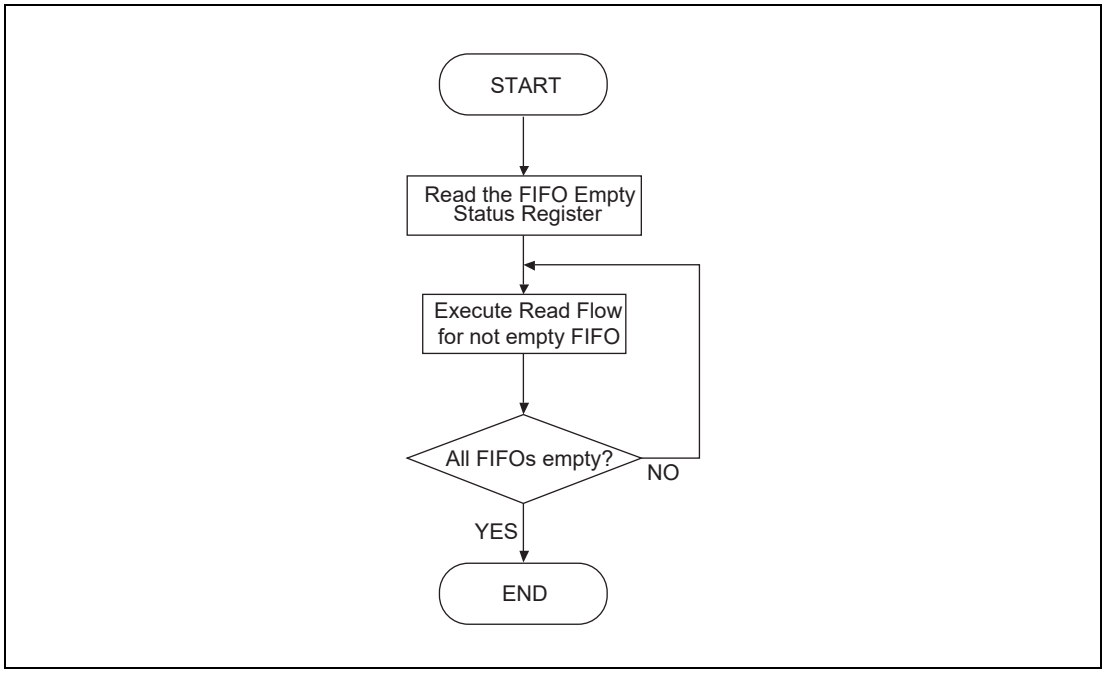

Figure 23.36 FIFO Buffer Message access Flow (example for polling case)

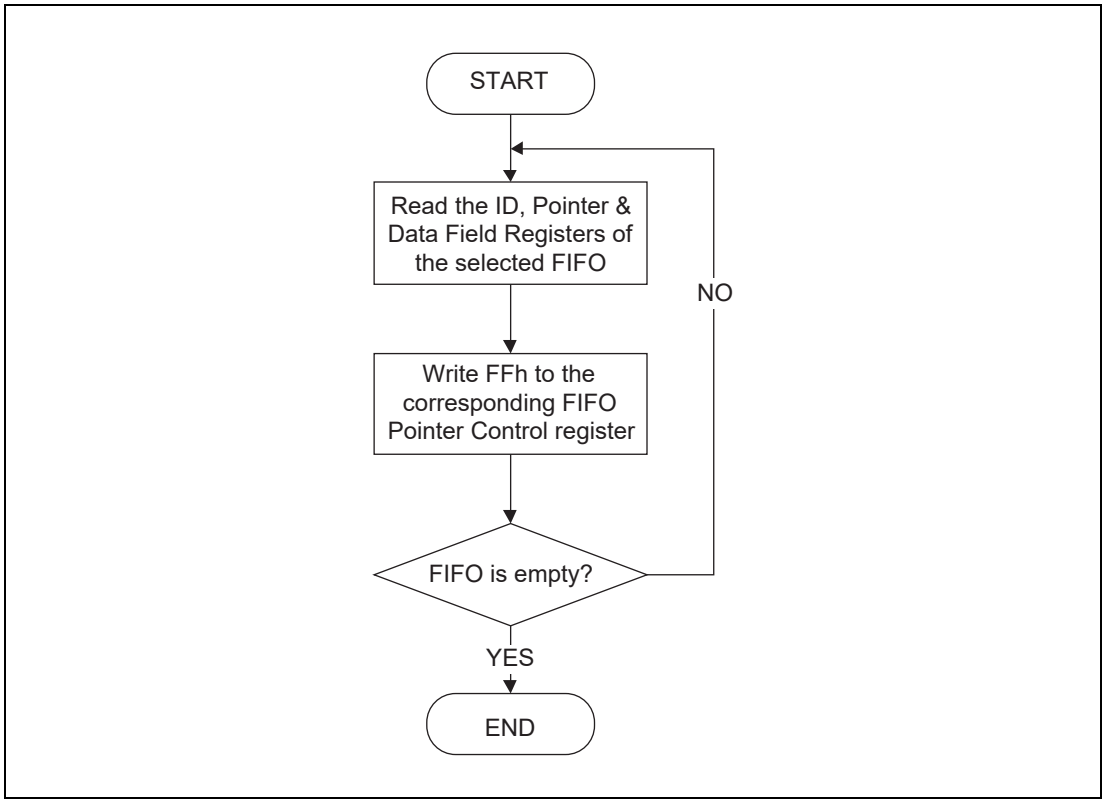

Figure 23.37 RX FIFO Buffer Read flow (example for polling case)

NOTE

When the next frame is received before clearing the completion interrupt flag of reception, the completion interrupt of reception is not set again.

Even if it clears an "interruption flag" after the completion processing of reception, the already received interrupt flag is not set.

It is necessary to perform the completion processing of reception even before the next completion of frame reception, and to clear an interruption flag.

When processing does not meet the deadline, after checking that receiving data is empty, interrupt flag is cleared and it checks that receiving data is empty again.

23.9.1.3 Timestamp

The Timestamp counter is a free-running counter that can be used to check reception time of an incoming message or transmission time of successful transmitted messages. The Timestamp counter value will be captured based on the RSCFDnCFDGFDCFG.TSCCFG[1:0] configuration (at the sample point of Start of Frame, point in time when the frame is valid, or for CANFD frames also at the sample point of the RES bit). For reception it is stored together with the message ID and Data into the target RX Message Buffer or RX/GW FIFO.

For transmit message the Timestamp counter value will be stored as part of the TX History List entry.

The counter can be clocked with the peripheral clock or with the CAN channel bit timing clock. The counter source clock can be configured via the RSCFDnCFDGCFG.TSSS bit of the Global Configuration Register. If it is 0_B, the peripheral clock is used. If it is 1_B, the selected CAN channel bit time clock is used.

The channel selection is done via the RSCFDnCFDGCFG.TSBTCS Bit of the Global Configuration Register.

Care has to be taken when using selected CAN channel bit time clock as clock source. In case of entering Channel Halt Mode or Channel Reset Mode, for this channel, the Timestamp counter is stopped. So, also for other CAN channels the Timestamp counter value will not be updated.

If peripheral clock is selected as Timestamp counter clock source Channel Modes are not influencing the Timestamp counter function.

The source clock for the Timestamp counter can be divided by a factor defined by the RSCFDnCFDGCFG.TSP bits (Timestamp Prescaler) in the Global Configuration Register.

The Timestamp counter can be reset to 0000_H via the RSCFDnCFDGCTR.TSRST bit (Timestamp Reset).

23.9.2 Transmission

There are several possible transmission configurations for each channel:

- Normal transmission
- FIFO transmission
- Gateway transmission
- TX Queue transmission
  A fixed number of transmission Message Buffers 64 [for U2A-EVA, U2A16, U2A8] and 32 [for U2A6] TX Message Buffers are dedicated for each channel. These Message Buffers are only used for transmission and cannot be configured for reception.
  Additionally transmission from TX Queue and/or Transmit/Receive FIFO in TX or GW mode can be configured in the following way (see **Figure 23.38, Channel Transmission Message Buffer Configuration** for an example for U2A-EVA, U2A16, U2A8):
  TX Queue: Up to 32 [for U2A-EVA, U2A16, U2A8] and 16 [for U2A6] transmission Message Buffers for one channel can be grouped to form a TX Queue with a common access window.
  Upper transmission Message Buffers are used to form the TXQ1 or TXQ3.
  Lower transmission Message Buffers are used to form the TXQ0 or TXQ2.
  Transmission control and status registers of these transmission Message Buffers should not be used.
  One Channel has four TX Queue.
  Each TXQ has each access window.
  - TXQ0 is transmission Message Buffer 0 of each channel.
  - TXQ1 is transmission Message Buffer 31 of each channel.
  - TXQ2 is transmission Message Buffer 32 of each channel.
  - TXQ3 is transmission Message Buffer 63 of each channel.

  When using TXQ1 and TXQ0 simultaneously, the sum of the depths of TXQ1 and TXQ0should not exceed 32 [for U2A-EVA, U2A16, U2A8] and 16 [for U2A6].When using TXQ3 and TXQ2 simultaneously, the sum of the depths of TXQ3 and TXQ2should not exceed 32 [for U2A-EVA, U2A16, U2A8] and 16 [for U2A6].
  Transmit/Receive FIFO (TX/GW mode): each Transmit/Receive FIFO in TX or GW mode is linked to a dedicated channel. Each channel has a fixed number of 3 Transmit/Receive FIFOs assigned to it. Within the channel, a Transmit/Receive FIFO configured in TX or GW mode, can be freely linked (assigned) between 32 and 63 [for U2A-EVA, U2A16, U2A8] and 47 [for U2A6] transmission Message Buffers (only one FIFO to one transmission Message Buffer).
  The Transmit/Receive FIFO Buffer then replaces the transmission Message Buffer linked to it.
  Transmission control and status registers of these transmission Message Buffers should not be used.

Refer to **Figure 23.27, Message Buffer Configuration** for information about Transmit/Receive FIFO Buffer assignment to related channels.

NOTE

Transmit/Receive FIFO buffers should not be linked to TX Message Buffers that are already part of a TX Queue.

Tx Message Buffer0	Tx Message Buffer0	Tx Queue 0	Tx Queue 0

Figure 23.38 Channel Transmission Message Buffer Configuration (1/2)

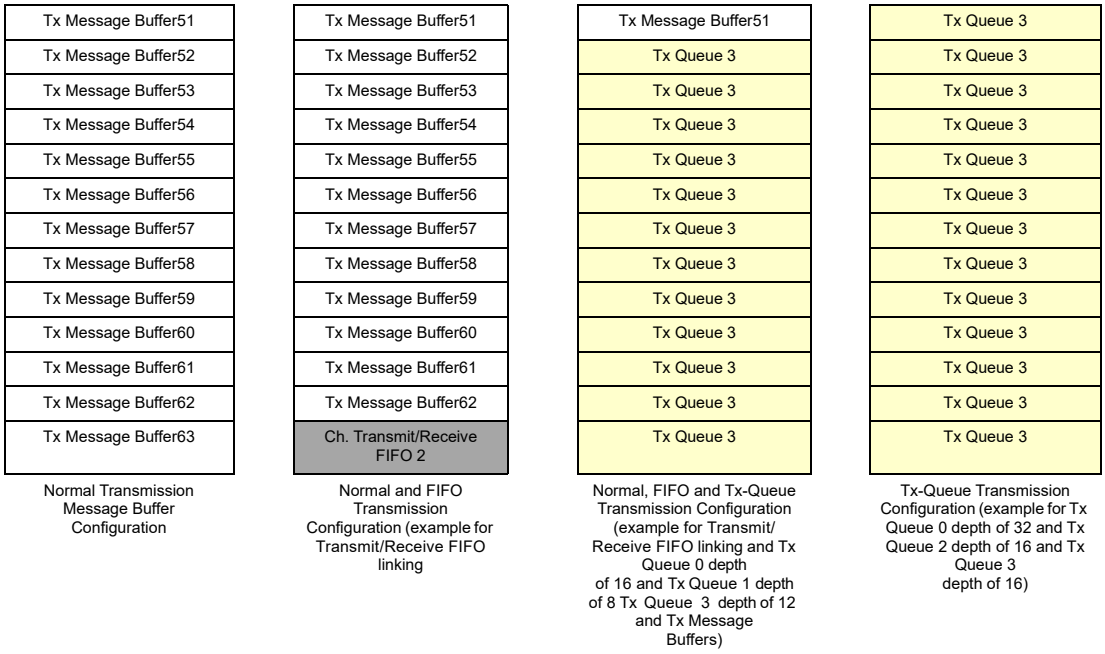

Figure 23.38 Channel Transmission Message Buffer Configuration (2/2)

23.9.2.1 Transmission Priority

If two or more transmission Message Buffers of a channel are configured for transmission, then the transmission priority in the RS-CANFD module can be selected from the following two modes:

- CAN ID priority
- Message Buffer number priority

The transmission priority mode is common for all Message Buffers and all CAN channels. It can be configured via the RSCFDnCFDGCFG.TPRI bit in the Global Configuration Register.

For Message Buffer number priority transmission, the smallest Message Buffer number with transmission request has the highest priority for transmission. This also includes the TX Message Buffers linked to the Transmit/Receive FIFO Buffers configured in TX mode or GW mode.

However, Message Buffer number priority should not be used if TX Queue is enabled.

For CAN ID priority transmission, ID priority complies with the CAN bus arbitration rule (as specified in ISO 11898-1 (2015) specification). All TX Message Buffers can enter the ID priority comparison for Message Buffers configured for transmission. This also includes the TX Message Buffers linked to the Transmit/Receive FIFO Buffers configured in TX mode or GW mode and includes the TX Queue Message Buffers.

If the ID of two or more Message Buffers is the same, then the smaller Message Buffer number will have higher priority for transmission.

Note: For Transmit/Receive FIFO Buffers configured in TX mode or GW mode, only the message currently being pointed to by the FIFO Read Pointer can be included in the transmission arbitration.

If the message is being transmitted from the FIFO, then the next pending Message within the same FIFO will be considered in the transmission arbitration.

In contrast to this, all transmission Message Buffers of a TX Queue will participate in internal transmission arbitration.

Figure 23.39 below shows the transmission configuration flow.

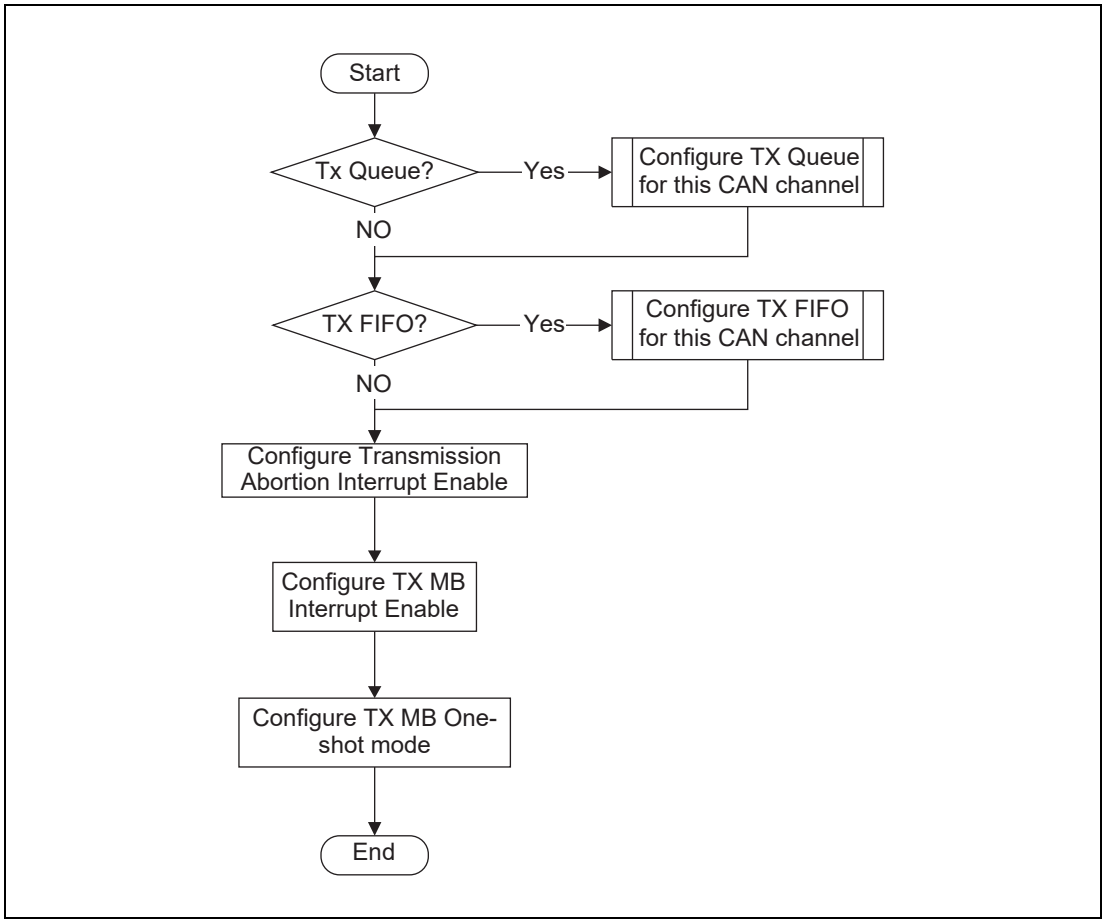

Figure 23.39 Transmission Configuration Flow

23.9.2.2 Normal Transmission

Each transmission Message Buffer has two modes of message transmission:

1. Regular Transmission Mode
   If the Message Buffer is placed in regular transmission mode, the data frame or remote frame set in that Message Buffer can be transmitted.
   Completion of regular transmission can be checked through the related TX Message Buffer Transmission Result Flag bits (RSCFDnCFDTMSTSp.TMTRF) in the TX Message Buffer Status Register. These bits are set to 10_B or 11_B when the regular transmission is successful.
   When arbitration is lost or an error occurs, message transmission will be attempted further if no transmission abort request is set for this transmission Message Buffer.
   New internal transmission arbitration for this channel will be performed considering all Message Buffers with transmission request.

2. One Shot Transmission Mode
   When the RSCFDnCFDTMCp.TMOM bit of the TX Message Buffer Control Register is set for a transmission Message Buffer, then the Message Buffer is placed in one-shot transmission mode and attempts to transmit a message only once.
   Completion of one shot transmission can be checked through the related TX Message Buffer Transmission Result Flag bits (RSCFDnCFDTMSTSp.TMTRF) in the TX Message Buffer Status Register. The RSCFDnCFDTMSTSp.TMTRF bits are set to 10_B or 11_B when the one shot transmission is successful.
   The RSCFDnCFDTMSTSp.TMTRF bits are set to 01_B when arbitration is lost or an error occurs

during the transmission of the related Message Buffer.
Further message transmission will not be attempted in this case.
The regular transmission request procedure after a configuration is shown in **Figure 23.40**.

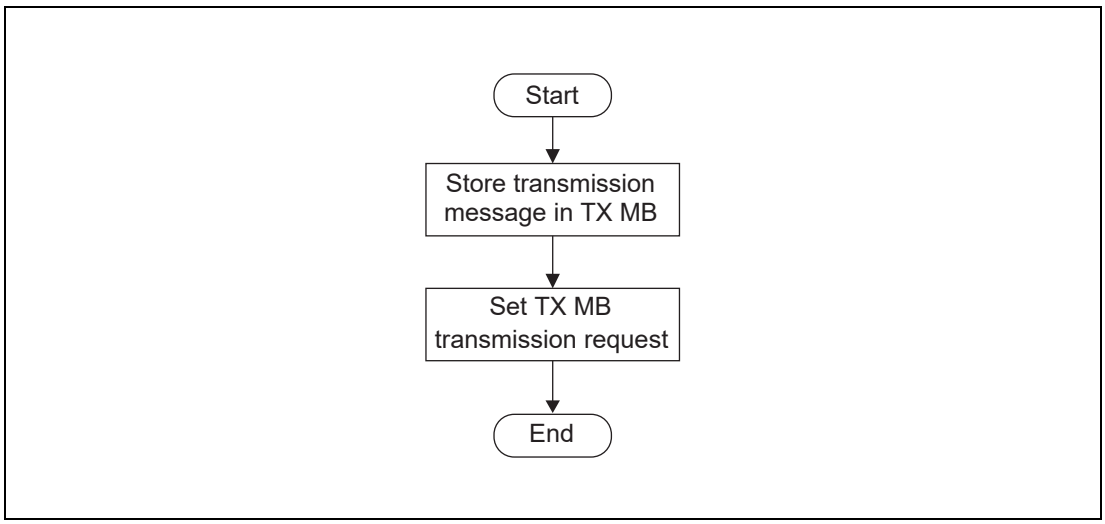

Figure 23.40 Transmission request procedure using normal TX Message Buffer mode

(1) TX Message Buffer control register setting

Table 23.149 shows configuration of the normal CAN transmission mode.

Table 23.149 Configuration of CAN transmission mode

Transmission Request RSCFDnCFDTMCp.TMTR	Transmission Abortion Request RSCFDnCFDTMCp.TMTAR	One Shot Enable RSCFDnCFDTMCp.TMOM	Communication activity
0	0	0	Message Buffer disabled
0	0	1	Message Buffer disabled
1	0	0	Configured as a transmission Message Buffer for a data frame or a remote frame
1	0	1	Configured as a one shot transmission Message Buffer for a data frame or a remote frame
1	1	0	Transmission abortion requested
1	1	1	One shot transmission abortion requested

The Configuration bits can be configured in the TX Message Buffer Control Register.

The **Figure 23.41** shows timings for successful transmission for two Message Buffers of one channel.

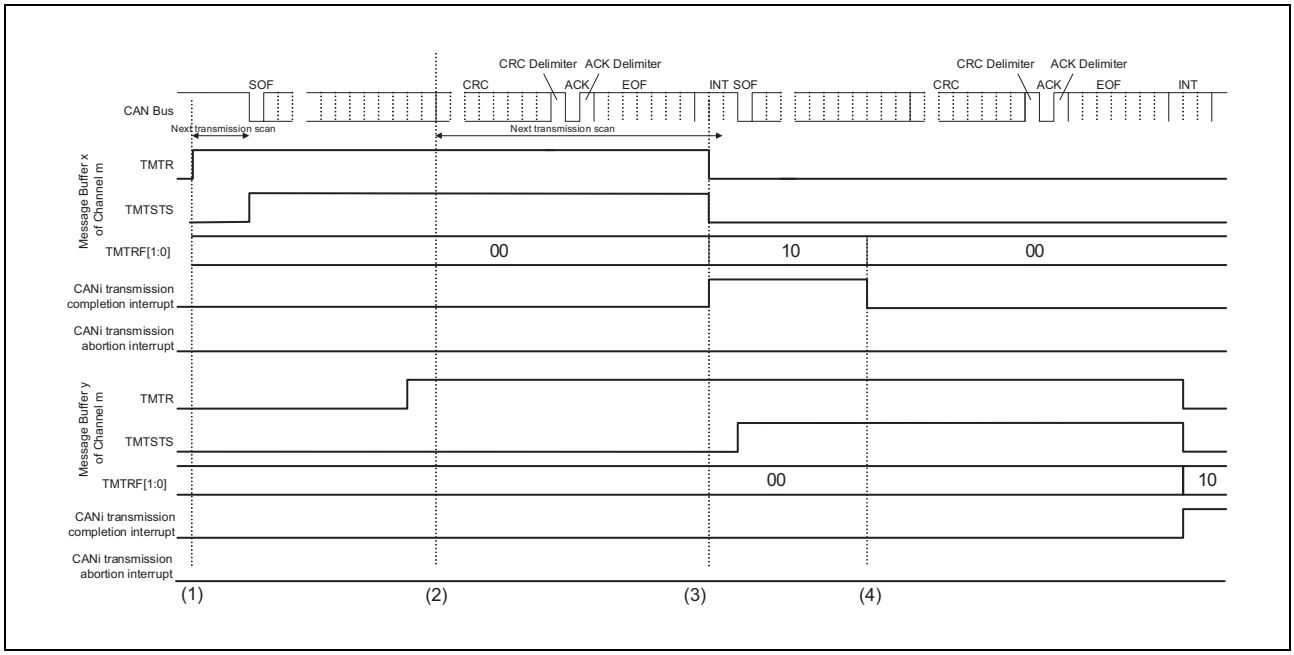

Figure 23.41 Timing of request and flag bits for successful transmission

(1) If the RSCFDnCFDTMCp.TMTR bit in the TX Message Buffer Control Register is set in the bus idle state, Message Buffer scanning procedure starts to decide the highest priority Message Buffer for transmission.
When the transmission Message Buffer is decided, the RSCFDnCFDTMSTSp.TMTSTS bit in the related TX Message Buffer Status Register is set (Transmitting/Transmitter), and CAN channel starts the transmission*1.

(2) At 1st Bit of CRC, the transmission scanning procedure starts for the next possible transmission when pending transmission requests exist.
The scan time could be delayed due to other transmission scan on other channels, but it will be finished before Intermission 3 to be able to continue transmission without any gaps.

(3) If the message has been successfully transmitted, the RSCFDnCFDTMSTSp.TMTRF[1:0] bits in the corresponding TX Message Buffer Status Register are set to 10_B and RSCFDnCFDTMSTSp.TMTSTS and the RSCFDnCFDTMCp.TMTR bits are cleared.
When the TMIE bits in the TX Message Buffer Interrupt Enable Configuration Register is set (Interrupt enabled), the CAN successful transmission interrupt request is generated.
To clear the related interrupt line the RSCFDnCFDTMSTSp.TMTRF flag bits have to be cleared.

(4) Before starting the next transmission, clear the RSCFDnCFDTMSTSp.TMTRF bits. Load the next message in the transmission Message Buffer and set the RSCFDnCFDTMCp.TMTR bit again.
RSCFDnCFDTMCp.TMTR bit cannot be set again before RSCFDnCFDTMSTSp.TMTRF[1:0] bits are cleared.

Note 1. If arbitration is lost after the CAN channel starts the transmission, the RSCFDnCFDTMSTSp.TMTSTS bit is cleared.
The transmission scanning procedure is performed again to search for the highest priority transmission Message Buffer from the beginning of the 1st CRC bit.
If an error occurs either during the transmission or following the loss of arbitration, then during Error Frame, the transmission scanning procedure is performed again to search for the highest priority transmission Message Buffer.

NOTE

The setting point of RSCFDnCFDTMSTSp.TMTSTS is not always fixed at the start of the SOF. It may be delayed up to the start of the standard ID due to the synchronization logic implemented for the PLL bypass.

The **Figure 23.42** shows timings for transmission abort for two Message Buffers of one channel.

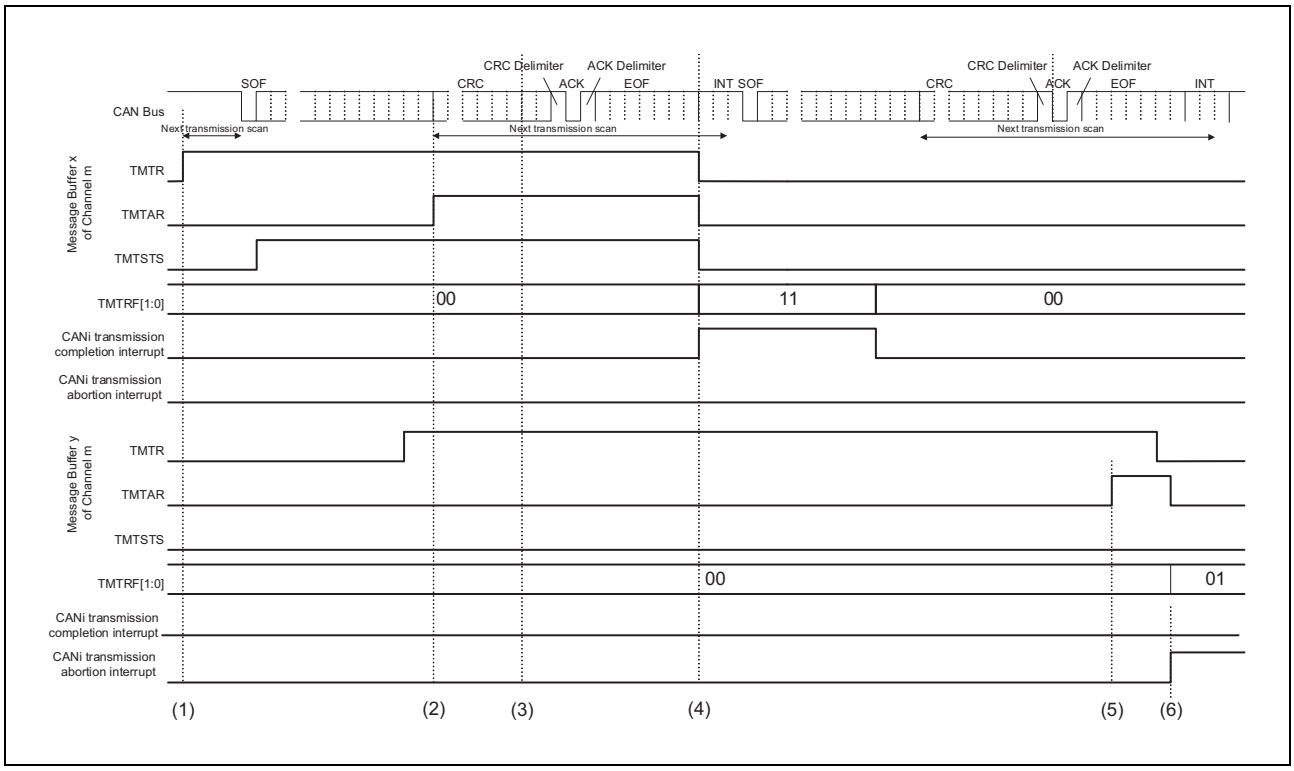

Figure 23.42 Timing of request and flag bits for transmission abort

(1) If the RSCFDnCFDTMCp.TMTR bit in the TX Message Buffer Control Register is set in the bus idle state, Message Buffer scanning procedure starts to decide the highest priority Message Buffer for transmission.
When the transmission Message Buffer is decided, the RSCFDnCFDTMSTSp.TMTSTS bit in the TX Message Buffer Status Register is set (Transmitting/Transmitter), and CAN channel starts the transmission*1.

(2) If the RSCFDnCFDTMCp.TMTAR bit is set when the related Message Buffer is already selected for transmission or currently transmitting then the message will not be aborted, if no error occurs or arbitration is lost.

(3) At 1st CRC bit, the transmission scanning procedure starts for the next transmission. In this example timing chart Message Buffer y is not selected as next transmission Message Buffer. The scan time could be delayed due to other transmission scan on other channels, but it will be finished before Intermission 3 to be able to continue transmission without any gaps.

(4) If the message has been successfully transmitted, the RSCFDnCFDTMSTSp.TMTRF[1:0] bits in the corresponding TX Message Buffer Status Register is set to 11_B and RSCFDnCFDTMSTSp.TMTSTS and the RSCFDnCFDTMCp.TMTR bits are cleared.
When the TMIE bits in the TX Message Buffer Interrupt Enable Configuration Register is set

(Interrupt enabled), the CAN successful transmission interrupt request is generated.
To clear the related interrupt line the RSCFDnCFDTMSTSp.TMTRF[1:0] bits has to be cleared.

(5) Another CAN node is transmitting on the CAN bus (RSCFDnCFDTMSTSp.TMTSTS not set!): if the RSCFDnCFDTMCp.TMTAR bit is set when the related channel is under transmission scan then the transmission request cannot be cleared.

(6) After internal processing time the transmission is aborted and the RSCFDnCFDTMSTSp.TMTRF[1:0] bits are set to 01_B.
If the Message Buffer is not transmitting or selected as next transmission Message Buffer or under transmit scan, then the abort is immediately accepted and the corresponding RSCFDnCFDTMSTSp.TMTRF[1:0] bits in the TX Message Buffer Status Register is set to 01_B.
In addition, RSCFDnCFDTMCp.TMTR, and RSCFDnCFDTMCp.TMTAR bits are cleared automatically.
When the transmission abort interrupt enable TAIE bit of the related Channel Control Register is set then an interrupt is generated for successful transmission abort.
To clear the related interrupt line the RSCFDnCFDTMSTSp.TMTRF[1:0] bits have to be cleared.

Note 1. If arbitration is lost after the CAN channel starts the transmission, the RSCFDnCFDTMSTSp.TMTSTS is cleared.
The transmission scanning procedure is performed again to search for the highest priority transmission Message Buffer from the beginning of the 1st CRC bit.
If an error occurs, either during the transmission, or following the loss of arbitration, then during Error Frame, the transmission scanning procedure is performed again to search for the highest priority transmission Message Buffer.

23.9.2.3 TX FIFO or GW FIFO Transmission

Three Transmit/Receive FIFO buffers are assigned to each channel. The 3 FIFO buffers could be linked to any normal TX Message Buffer position for this channel by the RSCFDnCFDCFCCk.CFTML bits in the Transmit/Receive FIFO Configuration / Control Register if configured in TX or GW mode.

When the transmission scan starts and the FIFO Buffer corresponding to this TX Message Buffer is enabled, then the relevant message in the FIFO Buffer will participate in the transmission scan.

Configuration of a TX Message Buffer linked to a FIFO Buffer configured in TX or GW mode should not be done.

(1) TX FIFO Operation

CAN Messages can be written into the TX FIFO by writing to the corresponding FIFO Access registers.

When the value FFH is written into the corresponding FIFO Pointer Control Register, then the Message Count of the related FIFO is incremented by 1.

Users should only write to the FIFO Pointer Control register after writing the complete message to the corresponding FIFO Access registers.

If the Message count matches the FIFO Depth, then the FIFO Full flag is set.

The oldest message in the TX FIFO is included in the scan for transmission by the corresponding RS-CANFD module channel logic.

When a message is successfully transmitted from the TX FIFO, the Message Count value is decremented by 1.

When all the messages from the FIFO are transmitted, the FIFO Empty flag is set.

The Interrupt generation conditions for the TX FIFO buffers can be configured by configuring the RSCFDnCFDCFCCk.CFIM bit in the corresponding Transmit/Receive FIFO Configuration / Control Register.

If RSCFDnCFDCFCCk.CFIM bit is 0_B, then interrupt is generated when last message is successfully transmitted from the TX FIFO buffer.

If RSCFDnCFDCFCCk.CFIM bit is 1_B, then interrupt is generated for every successfully transmitted message from the TX FIFO Buffer.

Transmit/Receive FIFO can set interrupt, when CAN frame transmitted is completed.

The Transmit/Receive FIFO Buffers configured in TX Mode can be disabled by clearing the RSCFDnCFDCFCCk.CFE bit in the Transmit/Receive FIFO Configuration / Control Register. If this bit is cleared to 0_B, the FIFO empty flag is set as described below:

- Immediately if the message from the TX FIFO is neither scheduled for the next transmission nor in transmission
- Following the transmission completion, the detection of an error on the CAN bus, loss of arbitration or transition to Channel or Global Test Mode if the transmission from the TX FIFO is already scheduled for transmission or already in transmission

NOTE

The Transmit/Receive FIFO buffer is considered as disabled after clearing the RSCFDnCFDCFCCk.CFE bit only when the Empty flag is set for the corresponding Transmit/ Receive FIFO Buffer.

Other possible messages pending from the TX FIFO are lost and their transmission needs to be requested again. Before RSCFDnCFDCFCCk.CFE is set again ensure that RSCFDnCFDCFSTSk.CFEMP bit is set and that there is no pending abort from the TX FIFO.

When the RSCFDnCFDCFCCk.CFE bit is cleared, the message read and write pointers of the FIFO are cleared and are no longer active. Hence, all messages in the FIFO buffers will be lost and no further message can be stored into the FIFO.

The FIFO transmission request procedure after a configuration is shown in **Figure 23.43**.

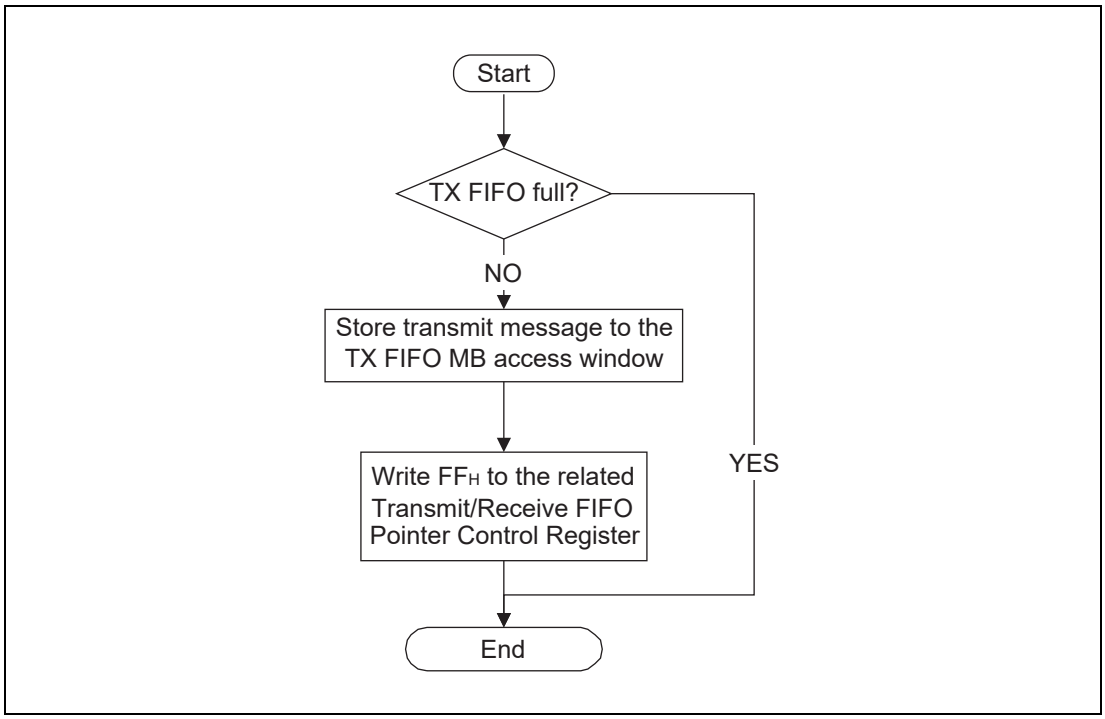

Figure 23.43 TX FIFO transmission request procedure

(2) GW FIFO Operation

The AFL entries for routing the received messages to GW FIFO buffers should be configured based on the requirements of the system. The matching AFL entry selects the GW FIFO Buffer for storage of a received message on any of the CAN channels.

When a message is successfully received and stored in a GW FIFO Buffer, then the FIFO Message Count in the corresponding FIFO Status Register is incremented by 1.

If the Message Count matches the FIFO Depth, then the FIFO Full flag is set.

The oldest message in the GW FIFO is included in the scan for transmission by the corresponding RS-CANFD module channel logic.

When a message is successfully transmitted from the GW FIFO, the Message Count value is decremented by 1.

When all the messages from the GW FIFO are transmitted, the FIFO Empty flag is set.

If a new message is stored into the FIFO when the FIFO Message count matches the FIFO Depth (FIFO Full condition), the FIFO Message Lost flag is set and the new message will be lost (no overwrite of already stored messages will take place).

The Interrupt generation conditions for the GW FIFO buffers can be configured by configuring the RSCFDnCFDCFCCk.CFIM bit in the corresponding Transmit/Receive FIFO Configuration / Control Register.

If RSCFDnCFDCFCCk.CFIM bit is 0_B, then RX interrupt flag is set when FIFO counter increments and reaches value configured by RSCFDnCFDCFCCk.CFIGCV and the TX interrupt flag is set when FIFO transmits the last message successfully.

If RSCFDnCFDCFCCk.CFIM bit is 1_B, then RX Interrupt flag is set at the end of storage of every received message and TX interrupt flag is set if a message is successfully transmitted from the FIFO.

Transmit/Receive FIFO can set interrupt, when CAN frame transmitted is completed.

Transmit/Receive FIFO can set interrupt, when CAN frame reception is completed.

Transmit/Receive FIFO can set interrupt, when FIFO is in full status in RX mode or GW mode.

In the case of RSCFDnCFDCFCCEk.CFBME = 1, it becomes FIFO buffering mode, send data is stored in Transmit/Receive FIFO, and transmission is stopped. Transmission will be started if it is set as RSCFDnCFDCFCCEk.CFBME = 0.

The Transmit/Receive FIFO Buffers configured in GW Mode can be disabled by clearing the RSCFDnCFDCFCCk.CFE bit in the Transmit/Receive FIFO Configuration / Control Register. If this bit is cleared, the GW FIFO becomes empty as described below:

- Immediately if the message from the GW FIFO is neither scheduled for the next transmission nor in transmission
- Following the transmission completion, the detection of an error on the CAN bus, loss of arbitration or transition to Channel or Global Test Mode if the transmission from the GW FIFO is already scheduled for transmission or already in transmission

Other possible messages pending from the GW FIFO are lost.

Before RSCFDnCFDCFCCk.CFE is set again ensure that the RSCFDnCFDCFSTSk.CFEMP bit is set and that there is no pending abort from the GW FIFO.

When the RSCFDnCFDCFCCk.CFE bit is cleared and the RSCFDnCFDCFSTSk.CFEMP bit is set, the message read and write pointers of the GW FIFO are cleared and are no longer active . Hence all messages in the GW FIFO buffers will be lost and no further message can be stored into the GW FIFO.

In applications intended to be used as CAN-to-CAN gateways it would be useful if the Error State Indication (ESI) information of the routing messages is not replaced by the sending node Error State Indication. For this, each channel has the control function register RSCFDnCFDCmFDCFG.ESIC to replace their own ESI information by the routing ESI information.

NOTE

If the sending node is error passive then the ESI bit will be sent anyway as Error passive (ESI = 1).

(3) Interval Timer for FIFO Transmission

For each Transmit/Receive FIFO in TX or GW mode it is possible to specify a delay between two consecutive messages that are configured for transmission from the same FIFO buffer. This delay is, called interval time. This interval time starts after the first message has been successfully transmitted from the FIFO buffer after the RSCFDnCFDCFCCk.CFE bit is set.

When the Transmit/Receive FIFO in TX or GW mode is enabled, then the first message will be transmitted without considering this interval time.

The Interval Timer will stop counting when:

FIFO is disabled by clearing the RSCFDnCFDCFCCk.CFE bit.

CAN channel is in CH_RESET mode.

The interval time is specified by the RSCFDnCFDCFCCk.CFITT value in the Transmit/Receive FIFO Configuration / Control Register and can be specified from 0 to 255 timer units.

The timer unit can be defined based on two different source clocks for the interval timer. To disable the interval timer for FIFO transmission a value of 0 should be selected.

The timer source can be selected by the configuration bit CFITSS in the Transmit/Receive FIFO Configuration / Control Register. For the timer source the CAN Bit Timing clock of the FIFO related channel or a global reference clock could be selected.

If CAN channel bit time clock is configured as clock source and the CAN channel enters CH_HALT or CH_RESET or CH_STOP mode, then the Interval Timer is stopped for that channel.

If peripheral clock is selected as Interval Timer clock source, then the Interval Timer is stopped only when the CAN channel is in CH_RESET or CH_STOP mode.

The reference clock can be used to configure the interval time in fixed time units. It is based on the peripheral clock. The reference clock prescaler value RSCFDnCFDGCFG.ITRCP in the Global Configuration Register defines the relation between the peripheral clock frequency/period and the reference clock period.

Refer to **Table 23.150** for RSCFDnCFDGCFG.ITRCP configuration values to achieve different reference clock periods based on the peripheral clock frequency/period.

Table 23.150 Configuration example for the FIFO interval timer reference clock

Reference clock Peripheral clock	1µs	100µs	500µs
16MHz / 62.5 ns	16	1600	8000
20MHz / 50 ns	20	2000	10000
32MHz / 31.25 ns	32	3200	16000
50MHz / 20 ns	50	5000	25000

Additionally the reference clock resolution can be specified by the Interval Timer Reference Clock Resolution Value RSCFDnCFDCFCCk.CFITR in the Transmit/Receive FIFO Configuration / Control Register.

The interval time is based on the reference clock period multiplied by the configured value (x1 or x10).

The reference clock based interval timer can be used to follow the requirements of the ISO 15765-2 Separation Time. The whole range for the Separation Time from 100 µs to 127 ms can be covered.

The specified interval time starts after successful transmission event (after EOF7 state of the CAN protocol).

When the interval time has elapsed, the next transmission request is raised by the related TX/GW FIFO. Hence, the interval time defines the minimum time between two messages transmitted from one FIFO.

The next message will earliest be sent after this interval time.

The **Figure 23.44** shows an example timing of the internal processing.

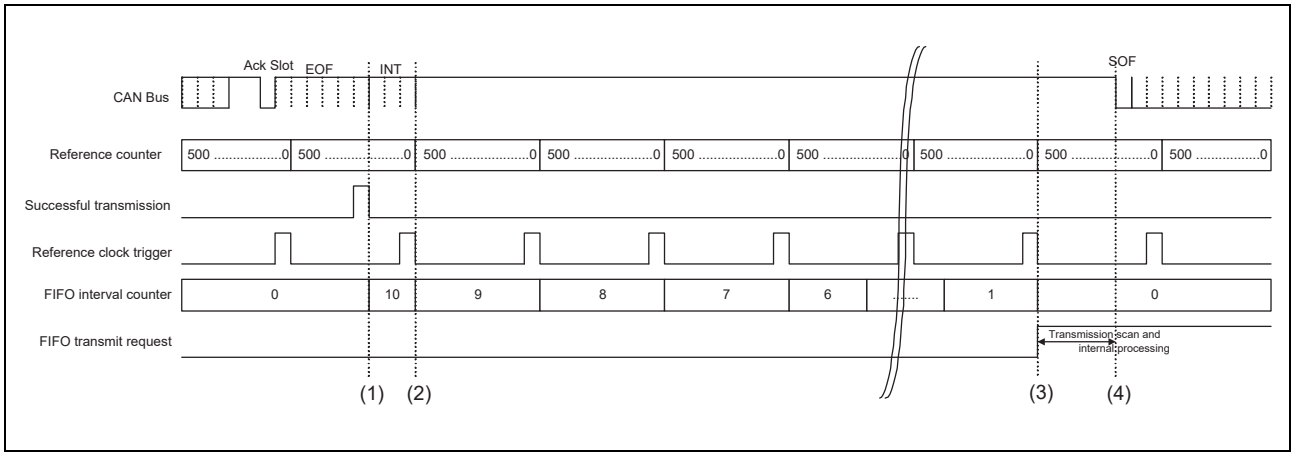

Figure 23.44 Example for interval processing time

The configuration for this timing above is following:

- Peripheral clock frequency = 50MHz
- Interval Timer Reference clock (RSCFDnCFDGCFG.ITRCP)= 500 times
- Reference clock due to the settings above = 10µs
- Transmit/Receive FIFO interval Timer Source Selection (RSCFDnCFDCFCCk.CFITSS)= 0
- Transmit/Receive FIFO Interval Timer Resolution (RSCFDnCFDCFCCk.CFITR)= 0
- Transmit/Receive FIFO Interval Transmission time (RSCFDnCFDCFCCk.CFITT)= 10 times
- Theoretical Message separation interval = 100 µs

(1) Internal FIFO interval timer is restarted with the occurrence of Successful transmission result. This restart is not synchronized to the Reference clock trigger. Therefore the first interval is counting less or equal to one Reference clock interval.

(2) With the next Reference clock trigger the FIFO interval timer is decremented and so on.

(3) When the FIFO interval timer reached the value “zero” the FIFO Transmit request is set.

(4) When the FIFO is selected for transmission then the transmission will start soon. Due to internal processing this usually takes less than 3 CAN bit time, between internal FIFO transmit request set (3) and actual transmission.

In worst case when multi events like reception scan, internal message routing, transmit scan on all channels happen, then it could take up to 1152 peripheral clock cycles.

As shown in **Figure 23.44**, it is not guaranteed that the minimum interval is always equal to the configured value. If a minimum time must never be breached, users should configure RSCFDnCFDCFCCk.CFITT to required minimum value+1

If further TX Message Buffers or TX/GW FIFOs are configured for transmission for the same channel the real delay between two messages transmitted from a TX FIFO can be much longer than specified by the interval time due to higher priority message transmission from these TX Message Buffers or TX/GW FIFOs.

Figure 23.45 shows a block diagram of the FIFO interval time generation circuit.

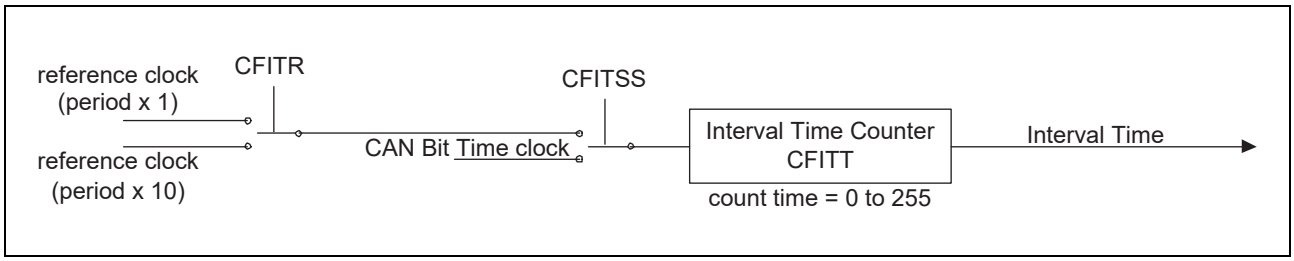

Figure 23.45 Block Diagram of FIFO interval timer

23.9.2.4 TX Queue

Each enabled TX Queue for a specific channel consists of 3 to 32 [for U2A-EVA, U2A16, U2A8] and 16 [for U2A6] TX Message Buffers, which are accessed via one access window. One Channel has four TX Queue. One TX Queue can be configured with a depth of 3 up to 32 [for U2A-EVA, U2A16, U2A8] and 16 [for U2A6] buffer and it is using the TX Message Buffer No. 0 as access window (Referred to TXQ0). The second TX Queue can be configured with a depth of 3 up to 32 [for U2A-EVA, U2A16, U2A8] and 16 [for U2A6] buffer and it is using the TX Message Buffer No. 31 as access window (Referred to TXQ1). The third TX Queue can be configured with a depth of 3 up to 32 [for U2A-EVA, U2A16, U2A8] and 16 [for U2A6] buffer and it is using the TX Message Buffer No. 32 as access window (Referred to TXQ2). The fourth TX Queue can be configured with a depth of 3 up to 32 [for U2A-EVA, U2A16, U2A8] and 16 [for U2A6] buffer and it is using the TX Message Buffer No. 63 as access window (Referred to TXQ3). All the Message of TXQ0, TXQ1, TXQ2 and TXQ3 enter the priority comparison for the transmission, which should be only ID Priority (RSCFDnCFDGCFG.TPRI = 0_B). The registers for TXQ0 are RSCFDnCFDTXQCC0m, RSCFDnCFDTXQSTS0m, and RSCFDnCFDTXQPCTR0m. The registers for TXQ1 are RSCFDnCFDTXQCC1m, RSCFDnCFDTXQSTS1m, and RSCFDnCFDTXQPCTR1m. The registers for TXQ2 are RSCFDnCFDTXQCC2m, RSCFDnCFDTXQSTS2m, and RSCFDnCFDTXQPCTR2m. The registers for TXQ3 are RSCFDnCFDTXQCC3m, RSCFDnCFDTXQSTS3m, and RSCFDnCFDTXQPCTR3m. As access window TX Message Buffer No.63 (TXQ3) or TX Message Buffer No.32 (TXQ2) or TX Message Buffer No.31 (TXQ1) or TX Message Buffer No.0 (TXQ0) is used, refer to related access registers TX Message Buffer ID Register (TMID), TX Message Buffer Pointer Register (TMPTR), TX Message Buffer Data Field 0 Register (TMDF0) and TX Message Buffer Data Field 1 Register (TMDF1).

The depth of each TXQ0 Buffer can be configured by writing to the RSCFDnCFDTXQCC0m. TXQDC[4:0] bits of the TX Queue Configuration / Control Register. TXQ0can set from TXMB0 to TXMB31 [for U2A-EVA, U2A16, U2A8] and TXMB15 [for U2A6] as a queue buffer at the maximum.

The 31 [for U2A-EVA, U2A16, U2A8] and 15 [for U2A6] available options for depth configuration are:

00000_B: TX Queue disabled

00001_B: reserved

00010_B: 3 Messages

:

11101_B: 30 Messages

11110_B: 31 Messages

11111_B: 32 Messages

The depth of each TXQ1 Buffer can be configured by writing to the RSCFDnCFDTXQCC1m.TXQDC[4:0] bits of the TX Queue Configuration / Control Register.

TXQ1 can set from TXMB31 [for U2A-EVA, U2A16, U2A8] and TXMB15 [for U2A6] to TXMB0 as a queue buffer at the maximum.

The 31 [for U2A-EVA, U2A16, U2A8] and 15 [for U2A6] available options for depth configuration are:

00000_B: TX Queue disabled

00001_B: reserved

00010_B: 3 Messages

:

11101_B: 30 Messages

11110_B: 31 Messages

11111_B: 32 Messages

The depth of each TXQ2 Buffer can be configured by writing to the RSCFDnCFDTXQCC2m.TXQDC[4:0] bits of the TX Queue Configuration / Control Register.

TXQ2 can set from TXMB32 to TXMB63 [for U2A-EVA, U2A16, U2A8] and TXMB47 [for U2A6] as a queue buffer at the maximum.

The 31 [for U2A-EVA, U2A16, U2A8] and 15 [for U2A6] available options for depth configuration are:

00000_B: TX Queue disabled

00001_B: reserved

00010_B: 3 Messages

:

11101_B: 30 Messages

11110_B: 31 Messages

11111_B: 32 Messages

The depth of each TXQ3 Buffer can be configured by writing to the RSCFDnCFDTXQCC3m.TXQDC[4:0] bits of the TX Queue Configuration / Control Register.

TXQ3 can set from TXMB63 [for U2A-EVA, U2A16, U2A8] and TXMB47 [for U2A6] to TXMB32 as a queue buffer at the maximum.

The 31 [for U2A-EVA, U2A16, U2A8] and 15 [for U2A6] available options for depth configuration are:

00000_B: TX Queue disabled

00001_B: reserved

00010_B: 3 Messages

:

11101_B: 30 Messages

11110_B: 31 Messages

11111_B: 32 Messages

When using TXQ1 and TXQ0 simultaneously, the depth of TXQ is 32 [for U2A-EVA, U2A16, U2A8] and 16 [for U2A6] or less in total.

When using TXQ3 and TXQ2 simultaneously, the depth of TXQ is 32 [for U2A-EVA, U2A16, U2A8] and 16 [for U2A6] or less in total.

Users should not access all the TX Message Buffers forming the TX Queue directly (except TX Message Buffer No. 63, TX Message Buffer No. 32, TX Message Buffer No. 31 and TX Message Buffer No. 0, which acts as TX Queue access window).

When RSCFDnCFDGAFLP0j.GAFLSRD is set and the RSCFDnCFDTXQCC00m.TXQGWE. RSCFDnCFDTXQCC1m.TXQGWE. RSCFDnCFDTXQCC2m.TXQGWE is also set, a receiving frame is stored in the target TXQ as send data by routing.

When RSCFDnCFDTXQCCn.TXQOWE bit is 1_B, the TX queue is in TX queue overwrite mode. If the message of the same ID is stored in TX Queue when a frame is received and it is stored in TX Queue, an old message will be overwritten by a new message. Therefore, an old message is not transmitted. When the old message of the same ID is transmitting and a CAN bus error and an arbitration-lost occur, the message of old ID is not resent.

When users use the function in GW mode and TX queue overwrite mode, the depth of TXQ (RSCFDnCFDTXQCC0m.TXQDC) should be configured to the value which is the various number of ID which is used in the TX queue plus 3. If it accesses by routing in gateway mode when a TXQ buffer is full, RSCFDnCFDTXQSTS.TXQMLT will be set and send data will be thrown away. Then the function is valid for the standard ID frame and is invalid for the extended ID frame.

Explanation of operation of the TXQ same ID over-writing function in GW mode is shown below.

Figure 23.46 Explanation of operation of the TXQ same ID over-writing function in GW mode

When a system writes in TXQ, a system should write in send data, after checking the state of TXQ.

Users should also not access or configure the related TX Message Buffer Control Register.

The messages stored to the TX Queue access window are internally stored to a free buffer of the TX Queue.

When the buffer is full then no further access should be done to the Queue, until it is no longer full. If it accesses by software writing in when the buffer of TXQ is full, send data will be overwritten.

The TX Queue can be disabled by clearing the TXQE bit in the TX Queue Configuration/Control Register. If this bit is cleared, the TX Queue empty flag is set as described below:

- Immediately if the message from the TX Queue is neither scheduled for the next transmission nor in transmission
- Following the transmission completion, the detection of an error on the CAN bus, loss of arbitration or transition to Channel or Global Test Mode if the transmission from the TX Queue is already scheduled for transmission or already in transmission

NOTE

The TX Queue is disabled only when the Empty flag is set after clearing the TXQE bit for the corresponding TX Queue.

Other possible messages pending from the TX Queue are lost and their transmission needs to be requested again.

Before TXQE is set again ensure that the RSCFDnCFDTXQSTSm.TXQEMP bit is set and that there is no pending abort from the TX Queue.

When the TXQE bit is cleared all messages in the TX Queue buffers will be lost and no further message should be stored into the TX Queue.

When a message has been stored to the TX Queue, FF_H must be written in to the TX Queue Pointer Control Register. This will set the transmit request automatically and change the internal Message Buffer pointer to the next free Message Buffer location of the TX Queue.

NOTE

If two messages with the same Identifier are stored in the TX Queue, then the order of transmission of these messages could be different from the order in which they were stored in the TX Queue.

To avoid this condition, it is important to confirm that the previous message with the same ID was successfully transmitted before a new Message with the same Identifier is stored in the TX Queue.

Or if TX queue overwrite mode is used, the frame of the same ID will be rewritten on a new frame.

For the TX Queue a dedicated interrupt can be enabled by setting the TXQIE bit of the TX Queue Configuration/Control Register.

The interrupt mode can be configured with the RSCFDnCFDTXQCCn.TXQIM bit of the same register either to generate an interrupt for every transmitted message or for the last transmitted message.

The TX Queue transmission request procedure after configuration is shown in **Figure 23.47**.

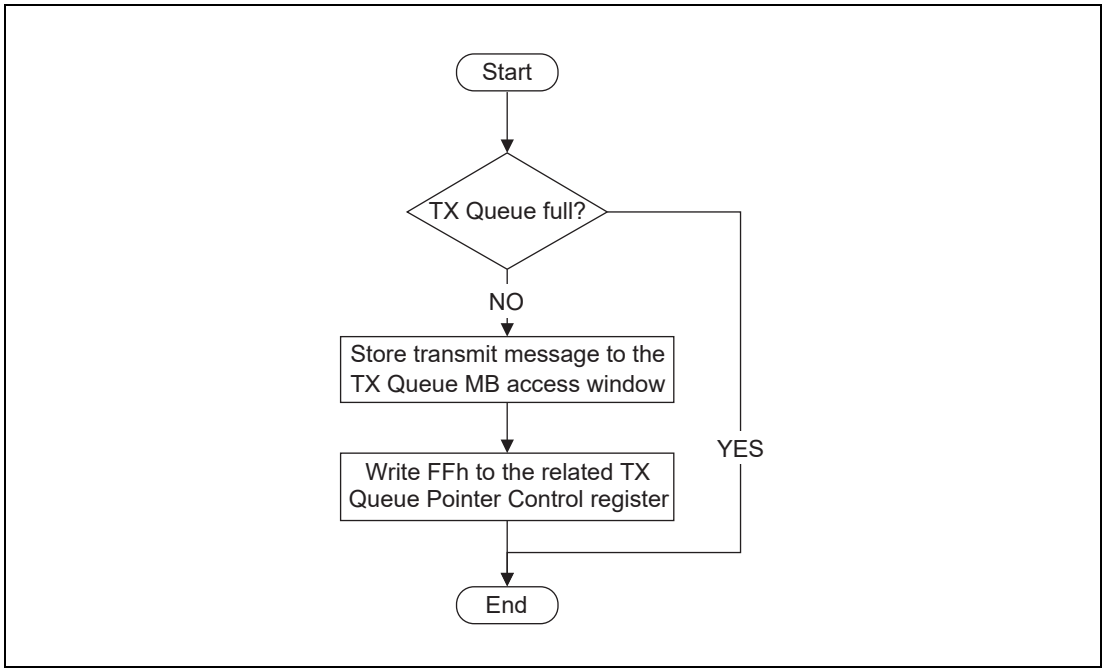

Figure 23.47 TX Queue transmission request

TXQ Name	Access window	Range width		Direction		HW Routing access point	CPU access point	DMA access point	Note	
		U2A-EVA, U2A16, U2A8	U2A6	U2A-EVA, U2A16, U2A8	U2A6				U2A-EVA, U2A16, U2A8	U2A6
TXQ0	TXMB0	0, 3-32	0, 3-16	TXMB0 -> TXMB31	TXMB0 -> TXMB15	Yes	Yes	Yes	When using both TXQ0/1, the number sum total of stages is 32 or less.	When using both TXQ0/1, the number sum total of stages is 16 or less.
TXQ1	TXMB31	0, 3-32	0, 3-16	TXMB31 -> TXMB0	TXMB15 -> TXMB0	Yes	Yes	No		
TXQ2	TXMB32	0, 3-32	0, 3-16	TXMB32 -> TXMB63	TXMB32 -> TXMB47	Yes	Yes	No	When using both TXQ2/3, the number sum total of stages is 32 or less.	When using both TXQ2/3, the number sum total of stages is 16 or less.
TXQ3	TXMB63	0, 3-32	0, 3-16	TXMB63 -> TXMB32	TXMB47 -> TXMB32	No	Yes	Yes		

TXQ0 can use HW Routing, CPU access, and DMA access.

HW Routing access, CPU access, and DMA access should not be used simultaneously.

The one access method is chosen.

23.9.2.5 TX History List

The TX History List function records the information of the successfully transmitted message in the TX History List Buffers for each CAN channel. Two THL Buffer are provided for each CAN channel and each THL Buffer can store up to 32 THL entries for a CAN channel.

The RSCFDnCFDTHLCCm.THLDTE bit of the TX History List Configuration / Control Register can be used to configure if only message information from TX FIFOs / TX Queue is stored or if all transmit message information from TX Queue, TX FIFO or normal TX Message Buffers should be stored in the TX History List for a CAN channel.

When a RSCFDnCFDTHLCCm.THLDGE bit is set up, the information on all the frames transmitted in GW mode is stored in THL.

Each transmit message can be individually configured for acceptance to the TX History List by the RSCFDnCFDCFID.THLEN bit in the Message Buffer Pointer Register.

The message information is stored to the TX History List Buffer of a CAN channel after the message is successfully transmitted on that CAN channel.

Storing to the List is not synchronized with the status of RSCFDnCFDTMSTSp.TMTRF[1:0] bits in the TX Message Buffer Status Register.

Due to internal processing, the storage to the List could happen with a delay after the successful transmission indication.

Storing the TX History List data can be recognized by the condition that the THLIF is set to 1 when the THLIE is configured to 1 or when the TX History List counter RSCFDnCFDTHLSTSm.THLMC[5:0] is increased.

The delay time is dependent on the number of channels due to internal processing.

Maximum delay time from setting the RSCFDnCFDTMSTSp.TMTRF to storing the TX History List data is 224 peripheral bus clock cycles.

The History list records following information of the transmitted message:

Buffer Type:

001: TX Message Buffer

010:TX FIFO

100:TX Queue

Buffer Number:

TX Message Buffer, TX Queue Message Buffer or TX Message Buffer Link for the Transmit/ Receive FIFO Buffer from which the transmission occurred. The number depends upon the Buffer Type, refer to **Table 23.151**.

Transmission ID:

Transmission Pointer stored in the transmission message

Transmit Timestamp:

Message timestamp captured at capture point as configured by RSCFDnCFDGFDCFG.TSCCFG.

Transmission Information Label:

Transmission information label stored in the transmission message.

Transmit Gateway Buffer indication:

In the case of the data transmitted from Gateway, RSCFDnCFDTHLACC0m.TGW bit is set to 1.

Table 23.151 TX History List Buffer Number entry (1/3)

Buffer Type / Buffer Number	001	010	100

1011110	Message Buffer 94		
1011111	Message Buffer 95		

The Transmission ID entry is used to identify which message of a TX FIFO or TX Queue has been successfully transmitted because the TX FIFO or TX Queue number alone is not sufficient.

Therefore, a unique number can be attached to each transmission message stored in a TX FIFO or TX Queue. This unique identification number should be written to the RSCFDnCFDCFFDCSTS.CFPTR[15:0] part of the Transmit/Receive FIFO Access Pointer Register for a TX FIFO or to the RSCFDnCFDTMFDCTR.TMPTR[15:0] part of the TX Message Buffer Pointer Register of the TX Queue access window Message Buffer.

When the message is successfully transmitted then this identification number is stored together with the other message related information to the TX History List and can be read via the Transmission ID (TID) of the TX History List Access Register.

Also for normal TX Message Buffers, the RSCFDnCFDTMFDCTR.TMPTR[15:0] part of the TX Message Buffer Pointer Register will be stored in the Transmission History List. Information label is the same.

Figure 23.48 shows a transmission preparation flow when TX History List is used.

Read access to the TX History List Access Register will be done for every single entry.

After reading one entry, FF_H has to be written to the corresponding TX History List Pointer Control Register to be able to access the next entry until TX History List is empty.

Figure 23.49 shows an example flow for processing the TX History List information.

The TX History Lists have dedicated interrupts, which can be configured with the RSCFDnCFDTHLCCm.THLIM bit of the corresponding TX History List Configuration / Control Register and enabled with the RSCFDnCFDTHLCCm.THLIE bit of the same registers, either to

generate an interrupt when the History List reached a filling level of 75% or for every new TX History List entry.

An entry lost indication is flagged by the RSCFDnCFDTHLSTSm.THLELT bit in the TX History List Status Register.

Status of this bit is also shown by the THLES bit in the Global Error Flag Register.

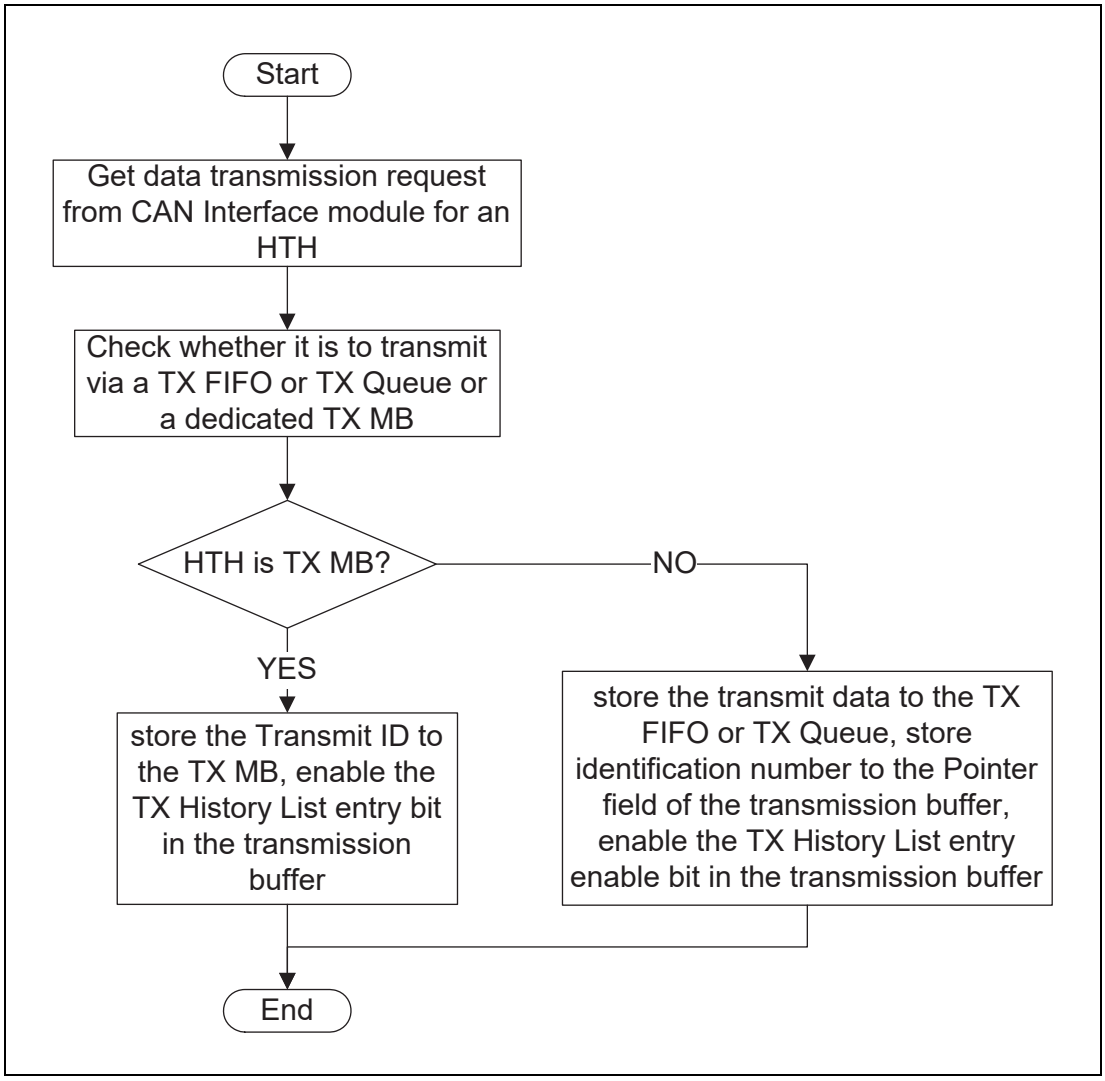

Figure 23.48 TX History List preparation flow

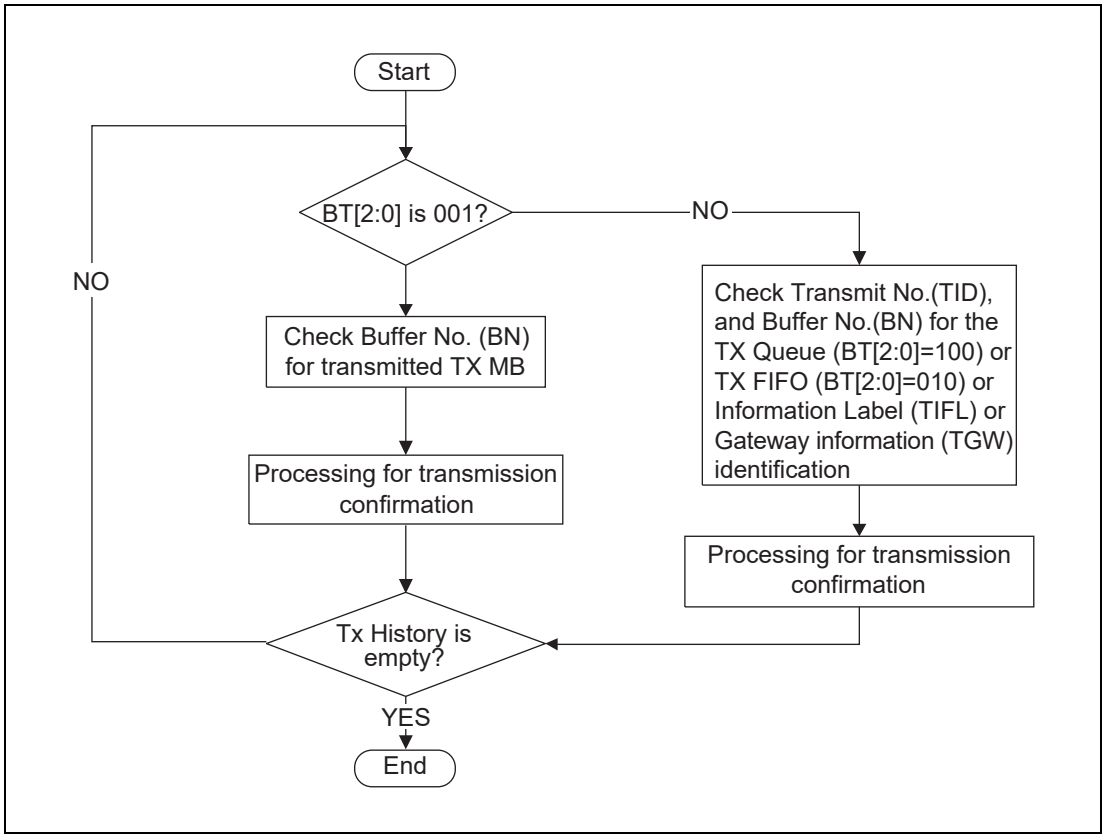

Figure 23.49 TX History List processing flow

23.9.2.6 TX data padding

If the data length code (DLC) of the transmitting message is higher number of data bytes than the buffer size. Then the data bytes beyond the restricted range will be replaced by bytes with the value of CC HEX.

This could happen for Transmit/Receive FIFOs configured as (TX or GW) when the transmit message DLC is higher than the RSCFDnCFDCFCCk.CFPLS.

This could also happens in CANFD only mode, if a Classical CAN Frame is configured with a DLC bigger than 8.

23.10 ECC Check

An ECC check mechanism is implemented in RS-CANFD to check consistency of data in the RAM.

Each memory location in the RAM consists of 39 bits. 32 bits are used for storage of user data and 7 bits are used for storage of ECC data. For each long-word (32 bits) memory location, ECC data is allocated. The value of this ECC data is calculated by the ECC generation logic.

The ECC check mechanism checks the data during read access from CAN side or CPU side to the RAM. If a single bit error is detected, then it is corrected and a flag is set in the ECC Status Register (Register is outside of CAN IP).

If multiple bit error is detected from CAN side read during the transmission scan, then the transmit request of the CAN channel which is under transmission scan will be suppressed and the corresponding RSCFDnCFDGERFL.EEFm bit is set. This is done to avoid transmission of corrupted data.

In general if multiple bit errors are detected then perform RAM test to check the RAM status. When no problem is found, make a transition to global reset mode and then make communication initialization again.

NOTE

If an error is detected by the ECC logic then the error address of the RAM access will be captured in the capture register which is part of the ECC macro (not RS-CANFD).

The captured RAM address will not match with the SFR address.

23.11 Test Mode

The RS-CANFD module can be configured into Test Modes to allow testing of certain features. These features are provided only for special purposes and care must be taken when configuring the RS-CANFD module in the test modes.

Note that all Test modes are mutually exclusive unless it is explicitly stated that some functions can be enabled across other test modes.

Users should not enable any combinations of the various Test modes specified in this Section.

The Test modes can be broadly split into 2 groups:

- Channel specific test modes
- Global test modes

23.11.1 Channel specific test modes

Each CAN channel can be configured into following test modes:

- Basic test mode
- Listen-only mode
- Self test mode 0 (External Loop back mode)
- Self test mode 1 (Internal Loop back mode)
- Restricted Operation Mode

23.11.1.1 Basic test mode

The Basic test mode is used for Restricted Operation Mode or CRC Error Test.

This mode can output value of CRC to CFDCnERFL.CRCREG, CFDCnFDCRC.CRCREG and CFDCnFDCRC.SCNT.

The Basic test mode should be used when a particular test setting needs to be enabled other than when in Listen-Only and Self-test modes

23.11.1.2 Listen-only mode

The ISO 11898-1 (2015) recommends an optional bus-monitoring mode. In this mode, the CAN channel is able to receive valid data frames and valid remote frames. However, it sends only recessive bits on the CAN bus and is not allowed to transmit.

If the CAN engine is required to send a dominant bit (ACK bit, overload flag, active error flag), the bit is routed internally so that the CAN engine monitors this as dominant. The external TX pin will remain in recessive state.

This mode can be used for Baud Rate detection. In this mode, an error interrupt is generated if a bus error occurs and the interrupt is enabled.

In this mode, it is not permitted to request transmission from any normal TX Message Buffer or TX- / GW-FIFO of this channel.

NOTE

If a message is stored in GW FIFO or Routing TXQ then users should ensure that the transmitting channel is not in Listen-only mode so that transmission is not requested for this channel from the GW FIFO or Routing TXQ.

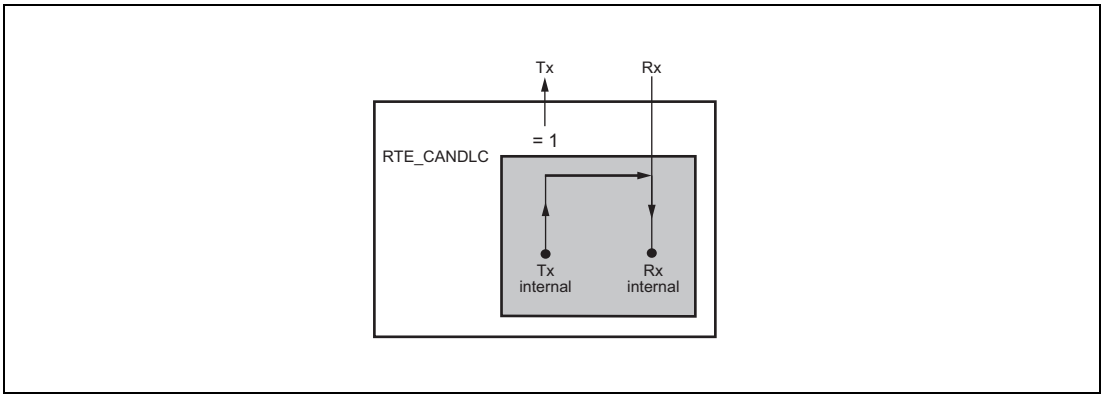

Figure 23.50 Listen-only mode

23.11.1.3 Self test mode 0 (External Loop back mode)

In Self Test Mode 0, the CAN engine treats its own transmitted messages as received messages via the CAN transceiver and can store them into its receive Message Buffers.

CAN node except Transceiver should be stop in this test.

So to receive its own transmitted messages, the engine generates its own Acknowledge bit.

This test can be used for CAN transceiver tests.

The Rx/TX pins should be connected to the transceiver.

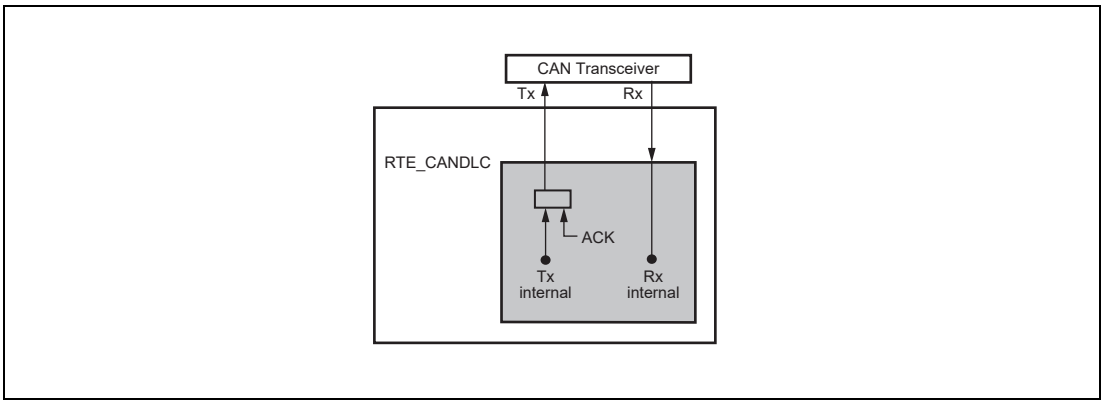

Figure 23.51 Self test mode 0 (External Loop back mode)

23.11.1.4 Self test mode 1 (Internal Loop back mode)

In Self Test Mode 1, the CAN engine treats its own transmitted messages as received messages and stores them into the receive buffer. This mode is provided for self-test functions. To be independent from external stimulation the CAN engine generates its own Acknowledge bit. In this mode the CAN engine performs an internal feedback from TX internal to Rx internal. The actual value of the external Rx input is disregarded by the CAN engine.

The external TX pin outputs only recessive bits.

The Rx/TX pins do not need to be connected to the CAN bus or any external device.

NOTE

The channel Pins are also disconnected from the Internal CAN Bus Communication line.

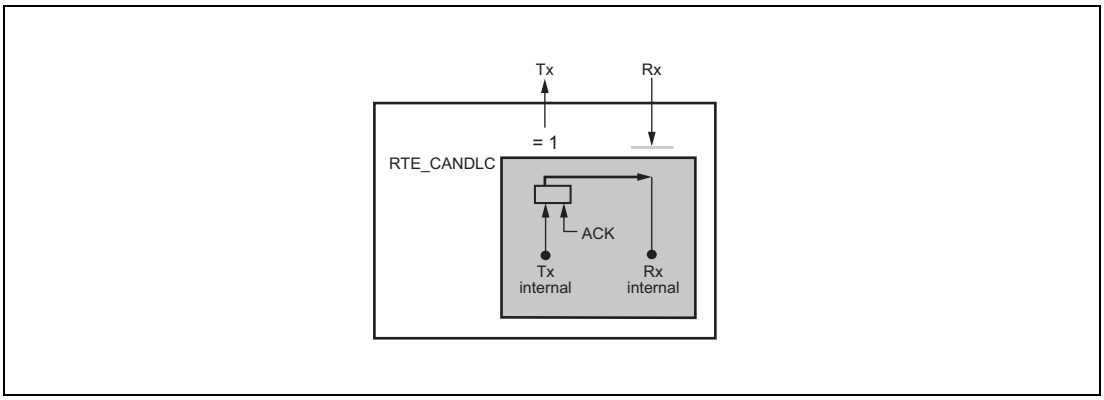

Figure 23.52 Self test mode 1 (Internal Loop back mode)

23.11.1.5 Restricted Operation Mode

In Restricted Operation Mode the CAN node is able to receive valid data and remote frames generating the Acknowledge bit.

Active Error and Overload frames cannot be transmitted instead it waits for the occurrence of bus idle condition to resynchronise itself to the CAN communication after an error or overload condition occurs

Moreover the Receive and Transmit Error Counter (REC and TEC) are frozen independently from the occurrence of errors.

The mode is specified as in ISO 11898-1 (2015); however it is permitted to set any transmit requested.

23.11.2 Global test modes

The RS-CANFD module can be configured into following test modes:

- RAM Test Mode
- Internal CAN Bus Communication Mode
- CRC Error Test

For following test modes are protected by a special SW procedure to enable the mode. This SW procedure enables the write access to the test mode by specific unlock Key, the related unlock key can be seen in the table below:

Table 23.152 Related Unlock Key

Test Mode	First Unlock key	Second Unlock key
RAM Test Mode	7575_H	$8A8A_H$

If the SW sequence of the two consecutive unlock key write accesses (word or long-word accesses) is interrupted by any other write access to the SFR or if incorrect data is written to the Global Lock Key Register then the corresponding Test mode cannot be set and the sequence should be re-started.

After the two unlock key write accesses, the next write access should be to set the corresponding Test mode Enable bit. If this is not followed, the unlock mechanism resets and the Test mode enable bit cannot be set and then the unlock sequence should be restarted.

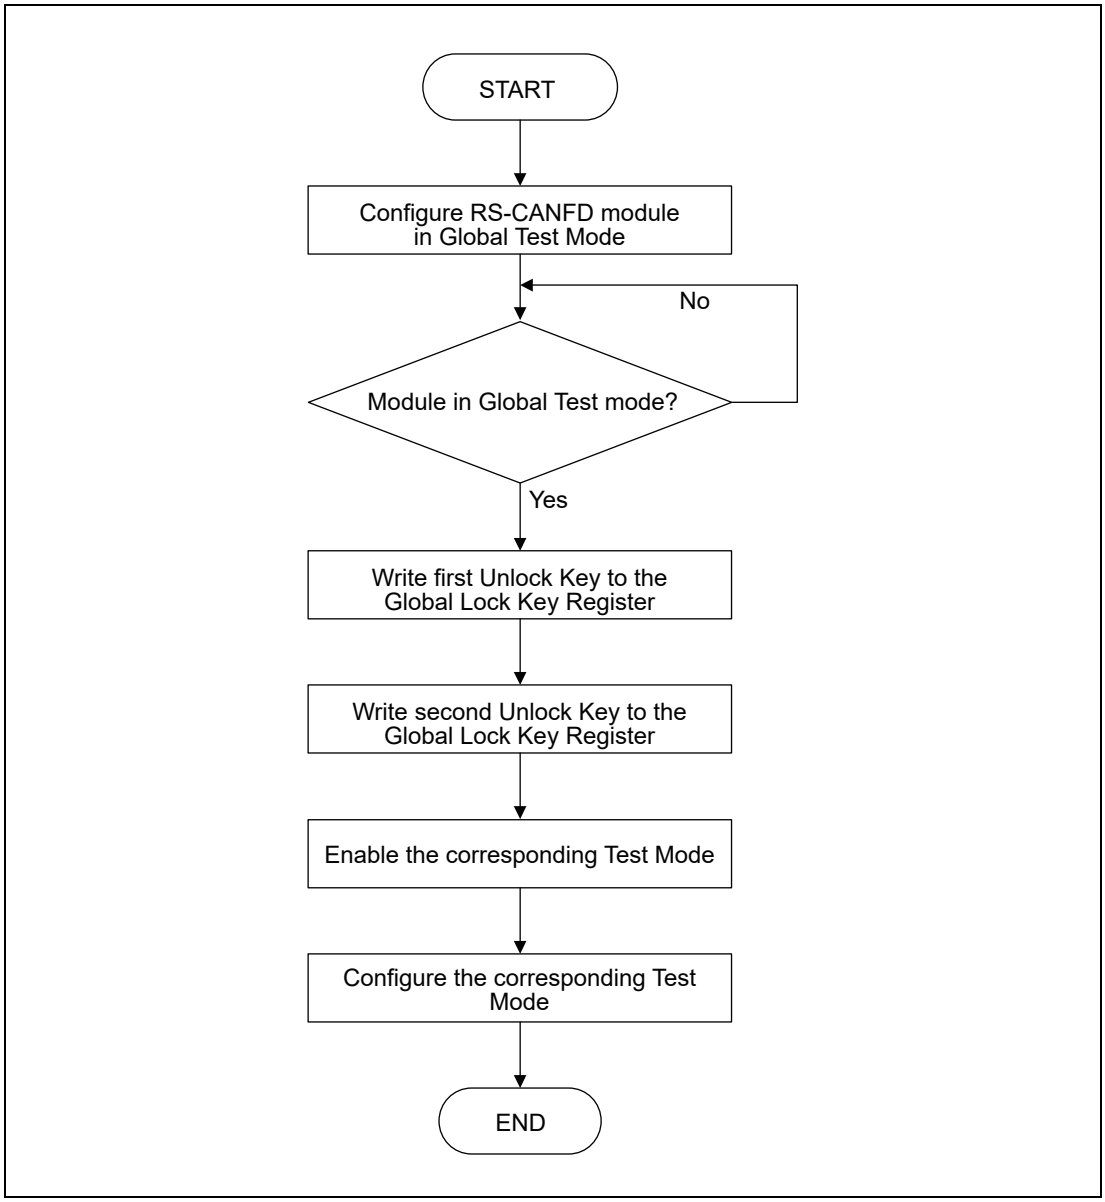

Figure 23.53 Unlock SW protection routine

23.11.2.1 RAM Test Mode

The RS-CANFD module can be configured in RAM Test Mode by setting the RSCFDnCFDGTSTCTR.RTME bit in the Global Test Control Register when the corresponding unlock key is written before. This is a special test mode, in which, the complete RAM area can be accessed.

NOTE

The actual RAM size is bigger than the RAM area initialized after HW Reset. Hence, ECC error flag (of the ECC macro) may be set if CPU reads data from this un-initialized RAM area while RS-CANFD module is in RAM Test Mode.

In this mode, the RAM area is split into number of pages (pn) of 256 Bytes each. Which can be accessed via RSCFDnCFDRPGACCr register.

The page should be selected for read / write access by writing to the RSCFDnCFDGTSTCFG.RTMPS[9:0] bits in the Global Test Control Register. Then, data can be read from or written in to the RAM Test Page Access Register.

Figure 23.54 shows the structure of the pages in the RAM when performing a RAM Test Mode.

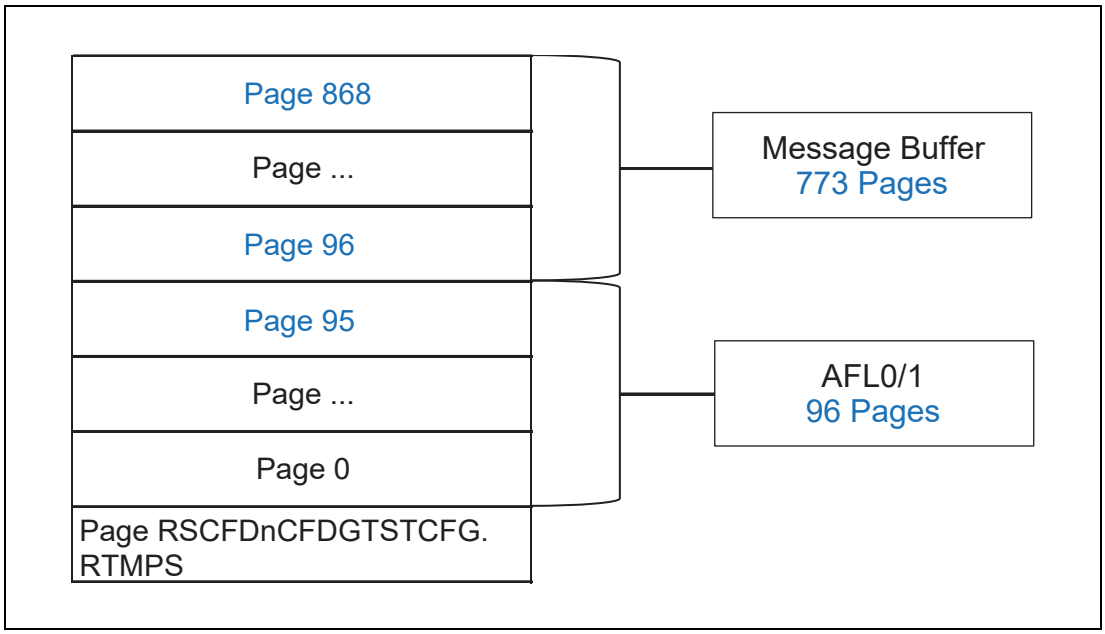

Figure 23.54 RAM page structure

For U2A-EVA, U2A16, U2A8:
The total available RAM size for 8 CAN channel version is 24576 bytes for the AFL RAM and 197888 bytes for the Message Buffer RAM.

For U2A6:
The total available RAM size for a 8 CAN channel version is 16384 bytes for the AFL RAM and 61696 bytes for the Message Buffer RAM.
The total available RAM size for a 4 CAN channel version is 8192 bytes for the AFL RAM and 30848 bytes for the Message Buffer RAM.

AFL RAM0/1 can treat RAM Test mode as one RAM.

The pn and RSCFDnCFDGTSTCFG.RTMPS[9:0] values for the AFL and MB RAMs are calculated in the following way:

pn = ceil(Total RAM size in Bytes / Number of Bytes per page)

AFL RAM:

pn = ceil(24576 / 256) = 96 Pages

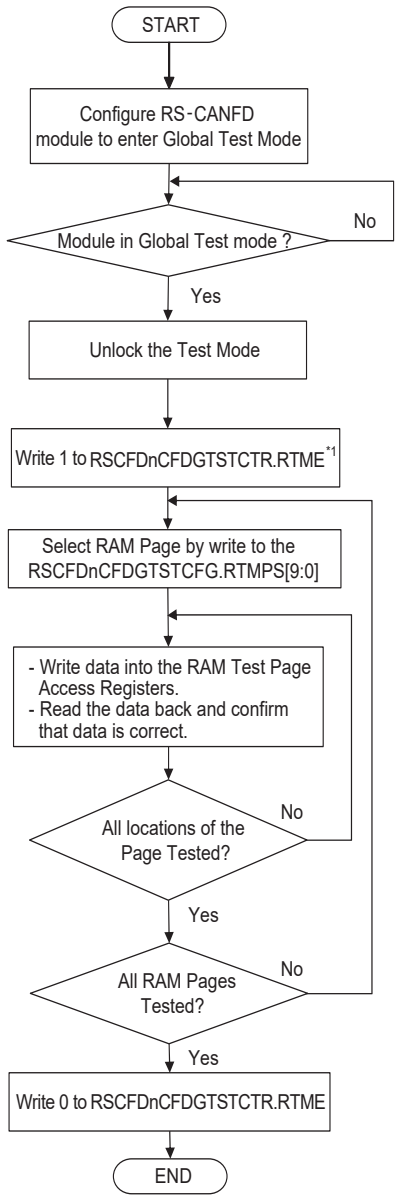
RSCFDnCFDGTSTCFG.RTMPS[9:0] = 0 to 95 (10'h5F) inclusive

MB RAM:

pn = ceil(197888 / 256) = 773 Pages

RSCFDnCFDGTSTCFG.RTMPS[9:0] = 96 to 868 (10'h364) inclusive

Figure 23.55 below shows the SW flow for RAM Test mode.



Note 1. Change into the following status before changing to RAMTEST.
Cancel of a request of transmission.
Disable of all the FIFO and TXQ.
Clear of the receiving flag of a receiving buffer.

Figure 23.55 RAM Test Mode SW flow

To exit this Test mode, the RSCFDnCFDGTSTCTR.RTME bit must be cleared. The RSCFDnCFDGTSTCTR.RTME bit is cleared by writing 0_B to it.

The RSCFDnCFDGTSTCTR.RTME bit is cleared automatically when the RS-CANFD module enters Global Reset mode from the Test mode.

23.11.2.2 Internal CAN Bus Communication Test Mode

The RS-CANFD module can be configured in Internal CAN Bus Communication Test Mode by setting the RSCFDnCFDGTSTCTR.ICBCTME bit in the Global Test Control Register. This is a special test mode, in which the CAN channels can be connected together internally to generate a CAN cluster within the RS-CANFD module.

Users should only use following sequence to enter Internal CAN Bus Communication Test Mode:

1. Configure all channels in Halt Mode and check that all channels have entered Halt mode (Global Test mode).
2. Write data into the Global Test Configuration Register to select the channels participating in the Internal CAN Bus Communication Test.
3. Set the RSCFDnCFDGTSTCTR.ICBCTME bit of the Global Test Control Register.
4. Check that RSCFDnCFDGTSTCTR.ICBCTME bit is set in the Global Test Control Register.

In this mode, the TxD outputs of the channels participating (configured) in Internal CAN Bus Communication Mode are connected together using AND gate. The output of the AND gate is connected to the RxD inputs of all participating channels to create a CAN cluster within the RS-CANFD module. The channels are isolated from the external CAN bus while the RS-CANFD module is in this test mode.

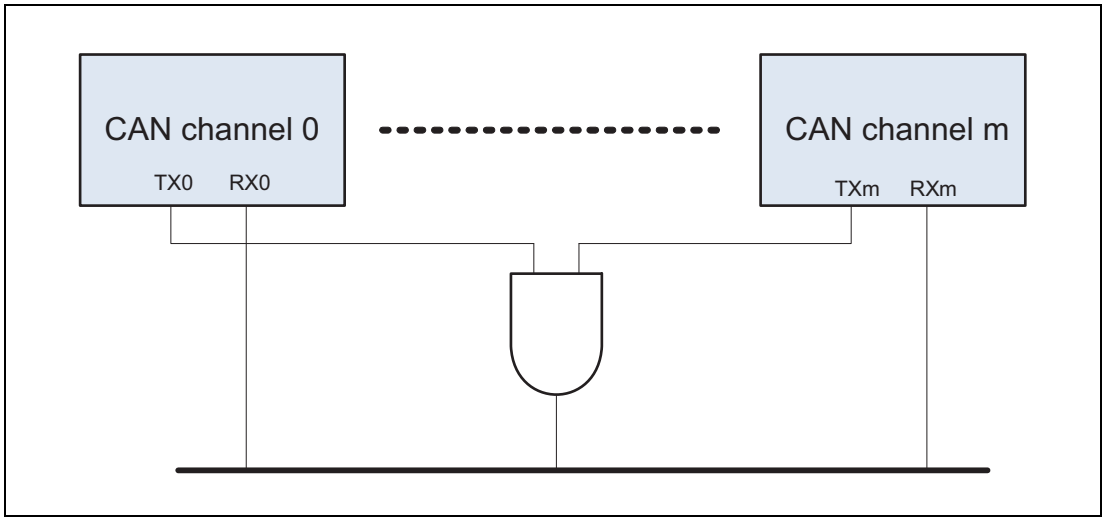


Figure 23.56 Internal CAN Bus connections

The AFL, Flat RX Message Buffers, FIFO Buffers, Flat TX Message Buffers and various registers can now be configured as normal to start communication between channels.

The channels not participating in Internal CAN Bus should only be configured in Halt Mode.

CRC Error Test

After the RS-CANFD module has been configured in Internal CAN Bus Communication Test Mode, the following sequence should be used to perform CRC Error testing. In the sequence below channel x is the reference transmitter RS-CANFD module and channel y is the receiver RS-CANFD module where (x, y = [0…m] and x ≠ y):

1. Configure channel x node to transmit 1 reference message

2. Set the RSCFDnCFDCyCTR.CRCT bit to 1_B, in order to invert the first bit of the incoming bit stream from channel x
3. Set the RSCFDnCFDTMCx.TMTR
4. Wait for the can_cherr_int[y] output signal to set to 1_B
5. Read either the RSCFDnCFDCyERFL.CRCREG or the RSCFDnCFDCyFDCRC.CRCREG (depending on the received frame type: Classical or FD). The value should be different from the received CRC value of the reference message from channel x.
6. Check that RSCFDnCFDCyERFL.CERR is 1_B

As the CRC generator logic is shared for RX and TX there is no need to create a separate TX CRC Error test.

23.12 RAM area configuration

The RAM area used in RS-CANFD can be split into the following groups as shown below in **Figure 23.57**:

- Rule Table area
- RX MB + FIFO Buffer area
- TX MB area
- THL area
- OTB area (One Time Buffer area is used for internal purpose)

Physically the RAM is split in two RAMs the AFL (Rule Table) RAM0 (RSCFDnCFDGAFLID and RSCFDnCFDGAFLP0), AFL (Rule Table) RAM1 (RSCFDnCFDGAFLM and RSCFDnCFDGAFLP1), and the Message Buffer RAM (RX, RX FIFO, Transmit/Receive FIFO, TX, THL and OTB).
The size of AFL RAM and MRAM changes with the number of channels.

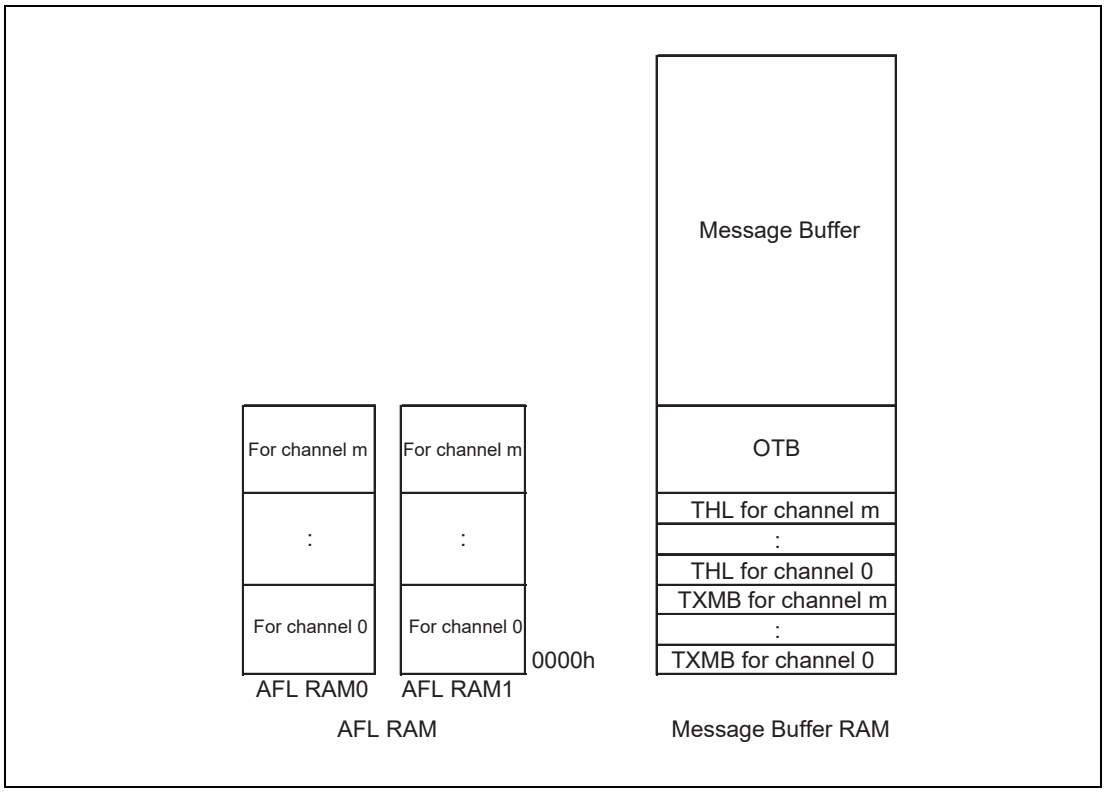

Figure 23.57 RAM area grouping

The Rule Table area always starts at AFL RAM address 0000_H and has a fixed size for a given number of channels.

The MRAM area starts with the TX-MB area at address 0000_H. The TX-MB area is followed immediately by the THL area which is then followed immediately by the OTB area. The size of the TX-MB, THL and OTB area is fixed for a given number of channels.

The OTB area is followed by the message buffer area. The massage buffer area size depends on the configuration of the flat RX MBs, RXFIFOs and CFIFOs. When all are configured the RX-MB area is followed by the RXFIFO area which is followed by the CFIFO area.

The configured MRAM area can be calculated then as follows.

MRAM_cfg = RXMB_MRAM_cfg + RXFIFO_MRAM_cfg + CFIFO_MRAM_cfg +
TXMB_MRAM_cfg +THL_MRAM_cfg + OTB_MRAM_cfg

RXMB_MRAM_cfg = (12 Bytes + RSCFDnCFDRMND.RMPLS) * RSCFDnCFDRMNB.NRXMB

RXFIFO_MRAM_cfg = SUM((12 Bytes + RSCFDnCFDRFCCx.RFPLS) * RSCFDnCFDRFCCx.RFDC)

CFIFO_MRAM_cfg = SUM((12 Bytes + RSCFDnCFDCFCCk.CFPLS) * RSCFDnCFDCFCCk.CFDC)

TXMB_MRAM_cfg = 4864 Bytes * m (For U2A-EVA, U2A16, U2A8) or 2432 Bytes * m (For U2A6)

THL_MRAM_cfg = 256 Bytes * m

OTB_MRAM_cfg = 160 Bytes * m

“x” means RX FIFO index = [0…no_of_RFIFOs-1]

“k” means Transmit/Receive FIFO index = [0 .. no_of_CFIFOs -1]

no_of_RFIFOs : Number of configured RX FIFOs

no_of_CFIFOs: Number of configured CFIFOs

NOTE

For RSCFDnCFDRFCCx.RFDC, RSCFDnCFDCFCCk.CFDC, RSCFDnCFDRMNB.RMPLS, RSCFDnCFDRMNB.NRXMB, RSCFDnCFDRFCCx.RFPLS, and RSCFDnCFDCFCCk.CFPLS the related number of bytes must be used.

The **Table 23.153** shows the calculation of the different RAM areas used for the AFL entries, OTB buffers, TX/RX message buffers and RX/Transmit/Receive FIFOs.

Table 23.153 AFL RAM and MRAM area calculation

RAM Name	RAM Property	RAM Area Calculation Method	RAM Values
	No. of Channels	(m+1)	8
AFL	Avg. rule entries per channel		192
	Max Rule entries	(m+1) * Avg. rule entries per channel	1536
	No. of Bytes in a rule entry	Fixed	16
	Number of Bytes AFL RAM	Max Rule entries * No. of Bytes in a rule entry	24576
TX MB	No. of TX MBs per channel	Fixed	64
	Max no. of TX MBs	(m+1) * No. of TX MBs per channel	512
	No. of Bytes needed for each TX MB	Fixed	76
	Number of Bytes in TX MB area	(m+1) * No. of TX MBs per channel * No. of Bytes needed for each TX MB	38912
THL	No. of entries in 1 THL buffer	Fixed	32
	Max no. of THL entries	(m+1) * No. of entries in 1 THL buffer	256
	No. of Bytes needed for each THL entry	Fixed	8
	Number of Bytes in THL area	Max no. of THL entries * No. of Bytes needed for each THL entry	2048
OTB	Avg. number of buffers for each channel		2
	Max no. of OTB entries	(m+1) * Avg. number of buffers for each channel	16
	No. of Bytes for OTB entry	Fixed	80
	Number of Bytes in OTB area	Max no. of OTB entries * No. of Bytes for OTB entry	1280
Message Buffer	No. of RX MBs per channel	Fixed	16
	Max no. of RX MBs	(m+1) * No. of RXMBs per channel	128
	No. of RX FIFOs	Fixed	8
	No. of Transmit/Receive FIFOs per channel	Fixed	3
	Max no. of Transmit/Receive FIFOs	(m+1) * No. of Transmit/Receive FIFOs per channel	24
	Avg. number of messages for RXMB and FIFO buffers for each channel		256
	No. of Bytes for each stored message	Fixed	-
	Average size of a Message Buffer in Bytes		76
	Number of Bytes in Message Pool area	(m+1) * Avg. number of messages for RXMB and FIFO buffers for each channel * (No. of Bytes for each stored message or Average size of a Message Buffer in Bytes based on CAN_FD_MODE)	155648
	Number of Bytes Message RAM	Number of Bytes in Message Pool area + Number of Bytes in OTB area + Number of Bytes in THL area	197888

23.12.1 Examples

The **Figure 23.58** below shows one possible configuration of a 8 channel version.

