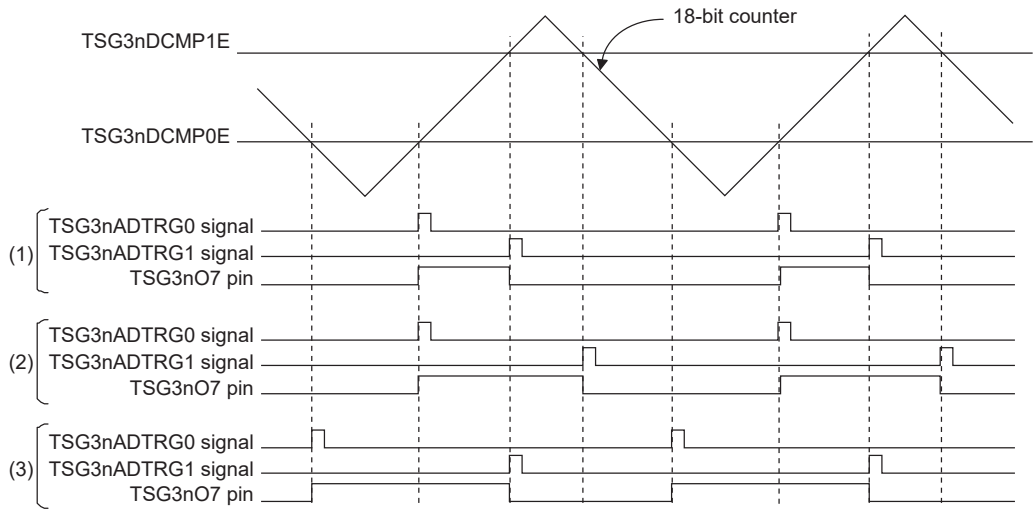
The TSG3nO7 pin can output a pulse of A/D conversion trigger (TSG3nIOC1.TSG3nTGS = 0) or diagnostic output (TSG3nIOC1.TSG3nTGS = 1). When outputting a pulse of A/D conversion trigger, the TSG3nO7 pin is activated at the rising edge of the TSG3nADTRG0 signal, and inactivated at the rising edge of the TSG3nADTRG1 signal. When the TSG3nADTRG0 signal is detected while the TSG3nO7 pin is active, the TSG3nO7 pin remains active. When the TSG3nADTRG1 signal is detected while the TSG3nO7 pin is inactive, the TSG3nO7 pin remains inactive. If TSG3nADTRG0 and TSG3nADTRG1 signal triggers occur simultaneously, the TSG3nO7 pin is inactivated.



Note: (1) When TSG3nDCMP0E register<TSG3nDCMP1E register, TSG3nCTL5 register = 0004_H, and TSG3nCTL6 register = 0010_H

(2) When TSG3nDCMP0E register<TSG3nDCMP1E register, TSG3nCTL5 register = 0004_H, and TSG3nCTL6 register = 0020_H

(3) When TSG3nDCMP0E register<TSG3nDCMP1E register, TSG3nCTL5 register = 0008_H, and TSG3nCTL6 register = 0010_H

Figure 35.12 Example of A/D Trigger Output Timing of TSG3nO7 Pin (TSG3nIOC1.TSG3nTGS = 0)

During diagnostic output, the active level is output on the TSG3nO7 pin with the width specified by the TSG3nCTL0.TSG3nDWD bit when the values of the TSG3nDCMP0E to TSG3nDCMP2E bits match that of the 18-bit counter. If a TSG3nDCMP0E to TSG3nDCMP2E value again matches the value of the 18-bit counter value while the diagnostic output on the TSG3nO7 pin is already at the active level, pulse output on the TSG3nO7 pin continues for the number of cycles of PCLK (8 or 16) set by the TSG3nDWD bit from the point of the later match.

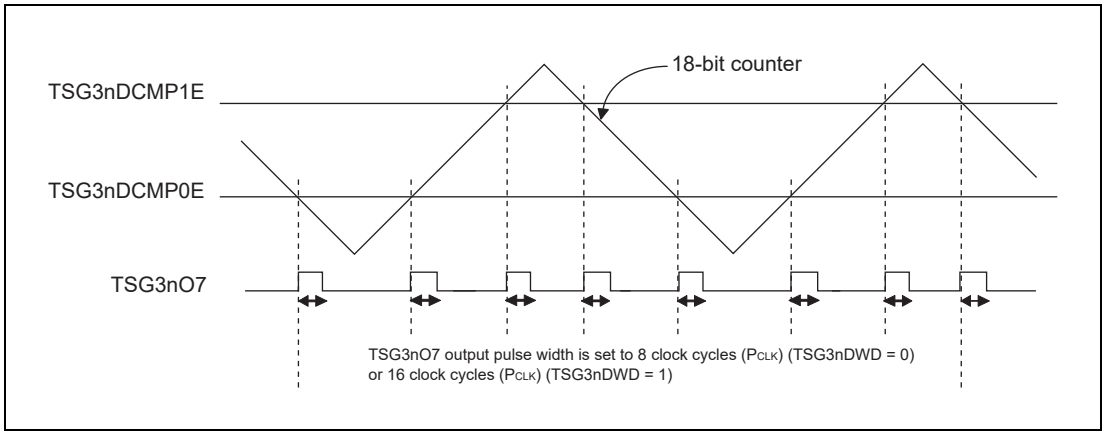


Figure 35.13 Example of TSG3nO7 Pin Diagnostic Pulse Output Timing (1) (TSG3nIOC1.TSG3nTGS = 1)

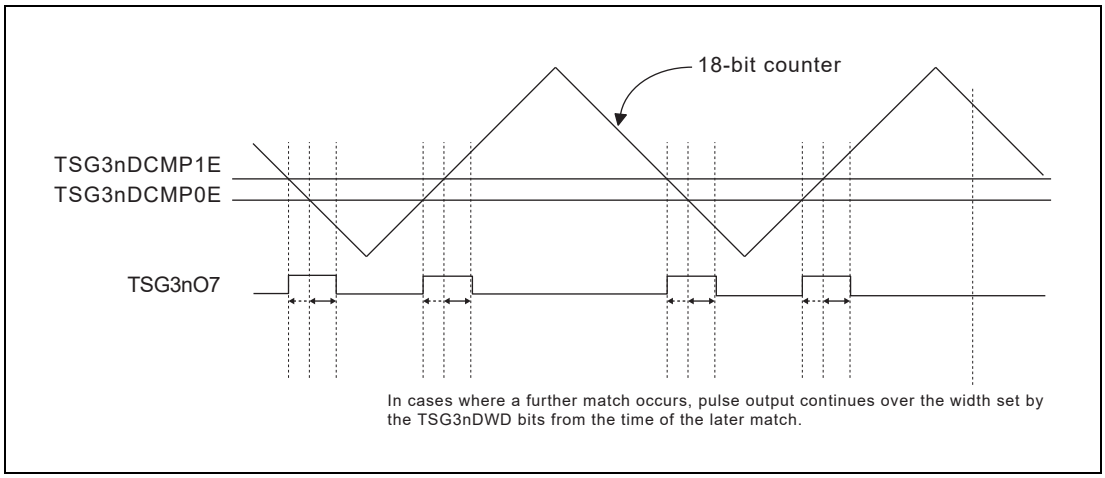

Figure 35.14 Example of TSG3nO7 Pin Diagnostic Pulse Output Timing (2) (with Pulse Output Width Overlapped)

35.4.1.5 Restart

Setting TSG3nTRG0.TSG3nTS to 1 or input to TSG3nTSST while the timer is operating (TSG3nSTR0.TSG3nTE = 1) leads to the following operations.

- Initializing the following counters;

  18-bit main counter, 18-bit sub-counter, interrupt skipping counter

- Initializing the following flags;

  TSG3nCUF, TSG3nSUF, TSG3nRSF, and TSG3nTE of the TSG3nSTR0 register

  TSG3nOPF2 to TSG3nOPF0 of the TSG3nSTR1 register (TSG3nTSF is not initialized)

  TSG3nPPF, TSG3nPEF, TSG3nTDF, TSG3nNDF, TSG3nPRF, and TSG3nPTF of the TSG3nSTR2 register (TSG3nTBF2 to TSG3nTBF20 are not initialized)

- Reloading the following registers;

  TSG3nCTL2, TSG3nCTL4, TSG3nIOC3, TSG3nCMP0, TSG3nCMP0E, TSG3nCMPmW (m = 1, 3, 5, 7, 9, or 11)

  TSG3nCMP1 to TSG3nCMP12, TSG3nCMP1E to TSG3nCMP12E

  TSG3nDCMP0W, TSG3nDCMP2, TSG3nDCMP0E to TSG3nDCMP2E

  TSG3nPAT0W, TSG3nPAT1W

  TSG3nCMPU, TSG3nCMPV, TSG3nCMPW

  TSG3nCMPUE, TSG3nCMPVE, TSG3nCMPWE

  TSG3nUPW, TSG3nVPW, TSG3nWPW

  TSG3nUPWE, TSG3nVPWE, TSG3nWPWE

  TSG3nHSPSHUE, TSG3nHSPSHVE, TSG3nHSPSHWE

  TSG3nHSPCMUE, TSG3nHSPCMVE, TSG3nHSPCMWE

- Reflecting the settings in the following register;

  TSG3nOPT0*1

The dead time is always inserted because the dead time counter continues counting while the dead time control registers TSG3nDTC0W and TSG3nDTC1W are reloaded on restart.

If the counter is restarted while diagnostic output is in progress, the output is initialized.

Note 1. The settings in the TSG3nOPT0 register bits are reflected at the timings described below:
For TSG3nSOC
Switching from 0 to 1: immediately after written
Switching from 1 to 0: when the register is reloaded
For TSG3nSTE, TSG3nPOT, TSG3nPSS, TSG3nIDC, and TSG3nPSC
• At the next timer cycle
• When the output patterns are switched

35.4.2 Match Interrupt

The TSG3n can generate interrupts such as a compare match interrupt (INTTSG3nIm), a peak interrupt (INTTSG3nIPEK), and a valley interrupt (INTTSG3nIVLY). For an error interrupt and warning interrupt (INTTSG3nIER and INTTSG3nIWN), see **Section 35.4.6, Error/Warning Interrupt**.

A period interrupt (INTTSG3nI0) is generated for each timer period. In HT-PWM mode, it is generated when the TSG3nDTC0 buffer register value matches with the 18-bit counter value. When the 18-bit counter performs sawtooth waveform operation (PWM mode, SP-PWM mode, 120-DC mode, and HSP-PWM mode), it is generated after the 18-bit counter value has matched with the TSG3nCMP0E buffer register value.

A compare-match interrupt (INTTSG3nIm) is generated by a match of the TSG3nCMPmE buffer register value with the 18-bit counter value depending on the compare register to be used in each operating mode (m = 1 to 12).

A peak interrupt (INTTSG3nIPEK) is generated in all the modes. In HT-PWM mode, it is generated when the 18-bit counter switches from incrementing to decrementing. When the 18-bit counter performs sawtooth waveform operation (PWM mode, SP-PWM mode, 120-DC mode, and HSP-PWM mode), it is generated after the 18-bit counter value has matched with the TSG3nCMP0E buffer register value (the same timing as an INTTSG3nI0 interrupt).

A valley interrupt (INTTSG3nIVLY) is generated when the 18-bit counter switches from decrementing to incrementing in HT-PWM mode.

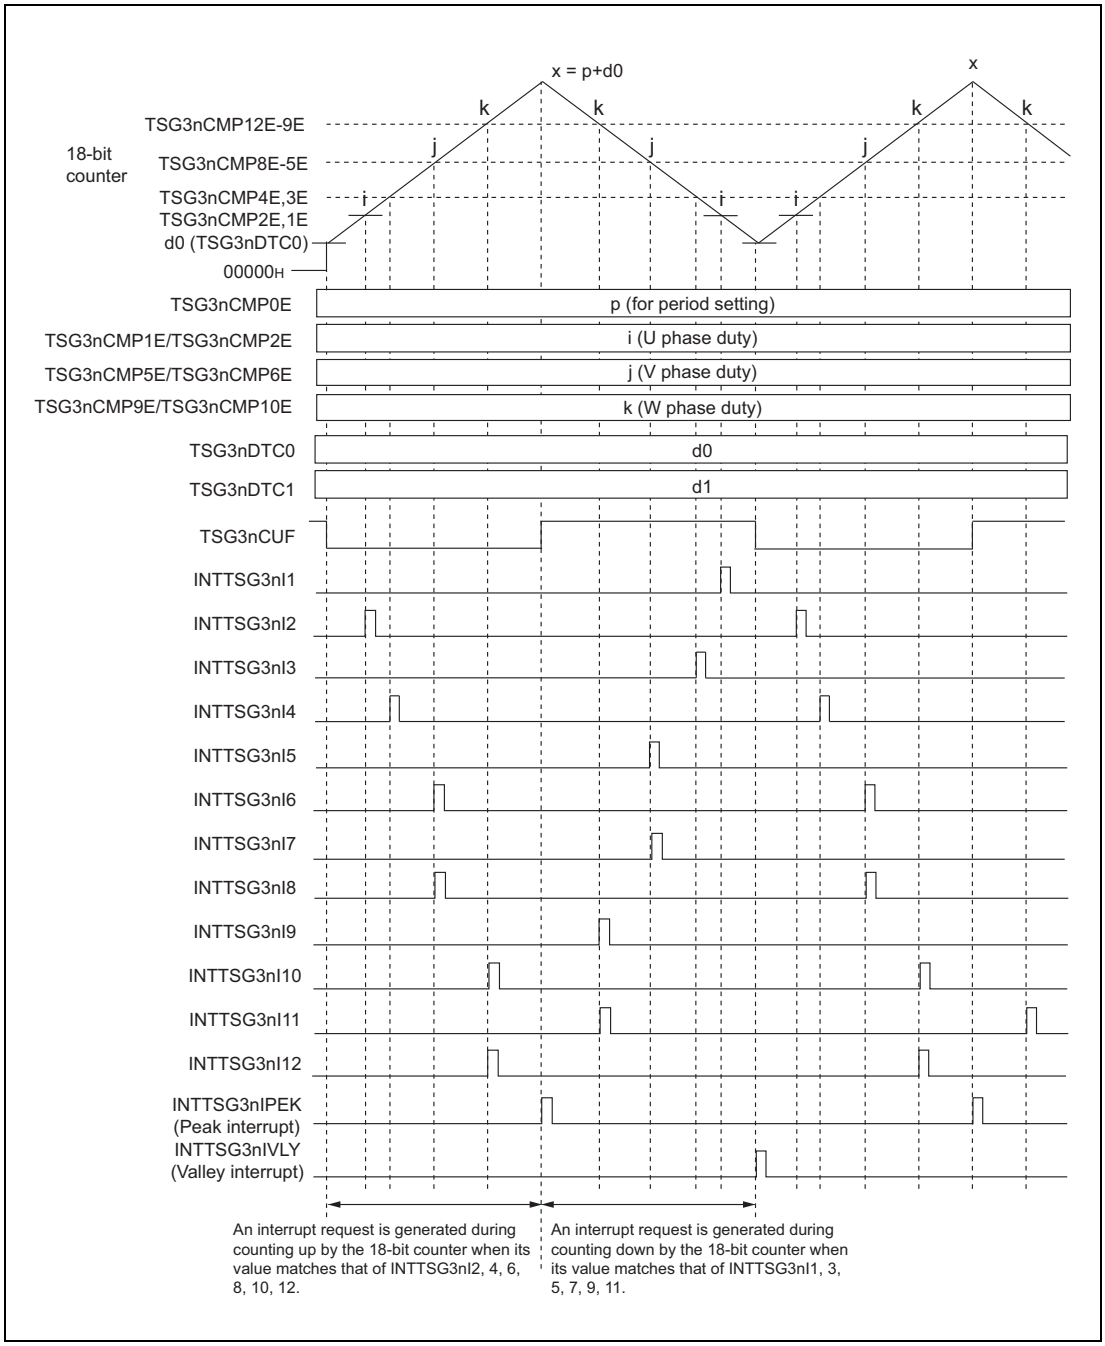

Figure 35.15 Interrupt Generation Example (Example of HT-PWM Mode)

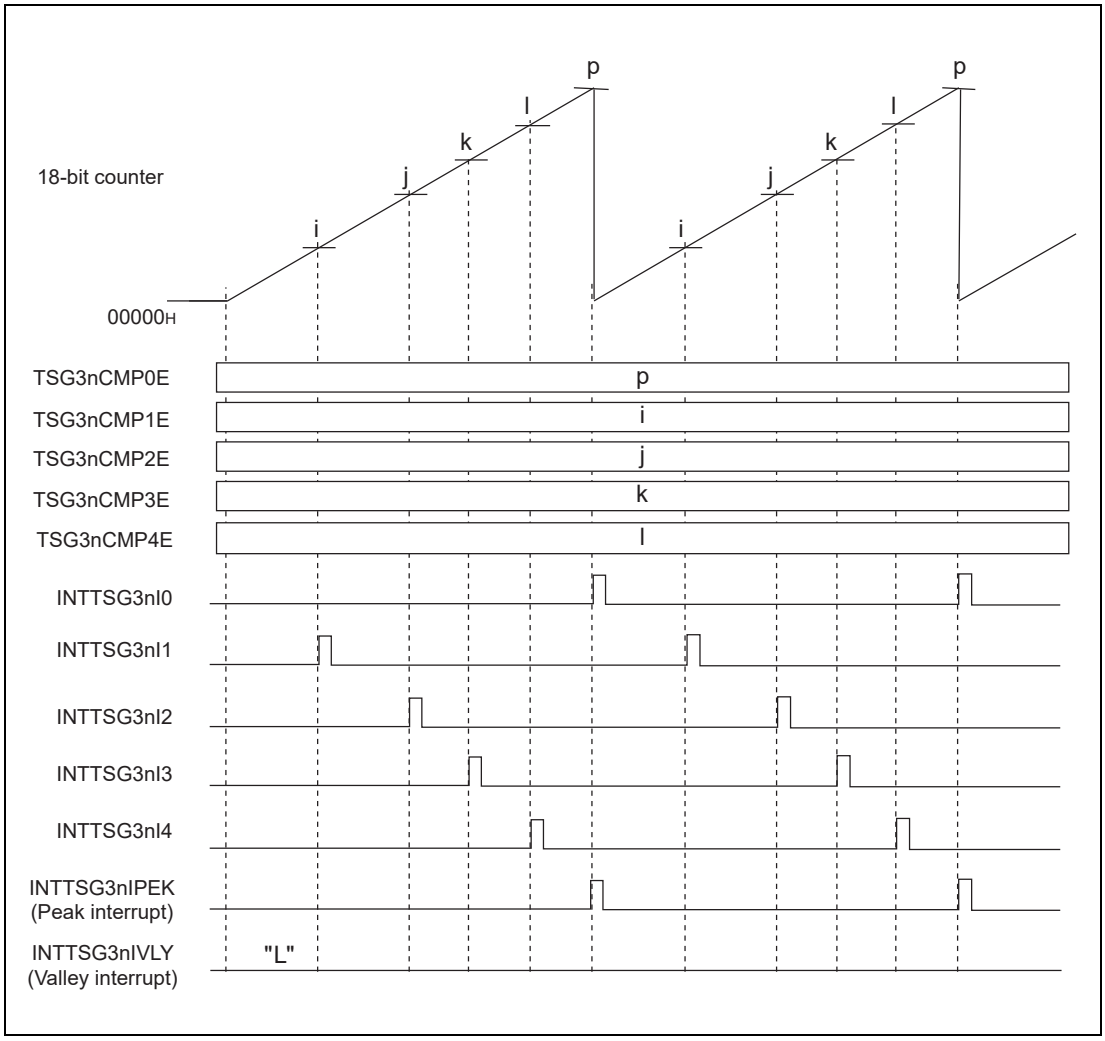

Figure 35.16 Interrupt Generation Example (Example of PWM Mode)

Interrupt in each mode (INTTSG3nI0-INTTSG3nI12, INTTSG3nIPEK, INTTSG3nIVLY, INTTSG3nIER, and INTTSG3nIWN) are listed in **Table 35.49**.

Table 35.49 List of Interrupts in Each Mode (1/5)

Operating Mode	INTTSG3nI0	INTTSG3nI1	INTTSG3nI2	INTTSG3nI3
PWM mode	TSG3nCMP0E compare match interrupt	TSG3nCMP1E compare match interrupt*1	TSG3nCMP2E compare match interrupt*1	TSG3nCMP3E compare match interrupt*1
HT-PWM mode	Period interrupt	TSG3nCMP1E compare match interrupt*2 when decrementing (TSG3nCUF = 1)	TSG3nCMP2E compare match interrupt*2 when incrementing (TSG3nCUF = 0)	TSG3nCMP3E compare match interrupt*2 when decrementing (TSG3nCUF = 1)
SP-PWM mode	TSG3nCMP0E compare match interrupt	TSG3nCMP1E compare match interrupt*1	TSG3nCMP2E compare match interrupt*1	—
120-DC mode	TSG3nCMP0E compare match interrupt	TSG3nCMP1E compare match interrupt*1	TSG3nCMP2E compare match interrupt*1	TSG3nCMP3E compare match interrupt*1
HSP-PWM mode	TSG3nCMP0E compare match interrupt	TSG3nCMP1E compare match interrupt*1	TSG3nCMP2E compare match interrupt*1	TSG3nCMP3E compare match interrupt*1

Note 1. A compare match interrupt is not generated when TSG3nCMP0E < TSG3nCMPmE (m = 1 to 12)

Note 2. A compare match interrupt is not generated when $00000_H \leq$ TSG3nCMPmE < TSG3nDTC0, (TSG3nCMP0E + TSG3nDTC0) < TSG3nCMPmE.

Table 35.49 List of Interrupts in Each Mode (2/5)

Operating Mode	INTTSG3nI4	INTTSG3nI5	INTTSG3nI6	INTTSG3nI7

35.4.3.1 Up Count Flag (TSG3nCUF and TSG3nSUF)

Name

Up count flag (TSG3nSTR0.TSG3nCUF and TSG3nSUF)

Description

There are following two up count flags.

TSG3nCUF is an up/down count flag of the 18-bit counter.

TSG3nSUF is an up/down count flag of the 18-bit sub-counter.

For both TSG3nCUF and TSG3nSUF, 0 means increment, and 1 means decrement.

TSG3nCUF and TSG3nSUF can be used only in HT-PWM mode.

Example of operation

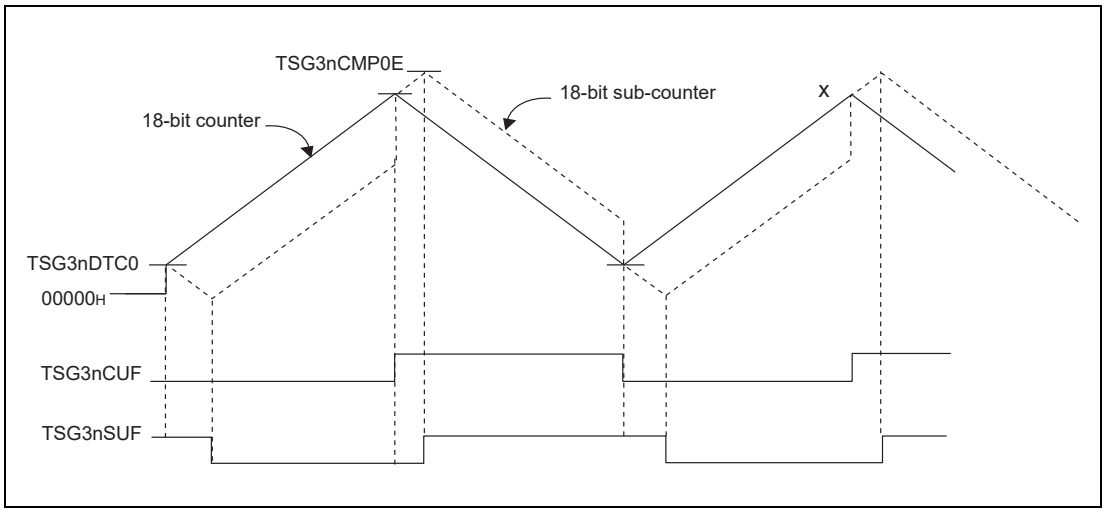

Figure 35.17 Example of Up count flag operation

NOTES

1. TSG3nCUF value is:
   0 (up count) when TSG3nDTC0 ≤ 18-bit counter ≤ (TSG3nCMP0E + TSG3nDTC0-2)
   1 (down count) when (TSG3nCMP0E + TSG3nDTC0) ≥ 18-bit counter ≥ TSG3nDTC0 + 2
2. TSG3nSUF value is:
   0 (up count) when 0 ≤ 18-bit sub-counter ≤ (TSG3nCMP0E + TSG3nDTC0 + TSG3nDTC1-2)
   1 (down count) when (TSG3nCMP0E + TSG3nDTC0 + TSG3nDTC1) ≥ 18-bit sub-counter ≥ 2

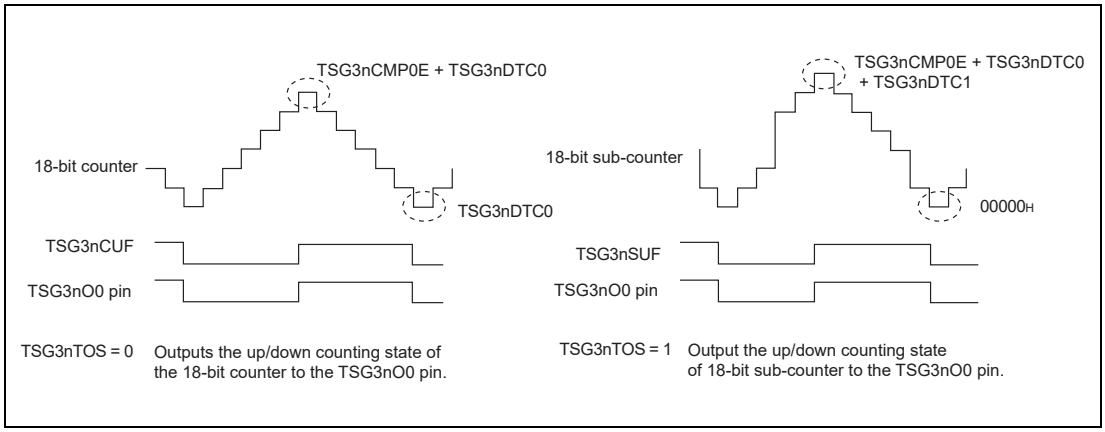

Figure 35.18 TSG3nO0 Pin Output depending onTSG3nIOC1.TSG3nTOS Setting

Operating Mode

TSG3nCUF and TSG3nSUF can be used only in HT-PWM mode.

35.4.3.2 Positive Phase and Inverse Phase Simultaneous Active State Detection Flag (TSG3nTBF0 to TSG3nTBF2)

Name

Positive phase and inverse phase simultaneous active state detection flag (TSG3nSTR2.TSG3nTBF0 to TSG3nTBF2 flags)

Description

When any of TSG3nCTL1.TSG3nTBA2 to TSG3nTBA0 is 1, TSG3nTBF0 to TSG3nTBF2 can detect the simultaneous active state of the positive phase and inverse phase of TSG3n.

When the simultaneous active state of the positive phase and inverse phase of the TSG3n is detected, the corresponding TSG3nTBF0 to TSG3nTBF2 flags are set to 1, and an error interrupt (INTTSG3nIER) is generated. The flags are cleared when 1 is written to TSG3nSTC.TSG3nTBR0 to TSG3nTBR2, respectively.

Example of operation

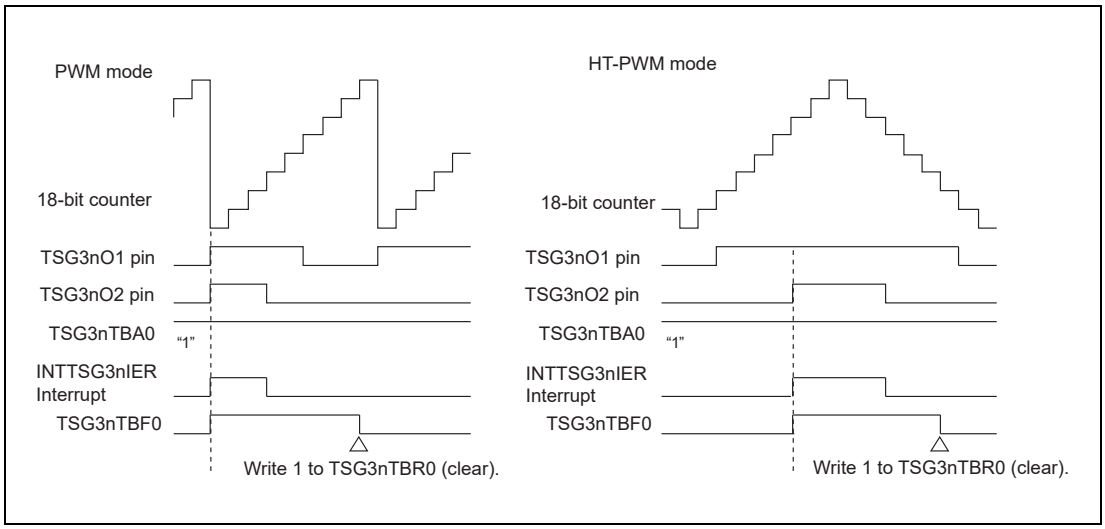

Figure 35.19 Example of Positive Phase and Inverse Phase Simultaneous Active State Detection Flag Operation

Operating Mode

Available in all operating modes.

CAUTION

TSG3nTBF0 to TSG3nTBF2 are valid only when TSG3nCTL1.TSG3nTBA0 to TSG3nTBA2 = 1 and TSG3nSTR0.TSG3nTE = 1.

35.4.3.3 Reload Request Flag (TSG3nRSF)

Name

Reload request flag (TSG3nSTR0.TSG3nRSF)

Description

TSG3nRSF is set to 1 when a reload request is generated (when a value is written to TSG3nCMP1E (TSG3nCMP1, TSG3nCMP1W, TSG3nCMPUE, TSG3nCMPU, TSG3nUPWE, TSG3nUPW, and TSG3nHSPCMUE)), and cleared to 0 when reload occurs and the value is transferred to all the buffer registers.

Example of operation

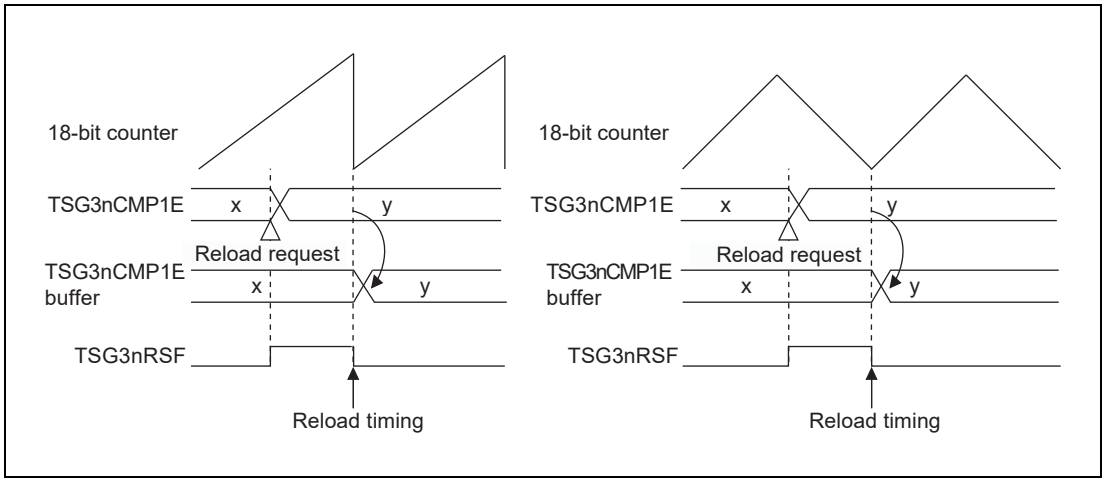

Figure 35.20 Example of Reload Request Flag Operation

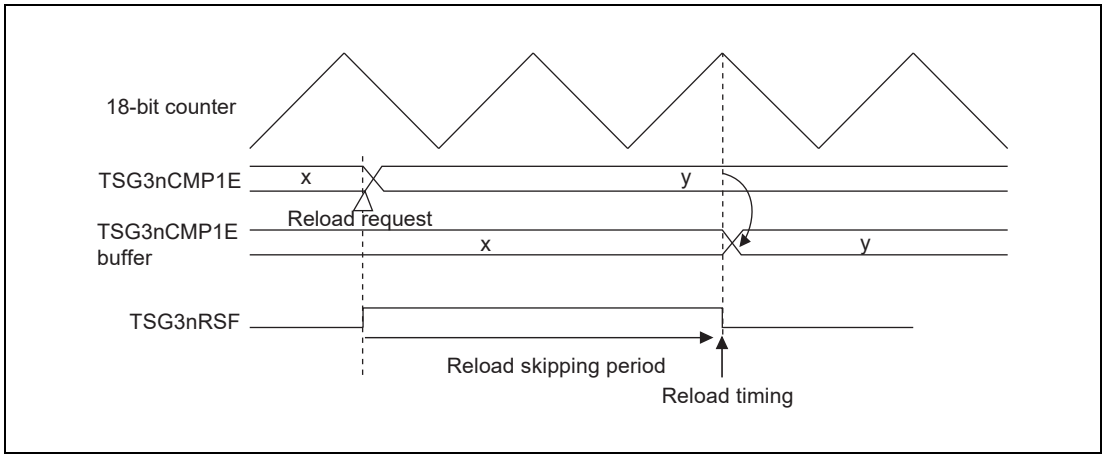

Figure 35.21 Reload Request Flag and Reload Skipping Period

Operating Mode

Available in all operating modes.

35.4.3.4 Noise Detection Flag (TSG3nNDF)

Name

Noise detection flag (TSG3nSTR2.TSG3nNDF)

Description

TSG3nNDF can detect that two or more pins of TSG3nPTSI2 to TSG3nPTSI0 have changed simultaneously (a noise is generated).

TSG3nNDF is set to 1 when two or more pins of TSG3nPTSI2 to TSG3nPTSI0 have changed simultaneously (a noise is generated), and a warning interrupt (INTTSG3nIWN) is generated. The TSG3nNDF flag is cleared to 0 when 1 is written to the TSG3nSTC.TSG3nNDR bit.

Example of operation

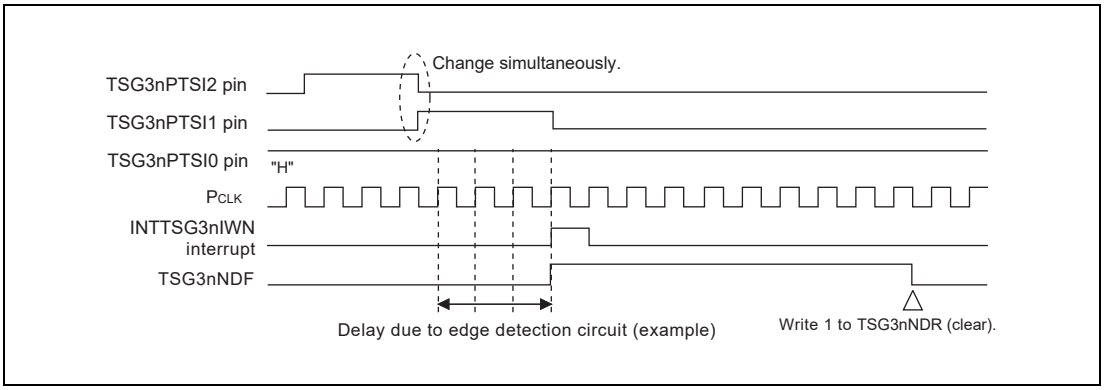

Figure 35.22 Example of Noise Detection Flag Operation

Operation mode

Available in all operating modes.

CAUTION

TSG3nNDF is valid only when TSG3nCTL1.TSG3nNDC = 1 and TSG3nSTR0.TSG3nTE = 1.

35.4.3.5 Pattern Order Detection Flag (TSG3nTSF)

Name

Pattern order detection flag (TSG3nSTR1.TSG3nTSF)

Description

TSG3nTSF can detect the order of patterns input to the TSG3nPTSI2 to TSG3nPTSI0 pins.

TSG3nTSF is set depending on the values input to the TSG3nPTSI2 to TSG3nPTSI0 pins as shown in the table below

Table 35.51 Pattern Order Detection Flag and Pattern Input Order

TSG3nTSF	Values input to TSG3nPTSI2 to TSG3nPTSI0 Pins
0	[1,0,1] → [1,0,0] → [1,1,0] → [0,1,0] → [0,1,1] → [0,0,1]
1	[1,0,1] ← [1,0,0] ← [1,1,0] ← [0,1,0] ← [0,1,1] ← [0,0,1]

Example of operation

(a) When Normal Input to TSG3nPTSI2 to TSG3nPTSI0 Pins is Detected

As shown in **Figure 35.23**, if the TSG3nPTSI2 to TSG3nPTSI0 pins change in the normal order, 0 or 1 is set according to the change order at the change timing.

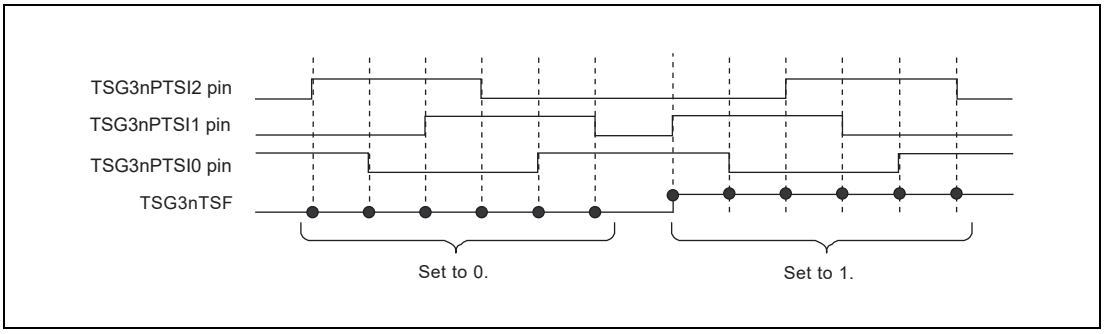

Figure 35.23 Example of Pattern Order Detection Flag Operation (Normal Operation)

(b) Detection of Change in Input Pattern Order

Immediately after TSG3n starts operation, the rotation direction cannot be determined. Therefore, TSG3nTSF cannot detect the change (normal or reverse rotation) in the patterns input to the TSG3nPTSI2 to TSG3nPTSI0 pins. To enable detection of change immediately after the beginning of operation, TSG3nPSC should be set before operation starts (when TSG3nTE = 0, the TSG3nPSC value is reflected).

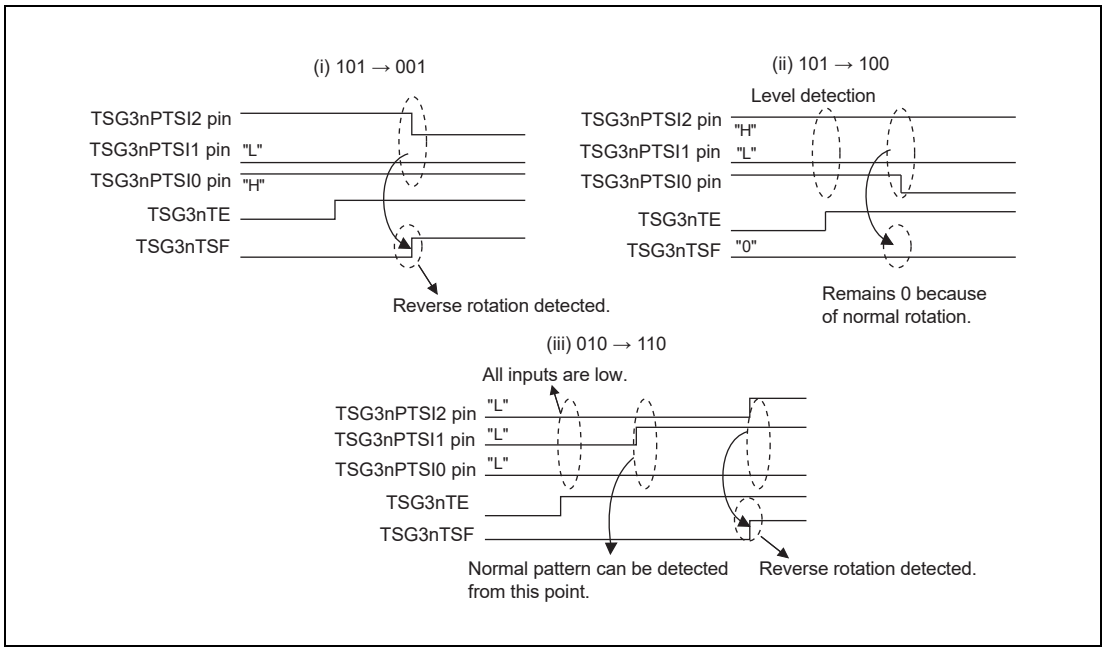

Figure 35.24 Example of Detecting Change (Normal/Reverse Rotation) in Pattern Input to TSG3nPTSI2 to TSG3nPTSI0 Pins

(c) When Abnormal Input to TSG3nPTSI2 to TSG3nPTSI0 Pins is Detected

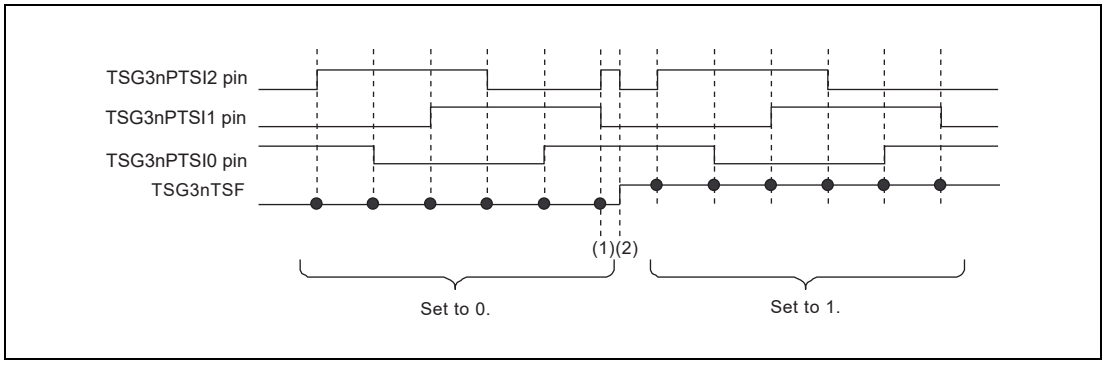

Figure 35.25 Example of Operation when Values Input to Two Pins of TSG3nPTSI2 to TSG3nPTSI0 Change (Abnormal Operation)

(1) TSG3nTSF does not change at this point because it expects the input pattern change to {0, 1, 0} or {0, 0, 1} (if values of two pins change, TSG3nTSF does not change).

(2) TSG3nPTSI2 to TSG3nPTSI0 pins are determined to have been changed from {1, 0, 1} to {0, 0,1}, and TSG3nTSF is set to 1.

Operation mode

Available in all operating modes.

35.4.3.6 Pattern Error Detection Flag (TSG3nPEF)

Name

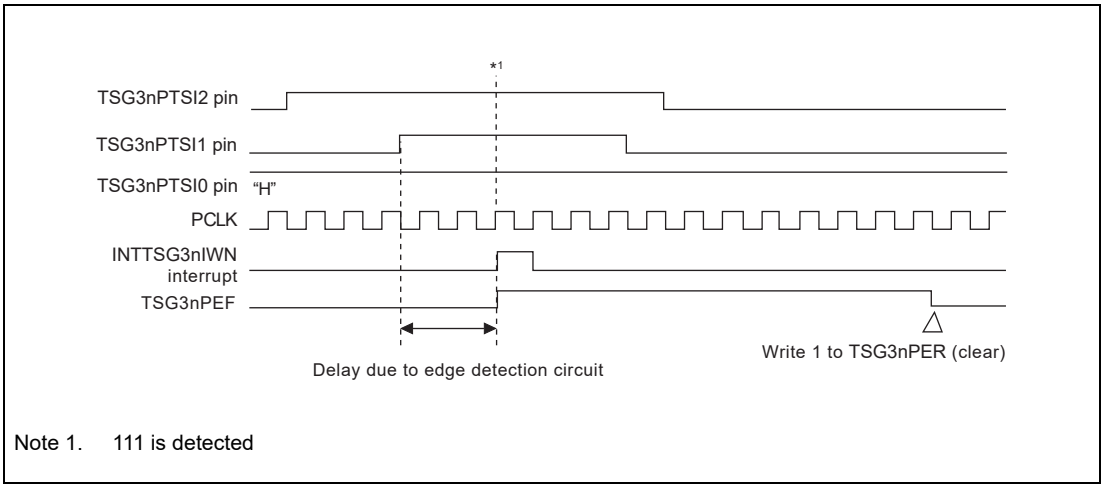
Pattern error detection flag (TSG3nSTR2.TSG3nPEF)

Description

TSG3nPEF can detect that 000 or 111 is input to the TSG3nPTSI2 to TSG3nPTSI0 pins.

TSG3nPEF is set to 1 when the levels of the TSG3nPTSI2 to TSG3nPTSI0 pins are 111 or 000, and a warning interrupt (INTTSG3nIWN) is generated. TSG3nPEF is cleared to 0 when 1 is written to TSG3nSTC.TSG3nPER.

Example of operation



Note 1. 111 is detected

Figure 35.26 Example of Pattern Error Detection Flag Operation (TSG3nPTSI2 to TSG3nPTSI0 Pins = 111)

Operation mode

Available in all operating modes.

CAUTIONS

TSG3nPEF is valid only when TSG3nCTL1.TSG3nPEC = 1 and TSG3nSTR0.TSG3nTE = 1.

35.4.3.7 Pattern Reversal Detection Flag (TSG3nPRF)

Name

Pattern reversal detection flag (TSG3nSTR2.TSG3nPRF)

Description

TSG3nPRF can detect that the pattern change order of the TSG3nPTSI2 to TSG3nPTSI0 pins have been reversed.

TSG3nPRF is set to 1 when the pattern order detection flag (TSG3nTSF) changes, and a warning interrupt (INTTSG3nIWN) is generated. However, immediately after TSG3nSTR0.TSG3nTE is set to 1, TSG3nPRF becomes valid at the timing of the second and subsequent change in TSG3nPTSI2 to TSG3nPTSI0 pins.

TSG3nPRF is cleared to 0 when 1 is written to the TSG3nSTC.TSG3nPRR bit.

Example of operation

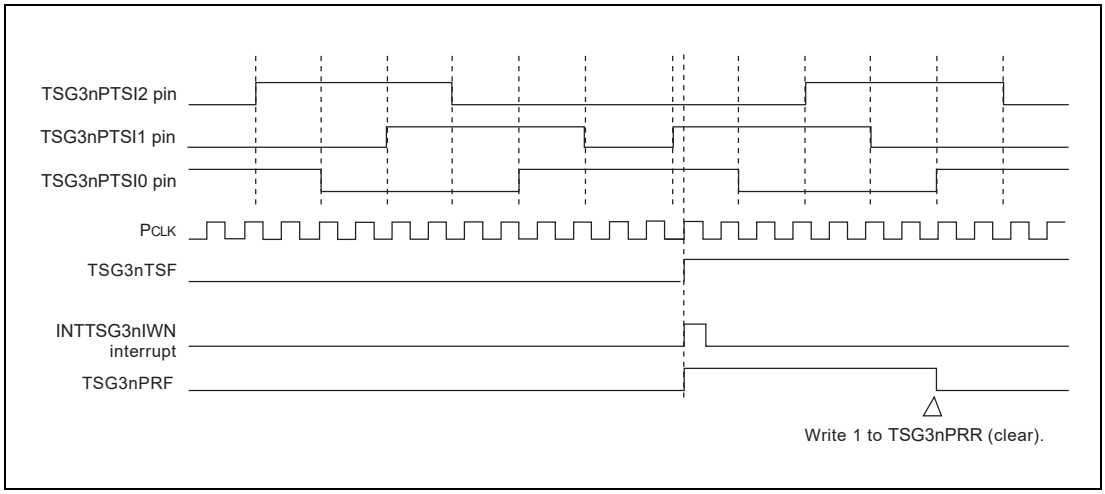


Figure 35.27 Example of Pattern Reversal Detection Flag Operation

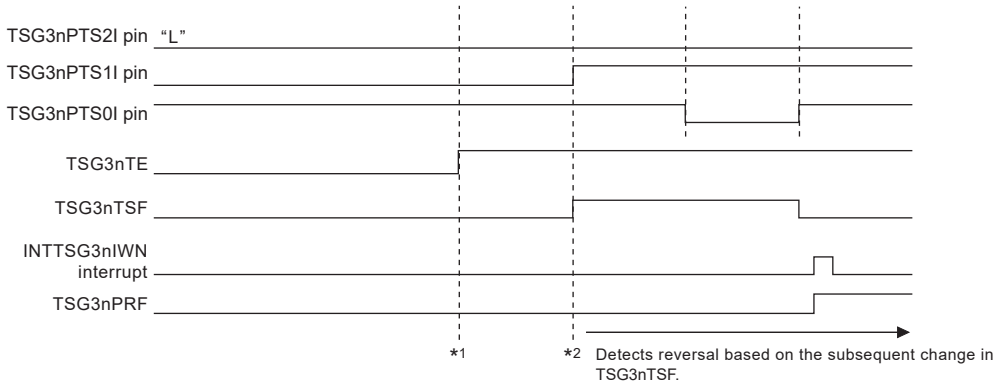

Note 1. Operation starts.

Note 2. If TSG3nTSF is set to 1 by the first change in the TSG3nPTSI2 to TSG3nPTSI0 pins immediately after TSG3nTE is set to 1, reversal is not detected.

Figure 35.28 Example of Operation immediately after TSG3nTE Flag in TSG3nSTR0 is Set to 1

Operation mode

Available in all operating modes.

CAUTION

TSG3nPRF is valid only when TSG3nCTL1.TSG3nPRC = 1 and TSG3nSTR0.TSG3nTE = 1.

35.4.3.8 TSG3nPTSI2 to TSG3nPTSI0 Pin Abnormal Toggle Detection Flag (TSG3nPTF)

Name

TSG3nPTSI2 to TSG3nPTSI0 pin abnormal toggle detection flag (TSG3nSTR2.TSG3nPTF)

Description

TSG3nPTF can detect that the values of the TSG3nPTSI2 to TSG3nPTSI0 pins change three or more times during the TSG3nOPCI0 or TSG3nOPCI1 signal trigger.

TSG3nPTF is set to 1 when the third trigger of TSG3nOPCI0 or TSG3nOPCI1 signal occurs simultaneously with the change in TSG3nPTSI2 to TSG3nPTSI0, and a warning interrupt (INTTSG3nIWN) is generated.

TSG3nPTF is cleared to 0 when 1 is written to TSG3nSTC.TSG3nPTR.

Example of operation

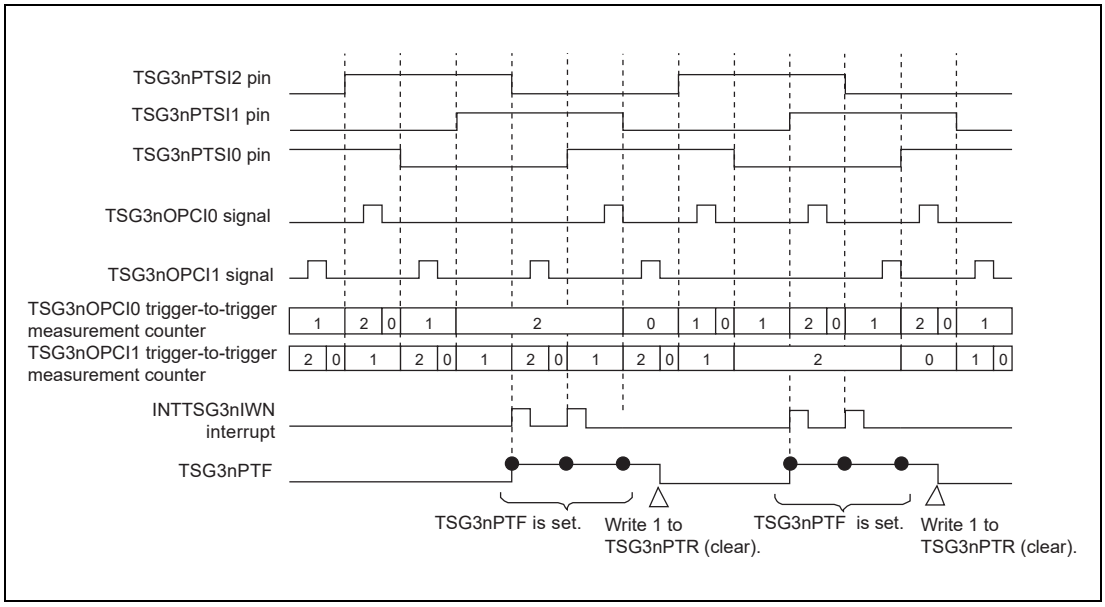

Figure 35.29 Example of TSG3nPTSI2 to TSG3nPTSI0 Pin Abnormal Toggle Detection Flag Operation

Operating mode

Available in all operating modes.

NOTES

1. TSG3nPTF is valid only when TSG3nCTL1.TSG3nPTC1 bit = 1 and TSG3nSTR0.TSG3nTE = 1.
2. When TSG3nPTC0 bit = 1 and TSG3nPTC1 bit = 1, TSG3nO1 to TSG3nO6 pin output switch control is automatically switched to pattern switch method (TSG3nOPT0.TSG3nPOT bit = 0) if an abnormal toggle is detected.

35.4.3.9 TSG3nOPCI0 and TSG3nOPCI1 Signal Simultaneous Trigger Detection Flag (TSG3nTDF)

Name

TSG3nOPCI0 and TSG3nOPCI1 signal simultaneous trigger detection flag (TSG3nSTR2.TSG3nTDF)

Description

TSG3nTDF can detect that TSG3nOPCI0 and TSG3nOPCI1 signals are generated simultaneously.

TSG3nTDF is set to 1 when the TSG3nOPCI0 and TSG3nOPCI1 signals are generated simultaneously, and a warning interrupt (INTTSG3nIWN) is generated. TSG3nTDF is cleared to 0 when 1 is written to TSG3nSTC.TSG3nTDR.

Example of operation

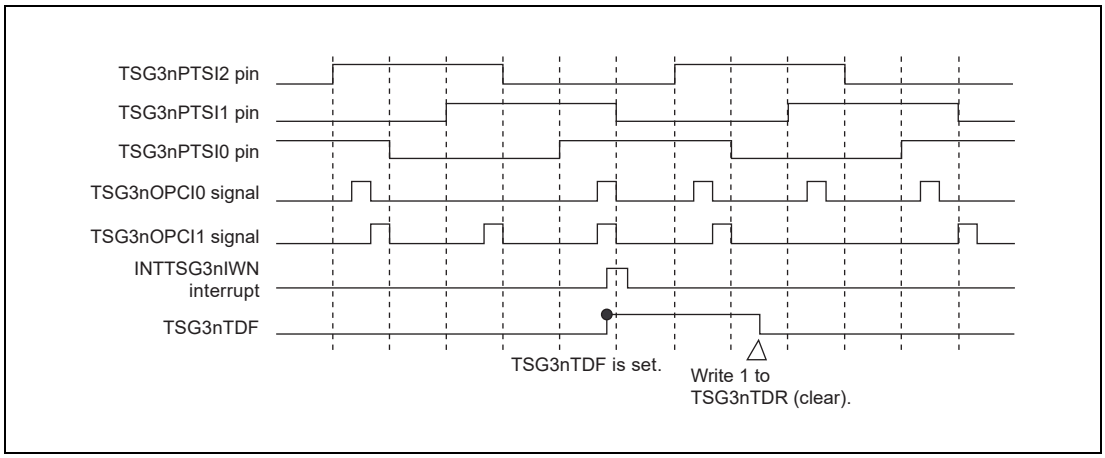

Figure 35.30 Example of TSG3nOPCI0 and TSG3nOPCI1 Signal Simultaneous Trigger Detection Flag Operation

Operating mode

Available in all operating modes.

CAUTION

TSG3nTDF is valid only when TSG3nCTL1.TSG3nTDC = 1 and TSG3nSTR0.TSG3nTE = 1.

35.4.3.10 Pattern Phase Difference Detection Flag (TSG3nPPF)

Name

Pattern phase difference detection flag (TSG3nSTR2.TSG3nPPF)

Description

TSG3nPPF can detect the phase difference between the input pattern (TSG3nPTSI2 to TSG3nPTSI0 pins) and the output pattern (TSG3nSTR1.TSG3nOPF2 to TSG3nOPF0 flags).

TSG3nPPF is set to 1 when the pattern phase difference is detected when the TSG3nOPCI0 and TSG3nOPCI1 signal triggers are input, and a warning interrupt (INTTSG3nIWN) is generated. TSG3nPPF remains 1 until it is cleared to 0 when 1 is written to TSG3nSTC.TSG3nPPR by software. When the phase difference is detected, TSG3nPPF is set at each operation clock cycle (PCLK). TSG3nPPF should be cleared to 0 when no phase difference occurs.

Table 35.52 Correspondence between Normal Input Patterns and Output Patterns

TSG3nPTSI2 to TSG3nPTSI0 pins (input)	“1,0,1”	“1,0,0”	“1,1,0”	“0,1,0”	“0,1,1”	“0,0,1”
TSG3nOPF2 to TSG3nOPF0 flags (output)	“0,0,1” “1,0,1” “1,0,0”	“1,0,1” “1,0,0” “1,1,0”	“1,0,0” “1,1,0” “0,1,0”	“1,1,0” “0,1,0” “0,1,1”	“0,1,0” “0,1,1” “0,0,1”	“0,1,1” “0,0,1” “1,0,1”

Example of operation

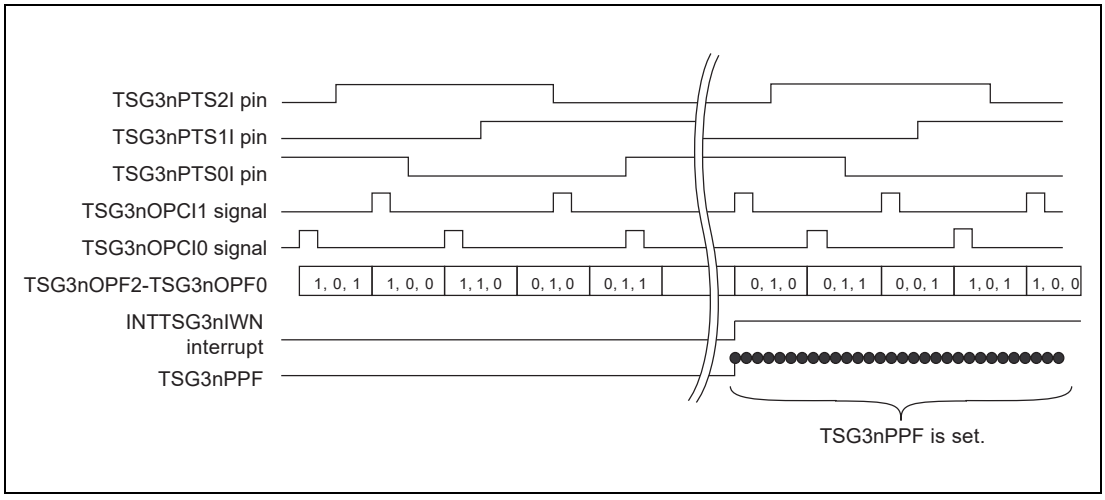

Figure 35.31 Example of Pattern Difference Detection Flag Operation

Operating mode

Available in all operating modes.

CAUTIONS

1. **TSG3nPPF is valid only when TSG3nCTL1.TSG3nPPC = 1 and TSG3nSTR0.TSG3nTE = 1.**
2. **When 000 or 111 is input to the TSG3nPTSI2 to TSG3nPTSI0 pins, or when TSG3nOPF2 to TSG3nOPF0 are set to 000 or 111, TSG3nPPF is not set.**

35.4.3.11 Timer Output Pattern Flag (TSG3nOPF2-TSG3nOPF0)

Name

Timer output pattern flag (TSG3nSTR1.TSG3nOPF2 to TSG3nOPF0)

Description

TSG3nOPF2 to TSG3nOPF0 flags indicate the timer output patterns.

For details, see **Section 35.4.7.4, 120-DC Mode**, and **Section 35.4.7.8, Software Output Control Function**.

Operating mode

Available in all operating modes.

35.4.3.12 Pattern Switch Detection Signal (TSG3nPTE)

Name

Pattern switch detection signal (TSG3nPTE signal)

Description

The TSG3nPTE signal toggles when the input pattern (TSG3nPTSI2 to TSG3nPTSI0 pins) changes.

The toggle pattern is determined by the TSG3nPSC bit (TSG3nOPT0.TSG3nPSS = 1).

Table 35.53 Change Timing of Pattern Switch Detection Signal (1/2)

- TSG3nPSC = 0

		TSG3nPTSI2-TSG3nPTSI0 Pins after Change							
		000	111	101	100	110	010	011	001
Current TSG3nPTSI2 to TSG3nPTSI0 pins	000	—	—	—	—	—	—	—	—
	111	—	—	—	—	—	—	—	—
	101	—	—	—	Toggle	—	—	—	—

Example of operation

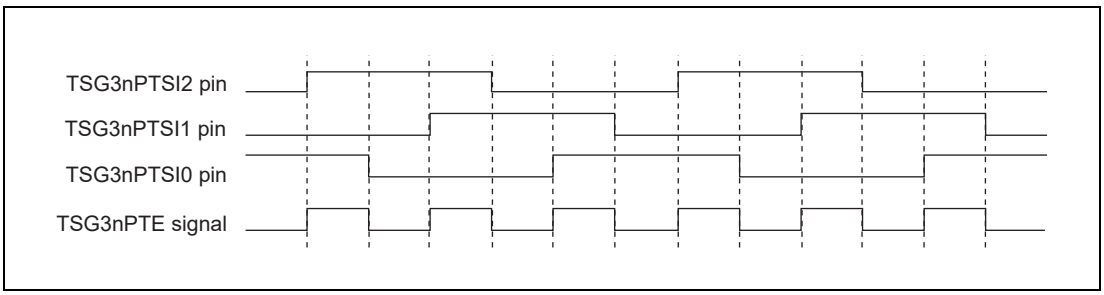

Figure 35.32 Example of Pattern Switch Detection Signal Operation

Operating mode

Available in all operating modes.

CAUTION

The TSG3nPTE signal is valid only when TSG3nIOC1.TSG3nPTS = 1 and TSG3nSTR0.TSG3nTE = 1.

35.4.4 Interrupt Skipping Function

Operation related to the interrupt skipping function is described below.

- Peak interrupts (INTTSG3nIPEK) and valley interrupts (INTTSG3nIVLY) can be skipped.
- TSG3nCTL4.TSG3nPIE enables outputting of the INTTSG3nIPEK interrupt and specifies whether to skip the interrupts.
- TSG3nCTL4.TSG3nVIE enables outputting of the INTTSG3nIVLY interrupt and specifies whether to skip the interrupts.

When TSG3nCTL3.TSG3nRIA is set to 1 (with reload skipping), reload is executed at the same timing as the interrupt after being skipped.

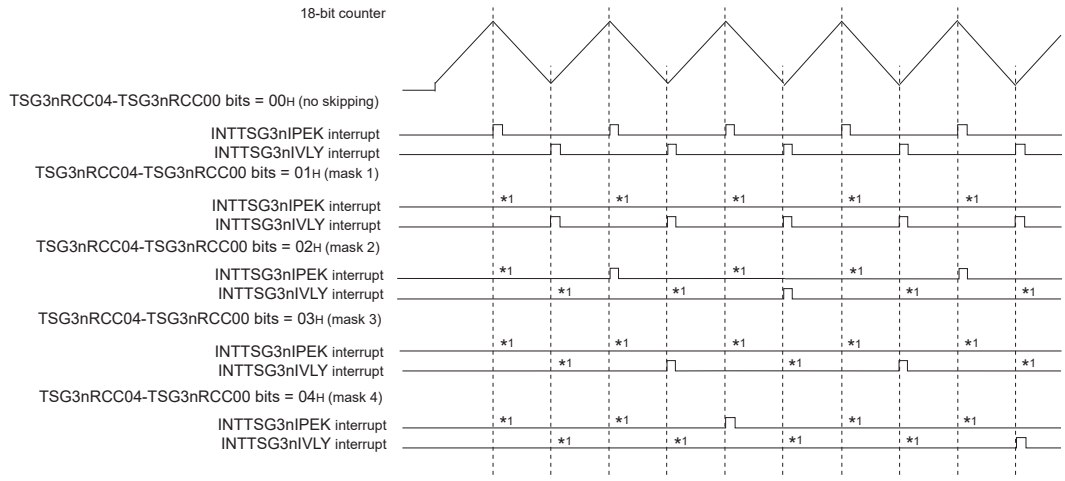
When TSG3nCTL3.TSG3nRIA is set to 0 (without reload skipping), reload is executed at the specified reload timing regardless of interrupt skipping.

CAUTION

When a value is written to TSG3nCTL4, and TSG3nRCC04 to TSG3nRCC00 are transferred to the buffer register, the interrupt skipping counter is cleared. Therefore, when the interrupt skipping function is used, interrupt interval may temporarily become longer. To avoid this, the interrupt skipping count should be changed with the reload timing being set to the interrupts skipped (TSG3nCTL3.TSG3nRIA = 1).

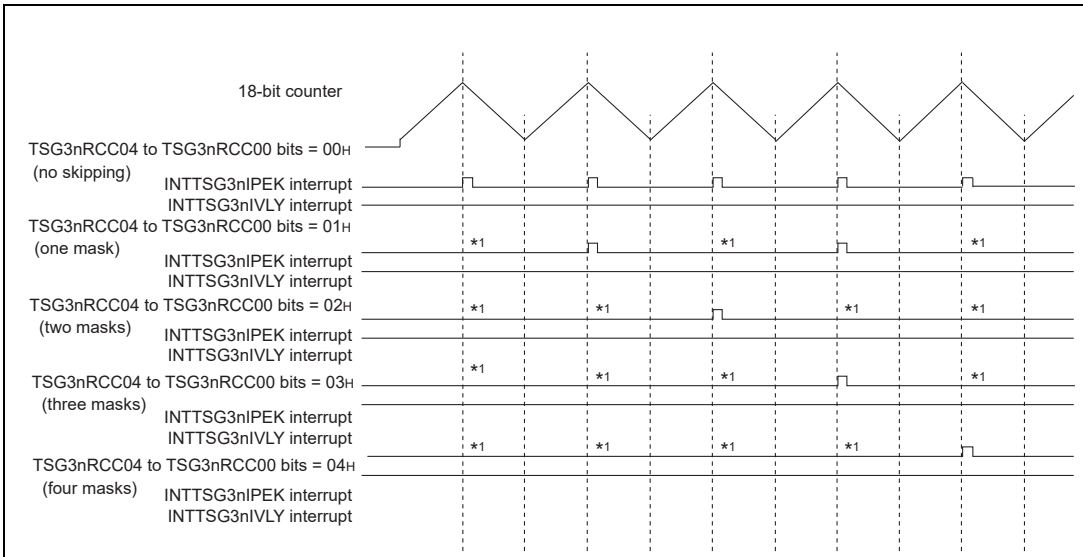
35.4.4.1 Operation of Interrupt Skipping Function

Timing diagram of interrupt skipping function in various conditions are shown in the following figures.



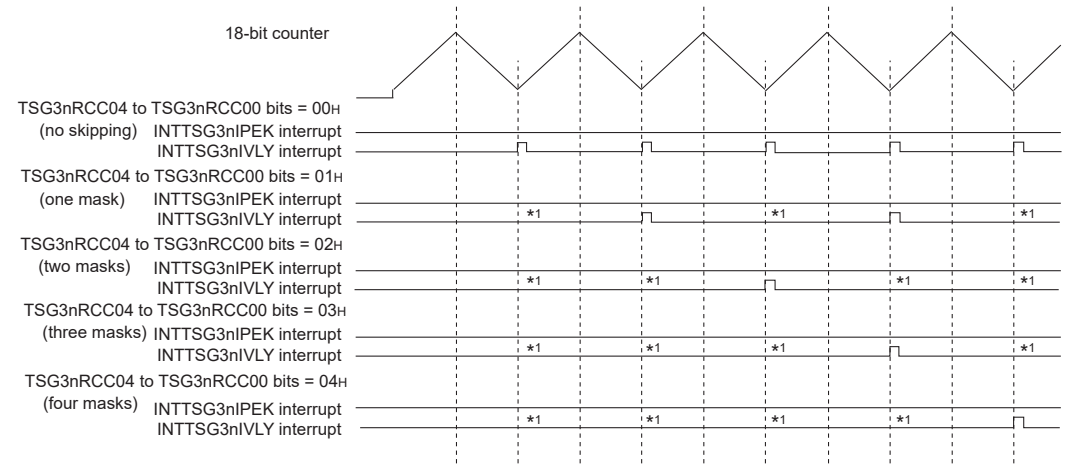
Note 1. Skipped interrupt request

Figure 35.33 Interrupt Skipping Operation when TSG3nPIE = 1 and TSG3nVIE = 1 in TSG3nCTL4 Register (Peak and Valley Interrupt Generation in HT-PWM Mode)



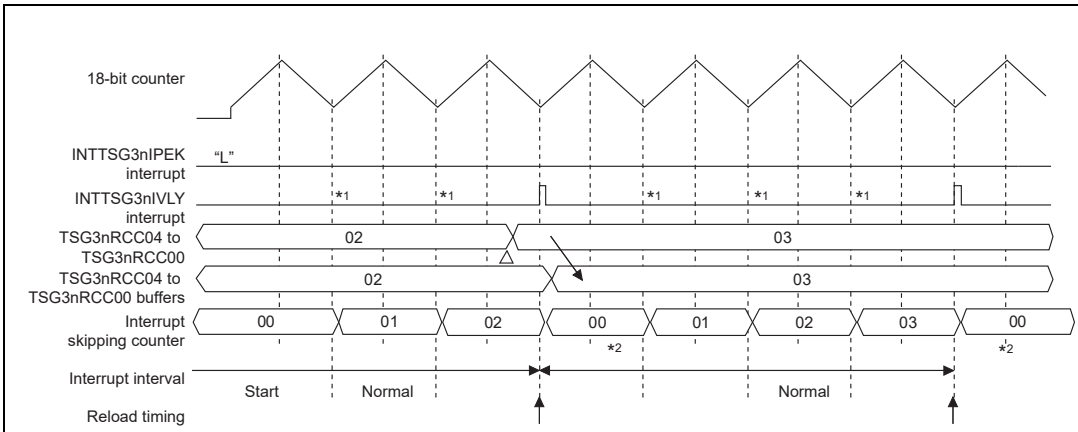
Note 1. Skipped interrupt request

Figure 35.34 Interrupt Skipping Operation when TSG3nPIE = 1 and TSG3nVIE = 0 in TSG3nCTL4 Register (only Peak Interrupt Generation in HT-PWM Mode)



Note 1. Skipped interrupt request

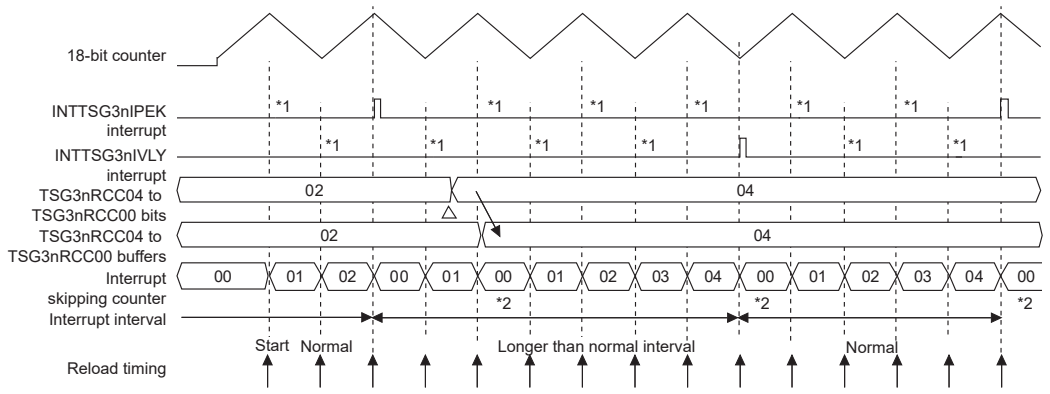
Figure 35.35 Interrupt Skipping Operation when TSG3nPIE = 0 and TSG3nVIE = 1 in TSG3nCTL4 Register (only Valley Interrupt Generation in HT-PWM Mode)



Note 1. Skipped interrupt request

Note 2. Interrupt skipping counter is cleared

Figure 35.36 When TSG3nRMC = 0, TSG3nRIA = 1 in TSG3nCTL3 Register (with Reload Skipping)

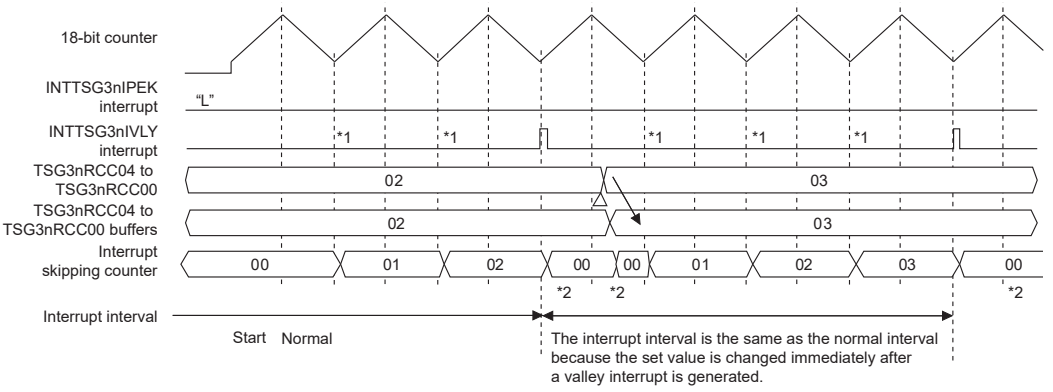


Note 1. Skipped interrupt request
Note 2. Interrupt skipping counter is cleared

Figure 35.37 When TSG3nRMC = 0, TSG3nRIA = 0 in TSG3nCTL3 Register (without Reload Skipping)

CAUTION

Interrupt interval might be longer.



Note 1. Skipped interrupt request
Note 2. Interrupt skipping counter is cleared

Figure 35.38 When TSG3nRMC = 1 in TSG3nCTL3 Register (Anytime Rewrite Mode)

NOTE

After rewriting, the value is reflected immediately regardless of the reload timing. The interrupt skipping counter is cleared when the value is transferred to the TSG3nRCC04 to TSG3nRCC00 buffers, not when the pertinent register is rewritten.

35.4.4.2 Example of Operation when Peak Interrupt is Generated (in PWM Mode)

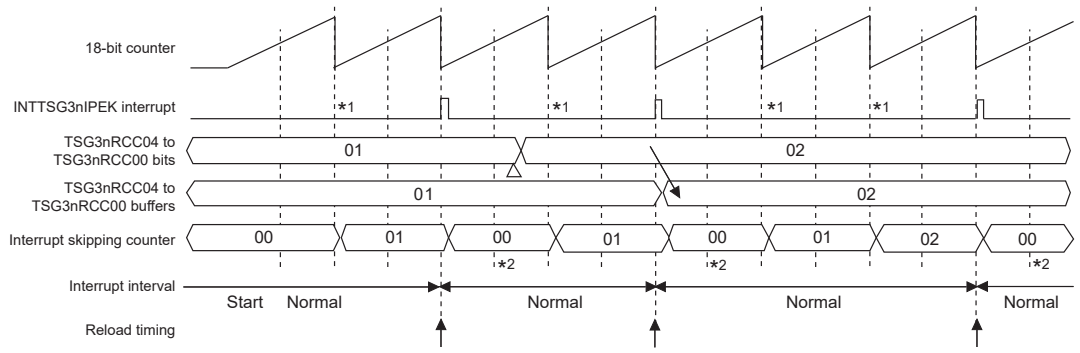
Operation related to the interrupt skipping function in PWM mode is described below.

- Peak interrupts (INTTSG3nIPEK) can be skipped. In PWM mode, it is generated by compare match of TSG3nCMP0E buffer register and 18-bit counter.
- TSG3nCTL4.TSG3nPIE enables outputting of the INTTSG3nIPEK interrupt and specifies whether to skip the interrupts.
- The setting of TSG3nCTL4.TSG3nVIE is disabled. At this time, the INTTSG3nIVLY interrupt is not generated.
  When TSG3nCTL3.TSG3nRIA is set to 1 (with reload skipping), reload is executed at the same timing as the interrupt after being skipped.

CAUTION

When a value is written to TSG3nCTL4, and TSG3nRCC04 to TSG3nRCC00 are transferred to the buffer register, the interrupt skipping counter is cleared. Therefore, when the interrupt skipping function is used, interrupt interval may be long temporarily. To avoid this, the interrupt skipping count should be changed with the reload timing being set to the interrupts skipped (TSG3nCTL3.TSG3nRIA = 1).

(1) Example of operation



Note 1. Skipped interrupt request
Note 2. Interrupt skipping counter is cleared.

Figure 35.39 When TSG3nCTL3.TSG3nRMC = 0, TSG3nRIA = 1, TSG3nCTL4.TSG3nPRE = 1 (Recommended Setting)

NOTE

When TSG3nCTL3.TSG3nRIA = 1, reload is executed at the same timing as the interrupt after being skipped.

35.4.5 A/D Conversion Trigger Function

A/D conversion trigger operation is described below.

The TSG3nDCMP0E, TSG3nDCMP1E, and TSG3nDCMP2E registers are used as compare registers of the A/D conversion trigger function.

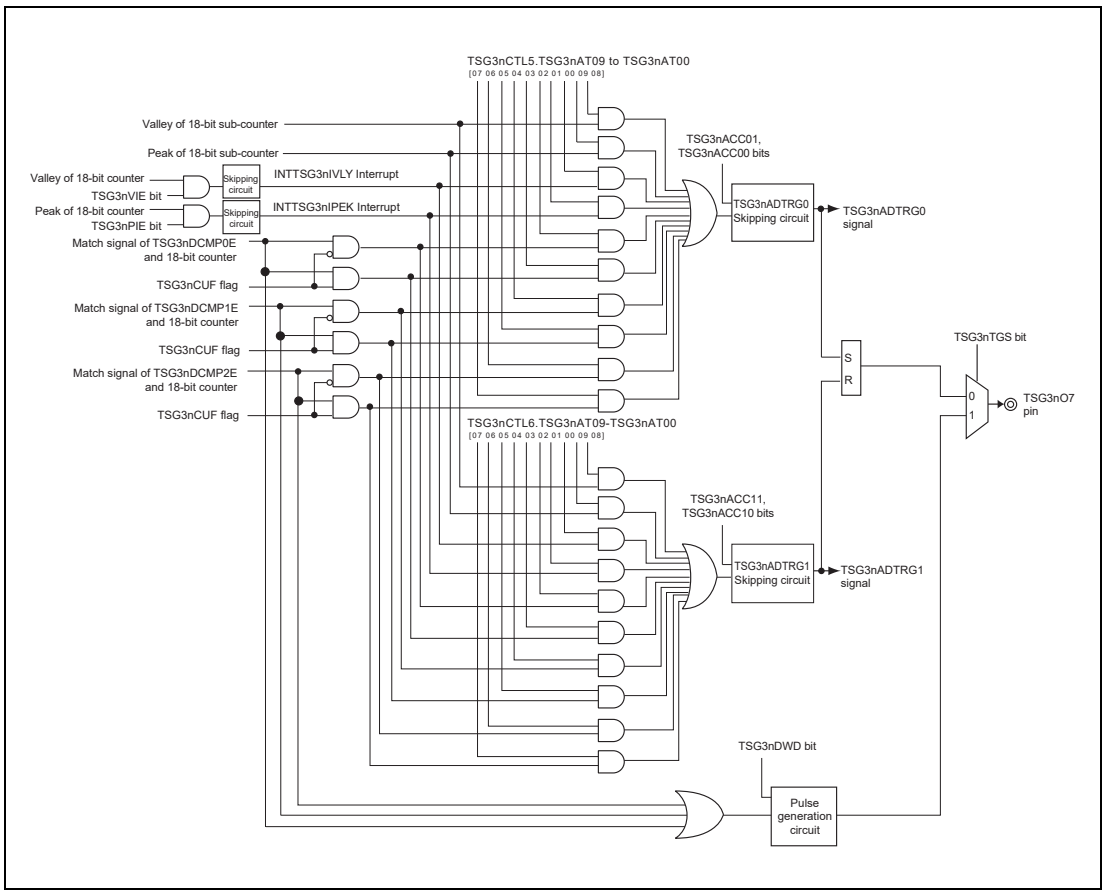


Figure 35.40 A/D Conversion Trigger and Diagnostic Output Control Circuit

As shown in **Figure 35.40**, a logical ORed signal can be generated by selecting the compare match of TSG3nDCMP0E to TSG3nDCMP2E with the 18-bit counter, a peak interrupt (INTTSG3nIPEK) and a valley interrupt (INTTSG3nIVLY) of the 18-bit counter, the peak timing of 18-bit sub-counter, and the valley timing of 18-bit sub-counter.

TSG3n has two channels of the identical A/D conversion trigger control circuits, which can be controlled independently. TSG3n also provides the A/D conversion trigger skipping function with the skipping rate of 1/1 (no skipping), 1/2, 1/4, or 1/8.

35.4.5.1 Operation of A/D Conversion Trigger

TSG3n has a function to generate A/D conversion start triggers (TSG3nADTRG0 and TSG3nADTRG1 signals) by selecting any of ten trigger sources as required. The trigger sources are selected by TSG3nAT09 to TSG3nAT00 in TSG3nCTL5 and TSG3nAT19 to TSG3nAT10 in TSG3nCTL6.

(1) TSG3nADTRG0/TSG3nADTRG1 Signal Output Control (TSG3nCTL5 and TSG3nCTL6)

[Trigger sources]

- TSG3nAT00/TSG3nAT10 = 1 : A valley interrupt (INTTSG3nIVLY) causes an A/D conversion trigger pulse to be generated.
- TSG3nAT01/TSG3nAT11 = 1 : A peak interrupt (INTTSG3nIPEK) causes an A/D conversion trigger pulse to be generated.
- TSG3nAT02/TSG3nAT12 = 1 : While the 18-bit counter is counting up, a TSG3nDCMP0E compare match enables A/D conversion trigger to be generated.
- TSG3nAT03/TSG3nAT13 = 1 : While the 18-bit counter is counting down, a TSG3nDCMP0E compare match enables A/D conversion trigger to be generated.
- TSG3nAT04/TSG3nAT14 = 1 : While the 18-bit counter is counting up, a TSG3nDCMP1E compare match enables A/D conversion trigger to be generated.
- TSG3nAT05/TSG3nAT15 = 1 : While the 18-bit counter is counting down, a TSG3nDCMP1E compare match enables A/D conversion trigger to be generated.
- TSG3nAT06/TSG3nAT16 = 1 : While the 18-bit counter is counting up, a TSG3nDCMP2E compare match enables A/D conversion trigger to be generated.
- TSG3nAT07/TSG3nAT17 = 1 : While the 18-bit counter is counting down, a TSG3nDCMP2E compare match enables A/D conversion trigger to be generated.
- TSG3nAT08/TSG3nAT18 = 1 : A valley timing of the 18-bit sub-counter (at a switch from decrementing to incrementing) enables A/D conversion trigger to be generated.
- TSG3nAT09/TSG3nAT19 = 1 : A peak timing of 18-bit sub-counter (at a switch from incrementing to decrementing) enables A/D conversion trigger to be generated.

[Skipping setting]

- TSG3nACC01, TSG3nACC00 and TSG3nACC11, TSG3nACC10 :
  Set the skipping rate of TSG3nADTRG0/TSG3nADTRG1

All A/D conversion triggers selected by TSG3nAT09 to TSG3nAT00 and TSG3nAT19 to TSG3nAT10 are logically ORed, and the resultant signals are subjected to skipping control specified by TSG3nACC01 and TSG3nACC00, and TSG3nACC11 and TSG3nACC10, and then the TSG3nADTRG0 and TSG3nADTRG1 signals are generated.

A peak interrupt (INTTSG3nIPEK) and a valley interrupt (INTTSG3nIVLY) selected by TSG3nAT00 and TSG3nAT01, and TSG3nAT10 and TSG3nAT11 are interrupt signals obtained after skipping. Therefore, they are output at the timing according to interrupt skipping control. If the interrupt output is not enabled by TSG3nCTL4.TSG3nPIE and TSG3nVIE, A/D conversion trigger is not output.

TSG3nACC01, TSG3nACC00, and TSG3nAT09 to TSG3nAT00, and TSG3nACC11, TSG3nACC10, and TSG3nAT19 to TSG3nAT10 can be rewritten during timer operation.

If A/D conversion trigger setting bits are rewritten during operation, the rewritten values are reflected on the A/D conversion trigger output status immediately. Such control bits are rewritten anytime regardless of operating modes. If a write access is made to TSG3nCTL5 and TSG3nCTL6 (including a rewrite of the same value), the A/D conversion trigger skipping counter is cleared and starts counting from zero.

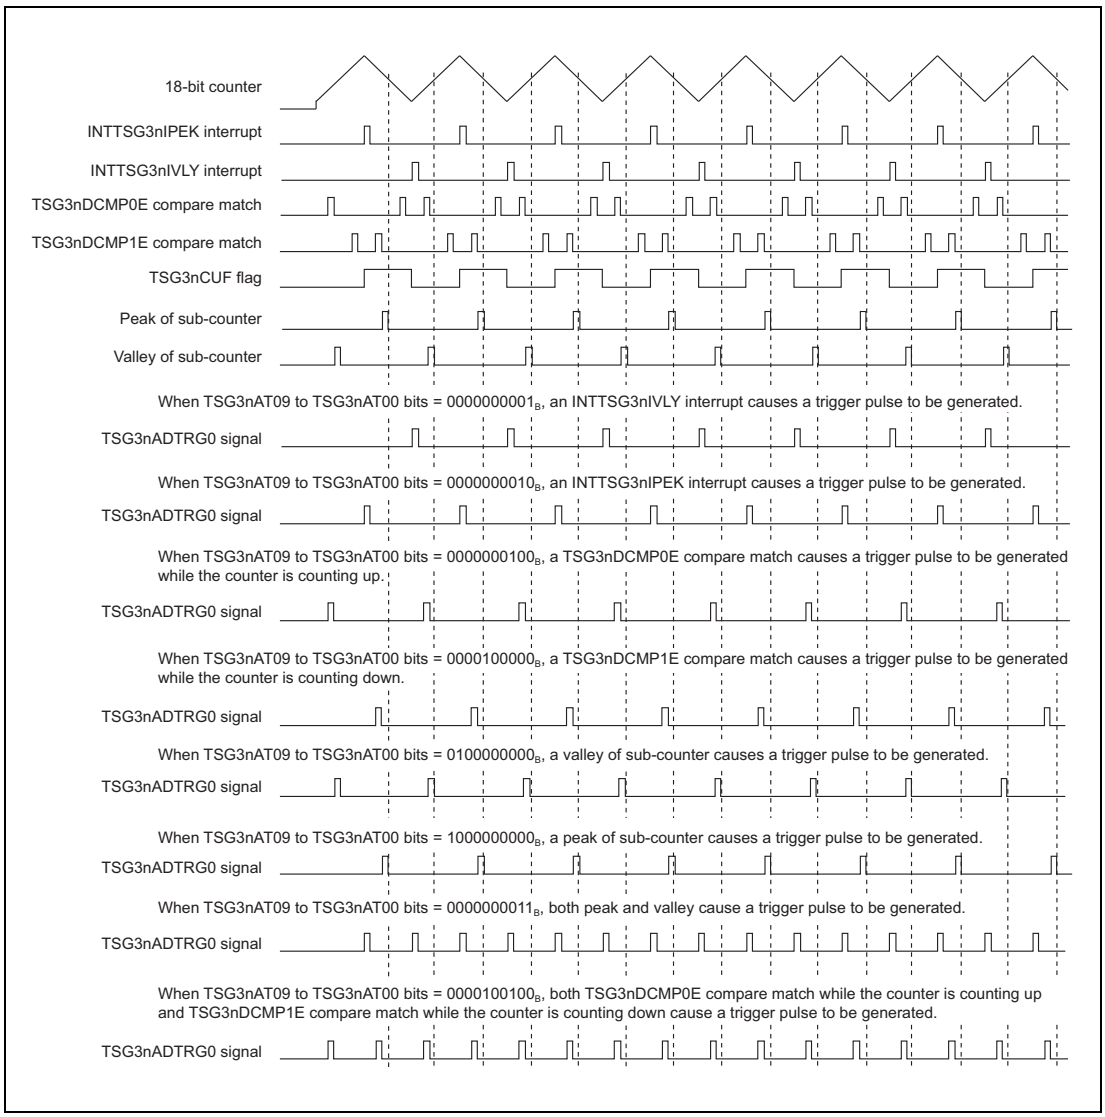

Figure 35.41 When TSG3nPIE = 1, TSG3nVIE = 1, and TSG3nRCC04 to TSG3nRCC00 = 00_H in TSG3nCTL4, and TSG3nACC01 and TSG3nACC00 = 00_B in TSG3nCTL5 (HT-PWM Mode)

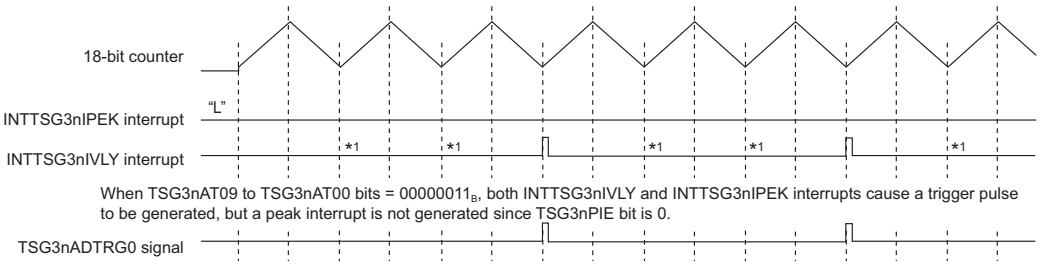
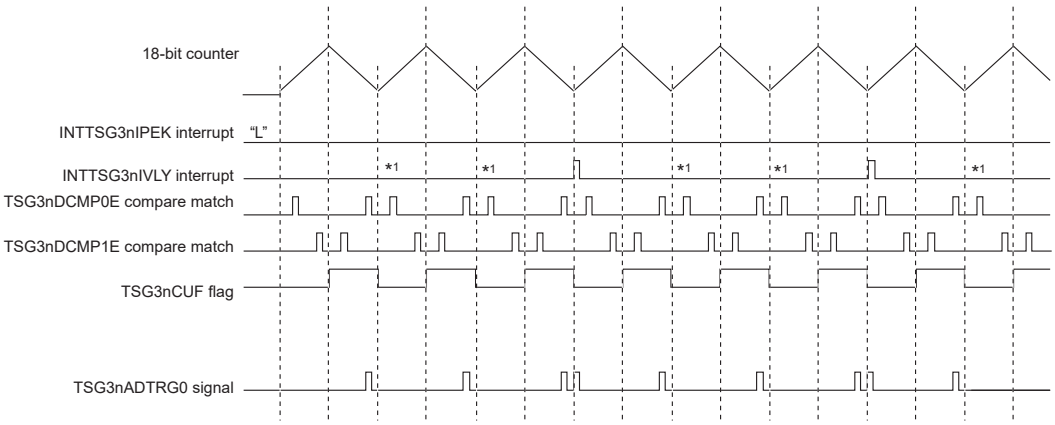


Note 1. Skipped interrupt request

Figure 35.42 When TSG3nPIE = 0, TSG3nVIE = 1, and TSG3nRCC04 to TSG3nRCC00 = 02_H in TSG3nCTL4 and TSG3nACC01 and TSG3nACC00 = 00_B in TSG3nCTL5 (HT-PWM Mode)



Note 1. Skipped interrupt request

Figure 35.43 When TSG3nPIE = 0, TSG3nVIE = 1, and TSG3nRCC04 to TSG3nRCC00 = 02_H in TSG3nCTL4 and TSG3nACC01 and TSG3nACC00 = 00_B, and TSG3nAT09 to TSG3nAT00 = 0000 1001_B in TSG3nCTL5 (HT-PWM Mode)

(2) A/D Conversion Trigger Skipping Function

Example of operation of the A/D conversion trigger skipping function is shown in **Figure 35.44**.

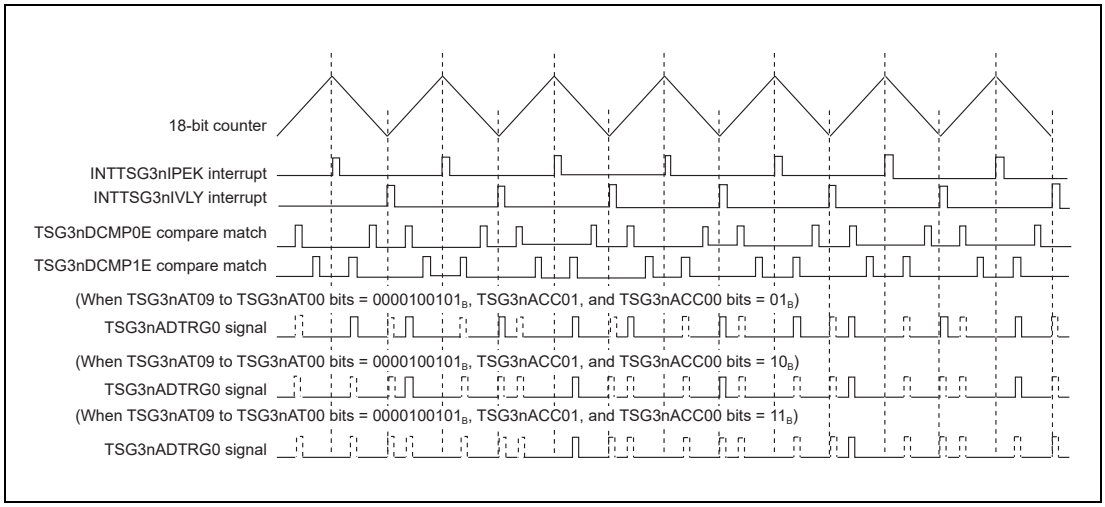


Figure 35.44 Example of Operation of A/D Conversion Trigger Skipping Function

NOTE

Broken-lined pulses indicate A/D conversion trigger pulses skipped by the A/D conversion trigger skipping function.

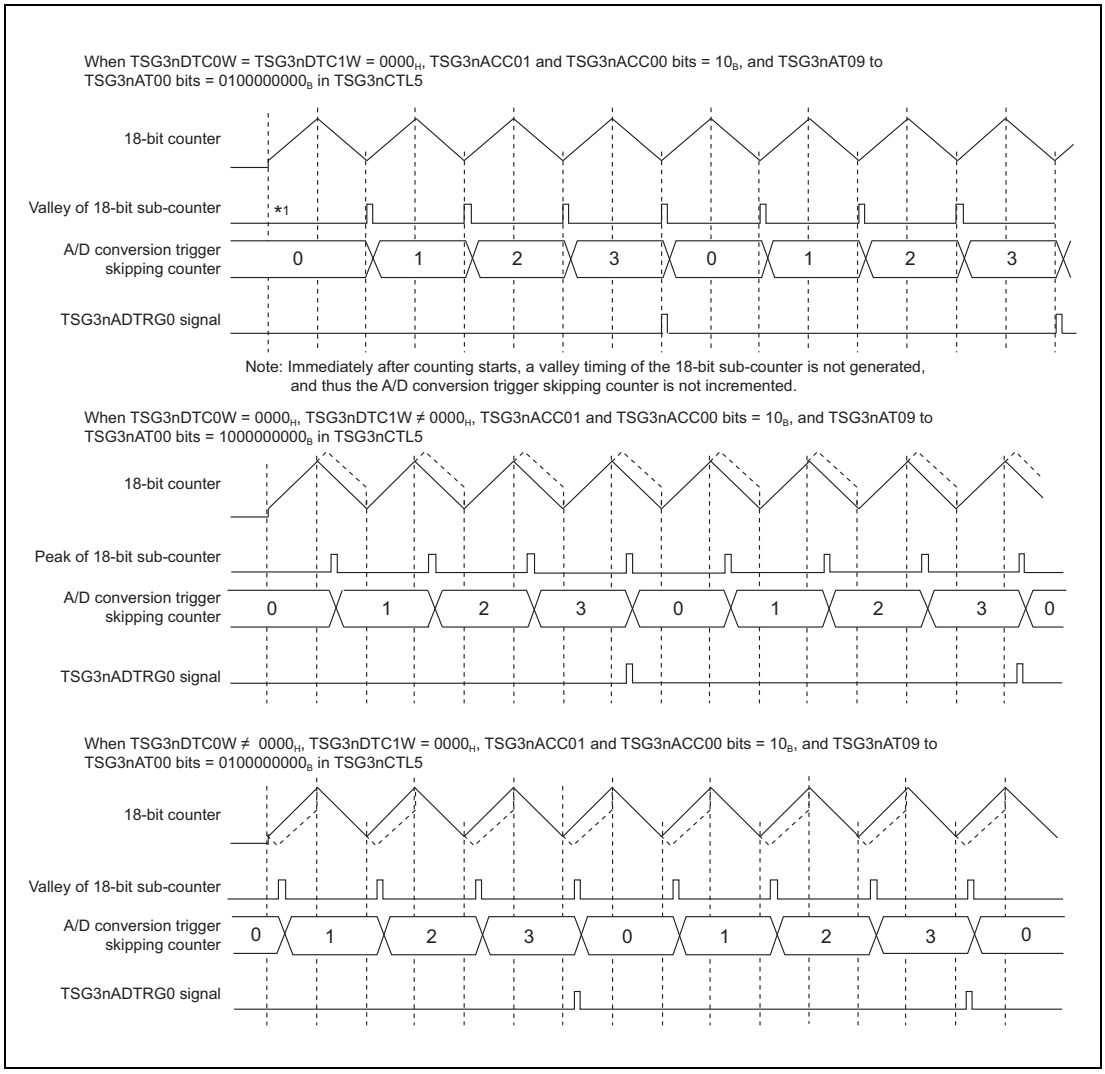

Figure 35.45 Example of Operation of A/D Conversion Trigger Skipping Function

(3) Notes on A/D Conversion Trigger

- If the same value is written to TSG3nDCMP0E, TSG3nDCMP1E or TSG3nDCMP2E, and the same condition (when the 18-bit counter increments or decrements) is set as the valid A/D conversion trigger, A/D conversion trigger skipping counter is incremented by one and one trigger pulse is output upon a match of the 18-bit counter with these registers.
- In PWM mode, SP-PWM mode, 120-DC mode, and HSP-PWM mode, a valley interrupt (INTTSG3nIVLY) is not generated. Only a peak interrupt (INTTSG3nIPEK) is valid.
- In 120-DC mode, when TSG3nS120DCO is set to 0, the 18-bit counter may be cleared during the carrier period due to switch of the output pattern. The A/D conversion trigger is not generated if TSG3nDCMP2E to TSG3nDCMP0E values do not match with the 18-bit counter value and a peak interrupt (INTTSG3nIPEK) is not generated.

35.4.6 Error/Warning Interrupt

35.4.6.1 Error Interrupt Function

If the simultaneous active state of the positive phase and inverse phase is detected after the error interrupt function is enabled (TSG3nIOC1.TSG3nEOC = 1), TSG3nSTR2.TSG3nTBF is set, and an error interrupt (INTTSG3nIER) of TSG3n is generated. Whether or not to detect an error of each phase (TSG3nO1 and TSG3nO2, TSG3nO3 and TSG3nO4, and TSG3nO5 and TSG3nO6 pins) can be selected by TSG3nCTL1.TSG3nTBA2 to TSG3nTBA0, respectively.

When an error occurs, outputs of the TSG3nO1 to TSG3nO6 pins can be set to high-impedance. For details, see **Section 36.4.1, Asynchronous Hi-Z Control Function**.

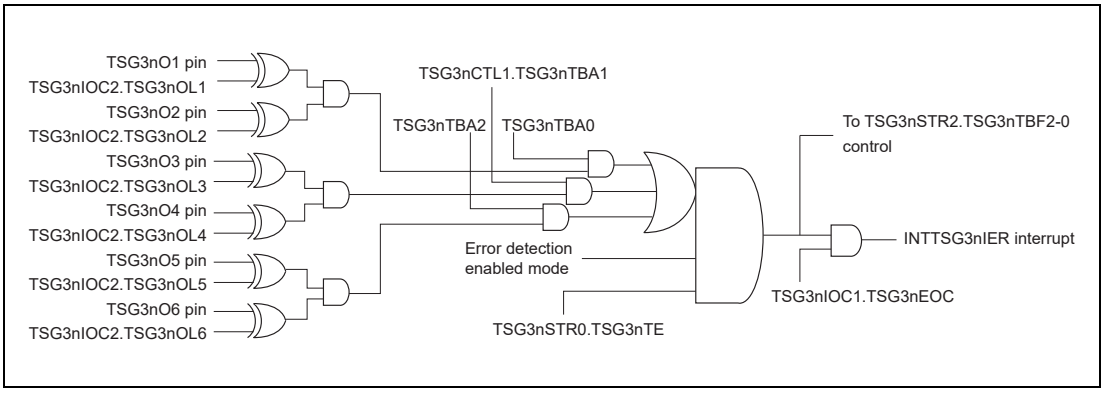

Figure 35.46 Error Interrupt (INTTSG3nIER) Generation Control Circuit

CAUTION

When an error interrupt is generated, the error status should be canceled (write 1 to TSG3nSTC.TSG3nTBR2 to TSG3nSTC.TSG3nTBR0) during error interrupt servicing. Otherwise, subsequent error interrupts are not generated.

(1) PWM Mode, 120-DC Mode and HSP-PWM Mode

In PWM mode and HSP-PWM mode, if TSG3nCMP1E and TSG3nCMP2E, and TSG3nCMP3E and TSG3nCMP4E are set so that the TSG3nO1 and TSG3nO2 pins output the active level simultaneously, an error interrupt (INTTSG3nIER) is generated. Likewise, if TSG3nCMP5E, TSG3nCMP6E, TSG3nCMP7E, TSG3nCMP8E, TSG3nCMP9E, TSG3nCMP10E, TSG3nCMP11E, and TSG3nCMP12E are set so that the TSG3nO3 and TSG3nO4, and TSG3nO5 and TSG3nO6 pins output the active level simultaneously, an error interrupt (INTTSG3nIER) is generated.

In 120-DC mode, if TSG3nCMP1E, TSG3nCMP2E, TSG3nCMP5E, TSG3nCMP6E, TSG3nCMP9E, TSG3nCMP10E, TSG3nCMP3E, TSG3nCMP4E, TSG3nCMP7E, TSG3nCMP8E, TSG3nCMP11E, TSG3nCMP12E, TSG3nPAT0W, and TSG3nPAT1W are set so that the TSG3nO1 and TSG3nO2 pins output the active level simultaneously, an error interrupt (INTTSG3nIER) is generated. With the same setting, the TSG3nO3 and TSG3nO4, and TSG3nO5 and TSG3nO6 pins also output the active level simultaneously and an error interrupt (INTTSG3nIER) is generated.

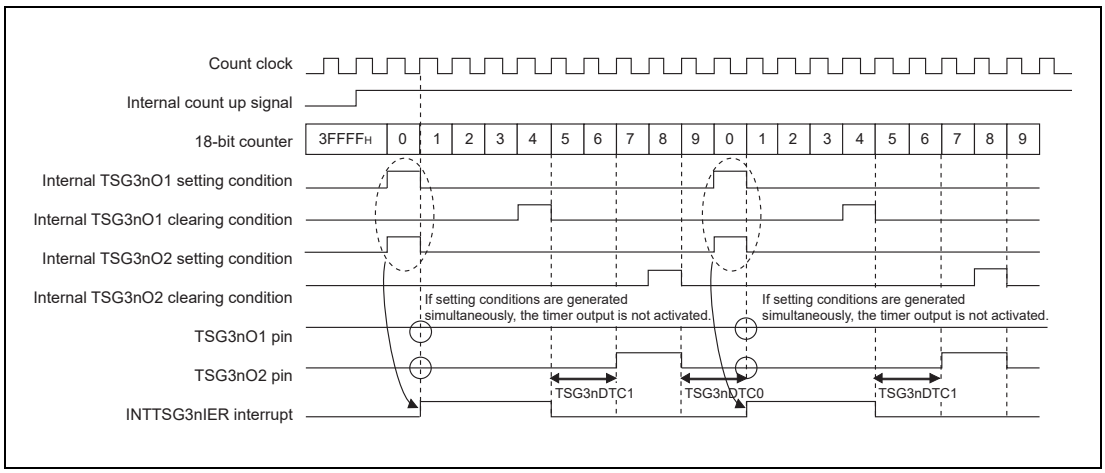

Figure 35.47 Example of Error Interrupt (INTTSG3nIER) Generation (PWM Mode)

NOTE

TSG3nO3 and TSG3nO4, and TSG3nO5 and TSG3nO6 behave the same.

When the active level of output is switched by manipulating TSG3nIOC2.TSG3nOL1 and TSG3nOL2, an error interrupt is generated as shown in the following figure.

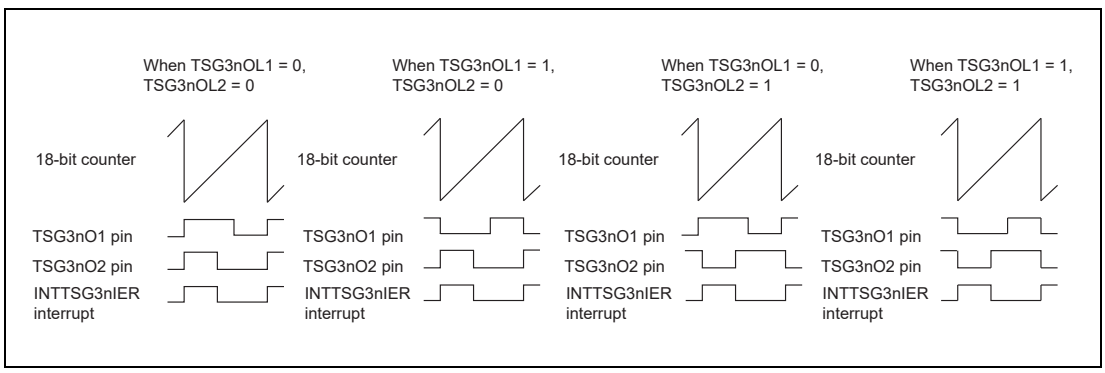

Figure 35.48 Example of Error Interrupt (INTTSG3nIER) Generation for each Active Level

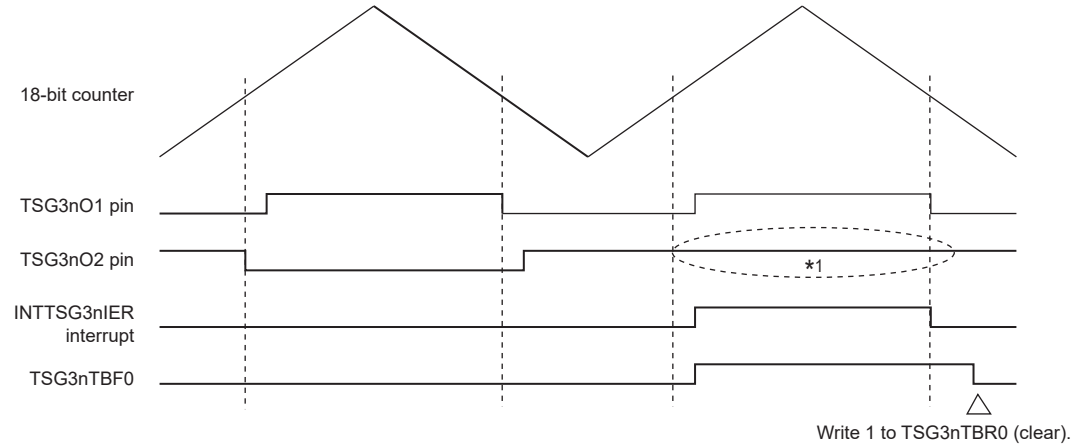
(2) HT-PWM Mode and SP-PWM Mode

When either TSG3n dead time control register 0 or 1 (TSG3nDTC0W or TSG3nDTC1W) is 0000_H, an error may occur.

NOTE

If an error occurs when the dead time control function is used (both TSG3nDTC0W and TSG3nDTC1W are not 0000_H), internal circuit failure may have occurred.



Note 1. TSG3nO2 pin control circuit failure occurs.

Figure 35.49 Example of Error Interrupt Operation

35.4.6.2 Warning Interrupt Function

TSG3n has a warning interrupt (INTTSG3nIWN).

Warning interrupt (INTTSG3nIWN) is generated when any of the following conditions is detected.

For details, see **Section 35.4.3, Flags**.

- When simultaneous change in two or more pins of TSG3nPTSI2 to TSG3nPTSI0 is detected:
  See **Section 35.4.3.4, Noise Detection Flag (TSG3nNDF)**.
- When reversal is detected of the TSG3nPTSI2 to TSG3nPTSI0 pins:
  See **Section 35.4.3.7, Pattern Reversal Detection Flag (TSG3nPRF)**.
- When 000 or 111 is detected from the TSG3nPTSI2 to TSG3nPTSI0 pins:
  See **Section 35.4.3.6, Pattern Error Detection Flag (TSG3nPEF)**.
- When a toggle of the TSG3nPTSI2 to TSG3nPTSI0 pins is generated three or more times between TSG3nOPCI0 and TSG3nOPCI1 signal triggers.:
  See **Section 35.4.3.8, TSG3nPTSI2 to TSG3nPTSI0 Pin Abnormal Toggle Detection Flag (TSG3nPTF)**.
- When the TSG3nOPCI0 and TSG3nOPCI1 signal triggers are detected simultaneously:
  See **Section 35.4.3.9, TSG3nOPCI0 and TSG3nOPCI1 Signal Simultaneous Trigger Detection Flag (TSG3nTDF)**.
- When the phase difference between the input pattern (TSG3nPTSI2 to TSG3nPTSI0 pins) and output pattern (TSG3nOPF2 to TSG3nOPF0) is detected:
  See **Section 35.4.3.10, Pattern Phase Difference Detection Flag (TSG3nPPF)**.

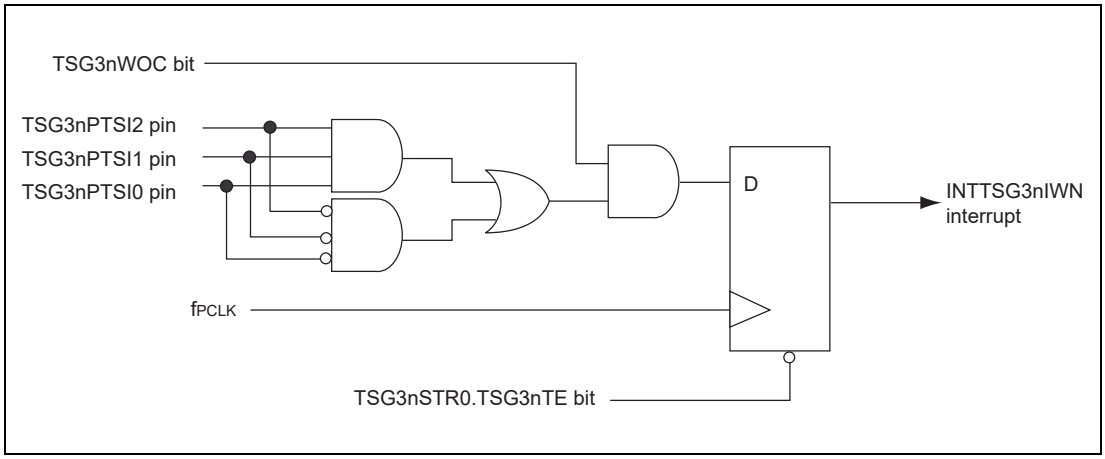


Figure 35.50 Detection of Abnormality of TSG3nPTSI2-TSG3nPTSI0 Pins

35.4.7 Operating Modes

35.4.7.1 PWM Mode

Overview

A PWM signal is output at the TSG3nO1 to TSG3nO6 pins according to set timing/clear timing of TSG3nCMP1E to TSG3nCMP12E registers with the PWM period set in the TSG3nCMP0E register.

Prerequisites

- Set the set timing to the compare register with an even number:
  TSG3nCMP2E (set timing of the TSG3nO1 output), TSG3nCMP4E (set timing of the TSG3nO2 output), TSG3nCMP6E (set timing of the TSG3nO3 output), TSG3nCMP8E (set timing of the TSG3nO4 output), TSG3nCMP10E (set timing of the TSG3nO5 output) and TSG3nCMP12E (set timing of the TSG3nO6 output)
- Set the clear timing to the compare register with an odd number:
  TSG3nCMP1E (clear timing of the TSG3nO1 output), TSG3nCMP3E (clear timing of the TSG3nO2 output), TSG3nCMP5E (clear timing of the TSG3nO3 output), TSG3nCMP7E (clear timing of the TSG3nO4 output), TSG3nCMP9E (clear timing of the TSG3nO5 output) and TSG3nCMP11E (clear timing of the TSG3nO6 output)

Functional description

Set the PWM period and set/clear timing of the TSG3nO1 to TSG3nO6 outputs. Set TSG3nTRG0.TSG3nTS = 1 to start the timer counter.

The TSG3nO1 to TSG3nO6 outputs are set to the inactive state at the same time the counting begins. The outputs are set to the active state by the match of the buffer registers TSG3nCMP2E, TSG3nCMP4E, TSG3nCMP6E, TSG3nCMP8E, TSG3nCMP10E, and TSG3nCMP12E with the 18-bit counter.

Next, the TSG3nO1 to TSG3nO6 outputs are set to the inactive state by the match of the buffer registers TSG3nCMP1E, TSG3nCMP3E, TSG3nCMP5E, TSG3nCMP7E, TSG3nCMP9E, and TSG3nCMP11E with the 18-bit counter.

During counting, a compare match interrupt (INTTSG3nI0 to INTTSG3nI12) is generated by the match of the buffer register TSG3nCMP0E-TSG3nCMP12E with the 18-bit counter.

CAUTION

Reload is executed when a value is written to the TSG3nCMP1E register while TSG3nCTL3.TSG3nRMC = 0. Therefore, even when it is needed to rewrite only the value of the TSG3nCMP0E register, a write operation to the TSG3nCMP1E register is necessary. When only the TSG3nCMP0E register is rewritten, reload is not done.

NOTE

The PWM mode is set when TSG3nCTL0.TSG3nMD2-TSG3nMD0 = 000_B.

(a) When TSG3nCMP0E and TSG3nCMP1E to TSG3nCMP12E are Not Rewritten during Timer Operation

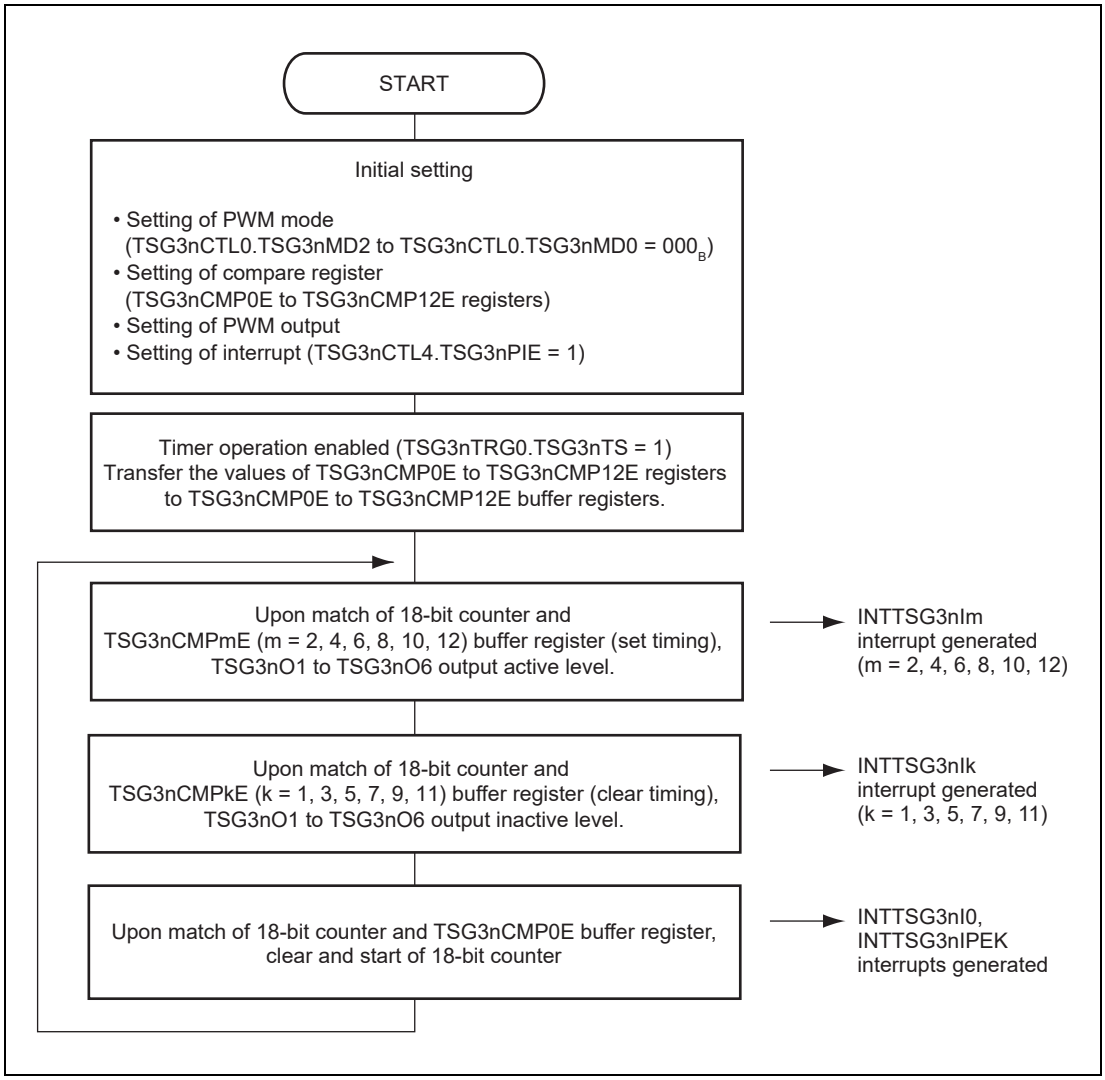

Figure 35.51 Basic Operation Flow of PWM Mode (1/2)

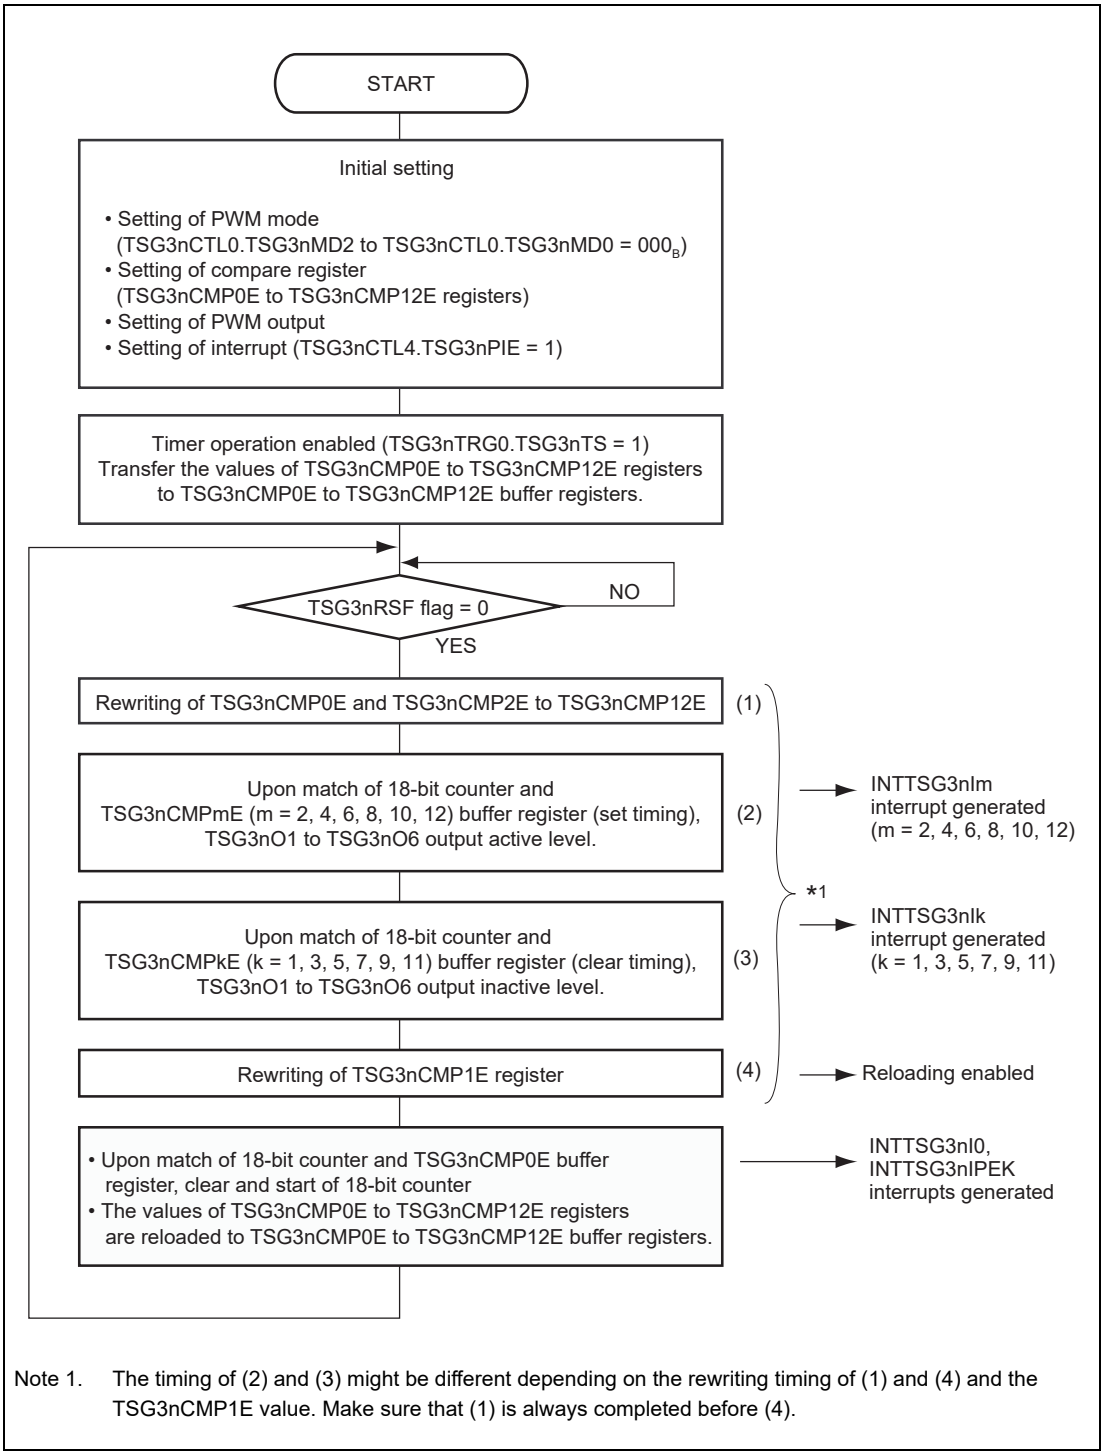
(b) When TSG3nCMP0E and TSG3nCMP1E to TSG3nCMP12E are Rewritten during Timer Operation



Note 1. The timing of (2) and (3) might be different depending on the rewriting timing of (1) and (4) and the TSG3nCMP1E value. Make sure that (1) is always completed before (4).

Figure 35.51 Basic Operation Flow of PWM Mode (2/2)

CAUTION

Rewrite compare registers after confirming that the reload request flag TSG3nRSF is 0.

(1) List of Operations in PWM Mode

Table 35.54 Counter Functions in PWM Mode

Operation		Setting condition
18-bit counter	Start	TSG3nTRG0.TSG3nTS = 0 → 1, or a simultaneous start trigger
	Clear	Compare match of TSG3nCMP0E buffer register and 18-bit counter
	Stop	TSG3nTRG1.TSG3nTT = 0 → 1

Table 35.55 Functions of Compare Registers and Dead Time Control Register in PWM Mode

Register	Rewriting Method	Rewrite during Operation	Function
TSG3nCMP0E	Reload/Anytime rewrite	Possible	Setting period
TSG3nCMPmE (m = 1 to 12)	Reload/Anytime rewrite	Possible	Setting set/clear timing
TSG3nDCMP0E, TSG3nDCMP1E, TSG3nDCMP2E	Reload/Anytime rewrite	Possible	Diagnostic output or A/D conversion trigger
TSG3nDTC0W, TSG3nDTC1W	Reload	Possible*1	Setting dead time

Note 1. For details, see **Section 35.4.7.1, (3) Controlling Dead Time in PWM Mode**.

Table 35.56 Timer Input Function in PWM Mode

Pin	Function
TSG3nCLKI	Clock enable input

Table 35.57 Timer Output Function in PWM Mode

Pin	Function
TSG3nOm (m = 1 to 6)	PWM output by compare match of TSG3nCMPkE buffer register and 18-bit counter (k = 1 to 12)
TSG3nO7	Diagnostic signal output or pulse output by A/D conversion trigger

Table 35.58 Interrupt Requests in PWM Mode

Interrupt	Function
INTTSG3nIm (m = 0 to 12)	Compare match of TSG3nCMPmE buffer register and 18-bit counter (m = 0 to 12)
INTTSG3nIER	Error (detection of simultaneous active state of TSG3nO1 and TSG3nO2, or TSG3nO3 and TSG3nO4, or TSG3nO5 and TSG3nO6)
INTTSG3nIVLY	—
INTTSG3nIPEK	Peak interrupt (generated at the same timing as INTTSG3nI0)
INTTSG3nIWN	Warning interrupt

Note: "—": Not available in PWM mode

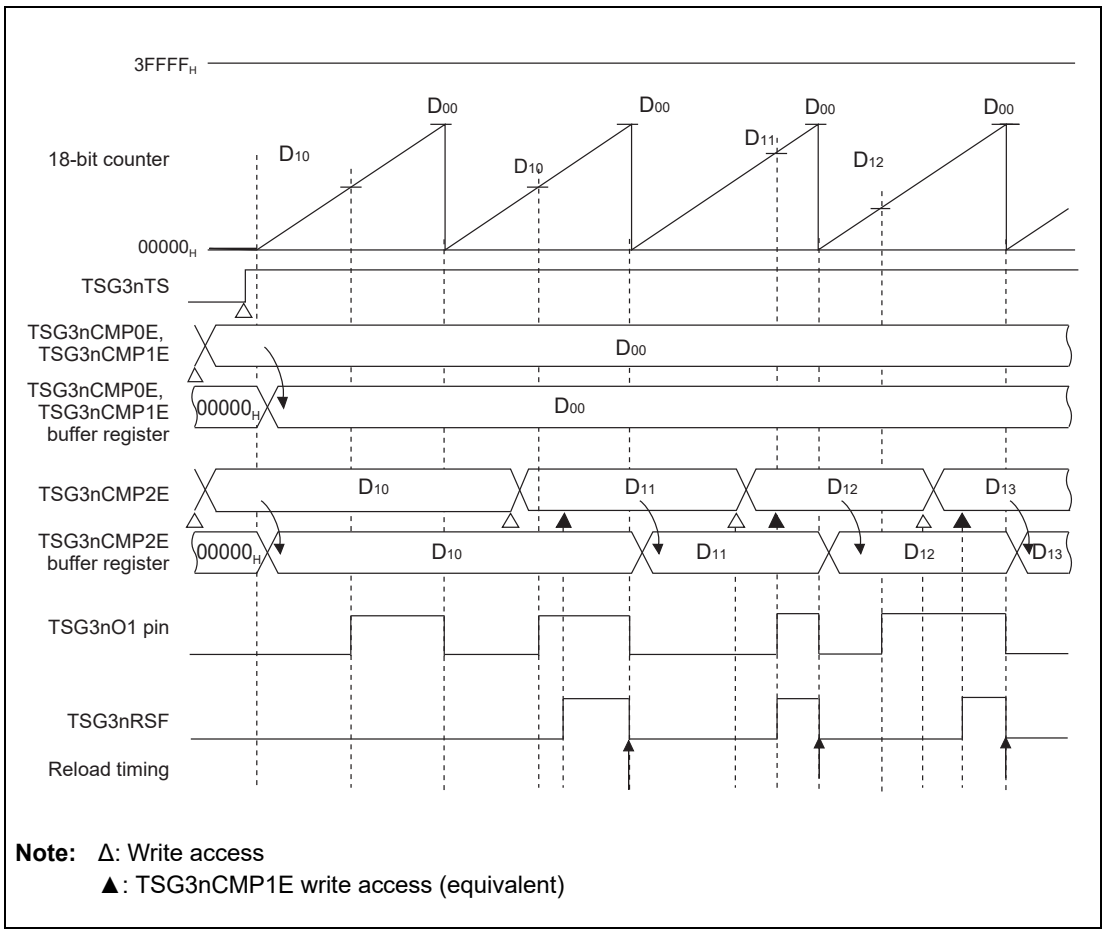
Table 35.59 Compare Match Timing in PWM Mode

Compare Match	Timing
TSG3nCMP0E	When 18-bit counter changes from TSG3nCMP0E to 00000_H
TSG3nCMPmE (m = 1 to 12)	After detecting the match of 18-bit counter and TSG3nCMPmE (m = 1 to 12)

Table 35.60 Example of Setting each Timer Output Condition in PWM Mode

Pin	Item	Output Period	Output Duty	
			Output Condition	Setting Condition
TSG3nOm (m = 1 to 6)	PWM output	(TSG3nCMP0E + 1) × count clock	Output an inactive level throughout one period (duty cycle 0%)	TSG3nCMPmE = TSG3nCMP (m + 1)E or TSG3nCMP (m + 1) E> TSG3nCMP0E (m = 1, 3, 5, 7, 9, 11)
			Output an active level of one count clock in one period	TSG3nCMPmE = TSG3nCMP (m + 1)E + 1 TSG3nCMP (m + 1)E = TSG3nCMPmE - 1 (m = 1, 3, 5, 7, 9, 11)
			Output an inactive level of one count clock in one period	TSG3nCMPmE = TSG3nCMP (m + 1)E - 1 TSG3nCMP (m + 1)E = TSG3nCMPmE + 1 (m = 1, 3, 5, 7, 9, 11)
			Output an active level throughout one period (duty cycle 100%)	TSG3nCMPmE > TSG3nCMP0E TSG3nCMP (m + 1)E ≤ TSG3nCMP0E (m = 1, 3, 5, 7, 9, 11)

When only TSG3nCMP2E is rewritten and TSG3nO1 is output (TSG3nIOC0.TSG3nTOE1 = 1, TSG3nIOC2.TSG3nOL1 = 0)



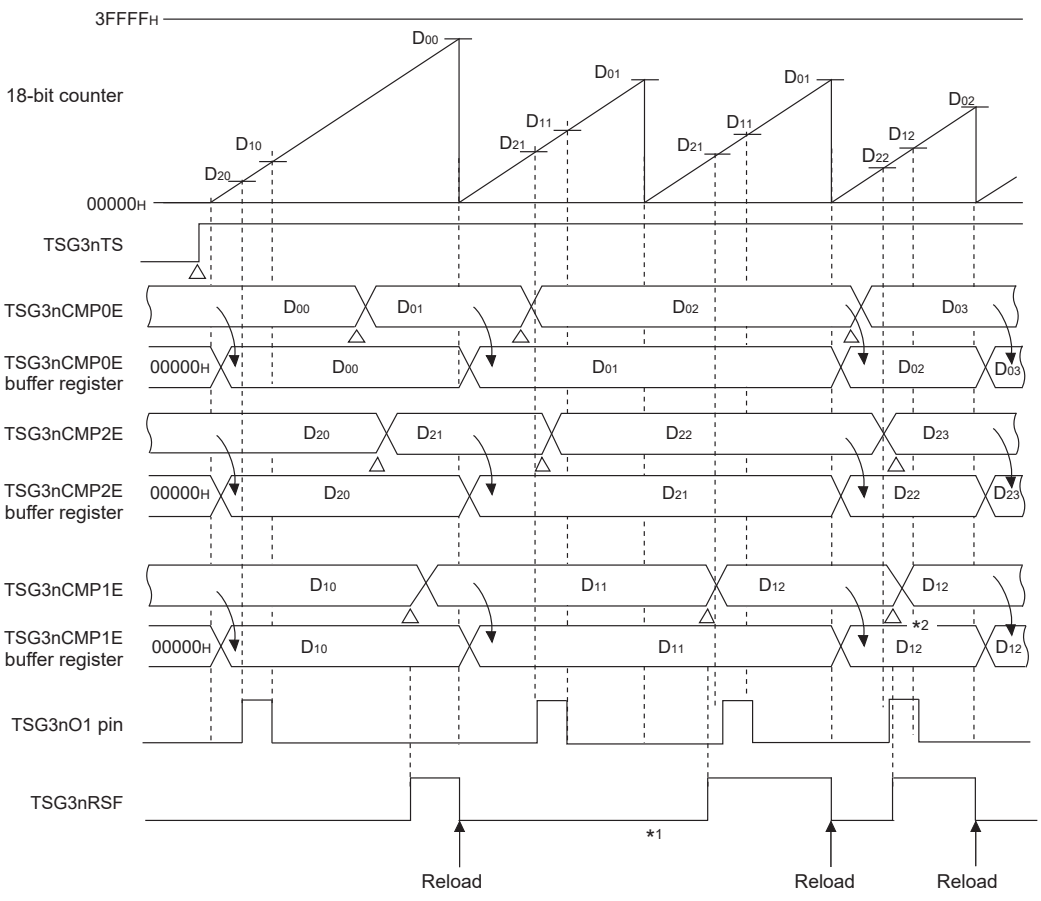
Note: Δ: Write access
▲: TSG3nCMP1E write access (equivalent)

Figure 35.52 Example of Basic Operation Timing of PWM Mode (1/2)

NOTES

1. D00: Set values of TSG3nCMP0E and TSG3nCMP1E (00000_H-$3FFFF_H$)
   D10, D11, D12 and D13: Set values of TSG3nCMP2E (00000_H-$3FFFF_H$)
2. TSG3nO1 (PWM) duty cycle = (TSG3nCMP1E-TSG3nCMP2E)×(count clock cycle)
   TSG3nO1 (PWM) period = (Set value of TSG3nCMP0E + 1)×(count clock cycle)
3. TSG3nO2-TSG3nO6 pins behave similarly to the TSG3nO1 pin

When TSG3nCMP0E-TSG3nCMP2E are rewritten, and TSG3nO1 is output (TSG3nIOC0.TSG3nTOE1 = 1, TSG3nIOC2.TSG3nOL1 = 0)



Note 1. The TSG3nCMP0E buffer register is not reloaded, because TSG3nCMP1E register was not rewritten.

Note 2. Equivalent writing

Note: Δ: Write access

Figure 35.52 Example of Basic Operation Timing of PWM Mode (2/2)

NOTES

1. D00, D01, D02, D03: Set value of TSG3nCMP0E (00000_H-$3FFFF_H$)
   D10, D11, D12, D13: Set value of TSG3nCMP1E (00000_H-$3FFFF_H$)
   D20, D21, D22, D23: Set value of TSG3nCMP2E (00000_H-$3FFFF_H$)
2. Outputs from TSG3nO2 to TSG3nO6 behave similarly to the TSG3nO1 pin.

(2) Interrupt/Reload Skipping Function in PWM Mode

By setting TSG3nCTL4.TSG3nPRE and TSG3nPIE to 1 and setting the TSG3nRCC04 to TSG3nRCC00 and TSG3nCTL3.TSG3nRIA, the reload and interrupt skipping function can be used.

By setting TSG3nPRE to 1 and setting the TSG3nRCC04 to TSG3nRCC00, the interrupt skipping function can be used.

(3) Controlling Dead Time in PWM Mode

By setting the dead time values in the TSG3nDTC0W and TSG3nDTC1W registers in PWM mode, it is possible to control the dead time. The dead time is controlled according to the switch timing of the TSG3nO1 and TSG3nO2 outputs, the TSG3nO3 and TSG3nO4 outputs, or the TSG3nO5 and TSG3nO6 outputs.

Table 35.61 Dead Time in PWM Mode

Switch Timing	Dead Time
TSG3nO1: High level to low level and TSG3nO2: Low level to high level	Value of TSG3nDTC1W register
TSG3nO2: High level to low level and TSG3nO1: Low level to high level	Value of TSG3nDTC0W register
TSG3nO3: High level to low level and TSG3nO4: Low level to high level	Value of TSG3nDTC1W register
TSG3nO4: High level to low level and TSG3nO3: Low level to high level	Value of TSG3nDTC0W register
TSG3nO5: High level to low level and TSG3nO6: Low level to high level	Value of TSG3nDTC1W register
TSG3nO6: High level to low level and TSG3nO5: Low level to high level	Value of TSG3nDTC0W register

NOTE

Dead time counter keeps operating even when operation stop (TSG3nTE = 0) setting collided with dead time insert timing, and the dead time set in TSG3nO1 and TSG3nO2 are always inserted.

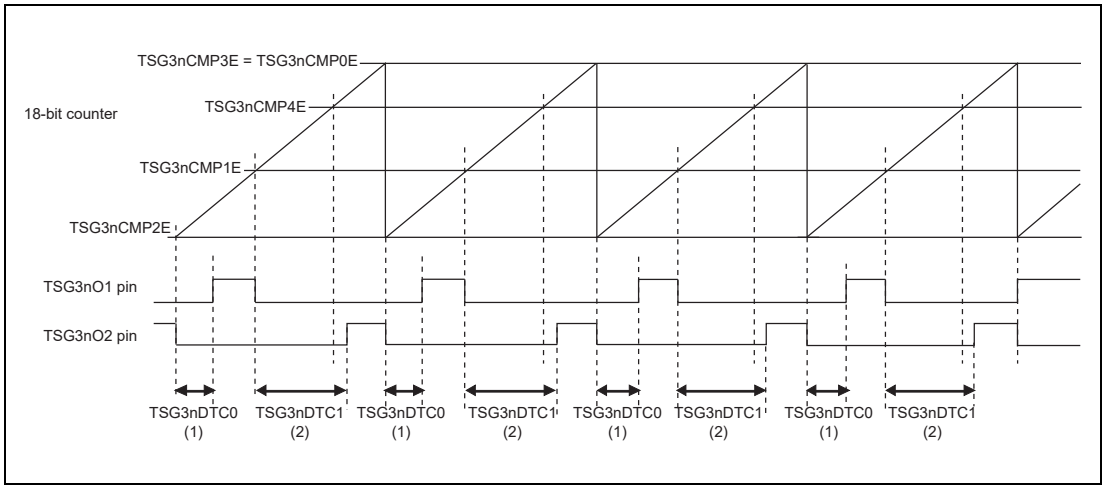


Figure 35.53 Example of Dead Time Control between TSG3nO1 and TSG3nO2 Outputs (1/2)

During (1), the dead time counter starts counting at the falling edge of the TSG3nO2 output. At this time, even after the 18-bit counter reaches 00000_H indicating that the TSG3nO1 output should be active, the TSG3nO1 output stays inactive because the dead time counter is still operating. The TSG3nO1 output becomes active at the timing when the dead time count operation ends.

At (2), the dead time counter starts counting at the falling edge of the TSG3nO1 output. Even after the match of the 18-bit counter and TSG3nCMP4E indicating that the TSG3nO2 output should be active, the TSG3nO2 output stays inactive because the dead time counter is still operating. The TSG3nO2 output becomes active at the timing when the dead time count operation ends.

NOTES

1. The TSG3nO1 and TSG3nO2 pins are set to active high
2. The TSG3nO3 and TSG3nO4 pins and the TSG3nO5 and TSG3nO6 pins outputs behave similarly.

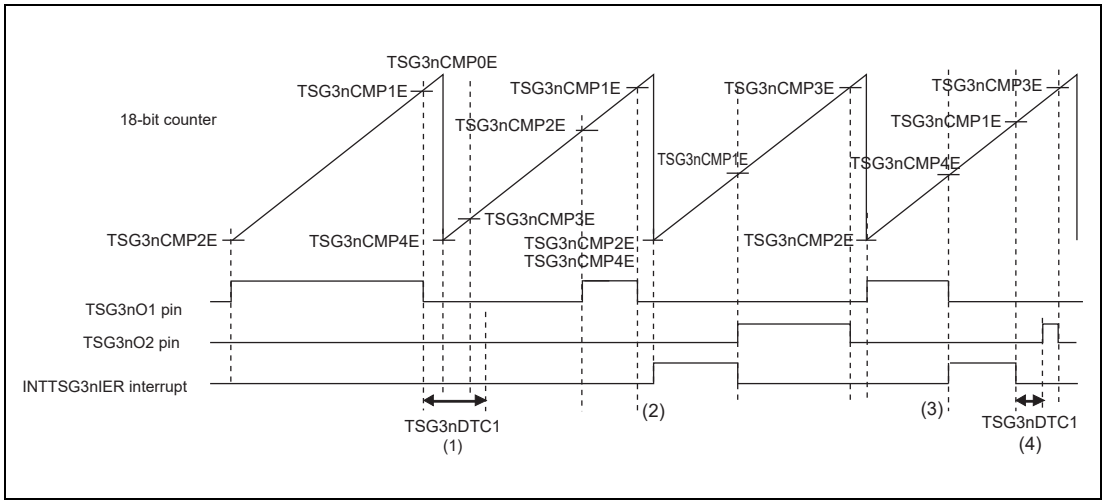

Figure 35.53 Example of Dead Time Control between TSG3nO1 and TSG3nO2 Outputs (2/2)

During (1), the dead time counter starts counting at the falling edge of the TSG3nO1 output. Even after the 18-bit counter reaches 00000_H and the match occurs between the 18-bit counter and TSG3nCMP4E indicating that the TSG3nO2 output should be active, the TSG3nO2 output stays inactive because the dead time counter is still operating. Moreover, since the TSG3nCMP3E register compare match occurs before the operation of the dead time counter ends, the TSG3nO2 output stays inactive.

TSG3nCMP1E + TSG3nDTC1 ≥ TSG3nCMP0E + TSG3nCMP3E
(TSG3nO2 stays inactive)

TSG3nCMP3E + TSG3nDTC0 ≥TSG3nCMP0E + TSG3nCMP1E
(TSG3nO1 stays inactive)

At (2), the INTTSG3nIER interrupt occurs because the TSG3nCMP2E register and the TSG3nCMP4E register are set so that the TSG3nO1 and TSG3nO2 outputs rise simultaneously. Here, both the TSG3nO1 and TSG3nO2 outputs become inactive.

At (3), compare match with the TSG3nCMP4E register while the TSG3nO1 output is active generates an INTTSG3nIER interrupt and both TSG3nO1 and TSG3nO2 outputs become inactive.

At (4), the falling edge (inactive) of the TSG3nO1 output is caused by the detection of simultaneous active state. The dead time counter starts counting after compare match with the TSG3nCMP1E register. After the end of the dead time counter operation, the TSG3nO2 output becomes active.

NOTES

1. The TSG3nO1 and TSG3nO2 pins are set to active high.
2. The TSG3nO3 and TSG3nO4 pins and the TSG3nO5 and TSG3nO6 pins outputs behave similarly.

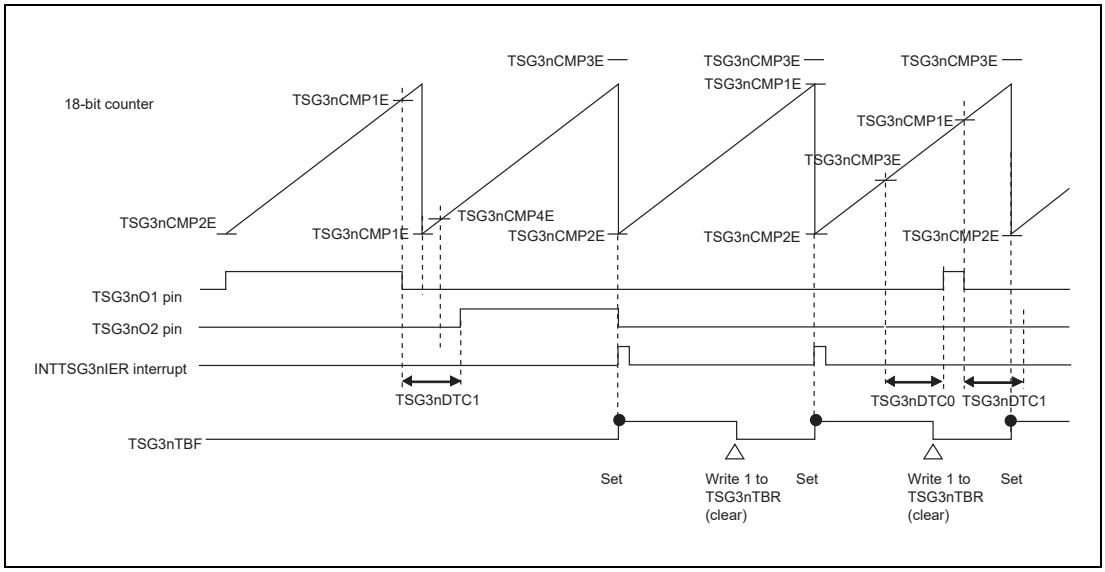

Figure 35.54 Example of 100% Duty Output at Dead Time Control

When the TSG3nO2 pin is set to duty cycle of 100% (TSG3nCMP3E ≥ TSG3nCMP0E + 1), the output of the TSG3nO1 pin is fixed to a low level. This control is intended to mask the active condition of TSG3nO1 output since the TSG3nO2 output is active before the TSG3nO1 output becomes active. In this case, the INTTSG3nIER interrupt is also generated because TSG3nO1 and TSG3nO2 outputs become high simultaneously.

NOTES

1. The TSG3nO1 and TSG3nO2 pins are set to active high.
2. The TSG3nO3 and TSG3nO4 pins and the TSG3nO5 and TSG3nO6 pins outputs behave similarly.

(4) Dead Time Rewriting during Timer Operation in PWM Mode

In PWM mode, it is possible to rewrite TSG3n dead time control registers TSG3nDTC0W and TSG3nDTC1W while counting. The new settings are active at reload timing. It is not possible to change the dead time setting by rewriting at any time.

To enable reloading, write to the TSG3nCMP1E register.

35.4.7.2 HT-PWM mode (High accuracy Triangular - Pulse Width Modulation mode)

Overview

In this mode, the 18-bit counter (up/down count by ± 2 bits, practically 17 bits) and the 18-bit compare registers (LSB is used to control additional pulse) are used to generate a 6-phase PWM signal.

Prerequisites

- Set the carrier wave period with TSG3nCMP0E.
- Set the duty cycle of the voltage data signals of the U phase, V phase, and W phase with TSG3nCMPUE, TSG3nCMPVE, and TSG3nCMPWE (The values set in TSG3nCMPUE, TSG3nCMPVE, and TSG3nCMPWE are reflected immediately to the corresponding TSG3nCMPmE (m = 1, 2, 5, 6, 9, 10)).
- Symmetric triangular wave control is described in this section. Refer to **Section 35.4.7.2 (10), Asymmetric Triangular Wave Control in HT-PWM Mode**, for asymmetric triangular wave control.

Functional description

In this mode, the carrier period and the duty cycle of the U phase, the V phase, and the W phase are configured. Counting up begins when TSG3nTRG0.TSG3nTS is set to 1.

The 18-bit counter counts up from TSG3nDTC0 as the minimum value, and counts down upon the match with the maximum value of TSG3nCMP0E + TSG3nDTC0.

The dead time is set with TSG3nDTC0 and TSG3nDTC1. TSG3nDTC0 sets the dead time of inverse phase (OFF) to positive phase (ON) switch and TSG3nDTC1 sets the dead time of positive phase (OFF) to inverse phase (ON) switch. The 10-bit counters (TSG3nDTT1 to TSG3nDTT3) for dead time generation load the set values of TSG3nDTC0 and TSG3nDTC1 by the compare match of the 18-bit counter and the TSG3nCMPm buffer register (m = 1, 2, 5, 6, 9, 10), and start down-counting.

INTTSG3nIm interrupts (m = 1, 2, 5, 6, 9, 10) are generated by the compare match of the 18-bit counter with TSG3nCMP1E, TSG3nCMP2E, TSG3nCMP5E, TSG3nCMP6E, TSG3nCMP9E, and TSG3nCMP10E buffer registers.

INTTSG3nIm interrupts (m = 3, 4, 7, 8, 11, 12) are generated by the compare match of the 18-bit counter with TSG3nCMP3E, TSG3nCMP7E, and TSG3nCMP11E buffer registers when counting down (TSG3nCUF = 1), and with TSG3nCMP4E, TSG3nCMP8E, and TSG3nCMP12E buffer registers when counting up (TSG3nCUF = 0).

NOTE

The HT-PWM mode is enabled when TSG3nCTL0.TSG3nMD2-TSG3nMD0 = 001_B.

(1) Block Diagram and Basic Timing Chart

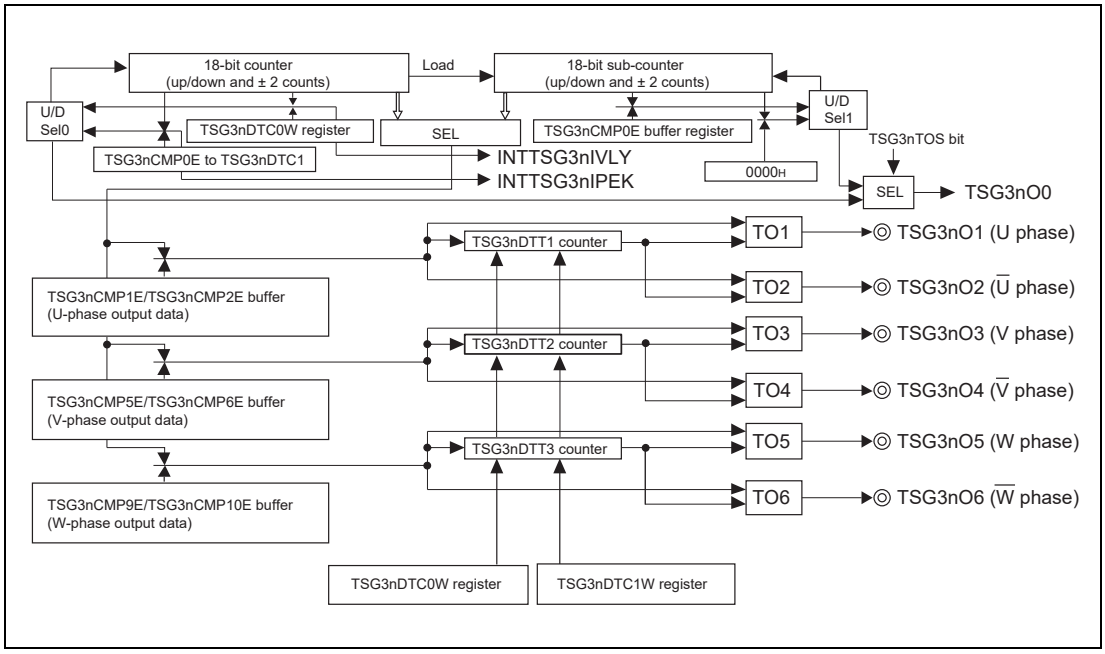

Figure 35.55 Block Diagram in HT-PWM Mode

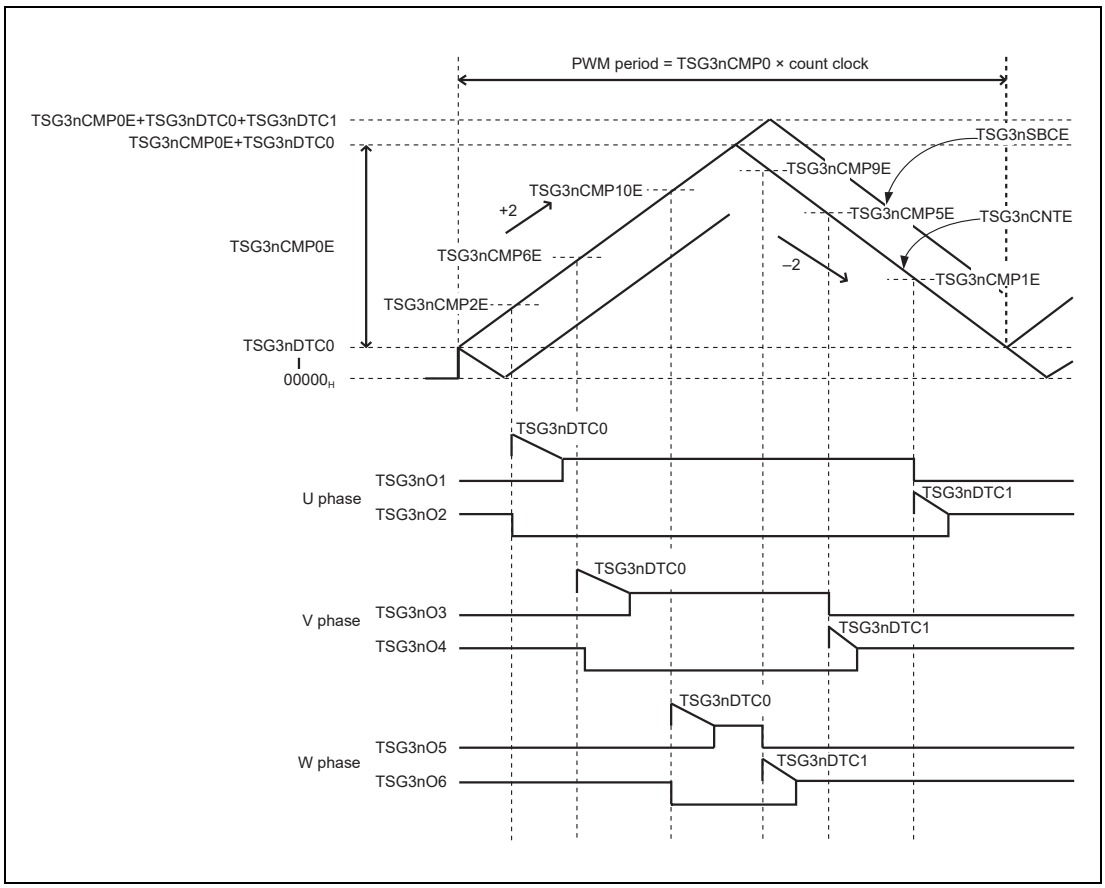

Figure 35.56 Basic Timing in HT-PWM Mode

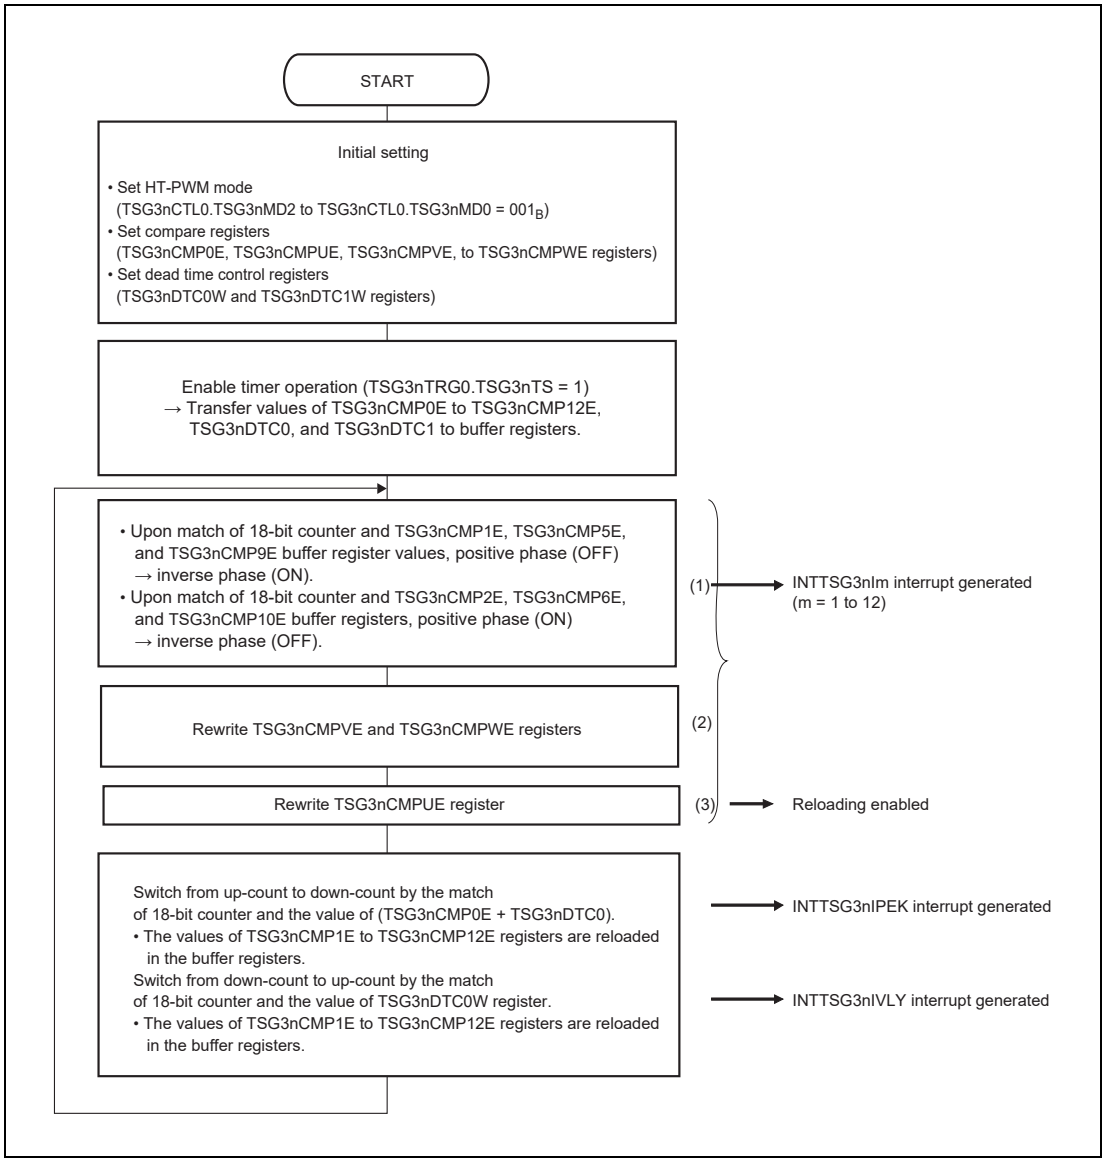

Figure 35.57 Basic Operation Flow in HT-PWM Mode

NOTE

- Write access to TSG3nCMPUE (TSG3nCMP1E) includes reloading enabling operation. Therefore, (3) must be done after (2).
- The INTTSG3nIPEK interrupt is generated only when TSG3nCTL4.TSG3nPIE = 1.
- The INTTSG3nIVLY interrupt is generated only when TSG3nCTL4.TSG3nVIE = 1.
- INTTSG3nI3, INTTSG3nI7, and INTTSG3nI11 outputs an interrupt at the match timing of TSG3nCMP3E, 7E, and 11E with TSG3nCNTE when counting down (TSG3nCUF = 1). INTTSG3nI4, INTTSG3nI8, and INTTSG3nI12 outputs an interrupt at the match timing of TSG3nCMP4E, 8E, and 12E with TSG3nCNTE when counting up (TSG3nCUF = 0).

(2) List of HT-PWM Mode Operations

Table 35.62 Counter Function in HT-PWM Mode

Operation		Setting Condition
18-bit counter	Start	TSG3nTRG0.TSG3nTS = 0 → 1 or simultaneous start trigger (counting up from TSG3nDTC0)
	Up count	Compare match of TSG3nDTC0 buffer register and 18-bit counter
	Down count	Compare match of TSG3nCMP0E + TSG3nDTC0 and 18-bit counter
	Clear	—
	Stop	TSG3nTRG1.TSG3nTT = 0 → 1
18-bit sub-counter	Start	TSG3nTRG0.TSG3nTS = 0 → 1 or simultaneous start trigger (counting down from TSG3nDTC0)
	Up count	Underflow
	Down count	Compare match of TSG3nCMP0E + TSG3nDTC0 + TSG3nDTC1 buffer register and 18-bit sub-counter
	Load	• TSG3nCMP0E + TSG3nDTC0: When value of 18-bit counter matches the value of buffer register TSG3nCMP0E + TSG3nDTC0 • TSG3nDTC0: When value of 18-bit counter matches the value of the buffer register TSG3nDTC0
	Clear	—
	Stop	TSG3nTRG1.TSG3nTT = 0 → 1

Table 35.63 Compare Register and Dead Time Control Register Functions in HT-PWM Mode

Register	Rewrite Method	Rewrite during Operation	Function
TSG3nCMP0E	Reload/Anytime rewrite	Possible	Setting period
TSG3nCMPUE	—	Possible	PWM control for U phase
TSG3nCMP1E, TSG3nCMP2E	Reload/Anytime rewrite		
TSG3nCMPVE	—	Possible	PWM control for V phase
TSG3nCMP5E, TSG3nCMP6E	Reload/Anytime rewrite		
TSG3nCMPWE	—	Possible	PWM control for W phase
TSG3nCMP9E, TSG3nCMP10E	Reload/Anytime rewrite		
TSG3nDCMP0E, TSG3nDCMP1E, TSG3nDCMP2E	Reload/Anytime rewrite	Possible	Diagnostic signal output or A/D conversion trigger
TSG3nDTC0W, TSG3nDTC1W	Reload	Possible conditionally	Period and dead time control

NOTE

- The rewritten values of TSG3nCMPUE, TSG3nCMPVE, and TSG3nCMPWE are set to TSG3nCMP1E, TSG3nCMP2E, TSG3nCMP5E, TSG3nCMP6E, TSG3nCMP9E and TSG3nCMP10E.
- For rewriting method of TSG3nDTC0 and TSG3nDTC1, see **Section 35.4.7.2(8)(a), TSG3nDTC0 and TSG3nDTC1 Rewriting**.

Table 35.64 Timer Output Function in HT-PWM Mode

Pin	Function
TSG3nO0	Active level output during up count, inactive level output at down count of the 18-bit counter/sub-counter
TSG3nO1	PWM output with dead time by compare match of TSG3nCMP1E buffer register and 18-bit counter (down count) and compare match of TSG3nCMP2E buffer register and 18-bit counter (up count) PWM output by compare match of TSG3nCMP1E buffer register and 18-bit sub-counter (during down counting) and compare match of TSG3nCMP2E buffer register and 18-bit sub-counter (during up counting) while TSG3nCMP1E < DTC0
TSG3nO2	Output negative phase with respect to TSG3nO1 (with dead time)
TSG3nO3	PWM output with dead time by compare match of TSG3nCMP5E buffer register and 18-bit counter (down count) and compare match of TSG3nCMP6E buffer register and 18-bit counter (up count). PWM output by compare match of TSG3nCMP3E buffer register and 18-bit sub-counter (during down counting) and compare match of TSG3nCMP6E buffer register and 18-bit sub-counter (during up counting) while TSG3nCMP5E < DTC0
TSG3nO4	Output negative phase with respect to TSG3nO3 (with dead time)
TSG3nO5	PWM output with dead time by compare match of TSG3nCMP9E buffer register and 18-bit counter (down count) and TSG3nCMP10E buffer register and 18-bit counter (up count). PWM output by compare match of TSG3nCMP5E buffer register and 18-bit sub-counter (during down counting) and compare match of TSG3nCMP10E buffer register and 18-bit sub-counter (during up counting) while TSG3nCMP9E < DTC0
TSG3nO6	Output negative phase with respect to TSG3nO5 (with dead time)
TSG3nO7	Diagnostic signal output or pulse output by A/D conversion trigger

NOTES

1. The target of TSG3nO0 status output can be switched with TSG3nIOC1.TSG3nTOS.
2. When the peak and valley values of the 18-bit sub-counter are set in TSG3nCMP1E and TSG3nCMP2E, clearing takes precedence.

Table 35.65 Interrupt Request in HT-PWM Mode

Interrupt	Function
INTTSG3nI0	Compare match of TSG3nDTC0 buffer register and 18-bit counter (periodic interrupt)
INTTSG3nIm (m = 1, 2, 5, 6, 9, 10)	Compare match of TSG3nCMPmE buffer register and 18-bit counter (m = 1, 2, 5, 6, 9, 10)
INTTSG3nIER	Error interrupt
INTTSG3nIVLY	Valley interrupt
INTTSG3nIPEK	Peak interrupt
INTTSG3nIWN	Warning interrupt

Table 35.66 Compare Match Timing in HT-PWM Mode

Compare Match	Timing
TSG3nCMP0E	When the 18-bit counter changes from TSG3nDTC0 to TSG3nDTC0 + 2
TSG3nCMPmE (m = 1, 2, 5, 6, 9, 10)	When 18-bit counter changes from TSG3nCMPmE to TSG3nCMPmE ± 2 (m = 1, 2, 5, 6, 9, 10)

Table 35.67 Example of Setting Each Timer Output Condition in HT-PWM Mode

Pin	Item	Output Period	Output Duty	
			Output Condition	Setting Condition
TSG3nO0	Toggle output	TSG3nCMP0E × count clock	Output an inactive level when counting up, and an active level when counting down.	—
TSG3nO1, TSG3nO3, TSG3nO5	PWM output	TSG3nCMP0E × count clock	Output an inactive level throughout one period (0% duty)	TSG3nCMP0E ≤ TSG3nCMPmE ≤ TSG3nCMP0E + TSG3nDTC0 + TSG3nDTC1 (m = U, V, W)
			Output an active level of one count clock in one period	TSG3nCMPmE = TSG3nCMP0E – 1 (m = U, V, W)
			Output an inactive level of one count clock in one period	TSG3nCMPmE = 0001_H (m = U, V, W)
			Output an active level throughout one period(100% duty)	TSG3nCMPmE = 0000_H (m = U, V, W)
TSG3nO2, TSG3nO4, TSG3nO6	PWM output		Output an inactive level throughout one period (0% duty)	TSG3nCMPmE ≤ TSG3nDTC0 + TSG3nDTC1 (m = U, V, W)
			Output an active level of one count clock in one period	TSG3nCMPm = TSG3nDTC0 + TSG3nDTC1 + 1 (m = U, V, W)
			Output an inactive level of one count clock in one period	TSG3nCMPmE = TSG3nCMP0E + TSG3nDTC0 + TSG3nDTC1 – 1 (m = U, V, W)
			Output an active level throughout one period (100% duty)	TSG3nCMPmE = TSG3nCMP0E + TSG3nDTC0 + TSG3nDTC1 (m = U, V, W)
TSG3nO7	Diagnostic signal output or pulse output by A/D conversion trigger	TSG3nCMP0E × count clock	See **Section 35.4.5, A/D Conversion Trigger Function**	

(3) Various Settings of HT-PWM Mode

Setting mode

HT-PWM mode is entered by setting TSG3nCTL0.TSG3nMD2-TSG3nMD0 to 001_B.

Setting timer output

The output pins TSG3nO1 to TSG3nO6 are controlled by setting TSG3nIOC0, TSG3nIOC2, and TSG3nIOC3.

The output pin TSG3nO0 indicates the up/down count status of the 18-bit counter or the 18-bit sub-counter. Switch between the 18-bit sub-counter and the 18-bit counter is done with the TSG3nIOC1.TSG3nTOS bit.

The TSG3nO7 pin provides output pulse as diagnostic output or A/D conversion trigger. The pin should be set as necessary.

Enabling error interrupt generation

Error interrupt (INTTSG3nIER) due to the detection of the simultaneous active state of the positive phase and inverse phase is enabled by setting TSG3nIOC1.TSG3nEOC to 1. In HT-PWM mode, no value specified in the compare register makes the positive phase and negative phase simultaneously active. For details, see **Section 35.4.6, Error/Warning Interrupt**.

Setting register rewriting timing with reload function

With TSG3nCTL3.TSG3nRMC, reload (simultaneous rewrite) or rewrite (anytime) is specified for the registers with reload function. The default setting is 0 (reload). To reload, set TSG3nCTL4.TSG3nPRE or TSG3nVRE to 1.

The reload timing is not generated if both TSG3nPRE bit and TSG3nVRE bit are set to 0.

When “anytime rewrite” is specified, unintended output may be generated depending on the rewrite timing.

Setting interrupts and skipping function

Interrupts and the skipping function are set with TSG3nCTL4. TSG3nPIE should be set to 1 when peak interrupt (INTTSG3nIPEK) is required and TSG3nVIE to 1 when valley interrupt (INTTSG3nIVLY) is required. To use the skipping function for peak/valley interrupts, set TSG3nRCC4 to TSG3nRCC0.

Setting A/D conversion trigger output

To set A/D conversion trigger 0 (TSG3nADTRG0 signal), use TSG3nCTL5.TSG3nAT09 to TSG3nAT00. With TSG3nAT09 to TSG3nAT00, A/D conversion trigger output is enabled or disabled at the match of 18-bit counter (during up count) with TSG3nDCMP2E to TSG3nDCMP0E, the match of the 18-bit counter (during down count) with TSG3nDCMP2E to TSG3nDCMP0E, the 18-bit counter peak interrupt (INTTSG3nIPEK), the 18-bit counter valley interrupt (INTTSG3nIVLY), the 18-bit sub-counter peak timing, and 18-bit sub-counter valley timing.

To set A/D conversion trigger 1 (TSG3nADTRG1 signal), use TSG3nCTL6.TSG3nAT19 to TSG3nAT10.

To set the match timing of 18-bit counter and TSG3nDCMP2E to TSG3nDCMP0E, set the compare value to the pertinent register.

The skipping function can be used for TSG3nADTRG0 and the TSG3nADTRG1 signals. Use TSG3nACC01, TSG3nACC00 of TSG3nCTL5, and TSG3nACC10, TSG3nACC11 of TSG3nCTL6 to select the skipping rate from 1/1 (no skipping), 1/2, 1/4, and 1/8.

CAUTION

Be sure to set TSG3nCTL5, TSG3nCTL6, and TSG3nDCMP2E to TSG3nDCMP0E correctly when the timing pulse of the A/D conversion trigger is output to TSG3nO7.

Setting dead time

The dead time can be set with TSG3nDTC0 and TSG3nDTC1.

The dead time is calculated by the following expressions:

PCLK × TSG3nDTC0

PCLK × TSG3nDTC1

TSG3nDTC0 can set the time between a change of TSG3nO2, TSG3nO4, and TSG3nO6 to the inactive state and a change of TSG3nO1, TSG3nO3, and TSG3nO5 to the active state, respectively.

TSG3nDTC1 can set the time between a change of TSG3nO1, TSG3nO3, TSG3nO5 to the inactive state and a change of TSG3nO2, TSG3nO4, and TSG3nO6 to the active state, respectively.

TSG3nDTC0 and TSG3nDTC1 can only be set to an even value.

Carrier period

Set the carrier period with TSG3nCMP0E according to the following expression:

TSG3nCMP0E = Carrier period/count clock period (PCLK)

The following requirements regarding the dead time must be satisfied when setting the TSG3nCMP0E register:

- TSG3nCMP0E + TSG3nDTC0 + TSG3nDTC1 ≤ 3FFFEH
- TSG3nCMP0E > TSG3nDTC0
- TSG3nCMP0E > TSG3nDTC1
- TSG3nCMP0E > 3 × MAX (TSG3nDTC0, TSG3nDTC1)
- TSG3nCMP0E: Even number

NOTE

MAX (A, B) indicates the larger value of A and B.

Setting duty (PWM width)

The duty of the U phase, the V phase, and the W phase is set with TSG3nCMPmE (m = U, V, W, or 1, 2, 5, 6, 9, and 10), respectively. The setting range of the compare registers is as follows:

$00000_H \leq$ TSG3nCMPmE $\leq$ TSG3nCMP0E + TSG3nDTC0 + TSG3nDTC1

LSB (least significant bit) of TSG3nCMPUE, TSG3nCMPVE, and TSG3nCMPWE indicates the setting of an additional pulse. For example, when TSG3nCMPUE = 00003_H, the change in the inverse phase (TSG3nO2 output) occurs one count clock later compared to the TSG3nCMPUE = 00002_H setting (when the 18-bit counter is up-counting). The additional pulse cannot be set to TSG3nCMP1E, TSG3nCMP2E, TSG3nCMP5E, TSG3nCMP6E, TSG3nCMP9E, or TSG3nCMP10E (only even numbers can be set to these registers).

(4) 18-bit counter Operation in HT-PWM Mode

The 18-bit counter is initialized to 00000_H and the value of TSG3nDTC0 is loaded immediately after the TSG3n timer operation starts (TSG3nTRG0.TSG3nTS = 1), and the counter is incremented by 2. After 18-bit counter reaches the value of TSG3nCMP0E + TSG3nDTC0, it is decremented by 2.

The following figure shows 18-bit counter operation.

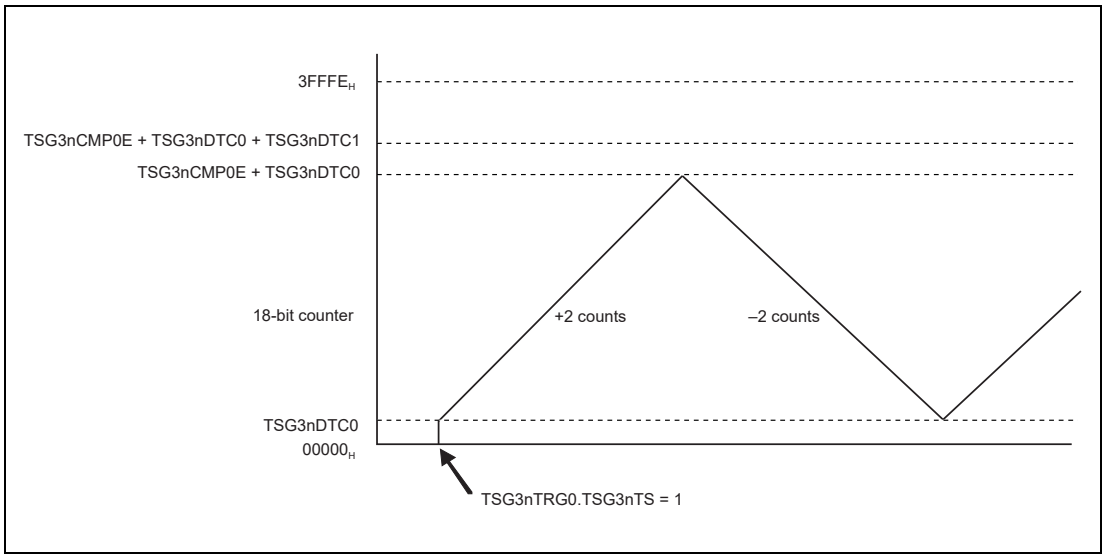

Figure 35.58 Example of 18-bit counter Operation in HT-PWM Mode

NOTE

Minimum 18-bit counter value: TSG3nDTC0
Maximum 18-bit counter value: TSG3nCMP0E + TSG3nDTC0
Carrier period: TSG3nCMP0E × count clock period (PCLK)

The 18-bit sub-counter is initialized to 00000_H and the value of TSG3nDTC0 is loaded immediately after the TSG3n timer operation starts (TSG3nTRG0.TSG3nTS = 1), and the counter is decremented by 2 until it reaches 00000_H, at which point increment by 2 begins. Next, the value of the 18-bit counter is loaded into the 18-bit sub-counter at a change timing of the 18-bit counter into the down count. Counting up by the 18-bit sub-counter continues until the value reaches the value of TSG3nCMP0E + TSG3nDTC0 + TSG3nDTC1, and then decrement by 2 begins. Similarly, when the 18-bit counter value matches the TSG3nDTC0 value, the 18-bit counter value is loaded to the 18-bit sub-counter and the down count is continued.