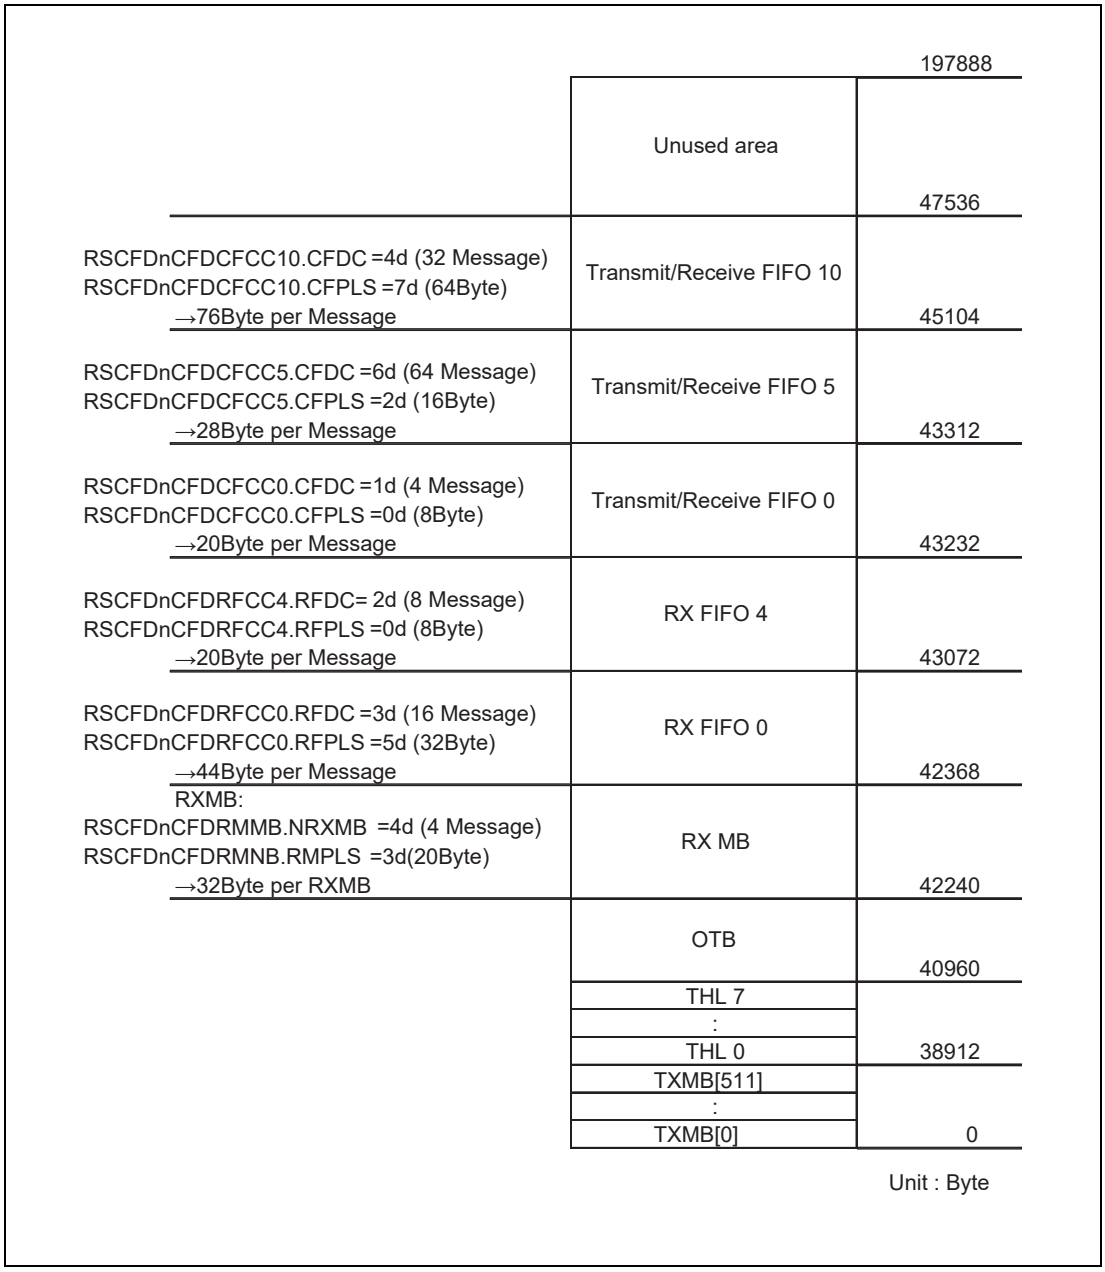

Figure 23.58 RX MB + FIFO buffers RAM area configuration examples of a RS-CANFD 8 channel version

23.12.2 num_ram_chan dependencies

Depending on the num_ram_chan[3:0] configuration the sizes of the AFLRAM and MRAM differs. Further the number of initialization cycles of the memory and the number of RAM test pages is different. Dedicated values can be found in the following table.

Table 23.154 Dedicated values (For U2A-EVA, U2A16, U2A8)

CH	num_ram_chan [3:0]	AFLRAM area size	MRAM area size	RAM initialization cycles (pclk cycle)	RAM Test RTMPS range*1	
1	0001_B	3072	24736	6186	00_H to $6C_H$	(108)
2	0010_B	6144	49472	12370	00_H to $D9_H$	(217)
3	0011_B	9216	74208	18554	00_H to 145_H	(325)
4	0100_B	12288	98944	24738	00_H to $1B2_H$	(434)
5	0101_B	15360	123680	30922	00_H to $21F_H$	(543)
6	0110_B	18432	148416	37106	00_H to $28B_H$	(651)
7	0111_B	21504	173152	43290	00_H to $2FB_H$	(760)
8	1000_B	24576	197888	49474	00_H to 364_H	(868)
8	0000_B	24576	197888	49474	00_H to 364_H	(868)

Note 1. 0001_B (1ch) : User should not access more than 160 Bytes in the last page
0010_B (2ch) : User should not access more than 64 Bytes in the last page
0011_B (3ch) : User should not access more than 224 Bytes in the last page

1000_B (8ch) : User can access all area in the last page
0000_B (8ch) : User can access all area in the last page
Other values are prohibited.

23.13 Bus traffic measurement

The idle time of the CAN bus can be measured using the clkc clock or clk_xincan clock. Bus traffic can be calculated based on the measurement results.

23.13.1 How to count the CAN bus idle time

Below is the concept of measuring the idle time of the CAN bus.

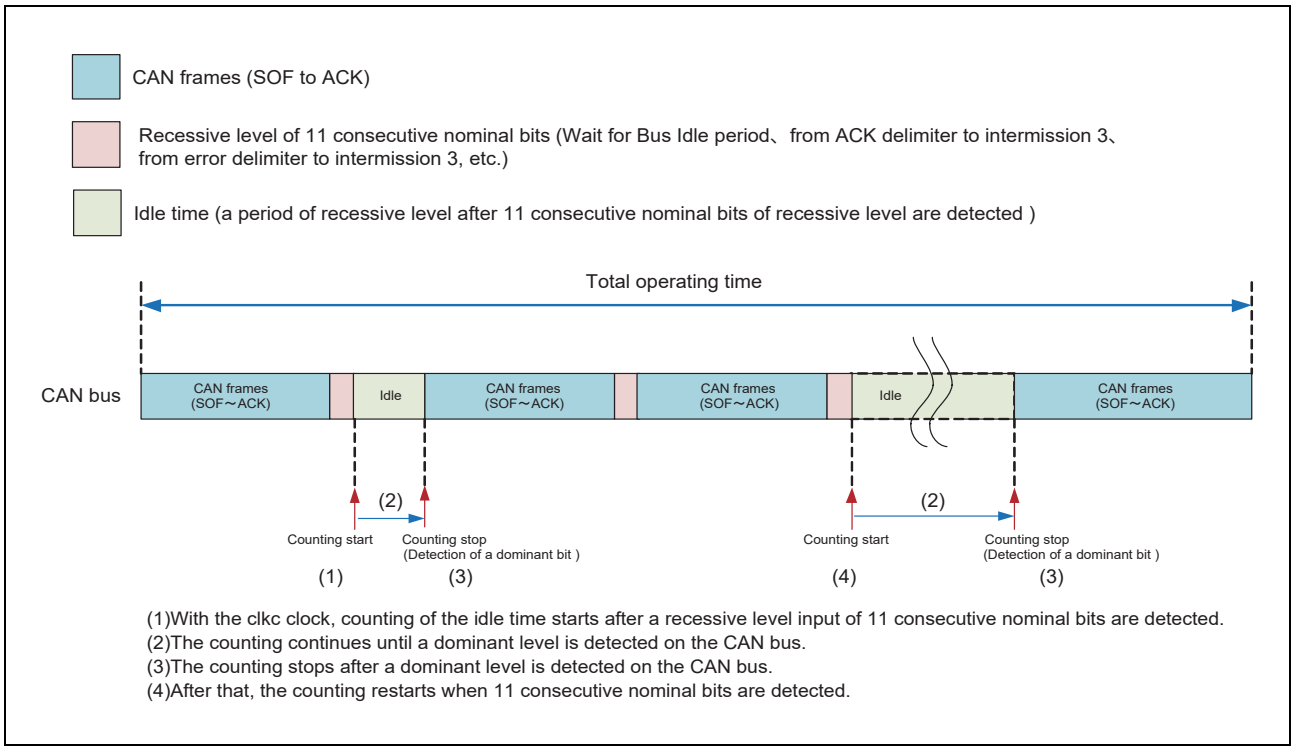

Figure 23.59 Concept of Measuring the Idle Time of the CAN Bus

23.13.2 Operations and measurement procedure

The following are the procedure for measuring the idle time of the CAN bus.

1. The channel to be measured transits to operation mode.
2. Write 1 to RSCFDnCFDCmBLCT.BLCE bit to set the measuring counter to operating mode.
3. Write 1 to RSCFDnCFDCmBLCT.BLCLD bit to clear the counter register.
4. RS-CAN-FD module detect a recessive level input of 11 consecutive nominal bits.
5. RS-CAN-FD module start counting the bus idle time.
6. RS-CAN-FD module detect a dominant level.
7. RS-CAN-FD module counting stops.
8. RS-CAN-FD module detect a recessive level input of 11 consecutive nominal bits.
9. RS-CAN-FD module counting starts.
10. Write 1 to RSCFDnCFDCmBLCT.BLCLD bit to clear the counter register and simultaneously load the counter value to RSCFDnCFDCmBLSTS.
11. Read the value of RSCFDnCFDCmBLSTS.

To stop the measurement counter, write 0 to RSCFDnCFDCmBLCT.BLCE bit.

To initialize the counter, write 1 to RSCFDnCFDCmBLCT.BLCLD bit.

This measurement will be enabled when the channel to be measured is in operation mode.

When the relevant channels are in reset mode, the counter will not operate.

Also, accurate measurements are not available in test mode.

Write 1 to RSCFDnCFDCmBLCT.BLCLD bit to clear the counter register and simultaneously load the value of the counter to RSCFDnCFDCmBLSTS.

The lower three bits of RSCFDnCFDCmBLSTS are fixed to 0.

Based on the values of the counter, software can calculate the CAN bus traffic according to the following formulas.

$$\frac{(\textit{Total operating time} - \textit{Total idle time})}{\textit{Total operating time}} = \frac{\textit{Bus operating time}}{\textit{Total operating time}} = \textit{Bus usage ratio}$$

Total idle time: a value read from RSCFDnCFDCmBLSTS × a clock cycle of clkc

Total operating time: a setting interval of RSCFDnCFDCmBLCT.BLCLD bit

Example) Below is a calculation example under the following conditions.

Conditions: nominal bit rate = 1Mbps

clkc clock = 40MHz (=25ns)

a setting interval of RSCFDnCFDCmBLCT.BLCLD bit = cycle of 1ms

a read value of RSCFDnCFDCmBLSTS register = $4E20_H$ (20000)

$$\frac{(\textit{Total operating time} - \textit{Total idle time})}{\textit{Total operating time}} = \frac{(\textit{1000000 ns} - \textit{20000} \times \textit{25 ns})}{\textit{1000000 ns}} = \textit{50 \%}$$

23.14 Flexible CAN mode

This is a mode in which it is possible to connect the CAN modules of 2 channels to a single CAN driver.

The pair of Channel in flexible CAN mode is as follows.

When RSCFDnCFDGFCMC.FLXC0 bit is set, Channel 0 and Channel 1 of a RS-CANFD module are Flexible CAN mode.

When RSCFDnCFDGFCMC.FLXC1 bit is set, Channel 2 and Channel 3 of a RS-CANFD module are Flexible CAN mode.

When RSCFDnCFDGFCMC.FLXC2 bit is set, Channel 4 and Channel 5 of a RS-CANFD module are Flexible CAN mode.

When RSCFDnCFDGFCMC.FLXC3 bit is set, Channel 6 and Channel 7 of a RS-CANFD module are Flexible CAN mode.

Channel m+1 uses TX/RX terminal of Channel m.

The TX/RX terminal of Channel m+1 cannot use.

In Flexible CAN mode, each channel performs communication processing independently.

However, when one of the channels transmits, the other channel will not return an acknowledge bit.

NOTE

When operating in Flexible CAN mode the error counters (TEC/REC) of the two CAN nodes are not synchronized with each other.

Flexible transmission buffer assignment configured in RSCFDnCFDGFTBAC register and Flexible CAN mode configured in RSCFDnCFDGFCMC register should not be used simultaneously.

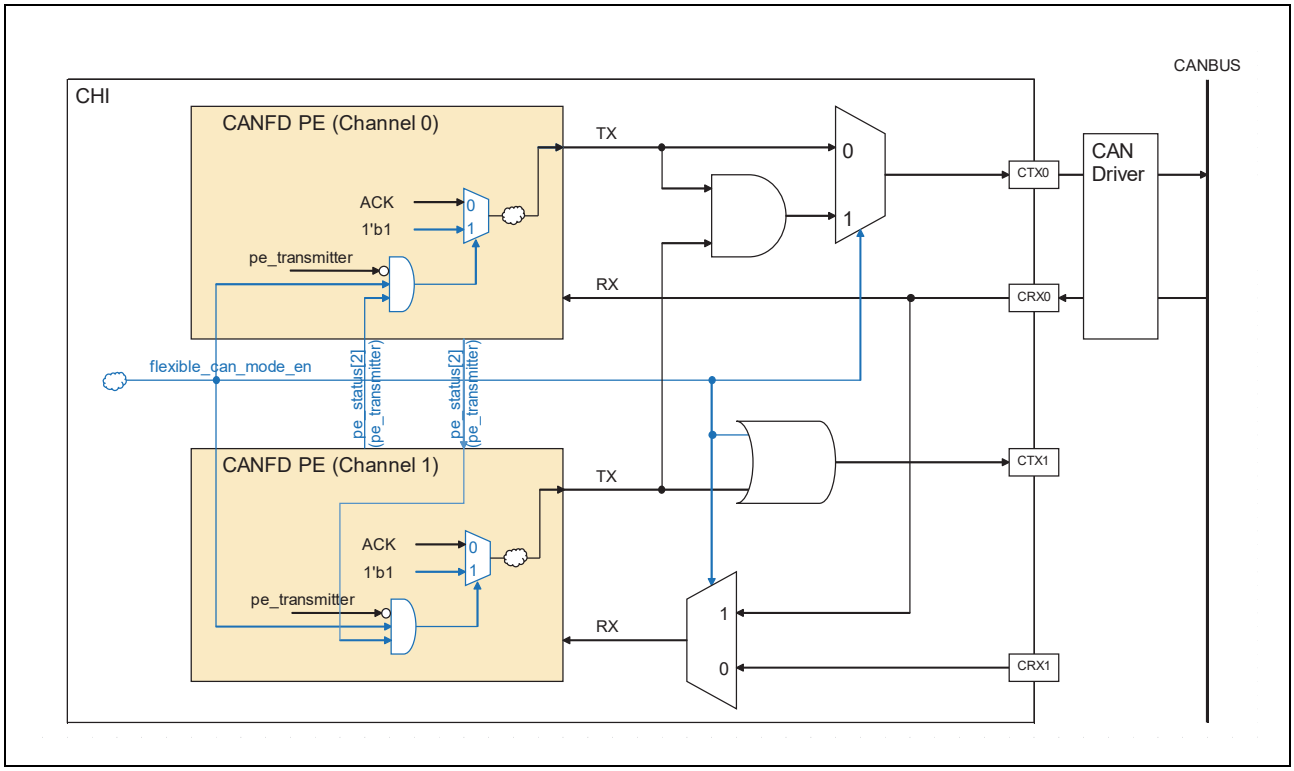

Figure 23.60 Diagram of the Flexible CAN

23.15 Flexible transmission buffer assignment

Each Channel has 64 [for U2A-EVA, U2A16, U2A8] and 32 [for U2A6] transmit buffers by exclusive use.

In order to correspond to an insufficient case by a TXMB, this Channel can rent a maximum of 32 [for U2A-EVA, U2A16, U2A8] and 16 [for U2A6] transmit buffers from the next Channel.

The buffer which can be rented becomes every four units by 4 to 32 [for U2A-EVA, U2A16, U2A8] and 16 [for U2A6] buffers.

The pair of Channel in flexible transmission buffer assignment is as follows.

When RSCFDnCFDGFTBAC.FLXMB0 bit is set, Flexible transmission buffer assignment between Channel 0 and Channel 1.

When RSCFDnCFDGFTBAC.FLXMB1 bit is set, Flexible transmission buffer assignment between Channel 2 and Channel 3.

When RSCFDnCFDGFTBAC.FLXMB2 bit is set, Flexible transmission buffer assignment between Channel 4 and Channel 5.

When RSCFDnCFDGFTBAC.FLXMB3 bit is set, Flexible transmission buffer assignment between Channel 6 and Channel 7.

Flexible transmission buffer assignment configured in RSCFDnCFDGFTBAC register and Flexible CAN mode configured in RSCFDnCFDGFCMC register should not be used simultaneously.

Interrupt of the rented buffer is outputted to interrupt of the renting channel.

When using TXQ by the rented buffer, TXQ should only set within the rented range.

The TXMB lent out operates in the mode of the channel to be used.

For example, when the channel 1 is a reset mode, using rented TXMB, transmission of the channel 0 is possible.

Moreover, rented TXMB is subject to the influence of the transmitting status, TX SCAN PROCESS, or transmitting abortion of the rented channel.

In the case of message buffer number priority mode, the priority of TXMB0 is high and the priority of TXMB95 (case which rented 32 buffers) becomes low. Priority of rented TXMB becomes low.

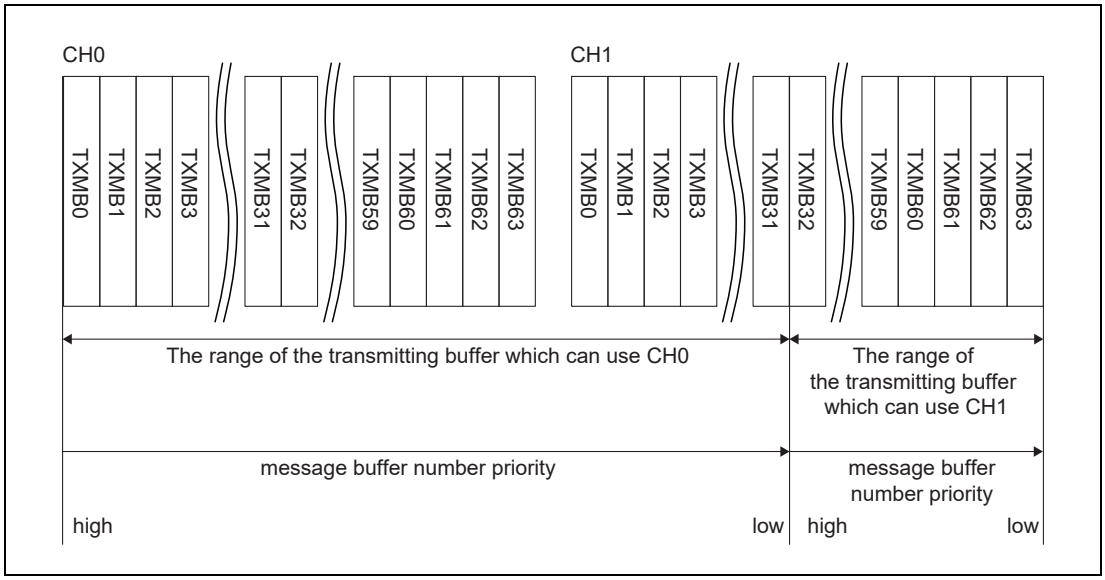

Figure 23.61 The priority of Message Buffer Number Priority Mode (Example of CH0:96 buf/CH1:32 buf)

The example of a rental channel 0 and channel 1 is shown below.

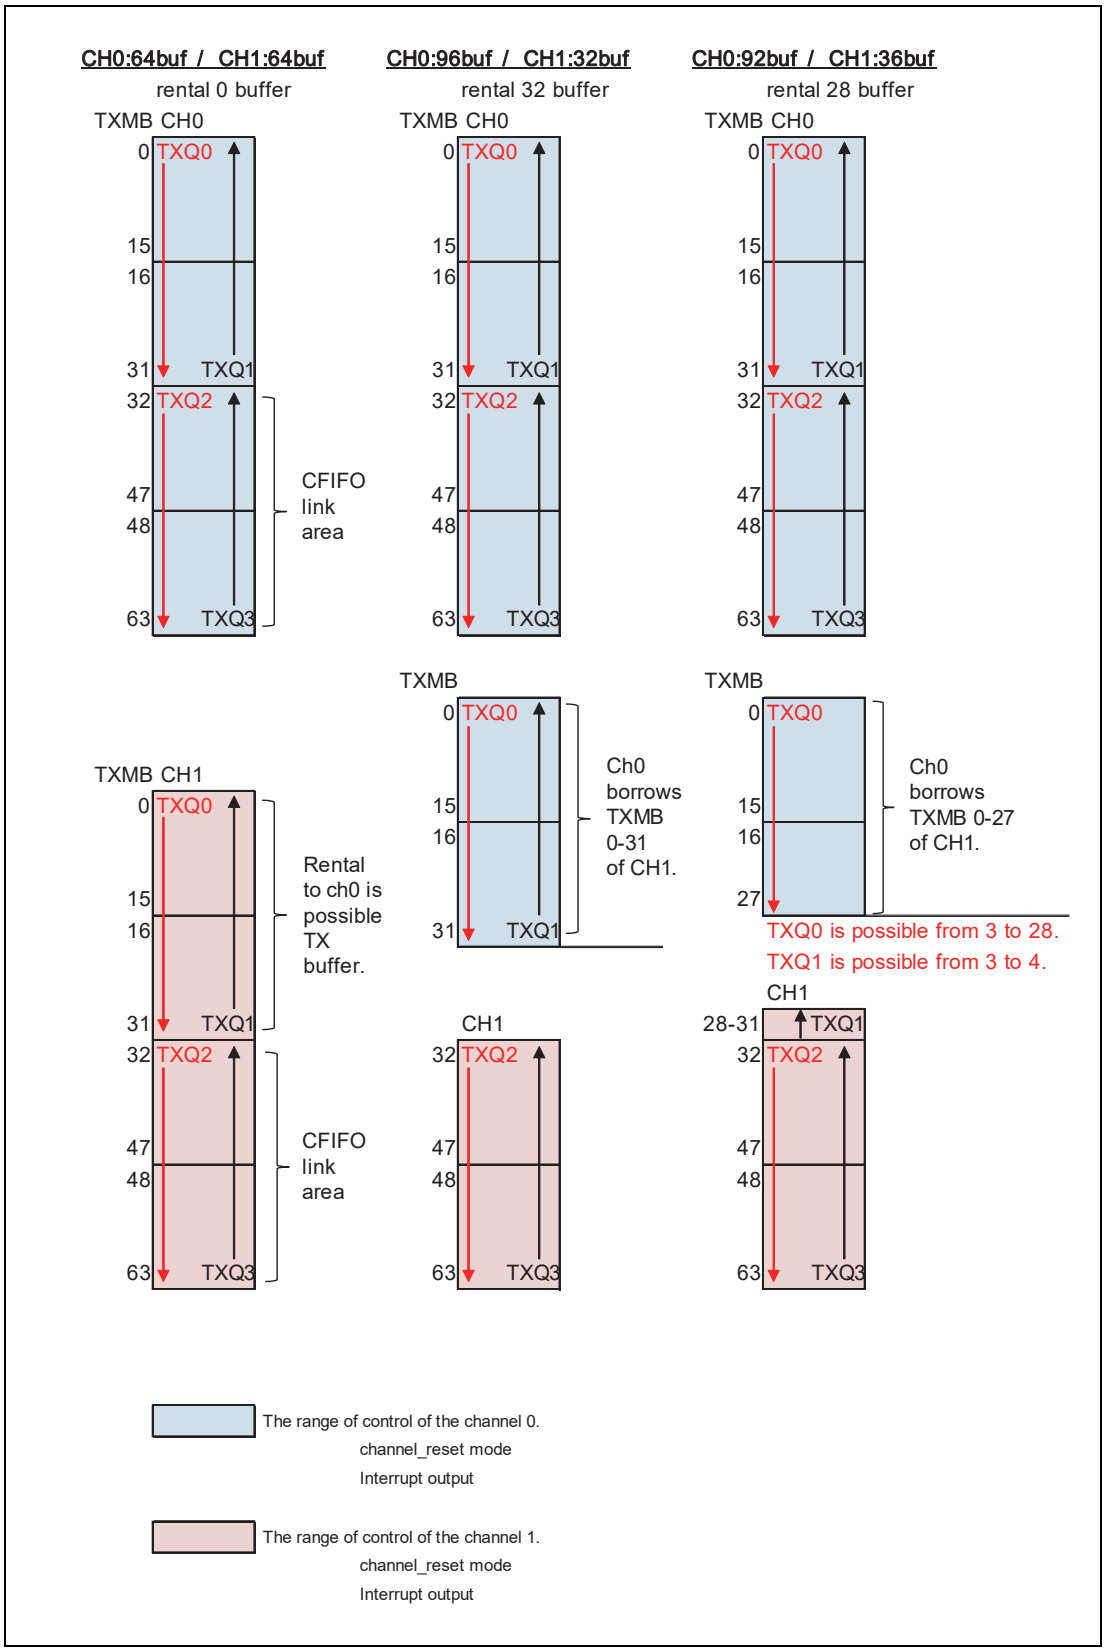

Figure 23.62 Flexible transmission buffer assignment (0, 32, 28 TXMB rental)

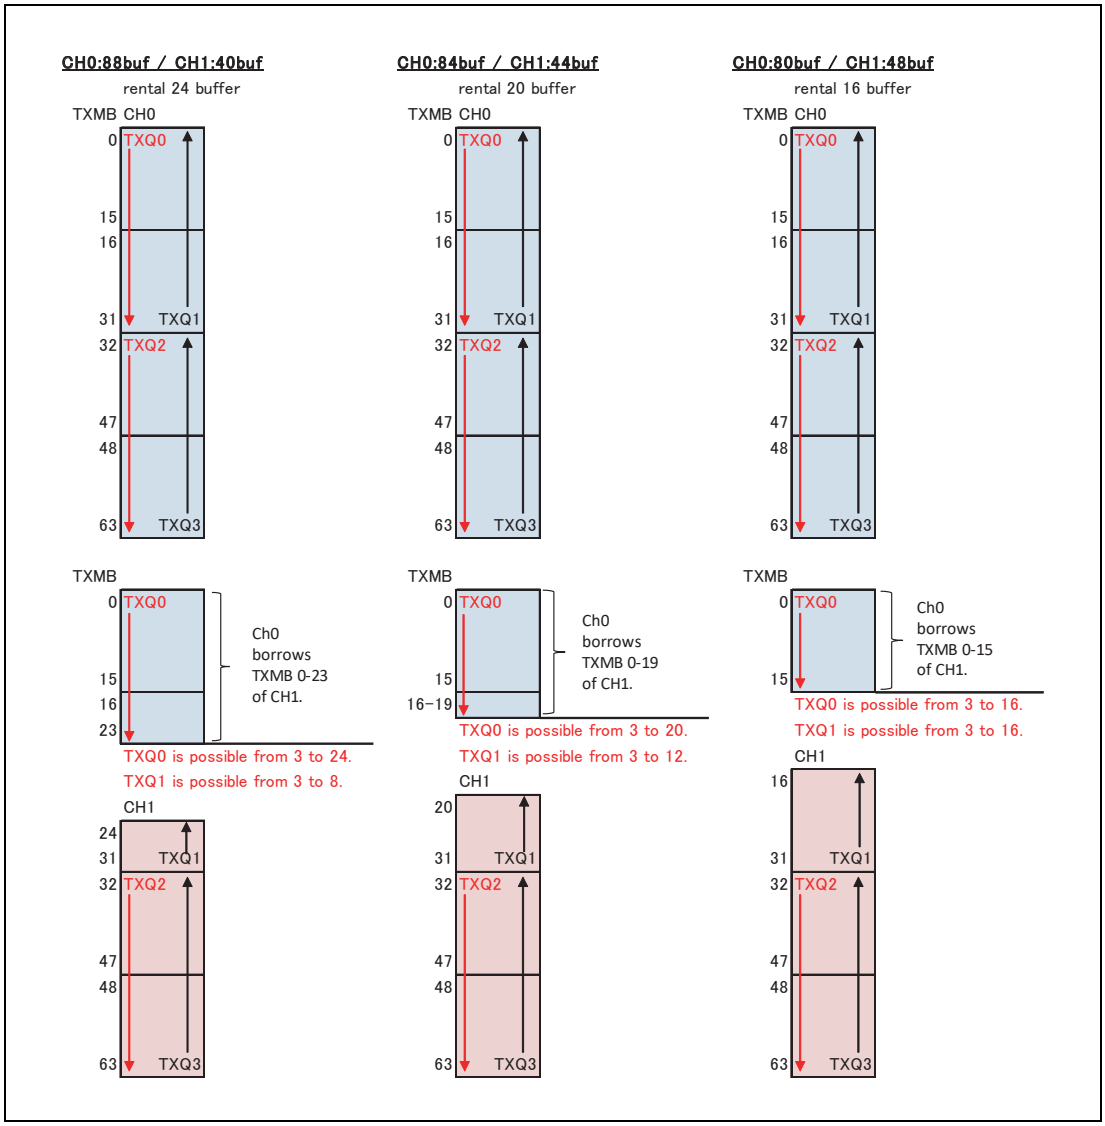

Figure 23.63 Flexible transmission buffer assignment (24, 20, 16 TXMB rental)

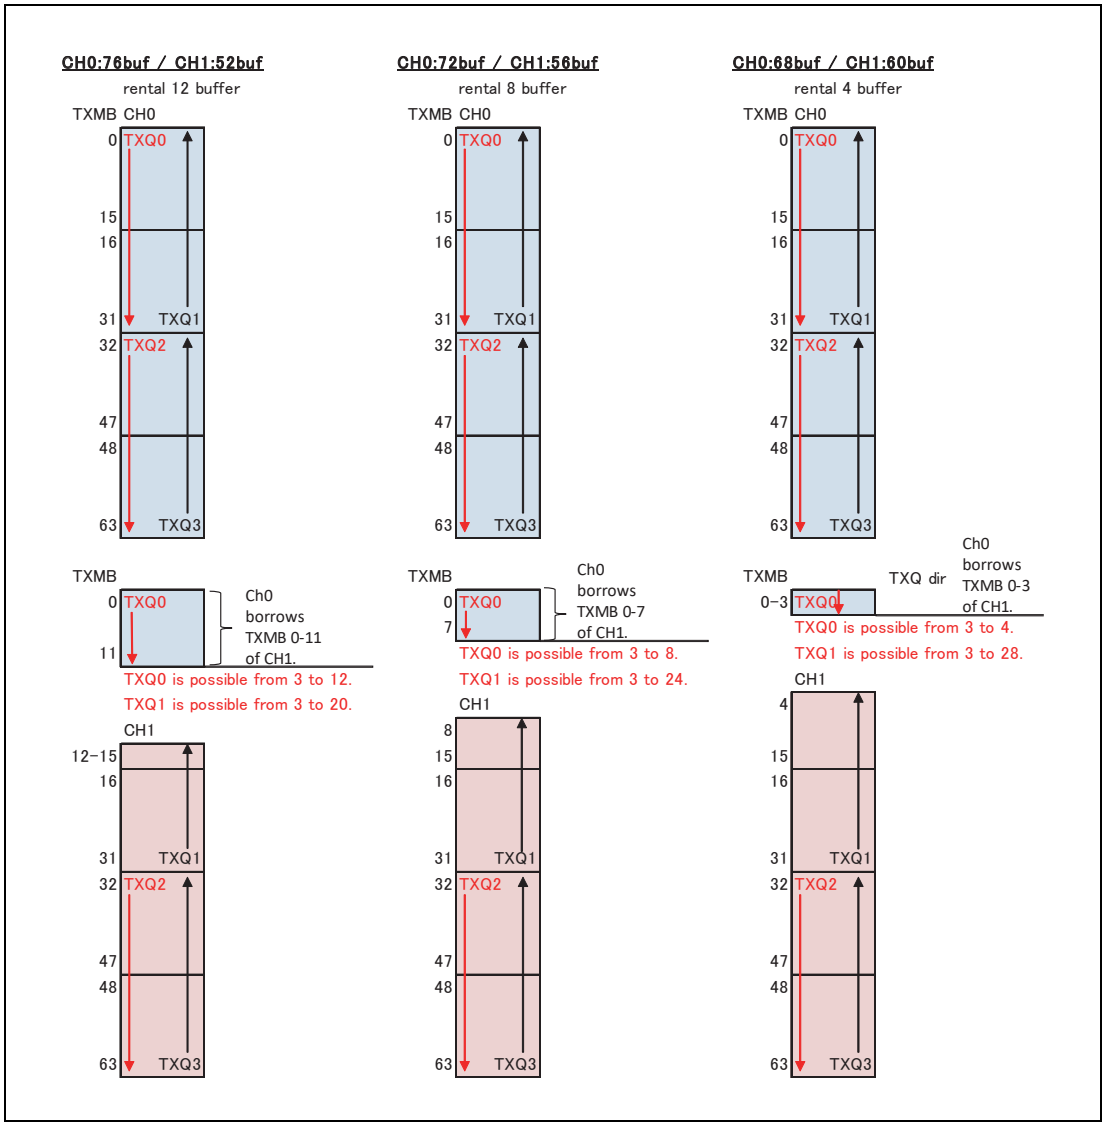

Figure 23.64 Flexible transmission buffer assignment (12, 8, 4 TXMB rental)

Section 24 FlexRay (FLXA)

The FlexRay IP-module performs communication according to the FlexRay protocol specification v2.1. With maximum specified sample clock the bitrate is 10 MBit/s. Additional bus driver (BD) hardware is required for connection to the physical layer.

24.1 Features FLXA for RH850/U2A-EVA

24.1.1 Number of Units

This microcontroller has the following number units of FlexRay.

Table 24.1 Number of Units

Product Name	RH850/ U2A-EVA (516 pins)	RH850/ U2A16 (516 pins)	RH850/ U2A16 (373pins)	RH850/ U2A16 (292 pins)	RH850/ U2A8 (373pins)	RH850/ U2A8 (292 pins)	RH850/ U2A6 (292 pins)	RH850/ U2A6 (176 pins)	RH850/ U2A6 (156 pins)	RH850/ U2A6 (144 pins)
Number of Units	2 (n = 0, 1)	2 (n = 0, 1)	2 (n = 0, 1)	2 (n = 0, 1)	2 (n = 0, 1)	2 (n = 0, 1)	1 (n = 0)	1 (n = 0)	1 (n = 0)	1 (n = 0)
Name	FLXAn									

Table 24.2 Index

Index	Description
n	The number of the FlexRay indicated by the letter “n” (n = 0,1).
m	The register number is identified by the index “m”, for example, FLXAnFRESIDm for the even Sync ID register.
p	The flag number is indicated by the letter “p” (p = (m – 1) × 32 to (m × 32 – 1)).

24.1.2 Register Base Addresses

All FlexRay register addresses are given as address offsets to the individual base address <FLXAn_base>.

The base address <FLXAn_base> of each FlexRay is listed in the following table:

Table 24.3 Register Base Addresses

Base Address Name	Base Addresses	Bus Group
<FLXA0_base>	$1002\ 0000_H$	H-Bus Group1
<FLXA1_base>	$1002\ 1000_H$	H-Bus Group2

24.1.3 Clock Supply

FlexRay provide one clock input.

Table 24.4 Clock Supply

Unit Name	Clock for the Unit	Supply Clock Name	Clock for Unit
FLXAn	Bus clock	CLK_HBUS	For H-Bus
	FlexRay sample clock	CLK_HSB	For FlexRay com

24.1.4 Interrupt Requests and Error Notifications

FlexRay can generate the following interrupt requests:

Table 24.5 Interrupt Requests

Interrupt Symbol Name	Unit Interrupt Signal	Description	Interrupt Number	sDMA Trigger Number	DTS Trigger Number
FLXA0					
INTFLXA0LINE0	INTFLXAnLINE0 (n = 0)	Line 0 interrupt for FLXA0	623	—	—
INTFLXA0LINE1	INTFLXAnLINE1 (n = 0)	Line 1 interrupt for FLXA0	624	—	—
INTFLXA0TIM0	INTFLXAnTIM0 (n = 0)	Timer 0 interrupt for FLXA0	625	—	—
INTFLXA0TIM1	INTFLXAnTIM1 (n = 0)	Timer 1 interrupt for FLXA0	626	—	—
INTFLXA0TIM2	INTFLXAnTIM2 (n = 0)	Timer 2 interrupt for FLXA0	627	—	—
INTFLXA0FDA	INTFLXAnFDA (n = 0)	FIFO data available interrupt for FLXA0	628	—	—
INTFLXA0FW	INTFLXAnFW (n = 0)	FIFO transfer warning interrupt for FLXA0	629	—	—
INTFLXA0OW	INTFLXAnOW (n = 0)	Output transfer warning interrupt for FLXA0	630	—	—
INTFLXA0OT	INTFLXAnOT (n = 0)	Output transfer done interrupt for FLXA0	631	—	—
INTFLXA0IQF	INTFLXAnIQF (n = 0)	Input queue full interrupt for FLXA0	632	—	—
INTFLXA0IQE	INTFLXAnIQE (n = 0)	Input queue empty interrupt for FLXA0	633	—	—
FLXA1					
INTFLXA1LINE0	INTFLXAnLINE0 (n = 1)	Line 0 interrupt for FLXA1	634	—	—
INTFLXA1LINE1	INTFLXAnLINE1 (n = 1)	Line 1 interrupt for FLXA1	635	—	—
INTFLXA1TIM0	INTFLXAnTIM0 (n = 1)	Timer 0 interrupt for FLXA1	636	—	—
INTFLXA1TIM1	INTFLXAnTIM1 (n = 1)	Timer 1 interrupt for FLXA1	637	—	—
INTFLXA1TIM2	INTFLXAnTIM2 (n = 1)	Timer 2 interrupt for FLXA1	638	—	—
INTFLXA1FDA	INTFLXAnFDA (n = 1)	FIFO data available interrupt for FLXA1	639	—	—
INTFLXA1FW	INTFLXAnFW (n = 1)	FIFO transfer warning interrupt for FLXA1	640	—	—
INTFLXA1OW	INTFLXAnOW (n = 1)	Output transfer warning interrupt for FLXA1	641	—	—
INTFLXA1OT	INTFLXAnOT (n = 1)	Output transfer done interrupt for FLXA1	642	—	—
INTFLXA1IQF	INTFLXAnIQF (n = 1)	Input queue full interrupt for FLXA1	643	—	—
INTFLXA1IQE	INTFLXAnIQE (n = 1)	Input queue empty interrupt for FLXA1	644	—	—

This module has no error notifications.

24.1.5 Reset Sources

FLXAn reset sources are listed in the following table. FLXAn is initialized by these reset sources.

Table 24.6 Reset Sources

Unit Name	Register Name	Reset Condition						
		Power On Reset	System Reset 1	System Reset 2	Application Reset	DeepSTOP Reset	Module Reset	JTAG Reset
FLXAn	All registers	√	√	√	√	√	√	—

24.1.6 External Input/Output Signals

Table 24.7 shows the pin information.

Table 24.7 External Input/Output Signals

Unit Signal Name	Outline	Alternative Port Pin Signals
FLXA0		
flx0_rxda_extfxr	Channel A receive data input	FLXA0RXDA
flx0_rxdb_extfxr	Channel B receive data input	FLXA0RXDB
flx0_fxr_txda	Channel A transmit data output	FLXA0TXDA
flx0_fxr_txdb	Channel B transmit data output	FLXA0TXDB
flx0_fxr_txena_n	Channel A transmit enable	FLXA0TXENA
flx0_fxr_txenb_n	Channel B transmit enable	FLXA0TXENB
flx0_stpwt_extfxr	Stop watch trigger input	FLXA0STPWT
FLXA1		
flx1_rxda_extfxr	Channel A receive data input	FLXA1RXDA
flx1_rxdb_extfxr	Channel B receive data input	FLXA1RXDB
flx1_fxr_txda	Channel A transmit data output	FLXA1TXDA
flx1_fxr_txdb	Channel B transmit data output	FLXA1TXDB
flx1_fxr_txena_n	Channel A transmit enable	FLXA1TXENA
flx1_fxr_txenb_n	Channel B transmit enable	FLXA1TXENB
flx1_stpwt_extfxr	Stop watch trigger input	FLXA1STPWT

24.1.7 Combinations of Pins and Ports

Combinations of FlexRay pins and ports are listed in the following table.

Table 24.8 Combinations of Pins and Ports

Function	Pin Name	Port Name	
		Group 1	Group 2
FLXA0	FLXA0RXDA	P20_14	P20_2
	FLXA0RXDB	P10_0	P20_3
	FLXA0TXDA	P10_4	P20_7
	FLXA0TXDB	P10_3	P20_6

24.2 Overview

24.2.1 Functional Overview

For communication on a FlexRay network, individual message buffers with up to 254 data bytes are configurable. The message buffer is a Message RAM that is configurable up to 128 message buffers. All functions concerning the handling of messages are implemented in the Message Handler. Those functions are the acceptance filtering, the transfer of messages between the two FlexRay Channel Protocol Controllers and the Message RAM, maintaining the transmission schedule as well as providing message status information.

The register set of the FlexRay IP-module can be accessed directly by an external Host via the module's Host interface. These registers are used to control/configure/monitor the FlexRay Channel Protocol Controllers, Message Handler, Global Time Unit, System Universal Control, Frame and Symbol Processing, Network Management, Interrupt Control, to access the Message RAM via Input / Output Buffer; and to control the data transfer between the Message RAM and the Local RAM/Cluster RAM.

The FlexRay IP-module supports the following features:

Item	Specification
Communication	Conformance with FlexRay protocol specification v2.1
Data transfer rate	Up to 10 M bit/s on each channel
FlexRay channels	2 (channels A and B)
Message buffer	Up to 128 message buffers are configurable. Message buffers are configurable with different payload length Each message buffer can be configured as a part of receive buffer, transfer buffer or receive FIFO. Filtering for slot counter, cycle counter or channel.
Message RAM	8-Kbyte message RAM can be configured as below. • 128 message buffers with up to 48-byte data section • 30 message buffers with 254-byte data section
FIFO	One configurable receive FIFO
Message Buffer Access	Access by the host CPU through input/output buffer Input buffer: a message transferred to the message RAM is retained. Output buffer: a message read from the message RAM is retained.
	Access by data transfer function Input transfer: the contents of the message buffer is transferred from the Local RAM/Cluster RAM to the message RAM by a request of the CPU Output transfer: the contents of the message buffer is transferred automatically to the Local RAM/Cluster RAM from the message RAM
Network management	Supported
Interrupts	Maskable module interrupts
Timer	Two absolute timers One relative timer One stop watch timer

24.2.2 Block Diagram

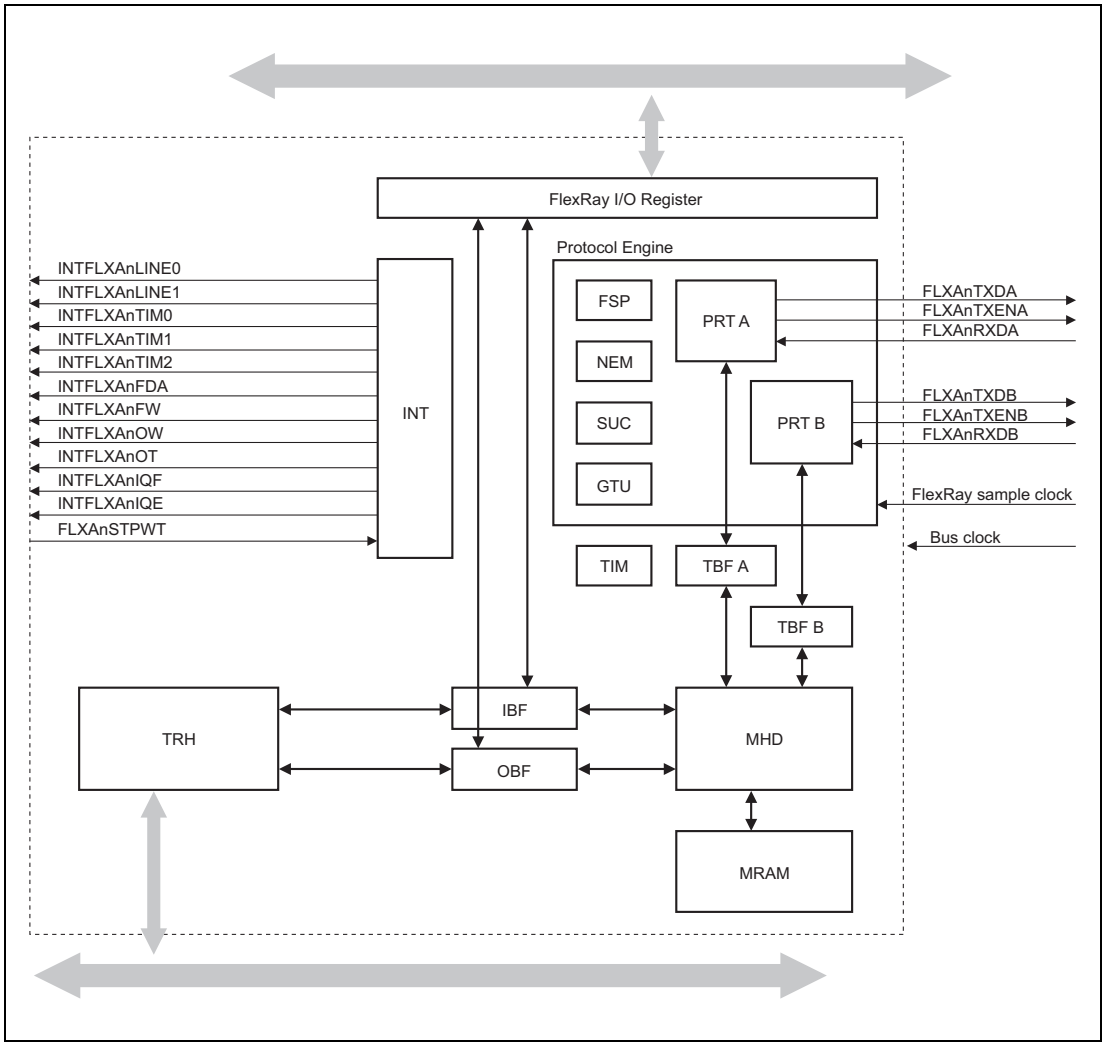

Figure 24.1 FlexRay IP Block Diagram

Input Buffer (IBF)

For write access to the message buffers configured in the Message RAM, the Host can write the header and data section for a specific message buffer to the Input Buffer. The Message Handler then transfers the data from the Input Buffer to the selected message buffer in the Message RAM.

Output Buffer (OBF)

For read access to a message buffer configured in the Message RAM the Message Handler transfers the selected message buffer to the Output Buffer. After the transfer has completed, the Host can read the header and data section of the transferred message buffer from the Output Buffer.

Message Handler (MHD)

The FlexRay Message Handler controls data transfers between the following components:

- Input / Output Buffer and Message RAM
- TBFRAMs of the two FlexRay Protocol Controllers and Message RAM

Message RAM (MRAM)

The Message RAM consists of a single-ported RAM that stores up to 128 FlexRay message buffers together with the related configuration data (header and data partition).

TBFRAM (TBF A/B)

Stores the data section of two complete messages.

FlexRay Channel Protocol Controller (PRT A/B)

The FlexRay Channel Protocol Controllers consist of shift register and FlexRay protocol FSM. They are connected to the TBFRAMs for intermediate message storage and to the physical layer via bus driver (BD).

They perform the following functionality:

- Control and check of bit timing
- Reception / transmission of FlexRay frames and symbols
- Check of header CRC
- Generation / check of frame CRC
- Interfacing to bus driver

Global Time Unit (GTU)

The Global Time Unit performs the following functions:

- Generation of microtick (µT)
- Generation of macrotick (MT)
- Fault tolerant clock synchronization by FTM algorithm
  - rate correction
  - offset correction
- Cycle counter
- Timing control of static segment
- Timing control of dynamic segment (minislotting)
- Support of external clock correction

System Universal Control (SUC)

The System Universal Control controls the following functions:

- Configuration
- Wakeup
- Startup
- Normal Operation
- Passive Operation

Frame and Symbol Processing (FSP)

The Frame and Symbol Processing controls the following functions:

- Checks the correct timing of frames and symbols
- Tests the syntactical and semantical correctness of received frames
- Sets the slot status flags

Network Management (NEM)

Handles the network management vector.

Interrupt Control (INT)

The Interrupt Controller performs the following functions:

- Provides error and status interrupt flags
- Enable / disable interrupt sources
- Assignment of interrupt sources to one of the two general module interrupt lines
- Enable / disable module interrupt lines

Timer (TIM)

The Timer module includes the following macrotick timer:

- two absolute timers
- one relative timer
- one stop watch timer

Transfer Handler (TRH)

Handles the data transfer between Local RAM/Cluster RAM and FlexRay module.

The Transfer Handler supports the following transfer types:

- Transfer of buffer configuration data from the Local RAM/Cluster RAM to the Message RAM
- Transfer of payload data for transmission buffers from the Local RAM/Cluster RAM to the Message RAM
- Transfer of buffer configuration data and payload data for transmission buffer from the Local RAM/Cluster RAM to the Message RAM
- Automatic transfer of payload data from receive buffer to the Local RAM/Cluster RAM upon frame reception
- Automatic transfer of payload data, buffer configuration data and message buffer status data from receive buffer to the Local RAM/Cluster RAM upon frame reception
- Automatic transfer of buffer configuration data and message buffer status data from the dedicated transmit/receive buffer to the Local RAM/Cluster RAM in response to slot status update
- Manual transfer of payload data, buffer configuration data and message buffer status data from the dedicated transmit/receive buffer to the Local RAM/Cluster RAM.

24.3 Registers

24.3.1 List of Registers

The FlexRay module allocates an address space as shown in **Table 24.9**.

Within this specification the “Values after reset” refers to the reset of the microcontroller. For registers in the address range <FLXAn_base> + 0010_H to <FLXAn_base> + $0FFF_H$ the “Value after reset” are also applicable when the software reset of the FlexRay module (using bit FLXAnFROC.OE) is applied.

The addresses in this specification are listed as offsets from a base address. The base address <FLXAn_base> must thus be added to the addresses.

For <FLXAn_base>, refer to **Section 24.1.2, Register Base Addresses**.

Table 24.9 List of Registers (1/4)

Register Name	Symbol	Value after Reset	Address	Access Size	Access Protection	
					HBG	Other

n = 1: HBG93

24.3.2 FlexRay Operation register

24.3.2.1 FLXAnFROC — FlexRay Operation Control Register

Access: This register can be read or written in 8-, 16-, or 32-bit units.

Address: <FLXAn_base> + 0004_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	T2IE	T1IE	T0IE
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	OEP	—	—	—	—	—	BEC	OE
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R/W	R	R	R	R	R	R/W	R/W

Table 24.10 FLXAnFROC Register Contents

Bit Position	Bit Name	Function
31 to 19	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
18	T2IE	Timer 2 interrupt enable Bit 0: Disabled 1: Enabled
17	T1IE	Timer 1 interrupt enable Bit 0: Disabled 1: Enabled
16	T0IE	Timer 0 interrupt enable Bit 0: Disabled 1: Enabled
15 to 8	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
7	OEP	Operation Enable bit Protection Bit 0: OE is unprotected 1: OE is protected
6 to 2	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
1	BEC	Byte Endian Control Bit 0: Little endian 1: Big endian
0	OE	Operation Enable Bit 0: Operation disabled, software reset of the FlexRay module 1: Operation enabled

(1) FLXAnFROC.T2IE

Timer 2 interrupt enable bit

This bit controls the timer 2 interrupt.

0: Disabled

No interrupt will be requested and the timer 2 interrupt line will be released if pending.

1: Enabled

Timer 2 interrupt will be asserted when FLXAnFROS.T2IS is 1.

(2) FLXAnFROC.T1IE

Timer 1 interrupt enable bit

The user should only set this bit to 1 when timer 1 interrupt is not enabled in the FlexRay Status interrupt enable register (bit FLXAnFRSIES.TI1E should be 0).

This bit controls the timer 1 interrupt.

0: Disabled

No interrupt will be requested and the timer 1 interrupt line will be released if pending.

1: Enabled

Timer 1 interrupt will be asserted when bit FLXAnFROS.T1IS is 1.

(3) FLXAnFROC.T0IE

Timer 0 interrupt enable bit

The user should only set this bit to 1 when timer 0 interrupt is not enabled in the FlexRay Status interrupt enable register (bit FLXAnFRSIES.TI0E should be 0).

This bit controls the timer 0 interrupt.

0: Disabled

No interrupt will be requested and the timer 0 interrupt line will be released if pending.

1: Enabled

Timer 0 interrupt will be asserted when bit FLXAnFROS.T0IS is 1.

(4) FLXAnFROC.OEP

Operation enable bit protection bit

This bit protects against unintended write access to the OE bit.

0: OE bit is unprotected

Write access to the OE bit is enabled

1: OE bit is protected

Write access to the OE bit is disabled

(5) FLXAnFROC.BEC

Byte endian control bit

The user should only change this bit when FLXAnFROS.OS is '1'.

This bit controls the byte order on reading and writing the FlexRay network management vector register (FLXAnFRNMVx), FlexRay write data section (FLXAnFRWRDSx) and FlexRay read data section (FLXAnFRRDDSx). This bit also controls the byte order when reading or writing FlexRay payload data using the data transfer function.

For details about the byte alignment, refer to **Section 24.4.17, Byte Alignment**.

0: Little endian

Byte alignment in FLXAnFRNMVx, FLXAnFRWRDSx and FLXAnFRRDDSx is in little endian style.

1: Big endian

Byte alignment in FLXAnFRNMVx, FLXAnFRWRDSx and FLXAnFRRDDSx is in big endian style.

(6) FLXAnFROC.OE

Operation enable bit

The user can only write to this bit when bit FLXAnFROC.OEP is 0.

The user should only write this bit with 0 when bit FLXAnFROS.OS is 1.

The user should only write this bit with 1 when bit FLXAnFROS.OS is 0 and the FlexRay sample clock is enabled.

This bit controls the operation state and serves the software reset of the FlexRay module. The operation status bit (FLXAnFROS.OS) indicates whether the FlexRay module is in reset state or not.

0: Operation disabled, software reset of the FlexRay module

Forcibly moves the FlexRay module to its reset state, whatever the state of the FlexRay module is.

1: Operation enabled

Reset state of the FlexRay module is released.

24.3.2.2 FLXAnFROS — FlexRay Operation Status Register

Do not rewrite this register using bit manipulation instructions.

Access: This register can be read or written in 8-, 16-, or 32-bit units.

Address: <FLXAn_base> + $000C_H$

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	T2IS	T1IS	T0IS
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	OS
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 24.11 FLXAnFROS Register Contents

Bit Position	Bit Name	Function
31 to 19	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
18	T2IS	Timer 2 Interrupt Status Bit 0: Timer 2 has not matched the conditions configured in the FLXAnFRT2C register 1: Timer 2 matched the conditions configured in the FLXAnFRT2C register
17	T1IS	Timer 1 Interrupt Status Bit 0: Timer 1 has not matched the conditions configured in the FLXAnFRT1C register 1: Timer 1 matched the conditions configured in the FLXAnFRT1C register
16	T0IS	Timer 0 Interrupt Status Bit 0: Timer 0 has not matched the conditions configured in the FLXAnFRT0C register 1: Timer 0 matched the conditions configured in the FLXAnFRT0C register
15 to 1	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
0	OS	Operation Status Bit 0: Operation disabled, reset state 1: Operation enabled

(1) FLXAnFROS.T2IS

Timer 2 Interrupt Status Bit

Writing 0 has no effect on the bit value.

This bit indicates that the timer 2 has matched the state configured in the FLXAnFRT2C register.

When the FLXAnFROC.T2IE bit is enabled and the FLXAnFROS.T2IS bit is set to 1, the timer 2 interrupt is generated.

[Clearing condition]

- This bit is cleared by writing 1 to the FLXAnFROS.T2IS bit.
- This bit is cleared when the FLXAnFROS.OS bit changes from 1 to 0.

[Setting condition]

- This bit is set when the state matches the state configured in the FLXAnFRT2C register.

(2) FLXAnFROS.T1IS

Timer 1 Interrupt Status Bit

Writing 0 has no effect on the bit value.

This bit indicates that the timer 1 has matched the state configured in the FLXAnFRT1C register.

When the FLXAnFROC.T1IE bit is enabled and the FLXAnFROS.T1IS bit is set to 1, the timer 1 interrupt is generated.

[Clearing condition]

- This bit is cleared by writing 1 to the FLXAnFROS.T1IS bit.
  This bit is cleared when the FLXAnFROS.OS bit changes from 1 to 0.

[Setting condition]

- This bit is set when the state becomes the state configured in the FLXAnFRT1C register.

(3) FLXAnFROS.T0IS

Timer 0 Interrupt Status Bit

Writing 0 has no effect on the bit value.

This bit indicates that the timer 0 has matched the state configured in the FLXAnFRT0C register.

When the FLXAnFROC.T0IE bit is enabled and the FLXAnFROS.T0IS bit is set to 1, the timer 0 interrupt is generated.

[Clearing condition]

- This bit is cleared by writing 1 to the FLXAnFROS.T0IS bit.
- This bit is cleared when the FLXAnFROS.OS bit changes from 1 to 0.

[Setting condition]

- This bit is set when the state becomes the state configured in the FLXAnFRT0C register.

(4) FLXAnFROS.OS

Operation Status Bit

This bit represents if the FlexRay module is in the reset or the operation state.

When bit FLXAnFROS.OS is 0 the FlexRay module gets initialized and registers mapped to the address area <FLXAn_base>+ 0010_H to <FLXAn_base> + $0FFF_H$ cannot be accessed; read access from these registers will return undefined data.

When bit FLXAnFROS.OS is 1 it is possible to access to the address area <FLXAn_base> + 0010_H to <FLXAn_base> + $0FFF_H$ and to perform FlexRay communication.

When bit FLXAnFROS.OS changes from 0 to 1 all registers in the address range <FLXAn_base> + 0010_H to <FLXAn_base> + $0FFF_H$ are set to the “Values after reset”.

[Clearing condition]

- When bit FLXAnFROC.OE is set to 0. It takes up to two peripheral bus clock cycles until bit FLXAnFROS.OS is set to 0.

[Setting condition]

- When bit FLXAnFROC.OE is set to 1 it takes up to four peripheral clock cycles of the clock with the lower frequency out of the FlexRay sample clock and peripheral bus clock until bit FLXAnFROS.OS is set to 1.

24.3.3 Special Registers

24.3.3.1 FLXAnFRLCK — FlexRay Lock Register

Access: This register can be read or written in 8-, 16-, or 32-bit units.

Address: <FLXAn_base> + $001C_H$

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	CLK[7:0]							
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 24.12 FLXAnFRLCK Register Contents

Bit Position	Bit Name	Function
31 to 8	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
7 to 0	CLK[7:0]	Configuration Lock Key Bit

(1) FLXAnFRLCK.CLK

Configuration Lock Key Bit

The Lock Register is write-only. Reading the register will return $0000\ 0000_H$.

To leave CONFIG state by writing bits FLXAnFRSUCC1.CMD[3:0] (command READY), the write operation has to be directly preceded by two write accesses to the Configuration Lock Key (unlock sequence). If the write sequence below is interrupted by other write accesses between the second write to the Configuration Lock Key and the write access to the FLXAnFRSUCC1 register, the CC remains in CONFIG state and the sequence has to be repeated.

First write: Bits FLXAnFRLCK.CLK[7:0] = "$1100\ 1110_B$" (CE_H)

Second write: Bits FLXAnFRLCK.CLK[7:0] = "$0011\ 0001_B$" (31_H)

Third write: Bits FLXAnFRSUCC1.CMD[3:0]

CAUTION

In case that the Host uses 8/16-bit accesses to write the listed bit fields, the user has to ensure that no "dummy accesses" e.g. to the remaining register bytes / words are inserted by the compiler.

24.3.4 Interrupt Registers

24.3.4.1 FLXAnFREIR — FlexRay Error Interrupt Register

Do not rewrite this register using bit manipulation instructions.

The flags are set when the CC detects one of the listed error conditions. The flags remain set until the Host clears them.

Access: This register can be read or written in 8-, 16-, or 32-bit units.

Address: <FLXAn_base> + 0020_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	TABB	LTVB	EDB	—	—	—	—	—	TABA	LTVA	EDA

Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 24.13 FLXAnFREIR Register Contents (1/2)

Bit Position	Bit Name	Function
31 to 27	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
26	TABB	Transmission Across Boundary Channel B Flag 0: No transmission across slot boundary detected on channel B 1: Transmission across slot boundary detected on channel B
25	LTVB	Latest Transmit Violation Channel B Flag 0: No latest transmit violation detected on channel B 1: Latest transmit violation detected on channel B
24	EDB	Error Detected on Channel B Flag 0: No error detected on channel B 1: Error detected on channel B
23 to 19	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
18	TABA	Transmission Across Boundary Channel A Flag 0: No transmission across slot boundary detected on channel A 1: Transmission across slot boundary detected on channel A
17	LTVA	Latest Transmit Violation Channel A Flag 0: No latest transmit violation detected on channel A 1: Latest transmit violation detected on channel A
16	EDA	Error Detected on Channel A Flag 0: No error detected on channel A 1: Error detected on channel A
15 to 12	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
11	MHF	Message Handler Constraints Flag 0: No Message Handler failure detected 1: Message Handler failure detected

Table 24.13 FLXAnFREIR Register Contents (2/2)

Bit Position	Bit Name	Function
10	IOBA	Illegal Output buffer Access Flag 0: No illegal Host access to Output Buffer occurred 1: Illegal Host access to Output Buffer occurred
9	IIBA	Illegal Input Buffer Access Flag 0: No illegal Host access to Input Buffer occurred 1: Illegal Host access to Input Buffer occurred
8	EFA	Empty FIFO Access Flag 0: No Host access to empty FIFO occurred 1: Host access to empty FIFO occurred
7	RFO	Receive FIFO Overrun Flag 0: No receive FIFO overrun detected 1: A receive FIFO overrun has occurred
6	AERR	Access error flag Flag 0: Access error is not detected. 1: Access error is detected.
5	CCL	CHI Command Locked Flag 0: CHI command accepted 1: CHI command not accepted
4	CCF	Clock Correction Failure Flag 0: No clock correction error 1: Clock correction failed
3	SFO	Sync Frame Overflow Flag 0: Number of received sync frames ≤ the FLXAnFRGTUC2.SNM bit 1: More sync frames received than configured by the FLXAnFRGTUC2.SNM bit
2	SFBM	Sync Frames Below Minimum Flag 0: Sync node: 1 or more sync frames received Non-sync node: 2 or more sync frames received 1: Less than the required minimum of sync frames received
1	CNA	Command Not Accepted Flag 0: CHI command accepted 1: CHI command not accepted
0	PEMC	POC Error Mode Changed Flag 0: Error mode has not changed 1: Error mode has changed

(1) FLXAnFREIR.TABB

Transmission Across Boundary Channel B Flag

Writing 0 has no effect on the bit value.

This bit is cleared when 1 is written.

The flag signals to the Host that a transmission across a slot boundary occurred for channel B.

(2) FLXAnFREIR.LTVB

Latest Transmit Violation Channel B Flag

Writing 0 has no effect on the bit value.

This bit is cleared when writing a 1 to it.

The flag signals a latest transmit violation on channel B to the Host.

(3) FLXAnFREIR.EDB

Error Detected on Channel B Flag

Writing 0 has no effect on the bit value.

This bit is cleared when writing a 1 to it.

This bit is set whenever one of bits FLXAnFRACS.SEDB, FLXAnFRACS.CEDB, FLXAnFRACS.CIB, and FLXAnFRACS.SBVB changes from 0 to 1.

(4) FLXAnFREIR.TABA

Transmission Across Boundary Channel A Flag

Writing 0 has no effect on the bit value.

This bit is cleared when writing a 1 to it.

The flag signals to the Host that a transmission across a slot boundary occurred for channel A.

(5) FLXAnFREIR.LTVA

Latest Transmit Violation Channel A Flag

Writing 0 has no effect on the bit value.

This bit is cleared when writing a 1 to it.

The flag signals a latest transmit violation on channel A to the Host.

(6) FLXAnFREIR.EDA

Error Detected on Channel A Flag

Writing 0 has no effect on the bit value.

This bit is cleared when writing a 1 to it.

This bit is set whenever one of bits FLXAnFRACS.SEDA, FLXAnFRACS.CEDA, FLXAnFRACS.CIA, and FLXAnFRACS.SBVA changes from 0 to 1.

(7) FLXAnFREIR.MHF

Message Handler Constraints Flag

Writing 0 has no effect on the bit value.

This bit is cleared when writing a 1 to it.

The flag signals a Message Handler constraints violation condition. It is set whenever one of the bits FLXAnFRMHDF.SNUA, FLXAnFRMHDF.SNUB, FLXAnFRMHDF.FNFA, FLXAnFRMHDF.FNFB, FLXAnFRMHDF.TBFA, FLXAnFRMHDF.TBFB, and FLXAnFRMHDF.WAHP changes from 0 to 1.

(8) FLXAnFREIR.IOBA

Illegal Output buffer Access Flag

Writing 0 has no effect on the bit value.

This bit is cleared when writing a 1 to it.

This flag is set by the CC when the Host requests the transfer of a message buffer from the Message RAM to the Output Buffer while bit FLXAnFROBCR.OBSYS is set to 1.

(9) FLXAnFREIR.IIBA

Illegal Input Buffer Access Flag

Writing 0 has no effect on the bit value.

This bit is cleared when writing a 1 to it.

This flag is set by the CC when the Host wants to modify a message buffer via Input Buffer and one of the following conditions applies:

1. The CC is not in CONFIG or DEFAULT_CONFIG state and the Host writes to the Input Buffer Command Request register to modify the
   - Header section of message buffer 0, 1 if configured for transmission in key slot
   - Header section of static message buffers with buffer number < FLXAnFRMRC.FDB[7:0] while bits FLXAnFRMRC.SEC[1:0] = “01”
   - Header section of any static or dynamic message buffer while bits FLXAnFRMRC.SEC[1:0] = “1x”
   - Header and / or data section of any message buffer belonging to the receive FIFO
2. The Host writes to any register of the Input Buffer while bit FLXAnFRIBCR.IBSYH is set to 1.

(10) FLXAnFREIR.EFA

Empty FIFO Access Flag

Writing 0 has no effect on the bit value.

This bit is cleared when writing a 1 to it.

This flag is set by the CC when the Host requests the transfer of a message from the receive FIFO via Output Buffer while the receive FIFO is empty.

(11) FLXAnFREIR.RFO

Receive FIFO Overrun Flag

Writing 0 has no effect on the bit value.

This bit is cleared when writing a 1 to it.

The flag is set by the CC when a receive FIFO overrun is detected. When a receive FIFO overrun occurs, the oldest message is overwritten with the actual received message. The actual state of the FIFO is monitored in register FLXAnFRFSR.

(12) FLXAnFREIR.AERR

Access error flag Flag

Writing 0 in this bit has no effect.

This bit is cleared when writing 1 to it.

Notifies of an access error.

When bit FLXAnFRMHDS.AMR, FLXAnFRMHDS.ATBF1, or FLXAnFRMHDS.ATBF2 changes from 0 to 1, this bit is set to 1.

(13) FLXAnFREIR.CCL

CHI Command Locked Flag

Writing 0 has no effect on the bit value.

This bit is cleared when writing a 1 to it.

The flag signals that the write access to the CHI command vector FLXAnFRSUCC1.CMD[3:0] bits was not successful because the execution of the previous CHI command has not yet completed. In this case bit FLXAnFREIR.CNA is also set to 1.

(14) FLXAnFREIR.CCF

Clock Correction Failure Flag

Writing 0 has no effect on the bit value.

This bit is cleared when writing a 1 to it.

This flag is set at the end of the communication cycle whenever one of the following errors occurred:

- Missing offset and / or rate correction
- Clock correction limit reached

The clock correction status is monitored in registers FLXAnFRCCEV and FLXAnFRSFS. A failure may occur during startup, therefore bit FLXAnFREIR.CCF should be set to 0 after the CC entered NORMAL_ACTIVE state.

(15) FLXAnFREIR.SFO

Sync Frame Overflow Flag

Writing 0 has no effect on the bit value.

This bit is cleared when writing a 1 to it.

It is set to 1 when either the number of sync frames received during the last communication cycle or the total number of different sync frame IDs received during the last double cycle exceeds the maximum number of sync frames as defined by the FLXAnFRGTUC2.SNM[3:0] bits.

(16) FLXAnFREIR.SFBM

Sync Frames Below Minimum Flag

Writing 0 has no effect on the bit value.

This bit is cleared when writing a 1 to it.

This flag is set to 1 at the end of a cycle if the number of sync frames received during the last communication cycle was below the limit required for rate or offset correction term calculation (i.e. missing offset and / or missing rate correction). The clock correction status is monitored in FLXAnFRCCEV and FLXAnFRSFS.

This flag may be set to 1 during startup. Therefore this flag should be set to 0 by the Host after the CC entered NORMAL_ACTIVE state.

(17) FLXAnFREIR.CNA

Command Not Accepted Flag

Writing 0 has no effect on the bit value.

This bit is cleared when writing a 1 to it.

The flag signals that the write access to the CHI command vector FLXAnFRSUCC1.CMD[3:0] bits was not successful because the requested command was not valid in the actual POC state, or because the CHI command was locked (FLXAnFREIR.CCL = 1).

(18) FLXAnFREIR.PEMC

POC Error Mode Changed Flag

Writing 0 has no effect on the bit value.

This bit is cleared when writing a 1 to it.

This flag is set to 1 whenever the error mode signaled by the FLXAnFRCCEV.ERRM[1:0] bits has changed.

24.3.4.2 FLXAnFRSIR — FlexRay Status Interrupt Register

Do not rewrite this register using bit manipulation instructions.

The flags are set when the CC detects one of the listed events. The flags remain set until the Host clears them.

Access: This register can be read or written in 8-, 16-, or 32-bit units.

Address: <FLXAn_base> + 0024_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 24.14 FLXAnFRSIR Register Contents (1/2)

Bit Position	Bit Name	Function
31 to 26	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
25	MTSB	MTS Received on Channel B Flag (vSS!ValidMTSB) 0: No MTS symbol received on channel B 1: MTS symbol received on channel B
24	WUPB	Wakeup Pattern Channel B Flag 0: No wakeup pattern received on channel B 1: Wakeup pattern received on channel B
23 to 18	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
17	MTSA	MTS Received on Channel A Flag (vSS!ValidMTSA) 0: No MTS symbol received on channel A 1: MTS symbol received on channel A
16	WUPA	Wakeup Pattern Channel A Flag 0: No wakeup pattern received on channel A 1: Wakeup pattern received on channel A
15	SDS	Start of Dynamic Segment Flag 0: Dynamic segment not yet started 1: Dynamic segment started
14	MBSI	Message Buffer Status Interrupt Flag 0: No message buffer status change of message buffer with MBI = 1 1: Message buffer status of at least one message buffer with MBI = 1 has changed
13	SUCS	Startup Completed Successfully Flag 0: No startup completed successfully 1: Startup completed successfully
12	SWE	Stop Watch Event Flag 0: No Stop Watch Event 1: Stop Watch Event occurred
11	TOBC	Transfer Output Buffer Completed Flag 0: No transfer completed 1: Transfer between Message RAM and Output Buffer completed

Table 24.14 FLXAnFRSIR Register Contents (2/2)

Bit Position	Bit Name	Function
10	TIBC	Transfer Input Buffer Completed Flag 0: No transfer completed 1: Transfer between Input Buffer and Message RAM completed
9	TI1	Timer Interrupt 1 Flag 0: No timer interrupt 1 1: Timer interrupt 1 occurred
8	TI0	Timer Interrupt 0 Flag 0: No timer interrupt 0 1: Timer interrupt 0 occurred
7	NMVC	Network Management Vector Changed Flag 0: No change in the network management vector 1: Network management vector changed
6	RFCL	Receive FIFO Critical Level Flag 0: Receive FIFO below critical level 1: Receive FIFO critical level reached
5	RFNE	Receive FIFO Not Empty Flag 0: Receive FIFO is empty 1: Receive FIFO is not empty
4	RXI	Receive Interrupt Flag 0: No ND flag of a receive buffer with MBI = 1 has been set to 1 1: At least one ND flag of a receive buffer with MBI = 1 has been set to 1
3	TXI	Transmit Interrupt Flag 0: No frame transmitted from a transmit buffer with MBI = 1 1: At least one frame was transmitted from a transmit buffer with MBI = 1
2	CYCS	Cycle Start Interrupt Flag 0: No communication cycle started 1: Communication cycle started
1	CAS	Collision Avoidance Symbol Flag 0: No bit pattern matching the CAS symbol received 1: Bit pattern matching the CAS symbol received
0	WST	Wakeup Status Flag 0: Wakeup status unchanged 1: Wakeup status changed

(1) FLXAnFRSIR.MTSB

MTS Received on Channel B Flag (vSS!ValidMTSB)

Writing 0 has no effect on the bit value.

This bit is cleared when writing a 1 to it.

Media Access Test symbol received on channel B during the preceding symbol window.

Updated by the CC for each channel at the end of the symbol window.

(2) FLXAnFRSIR.WUPB

Wakeup Pattern Channel B Flag

Writing 0 has no effect on the bit value.

This bit is cleared when writing a 1 to it.

This flag is set to 1 when a wakeup pattern was received on channel B in either of the following states:

- WAKEUP
- READY
- STARTUP

(3) FLXAnFRSIR.MTSA

MTS Received on Channel A Flag (vSS!ValidMTSA)

Writing 0 has no effect on the bit value.

This bit is cleared when writing a 1 to it.

Media Access Test symbol received on channel A during the preceding symbol window.

Updated by the CC for each channel at the end of the symbol window.

(4) FLXAnFRSIR.WUPA

Wakeup Pattern Channel A Flag

Writing 0 has no effect on the bit value.

This bit is cleared when writing a 1 to it.

This flag is set to 1 when a wakeup pattern was received on channel A in either of the following states:

- WAKEUP
- READY
- STARTUP

(5) FLXAnFRSIR.SDS

Start of Dynamic Segment Flag

Writing 0 has no effect on the bit value.

This bit is cleared when writing a 1 to it.

This flag is set by the CC when the dynamic segment starts.

(6) FLXAnFRSIR.MBSI

Message Buffer Status Interrupt Flag

Writing 0 has no effect on the bit value.

This bit is cleared when writing a 1 to it.

This flag is set by the CC when the message buffer status FLXAnFRMBS register has changed and if bit MBI of that message buffer is 1 (see **Table 24.106**).

(7) FLXAnFRSIR.SUCS

Startup Completed Successfully Flag

Writing 0 has no effect on the bit value.

This bit is cleared when writing a 1 to it.

This flag is set whenever a startup completed successfully and the CC entered NORMAL_ACTIVE state.

(8) FLXAnFRSIR.SWE

Stop Watch Event Flag

Writing 0 has no effect on the bit value.

This bit is cleared when writing a 1 to it.

This flag is set after a stop watch activation when the actual cycle counter and macrotick value are stored in the Stop Watch register (see **Section 24.3.5.4, FLXAnFRSTPW1 — FlexRay Stop Watch Register 1**).

(9) FLXAnFRSIR.TOBC

Transfer Output Buffer Completed Flag

Writing 0 has no effect on the bit value.

This bit is cleared when writing a 1 to it.

This flag is set whenever a transfer from the Message RAM to the Output Buffer has completed and bit FLXAnFROBCR.OBSYS has been reset by the Message Handler.

(10) FLXAnFRSIR.TIBC

Transfer Input Buffer Completed Flag

Writing 0 has no effect on the bit value.

This bit is cleared when writing a 1 to it.

This flag is set whenever a transfer from Input Buffer to the Message RAM has completed and bit FLXAnFRIBCR.IBSYS has been reset by the Message Handler.

(11) FLXAnFRSIR.TI1

Timer 1 Interrupt Flag

Writing 0 has no effect on the bit value.

This bit is cleared when writing a 1 to it.

This flag is set whenever timer 1 matches the conditions configured in register FLXAnFRT1C.

FlexRay timer 1 interrupt is generated when bit FLXAnFROC.T1IE is effective.

(12) FLXAnFRSIR.TI0

Timer 0 Interrupt Flag

Writing 0 has no effect on the bit value.

This bit is cleared when writing a 1 to it.

This flag is set whenever timer 0 matches the conditions configured in register FLXAnFRT0C.

FlexRay timer 0 interrupt is generated when bit FLXAnFROC.T0IE is effective.

(13) FLXAnFRSIR.NMVC

Network Management Vector Changed Flag

Writing 0 has no effect on the bit value.

This bit is cleared when writing a 1 to it.

This is set when a change in the Network Management Vector occurs.

(14) FLXAnFRSIR.RFCL

Receive FIFO Critical Level Flag

Writing 0 has no effect on the bit value.

This bit is cleared when writing a 1 to it.

This flag is set when the receive FIFO fill level indicated by bits FLXAnFRFSR.RFFL[7:0] is equal or greater than the critical level as configured by bit FLXAnFRFCL.CL.

(15) FLXAnFRSIR.RFNE

Receive FIFO Not Empty Flag

Writing 0 has no effect on the bit value.

This bit is cleared when writing a 1 to it.

This flag is set by the CC when a received valid frame was stored into the empty receive FIFO. The actual state of the receive FIFO is monitored in register FLXAnFRFSR.

(16) FLXAnFRSIR.RXI

Receive Interrupt Flag

Writing 0 has no effect on the bit value.

This bit is cleared when writing a 1 to it.

This flag is set by the CC whenever the set condition of a message buffers ND flag is fulfilled (see **Section 24.3.9.6, FLXAnFRNDATm — FlexRay New Data Register m (m = 1 to 4)**, and if bit MBI of that message buffer is set to 1 (see **Table 24.106**)

(17) FLXAnFRSIR.TXI

Transmit Interrupt Flag

Writing 0 has no effect on the bit value.

This bit is cleared when writing a 1 to it.

This flag is set by the CC at the end of frame transmission if bit MBI in the respective message buffer is set to 1 (see **Table 24.106**).

(18) FLXAnFRSIR.CYCS

Cycle Start Interrupt Flag

Writing 0 has no effect on the bit value.

This bit is cleared when writing a 1 to it.

This flag is set by the CC when a communication cycle starts.

(19) FLXAnFRSIR.CAS

Collision Avoidance Symbol Flag

Writing 0 has no effect on the bit value.

This bit is cleared when writing a 1 to it.

This flag is set by the CC during STARTUP state when a CAS or a potential CAS was received.

(20) FLXAnFRSIR.WST

Wakeup Status Flag

Writing 0 has no effect on the bit value.

This bit is cleared when writing a 1 to it.

This flag is set when flags FLXAnFRCCSV.WSV[2:0] change to a value other than UNDEFINED.

24.3.4.3 FLXAnFREILS — FlexRay Error Interrupt Line Select Register

This register assigns an interrupt generated by a specific error interrupt flag from register FLXAnFREIR to one of the two modules interrupt lines (FlexRay 0 interrupt, FlexRay 1 interrupt).

Access: This register can be read or written in 8-, 16-, or 32-bit units.

Address: <FLXAn_base> + 0028_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	TABBL	LTVBL	EDBL	—	—	—	—	—	TABAL	LTVAL	EDAL

24.3.4.4 FLXAnFRSILS — FlexRay Status Interrupt Line Select Register

This register assigns an interrupt generated by a specific status interrupt flag from register FLXAnFRSIR to one of the two module interrupt lines (FlexRay 0 interrupt, FlexRay 1 interrupt).

Access: This register can be read or written in 8-, 16-, or 32-bit units.

Address: <FLXAn_base> + $002C_H$

Value after reset: $0303\ FFFF_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

24.3.4.5 FLXAnFREIES — FlexRay Error Interrupt Enable Set Register

The settings in the FlexRay Error Interrupt Enable Set (FLXAnFREIES) and FlexRay Error Interrupt Enable Reset (FLXAnFREIER) register determine which status changes in the FlexRay Error Interrupt Register will result in an interrupt.

The enable bits are set by writing to FLXAnFREIES and reset by writing to FLXAnFREIER. Reading from both addresses will result in the same value.

Writing 0 has no effect on the bit value.

Writing a 1 sets the interrupt enable bit.

Access: This register can be read or written in 8-, 16-, or 32-bit units.

Address: <FLXAn_base> + 0030_H

Value after reset: $0000\ 0000_H$

24.3.4.6 FLXAnFREIER — FlexRay Error Interrupt Enable Reset Register

The settings in the FlexRay Error Interrupt Enable Set (FLXAnFREIES) and FlexRay Error Interrupt Enable Reset (FLXAnFREIER) register determine which status changes in the FlexRay Error Interrupt Register will result in an interrupt.

The enable bits are set by writing to FLXAnFREIES and reset by writing to FLXAnFREIER. Reading from both addresses will result in the same value.

Writing 0 has no effect on the bit value.

Writing a 1 clears the interrupt enable bit.

Access: This register can be read or written in 8-, 16-, or 32-bit units.

Address: <FLXAn_base> + 0034_H

Value after reset: $0000\ 0000_H$

24.3.4.7 FLXAnFRSIES — FlexRay Status Interrupt Enable Set Register

The settings in the FlexRay Status Interrupt Enable Set (FLXAnFRSIES) and FlexRay Status Interrupt Enable Reset (FLXAnFRSIER) register determine which status changes in the FlexRay Status Interrupt Register will result in an interrupt.

The enable bits are set by writing to FLXAnFRSIES and reset by writing to FLXAnFRSIER. Reading from both addresses will result in the same value.

Writing 0 has no effect on the bit value.

Writing a 1 sets the interrupt enable bit.

Access: This register can be read or written in 8-, 16-, or 32-bit units.

Address: <FLXAn_base> + 0038_H

Value after reset: $0000\ 0000_H$

24.3.5 FlexRay Timer Registers

24.3.5.1 FLXAnFRT0C — FlexRay Timer 0 Configuration Register

This register is an absolute timer. It specifies the point in time when a FlexRay timer 0 interrupt occurs as the values of cycle count and macrotick (MT). When the FlexRay timer 0 passes, bits FLXAnFRSIR.TI0 and FLXAnFROS.T0IS are set to 1. A timer 0 interrupt then occurs while bit FLXAnFROC.T0IE is effective.

CAUTION

The configuration of timer 0 is compared against the macrotick counter value, there is no separate counter for timer 0.

Access: This register can be read or written in 8-, 16-, or 32-bit units.

Address: <FLXAn_base> + 0044_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 24.22 FLXAnFRT0C Register Contents

Bit Position	Bit Name	Function
31, 30	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
29 to 16	T0MO[13:0]	Timer 0 Macrotick Offset Bit Timer 0 Macrotick Offset
15	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
14 to 8	T0CC[6:0]	Timer 0 Cycle Code Bit Timer 0 Cycle Code
7 to 2	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
1	T0MS	Timer 0 Mode Select Bit 0: Single-shot mode 1: Continuous mode
0	T0RC	Timer 0 Run Control Bit 0: Timer 0 halted 1: Timer 0 running

(1) FLXAnFRT0C.T0MO

Timer 0 Macrotick Offset Bit

Before reconfiguration of the timer, the timer has to be halted first by writing bit FLXAnFRT0C.T0RC to 0.

Configures the macrotick offset from the beginning of the communication cycle where the interrupt is to occur. The FlexRay timer 0 interrupt occurs at this offset for each cycle of the cycle set.

(2) FLXAnFRT0C.T0CC

Timer 0 Cycle Code Bit

Before reconfiguration of the timer, the timer has to be halted first by writing bit FLXAnFRT0C.T0RC to 0.

The 7-bit timer 0 cycle code determines the cycle set used for generation of the FlexRay timer 0 interrupt. For details about the configuration of the cycle code see **Section 24.4.8.2, Cycle Counter Filtering**.

(3) FLXAnFRT0C.T0MS

Timer 0 Mode Select Bit

Before reconfiguration of the timer, the timer has to be halted first by writing bit FLXAnFRT0C.T0RC to 0.

Configures the timer run mode. In Single-shot mode the timer is deactivated when the timer configuration matches the configured cycle counter and macrotick value.

(4) FLXAnFRT0C.T0RC

Timer 0 Run Control Bit

Timer 0 can be activated (set bit FLXAnFRT0C.T0RC to 1) when the POC is either in NORMAL_ACTIVE state or in NORMAL_PASSIVE state.

Timer 0 is deactivated when leaving NORMAL_ACTIVE state or NORMAL_PASSIVE state except for transitions between the two states.

24.3.5.2 FLXAnFRT1C — FlexRay Timer 1 Configuration Register

This register is a relative timer. After the specified number of macroticks (MT) has expired, a FlexRay timer 1 interrupt is asserted. When the FlexRay timer 1 passes, bits FLXAnFRSIR.TI1 and FLXAnFROS.T1IS are set to 1. A timer 1 interrupt then occurs while bit FLXAnFROC.T1IE is effective.

Access: This register can be read or written in 8-, 16-, or 32-bit units.

Address: <FLXAn_base> + 0048_H

Value after reset: $0002\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	T1MC[13:0]

Table 24.23 FLXAnFRT1C Register Contents

Bit Position	Bit Name	Function
31, 30	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
29 to 16	T1MC[13:0]	Specify timer 1 macrotick count value.
15 to 2	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
1	T1MS	Timer 1 Mode Select Bit 0: Single-shot mode 1: Continuous mode
0	T1RC	Timer 1 Run Control Bit 0: Timer 1 halted 1: Timer 1 running

(1) FLXAnFRT1C.T1MC

Timer 1 Macrotick Count Bit

Before reconfiguration of the timer, the timer has to be halted first by writing bit FLXAnFRT1C.T1RC to 0.

Valid values are 2 to 16383 MT in continuous mode

Valid values are 1 to 16383 MT in single-shot mode

When the configured macrotick count is reached the FlexRay timer 1 interrupt is generated.

(2) FLXAnFRT1C.T1MS

Timer 1 Mode Select Bit

Before reconfiguration of the timer, the timer has to be halted first by writing bit FLXAnFRT1C.T1RC to 0.

Configures the timer run mode. In Single-shot mode the timer is deactivated when the timer configuration matches the configured cycle counter and macrotick value.

(3) FLXAnFRT1C.T1RC

Timer 1 Run Control Bit

Timer 1 can be activated (set bit FLXAnFRT1C.T1RC to 1) as long as the POC is either in NORMAL_ACTIVE state or in NORMAL_PASSIVE state.

Timer 1 is deactivated when leaving NORMAL_ACTIVE state or NORMAL_PASSIVE state except for transitions between the two states.

24.3.5.3 FLXAnFRT2C — FlexRay Timer 2 Configuration Register

This register is an absolute timer. It specifies the point in time when a FlexRay timer 2 interrupt occurs as the values of cycle count and macrotick (MT). When the FlexRay timer 2 expires, FLXAnFROS.T2IS are set to '1'. A timer 2 interrupt then occurs while the FLXAnFROC.T2IE bit is effective.

FlexRay timer 2 has the same absolute timer features as FlexRay timer 0.

CAUTION

The configuration of timer 2 is compared against the macrotick counter value, there is no separate counter for timer 2.

Access: This register can be read or written in 8-, 16-, or 32-bit units.

Address: <FLXAn_base> + 0844_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	T2MO[13:0]

Table 24.24 FLXAnFRT2C Register Contents

Bit Position	Bit Name	Function
31, 30	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
29 to 16	T2MO[13:0]	Timer 2 Macrotick Offset Bit Timer 2 Macrotick Offset
15	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
14 to 8	T2CC[6:0]	Timer 2 Cycle Code Bit Timer 2 Cycle Code
7 to 2	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
1	T2MS	Timer 2 Mode Select Bit 0: Single-shot mode 1: Continuous mode
0	T2RC	Timer 2 Run Control Bit 0: Timer halted 1: Timer running

(1) FLXAnFRT2C.T2MO

Timer 2 Macrotick Offset Bit

Stop the timer by writing 0 to the FLXAnFRT2C.T2RC bit before changing the setting of the timer.

The T2MO bits are used to set the timing for generation of the timer 2 interrupt as an offset value in MT units from the position where the transfer cycle starts. That is, the timer 2 interrupt is generated at the offset position specified by the setting for the number of MT cycles.

(2) FLXAnFRT2C.T2CC

Timer 2 Cycle Code Bit

Stop the timer by writing 0 to bit FLXAnFRT2C.T2RC before changing the setting of the timer.

The T2CC bits are used to make the cycle setting for generation of the timer 2 interrupt as a 7-bit timer 2 cycle code. For details, see **Section 24.4.8.2, Cycle Counter Filtering**.

(3) FLXAnFRT2C.T2MS

Timer 2 Mode Select Bit

Stop the timer by writing 0 to bit FLXAnFRT2C.T2RC before changing the setting of the timer.

Set the execution mode of the timer. In single shot mode, the timer stops when the timer setting matched with the MT value of the cycle counter.

(4) FLXAnFRT2C.T2RC

Timer 2 Run Control Bit

The timer 2 can operate only when POC is in NORMAL_ACTIVE state or NORMAL_PASSIVE state (bit FLXAnFRT2C.T2RC is set to 1).

The timer 2 stops when it transits to other state except transition between NORMAL_ACTIVE state and NORMAL_PASSIVE state.

24.3.5.4 FLXAnFRSTPW1 — FlexRay Stop Watch Register 1

The stop watch is activated by the following trigger events.

- Input of a rising edge or falling edge to the FLXAnSTPWT pin
- FlexRay 0 interrupt or FlexRay 1 interrupt
- Writing bit FLXAnFRSTPW1.SSWT to 1

With the macrotick counter increment following next to the stop watch activation the actual cycle counter and macrotick values are captured in register FLXAnFRSTPW1 while the slot counter values for channel A and B are captured in register FLXAnFRSTPW2.

Access: This register can be read or written in 8-, 16-, or 32-bit units.

Address: <FLXAn_base> + $004C_H$

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	SMTV[13:0]													
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

	—	—	SCCV[5:0]						—	EINT1	EINT0	EETP	SSWT	EDGE	SWMS	ESWT
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 24.25 FLXAnFRSTPW1 Register Contents (1/2)

Bit Position	Bit Name	Function
31, 30	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
29 to 16	SMTV[13:0]	Stop Watch Event Occurrence Macrotick Value
15, 14	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
13 to 8	SCCV[5:0]	Stop Watch Event Occurrence Cycle Counter Value
7	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
6	EINT1	FlexRay Interrupt 1 Trigger Enable 0: Stop watch trigger by FlexRay 1 interrupt disabled 1: FlexRay 1 interrupt event triggers stop watch
5	EINT0	FlexRay 0 Interrupt Trigger Enable 0: Stop watch trigger by FlexRay 0 interrupt disabled 1: FlexRay interrupt 0 event triggers stop watch
4	EETP	External Trigger Pin Enable 0: Trigger by the FLXAnSTPWT pin is disabled. 1: Trigger by the FLXAnSTPWT pin is enabled.
3	SSWT	Software Stop Watch Trigger 0: Software trigger reset 1: Stop watch activated by software trigger
2	EDGE	Stop Watch Trigger Edge Select 0: Falling edge 1: Rising edge

Table 24.25 FLXAnFRSTPW1 Register Contents (2/2)

Bit Position	Bit Name	Function
1	SWMS	Stop Watch Mode Select 0: Single-shot mode 1: Continuous mode
0	ESWT	Hardware Stop Watch Trigger Enable 0: Stop watch trigger disabled 1: Stop watch trigger enabled

(1) FLXAnFRSTPW1.SMTV

Stop Watch Captured Macrotick Value

State of the macrotick counter when the stop watch event occurred.

(2) FLXAnFRSTPW1.SCCV

Stop Watch Captured Cycle Counter Value

State of the cycle counter when the stop watch event occurred.

(3) FLXAnFRSTPW1.EINT1

Enable FlexRay 1 Interrupt Trigger Bit

Enables stop watch trigger by FlexRay 1 interrupt when bit FLXAnFRSTPW1.ESWT is 1.

(4) FLXAnFRSTPW1.EINT0

Enable FlexRay 0 Interrupt Trigger Bit

Enables stop watch trigger by FlexRay 0 interrupt when bit FLXAnFRSTPW1.ESWT = 1.

(5) FLXAnFRSTPW1.EETP

External Trigger Pin Enable Bit

When bit FLXAnFRSTPW1.ESWT is set to 1, the FLXAnSTPWT pin event is treated as a stop watch trigger.

(6) FLXAnFRSTPW1.SSWT

Software Stop Watch Trigger Bit

Bits FLXAnFRSTPW1.ESWT and FLXAnFRSTPW1.SSWT cannot be set to 1 simultaneously. In this case the write access to the register is ignored, and both bits keep their previous values. Either the external stop watch trigger or the software stop watch trigger may be used.

Writing 1 in this bit activates the stop watch. This bit is reset to 0 after the cycle count and slot count, and macrotick (MT) value are stored in the FlexRay stop watch register.

(7) FLXAnFRSTPW1.EDGE

Stop Watch Trigger Edge Select Bit

(8) FLXAnFRSTPW1.SWMS

Stop Watch Mode Select Bit

(9) FLXAnFRSTPW1.ESWT

Enable Stop Watch Trigger Bit

Bits FLXAnFRSTPW1.ESWT and FLXAnFRSTPW1.SSWT cannot be set to 1 simultaneously. In this case the write access to the register is ignored, and both bits keep their previous values. Either the external stop watch trigger or the software stop watch trigger may be used.

If enabled, any of an external trigger pin input event, a FlexRay 0 interrupt event, or a FlexRay 1 interrupt event activates the stop watch.

In single-shot mode, this bit is reset to 0 after the cycle count and slot count, and macrotick (MT) value are stored in the FlexRay stop watch register.

24.3.5.5 FLXAnFRSTPW2 — FlexRay Stop Watch Register 2

Access: This register is a read-only register that can be read in 8-, 16-, or 32-bit units.

Address: <FLXAn_base> + 0050_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	SSCVB[10:0]

Table 24.26 FLXAnFRSTPW2 Register Contents

Bit Position	Bit Name	Function
31 to 27	Reserved	When read, the value after reset is returned.
26 to 16	SSCVB[10:0]	Stop Watch Captured Slot Counter Value Channel B
15 to 11	Reserved	When read, the value after reset is returned.
10 to 0	SSCVA[10:0]	Stop Watch Captured Slot Counter Value Channel A

(1) FLXAnFRSTPW2.SSCVB

Stop Watch Captured Slot Counter Value Channel B

State of the slot counter for channel B when the stop watch event occurred.

(2) FLXAnFRSTPW2.SSCVA

Stop Watch Captured Slot Counter Value Channel A

State of the slot counter for channel A when the stop watch event occurred.

24.3.6 CC Control Registers

This section describes the registers provided by the CC (Communication Controller) to allow the Host to control the operation of the CC. The FlexRay protocol specification requires the Host to write application configuration data in CONFIG state only. Consider that the configuration registers are not locked for writing in DEFAULT_CONFIG state.

The configuration data is reset when DEFAULT_CONFIG state is entered from reset. To change POC state from DEFAULT_CONFIG to CONFIG state the Host has to apply CHI command CONFIG. If the Host wants the CC to leave CONFIG state, the Host has to execute the lock release sequence as described in **Section 24.3.3.1, FLXAnFRLCK — FlexRay Lock Register**.

24.3.6.1 FLXAnFRSUCC1 — FlexRay SUC Configuration Register 1

Access: This register can be read or written in 8-, 16-, or 32-bit units.

Address: <FLXAn_base> + 0080_H

Value after reset: 0C40 1080_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 24.27 FLXAnFRSUCC1 Register Contents (1/2)

Bit Position	Bit Name	Function
31 to 28	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
27	CCHB	Connected to Channel B Bit Configures pChannels 0: Not connected to channel B 1: Node connected to channel B (value after reset)
26	CCHA	Connected to Channel A Bit Configures pChannels 0: Not connected to channel A 1: Node connected to channel A (value after reset)
25	MTSB	Select Channel B for MTS Transmission Bit 0: Channel B disabled for MTS transmission 1: Channel B selected for MTS transmission
24	MTSA	Select Channel A for MTS Transmission Bit 0: Channel A disabled for MTS transmission 1: Channel A selected for MTS transmission
23	HCSE	Halt due to Clock Sync Error Bit Configures pAllowHaltDueToClock 0: CC will enter / remain in NORMAL_PASSIVE 1: CC will enter HALT state
22	TSM	Transmission Slot Mode Bit Configures pSingleSlotEnabled 0: ALL Slot Mode 1: SINGLE Slot Mode (value after reset)

Table 24.27 FLXAnFRSUCC1 Register Contents (2/2)

Bit Position	Bit Name	Function
21	WUCS	Wakeup Channel Select Bit Configures pWakeupChannel 0: Send wakeup pattern on channel A 1: Send wakeup pattern on channel B
20 to 16	PTA[4:0]	Passive to Active Bit Configures pAllowPassiveToActive
15 to 11	CSA[4:0]	Cold Start Attempts Bit Configures gColdStartAttempts
10	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
9	TXSY	Transmit Sync Frame in Key Slot Bit Configures pKeySlotUsedForSync 0: No sync frame transmission in key slot, node is neither sync nor coldstart node 1: Key slot used to transmit sync frame, node is sync node
8	TXST	Transmit Startup Frame in Key Slot Bit Configures pKeySlotUsedForStartup 0: No startup frame transmission in key slot, node is non-coldstarter 1: Key slot used to transmit startup frame, node is leading or following coldstarter
7	PBSY	POC Busy Flag 0: POC not busy, bit FLXAnFRSUCC1.CMD writeable 1: POC is busy, bit FLXAnFRSUCC1.CMD locked
6 to 4	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
3 to 0	CMD[3:0]	CHI Command Vector Bit 0000: command_not_accepted 0001: CONFIG 0010: READY 0011: WAKEUP 0100: RUN 0101: ALL_SLOTS 0110: HALT 0111: FREEZE 1000: SEND_MTS 1001: ALLOW_COLDSTART 1010: RESET_STATUS_INDICATORS 1100: CLEAR_RAMS others: reserved

(1) FLXAnFRSUCC1.CCHB

Connected to Channel B Bit

The user can only write to these bits when bits FLXAnFRCCSV.POCS[5:0] are DEFAULT_CONFIG or CONFIG.

Configures whether the node is connected to channel B (pChannels).

(2) FLXAnFRSUCC1.CCHA

Connected to Channel A Bit

The user can only write to these bits when bits FLXAnFRCCSV.POCS[5:0] are DEFAULT_CONFIG or CONFIG.

Configures whether the node is connected to channel A (pChannels).

(3) FLXAnFRSUCC1.MTSB

Select Channel B for MTS Transmission Bit

The user can only write to these bits when bits FLXAnFRCCSV.POCS[5:0] are DEFAULT_CONFIG or CONFIG.

The FLXAnFRSUCC1.MTSB bit may also be changed outside DEFAULT_CONFIG or CONFIG state when the write to FLXAnFRSUCC1 register is directly preceded by the unlock sequence for the Configuration Lock Key as described in **Section 24.3.3.1, FLXAnFRLCK — FlexRay Lock Register**. This may be combined with CHI command SEND_MTS. If both bits FLXAnFRSUCC1.MTSA and FLXAnFRSUCC1.MTSB are set to 1 an MTS symbol will be transmitted on both channels when requested by writing 1000_B to the FLXAnFRSUCC1.CMD[3:0] bits.

The bit selects channel B for MTS symbol transmission.

(4) FLXAnFRSUCC1.MTSA

Select Channel A for MTS Transmission Bit

The user can only write to these bits when FLXAnFRCCSV.POCS[5:0] bits are DEFAULT_CONFIG or CONFIG.

Bit FLXAnFRSUCC1.MTSA may also be changed outside DEFAULT_CONFIG or CONFIG state when the write to FLXAnFRSUCC1 register is directly preceded by the unlock sequence for the Configuration Lock Key as described in **Section 24.3.3.1, FLXAnFRLCK — FlexRay Lock Register**. This may be combined with CHI command SEND_MTS. If both bits FLXAnFRSUCC1.MTSA and FLXAnFRSUCC1.MTSB are set to 1 an MTS symbol will be transmitted on both channels when requested by writing 1000_B to the FLXAnFRSUCC1.CMD[3:0] bits.

The bit selects channel A for MTS symbol transmission.

(5) FLXAnFRSUCC1.HCSE

Halt due to Clock Sync Error Bit

The user can only write to these bits when bits FLXAnFRCCSV.POCS[5:0] are DEFAULT_CONFIG or CONFIG.

Controls the transition to HALT state due to a clock synchronization error (pAllowHaltDueToClock).

(6) FLXAnFRSUCC1.TSM

Transmission Slot Mode Bit

The user can only write to these bits when bits FLXAnFRCCSV.POCS[5:0] is DEFAULT_CONFIG or CONFIG.

Selects the value after transmission slot mode reset (pSingleSlotEnabled).

In SINGLE slot mode the CC may only transmit in the preconfigured key slot. The key slot ID is configured in the header section of message buffer 0 respectively message buffers 0 and 1 depending on bit FLXAnFRMRC.SPLM.

In case FLXAnFRSUCC1.TSM = 1, message buffer 0 respectively message buffers 0,1 can be (re)configured in DEFAULT_CONFIG or CONFIG state only. In ALL slot mode the CC may transmit in all slots.

FLXAnFRSUCC1.TSM is a configuration bit which can only be set / reset by the Host.

The CC changes to ALL slot mode when the Host successfully applied the ALL_SLOTS command by writing 0101_B to bits FLXAnFRSUCC1.CMD[3:0] in POC states NORMAL_ACTIVE or NORMAL_PASSIVE. The actual slot mode is monitored by bits FLXAnFRCCSV.SLM[1:0].

(7) FLXAnFRSUCC1.WUCS

Wakeup Channel Select Bit

The user can only write to these bits when bits FLXAnFRCCSV.POCS[5:0] are DEFAULT_CONFIG or CONFIG.

With this bit the Host selects the channel on which the CC sends the Wakeup pattern (pWakeupChannel).

(8) FLXAnFRSUCC1.PTA

Passive to Active Bit

The user can only write to these bits when the FLXAnFRCCSV.POCS[5:0] bits is DEFAULT_CONFIG or CONFIG.

Valid values are 0 to 31 even / odd cycle pairs.

Defines the number of consecutive even / odd cycle pairs that must have valid clock correction terms before the CC is allowed to transit from NORMAL_PASSIVE to NORMAL_ACTIVE state (pAllowPassiveToActive).

If set to "00000_B" the CC is not allowed to transit from NORMAL_PASSIVE to NORMAL_ACTIVE state.

(9) FLXAnFRSUCC1.CSA

Cold Start Attempts Bit

The user can only write to these bits when the FLXAnFRCCSV.POCS[5:0] bits is DEFAULT_CONFIG or CONFIG.

Must be identical in all nodes of a cluster.

Valid values are 2 to 31.

Configures the maximum number of attempts that a cold starting node is permitted to try to start up the network without receiving any valid response from another node (gColdStartAttempts).

(10) FLXAnFRSUCC1.TXSY

Transmit Sync Frame in Key Slot Bit

The user can only write to these bits when the FLXAnFRCCSV.POCS[5:0] bits is DEFAULT_CONFIG or CONFIG.

Defines whether the key slot is used to transmit sync frames (pKeySlotUsedForSync).

CAUTION

The protocol requires that both bits FLXAnFRSUCC1.TXST and FLXAnFRSUCC1.TXSY are set for coldstart nodes.

(11) FLXAnFRSUCC1.TXST

Transmit Startup Frame in Key Slot Bit

The user can only write to these bits when bits FLXAnFRCCSV.POCS[5:0] are DEFAULT_CONFIG or CONFIG.

Defines whether the key slot is used to transmit startup frames (pKeySlotUsedForStartup).

CAUTION

The protocol requires that both bits FLXAnFRSUCC1.TXST and FLXAnFRSUCC1.TXSY are set for coldstart nodes.

(12) FLXAnFRSUCC1.PBSY

POC Busy Flag

Signals that the POC is busy and cannot accept a command from the Host. Bits FLXAnFRSUCC1.CMD[5:0] are locked against write accesses.

Set to 1 after reset during initialization of internal RAM blocks.

(13) FLXAnFRSUCC1.CMD

CHI Command Vector Bit

The Host may write any CHI command at any time, but certain commands are enabled only in certain POC states. If a command is not enabled, it will not be executed, the CHI command vector FLXAnFRSUCC1.CMD[3:0] bits will be reset to 0000_B = command_not_accepted, and flag FLXAnFREIR.CNA will be set to 1.