The following figure shows the 18-bit sub-counter operation.

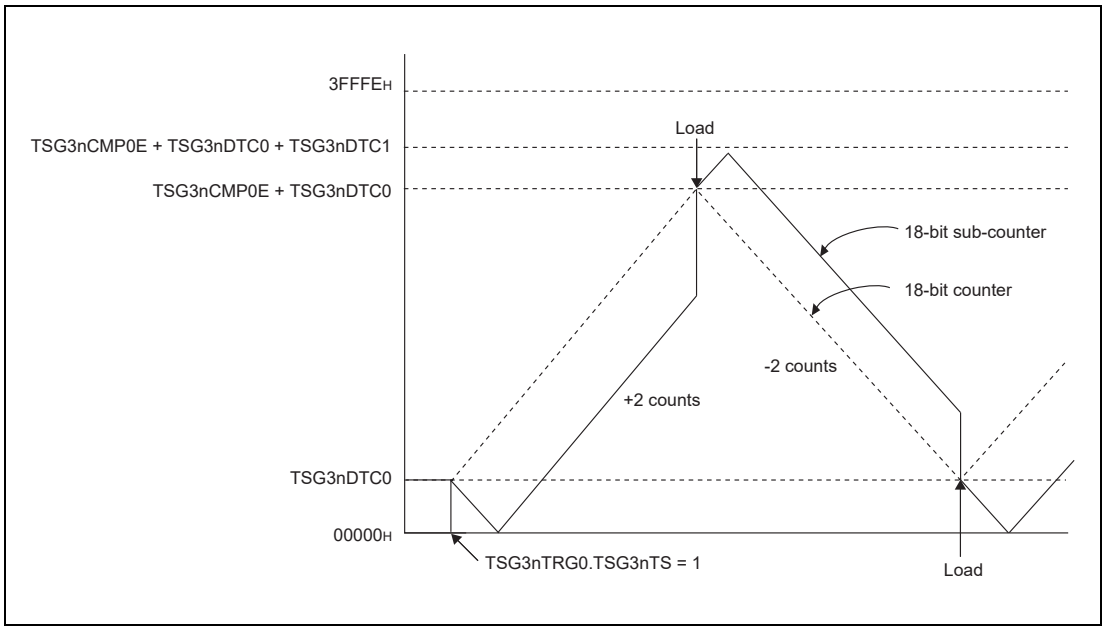

Figure 35.59 Example of 18-bit Sub-Counter Operation in HT-PWM Mode

NOTE

Minimum 18-bit sub-counter value: 00000_H
Maximum 18-bit sub-counter value: TSG3nCMP0E + TSG3nDTC0 + TSG3nDTC1

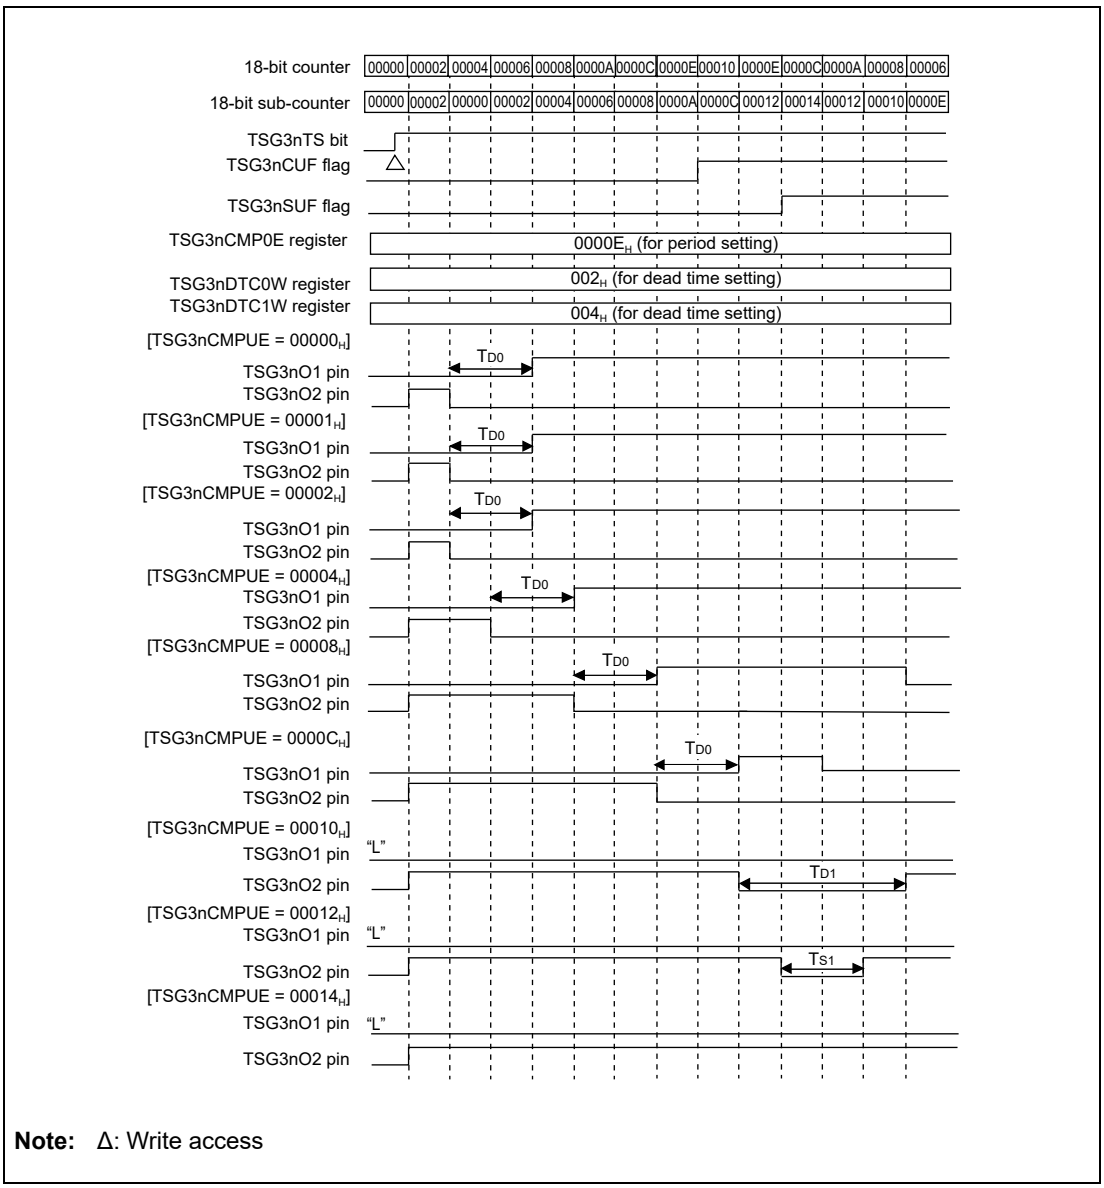
(5) Basic Operation of HT-PWM Mode

(a) Example of Timer Output Immediately after the Start of the TSG3n Timer Operation

The following figure shows the timing chart when TSG3nCMP0E = $0000E_H$, TSG3nDTC0 = 002_H, TSG3nDTC1 = 004_H and TSG3nCMPUE = 00000_H to 00014_H (excerpt). In this example, TSG3nIOC2.TSG3nOL1 to TSG3nOL6 = 000000_B.

When operation starts (TSG3nTRG0.TSG3nTS = 1), the level of the TSG3nO2 pin changes to active. Afterwards, if TSG3nCMPUE ≤ TSG3nDTC0, the TSG3nO2 pin is cleared after 1 count clock cycle.

The TSG3nO2 pin is cleared upon a match of the 18-bit counter and the compare register (TSG3nCMP2E), or a match of the 18-bit sub-counter and the compare register (TSG3nCMP2E) if TSG3nCMPUE ≥ TSG3nDTC0. Afterwards, the TSG3nO1 pin is set after the set dead time period (the TSG3nO1 pin is not set if TSG3nCMPUE ≥ TSG3nCMP0E).



Note: Δ: Write access

Figure 35.60 Example of Timer Output when TSG3nTS is Set to 1 (Initial Setting) in HT-PWM Mode

NOTES

1. TSG3nCMP0E = $0000E_H$, TSG3nDTC0 = 002_H, TSG3nDTC1 = 004_H
2. T_{D0}: Time depending on the dead time setting in the TSG3nDTC0W register
   T_{D1}: Time depending on the dead time setting in the TSG3nDTC1W register
   T_{S1}: Time determined by compare match of the 18-bit sub-counter and TSG3nCMPUE register, when TSG3nCMPUE >18-bit counter maximum value

(b) Example of Timer Output during TSG3n Timer Operation

The following figure shows the timing chart when TSG3nCMP0E = $0000E_H$, TSG3nDTC0 = 002_H, TSG3nDTC1 = 004_H, and TSG3nCMPUE is set to 00000_H-00014_H (excerpt). In this example, TSG3nIOC2.TSG3nOL1-TSG3nOL6 = 000000_B.

The range of the active (high level) width of a positive phase (TSG3nO1) output is $00000_H \leq$ TSG3nCMPUE $\leq$ TSG3nCMP0E (for the additional pulse). The range of the active (high level) width of an inverse phase (TSG3nO2) output is TSG3nDTC0 + TSG3nDTC1 $\leq$ TSG3nCMPUE $\leq$ TSG3nCMP0E + TSG3nDTC0 + TSG3nDTC1.

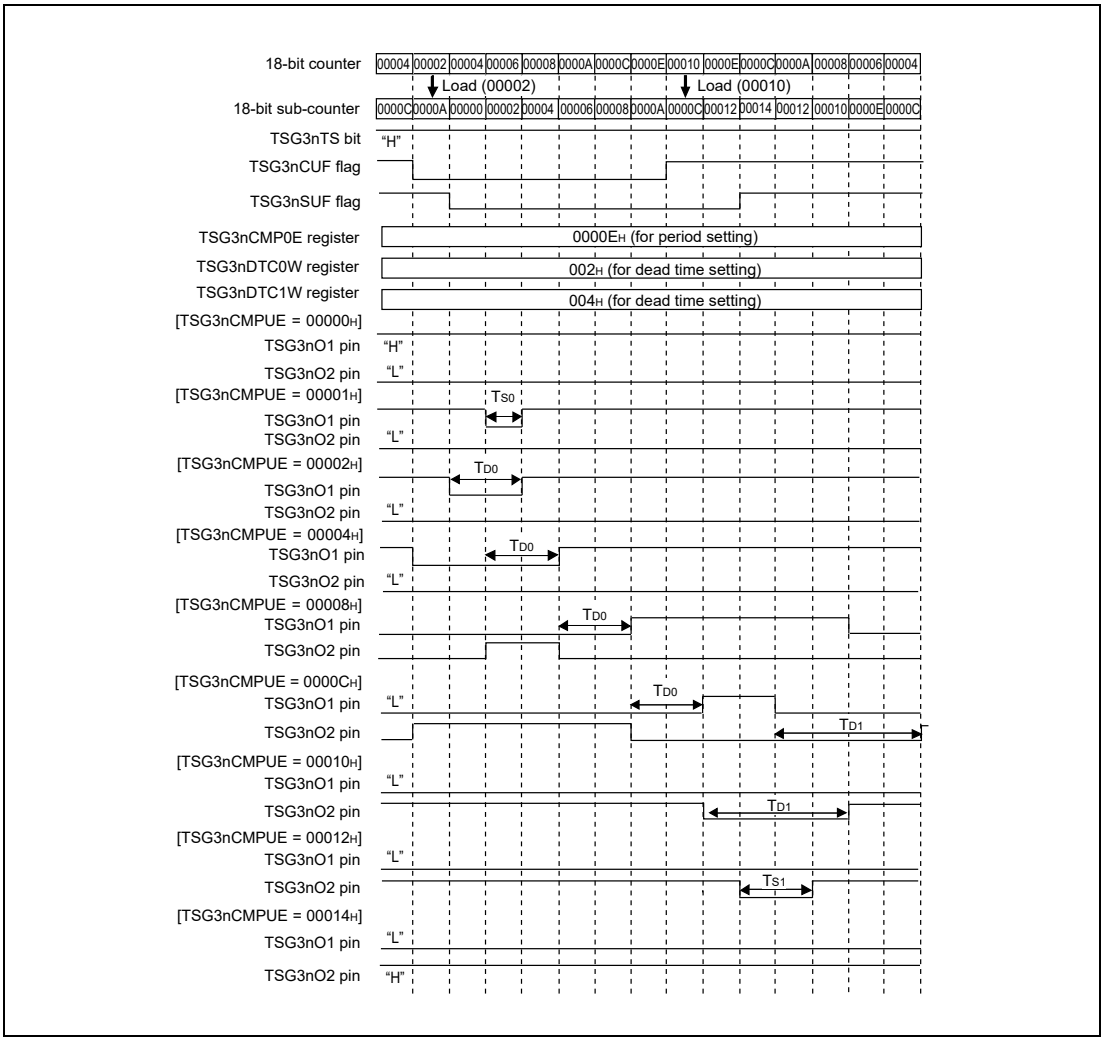


Figure 35.61 Example of Timer Output during TSG3n Operation in HT-PWM Mode

NOTES

1. TSG3nCMP0E = $0000E_H$, TSG3nDTC0 = 002_H, TSG3nDTC1 = 004_H
2. T_{D0}: Time depending on setting of the dead time in the TSG3nDTC0 register
   T_{D1}: Time depending on setting of the dead time in the TSG3nDTC1 register
   T_{S0}: Time determined by compare match of 18-bit sub-counter and the TSG3nCMPUE register, when TSG3nCMPUE < 18-bit counter minimum value
   T_{S1}: Time determined by compare match of the 18-bit sub-counter and the TSG3nCMPUE register, when TSG3nCMPUE > 18-bit counter maximum value

(6) Additional Pulse Control in HT-PWM Mode

The HT-PWM mode can generate an additional pulse by setting 1 to the LSB of the duty setting registers (TSG3nCMPUE, TSG3nCMPVE, and TSG3nCMPWE). This allows more precise control of the pulse duty than standard pulse control.

The following sections describe two examples of pulse output of TSG3nO1: additional pulse control is used in one example and additional pulse control is not used in another.

(a) Example of Pulse Output when Additional Pulse Control Is Used

Figure 35.62 shows the additional pulse control when an odd value is set to TSG3nCMPUE.

The arrows and numerical values show the duty cycle width of the TSG3nO1 output in one period.

As shown in **Figure 35.62**, when the additional pulse control is used, the output width of the TSG3nO1 (duty cycle) can be set within a range from 12 clock cycles to 0 clock cycles in one-clock-cycle step.

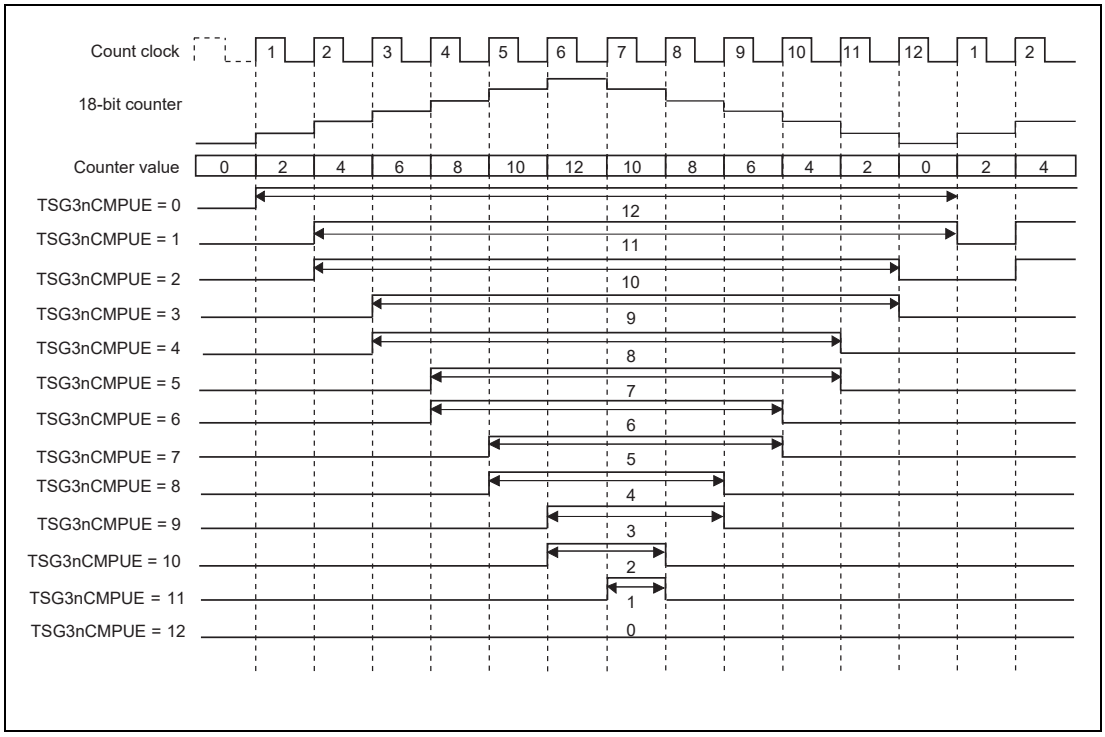

Figure 35.62 Example of TSG3nO1 Output when Additional Pulse Control Is Used in HT-PWM Mode

NOTE

TSG3nCMP0E = 12, TSG3nDTC0 = 0, TSG3nDTC1 = 0

(b) Example of Pulse Output when Additional Pulse Control Is Not Used

The arrows and numerical values in **Figure 35.63** show the duty cycle width of the TSG3nO1 output in one period.

When the additional pulse control is not used, the width of the TSG3nO1 output can be set within a range from 12 clock cycles to 0 clock cycles in two-clock-cycle step. In this case, the change in duty cycle is larger than that of the case when the additional pulse control is used.

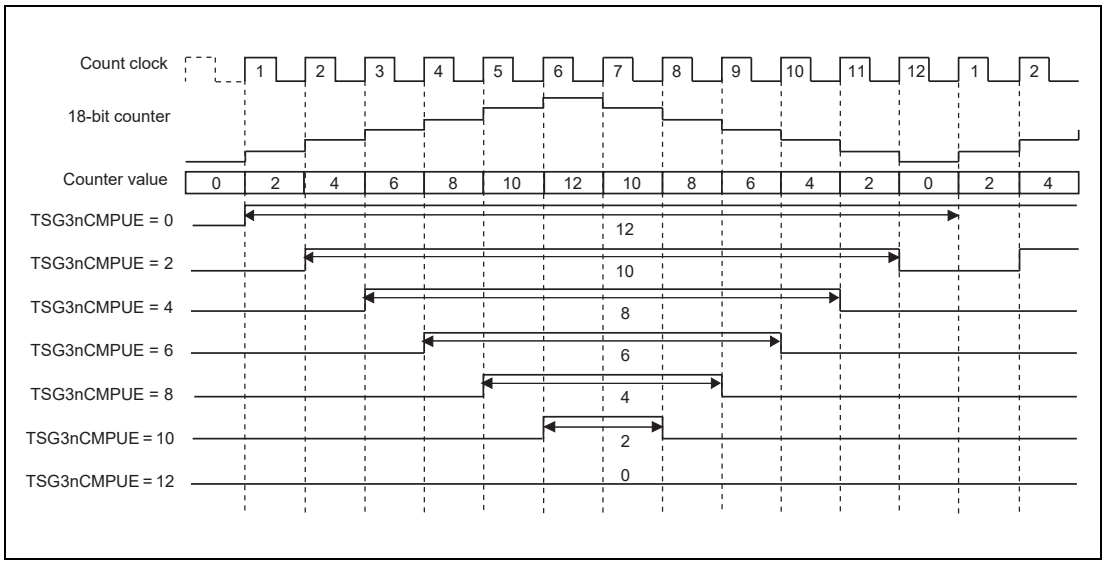

Figure 35.63 Example of TSG3nO1 Output when Additional Pulse Control Is Not Used in HT-PWM Mode

NOTE

TSG3nCMP0E = 12, TSG3nDTC0 = 0, TSG3nDTC1 = 0

(7) Dead Time Control in HT-PWM Mode

Duty setting are basically configured with the TSG3nCMPUE, TSG3nCMPVE, and TSG3nCMPWE registers in HT-PWM mode. The 6-phase PWM waveform of a variable duty is output by using these registers. To achieve the dead time control, there are two dead time control registers (TSG3nDTC0W and TSG3nDTC1W) and six 10-bit down counters that operate synchronously with the count clock of the 18-bit counter. TSG3nDTC0 is used for setting a dead time from a change of the inverse phase to the inactive state to a change of the positive phase to the active state. TSG3nDTC1 is used for setting a dead time from a change of the positive phase to the inactive state to a change of the inverse phase to the active state.

The following figure shows the output waveform when TSG3nDTC0 = x and TSG3nDTC1 = y.

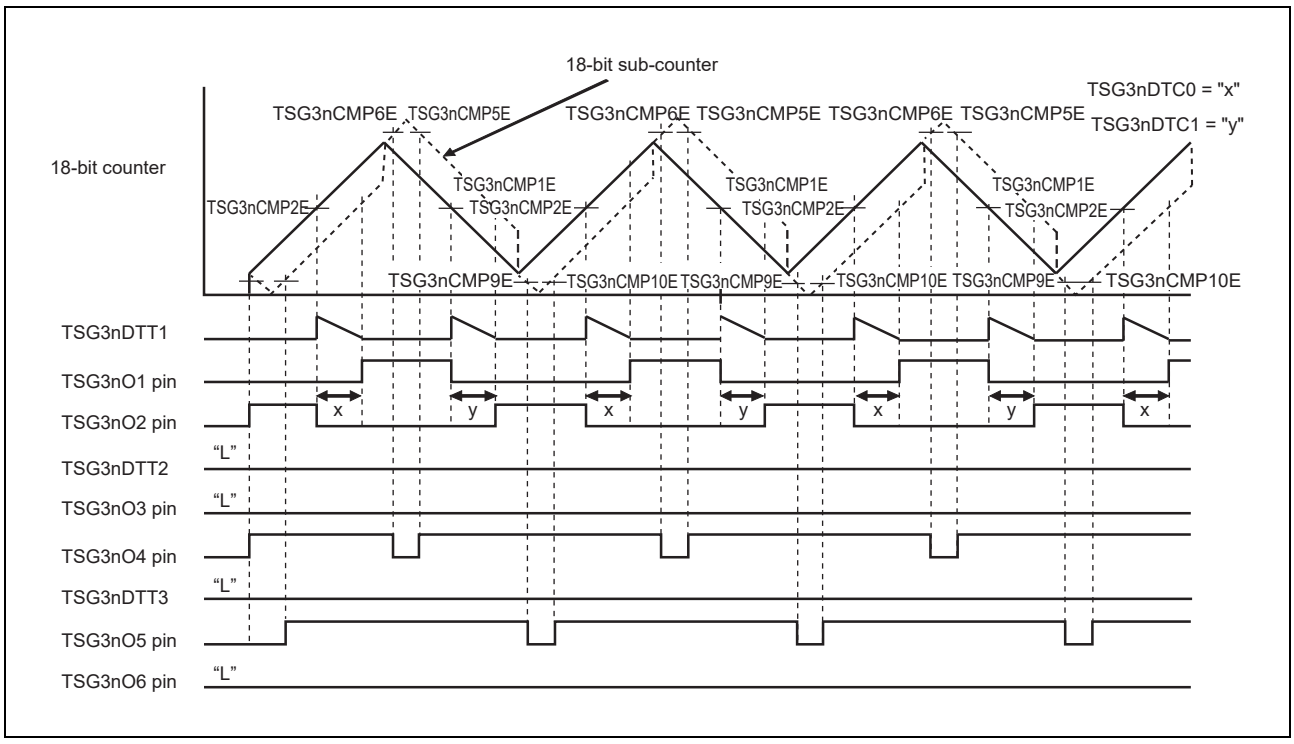

Figure 35.64 Example of Output Waveform with Dead Time in HT-PWM Mode

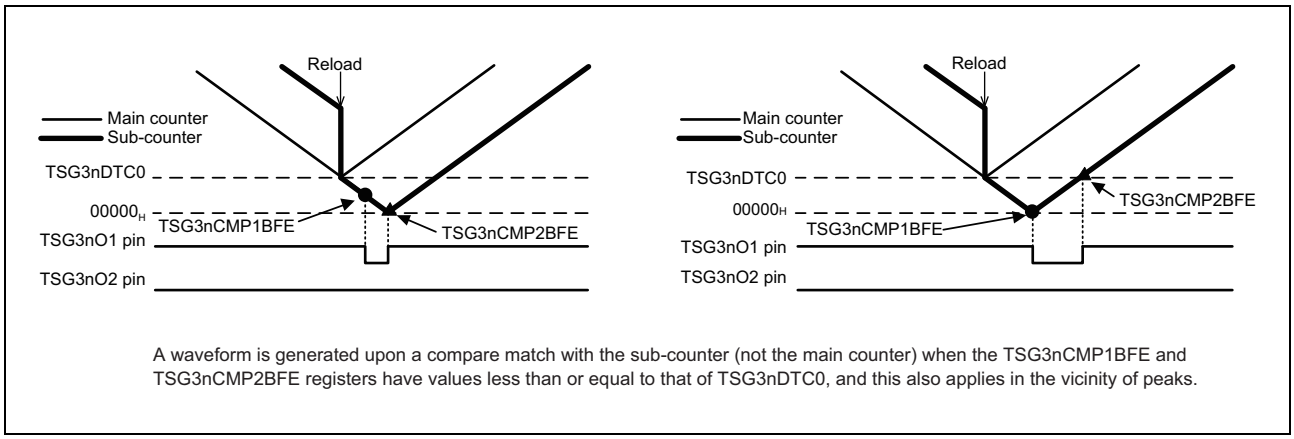

Figure 35.65 Example of Output Waveform near Trough after Reloading

(8) Notes Concerning Dead Time Control in HT-PWM Mode

(a) TSG3nDTC0 and TSG3nDTC1 Rewriting

It is possible to rewrite the dead time setting in TSG3nDTC0 and TSG3nDTC1 registers during timer operation.

CAUTIONS

1. **Rewrite TSG3nDTC0 and TSG3nDTC1 when the reload function is used (TSG3nRMC = 0).**
2. **The write protection code check function is applied when TSG3nDTC0 and TSG3nDTC1 are rewritten. For details, see the pertinent register descriptions (Section 35.3.43, Section 35.3.44, Section 35.3.63).**
3. **When the TSG3nCMP0E and TSG3nDTC1 are updated at the peak of the 18-bit counter:**
   If the set value of TSG3nCMPmE is greater than the updated TSG3nCMP0E + TSG3nDTC0 value (new maximum value of the main counter), the match interrupt (INTTSG3nIm) is not generated immediately after reloading (m = 2, 6, or 10).

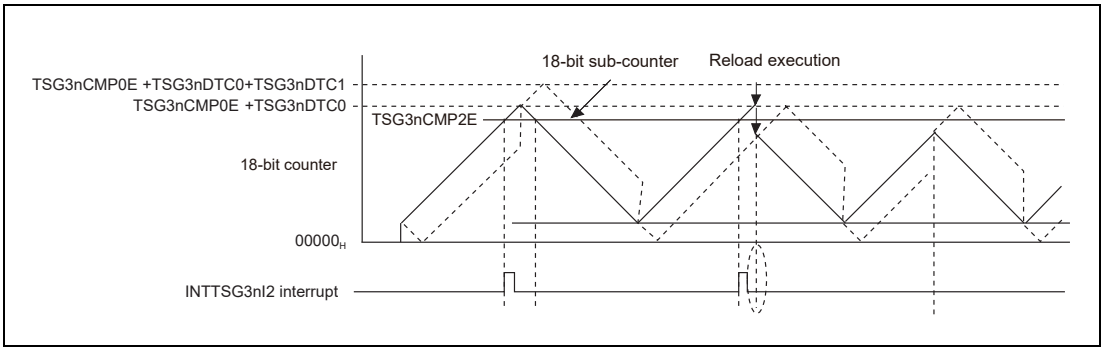

Figure 35.66 Example of Operation During Reloading at 18-Bit Counter Peak Timing

4. **When the TSG3nDTC0 is updated at the valley of the 18-bit counter:**
   If the TSG3nCMPmE set value is smaller than the updated TSG3nDTC0 value (new minimum value of the main counter), the match interrupt (INTTSG3nIm) is not generated immediately after reloading (m = 1, 5, or 9).

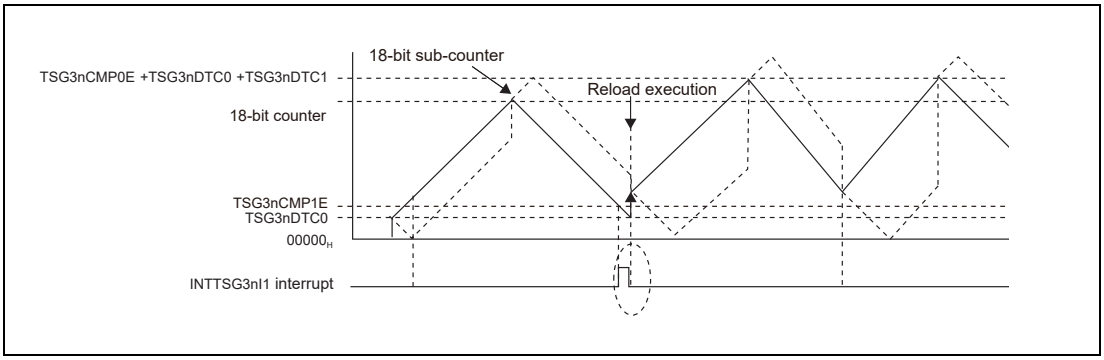

Figure 35.67 Example of Operation During Reloading at 18-Bit Counter Trough Timing

(9) Software Output Control Function in HT-PWM Mode

TSG3nOPT0.TSG3nSOC, TSG3nIDC, and TSG3nOPT1.TSG3nSPC2-TSG3nSPC0 are used in HT-PWM mode for software control of timer output control.

As shown in **Figure 35.68**, with TSG3nSTE = 0, the output control is switched immediately when TSG3nSOC is set to 1. If the dead time is set, the period of the dead time is guaranteed. After that, when TSG3nSOC is set to 0, output control is retained and at the reload timing, output control is switched to HT-PWM mode output control.

For details, refer to **Section 35.4.7.8, Software Output Control Function**.

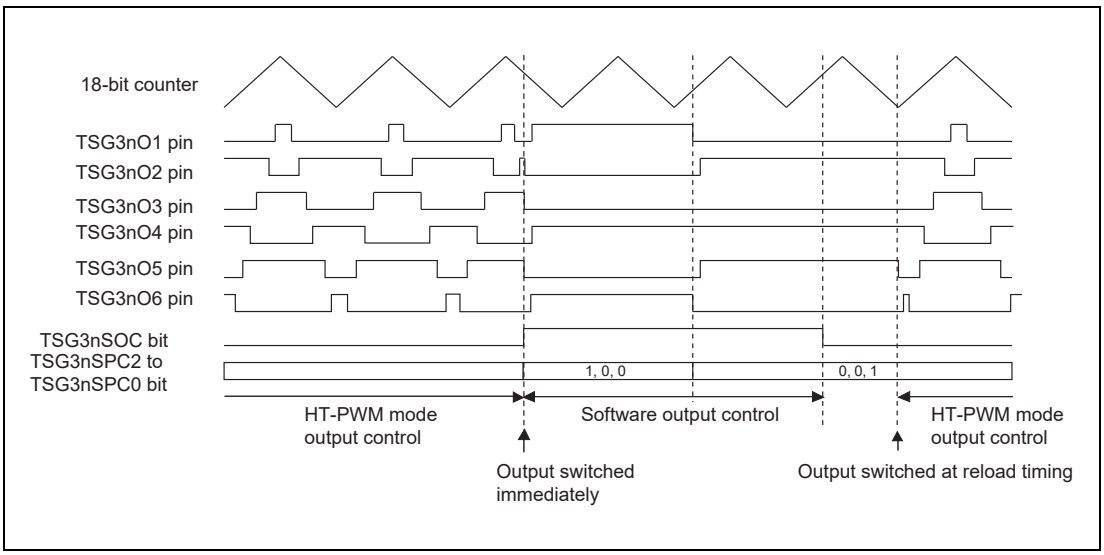

Figure 35.68 Example of Switching from HT-PWM Mode Control to Software Output Control

CAUTION

Use reload (simultaneous rewrite) mode (TSG3nCTL3.TSG3nRMC = 0) when software output control function is used.

(a) Procedure for Software Output Control

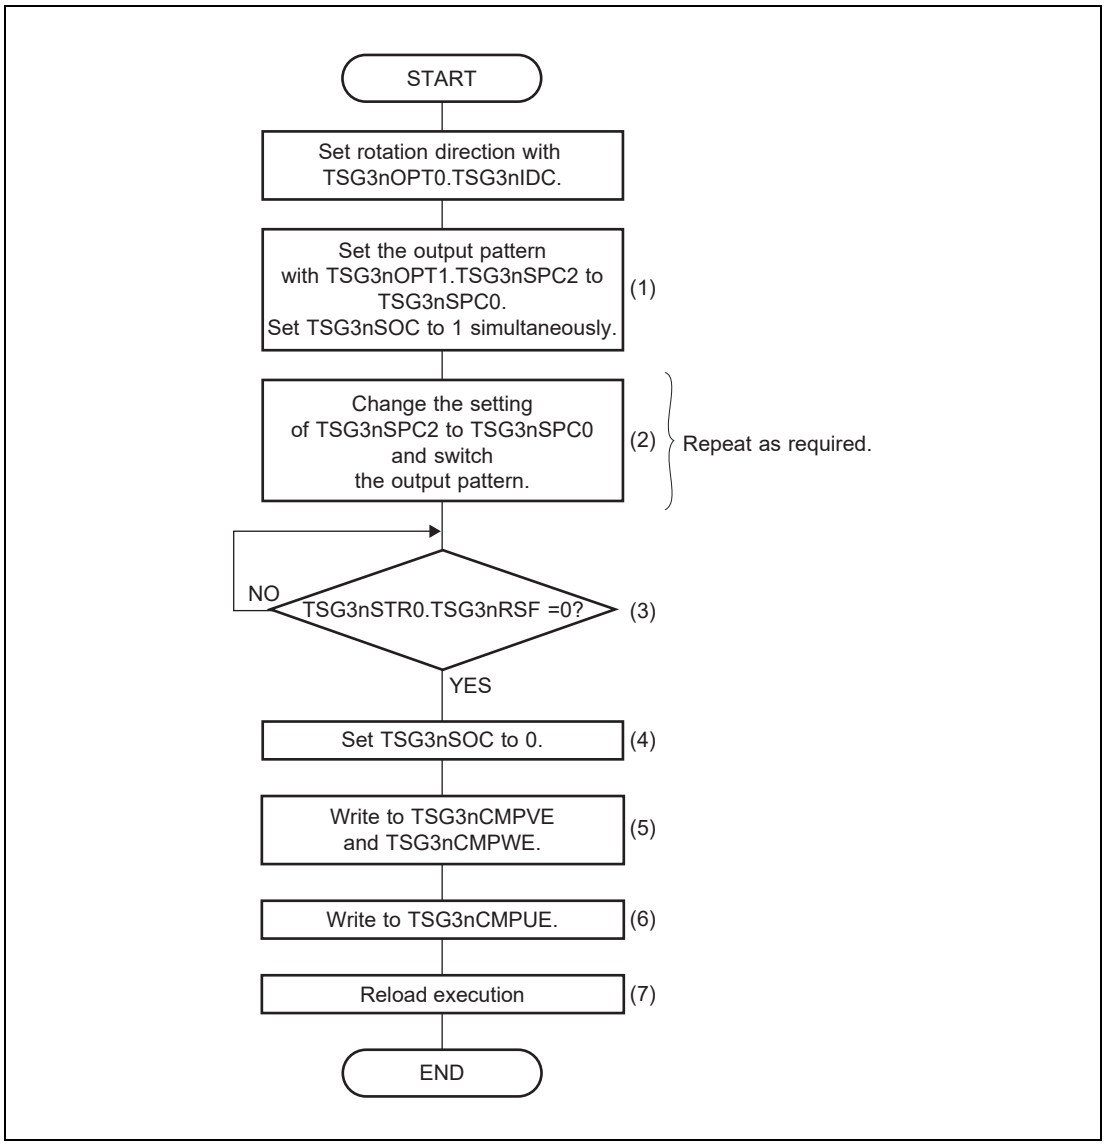

Figure 35.69 Flow of Software Output Control in HT-PWM Mode

The procedure for software output control is described below.

(1) Set the output pattern to the TSG3nOPT1.TSG3nSPC2-TSG3nSPC0. To enable software output control, set TSG3nOPT0.TSG3nSOC to 1 simultaneously.

(2) Change the output pattern setting of the TSG3nSPC2-TSG3nSPC0 to change the timer output.

(3) Confirm that reload request flag TSG3nSTR0.TSG3nRSF = 0. In case TSG3nRSF = 1, do not proceed to the following step until TSG3nRSF = 0.

(4) By setting TSG3nSOC = 0, the software control release process starts (it is not released yet at this point).

(5) Set the compare register settings that are required after the software output control is released. Proceed to the following step when the register setting is not required. When configuring the registers with the reload function, set them at this point.

(6) Write to TSG3nCMPUE (TSG3nCMP1E) to start reloading.

(7) Reload is executed and software output is released.

CAUTION

Execute reload after completing steps (3), (4), (5), and (6). When reload cannot be executed, the software output cannot be released.

(10) Asymmetric Triangular Wave Control in HT-PWM Mode

In HT-PWM mode, it is possible to control output by an asymmetric triangular waveform by setting the different timings for setting and clearing the U, V, and W phases.

The following describes the differences of the asymmetric triangular wave control from the symmetric triangular wave control.

(a) PWM Setting

When a symmetric triangular wave is used, the output control of each of the U phase, V phase, and W phase is done by setting the set timing and the clear timing to the same value in TSG3nCMPUE, TSG3nCMPVE, and TSG3nCMPWE, respectively. When an asymmetric triangular wave is used, the output control of each phase is done by setting TSG3nCMPmE as follows (m = 1, 2, 5, 6, 9, 10).

Prerequisites

- The clear timing of PWM of the voltage data signal of U, V and W phases is set with TSG3nCMP1E, TSG3nCMP5E, and TSG3nCMP9E.
- The set timing of PWM of the voltage data signal of U, V, and W phases is set with TSG3nCMP2E, TSG3nCMP6E, and TSG3nCMP10E.
- The set and clear timings of each phase can also be set with TSG3nCMP1E, TSG3nCMP2E, TSG3nCMP5E, TSG3nCMP6E, TSG3nCMP9E, and TSG3nCMP10E.
- TSG3nCMPmE can only be set to an even value (m = 1, 2, 5, 6, 9, 10).

(b) Timer Output

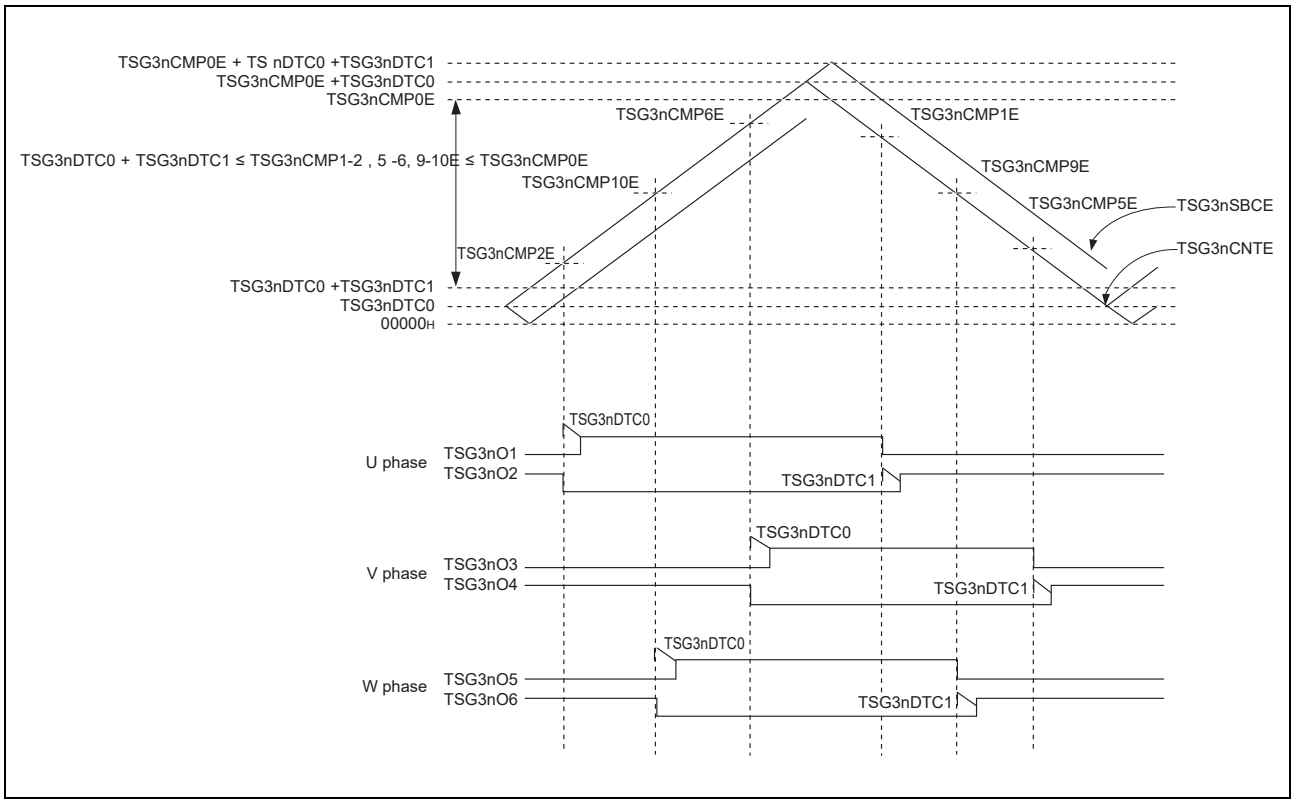

Figure 35.70 Example of Timer Output Waveform in HT-PWM Mode

NOTE

When output is controlled by the asymmetric triangular waveform, the following conditions apply to setting of TSG3nCMPmE (m = 1, 2, 5, 6, 9, 10).

- TSG3nDTC0+TSG3nDTC1 ≤ TSG3nCMPmE ≤ TSG3nCMP0E
- Only when TSG3nCMPmE = TSG3nCMP (m + 1) E, or TSG3nCMPmE = TSG3nCMP (m + 1) E + 2, it is possible to set TSG3nCMPmE under the condition 00000_H ≤ TSG3nCMPmE ≤ TSG3nCMP0E + TSG3nDTC0 + TSG3nDTC1, which also applies to the case where the symmetric triangular wave is used.

35.4.7.3 SP-PWM Mode (Shifted-pulse - Pulse Width Modulation Mode)

Overview

In this mode, a 6-phase PWM can be generated using the 18-bit counter and the 18-bit compare registers.

Prerequisites

- The PWM signal cycle is set in TSG3nCMP0E.
- The set timings of the U phase, V phase, and W phase are configured using TSG3nCMP2E, TSG3nCMP6E, and TSG3nCMP10E, while the clear timings of these phases are configured using TSG3nCMP1E, TSG3nCMP5E, and TSG3nCMP9E (when set timing and clear timing are used for control).
- The set timings of the U phase, V phase, and W phase are configured using TSG3nCMP2E, TSG3nCMP6E, and TSG3nCMP10E while the active periods of these phases are configured using TSG3nUPWE, TSG3nVPWE, and TSG3nWPWE. The sum of the set values of TSG3nCMP2E, TSG3nCMP6E, TSG3nCMP10E, and the set values of TSG3nUPWE, TSG3nVPWE, TSG3nWPWE are set to TSG3nCMP1E, TSG3nCMP5E, and TSG3nCMP9E respectively (when set timing and active period are used for control). The value after addition must be no greater than $3FFFF_H$. Otherwise, values having 19 or more bits are truncated.

Functional description

In this mode, the carrier period, the set timings, and the duty cycle of the U phase, V phase, and W phase are configured. The counting up begins when TSG3nTRG0.TSG3nTS is set to 1.

The 18-bit counter counts up from 00000_H and is cleared by match with TSG3nCMP0E.

The dead time is set with TSG3nDTC0 and TSG3nDTC1. TSG3nDTC0 sets the dead time of inverse phase (OFF) to positive phase (ON) switch while TSG3nDTC1 sets that of positive phase (OFF) to inverse phase (ON) switch. The 10-bit counters (TSG3nDTT1 to TSG3nDTT3) for dead time generation load the set values of TSG3nDTC0 and TSG3nDTC1 at compare match of the 18-bit counter with the TSG3nCMPmE buffer register (m = 1, 2, 5, 6, 9, 10) and start down-counting.

INTTSG3nIm interrupts (m = 1, 2, 5, 6, 9, 10) are generated by the compare match of the 18-bit counter with the TSG3nCMP1E, TSG3nCMP2E, TSG3nCMP5E, TSG3nCMP6E, TSG3nCMP9E, and TSG3nCMP10E buffer registers.

NOTE

SP-PWM mode is enabled when TSG3nCTL0.TSG3nMD2-TSG3nMD0 = 010_B.

(1) Basic Timing Chart

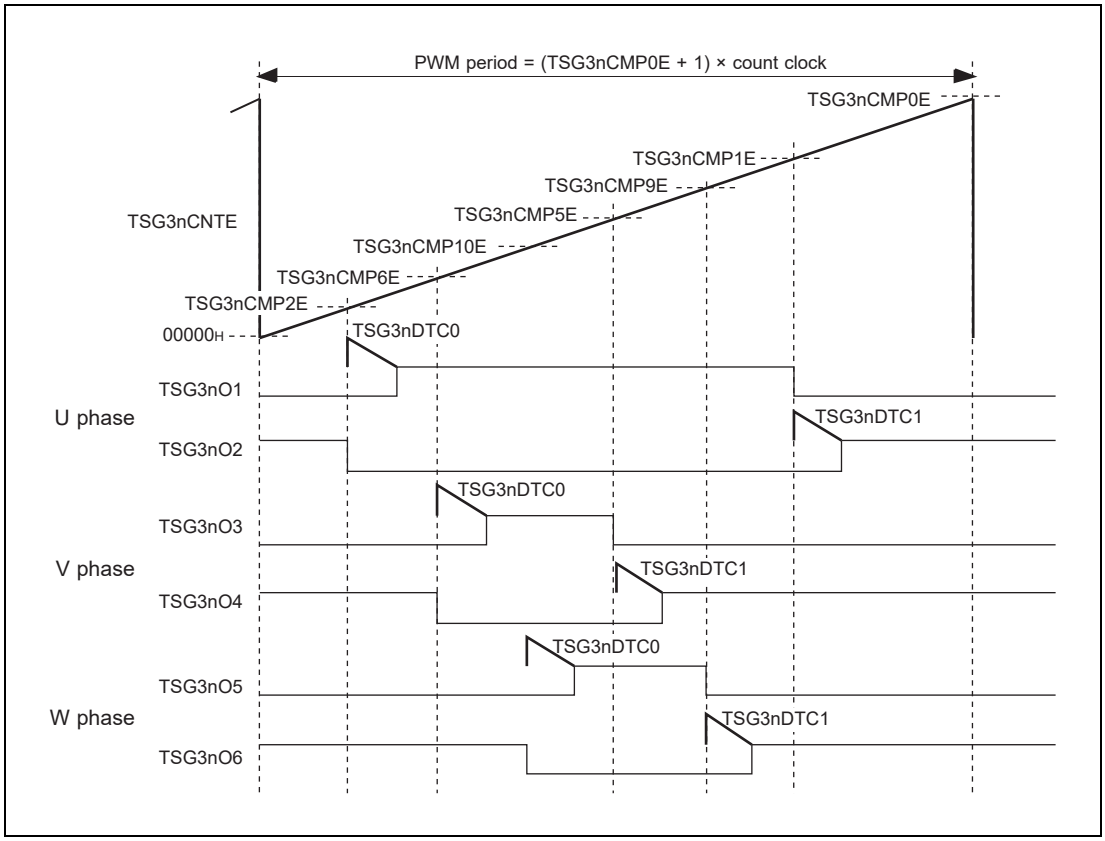

Figure 35.71 Basic Timing in SP-PWM Mode

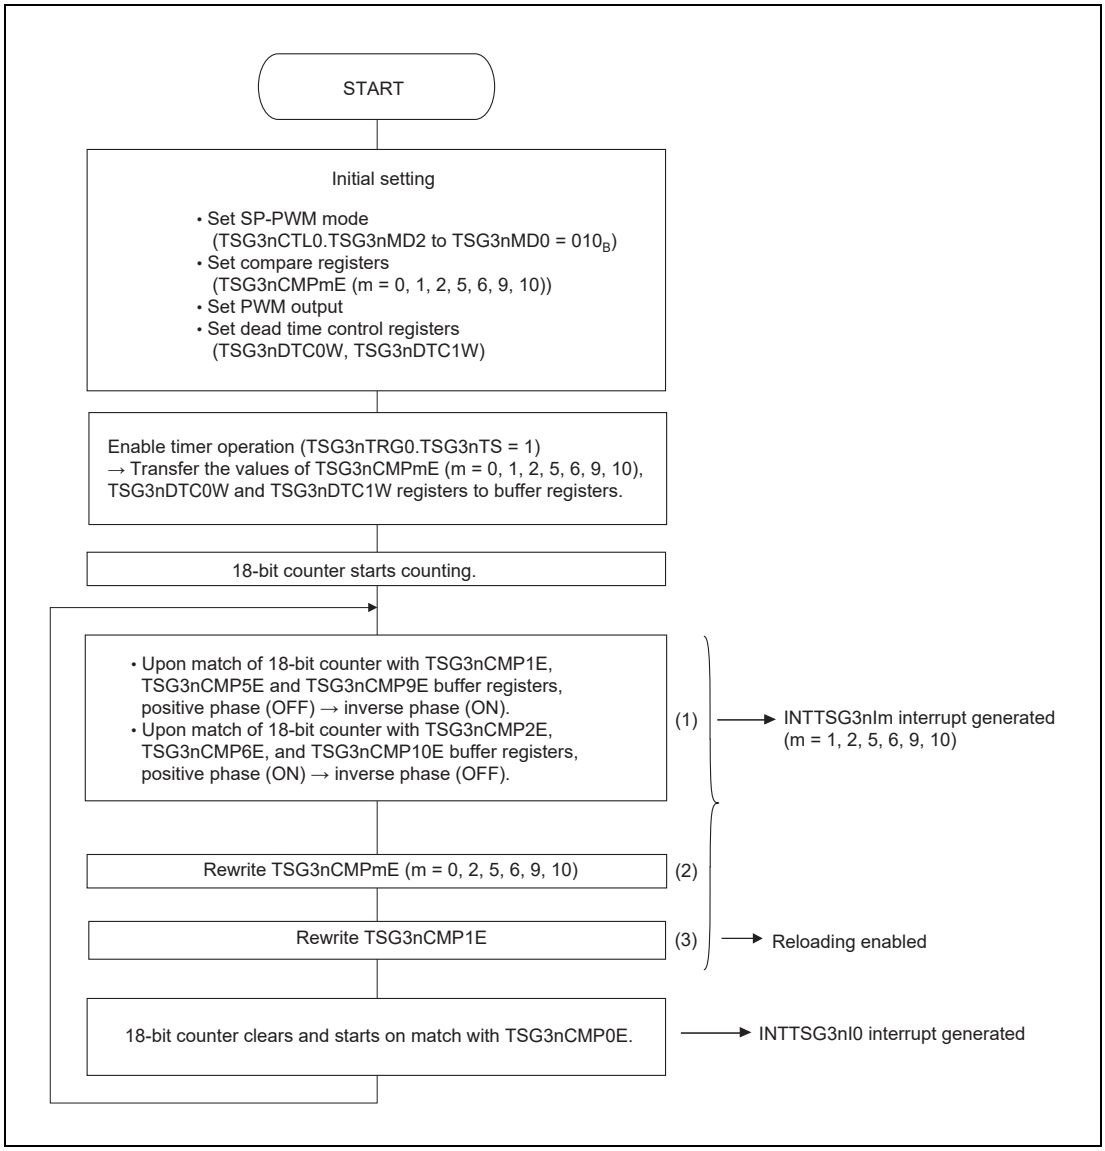

Figure 35.72 Basic Operation Flow in SP-PWM Mode

NOTE

The timing of (1) may be different depending on the rewriting timing of (2) and (3) and the TSG3nCMP1E value. Be sure to rewrite (2) before rewriting (3).

(2) List of SP-PWM Mode Operations

Table 35.68 Counter Functions in SP-PWM Mode

Operation		Setting Condition
18-bit counter	Start	TSG3nTRG0.TSG3nTS = 0 → 1 or simultaneous start trigger
	Clear	Compare match of TSG3nCMP0E buffer register with 18-bit counter
	Stop	TSG3nTRG1.TSG3nTT = 0 → 1

Table 35.69 Compare Registers and Dead Time Control Register Functions in SP-PWM Mode

Register	Rewriting Method	Rewrite during Operation	Function
TSG3nCMP0E	Reload/Anytime rewrite	Possible	Setting period
TSG3nUPWE	Reload/Anytime rewrite	Possible	PWM control for U phase
TSG3nCMP1E, TSG3nCMP2E	Reload/Anytime rewrite		
TSG3nVPWE	Reload/Anytime rewrite	Possible	PWM control for V phase
TSG3nCMP5E, TSG3nCMP6E	Reload/Anytime rewrite		
TSG3nWPWE,	Reload/Anytime rewrite	Possible	PWM control for W phase
TSG3nCMP9E, TSG3nCMP10E	Reload/Anytime rewrite		
TSG3nDCMP0E, TSG3nDCMP1E, TSG3nDCMP2E	Reload/Anytime rewrite	Possible	Diagnostic output or A/D conversion trigger
TSG3nDTC0W, TSG3nDTC1W	Reload	Possible	Period and dead time

Table 35.70 Timer Input Function in SP-PWM Mode

Pin	Function
TSG3nCLKI	Clock enable input

Table 35.71 Output Functions in SP-PWM Mode

Pin	Function
TSG3nO1	PWM output with dead time by compare match of TSG3nCMP1E buffer register (clear timing) or TSG3nCMP2E buffer register (set timing) with 18-bit counter
TSG3nO2	Output inverse phase with respect to TSG3nO1 (with dead time)
TSG3nO3	PWM output with dead time by compare match of TSG3nCMP5E buffer register (clear timing) or TSG3nCMP6E buffer register (set timing) with 18-bit counter
TSG3nO4	Output inverse phase with respect to TSG3nO3 (with dead time)
TSG3nO5	PWM output with dead time by compare match of the TSG3nCMP9E buffer register (clear timing) or the TSG3nCMP10E buffer register (set timing) with the 18-bit counter
TSG3nO6	Output inverse phase with respect to TSG3nO5 (with dead time)
TSG3nO7	Diagnostic signal output or pulse output by A/D conversion trigger

Table 35.72 Interrupt Requests in SP-PWM Mode

Interrupt	Function
INTTSG3nIm (m = 0, 1, 2, 5, 6, 9, 10)	Compare match of TSG3nCMPmE buffer register with 18-bit counter (m = 0, 1, 2, 5, 6, 9, 10)
INTTSG3nIER	Error
INTTSG3nIVLY	—
INTTSG3nIPEK	Peak interrupt (generated at the same timing as INTTSG3nI0 interrupt)
INTTSG3nIWN	Warning

Table 35.73 Compare Match Timing in SP-PWM Mode

Compare Match	Timing
TSG3nCMP0E	When 18-bit counter changes from TSG3nCMP0E to 00000_H
TSG3nCMPmE (m = 1, 2, 5, 6, 9, 10)	After match of 18-bit counter and TSG3nCMPmE is detected (m = 1, 2, 5, 6, 9, 10)

Table 35.74 Example of Setting Each Timer Output Condition in SP-PWM Mode

Pin	Item	Output Period	Output Duty	
			Output Condition	Setting Condition
TSG3nO1, TSG3nO3, TSG3nO5	PWM output	(TSG3nCMP0E + 1) × count clock	Output an inactive level throughout one period (duty 0%)	TSG3nCMPmE = TSG3nCMP (m + 1) E or TSG3nCMP (m + 1) E > TSG3nCMP0E (m = 1, 5, 9)
			Output an active level of one count clock in one period	TSG3nCMPmE = TSG3nCMP (m + 1) E + 1 TSG3nCMP (m + 1) E = TSG3nCMPmE – 1 (m = 1, 5, 9)
			Output an inactive level of one count clock in one period	TSG3nCMPmE = TSG3nCMP (m + 1) E - 1 TSG3nCMP (m + 1) E = TSG3nCMPmE + 1 (m = 1, 5, 9)
			Output an active level throughout one period (duty 100%)	TSG3nCMPmE > TSG3nCMP0E TSG3nCMP (m + 1) E ≤ TSG3nCMP0E (m = 1, 5, 9)
TSG3nO2, TSG3nO4, TSG3nO6	PWM output	(TSG3nCMP0E + 1) × count clock	Output an inactive level throughout one period (duty 0%)	TSG3nCMP (m – 1) E > TSG3nCMP0E (m = 2, 6, 10)
			Output an active level of one count clock in one period	TSG3nCMPmE = TSG3nCMP (m – 1) E - 1 TSG3nCMP (m – 1) E = TSG3nCMPmE + 1 (m = 2, 6, 10)
			Output an inactive level of one count clock in one period	TSG3nCMPmE = TSG3nCMP (m – 1) E + 1 TSG3nCMP (m – 1) E = TSG3nCMPmE – 1 (m = 2, 6, 10)
			Output an active level throughout one period (duty 100%)	TSG3nCMPmE = TSG3nCMP(m – 1)E or TSG3nCMPmE > TSG3nCMP0E (m = 2, 6, 10)
TSG3nO7	Diagnostic signal output or pulse output by A/D conversion trigger	(TSG3nCMP0E + 1) × count clock	Refer to **Section 35.4.5, A/D Conversion Trigger Function**.	

(3) Various Settings of SP-PWM Mode

Setting mode

SP-PWM mode is entered by setting TSG3nCTL0.TSG3nMD2-TSG3nMD0 to 010_B.

Setting timer output

The output pins TSG3nO1-TSG3nO6 are controlled by setting TSG3nIOC0, TSG3nIOC2, and TSG3nIOC3.

The TSG3nO7 pin provides output pulse as diagnostic output or A/D conversion trigger. The pin should be set as necessary.

Enabling error interrupt generation

Error interrupt (INTTSG3nIER) due to the detection of the simultaneous active state of the positive and inverse phases is enabled by setting TSG3nIOC1.TSG3nEOC to 1. For details, refer to **Section 35.4.6, Error/Warning Interrupt**.

Setting rewriting timing of register with reload function

With the TSG3nCTL3.TSG3nRMC, reload (simultaneous rewrite) or rewrite (anytime) is specified for the registers with reload function. The default setting is 0 (reload). To reload, set TSG3nCTL4.TSG3nPRE to 1.

No reload timing is generated when TSG3nPRE = 0.

When “anytime rewrite” is specified, unintended output may be generated depending on the rewrite timing.

Setting A/D conversion trigger output

The A/D conversion trigger 0 (TSG3nADTRG0 signal) is set with TSG3nCTL5.TSG3nAT09 to TSG3nAT00.

TSG3nAT09 to TSG3nAT00 is used to enable or disable the A/D conversion trigger output at the match of TSG3nDCMP2E to TSG3nDCMP0E with the 18-bit counter (up count).

TSG3nCTL6.TSG3nAT19 to TSG3nAT10 is used to set the A/D conversion trigger 1 (TSG3nADTRG1 signal).

To set the match timing of the 18-bit counter and TSG3nDCMP2E to TSG3nDCMP0E, set the compare value to each register.

The skipping function can be used for TSG3nADTRG0 and TSG3nADTRG1 signals. TSG3nACC00 and TSG3nACC01 of TSG3nCTL5, and TSG3nACC10 and TSG3nACC11 of TSG3nCTL6 can be used to select the skipping rate from 1/1 (no skipping), 1/2, 1/4, and 1/8.

CAUTION

- **Be sure to set TSG3nCTL5, TSG3nCTL6, and TSG3nDCMP2E to TSG3nDCMP0E correctly when the timing pulse of A/D conversion trigger is output to TSG3nO7.**
- **In SP-PWM mode, no valley interrupt (INTTSG3nIVLY) is generated. Therefore, TSG3nCTL5.TSG3nAT00 and TSG3nCTL6.TSG3nAT10 must be set to 0.**
- **In SP-PWM mode, the 18-bit sub-counter does not operate. Therefore, TSG3nAT09 and TSG3nAT08 in TSG3nCTL5, and TSG3nAT19 and TSG3nAT18 in TSG3nCTL6 must be set to 0.**
- **In SP-PWM mode, down counting by the 18-bit counter is not generated. Therefore, TSG3nAT07, TSG3nAT05, and TSG3nAT03 in TSG3nCTL5 and TSG3nAT17, TSG3nAT15, and TSG3nAT13 in TSG3nCTL6 should be set to 0.**

Setting dead time

The dead time can be set with TSG3nDTC0 and TSG3nDTC1.

The dead time is calculated by the following expressions:

PCLK × TSG3nDTC0

PCLK × TSG3nDTC1

TSG3nDTC0 can set the time between a change of TSG3nO2, TSG3nO4, and TSG3nO6 to the inactive state and a change of TSG3nO1, TSG3nO3, and TSG3nO5 to the active state, respectively.

TSG3nDTC1 can set the time between a change of TSG3nO1, TSG3nO3, and TSG3nO5 to the inactive state, and a change of TSG3nO2, TSG3nO4, and TSG3nO6 to the active state, respectively.

Carrier period

Set the carrier period with TSG3nCMP0E according to the following expression:

TSG3nCMP0E = (carrier period/count clock period) – 1

CAUTION

PWM output with 100% duty cannot be produced when TSG3nCMP0E = $3FFFF_H$.

Setting duty (PWM width)

The duty of U phase, V phase, and W phase is set with TSG3nCMPmE, TSG3nUPWE, TSG3nVPWE, and TSG3nWPWE (m = 1, 2, 5, 6, 9, 10), respectively.

- The set timings of the U phase, V phase, and W phase are configured using TSG3nCMP2E, TSG3nCMP6E, and TSG3nCMP10E, and the clear timings are configured using TSG3nCMP1E, TSG3nCMP5E, and TSG3nCMP9E (when set timing and clear timing are used for control).
- The set timings of U phase, V phase, and W phase are configured using TSG3nCMP2E, TSG3nCMP6E, and TSG3nCMP10E while the active periods of these phases are configured using TSG3nUPWE, TSG3nVPWE, and TSG3nWPWE.
  The sum of the set values of TSG3nCMP2E, TSG3nCMP6E, and TSG3nCMP10E, and the set values of TSG3nUPWE, TSG3nVPWE, and TSG3nWPWE are set to TSG3nCMP1E, TSG3nCMP5E, and TSG3nCMP9E respectively (when set timing and active period are used for control).

(4) Dead Time Control in SP-PWM mode

Duty setting registers are TSG3nCMPmE (m = 1, 2, 5, 6, 9, 10), TSG3nUPWE, TSG3nVPWE, and TSG3nWPWE and register for setting the period is TSG3nCMP0E. The 6-phase PWM waveform of a variable duty is output by using these registers. To achieve the dead time control, there are six 10-bit down counters that operate synchronously with the count clock of the 18-bit counter and two dead time control registers (TSG3nDTC0W and TSG3nDTC1W). TSG3nDTC0W is used for setting a dead time from a change of the inverse phase to the inactive state to a change of the positive phase to the active state. TSG3nDTC1W is used for setting a dead time from a change of the positive phase to the inactive state to a change of the inverse phase to the active state.

Dead time counter keeps operating even when operation stop (TSG3nTE = 0) setting collided with dead time insert timing, and the dead time set in TSG3nO1 and TSG3nO2 are always inserted.

The following figure shows an example of the output waveform.

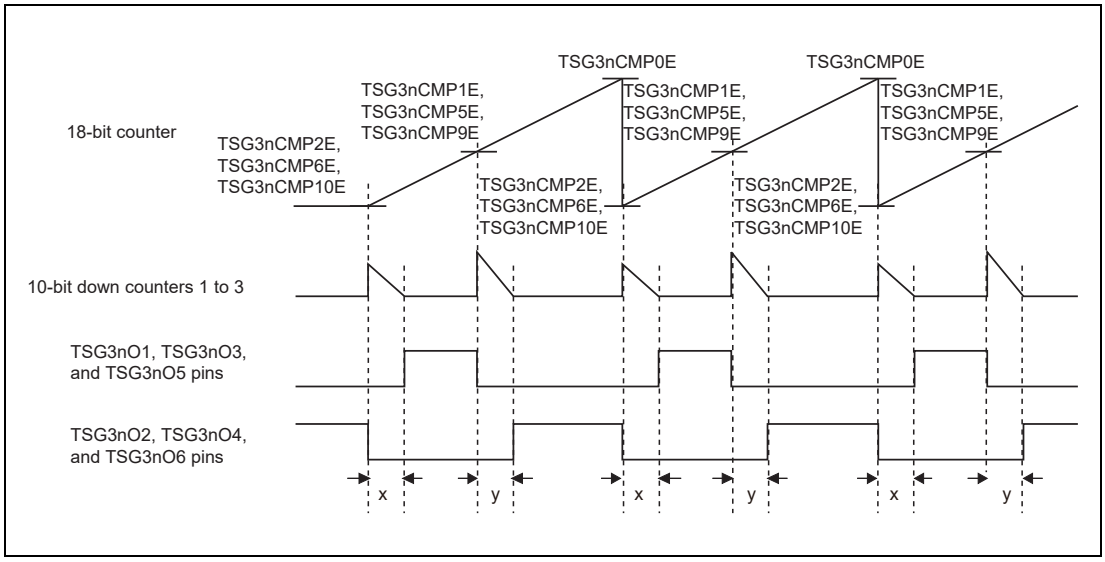

Figure 35.73 Example of Output Waveform in SP-PWM Mode

NOTE

x: TSG3nDTC0 register values, y: TSG3nDTC1 register values

(5) Software Output Control Function in SP-PWM Mode

TSG3nOPT0.TSG3nSOC, TSG3nIDC, and TSG3nOPT1.TSG3nSPC2 to TSG3nSPC0 are used to control timer output by software.

As shown in **Figure 35.74**, the output control is switched immediately when TSG3nSOC is set to 1. If the dead time is set, the period of the dead time is guaranteed. After that, when TSG3nSOC is set to 0, output control is retained, and at the reload timing, output control is switched to SP-PWM mode output control.

For details, refer to **Section 35.4.7.8, Software Output Control Function**.

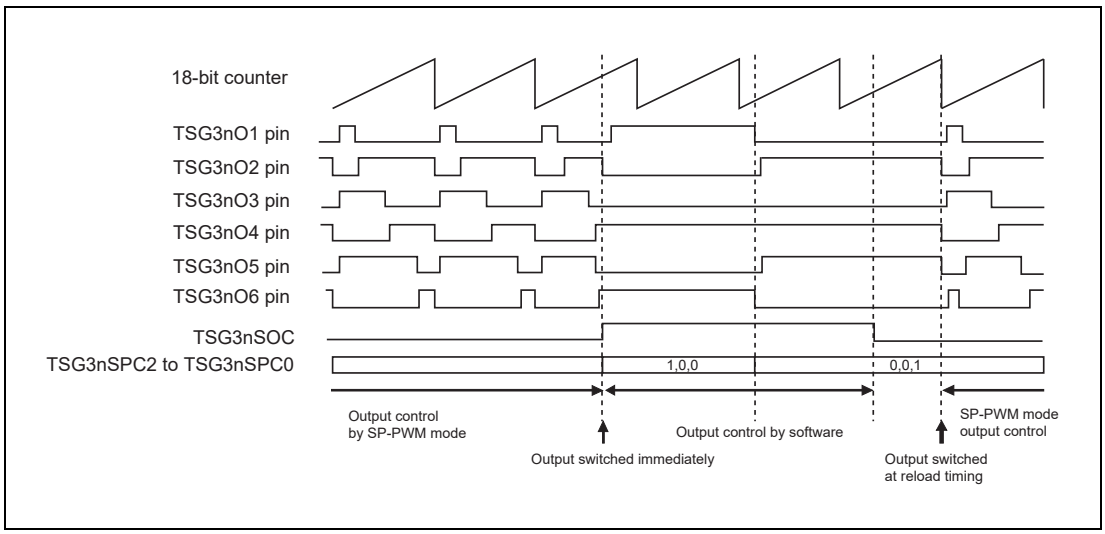

Figure 35.74 Example of Switching from SP-PWM Mode Control to Software Output Control

(a) Procedure for Software Output Control Processing

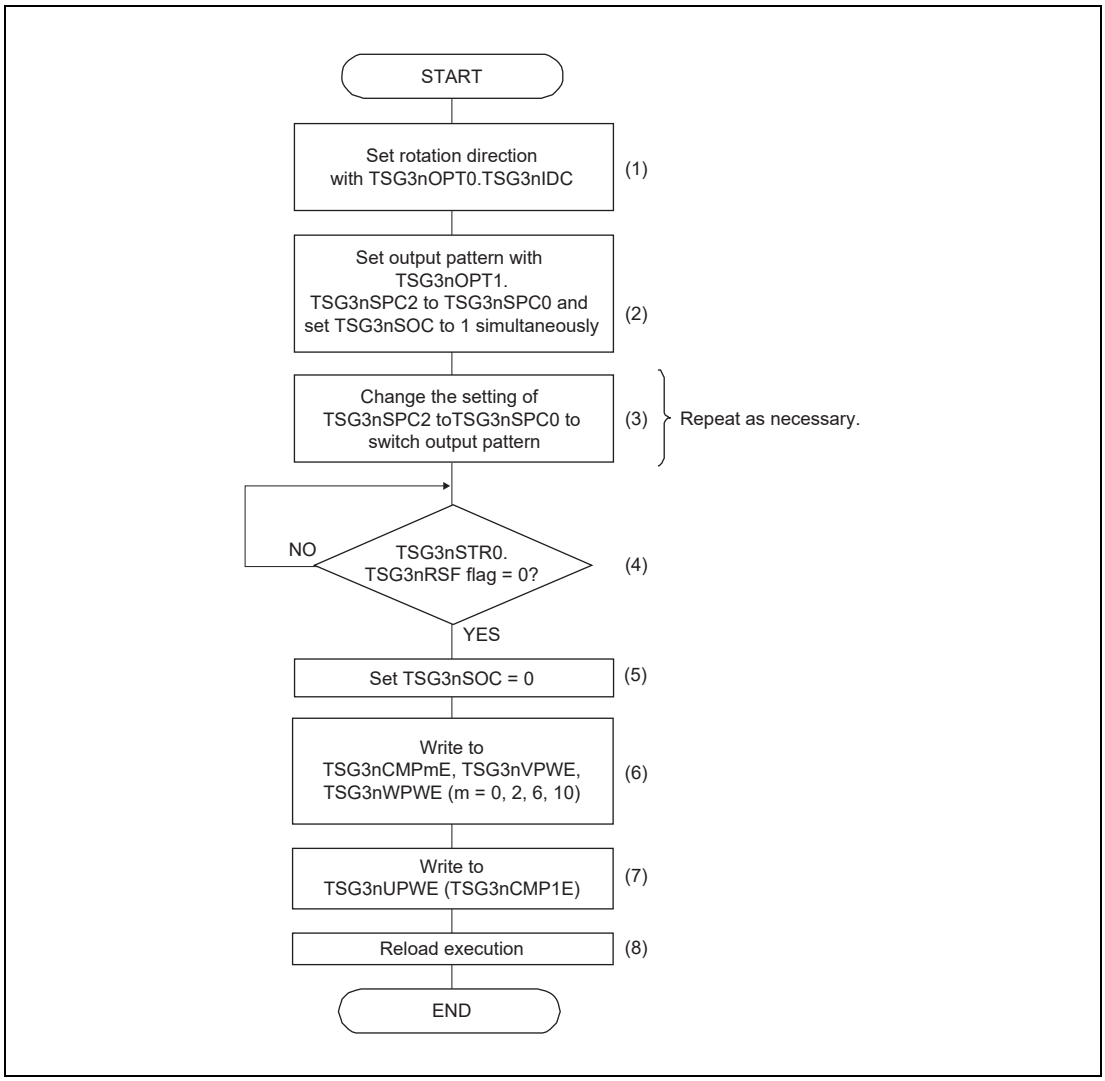

Figure 35.75 Flow of Software Output Control

The procedure for software output control is described below.

(1) Set TSG3nIDC to determine the electric current direction. The timer output has a 180-degree phase shift between when TSG3nIDC = 0 and when TSG3nIDC = 1. When this bit is rewritten with the software output control function, the output pattern will change according to the new setting at the next timer cycle.

(2) Set the output pattern in TSG3nSPC2-0. At the same time, set TSG3nSOC to 1 to switch to software output control mode.

(3) Change the output pattern setting for TSG3nSPC2-0 to change the timer output.

(4) Ensure that the reload request flag TSG3nRSF is 0. If TSG3nRSF is 1, do not proceed to the following step until TSG3nRSF = 0.

(5) By clearing TSG3nSOC to 0, software control release process starts (it is not released yet at this point).

(6) Configure the compare register settings that are required after the software output control is released. Proceed to the following step when the register configuration is not required. When configuring the registers with the reload function, configure them at this point.

(7) Write to TSG3nUPWE (TSG3nCMP1E) to start reloading.

(8) Reload is executed and software output control is released.

CAUTION

Be sure to execute reload after completing steps (4), (5), (6), and (7). Unless reload can be executed, software output control cannot be released

35.4.7.4 120-DC Mode

Overview

In this mode, PWM output period set to TSG3nCMP0E and timer output (TSG3nO1 to TSG3nO6) according to the duty cycle set with TSG3nCMP1E to TSG3nCMP12E are controlled with three types of pattern inputs (software output control method, pattern switch method, and trigger switch method) to perform 120-DC control.

Prerequisites

- Set the PWM period with TSG3nCMP0E.
- Set the PWM duty with TSG3nCMP1E to TSG3nCMP12E and set the output pattern with TSG3nPAT0W and TSG3nPAT1W.

Functional description

In this mode, configure the PWM period, the duty cycle with each compare register, and the pattern to be output with each pattern register. Counting up begins when TSG3nTRG0.TSG3nTS is set to 1.

The 18-bit counter starts counting from 00000_H, and is cleared by the match with TSG3nCMP0E.

INTTSG3nI1 to INTTSG3nI12 interrupts are generated by a compare match of the 18-bit counter and TSG3nCMP1E to TSG3nCMP12E buffer registers, respectively.

NOTE

120-DC mode is enabled when TSG3nCTL0.TSG3nMD2-TSG3nMD0 = 011_B.

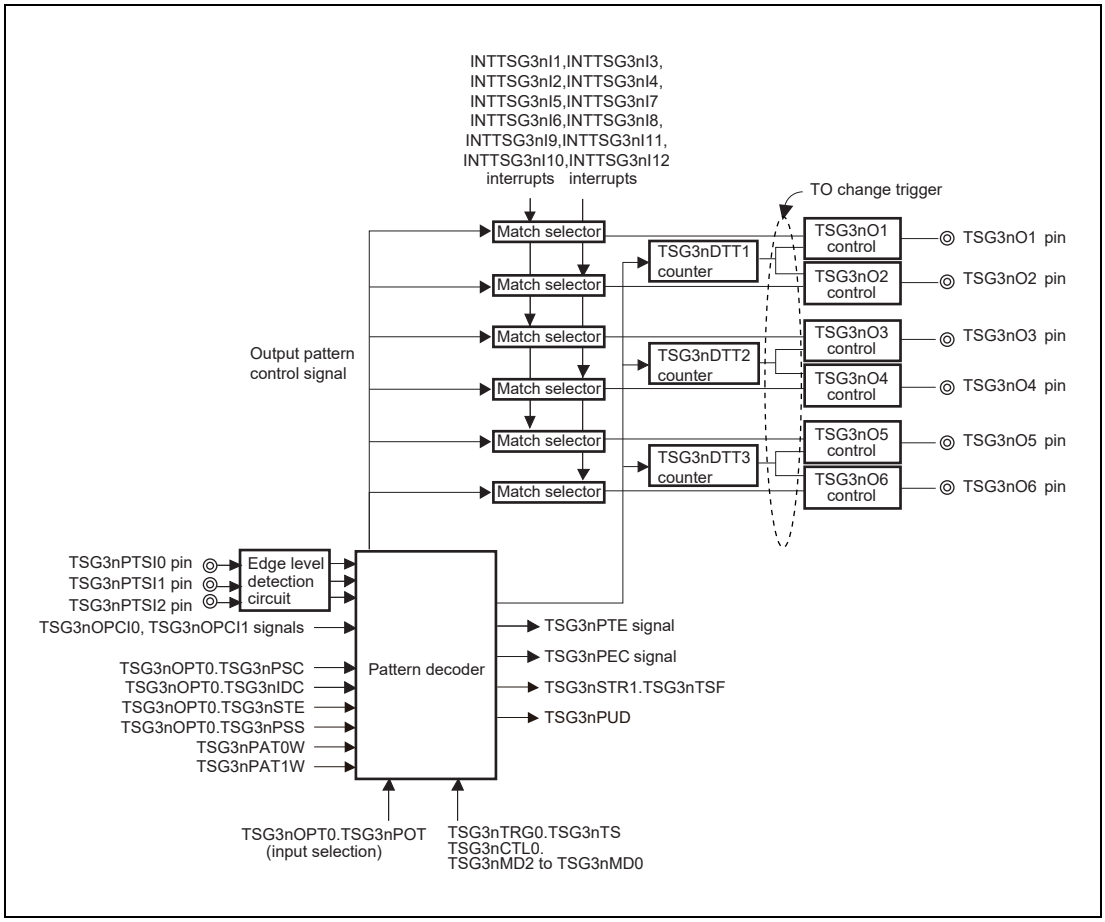

Figure 35.76 Block Diagram in 120-DC Mode

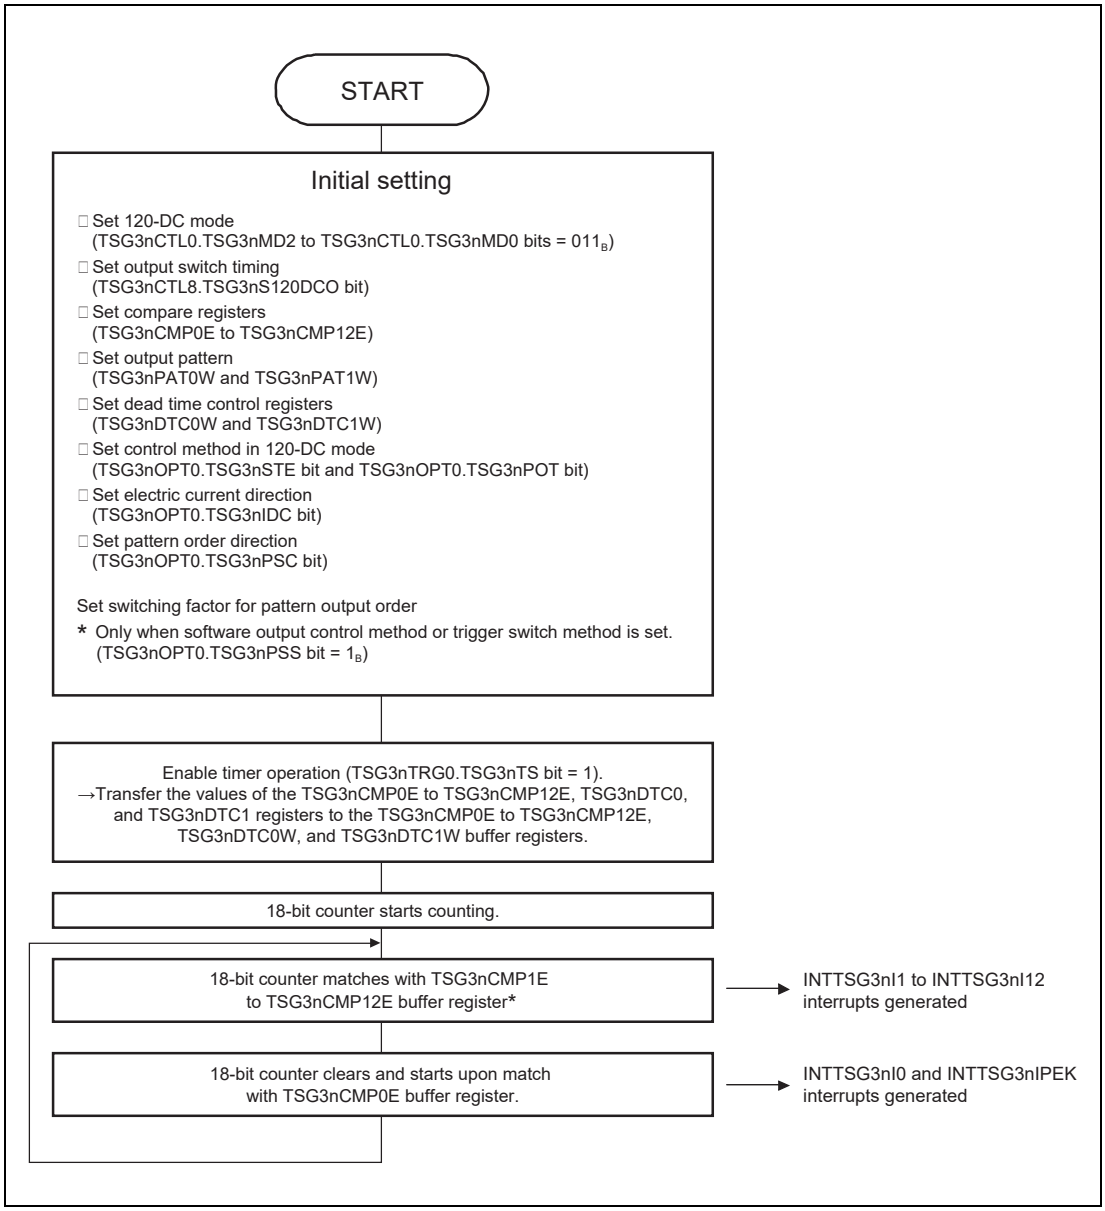

Figure 35.77 Basic Operation Flow in 120-DC Mode

NOTE

The 18-bit counter is not cleared by match of the 18-bit counter with the TSG3nCMP1E to TSG3nCMP12E buffer registers

(1) List of Operations in 120-DC Mode

Table 35.75 Counter Functions in 120-DC Mode

Operation		Setting Condition
18-bit counter	Start	TSG3nTRG0.TSG3nTS = 0 → 1 or simultaneous start trigger
	Clear	When TSG3nCTL8.TSG3nS120DCO is 0: timing of a match of TSG3nCMP0E value and 18-bit counter value or output pattern switch When TSG3nCTL8.TSG3nS120DCO is 1: timing of a match of TSG3nCMP0E value with 18-bit counter value
	Stop	TSG3nTRG1.TSG3nTT = 0 → 1

Table 35.76 Functions of Compare Registers and Dead Time Control Registers in 120-DC Mode

Register	Rewrite Method	Rewrite during Operation	Function
TSG3nCMP0E	Reload	Possible	Setting period
TSG3nCMPmE (m = 1-12)	Reload	Possible	Setting PWM duty
TSG3nDCMP0E, TSG3nDCMP1E, TSG3nDCMP2E	Reload	Possible	Diagnostic signal output or A/D conversion trigger
TSG3nDTC0W, TSG3nDTC1W	Reload	Possible	Setting dead time

Table 35.77 Timer Input Function in 120-DC Mode

Pin/Signal	Function
TSG3nCLKI pin	Clock enable input
TSG3nPTSI2-TSG3nPTSI0 pins	Pattern input (3 phases)
TSG3nOPCI0, TSG3nOPCI1 signals	Trigger input

Table 35.78 Timer Output Function in 120-DC Mode

Pin/Signal	Function
TSG3nO1 pin	PWM output (with dead time) according to a compare match of the TSG3nCMPmE buffer register (m = 1, 2, 5, 6, 9, 10) with the 18-bit counter and output pattern selected by TSG3nPAT0W setting.
TSG3nO2 pin	PWM output (with dead time) according to a compare match of the TSG3nCMPmE buffer register (m = 3, 4, 7, 8, 11, 12) with the 18-bit counter and output pattern selected by TSG3nPAT1W setting.
TSG3nO3 pin	PWM output (with dead time) according to a compare match of the TSG3nCMPmE buffer register (m = 1, 2, 5, 6, 9, 10) with the 18-bit counter and output pattern selected by TSG3nPAT0W setting.
TSG3nO4 pin	PWM output (with dead time) according to a compare match of the TSG3nCMPmE buffer register (m = 3, 4, 7, 8, 11, 12) with the 18-bit counter and output pattern selected by TSG3nPAT1W setting.
TSG3nO5 pin	PWM output (with dead time) according to a compare match of the TSG3nCMPmE buffer register (m = 1, 2, 5, 6, 9, 10) with the 18-bit counter and output pattern selected by TSG3nPAT0W setting.
TSG3nO6 pin	PWM output (with dead time) according to a compare match of the TSG3nCMPmE buffer register (m = 3, 4, 7, 8, 11, 12) with the 18-bit counter and output pattern selected by TSG3nPAT1W setting.
TSG3nO7 pin	Diagnostic signal output or pulse output by A/D conversion trigger
TSG3nPTE signal	Toggle signal by change in input pattern

Table 35.79 Interrupt Requests in 120-DC Mode

Interrupt	Function
INTTSG3nIm (m = 0 to 12)	Compare match of TSG3nCMPmE buffer register and 18-bit counter (m = 0 to 12)
INTTSG3nIER	Error
INTTSG3nIVLY	—
INTTSG3nIPEK	Peak interrupt (generated at the same timing as INTTSG3nI0)
INTTSG3nIWN	Warning interrupt

Table 35.80 Compare Match Timing in 120-DC Mode

Compare Match	Timing
TSG3nCMP0E	When 18-bit counter changes from TSG3nCMP0E to 00000_H
TSG3nCMPmE (m = 1 to 12)	After detecting the match of 18-bit counter and TSG3nCMPmE (m = 1 to 12)

Table 35.81 Example of Setting Each Timer Output Condition in 120-DC Mode

Pin	Item	Output Period	Output Duty	
			Output Condition	Setting Condition
TSG3nOm (m = 1 to 6)	PWM output	(TSG3nCMP0E + 1) × count clock	See **Section 35.4.7.4, (6) List of Output Patterns in 120-DC Mode**.	—
TSG3nO7	Diagnostic signal output or pulse output by A/D conversion trigger	(TSG3nCMP0E + 1) × count clock	See **Section 35.4.5, A/D Conversion Trigger Function**.	—

(2) Various Settings of 120-DC Mode

Setting mode

120-DC mode is entered by setting TSG3nCTL0.TSG3nMD2-TSG3nMD0 to 011_B.

Setting timer output

The output pins TSG3nO1 to TSG3nO6 are controlled by setting TSG3nIOC0, TSG3nIOC2, and TSG3nIOC3.
The TSG3nO7 pin provides output pulse as diagnostic output or A/D conversion trigger. The pin should be set as necessary.

Enabling error interrupt generation

With TSG3nIOC1.TSG3nEOC = 1, the error interrupt (INTTSG3nIER) generation is enabled when the simultaneous active state of the positive phase and inverse phase is detected. For details, see **Section 35.4.6, Error/Warning Interrupt**.

Setting register rewrite timing

Reloading the registers with the reload function is activated with TSG3nCTL3.TSG3nRMC (simultaneous rewrite; default setting is 0 = reload). To reload, set TSG3nCTL4.TSG3nPRE to 1.

The reload timing is not generated if TSG3nPRE is 0.

Setting A/D conversion trigger output

To set A/D conversion trigger 0 (TSG3nADTRG0 signal), use TSG3nCTL5.TSG3nAT09 to TSG3nAT00.
With TSG3nAT09 to TSG3nAT00, A/D conversion trigger output is enabled or disabled at the match of the 18-bit counter and TSG3nDCMP2E to TSG3nDCMP0E (during up count).
To set A/D conversion trigger 1 (TSG3nADTRG1 signal), use TSG3nCTL6.TSG3nAT19 to TSG3nAT10.

To set the match timing of the 18-bit counter and TSG3nDCMP2E to TSG3nDCMP0E, set the compare value to the pertinent register.
The skipping function can be used for TSG3nADTRG0 and TSG3nADTRG1 signals. Use TSG3nACC01, TSG3nACC00 of TSG3nCTL5, and TSG3nACC11, TSG3nACC10 of TSG3nCTL6 to select the skipping rate from 1/1 (no skipping), 1/2, 1/4, and 1/8.

CAUTION

- **Be sure to set TSG3nCTL5, TSG3nCTL6, and TSG3nDCMP2E to TSG3nDCMP0E correctly when the timing pulse of A/D conversion trigger is output to TSG3nO7.**
- **In 120-DC mode, a valley interrupt (INTTSG3nIVLY) is not generated. Therefore, TSG3nCTL5.TSG3nAT00 and TSG3nCTL6.TSG3nAT10 must be set to 0.**
- **In 120-DC mode, the 18-bit sub-counter does not operate. TSG3nAT09 and TSG3nAT08 in TSG3nCTL5, and TSG3nAT19 and TSG3nAT18 in TSG3nCTL6 must be set to 0.**
- **In 120-DC mode, the 18-bit counter does not decrement. Therefore, TSG3nAT07, TSG3nAT05, and TSG3nAT03 in TSG3nCTL5 and TSG3nAT17, TSG3nAT15, and TSG3nAT13 in TSG3nCTL6 must be set to 0.**

Setting dead time

The dead time can be set with TSG3nDTC0 and TSG3nDTC1.

The dead time is calculated by the following expressions

PCLK × TSG3nDTC0

PCLK × TSG3nDTC1

TSG3nDTC0 can set the time between a change of TSG3nO2, TSG3nO4, and TSG3nO6 to the inactive state and a change of TSG3nO1, TSG3nO3, and TSG3nO5 to the active state, respectively.

TSG3nDTC1 can set the time between a change of TSG3nO1, TSG3nO3, and TSG3nO5 to the inactive state to a change of TSG3nO2, TSG3nO4, and TSG3nO6 to the active state, respectively.

Carrier period

Set the carrier period with TSG3nCMP0E according to the following expression:

TSG3nCMP0E = (carrier period/count clock period) – 1

Setting duty (PWM width)

The duty of PWM output is set with TSG3nCMP1E to TSG3nCMP12E. The setting range of the compare registers is as follows:

$00000_H \leq$ TSG3nCMPmE $\leq$ TSG3nCMP0E + 1

CAUTION

Do not set TSG3nCMPmE = TSG3nCMP0E + 1 (m = 1 to 12) only when TSG3nCMP0E + 1 < TSG3nCMPmE, and TSG3nCMP0E = $3FFFF_H$.

Setting output PWM

In 120-DC mode, the output pins TSG3nO1, TSG3nO3, and TSG3nO5 are controlled by TSG3nCMP1E, TSG3nCMP2E, TSG3nCMP5E, TSG3nCMP6E, TSG3nCMP9E, and TSG3nCMP10E, and the output pins TSG3nO2, TSG3nO4, TSG3nO6 are controlled by TSG3nCMP3E, TSG3nCMP4E, TSG3nCMP7E, TSG3nCMP8E, TSG3nCMP11E, and TSG3nCMP12E. The duty cycle of a PWM period (TSG3nCMP0E) can be set with TSG3nCMP1E to TSG3nCMP12E. Setting TSG3nCMP1E to TSG3nCMP12E to 00000_H sets the PWM duty cycle to 0%. Setting TSG3nCMP1E to TSG3nCMP12E to TSG3nCMP0E + 1 value sets the PWM duty cycle to 100%. This allows chopping output control and rectangular wave output control.

(3) Control Methods in 120-DC Mode

Control methods in 120-DC mode are listed below.

Table 35.82 Control Method in 120-DC Mode

Control Method	Function
Software output control method	Switches the output pattern according to the TSG3nOPT1.TSG3nSPC2 to TSG3nSPC0 setting made by software.
Pattern switch method	Switches the output pattern by the pattern input signal of TSG3nPTSI0 to TSG3nPTSI2.
Trigger switch method	Switches the output pattern by the trigger switch method using the trigger input signals TSG3nOPCI0 and TSG3nOPCI1 or by the pattern input setting of TSG3nOPT1.TSG3nSPC2 to TSG3nSPC0 in the constant order.

Switch timing of timer output when changing input pattern of 120-DC mode can be set by TSG3nCTL8.TSG3nS120DCO.

Table 35.83 Setting of TSG3nS120DCO and Operation in 120-DC Mode

TSG3nS120DCO	Function
0	When input patterns are changed, the main counter (TSG3nCNTE) is cleared and the change of patterns is immediately reflected to timer output.
1	When input patterns are changed, the change of input patterns is reflected to timer output at the next timer cycle (after a match of the main counter (TSG3nCNTE) with TSG3nCMP0E).

Setting software output control method

Setting TSG3nOPT0.TSG3nSTE = 0 enables switching of output pattern by software output control. The TSG3nO1 to TSG3nO6 pin output is switched according to the settings of TSG3nOPT1.TSG3nSPC2 to TSG3nSPC0.

The pattern output order at the beginning of operation is set with TSG3nOPT0.TSG3nIDC and TSG3nOPT0.TSG3nPSC.

Operation of software output control method

The PWM output of TSG3nO1 to TSG3nO6 pins (PWM output defined by TSG3nCMP1E to TSG3nCMP12E) is selected using TSG3nOPT1.TSG3nSPC2 to TSG3nSPC0 configured by software. As for the control of the dead time, the dead time counter is activated at the falling edge of the signals in each phase and the dead time is inserted.

The 18-bit counter counts according to the carrier period set in TSG3nCMP0E. The 18-bit counter is cleared by match of the 18-bit counter and TSG3nCMP0E or by a write access to TSG3nOPT1.TSG3nSPC2 to TSG3nSPC0 (when TSG3nS120DCO = 0).

In this method, the pattern, which is decoded using information consisting of the output pattern (TSG3nSPC2 to TSG3nSPC0), the electric current direction control bit (TSG3nOPT0.TSG3nIDC), and order detection control bit (TSG3nOPT0.TSG3nPSC), is output. **Figure 35.98** shows the timer output when the output pattern is changed by software output control.

Immediately after the operation starts (TSG3nTRG0.TSG3nTS = 1), the output pattern of TSG3nSPC2 to TSG3nSPC0 and the pattern set with TSG3nIDC and TSG3nPSC (TSG3nOPT0.TSG3nPSS = 1) are output.

Setting pattern switch method

Setting TSG3nOPT0.TSG3nSTE to 1 and TSG3nPOT to 0 selects the pattern switch method. The TSG3nO1 to TSG3nO6 pin output pattern is changed at the change timing of the TSG3nPTSI2 to TSG3nPTSI0 pins.

The output pattern at the beginning of operation is set with TSG3nOPT0.TSG3nIDC and with TSG3nOPT0.TSG3nPSC. However, after determining the rotation direction (after the value is set to TSG3nSTR1.TSG3nTSF), the setting of TSG3nPSC is disabled.

Operation of pattern switch method

After level detection is performed for the pins (three inputs from the hall sensor), the level-detected signals are decoded. From the decoding result, the PWM output of TSG3nO1 to TSG3nO6 pins (PWM output defined by TSG3nCMP1E to TSG3nCMP12E value) is selected. To control the dead time, the dead time counter is activated at the falling timing of signals in each phase and the dead time is inserted.

The 18-bit counter is cleared by a match of the 18-bit counter value with the TSG3nCMP0E value or by a change of the input pattern (TSG3nPTSI2 to TSG3nPTSI0 pins) while TSG3nS120DCO is 0.

In this method, the pattern, which is decoded by using information on input pattern (TSG3nPTSI2 to TSG3nPTSI0), the electric current direction control bit (TSG3nOPT0.TSG3nIDC), and TSG3nPTSI2 to TSG3nPTSI0 pattern order detection flag (TSG3nSTR1.TSG3nTSF), is output. **Figure 35.80** to **Figure 35.83** show the timer output when TSG3nPTSI2 to TSG3nPTSI0 pin inputs change.

Immediately after the operation starts (TSG3nTRG0.TSG3nTS = 1), the output pattern set by the levels input on the TSG3nPTSI2 to TSG3nPTSI0 pins and by the TSG3nIDC and TSG3nPSC bits is produced. If a level on any of the TSG3nPTSI2 to TSG3nPTSI0 pins is changed, TSG3nTSF is determined by the direction of the change to the order. After the TSG3nTSF value is determined, the pattern set by the TSG3nTSF bit replaces the pattern set by the TSG3nPSC bit.

CAUTION

When connecting the three-phase pulse input signal to the TSG3nPTSI2 to TSG3nPTSI0 pins, confirm that the three-phase pulse input value and the patterns output from the TSG3nO1 to TSG3nO6 pins satisfy the expected conditions.
If the expected conditions are not satisfied, change the connection between the three-phase pulse input signal and the TSG3nPTSI2 to TSG3nPTSI0 pins.

Setting trigger switch method

Setting TSG3nOPT0.TSG3nSTE and TSG3nPOT to 1 selects the trigger switch method. The output patterns of pins TSG3nO1 to TSG3nO6 are changed at a rising edge of an external input (TSG3nOPCI1 and TSG3nOPCI0 signals).

For pattern output order, see **Section 35.4.7.4, (5) Operation in 120-DC Mode**.

The initial output pattern can be controlled with TSG3nOPT1.TSG3nSPC2 to TSG3nSPC0.

The initial pattern is output when the TSG3n operation starts (TSG3nTRG0.TSG3nTS = 1) after TSG3nSPC2 to TSG3nSPC0 are configured. For details, see **Section 35.4.7.4, (6) List of Output Patterns in 120-DC Mode**.

Operation of trigger switch method

With the trigger input switch method, the rising edges of the TSG3nOPCI0 and TSG3nOPCI1 signals are detected and the output switch timing is generated. The initial timer output pattern is set with TSG3nOPT1.TSG3nSPC2 to TSG3nSPC0. The subsequent output patterns are switched after rising of the TSG3nOPCI0 and TSG3nOPCI1 signals is detected. Furthermore, the output patterns can be switched by setting TSG3nOPT1.TSG3nSPC2 to TSG3nOPT1.TSG3nSPC0.

The 18-bit counter counts based on the carrier period set in TSG3nCMP0E. The 18-bit counter is cleared by match of the 18-bit counter and TSG3nCMP0E, by a write access to TSG3nOPT1.TSG3nSPC2 to TSG3nSPC0, or by detecting a rising of TSG3nOPCI0 and TSG3nOPCI1 signals. (When TSG3nS120DCO = 0)

For examples of operation in 120-DC mode when trigger input switch method is used, see **Figure 35.80** to **Figure 35.83**.

CAUTION

The initial pattern should be set according to the read input level of the port to which TSG3nPTSI2 to TSG3nPTSI0 pins are connected.

(4) Timer Output in 120-DC Mode

In 120-DC mode, the PWM output is controlled with TSG3nPAT0W, TSG3nPAT1W, and TSG3nCMP1E to TSG3nCMP12E. TSG3nPAT0W, TSG3nCMP1E, TSG3nCMP2E, TSG3nCMP5E, TSG3nCMP6E, TSG3nCMP9E, and TSG3nCMP10E are set to control the output of TSG3nO1, TSG3nO3, and TSG3nO5 pins. TSG3nPAT1W, TSG3nCMP3E, TSG3nCMP4E, TSG3nCMP7E, TSG3nCMP8E, TSG3nCMP11E, and TSG3nCMP12E are set to control the output of TSG3nO2, TSG3nO4, and TSG3nO6 pins.

With PWM output control, eight types of output patterns can be selected for each of TSG3nO1, TSG3nO3, and TSG3nO5 pins and TSG3nO2, TSG3nO4, and TSG3nO6 pins.

Table 35.84 TSG3nPAT0W Set Value and Output Control

PATmT Value	Output Control
000	Fixed to low
001	PWM output set with TSG3nCMP1E
010	PWM output set with TSG3nCMP2E
011	PWM output set with TSG3nCMP5E
100	PWM output set with TSG3nCMP6E
101	PWM output set with TSG3nCMP9E
110	PWM output set with TSG3nCMP10E
111	Fixed to high

Note: m = 0, 1, 2, 3, 4, 5

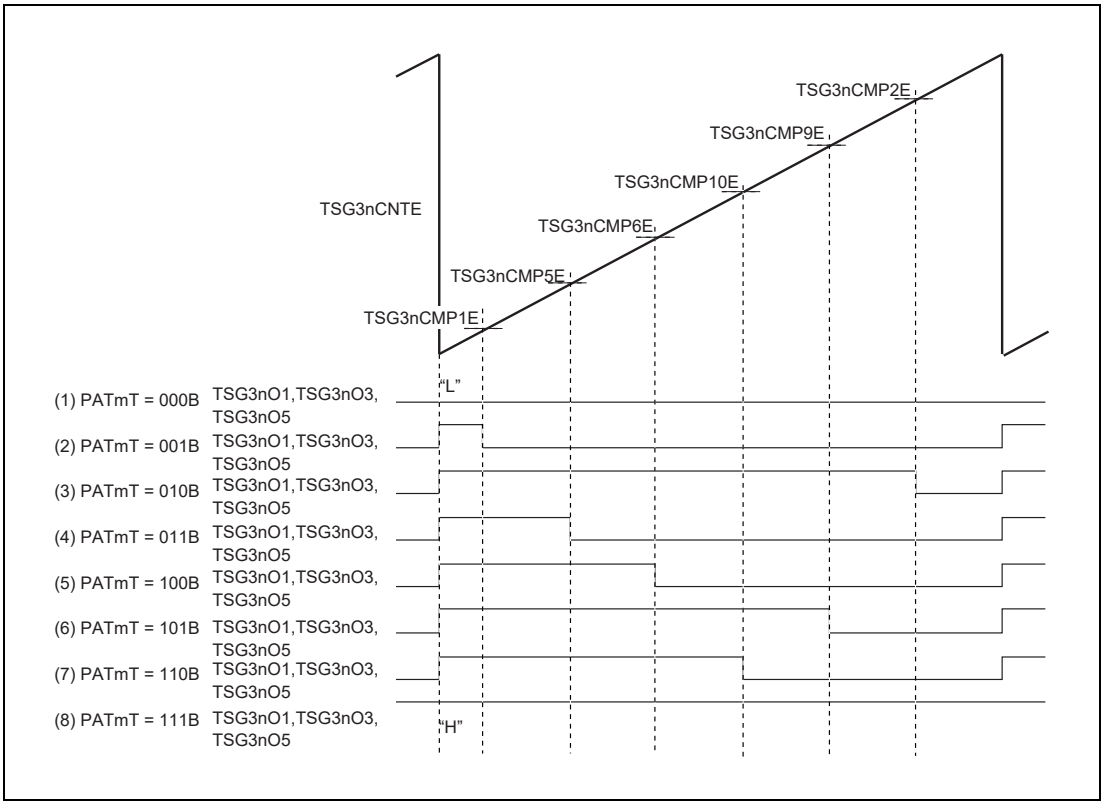

Figure 35.78 TSG3nO1, TSG3nO3, TSG3nO5 Pin Output of Each Output Pattern

Table 35.85 TSG3nPAT1W Set Value and Output Control

PATmB Value	Output Control
000	Fixed to low
001	PWM output set with TSG3nCMP3E

011	PWM output set with TSG3nCMP7E
100	PWM output set with TSG3nCMP8E
101	PWM output set with TSG3nCMP11E
110	PWM output set with TSG3nCMP12E
111	Fixed to high

Note: m = 0, 1, 2, 3, 4, 5

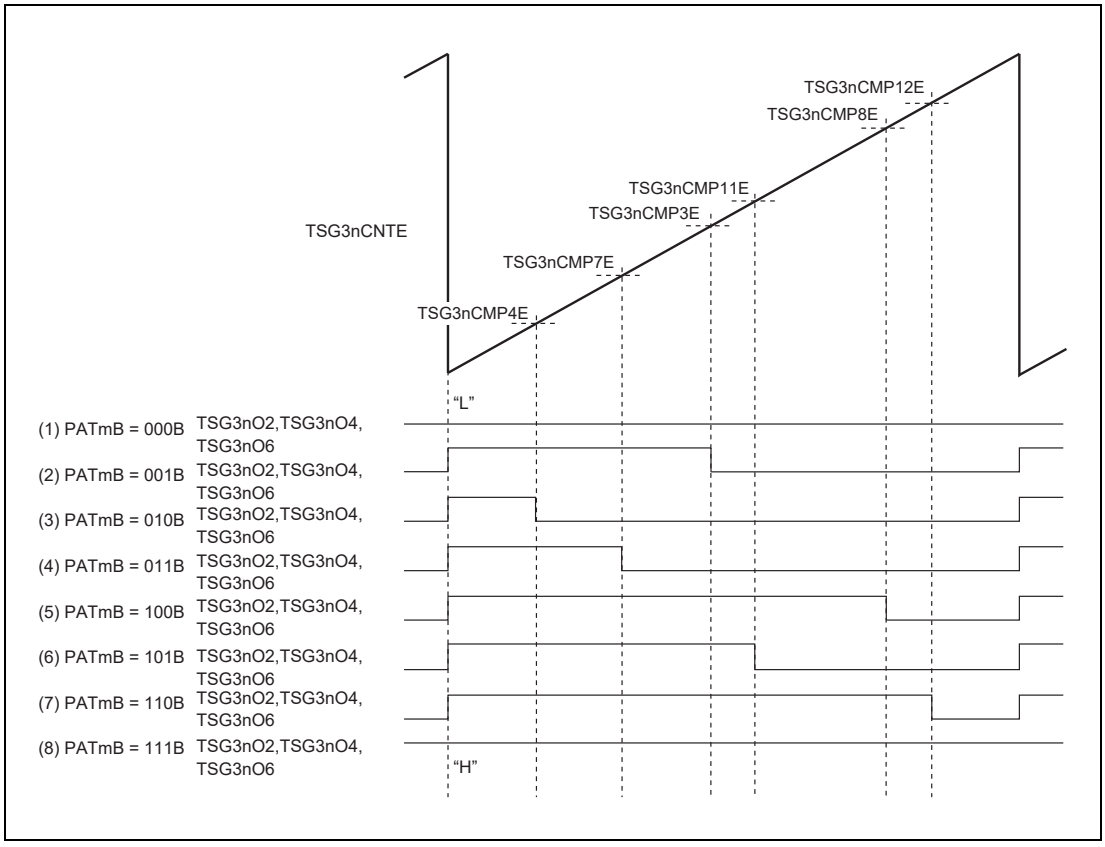

Figure 35.79 TSG3nO2, TSG3nO4, TSG3nO6 Pin Output of Each Output Pattern

(5) Operation in 120-DC Mode

Figure 35.80 to **Figure 35.83** show examples of operation in 120-DC mode.

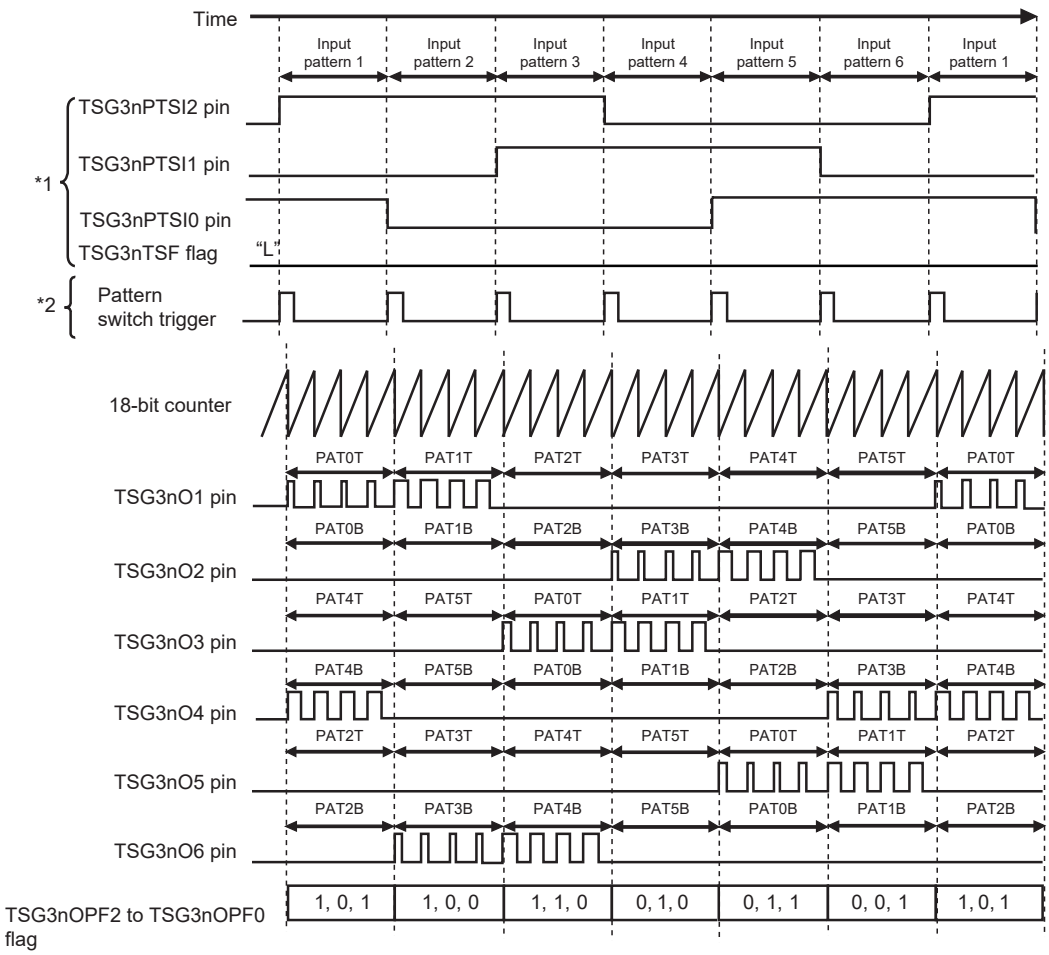
The TSG3nO1 to TSG3nO6 pins detect the input level change of the TSG3nPTSI2 to TSG3nPTSI0 pins, and then change the output pattern. The 18-bit counter produces sawtooth waveform and PWM output using TSG3nCMP0E to TSG3nCMP12E.

When TSG3nS120DCO = 0, the 18-bit counter is cleared to 00000_H each time the counter value matches with TSG3nCMP0E or a change in the TSG3nPTSI2 to TSG3nPTSI0 pins is detected. The timer output pattern is switched each time a change in the TSG3nPTSI2 to TSG3nPTSI0 pins is detected.

When TSG3nS120DCO = 1, the 18-bit counter is cleared to 00000_H when the counter value matches with TSG3nCMP0E but not cleared with a change in the TSG3nPTSI2 to TSG3nPTSI0 pins. The timer output pattern is switched to the one corresponding to the patterns of TSG3nPTSI2 to TSG3nPTSI0 pins at the next match timing of TSG3nCNTE and TSG3nCMP0E.

NOTE

PAT0T to PAT5T and PAT0B to PAT5B show PWM operation set by TSG3nCMP1E to TSG3nCMP12E, respectively.



Note 1. For pattern switch method (TSG3nOPT0.TSG3nSTE = 1, TSG3nOPT0.TSG3nPOT = 0)
Note 2. For trigger switch method (TSG3nOPT0.TSG3nSTE = 1, TSG3nOPT0.TSG3nPOT = 1)

(6) List of Output Patterns in 120-DC Mode

In 120-DC mode, the output pattern is determined according to the electric current direction (TSG3nOPT0.TSG3nIDC) and the pattern order direction.

Table 35.86 Selection of Pattern Order Direction in 120-DC Mode

TSG3nOPT0			Pattern Order Direction
TSG3nSTE	TSG3nPOT	TSG3nPSS	
0	—	1	TSG3nPSC
1	0	—	TSG3nTSF (TSG3nPSC only for initial setting at operation start)
1	1	1	TSG3nPSC

NOTE

Set {TSG3nPOT,TSG3nPSS} = {1,0} is prohibited.

Table 35.87 List of Output Patterns in 120-DC Mode (1/4)

Electric current direction: normal (TSG3nIDC = 0)
Pattern order direction: normal (TSG3nTSF = 0 or TSG3nPSC = 0)

	TSG3nOPT1.TSG3nSPC2-TSG3nSPC0*1/TSG3nSTR1.TSG3nOPF2-TSG3nOPF0							
Output pins	101	100	110	010	011	001	000	111

TSG3nO6	PAT5B	PAT0B	PAT1B	PAT2B	PAT3B	PAT4B	Low	Low

Note 1. When TSG3nSPC2 to TSG3nSPC0 are written while the values of TSG3nSTE and TSG3nPOT are 1, the output pattern changes. Thereafter, when a pattern switch trigger is generated on rising of the TSG3nOPCI0 and TSG3nOPCI1 signals, the output is switched according to the order of pattern switching. When TSG3nS120DCO = 0, the output is switched immediately. When TSG3nS120DCO = 1, the output is switched when the main counter (TSG3nCNTE) matches with TSG3nCMP0E (from the next timer cycle). TSG3nSPC2 to TSG3nSPC0 remain unchanged even if the output pattern is switched.

NOTES

Note 1. When TSG3nSPC2 to TSG3nSPC0 are written while the values of TSG3nSTE and TSG3nPOT are 1, the output pattern changes. Thereafter, when a pattern switch trigger is generated on rising of the TSG3nOPCI0 and TSG3nOPCI1 signals, the output is switched according to the order of pattern switching. When TSG3nS120DCO = 0, the output is switched immediately.
When TSG3nS120DCO = 1, the output is switched when the main counter (TSG3nCNTE) matches with TSG3nCMP0E (from the next timer cycle). TSG3nSPC2 to TSG3nSPC0 remain unchanged even if the output pattern is switched.

NOTES

1. PAT0T to PAT5T: PWM output set by TSG3nCMP1E, TSG3nCMP2E, TSG3nCMP5E, TSG3nCMP6E, TSG3nCMP9E, TSG3nCMP10E
2. PAT0B to PAT5B: PWM output set by TSG3nCMP3E, TSG3nCMP4E, TSG3nCMP7E, TSG3nCMP8E, TSG3nCMP11E, TSG3nCMP12E

(7) Operation Start Timing in 120-DC Mode

In 120-DC mode, when trigger switch control (TSG3nOPT0.TSG3nSTE=1, TSG3nOPT0.TSG3nPOT = 1) is used, pattern set with TSG3nOPT1.TSG3nSPC2 to TSG3nOPT1.TSG3nSPC0, TSG3nOPT0.TSG3nPSC, and TSG3nOPT0.TSG3nIDC can be output. However, when pattern switch control (TSG3nOPT0.TSG3nSTE=1, TSG3nOPT0.TSG3nPOT = 0) is used, the pattern of the TSG3nPTSI2 to TSG3nPTSI0 pins can be detected but the pattern order direction (TSG3nSTR1.TSG3nTSF) cannot be determined. Therefore, set the pattern order direction in TSG3nPSC when TSG3nTE is 0. The TSG3nPSC set value is loaded to TSG3nTSF, and the value can be used for the initial pattern setting.

- TSG3nOPT0.TSG3nSOC = 0, TSG3nPSC = 0, TSG3nPOT = 0, TSG3nIDC = 0, TSG3nSTE = 1

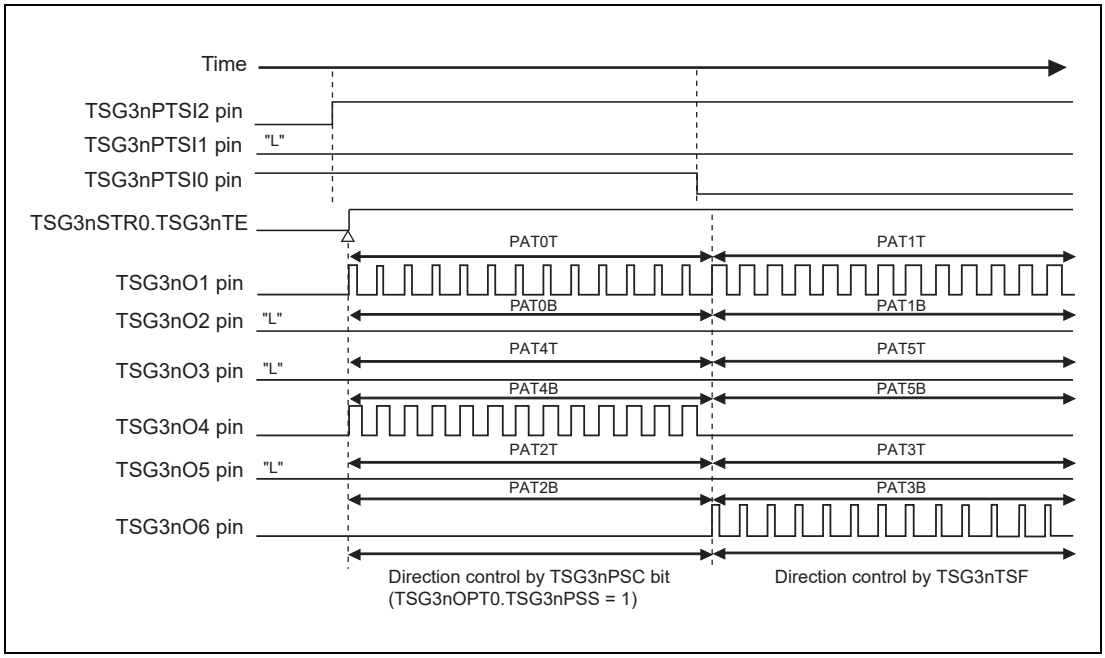

Figure 35.84 Control when Timer Output Starts in Normal Rotation (when Normal Pattern is Input)

- TSG3nOPT0.TSG3nSOC = 0, TSG3nPSC = 1, TSG3nPOT = 0, TSG3nIDC = 1, TSG3nSTE = 1

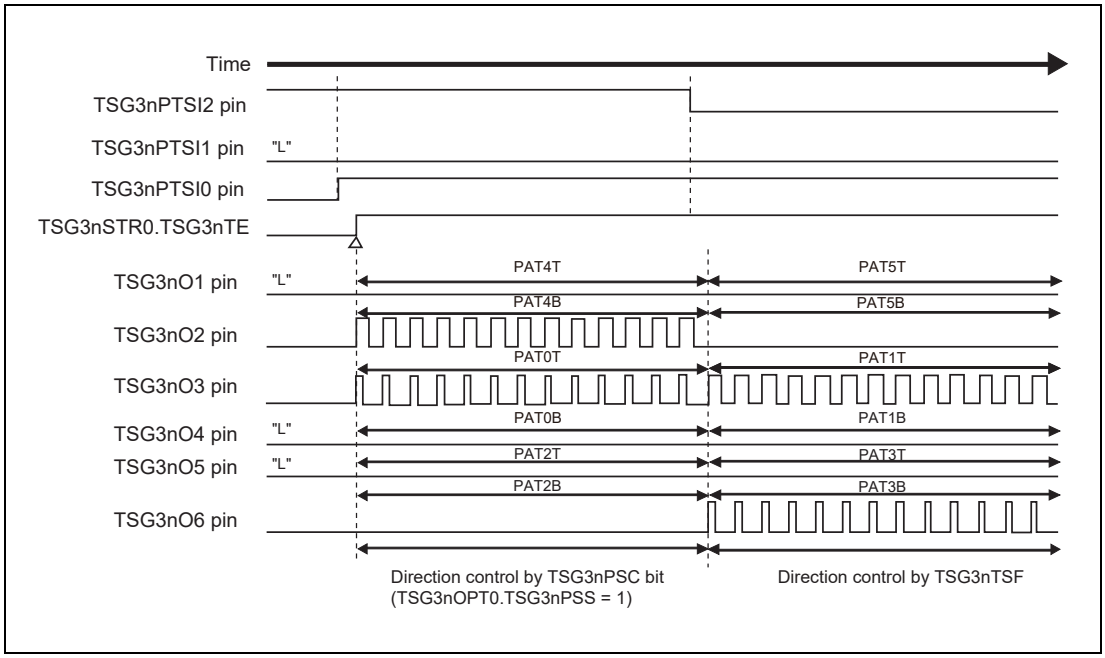

Figure 35.85 Control when Timer Output Starts in Reverse Rotation (when Normal Pattern is Input)

- TSG3nOPT0.TSG3nSOC = 0, TSG3nPSC = 0, TSG3nPOT = 0, TSG3nIDC = 0, TSG3nSTE = 1

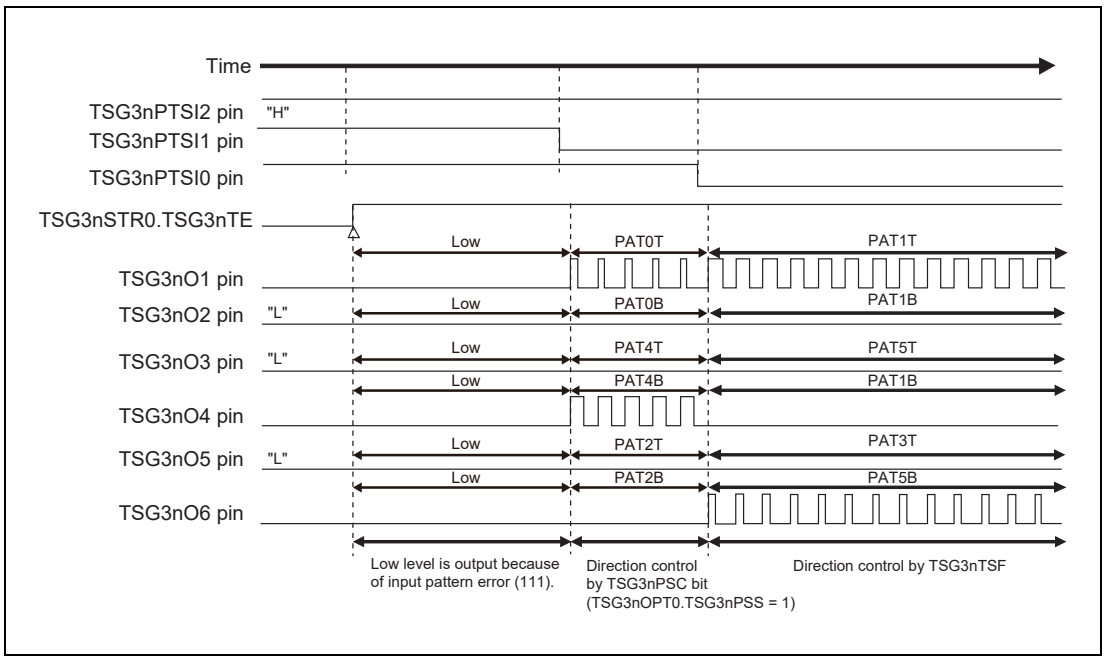

Figure 35.86 Control when Timer Output Starts in Normal Rotation (when Error Pattern is Input)

- TSG3nOPT0.TSG3nSOC = 0, TSG3nPSC = 1, TSG3nPOT = 0, TSG3nIDC = 1, TSG3nSTE = 1

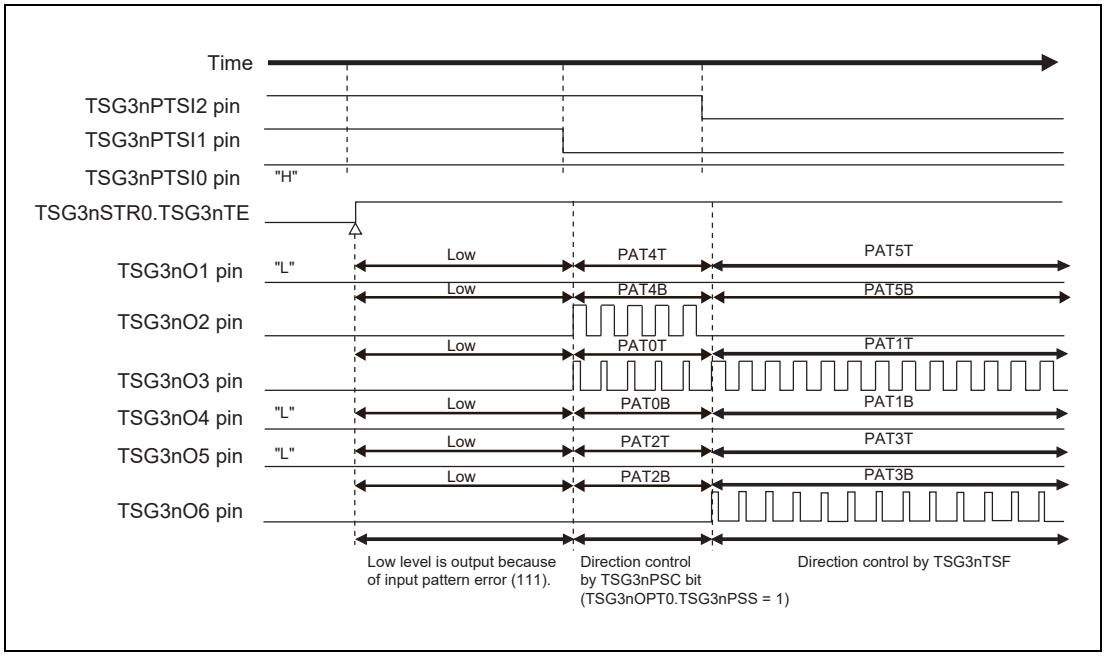

Figure 35.87 Control when Timer Output Starts in Reverse Rotation (when Error Pattern is Input)

(8) Output Switch Timing in 120-DC Mode (TSG3nS120DCO = 0)

As shown in **Figure 35.88** to **Figure 35.91**, in 120-DC mode, the external switch timing for output pattern (TSG3nOPCI0 and TSG3nOPCI1 signals, and TSG3nPTSI2 to TSG3nPTSI0 pins) is input irrespective of the 18-bit counter operation. When TSG3nS120DCO is 0, the output is switched to the new pattern by clearing the 18-bit counter using the pattern switch timing signal that is externally input.

In the pattern switch method, if a change in TSG3nPTSI2 to TSG3nPTSI0 pins occurs several times within one period, the output pattern is switched by clearing the 18-bit counter at each change. In the trigger switch method, if TSG3nOPCI0 and TSG3nOPCI1 signal trigger is input for several times within one period, the output pattern is switched by clearing the 18-bit counter each time the trigger is accepted.

If TSG3nSPC2 to TSG3nSPC0 are rewritten several times within one period, the output pattern is switched by clearing the 18-bit counter each time TSG3nSPC2 to TSG3nSPC0 are rewritten.

In case of a conflict between a rewrite to TSG3nOPT1.TSG3nSPC2 to TSG3nSPC0 and TSG3nOPCI0 and TSG3nOPCI1 trigger, rewriting of TSG3nSPC2 to TSG3nSPC0 takes precedence.

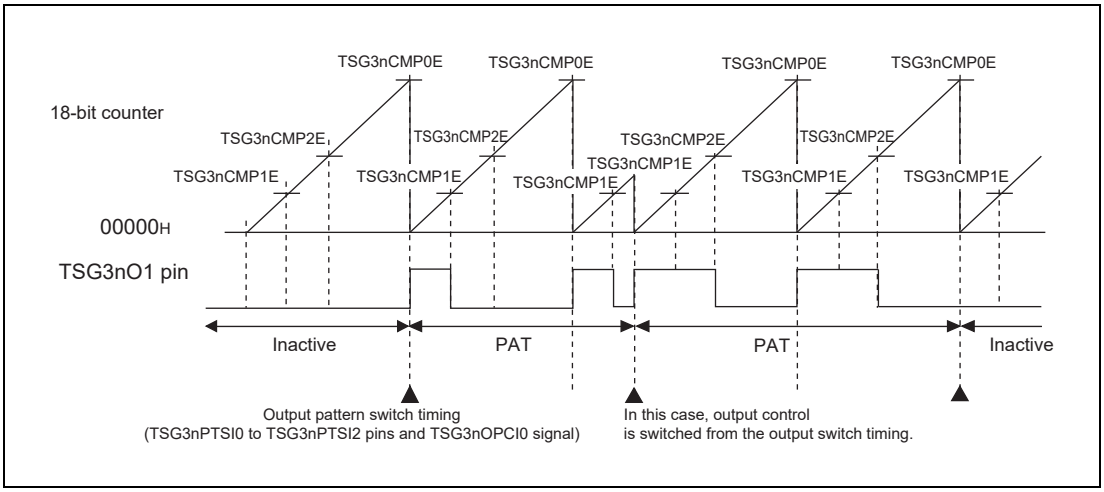

Figure 35.88 Output Switch Example (TSG3nPTSI2 to TSG3nPTSI0 Pins and TSG3nOPCI0 and TSG3nOPCI1 Signal Trigger Input)

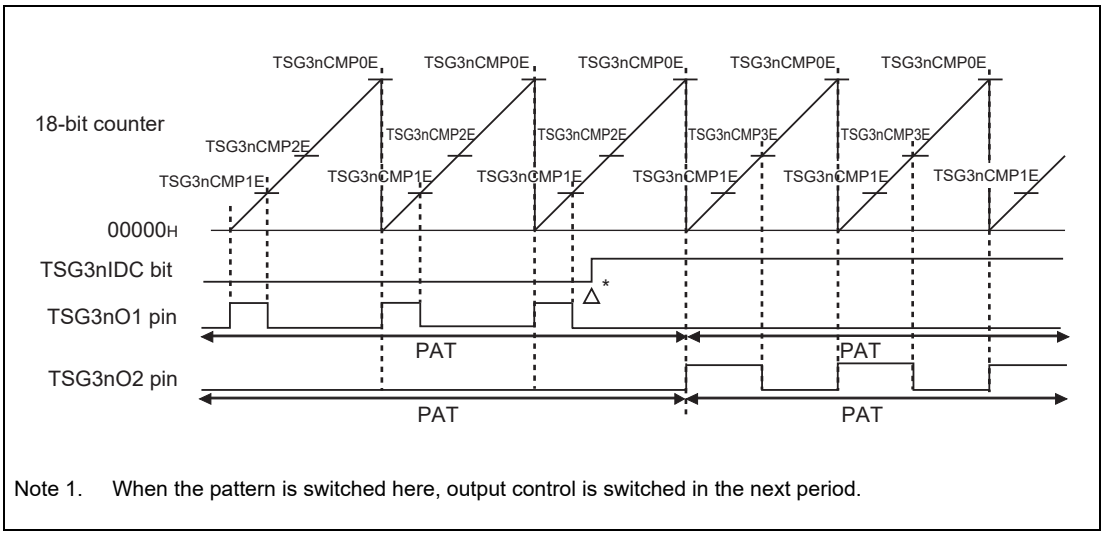


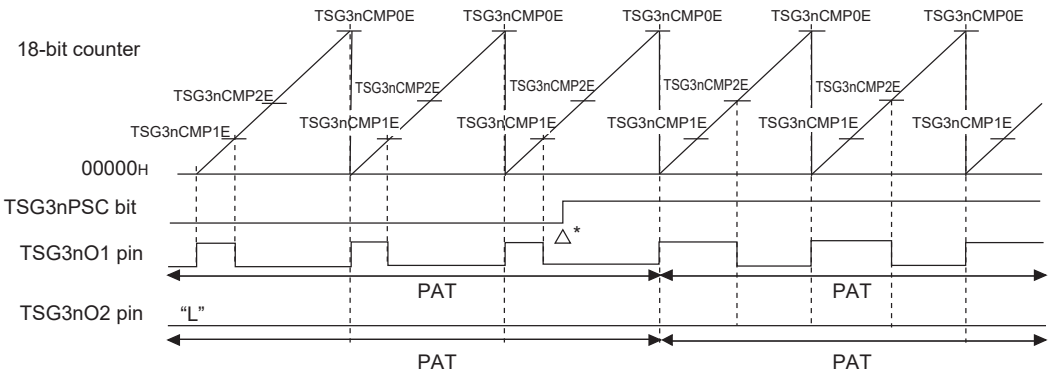
Note 1. When the pattern is switched here, output control is switched in the next period.

Figure 35.89 Output Switch Example (Switched by TSG3nOPT0.TSG3nIDC)

NOTE

If a change in the TSG3nPTSI2-0 pins occurs by the time next period when output control is switched by the TSG3nIDC bit, the 18-bit counter is cleared and output control is switched.

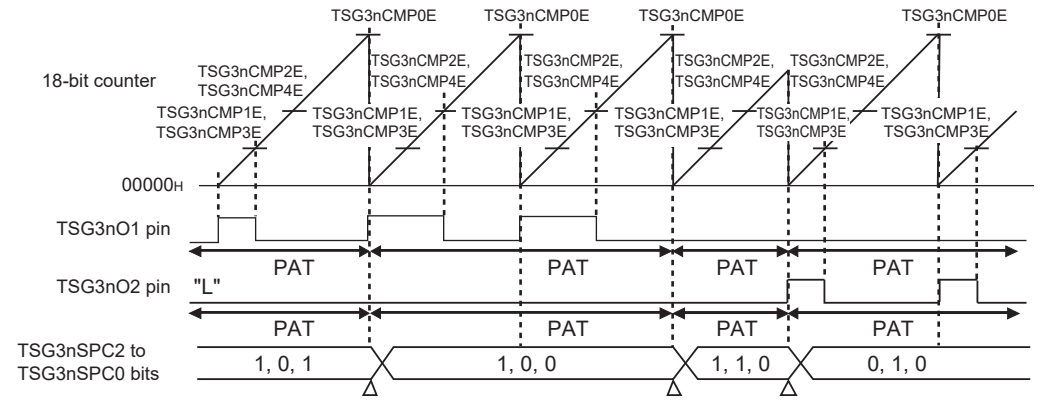
- TSG3nOPT0.TSG3nSTE =1, TSG3nOPT0.TSG3nPOT = 1



Note 1. When the pattern is switched here, output control is switched from the next period.

Figure 35.90 Output Switch Example (Switched by TSG3nOPT0.TSG3nPSC)

- TSG3nOPT0.TSG3nSOC = 0, TSG3nOPT0.TSG3nSTE =1, TSG3nOPT0.TSG3nPOT = 1



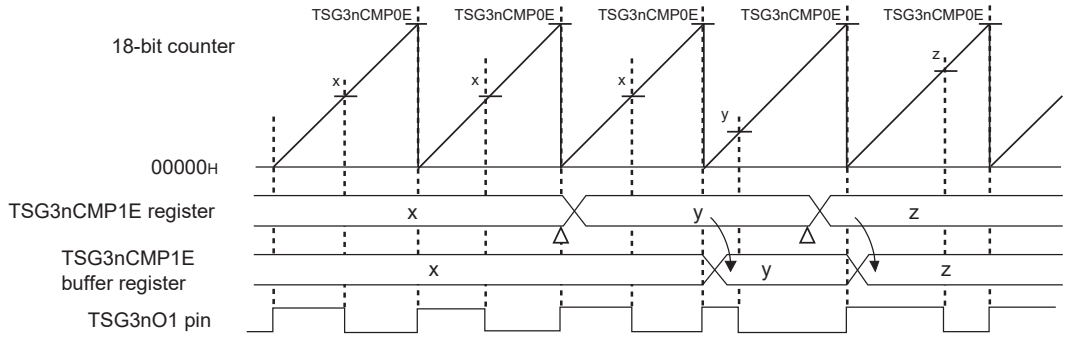
Note: Δ: Write access

Figure 35.91 Output Switch Example (Switched by TSG3nOPT1.TSG3nSPC2 to TSG3nSPC0)

(9) Compare Register Rewrite Timing in 120-DC Mode

Example of operation when TSG3nCMP1E is reloaded (rewritten simultaneously) is shown below.

Figure 35.92 shows an output example when TSG3nCMP1E is rewritten. After TSG3nCMP1E is changed, data is not transferred to the TSG3nCMP1E buffer register (changed data does not become valid) until the next reload timing; therefore, the specified output waveform can be obtained. However, do not write to TSG3nCMP1E again while the reload is suspended (period from when TSG3nCMP1E is changed to when simultaneous rewrite is executed). Be sure to read the reload request flag (TSG3nRSF) to confirm that the flag is 0 before writing to TSG3nCMP1E.



Note: Δ: Write access

Figure 35.92 Output Example when TSG3nCMP1E is Rewritten

(10) Dead Time Control in 120-DC Mode

In 120-DC mode, the dead time is controlled on falling of each phase, and the dead time is added.

The dead time set in TSG3nDTC1W is inserted on falling of the positive phase, and the dead time set in TSG3nDTC0W is inserted on falling of the inverse phase.

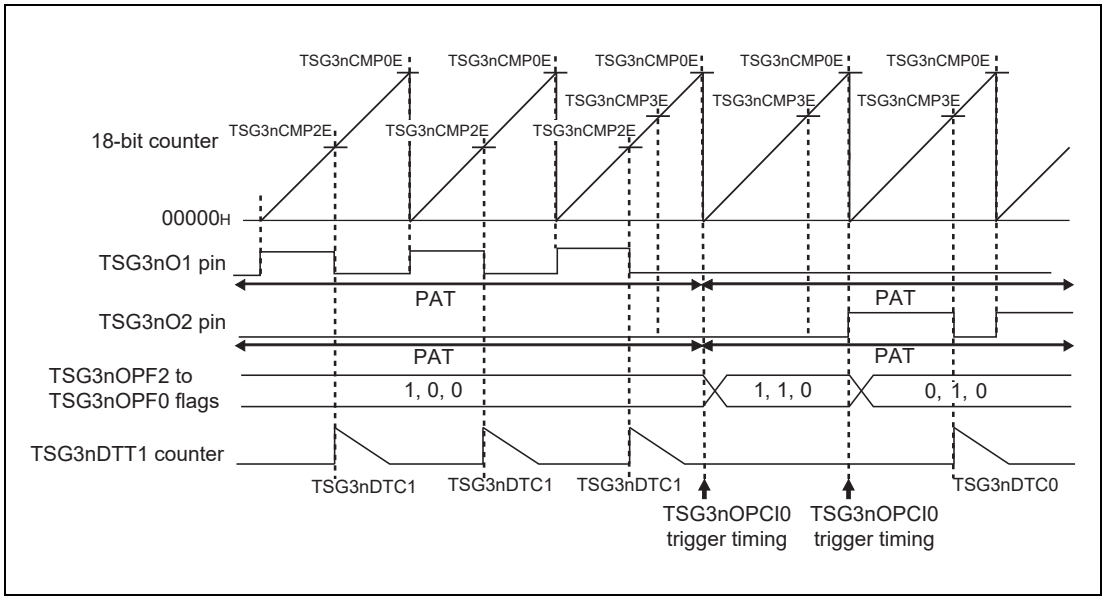


Figure 35.93 Output Switch Example

CAUTION

The dead time control method may affect the timer output. The timer output may not have the specified active level width due to the dead time control under the following conditions:

- **When noise is generated on the input pattern in the pattern switch method**
- **When a change in the input pattern occurs earlier than the PWM period in the pattern switch method**
- **When TSG3nOPT1.TSG3nSPC2 to TSG3nSPC0 are changed and the output pattern is forcibly changed in the trigger switch method**
- **When switch method is changed**
- **When the current direction control bit (TSG3nOPT0.TSG3nIDC) is changed**
- **When the software output control function is used**

(11) Output Switch in 120-DC Mode

In 120-DC mode, the output pattern can be controlled by writing values to TSG3nOPT1.TSG3nSPC2 to TSG3nSPC0 when the trigger switch method (TSG3nOPT0.TSG3nSTE = 1, and TSG3nPOT = 1) is used. The dead time is secured by hardware at the switch timing.

CAUTION

When 111_B or 000_B is written to TSG3nSPC2 to TSG3nSPC0, the TSG3nO1 to TSG3nO6 pins are driven low.

(12) Operation when Noise is Generated in TSG3nPTSI2 to TSG3nPTSI0 Pins in 120-DC Mode

Input to the TSG3nPTSI2 to TSG3nPTSI0 pins is assumed to be the hall sensor signals of the brushless DC motor. Depending on the system, a noise may be generated on the TSG3nPTSI2 to TSG3nPTSI0 pins. Operation when a noise is generated is described below.

For system product design, be sure to insert a noise filter circuit between the hall sensor and the TSG3nPTSI2 to TSG3nPTSI0 pins.

Figure 35.95 shows a case when a noise is generated on the TSG3nPTSI2 to TSG3nPTSI0 pins during operation with the pattern switch method used.

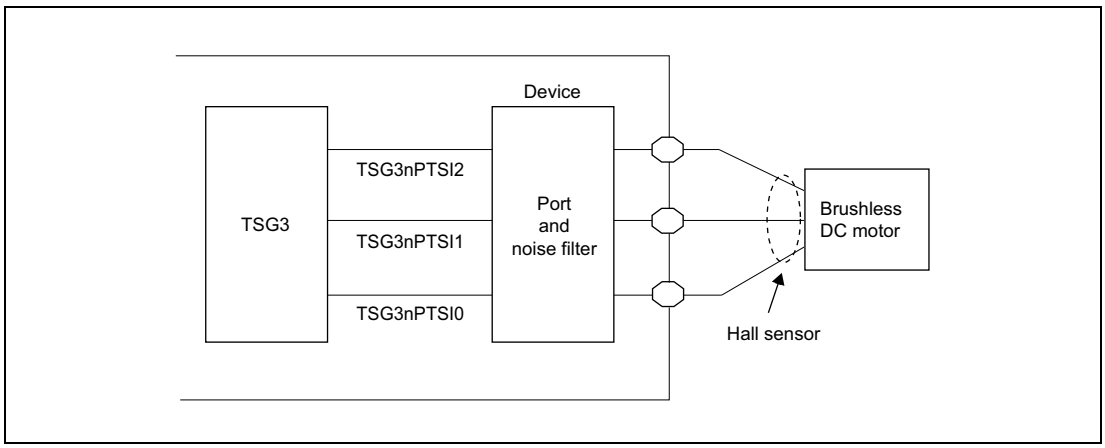

Figure 35.94 Example of Noise Filter Circuit Connection

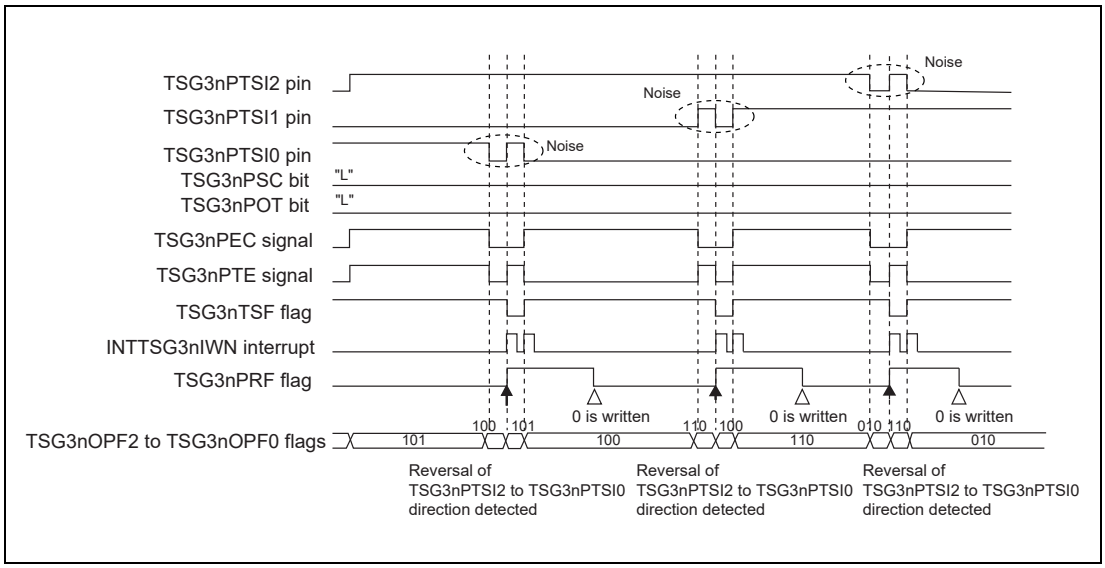

Figure 35.95 Example of Noise Generation at Level Change in TSG3nPTSI2 to TSG3nPTSI0 Pins (Pattern Switch Method)

(a) Change Timing of Input Pattern Change Detection Signal (TSG3nPTE)

The TSG3nPTE signal toggles when the input pattern (TSG3nPTSI2 to TSG3nPTSI0 pins) changes.

CAUTION

Be sure to specify the pattern order direction with the TSG3nPSC bit in the TSG3nOPT0 register (when the TSG3nPSS bit in the TSG3nOPT0 register is 1).

When TSG3nPSC = 0:

Table 35.88 TSG3nPTE Toggle Operation when TSG3nPSC is 0

		TSG3nPTSI2-TSG3nPTSI0 Pins after change							
		000	111	101	100	110	010	011	001

	001	—	—	Toggle	—	—	—	Toggle	—

(c) Change Timing of TSG3nO1 to TSG3nO6 Pins

- When the pattern switch method is used, the output pattern changes when the input signal of the TSG3nPTSI2 to TSG3nPTSI0 pins*1 changes. The output is also switched when two or more pins change simultaneously.
- When the trigger switch method is used, the output pattern changes at the rising edge of the TSG3nOPCI0 and TSG3nOPCI1 signals. The output also changes when data is written to TSG3nSPC2 to TSG3nSPC0*1 in TSG3nOPT0.

Note 1. When the input pattern changes to 000 or 111, the TSG3nO1-TSG3nO6 pins are driven low. The output pattern of TSG3nO1-TSG3nO6 changes immediately only when TSG3nS120DCO = 0. When TSG3nS120DCO = 1, the output pattern is switched when the main counter (TSG3nCNTE) matches with TSG3nCMP0E (from the next timer cycle).

(d) Change Timing of TSG3nTSF Flag

The TSG3nTSF flag toggles when the input pattern (TSG3nPTSI2 to TSG3nPTSI0 pins) changes

Table 35.91 Setting and Clearing of TSG3nTSF

		TSG3nPTSI2-TSG3nPTSI0 Pins after change							
		000	111	101	100	110	010	011	001
Current TSG3nPTSI2 to TSG3nPTSI0 Pins	000	—	—	—	—	—	—	—	—
	111	—	—	—	—	—	—	—	—
	101	—	—	—	0	—	—	—	1
	100	—	—	1	—	0	—	—	—
	110	—	—	—	1	—	0	—	—
	010	—	—	—	—	1	—	0	—
	011	—	—	—	—	—	1	—	0
	001	—	—	0	—	—	—	1	—

(e) Set Timing of TSG3nNDF Flag

This flag is set when two or more pins of the TSG3nPTSI2 to TSG3nPTSI0 pins change simultaneously, and cleared when 1 is written to the TSG3nNDR bit. The TSG3nNDF flag is valid when 1 is set to the TSG3nNDC bit.

(f) Set Timing of TSG3nPRF Flag

This flag is set when the TSG3nTSF flag changes, and cleared when 1 is written to the TSG3nPRR bit. The TSG3nPRF flag is valid when 1 is set to the TSG3nPRC bit.

(g) Set Timing of TSG3nPEF Flag

This flag is set when 000 or 111 is input to the TSG3nPTSI2 to TSG3nPTSI0 pins, and cleared when 1 is written to the TSG3nPER bit. The TSG3nPEF flag is valid when the TSG3nPEC bit is set to 1.

(13) Basic Control Flow in 120-DC Mode

In 120-DC mode, there are eight control states as listed in **Table 35.92**.

When TSG3nOPT0.TSG3nSTE = 1 and TSG3nPOT = 0, the pattern switch method is used for 120-DC control. This is defined as fixed phase control. The fixed phase control should be performed considering the factors such as delay from the hall sensor and delay from sensor level detection to timer output. However, acceleration or deceleration can be performed simply by changing the PWM duty.

When TSG3nOPT0.TSG3nSTE = 1 and TSG3nPOT = 1, the trigger switch method is selected for 120-DC control. This is defined as variable phase control. With the variable phase control, the timer output pattern is set prior to the hall sensor; therefore, acceleration or deceleration control according to the phase difference can be performed. However, control is more complex than the fixed phase control because offset width and predicted value with respect to the hall sensor should be considered. For details, **Section 41.2.3.10, Three-Phase Pulse Input Control Function**.

When TSG3nOPT0.TSG3nSTE = 1, TSG3nOPT0.TSG3nPOT = 1, and TSG3nPSS = 1, the pattern order direction of the motor can be set with the TSG3nPSC bit in the TSG3nOPT0 register. Set TSG3nPSC to 0 for normal rotation and set TSG3nPSC to 1 for reverse rotation.

The TSG3nIDC bit in the TSG3nOPT0 register sets the electric current direction. If the same value as the rotation direction of the motor (TSG3nPSC set value) is set, acceleration control is set. If the different value from the rotation direction of the motor is set, deceleration control is set.

Table 35.92 Timer Control Status

Status	TSG3nPSC in TSG3nOPT0	TSG3nTSF in TSG3nSTR1	TSG3nIDC in TSG3nOPT0	TSG3nPOT in TSG3nOPT0	Control
A	—	0	0	0	Normal rotation, acceleration, and fixed phase
B	0	—	0	1	Normal rotation, acceleration, and variable phase
C	0	—	1	1	Normal rotation, deceleration, and variable phase
D	—	0	1	0	Normal rotation, deceleration, and fixed phase
E	—	1	1	0	Reverse rotation, acceleration, and fixed phase
F	1	—	1	1	Reverse rotation, acceleration, and variable phase
G	1	—	0	1	Reverse rotation, deceleration, and variable phase
H	—	1	0	0	Reverse rotation, deceleration, and fixed phase

Generally, the state when the motor rotation stops is assumed to be the starting state and the control begins. First the fixed phase control is used to rotate the motor from the stopped state. Then, to accelerate the motor speed to the fast rotation, the variable phase control is switched on. Used in combination with encoder timer (ENCA), the variable phase control changes the timer output to a timing that is earlier than the change point (leading) of the hall sensors.

To decelerate the motor speed from fast rotation, the direction is switched to deceleration control by rewriting only TSG3nIDC in TSG3nOPT0. When the rotation count is reduced to low-speed rotation, the motor can be transitioned to the stopped state by decreasing the PWM duty.

State transition is shown in **Figure 35.96** and **Figure 35.97**.

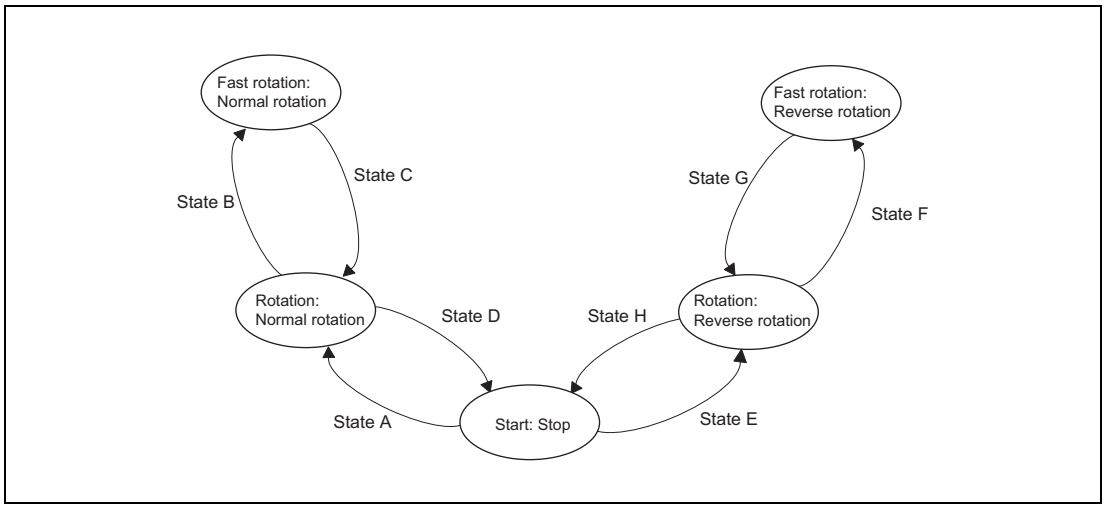

Figure 35.96 State Transition Diagram

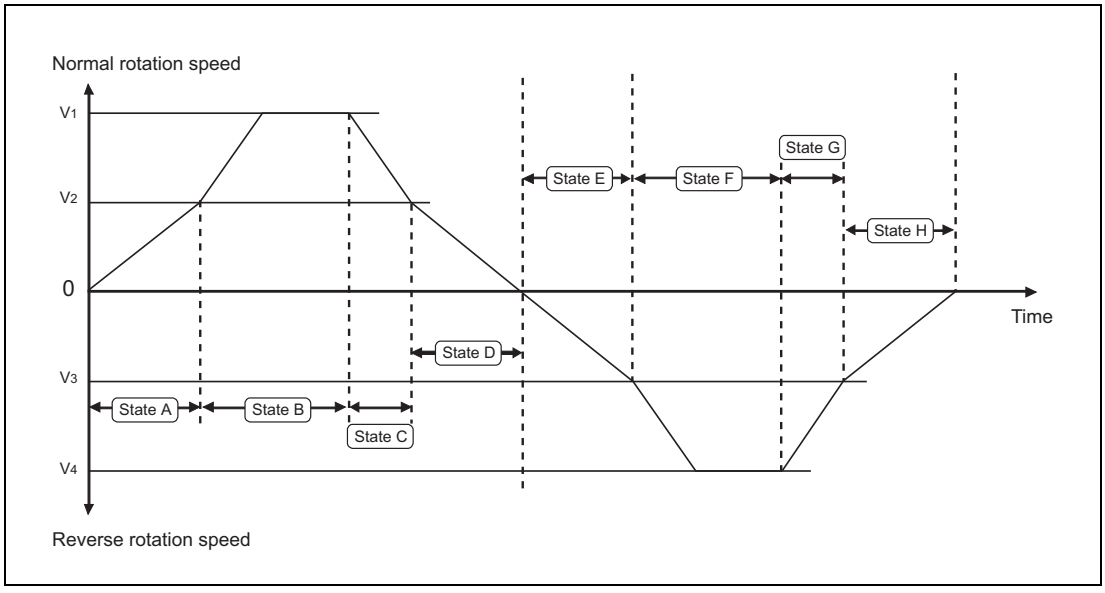

Figure 35.97 Relationship between State Transition and Rotation Speed of Motor

NOTE

V1 and V4: Fast rotation speed of normal rotation and reverse rotation

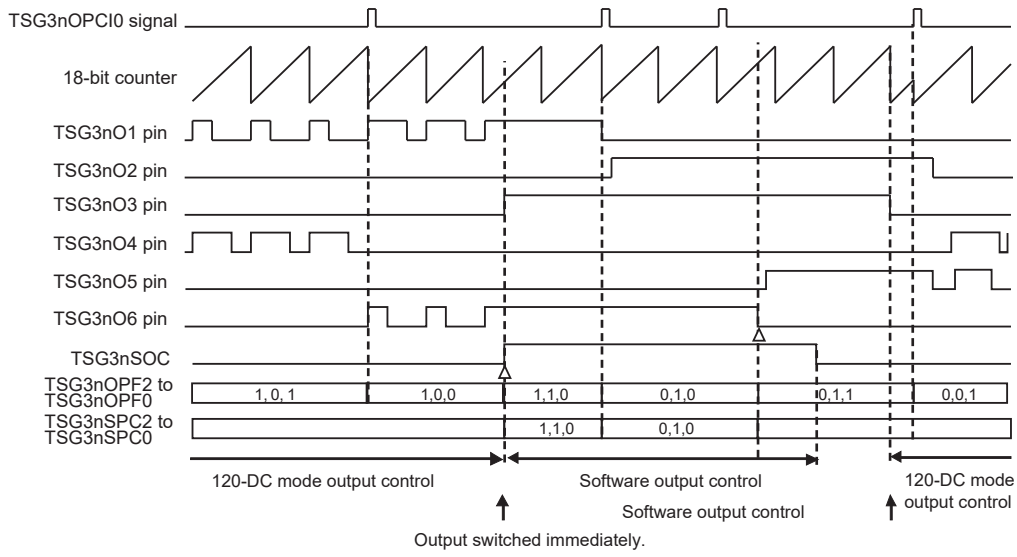
V2 and V3: Low rotation speed of normal rotation and reverse rotation

(14) Software Output Control Function in 120-DC Mode

TSG3nOPT0.TSG3nSOC and TSG3nIDC, and TSG3nOPT1.TSG3nSPC2 to TSG3nSPC0 are used in 120-DC mode for timer output control by software.

As shown in **Figure 35.98**, the output control is switched immediately when TSG3nSOC is set to 1. If the dead time is set, the period of the dead time period is guaranteed. After that, to switch the output control from software output control to 120-DC control, set TSG3nSOC to 0. At this timing, output control is retained and at the reload timing, output control is switched to 120-DC mode.

For details on software output control function, see **Section 35.4.7.8, Software Output Control Function**.



Note: Δ: Write access

Figure 35.98 Example of Switching from 120-DC Mode to Software Output Control Function

(a) Procedure for Software Output Control

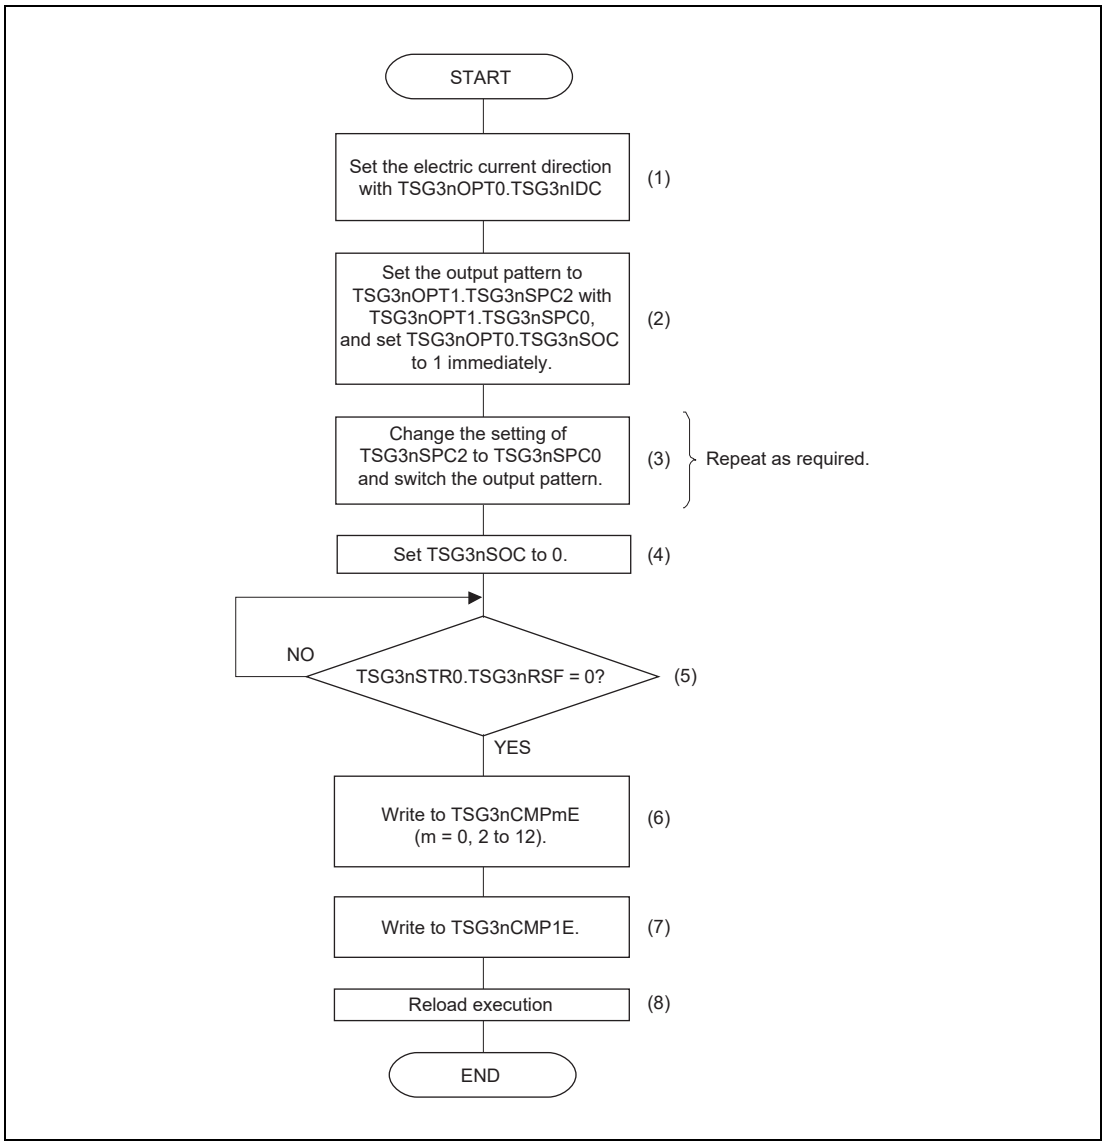


Figure 35.99 Process Flow of Software Output Control

The procedure for software output control is described below.

(1) Set the TSG3nIDC bit. The phase of the timer output with TSG3nIDC = 0 is different by 180 degrees from that with TSG3nIDC = 1. With the software output control function, the timer output will not change only by rewriting this bit. However, if the period match occurs before step (2), the output pattern of 120-DC control changes. Therefore, specify a schedule that will prevent the period match from occurring before step (2).

(2) Set the output pattern with TSG3nSPC2 to TSG3nSPC0. To enable software output control, set TSG3nSOC to 1 simultaneously.

(3) Change the output pattern setting of TSG3nSPC2 to TSG3nSPC0 to change the timer output.

(4) Confirm that the reload request flag (TSG3nRSF) = 0. If TSG3nRFS = 1, do not proceed to the following step until TSG3nRSF = 0.

(5) By setting TSG3nSOC = 0 the software control release process starts (it is not released yet at this point).

(6) Configure the compare register settings that are required after the software output control is released. Proceed to the following step when the register setting is not required. When setting the registers with the reload function, set them at this point.

(7) Write to TSG3nCMP1E to start reloading.

(8) Reload is executed and software output is released.

CAUTION

Execute reload after completing steps (4) to (7). When reload cannot be executed, the software output cannot be released.

35.4.7.5 HSP-PWM Mode (High accuracy Shifted-pulse - Pulse Width Modulation Mode)

Overview

In this mode, the 18-bit counter and the 18-bit compare register are used to generate a high accuracy sawtooth waveform PWM signal.

Prerequisites

- Set the PWM period to TSG3nCMP0E.
- Set PWM output width with the TSG3nHSPCMUE, TSG3nHSPCMVE, and TSG3nHSPCMWE registers. Set PWM shift width with the TSG3nHSPSHUE, TSG3nHSPSHVE, and TSG3nHSPSHWE registers. Set dead time with the TSG3nDTC0W and TSG3nDTC1W registers. The values set in these registers are immediately reflected to the corresponding TSG3nCMPmE (m = 1 to 12) based on the calculation described later.

Functional description

Set the PWM period, the dead time, and the PWM shift width. Then set the PWM output width. Counting up begins when TSG3nTRG0.TSG3nTS is set to 1.

The 18-bit counter starts counting from 00000_H and is cleared by the match with TSG3nCMP0E.

During counting, a compare match interrupt (INTTSG3nI0 to INTTSG3nI12) is generated by the match of the buffer register TSG3nCMP0E to TSG3nCMP12E with the 18-bit counter.

NOTE

The HSP-PWM mode is set when TSG3nCTL0.TSG3nMD2-TSG3nMD0 = 100_B.

(1) Basic Timing Chart

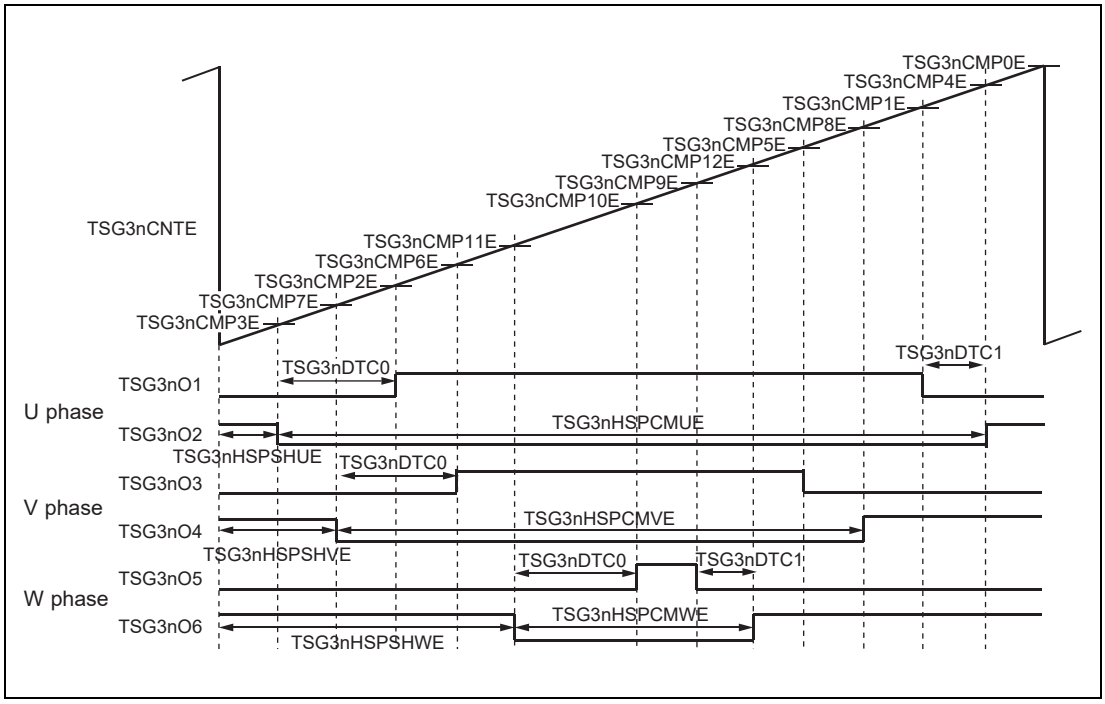

Figure 35.100 Basic Timing in HSP-PWM Mode

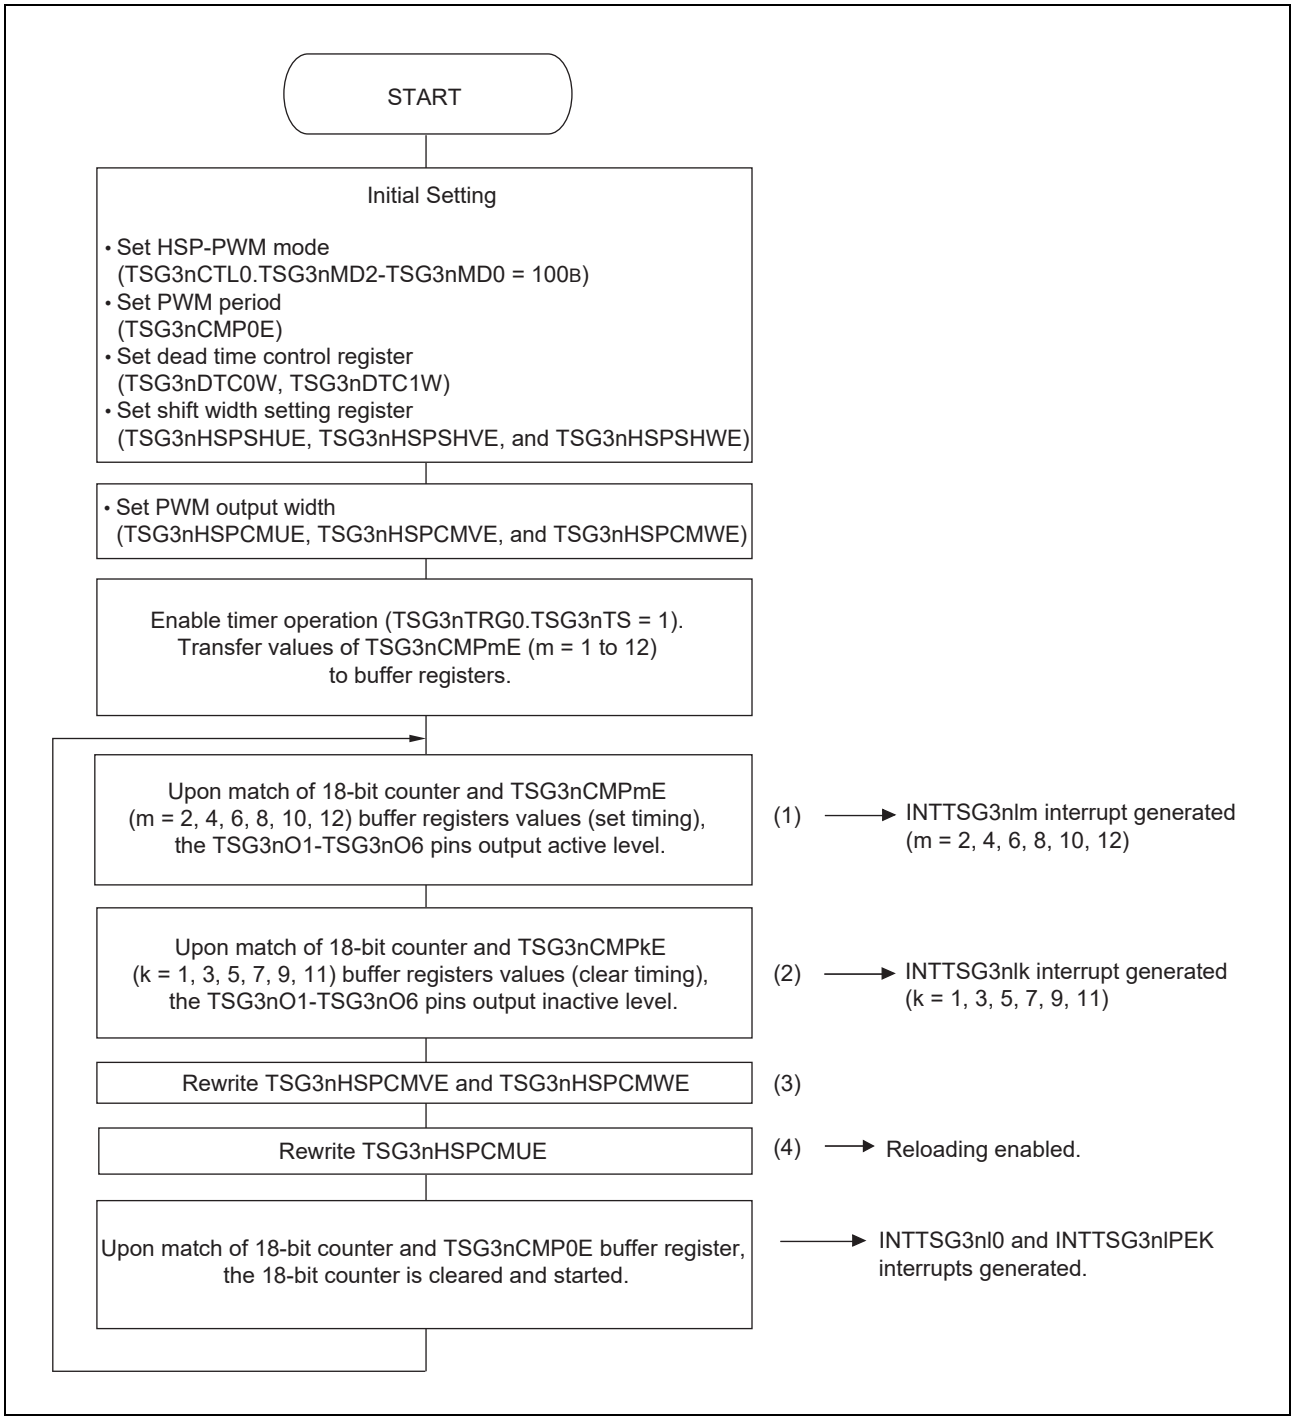

Figure 35.101 Basic Operation Flow in HSP-PWM Mode

NOTE

The timing may be different from the orders described above but be sure to execute (4) after (3).

CAUTIONS

1. **When changing the settings for PWM output width in the TSG3nHSPCMUE, VE, and WE registers during operation, set the TSG3nHSPCMUE register last. When only the settings for the V phase and W phase are changed but the PWM output width in the U phase is not, the existing value should be written back to the TSG3nHSPCMUE register.**
2. **After changing the PWM cycle by using the TSG3nCMP0E register, the PWM output width settings in the TSG3nHSPCMUE, VE, and WE registers must be reconfigured. Changing the settings for the PWM shift width in the TSG3nHSPSHUE, VE, and WE registers and the settings for the PWM cycle in the TSG3nCMP0E register at the same time is not allowed.**
3. **Reconfigure the settings for PWM output width in the TSG3nHSPCMUE, VE, and WE registers after changing the settings for PWM shift width in the TSG3nHSPSHUE, VE, and WE registers.**

(2) List of Operation in HSP-PWM

Table 35.93 Counter Function in HSP-PWM

Operation		Setting Condition
18-bit counter	Start	TSG3nTRG0.TSG3nTS = 0 → 1 or simultaneous start trigger
	Clear	Compare match of TSG3nCMP0E buffer register and 18-bit counter
	Stop	TSG3nTRG1.TSG3nTT = 0 → 1

Table 35.94 Functions of Compare Registers, Shift Width Setting Register, and Dead Time Control Register in HSP-PWM

Register	Rewriting Method	Rewrite during Operation	Function
TSG3nCMP0E	Reload	Possible	Setting period
TSG3nHSPCMUE	Reload	Possible	PWM control for U phase
TSG3nHSPSHUE			
TSG3nHSPCMVE	Reload	Possible	PWM control for V phase
TSG3nHSPSHVE			
TSG3nHSPCMWE	Reload	Possible	PWM control for W phase
TSG3nHSPSHWE			
TSG3nDCMP0E, TSG3nDCMP1E, TSG3nDCMP2E	Reload	Possible	Diagnostic output or A/D conversion trigger
TSG3nDTC0W, TSG3nDTC1W	Reload	Prohibited	Dead time

Table 35.95 Timer Output in HSP-PWM Mode

Pin	Function
TSG3nO1	PWM output by compare match of the TSG3nCMP1E buffer register (clear timing) or the TSG3nCMP2E buffer register (set timing) with the 18-bit counter.
TSG3nO2	PWM output by compare match of the TSG3nCMP3E buffer register (clear timing) or the TSG3nCMP4E buffer register (set timing) with the 18-bit counter.
TSG3nO3	PWM output by compare match of the TSG3nCMP5E buffer register (clear timing) or the TSG3nCMP6E buffer register (set timing) with the 18-bit counter.
TSG3nO4	PWM output by compare match of the TSG3nCMP7E buffer register (clear timing) or the TSG3nCMP8E buffer register (set timing) with the 18-bit counter.
TSG3nO5	PWM output by compare match of the TSG3nCMP9E buffer register (clear timing) or the TSG3nCMP10E buffer register (set timing) with the 18-bit counter.
TSG3nO6	PWM output by compare match of the TSG3nCMP11E buffer register (clear timing) or the TSG3nCMP12E buffer register (set timing) with the 18-bit counter.
TSG3nO7	Diagnostic signal output or pulse output by A/D conversion trigger

Table 35.96 Interrupt Request in HSP-PWM Mode

Interrupt	Function
INTTSG3nIm (m = 0 to 12)	Compare match of the TSG3nCMPmE buffer register with 18-bit counter
INTTSG3nIER	Error
INTTSG3nIVLY	—
INTTSG3nIPEK	Peak interrupt (generated at the same timing as INTTSG3nI0)
INTTSG3nIWN	Error

Table 35.97 Compare Match Timing in HSP-PWM Mode

Compare Match	Timing
TSG3nCMP0E	When 18-bit counter changes from TSG3nCMP0E to 00000_H
TSG3nCMPmE (m = 1 to 12)	After match of 18-bit counter and TSG3nCMPmE

(3) Various Settings of HSP-PWM Mode

Setting mode

HSP-PWM mode is entered by setting TSG3nCTL0.TSG3nMD2-TSG3nMD0 to 100_B.

Setting timer output

The output pins TSG3nO1-6 are controlled by setting TSG3nIOC0, TSG3nIOC2, and TSG3nIOC3.

The TSG3nO7 pin provides output pulse as diagnostic output or A/D conversion trigger. The pin should be set as necessary.

Enabling error interrupt generation

Error interrupt (INTTSG3nIER) due to the detection of the simultaneous active state of positive and inverse phases is enabled by setting TSG3nIOC1.TSG3nEOC to 1. For details, see **Section 35.4.6, Error/Warning Interrupt**.

Setting rewriting timing of register with reload function

This function is only available in reload mode. Set TSG3nCTL3.TSG3nRMC to 0.

Setting A/D conversion trigger output

The A/D conversion trigger 0 (TSG3nADTRG0 signal) is set with TSG3nCTL5.TSG3nAT09-TSG3nAT00.

TSG3nAT09-TSG3n00 is used to enable or disable the A/D conversion trigger output upon match of TSG3nDCMP2E-0E with 18-bit counter (up count).

TSG3nCTL6.TSG3nAT19-TSG3nAT10 is used to set the A/D conversion trigger 1 (TSG3nADTRG1 signal).

To set the match timing of the 18-bit counter and TSG3nDCMP2E-TSG3nDCMP0E, set the compare value to each register.

The skipping function can be used for TSG3nADTRG0, TSG3nADTRG1 signals. TSG3nACC01 and TSG3nACC00 of TSG3nCTL5, and TSG3nACC11 and TSG3nACC10 of TSG3nCTL6 can be used to select the skipping rate from 1/1 (no skipping), 1/2, 1/4, and 1/8.

CAUTION

- **Be sure to set TSG3nCTL5, TSG3nCTL6, and TSG3nDCMP2E-0E correctly when the timing pulse of A/D conversion trigger is output to TSG3nO7.**
- **In HSP-PWM mode, no valley interrupt (INTTSG3nIVLY) is generated. Therefore, SG3nCTL5.TSG3nAT00 and TSG3nCTL6.TSG3nAT10 must be set to 0.**
- **In HSP-PWM mode, the 18-bit sub-counter does not operate. Therefore, TSG3nCTL5.TSG3nAT09 and TSG3nAT08, and TSG3nCTL6.TSG3nAT19 and TSG3nAT18 must be set to 0.**
- **In HSP-PWM mode, down counting by the 18-bit counter is not generated. Therefore, TSG3nCTL5.TSG3nAT07, TSG3nAT05, and TSG3nAT03, and TSG3nCTL6.TSG3nAT17, TSG3nAT15, and TSG3nAT13 must be set to 0.**

Setting PWM period

Set the PWM period with TSG3nCMP0E.

The PWM period is calculated by the following expression:

PCLK × (TSG3nCMP0E + 1)

Setting PWM output width

The PWM output width is set with TSG3nHSPCMUE, TSG3nHSPCMVE, and TSG3nHSPCMWE (TSG3nCMP1E-12E).

Satisfy the following requirements when setting the TSG3nHSPCMUE, TSG3nHSPCMVE, and TSG3nHSPCMWE registers:

0 ≤ TSG3nHSPCMUE,TSG3nHSPCMVE, TSG3nHSPCMWE ≤ TSG3nCMP0E + TSG3nDTC0 + TSG3nDTC1 + 1

Set the PWM output width after setting TSG3nCMP0E, TSG3nHSPSHUE, TSG3nHSPSHVE, TSG3nHSPSHWE, TSG3nDTC0, and TSG3nDTC1.

Setting PWM shift width

PWM shift width is set with TSG3nHSPSHUE, TSG3nHSPSHVE, and TSG3nHSPSHWE.

Satisfy the following requirements when setting TSG3nHSPSHUE, TSG3nHSPSHVE, and TSG3nHSPSHWE.

TSG3nHSPSHUE, TSG3nHSPSHVE, TSG3nHSPSHWE ≤ TSG3nCMP0E

Setting dead time

The dead time can be set with TSG3nDTC0 and TSG3nDTC1.

The dead time is calculated by the following expressions:

PCLK × TSG3nDTC0

PCLK × TSG3nDTC1

TSG3nDTC0 can set the time between a change of TSG3nO2, TSG3nO4, and TSG3nO6 to the inactive state and a change of TSG3nO1, TSG3nO3, and TSG3nO5 to the active state, respectively.

TSG3nDTC1 can set the time between a change of TSG3nO1, TSG3nO3, and TSG3nO5 to the inactive state and a change of TSG3nO2, TSG3nO4, and TSG3nO6 to the active state, respectively.

Satisfy the following requirements when setting TSG3nDTC0 and TSG3nDTC 1.

(TSG3nCMP0E + TSG3nDTC0 + TSG3nDTC1 + 1) < $3FFFF_H$

TSG3nCMP0E > 3 × TSG3nDTC0

TSG3nCMP0E > 3 × TSG3nDTC1

CAUTION

Do not modify the settings of TSG3nDTC0 and TSG3nDTC1 during timer operation in HSP-PWM (TSG3nTE = 1). Set TSG3nDTC0 and TSG3nDTC1 while TSG3nTE = 0.

Set dead time in HSP-PWM mode. Do not set 0 to TSG3nDTC0 and TSG3nDTC1.

Settings prohibited in HSP-PWM Mode

In HSP-PWM mode, use the following registers and bits with the settings shown below.

Do not modify the settings during operation (TSG3nTE = 1).

Table 35.98 Setting Prohibited in HSP-PWM Mode

Bit Name	Setting Value	Description
TSG3nCTL3.TSG3nRMC	0	Available only in reload mode.
TSG3nIOC3.TSG3nTOL6-1	000000_B	Logical inverse of set/clear of PWM is prohibited (HSP-PWM mode limitation)
TSG3nOPT0.TSG3nSOC	0	Switching to software control function is prohibited.
TSG3nOPT0.TSG3nSTE	0	Operation setting of 120-DC mode and software control function (value after reset).
TSG3nOPT0.TSG3nPOT	0	Operation setting of 120-DC mode and software control function (value after reset).
TSG3nOPT0.TSG3nPSS	0	Operation setting of 120-DC mode and software control function (value after reset).
TSG3nOPT0.TSG3nIDC	0	Operation setting of 120-DC mode and software control function (value after reset).
TSG3nOPT0.TSG3nPSC	0	Operation setting of 120-DC mode and software control function (value after reset).
TSG3nOPT1.TSG3nSPC2-0	000_B	Operation setting of 120-DC mode and software control function (value after reset).
TSG3nPAT0W	0000000_H	Operation setting of 120-DC mode (value after reset).
TSG3nPAT1W	0000000_H	Operation setting of 120-DC mode (value after reset).

CAUTION

In HSP-PWM mode, no setting should be made directly to the TSG3nCMPmE register (m = 1 to 12).

The PWM output width and the PWM shift width should be set with TSG3nHSPCMUE, VE, and WE registers and TSG3nHSPSHUE, VE, and WE registers.

35.4.7.6 Compare Register Setting in HSP-PWM Mode

In HSP-PWM mode, the PWM output width is set with TSG3nHSPCMUE, VE and WE.

With a write access to TSG3nHSPCMUE, VE, and WE, TSG3 calculates and sets the values to TSG3nCMP1E-12E based on the values written to the followings:

- TSG3nCMP0E (PWM period setting)
- TSG3nDTC0 (dead time control 0)
- TSG3nDTC1 (dead time control 1)
- TSG3nHSPSHUE/VE/WE (PWM shift width setting)
- TSG3nHSPCMUE/VE/WE (PWM output width setting)

The high accuracy PWM is realized by these values.

The algorithm to set compare register values are listed in the following table.

Table 35.99 Algorithm for Compare Setting in HSP-PWM Mode

Value Set In HSPCMUE					CMP4E	CMP3E	CMP2E	CMP1E
HSPCMUE = 0					if (HSPSHUE = 0) 0 else HSPCMUE – 1 + HSPSHUE	CMP0E + 1	0	0
0	<	HSPCMUE	≤	DTC0 + DTC1	HSPCMUE – 1 + HSPSHUE	if (HSPSHUE = 0) CMP0E else HSPSHUE – 1	0	0
DTC0 + DTC1	<	HSPCMUE	≤	CMP0E	HSPCMUE – 1 + HSPSHUE	if (HSPSHUE = 0) CMP0E else HSPSHUE – 1	DTC0 – 1 + HSPSHUE	HSPCMUE – DTC1 – 1 + HSPSHUE
CMP0E	<	HSPCMUE	≤	CMP0E + DTC1 + 1	0	0	DTC0 – 1 + HSPSHUE	HSPCMUE – DTC1 – 1 + HSPSHUE
CMP0E + DTC1 + 1	<	HSPCMUE	<	CMP0E + DTC0 + DTC1 + 1	0	0	DTC0 – 1 + HSPSHUE	HSPCMUE – CMP0E – DTC1 – 2 + HSPSHUE
HSPCMUE = CMP0E + DTC0 + DTC1 + 1					0	0	DTC0 – 1 + HSPSHUE	CMP0E + 1

: For the colored cells, subtract CMP0E + 1 when the calculated result is greater than CMP0E.

NOTE

"TSG3n" is omitted from the register names used in the calculation.

35.4.7.7 Timer Output Operation in HSP-PWM Mode

TSG3nO1-6 output is set by compare match of TSG3nCNTE with TSG3nCMP2E, 4E, 6E, 8E, 10E, and 12E, respectively, and cleared by compare match of TSG3nCNTE with TSG3nCMP1E, 3E, 5E, 7E, 9E, and 11E, respectively.

When PWM output width is set in TSG3nHSPCMUE,VE, and WE, the value is set in the TSG3nCMP1E-12E registers based on the calculation described in **Section 35.4.7.6, Compare Register Setting in HSP-PWM Mode** that enables a high accuracy PWM output from 0% to 100%.

PWM output timing can be shifted by setting desired width to TSG3nHSPSHUE, VE, WE.

(1) When TSG3nHSPCMUE, VE, and WE (PWM output width setting) is set to 0

When 0 is set to TSG3nHSPCMUE (U phase PWM output width setting), 0 is set to TSG3nCMP1E, 2E, and 4E, and "TSG3nCMP0E+1" is set to TSG3nCMP3E.

Setting of TSG3nO1 by the match of TSG3nCNTE with TSG3nCMP2E and clearing by the match with TSG3nCMP1E occur simultaneously, but clearing takes precedence. Therefore, TSG3nO1 output is fixed to inactive.

Setting of TSG3nO2 by the match of TSG3nCNTE with TSG3nCMP4E occurs when TSG3nCNTE = 0. Since TSG3nCMP0E + 1 is set to TSG3nCMP3E, TSG3nCNTE does not match TSG3nCMP3E. Therefore, TSG3nO2 output is fixed to active.

The same operation applies to TSG3nO3-6, which are the output pins for V phase and W phase when 0 is set to TSG3nHSPCMVE (V phase PWM output width setting) and TSG3nHSPCMWE (W phase PWM output width setting).

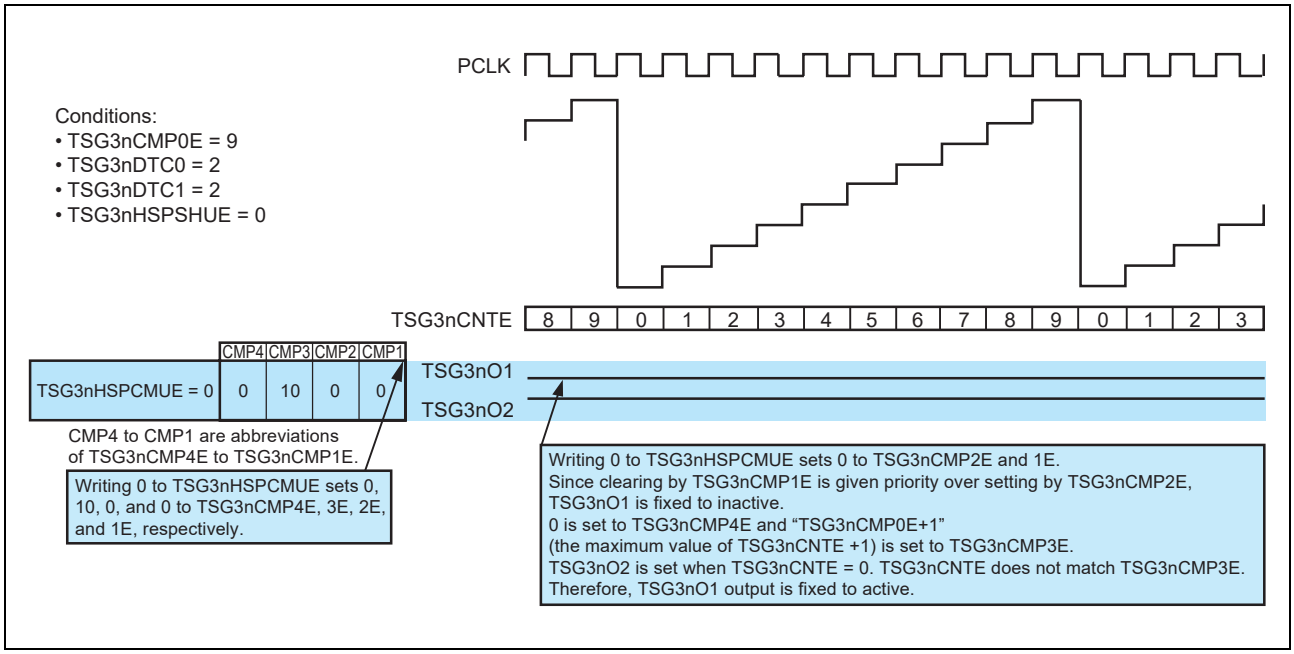

Figure 35.102 Waveform in HSP-PWM Mode (0 is set to TSG3nHSPCMUE)

(2) When TSG3nHSPCMUE/VE/WE (PWM output width setting) is set to the range 0 < TSG3nHSPCMUE ≤ TSG3nDTC0 + TSG3nDTC1

When the value within this range is set to TSG3nHSPCMUE (U phase PWM output width setting), 0 is set to TSG3nCMP1E and 2E, “TSG3nHSPCMUE set value - 1” is set to TSG3nCMP4E, and the value of the TSG3nCMP0E is set to TSG3nCMP3E.

Setting of TSG3nO1 by the match of TSG3nCNTE with TSG3nCMP2E and clearing by the match with TSG3nCMP1E occurs simultaneously, but clearing takes precedence. Therefore, TSG3nO1 output is fixed to inactive.

TSG3nO2 is cleared by the match of TSG3nCNTE with TSG3nCMP3E and set by the match with TSG3nCMP4E. Here, the output is shifted according to the set value in TSG3nHSPCMUE, that is, TSG3nO2 is inactive for one cycle during PWM period when 1 is set, two cycles when 2 is set, and three cycles when 3 is set, and so on.

When the value other than 0 is set to TSG3nHSPSHUE (PWM shift width), set/clear timing of TSG3nO2 is shifted to the right for the number of cycles set in TSG3nHSPSHUE.

The same condition applies to TSG3nO3-6, which are the output pins for V phase and W phase when the value of “0 < TSG3nHSPCMUE ≤ TSG3nDTC0 + TSG3nDTC1” is set to TSG3nHSPCMVE (V phase PWM output width setting) and TSG3nHSPCMWE (W phase PWM output width setting).

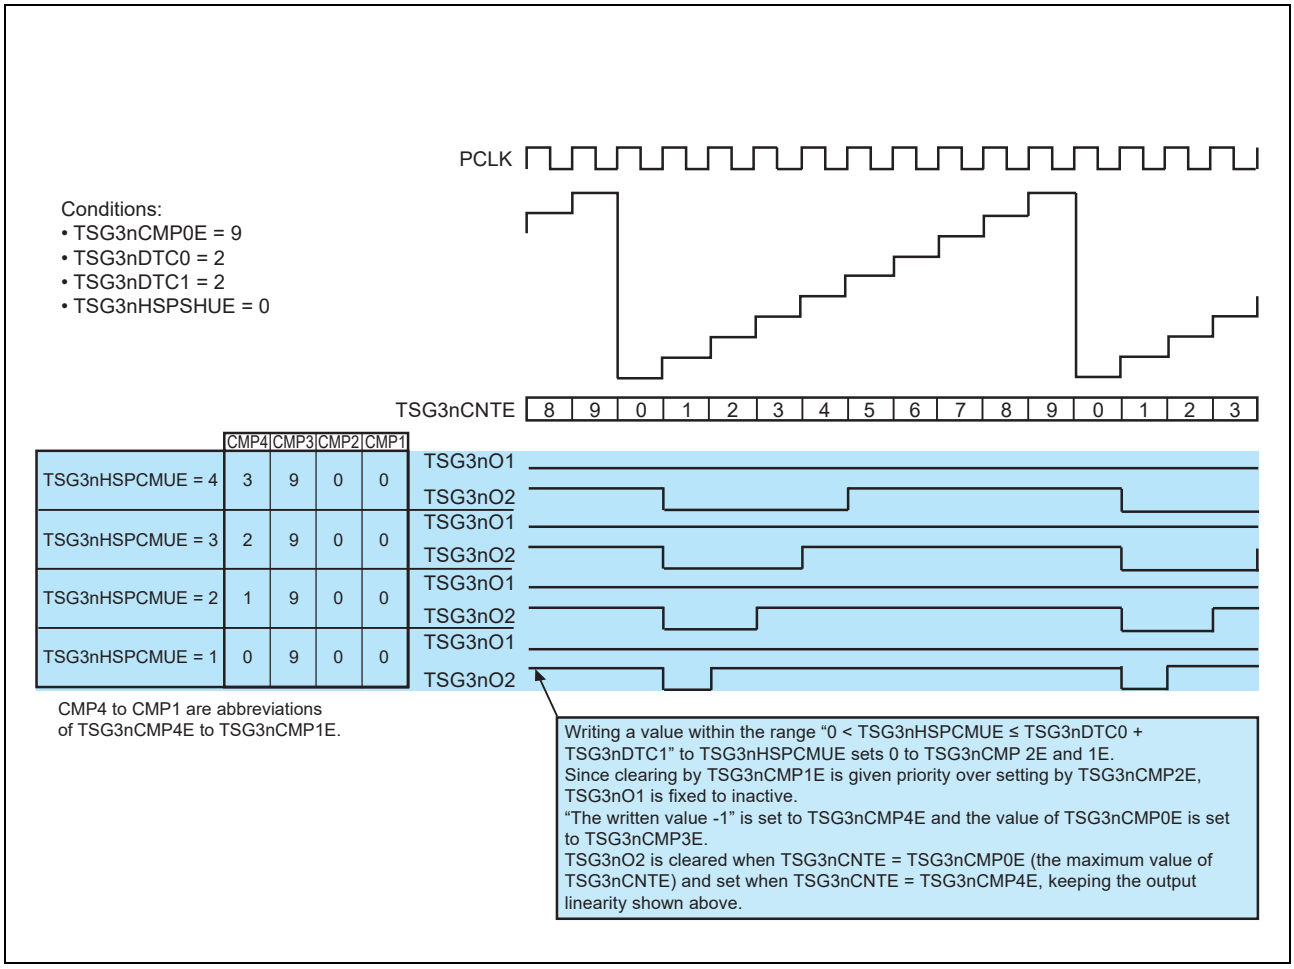

Figure 35.103 Waveform in HSP-PWM Mode (TSG3nHSPCMUE is set to 0 < TSG3nHSPCMUE ≤ TSG3nDTC0 + TSG3nDTC1)

(3) When TSG3nHSPCMUE/VE/WE (PWM Output Width Setting) is set to the range TSG3nDTC0 + TSG3nDTC1 <TSG3nHSPCMUE/VE/WE ≤ TSG3nCMP0E

When the value within this range is set to TSG3nHSPCMUE (U phase PWM output width setting), “TSG3nDTCD0 -1” is set to TSG3nCMP2E, “TSG3nHSPCMUE - TSG3nDTC1 - 1” is set to TSG3nCMP1E, “TSG3nHSPCMUE - 1” is set to TSG3nCMP4E, and the value of TSG3nCMP0E is set to TSG3nCMP3E.

TSG3nO1 is set by the match of TSG3nCNTE with TSG3nCMP2E and cleared by the match with TSG3nCMP1E while TSG3nO2 is set by the match of TSG3nCNTE with TSG3nCMP4E and cleared by the match with TSG3nCMP3E

Here, the outputs are shifted according to the set value in TSG3nHSPCMUE, that is, when “TSG3nDTC0 + TSG3nDTC1 + 1” is set, TSG3nO1 is active for one cycle during PWM period and TSG3nO2 is inactive for the cycles of “TSG3nDTC0 + TSG3nDTC1+ 1” during PWM period. When “TSG3nDTC0 + TSG3nDTC1 + 2” is set, TSG3nO1 is active for two cycles during PWM period and TSG3nO2 is inactive for the cycles of “TSG3nDTC0 + TSG3nDTC1+ 2” during PWM period, and so on.

When the value other than 0 is set to TSG3nHSPSHUE (PWM shift width), set/clear timing of TSG3nO1 and TSG3nO2 are shifted to the right for the number of cycles set in TSG3nHSPSHUE.

The same condition applies to TSG3nO3-6, which are the output pins for V phase and W phase when the value of “TSG3nDTC0 + TSG3nDTC1 <TSG3nHSPCMUE/VE/WE ≤ TSG3nCMP0E” is set to TSG3nHSPCMVE (V phase PWM output width setting) and TSG3nHSPCMWE (W phase PWM output width setting).

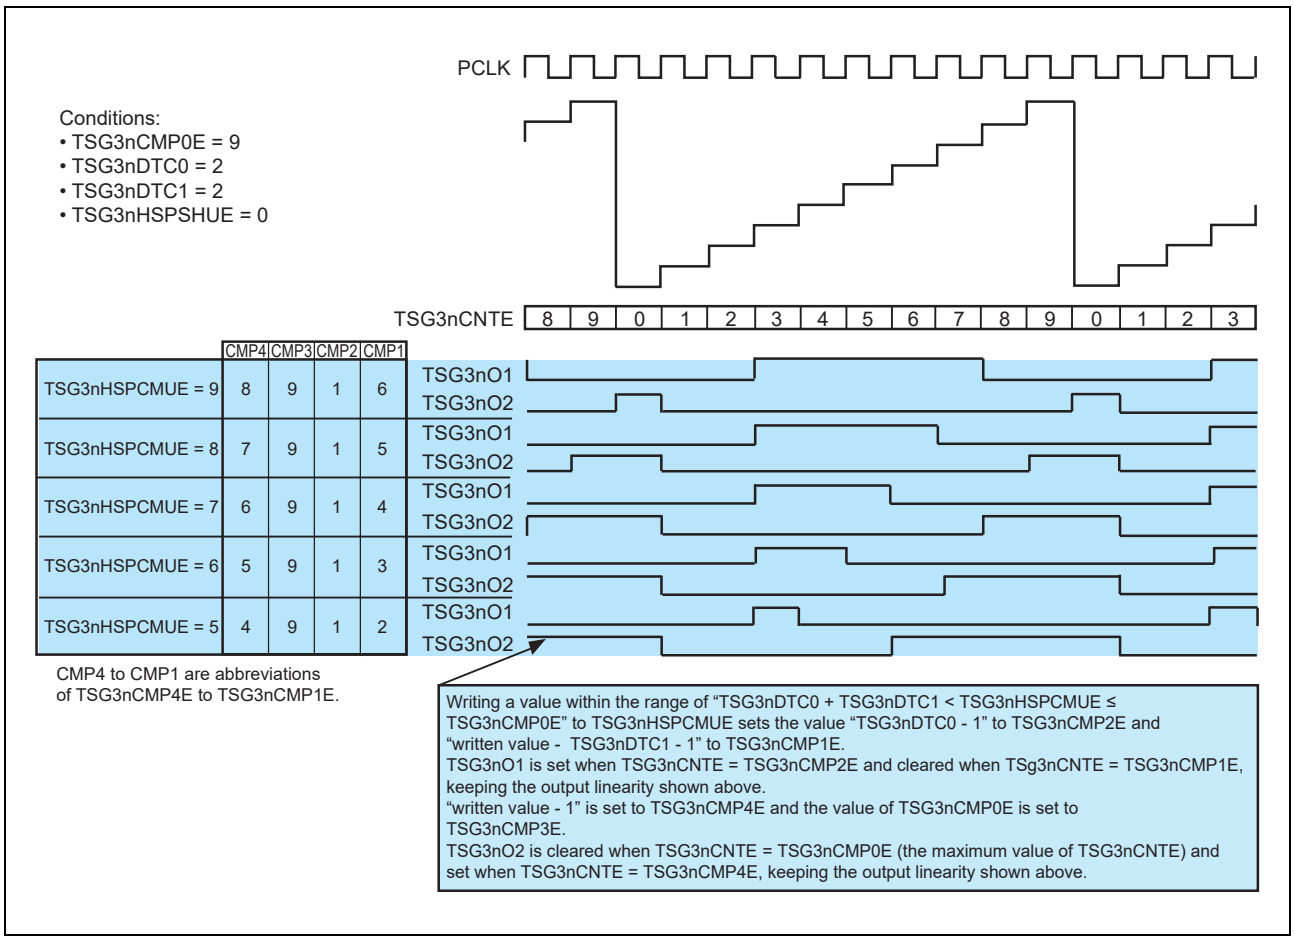

Figure 35.104 Waveform in HSP-PWM Mode (TSG3nHSPCMUE is set to TSG3nDTC0 + TSG3nDTC1 < TSG3nHSPCMUE ≤ TSG3nCMP0E)

(4) When TSG3nHSPCMUE/VE/WE (PWM Output Width Setting) is set to the range TSG3nCMP0E < TSG3nHSPCMUE/VE/ WE < TSG3nCMP0E + TSG3nDTC1 + 1

When the value within this range is set to TSG3nHSPCMUE (U phase PWM output width setting), “TSG3nDTC0 - 1” is set to TSG3nCMP2E, “TSG3nHSPCMUE - TSG3nDTC1 - 1” is set to TSG3nCMP1E, and 0 is set to TSG3nCMP3E and 4E.

TSG3nO1 is cleared by the match of TSG3nCNTE with TSG3nCMP1E and set by the match with TSG3nCMP2E.

Here, the output is shifted according to the set value in TSG3nHSPCMUE, that is, TSG3nO1 is inactive for the cycles of “TSG3nDTC0 + TSG3nDTC1” during PWM period when “TSG3nCMP0E + 1” is set, inactive for the cycles of “TSG3nDTC0 + TSG3nDTC1 - 1” during PWM period when “TSG3nCMP0E + 2” is set, and so on.

Setting of TSG3nO2 by the match of TSG3nCNTE with TSG3nCMP4E and clearing by the match with TSG3nCMP3E occur simultaneously, but clearing takes precedence. Therefore, TSG3nO2 output is fixed to inactive.

When the value other than 0 is set to TSG3nHSPSHUE (U phase PWM shift width), set/clear timing of TSG3nO1 is shifted to the right for the number of cycles set in TSG3nHSPSHUE.

The same condition applies to TSG3nO3-6, which are the output pins for V phase and W phase when the value of “TSG3nCMP0E < TSG3nHSPCMUE/VE/ WE < TSG3nCMP0E + TSG3nDTC1 + 1” is set to TSG3nHSPCMVE (V phase PWM output width setting) and TSG3nHSPCMWE (W phase PWM output width setting).

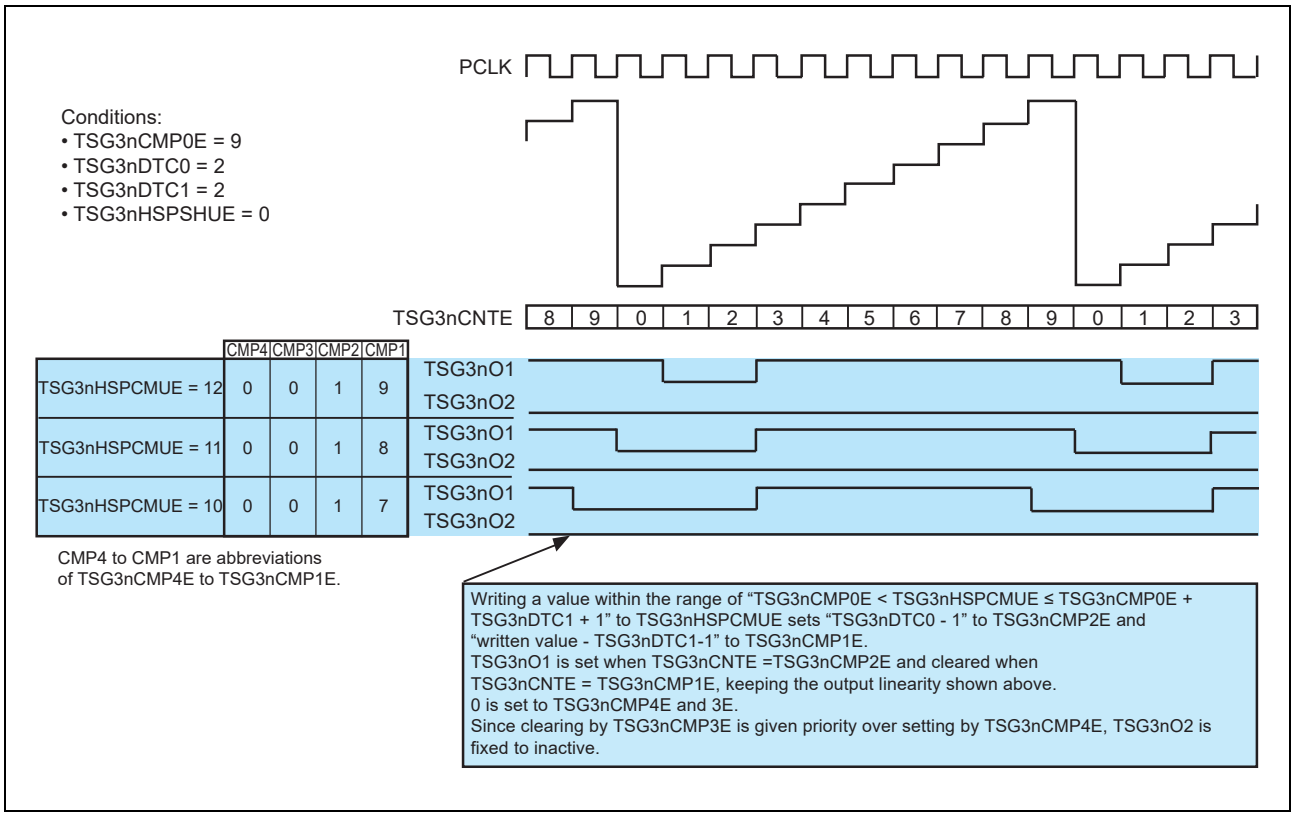

Figure 35.105 Waveform in HSP-PWM Mode (TSG3nHSPCMUE is set to TSG3nCMP0E < TSG3nHSPCMUE < TSG3nCMP0E + TSG3nDTC1 + 1)

(5) When TSG3nHSPCMUE/VE/WE (PWM Output Width Setting) is set to the range TSG3nCMP0E + TSG3nDTC1 + 1 < TSG3nHSPCMUE/VE/WE < TSG3nCMP0E + TSG3nDTC0 + TSG3nDTC1 + 1

When the value within this range is set to TSG3nHSPCMUE (U phase PWM output width setting), “TSG3nDTC0 - 1” is set to TSG3nCMP2E, “TSG3nHSPCMUE - TSG3nCMP0E - TSG3nDTC1 - 2” is set to TSG3nCMP1E, and 0 is set to TSG3nCMP3E and 4E.

TSG3nO1 is cleared by the match of TSG3nCNTE with TSG3nCMP1E and set by the match with TSG3nCMP2E. Here, the output is shifted according to the set value in TSG3nHSPCMUE, that is, TSG3nO1 is inactive for one cycle during PWM period when “TSG3nCMP0E + TSG3nDTC0 + TSG3nDTC1” (the maximum value of PWM output width - 1) is set, inactive for two cycles during PWM period when “TSG3nCMP0E + TSG3nDTC0 + TSG3nDTC1 - 1” (the maximum value of PWM output width - 2) is set, and so on.

Setting of TSG3nO2 by the match of TSG3nCNTE with TSG3nCMP4E and clearing by the match with TSG3nCMP3E occur simultaneously, but clearing takes precedence. Therefore, TSG3nO2 output is fixed to inactive.

When the value other than 0 is set to TSG3nHSPSHUE (U Phase PWM shift width), set/clear timing of TSG3nO1 is shifted to the right for the number of cycles set in TSG3nHSPSHUE.

The same condition applies to TSG3nO3-6, which are the output pins for V phase and W phase when the value of “TSG3nCMP0E + TSG3nDTC1 + 1 < TSG3nHSPCMUE/VE/WE < TSG3nCMP0E + TSG3nDTC0 + TSG3nDTC1 + 1” is set to TSG3nHSPCMVE (V phase PWM output width setting) and TSG3nHSPCMWE (W phase PWM output width setting).

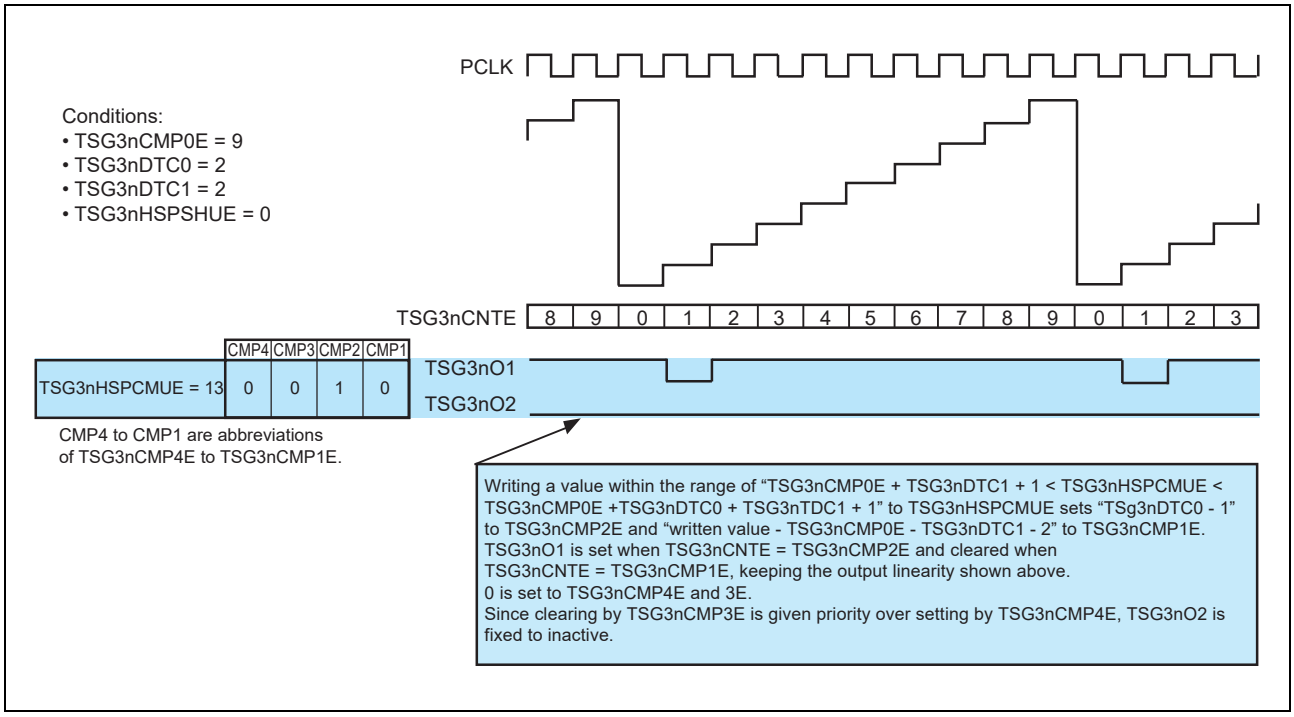

Figure 35.106 Waveform in HSP-PWM Mode (TSG3nHSPCMUE is set to TSG3nCMP0E + TSG3nDTC1 + 1 < TSG3nHSPCMUE < TSG3nCMP0E + TSG3nDTC0 + TSG3nDTC1 + 1)

(6) When TSG3nHSPCMUE/VE/WE (PWM Output Width Setting) is set to TSG3nCMP0E + TSG3nDTC0 + TSG3nDTC1 + 1

When “TSG3nCMP0E + TSG3nDTC0 + TSG3nDTC1” (the maximum value of PWM output width) is set to TSG3nHSPCMUE, “TSG3nDTC0 - 1” is set to TSG3nCMP2E, “TSG3nCMP0E + 1” is set to TSG3nCMP1E, and 0 is set to TSG3nCMP3E and 4E.

Setting of TSG3nO1 by the match of TSG3nCNTE with TSG3nCMP2E occurs when TSG3nCNTE = TSG3nDTC0 - 1.

Since TSG3nCMP0E + 1 is set to TSG3nCMP3E, TSG3nCNTE does not match TSG3nCMP3E. Therefore, TSG3nO1 output is fixed to active.

Setting of TSG3nO2 by the match of TSG3nCNTE with TSG3nCMP4E and clearing by the match with TSG3nCMP3E occur simultaneously, but clearing takes precedence. Therefore, TSG3nO2 output is fixed to inactive.

When the value other than 0 is set to TSG3nHSPSHUE, set timing of TSG3nO1 is shifted to the right for the number of cycles set in TSG3nHSPSHUE. Note that the set timing is shifted only at operation start (TSG3nTE from 0 to 1) because TSG3nO1 output is fixed to active. For the operation when operation start, see **Section 35.4.7.7, (8) Timer Output Operation at Operation Start in HSP-PWM Mode**.

The same condition applies to TSG3nO3-6, which are the output pins for V phase and W phase when “TSG3nCMP0E + TSG3nDTC0 + TSG3nDTC1 + 1” is set to TSG3nHSPCMVE (V phase PWM output width setting) and TSG3nHSPCMWE (W phase PWM output width setting).

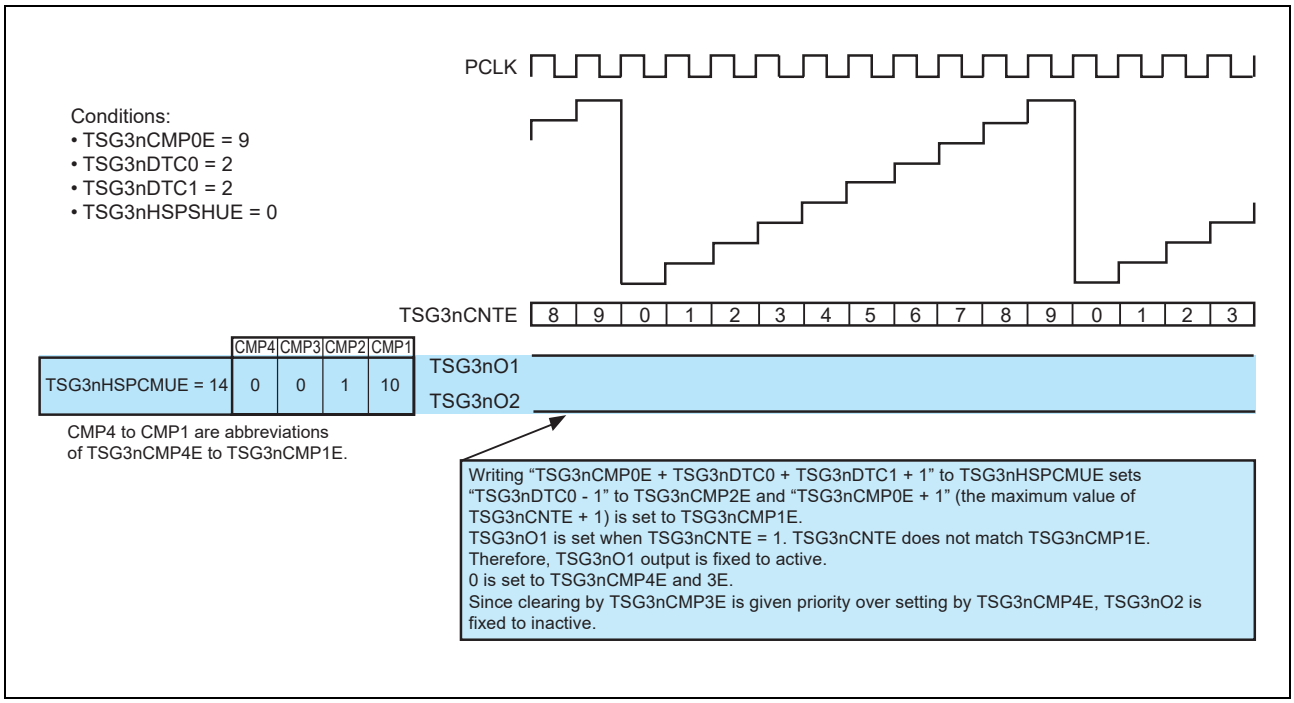

Figure 35.107 Waveform in HSP-PWM (TSG3nHSPCMUE is set to TSG3nCMP0E + TSG3nDTC0 + TSG3nDTC1 + 1)

NOTES

1. In HSP-PWM mode, TSG3nO1 and TSG3nO2 can be set at the same timing by setting the same value to TSG3nCMP4E and 2E. In this case, both TSG3nO1 and TSG3nO2 become inactive.
2. In HSP-PWM mode, dead time counter keeps operating even when TSG is stopped (TSG3nTE = 0) and the dead time set in TSG3nO1 and TSG3nO2 are always inserted.

(7) PWM Adjustment at Reload Timing in HSP-PWM Mode

In HSP-PWM mode, PWM output width is adjusted when TSG3nHSPCMUE/VE/WE (PWM output width setting) is modified during operation. TSG3nO1-6 are set/cleared at reload timing and immediately switched to the output reflecting the new PWM output width.

TSG3nO1-6 are forcibly set/cleared according to the following formula. Even for adjustment, the dead time set with TSG3nDTC0 and 1 is always inserted to TSG3nO1-6. If values are directly written to TSG3nCMP1-12E, output adjustment is not performed at reload timing.

Formula for reload adjustment operation

Table 35.100 Formula for Reload Adjustment Operation When TSG3nHSPSHUE/VE/WE is 0 (PWM shift width is set to 0)

Pin	Set	Clear
TSG3nO1/3/5	CMP0E + DTC1 + 1 < HSPCMUE/VE/WE	HSPCMUE/VE/WE ≤ CMP0E + DTC1 + 1
TSG3nO2/4/6	HSPCMUE/VE/WE = 0	0 < HSPCMUE/VE/WE

Table 35.101 Formula for Reload Adjustment Operation When TSG3nHSPSHUE/VE/WE is not 0 (PWM shift width is not set to 0)

Pin	Set	Clear
TSG3nO1/3/5	(i) CMP0E + DTC1 + 1 – HSPSHUE/VE/WE < HSPCMUE/VE/WE	HSPCMUE/VE/WE ≤ CMP0E + DTC1 + 1 – HSPSHUE/VE/WE
	(ii) (CMP0E + 1) × 2 + DTC1 – HSPSHUE/VE/WE < HSPCMUE/VE/WE	HSPCMUE/VE/WE ≤ (CMP0E + 1) × 2 + DTC1 – HSPSHUE/VE/WE
TSG3nO2/4/6	HSPCMUE/VE/WE ≤ CMP0E + 1 – HSPSHUE/VE/WE	CMP0E + 1 – HSPSHUE/VE/WE < HSPCMUE/VE/WE

If the value other than 0 is set as PWM shift width, set/clear condition for positive phase is determined whether the set shift width is greater than “CMP0E + DTC0 – 1” or not.

(i) HSPSHUE/VE/WE ≤ CMP0 – DTC0 + 1

(ii) HSPSHUE/VE/WE > CMP0 – DTC0 + 1

“TSG3n” is omitted from the register names used in the calculation.

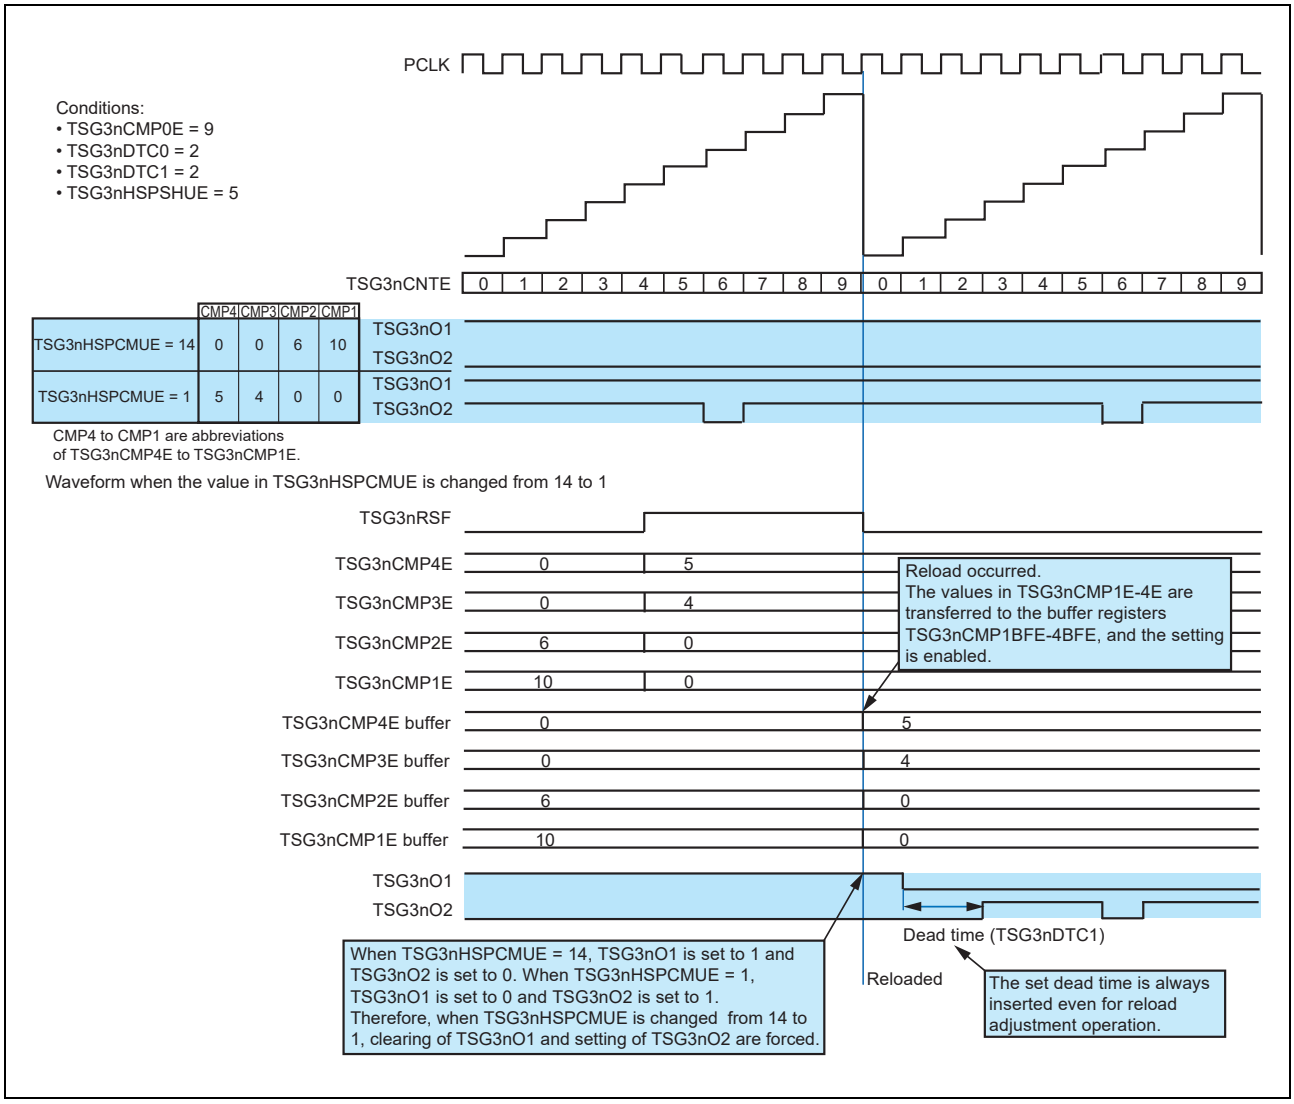

Figure 35.108 Detailed Timing Diagram of Reload Adjustment (Change of TSG3nHSPCMUE from 14 to 1)

(8) Timer Output Operation at Operation Start in HSP-PWM Mode

In HSP-PWM mode, TSG3nO1-6 are cleared when operation starts.

Then, TSG3nO1-6 are set/cleared as TSG3nCNTE counts up depending on the values set in TSG3nHSPCMUE/VE/WE (TSG3nCMP1E to 12E).

Even if TSG3nO1-6 are set before operation start and cleared at operation start, and then set again, the set dead time is always inserted.

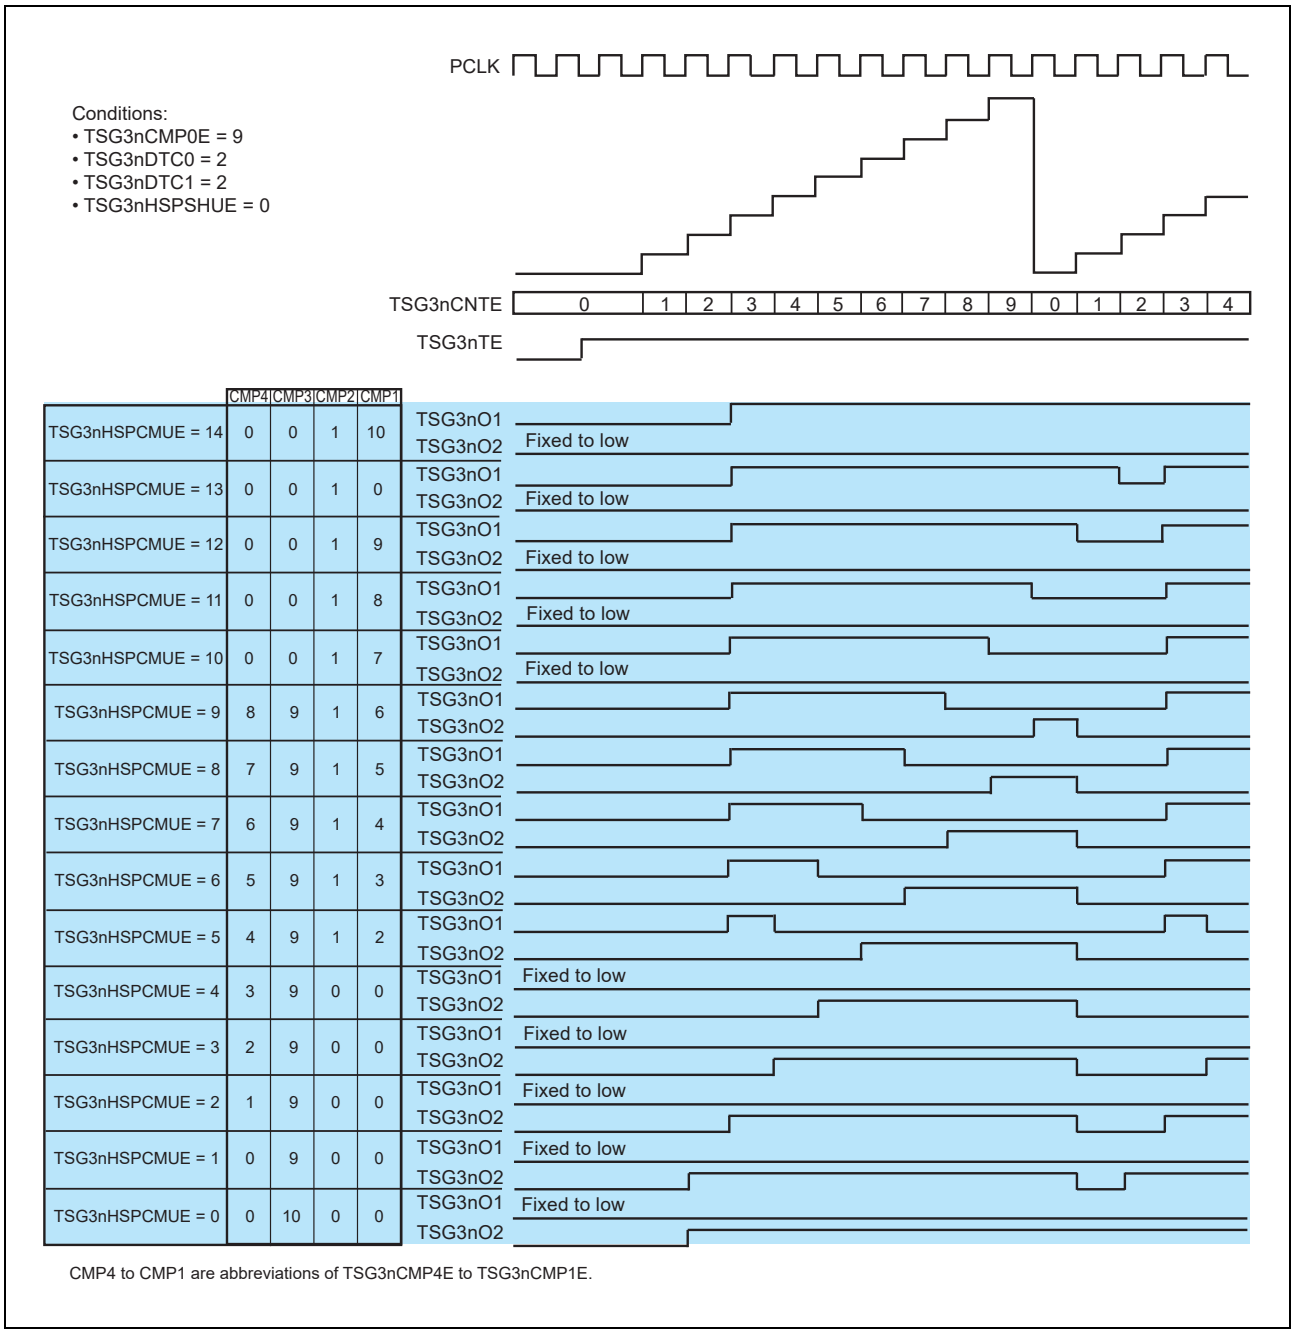

Figure 35.109 Timing Diagram of Operation Start in HSP-PWM Mode (TSG3nHSPSHUE = 0 (shift width is set to 0))

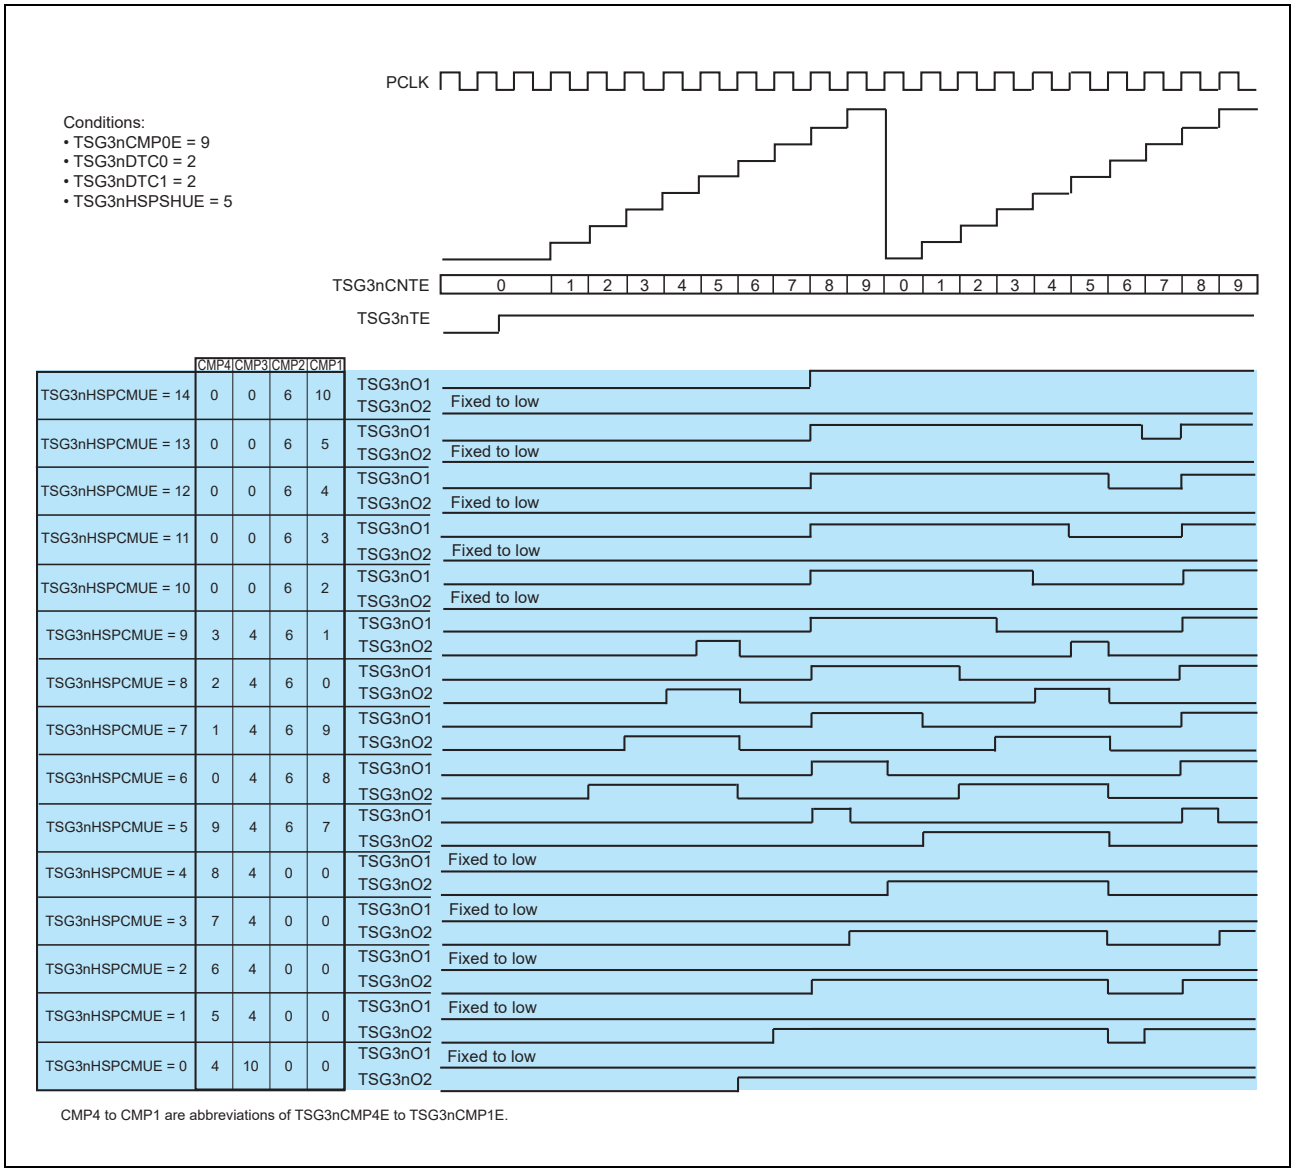

Figure 35.110 Timing Diagram of Operation Start in HSP-PWM Mode (TSG3nHSPSHUE = 5 (shift width is set to five clock cycles))

35.4.7.8 Software Output Control Function

Software output control function is available in any mode except HSP-PWM mode. This function can switch between six output patterns for the TSG3nO1 to TSG3nO6 pins using TSG3nOPT0.TSG3nSOC, TSG3nIDC, and TSG3nOPT0.TSG3nSPC2-0.

When TSG3nSOC is switched from 0 to 1, the output control method of the TSG3nO1 to TSG3nO6 pins is switched to the software output control immediately. On the other hand, when TSG3nSOC is switched from 1 to 0, the software output control is released at the reload timing.

Table 35.102 Registers Associated with Software Output Control Function

Register	Operation
TSG3nOPT0.TSG3nSOC	TSG3nSOC = 1
TSG3nOPT0.TSG3nSTE	TSG3nSTE = 0
TSG3nOPT1.TSG3nSPC2-TSG3nSPC0	Sets output patterns listed in the following **Table 35.103** and **Table 35.104**.
TSG3nOPT0.TSG3nIDC	Sets output pattern (electric current direction).

Table 35.103 Output Patterns by Software Output Control (TSG3nOPT0.TSG3nIDC = 0)

TSG3nOPT0.TSG3nSOC = 1, TSG3nSTE = 0, TSG3nIDC = 0

Section 36 Timer Option (TAPA)

This section contains a generic description of the Timer Option (TAPA).

The first part in this section describes the RH850/U2A-EVA specific properties, such as the number of units, register base addresses, etc.

The remainder of the section describes the functions and registers of the TAPA.

36.1 Features TAPA for RH850/U2A-EVA

36.1.1 Number of Units

This microcontroller has the following number of TAPA units.

Table 36.1 Number of Units

Product Name	RH850/ U2A-EVA (516 pins)	RH850/ U2A16 (516 pins)	RH850/ U2A16 (373 pins)	RH850/ U2A16 (292 pins)	RH850/ U2A8 (373 pins)	RH850/ U2A8 (292 pins)	RH850/ U2A6 (292 pins)	RH850/ U2A6 (176 pins)	RH850/ U2A6 (156 pins)	RH850/ U2A6 (144 pins)
Number of units	4 (n = 0 to 3)	4 (n = 0 to 3)	4 (n = 0 to 3)	4 (n = 0 to 3)	4 (n = 0 to 3)	4 (n = 0 to 3)	4 (n = 0 to 3)	3 (n = 0, 2, 3)	2 (n = 0, 3)	2 (n = 0, 3)
Name	TAPAn									

Table 36.2 Index

Index	Description
n	Throughout this section, the individual TAPA units are identified by the index “n” (n = 0 to 3), for example, TAPAnFLG for the TAPAn flag register.

36.1.2 Register Base Addresses

TAPA register addresses are given as offsets from the given base address. Each of the TAPAn base addresses <TAPAn_base> is listed in the following table.

Table 36.3 Register Base Addresses

Base Address Name	Base Address	Bus Group
<TAPA0_base>	FFBF 9000$_H$	P-Bus Group 5
<TAPA1_base>	FFBF 9100$_H$	P-Bus Group 5
<TAPA2_base>	FFBF 9200$_H$	P-Bus Group 5
<TAPA3_base>	FFBF 9300$_H$	P-Bus Group 5

36.1.3 Clock Supply

Clock supply by and to TAPA is listed in the following table.

Table 36.4 Clock Supply

Unit Name	Unit Clock Name	Supply Clock Name
TAPAn	PCLK	CLK_HSB

36.1.4 Interrupt Requests and Error Notifications

TAPAn interrupt requests are listed in the following table.

Table 36.5 Interrupt Requests

Unit Interrupt Name	Description	Interrupt Number	DMA Trigger Number	DTS Trigger Number
TAPA0				
INTTAPA0IPEK0	Peak interrupt 0	27	—	—
INTTAPA0IVLY0	Valley interrupt 0	28	—	—

This module has no error notifications.

36.1.5 Reset Sources

TAPAn reset sources are listed in the following table. TAPAn is initialized by these reset sources.

Table 36.6 Reset Sources

Unit Name	Register Name	Reset Condition						
		Power On Reset	System Reset 1	System Reset 2	Application Reset	DeepSTOP Reset	Module Reset	JTAG Reset
TAPAn	All registers	√	√	√	√	√	√	—

36.1.6 Internal Input/Output Signal

The internal input/output signals of TAPAn are listed below.

Table 36.7 Internal Input/Output Signals

TAPAn Signal	Function	Connected to
TAPA0		
TAPA0THASIN	TAPA0 asynchronous Hi-Z control signal*1	PIC1
TAPA0TSIM0	TAUD master channel interrupt signal (TAUD0: INTTAUD0I0,I NTTAUD0I2, INTTAUD0I8)	PIC1
TAPA0TUDCM0	TAUD master up/down signal (TAUD0: TAUD0UDC0, TAUD0UDC2, TAUD0UDC8)	PIC1
TAPA0TCDENS0	TAUD slave 0 match detect	PIC2
TAPA0TCDENS1	TAUD slave 1 match detect	PIC2
$\overline{\text{TAPA0THZOUT0}}$	TAPA0UP/TAPA0UN output buffers Hi-Z control output	Port
$\overline{\text{TAPA0THZOUT1}}$	TAPA0VP/TAPA0VN output buffers Hi-Z control output	Port
$\overline{\text{TAPA0THZOUT2}}$	TAPA0WP/TAPA0WN output buffers Hi-Z control output	Port
TAPA0TADOUT0	A/D trigger signal 0 output	PIC2
TAPA0TADOUT1	A/D trigger signal 1 output	PIC2
TAPA1		
TAPA1THASIN	TAPA1 asynchronous Hi-Z control signal	PIC1
$\overline{\text{TAPA1THZOUT0}}$	TAUD1O10, TAUD1O11 output buffers Hi-Z control output	Port
$\overline{\text{TAPA1THZOUT1}}$	TAUD1O12, TAUD1O13 output buffers Hi-Z control output	Port
$\overline{\text{TAPA1THZOUT2}}$	TAUD1O14, TAUD1O15 output buffers Hi-Z control output	Port
TAPA2		
TAPA2THASIN	TAPA2 asynchronous Hi-Z control signal	PIC1
$\overline{\text{TAPA2THZOUT0}}$	TSG30O1-TSG30O6 output buffers Hi-Z control output	Port
TAPA3		
TAPA3THASIN	TAPA3 asynchronous Hi-Z control signal	PIC1
$\overline{\text{TAPA3THZOUT0}}$	TSG31O-TSG31O6 output buffers Hi-Z control output	Port

Note 1. See **Section 41.2.3.13, Hi-Z Control Function** for details.

36.1.7 Peripheral Configuration

The following figure shows the peripheral configuration of TAPA.

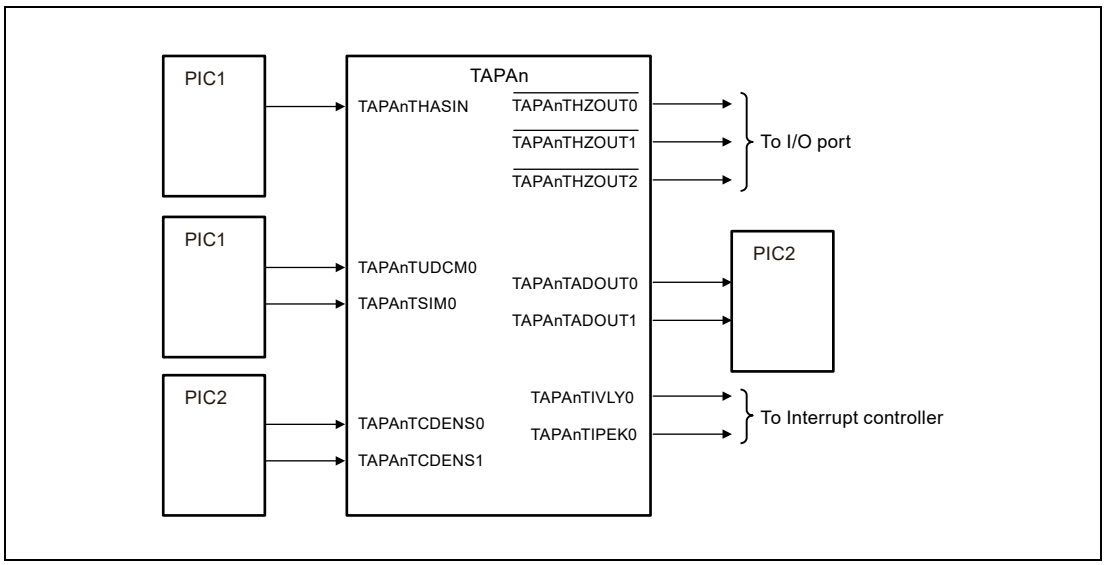

Figure 36.1 Peripheral Configuration of TAPA

The following describes the peripheral configuration of TAPA.

- TAPAnTHASIN: Hi-Z control asynchronous input signal

  This signal controls Hi-Z by the source selected in PIC1.

  For the sources that can be selected in PIC1, see **Section 41.2.3.13, Hi-Z Control Function**.

- TAPAnTUDCM0: TAUD master channel up/down input

- TAPAnTSIM0: TAUD master 0 INT input

  Peak and valley interrupts can be generated on TAUDn channels selected in PIC1.

  For TAUDn channels that can be selected in PIC1, see **Section 41.2.2.18, PIC1REG200 — Timer Input/Output Control Register 200** and **Section 41.2.2.19, PIC1REG210 — Timer Input/Output Control Register 210**.
  Only TAPA0 has this connection.

- TAPAnTCDENS0, TAPAnTCDENS1: TAUD slave channel match detection input

  The TAUDn channel interrupts selected in PIC2 can be handled as A/D conversion trigger outputs 0 and 1 (TAPAnTADOUT1 and TAPAnTADOUT0). For the TAUDn channel interrupts that can be selected in PIC, see **Section 36.4.3, A/D Converter Conversion Trigger Selection Function**.
  Only TAPA0 has this connection.

- TAPAnTADOUT1-0: A/D conversion trigger outputs 1 and 0

  The A/D conversion trigger signals generated on TAPAn are outputs to PIC2. The setting of the PIC2 can also be used to set these signals as triggers for A/D conversion. For the register specifications in the PIC2, see **Section 41.3.3.1, ADCJ Trigger Select Function**.
  Only TAPA0 has this connection.

36.2 Overview

36.2.1 Functional Overview

- Asynchronous Hi-Z control function
  Hi-Z control for TAUDn (n = 0, 1), TSG3n (n = 0, 1) output can be performed by using pin input or error signals.
- Interrupt signals output function
  Request signals for two types of interrupts, peak interrupts and valley interrupts, can be output by the INTn signals output by TAUDn (n = 0).
- A/D conversion start trigger selection function
  An A/D conversion start trigger can be output by the INTn signals output by TAUDn (n = 0).

36.2.2 Block Diagram

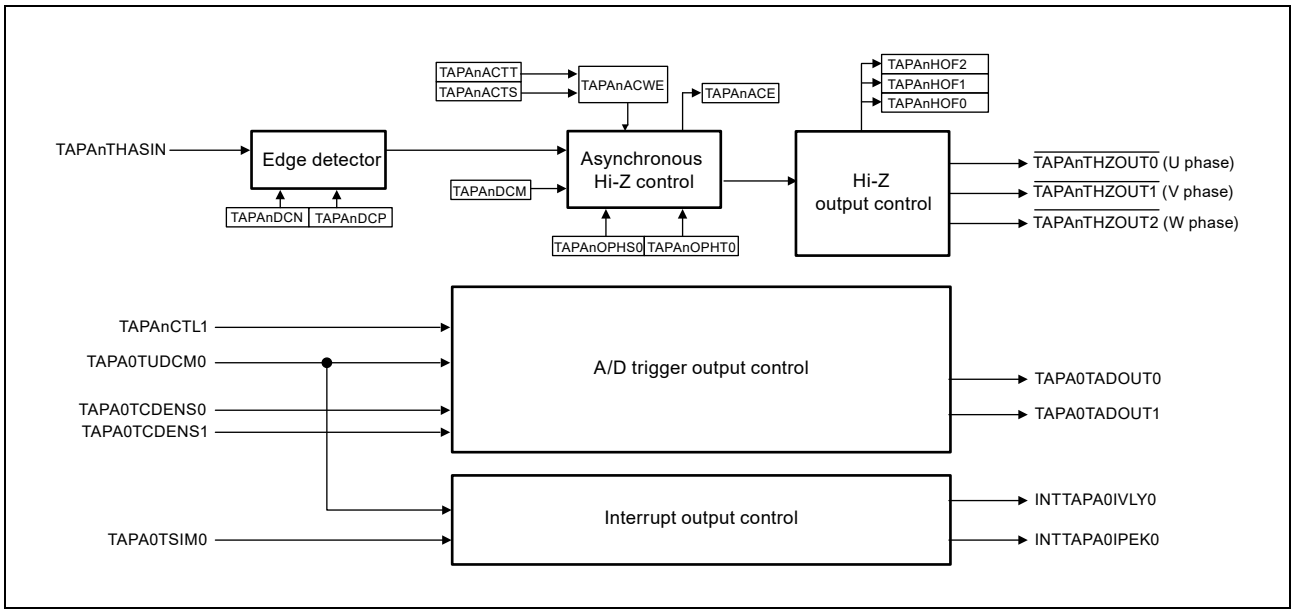

Figure 36.2 Block Diagram

36.2.3 Definition of Terms

Peak and valley interrupts - Peak and valley of timer counter.

In this document, the period from a TAUD counting-up status to generation of INT from the master channel is defined as a peak period, and this INT is defined as a peak interrupt.

In contrast, the period from a TAUD counting-down status to generation of INT from the master channel is defined as a valley period, and this INT is defined as a valley interrupt.

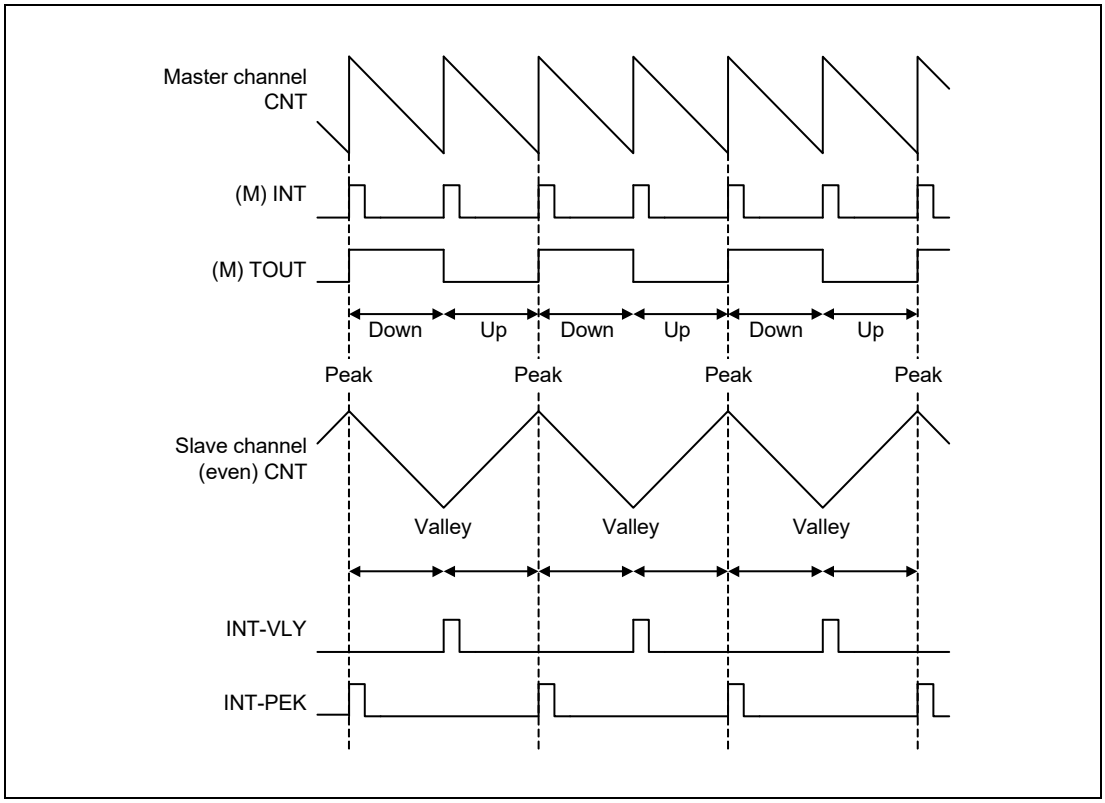

Figure 36.3 Peak and Valley Interrupts

36.3 Registers

36.3.1 List of Registers

TAPAn (n = 0 to 3) registers are listed in the following table.

<TAPAn_base> is defined in **Section 36.1.2, Register Base Addresses**.

Table 36.8 List of Registers

Module	Register Name	Symbol	Address	Access Protection	
				PBG	Other
TAPAn	TAPAn control register 0	TAPAnCTL0	<TAPAn_base> + 20_H	*2	—
TAPAn	TAPAn control register 1	TAPAnCTL1*1	<TAPAn_base> + 24_H	*2	—
TAPAn	TAPAn flag register	TAPAnFLG	<TAPAn_base> + 00_H	*2	—
TAPAn	TAPAn asynchronous control write enable register	TAPAnACWE	<TAPAn_base> + 04_H	*2	—
TAPAn	TAPAn asynchronous control start trigger register	TAPAnACTS	<TAPAn_base> + 08_H	*2	—
TAPAn	TAPAn asynchronous control stop trigger register	TAPAnACTT	<TAPAn_base> + $0C_H$	*2	—
TAPAn	TAPAn Hi-Z start trigger register	TAPAnOPHS	<TAPAn_base> + 14_H	*2	—
TAPAn	TAPAn Hi-Z stop trigger register	TAPAnOPHT	<TAPAn_base> + 18_H	*2	—

Note 1. TAPAnCTL1 is only available in TAPA0 (n = 0 only).

Note 2. n = 0: PBG51#10
n = 1: PBG51#11
n = 2: PBG51#12
n = 3: PBG51#13

36.3.2 TAPAnCTL0 — TAPAn Control Register 0

- This register is used to set up the asynchronous Hi-Z control function.
- The values of this register can be rewritten only when TAPAnFLG.TAPAnACE is 0 and TAUDnTEm for the corresponding TAUD's master channel is 0.

Access This register can be read or written in 16-bit units.

Address <TAPAn_base> + 20_H

Value after reset 0000_H

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	TAPAnDCM	TAPAnDCN	TAPAnDCP	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R	R

Table 36.9 TAPAnCTL0 Register Contents

Bit Position	Bit Name	Function
15 to 5	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
4	TAPAnDCM	Clear Condition Configuration This control bit specifies the clear conditions for Hi-Z control output. 0: Enables manipulation of TAPAnOPHT0 regardless of the TAPAnTHASIN signal input level. 1: Enables manipulation of TAPAnOPHT0 only if the TAPAnTHASIN signal input is inactive.
3, 2	TAPAnDCN, TAPAnDCP	Hi-Z Input Edge Selection These control bits specify the valid edge of TAPAnTHASIN.
1, 0	Reserved	When read, the value after reset is returned. When writing, write the value after reset.

TAPAn DCN	TAPAn DCP	Description
0	0	Does not detect valid edges
0	1	Detects a rising edge as the valid edge (active level = high)
1	0	Detects a falling edge as the valid edge (active level = low)
1	1	Setting is prohibited.

36.3.3 TAPAnCTL1 — TAPAn Control Register 1

This register is used to set up the asynchronous Hi-Z control function.

Access This register can be read or written in 8-bit units.

Address <TAPAn_base> + 24_H

Value after reset 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	TAPAnATS3	TAPAnATS2	TAPAnATS1	TAPAnATS0
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R/W	R/W	R/W	R/W

Table 36.10 TAPAnCTL1 Register Contents

Bit Position	Bit Name	Function
7 to 4	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
3, 2	TAPAnATS3, TAPAnATS2	A/D Conversion Trigger 1 Selection These are control bits that specify A/D conversion trigger output 1 (TAPA0TADOUT1).

TAPAnATS3	TAPAnATS2	Description
0	0	INT signal while the triangle wave is falling (counting down)
0	1	INT signal while the triangle wave is rising (counting up)
1	0	INT signal while the triangle wave is rising (counting up) or falling (counting down)
1	1	INT signal while the triangle wave is rising (counting up) or falling (counting down) and valley interrupt INTTAPA0IVLY0 signal

Bit Position	Bit Name	Function
1, 0	TAPAnATS1, TAPAnATS0	A/D Conversion Trigger 0 Selection These are control bits that specify A/D conversion trigger output 0 (TAPA0TADOUT0).

TAPAnATS1	TAPAnATS0	Description
0	0	INT signal while the triangle wave is falling (counting down)
0	1	INT signal while the triangle wave is rising (counting up)
1	0	INT signal while the triangle wave is rising (counting up) or falling (counting down)
1	1	INT signal and valley interrupt INTTAPA0IVLY0 signal while the triangle wave is rising (counting up) or falling (counting down)

36.3.4 TAPAnFLG — TAPAn Flag Register

This flag register is for asynchronous Hi-Z control.

Access This register is a read-only register that can be read in 16-bit units.

Address <TAPAn_base> + 00_H

Value after reset 0000_H

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	TAPAnHOF2	TAPAnHOF1	TAPAnHOF0	—	—	—	—	—	—	—	TAPAnACE
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 36.11 TAPAnFLG Register Contents

Bit Position	Bit Name	Function
15 to 11	Reserved	When read, the value after reset is returned.
10	TAPAnHOF2	W phase Hi-Z Control Monitor This bit is used to monitor the Hi-Z control status. 0: The present output of $\overline{\text{TAPAnTHZOUT2}}$ is high level. 1: The present output of $\overline{\text{TAPAnTHZOUT2}}$ is low level.
9	TAPAnHOF1	V phase Hi-Z Control Monitor This bit is used to monitor the Hi-Z control status. 0: The present output of $\overline{\text{TAPAnTHZOUT1}}$ is high level. 1: The present output of $\overline{\text{TAPAnTHZOUT1}}$ is low level.
8	TAPAnHOF0	U phase Hi-Z Control Monitor This bit is used to monitor the Hi-Z control status. 0: The present output of $\overline{\text{TAPAnTHZOUT0}}$ is high level. 1: The present output of $\overline{\text{TAPAnTHZOUT0}}$ is low level.
7 to 1	Reserved	When read, the value after reset is returned.
0	TAPAnACE	Asynchronous Hi-Z Control Enable 0: Indicates that the asynchronous Hi-Z control is stopped. 1: Indicates that the asynchronous Hi-Z control is enabled. The conditions for setting or clearing this bit are as follows: Clear condition: Writing 1 to TAPAnACTT while TAPAnACWE = 1 Set condition: Writing 1 to TAPAnACTS while TAPAnACWE = 1

Note: TAPAnHOFm (m = 1, 2) is enabled when TAPAn (n = 0, 1).

36.3.5 TAPAnACWE — TAPAn Asynchronous Control Write Enable Register

This register is used to enable writing for asynchronous Hi-Z control.

Access This register can be read or written in 8-bit units.

Address <TAPAn_base> + 04_H

Value after reset 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	TAPAnACWE
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R/W

Table 36.12 TAPAnACWE Register Contents

Bit Position	Bit Name	Function
7 to 1	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
0	TAPAnACWE	Asynchronous Control Write Enable This is a write-enable bit for asynchronous Hi-Z control. After 1 is written, this bit is automatically cleared to 0 by writing 1 to TAPAnACTS and TAPAnACTT. 0: Disables writing to TAPAnACTS and TAPAnACTT. 1: Enables writing to TAPAnACTS and TAPAnACTT.

36.3.6 TAPAnACTS — TAPAn Asynchronous Hi-Z Control Start Trigger Register

This register is used to enable the start trigger for asynchronous Hi-Z control.

Access This register is a write-only register that can be written in 8-bit units. This register is always read as 00_H.

Address <TAPAn_base> + 08_H

Value after reset 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	TAPAnACTS
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	W

Table 36.13 TAPAnACTS Register Contents

Bit Position	Bit Name	Function
7 to 1	Reserved	When writing, write the value after reset.
0	TAPAnACTS	Asynchronous Hi-Z Control Start Trigger This bit enables the start trigger for asynchronous Hi-Z control. The setting of this bit is valid only when TAPAnACWE = 1. 0: Writing 0 is ignored (no function). 1: Enables asynchronous Hi-Z control if TAPAnACWE = 1.

36.3.7 TAPAnACTT — TAPAn Asynchronous Hi-Z Control Stop Trigger Register

This bit enables the stop trigger for asynchronous Hi-Z control.

Access This register is a write-only register that can be written in 8-bit units. This register is always read as 00_H.

Address <TAPAn_base> + $0C_H$

Value after reset 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	TAPAnACTT
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	W

Table 36.14 TAPAnACTT Register Contents

Bit Position	Bit Name	Function
7 to 1	Reserved	When writing, write the value after reset.
0	TAPAnACTT	Asynchronous Hi-Z Control Stop Trigger This bit enables the stop trigger for asynchronous Hi-Z control. The setting of this bit is valid only when TAPAnACWE = 1. 0: Writing 0 is ignored (no function). 1: Disables asynchronous Hi-Z control if TAPAnACWE = 1.

36.3.8 TAPAnOPHS — TAPAn Hi-Z Start Trigger Register

This software trigger register is used to start Hi-Z control for motor control output pins.

Access This register is a write-only register that can be written in 8-bit units. This register is always read as 00_H.

Address <TAPAn_base> + 14_H

Value after reset 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	TAPAnOPHS0
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	W

Table 36.15 TAPAnOPHS Register Contents

Bit Position	Bit Name	Function
7 to 1	Reserved	When writing, write the value after reset.
0	TAPAnOPHS0	Hi-Z Control Start Trigger This bit starts Hi-Z control for motor control output pins. 0: Writing 0 is ignored (no function). 1: Starts Hi-Z control.

36.3.9 TAPAnOPHT — TAPAn Hi-Z Stop Trigger Register

This software trigger register is used to stop Hi-Z control for motor control output pins.

Access This register is a write-only register that can be written in 8-bit units. This register is always read as 00_H.

Address <TAPAn_base> + 18_H

Value after reset 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	TAPAnOPHT0
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	W

Table 36.16 TAPAnOPHT Register Contents

Bit Position	Bit Name	Function
7 to 1	Reserved	When writing, write the value after reset.
0	TAPAnOPHT0	Hi-Z Control Stop Trigger This bit stops Hi-Z control for motor control output pins. 0: Writing 0 is ignored (no function). 1: Stops Hi-Z control. Whether the setting of this bit is valid or invalid depends on the setting of TAPAnCTL0.TAPAnDCM.

36.4 Operation

36.4.1 Asynchronous Hi-Z Control Function

Abnormal operation in timer motor-control under CPU control leads to rotation of the externally connected motor also becoming abnormal. In such cases, this function forcibly sets the motor control output to the Hi-Z state, independently of control by the CPU.

36.4.1.1 Overview

The following method is available for controlling Hi-Z.

- Asynchronous input Hi-Z control by Hi-Z control asynchronous input signal (TAPAnTHASIN)
  - Controls the Hi-Z control output signals $\overline{\text{TAPAnTHZOUT0}}$ (U phase), $\overline{\text{TAPAnTHZOUT1}}$ (V phase), $\overline{\text{TAPAnTHZOUT2}}$ (W phase) asynchronously at TAPAn (n = 0, 1).
  - Controls the Hi-Z control output signals $\overline{\text{TAPAnTHZOUT0}}$ asynchronously at TAPAn (n = 2, 3).
- Motor control output in a Hi-Z state can be resumed by writing the Hi-Z stop trigger register (TAPAnOPHT0).
- The Hi-Z state of motor control output can also be specified by writing the Hi-Z control start trigger register (TAPAnOPHS).
- Setting PIC can enable or disable Hi-Z control input when an error occurs.

Table 36.17 Asynchronous Hi-Z Control and Its Operation

Function	Operation
Asynchronous Hi-Z control corresponding to the pin input	This function detects asynchronous pin inputs and forcibly stops TOUTn output from the corresponding timer module (TAUD, TSG3) in response. Device port outputs become Hi-Z while TAPAnTHASIN is active and until software sends a stop request.

36.4.2 System Configuration Example

A system configuration example is shown below, where an external error detection signal (the TAPAnESO signal, n = 0, 1) is used for Hi-Z control of the motor control outputs (TAPA0UP/ TAPA0UN/TAPA0VP/TAPA0VN/TAPA0WP/TAPA0WN, TAUD1O10/TAUD1O11/TAUD1O12/ TAUD1O13/TAUD1O14/TAUD1O15, TSG30O1/TSG30O2/TSG30O3/TSG30O4/TSG30O5/ TSG30O6, TSG31O1/TSG31O2/TSG31O3/TSG31O4/TSG31O5/TSG31O6).

When valid edges of the external error detection signal are detected, the level of the motor control outputs is set to Hi-Z.

Because the microcontroller might freeze when an error occurs, external error detection signals are continuously processed so that the motor control timer outputs can be set to Hi-Z even if no clock is supplied.

Note that an error is detected only when the valid edge of the error detection signal is detected. Therefore, no error is detected if the output level is fixed and the signal level does not change.

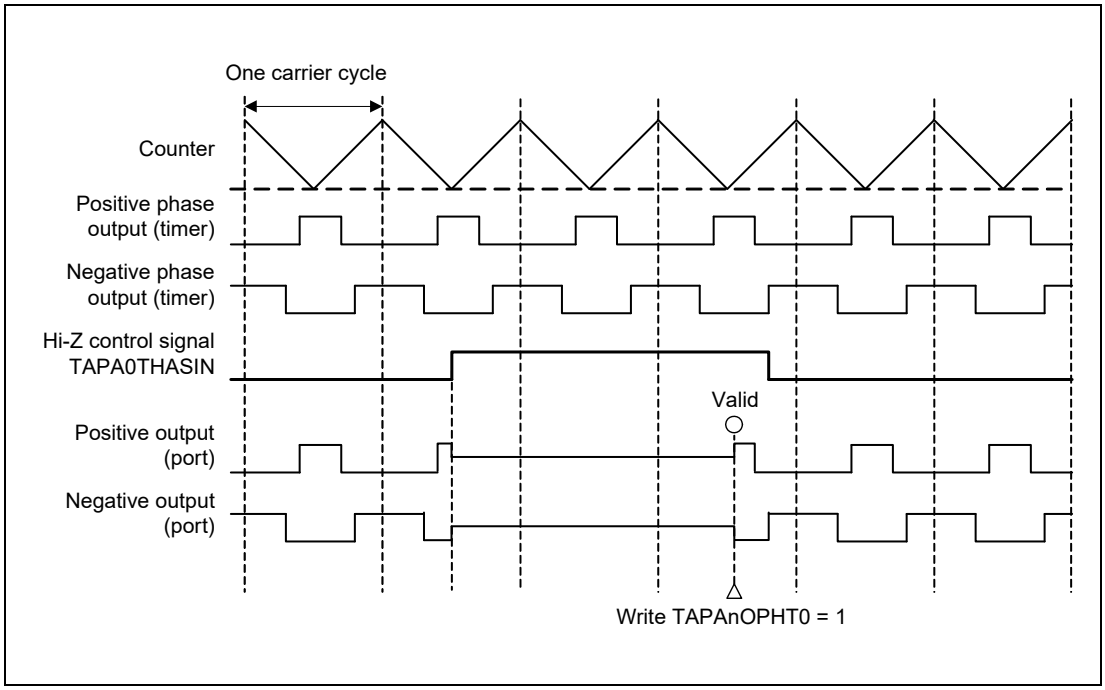
36.4.2.1 Basic Operation

Hi-Z control for motor control output pins can be started as follows:

- Detecting the valid edge of asynchronous Hi-Z control signal (TAPAnTHASIN)
- Setting the start trigger bit TAPAnOPHS.TAPAnOPHS0 of the Hi-Z control signal

The levels of the motor control output pins are set to Hi-Z until the stop trigger bit of the Hi-Z control signal (TAPAnOPHT.TAPAnOPHT0) is set. Note that whether the setting of TAPAnOPTH0 is valid or invalid depends on the setting of TAPAnCTL0.TAPAnDCM.

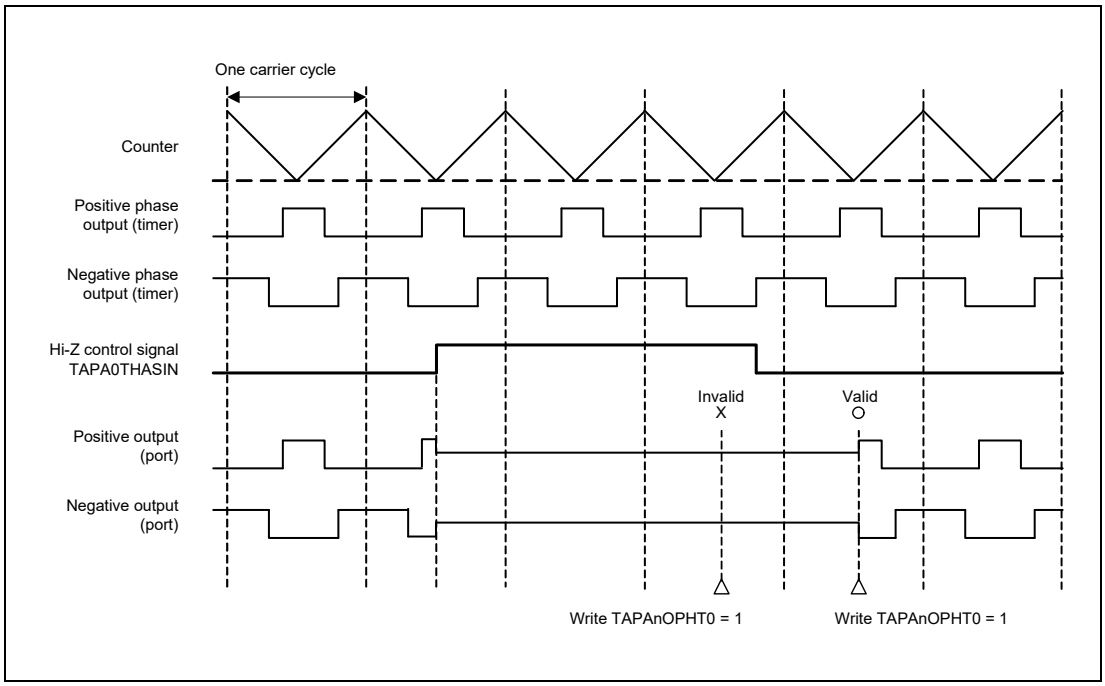
(1) Operation when TAPAnCTL0.TAPAnDCM = 0, TAPAnDCP = 1, and TAPAnDCN = 0



The motor control outputs are forcibly stopped (Hi-Z output) when the valid edge of TAPAnTHASIN is detected.

The motor control outputs restart when 1 is written to TAPAnOPHT.TAPAnOPHT0, regardless of the level of TAPAnTHASIN.

(2) Operation when TAPAnCTL0.TAPAnDCM = 1, TAPAnDCP = 1, and TAPAnDCN = 0



The motor control outputs are forcibly stopped (Hi-Z output) when the valid edge of TAPAnTHASIN is detected.

Writing 1 to the stop trigger bit (TAPAnOPHT.TAPAnOPHT0) of the Hi-Z control signal is ignored while TAPAnTHASIN is active (high level because TAPAnCTL0.TAPAnDCP is 1).

The motor control outputs restart when 1 is written to TAPAnOPHT.TAPAnOPHT0 after TAPAnTHASIN becomes inactive (low level because TAPAnCTL0.TAPAnDCP is 1).

36.4.2.2 Asynchronous Hi-Z Control Using Software Trigger

Hi-Z control for motor control output is possible by using the Hi-Z control start trigger bit TAPAnOPHS.TAPAnOPHS0 and Hi-Z control stop trigger bit TAPAnOPHT.TAPAnOPHT0.

(1) Function of Hi-Z control start trigger bit TAPAnOPHS.TAPAnOPHS0

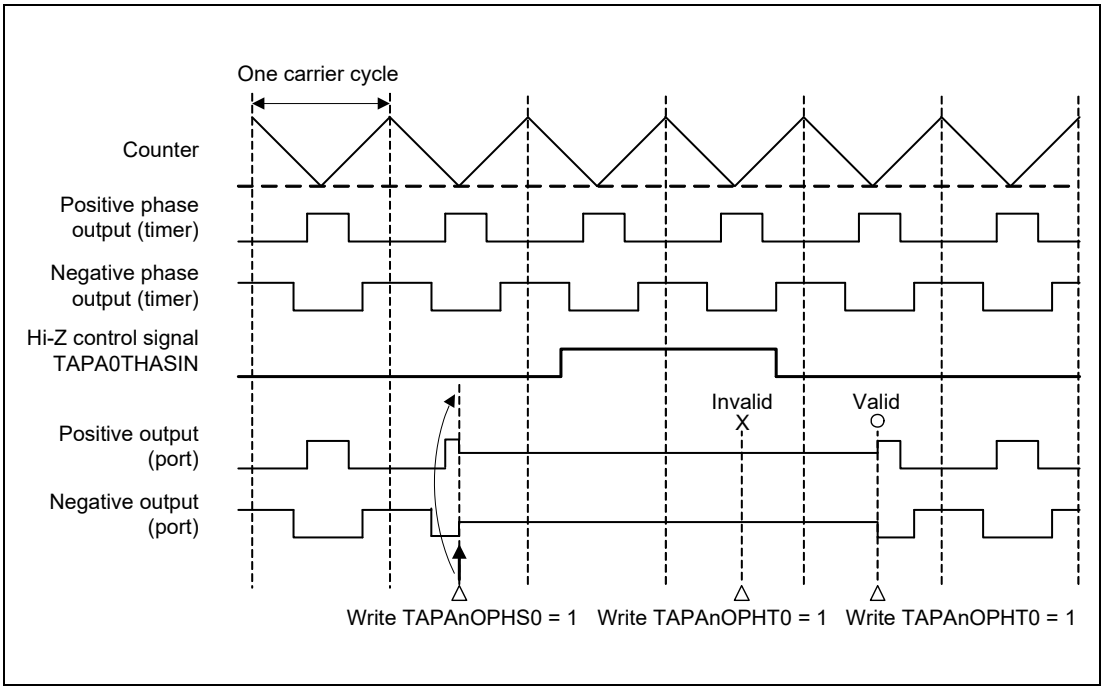
TAPAnDCM	Function
0/1	Writing 1 to TAPAnOPHS0 starts Hi-Z control and forcibly stops the motor control output (Hi-Z output).

(2) Function of Hi-Z control stop trigger bit TAPAnOPHT.TAPAnOPHT0

Whether the Hi-Z control stop trigger is valid or invalid depends on the conditions below:

TAPAnDCM	Function
0	Writing 1 to TAPAnOPHT0 stops Hi-Z control and restarts motor control output.
1	If TAPAnTHASIN is inactive, writing 1 to TAPAnOPHT0 stops Hi-Z control and restarts motor control output. If TAPAnTHASIN is active, writing 1 to TAPAnOPHT0 is ignored.

(3) Operation when TAPAnCTL0.TAPAnDCM = 1, TAPAnDCP = 1, and TAPAnDCN = 0



The motor control output (Hi-Z output) is forcibly stopped when 1 is written to TAPAnOPHS0.

After that, the level of the motor control output remains Hi-Z even if the rising edge of TAPAnTHASIN is detected.

Writing to TAPAnOPHT0 is ignored while TAPA0THASIN is active (high level because TAPAnDCN is 0 and TAPAnDCP is 1).

After detection of the falling edge of TAPA0THASIN, the motor control output restarts when 1 is written to TAPAnOPHT0 while TAPA0THASIN is inactive (low level because TAPAnDCN is 0 and TAPAnDCP is 1).

36.4.2.3 Operating Procedure

The operating procedure for the asynchronous input Hi-Z control function is shown below:

	Operation	Status of TAPA
Initial setup	Set up the TAPAnCTL0 register. Specify TAPAnDCP and TAPAnDCN to select the input edge. Specify TAPAnDCM to select the clear mode.	Asynchronous Hi-Z control stopped (TAPAnFLG.TAPAnACE = 0)
Start operation	Set up the TAPAnACWE register. Set TAPAnACWE to 1. Set up the TAPAnACTS register. Set TAPAnACTS to 1.	Writing to TAPAnACTS is enabled. Asynchronous Hi-Z control enabled (TAPAnFLG.TAPAnACE = 1)
During operation	Hi-Z control for the timer function outputs can be started by controlling the following: • TAPAnOPHS register • Asynchronous Hi-Z control signal (TAPA0THASIN) Hi-Z control for the timer function outputs can be stopped by controlling the following: • TAPAnOPHT register (If TAPAnDCM is 1, control by the TAPAnOPHT register is enabled only while TAPA0THASIN is inactive.) The TAPA operating status can always be read using the TAPAnFLG register.	Hi-Z control for the motor control output pins is started by detecting the valid edge of the asynchronous Hi-Z control signal (TAPA0THASIN) or by setting the Hi-Z control start trigger bit TAPAnOPHS0 to 1. Hi-Z control for the motor control output pins is stopped by setting the Hi-Z control stop trigger bit TAPAnOPHT0 to 1 according to the operation mode specified by the TAPAnDCM bit.
Stop operation	Set up the TAPAnACWE register. Set TAPAnACWE to 1. Set up the TAPAnACTT register. Set TAPAnACTT to 1.	Writing to TAPAnACTT is enabled. Asynchronous Hi-Z control stopped (TAPAnFLG.TAPAnACE = 0)

Restart

36.4.3 A/D Converter Conversion Trigger Selection Function

This function outputs the A/D converter conversion trigger signals TAPA0TADOUT0 and TAPA0TADOUT1 from the TAPA0TCDENS0 and TAPA0TCDENS1 signals, which are connected to a compare match interrupt based on the triangular carrier cycle of TAUD, or a valley interrupt signal (INTTAPA0IVLY0).

36.4.3.1 Configuration of A/D Converter Conversion Trigger Selection Function

Table 36.18 Signals Used for TAPA0TADOUT Generation

Output Signal	Slave Match Detection Signal	Valley Interrupt Signal
TAPA0TADOUT0	TAPA0TCDENS0	INTTAPA0IVLY0
TAPA0TADOUT1	TAPA0TCDENS1	INTTAPA0IVLY0

Table 36.19 Operation of TAPA0TADOUT1 According to the Setting of TAPAnCTL1.TAPAnATS[3:2]

TAPAnATS3	TAPAnATS2	Description
0	0	Outputs the INT signal from TAPA0TADOUT1 while the triangle wave is falling (counting down).
0	1	Outputs the INT signal from TAPA0TADOUT1 while the triangle wave is rising (counting up).
1	0	Outputs the INT signal from TAPA0TADOUT1 while the triangle wave is rising (counting up) or falling (counting down).
1	1	Outputs the INT signal while the triangle wave is rising (counting up) or falling (counting down) and valley interrupt INTTAPA0IVLY0 from TAPA0TADOUT1.

Table 36.20 Operation of TAPA0TADOUT0 According to the Setting of TAPAnCTL1.TAPAnATS[1:0]

TAPAnATS1	TAPAnATS0	Description
0	0	Outputs the INT signal from TAPA0TADOUT0 while the triangle wave is falling (counting down).
0	1	Outputs the INT signal from TAPA0TADOUT0 while the triangle wave is rising (counting up).
1	0	Outputs the INT signal from TAPA0TADOUT0 while the triangle wave is rising (counting up) or falling (counting down).
1	1	Outputs the INT signal while the triangle wave is rising (counting up) or falling (counting down) and valley interrupt INTTAPA0IVLY0 from TAPA0TADOUT0.

36.4.3.2 Block Diagram

The interrupt request signal of each channel of TAUD0 is masked and OR'ed, and output to TAPA0 as the TAUD0 trigger signal.

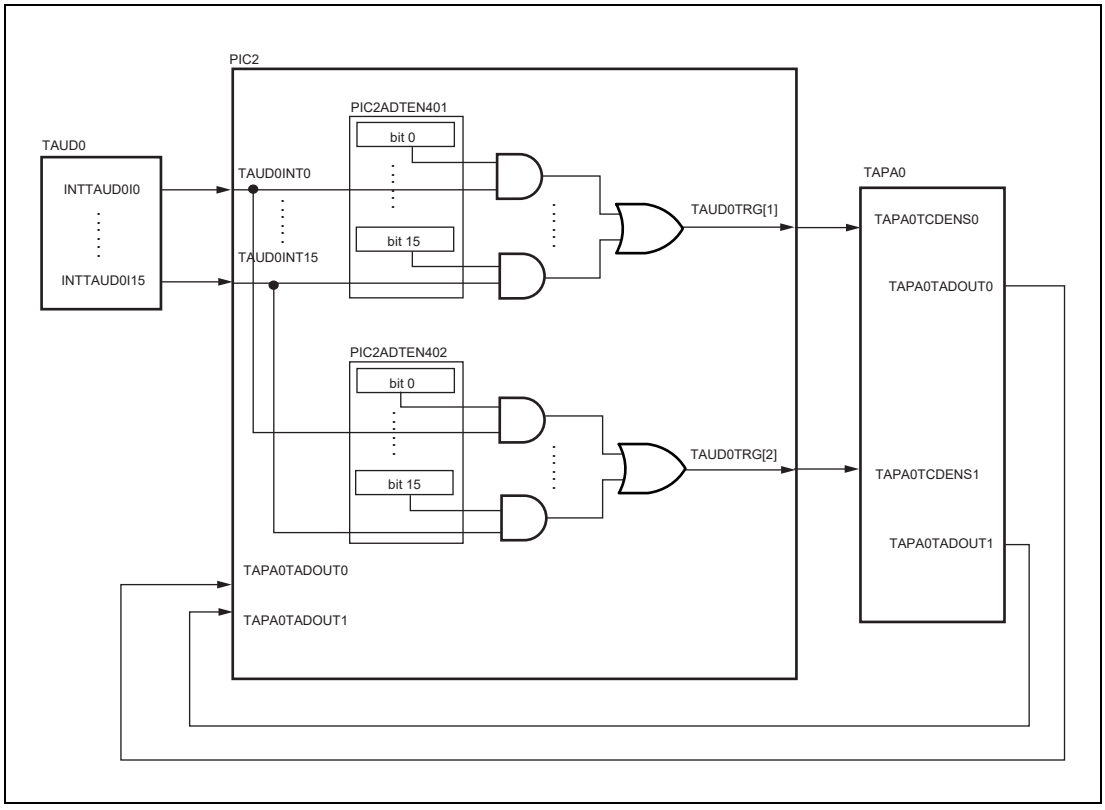


Figure 36.4 Block Diagram of A/D Conversion Trigger Selection Function

CAUTION

This function is only available for the scan groups 1 and 2 of ADCJ0-1. When using this function with the scan groups 1 and 2, select the TAUD trigger via TAPA. Do not select the TAUD trigger directly by the ADCJ trigger select function.

36.4.3.3 Waveforms of A/D Converter Conversion Trigger Output Control Operation in Triangle PWM Mode

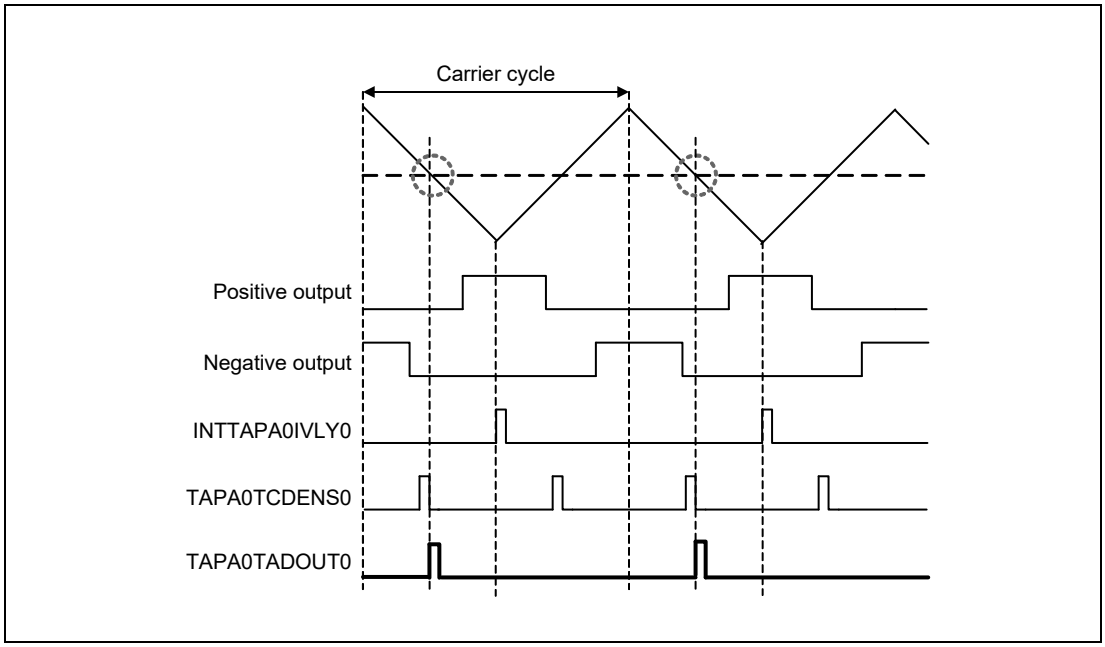

Figure 36.5 TAPAnATS[1:0] bits = 00_B: Output INT Signal while the Triangle Wave is Falling (Counting Down)

While the triangle wave is falling (counting down), the signals TAPA0TCDENS0 and TAPA0TCDENS1 are output as the A/D converter conversion trigger signals TAPA0TADOUT0 and TAPA0TADOUT1.

In this case, no A/D converter conversion trigger signal is output while the triangle wave is rising (counting up).

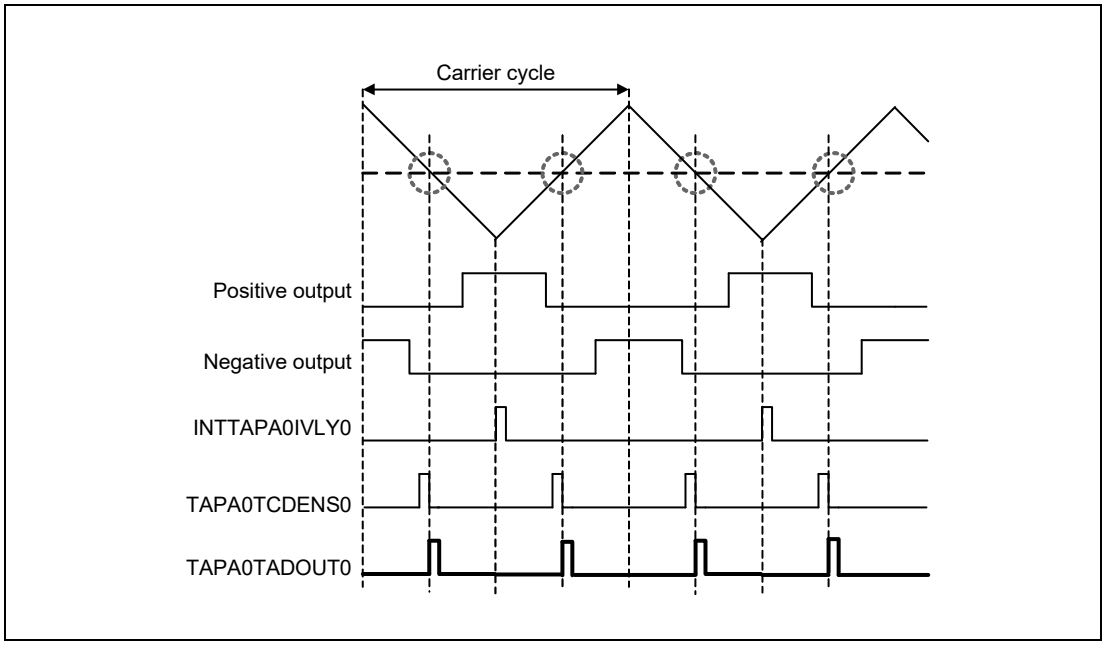

Figure 36.6 TAPAnATS[1:0] bits = 10_B: Output INT Signal while the Triangle Wave is Rising (Counting Up) or Falling (Counting Down)

The signals TAPA0TCDENS0 and TAPA0TCDENS1 are output as the A/D converter conversion trigger signals TAPA0TADOUT0 and TAPA0TADOUT1.

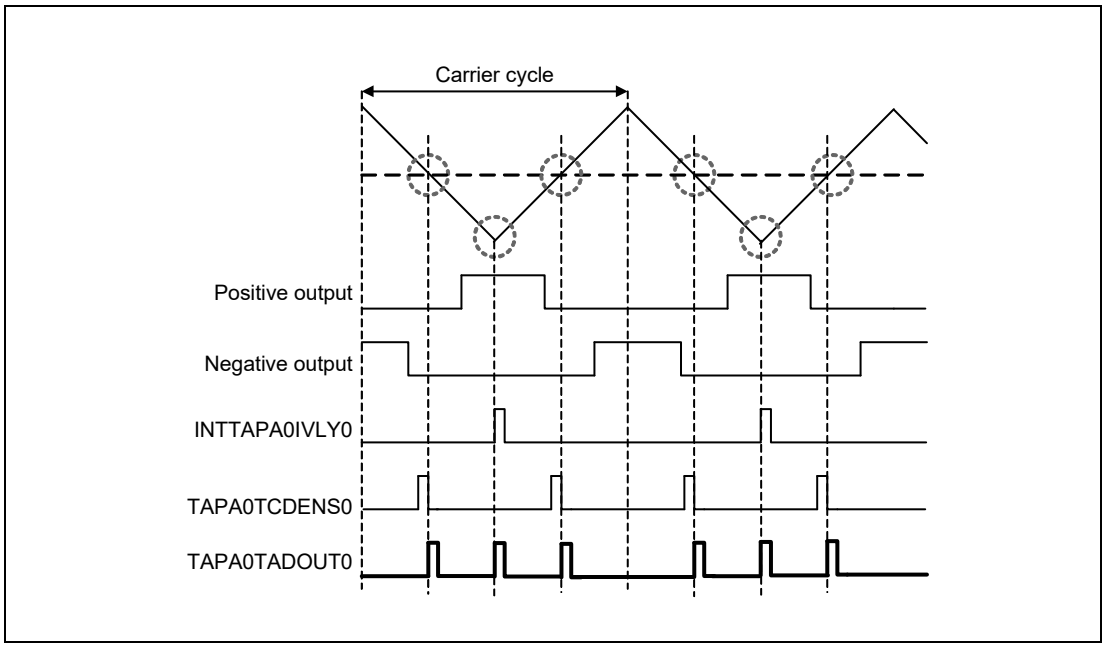

Figure 36.7 TAPAnATS[1:0] bits = 11B: Output of INT Signal and Valley Interrupt while the Triangle Wave is Rising (Counting Up) or Falling (Counting Down)

The signals TAPA0TCDENS0 and TAPA0TCDENS1 and valley interrupt INTTAPA0IVLY0 are output as the A/D converter conversion trigger signals TAPA0TADOUT0 and TAPA0TADOUT1.

36.4.3.4 Operating Procedure for A/D Converter Conversion Trigger Selection Function

The operating procedure for the A/D converter conversion trigger selection function is shown below.

	Operation	Status of TAUD and TAPA
Initial setup	Initialize TAUD. Specify the timer operation mode. Set up the TAPAnCTL1 register. Specify TAPAnATS[1:0] (TAPA0TADOUT0 setting). Specify TAPAnATS[3:2] (TAPA0TADOUT1 setting). Set up the PIC2ADTEN4nj and PIC0REG2n0 registers according to the signal to be used. Specify PIC2ADTEN4nj (TAPA0TCDENS0 or TAPA0TCDENS1 setting). Specify PIC0REG2n0 (INTTAPA0IVLY0 setting).	TAUD and TAPA stop the operation.
Start operation	Start the TAUD operation.	TAUD starts the count operation.
During operation	TAUD operates according to the setting of each function.	The A/D conversion trigger selection function outputs either TAPA0TADOUT0 according to the setting of TAPAnATS[1:0] or TAPA0TADOUT1 according to the setting of TAPAnATS[3:2], based on the interrupt TAPA0TCDENS1 or TAPA0TCDENS0, which is input from TAUD, and the valley interrupt INTTAPA0IVLY0, which is generated by TAPA.
Stop operation	Stop the TAUD operation.	TAUD stops the count operation.

Restart

Section 37 Timer Pattern Buffer (TPBA)

The Timer Pattern Buffer (TPBA) is 16-bit PWM timer with the duty setting buffer. TPBA is implemented 2 units.

37.1 Features of TPBA for RH850/U2A-EVA

37.1.1 Units and Channels

This microcontroller has the following number of TPBA units.

Each TPBA unit has one channel interface.

Table 37.1 Number of Units

Product Name	RH850/ U2A-EVA (516 pins)	RH850/ U2A16 (516 pins)	RH850/ U2A16 (373 pins)	RH850/ U2A16 (292 pins)	RH850/ U2A8 (373 pins)	RH850/ U2A8 (292 pins)	RH850/ U2A6 (292 pins)	RH850/ U2A6 (176 pins)	RH850/ U2A6 (156 pins)	RH850/ U2A6 (144 pins)
Number of units	2 (n = 0, 1)	2 (n = 0, 1)	2 (n = 0, 1)	2 (n = 0, 1)	2 (n = 0, 1)	2 (n = 0, 1)	2 (n = 0, 1)	2 (n = 0, 1)	2 (n = 0, 1)	2 (n = 0, 1)
Name	TPBAn									

Table 37.2 Index

Index	Description
n	Throughout this section, the individual TPBA units are identified by the index “n” (n = 0, 1); for example, TPBAnCTL is the TPBAn control register.
m	The number of buffers are indicated by the index “m” (m = 00 to 63).

37.1.2 Register Base Addresses

TPBA base addresses are listed in the following table.

TPBA register addresses are given as offsets from the base addresses in general.

Table 37.3 Register Base Addresses

Base Address Name	Base Address	Bus Group
<TPBA0_base>	FFBF A000$_H$	P-Bus Group 5
<TPBA1_base>	FFBF A800$_H$	P-Bus Group 5

37.1.3 Clock Supply

Clock supply by and to TPBA is listed in the following table.

Table 37.4 Clock Supply

Unit Name	Unit Clock Name	Supply Clock Name	Description
TPBAn	PCLK	CLK_HSB	Peripheral high speed clock

37.1.4 Interrupt Requests and Error Notifications

TPBA interrupt requests are listed in the following table.

Table 37.5 Interrupt and DMA/DTS Requests

Unit Interrupt Name	Description	Interrupt Number	DMA Trigger Number	DTS Trigger Number
TPBA0				
INTTPBA0IPRD	TPBA0 Period match detection interrupt	528	Group0-167	Group3-92
INTTPBA0IDTY	TPBA0 Duty match detection interrupt	529	Group0-168	Group3-93
INTTPBA0IPAT	TPBA0 Pattern number matching detection interrupt	530	Group0-169	Group3-94
TPBA1				
INTTPBA1IPRD	TPBA1 Period match detection interrupt	531	Group0-170	Group3-95
INTTPBA1IDTY	TPBA1 Duty match detection interrupt	532	Group0-171	Group3-96
INTTPBA1IPAT	TPBA1 Pattern number matching detection interrupt	533	Group0-172	Group3-97

This module has no error notifications.

37.1.5 Reset Sources

TPBA reset sources are listed in the following table. TPBAn is initialized by these reset sources.

Table 37.6 Reset Sources

Unit Name	Register Name	Reset Condition						
		Power On Reset	System Reset 1	System Reset 2	Application Reset	DeepSTOP Reset	Module Reset	JTAG Reset
TPBAn	All registers	√	√	√	√	√	√	—

37.1.6 External Input/Output Signals

External input/output signals of TPBA are listed in the following table.

Table 37.7 External Input/Output Signals

Unit Signal Name	I/O	Description	Alternative Port Pin Signal Name
TPBA0			
TPBA0O	O	Timer output	TPBA0O
TPBA1			
TPBA1O	O	Timer output	TPBA1O

37.2 Overview

37.2.1 Functional Overview

TPBAn is a 16-bit PWM timer with the duty setting buffer.

- Count clock resolution: Min. 12.5 ns (count clock: 80 MHz)
- 16-bit counter
- 16-bit duty register
- 16-bit period setting register
- 7-bit address counter register
- 7-bit pattern number setting register
- Interrupt request signals
  - Period-matched detection interrupt
  - Duty-cycle-matched detection interrupt
  - Number-of-patterns matched detection interrupt
- Number of duty patterns
  - 64 patterns (16 bits) or 128 patterns (8 bits)
- Automatic duty generation according to the number of patterns
- Output control by software
- The count clock can be selected from PCLK, PCLK/2, PCLK/4, and PCLK/8 according to the prescaler set value.
- Synchronous start with another timer

37.2.2 Block Diagram

The following block diagram shows the main components of TPBA.

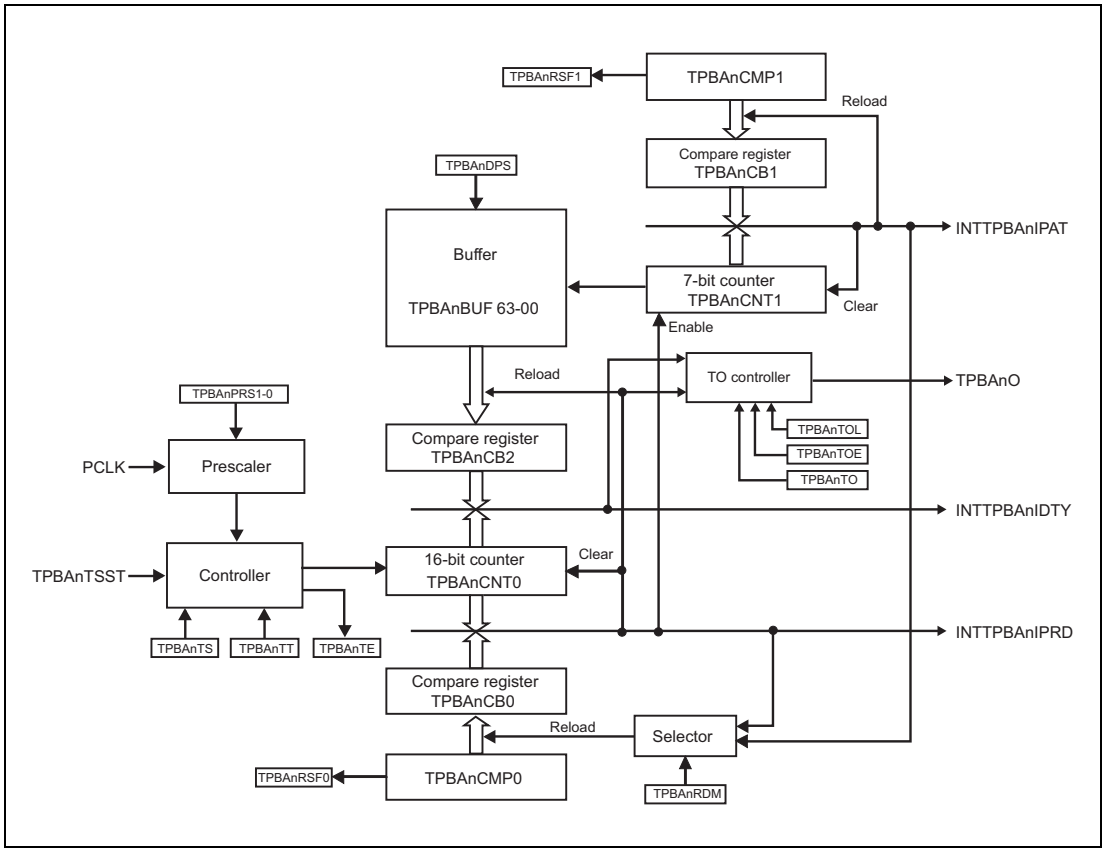

Figure 37.1 Block Diagram of TPBA

- TPBAnTSST Simultaneous start trigger (input by PIC function)

37.3 Registers

37.3.1 List of Registers

TPBA registers are listed in the following table.

For information on <TPBAn_base>, see **Section 37.1.2, Register Base Addresses**.

Table 37.8 List of Registers

Module Name	Register Name	Symbol	Address	Access size	Access Protection	
					PBG	Other
TPBAn	TPBAn control register	TPBAnCTL	<TPBAn_base> + 200_H	8	*1	—
	TPBAn reload data mode register	TPBAnRDM	<TPBAn_base> + 118_H	8	*1	—
	TPBAn reload status register	TPBAnRSF	<TPBAn_base> + 110_H	8	*1	—
	TPBAn reload data trigger register	TPBAnRDT	<TPBAn_base> + 114_H	8	*1	—
	TPBAn timer output enable register	TPBAnTOE	<TPBAn_base> + 120_H	8	*1	—
	TPBAn timer output register	TPBAnTO	<TPBAn_base> + $11C_H$	8	*1	—
	TPBAn timer output level register	TPBAnTOL	<TPBAn_base> + 124_H	8	*1	—
	TPBAn period setting register	TPBAnCMP0	<TPBAn_base> + 100_H	16	*1	—
	TPBAn duty setting register	TPBAnBUFm	<TPBAn_base> + m × 4_H	16	*1	—
	TPBAn pattern number setting register	TPBAnCMP1	<TPBAn_base> + 104_H	8	*1	—
	TPBAn timer counter register	TPBAnCNT0	<TPBAn_base> + 108_H	16	*1	—
	TPBAn address counter register	TPBAnCNT1	<TPBAn_base> + $10C_H$	8	*1	—
	TPBAn enable status register	TPBAnTE	<TPBAn_base> + 128_H	8	*1	—
	TPBAn start trigger register	TPBAnTS	<TPBAn_base> + $12C_H$	8	*1	—
	TPBAn stop trigger register	TPBAnTT	<TPBAn_base> + 130_H	8	*1	—

Note 1. n = 0: PBG51#14
n = 1: PBG51#15

37.3.2 TPBAnCTL — TPBAn Control Register

This register specifies the operation of the TPBAn.

Access: This register can be read/written in 8-bit units.

Address: <TPBAn_base> + 200_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	TPBAnPRS[1:0]		—	—	—	TPBAnDPS
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R/W	R/W	R	R	R	R/W

Table 37.9 TPBAnCTL Register Contents

Bit Position	Bit Name	Function
7, 6	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
5, 4	TPBAnPRS[1:0]	Selects the count clock.
3 to 1	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
0	TPBAnDPS	Selects the duty setting pattern mode. 0: 16 bits × 64 patterns mode 1: 8 bits × 128 patterns mode

TPBAnPRS1	TPBAnPRS0	Description
0	0	PCLK is selected.
0	1	PCLK/2 is selected.
1	0	PCLK/4 is selected.
1	1	PCLK/8 is selected.

CAUTION

This register should be set when the timer is stopped (TPBAnTE = 0). If this register is erroneously rewritten, set the register again after stopping the timer.

37.3.3 TPBAnRDM — TPBAn Reload Data Mode Register

This register controls the reload timing of the TPBAn period setting register and TPBAn timer output level register values.

Access: This register can be read/written in 8-bit units.

Address: <TPBAn_base> + 118_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	TPBAnRDM0
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R/W

Table 37.10 TPBAnRDM Register Contents

Bit Position	Bit Name	Function
7 to 1	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
0	TPBAnRDM0	Controls the reload timing of the TPBAn period setting register (TPBAnCMP0) and TPBAn timer output level register (TPBAnTOL) values. 0: Reloads the values synchronously with a number-of-patterns matched detection interrupt (INTTPBAnIPAT). 1: Reloads the values synchronously with a period-matched detection interrupt (INTTPBAnIPRD).

CAUTION

Although this register can be rewritten during operation, the rewritten value is reflected immediately. Accordingly, during operation, this register should be rewritten when the reload request flag (TPBAnRSF) is 0.

37.3.4 TPBAnRSF — TPBAn Reload Status Register

This register indicates whether or not reload requests from the corresponding registers have been generated.

Access: This register can be read in 8-bit units.

Address: <TPBAn_base> + 110_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	TPBAnRSF1	TPBAnRSF0
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R

Table 37.11 TPBAnRSF Register Contents

Bit Position	Bit Name	Function
7 to 2	Reserved	When read, the value after reset is returned.
1	TPBAnRSF1	Indicates whether or not a reload request from TPBAnCMP1 has been generated. 0: No reload request generated or reload completed. 1: Reload request has been generated. This bit is set to 1 when 1 is written to the TPBAnRDT1 bit in the TPBAnRDT register. This bit is cleared at the timing when reload is performed.
0	TPBAnRSF0	Indicates whether or not a reload request from TPBAnCMP0 and TPBAnTOL has been generated. 0: No reload request generated or reload completed. 1: Reload request has been generated. This bit is set to 1 when 1 is written to the TPBAnRDT0 bit in the TPBAnRDT register. This bit is cleared at the timing when reload is performed.

37.3.5 TPBAnRDT — TPBAn Reload Data Trigger Register

This register enables reload of the register values.

Access: This register can be written in 8-bit units. It is always read as 0.

Address: <TPBAn_base> + 114_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	TPBAnRDT1	TPBAnRDT0
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	W	W

Table 37.12 TPBAnRDT Register Contents

Bit Position	Bit Name	Function
7 to 2	Reserved	When writing, write the value after reset.
1	TPBAnRDT1	Enables reload of the TPBAnCMP1 values. 0: Write access is ignored. 1: Reload is enabled (TPBAnRSF1 is set to 1). The values are updated simultaneously at the next reload timing (reload).
0	TPBAnRDT0	Enables reload of the TPBAnCMP0 and TPBAnTOL values. 0: Write access is ignored. 1: Reload is enabled (TPBAnRSF0 is set to 1). The values are updated simultaneously at the next reload timing (reload).

37.3.6 TPBAnTOE — TPBAn Timer Output Enable Register

This register enables or disables the timer output.

Access: This register can be read/written in 8-bit units.

Address: <TPBAn_base> + 120_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	TPBAnTOE0
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R/W

Table 37.13 TPBAnTOE Register Contents

Bit Position	Bit Name	Function
7 to 1	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
0	TPBAnTOE0	Enables or disables the timer output (TPBAnO). 0: Disables the timer output based on counter operation. 1: Enables the timer output based on counter operation. • When the timer output is disabled, the level specified in TPBAnTO is output from the TPBAnO pin, and can be controlled by software. • When the timer output is enabled, TPBAnTO is set or cleared by the timer operation, and a PWM signal is output. Write access is prohibited (ignored).

37.3.7 TPBAnTO — TPBAn Timer Output Register

This register controls or reads timer output level.

Access: This register can be read/written in 8-bit units.

Address: <TPBAn_base> + $11C_H$

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	TPBAnTO0
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R/W

Table 37.14 TPBAnTO Register Contents

Bit Position	Bit Name	Function
7 to 1	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
0	TPBAnTO0	Sets or indicates the output level of TPBAnO pin • When the timer output is disabled (TPBAnTOE.TPBAnTOE0 = 0) 0: Outputs low level. 1: Outputs high level. The output level can be controlled by rewriting this register while the timer output is disabled. • When the timer output is enabled (TPBAnTOE.TPBAnTOE0 = 1) 0: Low level is being output by the timer output. 1: High level is being output by the timer output. When the timer output is enabled, rewrite to this register is ignored.

37.3.8 TPBAnTOL — TPBAn Timer Output Level Register

This register controls the timer output level.

Access: This register can be read/written in 8-bit units.

Address: <TPBAn_base> + 124_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	TPBAnTOL0
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R/W

Table 37.15 TPBAnTOL Register Contents

Bit Position	Bit Name	Function
7 to 1	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
0	TPBAnTOL0	Specifies the active level of the timer output. 0: High 1: Low. • Setting of this bit is enabled when the timer output is enabled (TPBAnTOE.TPBAnTOE0 = 1). • Setting of this bit is reflected when the timer output is started, and change of the output level is reflected at the next reload timing.

CAUTION

This register is a register to be reloaded. Rewrite during timer operation is reflected at the next reload timing. For details on reload, see **Section 37.4.2, Compare Register Rewrite Operation**.

37.3.9 TPBAnCMP0 — TPBAn Period Setting Register

This is a 16-bit compare register for setting the PWM period.

Access: This register can be read/written in 16-bit units.

Address: <TPBAn_base> + 100_H

Value after reset: 0000_H

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TPBAnCMP0															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 37.16 TPBAnCMP0 Register Setting

Operating Mode	PWM Period	Minimum Value (Period)	Maximum Value (Period)
8 bits	TPBAnCMP0 + 1	1	100_H
16 bits	TPBAnCMP0 + 1	1	10000_H

CAUTION

- The PWM period is (TPBAnCMP0 + 1) count clock periods. Accordingly, for PWM output with 100% duty cycle, the maximum settable value is $FFFE_H$ (FE_H).
- This register is a register to be reloaded. Rewrite during timer operation is reflected at the next reload timing. For details on reload, see **Section 37.4.2, Compare Register Rewrite Operation**.

37.3.10 TPBAnBUFm — TPBAn Duty Setting Register

This register is a 16 × 64 buffer register for duty setting.

Access: This register can be read/written in 16-bit units.

Address: <TPBAn_base> + m × 4_H

Value after reset: 0000_H

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TPBAnBUFm															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 37.17 TPBAnBUFm Register Contents

Bit Position	Bit Name	Function
15 to 0	TPBAnBUFm15 to TPBAnBUFm0	Sets the duty value. This register can set the duty value either in 16 bits × 64 patterns mode (TPBAnDPS = 0) or 8 bits × 128 patterns mode (TPBAnDPS = 1) by setting the TPBAnDPS bit. In either mode, this register is accessed in 16-bit units by the CPU. For details, see **Section 37.4.3, Duty Rewrite Operation**.

CAUTION

The value set to this register is transferred to the duty setting buffer register (TPBAnCB2) synchronously with a period-matched detection interrupt (INTTPBAnIPRD). Rewrite during timer operation is reflected immediately. For details, see **Section 37.4.3, Duty Rewrite Operation**.

- When duty setting register with 8 bits × 128 patterns is used, the duty is set in the range from 00_H to FF_H.

  The formula to output a waveform of duty 100% is: TPBAnBUFm = TPBAnCMP0 + 1 ≤ $00FF_H$.
  Therefore, when PWM output of duty 100% is required, the maximum value of TPBAnCMP0 is $00FE_H$. When TPBAnBUFm is greater than TPBAnCMP0 + 1, duty value exceeds 100%, but the output is restricted to 100%.
- When duty setting register with 16 bits × 64 patterns is used, the duty is set in the range from 0000H to $FFFF_H$.

  The formula to output a waveform of duty 100% is: TPBAnBUFm = TPBAnCMP0 + 1 ≤ $FFFF_H$.
  Therefore, when PWM output of duty 100% is required, the maximum value of TPBAnCMP0 is $FFFE_H$.
  When TPBAnBUFm is greater than TPBAnCMP0 + 1, the duty value exceeds 100%, but the output is restricted to 100%.

37.3.11 TPBAnCMP1 — TPBAn Pattern Number Setting Register

This register sets the number of PWM output patterns.

Access: This register can be read/written in 8-bit units.

Address: <TPBAn_base> + 104_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	TPBAnCMP1						
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 37.18 TPBAnCMP1 Register Contents

Bit Position	Bit Name	Function
7	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
6 to 0	TPBAnCMP1 [6:0]	Sets the number of patterns within the following range. TPBAnDPS = 0: 0 to 63 TPBAnDPS = 1: 0 to 127

CAUTION

- This register is a register to be reloaded. Rewrite during timer operation is reflected at the next reload timing. For details on reload, see **Section 37.4.2, Compare Register Rewrite Operation**.
- If 64 or a greater number is set as the number of patterns when the duty setting pattern is in 16 bits × 64 patterns mode (TPBAnDPS = 0), the address pointer changes from 63 to 00, and the duty value is transferred from 00 again. A number-of-patterns matched detection interrupt signal (INTTPBAnIPAT) is output by the match of the specified number of patterns and the lower 7-bit values of TPBAnCNT1.

37.3.12 TPBAnCNT0 — TPBAn Timer Counter Register

This register is a timer counter register that generates PWM output.

Access: This register can only be read in 16-bit units.

Address: <TPBAn_base> + 108_H

Value after reset: $FFFF_H$

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TPBAnCNT0															
Value after reset	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

16-bit counter

This register is a counter register through which the 16-bit counter value can be read.

37.3.13 TPBAnCNT1 — TPBAn Address Counter Register

This register is a counter register that indicates the address pointer to the duty setting register.

Access: This register can only be read in 8-bit units.

Address: <TPBAn_base> + $10C_H$

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	TPBAnCNT1						
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R

7-bit counter

This register is a counter register that indicates the address of the TPBAnBUFm register.

37.3.14 TPBAnTE — TPBAn Enable Status Register

This register indicates whether the timer counter is operating or stopped.

Access: This register can only be read in 8-bit units.

Address: <TPBAn_base> + 128_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	TPBAnTE0
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R

Table 37.19 TPBAnTE Register Contents

Bit Position	Bit Name	Function
7 to 1	Reserved	When read, the value after reset is returned.
0	TPBAnTE0	Indicates whether the timer counter is operating or stopped. 0: The timer counter is stopped. 1: The timer counter is operating. • The TPBAnTE0 bit is set to 1 when 1 is written to the TPBAnTS bit or when a simultaneous start trigger is input. • The TPBAnTE0 bit is cleared to 0 when 1 is written to the TPBAnTT bit.

37.3.15 TPBAnTS — TPBAn Start Trigger Register

This register controls the timer counter start trigger.

Access: This register can only be written in 8-bit units. It is always read as 0.

Address: <TPBAn_base> + $12C_H$

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	TPBAnTS0
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	W

Table 37.20 TPBAnTS Register Contents

Bit Position	Bit Name	Function
7 to 1	Reserved	When writing, write the value after reset.
0	TPBAnTS0	This bit is a trigger bit that enables the timer counter. 0: Write access is ignored. 1: Starts counting (TPBAnTE = 1).

CAUTION

Write access to this register during counting (TPBAnTE = 1) is ignored.

37.3.16 TPBAnTT — TPBAn Stop Trigger Register

This register controls the timer counter stop trigger.

Access: This register can only be written in 8-bit units. It is always read as 0.

Address: <TPBAn_base> + 130_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	TPBAnTT0
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	W

Table 37.21 TPBAnTT Register Contents

Bit Position	Bit Name	Function
7 to 1	Reserved	When writing, write the value after reset.
0	TPBAnTT0	This bit is a trigger bit that disables the timer counter. 0: Write access is ignored. 1: Disables counting (TPBAnTE = 0).

37.4 Function

37.4.1 Basic Operation

37.4.1.1 Basic Operation of 16-Bit Counter (TPBAnCNT0)

Counting start

The 16-bit counter (TPBAnCNT0) starts counting from the value after reset $FFFF_H$.

Counter clear

The 16-bit counter is cleared by the match of the counter value and the buffer register (TPBAnCB0) set value of TPBAnCMP0.

Counter read during counting

The 16-bit counter value during counting can be read through TPBAnCNT0.

37.4.1.2 Basic Operation of 7-Bit Counter (TPBAnCNT1)

Counting start

The 7-bit counter (TPBAnCNT1) is initialized to 00_H and starts counting. Subsequently, the counter value is incremented synchronously with a period-matched detection interrupt (INTTPBAnIPRD).

Counter clear

The 7-bit counter is cleared by the match of the counter value and the buffer register (TPBAnCB1) set value of TPBAnCPM1.

Counter read during counting

The 7-bit counter value during counting can be read through TPBAnCNT1. The read value indicates TPBAnBUFm in which the duty value to be transferred next is stored.

37.4.2 Compare Register Rewrite Operation

The following registers are rewritten by reload.

- TPBAnCMP0
- TPBAnCMP1
- TPBAnTOL

Reload mode (simultaneous rewrite function)

Writing to TPBAnRDT enables reload of the registers corresponding to the set bits (sets the reload request flag (TPBAnRSF.TPBAnRSFk)), and the values of all the registers to be reloaded are updated simultaneously at the next reload timing (reload).

The reload timing of TPBAnCMP0 and TPBAnTOL is set by TPBAnRDM.

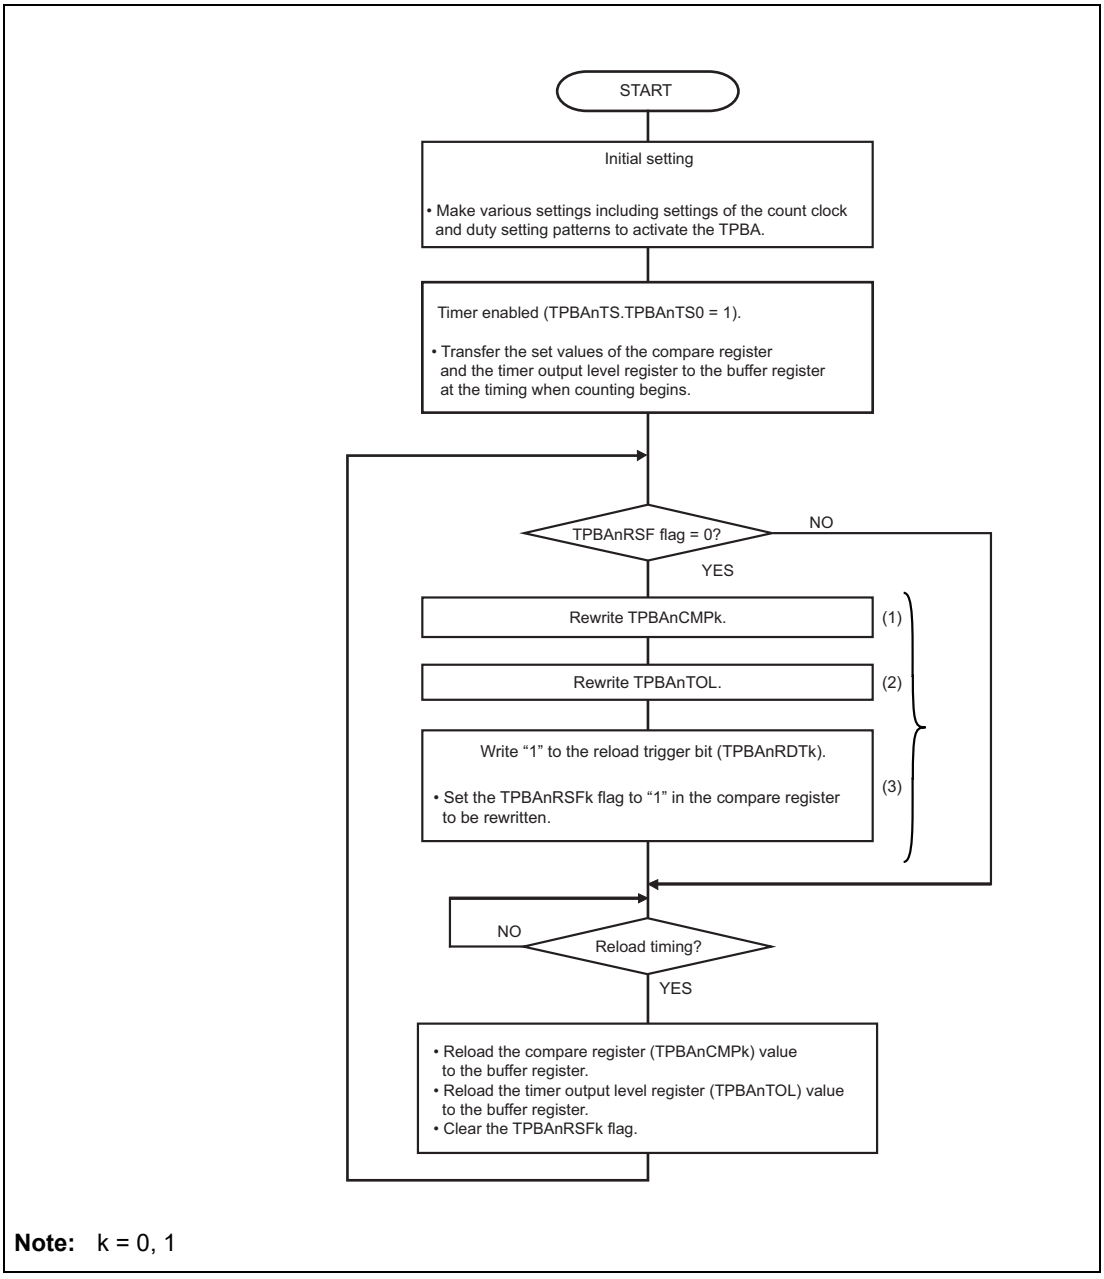
The reload timing of TPBAnCMP1 is the match timing (INTTPBAnIPAT) of the 7-bit counter (TPBAnCNT1) and the buffer register (TPBAnCB1) of TPBAnCMP1.

The registers to be reloaded should be rewritten when the reload request flag (TPBAnRSF.TPBAnRSFk) is 0.

Note: k = 0, 1

Setting Flow for Registers to Be Reloaded

The rewritten values of the registers to be reloaded (TPBAnCMP0, TPBAnCMP1, and TPBAnTOL) can be transferred to the respective buffer registers simultaneously at the reload timing.



Note: k = 0, 1

Figure 37.2 Basic Operation Flow of Reload (Simultaneous Rewrite Function)

CAUTION

Setting the TPBAnRDTk bit to 1 enables reload. Accordingly, the TPBAnRDTk bit should be rewritten after the registers to be reloaded have been rewritten.

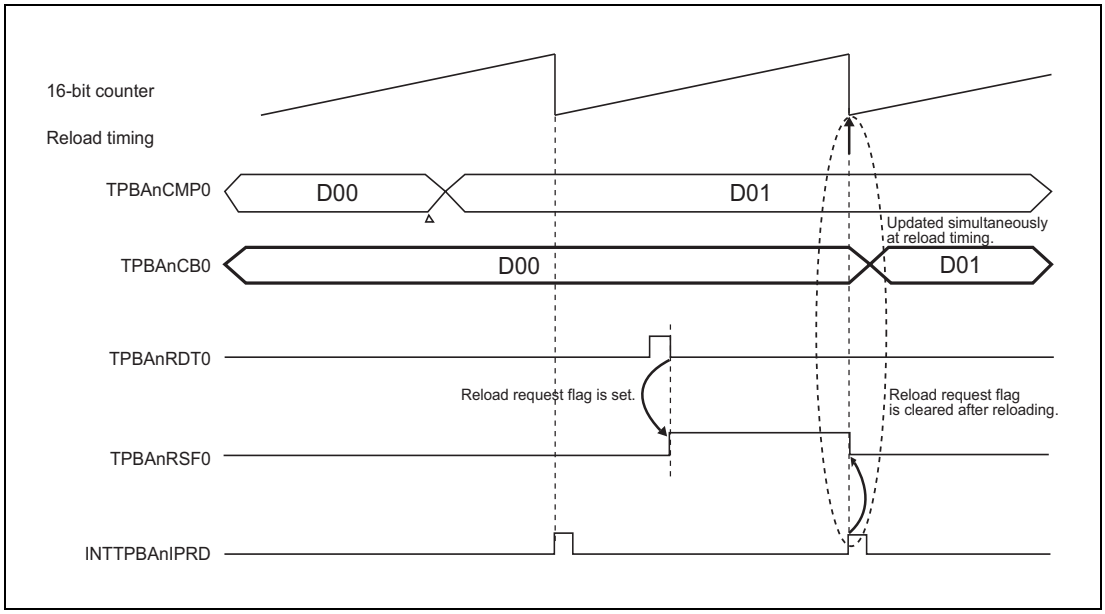


Figure 37.3 Simultaneous Rewrite Timing (TPBAnDPS = 0, TPBAnRDM = 0, and TPBAnTOL = 0)

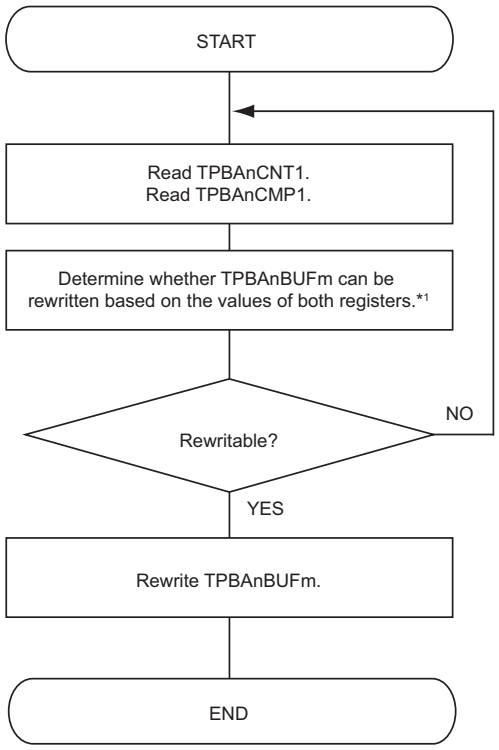
37.4.3 Duty Rewrite Operation

TPBAnBUFm can be rewritten during operation.

The rewritten setting is reflected immediately.

37.4.3.1 TPBAnBUFm Setting Flow



Note 1. Since TPBAnBUFm can be written immediately, it is recommended that this register be rewritten during the last duty cycle output (TPBAnCNT1 = 00_H) of the pattern period (the number of patterns specified by TPBAnCMP1).

Figure 37.4 Basic Rewrite Flow of TPBAnBUFm

37.4.3.2 Access to TPBAnBUFm

TPBAnBUFm is accessed in 16 bit units. The following shows the access in 16 bits × 64 patterns mode and the access in 8 bits × 128 patterns mode.

- In 16 bits × 64 patterns mode (TPBAnDPS = 0)
  This register is accessed by the CPU in units of one 16-bit pattern.

15 0	
Pattern 64	$00FC_H$
Pattern 63	$00F8_H$
:	:
Pattern 3	0008_H
Pattern 2	0004_H
Pattern 1	0000_H

- In 8 bits × 128 patterns mode (TPBAnDPS = 1)
  This register is accessed by the CPU in units of two 8-bit patterns.

15 8	7 0	
Pattern 128	Pattern 127	$00FC_H$
Pattern 126	Pattern 125	$00F8_H$
:	:	:
Pattern 6	Pattern 5	0008_H
Pattern 4	Pattern 3	0004_H
Pattern 2	Pattern 1	0000_H

37.4.3.3 Relationship between TPBAnCNT1 Read Value and TPBAnBUFm

The duty value of the currently output PWM waveform can be obtained by reading the TPBAnCNT1 count value during operation. TPBAnBUFm in which the currently output duty value is stored can be found by one of the following formulas.

Table 37.22 TPBAnBUFm Formula

TPBAnDPS Bit	Formula		
	TPBAnCNT1 ≠ 00_H		**TPBAnCNT1 = 00_H**
0: 16 bits × 64 patterns mode	TPBAnCNT1 - 01_H(1)		TPBAnCMP1(2)
1: 8 bits × 128 patterns mode	TPBAnCNT1 value is an odd number	TPBAnCNT1/2(3)	TPBAnCMP1/2(5)
	TPBAnCNT1 value is an even number	(TPBAnCNT1 / 2) - 01_H(4)	

(1) When TPBAnDPS = 0 and the TPBAnCNT1 ≠ 00_H
The applicable register is found by the formula TPBAnCNT1 – 01_H.
(Example) When TPBAnCNT1 = 08_H: 08_H – 01_H = 07_H → TPBA0BUF07

(2) When TPBAnDPS = 0 and the TPBAnCNT1 = 00_H
The applicable register is found by the TPBAnCMP1 value.
(Example) When TPBAnCMP1 = 08_H: TPBAnBUF08

(3) When TPBAnDPS = 1 and the TPBAnCNT1 = an odd number
The applicable register is found by the formula TPBAnCNT1 / 2
(Example) When TPBAnCNT1 = 07_H: 07_H / 02_H = 03_H → TPBAnBUF03 (lower 8 bits)

(4) When TPBAnDPS = 1 and the TPBAnCNT1 = an even number
The applicable register is found by the formula (TPBAnCNT1 / 2) – 01_H.
(Example) When TPBAnCNT1 = 08_H: (08_H / 02_H) – 01_H = 03_H → TPBAnBUF03 (upper 8 bits)

(5) When TPBAnDPS = 1 and the TPBAnCNT1 = 00_H
The applicable register is found by the formula TPBAnCMP1 / 2.
(Example) When TPBAnCMP1 = 08_H: 08_H / 2 = 04_H → TPBAnBUF04 (lower 8 bits)

37.4.4 Basic Operation Example

Overview

A PWM signal is output from the TPBAnO pin according to the PWM period set in the TPBAnCMP0 register and duty cycle set in the TPBAnBUF00 to TPBAnBUF63 registers.

Prerequisites

- Select 16 bits × 64 patterns mode or 8 bits × 128 patterns mode by setting TPBAnDPS.
- Set the duty cycle to TPBAnBUF00 to TPBAnBUF63.
- Set the number of patterns to TPBAnCMP1.

Functional description

Set the PWM period, the number of patterns, duty cycle, and level to be output. Set TPBAnTS.TPBSnTS0 = 1 (or input a simultaneous start trigger) to start incrementing the timer counter value.

The TPBAnO output is set to the active level at the same time the counting begins. TPBAnCNT1 is incremented, and points to the address of the buffer in which the subsequent duty value is stored.

The output is set to the inactive level by the match of the 16-bit counter and the TPBAnBUFm buffer register (TPBAnCB2).

The duty value is then transferred from TPBAnBUFm to the buffer register (TPBAnCB2) by the match of the 16-bit counter and the TPBAnCMP0 buffer register (TPBAnCB0). Then, TPBAnCNT1 is incremented, and a period-matched detection interrupt (INTTPBAnIPRD) is generated. The TPBAnO output is set to the active level after one count clock.

During counting, a duty-cycle-matched detection interrupt (INTTPBAnIDTY) is generated by the match of the 16-bit counter and the buffer register (TPBAnCB2) of TPBAnBUFm.

A number-of-patterns matched detection interrupt (INTTPBAnIPAT) is generated by the match of the 7-bit counter and the TPBAnCMP1 buffer register (TPBAnCB1).

37.4.4.1 List of Operations

Table 37.23 16-Bit Counter Function

Operation		Setting Condition
16-bit counter	Start	Writing 1 to TPBAnTS or set simultaneous start trigger.
	Clear	Compare match of TPBAnCMP0 buffer register and 16-bit counter
	Stop	Writing 1 to TPBAnTT

Table 37.24 7-Bit Counter Function

Operation		Setting Condition
7-bit counter	Start	Writing 1 to TPBAnTS or set simultaneous start trigger.
	Clear	Compare match of TPBAnCMP1 buffer register and 7-bit counter
	Stop	Writing 1 to TPBAnTT

Table 37.25 Functions of Compare Registers and Buffer Registers

Register (Data)	Buffer Register	Rewrite Method	Rewrite during Operation	Function
TPBAnCMP0	TPBAnCB0	Reload	Possible	Setting period
TPBAnCMP1	TPBAnCB1	Reload	Possible	Setting number of patterns
TPBAnBUFm	TPBAnCB2	Rewrite immediately	Possible	Setting duty
TPBAnTOL	TPBAnTOLB	Reload	Possible	Setting output level

Buffer Registers

The registers that specify period, the number of patterns, duty, and timer output level consist of data registers that a user can directly set and buffer registers that a user cannot directly set.

Table 37.26 Timer Output Function

Pin	Function
TPBAnO	• When output is enabled (TPBAnTOE = 01_H) PWM output by compare match of the TPBAnBUFm buffer register (TPBAnCB2) and the 16-bit counter • When output is disabled (TPBAnTOE = 00_H) TPBAnTO set value

Table 37.27 Interrupt Requests

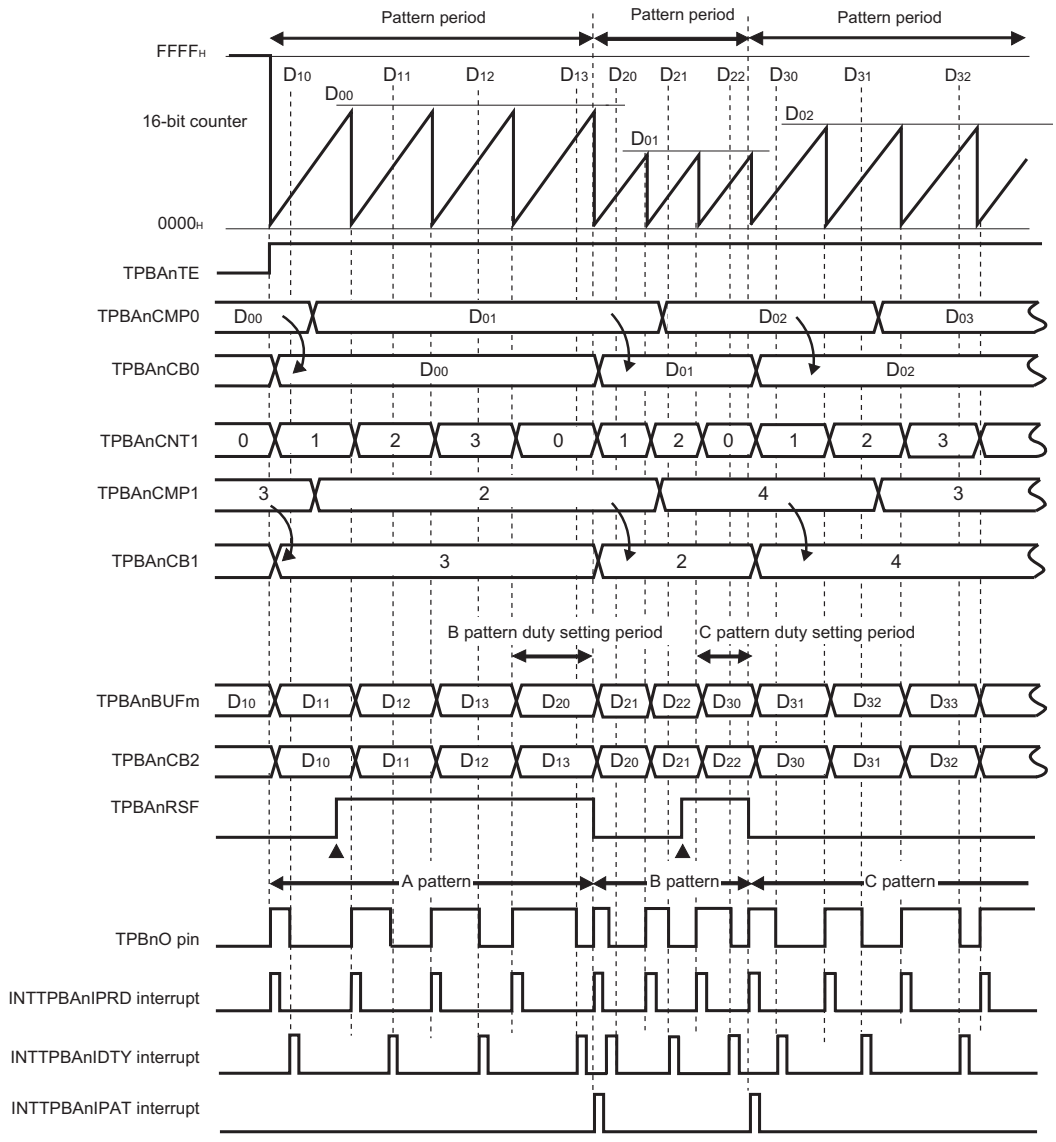
Interrupt	Function
INTTPBAnIPRD	Period-matched detection interrupt
INTTPBAnIDTY	Duty-cycle-matched detection interrupt
INTTPBAnIPAT	Number-of-patterns matched detection interrupt

Table 37.28 Compare Match Timing

Compare Match	Timing
TPBAnCMP0	When the 16-bit counter changes from match with TPBAnCMP0 to 0000_H.
TPBAnCMP1	When the 7-bit counter changes from match with TPBAnCMP1 to 01_H.
TPBAnBUFm	When the 16-bit counter matches with the buffer register (TPBAnCB2).

Table 37.29 Example of Setting Each Timer Output Condition

Pin	Item	Output Period	Output Duty	
			Output Condition	Setting Condition
TPBAnO	PWM output	(TPBAnCMP0 + 1) × count clock	Outputs an inactive level throughout one period (duty cycle 0%).	TPBAnBUFm = 0000_H
			Outputs an active level of one count clock in one period.	TPBAnBUFm = 0001_H
			Outputs an inactive level of one count clock in one period	TPBAnBUFm = TPBAnCMP0
			Outputs an active level throughout one period (duty cycle 100%).	TPBAnBUFm ≥ TPBAnCMP0 + 1



Note 1. PWM duty cycle = (TPBAnBUFm) / (TPBAnCMP0 set value + 1)
PWM period = (TPBAnCMP0 set value + 1) × (count clock period)

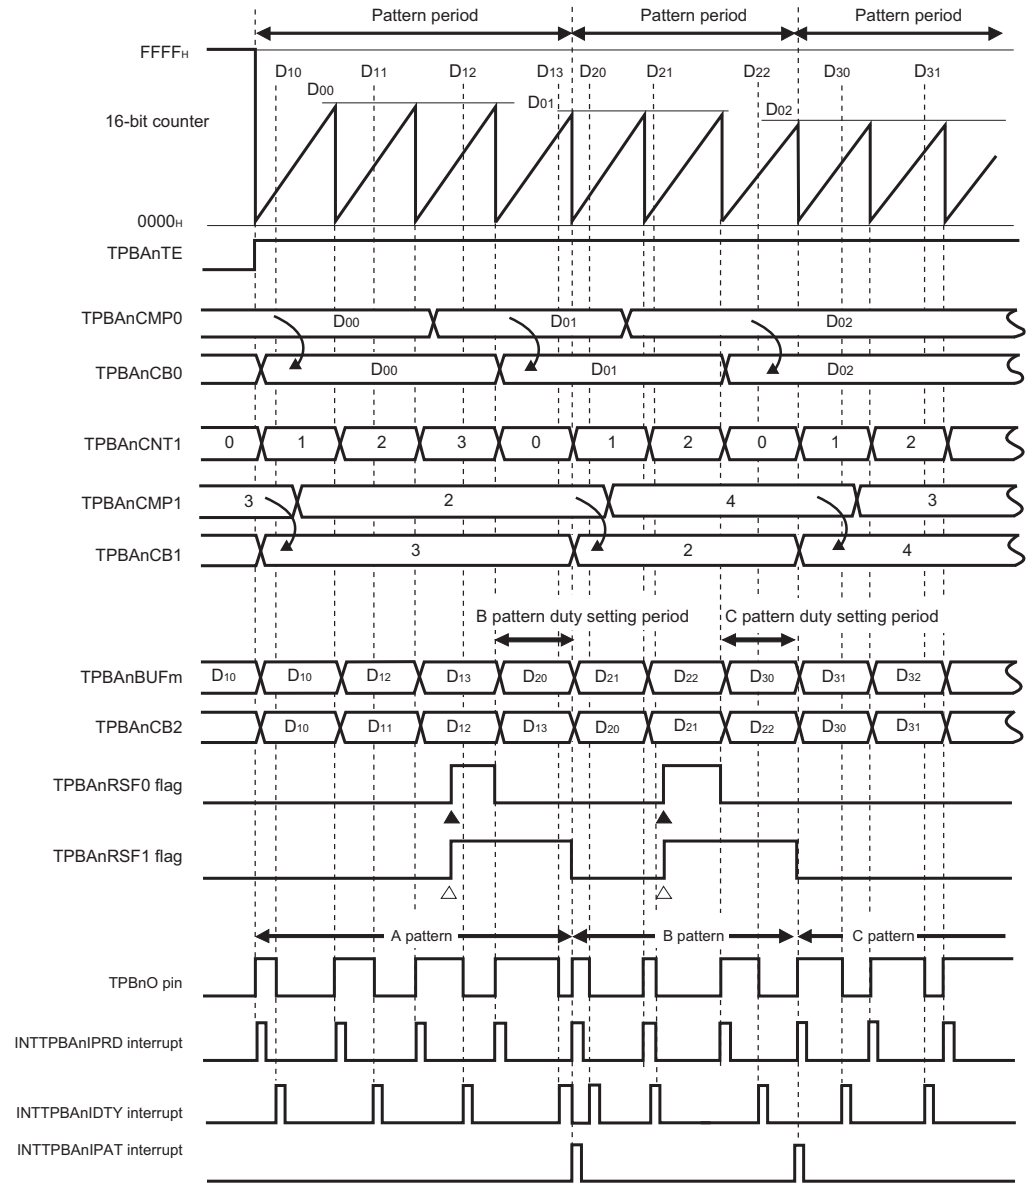
Note 2. ▲: Writing 1 to TPBAnRDT

Figure 37.5 Example of Basic Timing (1/2)

CAUTION

TPBAnO outputs active level 1 count clock after output of INTTPBAnIPRD and outputs inactive level at INTTPBAnIDTY output timing.

When a number-of-patterns matched detection interrupt is used as a trigger of the TPBAnCMP0 and TPBAnTOL reload timing (TPBAnIRDM.TPBAnRDM0 = 0 and TPBAnTOL = 0)



Note 1. PWM duty cycle = (TPBAnBUFm) / (TPBAnCMP0 set value + 1)
PWM period = (TPBAnCMP0 set value + 1) × (count clock period)
Note 2. ▲: Writing 1 to TPBAnRDT0
Note 3. Δ: Writing 1 to TPBAnRDT1

Figure 37.6 Example of Basic Timing (2/2)

CAUTION

TPBAnO outputs active level 1 count clock after output of INTTPBAnIPRD and outputs inactive level at INTTPBAnIDTY output timing.

When a period-matched detection interrupt is used as a trigger of the TPBAnCMP0 and TPBAnTOL reload timing (TPBAnIRDM.TPBAnRDM0 = 1 and TPBAnTOL = 0)

Section 38 Generic Timer Module (GTM)

Generic timer module (GTM) is a modular timer unit used to support body control and chassis & safety applications. It is designed to unload the CPU from a high interrupt load. Most of the task of GTM can run independently from the CPU.

The first part of this section describes all RH850/U2A-EVA specific properties, such as the number of units, register base addresses, etc. The remainder of the section describes the functions and registers of the units constituting GTM.

NOTE

Ignore the description of AXI Master/Slave function and submodules that are not supported in RH850/U2A-EVA Group. Regarding supported submodules in RH850/U2A-EVA Group, refer to **Section 38.28.1, GTM Device 358 Configuration**. Regarding actual register reset value, see **Section 38.28, GTM Device 358**.

38.1 Features of GTM for RH850/U2A-EVA

38.1.1 Number of Units

This microcontroller has the following number of GTM channels.

Table 38.1 Number of Units

Product Name	RH850/ U2A-EVA (516 pins)	RH850/ U2A16 (516 pins)	RH850/ U2A16 (373 pins)	RH850/ U2A16 (292 pins)	RH850/ U2A8 (373 pins)	RH850/ U2A8 (292 pins)	RH850/ U2A6 (292 pins)	RH850/ U2A6 (176 pins)	RH850/ U2A6 (156 pins)	RH850/ U2A6 (144 pins)

38.1.3 Number of Sub-Units and Channels

The table below shows the availability of the GTM.

Table 38.4 Sub-Units and Channels

Sub-module	Number of Instances	Instance name	Channels
ARU	1	—	—
BRC	0	—	—
PSM (FIFO, AFD, F2A)	0	—	—
CMU	1	—	—
CCM	4	—	—
TBU	1	—	3 (n = 0 to 2)
TIM	4	TIM0 to TIM3	8 (n = 0 to 7)
TOM	0	—	—
ATOM	4	ATOM0 to ATOM3	8 (n = 0 to 7)
DTM	8	CDTM0_DTM[i](i = 4, 5) CDTM1_DTM[i](i = 4, 5) CDTM2_DTM[i](i = 4, 5) CDTM3_DTM[i](i = 4, 5)	4 (n = 0 to 3)
MCS	4	MCS0 to MCS3	8 (n = 0 to 7)
MCFG	1	—	—
MAP	0	—	—
DPLL	0	—	—
SPE	0	—	—
ICM	1	—	—
CMP	1	—	—
MON	1	—	—

Table 38.5 Memory Size

	RH850/U2A-EVA, U2A16, U2A8, U2A6
Sub-module	Size
MCS RAM0	8 KB/instance
MCS RAM1	4 KB/instance

38.1.4 Register/RAM Base Address

GTM base addresses are listed in the following table. GTM register and RAM addresses are given as offsets from the base addresses in general.

Table 38.6 Register and RAM Base Addresses

Base Address Name	Base Address	Bus Group
<GTM0_base>	FF60 0000_H	P-Bus Group 6H
<GTM0_1_base>	FF70 6000_H	P-Bus Group 6H

38.1.5 Clock Supply

GTM clock supplies are listed in the following table.

Table 38.7 Clock Supply

Unit Name	Clock for the Unit	Supply Clock Name
GTM Cluster 0 to 3 (MCS0-3 and associated RAM)	GTM Main Clock	CLK_UHSB Switchable between 1/1 (high) and 1/2 (low) frequency.
	Register access clock	CLK_HSB

38.1.6 Interrupt Requests and Error Notifications

Mapping of ICM outputs to interrupts and DMA/DTS triggers is shown in the following table.

Table 38.8 Interrupt and DMA/DTS Requests (1/3)

Unit Interrupt Name	Description	Interrupt Number	DMA Trigger Number	DTS Trigger Number
GTMn				
INTGTMA0TIM00	TIM0 Shared interrupts (TIM0_IRQ0)	79	Group1-140	Group2-44
INTGTMA0TIM01	TIM0 Shared interrupts (TIM0_IRQ1)	80	Group1-141	Group2-45
INTGTMA0TIM02	TIM0 Shared interrupts (TIM0_IRQ2)	81	Group1-142	Group2-46
INTGTMA0TIM03	TIM0 Shared interrupts (TIM0_IRQ3)	82	Group1-143	Group2-47

Note 1. Only rising edge of timer output is effective.

This module has no error notification.

38.1.7 Reset Sources

The following table shows GTM reset sources and GTM responses to each reset source.

Table 38.9 Reset Sources

Register Name	Reset Condition						
	Power On Reset	System Reset 1	System Reset 2	Application Reset	DeepSTOP Reset	Module Reset	JTAG Reset
All registers	√	√	√	√	√	√	—

Note: GTM can be reset by a dedicated bit, which allows the software to set GTM in reset state without using external reset.

38.1.8 External Input and Output Pins

External input/output pins of GTM are listed below.

Table 38.10 Pin Function Information (1/2)

Pin Name	I/O	Description	Alternative Port Pin Signal

Note 1. Output buffer of these signals could be controlled to Hi-Z by PIC2.

38.2 Overview

38.2.1 Functional Overview

GTM consists of the following sub-modules.

- Advanced Routing Unit (ARU)
  - Data routing between GTM sub-modules.
- Clock Management Unit (CMU)
  - Clock pre-scaler for GTM internal and external clocks.
- Cluster Configuration Module (CCM)
  - Controlling cluster configurations:
    - Cluster’s clock frequency.
    - Module clock gating.
    - Status monitoring of the cluster's MCS bus master.
    - Address range protection.
- Time Base Unit (TBU)
  - Three independent 24-bit time bases.
  - One module counter for angular conversions.
  - Supporting the following modes:
    - Free Running Counter Mode.
    - Forward/Backward Counter Mode.
- Timer Input Module (TIM)
  - Filter, capture/compare with a time stamp and input signal timeout.
  - Input from other peripherals to GTM.
- ARU-connected Timer Output Module (ATOM)
  - Complex output waveform generation without CPU interactions with 24-bit time base counter.
  - Input signal to other peripherals.
- Dead Time Module (DTM)
  - Hardware support for dead time generation.
- Multi Channel Sequencer (MCS)
  - Programmable sequencer with RISC-like instruction set and dedicated RAM.
- Memory Configuration (MCFG)
  - Mapping MCS physical memory to MCS instances.
- Interrupt Concentrator Module (ICM)
  - Bundling GTM internal interrupts before they are routed to INTC and DMAC.
- Output Compare Unit (CMP)

– Support for safety relevant applications, compare of DTM outputs.

- Monitoring Unit (MON)
  – Monitoring GTM internal clocks and MCS functionality.

38.2.2 Block Diagram

The following figure shows interconnections between GTM-IP and other peripherals.

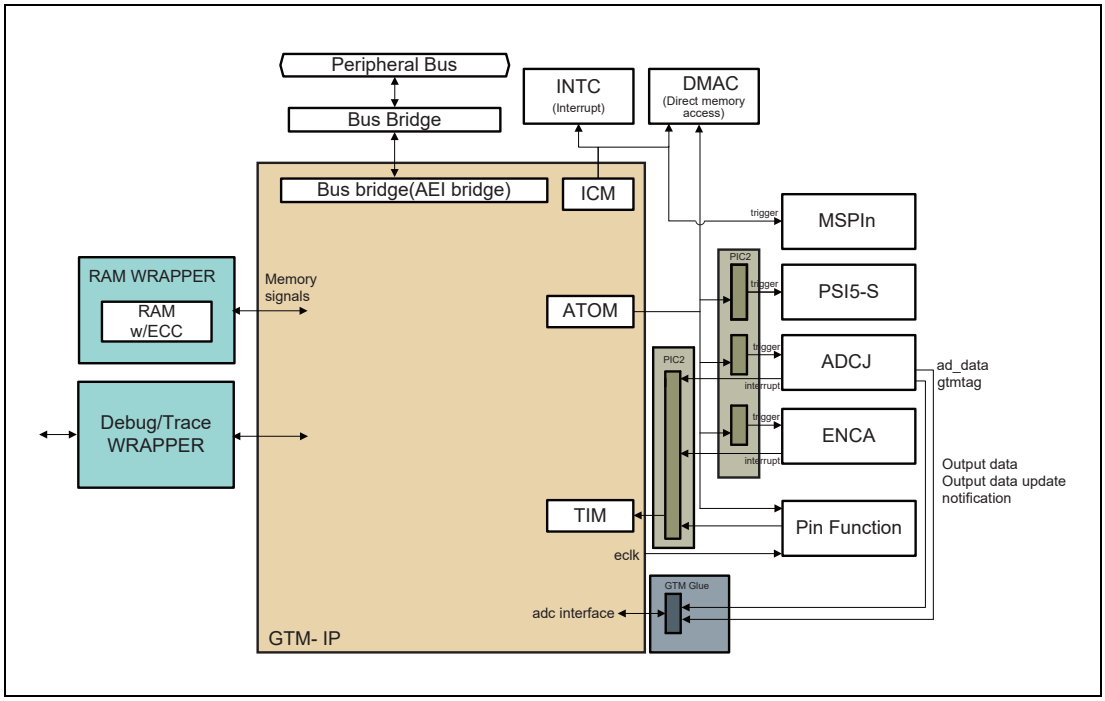

Figure 38.1 GTM integration diagram

38.3 Registers

38.3.1 List of Registers

GTM registers are listed in the following table.

For details about <GTM0_base> and <GTM0_1_base>, see **Section 38.1.4, Register/RAM Base Address**.

Table 38.11 List of Registers

Module name	Register Name	Symbol	Address	Access Size	Access Protection	
					PBG	Other
GTM0	All of GTM-IP registers	*1	<GTM0_base> + *1	32	PBG6H0#2	—
GTM0_1	GTM ADCI channel selection register 0	GTM_ADCI_CHSEL0	<GTM0_1_base> + 000_H	8, 16, 32	PBG6H0#2	—
	GTM ADCI channel selection register 1	GTM_ADCI_CHSEL1	<GTM0_1_base> + 004_H	8, 16, 32	PBG6H0#2	—

Note 1. For details of GTM-IP registers, refer to **Section 38.28.6, GTM Register and Memory Addresses**. Also, the access size of RAM has to be 32-bit wide.