In general the Host must check FLXAnFRSUCC1.PBSY before writing a new CHI command.

In case the previous CHI command has not yet completed, flag FLXAnFREIR.CCL is set to 1 together with FLXAnFREIR.CNA; the CHI command needs to be repeated.

Except for HALT state, a POC state change command applied while the CC is already in the requested POC state neither causes a state change nor will flag FLXAnFREIR.CNA be set.

Reading bits FLXAnFRSUCC1.CMD[3:0] show whether the last CHI command was accepted. The actual POC state is monitored by bits FLXAnFRCCSV.POCS[5:0].

- command_not_accepted

  Bits FLXAnFRSUCC1.CMD[3:0] are reset to 0000_B due to one of the following conditions:

  – Illegal command applied by the Host
  – Host applied command to leave CONFIG state without preceding config lock key
  – Host applied new command while execution of the previous Host command has not completed
  – Host writes command_not_accepted

When bits FLXAnFRSUCC1.CMD[3:0] are reset to 0000_B, FLXAnFREIR.CNA is set to 1, and if enabled an interrupt is generated. Commands which are not accepted are not executed.

CONFIG command

Go to POC state CONFIG when called in POC states DEFAULT_CONFIG, or READY. When called in HALT state the CC transits to POC state DEFAULT_CONFIG. When called in any other state, bits FLXAnFRSUCC1.CMD[3:0] will be reset to 0000_B = command_not_accepted.

READY command

Go to POC state READY when called in POC states CONFIG, NORMAL_ACTIVE, NORMAL_PASSIVE, STARTUP, or WAKEUP. When called in any other state, bits FLXAnFRSUCC1.CMD[3:0] will be reset to "0000_B" = command_not_accepted.

WAKEUP command

Go to POC state WAKEUP when called in POC state READY. When called in any other state, bits FLXAnFRSUCC1.CMD[3:0] will be reset to "0000_B" = command_not_accepted.

RUN command

Go to POC state STARTUP when called in POC state READY. When called in any other state, bits FLXAnFRSUCC1.CMD[3:0] will be reset to "0000_B" = command_not_accepted.

ALL_SLOTS command

Leave SINGLE slot mode and go to ALL-SLOTS mode after successful startup / integration at the next end of cycle when called in POC states NORMAL_ACTIVE or NORMAL_PASSIVE. When called in any other state, bits FLXAnFRSUCC1.CMD[3:0] will be reset to "0000_B" = command_not_accepted.

HALT command

Set halt request FLXAnFRCCSV.HRQ to 1 and go to POC state HALT at the next end of cycle when called in POC states NORMAL_ACTIVE or NORMAL_PASSIVE. When called in any other state, bits FLXAnFRSUCC1.CMD[3:0] will be reset to "0000_B" = command_not_accepted.

FREEZE command

Set the freeze status indicator FLXAnFRCCSV.FSI flag to 1 and go to POC state HALT immediately. Can be called from any state.

SEND_MTS command

Send single MTS symbol during the next following symbol window on the channel configured by the FLXAnFRSUCC1.MTSA and FLXAnFRSUCC1.MTSB bits, when called in POC state NORMAL_ACTIVE after CC entered ALL slot mode (the FLXAnFRCCSV.SLM[1:0] bits = "11"). When called in any other state, or when called while a previously requested MTS has not yet been transmitted, bits FLXAnFRSUCC1.CMD[3:0] will be reset to "0000_B" = command_not_accepted.

ALLOW_COLDSTART command

The command resets the FLXAnFRCCSV.CSI flag to enable the node to become leading coldstarter. When called in states DEFAULT_CONFIG, CONFIG, or HALT, bits FLXAnFRSUCC1.CMD[3:0] will be reset to "0000_B" = command_not_accepted. To become leading coldstarter it is also required that both FLXAnFRSUCC1.TXST and FLXAnFRSUCC1.TXSY bits are set.

RESET_STATUS_INDICATORS command

Resets status flags FLXAnFRCCSV.CSNI, FLXAnFRCCSV.CSAI and FLXAnFRCCSV.WSV to their values after reset. May be called in POC states READY and STARTUP. When called in any other state, bits FLXAnFRSUCC1.CMD[3:0] will be reset to "0000_B" = command_not_accepted.

CLEAR_RAMS command

Sets bit FLXAnFRMHDS.CRAM to 1 when called in DEFAULT_CONFIG or CONFIG state. When called in any other state, bits FLXAnFRSUCC1.CMD[3:0] will be reset to "0000_B" = command_not_accepted.

Bit FLXAnFRMHDS.CRAM is also set to 1 when the CC leaves reset. By setting bit FLXAnFRMHDS.CRAM all internal RAM blocks are initialized to zero. During the initialization of the RAMs, bit RSUCC1.PBSY will show POC busy. Access to the configuration and status registers is possible during execution of CHI command CLEAR_RAMS.

The initialization of the internal message RAM requires 2048 bus clock cycles. There should be no Host access to IBF or OBF during initialization of the internal RAM blocks after reset or after assertion of CHI command CLEAR_RAMS.

Before asserting CHI command CLEAR_RAMS, the Host should make sure that no transfer between Message RAM and IBF / OBF or the TBFRAMs is ongoing and that the data transfer handler has no effect (bits FLXAnFRITS.ITS and FLXAnFROTS.OTS are 0). This command also resets the Message Buffer Status registers FLXAnFRMHDS, FLXAnFRLDTS, FLXAnFRFSR, FLXAnFRMHDF, FLXAnFRTXRQ1 to FLXAnFRTXRQ4, FLXAnFRNDAT1 to FLXAnFRNDAT14, and FLXAnFRMBSC1 to FLXAnFRMBSC4.

CAUTIONS

1. **All accepted commands with exception of CLEAR_RAMS and SEND_MTS will cause a change of the POC state in the FlexRay domain after at most 8 cycles of the slower of the two clocks "bus clock" and "FlexRay sample clock", assumed that POC was not busy when the command was applied and that no POC state change was forced by bus activity in that time frame. Reading register FLXAnFRCCSV will show data that is additionally delayed by synchronization from the FlexRay domain to the bus clock domain. The maximum additional delay is 12 cycles of the slower of the two clocks 'bus clock' and "FlexRay sample clock".**
2. **When transfer is stopped by a FREEZE or READY command and then restarted as a leading ColdStart node, the startup frame may not be transmitted in cycle 0. This depends on the internal state of the FlexRay module. Such cases arise when the startup frame is set in a slot 1 to slot 7. This does not occur in a ColdStart after the reset of the microcontroller. Even if the above situation arises, the ColdStart will succeed on the second trial. Repetition prolongs the overall ColdStart process, but the ColdStart will not be obstructed by the earlier situation. To avoid this effect, allocate startup and sync frames to static slot 8 or a slot with a higher number.**

Table 24.28 below references the CHI commands from the *FlexRay Protocol Specification* (*Section 2.1.1.1, Table 2.2*) to the FlexRay CHI command vector FLXAnFRSUCC1.CMD[3:0] bits.

Table 24.28 Reference to CHI Host Command Summary from FlexRay Protocol Specification

CHI command	Where processed (POC States)	CHI Command Vector CMD
ALL_SLOTS	POC: normal active, POC: normal passive	ALL_SLOTS
ALLOW_COLDSTART	All except POC: default config, POC: config, POC: halt	ALLOW_COLDSTART
CONFIG	POC: default config, POC: ready	CONFIG
CONFIG_COMPLETE	POC: config	Unlock sequence & READY
DEFAULT_CONFIG	POC: halt	CONFIG
FREEZE	All	FREEZE
HALT	POC: normal active, POC: normal passive	HALT
READY	All except POC: default config, POC: config, POC: ready, POC: halt	READY
RUN	POC: ready	RUN
WAKEUP	POC: ready	WAKEUP

24.3.6.2 FLXAnFRSUCC2 — FlexRay SUC Configuration Register 2

Access: This register can be read or written in 8-, 16-, or 32-bit units.

Address: <FLXAn_base> + 0084_H

Value after reset: $0100\ 0504_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	LTN[3:0]				—	—	—	LT[20:16]				
Value after reset	0	0	0	0	0	0	0	1	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R/W	R/W	R/W	R/W	R	R	R	R/W	R/W	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	LT[15:0]															
Value after reset	0	0	0	0	0	1	0	1	0	0	0	0	0	1	0	0

Table 24.29 FLXAnFRSUCC2 Register Contents

Bit Position	Bit Name	Function
31 to 28	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
27 to 24	LTN[3:0]	Listen Timeout Noise Bit Configures (gListenNoise - 1)
23 to 21	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
20 to 0	LT[20:0]	Listen Timeout Bit Configures pdListenTimeout

(1) FLXAnFRSUCC2.LTN

Listen Timeout Noise Bit

The user can only write to these bits when bits FLXAnFRCCSV.POCS[5:0] are DEFAULT_CONFIG or CONFIG.

The range for gListenNoise is 2 to 16.

FLXAnFRSUCC2.LTN must be configured identical in all nodes of a cluster.

Configures the upper limit for startup and wakeup listen timeout in the presence of noise expressed as a multiple of pdListenTimeout.

CAUTION

The wakeup / startup noise timeout is calculated as follows:
pdListenTimeout × gListenNoise = FLXAnFRSUCC2.LT × (FLXAnFRSUCC2.LTN + 1)

(2) FLXAnFRSUCC2.LT

Listen Timeout Bit

The user can only write to these bits when bits FLXAnFRCCSV.POCS[5:0] are DEFAULT_CONFIG or CONFIG.

The range for pdListenTimeout is 1284 to 1283846 µT.

Configures wakeup / startup listen time out in µT.

24.3.6.3 FLXAnFRSUCC3 — FlexRay SUC Configuration Register 3

Access: This register can be read or written in 8-, 16-, or 32-bit units.

Address: <FLXAn_base> + 0088_H

Value after reset: $0000\ 0011_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

	—	—	—	—	—	—	—	—	WCF[3:0]				WCP[3:0]			
Value after reset	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	1
R/W	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 24.30 FLXAnFRSUCC3 Register Contents

Bit Position	Bit Name	Function
31 to 8	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
7 to 4	WCF[3:0]	Maximum Without Clock Correction Fatal Bit (transition to HALT state) Configures gMaxWithoutClockCorrectionFatal
3 to 0	WCP[3:0]	Maximum Without Clock Correction Passive Bit (transition to NORMAL_PASSIVE state) Configures gMaxWithoutClockCorrectionPassive

(1) FLXAnFRSUCC3.WCF

Maximum Without Clock Correction Fatal Bit (transition to HALT state)

The user can only write to these bits when bits FLXAnFRCCSV.POCS[5:0] are DEFAULT_CONFIG or CONFIG.

Valid values are 1 to 15 cycle pairs.

Must be identical in all nodes of a cluster.

Defines the number of consecutive even / odd cycle pairs with missing clock correction terms that will cause a transition from NORMAL_ACTIVE or NORMAL_PASSIVE to HALT state.

CAUTION

The transition to HALT state is prevented if the FLXAnFRSUCC1.HCSE bit is not set.

(2) FLXAnFRSUCC3.WCP

Maximum Without Clock Correction Passive Bit (transition to NORMAL_PASSIVE state)

The user can only write to these bits when bits FLXAnFRCCSV.POCS[5:0] are DEFAULT_CONFIG or CONFIG.

Valid values are 1 to 15 cycle pairs.

Must be identical in all nodes of a cluster.

Defines the number of consecutive even / odd cycle pairs with missing clock correction terms that will cause a transition from NORMAL_ACTIVE to NORMAL_PASSIVE state.

24.3.6.4 FLXAnFRNEMC — FlexRay NEM Configuration Register

Access: This register can be read or written in 8-, 16-, or 32-bit units.

Address: <FLXAn_base> + $008C_H$

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W

Table 24.31 FLXAnFRNEMC Register Contents

Bit Position	Bit Name	Function
31 to 4	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
3 to 0	NML[3:0]	Network Management Vector Length Bit Configures gNetworkManagementVectorLength

(1) FLXAnFRNEMC.NML

Network Management Vector Length Bit

The user can only write to these bits when bits FLXAnFRCCSV.POCS[5:0] are DEFAULT_CONFIG or CONFIG.

Valid values are 0 to 12 bytes.

The configured length must be identical in all nodes of a cluster.

These bits configure the length of the NM vector.

24.3.6.5 FLXAnFRPRTC1 — FlexRay PRT Configuration Register 1

Access: This register can be read or written in 8-, 16-, or 32-bit units.

Address: <FLXAn_base> + 0090_H

Value after reset: $084C\ 0633_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	RWP[5:0]						—	RXW[8:0]

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	BRP[1:0]		SPP[1:0]		—	CASM[6:0]							TSST[3:0]			
Value after reset	0	0	0	0	0	1	1	0	0	0	1	1	0	0	1	1
R/W	R/W	R/W	R/W	R/W	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 24.32 FLXAnFRPRTC1 Register Contents

Bit Position	Bit Name	Function
31 to 26	RWP[5:0]	Repetitions of Tx Wakeup Pattern Bit Configures pWakeupPattern
25	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
24 to 16	RXW[8:0]	Wakeup Symbol Receive Window Length Bit Configures gdWakeupSymbolRxWindow
15, 14	BRP[1:0]	Baud Rate Prescaler Bit Configures gdSampleClockPeriod and pSamplesPerMicrotick 00 = 10 Mbps 01 = 5 Mbps 10 = 2.5 Mbps 11 = 2.5 Mbps
13, 12	SPP[1:0]	Strobe Point Position Bit Configures Strobe point position 00 = Sample 5 01 = Sample 4 10 = Sample 6 11 = Sample 5
11	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
10 to 4	CASM[6:0]	Collision Avoidance Symbol Max Bit Configures gdCASRxLowMax
3 to 0	TSST[3:0]	Transmission Start Sequence Transmitter Bit Configures gdTSSTransmitter

(1) FLXAnFRPRTC1.RWP

Repetitions of Tx Wakeup Pattern Bit

The user can only write to these bits when bits FLXAnFRCCSV.POCS[5:0] are DEFAULT_CONFIG or CONFIG.

Valid values are 2 to 63.

Configures the number of repetitions (sequences) of the Tx wakeup symbol.

(2) FLXAnFRPRTC1.RXW

Wakeup Symbol Receive Window Length Bit

The user can only write to these bits when bits FLXAnFRCCSV.POCS[5:0] DEFAULT_CONFIG or CONFIG.

Valid values are 76 to 301 bit times.

Must be identical in all nodes of a cluster.

Configures the number of bit times used by the node to test the duration of the received wakeup pattern.

(3) FLXAnFRPRTC1.BRP

Baud Rate Prescaler Bit

The user can only write to these bits when bits FLXAnFRCCSV.POCS[5:0] are DEFAULT_CONFIG or CONFIG.

The Baud Rate Prescaler configures the baud rate on the FlexRay bus. The baud rates listed below are valid with a sample clock set to 80 MHz. One bit time always consists of 8 samples independent of the configured baud rate.

00 = 10 MBit/s

gdSampleClockPeriod = 12.5 ns = 1 × “sample clock”

pSamplesPerMicrotick = 2 (1 µT = 25 ns)

01 = 5 MBit/s

gdSampleClockPeriod = 25 ns = 2 × “sample clock”

pSamplesPerMicrotick = 1 (1 µT = 25 ns)

10, 11 = 2.5 MBit/s

gdSampleClockPeriod = 50 ns = 4 × “sample clock”

pSamplesPerMicrotick = 1 (1 µT = 50 ns)

(4) FLXAnFRPRTC1.SPP

Strobe Point Position Bit

The user can only write to these bits when bits FLXAnFRCCSV.POCS[5:0] are DEFAULT_CONFIG or CONFIG.

These bits specify the sample-counter position at which the Checker Core strobes in response to received bits.

The strobed bit value is determined by sampling at the timing specified by bits FLXAnFRPRTC1.SPP[1:0].

CAUTION

The current revision 2.1 of the FlexRay protocol requires that the FLXAnFRPRTC1.SPP[1:0] bits are 00. The alternate strobe point positions could be used to compensate for asymmetries in the physical layer.

(5) FLXAnFRPRTC1.CASM

Collision Avoidance Symbol Max Bit

The user can only write to these bits when bits FLXAnFRCCSV.POCS[5:0] are DEFAULT_CONFIG or CONFIG.

CASM6 is fixed to 1.

Valid values are 67 to 99 bit times.

Configures the upper limit of the acceptance window for a collision avoidance symbol (CAS).

(6) FLXAnFRPRTC1.TSST

Transmission Start Sequence Transmitter Bit

The user can only write to these bits when bits FLXAnFRCCSV.POCS[5:0] are is DEFAULT_CONFIG or CONFIG.

Valid values are 3 to 15 bit times.

Must be identical in all nodes of a cluster.

Configures the duration of the Transmission Start Sequence (TSS) in terms of bit times (1 bit time = 4 µT = 100ns @ 10Mbps).

24.3.6.6 FLXAnFRPRTC2 — FlexRay PRT Configuration Register 2

Access: This register can be read or written in 8-, 16-, or 32-bit units.

Address: <FLXAn_base> + 0094_H

Value after reset: $0F2D\ 0A0E_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 24.33 FLXAnFRPRTC2 Register Contents

Bit Position	Bit Name	Function
31, 30	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
29 to 24	TXL[5:0]	Wakeup Symbol Transmit Low Bit Configures gdWakeupSymbolTxLow
23 to 16	TXI[7:0]	Wakeup Symbol Transmit Idle Bit Configures gdWakeupSymbolTxIdle
15, 14	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
13 to 8	RXL[5:0]	Wakeup Symbol Receive Low Bit Configures gdWakeupSymbolRxLow
7, 6	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
5 to 0	RXI[5:0]	Wakeup Symbol Rx Idle Bit Configures gdWakeupSymbolRxIdle

(1) FLXAnFRPRTC2.TXL

Wakeup Symbol Transmit Low Bit

The user can only write to these bits when bits FLXAnFRCCSV.POCS[5:0] are DEFAULT_CONFIG or CONFIG.

Valid values are 15 to 60 bit times.

Must be identical in all nodes of a cluster.

Configures the number of bit times used by the node to transmit the low phase of the wakeup symbol.

(2) FLXAnFRPRTC2.TXI

Wakeup Symbol Transmit Idle Bit

The user can only write to these bits when bits FLXAnFRCCSV.POCS[5:0] are DEFAULT_CONFIG or CONFIG.

Valid values are 45 to 180 bit times.

Must be identical in all nodes of a cluster.

Configures the number of bit times used by the node to transmit the idle phase of the wakeup symbol.

(3) FLXAnFRPRTC2.RXL

Wakeup Symbol Receive Low Bit

The user can only write to these bits when bits FLXAnFRCCSV.POCS[5:0] are DEFAULT_CONFIG or CONFIG.

Valid values are 10 to 55 bit times.

Must be identical in all nodes of a cluster.

Configures the number of bit times used by the node to test the duration of the low phase of the received wakeup symbol.

(4) FLXAnFRPRTC2.RXI

Wakeup Symbol Rx Idle Bit

The user can only write to these bits when bits FLXAnFRCCSV.POCS[5:0] are DEFAULT_CONFIG or CONFIG.

Valid values are 14 to 59 bit times.

Must be identical in all nodes of a cluster.

Configures the number of bit times used by the node to test the duration of the idle phase of the received wakeup symbol.

24.3.6.7 FLXAnFRMHDC — FlexRay MHD Configuration Register

Access: This register can be read or written in 8-, 16-, or 32-bit units.

Address: <FLXAn_base> + 0098_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	SLT[12:0]												
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	SFDL[6:0]

R/W	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 24.34 FLXAnFRMHDC Register Contents

Bit Position	Bit Name	Function
31 to 29	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
28 to 16	SLT[12:0]	Start of Latest Transmit Bit Configures pLatestTx
15 to 7	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
6 to 0	SFDL[6:0]	Static Frame Data Length Bit Configures gPayloadLengthStatic

(1) FLXAnFRMHDC.SLT

Start of Latest Transmit Bit

The user can only write to these bits when bits FLXAnFRCCSV.POCS[5:0] are DEFAULT_CONFIG or CONFIG.

Valid values are 0 to 7981 minislots.

Configures the maximum minislot value allowed before inhibiting frame transmission in the dynamic segment of the cycle. There is no transmission in dynamic segment if FLXAnFRMHDC.SLT is set to zero.

(2) FLXAnFRMHDC.SFDL

Static Frame Data Length Bit

The user can only write to these bits when bits FLXAnFRCCSV.POCS[5:0] are DEFAULT_CONFIG or CONFIG.

Valid values are 0 to 127.

The payload length must be identical in all nodes of a cluster.

Configures the cluster-wide payload length for all frames sent in the static segment in double bytes.

24.3.6.8 FLXAnFRGTUC1 — FlexRay GTU Configuration Register 1

Access: This register can be read or written in 8-, 16-, or 32-bit units.

Address: <FLXAn_base> + $00A0_H$

Value after reset: $0000\ 0280_H$

Table 24.35 FLXAnFRGTUC1 Register Contents

Bit Position	Bit Name	Function
31 to 20	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
19 to 0	UT[19:0]	Setting of Communication Cycle in Microticks Bit Configures pMicroPerCycle

(1) FLXAnFRGTUC1.UT

Setting of Communication Cycle in Microticks Bit

The user can only write to these bits when bits FLXAnFRCCSV.POCS[5:0] are DEFAULT_CONFIG or CONFIG.

Valid values are 640 to 640000 µT.

Configures the duration of the communication cycle in microticks.

24.3.6.9 FLXAnFRGTUC2 — FlexRay GTU Configuration Register 2

Access: This register can be read or written in 8-, 16-, or 32-bit units.

Address: <FLXAn_base> + $00A4_H$

Value after reset: $0002\ 000A_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 24.36 FLXAnFRGTUC2 Register Contents

Bit Position	Bit Name	Function
31 to 20	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
19 to 16	SNM[3:0]	Sync Node Max Bit
15, 14	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
13 to 0	MPC[13:0]	Setting of Communication Cycle in Macrotick Bit Configures gMacroPerCycle

(1) FLXAnFRGTUC2.SNM

Sync Node Max Bit

The user can only write to these bits when bits FLXAnFRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

Valid values are 2 to 15.

Must be identical in all nodes of a cluster.

Maximum number of frames within a cluster with sync frame indicator bit SYN set to 1.

(2) FLXAnFRGTUC2.MPC

Setting of Communication Cycle in Macrotick Bit

The user can only write to these bits when bits FLXAnFRCCSV.POCS [5:0] are DEFAULT_CONFIG or CONFIG.

Valid values are 10 to 16000 MT.

The cycle length must be identical in all nodes of a cluster.

Configures the duration of one communication cycle in macroticks.

24.3.6.10 FLXAnFRGTUC3 — FlexRay GTU Configuration Register 3

Access: This register can be read or written in 8-, 16-, or 32-bit units.

Address: <FLXAn_base> + $00A8_H$

Value after reset: $0202\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	MIOB[6:0]							—	MIOA[6:0]

Table 24.37 FLXAnFRGTUC3 Register Contents

Bit Position	Bit Name	Function
31	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
30 to 24	MIOB[6:0]	Macrotick Initial Offset Channel B Bit Configures pMacroInitialOffset[B]
23	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
22 to 16	MIOA[6:0]	Macrotick Initial Offset Channel A Bit Configures pMacroInitialOffset[A]
15 to 8	UIOB[7:0]	Microtick Initial Offset Channel B Bit Configures pMicroInitialOffset[B]
7 to 0	UIOA[7:0]	Microtick Initial Offset Channel A Bit Configures pMicroInitialOffset[A]

(1) FLXAnFRGTUC3.MIOB

Macrotick Initial Offset Channel B Bit

The user can only write to these bits when bits FLXAnFRCCSV.POCS[5:0] are DEFAULT_CONFIG or CONFIG.

Valid values are 2 to 72 MT.

Must be identical in all nodes of a cluster.

Configures the number of macroticks between the static slot boundary and the subsequent macrotick boundary of the secondary time reference point based on the nominal macrotick duration.

(2) FLXAnFRGTUC3.MIOA

Macrotick Initial Offset Channel A Bit

The user can only write to these bits when bits FLXAnFRCCSV.POCS[5:0] are DEFAULT_CONFIG or CONFIG.

Valid values are 2 to 72 MT.

Must be identical in all nodes of a cluster.

Configures the number of macroticks between the static slot boundary and the subsequent macrotick boundary of the secondary time reference point based on the nominal macrotick duration.

(3) FLXAnFRGTUC3.UIOB

Microtick Initial Offset Channel B Bit

The user can only write to these bits when bits FLXAnFRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

Valid values are 0 to 240 µT.

Configures the number of microticks between the actual time reference point on channel B and the subsequent macrotick boundary of the secondary time reference point. The parameter depends on pDelayCompensation [B] and therefore has to be set for each channel independently.

(4) FLXAnFRGTUC3.UIOA

Microtick Initial Offset Channel A Bit

The user can only write to these bits when bits FLXAnFRCCSV.POCS [5:0] are DEFAULT_CONFIG or CONFIG.

Valid values are 0 to 240 µT.

Configures the number of microticks between the actual time reference point on channel A and the subsequent macrotick boundary of the secondary time reference point. The parameter depends on pDelayCompensation [A] and therefore has to be set for each channel independently.

24.3.6.11 FLXAnFRGTUC4 — FlexRay GTU Configuration Register 4

For details about configuration of FLXAnFRGTUC4.NIT and FLXAnFRGTUC4.OCS see **Section 24.4.2.5, Configuration of NIT Start and Offset Correction Start**.

Access: This register can be read or written in 8-, 16-, or 32-bit units.

Address: <FLXAn_base> + $00AC_H$

Value after reset: $0008\ 0007_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	OCS[13:0]													
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0
R/W	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	NIT[13:0]													
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1	1
R/W	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 24.38 FLXAnFRGTUC4 Register Contents

Bit Position	Bit Name	Function
31, 30	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
29 to 16	OCS[13:0]	Offset Correction Start Bit Configures (gOffsetCorrectionStart - 1)
15, 14	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
13 to 0	NIT[13:0]	Network Idle Time Start Bit Configures (gMacroPerCycle -gdNIT - 1)

(1) FLXAnFRGTUC4.OCS

Offset Correction Start Bit

The user can only write to these bits when bits FLXAnFRCCSV.POCS[5:0] are DEFAULT_CONFIG or CONFIG.

Valid values are 8 to 15998 MT.

For cluster consisting of E-Ray implementations only, it is sufficient to program FLXAnFRGTUC4.OCS = FLXAnFRGTUC4.NIT + 1.

Must be identical in all nodes of a cluster.

Determines the start of the offset correction within the NIT phase, calculated from start of cycle.

(2) FLXAnFRGTUC4.NIT

Network Idle Time Start Bit

The user can only write to these bits when bits FLXAnFRCCSV.POCS[5:0] are DEFAULT_CONFIG or CONFIG.

Valid values are 7 to 15997 MT.

Must be identical in all nodes of a cluster.

Configures the starting point of the Network Idle Time NIT at the end of the communication cycle expressed in terms of macroticks from the beginning of the cycle. The start of NIT is recognized if Macrotick = gMacroPerCycle -gdNIT -1 and the increment pulse of Macrotick is set.

24.3.6.12 FLXAnFRGTUC5 — FlexRay GTU Configuration Register 5

Access: This register can be read or written in 8-, 16-, or 32-bit units.

Address: <FLXAn_base> + $00B0_H$

Value after reset: $0E00\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	DEC[7:0]								—	—	—	CDD[4:0]

Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 24.39 FLXAnFRGTUC5 Register Contents

Bit Position	Bit Name	Function
31 to 24	DEC[7:0]	Decoding Correction Bit Configures pDecodingCorrection
23 to 21	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
20 to 16	CDD[4:0]	Cluster Drift Damping Bit Configures pClusterDriftDamping
15 to 8	DCB[7:0]	Delay Compensation Channel B Bit Configures pDelayCompensation[B]
7 to 0	DCA[7:0]	Delay Compensation Channel A Bit Configures pDelayCompensation[A]

(1) FLXAnFRGTUC5.DEC

Decoding Correction Bit

The user can only write to these bits when bits FLXAnFRCCSV.POCS[5:0] are DEFAULT_CONFIG or CONFIG.

Valid values are 14 to 143 µT.

Configures the decoding correction value in microticks used to determine the primary time reference point.

(2) FLXAnFRGTUC5.CDD

Cluster Drift Damping Bit

The user can only write to these bits when bits FLXAnFRCCSV.POCS[5:0] are DEFAULT_CONFIG or CONFIG.

Valid values are 0 to 20 µT.

Configures the cluster drift damping value in microticks used in clock synchronization to minimize accumulation of rounding errors.

(3) FLXAnFRGTUC5.DCB

Delay Compensation Channel B Bit

The user can only write to these bits when bits FLXAnFRCCSV.POCS[5:0] are DEFAULT_CONFIG or CONFIG.

Valid values are 0 to 200 µT.

Used to compensate for reception delays on channel B. This covers assumed propagation delay up to cPropagationDelayMax for microticks in the range of 0.0125 to 0.05µs. In practice, the minimum of the propagation delays of all sync nodes should be applied.

(4) FLXAnFRGTUC5.DCA

Delay Compensation Channel A Bit

The user can only write to these bits when bits FLXAnFRCCSV.POCS[5:0] are DEFAULT_CONFIG or CONFIG.

Valid values are 0 to 200 µT.

Used to compensate for reception delays on channel A. This covers assumed propagation delay up to cPropagationDelayMax for microticks in the range of 0.0125 to 0.05µs. In practice, the minimum of the propagation delays of all sync nodes should be applied.

24.3.6.13 FLXAnFRGTUC6 — FlexRay GTU Configuration Register 6

Access: This register can be read or written in 8-, 16-, or 32-bit units.

Address: <FLXAn_base> + $00B4_H$

Value after reset: $0002\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	MOD[10:0]										
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0
R/W	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

	—	—	—	—	—	ASR[10:0]										
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 24.40 FLXAnFRGTUC6 Register Contents

Bit Position	Bit Name	Function
31 to 27	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
26 to 16	MOD[10:0]	Maximum Oscillator Drift Bit Configures pdMaxDrift
15 to 11	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
10 to 0	ASR[10:0]	Accepted Startup Range Bit Configures pdAcceptedStartupRange

(1) FLXAnFRGTUC6.MOD

Maximum Oscillator Drift Bit

The user can only write to these bits when bits FLXAnFRCCSV.POCS[5:0] are DEFAULT_CONFIG or CONFIG.

Valid values are 2 to 1923 µT.

Maximum drift offset between two nodes that operate with unsynchronized clocks over one communication cycle in µT.

(2) FLXAnFRGTUC6.ASR

Accepted Startup Range Bit

The user can only write to these bits when bits FLXAnFRCCSV.POCS[5:0] are DEFAULT_CONFIG or CONFIG.

Valid values are 0 to 1875 µT.

Number of microticks constituting the expanded range of measured deviation for startup frames during integration.

24.3.6.14 FLXAnFRGTUC7 — FlexRay GTU Configuration Register 7

Access: This register can be read or written in 8-, 16-, or 32-bit units.

Address: <FLXAn_base> + $00B8_H$

Value after reset: $0002\ 0004_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	NSS[9:0]									
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0
R/W	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	SSL[9:0]									
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0	0
R/W	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 24.41 FLXAnFRGTUC7 Register Contents

Bit Position	Bit Name	Function
31 to 26	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
25 to 16	NSS[9:0]	Number of Static Slots Bit Configures gNumberOfStaticSlots
15 to 10	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
9 to 0	SSL[9:0]	Static Slot Length Bit Configures gdStaticSlot

(1) FLXAnFRGTUC7.NSS

Number of Static Slots Bit

The user can only write to these bits when bits FLXAnFRCCSV.POCS[5:0] are DEFAULT_CONFIG or CONFIG.

Valid values are 2 to 1023.

The number of static slots must be identical in all nodes of a cluster.

Configures the number of static slots in a cycle.

(2) FLXAnFRGTUC7.SSL

Static Slot Length Bit

The user can only write to these bits when bits FLXAnFRCCSV.POCS[5:0] are DEFAULT_CONFIG or CONFIG.

Valid values are 4 to 659 MT.

The static slot length must be identical in all nodes of a cluster.

Configures the length of a static slot in macroticks.

24.3.6.15 FLXAnFRGTUC8 — FlexRay GTU Configuration Register 8

Access: This register can be read or written in 8-, 16-, or 32-bit units.

Address: <FLXAn_base> + $00BC_H$

Value after reset: $0000\ 0002_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	NMS[12:0]												
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 24.42 FLXAnFRGTUC8 Register Contents

Bit Position	Bit Name	Function
31 to 29	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
28 to 16	NMS[12:0]	Number of Minislots Bit Configures gNumberOfMinislots
15 to 6	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
5 to 0	MSL[5:0]	Minislot Length Bit Configures gdMinislot

(1) FLXAnFRGTUC8.NMS

Number of Minislots Bit

The user can only write to these bits when bits FLXAnFRCCSV.POCS[5:0] are DEFAULT_CONFIG or CONFIG.

Valid values are 0 to 7986.

The number of minislots must be identical in all nodes of a cluster.

Configures the number of minislots within the dynamic segment of a cycle.

(2) FLXAnFRGTUC8.MSL

Minislot Length Bit

The user can only write to these bits when bits FLXAnFRCCSV.POCS[5:0] are DEFAULT_CONFIG or CONFIG.

Valid values are 2 to 63 MT.

The minislot length must be identical in all nodes of a cluster.

Configures the length of a minislot in macroticks.

24.3.6.16 FLXAnFRGTUC9 — FlexRay GTU Configuration Register 9

Access: This register can be read or written in 8-, 16-, or 32-bit units.

Address: <FLXAn_base> + $00C0_H$

Value after reset: $0000\ 0101_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	DSI[1:0]

Table 24.43 FLXAnFRGTUC9 Register Contents

Bit Position	Bit Name	Function
31 to 18	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
17, 16	DSI[1:0]	Dynamic Slot Idle Phase Bit Configures gdDynamicSlotIdlePhase
15 to 13	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
12 to 8	MAPO[4:0]	Minislot Action Point Offset Bit Configures gdMinislotActionPointOffset
7, 6	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
5 to 0	APO[5:0]	Action Point Offset Bit Configures gdActionPointOffset

(1) FLXAnFRGTUC9.DSI

Dynamic Slot Idle Phase Bit

The user can only write to these bits when bits FLXAnFRCCSV.POCS[5:0] are DEFAULT_CONFIG or CONFIG.

Valid values are 0 to 2 Minislot.

Must be identical in all nodes of a cluster.

Configures the duration of the dynamic slot idle phase in the number of minislots. The duration has to be greater or equal than the idle detection time.

(2) FLXAnFRGTUC9.MAPO

Minislot Action Point Offset Bit

The user can only write to these bits when bits FLXAnFRCCSV.POCS[5:0] are DEFAULT_CONFIG or CONFIG.

Valid values are 1 to 31 MT.

Must be identical in all nodes of a cluster.

Configures the action point offset in macroticks within the minislots of the dynamic segment.

(3) FLXAnFRGTUC9.APO

Action Point Offset Bit

The user can only write to these bits when bits FLXAnFRCCSV.POCS[5:0] are DEFAULT_CONFIG or CONFIG.

Valid values are 1 to 63 MT.

Must be identical in all nodes of a cluster.

Configures the action point offset in macroticks within static slots and symbol window.

24.3.6.17 FLXAnFRGTUC10 — FlexRay GTU Configuration Register 10

Access: This register can be read or written in 8-, 16-, or 32-bit units.

Address: <FLXAn_base> + $00C4_H$

Value after reset: $0002\ 0005_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 24.44 FLXAnFRGTUC10 Register Contents

Bit Position	Bit Name	Function
31 to 27	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
26 to 16	MRC[10:0]	Maximum Rate Correction Bit Configures pRateCorrectionOut
15, 14	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
13 to 0	MOC[13:0]	Maximum Offset Correction Bit Configures pOffsetCorrectionOut

(1) FLXAnFRGTUC10.MRC

Maximum Rate Correction Bit

The user can only write to these bits when bits FLXAnFRCCSV.POCS[5:0] are DEFAULT_CONFIG or CONFIG.

Valid values are 2 to 1923 µT.

Holds the maximum permitted rate correction value to be applied by the internal clock synchronization algorithm. The CC checks only the internal rate correction value against the maximum rate correction value (absolute value).

(2) FLXAnFRGTUC10.MOC

Maximum Offset Correction Bit

The user can only write to these bits when bits FLXAnFRCCSV.POCS[5:0] are DEFAULT_CONFIG or CONFIG.

Valid values are 5 to 15266 µT.

Holds the maximum permitted offset correction value (absolute value) to be applied by the internal clock synchronization algorithm (absolute value). The CC checks only the internal offset correction value against the maximum offset correction value.

24.3.6.18 FLXAnFRGTUC11 — FlexRay GTU Configuration Register 11

Access: This register can be read or written in 8-, 16-, or 32-bit units.

Address: <FLXAn_base> + $00C8_H$

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 24.45 FLXAnFRGTUC11 Register Contents

Bit Position	Bit Name	Function
31 to 27	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
26 to 24	ERC[2:0]	External Rate Correction Bit Configures pExternRateCorrection
23 to 19	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
18 to 16	EOC[2:0]	External Offset Correction Bit Configures pExternOffsetCorrection
15 to 10	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
9, 8	ERCC[1:0]	External Rate Correction Control Bit Configures vExternRateControl 00: External rate correction is prohibited. 01: External rate correction is prohibited. 10: Subtract 11: Add
7 to 2	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
1, 0	EOCC[1:0]	External Offset Correction Control Bit Configures vExternOffsetControl 00: External offset correction is prohibited. 01: External offset correction is prohibited. 10: Subtract 11: Add

(1) FLXAnFRGTUC11.ERC

External Rate Correction Bit

The user can only write to these bits when bits FLXAnFRCCSV.POCS[5:0] are DEFAULT_CONFIG or CONFIG.

Valid values are 0 to 7 µT.

Holds the external rate correction value in microticks to be applied by the internal clock synchronization algorithm. The value is subtracted / added from / to the calculated rate correction value. The value is applied during NIT.

(2) FLXAnFRGTUC11.EOC

External Offset Correction Bit

The user can only write to these bits when bits FLXAnFRCCSV.POCS[5:0] are DEFAULT_CONFIG or CONFIG.

Valid values are 0 to 7 µT.

Holds the external offset correction value in microticks to be applied by the internal clock synchronization algorithm. The value is subtracted / added from / to the calculated offset correction value. The value is applied during NIT.

(3) FLXAnFRGTUC11.ERCC

External Rate Correction Control Bit

Should be modified only outside NIT (Network Idle Time).

Writing the following values enables the external rate correction.

00 = External rate correction is prohibited.

01 = External rate correction is prohibited.

10 = Subtract

External rate correction value subtracted from calculated rate correction value

11 = Add

External rate correction value added to calculated rate correction value

(4) FLXAnFRGTUC11.EOCC

External Offset Correction Control Bit

Should be modified only outside NIT (Network Idle Time).

Writing the following values enables the external offset correction.

00 = External offset correction is prohibited.

01 = External offset correction is prohibited.

10 = Subtract

External offset correction value subtracted from calculated offset correction value

11 = Add

External offset correction value added to calculated offset correction value

24.3.7 CC Status Registers

During 8/16-bit accesses to status variables coded with more than 8/16-bit, the variable might be updated by the CC between two accesses (non-atomic read accesses).

24.3.7.1 FLXAnFRCCSV — FlexRay CC Status Vector Register

Access: This register is a read-only register that can be read in 8-, 16-, or 32-bit units.

Address: <FLXAn_base> + 0100_H

Value after reset: $0010\ 4000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	PSL[5:0]						RCA[4:0]					WSV[2:0]		
Value after reset	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Value after reset	0	1	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 24.46 FLXAnFRCCSV Register Contents (1/2)

Bit	Symbol	Function
31, 30	Reserved	When read, the value after reset is returned.
29 to 24	PSL[5:0]	POC Status Log Flag Status of FLXAnFRCCSV.POCS immediately before entering HALT state.
23 to 19	RCA[4:0]	Remaining Coldstart Attempts Flag Indicates vRemainingColdstartAttempts
18 to 16	WSV[2:0]	Wakeup Status Flag Indicates vPOC!WakeupStatus 000: UNDEFINED 001: RECEIVED_HEADER 010: RECEIVED_WUP 011: COLLISION_HEADER 100: COLLISION_WUP 101: COLLISION_UNKNOWN 110: TRANSMITTED 111: Reserved
15	Reserved	When read, the value after reset is returned.
14	CSI	Cold Start Inhibit Flag Indicates vColdStartInhibit 0: Cold starting of node enabled 1: Cold starting of node disabled
13	CSAI	Coldstart Abort Indicator Flag
12	CSNI	Coldstart Noise Indicator Flag Indicates vPOC!ColdstartNoise
11, 10	Reserved	When read, the value after reset is returned.
9, 8	SLM[1:0]	Slot Mode Flag Indicates vPOC!SlotMode 00: SINGLE 01: reserved 10: ALL_PENDING 11: ALL

Table 24.46 FLXAnFRCCSV Register Contents (2/2)

Bit	Symbol	Function
7	HRQ	Halt Request Flag Indicates vPOC!CHIHaltRequest
6	FSI	Freeze Status Indicator Flag Indicates vPOC!Freeze
5 to 0	POCS[5:0]	Protocol Operation Control Status Flag

(1) FLXAnFRCCSV.PSL

POC Status Log Flag

Set the value of bits FLXAnFRCCSV.POCS[5:0] immediately before entering HALT state.

Set to HALT when FREEZE command is applied during HALT state and FLXAnFRCCSV.FSI is not already set i.e. the HALT state was not reached by FREEZE command.

Reset to "000000_B" when leaving HALT state.

(2) FLXAnFRCCSV.RCA

Remaining Coldstart Attempts Flag

Indicates the number of remaining coldstart attempts (vRemainingColdstartAttempts).

The value after a reset during CONFIG and DEFAULT_CONFIG state is also bits FLXAnFRSUCC1.CSA[4:0].

The RUN command resets this counter to the maximum number of coldstart attempts as configured by the FLXAnFRSUCC1.CSA [4:0] bits.

(3) FLXAnFRCCSV.WSV

Wakeup Status Flag

Indicates the status of the current wakeup attempt (vPOC!WakeupStatus).

Reset to 0 when entering Wakeup state, by CHI command RESET_STATUS_INDICATORS, or by transition from DEFAULT_CONFIG to CONFIG state

000_B = UNDEFINED

Wakeup not yet executed by the CC.

001_B = RECEIVED_HEADER

Set when the CC finishes wakeup due to the reception of a frame header without coding violation on either channel in WAKEUP_LISTEN state.

010_B = RECEIVED_WUP

Set when the CC finishes wakeup due to the reception of a valid wakeup pattern on the configured wakeup channel in WAKEUP_LISTEN state.

011_B = COLLISION_HEADER

Set when the CC stops wakeup due to a detected collision during wakeup pattern transmission by receiving a valid header on either channel.

100_B = COLLISION_WUP

Set when the CC stops wakeup due to a detected collision during wakeup pattern transmission by receiving a valid wakeup pattern on the configured wakeup channel.

101_B = COLLISION_UNKNOWN

Set when the CC stops wakeup by leaving WAKEUP_DETECT state after expiration of the wakeup timer without receiving a valid wakeup pattern or a valid frame header.

110_B = TRANSMITTED

Set when the CC has successfully completed the transmission of the wakeup pattern.

111_B = reserved

(4) FLXAnFRCCSV.CSI

Cold Start Inhibit Flag

Indicates that the node is disabled from cold starting (vColdStartInhibit).

The flag is set to 1 whenever the POC enters READY state due to CHI command READY.

The flag has to be reset under control of the Host by CHI command ALLOW_COLDSTART (bits FLXAnFRSUCC1.CMD[3:0] are 1001_B).

(5) FLXAnFRCCSV.CSAI

Coldstart Abort Indicator Flag

Indicates that a coldstart attempt was aborted.

Reset by CHI command RESET_STATUS_INDICATORS or by transition from HALT to DEFAULT_CONFIG state or from READY to STARTUP state.

(6) FLXAnFRCCSV.CSNI

Coldstart Noise Indicator Flag

Indicates that the cold start procedure occurred under noisy conditions (vPOC!ColdstartNoise).

Reset by CHI command RESET_STATUS_INDICATORS or by transition from HALT to DEFAULT_CONFIG state or from READY to STARTUP state.

(7) FLXAnFRCCSV.SLM

Slot Mode Flag

Indicates the actual slot mode of the POC (vPOC!SlotMode) in states READY, WAKEUP, STARTUP, NORMAL_ACTIVE, and NORMAL_PASSIVE.

Default value is SINGLE. Changes to ALL, depending on FLXAnFRSUCC1.TSM.

In NORMAL_ACTIVE or NORMAL_PASSIVE state the CHI command ALL_SLOTS will change the slot mode from SINGLE over ALL_PENDING to ALL.

Set FLXAnFRSUCC1.TSM to SINGLE except for NORMAL_ACTIVE or NORMAL_PASSIVE.

(8) FLXAnFRCCSV.HRQ

Halt Request Flag

Indicates that a request from the Host has been received to halt the POC at the end of the communication cycle (vPOC!CHIHaltRequest).

Reset by transition from HALT to DEFAULT_CONFIG state or when entering READY state.

(9) FLXAnFRCCSV.FSI

Freeze Status Indicator Flag

Indicates that the POC has entered the HALT state due to CHI command, FREEZE (bits FLXAnFRSUCC1.CMD[3:0] are 0111_B) or due to an error condition requiring an immediate POC halt (vPOC!Freeze).

Reset by transition from HALT to DEFAULT_CONFIG state.

(10) FLXAnFRCCSV.POCS

Protocol Operation Control Status Flag

Indicates the actual state of operation of the CC Protocol Operation Control

$00\ 0000_B$ = DEFAULT_CONFIG state

$00\ 0001_B$ = READY state

$00\ 0010_B$ = NORMAL_ACTIVE state

$00\ 0011_B$ = NORMAL_PASSIVE state

$00\ 0100_B$ = HALT state

$00\ 1111_B$ = CONFIG state

Indicates the actual state of operation of the POC in the wakeup path

$01\ 0000_B$ = WAKEUP_STANDBY state

$01\ 0001_B$ = WAKEUP_LISTEN state

$01\ 0010_B$ = WAKEUP_SEND state

$01\ 0011_B$ = WAKEUP_DETECT state

Indicates the actual state of operation of the POC in the startup path

$10\ 0000_B$ = STARTUP_PREPARE state

$10\ 0001_B$ = COLDSTART_LISTEN state

$10\ 0010_B$ = COLDSTART_COLLISION_RESOLUTION state

$10\ 0011_B$ = COLDSTART_CONSISTENCY_CHECK state

$10\ 0100_B$ = COLDSTART_GAP state

$10\ 0101_B$ = COLDSTART_JOIN State

$10\ 0110_B$ = INTEGRATION_COLDSTART_CHECK state

$10\ 0111_B$ = INTEGRATION_LISTEN state

$10\ 1000_B$ = INTEGRATION_CONSISTENCY_CHECK state

$10\ 1001_B$ = INITIALIZE_SCHEDULE state

$10\ 1010_B$ = ABORT_STARTUP state

$10\ 1011_B$ = STARTUP_SUCCESS state

others = reserved

24.3.7.2 FLXAnFRCCEV — FlexRay CC Error Vector Register

Access: This register is a read-only register that can be read in 8-, 16-, or 32-bit units.

Address: <FLXAn_base> + 0104_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	PTAC[4:0]					ERRM[1:0]		—	—	CCFC[3:0]			
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 24.47 FLXAnFRCCEV Register Contents

Bit Position	Bit Name	Function
31 to 13	Reserved	When read, the value after reset is returned.
12 to 8	PTAC[4:0]	Passive to Active Count Flag Indicates vAllowPassiveToActive
7, 6	ERRM[1:0]	Error Mode Flag Indicates vPOC!ErrorMode 00: ACTIVE 01: PASSIVE 10: COMM_HALT 11: reserved
5, 4	Reserved	When read, the value after reset is returned.
3 to 0	CCFC[3:0]	Clock Correction Failed Counter Indicates vClockCorrectionFailed

(1) FLXAnFRCCEV.PTAC

Passive to Active Count Flag

Indicates the number of consecutive even / odd cycle pairs that have passed with valid rate and offset correction terms, while the node is waiting to transit from NORMAL_PASSIVE state to NORMAL_ACTIVE state. The transition takes place when this bit equals to the value of bits FLXAnFRSUCC1.PTA[4:0] –1.

Reset by transition from HALT to DEFAULT_CONFIG state or when entering READY state.

(2) FLXAnFRCCEV.ERRM

Error Mode Flag

Indicates the actual error mode of the POC (vPOC!ErrorMode).

Reset by transition from HALT to DEFAULT_CONFIG state or when entering READY state.

(3) FLXAnFRCCEV.CCFC

Clock Correction Failed Counter

Indicates the clock correction failed counter of the POC (vClockCorrectionFailed).

The Clock Correction Failed Counter is incremented by one at the end of any odd communication cycle where either the missing offset correction error or missing rate correction error are active.

The Clock Correction Failed Counter is reset to 0 at the end of an odd communication cycle if neither the offset correction failed nor the rate correction failed errors are active.

The Clock Correction Failed Counter stops at 15.

Reset by transition from HALT to DEFAULT_CONFIG state or when entering READY state.

24.3.7.3 FLXAnFRSCV — FlexRay Slot Counter Value Register

Access: This register is a read-only register that can be read in 8-, 16-, or 32-bit units.

Address: <FLXAn_base> + 0110_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	SCCB[10:0]

R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	SCCA[10:0]										
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 24.48 FLXAnFRSCV Register Contents

Bit Position	Bit Name	Function
31 to 27	Reserved	When read, the value after reset is returned.
26 to 16	SCCB[10:0]	Slot Counter Channel B Indicates vSlotCounter[B]
15 to 11	Reserved	When read, the value after reset is returned.
10 to 0	SCCA[10:0]	Slot Counter Channel A Indicates vSlotCounter[A]

(1) FLXAnFRSCV.SCCB

Slot Counter Channel B

Current slot counter value on channel B (vSlotCounter[B]). The value is incremented by the CC and reset at the start of a communication cycle.

Reset when leaving CONFIG state or when entering STARTUP state.

(2) FLXAnFRSCV.SCCA

Slot Counter Channel A

Current slot counter value on channel A (vSlotCounter[A]). The value is incremented by the CC and reset at the start of a communication cycle.

Reset when leaving CONFIG state or when entering STARTUP state.

24.3.7.4 FLXAnFRMTCCV — FlexRay Macrotick and Cycle Counter Value Register

Access: This register is a read-only register that can be read in 8-, 16-, or 32-bit units.

Address: <FLXAn_base> + 0114_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 24.49 FLXAnFRMTCCV Register Contents

Bit Position	Bit Name	Function
31 to 22	Reserved	When read, the value after reset is returned.
21 to 16	CCV[5:0]	Cycle Counter Value Indicates vCycleCounter
15, 14	Reserved	When read, the value after reset is returned.
13 to 0	MTV[13:0]	Macrotick Value Indicates vMacrotick

(1) FLXAnFRMTCCV.CCV

Cycle Counter Value

Current cycle counter value (vCycleCounter). The value is incremented by the CC at the start of a communication cycle.

Reset when leaving CONFIG state or when entering STARTUP state.

(2) FLXAnFRMTCCV.MTV

Macrotick Value

Current macrotick value (vMacrotick). The value is incremented by the CC and reset at the start of a communication cycle.

Reset when leaving CONFIG state or when entering STARTUP state.

24.3.7.5 FLXAnFRRCV — FlexRay Rate Correction Value Register

Access: This register is a read-only register that can be read in 8-, 16-, or 32-bit units.

Address: <FLXAn_base> + 0118_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Table 24.50 FLXAnFRRCV Register Contents

Bit Position	Bit Name	Function
31 to 12	Reserved	When read, the value after reset is returned.
11 to 0	RCV[11:0]	Rate Correction Value Flag Indicates vRateCorrection

(1) FLXAnFRRCV.RCV

Rate Correction Value Flag

Indicates internal rate correction value (vRateCorrection/ two's complement) before limitation. If the value of this bit exceeds the limits defined by bits FLXAnFRGTUC10.MRC[10:0], flag FLXAnFRSFS.RCLR is set to 1.

Reset when leaving CONFIG state or when entering STARTUP state.

CAUTION

The external rate correction value is added to the limited rate correction value.

24.3.7.6 FLXAnFROCV — FlexRay Offset Correction Value Register

Access: This register is a read-only register that can be read in 8-, 16-, or 32-bit units.

Address: <FLXAn_base> + $011C_H$

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	OCV[18:16]

Table 24.51 FLXAnFROCV Register Contents

Bit Position	Bit Name	Function
31 to 19	Reserved	When read, the value after reset is returned.
18 to 0	OCV[18:0]	Offset Correction Value Flag Indicates vOffsetCorrection

(1) FLXAnFROCV.OCV

Offset Correction Value Flag

Indicates offset correction value (vOffsetCorrection/ two's complement) before limitation. If the value of this bit exceeds the limits defined by bits FLXAnFRGTUC10.MOC[10:0], flag FLXAnFRSFS.OCLR is set to 1.

Reset when leaving CONFIG state or when entering STARTUP state.

CAUTION

The external offset correction value is added to the limited offset correction value.

24.3.7.7 FLXAnFRSFS — FlexRay Sync Frame Status Register

Access: This register is a read-only register that can be read in 8-, 16-, or 32-bit units.

Address: <FLXAn_base> + 0120_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	RCLR	MRCS	OCLR	MOCS
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	VSBO[3:0]				VSBE[3:0]				VSAO[3:0]				VSAE[3:0]			
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 24.52 FLXAnFRSFS Register Contents

Bit Position	Bit Name	Function
31 to 20	Reserved	When read, the value after reset is returned.
19	RCLR	Rate Correction Limit Reached Flag 0: Rate correction below limit 1: Rate correction limit reached
18	MRCS	Missing Rate Correction Signal Flag 0: Rate correction signal valid 1: Missing rate correction signal
17	OCLR	Offset Correction Limit Reached Flag 0: Offset correction below limit 1: Offset correction limit reached
16	MOCS	Missing Offset Correction Signal Flag 0: Offset correction signal valid 1: Missing offset correction signal
15 to 12	VSBO[3:0]	Valid Sync Frames Channel B, odd communication cycle
11 to 8	VSBE[3:0]	Valid Sync Frames Channel B, even communication cycle
7 to 4	VSAO[3:0]	Valid Sync Frames Channel A, odd communication cycle
3 to 0	VSAE[3:0]	Valid Sync Frames Channel A, even communication cycle

(1) FLXAnFRSFS.RCLR

Rate Correction Limit Reached Flag

The Rate Correction Limit Reached flag signals to the Host, that the rate correction value has exceeded its limit as defined by bits FLXAnFRGTUC10.MRC[10:0]. The flag is updated by the CC at start of offset correction phase.

Reset when leaving CONFIG state or when entering STARTUP state, INTEGRATION_COLDSTART_CHECK state or INTEGRATION_CONSISTENCY_CHECK state.

(2) FLXAnFRSFS.MRCS

Missing Rate Correction Signal Flag

The Missing Rate Correction flag signals to the Host, that no rate correction calculation can be performed because no pairs of even / odd sync frames were received. The flag is updated by the CC at start of offset correction phase.

Reset when leaving CONFIG state or when entering STARTUP state, INTEGRATION_COLDSTART_CHECK state or INTEGRATION_CONSISTENCY_CHECK state.

(3) FLXAnFRSFS.OCLR

Offset Correction Limit Reached Flag

The Offset Correction Limit Reached flag signals to the Host, that the offset correction value has exceeded its limit as defined by bits FLXAnFRGTUC10.MOC[10:0]. The flag is updated by the CC at start of offset correction phase.

Reset when leaving CONFIG state or when entering STARTUP state, INTEGRATION_COLDSTART_CHECK state or INTEGRATION_CONSISTENCY_CHECK state.

(4) FLXAnFRSFS.MOCS

Missing Offset Correction Signal Flag

The Missing Offset Correction flag signals to the Host, that no offset correction calculation can be performed because no sync frames were received. The flag is updated by the CC at start of offset correction phase.

Reset when leaving CONFIG state or when entering STARTUP state, INTEGRATION_COLDSTART_CHECK state or INTEGRATION_CONSISTENCY_CHECK state.

(5) FLXAnFRSFS.VSBO

Valid Sync Frames Channel B, odd communication cycle

These bits are only valid when bit FLXAnFRSUCC1.CCHB is 1.

Holds the number of valid sync frames received on channel B in the odd communication cycle. If transmission of sync frames is enabled by bit FLXAnFRSUCC1.TXSY the value is incremented by one. The value is updated during the NIT of each odd communication cycle.

Reset when leaving CONFIG state or when entering STARTUP state, INTEGRATION_COLDSTART_CHECK state or INTEGRATION_CONSISTENCY_CHECK state.

(6) FLXAnFRSFS.VSBE

Valid Sync Frames Channel B, even communication cycle

These bits are only valid when bit FLXAnFRSUCC1.CCHB is 1.

Holds the number of valid sync frames received on channel B in the even communication cycle. If transmission of sync frames is enabled by bit FLXAnFRSUCC1.TXSY the value is incremented by one. The value is updated during the NIT of each even communication cycle.

Reset when leaving CONFIG state or when entering STARTUP state, INTEGRATION_COLDSTART_CHECK state or INTEGRATION_CONSISTENCY_CHECK state.

(7) FLXAnFRSFS.VSAO

Valid Sync Frames Channel A, odd communication cycle

These bits are only valid when bit FLXAnFRSUCC1.CCHA is 1.

Holds the number of valid sync frames received on channel A in the odd communication cycle. If transmission of sync frames is enabled by bit FLXAnFRSUCC1.TXSY the value is incremented by one. The value is updated during the NIT of each odd communication cycle.

Reset when leaving CONFIG state or when entering STARTUP state, INTEGRATION_COLDSTART_CHECK state or INTEGRATION_CONSISTENCY_CHECK state.

(8) FLXAnFRSFS.VSAE

Valid Sync Frames Channel A, even communication cycle

These bits are only valid when bit FLXAnFRSUCC1.CCHA is 1.

Holds the number of valid sync frames received on channel A in the even communication cycle. If transmission of sync frames is enabled by bit FLXAnFRSUCC1.TXSY, the value is incremented by one. The value is updated during the NIT of each even communication cycle.

Reset when leaving CONFIG state or when entering STARTUP state, INTEGRATION_COLDSTART_CHECK state or INTEGRATION_CONSISTENCY_CHECK state.

24.3.7.8 FLXAnFRSWNIT — FlexRay Symbol Window and NIT Status Register

Symbol window related status information is updated by the CC at the end of the symbol window for each channel. NIT related status information is updated by the CC at the end of the NIT for each channel.

During startup the status data is not updated.

Access: This register is a read-only register that can be read in 8-, 16-, or 32-bit units.

Address: <FLXAn_base> + 0124_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Table 24.53 FLXAnFRSWNIT Register Contents (1/2)

Bit	Symbol	Function
31 to 12	Reserved	When read, the value after reset is returned.
11	SBNB	Slot Boundary Violation during NIT Channel B Flag 0: No slot boundary violation detected 1: Slot boundary violation during NIT detected on channel B
10	SENB	Syntax Error during NIT Channel B Flag 0: No syntax error detected 1: Syntax error during NIT detected on channel B
9	SBNA	Slot Boundary Violation during NIT Channel A Flag 0: No slot boundary violation detected 1: Slot boundary violation during NIT detected on channel A
8	SENA	Syntax Error during NIT Channel A Flag 0: No syntax error detected 1: Syntax error during NIT detected on channel A
7	MTSB	MTS Received on Channel B Flag 0: No MTS symbol received on channel B 1: MTS symbol received on channel B
6	MTSA	MTS Received on Channel A Flag 0: No MTS symbol received on channel A 1: MTS symbol received on channel A
5	TCSB	Transmission Conflict in Symbol Window Channel B Flag 0: No transmission conflict detected 1: Transmission conflict in symbol window detected on channel B
4	SBSB	Slot Boundary Violation in Symbol Window Channel B Flag 0: No slot boundary violation detected 1: Slot boundary violation during symbol window detected on channel B
3	SESB	Syntax Error in Symbol Window Channel B Flag 0: No syntax error detected 1: Syntax error during symbol window detected on channel B

Table 24.53 FLXAnFRSWNIT Register Contents (2/2)

Bit	Symbol	Function
2	TCSA	Transmission Conflict in Symbol Window Channel A Flag 0: No transmission conflict detected 1: Transmission conflict in symbol window detected on channel A
1	SBSA	Slot Boundary Violation in Symbol Window Channel A Flag 0: No slot boundary violation detected 1: Slot boundary violation during symbol window detected on channel A
0	SESA	Syntax Error in Symbol Window Channel A Flag 0: No syntax error detected 1: Syntax error during symbol window detected on channel A

(1) FLXAnFRSWNIT.SBNB

Indicates a Slot Boundary Violation during NIT Channel B Flag (vSS!BViolationB).

Reset when leaving CONFIG state or when entering STARTUP state.

(2) FLXAnFRSWNIT.SENB

Indicates a Syntax Error during NIT Channel B Flag (vSS!SyntaxErrorB).

Reset when leaving CONFIG state or when entering STARTUP state.

(3) FLXAnFRSWNIT.SBNA

Indicates a Slot Boundary Violation during NIT Channel A Flag (vSS!BViolationA).

Reset when leaving CONFIG state or when entering STARTUP state.

(4) FLXAnFRSWNIT.SENA

Indicates a Syntax Error during NIT Channel A Flag (vSS!SyntaxErrorA).

Reset when leaving CONFIG state or when entering STARTUP state.

(5) FLXAnFRSWNIT.MTSB

Indicates a MTS Received on Channel B Flag (vSS!ValidMTSB).

Media Access Test symbol received on channel B during the preceding symbol window. Updated by the CC for each channel at the end of the symbol window.

When this bit is set to 1, also bit FLXAnFRSIR.MTSB is set to 1.

Reset when leaving CONFIG state or when entering STARTUP state.

(6) FLXAnFRSWNIT.MTSA

Indicates a MTS Received on Channel A Flag (vSS!ValidMTSA).

Media Access Test symbol received on channel A during the preceding symbol window. Updated by the CC for each channel at the end of the symbol window.

When this bit is set to 1, also bit FLXAnFRSIR.MTSA is set to 1.

Reset when leaving CONFIG state or when entering STARTUP state.

(7) FLXAnFRSWNIT.TCSB

Indicates a Transmission Conflict in Symbol Window Channel B Flag (vSS!TxConflictB).

Reset when leaving CONFIG state or when entering STARTUP state.

(8) FLXAnFRSWNIT.SBSB

Indicates a Slot Boundary Violation in Symbol Window Channel B Flag (vSS!BViolationB).

Reset when leaving CONFIG state or when entering STARTUP state.

(9) FLXAnFRSWNIT.SESB

Indicates a Syntax Error in Symbol Window Channel B Flag (vSS!SyntaxErrorB).

Reset when leaving CONFIG state or when entering STARTUP state.

(10) FLXAnFRSWNIT.TCSA

Indicates a Transmission Conflict in Symbol Window Channel A Flag (vSS!TxConflictA).

Reset when leaving CONFIG state or when entering STARTUP state.

(11) FLXAnFRSWNIT.SBSA

Indicates a Slot Boundary Violation in Symbol Window Channel A Flag (vSS!BViolationA).

Reset when leaving CONFIG state or when entering STARTUP state.

(12) FLXAnFRSWNIT.SESA

Indicates a Syntax Error in Symbol Window Channel A Flag (vSS!SyntaxErrorA).

Reset when leaving CONFIG state or when entering STARTUP state.

24.3.7.9 FLXAnFRACS — FlexRay Aggregated Channel Status Register

Do not rewrite this register using bit manipulation instructions.

The aggregated channel status provides the Host with an accrued status of channel activity for all communication slots regardless of whether they are assigned for transmission or subscribed for reception.

The aggregated channel status also includes status data from the symbol window and the network idle time.

The status data is updated (set) after each slot and aggregated until it is reset by the Host.

During startup the status data is not updated.

Access: This register can be read or written in 8-, 16-, or 32-bit units.

Address: <FLXAn_base> + 0128_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 24.54 FLXAnFRACS Register Contents (1/2)

Bit Position	Bit Name	Function
31 to 13	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
12	SBVB	Slot Boundary Violation on Channel B Flag 0: No slot boundary violation observed 1: Slot boundary violation(s) observed on channel B
11	CIB	Communication Indicator Channel B Flag 0: No valid frame(s) received in slots containing any additional communication 1: Valid frame(s) received on channel B in slots containing any additional communication
10	CEDB	Content Error Detected on Channel B Flag 0: No frame with content error received 1: Frame(s) with content error received on channel B
9	SEDB	Syntax Error Detected on Channel B Flag 0: No syntax error observed 1: Syntax error(s) observed on channel B
8	VFRB	Valid Frame Received on Channel B Flag 0: No valid frame received 1: Valid frame(s) received on channel B
7 to 5	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
4	SBVA	Slot Boundary Violation on Channel A Flag 0: No slot boundary violation observed 1: Slot boundary violation(s) observed on channel A

Table 24.54 FLXAnFRACS Register Contents (2/2)

Bit Position	Bit Name	Function
3	CIA	Communication Indicator Channel A Flag 0: No valid frame(s) received in slots containing any additional communication 1: Valid frame(s) received on channel A in slots containing any additional communication
2	CEDA	Content Error Detected on Channel A Flag 0: No frame with content error received 1: Frame(s) with content error received on channel A
1	SEDA	Syntax Error Detected on Channel A Flag 0: No syntax error observed 1: Syntax error(s) observed on channel A
0	VFRA	Valid Frame Received on Channel A Flag 0: No valid frame received 1: Valid frame(s) received on channel A

(1) FLXAnFRACS.SBVB

Slot Boundary Violation on Channel B Flag

Writing 0 has no effect on the bit value.

This bit is cleared when writing a 1 to it.

One or more slot boundary violations were observed on channel B at any time during the observation period (static or dynamic slots, symbol window, and NIT).

When this flag changes from 0 to 1, bit FLXAnFREIR.EDB is set to 1.

Reset when leaving CONFIG state or when entering STARTUP state.

(2) FLXAnFRACS.CIB

Communication Indicator Channel B Flag

Writing 0 has no effect on the bit value.

This bit is cleared when writing a 1 to it.

One or more valid frames were received on channel B in slots that also contained any additional communication during the observation period, i.e. one or more slots received a valid frame AND had When any combination of either syntax error OR content error OR slot boundary violation.

When this flag changes from 0 to 1, bit FLXAnFREIR.EDB is set to 1.

Reset when leaving CONFIG state or when entering STARTUP state.

The FLXAnFRACS.CIB flag is also set when the slot boundary at the end of the slot is reached during the channel idle recognition phase while there is only a single frame in the slot.

(3) FLXAnFRACS.CEDB

Content Error Detected on Channel B Flag

Writing 0 has no effect on the bit value.

This bit is cleared when writing a 1 to it.

One or more frames with a content error were received on channel B in any static or dynamic slot during the observation period.

When this flag changes from 0 to 1, bit FLXAnFREIR.EDB is set to 1.

Reset when leaving CONFIG state or when entering STARTUP state.

(4) FLXAnFRACS.SEDB

Syntax Error Detected on Channel B Flag

Writing 0 has no effect on the bit value.

This bit is cleared when writing a 1 to it.

One or more syntax errors in static or dynamic slots, symbol window, and NIT were observed on channel B.

When this flag changes from 0 to 1, bit FLXAnFREIR.EDB is set to 1.

Reset when leaving CONFIG state or when entering STARTUP state.

(5) FLXAnFRACS.VFRB

Valid Frame Received on Channel B Flag

Writing 0 has no effect on the bit value.

This bit is cleared when writing a 1 to it.

One or more valid frames were received on channel B in any static or dynamic slot during the observation period.

Reset when leaving CONFIG state or when entering STARTUP state.

(6) FLXAnFRACS.SBVA

Slot Boundary Violation on Channel A Flag

Writing 0 has no effect on the bit value.

This bit is cleared when writing a 1 to it.

Slot boundary violations were observed on channel A at any time during the observation period (static or dynamic slots, symbol window, and NIT).

When this flag changes from 0 to 1, bit FLXAnFREIR.EDA is set to 1.

Reset when leaving CONFIG state or when entering STARTUP state.

(7) FLXAnFRACS.CIA

Communication Indicator Channel A Flag

Writing 0 has no effect on the bit value.

This bit is cleared when writing a 1 to it.

One or more valid frames were received on channel A in slots that also contained any additional communication during the observation period, i.e. one or more slots received a valid frame AND had any combination of either syntax error OR content error OR slot boundary violation.

When this flag changes from 0 to 1, the FLXAnFREIR.EDA bit is set to 1.

Reset when leaving CONFIG state or when entering STARTUP state.

The FLXAnFRACS.CIA flag is also set when the slot boundary at the end of the slot is reached during the channel idle recognition phase while there is only a single frame in the slot.

(8) FLXAnFRACS.CEDA

Content Error Detected on Channel A Flag

Writing 0 has no effect on the bit value.

This bit is cleared when writing a 1 to it.

One or more frames with a content error were received on channel A in any static or dynamic slot during the observation period.

When this flag changes from 0 to 1, bit FLXAnFREIR.EDA is set to 1.

Reset when leaving CONFIG state or when entering STARTUP state.

(9) FLXAnFRACS.SEDA

Syntax Error Detected on Channel A Flag

Writing 0 has no effect on the bit value.

This bit is cleared when writing a 1 to it.

One or more syntax errors in static or dynamic slots, symbol window, and NIT were observed on channel A.

When this flag changes from 0 to 1, bit FLXAnFREIR.EDA is set to 1.

Reset when leaving CONFIG state or when entering STARTUP state.

(10) FLXAnFRACS.VFRA

Valid Frame Received on Channel A Flag

Writing 0 has no effect on the bit value.

This bit is cleared when writing a 1 to it.

One or more valid frames were received on channel A in any static or dynamic slot during the observation period.

Reset when leaving CONFIG state or when entering STARTUP state.

24.3.7.10 FLXAnFRESIDm — FlexRay Even Sync ID Register m (m = 1 to 15)

Registers FLXAnFRESID1 to FLXAnFRESID15 hold the frame IDs of the sync frames received in even communication cycles used for clock synchronization up to the limit of gSyncNodeMax. The values are sorted in ascending order, with register FLXAnFRESID1 holding the lowest received sync frame ID. If the node itself transmits a sync frame in an even communication cycle, register FLXAnFRESID1 holds the respective sync frame ID as configured in message buffer 0 and flags FLXAnFRESID1.RXEA, FLXAnFRESID1.RXEB are set. The value is updated during the NIT of each even communication cycle.

Access: This register is a read-only register that can be read in 8-, 16-, or 32-bit units.

Address: <FLXAn_base> + 0130_H to <FLXAn_base> + 0168_H (<FLXAn_base> + 0130_H+(n-1) × 4)

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	RXEB	RXEA	—	—	—	—	EID[9:0]									
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 24.55 FLXAnFRESIDn (n=1 to 15) Register Contents

Bit Position	Bit Name	Function
31 to 16	Reserved	When read, the value after reset is returned.
15	RXEB	Received / Configured Even Sync ID on Channel B Flag 0: No sync frame received on channel B / node not configured to transmit sync frames 1: Sync frame received on channel B / node configured to transmit sync frames
14	RXEA	Received / Configured Even Sync ID on Channel A Flag 0: No sync frame received on channel A / node not configured to transmit sync frames 1: Sync frame received on channel A / node configured to transmit sync frames
13 to 10	Reserved	When read, the value after reset is returned.
9 to 0	EID[9:0]	Even Sync ID Flag (vsSyncIDListA,B even)

(1) FLXAnFRESIDn.RXEB

Received / Configured Even Sync ID on Channel B Flag

Signals that a sync frame corresponding to the stored even sync ID was received on channel B or that the node is configured to be a sync node with key slot = bits FLXAnFRESID1.EID[9:0].

Reset when leaving CONFIG state or when entering STARTUP state.

(2) FLXAnFRESIDn.RXEA

Received / Configured Even Sync ID on Channel A Flag

Signals that a sync frame corresponding to the stored even sync ID was received on channel A or that the node is configured to be a sync node with key slot = bits FLXAnFRESID1.EID[9:0].

Reset when leaving CONFIG state or when entering STARTUP state.

(3) FLXAnFRESIDn.EID

Even Sync ID Flag (vsSyncIDListA,B even)

Sync frame ID even communication cycle.

Reset when leaving CONFIG state or when entering STARTUP state.

24.3.7.11 FLXAnFROSIDm — FlexRay Odd Sync ID Register m (m = 1 to 15)

Registers FLXAnFROSID1 to FLXAnFROSID15 hold the frame IDs of the sync frames received in odd communication cycles used for clock synchronization up to the limit of gSyncNodeMax. The values are sorted in ascending order, with register FLXAnFROSID1 holding the lowest received sync frame ID. If the node itself transmits a sync frame in an odd communication cycle, register FLXAnFROSID1 holds the respective sync frame ID as configured in message buffer 0 and flags FLXAnFROSID1.RXOA, FLXAnFROSID1.RXOB are set. The value is updated during the NIT of each odd communication cycle.

Access: This register is a read-only register that can be read in 8-, 16-, or 32-bit units.

Address: <FLXAn_base> + 0170_H to <FLXAn_base> + $01A8_H$ (<FLXAn_base> + 0170_H+ (n-1) × 4)

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	RXOB	RXOA	—	—	—	—	OID[9:0]									
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 24.56 FLXAnFROSIDn Register Contents

Bit Position	Bit Name	Function
31 to 16	Reserved	When read, the value after reset is returned.
15	RXOB	Received / Configured Odd Sync ID on Channel B Flag 0: No sync frame received on channel B / node not configured to transmit sync frames 1: Sync frame received on channel B / node configured to transmit sync frames
14	RXOA	Received / Configured Odd Sync ID on Channel A Flag 0: No sync frame received on channel A / node not configured to transmit sync frames 1: Sync frame received on channel A / node configured to transmit sync frames
13 to 10	Reserved	When read, the value after reset is returned.
9 to 0	OID[9:0]	Odd Sync ID Flag (vsSyncIDListA,B odd)

(1) FLXAnFROSIDn.RXOB

Received / Configured Odd Sync ID on Channel B Flag

Signals that a sync frame corresponding to the stored odd sync ID was received on channel B or that the node is configured to be a sync node with key slot = bits FLXAnFROSID1.OID[9:0].

Reset when leaving CONFIG state or when entering STARTUP state.

(2) FLXAnFROSIDn.RXOA

Received / Configured Odd Sync ID on Channel A Flag

Signals that a sync frame corresponding to the stored odd sync ID was received on channel A or that the node is configured to be a sync node with key slot = bits FLXAnFROSID1.OID[9:0].

Reset when leaving CONFIG state or when entering STARTUP state.

(3) FLXAnFROSIDn.OID

Odd Sync ID Flag (vsSyncIDListA,B odd)

Sync frame ID odd communication cycle.

Reset when leaving CONFIG state or when entering STARTUP state.

24.3.7.12 FLXAnFRNMVm — FlexRay Network Management Vector Register m (m = 1 to 3)

The three network management registers hold the accrued NM vector (see **Section 24.4.7, Network Management**).

The CC updates the NM vector at the end of each communication cycle as long as the CC is either in NORMAL_ACTIVE or NORMAL_PASSIVE state.

FLXAnFRNMVm-bytes exceeding the configured NM vector length are not valid.

Access: This register is a read-only register that can be read in 8-, 16-, or 32-bit units.

Address: <FLXAn_base> + $01B0_H$ to <FLXAn_base> + $01B8_H$ (<FLXAn_base> + $01B0_H$ + (m-1) × 4)

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	NM[31:16]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	NM[15:0]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 24.57 FLXAnFRNMVn Register Contents

Bit Position	Bit Name	Function
31 to 0	NM[31:0]	NM Vector

(1) FLXAnFRNMVm.NM

NM Vector

The three network management vector registers hold the accrued NM vector (configurable 0 to 12 bytes). The NM vector to be held is generated by bit-wise logic OR for each NM vector received on each channel (valid static frames with PPI = 1) (see **Section 24.4.7, Network Management**).

FLXAnFRNMVm-bytes exceeding the configured NM vector length are not valid.

The Register Contents are updated at the end of each communication cycle as long as the CC is either in NORMAL_ACTIVE or NORMAL_PASSIVE state.

These bits are cleared when leaving CONFIG state or when entering STARTUP state.

24.3.8 Message Buffer Control Registers

24.3.8.1 FLXAnFRMRC — FlexRay Message RAM Configuration Register

The Message RAM Configuration register defines the number of message buffers assigned to the static segment, dynamic segment, and FIFO.

The Message RAM can be divided into up three different areas; Static Buffer area, Static and Dynamic Buffer area, FIFO area. If present, the Static Buffer area is starting at Message Buffer 0.

The start of the Static and Dynamic Buffer area is configured by bits FLXAnFRMRC.FDB[7:0]. Bits FLXAnFRMRC.FDB[7:0] define the end of the Static Buffer area. If no Static Buffer area is present, the Static and Dynamic Buffer area starts at Message Buffer 0.

The start of the FIFO area is configured by bits FLXAnFRMRC.FFB[7:0]. Bits FLXAnFRMRC.FFB[7:0] define the end of the previous area, which can be either the Static Buffer area or the Static and Dynamic Buffer area. If no Static Buffer area and no Static and Dynamic Buffer area is present, the FIFO area starts at Message Buffer 0.

With bits FLXAnFRMRC.LCB[7:0], the end of the last configured area is configured which can be the Static Buffer area, the Static and Dynamic Buffer area or the FIFO area.

Figure 24.2 shows an example configuration of the Message RAM where all there area are configured.

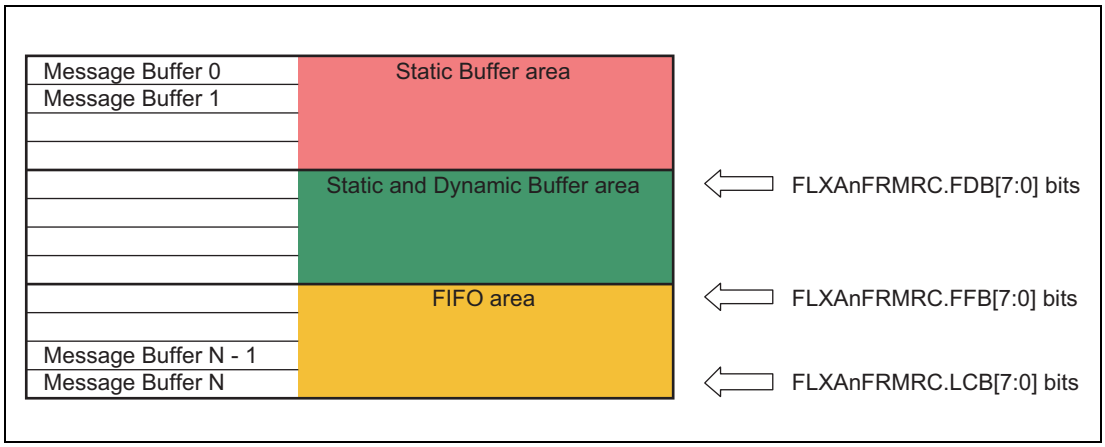

Figure 24.2 Message RAM Organization

CAUTIONS

1. **In case the node is configured as sync node (bit FLXAnFRSUCC1.TXSY = 1) or for single slot mode operation (bit FLXAnFRSUCC1.TSM = 1), message buffer 0 resp. 1 is reserved for sync frames or single slot frames and have to be configured with the node-specific key slot ID. In case the node is neither configured as sync node nor for single slot operation message buffer 0 resp. 1 is treated like all other message buffers.**
2. **The maximum number of header sections is 128. This means a maximum of 128 message buffers can be configured. The maximum length of a data section is 254 bytes. The length of the data section may be configured differently for each message buffer. For details see Section 24.4.13, Message RAM.**
3. **In case two or more message buffers are assigned to slot 1 by use of cycle filtering, all of them must be located either in the “Static Buffers” or at the beginning of the “Static + Dynamic Buffers” section.**

4. **The FlexRay protocol specification requires that each node has to send a frame in its key slot. Therefore at least message buffer 0 is reserved for transmission in the key slot. Due to this requirement a maximum number of 127 message buffers can be assigned to the FIFO. Nevertheless, a non protocol conform configuration without a transmission slot in the static segment would still be operational.**
5. **The payload length configured and the length of the data section need to be configured identical for all message buffers belonging to the FIFO via the FLXAnFRWRHS2.PLC[6:0] and FLXAnFRWRHS3.DP[6:0] bits. When the CC is not in DEFAULT_CONFIG or CONFIG state reconfiguration of message buffers belonging to the FIFO is locked.**

Access: This register can be read or written in 8-, 16-, or 32-bit units.

Address: <FLXAn_base> + 0300_H

Value after reset: $0180\ 0000_H$

Table 24.58 FLXAnFRMRC Register Contents

Bit Position	Bit Name	Function
31 to 27	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
26	SPLM	Sync Frame Payload Multiplex Bit 0: Only message buffer 0 locked against reconfiguration 1: Both message buffers 0 and 1 are locked against reconfiguration
25, 24	SEC[1:0]	Secure Buffers Bit 00: all buffers unlocked 01: static buffers locked, FIFO locked, limited transmission 10: all buffers locked 11: all buffers locked, limited transmission
23 to 16	LCB[7:0]	Last Configured Buffer Bit 0 to 127: Number of message buffers is FLXAnFRMRC.LCB + 1 128: No message buffer assigned to the FIFO
15 to 8	FFB[7:0]	First Buffer of FIFO Bit 0: All message buffers assigned to the FIFO 1 to 127: Message buffers from FLXAnFRMRC.FFB to FLXAnFRMRC.LCB assigned to the FIFO 128: No message buffer configured
7 to 0	FDB[7:0]	First Dynamic Buffer Bit 0: No group of message buffers exclusively for the static segment configured 1 to 127: Message buffers 0 to FLXAnFRMRC.FDB - 1 reserved for static segment 128: No dynamic message buffers configured

(1) FLXAnFRMRC.SPLM

Sync Frame Payload Multiplex Bit

The user can only write to these bits when FLXAnFRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

This bit is only evaluated if the node is configured as sync node (bit FLXAnFRSUCC1.TXSY = 1) or for single slot mode operation (bit FLXAnFRSUCC1.TSM = 1).

When this bit is set to 1 message buffers 0 and 1 are dedicated for sync frame transmission with different payload data on channel A and B.

When this bit is set to 0, sync frames are transmitted from message buffer 0 with the same payload data on all channels configured. Note that the channel filter configuration for message buffer 0 resp. message buffer 1 has to be chosen according to this bit setting.

(2) FLXAnFRMRC.SEC

Secure Buffers Bit

The user can only write to these bits when bits FLXAnFRCCSV.POCS[5:0] are DEFAULT_CONFIG or CONFIG.

Not evaluated when the CC is in DEFAULT_CONFIG or CONFIG state.

For temporary unlocking, see **Section 24.4.13.4, Host Handling of Access Errors**.

00_B = all buffers unlocked

Reconfiguration of message buffers enabled with numbers < FLXAnFRMRC.FFB enabled

Exception: In nodes configured for sync frame transmission or for single slot mode operation message buffer 0 (and if bit FLXAnFRMRC.SPLM = 1, also message buffer 1) is always locked

01_B = static buffers locked, FIFO locked, limited transmission

Reconfiguration of message buffers with numbers < FLXAnFRMRC.FDB and with numbers ≥ FLXAnFRMRC.FFB locked and transmission of message buffers for static segment with numbers ≥ FLXAnFRMRC.FDB disabled

10_B = all buffers locked

Reconfiguration of all message buffers locked

11_B = all buffers locked, limited transmission

Reconfiguration of all message buffers locked and transmission of message buffers for static segment with numbers ≥ FLXAnFRMRC.FDB disabled

(3) FLXAnFRMRC.LCB

Last Configured Buffer Bit

The user can only write to these bits when bits FLXAnFRCCSV.POCS[5:0] are DEFAULT_CONFIG or CONFIG.

When a Static and Dynamic Buffer area is configured (bits FLXAnFRMRC.FDB[7:0] < 128), the user should configure FLXAnFRMRC.LCB ≥ FLXAnFRMRC.FDB.

When a FIFO area is configured (bits FLXAnFRMRC.FFB[7:0] < 128), the user should configure bits FLXAnFRMRC.LCB[7:0] ≥ bits FLXAnFRMRC.FFB[7:0].

(4) FLXAnFRMRC.FFB

First Buffer of FIFO Bit

The user can only write to these bits when bits FLXAnFRCCSV.POCS[5:0] are DEFAULT_CONFIG or CONFIG.

When a Static and Dynamic Buffer area is configured (bits FLXAnFRMRC.FDB[7:0] < 128), the user should configure bits FLXAnFRMRC.FFB[7:0] > bits FLXAnFRMRC.FDB[7:0].

(5) FLXAnFRMRC.FDB

First Dynamic Buffer Bit

The user can only write to these bits when bits FLXAnFRCCSV.POCS[5:0] are DEFAULT_CONFIG or CONFIG.

24.3.8.2 FLXAnFRFRF — FlexRay FIFO Rejection Filter Register

The FIFO Rejection Filter defines a user specified sequence of bits to which channel, frame ID, and cycle count of the incoming frames are compared. Together with the FIFO Rejection Filter Mask this register determines whether a message is rejected by the FIFO.

Access: This register can be read or written in 8-, 16-, or 32-bit units.

Address: <FLXAn_base> + 0304_H

Value after reset: $0180\ 0000_H$

Table 24.59 FLXAnFRFRF Register Contents

Bit Position	Bit Name	Function
31 to 25	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
24	RNF	Reject Null Frames Bit 0: Null frames are stored in the FIFO 1: Reject all null frames
23	RSS	Reject in Static Segment Bit 0: FIFO also used for static segment 1: Reject messages in static segment
22 to 16	CYF[6:0]	Cycle Counter Filter Bit
15 to 13	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
12 to 2	FID[10:0]	Frame ID Filter Bit 0 to 2047: Frame ID filter values
1, 0	CH[1:0]	Channel Filter Bit 00: receive on both channels 01: receive only on channel B 10: receive only on channel A 11: no reception

(1) FLXAnFRFRF.RNF

Reject Null Frames Bit

The user can only write to these bits when bits FLXAnFRCCSV.POCS[5:0] are DEFAULT_CONFIG or CONFIG.

If this bit is set to 1, received null frames are not stored in the FIFO.

(2) FLXAnFRFRF.RSS

Reject in Static Segment Bit

The user can only write to these bits when bits FLXAnFRCCSV.POCS[5:0] are DEFAULT_CONFIG or CONFIG.

If this bit is set to 1, the FIFO is used only for the dynamic segment.

(3) FLXAnFRFRF.CYF

Cycle Counter Filter Bit

The user can only write to these bits when bits FLXAnFRCCSV.POCS[5:0] are DEFAULT_CONFIG or CONFIG.

The 7-bit cycle counter filter determines the cycle set to which frame ID and channel rejection filter are applied. In cycles not belonging to the cycle set specified by FLXAnFRFRF.CYF, all frames are rejected. For details about the configuration of the cycle counter filter see **Section 24.4.8.2, Cycle Counter Filtering**.

(4) FLXAnFRFRF.FID

Frame ID Filter Bit

The user can only write to these bits when bits FLXAnFRCCSV.POCS[5:0] are DEFAULT_CONFIG or CONFIG.

Determines the frame ID to be rejected by the FIFO. With the additional configuration of register FLXAnFRFRFM, the corresponding frame ID filter bits are ignored, which results in further rejected frame IDs. When bits FLXAnFRFRFM.MFID[10:0] are zero, a frame ID filter value of zero means that no frame ID is rejected.

(5) FLXAnFRFRF.CH

Channel Filter Bit

The user can only write to these bits when bits FLXAnFRCCSV.POCS[5:0] are DEFAULT_CONFIG or CONFIG.

If reception on both channels is configured, also in static segment always both frames (from channel A and B) are stored in the FIFO, even if they are identical.

24.3.8.3 FLXAnFRFRFM — FlexRay FIFO Rejection Filter Mask Register

The FlexRay FIFO Rejection Filter Mask specifies which of the corresponding frame ID filter bits are relevant for rejection filtering. If a bit is set to 1, it indicates that the corresponding bit in the FLXAnFRFRF register will not be considered for rejection filtering.

Access: This register can be read or written in 8-, 16-, or 32-bit units.

Address: <FLXAn_base> + 0308_H

Value after reset: $0000\ 0000_H$

Table 24.60 FLXAnFRFRFM Register Contents

Bit Position	Bit Name	Function
31 to 13	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
12 to 2	MFID[10:0]	Mask Frame ID Filter Bit 0: Corresponding frame ID filter bit is used for rejection filtering 1: Ignore corresponding frame ID filter bit.
1, 0	Reserved	When read, the value after reset is returned. When writing, write the value after reset.

(1) FLXAnFRFRFM.MFID

Mask Frame ID Filter Bit

The user can only write to these bits when bits FLXAnFRCCSV.POCS[5:0] are DEFAULT_CONFIG or CONFIG.

24.3.8.4 FLXAnFRFCL — FlexRay FIFO Critical Level Register

Access: This register can be read or written in 8-, 16-, or 32-bit units.

Address: <FLXAn_base> + $030C_H$

Value after reset: $0000\ 0080_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Table 24.61 FLXAnFRFCL Register Contents

Bit Position	Bit Name	Function
31 to 8	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
7 to 0	CL[7:0]	Critical Level Bit Critical Level

(1) FLXAnFRFCL.CL

Critical Level Bit

The user can only write to these bits when bits FLXAnFRCCSV.POCS[5:0] are DEFAULT_CONFIG or CONFIG.

When the receive FIFO fill level FLXAnFRFSR.RFFL is equal or greater than the critical level configured by bits FLXAnFRFCL.CL[7:0], the receive FIFO critical level flag FLXAnFRFSR.RFCL is set to 1.

If FLXAnFRFCL.CL is programmed to values > 128, bit FLXAnFRFSR.RFCL is never set to 1.

24.3.9 Message Buffer Status Registers

24.3.9.1 FLXAnFRMHDS — FlexRay Message Handler Status Register

Do not rewrite this register using bit manipulation instructions.

Access: This register can be read or written in 8-, 16-, or 32-bit units.

Address: <FLXAn_base> + 0310_H

Value after reset: $0000\ 0080_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 24.62 FLXAnFRMHDS Register Contents

Bit Position	Bit Name	Function
31	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
30 to 24	MBU[6:0]	Message Buffer Updated Flag
23	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
22 to 16	MBT[6:0]	Message Buffer Transmitted Flag
15	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
14 to 8	FMB[6:0]	Faulty Message Buffer Number Flag
7	CRAM	Clear all internal RAM's Flag 0: No execution of the CHI command CLEAR_RAMS 1: Execution of the CHI command CLEAR_RAMS ongoing
6	MFMB	Multiple Faulty Message Buffer Detection Flag 0 = No additional faulty message buffer. 1 = Additional faulty message buffer was detected while the FMBD flag is set to 1.
5	FMBD	Faulty Message Buffer Detection Flag 0 = No faulty message buffer. 1 = Message buffer referenced by bit FLXAnFRMHDS.FMB holds faulty data with a parity error.
4	ATBF2	TBFRAM B Access Error Flag 0 = No access error 1 = Access error occurred when reading the RAM B.
3	ATBF1	TBFRAM A Access Error Flag 0 = No access error. 1 = Access error occurred when reading the RAM A.
2	AMR	Message RAM Access Error Flag 0 = No access error 1 = Access error occurred when reading the Message RAM.
1, 0	Reserved	When read, the value after reset is returned. When writing, write the value after reset.

(1) FLXAnFRMHDS.MBU

Message Buffer Updated Flag

Number of message buffer that was updated last by the CC. For this message buffer the respective ND and / or MBC flag in the FLXAnFRNDAT1 to FLXAnFRNDAT4 registers and the FLXAnFRMBSC1 to FLXAnFRMBSC4 registers are also set to 1.

Reset when leaving CONFIG state or when entering STARTUP state.

Reset by the CHI command CLEAR_RAMS.

(2) FLXAnFRMHDS.MBT

Message Buffer Transmitted Flag

Number of last successfully transmitted message buffer.

If the message buffer is configured for single-shot mode, the respective TXR flag in the FLXAnFRTXRQ1 to FLXAnFRTXRQ4 registers was reset to 0.

Reset when leaving CONFIG state or when entering STARTUP state.

Reset by the CHI command CLEAR_RAMS.

(3) FLXAnFRMHDS.FMB

Faulty Message Buffer Number Flag

This flag indicates that an access error occurred when reading from the message buffer referenced by FLXAnFRMHDS.FMB.

The value of this flag is only valid when one of flags FLXAnFRMHDS.AMR, FLXAnFRMHDS.ATBF1, FLXAnFRMHDS.ATBF2, and FLXAnFRMHDS.FMBD is set to 1.

This flag is not updated while the FLXAnFRMHDS.FMBD flag is 1.

This flag is cleared by the CHI command CLEAR_RAMS.

(4) FLXAnFRMHDS.CRAM

Internal RAM Clear Flag

This flag indicates that the CHI command CLEAR_RAMS is ongoing (all bits of the message RAM, input buffer, output buffer and TBF are written to 0).

This flag is set by the CHI command CLEAR_RAMS.

(5) FLXAnFRMHDS.MFMB

Multiple Faulty Message Buffer Detection Flag

Writing 0 has no effect on the bit value.

This bit is cleared when writing 1 to it.

This bit indicates that an additional faulty message buffer was detected while the FLXAnFRMHDS.FMBD flag is set.

This bit is cleared by the CHI command CLEAR_RAMS.

(6) FLXAnFRMHDS.FMBD

Faulty Message Buffer Detection Flag

Writing 0 has no effect on the bit value.

This bit is cleared when writing 1 to it.

This bit indicates that the message buffer referenced by FLXAnFRMHDS.FMB holds faulty data due to an access error.

This bit is cleared by the CHI command CLEAR_RAMS.

(7) FLXAnFRMHD.ATBF2

TBFRAM B Access Error Flag

Writing 0 has no effect on the bit value.

This bit is cleared when writing 1 to it.

This flag indicates that an access error occurred when reading the TBFRAM B.

CAUTION

When this flag changes from 0 to 1, the FLXAnFREIR.AERR bit is set to 1. This flag can be reset by the CHI command CLEAR_RAMS.

(8) FLXAnFRMHD.ATBF1

TBFRAM A Access Error Flag

Writing 0 has no effect on the bit value.

This bit is cleared when writing 1 to it.

This flag indicates that an access error occurred when reading the TBFRAM A.

CAUTION

When this flag changes from 0 to 1, the FLXAnFREIR.AERR bit is set to 1. This flag can be reset by the CHI command CLEAR_RAMS.

(9) FLXAnFRMHDS.AMR

Message RAM Access Error Flag

Writing 0 has no effect on the bit value.

This bit is cleared when writing 1 to it.

This flag indicates that an access error occurred when reading the Message RAM.

CAUTION

When this flag changes from 0 to 1, the FLXAnFREIR.AERR bit is set to 1. This flag can be reset by the CHI command CLEAR_RAMS.

24.3.9.2 FLXAnFRLDTS — FlexRay Last Dynamic Transmit Slot Register

Access: This register is a read-only register that can be read in 8-, 16-, or 32-bit units.

Address: <FLXAn_base> + 0314_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	LDTB[10:0]										
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	LDTA[10:0]										
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 24.63 FLXAnFRLDTS Register Contents

Bit Position	Bit Name	Function
31 to 27	Reserved	When read, the value after reset is returned.
26 to 16	LDTB[10:0]	Last Dynamic Transmission Channel B Flag
15 to 11	Reserved	When read, the value after reset is returned.
10 to 0	LDTA[10:0]	Last Dynamic Transmission Channel A Flag

(1) FLXAnFRLDTS.LDTB

Last Dynamic Transmission Channel B Flag

Stores the value of vSlotCounter[B] at the time of the last frame transmission on channel B in the dynamic segment of this node.

It is updated at the end of the dynamic segment and is reset to zero if no frame was transmitted during the dynamic segment.

Reset when leaving CONFIG state or when entering STARTUP state.

Reset by the CHI command CLEAR_RAMS of channel B.

(2) FLXAnFRLDTS.LDTA

Last Dynamic Transmission Channel A Flag

Stores the value of vSlotCounter[A] at the time of the last frame transmission on channel A in the dynamic segment of this node.

It is updated at the end of the dynamic segment and is reset to zero if no frame was transmitted during the dynamic segment.

Reset when leaving CONFIG state or when entering STARTUP state.

Reset by the CHI command CLEAR_RAMS of channel A.

24.3.9.3 FLXAnFRFSR — FlexRay FIFO Status Register

Access: This register is a read-only register that can be read in 8-, 16-, or 32-bit units.

Address: <FLXAn_base> + 0318_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	RFFL[7:0]								—	—	—	—	—	RFO	RFCL	RFNE
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 24.64 FLXAnFRFSR Register Contents

Bit Position	Bit Name	Function
31 to 16	Reserved	When read, the value after reset is returned.
15 to 8	RFFL[7:0]	Receive FIFO Fill Level Flag
7 to 3	Reserved	When read, the value after reset is returned.
2	RFO	Receive FIFO Overrun Flag 0: No receive FIFO overrun detected 1: A receive FIFO overrun has been detected
1	RFCL	Receive FIFO Critical Level Flag 0: Receive FIFO below critical level 1: Receive FIFO critical level reached
0	RFNE	Receive FIFO Not Empty Flag 0: Receive FIFO is empty 1: Receive FIFO is not empty

(1) FLXAnFRFSR.RFFL

Receive FIFO Fill Level Flag

Indicates the number of FIFO buffers filled with new data not yet read by the Host. Maximum value is 128.

Reset when leaving CONFIG state or when entering STARTUP state.

Reset by the CHI command CLEAR_RAMS.

(2) FLXAnFRFSR.RFO

Receive FIFO Overrun Flag

The flag is set to 1 by the CC when a receive FIFO overrun is detected.

When a receive FIFO overrun occurs, the oldest message is overwritten with the actual received message. In addition, the FLXAnFREIR.RFO flag is set to 1.

The flag is cleared by the next FIFO read access issued by the Host.

Reset when leaving CONFIG state or when entering STARTUP state.

Reset by the CHI command CLEAR_RAMS.

(3) FLXAnFRFSR.RFCL

Receive FIFO Critical Level Flag

This flag is set to 1 when the value of the receive FIFO fill level FLXAnFRFSR.RFFL[7:0] is equal or greater than the critical level as configured by FLXAnFRFCL.CL.

When this bit changes from 0 to 1 bit FLXAnFRSIR.RFCL is set to 1, and if enabled, an interrupt is generated.

The flag is cleared by the CC as soon as the value of the FLXAnFRFSR.RFFL[7:0] bits drops below the value set in the FLXAnFRFCL.CL bit.

Reset when leaving CONFIG state or when entering STARTUP state.

Reset by the CHI command CLEAR_RAMS.

(4) FLXAnFRFSR.RFNE

Receive FIFO Not Empty Flag

This flag is set to 1 by the CC when a received valid frame (data or null frame depending on rejection mask) was stored in the FIFO. In addition, the FLXAnFRSIR.RFNE bit is set to 1.

The bit is reset to 0 after the Host has read all messages from the FIFO.

Reset when leaving CONFIG state or when entering STARTUP state.

Reset by the CHI command CLEAR_RAMS.

24.3.9.4 FLXAnFRMHDF — FlexRay Message Handler Constraints Flags Register

Do not rewrite this register using bit manipulation instructions.

Some constraints exist for the Message Handler regarding bus clock frequency, Message RAM configuration, and FlexRay bus traffic. To simplify software development, constraints violations are reported by setting flags in the FLXAnFRMHDF.

Access: This register can be read or written in 8-, 16-, or 32-bit units.

Address: <FLXAn_base> + $031C_H$

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 24.65 FLXAnFRMHDF Register Contents

Bit Position	Bit Name	Function
31 to 9	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
8	WAHP	Write Attempt to Header Partition Flag 0: No write attempt to header partition 1: Write attempt to header partition
7	TNSB	Transmission Not Started Channel B Flag 0: No transmission not started on channel B 1: Transmission not started on channel B
6	TNSA	Transmission Not Started Channel A Flag 0: No transmission not started on channel A 1: Transmission not started on channel A
5	TBFB	TBFB Access Failure B Flag 0: No TBFB access failure 1: TBFB access failure
4	TBFA	Temporary buffer Access Failure A Flag 0: No TBFA access failure 1: TBFA access failure
3	FNFB	Find Sequence Not Finished Channel B Flag 0: No find sequence not finished for channel B 1: Find sequence not finished for channel B
2	FNFA	Find Sequence Not Finished Channel A Flag 0: No find sequence not finished for channel A 1: Find sequence not finished for channel A
1	SNUB	Status Not Updated Channel B Flag 0: No overload condition occurred when updating MBS (FLXAnFRMBS) for channel B 1: Message buffer status (FLXAnFRMBS) for channel B not updated
0	SNUA	Status Not Updated Channel A Flag 0: No overload condition occurred when updating MBS (FLXAnFRMBS) for channel A 1: Message buffer status (FLXAnFRMBS) for channel A not updated

(1) FLXAnFRMHDF.WAHP

Write Attempt to Header Partition Flag

Writing 0 has no effect on the bit value.

This bit is cleared when writing a 1 to it.

Outside DEFAULT_CONFIG and CONFIG state this flag is set to 1 by the CC when the message handler tries to write message data into the header partition of the Message RAM due to faulty configuration of a message buffer. The write attempt is not executed, to protect the header partition from unintended write accesses.

When this flag changes from 0 to 1, the FLXAnFREIR.MHF flag is set to 1.

Reset when leaving CONFIG state or when entering STARTUP state.

Reset by the CHI command CLEAR_RAMS.

(2) FLXAnFRMHDF.TNSB

Transmission Not Started Channel B Flag

Writing 0 has no effect on the bit value.

This bit is cleared when writing a 1 to it.

This flag is set to 1 by the CC when the Message Handler was not ready to start a scheduled transmission on channel B at the action point of the configured slot.

When this flag changes from 0 to 1, flag FLXAnFREIR.MHF is set to 1.

Reset when leaving CONFIG state or when entering STARTUP state.

Reset by the CHI command CLEAR_RAMS.

(3) FLXAnFRMHDF.TNSA

Transmission Not Started Channel A Flag

Writing 0 has no effect on the bit value.

This bit is cleared when writing a 1 to it.

This flag is set by the CC when the Message Handler was not ready to start a scheduled transmission on channel A at the action point of the configured slot.

When this flag changes from 0 to 1, flag FLXAnFREIR.MHF is set to 1.

Reset when leaving CONFIG state or when entering STARTUP state.

Reset by the CHI command CLEAR_RAMS.

(4) FLXAnFRMHDF.TBFB

TBFB Access Failure Flag

Writing 0 has no effect on the bit value.

This bit is cleared when writing a 1 to it.

This flag is set to 1 by the CC when a read or write access to TBFB requested by PRT (Protocol controller) B could not complete within the available time.

When this flag changes from 0 to 1, flag FLXAnFREIR.MHF is set to 1.

Reset when leaving CONFIG state or when entering STARTUP state.

Reset by the CHI command CLEAR_RAMS.

(5) FLXAnFRMHDF.TBFA

TBFA Access Failure Flag

Writing 0 has no effect on the bit value.

This bit is cleared when writing a 1 to it.

This flag is set to 1 by the CC when a read or write access to TBFA requested by PRT A could not complete within the available time.

When this flag changes from 0 to 1, flag FLXAnFREIR.MHF is set to 1.

Reset when leaving CONFIG state or when entering STARTUP state.

Reset by the CHI command CLEAR_RAMS.

(6) FLXAnFRMHDF.FNFB

Find sequence Not Finished flag, channel B

Writing 0 has no effect on the bit's value.

Writing a 1 to the bit clears it.

This flag is set to 1 by the CC when the message handler, due to being overloaded, was not able to finish a find sequence (scan of message RAM for a matching message buffer).

When this flag changes from 0 to 1, flag FLXAnFREIR.MHF is also set to 1.

The value is reset on leaving the CONFIG state or entering the STARTUP state.

The value is also reset by the CLEAR_RAMS CHI command.

(7) FLXAnFRMHDF.FNFA

Find sequence Not Finished flag, channel A

Writing 0 has no effect on the bit value.

This bit is cleared when writing a 1 to it.

This flag is set to 1 by the CC when the Message Handler, due to overload condition, was not able to finish a find sequence (scan of Message RAM for matching message buffer).

When this flag changes from 0 to 1, flag FLXAnFREIR.MHF is set to 1.

Reset when leaving CONFIG state or when entering STARTUP state.

Reset by the CHI command CLEAR_RAMS.

(8) FLXAnFRMHDF.SNUB

Status Not Updated Channel B Flag

Writing 0 has no effect on the bit value.

This bit is cleared when writing a 1 to it.

This flag is set to 1 by the CC when the Message Handler, due to overload condition, was not able to update a message buffer's status (FLXAnFRMBS).

When this flag changes from 0 to 1, flag FLXAnFREIR.MHF is set to 1.

Reset when leaving CONFIG state or when entering STARTUP state.

Reset by the CHI command CLEAR_RAMS.

(9) FLXAnFRMHDF.SNUA

Status Not Updated Channel A Flag

Writing 0 has no effect on the bit value.

This bit is cleared when writing a 1 to it.

This flag is set to 1 by the CC when the Message Handler, due to overload condition, was not able to update a message buffer's status (FLXAnFRMBS).

When this flag changes from 0 to 1, flag FLXAnFREIR.MHF is set to 1.

Reset when leaving CONFIG state or when entering STARTUP state.