38.3.2 GTM_ADCI_CHSELn — GTM ADCI channel selection register n

Results of A/D conversion are stored in ADC_CH[y]_DATA registers (y = 0 to 31). Either registers 0 to 15 or registers 16 to 31 can be used based on GTM_ADCI_CHSELn.CHS. In addition a register designation is also based on GTMTAG (ADCJ). For more information about GTMTAG configuration, refer to **Section 43, Analog to Digital Converter (ADCJ)**. (n = 0, 1)

Access: This register can be read or written in 32-bit units.

Address: <GTM0_1_base> + n × 4_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	CHS
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Table 38.12 GTM_ADCI_CHSELn Register Contents

Bit Position	Bit Name	Function
31 to 1	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
0	CHS	The analog to digital conversion data storage territory related in GTMTAG of ADCJ is designated. 0: AD data is stored in ADC_CH[y]_DATA (y = 0 to 15) 1: AD data is stored in ADC_CH[y]_DATA (y = 16 to 31)

38.4 Introduction

38.4.1 Overview

This document is the specification for the Generic Timer Module (GTM). It contains a module framework with sub-modules of different functionality. These sub-modules can be combined in a configurable manner to form a complex timer module that serves different application domains and different classes within one application domain. Because of this scalability and configurability the timer is called generic.

The scalability and configurability is reached with an architecture philosophy where dedicated hardware sub-modules are located around a central routing unit (called Advanced Routing Unit (ARU)). The ARU can connect the sub-modules in a flexible manner. The connectivity is software programmable and can be configured during runtime.

Nevertheless, the GTM-IP is designed to unload the CPU or a peripheral core from a high interrupt load. Most of the tasks inside the GTM-IP can run-once setup by an external CPU-independent and in parallel to the software. There may be special situations, where the CPU has to take action but the goal of the GTM design was to reduce these situations to a minimum.

The hardware sub-modules have dedicated functionality's, e.g. there are timer input modules where incoming signals can be captured and characterized together with a notion of time. By combination of several sub-modules through the ARU complex functions can be established.

E.g. the signals characterized at an input module can be routed to a signal processing unit where an intermediate value about the incoming signal frequency can be calculated.

The modules that help to implement such complex functions are called infrastructure components further on. These components are present in all GTM variants. However, the number of these components may vary from device to device.

Other sub-modules have a more general architecture and can fulfill typical timer functions, e.g. there are PWM generation units. The third classes of sub-modules are those fulfilling a dedicated functionality for a certain application domain, e.g. the DPLL serves engine management applications. A fourth group of sub-modules is responsible for supporting the implementation of safety functions to fulfill a defined safety level. The module ICM is responsible for interrupt services and defines the fifth group.

The master communication from GTM to CPU works over module AXIM. The slave communication from CPU to GTM is doing by AXIS which is describing in an extra document called Module-Integration-Guide. Both module are collecting as interface components, the sixth group.

Each GTM-IP is build up therefore with sub-modules coming from those six groups. The application class is defined by the amount of components of those sub-modules integrated into the implemented GTM-IP.

38.4.2 Document Structure

The structure of this document is motivated out of the aforementioned sub-module classes. **Section 38.5, GTM Architecture** describes the dedicated GTM-IP implementation this specification is written for. It gives an overview about the implemented sub-modules.

The master interface to the CPU is describing in **Section 38.6, AXI Master**. The following **Section 38.7, Advanced Routing Unit (ARU)** up to **Section 38.14, Time Base Unit (TBU)** deals with the so called infrastructure components for routing, clock management and common time base functions. **Section 38.15, Timer Input Module (TIM)** to **Section 38.18, Dead Time Module (DTM)** describe the signal input and output modules while the following **Section 38.19, Multi Channel Sequencer (MCS)** explains the signal processing and generation sub-module with **Section 38.20, Memory Configuration (MCFG)** its memory configuration. The next **Section 38.21, TIM0 Input Mapping Module (MAP)** to **Section 38.23, Sensor Pattern Evaluation (SPE)** provides a detailed description of application specific modules like the MAP, DPLL and SPE. **Section 38.24, Interrupt Concentrator Module (ICM)** describes a module that bundles several interrupts coming from the other sub-modules and connect them to the outside world. The last **Section 38.25, Output Compare Unit (CMP)** to **Section 38.26, Monitor Unit (MON)** provides to safety related modules like CMP and MON sub-modules.

These sub-module groups are shown in the following table:

Chapter	Sub-module	Group
38.6	AXI Master	Master interface to the CPU
38.7	Advanced Routing Unit (ARU)	Infrastructural components
38.8	Broadcast Module (BRC)	Infrastructural components
38.9	First In First Out Module (FIFO)	Infrastructural components
38.10	AEI to FIFO Data Interface (AFD)	Infrastructural components
38.11	FIFO to ARU Unit (F2A)	Infrastructural components
38.12	Clock Management Unit (CMU)	Infrastructural components
38.13	Cluster Configuration Module (CCM)	Infrastructural components
38.14	Time Base Unit (TBU)	Infrastructural components
38.15	Timer Input Module (TIM)	IO Modules
38.16	Timer Output Module (TOM)	IO Modules
38.17	ARU-connected Timer Output Module (ATOM)	IO Modules
38.18	Dead Time Module (DTM)	IO Modules
38.19	Multi Channel Sequencer (MCS)	Signal generation and processing
38.20	Memory Configuration (MCFG)	Memory for signal generation and processing
38.21	TIM0 Input Mapping Module (MAP)	Application specific modules
38.22	Digital PLL Module (DPLL)	Application specific modules
38.23	Sensor Pattern Evaluation (SPE)	Application specific modules
38.24	Interrupt Concentrator Module (ICM)	Interrupt services
38.25	Output Compare Unit (CMP)	Safety features
38.26	Monitoring Unit (MON)	Safety features

38.5 GTM Architecture

38.5.1 Overview

As already mentioned in **Section 38.4, Introduction** the GTM-IP forms a generic timer platform that serves different application domains and different classes within these application domains. Depending on these multiple requirements of application domains multiple device configurations with different number of sub-modules (i.e. ATOM, BRC, MCS, PSM, SPE, TIM, TOM, DTM) and different number of channel per sub-module (if applicable) are possible. The device dependent configuration (i.e. the number of sub-modules) is listed in the device specific **Section 38.28, GTM Device 358**. The Parameter Storage Module (PSM) is only a virtual hierarchy and consists of the sub-modules F2A, FIFO and AFD.

The Cluster Dead Time Module (CDTM) is also a virtual hierarchy and consists of up to six DTM modules. It depends on the GTM device configuration which of the six DTM instances are available. Refer to **Section 38.28, GTM Device 358** for list of available DTM instances. In general, the first four DTM modules inside a CDTM[n] hierarchy are connected to the outputs of the TOM instance [n] of the cluster [n], the other two DTM instances are connected to the outputs of the ATOM instance [n] of this cluster [n].

The cluster view of a GTM-IP architecture is depicted in **Figure 38.2**. This is a generic figure which shows an exemplify GTM-IP device configuration.

The device dependent configuration (i.e. the count of sub-modules and channels per sub-module) is listed in the device specific **Section 38.28, GTM Device 358**.

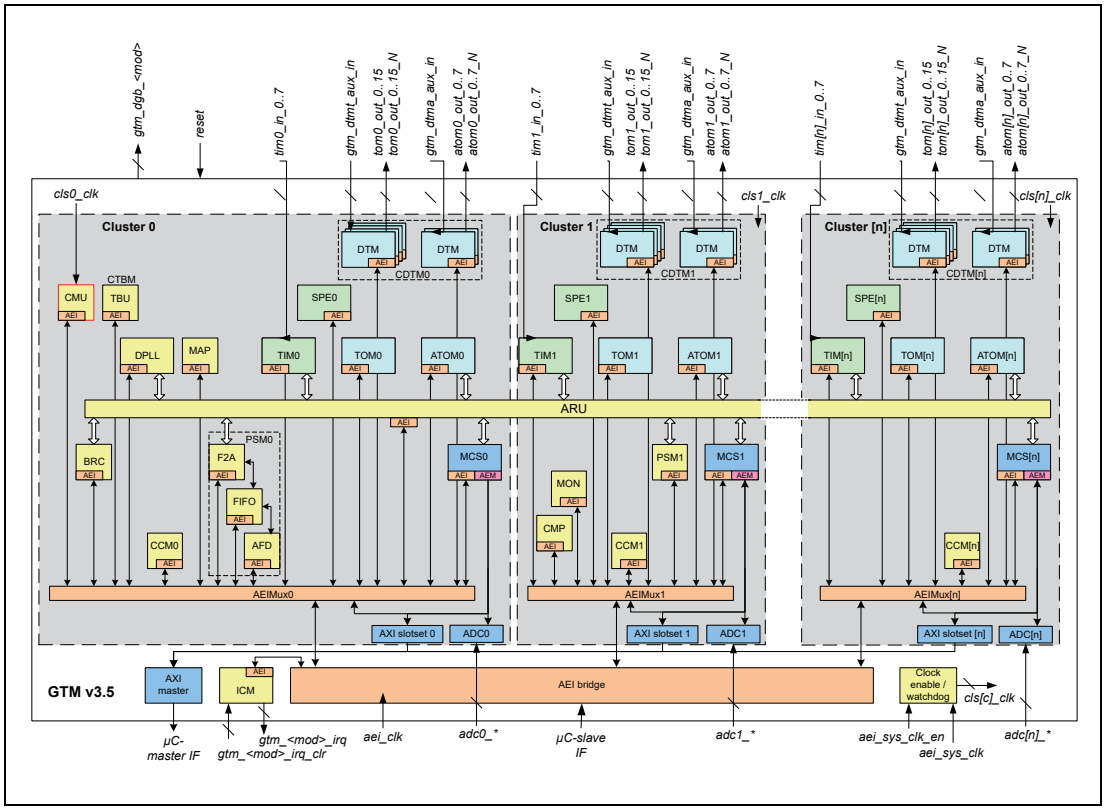

Figure 38.2 GTM Architecture Block Diagram

The GTM-IP is divided in multiple clusters 0 to n. A certain amount of modules exist in each cluster. The operating frequency of a cluster can be configured to OFF, aei_sys_clk or aei_sys_clk/2. The clock enable generation can be implemented internal to the GTM_IP or external. In case of an external enable generation aei_sys_clk_en is used to generate the internal clocks. In addition an enable watchdog is implemented to monitor the correctness of the external applied enable signals aei_sys_clk_en.

The central component of the GTM-IP is the Advanced Routing Unit (ARU) where most of the sub-modules are located around and connected to. This ARU forms together with the Broadcast (BRC) and the Parameter Storage Module (PSM) the infrastructural part of the GTM. The ARU is able to route data from a connected source sub-module to a connected destination sub-module. The routing is done in a deterministic manner with a round-robin scheduling scheme of connected channels which receive data from ARU and with a worst case round−trip time.

The routed data word size of the ARU is 53 bit. The data word can logically be split into three parts. These parts are shown in **Figure 38.3, ARU Data Word**. Bits 0 to 23 and bits 24 to 47 typically hold data for the operation registers of the GTM-IP. This can be, for example, the duty cycle and period duration of a measured PWM input signal or the output characteristic of an output PWM to be generated. Another possible content of Data0 and Data1 can be two 24 bit values of the GTM-IP time bases TBU_TS0, TBU_TS1 and TBU_TS2. Bits 48 to 52 can contain control bits to send control information from one sub-module to another. These ARU Control Bits (ACB) can have a different meaning for different sub-modules. It is also possible to route data from a source to a destination and the destination can act later on as source for another destination. These routes through the GTM-IP are further on called data streams. For a detailed description of the ARU sub-module, refer to **Section 38.7, Advanced Routing Unit (ARU)**.

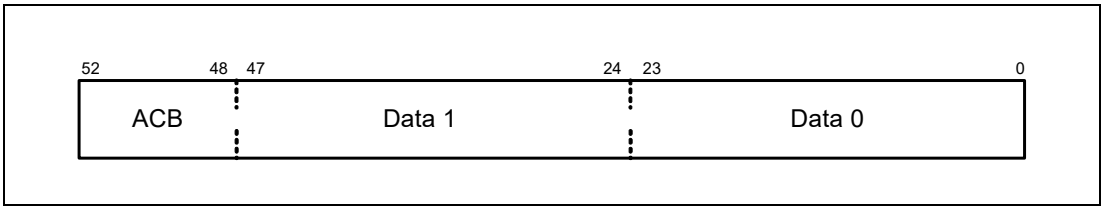

Figure 38.3 ARU Data Word

The BRC is able to distribute data from one source module to more than one destination modules connected to the ARU. The PSM sub-module consists of three sub-units, the AEI-to-FIFO Data Interface (AFD), FIFO-to-ARU Interface (F2A) and the FIFO itself. The PSM can serve as a data storage for incoming data characteristics or as parameter storage for outgoing data. This data is stored in a RAM that is logically located inside the FIFO sub-unit, but physically the RAM is implemented and integrated by the silicon vendor with his RAM implementation technology. Therefore, the GTM-IP provides the interface to the RAM at its module boundary. The AFD sub-unit is the interface between the FIFO and the GTM SoC system bus interface AEI (see **Section 38.5.2.1, GTM-IP Generic Bus Interface (AEI)** for detailed discussion). The F2A sub-unit is the interface between the FIFO sub-unit and the ARU.

Signals are transferred into the GTM-IP at the Timer Input Modules (TIM). These modules are able to filter the input signals and annotate additional information. Each channel is for example able to measure pulse high or low times and the period of a PWM signal in parallel and route the values to ARU for further processing. The internal operation registers of the TIM sub-module are 24 bits wide.

The Clock Management Unit (CMU) serves up to 13 different clocks for the GTM and up to three external clock pins GTM_ECLK0 to 2. It acts as a clock divider for the system clock. The counters implemented inside other sub-modules are typically driven from this sub-module.

Note that the CMU clocks are implemented as enable signals for the counters while the whole system runs with the GTM global clock SYS_CLK. This global clock typically corresponds to the micro controller bus clock the GTM-IP is connected to and should not exceed 100 MHz because of the power dissipation of the used transistors where the GTM is implemented with.

The TBU provides up to three independent common time bases for the GTM-IP. In general, the number of time bases depends on the implemented device. If three time bases are implemented, two of these time bases can also be clocked with the digital PLL (DPLL) sub_inc1 c and sub_inc2c outputs. The DPLL generates the higher frequent clock signals sub_inc1, sub_inc2, sub_inc1c and sub_inc2c on behalf of the frequencies of up to two input signals. These two input signals can be selected out of six incoming signals from the TIM0 sub-module. In this sub-module the incoming signals are filtered and transferred to the MAP sub-module where two of these six signals are selected for further processing inside the DPLL.

Signal outputs are generated with the Dead Time Module (DTM), Timer Output Modules (TOM) and the ARU-connected TOMs (ATOM). Each TOM channel is able to generate a PWM signal at its output. Because of the integrated shadow register even the generation of complex PWM outputs is possible with the TOM channels by serving the parameters with the CPU. It is possible to trigger TOM channels for a successor TOM sub-module through a trigger line between TOM(x)_CH(15) and TOM(x+1)_CH(0). But to avoid long trigger paths the GTM-IP integrator can configure after which TOM sub-module instance a register is placed into the trigger signal chain. Each register results in one SYS_CLK cycle delay of the trigger signal. Refer to device specification of silicon vendor for unregistered trigger chain length.

In addition, each TOM sub-module can integrate functions to drive one BLDC engine. This BLDC support is established together with the TIM and Sensor Pattern Evaluation (SPE) sub-module.

The ATOMs offer the additional functionality to generate complex output signals without CPU interaction by serving these complex waveform characteristics by other sub-modules that are connected to the ARU like the PSM or Multi Channel Sequencer (MCS). While the internal operation and shadow registers of the TOM channels are 16 bit wide, the operation and shadow registers of the ATOM channels are 24 bit wide to have a higher resolution and to have the opportunity to compare against time base values coming from the TBU.

It is possible to trigger ATOM channels for a successor ATOM sub-module through a trigger line between ATOM(x)_CH(7) and ATOM(x+1)_- CH(0). But to avoid long trigger paths the GTM-IP integrator can configure after which ATOM sub-module instance a register is placed into the trigger signal chain. Each register results in one SYS_CLK cycle delay of the trigger signal. Refer to device specification of silicon vendor for unregistered trigger chain length.

Together with the MCS the ATOM is able to generate an arbitrary predefined output sequence at the GTM-IP output pins. The output sequence is defined by instructions located in RAM connected to the MCS sub-module. The instructions define the points were an output signal should change or to react on other signal inputs. The output points can be one or two time stamps (or even angle stamp in case of an engine management system) provided by the TBU. Since the MCS is able to read data from the ARU it is also able to operate on incoming data routed from the TIM. Additionally, the MCS can process data that is located in its connected RAMs. The MCS RAM is located logically inside the MCS while the silicon vendor has to implement its own RAM technology there.

The two modules Compare Module (CMP) and Monitor Module (MON) implement safety related features. The CMP compares two output channels of the DTM and sends the result to the MON sub-module were the error is signaled to the CPU. The MON module is also able to monitor the ARU and CMU activities.

In the described implementation the sub-modules of the GTM-IP have a huge amount of different interrupt sources. These interrupt sources are grouped and concentrated by the Interrupt Concentrator Module (ICM) to form a much easier manageable bunch of interrupts that are visible outside of the GTM-IP.

On the GTM-IP top level there are some configurable signal connections from the signal output of the DTM modules to the input signals of the TIM modules.

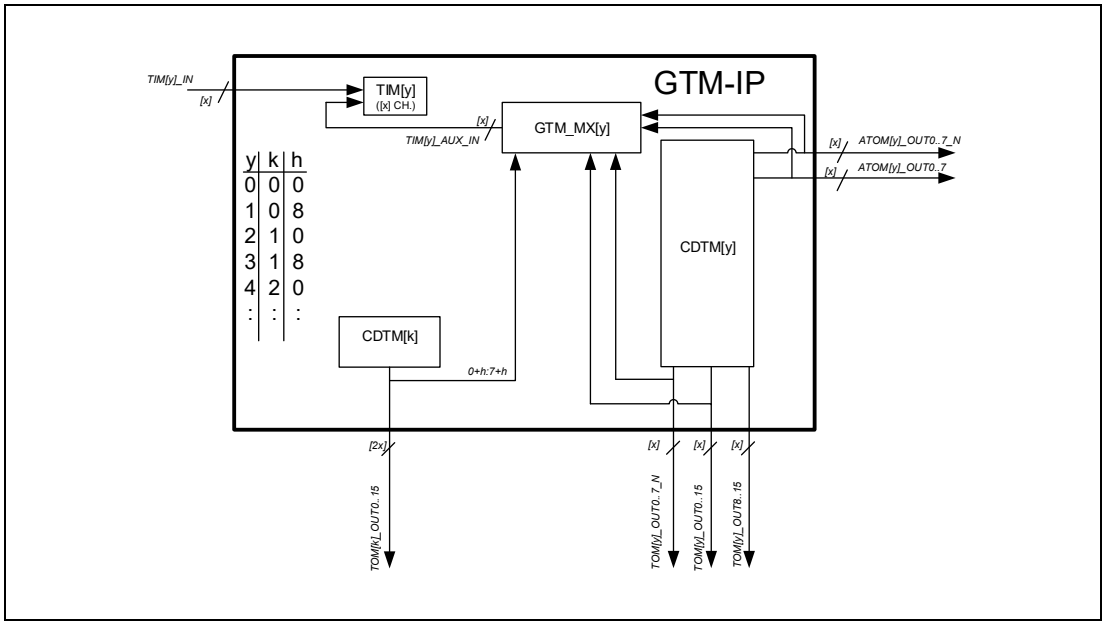

Figure 38.4 GTM-IP signal multiplex

The next diagram gives an overview of the connectivity for different configuration of GTM global bit SRC_IN_MUX of register GTM_CFG and the cluster configuration register CCM[y]_TIM_AUX_IN_SRC. The source selection is defined per channel with the bit SRC_CH[x] and SEL_OUT_N_CH[x] in the register CCM[y]_TIM_AUX_IN_SRC.

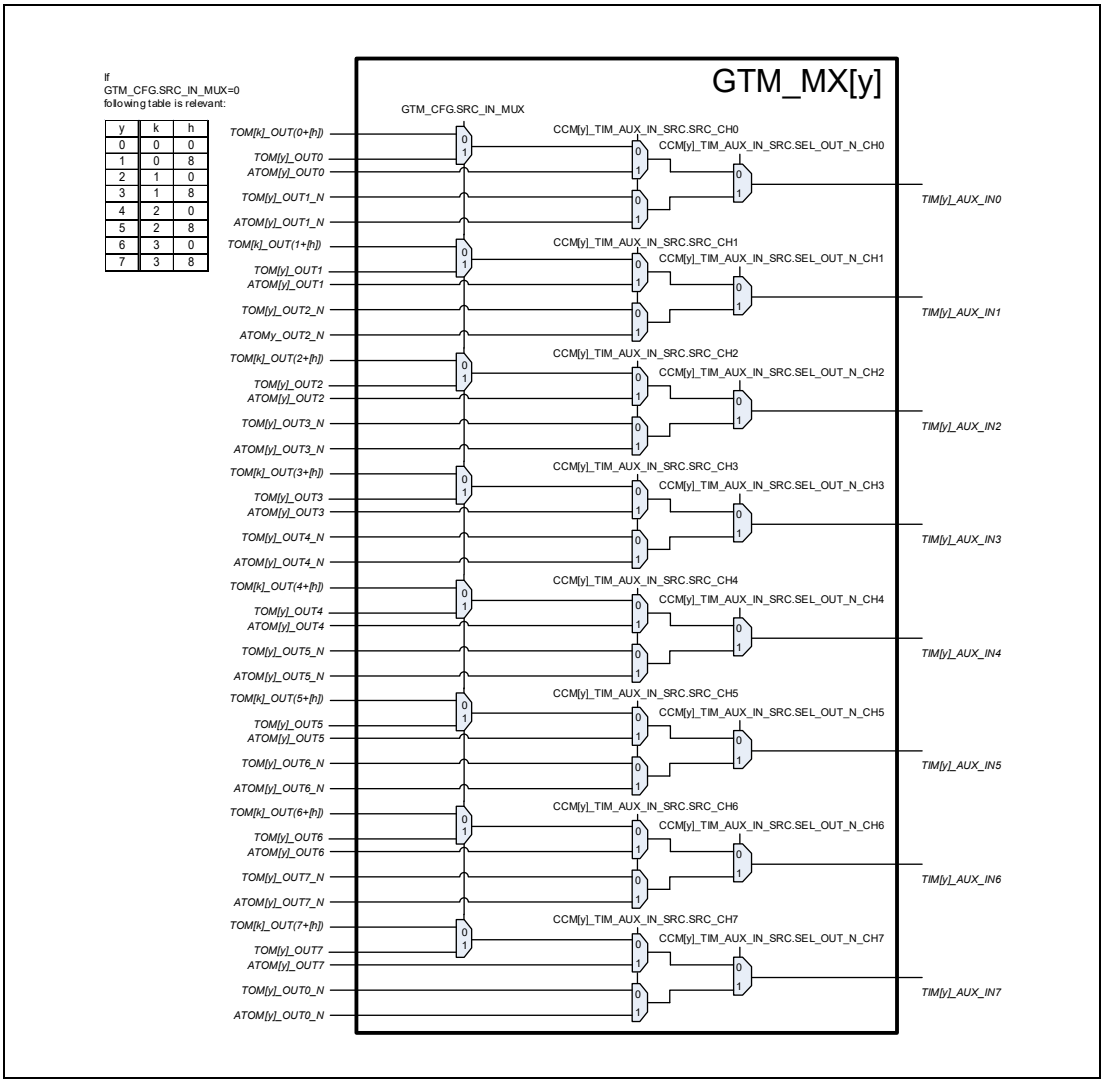

Figure 38.5 TIM auxiliary input multiplexing

The trigger out of TIM (i.e. the signals TIM[i]_EXT_CAPTURE(7:0) of each TIM instance i) are routed to ATOM instance [i] and TOM instance [i] with i=0...cITIM-1 (cITIM defines the number of available TIM instances, refer to device specific **Section 38.28, GTM Device 358**). This TIM trigger can be used to trigger inside the ATOM or TOM instance either a channel or the global control register of AGC or TGC0/TGC1 unit.

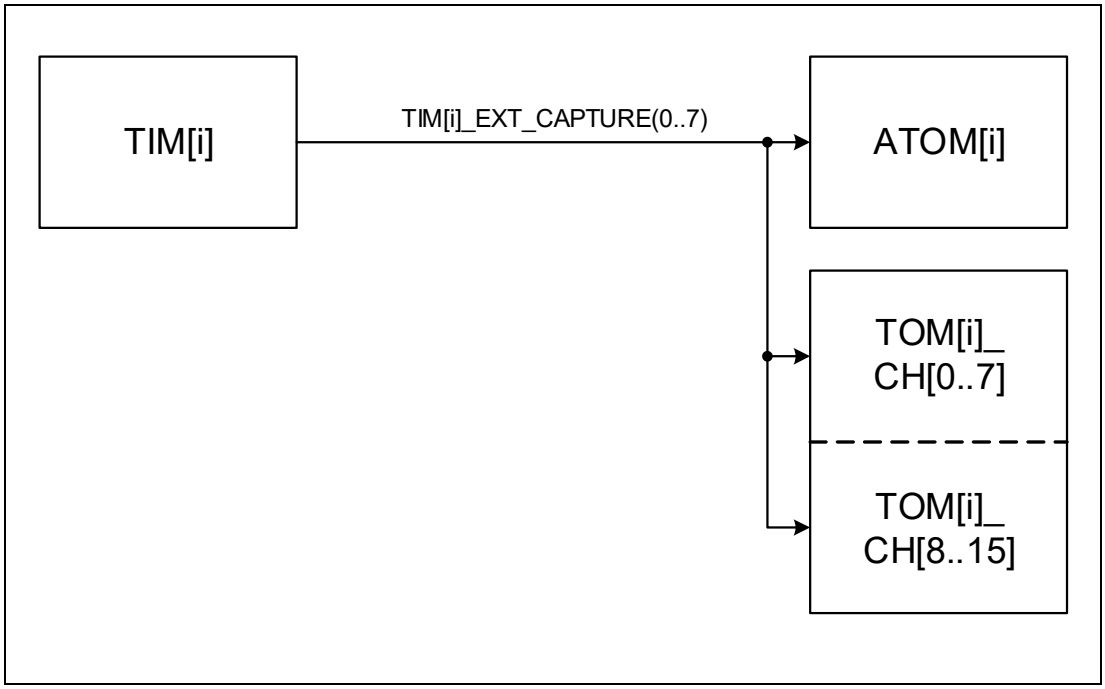

Figure 38.6 TIM external capture forwarding to TOM and ATOM

The trigger out of TIM (i.e. the signals TIM[i]_EXT_CAPTURE(7:0) of each TIM instance i) are additionally routed to the MCS instance [i]. This trigger forwarding can be enabled by register CCM[i]_EXT_CAP_EN.

38.5.2 GTM-IP Interfaces

In general the GTM-IP can be divided into four interface groups. Two interface groups represent the ports of the GTM-IP where incoming signals are assembled and outgoing signals are created. These interfaces are therefore connected to the GTM-IP input sub-module TIM and to the GTM-IP output sub-modules DTM.

Another interface is the bus master interface where the GTM-IP can be connected to the SoC system bus and actively drive read and write operations onto the SoC system bus. This generic bus interface is described in more detail in **Section 38.5.2.1, GTM-IP Generic Bus Interface (AEI)**.

Another interface is the bus slave interface where the GTM-IP can be connected to the SoC system bus to allow access to the GTM internal resources. Two options are provided for the slave interface: A generic bus interface being described in more detail in **Section 38.5.2.1**, and an AXI slave described in **Section 38.5.2.2, AXI Slave**.

The last interface is the interrupt controller interface. The GTM-IP provides several interrupt lines coming from the various sub-modules. These interrupt lines are concentrated inside the ICM and have to be adapted to the dedicated micro controller environment where each interrupt handling can look different. The interrupt concept is described in more detail in **Section 38.5.5, GTM-IP Interrupt Concept**.

38.5.2.1 GTM-IP Generic Bus Interface (AEI)

The GTM-IP is equipped with a generic bus interface that can be widely adapted to different SoC bus systems. This generic bus interface is called AE-Interface (AEI). The adaptation of the AEI to SoC buses is typically done with a bridge module translating the AEI signals to the SoC bus signals of the silicon vendor. The AEI bus signals are depicted in the following table:

Table 38.13 AEI bus signals

Signal name	I/O	Description	Bit width
AEI_SEL	I	GTM-IP select line	1
AEI_ADDR	I	GTM-IP address	32
AEI_PIPE	I	AEI Address phase signal	1
AEI_W1R0	I	Read/Write access	1
AEI_WDATA	I	Write data bus	32
AEI_RDATA	O	Read data bus	32
AEI_READY	O	Data ready signal	1
AEI_STATUS	O	AEI Access status	2

The AEI Status Signal may drive one of the following values:

Table 38.14 AEI Status Signal

AEI_STATUS	Description
00_B	No Error
01_B	Illegal Byte Addressing
10_B	Illegal Address Access
11_B	Unsupported Address

The signal value 00_B is returned if no error occurred during AEI access.

The signal value 01_B is returned if the bus address is not an integer multiple of 4 (byte addressing).

The signal value 11_B is returned if the address is not handled in the GTM.

The signal value 10_B is returned if the written register contains a protected bit field and the protection is active or if the register is temporarily not writable because of sub-module internal state or the clock of the relevant cluster is disabled or if a bit field which is not defined as read-only is written to a value unequal to "all zero" while the device dependency attribute of that bit field evaluates to false.

In case of an illegal write access signaled by status 10_B the register will not be modified.

NOTE

Exception for register CMU_CLK_CTRL. In case of write access signalled by aei_status 10_B the register will be modified each completely disabled bit.

CAUTION

aei_status 01_B is not supported in RH850/U2A-EVA Group.
When aei_status 10_B or 11_B is returned, error response will be notified to access bus master.

Reading registers will never return status 10_B.

The detailed list of register addresses with return status 10_B can be found in **Section 38.28, GTM Device 358**.

If a bit field of a register is defined as reserved, any write access to this bit field has no side effect and a read access to this bit field will always return the value 0.

If one or more encoding values of a bit field are defined as reserved values and nothing else is specified, the following default behavior is defined: The written value can be read back and the entire behavior of the circuit is undefined.

38.5.2.2 AXI Slave

(1) Functional Characteristics

The AXI slave to AEI split protocol adapter implements an AXI compliant slave interface and converts the access to be AEI split compatible. In addition it implements checks for the correctness of the AXI transaction within the given constraints of the AEI.

The block can be configured for different use-cases with generics. The supported generics are described in the following table:

- Full AMBA AXI 3.0 compliant
- Only 32 bit accesses
- 32 bit address
- 32 or 64 bit data
- No byte/halfword support
- Only aligned accesses
- Alignment check
- Single ID support
- No interleaved ID accesses
- Single burst address counter

- ID check for write data is executed
- Cache, protection and lock signals are not available (are ignored)
- Single clock operation
- Single low active asynchronous reset signal
- AEI split protocol
- Additional AEI sideband signals
- Support for two AXI Debugger IDs

(2) AXI to AEI Split Adapter Block

(a) Functional View

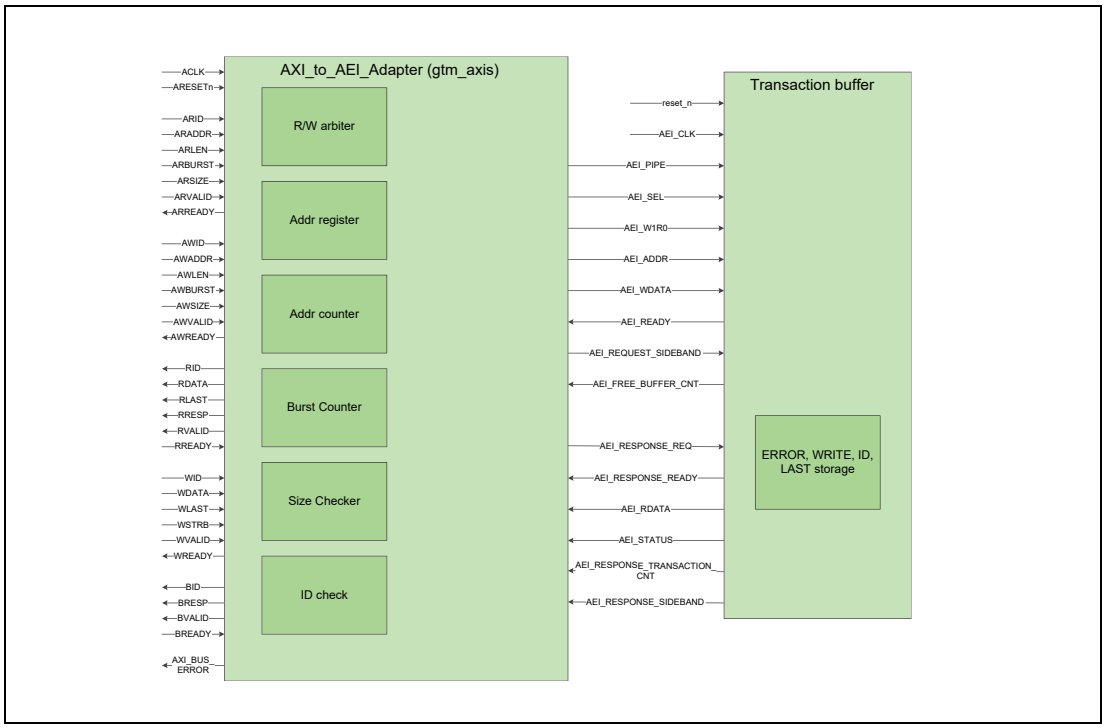

Figure 38.7 Block Diagram AXI slave

Figure 38.7 shows the basic modules of the adapter block. The transaction buffer is not part of the adapter block, but part of the block the adapter is integrated in.

(b) Entity Table

The block has an AXI slave interface on the "left" side and an AEI split master interface on the "right" side. **Table 38.15** described the block entity pins.

Table 38.15 Pin List (1/2)

Port Name	Width	Direction	Description
General AXI Signals			
ACLK	1	input	AXI reference clock
ARESETn	1	input	AXI reset signal (low active)
Read Address Channel			
ARID	Generic	input	AXI transaction ID, ID width can be selected via generic
ARADDR	32	input	AXI read address
ARLEN	4	input	AXI read burst length
ARBURST	2	input	AXI read burst type
ARSIZE	3	input	AXI read size, must always be b010, as we only allow word accesses
ARVALID	1	input	AXI read valid
ARREADY	1	output	AXI read ready
Write Address Channel			
AWID	Generic	input	AXI transaction ID, ID width can be selected via generic
AWADDR	32	input	AXI write address
AWLEN	4	input	AXI write burst length
AWBURST	2	input	AXI write burst type
AWSIZE	3	input	AXI write data size (must always be b010, as we only support 32bit accesses)
AWVALID	1	input	AXI write data valid
AWREADY	1	output	AXI write data ready
Read Data Channel			
RID	Generic	output	AXI transaction ID, ID width can be selected via generic
RDATA	Generic	output	AXI read data
RLAST	1	output	AXI real last in a burst signal
RRESP	2	output	AXI read response
RVALID	1	output	AXI read data valid
RREADY	1	input	AXI read data ready
Write	Data	Channel	
WID	Generic	input	AXI transaction ID, ID width can be selected via generic
WDATA	Generic	input	AXI write data
WLAST	1	input	AXI write last in a burst signal
WSTRB	4	input	AXI byte strobes (must by all high, as we only support full word access)
WVALID	1	input	AXI write data valid

Table 38.15 Pin List (2/2)

Port Name	Width	Direction	Description
WREADY	1	output	AXI write data ready
Write Response Channel			
BID	Generic	output	AXI transaction ID, ID width can be selected via generic
BRESP	2	output	AXI write response
BVALID	1	output	AXI write response valid
BREADY	1	input	AXI wire response ready
AEI Master Signals			
AEI_PIPE	1	output	AEI pipe signal (always 1)
AEI_SEL	1	output	AEI select
AEI_W1R0	1	output	AEI write/read selection
AEI_DEBUG_ACCESS	1	output	AEI debugger access
AEI_ADDR	32	output	AEI address
AEI_WDATA	32	output	AEI write data
AEI_READY	1	input	AEI ready
AEI_REQUEST_SIDEBAND	Generic	output	AEI request sideband signals, the slave shall provide this value when providing the related response
AEI_FREE_BUFFER_CNT	Generic	input	AEI number of free request entries
AEI_RESPONSE_REQ	1	output	AEI response request
AEI_RESPONSE_READY	1	input	AEI response ready
AEI_RDATA	32	input	AEI read data
AEI_STATUS	2	input	AEI transaction status AEI number of available response transactions Same width as AEI_FREE_CNT
AEI_RESPONSE_SIDEBAND	Generic	input	AEI response sideband signals. Here the slave shall provide the value from the related request
General AXI Signals			
AXI_BUS_ERROR	1	output	Illegal AXI transaction detected (system sideband signal)

38.5.3 ARU Routing Concept

One central concept of the GTM-IP is the routing mechanism of the ARU sub-module for data streams. Each data word transferred between the ARU and its connected sub-module is 53-bit wide. It is important to understand this concept in order to use the resources of the GTM-IP effectively. Each module that is connected to the ARU may provide an arbitrary number of ARU write channels and an arbitrary number of ARU read channels. In the following, the ARU write channels are named data sources and the ARU read channels are named data destinations.

The concept of the ARU intends to provide a flexible and resource efficient way for connecting any data source to an arbitrary data destination. In order to save resource costs, the ARU does not implement a switch matrix, but it implements a data router with serialized connectivity providing the same interconnection flexibility. **Figure 38.8** shows the ARU data routing principle. Data sources are marked with a green rectangle and the data destinations are marked with yellow rectangles. The dashed lines in the ARU depict the configurable connections between data sources and data destinations. A connection between a data source and a data destination is also called a data stream.

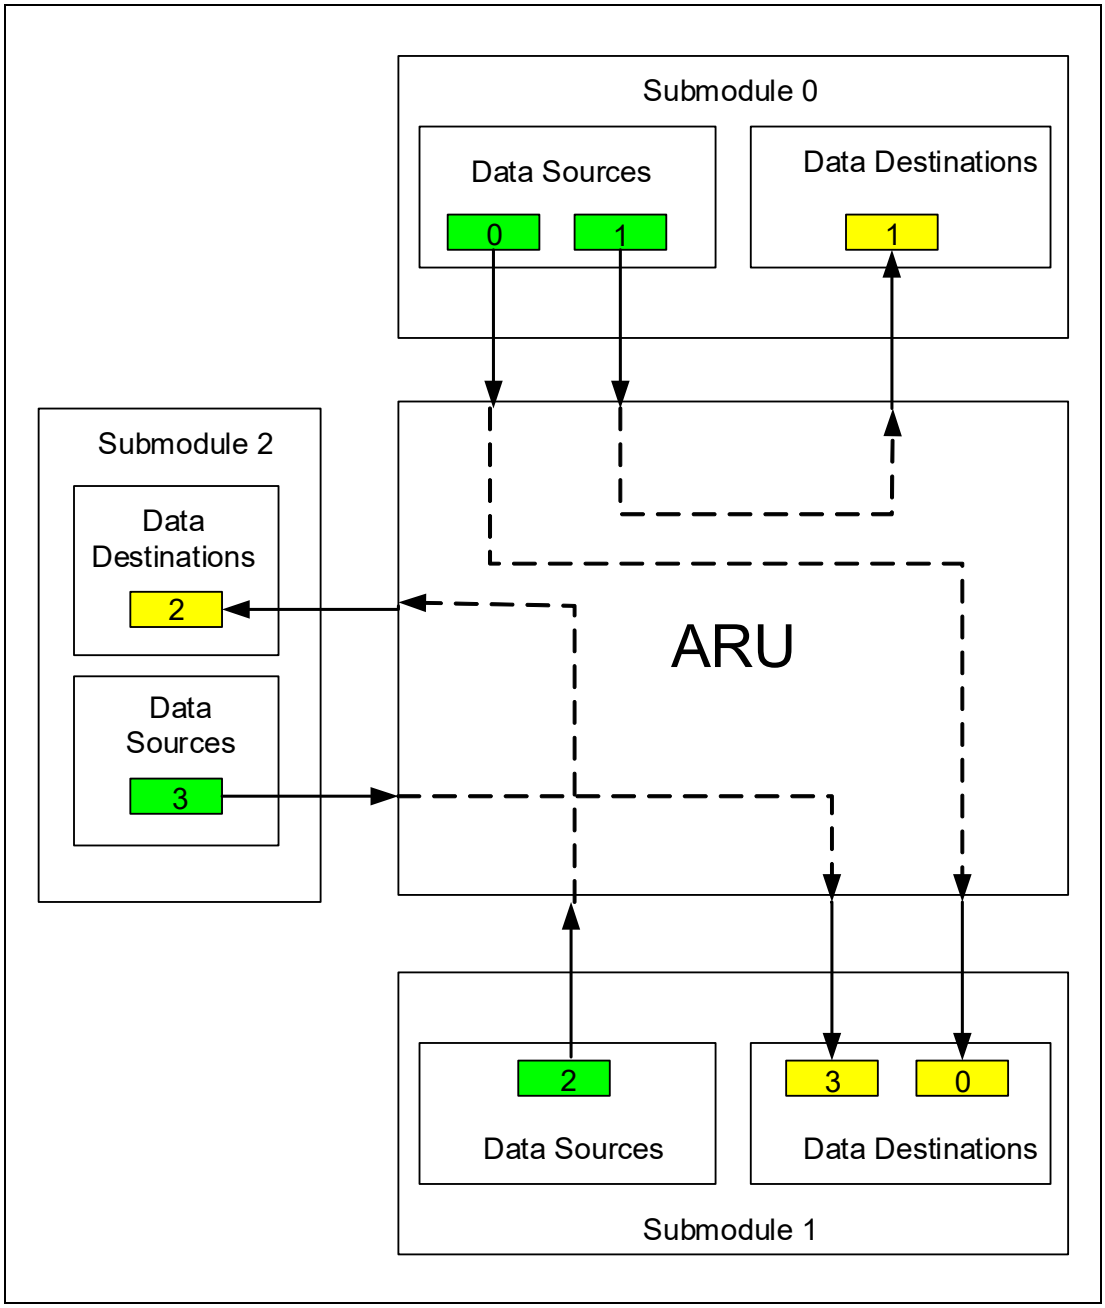

Figure 38.8 Principle of data routing using ARU

The configuration of the data streams is realized according to the following manner: Each data source has its fixed and unique source address: The ARU read ID. The fixed address of each data source is pointed out by the numbers in the green boxes of **Figure 38.8**. The address definitions of all available data sources in the GTM-IP can be obtained from **Table 38.520, ARU Write Addresses**. The connection from a specific data source to a specific data destination is defined by configuring the corresponding address of a data source (i.e. the ARU read ID) in the desired data destination. The configured address of each data destination is pointed out by the numbers in the yellow boxes of **Figure 38.8**.

Normally, the destination is idle and waits for data from the source. If the source offers new data, the destination does a destructive read, processes the data and goes idle again. The same data is never read twice.

There is one sub-module for which this destructive read access does not hold. This is the BRC sub-module configured in Maximal Throughput Mode. For a detailed description of this module, refer to **Section 38.8, Broadcast Module (BRC)**.

The functionality of the ARU is as follows: The ARU sequentially polls the data destinations of the connected modules in a round−robin order.

If a data destination requests new data from its configured data source and the data source has data available, the ARU delivers the data to the destination and it informs both, the data source and destination that the data is transferred. The data source marks the delivered ARU data as invalid which means that the destination consumed the data.

It should be noted that each data source should only be connected to a single data destination. This is because the destinations consume the data. If two destinations would reference the same source one destination would consume the data before the other destination could consume it. Since the data transfers are blocking, the second destination would block until it receives new data from the source. If a data source should be connected to more than one data destination the sub-module Broadcast (BRC) has to be used. On the other hand, the transfer from a data source to the ARU is also blocking, which means that the source channel can only provide new data to the ARU when an old data word is consumed by a destination. In order to speed up the process of data transfers, the ARU handles two different data destinations in parallel.

Following table gives an overview about the number of data destinations and data sources of each GTM-IP instance type.

Table 38.16 ARU source and destination address count per instance

Sub-module	Number of data sources per instance	Number of data destinations per instance
ARU	1	0
DPLL	24	24
TIM	8	0
MCS	24	8
BRC	22	12
TOM	0	0
ATOM	8	8
DTM	0	0
PSM	8	8
ICM	0	0
CPM	0	0
MON	0	0
CCM	0	0

(1) ARU Round Trip Time

The ARU uses a round-robin arbitration scheme with a fixed round trip time for all connected data destinations. This means that the time between two adjacent read requests resulting from a data destination channel always takes the round trip time, independently if the read request succeeds or fails.

(2) ARU Blocking Mechanism

Another important concept of the ARU is its blocking mechanism that is implemented for transferring data from a data source to a data destination. This mechanism is used by ARU connected sub-modules to synchronize the sub-modules to the routed data streams. **Figure 38.9** explains the blocking mechanism.

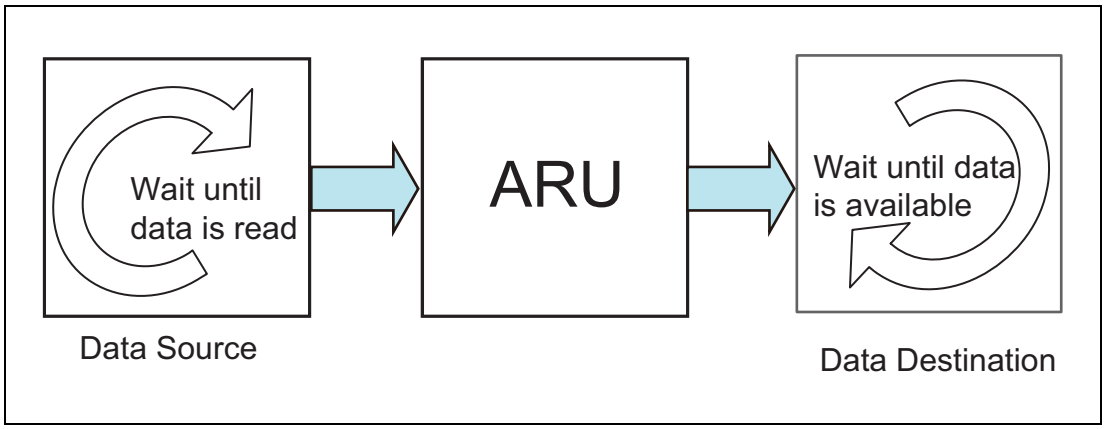

Figure 38.9 Graphical representation of ARU blocking mechanism

If a data destination requests data from a data source over the ARU but the data source does not have any data yet, it has to wait until the data source provides new data. In this case the sub-module that owns the data destination may perform other tasks. When a data source produces new data faster than a data destination can consume the data the source raises an error interrupt and signals that the data could not be delivered in time. The new data is marked as valid for further transfers and the old data is overwritten.

In any case the round trip time for the ARU has a fixed reset value for a specific device configuration. The end value of the roundtrip counter can be changed with a configuration register ARU_CADDR_END inside the ARU. For more details see the ARU specific chapter. Refer also to device specific **Section 38.28, GTM Device 358** of this specification for detailed information.

It is possible to reset the ARU roundtrip counter ARU_CADDR manually synchronous to CMU clock enable from configuration register inside CMU module. Refer to CMU specific chapter for more details. One exception is the BRC sub-module when configured in Maximal Throughput Mode. Refer to **Section 38.8, Broadcast Module (BRC)** for a detailed description.

38.5.4 GTM-IP Clock and Time Base Management (CTBM)

Inside the GTM-IP several subunits are involved in the clock and time base management of the whole GTM. **Figure 38.10** shows the connections and sub blocks involved in these tasks. The sub blocks involved are called Clock and Time Base Management (CTBM) modules further on.

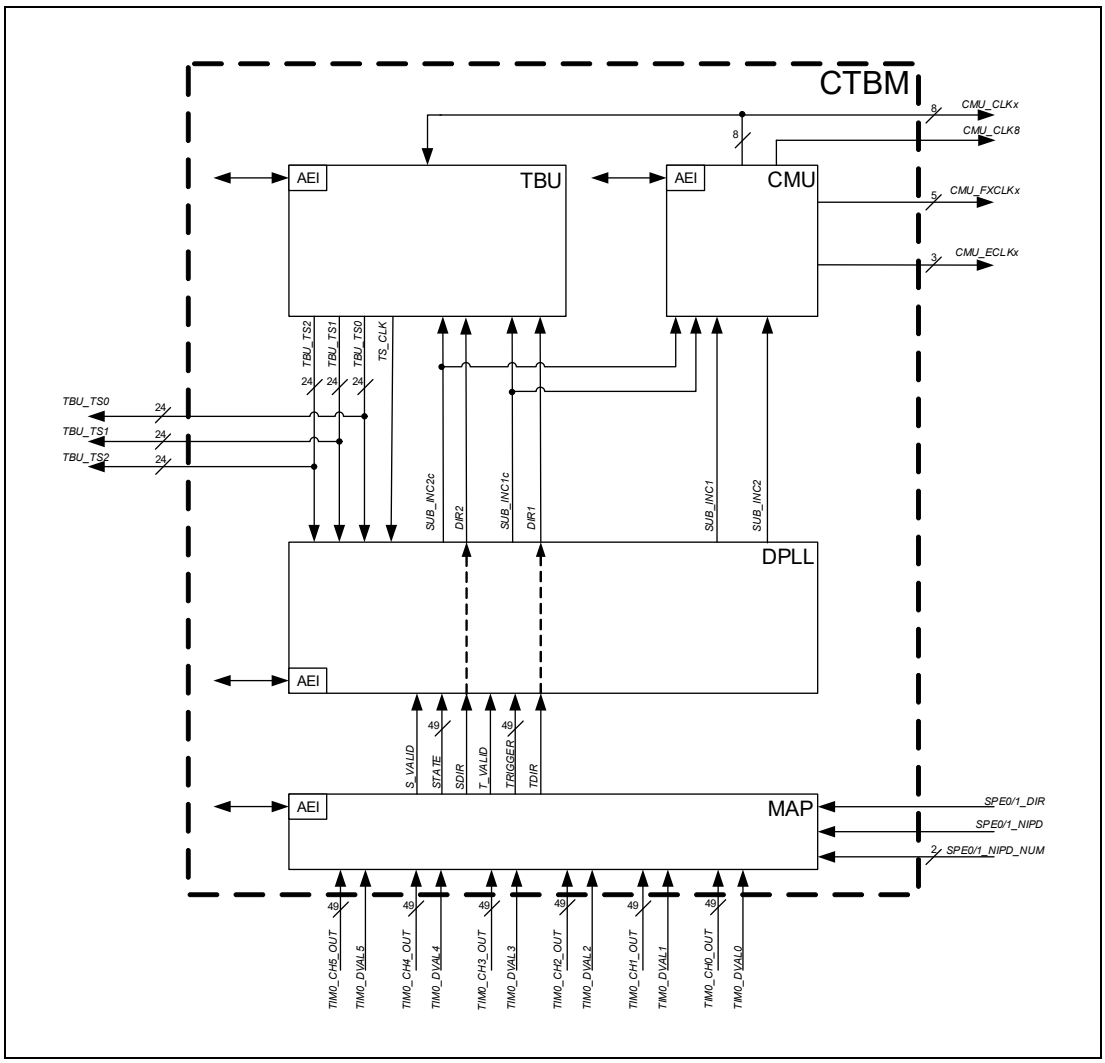

Figure 38.10 GTM-IP Clock and time base management architecture

One important module of the CTBM is the Clock Management Unit (CMU) which generates up to 14 clocks for the sub-modules of the GTM and up to three GTM external clocks CMU_ECLK[z] (z: 0 to 2). For a detailed description of the CMU functionality and clocks, refer to **Section 38.12, Clock Management Unit (CMU)**.

The five CMU_FXCLK[y] (y: 0 to 4) clocks are used by the TOM sub-module for PWM generation.

A maximum of nine CMU_CLK[x] (x: 0 to 8) clocks are used by other sub-modules of the GTM for signal generation.

Inside the Time Base Unit (TBU) one of CMU_CLK[x] (x: 0 to 7) clocks is used per channel to generate a common time base for the GTM.

Besides the CMU_CLK[x] signals, the TBU can use the compensated SUB_INC[i]c (i: 1, 2) signals coming from the DPLL sub-module for time base generation. This time base then typically represents an angle clock for an engine management system. For the meaning of compensated (SUB_INC[i]c) and

uncompensated (SUB_INC[i]) DPLL signals, refer to the DPLL **Section 38.22, Digital PLL Module (DPLL)**. The SUB_INC[i]c signals in combination with the two direction signal lines DIR[i] the TBU time base can be controlled to run forwards or backwards. The TBU functionality is described in **Section 38.14, Time Base Unit (TBU)**.

The TBU sub-module generates the three time base signals TBU_TS0, TBU_TS1 and TBU_TS2 which are widely used inside the GTM as common time bases for signal characterization and generation.

Besides the time base 1 and 2 which may represent a relative angle clock for an engine management system it is helpful to have an absolute angle clock for CPU/MCS internal angle algorithm calculations. This absolute angle clock is represented by the TBU base 3. The TBU channel 0 up to 2 are widely used inside the GTM as common time (channel 0, 1 and/or 2) or angle (channel 1 and/or 2) bases for signal characterization and generation. The TBU channel 3 is only configurable and readable by MCS0 or CPU.

As stated before, the DPLL sub-module provides the four clock signals SUB_INC[i] and SUB_INC[i]c which can be seen as a clock multiplier generated out of the two input signal vectors TRIGGER and STATE coming from the MAP sub-module. For a detailed description of the DPLL functionality refer to **Section 38.22, Digital PLL Module (DPLL)**.

The MAP sub-module is used to select the TRIGGER and STATE signals for the DPLL out of six input signals coming from TIM0 sub-module.

Besides this, the MAP sub-module is able to generate a TDIR (TRIGGER Direction) and SDIR (STATE Direction) signal for the DPLL and TBU coming from the SPE0 and SPE1 signal lines. The direction signals are generated out of a defined input pattern. For a detailed description of the MAP sub-module, refer to **Section 38.21, TIM0 Input Mapping Module (MAP)**.

38.5.4.1 Cyclic Event Compare

With the time base module (TBU) the GTM provides three counters, where the counter of TBU_CH0 represents a time and the counter TBU_CH1 and TBU_CH2 may represent a time (if clock source is CMU_CLK generated inside CMU) or an angle (if clock source is a DPLL sub_inc signal provided via CMU).

From application point of view it is necessary to divide the cyclic event counter representing time or angle into two parts, the past and the future. The border of past/future is a moving border depending on current time or angle value. The cyclic event counting and the moving border of past/future is depicted in the figure below.

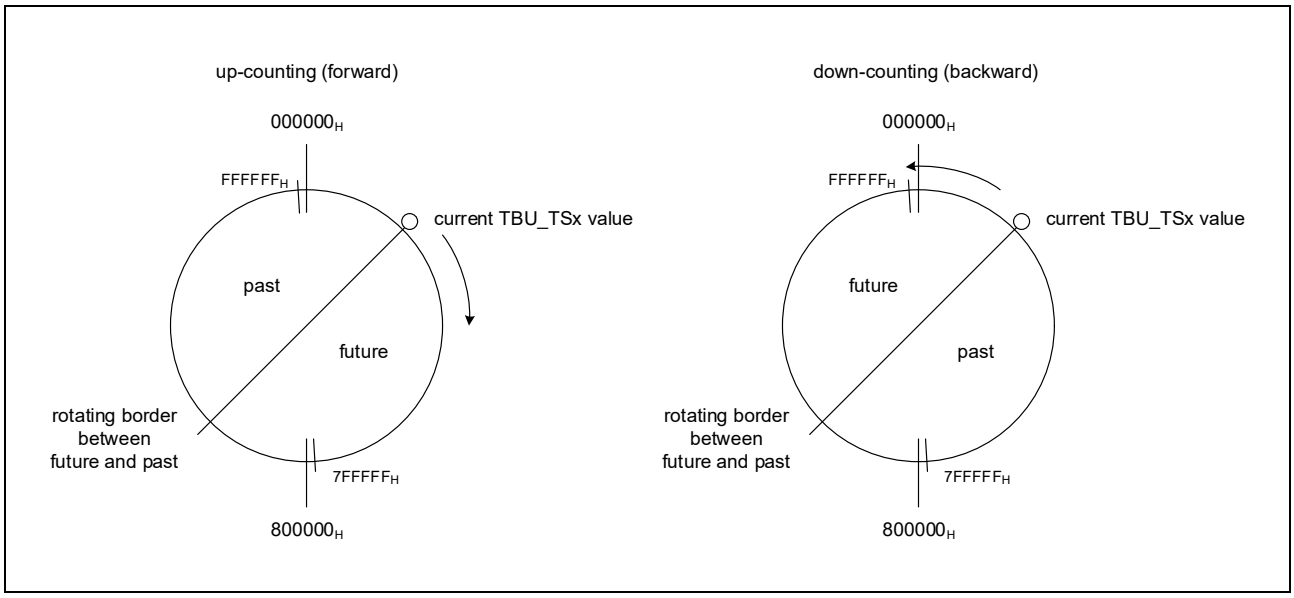

Figure 38.11 Cyclic event counter representing time or angle

Inside different sub-modules of GTM a greater−equal compare (in case of up-counting) or a less-equal compare (in case of down-counting) against a TBU base value (representing time or angle) always means that it is checked if the reference value is in relation to the current TBU value in the future or in the past.

38.5.5 GTM-IP Interrupt Concept

The sub-modules of the GTM-IP can generate thousands of interrupts on behalf of internal events. This high amount of interrupts is combined inside the Interrupt Concentrator Module (ICM) into interrupt groups. In these interrupt groups the GTM-IP sub-module interrupt signals are bundled to a smaller set of interrupts. From these interrupt sets, a smaller amount of interrupt signals is created and signaled outside of the GTM-IP as a signal GTM_<MOD>_IRQ, where <MOD> identifies the name of the corresponding GTM-IP sub-module.

Moreover, each output signal GTM_<MOD>_IRQ has a corresponding input signal GTM_<MOD>_IRQ_CLR that can be used for clearing the interrupts. These input signals can be used by the surrounding micro controller system as:

- acknowledge signal from a DMA controller
- validation signal from ADC
- clear signal from an GTM-external interrupt controller to do an atomic clear while entering an ISR routine

The controlling of the individual interrupts is done inside the sub-modules. If a sub-module consists of several sub-module channels that are most likely to work independent from each other (like TIM, PSM, MCS, TOM, and ATOM), each sub-module channel has its own interrupt control and status register set, named as interrupt set in the following. Other sub-modules (SPE, ARU, DPLL, BRC, CMP and global GTM functionality) have a common interrupt set for the whole sub-module.

The interrupt set consists of four registers: The IRQ_EN register, the IRQ_NOTIFY register, the IRQ_FORCINT register, and the IRQ_MODE register. While the registers IRQ_EN, IRQ_NOTIFY, and IRQ_FORCINT signalize the status and allow controlling of each individual interrupt source within an interrupt set, the register IRQ_MODE configures the interrupt mode that is applied to all interrupts that belong to the same interrupt set.

In order to support a wide variety of micro controller architectures and interrupt systems with different interrupt signal output characteristics and internal interrupt handling the following four modes can be configured:

- Level mode
- Pulse mode
- Pulse-Notify mode
- Single-Pulse mode

These interrupt modes are described in more details in the following subsections.

The register IRQ_EN allows the enabling and disabling of an individual interrupt within an interrupt set. Independent of the configured mode, only enabled interrupts can signalize an interrupts on its signal GTM_<MOD>_IRQ.

The register IRQ_NOTIFY collects the occurrence of interrupt events. The behavior for setting a bit in this register depends on the configured mode and thus it is described later on in the mode descriptions. Independent of the configured mode any write access with value ‘1’ to a bit in the register IRQ_NOTIFY always clears the corresponding IRQ_NOTIFY bit.

Moreover, the enabling of a disabled interrupt source with a write access to the register IRQ_EN also clears the corresponding bit in the IRQ_NOTIFY register but only if the error interrupt source EIRQ_EN is disabled. However, if the enabling of a disabled interrupt is simultaneous to an incoming interrupt event, the interrupt event is dominant and the register IRQ_NOTIFY is not cleared.

Additionally, each write access to the register IRQ_MODE, clears all bits in the IRQ_NOTIFY register. It should be notified that the clearing of IRQ_NOTIFY is applied independently of the written data (e.g. no mode change).

Thus, a secure way for reconfiguring the interrupt mode of an interrupt set, is to disable all interrupts of the interrupt set with the register IRQ_EN, define the new interrupt mode by writing register IRQ_MODE, followed by enabling the desired interrupts with the register IRQ_EN.

Thus, a secure way for reconfiguring the interrupt mode of an error interrupt set, is to disable all error interrupts of the error interrupt set with the register EIRQ_EN, define the new interrupt mode by writing register IRQ_MODE, followed by enabling the desired error interrupts with the register EIRQ_EN.

The register IRQ_FORCINT is used by software for triggering individual interrupts with a write access with value ‘1’. Since a write access to IRQ_FORCINT only generates a single pulse, IRQ_FORCINT is not implemented as a true register and thus any read access to IRQ_FORCINT always results with a value of ‘0’.

The mechanism for triggering interrupts with IRQ_FORCINT is globally disabled after reset. It has to be explicitly enabled by clearing the bit RF_PROT in the register GTM_CTRL (see **Section 38.5.9.3, GTM_CTRL**).

For the modules AEI-bridge, BRC, FIFO, TIM, MCS, DPLL, SPE and CMP each interrupt may configured to raise instead of the normal interrupt an error interrupt if enabled by the corresponding error interrupt enable bit in register EIRQ_EN. It is possible for one source to enable the normal interrupt and the error interrupt in parallel. Because both interrupt clear signals could reset the notify bit this is expected to cause problems in a system and therefore it is strongly recommended to not enable both interrupt types at the same point in time.

Similar to enabling an interrupt, the enabling of a disabled error interrupt source with a write access to the register EIRQ_EN also clears the corresponding bit in the IRQ_NOTIFY register only if the interrupt source IRQ_EN is disabled. However, if the enabling of a disabled error interrupt is simultaneous to an incoming interrupt event, the interrupt event is dominant and the register IRQ_NOTIFY is not cleared.

All enabled error interrupts are OR-combined inside the ICM and assigned to the dedicated GTM port gtm_err_irq. A corresponding input gtm_err_irq_clr allows the reset of this error interrupt from outside the GTM (hardware clear).

To be able to detect the module source of the error interrupt the ICM provides the register ICM_IRQG_MEI.

The error interrupt causing channel can be determined for the module FIFO by evaluating the ICM register ICM_IRQG_CEI0.

The error interrupt causing channel can be determined for the modules TIM by evaluating the ICM register ICM_IRQG_CEI1 to 2.

The error interrupt causing channel can be determined for the modules MCS with all possible channel by evaluating the ICM register

ICM_IRQG_MCS[i]_CEI. In case of usage only the first 8 channels of each MCS the error interrupt causing channel can be determined by evaluating the ICM register ICM_IRQG_CEI3 to 4.

38.5.5.1 Level interrupt mode

The default interrupt mode is the Level Interrupt Mode. In this mode each occurred interrupt event is collected in the register IRQ_NOTIFY, independent of the corresponding enable bit of register IRQ_EN and EIRQ_EN.

An interrupt event, which is defined as a pulse on the signal Int_out of **Figure 38.12**, may be triggered by the interrupt source of the sub-module or by software performing a write access to the corresponding register IRQ_FORCINT, with a disabled bit RF_PROT in register GTM_CTRL.

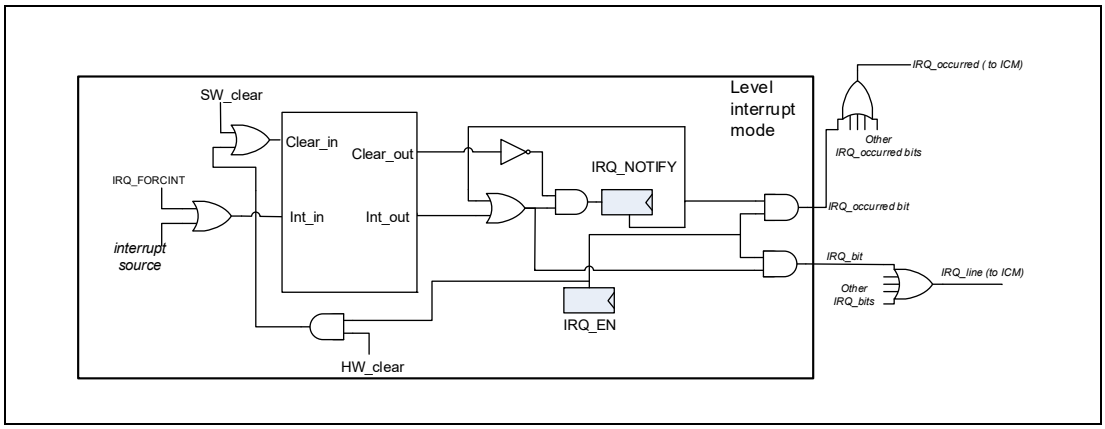

Figure 38.12 Level interrupt mode scheme

A collected interrupt bit in register IRQ_NOTIFY may be cleared by a clear event, which is defined as a pulse on signal Clear_out of **Figure 38.12**. A clear event can be performed by writing '1' to the corresponding bit in the register IRQ_NOTIFY leading to a pulse on signals SW_clear.

A clear event may also result from an externally connected signal GTM_<MOD>_IRQ_CLR, which is routed to the signal HW_clear of **Figure 38.12**. However, the hardware clear mechanism is only possible, if the corresponding interrupt is enabled by register IRQ_EN.

As **Table 38.17, Priority of Interrupt Events and Clear Events** shows, interrupt events are dominant in the case of a simultaneous interrupt event and clear event.

Table 38.17 Priority of Interrupt Events and Clear Events

Int_in	Clear_in	Int_out	Clear_out
0	0	0	0
0	1	0	1
1	0	1	0
1	1	1	0

As shown in **Figure 38.12** an occurred interrupt event is signaled as a constant signal level with value 1 to the signal IRQ_bit, if the corresponding interrupt is enabled in register IRQ_EN.

With exception of the sub-modules ARU and DPLL, the signal IRQ_bit is OR-combined with the neighboring IRQ_bit signals of the same interrupt set and they are routed as a signal IRQ_line to the interrupt concentrator module (ICM). The interrupt signals IRQ_bit of the sub-modules DPLL and ARU are routed directly as a signal IRQ_line to the sub-module ICM. In some cases (sub-modules TOM and ATOM) the ICM may further OR-combine several IRQ_line signals to an outgoing interrupt signal GTM_<MOD>_IRQ. In the other cases the IRQ_line signals are directly connected to the outgoing signals GTM_<MOD>_IRQ, within the sub-module ICM.

The signal IRQ_occurred is connected in a similar way as the signal IRQ_line, however this signal is used for monitoring the interrupt state of the register IRQ_NOTIFY in the registers of the ICM.

The additional error interrupt enable mechanism for level interrupt is shown below.

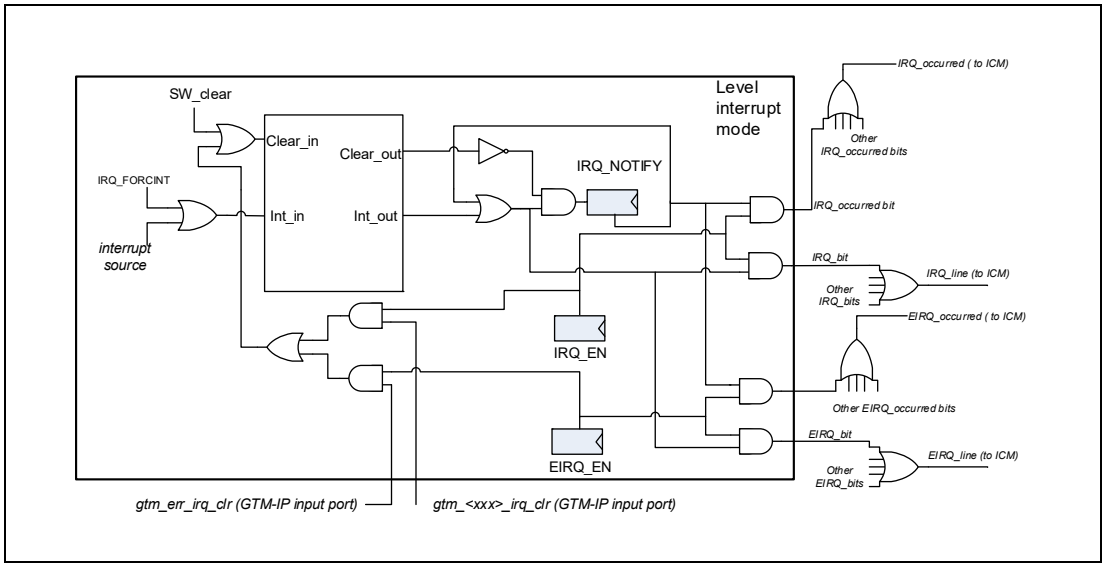

Figure 38.13 Level interrupt scheme for modules AEI-bridge, BRC, FIFO, TIM, MCS, DPLL, SPE, CMP

A collected interrupt bit in register IRQ_NOTIFY may be cleared by a clear event, which is defined as a pulse on signal Clear_out of **Figure 38.13**. A clear event can be performed by writing '1' to the corresponding bit in the register IRQ_NOTIFY leading to a pulse on signals SW_clear. A clear event may also result from the externally connected signal gtm_<MOD>_irq_clr or gtm_err_irq_clr, which is routed as an HW_clear to Clear_in of **Figure 38.13**. However, the hardware clear mechanism is only possible, if the corresponding interrupt or error interrupt is enabled by register IRQ_EN or EIRQ_EN.

As it can be seen from the **Figure 38.13** an occurred interrupt event is signaled as a constant signal level with value 1 to the signal IRQ_bit, if the corresponding interrupt is enabled in register IRQ_EN.

CAUTION

Level mode is not supported in RH850/U2A-EVA Group.

38.5.5.2 Pulse interrupt mode

The Pulse interrupt mode behavior can be observed from **Figure 38.14**.

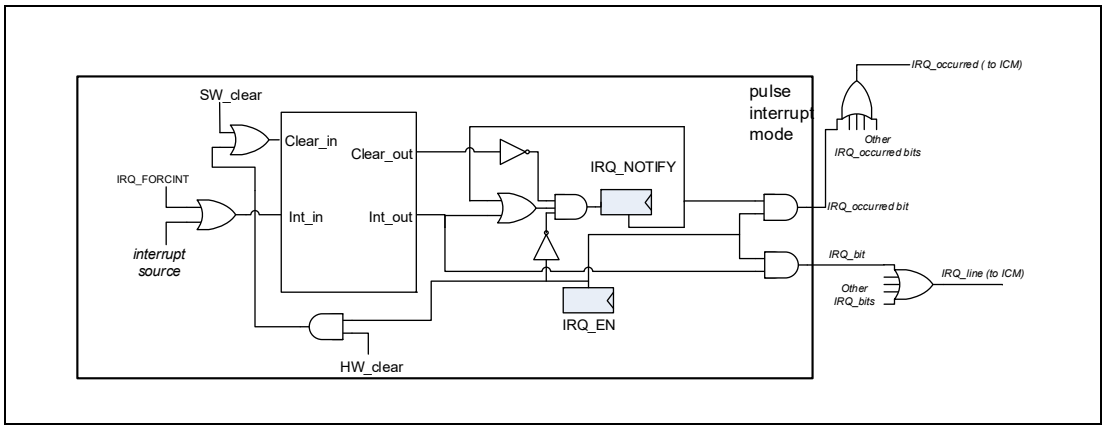

Figure 38.14 Pulse interrupt mode scheme

In Pulse Interrupt Mode each Interrupt Event will generate a pulse on the IRQ_bit signal if IRQ_EN is enabled. As it can be seen from the figure, the interrupt bit in IRQ_NOTIFY register is always cleared if IRQ_EN is enabled. However, if an interrupt is disabled in the register IRQ_EN, an occurred interrupt event is captured in the register IRQ_NOTIFY, in order to allow polling for disabled interrupts by software. Disabled interrupts may be cleared by an interrupt clear event.

In Pulse interrupt mode, the signal IRQ_occurred is always 0.

The additional error interrupt enable mechanism for pulse interrupt is shown below.

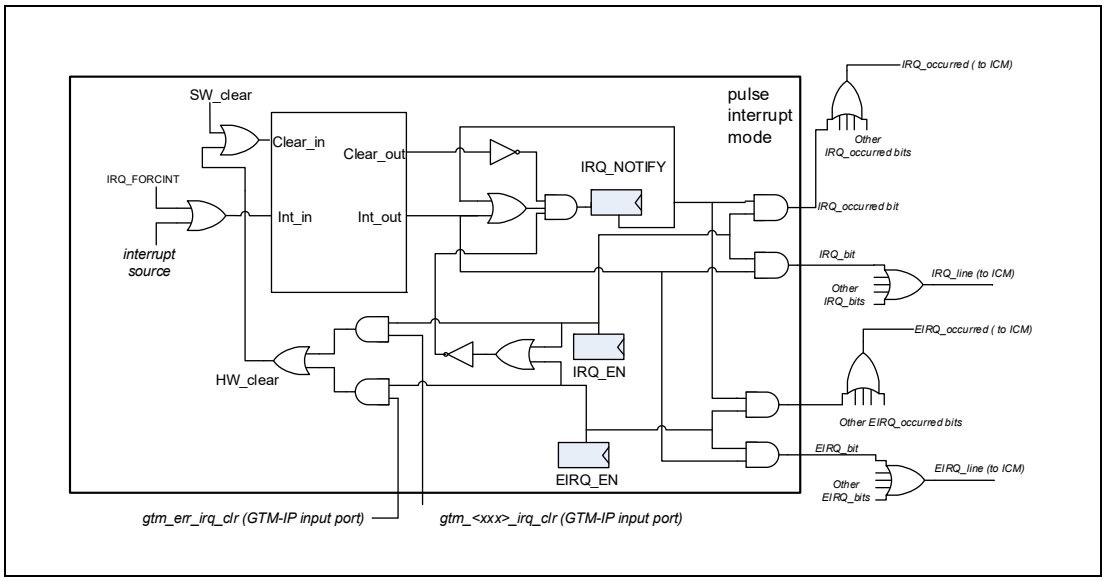

Figure 38.15 Pulse interrupt scheme for modules AEI-bridge, BRC, FIFO, TIM, MCS, DPLL, SPE, CMP

In Pulse Interrupt Mode each Interrupt Event will generate a pulse on the EIRQ_bit signal if EIRQ_EN is enabled.

As it can be seen from the figure, the interrupt bit in IRQ_NOTIFY register is always cleared if EIRQ_EN or IRQ_EN are enabled.

However, if an error interrupt is disabled in the register EIRQ_EN, an occurred error interrupt event is captured in the register IRQ_NOTIFY, in order to allow polling for disabled error interrupts by software.

Disabled error interrupts may be cleared by an error interrupt clear event.

In Pulse interrupt mode, the signal EIRQ_occurred is always 0.

38.5.5.3 Pulse-notify interrupt mode

In Pulse-notify Interrupt mode, all interrupt events are captured in the register IRQ_NOTIFY. If an interrupt is enabled by the register IRQ_EN, each interrupt event will also generate a pulse on the IRQ_bit signal. The signal IRQ_occurred will be high if interrupt is enabled in register IRQ_EN and the corresponding bit of register IRQ_NOTIFY is set. The Pulse-notify interrupt mode is shown in **Figure 38.16**.

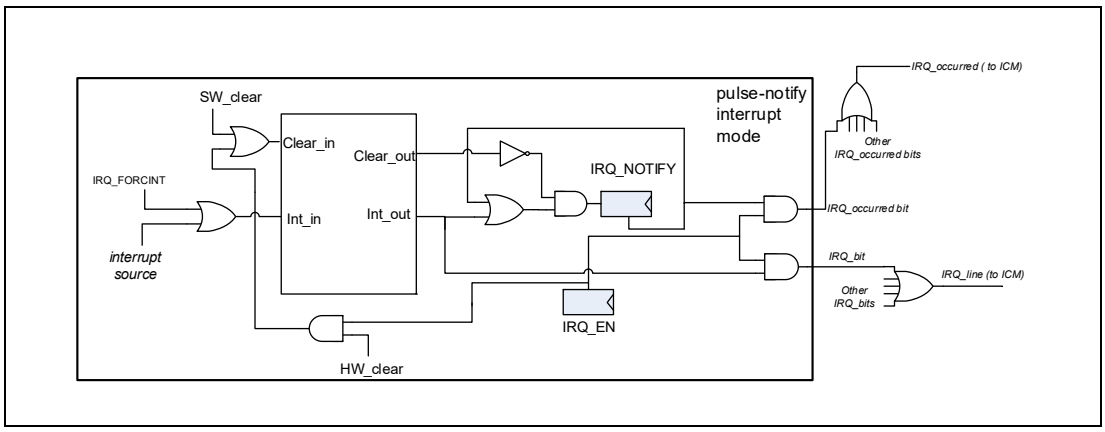

Figure 38.16 Pulse-notify interrupt mode scheme

The additional error interrupt enable mechanism for pulse-notify interrupt is shown below.

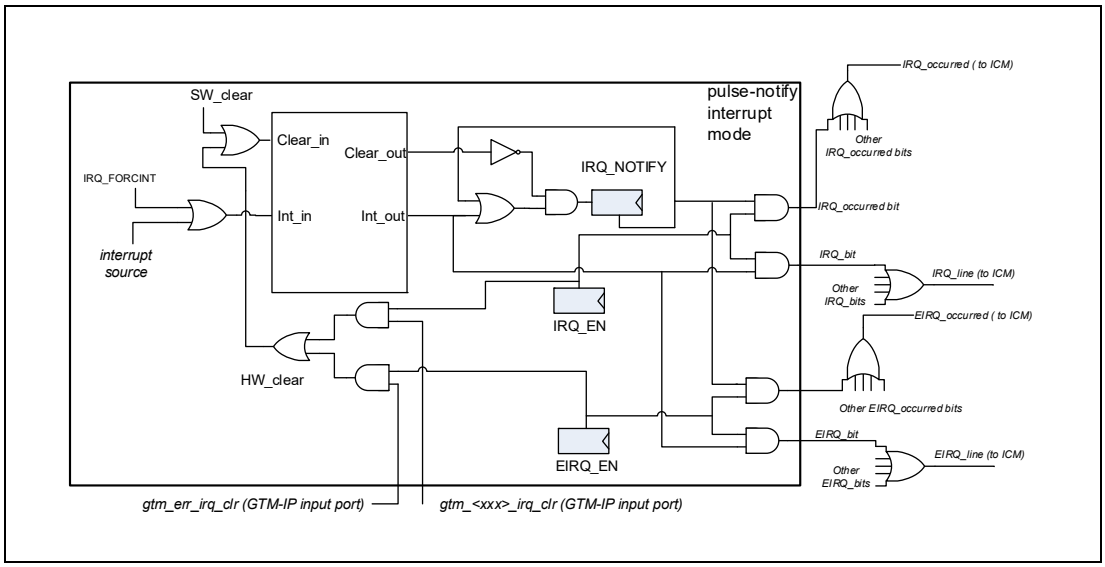

Figure 38.17 Pulse-notify interrupt scheme for modules AEI-bridge, BRC, FIFO, TIM, MCS, DPLL, SPE, CMP

In Pulse-notify Interrupt mode, all error interrupt events are captured in the register IRQ_NOTIFY. If an error interrupt is enabled by the register EIRQ_EN, each error interrupt event will also generate a

pulse on the EIRQ_bit signal. The signal EIRQ_occurred will be high if error interrupt is enabled in register EIRQ_EN and the corresponding bit of register IRQ_NOTIFY is set. The Pulse-notify interrupt mode for error interrupts is shown in **Figure 38.17**.

38.5.5.4 Single-pulse interrupt mode

In Single-pulse Interrupt Mode, an interrupt event is always captured in the register IRQ_NOTIFY, independent of the state of IRQ_EN. However, only the first interrupt event of an enabled interrupt within a common interrupt set is forwarded to signal IRQ_line. Additional interrupt events of the same interrupt set cannot generate pulses on the signal IRQ_line, until the corresponding bits in register IRQ_NOTIFY of enabled interrupts are cleared by a clear event. The IRQ_occurred signal line will be high, if the IRQ_EN and the IRQ_NOTIFY register bits are set. The Single-pulse interrupt mode is shown in **Figure 38.18**.

The only exceptions are the modules ARU and DPLL. In these modules the IRQ_occurred bit of each interrupt is directly connected (without OR-conjunction of neighboring IRQ_occurred bits) to the inverter for suppressing further interrupt pulses.

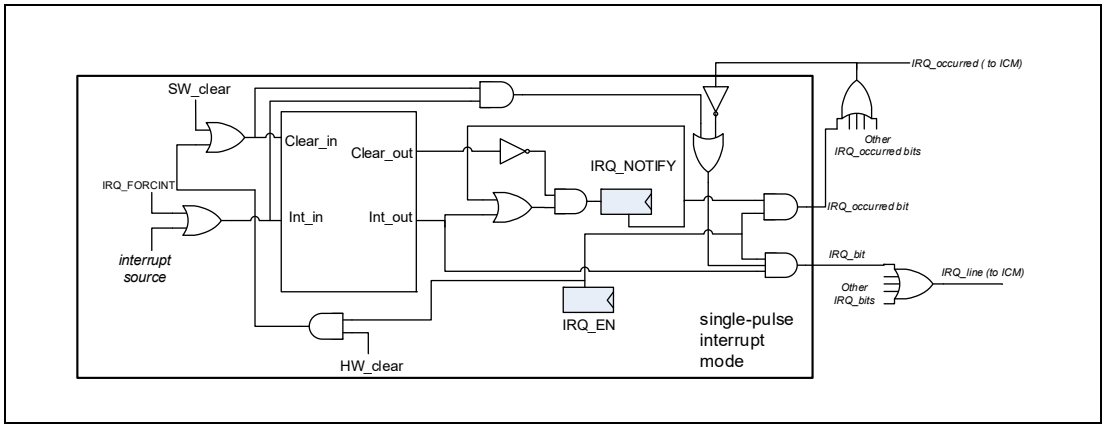

Figure 38.18 Single-pulse interrupt mode scheme

To avoid unexpected IRQ behavior in the single pulse mode, all desired interrupt sources should be enabled by a single write access to IRQ_EN and the notification bits should be cleared by a single write access to the register IRQ_NOTIFY.

The additional error interrupt enable mechanism for single-pulse interrupt is shown below

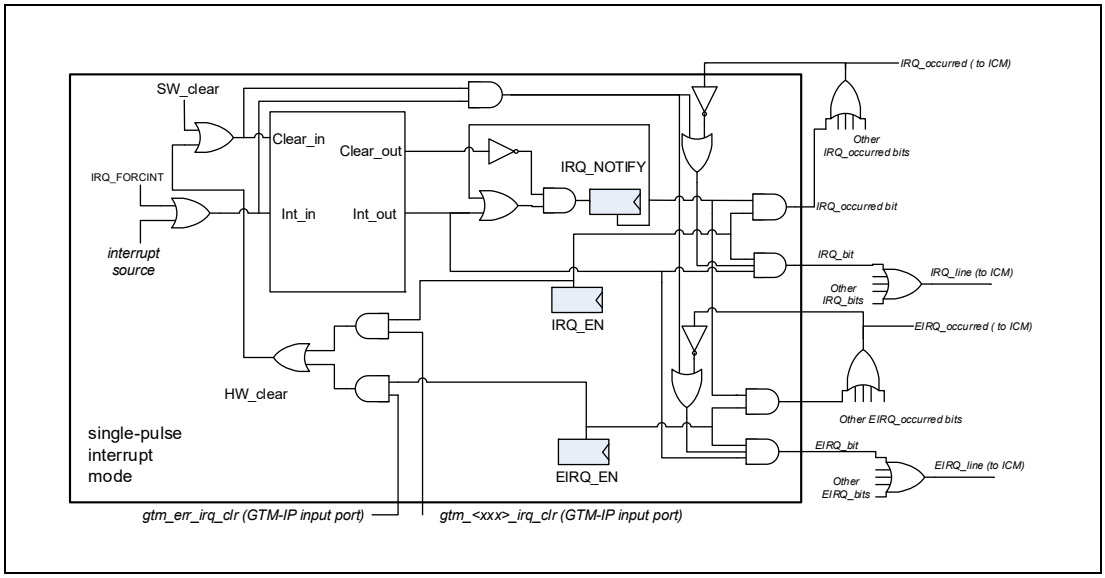

Figure 38.19 Single-pulse interrupt scheme for modules AEI-bridge, BRC, FIFO, TIM, MCS, DPLL, SPE, CMP

In Single-pulse Interrupt Mode, an error interrupt event is always captured in the register IRQ_NOTIFY, independent of the state of EIRQ_EN. However, only the first error interrupt event of an enabled error interrupt within a common error interrupt set is forwarded to signal EIRQ_line. Additional error interrupt events of the same error interrupt set cannot generate pulses on the signal EIRQ_line, until the corresponding bits in register IRQ_NOTIFY of enabled error interrupts are cleared by a clear event. The EIRQ_occurred signal line will be high, if the EIRQ_EN and the IRQ_NOTIFY register bits are set. The Single-pulse interrupt mode for error interrupts is shown in **Figure 38.19**.

To avoid unexpected EIRQ behavior in the single pulse mode, all desired error interrupt sources should be enabled by a single write access to EIRQ_EN and the notification bits should be cleared by a single write access to the register IRQ_NOTIFY.

The only exceptions are the modules ARU and DPLL. In these modules the EIRQ_occurred bit of each error interrupt is directly connected (without OR-conjunction of neighboring EIRQ_occurred bits) to the inverter for suppressing further error interrupt pulses.

38.5.5.5 GTM-IP Interrupt concentration method

Because of the grouping of interrupts inside the ICM, it can be necessary for the software to access the ICM sub-module first to determine the interrupt set that is responsible for an interrupt. A second access to the responsible register IRQ_NOTIFY is then necessary to identify the interrupt source, serve it and to reset the interrupt flag in register IRQ_NOTIFY afterwards. The interrupt flags are never reset by an access to the ICM. For a detailed description of the ICM sub-module, refer to **Section 38.24, Interrupt Concentrator Module (ICM)**.

38.5.6 GTM-IP Software Debugger Support

For software debugger support the GTM-IP comes with several features. E.g. status register bits must not be altered by a read access from a software debugger. To avoid this behavior to reset a status register bit by software, the CPU has to write a '1' explicitly to the register bit to reset its content.

The **Table 38.18** describes the behavior of some GTM-IP registers with special functionality on behalf of read accesses from the AEI bus interface.

Table 38.18 Register behavior in case of Software Debugger accesses

Module	Register	Description
AFD	AFD[i]_CH[z]_BUF_ACC	The FIFO read access pointers are not altered on behalf of a Debugger read access to this register
TIM	TIM[i]_CH[x]_GPR0/1	The overflow bit is not altered in case of a Debugger read access to this register.
TIM	TIM[i]_CH[x]_ECNT	The register is not cleared in case of a Debugger read access to this register.
ATOM	ATOM[i]_CH[x]_SR0/1	In SOMC mode a read access to this register by the Debugger does not release the channel for a new compare/match event.

Further on, some important states inside the GTM-IP sub-module have to be signaled to the outside world, when reached and should for example trigger the software debugger to stop program execution. For this internal state signaling, refer to the GTM-IP module integration guide.

The GTM provides an external signal gtm_halt, which disables clock signal SYS_CLK for debugging purposes. If SYS_CLK is disabled, a connected debugger can read any GTM related register and the GTM internal RAMs using AEI. Moreover, the debugger can also perform write accesses to the internal RAMs and to all GTM related registers in order to enable advanced debugging features (e.g. modifications of register contents in single step mode).

38.5.7 GTM-IP Programming conventions

To serve different application domains the GTM-IP is a highly configurable module with many configuration modes. In principle the sub-modules of the GTM-IP are intended to be configured at system startup to fulfill certain functionality for the application domain the micro controller runs in.

For example, a TIM input channel can be used to monitor an application specific external signal, and this signal has to be filtered. Therefore, the configuration of the TIM channel filter mode will be specific to the external signal characteristic. While it can be necessary to adapt the filter thresholds during runtime an adaptation of the filter mode during runtime is not reasonable. Thus, the change of the filter mode during runtime can lead to an unexpected behavior.

In general, the programmer has to be careful when reprogramming configuration registers of the GTM-IP sub-modules during runtime. It is recommended to disable the channels before reconfiguration takes place to avoid unexpected behavior of the GTM-IP.

38.5.8 GTM-IP TOP-Level Configuration Registers Overview

GTM-IP TOP-level contains following configuration registers:

Table 38.19 Register list

Symbol	Register Name	Details in Section
GTM_REV	GTM-IP Version control register	**38.5.9.1**
GTM_RST	GTM-IP Global reset register	**38.5.9.2**
GTM_CTRL	GTM-IP Global control register	**38.5.9.3**
GTM_AEI_ADDR_XPT	GTM-IP AEI Timeout exception address register	**38.5.9.4**
GTM_AEI_STA_XPT	GTM-IP Interrupt notification register	**38.5.9.5**
GTM_IRQ_NOTIFY	GTM-IP Interrupt notification register	**38.5.9.6**
GTM_IRQ_EN	GTM-IP Interrupt enable register	**38.5.9.7**
GTM_IRQ_FORCINT	GTM-IP Software interrupt generation register	**38.5.9.8**
GTM_IRQ_MODE	GTM-IP top level interrupts mode selection.	**38.5.9.9**
GTM_BRIDGE_MODE	GTM-IP AEI bridge mode register	**38.5.9.10**
GTM_BRIDGE_PTR1	GTM-IP AEI bridge pointer 1 register	**38.5.9.11**
GTM_BRIDGE_PTR2	GTM-IP AEI bridge pointer 2 register	**38.5.9.12**
GTM_MCS_AEM_DIS	GTM-IP MCS master port disable register	**38.5.9.13**
GTM_EIRQ_EN	GTM-IP Error interrupt enable register	**38.5.9.14**
GTM_CLS_CLK_CFG	GTM-IP Cluster Clock Configuration	**38.5.9.15**
GTM_CFG	GTM Configuration register	**38.5.9.16**

38.5.9 GTM-IP TOP-Level Configuration Registers Description

38.5.9.1 GTM_REV

Access: This register is a read-only register that can be read in 32-bit units.

Address: <GTM_base> + 00000_H

Value after reset: Undefined

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	DEV_CODE2				DEV_CODE1				DEV_CODE0				MAJOR			
Value after reset	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 38.20 GTM_REV Register Contents

Bit Position	Bit Name	Function
31 to 28	DEV_CODE2	Device encoding digit 2.
27 to 24	DEV_CODE1	Device encoding digit 1.
23 to 20	DEV_CODE0	Device encoding digit 0.
19 to 16	MAJOR	Major version number Define major version number of GTM-IP specification.
15 to 12	MINOR	Minor version number Define minor version number of GTM-IP specification.
11 to 8	NO	Delivery number Define delivery number of GTM-IP specification.
7 to 0	STEP	Release step GTM Release step.

NOTE

See device specific **Section 38.28, GTM Device 358** for reset value.

38.5.9.2 GTM_RST

Access: This register can be read or written in 32-bit units.

Address: <GTM_base> + 00004_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	BRIDGE_MODE_WRDIS	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit Position	Bit Name	Function
31 to 28	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
27	BRIDGE_MODE_WRDIS	GTM_BRIDGE_MODE write disable 0: Writing of GTM_BRIDGE_MODE register is enabled 1: Writing of GTM_BRIDGE_MODE register is disabled **NOTE** This bit is write protected by bit RF_PROT of **Section 38.5.9.3, GTM_CTRL**
26 to 1	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
0	RST	GTM-IP Reset 0: No reset action 1: Initiate reset action for all sub-modules **NOTES** 1. This bit is automatically cleared by hardware after it was written. Therefore, the register is always read as zero (0) by the software. 2. This bit is write protected by bit RF_PROT of **Section 38.5.9.3, GTM_CTRL**

38.5.9.3 GTM_CTRL

Access: This register can be read or written in 32-bit units.

Address: <GTM_base> + 00008_H

Value after reset: $0000\ 0001_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

	AEIM_CLUSTER				—	—	—	TO_VAL					—	—	TO_MODE	RF_PROT
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1
R/W	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R	R	R/W	R/W

Table 38.22 GTM_CTRL Register Contents

Bit Position	Bit Name	Function
31 to 16	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
15 to 12	AEIM_CLUSTER	AEIM_CLUSTER: AEIM cluster number **NOTES** 1. These bits show the number of the AEI master port cluster which throws the interrupts AEIM_USP_ADDR, AEIM_IM_ADDR and AEIM_USP_BE depending on the AEI master port access status. 2. If one of the corresponding irq notify bits (6:4) is set, this bit field will be frozen until the interrupt notify bits (6:4) are cleared.
11 to 9	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
8 to 4	TO_VAL	AEI timeout value. These bits define the number of cycles after which a timeout event occurs. When TO_VAL equals zero (0) the AEI timeout functionality is disabled.
3, 2	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
1	TO_MODE	AEI timeout mode. 0: Observe: If timeout_counter = 0 the address and rw signal in addition with timeout flag will be stored to the GTM_AEI_ADDR_XPT register. Following timeout_counter = 0 accesses will not overwrite the first entry in the aei_addr_timeout register. Clearing the timeout flag/aei_status error_code will reenable the storing of a next faulty access. 1: Abort: In addition to observe mode the pending access will be aborted by signalling an illegal module access on aei_status and sending ready. In case of a read deliver as data 0 by serving of next AEI accesses.
0	RF_PROT	RST and FORCINT protection. 0: SW RST (global), SW interrupt FORCINT, and SW RAM reset functionality is enabled 1: SW RST (global), SW interrupt FORCINT, and SW RAM reset functionality is disabled

38.5.9.4 GTM_AEI_ADDR_XPT

Access: This register is a read-only register that can be read in 32-bit units.

Address: <GTM_base> + $0000C_H$

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 38.24 GTM_AEI_STA_XPT Register Contents

Bit Position	Bit Name	Function
31 to 21	Reserved	When read, the value after reset is returned.
20	W1R0	AEI exception Read/Write flag. This bit field captures the address of the first AEI access resulting with a non-zero AEI status signal. The bit field can be cleared by clearing the interrupt flags AEI_USP_ADDR, AEI_USP_BE, and AEI_IM_ADDR in the register GTM_IRQ_NOTIFY.
19 to 0	ADDR	AEI exception address. This bit field captures the address of the first AEI access resulting with a non-zero AEI status signal. The bit field can be cleared by clearing the interrupt flags AEI_USP_ADDR, AEI_USP_BE, and AEI_IM_ADDR in the register GTM_IRQ_NOTIFY.

38.5.9.6 GTM_IRQ_NOTIFY

Access: This register can be read or written in 32-bit units.

Address: <GTM_base> + 00010_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 38.25 GTM_IRQ_NOTIFY Register Contents (1/3)

Bit Position	Bit Name	Function
31 to 28	CLK_EN_EXP_STATE	Expected clock enable state. This bit field defines the GTM expected clk enable state at occurrence of the CLK_EN_ERR event. Function only available with INT_CLK_EN_GEN = 0_B: 0000_B: Enable state for internal clock aei_sys_clk 0001_B: Enable state for internal clock aei_sys_clk/2 Other than above: Setting prohibited. **NOTE** Read as zero in case of INT_CLK_EN_GEN = 1_B.
27 to 24	CLK_EN_ERR_STATE	Erroneous clock enable state. This bit field defines the GTM external clk enable state at occurrence of the CLK_EN_ERR event. Function only available with INT_CLK_EN_GEN = 0_B: 0000_B: Enable state for internal clock aei_sys_clk 0001_B: Enable state for internal clock aei_sys_clk/2 Other than above: Setting prohibited. **NOTE** Read as zero in case of INT_CLK_EN_GEN = 1_B.
23 to 9	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
8	CLK_PER_ERR	Clock period error interrupt. 0: No interrupt occurred 1: CLK_PER_ERR interrupt was raised by clock enable watchdog **NOTES** 1. This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged. 2. Read as zero in case of INT_CLK_EN_GEN = 1_B.

Table 38.25 GTM_IRQ_NOTIFY Register Contents (2/3)

Bit Position	Bit Name	Function
7	CLK_EN_ERR	Clock enable error interrupt. 0: No interrupt occurred 1: CLK_EN_ERR interrupt was raised by clock enable watchdog **NOTES** 1. This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged. 2. Read as zero in case of INT_CLK_EN_GEN = 1_B.
6	AEIM_USP_BE	AEI master port unsupported byte enable interrupt. 0: No interrupt occurred 1: AEIM_USP_BE interrupt was raised by the AEI master port interface **NOTE** This bit will be cleared on a CPU write access of value ‘1’. A read access leaves the bit unchanged.
5	AEIM_IM_ADDR	AEI master port illegal Module address interrupt. 0: No interrupt occurred 1: AEIM_IM_ADDR interrupt was raised by the AEI master port interface **NOTE** This bit will be cleared on a CPU write access of value ‘1’. A read access leaves the bit unchanged.
4	AEIM_USP_ADDR	AEI master port unsupported address interrupt. 0: No interrupt occurred 1: AEIM_USP_ADDR interrupt was raised by the AEI master port interface **NOTE** This bit will be cleared on a CPU write access of value ‘1’. A read access leaves the bit unchanged.
3	AEI_USP_BE	AEI unsupported byte enable interrupt. 0: No interrupt occurred 1: AEI_USP_BE interrupt was raised by the AEI interface **NOTE** This bit will be cleared on a CPU write access of value ‘1’. A read access leaves the bit unchanged.
2	AEI_IM_ADDR	AEI illegal Module address interrupt. 0: No interrupt occurred 1: AEI_IM_ADDR interrupt was raised by the AEI interface **NOTE** This bit will be cleared on a CPU write access of value ‘1’. A read access leaves the bit unchanged.

Table 38.25 GTM_IRQ_NOTIFY Register Contents (3/3)

Bit Position	Bit Name	Function
1	AEI_USP_ADDR	AEI unsupported address interrupt. 0: No interrupt occurred 1: AEI_USP_ADDR interrupt was raised by the AEI interface **NOTE** This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.
0	AEI_TO_XPT	AEI timeout exception occurred. 0: No interrupt occurred 1: AEI_TO_XPT interrupt was raised by the AEI Timeout detection unit **NOTE** This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.

38.5.9.7 GTM_IRQ_EN

Table 38.29 GTM_BRIDGE_MODE Register Contents (1/2)

Bit Position	Bit Name	Function
31 to 24	BUFF_DPT	Buffer depth of AEI bridge. Signals the buffer depth of the GTM AEI bridge implementation. **NOTE** Reset value depends on the hardware configuration chosen by silicon vendor.
23 to 17	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
16	BRG_RST	Bridge software reset. 0: No bridge reset request. 1: Bridge reset request. **NOTE** This bit is cleared automatically after write.
15 to 13	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
12	SYNC_INPUT_REG	Additional pipelined stage in synchronous bridge mode 0: No additional pipelined stage implemented. 1: Additional pipelined stage implemented. All accesses in synchronous mode will be increased by one clock cycle. **NOTE** Reset value depends on the hardware configuration chosen by silicon vendor.
11, 10	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
9	BUFF_OVL	Buffer overflow register. 0: No buffer overflow occurred. 1: Buffer overflow occurred. A buffer overflow can occur while multiple aborts are issued by the external bus or a pipelined instruction is started while FBC = 0 (see **Section 38.5.9.11, GTM_BRIDGE_PTR1**).

Table 38.29 GTM_BRIDGE_MODE Register Contents (2/2)

Bit Position	Bit Name	Function
8	MODE_UP_PGR	Mode update in progress. 0: No update in progress. 1: Update in progress.
7 to 3	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
2	BYPASS_SYNC	Bypass synchronizer flipflops. Function only available with BRG_MODE = 1 0: synchronizer flip-flops in use, latency increase due to synchronization (aei_clk -> aei_sys_clk and back aei_sys_clk -> aei_clk). This setting must be used if aei_clk and aei_sys_clk operate fully asynchronous by independent clock sources. 1: synchronizer flip-flops are bypassed. No additional latency due to synchronization. This setting can be used if aei_clk and aei_sys_clk are generated by clock gating or clock division out of a common clock source. Clock edges on aei_clk and aei_sys_clk generated out of the same clock edge of the common clock source must have zero skew.
1	MSK_WR_RSP	Mask write response. 0: Do not mask the write response. Depending on the selected address the latency for execution can vary due to GTM internal arbitration. After this time the status of the access will be signaled by the signal AEI_STATUS to the bus interface. 1: Mask write response. The write buffer of the bridge is activated, the actual access will be stored to the write buffer and without latency on the bus interface the acceptance of the access is signaled. AEI_STATUS = 00_B will be signaled. In case of a full write buffer the actual access will be postponed until the next write buffer entry becomes free. **NOTES** 1. The status of the executed write accesses can be observed by using the notify bits AEI_USP_ADDR,AEI_IM_ADDR, AEI_USP_BE in the register GTM_IRQ_NOTIFY. 2. With active write buffer MSK_WR_RSP = 1, execution of actions can be delayed due to previous inserted write actions in the transaction buffer which wait to be serviced. This can lead to the fact that an access on the bus to a different peripheral than the GTM might be executed earlier in time than the write access buffered in the GTM. Applications must be setup up with this in mind otherwise unexpected operation can happen.
0	BRG_MODE	Defines the operation mode for the AEI bridge. 0: AEI bridge operates in sync_bridge mode 1: AEI bridge operates in async_bridge mode **NOTE** Reset value depends on the hardware configuration chosen by silicon vendor.

NOTE

All writable bits are protected by bit BRIDGE_MODE_WRDIS at **Section 38.5.9.2, GTM_RST**.

38.5.9.11 GTM_BRIDGE_PTR1

Access: This register is a read-only register that can be read in 32-bit units.

Address: <GTM_base> + 00034_H

Value after reset: $0xx0\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	RSP_TRAN_RDY						FBC						ABT_TRAN_PGR			
Value after reset	0	0	0	0	0	0	–	–	–	–	–	–	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	ABT_TRAN_PGR	TRAN_IN_PGR					FIRST_RSP_PTR					NEW_TRAN_PTR				
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 38.30 GTM_BRIDGE_PTR1 Register Contents

Bit Position	Bit Name	Function
31 to 26	RSP_TRAN_RDY	Response transactions ready. Amount of ready response transactions.
25 to 20	FBC	Free buffer count. Number of free buffer entries. **NOTE** Initial value depends on the hardware configuration chosen by silicon vendor. (see BUFF_DPT in **Section 38.5.9.10, GTM_BRIDGE_MODE**).
19 to 15	ABT_TRAN_PGR	Aborted transaction in progress pointer.
14 to 10	TRAN_IN_PGR	Transaction in progress pointer (acquire)
9 to 5	FIRST_RSP_PTR	First response pointer. Signals the actual value of first response pointer.
4 to 0	NEW_TRAN_PTR	New transaction pointer. Signals the actual value of the new transaction pointer.

NOTES

1. This register operates on the AEI_CLK domain.
2. This register holds diagnosis information about the AEI bus bridge. Each access to the GTM_IP will update the defined pointer bit fields. Depending on the mode of GTM_MODE_BRIDGE (BRG_MODE, MSK_WR_RESP), the AEI protocol and operating frequency which is use, the 4 pointer bit fields will change at different clock cycles relative to the start of the transaction. This leads to the fact that reading the register can show values not equal to the defined Initial Value, even directly after a write to GTM_BRIDGE_MODE with BRG_RST=1 was done.

38.5.9.12 GTM_BRIDGE_PTR2

Access: This register is a read-only register that can be read in 32-bit units.

Address: <GTM_base> + 00038_H

Value after reset: $0000\ 0000_H$

Table 38.34 GTM_CLS_CLK_CFG Register Contents

Bit Position	Bit Name	Function
31 to 8	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
7 to 0	CLS[k]_CLK_DIV	Cluster k Clock Divider 00_B: Cluster is disabled. 01_B: Cluster is enabled without clock divider. 10_B: Cluster is enabled with clock divider 2. 11_B: Setting prohibited. **NOTES** 1. These bits are only writable if bit field RF_PROT of register GTM_CTRL is cleared. 2. The configuration value CLS0_CLK_DIV defines the primary input clock period for CMU. 3. If CLS0_CLK_DIV is configured to a value 10_B (i.e. clock divider 2), the maximum CMU clock frequency for all other cluster c = 1..n is also limited to configured CMU clock frequency of cluster 0.

NOTES

1. The availability of configuration bits is indicated by value of bit CFG_CLOCK_RATE in register CCM[c]_HW_CFG.
   - If CFG_CLOCK_RATE=0, only the values 00_B and 01_B are valid for bit fields CLS[c]_CLK_DIV.
   - If CFG_CLOCK_RATE=1, only the values 00_B, 01_B and 10_B are valid for bit fields CLS[c]_CLK_DIV.
   - If CFG_CLOCK_RATE=1, limitation for some cluster are possible to disable high frequency clock usage.

   In this case only values 00_B and 10_B are valid for bit fields CLS[c]_CLK_DIV. Refer also to **Section 38.28, GTM Device 358** of this specification for detailed information.
2. Writing a value to a bit field CLS[c]_CLK_DIV that is not available in the device, an AEI status 10_B is returned. (with c = 0 to NCCM-1)

38.5.9.16 GTM_CFG

Access: This register can be read or written in 32-bit units.

Address: <GTM_base> + 00028_H

38.6 AXI Master

38.6.1 Functional Characteristics

The AXI transaction generator implements multiple AEI slave interfaces and an AXI compliant master interface. It includes the necessary registers, arbitration and bus state-machines.

- AEI standard protocol compliant
- 32 bit AEI interface
- Zero wait state register access
- Max 10 AEI slave interfaces (configurable via generic)
- Max 8 AXI transaction slots per AEI slave (configurable via generic)
- One common register set per AEI interface
- Full AMBA AXI 3.0 compliant
- 32 bit address
- 32 bit data
- Single accesses only (length is fixed to 1)
- All other AXI signals are programmable
- ID width configurable
- One "interrupt" line per slot

38.6.2 AXI Transaction Generator Block

38.6.2.1 Functional View

Figure 38.20 shows the basic modules of the AXI Transaction Generator block.

For each AEI interface one cluster module is implemented. This cluster module includes the register module. The transactions are then arbitrated and finally used to create the bus transactions.

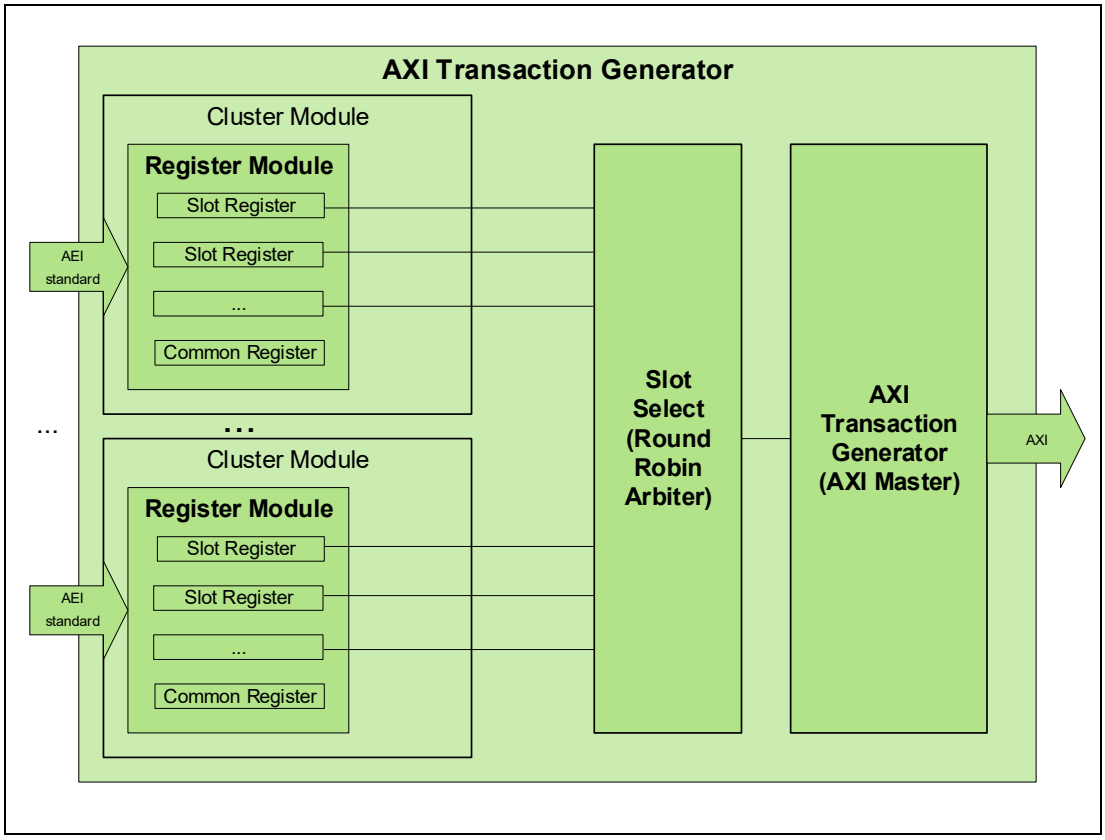

Figure 38.20 Block Diagram

38.6.3 Block Entity Table

The IP has a configurable number of AEI standard slave interfaces on the “left” side and an AXI master interface on the “right” side. **Table 38.36** describes the blocks entity pins.

(1) Pin list

Table 38.36 Pin list (1/3)

Port name	Width	Direction	Description
General Signals			
ACLK	1	Input	AXI port clock
ARESETN	1	Input	AXI port reset (always low active). Release of ARESTN must be synchronized to ACLK.
CLK	generic	input	AXIM port clocks. One clock per AEIM interface. ACLK/CLK must all fulfill synchronous timing relationships, but CLK may be gated.

Table 38.36 Pin list (2/3)

Port name	Width	Direction	Description
ENCLK	generic	Input	Gate enabled for AXIM clocks. Used to synchronize data between CLK/ACLK domains.
CLKOFF	generic	Input	AXIM port is in clock off state. This signals works as a synchronous reset for AEIM ports and overrules ENCLK to avoid hang-ups in ACLK/CLK synchronization.
RESET	1	input	Common AXIM ports reset signal. Active level is defined by generic. Release of RESET must be synchronized to CLK
GTM_HALT	1	Input	Debug signal. While GTM_HALT is asserted, no new requests are accepted by the AXI port. Pending AXI cycles are still completed.
AEI Signals (one set per AEI interface)			
AEIM_AXIM_DEBUG_ACCESS	1	Input	AEI Debug Access
AEIM_AXIM_SEL	1	input	AEI select
AEIM_AXIM_W1R0	1	input	AEI write/read selection
AEIM_AXIM_ADDR	8	input	AEI address MSBs
AEIM_AXIM_ADDR_LSB	2	Input	AEI address LSBs
AEIM_AXIM_WDATA	32	input	AEI write data
AEIM_AXIM_READY	1	output	AEI ready
AEIM_AXIM_RDATA	32	output	AEI read data
AEIM_AXIM_STATUS	2	output	AEI transaction status
AEIM_AXIM_IRQ	generic	output	AEI interrupt request
AEIM_AXIM_IRQ_CLR	generic	input	AEI interrupt clear
Read Address Channel			
ARID	generic	output	AXI transaction ID, ID width can be selected via generic
ARADDR	32	output	AXI read address
ARLEN	4	output	AXI read burst length (fixed to 0x0, as we only support single transactions)
ARBURST	2	output	AXI read burst type (fixed to 0x1 (INCR))
ARSIZE	3	output	AXI read size
ARLOCK	2	output	AXI lock type
ARCACHE	4	output	AXI cache type
ARPROT	3	output	AXI protection type
ARVALID	1	output	AXI read valid
ARREADY	1	input	AXI read ready
Write Address Channel			
AWID	generic	output	AXI transaction ID, ID width can be selected via generic
AWADDR	32	output	AXI write address

Table 38.36 Pin list (3/3)

Port name	Width	Direction	Description
AWLEN	4	output	AXI write burst length (fixed to 0x0, as we only support single transactions)
AWBURST	2	output	AXI write burst type (fixed to 0x1 (INCR))
AWSIZE	3	output	AXI write data size
AWLOCK	2	output	AXI lock type
AWCACHE	4	output	AXI cache type
AWPROT	3	output	AXI protection type
AWVALID	1	output	AXI write data valid
AWREADY	1	input	AXI write data ready
Read Data Channel			
RID	generic	input	AXI transaction ID, ID width can be selected via generic
RDATA	32	input	AXI read data
RLAST	1	input	AXI real last in a burst signal
RRESP	2	input	AXI read response
RVALID	1	input	AXI read data valid
RREADY	1	output	AXI read data ready
Write Data Channel			
WID	generic	output	AXI transaction ID, ID width can be selected via generic
WDATA	32	output	AXI write data
WLAST	1	output	AXI write last in a burst signal
WSTRB	4	output	AXI byte strobes
WVALID	1	output	AXI write data valid
WREADY	1	input	AXI write data ready
Write Response Channel			
BID	generic	input	AXI transaction ID, ID width can be selected via generic
BRESP	2	input	AXI write response
BVALID	1	input	AXI write response valid
BREADY	1	output	AXI wire response ready

38.6.3.1 Block Configuration

The block can be configured for different use-cases with generics. The support generics are described in the following **Table 38.37**.

(1) Generic List

Table 38.37 Generic list

Name	Type	Description
AXIM_ID_WIDTH_C	Integer	Width of the ID busses on the AXI slave interface. Range: 0 to 16, Default: 4
AXIM_DATA_WIDTH_C	Integer	Width of the DATA busses on the AXI interface; Allowed values are 32 and 64
AXI_ADDR_WIDTH_C	Integer	Width of the ADDR busses on the AXI interface; Allowed value is 32.
AXIM_INST_C	Integer	Number of supported AEI masters. Range: 1 to 16
AXIM_USED_C	Integer	Actual number of AEI masters: Range 1 to AXIM_INST_C
AXIM_SLOTS_C	Integer Array	Number of Slots per AEI master. One entry per AEI master. Range: 0 to 24
AXIM_POSTED_WRITE_C	Boolean	Enable posted write support
AXIM_SEC_ACC_C	Boolean	Allow AXI secure bus cycles (AxPROT[1]=0); Should be set to FALSE for most applications
AXIM_PRIV_ACC_C	Boolean	Allow AXI privileged bus cycles (AxPROT[0]=1); Should be set to FALSE or TRUE depending on application

Note: These generic are not implemented with VHDL generics statements. Instead the generics from below table represent constants declared inside the "gtm_scale_pack.vhd" VHDL package.

38.6.4 Detailed Architecture

38.6.4.1 Cluster Module

The cluster module holds all components which belong to one cluster of the GTM. It is intended to ease the layout separation of the different components. Each cluster implements a separate clock input, but clocks of all clusters and AXI port clock must fulfill synchronous timing relationships. Cluster clocks must be generated from the same base clock as AXI port clock (ACLK), but some clock cycles may be gated. Therefore the clock rate for each cluster can be different: CLK(cluster) = ACLK / n; n = 1...X (typical X=2) Signal synchronization between CLK and ACLK domains is supported by the ENCLK inputs. ENCLK(cluster)=”1” will identify active cluster clock edges to ACLK domain logic.

Cluster clocks may be disabled completely for longer time frames (e.g.: debugging). A disabled cluster clock is signaled by CLKOFF(cluster) input signal. This signal will overrule ENCLK(cluster) for CLK/ ACLK synchronization logic. Otherwise synchronization logic may hang if CLK is disabled. After a clock off phase, cluster state is reset. Therefore CLKOFFF must be active for at least one active clock cycle when clock off state is released. When one cluster leaves clock off state, system software must ensure that no active AXI cycle is pending for any slot of this cluster. Otherwise AXI responses from requests issued before entering clock off state may collide with newer slot requests, issued after release of clock off state.

38.6.4.2 Register Module

For each AEI slave interface one register module is instantiated. The register module is built from two building blocks, the slot registers, where one set for each available slot is implemented and a common register area where the slot allocation takes place. All register provide 1 cycle accesses; this means AEIM_AXIM_READY must be asserted in the same cycle as AEIM_AXIM_SEL is asserted. This is required for correct MCS operation. In debug mode (AEIM_AXIM_DEBUG_ACCESS=1) read accesses to registers must not have any side effects:

A debug read to the data register will not start a new AXI read cycle in auto-increment mode

A debug read to the REQUEST register will not allocate a new slot.

38.6.4.3 Slot Registers

In the slot registers all information needed for the AXI transaction is stored. The goal is to use as less registers as possible to reduce the number of required accesses by the controlling program. The Slot register block also includes a state machine to communicate with the following arbiter stage and the AXI transaction generator.

(1) Slot Registers

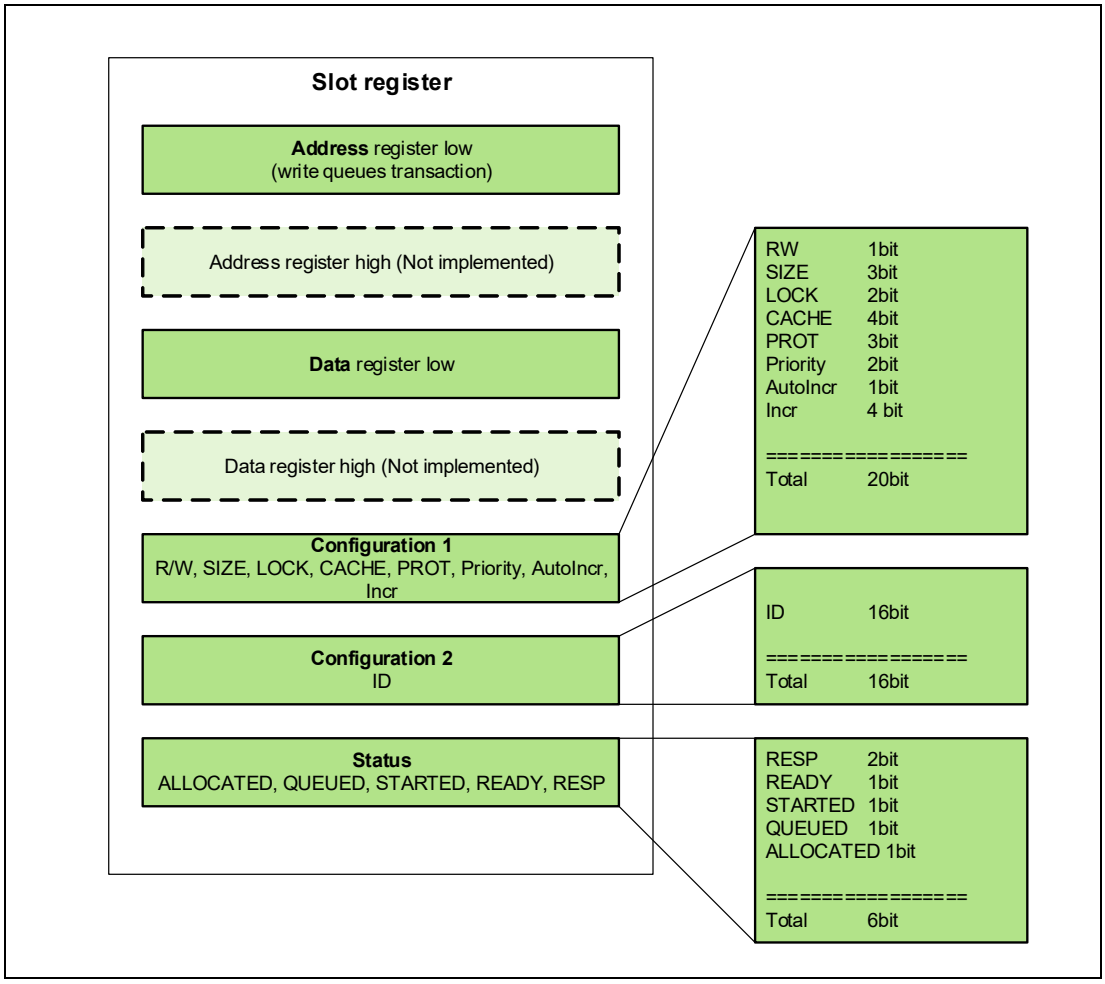

Figure 38.21 Slot Register

(2) Slot State Machine

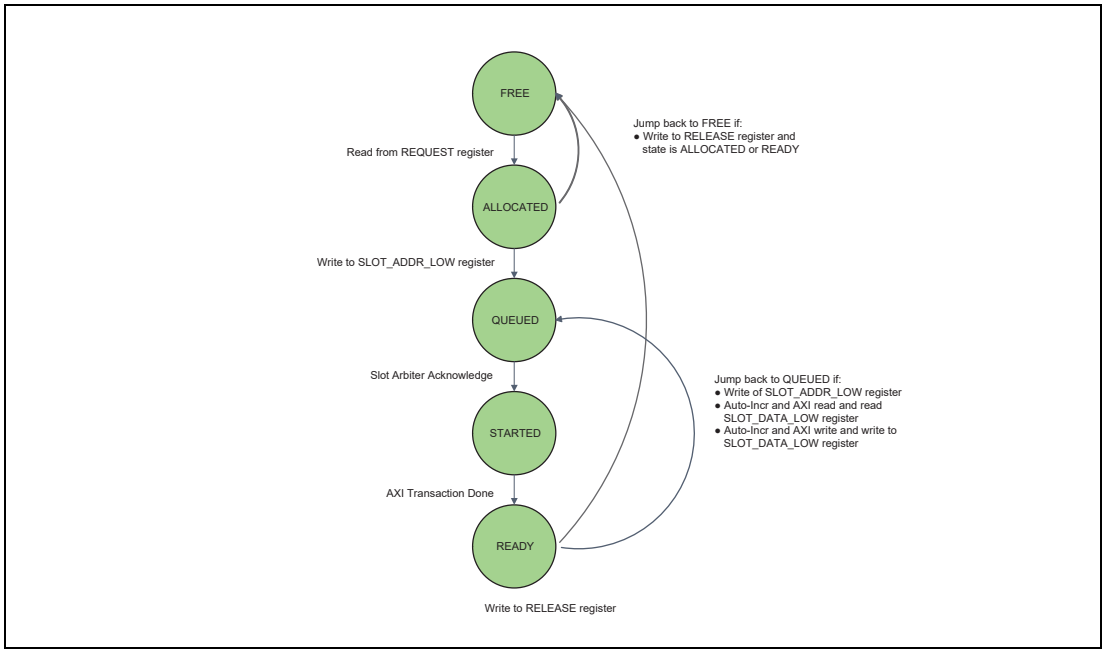

Figure 38.22 Slot State Machine

38.6.4.4 Interrupt Handling

Each slot provides one interrupt line to the corresponding MCS (AEIM_AXIM_IRQ). This interrupt line is set when the slot state changes from STARTED to READY. The interrupt is cleared by asserting the external input line “AEIM_AXIM_IRQ_CLR” for this slot.

38.6.4.5 Auto Increment

The module offers an address auto increment feature. If it is enabled, the address (inside the ADDR register) is incremented automatically after each transaction according to the INCR bit field in the CFG1 Register: New_ADDR <= ADDR + INCR To disable auto-increment, the auto-increment bit in the configuration register has to be cleared. There is one auto-increment adder per cluster. Each slot will request auto-increment processing from this shared resource whenever the last transaction has finished (Slot state changed from STARTED to READY). The new address is available inside the address register two clock cycles later.

38.6.4.6 Common Registers

The common registers are used for slot management. If an MCS thread wants to allocate a transaction slot it reads the REQUEST register. If a slot is available the return value is the number of the allocated slot in two codings. The lower 24bit are one-hot coded, each bit representing one slot.

The upper 8 bit are the allocated slot number in binary format. If no slot was available the maximum value of 0xFF is returned, the lower bytes are then 0x00 0x00 0x00. To release a slot, MCS must write a "1" to the corresponding bit in the RELEASE register. Via the FREE register it is possible to check which slots are still free. One bit for each implemented slot exists.

(1) Common Registers

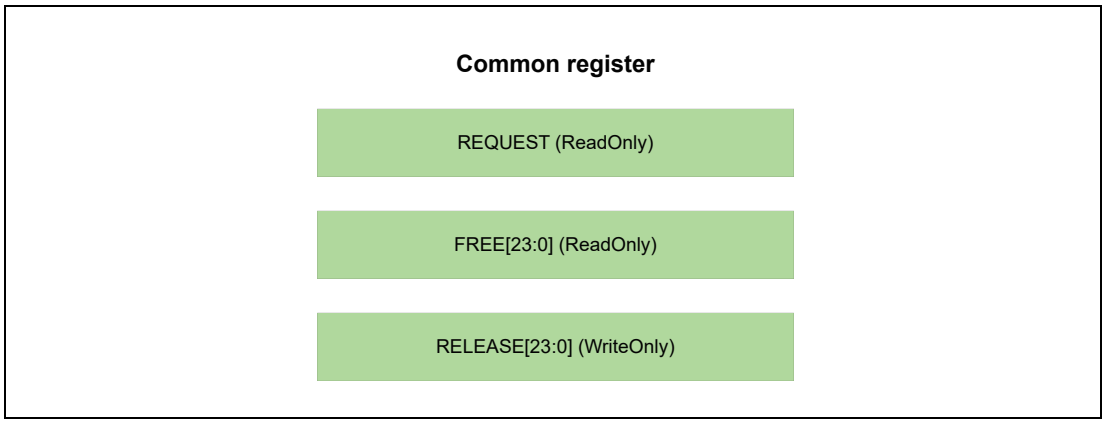

Figure 38.23 Common Registers

38.6.4.7 Arbitration Scheme

The slot arbiter should balance all slots in an equal manner. To achieve an equal load balancing over all slots, the arbiter must process all slots in parallel (flat). Also each slot request can be assigned to a priority level between 0 and 3 and the arbiter must select slots depending on this priority level. The slot arbiter will only accept new slot requests while input signal GTM_HALT="0". Slot requests already accepted when GTM_HALT changes from "1" to "0" are still forwarded to the AXI transaction generator. Therefore after asserting GTM_HALT up to two pending AXI transactions may still be issued to the AXI port.

(1) Arbiter implementation

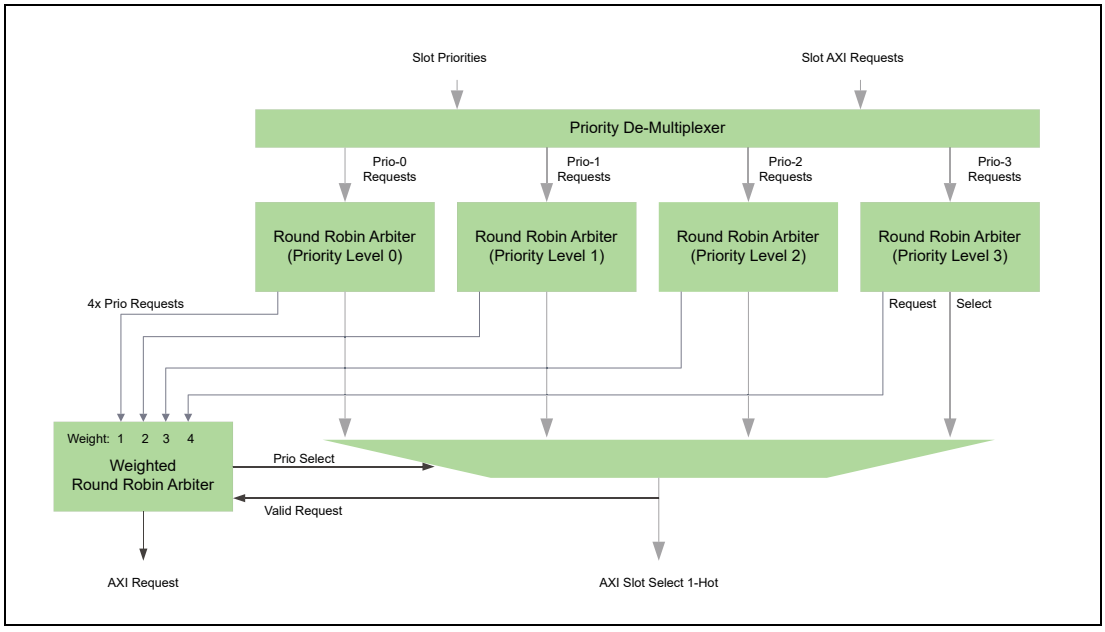

Figure 38.24 Arbiter Implementation

38.6.4.8 Round Robin Arbiter

The Round Robin Arbiter for each priority class must be configurable for the actual number of slots. For maximum GTM configurations this will be up to 80 inputs (10x8).

(1) Round Robin Arbiter

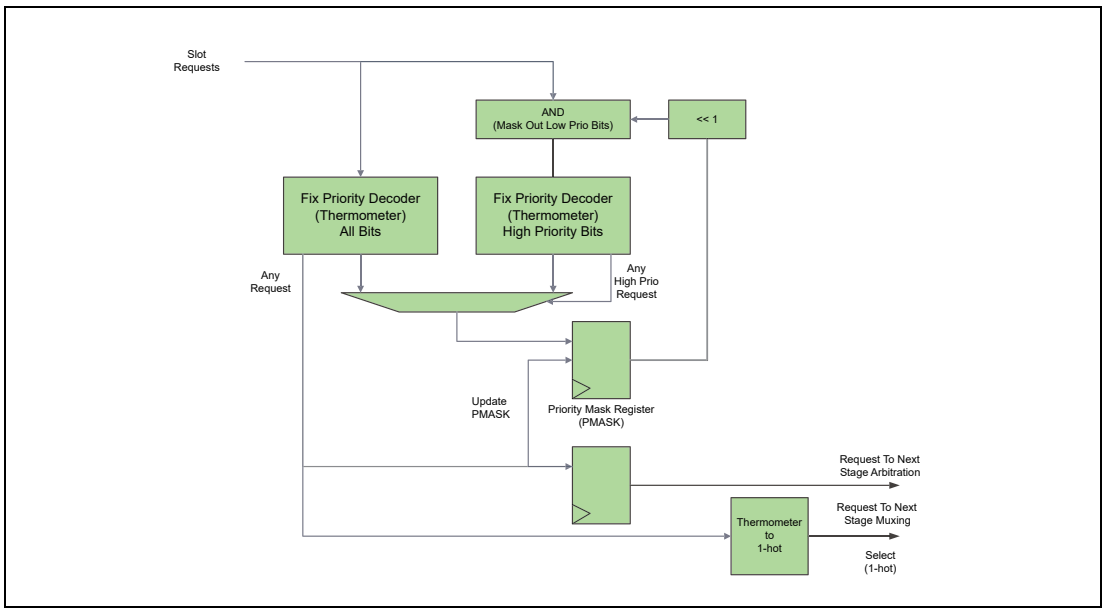

Figure 38.25 Round Robin Arbiter

38.6.4.9 Transaction Generator

The Transaction Generator creates the actual AXI bus transaction. It applies the transaction values to the right AXI lines and observes the bus until the transaction has been completed. If available the next transaction is immediately started. The Transaction Generator has output as well as input Flip-Flops to the AXI bus to ease the timing towards the NOC. Due to the pipelining of AXI handshake signals, the Transaction Generator can only initiate new transaction every second clock cycle. This is no limitation, because also the arbiter can deliver new requests with a maximum rate of every second clock cycle. The Transaction Generator will check the parameters for every requested AXI transaction for validity. If an invalid request is detected, the AXI Transaction Generator will not send a request to the AXI bus, instead it will directly respond to the requesting slot with an error response code (11_B).

Invalid transactions are:

1. Secure AXI cycle requested (PROT[1] = 0) and VHDL constant "axim_sec_acc_c" is set to false (default). In systems supporting ARM Trustzone technology, secure AXI bus cycles are reserved for the so call "Secure Monitor" software. Other bus master like GTM should not issue secure bus cycles.
2. Privileged AXI cycle requested (PROT[0] = 1) and VHDL constant "axim_priv_acc_c" is set to false. If privileged bus cycles are allowed depends on application. By default "axim_priv_acc_c" is set to true.
3. LOCK = 11_B (reserved value) or LOCK = 10_B (Hard Lock): An AXI cycle with LOCK = 10_B is a hard lock. It will lock all other bus cycles on the NOC interconnect until the bus lock is removed with an unlock bus cycle. This is dangerous. To avoid this, GTM must only use "soft locks" or "exclusive access locks" (LOCK = 01_B).

4. AXI cycles with SIZE greater 2 (greater 4 byte): AXI Transaction Generator will only support transactions not larger that the external data bus width, which is currently fixed to 32 bit.
5. Misaligned 2-byte bus cycles: If AxSIZE is configured for 2 bytes (001_B), the address must be aligned to 2 bytes (AxADDR[0] = 0).
6. Misaligned 4-byte bus cycles: If AxSIZE is configured for 4 bytes (010_B), the address must be aligned to 4 bytes (AxADDR[1:0] = 00_B).

38.6.4.10 Data Alignment

AXI Transaction Generator will shift the data from the slot DATA register to the correct AXI data bus lines, according to ADDR. Software must expect the data inside the data register always aligned to bit 0. For AXI operations with a size of less than 32 bits, the Transaction Generator will shift the data bytes to the according positions on the AXI data bus. For AXI read operations, the Transaction Generator will mask unused bytes. E.g.: If software wants to initiate a one byte AXI write transaction to address 3, it will program the data byte to bit 7.0 of the DATA register. AXI Transaction Generator will shift this byte to bits 31.24 of the AXI data bus. For AXI write operations, the Transaction Generator will calculate the correct AXI write strobe signals (WSTRB) depending on SIZE and ADDR.

38.6.5 AXIM Configuration Registers Description

Table 38.38 Axim Configuration Registers Description

Register name	Description	Details in Section
AXIM[i]_FREE	Slot allocation status	**38.6.6.1**
AXIM[i]_REQUEST	Slot request (allocation)	**38.6.6.2**
AXIM[i]_RELEASE	Slot release (de-allocation)	**38.6.6.3**
AXIM[i]_SLOT[x]_ADDR_LOW	Address bits 31:0 of AXI transaction	**38.6.6.4**
AXIM[i]_SLOT[x]_DATA_LOW	Data bits 31:0 of AXI transaction	**38.6.6.5**
AXIM[i]_SLOT[x]_CFG1	Slot configuration 1	**38.6.6.6**
AXIM[i]_SLOT[x]_CFG2	Slot configuration 2	**38.6.6.7**
AXIM[i]_SLOT[x]_STATUS	Slot status	**38.6.6.8**

38.6.6 AXIM Configuration Registers description

38.6.6.1 AXIM[i]_FREE

Access: This register is a read-only register that can be read in 32-bit units.

Address: <GTM_base> + 14000_H + (400_H × i)

Value after reset: 0000 0001_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 38.41 AXIM[i]_RELEASE Register Contents

Bit Position	Bit Name	Function
31 to 1	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
0	RELREQ0	A write to RELREQ will de-allocateone or more slots. Each bit in RELREQ represents one slot. 0: Don't change state of Slot(n) 1: De−allocate Slot(n)

Note: This bit field is self.clearing and always read as zero.

Note: Software should check if a release request will really result in slot de.allocation. Slot will only change state at release request if the slot has no pending request to the AXI Transaction Generator (Slot states ALLOCATED or READY).

38.6.6.4 AXIM[i]_SLOT[x]_ADDR_LOW

Access: This register can be read or written in 32-bit units.

Address: <GTM_base> +14020_H + (400_H × i) + (20_H × x)

Value after reset: 0000 0000_H

Table 38.43 AXIM[i]_SLOT[x]_DATA_LOW Register Contents

Bit Position	Bit Name	Function
31 to 0	AXI_DATA_LOW	AXI write operation (AXI_RW = 0): Data that is send out via AXI transaction. Software must configure this register before the AXI write operation is started. Data in AXI_DATA_LOW is aligned to bit 0. AXI Transaction Generator will apply the data to the correct AXI data lines depending on AXI_ADDR. If auto-increment is enabled (AUTO_INCR = 1) and the slot is in READY state. A write to this register will start a new AXI transaction (Slot state will change to QUEUED). AXI read operation (AXI_RW = 1): Data read by last AXI transaction. Software can read the received data after the AXI transaction has finished (Slot state = READY). Data in AXI_DATA_LOW is always aligned to bit 0. AXI Transaction Generator will shift the AXI data bus lines according to AXI_ADDR. Unused bytes (identified by AXI_SIZE) will be masked and are read as all 0. If auto-increment is enabled (AUTO_INCR = 1) and the slot is in READY state. A read to this register will start a new AXI transaction (Slot state will change to QUEUED)

38.6.6.6 AXIM[i]_SLOT[x]_CFG1

Access: This register can be read or written in 32-bit units.

Address: <GTM_base> +14030_H + (400_H × i) + (20_H × x)

Value after reset: 0000 0000_H

Table 38.46 AXIM[i]_SLOT[x]_STATUS Register Contents

Bit Position	Bit Name	Function
31 to 6	Reserved	When read, the value after reset is returned.
5, 4	RESP	AXI response from last AXI transaction 00_B: OK 01_B: EXOKAY 10_B: SLVERR 11_B: DECERR; If AXI Transaction Generator detects any invalid requests or responses (unexpected response ID), it will force response to this value.
3	READY	This bit represents the slot READY state. 0: AXI Transaction Generator has no finished request 1: AXI Transaction Generator has finished request
2	STARTED	This bit represents the slot STARTED state. 0: AXI request is not accepted by arbiter 1: AXI request is accepted by arbiter
1	QUEUED	This bit represents the slot QUEUED state. 0: AXI request is not queued for arbitration 1: AXI request is queued for arbitration
0	ALLOC	0: Slot is free 1: Slot is allocated **NOTE** This bit is asserted as long as the slot is allocated, also during states QUEUED, STARTED and READY. The slot state ALLOCATED is represented by ALLOC = 1 and QUEUED = STARTED = READY = 0

38.7 Advanced Routing Unit (ARU)

38.7.1 Overview

The Advanced Routing Unit (ARU) is a flexible infrastructure component for transferring 53-bit wide data (five control bits and two 24-bit values) between several sub-modules of the GTM core in a configurable manner.

Since the concept of the ARU has already been described in **Section 38.5.3, ARU Routing Concept**, this section only describes additional ARU features that can be used by the software for configuring and debugging ARU related data streams. Also the definition of 'streams' and 'channels' in the ARU context is done in **Section 38.5.3, ARU Routing Concept**.

The principle of ARU data routing is described in **Section 38.5.3, ARU Routing Concept**. In the real GTM implementation the ARU serves in parallel per clock period two individual data destinations, one destination at port ARU-0 and at port ARU-1. Both ARU ports ARU-0 and ARU-1 are running by default in parallel but can be configured in dynamic routing mode (see below) to run in an individual mode.

As already defined in the **Section 38.5.3, ARU Routing Concept**, the ARU read ID is the address of the data source that is configured in the data destination module. These ARU read ID's are selected by the individual counter of ARU ports ARU-0 and ARU-1. Via the ARU ports ARU-0 and ARU-1 with each ARU read ID two independent GTM sub-modules are addressed and served. The combination of ARU port (ARU-0 or ARU-1) and the ARU read ID addresses one ARU wdata source (i.e. the ARU write port of a GTM sub-module).

The assignment of ARU write ports of GTM sub-modules to the ARU ports ARU-0 and ARU-1 and the ARU read ID's is device depending and can be found in **Section 38.28, GTM Device 358**.

38.7.2 Special Data Sources

Besides the addresses of the sub-module related data sources as described in **Section 38.28.10.1, ARU Write Address Overview**, the ARU provides two special data sources that can be used for the configuration of data streams. These data sources are defined as follows:

Address $1FF_H$: Data source that provides always a 53 bit data word with zeros. A read access to this memory location will never block a requesting data destination.

Address $1FE_H$: Data source that never provides a data word. A read access to this memory location will always block a requesting data destination. This is the reset value of the read registers inside the data destinations.

Address 000_H: This address is reserved and can be used to bring data through the ARU registers ARU_DATA_H and ARU_DATA_L into the system by writing the write address 000_H into the ARU_ACCESS register. This means that software test data can be brought into the GTM-IP by the CPU.

38.7.3 ARU Access via AEI

Besides the data transfer between the connected sub-modules, there are two possibilities to access ARU data via the AEI.

38.7.3.1 Default ARU Access

The default ARU access incorporates the registers ARU_ACCESS, which is used for initiation of a read or write request and the registers ARU_DATA_H and ARU_DATA_L that provide the ARU data word to be transferred.

The status of a read or write transfer can be determined by polling specific bits in register ARU_ACCESS. Furthermore the acc_ack bit in the interrupt notify register is set after the read or write access is performed to avoid data loss e.g. on access cancelation.

A pending read or write request may also be canceled by clearing the associated bit.

In the case of a read request, the AEI access behaves as a read request initiated by a data destination of a module. The read request is served by the ARU immediately when no other destination has a pending read request. This means, that an AEI read access does not take part in the scheduling of the destination channels and that the time between two consecutive read accesses is not limited by the round trip time.

On the other hand, the AEI access has the lowest priority behind the ARU scheduler that serves the destination channels. Thus, in worst case, the read request is served after one round trip of the ARU, when all destination channels would request data at the same point in time.

In the case of the write request, the ARU provides the write data at the address defined by the ADDR bit field inside the ARU_ACCESS register.

To avoid data loss, the reserved ARU address 0x0 has to be used to bring data into the system. Otherwise, in case the address specified inside the ADDR bit field is defined for another sub-module that acts as a source at the ARU data loss may occur and no deterministic behavior is guaranteed.

This is because the regular source sub-module is not aware that its address is used by the ARU itself to provide data to a destination.

It is guaranteed that the ARU write data is send to the destination in case of both modules want to provide data at the same time.

Configuring both read and write request bits results in a read request, if the write request bit inside the register isn't already set. The read request bit will be set but not the write request bit. The following table describes the important cases of the bit 12 (RREQ) and bit 13 (WREQ) of the ARU_ACCESS register:

Table 38.47 ARU Access

AEI write access: aei_wdata (13:12)	Actual value of GTM0ARUACCESS (13:12)	Next value of GTM0ARUACCESS (13:12)	Comment
0 0	0 1	0 0	CanCel read request
0 0	1 0	0 0	Cancel write request
0 1	1 0	1 0	Unchanged register
1 0	0 1	0 1	Unchanged register
1 1	0 0	0 1	Both read and write request results in a read request
1 1	1 0	1 0	As before but WREQ bit is already set → unchanged register

38.7.3.2 Debug Access

The debug access mode enables to inspect routed data of configured data streams during runtime.

The ARU provides two independent debug channels, whereas each is configured by a dedicated ARU read address in register ARU_DBG_ACCESS0 and ARU_DBG_ACCESS1 respectively.

The registers ARU_DBG_DATA0_H and ARU_DBG_DATA0_L (ARU_DBG_DATA1_H and ARU_DBG_DATA1_L) provide read access to the latest data word that the corresponding data source sent through the ARU.

Any time when data is transferred through the ARU from a data source to the destination requesting the data the interrupt signal ARU_NEW_DATA0 _IRQ (ARU_NEW_DATA1 _IRQ) is raised.

For advanced debugging purposes, the interrupt signal can also be triggered by software using the register ARU_IRQ_FORCINT.

NOTE

The debug mechanism should not be used by the application, when a HW-Debugger is used to trace the ARU communication. In that case, the debug registers are used by the HW-Debugger to specify the ARU streams that should be traced.

38.7.4 ARU dynamic routing

A dynamic routing feature of the ARU is implemented and can be configured using the additional AEI registers: ARU_CTRL, ARU_[z]_DYN_CTRL, ARU_[z]_DYN_RDADDR, ARU_[z]_DYN_ROUTE_LOW, ARU_[z]_DYN_ROUTE_HIGH, ARU_[z]_DYN_ROUTE_SR_LOW and ARU_[z]_DYN_ROUTE_SR_HIGH. For further information see the register part of this chapter.

38.7.4.1 Dynamic routing - CPU controlled

The dynamic routing feature can be enabled separately for ARU-0 and ARU-1 by setting the corresponding bit fields of the register ARU_CTRL.

The enabling of the dynamic routing feature is synchronized to the normal routing scheme if ARU master ID-0 is addressed. The dynamic route will started with additional ARU master DYN_READ_ID0.

With the dynamic routing feature it is possible to insert additional ARU master ID's, DYN_READ_IDy (y:0.5), in a defined manner into the normal ARU routing scheme.

While inserting additional ARU master ID's the normal ARU routing scheme is paused. Therefore consider that inserting additional ARU master ID's will lengthen the normal routing scheme.

It is possible to configure 6 additional ARU master ID's in the ARU_[z]_DYN_ROUTE_LOW/_HIGH registers for both ARU-0 and ARU-1.

In the bit field DYN_CLK_WAIT of ARU_[z]_DYN_ROUTE_HIGH register the number of clock cycles has to be configured, after which one of the additional ARU master ID's will be inserted.

After each configured number of clock cycles the defined ARU master ID's will be inserted cyclic one after each other in the following manner: ... → DYN_READ_ID0 → DYN_READ_ID1→ DYN_READ_ID2 → DYN_READ_ID3 → DYN_READ_ID4 → DYN_READ_ID5 → DYN_READ_ID0 → ...

In the shadow registers ARU_[z]_DYN_ROUTE_SR_LOW/_HIGH further 6 ARU master, DYN_READ_IDy (y:6.11), can be configured.

The bit DYN_UPDATE_EN in the ARU_[z]_DYN_ROUTE_SR_HIGH register controls whether the ARU_[z]_DYN_ROUTE_LOW/_HIGH registers are updated from its shadow registers except DYN_UPDATE_EN, it is not updated. The update is executed once after writing ARU_[z]_DYN_ROUTE_SR_HIGH. If update started DYN_UPDATE_EN is reset.

With the DYN_ROUTE_SWAP option in the ARU_[z]_DYN_CTRL register it is possible to swap the registers ARU_[z]_DYN_ROUTE_LOW/HIGH with its shadow registers ARU_[z]_DYN_ROUTE_SR_LOW / HIGH. The swapping is executed always after the 6 ARU master DYN_READ_ID's are inserted. So it is possible to insert a maximum of 12 ARU master DYN_READ_ID's cyclic after each configured number of clock cycles. If swap started DYN_UPDATE_EN is reset.

Setting the bit field DYN_CLK_WAIT of ARU_[z]_DYN_ROUTE_HIGH register to zero, only the defined ARU master DYN_READ_ID's will be executed. The normal ARU routing scheme is stopped.

Setting the bit field DYN_CLK_WAIT of ARU_[z]_DYN_ROUTE_HIGH register to 15, only the normal ARU routing scheme is executed. Inserting of additional ID's is stopped.

To reset the ARU caddr counter and ARU dynamic route counter set bit ARU_ADDR_RSTGLB of CMU_GLB_CTRL following by a write access to register CMU_CLK_EN.

(1) Dynamic routing ring mode

In dynamic routing ring mode it is possible to use all 24 DYN_READ_ID's from both ARU-0 and ARU-1 by setting bit field ARU_DYN_RING_MODE in ARU_CTRL register to 1. In this mode all 4 registers ARU_[z]_DYN_ROUTE_LOW/_HIGH and ARU_[z]_DYN_ROUTE_SR_LOW/_HIGH are connected as a ring, so all 24 DYN_READ_ID's can be used from both ARU's. The ring structure is shown in **Figure 38.26**. The data register shift direction is shown by the arrows in the ring.

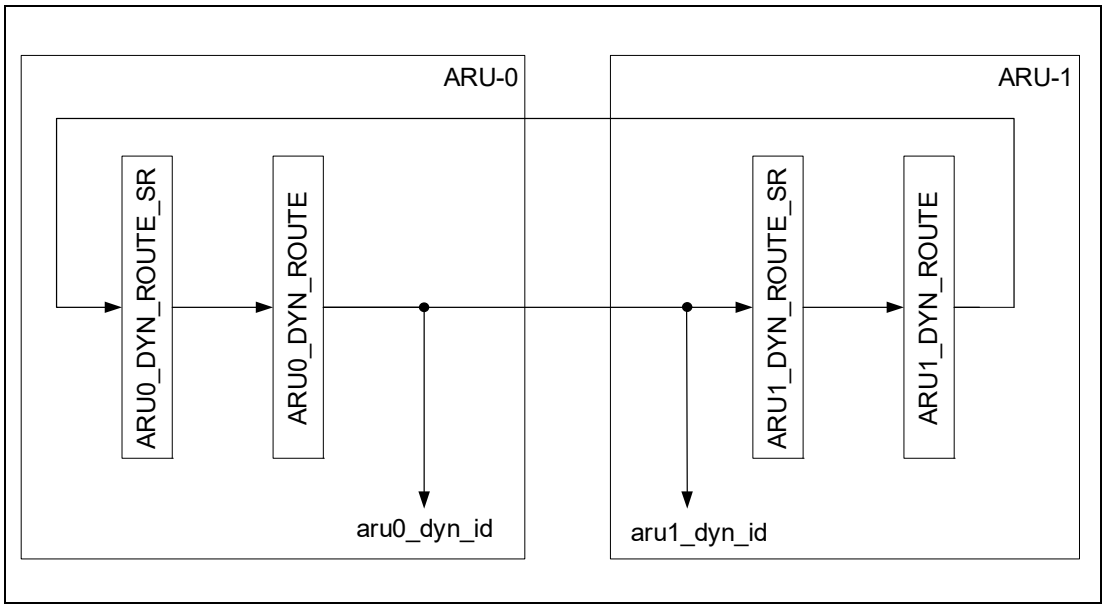

Figure 38.26 ARU dynamic routing - ring mode

Enabling the dynamic routing ring mode will automatically reset the caddr counter of both ARU-0 and ARU-1. This is necessary to synchronize both ARU's in this mode.

Enabling the dynamic routing ring mode will ignored DYN_ROUTE_SWAP and DYN_UPDATE_EN.

NOTE

DYN_ARU_UPDATE_EN should be disabled in dynamic routing ring mode.

It is possible to enable the dynamic routing ring mode for both ARU-0 and ARU-1 or only for one of the ARU's by setting the corresponding bit field ARU_0_DYN_EN/ARU_1_DYN_EN of the register ARU_CTRL. Because of the fact that to each ARU port ARU-0 and ARU-1 with the same ARU read ID two different GTM sub-modules are served it may make sense to enable ARU dynamic routing only for one port ARU-0 or ARU-1 if configured to ring-mode. The other port is then served in the default round robin manner.

In dynamic routing ring mode ARU_[z]_DYN_ROUTE_LOW/_HIGH and ARU_[z]_DYN_ROUTE_SR_LOW/_HIGH are not write-protected.

NOTE

Avoid modification of ARU_[z]_DYN_ROUTE_LOW/_HIGH and ARU_[z]_DYN_ROUTE_SR_LOW/_HIGH in active dynamic routing ring mode.

38.7.4.2 Dynamic routing – ARU controlled

Furthermore it is possible to reload the ARU_[z]_DYN_ROUTE_SR_LOW/_HIGH registers by ARU itself.

Therefore the ARU has its own master port which will be served in the normal ARU routing scheme. The ARU read address for this master port has to be configured in the register ARU_[z]_DYN_RDADDR.

This feature can be enabled by setting bit DYN_ARU_UPDATE_EN of ARU_[z]_DYN_CTRL register.

The following mapping of the ARU word to the ARU_[z]_DYN_ROUTE_LOW/_HIGH registers is implemented: ARU_[z]_DYN_ROUTE_SR_LOW(23:0) = aru_data(23:0)
ARU_[z]_DYN_ROUTE_SR_HIGH(28:0) = aru_data(52:24)

The bit field aru_data(51:48) controls the configuration bits DYN_CLK_WAIT and the bit aru_data(52) controls the configuration bit DYN_UPDATE_EN. Both functions are described in the **Section 38.7.4.1**.

In opposite to the dynamic routing scheme controlled from CPU/AEI (only the 6 additional ARU master DYN_REA_ID's are inserted) two additional ID's are served. One is the ARU master ID itself for reloading and the other is the default ID-0. The ID-0 is only added to the inserted routing scheme if bit field DYN_CLK_WAIT of ARU_[z]_DYN_ROUTE_HIGH is set to zero (only the inserted routing scheme is executed). This ensures that a debug access can take place even if only the inserted routing scheme is executed.

The following dynamic routing scheme is executed for 15 > DYN_CLK_WAIT > 0: ... → ARU-master_ID → DYN_READ_ID0 → DYN_READ_ID1

→ DYN_READ_ID2 → DYN_READ_ID3 → DYN_READ_ID4 → DYN_READ_ID5 → ARU-master_ID → ...

The following dynamic routing scheme is executed for DYN_CLK_WAIT = 0 : ... → ARU-master_ID → DYN_READ_ID0 → DYN_READ_ID1 → DYN_READ_ID2 → DYN_READ_ID3 → DYN_READ_ID4 → DYN_READ_ID5 → default_ID0 → ARU-master_ID → ...

With the possibility of reloading the dynamic routing scheme over ARU, a FIFO or MCS is able to deliver the dynamic routing scheme data.

38.7.5 ARU Interrupt Signals

The following table describes ARU interrupt signals:

Table 38.48 ARU Interrupt Signals

Signal	Description
ARU_NEW_DATA0_IRQ	Indicates that data is transferred through the ARU using debug channel ARU_DBG_ACCESS0.
ARU_NEW_DATA1_IRQ	Indicates that data is transferred through the ARU using debug channel ARU_DBG_ACCESS1.
ARU_ACC_ACK_IRQ	ARU access acknowledge IRQ.

38.7.6 ARU Configuration Registers Overview

The following table shows a conclusion of configuration registers address offsets and initial values.

Table 38.49 Register List

Symbol	Register Name	Details in Section
ARU_ACCESS	ARU access register	**38.7.7.1**
ARU_DATA_H	ARU access register upper data word	**38.7.7.2**
ARU_DATA_L	ARU access register lower data word	**38.7.7.3**
ARU_DBG_ACCESS0	Debug access channel 0	**38.7.7.4**
ARU_DBG_DATA0_H	Debug access 0 transfer register upper data word	**38.7.7.5**
ARU_DBG_DATA0_L	Debug access 0 transfer register lower data word	**38.7.7.6**
ARU_DBG_ACCESS1	Debug access channel 0	**38.7.7.7**
ARU_DBG_DATA1_H	Debug access 1 transfer register upper data word	**38.7.7.8**
ARU_DBG_DATA1_L	Debug access 1 transfer register lower data word	**38.7.7.9**
ARU_IRQ_NOTIFY	ARU Interrupt notification register	**38.7.7.10**
ARU_IRQ_EN	ARU Interrupt enable register	**38.7.7.11**
ARU_IRQ_FORCINT	Register for forcing the ARU_NEW_DATA_IRQ interrupt	**38.7.7.12**
ARU_IRQ_MODE	IRQ mode configuration register	**38.7.7.13**
ARU_CADDR_END	ARU caddr counter end value	**38.7.7.14**
ARU_CADDR	ARU caddr counter value	**38.7.7.15**
ARU_CTRL	ARU enable dynamic routing	**38.7.7.16**
ARU_[z]_DYN_CTRL	ARU z dynamic routing control register	**38.7.7.17**
ARU_[z]_DYN_RDADDR	ARU z read ID for dynamic routing	**38.7.7.18**
ARU_[z]_DYN_ROUTE_LOW	ARU z lower bits of DYN_ROUTE register	**38.7.7.19**
ARU_[z]_DYN_ROUTE_HIGH	ARU z higher bits of DYN_ROUTE register	**38.7.7.20**
ARU_[z]_DYN_ROUTE_SR_LOW	ARU z shadow register for ARU_[z]_DYN_ROUTE_LOW	**38.7.7.21**
ARU_[z]_DYN_ROUTE_SR_HIGH	ARU z shadow register for ARU_[z]_DYN_ROUTE_HIGH	**38.7.7.22**

38.7.7 ARU Configuration Registers Description

38.7.7.1 ARU_ACCESS

Access: This register can be read or written in 32-bit units.

Address: <GTM_base> + 00280_H

Value after reset: 0000 $01FE_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	WREQ	RREQ	—	—	—	ADDR								
Value after reset	0	0	0	0	0	0	0	1	1	1	1	1	1	1	1	0
R/W	R	R	R/W	R/W	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 38.50 ARU_ACCESS Register Contents (1/2)

Bit Position	Bit Name	Function
31 to 14	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
13	WREQ	Initiate write request 0: No write request is pending 1: Mark data in registers ARU_DATA_H and ARU_DATA_L as valid **NOTES** 1. This bit is cleared automatically after transaction. Moreover, it can be cleared by software to cancel a write request. 2. WREQ bit is only writable if RREQ bit is zero, so to switch from WREQ to RREQ a cancel request has to be performed before. 3. Configuring both RREQ and WREQ bits results in a read request, so WREQ bit will not be set 4. The data is provided at address ADDR. This address has to be programmed as the source address in the destination sub-module channel. In worst case, the data is provided after one full ARU round trip.
12	RREQ	Initiate read request 0: No read request is pending 1: Set read request to source channel addressed by ADDR **NOTES** 1. This bit is cleared automatically after transaction. Moreover, it can be cleared by software to cancel a read request. 2. RREQ bit is only writable if WREQ bit is zero, so to switch from RREQ to WREQ a cancel request has to be performed before. 3. Configuring both RREQ and WREQ bits results in a read request, so RREQ bit will be set if the WREQ bit of the register isn't already set. 4. The ARU read request on address ADDR is served immediately when no other destination has actually a read request when the RREQ bit is set by CPU. In a worst case scenario, the read request is served after one round trip of the ARU, but this is only the case when every destination channel issues a read request at consecutive points in time.

Table 38.50 ARU_ACCESS Register Contents (2/2)

Bit Position	Bit Name	Function
11 to 9	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
8 to 0	ADDR	ARU address Define the ARU address used for transferring data **NOTES** 1. For an ARU write request, the preferred address 0_H have to be used. 2. A write request to the address $1FF_H$ (always full address) or $1FE_H$ (always empty address) are ignored and doesn't have any effect. 3. ARU address bits ADDR are only writable if RREQ and WREQ bits are zero

Note: The register ARU_ACCESS can be used either for reading or for writing at the same point in time.

38.7.7.2 ARU_DATA_H

Access: This register can be read or written in 32-bit units.

Address: <GTM_base> + 00284_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	DATA												
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	DATA															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 38.51 ARU_DATA_H Register Contents

Bit Position	Bit Name	Function
31 to 29	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
28 to 0	DATA	Upper ARU data word Transfer upper ARU data word addressed by ADDR. The data bits 24 to 52 of an ARU word are mapped to the data bits 0 to 28 of this register

38.7.7.3 ARU_DATA_L

Access: This register can be read or written in 32-bit units.

Address: <GTM_base> + 00288_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	DATA												
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	DATA															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 38.52 ARU_DATA_L Register Contents

Bit Position	Bit Name	Function
31 to 29	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
28 to 0	DATA	Lower ARU data word **NOTES** 1. Transfer lower ARU data word addressed by ADDR. The data bits 0 to 23 of an ARU word are mapped to the data bits 0 to 23 of this register and the data bits 48 to 52 of an ARU word are mapped to the data bits 24 to 28 of this register when data is read by the CPU. 2. For writing data into the ARU by the CPU the bits 24 to 28 are not transferred to bit 48 to 52 of the ARU word. Only bits 0 to 23 are written to bits 0 to 23 of the ARU word.

38.7.7.4 ARU_DBG_ACCESS0

Access: This register can be read or written in 32-bit units.

Address: <GTM_base> + $0028C_H$

Value after reset: $0000\ 01FE_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Table 38.63 ARU_CADDR_END Register Contents

Bit Position	Bit Name	Function
31 to 7	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
6 to 0	CADDR_END	Set end value of ARU caddr counter **NOTES** 1. The ARU roundtrip counter aru_caddr runs from zero to caddr_end value. 2. Shorten the ARU roundtrip cycle by setting a smaller number than the defined reset value will cause that not all ARU-connected modules will be served. 3. Making the roundtrip cycle longer than the reset value would cause longer ARU roundtrip time and as a result some ARU-connected modules will not be served as fast as possible for this device. 4. The reset value is device-specific. For more information see **Section 38.28, GTM Device 358**. 5. This bit is write protected by bit RF_PROT of register GTM_CTRL.

38.7.7.15 ARU_CADDR

Access: This register is a read-only register that can be read in 32-bit units.

Address: <GTM_base> + $002FC_H$

Value after reset: Undefined

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	CADDR_1						
Value after reset	0	0	0	0	0	0	0	0	0	—	—	—	—	—	—	—
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

7 to 0	DYN_READ_ID9	DYN_READ_ID9 ARU read ID 9 ARU read ID 9 for dynamic routing. **NOTE** These bits are mapped to ARU data bits aru_data(31:24).

NOTE

This is the shadow register for register **Section 38.7.7.20, ARU_[z]_DYN_ROUTE_HIGH**.

38.8 Broadcast Module (BRC)

38.8.1 Overview

Since each write address for the sub-module channels of the GTM-IP that are able to write to the ARU can only be read by a single module, it is impossible to provide a data stream to different modules in parallel (This statement holds not for sources, which do not invalidate their data after the data were read by any consumer, e.g. DPLL).

To overcome this issue for regular modules, the sub-module Broadcast (BRC) enables to duplicate data streams multiple times.

The BRC sub-module provides 12 input channels as well as 22 output channels.

In order to clone an incoming data stream, the corresponding input channel can be mapped to zero or more output channels.

When mapped to zero no channel is read.

To destroy an incoming data stream, the EN_TRASHBIN bit inside the BRC_SRC_[z]_DEST register has to be set.

The total number of output channels that are assigned to a single input channel is variable. However, the total number of assigned output channels must be less than or equal to 22.

38.8.2 BRC Configuration

As it is the case with all other sub-modules connected to the ARU, the input channels can read arbitrary ARU address locations and the output channels provide the broadcast data to fixed ARU write address locations.

The associated write addresses for the BRC sub-module are fixed and can be obtained from **Section 38.27, Appendix A**.

The read address for each input channel is defined by the corresponding register BRC_SRC_[z]_ADDR (z: 0 to 11).

The mapping of an input channel to several output channels is defined by setting the appropriate bits in the register BRC_SRC_[z]_DEST (z: 0 to 11). Each output channel is represented by a single bit in the register BRC_SRC_[z]_DEST. The address of the output channel is defined in **Section 38.27, Appendix A**.

If no output channel bit is set within a register BRC_SRC_[z]_DEST, no data is provided to the corresponding ARU write address location from the defined read input specified by BRC_SRC_[z]_ADDR. This means that the channel does not broadcast any data and is disabled (reset state).

Besides the possibility of mapping an input channel to several output channels, the bit EN_TRASHBIN of register BRC_SRC_[z]_DEST may be set, which results in dropping an incoming data stream. In this case the data of an input channel defined by BRC_SRC_[z]_ADDR is consumed by the BRC module and not routed to any succeeding sub-module. In consequence, the output channels defined in the register BRC_SRC_[z]_DEST are ignored. Therefore, the bits 0 to 21 are set to zero (0) when trash bin functionality is enabled.

In general, the BRC sub-module can work in two independent operation modes. In the first operation mode the data consistency is guaranteed since a BRC channel requests only new data from a source when all destination channels for the BRC have consumed the old data value. This mode is called Data Consistency Mode (DCM).

In a second operation mode the BRC channel always requests data from a source and distributes this data to the destination regardless whether all destinations have already consumed the old data. This mode is called Maximum Throughput Mode (MTM).

MTM ensures that always the newest available data is routed through the system, while it is not guaranteed data consistency since some of the destination channels can be provided with the old data while some other destination channels are provided with the new data. If this is the case, the Data Inconsistency Detected Interrupt BRC_DID_IRQ[x] is raised but the channel continues to work.

Furthermore in MTM mode it is guaranteed that it is not possible to read a data twice by a read channel. This is blocked.

The channel mode can be configured inside the BRC_SRC_[z]_ADDR register.

To avoid invalid configurations of the registers BRC_SRC_[z]_DEST, the BRC also implements a plausibility check for these configurations.

If the software assigns an already used output channel to a second input channel, BRC performs an auto correction of the lastly configured register BRC_SRC_[z]_DEST and it triggers the interrupt BRC_DEST_ERR_IRQ.

Consider the following example for clarification of the auto correction mechanism. Assume that the following configuration of the 22 lower significant bits for the registers

BRC_SRC_[z]_DEST :

BRC_SRC_0_DEST : 00 0000 0000 1000 1000 0000_B

BRC_SRC_1_DEST : 00 0000 0000 0100 0000 0100_B

BRC_SRC_2_DEST : 00 0000 0000 0001 0100 0010_B

BRC_SRC_3_DEST : 00 0000 0000 0010 0001 1001_B

If the software overwrites the value for register BRC_SRC_2_DEST with BRC_SRC_2_DEST : 00 0000 0000 1001 0010 0010_B (changed bits are underlined), then the BRC releases an BRC_DEST_ERR_IRQ interrupt since bit 11 is already assigned in register BRC_SRC_0_DEST. The auto correction forces bit 11 to be cleared. The modifications of the bits 5 and 6 are accepted, since there is no violation with previous configurations. So the result of the write access mentioned above results in the following modified register configuration: BRC_SRC_2_DEST : 00 0000 0000 0001 0010 0010_B

For debug purposes, the interrupt BRC_DEST_ERR_IRQ can also be released by writing to register BRC_IRQ_FORCINT. Nevertheless, the interrupt has to be enabled to be visible outside of the GTM-IP.

38.8.3 BRC Interrupt Signals

Signal	Description
BRC_DEST_ERR_IRQ	Indicating configuration errors for BRC module
BRC_DID_IRQ[x]	Data inconsistency occurred in MTM mode (x:0..11)

38.8.4 BRC Configuration Registers Overview

BRC contains following configuration registers:

Table 38.72 Register List

Symbol	Register Name	Details in Section
BRC_SRC_[z]_ADDR	BRC read address for input channel z	**38.8.5.1**
BRC_SRC_[z]_DEST	BRC destination channels for input channel z	**38.8.5.2**
BRC_IRQ_NOTIFY	BRC interrupt notification register	**38.8.5.3**
BRC_IRQ_EN	BRC interrupt enable register	**38.8.5.4**
BRC_IRQ_FORCINT	BRC force interrupt register	**38.8.5.5**
BRC_IRQ_MODE	BRC interrupt mode configuration register	**38.8.5.6**
BRC_EIRQ_EN	BRC error interrupt enable register	**38.8.5.7**
BRC_RST	BRC software reset register	**38.8.5.8**

38.8.5 BRC Configuration Registers Description

38.8.5.1 BRC_SRC_[z]_ADDR

Access: This register can be read or written in 32-bit units.

Address: <GTM_base> + 00400_H + (8_H × z)

Value after reset: 0000 $01FE_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 38.74 BRC_SRC_[z]_DEST Register Contents

Bit Position	Bit Name	Function
31 to 23	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
22	EN_TRASHBIN	EN_TRASHBIN: Control trash bin functionality. 0: Trash bin functionality disabled 1: Trash bin functionality enabled **NOTE** When bit EN_TRASHBIN is enabled bits 0 to 21 are ignored for this input channel. Therefore, the bits 0 to 21 are set to zero (0) when trash bin functionality is enabled.
21 to 0	EN_DEST[21:0]	Enable BRC destination address k 0: Destination address k not mapped to source BRC_SRC_[z]_ADDR 1: Destination address k mapped to source BRC_SRC_[z]_ADDR **NOTE** The destination address k for BRC channel is defined in **Section 38.28.10.1**.

NOTES

1. The bits 0 to 21 are cleared by auto correction mechanism if a destination channel is assigned to multiple source channels.
2. When a BRC input channel is disabled (all EN_DEST[k] (k = 0 to 21) bits are reset to zero (0)), the internal states are reset to their reset value.

38.8.5.3 BRC_IRQ_NOTIFY

Access: This register can be read or written in 32-bit units.

Address: <GTM_base> + 00460_H

Table 38.80 BRC_RST Register Contents

Bit Position	Bit Name	Function
31 to 1	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
0	RST	Software reset 0: No action 1: Reset BRC **NOTE** This bit is cleared automatically after write by CPU. The channel registers are set to their reset values and channel operation is stopped immediately.

38.9 First In First Out Module (FIFO)

38.9.1 Overview

The FIFO unit is the storage part of the PSM sub-module. The F2A described in **Section 38.11, FIFO to ARU Unit (F2A)** and the AFD described in **Section 38.10, AEI to FIFO Data Interface (AFD)** implement the interface part of the FIFO sub-module to the ARU and the AEI bus. Each FIFO unit embeds eight logical FIFOs. These logical FIFOs are configurable in the following manner:

1. FIFO size (defines start and end address)
2. FIFO operation modes (normal mode or ring buffer operation mode)
3. Fill level control / memory region read protection

Each logical FIFO represents a data stream between the sub-modules of the GTM and the microcontroller connected to AFD sub-module (see **Section 38.10**). The FIFO RAM counts 1K words, where the word size is 29 bit. This gives the freedom to program or receive 24 bit of data together with the five control bits inside an ARU data word.

The FIFO unit provides three ports for accessing its content. One port is connected to the F2A interface, one port is connected to the AFD interface and one port has its own AEI bus interface.

The AFD interface has always the highest priority. Accesses to the FIFO from AFD interface and direct AEI interface in parallel — which means at the same time — is not possible, because both interfaces are driven from the same AEI bus interface of the GTM.

The priority between F2A and direct AEI interface can be defined by software. This can be done by using the register FIFO[i]_CH[z]_CTRL for all FIFO channels of the sub-module.

The FIFO is organized as a single RAM that is also accessible through the FIFO AEI interface connected to one of the FIFO ports. To provide the direct RAM access, the RAM is mapped into the address space of the microcontroller. The addresses for accessing the RAM via AEI can be found in **Section 38.28, GTM Device 358**.

After reset, the FIFO RAM isn't initialized by hardware.

The FIFO channels can be flushed individually. Each of the eight FIFO channels can be used either in normal FIFO operation mode or in ring buffer operation mode.

Beside the possibility of flushing each FIFO channel directly, a write access to FIFO[i]_CH[z]_END_ADDR or to FIFO[i]_CH[z]_START_ADDR will also flush the regarding channel which means that the read and write pointer and also the fill level of the regarding channel will be reset. In consequence of this existing data in the concerned FIFO channel are not longer valid- thereafter the channel is empty.

38.9.2 Operation Modes

38.9.2.1 FIFO Operation Mode

In normal FIFO operation mode the content of the FIFO is written and read in first-in first-out order, where the data is destroyed after it is delivered to the system bus or the F2A sub-module (see **Section 38.11**).

The upper and lower watermark registers (registers FIFO[i]_CH[z]_UPPER_WM and FIFO[i]_CH[z]_LOWER_WM) are used for controlling the FIFO s fill level. If the fill level falls below the lower watermark or it exceeds the upper watermark, an interrupt signal is triggered by the FIFO sub-module if enabled inside the FIFO[i]_IRQ_EN.

The interrupt signals are sent to the Interrupt Concentrator Module (ICM) (see **Section 38.24**). The ICM can also initiate specific DMA transfers.

38.9.2.2 Ring Buffer Operation Mode

The ring buffer mode can be used to provide a continuous data or configuration stream to the other GTM sub-modules without CPU interaction. In ring buffer mode the FIFO provides a continuous data stream to the F2A sub-module. The first word of the FIFO is delivered first and after the last word is provided by the FIFO to the ARU, the first word can be obtained again.

If in ring buffer mode the read pointer reaches the write pointer it will be set again to the configured start address. So the read pointer always rotates cyclic between the configured start address of the regarding FIFO channel (first written data) and the write pointer which points to the last written data of the channel.

It is possible to add data to the FIFO channel via the AEI to FIFO interface (AFD) using the register AFD[i]_CH[z]_BUF_ACC while running in ring buffer mode. The new written data will be added in the next ring buffer cycle. However, the register AFD[i]_CH[z]_BUF_ACC should not be read in ring buffer mode.

It is recommended to fill the FIFO channel first before enabling the data stream in the FIFO to ARU interface (F2A).

Modifications of the continuous data stream can be achieved by using direct memory access which is provided by the FIFO AEI interface.

38.9.2.3 DMA Hysteresis Mode

The DMA hysteresis mode can be enabled by setting bit DMA_HYSTERESIS = 1 in the FIFO[i]_CH[z]_IRQ_MODE register.

In the DMA hysteresis mode the lower and upper watermark will be masked to generate the DMA request (= fifo_irq) in the following manner.

If a DMA is writing data to a FIFO (configured by setting bit DMA_HYST_DIR = 1 in register FIFO[i]_CH[z]_IRQ_MODE), the DMA request will be generated by the lower watermark. The upper watermark does not generate a DMA request. The next DMA request will be generated by the next lower watermark until the upper watermark was reached.

If a DMA is reading data from a FIFO (configured by setting bit DMA_HYST_DIR = 0 in register FIFO[i]_CH[z]_IRQ_MODE), the DMA request will be generated by the upper watermark. The lower watermark does not generate a DMA request. The next DMA request will be generated by the next upper watermark until the lower watermark was reached.

NOTE

The watermarks have to achieve the following condition depending on the irq mode.

1. Level/Pulse/Pulse-Notify mode : upper watermark > lower watermark
2. Single-Pulse mode : upper watermark > lower watermark + 1

38.9.3 FIFO Interrupt Signals

Signal	Description
FIFO[i]*_CH[z]_EMPTY*	Indicating empty FIFO z (z = 0 to 7) was reached
FIFO[i]*_CH[z]_FULL*	Indicating full FIFO z (z = 0 to 7) was reached
FIFO[i]*_CH[z]_LOWER_WM*	Indicating FIFO z (z = 0 to 7) reached lower watermark.
FIFO[i]*_CH[z]_UPPER_WM*	Indicating FIFO z (z = 0 to 7) reached upper watermark.

38.9.4 FIFO Configuration Registers Overview

FIFO contains following configuration registers:

Table 38.81 Register List

Symbol	Register Name	Details in Section
FIFO[i]_CH[z]_CTRL	FIFOi channel z control register	**38.9.5.1**
FIFO[i]_CH[z]_END_ADDR	FIFOi channel z end address register	**38.9.5.2**
FIFO[i]_CH[z]_START_ADDR	FIFOi channel z start address register	**38.9.5.3**
FIFO[i]_CH[z]_UPPER_WM	FIFOi channel z upper watermark register	**38.9.5.4**
FIFO[i]_CH[z]_LOWER_WM	FIFOi channel z lower watermark register	**38.9.5.5**
FIFO[i]_CH[z]_STATUS	FIFOi channel z status register	**38.9.5.6**
FIFO[i]_CH[z]_FILL_LEVEL	FIFOi channel z fill level register	**38.9.5.7**
FIFO[i]_CH[z]_WR_PTR	FIFOi channel z write pointer register	**38.9.5.8**
FIFO[i]_CH[z]_RD_PTR	FIFOi channel z read pointer register	**38.9.5.9**
FIFO[i]_CH[z]_IRQ_NOTIFY	FIFOi channel z interrupt notification register	**38.9.5.10**
FIFO[i]_CH[z]_IRQ_EN	FIFOi channel z interrupt enable register	**38.9.5.11**
FIFO[i]_CH[z]_IRQ_FORCINT	FIFOi channel z force interrupt register	**38.9.5.12**
FIFO[i]_CH[z]_IRQ_MODE	FIFOi channel z interrupt mode control register	**38.9.5.13**
FIFO[i]_CH[z]_EIRQ_EN	FIFOi channel z error interrupt enable register	**38.9.5.14**
FIFO[i]_MEMORY	FIFO memory location	**38.9.5.15**

38.9.5 FIFO Configuration Registers Description

38.9.5.1 FIFO[i]_CH[z]_CTRL

Access: This register can be read or written in 32-bit units.

Address: <GTM_base> + 18400_H + (4000_H × i) + (40_H × z)

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	WULOCK	FLUSH	RAP	RBM
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W

Table 38.82 FIFO[i]_CH[z]_CTRL Register Contents

Bit Position	Bit Name	Function
31 to 4	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
3	WULOCK	RAM write unlock. Enable/disable direct RAM write access to the memory mapped FIFO region. 0: Direct RAM write access disabled 1: Direct RAM write access enabled **NOTE** Only the bit WULOCK of register FIFO[i]_CH0_CTRL enables/disables the direct RAM write access for all FIFO channel (whole FIFO RAM). The WULOCK bits of the other channels are writable but have no effect.
2	FLUSH	FIFO Flush control 0: Normal operation 1: Execute FIFO flush (bit is automatically cleared after flush) **NOTE** A FIFO Flush operation resets the FIFO[i]_CH[z]_FILL_LEVEL, FIFO[i]_CH[z]_WR_PTR and FIFO[i]_CH[z]_RD_PTR registers to their initial values.
1	RAP	RAM access priority 0: FIFO ports have higher access priority than AEI-IF 1: AEI-IF has higher access priority than FIFO ports **NOTE** The RAP bit is only functional in register FIFO_0_CTRL. The priority is defined for all FIFO channels there.
0	RBM	Ring buffer mode enable 0: Normal FIFO operation mode 1: Ring buffer mode

38.9.5.2 FIFO[i]_CH[z]_END_ADDR

Access: This register can be read or written in 32-bit units.

Address: <GTM_base> + 18404_H + (4000_H × i) + (40_H × z)

Value after reset: Undefined

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

28 to 0	DATA	FIFO memory location. **NOTE** Read as zero, should be written as zero.

38.10 AEI to FIFO Data Interface (AFD)

38.10.1 Overview

The AFD sub-module implements a data interface between the AEI bus and the FIFO sub-module, which consists of eight logical FIFO channels.

The AFD sub-module provides one buffer registers that are dedicated to the logical channels of the FIFO. Access to the corresponding FIFO channel is given by reading or writing this buffer registers AFD[i]_CH[z]_BUF_ACC.

An AEI write access to the buffer register where the corresponding FIFO channel is full will be ignored. The data will be lost.

An AEI read access to the buffer register where the corresponding FIFO channel is empty will be served with zero data.

38.10.2 AFD Configuration Registers Overview

AFD contains following configuration registers:

Table 38.97 Register List

Symbol	Register Name	Details in Section
AFD[i]_CH[z]_BUF_ACC	AFD i FIFO z buffer access register	**38.10.3.1**

38.10.3 AFD Configuration Register Description

38.10.3.1 AFD[i]_CH[z]_BUF_ACC

Access: This register can be read or written in 32-bit units.

Address: <GTM_base> + 18080_H + (4000_H × i) + (10_H × z)

Value after reset: 0000 0000_H

Table 38.98 AFD[i]_CH[z]_BUF_ACC Register Contents

Bit Position	Bit Name	Function
31 to 29	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
28 to 0	DATA	Read/write data from/to FIFO

38.11 FIFO to ARU Unit (F2A)

38.11.1 Overview

The F2A is the interface between the ARU and the FIFO sub-module. Since the data width of the ARU (ARU word) is 53 bit (two 24 bit values and five control bits) and the data width of the FIFO is only 29 bit, the F2A has to distribute the data from and to the FIFO channels in a configurable manner.

The data transfer between FIFO and ARU is organized with eight different streams that are connected to the eight different channels of the corresponding FIFO module. A stream represents a data flow from/to ARU to/from the FIFO via the F2A.

The general definition of 'channels' and 'streams' in the ARU context is done in **Section 38.5.3**.

Each FIFO channel can act as a write stream (data flow from FIFO to ARU) or as a read stream (data flow from ARU to FIFO).

Within these streams the F2A can transmit/receive the lower, the upper or both 24 bit values of the ARU together with the ARU control bits according to the configured transfer modes as described in **Section 38.11.2**.

Each stream can be enabled/disabled separately within the register F2A[i]_ENABLE. If a stream will be disabled, the stream data which are stored inside the F2A will be deleted. This is necessary to ensure, that no old data are transferred after enabling a stream.

38.11.2 Transfer modes

The F2A unit provides several transfer modes to map 29 bit data of the FIFO from/to 53 bit data of the ARU. E.g. it is configurable that the 24 bit FIFO data is written to the lower ARU data entry (means bits 0 to 23) or to the higher 24 bit ARU data entry (means bits 24 to 47). Bits 24 to 28 of the FIFO data entry (the five control bits) are written/read in both cases to/from bits 48 to 52 of the ARU entry.

When both values of the ARU have to be stored in the FIFO the values are stored behind each other inside the FIFO if the FIFO is not full.

If there is only space for one 24 bit data word plus the five control bits, the F2A transfers one part of the 53 bits first and then waits for transferring the second part before new data is requested from the ARU.

When two values from the FIFO have to be written to one ARU location the words have to be located behind each other inside the FIFO.

The transfer to ARU is only established when both parts could be read out of the FIFO otherwise if only one 29 bit word was provided by the FIFO the F2A waits until the second part is available before the data is made available at the ARU.

Figure 38.27 shows the data ordering of the FIFO when both ARU values must be transferred between ARU and FIFO.

When reading from the ARU the F2A first writes the lower word to the FIFO.

In case of writing to the ARU the F2A reads the lower word first from the FIFO, thus the lower word must be written first to the FIFO through the AFD interface.

NOTE

The five control bits (bits 48 to 52 of the ARU data word) are duplicated as bit 24 to 28 of both FIFO words in case of reading from ARU.

In the case of writing to the ARU, bits 24 to 28 of the last written FIFO word (the higher ARU word) are copied to bits 48 to 52 of the corresponding ARU location.

The transfer modes can be configured with the TMODE bits of registers F2A[i]_CH[z]_STR_CFG (x: 0 to 7).

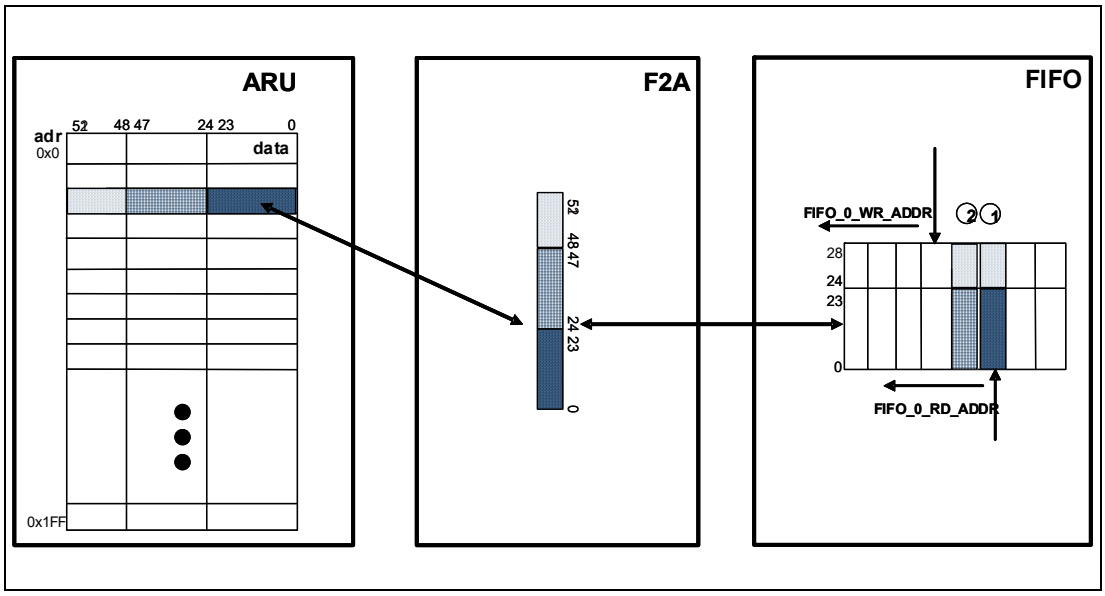

Figure 38.27 Data transfer of both ARU words between ARU and FIFO

38.11.3 Internal buffer mode

It is possible to use a FIFO channel as a buffer which is accessed only internally from ARU side. To do this, a read and a write stream of the F2A to one FIFO channel are needed. Therefore it is possible to reconfigure the upper 4.

F2A streams 4 to 7 to the lower 4 FIFO channels 0 to 3 in the following manner:

F2A stream 4 (+ F2A stream 0) → FIFO channel 0
F2A stream 5 (+ F2A stream 1) → FIFO channel 1
F2A stream 6 (+ F2A stream 2) → FIFO channel 2
F2A stream 7 (+ F2A stream 3) → FIFO channel 3

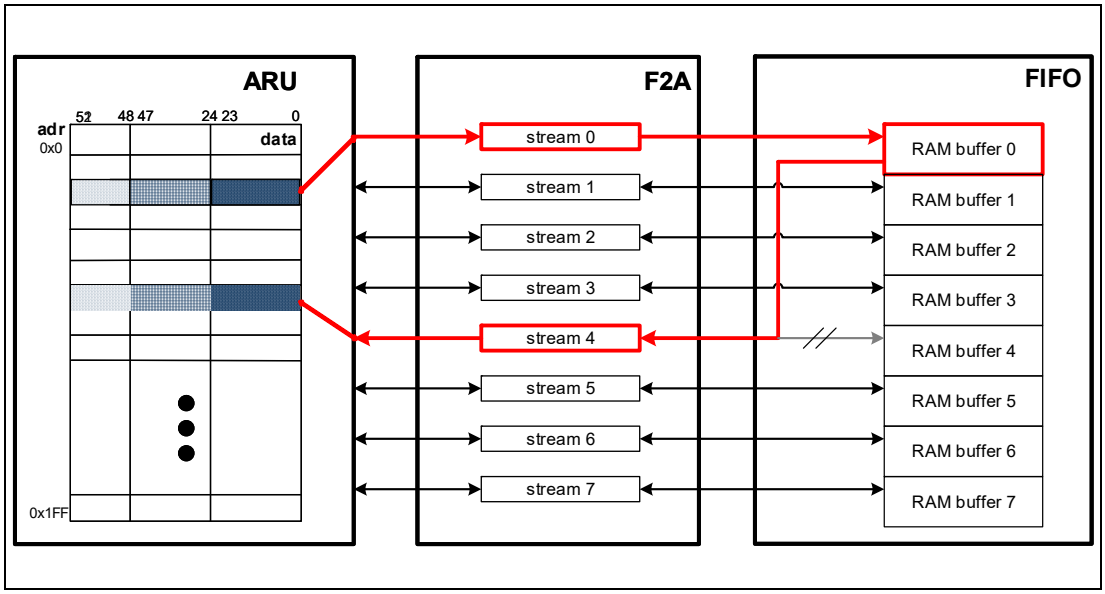

Figure 38.28 Reconfiguration of F2A stream 4 to FIFO channel 0

The configuration of each 4 upper F2A streams can be done separately for each stream in the configuration register F2A[i]_CTRL.

NOTE

The corresponding upper FIFO channel (4 to 7) cannot be used in this configuration.

38.11.4 F2A Configuration Registers Overview

F2A contains following configuration registers:

Table 38.99 Register List

Symbol	Register Name	Details in Section
F2A[i]_ENABLE	F2Ai stream activation register	**38.11.5.1**
F2A[i]_CH[z]_ARU_RD_FIFO	F2Ai ARU Read address register	**38.11.5.2**
F2A[i]_CH[z]_STR_CFG	F2Ai stream z configuration register	**38.11.5.3**

38.12 Clock Management Unit (CMU)

38.12.1 Overview

The Clock Management Unit (CMU) is responsible for clock generation of the counters and of the GTM-IP. The CMU consists of three sub-units that generate different clock sources for the whole GTM-IP. The primary clock source for this sub-module is the cluster 0 clock signal cls0_clk which is defined by the value of bit field CLS0_CLK_DIV in register GTM_CLS_CLK_CFG. **Figure 38.29** shows a block diagram of the CMU.

The Configurable Clock Generation (CFGU) sub-unit provides eight dedicated clock sources for the following GTM modules: TIM, ATOM, TBU, and MON. Each instance of such a module can choose an arbitrary clock source, in order to specify wide-ranging time bases.

The Fixed Clock Generation (FXU) sub-unit generates predefined non-configurable clocks CMU_FXCLK[y] (y: 0 to 4) for the TOM modules and the MON module. The CMU_FXCLK[y] signals are derived from the CMU_GCLK_EN signal generated by the Global Clock Divider. The dividing factors are defined as 2^0, 2^4, 2^8, 2^{12}, and 2^{16}.

The External Clock Generation (EGU) sub-unit is able to generate up to three chip external clock signals visible at CMU_ECLK[z] (z: 0 to 2) with a duty cycle of about 50%.

The External Clock Generation (EGU) sub-unit is able to generate clock CMU_CLK8 for module CCM to manage 2 clock domains.

The clock source signals CMU_CLK[x] (x: 0 to 7) and CMU_FXCLK[y] are implemented in form of enable signals for the corresponding registers, which means that the actual clock signal of all registers always use the CLS0_CLK signal.

The four configurable clock signals CMU_CLK0, CMU_CLK1, CMU_CLK6 and CMU_CLK7 are used for the TIM filter counters.

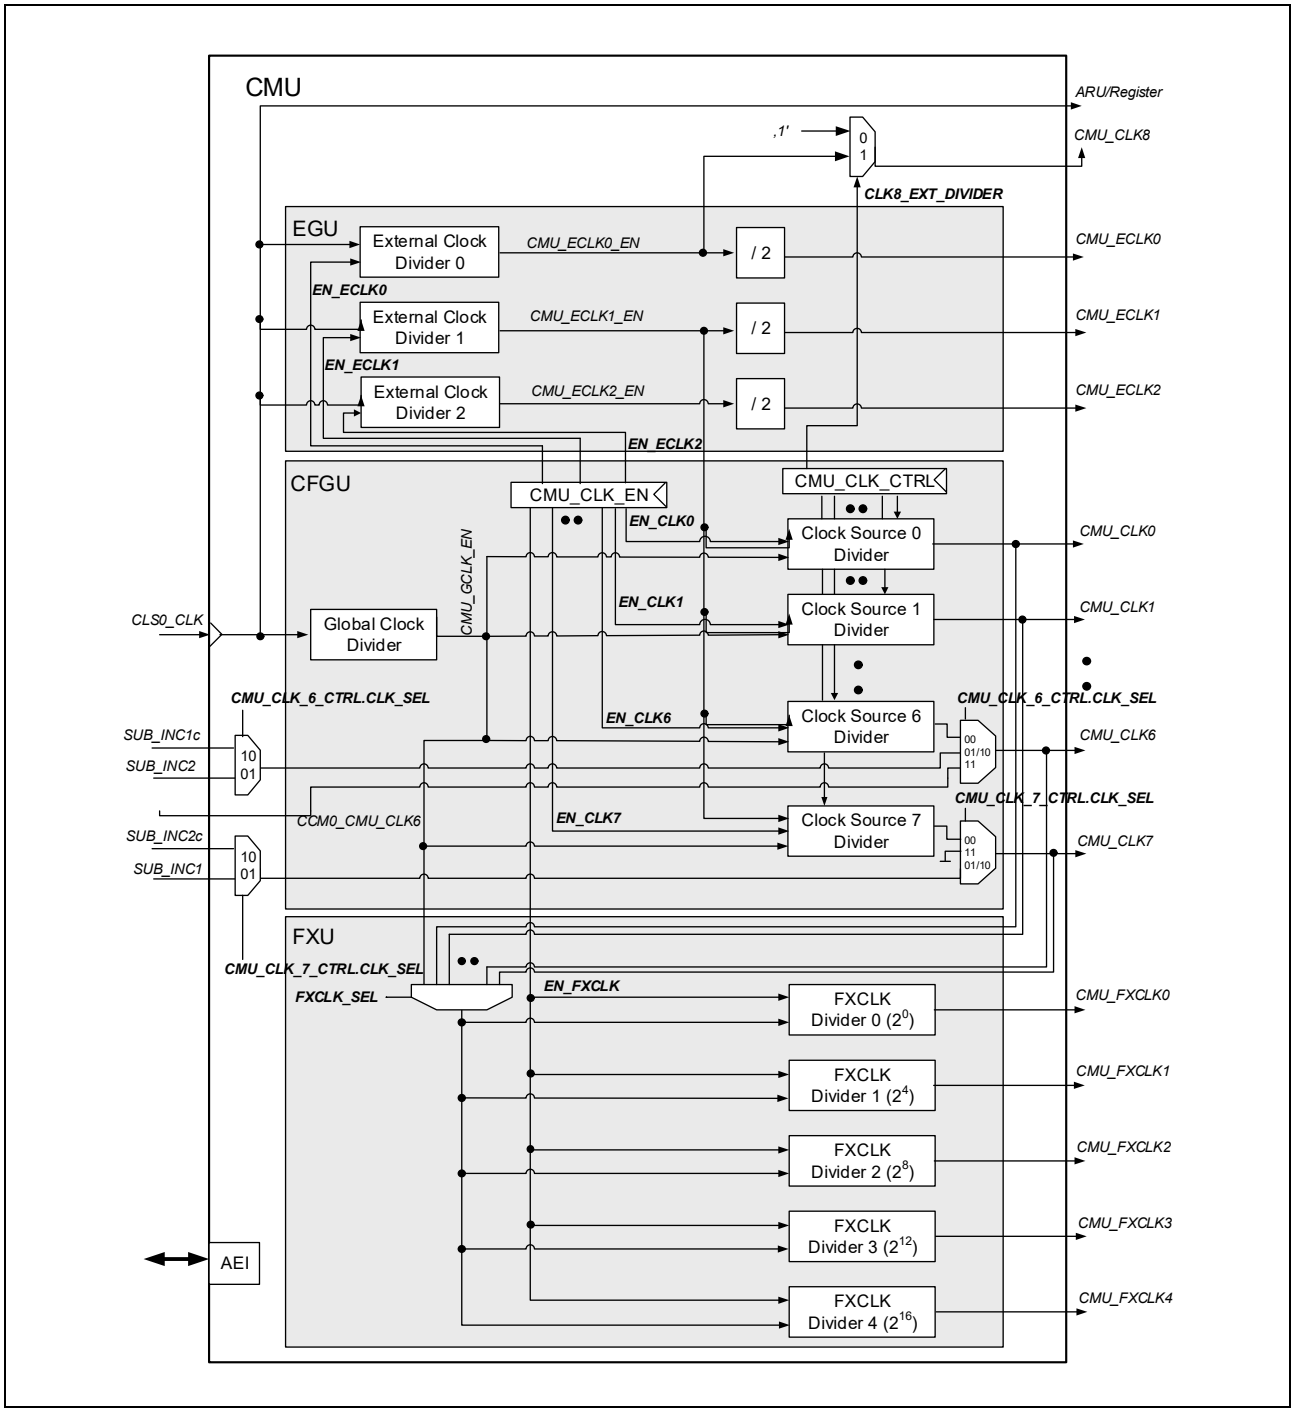

Figure 38.29 CMU Block Diagram

38.12.2 Global Clock Divider

The sub block Global Clock Divider can be used to divide the CMU primary source signal CLS0_CLK into a common subdivided clock signal.

The divided clock signal of the sub block Global Clock Divider is implemented as an enable signal that enables dedicated clocks from the CLS0_CLK signal to generate the user specified divided clock frequency.

The resulting fractional divider (Z/N) specified through equation:

$T_{CMU\_GCLK\_EN} = (Z/N) * T_{CLS0\_CLK}$ is implemented according the following algorithm

(Z: CMU_GCLK_NUM(23:0) ; N: CMU_GCLK_DEN(23:0) ; $Z \geq N > 0$):

(1) Set remainder (R), operand 1 (OP1) and operand 2 (OP2) register during INIT-phase (with implicit conversion to signed):
R = Z, OP1 = N, OP2 = N-Z;

(2) After leaving INIT-phase (at least one CMU_CLK[x] has been enabled) the sign of remainder R for each CLS0_CLK cycle will be checked:

(3) If $R \geq 0$ keep updating remainder and keep CMU_GCLK_EN = 0:
R = R-OP1;

(4) If R<0 update remainder and set CMU_GCLK_EN = 1:
R = R-OP2;

After at most (Z/N +1) subtractions (3) there will be a negative R and an active phase of the generated clock enable (for one cycle) will be triggered (4). The remainder R is a measure for the distance to a real Z/N clock and will be regarded for the next generated clock enable cycle phase. The new R value will be R = R + (Z-N). In the worst case the remainder R will sum up to an additional cycle in the generated clock enable period after Z-cycles. In the other cases equally distributed additional cycles will be inserted for the generated clock enable. If Z is an integer multiple of N no additional cycles will be included for the generated clock enable at all.

NOTE

For a better resource sharing all arithmetic has been reduced to subtractions and the initialization of the remainder R uses the complement of (Z-N).

38.12.3 Configurable Clock Generation Sub-unit (CFGU)

The CMU sub-unit CFGU provides up to eight configurable clock divider blocks that divide the common C MU_GCLK_EN signal into dedicated enable signals for the GTM-IP sub blocks.

The configuration of the eight different clock signals CMU_CLK[x] (x: 0 to 7) always depends on the configuration of the global clock enable signal CMU_GCLK_EN. Additionally, each clock source has its own configuration data, provided by the control register CMU_CLK_[x]_CTRL (x: 0 to 7).

According to the configuration of the Global Clock Divider, the configuration of the Clock Source x Divider is done by setting an appropriate value in the bit field CLK_CNT[x] of the register CMU_CLK_[x]_CTRL.

The frequency fx = 1/Tx of the corresponding clock enable signal CMU_CLK[x] can be determined by the unsigned representation of CLK_CNT[x] of the register CMU_CLK_[x]_CTRL in the following way:

$T_{CMU\_CLK[x]} = (CLK\_CNT[x] + 1) \times T_{CMU\_GCLK\_EN}$.

The corresponding wave form is shown in **Figure 38.30**.

Each clock signal CMU_CLK[x] can be enabled individually by setting the appropriate bit field EN_CLK[x] in the register CMU_CLK_EN.

However, individual enabling of CMU_CLK6 and CMU_CLK7 is only possible if the bit field CLK_SEL of register CMU_CLK_6_CTRL or CMU_CLK_7_CTRL is set to 0.

Alternatively, clock source six and seven (CMU_CLK6 and CMU_CLK7) may provide the signal SUB_INC1 and SUB_INC2 coming from module DPLL as clock enable signal depending on the bit field CLK_SEL of the register CMU_CLK_6_CTRL and CMU_CLK_7_CTRL.

CMU_CLK8 is switched by CLK8_EXT_DIVIDER of the register CMU_CLK_CTRL between CLS0_CLK and CMU_ECLK0.

To switch the clock reference CMU_GCLK_EN with CMU_ECLK1_EN an input selector are used in all Clock Source Divider. The CMU_ECLK1_EN source is enabled by setting the appropriate bit field CMU[x]_EXT_DIVIDER in the register CMU_CLK_CTRL.

To avoid unexpected behavior of the hardware, the configuration of register CMU_CLK_[x]_CTRL and CMU_CLK_CTRL can only be changed, when the corresponding clock signal CMU_CLK[x] and CMU_ECLK[1] is disabled.

Further, any changes to the registers CMU_GCLK_NUM and CMU_GCLK_DEN can only be performed, when all clock enable signals CMU_CLK[x] and the EN_FXCLK bit inside the CMU_CLK_EN register are disabled.

The clock source signals CMU_CLK[x] (x: 0 to 7) and CMU_FXCLK[y] are implemented in form of enable signals for the corresponding registers, which means that the actual clock signal of all registers always use the CLS0_CLK signal.

The hardware guarantees that all clock signals CMU_CLK[x] (x: 0 to 7), which were enabled simultaneous, are synchronized to each other.

Simultaneous enabling does mean that the bits EN_CLK[x] in the register CMU_CLK_EN are set by the same write access.

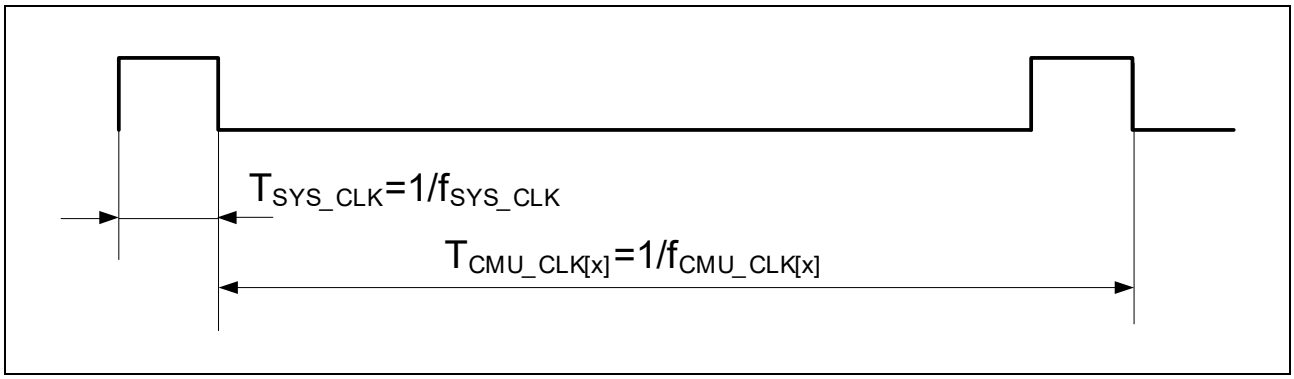

Figure 38.30 Wave Form of Generated Clock Signal CMU_CLK[x]

38.12.4 Fixed Clock Generation (FXU)

The FXU sub-unit generates fixed clock enables out of the CMU_GCLK_EN or one of the eight CMU_CLK[x] enable signal depending on the FXCLK_SEL bit field of the CMU_FXCLK_CTRL register. These clock enables are used for the PWM generation inside the TOM modules.

All clock enables CMU_FXCLK[y] can be enabled or disabled simultaneous by setting the appropriate bit field EN_FXCLK in the register CMU_CLK_EN.

The dividing factors are defined as 2^0, 2^4, 2^8, 2^{12}, and 2^{16}. The signals CMU_FXCLK[y] are implemented in form of enable signals for the corresponding registers (see also **Figure 38.30**).

38.12.5 External Generation Unit (EGU)

The EGU sub-unit generate up to three separate clock output signals CMU_ECLK[z] (z: 0 to 2). Each of these clock signals is derived from the corresponding External Clock Divider z sub block, which generates a clock signal derived from the GTM-IP input clock CLS0_CLK.
In contrast to the signals CMU_CLK[x] and CMU_FXCLK[y], which are treated as simple enable signals for the registers, the signals CMU_ECLK[z] have a duty cycle of about 50% that is used as a true clock signal for external peripheral components.
To manage a second global frequency CMU_GCLK_EN could be replaced by ECLK[1]_EN for CMU_CLK[x](x: 0 to 7). Also the all-time enabled CMU_CLK8 could be replaced by ECLK[0]_EN.

Each of the external clocks divider are enabled and disabled by setting the appropriate bit field EN_ECLK[z] in the register CMU_CLK_EN.
The clock frequencies $f_{CMU\_ECLK[z]} = 1/T_{CMU\_ECLK[z]}$ of the external clocks are controlled with the registers CMU_ECLK_[z]_NUM and CMU_ECLK_[z]_DEN as follows:

$T_{CMU\_ECLK[z]\_EN} = (ECLK[z]\_NUM / ECLK[z]\_DEN) \times T_{CLS0\_CLK}$

and is implemented according the following algorithm (Z: CMU_ECLK_[z]_NUM(23:0); N: CMU_ECLK_[z]_DEN(23:0); $Z \geq N > 0$; $Z \geq N$; CMU_ECLK[z] = '0'):

(1) Set remainder (R), operand 1 (OP1) and operand 2 (OP2) register during INIT-phase (with implicit conversion to signed): R = Z, OP1 = N, OP2 = N-Z;

(2) After leaving INIT-phase (CMU_ECLK[z] has been enabled) the sign of remainder R for each CLS0_CLK cycle will be checked:

(3) If $R \geq 0$ keep updating remainder and keep CMU_ECLK[z]: R = R-OP1;

(4) If $R < 0$ update remainder and toggle CMU_ECLK[z]: R = R-OP2;

After at most (Z/N +1) subtractions (3) there will be a negative R and an active phase of the generated clock enable (for one cycle) will be triggered (4). The remainder R is a measure for the distance to a real Z/N clock and will be regarded for the next generated clock toggle phase. The new R value will be R = R+(Z-N). In the worst case the remainder R will sum up to an additional cycle in the generated clock toggle period after Z-cycles. In the other cases equally distributed additional cycles will be inserted for the generated clock toggle. If Z is an integer multiple of N no additional cycles will be included for the generated clock toggle at all.

NOTE

For a better resource sharing all arithmetic has been reduced to subtractions and the initialization of the remainder R uses the complement of (Z–N).

The default value of the CMU_ECLK[z] output is low.

38.12.6 CMU Configuration Registers Overview

CMU contains following configuration registers:

Table 38.104 Register List

Symbol	Register Name	Details in Section
CMU_CLK_EN	CMU clock enable	**38.12.7.1**
CMU_GCLK_NUM	CMU global clock control numerator	**38.12.7.2**
CMU_GCLK_DEN	CMU global clock control denominator	**38.12.7.3**
CMU_CLK_[z]_CTRL	CMU control for clock source z	**38.12.7.4**
CMU_CLK_6_CTRL	CMU control for clock source 6	**38.12.7.5**

Table 38.105 CMU_CLK_EN Register Contents

Bit Position	Bit Name	Function
31 to 24	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
23, 22	EN_FXCLK	Enable all CMU_FXCLK, see bits 1, 0 **NOTE** An enable to EN_FXCLK from disable state will be reset internal fixed clock counters.
21, 20	EN_ECLK2	Enable ECLK 2 generation sub-unit, see bits 1, 0
19, 18	EN_ECLK1	Enable ECLK 1 generation sub-unit, see bits 1, 0
17, 16	EN_ECLK0	Enable ECLK 0 generation sub-unit, see bits 1, 0
15, 14	EN_CLK7	Enable clock source 7, see bits 1, 0
13, 12	EN_CLK6	Enable clock source 6, see bits 1, 0
11,10	EN_CLK5	Enable clock source 5, see bits 1, 0
9, 8	EN_CLK4	Enable clock source 4, see bits 1, 0
7, 6	EN_CLK3	Enable clock source 3, see bits 1, 0
5, 4	EN_CLK2	Enable clock source 2, see bits 1, 0
3, 2	EN_CLK1	Enable clock source 1, see bits 1, 0
1, 0	EN_CLK0	Enable clock source 0 00_B: Clock source is disabled (ignore write access) 01_B: Disable clock signal and reset internal states 10_B: Enable clock signal 11_B: Clock signal enabled (ignore write access) **NOTES** 1. Any read access to an EN_CLK[z], EN_ECLK[z] or EN_FXCLK bit field will always result in a value 00_B or 11_B indicating current state. A modification of the state is only performed with the values 01_B and 10_B. Writing the values 00_B and 11_B is always ignored. 2. Any disabling to EN_CLK[x] will be reset internal counters for configurable clocks.

38.12.7.2 CMU_GCLK_NUM

Access: This register can be read or written in 32-bit units.

Address: <GTM_base> + 00304_H

Value after reset: $0000\ 0001_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	CMU_GCLK_NUM							
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 38.106 CMU_GCLK_NUM Register Contents

Bit Position	Bit Name	Function
31 to 24	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
23 to 0	CMU_GCLK_NUM	Numerator for global clock divider. Defines numerator of the fractional divider. **NOTES** 1. Value can only be modified when all clock enables EN_CLK[x] and the EN_FXCLK are disabled. 2. The CMU hardware alters the content of CMU_GCLK_NUM and CMU_GCLK_DEN automatically to 1_H, if CMU_GCLK_NUM is specified less than CMU_GCLK_DEN or one of the values is specified with a value zero. Thus, a secure way for altering the values is writing twice to the register CMU_GCLK_NUM followed by a single write to register CMU_GCLK_DEN.

38.12.7.3 CMU_GCLK_DEN

Access: This register can be read or written in 32-bit units.

Address: <GTM_base> + 00308_H

Value after reset: $0000\ 0001_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 38.107 CMU_GCLK_DEN Register Contents

Bit Position	Bit Name	Function
31 to 24	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
23 to 0	GCLK_DEN	Denominator for global clock divider. Defines denominator of the fractional divider. **NOTES** 1. Value can only be modified when all clock enables EN_CLK[x] and the EN_FXCLK are disabled. 2. The CMU hardware alters the content of CMU_GCLK_NUM and CMU_GCLK_DEN automatically to 1_H, if CMU_GCLK_NUM is specified less than CMU_GCLK_DEN or one of the values is specified with a value zero. Thus, a secure way for altering the values is writing twice to the register CMU_GCLK_NUM followed by a single write to register CMU_GCLK_DEN.

38.12.7.4 CMU_CLK_[z]_CTRL

Access: This register can be read or written in 32-bit units.

Address: CMU_CLK_0_CTRL: <GTM_base> + $0030C_H$
CMU_CLK_1_CTRL: <GTM_base> + 00310_H
CMU_CLK_2_CTRL: <GTM_base> + 00314_H
CMU_CLK_3_CTRL: <GTM_base> + 00318_H
CMU_CLK_4_CTRL: <GTM_base> + $0031C_H$
CMU_CLK_5_CTRL: <GTM_base> + 00320_H

Value after reset: $0000\ 0000_H$

	—	—	—	—	—	—	—	—	—	—	—	—	FXCLK_SEL			
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W

Table 38.113 CMU_FXCLK_CTRL Register Contents

Bit Position	Bit Name	Function
31 to 4	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
3 to 0	FXCLK_SEL	Input clock selection for EN_FXCLK line. 0000_B: CMU_GCLK_EN selected. 0001_B: CMU_CLK0 selected. 0010_B: CMU_CLK1 selected. 0011_B: CMU_CLK2 selected. 0100_B: CMU_CLK3 selected. 0101_B: CMU_CLK4 selected. 0110_B: CMU_CLK5 selected. 0111_B: CMU_CLK6 selected. 1000_B: CMU_CLK7 selected. **NOTES** 1. This value can only be written, when the CMU_FXCLK generation is disabled. See bits 23 and 22 in register CMU_CLK_EN. 2. Other values for FXCLK_SEL are reserved and should not be used, but they behave like FXCLK_SEL = 0.

38.12.7.10 CMU_GLB_CTRL

Access: This register can be read or written in 32-bit units.

Address: <GTM_base> + 00348_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Table 38.114 CMU_GLB_CTRL Register Contents

Bit Position	Bit Name	Function
31 to 1	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
0	ARU_ADDR_RSTGLB	Reset ARU caddr counter and ARU dynamic route counter. **NOTES** 1. Writing value 1 to this bit field results in a request to reset the ARU caddr counter and ARU dynamic route counter. The next following write access to register CMU_CLK_EN applies the ARU caddr counter reset, ARU dynamic route counter reset and resets this bit. This feature can be used to synchronize the ARU round trip time to the CMU clocks. 2. This bit is write protected. Before writing to this bit set bit RF_PROT of register GTM_CTRL to 0.

38.12.7.11 CMU_CLK_CTRL

Access: This register can be read or written in 32-bit units.

Address: <GTM_base> + $0034C_H$

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Table 38.115 CMU_CLK_CTRL Register Contents

Bit Position	Bit Name	Function
31 to 9	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
8	CLK8_EXT_DIVIDER	Clock source selection for CMU_CLK8. 0: Use Clock Source CLS0_CLK 1: Use Clock Source CMU_ECLK0 **NOTE** Value can only be modified when EN_ECLK0 is disabled.
7 to 0	CLK[7:0]_EXT_DIVIDER	Clock source selection for CMU_CLK_[k]_CTRL. 0: Use Clock Source CMU_GCLK_EN 1: Use Clock Source CMU_ECLK1 **NOTE** Value can only be modified when clock enable EN_CLK[k] and EN_ECLK1 are disabled.

38.13 Cluster Configuration Module (CCM)

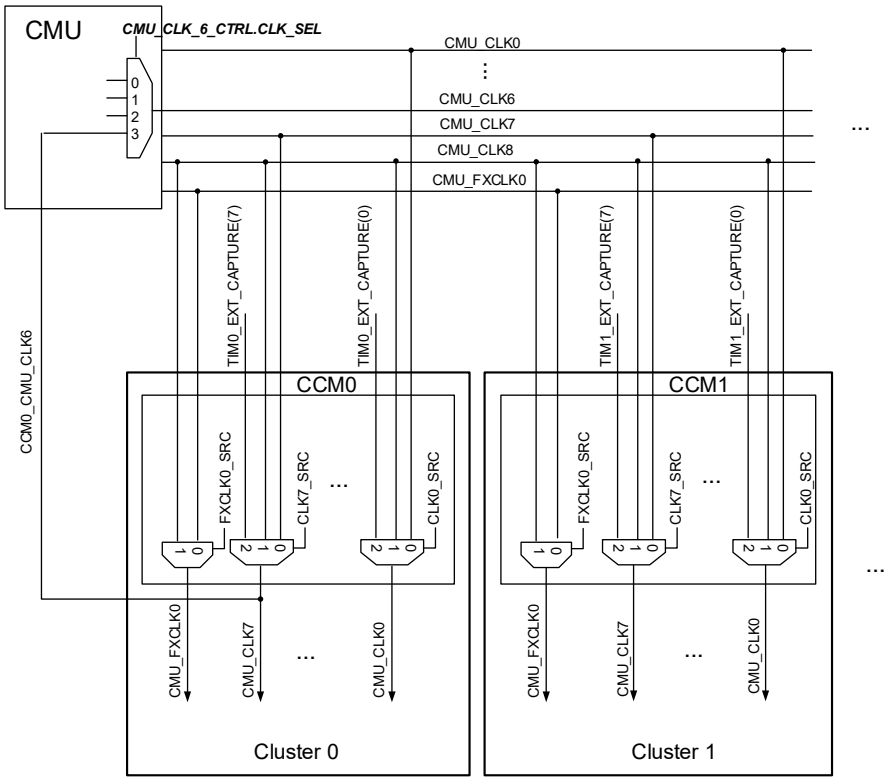
38.13.1 Overview

As already mentioned in **Section 38.5**, each sub-module of the GTM is aligned explicitly to a cluster. The Cluster Configuration Module (CCM) enables the configuration of several cluster specific options namely.

1. Cluster's clock frequency
2. Module clock gating
3. Status observation of the cluster's MCS bus master (AEM)
4. Address range protection
5. Global architecture configuration

The register CCM[i]_CFG allows disabling the system clock signal for unused sub modules of the i-th cluster. The registers CCM[i]_CMU_CLK_CFG and CCM[i]_CMU_FXCLK_CFG allows the configuration of various cluster clock frequencies.

Figure 38.31 shows important details about the wiring of the cluster's local clock signals.



The register CCM[i]_AEIM_STA captures the address and the reason of the first invalid AEIM bus master access of the cluster's MCS module.

Figure 38.31 Cluster Clock Signal Wiring

38.13.2 Address Range Protection

The CCM also provides up to NARP so called address range protectors (ARPs), where the number NARP depends on the actual device configuration (defined in **Section 38.28, GTM Device 358**). An ARP can be used to define a configurable write protected address range in order to support enhanced safety features. The address width of and ARP is also device dependent and it is determined by the parameter AAW as defined in **Section 38.28, GTM Device 358**.

The protected address range is mapped to the address range of the cluster's MCS RAM port.

Each ARP z (with z = 0 to NARP-1) can be configured by the registers CCM[i]_ARP[z]_CTRL and CCM[i]_ARP[z]_PROT, where the register CCM[i]_ARP[z]_CTRL enables to configure the size and base address offset for an ARP and the register CCM[i]_ARP[z]_PROT configures, that an MCS channel x with a set bit field WPROTx cannot write to the corresponding z-th ARP. Whenever an MCS channel x is writing to an ARP that does not allow a write access from channel x by the configuration register CCM[i]_ARP[z]_PROT, the write access is discard. The bit field WPROT_AEI of register CCM[i]_ARP[z]_CTRL allows to configure if a CPU write access (via AEI slave interface) to the z-th ARP is protected. If the CPU wants to write to the z-th ARP while WPROT_AEI is set, the write access will be discard and the AEI status signal will signalize an invalid module access.

NOTE

Considering the size and base address of an ARP, it should be noted that the configuration possibilities are limited. Details about the configuration can be found in the register description of MCS[i]_ARP[z]_CTRL.

The bit field DIS_PROT of register CCM[i]_ARP[z]_CTRL changes the meaning of an ARP configuration in a way that it explicitly allows an MCS channel x with a set bit field WPROTx to write to the z–th ARP. Accordingly, if the bit DIS_PROT is set while the bit WPROT_AEI is also set in the register CCM[i]_ARP[z]_CTRL, the z-th ARP explicitly allows a write access from the CPU to the z-th ARP. A meaningful application of an ARP z with a set bit field DIS_PROT for an MCS channel x has another ARP with a surrounding wider address range that is defining a write protection for MCS channel x and some other MCS channels. Since the address range of an ARP can surround another ARP it is possible to configure contradictory conditions for MCS channels or the CPU within the overlapping area (e.g. if ARP y surrounds ARP z and ARP y allows a write access for an MCS channel x but ARP z prohibits a write access for MCS channel x). In order to resolve this ambiguity, the following rule is defined: A write protection for a specific address c concerning MCS channel x (the CPU) is active, if and only if, address c is covered by at least one ARP with a cleared bit DIS_PROT and a set bit WPROTx (WPROT_AEI) and there exists no ARP covering address c with a set bit field DIS_PROT and a set bit field WPROTx (WPROT_AEI).

38.13.3 CCM Configuration Registers Overview

CCM contains following configuration registers:

Table 38.116 Register List

Symbol	Register Name	Details in Section
CCM[i]_PROT	CCMi Protection Register	**38.13.4.1**
CCM[i]_CFG	CCMi Configuration Register	**38.13.4.2**
CCM[i]_CMU_CLK_CFG	CCMi CMU Clock Configuration Register	**38.13.4.3**
CCM[i]_CMU_FXCLK_CFG	CCMi CMU Fixed Clock Configuration Register	**38.13.4.4**
CCM[i]_AEIM_STA	CCMi MCS Bus Master Status Register	**38.13.4.5**
CCM[i]_ARP[z]_CTRL	CCMi Address Range Protector z Control Register	**38.13.4.6**
CCM[i]_ARP[z]_PROT	CCMi Address Range Protector z Protection Register	**38.13.4.7**
CCM[i]_HW_CONF	CCMi Hardware Configuration Register	**38.13.4.8**
CCM[i]_TIM_AUX_IN_SRC	CCMi TIM AUX Input Source Register	**38.13.4.9**
CCM[i]_EXT_CAP_EN	CCMi External Capture Enable Register	**38.13.4.10**
CCM[i]_TOM_OUT	CCMi TOM Output Register	**38.13.4.11**
CCM[i]_ATOM_OUT	CCMi ATOM Output Register	**38.13.4.12**
CCM[i]_HW_CONF2	CCMi 2 Hardware Configuration Register	**38.13.4.13**

38.13.4 CCM Configuration Register Description

38.13.4.1 CCM[i]_PROT

Access: This register can be read or written in 32-bit units.

Address: <GTM_base> + $E21FC_H$ + (200_H × i)

Value after reset: $0000\ 0001_H$

Table 38.118 CCM[i]_CFG Register Contents (1/2)

Bit Position	Bit Name	Function
31, 30	TBU_DIR[k]	DIR1 input signal of module TBU. 0: Indicating forward direction 1: Indicating backward direction
29 to 18	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
17, 16	CLS_CLK_DIV	Cluster Clock Divider. 00_B: Cluster is disabled 01_B: Cluster is enabled without clock divider 10_B: Cluster is enabled with clock divider 2 11_B: Setting prohibited. **NOTE** The value of this bit field mirrors the bit field CLS[i]_CLK_DIV of register GTM_CLS_CLK_CFG, whereas i equals the cluster index.
15 to 8	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
7	EN_CMP_MON	Enable CMP and MON 0: Disable clock signal for modules CMP and MON. 1: Enable clock signal for modules CMP and MON. **NOTE** This bit is only writable if bit field CLS_PROT of register CCM[i]_PROT is cleared.
6	EN_PSM	Enable PSM 0: Disable clock signal for module PSM. 1: Enable clock signal for module PSM. **NOTE** This bit is only writable if bit field CLS_PROT of register CCM[i]_PROT is cleared.

Table 38.118 CCM[i]_CFG Register Contents (2/2)

Bit Position	Bit Name	Function
5	EN_BRC	EN_BRC: Enable BRC 0: Disable clock signal for module BRC. 1: Enable clock signal for module BRC. **NOTE** This bit is only writable if bit field CLS_PROT of register CCM[i]_PROT is cleared.
4	EN_DPLL_MAP	EN_DPLL_MAP: Enable DPLL and MAP 0_B: Disable clock signal for modules DPLL and MAP. 1_B: Enable clock signal for modules DPLL and MAP. **NOTE** This bit is only writable if bit field CLS_PROT of register CCM[i]_PROT is cleared.
3	EN_MCS	EN_MCS Enable MCS 0_B: Disable clock signal for module MCS. 1_B: Enable clock signal for module MCS. **NOTE** This bit is only writable if bit field CLS_PROT of register CCM[i]_PROT is cleared.
2	EN_ATOM_ADTM	EN_ATOM_ADTM: Enable ATOM and ADTM 0_B: Disable clock signal for modules ATOM and its related DTM modules. 1_B: Enable clock signal for modules ATOM and its related DTM modules. **NOTE** This bit is only writable if bit field CLS_PROT of register CCM[i]_PROT is cleared.
1	EN_TOM_SPE_TDTM	EN_TOM_SPE_TDTM: Enable TOM, SPE and TDTM 0_B: Disable clock signal for modules TOM, SPE, and its related DTM modules. 1_B: Enable clock signal for modules TOM, SPE, and its related DTM modules. **NOTE** This bit is only writable if bit field CLS_PROT of register CCM[i]_PROT is cleared.
0	EN_TIM	Enable TIM 0_B: Disable clock signal for sub module TIM. 1_B: Enable clock signal for sub module TIM. **NOTE** This bit is only writable if bit field CLS_PROT of register CCM[i]_PROT is cleared.

Note: The module specific clock enable registers (bit field EN_*) are only implemented if the corresponding module is available in the i-th cluster.

38.13.4.3 CCM[i]_CMU_CLK_CFG

Access: This register can be read or written in 32-bit units.

Address: <GTM_base> + $E21F0_H$ + (200_H × i)

Value after reset: 0000 0000_H

Table 38.119 CCM[i]_CMU_CLK_CFG Register Contents (1/2)

Bit Position	Bit Name	Function
31, 30	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
29, 28	CLK7_SRC	Clock 7 source signal selector 00_B: Use CMU_CLK7 signal of CMU as CCM[i]_CLK7_EN signal within Cluster. 01_B: Use CMU_CLK8 signal of CMU as CCM[i]_CLK7_EN signal within Cluster. 10_B: Use TIM[i]_EXT_CAPTURE7 signal as CCM[i]_CLK7_EN signal within Cluster. 11_B: Setting prohibited.
27, 26	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
25, 24	CLK6_SRC	Clock 6 source signal selector 00_B: Use CMU_CLK6 signal of CMU as CCM[i]_CLK6_EN signal within Cluster. 01_B: Use CMU_CLK8 signal of CMU as CCM[i]_CLK6_EN signal within Cluster. 10_B: Use TIM[i]_EXT_CAPTURE6 signal as CCM[i]_CLK6_EN signal within Cluster. 11_B: Setting prohibited.
23, 22	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
21, 20	CLK5_SRC	Clock 5 source signal selector 00_B: Use CMU_CLK5 signal of CMU as CCM[i]_CLK5_EN signal within Cluster. 01_B: Use CMU_CLK8 signal of CMU as CCM[i]_CLK5_EN signal within Cluster. 10_B: Use TIM[i]_EXT_CAPTURE5 signal as CCM[i]_CLK5_EN signal within Cluster. 11_B: Setting prohibited.
19, 18	Reserved	When read, the value after reset is returned. When writing, write the value after reset.

Table 38.119 CCM[i]_CMU_CLK_CFG Register Contents (2/2)

Bit Position	Bit Name	Function
17, 16	CLK4_SRC	Clock 4 source signal selector 00_B: Use CMU_CLK4 signal of CMU as CCM[i]_CLK4_EN signal within Cluster. 01_B: Use CMU_CLK8 signal of CMU as CCM[i]_CLK4_EN signal within Cluster. 10_B: Use TIM[i]_EXT_CAPTURE4 signal as CCM[i]_CLK4_EN signal within Cluster. 11_B: Setting prohibited.
15, 14	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
13, 12	CLK3_SRC	Clock 3 source signal selector 00_B: Use CMU_CLK3 signal of CMU as CCM[i]_CLK3_EN signal within Cluster. 01_B: Use CMU_CLK8 signal of CMU as CCM[i]_CLK3_EN signal within Cluster. 10_B: Use TIM[i]_EXT_CAPTURE3 signal as CCM[i]_CLK3_EN signal within Cluster. 11_B: Setting prohibited.
11, 10	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
9, 8	CLK2_SRC	Clock 2 source signal selector 00_B: Use CMU_CLK2 signal of CMU as CCM[i]_CLK2_EN signal within Cluster. 01_B: Use CMU_CLK8 signal of CMU as CCM[i]_CLK2_EN signal within Cluster. 10_B: Use TIM[i]_EXT_CAPTURE2 signal as CCM[i]_CLK2_EN signal within Cluster. 11_B: Setting prohibited.
7, 6	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
5, 4	CLK1_SRC	Clock 1 source signal selector 00_B: Use CMU_CLK1 signal of CMU as CCM[i]_CLK1_EN signal within Cluster. 01_B: Use CMU_CLK8 signal of CMU as CCM[i]_CLK1_EN signal within Cluster. 10_B: Use TIM[i]_EXT_CAPTURE1 signal as CCM[i]_CLK1_EN signal within Cluster. 11_B: Setting prohibited.
3, 2	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
1, 0	CLK0_SRC	Clock 0 source signal selector 00_B: Use CMU_CLK0 signal of CMU as CCM[i]_CLK0_EN signal within Cluster. 01_B: Use CMU_CLK8 signal of CMU as CCM[i]_CLK0_EN signal within Cluster. 10_B: Use TIM[i]_EXT_CAPTURE0 signal as CCM[i]_CLK0_EN signal within Cluster. 11_B: Setting prohibited.

Note: The bit fields of this register are only writable if bit field CLS_PROT of register CCM[i]_PROT is cleared.

38.13.4.4 CCM[i]_CMU_FXCLK_CFG

Access: This register can be read or written in 32-bit units.

Address: <GTM_base> + $E21F4_H$ + (200_H × i)

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W

Table 38.120 CCM[i]_CMU_FXCLK_CFG Register Contents

Bit Position	Bit Name	Function
31 to 4	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
3 to 0	FXCLK0_SRC	Fixed clock 0 source signal selector 0000_B: Use CMU_FXCLK0_EN signal of CMU as CCM[i]_FXCLK0_EN signal within Cluster. 0001_B: Use CMU_CLK8_EN signal of CMU as CCM[i]_FXCLK0_EN signal within Cluster. Other than above: Setting prohibited. **NOTE** These bits are only writable if bit field CLS_PROT of register CCM[i]_PROT is cleared.

38.13.4.5 CCM[i]_AEIM_STA

Access: This register can be read or written in 32-bit units.

Address: <GTM_base> + $E21D8_H$ + (200_H × i)

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	AEIM_XPT_STA		—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R/W	R/W	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	AEIM_XPT_ADDR															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 38.121 CCM[i]_AEIM_STA Register Contents

Bit Position	Bit Name	Function
31 to 26	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
25, 24	AEIM_XPT_STA	AEIM_XPT_STA: AEIM Exception status. 00_B: No invalid MCS bus master access occurred 01_B: Invalid byte addressing of MCS bus master access. 10_B: Illegal module access of MCS bus master access. 11_B: Invalid MCS bus master access to an unsupported address.
23 to 16	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
15 to 0	AEIM_XPT_ADDR	AEIM_XPT_ADDR: Exception Address. Invalid bus master (AEIM) address of MCS module.

Notes:

1. Only the first invalid AEIM bus master access of the MCS is updating this register with the invalid AEIM address (bit field AEIM_XPT_ADDR) and the reason of the invalid access (bit field AEIM_XPT_STA). A write access to this register (independent of the written data), always resets the bit fields AEIM_XPT_STA and AEIM_XPT_ADDR and the next invalid AEIM access is captured by this register, again.
2. If the i-th cluster does not provide an MCS module, this register is not available.

38.13.4.6 CCM[i]_ARP[z]_CTRL

Access: This register can be read or written in 32-bit units.

Address: <GTM_base> + $E2000_H$ + (200_H × i) + (8_H × z)

Value after reset: 0003 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	WPROT_AEI	—	—	—	—	—	—	DIS_PROT	—	—	—	—	SIZE			
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1
R/W	R	R	R	R	R	R	R/W	R/W	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	ADDR															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 38.122 CCM[i]_ARP[z]_CTRL Register Contents (1/2)

Bit Position	Bit Name	Function
31	WPROT_AEI	AEI slave write protection. 0: Write protection to address range from AEI slave is disabled. 1: Write protection to address range from AEI slave is enabled.
30 to 25	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
24	DIS_PROT	DIS_PROT: Disable ARP protection. 0: Bit WPROTx (WPROT_AEI) defines write protection for selected address range. 1: Bit WPROTx (WPROT_AEI) explicitly allows write access to selected address range. **NOTE** This bit field is only writable if bit field CLS_PROT of register CCM[i]_PROT is cleared.
23 to 20	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
19 to 16	SIZE	Size of ARP Size of memory range protector z. **NOTES** 1. The actual size of a protected memory range is defined as 2 SIZE address locations, whereas the bit field SIZE is interpreted as an unsigned integer number. 2. The values 0, 1 and 2 are not supported for this bit field and cannot be configured. A write access with such a value to this register signalizes an invalid module access at the AEI status signal and it sets the bit field SIZE to the value 3. 3. This bit field is only writable if bit field CLS_PROT of register CCM[i]_PROT is cleared.

Table 38.122 CCM[i]_ARP[z]_CTRL Register Contents (2/2)

Bit Position	Bit Name	Function
15 to 0	ADDR	ARP base address. Base address for address range protector z. **NOTES** 1. Only the bits 5 to AAW-1 of this bit field are implemented as registers. The bits AAW to 15 are reserved and always read and written as zeros. The bits 0 to 4 are functionally used for the definition of an ARP but they are always read and written as zeros. 2. The actual base address for a protected address range is only defined by the upper AAW-(SIZE +2) bits (bit position 2+ SIZE to bit position AAW-1) of bit field ADDR. The lower SIZE +2 bits (bit 0 to SIZE +1) are ignored for the address calculation and assumed as zeros. 3. This bit field is only writable if bit field CLS_PROT of register CCM[i]_PROT is cleared.

Note: The address range interval that is protected by this ARP can be calculated as [(ADDR AND NOT 4*(2SIZE-1)); (ADDR AND NOT 4*(2SIZE-1)) + 4*(2SIZE-1)] assuming a byte wise addressing, an unsigned integer representation for the bit fields SIZE and ADDR. NOT and AND are bitwise logical operators. The incrementation interval for neighboring memory location is always 4.

38.13.4.7 CCM[i]_ARP[z]_PROT

Access: This register can be read or written in 32-bit units.

Address: <GTM_base> + $E2004_H$ + (200_H × i) + (8_H × z)

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	WPROT7	WPROT6	WPROT5	WPROT4	WPROT3	WPROT2	WPROT1	WPROT0
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 38.123 CCM[i]_ARP[z]_PROT Register Contents

Bit Position	Bit Name	Function
31 to 8	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
7 to 0	WPROT[7:0]	Write Protection MCS channel k. 0: Write protection to ARP's address range for MCS channel 0 is disabled. 1: Write protection to ARP's address range for MCS channel 0 is enabled.

Notes:

1. Only the first T bits of this register (bit 0 to T-1) are functionally implemented. The other bits (bit T to 31) are reserved. Parameter T reflects the number of available MCS channels in the cluster's MCS module.
2. The bit fields of this register are only writable if bit field CLS_PROT of register CCM[i]_PROT is cleared.
3. The meaning of the bit fields WPROTx can be changed by the bit field DIS_PROT of register CCM[i]_ARP[z]_CTRL.

38.13.4.8 CCM[i]_HW_CONF

Access: This register is a read-only register that can be read in 32-bit units.

Address: <GTM_base> + $E21DC_H$ + (200_H × i)

Value after reset: Undefined

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	INT_CLK_EN_GEN	TOM_TRIG_INTCHAIN					ATOM_TRIG_INTCHAIN				IRQ_MODE_SINGLE_PULSE	IRQ_MODE_PULSE_NOTIFY	IRQ_MODE_PULSE	IRQ_MODE_LEVEL

R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 38.124 CCM[i]_HW_CONF Register Contents (1/3)

Bit Position	Bit Name	Function
31, 30	Reserved	When read, the value after reset is returned.
29	INT_CLK_EN_GEN	INT_CLK_EN_GEN: Internal clock enable generation 0: GTM external clock enable signals in use 1: GTM internal clock enable signals in use
28 to 24	TOM_TRIG_INTCHAIN	TOM internal trigger chain length without synchronization register It defines after which TOM channel count a synchronization register is introduced into trigger chain. Valid values are 1 to 16. 8 means that in channel 8 of the tom instances a synchronization register is placed.
23 to 20	ATOM_TRIG_INTCHAIN	ATOM internal trigger chain length without synchronization register It defines after which ATOM channel count a synchronization register is introduced into trigger chain. Valid values are 1 to 8. 4 means that in channel 4 of the atom instances a synchronization register is placed.
19	IRQ_MODE_SINGLE_PULSE	IRQ_MODE_SINGLE_PULSE 0: Single pulse mode not available 1: Single pulse mode available
18	IRQ_MODE_PULSE_NOTIFY	IRQ_MODE_PULSE_NOTIFY 0: Pulse notify mode not available 1: Pulse notify mode available
17	IRQ_MODE_PULSE	IRQ_MODE_PULSE 0: Pulse mode not available 1: Pulse mode available
16	IRQ_MODE_LEVEL	IRQ_MODE_LEVEL 0: Level mode not available 1: Level mode available
15	Reserved	When read, the value after reset is returned.
14	ARU_CONNECT_CONFIG	Defines number of parallel ARU ports 0: 2 ARU ports available (two independent counter) 1: 1 ARU port available

Table 38.124 CCM[i]_HW_CONF Register Contents (2/3)

Bit Position	Bit Name	Function
13	ERM	Enable RAM1 MSB for available MCS modules 0: MSB of MCS RAM1 address not used 1: MSB of MCS RAM1 address used **NOTE** The bit reflects the state of the configuration parameter ERM mentioned in the specification of MCFG.
12	RAM_INIT_RST	RAM initialization from reset 0: RAM is not initialized after reset 1: RAM is initialized after reset
11 to 9	TOM_TRIG_CHAIN	TOM trigger chain length without synchronization register It defines after which TOM instance count a synchronization register is introduced into trigger chain (after TOM_TRIG_<i> output if instance i and TOM_TRIG_<i+1> input of instance i+1). Valid values are 1 to 7. 1 means that after each instance a synchronization register is placed.
8	TOM_OUT_RST	TOM_OUT reset level 0: TOM_OUT reset level is '0' 1: TOM_OUT reset level is '1' **NOTE** This value represents the TOM output level after reset. The inverse value of this bit is the reset value of bit SL in all TOM channels.
7 to 5	ATOM_TRIG_CHAIN	ATOM trigger chain length without synchronization register It defines after which ATOM instance count a synchronization register is introduced into trigger chain (after ATOM_TRIG_<i> output if instance i and ATOM_TRIG_<i+1> input of instance i+1). Valid values are 1 to 7. 1 means that after each instance a synchronization register is placed.
4	ATOM_OUT_RST	ATOM_OUT reset level 0: ATOM_OUT reset level is '0' 1: ATOM_OUT reset level is '1' **NOTE** This value represents the ATOM output level after reset. The inverse value of this bit is the reset value of bit SL in all ATOM channels.
3	CFG_CLOCK_RATE	Clocks per ARU transfer 0: Each system clock an ARU transfer is scheduled 1: Each second system clock an ARU transfer is scheduled. ARU transfer rate is half the system clock frequency. **NOTE** This value defines also the availability of configuration bits in register GTM_CLS_CLK_CFG. if CFG_CLOCK_RATE = 0_B, only the values 00_B and 01_B are valid for bit fields CLS[x]x_CLK_DIV. If CFG_CLOCK_RATE = 1_B, only the values 00_B, 01_B and 10_B are valid for bit fields CLS[x]x_CLK_DIV.
2	SYNC_INPUT_REG	Additional pipelined stage in synchronous bridge mode 0: No additional pipelined stage implemented. 1: Additional pipelined stage implemented. All accesses in synchronous mode will be increased by one clock cycle. **NOTE** This register is only relevant (if existing) for synchronous bridge mode.

Table 38.124 CCM[i]_HW_CONF Register Contents (3/3)

Bit Position	Bit Name	Function
1	BRIDGE_MODE_RST	Bridge mode after reset 0: Bridge starts in synchronous mode after reset 1: Bridge starts in asynchronous mode after reset
0	GRSTEN	Global Reset Enable 0: Global GTM reset register disabled 1: Global GTM reset register enabled

Table 38.129 CCM[i]_HW_CONF2 Register Contents

Bit Position	Bit Name	Function
31 to 8	Reserved	When read, the value after reset is returned.
7	AXIM_POSTED_WRITE	Write transaction without response 0: Always use none–posted write. 1: Use none–posted write.
6	AXIM_SEC_ACC	Secure AXI master access constant 0: Secure AXI master access is not allowed. 1: Secure AXI master access is allowed.
5	AXIM_PRIV_ACC	Privileged AXI master access constant 0: Privileged AXI master access is not allowed. 1: Privileged AXI master access is allowed.
4 to 0	AXIM_ID_WIDTH	Defines which LSB of AXIM_ID are send to the bus How many lower of AXIM_D will be send to the bus

38.14 Time Base Unit (TBU)

38.14.1 Overview

The Time Base Unit TBU provides common time bases for the GTM-IP. The TBU sub-module is organized in channels, where the number of channels is device dependent. There are up to four channels implemented inside the TBU. The time base register TBU_CH0_BASE of TBU channel 0 is 27 bits wide and it is configurable whether the lower 24 bit or the upper 24 bit are provided to the GTM as signal TBU_TS0. The two TBU channels 1 and 2 have a time base register TBU_CH[y]_BASE (y: 1, 2) of 24 bit length. The time base register value TBU_TS[y] is provided to subsequent sub-modules of the GTM. The time base register of TBU channel 3 TBU_CH3_BASE is 24 bits wide. It is used as a modulo counter by TBU_CH3_BASE_MARK to get a relative angle clock to TBU_CH[y]_BASE. The absolute angle clock value for the current TBU_CH3_BASE is captured in TBU_CH3_BASE_CAPTURE. TBU_CH[y]_BASE = TBU_CH3_BASE_CAPTURE + ... + TBU_CH3_BASE - DIRy × TBU_CH3_BASE_MARK DIRy : direction value for time base y (y:1, 2) 0 up counter 1 down counter

NOTE

The right-hand sum is limited to 24 bit.

The TBU_UP[y] (y: 1, 2) signals are set to high for a single SYS_CLK period, whenever the corresponding signal TBU_TS[y] (y: 1, 2) is getting updated. The signal TBU_UP0_L is set to high for a single SYS_CLK period if the signal TBU_TS0 and TBU_TS0x is getting updated and TBU_UP0_H is set to high for a single SYS_CLK period, whenever the upper 24 bit of TBU_TS0 are updated.

The time base channels can run independently of each other and can be enabled and disabled synchronously by control bits in a global TBU channel enable register TBU_CHEN. **Figure 38.32** shows a block diagram of the Time Base Unit.

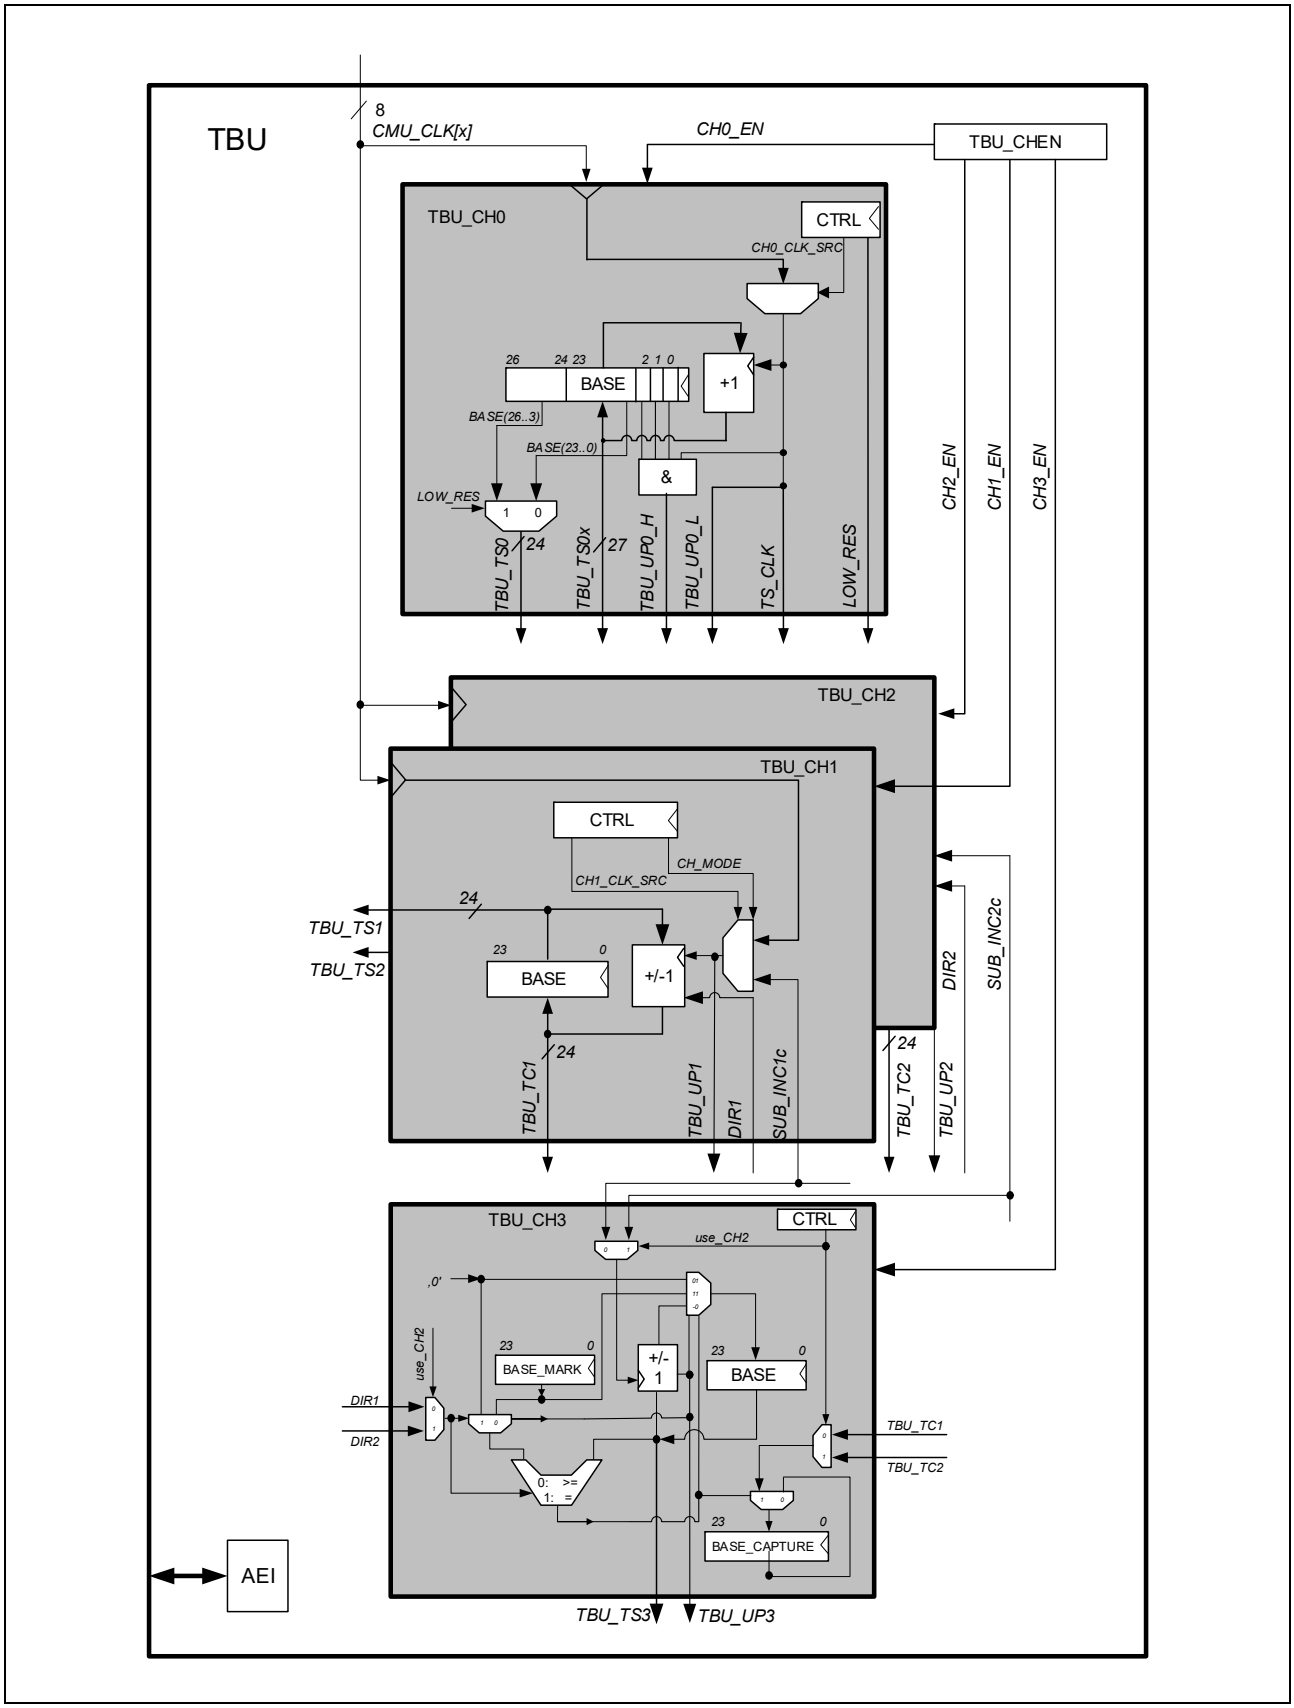

Figure 38.32 TBU Block Diagram

Dependent on the device a third TBU channel exists which offers the same functionality as the time base channel 1.

The configuration of the independent time base channels TBU_CH[z]_BASE is done via the AEI interface. The TBU channel 0 to 2 may select one of the eight CMU_CLK[x] (x: 0 to 7) signals coming from the CMU sub-module.

For TBU channels 1 and 2 an additional clock signal SUB_INC[y]c (y: 1, 2) coming from the DPLL can be selected as input clock for the TBU_CH[y]_BASE. This clock in combination with the DIR[y] signals determines the counter direction of the TBU_CH[y]_BASE.

The selected time stamp clock signal for the TBU_CH0 sub-unit is served via the TS_CLK signal line to the DPLL sub-module. The TS_CLK signal equals the signal TBU_UP0

38.14.2 TBU Channels

The time base values are generated within the TBU time base channels in two independent and one dependent operation modes.

In all modes, the time base register TBU_CH[z]_BASE (z: 0 to 3) can be initialized with a start value just before enabling the corresponding TBU channel.

Moreover, the time base register TBU_CH[z]_BASE (z: 0 to 3) can always be read in order to determine the actual value of the counter.

38.14.2.1 Independent Modes

(1) Free Running Counter Mode

TBU channel 0 provides a 27 bit counter in a free running counter mode. Dependent on the bit field LOW_RES of register TBU_CH0_CTRL, the lower 24 bits (bit 0 to 23) or the upper 24 bits (bits 3 to 26) are provided to the GTM sub-modules.

TBU channel 1 and 2 provides a 24 bit counter in a free running counter mode enabled by reset CH_MODE of register TBU_CH[y]_CTRL (y:1, 2).

In TBU Free running counter mode, the time base register TBU_CH[v]_BASE (v: 0 to 2) is updated on every specified incoming clock event by the selected signal CMU_CLK[x] (x: 0 to 8) (dependent on TBU_CH[v]_CTRL (v:0 to 2) register). In general the time base register TBU_CH[v]_BASE is incremented on every CMU_CLK[x] clock tick.

(2) Forward/Backward Counter Mode

TBU channel 1 and 2 provides a 24 bit forward/backward counter enabled by set CH_MODE of register TBU_CH[y]_CTRL (y:1, 2). In this mode the DIR[y] signal provided by the DPLL is taken into account.

The value of the time base register TBU_CH[y]_BASE is incremented in case when the DIR[y] signal equals 0 and decremented in case when the DIR[y] signal is 1.

38.14.2.2 Dependent Mode

(1) Modulo Counter Mode

TBU channel 3 provides a 24 bit forward/backward modulo counter. The clock SUB_INC[y]c and counter direction DIR[y] provided by DPLL is selected by use_CH2 of register TBU_CH3_CTRL.

The modulo value is defined in TBU_CH3_BASE_MARK. In forward counter mode if TBU_CH3_BASE value is reaching TBU_CH3_BASE_MARK TBU_CH3_BASE is reset and TBU_TS[y] is captured in TBU_CH3_BASE_CAPTURE. In backward counter mode if TBU_CH3_BASE value is reaching '0' TBU_CH3_BASE is set to TBU_CH3_BASE_MARK and TBU_TS[y] is captured in TBU_CH3_BASE_CAPTURE.

38.14.3 TBU Configuration Registers Overview

TBU contains following configuration registers:

Table 38.130 Register List

Symbol	Register Name	Details in Section
TBU_CHEN	TBU global channel enable	**38.14.4.1**
TBU_CH0_CTRL	TBU channel 0 control	**38.14.4.2**
TBU_CH0_BASE	TBU channel 0 base	**38.14.4.3**
TBU_CH1_CTRL	TBU channel 1 control	**38.14.4.4**
TBU_CH2_CTRL	TBU channel 2 control	**38.14.4.5**
TBU_CH[y]_BASE	TBU channel y base	**38.14.4.6**
TBU_CH3_CTRL	TBU channel 3 control	**38.14.4.7**
TBU_CH3_BASE	TBU channel 3 base	**38.14.4.8**
TBU_CH3_BASE_MARK	TBU channel 3 modulo value	**38.14.4.9**
TBU_CH3_BASE_CAPTURE	TBU channel 3 base captured	**38.14.4.10**

Note: In a typical application the Time Base Unit (TBU) considers channels 0, 1 and 3 only. In this case register addresses 0x20...0x2C are reserved and shall be read as zero. Channel 2 can be additionally implemented on special high-end application requirements.

38.14.4 TBU Configuration Registers Description

38.14.4.1 TBU_CHEN

Access: This register can be read or written in 32-bit units.

Address: <GTM_base> + 00100_H

Value after reset: $0000\ 0000_H$

38.15 Timer Input Module (TIM)

38.15.1 Overview

The Timer Input Module (TIM) is responsible for filtering and capturing input signals of the GTM. Several characteristics of the input signals can be measured inside the TIM channels. For advanced data processing the detected input characteristics of the TIM module can be routed through the ARU to subsequent processing units of the GTM.

Input characteristics mean either time stamp values of detected input rising or falling edges together with the new signal level or the number of edges received since channel enable together with the actual time stamp or PWM signal duration for a whole PWM period.

The architecture of TIM is shown in **Figure 38.33**.

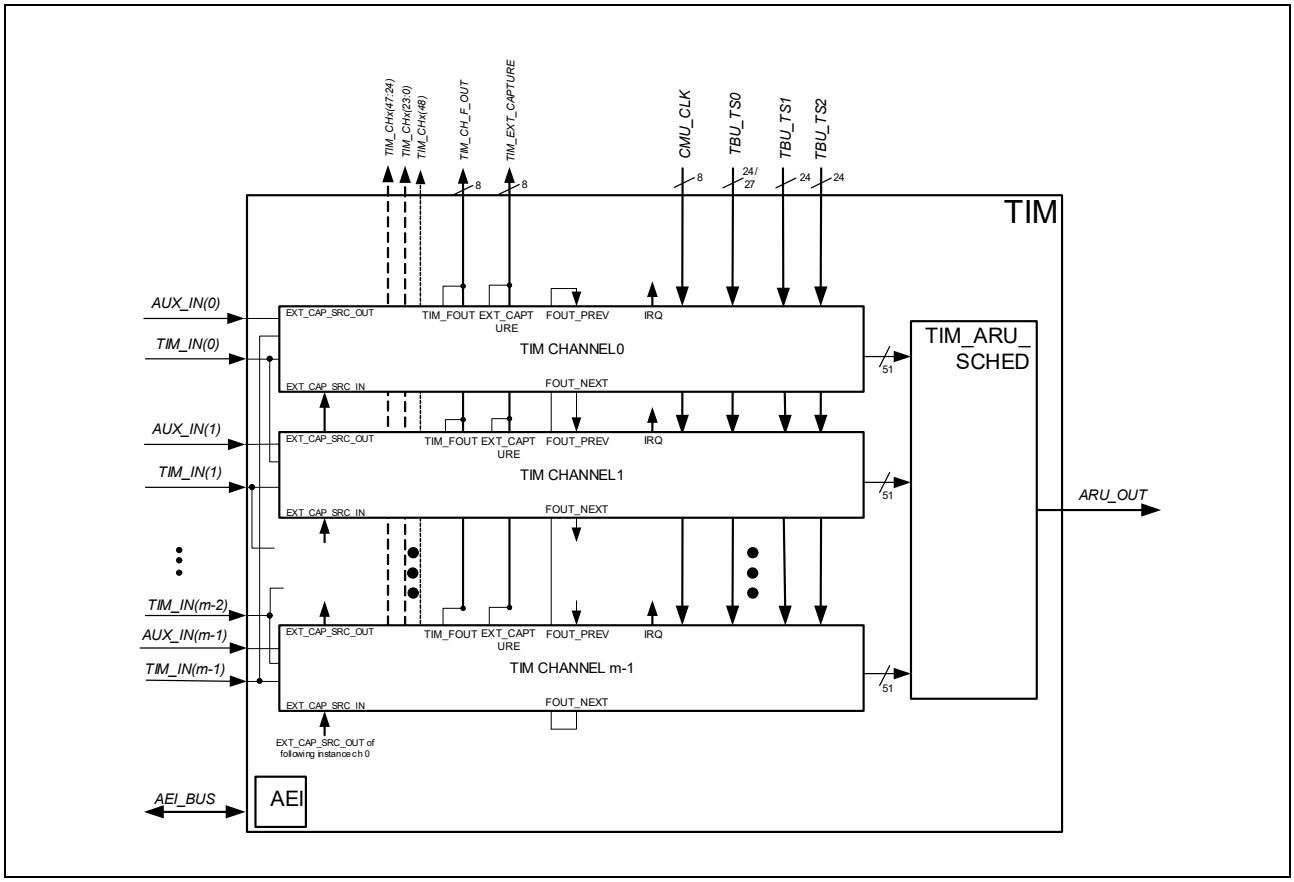

Figure 38.33 TIM Block Diagram

The number of channels m inside a TIM sub-module depends on the device.

Each of the m dedicated input signals are filtered inside the FLTx sub-unit of the TIM Module.

NOTE

The incoming input signals are synchronized to the clock SYS_CLK, resulting in a delay of two SYS_CLK periods for the incoming signals.

The measurement values can be read by the CPU directly via the AEI–Bus or they can be routed through the ARU to other sub-modules of the GTM.

For the GTM-IP TIM0 sub-module only, the dashed signal outputs TIM[i]_CH[x](23:0), TIM[i]_CH[x](47:24) and TIM[i]_CH[x](48) come from the TIM0 sub-module channels zero (0) to five (5) and are connected to MAP sub-module. There, they are used for further processing and for routing to the DPLL.

The two (three) time bases coming from the TBU are connected to the TIM channels to annotate time stamps to incoming signals. For TIM0 the extended 27 bit width time base TBU_TS0 is connected to the TIM channels, and the user has to select if the lower 24 bits (TBU_TS0(23:0)) or the higher 24 bits (TBU_TS0(26:3)) are stored inside the GPR0 and GPR1 registers.

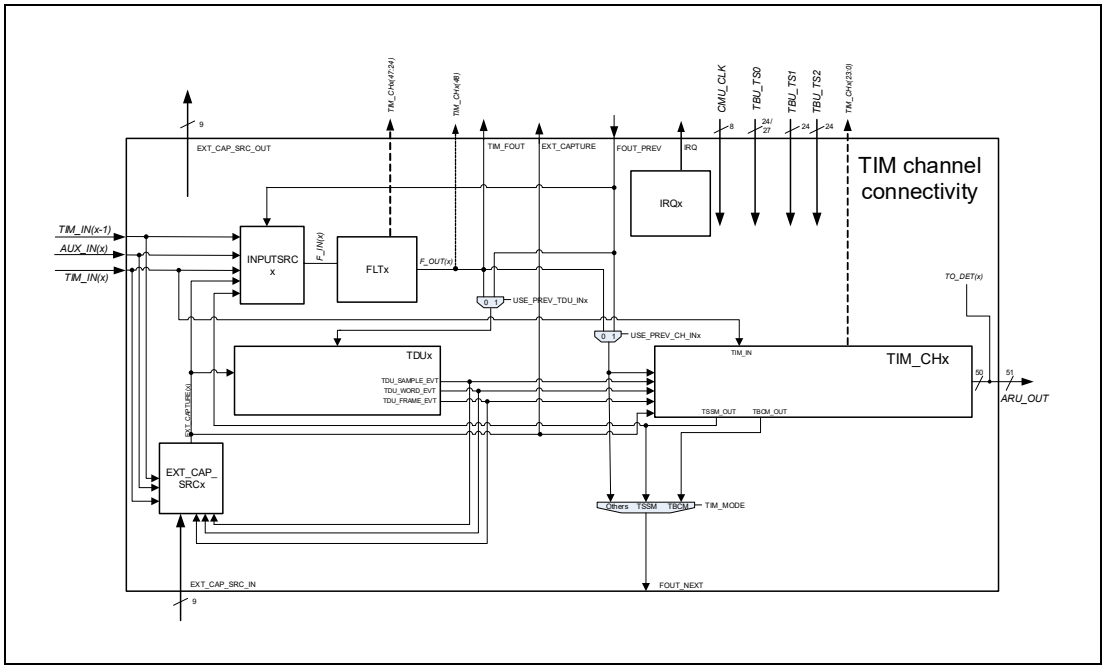

Figure 38.34 TIM channel internal connectivity

Above figure gives an overview of the channel internal connectivity of the sub units. The sub units with the major functionality are listed next: INPUT_SRCx: Select signal for processing by the Filter unit FLTx FLTx: The filter unit provides different filter mechanisms described in more detail in Chapter 13.2. TDUx: Timeout detection unit (no subsequent edge detected during a specified duration) TIM_CHx: Measurement unit; different measurements strategies configurable on the filtered signal IRQx: Local interrupt controller (enabling, status, ..) EXT_CAP_SRCx: Selects a local signal ext_capture(x) which is needed by certain functions Details are given in the next chapters.

Depending on the values of the configuration bit fields USE_PREV_TDU_INx, USE_PREV_CH_INx it is possible to operate on the signal of the local channel x or the previous channel x-1.

Depending on the value of the configuration bit field TIM_MODEx it is possible to provide different signals (via FOUT_NEXT) to the next channel.

In TBCM mode each capture event selected by the sensitive edges (CNTS) will be forwarded with the value of ECNT[0] to the following channel (via FOUT_NEXT).

38.15.1.1 Input source selection INPUTSRCx

It can be configured which source shall be used for processing in the FLT, TDU, TIM_CH units. It can be selected by the bit fields CICTRL and MODE_x, VAL_x in the register TIM[i]_IN_SRC which source is in use.

Alternatively the signal F_IN(x) can be generated by a 8 bit lookup table, which allows to define any function of 3 input sources.

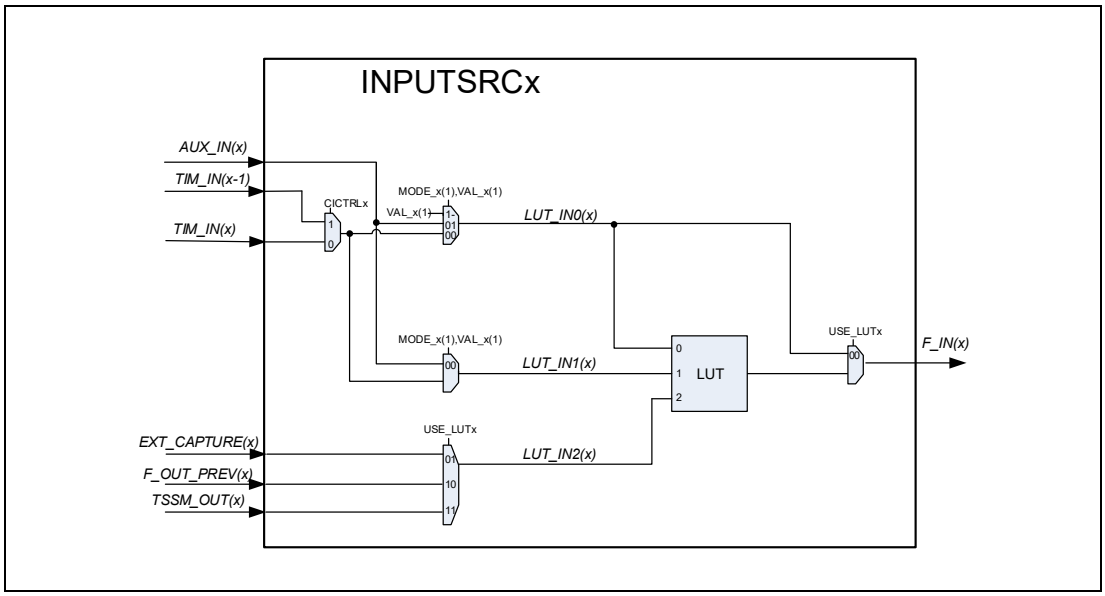

Figure 38.35 INPUTSRC Block Diagram

If USE_LUT = 00_B is set the lookup table signal generation is bypassed and the signal selection is performed as follows:

In a certain MODE_x, VAL_x combination the input signal F_IN(x) can be driven by VAL_x(1) with 0 or 1 directly.

Due to the fact that all 8 channels are bundled in the register TIM[i]_IN_SRC a synchronous control of all 8 input channels is possible.

Two adjacent channels can be combined by setting the CICTRL bit field in the corresponding TIM[i]_CH[x]_CTRL register. This allows for a combination of complex measurements on one input signal with two TIM channels.

The additional signal AUX_IN[x] can be selected as an input signal. The source of this signal is defined in **Figure 38.5, TIM auxiliary input multiplexing**.

If USE_LUT! = 00_B is set, the lookup table signal generation with following inputs is in use. See **Figure 38.35**:

Input LUT_INO(x) selection: TIM_IN(x) if CICTRLx = 0 and MODE_x (1) = 0 and VAL_x (1) = 0 TIM_IN(x–1) if CICTRLx = 1 and MODE_x (1) = 0

and VAL_x (1) = 0 AUX_IN(x) if MODE_x (1) = 0 and VAL_x (1) = 1 VAL_x (1) if MODE_x (1) = 1

Input LUT_IN1(x) selection: AUX_IN(x) if MODE_x (1) = 0 and VAL_x (1) = 0 TIM_IN(x) if CICTRLx = 0 TIM_IN(x–1) if CICTRLx = 1

Input LUT_IN2(x) selection: EXT_CAPTURE(x) if USE_LUT = 01_B FOUT_PREV(x) if USE_LUT = 10_B TSSM_OUT(x) if USE_LUT = 11_B

The lookup table is defined by the contents of the bit field TO_CNT2x. The lookup_table_index is defined by LUT_IN2(x) & LUT_IN1(x) &LUT_IN0(x). The signal F_IN(x) is generated by TO_CNT2x [lookup_table_index].

If USE_LUT! = 00_B is set, only limited functionality is available in the TDU. See bit field Slicing in the register TIM[i]_CH[x]_TDUV.

38.15.1.2 Input observation

It is possible to observe for all channels of one instance by reading TIM_INP_VAL the actual signal values of the following processing stages:

1. TIM_IN(7:0) signals after TIM input synchronization
2. TIM F_IN(7:0) signals after TIM INPUTSRC selection (input to TIM_FLT)
3. TIM F_OUT(7:0) signals after TIM filter functionality (output of TIM_FLT)

38.15.1.3 External capture source selection EXTCAPSRCx

Each channel can operate on an external capture signal EXT_CAPTURE. The source to use for this signal can be configured by the bit field EXT_CAP_SRCx in the register TIM[i]_CH[x]_ECTRL.

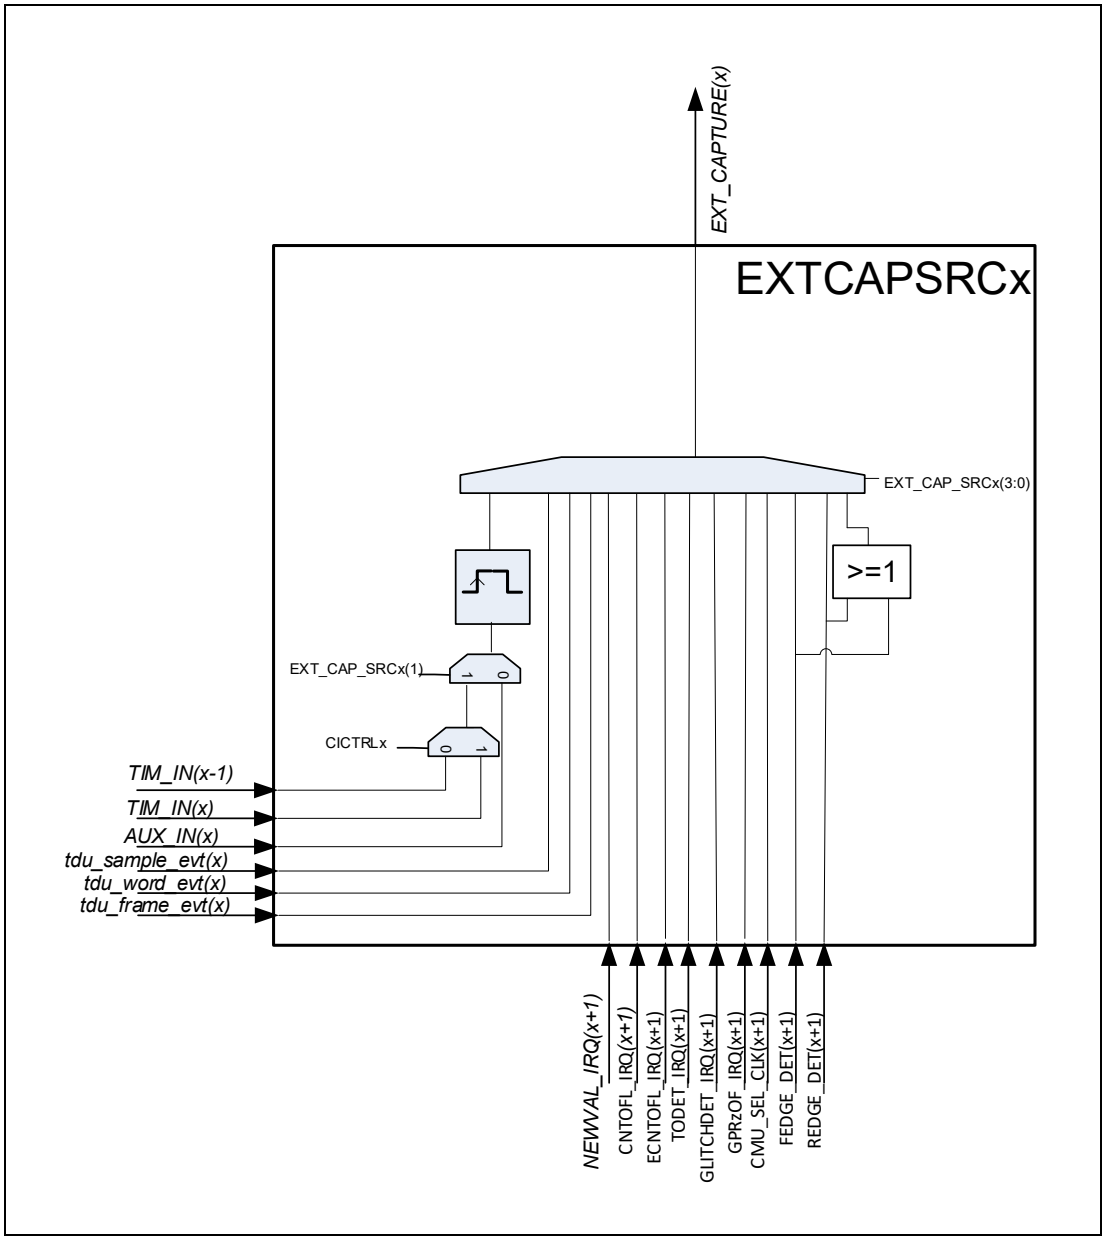

Figure 38.36 EXTCAPSRC Block Diagram

The external capture functionality can be enabled for the TIM channel x with the bit EXT_CAP_EN in the register TIM[i]_CH[x]_CTRL, it will trigger on each rising edge. A pulse generation for each rising edge of the selected input signal TIM_IN[x] and AUX_IN[x] is applied.

The six TIM channel interrupt sources can be triggered by the operation in the certain TIM channel modes. Alternatively they can be issued by a soft trigger using the corresponding bits in the register TIM[i]_CH[x+1]_FORCINT.

38.15.2 TIM Filter Functionality (FLT)

38.15.2.1 Overview

The TIM sub-module provides a configurable filter mechanism for each input signal. These filter mechanism is provided inside the FLT sub-unit.

FLT architecture is shown in **Figure 38.37**.

The filter includes a clock synchronization unit (CSU), an edge detection unit (EDU), and a filter counter associated to the filter unit (FLTU).

The CSU is synchronizing the incoming signal F_IN to the selected filter clock frequency, which is controlled with the bit field FLT_CNT_FRQ of register TIM[i]_CH[x]_CTRL.

The synchronized input signal F_IN_SYNC is used for further processing within the filter.

NOTE

Glitches with a duration go less than the selected CMU clock period is lost.

The filter modes can be applied individually to the falling and rising edges of an input signal. The following filter modes are available:

- Immediate edge propagation mode
- Individual de-glitch time mode (up/down counter)
- Individual de-glitch time mode (hold counter)
- Individual de-glitch time mode (reset counter)

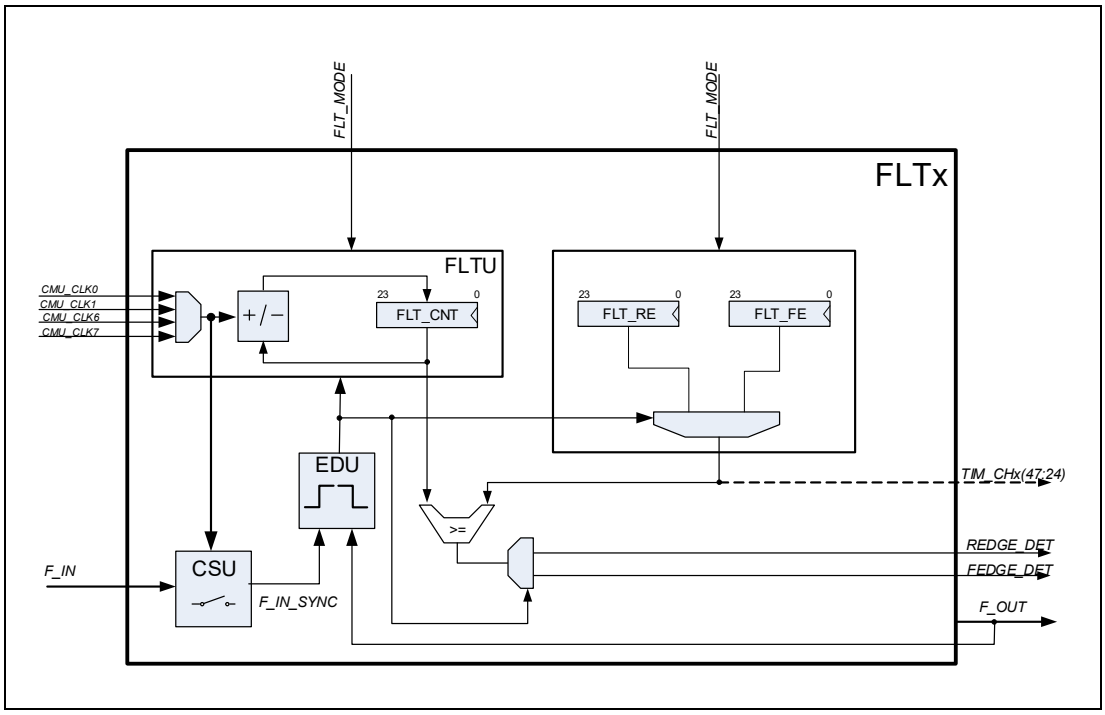

Figure 38.37 FLT Architecture

The filter parameters (deglitch and acceptance time) for the rising and falling edge can be configured inside the two filter parameter registers FLT_RE (rising edge) and FLT_FE (falling edge). The exact meaning of the parameter depends on the filter mode.

However the delay time T of both filter parameters FLT_xE can always be determined by: T = (FLT_xE +1)* T, whereas T is the clock period of the selected CMU clock signal in bit field FLT_CNT_FRQ of register TIM[i]_CH[x]_CTRL.

When a glitch is detected on an input signal a status flag GLITCHDET is set inside the TIM[i]_CH[x]_IRQ_NOTIFY register.

Table 38.141 gives an overview about the meanings for the registers FLT_RE and FLT_FE. In the individual deglitch time modes, the actual filter threshold for a detected regular edge is provided on the TIM[i]_CH[x](47:24) output line. In the case of immediate edge propagation mode, a value of zero is provided on the TIM[i]_CH[x](47:24) output line.

The TIM[i]_CH[x](47:24) output line is used by the MAP sub-module for further processing (see **Section 38.21**).

Table 38.141 Filter Parameter summary for the different Filter Modes

Filter mode	Meaning of FLT_RE	Meaning of FLT_FE
Immediate edge propagation	Acceptance time for rising edge	Acceptance time for falling edge
Individual de-glitch time (up/ down counter)	De-glitch time for rising edge	De-glitch time for falling edge
Individual de-glitch time (hold counter)	De-glitch time for rising edge	De-glitch time for falling edge
Individual de-glitch time (reset counter)	De-glitch time for rising edge	De-glitch time for falling edge

A counter FLT_CNT is used to measure the glitch and acceptance times.

The frequency of the FLT_CNT counter is configurable in bit field FLT_CNT_FRQ of register TIM[i]_CH[x]_CTRL.

The counter FLT_CNT can either be clock with the CMU_CLK0, CMU_CLK1, CMU_CLK6 or the CMU_CLK7 signal. These signals are coming from the CMU sub-module.

The FLT_CNT, FLT_FE and FLT_RE registers are 24-bit width. For example, when the resolution of the CMU_CLK0 signal is 50ns this allows maximal de-glitch and acceptance times of about 838ms for the filter.

38.15.2.2 TIM Filter Modes

(1) Immediate edge propagation mode

In immediate edge propagation mode after detection of an edge the new signal level on F_IN_SYNC is propagated to F_OUT with a delay of one T period and the new signal level remains unchanged until the configured acceptance time expires.

For each edge type the acceptance time can be specified separately in the FLT_RE and FLT_FE registers.

Each signal change on the input F_IN_SYNC during the duration of the acceptance time has no effect on the output signal level F_OUT of the filter but it sets the glitch GLITCHDET bit in the TIM[i]_CH[x]_IRQ_NOTIFY register.

After it expires an acceptance time the input signal F_IN_SYNC is observed and on signal level change the filter raises a new detected edge and the new signal level is propagated to F_OUT.

Independent of a signal level change the value of F_OUT is always set to F_IN_SYNC, when the acceptance time expires (see also **Figure 38.39**).

Figure 38.38 shows an example for the immediate edge propagation mode, in the case of rising edge detection. Both, the signal before filtering (F_IN) and after filtering (F_OUT) are shown. The acceptance time at1 is specified in the register FLT_RE.

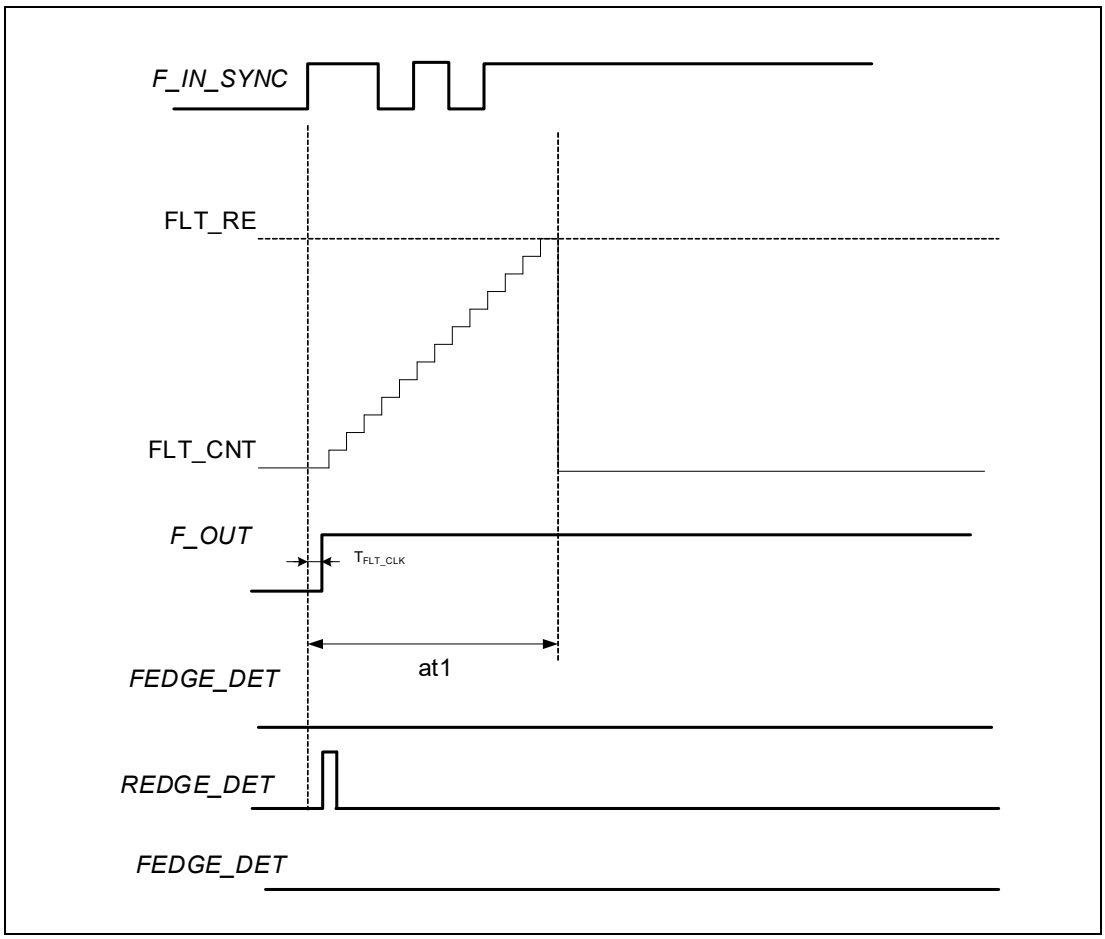

Figure 38.38 Immediate Edge Propagation Mode in the case of a rising edge

In immediate edge propagation mode the glitch measurement mechanism is not applied to the edge detection. Detected edges on F_IN_SYNC are transferred directly to F_OUT.

The counter FLT_CNT is incremented until acceptance time threshold is reached.

Figure 38.39 shows a more complex example of the TIM filter, in which both, rising and falling edges are configured in immediate edge propagation mode.

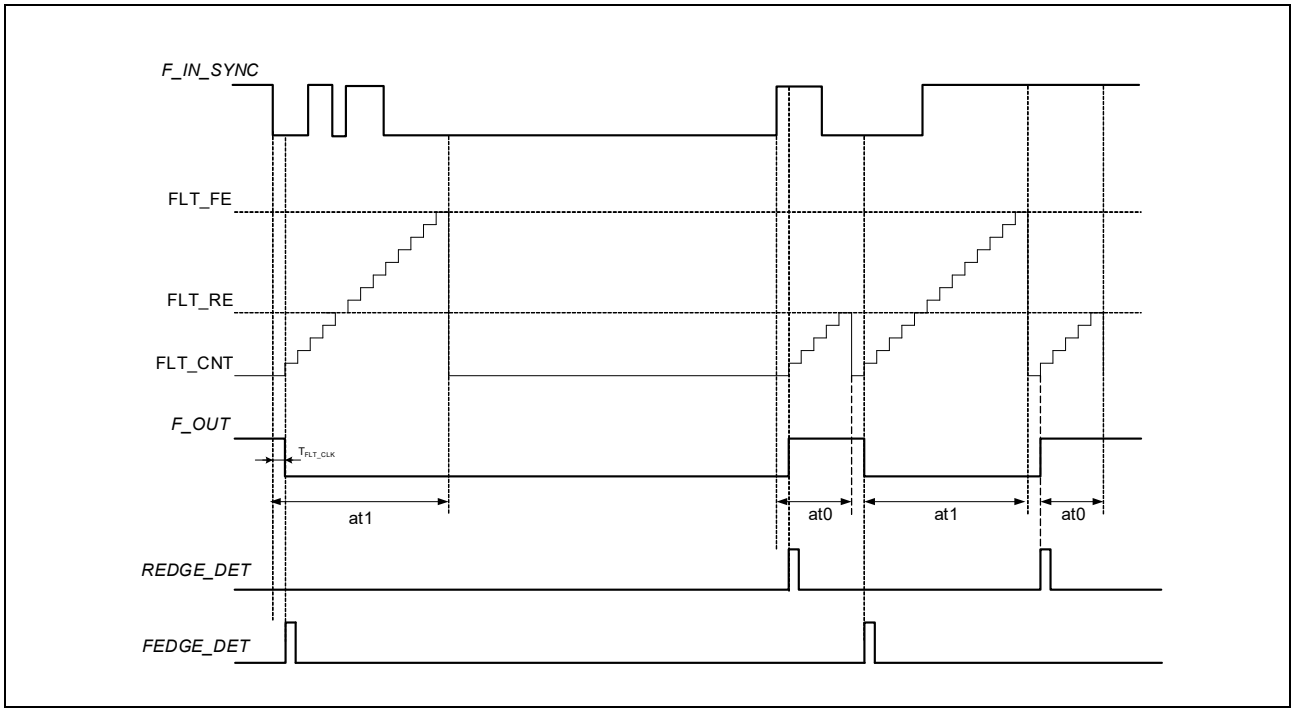

Figure 38.39 Immediate Edge Propagation Mode in the case of a rising and falling edge

If the FLT_CNT has reached the acceptance time for a specific signal edge and the signal F_IN_SYNC has already changed to the opposite level of F_OUT, the opposite signal level is set to F_OUT and the acceptance time measurement is started immediately. **Figure 38.39** shows this scenario at the detection of the first rising edge and the second falling edge.

(2) Individual de-glitch time mode (up/down counter)

In individual de-glitch time mode (up/down counter) each edge of an input signal can be filtered with an individual de-glitch threshold filter value mentioned in the registers FLT_RE and FLT_FE, respectively.

The filter counter register FLT_CNT is incremented when the signal level on F_IN_SYNC is unequal to the signal level on F_OUT and decremented if F_IN_SYNC equals F_OUT.

After FLT_CNT has reached a value of zero during decrementation the counter is stopped immediately.

If a glitch is detected a glitch detection bit GLITCHDET is set in the TIM[i]_CH[x]_IRQ_NOTIFY register.

The detected edge signal together with the new signal level is propagated to F_OUT after the individual de-glitch threshold is reached. **Figure 38.40** shows the behavior of the filter in individual de-glitch time (up/down counter) mode in the case of the rising edge detection.

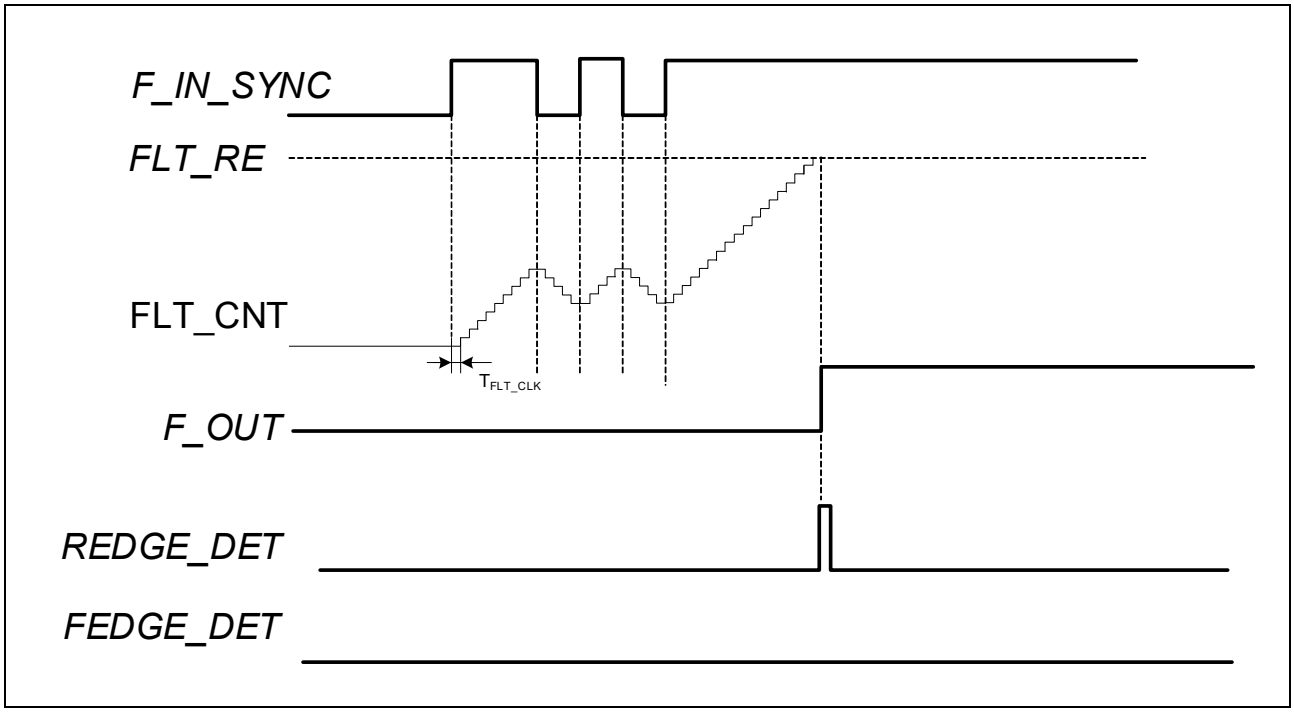

Figure 38.40 Individual De-glitch Time Mode (up/down counter) in the case of a rising edge

(3) Individual de-glitch time mode (hold counter)

In individual de-glitch time mode (hold counter) each edge of an input signal can be filtered with an individual de-glitch threshold filter value mentioned in the registers FLT_RE and FLT_FE, respectively.

The filter counter register FLT_CNT is incremented when the signal level on F_IN_SYNC is unequal to the signal level on F_OUT and the counter value of FLT_CNT is hold if F_IN equals F_OUT.

If a glitch is detected the glitch detection bit GLITCHDET is set in the TIM[i]_CH[x]_IRQ_NOTIFY register.

The detected edge signal together with the new signal level is propagated to F_OUT after the individual de-glitch threshold is reached. **Figure 38.41** shows the behavior of the filter in individual de-glitch time (hold counter) mode in the case of the rising edge detection.

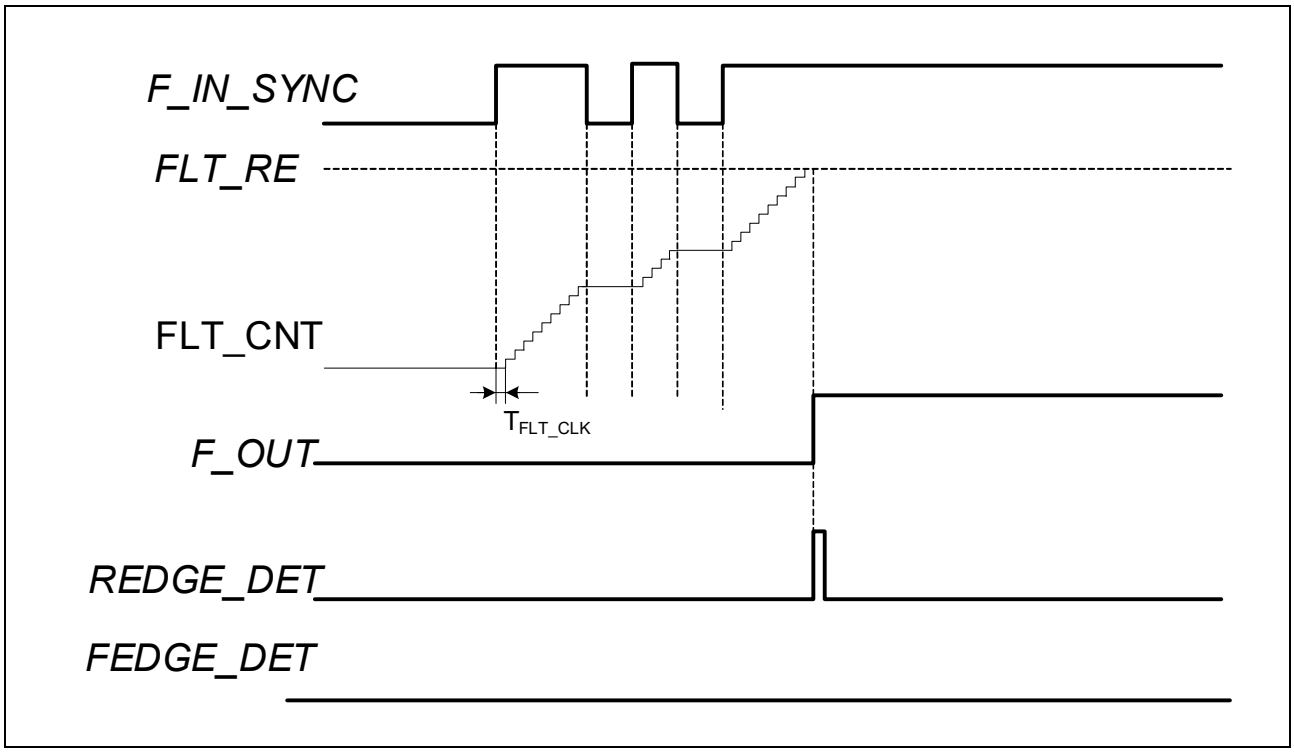

Figure 38.41 Individual De-Glitch Time Mode (hold counter) in the case of a rising edge

(4) Individual de-glitch Time Mode (reset counter)

In individual de-glitch time mode (reset counter) each edge of an input signal can be filtered with an individual de-glitch threshold filter value mentioned in the registers FLT_RE and FLT_FE, respectively.

The filter counter register FLT_CNT is incremented when the signal level on F_IN_SYNC is unequal to the signal level on F_OUT and the counter value of FLT_CNT is reset to 000000_H if F_IN equals F_OUT.

If a glitch is detected the glitch detection bit GLITCHDET is set in the TIM[i]_CH[x]_IRQ_NOTIFY register.

The detected edge signal together with the new signal level is propagated to F_OUT after the individual de-glitch threshold is reached. **Figure 38.42** shows the behavior of the filter in individual de-glitch time (reset counter) mode in the case of the rising edge detection.

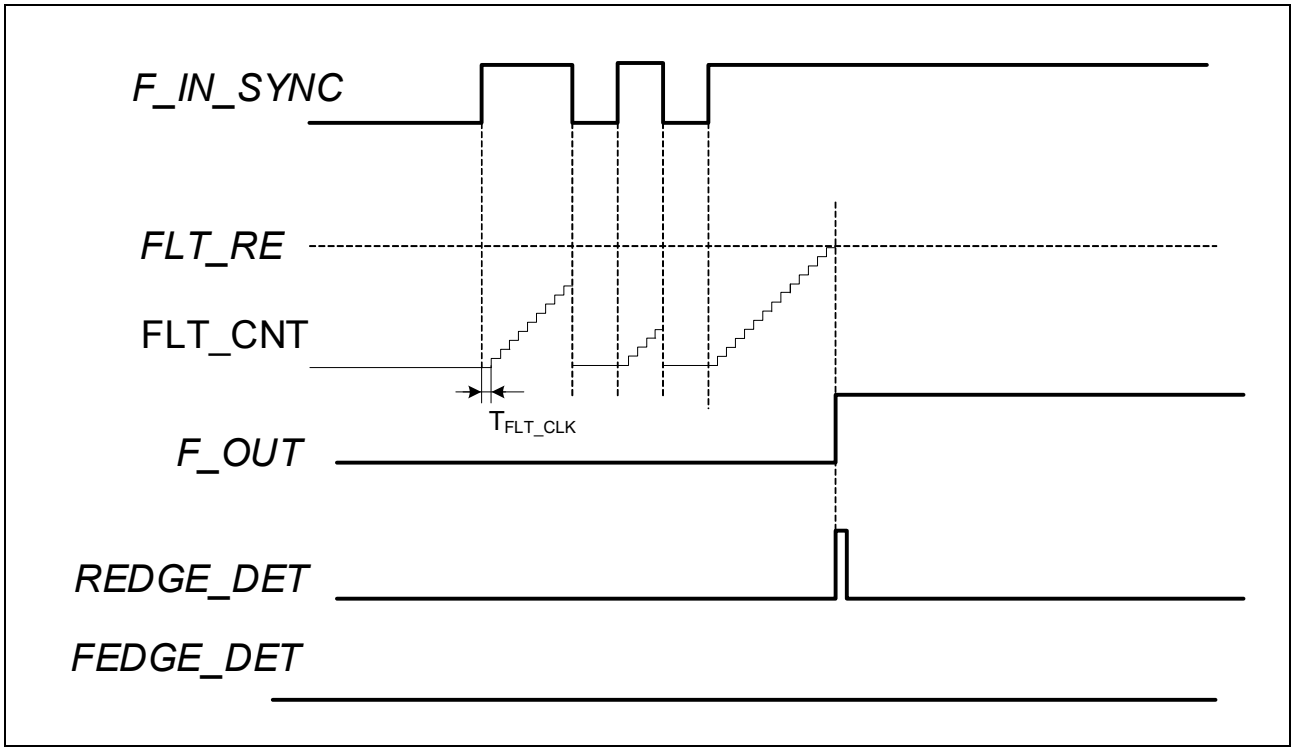

Figure 38.42 Individual De-glitch Time Mode (reset counter) in the case of a rising edge

(5) Immediate edge propagation and individual de-glitch mode

As already mentioned, the four different filter modes can be applied individually to each edge of the measured signal.

However, if one edge is configured with immediate edge propagation and the other edge with an individual deglitch mode (whether up/down counter or hold counter) a special consideration has to be applied.

Assume that the rising edge is configured for immediate edge propagation and the falling edge with individual deglitch mode (up/down counter) as shown in **Figure 38.43**.

If the falling edge of the incoming signal already occurs during the measuring of the acceptance time of the rising edge, the measurement of the deglitch time on the falling edge is started delayed, but immediately after the acceptance time measurement phase of the rising edge has finished.

Consequently, the deglitch counter can not measure the time T_{ERROR}, as shown in **Figure 38.43**.

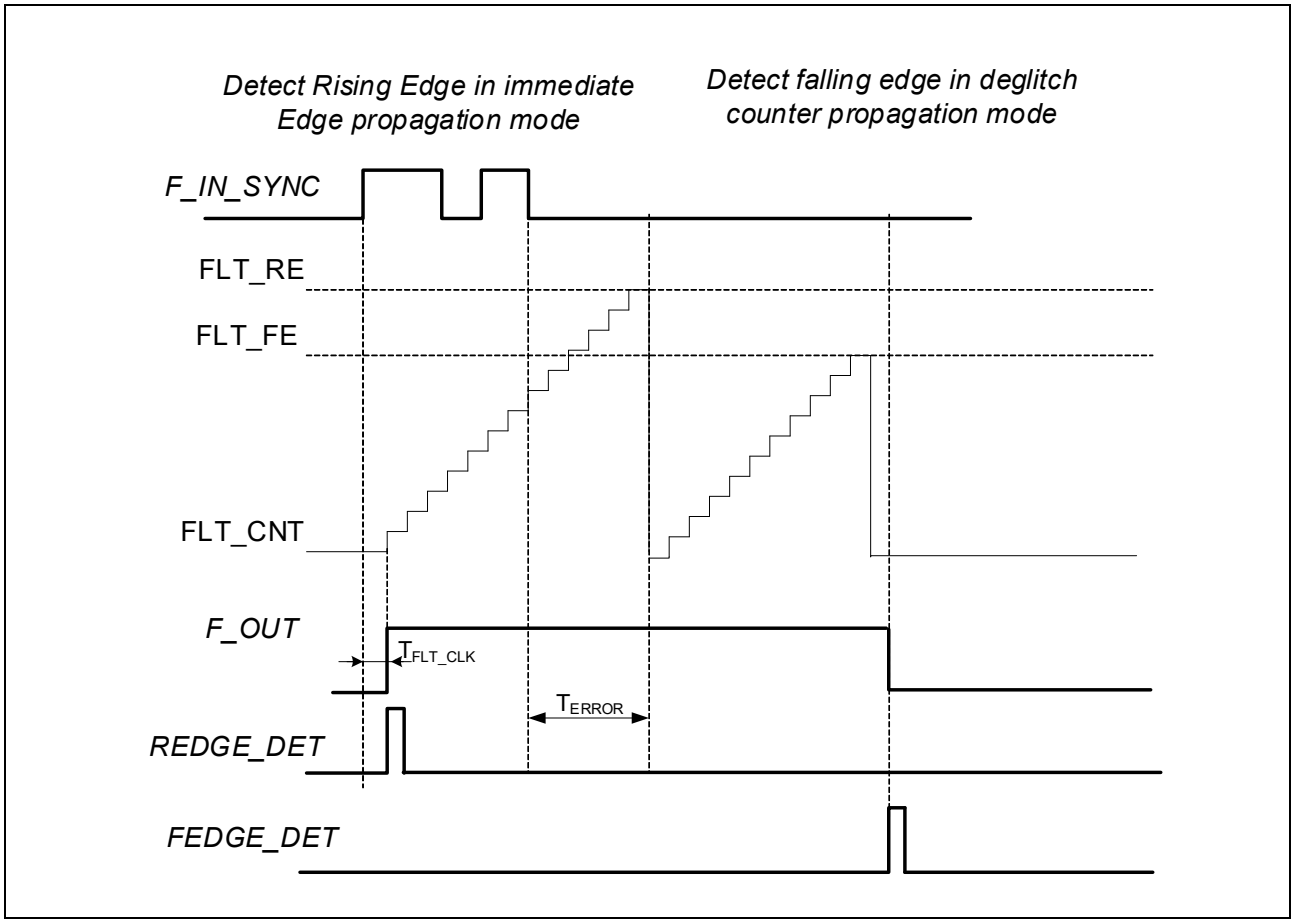

Figure 38.43 Mixed mode measurement

38.15.2.3 TIM Filter reconfiguration

If FLT_EN = 1 a change of FLT_RE or FLT_FE will take place immediately.

If FLT_EN = 1 a change of FLT_MODE_RE or FLT_MODE_FE will be used with the next occurring corresponding edge. If the mode is changed while the filter unit is processing a certain mode, it will end this edge filtering in the mode as started.

If FLT_EN = 1 a change of FLT_CTR_RE, FLT_CTR_FE, EFLT_CTR_RE or EFLT_CTR_FE will take place immediately.

38.15.3 Timeout Detection Unit (TDU)

The Timeout Detection Unit (TDU) is responsible for timeout detection of the TIM input signals.

Each channel of the TIM sub-module has its own Timeout Detection Unit (TDU) where a timeout event can be set up on the filtered input signal of the corresponding channel.

In each timeout unit exist 3 8 bit counter/comparator slices. A counter/comparator slice is shown below. The counter TO_CNT will increment by signal INC. The counter can be loaded with the value LOAD_VAL if LOAD = 1. GT_EVT will be 1 if TO_CNT > TOV is fulfilled. EQ_EVT will be 1 if TO_CNT = TOV is fulfilled.

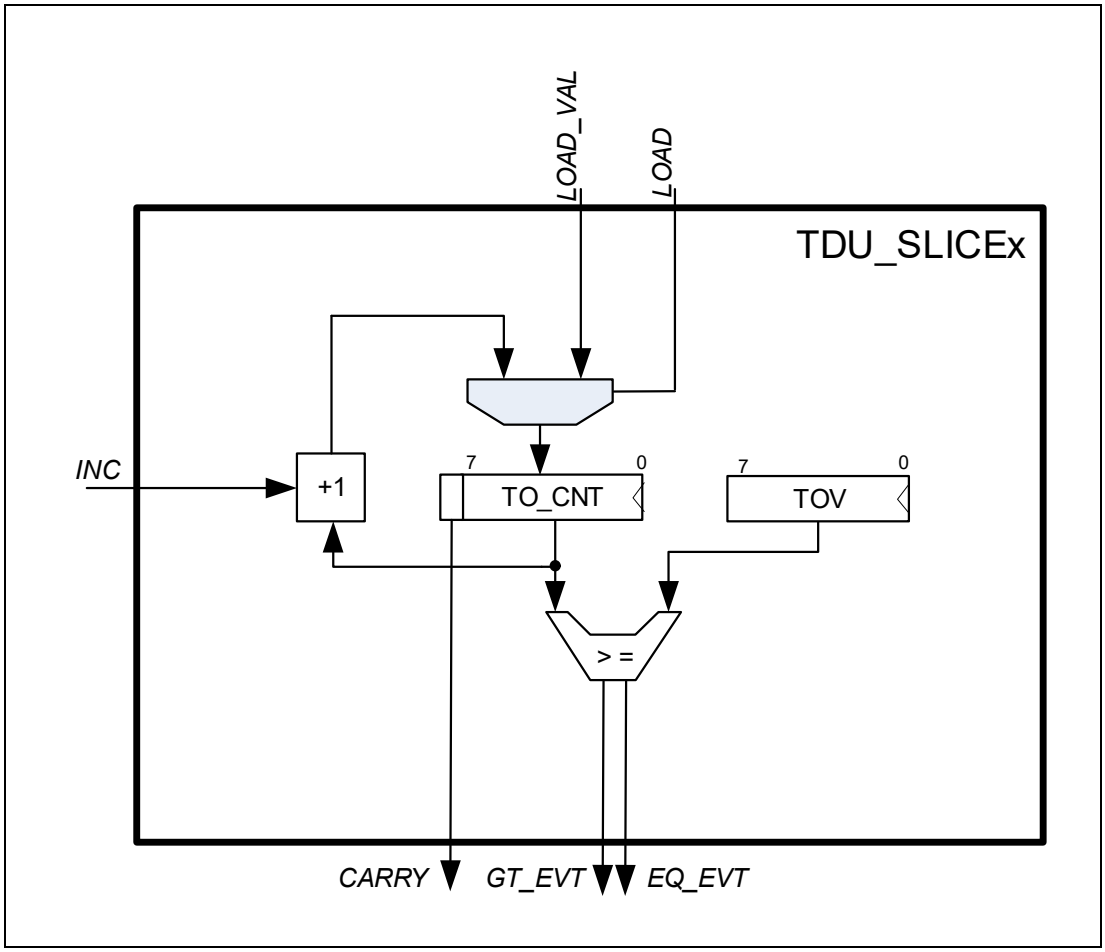

Figure 38.44 Counter/Comparator Slice

The counter/comparator slices can be cascaded depending on the application needs to operate as : 3 × 8 bit counter 1 × 16 bit counter and 1 × 8 bit counter 1 × 24 bit counter 2 × 8 bit counter. This allows the user to use the functions timeout on input signals local CMU clock prescaler 8 bit trigger event generation 8 bit (external capture, todet_irq) in parallel. With usage of the 3 × 8 bit counter it is possible to define different timeout values for the 2 signal levels.

Following table shows which functions can be used in parallel.

Table 38.142 Used Parallel Functions

Counter Type	Timeout Functionality	Generate Local TIM CMU clk	Source for External Capture to Previous Channel	Source for TODET_IRQ
24 bit	24 bit	no	tdu_timeout_evt tdu_sample_evt	tdu_timeout_evt tdu_sample_evt
1 × 8 bit 1 × 16 bit	16 bit local clk tdu_sample_evt usable	yes	tdu_timeout_evt, tdu_frame_evt, tdu_sample_evt	tdu_timeout_evt, tdu_frame_evt, tdu_sample_evt
3 × 8 bit	8 bit local clk tdu_sample_evt usable	yes	tdu_timeout_evt, tdu_sample_evt, tdu_word_evt, tdu_frame_evt	tdu_timeout_evt, tdu_sample_evt, tdu_word_evt, tdu_frame_evt
3 × 8 bit	no	yes	tdu_timeout_evt, tdu_sample_evt, tdu_word_evt, tdu_frame_evt	tdu_timeout_evt, tdu_sample_evt, tdu_word_evt, tdu_frame_evt
2 × 8 bit	no	no	tdu_timeout_evt, tdu_word_evt, tdu_frame_evt	tdu_timeout_evt, tdu_word_evt, tdu_frame_evt

Next table shows which of the available 8 bit resources are cascaded with a chosen SLICING.

Table 38.143 Which of the Available 8 bit Resources Are Cascaded with a Chosen SLICING (1/2)

Counter Type	Counters Count on	Counter Resource Generates	CLK Selection
24 bit	CNT on TCS	CNT= TO_CNT2 & TO_CNT1 & TO_CNT; TCMP = TOV2 & TOV1 &TOV; CNT ≥ TCMP generates tdu_sample_evt tdu_timeout_evt = tdu_sample_evt tdu_frame_evt = 0 tdu_word_evt = 0	TCS selected

Based on a chosen counter configuration by SLICING it is possible to control the start behavior of the counters by TDU_START in multiple ways. In addition the stopping of the counters can be controlled by TDU_STOP. Depending on the application needs it can be decided how the individual counter slices can be reset/reloaded by the configuration field TDU_RESYNC.

Depending on the counter configuration, up to 4 internal compare events tdu_timeout_evt, tdu_sample_evt, tdu_word_evt, tdu_frame_evt out of the 3 comparator slices can be generated. It can be chosen by TODET_IRQ_SRC which shall be used as TIM_TODETx_IRQ signal which will be accessible by the TODET bit inside the TIM[i]_CH[x]_IRQ_NOTIFY register The TDU architecture is shown in **Figure 38.45**.

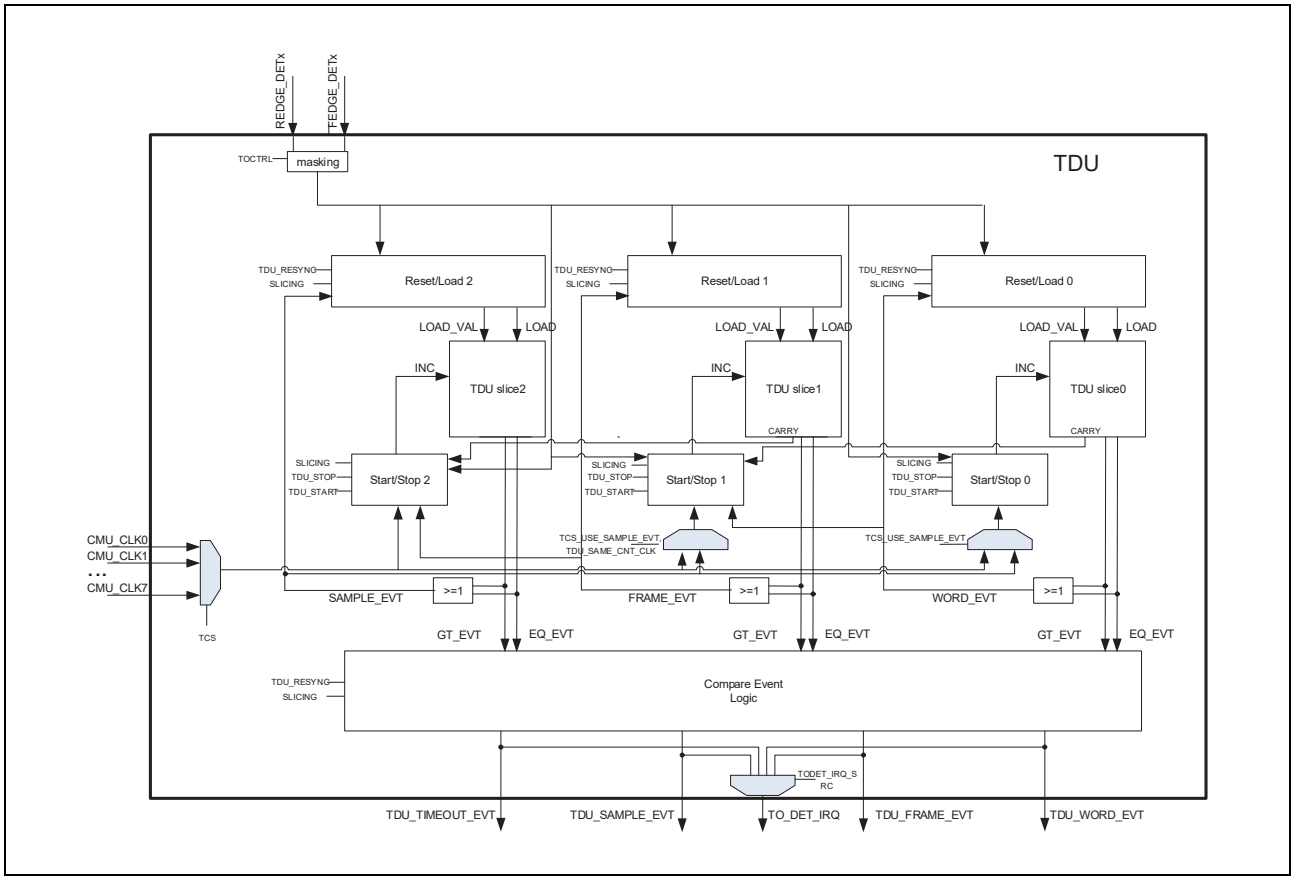

Figure 38.45 Architecture of the TDU Sub-unit

Each TDU_slice has its own start/stop control, based on the chosen configuration it will decide if the counter inside the TDU slice will increment on the resolution of the applied clock/event. The reset/load control decides based on the configuration settings and the compare result of the TDU slices those the counters TO_CNT, TO_CNT1, TO_CNT2 have to be reloaded. Depending on the chosen counter/ compare configuration the compare event logic will generate based on the compare results of the 3 TDU slices and the chosen resolution the events tdu_sample_evt, tdu_word_evt, tdu_frame_evt.

The primary resolution on which the TDU is working can be specified with the bit field TCS of the register TIM[i]_CH[x]_TDUV. The corresponding input signal CMU_CLKx will be used to clock the TDU. The individual timeout/counter values have to be specified in number of ticks of the selected input clock signal in the fields TOV, TOV1, TOV2 of the timeout value register TIM[i]_CH[x]_TDUV of the TIM channel x.

In case of cascading the bit slices by usage of SLICING and TCS_USE_SAMPLE_EVT and TDU_SAME_CLK the resolution for counting can be switched to the events tdu_sample_evt or tdu_word_evt. More details see table above.

The counter compare units start operation on occurrence of the first "start event" configured by TDU_START. They continue their operation until the first "stop event" configured by TDU_STOP occurs.

In case of occurrence of a start event and a compare/count resolution event in the same clock cycle, the counters will increment or reload/reset based on TDU_RESYNC immediately. No tdu_sample_evt, tdu_word_evt, tdu_frame_evt will be generated.

In case of occurrence of a stop event the counters will not change their values. In case of occurrence of a stop event and a compare/count resolution event in the same clock cycle the corresponding events tdu_sample_evt, tdu_word_evt, tdu_frame_evt will be generated.

In case of occurrence of a start event and a stop event in the same clock cycle the counters will not change their values. No tdu_sample_evt, tdu_word_evt, tdu_frame_evt will be generated.

The function of the timeout unit (configured to TDU_RESYNC = 0000_B, TDU_START = 000_B) can be started or stopped inside the TIM[i]_CH[x]_CTRL register by setting/resetting the TOCTRL bit.

Timeout detection can be enabled to be sensitive to falling, rising or both edges of the input signal by writing the corresponding values to the bit field TOCTRL.

The TDU generates an interrupt signal TIM_TODETx_IRQ whenever a timeout is detected for an individual input signal, and the TODET bit is set inside the TIM[i]_CH[x]_IRQ_NOTIFY register.

In addition, when the ARU access is enabled with the ARU_EN bit inside the TIM[i]_CH[x]_CTRL register, the actual values stored inside the registers TIM[i]_CH[x]_GPR0 and TIM[i]_CH[x]_GPR1 are sent together with the last stored signal level to the ARU if a timeout event TDU_TIMEOUT_EVT occurs.

To signal that a timeout occurred, the ARU_OUT(50) bit (ACB(2)) is set. The bit ACB(0) will be updated with the timeout event to the signal level on which the timeout was detected. Timeout signaling with ACB(2) is only possible with TODET_IRQ_SRC = 0000_B.

Thus, a destination could determine if a timeout occurred at the TIM input by evaluating ACB bit 2.

Since the TIM channel still monitors its input pin although the timeout happened, a valid edge could occur at the input pin while the timeout information is still valid at the ARU. In that case, the new edge associated data is stored inside the registers TIM[i]_CH[x]_GPR0 and TIM[i]_CH[x]_GPR1, the GPR overflow detected bit is set together in the ACB field (ACB(1)) with the timeout bit (ACB(2)) and the values are marked as valid to the ARU.

The ACB bit 2 is cleared, when a successful ARU write access by the TIM channel took place.

The ACB bit 1 is cleared, when a successful ARU write access by the TIM channel took place.

When a valid edge initiates an ARU write access which has not ended while a new timeout occurs the GPR overflow detected bit (ACB(1)) is set. The bit ACB(0) will be updated to the level on which the timeout occurred.

When a timeout occurred and initiates an ARU write access which has not ended while a new timeout occurs the GPR overflow detected bit (ACB(1)) is not set.

The following table clarifies the meaning of the ACB Bits for valid data provided by a TIM channel:

Table 38.144 The ACB Bits for Valid Data Provided by a TIM Channel

ACB4/3	ACB2	ACB1	ACB0	Description
dc	0	0	SL	Valid edge detected
dc	0	1	SL	Input edge overwritten by subsequent edge
dc	1	0	SL	Timeout detected without valid edge
dc	1	1	SL	Timeout detected with subsequent valid edge detected

38.15.4 TIM Channel Architecture

38.15.4.1 Overview

Each TIM channel consist of an input edge counter ECNT, a Signal Measurement Unit (SMU) with a counter CNT, a counter shadow register CNTS for SMU counter and two general purpose registers GPR0 and GPR1 for value storage.

The value TOV of the timeout register TIM[i]_CH[x]_TDU is provided to TDU sub-unit of each individual channel for timeout measurement.

The architecture of the TIM channel is depicted in **Figure 38.46**.

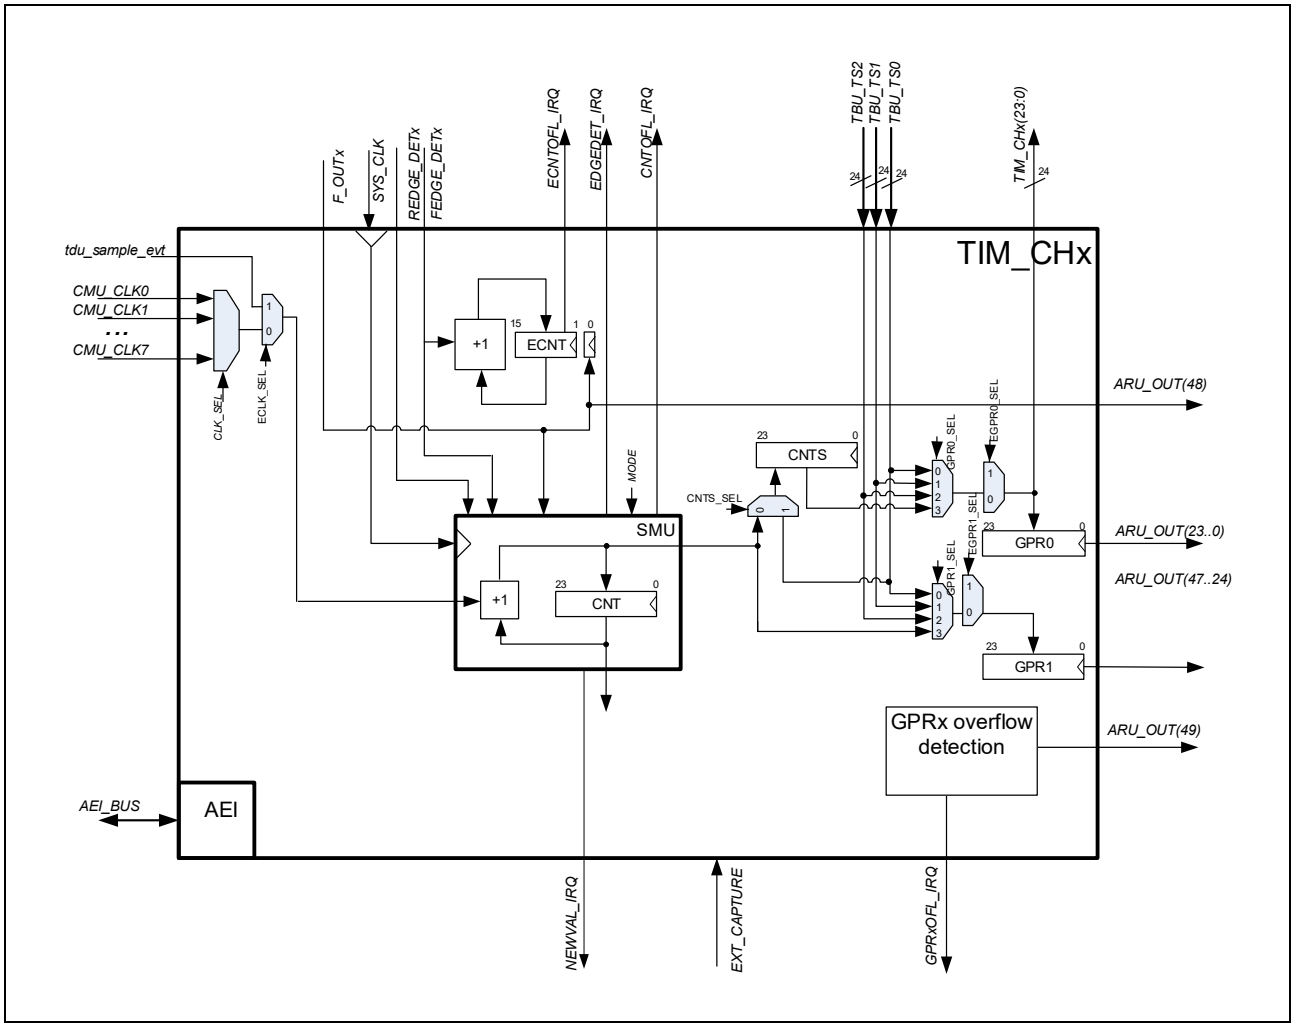

Figure 38.46 TIM Channel Architecture

Each TIM channel receives both input trigger signals REDGE_DETx and FEDGE_DETx, generated by the corresponding filter module in order to signalize a detected echo of the input signal F_INx. The signal F_OUTx shows the filtered signal of the channel's input signal F_INx.

The edge counter ECNT counts every incoming filtered edge (rising and falling). The counter value is uneven in case of detected rising, and even in case of detected falling edge. Thus, the input signal level is part of the counter and can be obtained by bit 0 of ECNT. (However, the actual counter implementation counts only falling edges on ECNT[n:1] bits. It generates ECNT by composing the ECNT[n:1] bits with F_OUTx as bit 0).

Thus, the whole ECNT counter value is always odd, when a positive edge was received and always even, when a negative edge was received.

The current ECNT[7:0] register content is made visible on the bits 31 down to 24 of the registers GPR0, GPR1, and CNTS. This allows the software to detect inconsistent read accesses to registers GPR0, GPR1, and CNTS. However, the update strategy of these registers depends on the selected TIM modes, and thus the consistency check has to be adapted carefully.

It can be chosen with the bit field FR_ECNT_OFL when an ECNT overflow is signaled on ECNTOFL. An ECNT overflow can be signaled on 8 bit or full range resolution.

While reading the register TIM[i]_CH[x]_ECNT the bit ECNT[0] shows the input signal value F_OUTx independent of the state (enabled/disabled) of the channel. If a channel gets disabled (OSM mode or resetting TIM_EN) the content of TIM[i]_CH[x]_ECNT will be frozen until a read of the register takes place. This read will reset the ECNT counter. Continuing reads will show the input signal value in bit ECNT[0] again.

When new data is written into GPR0 and GPR1 the NEWVAL bit is set in TIM[i]_CH[x]_IRQ_NOTIFY register and depending on corresponding enable bit value the NEWVALx_IRQ interrupt is raised.

Each TIM input channel has an ARU connection for providing data via the ARU to the other GTM sub-modules. The data provided to the ARU depends on the TIM channel mode and its corresponding adjustments (e.g. multiplexer configuration).

The bit ARU_EN of register TIM[i]_CH[x]_CTRL decides, whether the measurement results of registers GPR0 and GPR1 are consumed by another sub-module via ARU (ARU_EN = 1) or the CPU via AEI (ARU_EN = 0).

To guarantee a consistent delivery of data from the GPR0 and GPR1 registers to the ARU or the CPU each TIM channel has to ensure that the data is consumed before it is overwritten with new values.

If new data was produced by the TIM channel (bit NEWVAL is set inside TIM[i]_CH[x]_IRQ_NOTIFY register) while the old data is not consumed by the ARU (ARU_EN = 1) or CPU (ARU_EN = 0), the TIM channel sets the GPROFL bit inside the status register TIM[i]_CH[x]_IRQ_NOTIFY and it overwrites the data inside the registers GPR0 and GPR1. In addition when ARU_EN = 1 the bit ACB(1) is set to 1 to indicate the overflow in the ARU data.

If the CPU is selected as consumer for the registers GPR0 and GPR1 (ARU_EN = 0), the acknowledge for reading out data is performed by a read access to the register GPR0. Thus, register GPR1 should be read always before GPR0.

If the ARU is selected as consumer for the registers GPR0 and GPR1 (ARU_EN = 1), the acknowledge for reading out data is performed by the ARU itself. However, the registers GPR0 and GPR1 could be read by CPU without giving an acknowledge.

38.15.4.2 TIM Channel Modes

The TIM provides seven different measurement modes that can be configured with the bit field TIM_MODE of register TIM[i]_CH[x]_CTRL.

The measurement modes are described in the following subsections. Besides these different basic measurement modes, there exist distinct configuration bits in the register TIM[i]_CH[x]_CTRL for a more detailed controlling of each mode. The meanings of these bits are as follows:

- DSL: control the signal level for the measurement modes (e.g. if a measurement is started with rising edge or falling edge, or if high level pulses or low level pulses are measured.
- EGPR0_SEL, GPR0_SEL and EGPR1_SEL, GPR1_SEL: control the actual content of the registers GPR0 and GPR1 after a measurement has finished.
- CNTS_SEL: control the content of the registers CNTS. The actual time for updating the CNTS register is mode dependent.
- OSM: activate measurement in one-shot mode or continuous mode. In one-shot mode only one measurement cycle is performed and after that the channel is disabled.
- NEWVAL: The NEWVAL IRQ interrupt is triggered at the end of a measurement cycle, signaling that the registers GPR0 and GPR1 are updated.
- ARU_EN: enables sending of the registers GPR0 and GPR1 together with the actual signal level (in bit 48) and the overflow signal GPROFL (in bit 49), and the timeout status information (bit 50) to the ARU.
- EXT_CAP_EN: forces an update of the registers GPR0 and GPR1 and CNTS (TIM channel mode dependent) only on each rising edge of the EXT_CAPTURE signal and triggers a NEWVAL IRQ interrupt. If this mode is disabled the NEWVAL IRQ interrupt is triggered at the end of each measurement cycle.

For each channel the source of the EXT_CAPTURE signal can be configured with the bit fields EXT_CAP_SRC in the register TIM[i]_CH[x]_ECTRL.

(1) TIM PWM Measurement Mode (TPWM)

In TIM PWM Measurement Mode the TIM channel measures duty cycle and period of an incoming PWM signal. The DSL bit defines the polarity of the PWM signal to be measured.

When measurement of pulse high time and period is requested (PWM with a high level duty cycle, DSL = 1) and IMM_START = 0, the channel starts measuring after the first rising edge is detected by the filter.

If IMM_START = 1 the measurement starts immediately after activating the channel by TIM_EN = 1.

Measurement is done with the CNT register counting with the configured clock coming from CMU_CLKx until a falling edge is detected.

Assume: SWAP_CAPTURE =0, ECNT_RESET = 0

Then the counter value is stored inside the shadow register CNTS (if CNTS_SEL = 0) and the counter CNT counts continuously until the next rising edge is reached.

On this following rising edge the content of the CNTS register is transferred to GPR0 and the content of CNT register is transferred to GPR1, assuming settings for the selectors EGPR0_SEL =0, GPR0_SEL = 11 and EGPR1_SEL = 0, GPR1_SEL = 11. By this, GPR0 contains the duty cycle length and GPR1 contains the period.

NOTE

The bits 1 to 7 of the ECNT may be used to check data consistency of the registers GPR0 and GPR1.

In addition the CNT register is cleared NEWVAL status bit inside of TIM[i]_CH[x]_IRQ_NOTIFY status register and depending on corresponding interrupt enable condition TIM_NEWVALx_IRQ interrupt is raised.

The CNTS register update is not performed until the measurement is started. Afterwards each edge leaving the level defined by DSL is performing a CNTS register update.

If a PWM with a low level duty cycle should be measured (DSL = 0) and IMM_START = 0, the channel waits for a falling edge until measurement is started. On this edge the low level duty cycle time is stored first in CNTS and then finally in GPR0 and the period is stored in GPR1.

When a PWM period was successfully measured, the data in the registers GPR0 and GPR1 is marked as valid for reading by the ARU when the ARU_EN bit is set inside TIM[i]_CH[x]_CTRL register, the NEWVAL bit is set inside the TIM[i]_CH[x]_IRQ_NOTIFY register, and a new measurement is started.

If the preceding PWM values were not consumed by a reader attached to the ARU (ARU_EN bit enabled) or by the CPU the TIM channel set GPROFL status bit in TIM[i]_CH[x]_IRQ_NOTIFY and depending on corresponding interrupt enable bit value raises a GPROFL_IRQ and overwrites the old values in GPR0 and GPR1. A new measurement is started afterwards.

If the register CNT produces an overflow during the measurement, the bit CNTOFL is set inside the register TIM[i]_CH[x]_IRQ_NOTIFY and interrupt TIM_CNTOFL[x]_IRQ is raised depending on corresponding interrupt enable condition.

If the register ECNT produces an overflow during the measurement, the bit ECNTOFL is set inside the register TIM[i]_CH[x]_IRQ_NOTIFY and interrupt TIM_ECNTOFL[x]_IRQ is raised depending on corresponding interrupt enable condition.

If ECNT_RESET = 0 the counter CNT will be reset to 0 on active edge (defined by DSL) of the input signal. If ECNT_RESET = 1 the counter CNT will be reset to 0 on each edge of the input signal.

Assume EXT_CAP_EN = 0 and SWAP_CAPTURE = 0: On every input edge to the active level defined by DSL will capture the data selected by EGPR1_SEL, GPR1_SEL to the registers GPR1. Every edge to the inactive level will capture the data selected by CNTS_SEL to the registers CNTS.

Assume EXT_CAP_EN = 0 and SWAP_CAPTURE = 1: On every input edge to the inactive level defined by DSL will capture the data selected by EGPR1_SEL, GPR1_SEL to the registers GPR1. Every edge to the active level will capture the data selected by CNTS_SEL to the registers CNTS.

(a) External capture TIM PWM Measurement Mode (TPWM)

If external capture is enabled EXT_CAP_EN = 1, the pwm measurement is done continuously. The actual measurement values are captured to GPRx if an external capture event occurs.

On every external capture event the data selected by CNTS_SEL, EGPR0_SEL, GPR0_SEL will be captured to the registers CNTS, GPR0.

If SWAP_CAPTURE = 0 every external capture event will capture the data selected by EGPR1_SEL, GPR1_SEL to the registers GPR1. Every input edge to the level ! = DSL will capture the data selected by CNTS_SEL to the registers CNTS.

If SWAP_CAPTURE = 1 every input edge to the inactive level ! = DSL will capture the data selected by EGPR1_SEL, GPR1_SEL to the registers GPR1.

Assume SWAP_CAPTURE = 0:

Operation is done depending on CMU clock, ISL, DSL bit and the input signal value defined in next table (Assume CNTS_SEL= 0):

Table 38.145 Operation is done depending on CMU clock, ISL, DSL bit and the input signal value defined in next table (Assume CNTS_SEL= 0)

Input signal F_OUTx	Selected CMU Clock	External capture	ISL	DSL	Action description
0	1	0	—	0	CNT++
1	1	0	—	0	no
Rising edge	—	0	0	0	capture CNT value in CNTS
Falling edge	—	0	0	0	CNT = 0
Rising edge	—	0	1	0	no
Falling edge	—	0	1	0	capture CNT value in CNTS; CNT = 0
1	1	0	—	1	CNT++
0	1	0	—	1	no
Falling edge	—	0	0	1	capture CNT value in CNTS
Rising edge	—	0	0	1	CNT = 0
Falling edge	—	0	1	1	no
Rising edge	—	0	1	1	capture CNT value in CNTS; CNT = 0
—	—	Rising edge	—	—	do GPRx capture; issue NEWVAL_IRQ
—	0	0	—	—	no

The CNTS register update is not performed until the measurement is started (first edge defined by DSL is detected). Afterwards the update of the CNTS register is defined by ISL, DSL combinations in the table above.

(2) TIM Pulse Integration Mode (TPIM)

In TIM Pulse Integration Mode each TIM channel is able to measure a sum of pulse high or low times on an input signal, depending on the selected signal level bit DSL of register TIM[i]_CH[x]_CTRL register.

If IMM_START = 0 the pulse integration measurement is started with occurrence of the first edge defined by DSL on the input signal. If IMM_START = 1 the measurement starts immediately after activating the channel by TIM_EN = 1.

The pulse times are measured by incrementing the TIM channel counter CNT until the counter is stopped with occurrence of a input signal edge to the opposite signal level defined by DSL.

The counter CNT counts with the CMU_CLKx clock specified by the CLK_SEL bit field of the TIM[i]_CH[x]_CTRL register.

The CNT register is reset at the time the channel is activated (enabling via AEI write access) and it accumulates pulses while the channel is staying enabled.

Assume EXT_CAP_EN = 0 and SWAP_CAPTURE = 0: After measurement is started, every falling (DSL = 1) or rising (DSL = 0) input edge will issue a TIM_NEWVALx_IRQ interrupt, and the registers CNTS, GPR0 and GPR1 are updated according to settings of its corresponding input multiplexers, using the bits EGPR0_SEL, EGPR1_SEL, GPR0_SEL, GPR1_SEL and CNTS_SEL.

NOTE

The bits 1 to 7 of the ECNT may be used to check data consistency of the registers GPR0 and GPR1.

Assume EXT_CAP_EN = 0 and SWAP_CAPTURE = 1: After measurement is started, every falling (DSL-1) or rising (DSL = 0) input edge will issue a TIM_NEWVALx_IRQ interrupt, and the registers CNTS, GPR0 are updated according to settings of its corresponding input multiplexers, using the bits EGPR0_SEL, GPR0_SEL and CNTS_SEL. Every input edge to the active level defined by DSL (rising DSL = 1; falling DSL = 0) will capture the data selected by EGPR1_SEL, GPR1_SEL to the registers GPR1.

When the ARU_EN bit is set inside the TIM[i]_CH[x]_CTRL register the measurement results of the registers GPR0 and GPR1 can be send to subsequent sub-modules attached to the ARU.

(a) External capture TIM Pulse Integration Mode (TPIM)

If external capture is enabled EXT_CAP_EN = 1, the pulse integration is done until next external capture event occurs.

On every external capture event the data selected by CNTS_SEL, EGPR0_SEL, GPR0_SEL will be captured to the registers CNTS, GPR0.

If SWAP_CAPTURE = 0 every external capture event will capture the data selected by EGPR1_SEL, GPR1_SEL to the registers GPR1.

If SWAP_CAPTURE = 1 every input edge to the inactive level ! = DSL will capture the data selected by EGPR1_SEL, GPR1_SEL to the registers GPR1.

Assume SWAP_CAPTURE = 0; IMM_START = 0:

Operation is done depending on CMU clock, DSL bit and the input signal value defined in next table (inc_cnt = false if TIM channel is enabled):

Table 38.146 Operation Depending on CMU Clock, DSL and the Input Signal Value (inc_cnt = false if TIM Channel Is Enabled)

Input signal F_OUTx	Selected CMU Clock	External capture	ISL	DSL	Action description
Falling edge	—	0	—	0	inc_cnt = true
Rising edge	—	0	—	0	if inc_cnt = true then { do capture GPRx, CNTS; issue NEWVAL_IRQ } inc_cnt = false
Rising edge	—	0	—	1	inc_cnt = true
Falling edge	—	0	—	1	if inc_cnt = true then { do capture GPRx, CNTS; issue NEWVAL_IRQ } inc_cnt = false
—	1	0	—	—	if inc_cnt = true then CNT++;
—	—	Rising edge	—	—	do capture GPRx, CNTS; issue NEWVAL_IRQ; CNT=0
—	0	0	—	—	no

(3) TIM Input Event Mode (TIEM)

In TIM Input Event Mode the TIM channel is able to count edges.

It is configurable if rising, falling or both edges should be counted. This can be done with the bit fields DSL and ISL in TIM[i]_CH[x]_CTRL register.

In addition, a TIM[i]_NEWVAL[x]_IRQ interrupt is raised when the configured edge was received and this interrupt was enabled.

The counter register CNT is used to count the number of edges, and the bit fields EGPR0_SE L, EGPR1_SE L, GPR0_SEL, GPR1_SEL, and CNTS_SEL can be used to configure the desired update values for the registers GPR0, GPR1 and CNTS. These register are updated whenever the edge counter CNT is incremented due to the arrival of a desired edge.

If the preceding data was not consumed by a reader attached to the ARU or by the CPU the TIM channel sets GPROFL status bit and raises a GPROFL[x]_IRQ if it was enabled in TIM[i]_CH[x]_IRQ_EN register and overwrites the old values in GPR0 and GPR1 with the new ones.

If the register CNT produces an overflow during the measurement, the bit CNTOFL is set inside the register TIM[i]_CH[x]_IRQ_NOTIFY and interrupt TIM_CNTOFL[x]_IRQ is raised depending on corresponding interrupt enable condition.

If the register ECNT produces an overflow during the measurement, the bit ECNTOFL is set inside the register TIM[i]_CH[x]_IRQ_NOTIFY and interrupt TIM_ECNTOFL[x]_IRQ is raised depending on corresponding interrupt enable condition.

The TIM Input Event Mode does not depend on the bit field CLK_SEL of register TIM[i]_CH[x]_CTRL.

(a) External capture TIM Input Event Mode (TIEM)

If external capture is enabled, capturing is done depending on the DSL, ISL bit and the input signal value defined in next table:

Table 38.147 Capturing Depended on the DSL, ISL and the Input Signal Value, If External Capture Is Enabled

Input signal F_OUTx	External capture	ISL	DSL	Action description
—	Rising edge	1	—	do capture; issue NEWVAL_IRQ; CNT++
—	0	1	—	no
1	Rising edge	0	1	do capture; issue NEWVAL_IRQ; CNT++
0	—	0	1	no
0	Rising edge	0	0	do capture; issue NEWVAL_IRQ; CNT++
1	—	0	0	no

(4) TIM Input Prescaler Mode (TIPM)

In the TIM Input Prescaler Mode the number of edges which should be detected before a TIM[i]_NEWVAL[x]_IRQ is raised is programmable.

In this mode it must be specified in the CNTS register after how many edges the interrupt has to be raised.

A value of 0 in CNTS means that after one edge an interrupt is raised and a value of 1 means that after two edges an interrupt is raised, and so on.

The edges to be counted can be selected by the bit fields DSL and ISL of register TIM[i]_CH[x]_CTRL.

With each triggered interrupt, the registers GPR0 and GPR1 are updated according to bits EGPR0_SEL, EGPR1_SEL, GPR0_SEL and GPR1_SEL.

If the register ECNT produces an overflow during the measurement, the bit ECNTOFL is set inside the register TIM[i]_CH[x]_IRQ_NOTIFY and interrupt TIM_ECNTOFL[x]_IRQ is raised depending on corresponding interrupt enable condition.

The TIM Input Prescaler Mode does not depend on the bit field CLK_SEL of register TIM[i]_CH[x]_CTRL.

(a) External capture TIM Input Prescaler Mode (TIPM)

If external capture is enabled, the external capture events are counted instead of the input signal edges.

Operation is done depending on the external capture signal, DSL, ISL bit and the input signal value defined in next table:

Table 38.148 Operation Depending on the External Capture Signal, DSL, ISL and the Input Signal Value

Input signal F_OUTx	External capture	ISL	DSL	Action description
—	Rising edge	1	—	if CNT ≥ CNTS then do capture; issue NEWVAL_IRQ; CNT=0 else CNT++ endif
—	0	1	—	no
1	Rising edge	0	1	if CNT ≥ CNTS then do capture; issue NEWVAL_IRQ; CNT=0 else CNT++ endif
0	—	0	1	no
0	Rising edge	0	0	if CNT ≥ CNTS then do capture; issue NEWVAL_IRQ; CNT=0 else CNT++ endif
1	—	0	0	no

(5) TIM Bit Compression Mode (TBCM)

The TIM Bit Compression Mode can be used to combine all filtered input signals of a TIM sub-module to a parallel m bit data word, which can be routed to the ARU, where m is the number of channels available in the TIM sub-module.

Figure 38.47 gives an overview of the TIM bit compression mode.

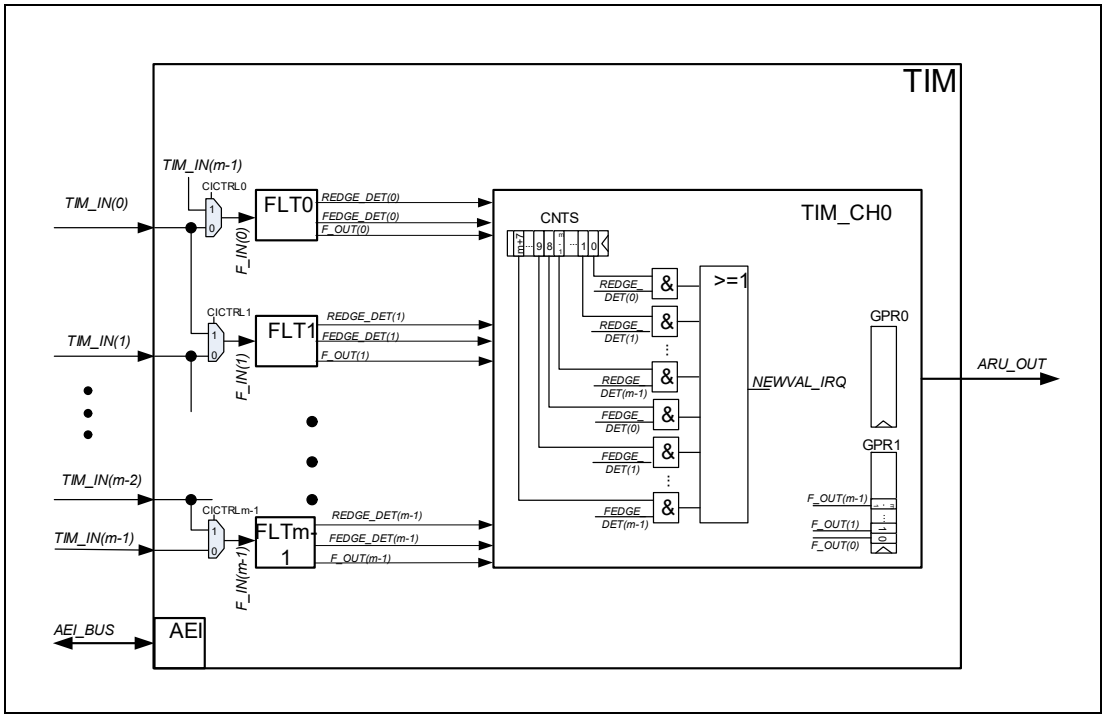

Figure 38.47 TIM Bit Compression Mode

The register CNTS of a channel is used to configure the event that releases the NEWVAL_IRQ and samples the input signals F_IN(0) to F_IN(m-1) in ascending order as a parallel data word in GPR1.

The bits 0 to m-1 of the CNTS register are used to select the REDGE_DET signals of the TIM filters 0 to m-1 as a sampling event, and the bits 8 to (7+ m) are used to select the FEDGE_DET signals of the TIM filters 0 to m-1, respectively. If multiple events are selected, the events are OR-combined (see also **Figure 38.47**).

EGPR0_SE L, GPR0_SEL selects the timestamp value, which is routed through the ARU. GPR1_SEL is not applicable in TBCM mode.

If the bit ARU_EN of register TIM[i]_CH[x]_CTRL is set, the sampled data of register GPR1 is routed together with a time stamp of register GPR0 to the ARU, whenever the NEWVAL_IRQ is released.

In TIM Bit compression mode, the register ECNT increments with each NEWVAL_IRQ, which means that the value of ECNT may depend on all m input signals. Consequently, the LSB of ECNT does not reflect the actual level of the input signal TIM_IN(x).

If the register ECNT produces an overflow during the measurement, the bit ECNTOFL is set inside the register TIM[i]_CH[x]_IRQ_NOTIFY and interrupt TIM_ECNTOFL[x]_IRQ is raised depending on corresponding interrupt enable condition.

The TIM Bit Compression Mode does not depend on the bit field CLK_SEL of register TIM[i]_CH[x]_CTRL.

(a) External capture Bit Compression Mode (TBCM)

If external capture is enabled, capturing is done depending on the DSL, ISL bit and the input signal value defined in next table:

Table 38.149 Capturing Depended on the DSL, ISL and the Input Signal Value, If External Capture Is Enabled

Input signal F_OUTx	External capture	ISL	DSL	Action description
—	Rising edge	1	—	do capture; issue NEWVAL_IRQ; CNT++
—	0	1	—	no
1	Rising edge	0	1	do capture; issue NEWVAL_IRQ; CNT++
0	—	0	1	no
0	Rising edge	0	0	do capture; issue NEWVAL_IRQ; CNT++
1	—	0	0	no

(6) TIM Gated Periodic Sampling Mode (TGPS)

In the TIM Gated Periodic Sampling Mode the number of CMU clock cycles which should elapse before capturing and raising TIM[i]_NEWVAL[x]_IRQ is programmable. In this mode it must be specified in the CNTS register after how many CMU clock cycles the interrupt has to be raised.

A value of 0 in TIM[i]_CH[x]_CNTS means that after one CLK_SEL edge a trigger/interrupt is raised, and a value of 1 means that after two edges a trigger/interrupt is raised, and so on.

In the TIM[i]_CH[x]_CNT register the elapsed cycles were incremented and compared against TIM[i]_CH[x]_CNTS. If TIM[i]_CH[x]_CNT is greater or equal to TIM[i]_CH[x]_CNTS a trigger will be raised. This allows by writing a value to TIM[i]_CH[x]_CNTS that the actual period time can be changed on the fly.

Operation is done depending on CMU clock, DSL, ISL bit and the input signal value defined in next table:

Table 38.150 Operation depending on CMU clock, DSL, ISL and the input signal value

Input signal F_OUTx	Selected CMU Clock	External capture	ISL	DSL	Action description
—	1	0	1	—	if CNT ≥ CNTS then do capture; issue NEWVAL_IRQ; CNT=0 else CNT++ endif
0	0	0	0	1	no
1	1	0	0	1	if CNT ≥ CNTS then do capture; issue NEWVAL_IRQ; CNT=0 else CNT++ endif
0	0	—	0	1	no
0	1	0	0	0	if CNT ≥ CNTS then do capture; issue NEWVAL_IRQ; CNT=0 else CNT++ endif
1	0	0	0	0	no
—	0	0	—	—	no

In this mode the TIM[i]_CH[x]_GPR1 operates as a shadow register for TIM[i]_CH[x]_CNTS. This would allow that the period for the next sampling period could be specified. The update of TIM[i]_CH[x]_CNTS will only take place once on a trigger if the TIM[i]_CH[x]_GPR1 was written by the CPU. This means that the captured value from the previous trigger can be read by the CPU from TIM[i]_CH[x]_GPR1 and afterwards the new sampling period for the next sampling period (the one after the actual sampling period) could be written.

With each triggered interrupt, the registers GPR0 and GPR1 are updated according to bits GPR0_SEL, GPR1_SEL, EGPR0_SEL and EGPR1_SEL.

When selecting ECNT as a source for the capture registers, GPRx will show the edge count and the input signal value at point of capture.

Selecting GPR0_SEL = '11' and EGPR0_SEL = '0' for TIM channel 0 all 8 TIM input signals will be captured to GPR0[7:0].

In the TGPS Mode the bit field CLK_SEL of register TIM[i]_CH[x]_CTRL will define the selected CMU clock which will be used.

The behavior of the ECNT counter is configurable by ECNT_RESET. If set to 1 on each interrupt (period expired) the ECNT will be reset.

Otherwise it operates in wrap around mode.

If the register ECNT produces an overflow during the measurement, the bit ECNTOFL is set inside the register TIM[i]_CH[x]_IRQ_NOTIFY and interrupt TIM_ECNTOFL[x]_IRQ is raised depending on corresponding interrupt enable condition.

(a) External capture TIM Gated Periodic Sampling Mode (TGPS)

If external capture is enabled, the external capture events will capture the GPRx, reset the counter CNT and issue a NEWVAL_IRQ.

Operation is done depending on the CMU clock, external capture signal, DSL, ISL bit and the input signal value defined in next table:

Table 38.151 Operation depending on the CMU clock, external capture signal, DSL, ISL and the input signal value

Input signal F_OUTx	Selected CMU Clock	External capture	ISL	DSL	Action description
—	1	0	1	—	if CNT ≥ CNTS then do capture; issue NEWVAL_IRQ; CNT=0 else CNT++ endif
0	0	0	0	1	no
1	1	0	0	1	if CNT ≥ CNTS then do capture; issue NEWVAL_IRQ; CNT=0 else CNT++ endif
0	0	—	0	1	no
0	1	0	0	0	if CNT ≥ CNTS then do capture; issue NEWVAL_IRQ; CNT=0 else CNT++ endif
1	0	0	0	0	no
—	0	0	—	—	no
—	—	Rising edge	—	—	do capture; issue NEWVAL_IRQ; CNT =0

(7) TIM Serial Shift Mode (TSSM)

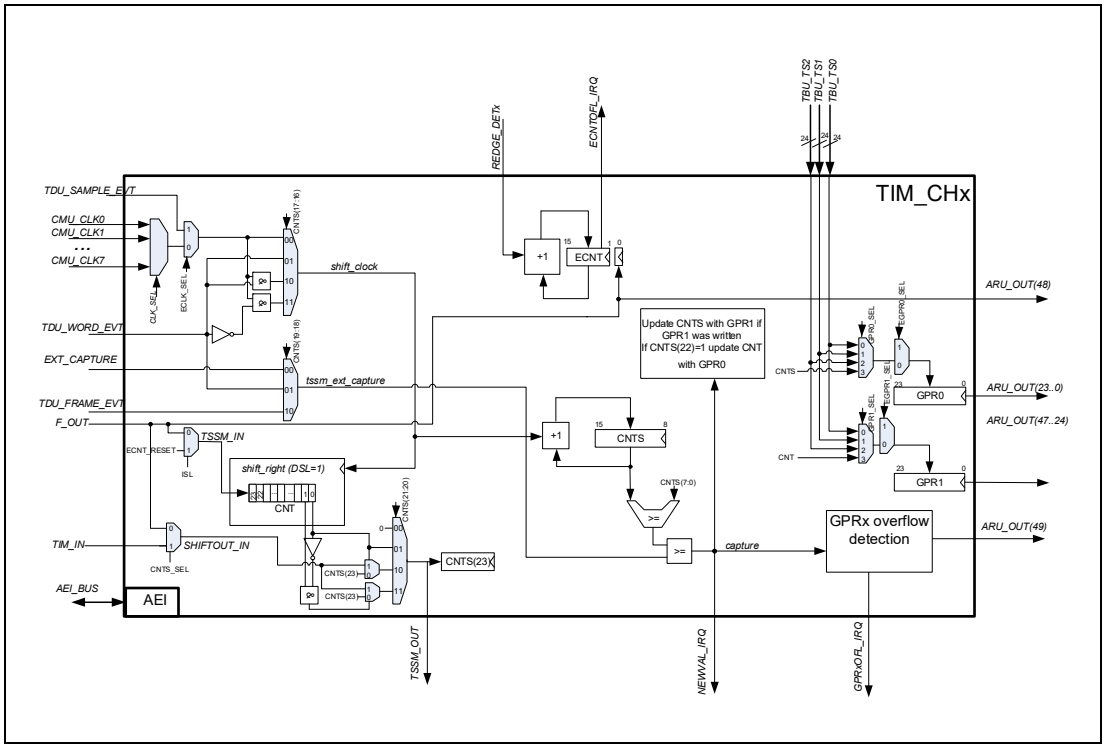

Figure 38.48 TIM Serial Shift Mode

In the TIM Serial Shift Mode on each shift clock event the actual value of the input signal TSSM_INx will be registered in dependence of DSL in the register TIM[i]_CH[x]_CNT. If ISL = 0 is set FOUTx will be used as shift in value TSSM_INx, with ISL = 1 the bit field ECNT_RESET defines the value for TSSM_INx. With DSL = 0 TSSM_INx will be stored in TIM[i]_CH[x]_CNT[0] and TIM[i]_CH[x]_CNT[22:0] will be shifted left.