Reset by the CHI command CLEAR_RAMS.

24.3.9.5 FLXAnFRTXRQm — FlexRay Transmission Request m (m = 1 to 4)

The four registers reflect the state of the TXR flags of all configured message buffers. The flags are evaluated for transmit buffers only. If the number of configured message buffers is less than 128, the remaining TXR flags have no meaning.

Access: This register is a read-only register that can be read in 8-, 16-, or 32-bit units.

Address: <FLXAn_base> + 0320_H to <FLXAn_base> + $032C_H$ (<FLXAn_base> + 0320_H + (m–1) × 4)

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	TXRp[31:16]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TXRp[15:0]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 24.66 FLXAnFRTXRQm Register Contents

Bit Position	Bit Name	Function
31 to 0	TXRp[31:0]	Transmission Request Flag p

(1) FLXAnFRTXRQm.TXRp (p = (m – 1) × 32 to (m × 32 – 1))

Transmission Request Flag p

If the flag is set to 1, the respective message buffer is ready for transmission respectively transmission of this message buffer is in progress.

In single-shot mode the flags are reset to 0 after transmission has completed.

This bit is cleared by the CHI command CLEAR_RAMS.

24.3.9.6 FLXAnFRNDATm — FlexRay New Data Register m (m = 1 to 4)

The four registers reflect the state of the ND flags of all configured message buffers. ND flags belonging to transmit buffers have no meaning. If the number of configured message buffers is less than 128, the remaining ND flags have no meaning.

Access: This register is a read-only register that can be read in 8-, 16-, or 32-bit units.

Address: <FLXAn_base> + 0330_H to <FLXAn_base> + $033C_H$ (<FLXAn_base> + 0330_H + (m-1) × 4)

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	NDp[31:16]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

	NDp[15:0]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 24.67 FLXAnFRNDATm Register Contents

Bit Position	Bit Name	Function
31 to 0	NDp[31:0]	New Data Flag p

(1) FLXAnFRNDATm.NDp (p = (m – 1) × 32 to (m × 32 – 1))

New Data Flag p

The flags are set to 1 when a valid received data frame matches the message buffer's filter configuration, independent of the payload length received or the payload length configured for that message buffer.

The flags are not set to 1 after reception of null frames except for message buffers belonging to the receive FIFO.

An ND flag is reset to 0 when the header section of the corresponding message buffer is reconfigured or when the data section has been transferred to the Output Buffer.

Reset when leaving CONFIG state or when entering STARTUP state.

This bit is cleared by the CHI command CLEAR_RAMS.

24.3.9.7 FLXAnFRMBSCm — FlexRay Message Buffer Status Changed Register m (m = 1 to 4)

The four registers reflect the state of the MBC flags of all configured message buffers. If the number of configured message buffers is less than 128, the remaining MBC flags have no meaning.

Access: This register is a read-only register that can be read in 8-, 16-, or 32-bit units.

Address: <FLXAn_base> + 0340_H to <FLXAn_base> + $034C_H$ (<FLXAn_base> + 0340_H + (m–1) × 4)

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	MBCp[31:16]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	MBCp[15:0]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 24.68 FLXAnFRMBSCm Register Contents

Bit Position	Bit Name	Function
31 to 0	MBCp[31:0]	Message Buffer Status Changed Flag p

(1) FLXAnFRMBSCm.MBCp (p = (m – 1) × 32 to (m × 32 – 1))

Message Buffer Status Changed Flag p

Indicates whether the Message Handler has changed one of the status flags VFRA, VFRB, SEOA, SEOB, CEOA, CEOB, SVOA, SVOB, TCIA, TCIB, ESA, ESB, MLST, FTA, FTB in the header section (see **Section 24.3.11.5, FLXAnFRMBS — FlexRay Message Buffer Status Register** and **Section 24.4.13.1, Header Partition**) of the respective message buffer.

An MBC flag is reset to 0 when the header section of the corresponding message buffer is reconfigured or when it has been transferred to the Output Buffer.

Reset when leaving CONFIG state or when entering STARTUP state.

This bit is cleared by the CHI command CLEAR_RAMS.

24.3.10 Input Buffer

Double buffer structure consisting of Input Buffer Host and Input Buffer Shadow. While the Host can write to Input Buffer Host, the transfer to the Message RAM is done from Input Buffer Shadow. The Input Buffer holds the header and data sections to be transferred to the selected message buffer in the Message RAM. It is used to configure the message buffers in the Message RAM and to update the data sections of transmit buffers.

When updating the header section of a message buffer in the Message RAM from the Input Buffer, the Message Buffer Status as described in **Section 24.3.11.5, FLXAnFRMBS — FlexRay Message Buffer Status Register** is automatically reset to zero.

The header sections of message buffers belonging to the receive FIFO can only be (re)configured when the CC is in DEFAULT_CONFIG or CONFIG state. For those message buffers only the payload length configured and the data pointer need to be configured via bits FLXAnFRWRHS2.PLC[6:0] and bits FLXAnFRWRHS3.DP[10:0]. All information required for acceptance filtering is taken from the FIFO rejection filter and the FIFO rejection filter mask.

The data transfer between Input Buffer (IBF) and Message RAM is described in detail in **Section 24.4.12.2, Host access to Message RAM**.

These registers cannot be written when the input data transfer function shown in **Section 24.4.16.1, Input Data Transfer** is used and the FLXAnFRITS.ITS bit is 1.

24.3.10.1 FLXAnFRWRDSm — FlexRay Write Data Section Register m (m = 1 to 64)

This register holds the data words to be transferred to the data section of the specified message buffer. The number of data words written to the Message RAM is defined by the payload length configured in bits FLXAnFRWRHS2.PLC[6:0].

Access: This register can be read or written in 8-, 16-, or 32-bit units.

Address: <FLXAn_base> + 0400_H to <FLXAn_base> + $04FC_H$(<FLXAn_base> + 0400_H+(m–1) × 4)

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	MD[31:16]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	MD[15:0]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 24.69 FLXAnFRWRDSm Register Contents

Bit Position	Bit Name	Function
31 to 0	MD[31:0]	Message Data Bit

(1) FLXAnFRWRDSm.MD

Message Data Bit

Reset by the CHI command CLEAR_RAMS.

CAUTIONS

1. In case the FLXAnFRWRHS2.PLC[6:0] bits specifies an odd payload length, the remaining message data bytes are unused.
2. When writing to the FLXAnFRWRDSm register, all bytes have to be written by one 32-bit access, two consecutive 16-bit accesses, or four consecutive 8- bit accesses before the transfer from the Input Buffer to the Message RAM is started. If not all bytes of a 32- bit word have been written by the Host (8/16-bit access only), the FLXAnFRWRDSm register holds partly undefined data.

24.3.10.2 FLXAnFRWRHS1 — FlexRay Write Header Section Register 1

Access: This register can be read or written in 8-, 16-, or 32-bit units.

Address: <FLXAn_base> + 0500_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 24.70 FLXAnFRWRHS1 Register Contents

Bit Position	Bit Name	Function
31, 30	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
29	MBI	Message Buffer Interrupt Bit 0: The corresponding message buffer interrupt is disabled 1: The corresponding message buffer interrupt is enabled
28	TXM	Transmission Mode Setting Bit 0: Continuous mode 1: Single-shot mode
27	PPIT	Payload Preamble Indicator Transmit Bit 0: Payload Preamble Indicator is set to 0 1: Payload Preamble Indicator is set to 1
26	CFG	Message Buffer Direction Configuration Bit 0: The corresponding buffer is configured as Receive Buffer 1: The corresponding buffer is configured as Transmit Buffer
25,24	CH[1:0]	Channel Filter Control Bit
23	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
22 to 16	CYC[6:0]	Cycle Code Bit
15 to 11	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
10 to 0	FID[10:0]	Frame ID Bit

(1) FLXAnFRWRHS1.MBI

Message Buffer Interrupt Enable Bit

This bit enables the message buffer interrupt.

After a dedicated receive buffer has been updated by the Message Handler, bit FLXAnFRSIR.RXI and /or bit FLXAnFRSIR.MBSI are set to 1. After a transmission has completed bit FLXAnFRSIR.TXI is set to 1.

(2) FLXAnFRWRHS1.TXM

Transmission Mode Setting Bit

This bit selects transmit mode of the corresponding message buffer. For transmit mode, see **Section 24.4.9.3, Transmit Buffers**.

(3) FLXAnFRWRHS1.PPIT

Payload Preamble Indicator Transmit Bit

This bit is used to control the state of the Payload Preamble Indicator in transmit frames of the corresponding message buffer.

If the bit is set to 1 in a static message buffer, the respective message buffer holds network management information.

If the bit is set to 1 in a dynamic message buffer the first two bytes of the payload segment may be used for message ID filtering by the receiver. Message ID filtering of received FlexRay frames is not supported by the FlexRay module, but can be done by the Host.

(4) FLXAnFRWRHS1.CFG

Message Buffer Direction Configuration Bit

This bit is used to configure the corresponding buffer as transmit buffer or as receive buffer. For message buffers belonging to the receive FIFO the bit is not evaluated.

When an unused 32-bit or larger area is not allocated to the head of the data partition, set the data section of the message buffer that is allocated immediately after the header partition (of the last buffer) as a transmit buffer by setting this bit to 1.

(5) FLXAnFRWRHS1.CH

Channel Filter Control Bit

The 2-bit channel filtering field associated with each buffer serves as a filter for receive buffers, and as a control field for transmit buffers.

CH[1:0]	Transmit Buffer transmit frame on	Receive Buffer store frame received from
00	No transmission	Ignore frame
01	Channel A	Channel A
10	Channel B	Channel B
11	Both channels (static segment only)	Channel A or B (store first semantically valid frame; static segment only)

CAUTION

If a message buffer is configured for the dynamic segment and both bits of the channel filtering field are set to 1, no frames are transmitted resp. received frames are ignored (same function as CH = “00_B”)

(6) FLXAnFRWRHS1.CYC

Cycle Code Bit

The 7-bit cycle code determines the cycle set used for cycle counter filtering.

For details about the configuration of the cycle code **Section 24.4.8.2, Cycle Counter Filtering**.

(7) FLXAnFRWRHS1.FID

Frame ID Bit

Frame ID of the selected message buffer. The frame ID defines the slot number for transmission / reception of the respective message.

Message buffers with frame ID = 0 are considered as not valid.

24.3.10.3 FLXAnFRWRHS2 — FlexRay Write Header Section Register 2

Access: This register can be read or written in 8-, 16-, or 32-bit units.

Address: <FLXAn_base> + 0504_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	PLC[6:0]						
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	CRC[10:0]										
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 24.71 FLXAnFRWRHS2 Register Contents

Bit Position	Bit Name	Function
31 to 23	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
22 to 16	PLC[6:0]	Payload Length Configured Bit
15 to 11	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
10 to 0	CRC[10:0]	Header CRC Bit (vRF!Header!HeaderCRC) Receive Buffer: Configuration not required Transmit Buffer: Header CRC is configured

(1) FLXAnFRWRHS2.PLC

Payload Length Configured Bit

Length of data section (number of 2-byte words) as configured by the Host.

During static segment the static frame payload length as configured by bits FLXAnFRMHDC.SFDL[6:0] defines the payload length for all static frames. If the payload length configured by bits FLXAnFRWRHS2.PLC[6:0] is shorter than this value padding bytes are inserted to ensure that frames have proper physical length. The padding pattern is "0000_H" (see **Section 24.4.9.3, Transmit Buffers**).

(2) FLXAnFRWRHS2.CRC

Header CRC Bit (vRF!Header!HeaderCRC)

Setting of the receive buffer is not required.

Transmitting of the message buffer needs the header CRC calculation and setting.

For calculation of the header CRC the payload length of the frame send on the bus has to be considered. In static segment the payload length of all frames is configured by bits FLXAnFRMHDC.SFDL[6:0].

24.3.10.4 FLXAnFRWRHS3 — FlexRay Write Header Section Register 3

Access: This register can be read or written in 8-, 16-, or 32-bit units.

Address: <FLXAn_base> + 0508_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Table 24.72 FLXAnFRWRHS3 Register Contents

Bit Position	Bit Name	Function
31 to 11	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
10 to 0	DP[10:0]	Data Pointer Bit

(1) FLXAnFRWRHS3.DP

Data Pointer Bit

Configures the pointer to the first 32-bit word of the data section of the addressed message buffer in the Message RAM.

24.3.10.5 FLXAnFRIBCM — FlexRay Input Buffer Command Mask Register

Configures how the message buffer in the Message RAM selected by register FLXAnFRIBCR is updated. When IBF Host and IBF Shadow are swapped, also mask bits FLXAnFRIBCM.LHSH, FLXAnFRIBCM.LDSH, and FLXAnFRIBCM.STXRH are swapped with bits FLXAnFRIBCM.LHSS, FLXAnFRIBCM.LDSS, and FLXAnFRIBCM.STXRS.

Access: This register can be read or written in 8-, 16-, or 32-bit units.

Address: <FLXAn_base> + 0510_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	STXRS	LDSS	LHSS
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	STXRH	LDSH	LHSH
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W

Table 24.73 FLXAnFRIBCM Register Contents

Bit Position	Bit Name	Function
31 to 19	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
18	STXRS	Set Transmission Request Shadow Flag 0: Reset TXR flag 1: Set TXR flag, transmit buffer released for transmission (operation ongoing or finished)
17	LDSS	Load Data Section Shadow Flag 0: Data section is not updated 1: Data section selected for transfer from Input Buffer to the Message RAM (transfer ongoing or finished)
16	LHSS	Load Header Section Shadow Flag 0: Header section is not updated 1: Header section selected for transfer from Input Buffer to the Message RAM (transfer ongoing or finished)
15 to 3	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
2	STXRH	Set Transmission Request Host Bit 0: Reset TXR flag 1: Set TXR flag, transmit buffer released for transmission
1	LDSH	Load Data Section Host Bit 0: Data section is not updated 1: Data section selected for transfer from Input Buffer to the Message RAM
0	LHSH	Load Header Section Host Bit 0: Header section is not updated 1: Header section selected for transfer from Input Buffer to the Message RAM

(1) FLXAnFRIBCM.STXRS

Set Transmission Request Shadow Flag

(2) FLXAnFRIBCM.LDSS

Load Data Section Shadow Flag

(3) FLXAnFRIBCM.LHSS

Load Header Section Shadow Flag

(4) FLXAnFRIBCM.STXRH

Set Transmission Request Host Bit

If this bit is set to 1, the TXR flag for the selected message buffer is set in the FLXAnFRTXRQ1 to FLXAnFRTXRQ4 registers to release the message buffer for transmission. In single-shot mode the flag is cleared by the CC after transmission has completed.

TXR is evaluated for transmit buffers only.

(5) FLXAnFRIBCM.LDSH

Set Load Data Section Host Bit

(6) FLXAnFRIBCM.LHSH

Set Load Header Section Host Bit

24.3.10.6 FLXAnFRIBCR — FlexRay Input Buffer Command Request Register

When the Host writes the number of the target message buffer in the Message RAM to bits FLXAnFRIBCR.IBRH[6:0], IBF Host and IBF Shadow are swapped. In addition the message buffer numbers stored under bits FLXAnFRIBCR.IBRH[6:0] and bits FLXAnFRIBCR.IBRS[6:0] are also swapped (see **Section 24.4.12.2, (1) Data Transfer from Input Buffer to Message RAM**).

With this write operation bit FLXAnFRIBCR.IBSYS is set to 1. The Message Handler then starts to transfer the contents of IBF Shadow to the message buffer in the Message RAM selected by bits FLXAnFRIBCR.IBRS[6:0].

While the Message Handler transfers the data from IBF Shadow to the target message buffer in the Message RAM, the Host may write the next message into the IBF Host. After the transfer between IBF Shadow and the Message RAM has completed, bit FLXAnFRIBCR.IBSYS is set back to 0 and the next transfer to the Message RAM may be started by the Host by writing the respective target message buffer number to bits FLXAnFRIBCR.IBRH[6:0].

If a write access to bits FLXAnFRIBCR.IBRH[6:0] occurs while bit FLXAnFRIBCR.IBSYS is 1, bit FLXAnFRIBCR.IBSYH is set to 1. After completion of the ongoing data transfer from IBF Shadow to the Message RAM, IBF Host and IBF Shadow are swapped, bit FLXAnFRIBCR.IBSYH is reset to 0. Bit FLXAnFRIBCR.IBSYS remains set to 1, and the next transfer to the Message RAM is started. In addition the message buffer numbers stored under bits FLXAnFRIBCR.IBRH[6:0] and bits FLXAnFRIBCR.IBRS[6:0] are also swapped.

Any write access to an Input Buffer register while both bit FLXAnFRIBCR.IBSYS and bit FLXAnFRIBCR.IBSYH are set to 1 will cause the error flag FLXAnFREIR.IIBA to be set to 1.

Access: This register can be read or written in 8-, 16-, or 32-bit units.

Address: <FLXAn_base> + 0514_H

Value after reset: 00000000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 24.74 FLXAnFRIBCR Register Contents (1/2)

Bit Position	Bit Name	Function
31	IBSYS	Input Buffer Busy Shadow Flag 0: Transfer between IBF Shadow and Message RAM completed 1: Transfer between IBF Shadow and Message RAM in progress
30 to 23	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
22 to 16	IBRS[6:0]	Input Buffer Request Shadow Flag
15	IBSYH	Input Buffer Busy Host Flag 0: No request pending 1: Request while transfer between IBF Shadow and Message RAM in progress

Table 24.74 FLXAnFRIBCR Register Contents (2/2)

Bit Position	Bit Name	Function
14 to 7	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
6 to 0	IBRH[6:0]	Input Buffer Request Host Bit

(1) FLXAnFRIBCR.IBSYS

Input Buffer Busy Shadow Flag

Set to 1 after writing bits FLXAnFRIBCR.IBRH[6:0].

This bit indicates transmitting between the IBF Shadow and the Message RAM is ongoing.

When the transfer between IBF Shadow and the Message RAM has completed, FLXAnFRIBCR.IBSYS is set back to 0.

(2) FLXAnFRIBCR.IBRS

Input Buffer Request Shadow Flag

Number of the target message buffer actually updated / lately updated.

(3) FLXAnFRIBCR.IBSYH

Input Buffer Busy Host Flag

Set to 1 by writing bits FLXAnFRIBCR.IBRH[6:0] while bit FLXAnFRIBCR.IBSYS is still 1.

This bit indicates transmitting between the IBF Shadow and the Message RAM is ongoing.

After the ongoing transfer between IBF Shadow and the Message RAM has completed, the FLXAnFRIBCR.IBSYH is set back to 0.

(4) FLXAnFRIBCR.IBRH

Input Buffer Request Host Bit

Selects the target message buffer in the Message RAM for data transfer from Input Buffer.

24.3.11 Output Buffer

Double buffer structure consisting of Output Buffer Host and Output Buffer Shadow. Used to read out message buffers from the Message RAM. While the Host can read from Output Buffer Host, the Message Handler transfers the selected message buffer from Message RAM to Output Buffer Shadow. The data transfer between Message RAM and Output Buffer (OBF) is described in **Section 24.4.12.2 (2), Data Transfer from Message RAM to Output Buffer**.

These registers cannot be written when the output data transfer function shown in **Section 24.4.16.2, Output Data Transfer**, in Output Data Transfer is used and the FLXAnFROTS.OTS bit is 1.

24.3.11.1 FLXAnFRRDDSm — FlexRay Read Data Section Register m (m = 1 to 64)

Holds the data words read from the data section of the addressed message buffer. This register holds the data wards to be transferred to the data section of the specified message buffer. The number of data words (DWn) read from the Message RAM is defined by the payload length configured in bits FLXAnFRRDHS2.PLC[6:0].

Access: This register is a read-only register that can be read in 8-, 16-, or 32-bit units.

Address: <FLXAn_base> + 0600_H to <FLXAn_base> + $06FC_H$ (<FLXAn_base> + 0600_H + (m–1) × 4)

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	MD[31:16]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 24.75 FLXAnFRRDDSm Register Contents

Bit Position	Bit Name	Function
31 to 0	MD[31:0]	Message Data

(1) FLXAnFRRDDSm.MD

Message Data Flag

Cleared by the CHI command CLEAR_RAMS.

CAUTION

In case the FLXAnFRWRHS2.PLC[6:0] bits specifies an odd payload length, the remaining message data bytes are unused.

24.3.11.2 FLXAnFRRDHS1 — FlexRay Read Header Section Register 1

Access: This register is a read-only register that can be read in 8-, 16-, or 32-bit units.

Address: <FLXAn_base> + 0700_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	MBI	TXM	PPIT	CFG	CH[1:0]		—	CYC[6:0]						
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 24.76 FLXAnFRRDHS1 Register Contents

Bit Position	Bit Name	Function
31, 30	Reserved	When read, the value after reset is returned.
29	MBI	Message Buffer Interrupt Flag
28	TXM	Transmission Mode Flag
27	PPIT	Payload Preamble Indicator Transmit Flag
26	CFG	Message Buffer Direction Configuration Flag
25, 24	CH[1:0]	Channel Filter Control Flag
23	Reserved	When read, the value after reset is returned.
22 to 16	CYC[6:0]	Cycle Code
15 to 11	Reserved	When read, the value after reset is returned.
10 to 0	FID[10:0]	Frame ID

(1) FLXAnFRRDHS1.MBI

Message Buffer Interrupt Flag

Values as configured by the Host via bit FLXAnFRWRHS1.MBI.

In case that the message buffer read from the Message RAM belongs to the receive FIFO this bit is set to 0.

(2) FLXAnFRRDHS1.TXM

Transmission Mode Flag

Values as configured by the Host via bit FLXAnFRWRHS1.TXM.

In case that the message buffer read from the Message RAM belongs to the receive FIFO this bit is set to 0.

(3) FLXAnFRRDHS1.PPIT

Payload Preamble Indicator Transmit Flag

Values as configured by the Host via bit FLXAnFRWRHS1.PPIT.

In case that the message buffer read from the Message RAM belongs to the receive FIFO this bit is set to 0.

(4) FLXAnFRRDHS1.CFG

Message Buffer Direction Configuration Flag

Values as configured by the Host via bit FLXAnFRWRHS1.CFG.

In case that the message buffer read from the Message RAM belongs to the receive FIFO this bit is set to 0.

(5) FLXAnFRRDHS1.CH

Channel Filter Control Flag

Values as configured by the Host via bit FLXAnFRWRHS1.CH.

In case that the message buffer read from the Message RAM belongs to the receive FIFO these bits are set to 0.

(6) FLXAnFRRDHS1.CYC

Cycle Code

Values as configured by the Host via bit FLXAnFRWRHS1.CYC.

In case that the message buffer read from the Message RAM belongs to the receive FIFO these bits are set to 0.

(7) FLXAnFRRDHS1.FID

Frame ID

Values as configured by the Host via bit FLXAnFRWRHS1.FID.

In case that the message buffer read from the Message RAM belongs to the receive FIFO these bits are holding the received frame ID.

24.3.11.3 FLXAnFRRDHS2 — FlexRay Read Header Section Register 2

Access: This register is a read-only register that can be read in 8-, 16-, or 32-bit units.

Address: <FLXAn_base> + 0704_H

Value after reset: $0000\ 0000_H$

CAUTION

For message buffers belonging to the Static Buffer area or Static and Dynamic Buffer area, the FLXAnFRRDHS2 register is updated from data frames only.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	PLR[6:0]							—	PLC[6:0]						
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	CRC[10:0]										
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 24.77 FLXAnFRRDHS2 Register Contents

Bit Position	Bit Name	Function
31	Reserved	When read, the value after reset is returned.
30 to 24	PLR[6:0]	Payload Length Received Flag (vRF!Header!Length)
23	Reserved	When read, the value after reset is returned.
22 to 16	PLC[6:0]	Payload Length Configuration Flag
15 to 11	Reserved	When read, the value after reset is returned.
10 to 0	CRC[10:0]	Header CRC Flag (vRF!Header!HeaderCRC)

(1) FLXAnFRRDHS2.PLR

Payload Length Received Flag (vRF!Header!Length)

Payload length (vRF!Header!Length) value updated from received data frames (exception: if message buffer belongs to the receive FIFO FLXAnFRRDSH2.PLR is also updated from received null frames).

(2) FLXAnFRRDHS2.PLC

Payload Length Configuration Flag

Length of data section (number of 2-byte words) as configured by the Host.

(3) FLXAnFRRDHS2.CRC

Header CRC Flag (vRF!Header!HeaderCRC)

Receive Buffer: Header CRC (vRF!Header!HeaderCRC) updated from received data frames

Transmit Buffer: Header CRC configured by the Host

(4) Data storage

When a message is stored into a message buffer the following behavior with respect to payload length received and payload length configured is implemented:

Bits FLXAnFRRDHS2.PLR[6:0] > Bits FLXAnFRRDHS2.PLC[6:0]:

The payload data stored in the message buffer is truncated to the payload length configured if bits FLXAnFRRDHS2.PLC[6:0] even or else truncated to bits FLXAnFRRDHS2.PLC[6:0] + 1.

Bits FLXAnFRRDHS2.PLR[6:0] <= Bits FLXAnFRRDHS2.PLC[6:0]:

The received payload data is stored into the message buffers data section. The remaining data bytes of the data section as configured by bits FLXAnFRRDHS2.PLC[6:0] are filled with undefined data.

Bits FLXAnFRRDHS2.PLR[6:0] = zero:

The message buffer’s data section is filled with undefined data

Bits FLXAnFRRDHS2.PLC[6:0] = zero:

Message buffer has no data section configured. No data is stored into the message buffer's data section.

CAUTIONS

1. The Message RAM is organized in 4-byte words. When received data is stored into a message buffer's data section, the number of 2-byte data words written into the message buffer is the FLXAnFRRDHS2.PLC[6:0] bits rounded to the next even value.
2. The FLXAnFRRDHS2.PLC[6:0] bits should be configured identical for all message buffers belonging to the receive FIFO. Header 2 is updated from data frames only.
   For message buffers belonging to the Static Buffer area or Static and Dynamic Buffer area, the FLXAnFRRDHS2 register is updated from data frames only.

24.3.11.4 FLXAnFRRDHS3 — FlexRay Read Header Section Register 3

CAUTION

For message buffers belonging to the Static Buffer area or Static and Dynamic Buffer area, the FLXAnFRRDHS3 register is updated from data frames only.

Access: This register is a read-only register that can be read in 8-, 16-, or 32-bit units.

Address: <FLXAn_base> + 0708_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 24.78 FLXAnFRRDHS3 Register Contents

Bit Position	Bit Name	Function
31, 30	Reserved	When read, the value after reset is returned.
29	RES	Reserved Bit Indicator Flag (vRF!Header!Reserved)
28	PPI	Payload Preamble Indicator (vRF!Header!PPIndicator)
27	NFI	Null Frame Indicator Flag (vRF!Header!NFIndicator) 0: Up to now no data frame has been stored into the respective message buffer 1: At least one data frame has been stored into the respective message buffer
26	SYN	Sync Frame Indicator Flag (vRF!Header!SyFIndicator) 0: The received frame is not a sync frame 1: The received frame is a sync frame
25	SFI	Startup Frame Indicator Flag (vRF!Header!SuFIndicator) 0: The received frame is not a startup frame 1: The received frame is a startup frame
24	RCI	Received on Channel Indicator Flag (vSS!Channel) 0: Frame received on channel B 1: Frame received on channel A
23, 22	Reserved	When read, the value after reset is returned.
21 to 16	RCC[5:0]	Receive Cycle Counter (vRF!Header!CycleCount)
15 to 11	Reserved	When read, the value after reset is returned.
10 to 0	DP[10:0]	Data Pointer Flag

(1) FLXAnFRRDHS3.RES

Reserved Bit Flag (vRF!Header!Reserved)

Reflects the state of the received reserved bit. The reserved bit is transmitted as 0.

(2) FLXAnFRRDHS3.PPI

Payload Preamble Indicator Flag (vRF!Header!PPIndicator)

The payload preamble indicator defines whether a network management vector or message ID is contained within the payload segment of the received frame.

0 = The payload segment of the received frame does not contain a network management vector nor a message ID

1 = Static segment: Network management vector in the first part of the payload
Dynamic segment: Message ID in the first part of the payload

(3) FLXAnFRRDHS3.NFI

Null Frame Indicator Flag (vRF!Header!NFIndicator)

Is set to 1 after storage of the first received data frame.

(4) FLXAnFRRDHS3.SYN

Sync Frame Indicator Flag (vRF!Header!SyFIndicator)

A sync frame is marked by the sync frame indicator.

(5) FLXAnFRRDHS3.SFI

Startup Frame Indicator Flag (vRF!Header!SuFIndicator)

A startup frame is marked by the startup frame indicator.

(6) FLXAnFRRDHS3.RCI

Received on Channel Indicator Flag (vSS!Channel)

Indicates the channel from which the received data frame was taken to update the respective receive buffer.

(7) FLXAnFRRDHS3.RCC

Receive Cycle Counter (vRF!Header!CycleCount)

Cycle counter value updated from received data frame.

(8) FLXAnFRRDHS3.DP

Data Pointer Flag

Pointer to the first 32-bit word of the data section of the addressed message buffer in the Message RAM.

The bit value is the same as that set in bit FLXAnFRWRHS3.DP

24.3.11.5 FLXAnFRMBS — FlexRay Message Buffer Status Register

The message buffer status is updated by the CC with respect to the assigned channel(s) latest at the end of the slot following the slot assigned to the message buffer.

The flags are updated only when the CC is in NORMAL_ACTIVE or NORMAL_PASSIVE state.

If only one channel (A or B) is assigned to a message buffer, the channel-specific status flags of the other channel are written to zero. If both channels are assigned to a message buffer, the channel-specific status flags of both channels are updated.

The message buffer status is updated only when the slot counter reached the configured frame ID and when the cycle counter filter matched. When the Host updates a message buffer via Input Buffer, all FLXAnFRMBS flags are reset to zero independent of which FLXAnFRIBCM bits are set or not.

For details about receive / transmit filtering see **Section 24.4.8, Filtering and Masking**, **Section 24.4.9, Transmit Process** and **Section 24.4.10, Receive Process**.

Whenever the Message Handler changes one of the flags FLXAnFRMBS.VFRA, FLXAnFRMBS.VFRB, FLXAnFRMBS.SEOA, FLXAnFRMBS.SEOB, FLXAnFRMBS.CEOA, FLXAnFRMBS.CEOB, FLXAnFRMBS.SVOA, FLXAnFRMBS.SVOB, FLXAnFRMBS.TCIA, FLXAnFRMBS.TCIB, FLXAnFRMBS.ESA, FLXAnFRMBS.ESB, FLXAnFRMBS.MLST, FLXAnFRMBS.FTA, FLXAnFRMBS.FTB the respective message buffer's MBC flag in registers FLXAnFRMBSC1 to FLXAnFRMBSC4 is set.

Access: This register is a read-only register that can be read in 8-, 16-, or 32-bit units.

Address: <FLXAn_base> + $070C_H$

Value after reset: $0000\ 0000_H$

13	Reserved	When read, the value after reset is returned.
12	MLST	Message Lost Flag 0: No message lost 1: Unprocessed message was overwritten
11	ESB	Empty Slot Channel B Flag 0: Bus activity detected in the assigned slot on channel B 1: No bus activity detected in the assigned slot on channel B
10	ESA	Empty Slot Channel A Flag 0: Bus activity detected in the assigned slot on channel A 1: No bus activity detected in the assigned slot on channel A
9	TCIB	Transmission Conflict Indication Channel B Flag (vSS!TxConflictB) 0: No transmission conflict occurred on channel B 1: Transmission conflict occurred on channel B
8	TCIA	Transmission Conflict Indication Channel A Flag (vSS!TxConflictA) 0: No transmission conflict occurred on channel A 1: Transmission conflict occurred on channel A
7	SVOB	Slot Boundary Violation Observed on Channel B Flag (vSS!BViolationB) 0: No slot boundary violation observed on channel B 1: Slot boundary violation observed on channel B
6	SVOA	Slot Boundary Violation Observed on Channel A Flag (vSS!BViolationA) 0: No slot boundary violation observed on channel A 1: Slot boundary violation observed on channel A
5	CEOB	Content Error Observed on Channel B Flag (vSS!ContentErrorB) 0: No content error observed on channel B 1: Content error observed on channel B
4	CEOA	Content Error Observed on Channel A Flag (vSS!ContentErrorA) 0: No content error observed on channel A 1: Content error observed on channel A
3	SEOB	Syntax Error Observed on Channel B Flag (vSS!SyntaxErrorB) 0: No syntax error observed on channel B 1: Syntax error observed on channel B
2	SEOA	Syntax Error Observed on Channel A Flag (vSS!SyntaxErrorA) 0: No syntax error observed on channel A 1: Syntax error observed on channel A
1	VFRB	Valid Frame Received on Channel B (vSS!ValidFrameB) 0: No valid frame received on channel B 1: Valid frame received on channel B
0	VFRA	Valid Frame Received on Channel A Flag (vSS!ValidFrameA) 0: No valid frame received on channel A 1: Valid frame received on channel A

(1) FLXAnFRMBS.RESS

Reserved Bit Status Flag (vRF!Header!Reserved)

Reflects the state of the received reserved bit. The reserved bit is transmitted as 0.

For receive buffers (bit FLXAnFRWRHS1.CFG = 0) this bit is updated from both valid data and null frames. If no valid frame was received, the previous value is maintained. For transmit buffers the flag has no meaning and should be ignored.

(2) FLXAnFRMBS.PPIS

Payload Preamble Indicator Status Flag (vRF!Header!PPIndicator)

The payload preamble indicator defines whether a network management vector or message ID is contained within the payload segment of the received frame.

For receive buffers (bit FLXAnFRWRHS1.CFG = 0) this bit is updated from both valid data and null frames. If no valid frame was received, the previous value is maintained. For transmit buffers the flag has no meaning and should be ignored.

0 = PPI indicator set to 0
The payload segment of the received frame does not contain a network management vector or a message ID

1 = PPI indicator set to 1
Static segment: Network management vector at the beginning of the payload
Dynamic segment: Message ID at the beginning of the payload

(3) FLXAnFRMBS.NFIS

Null Frame Indicator Status Flag (vRF!Header!NFIndicator)

If set to 0 the payload segment of the received frame contains no usable data.

For receive buffers (bit FLXAnFRWRHS1.CFG = 0) this bit is updated from both valid data and null frames. If no valid frame was received, the previous value is maintained. For transmit buffers the flag has no meaning and should be ignored.

(4) FLXAnFRMBS.SYNS

Sync Frame Indicator Status Flag (vRF!Header!SyFIndicator)

A sync frame is marked by the sync frame indicator.

For receive buffers (bit FLXAnFRWRHS1.CFG = 0) this bit is updated from both valid data and null frames. If no valid frame was received, the previous value is maintained. For transmit buffers the flag has no meaning and should be ignored.

(5) FLXAnFRMBS.SFIS

Startup Frame Indicator Status Flag (vRF!Header!SuFIndicator)

The startup frame indicator specifies a startup frame.

For receive buffers (bit FLXAnFRWRHS1.CFG = 0) this bit is updated from both valid data and null frames. If no valid frame was received, the previous value is maintained. For transmit buffers the flag has no meaning and should be ignored.

(6) FLXAnFRMBS.RCIS

Received on Channel Indicator Status Flag (vSS!Channel)

Indicates the channel on which the frame was received.

For receive buffers (bit FLXAnFRWRHS1.CFG = 0) this bit is updated from both valid data and null frames. If no valid frame was received, the previous value is maintained. For transmit buffers the flag has no meaning and should be ignored.

(7) FLXAnFRMBS.CCS

Cycle Count Status Flag

Actual cycle count when status was updated.

(8) FLXAnFRMBS.FTB

Frame Transmitted on Channel B Flag

Indicates that this node has transmitted a data frame in the configured slot on channel B.

CAUTION

The FlexRay protocol specification requires that this bit can only be reset by the Host. Therefore, the Cycle Count Status FLXAnFRMBS.CCS bit for this bit is only valid for the cycle where the bit is set to 1.

(9) FLXAnFRMBS.FTA

Frame Transmitted on Channel A Flag

Indicates that this node has transmitted a data frame in the configured slot on channel A.

CAUTION

The FlexRay protocol specification requires that this bit can only be reset by the Host. Therefore the Cycle Count Status FLXAnFRMBS.CCS bit for this bit is only valid for the cycle where this bit is set to 1.

(10) FLXAnFRMBS.MLST

Message Lost Flag

The flag is set in case the Host did not read the message before the message buffer was updated from a received data frame.

Not affected by reception of null frames except for message buffers belonging to the receive FIFO. Bits FLXAnFRNDATm.NDp is reset to 0 by a Host write to the message buffer via IBF or when a new message is stored into the message buffer after the message buffers ND flag was reset to 0 by reading out the message buffer via OBF.

(11) FLXAnFRMBS.ESB

Empty Slot Channel B Flag

In an empty slot, there is no activity on the bus. This means that any frame transmission is not detected. This state can be checked in static and dynamic slots.

(12) FLXAnFRMBS.ESA

Empty Slot Channel A Flag

In an empty slot, there is no activity on the bus. This means that any frame transmission is not detected. This state can be checked in static and dynamic slots.

(13) FLXAnFRMBS.TCIB

Transmission Conflict Indication Channel B Flag (vSS!TxConflictB)

A transmission conflict indication is set to 1 if a transmission conflict has occurred on channel B.

(14) FLXAnFRMBS.TCIA

Transmission Conflict Indication Channel A Flag (vSS!TxConflictA)

A transmission conflict indication is set if a transmission conflict has occurred on channel A.

(15) FLXAnFRMBS.SVOB

Slot Boundary Violation Observed on Channel B Flag (vSS!BViolationB)

A slot boundary violation (channel active at the start or at the end of the assigned slot) was observed on channel B.

(16) FLXAnFRMBS.SVOA

Slot Boundary Violation Observed on Channel A Flag (vSS!BViolationA)

A slot boundary violation (channel active at the start or at the end of the assigned slot) was observed on channel A.

(17) FLXAnFRMBS.CEOB

Content Error Observed on Channel B Flag (vSS!ContentErrorB)

A content error was observed in the assigned slot on channel B.

(18) FLXAnFRMBS.CEOA

Content Error Observed on Channel A Flag (vSS!ContentErrorA)

A content error was observed in the assigned slot on channel A.

(19) FLXAnFRMBS.SEOB

Syntax Error Observed on Channel B Flag (vSS!SyntaxErrorB)

A syntax error was observed in the assigned slot on channel B.

(20) FLXAnFRMBS.SEOA

Syntax Error Observed on Channel A Flag (vSS!SyntaxErrorA)

A syntax error was observed in the assigned slot on channel A.

(21) FLXAnFRMBS.VFRB

Valid Frame Received on Channel B Flag (vSS!ValidFrameB)

A valid frame indication is set if a valid frame was received on channel B.

(22) FLXAnFRMBS.VFRA

Valid Frame Received on Channel A Flag (vSS!ValidFrameA)

A valid frame indication is set if a valid frame was received on channel A.

24.3.11.6 FLXAnFROBCM — FlexRay Output Buffer Command Mask Register

Configures how the Output Buffer is updated from the message buffer in the Message RAM selected by bits FLXAnFROBCR.OBRS[6:0].

Mask bits FLXAnFROBCM.RDSS and FLXAnFROBCM.RHSS are copied to the register internal storage when a Message RAM transfer is requested by bit FLXAnFROBCR.REQ.

When OBF Host and OBF Shadow are swapped, mask bits FLXAnFROBCM.RDSH and FLXAnFROBCM.RHSH are swapped with the register internal storage to keep them attached to the respective Output Buffer transfer.

The data transfer between Output Buffer and Message RAM is described in detail in **Section 24.4.12.2 (2), Data Transfer from Message RAM to Output Buffer**.

CAUTION

After the transfer of the header section from the Message RAM to OBF Shadow has completed, the message buffer status changed flag MBC of the selected message buffer in the FLXAnFRMBSC1 to FLXAnFRMBSC4 registers is cleared. After the transfer of the data section from the Message RAM to OBF Shadow has completed, the new data flag ND of the selected message buffer in the FLXAnFRNDAT1 to FLXAnFRNDAT4 registers is cleared.

Access: This register can be read or written in 8-, 16-, or 32-bit units.

Address: <FLXAn_base> + 0710_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 24.80 FLXAnFROBCM Register Contents

Bit Position	Bit Name	Function
31 to 18	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
17	RDSH	Read Data Section Host Flag 0: Data section is not read 1: Data section selected for transfer from Message RAM to Output Buffer
16	RHSH	Read Header Section Host Flag 0: Header section is not read 1: Header section selected for transfer from Message RAM to Output Buffer
15 to 2	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
1	RDSS	Read Data Section Shadow Bit 0: Data section is not read 1: Data section selected for transfer from Message RAM to Output Buffer
0	RHSS	Read Header Section Shadow Bit 0: Header section is not read 1: Header section selected for transfer from Message RAM to Output Buffer

(1) FLXAnFROBCM.RDSH

Read Data Section Host Flag

(2) FLXAnFROBCM.RHSH

Read Header Section Host Flag

(3) FLXAnFROBCM.RDSS

Read Data Section Shadow Bit

(4) FLXAnFROBCM.RHSS

Read Header Section Shadow Bit

24.3.11.7 FLXAnFROBCR — FlexRay Output Buffer Command Request Register

After setting bit FLXAnFROBCR.REQ to 1 while FLXAnFROBCR.OBSYS is 0, FLXAnFROBCR.OBSYS is automatically set to 1, bits FLXAnFROBCR.OBRS[6:0] is copied to the register internal storage, mask bits FLXAnFROBCM.RDSS and FLXAnFROBCM.RHSS are copied to register FLXAnFROBCM internal storage, and the transfer of the message buffer selected by bits FLXAnFROBCR.OBRS[6:0] from the Message RAM to OBF Shadow is started. When the transfer between the Message RAM and OBF Shadow has completed, this is signaled by setting FLXAnFROBCM.OBSYS back to 0.

By setting bit FLXAnFROBCR.VIEW to 1 while FLXAnFROBCR.OBSYS is 0, OBF Host and OBF Shadow are swapped. Additionally mask bits FLXAnFROBCM.RDSH and FLXAnFROBCM.RHSH are swapped with the register FLXAnFROBCM internal storage to keep them attached to the respective Output Buffer transfer. bits FLXAnFROBCR.OBRH[6:0] signals the number of the message buffer currently accessible by the Host.

If bits FLXAnFROBCR.REQ and FLXAnFROBCR.VIEW are set to 1 with the same write access while FLXAnFROBCR.OBSYS is 0, FLXAnFROBCR.OBSYS is automatically set to 1 and OBF Shadow and OBF Host are swapped. Additionally mask bits FLXAnFROBCM.RDSH and FLXAnFROBCM.RHSH are swapped with the registers internal storage to keep them attached to the respective Output Buffer transfer. Afterwards FLXAnFROBCR.OBRS is copied to the register internal storage, and the transfer of the selected message buffer from the Message RAM to OBF Shadow is started. While the transfer is ongoing the Host can read the message buffer transferred by the previous transfer from OBF Host. When the current transfer between Message RAM and OBF Shadow has completed, this is signaled by setting FLXAnFROBCR.OBSYS back to 0.

Any write access to bits FLXAnFROBCR[15:8] while FLXAnFROBCR.OBSYS is set to 1 will cause bit FLXAnFREIR.IOBA to be set to 1. n this case, this write access has no effect and the Output Buffer will not be changed.

The data transfer between Output Buffer and Message RAM is described in detail in **Section 24.4.12.2 (2), Data Transfer from Message RAM to Output Buffer**.

Access: This register can be read or written in 8-, 16-, or 32-bit units.

Address: <FLXAn_base> + 0714_H

Value after reset: $0000\ 0000_H$

Table 24.81 FLXAnFROBCR Register Contents

Bit Position	Bit Name	Function
31 to 23	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
22 to 16	OBRH[6:0]	Output Buffer Request Host Flag
15	OBSYS	Output Buffer Busy Shadow Flag 0: No transfer in progress 1: Transfer between Message RAM and OBF Shadow in progress
14 to 10	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
9	REQ	Request Message RAM Transfer Bit 0: No request 1: Transfer to OBF Shadow requested
8	VIEW	View Shadow Buffer Bit 0: No action 1: Swap OBF Shadow and OBF Host
7	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
6 to 0	OBRS[6:0]	Output Buffer Request Shadow Bit

(1) FLXAnFROBCR.OBRH

Output Buffer Request Host Flag

Number of message buffer currently accessible by the Host via the FLXAnFRRDHS1 to FLXAnFRRDHS3, FLXAnFRMBS, and FLXAnFRRDDS1 to FLXAnFRRDDS64 registers.

By writing bit FLXAnFROBCR.VIEW to 1 OBF Shadow and OBF Host are swapped and the transferred message buffer is accessible by the Host.

(2) FLXAnFROBCR.OBSYS

Output Buffer Busy Shadow Flag

Set to 1 after setting bit FLXAnFROBCR.REQ. When the transfer between the Message RAM and OBF Shadow has completed, FLXAnFROBCR.OBSYS is set back to 0.

(3) FLXAnFROBCR.REQ

Request Message RAM Transfer Bit

Only writeable while bit FLXAnFROBCR.OBSYS = 0.

Requests transfer of message buffer addressed by bits FLXAnFROBCR.OBRS[6:0] from Message RAM to OBF Shadow.

(4) FLXAnFROBCR.VIEW

View Shadow Buffer Bit

Only writeable while bit FLXAnFROBCR.OBSYS = 0.

Toggles between OBF Shadow and OBF Host.

(5) FLXAnFROBCR.OBRS

Output Buffer Request Shadow Bit

Only writeable while bit FLXAnFROBCR.OBSYS = 0.

Number of source message buffer to be transferred from the Message RAM to OBF Shadow.

If the number of the first message buffer of the receive FIFO is written to this register the Message Handler transfers the message buffer addressed by the GET Index (GIDX, see **Section 24.4.11, FIFO Function**) to OBF Shadow.

24.3.12 Data Transfer Control Register

24.3.12.1 FLXAnFRITC — FlexRay Input Transfer Configuration Register

Access: This register can be read or written in 8-, 16-, or 32-bit units.

Address: <FLXAn_base> + 0800_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	ITM[6:0]						
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	IQEIE	IQFIE	—	—	—	—	—	—	IQHR	ITE
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R/W	R/W	R	R	R	R	R	R	R/W	R/W

Table 24.82 FLXAnFRITC Register Contents

Bit Position	Bit Name	Function
31 to 23	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
22 to 16	ITM[6:0]	Input queue Table Max Bit These bits configure the number of entries in the input pointer table the input buffer handler is capable to maintain in the input queue.
15 to 10	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
9	IQEIE	Input Queue Empty Interrupt Enable Bit 0: Disabled 1: Enabled
8	IQFIE	Input Queue Full Interrupt Enable Bit 0: Disabled 1: Enabled
7 to 2	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
1	IQHR	Input Queue Halt Request Bit 0: Input queue run request 1: Input queue halt request
0	ITE	Input Transfer Enable Bit 0: Operation Disable request 1: Operation Enable request

(1) FLXAnFRITC.ITM

Input queue Table Max Bit

The user can only write to this bit when bit FLXAnFRITS.ITS is 0.

These bits configure the number of entries in the input pointer table the input buffer handler is capable to maintain in the input queue.

Valid values are 00_H (1 queue entry) to $7F_H$ (128 queue entries).

Note that each entry requires two long words in the input pointer table.

(2) FLXAnFRITC.IQEIE

Input Queue Empty Interrupt Enable Bit

This bit controls the input queue empty interrupt.

0: Disabled
No interrupt will be generated and the input queue empty interrupt line will be released.

1: Enabled
Input queue empty interrupt will be generated when bit FLXAnFRITS.IQEIS is 1.

(3) FLXAnFRITC.IQFIE

Input Queue Full Interrupt Enable Bit

This bit controls the input queue full interrupt.

0: Disabled
No interrupt will be generated and the input queue full interrupt line will be released.

1: Enabled
Input queue full interrupt will be generated when bit FLXAnFRITS.IQFIS is 1.

(4) FLXAnFRITC.IQHR

Input Queue Halt Request Bit

The IQHR bit should not be set to 1 when FLXAnFRITS.ITS is 0.

This bit requests a halt of the input queue.

The status of the halt request is shown in the FLXAnFRITS.IQH register.

Refer to **Section 24.4.16.1, (5) Halting the input queue** about usage of this bit.

0: Input queue run request
The input queue resumes their operation.

1: Input queue halt request
The input queue gets halted. An active input transfer will be completed but no further transfer request will start.

(5) FLXAnFRITC.ITE

Input Transfer Enable Bit

The user should only set this bit to 1 when bit FLXAnFRIBCR.IBSYS is 0.

The user should only set this bit to 0 when bit FLXAnFRITC.IQHR is 0. Otherwise committed input transfers get lost.

This bit controls the operation mode of the input transfer queue.

The operation status of the input transfer queue function is shown in bit FLXAnFRITS.ITS.

Refer to **Section 24.4.16.1 (1), Activation and deactivation** about usage of this bit.

0: Operation Disable request
The input transfer queue is disabled when it becomes empty.

1: Operation Enable request
The input transfer queue is enabled. Input data structures are transferred to the FlexRay internal message RAM.

24.3.12.2 FLXAnFROTC — FlexRay Output Transfer Configuration Register

Access: This register can be read or written in 8-, 16-, or 32-bit units.

Address: <FLXAn_base> + 0804_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	FTM[4:0]				
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	FWIE	OWIE	FIE	OIE	—	—	—	—	—	—	OTCS	OTE
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R/W	R/W	R/W	R/W	R	R	R	R	R	R	R/W	R/W

Table 24.83 FLXAnFROTC Register Contents

Bit Position	Bit Name	Function
31 to 21	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
20 to 16	FTM[4:0]	FIFO Table Max Bit Configures the number of FIFO entries the output transfer handler is capable to maintain in the Local RAM/Cluster RAM.
15 to 12	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
11	FWIE	FIFO transfer Warning Interrupt Enable Bit 0: Disabled 1: Enabled
10	OWIE	Output transfer Warning Interrupt Enable Bit 0: Disabled 1: Enabled
9	FIE	FIFO transfer Interrupt Enable Bit 0: Disabled 1: Enabled
8	OIE	Output transfer Interrupt Enable Bit 0: Disabled 1: Enabled
7 to 2	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
1	OTCS	Output Transfer Condition Select Bit 0: New data only mode 1: New data and status changed mode
0	OTE	Output Transfer Enable Bit 0: Operation Disable request 1: Operation Enable request

(1) FLXAnFROTC.FTM

FIFO Table Max Bit

The user can only write to these bits when bit FLXAnFROTS.OTS is 0.

Configures the number of FIFO entries the output transfer handler is capable to maintain in the Local RAM/Cluster RAM.

Valid values are 00_H (1 FIFO entry) to $1F_H$ (32 FIFO entries).

(2) FLXAnFROTC.FWIE

FIFO transfer Warning Interrupt Enable Bit

This bit controls the FIFO transfer warning interrupt.

0: Disabled
No interrupt will be generated and the FIFO transfer warning interrupt line will be released.

1: Enabled
FIFO transfer warning interrupt will be generated when bit FLXAnFROTS.FWIS is 1.

(3) FLXAnFROTC.OWIE

Output transfer Warning Interrupt Enable Bit

This bit controls the output transfer warning interrupt.

0: Disabled
No interrupt will be generated and the output transfer warning interrupt line will be released.

1: Enabled
Output transfer warning interrupt will be generated when bit FLXAnFROTS.OWIS is 1.

(4) FLXAnFROTC.FIE

FIFO transfer Interrupt Enable Bit

This bit controls the FIFO transfer interrupt.

0: Disabled
No interrupt will be generated and the FIFO transfer interrupt line will be released.

1: Enabled
FIFO transfer interrupt will be generated when bit FLXAnFROTS.FIS is 1.

(5) FLXAnFROTC.OIE

Output transfer Interrupt Enable Bit

This bit controls the output transfer interrupt.

0: Disabled
No interrupt will be generated and the output transfer interrupt line will be released.

1: Enabled
Output transfer interrupt will be generated when bit FLXAnFROTS.OTIS is 1.

(6) FLXAnFROTC.OTCS

Output Transfer Condition Select Bit

The user can only write to this bit when bit FLXAnFROTS.OTS is 0.

This bit controls the output transfer condition.

0: New data only mode
Bits FLXAnFRNDATm.NDp are used to detect a transfer condition for dedicated receive buffer.

1: New data and status changed mode
Bits FLXAnFRNDATm.NDp and FLXAnFRMBSCm. are used to detect a transfer condition for dedicated transmit and receive buffer.

(7) FLXAnFROTC.OTE

Output Transfer Enable Bit

The user should only set this bit to 1 when bit FLXAnFROBCR.OBSYS is 0.

This bit controls the operation mode of the output transfer function.

The operation status of the output buffer transfer function is shown in FLXAnFROTS.OTS.

Refer to **Section 24.4.16.2, (1) Activation and deactivation** about usage of this bit.

0: Operation Disable request
The output buffer transfer gets disabled.
An active message buffer transfer will be completed but no further transfer will start.

1: Operation Enable request
The output buffer transfer gets enabled. Message buffers are transferred from the FlexRay internal message RAM to output data structures.

The user should not change the E-Ray message RAM configuration by writing to the FLXAnFRMRC register.

24.3.12.3 FLXAnFRIBA — FlexRay Input Pointer Table Base Address Register

Access: This register can be read or written in 8-, 16-, or 32-bit units.

Address: <FLXAn_base> + 0808_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	ITA[31:16]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	ITA[15:0]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 24.84 FLXAnFRIBA Register Contents

Bit Position	Bit Name	Function
31 to 0	ITA[31:0]	Input Table Base Address Bit These bits configure the base address of the input pointer table.

(1) FLXAnFRIBA.ITA

Input Table Base Address Bit

The user can only write to this bit when FLXAnFRITS.ITS is 0.

The address should be 32 bit aligned, thus the bits FLXAnFRIBA.ITA[1:0] are always 0.

These bits configure the base address of the input pointer table.

The table is used for the input transfer queue transferring message buffers from the Local RAM/Cluster RAM into the FlexRay internal message RAM.

The size of the input queue is configured in bits FLXAnFRITC.ITM[6:0].

Note that each entry requires two long words in the input pointer table.

24.3.12.4 FLXAnFRFBA — FlexRay FIFO Pointer Table Base Address Register

Access: This register can be read or written in 8-, 16-, or 32-bit units.

Address: <FLXAn_base> + $080C_H$

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	FTA[31:16]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 24.85 FLXAnFRFBA Register Contents

Bit Position	Bit Name	Function
31 to 0	FTA[31:0]	FIFO pointer Table Base Address Bit These bits configure the base address of the FIFO pointer table.

(1) FLXAnFRFBA.FTA

FIFO pointer Table Base Address Bit

The user can only write to this bit when FLXAnFROTS.OTS is 0.

The address should be 32 bit aligned, thus the bits FLXAnFRFBA.FTA[1:0] are always 0.

These bits configure the base address of the FIFO pointer table.

The table is used for message buffers transferred from the FlexRay internal FIFO to the Local RAM/ Cluster RAM.

The size of the FIFO is configured in bits FLXAnFROTC.FTM[4:0].

24.3.12.5 FLXAnFROBA — FlexRay Output Pointer Table Base Address Register

Access: This register can be read or written in 8-, 16-, or 32-bit units.

Address: <FLXAn_base> + 0810_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	OTA[31:16]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 24.86 FLXAnFROBA Register Contents

Bit Position	Bit Name	Function
31 to 0	OTA[31:0]	Output pointer Table Base Address Bit These bits configure the base address of the output pointer table.

(1) FLXAnFROBA.OTA

Output pointer Table Base Address Bit

The user can only write to this bit when FLXAnFROTS.OTS is 0.

The address should be 32 bit aligned, thus the bits FLXAnFROBA.OTA[1:0] are always 0.

These bits configure the base address of the output pointer table.

The table is used for message buffers transferred from the FlexRay internal message RAM to the Local RAM/Cluster RAM.

The size of the table depends on the utilization of the FlexRay internal message RAM and can have up to 128 entries.

24.3.12.6 FLXAnFRIQC — FlexRay Input Queue Control Register

Access: This register is a write-only register that can be written in 8-, 16-, or 32-bit units.

Address: <FLXAn_base> + 0814_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	IMBNR[6:0]						
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	W	W	W	W	W	W	W

Table 24.87 FLXAnFRIQC Register Contents

Bit Position	Bit Name	Function
31 to 7	Reserved	When writing, write the value after reset.
6 to 0	IMBNR[6:0]	Input Message Buffer NumbeR Bit Message buffer number added to the input queue

(1) FLXAnFRIQC.IMBNR

Input Message Buffer NumbeR Bit

The user can only write to this bit when FLXAnFRITS.IQFP is 0.

The user should not write to this register when FLXAnFRITS.ITS is 0 or when FLXAnFRITC.ITE is 0.

These bits are read as 0.

This value specifies the message buffer added to the input queue.

The number has to be identical to FLXAnFRWRHS4.IMBNR[6:0] (see **Section 24.4.16.1, (3) Input pointer table**) of the input pointer table.

The address to the input data structure has to be provided in the input pointer table at the put index (bit FLXAnFRITS.IPIDX[6:0]) before writing to this register.

Writing to this register increments the input put index (bit FLXAnFRITS.IPIDX[6:0]).

24.3.12.7 FLXAnFRUIR — FlexRay User Input Transfer Request Register

Access: This register can be read or written in 8-, 16-, or 32-bit units.

Address: <FLXAn_base> + 0818_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	UIDX[7:0]							
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 24.88 FLXAnFRUIR Register Contents

Bit Position	Bit Name	Function
31 to 8	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
7 to 0	UIDX[7:0]	User requested Input inDeX Bit Input pointer table index requested for input transfer

(1) FLXAnFRUIR.UIDX

User requested Input inDeX Bit

The user can only write to this bit when bit FLXAnFRITS.UIRP is 0.

The user should not write to this register when bit FLXAnFRITS.ITS is 0.

The user should not write to this register when bit FLXAnFRITS.UIRP is 1.

The user should not write to this register when bit FLXAnFRITS.IQH is 1.

The user should only write bits FLXAnFRITC.ITM[6:0] +1 to this register.

This value specifies the input pointer table index for the requested input transfer.

The address to the input data structure has to be provided in the input pointer table at the index FLXAnFRUIR.UIDX[7:0] before writing to this register.

When writing to this register, the requested input data structure will be transferred from input data structure position to the FlexRay internal message RAM.

In opposite to queued input transfers the related FLXAnFRDA.DA flag is not influenced by the user input transfer.

24.3.12.8 FLXAnFRUOR — FlexRay User Output Transfer Request Register

Access: This register can be read or written in 8-, 16-, or 32-bit units.

Address: <FLXAn_base> + $081C_H$

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	URDS	—	—	UMBNR[6:0]						
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R/W	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 24.89 FLXAnFRUOR Register Contents

Bit Position	Bit Name	Function
31 to 10	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
9	URDS	User request Read Data Section Bit 0: Data section is not transferred 1: Data section is transferred
8, 7	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
6 to 0	UMBNR[6:0]	User requested output Message Buffer NumbeR Bit Message buffer number requested for output transfer

(1) FLXAnFRUOR.URDS

User request Read Data Section Bit

The user can only write to this bit when bit FLXAnFROTS.UORP is 0.

The user should not write to this register when bit FLXAnFROTS.OTS is 0.

The user should not write to this register when bit FLXAnFROTS.UORP is 1.

0: Data section is not transferred

The data section of the message buffer selected by the bits FLXAnFRUOR.UMBNR[6:0] is not requested

1: Data section is transferred

The data section of the message buffer selected by the bits FLXAnFRUOR.UMBNR[6:0] is requested

(2) FLXAnFRUOR.UMBNR

User requested output Message Buffer NumbeR Bit

The user can only write to this bit when bit FLXAnFROTS.UORP is 0.

The user should not write to this register when bit FLXAnFROTS.OTS is 0.

The user should not write to this register when bit FLXAnFROTS.UORP is 1.

The user should restrict this bit to dedicated receive and transmit buffers when the FlexRay module is not in the CONFIG state.

When writing to this register, the contents of the message buffer will be transferred to a given area. The destination will be the area specified by the value in the output pointer table.

The data to be transferred can be specified by setting the URDS bit whether to transfer the header section only or to include the data section.

24.3.13 Data Transfer Status Register

24.3.13.1 FLXAnFRITS — FlexRay Input Transfer Status Register

Do not rewrite this register using bit manipulation instructions.

Access: This register can be read or written in 8-, 16-, or 32-bit units.

Address: <FLXAn_base> + 0820_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	IGIDX[6:0]							—	IPIDX[6:0]						
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

R/W	R	R	R	R	R	R	R/W	R/W	R	R	R	R	R	R	R	R

Table 24.90 FLXAnFRITS Register Contents

Bit Position	Bit Name	Function
31	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
30 to 24	IGIDX[6:0]	Input queue Get InDeX Bit Represents the get index of the input pointer table
23	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
22 to 16	IPIDX[6:0]	Input queue Put InDeX Bit Represents the put index of the input pointer table
15 to 13	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
12	IQFP	Input Queue Full condition Pending Bit 0: Entries in the input queue are available 1: All entries in the input queue are occupied
11, 10	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
9	IQEIS	Input Queue Empty Interrupt Status Bit 0: No input queue empty condition detected 1: Input queue empty condition detected
8	IQFIS	Input Queue Full Interrupt Status Bit 0: No input queue full condition detected 1: Input queue full condition detected
7 to 3	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
2	UIRP	User Input transfer Request Pending Bit 0: No user input transfer request pending 1: User input transfer request pending
1	IQH	Input Queue Halted Bit 0: Input queue not halted 1: Input queue halted
0	ITS	Input Transfer Status Bit 0: Disabled 1: Enabled

(1) FLXAnFRITS.IGIDX

Input queue Get InDeX Bit

These bits are only valid when bit FLXAnFRITS.IQH is 1

These bits represent the input pointer index the input queue handler will transfer next.

Valid values are 00_H to FLXAnFRITC.ITM.

The get index is incremented when the input data structure has been transferred from the Local RAM/ Cluster RAM and the related FLXAnFRDA.DA flag is cleared.

The index is set to 00_H when bit FLXAnFRITS.ITS changes from 0 to 1.

(2) FLXAnFRITS.IPIDX

Input queue Put InDeX Bit

These bits represent the index where the next input data structure pointer in the input pointer table should be stored.

Valid values are 00_H to FLXAnFRITC.ITM.

After reaching the maximum value the put index continues from 00_H.

The index is incremented when writing to bits FLXAnFRIQC.IMBNR[6:0].

The index is set to 00_H when bit FLXAnFRITS.ITS changes from 0 to 1.

(3) FLXAnFRITS.IQFP

Input Queue Full condition Pending Bit

This bit represents that the input queue is full.

There should be no further input transfer requests, by writing to bits FLXAnFRIQC.IMBNR[6:0], as long as this bit is 1.

[Clearing condition]

- This bit is cleared when there is one free entry in the input queue.

[Setting condition]

- This bit is set when all entries in the input queue are occupied.

(4) FLXAnFRITS.IQEIS

Input Queue Empty Interrupt Status Bit

Writing 0 has no effect on the bit value.

If enabled in bit FLXAnFRITC.IQEIE, the input queue empty interrupt is generated when this bit is 1.

[Clearing condition]

- This bit is cleared when writing a 1 to FLXAnFRITS.IQEIS.
- This bit is cleared when bit FLXAnFRITS.ITS changes from 0 to 1.

[Setting condition]

- This bit is set when all pending input transfers have been processed and consequently the input queue becomes empty.

(5) FLXAnFRITS.IQFIS

Input Queue Full Interrupt Status Bit

Writing 0 has no effect on the bit value.

If enabled in bit FLXAnFRITC.IQFIE the input queue full interrupt is generated when FLXAnFRITS.IQFIS is 1.

This flag is intended as interrupt status flag. It does not represent the current input queue status; for this status refer to bit FLXAnFRITS.IQFP.

[Clearing condition]

- This bit is cleared when writing a 1 to FLXAnFRITS.IQFIS.
- This bit is cleared when bit FLXAnFRITS.ITS changes from 0 to 1.

[Setting condition]

- This bit is set when all entries in the input queue are occupied.

(6) FLXAnFRITS.UIRP

User Input transfer Request Pending Bit

This bit represents that a user input transfer is still pending.

There should be no further write access to bits FLXAnFRUIR.UIDX[7:0] when this bit is 1.

[Clearing condition]

- This bit is cleared when the user input transfer request is processed by the input transfer handler.

[Setting condition]

- This bit is set when writing to bits FLXAnFRUIR.UIDX[7:0].

(7) FLXAnFRITS.IQH

Input Queue Halted Bit

This bit represents the status of the input queue.

There should be no further write access to bits FLXAnFRUIR.UIDX[7:0] when this bit is 1.

[Clearing condition]

- This bit is cleared when bit FLXAnFRITC.IQHR is set to 0.

[Setting condition]

- This bit is set immediately when bit FLXAnFRITC.IQHR is set to 1 and there is no ongoing input transfer.
- This bit is set only after an ongoing input transfer has been completed and bit FLXAnFRITC.IQHR is set to 1.

(8) FLXAnFRITS.ITS

Input Transfer Status Bit

This bit represents the status of the input queue handler.

While this bit is 1, there should be no read or write access to the address area <FLXAn_base> + 0400_H to <FLXAn_base> + $05FF_H$ and there should be no CLEAR_RAMS command applied to bits FLXAnFRSUCC1.CMD[3:0].

The input transfer queue indexes and related status flags are set to 0 when bit FLXAnFRITS.ITS changes from 0 to 1.

[Clearing condition]

- This bit is cleared immediately when bit FLXAnFRITC.ITE is set to 0 and there are no pending input transfers
- This bit is cleared after all pending requests have been processed and bit FLXAnFRITC.ITE is 0.

[Setting condition]

- This bit is set when bit FLXAnFRITC.ITE is set to 1.

24.3.13.2 FLXAnFROTS — FlexRay Output Transfer Status Register

Do not rewrite this register using bit manipulation instructions.

Access: This register can be read or written in 8-, 16-, or 32-bit units.

Address: <FLXAn_base> + 0824_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	FFL[5:0]						—	—	—	FGIDX[4:0]				
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 24.91 FLXAnFROTS Register Contents (1/2)

Bit Position	Bit Name	Function
31, 30	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
29 to 24	FFL[5:0]	FIFO Fill Level Bit Represent the number of unprocessed output FIFO structures
23 to 21	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
20 to 16	FGIDX[4:0]	FIFO Get InDeX Bit Represent the get index in the FIFO pointer table
15	FWP	FIFO transfer Warning condition Pending Bit 0: No FIFO transfer warning condition pending 1: FIFO transfer warning condition pending
14	OWP	Output transfer Warning condition Pending 0: No output transfer warning condition pending 1: Output transfer warning condition pending
13	FDA	FIFO Data Available Bit 0: No available FIFO structures 1: FIFO structures available at current FLXAnFROTS.FGIDX index
12	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
11	FWIS	FIFO transfer Warning Interrupt Status Bit 0: No FIFO transfer warning condition detected 1: FIFO transfer warning condition detected
10	OWIS	Output transfer Warning Interrupt Status Bit 0: No output transfer warning condition detected 1: Output transfer warning condition detected
9	FIS	FIFO transfer Interrupt Status Bit 0: No FIFO structure updated in Local RAM/Cluster RAM 1: FIFO structure updated in Local RAM/Cluster RAM
8	OTIS	Output transfer Interrupt Status Bit 0: No output structure updated in Local RAM/Cluster RAM 1: Output structure updated in Local RAM/Cluster RAM
7 to 3	Reserved	When read, the value after reset is returned. When writing, write the value after reset.

Table 24.91 FLXAnFROTS Register Contents (2/2)

Bit Position	Bit Name	Function
2	UORP	User Output transfer Request Pending Bit 0: No user output transfer request pending 1: User output transfer request pending
1	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
0	OTS	Output Transfer Status Bit 0: Disabled 1: Enabled

(1) FLXAnFROTS.FFL

FIFO Fill Level Bit

These bits represent the number of available output FIFO structures in the Local RAM/Cluster RAM.

Valid values are 00_H to FLXAnFROTC.FTM+1.

The value 00_H represents that the FIFO is empty.

The value FLXAnFROTC.FTM+1 represents that the FIFO is full and no further FIFO transfers will be done.

The FIFO fill level is incremented when a FIFO data structure has been transferred from the FlexRay internal FIFO into the Local RAM/Cluster RAM.

The FIFO fill level is decremented when the user releases a FIFO data structure in the Local RAM/ Cluster RAM by writing 1 to bit FLXAnFROTS.FDA.

The FIFO fill level is set to 00_H when bit FLXAnFROTS.OTS changes from 0 to 1.

(2) FLXAnFROTS.FGIDX

FIFO Get InDeX Bit

These bits represent the index where the current output data structure pointer in the FIFO pointer table is available for reading.

Valid values are 00_H to FLXAnFROTC.FTM.

After reaching the maximum value the get index continues from 00_H.

The index is incremented when a FIFO data structure is released by writing 1 to bit FLXAnFROTS.FDA.

The index is set to 00_H when bit FLXAnFROTS.OTS changes from 0 to 1.

(3) FLXAnFROTS.FWP

FIFO transfer Warning condition Pending Bit

This bit represents the FIFO transfer warning condition.

[Clearing condition]

- This bit is cleared when there are free output data structures (FLXAnFROTS.FFL ≤ FLXAnFROTC.FTM).

This bit is cleared when bit FLXAnFROTS.OTS changes from 0 to 1.

[Setting condition]

- This bit is set when the output transfer handler detects a transfer condition for FIFO message buffers but there are no free output data structures (FLXAnFROTS.FFL = FLXAnFROTC.FTM+1).

(4) FLXAnFROTS.OWP

Output transfer Warning condition Pending Bit

This bit represents the output transfer warning condition.

[Clearing condition]

- This bit is cleared, when all output structure pointers that have a pending output handler transfer condition detected, are released (for dedicated transmit and receive message buffers or a user output transfer request).

[Setting condition]

- This bit is set when the output transfer handler detects a transfer condition (for dedicated transmit and receive message buffers or a user output transfer request) but the related output structure pointer was not yet released by the application (data available flag is still set to 1).
- This bit is set when the output transfer handler detects a transfer condition for dedicated transmit and receive message buffers but there is a pending input transfer for the same message buffer (data available flag is set to 1 due to the input transfer request).

(5) FLXAnFROTS.FDA

FIFO Data Available Bit

Writing 0 has no effect on the bit value.

When this bit is 1, the next valid output data structure is available.

The related data structure pointer is in the FIFO pointer table at FLXAnFROTS.FGIDX.

Writing 1 to FLXAnFROTS.FDA

- increments FLXAnFROTS.FGIDX[4:0] and
- decrements the FIFO fill level (FLXAnFROTS.FFL)

If there are still unprocessed data structures FLXAnFROTS.FDA remains 1.

[Clearing condition]

- This bit is cleared when writing 1 to FLXAnFROTS.FDA and the FIFO fill level becomes 00_H.
- This bit is cleared when bit FLXAnFROTS.OTS changes from 0 to 1.

[Setting condition]

- This bit is set when there is at least one FIFO data structure available in the Local RAM/Cluster RAM.

(6) FLXAnFROTS.FWIS

FIFO transfer Warning Interrupt Status Bit

Writing 0 has no effect on the bit value.

If enabled in bit FLXAnFROTC.FWIE, the FIFO transfer warning interrupt is generated when this bit is 1.

[Clearing condition]

- This bit is cleared when writing a 1 to FLXAnFROTS.FWIS.
- This bit is cleared when bit FLXAnFROTS.OTS changes from 0 to 1.

[Setting condition]

- This bit is set when the output transfer handler detects a transfer condition for FIFO message buffers but there are no free output data structures (FLXAnFROTS.FFL = FLXAnFROTC.FTM+1).

(7) FLXAnFROTS.OWIS

Output transfer Warning Interrupt Status Bit

Writing 0 has no effect on the bit value.

If enabled in bit FLXAnFROTC.OWIE, the FIFO transfer warning interrupt is generated when this bit is 1.

[Clearing condition]

- This bit is cleared when writing a 1 to this bit.
- This bit is cleared when bit FLXAnFROTS.OTS changes from 0 to 1.

[Setting condition]

- This bit is set when the output transfer handler detects a transfer condition (for dedicated transmit and receive message buffers or a user output transfer request) but the related output structure pointer was not yet released by the application (data available flag is still set to 1).
- This bit is set when the output transfer handler detects a transfer condition for dedicated transmit and receive message buffers but there is a pending input transfer for the same message buffer (data available flag is set to 1 due to the input transfer request).

(8) FLXAnFROTS.FIS

FIFO transfer Interrupt Status Bit

Writing 0 has no effect on the bit value.

If enabled in bit FLXAnFROTC.FIE, the FIFO transfer interrupt is generated when this bit is 1.

[Clearing condition]

- This bit is cleared when writing a 1 to this bit.
- This bit is cleared when bit FLXAnFROTS.OTS changes from 0 to 1.

[Setting condition]

- This bit is set when a FIFO data structure is updated by the transfer handler or bits FLXAnFROTS.FFL[5:0] changes from 00_H to 01_H.

(9) FLXAnFROTS.OTIS

Output transfer Interrupt Status Bit

Writing 0 has no effect on the bit value.

If enabled in bit FLXAnFROTC.OIE, the output transfer interrupt is generated when this bit is 1.

[Clearing condition]

- This bit is cleared when writing a 1 to bit FLXAnFROTS.OTIS.
- This bit is cleared when bit FLXAnFROTS.OTS changes from 0 to 1.

[Setting condition]

- This bit is set when an output data structure is updated by the transfer handler (from a dedicated transmit or receive message buffer or by a user output transfer request).

(10) FLXAnFROTS.UORP

User Output transfer Request Pending Bit

This bit represents that a user output transfer is still pending.

There should be no further write access to bits FLXAnFRUOR.UMBNR[6:0] when this bit is 1.

[Clearing condition]

- This bit is cleared when the user output transfer request is processed by the output transfer handler.
- This bit is cleared when the bit FLXAnFROTS.OTS changes from 0 to 1.

[Setting condition]

- This bit is set when writing to bit FLXAnFRUOR.UMBNR.

(11) FLXAnFROTS.OTS

Output Transfer Status Bit

This bit represents the status of the output transfer handler.

While this bit is 1, there should be no read or write access to the address area <FLXAn_base> + 0600_H to <FLXAn_base> + $07FF_H$ and there should be no CLEAR_RAMS command applied to bits FLXAnFRSUCC1.CMD[3:0].

While this bit is 1, the user should not change the E-Ray message RAM configuration by writing to the FLXAnFRMRC register.

The output handler transfer indexes and related status flags are set to 0 when this bit changes from 0 to 1.

[Clearing condition]

- This bit is cleared immediately when bit FLXAnFROTC.OTE is set to 0 and there are no ongoing output transfers.
- This bit is cleared after an ongoing transfer has been completed and bit FLXAnFROTC.OTE is 0.

[Setting condition]

- This bit is set when bit FLXAnFROTC.OTE is set to 1.

24.3.13.3 FLXAnFRAES — FlexRay Access Error Status Register

Do not rewrite this register using bit manipulation instructions.

Access: This register can be read or written in 8-, 16-, or 32-bit units.

Address: <FLXAn_base> + 0828_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	MAE	FAE	OAE	IAE	EIDX[7:0]							
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R/W	R/W	R/W	R/W	R	R	R	R	R	R	R	R

Table 24.92 FLXAnFRAES Register Contents

Bit Position	Bit Name	Function
31 to 12	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
11	MAE	Multiple Access Errors Bit 0: No multiple access errors occurred 1: Multiple access errors occurred
10	FAE	FIFO transfer Access Error Bit 0: No access error occurred during FIFO transfer 1: Access error occurred during FIFO transfer
9	OAE	Output transfer Access Error Bit 0: No access error occurred during output transfer 1: Access error occurred during output transfer
8	IAE	Input transfer Access Error Bit 0: No access error occurred during input transfer 1: Access error occurred during input transfer
7 to 0	EIDX[7:0]	Error InDeX Bit Data structure pointer index number

(1) FLXAnFRAES.MAE

Multiple Access Errors Bit

Writing 0 has no effect on the bit value.

This bit represents that there were multiple access errors during a data transfer.

[Clearing condition]

- This bit is cleared when writing a 1 to FLXAnFRAES.MAE.

[Setting condition]

- This bit is set when one of the bits FLXAnFRAES.FAE, FLXAnFRAES.OAE and FLXAnFRAES.IAE is set and one of the conditions below is met:
  - an access to an protected address occurred during a FIFO data transfer or
  - an access to an protected address occurred during an output data transfer or

– an access to an protected address occurred during an input data transfer

(2) FLXAnFRAES.FAE

FIFO transfer Access Error Bit

Writing 0 has no effect on the bit value.

This bit represent that there was an access error during a FIFO data transfer.

[Clearing condition]

- This bit is cleared when writing a 1 to FLXAnFRAES.FAE.

[Setting condition]

- This bit is set when a Local RAM/Cluster RAM access error was detected during a FIFO transfer and bits FLXAnFRAES.OAE, FLXAnFRAES.IAE and FLXAnFRAES.MAE are 0.

(3) FLXAnFRAES.OAE

Output transfer Access Error Bit

Writing 0 has no effect on the bit value.

This bit represent that there was an access error during a output data transfer.

[Clearing condition]

- This bit is cleared when writing a 1 to FLXAnFRAES.OAE.

[Setting condition]

- This bit is set when a Local RAM/Cluster RAM access error was detected during an output transfer and bits FLXAnFRAES.FAE, FLXAnFRAES.IAE and FLXAnFRAES.MAE are 0.

(4) FLXAnFRAES.IAE

Input transfer Access Error Bit

Writing 0 has no effect on the bit value.

This bit represent that there was an access error during an input data transfer.

[Clearing condition]

- This bit is cleared when writing a 1 to FLXAnFRAES.IAE.

[Setting condition]

- This bit is set when a Local RAM/Cluster RAM access error was detected during an input transfer and bits FLXAnFRAES.OAE, FLXAnFRAES.FAE and FLXAnFRAES.MAE are 0.

(5) FLXAnFRAES.EIDX

Error InDeX Bit

This value is only valid when one of the bits FLXAnFRAES.FAE, FLXAnFRAES.OAE and FLXAnFRAES.IAE is 1.

When bit FLXAnFRAES.FAE is 1, FLXAnFRAES.EIDX holds the used FIFO put index when the access error has occurred.

When the bit FLXAnFRAES.OAE is '1', FLXAnFRAES.EIDX holds the used output table entry (which is related to message buffer number) when the access error has occurred.

When the bit FLXAnFRAES.IAE is '1', FLXAnFRAES.EIDX holds the used input pointer table get index when the access error has occurred during the input transfer or user requested input transfer.

These bits are updated when one of the bits FLXAnFRAES.FAE, FLXAnFRAES.OAE and FLXAnFRAES.IAE is changing from 0 to 1.

24.3.13.4 FLXAnFRAEA — FlexRay Access Error Address Register

Access: This register is a read-only register that can be read in 8-, 16-, or 32-bit units.

Address: <FLXAn_base> + $082C_H$

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	AEA[31:16]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	AEA[15:0]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 24.93 FLXAnFRAEA Register Contents

Bit Position	Bit Name	Function
31 to 0	AEA[31:0]	Access Error Address Bit Address in the Local RAM/Cluster RAM when an access error has occurred

(1) FLXAnFRAEA.AEA

Access Error Address Bit

This value is only valid when one of the bits FLXAnFRAES.FAE, FLXAnFRAES.OAE and FLXAnFRAES.IAE is 1.

These bits represent the address of the access error indicated in the FLXAnFRAES register.

These bits are updated when one of the bits FLXAnFRAES.FAE, FLXAnFRAES.OAE and FLXAnFRAES.IAE is changing from 0 to 1.

24.3.13.5 FLXAnFRDAm — FlexRay message Data Available Register m (m = 0 to 3)

Do not rewrite this register using bit manipulation instructions.

Access: This register can be read or written in 8-, 16-, or 32-bit units.

Address: <FLXAn_base> + 0830_H to <FLXAn_base> + $083C_H$ (<FLXAn_base> + 0830_H + m × 4)

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	DAp[31:16]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 24.94 FLXAnFRDAm Register Contents

Bit Position	Bit Name	Function
31 to 0	DAp[31:0]	Data Available Bit p 0: No data available for destination 1: Data available for destination

(1) FLXAnFRDAm.DAp (p = m × 32 to ((m + 1) × 32) – 1)

Data Available Bit p

The user should not write a 1 to bits that are 0.

To maintain the status of input transfers, the user should not clear bits related to input transfers.

This register is used for input and output transfers.

Each flag corresponds to a FlexRay message buffer.

[Clearing condition]

- Input transfer:
  This bit is cleared when the input data structure has been transferred from the Local RAM/Cluster RAM. The data structure and the data structure pointer can be changed when the related flag is 0.
- Output transfer:
  This bit is cleared when writing a 1 to it.

[Setting condition]

- Input transfer:
  This bit is set when the corresponding message buffer number has been written to bits FLXAnFRIQC.IMBNR[6:0].
  As long as this bit is 1, the input data structure and the data structure pointer corresponding to this input transfer request should not be changed.
- Output transfer:
  This bit is set when the output data structure corresponding to this message buffer has been

updated.
As long as this bit is 1, the data structure is stable; no further update of the data structure will be done by the output handler. While this bit is 1, the application is allowed to change the output data structure pointer in the output pointer table for this message buffer number.

24.4 Operation

This chapter describes the FlexRay implementation together with the related FlexRay protocol features. More information about the FlexRay protocol itself can be found in the FlexRay protocol specification.

24.4.1 FlexRay Module Operation Control

24.4.1.1 FlexRay Module Enable

After a reset or after the FlexRay module has been disabled (following **Section 24.4.1.2, FlexRay Module Disable**) the FlexRay module is in the reset state (bit FLXAnFROS.OS is 0) and the clocks of the FlexRay core module are disabled.

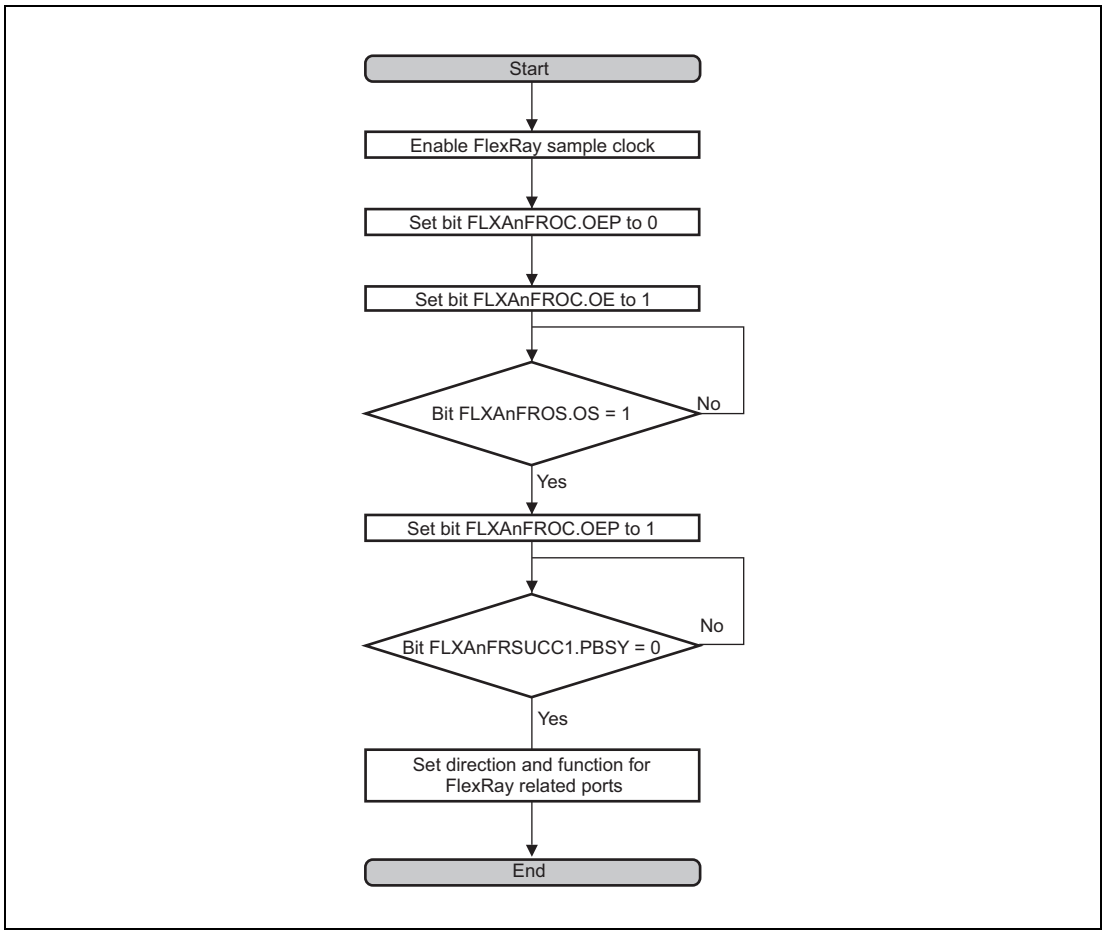

Figure 24.3 FlexRay Enable Processing Flow

24.4.1.2 FlexRay Module Disable

The FlexRay module can be disabled at any time. However, it is recommended to disable the FlexRay module using bit FLXAnFROC.OE only when the FlexRay module is in HALT, CONFIG or DEFAULT_CONFIG state. Resetting the FlexRay module in any other state will terminate any ongoing FlexRay communication.

If the data transfer function is used, it is also required to disable this function before disabling the FlexRay module (see **Section 24.4.16.1, (1) Activation and deactivation** for suspending input transfer function and **Section 24.4.16.2, (1) Activation and deactivation** for suspending output transfer).

The following flow should be executed to disable the FlexRay module.

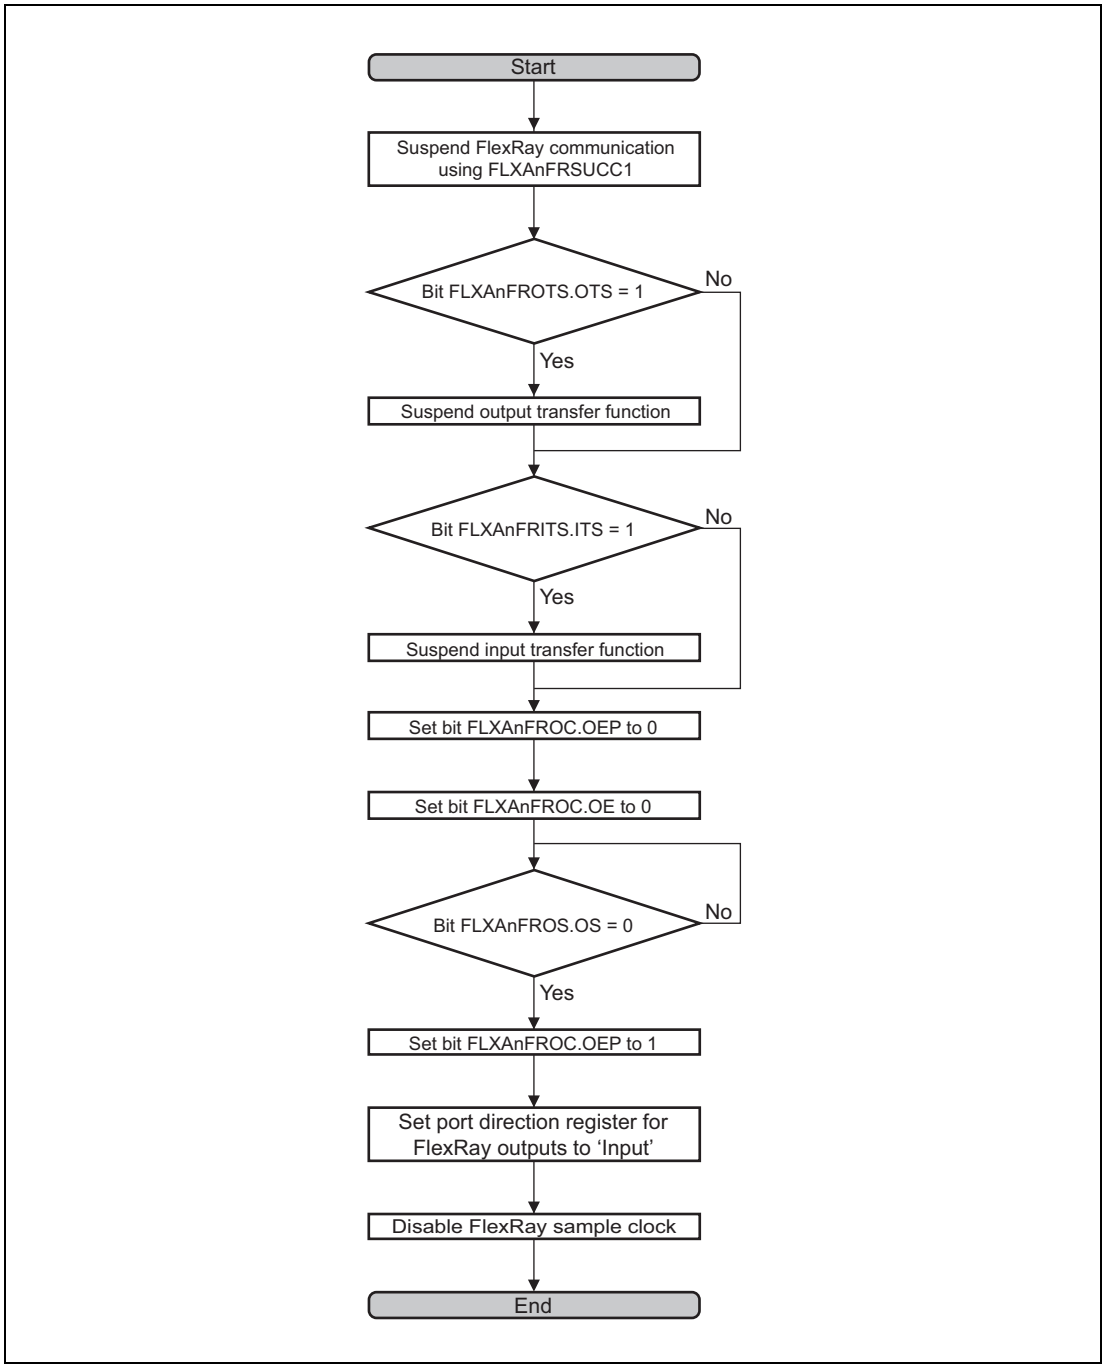

Figure 24.4 FlexRay Disable Processing Flow

24.4.2 Communication Cycle

Communication on FlexRay networks is based on frames and symbols. The wakeup symbol (WUS) and the collision avoidance symbol (CAS) are transmitted outside the communication cycle to setup the time schedule. Frames and media access test symbols (MTS) are transmitted inside the communication cycle.

A FlexRay communication cycle consists of the following elements:

- Static Segment
- Dynamic Segment (optional)
- Symbol Window (optional)
- Network Idle Time (NIT)

Static segment, dynamic segment, and symbol window form the Network Communication Time (NCT). For each communication channel the slot counter starts at 1 and counts up until the end of the dynamic segment is reached. Both channels share the same arbitration grid which means that they use the same synchronized macrotick.

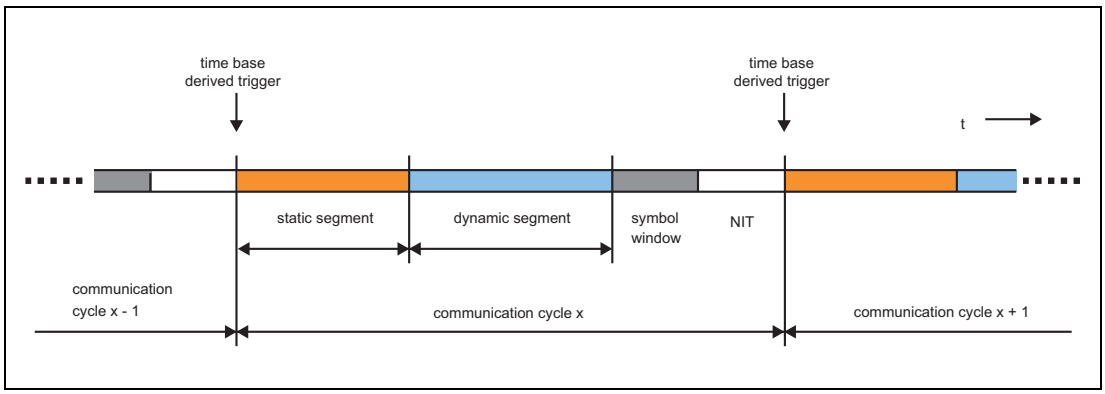

Figure 24.5 Structure of Communication Cycle

24.4.2.1 Static Segment

The Static Segment is characterized by the following features:

- Time slots of fixed length (optionally protected by bus guardian)
- Start of frame transmission at action point of the respective static slot
- Payload length same for all frames on both channels

Parameters:

Number of Static Slots (FLXAnFRGTUC7.NSS[9:0])

Static Slot Length (FLXAnFRGTUC7.SSL[9:0])

Payload Length Static (FLXAnFRMHDC.SFDL[6:0])

Action Point Offset (FLXAnFRGTUC9.APO[5:0])

24.4.2.2 Dynamic Segment

The Dynamic Segment is characterized by the following features:

- All controllers have bus access (no bus guardian protection possible)
- Variable payload length and duration of slots, different for both channels
- Start of transmission at minislot action point

Parameters:

Number of Minislots (FLXAnFRGTUC8.NMS[12:0])

Minislot Length (FLXAnFRGTUC8.MSL[5:0])

Minislot Action Point Offset (FLXAnFRGTUC9.MAPO[4:0])

Start of Latest Transmit (last minislot) (FLXAnFRMHDC.SLT[12:0])

24.4.2.3 Symbol Window

During the symbol window only one media access test symbol (MTS) may be transmitted per channel. MTS symbols are send in NORMAL_ACTIVE state to test the bus guardian.

The symbol window is characterized by the following features:

- Send single symbol
- Transmission of the MTS symbol starts at the symbol windows action point

Parameters:

Symbol Window Action Point Offset (FLXAnFRGTUC9.APO[4:0]) (same as for static slots)

Network Idle Time Start (FLXAnFRGTUC4.NIT[13:0])

24.4.2.4 Network Idle Time (NIT)

During network idle time the CC has to perform the following tasks:

- Calculate clock correction terms (offset and rate)
- Distribute offset correction over multiple macroticks after offset correction start
- Perform cluster cycle related tasks

Parameters:

Network Idle Time Start (FLXAnFRGTUC4.NIT[13:0])

Offset Correction Start (FLXAnFRGTUC4.OCS[13:0])

24.4.2.5 Configuration of NIT Start and Offset Correction Start

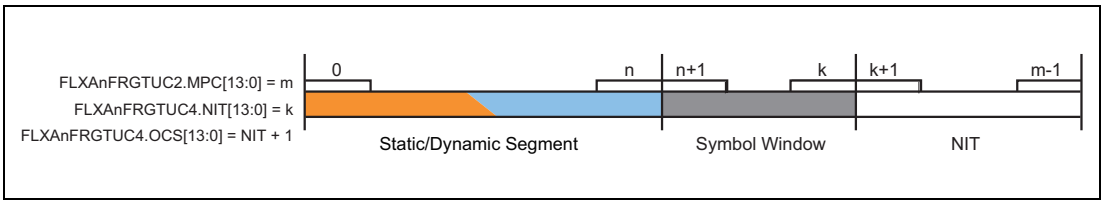

Figure 24.6 Configuration of NIT Start and Offset Correction Start

The number of macroticks per cycle gMacroPerCycle is assumed to be m. It is configured by programming FLXAnFRGTUC2.MPC[13:0] = m.

The static / dynamic segment starts with macrotick 0 and ends with macrotick n:

n = static segment length + dynamic segment offset + dynamic segment length – 1MT

= gNumberOfStaticSlots × gdStaticSlot + dynamic segment offset + gNumberOfMinislots × gdMinislot – 1 MT

The static segment length is configured by FLXAnFRGTUC7.SSL[9:0] and FLXAnFRGTUC7.NSS[9:0].

The dynamic segment length is configured by FLXAnFRGTUC8.MSL[5:0] and FLXAnFRGTUC8.NMS[12:0].

The dynamic segment offset is:

If gdActionPointOffset ≤ gdMinislotActionPointOffset:

dynamic segment offset = 0 MT

Else if gdActionPointOffset > gdMinislotActionPointOffset:

dynamic segment offset = gdActionPointOffset -gdMinislotActionPointOffset

The NIT starts with macrotick k+1 and ends with the last macrotick of cycle m-1. It has to be configured by setting FLXAnFRGTUC4.NIT[13:0] = k.

For the FlexRay module the offset correction start is required to be FLXAnFRGTUC4.OCS[13:0] ≥ FLXAnFRGTUC4.NIT[13:0] + 1 = k + 1.

The length of symbol window results from the number of macroticks between the end of the static / dynamic segment and the beginning of the NIT. It can be calculated by the number of macroticks (k – n).

24.4.3 Communication Modes

The FlexRay Protocol Specification defines the Time-Triggered Distributed (TT-D) mode.

24.4.3.1 Time-triggered Distributed (TT-D)

In TT-D mode the following configurations are possible:

- Pure static: Minimum 2 static slots + symbol window (optional)
- Mixed static/dynamic: Minimum 2 static slots + dynamic segment + symbol window (optional)

A minimum of two coldstart nodes needs to be configured for distributed time-triggered operation. Two fault-free coldstart nodes are necessary for the cluster startup. Each startup frame must be a sync frame, therefore all coldstart nodes are sync nodes.

24.4.4 Clock Synchronization

In TT-D mode a distributed clock synchronization is used. Each node individually synchronizes itself to the cluster by observing the timing of received sync frames from other nodes.

24.4.4.1 Global Time

Activities in a FlexRay node, individual nodes independently operate. Operations including communication, are based on the concept of a global time. It is the clock synchronization mechanism that differentiates the FlexRay cluster from other node collections with independent clock mechanisms. The global time is a vector of two values; the cycle (cycle counter) and the cycle time (macrotick counter).

Cluster specific:

- Macrotick (MT) = basic unit of time measurement in a FlexRay network, a macrotick consists of an integer number of microticks (µT)
- Cycle length = duration of a communication cycle in units of macroticks (MT)

24.4.4.2 Local Time

Internally, nodes time their behavior with microtick resolution. Microticks are time units derived from the oscillator clock tick of the specific node. Therefore microticks are controller-specific units. They may have different duration in different controllers. The precision of a node's local time difference measurements is a microtick (µT).

Node specific:

- Oscillator clock → prescaler → microtick (µT)
- µT = basic unit of time measurement in a CC, clock correction is done in units of µTs
- Cycle counter + macrotick counter = nodes local view of the global time

24.4.4.3 Synchronization Process

Clock synchronization is performed by means of sync frames. Only preconfigured nodes (sync nodes) are allowed to send sync frames. In a two-channel cluster a sync node has to send its sync frame on both channels.

For synchronization in FlexRay the following constraints have to be considered:

- Max. one sync frame per node in one communication cycle
- Max. 15 sync frames per cluster in one communication cycle
- Every node has to use a preconfigured number of sync frames (FLXAnFRGTUC2.SNM[3:0]) for clock synchronization
- Minimum of two sync nodes required for clock synchronization and startup

For clock synchronization the time difference between expected and observed arrival time of sync frames received during the static segment is measured. In a two channel cluster the sync node has to be configured to send sync frames on both channels. The calculation of correction terms is done during NIT (offset: every cycle, rate: every odd cycle) by using an FTM algorithm. For details see *FlexRay protocol specification v2.1, chapter 8*.

(1) Offset (phase) Correction

- Only deviation values measured and stored in the current cycle used
- For a two channel node the smaller value will be taken
- Calculation during NIT of every communication cycle
- Offset correction value calculated in even cycles used for error checking only
- Checked against limit values
- Correction value is a signed integer number of µTs
- Correction done in odd numbered cycles, distributed over the macroticks beginning at offset correction start up to cycle end (end of NIT) to shift nodes next start of cycle (MTs lengthened / shortened)

(2) Rate (frequency) Correction

- Pairs of deviation values measured and stored in even / odd cycle pair used
- For a two channel node the average of the differences from the two channels is used
- Calculated during NIT of odd numbered cycles
- Cluster drift damping is performed using global damping value
- Checked against limit values
- Correction value is a signed integer number of µTs
- Distributed over macroticks comprising the next even / odd cycle pair (MTs lengthened / shortened)

(3) Sync Frame Transmission

Sync frame transmission is only possible from buffer 0 and 1. Message buffer 1 may be used for sync frame transmission in case that sync frames should have different payloads on the two channels. In this case bit FLXAnFRMRC.SPLM has to be programmed to 1.

Message buffers used for sync frame transmission have to be configured with the key slot ID and can be (re)configured in DEFAULT_CONFIG or CONFIG state only. For nodes transmitting sync frames, bit FLXAnFRSUCC1.TXSY must be set to 1.

(4) External Clock Synchronization

During normal operation, independent clusters can drift significantly. If synchronous operation across independent clusters is desired, external synchronization is necessary; even though the nodes within each cluster are synchronized. This can be accomplished with synchronous application of host-deduced rate and offset correction terms to the clusters.

- External offset / rate correction value is a signed integer
- External offset / rate correction value is added to calculated offset / rate correction value
- Aggregated offset / rate correction term (external + internal) is not checked against configured limits

24.4.5 Error Handling

The implemented error handling concept is intended to ensure that, in case of a lower layer protocol error in one single node, communication between non-affected nodes can be maintained. In some cases, higher layer program activity is required for the CC to resume normal operation. A change of the error handling state will set FLXAnFREIR.PEMC to 1 and may trigger an interrupt to the Host if enabled. The actual error mode is signaled by FLXAnFRCCEV.ERRM[1:0].

Table 24.95 Error Modes of the POC (Degradation Model)

Error Mode	Activity
ACTIVE	Full operation, State: NORMAL_ACTIVE The CC is fully synchronized and supports the cluster wide clock synchronization. The host is informed of any error condition(s) or status change by interrupt (if enabled) or by reading the error and status interrupt flags from registers FLXAnFREIR and FLXAnFRSIR.
PASSIVE	Reduced operation, State: NORMAL_PASSIVE, CC self rescue allowed The CC stops transmitting frames and symbols, but received frames are still processed. Clock synchronization mechanisms are continued based on received frames. No active contribution to the cluster wide clock synchronization. The host is informed of any error condition(s) or status change by interrupt (if enabled) or by reading the error and status interrupt flags from registers FLXAnFREIR and FLXAnFRSIR.
COMM_HALT	Operation halted, State: HALT, CC self rescue not allowed The CC stops frame and symbol processing, clock synchronization processing, and the macrotick generation. The host has still access to error and status information by reading the error and status interrupt flags from registers FLXAnFREIR and FLXAnFRSIR. The bus drivers are disabled.

24.4.5.1 Clock Correction Failed Counter

When the Clock Correction Failed Counter reaches the “maximum without clock correction passive” limit defined by FLXAnFRSUCC3.WCP[3:0], the POC transits from NORMAL_ACTIVE to NORMAL_PASSIVE state. When it reaches the “maximum without clock correction fatal” limit defined by FLXAnFRSUCC3.WCF[3:0], it transits from NORMAL_ACTIVE or NORMAL_PASSIVE to HALT state.

The Clock Correction Failed Counter (FLXAnFRCCEV.CCFC[3:0]) allows the Host to monitor the duration of the inability of a node to compute clock correction terms after the CC passed protocol startup phase. It will be incremented by one at the end of any odd communication cycle during which either the missing offset correction FLXAnFRSFS.MOCS or the missing rate correction FLXAnFRSFS.MRCS flag is set to 1.

The Clock Correction Failed Counter is reset to zero at the end of an odd communication cycle if neither the missing offset correction FLXAnFRSFS.MOCS nor the missing rate correction FLXAnFRSFS.MRCS flag is set to 1.

The Clock Correction Failed Counter stops incrementing when the “maximum without clock correction fatal” value FLXAnFRSUCC3.WCF is reached (i.e. incrementing the counter at its maximum value will not cause it to wrap around back to zero). The Clock Correction Failed Counter is initialized to zero when the CC enters READY state or when NORMAL_ACTIVE state is entered.

CAUTION

The transition to HALT state is prevented if the FLXAnFRSUCC1.HCSE bit is not set to 1.

24.4.5.2 Passive to Active Counter

The passive to active counter controls the transition of the POC from NORMAL_PASSIVE to NORMAL_ACTIVE state. FLXAnFRSUCC1.PTA[4:0] defines the number of consecutive valid even/odd cycle pairs that must have valid clock correction terms before the CC is allowed to transit from NORMAL_PASSIVE to NORMAL_ACTIVE state. If FLXAnFRSUCC1.PTA[4:0] is set to 0 the CC is not allowed to transit from NORMAL_PASSIVE to NORMAL_ACTIVE state.

24.4.5.3 HALT Command

In case the Host wants to stop FlexRay communication of the local node it can bring the CC into HALT state by asserting the HALT command. This can be done by writing 0110 to bits FLXAnFRSUCC1.CMD[3:0]. In order to shut down communication on an entire FlexRay network, a higher layer protocol is required to assure that all nodes apply the HALT command at the same time.

The POC state from which the transition to HALT state took place can be read from flags FLXAnFRCCSV.PSL[5:0].

When called in NORMAL_ACTIVE or NORMAL_PASSIVE state the POC transits to HALT state at the end of the current cycle. When called in any other state, bits FLXAnFRSUCC1.CMD[3:0] will be reset to “0000” = command_not_accepted and bit FLXAnFREIR.CNA is set to 1. If enabled an interrupt to the Host is generated.

24.4.5.4 FREEZE Command

In case the Host detects a severe error condition it can bring the CC into HALT state by asserting the FREEZE command. This can be done by writing 0111 to bits FLXAnFRSUCC1.CMD[3:0]. The FREEZE command triggers the entry of the HALT state immediately regardless of the actual POC state.

The POC state from which the transition to HALT state took place can be read from flags FLXAnFRCCSV.PSL[5:0].

CAUTION

When transfer is stopped by a FREEZE or READY command and then restarted as a leading ColdStart node, the startup frame may not be transmitted in cycle 0. This depends on the internal state of the FlexRay module. Such cases arise when the startup frame is set in a slot 1 to slot 7. This does not occur in a ColdStart after the reset of the microcontroller. Even if the above situation arises, the ColdStart will succeed on the second trial. Repetition prolongs the overall ColdStart process, but the ColdStart will not be obstructed by the earlier situation. To avoid this effect, allocate startup and sync frames to static slot 8 or a slot with a higher number.

24.4.6 Communication Controller States

24.4.6.1 Communication Controller State Diagram

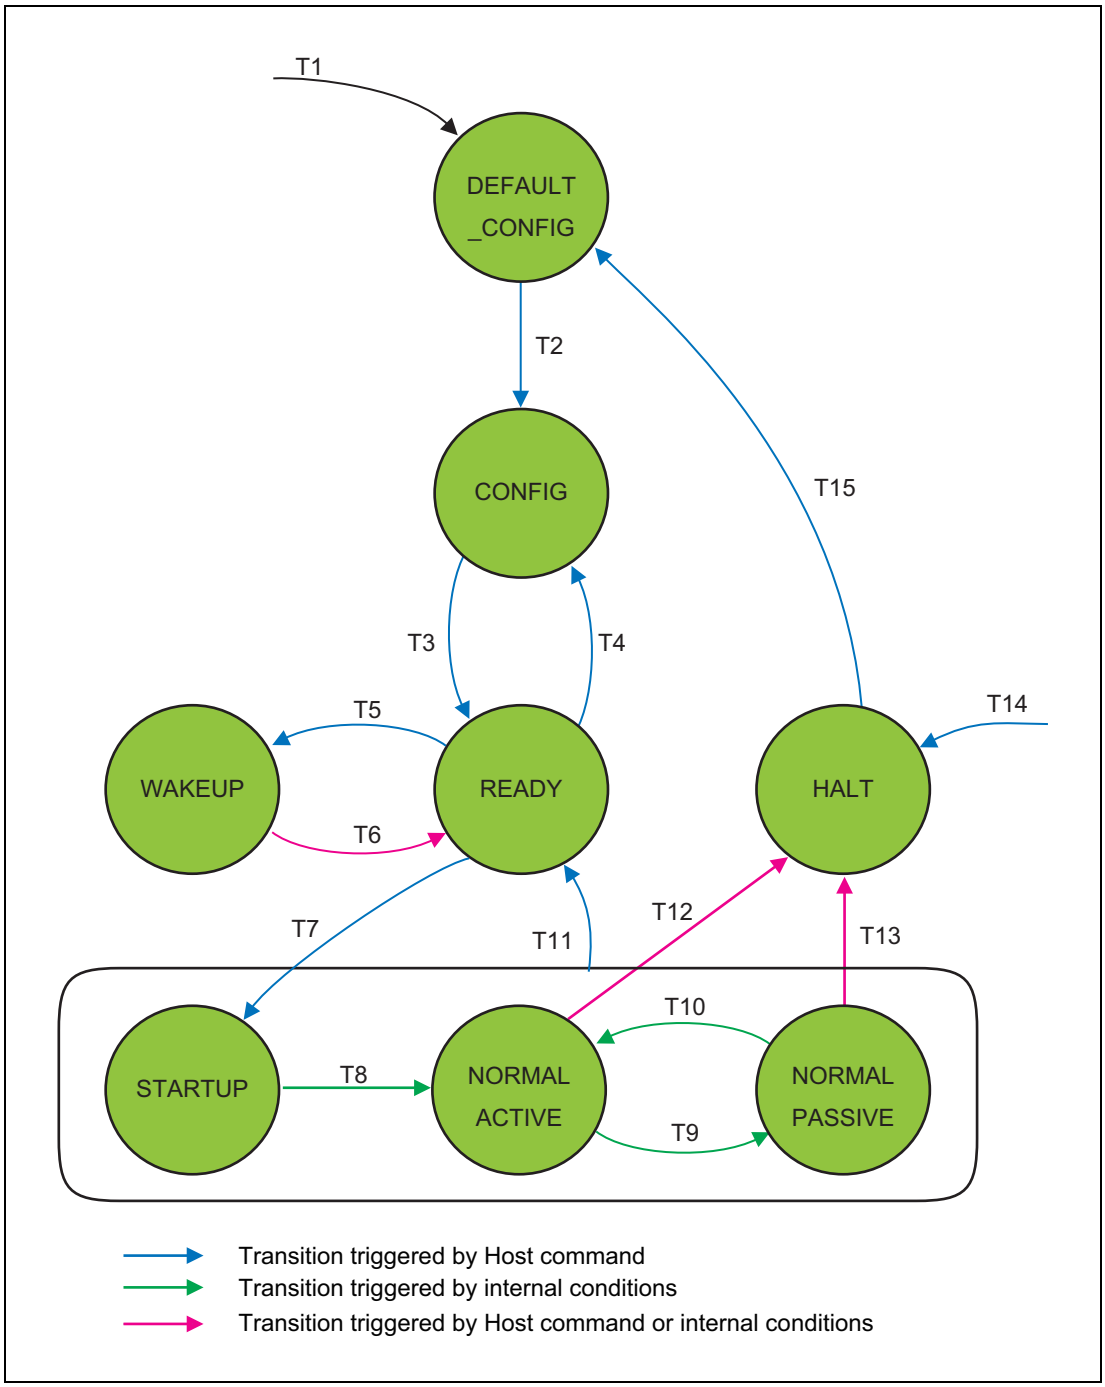

Figure 24.7 Overall State Diagram of FlexRay Communication Controller

State transitions are controlled by reset, rxda_extfxr, rxdb_extfxr, by the POC state machine, and by the CHI Command Vector FLXAnFRSUCC1.CMD[3:0].

The CC transits from all states to HALT state after application of the FREEZE command (FLXAnFRSUCC1.CMD[3:0] = “0111”).

Table 24.96 State Transitions of FlexRay Overall State Machine

T#	Condition	From	To
1	Reset	All States	DEFAULT_CONFIG
2	Command CONFIG: FLXAnFRSUCC1.CMD[3:0] = “0001”	DEFAULT_CONFIG	CONFIG
3	Unlock sequence followed by command READY: FLXAnFRSUCC1.CMD[3:0] = “0010”	CONFIG	READY
4	Command CONFIG: FLXAnFRSUCC1.CMD[3:0] = “0001”	READY	CONFIG
5	Command WAKEUP: FLXAnFRSUCC1.CMD[3:0] = “0011”	READY	WAKEUP
6	Complete transmission of wakeup pattern, received WUP or received frame header, wakeup collision or command READY: FLXAnFRSUCC1.CMD[3:0] = “0010”	WAKEUP	READY
7	Command RUN: FLXAnFRSUCC1.CMD[3:0] = “0100”	READY	STARTUP
8	Successful STARTUP	STARTUP	NORMAL_ACTIVE

12	Clock Correction Failed counter reached Maximum Without Clock Correction Fatal limit configured by FLXAnFRSUCC3.WCF[3:0] when bit FLXAnFRSUCC1.HCSE set to 1 or command HALT, FLXAnFRSUCC1.CMD[3:0] = “0110”	NORMAL_ACTIVE	HALT
13	Clock Correction Failed counter reached Maximum Without Clock Correction Fatal limit configured by FLXAnFRSUCC3.WCF[3:0] when bit FLXAnFRSUCC1.HCSE set to 1, or command HALT: FLXAnFRSUCC1.CMD[3:0] = “0110”	NORMAL_PASSIVE	HALT
14	Command FREEZE: FLXAnFRSUCC1.CMD[3:0] = “0111”	All States	HALT
15	Command CONFIG: FLXAnFRSUCC1.CMD[3:0] = “0001”	HALT	DEFAULT_CONFIG

24.4.6.2 DEFAULT_CONFIG State

In DEFAULT_CONFIG state, the CC is stopped. All configuration registers are accessible and the pins to the physical layer are in their inactive state.

The CC enters this state

- When the reset is applied (the reset of the microcontroller or the software reset of the FlexRay module)
- When exiting from HALT state

To leave DEFAULT_CONFIG state, the Host has to write 0001 to bits FLXAnFRSUCC1.CMD[3:0]. The CC then transits to CONFIG state.

24.4.6.3 CONFIG State

In CONFIG state, the CC is stopped. All configuration registers are accessible and the pins to the physical layer are in their inactive state. This state is used to initialize the CC configuration.

The CC enters this state

- When exiting from DEFAULT_CONFIG state
- When exiting from READY state

When the state has been entered via HALT and DEFAULT_CONFIG state, the Host can analyze status information and configuration. Before leaving CONFIG state, the Host has to assure that the configuration is fault-free.

To leave CONFIG state, the Host has to perform the unlock sequence as described is **Section 24.3.3.1, FLXAnFRLCK — FlexRay Lock Register**. Directly after unlocking the CONFIG state the Host has to write bits FLXAnFRSUCC1.CMD[3:0] to enter the next state.

CAUTION

Status bits FLXAnFRMHDS[14:0], registers FLXAnFRTXRQ1 to FLXAnFRTXRQ4, and status data stored in the Message RAM are not affected by the transition of the POC from CONFIG to READY state.

When the CC is in CONFIG state it is also possible to bring the CC into a power saving mode by halting the module clocks (bus clock and sample clock). To do this the Host has to assure that all Message RAM transfers have finished before turning off the clocks.

24.4.6.4 READY State

After unlocking CONFIG state and writing 0010_B to FLXAnFRSUCC1.CMD[3:0], the CC enters READY state. From this state the CC can transit to WAKEUP state and perform a cluster wakeup or to STARTUP state to perform a coldstart or to integrate into a running cluster.

The CC enters this state

- When exiting from CONFIG, WAKEUP, STARTUP, NORMAL_ACTIVE, or NORMAL_PASSIVE state by writing 0010_B to FLXAnFRSUCC1.CMD[3:0] (READY command).

The CC exits from this state

- To CONFIG state by writing 0001_B to FLXAnFRSUCC1.CMD[3:0] (CONFIG command)
- To WAKEUP state by writing 0011_B to FLXAnFRSUCC1.CMD[3:0] (WAKEUP command)
- To STARTUP state by writing 0100_B to FLXAnFRSUCC1.CMD[3:0] (RUN command)

Internal counters and the CC status flags are reset when the CC enters STARTUP state.

CAUTION

Status bits FLXAnFRMHDS[14:0], registers FLXAnFRTXRQ1 to FLXAnFRTXRQ4, and status data stored in the Message RAM are not affected by the transition of the POC from READY to STARTUP state.

24.4.6.5 WAKEUP State

The description below is intended to help configuring wakeup for the FlexRay IP-module. A detailed description of the wakeup procedure together with the respective SDL diagrams can be found in the FlexRay protocol specification v2.1, section 7.1.

The CC enters this state

- When exiting from READY state by writing 0011_B to bits FLXAnFRSUCC1.CMD[3:0] (WAKEUP command).

The CC exits from this state to READY state

- After complete non-aborted transmission of wakeup pattern (WUP)
- After WUP reception
- After detecting a WUP collision
- After reception of a frame header
- By writing 0010_B to bits FLXAnFRSUCC1.CMD[3:0] (READY command)

The cluster wakeup must precede the communication startup in order to ensure that all nodes in a cluster are awake. The minimum requirement for a cluster wakeup is that all bus drivers are supplied with power. A bus driver has the ability to wake up the other components of its node when it receives a wakeup pattern on its channel. At least one node in the cluster needs an external wakeup source.

The Host completely controls the wakeup procedure. It is informed about the state of the cluster by the bus driver and the CC and configures bus guardian (if available) and CC to perform the cluster wakeup. The CC provides to the Host the ability to transmit a special wakeup pattern on each of its available channels separately. The CC needs to recognize the wakeup pattern only during WAKEUP state.

Wakeup may be performed on only one channel at a time. The Host has to configure the wakeup channel while the CC is in CONFIG state by writing the FLXAnFRSUCC1.WUCS bit. The CC ensures that ongoing communication on this channel is not disturbed. The CC cannot guarantee that all nodes connected to the configured channel awake upon the transmission of the wakeup pattern, since these nodes cannot give feedback until the startup phase. The wakeup procedure enables single-channel devices in a two-channel system to trigger the wakeup, by only transmitting the wakeup pattern on the single channel to which they are connected. Any coldstart node that deems a system startup necessary will then wake the remaining channel before initiating communication startup.

The wakeup procedure tolerates any number of nodes simultaneously trying to wakeup a single channel and resolves this situation such that only one node transmits the pattern. Additionally the wakeup pattern is collision resilient, so even in the presence of a fault causing two nodes to simultaneously transmit a wakeup pattern, the resulting collided signal can still wake the other nodes.

After wakeup the CC returns to READY state and signals the change of the wakeup status to the Host by setting flag FLXAnFRSIR.WST. The wakeup status vector can be read from FLXAnFRCCSV.WSV[2:0]. If a valid wakeup pattern was received also either flag FLXAnFRSIR.WUPA or flag FLXAnFRSIR.WUPB is set to 1.

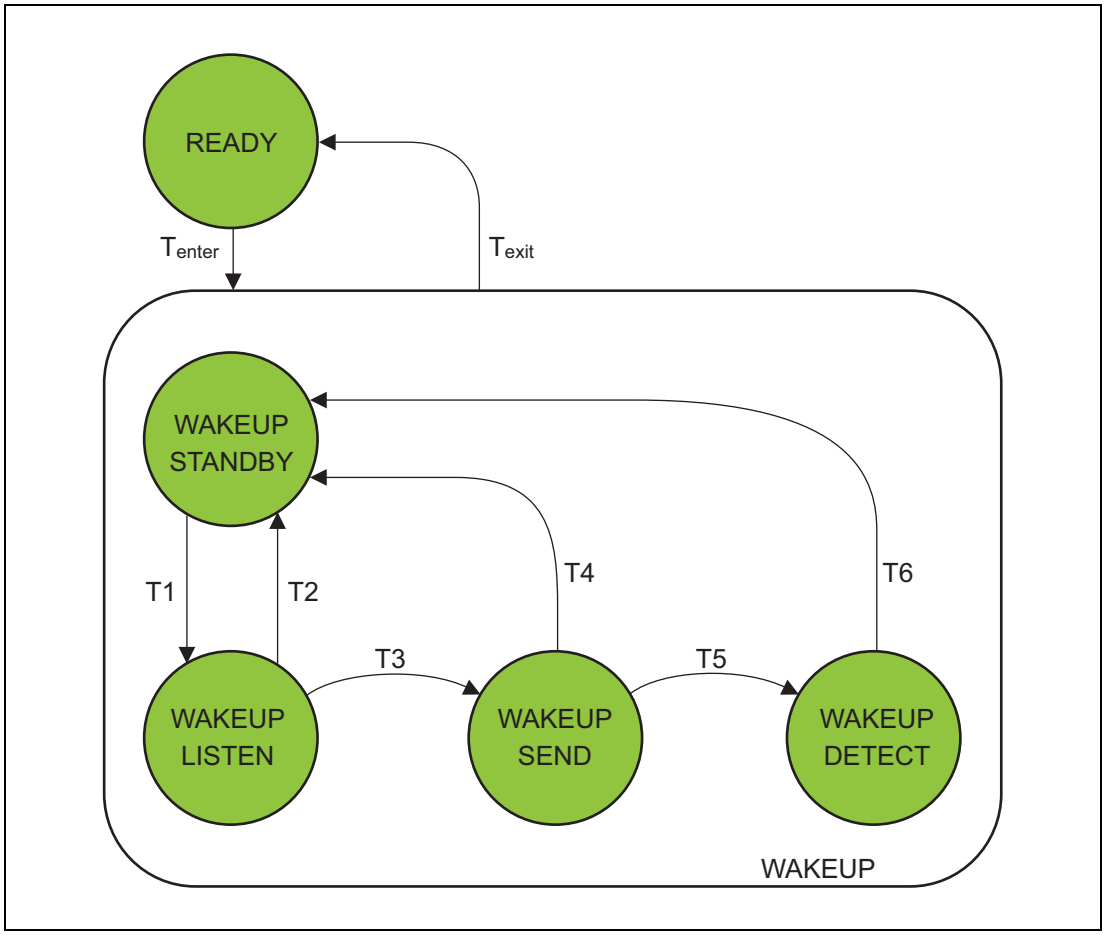

Figure 24.8 Structure of POC State WAKEUP

Table 24.97 State Transitions WAKEUP

T#	Condition	From	To
enter	Host commands change to WAKEUP state by writing 0011 to FLXAnFRSUCC1.CMD[3:0] (WAKEUP command)	READY	WAKEUP
1	CHI command WAKEUP triggers wakeup FSM to transit to WAKEUP_LISTEN state	WAKEUP_STANDBY	WAKEUP_LISTEN
2	Received WUP on wakeup channel selected by bit FLXAnFRSUCC1.WUCS or frame header on either available channel	WAKEUP_LISTEN	WAKEUP_STANDBY
3	Timer event	WAKEUP_LISTEN	WAKEUP_SEND
4	Complete, non-aborted transmission of wakeup pattern	WAKEUP_SEND	WAKEUP_STANDBY
5	Collision detected	WAKEUP_SEND	WAKEUP_DETECT
6	Wakeup timer expired or WUP detected on wakeup channel selected by bit FLXAnFRSUCC1.WUCS or frame header received on either available	WAKEUP_DETECT	WAKEUP_STANDBY
exit	Wakeup completed (after T2 or T4 or T6) or Host commands change to READY state by writing 0010 to FLXAnFRSUCC1.CMD[3:0] (READY command). This command also resets the wakeup FSM to WAKEUP_STANDBY state	WAKEUP	READY

The WAKEUP_LISTEN state is controlled by the wakeup timer and the wakeup noise timer. The two timers are controlled by the parameters Listen Timeout (bits FLXAnFRSUCC2.LT[20:0]) and Listen Timeout Noise (bits FLXAnFRSUCC2.LTN[3:0]). Listen Timeout enables a fast cluster wakeup in case of a noise free environment, while Listen Timeout Noise enables wakeup under more difficult conditions regarding noise interference.

In WAKEUP_SEND state the CC transmits the wakeup pattern on the configured channel and checks for collisions. After return from wakeup the Host has to bring the CC into STARTUP state by CHI command RUN.

In WAKEUP_DETECT state the CC attempts to identify the reason for the wakeup collision detected in WAKEUP_SEND state. The monitoring is bounded by the expiration of listen timeout as configured by bits FLXAnFRSUCC2.LT[20:0]. Either the detection of a wakeup pattern indicating a wakeup attempt by another node or the reception of a frame header indicating ongoing communication, causes the direct transition to READY state. Otherwise WAKEUP_DETECT is left after expiration of listen timeout; in this case the reason for wakeup collision is unknown.

The Host has to be aware of possible failures of the wakeup and act accordingly. It is advisable to delay any potential startup attempt of the node having instigated the wakeup by the minimal time it takes another coldstart node to become awake and to be configured.

The FlexRay Protocol Specification recommends that two different CCs shall awake the two channels.

(1) Host activities

The host must coordinate the wakeup of the two channels and must decide whether, or not, to wake a specific channel. The sending of the wakeup pattern is initiated by the Host. The wakeup pattern is detected by the remote BDs and signaled to their local Host.

Wakeup procedure controlled by Host (single-channel wakeup):

- Configure the CC in CONFIG state
  - Select wakeup channel by programming bit FLXAnFRSUCC1.WUCS
- Check local BDs whether a WUP was received
- Activate BD of selected wakeup channel
- Command CC to enter READY state
- Command CC to start wakeup on the configured channel by writing 0011 to bits FLXAnFRSUCC1.CMD[3:0]
  - CC enters WAKEUP
  - CC returns to READY state and signals status of wakeup attempt to the Host
- Wait predefined time to allow the other nodes to wakeup and configure themselves
- Coldstart node:
  - In a dual channel cluster wait for WUP on the other channel
  - Reset coldstart inhibit flag FLXAnFRCCSV.CSI by writing 1001_B to bits FLXAnFRSUCC1.CMD[3:0] (ALLOW_COLDSTART command)
- Command CC to enter startup by writing 0100_B to bits FLXAnFRSUCC1.CMD[3:0] (RUN command)

Wakeup procedure triggered by BD:

- Wakeup recognized by BD
- BD triggers power-up of Host (if required)
- BD signals wakeup event to Host
- Host configures its local CC
- If necessary, Host commands wakeup of second channel and waits predefined time to allow the other nodes to wakeup and configure themselves
- Host commands CC to enter STARTUP state by writing 0100 to bits FLXAnFRSUCC1.CMD[3:0] (RUN command)

(2) Wakeup pattern (WUP)

The wakeup pattern (WUP) is composed of at least two wakeup symbols (WUS). Wakeup symbol and wakeup pattern are configured by registers FLXAnFRPRTC1 and FLXAnFRPRTC2.

- Single channel wakeup, wakeup symbol may not be sent on both channels at the same time
- Wakeup symbol collision resilient for at least two sending nodes (two overlapping wakeup symbols always recognizable)
- Wakeup symbol must be configured identical in all nodes of a cluster
- Wakeup symbol transmit low time configured by bits FLXAnFRPRTC2.TXL[5:0]
- Wakeup symbol idle time used to listen for activity on the bus, configured by bits FLXAnFRPRTC2.TXI[7:0]
- A wakeup pattern composed of at least two Tx-wakeup symbols needed for wakeup
- Number of repetitions configurable by bits FLXAnFRPRTC1.RWP[5:0] (2 to 63 repetitions)
- Wakeup symbol receive window length configured by bits FLXAnFRPRTC1.RXW[8:0]
- Wakeup symbol receive low time configured by bits FLXAnFRPRTC2.RXL[5:0]
- Wakeup symbol receive idle time configured by bits FLXAnFRPRTC2.RXI[5:0]

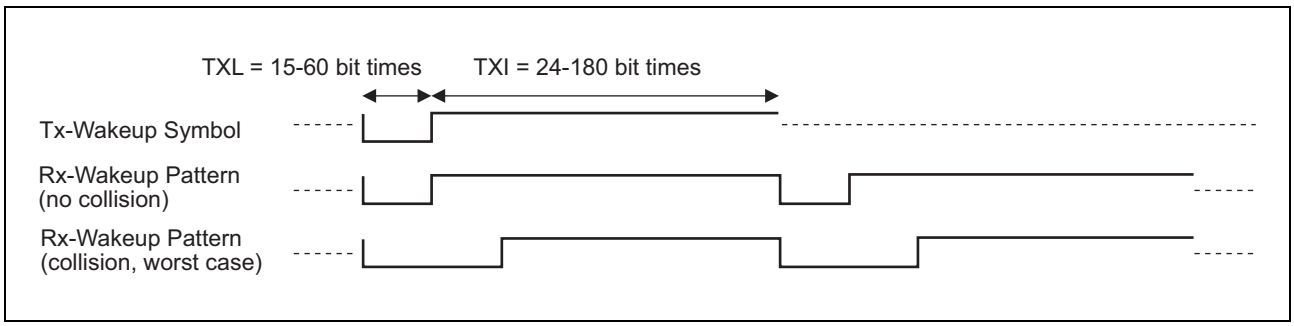

Figure 24.9 Timing of Wakeup Pattern

24.4.6.6 STARTUP State

The description below is intended to help configuring startup for the FlexRay module. A detailed description of the startup procedure together with the respective SDL diagrams can be found in the *FlexRay protocol specification v2.1*, *section 7.2*.

Any node entering STARTUP state that has coldstart capability should assure that both channels attached have been awakened before initiating coldstart.

It cannot be assumed that all nodes and stars need the same amount of time to become completely awake and to be configured. Since at least two nodes are necessary to start up the cluster communication, it is advisable to delay any potential startup attempt of the node having instigated the wakeup by the minimal amount of time it takes another coldstart node to become awake, to be configured and to enter startup. It may require several hundred milliseconds (depending on the hardware used) before all nodes and stars are completely awakened and configured.

Startup is performed on all channels synchronously. During startup, a node only transmits startup frames. Startup frames are both sync frames and null frames during startup.

A fault-tolerant, distributed startup strategy is specified for initial synchronization of all nodes. In general, a node may enter NORMAL_ACTIVE state via (see **Figure 24.10**):

- Coldstart path initiating the schedule synchronization (LeadingColdstart node)
- Coldstart path joining other coldstart nodes (FollowingColdstart node)
- Integration path integrating into an existing communication schedule (all other nodes)

A coldstart attempt begins with the transmission of a collision avoidance symbol (CAS). Only a coldstart node that had transmitted the CAS transmits frames in the first four cycles after the CAS, it is then joined firstly by the other coldstart nodes and afterwards by all other nodes.

A coldstart node has bits FLXAnFRSUCC1.TXST and FLXAnFRSUCC1.TXSY set to 1. Message buffer 0 holds the key slot ID which defines the slot number where the startup frame is send. In the frame header of the startup frame the startup frame indicator bit is set to 1.

In clusters consisting of three or more nodes, at least three nodes shall be configured to be coldstart nodes. In clusters consisting of two nodes, both nodes must be coldstart nodes. At least two fault-free coldstart nodes are necessary for the cluster to startup.

Each startup frame must also be a sync frame; therefore each coldstart node will also be a sync node. The number of coldstart attempts is configured by bits FLXAnFRSUCC1.CSA[4:0].

A non-coldstart node requires at least two startup frames from distinct nodes for integration. It may start integration before the coldstart nodes have finished their startup. It will not finish its startup until at least two coldstart nodes have finished their startup.

Both non-coldstart nodes and coldstart nodes start passive integration via the integration path as soon as they receive sync frames from which to derive the TDMA schedule information. During integration, the node has to adapt its own clock to the global clock (rate and offset) and has to make its cycle time consistent with the global schedule observable at the network. Afterwards, these settings are checked for consistency with all available network nodes. The node can only leave the integration phase and actively participate in communication when these checks are passed.

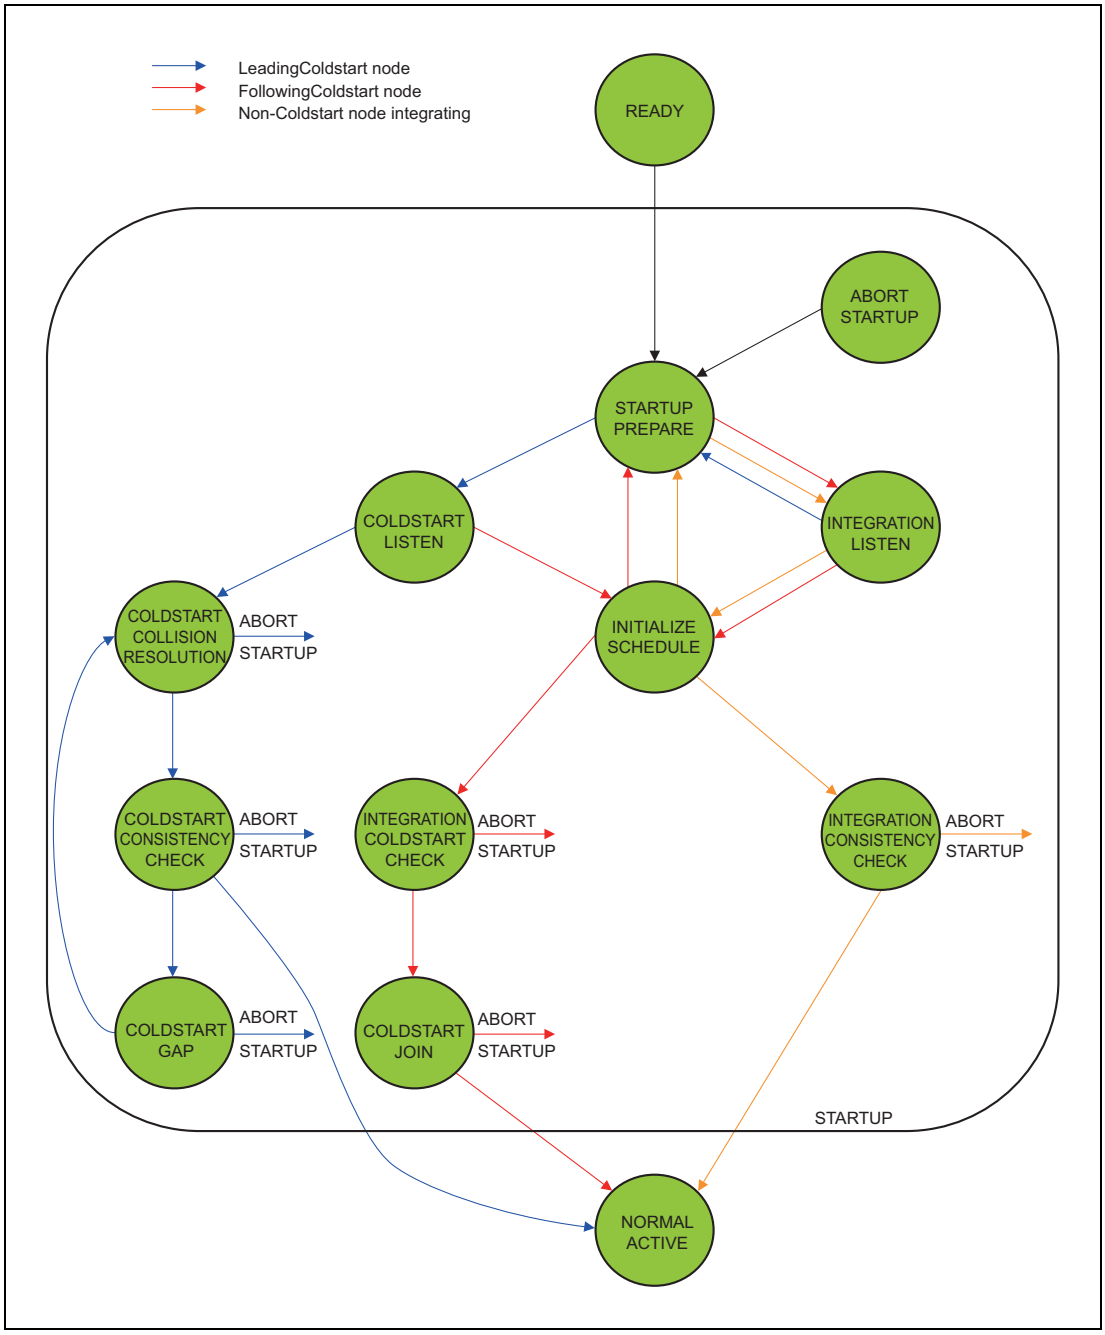

Figure 24.10 State Diagram Time-Triggered Startup

(1) Coldstart Inhibit Mode

In coldstart inhibit mode the node is prevented from initializing the TDMA communication schedule. If bit FLXAnFRCCSV.CSI is set to 1, the node is not allowed to initialize the cluster communication, i.e. entering the coldstart path is prohibited. The node is allowed to integrate to a running cluster or to transmit startup frames after another coldstart node started the initialization of the cluster communication.

The coldstart inhibit bit FLXAnFRCCSV.CSI is set to 1 whenever the POC enters READY state. The bit has to be cleared under control of the Host by CHI command ALLOW_COLDSTART (bits FLXAnFRSUCC1.CMD[3:0] = "1001_B")

(2) Startup Timeouts

The CC supplies two different µT timers supporting two timeout values, startup timeout and startup noise timeout. The two timers are started when the CC enters the COLDSTART_LISTEN state. The expiration of either of these timers causes the node to leave the initial sensing phase (COLDSTART_LISTEN state) with the intention of starting up communication.

CAUTION

The startup and startup noise timers are identical with the wakeup and wakeup noise timers and use the same configuration values FLXAnFRSUCC2.LT[20:0] and FLXAnFRSUCC2.LTN[3:0].

(a) Startup Timeout

The startup timeout limits the listen time used by a node to determine if there is already communication between other nodes or at least one coldstart node actively requesting the integration of others. The startup timer is configured by programming bits FLXAnFRSUCC2.LT[20:0] (see **Section 24.3.6.2, FLXAnFRSUCC2 — FlexRay SUC Configuration Register 2**).

The startup timeout is:

pdListenTimeout = FLXAnFRSUCC2.LT[20:0]

The startup timer is restarted upon:

- Entering the COLDSTART_LISTEN state
- Both channels reaching idle state while in COLDSTART_LISTEN state

The startup timer is stopped:

- If communication channel activity is detected on one of the configured channels while the node is in the COLDSTART_LISTEN state
- When the COLDSTART_LISTEN state is left

Once the startup timeout expires, neither an overflow nor a cyclic restart of the timer is performed. The timer status is kept for further processing by the startup state machine.

(b) Startup Noise Timeout

At the same time the startup timer is started for the first time (transition from STARTUP_PREPARE state to COLDSTART_LISTEN state), the startup noise timer is started. This additional timeout is used to improve reliability of the startup procedure in the presence of noise. The startup noise timeout is configured by programming bits FLXAnFRSUCC2.LTN[3:0] (see **Section 24.3.6.2, FLXAnFRSUCC2 — FlexRay SUC Configuration Register 2**).

The startup noise timeout:

pdListenTimeout × gListenNoise = FLXAnFRSUCC2.LT[20:0] × (FLXAnFRSUCC2.LTN[3:0] + 1)

The startup noise timer is restarted upon:

- Entering the COLDSTART_LISTEN state
- Reception of correctly decoded headers or CAS symbols while the node is in COLDSTART_LISTEN state

The startup noise timer is stopped when the COLDSTART_LISTEN state is left.

Once the startup noise timeout expires, neither an overflow nor a cyclic restart of the timer is performed. The status is kept for further processing by the startup state machine. Since the startup noise timer won't be restarted when random channel activity is sensed, this timeout defines the fall-back solution that guarantees that a node will try to start up the communication cluster even in the presence of noise.

(3) Path of Leading Coldstart Node (initiating coldstart)

When a coldstart node enters COLDSTART_LISTEN, it listens to its attached channels.

If no communication is detected, the node enters the COLDSTART_COLLISION_RESOLUTION state and commences a coldstart attempt. The initial transmission of a CAS symbol is succeeded by the first regular cycle. This cycle has the number zero.

From cycle zero on, the node transmits its startup frame. Since each coldstart node may perform a coldstart attempt, it may occur that several nodes simultaneously transmit the CAS symbol and enter the coldstart path. This situation is resolved during the first four cycles after CAS transmission.

As soon as a node that initiates a coldstart attempt receives a CAS symbol or a frame header during these four cycles, it re-enters the COLDSTART_LISTEN state. Thereby, only one node remains in this path. In cycle four, other coldstart nodes begin to transmit their startup frames.

After four cycles in COLDSTART_COLLISION_RESOLUTION state, the node that initiated the coldstart enters the COLDSTART_CONSISTENCY_CHECK state. It collects all startup frames from cycle four and five and performs the clock correction. If the clock correction does not deliver any errors and it has received at least one valid startup frame pair, the node leaves COLDSTART_CONSISTENCY_CHECK and enters NORMAL_ACTIVE state.

The number of coldstart attempts that a node is allowed to perform is configured by FLXAnFRSUCC1.CSA[4:0]. The number of remaining coldstarts attempts can be read from FLXAnFRCCSV.RCA[4:0]. The number of remaining coldstart attempts is reduced by one for each attempted coldstart. A node may enter the COLDSTART_LISTEN state only if this value is larger than one and it may enter the COLDSTART_COLLISION_RESOLUTION state only if this value is larger than zero. If the number of coldstart attempts is one, coldstart is inhibited but integration is still possible.

(4) Path of Following Coldstart Node (responding to Leading Coldstart Node)

When a coldstart node enters the COLDSTART_LISTEN state, it tries to receive a valid pair of startup frames to derive its schedule and clock correction from the leading coldstart node.

As soon as a valid startup frame has been received the INITIALIZE_SCHEDULE state is entered. If the clock synchronization can successfully receive a matching second valid startup frame and derive a schedule from this, the INTEGRATION_COLDSTART_CHECK state is entered.

In INTEGRATION_COLDSTART_CHECK state it is assured that the clock correction can be performed correctly and that the coldstart node from which this node has initialized its schedule is still available. The node collects all sync frames and performs clock correction in the following double-cycle. If clock correction does not signal any errors and if the node continues to receive sufficient frames from the same node it has integrated on, the COLDSTART_JOIN state is entered.

In COLDSTART_JOIN state following coldstart nodes begin to transmit their own startup frames and continue to do so in subsequent cycles. Thereby, the leading coldstart node and the nodes joining it can check if their schedules agree with each other. If the clock correction signals any error, the node aborts the integration attempt. If a node in this state sees at least one valid startup frame during all even cycles in this state and at least one valid startup frame pair during all double cycles in this state, the node leaves COLDSTART_JOIN state and enters NORMAL_ACTIVE state. Thereby it leaves STARTUP at least one cycle after the node that initiated the coldstart.

(5) Path of Non-coldstart Node

When a non-coldstart node enters the INTEGRATION_LISTEN state, it listens to its attached channels.

As soon as a valid startup frame has been received, the INITIALIZE_SCHEDULE state is entered. If the clock synchronization can successfully receive a matching second valid startup frame and derive a schedule from this, the INTEGRATION_CONSISTENCY_CHECK state is entered.

In INTEGRATION_CONSISTENCY_CHECK state the node verifies that the clock correction can be performed correctly and that enough coldstart nodes (at least 2) are sending startup frames that agree with the node's own schedule. Clock correction is activated, and if any errors are signaled, the integration attempt is aborted.

During the first even cycle in this state, either two valid startup frames or the startup frame of the node that this node has integrated on must be received; otherwise the node aborts the integration attempt.

During the first double-cycle in this state, either two valid startup frame pairs or the startup frame pair of the node that this node has integrated on must be received; otherwise the node aborts the integration attempt.

If after the first double-cycle less than two valid startup frames are received within an even cycle, or less than two valid startup frame pairs are received within a double-cycle, the startup attempt is aborted.

Nodes in this state need to see two valid startup frame pairs for two consecutive double-cycles each to be allowed to leave STARTUP and enter NORMAL_OPERATION. Consequently, they leave startup at least one double-cycle after the node that initiated the coldstart and only at the end of a cycle with an odd cycle number.

24.4.6.7 NORMAL_ACTIVE State

As soon as the node that transmitted the first CAS symbol (resolving the potential access conflict and entering STARTUP via coldstart path) and one additional node have entered the NORMAL_ACTIVE state, the startup phase for the cluster has finished. In the NORMAL_ACTIVE state, all configured messages are scheduled for transmission. This includes all data frames as well as the sync frames. Rate and offset measurement is started in all even cycles (even / odd cycle pairs required).

In NORMAL_ACTIVE state the CC supports regular communication functions

- The CC performs transmissions and reception on the FlexRay bus as configured
- Clock synchronization is running
- The Host interface is operational

The CC exits from that state to

- HALT state by writing 0110_B to bits FLXAnFRSUCC1.CMD[3:0] (HALT command, at the end of the current cycle)
- HALT state by writing 0111_B to bits FLXAnFRSUCC1.CMD[3:0] (FREEZE command, immediately)
- HALT state due to change of the error state from ACTIVE to COMM_HALT
- NORMAL_PASSIVE state due to change of the error state from ACTIVE to PASSIVE
- READY state by writing 0010_B to bits FLXAnFRSUCC1.CMD[3:0] (READY command)

24.4.6.8 NORMAL_PASSIVE State

NORMAL_PASSIVE state is entered from NORMAL_ACTIVE state when the error state changes from ACTIVE to PASSIVE.

In NORMAL_PASSIVE state, the node is able to receive all frames (node is fully synchronized and performs clock synchronization). Contrary to the NORMAL_ACTIVE state, the node does not actively participate in communication, i.e. neither symbols nor frames are transmitted.

In NORMAL_PASSIVE state

- The CC performs reception on the FlexRay bus
- The CC does not transmit any frames or symbols on the FlexRay bus
- Clock synchronization is running
- The Host interface is operational

The CC exits from this state to

- HALT state by writing 0110_B to bits FLXAnFRSUCC1.CMD[3:0] (HALT command, at the end of the current cycle)
- HALT state by writing 0111_B to bits FLXAnFRSUCC1.CMD[3:0] (FREEZE command, immediately)
- HALT state due to change of the error state from PASSIVE to COMM_HALT
- NORMAL_ACTIVE state due to change of the error state from PASSIVE to ACTIVE.
  The transition takes place when bits FLXAnFRCCEV.PTAC[4:0] equals bits FLXAnFRSUCC1.PTA[4:0] - 1
- To READY state by writing 0010_B to bits FLXAnFRSUCC1.CMD[3:0] (READY command)

24.4.6.9 HALT State

In this state all communication (reception and transmission) is stopped.

The CC enters this state

- By writing 0110_B to bits FLXAnFRSUCC1.CMD[3:0] (HALT command) while the CC is in NORMAL_ACTIVE or NORMAL_PASSIVE state
- By writing 0111_B to bits FLXAnFRSUCC1.CMD[3:0] (FREEZE command) from all states
- When exiting from NORMAL_ACTIVE state because the clock correction failed counter reached the “maximum without clock correction fatal” limit and FLXAnFRSUCC1.HCSE is set to 1
- When exiting from NORMAL_PASSIVE state because the clock correction failed counter reached the “maximum without clock correction fatal” limit and FLXAnFRSUCC1.HCSE is set to 1

The CC exits from this state to DEFAULT_CONFIG state

- By writing 0001_B to bits FLXAnFRSUCC1.CMD[3:0] (CONFIG command)

When the CC enters HALT state, all configuration and status data is maintained for analyzing purposes.

When the Host writes 0110_B to bits FLXAnFRSUCC1.CMD[3:0] (HALT command), the CC sets flag FLXAnFRCCSV.HRQ to 1 and enters HALT state at the next end of cycle.

When the Host writes 0111_B to bits FLXAnFRSUCC1.CMD[3:0] (FREEZE command), the CC enters HALT state immediately and sets flag FLXAnFRCCSV.FSI to 1.

The POC state from which the transition to HALT state took place can be read from FLXAnFRCCSV.PSL[5:0].

24.4.7 Network Management

The accrued Network Management (NM) vector can be read from registers FLXAnFRNMV1 to FLXAnFRNMV3. The CC performs a bit-wise OR operation over all NM vectors out of all received valid NM frames with the Payload Preamble Indicator (PPI) bit set. Only static frames may be configured to hold NM information. The CC updates the NM vector at the end of each cycle.

The length of the NM vector can be configured from 0 to 12 bytes by bits FLXAnFRNEMC.NML[3:0]. The NM vector length must be configured identically in all nodes of a cluster.

To configure a transmit buffer to send FlexRay frames with the PPI bit set as 1, bit PPIT in the header section of the respective transmit buffer has to be set to 1 via bit FLXAnFRWRHS1.PPIT. In addition the Host has to write the NM information to the data section of the respective transmit buffer.

The evaluation of the NM vector has to be done by the application running on the Host.

CAUTIONS

1. **In case a message buffer is configured for transmission / reception of network management frames, the payload length configured in header 2 of that message buffer should be equal or greater than the length of the NM vector configured by the FLXAnFRNEMC.NML[3:0] bits.**
2. **When the CC transits to HALT state, the cycle count is not incremented and therefore the NM vector is not updated. In this case FLXAnFRNMV1 to FLXAnFRNMV3 holds the value from the cycle before.**

24.4.8 Filtering and Masking

Filtering is done by comparison of the configuration of assigned message buffers against actual slot and cycle counter values and channel ID (channel A, B). A message buffer is only updated / transmitted if the required matches occur.

Filtering is done on:

- Slot Counter
- Cycle Counter
- Channel ID

The following filter combinations for acceptance / transmit filtering are allowed:

- Slot Counter + Channel ID
- Slot Counter + Cycle Counter + Channel ID

All configured filters must match in order to store a received message in a message buffer.

CAUTION

For the FIFO the acceptance filter is configured by the FIFO Rejection Filter (FLXAnFRFRF) and the FIFO Rejection Filter Mask (FLXAnFRFRFM).

A message will be transmitted in the time slot corresponding to the configured frame ID on the configured channel(s). If cycle counter filtering is enabled the configured cycle filter value must also match.

24.4.8.1 Slot Counter Filtering

Every transmit and receive buffer contains a frame ID stored in the header section. This frame ID is compared against the actual slot counter value in order to assign receive and transmit buffers to the corresponding slot.

If two or more message buffers are configured with the same frame ID and channel ID, and if they have a matching cycle counter filter value for the same slot, then the message buffer with the lowest message buffer number is used.

24.4.8.2 Cycle Counter Filtering

Cycle counter filtering is based on the notion of a cycle set. For filtering purposes, a match is detected if any one of the elements of the cycle set is matched. The cycle set is defined by the cycle code field in header section 1 of each message buffer.

If message buffer 0 resp. 1 is configured to hold the startup / sync frame or the single slot frame by bits FLXAnFRSUCC1.TXST, FLXAnFRSUCC1.TXSY, and FLXAnFRSUCC1.TSM, cycle counter filtering for message buffer 0 resp. 1 shall be disabled.

CAUTION

Sharing of a static time slot via cycle counter filtering between different nodes of a FlexRay network is not allowed.

The set of cycle numbers belonging to a cycle set is determined as described in **Table 24.98**.

Table 24.98 Definition of cycle set

Cycle Code	Matching Cycle Counter Values
$000000x_B$	all Cycles
$000001c_B$	every second Cycle at (Cycle Count) mod2 = c
$00001cc_B$	every fourth Cycle at (Cycle Count) mod4 = cc
$0001ccc_B$	every eighth Cycle at (Cycle Count) mod8 = ccc
$001cccc_B$	every sixteenth Cycle at (Cycle Count) mod16 = cccc
$01ccccc_B$	every thirty-second Cycle at (Cycle Count) mod32 = ccccc
$1cccccc_B$	every sixty-fourth Cycle at (Cycle Count) mod64 = cccccc

Table 24.99 below gives some examples for valid cycle sets to be used for cycle counter filtering.

Table 24.99 Examples for valid cycle sets

Cycle Code	Matching Cycle Counter Values
0000011_B	1-3-5-7-…. -63
0000100_B	0-4-8-12-…. -60
0001110_B	6-14-22-30-…. -62
0011000_B	8-24-40-56
0100011_B	3-35
1001001_B	9

The received message is stored only if the cycle counter value of the cycle during which the message is received matches an element of the receive buffer's cycle set. Channel ID and frame ID must also be met.

The content of a transmit buffer is transmitted on the configured channel(s) when an element of the cycle set matches the current cycle counter value. Channel ID and frame ID must also be met.

24.4.8.3 Channel ID Filtering

There is a 2-bit channel filtering field (CH) located in the header section of each message buffer in the Message RAM. It serves as a filter for receive buffers, and as a control field for transmit buffers (see **Table 24.100**).

Table 24.100 Channel filtering configuration

CH[1:0]	**Transmit Buffer** transmit frame	**Receive Buffer store valid receive frame**
00	no transmission	ignore frame
01	on channel A	received on channel A
10	on channel B	received on channel B
11	on both channels (static segment only)	received on channel A or B (store first semantically valid frame, static segment only)

The contents of a transmit buffer is transmitted on the channels specified in the channel filtering field when the slot counter filtering and cycle counter filtering criteria are also met. Only in static segment a transmit buffer may be set up for transmission on both channels (CH = "11_B").

Valid received frames are stored if they are received on the channels specified in the channel filtering field when the slot counter filtering and cycle counter filtering criteria are also met. Only in static segment a receive buffer may be setup for reception on both channels (CH = "11").

CAUTION

If a message buffer is configured for the dynamic segment and both bits of the channel filtering field are set to 1, no frames are transmitted resp. received frames are ignored (same function as CH = "00").

24.4.8.4 FIFO Filtering

For FIFO filtering registers FLXAnFRFRF and FLXAnFRFRFM are used. The FIFO filter consists of channel filter bits FLXAnFRFRF.CH[1:0], frame ID filter bits FLXAnFRFRF.FID[10:0], and cycle counter filter bits FLXAnFRFRF.CYF[6:0]. Registers FLXAnFRFRF and FLXAnFRFRFM can be configured in DEFAULT_CONFIG or CONFIG state only. The filter configuration in the header section of message buffers belonging to the FIFO is ignored.

The 7-bit cycle counter filter determines the cycle set to which frame ID and channel rejection filter are applied. In cycles not belonging to the cycle set specified by FLXAnFRFRF.CYF, all frames are rejected.

A valid received frame is stored in the FIFO if channel ID, frame ID, and cycle counter are not rejected by the configured rejection filter and rejection filter mask, and if there is no matching dedicated receive buffer.

24.4.9 Transmit Process

24.4.9.1 Static Segment

For the static segment, if there are several messages pending for transmission, the message with the frame ID corresponding to the next sending slot is selected for transmission.

The data section of transmit buffers assigned to the static segment can be updated until the end of the preceding time slot. This means that a transfer from the Input Buffer has to be started by writing to the Input Buffer Command Request register latest at this time.

24.4.9.2 Dynamic Segment

In the dynamic segment, if several messages are pending, the message with the highest priority (lowest frame ID) is selected next. In the dynamic segment different slot counter sequences on channel A and channel B are possible (concurrent sending of different frame IDs on both channels).

The data section of transmit buffers assigned to the dynamic segment can be updated until the end of the preceding slot. This means that a transfer from the Input Buffer has to be started by writing to the Input Buffer Command Request register latest at this time.

The start of latest transmit configured by bits FLXAnFRMHDC.SLT[12.0] defines the maximum minislot value allowed before inhibiting new frame transmission in the dynamic segment of the current cycle.

24.4.9.3 Transmit Buffers

FlexRay message buffers can be configured as transmit buffers by programming bit CFG in the header section of the respective message buffer to 1 via FLXAnFRWRHS1.

There exist the following possibilities to assign a transmit buffer to the CC channels:

- Static segment: channel A or channel B,
  channel A and channel B
- Dynamic segment: channel A or channel B

Message buffer 0 resp. 1 is dedicated to hold the startup frame, the sync frame, or the designated single slot frame as configured by FLXAnFRSUCC1.TXST, FLXAnFRSUCC1.TXSY, and FLXAnFRSUCC1.TSM. In this case, it can be reconfigured in DEFAULT_CONFIG or CONFIG state only. This ensures that any node transmits at most one startup / sync frame per communication cycle. Transmission of startup / sync frames from other message buffers is not possible.

All other message buffers configured for transmission in static or dynamic segment are reconfigurable during runtime depending on the configuration of bits FLXAnFRMRC.SEC[1.0] (see **Section 24.4.12.1, Reconfiguration of Message Buffers**). Due to the organization of the data partition in the Message RAM (reference by data pointer), reconfiguration of the configured payload length and the data pointer in the header section of a message buffer may lead to erroneous configurations.

If a message buffer is reconfigured (header section updated) during runtime, it may happen that this message buffer is not send out in the respective communication cycle.

The CC does not have the capability to calculate the header CRC. The Host is supposed to provide the header CRCs for all transmit buffers. If network management is required, the Host has to set the PPIT bit in the header section of the respective message buffer to 1 and write the network management information to the data section of the message buffer (see **Section 24.4.7, Network Management**).

The payload length field configures the payload length in 2-byte words. If the configured payload length of a static transmit buffer is shorter than the payload length configured for the static segment by

FLXAnFRMHDC.SFDL[6.0], the CC generates padding bytes to ensure that frames have proper physical length. The padding pattern is "0000_H".

CAUTION

In case of an odd payload length (PLC = 1, 3, 5, so on) the application has to write zero to the last 16 bit of the message buffers data section to ensure that the padding pattern is 0000_H.

Each transmit buffer provides a transmission mode flag TXM that allows the Host to configure the transmission mode for the transmit buffer. If this bit is set, the transmitter operates in the single-shot mode. If this bit is cleared, the transmitter operates in the continuous mode.

In single-shot mode the CC resets the respective TXR flag to 0 after transmission has completed. Now the Host may update the transmit buffer.

In continuous mode, the CC does not reset the respective transmission request flag TXR to 0 after successful transmission. In this case a frame is sent out each time the filter criteria match. The TXR flag can be reset to 0 by the Host by writing the respective message buffer number to the FLXAnFRIBCR register while bit FLXAnFRIBCM.STXRH is set to 0.

If two or more transmit buffers meet the filter criteria simultaneously, the transmit buffer with the lowest message buffer number will be transmitted in the respective slot.

24.4.9.4 Frame Transmission

The following steps are required to prepare a message buffer for transmission:

- Configure the transmit buffer in the Message RAM via registers FLXAnFRWRHS1 to FLXAnFRWRHS3
- Write the data section of the transmit buffer via register FLXAnFRWRDSm
- Transfer the configuration and message data from Input Buffer to the Message RAM by writing the number of the target message buffer to register FLXAnFRIBCR
- If configured in register FLXAnFRIBCM, the transmission request flag TXR for the respective message buffer will be set as soon as the transfer has completed, and the message buffer is ready for transmission.
- Check whether the message buffer has been transmitted by checking the respective TXR bit (TXR = 0) in the FLXAnFRTRXQ1 to FLXAnFRTRXQ4 registers (single-shot mode only).

After transmission has completed, the respective TXR flag in the FLXAnFRTXRQ1 to FLXAnFRTXRQ4 registers is reset to 0 (single-shot mode), and, if bit MBI in the header section of the message buffer is set to 1, bit FLXAnFRSIR.TXI is set to 1. If enabled, an interrupt is generated.

24.4.9.5 Null Frame Transmission

If in static segment the Host does not set the transmission request flag to 1 before transmit time, the CC transmits a null frame with the null frame indication bit set to 0 and the payload data set to zero.

In the following cases the CC transmits a null frame:

- If the message buffer with the lowest message buffer number matching the filter criteria does not have its transmission request flag set (TXR = 0) to 1.
- No transmit buffer configured for the slot has a cycle counter filter that matches the current cycle. In this case, no message buffer status FLXAnFRMBS is updated.

Null frames are not transmitted in the dynamic segment.

24.4.10 Receive Process

24.4.10.1 Dedicated Receive Buffers

A portion of the FlexRay message buffers can be configured as dedicated receive buffers by programming bit CFG in the header section of the respective message buffer to 0 via FLXAnFRWRHS1.

The following possibilities exist to assign a receive buffer to the CC channels:

- Static segment: channel A or channel B,
  channel A and channel B (the CC stores the first semantically valid frame)
- Dynamic segment: channel A or channel B

The CC transfers the payload data of valid received messages from the shift register of the FlexRay channel protocol controller (channel A or B) to the receive buffer with the matching filter configuration. A receive buffer stores all frame elements except the frame CRC.

All message buffers configured for reception in static or dynamic segment are reconfigurable during runtime depending on the configuration of bits FLXAnFRMRC.SEC[1.0] (see **Section 24.4.12.1, Reconfiguration of Message Buffers**). If a message buffer is reconfigured (header section updated) during runtime it may happen that in the respective communication cycle a received message is lost.

If two or more receive buffers meet the filter criteria simultaneously, the receive buffer with the lowest message buffer number is updated with the received message.

24.4.10.2 Frame Reception

The following steps are required to prepare a dedicated message buffer for reception:

- Configure the receive buffer in the Message RAM via registers FLXAnFRWRHS1 to FLXAnFRWRHS3
- Transfer the configuration from Input Buffer to the Message RAM by writing the number of the target message buffer to register FLXAnFRIBCR

Once these steps are performed, the message buffer functions as an active receive buffer and participates in the internal acceptance filtering process which takes place every time the CC receives a message. The first matching receive buffer is updated from the received message.

If a valid payload segment was stored in the data section of a message buffer, the respective ND flag in the FLXAnFRNDAT1 to FLXAnFRNDAT4 registers is set to 1, and, if bit MBI in the header section of that message buffer is set to 1, bit FLXAnFRSIR.RXI is set to 1. If enabled, an interrupt is generated.

In case that bit ND was already set to 1 when the Message Handler updates the message buffer, bit FLXAnFRMBS.MLST of the respective message buffer is set to 1 and the unprocessed message data is lost.

If no frame, a null frame, or a corrupted frame was received in a slot, the data section of the message buffer configured for this slot is not updated. In this case only the respective message buffer status FLXAnFRMBS is updated.

When the Message Handler changed the message buffer status FLXAnFRMBS in the header section of a message buffer, the respective MBC flag in the FLXAnFRMBSC1 to FLXAnFRMBSC4 registers is set to 1, and if bit MBI in the header section of that message buffer is set, bit FLXAnFRSIR.MBSI is set to 1. If enabled an interrupt is generated.

If the payload length of a received frame PLR is longer than the value programmed by PLC in the header section of the respective message buffer, the data field stored in the message buffer is truncated to that length.

To read a receive buffer from the Message RAM via the Output Buffer, proceed as described in **Section 24.4.12.2, (2) Data Transfer from Message RAM to Output Buffer**.

CAUTION

The ND and MBC flags are automatically cleared by the Message Handler when the payload data and the header of a received message have been transferred to the Output Buffer, respectively.

24.4.10.3 Null Frame Reception

The payload segment of a received null frame is not copied into the matching dedicated receive buffer. If a null frame has been received, only the message buffer status FLXAnFRMBS of the matching message buffer is updated from the received null frame. All bits in header 2 and 3 of the matching message buffer remain unchanged. They are updated from received data frames only.

When the Message Handler changed the message buffer status FLXAnFRMBS in the header section of a message buffer, the respective MBC flag in the FLXAnFRMBSC1 to FLXAnFRMBSC4 register is set to 1, and if bit MBI in the header section of that message buffer is set to 1, flag FLXAnFRSIR.MBSI is set to 1. If enabled, an interrupt is generated.

24.4.11 FIFO Function

24.4.11.1 Description

A portion of the message buffers can be configured as a cyclic First-In-First-Out (FIFO) buffer. The group of message buffers belonging to the FIFO is contiguous in the register map starting with the message buffer referenced by FLXAnFRMRC.FFB[7.0] and ending with the message buffer referenced by FLXAnFRMRC.LCB[7.0]. Up to 127 message buffers can be assigned to the FIFO.

Every valid incoming message not matching with any dedicated receive buffer but passing the programmable FIFO filter is stored into the FIFO. In this case frame ID, payload length, receive cycle count, and the message buffer status FLXAnFRMBS of the addressed FIFO message buffer are overwritten with frame ID, payload length, receive cycle count, and the status from the received frame. When Flag FLXAnFRSIR.RFNE is set to 1, it shows that the FIFO is not empty. When bit FLXAnFRSIR.RFCL is set to 1, it shows that the receive FIFO fill level (FLXAnFRFSR.RFFL[7.0]) is equal or greater than the critical level as configured by FLXAnFRFCL.CL. When bit FLXAnFREIR.RFO is set to 1, it shows that a FIFO overrun has been detected. If interrupts are enabled, interrupt requests are generated.

If null frames are not rejected by the FIFO rejection filter, the null frames will be treated like data frames when they are stored into the FIFO.

There are two index registers associated with the FIFO. The PUT Index Register (PIDX) is an index to the next available location in the FIFO. When a new message has been received it is written into the message buffer addressed by the PIDX register. The PIDX register is then incremented and addresses the next available message buffer. If the PIDX register is incremented past the highest numbered message buffer of the FIFO, the PIDX register is loaded with the number of the first (lowest numbered) message buffer in the FIFO chain. The GET Index Register (GIDX) is used to address the next message buffer of the FIFO to be read. The GIDX register is incremented after transfer of the contents of a message buffer belonging to the FIFO to the Output Buffer. The PUT Index Register and the GET Index Register are not accessible by the Host.

The FIFO is completely filled when the PUT index (PIDX) reaches the value of the GET index (GIDX). When the next message is written to the FIFO before the oldest message has been read, both PUT index and GET index are incremented and the new message overwrites the oldest message in the FIFO. This will set FIFO overrun flag FLXAnFREIR.RFO to 1.

A FIFO non empty status is detected when the PUT index (PIDX) differs from the GET index (GIDX). In this case flag FLXAnFRSIR.RFNE is set to 1. This indicates that there is at least one received message in the FIFO. The FIFO empty, FIFO not empty, and the FIFO overrun states are explained in **Figure 24.11** for a three message buffer FIFO.

The programmable FlexRay FIFO Rejection Filter (FLXAnFRFRF) defines a filter pattern for messages to be rejected. The FIFO filter consists of channel filter, frame ID filter, and cycle counter filter. If bit FLXAnFRFRF.RSS is set to 1, all messages received in the static segment are rejected by the FIFO. If bit FLXAnFRFRF.RNF is set to 1, received null frames are not stored in the FIFO.

The FlexRay FIFO Rejection Filter Mask (FLXAnFRFRFM) specifies which bits of the frame ID filter in the FIFO Rejection Filter register are marked 'don't care' for rejection filtering.

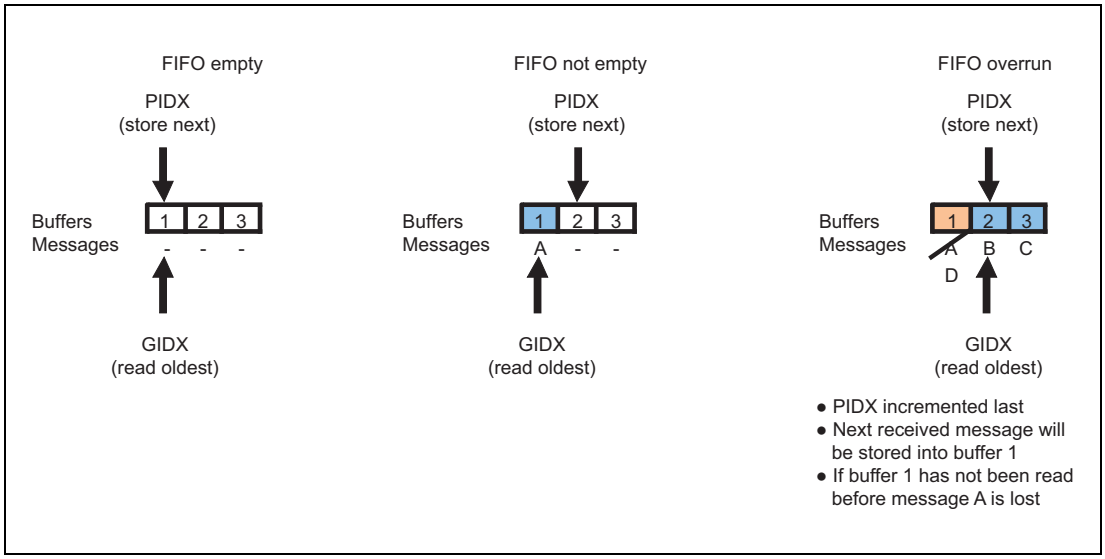

Figure 24.11 FIFO Status: Empty, Not Empty, Overrun

24.4.11.2 Configuration of the FIFO

(Re)configuration of message buffers belonging to the FIFO is only possible when the CC is in DEFAULT_CONFIG or CONFIG state. While the CC is in DEFAULT_CONFIG or CONFIG state, the FIFO function is not available.

For all message buffers belonging to the FIFO the payload length configured should be programmed to the same value via bits FLXAnFRWRHS2.PLC[6.0]. The data pointer to the first 32-bit word of the data section of the respective message buffer in the Message RAM has to be configured via bits FLXAnFRWRHS3.DP[10.0].

All information required for acceptance filtering is taken from the FIFO rejection filter and the FIFO rejection filter mask. The values configured in the header sections of the message buffers belonging to the FIFO are, with exception of DP and PLC, irrelevant.

CAUTIONS

1. **It is recommended to program the MBI bits of the message buffers belonging to the FIFO to 0 via FLXAnFRWRHS1.MBI to avoid generation of RX interrupts.**
2. **If the payload length of a received frame is longer than the value programmed by FLXAnFRWRHS2.PLC in the header section of the respective message buffer, the data field stored in a message buffer of the FIFO is truncated to that length.**

24.4.11.3 Access to the FIFO

(1) When the output buffer is used:

For FIFO access outside DEFAULT_CONFIG and CONFIG state, the Host has to trigger a transfer from the Message RAM to the Output Buffer by writing the number of the first message buffer of the FIFO (referenced by FLXAnFRMRC.FFB[7.0]) to the register FLXAnFROBCR. The Message Handler then transfers the message buffer addressed by the GET Index Register (GIDX) to the Output Buffer. After this transfer the GET Index Register (GIDX) is incremented.

(2) When the data transfer function is used:

The message received in FIFO can be transferred to the Local RAM/Cluster RAM by using the output data transfer function. For the output data transfer function, see **Section 24.4.16.2, Output Data Transfer**, Output Data Transfer.

24.4.12 Message Handling

The Message Handler controls data transfers between the Input / Output Buffer and the Message RAM and between the Message RAM and the two TBFs.

Access to the message buffers stored in the Message RAM is done under control of the Message Handler state machine. This avoids conflicts between accesses of the two FlexRay channel protocol controllers and the Host to the Message RAM.

Frame IDs of message buffers assigned to the static segment have to be in the range from 1 to bits FLXAnFRGTUC7.NSS[9:0]. Frame IDs of message buffers assigned to the dynamic segment have to be in the range from bits FLXAnFRGTUC7.NSS[9:0] + 1 to 2047.

Received messages with no matching dedicated receive buffer (static or dynamic segment) are stored in the receive FIFO (if configured) if they pass the FIFO rejection filter.

Access of the Host to the message buffer contents using the input or output buffer function is described in this subsection. Access to the message buffer contents using the data transfer function is mentioned in **Section 24.4.16, Usage of Data Transfer**.

24.4.12.1 Reconfiguration of Message Buffers

In case that an application needs to operate with more than 128 different messages, static and dynamic message buffers may be reconfigured during FlexRay operation. This is done by updating the header section of the respective message buffer via Input Buffer registers FLXAnFRWRHS1 to FLXAnFRWRHS3.

Reconfiguration has to be enabled via control bit FLXAnFRMRC.SEC in the Message RAM Configuration register.

If a message buffer has not been transmitted / updated from a received frame before reconfiguration starts, the respective message is lost.

The point in time when a reconfigured message buffer is ready for transmission / reception according to the reconfigured frame ID depends on the actual state of the slot counter when the update of the header section has completed. Therefore it may happen that a reconfigured message buffer is not transmitted / updated from a received frame in the cycle where it was reconfigured.

The Message RAM is scanned according to **Table 24.101** below.

Table 24.101 Scan of Message RAM

Start of Scan in Slot	Scan for Slots
1	2 to 15, 1 (next cycle)
8	16 to 23, 1 (next cycle)
16	24 to 31, 1 (next cycle)
24	32 to 39, 1 (next cycle)
....	....

A Message RAM scan is terminated with the start of NIT regardless whether it has completed or not. The scan of the Message RAM for slots 2 to 15 starts at the beginning of slot 1 of the actual cycle. The scan of the Message RAM for slot 1 is done in the cycle before by checking in parallel to each scan of the Message RAM whether there is a message buffer configured for slot 1 of the next cycle.

The number of the first dynamic message buffer is configured by bits FLXAnFRMRC.FDB[7:0]. In case a Message RAM scan starts while the CC is in dynamic segment, the scan starts with the message buffer number configured by bit FLXAnFRMRC.FDB.

In case a message buffer should be reconfigured to be used in slot 1 of the next cycle, the following has to be considered:

- If the message buffer to be reconfigured for slot 1 is part of the “Static Buffers”, it will only be found if it is reconfigured before the last Message RAM scan in the static segment of the actual cycle evaluates this message buffer.
- If the message buffer to be reconfigured for slot 1 is part of the “Static + Dynamic Buffers”, it will be found if it is reconfigured before the last Message RAM scan in the actual cycle evaluates this message buffer.
- The start of NIT terminates the Message RAM scan. In case the Message RAM scan has not evaluated the reconfigured message buffer until this point in time, the message buffer will not be considered for the next cycle.

CAUTION

Reconfiguration of message buffers may lead to the loss of messages and therefore has to be used very carefully. In worst case (reconfiguration in consecutive cycles) it may happen that a message buffer is never transmitted / updated from a received frame.

24.4.12.2 Host access to Message RAM

The message transfer between Input Buffer and Message RAM as well as between Message RAM and Output Buffer is triggered by the Host by writing the number of the target / source message buffer to be accessed to FLXAnFRIBCR or FLXAnFROBCR register.

The FLXAnFRIBCM and FLXAnFROBCM registers can be used to write / read header and data section of the selected message buffer separately.

If bit FLXAnFRIBCM.STXR is set to 1, the transmission request flag TXR of the selected message buffer is automatically set to 1 after the message buffer has been updated. If bit FLXAnFRIBCM.STXR is reset to 0, the transmission request flag TXR of the selected message buffer is reset. This can be used to stop transmission from message buffers operated in continuous mode.

Input Buffer (IBF) and Output Buffer (OBF) are build up as a double buffer structure. One half of this double buffer structure is accessible by the Host (IBF Host / OBF Host), while the other half (IBF Shadow / OBF Shadow) is accessed by the Message Handler for data transfers between IBF / OBF and Message RAM.

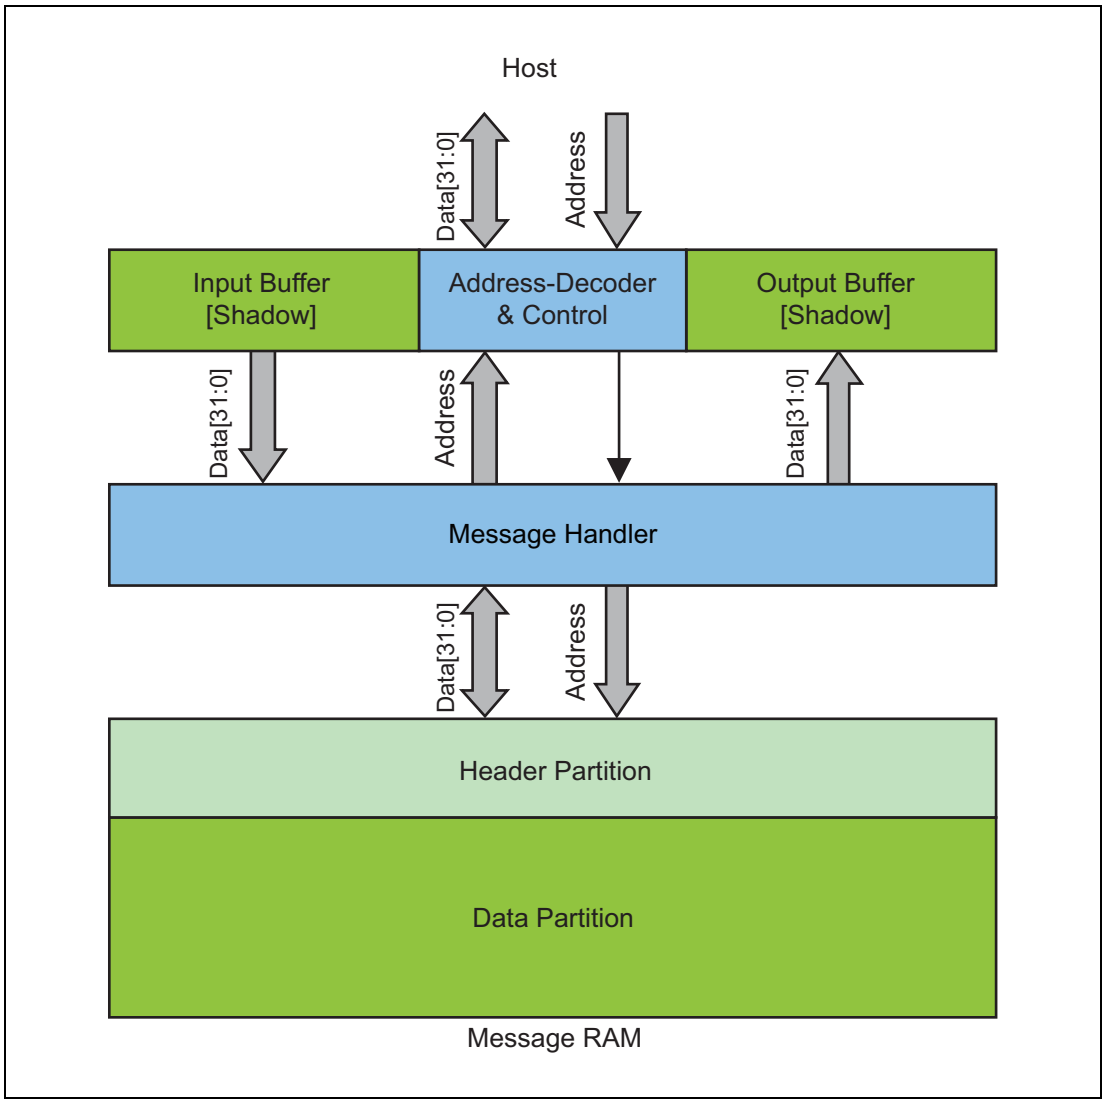

Figure 24.12 Host access to Message RAM

(1) Data Transfer from Input Buffer to Message RAM

To configure / update a message buffer in the Message RAM, the Host has to write the data to FLXAnFRWRDSm and the header to FLXAnFRWRHS1 to FLXAnFRWRHS3. The specific action is selected by configuring the FlexRay Input Buffer Command Mask FLXAnFRIBCM.

When the Host writes the number of the target message buffer in the Message RAM to bits FLXAnFRIBCR.IBRH[6:0], IBF Host and IBF Shadow are swapped (see **Figure 24.13**).

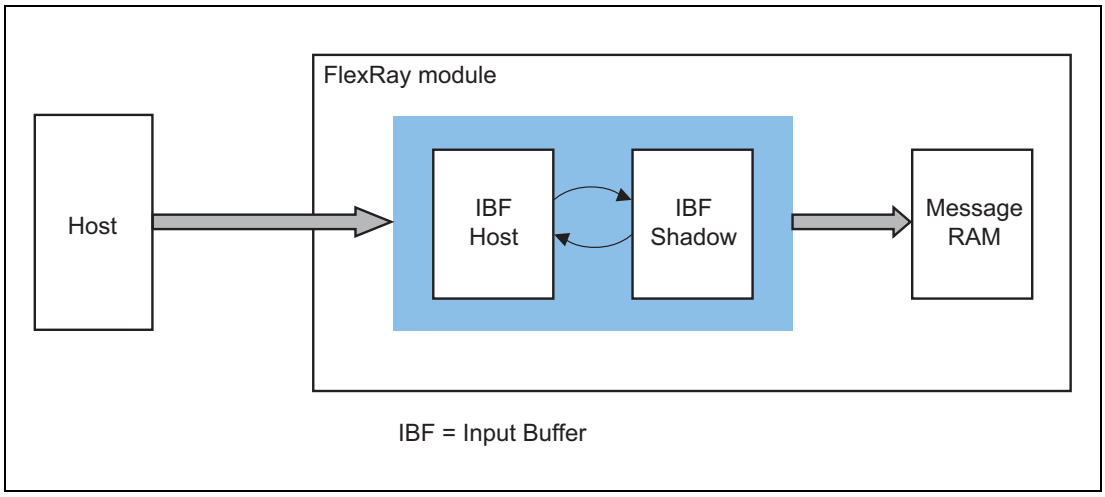

Figure 24.13 Double Buffer Structure Input Buffer

In addition the bits in the FLXAnFRIBCM and FLXAnFRIBCR registers are also swapped to keep them attached to the respective IBF section (see **Figure 24.14**).

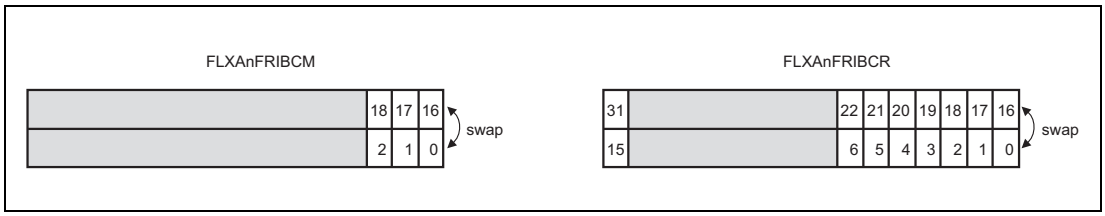

Figure 24.14 Swapping of FLXAnFRIBCM and FLXAnFRIBCR bits

With this write operation bit FLXAnFRIBCR.IBSYS is set to 1. The Message Handler then starts to transfer the contents of IBF Shadow to the message buffer in the Message RAM selected by bits FLXAnFRIBCR.IBRS[6:0].

While the Message Handler transfers the data from IBF Shadow to the target message buffer in the Message RAM, the Host may write the next message to IBF Host. After the transfer between IBF Shadow and the Message RAM has completed, bit FLXAnFRIBCR.IBSYS is set back to 0 and the next transfer to the Message RAM may be started by the Host by writing the respective target message buffer number to bits FLXAnFRIBCR.IBRH[6:0].

If a write access to bits FLXAnFRIBCR.IBRH[6:0] occurs while FLXAnFRIBCR.IBSYS is 1, FLXAnFRIBCR.IBSYH is set to 1. After completion of the ongoing data transfer from IBF Shadow to the Message RAM, IBF Host and IBF Shadow are swapped, FLXAnFRIBCR.IBSYH is reset to 0, FLXAnFRIBCR.IBSYS remains set to 1, and the next transfer to the Message RAM is started. In addition the message buffer numbers stored under bits FLXAnFRIBCR.IBRH[6:0] and FLXAnFRIBCR.IBRS[6:0] and the command mask flags are also swapped.

Example of a 8/16/32-bit Host access sequence:

Configure / update k-th message buffer via IBF

- Wait until FLXAnFRIBCR.IBSYH is reset
- Write data section to FLXAnFRWRDSm
- Write header section to FLXAnFRWRHS1 to FLXAnFRWRHS3
- Write Command Mask: write FLXAnFRIBCM.STXRH, FLXAnFRIBCM.LDSH, FLXAnFRIBCM.LHSH
- Demand data transfer to target message buffer: write FLXAnFRIBCR.IBRH[6:0]

Configure / update (k+1)th message buffer via IBF

- Wait until FLXAnFRIBCR.IBSYH is reset
- Write data section to FLXAnFRWRDSm
- Write header section to FLXAnFRWRHS1 to FLXAnFRWRHS3
- Write Command Mask: write FLXAnFRIBCM.STXRH, FLXAnFRIBCM.LDSH, FLXAnFRIBCM.LHSH
- Demand data transfer to target message buffer: set bits FLXAnFRIBCR.IBRH[6:0]

CAUTION

Any write access to IBF while bit FLXAnFRIBCR.IBSYH is 1 will set bit FLXAnFREIR.IIBA to 1. In this case the write access has no effect.

Table 24.102 Assignment of FLXAnFRIBCM Bits

Pos.	Access	Bit	Function
18	R	STXRS	Set Transmission Request Shadow ongoing or finished
17	R	LDSS	Load Data Section Shadow ongoing or finished
16	R	LHSS	Load Header Section Shadow ongoing or finished
2	R/W	STXRH	Set Transmission Request Host
1	R/W	LDSH	Load Data Section Host
0	R/W	LHSH	Load Header Section Host

Table 24.103 Assignment of FLXAnFRIBCR Bits

Pos.	Access	Bit	Function
31	R	IBSYS	IBF Busy Shadow, signals ongoing transfer from IBF Shadow to Message RAM
22 to 16	R	IBRS[6:0]	IBF Request Shadow, number of message buffer currently / lately updated
15	R	IBSYH	IBF Busy Host, transfer request pending for message buffer referenced by IBRH[6:0]
6 to 0	R/W	IBRH[6:0]	IBF Request Host, number of message buffer to be updated next

(2) Data Transfer from Message RAM to Output Buffer

To read a message buffer from the Message RAM, the Host has to write to register FLXAnFROBCR to trigger the data transfer as configured in FLXAnFROBCM. After the transfer has completed, the Host can read the transferred data from FLXAnFRRDDSm, FLXAnFRRDHS1 to FLXAnFRRDHS3, and FLXAnFRMBS.

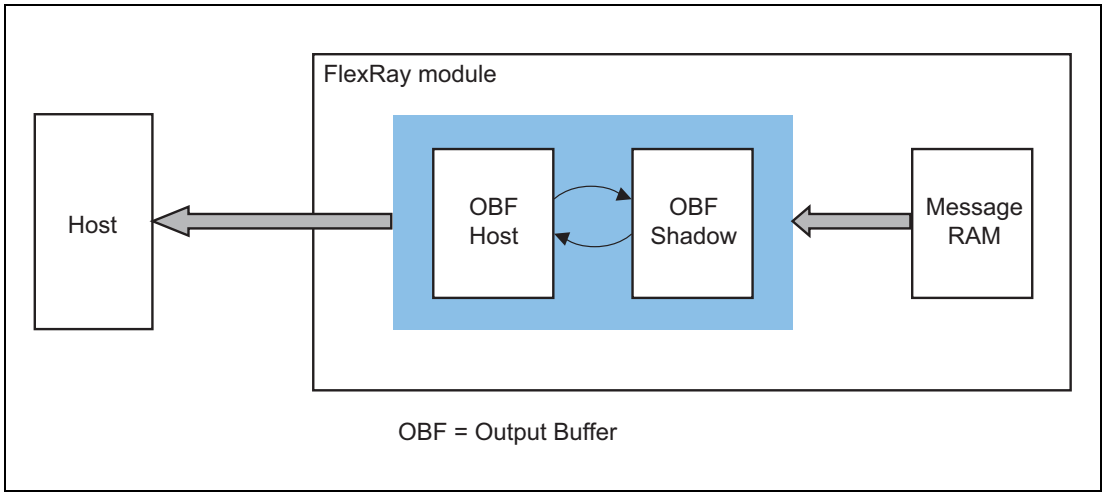

Figure 24.15 Double buffer structure Output Buffer

OBF Host and OBF Shadow as well as bits FLXAnFROBCM.RHSS, FLXAnFROBCM.RDSS, FLXAnFROBCM.RHSH, FLXAnFROBCM.RDSH and bits FLXAnFROBCR.OBRS[6:0], FLXAnFROBCR.OBRH[6:0] are swapped under control of bits FLXAnFROBCR.VIEW and FLXAnFROBCR.REQ.

Writing bit FLXAnFROBCR.REQ to 1 copies bits FLXAnFROBCM.RHSS, FLXAnFROBCM.RDSS and bits FLXAnFROBCR.OBRS[6:0] to an internal storage (see **Figure 24.16**).

After setting bit FLXAnFROBCR.REQ to 1, FLXAnFROBCR.OBSYS is set to 1, and the transfer of the message buffer selected by bits FLXAnFROBCR.OBRS[6:0] from the Message RAM to OBF Shadow is started. After the transfer between the Message RAM and OBF Shadow has completed, bit FLXAnFROBCR.OBSYS is set back to 0. Bits FLXAnFROBCR.REQ and FLXAnFROBCR.VIEW can only be set to 1 while bit FLXAnFROBCR.OBSYS is 0.

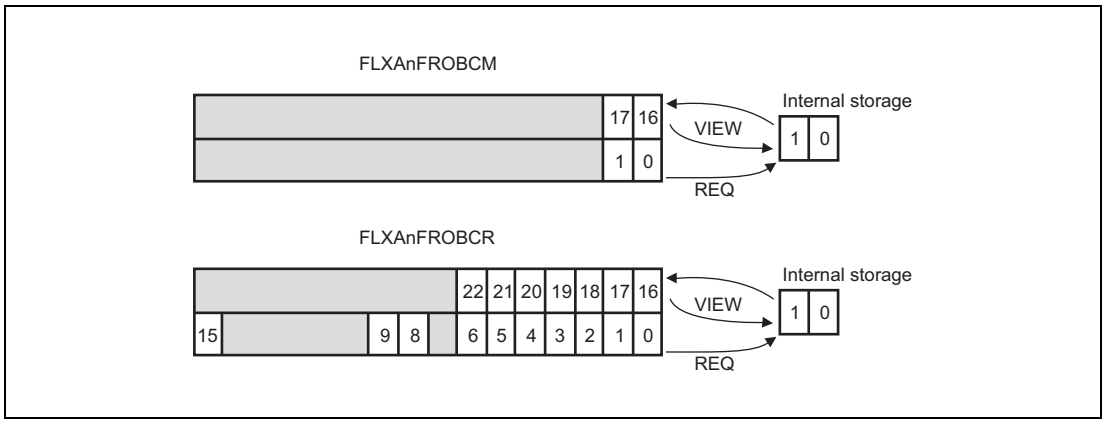

Figure 24.16 Swapping of FLXAnFROBCM and FLXAnFROBCR bits

OBF Host and OBF Shadow are switched by setting bit FLXAnFROBCR.VIEW to 1 while bit FLXAnFROBCR.OBSYS is 0 (see **Figure 24.15**).

In addition, bits FLXAnFROBCR.OBRH[6:0] and bits FLXAnFROBCM.RHSH and FLXAnFROBCM.RDSH are switched with the registers internal storage thus assuring that the message buffer number stored in bits FLXAnFROBCR.OBRH[6:0] and the mask configuration stored in FLXAnFROBCM.RHSH, FLXAnFROBCM.RDSH match the transferred data stored in OBF Host (see **Figure 24.16**).

Now the Host can read the transferred message buffer from OBF Host while the Message Handler may transfer the next message from the Message RAM to OBF Shadow.

If bits REQ and VIEW are set to 1 with the same write access while FLXAnFROBSYS is 0, FLXAnFROBSYS is automatically set to 1 and OBF Shadow and OBF Host are swapped. Additionally mask bits FLXAnFROBCM.RDSH and FLXAnFROBCM.RHSH are swapped with the registers internal storage to keep them attached to the respective Output Buffer transfer. Afterwards bits FLXAnFROBCR.OBRS[6:0] are copied to the register internal storage, mask bits FLXAnFROBCM.RDSS and FLXAnFROBCM.RHSS are copied to register FLXAnFROBCM internal storage, and the transfer of the selected message buffer from the Message RAM to OBF Shadow is started. While the transfer is ongoing the Host can read the message buffer transferred by the previous transfer from OBF Host. When the current transfer between Message RAM and OBF Shadow has completed, this is signaled by setting FLXAnFROBCR.OBSYS back to 0.

Example of an 8/16/32-bit Host access to a single message buffer:

If a single message buffer has to be read out, two separate write accesses to FLXAnFROBCR.REQ and FLXAnFROBCR.VIEW are necessary:

- Wait until FLXAnFROBCR.OBSYS is reset
- Write Output Buffer Command Mask FLXAnFROBCM.RHSS, FLXAnFROBCM.RDSS
- Request transfer of message buffer to OBF Shadow by writing FLXAnFROBCR.OBRS[6:0] and FLXAnFROBCR.REQ (in case of and 8-bit Host interface, FLXAnFROBCR.OBRS[6:0] have to be written before FLXAnFROBCR.REQ).
- Wait until FLXAnFROBCR.OBSYS is reset
- Toggle OBF Shadow and OBF Host by writing FLXAnFROBCR.VIEW = 1
- Read out transferred message buffer by reading FLXAnFRRDDSm, FLXAnFRRDHS1 to FLXAnFRRDHS3, and FLXAnFRMBS

Example of an 8/16/32-bit Host access sequence:

Request transfer of 1st message buffer to OBF Shadow

- Wait until FLXAnFROBCR.OBSYS is reset
- Write Output Buffer Command Mask FLXAnFROBCM.RHSS, FLXAnFROBCM.RDSS for 1st message buffer
- Request transfer of 1st message buffer to OBF Shadow by writing bits FLXAnFROBCR.OBRS[6:0] and FLXAnFROBCR.REQ (in case of accessing to the FLXAnFROBCR register in 8-bit units, bits FLXAnFROBCR.OBRS[6:0] have to be written before FLXAnFROBCR.REQ).

Toggle OBF Shadow and OBF Host to read out 1st transferred message buffer and request transfer of 2nd message buffer:

- Wait until FLXAnFROBCR.OBSYS is reset to 0
- Write Output Buffer Command Mask FLXAnFROBCM.RHSS, FLXAnFROBCM.RDSS for 2nd message buffer
- Toggle OBF Shadow and OBF Host and start transfer of 2nd message buffer to OBF Shadow simultaneously by writing FLXAnFROBCR.OBRS[6:0] of 2nd message buffer, bits FLXAnFROBCR.REQ, and FLXAnFROBCR.VIEW (in case of and 8-bit access to register FLXAnFROBCR, bits FLXAnFROBCR.OBRS[6:0] have to be written before bits FLXAnFROBCR.REQ and FLXAnFROBCR.VIEW).
- Read out 1st transferred message buffer by reading FLXAnFRRDDSm, FLXAnFRRDHS1 to FLXAnFRRDHS3, and FLXAnFRMBS

Demand access to last requested message buffer without request of another message buffer:

- Wait until FLXAnFROBCR.OBSYS is reset to 0
- Demand access to last transferred message buffer by writing FLXAnFROBCR.VIEW
- Read out last transferred message buffer by reading FLXAnFRRDDSm, FLXAnFRRDHS1 to FLXAnFRRDHS3, and FLXAnFRMBS

Table 24.104 Assignment of FLXAnFROBCM bits

Pos.	Access	Bit	Function
17	R	RDSH	Data Section available for Host access
16	R	RHSH	Header Section available for Host access
1	R/W	RDSS	Read Data Section Shadow
0	R/W	RHSS	Read Header Section Shadow

Table 24.105 Assignment of FLXAnFROBCR bits

Pos.	Access	Bit	Function
22 to 16	R	OBRH[6:0]	OBF Request Host, number of message buffer available for Host access
15	R	OBSYS	OBF Busy Shadow, signals ongoing transfer from Message RAM to OBF Shadow
9	R/W	REQ	Request Transfer from Message RAM to OBF Shadow
8	R/W	VIEW	View OBF Shadow, swap OBF Shadow and OBF Host
6 to 0	R/W	OBRS[6:0]	OBF Request Shadow, number of message buffer for next request

24.4.12.3 FlexRay Protocol Controller Access to Message RAM

The two TBFs (A,B) are used to buffer the data for transfer between the two FlexRay Protocol Controllers and the Message RAM.

Each TBF is build up as a double buffer, able to store two complete FlexRay messages. There is always one buffer assigned to the corresponding Protocol Controller while the other one is accessible by the Message Handler.

If e.g. the Message Handler writes the next message to be sent to TBF Tx, the FlexRay Channel Protocol Controller can access TBF Rx to store the message it is actually receiving. During transmission of the message stored in TBFTx, the Message Handler transfers the last received message stored in TBF Rx to the Message RAM (if it passes acceptance filtering) and updates the respective message buffer.

Data transfers between the TBFs and the shift registers of the FlexRay Channel Protocol Controllers are done in words of 32 bit. This enables the use of a 32 bit shift register independent of the length of the FlexRay messages.

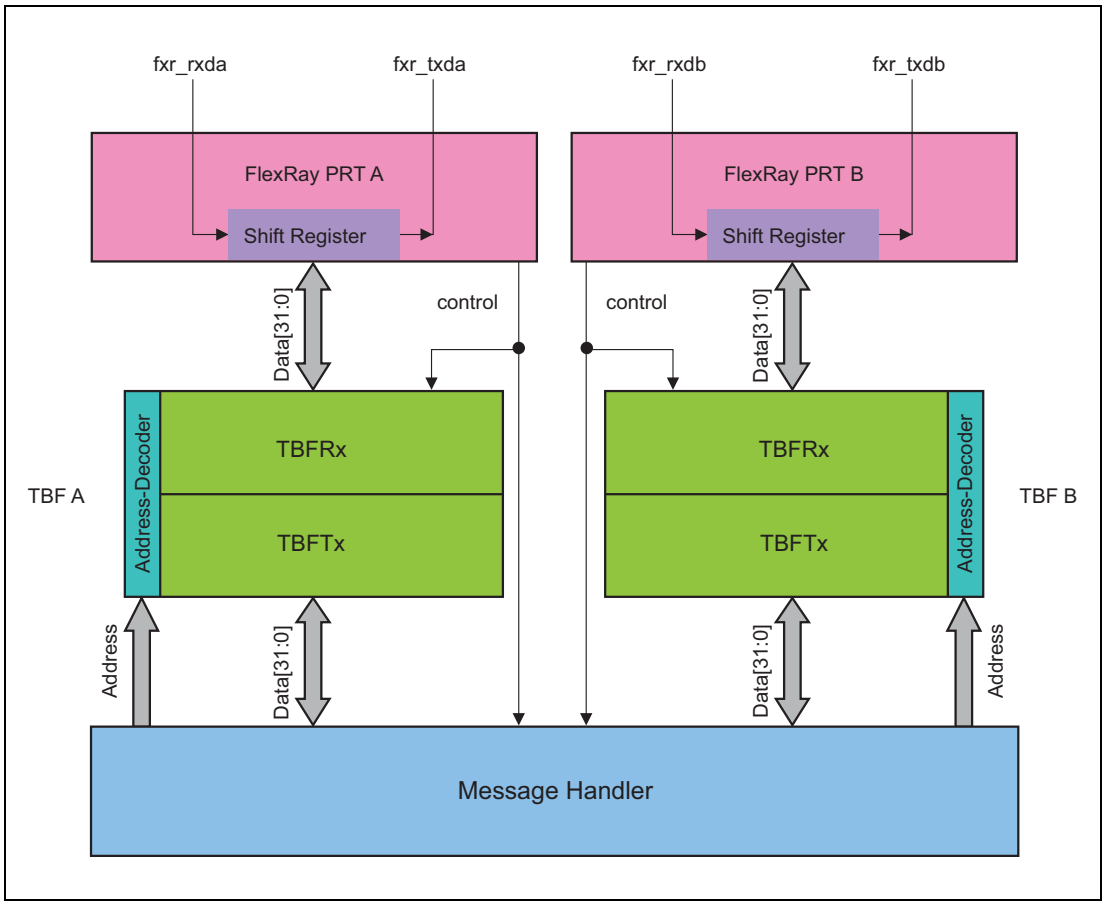

Figure 24.17 Access to TBFs

24.4.13 Message RAM

To avoid conflicts between Host access to the Message RAM and FlexRay message reception / transmission, the Host cannot directly access the message buffers in the Message RAM. These accesses are handled via the Input and Output Buffers. The Message RAM is able to store up to 128 message buffers depending on the configured payload length.

The Message RAM is able to store up to 2048 32-bit words. To achieve the required flexibility with respect to different numbers of data bytes per FlexRay frame (0 to 254), the Message RAM has a structure as shown in **Figure 24.18**.

When a message buffer of the data section to be allocated immediately after to the header partition is set as a reception buffer (bit FLXAnFRWRHS1.CFG to 0) or reception FIFO buffer, set a 32-bit unused area (minimum) at the beginning of the data section. In this case, the data partition is allowed to start at Message RAM word number: ((bits FLXAnFRMRC.LCB[7:0] + 1) × 4) + 1.

When a message buffer of the data section to be allocated immediately after to the header partition is set as a transmit buffer (bit FLXAnFRWRHS1.CFG to 1), the data partition is allowed to start at Message RAM word number: (bits FLXAnFRMRC.LCB[7:0] + 1) × 4.

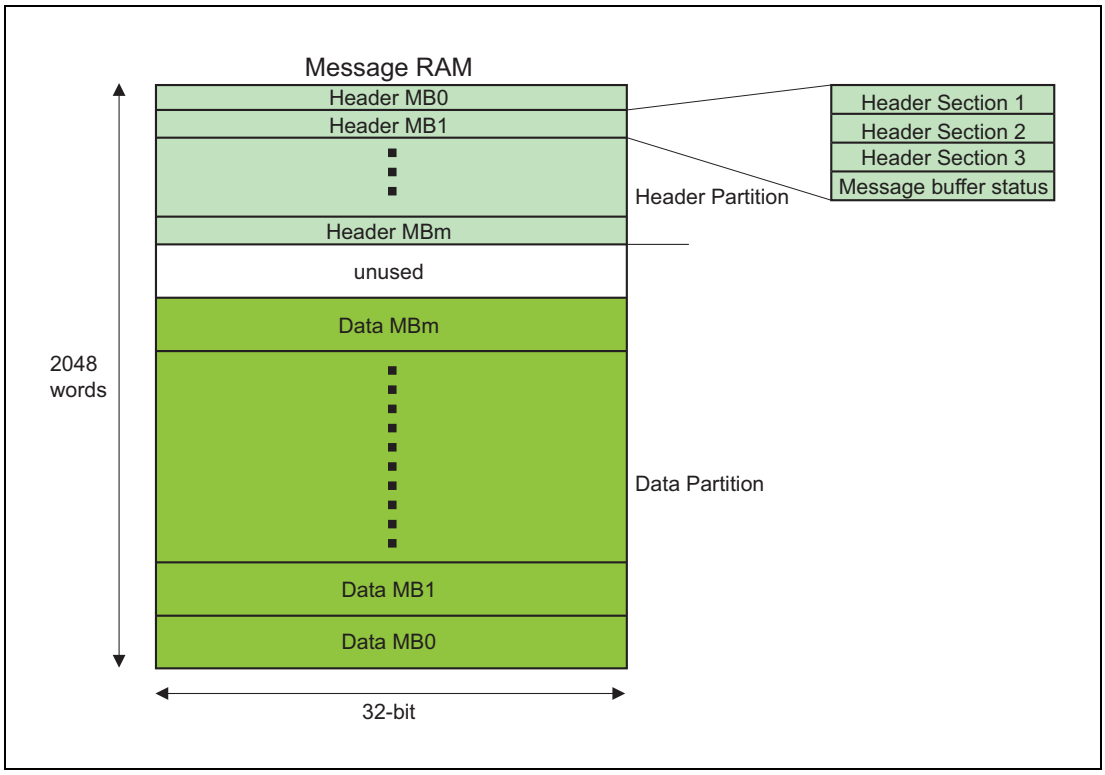

Figure 24.18 Configuration Example of Message Buffers in the Message RAM

Header Partition

Stores header sections of the configured message buffers:

- Supports a maximum of 128 message buffers
- Each message buffer has a header section of four 32 bit words
- Header 3 of each message buffer holds the 11-bit data pointer to the respective data section in the data partition

Data Partition

Flexible storage of data sections with different length. Some maximum values are:

- 30 message buffers with 254 byte data section each
- Or 56 message buffers with 128 byte data section each
- Or 128 message buffers with 48 byte data section each

CAUTION

header partition + data partition may not occupy more than 2048 32-bit words.

24.4.13.1 Header Partition

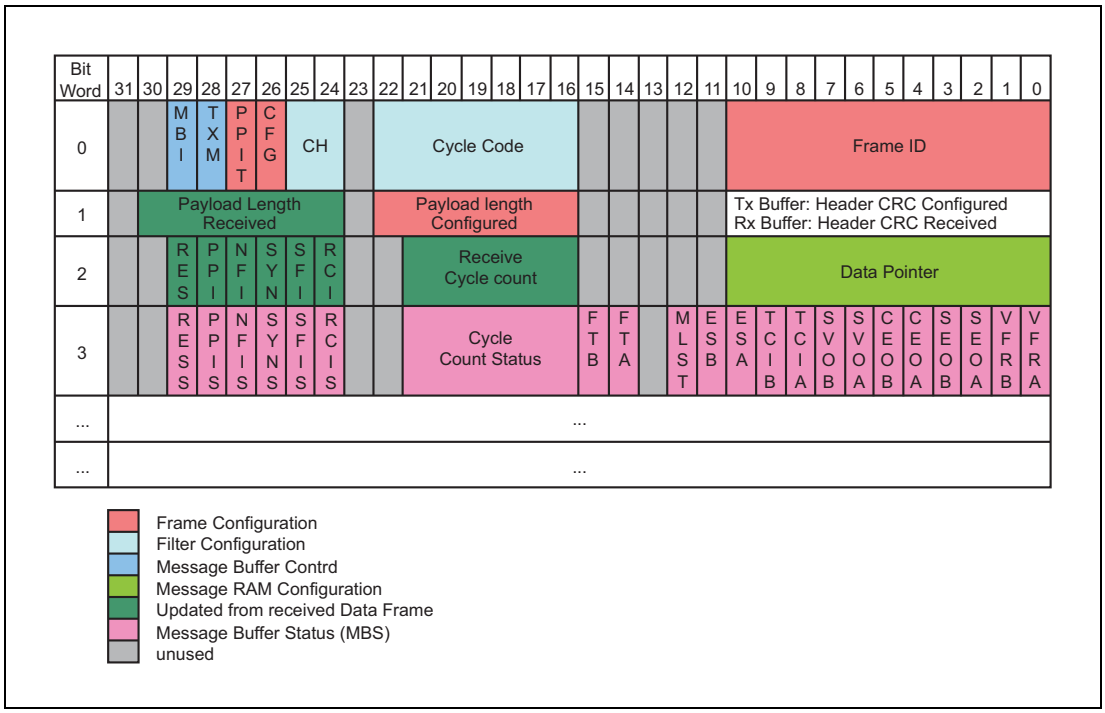
The elements used for configuration of a message buffer as well as the actual message buffer status are stored in the header partition of the Message RAM as listed in **Table 24.106** below. Configuration of the header sections of the message buffers is done via IBF (FLXAnFRWRHS1 to FLXAnFRWRHS3). Read access to the header sections is done via OBF (FLXAnFRRDHS1 to FLXAnFRRDHS3 + FLXAnFRMBS). The data pointer has to be calculated by the user to define the starting point of the data section for the respective message buffer in the data partition of the Message RAM. The data pointer should not be modified during runtime. For message buffers belonging to the receive FIFO (re)configuration is possible in DEFAULT_CONFIG or CONFIG state only.

The header section of each message buffer occupies four 32-bit words in the header partition of the Message RAM. The header of message buffer 0 starts with the first word in the Message RAM.

For transmit buffers the Header CRC has to be calculated by the Host.

Payload Length Received PLR, Receive Cycle Count RCC, Received on Channel Indicator RCI, Startup Frame Indicator SFI, Sync Frame Indicator SYN, Null Frame Indicator NFI, Payload Preamble Indicator PPI, and Reserved Bit RES are updated from received valid data frames only.

Table 24.106 Header Section of a Message Buffer in the Message RAM



(1) Header section 1 (word 0)

Write access via FLXAnFRWRHS1, read access via FLXAnFRRDHS1:

- Frame ID
  - Slot counter filtering configuration
- Cycle Code
  - Cycle counter filtering configuration
- CH
  - Channel filtering configuration
- CFG
  - Message buffer direction configuration: receive / transmit
- PPIT
  - Payload Preamble Indicator Transmit
- TXM
  - Transmit mode configuration: single-shot / continuous
- MBI
  - Message buffer receive / transmit interrupt enable

(2) Header section 2 (word 1)

Write access via FLXAnFRWRHS2, read access via FLXAnFRRDHS2:

- Header CRC
  - Transmit Buffer: Configured by the Host (calculated from frame header)
  - Receive Buffer: Updated from received frame
- Payload Length Configured
  - Length of data section (2-byte words) as configured by the Host
- Payload Length Received
  - Length of payload segment (2-byte words) stored from received frame

(3) Header section 3 (word 2)

Write access via FLXAnFRWRHS3, read access via FLXAnFRRDHS3:

- Data Pointer
  - Pointer to the beginning of the corresponding data section in the data partition

Read access via FLXAnFRRDHS3, valid for receive buffers only, updated from received frames:

- Receive Cycle Count
  - Cycle count from received frame
- RCI
  - Received on Channel Indicator

- SFI
  - Startup Frame Indicator
- SYN
  - Sync Frame Indicator
- NFI
  - Null Frame Indicator
- PPI
  - Payload Preamble Indicator
- RES
  - Reserved bit

(4) Message Buffer Status FLXAnFRMBS (word 3)

Read access via FLXAnFRMBS, updated by the CC at the end of the configured slot.

- VFRA
  - Valid Frame Received on channel A
- VFRB
  - Valid Frame Received on channel B
- SEOA
  - Syntax Error Observed on channel A
- SEOB
  - Syntax Error Observed on channel B
- CEOA
  - Content Error Observed on channel A
- CEOB
  - Content Error Observed on channel B
- SVOA
  - Slot boundary Violation Observed on channel A
- SVOB
  - Slot boundary Violation Observed on channel B
- TCIA
  - Transmission Conflict Indication channel A
- TCIB
  - Transmission Conflict Indication channel B
- ESA
  - Empty Slot Channel A

- ESB
  - Empty Slot Channel B
- MLST
  - Message LoST
- FTA
  - Frame Transmitted on Channel A
- FTB
  - Frame Transmitted on Channel B
- Cycle Count Status
  - Actual cycle count when status was updated
- RCIS
  - Received on Channel Indicator Status
- SFIS
  - Startup Frame Indicator Status
- SYNS
  - Sync Frame Indicator Status
- NFIS
  - Null Frame Indicator Status
- PPIS
  - Payload Preamble Indicator Status
- RESS
  - Reserved bit Status

24.4.13.2 Data Partition

The data partition of the Message RAM stores the data sections of the message buffers configured for reception / transmission as defined in the header partition. The number of data bytes for each message buffer can vary from 0 to 254. To optimize the data transfer between the shift registers of the two FlexRay Protocol Controllers and the Message RAM as well as between the Host interface and the Message RAM, the physical width of the Message RAM is set to 4 bytes.

The data partition starts after the last word of the header partition. When configuring the message buffers in the Message RAM the user has to assure that the data pointers point to addresses within the data partition. **Table 24.107** below shows an example how the data sections of the configured message buffers can be stored in the data partition of the Message RAM.

The beginning and the end of a message buffer's data section is determined by the data pointer and the payload length configured in the message buffer's header section, respectively. This enables a flexible usage of the available RAM space for storage of message buffers with different data length.

If the size of the data section is an odd number of 2-byte words, the remaining 16 bits in the last 32bit word are unused (see **Table 24.107** below).

Table 24.107 Example for Structure of the Data Partition in the Message RAM

Bit Word	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

2047	unused								unused								MB0 Data5								MB0 Data4							

24.4.13.3 Message Data Integrity Check

There is a data integrity checking mechanism implemented in the FlexRay core to assure the integrity of the data stored in the related RAM. Each RAM has a checksum generator / checker attached as shown in **Figure 24.19**.