With DSL = 1 TSSM_OUTx will be stored in TIM[i]_CH[x]_CNT[23] and TIM[i]_CH[x]_CNT[23:1] will be shifted right. Operation is done depending on the shift clock, external capture signal, DSL, ISL bit and the input signal value defined in next table:

Table 38.152 Operation Depending on the Shift Clock, External Capture Signal, DSL, ISL and the Input Signal Value (1/2)

Input signal TSSM_INx	Shift clock	External capture	ISL	DSL	Action description
—	0	0	—	—	no
—	—	1	—	—	if EXT_CAP_EN=1 then see function table in next chapter else no endif
value	1	0	0	0	CNT[23:1]= CNT[22:0]; CNT[0] =value if CNTS[15:8] ≥ CNTS[7:0] then do capture; issue NEWVAL_IRQ; CNTS[15:8]=0 else CNTS[15:8]++ endif

Table 38.152 Operation Depending on the Shift Clock, External Capture Signal, DSL, ISL and the Input Signal Value (2/2)

Input signal TSSM_INx	Shift clock	External capture	ISL	DSL	Action description
value	1	0	0	1	CNT[22:0]= CNT[23:1]; CNT[23]=value if CNTS[15:8] ≥ CNTS[7:0] then do capture; issue NEWVAL_IRQ; CNTS[15:8]=0 else CNTS[15:8]++ endif
value	1	0	1	0	CNT[23:1]= CNT[22:0]; CNT[0]= value if CNTS[15:8] ≥ CNTS[7:0] then do capture; issue NEWVAL_IRQ; CNTS[15:8]=0 CNT[23:0]=ECNT_RESET else CNTS[15:8]++ endif
value	1	0	1	1	CNT[22:0]= CNT[23:1]; CNT[23]= value if CNTS[15:8] ≥ CNTS[7:0] then do capture; issue NEWVAL_IRQ; CNTS[15:8]=0 CNT[23:0]=ECNT_RESET else CNTS[15:8]++ endif

The register TIM[i]_CH[x]_CNTS[7:0] define the amount of bits which will be stored inside TIM[i]_CH[x]_CNT.

Each shift clock will increment the register TIM[i]_CH[x]_CNTS[15:8]. If the condition TIM[i]_CH[x]_CNTS[15:8] ≥ TIM[i]_CH[x]_CNTS[7:0] is met a capture event is raised and TIM[i]_NEWVAL[x]_IRQ is asserted.

With each capture event the registers GPR0 and GPR1 are updated according to bits GPR0_SEL, GPR1_SEL, EGPR0_SEL and EGPR1_SEL.

If the bit field ISL is set to 1 the register bits TIM[i]_CH[x]_CNT are set to the value defined by ECNT_RESET in case of a capture event.

In this mode the TIM[i]_CH[x]_GPR1 operates as a shadow register for TIM[i]_CH[x]_CNTS. This allows that the amount of bits to sample can be specified. The update of TIM[i]_CH[x]_CNTS will only take place once on a trigger if the TIM[i]_CH[x]_GPR1 was written by the CPU. This means that the captured value from the previous trigger can be read by the CPU from TIM[i]_CH[x]_GPR1 and afterwards the new amount of bits to sample for the next sampling period (the one after the actual sampling period) could be written.

The shift clock which will be in use is selectable by TIM[i]_CH[x]_CNTS[17:16] : 00_B : source selection by USE_TDU_CLK_SRC is in use. It can be set to any CMU_CLK source or to the local TDU sample clock tdu_sample_evt. 01_B : the tdu_word_evt signal will be used as shift clock source. 10_B : the clk source selected by USE_TDU_CLK_SRC is used and gated with tdu_word_evt. If tdu_word_evt=0 then shift clock will be 0. 11_B : the clk source selected by USE_TDU_CLK_SRC is used and gated with tdu_word_evt. If tdu_word_evt=1 then shift clock will be 0.

(a) Signal Generation with TIM Serial Shift Mode

If TIM[i]_CH[x]_CNTS[22] is 1 the TIM[i]_CH[x]_GPR0 operates as a shadow register for TIM[i]_CH[x]_CNT. This allows that the bits for shifting out can be specified. The update of TIM[i]_CH[x]_CNT will only take place once on a trigger if the TIM[i]_CH[x]_GPR0 was written by the CPU. This means that the captured value from the previous trigger can be read by the CPU from TIM[i]_CH[x]_GPR0 and afterwards the new bits to shift out could be written.

In addition the TIM Serial Shift Mode is able to generate a signal TSSM_OUT which can be used internally to the TIM channel. On each system clock the value for TSSM_OUT is generated as defined next. The actual value can be read by the register bit TIM[i]_CH[x]_CNTS[23].

Following functionality for TSSM_OUTx is selectable by TIM[i]_CH[x]_CNTS[21:20]: 00_B: Constant output; TSSM_OUTx = 0. 01_B : Shift output; If DSL = 0 (shift left) then TSSM_OUTx = TIM[i]_CH[x]_CNT[23] else (shift right) TSSM_OUTx = TIM[i]_CH[x]_CNT[0]. 10_B: Latched output; If DSL = 0 and TIM[i]_CH[x]_CNT[23] =1 then TSSM_OUTx = SHIFTOUT_INx elsif DSL = 1 and TIM[i]_CH[x]_CNT[0] =1 then TSSM_OUTx = SHIFTOUT_INx. 10_B: Registered output; If DSL = 0 and TIM[i]_CH[x]_CNT[23:22] = 01_B then TSSM_OUTx = SHIFTOUT_INx elsif DSL =1 and TIM[i]_CH[x]_CNT[1:0] = 10_B then TSSM_OUTx = SHIFTOUT_INx. In case of registered or latched output mode the signal

SHIFTOUT_INx is selectable by CNTS_SEL. If CNTS_SEL = 0 is set FOUTx will be used for SHIFTOUT_INx, with CNTS_SEL = 1 the signal TIM_INx is in us for SHIFTOUT_INx.

(b) External capture TIM Serial Shift Mode (TSSM)

If external capture is enabled (EXT_CAP_EN = 1), the external capture events will capture the GPRx, reset the counter CNT depending on ISL and issue a NEWVAL_IRQ. Functionality from previous table will be applied.

The source which will be used as external capture event for TSSM mode is selectable by TIM[i]_CH[x]_CNTS[19:18] : 00_B : source selection by EXT_CAP_SRC is in use. 01_B : tdu_word_evt signal will be used as source. 10_B : tdu_frame_evt signal will be used as source. 11_B : reserved Operation is done depending on the shift clock, external capture signal, DSL, ISL bit and the input signal value defined in next table:

Table 38.153 Operation depending on the shift clock, external capture signal, DSL, ISL and the input signal value

Input signal F_OUTx	Shift clock	tssm_ext_capture	ISL	DSL	Action description
—	0	1	1	—	do capture; issue NEWVAL_IRQ; CNTS[15:8]=0 CNT[23:0]=ECNT_RESET
—	0	1	0	—	do capture; issue NEWVAL_IRQ; CNTS[15:8]=0
value	1	1	1	0	CNT[23:1]= CNT[22:0]; CNT[0]=value do capture; issue NEWVAL_IRQ; CNTS[15:8]=0 CNT[23:0]=ECNT_RESET
value	1	1	1	1	CNT[22:0]= CNT[23:1]; CNT[23]=value do capture; issue NEWVAL_IRQ; CNTS[15:8]=0 CNT[23:0]=ECNT_RESET
value	1	1	0	0	CNT[23:1]= CNT[22:0]; CNT[0]=value do capture; issue NEWVAL_IRQ; CNTS[15:8]=0
value	1	1	0	1	CNT[22:0]= CNT[23:1]; CNT[23]=value do capture; issue NEWVAL_IRQ; CNTS[15:8]=0

38.15.5 MAP Sub-module Interface

The GTM-IP provides one dedicated TIM sub-module TIM0 where channels zero (0) to five (5) are connected to the MAP sub-module described in **Section 38.21**. There, the TIM0 sub-module channels provide the input signal level together with the actual filter value and the annotated time stamp for the edge together in a 49 bit wide signal to the MAP sub-module. This 49 bit wide data signal is marked as valid with a separate valid signal tim0_map_dval[x] (x: 0 to 5).

Table 38.154 Structure of map data

tim0_map_data[x](48)	signal level bit from tim0_ch[x]
tim0_map_data[x](47:24)	actual filter value TIM0_CH[x]_FLT_RE/ TIM0_CH[x]_FLT_FE if corresponding channel x bit field FLT_MODE_RE/ FLT_MODE_FE is 1 else 0 is assigned.
tim0_map_data[x](23:0)	time stamp value selected by TBU0_SEL, GRP0_SEL, EGPR0_SEL, CNTS_SEL of channel x if bit field TIM_EN= 1
tim0_map_dval[x]	mark tim0_map_data[x] valid for one clock cycle

Note: With TIM_EN = 1 the MAP interface starts operation, it is not dependent on the setting of the bit fields TIM_MODE, ISL, DSL.

Note: While the MAP interface is in use the following guidelines have to be fulfilled, otherwise inconsistent filter values can be transferred.
Change TIM0_CH[x]_FLT_RE only between occurrence of rising and falling edge. Change TIM0_CH[x]_FLT_FE only between occurrence of falling and rising edge.

38.15.6 TIM Interrupt Signals

Table 38.155 TIM Interrupt Signals Table

Signal	Description
TIM[i]_NEWVAL[x]_IRQ	New measurement value detected by SMU of channel x (x: 0 to m–1)
TIM[i]_ECNTOFL[x]_IRQ	ECNT counter overflow of channel x (x: 0 to m–1)
TIM[i]_CNTOFL[x]_IRQ	SMU CNT counter overflow of channel x (x: 0 to m–1)
TIM[i]_GPROFL[x]_IRQ	GPR0 and GPR1 data overflow, old data was not read out before new data has arrived at input pin of channel x (x: 0 to m–1)
TIM[i]_TODET[x]_IRQ	Time out reached for input signal of channel x (x: 0 to m–1)
TIM[i]_GLITCHDET[x]_IRQ	A glitch was detected by the TIM filter of channel x (x: 0 to m–1)

38.15.7 TIM Configuration Registers Overview

TIM contains following configuration registers:

Table 38.156 Register list

Symbol	Register Name	Detail in Section
TIM[i]_CH[x]_CTRL	TIMi channel x control register	**38.15.8.1**, **38.15.8.2**
TIM[i]_CH[x]_ECTRL	TIMi channel x extended control register	**38.15.8.19**
TIM[i]_CH[x]_FLT_RE	TIMi channel x filter parameter 0 register	**38.15.8.3**
TIM[i]_CH[x]_FLT_FE	TIMi channel x filter parameter 1 register	**38.15.8.4**
TIM[i]_CH[x]_TDUV	TIMi channel x TDU control register	**38.15.8.16**
TIM[i]_CH[x]_TDUC	TIMi channel x TDU counter register	**38.15.8.17**
TIM[i]_CH[x]_GPR0	TIMi channel x general purpose 0 register	**38.15.8.5**
TIM[i]_CH[x]_GPR1	TIMi channel x general purpose 1 register	**38.15.8.6**
TIM[i]_CH[x]_CNT	TIMi channel x SMU counter register	**38.15.8.7**
TIM[i]_CH[x]_ECNT	TIMi channel x SMU edge counter register	**38.15.8.18**
TIM[i]_CH[x]_CNTS	TIMi channel x SMU shadow counter register	**38.15.8.8**
TIM[i]_CH[x]_IRQ_NOTIFY	TIMi channel x interrupt notification register	**38.15.8.9**
TIM[i]_CH[x]_IRQ_EN	TIMi channel x interrupt enable register	**38.15.8.10**
TIM[i]_CH[x]_EIRQ_EN	TIMi channel x error interrupt enable register	**38.15.8.15**
TIM[i]_CH[x]_IRQ_FORCINT	TIMi channel x force interrupt register	**38.15.8.11**
TIM[i]_CH[x]_IRQ_MODE	TIMi interrupt mode configuration register	**38.15.8.12**
TIM[i]_RST	TIMi global software reset register	**38.15.8.13**
TIM[i]_IN_SRC	TIMi AUX IN source selection register	**38.15.8.14**
TIM[i]_INP_VAL	TIMi input value observation register	**38.15.8.20**

38.15.8 TIM Configuration Registers Description

38.15.8.1 TIM[i]_CH[x]_CTRL (x = 0 to 7)

Access: This register can be read or written in 32-bit units.

Address: <GTM_base> + 1024_H + (800_H × i) + (80_H × x)

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	TOCTRL		EGPR1_SEL	EGPR0_SEL	FR_ECNT_OFL	CLK_SEL			FLT_CTR_FE	FLT_MODE_FE	FLT_CTR_RE	FLT_MODE_RE	EXT_CAP_EN	FLT_CNT_FRQ		FLT_EN
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 38.157 TIM[i]_CH[x]_CTRL Register Contents (1/4)

Bit Position	Bit Name	Function
31, 30	TOCTRL	Timeout control 00_B: Timeout feature disabled 11_B: Timeout feature enabled for both edges 01_B: Timeout feature enabled for rising edge only 10_B: Timeout feature enabled for falling edge only **NOTE** It has to mention that writing of TOCTRL= 0 will every time stop the TDU, independent of the previous state of TOCTRL.
29	EGPR1_SEL	Extension of GPR1_SEL bit field. Details described in GPR1_SEL bit field.
28	EGPR0_SEL	Extension of GPR0_SEL bit field. Details described in GPR0_SEL bit field.
27	FR_ECNT_OFL	Extended Edge counter overflow behavior 0: Overflow will be signalled on ECNT bit width = 8 1: Overflow will be signalled on EECNT bit width (full range)
26 to 24	CLK_SEL	CMU clock source select for channel. If ECLK_SEL = 0: 000_B: CMU_CLK0 selected 001_B: CMU_CLK1 selected 010_B: CMU_CLK2 selected 011_B: CMU_CLK3 selected 100_B: CMU_CLK4 selected 101_B: CMU_CLK5 selected 110_B: CMU_CLK6 selected 111_B: CMU_CLK7 selected If ECLK_SEL = 1: 000_B: tdu_sample_evt of TDU selected 001_B: Reserved 010_B: Reserved 011_B: Reserved 100_B: Reserved 101_B: Reserved 110_B: Reserved 111_B: Reserved

Table 38.157 TIM[i]_CH[x]_CTRL Register Contents (2/4)

Bit Position	Bit Name	Function
23	FLT_CTR_FE	Filter counter mode for falling edge. If FLT_MODE_FE = 1 / FLT_MODE_FE = 0 EFLT_CTR_FE, FLT_CTR_FE: 00_B = Up-Down Counter individual de-glitch mode / Immediate edge propagation mode 01_B = Hold Counter individual de-glitch mode / Immediate edge propagation mode 10_B = Reset Counter individual de-glitch mode / reserved 11_B = reserved / reserved
22	FLT_MODE_FE	Filter mode for falling edge. 0: Immediate edge propagation mode 1: Individual de-glitch mode
21	FLT_CTR_RE	Filter counter mode for rising edge. If FLT_MODE_RE = 1 / FLT_MODE_RE = 0 EFLT_CTR_RE, FLT_CTR_RE: 00_B = Up-Down Counter individual de-glitch mode / Immediate edge propagation mode 01_B = Hold Counter individual de-glitch mode / Immediate edge propagation mode 10_B = Reset Counter individual de-glitch mode / reserved 11_B = reserved / reserved
20	FLT_MODE_RE	Filter mode for rising edge. 0: Immediate edge propagation mode 1: Individual de-glitch mode
19	EXT_CAP_EN	Enables external capture mode. The selected TIM mode is only sensitive to external capture pulses the input event changes are ignored. 0: External capture disabled 1: External capture enabled
18, 17	FLT_CNT_FRQ	Filter counter frequency select 00_B: FLT_CNT counts with CMU_CLK0 01_B: FLT_CNT counts with CMU_CLK1 10_B: FLT_CNT counts with CMU_CLK6 11_B: FLT_CNT counts with CMU_CLK7
16	FLT_EN	Filter enable for channel x (x = 0 to 7) 0: Filter disabled and internal states are reset 1: Filter enabled **NOTE** If the filter is disabled all filter related units (including CSU) are bypassed, which means that the signal F_IN is directly routed to signal F_OUT.
15	ECNT_RESET	Enables resetting of counter in certain modes If TIM_MODE = 101_B (TGPS) / TIM_MODE = 000_B (TPWM) 0: ECNT counter operating in wrap around mode / ECNT counter operating in wrap around mode, CNT is reset on active input edge defined by DSL 1: ECNT counter is reset with periodic sampling / ECNT counter operating in wrap around mode, CNT is reset on active and inactive input edge else ECNT counter operating in wrap around mode; **NOTE** In TIM_MODE = 110_B (TSSM) the bit field ECNT_RESET defines the initial polarity for the shift register.
14	ISL	Ignore signal level 0: Use DSL bit for selecting active signal level (TIEM) 1: Ignore DSL and treat both edges as active edge (TIEM) This bit is mode dependent and will have different meanings (see details in the TIM Channel mode description).

Table 38.157 TIM[i]_CH[x]_CTRL Register Contents (3/4)

Bit Position	Bit Name	Function
13	DSL	Signal level control 0: Measurement starts with falling edge (low level measurement) 1: Measurement starts with rising edge (high level measurement) **NOTE** In TIM_MODE = 110_B (TSSM) the bit field DSL defines the shift direction. 0 = Shift left 1 = Shift right
12	CNTS_SEL	Selection for CNTS register 0: Use CNT register as input 1: Use TBU_TS0 as input **NOTE** CNTS_SEL in TSSM mode selects the source signal for registered or latched shift out operation. 0 = use F_OUTx 1 = use TIM_INx
11, 10	GPR1_SEL	Selection for GPR1 register If EGPR1_SEL =0: 00_B: Use TBU_TS0 as input 01_B: Use TBU_TS1 as input 10_B: Use TBU_TS2 as input 11_B: Use CNT as input If EGPR1_SEL =1: 00_B: Use ECNT as input 01_B: Use TIM_INP_VAL as input 10_B: Reserved 11_B: Reserved **NOTES** 1. In TBCM mode: EGPR1_SEL = 1, GPR1_SEL = 01 selects TIM_INP_VAL as input, in all other cases TIM Filter F_OUT is used. 2. If a reserved value is written to the EGPR1_SEL, GPR1_SEL bit fields, the hardware will use TBU_TS0 input.
9, 8	GPR0_SEL	Selection for GPR0 register If EGPR0_SEL =0: 00_B: Use TBU_TS0 as input 01_B: Use TBU_TS1 as input 10_B: Use TBU_TS2 as input 11_B: Use CNTS as input; if TGPS mode in channel = 0 is selected use TIM Filter F_OUT as input If EGPR0_SEL =1: 00_B: Use ECNT as input 01_B: Use TIM_INP_VAL as input 10_B: Reserved 11_B: Reserved **NOTE** If a reserved value is written to the EGPR0_SEL, GPR0_SEL bit fields, the hardware will use TBU_TS0 input.
7	Reserved	When read, the value after reset is returned. When writing, write the value after reset.

Table 38.157 TIM[i]_CH[x]_CTRL Register Contents (4/4)

Bit Position	Bit Name	Function
6	CICTRL	Channel Input Control. 0: Use signal TIM_IN(x) as input for channel x 1: Use signal TIM_IN(x-1) as input for channel x (or TIM_IN(m-1) if x is 0)
5	ARU_EN	GPR0 and GPR1 register values routed to ARU 0: Registers content not routed 1: Registers content routed
4	OSM	One-shot mode 0: Continuous operation mode 1: One-shot mode **NOTE** After finishing the action in one-shot mode the TIM_EN bit is cleared automatically.
3 to 1	TIM_MODE	TIM channel x (x = 0 to 7) mode 000_B: PWM Measurement Mode (TPWM) 001_B: Pulse Integration Mode (TPIM) 010_B: Input Event Mode (TIEM) 011_B: Input Prescaler Mode (TIPM) 100_B: Bit Compression Mode (TBCM) 101_B: Gated Periodic Sampling Mode (TGPS) 110_B: Serial Shift Mode (TSSM) **NOTES** 1. If an undefined value is written to the TIM_MODE register, the hardware switches automatically to TIM_MODE = 000_B(TPWM mode). 2. The TIM_MODE register should not be changed while the TIM channel is enabled. 3. If the TIM channel is enabled and operating in TPWM or TPIM mode after the first valid edge defined by DSL has occurred, a reconfiguration of DSL,ISL,TIM_MODE will not change the channel behavior. Reading these bit fields after reconfiguration will show the newly configured settings but the initial channel behavior will not change. Only a disabling of the TIM channel by setting TIM_EN = 0 and reenabling with TIM_EN = 1 will change the channel operation mode.
0	TIM_EN	TIM channel x (x = 0 to 7) enable 0: Channel disabled 1: Channel enabled **NOTES** 1. Enabling of the channel resets the registers ECNT, TIM[i]_CH[x]_CNT, TIM[i]_CH[x]_GPR0, and TIM[i]_CH[x]_GPR1 to their reset values. 2. After finishing the action in one-shot mode the TIM_EN bit is cleared automatically. Otherwise, the bit must be cleared manually.

38.15.8.2 TIM[i]_CH[x]_CTRL (i = 0, x = 0 to 7)

Access: This register can be read or written in 32-bit units.

Address: <GTM_base> + 1024_H + (800_H × i) + (80_H × x)

Value after reset: 0000 0000_H

Table 38.158 TIM[i]_CH[x]_CTRL Register Contents (1/4)

Bit Position	Bit Name	Function
31, 30	TOCTRL	Timeout control 00_B: Timeout feature disabled 01_B: Timeout feature enabled for rising edge only 10_B: Timeout feature enabled for falling edge only 11_B: Timeout feature enabled for both edges **NOTE** It has to mention that writing of TOCTRL = 0 will every time stop the TDU, independent of the previous state of TOCTRL.
29	EGPR1_SEL	Extension of GPR1_SEL bit field. Details described in GPR1_SEL bit field.
28	EGPR0_SEL	Extension of GPR0_SEL bit field. Details described in GPR0_SEL bit field.
27	FR_ECNT_OFL	Extended Edge counter overflow behavior 0: Overflow will be signalled on ECNT bit width = 8 1: Overflow will be signalled on EECNT bit width (full range)
26 to 24	CLK_SEL	CMU clock source select for channel. If ECLK_SEL =0: 000_B: CMU_CLK0 selected 001_B: CMU_CLK1 selected 010_B: CMU_CLK2 selected 011_B: CMU_CLK3 selected 100_B: CMU_CLK4 selected 101_B: CMU_CLK5 selected 110_B: CMU_CLK6 selected 111_B: CMU_CLK7 selected If ECLK_SEL =1: 000: tdu_sample_evt of TDU selected Other than above: Setting prohibited.
23	FLT_CTR_FE	Filter counter mode for falling edge. If FLT_MODE_FE=1 / FLT_MODE_FE=0 EFLT_CTR_FE, FLT_CTR_FE: 00_B: Up-Down Counter individual de-glitch mode / Immediate edge propagation mode 01_B: Hold Counter individual de-glitch mode / Immediate edge propagation mode 10_B: Reset Counter individual de-glitch mode / reserved 11_B: Setting prohibited

Table 38.158 TIM[i]_CH[x]_CTRL Register Contents (2/4)

Bit Position	Bit Name	Function
22	FLT_MODE_FE	Filter mode for falling edge. 0: Immediate edge propagation mode 1: Individual de-glitch mode
21	FLT_CTR_RE	Filter counter mode for rising edge. If FLT_MODE_RE = 1 / FLT_MODE_RE = 0 EFLT_CTR_RE, FLT_CTR_RE: 00_B: Up-Down Counter individual de-glitch mode / Immediate edge propagation mode 01_B: Hold Counter individual de-glitch mode / Immediate edge propagation mode 10_B: Reset Counter individual de-glitch mode / reserved 11_B: reserved / reserved
20	FLT_MODE_RE	Filter mode for rising edge. 0: Immediate edge propagation mode 1: Individual de-glitch mode
19	EXT_CAP_EN	Enables external capture mode. The selected TIM mode is only sensitive to external capture pulses the input event changes are ignored. 0: External capture disabled 1: External capture enabled
18, 17	FLT_CNT_FRQ	Filter counter frequency select 00_B: FLT_CNT counts with CMU_CLK0 01_B: FLT_CNT counts with CMU_CLK1 10_B: FLT_CNT counts with CMU_CLK6 11_B: FLT_CNT counts with CMU_CLK7
16	FLT_EN	Filter enable for channel x (x = 0 to 7) 0: Filter disabled and internal states are reset 1: Filter enabled **NOTE** If the filter is disabled all filter related units (including CSU) are bypassed, which means that the signal F_IN is directly routed to signal F_OUT.
15	ECNT_RESET	Enables resetting of counter in certain modes If TIM_MODE = 101_B (TGPS) / TIM_MODE = 000_B (TPWM) 0: ECNT counter operating in wrap around mode / ECNT counter operating in wrap around mode, CNT is reset on active input edge defined by DSL 1: ECNT counter is reset with periodic sampling / ECNT counter operating in wrap around mode, CNT is reset on active and inactive input edge else ECNT counter operating in wrap around mode; **NOTE** In TIM_MODE = 110_B (TSSM) the bit field ECNT_RESET defines the initial polarity for the shift register.
14	ISL	Ignore signal level 0: Use DSL bit for selecting active signal level (TIEM) 1: Ignore DSL and treat both edges as active edge (TIEM) This bit is mode dependent and will have different meanings (see details in the TIM Channel mode description).
13	DSL	Signal level control 0: Measurement starts with falling edge (low level measurement) 1: Measurement starts with rising edge (high level measurement) **NOTE** In TIM_MODE = 110_B (TSSM) the bit field DSL defines the shift direction. 0 = Shift left 1 = Shift right

Table 38.158 TIM[i]_CH[x]_CTRL Register Contents (3/4)

Bit Position	Bit Name	Function
12	CNTS_SEL	Selection for CNTS register 0: Use CNT register as input 1: Use TBU_TS0 as input **NOTE** The functionality of the CNTS_SEL is disabled in the modes TIPM and TBCM.
11, 10	GPR1_SEL	Selection for GPR1 register If EGPR1_SEL = 0: 00_B: Use TBU_TS0 as input 01_B: Use TBU_TS1 as input 10_B: Use TBU_TS2 as input 11_B: Use CNT as input If EGPR1_SEL =1: 00_B: Use ECNT as input 01_B: Use TIM_INP_VAL as input Other than above: Setting prohibited. **NOTES** 1. In TBCM mode: EGPR1_SEL=1, GPR1_SEL=01 selects TIM_INP_VAL as input, in all other cases TIM Filter F_OUT is used. 2. If a reserved value is written to the EGPR1_SEL, GPR1_SEL bit fields, the hardware will use TBU_TS0 input.
9, 8	GPR0_SEL	Selection for GPR0 register If EGPR0_SEL = 0: 00_B: Use TBU_TS0 as input 01_B: Use TBU_TS1 as input 10_B: Use TBU_TS2 as input 11_B: Use CNTS as input; if TGPS mode in channel = 0 is selected use TIM Filter F_OUT as input If EGPR0_SEL =1: 00_B: Use TBU_TS0 as input / use ECNT as input 01_B: Use TBU_TS1 as input / use TIM_INP_VAL as input 10_B: Use TBU_TS2 as input / reserved 11_B: Use CNTS as input; if TGPS mode in channel = 0 is selected use TIM Filter F_OUT as input / reserved **NOTE** If a reserved value is written to the EGPR0_SEL, GPR0_SEL bit fields, the hardware will use TBU_TS0 input.
7	TBU0_SEL	TBU_TS0 bits input select for TIM0_CH[x]_GPRz (z: 0, 1) 0: Use TBU_TS0(23 to 0) to store in TIM0_CH[x]_GPR0/TIM0_CH[x]_GPR1 1: Use TBU_TS0(26 to 3) to store in TIM0_CH[x]_GPR0/TIM0_CH[x]_GPR1 **NOTE** This bit is only applicable for TIM0
6	CICTRL	Channel Input Control. 0: Use signal TIM_IN(x) as input for channel x 1: Use signal TIM_IN(x-1) as input for channel x (or TIM_IN(m-1) if x is 0)
5	ARU_EN	GPR0 and GPR1 register values routed to ARU 0: Registers content not routed 1: Registers content routed

Table 38.158 TIM[i]_CH[x]_CTRL Register Contents (4/4)

Bit Position	Bit Name	Function
4	OSM	One-shot mode 0: Continuous operation mode 1: One-shot mode **NOTE** After finishing the action in one-shot mode the TIM_EN bit is cleared automatically.
3 to 1	TIM_MODE	TIM channel x (x = 0 to m-1) mode 000_B: PWM Measurement Mode (TPWM) 001_B: Pulse Integration Mode (TPIM) 010_B: Input Event Mode (TIEM) 011_B: Input Prescaler Mode (TIPM) 100_B: Bit Compression Mode (TBCM) 101_B: Gated Periodic Sampling Mode (TGPS) 110_B: Serial Shift Mode (TSSM) **NOTES** 1. If an undefined value is written to the TIM_MODE register, the hardware switches automatically to TIM_MODE = 000_B (TPWM mode). 2. The TIM_MODE register should not be changed while the TIM channel is enabled. 3. If the TIM channel is enabled and operating in TPWM or TPIM mode after the first valid edge defined by DSL has occurred, a reconfiguration of DSL, ISL, TIM_MODE will not change the channel behavior. Reading these bit fields after reconfiguration will show the newly configured settings but the initial channel behavior will not change. Only a disabling of the TIM channel by setting TIM_EN = 0 and reenabling with TIM_EN = 1 will change the channel operation mode.
0	TIM_EN	TIM channel x (x = 0 to m-1) enable 0: Channel disabled 1: Channel enabled **NOTES** 1. Enabling of the channel resets the registers ECNT, TIM[i]_CH[x]_CNT, TIM[i]_CH[x]_GPR0, and TIM[i]_CH[x]_GPR1 to their reset values. 2. After finishing the action in one-shot mode the TIM_EN bit is cleared automatically. Otherwise, the bit must be cleared manually.

38.15.8.3 TIM[i]_CH[x]_FLT_RE (x = 0 to 7)

Access: This register can be read or written in 32-bit units.

Address: <GTM_base> + $101C_H$ + (800_H × i) + (80_H × x)

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	FLT_RE

Table 38.161 TIM[i]_CH[x]_GPR0 Register Contents

Bit Position	Bit Name	Function
31 to 24	ECNT	Edge counter. **NOTES** 1. The ECNT counts every incoming filtered edge (rising and falling). The counter value is uneven in case of detected rising, and even in case of detected falling edge. Thus, the input signal level is part of the counter and can be obtained by bit 0 of ECNT. 2. The ECNT register is reset to its initial value when the channel is enabled. 3. Bit 0 depends on the input level coming from the filter unit and defines the reset value immediately.
23 to 0	GPR0	Input signal characteristic parameter 0. **NOTES** 1. The content of this register has different meaning for the TIM channels modes. The content directly depends on the bit fields EGPR0_SEL, GPR0_SEL of register TIM[i]_CH[x]_CTRL. 2. The content of this register can only be written in TIM channel mode TSSM.

38.15.8.6 TIM[i]_CH[x]_GPR1(x = 0 to 7)

Access: This register can be read or written in 32-bit units.

Address: GTM_base> + 1004_H + (800_H × i) + (80_H × x)

Value after reset: Undefined

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	ECNT								GPR1							
Value after reset	—	—	—	—	—	—	—	—	0	0	0	0	0	0	0	0

Table 38.162 TIM[i]_CH[x]_GPR1 Register Contents

Bit Position	Bit Name	Function
31 to 24	ECNT	Edge counter. **NOTES** 1. The ECNT counts every incoming filtered edge (rising and falling). The counter value is uneven in case of detected rising, and even in case of detected falling edge. Thus, the input signal level is part of the counter and can be obtained by bit 0 of ECNT. 2. The ECNT register is reset to its initial value when the channel is enabled. 3. Bit 0 depends on the input level coming from the filter unit and defines the reset value immediately.
23 to 0	GPR1	Input signal characteristic parameter 1. **NOTES** 1. The content of this register has different meaning for the TIM channels modes. The content directly depends on the bit fields EGPR1_SEL, GPR1_SEL of register TIM[i]_CH[x]_CTRL. 2. In TBCM mode if EGPR1_SEL = 1, GPR1_SEL = 01 then TIM_INP_VAL is used as input in all other cases TIM Filter F_OUT is used as input and Bits GPR1(23:8) = 0 3. The content of this register can only be written in TIM channel mode TGPS and TSSM.

38.15.8.7 TIM[i]_CH[x]_CNT (x = 0 to 7)

Access: This register is a read-only register that can be read in 32-bit units.

Address: <GTM_base> + 1008_H + (800_H × i) + (80_H × x)

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 38.165 TIM[i]_CH[x]_IRQ_NOTIFY Register Contents

Bit Position	Bit Name	Function
31 to 6	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
5	GLITCHDET	Glitch detected on channel x, (x = 0 to m-1). 0: No glitch detected for last edge 1: Glitch detected for last edge **NOTE** This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.
4	TODET	Timeout reached for input signal of channel x, (x = 0 to m-1). See bit 0.
3	GPROFL	GPR0 and GPR1 data overflow, old data not read out before new data has arrived at input pin, (x = 0 to m-1). See bit 0.
2	CNTOFL	SMU CNT counter overflow of channel x, (x = 0 to m-1). See bit 0.
1	ECNTOFL	ECNT counter overflow of channel x, (x = 0 to m-1). See bit 0.
0	NEWVAL	New measurement value detected by in channel x (x =0 to m-1) 0: No event was occurred 1: NEWVAL was occurred on the TIM channel **NOTE** This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.

38.15.8.10 TIM[i]_CH[x]_IRQ_EN (x = 0 to 7)

Access: This register can be read or written in 32-bit units.

Address: <GTM_base> + 1030_H + (800_H × i) + (80_H × x)

Value after reset: 0000 0000_H

Table 38.170 TIM[i]_IN_SRC Register Contents (1/2)

Bit Position	Bit Name	Function
31, 30	MODE_7	Input source to Channel 7, see bits 3, 2.
29, 28	VAL_7	Value to be fed to Channel 7, see bits 1, 0.
27, 26	MODE_6	Input source to Channel 6, see bits 3, 2.
25, 24	VAL_6	Value to be fed to Channel 6, see bits 1, 0.
23, 22	MODE_5	Input source to Channel 5, see bits 3, 2.
21, 20	VAL_5	Value to be fed to Channel 5, see bits 1, 0.
19, 18	MODE_4	Input source to Channel 4, see bits 3, 2.
17, 16	VAL_4	Value to be fed to Channel 4, see bits 1, 0.
15, 14	MODE_3	Input source to Channel 3, see bits 3, 2.
13, 12	VAL_3	Value to be fed to Channel 3, see bits 1, 0.
11, 10	MODE_2	Input source to Channel 2, see bits 3, 2.
9, 8	VAL_2	Value to be fed to Channel 2, see bits 1, 0.
7, 6	MODE_1	Input source to Channel 1, see bits 3, 2.
5, 4	VAL_1	Value to be fed to Channel 1, see bits 1, 0.
3, 2	MODE_0	Input source to Channel 0 Multi-core encoding in use (MODE_x(1) defines the state of the signal) 00_B: State is 0 (ignore write access) 01_B: Change state to 0 10_B: Change state to 1 11_B: State is 1 (ignore write access) Function table: MODE_x(1) = 0, VAL_x(1) = 0: The input signal defined by bit field CICTRL of the TIM channel is used as input source. MODE_x(1) = 0, VAL_x(1) = 1: The signal TIM_AUX_IN of the TIM channel is used as input source. MODE_x(1) = 1: The state VAL_x(1) defines the input level for the TIM channel. **NOTE** Any read access to a MODE_x bit field will always result in a value 00 or 11 indicating current state. A modification of the state is only performed with the values 01 and 10. Writing the values 00 and 11 is always ignored.

Table 38.170 TIM[i]_IN_SRC Register Contents (2/2)

Bit Position	Bit Name	Function
1, 0	VAL_0	Value to be fed to Channel 0 Multicore encoding in use (VAL_x(1) defines the state of the signal) 00_B: State is 0 (ignore write access) 01_B: Change state to 0 10_B: Change state to 1 11_B: State is 1 (ignore write access) Function depends on the combination of VAL_x(1) and MODE_x(1) see MODE_0 description. **NOTE** Any read access to a VAL_x bit field will always result in a value 00 or 11 indicating current state. A modification of the state is only performed with the values 01 and 10. Writing the values 00 and 11 is always ignored.

38.15.8.15 TIM[i]_CH[x]_EIRQ_EN (x = 0 to 7)

Access: This register can be read or written in 32-bit units.

Bit Position	Bit Name	Function
31	USE_PREV_CH_IN	Select input data source for TIM channel. 0: Use input data of local filter unit for channel measurements 1: Use input data of previous channel (after filter unit) for channel measurements
30	ECLK_SEL	Extension of bit field CLK_SEL. Details described in CLK_SEL bit field of register TIM[i]_CH[x]_CTRL.
29	IMM_START	Start immediately the measurement 0: Start with first active edge the measurement 1: Start immediately after enable (TIM_EN=1) the measurement This bit is only applicable in TPWM and TPIM mode. Set to 0 in all other modes.
28	SWAP_CAPTURE	swap point of time of capturing CNTS and GPR1 0: Inactive edge will capture data in CNTS; NEWVAL_IRQ event will capture data in GPR1 1: Swap time of capture: inactive edge will capture data in GPR1; NEWVAL_IRQ event will capture data in CNTS This bit is only applicable in TPWM and TPIM mode. Set to 0 in all other modes.
27, 26	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
25	EFLT_CTR_FE	Extension of bit field FLT_CTR_FE. Details described in FLT_CTR_FE bit field of register TIM[i]_CH[x]_CTRL.
24	EFLT_CTR_RE	Extension of bit field FLT_CTR_RE. Details described in FLT_CTR_RE bit field of register TIM[i]_CH[x]_CTRL.
23, 22	USE_LUT	Generate Filter input by lookup table 00_B: Lookup table not in use, lut_in0(x) used as filter input 01_B: Use 3 bit lookup table with index = ext_capture(x) & lut_in1(x) & lut_in0(x). Filter input is defined by TO_CNT2[index]. 10_B: Use 3 bit lookup table with index = fout_prev(x) & lut_in1(x) & lut_in0(x). Filter input is defined by TO_CNT2[index]. 11_B: Use 3 bit lookup table with index = tssm_out(x) & lut_in1(x) & lut_in0(x). Filter input is defined by TO_CNT2[index].
21, 20	Reserved	When read, the value after reset is returned. When writing, write the value after reset.

Table 38.175 TIM[i]_CH[x]_ECTRL Register Contents (2/4)

Bit Position	Bit Name	Function
19 to 16	TDU_RESYNC	Defines condition which will resynchronize the TDU unit. Behavior with SLICING! = 11_B: 0000_B: Reset counter TO_CNT2 on each active edge selected by TOCTRL or tdu_timeout_evt or on tdu_start_000_event (see Note); reset counters TO_CNT,TO_CNT1 on tdu_timeout_evt or on tdu_start_000_event (see Note); if SLICING= 10_B and TO_CTRL= –1 then reset TO_CNT on rising input edge; if SLICING= 10_B and TO_CTRL= 1– then reset TO_CNT1 on falling input edge; if SLICING! = 10_B then reset counters TO_CNT,TO_CNT1 on each active edge selected by TOCTRL; 0—1: If SLICING= 10_B and TO_CTRL= x1 then reset TO_CNT on rising input edge; if SLICING= 10_B and TO_CTRL= 1– then reset TO_CNT1 on falling input edge; if SLICING! = 10_B then reset counters TO_CNT, TO_CNT1 on each active edge selected by TOCTRL; if SLICING= 00_B then reset TO_CNT2 on each active edge selected by TOCTRL; 0x1–: Reset counters TO_CNT on tdu_word_evt; 01—: Reset counter TO_CNT1 on tdu_frame_evt; if SLICING= 01_B then reset TO_CNT on tdu_frame_evt; 1000_B: Reset counters TO_CNT,TO_CNT1,TO_CNT2 on event selected by EXT_CAP_SRC; 1—: If SLICING!= 00_B then reset counter TO_CNT2 on tdu_sample_evt; 1—1: Reset counter TO_CNT2 on each active edge selected by TOCTRL; if SLICING= 10_B and TO_CTRL= –1 then reset TO_CNT on rising input edge; if SLICING= 10_B and TO_CTRL= 1– then reset TO_CNT1 on falling input edge; if SLICING! = 10_B then reset counters TO_CNT, TO_CNT1 on each active edge selected by TOCTRL; 1–1–: Reset counters TO_CNT on tdu_word_evt; 11—: Reset counter TO_CNT1 on tdu_frame_evt; if SLICING=01_B then reset TO_CNT on tdu_frame_evt; Behavior with SLICING = 11_B: 0000_B: Load counter TO_CNT with TOV2 on each active edge selected by TOCTRL or tdu_timeout_evt or on tdu_start_000_event (see Note); reset counter TO_CNT1 on each active edge selected by TOCTRL or tdu_timeout_evt or on tdu_start_000_event (see Note) —1: Load counter TO_CNT with TOV2 on each active edge selected by TOCTRL; reset counter TO_CNT1 on each active edge selected by TOCTRL 0–1–: Load counter TO_CNT with TOV2 on tdu_word_evt 1–1–: Reset counter TO_CNT on tdu_word_evt –1—: Reset counter TO_CNT1 on tdu_frame_evt 1000_B: Load counter TO_CNT with TOV2; reset counter TO_CNT1 on event selected by EXT_CAP_SRC **NOTE** tdu_start_000_event is defined as: Each writing of TOCTRL!=0 (independent of current TOCTRL) while TDU_START=000_B and TDU is stopped (initially or stopped by TDU_STOP event). This event will last 1 system clock cycle.
15	Reserved	When read, the value after reset is returned. When writing, write the value after reset.

Table 38.175 TIM[i]_CH[x]_ECTRL Register Contents (3/4)

Bit Position	Bit Name	Function
14 to 12	TDU_STOP	Defines condition which will stop the TDU unit. 000_B: Immediate stop counting of TDU on tdu_toctrl_0_event (see Note) 001_B: stop counting of TDU on tdu_word_evt or on tdu_toctrl_0_event (see Note) 010_B: stop counting of TDU on tdu_frame_evt or on tdu_toctrl_0_event (see Note) 011_B: stop counting of TDU on tdu_timeout_evt or on tdu_toctrl_0_event (see Note) 100_B: stop counting of TDU on external capture event or on tdu_toctrl_0_event (see Note) 101_B: if SLICING =10_B|11_B then stop counting of TO_CNT on tdu_word_evt or on tdu_toctrl_0_event (see Note); stop counting of TO_CNT1 on tdu_frame_evt or on tdu_toctrl_0_event (see Note); stop counting of TO_CNT2 on tdu_toctrl_0_event (see Note); else reserved, no action performed $11–_B$: reserved, no action performed **NOTE** tdu_toctrl_0_event is defined as: Each writing of TOCTRL = 0 (independent of current TOCTRL) while TDU is started. This event will last 1 system clock cycle.
11	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
10 to 8	TDU_START	Defines condition which will start the TDU unit. 000_B: start once immediate on tdu_start_000_event (see Note) 001_B: start once with occurrence of first cmu_clk selected by CLK_SEL when measure unit is enabled by TIM_EN = 1 010_B: start once with occurrence of first active edge selected by TOCTRL; restart on tdu_frame_evt if TDU is stopped 011_B: start once with occurrence of first active edge selected by TOCTRL 100_B: start/restart with occurrence of external capture event (if TDU is stopped, restart again) 101_B: start/restart with occurrence of first cmu_clk selected by CLK_SEL when measure unit is enabled by TIM_EN = 1 (if TDU is stopped, restart again) 110_B: start once with occurrence of external capture event; restart on tdu_frame_evt if TDU is stopped 111_B: start/restart with occurrence of first active edge selected by TOCTRL (if TDU is stopped, restart again) **NOTES** 1. tdu_start_000_event is defined as: Each writing of TOCTRL! = 0 (independent of current TOCTRL) while TDU_START = 000_B and TDU is stopped (initially or stopped by TDU_STOP event). This event will last 1 system clock cycle. 2. In mode SLICING = 11_B every start/restart will load the TO_CNT with value TOV2.
7, 6	TODET_IRQ_SRC	Selection of source for TODET_IRQ 00_B: use tdu_timeout_evt 01_B: use tdu_word_evt 10_B: use tdu_frame_evt 11_B: use tdu_sample_evt **NOTE** With TODET_IRQ_SRC = 00_B the ACB bit 2 will be driven by signal tdu_timeout_evt, if TODET_IRQ_SRC! = 00_B ACB2 will be 0.
5	USE_PREV_TDU_IN	Select input data source for TDU. 0: use input data of local filter for TDU 1: use input data of previous channel (after filter unit) for TDU
4	Reserved	When read, the value after reset is returned. When writing, write the value after reset.

38.16 Timer Output Module (TOM)

38.16.1 Overview

The Timer Output Module (TOM) offers up to 16 independent channels (index x) to generate simple PWM signals at each output pin TOM[i]_CH[x]_OUT.

Additionally, at TOM output TOM[i]_CH15_OUT a pulse count modulated signal can be generated.

The architecture of the TOM sub-module is depicted in **Figure 38.49**.

Indices and their range as used inside this chapter are:

nTOM= number of TOM instances in the device, refer to device specific **38.28, GTM Device 358** for correct value.

i=0..nTOM-1

x=0..15 (number of channels)

y=0,1

z=0..7

The register and bitfield names which are used inside this chapter has the following meaning:

SR0 = TOM[i]_CH[x]_SR0

SR1 = TOM[i]_CH[x]_SR1

CM0 = TOM[i]_CH[x]_CM0

CM1 = TOM[i]_CH[x]_CM1

CN0 = TOM[i]_CH[x]_CN0

CLK_SRC_SR = TOM[i]_CH[x]_CTRL.CLK_SRC_SR

SL = TOM[i]_CH[x]_CTRL.SL

All figures in this chapter which are shown block diagrams or gate schematics are drawn in principal to show specific functionality. They don't have the claim of completeness and do not represent the real implementation of the design.

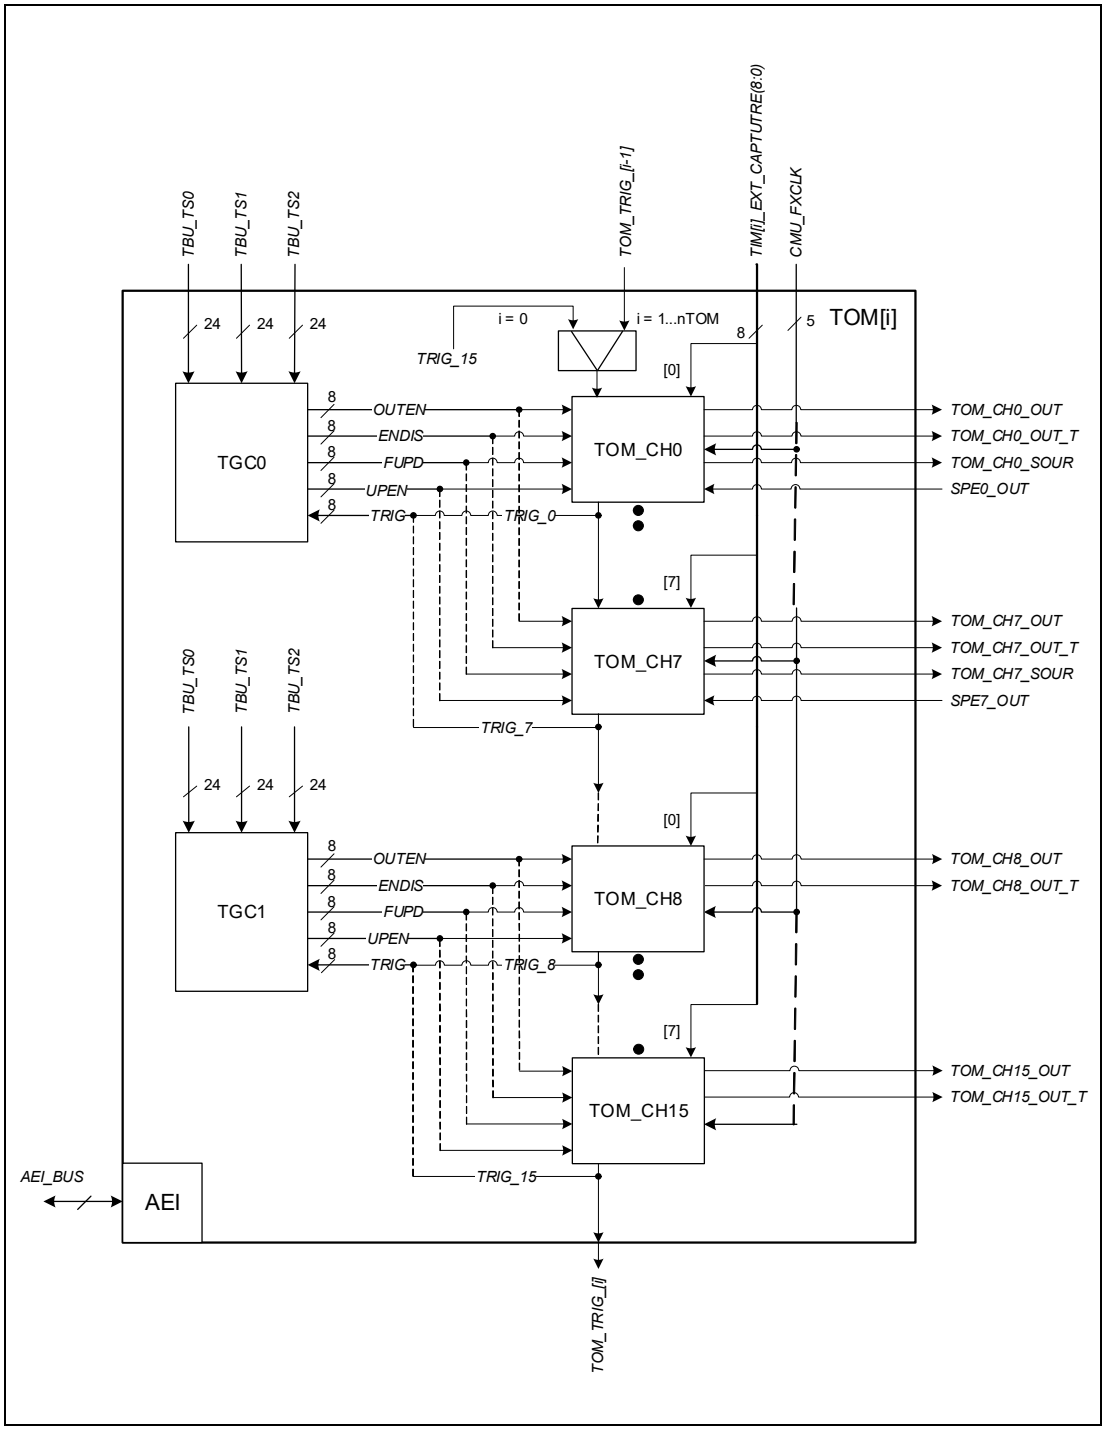

Figure 38.49 TOM block diagram

The two sub-modules TGC0 and TGC1 are global channel control units that control the enabling/ disabling of the channels and their outputs as well as the update of their period and duty cycle register.

The module TOM receives two (three) timestamp values TBU_TS0, TBU_TS1 (and TBU_TS2) in order to realize synchronized output behavior on behalf of a common time base.

The 5 dedicated clock line inputs CMU_FXCLK are providing divided clocks that can be selected to clock the output pins.

The trigger signal TOM_TRIGIN[i-1] of TOM instance i comes from the preceding instance i-1, the trigger TOM_TRIGOUT[i] is routed to succeeding instance i+1. The purpose of the trigger signal is explained later.

NOTE

TOM0 is connected to its own output TOM_TRIG_0, i.e. the last channel of TOM instance 0 can trigger the first channel of TOM instance 0 (this path is registered, which means delayed by one SYS_CLK period).

38.16.2 TOM Global Channel Control (TGC0, TGC1)

38.16.2.1 Overview

There exist two global channel control units (TGC0 and TGC1) to drive a number of individual TOM channels synchronously by external or internal events.

Each TGC[y] can drive up to eight TOM channels where TGC0 controls TOM channels 0 to 7 and TGC1 controls TOM channels 8 to 15.

The TOM sub-module supports four different kinds of signaling mechanisms:

- Global enable/disable mechanism for each TOM channel with control register TOM[i]_TGC[y]_ENDIS_CTRL and status register TOM[i]_TGC[y]_ENDIS_STAT
- Global output enable mechanism for each TOM channel with control register TOM[i]_TGC[y]_OUTEN_CTRL and status register TOM[i]_TGC[y]_OUTEN_STAT
- Global force update mechanism for each TOM channel with control register TOM[i]_TGC[y]_FUPD_CTRL
- Update enable of the register CM0, CM1 and CLK_SRC for each TOM channel with the control bit field UPEN_CTRL[z] of TOM[i]_TGC[y]_GLB_CTRL

38.16.2.2 TGC Sub-unit

Each of the first three individual mechanisms (enable/disable of the channel, output enable and force update) can be driven by three different trigger sources. The three trigger sources are:

- The host CPU (bit HOST_TRIG of register TOM[i]_TGC[y]_GLB_CTRL)
- The TBU time stamp (signal TBU_TS0, TBU_TS1, TBU_TS2 if available)
- The internal trigger signal TRIG (bunch of trigger signals TRIG_[x]) which can be either the trigger TRIG_CCU0 of channel x, the trigger of preceding channel x-1 (i.e. signal TRIG_[x–1]) or the external trigger TIM_EXT_CAPTURE(t) of assigned TIM channel t.

The first way is to trigger the control mechanism by a direct register write access via host CPU (bit HOST_TRIG of register ATOM[i]_TGC[y]_GLB_CTRL).

The second way is provided by a compare match trigger on behalf of a specified time base coming from the module TBU (selected by bits TBU_SEL) and the time stamp compare value defined in the bit field ACT_TB of register TOM[i]_TGC[y]_ACT_TB.

NOTE

A signed compare of ACT_TB and selected TBU_TS[x] with x = 0, 1, 2 is performed.

The third possibility is the input TRIG (bunch of trigger signals TRIGOUT[x]) coming from the TOM channels 0 to 7/8 to 15.

The corresponding trigger signal TRIGOUT[x] coming from channel [x] can be masked by the register TOM[i]_TGC[y]_INT_TRIG.

To enable or disable each individual TOM channel, the register TOM[i]_TGC[y]_ENDIS_CTRL and/or TOM[i]_TGC[y]_ENDIS_STAT have to be used.

The register TOM[i]_TGC[y]_ENDIS_STAT controls directly the signal ENDIS. A write access to this register is possible.

The register TOM[i]_TGC[y]_ENDIS_CTRL is a shadow register that overwrites the value of register TOM[i]_TGC[y]_ENDIS_STAT if signal CTRL_TRIG raises.

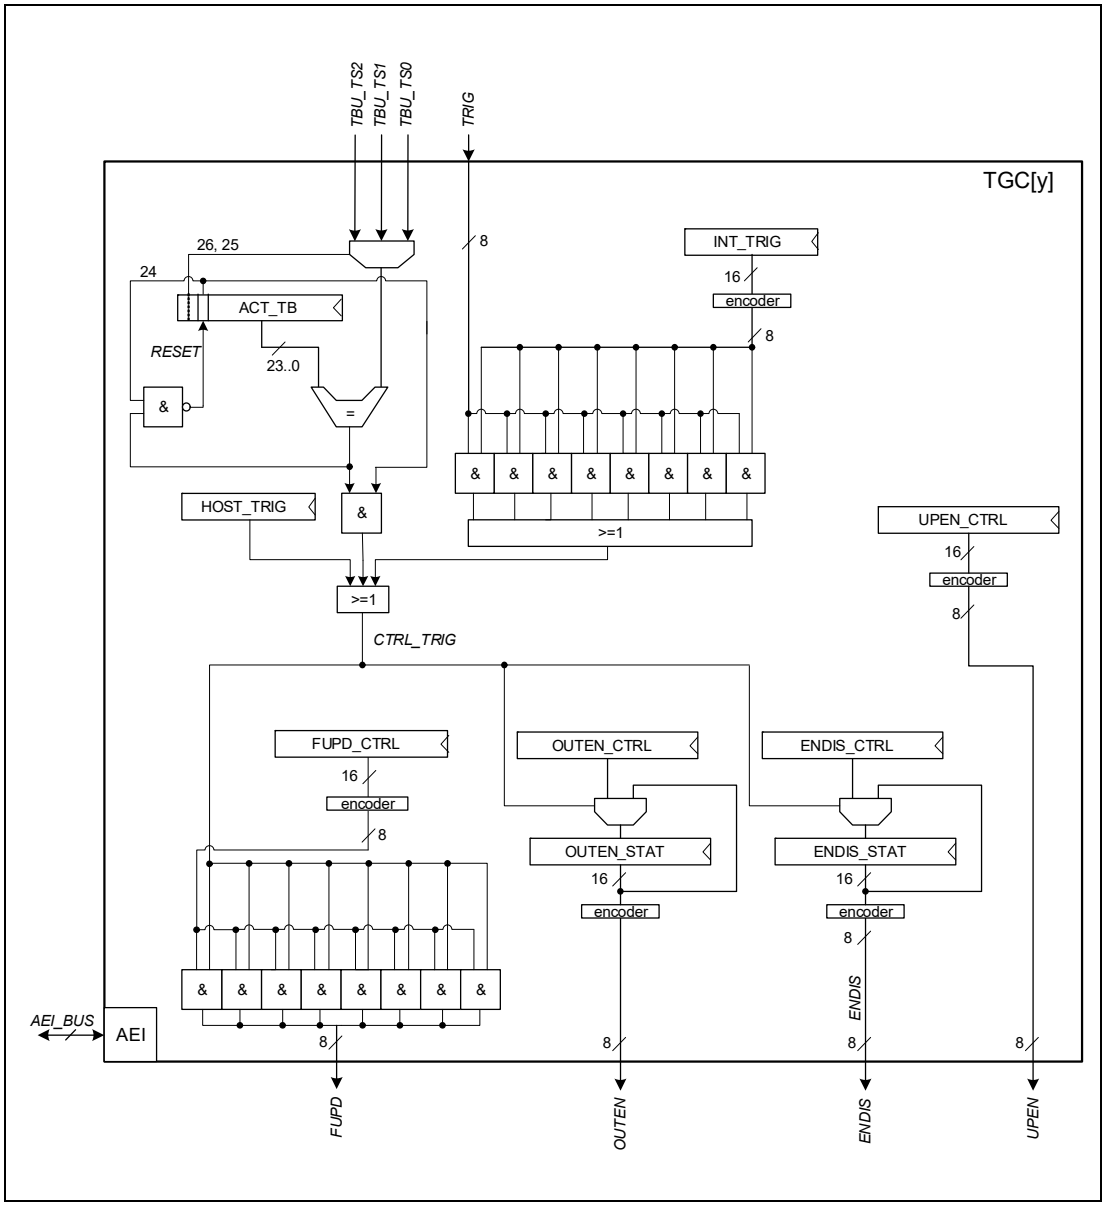

Figure 38.50 TOM Global channel control mechanism

The output of the individual TOM channels can be controlled using the register TOM[i]_TGC[y]_OUTEN_CTRL and TOM[i]_TGC[y]_OUTEN_STAT.

The register TOM[i]_TGC[y]_OUTEN_STAT controls directly the signal OUTEN. A write access to this register is possible.

The register TOM[i]_TGC[y]_OUTEN_CTRL is a shadow register that overwrites the value of register TOM[i]_TGC[y]_OUTEN_STAT if one of the three trigger conditions matches.

If a TOM channel is disabled by the register TOM[i]_TGC[y]_OUTEN_STAT, the actual value of the channel output at TOM_CH[x]_OUT is defined by the signal level bit (SL) defined in the channel control register TOM[i]_CH[x]_CTRL. If the output is enabled, the output at TOM_CH[x]_OUT depends on value of register SOUR (see **Figure 38.50**).

The register TOM[i]_TGC[y]_FUPD_CTRL defines which of the TOM channels receive a FORCE_UPDATE event if the trigger signal CTRL_TRIG is raised.

NOTE

The force update request is stored and executed synchronized to the selected CMU_FXCLK_EN.

The register bits UPEN_CTRL[z] defines for which TOM channel the update of the working register CM0, CM1 and CLK_SRC by the corresponding shadow register SR0, SR1 and CLK_SRC_SR is enabled. If update is enabled, the register CM0, CM1 and CLK_SRC will be updated on reset of counter register CN0 (see **Figure 38.52** and **Figure 38.53**). An exception is the configuration of SR0_TRIG = 1 which enable the trigger generation defined by SR0. Then CM0 is not updated with SR0.

38.16.3 TOM Channel

Each individual TOM channel comprises a Counter Compare Unit 0 (CCU0) which contains the counter register CN0 and the period register CM0, a Counter Compare Unit 1 (CCU1) which contains the duty cycle register CM1 and the Signal Output Generation Unit (SOU) which contains the output register SOUR (see **Figure 38.51**). The architecture is depicted in **Figure 38.51** for channels 0 to 7 and in **Figure 38.51** for channels 8 to 15.

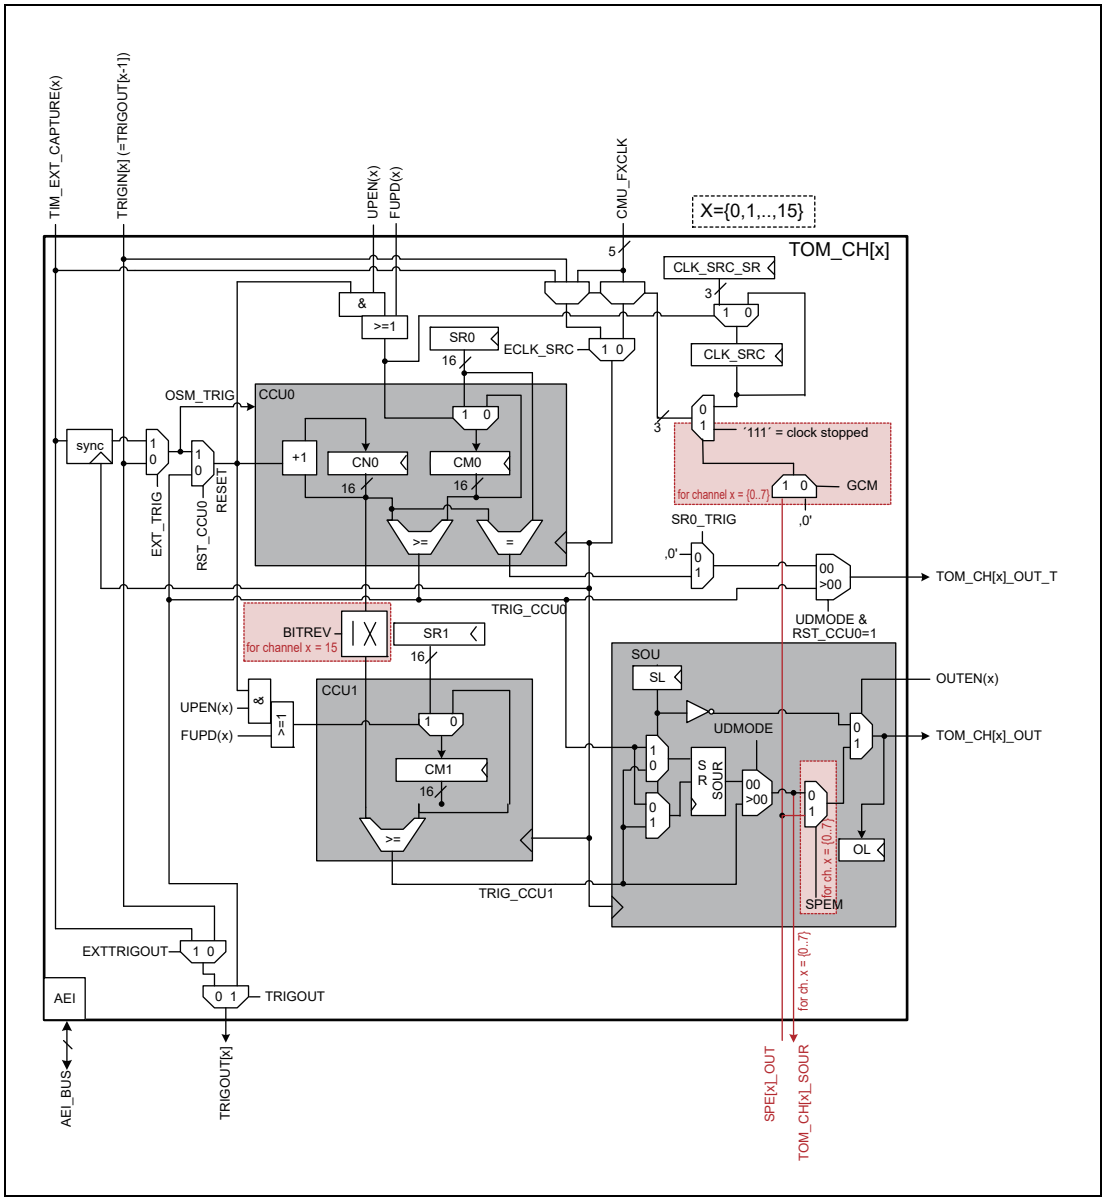

Figure 38.51 TOM Channel 0..15 architecture

The CCU0 contains a counter CN0 which is clocked with the selected clock enable signal from CMU_FXCLK_EN provided from outside of the sub-module.

Depending on configuration bits RST_CCU0 of register TOM[i]_CH[x]_CTRL the counter register CN0 can be reset either when the counter value is equal to the compare value CM0 (i.e. CN0 counts only from 0 to CM0-1 and is then reset to 0) or when signaled by the TOM[i] trigger signal TRIGIN[x] (=TRIGOUT[x-1] of the preceding channel [x-1] (which can also be the last channel of preceding instance TOM[i-1]) or the trigger signal TIM_EXT_CAPTURE(x) of the assigned TIM channel [x].

As an exception, the input TRIG_[0] of instance TOM0 is triggered by its own last channel x (x=15) via signal TRIGOUT[15].

When the counter register CN0 is greater or equal than the value CM0 (in fact CM0 -1), the sub-unit CCU0 triggers the SOU sub-unit and the succeeding TOM sub-module channel (signal TRIG_CCU0).

In the sub-unit CCU1 the counter register CN0 is compared with the value of register CM1. If CN0 is greater or equal than CM1 the sub-unit CCU1 triggers the SOU sub-unit (signal TRIG_CCU1).

If counter CN0 of channel x is reset by its own CCU0 unit (i.e. the compare match of CN0 ≥ CM0 -1 configured by RST_CCU0 = 0), following statements are valid:

1. CN0 counts from 0 to CM0 -1 and is then reset to 0.
2. When CN0 is reset from CM0 to 0, an edge to SL is generated.
3. When CN0 is incrementing and reaches CN0 > CM1, an edge to !SL is generated.
4. If CM0 = 0 or CM0 = 1, the counter CN0 is constant 0.
5. If CM1 = 0, the output is !SL = 0% duty cycle
6. If CM1 ≥ CM0 and CM0 >1, the output is SL = 100% duty cycle

If the counter register CN0 of channel x is reset by the trigger signal coming from another channel or the assigned TIM module (configured by RST_CCU0 = 1), following statements are valid:

1. CN0 counts from 0 to MAX-1 and is then reset to 0 by trigger signal
2. CM0 defines the edge to SL value, CM1 defines the edge to !SL value
3. If CM0 = CM1, the output switches to SL if CN0 = CM0 = CM1 (CM0 has higher priority)
4. If CM0 = 0 and CM1 = MAX, the output is SL = 100% duty cycle
5. If CM0 > MAX, the output is !SL = 0% duty cycle, independent of CM1

The hardware ensures that for both 0% and 100% duty cycle no glitch occurs at the output of the TOM channel.

The SOU sub-unit is responsible for output signal generation. On a trigger TRIG_CCU0 from sub-unit CCU0 or TRIG_CCU1 from sub-unit CCU1 an SR flip-flop of sub-unit SOU is either set or reset. If it is set or reset depends on the configuration bit SL of the control register TOM[i]_CH[x]_CTRL. The initial signal output level for the channel is the reverse value of the bit SL.

Figure 38.54 clarifies the PWM output behavior with respect to the SL bit definition.

The output level on the TOM channel output pin TOM[i]_CH[x]_OUT is captured in bit OL of register TOM[i]_CH[x]_STAT.

38.16.3.1 Duty cycle, Period and Clock Frequency Update Mechanisms

The two action register CM0 and CM1 can be reloaded with the content of the shadow register SR0 and SR1. The register CLK_SRC that determines the clock frequency of the counter register CN0 can be reloaded with its shadow register CLK_SRC_SR (bit field in register TOM[i]_CH[x]_CTRL).

The update of the register CM0, CM1 and CLK_SRC with the content of its shadow register is done when the reset of the counter register CN0 is requested (via signal RESET). This reset of CN0 is done if the comparison of CN0 greater or equal than CM0 is true or when the reset is triggered by another TOM channel [x-1] via the signal TRIGIN[x] (=TRIGOUT[x-1]) or when signaled via the signal TIM_EXT_CAPTURE(x) of the assigned TIM channel [x].

With the update of the register CLK_SRC at the end of a period a new counter CN0 clock frequency can easily be adjusted.

In case of RST_CCU0=1 and update enabled by UPEN_CTRL[z] the register CM0, CM1 and CLK_SRC will be updated when CN0 is reset.

An update of duty cycle, period and counter CN0 clock frequency becoming effective synchronously with start of a new period can easily be reached by performing following steps:

1. Disable the update of the action register with the content of the corresponding shadow register by setting the channel specific configuration bit UPEN_CTRL[z] of register TOM[i]_TGC[y]_GLB_CTRL to '0'.
2. Write new desired values to SR0, SR1, CLK_SRC_SR
3. Enable update of the action register by setting the channel specific configuration bit UPEN_CTRL[z] of register TOM[i]_TGC[y]_GLB_CTRL to '1'.

(1) Synchronous Update Of Duty Cycle Only

A synchronous update of only the duty cycle can be done by simply writing the desired new value to register SR1 without preceding disable of the update mechanism (as described in the chapter above). The new duty cycle is then applied in the period following the period where the update of register SR1 was done.

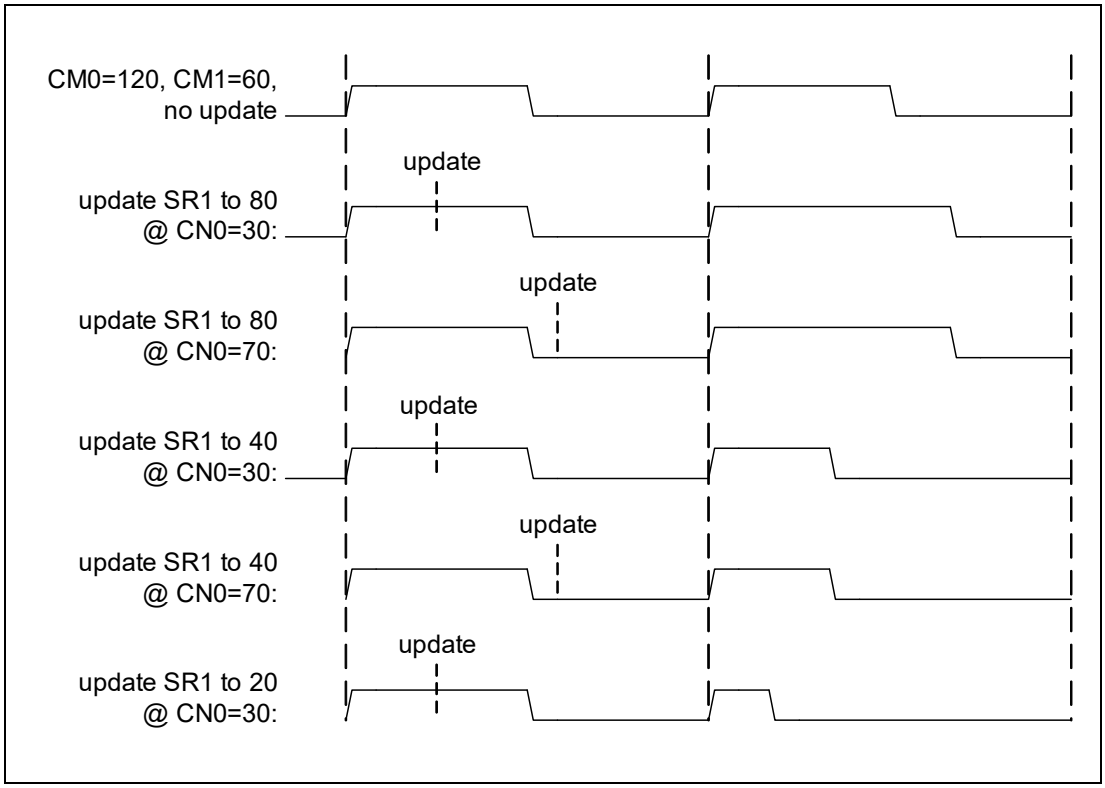

Figure 38.52 Synchronous update of duty cycle

(2) Asynchronous Update Of Duty Cycle Only

If the update of the duty cycle should be performed independent of the start of a new period (asynchronous), the desired new value can be written directly to register CM1. In this case it is recommended to additionally either disable the synchronous update mechanism as a whole (i.e. clearing bits UPEN_CTRL[z] of corresponding channel [x] in register TOM[i]_TGX[y]_GLB_CTRL) or updating SR1 with the same value as CM1 before writing to CM1. Depending on the point of time of the update of CM1 in relation to the actual value of CN0 and CM1, the new duty cycle is applied in the current period or the following period (see **Figure 38.52**). In any case the creation of glitches are avoided. The new duty cycle may jitter from update to update by a maximum of one period (given by CM0). However, the period remains unchanged.

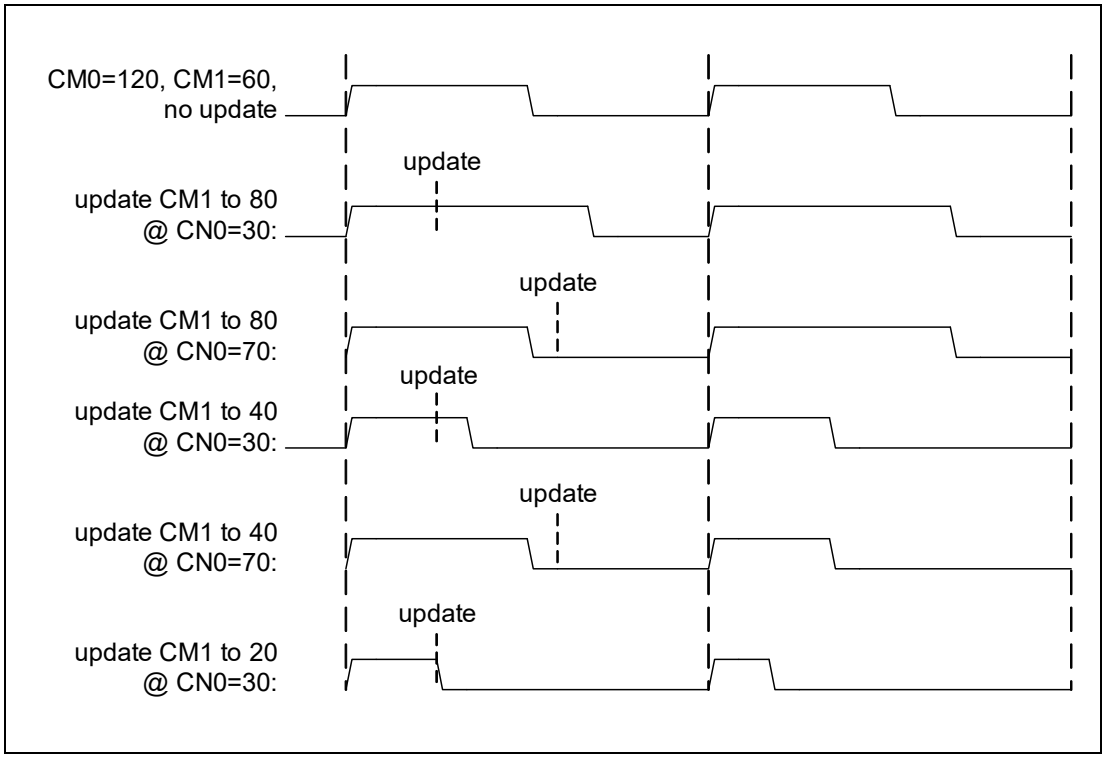

Figure 38.53 Asynchronous update of duty cycle

38.16.3.2 Continuous Counting Up Mode

In continuous mode the TOM channel starts incrementing the counter register CN0 once it is enabled by setting the corresponding bits in register TOM[i]_TGC[y]_ENDIS_STAT (refer to **Section 38.16.2.2** for details of enabling a TOM channel).

The signal level of the generated output signal can be configured with the configuration bit SL of the channel configuration register TOM[i]_CH[x]_CTRL.

If the counter CN0 is reset from CM0 back to zero, the first edge of a period is generated at TOM[i]_CH[x]_OUT.

The second edge of the period is generated if CN0 has reached CM1.

Every time the counter CN0 has reached the value of CM0 it is reset back to zero and proceeds with incrementing.

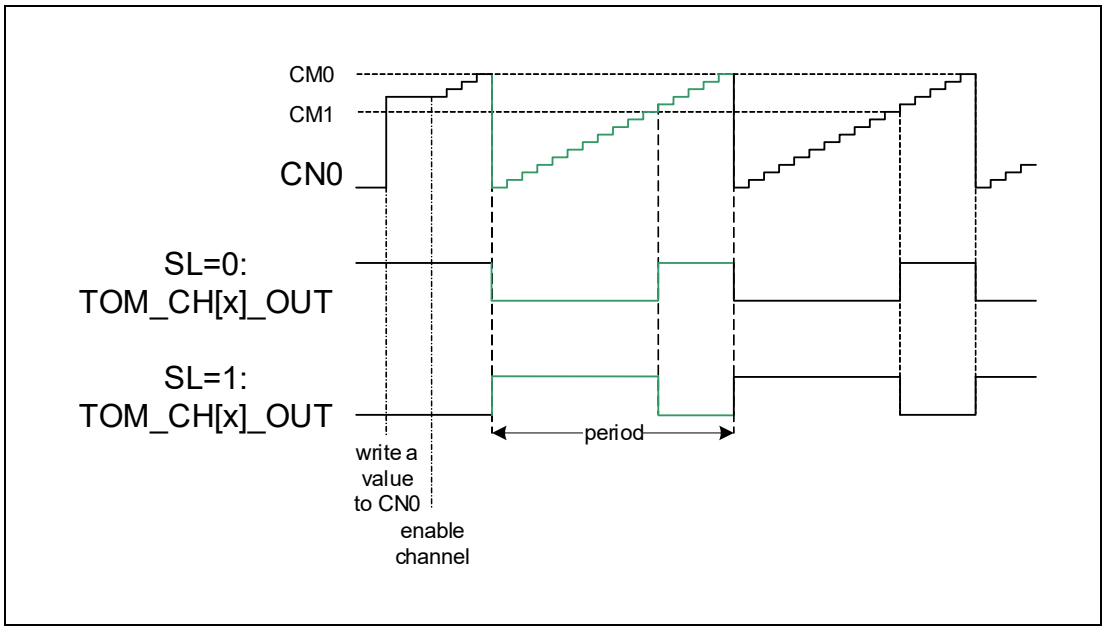

Figure 38.54 PWM Output with respect to configuration bit SL in continuous mode

38.16.3.3 Continuous Counting Up-Down Mode

In continuous mode, if CN0 counts up and down (UDMODE! = 00), depending on configuration bits RST_CCU0 of register TOM[i]_CH[x]_CTRL the counter register CN0 changes direction either when the counter value is equal to the compare value CM0, has counted down to 0 or when triggered by the TOM[i] trigger signal TRIGIN[x] (= TRIGOUT[x-1]) of the preceding channel [x-1] (which can also be the last channel of preceding instance TOM[i-1]) or the trigger signal TIM_EXT_CAPTURE(x) of the assigned TIM channel [x]. In this case, if UPEN_CTRL[x] = 1, also the working register CM0, CM1 and CLK_SRC are updated depending on UDMODE.

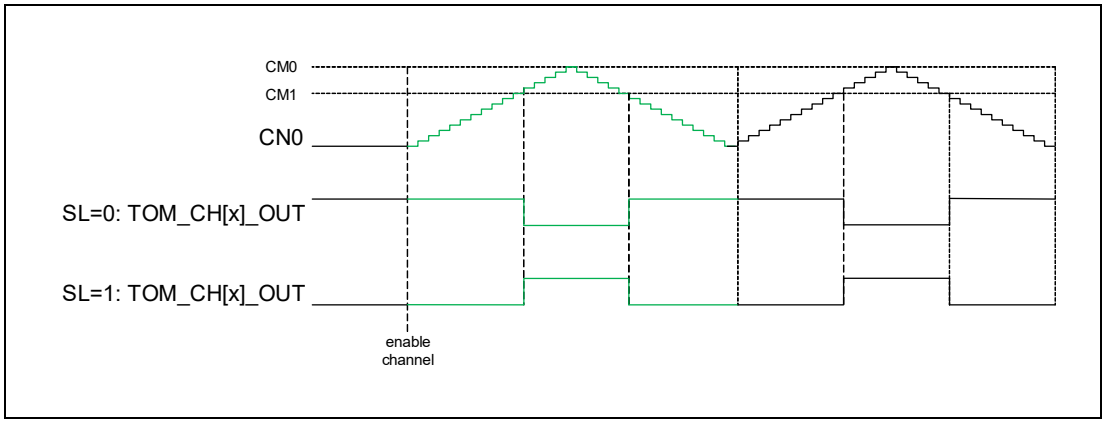

Figure 38.55 PWM Output behavior with respect to the SL bit in the TOM[i]_CH[x]_CTRL register if UDMODE! = 00_B

The clock of the counter register CN0 can be one of the CMU clocks CMU_FXCLK_EN[x]. The clock for CN0 is defined by CLK_SRC_SR value in register TOM[i]_CH[x]_CTRL. The duration of a period in multiples of selected CN0 counter clock ticks is defined by the CM0 configuration value (i.e. CM0 defines half of period in up-down mode). CM1 defines the duty cycle value in clock ticks of selected CN0 counter clock (i.e. CM0 defines half of duty cycle in up-down mode).

If counter CN0 of channel x is reset by its own CCU0 unit (i.e. the compare match of CN0 ≥ CM0 configured by RST_CCU0 = 0), following statements are valid:

1. CN0 counts continuously first up from 0 to CM0-1 and then down to 0.
2. If CN0 ≥ CM1, the output is set to SL
3. If CM1 = 0, the output is SL (i.e. 100% duty cycle)
4. If CM1 ≥ CM0, the output is !SL (i.e. 0% duty cycle)
5. On output TOM[i]_CH[x]_OUT a PWM signal is generated. The period is defined by CM0, the duty cycle is defined by CM1.

This behavior is depicted in **Figure 38.55**.

If the counter register CN0 of channel x is reset by the trigger signal coming from another channel or the assigned TIM module (configured by RST_CCU0 = 1), following statements are valid:

1. CN0 counts continuously first up. On a trigger signal the counter switches to count down mode. If CN0 has reached 0, it switches to count up mode.
2. If CN0 ≥ CM1, the output is set to SL
3. If CM1 = 0, the output is SL (i.e. 100% duty cycle)
4. If CM1 ≥ CM0, the output is !SL (i.e. 0% duty cycle)

5. On output TOM[i]_CHx]_OUT a PWM signal is generated. The period is defined by the CCU0 trigger of triggering channel, the duty cycle is defined by CM1.
6. On output TOM[i]_CHx]_OUT_T a PWM signal is generated. The period is defined by the CCU0 trigger of triggering channel, the duty cycle is defined by CM0.

This behavior is depicted in **Figure 38.56**.

NOTE

In case of up-down counter mode and RST_CCU0 = 1 it is recommended that

1. The triggering channel and the triggered channel are both running in up–down mode
2. The time between two trigger signals is equal to the time needed for CN0 of triggered channel to count back to 0 and again up to the same upper value.

The second recommendation can be reached by synchronizing the start of triggering channel and of triggered channel, i.e. let both channel start with a CN0 value 0.

NOTE

If there is a synchronization register in the trigger chain (indicated by value TOM_TRIG_CHAIN in register CCM[i]_HW_CONF), the additional delay of the trigger by one clock period has to be taken into account by starting at triggering channel with a CN0 value 1 (+1 compared to CN0 of triggered channel).

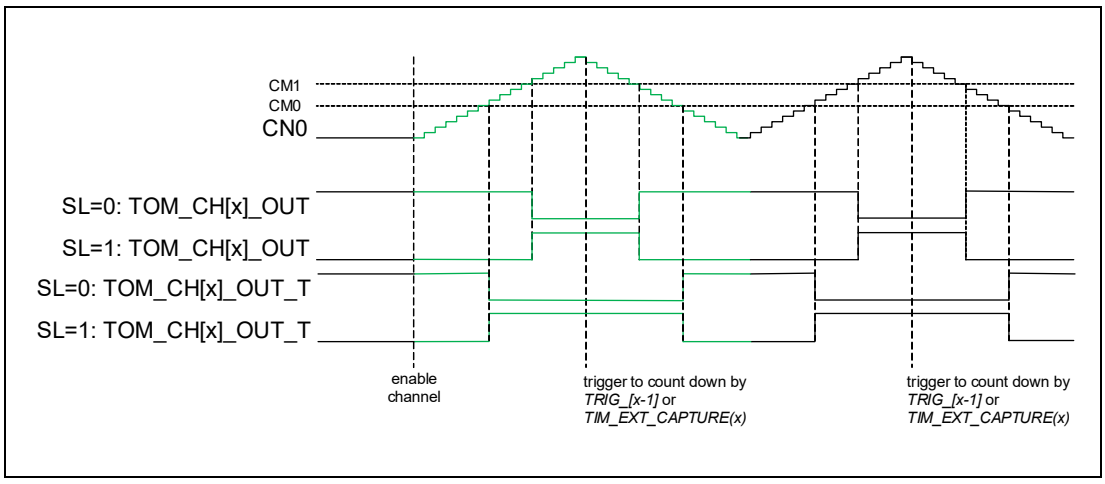

Figure 38.56 PWM Output behavior in case of RST_CCU0 = 1 and UDMODE! = 00

38.16.3.4 One-shot Counting Up Mode

In one-shot mode, the TOM channel generates one pulse with a signal level specified by the configuration bit SL in the channel [x] configuration register TOM[i]_CH[x]_CTRL.

First the channel has to be enabled by setting the corresponding TOM[i]_TGC[y]_ENDIS_STAT value and the one-shot mode has to be enabled by setting bit OSM in register TOM[i]_CH[x]_CTRL.

In one-shot mode the counter CN0 will not be incremented once the channel is enabled.

A write access to the register CN0 triggers the start of pulse generation (i.e. the increment of the counter register CN0).

If SPE mode of TOM[i] channel 2 is enabled (set bit SPEM of register TOM[i]_CH2_CTRL), also the trigger signal SPE[i]_NIPD can trigger the reset of register CN0 to zero and a start of the pulse generation.

The new value of CN0 determines the start delay of the first edge. The delay time of the first edge is given by (CM0-CN0) multiplied with period defined by current value of CLK_SRC.

If the counter CN0 is reset from CM0 back to zero, the first edge at TOM[i]_CH[x]_OUT is generated.

To avoid an update of CMx register with content of SRx register at this point in time, the automatic update should be disabled by setting UPEN_CTRL[x] = 00 (in register TOM[i]_TGC[y]_GLB_CTRL)

The second edge is generated if CN0 is greater or equal than CM1 (i.e. CN0 was incremented until it has reached CM1 or CN0 is greater than CM1 after an update of CM1).

If the counter CN0 has reached the value of CM0 a second time, the counter stops.

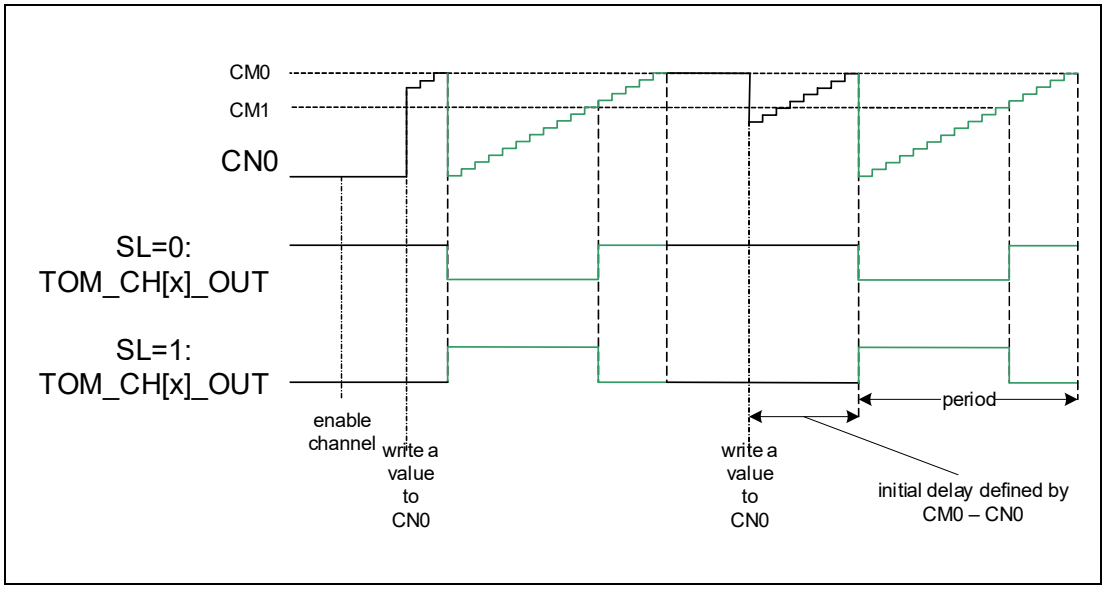

Figure 38.57 PWM Output with respect to configuration bit SL in one-shot mode: trigger by writing to CN0

Further output of single periods can be started by a write access to register CN0.

If CN0 is already incrementing (i.e. started by writing to CN0 a value CN0start < CM0), the affect of a second write access to CN0 depends on the phase of CN0:

phase 1: Update of CN0 before CN0 reaches first time CM0

phase 2: Update of CN0 after CN0 has reached first time CM0 but is less than CM1

phase 3: Update of CN0 after CN0 has reached first time CM0 and CN0 is greater than or equal CM1

In phase 1: Writing to counter CN0 a value CN0new < CM0 leads to a shift of first edge (generated if CN0 reaches CM0 first time) by the time CM0-CN0new.

In phase 2: Writing to incrementing counter CN0 a value CN0new < CM1 while CN0old is below CM1 leads to a lengthening of the pulse. The counter CN0 stops if it reaches CM0.

In phase 3: Writing to incrementing counter CN0 a value CN0new while CN0old is already greater than or equal CM1 leads to an immediate restart of a single pulse generation inclusive the initial delay defined by CM0 - CN0new.

If a channel is configured to one-shot mode and configuration bit OSM_TRIG is set to 1, the trigger signal OSM_TRIG (i.e. TRIGIN[x] or TIM_EXT_CAPTURE(x)) triggers start of one pulse generation.

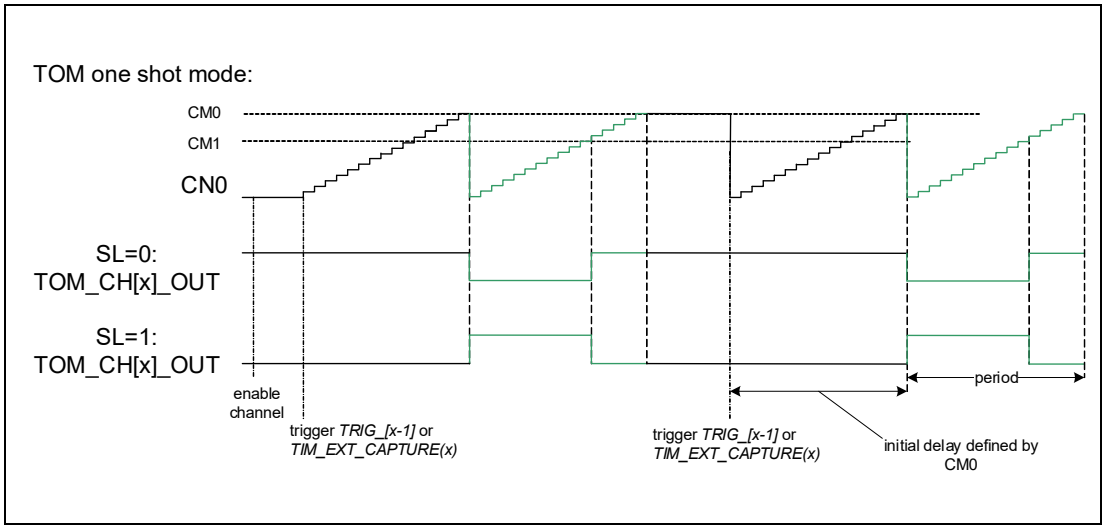

Figure 38.58 PWM Output with respect to configuration bit SL in one-shot mode: trigger by TRIGIN[x]/TRIGOUT[x-1] or TIM_EXT_CAPTURE(x)

38.16.3.5 One-shot Counting Up-Down Mode

The TOM channel can operate in one-shot counting up-down mode when the bit OSM = 1 and the UDMODE! = 00. One-shot mode means that a single pulse with the pulse level defined in bit SL is generated on the output line.

First the channel has to be enabled by setting the corresponding ENDIS_STAT value.

In One-shot mode the counter CN0 will not be incremented once the channel is enabled.

A write access to the register CN0 triggers the start of pulse generation (i.e. the increment of the counter register CN0).

To avoid an update of CMx register with content of SRx register at this point in time, the automatic update should be disabled by setting UPEN_CTRL[x] = 00 (in register TOM[i]_CH[x]_CTRL)

If the counter CN0 is greater or equal than CM1, the output TOM[i]_CH[x]_OUT is set to SL value.

If the counter CN0 is less than CM1, the output TOM[i]_CH[x]_OUT is set to !SL value.

If the counter CN0 has reached the value 0 (by counting down), it stops.

The new value of CN0 determines the start delay of the first edge. The delay time of the first edge is given by (CM1-CN0) multiplied with period defined by current value of CLK_SRC.

Figure 38.59 depicts the pulse generation in one-shot mode.

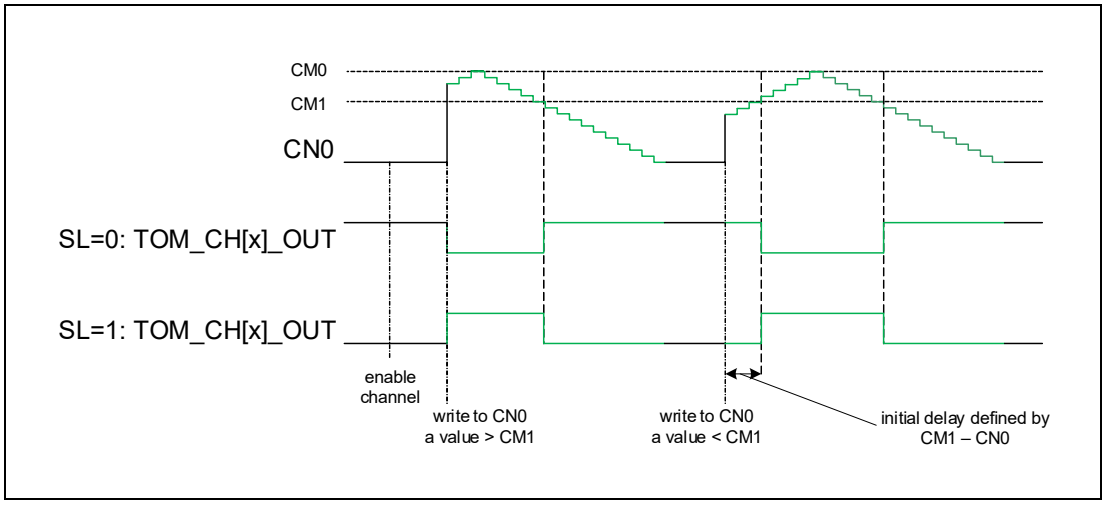

Figure 38.59 PWM Output with respect to configuration bit SL in one-shot counting up-down mode and UDMODE! = 00: trigger by writing to CN0

Further output of single pulses can be started by writing to register CN0.

If a channel is configured to one-shot counting up–down mode and configuration bit OSM_TRIG is set to 1, the trigger signal OSM_TRIG (i.e. TRIGIN[x] or TIM_EXT_CAPTURE(x)) triggers start of one pulse generation.

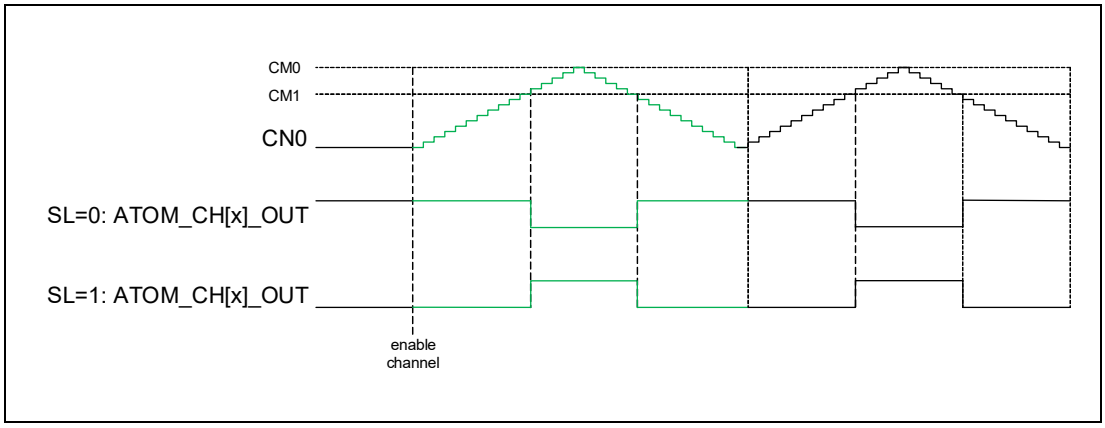

Figure 38.60 PWM Output with respect to configuration bit SL in one-shot counting up-down mode and UDMODE! = 00: trigger by TRIGIN[x-1] or TIM_EXT_CAPTURE(x)

38.16.3.6 Pulse Count Modulation Mode

At the output TOM[i]_CH15_OUT a pulse count modulated signal can be generated instead of the simple PWM output signal.

Figure 38.61 outlines the circuit for Pulse Count Modulation.

The PCM mode is enabled by setting bit BITREV to 1.

With the configuration bit BITREV =1 a bit-reversing of the counter output CN0 is configured. In this case the bits LSB and MSB are swapped, the bits LSB+1 and MSB–1 are swapped, the bits LSB+2 and MSB-2 are swapped and so on.

The effect of bit-reversing of the CN0 register value is shown in the following **Figure 38.61**.

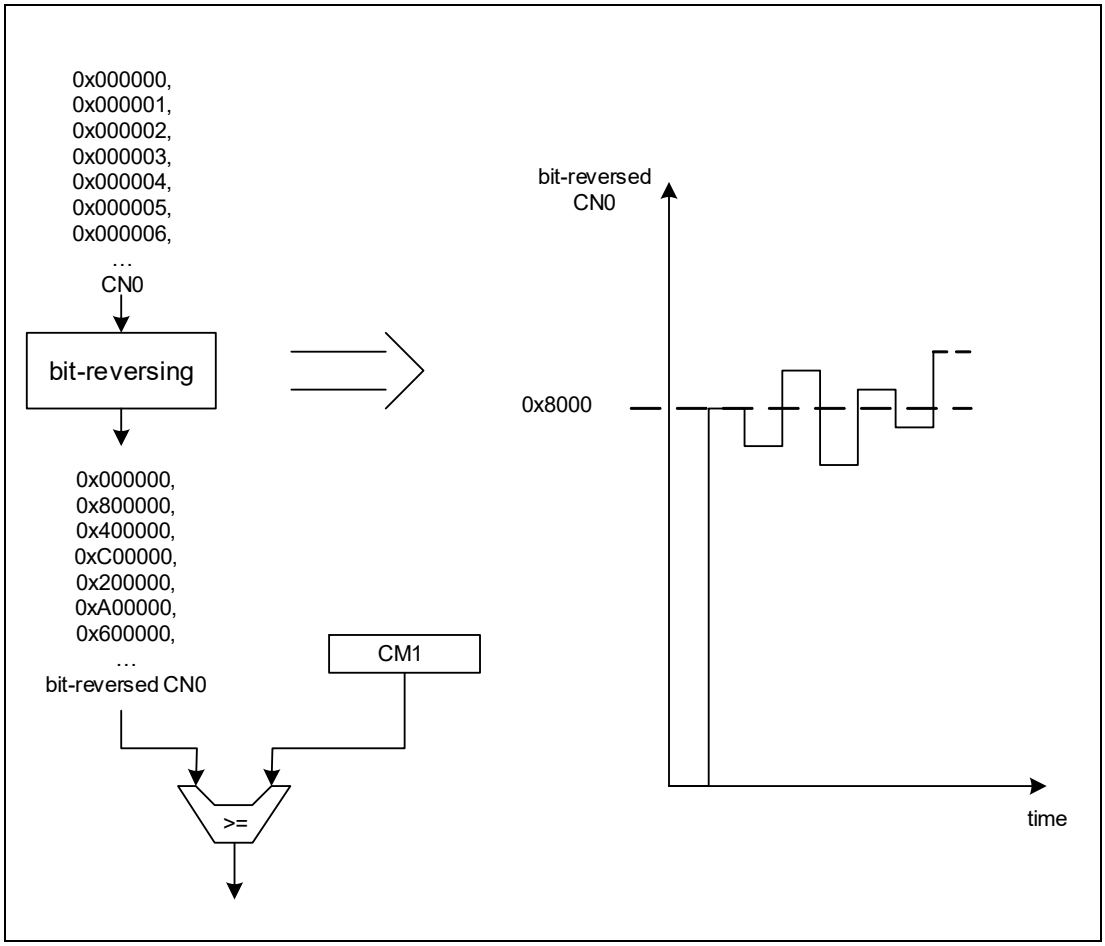

Figure 38.61 Bit reversing of counter CN0 output

In the PCM mode the counter register CN0 is incremented by every clock tick depending on configured CMU clock (CMU_FXCLK).

The output of counter register CN0 is first bit-reversed and then compared with the configured register value CM1.

If the bit-reversed value of register CN0 is greater than CM1, the SR flip-flop of sub-module SOU is set (depending on configuration register SL) otherwise the SR flip-flop is reset. This generates at the output TOM[i]_CH15_OUT a pulse count modulated signal.

In PCM mode the CM0 register - in which the period is defined - normally has to be set to its maximum value $FFFF_H$.

To reduce time period of updating duty cycle value in CM1 register, it is additionally possible to setup period value in CM0 register to smaller values than maximum value as described before. Possible values for CM0 register are each even numbered values to the power of 2 e.g. 8000_H, 4000_H, 2000_H .... In this case the duty cycle has to be configured in the following manner. Depending on how much the period in CM0 register is decreased - means shifted right starting from 10000_H - the duty cycle in CM1 register has to be shifted left (= rotated: shift MSB back into LSB) with same value, e.g. :

Period CM0 = 0100_H → shifted 8 bits right from 10000_H

→ so duty cycle has to be shifted left 8 bit:

e.g. 50% duty cycle = 00080_H → shift 8 bits left→ CM1 = 8000_H

More examples:

period CM0	→	duty cycle	→	shift	→	CM1
$FFFF_H$	→	8000_H	→	no shift	→	8000_H
8000_H	→	4000_H	→	shift 1 bit left	→	8000_H
4000_H	→	1000_H	→	shift 2 bits left	→	4000_H
2000_H	→	$0FFF_H$	→	shift 3 bits left	→	$7FF8_H$
1000_H	→	0333_H	→	shift 4 bits left	→	3330_H
0800_H	→	0055_H	→	shift 5 bits left	→	$0AA0_H$
...						
0020_H	→	0008_H	→	shift 11 bits left	→	4000_H
0010_H	→	0005_H	→	shift 12 bits left	→	5000_H
...						

NOTE

In this mode the interrupt CCU1TC (see register TOM[i]_CH[x]_IRQ_NOTIFY) is set every time if bit reverse value of CN0 is greater or equal than CM1 which may be multiple times during one period. Therefore, from application point of view it is not useful to enable this interrupt.

38.16.3.7 Trigger Generation

For applications with constant PWM period defined by CM0, it is not necessary to update regularly the CM0 register with SR0 register. For these applications the SR0 register can be used to define an additional output signal and interrupt trigger event. If bit SR0_TRIG in register TOM[i]_CH[x]_CTRL is set, the register SR0 is no longer used as a shadow register for register CM0. Instead, SR0 is compared against CN0 and if both are equal, a pulse of signal level '1' is generated at the output TOM[i]_CH[x]_OUT_T. The bit SR0_TRIG should only be set if bit RST_CCU0 of this channel is 0.

If bit SR0_TRIG is set the interrupt notify flag CCU1TC is no longer set on a compare match of CM1 and CN0. Instead, the CCU1TC interrupt notify flag is set in case of a compare equal match of SR0 and CN0.

With configuration bit TRIG_PULSE one can select if the output TOM[i]_CH[x]_OUT_T is high as long as CN0 = SR0 (TRIG_PULSE = 0) or if there will be only one pulse of length one SYS_CLK period when CN0 becomes SR0 (TRIG_PULSE = 1).

The TOM output signal routing to DTM or GTM-IP top level is described in **Section 38.18.9, DTM Configuration Register Description**.

38.16.4 TOM BLDC Support

The TOM sub-module offers in combination with the SPE sub-module a BLDC support. To drive a BLDC engine TOM channels 0 to 7 can be used.

The BLDC support can be configured by setting the SPEM bit inside the TOM[i]_CH[z]_CTRL register. When this bit is set the TOM channel output is controlled through the SPE_OUT(z) signal coming from the SPE sub-module (see **Figure 38.51**). Refer to **Section 38.23, Sensor Pattern Evaluation (SPE)** for a detailed description of the SPE sub-module.

The TOM[i]_CH2, 6, 7, 8 or 9 can be used together with the SPE module to trigger a delayed update of the SPE_OUT_CTRL register (i.e.commutation delay) after new input pattern detected by SPE (signaled by SPE[i]_NIPD). This feature is configured on TOM[i]_CH2, 6, 7, 8 or 9 by setting SPE_TRIG = 1 and OSM = 1. With this configuration the TOM channel i generates one single PWM pulse on trigger by signal SPE_NIPD.

For details, refer to chapter of SPE sub-module description.

38.16.5 TOM Gated Counter Mode

Each TOM - SPE module combination provides also the feature of a gated counter mode. This is reached by using the FSOI input of a TIM module to gate the clock of a CCU0 sub-module. To configure this mode, register of module SPE should be set as following:

1. The SPE should be enabled (bit SPE_EN = 1),
2. All three TIM inputs should be disabled (SIE0 = SIE1 = SIE2 = 0),
3. SPE[i]_OUT_CTRL should be set to 00005555_H (set SPE_OUT() to '0'),
4. Mode FSOM should be enabled (FSOM = 1),
5. Set in bit field FSOL bit c if channel c of module TOM is chosen for gated counter mode

Additionally in module TOM

1. The SPE mode should be disabled (SPEM = 0) and
2. The gated counter mode should be enabled (GCM = 1)

As a result of this configuration, the counter CN0 in sub-module CCU0 of TOM channel c counts as long as input FSOI is '0'.

38.16.6 TOM Interrupt Signals

Signal	Description
TOM_CCU0TCx_IRQ	CCU0 Trigger condition interrupt for channel x
TOM_CCU1TCx_IRQ	CCU1 Trigger condition interrupt for channel x

38.16.7 TOM Configuration Registers Overview

TOM contains following configuration registers:

Table 38.177 Register list

Symbol	Register Name	Detail in Section
TOM[i]_TGC[y]_GLB_CTRL	TOMi TGC y global control register	**38.16.8.1**
TOM[i]_TGC[y]_ENDIS_CTRL	TOMi TGC y enable/disable control register	**38.16.8.2**

Table 38.181 TOM[i]_TGC[y]_ACT_TB Register Contents

Bit Position	Bit Name	Function
31 to 27	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
26, 25	TBU_SEL	Selection of time base used for comparison 00_B: TBU_TS0 selected 01_B: TBU_TS1 selected 10_B: TBU_TS2 selected 11_B: Same as 00_B **NOTE** The bit combination 10 is only applicable if the TBU of the device contains three time base channels. Otherwise, this bit combination is also reserved. Refer to **Figure 38.2, GTM Architecture Block Diagram** to determine the number of channels for TBU of this device.
24	TB_TRIG	Set trigger request 0: No trigger request 1: Set trigger request **NOTE** This flag is reset automatically if the selected time base unit (TBU_TS0 or TBU_TS1 or TBU_TS2 if present) has reached the value ACT_TB and the update of the register were triggered.
23 to 0	ACT_TB	Specifies the signed compare value with selected signal TBU_TS[x], x = 0 to 2. If selected TBU_TS[x] value is in the interval [ACT_TB–$007FFFFF_H$, ACT_TB] the event is in the past and the trigger is generated immediately. Otherwise the event is in the future and the trigger is generated if selected TBU_TS[x] is equal to ACT_TB.

38.16.8.5 TOM[i]_TGC[y]_OUTEN_CTRL

Access: This register can be read or written in 32-bit units.

Address: <GTM_base> + 8078_H + (800_H × i) + (200_H × y)

Table 38.186 TOM[i]_CH[x]_CTRL Register Contents (1/4)

Bit Position	Bit Name	Function
31	FREEZE	0: A channel disable/enable may change internal register and output register 1: A channel enable/disable does not change an internal or output register but stops counter CN0
30	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
29	GCM	Gated Counter Mode enable 0: Gated Counter mode disabled 1: Gated Counter mode enabled **NOTE** The Gated Counter mode is only available for TOM instances connected to a SPE module and only for channels 0 to 7.
28	SPEM	SPE output mode enable for channel. 0: SPE output mode disabled: TOM[i]_CH[x]_OUT defined by TOM[i] channel x SOUR register 1: SPE output mode enabled: TOM[i]_CH[x]_OUT is defined by SPE[i]_OUT[x] **NOTES** 1. The SPE output mode is only implemented for TOM instances connected to a SPE module and only for TOM channels 0 to 7. 2. On TOM channel 2, 6 and 7 SPEM = 1 has special meaning. If SPEM = 1, the signal SPE_NIPD triggers the reset of CN0. If SPEM = 1 and OSM = 1, the signal SPE_NIPD triggers the start of single pulse generation. 3. For TOM channel 2, 6 and 7 this bit defines in combination with bit SPE_TRIG the source of output pin TOM[i]_CH[x]_OUT and if CN0 can be reset by TOM input signal SPE[i]_NIPD.
27	BITREV	Bit-reversing of output of counter register CN0. **NOTE** This bit enables the PCM mode of channel 15.

Table 38.186 TOM[i]_CH[x]_CTRL Register Contents (2/4)

Bit Position	Bit Name	Function
26	OSM	One-shot mode. In this mode the counter CN0 counts for only one period. The length of period is defined by CM0. A write access to the register CN0 triggers the start of counting. 0: One-shot mode disabled 1: One-shot mode enabled
25	SPE_TRIG	SPE trigger to reset CN0 If SPEM = 0: 0: TOM[i]_CH[x]_OUT defined by TOM[i] channel x SOUR register, CN0 reset is defined by configuration of bit RST_CCU0 1: TOM[i]_CH[x]_OUT defined by TOM[i] channel x SOUR register, CN0 is reset by signal SPE[i]_NIPD If SPEM = 1: 0: TOM[i]_CH[x]_OUT is defined by SPE[i]_OUT[x], CN0 is reset by signal SPE[i]_NIPD 1: TOM[i]_CH[x]_OUT is defined by SPE[i]_OUT[x], CN0 reset is defined by configuration of bit RST_CCU0 For TOM channel 2, 6 and 7 this bit defines in combination with bit SPEM the source of output pin TOM[i]_CH[x]_OUT and if CN0 can be reset by TOM input signal SPE[i]_NIPD. **NOTES** 1. For TOM channel 8 and 9 this bit defines only if CN0 reset is defined by input signal SPE[i]_NIPD or by configuration of RST_CCU0. The output TOM[i]_CH[x]_OUT is not affected. The configuration bit SPEM is not available for these channels and thus assumed to be 0. 2. If a configuration of SPEM | SPE_TRIG = 0 | 1 or 1 | 0 is chosen (i.e. CN0 is reset by signal SPE[i]_NIPD), the one-shot mode in corresponding TOM channel should also be enabled by setting bit OSM = 1 to generate one PWM pulse in case of trigger SPE[i]_NIPD. 3. In SPE module one of the trigger signals TOM[i]_CH2_TRIG_CCU1, TOM[i]_CH6_TRIG_CCU1, TOM[i]_CH7_TRIG_CCU1, TOM[i]_CH8_TRIG_CCU1, or TOM[i]_CH9_TRIG_CCU1 can be used to trigger the update of register SPE[i]_OUT_CTRL.
24	TRIGOUT	Trigger output selection (output signal TRIGOUT[x]) of module TOM_CH[x] 0: TRIGOUT[x] is TRIGIN[x] or TIM_EXT_CAPTURE(x). 1: TRIGOUT[x] is TRIG_CCU0
23	EXTTRIGOUT	Select TIM_EXT_CAPTURE(x) as potential output signal TRIGOUT[x] 0: Signal TRIGIN[x] is selected as output on TRIGOUT[x] (if TRIGOUT= 0) 1: Signal TIM_EXT_CAPTURE(x) is selected as output on TRIGOUT[x] (if TRIGOUT=0)
22	EXT_TRIG	Select TIM_EXT_CAPTURE(x) as trigger signal 0: Signal TIM_[x-1] is selected as trigger to reset CN0 or to start single pulse generation. 1: Signal TIM_EXT_CAPTURE(x) is selected
21	OSM_TRIG	Enable trigger of one-shot pulse by trigger signal OSM_TRIG 0: Signal OSM_TRIG cannot trigger start of single pulse generation 1: Signal OSM_TRIG can trigger start of single pulse generation (only if bit OSM = 1) **NOTE** This bit should only be set if bit OSM = 1 and bit RST_CCU0 = 0.

Table 38.186 TOM[i]_CH[x]_CTRL Register Contents (3/4)

Bit Position	Bit Name	Function
20	RST_CCU0	Reset source of CCU0 0: Reset counter register CN0 to 0 on matching comparison CM0 1: Reset counter register CN0 to 0 on trigger TRIGIN[x] or TIM_EXT_CAPTURE(x). **NOTE** This bit should only be set if bit OSM = 0 (i.e. in continuous mode)
19, 18	UDMODE	Up-down counter mode 00_B: Up-down counter mode disabled: CN0 counts always up 01_B: Up-down counter mode enabled: CN0 counts up and down, CM0, CM1 are updated if CN0 reaches 0 (i.e. changes from down to up) 10_B: Up-down counter mode enabled: CN0 counts up and down, CM0, CM1 are updated if CN0 reaches CM0 (i.e. changes from up to down) 11_B: Up-down counter mode enabled: CN0 counts up and down, CM0, CM1 are updated if CN0 reaches 0 or CM0 (i.e. changes direction)
17	TRIG_PULSE	Trigger output pulse length of one SYS_CLK period 0: Output on TOM[i]_OUT[x]_T is 1 as long as CN0=SR0 (if SR0_TRIG = 1) 1: Output on TOM[i]_OUT[x]_T is 1 for only one SYS_CLK period if CN0 = SR0 (if SR0_TRIG = 1)
16	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
15	ECLK_SRC	Extend CLK_SRC 0: CLK_SRC_SR set 1 selected (see bit CLK_SRC_SR) 1: CLK_SRC_SR set 2 selected (see bit CLK_SRC_SR)
14 to 12	CLK_SRC_SR	Clock source select for channel If ECLK_SRC = 0: 000_B: CMU_FXCLK (0) selected 001_B: CMU_FXCLK (1) selected 010_B: CMU_FXCLK (2) selected 011_B: CMU_FXCLK (3) selected 100_B: CMU_FXCLK (4) selected 101_B: Clock of channel stopped 110_B: Clock of channel stopped 111_B: Clock of channel stopped If ECLK_SRC = 1: 000_B: CMU_FXCLK (0) selected 001_B: CMU_FXCLK (1) selected 010_B: CMU_FXCLK (2) selected 011_B: CMU_FXCLK (3) selected 100_B: CMU_FXCLK (4) selected 101_B: TRIG[x–1] selected 110_B: TIM_EXT_CAPTURE[x] selected 111_B: Reserved The register CLK_SRC is updated with the value of CLK_SRC_SR together with the update of register CM0 and CM1. The input of the FX clock divider depends on the value of FXCLK_SEL (see CMU). **NOTES** 1. This register is a shadow register for the register CLK_SRC. Thus, if the CMU_CLK source for PWM generation should be changed during operation, the old CMU_CLK has to operate until the update of the ATOM channels internal CLK_SRC register by the CLK_SRC_SR content is done either by an end of a period or a forced update. 2. If clock of channel is stopped (i.e. ECLK_SRC = 0 and CLK_SRC = 101/110/111), the channel can only be restarted by resetting CLK_SRC_SR to a value of 000 to 100 and forcing an update via the force update mechanism.

Table 38.186 TOM[i]_CH[x]_CTRL Register Contents (4/4)

Bit Position	Bit Name	Function
11	SL	Signal level for duty cycle 0: Low signal level 1: High signal level If the output is disabled, the output TOM_OUT[x] is set to inverse value of SL. **NOTE** Reset value depends on the hardware configuration chosen by silicon vendor.
10 to 8	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
7	SR0_TRIG	SR0 is used to generate a trigger on output TOM[i]_CH[x]_OUT_T if equal to CN0. 0: SR0 is used as a shadow register for register CM0. 1: SR0 is not used as a shadow register for register CM0. SR0 is compared with CN0 and if both are equal, a trigger pulse is generated at output TOM[i]_CH[x]_OUT_T. **NOTE** This bit should only be set if RST_CCU0 of this channel is 0.
6 to 0	Reserved	When read, the value after reset is returned. When writing, write the value after reset.

38.16.8.10 TOM[i]_CH[x]_CN0

Access: This register can be read or written in 32-bit units.

Address: <GTM_base> + 8014_H + (800_H × i) + (40_H × x)

38.17 ARU-connected Timer Output Module (ATOM)

38.17.1 Overview

The ARU-connected Timer Output Module (ATOM) is able to generate complex output signals without CPU interaction due to its connectivity to the ARU. Typically, output signal characteristics are provided over the ARU connection through sub-modules connected to ARU like e.g. the MCS, DPLL or PSM. Each ATOM sub-module contains eight output channels which can operate independently from each other in several configurable operation modes. A block diagram of the ATOM sub-module is depicted in **Figure 38.62**.

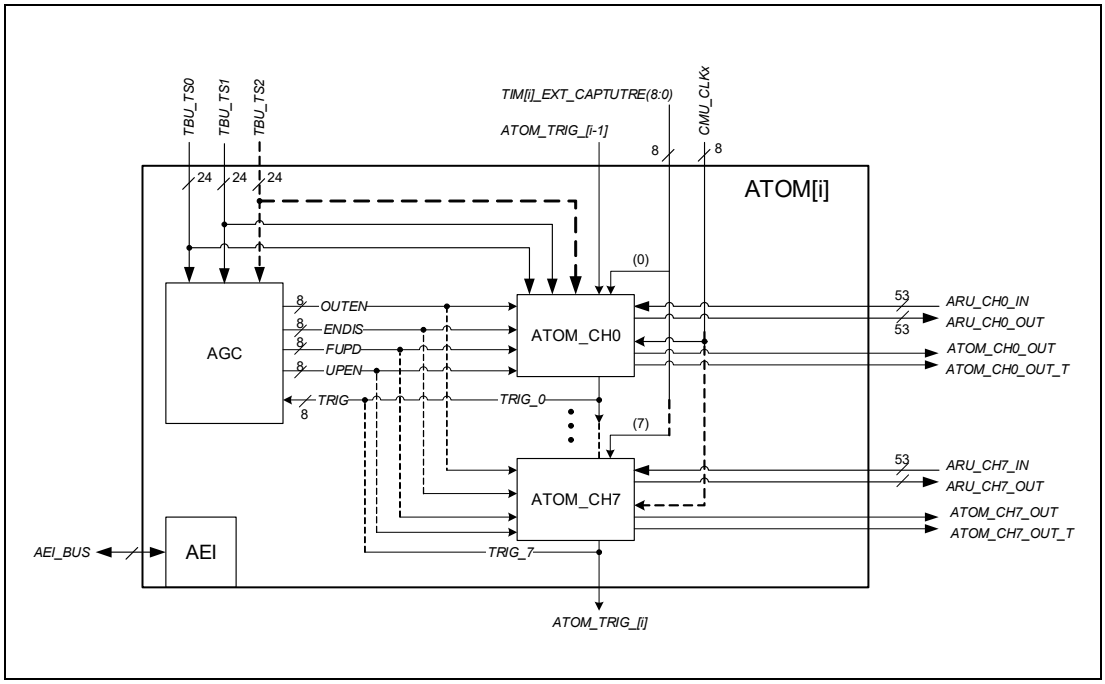

Figure 38.62 ATOM block diagram

The architecture of the ATOM sub-module is similar to the TOM sub-module, but there are some differences. First, the ATOM integrates only eight output channels. Hence, there exists one ATOM Global Control sub-unit (AGC) for the ATOM channels. The ATOM is connected to the ARU and can set up individual read requests from the ARU and write requests to the ARU. Furthermore, the ATOM channels are able to generate signals on behalf of time stamps and the ATOM channels are able to generate a serial output signal on behalf of an internal shift register.

Each ATOM channel provides five modes of operation:

- ATOM Signal Output Mode Immediate (SOMI)
- ATOM Signal Output Mode Compare (SOMC)
- ATOM Signal Output Mode PWM (SOMP)
- ATOM Signal Output Mode Serial (SOMS)
- ATOM Signal Output Mode Buffered Compare (SOMB)

These modes are described in more detail in **Section 38.17.3, ATOM Channel Modes**.

The ATOM channels operation registers (e.g. counter, compare registers) are 24 bit wide. Moreover, the input clocks for the ATOM channels come from the configurable CMU_CLKx signals of the CMU

sub-module. This gives the freedom to select a programmable input clock for the ATOM channel counters. The ATOM channel is able to generate a serial bit stream, which is shifted out at the ATOM[i]_CH[x]_OUT output.

When configured in this serial shift mode (SOMS) the selected CMU clock defines the shift frequency.

Each ATOM channel provides a so called operation and shadow register set. With this architecture it is possible to work with the operation register set, while the shadow register set can be reloaded with new parameters over CPU and/or ARU.

When update via ARU is selected, it is possible to configure for ATOM SOMP mode if both shadow registers are updated via ARU or only one of the shadow registers is updated.

On the other hand, the shadow registers can be used to provide data to the ARU when one or both of the compare units inside an ATOM channel match. This feature is only applicable in SOMC mode.

In TOM channels it is possible to reload the content of the operation registers with the content of the corresponding shadow registers and change the clock input signal for the counter register simultaneously. This simultaneous change of the input clock frequency together with reloading the operation registers is also implemented in the ATOM channels.

In addition to the feature that the CPU can select another CMU_CLKx during operation (i.e. updating the shadow register bit field CLK_SRC_SR of the ATOM[i]_CH[x]_CTRL register), the selection can also be changed via the ARU. Then, for the clock source update, the ACBI register bits of the ATOM[i]_CH[x]_STAT register are used as a shadow register for the new clock source.

In general, the behavior of the compare units CCU0 and CCU1 and the output signal behavior is controlled with the ACB bit field inside the ATOM[i]_CH[x]_CTRL register when the ARU connection is disabled and the behavior is controlled via ARU through the ACBI bit field of the ATOM[i]_CH[x]_STAT register, when the ARU is enabled.

Since the ATOM is connected to the ARU, the shadow registers of an ATOM channel can be reloaded via the ARU connection or via CPU over its AEI interface. When loaded via the ARU interface, the shadow registers act as a buffer between the ARU and the channel operation registers. Thus, a new parameter set for a PWM can be reloaded via ARU into the shadow registers, while the operation registers work on the actual parameter set.

The trigger signal ATOM_TRIG_[i-1] of ATOM instance i comes from the preceding instance i-1, the trigger ATOM_TRIG_[i] is routed to succeeding instance i+1.

NOTE

ATOM0 is connected to its own output ATOM_TRIG_0, i.e. the last channel of ATOM instance 0 can trigger the first channel of ATOM instance 0 (this path is registered, which means delayed by one SYS_CLK period).

38.17.1.1 ATOM Global Control (AGC)

Synchronous start, stop and update of work register of up to 8 channels is possible with the AGC sub-unit. This sub-unit has the same functionality as the TGC sub-unit of the TOM sub-module.

(1) Overview

There exists one global channel control unit (AGC) to drive a number of individual ATOM channels synchronously by external or internal events.

An AGC can drive up to eight ATOM channels.

The ATOM sub-module supports four different kinds of signaling mechanisms:

- Global enable/disable mechanism for each ATOM channel with control register ATOM[i]_AGC_ENDIS_CTRL and status register ATOM[i]_AGC_ENDIS_STAT
- Global output enable mechanism for each ATOM channel with control register ATOM[i]_AGC_OUTEN_CTRL and status register ATOM[i]_AGC_OUTEN_STAT
- Global force update mechanism for each ATOM channel with control register ATOM[i]_AGC_FUPD_CTRL
- Update enable of the register CM0, CM1 and CLK_SRC for each ATOM channel with the control bit field UPEN_CTRL[z] of ATOM[i]_AGC_GLB_CTRL

(2) AGC Sub-unit

Each of the first three individual mechanisms (enable/disable of the channel, output enable and force update) can be driven by three different trigger sources. The three trigger sources are:

- The host CPU (bit HOST_TRIG of register ATOM[i]_AGC_GLB_CTRL)
- The TBU time stamp (signal TBU_TS0 to 2 if available)
- The internal trigger signal TRIG (bunch of trigger signals TRIG_[x]) which can be either the trigger TRIG_CCU0 of channel x, the trigger of preceding channel x–1 (i.e. signal TRIG_[x–1]) or the external trigger TIM_EXT_CAPTURE(x) of assigned TIM channel x.

The first way is to trigger the control mechanism by a direct register write access via host CPU (bit HOST_TRIG of register ATOM[i]_AGC_GLB_CTRL).

The second way is provided by a compare match trigger on behalf of a specified time base coming from the module TBU (selected by bits TBU_SEL) and the time stamp compare value defined in the bit field ACT_TB of register ATOM[i]_AGC_ACT_TB.

NOTE

A cyclic event compare of ACT_TB and selected TBU_TS [x] is performed.

The third possibility is the input TRIG (bunch of trigger signals TRIG_[x]) coming from the ATOM channels 0 to 7.

The corresponding trigger signal TRIG_[x] coming from channel [x] can be masked by the register ATOM[i]_AGC_INT_TRIG.

To enable or disable each individual ATOM channel, the registers ATOM[i]_AGC_ENDIS_CTRL and/or ATOM[i]_AGC_ENDIS_STAT have to be used.

The register ATOM[i]_AGC_ENDIS_STAT controls directly the signal ENDIS. A write access to this register is possible.

The register ATOM[i]_AGC_ENDIS_CTRL is a shadow register that overwrites the value of register ATOM[i]_AGC_ENDIS_STAT if one of the three trigger conditions matches.

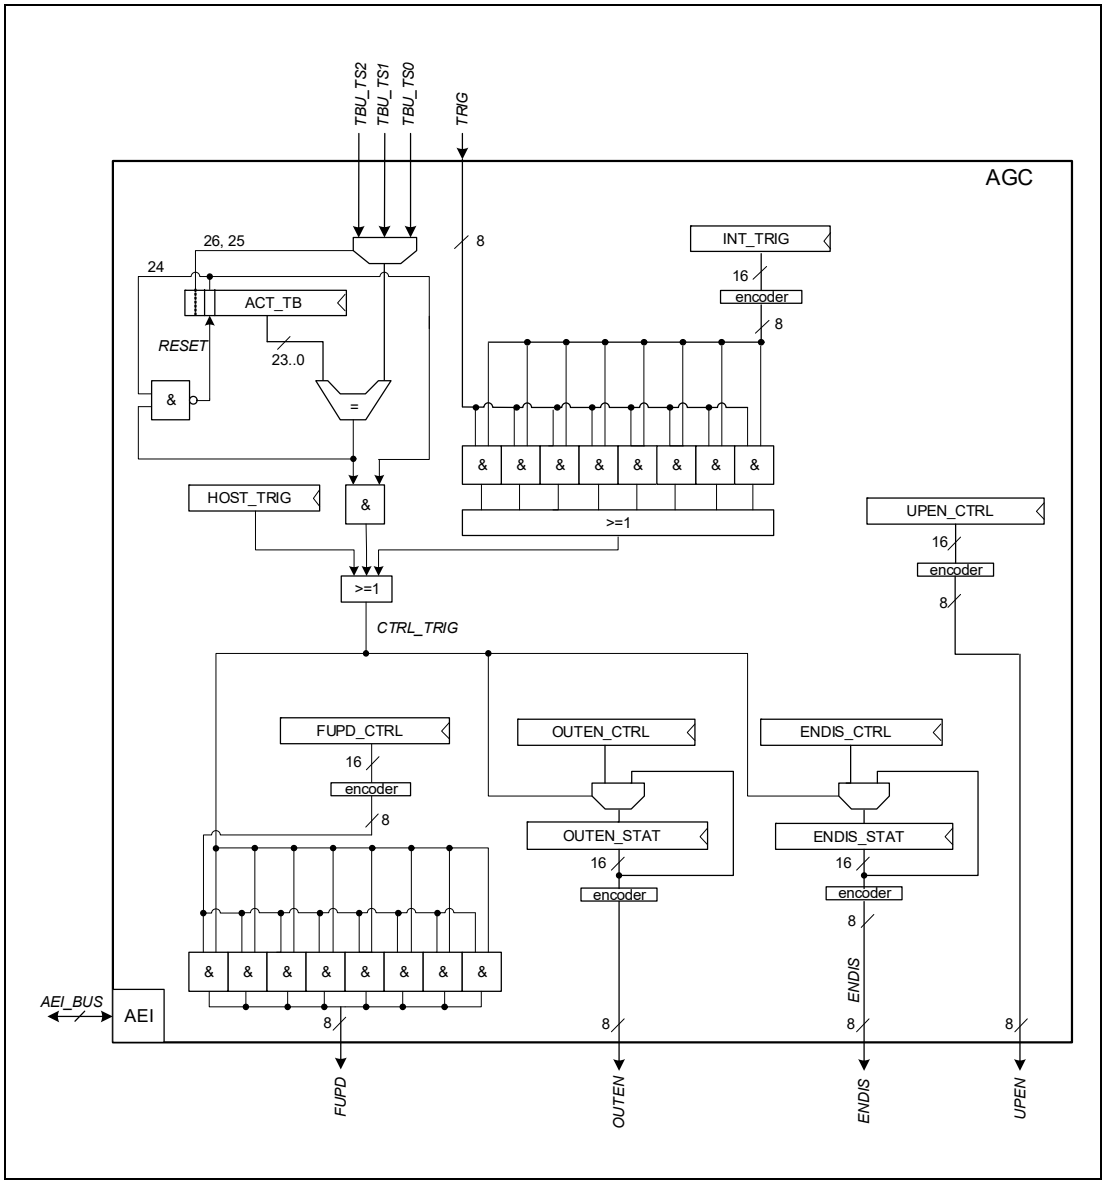

Figure 38.63 ATOM Global channel control mechanism

The output of the individual ATOM channels can be controlled using the register ATOM[i]_AGC_OUTEN_CTRL and ATOM[i]_AGC_OUTEN_STAT.

The register ATOM[i]_AGC_OUTEN_STAT controls directly the signal OUTEN. A write access to this register is possible.

The register ATOM[i]_AGC_OUTEN_CTRL is a shadow register that overwrites the value of register ATOM[i]_AGC_OUTEN_STAT if one of the three trigger conditions matches.

If an ATOM channel is disabled by the register ATOM[i]_AGC_OUTEN_STAT, the actual value of the channel output at ATOM_CH[x]_OUT is defined by the signal level bit (SL) defined in the channel control register ATOM[i]_CH[x]_CTRL. If the output is enabled, the output at ATOM_CH[x]_OUT depends on value of Flip-flop SOUR.

The register ATOM[i]_AGC_FUPD_CTRL defines which of the ATOM channels receive a FORCE_UPDATE event if the trigger signal CTRL_TRIG is raised.

NOTE

In SOMP mode the force update request is stored and executed synchronized to the selected CMU_CLK. In all other modes the force update request is executed immediately.

The register bits UPEN_CTRL[x] defines for which ATOM channel the update of the working register CM0, CM1 and CLK_SRC by the corresponding shadow register SR0, SR1 and CLK_SRC_SR is enabled. If update is enabled, the register CM0, CM1 and CLK_SRC will be updated on reset of counter register CN0 (see **Figure 38.64**).

38.17.1.2 ATOM Channel Mode Overview

Each ATOM channel offers the following different operation modes:

In ATOM Signal Output Mode Immediate (SOMI), the ATOM channels generate an output signal immediately after receiving an ARU word according to the two signal level output bits of the ARU word received through the ACBI bit field. Due to the fact, that the ARU destination channels are served in a round robin order, the output signal can jitter in this mode with a jitter of the ARU round trip time.

In ATOM Signal Output Mode Compare (SOMC), the ATOM channel generates an output signal on behalf of time stamps that are located in the ATOM operation registers. These time stamps are compared with the time stamps, the TBU generates. The ATOM is able to receive new time stamps either by CPU or via the ARU. The new time stamps are directly loaded into the channels operation register. The shadow registers are used as capture registers for two time base values, when a compare match of the channels operation registers occurs.

In ATOM Signal Output Mode PWM (SOMP), the ATOM channel is able to generate simple and complex PWM output signals like the TOM sub-module by comparing its operation registers with a sub-module internal counter. In difference to the TOM, the ATOM shadow registers can be reloaded by the CPU and by the ARU in the background, while the channel operates on the operation registers.

In ATOM Signal Output Mode Serial (SOMS), the ATOM channel generates a serial output bit stream on behalf of a shift register. The number of bits shifted and the shift direction is configurable. The shift frequency is determined by one of the CMU_CLKx clock signals. Refer to **Section 38.17.3.4, ATOM Signal Output Mode Serial (SOMS)** for further details.

In ATOM Signal Output Buffered Compare (SOMB), the ATOM channel generates an output signal on behalf of time stamps that located in the ATOM operation registers. These time stamps are compared with the time stamps, the TBU generates. The ATOM is able to receive new compare values either by CPU or via the ARU. The new compare values received via ARU are stored first in the shadow register and only if previous compare match is occurred, the operation register are updated with the content of the shadow register.

38.17.2 ATOM Channel Architecture

Each ATOM channel is able to generate output signals according to five operation modes. The architecture of the ATOM channels is similar to the architecture of the TOM channels. The general architecture of an ATOM channel is depicted in **Figure 38.64**.

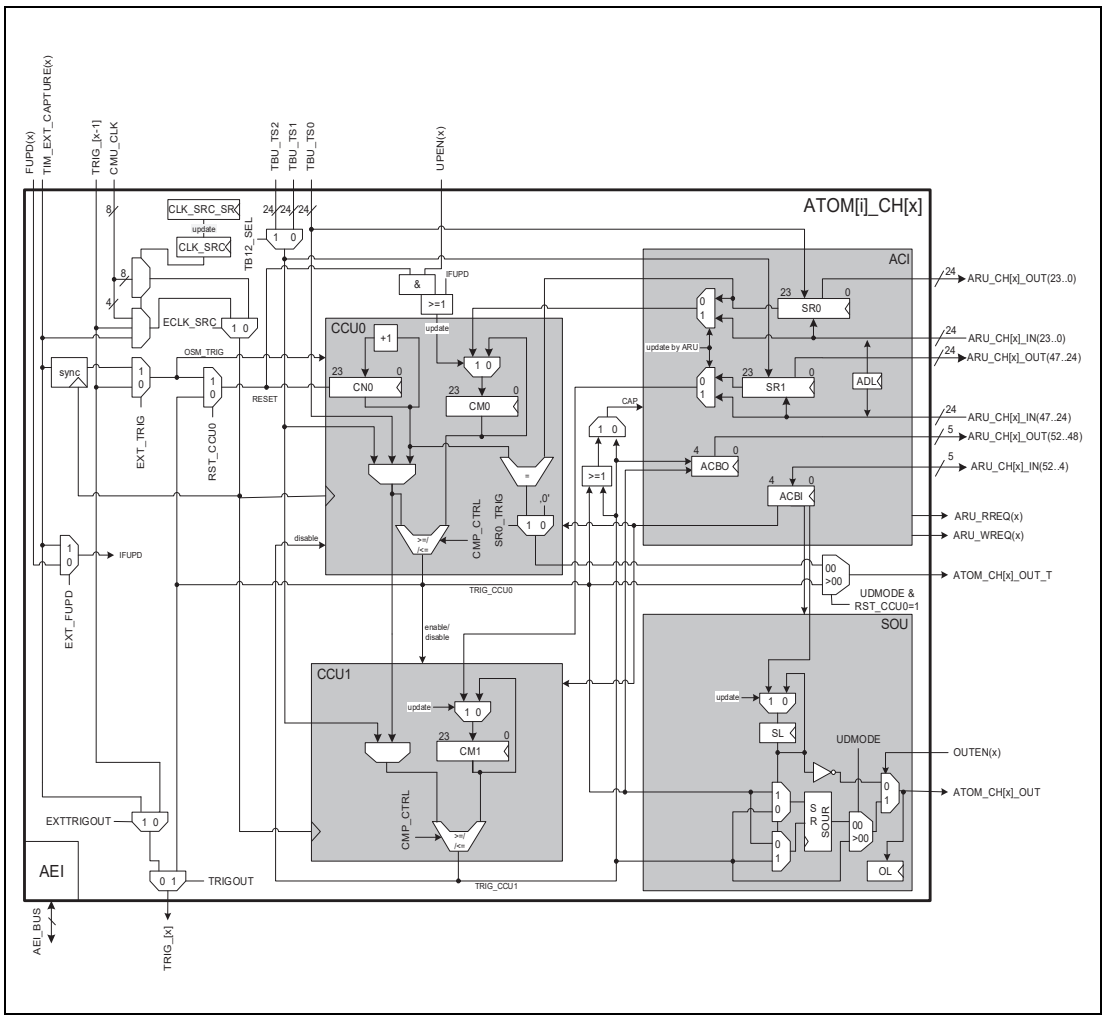

Figure 38.64 ATOM channel architecture

In all ATOM channels the operation registers CN0, CM0 and CM1 and the shadow registers SR0 and SR1 are the 24 bit width. The comparators inside CCU0 and CCU1 provide a selectable signed greater-equal or less-equal comparison to compare against the GTM time bases TBU_TS0, TBU_TS1 and, if available, TBU_TS2. Refer to TBU **Section 38.14, Time Base Unit (TBU)** for further details. The CCU0 and CCU1 units have different tasks for the different ATOM channel modes.

The cyclic event compare is used to detect time base overflows and to guarantee, that a compare match event can be set up for the future even when the time base will first overflow and then reach the compare value.

NOTE

For a correct behavior of this cyclic event compare, the new compare value must not be specified larger/smaller than half of the range of the total time base value ($7FFFFF_H$).

In SOMC/SOMB mode, the two compare units CCUx can be used in combination to each other. When used in combination, the trigger lines TRIG_CCU0 and TRIG_CCU1 can be used to enable/disable the other compare unit on a match event. Refer to **Section 38.17.3.2, ATOM Signal Output Mode Compare (SOMC)** and **Section 38.17.3.5, ATOM Signal Output Mode Buffered Compare (SOMB)** for further details.

The Signal Output Unit (SOU) generates the output signal for each ATOM channel. This output signal level depends on the ATOM channel mode and on the SL bit of the ATOM[i]_CH[x]_CTRL register in combination with the two control bits. These two control bits ACB(1) and ACB(0) can either be received via CPU in the ACB register field of the ATOM[i]_CH[x]_CTRL register or via ARU in the ACBI bit field of the ATOM[i]_CH[x]_STAT register.

The SL bit in the ATOM[i]_CH[x]_CTRL register defines in all modes the operational behavior of the ATOM channel.

When the channel and its output are disabled, the output signal level of the channel is the inverse of the SL bit.

In SOMI, SOMC and SOMB mode the output signal level depends on the SL, ACB0 and ACB1 bits. In SOMP mode the output signal level depends on the two trigger signals TRIG_CCU0 and TRIG_CCU1 since theses two triggers define the PWM timing characteristics and the SL bit defines the level of the duty cycle. In SOMS mode the output signal level is defined by the bit pattern that has to be shifted out by the ATOM channel. The bit pattern is located inside the CM1 register.

The ARU Communication Interface (ACI) sub-unit is responsible for requesting data routed through ARU to the ATOM channel in SOMI, SOMP, SOMB and SOMS modes, and additionally for providing data to the ARU in SOMC mode.

In SOMC mode the ACI shadow registers have a different behavior and are used as output buffer registers for data send to ARU.

38.17.2.1 ARU Communication Interface

The ATOM channels have an ARU Communication Interface (ACI) sub-unit. This sub-unit is responsible for data exchange from and to the ARU. This is done with the two implemented registers SR0, SR1, and the ACBI and ACBO bit fields that are part of the ATOM[i]_CH[x]_STAT register. The ACI architecture is shown in **Figure 38.65**.

If the ARU_EN bit is set inside the ATOM[i]_CH[x]_CTRL register, the ATOM channel is enabled by setting the enable bits inside the ATOM[i]_AGC_ENDIS_STAT register and the CPU hasn't written data not equal to zero into the CM0, CM1, SR0, SR1 register, the ATOM channel will first request data from the ARU before the signal generation starts in SOMP, SOMS, SOMC and SOMB mode.

NOTES

1. If in SOMP mode there is data inside the CM0 or SR0 register not equal to 0 the channel counter CN0 will start counting immediately, regardless whether the channel has received ARU data yet.
2. If in SOMS mode there is data inside the CM0 or SR0 register not equal to 0 the channel will start shifting immediately, regardless whether the channel has received ARU data yet.

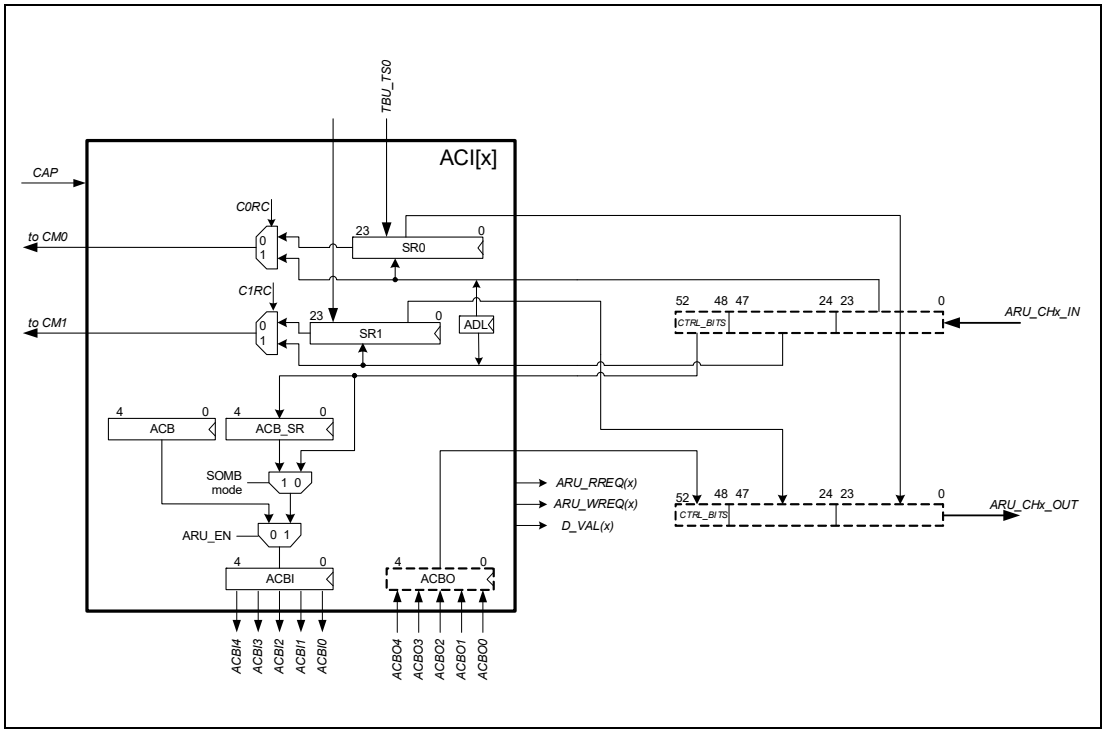

Figure 38.65 ACI architecture overview

Incoming ARU data (53 bit width signal ARU_CHx_IN) is split into three parts by the ACI and communicated to the ATOM channel registers. In SOMI, SOMP, SOMS and SOMB modes incoming ARU data ARU_CHx_IN is split in a way that the lower 24 bits of the ARU data (23 down to 0) are stored in the SR0 register, the upper bits (47 down to 24) are stored in the SR1 register. The bits 52 down to 48 (CTRL_BITS) are stored in SOMI, SOMP and SOMS mode in the ACBI bit field of the register ATOM[i]_CH[x]_STAT, in SOMB mode in the internal ACB_SR register.

The ATOM channel has to ensure, that in a case when the channel operation registers CM0 and CM1 are updated with the SR0 and SR1 register content and an ARU transfer to these shadow registers

happens in parallel that either the old data in both shadow registers is transferred into the operation registers or both new values from the ARU are transferred.

In SOMC mode incoming ARU data ARU_CHx_IN is written directly to the ATOM channel operation register in the way that the lower 24 bits (23 down to 0) are written to CM0, and the bits 47 down to 24 are written to register CM1. The bits 52 down to 48 are stored in the ACBI bit field of the ATOM[i]_CH[x]_STAT register and control the behavior of the compare units and the output signal of the ATOM channel.

In SOMC mode the SR0 and SR1 registers serve as capture registers for the time stamps coming from TBU whenever a compare match event is signaled by the CCU0 and/or CCU1 sub-units via the CAP signal line. These two time stamps are then provided together with actual ATOM channel status information located in the ACBO bit field to the ARU at the dedicated ARU write address of the ATOM channel when the ARU is enabled.

The encoding of the ARU control bits in the different ATOM operation modes is described in more detail in the following chapters.

38.17.3 ATOM Channel Modes

As described above, each ATOM channel can operate independently from each other in one of five dedicated output modes:

- ATOM Signal Output Mode Immediate (SOMI)
- ATOM Signal Output Mode Compare (SOMC)
- ATOM Signal Output Mode PWM (SOMP)
- ATOM Signal Output Mode Serial (SOMS)
- ATOM Signal Output Mode Buffered Compare (SOMB)

The Signal Output Mode PWM (SOMP) is principally the same like the output mode for the TOM sub-module. In addition, it is possible to reload the shadow registers via the ARU without the need of a CPU interaction. The other modes provide additional functionality for signal output control. All operation modes are described in more detail in the following sections.

NOTE

In any output mode, if a channel is enabled, one-shot mode is disabled (OSM = 0; only used in modes SOMP and SOMS) and CM0 ≥ CN0, the counter CN0 is incrementing until it reaches CM0. To avoid unintended counting of CN0 after enabling a channel, it is recommended to reset a channel (or at least CN0 and CM0) before any change on the mode bits MODE, ARU_EN and OSM.

The ACB bitfield of ATOM[i]_CH[x]_CTRL register has a different mapping regarding the ATOM channel mode. Refer to table as below

Table 38.197 Coding of ACB bitfield of ATOM[i]_CH[x]_CTRL register (1/2)

Mode	Name/(Bit)	Description	Coding	Notes
SOMI	ACB0/(4)	ACB0 bit 0	0_B: Set output to inverse bit 1_B: Set output to SL bit	
	--/(8:5)	Not used		
SOMC	ACB10/(5:4)	Signal level Control	00_B: No signal level change at output (exception in tables **Table 38.201, ATOM CCUx Serve first definition ACB42 = 000** and **Table 38.202, ATOM CCUx Serve first definition ACB42 = 001** mode ACB42=001). 01_B: Set output signal level to 1 when SL bit = 0 else output signal level to 0. 10_B: Set output signal level to 0 when SL bit = 0 else output signal level to 1. 11_B: Toggle output signal level (exception in tables **Table 38.201, ATOM CCUx Serve first definition ACB42 = 000** and **Table 38.202, ATOM CCUx Serve first definition ACB42 = 001** mode ACB42=001).	
SOMC	ACB42/(8:6)	Compare strategy	000_B: Compare in CCU0 and CCU1 in parallel, disable the CCUx on a compare match on either of compare units. Use TBU_TS0 in CCU0 and TBU_TS1 or TBU_TS2 in CCU1. 001_B: Compare in CCU0 and CCU1 in parallel, disable the CCUx on a compare match on either compare units. Use TBU_TS0 in CCU0 and TBU_TS1 or TBU_TS2 in CCU1. 010_B: Compare in CCU0 only against TBU_TS0. 011_B: Compare in CCU1 only against TBU_TS1 or TBU_TS2. 100_B: Compare first in CCU0 and then in CCU1. Use TBU_TS0. 101_B: Compare first in CCU0 and then in CCU1. Use TBU_TS1 or TBU_TS2. 110_B: Compare first in CCU0 and then in CCU1. Use TBU_TS0 in CCU0 and TBU_TS1 or TBU_TS2 in CCU1. 111_B: Cancel pending compare events.	**Note:** These bits are only applicable if ARU_EN = '0'. **Note:** Independent of ARU_EN, a writing of 111_B cancels any pending CCU0 or CCU1 compare.
SOMP	ADL/(5:4)	ARU data select	00_B: Load both ARU words into shadow registers. 01_B: Load ARU low word (Bits 23..0) into shadow register SR0. 10_B: Load ARU high word (Bits 47..24) into shadow register SR1. 11_B: Reserved.	
	BITREV/(6)	PCM mode enable	0_B/1_B: Bit-reversing of output of counter register CN0. This bit enables the PCM mode.	**Note:** It is device specific, in which channel the PCM mode is available. Refer to device specific **38.28, GTM Device 358** for this information.
	SR0_TRIG/(7)	SR0 used for ATOM[i]_CH[x]_OUT_T	0_B: SR0 is used as a shadow register for register CM0. 1_B: SR0 is not used as a shadow register for register CM0. SR0 is compared with CN0 and if both are equal, a trigger pulse is generated at output ATOM[i]_CH[x]_OUT_T.	**Note:** This bit may only be set if RST_CCU0 of this channel is 0.

Table 38.197 Coding of ACB bitfield of ATOM[i]_CH[x]_CTRL register (2/2)

Mode	Name/(Bit)	Description	Coding	Notes
SOMS	ACB0/(4)	Shift direction	0_B: Right shift of data is started from bit 0 of CM1. 1_B: Left shift of data is started from bit 23 of CM1.	**Note:** The data that has to be shifted out has to be aligned inside the CM1 register according to the defined shift direction. **Note:** This bit is only applicable if ARU_EN = 0. **Note:** If the direction (ACB0) is changed the output ATOM_OUT[x] switches immediately to the other 'first' bit of CM1 (bit 0 if ACB0 = 0, bit 23 if ACB0 = 1).
	--/(6:5)	Not used		
	DSO/(7)	Double shift output	0_B: CM1 is used as a 24 bit shift register. 1_B: CM1 is split into two 12 bit shift register.	**Note:** If DSO=1, only shift right is possible.
	--/(8)	Not used		
SOMB	ACB10/(5:4)	Signal level control	00_B: No signal level change at output. 01_B: Set output signal level to 1 when SL bit = 0 else output signal level to 0. 10_B: Set output signal level to 0 when SL bit = 0 else output signal level to 1. 11_B: Toggle output signal level. For details: **Table 38.208, ATOM SOMB output control by ACBI[1:0] and SL**	**Note:** These bits are only applicable if ARU_EN = 0.
	ACB42/(8:6)	Compare strategy	000_B: Reserved. Has no effect. 001_B: Reserved. Has no effect. 010_B: Compare in CCU0 only against TBU_TS0. 011_B: Compare in CCU1 only against TBU_TS1 or TBU_TS2. 100_B: Compare first in CCU0 and then in CCU1. Use TBU_TS0. 101_B: Compare first in CCU0 and then in CCU1. Use TBU_TS1 or TBU_TS2. 110_B: Compare first in CCU0 and then in CCU1. Use TBU_TS0 in CCU0 and TBU_TS1 or TBU_TS2 in CCU1. 111_B: Cancel pending comparisons independent on ARU_EN. For details: **Table 38.207, ATOM SOMB compare strategies**	**Note:** These bits are only applicable if ARU_EN = 0.

38.17.3.1 ATOM Signal Output Mode Immediate (SOMI)

In ATOM Signal Output Mode Immediate (SOMI), the ATOM channel generates output signals on the ATOM[i]_CH[x]_OUT output port immediate after update of the bit ACBI(0) of register ATOM[i]_CH[x]_STAT or ACB(0) bit of register ATOM[i]_CH[x]_CTRL.

If ARU access is enabled by setting bit ARU_EN in register ATOM[i]_CH[x]_CTRL, the update of the output ATOM[i]_CH[x]_OUT depends on the bit ACBI(0) of register ATOM[i]_CH[x]_STAT received at the ACI sub-unit and the bit SL bit of register ATOM[i]_CH[x]_CTRL. The remaining 48 ARU bits (47 down to 0) have no meaning in this mode.

If ARU access is disabled, the update of the output ATOM[i]_CH[x]_OUT depends on the bit ACB(0) and the bit SL of register ATOM[i]_CH[x]_CTRL.

The initial ATOM channel port pin ATOM[i]_CH[x]_OUT signal level has to be specified by the SL bit field of the ATOM[i]_CH[x]_CTRL register when OUTEN_CTRL register bit field OUTEN_CTRLx is disabled (see **Section 38.17.6.5, ATOM[i]_AGC_OUTEN_CTRL**) for details.

In SOMI mode the output behavior depends on the SL bit of register ATOM[i]_CH[x]_CTRL and the bit ACBI(0) of the ATOM[i]_CH[x]_STAT register or the bit ACB0 of register ATOM[i]_CH[x]_CTRL:

(1) Output behavior in SOMI mode

SL	ACBI(0)/ACB(0)	Output behavior
0	0	Set output to inverse of SL (1)
0	1	Set output to SL (0)
1	0	Set output to inverse of SL (0)
1	1	Set output to SL (1)

The signal level bit ACBI(0) is transferred to the SOU sub-unit of the ATOM and made visible at the output port according to the table above immediately after the data was received by the ACI. This can introduce a jitter on the output signal since the ARU channels are served in a time multiplexed fashion.

(2) ATOM[i]_CH[x]_CTRL in SOMI mode

Access: This register can be read or written in 32-bit units.

Address: <GTM_base> + $E8004_H$ + (800_H × i) + (40_H × x)

38.17.3.2 ATOM Signal Output Mode Compare (SOMC)

(1) Overview

In ATOM Signal Output Mode Compare (SOMC) the output action is performed in dependence of the comparison between input values located in CM0 and/or CM1 registers and the two (three) time base values TBU_TS0 or TBU_TS1 (or TBU_TS2) provided by the TBU. For a description of the time base generation refer to the TBU specification in **Section 38.14**. It is configurable, which of the two (three) time

bases is to be compared with one or both values in CM0 and CM1.

The behavior of the two compare units CCU0 and CCU1 is controlled either with the bits 4 down to 2 of ACB bit field inside the ATOM[i]_CH[x]_CTRL register, when the ARU connection is disabled or with the ACBI bit field of the ATOM[i]_CH[x]_STAT register, when the ARU is enabled. In that case the ACB bit field is updated via the ARU control bits 52 down to 48.

The CCUx trigger signals TRIG_CCU0 and TRIG_CCU1 always create edges, dependent on the predefined signal level in SL bit in combination with two control bits that can be specified by either ARU or CPU within the aforementioned ATOM[i]_CH[x]_CTRL or ATOM[i]_CH[x]_STAT registers.

In SOMC mode the channel is always disabled after the specified compare match event occurred. The shadow registers are used to store two time stamp values at the match time. The channel compare can be re-enabled by first reading the shadow registers, either by CPU or ARU and by providing new data for CMx registers through CPU or ARU. For a detailed description refer to **Section 38.17.3.2, (2) SOMC Mode under CPU control** and **Section 38.17.3.2, (3) SOMC Mode under ARU control**.

If three time bases exist for the GTM-IP there must be a preselection between TBU_TS1 and TBU_TS2 for the ATOM channel. This can be done with TB12_SEL bit in the ATOM[i]_CH[x]_CTRL register.

The comparison in CCU0/1 with time base TBU_TS1 or TBU_TS2 can be done on a greater-equal or less-equal compare according to the CMP_CTRL bit. This control bit has no effect to a compare unit CCU0 or CCU1 that compares against TBU_TS0. In this case always a greater-equal compare is done. The bit CMP_CTRL is part of the ATOM[i]_CH[x]_CTRL register.

When configured in SOMC mode, the channel port pin has to be initialized to an initial signal level. This initial level after enabling the ATOM channel is determined by the SL bit in the ATOM[i]_CH[x]_CTRL register. If the output is disabled, the signal level is set to the inverse level of the SL bit.

If the channel is disabled, the register SOUR is set to the SL bit in the ATOM[i]_CH[x]_CTRL register.

On a compare match event the shadow register SR0 and SR1 are used to capture the TBU time stamp values. SR0 always holds TBU_TS0 and SR1 either holds TBU_TS1 or TBU_TS2 dependent on the TB12_SEL bit in the ATOM[i]_CH[x]_CTRL register.

NOTE

When the channel is disabled and the compare registers are written, the compare registers CMx are loaded with the written value and the channel starts with the comparison on behalf of this values, when the channel is enabled.

(2) SOMC Mode under CPU control

As already mentioned above the ATOM channel can be controlled either by CPU or by ARU. When the channel should be controlled by CPU, the ARU_EN bit inside the ATOM[i]_CH[x]_CTRL register has to be reset.

The output of the ATOM channel is set on a compare match event depending on the ACB10 bit field in combination with the SL bit both located in the ATOM[i]_CH[x]_CTRL register. The output behavior according to the ACB10 bit field in the control register is shown in the following table:

The capture/compare strategy of the two CCUx units can be controlled with the ACB42 bit field inside the ATOM[i]_CH[x]_CTRL register.

The meaning of these bits is shown in the following table:

Table 38.199 Output behavior according to the ACB10 bit field in the control register

SL	ACB10(5)	ACB10(4)	Output Behavior
0	0	0	No signal level change at output (exception in **Table 38.202, ATOM CCUx Serve first definition ACB42 = 001**)
0	0	1	Set output signal level to 1
0	1	0	Set output signal level to 0
0	1	1	Toggle output signal level (exception in **Table 38.202, ATOM CCUx Serve first definition ACB42 = 001**)
1	0	0	No signal level change at output (exception in **Table 38.202, ATOM CCUx Serve first definition ACB42 = 001**)
1	0	1	Set output signal level to 0
1	1	0	Set output signal level to 1
1	1	1	Toggle output signal level (exception in **Table 38.202, ATOM CCUx Serve first definition ACB42 = 001**)

The capture/compare strategy of the two CCUx units can be controlled with the ACB42 bit field inside the ATOM[i]_CH[x]_CTRL register. The meaning of these bits is shown in the following table.

Table 38.200 The capture/Compare strategy of the two CCUx (1/2)

ACB42(8)	ACB42(7)	ACB42(6)	CCUx control
0	0	0	Serve First: Compare in CCU0 using TBU_TS0 and in parallel in CCU1 using TBU_TS1 or TBU_TS2. Disable other CCUx on compare match. Output signal level on the compare match of the matching CCUx unit is defined by combination of SL, ACB10(5) and ACB10(4). Details see **Table 38.202, ATOM CCUx Serve first definition ACB42 = 001**.
0	0	1	Serve First: Compare in CCU0 using TBU_TS0 and in parallel in CCU1 using TBU_TS1 or TBU_TS2. Disable other CCUx on compare match. Output signal level on the compare match of the matching CCUx unit is defined by combination of SL, ACB10(5) and ACB10(4). Details see **Table 38.202, ATOM CCUx Serve first definition ACB42 = 001**.
0	1	0	Compare in CCU0 only, use time base TBU_TS0. Output signal level is defined by combination of SL, ACB10(5) and ACB10(4) bits.
0	1	1	Compare in CCU1 only, use time base TBU_TS1 or TBU_TS2. Output signal level is defined by combination of SL, ACB10(5) and ACB10(4) bits.
1	0	0	Serve Last: Compare in CCU0 and then in CCU1 using TBU_TS0. Output signal level when CCU0 matches is defined by combination of SL, ACB10(5) and ACB10(4). On the CCU1 match the output level is toggled.

Table 38.200 The capture/Compare strategy of the two CCUx (2/2)

ACB42(8)	ACB42(7)	ACB42(6)	CCUx control
1	0	1	Serve Last: Compare in CCU0 and then in CCU1 using TBU_TS1 or TBU_TS2. Output signal level when CCU0 matches is defined by combination of SL, ACB10(5) and ACB10(4). On the CCU1 match the output level is toggled.
1	1	0	Serve Last: Compare in CCU0 using TBU_TS0 and then in CCU1 using TBU_TS1 or TBU_TS2. Output signal level when CCU1 matches is defined by combination of SL, ACB10(5) and ACB10(4).
1	1	1	Cancels pending comparison independent on ARU_EN.

The behavior of the ACBI / ACB42 bit combinations 000 and 001 is described in more detail in **Table 38.201** and **Table 38.202**.

If the ATOM channel is enabled, the CM0 and/or CM1 registers and the ACB42 bit field of the ATOM[i]_CH[x]_CTRL register can be updated by the CPU as long as the first match event occurs in case of a 'serve last' compare strategy or as long as the overall match event in case of the other compare strategies.

After a compare match event that causes an update of the shadow registers SR0/SR1 and before reading the SR0 and/or SR1 register via ARU, the update of the registers CM0 and/or CM1 is possible but has no effect.

To set up a new compare action, first the SR0 and/or SR1 register containing captured values have to be read and then new compare values have to be written into the register CM0 and/or CM1.

Which CMx register has to be updated depends on the compare strategy defined in the ACB42 bit field of the channel control register. Since the channel immediately starts with the comparison after the CMx register was/were written, the compare strategy has to be updated before the CMx registers are written.

For the 'serve last' compare strategies, if the register CM0 and CM1 are updated, it can happen that one or both compare values are already located in the past. In any way the ATOM channel will first wait until both compare values are written before it starts the time base comparisons to avoid a deadlock.

The CPU can check at any time if at least one of the ATOM channels' capture compare register contains valid data and waits for a compare event to happen. This is signaled by the DV bit inside the ATOM[i]_CH[x]_STAT register.

NOTE

For 'serve last' compare strategies, if DV bit is currently not set, writing to CM0 or CM1 sets immediately the DV bit although the compare is only started if both values are written.

An exception for update of register CM0/CM1 exists in SOMC mode and CCUx control mode 'serve last'. If in this mode the CCU0 compare match event occurred, the update of register CM0/CM1 via CPU is blocked until the CCU1 compare match event.

In the 'serve last' mode (ACB42 = 100 or ACB42 = 101) it is possible to generate very small spikes on the output pin by loading CM0 and CM1 with two time stamp values for TBU_TS0, TBU_TS1 or TBU_TS2 close together. The output pin will then be set or reset dependent on the SL bit and the

specified ACB10(5) and ACB10(4) bits in the ACB10 bit field of the ATOM[i]_CH[x]_CTRL register on the first match event and the output will toggle on the second compare event in the CCU1 compare unit.

NOTE

The bigger (smaller) time stamp has to be loaded into the CM1 register, since the CCU0 will enable the CCU1 once it has reached its comparison time stamp. The order of the comparison time stamps depends on the defined greater-equal or less-equal comparison of the CCUx units.

In addition to storing the captured time stamps in the shadow registers, the ATOM channel provides the result of the compare match event in the ACBO(4) and ACBO(3) bits of the ATOM[i]_CH[x]_STAT register. The meaning of the bits is shown in the following table:

Table 38.203 Compare match event ACBO(4) and ACBO(3) bits of ATOM[i]_CH[x]_STAT

ACBO(4)	ACBO(3)	Indication
0	1	CCU0 compare match occurred
1	0	CCU1 compare match occurred

NOTE

In case of the 'serve last' compare strategy, when the bit SLA in the ATOM[i]_CH[x]_CTRL register is not set, the ACBO(4) bit is always set and the ACBO(3) bit is always reset after the compare match event occurred.

The ACBO bit field is reset, when the DV bit is set.

Depending on the capture compare unit where the time base matched the interrupt CCU0TCx_IRQ or CCU1TCx_IRQ is raised.

NOTE

In case of 'serve first' compare strategy, if both events CCU0 and CCU1 occur at the same point in time, both interrupts will be raised.

The behavior of an ATOM channel in SOMC mode under CPU control is depicted in **Figure 38.66**.

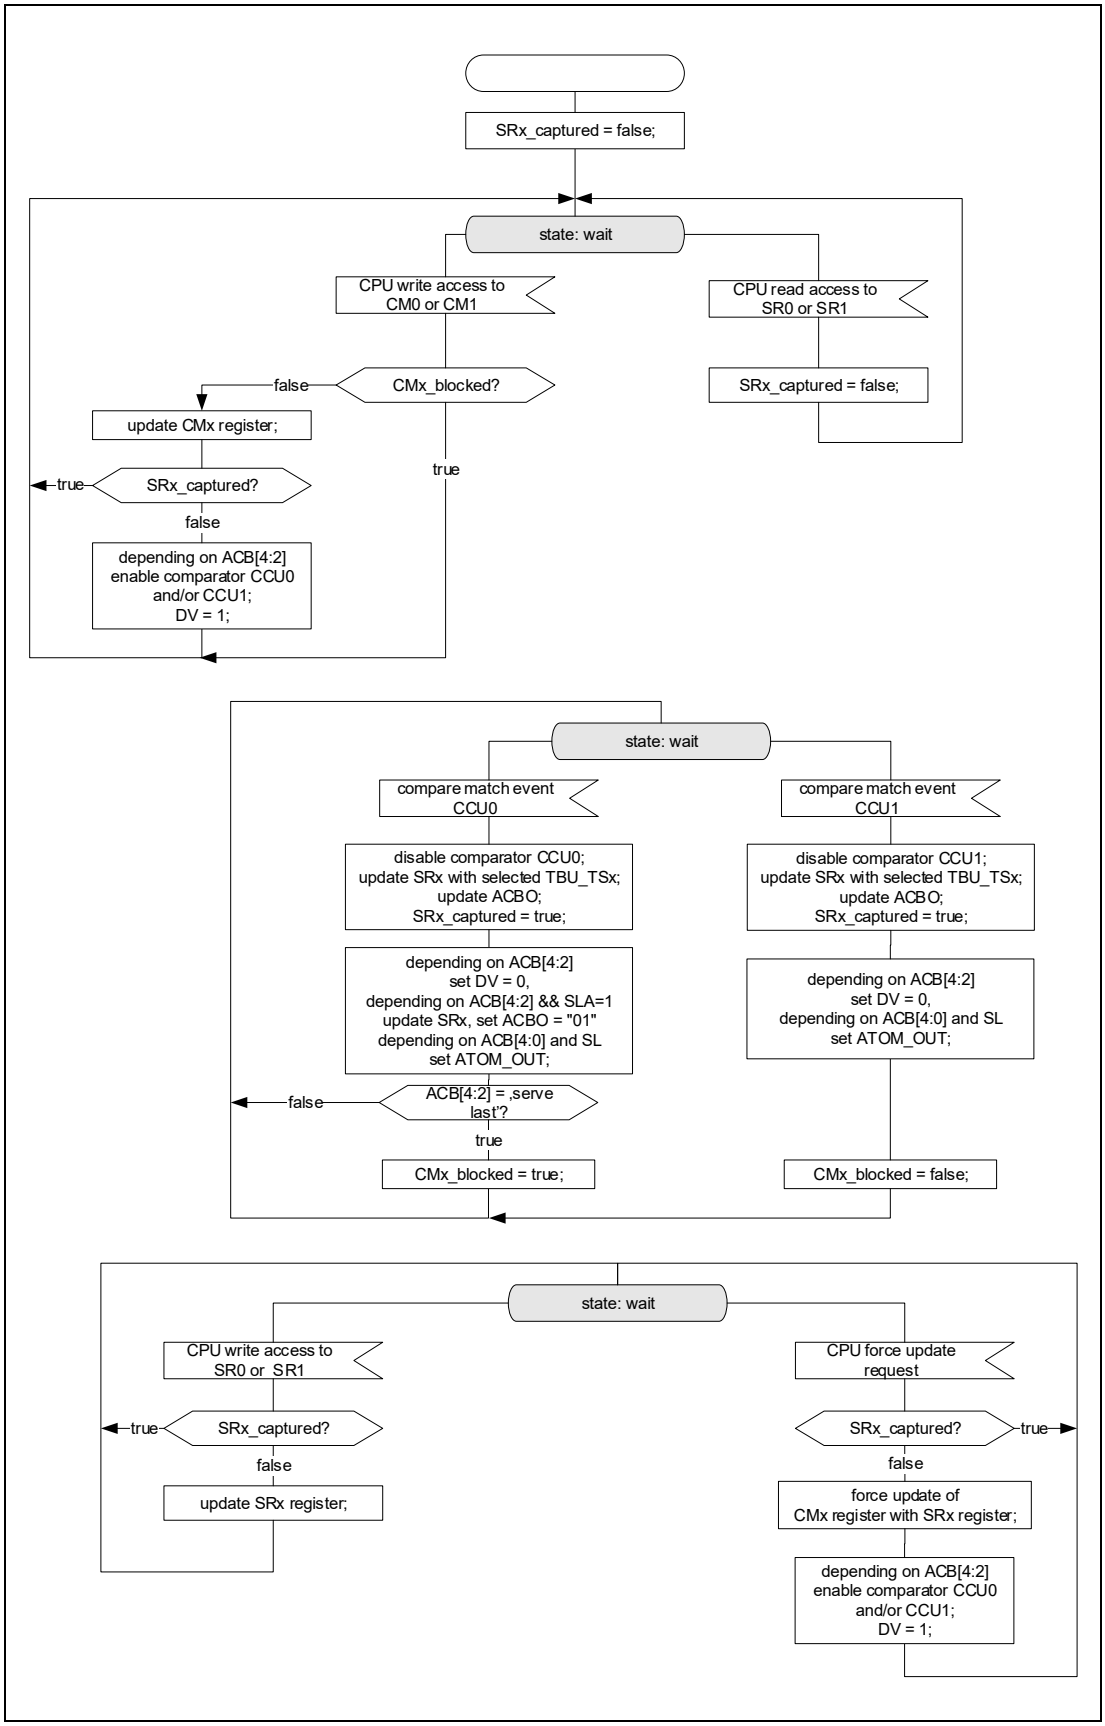

Figure 38.66 SOMC state diagram for channel under CPU control

(3) SOMC Mode under ARU control

When the channel should be controlled by ARU, the ARU_EN bit inside the ATOM[i]_CH[x]_CTRL register has to be set.

In case, the ATOM channel is under ARU control the content for the compare registers CM0 and CM1 as well as the update of the compare strategy can be loaded via the 53 bit ARU word.

The ARU word 23 to 0 is loaded into the CM0 register while the ARU word 47 to 24 is loaded into the CM1 register. The five ARU control bits 52 to 48 are loaded into the ACBI bit field of the ATOM[i]_CH[x]_STAT register and control the channel compare strategy as well as the output behavior in case of compare match events.

For the five ARU control bits 52 to 48 the bits 49 and 48 are loaded into the ACBI bits 1 and 0. The output behavior also depends on the setting of the SL bit inside of the ATOM[i]_CH[x]_CTRL register and is shown in the following table:

Table 38.204 Output behavior depends on SL bit inside of the ATOM[i]_CH[x]_CTRL and ACBI bits 1 and 0

SL	ACBI(1)	ACBI(0)	Output behavior
0	0	0	No signal level change at output (exception in **Table 38.201** and **Table 38.202**)
0	0	1	Set output signal level to 1
0	1	0	Set output signal level to 0
0	1	1	Toggle output signal level (exception in **Table 38.201** and **Table 38.202**)
1	0	0	No signal level change at output (exception in **Table 38.201** and **Table 38.202**)
1	0	1	Set output signal level to 0
1	1	0	Set output signal level to 1
1	1	1	Toggle output signal level (exception in **Table 38.201** and **Table 38.202**)

For the five ARU control bits 52 to 48 the bits 52 to 50 are loaded into the ACBI bits 4 to 2. With these three bits the capture/compare units CCUx can be controlled as shown in the following table:

Table 38.205 Capture/compare units CCUx controlled by ACBI bits 4 to 2 (1/2)

ACBI(4)	ACBI(3)	ACBI(2)	CCUx control
0	0	0	Serve First: Compare in CCU0 using *TBU_TS0* and in parallel in CCU1 using *TBU_TS1* or *TBU_TS2*. Disable other CCUx on compare match. Output signal level on the compare match of the matching CCUx unit is defined by combination of SL, ACBI(1) and ACBI(0). Details see **Table 38.202**.
0	0	1	Serve First: Compare in CCU0 using *TBU_TS0* and in parallel in CCU1 using *TBU_TS1* or *TBU_TS2*. Disable other CCUx on compare match. Output signal level on the compare match of the matching CCUx unit is defined by combination of SL, ACBI(1) and ACBI(0). Details see **Table 38.201**.
0	1	0	Compare in CCU0 only, use time base *TBU_TS0*. Output signal level is defined by combination of SL, ACBI(1) and ACBI(0) bits.
0	1	1	Compare in CCU1 only, use time base *TBU_TS1* or *TBU_TS2*. Output signal level is defined by combination of SL, ACBI(1) and ACBI(0) bits.

Table 38.205 Capture/compare units CCUx controlled by ACBI bits 4 to 2 (2/2)

ACBI(4)	ACBI(3)	ACBI(2)	CCUx control
1	0	0	Serve Last: Compare in CCU0 and then in CCU1 using *TBU_TS0*. Output signal level when CCU0 matches is defined by combination of SL, ACBI(1) and ACBI(0). On the CCU1 match the output level is toggled.
1	0	1	Serve Last: Compare in CCU0 and then in CCU1 using *TBU_TS1* or *TBU_TS2*. Output signal level when CCU0 matches is defined by combination of SL, ACBI(1) and ACBI(0). On the CCU1 match the output level is toggled.
1	1	0	Serve Last: Compare in CCU0 using *TBU_TS0* and then in CCU1 using *TBU_TS1* or *TBU_TS2*. Output signal level when CCU1 matches is defined by combination of SL, ACBI(1) and ACBI(0).
1	1	1	Change ARU read address to ATOM_RDADDR1 DV flag is not set. Neither ACBI(1) nor ACBI(0) is evaluated.

Note: The bit combination 111_B for the ACBI(4), ACBI(3) and ACBI(2) bits forces the channel to request new compare values from another destination read address defined in the ATOM_RDADDR1 bit field of the ATOM[i]_CH[x]_RDADDR register. After data was successfully received and the compare event occurred the ATOM channel switches back to ATOM_RDADDR0 to receive the next data from there.

After the specified compare match event, the captured time stamps are stored in SR0 and SR1 and the compare result is stored in the ACBO bit field of the ATOM[i]_CH[x]_STAT register. The meaning of the ACBO(4) and ACBO(3) bits of the ATOM[i]_CH[x]_STAT is shown in the following table:

Table 38.206 Compare match event ACBO(4) and ACBO(3) bits of ATOM[i]_CH[x]_STAT

ACBO(4)	ACBO(3)	Return value to ARU
0	1	CCU0 compare match occurred
1	0	CCU1 compare match occurred

Note: In case of the “serve last” compare strategy, when the bit SLA in the ATOM[i]_CH[x]_CTRL register is not set, the ACBO(4) bit is always set and the ACBO(3) bit is always reset after the compare match event occurred.

The ACBO bit field is reset, when the DV bit is set.

Depending on the capture compare unit where the time base matched the interrupt CCU0TCx_IRQ or CCU1TCx_IRQ is raised.

When CCU0 and CCU1 is used for comparison it is possible to generate very small spikes on the output pin by loading CM0 and CM1 with two time stamp values for TBU_TS0, TBU_TS1 or TBU_TS2 close together. The output pin will then be set or reset dependent on the SL bit and the specified ACBI(0) and ACBI(1) bits in the ACBI bit field of the ATOM[i]_CH[x]_STAT register on the first match event and the output will toggle on the second match event.

NOTE

The bigger (smaller) time stamp has to be loaded into the CM1 register, since the CCU0 will enable the CCU1 once it has reached its comparison time stamp. The order of the comparison time stamps depends on the defined greater-equal or less-equal comparison of the CCUx units.

For compare strategy 'serve last' the CCU0 and CCU1 compare match may occur sequentially. During different phases of compare match the CPU access rights to register CM0 and CM1 as well as to WR_REQ bit is different. For the case of bit ABM = 0 and EUPM = 0 (register ATOM[i]_CH[x]_CTRL) these access rights by CPU to register CM0 and CM1 and the WR_REQ are depicted in the following figure.

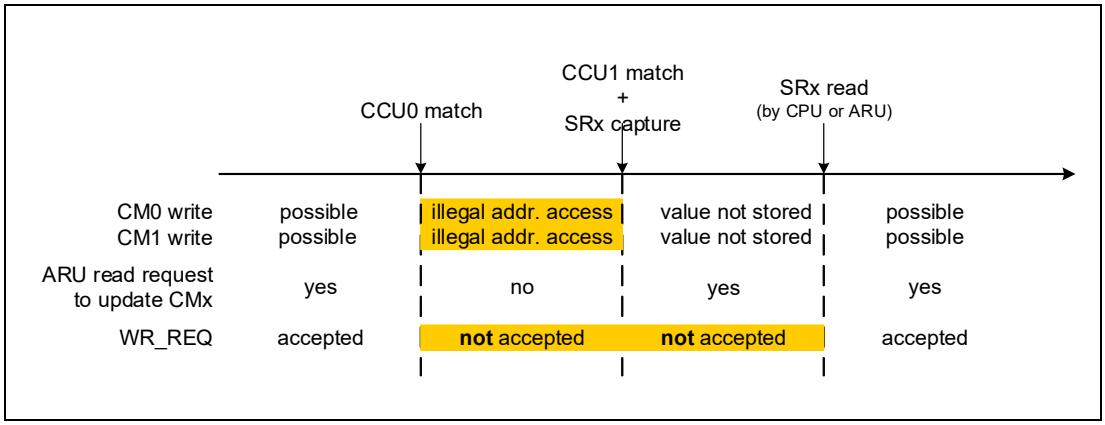

Figure 38.67 CPU access rights in case of compare strategy 'serve last', ABM = 0 and EUPM = 0

For the case of bit ABM = 1 and EUPM = 0 (register ATOM[i]_CH[x]_CTRL) these access rights by CPU to register CM0 and CM1 and the WR_REQ are depicted in the following figure.

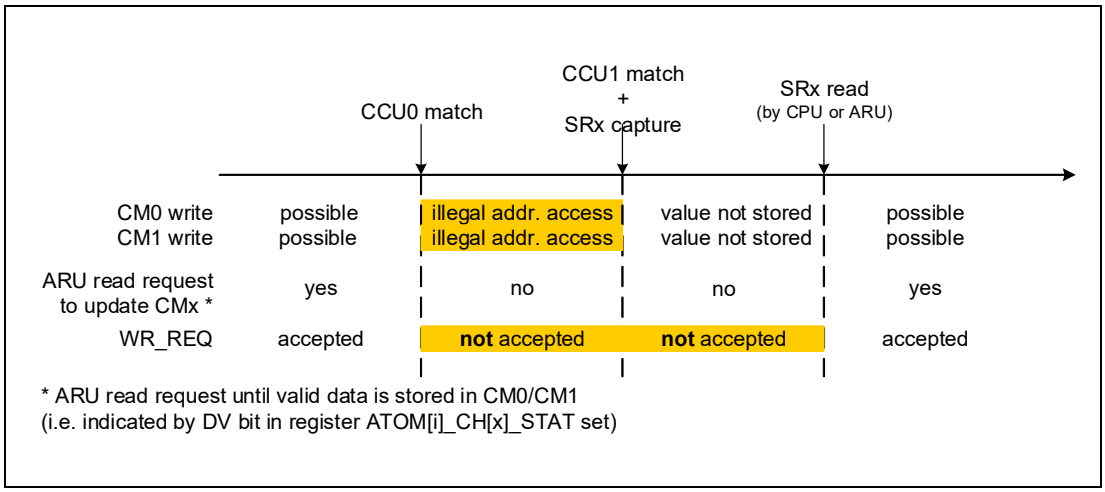

Figure 38.68 CPU access rights in case of compare strategy 'serve last', ABM = 1 and EUPM = 0

For the case of bit EUPM = 1 (register ATOM[i]_CH[x]_CTRL), after CCU0 compare match (and before CCU1 compare match) an update of CM1 as well as a late update via WR_REQ is possible. The value is used for compare. After CCU0 compare match an update of CM0 is not possible, means the value is not stored. The ARU read request is not paused between the compare matches. This behavior is depicted in the following figures.

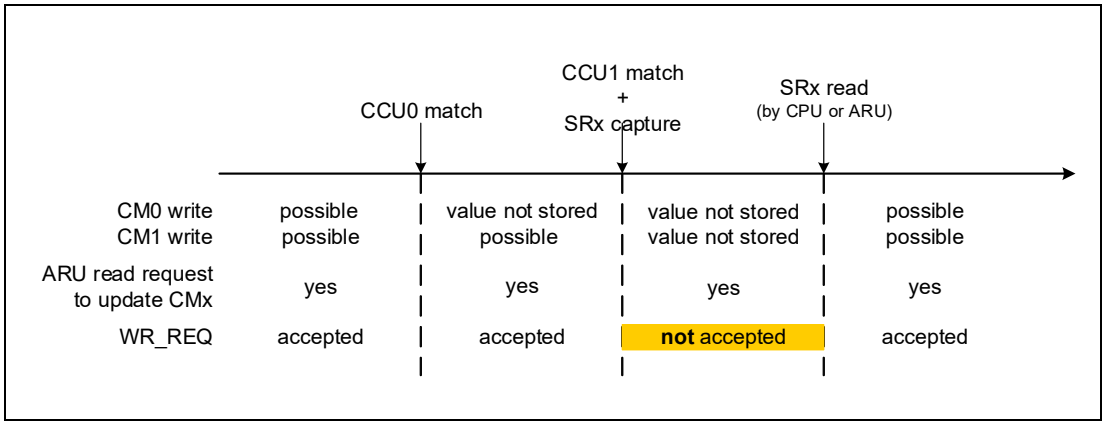

Figure 38.69 CPU access rights in case of compare strategy 'serve last', ABM = 0 and EUPM = 1

The behavior in case of EUPM = 1 and ABM = 1 is depicted in the following figure:

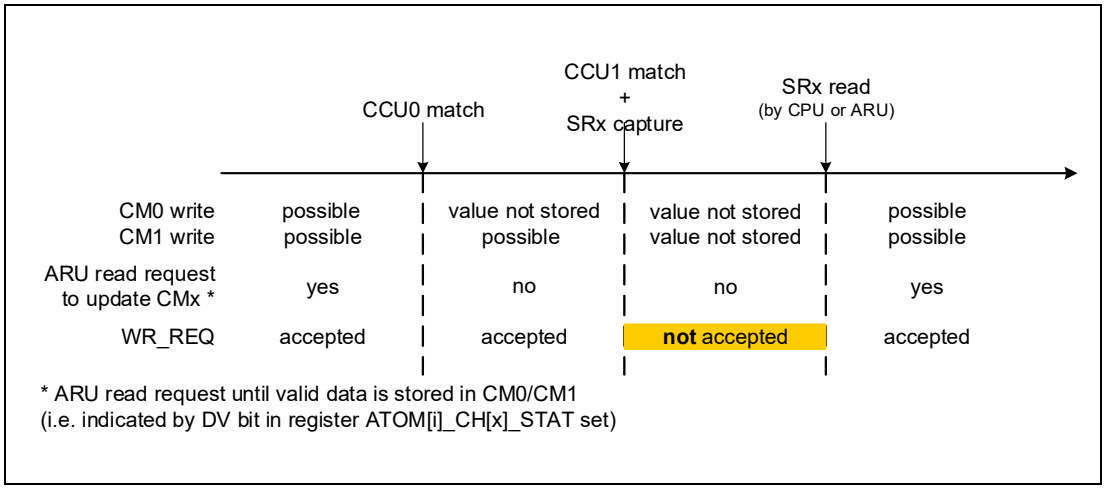

Figure 38.70 CPU access rights in case of compare strategy 'serve last', ABM = 1 and EUPM = 1

In case of EUPM =1 a write access to CM0 or CM1 never causes an AEI write status 10.

(a) ARU Non-Blocking mode

When the compare registers are updated via ARU the update behavior of the channel is configurable with the ABM bit inside the ATOM[i]_CH[x]_CTRL register. When the ABM bit is reset, the ATOM channel is in ARU non-blocking mode.

In the ARU non-blocking mode, data received via ARU is continuously transferred to the registers CM0 and CM1 and the bit field ACBI of register ATOM[i]_CH[x]_STAT as long as no specified compare match event occurs.

After a compare match event that causes an update of the shadow register SR0/SR1 and before reading the SR0 / SR1 register via CPU or ARU, the update of the registers CM0 / CM1 via CPU or ARU is possible but the data is not accepted to be valid (no DV bit is set i register ATOM[i]_CH[x]_CTRL).

To set up a new compare action, first the SR0 / SR1 register containing captured values have to be read and then new compare values have to be written into the register CM0 / CM1. This can be done either by ARU or by CPU.

When the CPU does the register accesses, only one of the shadow registers has to be read. Dependent on the compare strategy, the CPU has to write one or both of the compare registers.

An exception for update of register CM0/CM1 exists in SOMC mode and CCUx control mode 'serve last' if EUPM=0. If in this mode the CCU0 compare match event occurred, the update of register CM0/CM1 via CPU is not possible until the CCU1 compare match event occurs.

NOTE

A write access to either CM0 or CM1 in this case leads to a write status 10.

The CPU can check at any time if the ATOM channel has received valid data from the ARU and waits for a compare event to happen. This is signaled by the DV bit inside the ATOM[i]_CH[x]_STAT register.

The behavior of an ATOM channel in SOMC mode, when ARU is enabled and ARU blocking mode is disabled is shown in **Figure 38.71**.

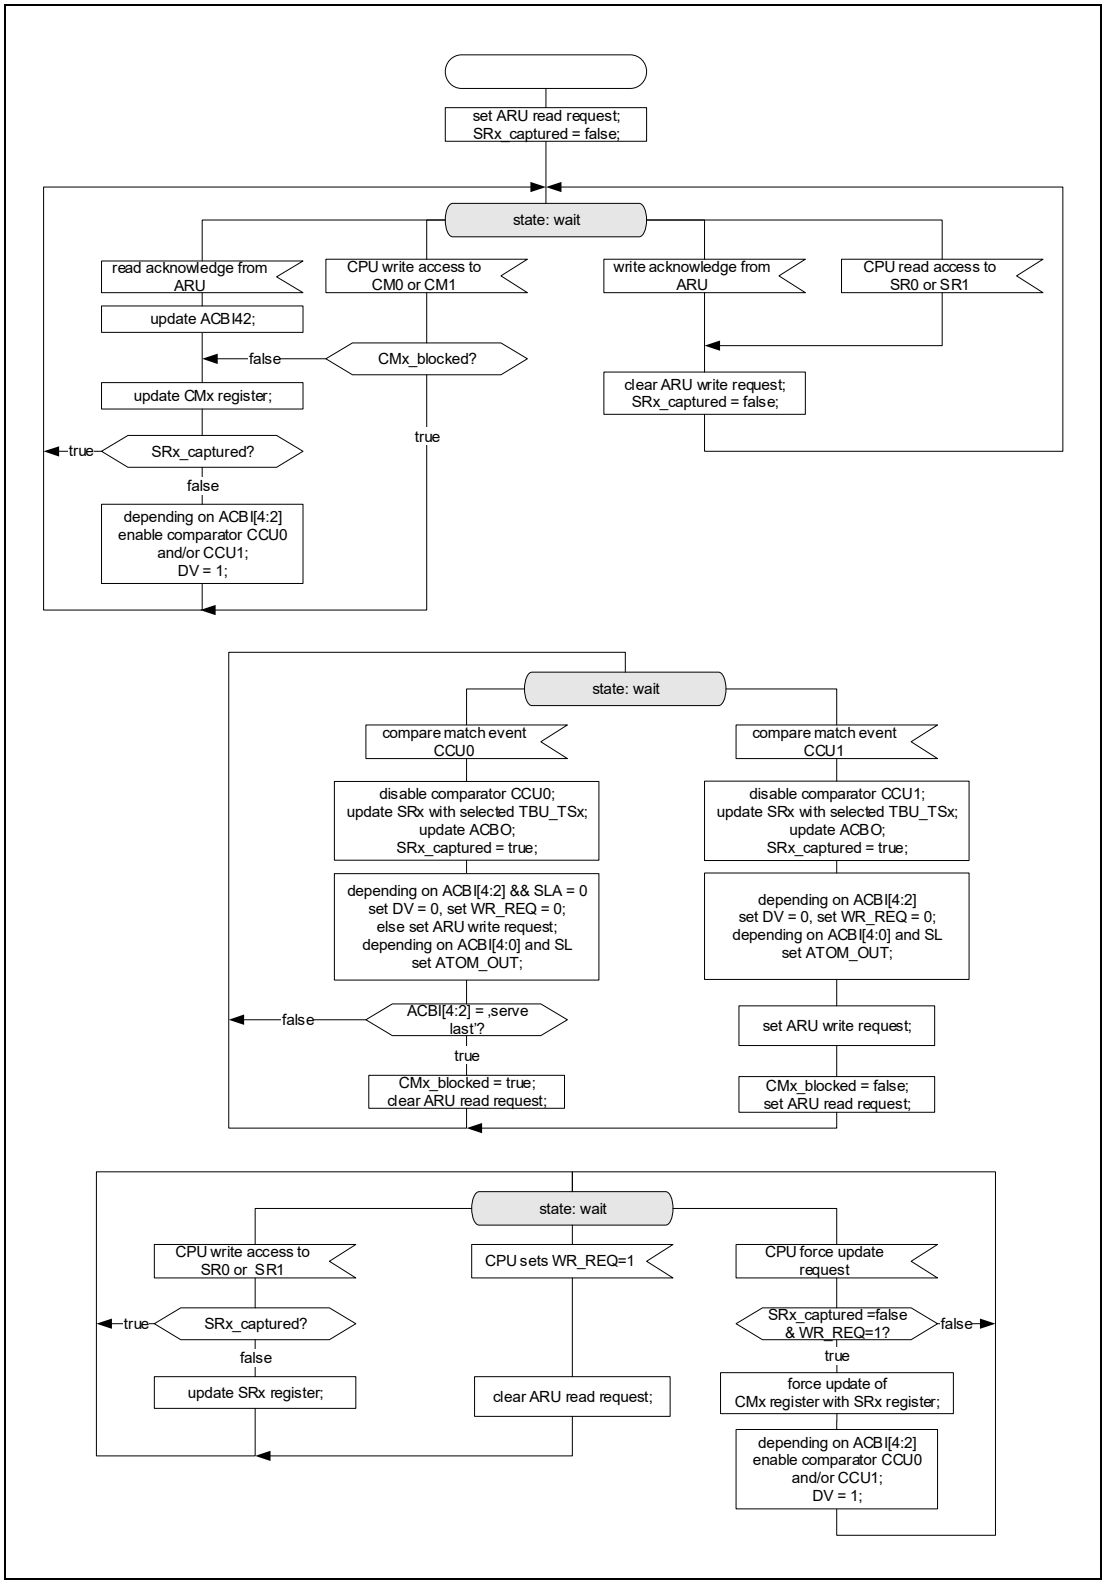

Figure 38.71 SOMC State diagram for SOMC mode, ARU enabled, ABM disabled

(b) ARU Blocking mode

When the compare registers are updated by ARU, the ATOM channel can be configured to receive ARU data in a blocking manner. This can be configured by setting the ABM bit in the ATOM[i]_CH[x]_CTRL register.

If the ABM and ARU_EN bits are set, depending on compare strategy, CM0 and/or CM1 can be updated via ARU with new compare values.

If the compare registers CM0 and/or CM1 are accepting these new data to be valid (indicated by bit DV in register ATOM[i]_CH[x]_STAT), the ATOM channel stops requesting new data via ARU and waits for the compare match event to happen.

When the specified compare match event happens, the shadow registers SR0 and SR1 are updated together with the ACBO bits in the ATOM[i]_CH[x]_STAT register. The data in the shadow registers is marked as valid for the ARU and the DV bit or register ATOM[i]_CH[x]_CTRL is reset.

If the register SR0 and SR1 holding the captured TBU time stamp values are read by either the ARU or the CPU, the next write access to or update of the register CM0 or CM1 via ARU or the CPU enables the new compare match check again.

At least one of the registers SR0 or SR1 has to be read either via ARU or by CPU, before new data is requested via ARU.

NOTE

In case of ABM=1 the application has to handle the situation that the ATOM does not request update of new data for CM0/CM1 until the captured values are read. E.g. if an MCS task starts to write via ARU new data (with AWR(I) command) after capture of data in SR0/SR1, the task sticks in the command until captured data is read by another task via ARU or via the CPU interface.

The CPU can check at any time if the ATOM channel has received valid data from the ARU and waits for a compare event to happen. This is signaled by a set DV bit inside the ATOM[i]_CH[x]_STAT register.

The behavior of an ATOM channel in SOMC mode, when ARU is enabled and ARU blocking mode is enabled is shown in **Figure 38.72**.

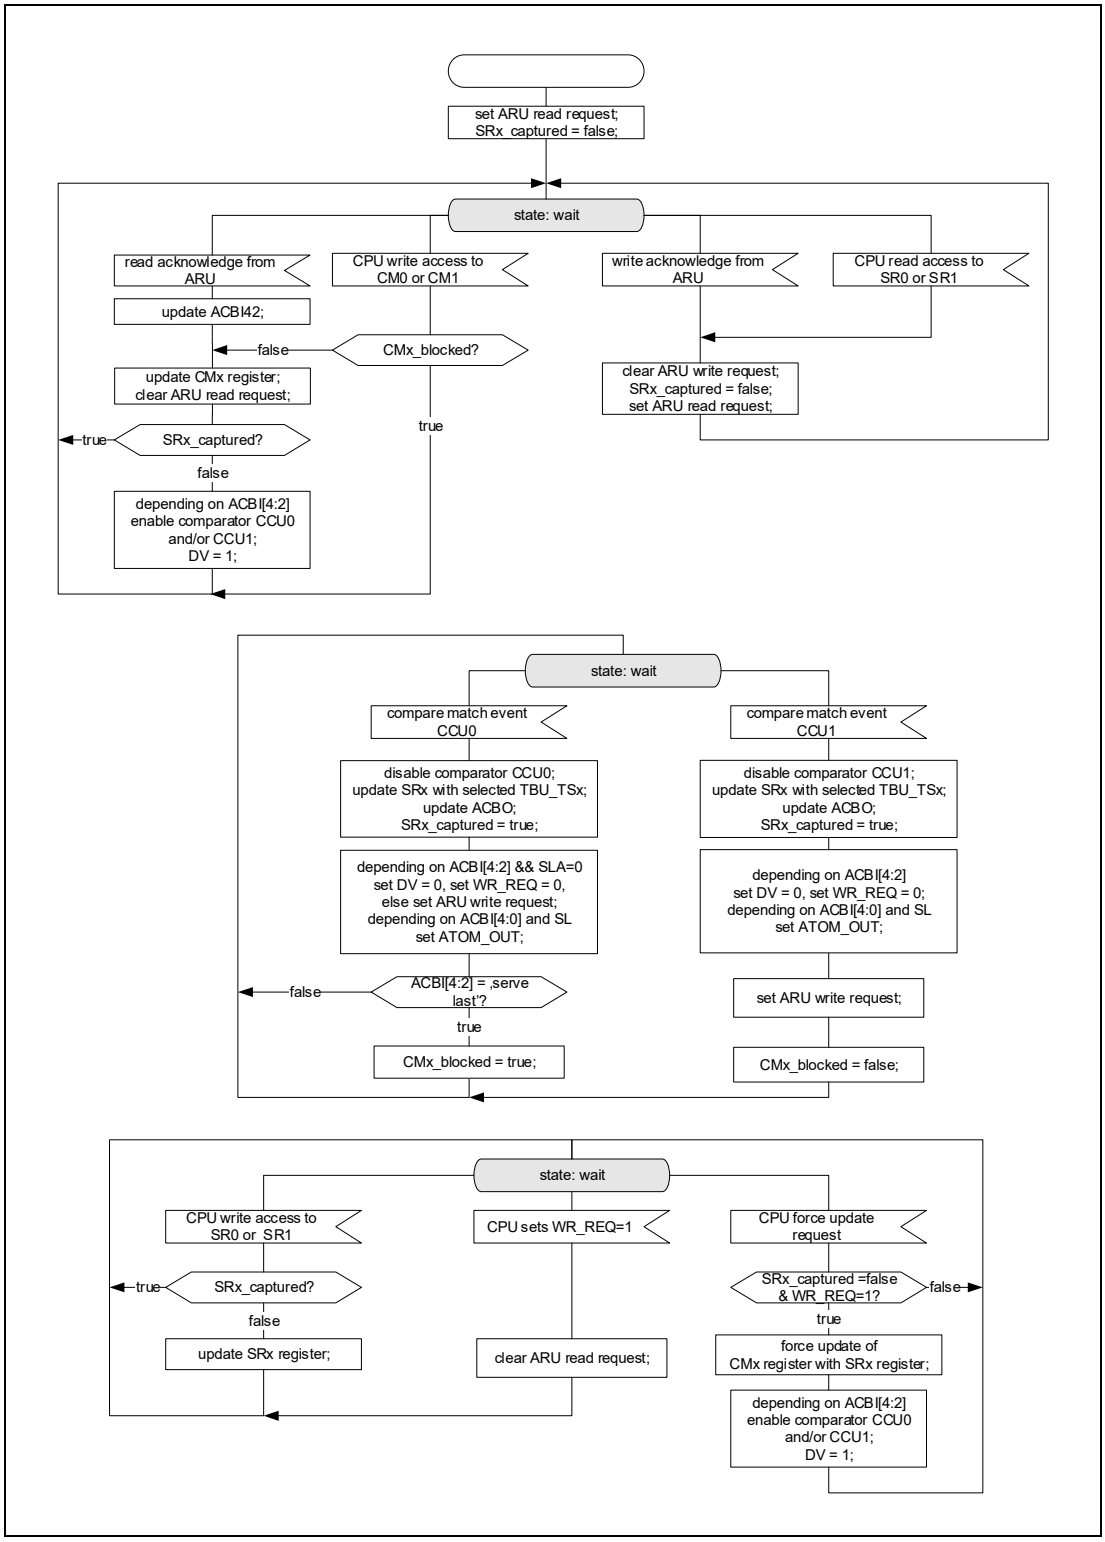

Figure 38.72 SOMC State diagram for SOMC mode, ARU enabled and ABM enabled

(c) ATOM SOMC Late update mechanism

Although, the ATOM channel may be controlled by data received via the ARU, the CPU is able to request at any time a late update of the compare register. This can be initiated by setting the WR_REQ bit inside the ATOM[i]_CH[x]_CTRL register. By doing this, the ATOM will request no further data from ARU (if ARU access was enabled). The channel will in any case continue to compare against the

values stored inside the compare registers (if bit DV was set). The CPU can now update the new compare values until the compare event happens by writing to the shadow registers, and force the ATOM channel to update the compare registers by writing to the force update register bits in the AGC register.

If the WR_REQ bit is set and a compare match event happens, any further access to the shadow registers SR0, SR1 is blocked and the force update of this channel is blocked. In addition, the WRF bit is set in the ATOM[i]_CH[x]_STAT register. Thus, the CPU can determine that the late update failed by reading the WRF bit.

In case of bit EUPM =0 (register ATOM[i]_CH[x]_CTRL) the following statements are true:

If a compare match event already happened, the WR_REQ bit could not be set until the channel is unlocked for a new compare match event by reading the shadow registers. In addition, the WRF bit is set if the CPU tries to write the WR_REQ bit in that case.

In case of bit EUPM = 1 (register ATOM[i]_CH[x]_CTRL) the following statements are true:

If in case of 'serve last' strategy a CCU1 or in any other compare strategy a CCU0 or CCU1 compare match event already happened, the WR_REQ bit could not be set until the channel is unlocked for a new compare match event by reading the shadow registers. In addition, the WRF bit is set if the CPU tries to write the WR_REQ bit in that case.

In general, for a late update the following has to be taken into account:

If between a correct WR_REQ bit set, a correct shadow register write, and before the force update is requested by the AGC a match event occurs on the old compare values, the WRF bit will be set. The force update will be blocked.

The WRF bit will be set in any case if the CPU tries to write to a blocked shadow register.

The WR_REQ bit and the DV bit will be reset on a compare match event.

After a capture event for register SR0 and/or SR1 the force update mechanism will be blocked until a read access to the register SR0 or SR1 by either the ARU or the CPU happens. Writing to SR0 or SR1 after compare match causes an AEI write status 10_B.

The ATOM SOMC late update mechanism from CPU is shown in **Figure 38.73**.

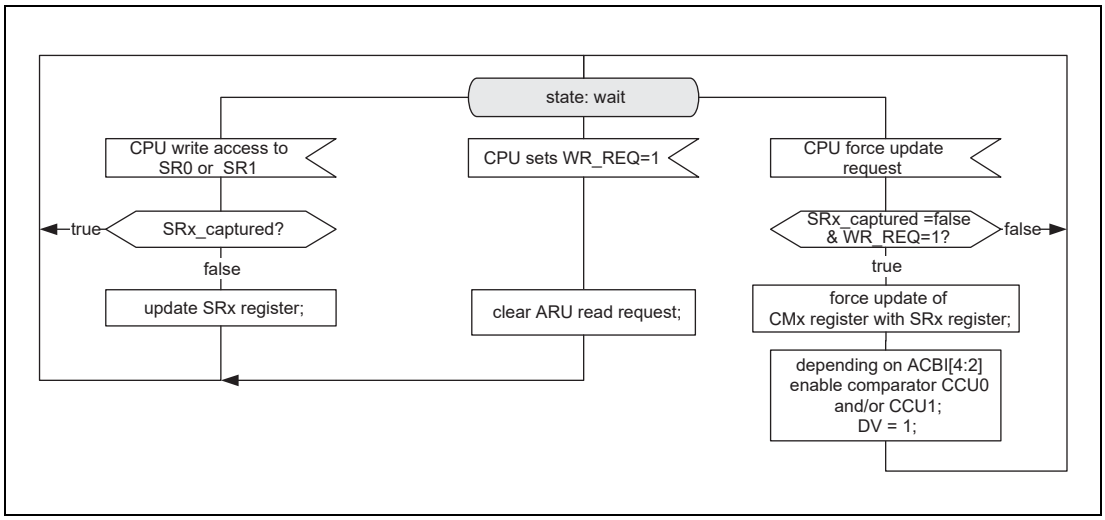

Figure 38.73 SOMC State diagram for late update requests by CPU

38.17.3.3 ATOM Signal Output Mode PWM (SOMP)

In ATOM Signal Output Mode PWM (SOMP) the ATOM sub-module channel is able to generate complex PWM signals with different duty cycles and periods. Duty cycles and periods can be changed synchronously and asynchronously. Synchronous change of the duty cycle and/or period means that the duty cycle or period duration changes after the end of the preceding period. An asynchronous change of period and/or duty cycle means that the duration changes during the actual running PWM period.

The signal level of the pulse generated inside the period can be configured inside the channel control register (SL bit of ATOM[i]_CH[x]_CTRL register). The initial signal output level for the channel is the inverse pulse level defined by the SL bit. **Figure 38.74** depicts this behavior.

The counter CN0 of each channel can run in two different modes depending on configuration of UDMODE in register ATOM[i]_CH[x]_CTRL.

By default the counter counts only up until it reaches CM0 and is then reset to 0. In the up down counter mode CN0 switches between counting up and counting down.

(1) Continuous Counting Up Mode

In SOMP mode with UDMODE = 00_B (i.e. CN0 counts only up), depending on configuration bits RST_CCU0 of register ATOM[i]_CH[x]_CTRL the counter register CN0 can be reset either when the counter value is equal to the compare value CM0 (i.e. CN0 counts only from 0 to CM0 -1 and is then reset to 0) or when signaled by the ATOM[i] trigger signal TRIG_[x-1] of the preceding channel [x-1] (which can also be the last channel of preceding instance TOM[i-1]) or the trigger signal TIM_EXT_CAPTURE(x) of the assigned TIM channel [x]. In this case, if UPEN_CTRL[x] = 1, also the working register CM0, CM1 and CLK_SRC are updated.

NOTE

As an exception, the input TRIG_[0] of instance ATOM0 is triggered by its own last channel 15 via signal TRIG_15

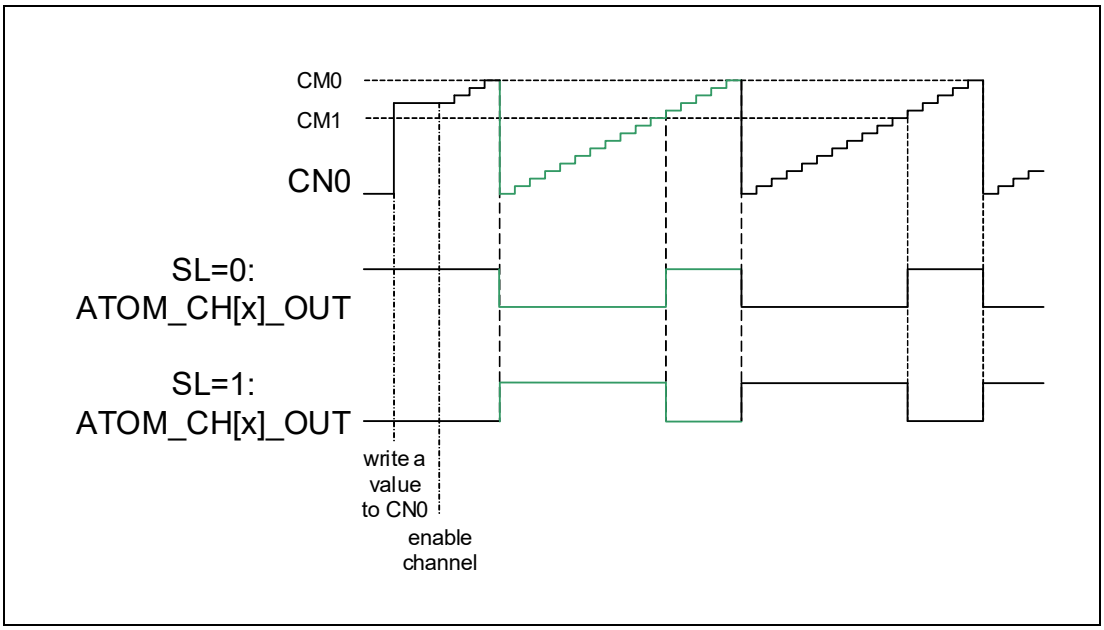

Figure 38.74 PWM Output behavior with respect to the SL bit in the ATOM[i]_CH[x]_CTRL register if UDMODE = 00_B

On an asynchronous update, it is guaranteed, that no spike occurs at the output port of the channel due to a too late update of the operation registers. The behavior of the output signal due to the different possibilities of an asynchronous update during a PWM period is shown in **Figure 38.75**.

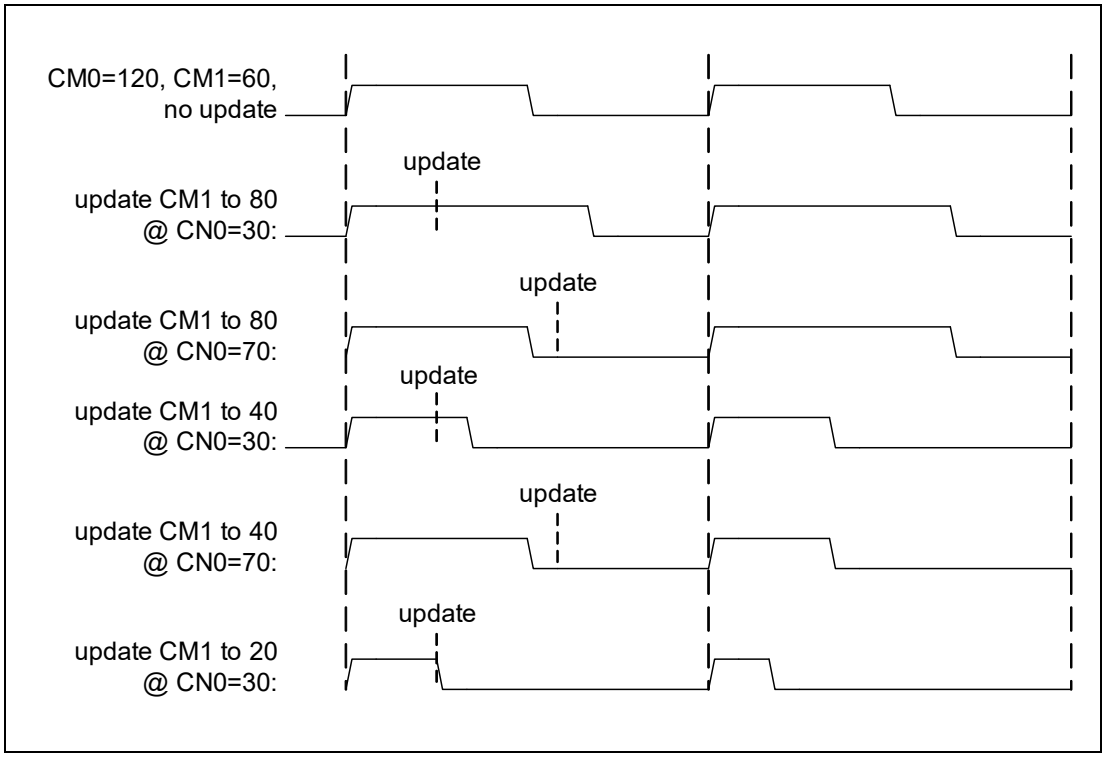

Figure 38.75 PWM Output behavior in case of an asynchronous update of the duty cycle

The duration of the pulse high or low time and period is measured with the counter in sub-unit CCU0. The trigger of the counter is one of the eight CMU clock signals configurable in the channel control register ATOM[i]_CH[x]_CTRL. The register CM0 holds the duration of the period and the register CM1 holds the duration of the duty cycle in clock ticks of the selected CMU clock.

If counter CN0 of channel x is reset by its own CCU0 unit (i.e. the compare match of CN0 ≥ CM0 -1 configured by RST_CCU0 = 0), following statements are valid:

1. CN0 counts from 0 to CM0 -1 and is then reset to 0
2. When CN0 is reset from CM0 to 0, an edge to SL is generated.
3. When CN0 is incrementing and reaches CN0 > CM1, an edge to !SL is generated.
4. If CM0 = 0 or CM0 = 1, the counter CN0 is constant 0.
5. If CM1 = 0, the output is !SL = 0% duty cycle
6. If CM1 ≥ CM0 and CM0 >1, the output is SL = 100% duty cycle

If the counter register CN0 of channel x is reset by the trigger signal coming from another channel or the assigned TIM module (configured by RST_CCU0 = 1), following statements are valid:

- CN0 counts from 0 to MAX–1 and is then reset to 0 by trigger signal – CM0 defines the edge to SL value, CM1 defines the edge to !SL value.
- If CM0 = CM1, the output switches to SL if CN0 = CM0 = CM1 (CM0 has higher priority) – if CM0 =0 and CM1 =MAX, the output is SL = 100% duty cycle – if CM0 > MAX, the output is

!SL = 0% duty cycle, independent of CM1.

In case the counter value CN0 reaches the compare value in register CM0 (in fact CM0 –1) or the channel receives an external update trigger

via the FUPD(x) signal, a synchronous update is performed. A synchronous update means that the registers CM0 and CM1 are updated with the content of the shadow registers SR0 and SR1 and the CLK_SRC register is updated with the value of the CLK_SRC_SR register.

The clock source for the counter can be changed synchronously at the end of a period. If ARU access is disabled, this is done by using the bit field CLK_SRC_SR of register ATOM[i]_CH[x]_CTRL as shadow registers for the next CMU clock source.

(2) Continuous Counting Up-Down Mode

In SOMP mode, if CN0 counts up and down (UDMODE! = 00_B), depending on configuration bit RST_CCU0 of register ATOM[i]_CH[x]_CTRL the counter register CN0 changes the direction either when the counter value is equal to the compare value CM0 (in fact CM0 -1), has counted down to 0 or when triggered by the ATOM[i] trigger signal TRIG_[x-1] of the preceding channel [x-1] (which can also be the last channel of preceding instance ATOM[i-1]) or the trigger signal TIM_EXT_CAPTURE(x) of the assigned TIM channel [x]. In this case, if UPEN_CTRL[x] = 1, also the working register CM0, CM1 and CLK_SRC are updated depending on UDMODE.

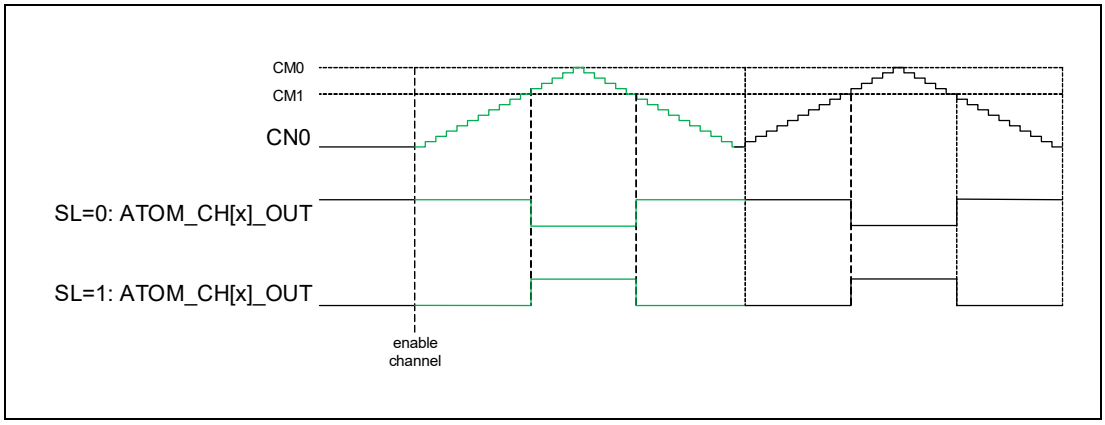

Figure 38.76 PWM Output behavior with respect to the SL bit in the ATOM[i]_CH[x]_CTRL register if UDMODE! = 00_B

The clock of the counter register CN0 can be one of the CMU clocks CMU_CLK[x]. If ARU_EN = 0, the clock for CN0 is defined by CLK_SRC_SR value in register ATOM[i]_CH[x]_CTRL. If ARU_EN = 1, the clock for CN0 is defined by CLK_SRC value received via ARU. The duration of a period in multiples of selected CN0 counter clock ticks is defined by the CM0 configuration value (i.e. CM0 defines half of period in up-down mode). CM1 defines the duty cycle value in clock ticks of selected CN0 counter clock (i.e. CM0 defines half of duty cycle in up-down mode).

If counter CN0 of channel x is reset by its own CCU0 unit (i.e. the compare match of CN0 ≥ CM0 –1 configured by RST_CCU0 = 0), following statements are valid:

1. CN0 counts continuously first up from 0 to CM0 -1 and then down to 0.
2. If CN0 ≥ CM1, the output is set to SL
3. If CM1 = 0, the output is SL (i.e. 100% duty cycle)
4. If CM1 ≥ CM0, the output is !SL (i.e. 0% duty cycle)

5. On output ATOM[i]_CH[x]_OUT a PWM signal is generated. The period is defined by CM0, the duty cycle is defined by CM1.

This behavior is depicted in **Figure 38.76**.

If the counter register CN0 of channel x is reset by the trigger signal coming from another channel or the assigned TIM module (configured by RST_CCU0 = 1), following statements are valid:

1. CN0 counts continuously first up. On a trigger signal the counter switches to count down mode. If CN0 has reached 0, it counts up again.
2. If CN0 ≥ CM1, the output is set to SL
3. If CM1 = 0, the output is SL (i.e. 100% duty cycle)
4. If CM1 ≥ CM0, the output is !SL (i.e. 0% duty cycle)
5. On output ATOM[i]_CH[x]_OUT a PWM signal is generated. The period is defined by the CCU0 trigger of triggering channel, the duty cycle is defined by CM1.
6. On output ATOM[i]_CH[x]_OUT_T a PWM signal is generated. The period is defined by the CCU0 trigger of triggering channel, the duty cycle is defined by CM0.

This behavior is depicted in **Figure 38.77**.

NOTES

1. In case of up-down counter mode and RST_CCU0 = 1 it is recommended that – the triggering channel and the triggered channel are both running in up-down mode and that – the time between two trigger signals is equal to the time needed for CN0 of triggered channel to count back to 0 and again up to the same upper value. The second recommendation can be reached by synchronizing the start of triggering channel and of triggered channel, i.e. let both channel start with a CN0 value 0.
2. If there is a synchronization register in the trigger chain (indicated by value ATOM_TRIG_CHAIN in register CCM[i]_HW_CONF), the additional delay of the trigger by one clock period has to be taken into account by starting at triggering channel with a CN0 value 1 (+1 compared to CN0 of triggered channel).

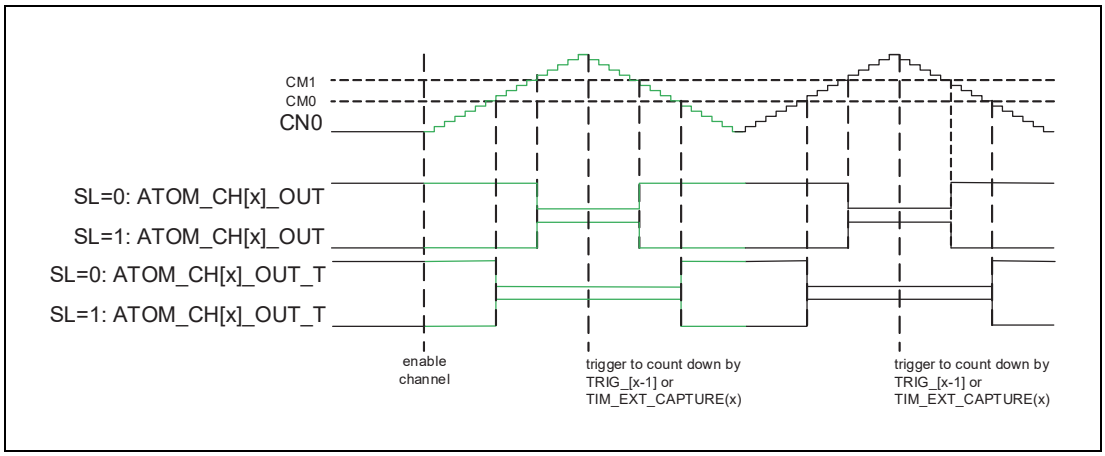

Figure 38.77 PWM Output behavior in case of RST_CCU0 = 1

(3) ARU controlled update

If ARU access is enabled, the bits ACBI(4), ACBI(3) and ACBI(2) received via ARU and stored in register ATOM_[i]_CH[x]_STAT are used as shadow register for the update of the CMU clock source register CLK_SRC.

For the synchronous update mechanism the generation of a complex PWM output waveform is possible without CPU interaction by reloading the shadow registers SR0, SR1 and the ACBI bit field over the ACI sub-unit from the ARU, while the ATOM channel operates on the CM0 and CM1 registers.

This internal update mechanism is established, when the old PWM period ends. The shadow registers are loaded into the operation registers, the counter register is reset, the new clock source according to the CLK_SRC_SR and ACBI(4), ACBI(3) and ACBI(2) bits is selected and the new PWM generation starts.

In parallel, the ATOM channel issues a read request to the ARU to reload the shadow registers with new values while the ATOM channel operates on the operation registers. To guarantee the reloading, the PWM period must not be smaller than the worst case ARU round trip time and source for the PWM characteristic must provide the new data within this time. Otherwise, the old PWM values are used from the shadow registers.

When updated over the ARU the user has to ensure that the new period duration is located in the lower (bits 23 to 0) and the duty cycle duration is located in the upper (bits 47 to 24) ARU data word and the new clock source is specified in the ARU control bits 52 to 50.

This pipelined data stream character is shown in **Figure 38.78**.

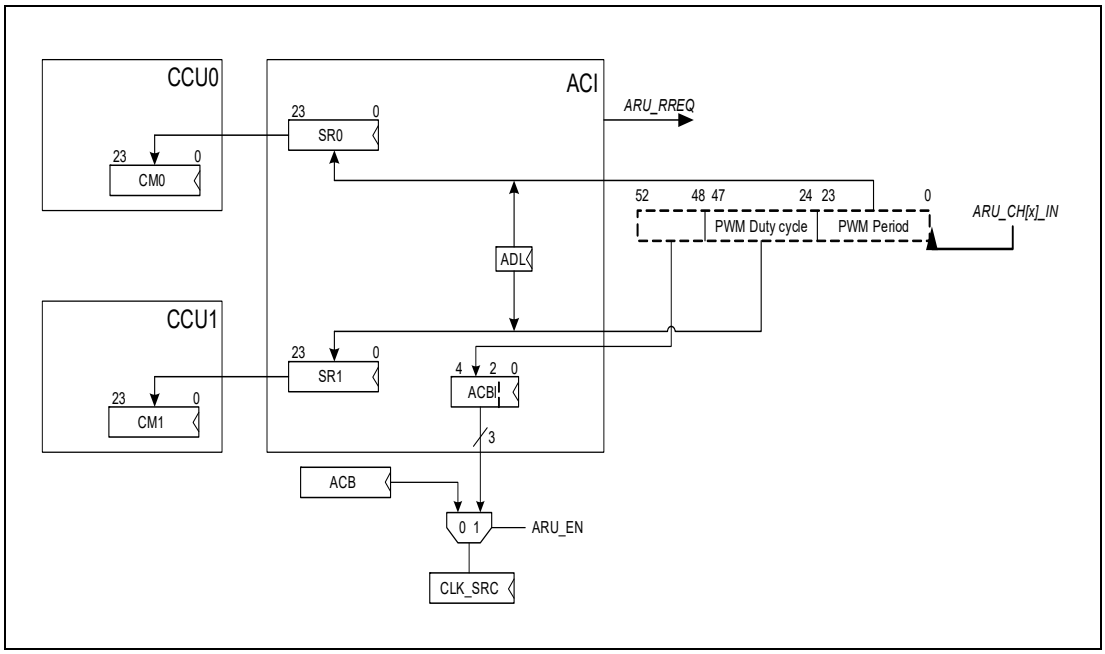

Figure 38.78 ARU Data input stream pipeline structure for SOMP mode

When an ARU transfer is in progress which means the ARU_RREQ is served by the ARU, the ACI locks the update mechanism of CM0, CM1 and CLK_SRC until the read request has finished. The CCU0 and CCU1 operate on the old values when the update mechanism is locked.

(4) CPU controlled update

The shadow registers SR0 and SR1 can also be updated over the AEI bus interface. In this case, ARU_EN hat to be set to 0. When updated via the AEI bus the CM0 and CM1 update mechanism has to be locked via the AGC_GLB_CTRL register with the UPENx signal in the AGC sub-unit. To select the new clock source in this case, the CPU has to write to the CLK_SRC_SR bit field of the ATOM[i]_CH[x]_CTRL register.

For an asynchronous update of the duty cycle and/or period the new values must be written directly into the compare registers CM0 and/or CM1 while the counter CN0 continues counting. This update can be done only via the AEI bus interface immediately by the CPU or by the FUPD(x) trigger signal triggered from the AGC global trigger logic. Values received through the ARU interface are never loaded asynchronously into the operation registers CM0 and CM1. Therefore, the ATOM channel can generate a PWM signal on the output port pin ATOM[i]_CH[x]_OUT on behalf of the content of the CM0 and CM1 registers, while it receives new PWM values via the ARU interface ACI in its shadow registers.

On a compare match of CN0 and CM0 or CM1 the output signal level of ATOM[i]_CH[x]_OUT is toggled according to the signal level output bit SL in the ATOM[i]_CH[x]_CTRL register.

Thus, the duty cycle output level can be changed during runtime by writing the new duty cycle level into the SL bit of the channel configuration register. The new signal level becomes active for the next trigger CCU_TRIGx (since bit SL is written).

Since the ATOM[i]_CH[x]_OUT signal level is defined as the reverse duty cycle output level when the ATOM channel is enabled, a PWM period can be shifted earlier by writing an initial offset value to CN0 register. By doing this, the ATOM channel first counts until CN0 reaches CM0 and then it toggles the output signal at ATOM[i]_CH[x]_OUT.

(5) One-shot Counting Up Mode

The ATOM channel can operate in One-shot mode when the OSM bit is set in the channel control register. One-shot mode means that a single pulse with the pulse level defined in bit SL is generated on the output line.

First the channel has to be enabled by setting the corresponding ENDIS_STAT value.

In one-shot mode the counter CN0 will not be incremented once the channel is enabled.

A write access to the register CN0 triggers the start of pulse generation (i.e. the increment of the counter register CN0).

If the counter CN0 is reset from CM0 –1 back to zero, the first edge at ATOM[i]_CH[x]_OUT is generated.

To avoid an update of CMx register with content of SRx register at this point in time, the automatic update should be disabled by setting UPEN_CTRL[x] = 00_B (in register ATOM[i]_CH[x]_CTRL).

The second edge is generated if CN0 is greater or equal than CM1 (i.e. CN0 was incremented until it has reached CM1 or CN0 is greater than CM1 after an update of CM1).

If the counter CN0 has reached the value of CM0 –1 a second time, the counter stops.

The new value of CN0 determines the start delay of the first edge. The delay time of the first edge is given by (CM0–CN0) multiplied with period defined by current value of CLK_SRC.

Figure 38.79 depicts the pulse generation in SOMP one-shot mode.

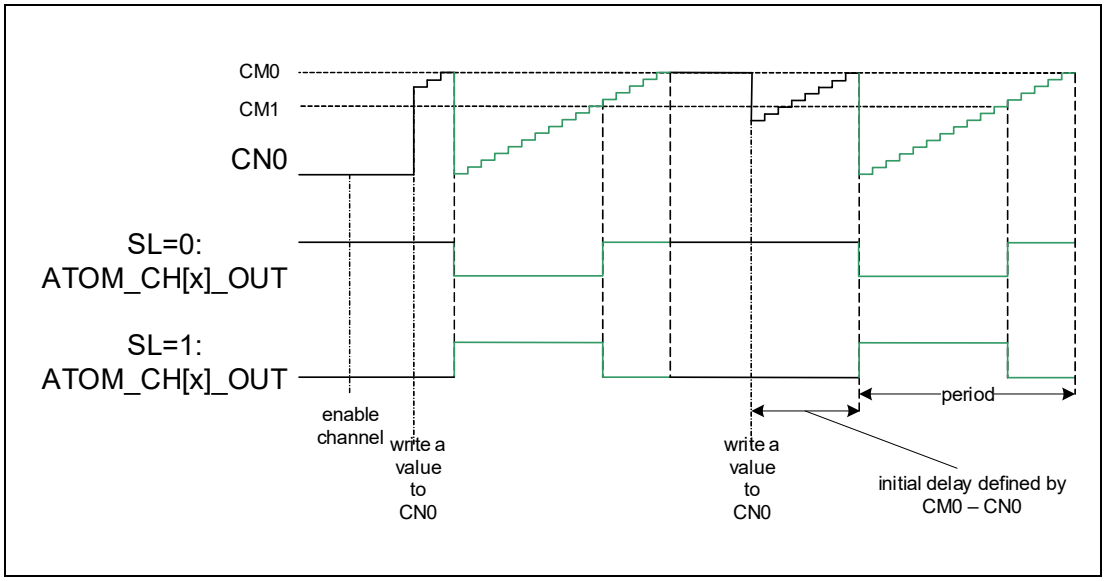

Figure 38.79 PWM Output with respect to configuration bit SL in One-shot counting up mode: trigger by writing to CN0

Further output of single pulses can be started by a write access to register CN0.

If CN0 is already incrementing (i.e. started by writing to CN0 a value CN0start < CM0), the effect of a second write access to CN0 depends on the phase of CN0:

phase 1: update of CN0 before CN0 reaches first time CM0 (in fact CM0 –1)

phase 2: update of CN0 after CN0 has reached first time CM0 (in fact CM0 –1) but is less than CM1

phase 3: update of CN0 after CN0 has reached first time CM0 (in fact CM0 –1) and CN0 is greater than or equal CM1

In phase 1: writing to counter CN0 a value CN0new < CM0 leads to a shift of first edge (generated if CN0 is reset first time from CM0 –1 back to 0) by the time CM0 –CN0new.

In phase 2: writing to incrementing counter CN0 a value CN0new < CM1 while CN0old is below CM1 leads to a lengthening of the pulse. The counter CN0 stops if it reaches CM0.

In phase 3: Writing to incrementing counter CN0 a value CN0new while CN0old is already greater than or equal CM1 leads to an immediate restart of a single pulse generation inclusive the initial delay defined by CM0 – CN0new.

If a channel is configured to one-shot mode and configuration bit OSM_TRIG is set to 1, the trigger signal OSM_TRIG (i.e. TRIG_[x–1] or TIM_EXT_CAPTURE(x)) triggers start of one pulse generation.

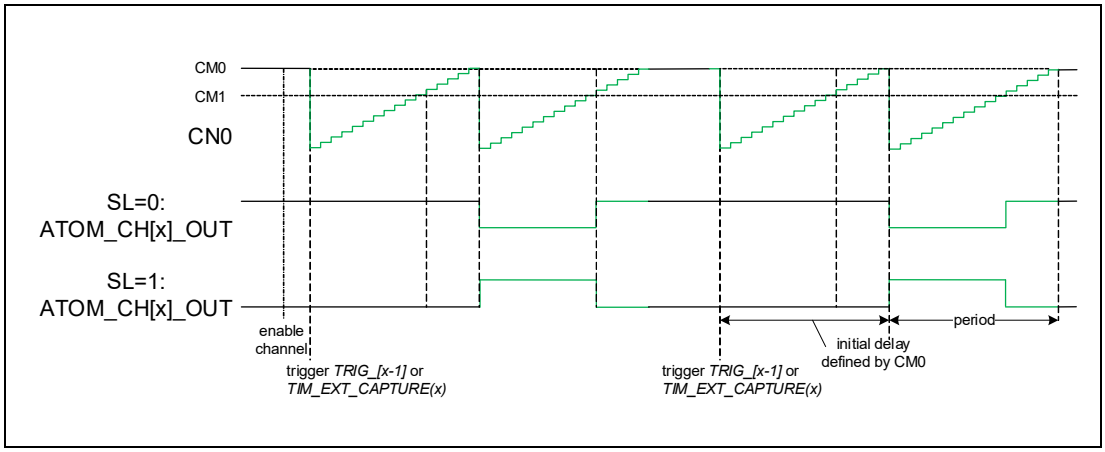

Figure 38.80 PWM Output with respect to configuration bit SL in one-shot mode: trigger by TRIG_[x–1] or TIM_EXT_CAPTURE(x)

(6) One-shot Counting Up-Down Mode

The ATOM channel can operate in one-shot counting up-down mode when the bit OSM = 1 and the UDMODE! = 00_B. One-shot mode means that a single pulse with the pulse level defined in bit SL is generated on the output line.

First the channel has to be enabled by setting the corresponding ENDIS_STAT value.

In one-shot mode the counter CN0 will not be incremented once the channel is enabled.

A write access to the register CN0 triggers the start of pulse generation (i.e. the increment of the counter register CN0).

To avoid an update of CMx register with content of SRx register at this point in time, the automatic update should be disabled by writing UPEN_CTRL[x] = 01_B (see register ATOM[i]_AGC_GLB_CTRL).

If the counter CN0 is greater or equal than CM1, the output ATOM[i]_CH[x]_OUT is set to SL value.

If the counter CN0 is less than CM1, the output ATOM[i]_CH[x]_OUT is set to !SL value.

If the counter CN0 has reached the value 0 (by counting down), it stops.

The new value of CN0 determines the start delay of the first edge. The delay time of the first edge is given by (CM1–CN0) multiplied with period defined by current value of CLK_SRC.

Figure 38.81 depicts the pulse generation in SOMP one-shot mode.

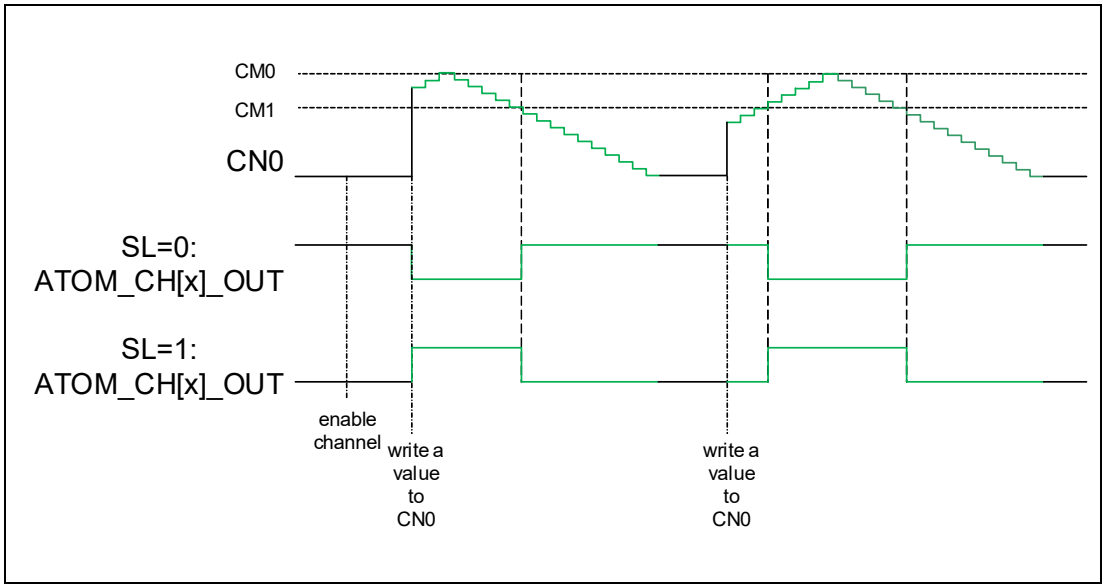

Figure 38.81 PWM Output with respect to configuration bit SL in one-shot counting up-down mode: trigger by writing to CN0

Further output of single pulses can be started by writing to register CN0.

If a channel is configured to one-shot counting up-down mode and configuration bit OSM_TRIG is set to 1, the trigger signal OSM_TRIG (i.e. TRIG_[x–1] or TIM_EXT_CAPTURE(x)) triggers start of one pulse generation.

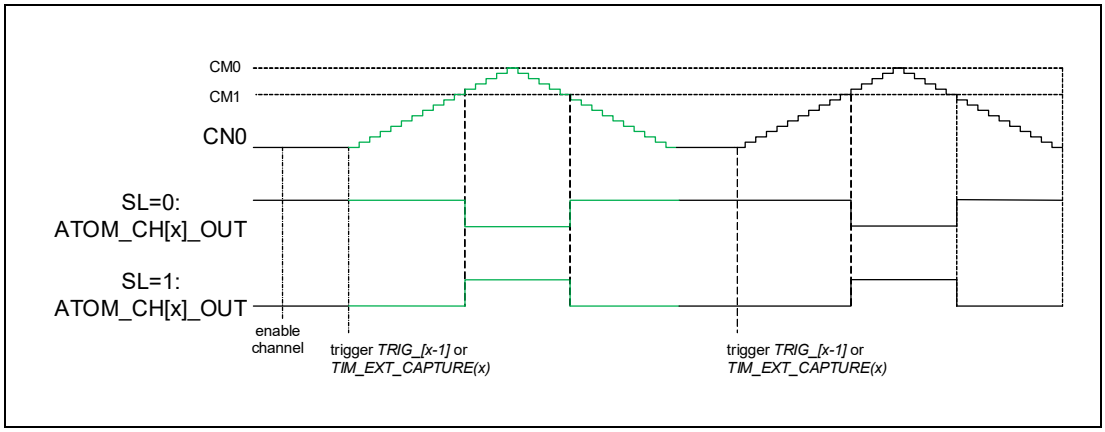

Figure 38.82 PWM Output with respect to configuration bit SL in one-shot counting up-down mode: trigger by TRIG_[x–1] or TIM_EXT_CAPTURE(x)

(7) Pulse Count Modulation Mode

At the output ATOM[i]_CH[x]_OUT a pulse count modulated signal can be generated instead of the simple PWM output signal in SOMP mode.

The PCM mode is enabled by setting bit BITREV to 1 (bit 6 in ATOM[i]_CH[x]_CTRL register).

NOTE

It is device specific, in which channel the PCM mode is available. Refer to device specific **38.28, GTM Device 358** for this information.

With the configuration bit BITREV =1 a bit-reversing of the counter output CN0 is configured. In this case the bits LSB and MSB are swapped, the bits LSB + 1 and MSB–1 are swapped, the bits LSB + 2 and MSB–2 are swapped and so on.

The effect of bit-reversing of the CN0 register value is shown in the following **Figure 38.83**.

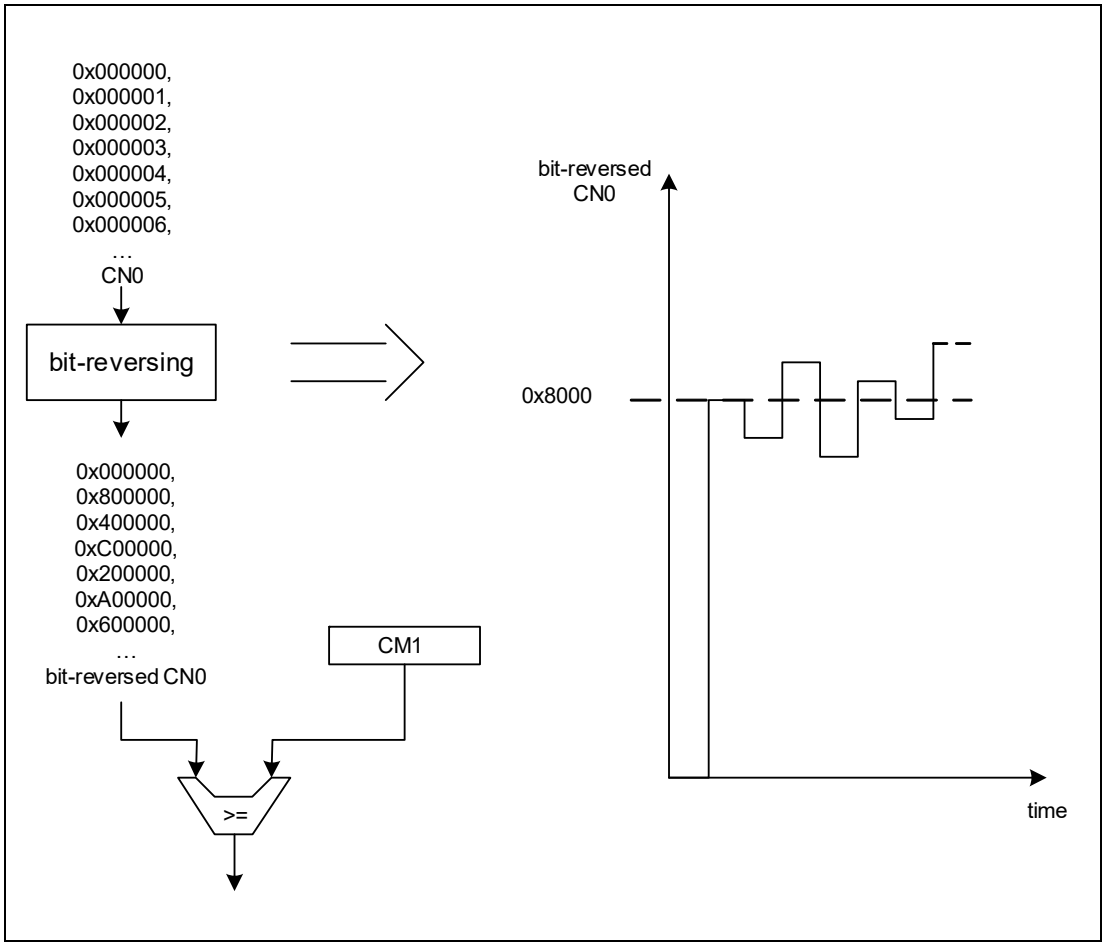

Figure 38.83 Bit reversing of counter CN0 output

In the PCM mode the counter register CN0 is incremented by every clock tick depending on configured CMU clock (CMU_CLK).

The output of counter register CN0 is first bit–reversed and then compared with the configured register value CM1.

If the bit-reversed value of register CN0 is greater or equal than CM1, the SR-FlipFlop of sub-module SOU is set (i.e. set to inverse value of SL) otherwise the SR–FlipFlop is reset (i.e. to the value of SL). This generates at the output ATOM[i]_CH[x]_OUT a pulse count modulated signal.

In PCM mode the CM0 register – in which the period is defined – normally has to be set to its maximum value $FFFFFF_H$.

To reduce time period of updating duty cycle value in CM1 register, it is additionally possible to setup period value in CM0 register to smaller values than maximum value as described before.

Possible values for CM0 register are each even numbered values to the power of 2 e.g. 800000_H, 400000_H, 200000_H ... .

In this case the duty cycle has to be configured in the following manner.

Depending on how much the period in CM0 register is decreased – means shifted right starting from 1000000_H – the duty cycle in CM1 register has to be shifted left (= rotated: shift MSB back into LSB) with same value, e.g. :

period CM0 = 001000_H → shifted 8 bits right from 1000000_H

→ so duty cycle has to be shifted left 8 bit:

e.g. 50% duty cycle = 0008000_H → shift 8 bits left → CM1 = 800000_H

More examples:

period CM0	→	duty cycle	→	shift	→	CM1
$FFFFFF_H$	→	800000_H	→	no shift	→	800000_H
800000_H	→	400000_H	→	shift 1 bit left	→	800000_H
400000_H	→	100000_H	→	shift 2 bits left	→	400000_H
200000_H	→	$0FFFFF_H$	→	shift 3 bits left	→	$7FFFF8_H$
100000_H	→	033333_H	→	shift 4 bits left	→	333330_H
080000_H	→	005555_H	→	shift 5 bits left	→	$0AAAA0_H$
...						
000020_H	→	000008_H	→	shift 19 bits left	→	400000_H
000010_H	→	000005_H	→	shift 20 bits left	→	500000_H
...						

NOTE

In this mode the interrupt CCU1TC (see register ATOM[i]_CH[x]_IRQ_NOTIFY) is set every time if bit reverse value of CN0 is greater or equal than CM1 which may be multiple times during one period. Therefore, from application point of view it is not useful to enable this interrupt.

(8) Trigger generation

For applications with constant PWM period defined by CM0, it is not necessary to update regularly the CM0 register with SR0 register.

For these applications the SR0 register can be used to define an additional output signal and interrupt trigger. If bit SR0_TRIG in register ATOM[i]_CH[x]_CTRL is set, the register SR0 is no longer used as a shadow register for register CM0. Instead, SR0 is compared against CN0 and if both are equal, a pulse of signal level 1 is generated at the output ATOM[i]_CH[x]_OUT_T. The bit SR0_TRIG should only be set if bit RST_CCU0 of this channel is 0.

NOTE

If ARU_EN =1 and both SR0 and SR1 are updated via ARU, the new SR0 value is used immediately after update. Update of SR0 via ARU can be suppressed by ADL configuration in register ATOM[i]_CH[x]_CTRL.

If bit SR0_TRIG is set the interrupt notify flag CCU1TC is no longer set on a compare match of CM1 and CN0. Instead, the CCU1TC interrupt notify flag is set in case of a compare equal match of SR0 and CN0.

With configuration bit TRIG_PULSE one can select if the output ATOM[i]_CH[x]_OUT_T is high as long as CN0 = SR0 (TRIG_PULSE = 0) or if there will be only one pulse of length one SYS_CLK period when CN0 becomes SR0 (TRIG_PULSE = 1).

The ATOM output signal routing to DTM or GTM-IP top level is described in **Section 38.18.7, DTM connections on GTM-IP top level**.

38.17.3.4 ATOM Signal Output Mode Serial (SOMS)

In ATOM Signal Output Mode Serial (SOMS) the ATOM channel acts as a serial output shift register where the content of the CM1 register in the CCU1 unit is shifted out whenever the unit is triggered by the selected CMU_CLK input clock signal. The shift direction is configurable with the ACB(0) bit inside the ATOM[i]_CH[x]_CTRL register when ARU is disabled and the ACBI(0) bit inside the ATOM[i]_CH[x]_STAT register when ARU is enabled.

The data inside the CM1 register has to be aligned according to the selected shift direction in the ACB(0)/ACBI(0) bit. This means that when a right shift is selected, that the data word has to be aligned to bit 0 of the CM1 register and when a left shift is selected, that the data has to be aligned to bit 23 of the CM1 register.

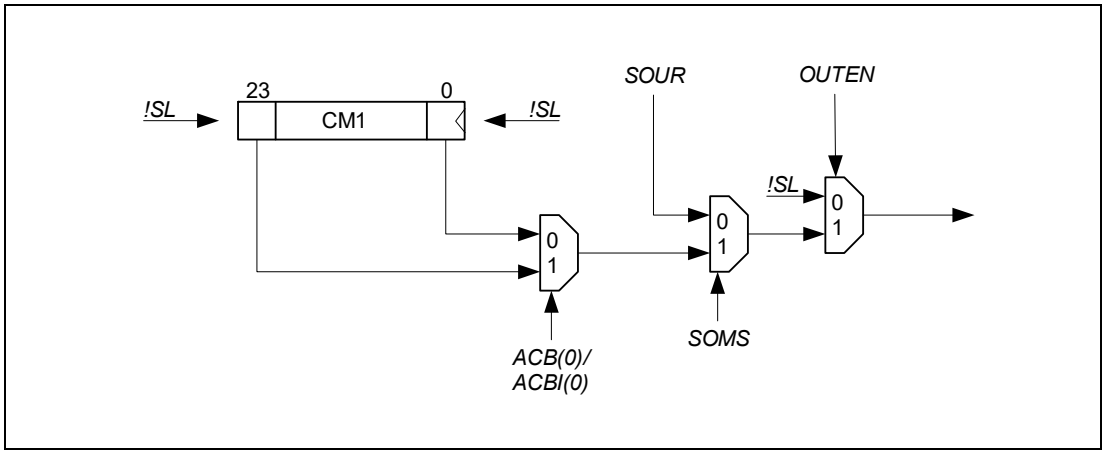

Figure 38.84 SOMS Mode output generation

Figure 38.84 shows the output generation in case of SOMS mode is selected.

In SOMS mode CCU0 runs in counter/compare mode and counts the number of bits shifted out so far. The total number of bits that should be shifted is defined as CM0. The total number of bits that are visible at ATOM_OUT is CM0 + 1.

When the output is disabled the ATOM_OUT is set to the inverse SL bit definition.

When the content of the CM1 register is shifted out, the inverse signal level is shifted into the CM1 register.

When the output is enabled while UPEN_CTRL[x] is disabled, the ATOM_OUT signal level is defined by CM1 bit 0 or 23, dependent on the shift direction defined by ACB(0) or ACBI(0) register setting. **Figure 38.85** should clarify the ATOM channel startup behavior in this case for right shift. For left shift the CM1 bit 0 in **Figure 38.85** has to be replaced by CM1 bit 23.

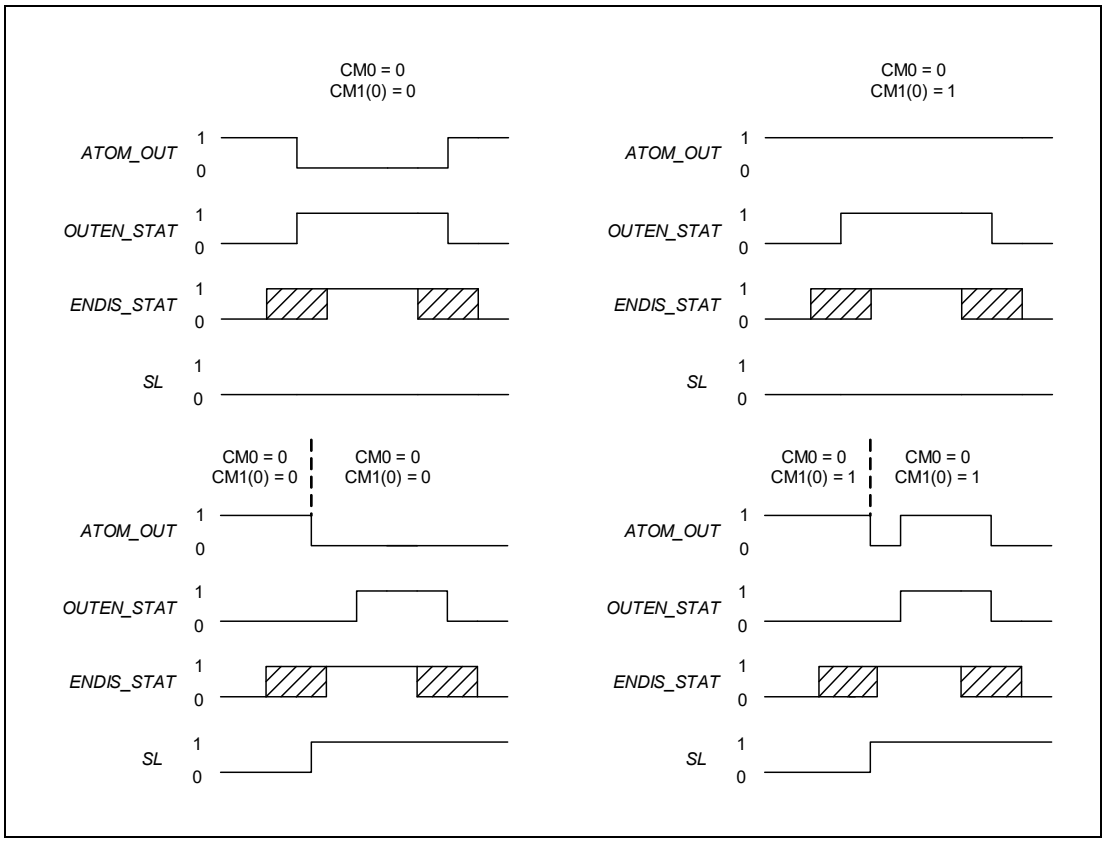

Figure 38.85 SOMS Output signal level at startup, UPEN_CTRL[x] disabled

If UPEN_CTRL[x] is set and the channel is enabled, the output level is defined by bit 0 or 23 of CM1 register dependent on the shift direction.

Figure 38.86 shows the output behavior in that case.

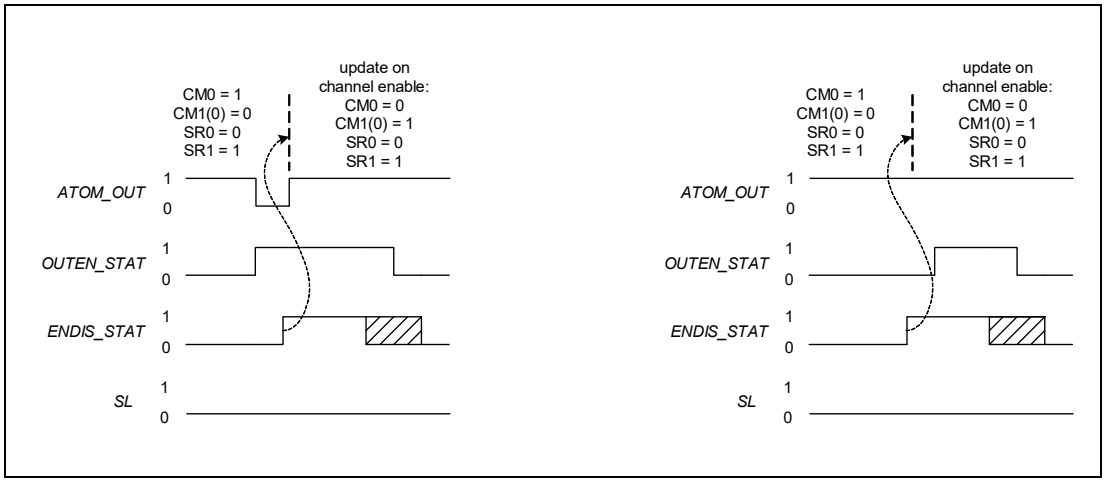

Figure 38.86 SOMS Output signal level at startup, UPEN_CTRL[x] enabled

When the serial data to be shifted is provided via ARU the number of bits that should be shifted has to be defined in the lower 24 bits of the ARU word (23 to 0) and the data that is to be shifted has to be defined in the ARU bits 47 to 24 aligned according to the shift direction. This shift direction has to be defined in the ARU word bit 48 (ACB0 bit).

If bit UPEN_CTRL[x] of a channel x is set, after update of CM0/CM1 register with the content of the SR0 / SR1 register, a new ARU read request is set up.

If bit UPEN_CTRL[x] of a channel x is not set, no (further) ARU read request is set up (because the SR0 / SR1 register are never used for update) and the ATOM may stop shifting after CN0 has reached CM0.

NOTE

In this case also no automatic restart of shifting is possible.

If a channel is enabled with the settings SOMS mode and ARU_EN = 1, the first received values from ARU are stored in register SR0 and SR1. If CN0 and CM0 are 0 (i.e. CN0 is not counting) and the update of channel x is enabled (UPEN_CTRL[x] = 1), an immediate update of the register CM0 and CM1 is also done. This update of CM0 and CM1 triggers the start of shifting.

It is recommended to configure the ATOM channel in One-shot mode when the ARU_EN bit is not set, since the ATOM channel would reload new values from the shadow registers when CN0 reaches CM0.

(1) SOMS mode with ARU_EN = 1 and OSM = 0, UPEN_CTRL[x] = 1:

In case of bit ARU_EN is set and bit OSM is not set, the channel is running in the SOMS continuous mode. Then, if the content of the CM0 register equals the counter CN0, the CM0 and CM1 registers are reloaded with the SR0 and SR1 content and new values are requested from the ARU. If the update of the shadow registers does not happen before CN0 reaches CM0 the old values of SR0 and SR1 are used to reload the operation registers.

In contrast to controlling the channel via AEI, the shift direction defined by ARU word bit 48 has only effect after the update of CMx operation registers from the SRx registers.

(2) SOMS mode with ARU_EN = 1 and OSM = 1, UPEN_CTRL[x] = 1:

In case of bit ARU_EN is set and bit OSM is set, the channel is running in the SOMS one-shot mode. Then, if the content of the CM0 register equals the counter CN0 and if new values are available in SR0 and SR1 (bit DV set), the CM0 and CM1 registers are reloaded with the SR0 and SR1 content and new values are requested from the ARU. If no new values are available in SR0 and SR1, the register CM0 and CM1 will not be updated, the counter CN0 stops and the ATOM channel continues to request new data from ARU. A later reception of new ARU data in SR0 and SR1 will immediately force the update of the register CM0 and CM1 and restart the counter CN0.

(3) SOMS mode with ARU_EN = 0 and OSM = 0, UPEN_CTRL[x] = 1:

In case of bit ARU_EN is not set and bit OSM is not set, the ATOM channel updates its CM0/CM1 register with the content of the SR0/SR1 register and restarts shifting immediately. The first bit of new CM1 register value will be applied at the output without any gap to the last bit of the previous CM1 register value.

(4) SOMS mode with ARU_EN = 0 and OSM = 1, UPEN_CTRL[x] = 1:

In case of bit ARU_EN is not set and bit OSM is set, the ATOM channel stops shifting when CN0 reaches CM0 and no update of CM0 and CM1 is performed.

Then, the shifting of the channel can be restarted again by writing a zero to the CN0 register again.

The writing of a zero to CN0 causes also an immediate update of CM0/CM1 register with the content of SR0/SR1 register.

(5) SOMS mode with double output

If in SOMS mode additionally the mode bit DSO is set (in register ATOM[i]_CH[x]_CTRL) two 12 bit data streams can be shifted out on the outputs ATOM_OUT and ATOM_OUT_T in parallel. This is reached by splitting the register CM1 into two parts. The lower 12 bits are used as a shift register of output ATOM_OUT (i.e. bit 0 is assigned to output ATOM_OUT), the upper 12 bits are used as a shift register of output ATOM_OUT_T (i.e. bit 12 is assigned to output ATOM_OUT_T). On bit 23 and 11 of register CM1 the value !SL is shifted in.

NOTE

In this mode only shift right is possible. Bit ACB0 is ignored.

This behavior is depicted in the following figure:

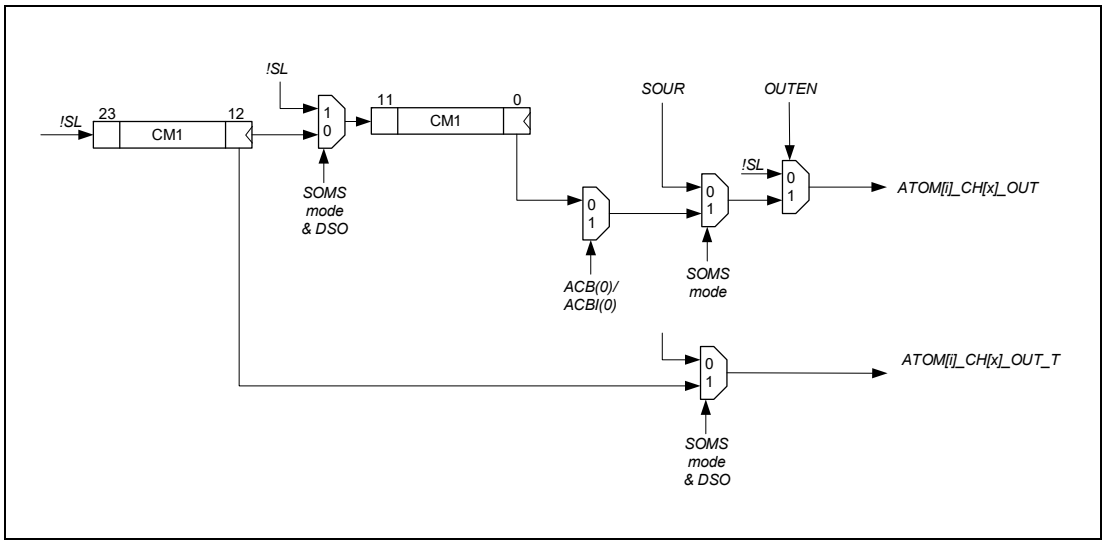

Figure 38.87 Double Output Shift Mode

(6) Interrupts in SOMS mode

In ATOM Signal Output Mode Serial only the interrupt CCU0TC (ATOM[i]_CH[x]_IRQ_NOTIFY) in case of CN0 ≥ CM0 is generated. The interrupt CCU1TC has no meaning and is not generated.

38.17.3.5 ATOM Signal Output Mode Buffered Compare (SOMB)

(1) Overview

In ATOM Signal Output Mode buffered Compare (SOMB) the output action is performed according to the comparison result of the input values located in CM0 and/or CM1 registers and the two (three) time base values TBU_TS0 or TBU_TS1 (or TBU_TS2) provided by the TBU. For a description of the time base generation refer to the TBU specification in **Section 38.14**. It is configurable, which of the two (three) time bases is to be compared with one or both values in CM0 and CM1.

The compare strategy of the two compare units CCU0 and CCU1 is controlled by the value of bit field ACBI of register ATOM[i]_CH[x]_STAT.

Table 38.207 ATOM SOMB compare strategies

ACBI(4)	ACBI(3)	ACBI(2)	CCUx control
0	0	0	Reserved. Has no effect.
0	0	1	Reserved. Has no effect.
0	1	0	Compare in CCU0 only, use time base *TBU_TS0*. Output signal level is defined by combination of SL, ACB10/ACBI(1..0) bits.
0	1	1	Compare in CCU1 only, use time base *TBU_TS1* or *TBU_TS2*. Output signal level is defined by combination of SL, ACBI[1:0] bits.
1	0	0	Serve Last: Compare in CCU0 and then in CCU1 using *TBU_TS0*. Output signal level when CCU0 matches is defined by combination of SL, ACBI[1:0]. On the CCU1 match the output level is toggled.
1	0	1	Serve Last: Compare in CCU0 and then in CCU1 using *TBU_TS1* or *TBU_TS2*. Output signal level when CCU0 matches is defined by combination of SL, ACBI[1:0]. On the CCU1 match the output level is toggled.
1	1	0	Serve Last: Compare in CCU0 using *TBU_TS0* and then in CCU1 using *TBU_TS1* or *TBU_TS2*. Output signal level when CCU1 matches is defined by combination of SL, ACBI[1:0]
1	1	1	Cancels pending comparison independent on ARU_EN

This bit field is only readable by CPU. If ARU is disabled, the bit field ACBI can only be updated with the value of bit field ACB of register ATOM[i]_CH[x]_CTRL. If ARU is enabled, the ACBI bit field can be updated with the value of shadow register ACB_SR which contains a value received via ARU or the value of bit field ACB of register ATOM[i]_CH[x]_CTRL.

The table below lists all valid control configurations for bit field ACBI of register ATOM[i]_CH[x]_STAT.

The CCUx trigger signals TRIG_CCU0 and TRIG_CCU1 creates edges depending on the combination of the predefined signal level in SL bit and the two control bits ACBI[1:0].

In SOMB mode, if ARU access is enabled, the new compare values received via ARU are always stored in the shadow register SR0 and SR1 and the ACB bits are stores in an internal register ACB_SR.

If the scheduled compare matches in CCU0 and/or CCU1 are occurred and the SRx register contain new valid values, the register CM0 and CM1 are updated automatically with the content of the corresponding SRx register, the ACBI bit field is updated with the content of internal ACB_SR register and the DV bit of register ATOM[i]_CH[x]_STAT is set. If the SRx register and the CMx register contain no valid value, the compare units are waiting in an idle state.

On a compare match of one of the compare units CCUx units the output ATOM_OUT is set according to combination of ACBI bit 1 down to 0 (in register ATOM[i]_CH[x]_STAT) and the SL bit of register ATOM[i]_CH[x]_CTRL.

Table 38.208 ATOM SOMB output control by ACBI[1:0] and SL

SL	ACBI(1)	ACBI(0)	Output Behavior
0	0	0	No signal level change at output.
0	0	1	Set output signal level to 1.
0	1	0	Set output signal level to 0.
0	1	1	Toggle output signal level.
1	0	0	No signal level change at output.
1	0	1	Set output signal level to 0.
1	1	0	Set output signal level to 1.
1	1	1	Toggle output signal level.

In opposite to SOMC mode no time stamp value of TBU is captured in SRx register.

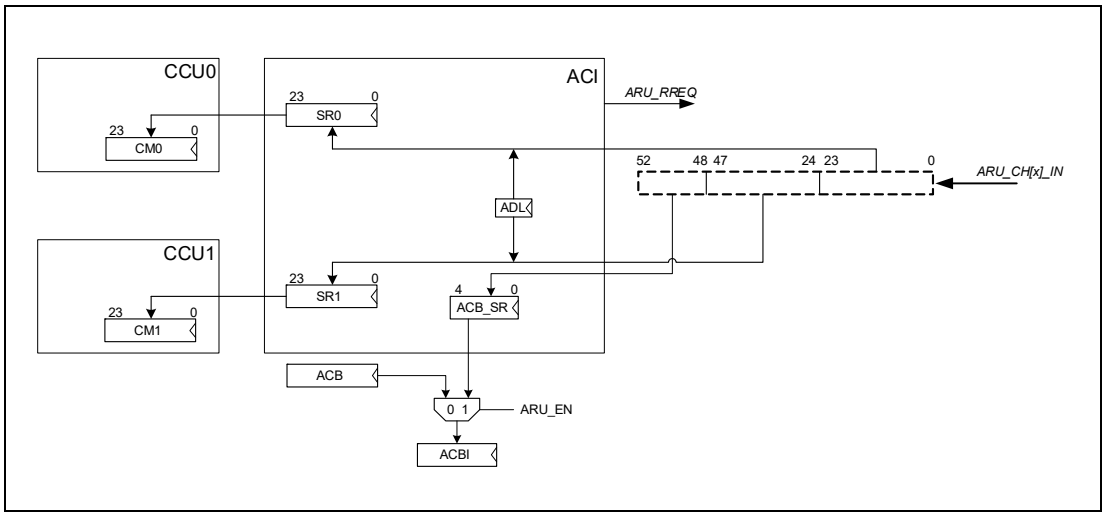

Figure 38.88 ARU interface behavior in SOMB mode

The flag DV of register ATOM[i]_CH[x]_STAT indicates that at least one of the CMx register contains valid data and a compare event may be pending (if channel is enabled). The DV flag is reset if none of the CMx register contains valid data.

(2) SOMB under CPU control

If bit ARU_EN of register ATOM[i]_CH[x]_CTRL is not set, the ATOM channel can only be controlled via CPU.

Writing to one of the CMx register sets automatically the DV bit to validate the new compare value. A comparison depending on value ACBI of register ATOM[i]_CH[x]_STAT is started immediately. Because only the ACB bit of register ATOM[i]_CH[x]_CTRL can be written and this bit field serves as a shadow register for the work register ACBI (bit field of register ATOM[i]_CH[x]_STAT), it is recommended to first update the ACB bit field before updating CMx / SRx register.

The compare strategy is controlled by the value stored in bit field ACBI of register ATOM[i]_CH[x]_STAT. If ARU is disabled, this bit field can only be updated with the value of bit field ACB of register ATOM[i]_CH[x]_CTRL.

The update of bit field ACBI can be triggered by a forced update or the normal update mechanism controlled by bit UPEN_CTRL[x] in register ATOM[i]_AGC_GLB_CTRL.

Writing to one of the SRx register and triggering a forced update, updates the CMx register with the value of SRx register and the ACBI bit field with the content of ACB bit field of register ATOM[i]_CH[x]_CTRL. A new comparison is started.

Writing to one of the SRx register while update of CMx register is disabled (UPEN_CTRL[x] = 0 in ATOM[i]_AGC_GLB_CTRL) and enabling update afterwards, triggers the update of CMx register and the ACBI bit field and starts comparison if previous comparison is finished (DV bit was reset).

If ARU access is disabled (ARU_EN = 0), a force update updates the CMx register with the content of SRx register and the ACBI bit field with the content of ACB bit field of register ATOM[i]_CH[x]_CTRL.

(3) SOMB under ARU control

If both compare units CCU0/CCU1 are finished with previous job (depending on compare strategy) and the SRx register contain no new value, they are waiting until new data was received via ARU and stored in SRx register. Then, an immediately update takes place.

If both compare units are finished with previous job (depending on compare strategy) and there are new data available in SRx register, the update the CMx register with the value of the SRx register and the ACBI bit field with the value of internal ACB_SR register takes place and a new compare job is started immediately.

After an update of the CMx register, a new ARU read request is set.

New compare values received via the ARU are stored in shadow register SRx. The ACB bits received via ARU are stored in the internal register ACB_SR.

If ARU access is enabled (ARU_EN = 1), a force update updates the CMx register with the content of SRx register and the ACBI bit field with the content of internal ACB_SR register.

For compare strategy 'serve last' the CCU0 and CCU1 compare match may occur sequentially. During different phases of compare match the CPU access rights to register CM0 and CM1 as well as to WR_REQ bit is different. These access rights by CPU to register CM0 and CM1 and the WR_REQ are depicted in the following figure for the case of EUPM = 0 (register ATOM[i]_CH[x]_CTRL)

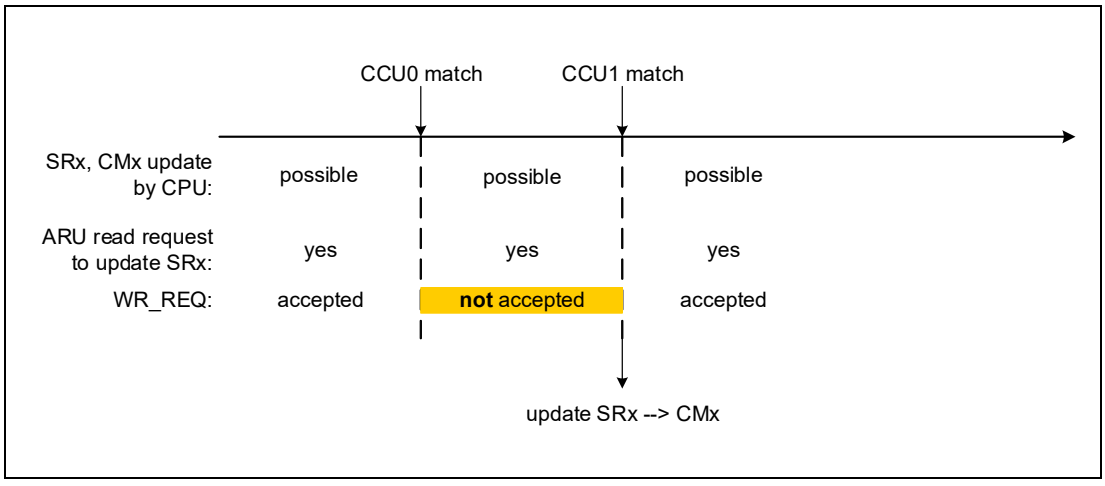

Figure 38.89 CPU access rights in case of compare strategy 'serve last' and EUPM = 0

The access rights by CPU to register CM0 and CM1 and the WR_REQ are depicted in the following figure for the case of EUPM = 1 (register ATOM[i]_CH[x]_CTRL)

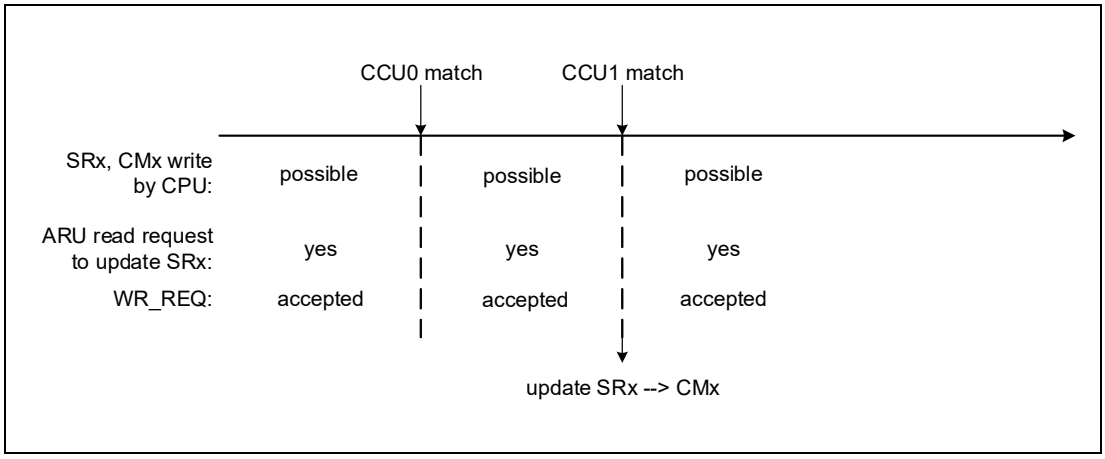

Figure 38.90 CPU access rights in case of compare strategy 'serve last' in case of EUPM = 1

(a) ARU Non-blocking mode

If bit ABM in register ATOM[i]_CH[x]_CTRL is not set, the ARU blocking mode is disabled. In this case the ATOM channel is continuously reading via ARU and storing new values in the SRx register and the ACB shadow register ACB_SR.
If ARU_EN is not set, the bit ABM has no meaning.

(b) ARU Blocking mode

If bit ABM in register ATOM[i]_CH[x]_CTRL is set, the ARU blocking mode is enabled. In this case the ATOM channel stops requesting new SRx values via ARU after reception of a new SRx value and restarts requesting a new value via ARU after compare match on both compare units (depending on compare strategy) followed by the immediate update of the CMx register with content of SRx register and an update of ACBI with the content of ACB_SR.

If ARU_EN is not set, the bit ABM has no meaning.

(c) Late Update by CPU

Although, the ATOM channel may be controlled by data received via the ARU, the CPU is able to request at any time a late update of the compare register. This can be initiated by setting the WR_REQ bit inside the ATOM[i]_CH[x]_CTRL register.

If none of the two compare match event happened, the ATOM channel accepts the setting of WR_REQ bit. In this case, the ATOM will request no further data from ARU (if ARU access was enabled) and will disable the update of CMx register with the content of SRx register on a compare match event.

If at least one of the requested compare match events happened (depending on strategy) the WR_REQ bit is not set and the WRF flag in register ATOM[i]_CH[x]_STAT is set to indicate that the late update was not successful.

The channel will in any case continue to compare against the values stored inside the compare registers (if bit DV was set). The CPU can now update the compare values by writing to the shadow registers and force the ATOM channel to update the compare registers by writing to the force update register bits in the AGC register.

With a force update the WR_REQ bit is reset automatically and the ARU read request is set up again (if ARU access was enabled).

38.17.4 ATOM Interrupt Signals

Signal	Description
CCU0TCx_IRQ	CCU0 Trigger condition interrupt for channel x
CCU1TCx_IRQ	CCU1 Trigger condition interrupt for channel x

38.17.5 ATOM Configuration Registers Overview

ATOM contains following configuration registers:

Table 38.209 Register list

Symbol	Register Name	Detail in Section
ATOM[i]_AGC_GLB_CTRL	ATOMi AGC global control register	**38.17.6.1**
ATOM[i]_AGC_ENDIS_CTRL	ATOMi AGC enable/disable control register	**38.17.6.2**
ATOM[i]_AGC_ENDIS_STAT	ATOMi AGC enable/disable status register	**38.17.6.3**
ATOM[i]_AGC_ACT_TB	ATOMi AGC action time base register	**38.17.6.4**
ATOM[i]_AGC_OUTEN_CTRL	ATOMi AGC output enable control register	**38.17.6.5**
ATOM[i]_AGC_OUTEN_STAT	ATOMi AGC output enable status register	**38.17.6.6**
ATOM[i]_AGC_FUPD_CTRL	ATOMi AGC force update control register	**38.17.6.7**
ATOM[i]_AGC_INT_TRIG	ATOMi AGC internal trigger control register	**38.17.6.8**
ATOM[i]_CH[x]_CTRL	ATOMi channel x control register	**38.17.6.9**
ATOM[i]_CH[x]_STAT	ATOMi channel x status register	**38.17.6.10**

Table 38.210 ATOM[i]_AGC_GLB_CTRL Register Contents

Bit Position	Bit Name	Function
31 to 16	UPEN_CTRL [7:0]	ATOM channel 0 enable update of register CM0, CM1 and CLK_SRC from SR0, SR1 and CLK_SRC_SR. READ access: 00_B: Update disabled 01_B: — 10_B: — 11_B: Update enabled WRITE access: 00_B: Don't care, bits will not be change 01_B: Disable update 10_B: Enable update 11_B: Don't care, bits will not be changed
15 to 8	RST_CH[7:0]	Software reset of channel [7:0] 0: No action 1: Reset channel **NOTE** This bit is cleared automatically after write by CPU. The channel registers are set to their reset values and channel operation is stopped immediately. The output register of SOU unit is reset to inverse reset value of SL bit.
7 to 1	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
0	HOST_TRIG	Trigger request signal (see AGC) to update the register ENDIS_STAT and OUTEN_STAT 0: No trigger request 1: Set trigger request **NOTE** This flag is reset automatically after triggering the update

38.17.6.2 ATOM[i]_AGC_ENDIS_CTRL

Access: This register can be read or written in 32-bit units.

Address: $E8044_H + (800_H \times i)$

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 38.211 ATOM[i]_AGC_ENDIS_CTRL Register Contents

Bit Position	Bit Name	Function
31 to 16	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
15 to 0	ENDIS_CTRL [7:0]	ATOM channel k enable/disable update value. 00_B: Don't care, bits 1:0 of register ENDIS_STAT will not be changed on an update trigger 01_B: Disable channel on an update trigger 10_B: Enable channel on an update trigger 11_B: Don't change bits 1:0 of this register **NOTES** 1. If FREEZE = 0 and an ATOM channel is disabled, the counter CN0 is stopped and the output register of SOU unit is set to the inverse value of control bit SL. On an enable event, the counter CN0 starts counting from its current value. 2. If FREEZE = 1 and an ATOM channel is disabled, the counter CN0 is stopped (SOMP, SOMS mode) and each comparison is stopped (SOMC, SOMB mode). On an enable event, the counter CN0 starts counting from its current value or a comparison is restarted. 3. If the output is disabled (OUTEN[k] = 0), the ATOM channel k output ATOM_OUT[k] is the inverted value of bit SL.

38.17.6.3 ATOM[i]_AGC_ENDIS_STAT

Access: This register can be read or written in 32-bit units.

Address: $E8048_H + (800_H \times i)$

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 38.212 ATOM[i]_AGC_ENDIS_STAT Register Contents

Bit Position	Bit Name	Function
31 to 16	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
15 to 0	ENDIS_STAT [7:0]	ATOM channel k enable/disable 00_B: Don't care, bits 1:0 of register ENDIS_STAT will not be changed on an update trigger 01_B: Disable channel on an update trigger 10_B: Enable channel on an update trigger 11_B: Don't change bits 1:0 of this register **NOTES** 1. If FREEZE = 0 and an ATOM channel is disabled, the counter CN0 is stopped and the output register of SOU unit is set to the inverse value of control bit SL. On an enable event, the counter CN0 starts counting from its current value. 2. If FREEZE = 1 and an ATOM channel is disabled, the counter CN0 is stopped (SOMP, SOMS mode) and each comparison is stopped (SOMC, SOMB mode). On an enable event, the counter CN0 starts counting from its current value or a comparison is restarted.

38.17.6.4 ATOM[i]_AGC_ACT_TB

Access: This register can be read or written in 32-bit units.

Address: $E804C_H + (800_H \times i)$

Value after reset: $0000\ 0000_H$

Table 38.213 ATOM[i]_AGC_ACT_TB Register Contents

Bit Position	Bit Name	Function
31 to 27	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
26, 25	TBU_SEL	Selection of time base used for comparison 00_B: TBU_TS0 selected 01_B: TBU_TS1 selected 10_B: TBU_TS2 selected 11_B: Same as 00 **NOTE** The bit combination 10 is only applicable if the TBU of the device contains three time base channels. Otherwise, this bit combination is also reserved. Refer to **Figure 38.2** to determine the number of channels for TBU of this device.
24	TB_TRIG	Set trigger request 0: No trigger request 1: Set trigger request **NOTE** This flag is reset automatically if the selected time base unit (TBU_TS0 or TBU_TS1 or TBU_TS2 if present) has reached the value ACT_TB and the update of the register were triggered.
23 to 0	ACT_TB	Specifies the signed compare value with selected signal TBU_TS[x], x = 0 to 2. If selected TBU_TS[x] value is in the interval [ACT_TB–$007FFFFF_H$,ACT_TB] the event is in the past and the trigger is generated immediately. Otherwise the event is in the future and the trigger is generated if selected TBU_TS[x] is equal to ACT_TB.

38.17.6.5 ATOM[i]_AGC_OUTEN_CTRL

Access: This register can be read or written in 32-bit units.

Address: $E804C_H + (800_H \times i)$

Value after reset: $0000\ 0000_H$

Table 38.218 ATOM[i]_CH[x]_CTRL Register Contents (1/6)

Bit Position	Bit Name	Function
31	FREEZE	0: A channel disable/enable may change internal register and output register 1: A channel enable/disable does not change an internal or output register but stops counter CN0 (in SOMP mode), comparison (in SOMC/SOMB mode) and shifting (in SOMS mode) **NOTE** If channel is disabled and output is enabled, in SOMP mode with UDMODE! = 00_B the output is depending directly on SL bit, independent on FREEZE mode.
30	SOMB	SOMB mode 0: ATOM channel mode defined by bit field MODE 1: ATOM SOMB mode enabled **NOTE** This bit is only applicable in SOMB mode.
29	EXT_FUPD	External forced update 0: Use FUPD(x) signal from AGC to force update 1: Use TIM_EXT_CAPTURE signal to force update **NOTE** This bit is only applicable in SOMP and SOMS mode.
28	Reserved	When read, the value after reset is returned. When writing, write the value after reset.

Table 38.218 ATOM[i]_CH[x]_CTRL Register Contents (2/6)

Bit Position	Bit Name	Function
27	ABM	ARU blocking mode 0: ARU blocking mode disabled: ATOM reads continuously from ARU and updates CM0,CM1 and ACB bits in case of SOMC mode or SR0, SR1 and ACB bits in case of SOMB mode independent of pending compare match event. 1: ARU blocking mode enabled: after update of CM0, CM1 and ACB bit in case of SOMC mode or SR0, SR1 and ACB bits in case of SOMB mode via ARU, no new data is read via ARU until compare match event occurred and in case of SOMC mode SR0 and/or SR1 are read. **NOTE** This bit is only applicable in SOMC and SOMB mode.
26	OSM	One-shot mode 0: Continuous PWM generation after channel enable 1: A single pulse is generated **NOTE** This bit is only applicable in SOMP and SOMS modes.
25	SLA	'Serve last' ARU communication strategy 0: Capture SRx time stamps after CCU0 match event not provided to ARU 1: Capture SRx time stamps after CCU0 match event provided to ARU **NOTES** 1. This bit is only applicable in SOMC mode. 2. The setting of this bit has only effect, when ACBI (4:2) is configured for 'serve last' compare strategy (100_B, 101_B, or 110_B). 3. When this bit is not set, the captured time stamps in the shadow registers SRx are only provided after the CCU1 match occurred. The ACBO(4:3) bits always return 10_B in that case. 4. By setting this bit, the ATOM channel also provides the captured time stamps after the CCU0 match event to the ARU. The ACBO(4:3) bits are set to 01_B in that case. After the CCU1 match event, the time stamps are captured again in the SRx registers and provided to the ARU. The ACBO(4:3) bits are set to 10_B. When the data in the shadow registers after the CCU0 match was not consumed by an ARU destination and the CCU1 match occurs, the data in the shadow registers is overwritten by the new captured time stamps. The ATOM channel does not request new data from the ARU when the CCU0 match values are read from an ARU destination.
24	TRIGOUT	Trigger output selection (output signal TRIG_CHx) of module ATOM_CHx. 0: TRIG_[x] is TRIG_[x–1] or TIM_EXT_CAPTURE(x). 1: TRIG_[x] is TRIG_CCU0 **NOTE** This bit is only applicable in SOMP, SOMC and SOMB mode.
23	EXTTRIGOUT	Select TIM_EXT_CAPTURE(x) as potential output signal TRIG_[x] 0: Signal TRIG_[x–1] is selected as output on TRIG_[x] (if TRIGOUT = 0) 1: Signal TIM_EXT_CAPTURE(x) is selected as output on TRIG_[x] (if TRIGOUT = 0) **NOTE** This bit is only applicable in SOMP, SOMC and SOMB mode.

Table 38.218 ATOM[i]_CH[x]_CTRL Register Contents (3/6)

Bit Position	Bit Name	Function
22	EXT_TRIG	Select TIM_EXT_CAPTURE(x) as trigger signal 0: Signal TIM_[x–1] is selected as trigger to reset CN0 or to start single pulse generation. 1: Signal TIM_EXT_CAPTURE(x) is selected **NOTE** This bit is only applicable in SOMP mode.
21	OSM_TRIG	Enable trigger of one-shot pulse by trigger signal OSM_TRIG 0: Signal OSM_TRIG cannot trigger start of single pulse generation 1: Signal OSM_TRIG can trigger start of single pulse generation (only if bit OSM = 1) **NOTES** 1. This bit should only be set if bit OSM = 1 and bit RST_CCU0 = 0. 2. This bit is only applicable in SOMP mode.
20	RST_CCU0	Reset source of CCU0 0: Reset counter register CN0 to 0 on matching comparison with CM0 1: Reset counter register CN0 to 0 on trigger TRIG_[x–1] or TIM_EXT_CAPTURE(x) **NOTES** 1. If RST_CCU0 = 1 and UPEN_CTRLx=1 are set, TRIG_[x–1] or TIM_EXT_CAPTURE(x) triggers also the update of work register (CM0, CM1 and CLK_SRC). 2. This bit is only applicable in SOMP mode. 3. This bit should only be set if bit OSM = 0 (i.e. in continuous mode)
19, 18	UDMODE	Up/down counter mode 00: Up/down counter mode disabled: CN0 counts always up 01: Up/down counter mode enabled: CN0 counts up and down, CM0, CM1 are updated if CN0 reaches 0 (i.e. changes from down to up) 10: Up/down counter mode enabled: CN0 counts up and down, CM0, CM1 are updated if CN0 reaches CM0 (i.e. changes from up to down) 11: Up/down counter mode enabled: CN0 counts up and down, CM0, CM1 are updated if CN0 reaches 0 or CM0 (i.e. changes direction) **NOTE** This mode is only applicable in SOMP mode.
17	TRIG_PULSE	Trigger output pulse length of one SYS_CLK period 0: Output on ATOM[i]_OUT[x]_T is '1' as long as CN0_SR0 (if SR0_TRIG = 1) 1: Output on ATOM[i]_OUT[x]_T is '1' for only one SYS_CLK period if CN0 = SR0 (if SR0_TRIG = 1) **NOTE** This bit is only applicable in SOMP mode.

Table 38.218 ATOM[i]_CH[x]_CTRL Register Contents (4/6)

Bit Position	Bit Name	Function
16	WR_REQ	CPU Write request bit for late compare register update. 0: No late update requested by CPU 1: Late update requested by CPU **NOTES** 1. The CPU can disable subsequent ARU read requests by the channel and can update the shadow registers with new compare values, while the compare units operate on old compare values received by former ARU accesses, if occurred. 2. On a compare match event, the WR_REQ bit will be reset by hardware. 3. At the point of the force update only the shadow registers SR0 and SR1 are transferred into the CM0, CM1 registers. The output action is still defined by the ACBI bit field described by the ARU together with the old compare values for CM0/CM1. 4. This bit is only applicable in SOMC and SOMB mode.
15	ECLK_SRC	Extend CLK_SRC 0: CLK_SRC_SR set 1 selected 1: CLK_SRC_SR set 2 selected **NOTES** 1. See bit CLK_SRC_SR description for details. 2. This bit is only applicable in SOMP and SOMS mode.
14 to 12	CLK_SRC_SR	CMU clock source (SOMS)/shadow register for CMU clock source (SOMP). If ECLK_SRC = 0 000: CMU_CLK0 selected 001: CMU_CLK1 selected 010: CMU_CLK2 selected 011: CMU_CLK3 selected 100: CMU_CLK4 selected 101: CMU_CLK5 selected 110: CMU_CLK6 selected 111: CMU_CLK7 selected If ECLK_SRC = 1 000: CMU_CLK0 selected 001: CMU_CLK1 selected 010: CMU_CLK2 selected 011: Reserved 100: Clock stopped 101: TRIG[x–1] selected 110: TIM_EXT_CAPTURE[x] selected 111: CMU_CLK7 selected **NOTES** 1. This register is a shadow register for the register CLK_SRC. Thus, if the CMU_CLK source for PWM generation should be changed during operation, the old CMU_CLK has to operate until the update of the ATOM channels internal CLK_SRC register by the CLK_SRC_SR content is done either by an end of a period or a forced update. 2. After (channel) reset the selected CLK_SRC value is the SYS_CLK (input of Global Clock Divider). To use in SOMP mode one of the CMU_CLKx, it is recommended to perform a forced update of CLK_SRC with the value of CLK_SRC_SR value before/with enabling the channel. 3. In case of ECLK_SRC=1 and CLK_SRC_SR =011_B/100_B/101_B/110_B a force update leads to an immediate update of CM0, CM1 and CLK_SRC. 4. This bitfield is only applicable in SOMP, SOMS and SOMI mode.

Table 38.218 ATOM[i]_CH[x]_CTRL Register Contents (5/6)

Bit Position	Bit Name	Function
11	SL	Initial signal level. 0: Low signal level 1: High signal level **NOTES** 1. Reset value depends on the hardware configuration chosen by silicon vendor. 2. If the output is disabled, the output ATOM_OUT[x] is set to inverse SL independent of the ATOM channel mode. 3. In SOMS mode: the inverse value of SL is shifted into the CM1 register. 4. If FREEZE = 0 and the channel is disabled, in SOMP, SOMI, SOMS the internal register SOUR inside ATOM sub unit SOU is set to the inverse value of SL. By enabling the channel the register SOUR is not changed. Thus, if the output is enabled afterwards, the output ATOM_OUT[x] is the inverse value of SL. 5. If FREEZE = 0 and the channel is disabled, in SOMC mode the internal register SOUR inside ATOM sub unit SOU is set to the value of SL. By enabling the channel the register SOUR is not changed. Thus, if the output is enabled and the channel is disabled, the output ATOM_OUT[x] is the value of SL. 6. If FREEZE = 1 and the channel is disabled, the output register of SOU unit is not changed and output ATOM_OUT[x] is not changed.
10	EUPM	Extended update mode 0: No extended update of CM0 and CM1 via CPU or ARU 1: Extended update mode in case of compare strategy 'serve last': update of CM1 after CCU0 compare match possible via ARU or CPU. **NOTES** 1. If EUPM = 1 a write access to CM0 or CM1 never causes an AEI write status 10_B. 2. This bit is only applicable in SOMC and SOMB mode.
9	CMP_CTRL	CMP_CTRL: CCUx compare strategy select. 0: Greater-equal compare against TBU time base values (TBU_TSx ≥ CMx) 1: Less-equal compare against TBU time base values (TBU_TSx ≤ CMx) **NOTES** 1. The compare unit CCU0 or CCU1 that compares against TBU_TS0 (depending on CCUx control mode defined by ACBI(4:2) or ACB42) always performs a greater-equal comparison, independent on CMP_CTRL bit. 2. This bit is only applicable in SOMC and SOMB mode.
8 to 4	ACB	ATOM Mode control bits. **NOTE** These bits have different meaning in the different ATOM channel modes. Refer to **Table 38.197** for further details.
3	ARU_EN	ARU_EN: ARU Input stream enable. 0: ARU Input stream disabled 1: ARU Input stream enabled

Table 38.218 ATOM[i]_CH[x]_CTRL Register Contents (6/6)

Bit Position	Bit Name	Function
2	TB12_SEL	Select time base value TBU_TS1 or TBU_TS2. 0: TBU_TS1 selected for comparison 1: TBU_TS2 selected for comparison • SOMI: Not used • SOMC: Used • SOMB: Used • SOMP: Not used • SOMS: Not used **NOTE** This bit is only applicable if three time bases are present in the GTM-IP. Otherwise, this bit is reserved.
1, 0	MODE	ATOM channel mode select. 00: ATOM Signal Output Mode Immediate (SOMI) 01: ATOM Signal Output Mode Compare (SOMC) 10: ATOM Signal Output Mode PWM (SOMP) 11: ATOM Signal Output Mode Serial (SOMS) **NOTE** Not used in SOMB mode.

38.17.6.10 ATOM[i]_CH[x]_STAT

Access: This register can be read or written in 32-bit units.

Address: $E801C_H + (800_H \times i) + (80_H \times x)$

Value after reset: $0000\ 000x_H$

Bit Position	Bit Name	Function
31 to 29	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
28 to 24	ACBO	ATOM Internal status bits. ACBO[3] = 1: CCU0 Compare match occurred ACBO[4] = 1: CCU1 Compare match occurred **NOTES** 1. These bits are only set in SOMC mode. 2. ACBO is reset to 00000_B on an update of register CM0 or CM1 (via ARU or CPU) 3. In SOMC mode these bits are sent as ARU control bits 52 to 48.
23	DR	ARU data rejected flag 0: Received ARU data stored 1: Received ARU data rejected **NOTE** The flag is cleared if valid data is received and stored via ARU.
22	WRF	Write request of CPU failed for late update. 0: Late update was successful, CCUx units wait for comparison 1: Late update failed **NOTES** 1. The bit WRF can be reset by writing a 1 to it. 2. This bit is only applicable in SOMC and SOMB mode.

Table 38.219 ATOM[i]_CH[x]_STAT Register Contents (2/2)

Bit Position	Bit Name	Function
21	DV	Valid ARU Data stored in compare registers. 0: No valid data stored in register CM0 and/or CM1, no comparison is activated 1: Valid data stored in CM0 and/or CM1, comparison activated **NOTE** This bit is only applicable in SOMC and SOMB mode. The CPU can determine the status of the ARU transfers with this bit. After the compare event occurred, the bit is reset by hardware.
20 to 16	ACBI	ATOM Mode control bits. **NOTES** 1. For ATOM SOMI, SOMC, SOMP and SOMS mode this register serves as a mirror for the five ARU control bits received through the ARU interface. The bits are valid, when the DV bit is set. 2. For SOMB mode this bit field serves as the work register of the compare strategy. It can be updated with the value of bit field ACB of register ATOM[i]_CH[x]_CTRL or the value of internal shadow register ACB_SR.
15 to 1	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
0	OL	Actual output signal level of ATOM_CHx_OUT. 0: Output signal level is low 1: Output signal level is high **NOTE** Reset value is the inverted value of bit SL which depends on the hardware configuration chosen by silicon vendor.

38.17.6.11 ATOM[i]_CH[x]_RDADDR

Access: This register can be read or written in 32-bit units.

Address: $E8000_H + (800_H \times i) + (80_H \times x)$

Value after reset: $01FE\ 01FE_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	RDADDR1								
Value after reset	0	0	0	0	0	0	0	1	1	1	1	1	1	1	1	0
R/W	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	RDADDR0

Table 38.220 ATOM[i]_CH[x]_RDADDR Register Contents

Bit Position	Bit Name	Function
31 to 25	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
24 to 16	RDADDR1	ARU Read address 1. **NOTES** 1. This read address is only applicable in SOMC mode. 2. The ATOM channel switches to this read address, when requested in the ARU control bits 52 to 48 with the pattern “111——”. The channel switches back to the RDADDR0 after one ARU data package was received on RDADDR1 and the compare match event is occurred. 3. This bit field is only writable if channel is disabled.
15 to 9	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
8 to 0	RDADDR0	ARU Read address 0. **NOTES** 1. This read address is used by the ATOM channel to receive data from the ARU immediately after the channel and ARU access is enabled (see ATOM[i]_CH[x]_CTRL register for details). 2. This bit field is only writable if channel is disabled.

38.17.6.12 ATOM[i]_CH[x]_CN0

Access: This register can be read or written in 32-bit units.

38.18 Dead Time Module (DTM)

38.18.1 Overview

The following figure gives an overview of the structure of the Dead Time Module (DTM).

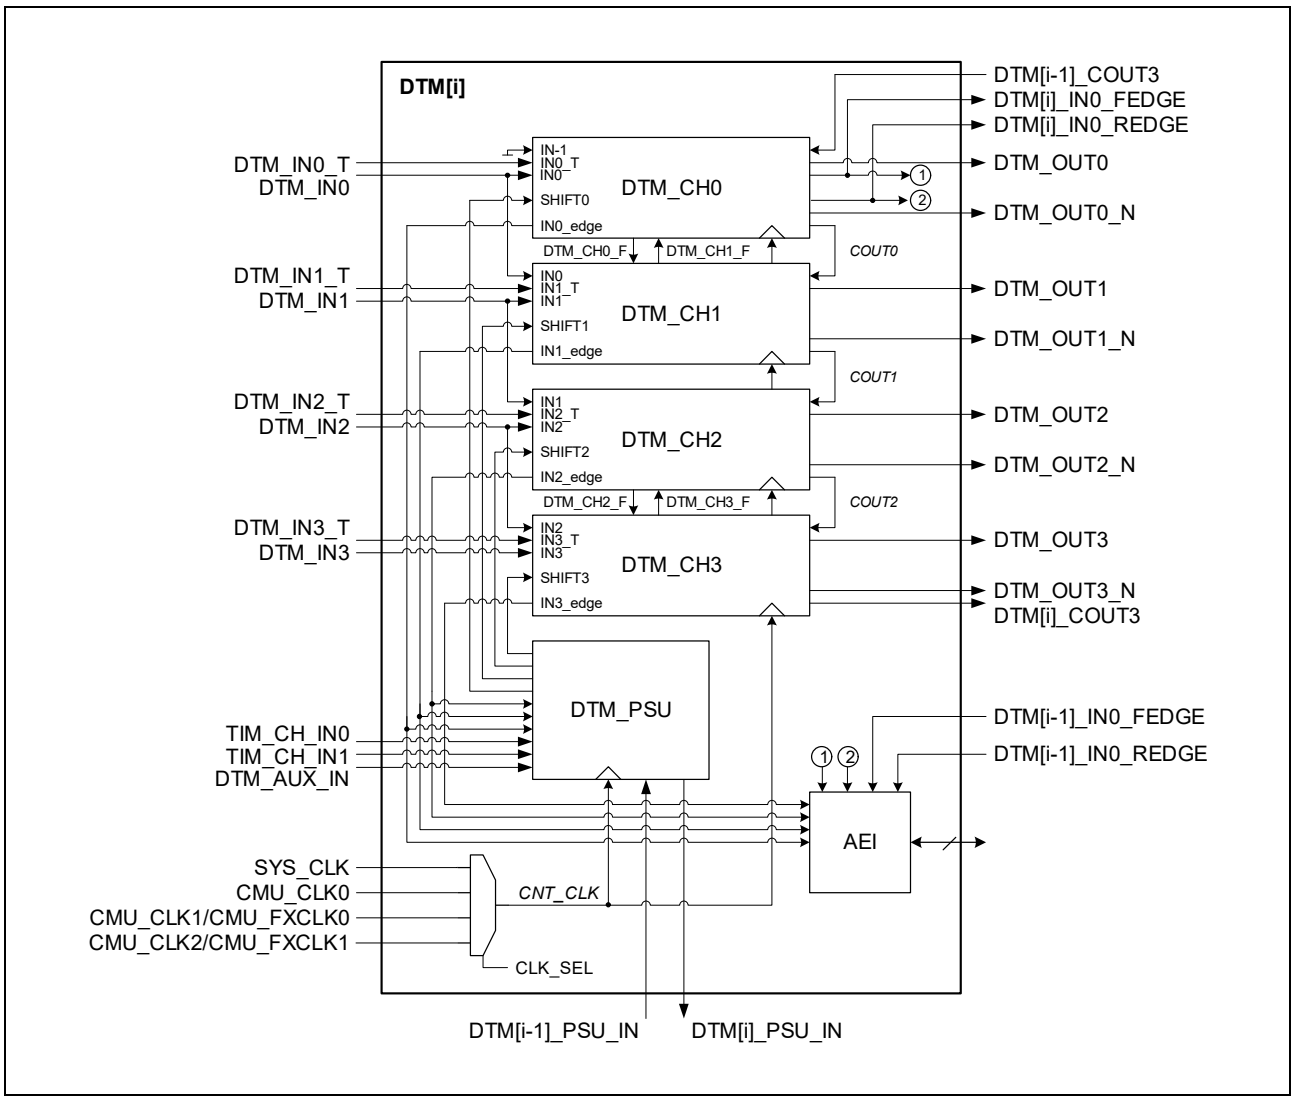

Figure 38.91 DTM block diagram

The main function of the DTM is to derive for each input DTM_IN0 to DTM_IN3 the individual inverse signal (DTM[i]_OUT[x]_N) and to apply an edge specific delay between the edge of the original signal and the edge of the derived inverted signal (i.e., the dead time). This function is mainly used for controlling of half bridges.

A second function provided by DTM is to set the outputs of one channel to the value of the preceding channel if requested by a trigger on input TIM_CH_IN0, TIM_CH_IN1 or DTM_AUX_IN. This feature allows a phase shift on one PWM signal to the phase of the preceding PWM signal up to the next edge on this channel.

The third function provided by DTM is to (N)AND/(N)OR/X(N)OR combine the input DTM_IN[x] signal of one DTM channel with the signal on input TIM_CH_IN0, TIM_CH_IN1 or DTM_AUX_IN (selected inside DTM_PSU and assigned to one of the signals SHIFT[x]) or with the combinational output (signal COUT[x]) of preceding channel. As a result COUT2 may be the combined signal of

DTM_IN0 and TIM_CH_IN0, TIM_CH_IN1 or DTM_AUX_IN and the signal DTM_IN1. For COUT3 this chain can be combined again with signal DTM_IN3.

The outputs of each channel may be swapped individually to provide the function of combining signals on each output of a channel.

In general, the DTM instances are placed behind the TOM and the ATOM instances, i.e., the outputs TOM_OUT[x] and TOM_OUT[x]_T or ATOM_OUT[x] and ATOM_OUT[x]_T are each routed to the DTM instance inputs DTM_IN[y] and DTM_IN[y]_T. Four DTM instances behind a TOM instance i and two DTM instances behind an ATOM instance i are grouped together in a Cluster DTM hierarchy called CDTM[i]. The connections between DTM and the modules TOM and ATOM are depicted in **Figure 38.92, Connections of TIM, TOM and ATOM to DTM**.

Depending on device configuration, not every DTM instance is available. E.g. a device may only have one DTM connected to the first four channels of ATOM. In this case, the other four channels (4 to 7) are connected directly to GTM outputs. For detailed information, which DTM instance is available, refer to corresponding device specific **Section 38.28, GTM Device 358** of this specification.

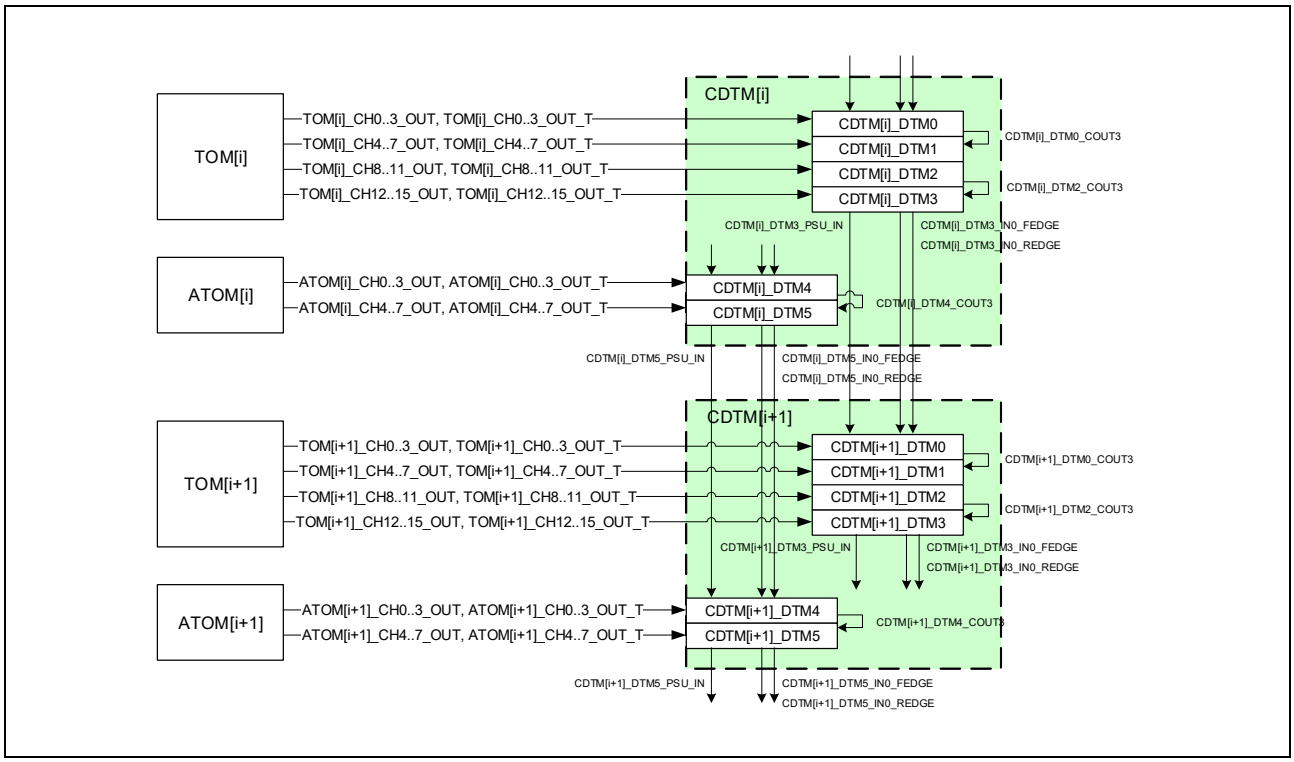

Figure 38.92 Connections of TIM, TOM and ATOM to DTM

Additionally, the DTM instances have inputs TIM_CH_IN0 / TIM_CH_IN1 which are driven by TIM output signals TIM[i]_CH[x]_F_OUT. There are two configurations of TIM to DTM connections possible depending on the DTM channel specific configuration bit TIM_SEL. In case of TIM_SEL = 0 the connected TIM input may not be of the same cluster as the DTM. In case of TIM_SEL = 1 the TIM input is of the same cluster as the DTM.

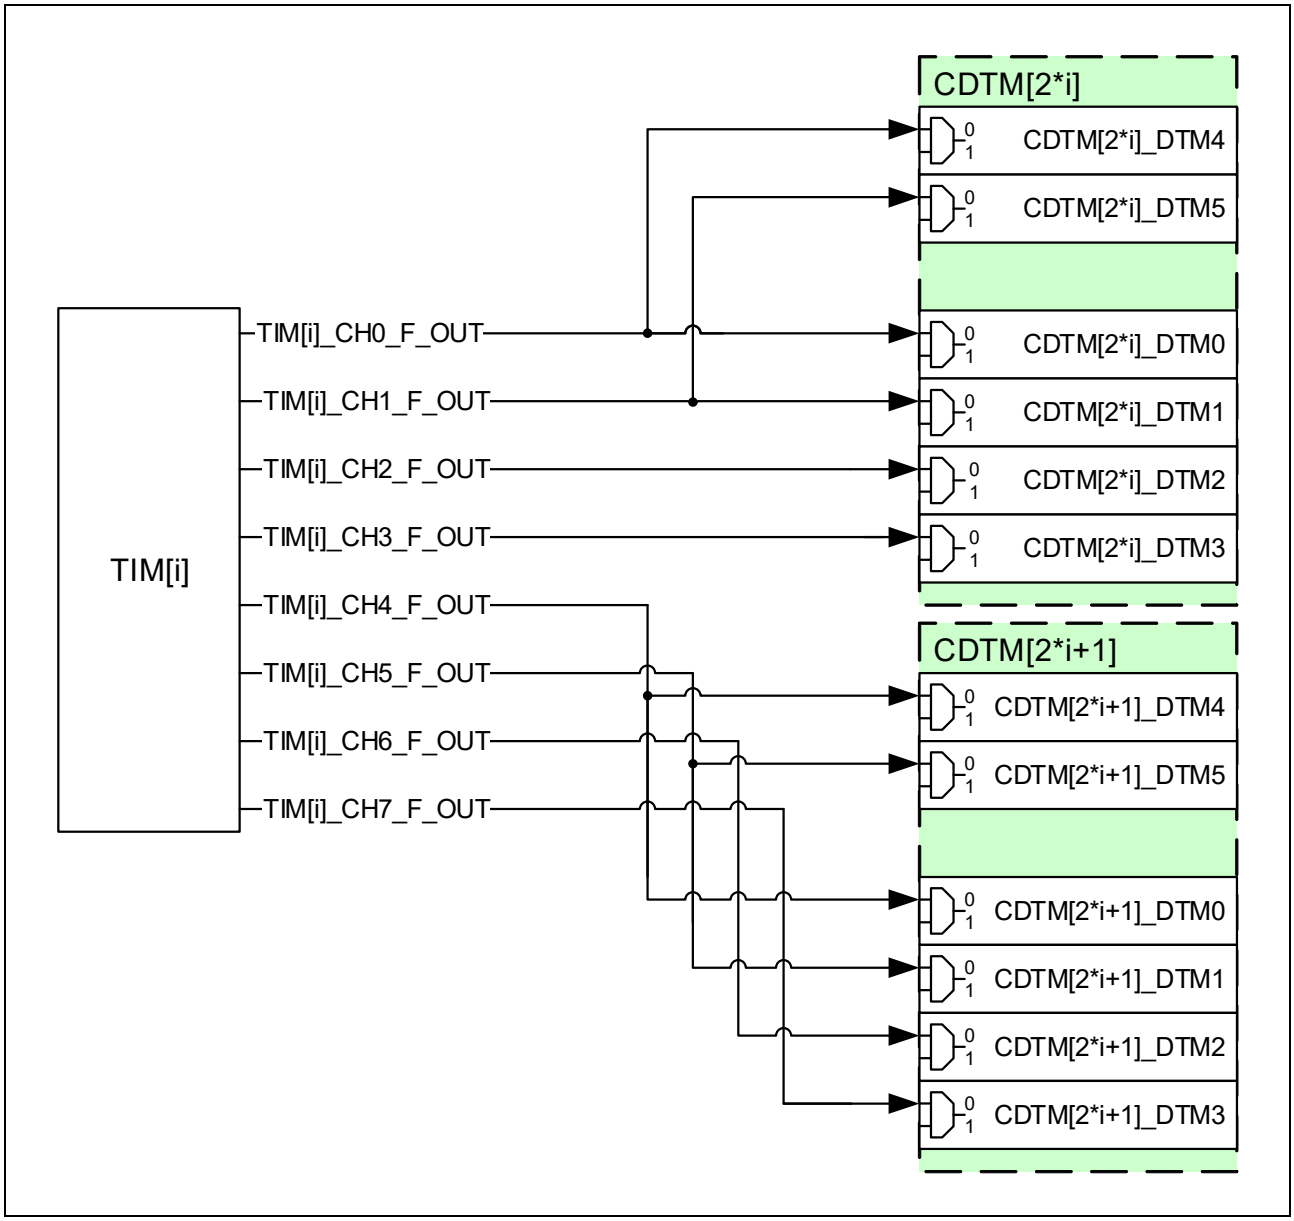

Figure 38.93 Connections of TIM to DTM inputs TIM_CH_IN0/TIM_CH_IN1 for TIM_SEL = 0

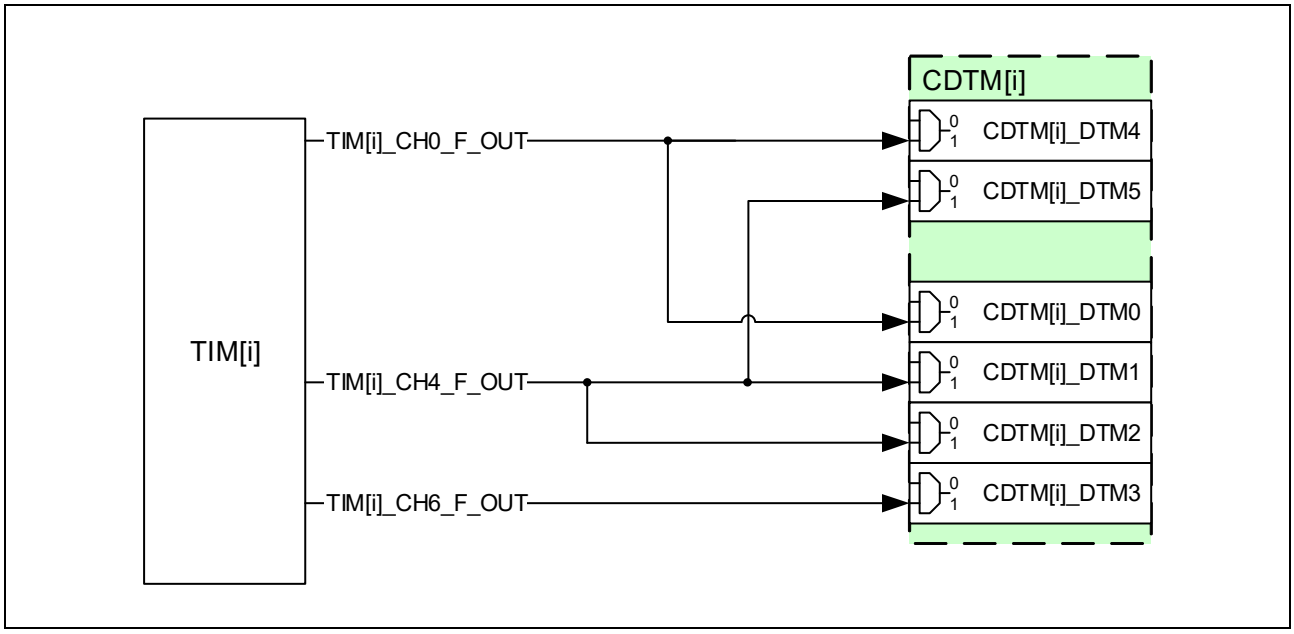

Figure 38.94 Connections of TIM to DTM inputs TIM_CH_IN0/TIM_CH_IN1 for TIM_SEL = 1

There are also connections between DTM instances of same CDTM instance. For each pair of DTM instance 2i and 2i+1 the combinatorial output COUT(3) of DTM[2i] channel 3 is connected to DTM[2i+1] channel 0 COUT(0–1). With this a combinatorial chain over two neighbored DTM instances can be configured. If one of the two neighbored DTM instances is not available (i.e. it is an empty instance) the inputs used for connections between two neighbored DTM instances are left open.

NOTE

For channel x = 0 of DTM instance 2i input signals COUT[x–1] is unused and I1SEL_[x] is defined as 0.

An additional link between DTM instances behind an ATOM is a forwarding of DTM[i]_PSU_IN signal to next available instance of DTM behind an ATOM (e.g. DTM[i+1]_PSU_IN). The same link is available between all available DTM behind a TOM.

NOTE:

For unavailable DTM[i] instances (i.e. the instance DTM[i] is called empty) the signal DTM[i–1]_PSU_IN is passed through empty instance DTM[i] to DTM[i+1]_PSU_IN, DTM[i–1]_IN0_FEDGE and DTM[i–1]_IN0_REDGE are passed through DTM[i] to DTM[i+1]_IN0_FEDGE and DTM[i+1]_IN0_REDGE.

Further connections between neighbored DTM instances are depicted in the following figure:

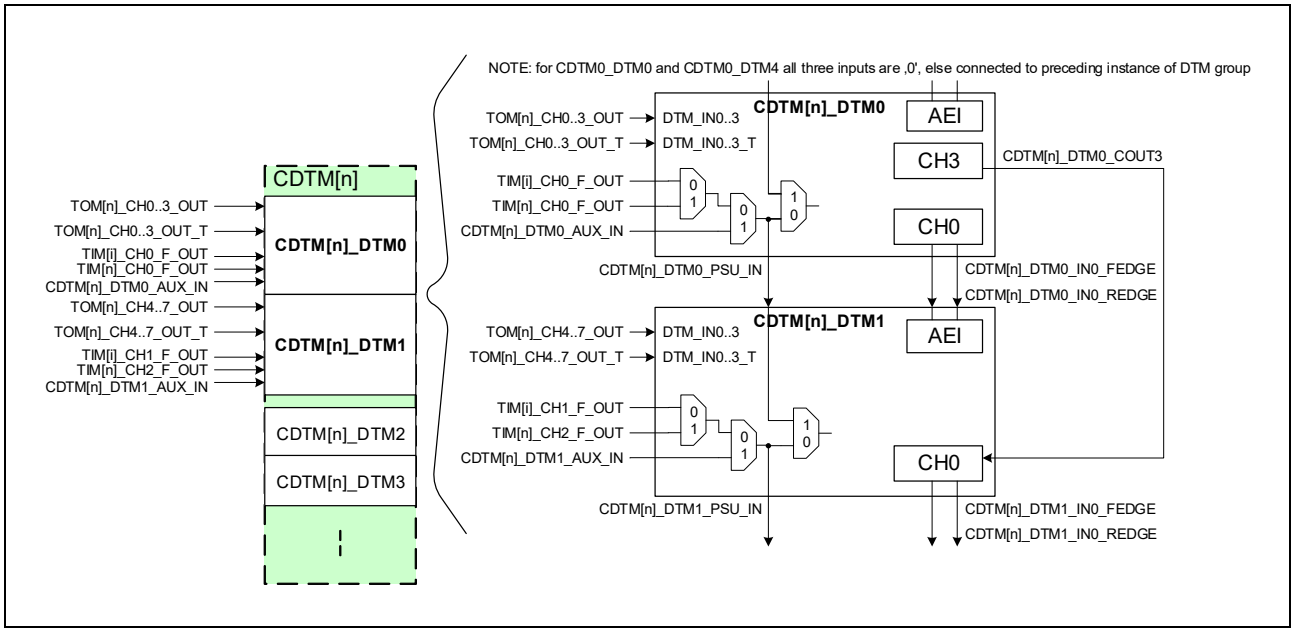

Figure 38.95 Connections between DTM instances

38.18.2 DTM Channel

The following figure depicts the functions of a DTM channel.

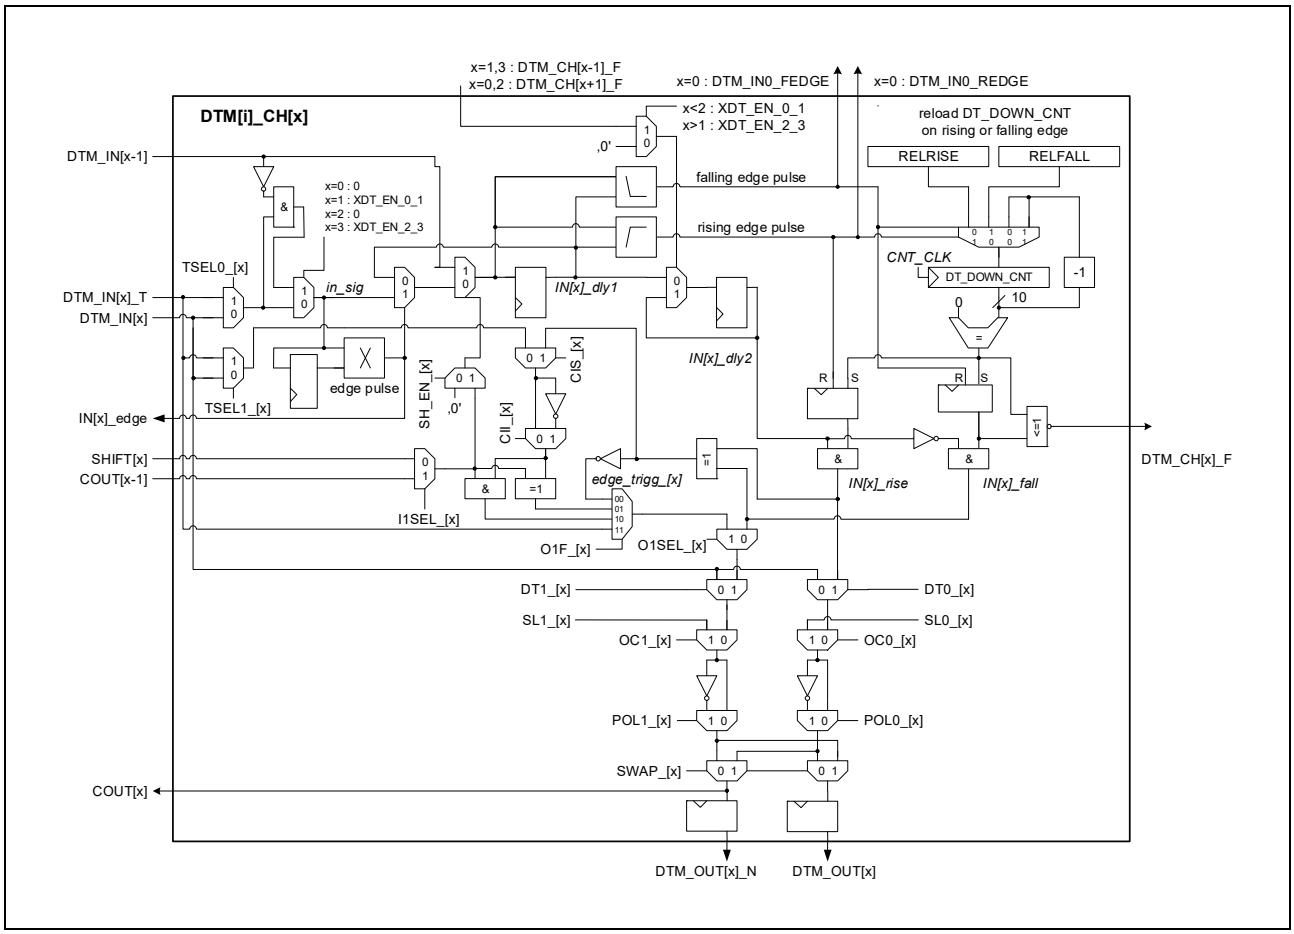

Figure 38.96 DTM channel overview

The main feature of each channel is to derive the inverse signal out of the input signal DTM_IN[x], apply an edge dependent delay on the two resulting signal paths and provide these signals at the outputs DTM[i]_OUT[x] and DTM[i]_OUT[x]_N.

There are two possibilities to apply dead time on GTM output signals. One is to use one DTM channel per TOM/ATOM channel and generate inside the DTM the second inverse signal. This is called the standard dead time generation. The second way is to generate two signals out of two TOM/ATOM channel and to apply inside the DTM only the dead time by using two cross linked DTM channel. This is called the cross dead time generation.

38.18.2.1 Standard dead time generation

The dead time can be configured for each edge individually. The bit field RELRISE in register DTM[i]_CH[x]_DTV contains the reload value for the counter and defines the delay for rising edges in multiples of selected clock ticks. The bit field RELFALL in register DTM[i]_CH[x]_DTV contains the reload value for the counter and defines the delay for falling edges in multiples of selected clock ticks.

The counter is reloaded with the value of RELRISE on a rising edge and reloaded with the value of RELFALL on a falling edge on input DTM_IN[x] (or DTM_IN[x–1] in case of shift enable SH_EN_[x]). On a reload of the counter the flip-flop following the counter output comparator is reset and stays reset until the counter has reached 0. After reload, the counter DT_DOWN_CNT counts down until it reaches 0 and stops at 0.

The signal flow for function of standard dead time signal generation is depicted in following figure

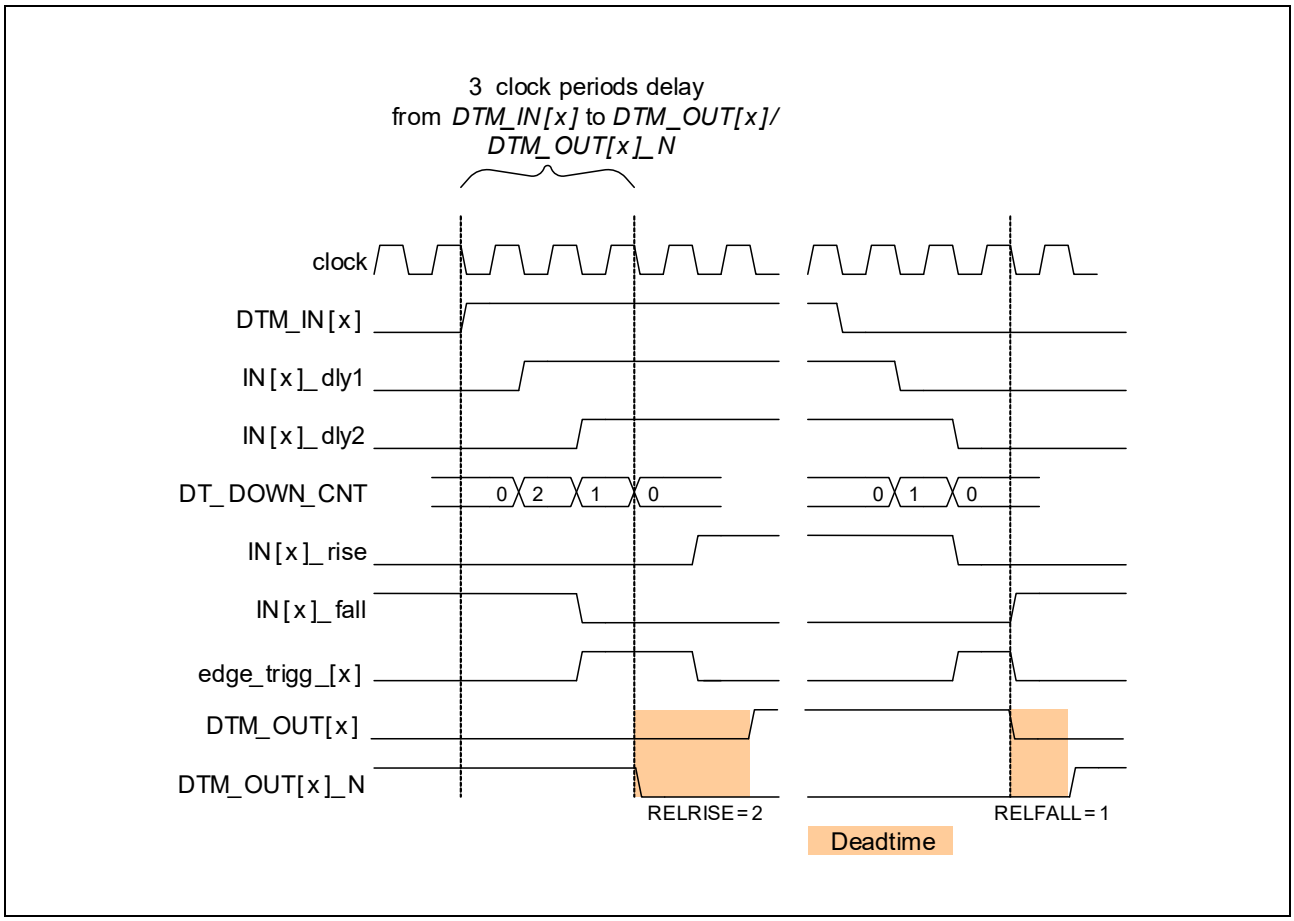

Figure 38.97 Wave signals for function of dead time generation

NOTES

1. The delay from the input signal DTM_IN[x] to the output signals DTM[i]_OUT[x] and DTM[i]_OUT[x]_N is three system clock periods by disabled feed through (see DT0/1_[x] in DTM[i]_CH_CTRL2).
2. The delay from the input signal DTM_IN[x] to the output signals DTM[i]_OUT[x] and DTM[i]_OUT[x]_N is one system clock periods by enabled feed through (see DT0/1_[x] in DTM[i]_CH_CTRL2).
3. The delay from the input signal DTM_IN[x]_T to the output signals DTM[i]_OUT[x] and DTM[i]_OUT[x]_N is three system clock periods in case of disabled feed through (see O1F_[x] and O1SEL_[x] in DTM[i]_CH_CTRL2).
4. The delay from the input signal DTM_IN[x]_T to the output signals DTM[i]_OUT[x] and DTM[i]_OUT[x]_N is one system clock periods in case of enabled feed through (see O1F_[x] and O1SEL_[x] in DTM[i]_CH_CTRL2).
5. The reset level of the output signals DTM[i]_OUT[x] connected from ATOM module depends on the hardware configuration value atom_out_reset_level_c chosen by silicon vendor.
6. The reset level of the output signals DTM[i]_OUT[x]_N connected from ATOM module is defined by the inverse hardware configuration value atom_out_reset_level_c chosen by silicon vendor.
7. The reset level of the output signals DTM[i]_OUT[x] connected from TOM module is defined by the hardware configuration value tom_out_reset_level_c chosen by silicon vendor.
8. The reset level of the output signals DTM[i]_OUT[x]_N connected from TOM module is defined by the inverse hardware configuration value tom_out_reset_level_c chosen by silicon vendor.

38.18.2.2 Cross channel dead time

A second way to apply a dead time value on two output signals is the cross channel dead time. In opposite to the dead time described in **Section 38.18.2.1** the cross channel dead time mode does not generate out of one signal the corresponding inverse signal but tries to apply the dead time on the input signals of two neighbored DTM channel. To do this, two neighbored DTM input signals (on DTM channel (2k) and (2k+1) for k = 0, 1) are cross linked together in the way that a falling edge on one channel leads to a hold phase of current signal value on the cross linked channel.

This behavior is reached by the following: A falling edge on e.g. channel (2k) reloads the DT_DOWN_CNT with the value of RELFALL. While this counter is counting down, the output signal of the cross linked channel (2k+1) keeps its value. If the counter DT_DOWN_CNT has reached 0 again, the channel (2k+1) output is released and can follow the value on its input. The timing of the cross channel dead time is depicted in **Figure 38.98**.

The following **Figure 38.98** shows the behavior in case of input edges at DTM_IN[2k] and DTM_IN[2k+1] occur at the same point in time. Then the falling edge is forwarded immediately (with only two clock cycles delay) and the rising edge is delayed additionally by the number of clock ticks specified by the RELFALL parameter of the cross linked channel.

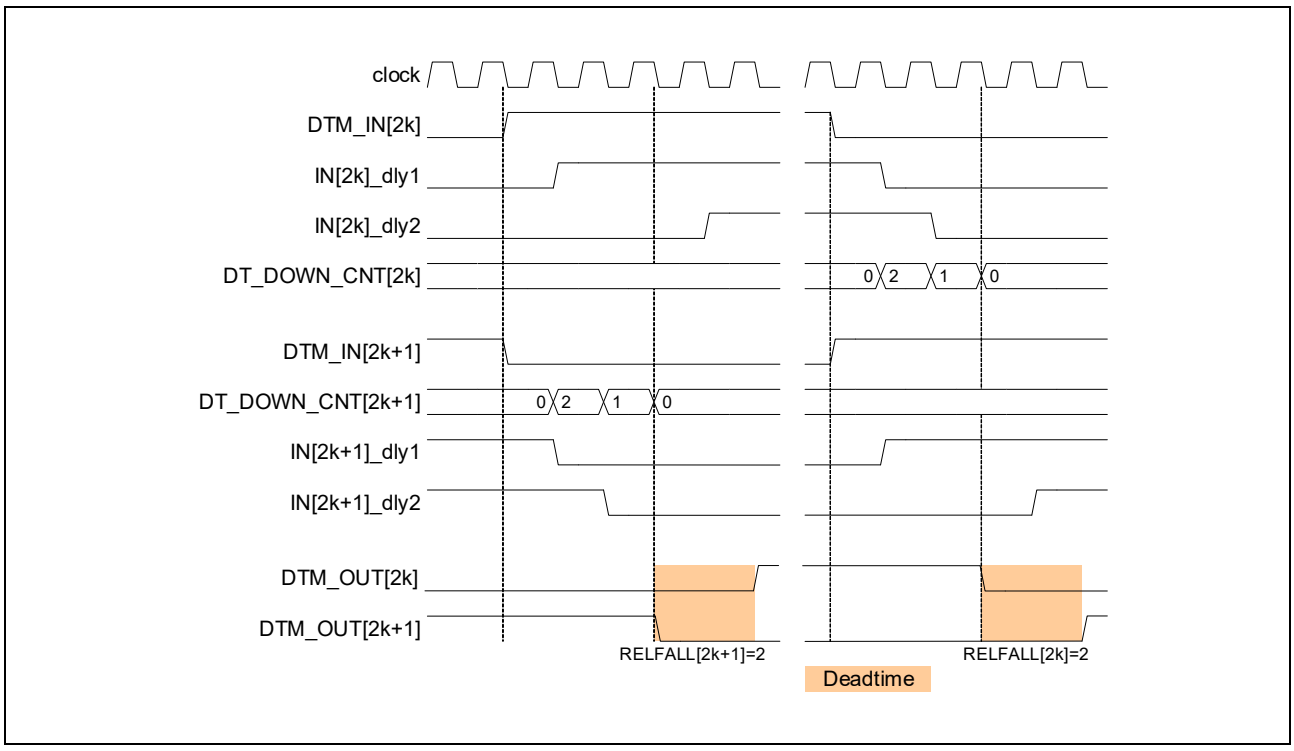

Figure 38.98 Cross channel dead time timing diagram

In case of high level (i.e. 1) at the DTM inputs DTM_IN[2k] and DTM_IN[2k+1] at the same point in time, the channel of (2k) has higher priority than the corresponding channel (2k+1). This means that in this case the input DTM_IN[2k+1] is forced immediately at channel input to low level (i.e. 0). As a result the DTM output of channel DTM_OUT[2k+1] can never be high if the cross linked channel DTM_OUT[2k] is high.

38.18.3 Phase Shift Control Unit

The phase shift unit (DTM_PSU) is depicted in the following figure. It supports the second major function of the DTM module to allow phase shifting of PWM signal on one of the channels.

This feature allows a phase shift on one PWM signal to the phase of the preceding PWM signal up to the next edge on this channel.

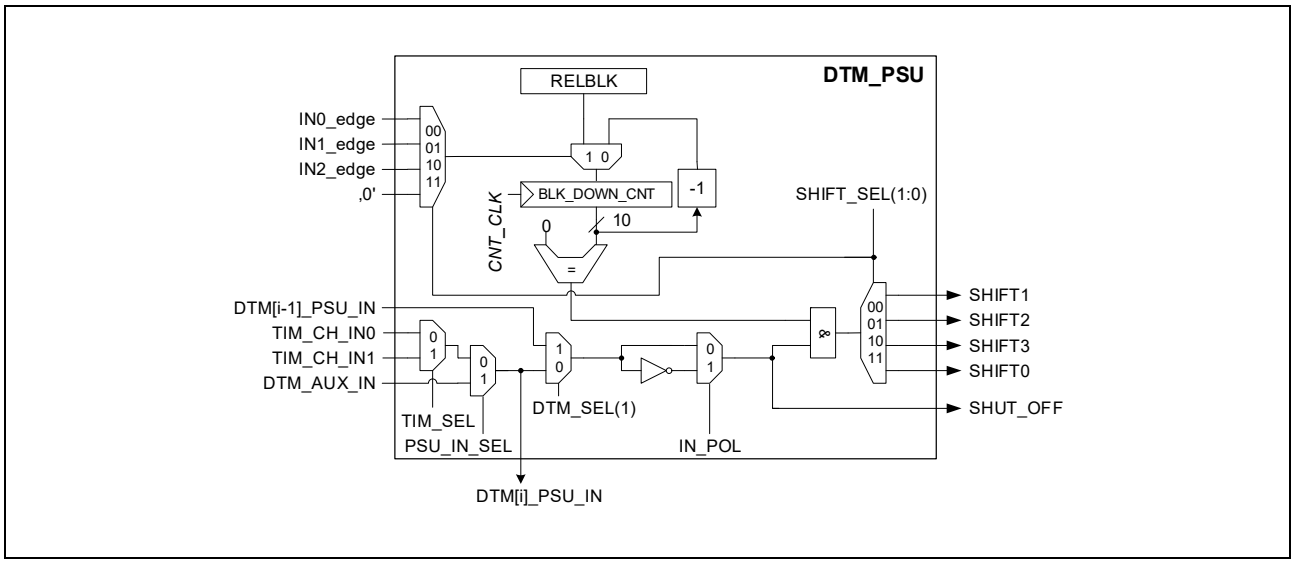

Figure 38.99 Phase Shift Unit overview

This sub-module provides an additional counter BLK_DOWN_CNT and reload register RELBLK (bit field of register DTM[i]_PS_CTRL). The counter is reloaded on an edge detected on one of the selected signals IN0_edge to IN2_edge (selected by bit field SHIFT_SEL in register DTM[i]_PS_CTRL). Then, the counter counts down until it reaches 0. While the counter is counting down, it blocks the trigger (i.e. the selected one of the signals SHIFT[x]) of one of the channels by one of the input signals TIM_CH_IN0, TIM_CH_IN1 or DTM_AUX_IN.

If the counter BLK_DOWN_CNT is not counting, a pulse on the input TIM_CH_IN0, TIM_CH_IN1 or DTM_AUX_IN is forwarded to one of the selected DTM_PSU outputs SHIFT[x]. This signal triggers in the selected channel (if SH_EN_x = 1) the update of the first flip-flop on channel x (i.e. representing IN[x]_DLY) to the input value DTM_IN[x–1] of the preceding channel. If this update leads to an edge, the succeeding part of DTM channel derives the inverse signal and applies the corresponding dead time (i.e. the edge delay) to the output signals of the channel.

NOTE

For channel x = 0 input signals DTM_IN[x–1] is unused and SH_EN_[x] is defined as 0.

The following figure shows an example of phase shifting on channel 1.

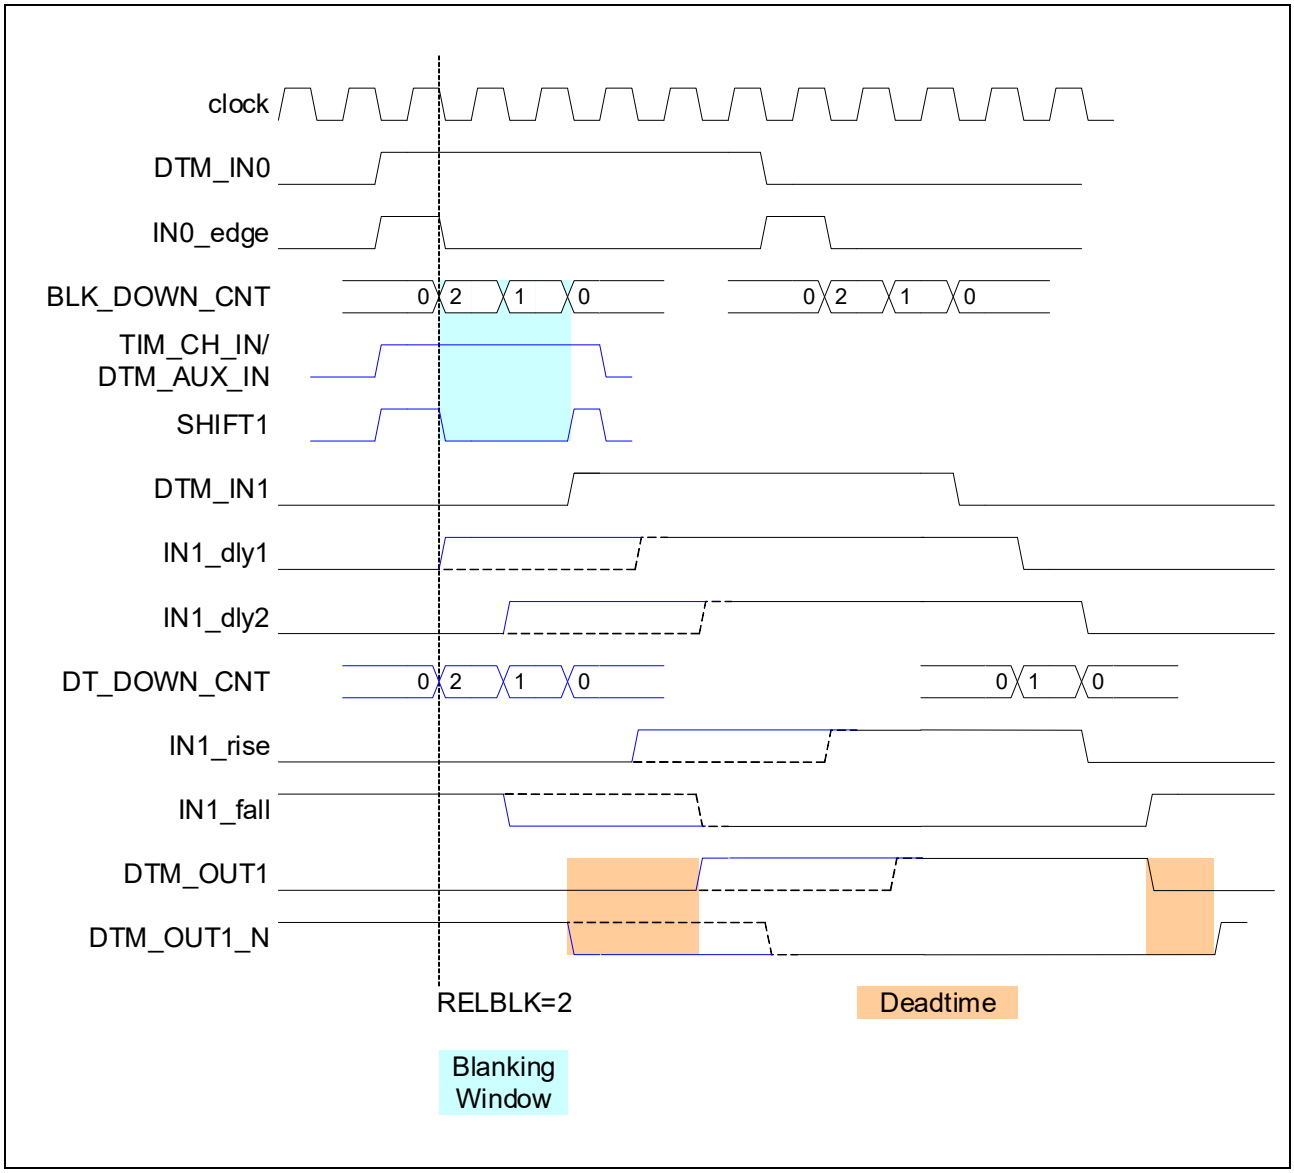

Figure 38.100 Example wave of phase shift on channel 1

38.18.4 Multiple output signal combination

Each channel provides additionally the possibility to combine the channel inputs DTM_IN[x] and SHIFT[x] or COUT[x–1] (selected by I1SEL_[x]) by an AND or an XOR gate (selected by O1F_[x]).

It is recommended to use the combination of signals only if bit field RELBLK of register DTM[i]_PS_CTRL is 0. Otherwise, the signal TIM_CH_IN0, TIM_CH_IN1 or DTM_AUX_IN may be disturbed by the blanking window counter.

Together with the inverter inside sub-module DTM_PSU (selected by IN_POL), the inverter on each output of a channel (selected by POL0_[x] / POL1_[x]) and the possibility to change polarity of DTM_IN[x] inside connected TOM/ATOM channel, a (N)AND, (N)OR or X(N)OR combination of the signals is possible.

38.18.4.1 Combination of input signal TIM_CH_IN/AUX_IN with TOM/ATOM signal

If the input selection I1SEL_[x] of a channel x is set to 0, the output selection O1SEL_[x] is set to 1 and SWAP_[x] is set to 0, depending on PSU_IN_SEL either TIM_CH_IN0, TIM_CH_IN1 or DTM_AUX_IN can be combined with signal DTM_IN[x]. The function of combination on DTM output DTM[i]_OUT[x]_N (and also COUT[x]) is defined by O1F_[x] in the following way:

Table 38.230 The function of combination on DTM output DTM[i]_OUT[x]_N

	O1F_x	POL1_x	IN_POL	(A)TOM output inverted
XOR	01	0	0	no
AND	10	0	0	no
XNOR	01	1	0	no
NAND	10	1	0	no
XNOR	01	1	1	yes
OR	10	1	1	yes
XOR	01	0	1	yes
NOR	10	0	1	yes

Note: The inversion of the (A)TOM output can be reached by switching the SL bit (for TOM and ATOM SOMP/SOMC mode).

38.18.4.2 Combination of multiple TOM/ATOM output signals

If the input selection I1SEL_[x] of a channel x (with x = 1 to 3) is set to 1, the output selection O1SEL_[x] is set to 1 and SWAP_[x] is set to 0, the output of the preceding DTM channel COUT[x–1] can be combined with signal DTM_IN[x]. The function of combination on DTM output DTM[i]_OUT[x]_N (and also COUT[x]) is defined by O1F_[x] in the following way:

Table 38.231 Function of combination on DTM on channel x = 1..3 output DTM[i]_OUT[x]_N (and also COUT[x])

	O1F_x	POL1_x	POL1_x-1	(A)TOM output inverted
XOR	01	0	0	no
AND	10	0	0	no
XNOR	01	1	0	no
NAND	10	1	0	no
XNOR	01	1	1	yes
OR	10	1	1	yes
XOR	01	0	1	yes
NOR	10	0	1	yes

By setting I1SEL_[x] to 1 on all four channel, a combination of all four signals DTM_IN0 to DTM_IN3 can be achieved (combinatorial chain).

To allow also combination of signals generated for output DTM[i]_OUT[x], the outputs 0 and 1 can be swapped by setting bit SWAP_ [x] for channel x.

38.18.4.3 Pulse generation on edge

Another feature of the DTM is to generate on the second output DTM[i]_OUT[x]_N a pulse on every edge of corresponding input signal DTM[i]_IN[x]. This can be reached by configuring O1SEL_[x] to 1, i.e. selecting signal edge_trigg_[x] as the output signal (O1F_[x] has to be 00_B). The signal edge_trigg_[x] is depicted in **Figure 38.97**.

The pulse length can be adjusted individually for each edge type by the configuration value REL_RISE and REL_FALL of register DTM[i]_CH[x]_DV. The parameter REL_RISE defines the pulse length in case of a rising edge on input DTM[i]_IN[x], the parameter REL_FALL define the pulse length in case of a falling edge on input DTM[i]_IN[x].

The generated edge signal edge_trigg_[x] can be combined with the output signal of the preceding DTM channel x–1 at channel input COUT[x–1] (see **Figure 38.96, DTM channel overview**). With the configuration of CIS[x] = 1 and I1SEL_[x] = 1, CII[x] =0 and POL1_[x] = 1, the signal edge_trigg_[x] of channel x is ORed with the inverse signal at channel input COUT[x.1]. The signal at COUT[x.1] can be inverted by changing POL1_[x.1] of channel x.1.

As a result of this configuration one can generate at each edge on DTM input DTM_IN[x] a pulse signal and OR-combine these generated pulse signals with the generated signal of preceding DTM channel. If the combinatorial chain is configured over all four DTM channel the final signal is available at last DTM output DTM_OUT3_N.

38.18.5 Synchronous update of channel control register 2

It is possible to use the shadow register DTM[i]_CH_CTRL2_SR and a selected edge of one of the channel 0 to 3 to update the work register DTM[i]_CH_CTRL2. The update mechanism and its configuration are depicted in the following figure.

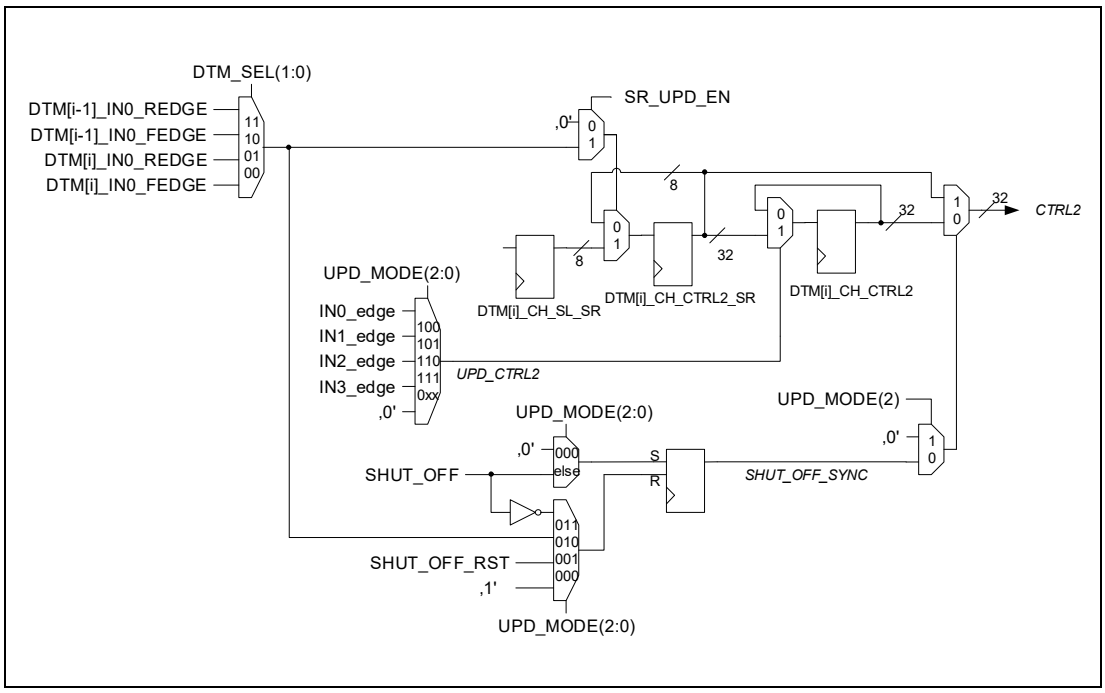

Figure 38.101 Synchronous update mechanism of register DTM[i]_CH_CTRL2

If enabled by the bit field UPD_MODE of register DTM[i]_CTRL (i.e. UPD_MODE = 1xx), the register DTM[i]_CH_CTRL2_SR serves as a shadow register of register DTM[i]_CH_CTRL2. The update is then triggered by an edge on one of the selected inputs DTM_IN0 to DTM_IN3.

The synchronous update allows the user to change output polarity, the selection of constant signal level, the constant signal level itself and the switch to/from feed through path on all four channels in parallel synchronized to one of the input edges on DTM_IN0 to DTM_IN3.

38.18.6 DTM output shut off

A fast shut off for the eight outputs of DTM instance i can be triggered by one of the two assigned inputs TIM[n]_CH_IN or DTM[i]_AUX_IN or the two inputs TIM[m]_CH_IN or DTM[i–1]_AUX_IN of the previous DTM instance i–1. The selection of the trigger signal source is done by the bits PSU_IN_SEL and DTM_SEL(1) (see **Figure 38.99**). The selected trigger signal is named SHUT_OFF. Enabling of the shut off feature is done by setting UPD_MODE(2:0) to one of the values 001_B, 010_B or 011_B.

The shut off behavior of the DTM outputs is defined by the value of register DTM[i]_CH_CTRL2_SR. If the shut off feature is enabled by UPD_MODE, as long as the signal SHUT_OFF_SYNC is 0, the register DTM[i]_CH_CTRL2 defines the output signal behavior. If the signal SHUT_OFF_SYNC is 1, the register DTM[i]_CH_CTRL2_SR defines the output signal behavior. The signal SHUT_OFF_SYNC is set to 1 if signal SHUT_OFF switches to 1. The reset depends on value of UPD_MODE(2:0).