When data is written to a RAM, the local checksum generator generates the checksum. The checksum is stored together with the respective data word. The checksum is checked each time a data word is read from a RAM.

If a checksum error is detected, the respective access error flag is set. The access error flags (bits AMR, ATBF1, and ATBF2) and the faulty message buffer indicators (bits FMBD, MFMB, and FMB) are located in the FlexRay Message Handler Status register (FLXAnFRMHDS). These single access error flags control the error interrupt flag (bit FLXAnFREIR.AERR).

Figure 24.19 shows the data paths between the Input Buffer, TBF and Message RAM.

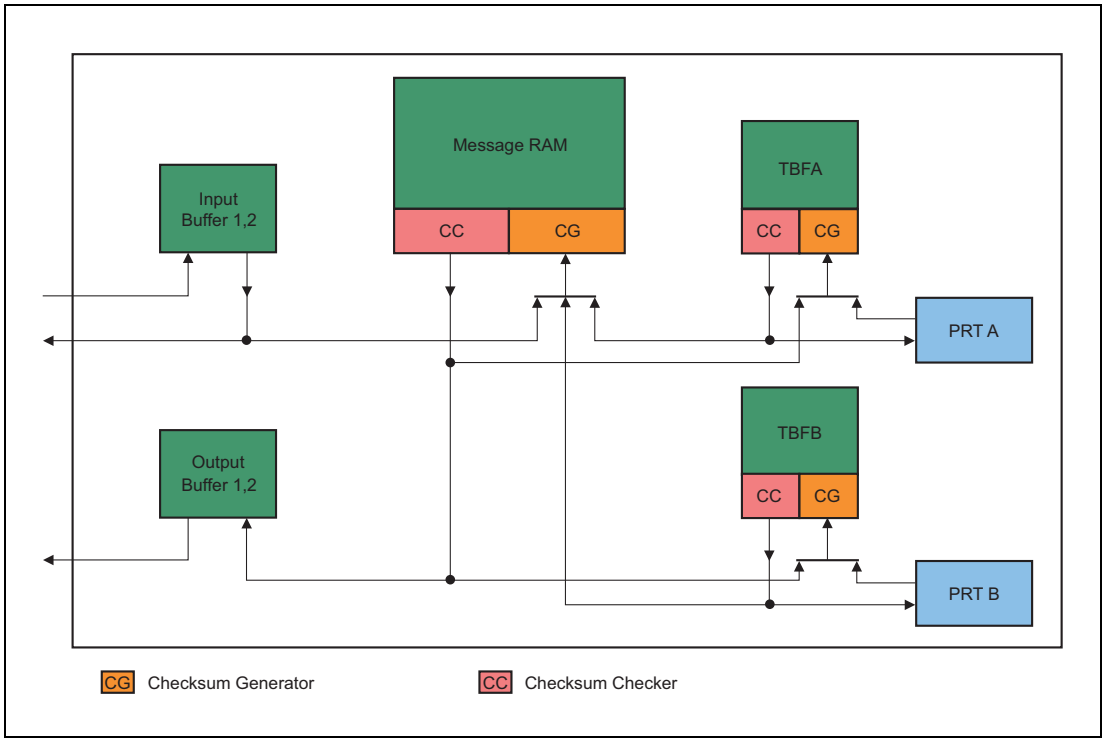

Figure 24.19 Checksum Generation and Check

When an access error has been detected the following actions will be performed:

In all cases:

- The respective access error flag in FLXAnFRMHDS register is set
- The access error flag FLXAnFREIR.AERR is set and, if enabled, a module interrupt to the Host will be generated.

Additionally in specific cases:

(1) Access error during data transfer from Input Buffer 1, 2 to Message RAM when reading header section of respective message buffer from Message RAM:

- FLXAnFRMHDS.AMR is set.
- FLXAnFRMHDS.FMBD bit is set to indicate that bits FLXAnFRMHDS.FMB[6:0] point to a faulty message buffer.
- Bits FLXAnFRMHDS.FMB[6:0] indicate the number of the faulty message buffer.
- The data section of the respective message buffer is not updated.
- Transmit buffer: Transmission request for the respective message buffer is not set.

(2) Access error during scan of header sections in Message RAM:

- FLXAnFRMHDS.AMR is set.
- Bit FLXAnFRMHDS.FMBD is set to indicate that bits FLXAnFRMHDS.FMB[6:0] point to a faulty message buffer.
- Bits FLXAnFRMHDS.FMB[6:0] indicate the number of the faulty message buffer.
- Ignore message buffer (message buffer is skipped).

(3) Access error during data transfer from Message RAM to TBFA and TBFB:

- FLXAnFRMHDS.AMR is set.
- Bit FLXAnFRMHDS.FMBD is set to indicate that bits FLXAnFRMHDS.FMB[6:0] point to a faulty message buffer.
- Bits FLXAnFRMHDS.FMB[6:0] indicate the number of the faulty message buffer.
- Frame not transmitted, frames already in transmission are invalidated by setting the frame CRC to zero.

(4) Access error during data transfer from TBFA and TBFB to Message RAM when reading header section of respective message buffer from Message RAM:

- FLXAnFRMHDS.AMR is set.
- FLXAnFRMHDS.FMBD bit is set to indicate that bits FLXAnFRMHDS.FMB[6:0] point to a faulty message buffer.
- Bits FLXAnFRMHDS.FMB[6:0] indicate the number of the faulty message buffer.
- The data section of the respective message buffer is not updated.

(5) Access error during data transfer from Message RAM to Output Buffer:

- The FLXAnFRMHDS.AMR bit is set to 1.
- FLXAnFRMHDS.FMBD bit is set to indicate that bits FLXAnFRMHDS.FMB[6:0] point to a faulty message buffer.
- Bits FLXAnFRMHDS.FMB[6:0] indicate the number of the faulty message buffer.

(6) Access error during a data transfer from TBFA and TBFB to Protocol Controller 1, 2:

- FLXAnFRMHDS.ATBF1, 2 bit is set.
- Frames already in transmission are invalidated by setting the frame CRC to zero.

(7) Access error during data transfer from TBFA and TBFB to Message RAM when reading TBFA and TBFB:

- FLXAnFRMHDS.ATBF1, 2 bit is set.
- FLXAnFRMHDS.FMBD bit is set to indicate that bits FLXAnFRMHDS.FMB[6:0] point to a faulty message buffer.
- Bits FLXAnFRMHDS.FMB[6:0] indicate the number of the faulty message buffer.

(8) Access error during data read of TBFA and TBFB:

When an access error occurs while the Message Handler read a frame with network management information (PPI = 1) from the TBFA and TBFB, the corresponding network management vector registers FLXAnFRNMV1 to 3 are not updated from this frame.

24.4.13.4 Host Handling of Access Errors

Access error caused by bit flips can be fixed by:

(1) Self-healing

Access errors located in the Data Section of Message RAM, TBFA or TBFB are overwritten with the next write access to the disturbed bit(s) caused by Host access or by FlexRay communication.

(2) CLEAR_RAMS Command

The POC command CLEAR_RAMS initializes the message RAM to zero, when called in the DEFAULT_CONFIG or CONFIG state.

(3) Temporary Unlocking of Header Section

An access error in the header section of a locked message buffer can be fixed by a transfer from the Input Buffer to the locked buffer Header Section. For this transfer, the write access to the FLXAnFRIBCR register (specifying the message buffer number) must be immediately preceded by the unlock sequence normally used to leave CONFIG state (see **Section 24.3.3.1, FLXAnFRLCK — FlexRay Lock Register**).

For that single transfer the respective message buffer header is unlocked, regardless whether it belongs to the FIFO or whether its locking is controlled by FLXAnFRMRC.SEC, and will be updated with new data.

24.4.14 Interrupts

In general, interrupts provide a close link to the protocol timing as they are triggered almost immediately when an error or status change is detected by the CC, a frame is received or transmitted, a configured timer interrupt is activated, or a stop watch event occurred. This enables the Host to react very quickly on specific error conditions, status changes, or timer events. On the other hand too many interrupts can cause the Host to miss deadlines required for the application. Therefore the CC supports enable / disable controls for each individual interrupt source separately.

An interrupt may be triggered when

- An error was detected
- A status flag is set to 1
- A timer reaches a preconfigured value
- A message transfer from Input Buffer to Message RAM or from Message RAM to Output Buffer has completed
- A message transfer from the Local RAM/Cluster RAM to Message RAM or from Message RAM to Local RAM/Cluster RAM has completed
- A stop watch event occurred

Tracking status and generating interrupts when a status change or an error occurs are two independent tasks. Regardless of whether an interrupt is enabled or not, the corresponding status is tracked and indicated by the CC. The Host has access to the actual status and error information by reading registers FLXAnFREIR, FLXAnFRSIR, FLXAnFROS, FLXAnFROTS and FLXAnFRITS.

The general purpose interrupt lines to the Host, FlexRay Line 0 Interrupt, and FlexRay Line 1 Interrupt are controlled by the interrupts enabled by the FLXAnFREIES and FLXAnFRSIES registers. In addition each of the two interrupt lines can be enabled / disabled separately by programming bit FLXAnFRILE.EINT0 and FLXAnFRILE.EINT1.

The input data transfer interrupt lines to the Host, FlexRay input queue empty interrupt, FlexRay input queue full interrupt, are controlled by the enabled interrupts in FLXAnFRITS. In addition, each of the input data transfer interrupts can be enabled or disabled separately by setting the related bits in FLXAnFRITC.

The output data transfer interrupt lines to the Host, FlexRay FIFO transfer warning interrupt, FlexRay output transfer warning interrupt, FlexRay FIFO transfer interrupt, FlexRay output transfer interrupt, are controlled by the enabled interrupts in FLXAnFROTS. In addition each of the output data transfer interrupts can be enabled or disabled separately by setting the related bits in FLXAnFROTC.

The three timer interrupts lines to the Host are controlled by the enabled interrupts in FLXAnFROS. In addition each of the interrupt lines can be enabled or disabled separately by setting bit FLXAnFROC.T0IE, FLXAnFROC.T1IE and FLXAnFROC.T2IE.

When a transfer between IBF/OBF and the Message RAM has completed bit FLXAnFRSIR.TIBC or FLXAnFRSIR.TOBC is set to 1.

An stop watch event is generated by the stpwt_extfxr pin input.

24.4.16 Usage of Data Transfer

The data transfer function is for the transfer of FlexRay messages between the FlexRay module's internal message RAM and areas of user RAM such as Local RAM/Cluster RAM.

Data transfer from an area of user RAM to the internal message RAM (input) is started by software. Input transfer is used to set up a message buffer or to update data for transmission.

Data transfer from the internal message RAM to an area of user RAM (output) starts in response to the following events.

- Data are stored in the reception message buffer or the internal FIFO buffer of the FlexRay module.
- The state of a slot changes.
- The user issues a transfer request.

An area of the user RAM needs to be secured for the data to be transferred. The data are transferred in a defined structure.

Access to the input and output buffers by the CPU is prohibited while this function is in use.

24.4.16.1 Input Data Transfer

When the automatic input data transfer function is enabled, committed input data structures are transferred from the Local RAM/Cluster RAM to the FlexRay internal message RAM with minimum CPU support.

(1) Activation and deactivation

The input data transfer function should be activated before usage. The activation of the input transfer handler initializes the input queue put index (FLXAnFRITS.IPIDX[6:0]) and get index (FLXAnFRITS.IGIDX[6:0]) to zero. Also the interrupt status bits in the FLXAnFRITS register (IQEIS and IQFIS) are set to 0.

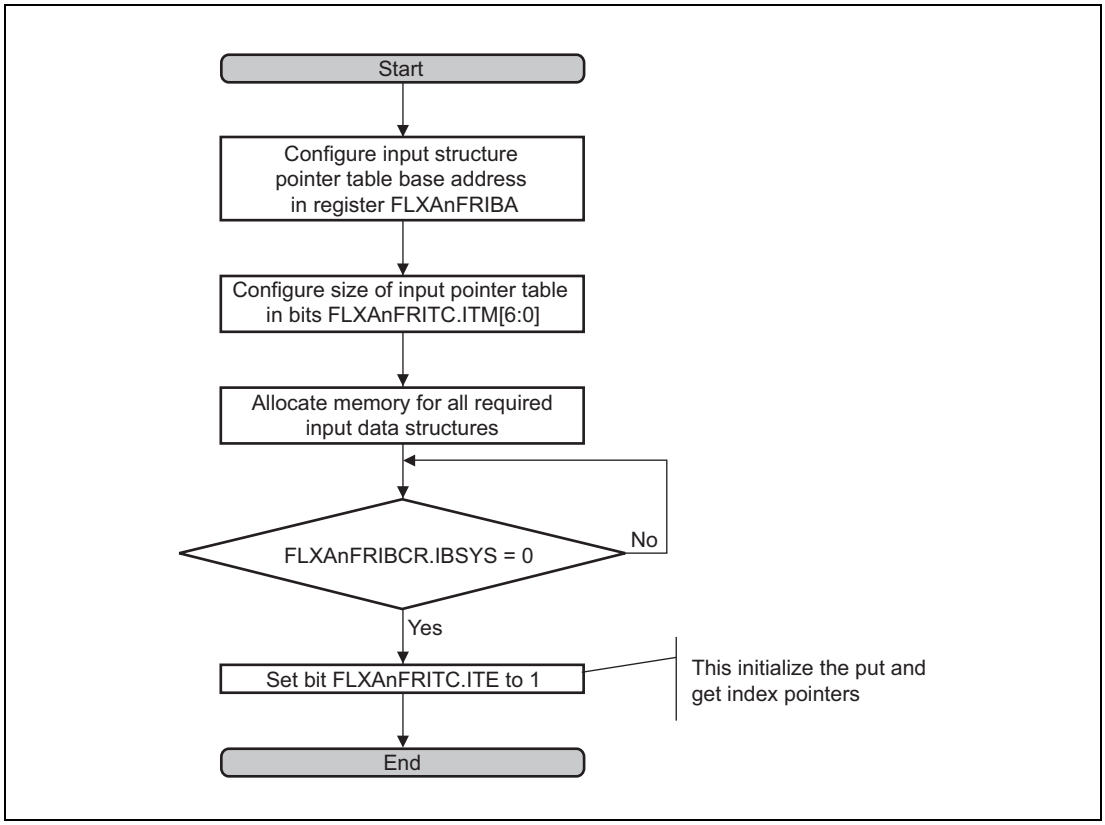

Figure 24.20 Input Transfer Enable Processing Flow

A deactivation request of the input transfer function can be made at any time. The input queue put index and the input queue status are maintained independently from the input transfer function state.

Before the transfer function gets disabled (bit FLXAnFRITS.ITS = 0), user requested input transfers and all committed input transfers will be completed.

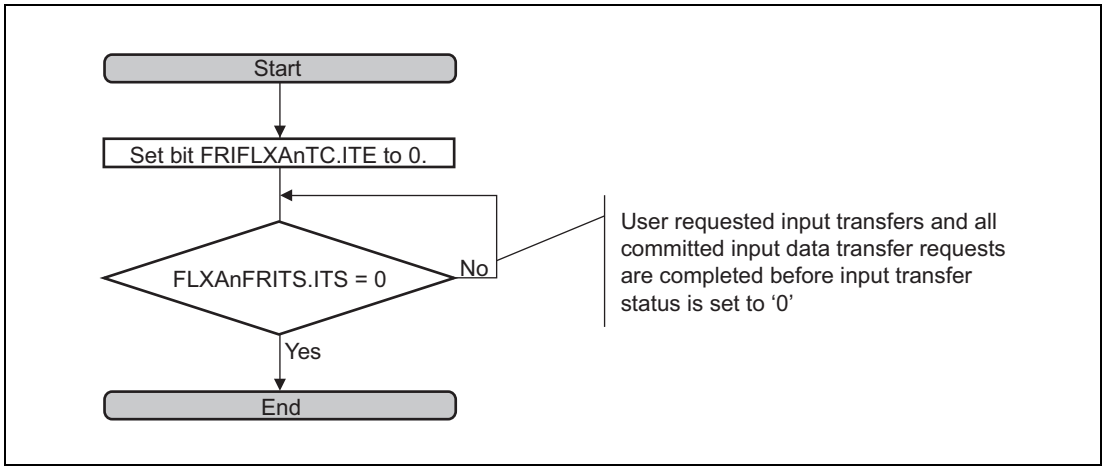

Figure 24.21 Input Transfer Disable Processing Flow

(2) Input data structure

The application has to reserve a location in the Local RAM/Cluster RAM to provide the content for message buffer configuration (input data structure).

The location of this input data structure needs to be defined by an input data structure pointer also located in the Local RAM/Cluster RAM.

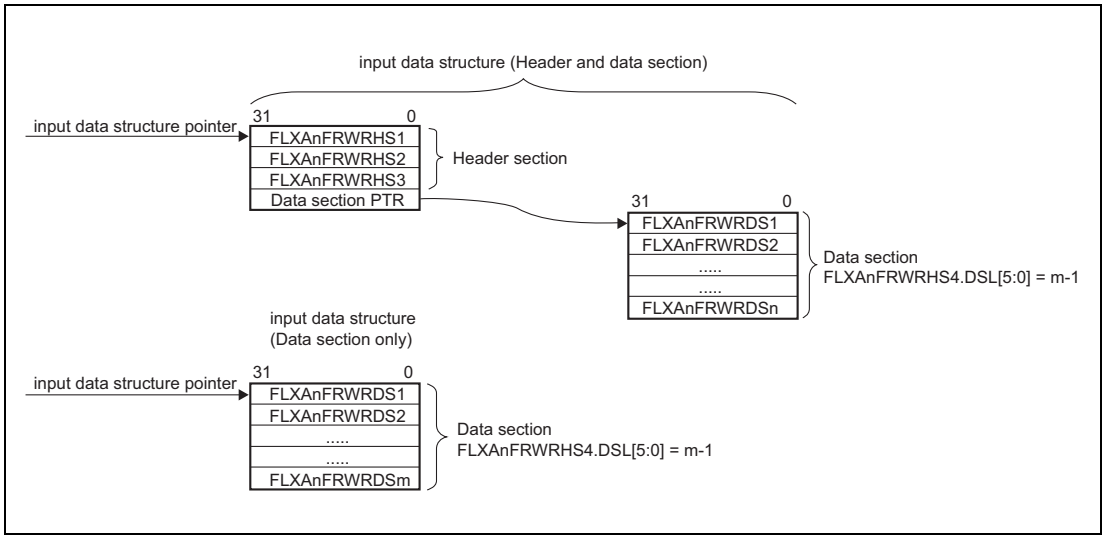

Figure 24.22 Input data structure

In general the input data structure consists of two sections, the header and the data section.

The header section consists of FLXAnFRWRHS1, FLXAnFRWRHS2, FLXAnFRWRHS3 and the data section pointer.

For bit alignment and bit function in the header section, see **Section 24.4.13.1, Header Partition**.

Depending on the settings in the control field (FLXAnFRWRHS4) located in the input pointer table, the data structure pointer is a reference to the address of FLXAnFRWRHS1 or FLXAnFRWRDS1. The data structure pointer has to be aligned to a 32 bit address.

If bit FLXAnFRWRHS4.LHS is set to 1, it is required to provide a valid header section. In this case FLXAnFRWRHS1 is the first element of the data structure.

If bit FLXAnFRWRHS4.LHS is set to 0, a header section is not required. In this case FLXAnFRWRDS1 is the first element of the data structure.

If bit FLXAnFRWRHS4.LDS is set to 1, it is required to provide a valid data section. The pointer to the data section is a reference to the address of the first payload long word (FLXAnFRWRDS1) and has to be aligned to a 32 bit address.

If bit FLXAnFRWRHS4.LDS is set to 0, a data section is not required. The data section pointer is not evaluated by the input handler.

The length of the data section and the size to be allocated in the Local RAM/Cluster RAM depends on the configuration of bits FLXAnFRWRHS4.DSL[5:0].

For the transfer into the FlexRay core internal message RAM the number of 16 bit words configured by bits FLXAnFRWRHS2.PLC[6:0] is used. The application has to ensure, that a proper number of data words is provided in the Local RAM/Cluster RAM. In case the buffer is configured by bits FLXAnFRWRHS2.PLC[6:0] to hold an odd payload length, the application has to write zero to the last 16 bit of the payload section to ensure that the padding data is all zero.

(3) Input pointer table

To transfer data from the input data structures located in the Local RAM/Cluster RAM to the FlexRay internal message RAM the related input data structure pointer and control field needs to be added to the input pointer table which is located in the Local RAM/Cluster RAM.

The location of the first element of this table is identified by the input pointer table base address (FLXAnFRIBA.ITA[31:0]). This base address has to be aligned to a 32 bit address.

The maximum number of input requests that can be queued is defined by the Input queue Table Max register (FLXAnFRITC.ITM[6:0]).

Each Input pointer table entry requires two long words. The required address range of the input pointer table for the queued transfer requests can be calculated by

Input pointer table size (byte) = (((FLXAnFRTTC.ITM[6:0] + 1) × 2) × 4)

Equation 1

The input pointer entry for the user requested input transfer should be added after the end of the input pointer table.

The pointer table index related to this entry and hence the number to be written to FLXAnFRUIR.UIDX[7:0], is FLXAnFRITC.ITM[6:0] + 1. The address in the input pointer table related to the user requested input transfer (user input address) can be calculated by

User input address = FLXAnFRIBA.ITA[31:0] + Input pointer table size

Equation 2

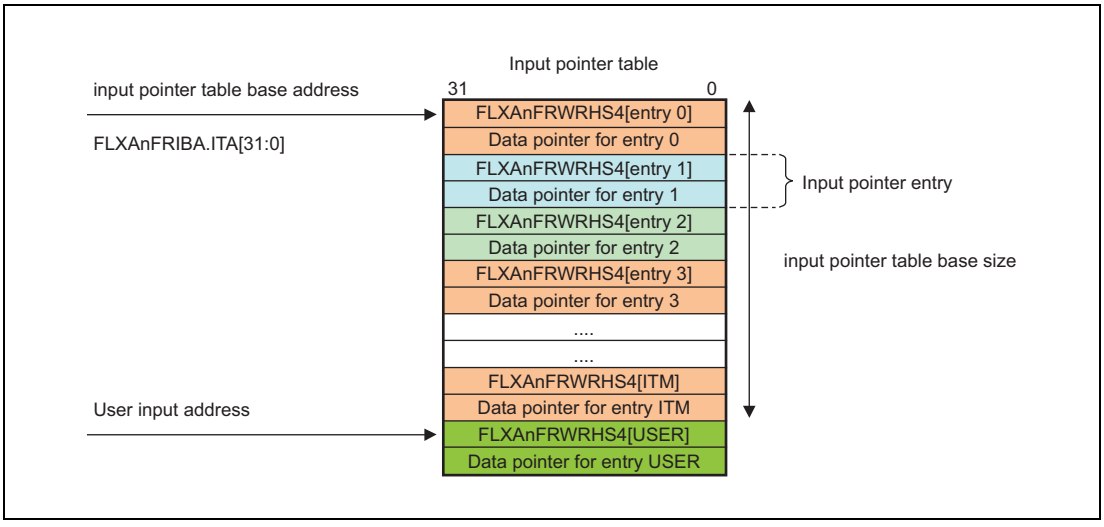

Figure 24.23 Input pointer table

The input pointer table holds the control field FLXAnFRWRHS4 and the pointers to the Local RAM/ Cluster RAM location where the message buffer content (header section and/or data section) is stored.

The application has to write FLXAnFRWRHS4 and the input data structure pointer at the addresses in the input pointer table related to the put index position before a transfer request is initiated.

FLXAnFRWRHS4:

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	DSL[5:0]					
Value after reset	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
R/W	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	INV	STR	LDS	LHS	—	IMBNR[6:0]						
Value after reset	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
R/W	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Table 24.109 FLXAnFRWRHS4 Register Contents

Bit Position	Bit Name	Function
31 to 22	Reserved	When read, an undefined value is read. When writing, always write 0.
21 to 16	DSL[5:0]	Data Section Length Bit Specifies the length of the data section in terms of 32 bit values.
15 to 12	Reserved	When read, an undefined value is read. When writing, always write 0.
11	INV	Invalidate entry Bit 0: The data structure is valid and will be transferred to the FlexRay internal message RAM. 1: The data structure is invalid. FlexRay internal message RAM is not updated using this input pointer entry.
10	STR	Set transmission request Bit 0: The bit FLXAnFRTXRQm.TXRp for the message buffer selected by the bits IMBNR[6:0] is set to 0. No data from this message buffer is transmitted. 1: The bit FLXAnFRTXRQm.TXRp for the message buffer selected by the bits IMBNR[6:0] is set to 1 to release the message buffer for transmission The application should not set the bit STR to 1 for receive buffers.
9	LDS	Load data section Bit 0: No update of data section. 1: Data section for the message buffer selected by the bits IMBNR[6:0] is updated.
8	LHS	Load header section Bit 0: No update of header section. 1: Header section for the message buffer selected by the bits IMBNR[6:0] is updated.
7	Reserved	When read, an undefined value is read. When writing, always write 0.
6 to 0	IMBNR[6:0]	Message buffer number to be updated Bit Selects the target message buffer number in the FlexRay internal message RAM for transfer

Note that the LHS bit should not be set for protected message buffers.

The bit LDS defines if the data section of the message buffer selected by the bits IMBNR[6:0] should be updated.

If LDS is set to 1 (DSL[5:0] + 1) 32 bit words of payload data are transferred from the Local RAM/ Cluster RAM to the message buffer selected by the bits IMBNR[6:0].

If LDS is set to 0 no payload data is transferred from the Local RAM/Cluster RAM.

Note that the payload transferred is independent from the configured payload length (bits FLXAnFRWRHS2.PLC[6:0]).

The bit INV can be used to invalidate a committed data structure. This bit should be only used to cancel the transfer of committed data structures when the input queue is halted (see **Section 24.4.16.2, (5) Transfer function of dedicated message buffers**).

When this bit is set to 1 the message buffer number (IMBNR[6:0]) is not updated. When the bit is set to 0 the message buffer number (IMBNR[6:0]) is updated.

(4) Transfer function of input data structure

To use the input data structure transfer function the input transfer has to be activated (see **Section 24.4.16.1, (1) Activation and deactivation**). The activation process requires the setup of the input pointer table (see **Section 24.4.16.1, (3) Input pointer table**) in order to specify the source location (input data structures) for the data structures to be transferred. When the input transfer gets enabled the get index pointer is initialized to zero.

All FlexRay internal message buffers can be updated using the input transfer queue which is built in the input pointer table. The application has to write the pointer and control field (table entry) to the data structure to be transferred into the input pointer table. For that purpose the application has to maintain a put index for the input pointer table that indicates where the pointer has to be written to.

To commit this table entry to the input handler, the application has to write the target message buffer number to the input queue control register (bits FLXAnFRIQC.IMBNR[6:0]). Afterwards the application has to increment the application internal put index.

By writing to the input queue control register the data available bits (FLXAnFRDAm.DA[31:0]) are automatically set to 1. The input transfer handler also maintains the put index pointer in the status register (FLXAnFRITS.IPIDX[6:0]).

In case the input queue gets full (number of queued input transfer requests is equal to the input queue table size) FLXAnFRITS.IQFP and FLXAnFRITS.IQFIS are set to 1. The input queue full condition pending flag (FLXAnFRITS.IQFP) changes from 1 to 0 when there are entries in the input queue available, whereby the input queue full interrupt status flag (FLXAnFRITS.IQFIS) needs to be cleared by the application.

The application should not make any further write access to bits FLXAnFRIQC.IMBNR[6:0] as long as bit FLXAnFRITS.IQFP is 1.

In case the input queue gets empty (number of queued input transfer requests changes to zero) FLXAnFRITS.IQEIS is set to 1. The input queue empty interrupt status flag (FLXAnFRITS.IQEIS) needs to be cleared by the application.

The transfer of the input data structures to the FlexRay message RAM is controlled by a get index pointer which is handled inside the FlexRay module and flagged in bits FLXAnFRITS.IGIDX[6:0]. Note that the index is referring to the input entry and not the address offset in the input pointer table.

If the input queue is not empty, the transfer handler reads out the input pointer table entry of the transfer queue and starts the transfer of the input data structure from the address the input pointer is referring to. When all required data words are transferred to the FlexRay module, the data available flag for the transferred message buffer number is set to 0 and the get index in the transfer handler is incremented by one.

In case of an invalidated data structure (see **Section 24.4.16.1, (5) Halting the input queue**) no FlexRay internal message buffer is updated and the related data available flag is automatically set to 0. The change of the data available flag can be used to confirm the cancellation a transmit request.

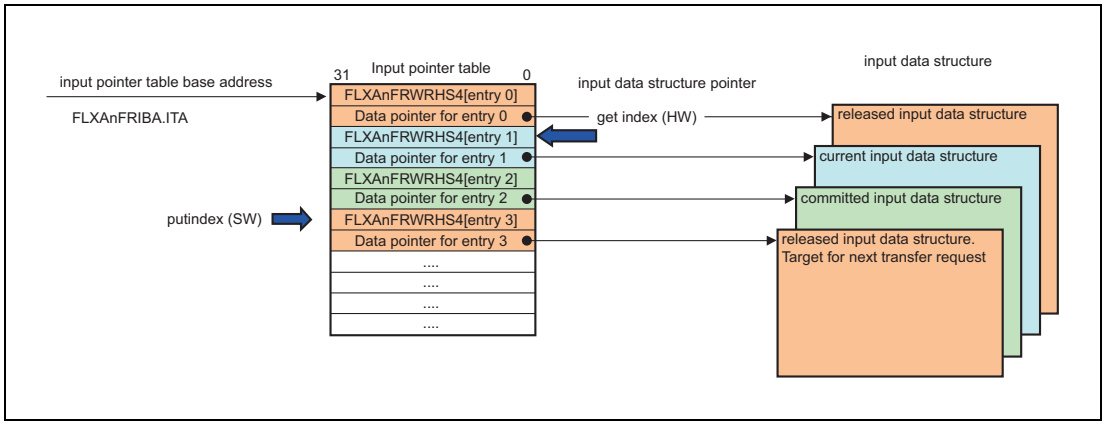

Figure 24.24 Input Pointer Table

Receive message buffers can be also configured using the input data transfer by setting up the required header sections and mark only the header section (FLXAnFRWRHS4.LDS = 0, FLXAnFRWRHS4.LHS = 1) to be updated in the FlexRay module.

(5) Halting the input queue

Committed data structures cannot be removed, but can be invalidated or updated when the input queue is halted.

To cancel data structures already committed to the input queue, the queue can be halted by writing a 1 to FLXAnFRITC.IQHR.

After the ongoing input transfer has been completed the queue is halted and FLXAnFRITS.IQH changes from 0 to 1.

To invalidate an entry of the input queue FLXAnFRWRHS4.INV has to be set to 1. All other bits in FWRHS4 should be unchanged.

The following processing flow shall be used to analyze whether a committed message has been already transferred to the FlexRay internal message RAM or not.

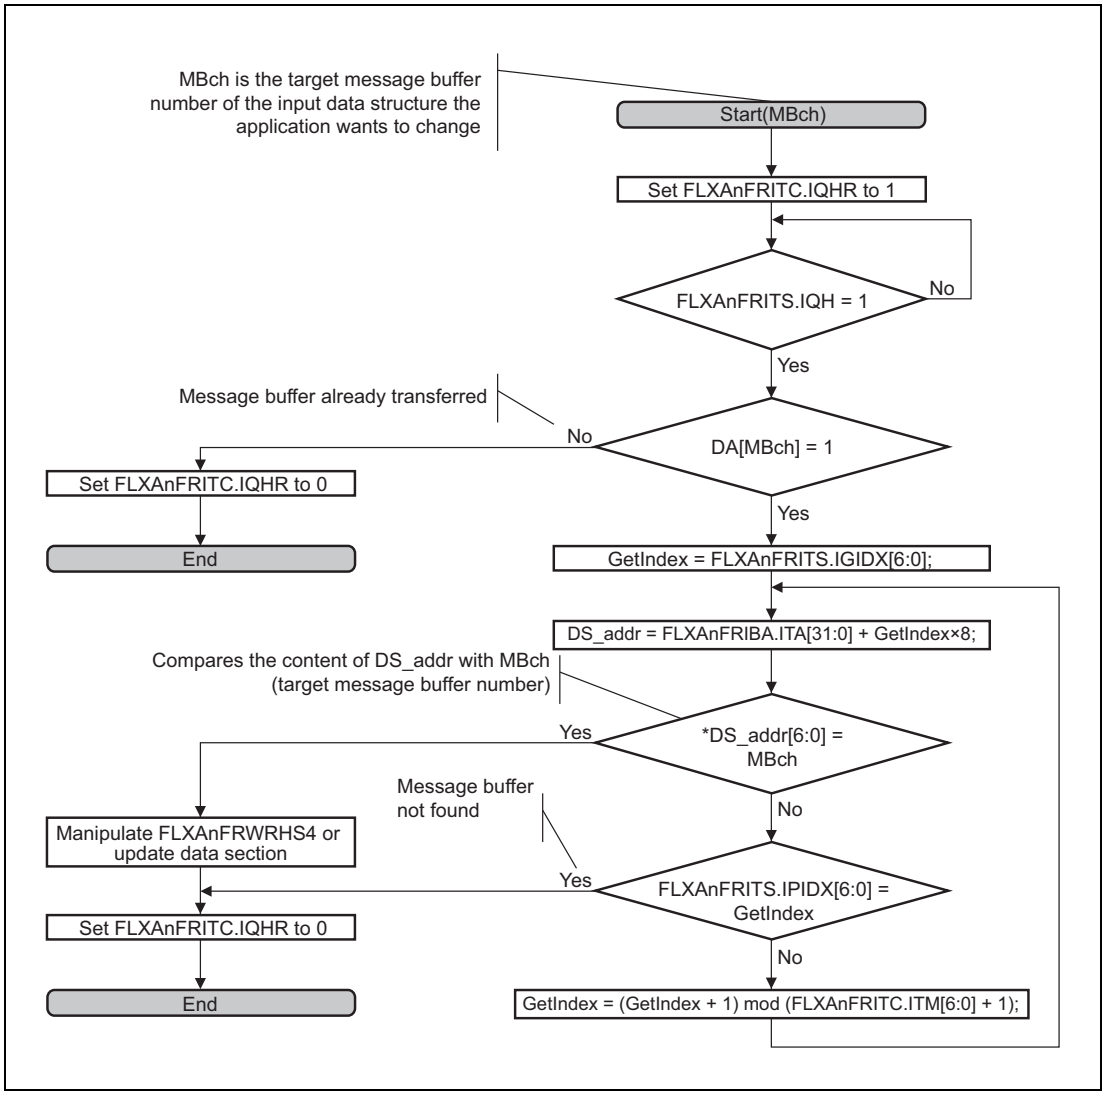

Figure 24.25 Input Table Analysis

In case the message buffer was already transferred to the FlexRay internal message RAM, the user input transfer request can be used to bypass the actual queue and update the required message buffer (see **Section 24.4.16.1, (6) Transfer function of user requested input transfers**).

(6) Transfer function of user requested input transfers

To use this function the input transfer has to be activated (see **Section 24.4.16.1, (1) Activation and deactivation**).

The application is capable, by using FLXAnFRUIR.UIDX[7:0], to request a transfer of an input data structure. The user input transfer request is serviced first.

The application has to write the pointer and control field (table entry) to the data structure to be transferred into the input pointer table. The table entry for the user input transfer request should be added after the end of the input pointer table (see **Section 24.4.16.1, (3) Input pointer table**).

To commit this table entry to the input handler, the application has to write the index (FLXAnFRITC.ITM[6:0] +1) to the user input transfer request register (FLXAnFRUIR.UIDX[7:0]).

By writing to the user input transfer request register, the user input transfer request pending flag (FLXAnFRITS.UIRP) is automatically set to 1.

As long this flag is 1 the application should not make any further user input transfer requests.

The user input transfer request pending flag (FLXAnFRITS.UIRP) changes from 1 to 0 when the requested input transfer is completed. As next the pending transfers are processed.

24.4.16.2 Output Data Transfer

When the output data transfer function is enabled, received messages (either in dedicated message buffers or in the FlexRay receive FIFO) are transferred to the Local RAM/Cluster RAM by the output data handler. The output data handler can also transfer the message buffer content to the Local RAM/ Cluster RAM on application request. When enabled the output handler is also capable to initiate a transfer when the message buffer status has changed.

(1) Activation and deactivation

The output data transfer function should be activated before usage. The activation of the output transfer handler will initialize the FIFO put and get index pointer and FIFO fill level (FLXAnFROTS.FGIDX[4:0] and FLXAnFROTS.FFL[5:0]) to zero, set the bits FLXAnFROTS.FDA, FLXAnFROTS.OWP, FLXAnFROTS.FWP and FLXAnFROTS.UORP to 0. Also the interrupt status flags FLXAnFROTS.OTIS, FLXAnFROTS.FIS, FLXAnFROTS.OWIS and FLXAnFROTS.FWIS) are set to 0.

The activation has no influence to the data available flags (FLXAnFRDAm.DA[31:0]) which are related to the dedicated buffers; these flags have to be cleared by the application.

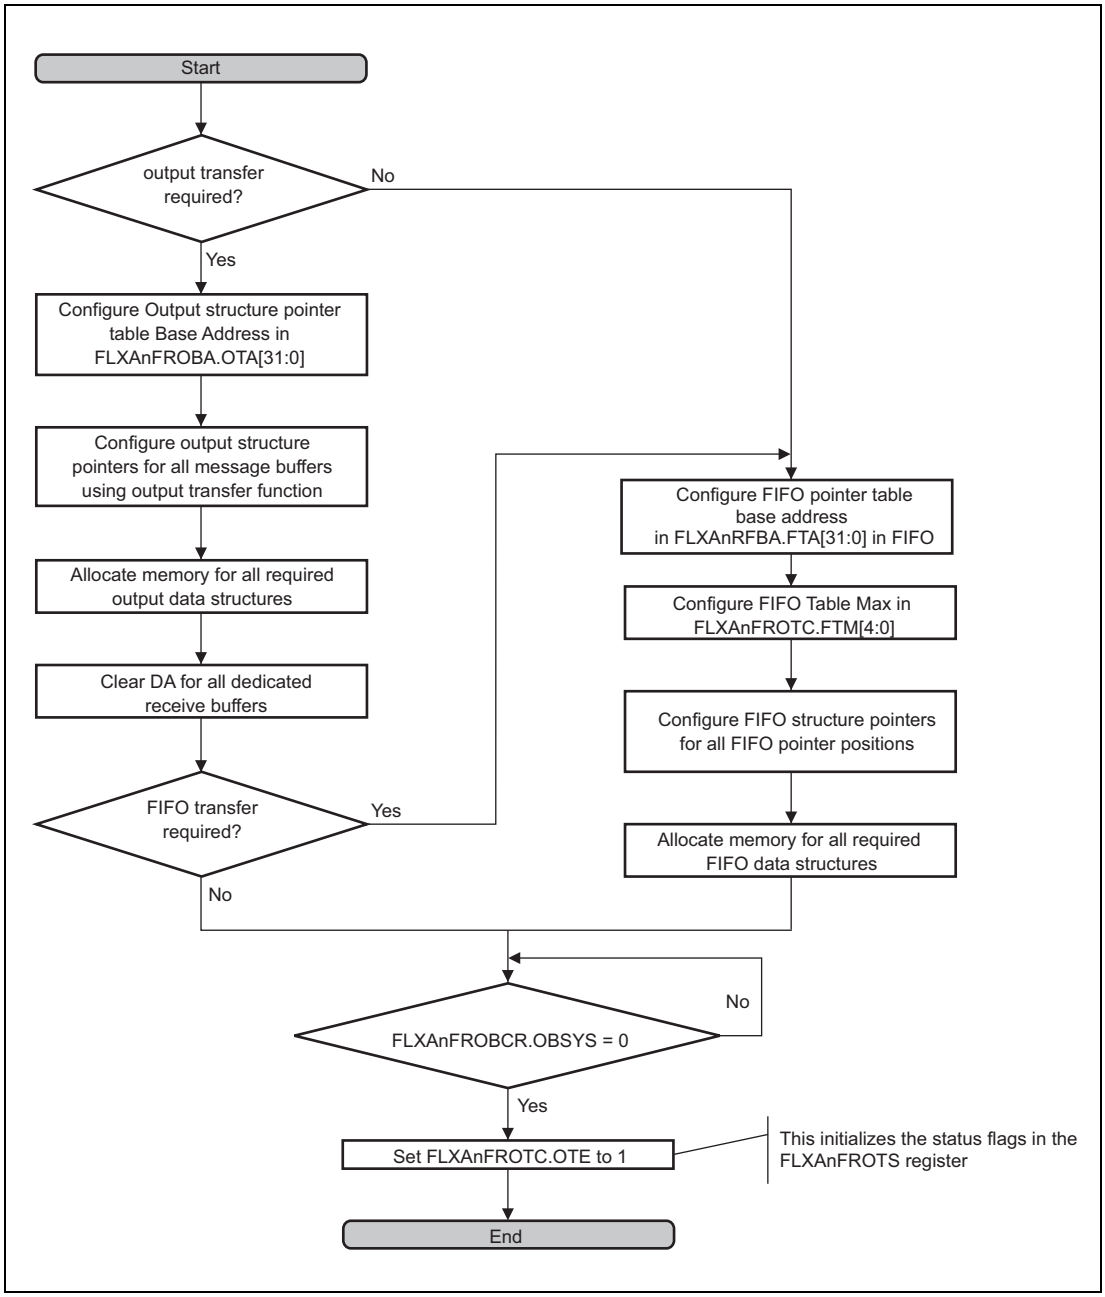

Figure 24.26 Output Transfer Enable Processing Flow

A deactivation request of the output data transfer function can be made at any time. An ongoing transfer will be completed and the completion of this transfer will be flagged. During this time FLXAnFROTS.OTS remains 1.

When FLXAnFROTS.OTS changes from 1 to 0, the output transfer function is deactivated. The data available status flags and the FIFO get index are still retained when the output transfer function is disabled.

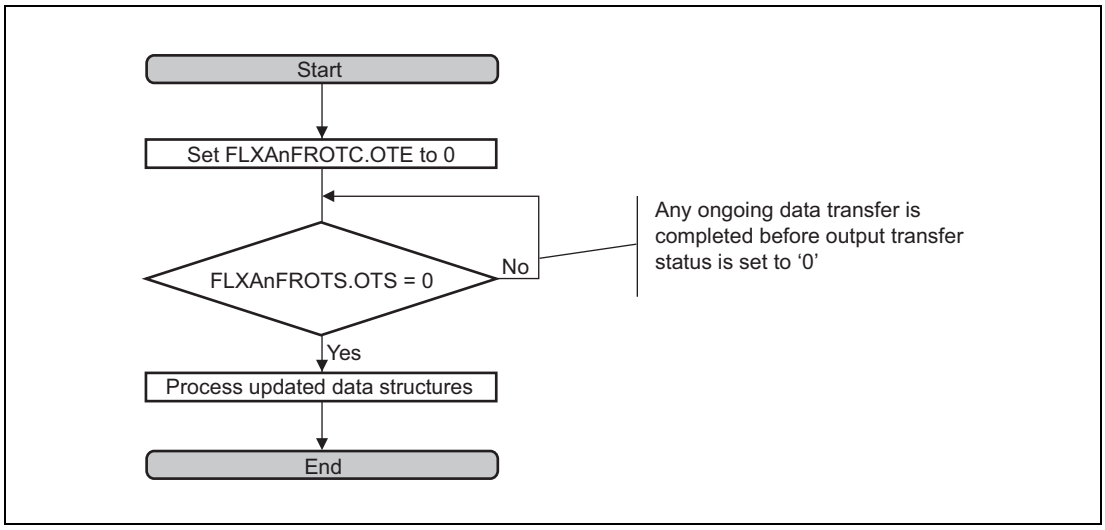

Figure 24.27 Output Transfer Disable Processing Flow

(2) Output transfer data structure

The data in the Local RAM/Cluster RAM is stored in an output data structure. The location of the output data structures are determined by output data structure pointers also located in the Local RAM/ Cluster RAM. The output data structure and indexing is visualized in **Figure 24.28**.

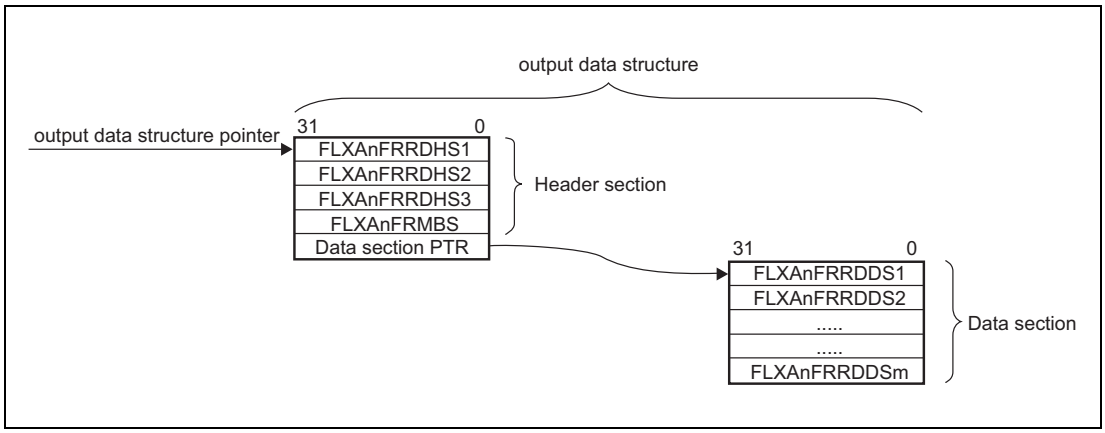

Figure 24.28 Output Data Structure

The output data structure consists of two sections, the header and data section. The header section consists of FLXAnFRRDHS1, FLXAnFRRDHS2, FLXAnFRRDHS3, FLXAnFRMBS and the data section pointer. FLXAnFRRDHS1 is the first element of the structure and has to be aligned to a 32 bit address. The data structure pointer is a reference to the address of FLXAnFRRDHS1. For information about the bit alignment and bit function within the header section refer to **Section 24.4.13.1, Header Partition**.

FLXAnFRRDDS1 is the first element of the data section. The data section pointer needs to be aligned with a 32-bit address corresponding to the FLXAnFRRDDS1 address.

The length of the data section as well as the total structure size to be allocated in the Local RAM/ Cluster RAM depends on the configured payload length (bits FLXAnFRRDHS2.PLC[6:0]) of the related message buffer. In case the configured payload length is an odd number of words or the received payload length (bits FLXAnFRRDHS2.PLR[6:0]) is smaller than the configured payload length, the remaining data words in the Local RAM/Cluster RAM are unused and should not be used by the application.

The output data structure is identical for all three kinds of output transfers. In case only the header section is transferred the data section pointer is not evaluated by the output handler and the data section remains unchanged.

(3) Output pointer table

For the output data transfer function the application needs to setup an output pointer table in the Local RAM/Cluster RAM. The location of the first element of this table should be programmed into the output pointer table base address (bits FLXAnFROBA.OTA[6:0]). This base address has to be aligned to a 32 bit address.

The size of the output pointer table is defined by the maximum of: the last configured dedicated message buffer and the highest message buffer number which will be used for the user output transfer request.

The output pointer table holds pointers (output data structure pointers) to the Local RAM/Cluster RAM. location where a memory space is reserved for the target message buffer content (header section and data section).

There is a fixed linear relationship between the address of the entries in the output pointer table and the number of the related message buffers (see **Figure 24.29**): the output pointer table starts with the entry for message buffer number 0 at the address configured in bits FLXAnFROBA.OTA[31:0] and continues in ascending order for each following message buffer number, by 32 bit aligned address (e.g. message buffer 1 at output pointer table address FLXAnFROBA.OTA[31:0] + 4, message buffer 2 at output pointer table address FLXAnFROBA.OTA[31:0] + 8, etc.) for all possible message buffers.

When a set of bit FLXAnFRNDATm.NDp is the only transfer condition (FLXAnFROTC.OTCS is set to 0), only message buffers configured as a dedicated receive buffer or that will be used for user output transfer requests need have valid pointer entries.

When a set of bit FLXAnFRNDATm.NDp or FLXAnFRMBSCm.MBCp is the transfer condition (FLXAnFROTC.OTCS is set to 1), all dedicated receive buffer and dedicated transmit buffers need to have valid pointer entries.

(4) FIFO output pointer table

The FlexRay module internal FIFO can be extended by a queued buffer structure in the Local RAM/ Cluster RAM.

If the FlexRay module internal FIFO is used the application needs to setup the FIFO output pointer table. The location of the first element of this table is identified by the FIFO pointer table base address (bits FLXAnFRFBA.FTA[31:0]). This base address has to be aligned to a 32 bit address.

The size of the FIFO pointer table and hence the maximum number of messages that can be added to the queue, is defined by FIFO Table Max (bits FLXAnFROTC.FTM[4:0]).

The FIFO pointer table holds pointers (output data structure pointers) to the Local RAM/Cluster RAM location where a memory space is reserved the target message buffer content (header section and data section). For each table entry a data pointer shall be configured in this table.

(5) Transfer function of dedicated message buffers

To use this transfer function the output transfer has to be activated (see **Section 24.4.16.2, (1) Activation and deactivation**). The activation process requires to setup the output pointer table (see **Section 24.4.16.2, (3) Output pointer table**) in order to specify the destination location (output data structures) for the data to transfer. **Figure 24.29** shows how the output pointer table references the output data structures.

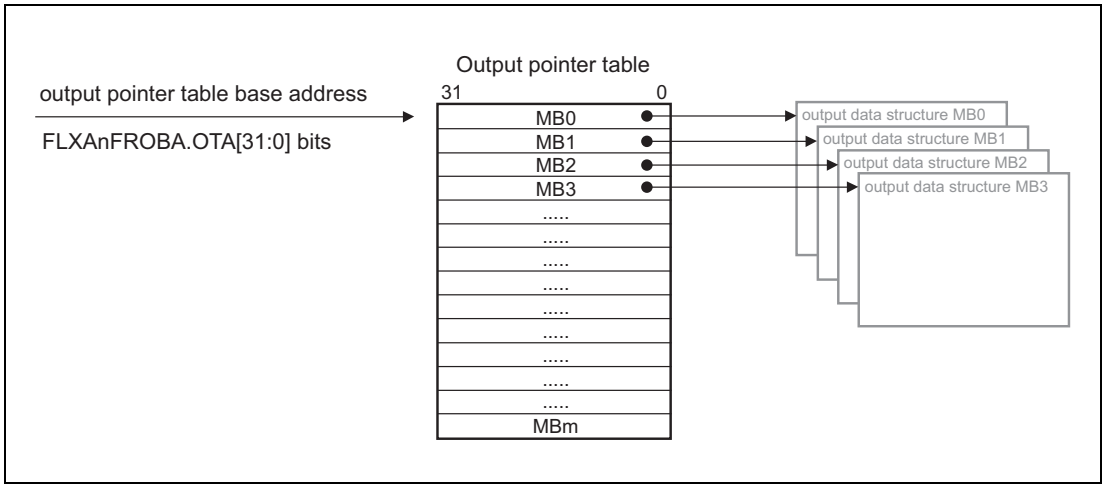

Figure 24.29 Output Data Structure and Indexing

With FLXAnFROTC.OTCS the output transfer condition can be selected between the 'New data only mode' and the 'New data and status changed mode'.

In the 'New data only mode' an output data transfer is initiated when a valid FlexRay data frame has been stored into a dedicated receive buffer which causes the related FLXAnFRNDATm.NDp flag to set. The FLXAnFRNDATm.NDp flag is automatically set to 0 during the transfer procedure. The header section is also transferred and hence the FLXAnFRMBSCm.MBCp flag is set to 0.

In the 'New data and status changed mode' an output data transfer is initiated as described in the 'New data only mode'. In addition an output data transfer is initiated when only the message buffer status has been changed which causes the related FLXAnFRMBSCm.MBCp flag to be set. In this case only the header section is transferred. The FLXAnFRMBSCm.MBCp flag is automatically set to 0 during the transfer procedure.

After transferring the message buffer data from the FlexRay internal message RAM to the output data structure the corresponding data available flag in the FLXAnFRDAm (m = 0 to 3) registers is set to 1. The update of the output data structure is also flagged by the setting of the output transfer interrupt status flag (FLXAnFROTS.OTIS).

As long as the data available flag remains 1 the corresponding output data structure will not be updated.

In the case

- the data available flag is 1 and a valid received message was stored or
- when FLXAnFROTC.OTCS is 1 and the message buffer status was updated,

the output transfer warning interrupt flag (FLXAnFROTS.OWIS) is set to 1 notifying the application that new data is available but the output data structure transfer cannot be processed. In addition FLXAnFROTS.OWP is set to 1 that continuously flags that status of the output transfer warning condition.

If a valid receive message in the FlexRay internal message RAM is overwritten by an additional receive message, the message lost flag (FLXAnFRMBS.MLST) is set to 1. This flag can be evaluated after the message buffer has been transferred into an output data structure.

Following sections are giving a guidance how output data structures can be handled.

(a) Data section copy method

One option is to copy the information from the output data structure to a different location of the Local RAM/Cluster RAM and then release the output data structure by clearing the related data available flag. The application should use the copied information for further processing.

(b) Data structure pointer method

A different option is to modify the output data structure pointer in the output pointer table and to release the output data structure by clearing the related data available flag. The changed output data pointer should refer to a free data structure. The application should use the old data structure for further processing.

(c) Data section pointer method

A third option is to modify the data section pointer in the output data structure and to release the output data structure by clearing the related data available flag. The changed data section pointer should refer to a free memory area. The application should use the old data section for further processing by forwarding the data section pointer.

(6) Transfer function of FIFO message buffers

To use this buffer transfer function the output transfer has to be activated (see **Section 24.4.16.2, (1) Activation and deactivation**). The activation process requires the setup of the FIFO pointer table (see **Section 24.4.16.2, (4) FIFO output pointer table**) in order to specify a location in the Local RAM/Cluster RAM reserved for the storage of the required output data structures.

A FIFO data transfer is initiated when a valid FlexRay data frame has been stored in the FlexRay internal FIFO.

After transfers from the internal FIFO to the output data structure, the FIFO interrupt status flag (FLXAnFROTS.FIS) and FIFO data available bit (FLXAnFROTS.FDA) are set to 1. The bit FLXAnFROTS.FIS can be used as an interrupt source. The bit FLXAnFROTS.FDA indicates that the FIFO is not empty.

The size of the output structure is up to the maximum number of entries in the FIFO table (as set by the FLXAnFROTC.FTM[4:0] bits).

The transfer to the extended FIFO buffer structure is controlled by index pointers. This put index is controlled by the FIFO transfer handler and is incremented after transferring a message to the output data structure.

The FIFO reception handler also maintains a get index which is indicated in FLXAnFROTS.FGIDX[4:0]. The value of this get index is known by the application by either reading the status or maintaining a software variable. The get index (the value after a reset is 00000_B) is incremented by one when the application releases the oldest entry of the FIFO queue by writing 1 to FLXAnFROTS.FDA. By comparing the put index and the get index the FIFO handler knows about the current fill level of the queued buffer structure.

The current FIFO fill level is flagged in FLXAnFROTS.FFL[5:0]. When FLXAnFROTS.FDA is 1, there is at least one entry in the FIFO queue.

In case the queued buffer structure in the Local RAM/Cluster RAM is full (FLXAnFROTS.FFL[5:0] = FLXAnFROTC.FTM[4:0] + 1), no further transfers are initialized, new messages remain in the FlexRay internal FIFO and the FIFO transfer warning interrupt status flag (FLXAnFROTS.FWIS) is set to 1.

In case the FlexRay internal FIFO structure becomes full, messages in the FlexRay internal FIFO structure may be overwritten. The related status flags and configuration registers of the FlexRay core module can be used to generate desired warning notifications.

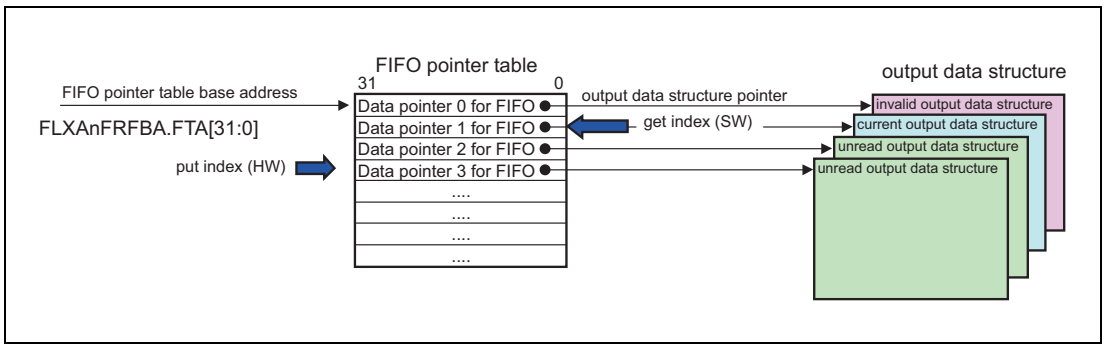

Figure 24.30 FIFO Pointer Table

(7) Transfer function of user output transfer requests

To use this transfer function the output transfer has to be activated (see **Section 24.4.16.2, (1) Activation and deactivation**). The activation process requires to setup the output pointer table (see **Section 24.4.16.2, (3) Output pointer table**) in order to specify the location in the Local RAM/ Cluster RAM reserved for the transfer of the data (output data structures).

The application is capable, by using FLXAnFRUOR.UMBNR[6:0], to request a transfer of dedicated message buffer to an output data structure. Except in CONFIG state, message buffers which are part of the FlexRay internal FIFO should not be requested.

The header section is always transferred to the output data structure. The transfer of the data section can be enabled by setting FLXAnFRUOR.URDS to 1. The selected message buffer content is stored in the output data structure location determined by the pointers in the output pointer table.

The data available status and transfer blocking by bits FLXAnFRDAm.DA[31:0] is also used for the user requested transfers. Therefore bits FLXAnFRDAm.DA[31:0] related to the requested buffer number (FLXAnFRUOR.UMBNR[6:0]) should be released before making the transfer request.

After writing to FLXAnFRUOR.UMBNR[6:0], the bit FLXAnFROTS.UORP is set to 1 to indicate that there is a pending user transfer request. When the transfer has been processed the bit FLXAnFROTS.UORP is set to 0, the bit FLXAnFROTS.OTIS is set to 1 and bits FLXAnFRDAm.DA[31:0] related to the requested buffer number (FLXAnFRUOR.UMBNR[6:0]) are set to 1.

User output transfer requests cannot be queued. The application should check the bit FLXAnFROTS.UORP before writing to FLXAnFRUOR.UMBNR[6:0].

User output transfer requests should not be made for message buffers which are pending in the input transfer queue.

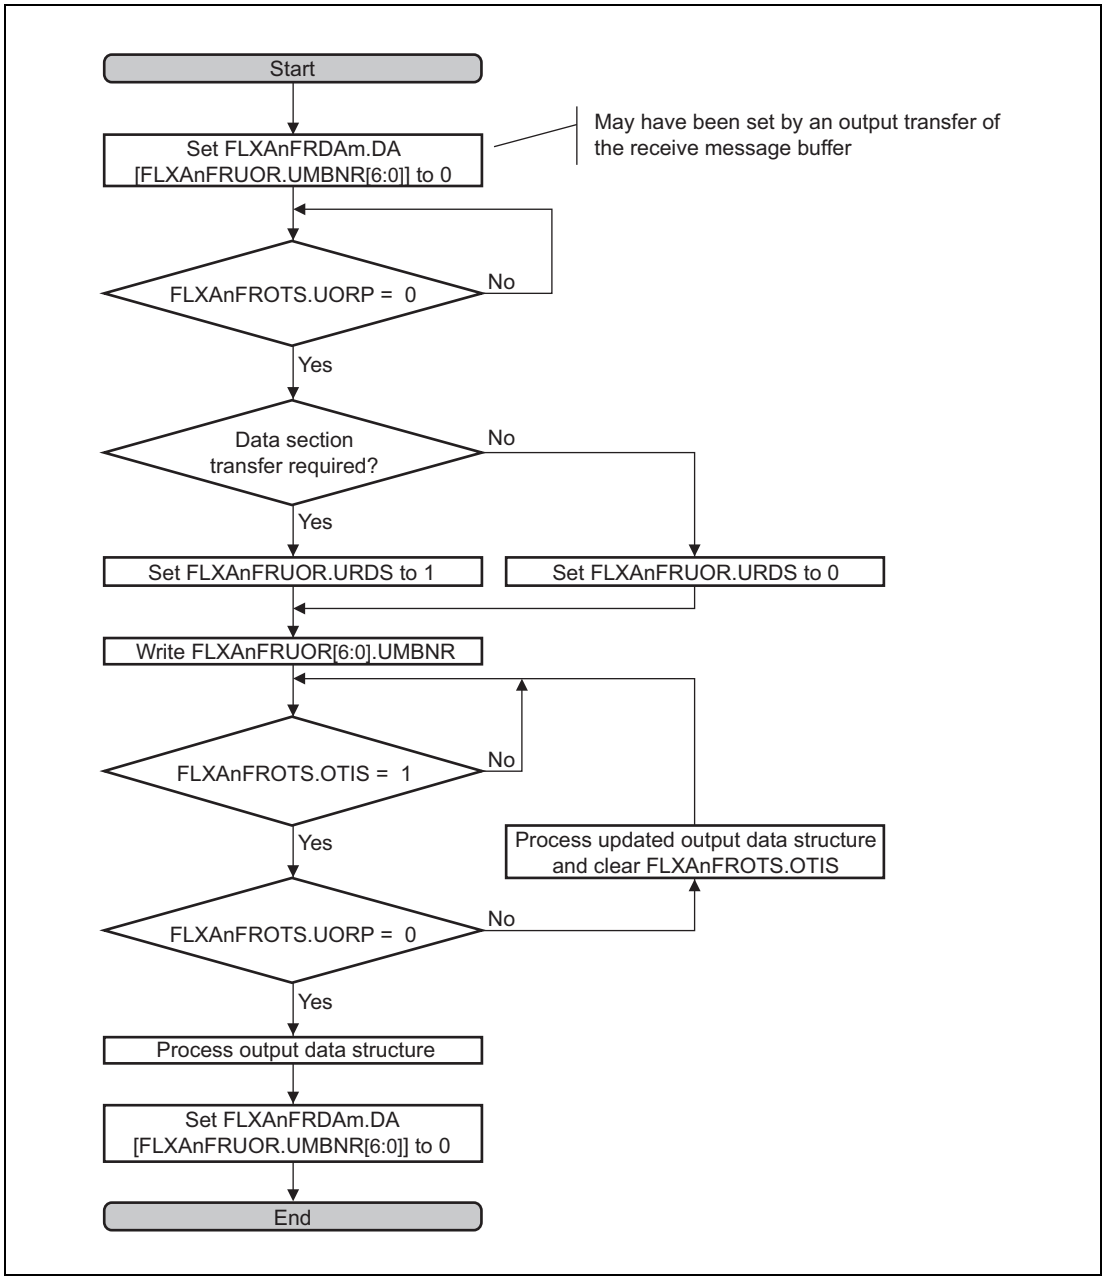

Figure 24.31 User Output Transfer Request Processing Flow

Note that it may be possible that the data structure addressed by a user request is being updated due to a receive message buffer update (which causes bits FLXAnFRDAm.DA[31:0] being set). This set FLXAnFRDAm.DA flags inhibits the user output transfer request. Therefore polling FLXAnFROTS.UORP is not a secure method to identify when the transfer of a requested message buffer has been completed. The bits FLXAnFROTS.OTIS or bits FLXAnFRDAm.DA[31:0] can be used instead. The exact flow depends on the software architecture.

24.4.16.3 Data Structure Transfer Scheduling

Cyclically the different types of transfer requests are checked. In order to guarantee a certain transfer time the different types of transfers have different priorities.

Use requested input transfers have highest priority followed by the transfer of data structures committed into the active input transfer queue. No new output transfer will be started as long as there is a pending input transfer request.

The three output transfer request types are checked in a specific order:

(1) All dedicated message buffers in ascending order

When FLXAnFROTC.OTCS is set to 0, set flags FLXAnFRNDATm.NDp are causing a transfer of the message buffer to the output data structure if the destination area is free (bits FLXAnFRDAm.DA[31:0] are 0).

When FLXAnFROTC.OTCS is set to 1, set flags FLXAnFRNDATm.NDp or set flags in the FLXAnFRMBSCm.MBC[31:0] register are causing a transfer of the message buffer to the output data structure if the destination area is free (bits FLXAnFRDAm.DA[31:0] are 0).

(2) FlexRay internal FIFO

When the FlexRay internal FIFO is not empty and there is a free destination area, one FIFO message is transferred into the output data structure specified by the FIFO pointer table.

(3) User output request

If there is a pending user output transfer request, one message buffer is transferred into the corresponding output data structure.

The check sequence is suspended when an input transfer occurs.

24.4.16.4 Behavior in Case of Data Transfer Access Error

The memory areas accessed by the data transfer function may be protected by a memory protection unit (MPU). When the MPU flags an access to a protected address caused by an input or output transfer, an access error event is generated and the related bit in the FLXAnFRAES register is set.

The ongoing transfer is immediately terminated but succeeding transfers are processed and may generate further access errors. Any following access errors are only flagged in FLXAnFRAES.MAE. The other status flags are not updated.

(1) Access error during input transfer

When an access error occurs during an input transfer:

- The ongoing transfer is immediately terminated. The FlexRay internal message RAM will not be updated
- The address, the FlexRay module wanted to access to, is captured in the FLXAnFRAEA register
- FLXAnFRAES.IAE is set to 1
- The input pointer table index is flagged in FLXAnFRAES.EIDX[7:0]
- In case of an normal input transfer the to the transfer related bits FLXAnFRDAm.DA[31:0] is set to 0
- In case of a user input transfer request FLXAnFRITS.UIRP is set to 0

With the given status information the application is able to identify and correct the faulty data structure.

In addition the application needs to clear the input access error flag (FLXAnFRAES.IAE).

(2) Access error during output transfer

When an access error occurs during an output transfer:

- The ongoing transfer is immediately terminated but the update of the data structure may have started.
- The address, the FlexRay module wanted to access to, is captured in the FLXAnFRAEA register
- FLXAnFRAES.OAE is set to 1
- The output pointer table index is flagged in FLXAnFRAES.EIDX[7:0]
- In case of an normal output transfer the to the transfer related bits FLXAnFRDAm.DA[31:0] remains 0 and no output transfer interrupt is generated
- In case of a user output transfer request FLXAnFROTS.UORP is set to 0

With the given status information the application is able to identify and correct the faulty data structure. The data structure in the Local RAM/Cluster RAM cannot be treated as valid.

In addition the application needs to clear the output access error flag (FLXAnFRAES.OAE).

The FlexRay module internal transfer of the message buffer is completed before the Local RAM/ Cluster RAM access error is detected. The output transfer will not be re-initiated. To avoid loss of data, the application can perform a user output transfer request of this message buffer to a correct Local RAM/Cluster RAM location.

(3) Access error during FIFO transfer

When an access error occurs during an FIFO transfer:

- The ongoing transfer is immediately terminated
- The address, the FlexRay module wanted to access to, is captured in the FLXAnFRAEA register
- FLXAnFRAES.FAE is set to 1
- The FIFO pointer table index is flagged in FLXAnFRAES.EIDX[7:0]
- The FIFO index pointer are not changed and hence the FIFO status flags are unchanged

With the given status information the application is able to identify and correct the faulty data structure.

In addition the application needs to clear the FIFO access error flag (FLXAnFRAES.FAE).

The data in the Local RAM/Cluster RAM cannot be treated as valid and is not released to the application. The message cannot be recovered.

24.4.16.5 Behaviors in Case of RAM Read Errors

The FlexRay internal message RAM has an ECC checking mechanism. In case an uncorrectable RAM read error occurs, the application has to analyze the status in the FLXAnFRMHDS register and react as described in **Section 24.4.16.3, Data Structure Transfer Scheduling**. The input and output transfer handler reacts also on these errors detected in the message RAM when the error is related to an active transfer.

In addition, the TBFA and TBFB have an ECC checking mechanism as well. An uncorrectable RAM read errors does not impact the data transfer functionality but have to be handled as described in **Section 24.4.13.1, (4) Message Buffer Status FLXAnFRMBS (word 3)**.

In all cases, data causing a read error is never transferred to the Local RAM/Cluster RAM. If there is no recovery available in the application, the message is lost.

(1) Read error during transfer from TBF to MBF

This internal transfer is done for each valid FlexRay message received.

A read error can only occur when reading the header section in the FlexRay Message RAM (see read error flags in FLXAnFRMHDS). In this case, the message buffer needs to be re-configured.

For dedicated receive message buffers, the related flags FRNDATm.ND[31:0] will not get set. Consequently the affected message buffer will not be transferred to the output data structure.

For the FlexRay internal FIFO buffers, flags FRNDATm.ND[31:0] are not set but the FlexRay internal FIFO put index is incremented. Due to this, a transfer procedure from the FlexRay internal FIFO buffer to the output buffer is started. However, if the read error is still present in the header section, updating of the output data structure will not start (see **Section 24.4.16.5, (2) Read error during transfer from MBF to OBF**); thus the data in the Local RAM/Cluster RAM remains correct.

Note that the correction or any other reconfiguration of FIFO related to message buffers while there are pending FIFO transfers may result in incorrect data in the Local RAM/Cluster RAM. It is strongly recommended to deactivate the output data transfer before starting the reconfiguration and flush the FlexRay internal FIFO before reactivation of the output data transfer.

(2) Read error during transfer from MBF to OBF

This internal transfer is done for every output data transfer (dedicated reception, FIFO, user requested).

A read error can occur in the header and data section (see read error flags in FLXAnFRMHDS). In both cases the message gets lost. If the error is located in the header section, the message buffer needs to be re-configured. If the error is located in the data section, the error is corrected with the next data section update.

When a read error occurs during the transfer from the message RAM to the output buffer, the output data structure will not be updated and the data available will not be set to 1. The FIFO put index and the FIFO fill level are not changed also.

In case of user output transfer request, FLXAnFROTS.UORP is set to 0 even if there was no update of the output data structure.

(3) Read error during transfer from IBF to MBF

This internal transfer is done for every input data transfer.

A read error can occur only when there is no update of the header section requested (the bit LHS in FLXAnFRWRHS4 is set to 0) due to the reading of the header section from the message RAM (see read error flags in FLXAnFRMHDS). In this case, the message buffer needs to be re-configured.

When a read error occurs during the input data transfer, the actually transferred message in the input queue gets lost.

(4) Message RAM read errors

Read errors when reading the header section are flagged in the FLXAnFRMHDS register.

Depending on the buffer type and set buffer protection, a reconfiguration of the message buffer may not be possible.

The input transfer function cannot be used to reconfigure a locked message buffer using the method described in **Section 24.4.13.4, (3) Temporary Unlocking of Header Section**.

Before reconfiguring a locked buffer, the user should disable the input transfer function and the output transfer function.

24.4.17 Byte Alignment

The alignment of the bytes received by the FlexRay protocol and the alignment of the bytes required by the application may be different. The FlexRay module provides with FLXAnFROC.BEC a byte alignment function to support different byte ordering styles.

Figure 24.32 shows the payload byte alignment in a FlexRay frame.

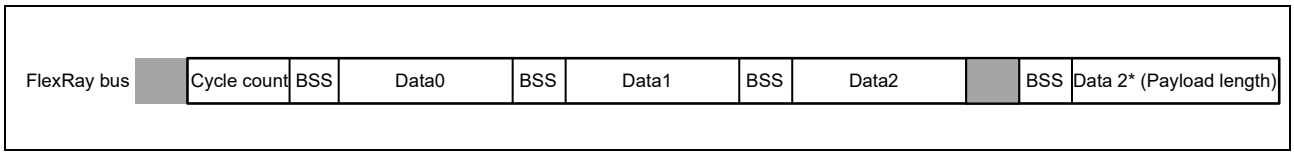

Figure 24.32 Byte Alignment on the FlexRay Bus

24.4.17.1 Little Endian Alignment

When FLXAnFROC.BEC is 0, the byte alignment is set to Little Endian.

(1) FLXAnFRNMVm (m = 1 to 3)

The byte alignment of the NMV bytes is as follows.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
FLXAn FRNMV1	Data 3								Data 2								Data 1								Data 0							
FLXAn FRNMV2	Data 7								Data 6								Data 5								Data 4							
FLXAn FRNMV3	Data 11								Data 10								Data 9								Data 8							

(2) FLXAnFRWRDSx (x = 1 to 64)

The byte alignment for the message payload in the FlexRay input buffer and the input data structure is as follows.

- FLXAnFRWRDSx.MD[7:0] = Data4x-4
- FLXAnFRWRDSx.MD[15:8] = Data4x-3
- FLXAnFRWRDSx.MD[23:16] = Data4x-2
- FLXAnFRWRDSx.MD[31:24] = Data4x-1

Transmission order on the FlexRay bus is FLXAnFRWRDSx.MD[7:0], FLXAnFRWRDSx.MD [15:8], FLXAnFRWRDSx.MD [23:16], FLXAnFRWRDSx.MD [31:24] with the most significant bit (MSB) transmitted first.

(3) FLXAnFRRDDSx (x = 1 to 64)

The byte alignment for the message payload in the FlexRay output buffer and the output data structure are as follows.

- FLXAnFRRDDSx.MD[7:0] = Data4x-4
- FLXAnFRRDDSx.MD[15:8] = Data4x-3
- FLXAnFRRDDSx.MD[23:16] = Data4x-2
- FLXAnFRRDDSx.MD[31:24] = Data4x-1

Reception order on the FlexRay bus is FLXAnFRRDDSx.MD[7:0], FLXAnFRRDDSx.MD[15:8], FLXAnFRRDDSx.MD[23:16], FLXAnFRRDDSx.MD[31:24] with the most significant bit (MSB) received first.

24.4.17.2 Big Endian Alignment

When FLXAnFROC.BEC is '1', the byte alignment is set to Big Endian.

(1) FLXAnFRNMVm (m = 1 to 3)

The byte alignment of the NMV bytes is as follows.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
FLXAn FRNMV1	Data 0								Data 1								Data 2								Data 3							
FLXAn FRNMV2	Data 4								Data 5								Data 6								Data 7							
FLXAn FRNMV3	Data 8								Data 9								Data 10								Data 11							

(2) FLXAnFRWRDSx (x = 1 to 64)

The byte alignment for the message payload in the FlexRay input buffer and the input data structure are as follows.

- FLXAnFRWRDSx.MD[7:0] = Data4x-1
- FLXAnFRWRDSx.MD[15:8] = Data4x-2
- FLXAnFRWRDSx.MD[23:16] = Data4x-3
- FLXAnFRWRDSx.MD[31:24] = Data4x-4

Transmission order on the FlexRay bus is FLXAnFRWRDSx.MD[31:24], FLXAnFRWRDSx.MD[23:16], FLXAnFRWRDSx.MD[15:8], and FLXAnFRWRDSx.MD[7:0] with the most significant bit (MSB) transmitted first.

(3) FLXAnFRRDDSx (x = 1 to 64)

The byte alignment for the message payload in the FlexRay output buffer and the output data structure are as follows.

- FLXAnFRRDDSx.MD[7:0] = Data4x-1
- FLXAnFRRDDSx.MD[15:8] = Data4x-2
- FLXAnFRRDDSx.MD[23:16] = Data4x-3
- FLXAnFRRDDSx.MD[31:24] = Data4x-4

Reception order on the FlexRay bus is FLXAnFRRDDSx.MD[31:24], FLXAnFRRDDSx.MD [23:16], FLXAnFRRDDSx.MD[15:8], FLXAnFRRDDSx.MD[7:0] with the most significant bit (MSB) received first.

Section 25 Ethernet AVB (ETNB)

This section contains a generic description of the Ethernet AVB (ETNB).

The first part in this section describes properties specific to the RH850/U2A-EVA, such as the number of units, register base addresses, etc. The remainder of the section describes the functions and registers of the ETNB.

CAUTION

Read URAM in this manual as Local RAM/Global RAM/Retention RAM.

Read AXI BUS in this manual as AHB BUS.

25.1 Features of ETNB for RH850/U2A-EVA

25.1.1 Number of Units and Channels

This microcontroller has the following number of ETNB units.

Table 25.1 Number of Units (100 Mbps Ether)

Product Name	RH850/ U2A-EVA (516 pins)	RH850/ U2A16 (516 pins)	RH850/ U2A16 (373 pins)	RH850/ U2A16 (292 pins)	RH850/ U2A8 (373 pins)	RH850/ U2A8 (292 pins)	RH850/ U2A6 (292 pins)	RH850/ U2A6 (176 pins)	RH850/ U2A6 (156 pins)	RH850/ U2A6 (144 pins)
Number of Units	1	1	1	1	1	1	1	1	—	1
Name	ETNBn (n = 0)									

Table 25.2 Number of Units (1 Gbps Ether)

Product Name	RH850/ U2A-EVA (516 pins)	RH850/ U2A16 (516 pins)	RH850/ U2A16 (373 pins)	RH850/ U2A16 (292 pins)	RH850/ U2A8 (373 pins)	RH850/ U2A8 (292 pins)	RH850/ U2A6 (292 pins)	RH850/ U2A6 (176 pins)	RH850/ U2A6 (156 pins)	RH850/ U2A6 (144 pins)
Number of Units	1	1	1	1	1	1	—	—	—	—
Name	ETNBn (n = 1)									

Table 25.3 Index

Index	Description
n	Throughout this section, the individual ETNB units of Fast Ethernet and Gigabit Ethernet are identified by the index “n”. ETNB0 is for Fast Ethernet and ETNB1 is for Gigabit Ethernet.

25.1.2 Register Base Addresses

The ETNB base address is listed in the following table.

The ETNB register addresses are given as offsets from the base address.

Table 25.4 Register Base Addresses

Base Address Name	Base Address	Bus Group
<ETNB0_base>	FF0A 2000_H	P-Bus Group 9
<ETNB1_base>	FF0A 4000_H	P-Bus Group 9

25.1.3 Clock Supply

The ETNB clock supply is shown in the following table.

Table 25.5 Clock Supply

Unit Name	Clock for the Unit	Supply Clock Name
ETNBn	clk_axi	CLK HBUS
	clk_chi	CLK HBUS
	Register access clock	CLK HBUS

CAUTION

Minimum frequency of the clock clk_axi and clk_chi is:

- **62.5 MHz when E-MAC works in 1000 Mbps mode (ETNBnGECMR.SPEED = 1)**
- **12.5 MHz when E-MAC works in 100 Mbps mode (ETNBnGECMR.SPEED = 0)**

25.1.4 Interrupt Requests and Error Notifications

The ETNB interrupt requests are listed in the following table.

Table 25.6 Interrupt Requests

Unit Interrupt Signal	Description	Interrupt Number	DMA Trigger Number
ETNB0			
INTETNB0DATA	Data related interrupt	645	—
INTETNB0ERR	Error related interrupt	646	—
INTETNB0MNG	Management related interrupt	647	—
INTETNB0MAC	MAC interrupt	648	—
ETNB1			
INTETNB1DATA	Data related interrupt	649	—
INTETNB1ERR	Error related interrupt	650	—
INTETNB1MNG	Management related interrupt	651	—
INTETNB1MAC	MAC interrupt	652	—
INTETNB1STA	SGMII interrupt	653	—

This module has no error notifications.

25.1.5 Reset Sources

The ETNB reset sources are listed in the following table. ETNB is initialized by these reset sources.

Table 25.7 Reset Sources (RH850/U2A-EVA)

Unit Name	Register Name	Reset Condition						
		Power On Reset	System Reset 1	System Reset 2	Application Reset	DeepSTOP Reset	Module Reset	JTAG Reset
ETNB0	All registers	√	√	√	√	√	√	—
ETNB1	ETNB1SGSDS ETNB1SGCLKSEL ETNB1SGRCIE	√	√	√	√	√	—	—
	Other than above	√	√	√	√	√	√*1	—

Note 1. When reset by module reset.
Need to wait module reset assertion until turning off the power of SGMII SerDes.
Power status can be checked by ETNB1SGSDS.PWS bit.

25.1.6 External Input/Output Signals

External input/output signals of ETNB are listed below.

Table 25.8 ETNBn Input/Output Signals

Unit Signal Name	I/O	Description	Alternative Port Pin Signal
ETNB0			
AVB_TX_CLK	I	MII transmit clock signal	ETNB0TXCLK
AVB_RX_CLK	I	MII receive clock signal	ETNB0RXCLK
AVB_TX_EN	O	MII/RMII transmit data enable signal	ETNB0TXEN
AVB_TXD[3:0](MII)/ AVB_TXD[1:0](RMII)	O	MII/RMII transmit data signal	ETNB0TXD[3:0](MII)/ ETNB0TXD[1:0](RMII)
AVB_TX_ER	O	MII transmit error signal	ETNB0TXER
AVB_RX_DV	I	MII receive data valid signal	ETNB0RXDV
AVB_RXD[3:0](MII)/ AVB_RXD[1:0](RMII)	I	MII/RMII receive data signal	ETNB0RXD[3:0](MII)/ ETNB0RXD[1:0](RMII)
AVB_RX_ER	I	MII/RMII receive error signal	ETNB0RXER
RMII_REF50CK	I	RMII reference clock signal	ETNB0REFCLK
RMII_CRS_DV	I	RMII receive data valid signal	ETNB0CRS_DV
AVB_MDC	O	PHY management clock signal	ETNB0MDC
AVB_MDIO	I/O	PHY management transfer data signal	ETNB0MDIO
AVB_LINK	I	PHY link status signal	ETNB0LINKSTA
AVB_MAGIC	O	Wake-On-LAN. This signal indicates that a Magic Packet™*1 has been received	ETNB0WOL
ETNB1			
TX_DATAN	O	SGMII Tx serial data outputs (negative)	TX_DATAN
TX_DATAP	O	SGMII Tx serial data outputs (positive)	TX_DATAP
RX_CLKN*2	I	SGMII Rx ddr clock inputs (negative)	RX_CLKN
RX_CLKP*2	I	SGMII Rx ddr clock inputs (positive)	RX_CLKP
RX_DATAN	I	SGMII Rx serial data inputs (negative)	RX_DATAN
RX_DATAP	I	SGMII Rx serial data inputs (positive)	RX_DATAP
REFCLK	I	SGMII Reference clock input (25 MHz)	ETNB1REFCLK
AVB_TX_CLK	I	MII transmit clock signal	ETNB1TXCLK
AVB_RX_CLK	I	MII receive clock signal	ETNB1RXCLK
AVB_TX_EN	O	MII transmit data enable signal	ETNB1TXEN
AVB_TXD[3:0]	O	MII transmit data signal	ETNB1TXD[3:0]
AVB_TX_ER	O	MII transmit error signal	ETNB1TXER
AVB_RX_DV	I	MII receive data valid signal	ETNB1RXDV
AVB_RXD[3:0]	I	MII receive data signal	ETNB1RXD[3:0]
AVB_RX_ER	I	MII receive error signal	ETNB1RXER
AVB_MDC	O	PHY management clock signal	ETNB1MDC
AVB_MDIO	I/O	PHY management transfer data signal	ETNB1MDIO
AVB_LINK*3	I	PHY link status signal	ETNB1LINKSTA
AVB_PHY_INT	I	PHY interrupt information	ETNB1PHYINT
AVB_MAGIC	O	Wake-On-LAN. This signal indicates that a Magic Packet™*1 has been received	ETNB1WOL

Note 1. Magic Packet™ is a trademark of Advanced Micro Devices, inc.

Note 2. Use for RH850/U2A-EVA (BGA-516) only.

Note 3. Supported by RH850/U2A-EVA (BGA-516) and RH850/U2A16 (BGA-516) only.

25.2 Overview

25.2.1 Functional Overview

Table 25.9 lists the specifications of the ETNB.

Table 25.9 Specifications of ETNBn

Item	Description
Protocol	Flow control conforming with the IEEE 802.3x standard
Communication interface*3	For ETNB0: • RMII (Reduced Media Independent Interface) • MII (Media Independent Interface) For ETNB1: • SGMII (Serial Gigabit Media Independent Interface) • MII*1 (Media Independent Interface)
Transfer speed	For ETNB0: • 100 Mbps • 10 Mbps For ETNB1: • 1000 Mbps • 100 Mbps • 10 Mbps
Transfer mode	Full-duplex mode
AVB function	• Conforming with the following standards stipulated for IEEE 802.1BA. – IEEE 802.1AS (time synchronization protocol) – IEEE 802.1Qav (real-time transfer) – IEEE 802.1Qat (stream reservation protocol) * IEEE 802.1Qat should be supported by software. • Descriptor management system • IEEE 1722 (AVTP presentation timestamp)
Transmit/Receive FIFO	For transmission: 16 Kbytes For reception: 8 Kbytes
Magic Packet™	Detection of Magic Packet™*2 and Wake-On-LAN signal output

Note 1. RH850/U2A16 (373 pins), RH850/U2A16 (292 pins), RH850/U2A8 (373 pins) and RH850/U2A8 (292 pins) do not support MII.

Note 2. Magic Packet™ is a trademark of Advanced Micro Devices, Inc.

Note 3. For ETNB0 MII/RMII select and ETNB1 MII/SGMII select, refer to **Section 51.12.14, OPBT8 — Option Byte 8**.
For SGMII transmitter polarity inversion, SGMII receiver polarity inversion, SGMII output amplitude control and SGMII receiver termination selectors, refer to **Section 51.12.20, OPBT14 — Option Byte 14**.

25.3 Register Descriptions

25.3.1 List of Registers

The following table lists the ETNB registers.

For details about <ETNBn_base>, see **Section 25.1.2, Register Base Addresses**.

Table 25.10 List of Registers (1/3)

Unit name	Register Name	Abbreviation	Address	Access Protection	
				PBG	Other
Ethernet AVB Registers					
	AVB-DMAC mode register	ETNBnCCC	<ETNBn_base> + 0000_H	*1	—
	Descriptor base address table register	ETNBnDBAT	<ETNBn_base> + 0004_H	*1	—
	Descriptor base address load request register	ETNBnDLR	<ETNBn_base> + 0008_H	*1	—
	AVB-DMAC status register	ETNBnCSR	<ETNBn_base> + $000C_H$	*1	—
	Current descriptor address register q (q = 0 to 21)	ETNBnCDARq	<ETNBn_base> + 0010_H + q × 4_H	*1	—
	Error status register	ETNBnESR	<ETNBn_base> + 0088_H	*1	—
	RMII interface mode register	ETNBnRIMR	<ETNBn_base> + $008C_H$	*1	—
	Receive configuration register	ETNBnRCR	<ETNBn_base> + 0090_H	*1	—
	Receive queue configuration register i (i = 0 to 4)	ETNBnRQCi	<ETNBn_base> + 0094_H + i × 4_H	*1	—
	Receive padding configuration register	ETNBnRPC	<ETNBn_base> + $00B0_H$	*1	—
	Unread frame counter warning level register	ETNBnUFCW	<ETNBn_base> + $00BC_H$	*1	—
	Unread frame counter stop level configuration register	ETNBnUFCS	<ETNBn_base> + $00C0_H$	*1	—
	Unread frame counter register i (i = 0 to 4)	ETNBnUFCVi	<ETNBn_base> + $00C4_H$ + i × 4_H	*1	—
	Unread frame counter decrement register i (i = 0 to 4)	ETNBnUFCDi	<ETNBn_base> + $00E0_H$ + i × 4_H	*1	—
	Separation filter offset register	ETNBnSFO	<ETNBn_base> + $00FC_H$	*1	—
	Separation filter pattern register i (i = 0 to 31)	ETNBnSFPi	<ETNBn_base> + 0100_H + i × 4_H	*1	—
	Separation filter value register i (i = 0, 1)	ETNBnSFVi	<ETNBn_base> + $01B8_H$ + i × 4_H	*1	—
	Separation filter mask register i (i = 0, 1)	ETNBnSFMi	<ETNBn_base> + $01C0_H$ + i × 4_H	*1	—
	Separation filter load register	ETNBnSFL	<ETNBn_base> + $01C8_H$	*1	—
	Payload CRC register	ETNBnPCRC	<ETNBn_base> + $01CC_H$	*1	—
	Transmit configuration register	ETNBnTGC	<ETNBn_base> + 0300_H	*1	—
	Transmit configuration control register	ETNBnTCCR	<ETNBn_base> + 0304_H	*1	—
	Transmit status register	ETNBnTSR	<ETNBn_base> + 0308_H	*1	—
	Timestamp FIFO access register 0	ETNBnTFA0	<ETNBn_base> + 0310_H	*1	—
	Timestamp FIFO access register 1	ETNBnTFA1	<ETNBn_base> + 0314_H	*1	—
	Timestamp FIFO access register 2	ETNBnTFA2	<ETNBn_base> + 0318_H	*1	—
	Version and release register	ETNBnVRR	<ETNBn_base> + $031C_H$	*1	—
	CBS increment value register c (c = 0, 1)	ETNBnCIVRc	<ETNBn_base> + 0320_H + c × 4_H	*1	—
	CBS decrement value register c (c = 0, 1)	ETNBnCDVRc	<ETNBn_base> + 0328_H + c × 4_H	*1	—

Table 25.10 List of Registers (2/3)

Unit name	Register Name	Abbreviation	Address	Access Protection	
				PBG	Other
Ethernet AVB Registers					
	CBS upper limit register c (c = 0, 1)	ETNBnCULc	<ETNBn_base> + 0330_H + c × 4_H	*1	—
	CBS lower limit register c (c = 0, 1)	ETNBnCLLc	<ETNBn_base> + 0338_H + c × 4_H	*1	—
	Descriptor interrupt control register	ETNBnDIC	<ETNBn_base> + 0350_H	*1	—
	Descriptor interrupt status register	ETNBnDIS	<ETNBn_base> + 0354_H	*1	—
	Error interrupt control register	ETNBnEIC	<ETNBn_base> + 0358_H	*1	—
	Error interrupt status register	ETNBnEIS	<ETNBn_base> + $035C_H$	*1	—
	Receive interrupt control register 0	ETNBnRIC0	<ETNBn_base> + 0360_H	*1	—
	Receive interrupt status register 0	ETNBnRIS0	<ETNBn_base> + 0364_H	*1	—
	Receive interrupt control register 1	ETNBnRIC1	<ETNBn_base> + 0368_H	*1	—
	Receive interrupt status register 1	ETNBnRIS1	<ETNBn_base> + $036C_H$	*1	—
	Receive interrupt control register 2	ETNBnRIC2	<ETNBn_base> + 0370_H	*1	—
	Receive interrupt status register 2	ETNBnRIS2	<ETNBn_base> + 0374_H	*1	—
	Transmit interrupt control register	ETNBnTIC	<ETNBn_base> + 0378_H	*1	—
	Transmit interrupt status register	ETNBnTIS	<ETNBn_base> + $037C_H$	*1	—
	Interrupt summary status register	ETNBnISS	<ETNBn_base> + 0380_H	*1	—
	Common interrupt enable register	ETNBnCIE	<ETNBn_base> + 0384_H	*1	—
	Receive interrupt control register 3	ETNBnRIC3	<ETNBn_base> + 0388_H	*1	—
	Receive interrupt status register 3	ETNBnRIS3	<ETNBn_base> + $038C_H$	*1	—
	Receive interrupt enable register 0	ETNBnRIE0	<ETNBn_base> + 0460_H	*1	—
	Receive interrupt enable register 1	ETNBnRIE1	<ETNBn_base> + 0468_H	*1	—
	Receive interrupt enable register 2	ETNBnRIE2	<ETNBn_base> + 0470_H	*1	—
	Receive interrupt enable register 3	ETNBnRIE3	<ETNBn_base> + 0488_H	*1	—
	Receive interrupt disable register 0	ETNBnRID0	<ETNBn_base> + 0464_H	*1	—
	Receive interrupt disable register 1	ETNBnRID1	<ETNBn_base> + $046C_H$	*1	—
	Receive interrupt disable register 2	ETNBnRID2	<ETNBn_base> + 0474_H	*1	—
	Receive interrupt disable register 3	ETNBnRID3	<ETNBn_base> + $048C_H$	*1	—
	gPTP configuration control register	ETNBnGCCR	<ETNBn_base> + 0390_H	*1	—
	Transmit interrupt enable register	ETNBnTIE	<ETNBn_base> + 0478_H	*1	—
	Transmit interrupt disable register	ETNBnTID	<ETNBn_base> + $047C_H$	*1	—
	gPTP maximum transit time register	ETNBnGMTT	<ETNBn_base> + 0394_H	*1	—
	gPTP presentation time comparison register	ETNBnGPTC	<ETNBn_base> + 0398_H	*1	—
	gPTP timer increment register	ETNBnGTI	<ETNBn_base> + $039C_H$	*1	—
	gPTP timer offset register i (i = 0 to 2)	ETNBnGTOi	<ETNBn_base> + $03A0_H$ + i × 4_H	*1	—
	gPTP interrupt control register	ETNBnGIC	<ETNBn_base> + $03AC_H$	*1	—
	gPTP interrupt status register	ETNBnGIS	<ETNBn_base> + $03B0_H$	*1	—
	gPTP timer capture register i (i = 0 to 2)	ETNBnGCTi	<ETNBn_base> + $03B8_H$ + i × 4_H	*1	—
	gPTP status register	ETNBnGSR	<ETNBn_base> + $03C4_H$	*1	—
	gPTP presentation time FIFO register i (i = 0 to 3)	ETNBnGPTFi	<ETNBn_base> + $03E0_H$ + i × 4_H	*1	—
	E-MAC mode register	ETNBnECMR	<ETNBn_base> + 0500_H	*1	—

Table 25.10 List of Registers (3/3)

Unit name	Register Name	Abbreviation	Address	Access Protection	
				PBG	Other
Ethernet AVB Registers					
	Receive frame length register	ETNBnRFLR	<ETNBn_base> + 0508_H	*1	—
	E-MAC status register	ETNBnECSR	<ETNBn_base> + 0510_H	*1	—
	E-MAC interrupt permission register	ETNBnECSIPR	<ETNBn_base> + 0518_H	*1	—
	PHY interface register	ETNBnPIR	<ETNBn_base> + 0520_H	*1	—
	PHY LINK status register	ETNBnPLSR	<ETNBn_base> + 0528_H	*1	—
	PHY interrupt polarity register	ETNBnPIPR	<ETNBn_base> + $052C_H$	*1	—
	Auto PAUSE frame time parameter register	ETNBnAPFTP	<ETNBn_base> + 0554_H	*1	—
	Manual PAUSE frame register	ETNBnMPR	<ETNBn_base> + 0558_H	*1	—
	PAUSE frame transmit counter	ETNBnPFTCR	<ETNBn_base> + $055C_H$	*1	—
	PAUSE frame receive counter	ETNBnPFRCR	<ETNBn_base> + 0560_H	*1	—
	Automatic PAUSE frame retransmit count register	ETNBnTPAUSER	<ETNBn_base> + 0564_H	*1	—
	PAUSE frame transmit times counter	ETNBnPFTTCR	<ETNBn_base> + 0568_H	*1	—
	E-MAC mode register 2	ETNBnGECMR	<ETNBn_base> + $05B0_H$	*1	—
	MAC address high register	ETNBnMAHR	<ETNBn_base> + $05C0_H$	*1	—
	MAC address low register	ETNBnMALR	<ETNBn_base> + $05C8_H$	*1	—
	CRC error frame receive counter register	ETNBnCEFCR	<ETNBn_base> + 0740_H	*1	—
	Frame receive error counter register	ETNBnFRECR	<ETNBn_base> + 0748_H	*1	—
	Too-short frame receive counter register	ETNBnTSFRCR	<ETNBn_base> + 0750_H	*1	—
	Too-long frame receive counter register	ETNBnTLFRCR	<ETNBn_base> + 0758_H	*1	—
	Residual-bit frame receive counter register	ETNBnRFCR	<ETNBn_base> + 0760_H	*1	—
	Multicast address frame receive counter register	ETNBnMAFCR	<ETNBn_base> + 0778_H	*1	—
SGMII Interface Related Registers					
	SGMII operation mode configuration register	ETNB1SGOPMC	<ETNB1_base> + 1000_H	PBG90#7	—
	SGMII operation mode status register	ETNB1SGOPMS	<ETNB1_base> + 1004_H	PBG90#7	—
	SGMII software reset register	ETNB1SGSRST	<ETNB1_base> + 1008_H	PBG90#7	—
	SGMII interrupt status register	ETNB1SGINTS	<ETNB1_base> + $100C_H$	PBG90#7	—
	SGMII interrupt mask register	ETNB1SGINTM	<ETNB1_base> + 1010_H	PBG90#7	—

n = 1: PBG90#7

25.3.2 Ethernet AVB Registers

25.3.2.1 ETNBnCCC — AVB-DMAC Mode Register

The ETNBnCCC register specifies the operating mode of the AVB-DMAC.

Access: ETNBnCCC can be read or written in 32-bit units.
ETNBnCCCL and ETBnCCCH can be read or written in 16-bit units.
ETNBnCCCLL, ETBnCCCLH, ETNBnCCCHL, ETNBnCCCHH can be read or written in 8-bit units.

Address: ETNBnCCC: <ETNBn_base> + 0000_H
ETNBnCCCL: <ETNBn_base> + 0000_H
ETNBnCCCH: <ETNBn_base> + 0002_H
ETNBnCCCLL: <ETNBn_base> + 0000_H
ETNBnCCCLH: <ETNBn_base> + 0001_H
ETNBnCCCHL: <ETNBn_base> + 0002_H
ETNBnCCCHH: <ETNBn_base> + 0003_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 25.11 ETNBnCCC Register Contents (1/2)

Bit Position	Bit Name	Function
31 to 26	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
25	FCE	Flow Control Enable 0: Flow control disabled 1: Flow control enabled
24	LBME	Loopback Mode Enable 0: Normal operation 1: Loopback mode is enabled.
23 to 21	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
20	BOC	Byte Order Configuration 0: First Ethernet byte in URAM[7:0] 1: First Ethernet byte in URAM[31:24]
19, 18	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
17, 16	CSEL[1:0]	gPTP Clock Select 00_B: gPTP is not in use. 01_B: Peripheral bus clock (clk_chi) 10_B: Ethernet transmission clock 11_B: Setting prohibited
15 to 9	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
8	DTSR	Data Transfer Suspend Request 0: Normal operation 1: Requests suspension

Table 25.11 ETNBnCCC Register Contents (2/2)

Bit Position	Bit Name	Function
7	GAC	gPTP Active in Config 0: Normal operation 1: gPTP support active in configuration mode
6 to 2	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
1, 0	OPC[1:0]	Operating Mode Configuration 00_B: Reset mode 01_B: Configuration mode 10_B: Operation mode 11_B: Standby mode

FCE: Flow Control Enable Bit

This bit enables the flow control support of MAC.

When flow control is enabled, the MAC gets informed about the Rx-FIFO level (Rx-FIFO fill level reached ETNBnRCR.RFCL).

LBME: Loopback Mode Enable Bit

This bit enables loopback mode.

In loopback mode, the transmission lines are internally connected to the reception lines. When loopback mode is to be used, the Ethernet transmission clock or the reference clock must be supplied to the MII/RMII/SGMII interface. A received clock signal is not required for the MII interface. Writing to this bit is only possible when the current operating mode is configuration mode.

CAUTION

Data for transmission are still output normally. To eliminate effects on external modules, pin control should be applied to block the output of data. For details about the pin control, see Section 2, Pin Functions.

BOC: Byte Order Configuration Bit

This bit specifies the assignment of the first byte of received Ethernet frames when it is allocated to the URAM.

This setting of this register does not affect the descriptor format and filter parameters of the URAM.

Writing to this bit is only possible when the current operating mode is configuration mode.

The CPU can only write 0 to this bit.

Figure 25.3 and **Figure 25.4** show how data from frames received via the Ethernet connection are stored in the URAM.

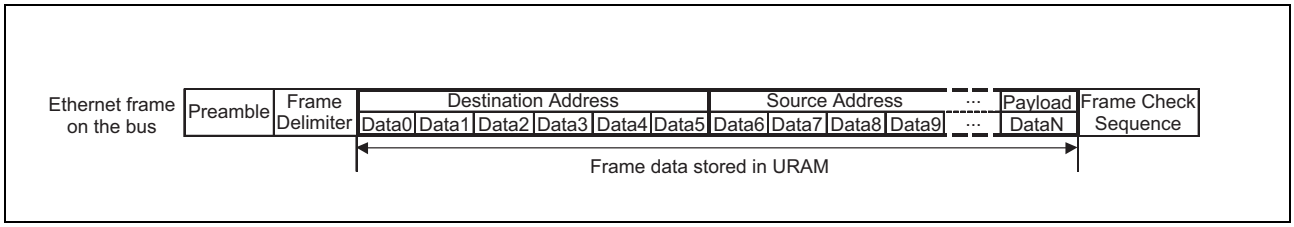

Figure 25.3 Data of Ethernet Frame Received

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

DPTR+4	Data7								Data6								Data5								Data4							
DPTR+8	Data11								Data10								Data9								Data8							

Figure 25.4 When ETNBnCCC.BOC = 0

CSEL[1:0]: gPTP Clock Select Bits

These bits select the clock source for the gPTP timer.
Writing to these bits is only possible when the current operating mode is configuration mode and ETNBnCCC.GAC is 0, or when the current operating mode is reset mode and writing 1 to ETNBnCCC.GAC and writing 01_B to ETNBnCCC.OPC by same write access.

DTSR: Data Transfer Suspend Request Bit

This bit can suspend access to the URAM.

The access is suspended on completion of the transfer of the frame currently being transferred.

This function disables access to the URAM without affecting normal operation of the AVB-DMAC. Use this bit when exclusive control over the contents of the URAM is necessary, for example, in checking its integrity.

CAUTION

The transmission and reception queues are not processed while access is suspended. Change neither the AVB-DMAC settings nor the mode until the suspend request is given by ETNBnCCC.DTSR and later the value of ETNBnCSR.DTS is updated.

GAC: gPTP Active in Config Bit

These bit enables the gPTP support of the AVB-DMAC in configuration mode. Function of gPTP support in operation mode and standby mode is not influenced by this bit. When gPTP support is active in configuration mode, ETNBnCCC.CSEL defines the timer clock source.

Writing 1 to this bit is only possible when the current operating mode is reset mode and 01_B is written to ETNBnCCC.OPC by the same write access.

OPC[1:0]: Operating Mode Configuration Bits

These bits specify the operating mode.

For the operating modes, see **Section 25.4.1.1, Operating Modes**.

Writing to this bit is possible in any of the operating modes, but should not be done after the application system has issued a Power Off request.

Do not write 11_B to these bits when ETNBnCCC.GAC is 1.

CAUTION

In RMII mode, after entering reset mode by writing 00_B to OPC[1:0], it is necessary to assert Module Reset by SWMRESA_ETNB.SWMRESA_ETNB0 to initialize RMII circuit. This caution just applies for U2A-EVA.

25.3.2.2 ETNBnDBAT — Descriptor Base Address Table Register

The ETNBnDBAT register is used to set the base address of the descriptor table.

Access: This register can be read or written in 32-bit units.

Address: <ETNBn_base> + 0004_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	TA[31:16]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 25.12 ETNBnDBAT Register Contents

Bit Position	Bit Name	Function
31 to 0	TA[31:0]	Descriptor Base Table Address Base address of the descriptor table in the URAM

CAUTION

The setting of this bit must be a multiple of four (Bit 0 and bit 1 must be set to “0”).

TA[31:0]: Descriptor Base Table Address Bits

These bits specify the base address of the descriptor table in the URAM.

For the structure of the descriptor base address table, see **Section 25.4.3, Descriptors**.

Writing to this bit is only possible when the current operating mode is configuration mode.

25.3.2.3 ETNBnDLR — Descriptor Base Address Load Request Register

Access: This register can be read or written in 32-bit units.

Address: <ETNBn_base> + 0008_H

Value after reset: $003F\ FFFF_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 25.13 ETNBnDLR Register Contents (1/3)

Bit Position	Bit Name	Function
31 to 22	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
21	LBA21	Base Address Load Request (Rx17: Stream 15) 0: No load request is issued. 1: When written: A request for loading the corresponding base address is issued. When read: The given base address is being loaded.
20	LBA20	Base Address Load Request (Rx16: Stream 14) 0: No load request is issued. 1: When written: A request for loading the corresponding base address is issued. When read: The given base address is being loaded.
19	LBA19	Base Address Load Request (Rx15: Stream 13) 0: No load request is issued. 1: When written: A request for loading the corresponding base address is issued. When read: The given base address is being loaded.
18	LBA18	Base Address Load Request (Rx14: Stream 12) 0: No load request is issued. 1: When written: A request for loading the corresponding base address is issued. When read: The given base address is being loaded.
17	LBA17	Base Address Load Request (Rx13: Stream 11) 0: No load request is issued. 1: When written: A request for loading the corresponding base address is issued. When read: The given base address is being loaded.
16	LBA16	Base Address Load Request (Rx12: Stream 10) 0: No load request is issued. 1: When written: A request for loading the corresponding base address is issued. When read: The given base address is being loaded.
15	LBA15	Base Address Load Request (Rx11: Stream 9) 0: No load request is issued. 1: When written: A request for loading the corresponding base address is issued. When read: The given base address is being loaded.

Table 25.13 ETNBnDLR Register Contents (2/3)

Bit Position	Bit Name	Function
14	LBA14	Base Address Load Request (Rx10: Stream 8) 0: No load request is issued. 1: When written: A request for loading the corresponding base address is issued. When read: The given base address is being loaded.
13	LBA13	Base Address Load Request (Rx9: Stream 7) 0: No load request is issued. 1: When written: A request for loading the corresponding base address is issued. When read: The given base address is being loaded.
12	LBA12	Base Address Load Request (Rx8: Stream 6) 0: No load request is issued. 1: When written: A request for loading the corresponding base address is issued. When read: The given base address is being loaded.
11	LBA11	Base Address Load Request (Rx7: Stream 5) 0: No load request is issued. 1: When written: A request for loading the corresponding base address is issued. When read: The given base address is being loaded.
10	LBA10	Base Address Load Request (Rx6: Stream 4) 0: No load request is issued. 1: When written: A request for loading the corresponding base address is issued. When read: The given base address is being loaded.
9	LBA9	Base Address Load Request (Rx5: Stream 3) 0: No load request is issued. 1: When written: A request for loading the corresponding base address is issued. When read: The given base address is being loaded.
8	LBA8	Base Address Load Request (Rx4: Stream 2) 0: No load request is issued. 1: When written: A request for loading the corresponding base address is issued. When read: The given base address is being loaded.
7	LBA7	Base Address Load Request (Rx3: Stream 1) 0: No load request is issued. 1: When written: A request for loading the corresponding base address is issued. When read: The given base address is being loaded.
6	LBA6	Base Address Load Request (Rx2: Stream 0) 0: No load request is issued. 1: When written: A request for loading the corresponding base address is issued. When read: The given base address is being loaded.
5	LBA5	Base Address Load Request (Rx1: Network Control) 0: No load request is issued. 1: When written: A request for loading the corresponding base address is issued. When read: The given base address is being loaded.
4	LBA4	Base Address Load Request (Rx0: Best Effort) 0: No load request is issued. 1: When written: A request for loading the corresponding base address is issued. When read: The given base address is being loaded.

Table 25.13 ETNBnDLR Register Contents (3/3)

Bit Position	Bit Name	Function
3	LBA3	Base Address Load Request (Tx3: Stream Class A) 0: No load request is issued. 1: When written: A request for loading the corresponding base address is issued. When read: The given base address is being loaded.
2	LBA2	Base Address Load Request (Tx2: Stream Class B) 0: No load request is issued. 1: When written: A request for loading the corresponding base address is issued. When read: The given base address is being loaded.
1	LBA1	Base Address Load Request (Tx1: Network Control) 0: No load request is issued. 1: When written: A request for loading the corresponding base address is issued. When read: The given base address is being loaded.
0	LBA0	Base Address Load Request (Tx0: Best Effort) 0: No load request is issued. 1: When written: A request for loading the corresponding base address is issued. When read: The given base address is being loaded.

LBAq (q = 0 to 21): Base Address Load Request Bits

Each bit is used to issue requests to load base addresses and to indicate that a base address is currently being loaded.

Setting this bit to 1 issues a request for loading the descriptor base address for the queue q.

If transfer is currently in progress, loading is executed on completion of transfer for the current frame.

Completion of loading leads to automatic setting of the corresponding bit to 0.

For transmission queues, base address load requests are executed even while fetching is in progress (the transmit start request bit in the transmit configuration control register (ETNBnTCCR.TSRQt) is 1). Therefore, be sure to check that fetching is not in progress before issuing a request.

Writing to a bit of this register is only possible when the current operating mode is operation mode.

Only 1 can be written to this bit.

25.3.2.4 ETNBnCSR — AVB-DMAC Status Register

The ETNBnCSR register is used to indicate the operating mode in which the AVB-DMAC is running and communications states.

Access: This register is a read-only register that can be read in 32-bit units.

Address: <ETNBn_base> + $000C_H$

Value after reset: $0000\ 0001_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 25.14 ETNBnCSR Register Contents

Bit Position	Bit Name	Function
31 to 21	Reserved	When read, the value after reset is returned.
20	RPO	Receive Process Status 0: Normal operation 1: Reception is in progress.
19	TPO3	Transmit Process Status 3 (Stream Class A) 0: Normal operation 1: Transmission is in progress.
18	TPO2	Transmit Process Status 2 (Stream Class B) 0: Normal operation 1: Transmission is in progress.
17	TPO1	Transmit Process Status 1 (Network Control) 0: Normal operation 1: Transmission is in progress.
16	TPO0	Transmit Process Status 0 (Best Effort) 0: Normal operation 1: Transmission is in progress.
15 to 9	Reserved	When read, the value after reset is returned.
8	DTS	Data Transmission Suspended Status 0: Normal operation 1: Transmission is suspended.
7 to 4	Reserved	When read, the value after reset is returned.
3 to 0	OPS[3:0]	Operating Mode Status 0001_B: Reset mode 0010_B: Configuration mode 0100_B: Operation mode 1000_B: Standby mode Other settings are prohibited.

RPO: Receive Process Status Bit

This bit indicates whether a reception queue contains an unread received frame.

This bit being set to 1 indicates that a received frame is yet to be stored in the URAM.

- [Clearing conditions]
  - The current operating mode changes from operation mode.
  - Received frames in the reception FIFO all being stored in the URAM.
- [Setting condition]
  - A received frame being stored in the reception FIFO (but not yet in the URAM)

TPO3: Transmit Process Status 3 Bit

This bit indicates whether a class A stream is being transmitted.

When this bit is set to 1, it indicates that the AVB-DMAC is fetching data for transmission from the URAM or E-MAC is transmitting data.

- [Clearing conditions]
  - The current operating mode changes from operation mode.
  - Completion of transfer of all frames for transmission from the transmission FIFO (the transmit start request bit in the transmit configuration control register (ETNBnTCCR.TSRQ3) is set to 0)
- [Setting condition]
  - Transmission being started (by writing 1 to the transmit start request bit in the transmit configuration control register (ETNBnTCCR.TSRQ3))

TPO2: Transmit Process Status 2 Bit

This bit indicates whether a class B stream is being transmitted.

When this bit is set to 1, it indicates that the AVB-DMAC is fetching data for transmission from the URAM or E-MAC is transmitting data.

- [Clearing conditions]
  - The current operating mode changes from operation mode.
  - Completion of transfer of all frames for transmission from the transmission FIFO (the transmit start request bit in the transmit configuration control register (ETNBnTCCR.TSRQ2) is set to 0)
- [Setting condition]
  - Transmission being started (by writing 1 to the transmit start request bit in the transmit configuration control register (ETNBnTCCR.TSRQ2))

TPO1: Transmit Process Status 1 Bit

This bit indicates whether a network control is being transmitted.

When this bit is set to 1, the AVB-DMAC is fetching data in the URAM or E-MAC is transmitting data.

- [Clearing conditions]
  - The current operating mode changes from operation mode.
  - Completion of transfer of all frames for transmission from the transmission FIFO (the transmit start request bit in the transmit configuration control register (ETNBnTCCR.TSRQ1) is set to 0)
- [Setting condition]
  - Transmission being started (by writing 1 to the transmit start request bit in the transmit configuration control register (ETNBnTCCR.TSRQ1))

TPO0: Transmit Process Status 0 Bit

This bit indicates whether a best effort is being transmitted.

When this bit is set to 1, the AVB-DMAC is fetching data in the URAM or E-MAC is transmitting data.

- [Clearing conditions]
  - The current operating mode changes from operation mode.
  - Completion of transfer of all frames for transmission from the transmission FIFO (the transmit start request bit in the transmit configuration control register (ETNBnTCCR.TSRQ0) is set to 0)
- [Setting condition]
  - Transmission being started (by writing 1 to the transmit start request bit in the transmit configuration control register (ETNBnTCCR.TSRQ0))

DTS: Data Transmission Suspend Status Bit

This bit indicates whether access to the URAM is enabled.

- [Clearing condition]
  - The current operating mode is not operation mode.
  - The data transmission suspend request bit in the AVB-DMAC mode register (ETNBnCCC.DTSR) being 0.
- [Setting condition]
  - Access to the URAM not proceeding while the data transmission suspend request bit (ETNBnCCC.DTSR) in the AVB-DMAC mode register is 1 (if the URAM is being accessed, this bit is set to 1 on completion of access).

OPS[3:0]: Operating Mode Status Bits

These bits indicate the current operating mode.

For the operating modes, see **Section 25.4.1.1, Operating Modes**.

25.3.2.5 ETNBnCDARq — Current Descriptor Address Register q (q = 0 to 21)

The ETNBnCDARq register indicates the current descriptor address.

Access: This register is a read-only register that can be read in 32-bit units.

Address: <ETNBn_base> + 0010_H + q × 4_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 25.15 ETNBnCDARq Register Contents

Bit Position	Bit Name	Function
31 to 0	CDA[31:0]	Current Descriptor Address The address of the current descriptors for the transmission/receive queues q

CDA[31:0]: Current Descriptor Address Bits

ETNBnCDAR0 to ETNBnCDAR3 indicate the addresses of the current descriptors for the corresponding transmission queues while ETNBnCDAR4 to ETNBnCDAR21 indicate the addresses of the current descriptors for the corresponding reception queues.

If the operating mode is changed to operation mode, contents of this bits are changed to (ETNBnDBAT + q × 8).

Also, when the descriptor base address load request register (ETNBnDLR) issues a load request, the contents of the corresponding register are set in the descriptor base address table register (ETNBnDBAT).

Conditions for updating:

These bits are set to 0 when the operating mode is not operation mode.

This register is updated when a descriptor to a queue is processed.

25.3.2.6 ETNBnESR — Error Status Register

Access: This register is a read-only register that can be read in 32-bit units.

Address: <ETNBn_base> + 0088_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 25.16 ETNBnESR Register Contents

Bit Position	Bit Name	Function
31 to 13	Reserved	When read, the value after reset is returned.
12	EIL	Error Information Lost 0: No loss of error information 1: Lost of error information detected
11 to 8	ET[3:0]	Error Type 0000_B: Read descriptor from URAM 0001_B: Write descriptor to URAM 0010_B: Interpret read descriptor 0011_B: Tx-Buffer is corrupted 0100_B: Read data from URAM 0101_B: Write data or timestamp to URAM 0110_B: Reading from received FIFO 0111_B: Received FIFO is corrupted 1000_B: Frame size error during reception detected 1001_B: Frame size error during transmission detected 1010_B: Tx-Buffer overflow 1011_B: AVTP FIFO error
7 to 5	Reserved	When read, the value after reset is returned.
4 to 0	EQN[4:0]	Error Queue Number

EIL: Error Information Lost Bit

This bit indicates that error information detected by Ethernet AVB is lost because the previous reported error has not been processed by CPU.

[Changing condition]

- This bit is set to 0 when leaving OPERATION mode.
- This bit is set to 0 when CPU writes 0 to the queue error flag (ETNBnEIS.QEF) of the error interrupt status register.
- This bit is set to 1 when the set condition of the queue error flag (ETNBnEIS.QEF) is fulfilled while the queue error flag (ETNBnEIS.QEF) is 1.

ET[3:0]: Error Type Bits

These bits indicate details about the transfer stage which was handled when Ethernet AVB has detected an error.

When a fault relates to the read descriptor (ETNBnESR.ET = 0000_B or 0010_B), the CPU needs to correct the faulty descriptor so that the related queues can continue processing. If a queue halts at a faulty descriptor, ETNBnCDARq.CDA (q = ETNBnESR.EQN) directly checks the faulty descriptor.

When the fault is related to descriptor writing (ETNBnESR.ET = 0001_B), CPU needs recognize the not-updated or incorrectly updated descriptor in queue ETNBnESR.EQN. The write problem is not influencing how Ethernet AVB processes the descriptor chain.

When the fault is related to the Tx-Buffer (ETNBnESR.ET = 0011_B) CPU needs to clean-up the Tx-Buffer to correct the buffer control configuration.

All other errors are transient in nature and may be corrected by continuation of HW or SW operation; so there is no strong demand on CPU interaction. For details of the error processing, **Section 25.4.2.3, Checking Integrity**.

The CPU can only evaluate these bits when the queue error flag (ETNBnEIS.QEF) is 1.

[Changing condition]

– These bits are updated when the queue error flag (ETNBnEIS.QEF) setting conditions are satisfied and ETNBnEIS.QEF is set to 0.

EQN[4:0]: Error Queue Number Bits

These bits indicate the queue number which was handled when Ethernet AVB has detected an error.

A fault reported for ETNBnESR.EQN = 0 to 3 is related to transmit queue t = 0 to 3.
From ETNBnESR.EQN = 4 the fault is related to receive queue r = ETNBnESR.EQN - 4.

The CPU can only evaluate these bits when the queue error flag (ETNBnEIS.QEF) is 1.

The CPU can not evaluate these bits when the error type bit (ETNBnESR.ET) of the error status register is 0011_B, 0111_B, or 1011_B.

[Changing condition]

– These bits are updated when the set condition of the queue error flag (ETNBnEIS.QEF) is fulfilled and the queue error flag (ETNBnEIS.QEF) is 0.

25.3.2.7 ETNBnRIMR - RMII Interface Mode Register

The ETNBnRIMR register specifies the operating mode for the RMII interface.
This register is only valid in RMII mode.
The setting in this register must not be changed while transmission or reception is enabled.

Access: This register can be read or written in 32-bit units.
Address: <ETNBn_base> + $008C_H$
Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 25.17 ETNBnRIMR Register Contents

Bit Position	Bit Name	Function
31 to 1	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
0	SPEED	RMII Transfer Rate 0: 10 Mbps 1: 100 Mbps

25.3.2.8 ETNBnRCR — Receive Configuration Register

The ETNBnRCR register is used to configure receive-relating settings of the AVB-DMAC.

Access: This register can be read or written in 32-bit units.

Address: <ETNBn_base> + 0090_H

Value after reset: $1800\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	RFCL[12:0]

Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W

Table 25.18 ETNBnRCR Register Contents

Bit Position	Bit Name	Function
31 to 29	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
28 to 16	RFCL[12:0]	Receive FIFO Warning Level Recommended value: 1800_H
15 to 6	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
5	ETS2	Timestamp Enable (Stream) 0: Timestamp is disabled. 1: Timestamp is enabled. Recommended value: 0
4	ETS0	Timestamp Enable (Best Effort) 0: Timestamp is disabled. 1: Timestamp is enabled. Recommended value: 0
3, 2	ESF[1:0]	Stream Filtering Select Settings for reception queues 2 to 17 00_B: Filtering is disabled. Frames are processed in queue 0 (best effort). 01_B: The filter for separating AVB stream frames from non-AVB stream frames is enabled; non-matching stream frames are processed in queue 0 (best effort). 10_B: The separation filter is enabled for AVB stream frames. Non-matching stream frames are discarded. 11_B: The separation filter is enabled for AVB stream frames. Non-matching stream frames are handled with queue 0 (best effort). Recommended value: 10 or 11
1	ENCF	Network Control Filtering Enable Setting for reception queue 1 (network control) 0: Network control is disabled. 1: Network control is enabled.
0	EFFS	Error Frame Enable 0: Error frames are disabled. 1: Error frames are enabled. Recommended value: 0

RFCL[12:0]: Receive FIFO Warning Level Bits

These bits set the caution level for the reception FIFO and are used to maintain the priority order of the storage of received data and the fetching of data for transmission.

If the reception FIFO contains less data than this level, processing of both transmission and reception queues becomes pending.

If the reception FIFO contains more data than this level, only data in the reception queue are transferred, and processing of the transmission queue becomes pending.

Writing to this bit is only possible when the current operating mode is configuration mode.

CAUTION

In the case of this LSI chip, set these bits to 1800_H.

ETS2: Timestamp Enable (Stream) Bit

This bit enables timestamp information included in reception queues 2 to 17.

Writing to this bit is only possible when the current operating mode is configuration mode.

Set this bit to 1 when use the extended descriptor.

ETS0: Timestamp Enable (Best Effort) Bit

This bit enables timestamp information included in reception queue 0.

Writing to this bit is only possible when the current operating mode is configuration mode.

Set this bit to 1 when use the extended descriptor.

ESF[1:0]: Stream Filtering Select Bits

These bits select separation filtering to reception queues 2 to 17.

The queue-dependent separation filter can be used in combination with the identification of AVB stream frames.

When the value is 00_B, filtering is disabled and frames from streams are processed in reception queue 0 (best effort).

When the value is 01_B, the separation filter is enabled for both AVB stream frames and non-AVB stream frames; frames from non-matching streams are processed in reception queue 0 (best effort).

When the value is 10_B, the separation filter is enabled for AVB stream frames; frames from non-matching streams are discarded.

When the value is 11_B, the separation filter is enabled for AVB stream frames; frames from non-matching streams are processed in reception queue 0 (best effort).

For separation filtering, see **Section 25.4.4.1(1), Separation Filtering**.

Writing to this bit is only possible when the current operating mode is configuration mode.

ENCF: Enable Network Control Filtering Bit

Enables the AVB network control frame for reception queue 1.

When reception queue 1 is disabled, a received frame is stored in reception queue 0 (best effort).

Writing to this bit is only possible when the current operating mode is configuration mode.

EFFS: Enable Error Frame Bit

Enables or disables the reception of frames that have been classified as error frames by the E-MAC.

Received error frames are stored in reception queue 0 (best effort).

An indicator of error detection by the E-MAC during reception is stored in the descriptor (DESCR.MSC).

Writing to this bit is only possible when the current operating mode is configuration mode.

25.3.2.9 ETNBnRQCi — Receive Queue Configuration Register i (i = 0 to 4)

The ETNBnRQCi register configures the settings of receive queue (r = 0+i × 4 to 3+i × 4).*1

Access: ETNBnRQCi can be read or written in 32-bit units.
ETNBnRQCiL and ETNBnRQCiH can be read or written in 16-bit units.*2
ETNBnRQCiLL, ETNBnRQCiLH, ETNBnRQCiHL, ETNBnRQCiHH can be read or written in 8-bit units.*2

Address: ETNBnRQCi: <ETNBn_base> + 0094_H + i × 4_H
ETNBnRQCiL: <ETNBn_base> + 0094_H + i × 4_H
ETNBnRQCiH: <ETNBn_base> + 0094_H + i × 4_H + 2_H
ETNBnRQCiLL: <ETNBn_base> + 0094_H + i × 4_H
ETNBnRQCiLH: <ETNBn_base> + 0094_H + i × 4_H + 1_H
ETNBnRQCiHL: <ETNBn_base> + 0094_H + i × 4_H + 2_H
ETNBnRQCiHH: <ETNBn_base> + 0094_H + i × 4_H + 3_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	PIAr (r = 3 + i × 4)*3	UFCCr[1:0] (r = 3 + i × 4)*3		—	—	RSMr[1:0] (r = 3 + i × 4)*3		—	PIAr (r = 2 + i × 4)*3	UFCCr[1:0] (r = 2 + i × 4)*3		—	—	RSMr[1:0] (r = 2 + i × 4)*3

R/W	R	R/W	R/W	R/W	R	R	R/W	R/W	R	R/W	R/W	R/W	R	R	R/W	R/W

Note 1. The ETNBnRQC4 register corresponds to reception queues from 16 and 17.

Note 2. The ETNBnRQC4 register corresponds to ETNBnRQC4, ETNBnRQC4L, ETNBnRQC4LL, and ETNBnRQC4LH only.

Note 3. The ETNBnRQC4 register corresponds to RSM16[1:0], UFCC16[1:0], RSM17[1:0], and UFCC17[1:0] only and bits from 16 to 31 are reserved bits.

Table 25.19 ETNBnRQCi Register Contents (1/2)

Bit Position	Bit Name	Function
31	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
30	PIAr	Packed Incremental Data Area (Receive Queue 3 + i × 4) This bit defines how addresses inside the incremental data area of reception queue 3 + i × 4 are handled.
29, 28	UFCCr[1:0]	Unread Frame Counter Configuration (Receive Queue 3 + i × 4) These bits set the unread frame counter used in reception queue 3 + i × 4.
27, 26	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
25, 24	RSMr[1:0]	Receive Synchronous Mode (Receive Queue 3 + i × 4) 00_B: Mode with write-back Other than 00_B: Setting prohibited
23	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
22	PIAr	Packed Incremental Data Area (Receive Queue 2 + i × 4) This bit defines how addresses inside the incremental data area of reception queue 2 + i × 4 are handled.
21, 20	UFCCr[1:0]	Unread Frame Counter Configuration (Receive Queue 2 + i × 4) These bits set the unread frame counter used in reception queue 2 + i × 4.
19, 18	Reserved	When read, the value after reset is returned. When writing, write the value after reset.

Table 25.19 ETNBnRQCi Register Contents (2/2)

Bit Position	Bit Name	Function
17, 16	RSMr[1:0]	Receive Synchronous Mode (Receive Queue 2 + i × 4) 00_B: Mode with write-back Other than 00_B: Setting prohibited
15	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
14	PIAr	Packed Incremental Data Area (Receive Queue 1 + i × 4) This bit defines how addresses inside the incremental data area of reception queue 1 + i × 4 are handled.
13, 12	UFCCr[1:0]	Unread Frame Counter Configuration (Receive Queue 1 + i × 4) These bits set the unread frame counter used in reception queue 1 + i × 4.
11, 10	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
9, 8	RSMr[1:0]	Receive Synchronous Mode (Receive Queue 1 + i × 4) 00_B: Mode with write-back Other than 00_B: Setting prohibited
7	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
6	PIAr	Packed Incremental Data Area (Receive Queue 0 + i × 4) This bit defines how addresses inside the incremental data area of reception queue 0 + i × 4 are handled.
5, 4	UFCCr[1:0]	Unread Frame Counter Configuration (Receive Queue 0 + i × 4) These bits set the unread frame counter used in reception queue 0 + i × 4.
3, 2	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
1, 0	RSMr[1:0]	Receive Synchronous Mode (Receive Queue 0 + i × 4) 00_B: Mode with write-back Other than 00_B: Setting prohibited

PIAr (r = 0 to 17): Packed Incremental Data Area Bit

This bit defines how addresses inside the incremental data area of queue r are handled.
When this bit is 0, frame data in incremental data area starts always at a 32 bit address. Depending on received frame length there are up to 3 undefined bytes between two frames in URAM.
When this bit is 1, there will no gaps generated between two frames in incremental data area.
Writing to the bit is only possible when the current operating mode is configuration mode.

UFCCr[1:0] (r = 0 to 17): Unread Frame Counter Configuration Bits

These bits set the unread frame counter for reception queue r.
With the AVB-DMAC, four patterns of settings are available for the unread frame counter. Use the unread frame counter stop level configuration register (ETNBnUFCS) to set the warning level and stop level of the unread frame counter.
Set the pattern number (0 to 3) set in the unread frame counter stop level configuration register (ETNBnUFCS) in these bits.
When the value is 00_B, the stop function is disabled.
Writing to the bits is only possible when the current operating mode is configuration mode.

RSMr[1:0] (r = 0 to 17): Receive Synchronous Mode Bits

These bits set receive synchronous mode.
Set 00_B in these bits.
For receive synchronous mode, see **Section 25.4.4.3(3), Mode with Write-Back**.
Writing to the bits is only possible when the current operating mode is configuration mode.

25.3.2.10 ETNBnRPC — Receive Padding Configuration Register

The ETNBnRPC register is used to set padding for received frames.

Access: This register can be read or written in 32-bit units.

Address: <ETNBn_base> + $00B0_H$

Value after reset: $0000\ 0100_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	DCNT[7:0]							
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	PCNT[2:0]			—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	1	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R/W	R/W	R/W	R	R	R	R	R	R	R	R

Table 25.20 ETNBnRPC Register Contents

Bit Position	Bit Name	Function
31 to 24	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
23 to 16	DCNT[7:0]	Stored Data Counter These bits specify the amount of data to be stored with the descriptor. The setting is in words. I.e. 1 in the counter indicates 1 word (4 bytes).
15 to 11	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
10 to 8	PCNT[2:0]	Stored Padding Counter These bits indicate the amount of padding to be stored in data areas for descriptors. The setting is in words. I.e. 1 in the counter indicates 1 word (4 bytes).
7 to 0	Reserved	When read, the value after reset is returned. When writing, write the value after reset.

CAUTION

Padding can be used to extend frame lengths, but frame lengths should not exceed 4 Kbytes.

DCNT[7:0]: Stored Data Counter Bits

These bits specify the amount of the frame data (1 to 255) to be stored following the padding. Counting by one indicates one word (4 bytes). For example, when these bits are set to 47, the amount of data is 47 words (= 188 bytes).

When these bits are 0, all received data is stored following the initial padding.

Writing to the bits is only possible when the current operating mode is configuration mode.

For details on padding, see **Section 25.4.4.3(2)(c), Padding**.

PCNT[2:0]: Stored Padding Counter Bits

These bits specify the amount of padding (1 to 7) to be appended to the URAM. Counting by one indicates one word (4 bytes). For example, when these bits are set to 1, the amount of padding is one word (= 4 bytes).

Writing to the bits is only possible when the current operating mode is configuration mode.

For details on padding, see **Section 25.4.4.3(2)(c), Padding**.

25.3.2.11 ETNBnUFCW — Unread Frame Counter Warning Level Register

Access: This register can be read or written in 32-bit units.

Address: <ETNBn_base> + $00BC_H$

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	WL3[5:0]						—	—	WL2[5:0]					
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R	R	R/W	R/W	R/W	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	WL1[5:0]						—	—	WL0[5:0]					
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R	R	R/W	R/W	R/W	R/W	R/W	R/W

Table 25.21 ETNBnUFCW Register Contents

Bit Position	Bit Name	Function
31, 30	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
29 to 24	WL3[5:0]	Warning Level 3 Number of unread frames to reach warning level.
23, 22	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
21 to 16	WL2[5:0]	Warning Level 2 Number of unread frames to reach warning level.
15, 14	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
13 to 8	WL1[5:0]	Warning Level 1 Number of unread frames to reach warning level.
7, 6	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
5 to 0	WL0[5:0]	Warning Level 0 Number of unread frames to reach warning level.

WLj[5:0]: Warning Level j (j = 0 to 3)

These bits define a warning level which can be used by the unread frame counters of receive queues. Each receive queue can select one of the 4 common warning level configurations.

When these bits are 0, in configuration j the warning level function is disabled.

The CPU can only write to these bits if ETNBnCSR.OPS is CONFIG.

The CPU should not write 63 to these bits.

25.3.2.12 ETNBnUFCS — Unread Frame Counter Stop Level Configuration Register

The ETNBnUFCS register sets the stop levels for unread frames.

Access: This register can be read or written in 32-bit units.

Address: <ETNBn_base> + $00C0_H$

Value after reset: $0000\ 0000_H$

Table 25.22 ETNBnUFCS Register Contents

Bit Position	Bit Name	Function
31, 30	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
29 to 24	SL3[5:0]	Stop Level 3 Unread frame count stop level 3
23, 22	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
21 to 16	SL2[5:0]	Stop Level 2 Unread frame count stop level 2
15, 14	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
13 to 8	SL1[5:0]	Stop Level 1 Unread frame count stop level 1
7, 6	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
5 to 0	SL0[5:0]	Stop Level 0 Unread frame count stop level 0 The write value should be 0.

SL0 to SL3[5:0]: Stop Level 0 to 3 Bits

These bits set the stop levels for unread frames.

One of the four stop levels from 0 to 3 can be set for each reception queue. When these bits are set to 0, the stop function is disabled. The level to be used is specified by the receive queue configuration register i (ETNBnRQCi) (i = 0 to 4).

Writing to the bits is only possible when the current operating mode is configuration mode.

25.3.2.13 ETNBnUFCVi — Unread Frame Counter Register i (i = 0 to 4)

The ETNBnUFCVi register indicates the number of unread frames in reception queues r (r=0 + i × 4 to 3 + i × 4).*1

Access: This register is a read-only register that can be read in 32-bit units.

Address: <ETNBn_base> + $00C4_H$ + i × 4_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

	—	—	CVr[5:0](r = 1 + i × 4)*2						—	—	CVr[5:0](r = 0 + i × 4)*2					
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Note 1. The ETNBnUFCV4 register corresponds to reception queues from 16 to 17.

Note 2. The ETNBnUFCV4 register corresponds to CV16[5:0] and CV17[5:0] only and bits from 16 to 31 are reserved bits.

Table 25.23 ETNBnUFCVi Register Contents

Bit Position	Bit Name	Function
31, 30	Reserved	When read, the value after reset is returned.
29 to 24	CVr[5:0]	Unread Frame Count 3 + 4 × i Number of unread frames in reception queue 3 + 4 × i
23, 22	Reserved	When read, the value after reset is returned.
21 to 16	CVr[5:0]	Unread Frame Count 2 + 4 × i Number of unread frames in reception queue 2 + 4 × i
15, 14	Reserved	When read, the value after reset is returned.
13 to 8	CVr[5:0]	Unread Frame Count 1 + 4 × i Number of unread frames in reception queue 1 + 4 × i
7, 6	Reserved	When read, the value after reset is returned.
5 to 0	CVr[5:0]	Unread Frame Count 0 + 4 × i Number of unread frames in reception queue 0 + 4 × i

CVr[5:0] (r = 0 to 17): Unread Frame Count r Bits

These bits indicate the number of unread frames in reception queue r.

The number of unread frames is decremented by the value that is written to the unread frame counter decrement register i (ETNBnUFCDi).

For a description of how to use unread frames, refer to **Section 25.4.4.4, Unread Frame Counters**.

Conditions for updating:

The bits are set to 0 when the operating mode is not operation mode and when the descriptor base address load request register (ETNBnDLR) issues a base address load request.

The number is incremented when data received in reception queue r are stored normally. The maximum increment is $3F_H$. If the value exceeds $3F_H$, incrementation will not proceed.)

The number is decremented by the value written to the unread frame counter decrement register i (ETNBnUFCDi).

25.3.2.14 ETNBnUFCDi — Unread Frame Counter Decrement Register i (i = 0 to 4)

The ETNBnUFCDi register is used to decrement unread counters of reception queues r (r = 0 + i × 4 to 3 + i × 4).*1

Access: ETNBnUFCDi can be read or written in 32-bit units.
ETNBnUFCDiL and ETNBnUFCDiH can be read or written in 16-bit units.*2
ETNBnUFCDiLL, ETNBnUFCDiLH, ETNBnUFCDiHL, ETNBnUFCDiHH can be read or written in 8-bit units.*2

Address: ETNBnUFCDi: <ETNBn_base> + $00E0_H$ + i × 4_H
ETNBnUFCDiL: <ETNBn_base> + $00E0_H$ + i × 4_H
ETNBnUFCDiH: <ETNBn_base> + $00E0_H$ + i × 4_H + 2_H
ETNBnUFCDiLL: <ETNBn_base> + $00E0_H$ + i × 4_H
ETNBnUFCDiLH: <ETNBn_base> + $00E0_H$ + i × 4_H + 1_H
ETNBnUFCDiHL: <ETNBn_base> + $00E0_H$ + i × 4_H + 2_H
ETNBnUFCDiHH: <ETNBn_base> + $00E0_H$ + i × 4_H + 3_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R	R	R/W	R/W	R/W	R/W	R/W	R/W

Note 1. The ETNBnUFCD4 register corresponds to reception queues from 16 to 17.

Note 2. The ETNBnUFCD4 register corresponds to ETNBnUFCD4, ETNBnUFCD4L, ETNBnUFCD4LL, and ETNBnUFCD4LH only.

Note 3. The ETNBnUFCD4 register corresponds to DV16[5:0] and DV17[5:0] only and bits from 16 to 31 are reserved bits.

Table 25.24 ETNBnUFCDi Register Contents

Bit Position	Bit Name	Function
31, 30	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
29 to 24	DVr[5:0]	Unread Frame Decrement Value 3 + 4 × i Unread frame decrement value for reception queue 3 + 4 × i
23, 22	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
21 to 16	DVr[5:0]	Unread Frame Decrement Value 2 + 4 × i Unread frame decrement value for reception queue 2 + 4 × i
15, 14	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
13 to 8	DVr[5:0]	Unread Frame Decrement Value 1 + 4 × i Unread frame decrement value for reception queue 1 + 4 × i
7, 6	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
5 to 0	DVr[5:0]	Unread Frame Decrement Value 0 + 4 × i Unread frame decrement value for reception queue 0 + 4 × i

DVr[5:0] (r = 0 to 17): Unread Frame Decrement Value r Bits

These bits set the decrement value for unread frames in reception queue r. The value of an unread frame counter register i (ETNBnUFCVi) (i = 0 to 4) is decremented by the value set in the corresponding bits of this register.

Write $3F_H$ to these bits to reset the unread counters in reception queue r.

These bits are always read as 0.

25.3.2.15 ETNBnSFO — Separation Filter Offset Register

The ETNBnSFO register sets an offset into frames for use by the separation filter.

Access: This register can be read or written in 32-bit units.

Address: <ETNBn_base> + $00FC_H$

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	FBP[5:0]					
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W

Table 25.25 ETNBnSFO Register Contents

Bit Position	Bit Name	Function
31 to 6	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
5 to 0	FBP[5:0]	First Byte Position Position of the first byte of Ethernet frames in the separation filter

FBP[5:0]: First Byte Position Bits

These bits set the position of the first byte of Ethernet frames in the separation filter.

When these bits are 0, the separation filter starts from the top of each Ethernet frame (first byte of the destination address). For bytes in Ethernet frames, see **Figure 25.3, Data of Ethernet Frame Received**, in **Section 25.3.2, Ethernet AVB Registers**.

Writing to the bits is only possible when the current operating mode is configuration mode.

For separation filtering, see **Section 25.4.4.1(1), Separation Filtering**.

[Condition for Changing]

These bits are updated to the value of ETNBnSFVi.LV[5:0] when ETNBnSFL.LC changes from 30 (Load ETNBnSFO.FBP) to 31 while the current operating mode is operation mode.

CAUTION

Received frames having fewer bytes than the setting of these bits + 8 bytes do not match the separation filter. In this case, the data will either be sorted into a reception queue or discarded in accord with the setting of the separation filtering select bits in the receive configuration register (ETNBnRCR.ESF).

25.3.2.16 ETNBnSFPi — Separation Filter Pattern Register i (i = 0 to 31)

The ETNBnSFPi register configures the pattern of the separation filter used for reception queues 2 to 17.

Access: This register can be read or written in 32-bit units.

Address: <ETNBn_base> + 0100_H + i × 4_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	FPs[31:16] *2(s = reception queue r - 2)															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	FPs[15:0]*1 (s = reception queue r - 2)															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Note 1. In this case, i is an even number. When i is an odd number, FPs[47:32]

Note 2. In this case, i is an even number. When i is an odd number, FPs[63:48]

Table 25.26 ETNBnSFPi Register Contents

Bit Position	Bit Name	Function
31 to 0	FPs[63:0]	Separation Filter Pattern These bits set the pattern of the separation filter. The 64-bit filter pattern is set for each queue.

FPs[63:0] (s = 0 to 15): Separation Filter Pattern Bits

These bits set the pattern for a separation filter to be used with reception queues 2 to 17 (for streams 0 to 15).

Each queue has space of 64-bit. Reception queue 2 (Stream 0) uses ETNBnSFP0 and ETNBnSFP1. Reception queue 17 (Stream 15) uses ETNBnSFP30 and ETNBnSFP31.

The separation filter passes a frame when, after masking by the mask value set in the separation filter mask register (ETNBnSFMi), data from received frames match the value defined in these bits.

ETNBnSFPi.FPs[7:0] (where i is an even number) are used for the byte of Ethernet frame data specified by the separation filter offset register, while ETNBnSFPi.FPs[63:56] (where i is the odd number) are used for the byte at the address specified by the separation filter offset register (ETNBnSFO) + 7.

Writing to the bits is only possible when the current operating mode is configuration mode.

For separation filtering, see **Section 25.4.4.1(1), Separation Filtering**.

[Condition for Changing]

These bits are updated to the value of ETNBnSFVi.LV[63:0] when ETNBnSFL.LC changes from s (Load ETNBnSFPi.FPs) to 31 while the current operating mode is operation mode.

25.3.2.17 ETNBnSFVi — Separation Filter Value register i (i = 0 or 1)

The ETNBnSFVi register sets the 64-bit value to be loaded for separation filter registers.

Access: This register can be read or written in 32-bit units.

Address: <ETNBn_base> + $01B8_H$ + i × 4_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	LV[31:16]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 25.27 ETNBnSFVi Register Contents

Bit Position	Bit Name	Function
31 to 0	LV[31:0]	Load Value Value used to update separation filtering during operation mode

LV[31:0]: Load Value Bits

These bits set the 64-bit value to be loaded into separation filter registers (ETNBnSFO.FBP, ETNBnSFMi.CFM, ETNBnSFPi.FPs). The value is loaded when writing to ETNBnSFL.LC. When loading the First Byte Position (ETNBnSFO.FBP), ETNBnSFVi.LV[63:6] are ignored. Writing to the bit is only possible when the current operating mode is operation mode, and the current value of ETNBnSFL.LC is 31.

These bits are set to 0 when leaving operation mode.

25.3.2.18 ETNBnSFMi — Separation Filter Mask Register i (i = 0 or 1)

The ETNBnSFMi register sets the mask value of the separation filter used for reception queue 2 to 17.

Access: This register can be read or written in 32-bit units.

Address: <ETNBn_base> + $01C0_H$ + i × 4_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	CFM[31 + 32 × i: 16 + 32 × i]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	CFM[15 + 32 × i: 0 + 32 × i]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 25.28 ETNBnSFMi Register Contents

Bit Position	Bit Name	Function
31 to 0	CFM[63:0]	Separation Filter Mask These bits set the mask value for the separation filter.

CFM[63:0]: Separation Filter Mask Bits

These bits set the mask value for the separation filter for use with the corresponding reception queue 2 to 17 (stream 0 to 15).

ETNBnSFM0.CFM[7:0] are used for bytes of Ethernet frame data specified by the separation filter offset register, while ETNBnSFM1.CFM[63:56] are used for the separation filter offset register (ETNBnSFO) + 7.

Frame data at the positions of mask bits that are set to 0 are masked; that is, they do not affect pattern-matching by the separation filter.

Writing to the bits is only possible when the current operating mode is configuration mode.

For separation filtering, see **Section 25.4.4.1(1), Separation Filtering**.

[Condition for Changing]

These bits are updated to the value of ETNBnSFVi.LV[63:0] when ETNBnSFL.LC from 29 (Load ETNBnSFMi.CFM) to 31 while the current operating mode is operation mode.

25.3.2.19 ETNBnSFL — Separation Filter Load Register

The ETNBnSFL register controls update of separation filter configuration while the operating mode is operation mode.

Access: This register can be read or written in 32-bit units.

Address: <ETNBn_base> + $01C8_H$

Value after reset: $0000\ 001F_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	LC[4:0]				
Value after reset	0	0	0	0	0	0	0	0	0	0	0	1	1	1	1	1
R/W	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W

Table 25.29 ETNBnSFL Register Contents

Bit Position	Bit Name	Function
31 to 5	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
4 to 0	LC[4:0]	Load Command 0 to 15: Load of ETNBnSFPi.FPs with s = ETNBnSFL.LC 16 to 28: Invalid 29: Load of ETNBnSFMi.CFM 30: Load of ETNBnSFO.FBP 31: No pending load request

LC[4:0]: Load Command Bits

These bits control update of separation filter configuration while the operating mode is operation mode.
By writing 30 to these bits CPU triggers an update of First Byte Position (ETNBnSFO.FBP) value.
By writing 29 to these bits CPU triggers an update of Common Filter Mask (ETNBnSFMi.CFM) value.
By writing number between 0 to 15 to these bits CPU triggers an update of Filter Pattern s (ETNBnSFPi.FPs) value. The number written to ETNBnSFL.LC defines the index s of the updated Filter Pattern.

Writing to the bit is only possible when the current operating mode is operation mode, and the current value of ETNBnSFL.LC is 31.
These bits are set to 31 when the requested update has been processed, or when leaving operation mode.

25.3.2.20 ETNBnPCRC — Payload CRC Register

The ETNBnPCRC register is used to set the number of the first data byte in received frame to check a potential payload CRC.

Access: This register can be read or written in 32-bit units.

Address: <ETNBn_base> + $01CC_H$

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 25.30 ETNBnPCRC Register Contents

Bit Position	Bit Name	Function
31 to 10	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
9 to 0	CAS[9:0]	Crc Area Start Number of 1st byte included in payload CRC calculation

CAS[9:0]: CRC Area Start Bits

These bits are used to set the number of the first data byte in received frame to check a potential payload CRC. For details, see **Section 25.4.4.5, Payload CRC support**.
Writing to the bit is only possible when the current operating mode is operation mode.
The value of CAS must be in the range 0 to 255.
These bits are set to 0 when leaving operation mode.

25.3.2.21 ETNBnTGC — Transmit Configuration Register

The ETNBnTGC register configures the transmission-relating settings of the AVB-DMAC.

Access: This register can be read or written in 32-bit units.

Address: <ETNBn_base> + 0300_H

Value after reset: $0022\ 2200_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 25.31 ETNBnTGC Register Contents (1/2)

Bit Position	Bit Name	Function
31 to 22	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
21, 20	TBD3[1:0]	Transmit FIFO Size (Stream Class A) Number of frames to be fetched from transmission queue 3 (for stream class A) **CAUTION** Write 10_B to these bits.
19, 18	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
17, 16	TBD2[1:0]	Transmit FIFO Size (Stream Class B) Number of frames to be fetched from transmission queue 2 (for stream class B) **CAUTION** Write 10_B to these bits.
15, 14	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
13, 12	TBD1[1:0]	Transmit FIFO Size (Network Control) Number of frames to be fetched from transmission queue 1 (for network control) **CAUTION** Write 10_B to these bits.
11, 10	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
9, 8	TBD0[1:0]	Transmit FIFO Size (Best Effort) Number of frames to be fetched from transmission queue 0 (for best effort) **CAUTION** Write 10_B to these bits.

Table 25.31 ETNBnTGC Register Contents (2/2)

Bit Position	Bit Name	Function
7, 6	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
5, 4	TQP[1:0]	Transmit Queue Priority 00: Non-AVB mode 01: AVB mode 1 10: Setting prohibited 11: AVB mode 2
3	TSM3	Transmit Synchronous Mode (Stream Class A) 0: With write-back 1: Setting prohibited
2	TSM2	Transmit Synchronous Mode (Stream Class B) 0: With write-back 1: Setting prohibited
1	TSM1	Transmit Synchronous Mode (Network Control) 0: With write-back 1: Setting prohibited
0	TSM0	Transmit Synchronous Mode (Best Effort) 0: With write-back 1: Setting prohibited

TBDt[1:0] (t = 0 to 3):
Transmit FIFO Size (Stream Class A/ Stream Class B/Network Control/Best Effort) Bits

These bits set the sizes of the transmission FIFO buffers for use with each of the transmission queues.

Writing to these bits is only possible when the current operating mode is configuration mode.

Set these bits to 2 ("10_B").

TQP[1:0]: Transmit Queue Priority Bits

These bits set the priority of the transmission queues.

00_B: Non-AVB mode: Q3→Q2→Q1→Q0

01_B: AVB mode 1: Q3 (CBS)→Q2 (CBS)→Q1→Q0

10_B: Setting prohibited

11_B: AVB mode 2: Q1→Q3 (CBS)→Q2 (CBS)→Q0

For the credit-based shaping (CBS) algorithm, see **Section 25.4.6, CBS (Credit-Based Shaping)**.

The CBS algorithm is invalidated in non-AVB mode (i.e. when the value is "00_B").

Writing to the bits is only possible when the current operating mode is configuration mode.

TSM0 to TSM3: Transmit Synchronous Mode Bits

These bits set Transmit synchronous mode.

Writing to these bits is only possible when the current operating mode is configuration mode.

Set these bits to 0.

25.3.2.22 ETNBnTCCR — Transmit Configuration Control Register

The ETNBnTCCR register controls transmission by the AVB-DMAC and is used to make related settings.

Access: ETNBnTCCR can be read or written in 32-bit units.
ETNBnTCCRL can be read or written in 16-bit units.
ETNBnTCCRLL, ETNBnTCCRLH can be read or written in 8-bit units.

Address: ETNBnTCCR: <ETNBn_base> + 0304_H
ETNBnTCCRL: <ETNBn_base> + 0304_H
ETNBnTCCRLL: <ETNBn_base> + 0304_H
ETNBnTCCRLH: <ETNBn_base> + 0304_H + 1_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	MFR	MFEN

Table 25.32 ETNBnTCCR Register Contents

Bit Position	Bit Name	Function
31 to 18	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
17	MFR	MAC status FIFO Release 0: No request to MAC status FIFO 1: Release oldest entry of MAC status FIFO
16	MFEN	MAC status FIFO Enable 0: Disabled 1: Enabled
15 to 10	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
9	TFR	Timestamp FIFO Release 0: (Not operating) 1: Releases the oldest entry in the timestamp FIFO.
8	TFEN	Timestamp FIFO Enable 0: Recording of transmission timestamps in the timestamp FIFO is disabled. 1: Recording of transmission timestamps in the timestamp FIFO is enabled.
7 to 4	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
3	TSRQ3	Transmit Start Request (Queue 3 (Stream Class A)) 0: Transmission queue is empty or stopped. 1: When written: A transmission start request is issued. When read: Wait for transmission process to fetch is performed.
2	TSRQ2	Transmit Start Request (Queue 2 (Stream Class B)) 0: Transmission queue is empty or stopped. 1: When written: A transmission start request is issued. When read: Wait for transmission process to fetch is performed.
1	TSRQ1	Transmit Start Request (Queue 1 (Network Control)) 0: Transmission queue is empty or stopped. 1: When written: A transmission start request is issued. When read: Wait for transmission process to fetch is performed.

Table 25.32 ETNBnTCCR Register Contents

Bit Position	Bit Name	Function
0	TSRQ0	Transmit Start Request (Queue 0 (Best Effort)) 0: Transmission queue is empty or stopped. 1: When written: A transmission start request is issued. When read: Wait for transmission process to fetch is performed.

TFR: Timestamp FIFO Release Bit

This bit makes the timestamp FIFO release the oldest entry.

For a description of how to use the timestamp FIFO, see **Section 25.4.5.4, Timestamping in Transmission**.

TFEN: Timestamp FIFO Enable Bit

This bit enables storage in the timestamp FIFO.

When it is set, timestamp information is stored for descriptors with DESCR.TSR set to 1 (for DESCR.TSR, see **Section 25.4.5.2(2), Configuration of Transmission Frame Data Descriptors**).

When 0 is set in this bit, all timestamp FIFO entries are invalidated.

For a description of how to use the timestamp FIFO, see **Section 25.4.5.4, Timestamping in Transmission**.

TSRQt (t = 0 to 3): Transmit Start Request (Queue t) Bit

This bit issues a request to start transmission for transmission queue t.

When read, this bit being set to 1 indicates that transmission queue t has a frame that has not yet been fetched to the transmission FIFO.

Frame transmission by the E-MAC is processed independently from fetching to the transmission FIFO. The timing of transmission from a queue depends on the priority order of transmission.

For the scheduling of transmission queues, see **Section 25.4.5.1, Transmission Modes**.

Writing to this bit is only possible when the current operating mode is Operation mode.

Only 1 can be written to the bit. Writing 0 to the bit has no effect.

Conditions for updating:

The bit is set to 0 when the operating mode is not operation mode, when a descriptor of type EEMPTY, FEMPTY or LEMPTY (no usable data) is processed, when an EOS descriptor is processed, or when a descriptor with defective data is processed.

25.3.2.23 ETNBnTSR — Transmit Status Register

The ETNBnTSR register indicates the state of transmission by the AVB-DMAC.

Access: This register is a read-only register that can be read in 32-bit units.

Address: <ETNBn_base> + 0308_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	MFFL[4:0]				
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	TFFL[2:0]			—	—	—	—	CCS1[1:0]		CCS0[1:0]	
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 25.33 ETNBnTSR Register Contents

Bit Position	Bit Name	Function
31 to 21	Reserved	When read, the value after reset is returned.
20 to 16	MFFL[4:0]	MAC status FIFO Fill Level Number of entries stored in the MAC status FIFO.
15 to 11	Reserved	When read, the value after reset is returned.
10 to 8	TFFL[2:0]	Timestamp FIFO Count Number of timestamp FIFOs
7 to 4	Reserved	When read, the value after reset is returned.
3, 2	CCS1[1:0]	CBS Counter Status 1 (Class A) 00_B: The current credit value is within the range. 01_B: The current credit value is less than or equal to the lower limit. 10_B: The current credit value is greater than or equal to the upper limit. 11_B: (Reserved)
1, 0	CCS0[1:0]	CBS Counter Status 0 (Class B) 00_B: The current credit value is within the range. 01_B: The current credit value is less than or equal to the lower limit. 10_B: The current credit value is greater than or equal to the upper limit. 11_B: (Reserved)

MFFL[4:0]: MAC status FIFO Fill Level

These bits indicate the number of entries available in the MAC status FIFO.

If this value is 0, the FIFO is empty. If this value is 16, the FIFO is full. The values 17 to 31 are reserved.

Conditions for updating:

- These bits are set to 0 when leaving OPERATION mode.
- These bits are set to 0 when ETNBnTCCR.MFEN is 0.
- This value is incremented when frame with DESCR.MSR has been transmitted by MAC, ETNBnTCCR.MFEN is 1 and ETNBnTSR.MFFL is not 16.
- This value is incremented when MAC detects an error during transmission, ETNBnTCCR.MFEN

is 1 and ETNBnTSR.MFFL is not 16.

- This value is decremented when 1 is written to ETNBnTCCR.MFR and ETNBnTSR.MFFL is not 0.

TFFL[2:0]: Timestamp FIFO Count Bits

These bits indicate the number of timestamps in the timestamp FIFO.

The value 0 indicates it is empty and the value 3 indicates it is full (values 4 to 7 are reserved).

Conditions for updating:

- The bits are set to 0 when the operating mode is not operation mode or when the timestamp FIFO enable bit in the transmit configuration control register (ETNBnTCCR.TFEN) = 0.
- When the timestamp FIFO enable bit (ETNBnTCCR.TFEN) is 1 and these bits are not 3, the value of these bits is incremented after a frame with DESCR.TSR set has been transmitted by the E-MAC (for DESCR.TSR, see **Section 25.4.5.2(2), Configuration of Transmission Frame Data Descriptors**).

  The value of these bits is decremented if it is not 0 when 1 is written to the timestamp FIFO release bit in the transmit configuration control register (ETNBnTCCR.TFR).

CCS0 and CCS1[1:0]: CBS Counter Status 0 and 1 Bits

These bits indicate the CBS (credit-based shaping) state of stream data transmission queues 0 and 1. If the calculated credit value is outside the range specified by CBS upper limit register c (ETNBnCULc) and CBS lower limit register c (ETNBnCLLc), it falls outside the range for CBS.

Conditions for updating:

- The bits are set to 00_B when the operating mode is not operation mode.
- When the determined credit value is within the range, 00_B is set.
- If the determined credit value is lower than the CBS lower limit register c (ETNBnCLLc), 01_B is set.
- If the determined credit value is higher than the upper limit register c (ETNBnCULc), 10_B is set.

25.3.2.24 ETNBnTFA0 — Timestamp FIFO Access Register 0

ETNBnTFA0 indicates the nano seconds portion of the timestamp value.

Access: This register is a read-only register that can be read in 32-bit units.

Address: <ETNBn_base> + 0310_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	TSV[31:16]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TSV[15:0]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 25.34 ETNBnTFA0 Register Contents

Bit Position	Bit Name	Function
31 to 0	TSV[31:0]	Timestamp Value

TSV[79:0]: Timestamp Value Bits

These 80 bits consist of ETNBnTFA0.TSV[31:0], ETNBnTFA1.TSV[63:32], and ETNBnTFA2.TSV[79:64], which together indicate the oldest timestamp value stored in the timestamp FIFO.

Once the timestamp FIFO is full, no further timestamp values are stored.

Conditions for updating:

- The bits are set to $0000\ 0000_H$ when the operating mode is not operation mode.
- The register is updated whenever a value is stored in the timestamp FIFO (when the timestamp FIFO count bit in the transmit status register (ETNBnTSR.TFFL) changes from 0 to 1).
- The register is updated when the oldest entry is released (when the timestamp FIFO release bit in the transmit configuration control register (ETNBnTCCR.TFR) is set to 1).

25.3.2.25 ETNBnTFA1 — Timestamp FIFO Access Register 1

The ETNBnTFA1 register indicates the lower seconds portion of the timestamp value.

Access: This register is a read-only register that can be read in 32-bit units.

Address: <ETNBn_base> + 0314_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	TSV[63:48]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TSV[47:32]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 25.35 ETNBnTFA1 Register Contents

Bit Position	Bit Name	Function
31 to 0	TSV[63:32]	Timestamp Value

TSV[63:32]: Timestamp Value Bits

For details, see **Section 25.3.2.24, ETNBnTFA0 — Timestamp FIFO Access Register 0**.

25.3.2.26 ETNBnTFA2 — Timestamp FIFO Access Register 2

The ETNBnTFA2 register indicates the timestamp tag and the higher seconds portion of the timestamp value.

Access: This register is a read-only register that can be read in 32-bit units.

Address: <ETNBn_base> + 0318_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	TST[9:0]									
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TSV[79:64]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 25.36 ETNBnTFA2 Register Contents

Bit Position	Bit Name	Function
31 to 26	Reserved	When read, the value after reset is returned.
25 to 16	TST[9:0]	Timestamp Tag
15 to 0	TSV[79:64]	Timestamp Value

TST[9:0]: Timestamp Tag Bits

These bits indicate the contents of the DESCR.TAG bit within the descriptor for frame transmission. These values are used to check the correlation between frames within the transmission queue and the timestamp values (timestamp FIFO access register 0 to 2 (ETNBnTFA0 to 2)) which can be placed in the FIFO.

For transmit frame tagging, **Section 25.4.5.4, Timestamping in Transmission**.

Conditions for updating:

- The bits are set to 000_H when the operating mode is not operation mode.
- The bits are updated when a value is stored in the timestamp FIFO (when the value of the timestamp FIFO count bit in the transmit status register (ETNBnTSR.TFFL) changes from 0 to 1).
- The bits are updated when the oldest entry has been released (1 is set in the timestamp FIFO release bit in the transmit configuration control register (ETNBnTCCR.TFR)).

TSV[79:64]: Timestamp Value Bits

For details, see **Section 25.3.2.24, ETNBnTFA0 — Timestamp FIFO Access Register 0**.

25.3.2.27 ETNBnVRR — AVB-DMAC Version Register

The ETNBnVRR register indicates the version of the AVB-DMAC.

Access: This register is a read-only register that can be read in 32-bit units.

Address: <ETNBn_base> + $031C_H$

Value after reset: $0000\ E300_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 25.37 ETNBnVRR Register Contents

Bit Position	Bit Name	Function
31 to 0	VC[31:0]	Version Code Version code of AVB-DMAC

VC[31:0]: Version Code Bits

These bits indicates the version of the AVB-DMAC.

$0000\ 0000_H$: RAVBES1/2

$0000\ E300_H$: RAVBES3

25.3.2.28 ETNBnCIVRc — CBS Increment Value Register c (c = 0 or 1)

The ETNBnCIVR0 register sets the increment in the CBS algorithm for transmission queue 2 (for stream class B) and the ETNBnCIVR1 register sets the increment in the CBS algorithm for transmission queue 3 (for stream class A).

Access: This register can be read or written in 32-bit units.

Address: <ETNBn_base> + 0320_H + c × 4_H

Value after reset: $0000\ 0001_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 25.38 ETNBnCIVRc Register Contents

Bit Position	Bit Name	Function
31 to 0	CIV[31:0]	CBS Increment Value Setting value: 1 to 65535 ($0000\ 0001_H$ to $0000\ FFFF_H$)

CIV[31:0]: CBS Increment Value Bits

These bits set the increment for the CBS algorithm.

Set a value in the range from 1 to 65535 ($0000\ 0001_H$ to $0000\ FFFF_H$).

The value to be written to these bits depends on the Ethernet bit rate and clk_chi (peripheral bus clock). For details, see **Section 25.4.6, CBS (Credit-Based Shaping)**.

25.3.2.29 ETNBnCDVRc — CBS Decrement Value Register c (c = 0 or 1)

The ETNBnCDVR0 register sets the decrement in the CBS algorithm for transmission queue 2 (for stream class B).

The ETNBnCDVR1 register sets the decrement in the CBS algorithm for transmission queue 3 (for stream class A).

Access: This register can be read or written in 32-bit units.

Address: <ETNBn_base> + 0328_H + c × 4_H

Value after reset: FFFF $FFFF_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit Position	Bit Name	Function
31 to 0	CDV[31:0]	CBS Decrement Value Setting value: -1 to -65536 (FFFF $FFFF_H$ to FFFF 0000_H)

CDV[31:0]: CBS Decrement Value Bits

These bits set the decrement for the CBS algorithm.

Set a negative value from -1 to -65536 (FFFF $FFFF_H$ to FFFF 0000_H).

The value to be written to these bits depends on the Ethernet bit rate and clk_chi (peripheral bus clock). For details, see **Section 25.4.6, CBS (Credit-Based Shaping)**.

25.3.2.30 ETNBnCULc — CBS Upper Limit Register c (c = 0 or 1)

The ETNBnCUL0 register sets the upper limit for credit values calculated by using the CSB algorithm for transmission queue 2 (for stream class B).

The ETNBnCUL1 register sets the upper limit for credit values calculated by using the CSB algorithm for transmission queue 3 (for stream class A).

Access: This register can be read or written in 32-bit units.

Address: <ETNBn_base> + 0330_H + c × 4_H

Value after reset: $7FFF\ FFFF_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 25.40 ETNBnCULc Register Contents

Bit Position	Bit Name	Function
31 to 0	ULV[31:0]	CBS Upper Limit Upper limit on CBS values

ULV[31:0]: CBS Upper Limit Bits

These bits set the upper limit for credit values calculated by using the CBS algorithm.

The setting is a limiting value for error detection and does not normally affect operation of the algorithm.

Write a positive value to these bits.

For details, see **Section 25.4.6, CBS (Credit-Based Shaping)**.

25.3.2.31 ETNBnCLLc — CBS Lower Limit Register c (c = 0 or 1)

The ETNBnCLL0 register sets the lower limit for credit values calculated by using the CSB algorithm for transmission queue 2 (for stream class B).

The ETNBnCLL1 register sets the lower limit for credit values calculated by using the CSB algorithm for transmission queue 3 (for stream class A).

Access: This register can be read or written in 32-bit units.

Address: <ETNBn_base> + 0338_H + c × 4_H

Value after reset: $8000\ 0001_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 25.41 ETNBnCLLc Register Contents

Bit Position	Bit Name	Function
31 to 0	LLV[31:0]	CBS Lower Limit Lower limit on CBS values

LLV[31:0]: CBS Lower Limit Bits

These bits set the lower limit for credit values calculated by using the CBS algorithm.

The setting is a limiting value for error detection and does not normally affect operation of the algorithm.

Write a negative value to these bits.

For details, see **Section 25.4.6, CBS (Credit-Based Shaping)**.

25.3.2.32 ETNBnDIC — Descriptor Interrupt Control Register

The ETNBnDIC register is used to control descriptor interrupts 1 to 15.

Access: This register can be read or written in 32-bit units.

Address: <ETNBn_base> + 0350_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

0	Reserved	When read, the value after reset is returned. When writing, write the value after reset.

DPEi (i = 1 to 15): Descriptor Interrupt Enable Bits

When interrupts are allowed, and if an interrupt source occurs (descriptor interrupt status bit of the descriptor interrupt status register (ETNBnDIS 1 to 15) = 1), an interrupt is generated.

25.3.2.33 ETNBnDIS — Descriptor Interrupt Status Register

The ETNBnDIS register indicates the state of descriptor interrupts.

Access: This register can be read or written in 32-bit units.

Address: <ETNBn_base> + 0354_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

5	DPF5	Descriptor Interrupt Status 5 0: The interrupt is not pending. 1: The interrupt is pending.

Table 25.43 ETNBnDIS Register Contents (2/2)

Bit Position	Bit Name	Function
4	DPF4	Descriptor Interrupt Status 4 0: The interrupt is not pending. 1: The interrupt is pending.
3	DPF3	Descriptor Interrupt Status 3 0: The interrupt is not pending. 1: The interrupt is pending.
2	DPF2	Descriptor Interrupt Status 2 0: The interrupt is not pending. 1: The interrupt is pending.
1	DPF1	Descriptor Interrupt Status 1 0: The interrupt is not pending. 1: The interrupt is pending.
0	Reserved	When read, the value after reset is returned. When writing, write the value after reset.

DPFi (i = 1 to 15): Descriptor Interrupt Status Bits

When DESCR.DIE is 1 to 15 (0001_B to 1111_B), the corresponding bit indicates completion of the processing of a descriptor within the reception or transmission queue.

When DESCR.DIE is 0, the descriptor interrupt is not generated.

Only 0 can be written to these bits.

[Conditions for Changing]

– The bit is set to 0 when the operating mode is not operation mode.

– The bit is set to 1 after a descriptor with DESCR.DIE set to the corresponding number from 1 to 15 (0001_B to 1111_B) is processed.

25.3.2.34 ETNBnEIC — Error Interrupt Control Register

The ETNBnEIC register controls the AVB-DMAC-related error interrupts.

Access: This register can be read or written in 32-bit units.

Address: <ETNBn_base> + 0358_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

R/W	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 25.44 ETNBnEIC Register Contents

Bit Position	Bit Name	Function
31 to 11	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
10	TBFE	Tx-Buffer Full Interrupt Enable 0: Disabled 1: Enabled
9	MFFE	MAC Status FIFO Full Interrupt Enable 0: Disabled 1: Enabled
8	TFFE	Timestamp FIFO Full-Error Interrupt Enable 0: Disabled 1: Enabled
7	CULE1	CBS Upper Limit Error Interrupt Enable (Class A) 0: Disabled 1: Enabled
6	CULE0	CBS Upper Limit Error Interrupt Enable (Class B) 0: Disabled 1: Enabled
5	CLLE1	CBS Lower Limit Error Interrupt Enable (Class A) 0: Disabled 1: Enabled
4	CLLE0	CBS Lower Limit Error Interrupt Enable (Class B) 0: Disabled 1: Enabled
3	SEE	Separation Error interrupt Enable 0: Disabled 1: Enabled
2	QEE	Queue Error interrupt Enable 0: Disabled 1: Enabled
1	MTEE	MAC Transmission Error interrupt Enable 0: Disabled 1: Enabled
0	MREE	MAC Reception Error interrupt Enable 0: Disabled 1: Enabled

TBFE: Tx-Buffer Full Interrupt Enable

While this bit is 1 an interrupt will be generated when ETNBnEIS.TBFF is 1.

MFFE: MAC status FIFO Full Interrupt Enable

While this bit is 1 an interrupt will be generated when ETNBnEIS.MFFF is 1.

TFFE: Timestamp FIFO Full-Error Interrupt Enable Bits

When the timestamp FIFO is full (the timestamp FIFO full error interrupt status bits of the error interrupt status register (ETNBnEIS.TFFF) = 1) and the interrupt is enabled, the interrupt is issued.

CULE1: CBS Upper Limit Error Interrupt Enable Bit (Class A)

When the CBS of Class A reached the upper limit value (CBS upper limit error interrupt status bit (Class A) (ETNBnEIS.CULF1) = 1) and the interrupt is enabled, an interrupt occurs.

CULE0: CBS Upper Limit Error Interrupt Enable Bit (Class B)

When the CBS of Class B reached the upper limit value (CBS upper limit error interrupt status bit (Class B) (ETNBnEIS.CULF0) = 1) and the interrupt is enabled, an interrupt occurs.

CLLE1: CBS Lower Limit Error Interrupt Enable Bit (Class A)

When the CBS of Class A reached the lower limit value (CBS lower limit error interrupt status bit (Class A) (ETNBnEIS.CLLF1) = 1) and the interrupt is enabled, an interrupt occurs.

CLLE0: CBS Lower Limit Error Interrupt Enable Bit (Class B)

When the CBS of Class B reached the lower limit value (CBS lower limit error interrupt status bit (Class B) (ETNBnEIS.CLLF0)=1) and the interrupt is enabled, an interrupt occurs.

SEE: Separation Error interrupt Enable Bit

When the separation error flag (ETNBnEIS.SEF) is set to 1 and the interrupt is enabled, an interrupt occurs.

QEE: Queue Error interrupt Enable Bit

When the queue error flag (ETNBnEIS.QEF) is set to 1 and the interrupt is enabled, an interrupt occurs.

MTEE: MAC Transmission Error interrupt Enable Bit

When the MAC transmission error flag (ETNBnEIS.MTEF) is set to 1 and the interrupt is enabled, an interrupt occurs.

MREE: MAC Reception Error interrupt Enable Bit

When the MAC reception error flag (ETNBnEIS.MREF) is set to 1 and the interrupt is enabled, an interrupt occurs.

25.3.2.35 ETNBnEIS — Error Interrupt Status Register

The ETNBnEIS register indicates the states of AVB-DMAC-related error interrupts.

Access: This register can be read or written in 32-bit units.

Address: <ETNBn_base> + $035C_H$

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	QFS
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	TBFF	MFFF	TFFF	CULF1	CULF0	CLLF1	CLLF0	SEF	QEF	MTEF	MREF
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 25.45 ETNBnEIS Register Contents (1/2)

Bit Position	Bit Name	Function
31 to 17	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
16	QFS	Queue Full Summary 0: The interrupt is not pending. 1: The interrupt is pending.
15 to 11	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
10	TBFF	Tx-Buffer Full Flag 0: The interrupt is not pending. 1: The interrupt is pending.
9	MFFF	MAC Status FIFO Full Flag 0: The interrupt is not pending. 1: The interrupt is pending.
8	TFFF	Timestamp FIFO Full Flag 0: The interrupt is not pending. 1: The interrupt is pending.
7	CULF1	CBS Upper Limit reached Flag 1 (Class A) 0: The interrupt is not pending. 1: The interrupt is pending.
6	CULF0	CBS Upper Limit reached Flag 0 (Class B) 0: The interrupt is not pending. 1: The interrupt is pending.
5	CLLF1	CBS Lower Limit reached Flag 1 (Class A) 0: The interrupt is not pending. 1: The interrupt is pending.
4	CLLF0	CBS Lower Limit reached Flag 0 (Class B) 0: The interrupt is not pending. 1: The interrupt is pending.
3	SEF	Separation Error Flag 0: The interrupt is not pending. 1: The interrupt is pending.
2	QEF	Queue Error Flag 0: The interrupt is not pending. 1: The interrupt is pending.

Table 25.45 ETNBnEIS Register Contents (2/2)

Bit Position	Bit Name	Function
1	MTEF	MAC Transmission Error Flag 0: The interrupt is not pending. 1: The interrupt is pending.
0	MREF	MAC Reception Error Flag 0: The interrupt is not pending. 1: The interrupt is pending.

QFS: Queue Full Error Status Bit

With the interrupts enabled, this bit indicates that a queue is full (the receive queue r full interrupt status bit (QFFr) or the receive FIFO full interrupt status bit (RFFF) in receive interrupt status register 2 (ETNBnRIS2) = 1).

[Conditions for Changing]

– If the receive queue r full interrupt status bit (ETNBnRIS2.QFFr) and the receive queue r full interrupt enable bit in the receive interrupt control register 2 (ETNBnRIC2.QFEr) are updated, this bit is also updated.

– If the receive FIFO full interrupt status bit (ETNBnRIS2.RFFF) and the receive FIFO full interrupt enable bit (ETNBnRIC2.RFFE) are updated, this bit is also updated.

TBFF: Tx-Buffer Full Flag

This bit indicates that fetching transmit data was delayed because the Tx-Buffer has no sufficient storage available to store fetched frame. It depends on configuration of ETNBnTGC.TBDt if a full Tx-Buffer is expected during normal operation.

No frame gets lost but transmission priority may be influenced.

The CPU can only write 0 to this bit.

[Conditions for Changing]

This bit is set to 0 when leaving OPERATION mode.

This bit is set to 1 when frame data has been fetched from URAM but there is no storage available in Tx-Buffer.

MFFF: MAC status FIFO Full Flag

This bit indicates that a transmission MAC status is overwritten because the MAC status FIFO is full (overwrite condition).

The CPU can only write 0 to this bit.

[Conditions for Changing]

This bit is set to 0 when leaving OPERATION mode.

This bit is set to 1 when a frame with DESCR.MSR has been transmitted by MAC, ETNBnTCCR.MFEN is 1 and ETNBnTSR.MFFL is 16.

This bit is set to 1 when MAC detects an error during transmission and ETNBnTSR.MFFL is 16.

TFFF: Timestamp FIFO Full-Error Interrupt Status Bit

This bit indicates that a new transmission timestamp has been discarded due to the timestamp FIFO being full (i.e. has reached the overrun state).

Only 0 can be written to the bit.

[Conditions for Changing]

- The bit is set to 0 when the operating mode is not operation mode.
- The bit is set to 1 when a frame with DESCR.TSR set is transmitted while the timestamp FIFO enable bit in the transmit configuration control register (ETNBnTCCR.TFEN) is set to 1 and the timestamp FIFO count bit in the transmit status register (ETNBnTSR.TFFL) is set to 3.

CULF1: CBS Upper Limit Error Interrupt Status Bit (Class A)

This bit indicates that CBS counter 1 has exceeded the set upper limit (ETNBnCUL1.ULV in the CBS upper limit register c (ETNBnCULc)).

Only 0 can be written to the bit.

[Conditions for Changing]

- This bit is set to 0 when the operating mode is not operation mode.
- This bit is set to 1 when the value of the CBS counter status 1 (Class A) bits in the transmit status register (ETNBnTSR.CCS1) change from 00_B (within the range) to 10_B (indicating a value equal to or higher than the upper limit).

CULF0: CBS Upper Limit Error Interrupt Status Bit (Class B)

This bit indicates that CBS counter 0 has exceeded the set upper limit (ETNBnCUL0.ULV in the CBS upper limit register c (ETNBnCULc)).

Only 0 can be written to the bit.

[Conditions for Changing]

- The bit is set to 0 when the operating mode is not operation mode.
- The bit is set to 1 when the value of the CBS counter status 0 (Class B) (ETNBnTSR.CCS0) bit in the transmit status register changes from 00_B (within the range) to 10_B (indicating a value over the upper limit).

CLLF1: CBS Lower Limit Error Interrupt Status Bit (Class A)

This bit indicates that CBS counter 1 has fallen below the set lower limit (ETNBnCLL1.LLV in CBS lower limit register c (ETNBnCLLc)).

Only 0 can be written to the bit.

[Conditions for Changing]

- The bit is set to 0 when the operating mode is not operation mode.
- The bit is set to 1 when the value of the CBS counter status 1 (Class A) bit in the transmit status register (ETNBnTSR.CCS1) changes from 00_B (within the range) to 01_B (indicating a value less than the lower limit).

CLLF0: CBS Lower Limit Error Interrupt Status Bit (Class B)

This bit indicates that CBS counter 0 has fallen below the set lower limit (ETNBnCLL0.LLV in the CBS lower limit register c (ETNBnCLLc)).

Only 0 can be written to the bit.

[Conditions for Changing]

- The bit is set to 0 when the operating mode is not operation mode.
- The bit is set to 1 when the value of the CBS counter status 0 (Class B) bit in the transmit status register (ETNBnTSR.CCS0) changes from 00_B (within the range) to 01_B (indicating a value less than the lower limit).

SEF: Separation Error Flag

This bit indicates that a received frame was discarded because it has not matched any configured separation filter for AVB stream data frames.

The CPU can only write 0 to this bit.

[Changing condition]

- This bit is set to 0 when leaving OPERATION mode.
- This bit is set to 1 when a valid AVB stream data frame was received by MAC but discarded because the separation filter select bits in the receive configuration register (ETNBnRCR.ESF) are 10_B and no separation filter has matched.

QEF: Queue Error Flag

This bit indicates that an error has been detected while processing reception or transmit queue.

Detail about the detected error is indicated by the error status register (ETNBnESR).

For details of the error processing, **Section 25.4.2.3, Checking Integrity**.

The CPU can only write 0 to this bit.

[Changing condition]

- This bit is set to 0 when the operating mode changes from operation mode.
- This bit is set to 1 when a state of error is detected.

MTEF: MAC Transmission Error Flag

This bit indicates that the MAC has detected a fault during transmission.

For details, the MAC registers have to be checked.

The CPU can only write 0 to this bit.

[Changing condition]

- This bit is set to 0 when the operating mode changes from operation mode.
- This bit is set to 1 when MAC detects an error during frame transmission.

MREF: MAC Reception Error Flag

This bit indicates that the MAC has detected a fault during reception.

For details, the MAC registers have to be checked.

NOTE

When the storage of faulty received frames (ETNBnRCR.EFFS) is enabled, the MAC error code (DESCR.MSC) is stored in the descriptor. By evaluating this information CPU can identify corrupted frames in URAM.

The CPU can only write 0 to this bit.

[Changing condition]

- This bit is set to 0 when leaving OPERATION mode.
- This bit is set to 1 when E-MAC detects an error during frame reception.

25.3.2.36 ETNBnRIC0 — Receive Interrupt Control Register 0

The ETNBnRIC0 register controls the AVB-DMAC receive interrupts.

Access: This register can be read or written in 32-bit units.

Address: <ETNBn_base> + 0360_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

0	FRE0	Receive Frame Interrupt Enable 0 (Best Effort) 0: Disabled 1: Enabled

FREr (r = 0 to 17): Receive Frame Interrupt Enable Bits

When interrupts are allowed, and if an interrupt source occurs (receive interrupt status bit in the receive interrupt status register (ETNBnRIS0.FRF0 to 17) = 1), an interrupt is generated.

[Changing condition]

– This bit is set to 0 when writing 1 to ETNBnRID0.FRDr.

– This bit is set to 1 when writing 1 to ETNBnRIE0.FRSr.

25.3.2.37 ETNBnRIS0 — Receive Interrupt Status Register 0

The ETNBnRIS0 register indicates the states of the AVB-DMAC receive interrupts.

Access: This register can be read or written in 32-bit units.

Address: <ETNBn_base> + 0364_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

4	FRF4	Receive Frame Interrupt Status 4 (Stream 2) 0: The interrupt is not pending. 1: The interrupt is pending.
3	FRF3	Receive Frame Interrupt Status 3 (Stream 1) 0: The interrupt is not pending. 1: The interrupt is pending.
2	FRF2	Receive Frame Interrupt Status 2 (Stream 0) 0: The interrupt is not pending. 1: The interrupt is pending.
1	FRF1	Receive Frame Interrupt Status 1 (Network Control) 0: The interrupt is not pending. 1: The interrupt is pending.
0	FRF0	Receive Frame Interrupt Status 0 (Best Effort) 0: The interrupt is not pending. 1: The interrupt is pending.

FRFr (r = 0 to 17): Receive Frame Interrupt Status Bits

Each bit indicates that a corresponding frame has been stored normally in reception queues 0 to 17 and that data is queued for CPU processing.

Only 0 can be written to the bit.

[Conditions for Changing]

- A bit is set to 0 when the operating mode is not operation mode.
- A bit is set to 0 when a value is written to the unread frame counter decrement register i (ETNBnUFCDi) (i = 0 to 4), and this decrements the value of unread frame counter register i (ETNBnUFCVi) (i = 0 to 4) to 0.
- When a frame is stored normally in a reception queue, the corresponding bit is set to 1.

25.3.2.38 ETNBnRIC1 — Receive Interrupt Control Register 1

The ETNBnRIC1 register controls AVB-DMAC receive interrupts.

Access: This register can be read or written in 32-bit units.

Address: <ETNBn_base> + 0368_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	RFWE	—	—	—	—	—	—	—	—	—	—	—	—	—	RWE17	RWE16

Table 25.48 ETNBnRIC1 Register Contents

Bit Position	Bit Name	Function
31	RFWE	Receive FIFO Warning Interrupt Enable 0: Disabled 1: Enabled
30 to 18	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
17 to 0	RWEr (r = 17 to 0)	Reception Warning Interrupt Enable 0: Disabled 1: Enabled

RFWE: Receive FIFO Warning Interrupt Enable Bit

While this bit is 1 an interrupt will be generated when ETNBnRIS1.RFWF is 1.

[Conditions for Changing]

– This bit is set to 0 when writing 1 to ETNBnRID1.RFWD.

– This bit is set to 1 when writing 1 to ETNBnRIE1.RFWS.

RWEr: Receive Warning Interrupt Enable Bit (r = 0 to 17)

While this bit is 1 an interrupt will be generated when ETNBnRIS1.RWFr is 1.

[Conditions for Changing]

– This bit is set to 0 when writing 1 to ETNBnRID1.RWDr.

– This bit is set to 1 when writing 1 to ETNBnRIE1.RWSr.

25.3.2.39 ETNBnRIS1 — Receive Interrupt Status Register 1

The ETNBnRIS1 register indicates the states of AVB-DMAC receive interrupts.

Access: This register can be read or written in 32-bit units.

Address: <ETNBn_base> + $036C_H$

Value after reset: $0000\ 0000_H$

17	RWF17	Receive Warning Flag 17 (Stream) 0: The interrupt is not pending. 1: Unread frame counter warning level reached.
16	RWF16	Receive Warning Flag 16 (Stream) 0: The interrupt is not pending. 1: Unread frame counter warning level reached.
15	RWF15	Receive Warning Flag 15 (Stream) 0: The interrupt is not pending. 1: Unread frame counter warning level reached.
14	RWF14	Receive Warning Flag 14 (Stream) 0: The interrupt is not pending. 1: Unread frame counter warning level reached.
13	RWF13	Receive Warning Flag 13 (Stream) 0: The interrupt is not pending. 1: Unread frame counter warning level reached.
12	RWF12	Receive Warning Flag 12 (Stream) 0: The interrupt is not pending. 1: Unread frame counter warning level reached.
11	RWF11	Receive Warning Flag 11 (Stream) 0: The interrupt is not pending. 1: Unread frame counter warning level reached.
10	RWF10	Receive Warning Flag 10 (Stream) 0: The interrupt is not pending. 1: Unread frame counter warning level reached.
9	RWF9	Receive Warning Flag 9 (Stream) 0: The interrupt is not pending. 1: Unread frame counter warning level reached.
8	RWF8	Receive Warning Flag 8 (Stream) 0: The interrupt is not pending. 1: Unread frame counter warning level reached.

Table 25.49 ETNBnRIS1 Register Contents (2/2)

Bit Position	Bit Name	Function
7	RWF7	Receive Warning Flag 7 (Stream) 0: The interrupt is not pending. 1: Unread frame counter warning level reached.
6	RWF6	Receive Warning Flag 6 (Stream) 0: The interrupt is not pending. 1: Unread frame counter warning level reached.
5	RWF5	Receive Warning Flag 5 (Stream) 0: The interrupt is not pending. 1: Unread frame counter warning level reached.
4	RWF4	Receive Warning Flag 4 (Stream) 0: The interrupt is not pending. 1: Unread frame counter warning level reached.
3	RWF3	Receive Warning Flag 3 (Stream) 0: The interrupt is not pending. 1: Unread frame counter warning level reached.
2	RWF2	Receive Warning Flag 2 (Stream) 0: The interrupt is not pending. 1: Unread frame counter warning level reached.
1	RWF1	Receive Warning Flag 1 (Stream) 0: The interrupt is not pending. 1: Unread frame counter warning level reached.
0	RWF0	Receive Warning Flag 0 (Stream) 0: The interrupt is not pending. 1: Unread frame counter warning level reached.

RFWF: Receive FIFO Warning Flag

This bit indicates that the reception FIFO has reached configured critical warning level.

Only 0 can be written to the bit.

[Conditions for Changing]

- The bit is set to 0 when the operating mode is not operation mode.
- The bit is set to 1 when a complete frame is received in the reception FIFO and the fill level goes above the configured critical warning level during reception of this frame (ETNBnRCR.RFCL).

RWFr: Reception Warning Flag (r = 0 to 17)

This bit indicates that the unread frame counter of receive queue r has reached the configured warning level.

Only 0 can be written to the bit.

[Conditions for Changing]

– The bit is set to 0 when the operating mode is not operation mode.
– The bit is set to 0 when CPU request a reload of the base address (ETNBnDLR.LBAq is 1 q = r +4).
– This bit is set to 0 when CPU writes to ETNBnUFCDi.DVr and ETNBnUFCVi.CVr is decremented to a value less than the selected warning level ETNBnUFCW.WLj.
– This bit is set to 1 when a frame is stored in queue r and the unread frame counter value r is incremented to the selected warning level j (ETNBnUFCVi.CVr +1 == ETNBnUFCW.WLj)

25.3.2.40 ETNBnRIC2 — Receive Interrupt Control Register 2

The ETNBnRIC2 register controls AVB-DMAC receive interrupts.

Access: This register can be read or written in 32-bit units.

Address: <ETNBn_base> + 0370_H

Value after reset: $0000\ 0000_H$

0	QFE0	Receive Queue 0 (Best Effort) Full Interrupt Enable 0: Disabled 1: Enabled

RFFE: Receive FIFO Full Interrupt Enable Bit

When interrupts are allowed, and if the reception FIFO becomes full (the reception FIFO full interrupt status bit (ETNBnRIS2.RFFF) = 1 in receive interrupt status register 2), an interrupt is generated.

[Changing condition]

– This bit is set to 0 when writing 1 to ETNBnRID2.RFFD.

– This bit is set to 1 when writing 1 to ETNBnRIE2.RFFS.

QFEr (r = 0 to 17): Receive Queue r Full Interrupt Enable Bits

When interrupts are allowed, and if a receive queue (0 to 17) becomes full (the receive queue r full interrupt status bit (ETNBnRIS2.QFF0 to 17) = 1 in receive interrupt status register 2), an interrupt is generated.

[Changing condition]

– This bit is set to 0 when writing 1 to ETNBnRID2.QFDr.

– This bit is set to 1 when writing 1 to ETNBnRIE2.QFSr.

25.3.2.41 ETNBnRIS2 — Receive Interrupt Status Register 2

The ETNBnRIS2 register indicates the states of the AVB-DMAC receive interrupts.

Access: This register can be read or written in 32-bit units.

Address: <ETNBn_base> + 0374_H

Value after reset: $0000\ 0000_H$

3	QFF3	Receive Queue 3 (Stream 1) Full Interrupt Status 0: The interrupt is not pending. 1: The interrupt is pending.
2	QFF2	Receive Queue 2 (Stream 0) Full Interrupt Status 0: The interrupt is not pending. 1: The interrupt is pending.
1	QFF1	Receive Queue 1 (Network Control) Full Interrupt Status 0: The interrupt is not pending. 1: The interrupt is pending.
0	QFF0	Receive Queue 0 (Best Effort) Full Interrupt Status 0: The interrupt is not pending. 1: The interrupt is pending.

RFFF: Receive FIFO Full Interrupt Status Bit

This bit indicates that a frame was received but storing it was not possible due to the reception FIFO being full.

When receiving a frame is not possible, the frame will be discarded.

Other information regarding discarded frames is not retained. Even if the frame is not discarded, this bit may also be set to 1 if the E-MAC determines that the frame is an error frame

Only 0 can be written to the bit.

[Conditions for Changing]

- The bit is set to 0 when the operating mode is not operation mode.
- The bit is set to 1 when the reception FIFO cannot hold received frame data.

QFFr (r = 0 to 17): Receive r Full Interrupt Status Bits

These bits indicate that reception queue r did not have space for storing a received frame.

A reception queue is treated as full when it has no descriptors (descriptor type (DESCR.DT) = FEMPTY, FEMPTY_IS, FEMPTY_IC, or FEMPTY_ND) available or reaches the set level for stopping.

CAUTION

If no FEMPTY descriptors or no empty space for descriptors remains in the queue during storing of a divided frame (see **Section 25.4.4.3(b), Storing Frame Data as Divided Frames**), an error frame is stored in the queue. Such error frames are treated as descriptor sequence errors.

Reading descriptor may be one or more storage elements ahead from actual storage in URAM. ETNBnCDARq.CDA provides information where queue has been stopped.

The CPU can only write 0 to this bit.

[Conditions for Changing]

- A bit is set to 0 when the operating mode is not operation mode.
- A bit is set to 1 when reception queue r has no space available for storage.
- A bits is set to 1 when a SW defined stop point (EOS descriptor) reached within a split frame.
- A bit is set to 1 when the unread frame counter (unread frame counter register i (ETNBnUFCVi) (i = 0 to 4)) reaches the set level for stopping.

25.3.2.42 ETNBnTIC — Transmit Interrupt Control Register

Access: This register can be read or written in 32-bit units.

Address: <ETNBn_base> + 0378_H

1	FTE1	Frame Transmitted Interrupt Enable 1 0: Disabled 1: Enabled
0	FTE0	Frame Transmitted Interrupt Enable 0 0: Disabled 1: Enabled

TDPEt: Transmit Descriptor Processed Interrupt Enable t (t = 0 to 3)

While this bit is 1 an interrupt will be generated when ETNBnTIS.TDPFt is 1.

[Conditions for Changing]

- The bit is set to 0 when writing 1 to ETNBnTID.TDPDt.
- The bit is set to 1 when writing 1 to ETNBnTIE.TDPSt.

MFWE: MAC Status FIFO Warning Interrupt Enable

While this bit is 1 an interrupt will be generated when ETNBnTIS.MFWF is 1.

[Conditions for Changing]

- The bit is set to 0 when writing 1 to ETNBnTID.MFWD.
- The bit is set to 1 when writing 1 to ETNBnTIE.MFWS.

MFUE: MAC Status FIFO Updated Interrupt Enable

While this bit is 1 an interrupt will be generated when ETNBnTIS.MFUF is 1.

[Conditions for Changing]

- The bit is set to 0 when writing 1 to ETNBnTID.MFUD.
- The bit is set to 1 when writing 1 to ETNBnTIE.MFUS.

TFWE: Timestamp FIFO Warning Interrupt Enable

While this bit is 1 an interrupt will be generated when ETNBnTIS.TFWF is 1.

[Conditions for Changing]

- The bit is set to 0 when writing 1 to ETNBnTID.TFWD.
- The bit is set to 1 when writing 1 to ETNBnTIE.TFWS.

TFUE: Timestamp FIFO Update Interrupt Enable

While this bit is 1 an interrupt will be generated when ETNBnTIS.TFUF is 1.

[Conditions for Changing]

- The bit is set to 0 when writing 1 to ETNBnTID.TFUD.
- The bit is set to 1 when writing 1 to ETNBnTIE.TFUS.

FTEt: Frame Transmitted Interrupt Enable t (t = 0 to 3)

While this bit is 1 an interrupt will be generated when ETNBnTIS.FTFt is 1.

[Conditions for Changing]

- The bit is set to 0 when writing 1 to ETNBnTID.FTDt.
- The bit is set to 1 when writing 1 to ETNBnTIE.FTSt.

25.3.2.43 ETNBnTIS — Transmit Interrupt Status Register

The ETNBnTIS register indicates the states of the AVB-DMAC transmit interrupts.

Access: This register can be read or written in 32-bit units.

Address: <ETNBn_base> + $037C_H$

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	TDPF3	TDPF2	TDPF1	TDPF0
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	MFWF	MFUF	TFWF	TFUF	—	—	—	—	FTF3	FTF2	FTF1	FTF0
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R/W	R/W	R/W	R/W	R	R	R	R	R/W	R/W	R/W	R/W

Table 25.53 ETNBnTIS Register Contents (1/2)

Bit Position	Bit Name	Function
31 to 20	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
19	TDPF3	Transmit Descriptor Processed Flag 3 0: The interrupt is not pending. 1: The descriptor interrupt is pending.
18	TDPF2	Transmit Descriptor Processed Flag 2 0: The interrupt is not pending. 1: The descriptor interrupt is pending.
17	TDPF1	Transmit Descriptor Processed Flag 1 0: The interrupt is not pending. 1: The descriptor interrupt is pending.
16	TDPF0	Transmit Descriptor Processed Flag 0 0: The interrupt is not pending. 1: The descriptor interrupt is pending.
15 to 12	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
11	MFWF	MAC status FIFO Warning Flag 0: The interrupt is not pending. 1: The Tx Status FIFO has reached the warning level.
10	MFUF	MAC status FIFO Update Flag 0: The interrupt is not pending. 1: The Tx Status FIFO has been updated.
9	TFWF	Timestamp FIFO Warning Flag 0: The interrupt is not pending. 1: The timestamp FIFO has reached the warning level.
8	TFUF	Timestamp FIFO Update Flag 0: The interrupt is not pending. 1: The timestamp FIFO has been updated.
7 to 4	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
3	FTF3	Frame Transmitted Flag 3 0: The interrupt is not pending. 1: Frame transmitted by MAC.

Table 25.53 ETNBnTIS Register Contents (2/2)

Bit Position	Bit Name	Function
2	FTF2	Frame Transmitted Flag 2 0: The interrupt is not pending. 1: Frame transmitted by MAC.
1	FTF1	Frame Transmitted Flag 1 0: The interrupt is not pending. 1: Frame transmitted by MAC.
0	FTF0	Frame Transmitted Flag 0 0: The interrupt is not pending. 1: Frame transmitted by MAC.

TDPFt: Transmit Descriptor Processed Flag t (t = 0 to 3)

This bit indicates that a descriptor in transmit queue t has been processed where DESCR.DIE is 0001_B.

Only 0 can be written to the bit.

[Conditions for Changing]

- The bit is set to 0 when the operating mode is not operation mode.
- The bit is set to 1 when the descriptor in transmit queue t has been processed where DESCR.DIE is 1.

NOTE

The descriptor with DESCR.DIE is 1, which sets this bit, sets in addition the universal descriptor interrupt ETNBnDIS.DPF1.

MFWF: MAC Status FIFO Warning Flag

This bit indicates that the warning level of the MAC status FIFO (12 out of 16 entries) has been reached.

Only 0 can be written to the bit.

[Conditions for Changing]

- The bit is set to 0 when the operating mode is not operation mode.
- This bit is set to 0 when ETNBnTCCR.MFEN is 0.
- This bit is set to 0 when writing 1 to ETNBnTCCR.MFR.
- This bit is set to 1 when a frame with DESCR.MSR has been transmitted by MAC and the MAC Status FIFO contains already 11 entries (ETNBnTSR.MFFL is 11).
- The bits is set to 1 when MAC detects an error during transmission and the MAC Status FIFO contains already 11 entries (ETNBnTSR.MFFL is 11).

MFUF: MAC Status FIFO Updated Flag

This bit indicates that the MAC status FIFO has been updated after the MAC has transmitted a frame.

Only 0 can be written to the bit.

[Conditions for Changing]

- The bit is set to 0 when the operating mode is not operation mode.
- This bit is set to 0 when ETNBnTCCR.MFEN is 0.
- This bit is set to 0 when writing 1 to ETNBnTCCR.MFR.
- This bit is set to 1 when a frame with DESCR.MSR has been transmitted by MAC and ETNBnTCCR.MFEN is 1.
- The bits is set to 1 when MAC detects an error during transmission and ETNBnTCCR.MFEN is 1.

TFWF: Timestamp FIFO Warning Flag

This bit indicates that the warning level of the transmission timestamp FIFO (2 out of 3 entries) has been reached.

Only 0 can be written to the bit.

[Conditions for Changing]

- The bit is set to 0 when the operating mode is not operation mode.
- This bit is set to 0 when ETNBnTCCR.TFEN is 0.
- This bit is set to 0 when writing 1 to ETNBnTCCR.TFR.
- This bit is set to 1 when a frame with DESCR.TSR has been transmitted by MAC and the timestamp FIFO contains already 1 entries (ETNBnTSR.TFFL is 1).

TFUF: Timestamp FIFO Update Flag

This bit indicates that the transmission timestamp FIFO has been updated.

Only 0 can be written to the bit.

[Conditions for Changing]

- The bit is set to 0 when the operating mode is not operation mode.
- This bit is set to 0 when ETNBnTCCR.TFEN is 0.
- This bit is set to 0 when writing 1 to ETNBnTCCR.TFR.
- This bit is set to 1 when a frame with DESCR.TSR has been transmitted by MAC and the ETNBnTCCR.TFEN is 1.

FTFt: Frame Transmitted Flag t (t = 0 to 3)

This bit indicates that from transmit queue a frame is transmitted by MAC.

Only 0 can be written to the bit.

[Conditions for Changing]

- The bit is set to 0 when the operating mode is not operation mode.
- This bit is set to 1 when a frame from transmit queue t has been transmitted by the MAC.

NOTE

This interrupt flag refers to the end of frame is transmission by MAC whereas the descriptor interrupt (ETNBnDIS.DPFi) refer to the end of processing storage element.

25.3.2.44 ETNBnISS — Interrupt Summary Status Register

Access: This register is a read-only register that can be read in 32-bit units.

Address: <ETNBn_base> + 0380_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	DPM15	DPM14	DPM13	DPM12	DPM11	DPM10	DPM9	DPM8	DPM7	DPM6	DPM5	DPM4	DPM3	DPM2	DPM1	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 25.54 ETNBnISS Register Contents (1/2)

Bit Position	Bit Name	Function
31	DPM15	Descriptor Processed Mirror 15 0: The interrupt is not pending. 1: The interrupt is pending.
30	DPM14	Descriptor Processed Mirror 14 0: The interrupt is not pending. 1: The interrupt is pending.
29	DPM13	Descriptor Processed Mirror 13 0: The interrupt is not pending. 1: The interrupt is pending.
28	DPM12	Descriptor Processed Mirror 12 0: The interrupt is not pending. 1: The interrupt is pending.
27	DPM11	Descriptor Processed Mirror 11 0: The interrupt is not pending. 1: The interrupt is pending.
26	DPM10	Descriptor Processed Mirror 10 0: The interrupt is not pending. 1: The interrupt is pending.
25	DPM9	Descriptor Processed Mirror 9 0: The interrupt is not pending. 1: The interrupt is pending.
24	DPM8	Descriptor Processed Mirror 8 0: The interrupt is not pending. 1: The interrupt is pending.
23	DPM7	Descriptor Processed Mirror 7 0: The interrupt is not pending. 1: The interrupt is pending.
22	DPM6	Descriptor Processed Mirror 6 0: The interrupt is not pending. 1: The interrupt is pending.
21	DPM5	Descriptor Processed Mirror 5 0: The interrupt is not pending. 1: The interrupt is pending.
20	DPM4	Descriptor Processed Mirror 4 0: The interrupt is not pending. 1: The interrupt is pending.

Table 25.54 ETNBnISS Register Contents (2/2)

Bit Position	Bit Name	Function
19	DPM3	Descriptor Processed Mirror 3 0: The interrupt is not pending. 1: The interrupt is pending.
18	DPM2	Descriptor Processed Mirror 2 0: The interrupt is not pending. 1: The interrupt is pending.
17	DPM1	Descriptor Processed Mirror 1 0: The interrupt is not pending. 1: The interrupt is pending.
16 to 14	Reserved	When read, the value after reset is returned.
13	CGIM	Combined gPTP Interrupt Mirror 0: The interrupt is not pending. 1: The interrupt is pending.
12	RFWM	Receive FIFO Warning Mirror 0: The interrupt is not pending. 1: The interrupt is pending.
11	MFWM	MAC Status FIFO Warning Mirror 0: The interrupt is not pending. 1: The interrupt is pending.
10	MFUM	MAC Status FIFO Updated Mirror 0: The interrupt is not pending. 1: The interrupt is pending.
9	TFWM	Timestamp FIFO Warning Mirror 0: The interrupt is not pending. 1: The interrupt is pending.
8	TFUM	Timestamp FIFO Update Mirror 0: The interrupt is not pending. 1: The interrupt is pending.
7	MM	MAC Mirror 0: The interrupt is not pending. 1: The interrupt is pending.
6	EM	Error Mirror 0: The interrupt is not pending. 1: The interrupt is pending.
5 to 3	Reserved	When read, the value after reset is returned.
2	FTM	Frame Transmitted Mirror 0: The interrupt is not pending. 1: The interrupt is pending.
1	RWM	Receive Warning Mirror 0: The interrupt is not pending. 1: The interrupt is pending.
0	FRM	Frame Received Mirror 0: The interrupt is not pending. 1: The interrupt is pending.

DPMi: Descriptor Processed Mirror i (i = 1 to 15)

[Conditions for Changing]

This bit is set when any matching pair of ETNBnDIC.DPEi enable and ETNBnDIS.DPFi flag are both 1.

CGIM: Combined gPTP Interrupt Mirror

This bit indicates that at least one enabled gPTP interrupt (ETNBnGIC and ETNBnGIS) is 1.

[Conditions for Changing]
This bit is updated when ETNBnGIC or ETNBnGIS changes.

RFWM: Receive FIFO Warning Mirror

This bit indicates that ETNBnRIS1.RFWF is 1 and ETNBnRIC1.RFWE is 1.

[Conditions for Changing]
This bit is updated ETNBnRIS1.RFWF or ETNBnRIC1.RFWE changes.

MFWM: MAC Status FIFO Warning Mirror

This bit indicates that ETNBnTIS.MFWF is 1 and ETNBnTIC.MFWE is 1.

[Conditions for Changing]
This bit is updated when ETNBnTIS.MFWF or ETNBnTIC.MFWE changes.

MFUM: MAC Status FIFO Updated Mirror

This bit indicates that ETNBnTIS.MFUF is 1 and ETNBnTIC.MFUE is 1.

[Conditions for Changing]
This bit is updated ETNBnTIS.MFUF or ETNBnTIC.MFUE changes.

TFWM: Timestamp FIFO Warning Mirror

This bit indicates that ETNBnTIS.TFWF is 1 and ETNBnTIC.TFWE is 1.

[Conditions for Changing]
This bit is updated when ETNBnTIS.TFWF or ETNBnTIC.TFWE changes.

TFUM Timestamp FIFO Update Mirror

This bit indicates that ETNBnTIS.TFUF is 1 and ETNBnTIC.TFUE is 1.

[Conditions for Changing]
This bit is updated ETNBnTIS.TFUF or ETNBnTIC.TFUE changes.

MM: MAC Mirror

This bit indicates that there is a pending interrupt request issued by MAC.

For details about MAC interrupt sources, interrupt enabling and timing refer to **Section 25.4.12.1, Flow of E-MAC Initialization**.

NOTE

The MAC is able to assert interrupt also in CONFIG and STANDBY mode.

EM: Error Mirror

This bit indicates that at least one valid flag in ETNBnEIS is 1 or ETNBnEIS.QFS is 1.

[Conditions for Changing]
This bit is updated when ETNBnEIS or ETNBnEIC changes.

FTM: Frame Transmitted Mirror

[Conditions for Changing]

- This bit is set when any matching pair of ETNBnTIC.FTEt enable and ETNBnTIS.FTFt flag are both 1.
- This bit is set when any matching pair of ETNBnTIC.TDPEt enable and ETNBnTIS.TDPFt flag are both 1.

RWM: Reception Warning Mirror

[Conditions for Changing]
This bit is set when any matching pair of ETNBnRIC1.RWEr enable and ETNBnRIS1.RWFr flag are both 1.

FRM: Frame Received Mirror

[Conditions for Changing]

- This bit is set when any matching pair of ETNBnRIC0.FREr enable and ETNBnRIS0.FRFr flag are both 1.
- This bit is set when any matching pair of ETNBnRIC3.RDPEr enable and ETNBnRIS3.RDPFr flag are both 1.

25.3.2.45 ETNBnCIE — Common Interrupt Enable Register

This register is not available for RH850/U2A.

Access: This register can be read or written in 32-bit units.

Address: <ETNBn_base> + 0384_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	RFFL	RFWL	CL0M	RQFM
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	CTIE	—	—	—	—	—	—	—	CRIE
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R/W	R	R	R	R	R	R	R	R/W

Table 25.55 ETNBnCIE Register Contents

Bit Position	Bit Name	Function
31 to 20	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
19	RFFL	Rx-FIFO Full interrupt Line select 0: Interrupt line A used for this notification 1: Interrupt line B used for this notification
18	RFWL	Rx-FIFO Warning interrupt Line select 0: Interrupt line A used for this notification 1: Interrupt line B used for this notification
17	CL0M	Common Line 0 Mode 0: Use common interrupt line 0 1: Use queue specific interrupt line 0
16	RQFM	Reception Queue Full Mode 0: Use for error interrupt line 1: Use for queue specific interrupt line
15 to 9	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
8	CTIE	Common Transmit Interrupt Enable 0: Disabled 1: Enabled
7 to 1	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
0	CRIE	Common Receive Interrupt Enable 0: Disabled 1: Enabled

RFFL: Rx-FIFO Full interrupt Line select

This bit selects the interrupt line of notification flagged by ETNBnRIS2.RFFF.

It is recommended to disable interrupt before change the line.

RFWL: Rx-FIFO Warning interrupt Line select

This bit selects the interrupt line of notification flagged by ETNBnRIS1.RFWF.

It is recommended to disable interrupt before change the line.

CL0M: Common Line 0 Mode

This bit controls if all data related interrupts using a common interrupt line or if queue specific interrupt lines for data related interrupts are used. The selected mode has no influence to internal flagging in RAVBES SFR (e.g. ETNBnISS).

To prevent interrupt notifications on different lines, it is recommended to set all ETNBnCIE.CTIE and ETNBnCIE.CRIE to 0 when this bit is 1.

RQFM: Reception Queue Full Mode

This bit controls if queue full notification is mapped to error interrupt line or to queue data interrupt line. The selected mode has no influence to internal flagging in RAVBES SFR (e.g. ETNBnISS).

CTIE: Common Transmit Interrupt Enable

This bit controls transmit related interrupt line outputs of RAVBES. It has no influence to internal flagging in RAVBES SFR (e.g. ETNBnISS).

These lines are controlled by this bit:
Line0_Tx[3:0] -- individual transmit queue interrupts

Transmission interrupts mapped on other lines are not influenced.

CRIE: Common Receive Interrupt Enable

This bit controls receive related interrupt line outputs of RAVBES. It has no influence to internal flagging in RAVBES SFR (e.g. ETNBnISS).

These lines are controlled by this bit:
Line0_Rx[17:0] -- individual receive queue interrupts

Receive interrupts mapped on other lines are not influenced.

25.3.2.46 ETNBnRIC3 — Receive Interrupt Control Register 3

Access: This register can be read or written in 32-bit units.

Address: <ETNBn_base> + 0388_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	RDPE 17	RDPE 16
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	RDPE 15	RDPE 14	RDPE 13	RDPE 12	RDPE 11	RDPE 10	RDPE9	RDPE8	RDPE7	RDPE6	RDPE5	RDPE4	RDPE3	RDPE2	RDPE1	RDPE0
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 25.56 ETNBnRIC3 Register Contents

Bit Position	Bit Name	Function
31 to 18	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
17 to 0	RDPEr (r = 17 to 0)	Receive Descriptor Processed Interrupt Enable r 0: Disabled 1: Enabled

RDPEr: Receive Descriptor Processed Interrupt Enable r (r = 0 to 17)

While this bit is 1 an interrupt will be generated when ETNBnRIS3.RDPFr is 1.

[Conditions for Changing]

– This bit is set to 0 when writing 1 to ETNBnRID3.RDPDr.

– This bit is set to 1 when writing 1 to ETNBnRIE3.RDPSr.

25.3.2.47 ETNBnRIS3 — Receive Interrupt Status Register 3

Access: This register can be read or written in 32-bit units.

Address: <ETNBn_base> + $038C_H$

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	RDPF17	RDPF16
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 25.57 ETNBnRIS3 Register Contents (1/2)

Bit Position	Bit Name	Function
30 to 18	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
17	RDPF17	Receive Descriptor Processed Flag 17 (Stream) 0: The interrupt is not pending. 1: The interrupt is pending.
16	RDPF16	Receive Descriptor Processed Flag 16 (Stream) 0: The interrupt is not pending. 1: The interrupt is pending.
15	RDPF15	Receive Descriptor Processed Flag 15 (Stream) 0: The interrupt is not pending. 1: The interrupt is pending.
14	RDPF14	Receive Descriptor Processed Flag 14 (Stream) 0: The interrupt is not pending. 1: The interrupt is pending.
13	RDPF13	Receive Descriptor Processed Flag 13 (Stream) 0: The interrupt is not pending. 1: The interrupt is pending.
12	RDPF12	Receive Descriptor Processed Flag 12 (Stream) 0: The interrupt is not pending. 1: The interrupt is pending.
11	RDPF11	Receive Descriptor Processed Flag 11 (Stream) 0: The interrupt is not pending. 1: The interrupt is pending.
10	RDPF10	Receive Descriptor Processed Flag 10 (Stream) 0: The interrupt is not pending. 1: The interrupt is pending.
9	RDPF9	Receive Descriptor Processed Flag 9(Stream) 0: The interrupt is not pending. 1: The interrupt is pending.
8	RDPF8	Receive Descriptor Processed Flag 8 (Stream) 0: The interrupt is not pending. 1: The interrupt is pending.
7	RDPF7	Receive Descriptor Processed Flag 7 (Stream) 0: The interrupt is not pending. 1: The interrupt is pending.

Table 25.57 ETNBnRIS3 Register Contents (2/2)

Bit Position	Bit Name	Function
6	RDPF6	Receive Descriptor Processed Flag 6 (Stream) 0: The interrupt is not pending. 1: The interrupt is pending.
5	RDPF5	Receive Descriptor Processed Flag 5 (Stream) 0: The interrupt is not pending. 1: The interrupt is pending.
4	RDPF4	Receive Descriptor Processed Flag 4 (Stream) 0: The interrupt is not pending. 1: The interrupt is pending.
3	RDPF3	Receive Descriptor Processed Flag 3 (Stream) 0: The interrupt is not pending. 1: The interrupt is pending.
2	RDPF2	Receive Descriptor Processed Flag 2 (Stream) 0: The interrupt is not pending. 1: The interrupt is pending.
1	RDPF1	Receive Descriptor Processed Flag 1 (Network Control) 0: The interrupt is not pending. 1: The interrupt is pending.
0	RDPF0	Receive Descriptor Processed Flag 0 (Best Effort) 0: The interrupt is not pending. 1: The interrupt is pending.

RDPFr: Receive Descriptor Processed Flag r (r = 0 to 17)

This bit indicates that descriptor in reception queue r has been processed where DESCR.DIE is 0001_B.

Only 0 can be written to the bit.

[Conditions for Changing]

– The bit is set to 0 when the operating mode is not operation mode.

– The bit is set to 1 when the descriptor in reception queue r has been processed where DESCR.DIE is 1.

NOTE

The descriptor with DESCR.DIE is 1, which sets this bit, sets in addition the universal descriptor interrupt ETNBnDIS.DPF1.

25.3.2.48 ETNBnGCCR — gPTP Configuration Control Register

The ETNBnGCCR register is used to set and control the gPTP (generalized precision time protocol).

Access: ETNBnGCCR can be read or written in 32-bit units.
ETNBnGCCRL,ETNBnGCCRH can be read or written in 16-bit units.
ETNBnGCCRLL, ETNBnGCCRLH, ETNBnGCCRHL can be read or written in 8-bit units.

Address: ETNBnGCCR: <ETNBn_base> + 0390_H
ETNBnGCCRL: <ETNBn_base> + 0390_H
ETNBnGCCRLL: <ETNBn_base> + 0390_H

Table 25.58 ETNBnGCCR register contents (1/2)

Bit Position	Bit Name	Function
31 to 23	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
22 to 20	LI[2:0]	Load Index Index number of compare unit to be loaded.
19	SPC	Start Periodic Comparison 0: Absolute comparison value updated by ETNBnGCCR.LPTC request 1: Periodic comparison value updated by ETNBnGCCR.LPTC request
18 to 10	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
9, 8	TCSS[1:0]	Timer Capture Source Select 00_B: gPTP timer value 01_B: Adjusted gPTP timer value 10_B: AVTP presentation time 11_B: No change
7, 6	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
5	LMTT	Maximum Transit Time Configuration Request 0: Setting completed 1: When written: Issue a configuration request. When read: Completion of settings is pending.
4	LPTC	Presentation Time Compare Value Configuration Request 0: Setting completed 1: When written: Issue a configuration request. When read: Completion of settings is pending.
3	LTI	Timer Increment Value Configuration Request 0: Setting completed 1: When written: Issue a configuration request. When read: Completion of settings is pending.

Table 25.58 ETNBnGCCR register contents (2/2)

Bit Position	Bit Name	Function
2	LTO	Timer Offset Value Configuration Request 0: Setting completed 1: When written: Issue a configuration request. When read: Completion of settings is pending.
1, 0	TCR[1:0]	Timer Control Request 00_B: Timer control is not requested. 01_B: gPTP/AVTP presentation time reset 10_B: Continuous capture of AVTP to ETNBnGCTi.CTV 11_B: Captures the value set in the TCSS bit.

LI[2:0]: Load Index bits

These bits define the target unit to be updated by ETNBnGCCR.LPTC.
Writing to these bits is only possible when ETNBnGCCR.LPTC is 0.

SPC: Start periodic Comparison bit

This bit defines if the absolute comparison value or the periodicity value is updated to the value of ETNBnGPTC.PTCV on ETNBnGCCR.LPTC request.

Periodic comparison starts when updating the periodic comparison value; periodic comparison stops when updating the absolute comparison value.

Writing to these bits is only possible when ETNBnGCCR.LPTC is 0.

TCSS[1:0]: Timer Capture Source Selection Bit

These bits select the source used for updating the captured timer register (gPTP timer capture register (ETNBnGCTi.CTV)).

When writing 11_B to these bit, the write to ETNBnGCCR.TCSS is ignored and ETNBnGCCR.TCSS keeps its old value. This allows changing other parts of ETNBnGCCR without effecting an ongoing capture sequence.
Writing 00_B, 01_B, 10_B to these bits is only possible when ETNBnGCCR.TCR is 00_B.

LMTT: Maximum Transit Time Configuration Request Bit

This bit issues requests for configuring the gPTP maximum transit time configuration register (ETNBnGMTT).

Only 1 can be written to the bit.

[Conditions for Changing]

- The bit is set to 0 when the operating mode is not operation and ETNBnCCC.GAC is 0.
- The bit is set to 0 when the value of the gPTP maximum transit time configuration register (ETNBnGMTT) is loaded.

LPTC: Presentation Time Compare Value Configuration Request Bit

This bit issues requests for configuring the gPTP presentation time comparison register (ETNBnGPTC).

Only 1 can be written to the bit.

Writing to this bit is only possible when the current operating mode is configuration mode and ETNBnCCC.GAC is 0.

Do not write 1 to this bit when AVTP FIFO of selected compare unit is in use.

[Conditions for Changing]

– The bit is set to 0 when the operating mode is not operation mode and ETNBnCCC.GAC is 0.
– The bit is set to 0 when the value of the gPTP presentation time comparison register (ETNBnGPTC) is loaded.

LTI: Timer Increment Value Configuration Request Bit

This bit issues requests for configuring the gPTP timer increment configuration register (ETNBnGTI).

Only 1 can be written to the bit.

[Conditions for Changing]

– The bit is set to 0 when the operating mode is not operation mode and ETNBnCCC.GAC is 0.
– The bit is set to 0 when the value of the gPTP timer increment configuration register (ETNBnGTI) is loaded.

LTO: Timer Offset Value Configuration Request Bit

This bit issues requests for configuring gPTP timer offset configuration register i (ETNBnGTOi).

Only 1 can be written to the bit.

[Conditions for Changing]

– The bit is set to 0 when the operating mode is not operation mode and ETNBnCCC.GAC is 0.
– The bit is set to 0 when the value of gPTP timer offset configuration register i (ETNBnGTOi) is loaded.

TCR[1:0]: Timer Control Request Bits

These bits issue requests for controlling the gPTP timer.

The source selection (ETNBnGCCR.TCSS) can be done by same write access.

Writing to the bits is only possible when the current operating mode is operation mode, or when the current operation mode is configuration mode and ETNBnCCC.GAC is 1.

Do not write to the bits when the gPTP timer clock select bit in the AVB-DMAC mode register is 00_B.

Writing to the bits is only possible when ETNBnGCCR.TCR is 00_B or 10_B.

Do not write other values than 11_B to the bits when ETNBnGCCR.TCR is 10_B.

Continuous capture (10_B) can be used only for AVTP presentation time value (ETNBnGCCR.TCSS is 10_B).

[Conditions for Changing]

– The bits are set to 00_B when the operating mode is not operation mode and ETNBnCCC.GAC is 0.
– The bits are set to 00_B on completion of the requested processing.

25.3.2.49 ETNBnRIE0 — Reception Interrupt Enable register 0

Access: This register can be read or written in 32-bit units.

Address: <ETNBn_base> + 0460_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit Position	Bit Name	Function
31	RFWS	Rx-FIFO Warning interrupt Set 0: No change of ETNBnRIC1.RFWE 1: Set ETNBnRIC1.RFWE to 1
30 to 18	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
17 to 0	RWSr	Reception Warning interrupt Set r 0: No change of ETNBnRIC1.RWEr 1: Set ETNBnRIC1.RWEr to 1

RFWS: Rx-FIFO Warning interrupt Set

This bit supports interrupt enable. It controls set of ETNBnRIC1.RFWE.
This bit is always read as 0.

RWSr: Reception Warning interrupt Set r (r = 0 to 17)

This bit supports interrupt enable. It controls set of ETNBnRIC1.RWEr.
This bit is always read as 0.

25.3.2.52 ETNBnRID1 — Reception Interrupt Disable register 1

Access: This register can be read or written in 32-bit units.

Address: <ETNBn_base> + $046C_H$

Value after reset: $0000\ 0000_H$

Table 25.67 ETNBnTIE Register Contents

Bit Position	Bit Name	Function
31 to 20	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
19 to 16	TDPSt (t = 3 to 0)	Transmit Descriptor Processed Interrupt Set t 0: No change of ETNBnTIC.TDPEt 1: Set ETNBnTIC.TDPEt to 1
15 to 12	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
11	MFWS	MAC Status FIFO Warning Interrupt Set 0: No change of ETNBnTIC.MFWE 1: Set ETNBnTIC.MFWE to 1
10	MFUS	MAC Status FIFO Updated Interrupt Set 0: No change of ETNBnTIC.MFUE 1: Set ETNBnTIC.MFUE to 1
9	TFWS	Transtamp FIFO Warning Interrupt Set 0: No change of ETNBnTIC.TFWE 1: Set ETNBnTIC.TFWE to 1
8	TFUS	Transtamp FIFO Updated Interrupt Set 0: No change of ETNBnTIC.TFUE 1: Set ETNBnTIC.TFUE to 1
7 to 4	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
3 to 0	FTSt[3:0] (t = 3 to 0)	Frame Transmitted Interrupt Set t 0: No change of ETNBnTIC.FTEt 1: Set ETNBnTIC.FTEt to 1

TDPSt: Transmit Descriptor Processed interrupt Set t (t = 0 to 3)

This bit supports interrupt enable. It controls set of ETNBnTIC.TDPEt.

This bit is always read as 0.

MFWS: MAC status FIFO Warning interrupt Set

This bit supports interrupt enable. It controls set of ETNBnTIC.MFWE.

This bit is always read as 0.

MFUS: MAC status FIFO Updated interrupt Set

This bit supports interrupt enable. It controls set of ETNBnTIC.MFUE.

This bit is always read as 0.

TFWS: Timestamp FIFO Warning interrupt Set

This bit supports interrupt enable. It controls set of ETNBnTIC.TFWE.

This bit is always read as 0.

TFUS: Timestamp FIFO Updated interrupt Set

This bit supports interrupt enable. It controls set of ETNBnTIC.TFUE.

This bit is always read as 0.

FTSt: Frame Transmitted interrupt Set t (t = 0 to 3)

This bit supports interrupt enable. It controls set of ETNBnTIC.FTEt.

This bit is always read as 0.

25.3.2.58 ETNBnTID — Transmission Interrupt Disable Register

Access: This register can be read or written in 32-bit units.

Address: <ETNBn_base> + $047C_H$

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 25.68 ETNBnTID Register Contents

Bit Position	Bit Name	Function
31 to 20	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
19 to 16	TDPDt (t = 3 to 0)	Transmit Descriptor Processed interrupt Disable t 0: No change of ETNBnTIC.TDPEt 1: Set ETNBnTIC.TDPEt to 0
15 to 12	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
11	MFWD	MAC status FIFO Warning interrupt Disable 0: No change of ETNBnTIC.MFWE 1: Set ETNBnTIC.MFWE to 0
10	MFUD	MAC status FIFO Updated interrupt Disable 0: No change of ETNBnTIC.MFUE 1: Set ETNBnTIC.MFUE to 0
9	TFWD	Timestamp FIFO Warning interrupt Disable 0: No change of ETNBnTIC.TFWE 1: Set ETNBnTIC.TFWE to 0
8	TFUD	Timestamp FIFO Updated interrupt Disable 0: No change of ETNBnTIC.TFUE 1: Set ETNBnTIC.TFUE to 0
7 to 4	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
3 to 0	FTDt (t = 3 to 0)	Frame Transmitted interrupt Disable t 0: No change of TIC.FTEt 1: Set ETNBnTIC.FTEt to 0

TDPDt: Transmit Descriptor Processed interrupt Disable t (t = 0 to 3)

This bit supports interrupt enable. It controls set of ETNBnTIC.TDPEt.

This bit is always read as 0.

MFWD: MAC status FIFO Warning interrupt Disable

This bit supports interrupt enable. It controls set of ETNBnTIC.MFWE.

This bit is always read as 0.

MFUD: MAC status FIFO Updated interrupt Disable

This bit supports interrupt enable. It controls set of ETNBnTIC.MFUE.

This bit is always read as 0.

TFWD: Timestamp FIFO Warning interrupt Disable

This bit supports interrupt enable. It controls set of ETNBnTIC.TFWE.

This bit is always read as 0.

TFUD: Timestamp FIFO Updated interrupt Disable

This bit supports interrupt enable. It controls set of ETNBnTIC.TFUE.

This bit is always read as 0.

FTDt: Frame Transmitted interrupt Disable t (t = 0 to 3)

This bit supports interrupt enable. It controls set of ETNBnTIC.FTEt.

This bit is always read as 0.

25.3.2.59 ETNBnGMTT — gPTP Maximum Transit Time Configuration Register

The ETNBnGMTT register sets the maximum time for transitions of the gPTP timer.

Access: This register can be read or written in 32-bit units.

Address: <ETNBn_base> + 0394_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	MTTV[31:16]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 25.69 ETNBnGMTT register contents

Bit Position	Bit Name	Function
31 to 0	MTTV[31:0]	Maximum Transit Time The maximum transition time for addition to the presentation time

MTTV[31:0]: Maximum Transit Time Bits

These bits set the maximum transition time for use in calculating AVTP presentation times.

Write the desired setting to the bits, then issue the configuration request by setting the maximum transit time configuration request bit in the gPTP configuration control register (ETNBnGCCR.LMTT) to 1.

CAUTION

Do not write a value to these bits when the operating mode is operation mode and the maximum transit time configuration request bit (ETNBnGCCR.LMTT) is 1.

Do not write a value to these bits when the gPTP Active in Config bit (ETNBnCCC.GAC) is 1 and the maximum transit time configuration request bit (ETNBnGCCR.LMTT) is 1.

25.3.2.60 ETNBnGPTC — gPTP Presentation Time Comparison Register

The ETNBnGPTC register sets a value for comparison with presentation times in the gPTP timer.

Access: This register can be read or written in 32-bit units.

Address: <ETNBn_base> + 0398_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	PTCV[31:16]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Table 25.70 ETNBnGPTC register contents

Bit Position	Bit Name	Function
31 to 0	PTCV[31:0]	Presentation Time Comparison Value Value for comparison with the gPTP presentation times

PTCV[31:0]: Presentation Time Comparison Value Bits

These bits set a value for comparison with AVTP timer values to which a maximum transit time is not appended.

Write the desired setting to the bits, then issue the configuration request by setting the presentation time comparison value configuration request bit in the gPTP configuration control register (ETNBnGCCR.LPTC) to 1.

CAUTION

Do not write a value to these bits when the presentation time comparison value configuration request bit (ETNBnGCCR.LPTC) is 1. Do not write the range of 0 to 3FFF FFFF$_H$ to the bits when they are defining the period value of AVTP comparison unit (controlled by ETNBnGCCR.SPC).

25.3.2.61 ETNBnGTI — gPTP Timer Increment Configuration Register

The ETNBnGTI register sets the increment for the gPTP timer.

Access: This register can be read or written in 32-bit units.

Address: <ETNBn_base> + $039C_H$

Value after reset: $0000\ 0001_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	TIV[27:16]											
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TIV[15:0]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 25.71 ETNBnGTI register contents

Bit Position	Bit Name	Function
31 to 28	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
27 to 0	TIV[27:0]	gPTP Timer Increment Value Increment for the gPTP timer

TIV[27:0]: Bits (gPTP Timer Increment Value)

When the gPTP clock select bits in the AVB-DMAV mode register (ETNBnCCC.CSEL) are selecting a clock signal, these bits set the value by which the timer is incremented each time a cycle of that clock signal elapses.

Write the desired setting to the bits, then issue the configuration request by setting the timer increment value configuration request bit in the gPTP configuration control register (ETNBnGCCR.LTI) to 1.

CAUTIONS

1. **Do not write a value to these bits when the operating mode is operation mode and the timer increment value configuration request bit (ETNBnGCCR.LTI) is 1. Do not write 0 to the bits.**
2. **Do not write a value to these bits when the gPTP active in config bit (ETNBnCCC.GAC) is 1 and the timer increment value configuration request bit (ETNBnGCCR.LTI) is 1.**
3. **Do not program increment values less than $0010\ 0000_H$ (For calculation, refer to Section 25.4.5.1, Transmission Modes).**

25.3.2.62 ETNBnGTOi — gPTP Timer Offset Configuration Register i (i = 0 to 2)

The ETNBnGTOi register sets an offset value for the gPTP timer.

The offset value is added to the combination of bits 0 to 31 in ETNBnGTO0, 32 to 63 in ETNBnGTO1, and 64 to 79 in ETNBnGTO2, which together make up the gPTP timer.

Access: This register can be read or written in 32-bit units.

Address: ETNBnGTO0: <ETNBn_base> + $03A0_H$
ETNBnGTO1: <ETNBn_base> + $03A4_H$
ETNBnGTO2: <ETNBn_base> + $03A8_H$

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	TOV[31 + 32 × i:16 + 32 × i]*1															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TOV[15 + 32 × i:0 + 32 × i]*1															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Note 1. ETNBnGTO2 register corresponds to TOV[79:64] only and bits from 16 to 31 are reserved bits.

Table 25.72 ETNBnGTOi register contents

Bit Position	Bit Name	Function
31 to 0	TOV[95:0]	Timer Offset Value Offset value for the gPTP timer

TOV[79:0]: Timer Offset Value Bits

This is an 80-bit value consisting of the settings in ETNBnGTO0.TOV[31:0], ETNBnGTO1.TOV[63:32], and ETNBnGTO2.TOV[79:64], and is used to set an offset for adding to the value of the gPTP timer.

Write the desired setting to the bits, then issue the configuration request by setting the timer offset value configuration request bit in the gPTP configuration control register (ETNBnGCCR.LTO) to 1.

CAUTIONS

1. **Do not write a value to these bits when the operating mode is operation mode and the timer offset value configuration request bit (ETNBnGCCR.LTO) is 1.**
2. **Write 0000_H to ETNBnGTO2.TOV[95:80].**
3. **Set a value in the range from 0 to 10^9-1 ($0000\ 0000_H$ to $3B9A\ C9FF_H$) in ETNBnGTO0.TOV[31:0].**
4. **Do not write to these bits when ETNBnGCCR.LTO is 1 while ETNBnCCC.GAC is 1.**

25.3.2.63 ETNBnGIC — gPTP Interrupt Control Register

The ETNBnGIC register is used to control gPTP-related interrupts.

Access: This register can be read or written in 32-bit units.

Address: <ETNBn_base> + $03AC_H$

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

R/W	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R

Table 25.73 ETNBnGIC register contents

Bit Position	Bit Name	Function
31 to 10	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
9	PTME7	Presentation Time Match Interrupt Enable 7 0: Disabled 1: Enabled
8	PTME6	Presentation Time Match Interrupt Enable 6 0: Disabled 1: Enabled
7	PTME5	Presentation Time Match Interrupt Enable 5 0: Disabled 1: Enabled
6	PTME4	Presentation Time Match Interrupt Enable 4 0: Disabled 1: Enabled
5	PTME3	Presentation Time Match Interrupt Enable 3 0: Disabled 1: Enabled
4	PTME2	Presentation Time Match Interrupt Enable 2 0: Disabled 1: Enabled
3	PTME1	Presentation Time Match Interrupt Enable 1 0: Disabled 1: Enabled
2	PTME0	Presentation Time Match Interrupt Enable 0 0: Disabled 1: Enabled
1, 0	Reserved	When read, the value after reset is returned. When writing, write the value after reset.

PTMEi (i = 0 to 7) Presentation Time Match Interrupt Enable Bit

When this bit is 1, setting of the presentation time match interrupt flag in the gPTP interrupt status register (ETNBnGIS.PTMFi) to 1 leads to generation of that interrupt.

25.3.2.64 ETNBnGIS — gPTP Interrupt Status Register

The ETNBnGIS register indicates the state of the gPTP-related interrupt.

Access: This register can be read or written in 32-bit units.

Address: <ETNBn_base> + $03B0_H$

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R

Table 25.74 ETNBnGIS register contents

Bit Position	Bit Name	Function
31 to 10	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
9	PTMF7	Presentation Time Match Interrupt Flag 7 0: The interrupt is not pending. 1: The interrupt is pending.
8	PTMF6	Presentation Time Match Interrupt Flag 6 0: The interrupt is not pending. 1: The interrupt is pending.
7	PTMF5	Presentation Time Match Interrupt Flag 5 0: The interrupt is not pending. 1: The interrupt is pending.
6	PTMF4	Presentation Time Match Interrupt Flag 4 0: The interrupt is not pending. 1: The interrupt is pending.
5	PTMF3	Presentation Time Match Interrupt Flag 3 0: The interrupt is not pending. 1: The interrupt is pending.
4	PTMF2	Presentation Time Match Interrupt Flag 2 0: The interrupt is not pending. 1: The interrupt is pending.
3	PTMF1	Presentation Time Match Interrupt Flag 1 0: The interrupt is not pending. 1: The interrupt is pending.
2	PTMF0	Presentation Time Match Interrupt Flag 0 0: The interrupt is not pending. 1: The interrupt is pending.
1, 0	Reserved	When read, the value after reset is returned. When writing, write the value after reset.

PTMFi (i = 0 to 7) Presentation Time Match Interrupt Flag Bit

This bit indicates that the AVTP timer value has matched the configured comparison value of AVTP comparator i. Only 0 can be written to the bit.

[Conditions for Changing]

– This bit is set to 0 when the current operating mode changes from operation mode and ETNBnCCC.GAC is 0.
– This bit is set to 1 when the AVTP timer value reaches or exceeds the comparison value of AVTP comparator i.

25.3.2.65 ETNBnGCTi — gPTP Timer Capture Register i (i = 0 to 2)

The ETNBnGCTi registers form an 80-bit register that captures the gPTP timer value.

Access: This register can be read or written in 32-bit units.

Address: ETNBnGCT0: <ETNBn_base> + $03B8_H$
ETNBnGCT1: <ETNBn_base> + $03BC_H$
ETNBnGCT2: <ETNBn_base> + $03C0_H$

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	CTV[31 + 32 × i:16 + 32 × i]*1															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	CTV[15 + 32 × i:0 + 32 × i]*1															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Note 1. ETNBnGCT2 register corresponds to CTV[79:64] only and bits from 16 to 31 are reserved bits.

Table 25.75 ETNBnGCTi register contents

Bit Position	Bit Name	Function
31 to 0	CTV[95:0]	gPTP Timer Capture Value Captured timer value

CTV[79:0]: gPTP Timer Capture Value Bits

These 80 bits consist of ETNBnGCT0.CTV[31:0], ETNBnGCT1.CTV[63:32] and ETNBnGCT2.CTV[79:64], which together indicate captured timer values.

When 00_B (value of the gPTP timer) or 01_B (adjusted gPTP timer value) is selected by the timer capture source select bits in the gPTP configuration control register (ETNBnGCCR.TCSS), the corresponding 80-bit values are stored in these bits.

When 10_B (AVTP presentation time) is selected by the timer capture source select bits (ETNBnGCCR.TCSS), the corresponding 32-bit values are stored in these bits (ETNBnGCT0.CTV[31:0]).

In case of continuous update (ETNBnGCCR.TCR is 10_B) CPU should only use 32-bit read access to get consistent value.

Do not read the value while the value of the timer control request bits (ETNBnGCCR.TCR) is 11_B because this indicates that storage is still in progress.

[Condition for Changing]
These bits are updated to the selected timer value with the capture request has been processed.

CAUTION

Write 0000_H to ETNBnGCT2.CTV[95:80].

25.3.2.66 ETNBnGSR — gPTP Status Register

The ETNBnGSR register indicates the status of the gPTP.

Access: This register is a read-only register that can be read in 32-bit units.

Address: <ETNBn_base> + $03C4_H$

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit Position	Bit Name	Function
3	PCM3	Periodic Comparison Mode 3 0: Single shot comparison 1: Periodic comparison
2	PCM2	Periodic Comparison Mode 2 0: Single shot comparison 1: Periodic comparison
1	PCM1	Periodic Comparison Mode 1 0: Single shot comparison 1: Periodic comparison
0	PCM0	Periodic Comparison Mode 0 0: Single shot comparison 1: Periodic comparison

AFUi (i = 0 to 3): AVTP FIFO Update Bit

This bit indicates an ongoing update of the AVTP-FIFO of compare unit i. When this bit is 0, the AVTP-FIFO is able to process adding new values.

[Clearing conditions]

- The current operating mode changes from operation mode and ETNBnCCC.GAC is 0.
- AVTP compare value is added to the AVTP-FIFO.

[Setting condition]

- CPU writes a new value to ETNBnGPTFi.PTFV and ETNBnGSR.AFFLi is not 15.

AFFLi[3:0] (i = 0 to 3): AVTP FIFO Fill Level Bits

These bits indicate the number of AVTP timestamps pending in AVTP-FIFO of compare unit i. The timestamps are provided by CPU and taken by compare unit when no comparison on AVTP comparator i is active.

[Clearing conditions]

- The current operating mode changes from operation mode and ETNBnCCC.GAC is 0.
- AVTP compare value is added to the AVTP-FIFO.

[Conditions for Updating]

- This value is incremented when a new value is added to AVTP-FIFO (ETNBnGSR.AFUi changes to 0).
- This value is decremented when a timestamp value from FIFO has been loaded to the AVTP comparator.

PCMi (i = 0 to 7): Periodic Comparison Mode Bit

This bit indicates if single shot or periodic comparison mode is active on AVTP comparator unit i.

[Clearing conditions]

- The current operating mode changes from operation mode and ETNBnCCC.GAC is 0.
- The last match has happen after CPU has requested entering single shot mode.

[Setting condition]

- A period value for the AVTP comparator is loaded.

25.3.2.67 ETNBnGPTFi — gPTP Presentation Time FIFO Register i (i = 0 to 3)

The ETNBnGPTFi register is used to control the gPTP FIFO.

Access: This register can be read or written in 32-bit units.

Address: ETNBnGPTF0: <ETNBn_base> + $03E0_H$
ETNBnGPTF1: <ETNBn_base> + $03E4_H$
ETNBnGPTF2: <ETNBn_base> + $03E8_H$
ETNBnGPTF3: <ETNBn_base> + $03EC_H$

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	PTFV[31:16]

Table 25.77 ETNBnGPTFi Register Contents

Bit Position	Bit Name	Function
31 to 0	PTFV[31:0]	Presentation Time FIFO Value

PTFV[31:0]: Presentation Time FIFO Value Bits

These bits define a value to be compared with the AVTP timer value (without Max Transit Time added). When writing to this register the value is added to AVTP-FIFO of comparator unit i.
These bits are always read as 0.
The CPU cannot write to these bits if the current operating mode is configuration mode and ETNBnCCC.GAC is 0.

The CPU should not write to these bits when ETNBnGSR.PCMi is 1.
The CPU should not write to these bits when ETNBnGSR.AFUi is 1.
The CPU should not write to these bits when ETNBnGSR.AFFLi is 15.

25.3.2.68 ETNBnECMR — E-MAC Mode Register

ETNBnECMR is used to specify the operating mode of the E-MAC. The settings in this register are normally made in the initialization process following a reset.

The operating mode settings must not be changed while the transmission and reception functions are enabled (i.e. while the RE or TE bit in this register is 1).

Access: This register can be read or written in 32-bit units.

Address: <ETNBn_base> + 0500_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 25.78 ETNBnECMR Register Contents (1/2)

Bit Position	Bit Name	Function
31 to 27	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
26	TRCCM	Counter Clear Mode 0: Writing to the counter register leads to the register being cleared to 0. 1: Reading from the counter register leads to the register being cleared to 0.
25, 24	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
23	RCSC	Checksum Calculation 0: Checksums are not automatically calculated. 1: Checksums are automatically calculated.
22	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
21	DPAD	Data Padding 0: Padding to make up 60 bytes is inserted in data for transmission when fewer than 60 bytes are to be transmitted. 1: Padding is not inserted in data for transmission when fewer than 60 bytes are to be transmitted and the data are transmitted without being changed.
20	RZPF	PAUSE Frame Reception with Time = 0 0: Reception of PAUSE frames with the TIME parameter value 0 is disabled. 1: Reception of PAUSE frames with the TIME parameter value 0 is enabled.
19	ZPF	PAUSE Frame Usage with TIME = 0 Enable • PAUSE frame usage with TIME = 0 enable (in full-duplex mode) 0: Control in response to and for the sending of PAUSE frames with the TIME parameter value 0 is disabled. 1: Control in response to and for the sending of PAUSE frames with the TIME parameter value is 0 is enabled.
18	PFR	PAUSE Frame Receive Mode 0: PAUSE frames are not transferred to the AVB-DMAC. 1: PAUSE frames are transferred to the AVB-DMAC.

Table 25.78 ETNBnECMR Register Contents (2/2)

Bit Position	Bit Name	Function
17	RXF	Reception Flow Control Operation Mode 0: Flow control for the receiving port (reception of PAUSE frame) is disabled. 1: Flow control for the receiving port (reception of PAUSE frame) is enabled.
16	TXF	Transmission Flow Control Operation Mode 0: Flow control for the transmitting port is disabled (PAUSE frames are not automatically transmitted). 1: Flow control for the transmitting port is enabled (PAUSE frames are automatically transmitted as required).
15 to 10	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
9	MPDE	Magic Packet™ Detection Enable 0: Magic Packet™ detection is not enabled. 1: Magic Packet™ detection is enabled.
8, 7	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
6	RE	Reception Enable 0: Reception is disabled. 1: Reception is enabled.
5	TE	Transmission Enable 0: Transmission is disabled. 1: Transmission is enabled.
4 to 2	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
1	DM	Mode selection 0: Half-duplex mode 1: Full-duplex mode Setting this bit to 0 is prohibited
0	PRM	Promiscuous Mode 0: Normal operation 1: Promiscuous mode operation

TRCCM: Counter Clear Mode Bit

This bit sets the method for clearing the counter register. Refer to the descriptions of the counter registers.

RCSC: Checksum Calculation Bit

Setting this bit to 1 enables automatic calculation of checksums for the data field in received frames.

Only the data field of an Ethernet frame is in the scope of checksum calculation. Specifically, the checksum is calculated from the data field, which follows the length/type field and is followed by the CRC field. Calculation only involves 16-bit addition; it does not involve bit inversion.

DPAD: Data Padding Control Bit

This bit specifies padding or non-padding of data when less than 60 bytes are to be transmitted.

When this bit is set to 1, data are transmitted without padding; when it is set to 0, data are padded to make up 60-byte units for transmission.

RZPF: PAUSE Frame Reception with Time = 0 Bit

This bit is set to 0, received PAUSE frames with the Timer value 0 are discarded.

This bit is set to 1, release from the transmission wait state follows reception of a PAUSE frame with the Timer value 0.

ZPF: PAUSE Frame Usage with TIME = 0 Enable

- PAUSE frame usage with TIME = 0 enable (In full-duplex mode)

When this bit is set to 0, the next frame to be transmitted is not transmitted until the time specified by the Timer value has elapsed.

Received PAUSE frames with the Timer value 0 are discarded.

When this bit is set to “1”, if the amount of data in the reception FIFO becomes less than the setting of the receive FIFO warning level bits in the receive configuration register (ETNBnRCR.RFCL) before the time specified by the Timer value elapses, a PAUSE frame with a Timer value of 0 is automatically transmitted. If the interface is in the transmission wait state, it is released from that state on receiving a PAUSE frame with a Timer value of 0.

PFR: PAUSE Frame Receive Mode Bit

This bit specifies whether PAUSE frames are transferred to the AVB-DMAC.

RXF: Operating Mode for Flow Control in Reception Bit

This bit is set to 1 and a PAUSE frame is received, a next frame to be transmitted is not transmitted until the time indicated by the Timer value in the PAUSE frame has elapsed. However, the transmission of a current frame is continued. The number of received PAUSE frames is also counted. For details, see **Section 25.3.2.77, ETNBnPFRCR — PAUSE Frame Receive Counter**.

Setting this bit to 0 disables PAUSE frame detection.

TXF: Operating Mode for Flow Control in Transmission Bit

This bit enables or disables flow control in transmission.

Setting this bit to 0 disables PAUSE frame detection.

MPDE: Magic Packet™ Detection Enable Bit

Then MPDE bit enables or disables Magic Packet™ detection by hardware to allow activation via the Ethernet connection.

RE: Reception Enable Bit

When this bit is switched from the receive function enabled (RE = 1) to the receive function disabled (RE = 0), and if there is a frame is being received, the receive function remains enabled until the reception of the frame finishes.

TE: Transmission Enable Bit

When this bit is switched from the transmit function enabled (TE = 1) to the transmit function disabled (TE = 0), and if there is a frame being transmitted, the transmit function remains enabled until the transmission of the frame finishes.

DM: Duplex Mode Bit

This bit selects full- or half-duplex operation.

PRM: Promiscuous Mode Bit

This bit enables all Ethernet frames to be received. All Ethernet frames means all receivable frames, irrespective of differences or enabled/disabled status (destination address, broadcast address, multicast bit, etc.).

25.3.2.69 ETNBnRFLR — Receive Frame Length Register

The ETNBnRFLR register specifies the maximum length (in bytes) of frames that can be received by this LSI.

This register must not be changed while reception is enabled (while the reception enable bit (ETNBnECMR.RE) in the E-MAC mode register is set to “1”).

Access: This register can be read or written in 32-bit units.

Address: <ETNBn_base> + 0508_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	RFL[17:16]	
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 25.79 ETNBnRFLR Register Contents

Bit Position	Bit Name	Function
31 to 18	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
17 to 0	RFL[17:0]	Receive Frame Length Setting value Check value 00000_H: 1,518 bytes : : $005EE_H$: 1,518 bytes $005EF_H$: 1,519 bytes $005F0_H$: 1,520 bytes : : $1FFFF_H$: 131,071 bytes 20000_H: 131,072 bytes : : $3FFFF_H$: 131,072 bytes

RFL[17:0]: Receive Frame Length Bits

Frame data described here refers to all fields from the destination address up to the CRC data. Frame contents from the destination address up to the data are actually transferred to memory. CRC data are not included in the transfer. When more data than the specified number of bytes are received, the portion of data that exceeds the specified value is discarded.

CAUTIONS

The prepared descriptor data size is just the specified value (ETNBnRFLR.RFL[17:0]). Therefore descriptor data size must be more than ETNBnRFLR.RFL[17:0] if you will receive such the Too-Long Frame.

25.3.2.70 ETNBnECSR — E-MAC Status Register

The ETNBnECSR register indicates the state of the E-MAC. The CPU can be notified of the state. For bits that generate an interrupt, the interrupt can be enabled or disabled by the corresponding bit in the E-MAC Interrupt Permission Register (ETNBnECSIPR) described in **Section 25.3.2.71, ETNBnECSIPR — E-MAC Interrupt Permission Register**.

Access: This register can be read or written in 32-bit units.

Address: <ETNBn_base> + 0510_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	—	—	—	—	—	—	—	—	—	—	—	—	PHYI	LCHNG	MPD	ICD
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W

Table 25.80 ETNBnECSR Register Contents

Bit Position	Bit Name	Function
31 to 4	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
3	PHYI	PHY interrupt terminal state bit 0: PHY interrupt terminal (AVB_PHY_INT) is not asserted. 1: PHY interrupt terminal (AVB_PHY_INT) is asserted.
2	LCHNG	Link signal change bit 0: Change of Link status signal (AVB_LINK) is not detected. 1: Change of Link status signal (AVB_LINK) is detected.
1	MPD	Magic Packet™ Detection 0: Magic Packet™ has not been detected. 1: Magic Packet™ has been detected.
0	ICD	Illegal Carrier Detection 0: PHY-LSI has not detected an illegal carrier on the line. 1: PHY-LSI has detected an illegal carrier on the line.

PHYI: PHY Interrupt Pin State Bit

This bit indicates the PHY interrupt pin (AVB_PHY_INT), which is input from the PHY-LSI.

LCHNG: Link Signal Change Bit

This bit indicates a transition of the link status signal (AVB_LINK) input from the PHY-LSI from high to low or low to high.

However, signal changes may also be detected at times when the link status signal (AVB_LINK) function is selected.

To check the current link state, refer to the link status pin state bit in the PHY status register (ETNBnPLSR.LINK).

Writing 1 to this bit clears it to 0.

MPD: Magic Packet™ Detection Bit

This bit indicates that a Magic Packet™ has been detected on the line.

Writing 1 to this bit clears it to 0.

ICD: Illegal Carrier Detection Bit

This bit indicates that the PHY-LSI has detected an illegal carrier on the line. If a change in the signal input from the PHY-LSI occurs in a period shorter than the software recognition period, the correct information may not be obtained. Refer to the timing specification for the PHY-LSI used.

Writing 1 to this bit clears it to 0.

25.3.2.71 ETNBnECSIPR — E-MAC Interrupt Permission Register

The ETNBnECSIPR register instructs permission of interrupt sources reported by the ETNBnECSR register. The bits can permit interrupts corresponding to the ETNBnECSR bits.

Access: This register can be read or written in 32-bit units.

Address: <ETNBn_base> + 0518_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	PHYIM	LINKIM	MPDIP	ICDIP
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W

Table 25.81 ETNBnECSIPR Register Contents

Bit Position	Bit Name	Function
31 to 4	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
3	PHYIM	PHY Interrupt Mask 0: Interrupts by the PHYI setting prohibited. 1: Interrupts by the PHYI setting permitted.
2	LINKIM	LINK Interrupt Mask 0: Interrupts by the LINKI setting prohibited. 1: Interrupts by the LINKI setting permitted.
1	MPDIP	Magic Packet™ Detect Interrupt Enable 0: Interrupts on setting of the MPD bit is disabled. 1: Interrupts on setting of the MPD bit is enabled.
0	ICDIP	False Carrier Detect Interrupt Enable 0: Interrupts by the ICD bit setting prohibited. 1: Interrupt by the ICD bit setting permitted.

PHYIM: PHY Interrupt Mask Bit

When this bit is set to “1”, an interrupt occurs.

LINKIM: Link Signal Change Interrupt Enable Bit

When this bit is set to “1” and the link signal change bit (ETNBnECSR.LCHNG) in the E-MAC status register is set to “1”, an interrupt occurs.

MPDIP: Magic Packet™ Detect Interrupt Enable Bit

Setting this bit to 1 selects interrupt generation on setting of the Magic Packet™ detection bit (ETNBnECSR.MPD) in the E-MAC status register to 1.

ICDIP: Illegal Carrier Detect Interrupt Enable Bit

Setting this bit to 1 selects interrupt generation on setting of the illegal carrier detection bit (ETNBnECSR.ICD) in the E-MAC status register to 1.

25.3.2.72 ETNBnPIR — PHY Interface Register

The ETNBnPIR register provides a means of access to the PHY-LSI internal registers via the MII.

Access: This register can be read or written in 32-bit units.

Address: <ETNBn_base> + 0520_H

Value after reset: 0000 $000X_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W

Table 25.82 ETNBnPIR Register Contents

Bit Position	Bit Name	Function
31 to 4	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
3	MDI	MII Management Data-In Indicates the level of the ETNBnMDIO pin.
2	MDO	MII Management Data-Out Stores data to output from the ETNBnMDIO pin.
1	MMD	MII Management Mode 0: Read direction is specified. 1: Write direction is specified.
0	MDC	MII Management Data Clock The value set in this bit is output from the ETNBnMDC pin, which supplies the management data clock for the MII.

MDI: MII Management Data-In Bit

This bit indicates the level of the ETNBnMDIO pin.

MDO: MII Management Data-Out Bit

This bit stores data to output from the ETNBnMDIO pin.

The ETNBnMDIO pin outputs data when the MMD bit is set to 1 (to specify writing as the direction). Data are not output while the MMD bit is set to 0 (to specify reading as the direction).

MMD: MII Management Mode Bit

This bit specifies the direction for data through MDIO (reading or writing).

MDC: MII Management Data Clock Bit

Values set in this bit are output on the ETNBnMDC pin to supply the MII with the management data clock. For the method of access to the MII registers, see **Section 25.4.13, Connection to PHY-LSI**.

25.3.2.73 ETNBnPLSR — PHY LINK Status Register

The ETNBnPLSR register is used to check the status of PHY LINK pins.

Access: This register is a read-only register that can be read in 32-bit units.

Address: <ETNBn_base> + 0528_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	LINK
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 25.83 ETNBnPLSR Register Contents

Bit Position	Bit Name	Function
31 to 1	Reserved	When read, the value after reset is returned.
0	LINK	When read, this bit returns the state of the ETNBnLINKSTA pin.

25.3.2.74 ETNBnAPFTP — Auto PAUSE Frame Time Parameter Register

The ETNBnAPFTP register is used to set the value for the TIME parameter of automatically generated PAUSE frame.

When a PAUSE frame is automatically transmitted, the value set in this register is used as its TIME parameter.

Access: This register can be read or written in 32-bit units.

Address: <ETNBn_base> + 0554_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	APFTP[15:0]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 25.84 ETNBnAPFTP Register Contents

Bit Position	Bit Name	Function
31 to 16	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
15 to 0	APFTP[15:0]	Automatic PAUSE Frame Time Parameter Set a time parameter value of the Automatic PAUSE Frame.*1*2 0000_H: Setting prohibited 0001_H: 1 × 512 bit-period 0002_H: 2 × 512 bit-period : : $FFFF_H$: 65535 × 512 bit-period

Note 1. The bit-period changes relative to the transfer speed.
100 Mbps: 1 bit-period = 10ns
10 Mbps: 1 bit-period = 100ns

Note 2. When setting the Transmission flow control operation mode bit (ETNBnECMR.TXF) in the E-MAC mode register to “1”, set this register value other than $0000\ 0000_H$.

APFTP[15:0]: Auto Pause Frame Time Parameter

These bit configure the time parameter value for the transmit of Auto Pause Frame.

The unit of the setting value is 512 bit-period.

25.3.2.75 ETNBnMPR — Manual PAUSE Frame Register

The ETNBnMPR register is used to set the value for the TIME parameter of manually generated PAUSE frames. When a PAUSE frame is manually transmitted, the value set in this register is used as its TIME parameter.

Access: This register can be read or written in 32-bit units.

Address: <ETNBn_base> + 0558_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	MP[15:0]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 25.85 ETNBnMPR Register Contents

Bit Position	Bit Name	Function
31 to 16	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
15 to 0	MP[15:0]	Manual PAUSE These bits set the TIME parameter value of a manual PAUSE frame.*1 0000_H: Setting prohibited 0001_H: 1 × 512 bit-period 0002_H: 2 × 512 bit-period :: $FFFF_H$: 65535 × 512 bit-period

Note 1. The bit-period changes relative to the transfer speed.
100 Mbps: 1 bit-period = 10ns
10 Mbps: 1 bit-period = 100ns

MP[15:0]: Manual PAUSE Bits

These bits set the value of the TIME parameter in manually generated PAUSE frames.

The unit for the setting is 512 bit periods.

25.3.2.76 ETNBnPFTCR — PAUSE Frame Transmit Counter

The ETNBnPFTCR register is a counter that indicates the number of times PAUSE frames have been transmitted.

Access: This register is a read-only register that can be read in 32-bit units.

Address: <ETNBn_base> + $055C_H$

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 25.86 ETNBnPFTCR Register Contents

Bit Position	Bit Name	Function
31 to 16	Reserved	When read, the value after reset is returned.
15 to 0	PFTXC[15:0]	PAUSE Frame Transmit Counter These bits indicates the number of transmitted PAUSE frames.

PFTXC[15:0]: PAUSE Frame Transmit Counter Bits

These bits indicate the total number of PAUSE frames that have been transmitted (both manually and automatically).

The bits are cleared to 0 when they are read.

If counting up and clearing of the counter coincide, clearing the counter takes priority.

25.3.2.77 ETNBnPFRCR — PAUSE Frame Receive Counter

The ETNBnPFRCR register is a counter that indicates the number of times PAUSE frames have been received.

Access: This register is a read-only register that can be read in 32-bit units.

Address: <ETNBn_base> + 0560_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 25.87 ETNBnPFRCR Register Contents

Bit Position	Bit Name	Function
31 to 16	Reserved	When read, the value after reset is returned.
15 to 0	PFRXC[15:0]	PAUSE Frame Receive Counter Counter for counting the number of received PAUSE frames

PFRXC[15:0]: PAUSE Frame Receive Counter Bits

These bits indicate the number of PAUSE frames that have been received when flow control in reception is enabled (the RXF bit in ETNBnECMR = 1).

The bits are cleared to 0 when they are read.

If counting up and clearing the counter coincide, clearing the counter takes priority.

25.3.2.78 ETNBnMAHR — MAC Address High Register

The ETNBnMAHR register specifies the 32 higher-order bits of the 48-bit MAC address. The settings in this register are normally made in the initialization process after a reset.

This register must not be changed while transmission or reception is enabled (E-MAC mode register reception enable bit (ETNBnECMR.RE) is set to “1” or transmission enable bit (ETNBnECMR.TE) is set to “1”).

Access: This register can be read or written in 32-bit units.

Address: <ETNBn_base> + $05C0_H$

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	MA[47:32]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 25.88 ETNBnMAHR Register Contents

Bit Position	Bit Name	Function
31 to 0	MA[47:16]	MAC Address Bits 47 to 16 These bits are used to set the 32 higher-order bits of the MAC address.

MA[47:16]: MAC Address Bits 47 to 16

These bits are used to set the 32 higher-order bits of the MAC address.

For example, if the MAC address is 01-23-45-67-89-AB (hexadecimal), set $0123\ 4567_H$ in the this register.

25.3.2.79 ETNBnMALR — MAC Address Low Register

The ETNBnMALR register specifies the 16 lower-order bits of the 48-bit MAC address. The settings in this register are normally made in the initialization process after a reset.

This register must not be changed while transmission or reception is enabled (E-MAC mode register reception enable bit (ETNBnECMR.RE) is set to “1” or transmission enable bit (ETNBnECMR.TE) is set to “1”).

Access: This register can be read or written in 32-bit units.

Address: <ETNBn_base> + $05C8_H$

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 25.89 ETNBnMALR Register Contents

Bit Position	Bit Name	Function
31 to 16	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
15 to 0	MA[15:0]	MAC Address Bits 15 to 0 These bits are used to set the 16 lower-order bits of the MAC address.

MA[15:0]: MAC Address Bits 15 to 0

These bits are used to set the 16 lower-order bits of the MAC address.

For example, if the MAC address is 01-23-45-67-89-AB (hexadecimal), set $89AB_H$ in the ETNBnMALR register.

25.3.2.80 ETNBnCEFCR — CRC Error Frame Receive Counter Register

The ETNBnCEFCR register is a counter that indicates the number of times frames with CRC errors were received. Counting up stops when the value in this register reaches 0000 $FFFF_H$.

Access: This register can be read or written in 32-bit units.

Address: <ETNBn_base> + 0740_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 25.90 ETNBnCEFCR Register Contents

Bit Position	Bit Name	Function
31 to 16	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
15 to 0	CEFC[15:0]	CRC Error Frame Counter These bits indicate the number of CRC error frames received.

CEFC[15:0]: CRC Error Frame Counter Bits

These bits indicate the number of received frames having CRC errors.

The bits are cleared to “0” when they are read while the counter clear mode bit (ETNBnECMR.TRCCM) in the E-MAC mode register is set to “1”.

When ETNBnECMR.TRCCM = 0, they are cleared to 0 by the writing of any value to this register.

25.3.2.81 ETNBnFRECR — Frame Receive Error Counter Register

The ETNBnFRECR register is a counter that indicates the number of frame receive errors were generated by input on the ETNBnRXER pin from the PHY-LSI. Counting up stops when the value in this register reaches 0000 $FFFF_H$.

Access: This register can be read or written in 32-bit units.

Address: <ETNBn_base> + 0748_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 25.91 ETNBnFRECR Register Contents

Bit Position	Bit Name	Function
31 to 16	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
15 to 0	FREC[15:0]	Frame Receive Error Counter These bits indicate the number of errors during frame reception.

FREC[15:0]: Frame Receive Error Counter Bits

These bits indicate the number of errors during frame reception.

The bits are cleared to 0 when they are read while the counter clear mode bit (ETNBnECMR.TRCCM) in the E-MAC mode register is set to 1.

When ETNBnECMR.TRCCM = 0, they are cleared to 0 by the writing of any value to this register.

25.3.2.82 ETNBnTSFRCR — Too-Short Frame Receive Counter Register

The ETNBnTSFRCR register is a counter that indicates the number of received frames that were fewer than 64 bytes in length. Counting stops when the value in this register reaches 0000 $FFFF_H$.

Access: This register can be read or written in 32-bit units.

Address: <ETNBn_base> + 0750_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Table 25.92 ETNBnTSFRCR Register Contents

Bit Position	Bit Name	Function
31 to 16	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
15 to 0	TSFRC[15:0]	Too-Short Frame Receive Counter These bits indicate the number of frames received with a length of less than 64 bytes.

TSFRCR[15:0]: Too-Short Frame Receive Counter Bits

These bits indicate the number of received frames that were fewer than 64 bytes in length.

The bits are cleared to 0 when they are read while the counter clear mode bit (ETNBnECMR.TRCCM) in the E-MAC mode register is set to 1.

When ETNBnECMR.TRCCM = 0, they are cleared to 0 by the writing of any value to this register.

25.3.2.83 ETNBnTLFRCR — Too-Long Frame Receive Counter Register

The ETNBnTLFRCR register is a counter that indicates the number of received frames that were longer than the value specified in the receive frame length register (ETNBnRFLR). Counting up stops when the value in this register reaches 0000 $FFFF_H$.

Access: This register can be read or written in 32-bit units.

Address: <ETNBn_base> + 0758_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 25.93 ETNBnTLFRCR Register Contents

Bit Position	Bit Name	Function
31 to 16	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
15 to 0	TLFC[15:0]	Too-Long Frame Receive Counter These bits indicate the number of frames received with a length exceeding the value in ETNBnRFLR.

TLFRCR[15:0]: Too-Long Frame Receive Counter Bits

These bits indicate the number of received frames that were longer than the value in ETNBnRFLR.

The bits are cleared to 0 when they are read while the counter clear mode bit (ETNBnECMR.TRCCM) in the E-MAC mode register is set to 1.

When ETNBnECMR.TRCCM = 0, they are cleared to 0 by the writing of any value to this register.

25.3.2.84 ETNBnRFCR — Residual-Bit Frame Receive Counter Register

The ETNBnRFCR register is a counter that indicates the number of received frames containing "residual bits" (trailing bits not making up an 8-bit unit). Counting up stops when the value in this register reaches 0000 $FFFF_H$.

Access: This register can be read or written in 32-bit units.

Address: <ETNBn_base> + 0760_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 25.94 ETNBnRFCR Register Contents

Bit Position	Bit Name	Function
31 to 16	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
15 to 0	RFC[15:0]	Residual-Bit Frame Receive Counter These bits indicate the number of received frames containing residual bits.

RFC[15:0]: Residual-Bit Frame Receive Counter Bits

These bits indicate the number of received frames containing residual bits.

The bits are cleared to 0 when they are read while the counter clear mode bit (ETNBnECMR.TRCCM) in the E-MAC mode register is set to 1.

When ETNBnECMR.TRCCM = 0, they are cleared to 0 by the writing of any value to this register.

25.3.2.85 ETNBnMAFCR — Multicast Address Frame Receive Counter Register

The ETNBnMAFCR register is a counter that indicates the number of received frames for which a multicast address was specified. Counting up stops when the value in this register reaches 0000 FFFF$_H$.

Access: This register can be read or written in 32-bit units.

Address: <ETNBn_base> + 0778$_H$

Value after reset: 0000 0000$_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 25.95 ETNBnMAFCR Register Contents

Bit Position	Bit Name	Function
31 to 16	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
15 to 0	MAFC[15:0]	Multicast Address Frame Counter These bits indicate the number of multicast frames that have been received.

MAFC[15:0]: Multicast Address Frame Counter Bits

These bits indicate the number of multicast frames that have been received.

The bits are cleared to 0 when they are read while the counter clear mode bit (ETNBnECMR.TRCCM) in the E-MAC mode register is set to 1.

When ETNBnECMR.TRCCM = 0, they are cleared to 0 by the writing of any value to this register.

25.3.2.86 ETNBnPIPR — PHY Interrupt Polarity Register

The ETNBnPIPR register is used to set the active sense of AVB_PHY_INT pin.

Access: This register can be read or written in 32-bit units.

Address: <ETNBn_base> + $052C_H$

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Table 25.96 ETNBnPIPR Register Contents

Bit Position	Bit Name	Function
31 to 1	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
0	PHYIP	PHY Interrupt Input Pin Polarity This bit sets the active sense of the PHY interrupt pin (AVB_PHY_INT). For the active sense, refer to the specifications of the PHY-LSI to be connected. 0: PHY interrupt pin (AVB_PHY_INT) is active low (the low level triggers the interrupt state) 1: PHY interrupt pin (AVB_PHY_INT) is active high (the high level triggers the interrupt state)

NOTE

Only ETNB1 (Gigabit Ethernet) supports this function.

25.3.2.87 ETNBnTPAUSER — Automatic PAUSE Frame Retransmit Count Register

The ETNBnTPAUSER register is used to set the value for upper limit number of auto generated PAUSE frames.

The setting in this register must not be changed while transmission is enabled.

Access: This register can be read or written in 32-bit units.

Address: <ETNBn_base> + 0564_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 25.97 ETNBnTPAUSER Register Contents

Bit Position	Bit Name	Function
31 to 16	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
15 to 0	PFRTULMT[15:0]	Pause Frame Retry Upper Limit These bits set the value for upper limit time of auto generated PAUSE frames while Receive FIFO caution. For the active sense, refer to the specifications of the PHY-LSI to be connected. 0000_B: unlimited 0001_B: 1 times 0002_B: 2 times : $FFFF_B$: 65535 times

25.3.2.88 ETNBnPFTTCR — PAUSE Frame Retransmit Counter Register

The ETNBnPFTTCR register is counter that indicates the number of times auto PAUSE frames have been transmit.

Access: This register is a read-only register that can be read in 32-bit units.

Address: <ETNBn_base> + 0568_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 25.98 ETNBnPFTTCR Register Contents

Bit Position	Bit Name	Function
31 to 16	Reserved	When read, the value after reset is returned.
15 to 0	PFRTC[15:0]	Pause Frame Retry Counter These bits indicate the number of auto PAUSE frames that have been transmit while Receive FIFO caution. The bits are cleared to 0 when they are read and receive FIFO caution start.

25.3.2.89 ETNBnGECMR — E-MAC Mode Register 2

The ETNBnGECMR register specifies the operating mode for the E-MAC.

The setting in the ETNBnGECMR register must not be changed while transmission or reception is enabled.

Access: This register can be read or written in 32-bit units.

Address: <ETNBn_base> + $05B0_H$

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	SPEED
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Table 25.99 ETNBnGECMR Register Contents

Bit Position	Bit Name	Function
31 to 1	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
0	SPEED	Transfer Speed Setting This bit sets the transfer rate. 0: Transfer is at 100 Mbps/10 Mbps 1: Transfer is at 1000 Mbps For ETNB0, setting this bit to 1 is prohibited.

NOTE

For ETNB0, setting SPEED = 1 is not allowed.

25.3.3 SGMII Interface Related Registers

25.3.3.1 ETNB1SGOPMC — Operation Mode Configuration Register

Access: This register can be read or written in 32-bit units.

Address: <ETNB1_base> + 1000_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

	—	—	—	—	—	—	—	—	—	—	—	LINK	SPEED[1:0]		DUPLEX	MODE
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 25.101 ETNB1SGOPMS Register Contents

Bit Position	Bit Name	Function
31 to 18	Reserved	When read, the value after reset is returned.
17, 16	XMIT[1:0]	Internal Operation State 00_B: Idle state 01_B: Configuration state 10_B: Data Communication state 11_B: Reserved SGMII interface can perform data communication only when XMIT[1:0] = 10_B (Data communication state). When ETNB1SGOPMC.MODE = 1, these bits are fixed to 10_B. When ETNB1SGOPMC.MODE = 0, these bits change to 10_B after Auto-Negotiation with PHY-LSI is completed.
15 to 5	Reserved	When read, the value after reset is returned.
4	LINK	Link State This bit indicates the link state reported from the PHY-LSI. 0: Link-down 1: Link-up This bit is fixed to 1 when ETNB1SGOPMC.MODE = 1.
3, 2	SPEED[1:0]	Transfer Rate 00_B: 10 Mbps 01_B: 100 Mbps 10_B: 1000 Mbps 11_B: Reserved When ETNB1SGOPMC.MODE = 1, these bits indicate the value set in ETNB1SGOPMC.SPEED[1:0]. When ETNB1SGOPMC.MODE = 0, these bits indicate the value determined by Auto-Negotiation with PHY-LSI.
1	DUPLEX	Transfer Mode 0: Half-duplex mode (Setting prohibited) 1: Full-duplex mode When ETNB1SGOPMC.MODE = 1, these bits indicate the value set in ETNB1SGOPMC.DUPLEX. When ETNB1SGOPMC.MODE = 0, these bits indicate the value determined by Auto-Negotiation with PHY-LSI
0	MODE	Operation Mode 0: Auto-Negotiation process with PHY-LSI is not bypassed. 1: Auto-Negotiation process with PHY-LSI is bypassed. This bit indicates the value set in ETNB1SGOPMC.MODE.

25.3.3.3 ETNB1SGSRST — Software Reset Register

Access: This register can be read or written in 32-bit units.

Address: <ETNB1_base> + 1008_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 25.103 ETNB1SGINTS Register Contents

Bit Position	Bit Name	Function
31 to 2	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
1	URDYI	Un-ready Interrupt 0: No interrupt 1: Indicates that the SGMII interface has changed a state in which it can perform data communication to one in which it cannot. (The value of ETNB1SGOPMS.XMIT[1:0] has changed from 10_B to another value.) This bit is cleared to 0 by writing 1 to this bit.
0	RDYI	Ready Interrupt 0: No interrupt 1: Indicates that the SGMII interface has changed a state in which it cannot perform data communication to one in which it can. (The value of ETNB1SGOPMS.XMIT[1:0] has changed from a value other than 10_B to 10_B.) This bit is cleared to 0 by writing 1 to this bit.

NOTE

This Register is valid only when ETNB1SGOPMC.MODE = 0.

25.3.3.5 ETNB1SGINTM — Interrupt Mask Register

Access: This register can be read or written in 32-bit units.

Address: <ETNB1_base> + 1010_H

Value after reset: $0000\ 0003_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 25.105 ETNB1SGLTVC Register Contents

Bit Position	Bit Name	Function
31 to 18	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
17 to 0	LINK_TIMER [17:0]	LINK_TIMER Specifies the number of cycles to ensure the LINK_TIMER period specified as standard in units of 8 ns (the period for one cycle at 125 MHz). Standard value: 1.6 ms (8 ns × initial value of 200,000 cycles) These bits should be changed only for debugging purposes.

NOTE

This Register is valid only when ETNB1SGOPMC.MODE = 0.

25.3.3.7 ETNB1SGCECT — Code Error Counter Register

Access: This register can be read or written in 32-bit units.

Address: <ETNB1_base> + 1018_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	CER_CNT[15:0]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 25.106 ETNB1SGCECT Register Contents

Bit Position	Bit Name	Function
31 to 16	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
15 to 0	CER_CNT[15:0]	Code Error Counter These bits are used to count the number of code errors. These bits are initialized by writing 0000_H to these bits.

25.3.3.8 ETNB1SGRECT — Running Disparity Error Counter Register

Access: This register can be read or written in 32-bit units.

Address: <ETNB1_base> + $101C_H$

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	RER_CNT[15:0]

Table 25.107 ETNB1SGRECT Register Contents

Bit Position	Bit Name	Function
31 to 16	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
15 to 0	RER_CNT[15:0]	Running Disparity Error Counter These bits are used to count the number of running disparity errors. These bits are initialized by writing 0000_H to these bits.

25.3.3.9 ETNB1SGSDS — SGMII SerDes Status Register

The ETNB1SGSDS register indicates the status of SGMII SerDes.

Access: This register is a read-only register that can be read in 8-bit units

Address: <ETNB1_base> + 1800_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	SUC	PWS[1:0]	
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R

Table 25.108 ETNB1SGSDS Register Contents

Bit Position	Bit Name	Function
7 to 3	Reserved	When read, the value after reset is returned.
2	SUC	Startup Completion Flag 0: Startup not completed 1: Startup completed
1, 0	PWS[1:0]	Power Status 00_B: Off 01_B: During power-on sequence 10_B: During power-off sequence 11_B: On

25.3.3.10 ETNB1SGCLKSEL — SGMII Reference Clock Select Register

The ETNB1SGCLKSEL register is used to select the SGMII reference clock.

Access: This register can be read or written in 8-bit units

Address: <ETNB1_base> + 1804_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	SEL
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R/W

Table 25.109 ETNB1SGCLKSEL Register Contents

Bit Position	Bit Name	Function
7 to 1	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
0	SEL	Reference Clock Select 0: External clock (25 MHz) 1: Internal MOSC clock (20 MHz) This setting is allowed only when MOSC is 20 MHz.

25.3.3.11 ETNB1SGRCIE — SGMII Reference Clock Input Enable Register

The ETNB1SGRCIE register is used to enable the SGMII reference clock input.

Access: This register can be read or written in 8-bit units

Address: <ETNB1_base> + 1808_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	RCIE
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R/W

Table 25.110 ETNB1SGRCIE Register Contents

Bit Position	Bit Name	Function
7 to 1	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
0	RCIE	Reference Clock Input Enable 0: Disable 1: Enable The CPU can only write 1 to this bit. This bit is automatically cleared in SGMII SerDes power-off sequence.

25.4 Operation

The Ethernet AVB consists of the following functional units:

- DMA transfer controller (AVB-DMAC): Handles DMA transfer between the data storage areas for reception and transmission in the URAM and the reception and transmission FIFO buffers
- MAC controller (E-MAC): Handles transfer between the reception and transmission FIFO buffers and the MII/RMII/SGMII

Using its direct memory access (DMA) function, the AVB-DMAC handles DMA transfer of frame data between the destinations for storing Ethernet frame data for transmission and reception in the URAM and the FIFO buffers for reception and transmission. Data cannot be directly read from or written to the FIFO buffers.

To handle DMA transfer, the AVB-DMAC requires information that includes the addresses for storage of data for transmission and received data. The information is referred to as descriptors. The AVB-DMAC reads data for transmission from the storage area for data to be transmitted and writes received data to the storage area for received data according to the information described in descriptors. The descriptors are placed in the URAM. Arranging multiple descriptors in descriptor lists allows the continuous reception or transmission of multiple Ethernet frames.

The E-MAC supports a MII/RMII/SGMII, which provides an interface format for the externally connected PHY-LSI. The E-MAC constructs Ethernet frames from data written to the transmission FIFO and transmits these frames to the MII/RMII/SGMII. It also performs CRC checking of Ethernet frames received from the MII/RMII/SGMII and writes the frames to the reception FIFO.

25.4.1 AVB-DMAC Operating Modes

Figure 25.5 illustrates the operating modes of the AVB-DMAC.

Transitions of AVB-DMAC operating mode are under the control of the items listed below.

- CPU operating mode (hardware reset)
- Configuration of the operating mode configuration bits (ETNBnCCC.OPC) in the AVB-DMAC mode register

The current operating mode can be determined by reading the operating mode status bits in the AVB-DMAC status register (ETNBnCSR.OPS).

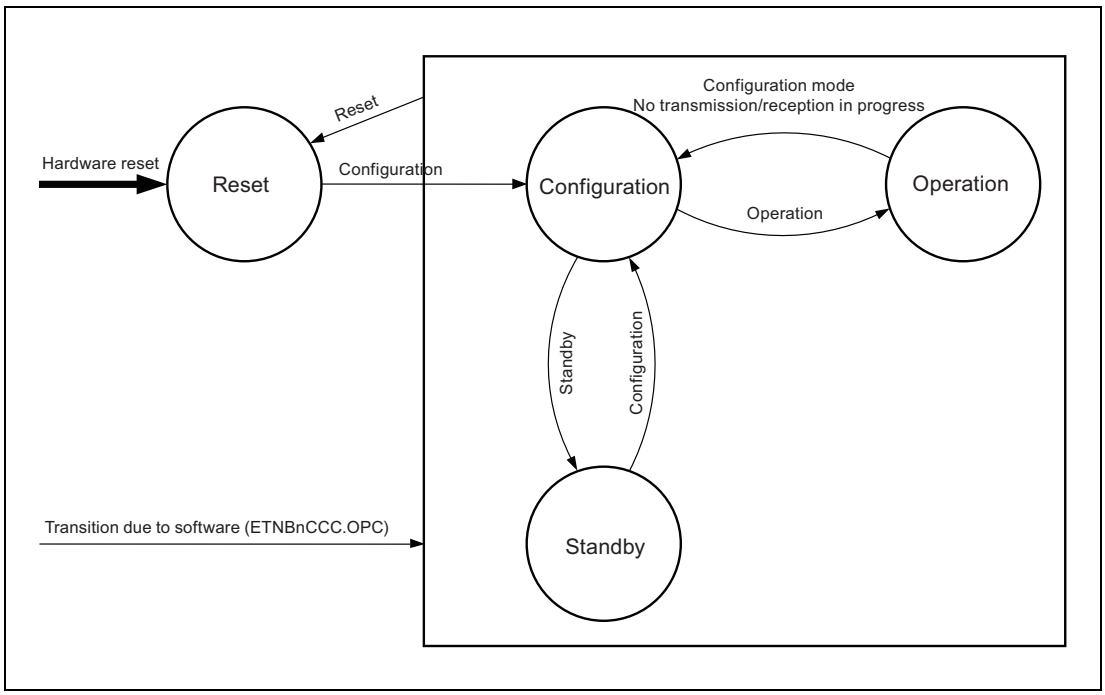

Figure 25.5 Operating Mode of AVB-DMAC

25.4.1.1 Operating Modes

(1) Reset mode

After a hardware reset, the AVB-DMAC enters reset mode.
In reset mode, only the AVB-DMAC operating mode control function is controllable and other functions are all stopped. This mode is designed for reduced power when the Ethernet function is not necessary.

(2) Configuration mode

In configuration mode, various settings for the AVB-DMAC can be made.
The operating functions are stopped and all status registers are initialized to their reset values.
The E-MAC functions in this mode.
By ETNBnCCC.GAC it is possible to enable gPTP support already in this mode.

(3) Operation mode

In operation mode, all functions of the AVB-DMAC can operate.
Ethernet communications can only proceed in this mode.
In operation mode, do not set E-MAC again.

(4) Standby mode

In standby mode, the E-MAC can only be used to control the operating mode. Other functions cannot be used.
When ETNBnCCC.GAC is 1, CPU should not enter this mode.

25.4.1.2 How to Set the Operating Mode

Set the operating mode configuration bits in the AVB-DMAC mode register (ETNBnCCC.OPC) to select the operating mode. Furthermore, the current operating mode can be checked by reading the operating mode status bits in the AVB-DMAC status register (ETNBnCSR.OPS).

Transitions other than from operation mode to configuration mode are made after the value is written to the operating mode configuration bits (ETNBnCCC.OPC) (**Figure 25.6**).

For transitions from operation mode to configuration mode, follow the procedure in **Figure 25.7** because any transmission and reception in progress will be executed before the transition to configuration mode.

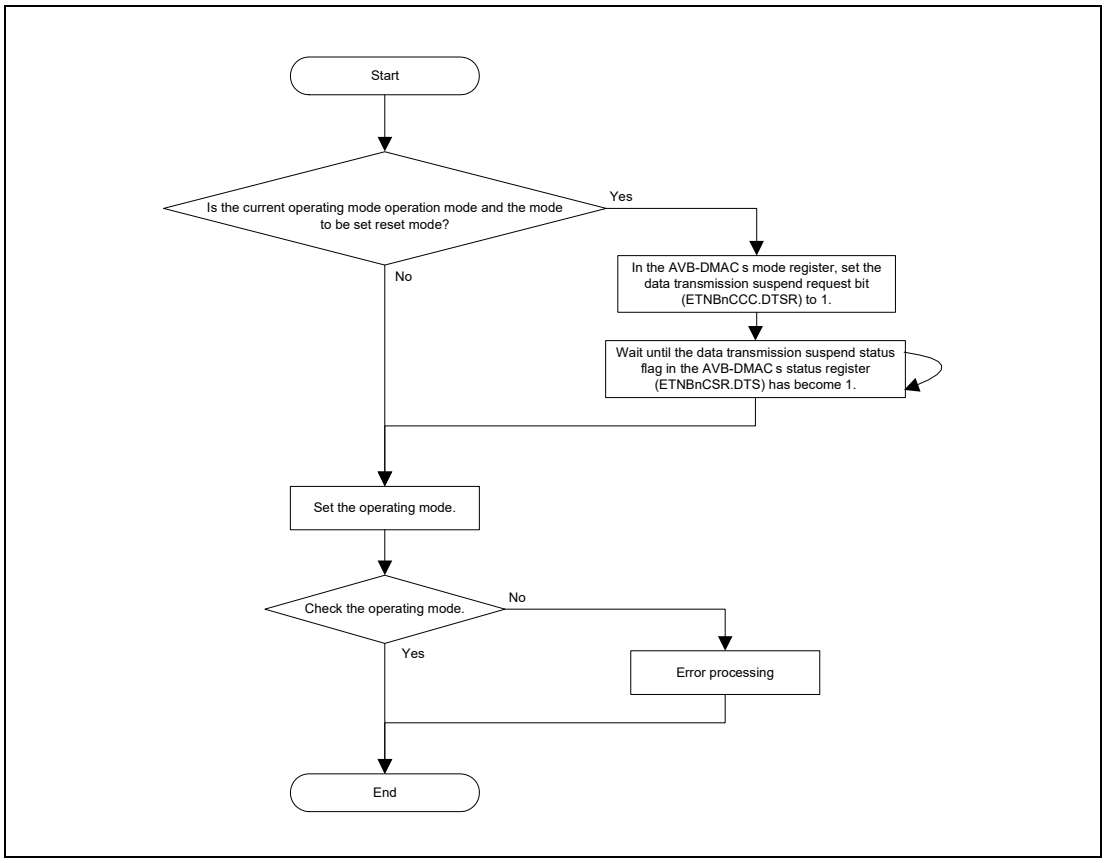

Figure 25.6 Flow for Transitions of Operating Mode (Other than from Operation Mode to Configuration Mode)

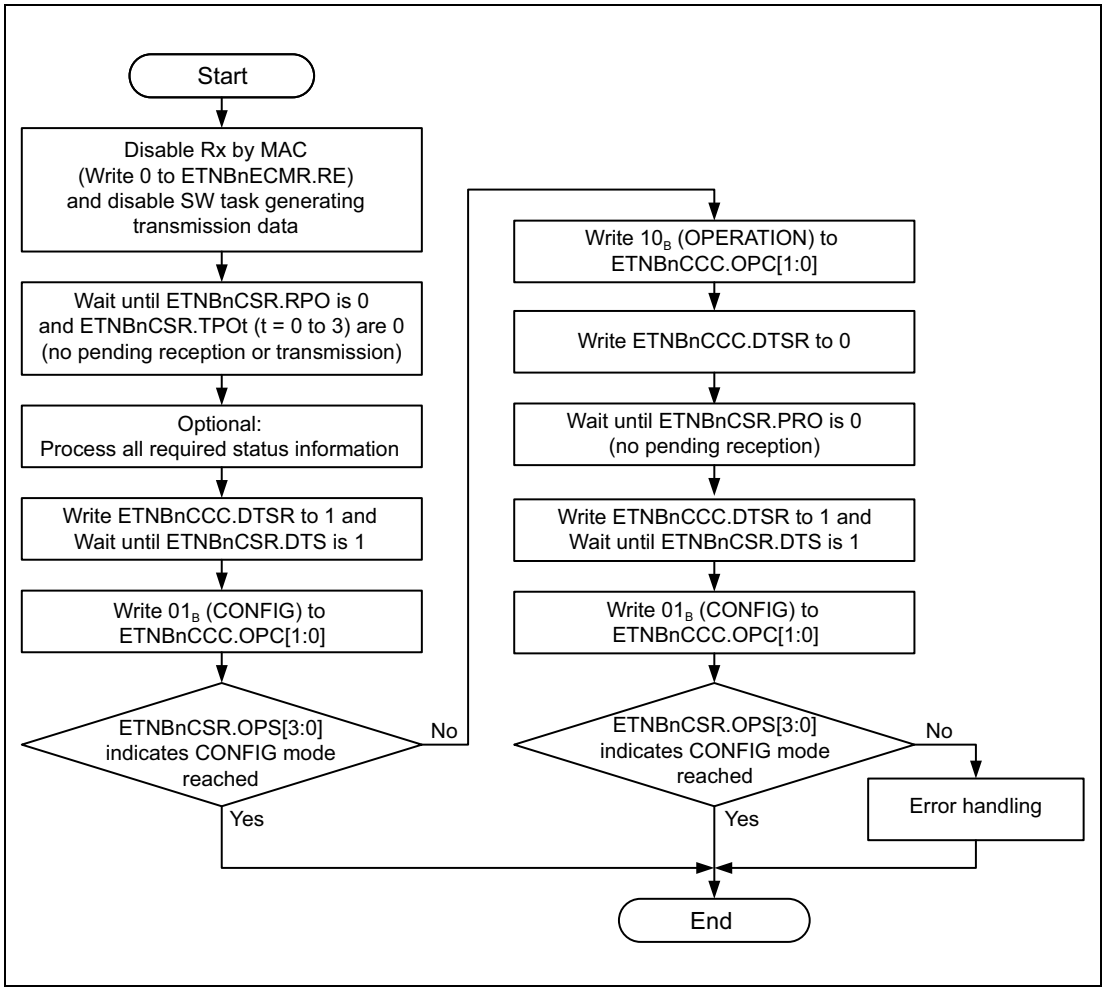

Figure 25.7 Flow for Transitions of Operating Mode (from Operation Mode to Configuration Mode)

In the transition from operation mode to configuration mode, the AVB-DMAC executes the following operations before the transition is completed. Read the operating mode status bits in the AVB-DMAC status register (ETNBnCSR.OPS) to check that the transition to configuration mode has been completed.

- If the transfer of a frame between the reception FIFO and URAM is in progress, this is completed (other received frames remaining in the FIFO and any frames that are subsequently received by the E-MAC are discarded).
- If the transfer of a frame is in progress between the transmission FIFO and URAM, this is completed
  (frames for transmission remaining in the URAM will not be transmitted).
- All frames for transmission in the transmission FIFO are transferred to the E-MAC.

Notes:

When the operating mode shifts to configuration mode, all status registers are cleared.

We recommend following the procedure below in the case of this transition.

1. Disable reception.
2. Since reception actually stopping after being disabled requires time, wait for an interval equivalent to that for reception of a maximum length packet.

3. Stop the software task that is generating data for transmission.
4. Wait until the receive process status bit (ETNBnCSR.RPO) and the transmit process status bits (ETNBnCSR.TPO0 to 3) in the AVB-DMAC status register are set to 0.
5. Capture all of the required status information.
6. Set the operating mode configuration bits in the AVB-DMAC mode register (ETNBnCCC.OPC) to initiate the transition to configuration mode.

25.4.1.3 Operating Mode Transitions Due to Hardware

The following hardware factors can also initiate transitions of the AVB-DMAC operating mode.

(1) Hardware reset

Resetting of the LSI chip leads to resetting of the entire EthernetAVB module. The operating mode shifts to reset mode.

25.4.2 Common Control for Transmission and Reception

25.4.2.1 Initialization Procedure

Figure 25.8 shows the overall initialization procedure in outline.

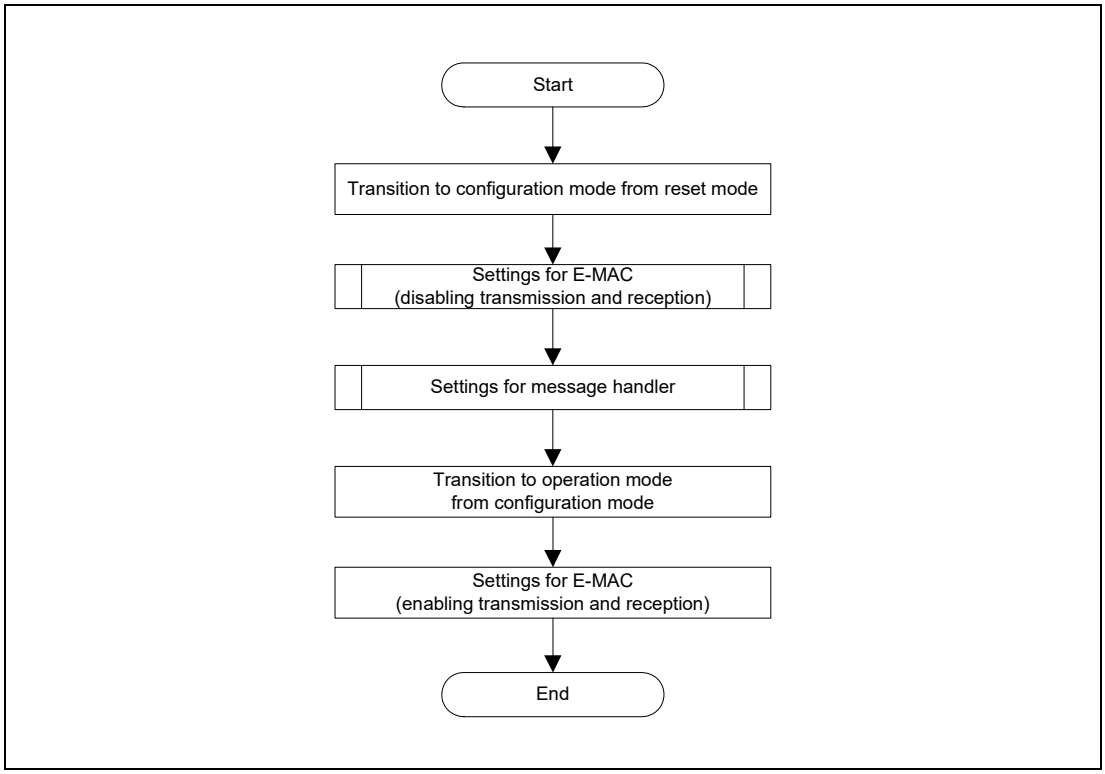

Figure 25.8 Outline of the Initialization Procedure

(1) Initializing the Receiver Section

Before starting reception, follow the procedure below.

Set the operating mode to operation mode or standby mode, and do not enable reception until the settings for the AVB-DMAC are completed.

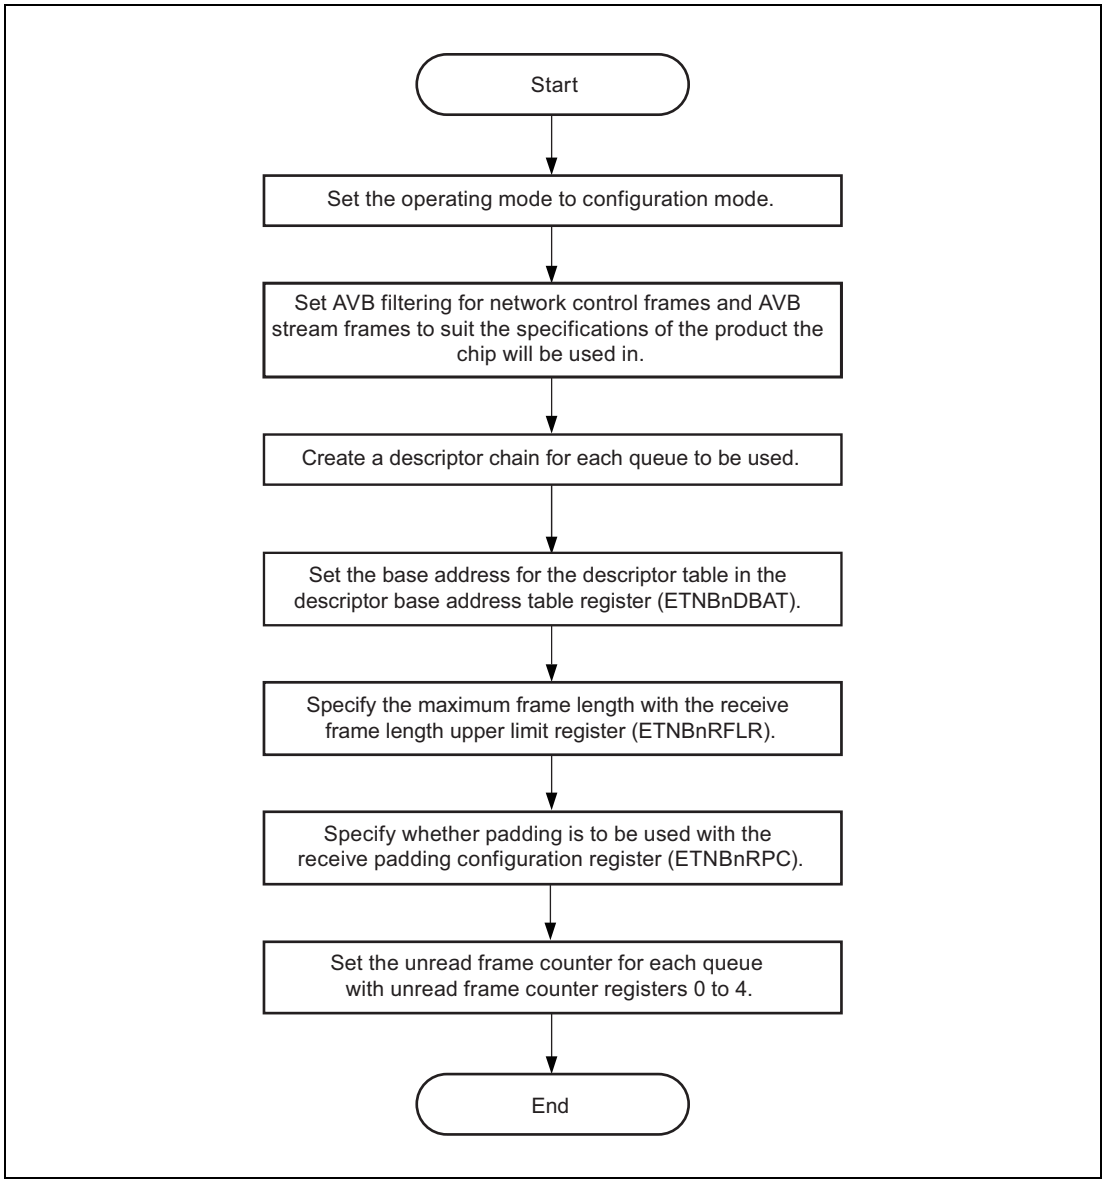

Figure 25.9 Procedure for Initializing the Receiver Section

(2) Initializing the Transmitter Section

Figure 25.10 illustrates initialization of the transmitter section.

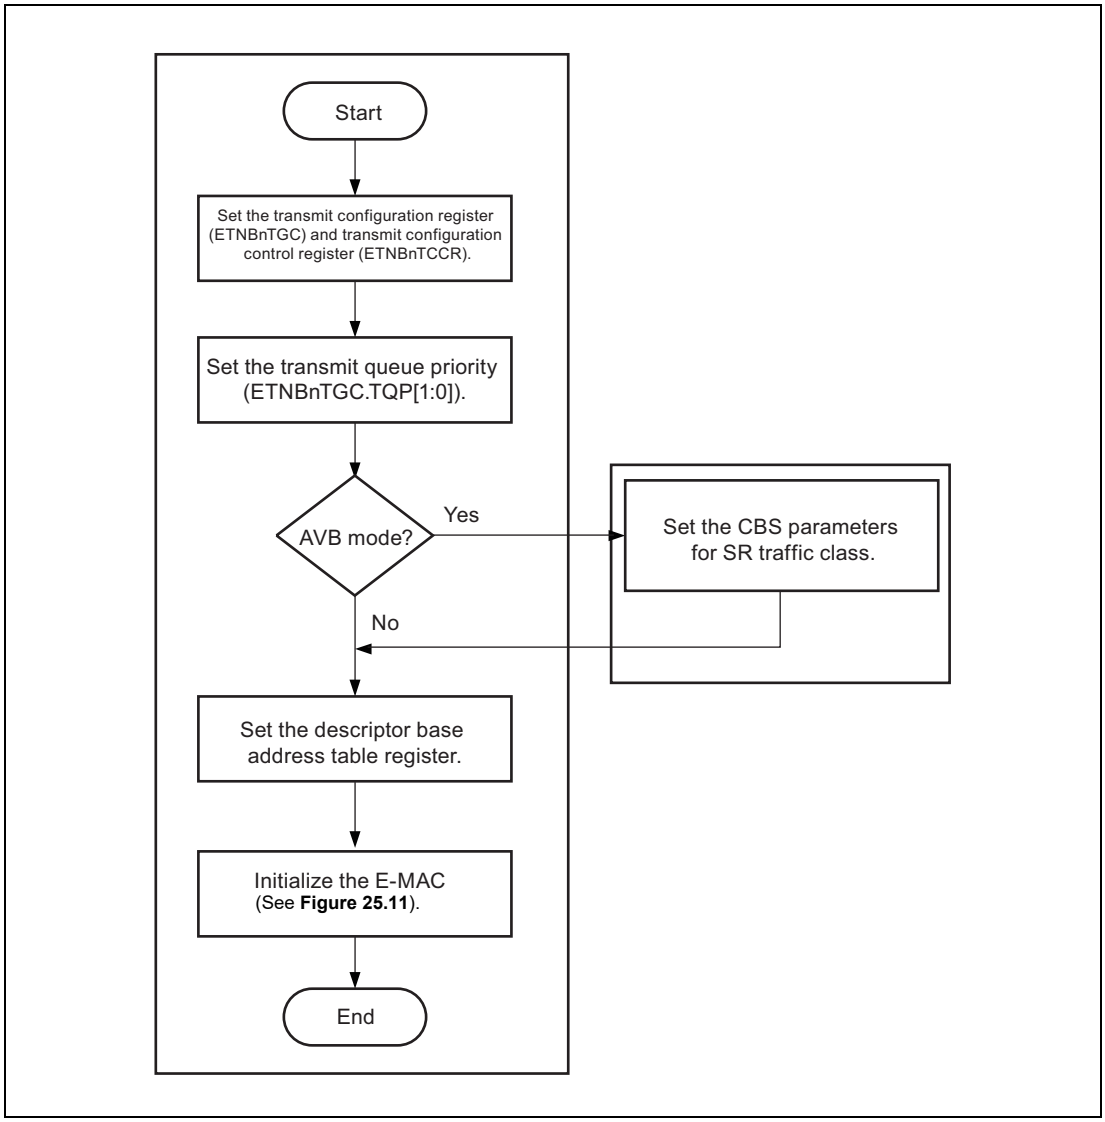

Figure 25.10 Procedure for Initializing the Transmitter Section

(3) Configuration the E-MAC Block

Figure 25.11 illustrates configuration of the E-MAC block.

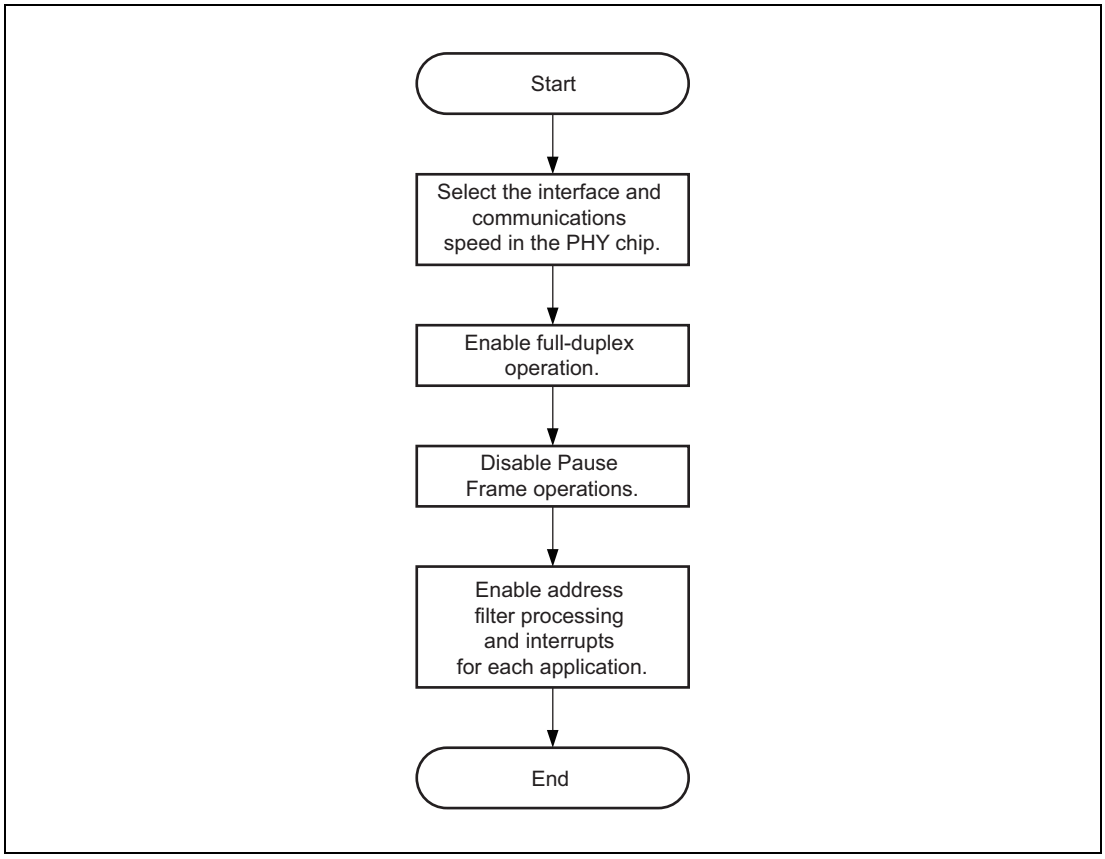

Figure 25.11 Procedure for Configuration the E-MAC Block

(4) Configuration the Message Handler Section

Figure 25.12 illustrates configuration the message handler section.

For a description of how to set up the descriptors and the CBS traffic shaping parameters, see **Section 25.4.3, Descriptors**, and **Section 25.4.6, CBS (Credit-Based Shaping)**.

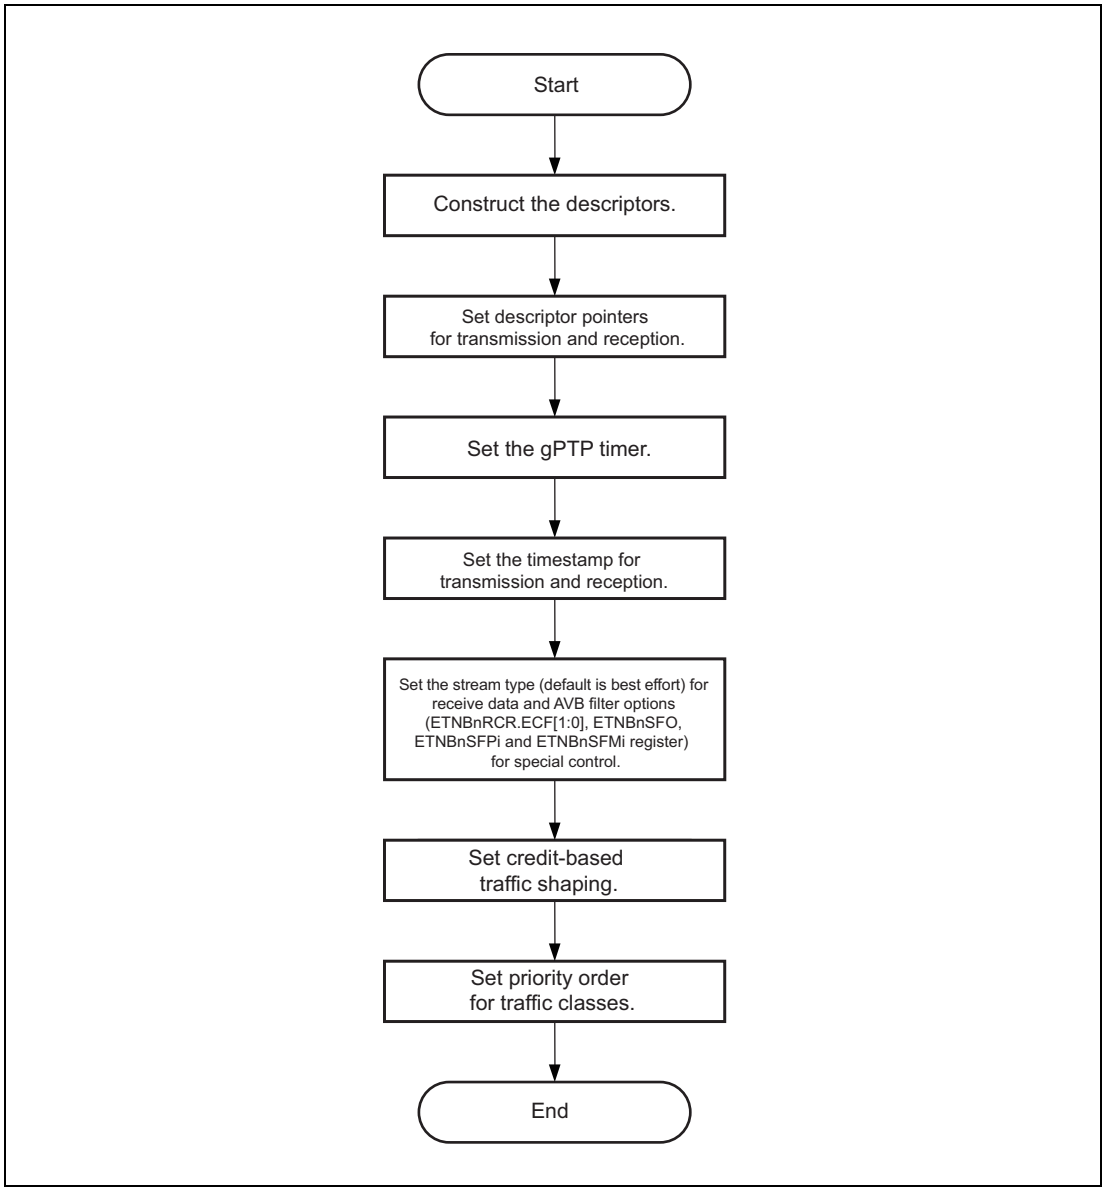

Figure 25.12 Configuration the Message Handler Section

25.4.2.2 Scheduling Reception and Transmission

The AVB-DMAC normally has independent buses for transmission and reception. Furthermore, the four processes of fetching, storing, transmission and reception are basically independent of one another. Fetching and storing, however, share the same bus master so cannot be executed simultaneously. Access to the bus master is controlled by the scheduler.

Figure 25.13 is a schematic view of AVB-DMAC operations in transmission and reception.

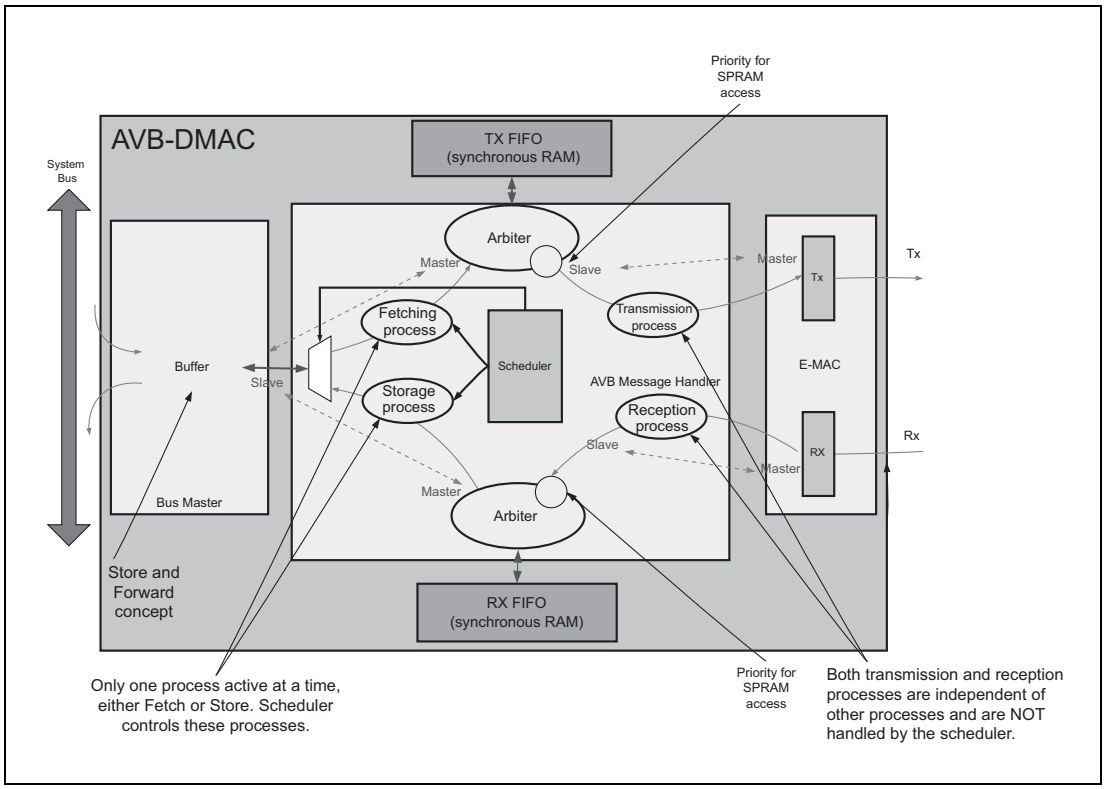

Figure 25.13 Schematic View of AVB-DMAC Operations in Transmission and Reception

Storing and fetching are alternately performed. When the number of frames held by the reception FIFO reaches the warning level, storing takes precedence over fetching.

(1) Relationship between Transmission Queue Numbers and Traffic Classes

In fetching, the relationships between the transmission queues and traffic classes are fixed, so the priority specified by the transmit queue priority bits in the transmit configuration register (ETNBnTGC.TQP) has no effect.

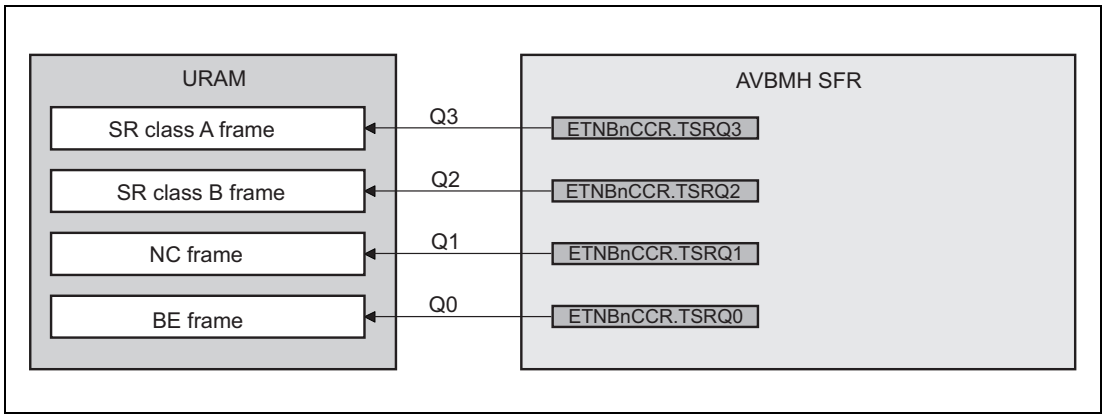

Figure 25.14 Class Associations of Queues for the Scheduler

In fetching, the credit values for stream classes A and B are not taken into account. Behavior depends on the setting of the transfer FIFO size configuration bits in the transfer configuration registers (ETNBnTGC.TBDt) and on the frame size that can be fetched to the transmission FIFO.

When the transmit queue priority bits in the transmit configuration register (ETNBnTGC.TQP) are 00_B or 01_B, the priority order is Q3 → Q 2 → Q1 → Q0.

When the transmit queue priority bits in the transmit configuration register (ETNBnTGC.TQP) are 11_B, the priority order is Q1 → Q3 → Q2 → Q0.

25.4.2.3 Checking Integrity

The AVB-DMAC is capable of detecting and identifying errors produced in the processing of Ethernet frames and in the transfer of frame data for transmission and reception.

(1) Concept of Integrity Checking in Reception

The purpose of receive integrity check is to prevent error frames from being stored in the URAM.

If an error frame is stored, information to identify the frame as an error frame is appended to the data from the frame in the URAM.

CAUTION

If a special descriptor chain is to be used for header/data separation on reception, an error that breaks the sequence may lead to storage space for synchronization running out. In such cases, software interaction or re-synchronization via the EOS descriptor is required.

(2) Concept of Integrity Checking in Transmission

The purpose of integrity checking in transmission is to prevent the transmission of broken frames.

Since transmission of a frame by the E-MAC can neither be stopped nor disabled once it has started, this check involves intensive monitoring for problems that can arise during fetching.

(3) Items for Monitoring in Both Reception and Transmission

(a) Errors in access to the URAM for reading of descriptors

The same descriptor may be processed again because the current descriptor address (ETNBnCDARq.CDA) is not changed.

If this problem occurs in a divided frame, the sequence may be broken.

In reception

- The received frame will be lost.
- The same problem will occur for the next frame of data received for the same queue.

In transmission

- The transmit start request bit in the transmit configuration control register (ETNBnTCCR.TSRQt) is set to 0.
- The frame will be lost from the transmission FIFO.

Errors in access to read descriptors from the URAM are detected from the response signal of the AXI-Bus.

(b) Illegal configuration of a descriptor by an application

The same descriptor may be processed again because the current descriptor address (ETNBnCDARq.CDA) is not changed.

If this problem occurs in a divided frame, the sequence may be broken.

In reception

- The received frame will be lost.

- The same problem will occur for the next frame of data received for the same queue.

In transmission

- The transmit start request bit in the transmit configuration control register (ETNBnTCCR.TSRQt) is set to 0.
- The frame will be lost from the transmission FIFO.

(c) Errors in access to the URAM for writing of descriptors

As in the case where no error occurs, the current descriptor address (ETNBnCDARq.CDA) and the transmit start request bit in the transmit configuration control register (ETNBnTCCR.TSRQt) are updated.

As DESCR.DT was not updated, hardware and software synchronization may have been disengaged.

Errors in access to write descriptors to the URAM are detected from the response signal of the AXI-Bus.

(4) Items for Monitoring in Reception

(a) Errors in access to the URAM for writing of data or timestamps

- As in the case where no error occurs, the current descriptor address (ETNBnCDARq.CDA) is updated.
- DESCR.EI is set to indicate incorrect contents.
- When an access error occurs in a divided frame, the descriptor sequence may be damaged and queues may be unusable.

Errors in access to write data or descriptors to the URAM are detected from the response signal of the AXI-Bus.

(b) Errors in Access for Reading from the Reception FIFO

- As in the case where no error occurs, the current descriptor address (ETNBnCDARq.CDA) is updated.
- DESCR.EI is set to indicate incorrect contents.
- When an access error occurs in a divided frame, the descriptor sequence may be damaged and queues may be unusable.
- Errors of this type are detected by the ECC checker for the reception FIFO. For details of this ECC function, see **Section 44.3.10, ECC for Peripheral RAM**.

(c) Damaged Data in the Reception FIFO

- Received frames are all invalidated.
- All frames stored in reception FIFO are discarded. At this time, the number of frames and queue information cannot be captured.

If damaged data in the reception FIFO is an error due to the reception FIFO, this is detected by the AVB-DMAC.

(5) Items for Monitoring in Transmission

(a) Errors in Access for Reading Data from the URAM

- Data that have already been fetched are discarded from the transmission FIFO.
- When an error of this type occurs during processing of an FSINGLE or FEND descriptor:
  As in the case where no error occurs, the current descriptor address (ETNBnCDARq.CDA) and the transmit start bit in the transmit configuration control register (ETNBnTCCR.TSRQt) are updated. Fetching resumes after the error frame.
- When an error of this type occurs during processing of an FSTART or FMID descriptor:
  - The current descriptor address (ETNBnCDARq.CDA) is not updated.
  - The transmit start bit in the transmit configuration control register (ETNBnTCCR.TSRQt) is set to 0.

Errors in access to read data from the URAM are detected from the response signal of the AXI-Bus.

(b) Overflow of the Transmission FIFO

- As in the case where no error occurs, the current descriptor address (ETNBnCDARq.CDA) and the transmit start bit in the transmit configuration control register (ETNBnTCCR.TSRQt) are updated. Fetching resumes after the error frame.
- The frame will be discarded from the FIFO.

(c) Errors in Access for Reading of the Transmission FIFO

The AVB-DMAC is incapable of detecting an error in reading of the transmission FIFO, resulting in the transmission of a broken frame.

Errors of this type are detected by the ECC checker for the transmission FIFO. For details of this ECC function, see **Section 44.3.10, ECC for Peripheral RAM**.

(d) Frame size error during transmission

- As in the case where no error occurs, the current descriptor address (ETNBnCDARq.CDA) and the transmit start bit in the transmit configuration control register (ETNBnTCCR.TSRQt) are updated. Fetching resumes after the error frame.

A transmit frame size error is detected when the size setting in one or more (in the case of a divided frame) descriptors for frame transmission is 2044 or more bytes. Such frames are cut out and transmitted.

(e) Damaged Data in the Transmission FIFO

- Fetching is not affected by damaged data.
- Since damaged data from the FIFO is only detected during frame transmission, an unexpected frame data may be transmitted.

If damaged data in the transmission FIFO is an error due to the transmission FIFO, this is detected by the AVB-DMAC.

25.4.3 Descriptors

25.4.3.1 Data Representation in URAM

The AVB-DMAC transfers data for transmission and received data to and from the application software via the URAM.

The memory in the URAM for use by the AVB-DMAC is configured with control structures referred to as descriptors and associated areas to which the frame data are allocated. Dividing the memory into a control area and data area allows the flexible allocation of frame data to the URAM. This enables sharing of the areas to which frame data are allocated and the use of non-contiguous areas. Frame data can be copied without using the CPU. Arbitration that ensures hardware and software access to the memory area is also available without using the AVB-DMAC.

Figure 25.15 shows an example of the memory maps for descriptors and the descriptor data area in the URAM.

A descriptor consists of its type (DESCR.DT), which controls the descriptor functions, a descriptor pointer (DESCR.DPTR) indicating the start address for storage of the frame data in the descriptor area, and the data size field (DESCR.DS), indicating the amount of frame data. Respective descriptors can generate interrupts after completion of processing. Enabling and disabling of the interrupt is controlled by the descriptor interrupt enable bits (DESCR.DIE).

The descriptor may also hold information related to content. This information does not affect general descriptor functions. It provides information other than the frame data proper, such as on the state of reception.

For details, see **Section 25.4.4.2, Setting Up Reception Descriptors**, and **Section 25.4.5.2, Setting Up Transmission Descriptors**.