There are three different ways to reset the signal SHUT_OFF_SYNC to 0: – the CPU writes a 1 to bit SHUT_OFF_RST of register DTM_CH_CTRL1 – synchronous to an edge on DTM channel 0 input of this DTM instance i or on an edge on DTM channel 0 input of preceding DTM instance i–1. – asynchronous if signal SHUT_OFF switches back to 0 Additionally, setting UPD_MODE(2:0) to a value 000_B or $1xx_B$ resets also the signal S HUT_OFF_SYNC. **Figure 38.101** depicts the shut off feature and the different shut off release possibilities.

NOTE

The reset of SHUT_OFF_SYNC has lower priority than the set of this signal.

A second shadow register DTM[i]_CH_SR exist for the eight SL bits (SLx_y_SR) of the shadow register DTM[i]_CH_CTRL2_SR. If enabled by configuration bit SR_UPD_EN of register DTM[i]_CTRL, the update of SL bits of register DTM[i]_CH_CTRL2_SR can be triggered by one of the signals selected by bit field DTM_SEL of register DTM[i]_CTRL. This trigger signal is either the rising or the falling edge detected on DTM[i]_IN0 of instance i or the rising or the falling edge on DTM[i–1]_IN0 of preceding instance i–1.

As depicted in **Figure 38.93**, **Figure 38.94** and **Figure 38.99** the DTM input signal TIM_CH_IN0, TIM_CH_IN1 or DTM_AUX_IN can be forwarded to the succeeding instance. Thus, it can be used to trigger shut off in two consecutive DTM instances.

38.18.7 DTM connections on GTM-IP top level

The DTM, if present, is placed behind the outputs of a TOM or ATOM. The outputs of the DTM are routed directly to the top level ports of GTM-IP. If there is a DTM placed behind a TOM or ATOM depends on the GTM-IP device configuration. In case of a DTM behind a TOM or ATOM, the outputs (A)TOM_OUT and (A)TOM_OUT_T are connected to DTM inputs DTM_IN and DTM_IN_T. The outputs of the DTM are routed directly to the top level of GTM-IP. The behavior of DTM after reset is shown in **Figure 38.102**

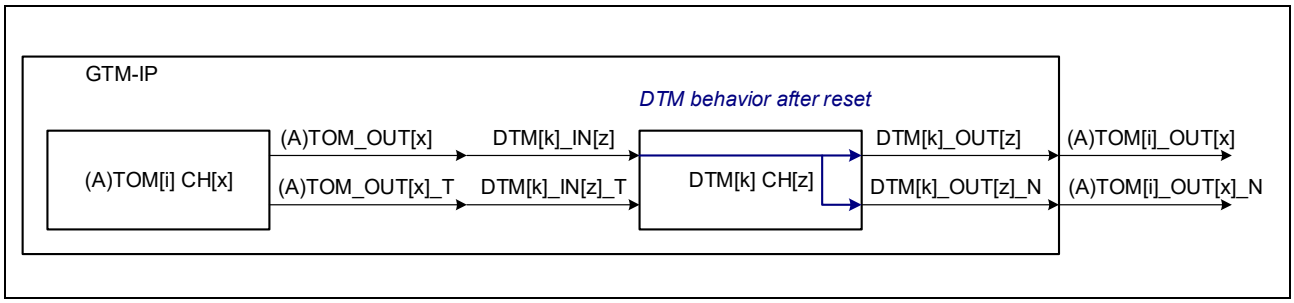

Figure 38.102 DTM behavior after reset

To route the signal DTM[k]_IN[z]_T to the DTM output DTM_[k]_OUT[z]_N, the following DTM channel configuration has to be chosen:

O1F_[x] = 11_B, O1SEL_[x] = 1 and DT1_[x] = 1.

The signals names and the signal routing in the case of no DTM instance is placed behind a TOM or ATOM is shown in **Figure 38.103**.

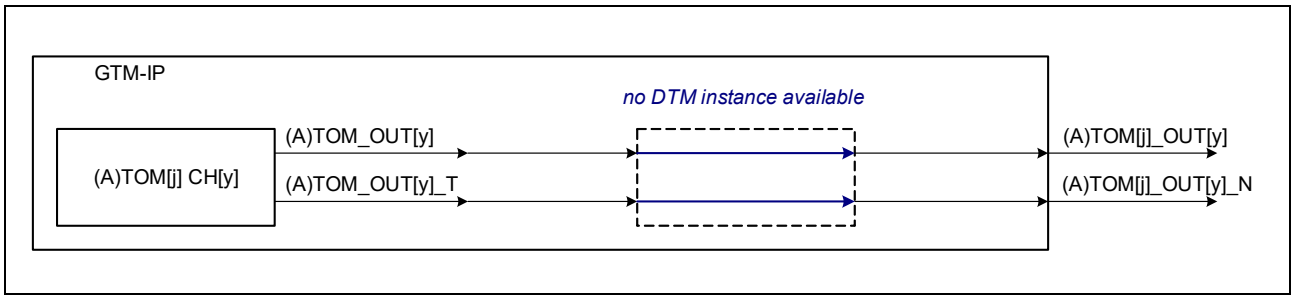

Figure 38.103 (A)TOM output signal routing in case of no DTM instance available

38.18.8 Configuration Register Overview

The following table gives an overview of the DTM configuration register.

Table 38.232 Register list

Symbol	Register Name	Details in Section
CDTM[i]_DTM[j]_CTRL	CDTMi DTMj global configuration and control register	**38.18.9.1**
CDTM[i]_DTM[j]_CH_CTRL1	CDTMi DTMj channel control register 1	**38.18.9.2**

38.19 Multi Channel Sequencer (MCS)

38.19.1 Overview

The Multi Channel Sequencer (MCS) sub module is a generic data processing module that is connected to the ARU. One of its major applications is to calculate complex output sequences that may depend on the time base values of the TBU and are processed in combination with the ATOM sub module. Other applications can use the MCS sub module to perform extended data processing of input data resulting from the TIM sub module. Moreover, some applications may process data provided by the CPU within the MCS sub module, and the calculated results are sent to the outputs using the ATOM sub modules.

Table 38.241 summarizes all available generic design parameters of the MCS hardware structure.:

Table 38.241 Generic Design Parameters

Design Parameter	Description
W	Word width of the data path
T	Number of available MCS channels
RDW	RAM data width of connected RAM
RAW	RAM address width used by the MCS for addressing memory
USR	Use second RAM port (0 – one RAM port available, 1 – two RAM ports available)
BAW	Bus Master Address Width
BDW	Bus Master Data Width
URIP	Use RAM input pipeline registers (0 – no register, 1 – use register)
UROP	Use RAM output pipeline registers (0 – no register, 1 – use register)
UDP	Use Decoder Pipeline register (0 – no register, 1 – use register)
UAP	Use ALU Pipeline register (0 – no register, 1 – use register)
NPS	Total number of pipeline stages (with NPS = 3 + URIP + UROP + UDP + UAP)

All MCS instances in the GTM use the values T=8, W=24, RDW=32, RAW=12, USR=1, BAW = 14, BDW = 32, URIP = 1, UROP = 1, UDP = 1, UAP = 1, and NPS = 7.

38.19.2 Architecture

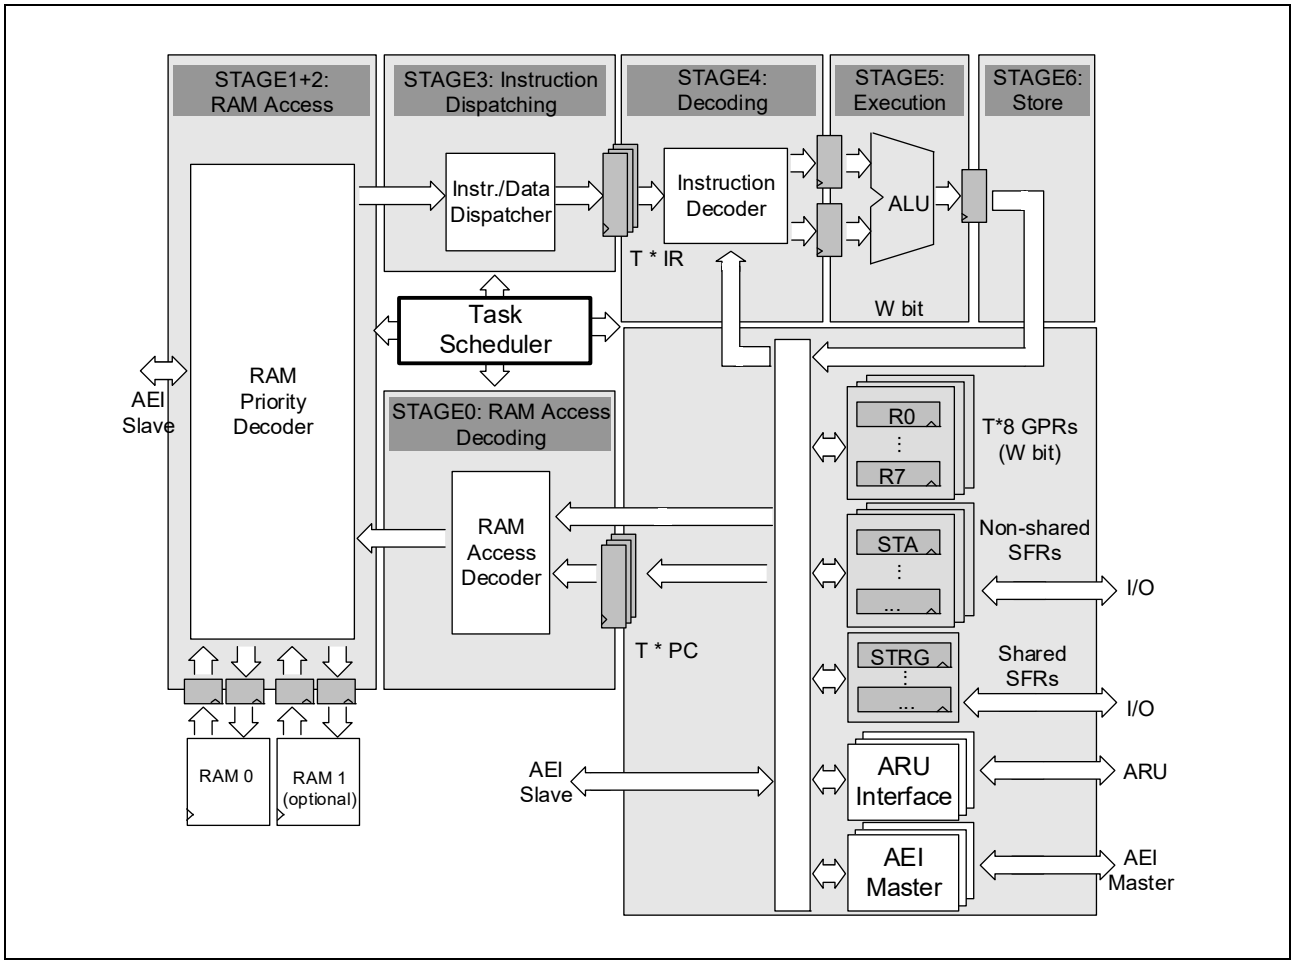

Figure 38.104 MCS Architecture block diagram

Figure 38.104 gives an overview of the MCS architecture assuming that all pipeline registers are implemented.

The data path of the MCS is shared by T so called MCS-channels, whereas each MCS-channel executes a dedicated micro-program that is stored inside the RAM connected to the MCS module.

The connected RAM may contain arbitrary sized code and data sections that are accessible by all MCS-channels and an externally connected master (e.g. a CPU) via AEI Slave interface. More details about the RAM can be found in **Section 38.19.4, Memory Organization**.

An MCS-channel can also be considered as an individual task of a processor that is scheduled to the commonly used data path at a specific point in time. The execution of the different MCS-channels on the different pipeline stages is controlled by a central hardware related task scheduler, which enables immediate task switches in parallel to the program execution. Details about the task scheduler and the available scheduling algorithms can be found in **Section 38.19.3, Scheduling**.

Typically, if data has to be exchanged between different MCS-channels and/or the CPU, the connected RAM, which is accessible by all MCS-channels and the CPU, can be used.

Besides the commonly used data path, each MCS channel has

1. A set of eight General Purpose Registers (GPRs), each W bit wide,
2. A set of non-shared Special Function Registers (SFRs) that are only accessible within a dedicated MCS channels,
3. A set of shared SFRs that are accessible by all MCS channels,
4. A channel specific instruction register (IR),
5. A channel specific program counter register (PC),
6. A dedicated ARU interface for communication with other ARU connected modules,
7. And an AEI Bus Master Interface for controlling other GTM sub modules.

Generally, the GPRs of an MCS channel x are only accessible by its corresponding MCS channel x. However, the MCS provides a configuration that allows an MCS channel x to access the GPRs of its successor MCS channel x+1. This feature can be used to enlarge the number of registers for a specific MCS channel x and/or to exchange data between neighboring channels.

For safety reasons, the register MCS[i]_REG_PROT can be used to define write protections for the neighboring registers of the individual MCS channels.

In order to enable synchronization between different MCS channels and/or the CPU, the MCS provides a common 24 bit wide trigger register that can be accessed as a shared SFR by all MCS channels located in the same module. Writing to STRG sets bits and writing to CTRG clears bits in the common trigger register. To enable triggering of MCS-channels by CPU, the CPU can set bits in the common trigger register by writing to MCS[i]_STRG and clear bits by writing to MCS[i]_CTRG.

Considering the architecture in the figure above and assuming that all available pipeline stages are implemented (the generic parameters URIP, UROP, UDP, and UAP are set to 1), the main actions of the different pipeline stages are as follows:

1. Pipeline stage 0 performs a setup of address, input data, and control signals for the next RAM access of a specific MCS-channel.
2. The actual RAM access of a specific MCS-channel is executed in pipeline stage 1 and 2, assuming an external connection of a synchronous RAM with a latency of one clock cycle.
3. Pipeline stage 3 performs pre-decoding and dispatching of instructions and data resulting from the RAM.
4. In pipeline stage 4 the instructions are decoded and data from the registers are loaded.
5. After that, in pipeline stage 5 the instruction is executed meaning that arithmetic operations are applied.
6. Finally, in pipeline stage 6 the calculated results are stored in the registers.

If any of the pipeline registers is not implemented, the adjacent pipeline stages are merged and thus processed within the same clock cycle.

The RAM priority decoder arbitrates RAM accesses that are requested by the CPU via AEI and by the active MCS-channel. If both, CPU and an MCS-channel request a memory access to the same memory module the MCS-channel is prioritized.

Since the internal registers of the MCS can be updated by different sources (MCS write access by various instructions, CPU write access via AEI slave, MCS write access by neighboring channel) a write conflict occurs if more than one source wants to write to the same register. In this case the result of the register is unpredictable. However, the software should setup its application in a way that such conflicts do not occur.

One exception is the common trigger register, which may be written by multiple sources (different MCS channels and CPU) in order to enable triggering of different MCS channels. Typically, the software should setup its application in a manner that different sources should not write the same bits in the trigger register.

38.19.3 Scheduling

The MCS provides a hardware related task scheduler, which globally controls the execution of the tasks in the different pipeline stages.

The task scheduler implements four different scheduling modes, that can be selected by the SCD_MODE bit field in the MCS[i]_CTRL_STAT register. Depending on the selected scheduling mode, the task scheduler is selecting a dedicated MCS channel that will be executed in pipeline stage 0 in the next clock cycle. Additionally, MCS channels that are already present in the pipeline are shifted to its successor pipeline stage, with each clock cycle. This means, that the execution time of an MCS-channel in a specific pipeline stage is always one clock cycle.

The MCS task scheduler may also schedule an empty cycle to pipeline stage 0, in order to grant a time slice to the CPU for accessing the connected RAM.

NOTE

If the task scheduler assigns an MCS channel to pipeline stage 0, but this channel does not access the RAM, the CPU can access the corresponding RAM, even if the scheduler did not reserve an empty clock cycle.

In the following, the available scheduling modes are described.

38.19.3.1 Round Robin Scheduling

The Round Robin Scheduling Mode implements the simplest scheduling algorithm. This algorithm schedules a predefined set of MCS channels in the range [0; SCD_CH] in ascending order. After the last channel SCD_CH has been assigned to the pipeline, an empty cycle is scheduled in order to enable RAM access for the CPU. The parameter SCD_CH can be controlled by the register MCS[i]_CTRL_STAT. If the value of SCD_CH is greater than T-1, the scheduler assumes a value of T-1 for bit field SCD_CH.

Figure 38.105 shows a timing example of the Round Robin Scheduling with T = 8 MCS-channels (marked as C_0 to C_7) that are scheduled together with a CPU access to a pipeline with and NPS = 7 stages. It is assumed that bit field SCD_CH is set to 7.

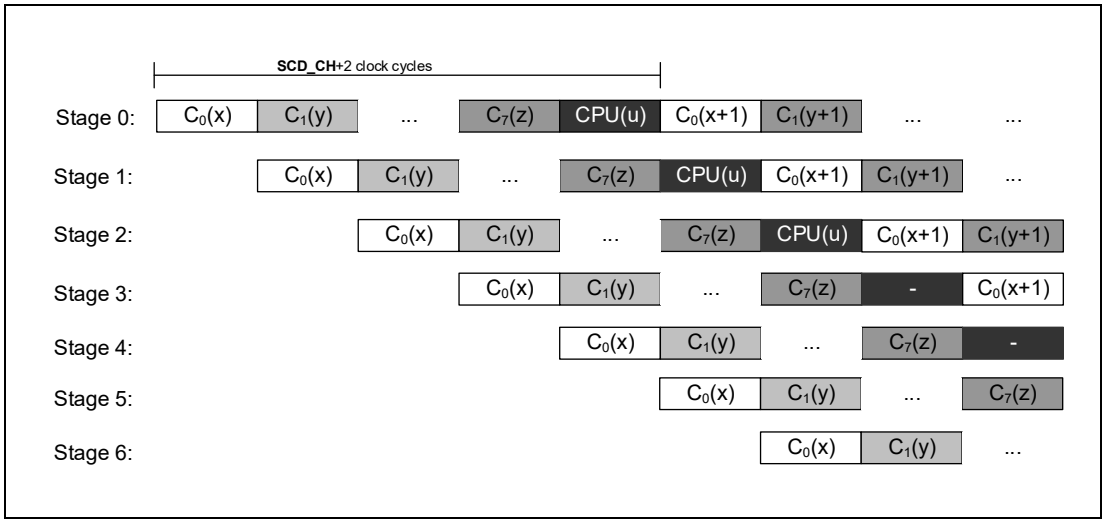

Figure 38.105 Timing of Round Robin Scheduling

The identifier Ci(x) denotes that MCS-channel i is currently executing the instruction or data located in the memory at position x in the corresponding pipeline stage. The figure shows, which MCS-channel is activated in specific pipeline stage at a specific point in time.

Moreover, the figure shows, that the Round Robin scheduling is always repeated after SCD_CH+2 clock cycles, which means that the time duration of an instruction cycle is SCD_CH+2 clock cycles. However, if the value SCD_CH + 2 is less than NPS, the duration of an instruction cycle is limited by the depth of the pipeline to NPS clock cycles. Thus the effective execution time of a single cycle instruction is always MIN(SCD_CH+2, NPS) clock cycles, ignoring the latency of the pipeline.

If NPS is greater than T+1, NPS–T–1 additional empty cycles are inserted at the end of a round trip cycle. In this case the round trip time for the scheduler is determined by NPS, and thus the time duration for an instruction cycle is always NPS clock cycles.

The Round Robin scheduling algorithm has the characteristic that it fairly distributes all time slices to all MCS-channels and the CPU. This means, that the program execution time of a specific task is independent from the activity of any neighboring task or the CPU RAM access, and thus a correct estimation of the actual program execution time is very easy. However, the round-robin scheduling may waste clock cycles by scheduling MCS-channels that are not ready to execute an instruction (e.g. MCS-channel is disabled by CPU). The following scheduling modes overcome this issue.

38.19.3.2 Accelerated Scheduling

In order to improve the computational performance, the accelerated scheduling mode provides two key features. Firstly, the scheduler only selects MCS-channels that are not suspended and thus can actually execute an instruction. Secondly, the scheduler applies instruction prefetching to minimize empty cycles in the pipeline. An MCS-channel is marked as suspended due to one of the reasons:

1. An MCS-channel is executing a read or write request to an ARU connected sub module (instruction ARD, AWR, ARDI, AWRI, NARD, NARDI).
2. An MCS-channel is executing a read or write request at its bus master interface (instruction BRD, BWR, BRDI, BWRI).
3. An MCS-channel waits on a register match event (e.g. instruction WURM), in order to wait on a desired register value (e.g. trigger event from another MCS channel).
4. An MCS-channel is disabled.

In the case of instruction prefetching, the scheduler will assign an MCS-channel C_p to pipeline stage 0, which is already present in another pipeline stage. This means, that the execution of the last instruction of C_p located in the memory MEM(PC/4) is not yet finished completely, whereas PC is the current value of the program counter of MCS-channel C_p. Thus, the newly scheduled MCS-channel C_p will prefetch a successor instruction MEM(PC/4+PFO) under the assumption that there will be no branch and no memory access in the program between the instructions MEM(PC/4) and MEM(PC/4+PFO). The prefetch offset value PFO is determined by counting the number of already scheduled MCS channels C_p in the pipeline. However, if the assumption fails, the pipeline will be flushed by replacing all MCS-channel Cp of the pipeline with an empty cycle, as soon as the instruction decoder detects a branch or a memory access. All other MCS channels unequal to MCS channel C_p within are not affected by the flushing action. The flushing action is always synchronized to the last pipeline stage NPS-1.

Besides the flushing conditions mentioned above, there exist also other conditions that cause a flush of the pipeline for a specific MCS-channel. In the following all possible flushing events are summarized:

1. An MCS-channel is enabled.
2. An MCS-channel is entering a suspended state.
3. An MCS-channel is taking a conditional or unconditional branch (instruction JMP, JBS, JBC, CALL, RET, JMPI, JBSI, JBCI, CALLI).
4. An MCS-channel accessing memory for data transfer (instruction MRD, MWR, MRDI, MWRI, MRDIO, MWRIO, MWRL, MWRIL, PUSH, POP).
5. An MCS-channel is executing a read or write request at its bus master interface (instruction BRD, BWR, BRDI, BWRI).
6. An MCS-channel is modifying the trigger register (write access to CTRG or STRG) and the same channel is reading back this register (read access to CTRG or STRG) while the delay between both accesses is less than UAP+UDP+1 clock cycles.

In general, each MCS-channel can accept instruction prefetching. However, there are some cases in which an upcoming flushing of the pipeline can be easily detected by the MCS hardware due to evaluation of internal states. Therefore, it is defined that an MCS-channel accepts instruction prefetching only under the following conditions:

1. An MCS-channel is currently not in the second cycle of a two-cycle control flow instruction (instruction CALL, RET).
2. An MCS-channel is currently not in the second cycle of a three-cycle memory access instruction (instruction MWRL, MWRIL).

The accelerated scheduling mode guarantees, that the time duration of an instruction cycle varies between 1 and T+1 cycles. Hence, a single cycle instructions has an effective execution time between 1 to T+1 clock cycles, depending on the number of suspended MCS-channels and the actual instruction sequence. The worst case execution time occurs if all channels are active and the CPU also accesses the RAM. The best case occurs e.g. if only one MCS-channel is enabled and the executed program sequence has only linear code without branches and memory access.

The algorithm of the accelerated scheduling mode first, evaluates the state of all available MCS-channels as well as a CPU request to the RAMs and then it decides if a specific MCS-channel or an empty cycle is assigned to pipeline stage 0 in the next clock cycle.

NOTE

The accelerated scheduling mode treats RAM access requests from the CPU in a similar manner as MCS-channels, which means that empty cycles for RAM requests are only inserted into the pipeline if there is an active RAM request from the CPU or no other task can be scheduled.

In order to fairly trade all available MCS-channels as well as CPU RAM requests and to guarantee a worst case execution time of T+1 clock cycles, an additional task prioritization scheme is applied that dynamically prioritizes all MCS-channels and a CPU memory access depending on the history of the scheduler's decisions. The algorithm of the accelerated scheduler mode is executed every clock cycle and it works in the following manner:

1. Try to find an MCS-channel C_r with highest priority that is not suspended and not already scheduled to the pipeline stages 0 to NPS-2. If C_r is found assign C_r to pipeline stage 0 and finish scheduling for current clock cycle.
2. Otherwise, try to find an MCS-channel C_p with highest priority that is not suspended and accepts instruction prefetching. If C_p is found assign C_p to pipeline stage 0 and finish scheduling for current clock cycle.
3. Otherwise, try to find an MCS-channel C_s with highest priority that is suspended and accepts instruction prefetching. If C_s is found assign C_s to pipeline stage 0 and finish scheduling for current clock cycle.
4. Otherwise, assign an empty cycle to pipeline stage 0 and finish scheduling for current clock cycle.

The underlying task prioritization scheme tracks the history of the scheduled MCS-channels in a list consisting of T+1 items. The list is initialized with all MCS-channels followed by a reserved time slot for the CPU RAM access. The position of an MCS-channel within this list implicitly defines the priority, while the back of this list holds the MCS-channel with highest priority. Whenever the

scheduling algorithm described above has found an MCS-channel C_r or C_p to be scheduled in the next clock cycle, it removes this item from the list and put it to the front of the list. In order to fairly prioritize all MCS-channels, the algorithm also moves the item at the back of the list to the second position in the list, after the inserted scheduled front item. Since the list always contains all possible MCS-channels and with each clock cycles each nonscheduled item is moved at least one position towards the end of list, it is obvious that each MCS-channel will have the highest priority not later than T+1 clock cycles.

Figure 38.106 shows a timing example of the accelerated scheduling with NPS=7 pipeline stages.

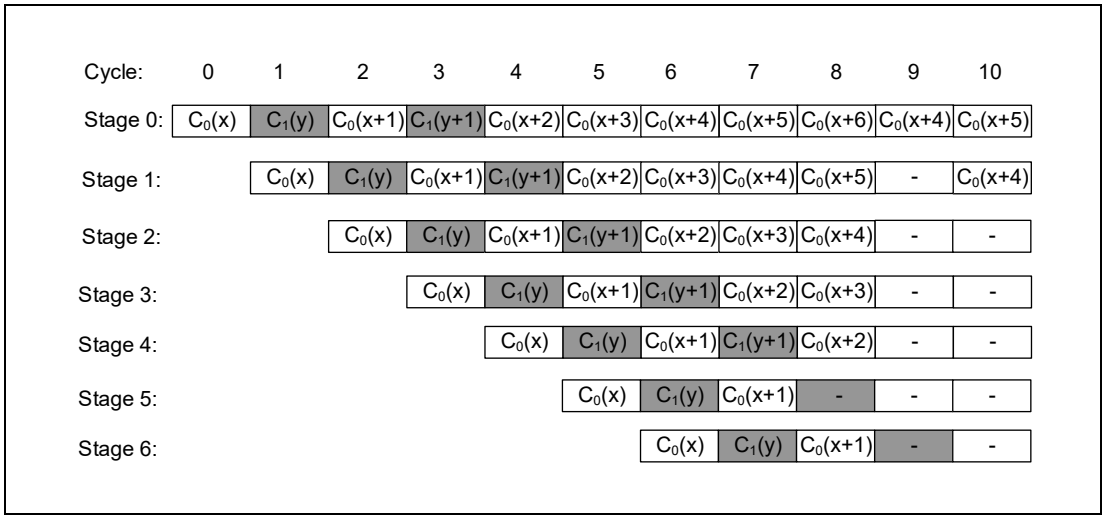

Figure 38.106 Timing of Accelerated Scheduling

The example assumes that initially MCS-channels 0 and 1 are enabled and the program for each MCS-channel is located in the RAM as follows:

Table 38.242 MCS Code example for Accelerated Scheduling

MCS-Channel 0		MCS-Channel 1	
Memory Location	**Instruction**	**Memory Location**	**Instruction**
x+0	ADDL R0, 7	x+0	WURM STRG, R1, $FFFF_H$
x+1	JBC STA, Z, x+4	x+1	ADDL R2, 5
x+2	MOVL R2, 5	x+2	ADD R3, R2

The example assumes that initially MCS-channels 0 and 1 are enabled and the program for each MCS-channel is located in the RAM as shown in **Table 38.242**. Since both channels are ready to run, the scheduler fairly selects the channels in an alternating order, as it can be obtained in stage 0 at the clock cycles before cycle 5. Since MCS-channel 1 is entering suspended state (to wait on a trigger bit) at cycle 7 in stage 6 with the instruction of memory location y, the scheduler will only select MCS-channel 0 in the following by applying instruction prefetching. Moreover, entering the suspended state in channel 1 also flushes the remaining channels 1 out of the pipeline.

NOTE

The scheduler applies instruction prefetching during the whole sequence, due to the fact that the number of enabled channels is always less than the available number of pipeline stages NPS.

The actual state of pipeline in cycle 9 and 10 depends on conditional branch instruction of memory location x + 3 (cycle 8 stage 6). If the branch is not taken, the linear code execution of MCS-channel 0 is continued. However, if the branch to memory location x+4 is taken, as shown in the Figure, the scheduler will fetch the instruction C_0 (x+4) in cycle 9 at stage 0 and flush the stages 1 to NPS-1.

NOTE

The flushing of the pipeline only concerns the prefetched instructions of the MCS-channel that is currently executed in the last stage. If pipeline stage 1 of cycle 9 would belong to another channel than 0, only the stages greater than 2 would have been flushed.

38.19.3.3 Single Prioritization Scheduling

The Single Prioritization Scheduling mode is an extended variant of the Accelerated Scheduling mode, which additionally applies a task prioritization of a single MCS-channel. In this mode, the bit field SCD_CH of register MCS[i]_CTRL_STAT is used to identify a dedicated MCS-channel that is always preferred during scheduling. This means, that the scheduler will assign preferred MCS-channel SCD_CH to pipeline stage 0, as long as this channel is not suspended. If the preferred MCS-channel is entering its suspended state, the scheduling algorithm switches to the accelerated scheduling as previously described in **Section 38.19.3.2, Accelerated Scheduling**. Whenever the MCS-channel SCD_CH is resuming from its suspended state, the scheduler switches back and assign the channel SCD_CH to pipeline stage 0 until the next suspension event occurs. If the bit field SCD_CH contains the value T or higher, the task scheduler will always prioritize CPU access to the RAM. This means, whenever the task scheduler detects that the CPU wants to access an MCS.RAM, the scheduler will assign an empty cycle into pipeline stage 0. If the CPU does not access the RAM any more, it switches back to the accelerated mode, as described previously in **Section 38.19.3.2, Accelerated Scheduling**.

In consequence, the Single Prioritization Scheduling mode cannot guarantee a maximum time duration of an instruction cycle for the overall execution of all MCS-channels, since it strongly depends on the activity of the prioritized MCS-channel SCD_CH. However, the Single Prioritization Scheduling mode provides the fastest possible execution for MCS-channel SCD_CH. Moreover, during the time spawn, in which the prioritized MCS-channel SCD_CH is suspended, this mode guarantees a duration of 1 to T+1 clock cycles of an instruction cycle for all non-prioritized channels.

NOTE

If an MCS program is being executed in Single Prioritization Scheduling mode, the CPU cannot access the MCS RAM from which the prioritized program code is fetched. In this case the CPU RAM access will be blocked until the prioritized MCS channel is entering its suspended state. If data needs to be exchanged between CPU and a prioritized MCS channel, either the general purpose registers or the opposite RAM module (if USR = 1) should be used.

38.19.3.4 Multiple Prioritization Scheduling

The Multiple Prioritization Scheduling mode is an extended variant of the Accelerated Scheduling mode, which additionally applies a task prioritization for multiple MCS-channels. In this mode, the bit field SCD_CH of register MCS[i]_CTRL_STAT is used to identify a set of dedicated MCS-channels, which are always preferred during scheduling. The identifiers of the prioritized MCS-channels are in the range [0; SCD_CH] and the non-prioritized channels are in the range [SCD_CH +1; T.1]. The individual priority for the set of prioritized MCS-channels is applied in descending order, which means that MCS-channel 0 has the highest priority, followed MCS-channel 1, which has the second highest priority, and so on. The non-prioritized MCS-channels do not have any priority. A value of T.1 or higher for the bit field SCD_CH means that all T MCS-channels are prioritized MCS-channels. With each clock cycle, the Multiple Prioritization Scheduling mode will assign the non-suspended MCS-channel with the highest priority from the set of prioritized MCS-channels to pipeline stage 0, as long as there are non-suspended prioritized MCS-channels available. If all prioritized MCS-channels are suspended, the scheduling algorithm switches to the accelerated scheduling as previously described in **Section 38.19.3.2, Accelerated Scheduling** and it schedules the non-prioritized channels. Whenever a prioritized MCS-channel is resuming from its suspended state, the scheduler switches back and applies the described prioritization scheme until the next suspension event of occurs.

In consequence, the Multiple Prioritization Scheduling mode cannot guarantee a maximum time duration of an instruction cycle for the overall execution of all MCS-channels, since it strongly depends on the activity of the prioritized MCS-channels. However, the Multiple Prioritization Scheduling mode provides the fastest possible execution for prioritized MCS-channels. Moreover, during the time spawn, in which all prioritized MCS-channels are suspended, this mode guarantees a duration of 1 to T+1 clock cycles of an instruction cycle for all non-prioritized channels.

NOTE

If an MCS program is being executed in Multiple Prioritization Scheduling mode, the CPU cannot access the MCS RAM from which the prioritized program code is fetched. In this case the CPU RAM access will be blocked until the last prioritized MCS channel is entering its suspended state. If data needs to be exchanged between CPU and a prioritized MCS channel, either the general purpose registers or the opposite RAM module (if USR = 1) should be used.

38.19.4 Memory Organization

The MCS module supports a memory layout of up to 2^(RAW+USR) memory locations each RDW bit wide leading to a maximum byte wise address range from 0 to 2^(RAW+USR+2) –1.

If two RAM ports are used (USR = 1) the entire address space of the MCS is divided into two seamless memory pages.

Further, if the GTM provides a memory configuration sub module (MCFG), memory page 0 begins from (byte wise) address 0 and ranges to address MP0-4 and memory page 1 ranges from MP0 to MP1-4, while MP0 and MP1 are configuration parameters provided by MCFG. If USR is 1 but there is no MCFG module available, the actual parameters MP0 and MP1 can be found in **Section 38.28, GTM Device 358**. The base address for accessing the memory via AEI can also be found in **Section 38.28, GTM Device 358**.

The RAM priority decoder of the MCS will always handle a RAM access from an MCS channel with a higher priority compared to a RAM access from AEI.

However, if a set of active MCS channels are only accessing one common RAM port, the MCS will grant any AEI accesses to the other RAM port in parallel to the related RAM accesses of the running MCS channels, which means that AEI may get the full bandwidth to a dedicated RAM.

Basically, the actual access time to the RAMs via AEI depends on the actual scheduling mode and the activity of tasks. In the modes Round Robin Scheduling and Accelerated Scheduling the scheduler guarantees a maximum write access time of T + 4 clock cycles and a maximum read access time of T + 6 clock cycles. In the scheduling modes Single Prioritization Scheduling and Multiple Prioritization Scheduling, the scheduler cannot guarantee a maximum access time for AEI RAM access.

Depending on the silicon vendor configuration, the connected RAM pages are initialized with zeros in the case of an MCS module reset.

If an ECC Error occurs while an MCS-channel reads data from a memory module, the corresponding MCS-channel is disabled and the ERR bit in register STA is raised.

If the GTM sub module CCM provides several so called address range protectors (ARPs), some code and data sections of the MCS RAM can be write protected. If an MCS channels x writes to such a protected memory region, the MCS channel x is halted, the ERR bit in register STA is set and the bit field ERR_SRC_ID of register MCS[i]_CTRL_STAT is updated.

38.19.5 AEI Bus Master Interface

The MCS module provides an AEI bus master interface, which enables to communicate with externally connected modules. The data width of this interface is BDW bit and the address width is BAW bit leading to a maximum byte wise address ranging from 0 to 2^{BAW+2}-1. The bus master interface is shared among all available MCS channels meaning that each MCS channel may initiate a read or write access on the bus but only one channel can be served at a specific point in time.

However, the AEI bus master interface guarantees, that a bus access is always completed within two instruction cycles and bus access of different MCS channels do not modify the latency of each other. The only exceptions are bus accesses to RAM modules (e.g. accessing memory location in a DPLL RAM or FIFO RAM). AEI bus master accesses to RAM modules cannot be completed within a single clock cycle and thus additional wait cycles have to be inserted into the bus protocol leading to the fact that the MCS channel that is accessing the RAM is entering a suspended state. Moreover, if an MCS channel is accessing a RAM module, the latency of a bus access in another MCS channel can also be modified even if the neighboring channel is accessing only a configuration register.

The AEI bus master interface of an MCS module is connected to AEI slave interface GTM-IP in order to control the sub modules of the GTM within MCS. However, it is not possible to access the entire GTM by a single MCS module. The n-th MCS instance can only access the GTM sub modules that are located within the n-th cluster of the GTM.

Additionally, the address map for accessing GTM with the AEI bus master interface of an MCS differs from the address map for an externally connected CPU that is using the GTM's AEI slave interface. The address map for accessing GTM with the AEI bus master interface of an MCS can be found in **Section 38.28, GTM Device 358**.

Since the sub modules of the GTM can be accessed by the CPU and the AEI bus master of an MCS, the GTM-IP provides an additional arbitration scheme to manage parallel accesses from both master interfaces. If CPU and an MCS want to access a GTM sub module of the same cluster, the arbiter will grant the access to the MCS. However, if the CPU and all the MCS instances want to access GTM sub modules of different clusters, the accesses can be executed in parallel.

The AEI bus master interface can be controlled by the MCS instructions BRD, BRDI, BWR, and BWRI. These instructions are described in **Section 38.19.8, Instruction Set**.

38.19.6 ADC Interface

The clusters of the GTM can provide a dedicated interface for the connection of up to 32 external Analog-Digital-Converter (ADC) channels, which can be mapped arbitrarily to physical instances of single- or multi-channel ADCs. See **Section 38.28, GTM Device 358** for details about the availability of ADC interfaces. An ADC Interface is directly mapped into the address map of the AEI bus master interface of the current cluster's MCS meaning that the available AEI bus master instructions (BRD and BRDI as described in **Section 38.19.8, Instruction Set**) are used to control the connected ADCs. Since the control of the connected ADCs is silicon vendor specific, the GTM specification does not provide a complete specification for controlling connected ADCs. However, to ensure software compatibility at least for the basic features of an ADC, the functionality described in the following are common to all silicon vendors.

38.19.6.1 Basic ADC Functions

The address map of the AEI bus master interface reserves two unique address items for each ADC channel. The address items can be referred by the labels ADC_CH[y]_DATA and ADC_CH[y]_STA for the channel y in the range from 0 to 31. The actual address for these labels can be found in **Section 38.28, GTM Device 358**. The MCS can read from address ADC_CH[y]_DATA in order to get the conversion result of the ADC that is connected to ADC channel y. The conversion result is represented as a signed 24 bit value and it is stored in the register A (A ∈GREG) as referred by the corresponding MCS instruction BRD or BRDI. Additionally, each read access to ADC_CH[y]_DATA triggers the ADC that is connected to channel y. Any read access to ADC_CH[y]_DATA also provides 8 status bits that are stored in register MHB. The bit MHB [7] has always the mnemonic ADC_ACK and the bit MHB [6] has always the mnemonic ADC_NEW_DATA. If bit ADC_ACK is set the result of the data conversion (register A) and the corresponding status bits (bits MHB [6:0]) are validated. If ADC_NEW_DATA is set the current conversion result is new and has never been read by a previous bus read access. The meaning of the bits MHB [5:0] are vendor specific.

Otherwise, if ADC_ACK is cleared the read data is invalid and the MHB [4:0] indicate the channel identifier (with MHB [4:0] ≠ y) that is currently processed by the ADC. A write access to ADC_CH[y]_DATA has no functionality and is always ignored. The MCS can read from address ADC_CH[y]_STA to get additional 31-bit wide vendor specific status information of ADC channel y. The lower 24 bits of the status information is stored in register A (A ∈ GREG) as referred by the corresponding MCS instruction BRD or BRDI. The upper 7 bit of the status information is stored in register MHB [6:0]. The bit MHB [7] has always the mnemonic ADC_ACK. If bit ADC_ACK is set the result of status information in register A and bits MHB [6:0] are validated. Otherwise, if ADC_ACK is cleared the status information is invalid.

A write access to ADC_CH[y]_STA has no functionality and is always ignored. Any read or write access to a register ADC_CH[y]_STA or ADC_CH[y]_DATA updates the AEI status signal that is evaluated in the sub module CCM. The following status information is defined for the AEI status values:

00: No error occurred

01: Optional information register not implemented (only register ADC_CH[y]_STA)

10: Illegal ADC access (e.g. ADC not enabled)

11: Unsupported address (ADC channel y not available)

NOTE

If the received status AEI is unequal to "00" ADC_NEW_DATA is always set and ADC_ACK is always cleared.

CAUTION

ADC_CH[y]_STA has no information and returns the same value as ADC_CH[y]_DATA when read.
Bit 31 of ADC_CH[y]_DATA is always read as 1, and bits 29 to 24 of ADC_CH[y]_DATA are always read as 0.

38.19.7 AXI Bus Master Interface

The GTM provides an AXI bus master interface which allows to initiate bus transactions externally to the GTM. Details about the connection of this bus interface can be found in the specification of the microcontroller. The GTM integrates a central AXI transaction generator module that is controlling and arbitrating the entire AXI master communication of the GTM. This module provides up to 24 communication slots to a cluster of the GTM which implements an MCS instance. In order to control the common AXI master functionality and the functionality of the dedicated AXI communication slots the AEI bus master interface of the MCS provides direct access to the central AXI transaction generator module. This means that the AXI bus master interface is controlled with the standard AEI bus master instructions (instruction BRD, BRDI, BWR, and BWRI).

A detailed explanation about how to use AXI bus master interface can be found in **Section 38.6, AXI Master**.

The actual address map of the AXI bus master interface can be found in **Section 38.28, GTM Device 358**.

38.19.8 Instruction Set

This section describes the entire instruction set of the MCS sub module. First, a brief overview over all available instructions is given and a detailed description of each instruction can be found in **Section 38.19.8, (1) MOVL Instruction** and the following sections.

In general, each instruction is RDW bit wide but the duration of each instruction varies between several instruction cycles. As already described in **Section 38.19.3, Scheduling**, the number of required clock cycles for an instruction cycle can be fixed or variable, depending on the selected scheduling mode. In the case of the Round Robin Scheduling, the duration is fixed with T+1 clock cycles, in the case of the Accelerated Scheduling the duration is variable in the range between 1 and T+1 clock cycles, and in all other Scheduling modes the duration is also variable and may even be more than T+1 clock cycles, depending on the application.

Before the available instructions are described, some commonly used terms, abbreviations and expressions are introduced:

Table 38.243 Instruction set (1/2)

Instruction	Description
OREG	The operation register set OREG = {R0 to R7} ∪ { STA, ACB, CTRG, STRG, TBU_TS0, TBU_TS1, TBU_TS2, MHB} include all MCS accessible internal channel specific GPRs {R0 to R7} and the sub set {STA, ACB, CTRG, STRG, TBU_TS0, TBU_TS1, TDU_TS2, MHB} of SFRs.
XOREG	The extended operation register set XOREG = OREG∪{RS0 to RS7} ∪ {GMI0, GMI1, DSTA, DSTAX} extends the operation registers set OREG by the GPRs of the succeeding MCS channel {RS0 to RS7} and the SFRs {GMI0, GMI1, DSTA, DSTAX, AXIMI}.
WXREG	The extended wait instruction operation register set WXREG = OREG ∪ {GMI0, GMI1, DSTA, DSTAX} extends the operation registers set OREG by the SFRs {GMI0, GMI1, DSTA, DSTAX, AXIMI}.
AREG	The ARU register set AREG = {R0 to R7, ZERO} includes all the registers that can be written by incoming ARU transfers (ARD, ARDI, NARD, and NARDI instructions). These registers include all eight general purpose registers. The dummy register ZERO may be used to discard an incoming 24 bit ARU word.
GREG	The general purpose register set GREG = {R0 to R7} includes all the channel specific GPRs without GPRs of neighboring channels.
BAREG	The base address register set BAREG = OREG∪{RS0 to RS7} extends the register set OREG by the GPRs of neighboring channels. If the extended operation register set XOREG is disabled (bit EN_XOREG of register MCS[i]_CTRL_STAT is cleared) the sets XOREG, WXREG, and BAREG only contains the operation register set OREG. In the following, the register sets OREG, XOREG, GREG, WXREG, BAREG and AREG are referred by the instructions. Typically, an operation announces W data bits. Whenever, a register of a register set implements less than W bits, it is assumed that these register bits only define the LSBs of an operation. The missing MSBs are always read and written as zeros.
WLIT	The set WLIT = {0,1, ..., 2^{W} –1} is a W bit wide literal value used for encoding immediate operands.
ALIT	The set ALIT = {0,1, ..., $2^{RAW+USR}$ –1} is a RAW + USR bit wide literal value used for encoding memory addresses.
AOLIT	The set AOLIT = {–$2^{RAW+USR}$, ..., –1,0,1, ..., $2^{RAW+USR}$ –1} is a RAW + USR bit wide literal value used for encoding relative memory address offsets.
ARDLIT	The set ARDLIT = {0,1, ..., 2^{9} –1} is a 9 bit literal used for ARU read addresses.
AWRLIT	The set AWRLIT = {0,1, ..., 23} is used as ARU write indexes, selecting one of the 24 ARU write address.
BALIT	The set BALIT = {0,1, ..., 2^{BAW} –1} is a BAW bit wide literal used for encoding bus master addresses.
SFTLIT	The set SFTLIT = {0,1, ..., W} is used as literal value for shift instructions.
BWSLIT	The set BWSLIT = {1, ..., W} is used as literal value for multiplication instructions.
BITLIT	The set BITLIT = {0,1, ..., 15} is a 4 bit literal used for bit indexing.
XBITLIT	The set XBITLIT = {0,1, ..., W–1} is a literal used for bit indexing of register bits.
MSKLIT	The set MSKLIT = {0,1, ..., 2^{16} –1} is a 16 bit literal used for bit-masking.
BIT SELECTION	The expression VAR[i] represents the i-th bit of a variable VAR
BIT RANGE SELECTION	The expression VAR[m:n] represents the bit slice of variable VAR that is ranging from bit n to bit m.

Table 38.243 Instruction set (2/2)

Instruction	Description
MEMORY ADDRESSING	The expression MEM(X) represents the RDW bit wide value at location x (x 2 ALIT) of the memory. The expression MEM(x)[m:n] represents the bit slice ranging from bit n to m of the RDW bit wide word at memory location x.
ARU ADDRESSING	In the case of ARU reading, the expression ARU(x) represents the 2*W+5 bit wide ARU word of ARU channel at read address x (x 2 ARDLIT). In the case of ARU writing, the expression ARU(x) represents a 2*W+5 bit wide ARU word that is written to an ARU channel indexed by the index x (x 2 AWRLIT). The index x selects a single ARU write channel from the pool of the MCS sub module's allocated ARU write channels. An MCS sub module has 24 dedicated ARU write channels, indexed by values 0 to 23. The expression ARU(x)[m:n] represents the bit slice ranging from bit n to m of the 2*W+5 bit wide ARU word.
BUS MASTER ADDRESSING	In the case of reading/writing from the bus master interface, the expression BUS(x) represents the BDW bit wide data word that is read/written at address x (x 2 BALIT). The expression BUS(x)[m:n] represents the bit slice ranging from bit n to m of the BDW bit wide data word at the bus.

The individual instructions are decoded by evaluating the bits '0' and '1' at its expected positions, as mentioned in field encoding of the individual instructions below, whereas the leftmost bit indicates the most significant bit and the rightmost bit indicated the lowest significant bit. If the instruction decoder detects an invalid combination of these bits, the corresponding MCS-channel is disabled and the ERR bit in the register STA is set. Bit positions marked as '–' are not relevant for the corresponding instruction and they are ignored completely during instruction decoding.

The bit position 'a_i', 'b_i', and 'c_i' are used for binary encoding of the instruction arguments A, B, and C. The actual decimal value of an argument A, B, and C can be obtained by adding up the products $a_i * 2^i$, $b_i * 2^i$, and $c_i * 2^i$ respectively.

Each instruction can also set the ERR bit of register STA and stop the program execution, if a register write protection of an associated MCS channel is activated by the register MCS[i]_REG_PROT. This behavior is not explicitly mentioned in the instruction descriptions below. If an error occurs due to a write access to a protected register it is ensured that the protected register is not overwritten. However, it is not ensured that other operations (e.g. updating of the PC) of the bad instruction are executed.

Table 38.244 summarizes the entire instruction set of the MCS and **Table 38.249** shows the encoding of the individual instructions.

Table 38.244 Instruction Set Summary (1/4)

Class	Mnemonic	Operation	Instruction cycles	Synopsis
Data transfer	MOVL A, C	A ← C	1	Move Literal, A in OREG, C in WLIT
	MOV A, B	A ← B	1	Move, A in XOREG, B in XOREG
	MRD A, C	A ← MEM(C)[W-1:0]; MHB ← MEM(C)[RDW-1:W]	2*1	Memory Read, A in OREG, C in ALIT
	MWR A, C	MEM(C)[W-1:0] ← A; MEM(C)[RDW-1:W] ← MHB	2*1	Memory Write, A in OREG, C in ALIT
	MRDI A, B [, C]	A ← MEM(B[RAW+USR+1:2]+C)[W-1:0]; MHB ←MEM(B[RAW+USR+1:2]+C)[RDW-1:W]	2*1	Memory Read Indirect, A in OREG, B in OREG, C in AOLIT (default C=0)
	MWRI A, B [, C]	MEM(B[RAW+USR+1:2]+C)[W-1:0] ← A; MEM(B[RAW+USR+1:2]+C)[RDW-1:W] ← MHB	2*1	Memory Write Indirect, A in OREG, B in OREG, C in AOLIT (default C=0)
	MRDIO A, B	A ← MEM(B[RAW+USR+1:2] + R5[RAW+USR+1:2])[W-1:0]; MHB ← MEM(B[RAW+USR+1:2] + R5[RAW+USR+1:2])[RDW-1:W]	2*1	Memory Read Indirect with Offset, A in XOREG, B in BAREG

	NOP		1	No Operation

Note 1. Not faster than 1+NPS clock cycles due to pipeline flushing.
Note 2. Not faster than 1+2*NPS clock cycles due to pipeline flushing.
Note 3. Not faster than NPS clock cycles due to pipeline flushing.
Note 4. If the jump is executed, it is not faster than NPS clock cycles due to pipeline flushing.
Note 5. Not faster than 2*NPS clock cycles due to pipeline flushing.
Note 6. If the MCS is configured in Single Prioritization or Multiple Prioritization Scheduling Mode the worst case latency for reactivating a prioritized MCS-channel is 2+NPS clock cycles.
Note 7. Always faster than one ARU round trip cycle.
Note 8. Suspends current MCS-channel if addressed slave inserts at least one wait cycle otherwise 1 instruction cycle
Note 9. Not faster than C+NPS-1 clock cycles due to pipeline flushing.
Note 10. Not faster than C+3+NPS clock cycles due to pipeline flushing.

(1) MOVL Instruction

Syntax: MOVL A, C

Encoding: $0001a_3 a_2 a_1 a_0 c_{23} c_{22} c_{21} c_{20} c_{19} c_{18} c_{17} c_{16} c_{15} c_{14} c_{13} c_{12} c_{11} c_{10} c_9 c_8 c_7 c_6 c_5 c_4 c_3 c_2 c_1 c_0$

Operation: A ← C

Status: Z

Duration: 1 instruction cycle

Description: Transfer literal value C (C ∈ WLIT) to register A (A∈ OREG).
The zero bit Z of status register STA is set, if the transferred value is zero, otherwise the zero bit is cleared.
The program counter PC is incremented by the value 4.

(2) MOV Instruction

Syntax: MOV A, B

Encoding: $1010a_3 a_2 a_1 a_0 b_3 b_2 b_1 b_0 0000\text{-}a_4\text{-}b_4$ ----------

Operation: A ← B

Status: Z

Duration: 1 instruction cycle

Description: Transfer register B (B ∈ OREG) to register A (A ∈ OREG).
The zero bit Z of status register STA is set, if the transferred value is zero, otherwise the zero bit is cleared.
The program counter PC is incremented by the value 4.

(3) MRD Instruction

Syntax: MRD A, C

Encoding: $1010a_3a_2a_1a_0$----$0001c_{15}c_{14}c_{13}c_{12}c_{11}c_{10}c_9c_8c_7c_6c_5c_4c_3c_2$--

Operation: A ← MEM(C)[W-1:0];
MHB ← MEM(C)[RDW-1:W]

Status: Z

Duration: 2 instruction cycles but not faster than 1+NPS clock cycles due to pipeline flushing.

Description: Transfer the lower W bits of memory content at location C (C ∈ ALIT) to register A (A ∈ OREG).
The upper RDW-W bits of the memory content at location C are transferred to the MHB register.
The zero bit Z of status register STA is set, if the lower W bits of the transferred value are zero, otherwise the zero bit is cleared.
If the MHB register is selected as destination register A (A ∈ OREG), the bits 0 to RDW-W-1 of the referred memory location are transferred to MHB.
The program counter PC is incremented by the value 4.

(4) MWR Instruction

Syntax: MWR A, C

Encoding: $1010a_3a_2a_1a_0$----$0010c_{15}c_{14}c_{13}c_{12}c_{11}c_{10}c_9c_8c_7c_6c_5c_4c_3c_2$--

Operation: MEM(C)[W-1:0] ← A;
MEM(C)[RDW-1:W] ← MHB

Status: —

Duration: 2 instruction cycles but not faster than 1+NPS clock cycles due to pipeline flushing.

Description: Transfer W bit value of register A (A ∈ OREG) together with the MHB register to the memory at location C (C ∈ ALIT).
The W bit value of register A is stored in the lower significant bits (bit 0 to W-1) of the memory location.
The MHB register is stored in bits W to RDW-W-1 of the referred memory location.
The program counter PC is incremented by the value 4.

(5) MWRL Instruction

Syntax: MWRL A, C

Encoding: $1010a_3a_2a_1a_0$----$0111c_{15}c_{14}c_{13}c_{12}c_{11}c_{10}c_9c_8c_7c_6c_5c_4c_3c_2$--

Operation: MEM(C)[W-1:0] ← A

Status: —

Duration: 3 instruction cycles but not faster than 1+2*NPS clock cycles due to pipeline flushing.

Description: Transfer W bit value of register A (A ∈ OREG) to memory at location C (C ∈ ALIT).
The W bit value of register A is stored in the lower significant bits (bit 0 to W-1) of the memory location and the bits W to RDW-W are left unchanged.
The program counter PC is incremented by the value 4.
It should be noted that this operation is not an atomic instruction.

(6) MRDI Instruction

Syntax: MRDI A, B [, C]

Encoding: 1010a_3 a_2 a_1 a_0 b_3 b_2 b_1 b_0 0011c_{15} c_{14} c_{13} c_{12} c_{11} c_{10} c_9 c_8 c_7 c_6 c_5 c_4 c_3 c_2 --

Operation: A←MEM((B[RAW+USR+1:2] + C) AND MASK)[W–1:0]
MHB←MEM((B[RAW+USR+1:2] + C) AND MASK)[RDW–1:W]

Status: Z

Duration: 2 instruction cycles but not faster than 1+NPS clock cycles due to pipeline flushing.

Description: Transfer the bits 0 to W–1 of a memory location to register A (A ∈ OREG) using indirect addressing.
The upper RDW–W bits of this memory location are transferred to MHB register.
The memory location where to read from depends on register B (B ∈ OREG) and literal C (C ∈ AOLIT) and it is defined as ((B[RAW+USR+1:2] + C) AND MASK), where AND is a bitwise AND conjunction and MASK is a bit mask value 2^(RAW+USR)-1.
If the optional operand C is not available in the assembler syntax, the MCS assembler generates code with a default value of 0 for operand C. The zero bit Z of status register STA is set, if the transferred bits 0 to W–1 are zero, otherwise the zero bit is cleared. If the MHB register is selected as destination register A (A ∈ OREG), the bits 0 to RDW–W–1 of the referred memory location are transferred to MHB. The program counter PC is incremented by the value 4.

(7) MRDIO Instruction

Syntax: MRDIO A, B

Encoding: 1010a_3 a_2 a_1 a_0 b_3 b_2 b_1 b_0 1101-a_4 -b_4 ----------

Operation: A←MEM((B[RAW+USR+1:2] + R5[RAW+USR+1:2]) AND MASK)[W–1:0]
MHB←MEM((B[RAW+USR+1:2] + R5[RAW+USR+1:2]) AND MASK)[RDW–1:W]

Status: Z

Duration: 2 instruction cycles but not faster than 1+NPS clock cycles due to pipeline flushing.

Description: Transfer the bits 0 to W–1 of a memory location to register A (A ∈ XOREG) using indirect addressing with offset calculation.
The upper RDW–W bits of this memory location are transferred to MHB register.
The memory location where to read from depends on register B (B ∈ BAREG) and register R5 and it is defined as ((B[RAW+USR+1:2] +R5[RAW+USR+1:2]) AND MASK), where AND is a bitwise AND conjunction and MASK is a bit mask value

2^(RAW+USR)-1.
The zero bit Z of status register STA is set, if the transferred bits 0 to W–1 are zero, otherwise the zero bit is cleared.
If the MHB register is selected as destination register A, the bits 0 to RDW–W–1 of the referred memory location are transferred to MHB.
The program counter PC is incremented by the value 4.

(8) MWRI Instruction

Syntax: MWRI A, B [, C]

Encoding: $1010a_3a_2a_1a_0b_3b_2b_1b_0 0100c_{15}c_{14}c_{13}c_{12}c_{11}c_{10}c_9c_8c_7c_6c_5c_4c_3c_2$--

Operation: MEM(B[RAW+USR+1:2] + C)AND MASK)[W-1:0] ← A;
MEM(B[RAW+USR+1:2] + C)AND MASK)[RDW-1:W] ← MHB

Status: —

Duration: 2 instruction cycles but not faster than 1+NPS clock cycles due to pipeline flushing.

Description: Transfer value of register A (A ∈ OREG) to the least significant bits 0 to W–1 of a memory location using indirect addressing.
The MHB register is moved to the bits W to RDW-1 at the same memory location.
If the optional operand C is not available in the assembler syntax, the MCS assembler generates code with a default value of 0 for operand C.
The memory location where to write to depends on register B (B ∈ OREG) and literal C (C ∈ AOLIT) and it is defined as ((B[RAW+USR+1:2] + C) AND MASK), where AND is a bitwise AND conjunction and MASK is a bit mask value $2^{RAW+USR}$-1.
The program counter PC is incremented by the value 4.

(9) MWRIO Instruction

Syntax: MWRIO A, B

Encoding: $1010a_3a_2a_1a_0b_3b_2b_1b_0 1110\text{-}a_4\text{-}b_4$ ----------

Operation: MEM((B[RAW+USR+1:2] + R5[RAW+USR+1:2]) AND MASK)[W–1:0]←A;
MEM((B[RAW+USR+1:2] + R5[RAW+USR+1:2]) AND MASK)[RDW–1:W]←MHB

Status: —

Duration: 2 instruction cycles but not faster than 1+NPS clock cycles due to pipeline flushing.

Description: Transfer value of register A (A ∈ XOREG) to the LSBs 0 to W–1 of a memory location using indirect addressing with offset calculation.
The MHB register is moved to the bits W to RDW–1 at the same memory location.
The memory location where to write to depends on register B (B ∈ BAREG) and register R5 and it is defined as ((B[RAW+USR+1:2] + R5[RAW+USR+1:2]) AND MASK), where AND is a bitwise AND conjunction and MASK is a bit mask value $2^{RAW+USR}$-1.
The program counter PC is incremented by the value 4.

(10) MWRIL Instruction

Syntax: MWRIL A, B

Encoding: $1010a_3a_2a_1a_0b_3b_2b_1b_0 1000$----------

Operation: MEM(B[RAW+USR+1:0])[W-1:0] ← A;

Status: —

Duration: 3 instruction cycles but not faster than 1+2*NPS clock cycles due to pipeline flushing.

Description: Transfer W bit value of A (A ∈ OREG) to memory using indirect addressing.
The memory location where to write to is defined by the bits 2 to RAW+1 of register B (B ∈ OREG).
The W bit value is stored in the LSBs (bit 0 to W-1) of the memory location and the bits W to RDW–1 are left unchanged.
The program counter PC is incremented by the value 4.
This operation is not an atomic instruction.

(11) POP Instruction

Syntax: POP A

Encoding: $1010a_3a_2a_1a_0$----0101----------

Operation:
A ← MEM(R7[RAW+USR+1:2])[W-1:0];
MHB ← MEM(R7[RAW+USR+1:2])[RDW–1:W];
R7 ← R7 – 4;
SP_CNT ← SP_CNT – 1

Status: Z, EN

Duration: 2 instruction cycles but not faster than 1+NPS clock cycles due to pipeline flushing.

Description:
Transfer the lower significant bits (bit 0 to W–1) from the top of stack to register A (A ∈ OREG \\ {R7}), followed by decrementing the stack pointer register R7 with the value 4.
The upper bits W to RDW-1 from the top of the stack are transferred to register MHB.
If the MHB register is selected as destination register A (A ∈ OREG \\ {R7}), the bits 0 to RDW–W–1 from the top of the stack are transferred to MHB.
The memory location for the top of the stack is identified by the bits 2 to RAW+1 of the stack pointer register R7.
The zero bit Z of status register STA is set, if the lower W bit of the transferred value is zero, otherwise the zero bit is cleared.
The program counter PC is incremented by the value 4.
The SP_CNT bit field inside the MCS[i]_CH[x]_CTRL register is decremented.
If an underflow on the SP_CNT bit field occurs, the STK_ERR[i]_IRQ is raised.
If an underflow on the SP_CNT bit field occurs and the bit HLT_SP_OFL of register MCS[i]_CTRL is set, the current MCS-channel is disabled by clearing the EN bit of STA.

(12) PUSH Instruction

Syntax: PUSH A

Encoding: $1010a_3a_2a_1a_0$----0110----------

Operation:
R7 ← R7 + 4;
MEM(R7[RAW+USR+1:2])[W-1:0] ← A;
MEM(R7[RAW+USR+1:2])[RDW-1:W] ← MHB
SP_CNT ← SP_CNT + 1;

Status: EN

Duration: 2 instruction cycles but not faster than 1+NPS clock cycles due to pipeline flushing.

Description:
Increment the stack pointer register R7 with the value 4, followed by transferring a W bit value of operand A (A ∈ OREG \\ {R7}) together with a MHB register to the new top of the stack. The W bit value of A is stored in the bits 0 to W-1 of the memory location.
The content of the MHB register is stored in the bit W to RDW-1 of the memory location.
The memory location for the top of the stack is referred by the bits 2 to RAW+1 of the stack pointer register.
The program counter PC is incremented by the value 4.
The SP_CNT bit field inside the MCS[i]_CH[x]_CTRL register is incremented.
If an overflow on the SP_CNT bit field occurs, the STK_ERR[i]_IRQ is raised.
If an overflow on the SP_CNT bit field occurs and the bit HLT_SP_OFL of register MCS[i]_CTRL is set, the current MCS-channel is disabled by clearing the EN bit of STA.
If an overflow on the SP_CNT bit field occurs and the bit HLT_SP_OFL of register MCS[i]_CTRL is set, the memory write operation for the A and MHB is discard.

(13) ARD Instruction

Syntax: ARD A, B, C

Encoding: $1011a_3 a_2 a_1 a_0 b_3 b_2 b_1 b_0$ 0000-------$c_8 c_7 c_6 c_5 c_4 c_3 c_2 c_1 c_0$

Operation:
A ← ARU(C)[W-1:0];
B ← ARU(C)[2*W-1:W];
ACB ← ARU(C)[4+2*W:2*W]

Status: CAT, SAT

Duration: Suspends current MCS-channel until ARU transfer finished.

Description: Perform a blocking read access to the ARU and transfer both W bit values received at the ARU port to the registers A and B (A ∈ AREG, B ∈ AREG), whereas A holds the lower W bit ARU word and B holds the upper W bit ARU word.
If A and B see the same register, only the upper W bit ARU word is stored and the lower W bit ARU word is discard.
If any transferred W bit value from the ARU should not stored in a register, the dummy register ZERO ∈ AREG can be selected in A or B to discard the corresponding ARU data. The binary encoding of the address for the dummy register ZERO can be chosen by an arbitrary value within the range 8 to 15.
The received ARU control bits are stored in the register ACB.
The literal C (C ∈ ARDLIT) define the ARU address where to read from.
At the beginning of the instruction execution the CAT bit in the register STA is always cleared. After the execution of the instruction the SAT flag of the register STA is updated in order to show if the transfer was successful (SAT = 1) or if the transfer failed (SAT = 0) due to a cancellation by the CPU.
The program counter PC is incremented by the value 4.

(14) ARDI Instruction

Syntax: ARDI A, B

Encoding: $1011a_3 a_2 a_1 a_0 b_3 b_2 b_1 b_0$ 0100----------

Operation:
A ← ARU(R6[8:0])[W-1:0];
B ← ARU(R6[8:0])[2*W-1:W];
ACB ← ARU(R6[8:0])[4+2*W:2*W]

Status: CAT, SAT

Duration: Suspends current MCS-channel until ARU transfer finished.

Description: Perform a blocking read access to the ARU and transfer both W bit values received at the ARU port to the registers A and B (A ∈ AREG, B ∈ AREG), whereas A holds the lower W bit ARU word and B holds the upper W bit ARU word.
If A and B refer to the same register, only the upper W bit ARU word is stored and the lower W bit ARU word is discarded.
If any transferred W bit value from the ARU should not be stored in a register, the dummy register ZERO ∈ AREG can be selected in A or B to discard the corresponding ARU data. The binary encoding of the address for the dummy register ZERO can be chosen by an arbitrary value within the range 8 to 15.
The received ARU control bits are stored in the register ACB.
The read address is obtained from the bits 0 to 8 of the channels register R6.
At the beginning of the instruction execution the CAT bit in register STA is always cleared. After the execution of the instruction the SAT flag of the register STA is updated in order to show if the transfer was successful (SAT = 1) or if the transfer failed (SAT = 0) due to a cancellation by the CPU.
The program counter PC is incremented by the value 4.

(15) AWR Instruction

Syntax: AWR A, B, C

Encoding: $1011a_3a_2a_1a_0b_3b_2b_1b_0$ 0001----------$c_4c_3c_2c_1c_0$

Operation:
ARU(C)[W-1:0] ← A;
ARU(C)[2*W-1:W] ← B;
ARU(C)[4+2*W:2*W] ← ACB;

Status: CAT, SAT

Duration: Suspends current MCS-channel until ARU transfer finished.

Description: Perform a blocking write access to the ARU and transfer two W bit values to the ARU port using the registers A and B (A ∈ OREG, B ∈ OREG), whereas A holds the lower W bit ARU word and B holds the upper W bit ARU word.
The ARU control bits are taken from the register ACB.
The literal C (C ∈ AWRLIT) defines an index into the pool of ARU write addresses that are used for writing data. This index is mapped to an ARU write address as shown in column "MCS write index" of table "ARU Write Addresses" in **Section 38.28, GTM Device 358**.
Each MCS sub module has a pool of several write addresses that can be shared between all MCS-channels arbitrarily.
At the beginning of the instruction execution the CAT bit of the register STA is always cleared. After the execution of the instruction the SAT flag of the register STA is updated in order to show if the transfer was successful (SAT = 1) or if the transfer failed (SAT = 0) due to a cancellation by the CPU.
The program counter PC is incremented by the value 4.

(16) AWRI Instruction

Syntax: AWRI A, B

Encoding: $1011a_3a_2a_1a_0b_3b_2b_1b_0$ 0101----------

Operation:
ARU(R6[4:0])[W-1:0] ← A;
ARU(R6[4:0])[2*W-1:W] ← B;
ARU(R6[4:0])[4+2*W:2*W] ← ACB;

Status: CAT, SAT

Duration: Suspends current MCS-channel until ARU transfer finished.

Description: Perform a blocking write access to the ARU and transfer two W bit values to the ARU port using the registers A and B (A ∈ OREG, B ∈ OREG), whereas A holds the lower W bit ARU word and B holds the upper W bit ARU word.
The ARU control bits are taken from the register ACB.
The bits 0 to 4 of the register R6 define an index into the pool of ARU write addresses that are used for writing data. This index is mapped to an ARU write address as shown in column "MCS write index" of table "ARU Write Addresses" in **Section 38.28, GTM Device 358**.
Each MCS sub module has a pool of several write addresses that can be shared between all MCS-channels arbitrarily.
At the beginning of the instruction execution the CAT bit of the register STA is always cleared. After the execution of the instruction the SAT flag of the register STA is updated in order to show if the transfer was successful (SAT = 1) or if the transfer failed (SAT = 0) due to a cancellation by the CPU.
The program counter PC is incremented by the value 4.

(17) NARD Instruction

Syntax: NARD A, B, C

Encoding: $1011 a_3 a_2 a_1 a_0 b_3 b_2 b_1 b_0$ 0010-------$c_8 c_7 c_6 c_5 c_4 c_3 c_2 c_1 c_0$

Operation:
A ← ARU(C)[W-1:0];
B ← ARU(C)[2*W:W];
ACB ← ARU(C)[4+2*W:2*W]

Status: SAT

Duration: Suspends current MCS-channel until the ARU is selecting the MCS-channel.

Description: Perform a non-blocking read access to the ARU trying to transfer both W bit values received at the ARU port to the registers A and B (A ∈ AREG, B ∈ AREG), whereas A holds the lower W bit ARU word, B holds the upper W bit ARU word, and the ACB register holds the received ARU control bits. The literal C (C ∈ ARDLIT) define the ARU address where to read from.
Non-blocking ARU read access means that the instruction is suspending the MCS channel until the ARU scheduler is selecting the requesting MCS channel. If the transfer finished successfully, the bit SAT of the register STA is set and the transferred values are stored in the registers A, B, and ACB. If the transfer failed due to missing data at the requested source, the bit SAT of the register STA is cleared and registers A, B, and ACB are not changed.
If A and B refer to the same register, only the upper W bit ARU word is stored and the lower W bit ARU word is discard.
If any transferred W bit value from the ARU should not stored in a register, the dummy register ZERO ∈ AREG can be selected in A or B to discard the corresponding ARU data. The binary encoding of the address for the dummy register ZERO can be chosen by an arbitrary value within the range 8 to 15.
The program counter PC is incremented by the value 4.

(18) NARDI Instruction

Syntax: NARDI A, B

Encoding: $1011a_3a_2a_1a_0b_3b_2b_1b_0$0011----------

Operation:
A ← ARU(R6[8:0])[W-1:0];
B ← ARU(R6[8:0])[2*W-1:W];
ACB ← ARU(R6[8:0])[4+2*W:2*W]

Status: SAT

Duration: Suspends current MCS-channel until the ARU is selecting the MCS-channel.

Description: Perform a non-blocking read access to the ARU trying to transfer both W bit values received at the ARU port to the registers A and B (A ∈ AREG, B ∈ AREG), whereas A holds the lower W bit ARU word, B holds the upper W bit ARU word, and the ACB register holds the received ARU control bits. The read address is obtained from the bits 0 to 8 of the channels register R6.
Non-blocking ARU read access means that the instruction is suspending the MCS channel until the ARU scheduler is selecting the requesting MCS channel. If the transfer finished successfully, the bit SAT of the register STA is set and the transferred values are stored in the registers A, B, and ACB. If the transfer failed due to missing data at the requested source, the bit SAT of the register STA is cleared and registers A, B, and ACB are not changed.
If A and B refer to the same register, only the upper W bit ARU word is stored and the lower 24 bit ARU word is discard.
If any transferred W bit value from the ARU should not stored in a register, the dummy register ZERO ∈ AREG can be selected in A or B to discard the corresponding ARU data. The binary encoding of the address for the dummy register ZERO can be chosen by an arbitrary value within the range 8 to 15.
The program counter PC is incremented by the value 4.

(19) BRD Instruction

Syntax: BRD A, C

Encoding: 1010-a_2 a_1 a_0----1001c_{15} c_{14} c_{13} c_{12} c_{11} c_{10} c_9 c_8 c_7 c_6 c_5 c_4 c_3 c_2--

Operation: A ← BUS(C)[W–1:0];
MHB ← BUS(C)[BDW–1:W]

Status: –

Duration: Suspends current MCS-channel if addressed slave inserts at least one wait cycle (e.g. accessing a RAM module) otherwise 1 instruction cycle.

Description: Initiate a read access at the bus master interface using the address C (C ∈ BALIT) and transfer the lower W bits of the received data to register A (A ∈ GREG).
The upper BDW-W bits of the received data are transferred to the MHB register.
If the delay between the a BRD instruction and its successor instruction is one or two system clock cycles (e.g. in accelerated scheduling mode) and the successor instruction is reading data resulting from the BRD instruction, a data hazard in the pipeline occurs resulting in a pipeline flush. This means, if very fast program execution is required (e.g. only one task is activated in accelerated scheduling mode) a program sequence like BRD R1, 0x0288; ADD R3, R1; (9 clock cycles) can be accelerated by reformulating the sequence as BRD R1, 0x0288; NOP; NOP; ADD R3, R1; (4 clock cycles).
Since the MHB register is always transferred via AEI bus master it also figures out another data dependency, which can cause a data hazard resulting in a pipeline flush. Therefore a sequence like BRD R1, 0x0288; BWR R3, 0x304 (9 clock cycles) could also be optimized by the sequence BRD R1, 0x0288; NOP; NOP; BWR R3, 0x304(4 clock cycles).
The program counter PC is incremented by the value 4.

(20) BWR Instruction

Syntax: BWR A, C

Encoding: 1010-a_2 a_1 a_0----1010c_{15} c_{14} c_{13} c_{12} c_{11} c_{10} c_9 c_8 c_7 c_6 c_5 c_4 c_3 c_2--

Operation: BUS(C)[W–1:0] ← A;
BUS(C)[BDW–1:W] ← MHB

Status: –

Duration: Suspends current MCS-channel if addressed slave inserts at least one wait cycle (e.g. accessing a RAM module) otherwise 1 instruction cycle.

Description: Initiate a write access at the bus master interface using the address C (C ∈ BALIT) and transfer the content of register A (A ∈ GREG) to the bits 0 to W-1 of the bus.
The content of the MHB register is transferred to the bits W to BDW-W-1 of the bus.
The program counter PC is incremented by the value 4.

(21) BRDI Instruction

Syntax: BRDI A, B

Encoding: 1010-$a_2 a_1 a_0$-$b_2 b_1 b_0$1011----------

Operation: A ← BUS(B[BAW+1:2])[W–1:0];
MHB ← BUS(B[BAW+1:2])[BDW–1:W]

Status: –

Duration: Suspends current MCS-channel if addressed slave inserts at least one wait cycle (e.g. accessing a RAM module) otherwise 1 instruction cycle.

Description: Initiate a read access at the bus master interface using indirect addressing and transfer the lower W bits of the received data to register A (A ∈ GREG).
The upper BDW-W bits of the received data are transferred to the MHB register.
The address for the transfer is identified by the bits 2 to BAW+1 of register B (B ∈ GREG).
If the delay between the a BRDI instruction and its successor instruction is one or two system clock cycles (e.g. in accelerated scheduling mode) and the successor instruction is reading data resulting from the BRDI instruction, a data hazard in the pipeline occurs resulting in a pipeline flush. This means, if very fast program execution is required (e.g. only one task is activated in accelerated scheduling mode) a program sequence like BRDI R1, R6; ADD R3, R1; (9 clock cycles) can be accelerated by reformulating the sequence as BRDI R1, R6; NOP; NOP; ADD R3, R1; (4 clock cycles).
Since the MHB register is always transferred via AEI bus master it also figures out another data dependency, which can cause a data hazard resulting in a pipeline flush. Therefore a sequence like BRDI R1, R2; BWRI R3, R4 (9 clock cycles) could also be optimized by the sequence BRDI R1, R2; NOP; NOP; BWRI R3, R4 (4 clock cycles).
The program counter PC is incremented by the value 4.

(22) BWRI Instruction

Syntax: BWRI A, B

Encoding: 1010-$a_2 a_1 a_0$-$b_2 b_1 b_0$1100----------

Operation: BUS(B[BAW+1:2])[W–1:0] ← A;
BUS(B[BAW+1:2])[BDW–1:W] ← MHB

Status: –

Duration: Suspends current MCS-channel if addressed slave inserts at least one wait cycle (e.g. accessing a RAM module) otherwise 1 instruction cycle.

Description: Initiate a write access at the bus master interface using the indirect addressing and transfer the content of register A (A ∈ GREG) to the bits 0 to W-1 of the bus.
The content of the MHB register is transferred to the bits W to BDW-W-1 of the bus.
The address for the transfer is identified by the bits 2 to BAW+1 of register B (B ∈ GREG).
The program counter PC is incremented by the value 4.

(23) ADDL Instruction

Syntax: ADDL A, C

Encoding: $0010a_3 a_2 a_1 a_0 c_{23} c_{22} c_{21} c_{20} c_{19} c_{18} c_{17} c_{16} c_{15} c_{14} c_{13} c_{12} c_{11} c_{10} c_9 c_8 c_7 c_6 c_5 c_4 c_3 c_2 c_1 c_0$

Operation: A ← A + C

Status: Z, CY, N, V

Duration: 1 instruction cycle

Description: Perform addition operation of a register A (A ∈ OREG) with a W bit literal value C (C ∈ WLIT) and store the result in register A.
The zero bit Z of status register STA is set, if the calculated value is zero, otherwise the zero bit is cleared.
The carry bit CY of status register STA is set, if an unsigned overflow/underflow occurred during addition, otherwise the bit is cleared. An unsigned overflow has occurred when the result of the operation cannot be represented in the interval $[0; 2^W-1]$, assuming that both operands A and C are unsigned values within the interval $[0; 2^W-1]$.
The overflow bit V of status register STA is set, if a signed overflow/underflow occurred during addition, otherwise the bit is cleared. A signed overflow/underflow has occurred when the result of the operation cannot be represented in the interval $[-2^{W-1}; 2^{W-1}-1]$, assuming that both operands A and C are signed values within the interval $[-2^{W-1}; 2^{W-1}-1]$.
The negative bit N of status register STA equals the MSB of the operation result, in order to determine if a calculated signed result is negative (N=1) or positive (N=0), assuming that no overflow/underflow occurred.
The program counter PC is incremented by the value 4.

(24) ADD Instruction

Syntax: ADD A, B

Encoding: $1100a_3 a_2 a_1 a_0 b_3 b_2 b_1 b_0$ 0000-a_4-b_4 ----------

Operation: A ← A + B

Status: Z, CY, N, V

Duration: 1 instruction cycle

Description: Perform addition operation of a register A (A ∈ OREG) with an operand B (B ∈ OREG). The result is stored in the register A.
The zero bit Z of status register STA is set, if the calculated value is zero, otherwise the zero bit is cleared.
The carry bit CY of status register STA is set, if an unsigned overflow occurred during addition, otherwise the bit is cleared. An unsigned overflow has occurred when the result of the operation cannot be represented in the interval $[0; 2^W-1]$, assuming that both operands A and B are unsigned values within the interval $[0; 2^W-1]$.
The overflow bit V of status register STA is set, if a signed overflow/underflow occurred during addition, otherwise the bit is cleared. A signed overflow/underflow has occurred when the result of the operation cannot be represented in the interval $[-2^{W-1}; 2^{W-1}-1]$, assuming that both operands A and B are signed values within the interval $[-2^{W-1}; 2^{W-1}-1]$.
The negative bit N of status register STA equals the MSB of the operation result, in order to determine if a calculated signed result is negative (N=1) or positive (N=0), assuming that no overflow/underflow occurred.
The program counter PC is incremented by the value 4.

(25) ADDC Instruction

Syntax: ADDC A, B

Encoding: 1101a_3 a_2 a_1 a_0 b_3 b_2 b_1 b_0 0110-a_4 -b_4 ----------

Operation: A ← A + B + CY

Status: Z, CY, N, V

Duration: 1 instruction cycle

Description: Perform addition operation of a register A (A ∈ XOREG) with an operand B (B ∈ XOREG) and the carry flag CY. The result is stored in the register A.
The zero bit Z of status register STA is set, if the calculated value is zero, otherwise the zero bit is cleared.
The carry bit CY of status register STA is set, if an unsigned overflow occurred during addition, otherwise the bit is cleared. An unsigned overflow has occurred when the result of the operation cannot be represented in the interval [0; 2^W-1], assuming that both operands A and B are unsigned values within the interval [0; 2^W-1].
The overflow bit V of status register STA is set, if a signed overflow/underflow occurred during addition, otherwise the bit is cleared. A signed overflow/underflow has occurred when the result of the operation cannot be represented in the interval [-2^{W-1}; 2^{W-1}-1], assuming that both operands A and B are signed values within the interval [-2^{W-1}; 2^{W-1}-1].
The negative bit N of status register STA equals the MSB of the operation result, in order to determine if a calculated signed result is negative (N=1) or positive (N=0), assuming that no overflow/underflow occurred.
The program counter PC is incremented by the value 4.

(26) SUBL Instruction

Syntax: SUBL A, C

Encoding: 0011a_3 a_2 a_1 a_0 c_{23} c_{22} c_{21} c_{20} c_{19} c_{18} c_{17} c_{16} c_{15} c_{14} c_{13} c_{12} c_{11} c_{10} c_9 c_8 c_7 c_6 c_5 c_4 c_3 c_2 c_1 c_0

Operation: A ← A - C

Status: Z, CY, N, V

Duration: 1 instruction cycle

Description: Perform subtraction operation of a register A (A ∈ OREG) with a W bit literal value C (C ∈ WLIT). The result is stored in register A.
The zero bit Z of status register STA is set, if the calculated value is zero, otherwise the zero bit is cleared.
The carry bit CY of status register STA is set, if an unsigned underflow occurred during subtraction, otherwise the bit is cleared. An unsigned underflow has occurred when the result of the operation cannot be represented in the interval [0; 2^W-1], assuming that both operands A and C are unsigned values within the interval [0; 2^W-1].
The overflow bit V of status register STA is set, if a signed overflow/underflow occurred during subtraction, otherwise the bit is cleared. A signed overflow/underflow has occurred when the result of the operation cannot be represented in the interval [-2^{W-1}; 2^{W-1}-1], assuming that both operands A and C are signed values within the interval [-2^{W-1}; 2^{W-1}-1].
The negative bit N of status register STA equals the MSB of the operation result, in order to determine if a calculated signed result is negative (N=1) or positive (N=0), assuming that no overflow/underflow occurred.
The program counter PC is incremented by the value 4.

(27) SUB Instruction

Syntax: SUB A, B

Encoding: $1100a_3\,a_2\,a_1\,a_0\,b_3\,b_2\,b_1\,b_0\,0001\text{-}a_4\text{-}b_4$ ----------

Operation: A ← A – B

Status: Z, CY, N, V

Duration: 1 instruction cycle

Description: Perform subtraction operation of a register A (A ∈ OREG) with an operand B (B ∈ OREG). The result is stored in register A.
The zero bit Z of status register STA is set, if the calculated value is zero, otherwise the zero bit is cleared.
The carry bit CY of status register STA is set, if an unsigned underflow occurred during subtraction, otherwise the bit is cleared. An unsigned underflow has occurred when the result of the operation cannot be represented in the interval [0; 2^W-1], assuming that both operands A and B are unsigned values within the interval [0; 2^W-1].
The overflow bit V of status register STA is set, if a signed overflow/underflow occurred during subtraction, otherwise the bit is cleared. A signed overflow/underflow has occurred when the result of the operation cannot be represented in the interval [-2^{W-1}; 2^{W-1}-1], assuming that both operands A and B are signed values within the interval [-2^{W-1}; 2^{W-1}-1].
The negative bit N of status register STA equals the MSB of the operation result, in order to determine if a calculated signed result is negative (N=1) or positive (N=0), assuming that no overflow/underflow occurred.
The program counter PC is incremented by the value 4.

(28) SUBC Instruction

Syntax: SUBC A, B

Encoding: $1101a_3\,a_2\,a_1\,a_0\,b_3\,b_2\,b_1\,b_0\,0111\text{-}a_4\text{-}b_4$ ----------

Operation: A ← A – B – CY

Status: Z, CY, N, V

Duration: 1 instruction cycle

Description: Perform subtraction operation of a register A (A ∈ XOREG) with an operand B (B ∈ XOREG) and the carry flag CY. The result is stored in register A.
The zero bit Z of status register STA is set, if the calculated value is zero, otherwise the zero bit is cleared.
The carry bit CY of status register STA is set, if an unsigned underflow occurred during subtraction, otherwise the bit is cleared. An unsigned underflow has occurred when the result of the operation cannot be represented in the interval [0; 2^W-1], assuming that both operands A and B are unsigned values within the interval [0; 2^W-1].
The overflow bit V of status register STA is set, if a signed overflow/underflow occurred during subtraction, otherwise the bit is cleared. A signed overflow/underflow has occurred when the result of the operation cannot be represented in the interval [-2^{W-1}; 2^{W-1}-1], assuming that both operands A and B are signed values within the interval [-2^{W-1}; 2^{W-1}-1].
The negative bit N of status register STA equals the MSB of the operation result, in order to determine if a calculated signed result is negative (N=1) or positive (N=0), assuming that no overflow/underflow occurred.
The program counter PC is incremented by the value 4.

(29) NEG Instruction

Syntax: NEG A, B

Encoding: $1100a_3\,a_2\,a_1\,a_0\,b_3\,b_2\,b_1\,b_0\,0010\text{-}a_4\text{-}b_4$ ----------

Operation: A ← –B

Status: Z, N, V

Duration: 1 instruction cycle

Description: Perform negation operation (2's Complement) with an operand B (B ∈ OREG) and store the result in a register A (A ∈ OREG).
The zero bit Z of status register STA is set, if the calculated value is zero, otherwise the zero bit is cleared.
The overflow bit V of status register STA is set, if a signed overflow/underflow occurred during subtraction, otherwise the bit is cleared. A signed overflow/underflow has occurred when the result of the operation cannot be represented in the interval $[-2^{W-1}; 2^{W-1}-1]$, assuming that both operands A and B are signed values within the interval $[-2^{W-1}; 2^{W-1}-1]$.
The negative bit N of status register STA equals the MSB of the operation result, in order to determine if a calculated signed result is negative (N = 1) or positive (N = 0), assuming that no overflow/underflow occurred.
The program counter PC is incremented by the value 4.

(30) ANDL Instruction

Syntax: ANDL A, C

Encoding: $0100a_3\,a_2\,a_1\,a_0\,c_{23}\,c_{22}\,c_{21}\,c_{20}\,c_{19}\,c_{18}\,c_{17}\,c_{16}\,c_{15}\,c_{14}\,c_{13}\,c_{12}\,c_{11}\,c_{10}\,c_9\,c_8\,c_7\,c_6\,c_5\,c_4\,c_3\,c_2\,c_1\,c_0$

Operation: A ← A AND C

Status: Z

Duration: 1 instruction cycle

Description: Perform bitwise AND conjunction of a register A (A ∈ OREG) with a W bit literal value C (C ∈ WLIT) and store the result in register A.
The zero bit Z of status register STA is set, if the calculated value is zero, otherwise the zero bit is cleared.
The program counter PC is incremented by the value 4.

(31) AND Instruction

Syntax: AND A, B

Encoding: $1100a_3\,a_2\,a_1\,a_0\,b_3\,b_2\,b_1\,b_0\,0011\text{-}a_4\text{-}b_4$ ----------

Operation: A ← A AND B

Status: Z

Duration: 1 instruction cycle

Description: Perform bitwise AND conjunction of a register A (A ∈ OREG) with an operand B (B ∈ OREG) and store the result in register A.
The zero bit Z of status register STA is set, if the calculated value is zero, otherwise the zero bit is cleared.
The program counter PC is incremented by the value 4.

(32) ORL Instruction

Syntax: ORL A, C

Encoding: $0101 a_3 a_2 a_1 a_0 c_{23} c_{22} c_{21} c_{20} c_{19} c_{18} c_{17} c_{16} c_{15} c_{14} c_{13} c_{12} c_{11} c_{10} c_9 c_8 c_7 c_6 c_5 c_4 c_3 c_2 c_1 c_0$

Operation: A ← A OR C

Status: Z

Duration: 1 instruction cycle

Description: Perform bitwise OR conjunction of a register A (A ∈ OREG) with a W bit literal value C (C ∈ WLIT) and store the result in register A.
The zero bit Z of status register STA is set, if the calculated value is zero, otherwise the zero bit is cleared.
The program counter PC is incremented by the value 4.

(33) OR Instruction

Syntax: OR A, B

Encoding: $1100 a_3 a_2 a_1 a_0 b_3 b_2 b_1 b_0$ 0100-a_4-b_4 ----------

Operation: A ← A OR B

Status: Z

Duration: 1 instruction cycle

Description: Perform bitwise OR conjunction of a register A (A ∈ OREG) with an operand B (B ∈ OREG) and store the result in register A.
The zero bit Z of status register STA is set, if the calculated value is zero, otherwise the zero bit is cleared.
The program counter PC is incremented by the value 4.

(34) XORL Instruction

Syntax: XORL A, C

Encoding: $0110 a_3 a_2 a_1 a_0 c_{23} c_{22} c_{21} c_{20} c_{19} c_{18} c_{17} c_{16} c_{15} c_{14} c_{13} c_{12} c_{11} c_{10} c_9 c_8 c_7 c_6 c_5 c_4 c_3 c_2 c_1 c_0$

Operation: A ← A XOR C

Status: Z

Duration: 1 instruction cycle

Description: Perform bitwise XOR conjunction of a register A (A ∈ OREG) with a W bit literal value C (C ∈ WLIT) and store the result in register A.
The zero bit Z of status register STA is set, if the calculated value is zero, otherwise the zero bit is cleared.
The program counter PC is incremented by the value 4.

(35) XOR Instruction

Syntax: XOR A, B

Encoding: $1100a_3 a_2 a_1 a_0 b_3 b_2 b_1 b_0$ 0101-a_4-b_4 ----------

Operation: A ← A XOR B

Status: Z

Duration: 1 instruction cycle

Description: Perform bitwise XOR conjunction of a register A (A ∈ XOREG) with an operand B (B ∈ XOREG) and store the result in register A.
The zero bit Z of status register STA is set, if the calculated value is zero, otherwise the zero bit is cleared.
The program counter PC is incremented by the value 4.

(36) SHR Instruction

Syntax: SHR A, C

Encoding: $1100a_3 a_2 a_1 a_0$ ----0110-a_4 ---------$c_4 c_3 c_2 c_1 c_0$

Operation: A ← A >> C

Status: Z, CY

Duration: 1 instruction cycle

Description: Perform right shift operation C (C ∈ SFTLIT) times of register A (A ∈ XOREG). The MSBs that are shifted into A are cleared.
The zero bit Z of status register STA is set, if the calculated value is zero, otherwise the zero bit is cleared.
The carry bit CY of status register STA is updated to the last LSB that is shifted out of the register. If the shift value C is 0 the carry bit CY is cleared.
The program counter PC is incremented by the value 4.

(37) SHL Instruction

Syntax: SHL A, C

Encoding: $1100a_3 a_2 a_1 a_0$ ----0111-a_4 ---------$c_4 c_3 c_2 c_1 c_0$

Operation: A ← A << C

Status: Z, CY

Duration: 1 instruction cycle

Description: Perform left shift operation C (C ∈ SFTLIT) times of register A (A ∈ XOREG). The LSBs that are shifted into A are cleared.
The zero bit Z of status register STA is set, if the calculated value is zero, otherwise the zero bit is cleared.
The carry bit CY of status register STA is updated to the previous MSB that is shifted out of the register. If the register A contains less than W bits, or if C is 0 the carry bit CY is always cleared.
The program counter PC is incremented by the value 4.

(38) ASRU Instruction

Syntax: ASRU A, B

Encoding: 1101a_3 a_2 a_1 a_0 b_3 b_2 b_1 b_0 0100-a_4 -b_4 ----------

Operation: A ← A >> B

Status: Z

Duration: 1 instruction cycle

Description: Perform arithmetic unsigned right shift operation, which means that the unsigned operand of register A (A ∈ XOREG) is right shifted B times (B ∈ XOREG). Operand B is also an unsigned type. The MSBs that are shifted into A are cleared.
The zero bit Z of status register STA is set, if the calculated value is zero, otherwise the zero bit is cleared.
The program counter PC is incremented by the value 4.

(39) ASRS Instruction

Syntax: ASRS A, B

Encoding: 1101a_3 a_2 a_1 a_0 b_3 b_2 b_1 b_0 0101-a_4 -b_4 ----------

Operation: A ← A >> B

Status: Z

Duration: 1 instruction cycle

Description: Perform arithmetic signed right shift operation, which means that the signed operand of register A (A ∈ XOREG) is right shifted B times (B ∈ XOREG). Operand B is an unsigned type. The operation also performs a sign extension, which means that value of the MSBs that are shifted into A are determined by the MSB of the original operand A.
The zero bit Z of status register STA is set, if the calculated value is zero, otherwise the zero bit is cleared.
The program counter PC is incremented by the value 4.

(40) ASL Instruction

Syntax: ASL A, B

Encoding: 1101a_3 a_2 a_1 a_0 b_3 b_2 b_1 b_0 0011-a_4 -b_4 ----------

Operation: A ← A << B

Status: Z, CY, V

Duration: 1 instruction cycle

Description: Perform arithmetic left shift operation for signed and unsigned numbers, which means that the operand of register A (A ∈ XOREG) is left shifted B times (B ∈ XOREG). Operand B is always an unsigned type.
The carry bit CY of status register STA is set, if an unsigned overflow occurred during shifting, otherwise the bit is cleared. An unsigned overflow has occurred if the calculated result $A*2^B$ cannot be represented in the interval [0; 2^W-1], assuming that both operands A and B are unsigned values within the interval [0; 2^W-1].
The overflow bit V of status register STA is set, if a signed overflow/underflow occurred during shifting, otherwise the bit is cleared. A signed overflow/underflow has occurred when the calculated result $A*2^B$ cannot be represented in the interval [-2^{W-1}; 2^{W-1}-1], assuming that signed operand A is within the interval [-2^{W-1}; 2^{W-1}-1] and the unsigned operand B is within the interval [0; 2^{W-1}-1].
The zero bit Z of status register STA is set, if the calculated value is zero, otherwise the zero bit is cleared.
The program counter PC is incremented by the value 4.

(41) MULU Instruction

Syntax: MULU A, B[, C]

Encoding: $1100a_3 a_2 a_1 a_0 b_3 b_2 b_1 b_0\ 1000\text{-}a_4\ \text{-}b_4\ \text{-------}c_4 c_3 c_2 c_1 c_0$

Operation: [[R4,] A] ← A[(C–1):0] * B[(C–1):0]

Status: Z

Duration: 1 instruction cycle

Description: Perform an unsigned multiplication operation of an operand A (A ∈ XOREG if C is less than or equal to W/2; A ∈ XOREG \\ {R4} if C is greater than W/2) with an operand B (B ∈ XOREG). The multiplication is only performed with the bits 0 to C–1 (C ∈ BWSLIT) of both operands A and B and the bits C to W–1 are ignored. If C is less than or equal to W/2, the product of the multiplication is stored in register A and register R4 is left unchanged. If C is greater than W/2, the bits 0 to W–1 are stored in A and the bits W to 2*C–1 are stored in R4. The results stored in the registers are always zero extended to W bits. If the optional operand C is not specified in the assembler code, the MCS assembler generates code with a default value of W for operand C. The zero bit Z of status register STA is set, if the calculated product is zero, otherwise the zero bit is cleared.

If the delay between the a MULU instruction and its successor instruction is one system clock cycles (e.g. in accelerated scheduling mode) and the successor instruction is either a WURM, WURMX, WURCX, WUCE, BRDI, BWR, or BWRI instruction that is accessing the multiplication result as argument a data hazard in the pipeline occurs resulting in a pipeline flush. This means, if very fast program execution is required (e.g. only one task is activated in accelerated scheduling mode) a program sequence like MULU R1, R2; BWRI R1, R3; (9 clock cycles) can be accelerated by reformulating the sequence as MULU R1, R2; NOP; BWRI R1, R3; (3 clock cycles).

The program counter PC is incremented by the value 4.

(42) MULS Instruction

Syntax: MULS A, B[, C]

Encoding: 1100a_3 a_2 a_1 a_0 b_3 b_2 b_1 b_0 1001-a_4 -b_4 -------c_4 c_3 c_2 c_1 c_0

Operation: [[R4,] A] ← A[(C–1):0] * B[(C–1):0]

Status: Z, N

Duration: 1 instruction cycle

Description: Perform a signed multiplication operation of an operand A (A ∈ XOREG if C is less than or equal to W/2; A ∈ XOREG \\ {R4} if C is greater than W/2) with an operand B (B ∈ XOREG). The multiplication is only performed with the bits 0 to C–1 (C ∈ BWSLIT) of both operands A and B, in which bit C–1 is used as sign bit ($–2^{(C–1)}$) and the bits C to W–1 are ignored. If C is less than or equal to W/2, the product of the multiplication is stored in register A and register R4 is left unchanged. If C is greater than W/2, the bits 0 to W–1 are stored in A and the bits W to 2*C–1 are stored in R4. The results stored in the registers are always sign extended to W bits. If the optional operand C is not specified in the assembler code, the MCS assembler generates code with a default value of W for operand C. The zero bit Z of status register STA is set, if the calculated product is zero, otherwise the zero bit is cleared. The negative bit N of status register STA equals the MSB of the operation result, in order to determine if a calculated signed result is negative (N=1) or positive (N=0).
If the delay between the a MULS instruction and its successor instruction is one system clock cycles (e.g. in accelerated scheduling mode) and the successor instruction is either a WURM, WURMX, WURCX, WUCE, BRDI, BWR, or BWRI instruction that is accessing the multiplication result as argument a data hazard in the pipeline occurs resulting in a pipeline flush. This means, if very fast program execution is required (e.g. only one task is activated in accelerated scheduling mode) a program sequence like MULS R1, R2; BWRI R1, R3; (9 clock cycles) can be accelerated by reformulating the sequence as MULS R1, R2; NOP; BWRI R1, R3; (3 clock cycles).
The program counter PC is incremented by the value 4.

(43) DIVU Instruction

Syntax: DIVU A, B[, C]

Encoding: 1100a_3 a_2 a_1 a_0 b_3 b_2 b_1 b_0 1010-a_4 -b_4 -------c_4 c_3 c_2 c_1 c_0

Operation: R4 ← A[(C–1):0] – B[(C–1):0] * [A[(C–1):0] / B[(C–1):0]];
A ← [A[(C–1):0] / B[(C–1):0]]

Status: CY, Z, ERR

Duration: C instruction cycles but not faster than C+NPS–1 clock cycles due to pipeline flushing.

Description: Perform an unsigned division operation of operand A (A ∈ XOREG \\ {R4, B}) divided by operand B (B ∈ XOREG \\ {R4, A}).
The division is only performed with the bits 0 to C–1 (C ∈ BWSLIT) of the operands and the remaining bits C to W–1 are ignored. This means that the dynamic range of A and B is defined in the interval [0; 2^C-1]. The integral part of the quotient is stored in the register A and the remainder of the division is stored in register R4. The resulting quotient A and remainder R4 are always zero extended to W bits. If the optional operand C is not specified in the assembler code, the MCS assembler generates code with a default value of W for operand C. If the bits 0 to C–1 of operand B are zero, the MCS channel is disabled and the ERR bit in the status register STA is set. The zero bit Z of status register STA is set, if the calculated quotient in A is zero, otherwise the zero bit is cleared. The carry bit CY of status register STA is set, if the calculated remainder in R4 is not zero, otherwise the zero bit is cleared.
The program counter PC is incremented by the value 4.

(44) DIVS Instruction

Syntax: DIVS A, B[, C]

Encoding: 1100a_3 a_2 a_1 a_0 b_3 b_2 b_1 b_0 1011-a_4 -b_4 -------c_4 c_3 c_2 c_1 c_0

Operation: R4 ← A[(C–1):0] – B[(C–1):0] * [A[(C–1):0] / B[(C–1):0]];
A ← [A[(C–1):0] / B[(C–1):0]]

Status: CY, Z, N, V, ERR

Duration: C + 4 instruction cycles but not faster than C+3+NPS clock cycles due to pipeline flushing.

Description: Perform a signed division operation of operand A (A ∈ XOREG \\ {R4, B}) divided by operand B (B ∈ XOREG \\ {R4, A}). The division is only performed with the bits 0 to C–1 (C ∈ BWSLIT) of both operands, in which bit C–1 is used as sign bit ($–2^{C-1}$) and the bits C to W–1 are ignored. This means that the dynamic range of A[(C–1):0] and B[(C–1):0] is defined in the interval [-2^{C-1}; 2^{C-1}-1]. The integral part of the quotient is stored in the register A and the remainder of the division is stored in register R4. The resulting quotient A and remainder R4 are always sign extended to W bits. The integral part of the quotient is always truncated towards 0. The sign of the remainder is always the same sign as the dividend A[(C–1):0]. The absolute value of the remained is always less than the divisor B[(C–1):0]. If the optional operand C is not specified in the assembler code, the MCS assembler generates code with a default value of W for operand C. If the bits 0 to C–1 of operand B are zero, the MCS channel is disabled and the ERR bit in the status register STA is set. The zero bit Z of status register STA is set, if the calculated quotient in A is zero, otherwise the zero bit is cleared. The carry bit CY of status register STA is set, if the calculated remainder in R4 is not zero, otherwise the zero bit is cleared. The overflow bit V of status register STA is set, if the calculated quotient in A cannot be represented in the interval [-2^{W-1}; 2^{W-1}-1], otherwise the overflow bit is cleared. The negative bit N of status register STA equals the MSB of the quotient, in order to determine if a calculated signed result is negative (N=1) or positive (N=0).
The program counter PC is incremented by the value 4.

(45) MINU Instruction

Syntax: MINU A, B

Encoding: 1100a_3 a_2 a_1 a_0 b_3 b_2 b_1 b_0 1100-a_4 -b_4 ----------

Operation: A ← MIN(A, B)

Status: Z

Duration: 1 instruction cycle

Description: Determine the minimum of an unsigned operand A (A ∈ XOREG) and an unsigned operand B (B ∈ XOREG). If A is less than or equal to B, A is left unchanged. Otherwise, if A is greater than B, the operand B is moved to A.
The zero bit Z of status register STA is set, if the calculated result of A is zero, otherwise the zero bit is cleared.

(46) MINS Instruction

Syntax: MINS A, B

Encoding: $1100a_3\,a_2\,a_1\,a_0\,b_3\,b_2\,b_1\,b_0\,1101\text{-}a_4\text{-}b_4$ ----------

Operation: A ← MIN(A, B)

Status: Z

Duration: 1 instruction cycle

Description: Determine the minimum of a signed operand A (A ∈ XOREG) and a signed operand B (B ∈ XOREG). If A is less than or equal to B, A is left unchanged. Otherwise, if A is greater than B, the operand B is moved to A.
The zero bit Z of status register STA is set, if the calculated result of A is zero, otherwise the zero bit is cleared.

(47) MAXU Instruction

Syntax: MAXU A, B

Encoding: $1100a_3\,a_2\,a_1\,a_0\,b_3\,b_2\,b_1\,b_0\,1110\text{-}a_4\text{-}b_4$ ----------

Operation: A ← MAX(A, B)

Status: Z

Duration: 1 instruction cycle

Description: Determine the maximum of an unsigned operand A (A ∈ XOREG) and an unsigned operand B (B ∈ XOREG). If A is greater than or equal to B, A is left unchanged. Otherwise, if A is less than B, the operand B is moved to A.
The zero bit Z of status register STA is set, if the calculated result of A is zero, otherwise the zero bit is cleared.

(48) MAXS Instruction

Syntax: MAXS A, B

Encoding: $1100a_3\,a_2\,a_1\,a_0\,b_3\,b_2\,b_1\,b_0\,1111\text{-}a_4\text{-}b_4$ ----------

Operation: A ← MAX(A, B)

Status: Z

Duration: 1 instruction cycle

Description: Determine the maximum of a signed operand A (A ∈ XOREG) and a signed operand B (B ∈ XOREG). If A is greater than or equal to B, A is left unchanged. Otherwise, if A is less than B, the operand B is moved to A.
The zero bit Z of status register STA is set, if the calculated result of A is zero, otherwise the zero bit is cleared.

(49) ATUL Instruction

Syntax: ATUL A, C

Encoding: $0111a_3 a_2 a_1 a_0 c_{23} c_{22} c_{21} c_{20} c_{19} c_{18} c_{17} c_{16} c_{15} c_{14} c_{13} c_{12} c_{11} c_{10} c_9 c_8 c_7 c_6 c_5 c_4 c_3 c_2 c_1 c_0$

Operation: A – C

Status: Z, CY

Duration: 1 instruction cycle

Description: Arithmetic Test with an unsigned operand A (A ∈ OREG) and an unsigned W bit literal value C (C ∈ WLIT).
The carry bit CY of status register STA is set if unsigned operand A is less than unsigned literal C.
Otherwise, the carry bit CY of status register STA is cleared if unsigned operand A is greater than or equal to unsigned literal C.
The zero bit Z of status register STA is set, if A equals to C.
Otherwise, the zero bit Z of status register STA is cleared, if A is unequal to C.
The program counter PC is incremented by the value 4.

(50) ATU Instruction

Syntax: ATU A, B

Encoding: $1101a_3 a_2 a_1 a_0 b_3 b_2 b_1 b_0$ 0000-a_4 -b_4 ----------

Operation: A – B

Status: Z, CY

Duration: 1 instruction cycle

Description: Arithmetic Test with an unsigned operand A (A ∈ XOREG) and an unsigned operand B (B ∈ XOREG).
The carry bit CY of status register STA is set if unsigned operand A is less than unsigned operand B.
Otherwise, the carry bit CY of status register STA is cleared if unsigned operand A is greater than or equal to unsigned operand B.
The zero bit Z of status register STA is set, if A equals to B.
Otherwise, the zero bit Z of status register STA is cleared, if A is unequal to B. The program counter PC is incremented by the value 4.

(51) ATSL Instruction

Syntax: ATSL A, C

Encoding: $1000a_3 a_2 a_1 a_0 c_{23} c_{22} c_{21} c_{20} c_{19} c_{18} c_{17} c_{16} c_{15} c_{14} c_{13} c_{12} c_{11} c_{10} c_9 c_8 c_7 c_6 c_5 c_4 c_3 c_2 c_1 c_0$

Operation: A - C

Status: Z, CY

Duration: 1 instruction cycle

Description: Arithmetic Test with a signed operand A (A ∈ OREG) and a signed W bit literal value C (C ∈WLIT).
The carry bit CY of status register STA is set if signed operand A is less than signed literal C.
Otherwise, the carry bit CY of status register STA is cleared if signed operand A is greater than or equal to signed literal C.
The zero bit Z of status register STA is set, if A equals to C.
Otherwise, the zero bit Z of status register STA is cleared, if A is unequal to C.
The program counter PC is incremented by the value 4.

(52) ATS Instruction

Syntax: ATS A, B

Encoding: 1101a_3 a_2 a_1 a_0 b_3 b_2 b_1 b_0 0001-a_4 -b_4 ----------

Operation: A – B

Status: Z, CY

Duration: 1 instruction cycle

Description: Arithmetic Test with a signed operand A (A ∈ XOREG) and a signed operand B (B ∈ XOREG).
The carry bit CY of status register STA is set if signed operand A is less than signed operand B.
Otherwise, the carry bit CY of status register STA is cleared if signed operand A is greater than or equal to signed operand B.
The zero bit Z of status register STA is set, if A equals to B.
Otherwise, the zero bit Z of status register STA is cleared, if A is unequal to B. The program counter PC is incremented by the value 4.

(53) BTL Instruction

Syntax: BTL A, C

Encoding: 1001a_3 a_2 a_1 a_0 c_{23} c_{22} c_{21} c_{20} c_{19} c_{18} c_{17} c_{16} c_{15} c_{14} c_{13} c_{12} c_{11} c_{10} c_9 c_8 c_7 c_6 c_5 c_4 c_3 c_2 c_1 c_0

Operation: A AND C

Status: Z

Duration: 1 instruction cycle

Description: Bit test of an operand A (A ∈ OREG) with a W bit literal bit mask C (C ∈ WLIT).
The bit test is performed by applying a bitwise logical AND operation with operand A and the bit mask C without storing the result.
The zero bit Z of status register STA is set, if the calculated value is zero, otherwise the zero bit is cleared.
The program counter PC is incremented by the value 4.

(54) BT Instruction

Syntax: BT A, B

Encoding: 1101a_3 a_2 a_1 a_0 b_3 b_2 b_1 b_0 0010-a_4 -b_4 ----------

Operation: A AND B

Status: Z

Duration: 1 instruction cycle

Description: Bit test of an operand A (A ∈ XOREG) with an operand B (B ∈ XOREG), whereas usually one of the operands is a register holding a bit mask.
The bit test is performed by applying a bitwise logical AND operation with register A and register B without storing the result.
The zero bit Z of status register STA is set, if the calculated value is zero, otherwise the zero bit is cleared.
The program counter PC is incremented by the value 4.

(55) SETB Instruction

Syntax: SETB A, B

Encoding: 1011a_3 a_2 a_1 a_0 b_3 b_2 b_1 b_0 0110-a_4 -b_4 ----------

Operation: A[B[4:0]] ? 1

Status: Z

Duration: 1 instruction cycle

Description: Set the B[4:0]–th bit (B ∈ XOREG) of an operand A (A ∈ XOREG) to true. Only the bits 0 to 4 of operand B are used as bit index of operand A and the other bits of B are ignored. If the value B[4:0] is greater than or equal to W, the operation of SETB does not modify operand A but the status flag Z is updated.
The instruction SETB performs an implicit read-modify-write operation meaning that the entire content of A is read first and after manipulating the desired bit the entire content of A is written back. This implementation may cause undesired results in special function registers and therefore it should be used carefully.
The zero bit Z of status register STA is set if the modified value of A is zero, otherwise the bit Z is cleared. The Z bit is set e.g. if the B[4:0]-th bit of A is not writable, its value is zero and all other bits of A are cleared.
The program counter PC is incremented by the value 4.

(56) CLRB Instruction

Syntax: CLRB A, B

Encoding: 1011a_3 a_2 a_1 a_0 b_3 b_2 b_1 b_0 0111-a_4 -b_4 ----------

Operation: A[B[4:0]] ? 0

Status: Z

Duration: 1 instruction cycle

Description: Clear the B[4:0].th bit (B ∈ XOREG) of an operand A (A ∈ XOREG). Only the bits 0 to 4 of operand B are used as bit index of operand A and the other bits of B are ignored. If the value B[4:0] is greater than or equal to W, the operation of CLRB does not modify operand A but the status flag Z is updated.
The instruction CLRB performs an implicit read-modify-write operation meaning that the entire content of A is read first and after manipulating the desired bit the entire content of A is written back. This implementation may cause undesired results in special function registers and therefore it should be used carefully.
The zero bit Z of status register STA is set if the modified value of A is zero, otherwise the zero bit is cleared.
The program counter PC is incremented by the value 4.

(57) XCHB Instruction

Syntax: XCHB A, B

Encoding: 1010a_3 a_2 a_1 a_0 b_3 b_2 b_1 b_0 1111-a_4 -b_4 ----------

Operation: A[B[4:0]] ? CY

Status: Z, CY

Duration: 1 instruction cycle

Description: Exchange the B[4:0]-th bit (B ∈ XOREG) of an operand A (A ∈ XOREG) with the CY bit in the status register. Only the bits 0 to 4 of operand B are used as bit index of operand A and the other bits of B are ignored. If the value B[4:0] is greater than or equal to W, the operation of XCHB does not modify operand A but the status flag Z is updated and the bit CY is cleared.
The instruction XCHB performs an implicit read-modify-write operation meaning that the entire content of A is read first and after manipulating the desired bit the entire content of A is written back. This implementation may cause undesired results in special function registers and therefore it should be used carefully.
The zero bit Z of status register STA is set if the modified value of A is zero, otherwise the zero bit is cleared.
The program counter PC is incremented by the value 4.

(58) JMP Instruction

Syntax: JMP C

Encoding: 1110--------0000c_{15} c_{14} c_{13} c_{12} c_{11} c_{10} c_9 c_8 c_7 c_6 c_5 c_4 c_3 c_2 --

Operation: PC ← C << 2

Status: —

Duration: 1 instruction cycle but not faster than NPS clock cycles due to pipeline flushing.

Description: Execute unconditional jump to the memory location C (C ∈ ALIT).
The program counter PC is loaded with literal C.

(59) JBS Instruction

Syntax: JBS A, B, C

Encoding: 1110a_3 a_2 a_1 a_0 b_3 b_2 b_1 b_0 0001c_{15} c_{14} c_{13} c_{12} c_{11} c_{10} c_9 c_8 c_7 c_6 c_5 c_4 c_3 c_2 --

Operation: PC ← C << 2 if A[B] is set
PC ← PC + 4 if A[B] is clear

Status: —

Duration: 1 instruction cycle but if the jump is executed, it is not faster than NPS clock cycles due to pipeline flushing.

Description: Execute conditional jump to the memory location C (C ∈ ALIT).
The program counter PC is loaded with literal C, if the bit at position B (B ∈ BITLIT) of operand A (A ∈ OREG) is set.
Otherwise, if the bit is cleared, the program counter PC is incremented by the value 4.

(60) JBC Instruction

Syntax: JBC A, B, C

Encoding: 1110a_3 a_2 a_1 a_0 b_3 b_2 b_1 b_0 0010c_{15} c_{14} c_{13} c_{12} c_{11} c_{10} c_9 c_8 c_7 c_6 c_5 c_4 c_3 c_2 --

Operation: PC ← C << 2 if A[B] is set
PC ← PC + 4 if A[B] is clear

Status: —

Duration: 1 instruction cycle but if the jump is executed, it is not faster than NPS clock cycles due to pipeline flushing.

Description: Execute conditional jump to the memory location C (C ∈ ALIT).
The program counter PC is loaded with literal C if the bit at position B (B ∈ BITLIT) of operand A (A ∈ OREG) is cleared.
Otherwise, if the bit is set the program counter PC is incremented by the value 4.

(61) CALL Instruction

Syntax: CALL C

Encoding: 1110--------0011c_{15} c_{14} c_{13} c_{12} c_{11} c_{10} c_9 c_8 c_7 c_6 c_5 c_4 c_3 c_2 --

Operation: R7 ← R7 + 4;
MEM(R7[RAW+USR+1:2])[RAW+USR+1:0] ← PC + 4;
PC ← C << 2;
SP_CNT ← SP_CNT + 1

Status: EN

Duration: 2 instruction cycles but not faster than 2*NPS clock cycles due to pipeline flushing.

Description: Call subprogram at memory location C (C ∈ ALIT).
The stack pointer register R7 is incremented by the value 4.
The memory location for the top of the stack is identified by the bits 2 to RAW+1 of the stack pointer register.
After the stack pointer is incremented, the incremented value of the PC is transferred to the top of the stack.
The program counter PC is loaded with literal C.
The SP_CNT bit field inside the MCS[i]_CH[x]_CTRL register is incremented. If an overflow on the SP_CNT bit field occurs, the STK_ERR[i]_IRQ is raised.
If an overflow on the SP_CNT bit field occurs and the bit HLT_SP_OFL of register MCS[i]_CTRL_STAT is set, the channel current MCS-channel is disabled by clearing the EN bit of STA.
If an overflow on the SP_CNT bit field occurs and the bit HLT_SP_OFL of register MCS[i]_CTRL_STAT is set, the memory write operation of the incremented PC is discarding.

(62) RET Instruction

Syntax: RET

Encoding: 1110--------0100----------

Operation: PC ← MEM(R7[RAW+USR+1:2])[RAW+USR+1:2] << 2;
R7 ← R7 – 4;
SP_CNT ← SP_CNT – 1

Status: EN

Duration: 2 instruction cycles but not faster than 2*NPS clock cycles due to pipeline flushing.

Description: Return from subprogram.
The program counter PC is loaded with current value on the top of the stack.
Finally, the stack pointer register R7 is decremented by the value 4.
The memory location for the top of the stack is identified by the bits 2 to RAW+1 of the stack pointer register.
The SP_CNT bit field inside the MCS[i]_CH[x]_CTRL register is decremented.
If an underflow on the SP_CNT bit field occurs, the STK_ERR[i]_IRQ is raised.
If an underflow on the SP_CNT bit field occurs and the bit HLT_SP_OFL of register MCS[i]_CTRL is set, the channel current MCS-channel is disabled by clearing the EN bit of STA.

(63) JMPI Instruction

Syntax: JMPI

Encoding: 1110--------0101----------

Operation: PC ← R6[RAW+USR+1:2] << 2

Status: —

Duration: 1 instruction cycle but not faster than NPS clock cycles due to pipeline flushing.

Description: Execute indirect unconditional jump to the memory location provided in register R6.
The destination address is only defined by the bits 2 to RAW+USR+1 of R6 and the other bits are ignored.
The program counter PC is loaded with (R6[RAW+USR+1:2] << 2).

(64) JBSI Instruction

Syntax: JBSI A, B

Encoding: $1110a_3 a_2 a_1 a_0 b_3 b_2 b_1 b_0$ 0110-a_4-b_4 ----------

Operation: PC ← R6[RAW+USR+1:2] << 2 if A[B] is set
PC ← PC + 4 if A[B] is clear

Status: —

Duration: 1 instruction cycle but if the jump is executed it is not faster than NPS clock cycles due to pipeline flushing.

Description: Execute indirect conditional jump to the memory location provided in register R6. The destination address is only defined by the bits 2 to RAW+USR+1 of R6 and the other bits are ignored.
The program counter PC is loaded with (R6[RAW+USR+1:2] << 2) only if the bit at position B (B ∈ XBITLIT) of operand A (A ∈ XOREG) is set.
Otherwise, if the bit is cleared the program counter PC is incremented by the value 4.

(65) JBCI Instruction

Syntax: JBCI A, B

Encoding: 1110a_3 a_2 a_1 a_0 b_3 b_2 b_1 b_0 0111-a_4 -b_4 ----------

Operation: PC ← R6[RAW+USR+1:2] << 2 if A[B] is clear
PC ← PC + 4 if A[B] is set

Status: —

Duration: 1 instruction cycle but if the jump is executed it is not faster than NPS clock cycles due to pipeline flushing.

Description: Execute indirect conditional jump to the memory location provided in register R6. The destination address is only defined by the bits 2 to RAW+USR+1 of R6 and the other bits are ignored.
The program counter PC is loaded with (R6[RAW+USR+1:2] << 2) only if the bit at position B (B ∈ XBITLIT) of operand A (A ∈ XOREG) is cleared.
Otherwise, if the bit is set the program counter PC is incremented by the value 4.

(66) CALLI Instruction

Syntax: CALLI

Encoding: 1110--------0111----------

Operation: R7 ← R7 + 4;
MEM(R7[RAW+USR+1:2])[RAW+USR+1:0] ← PC + 4;
PC ← R6[RAW+USR+1:2] << 2;
SP_CNT ← SP_CNT + 1

Status: EN

Duration: 2 instruction cycles but not faster than 2*NPS clock cycles due to pipeline flushing.

Description: Call subprogram indirectly, where the register R6 is identifying the target memory location. The destination address is only defined by the bits 2 to RAW+USR+1 of R6 and the other bits are ignored.
The stack pointer register R7 is incremented by the value 4.
The memory location for the top of the stack is identified by the bits 2 to RAW+1 of the stack pointer register.
After the stack pointer is incremented, the incremented value of the PC is transferred to the top of the stack.
The program counter PC is loaded with (R6[RAW+USR+1:2] << 2), The SP_CNT bit field inside the MCS[i]_CH[x]_CTRL register is incremented.
If an overflow on the SP_CNT bit field occurs, the STK_ERR[i]_IRQ is raised.
If an overflow on the SP_CNT bit field occurs and the bit HLT_SP_OFL of register MCS[i]_CTRL_STAT is set, the channel current MCS-channel is disabled by clearing the EN bit of STA.
If an overflow on the SP_CNT bit field occurs and the bit HLT_SP_OFL of register MCS[i]_CTRL_STAT is set, the memory write operation of the incremented PC is discarding.

(67) WURM Instruction

Syntax: WURM A, B, C

Encoding: $1111 a_3 a_2 a_1 a_0 b_3 b_2 b_1 b_0 0000 c_{15} c_{14} c_{13} c_{12} c_{11} c_{10} c_9 c_8 c_7 c_6 c_5 c_4 c_3 c_2 c_1 c_0$

Operation: Wait until register match.

Status: CWT

Duration: Suspends current MCS-channel. If the MCS is configured in Single Prioritization or Multiple Prioritization Scheduling Mode, the worst case latency for reactivating a prioritized MCS-channel is 2+NPS clock cycles. This is the delay between the match event of the corresponding WURM instruction and the beginning of the following MCS instruction.

Description: Suspend current MCS-channel until the following register match condition occurs: A = (B AND MASK), whereas A ∈ OREG, B ∈ OREG, AND is a bitwise AND operation with bitmask MASK. The bits 16 to 23 of MASK are set to true and the bits 0 to 15 are copied from the instructions literal C ∈ MSKLIT. If the match condition evaluates to true, the suspended MCS channel is resumed and the program counter PC is incremented by the value 4 meaning that the MCS channel continues its program. However, if the match condition is true at the beginning of the instruction execution, the instruction does not suspend the channel and the program counter PC is incremented by the value 4. At the beginning of the instruction execution the CWT bit in the register STA is always cleared. After the execution of the instruction the CWT bit is updated in order to show if the instruction finished successfully (CWT = 0) or it was canceled by the CPU (CWT = 1). This instruction can be used to wait for one or more trigger events generated by other MCS-channels or the CPU. In this case register B is the trigger register STRG, A is a general purpose register holding the bits with the trigger condition to wait for and C is the bitmask that enables trigger bits of interest. The trigger bits can be set by other MCS channels with a write access (e.g. using a MOVL instruction) to the STRG register or the CPU with a write access to the MCS[i]_STRG register. The trigger bits are not cleared automatically by hardware after resuming an MCS-channel, but they have to be cleared explicitly with a write access to the register CTRG by the MCS-channel or with a write access to the register MCS[i]_CTRG by the CPU.

NOTE

More than one channel can wait for the same trigger bit to continue.

(68) WURMX Instruction

Syntax: WURMX A, B

Encoding: $1111 a_3 a_2 a_1 a_0 b_3 b_2 b_1 b_0 0001 \text{---} b_4$ ----------

Operation: Wait until extended register match.

Status: CWT

Duration: Suspends current MCS-channel. If the MCS is configured in Single Prioritization or Multiple Prioritization Scheduling Mode, the worst case latency for reactivating a prioritized MCS-channel is 2+NPS clock cycles. This is the delay between the match event of the corresponding WURMX instruction and the beginning of the following MCS instruction.

Description: Suspend current MCS-channel until the following register match condition occurs: A = B AND R6, whereas A ∈ OREG, B ∈ WXREG, and AND is a bitwise AND operation. If the match condition evaluates to true, the suspended MCS channel is resumed and the program counter PC is incremented by the value 4 meaning that the MCS channel continues its program. However, if the match condition is true at the beginning of the instruction execution, the instruction does not suspend the channel and the program counter PC is incremented by the value 4. At the beginning of the instruction execution the CWT bit in the register STA is always cleared. After the execution of the instruction the CWT bit is updated in order to show if the instruction finished successfully (CWT = 0) or it was canceled by the CPU (CWT = 1).

(69) WURCX Instruction

Syntax: WURCX A, B

Encoding: $1111 a_3 a_2 a_1 a_0 b_3 b_2 b_1 b_0 0010 \text{---} b_4$ ----------

Operation: Wait until extended register change.

Status: CWT

Duration: Suspends current MCS-channel. If the MCS is configured in Single Prioritization or Multiple Prioritization Scheduling Mode, the worst case latency for reactivating a prioritized MCS-channel is 2+NPS clock cycles. This is the delay between the match event of the corresponding WURCX instruction and the beginning of the following MCS instruction.

Description: Suspend current MCS-channel until the following register change condition occurs: A 6= B AND R6, whereas A ∈ OREG, B ∈ WXREG, and AND is a bitwise AND operation. If the change condition evaluates to true, the suspended MCS channel is resumed and the program counter PC is incremented by the value 4 meaning that the MCS channel continues its program. However, if the change condition is true at the beginning of the instruction execution, the instruction does not suspend the channel and the program counter PC is incremented by the value 4. At the beginning of the instruction execution the CWT bit in the register STA is always cleared. After the execution of the instruction the CWT bit is updated in order to show if the instruction finished successfully (CWT = 0) or it was canceled by the CPU (CWT = 1).
The WURCX instruction can be used for observation of volatile registers (e.g. register DSTAX) in order to react on status signal changes.

(70) WUCE Instruction

Syntax: WUCE A, B

Encoding: $1111 a_3 a_2 a_1 a_0 b_3 b_2 b_1 b_0 0011$----------

Operation: Wait until cyclic event.

Status: CWT

Duration: Suspends current MCS-channel. If the MCS is configured in Single Prioritization or Multiple Prioritization Scheduling Mode, the worst case latency for reactivating a prioritized MCS-channel is 2+NPS clock cycles. This is the delay between the match event of the corresponding WUCE instruction and the beginning of the following MCS instruction.

Description: Suspend current MCS-channel until a cyclic event compare matches. The meaning of a cyclic event is described in **Section 38.5.4.1, Cyclic Event Compare**. The WUCE instruction can be used to synchronize an MCS program to a cyclic event generated by a TBU channel. If the event is in the future, the MCS channel suspends until the event occurs. If the event is in the past, the WUCE instruction is finished immediately. The cyclic event compare is used to detect time base overflows and to guarantee, that a compare match event can be set up for the future even when the time base will first overflow and then reach the compare value.

NOTE

For a correct behavior of this cyclic event compare, the compare value must not be specified larger/smaller than half of the range of the total time base value ($7FFFFF_H$).

The actual implementation of the WUCE implementation simply performs the subtraction B–A with each clock cycle and it suspends the MCS channel as long as bit W-1 of the subtraction result is set. If the bit W-1 of the subtraction result is cleared the MCS channel is resumed immediately. In order to setup a WUCE instruction correctly, the counting direction of the TBU channel has to be considered. If the TBU channel is counting forward (incrementing), the operand A (A ∈ OREG) must refer the compare value and operand B (B ∈ OREG) must refer the desired TBU counter register (e.g. TBU_TS0). On the other hand, if the TBU channel is counting backward (decrementing), the operand A refers the desired TBU counter register and operand B refers the compare value. If the comparison condition evaluates to true, the suspended MCS channel is resumed and the program counter PC is incremented by the value 4 meaning that the MCS channel continues its program. However, if the condition is true at the beginning of the instruction execution, the instruction does not suspend the channel and the program counter PC is incremented by the value 4. At the beginning of the instruction execution the CWT bit in the register STA is always cleared. After the execution of the instruction the CWT bit is updated in order to show if the instruction finished successfully (CWT = 0) or it was canceled by the CPU (CWT = 1).

(71) NOP Instruction

Syntax: NOP

Encoding: 0000----------

Operation: —

Status: —

Duration: 1 instruction cycle

Description: No operation is performed.
The program counter PC is incremented by the value 4.

38.19.9 MCS Internal Register Overview

Table 38.245 Register list

Symbol	Register Name	Details in Section
R[y]	General Purpose Register y	**38.19.10.1**
RS[y]	Mirror of succeeding channels register R[y]	**38.19.10.2**
STA	Control and status register	**38.19.10.3**
ACB	ARU Control Bit Register	**38.19.10.4**
CTRG	Clear Trigger Bits Register	**38.19.10.5**
STRG	Set Trigger Bits Register	**38.19.10.6**
TBU_TS0	TBU Timestamp TS0 Register	**38.19.10.7**
TBU_TS1	TBU Timestamp TS1 Register	**38.19.10.8**
TBU_TS2	TBU timestamp TS2 register	**38.19.10.9**
MHB	Memory high bits register	**38.19.10.10**
GMI0	GTM module interrupt 0 register	**38.19.10.11**
GMI1	GTM module interrupt 1 register	**38.19.10.12**
DSTA	DPLL status register	**38.19.10.13**
DSTAX	DPLL extended status register	**38.19.10.14**
AXIMI	AXI Master interrupt register	**38.19.10.15**

38.19.10 MCS Internal Register Description

This section describes the MCS internal registers that can be directly addressed with the MCS instruction set. Many of the registers can also be addressed by the CPU but with another Register Label (for details see **Section 38.19.12, MCS Configuration Registers Description**). Some of the internal registers are also shared between neighboring MCS channels.

38.19.10.1 R[y]

Access: This register can be read or written in 24-bit units.

Address: —

Value after reset: Undefined

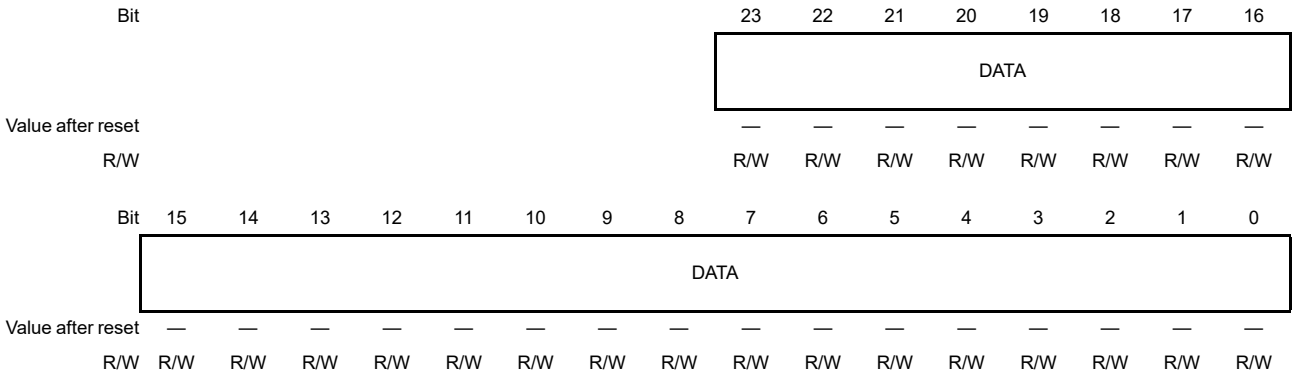

Table 38.246 R[y] Register Contents

Bit Position	Bit Name	Function
23 to 0	DATA	Data field of general purpose register.

Note: Register R4 is also used as destination register of upper multiplication result from instructions MULU and MULS.
Register R5 is also used as offset register for the instructions MRDIO and MWRIO.
Register R6 is also used as a mask register for the instruction WURMX and WURCX.
Register R6 is also used as address destination register for the instructions JMPI, JBSI, JBCI, and CALLI.
Register R6 used also as index/address register for indirect ARU addressing instructions.
Register R7 is also used as stack pointer register, if stack operations are used in the MCS micro program.

38.19.10.2 RS[y]

Access: This register can be read or written in 24-bit units.

Address: —

Value after reset: Undefined

Bit	23	22	21	20	19	18	17	16
	DATA							
Value after reset	—	—	—	—	—	—	—	—
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	DATA															
Value after reset	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 38.247 RS[y] Register Contents

Bit Position	Bit Name	Function
23 to 0	DATA	Data field of general purpose register.

Note 1. The register RS[y] (with y = 0 ... 7) mirrors the internal general purpose register R[y] of the succeeding MCS channel. The successor of MCS channel T-1 is MCS channel 0.

Note 2. The registers RS[y] can only be accessed if bit EN_XOREG of register MCS[i]_CTRL_STAT is set.

38.19.10.3 STA

Access: This register can be read or written in 24-bit units.

Address: —

Value after reset: Undefined

Bit	23	22	21	20	19	18	17	16
	—	—	—	—	—	SP_CNT		
Value after reset	—	—	—	—	—	—	—	—
R/W	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	SAT	CWT	CAT	N	V	Z	CY	MCA	ERR	IRQ	EN
Value after reset	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W

Table 38.248 STA Register Contents (1/4)

Bit Position	Bit Name	Function
23 to 19	Reserved	When read, an undefined value is read. When writing, always write 0.
18 to 16	SP_CNT	Stack pointer counter value. **NOTE** Actual stack depth of channel. The bit field is incremented on behalf of a CALL or PUSH instruction and decremented on behalf of a RET or POP instruction. The MCS channel STK_ERR_IRQ is raised, when an overflow or underflow is detected on this bit field.
15 to 11	Reserved	When read, an undefined value is read. When writing, always write 0.
10	SAT	Successful ARU transfer bit. 0: Latest ARU data transfer failed. 1: Latest ARU data transfer finished successfully. **NOTE** This bit is always updated after the execution of ARU instructions in order to show if the ARU data transfer was successful or not. In the case of non-blocking ARU instructions (NARD, NARDI) a cleared SAT flag signalizes that the data source has no data available and in the case of blocking ARU instructions (ARD, ARDI, AWR, AWRI) a cleared SAT flag signalizes that the data transfer was canceled by the CPU.
9	CWT	Cancel WURM instruction bit. 0: No cancellation request for waiting instruction. 1: CPU requested cancellation for waiting instruction. **NOTE** This bit is always cleared at the beginning of the execution of a WURM, WURMX, or WURCX instruction. A cancellation request can be applied by a write request to register MCS[i]_CWT. If the MCS program needs to detect a cancellation request it should evaluate the bit CWT immediately after the cancelled instruction.

Table 38.248 STA Register Contents (2/4)

Bit Position	Bit Name	Function
8	CAT	Cancel ARU transfer bit. 0: No cancellation request for ARU transfer. 1: CPU requested cancellation for ARU transfer. **NOTE** This bit is always cleared at the beginning of the execution of a blocking ARU instruction. A cancellation request can be applied by a write request to register MCS[i]_CAT. If the MCS program needs to detect a cancellation request it should evaluate the bit CAT immediately after the cancelled instruction.
7	N	Negative bit. The negative bit is updated by arithmetic instructions in order to indicate a negative result.
6	V	Overflow bit. The overflow bit is updated by arithmetic instructions in order to indicate a signed under/overflow.
5	Z	Zero bit. The zero bit is updated by several arithmetic, logic and data transfer instructions to indicate a result of zero.
4	CY	Carry bit. The carry bit is updated by several arithmetic and logic instructions. In arithmetic operations, the carry bit indicates an unsigned under/overflow.
3	MCA	MON Activity signalling for MCS channel. 0: No activity signalled to sub module MON. 1: Activity signalled to sub module MON. **NOTE** When this bit is set the corresponding channel in the MON sub module register MON_ACTIVITY is set (see **Section 38.26.8.2, MON_ACTIVITY_0**. This bit is automatically cleared after writing it by the MCS channel program.

Table 38.248 STA Register Contents (3/4)

Bit Position	Bit Name	Function
2	ERR	Set Error Signal. READ access 0: No Error occurred 1: Error occurred. WRITE access 0: No action. 1: Set Error bit. **NOTES** 1. The ERR bit of an MCS-channel reflects an Error status that may be caused by one of the following conditions: – MCS-channel sets the ERR bit by software (e.g. with instruction MOVL STA, 0x4) – ECC RAM Error occurred while accessing the connected RAM (also disables the MCS-channel by clearing bit EN and the first error occurred updates bit field ERR_SRC_ID of register MCS[i]_CTRL_STAT) – Decoding an instruction with an invalid opcode (also disables the MCS-channel by clearing bit EN and the first error occurred updates bit field ERR_SRC_ID of register MCS[i]_CTRL_STAT) – A memory address range overflow occurred (also disables the MCS-channel by clearing bit EN and the first error occurred updates bit field ERR_SRC_ID of register MCS[i]_CTRL_STAT) – Division by zero resulting from a DIVU or DIVS instruction (also disables the MCS-channel by clearing bit EN and the first error occurred updates bit field ERR_SRC_ID of register MCS[i]_CTRL_STAT). – MCS channel wants to write to a GPR that is write protected by register MCS[i]_REG_PROT (also disables the MCS-channel by clearing bit EN and the first error occurred updates bit field ERR_SRC_ID of register MCS[i]_CTRL_STAT). – MCS channel wants to write to a protected memory range defined by an address range protector (ARP) of the sub module CCM (also disables the MCS-channel by clearing bit EN and the first error occurred updates bit field ERR_SRC_ID of register MCS[i]_CTRL_STAT). – MCS channel performs an invalid AEI bus master access while the bit field HLT_AEIM_ERR of register MCS[i]_CTRL_-STAT is set (also disables the MCS-channel by clearing bit EN and the first error occurred updates bit field ERR_SRC_ID of register MCS[i]_CTRL_STAT) 2. If the ERR bit is set due to a memory address range overflow any read or write access to the RAM is blocked. 3. If the GTM includes a MON sub module, the ERR signal is always captured by this module. 4. An MCS-channel can set the error bit by writing value 1 to bit ERR. Writing a value 0 to this bit does not cancel the error signal, and thus has no effect. In Addition, writing a value 1 to ERR always triggers the ERR interrupt, independently from the current state of the error signal. 5. The ERR bit can only be cleared by CPU, by writing a 1 to the MCS[i]_ERR register (see **Section 38.19.12.18, MCS[i]_ERR**). 6. An MCS-channel can read the ERR bit in order to determine the current state of the error signal. The MCS-channel reads a value 1 if an ERR occurred previously, but not cleared by CPU. If an MCS-channel reads a value 0 no error was set or it has been cleared by CPU.

Table 38.248 STA Register Contents (4/4)

Bit Position	Bit Name	Function
1	IRQ	Trigger IRQ. READ access 0: No interrupt pending in MCS-channel x. 1: Interrupt is pending in MCS-channel x. WRITE access 0: No action. 1: Trigger interrupt. **NOTES** 1. An MCS-channel triggers an IRQ by writing value 1 to bit IRQ. Writing a value 0 to this bit does not cancel the IRQ, and thus has no effect. 2. This bit mirrors bit 0 of the register MCS[i]_CH[x]_IRQ_NOTIFY. 3. The IRQ bit can only be cleared by CPU, by writing a 1 to the corresponding MCS[i]_CH[x]_IRQ_NOTIFY register (see **Section 38.19.12.6, MCS[i]_CH[x]_IRQ_NOTIFY**). 4. An MCS-channel can read the IRQ bit in order to determine the current state of the IRQ handling. The MCS-channel reads a value 1 if an IRQ was released but not cleared by CPU. If an MCS-channel reads a value 0 no IRQ was released or it has been cleared by CPU. 5. If NPS > 5 and an MCS program triggers the IRQ (e.g. by MOVL STA, 0x2) the actual interrupt event is delayed by NPS–5 clock cycles, which means that an immediate read of the interrupt notify flag (e.g. by MOV R2, STA) may signalize the state of the IRQ bit before the trigger.
0	EN	Enable current MCS-channel. 0: Disable current MCS-channel. 1: Enable current MCS-channel.

Note: Writing to bits of the register STA with instructions that do implicitly a read−modify−write operation (e.g. "ANDL STA, 0xFFFFFE", "OR STA, R0", or "SETB STA, R0") is dangerous, since writing back the possibly modified content of the read access (which reflects status information) may cause undesirable results.
A secure way for writing to bits of this register is to use instructions that do not read the content (e.g. use instructions MOVL).

NOTES

1. The trigger bits TRGx are accessible by all MCS channels as well as the CPU. Setting a trigger bit can be performed with the STRG register, in the case of an MCS-channel or the MCS[i]_STRG register in the case of the CPU. Clearing a trigger bit can be performed with the CTRG register, in the case of an MCS-channel or the MCS[i]_CTRG register in the case of the CPU. Trigger bits can be used for signalizing specific events to MCS-channels or the CPU. An MCS-channel suspended with a WURM instruction can be resumed by setting the appropriate trigger bit.
2. Besides setting the trigger bits with register STRG/MCS[i]_STRG, the k-th trigger bit TRGk (with k < 16) can also be set by the external capture event that is enabled by the k-th bit of register CCM[i]_EXT_CAP_EN. If bit k bit is disabled, the k-th trigger bit TRGk can only be set by MCS or CPU.
3. The result of a read access to this register differs in dependency of the bit field EN_TIM_FOUT of register MCS[i]_CTRL_STAT.

CAUTION

Writing to bits of the register CTRG with instructions that do implicitly a read-modify-write operation (e.g. "OR CTRG, R0" or "SETB CTRG, R0") is dangerous, since writing back the possibly modified content of the read access (which reflects status information) may cause undesirable results. A secure way for writing to bits of this register is to use instructions that do not read the content (e.g. use instructions MOVL).

15 to 8	TTA_IP1_CH[x]_IRQ	Neighboring TIM, TOM, ATOM IRQs. READ access: 0: Logical OR conjunction of IRQ signals TIM[i+1]_CH[x]_IRQ, TOM[i+1]_CH[2*x]_IRQ, TOM[i+1]_CH[2*x+1]_IRQ, and ATOM[i+1]_CH[x]_IRQ is false 1: Logical OR conjunction of IRQ signals TIM[i+1]_CH[x]_IRQ, TOM[i+1]_CH[2*x]_IRQ, TOM[i+1]_CH[2*x+1]_IRQ, and ATOM[i+1]_CH[x]_IRQ is true WRITE access: 0: No action 1: Trigger hw_clear signal on the connected IRQs
7 to 0	MCS_IP1_CH[x]_IRQ	IRQ signal MCS[i+1]_CH[x]_IRQ. READ access: 0: IRQ signal MCS[i+1]_CH[x]_IRQ is cleared 1: IRQ signal MCS[i+1]_CH[x]_IRQ is set WRITE access: 0: No action 1:Trigger hw_clear signal on the connected IRQs

CAUTION

Writing to bits of the register GMI1 with instructions that do implicitly a read-modify-write operation (e.g. "OR GMI1, R0" or "SETB GMI1, R0") is dangerous, since writing back the possibly modified content of the read access (which reflects status information) may cause undesirable results. A secure way for writing to bits of this register is to use instructions that do not read the content (e.g. use instructions MOVL).

38.19.10.13 DSTA

Access: This register can be read or written in 24-bit units.

Address: —

Value after reset: Undefined

Bit	23	22	21	20	19	18	17	16

16	TASI	Trigger Active Slope Interrupt. READ access: 0: IRQ signal TASI of DPLL is cleared 1: IRQ signal TASI of DPLL is set WRITE access: 0: No Action 1:Trigger hw_clear signal on the connected IRQs
15 to 8	STA_S	Status State FSM. Actual status of DPLL State FSM. The description of the FSM states can be found in **Section 38.22.18.48, DPLL_STA**.

Table 38.258 DSTA Register Contents (2/2)

Bit Position	Bit Name	Function
7 to 0	STA_T	Status Trigger FSM. Actual status of DPLL Trigger FSM. The description of the FSM states can be found in **Section 38.22.18.48, DPLL_STA**.

NOTES

1. This register is only implemented in MCS instance 0. In other MCS instances, a read access always returns 0 and a write access is always ignored.
2. Writing to bits of the register DSTA with instructions that do implicitly a read-modify-write operation (e.g. "OR DSTA, R0" or "SETB DSTA, R0") is dangerous, since writing back the possibly modified content of the read access (which reflects status information) may cause undesirable results. A secure way for writing to bits of this register is to use instructions that do not read the content (e.g. use instructions MOVL).

38.19.10.14 DSTAX

Access: This register can be read or written in 24-bit units.

15 to 4	Reserved	When read, an undefined value is read. When writing, always write 0.

Table 38.259 DSTAX Register Contents (2/2)

Bit Position	Bit Name	Function
3	INC_CNT2_FLAG	DPLL INC_CNT2 Flag. DPLL status state flag as described in bit field definition INC_CNT2_FLAG of register DPLL_STA_FLAG (**Section 38.22.18.54, DPLL_STA_FLAG**).
2	INC_CNT1_FLAG	DPLL INC_CNT1 Flag. DPLL status state flag as described in bit field definition INC_CNT1_FLAG of register DPLL_STA_FLAG (**Section 38.22.18.54, DPLL_STA_FLAG**)
1	STA_FLAG_S	DPLL status state flag. DPLL status state flag as described in bit field definition STA_FLAG_S of register DPLL_STA_FLAG (**Section 38.22.18.54, DPLL_STA_FLAG**).
0	STA_FLAG_T	DPLL status trigger flag. DPLL status trigger flag as described in bit field definition STA_FLAG_T of register DPLL_STA_FLAG (**Section 38.22.18.54, DPLL_STA_FLAG**).

NOTES

1. This register is only implemented in MCS instance 0. In other MCS instances, a read access always returns 0 and a write access is always ignored.
2. Writing to bits of the register DSTAX with instructions that do implicitly a read-modify-write operation (e.g. "OR DSTAX, R0" or "SETB DSTAX, R0") is dangerous, since writing back the possibly modified content of the read access (which reflects status information) may cause undesirable results. A secure way for writing to bits of this register is to use instructions that do not read the content (e.g. use instructions MOVL).

38.19.10.15 AXIMI

Access: This register can be read or written in 24-bit units.

Address: —

Value after reset: Undefined

Bit	23	22	21	20	19	18	17	16

Table 38.260 AXIMI Register Contents

Bit Position	Bit Name	Function
23 to 0	AEIM_AXIM_IRQ[x]	IRQ signal of AXI bus master slot x. READ access: 0: IRQ signal AEIM_AXIM_IRQ[x] is cleared 1: IRQ signal AEIM_AXIM_IRQ[x] is set WRITE access: 0: No action 1: Trigger signal AEIM_AXIM_IRQ_CLR[i]

CAUTION

Writing to bits of the register AXIMI with instructions that do implicitly a read-modify-write operation (e.g. "OR AXIMI, R0" or "SETB AXIMI, R0") is dangerous, since writing back the possibly modified content of the read access (which reflects status information) may cause undesirable results. A secure way for writing to bits of this register is to use instructions that do not read the content (e.g. use instructions MOVL).

38.19.11 MCS Configuration Registers Overview

The MCS Configuration registers of the MCS module are accessible by the AEI bus interface. Some of these registers simply mirror MCS Internal registers to the AEI. Details can be found in the table below and in the individual register descriptions.

Table 38.261 Register list

Symbol	Register Name	Details in Section
MCS[i]_CH[x]_CTRL	MCSi channel x control register	**38.19.12.1**
MCS[i]_CH[x]_ACB	MCSi channel x ARU control Bit register	**38.19.12.4**
MCS[i]_CH[x]_MHB	MCSi channel x memory high byte register	**38.19.12.5**
MCS[i]_CH[x]_PC	MCSi channel x program counter register	**38.19.12.2**
MCS[i]_CH[x]_R[y]	MCSi channel x general purpose register y	**38.19.12.3**
MCS[i]_CH[x]_IRQ_NOTIFY	MCSi channel x interrupt notification register	**38.19.12.6**
MCS[i]_CH[x]_IRQ_EN	MCSi channel x interrupt enable register	**38.19.12.7**
MCS[i]_CH[x]_IRQ_FORCINT	MCSi channel x force interrupt register	**38.19.12.8**
MCS[i]_CH[x]_IRQ_MODE	MCSi channel x IRQ mode configuration register	**38.19.12.9**
MCS[i]_CH[x]_EIRQ_EN	MCSi channel x error interrupt enable register	**38.19.12.10**
MCS[i]_CTRL_STAT	MCSi control and status register	**38.19.12.11**
MCS[i]_REG_PROT	MCSi write protection register	**38.19.12.12**
MCS[i]_CTRG	MCSi clear trigger control register	**38.19.12.13**
MCS[i]_STRG	MCSi set trigger control register	**38.19.12.14**
MCS[i]_RESET	MCSi reset register	**38.19.12.15**
MCS[i]_CAT	MCSi cancel ARU transfer instruction	**38.19.12.16**
MCS[i]_CWT	MCSi cancel waiting instruction	**38.19.12.17**
MCS[i]_ERR	MCSi error register	**38.19.12.18**
MCS[i]_MEM	MCSi memory region	**38.19.12.19**

38.19.12 MCS Configuration Registers Description

38.19.12.1 MCS[i]_CH[x]_CTRL

Access: This register can be read or written in 32-bit units.

Address: <GTM_base> + 1000_H× i + 80_H× x + $F0020_H$

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	SP_CNT		
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	SAT	CWT	CAT	N	V	Z	CY	—	ERR	IRQ	EN
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Table 38.262 MCS[i]_CH[x]_CTRL Register Contents (1/3)

Bit Position	Bit Name	Function
31 to 19	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
18 to 16	SP_CNT	Stack pointer counter value. Actual stack depth of channel. The bit field is incremented on behalf of a CALL or PUSH instruction and decremented on behalf of a RET or POP instruction. The MCS channel STK_ERR_IRQ is raised, when an overflow or underflow is detected on this bit field.
15 to 11	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
10	SAT	Successful ARU transfer bit. **NOTE** This bit is read only and it mirrors the internal state of the ARU transfer status flag SAT.
9	CWT	Cancel WURM instruction state. READ access: 0: No cancellation request for waiting instruction 1: CPU requested cancellation for waiting instruction **NOTES** 1. This bit is always cleared at the beginning of the execution of a WURM, WURMX, or WURCX instruction. A cancellation request can be applied by a write request to register MCS[i]_CWT. If the MCS program needs to detect a cancellation request it should evaluate the bit CWT immediately after the canceled instruction. 2. This bit is read only and it mirrors the internal cancel WURM instruction status flag CWT.

Table 38.262 MCS[i]_CH[x]_CTRL Register Contents (2/3)

Bit Position	Bit Name	Function
8	CAT	Cancel ARU transfer state. 0: No cancellation request for ARU transfer 1: CPU requested cancellation for ARU transfer **NOTES** 1. This bit is always cleared at the beginning of the execution of a blocking ARU instruction. A cancellation request can be applied by a write request to register MCS[i]_CAT. If the MCS program needs to detect a cancellation request it should evaluate the bit CAT immediately after the canceled instruction. 2. This bit is read only and it mirrors the internal state of the ARU transfer status flag CAT.
7	N	Negative bit state. **NOTE** This bit is read only and it mirrors the internal zero flag N.
6	V	Overflow bit state. **NOTE** This bit is read only and it mirrors the internal carry flag V.
5	Z	Zero bit state. **NOTE** This bit is read only and it mirrors the internal zero flag Z.
4	CY	Carry bit state. **NOTE** This bit is read only and it mirrors the internal carry flag CY.
3	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
2	ERR	Error state. 0: No error signal pending in MCS-channel x 1: Error signal is pending in MCS-channel x **NOTE** This bit is read only and it mirrors the internal error state.
1	IRQ	Interrupt state. 0: No interrupt pending in MCS-channel x 1: Interrupt is pending in MCS-channel x **NOTE** This bit is read only and it mirrors the internal IRQ state.

Table 38.262 MCS[i]_CH[x]_CTRL Register Contents (3/3)

Bit Position	Bit Name	Function
0	EN	Enable/Disable Request of MCS-channel x. READ access: 0: MCS channel x is disabled 1: MCS channel x is enabled WRITE access: 0: Request for disabling MCS-channel x 1: Request for enabling MCS-channel x **NOTES** 1. Enabling or disabling of an MCS-channel is synchronized to the ending of an instruction and thus it may take several clock cycles, e.g. active memory transfers or pending WURM instruction have to be finished before disabling the MCS-channel. The current internal state of a channel can be obtained by reading the bit EN. 2. To disable an MCS channel reliably the EN bit should be cleared followed by setting the CAT and CWT bit in order to cancel any pending waiting or ARU instructions. 3. The EN bit is write protected during RAM reset phase.

38.19.12.2 MCS[i]_CH[x]_PC

Access: This register can be read or written in 32-bit units.

Address: <GTM_base> + 1000_H× i + 80_H× x + $F0040_H$

Value after reset: 0000 0000+4*x_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

	PC															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 38.263 MCS[i]_CH[x]_PC Register Contents

Bit Position	Bit Name	Function
31 to 16	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
15 to 0	PC	Current Program Counter. **NOTES** 1. The program counter is only writable if the corresponding MCS-channel is disabled. The bits 0 and 1 are always written as zeros. 2. The actual width of the program counter depends on the MCS configuration. The actual width is RAW+USR+2 bits meaning that only the bits 0 to RAW+USR+1 are available and the other bits (RAW+USR+2 to 31) are reserved.

38.19.12.3 MCS[i]_CH[x]_R[y]

Access: This register can be read or written in 32-bit units.

Address: MCS[i]_CH[x]_R0: <GTM_base> + 1000_H× i + 80_H× x + $F0000_H$
MCS[i]_CH[x]_R1: <GTM_base> + 1000_H× i + 80_H× x + $F0004_H$
MCS[i]_CH[x]_R2: <GTM_base> + 1000_H× i + 80_H× x + $F0008_H$
MCS[i]_CH[x]_R3: <GTM_base> + 1000_H× i + 80_H× x + $F000C_H$
MCS[i]_CH[x]_R4: <GTM_base> + 1000_H× i + 80_H× x + $F0010_H$
MCS[i]_CH[x]_R5: <GTM_base> + 1000_H× i + 80_H× x + $F0014_H$
MCS[i]_CH[x]_R6: <GTM_base> + 1000_H× i + 80_H× x + $F0018_H$
MCS[i]_CH[x]_R7: <GTM_base> + 1000_H× i + 80_H× x + $F001C_H$

Value after reset: $0000\ 0000_H$

Table 38.267 MCS[i]_CH[x]_IRQ_NOTIFY Register Contents (1/2)

Bit Position	Bit Name	Function
31 to 3	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
2	ERR_IRQ	MCS channel x ERR interrupt. READ access: 0: IRQ notify flag is cleared 1: IRQ notify flag is set WRITE access: 0: No action 1: Clear IRQ notify flag **NOTES** 1. If the ERR bit of register STA is triggered the ERR_IRQ will also be set. 2. This bit will be cleared on a CPU write access with a value ‘1’. A read access leaves the bit unchanged.
1	STK_ERR_IRQ	Stack counter overflow/underflow of channel x. READ access: 0: IRQ notify flag is cleared 1: IRQ notify flag is set WRITE access: 0: No action 1: Clear IRQ notify flag **NOTE** This bit will be cleared on a CPU write access with a value ‘1’. A read access leaves the bit unchanged.

Table 38.267 MCS[i]_CH[x]_IRQ_NOTIFY Register Contents (2/2)

Bit Position	Bit Name	Function
0	MCS_IRQ	Interrupt request by MCS-channel x. READ access: 0: IRQ notify flag is cleared 1: IRQ notify flag is set WRITE access: 0: No action 1: Clear IRQ notify flag **NOTES** 1. This bit will be cleared on a CPU write access with a value '1'. A read access leaves the bit unchanged. 2. By writing a '1' to this register, the IRQ flag in the MCS channel status register STA is cleared.

38.19.12.7 MCS[i]_CH[x]_IRQ_EN

Access: This register can be read or written in 32-bit units.

Table 38.272 MCS[i]_CTRL_STAT Register Contents (1/3)

Bit Position	Bit Name	Function
31 to 27	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
26	HLT_AEIM_ERR	Halt on AEI bus master error. 0: Ignore invalid AEI bus master access 1: Halt MCS-channel on invalid AEI bus master access **NOTES** 1. If the register HLT_AEIM_ERR is set and an MCS channel x is executing an invalid bus master access, the MCS channel x is halted, the ERR bit of its register STA is set and the bit field ERR_SRC_ID of this register is updated. 2. If the bus master is accessing a slave that does not insert wait cycles (e.g. register access) it takes two additional clock cycles until the MCS channel is halted. Within that time spawn the MCS channel can continue with its program execution, depending on the selected scheduling mode. 3. The registers AEIM_XPT_STA and AEIM_XPT_ADDR of the GTM sub module CCM are always updated on the first invalid AEI bus master access, independently of the state of HLT_AEIM_ERR.
25	EN_XOREG	Enable extended register set. 0: Extended operation register sets XOREG, BAREG, and WXREG are disabled 1: Extended operation register sets XOREG, BAREG, and WXREG are enabled **NOTE** If the extended operation register sets are disabled, the MCS instructions can only use the subset OREG of the register set as arguments in the instructions. In this case the upper address bits in the instructions are always read as zeros, which leads to unexpected results of the MCS program if arguments A or B refer a register that is not part or OREG.
24	EN_TIM_FOUT	Enable routing of TIM[i]_CH[x]_F_OUT signal. 0: Read access to register CTRG/MCS[i]_CTRG provides state of the internal trigger registers. 1: Read access to register CTRG/MCS[i]_CTRG provides state of the external signal TIM[i]_CH[x]_F_OUT.

Table 38.272 MCS[i]_CTRL_STAT Register Contents (2/3)

Bit Position	Bit Name	Function
23	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
22 to 20	ERR_SRC_ID	Error source identifier. 000_B: No HW generated Error occurred 001_B: Detected ECC error 010_B: Detected memory overflow 011_B: Detected invalid opcode 100_B: Divide by zero 101_B: Invalid register write access to GPR from write protected channel 110_B: Invalid memory write access to protected memory region 111_B: Invalid AEI bus master access **NOTE** This register is updated once, if an error was detected by the MCS. The register is set to its initial value 000 after each write access to an existing ERR bit in the register MCS[i]_ERR. If multiple errors occur, ERR_SRC_ID is holding the first type of error which has occurred.
19, 18	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
17	HLT_SP_OFL	Halt on stack pointer overflow. 0: No halt on MCS-channel stack pointer counter over/underflow. 1: MCS-channel is disabled if a stack pointer counter over/underflow occurs.
16	RAM_RST	RAM reset bit READ access: 0: No RAM reset is active 1: MCS currently resets RAM content WRITE access: 0: No action 1: Initiate RAM reset **NOTES** 1. The RAM reset initializes the memory content with zeros. RAM access and enabling of MCS channels is disabled during active RAM reset. 2. This bit is only writable if the bit RF_PROT in register GTM_CTRL is cleared and all MCS-channels are disabled. 3. The actual reset values of this bit depends on the silicon vendor configuration. The reset value is 1, if the RAM reset is performed together with the sub module reset, otherwise the reset value is 0. If the reset value is 1, the reset value is changed to 0 by hardware, when the RAM reset finished.
15 to 12	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
11 to 8	SCD_CH	Channel selection for scheduling algorithm. MCS-channel identifier used by several scheduling modes in different ways. Details about its usage can be found in **Section 38.19.3**. **NOTE** The actual width of the bit field SCD_CH is calculated as $\lceil \log2(T+1) \rceil$. Unused MSBs are reserved and read as zero.
7 to 2	Reserved	When read, the value after reset is returned. When writing, write the value after reset.

Table 38.272 MCS[i]_CTRL_STAT Register Contents (3/3)

Bit Position	Bit Name	Function
1, 0	SCD_MODE	Select MCS scheduling mode 00_B: Accelerated Scheduling. 01_B: Round Robin Scheduling. 10_B: Single Priority Scheduling. 11_B: Multiple Priority Scheduling.

38.19.12.12 MCS[i]_REG_PROT

Access: This register can be read or written in 32-bit units.

Address: <GTM_base> + 1000_H× i + $F0060_H$

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 38.273 MCS[i]_REG_PROT Register Contents

Bit Position	Bit Name	Function
31 to 16	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
15 to 0	WPROT[7:0]	Register Write Protection of MCS-channel k. 00_B: No register write protection activated 01_B: Predecessor MCS channel cannot write to its RS[y] registers 10_B: Current MCS channel cannot write to its R[y] registers 11_B: Reserved

NOTES

1. Only the first T bit fields of this register (bit 0 to 2*T-1) are functionally implemented. The other bits (bit 2*T to 31) are reserved bit fields.
2. The predecessor channel of MCS channel 0 is MCS channel T-1.
3. If an MCS channel x is writing to a general purpose register that is write protected by register MCS[i]_REG_PROT the ERR bit of the register STA is set, the MCS channel x is halted and the ERR_SRC_ID bit field of register MCS[i]_CTRL_STAT is updated.
4. This register is only writable if the bit RF_PROT in register GTM_CTRL is cleared.

38.19.12.13 MCS[i]_CTRG

Access: This register can be read or written in 32-bit units.

Address: <GTM_base> + 1000_H× i + $F0028_H$

Value after reset: 0000 0000_H

Table 38.274 MCS[i]_CTRG Register Contents

Bit Position	Bit Name	Function
31 to 24	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
23 to 16	TRG[23:16]	Trigger bit [23:16]. READ access: 0: Trigger bit is cleared 1: Trigger bit is set WRITE access: 0: No action 1: Clear trigger bit
15 to 0	TRG[15:0]	Trigger bit [7:0]. READ access: if bitfield EN_TIM_FOUT = 0 0: Trigger is cleared 1: Trigger is set Trigger bit i[15:8]. READ access: if bitfield EN_TIM_FOUT = 1 0: Input signal TIM[i]_CH0_F_OUT is cleared 1: Input signal TIM[i]_CH0_F_OUT is set WRITE access: 0: No action 1: Clear trigger bit

NOTES

1. The trigger bits TRGx are accessible by all MCS channels as well as the CPU. Setting a trigger bit can be performed with the STRG register, in the case of an MCS-channel or the MCS[i]_STRG register in the case of the CPU. Clearing a trigger bit can be performed with the CTRG register, in the case of an MCS-channel or the MCS[i]_CTRG register in the case of the CPU. Trigger bits can be used for signalizing specific events to MCS-channels or the CPU. An MCS-channel suspended with a WURM instruction can be resumed by setting the appropriate trigger bit.
2. Besides setting the trigger bits with register STRG/MCS[i]_STRG, the k-th trigger bit TRGk (with k < 16) can also be set by the external capture event that is enabled by the k-th bit of register CCM[i]_EXT_CAP_EN. If bit k bit is disabled, the k-th trigger bit TRGk can only be set by MCS or CPU.
3. In the scheduling modes Accelerated Scheduling and Round Robin Scheduling, a write access to MCS[i]_CTRG may take up to T + 1 clock cycles, since the write access is scheduled to the next CPU time slot determined by the MCS scheduler. In the modes Single Prioritization Scheduling and Multiple Prioritization Scheduling, no upper limit access time for a write access to MCS[i]_CTRG can be guaranteed. The High Prioritized tasks have to be disabled in order to guarantee fast write access to MCS[i]_CTRG.
4. The result of a read access to this register differs in dependency of the bit field EN_TIM_FOUT of register MCS[i]_CTRL_STAT.

38.19.12.14 MCS[i]_STRG

Access: This register can be read or written in 32-bit units.

Table 38.275 MCS[i]_STRG Register Contents

Bit Position	Bit Name	Function
31 to 24	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
23 to 0	TRG[23:0]	Trigger bit [23:0]. READ access: 0: Trigger bit is cleared 1: Trigger bit is set WRITE access: 0: No action 1: Set trigger bit **NOTES** 1. The trigger bits TRGx are accessible by all MCS channels as well as the CPU. Setting a trigger bit can be performed with the STRG register, in the case of an MCS-channel or the MCS[i]_STRG register in the case of the CPU. Clearing a trigger bit can be performed with the CTRG register, in the case of an MCS-channel or the MCS[i]_CTRG register in the case of the CPU. Trigger bits can be used for signalizing specific events to MCS-channels or the CPU. An MCS-channel suspended with a WURM instruction can be resumed by setting the appropriate trigger bit. 2. Besides setting the trigger bits with register STRG/MCS[i]_STRG, the k-th trigger bit TRGk (with k < 16) can also be set by the external capture event that is enabled by the k-th bit of register CCM[i]_EXT_CAP_EN. If bit k bit is disabled, the k-th trigger bit TRGk can only be set by MCS or CPU. 3. In the scheduling modes Accelerated Scheduling and Round Robin Scheduling, a write access to MCS[i]_STRG may take up to T + 1 clock cycles, since the write access is scheduled to the next CPU time slot determined by the MCS scheduler. In the modes Single Prioritization Scheduling and Multiple Prioritization Scheduling, no upper limit access time for a write access to MCS[i]_STRG can be guaranteed. The High Prioritized tasks have to be disabled in order to guarantee fast write access to MCS[i]_STRG.

38.19.12.15 MCS[i]_RESET

Access: This register can be read or written in 32-bit units.

Bit Position	Bit Name	Function
31 to 9	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
8 to 0	RST[8:0]	Software reset of channel [8:0] READ access: 0: No status WRITE access: 0: No action 1: Reset channel [8:0] **NOTES** 1. The RSTx (x = 0 ...T-1) bits is cleared automatically after write access of CPU. All channel related registers of channel x are set to their reset values and channel operation is stopped immediately. 2. Channel related registers of channel x are all registers MCS[i]_CH[x]_*, all MCS internal registers accessible by the corresponding channel, with exception of the common trigger register (accessed by MCS[i]_CTRG/ MCS[i]_STRG).

38.19.12.16 MCS[i]_CAT

Access: This register can be read or written in 32-bit units.

Address: <GTM_base> + 1000_H× i + $F006C_H$

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 38.279 MCS[i]_ERR Register Contents

Bit Position	Bit Name	Function
31 to 8	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
7 to 0	ERR[7:0]	Error State of MCS-channel [7:0]. READ access: 0: Error bit is cleared 1: Error bit is set WRITE access: 0: No action 1: Clear error bit **NOTES** 1. The CPU can read the ERRx (x = 0...T-1) bits in order to determine the current error state of the corresponding MCS-channel x. 2. The error state is also evaluated by the sub module MON, if this module is available. 3. Writing a value 1 to this bit resets the corresponding error state and resets the channel internal ERR bit in the STA and channel CTRL registers. Moreover, each write access to this bit also sets the ERR_SRC_ID bit field of register MCS[i]_CTRL_STAT to its reset value.

38.19.12.19 MCS[i]_MEM

Access: This register can be read or written in 32-bit units.

38.20 Memory Configuration (MCFG)

38.20.1 Overview

The Memory Configuration sub-module (MCFG) is an infrastructure module that organizes physical memory blocks and maps them to the RAM ports 0 and 1 of available Multi Channel Sequencer (MCS) modules.

The following parameters are design variables for the MCFG hardware structure that can vary in its range for different devices:

- MAW - Memory address width of a large physical memory block.
- ERM - Enable RAM1 MSB (0 - RAM1 MSB disabled,
  1 - RAM1 MSB enabled,

The actual values for these parameters can be obtained from the device specific **Section 38.28, GTM Device 358**. It should be noted that the actual value of the parameter ERM can be obtained by the bit ERM of the register CCM[i]_HW_CONF.

Depending on the value of parameter ERM, the MCFG module assumes externally connected physical RAM modules with different sizes. If ERM = 0, MCFG assumes that each MCS instance provides a large physical memory block with 2^{MAW} memory locations each 32-bit wide which leads to a RAM module with 2^{MAW+2} memory addresses. Further each MCS instance provides a small physical memory block with 2^{MAW-1} memory locations each 32-bit wide leading to a RAM module with 2^{MAW+1}(byte wise) memory addresses. If ERM = 1, MCFG assumes that each MCS instance provides two large physical memory block each with 2^{MAW} memory locations each 32-bit leading to a RAM module with 2^{MAW+2}(byte wise) memory addresses.

In order to support different memory sizes for different MCS instances, the MCFG module provides three layout configurations for reorganization of memory pages mapped to the RAM ports of neighboring MCS modules. **Table 38.281, Memory Layout Configurations (ERM = 0)** shows all layout configurations for the case that ERM = 0 and **Table 38.283, Memory Layout Configurations (ERM = 1)** shows the layout configurations for the case that ERM = 1. Each box in these pictures represents a physical memory block.

The layout configuration DEFAULT is always assigning a memory block of size $2^{MAW} \times 32$ bits to MCS RAM port 0. Depending on ERM, RAM port 1 of each MCS is whether assigned to a memory block of size $2^{MAW-1} \times 32$ bits (ERM = 0) or a memory block of size $2^{MAW} \times 32$ bits (ERM = 1).

The layout configuration SWAP is swapping the memory block assigned to RAM port 1 of the current MCS instance with the memory block assigned to RAM port 0 of the successive MCS instance. If ERM = 0, this means that the memory of the current MCS instance is increased by $2^{MAW-1} \times 32$ bits but the memory of the successor is decreased by $2^{MAW-1} \times 32$ bits compared to the DEFAULT configuration. If ERM = 1, the SWAP configuration has no effect on the memory sizes of the individual MCS instances.

The layout configuration BORROW is borrowing the memory block assigned to RAM port 0 of the successive MCS instance for the current instance. This means, the memory of the current MCS module is increased by $2^{MAW} \times 32$ bits but the memory of the successor is decreased by $2^{MAW} \times 32$ bits compared to the DEFAULT configuration.

Considering the order the mentioned MCS modules, it should be noted that the successor of the last MCS instance is the first MCS instance MCS0.

The actual sizes of the memory pages mapped to the MCS RAM ports 0 and 1 depends on the layout configuration for of current instance MCS[i] and the layout configuration of the preceding memory

instance MCS[i-1]. The sizes of these memory pages can be obtained by the layout parameters MP0 and MP1, as described in the specification of the MCS.

Table 38.282, Memory Layout Parameters (ERM = 0) and **Table 38.284, Memory Layout Parameters (ERM = 1)** summarize the layout parameters MP0 and MP1 of MCS instance MCS[i] for the case that ERM = 0 and ERM = 1. Note that the predecessor of instance MCS0 is last available MCS instance.

The addressing of memory port 0 ranges from 0 to MP0–4 and the addressing of memory page 1 ranges from MP0 to MP1–4.

This document assumes that the GTM implementation embeds 8 MCS instances. However, the actual number of implemented MCS instances can be obtained from **Section 38.28, GTM Device 358**.

Table 38.286 MCFG_CTRL Register Contents (1/2)

Bit Position	Bit Name	Function
31 to 20	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
19, 18	MEM9	Configure Memory pages for MCS-instance MCS9. 00_B: DEFAULT configuration 01_B: SWAP configuration 10_B: BORROW configuration 11_B: Reserved
17,16	MEM8	Configure Memory pages for MCS-instance MCS8. 00_B: DEFAULT configuration 01_B: SWAP configuration 10_B: BORROW configuration 11_B: Reserved
15, 14	MEM7	Configure Memory pages for MCS-instance MCS7. 00_B: DEFAULT configuration 01_B: SWAP configuration 10_B: BORROW configuration 11_B: Reserved
13, 12	MEM6	Configure Memory pages for MCS-instance MCS6. 00_B: DEFAULT configuration 01_B: SWAP configuration 10_B: BORROW configuration 11_B: Reserved
11, 10	MEM5	Configure Memory pages for MCS-instance MCS5. 00_B: DEFAULT configuration 01_B: SWAP configuration 10_B: BORROW configuration 11_B: Reserved
9, 8	MEM4	Configure Memory pages for MCS-instance MCS4. 00_B: DEFAULT configuration 01_B: SWAP configuration 10_B: BORROW configuration 11_B: Reserved

Table 38.286 MCFG_CTRL Register Contents (2/2)

Bit Position	Bit Name	Function
7, 6	MEM3	Configure Memory pages for MCS-instance MCS3. 00_B: DEFAULT configuration 01_B: SWAP configuration 10_B: BORROW configuration 11_B: Reserved
5, 4	MEM2	Configure Memory pages for MCS-instance MCS2. 00_B: DEFAULT configuration 01_B: SWAP configuration 10_B: BORROW configuration 11_B: Reserved
3, 2	MEM1	Configure Memory pages for MCS-instance MCS1. 00_B: DEFAULT configuration 01_B: SWAP configuration 10_B: BORROW configuration 11_B: Reserved
1, 0	MEM0	Configure Memory pages for MCS-instance MCS0. 00_B: DEFAULT configuration 01_B: SWAP configuration 10_B: BORROW configuration 11_B: Reserved

Note 1. It should be noted that the actual GTM-IP implementation may embed less MCS instances than mentioned in this register (see [1]). In this case this register only implements the register bits for available MCS instances.

Note 2. This register is only writable if the bit RF_PROT in register GTM_CTRL is cleared.

38.21 TIM0 Input Mapping Module (MAP)

38.21.1 Overview

The MAP sub-module generates the two input signals TRIGGER and STATE for the sub-module DPLL by evaluating the output signals of the channel 0 up to channel 5 of sub-module TIM0. By using the TIM as input sub-module, the filtering of the input signals can be done inside the TIM channels themselves. The MAP sub-module architecture is depicted in **Figure 38.107**.

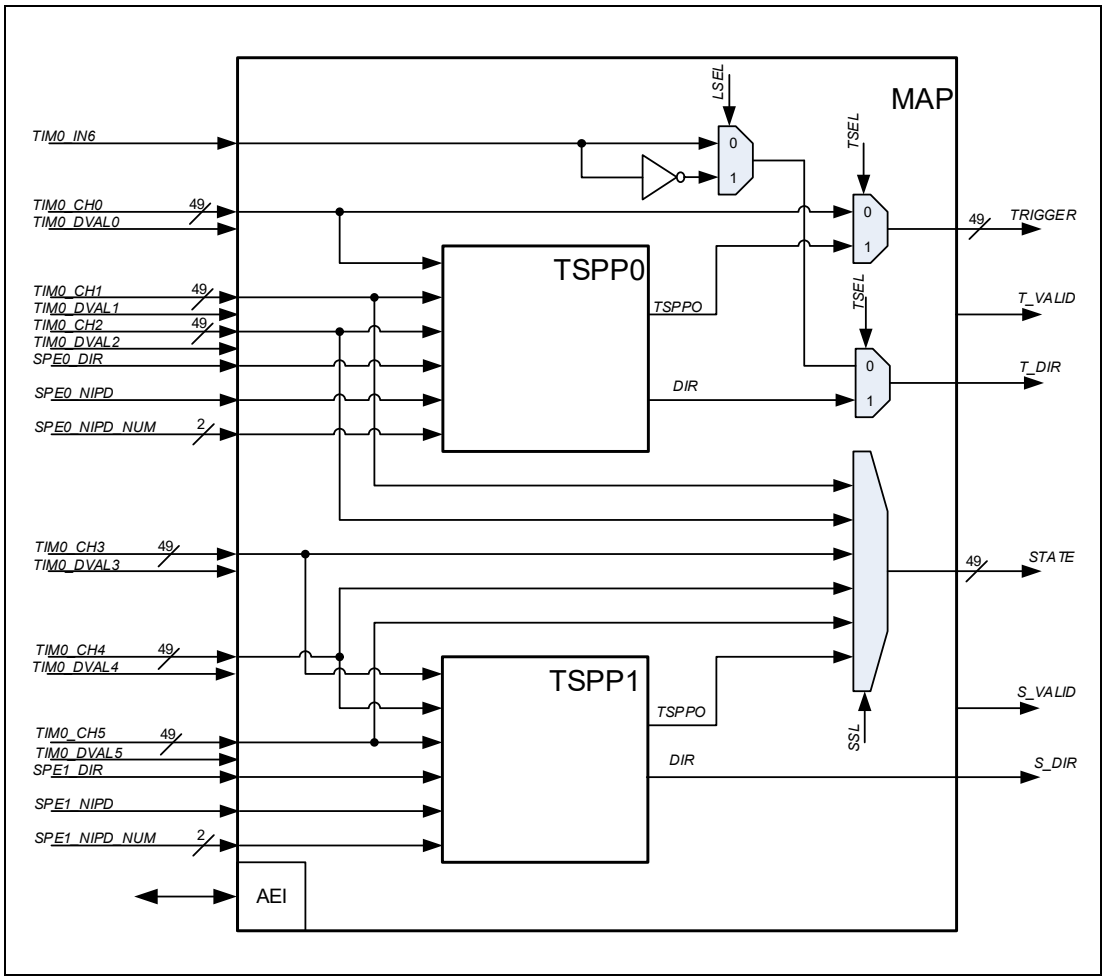

Figure 38.107 MAP sub-module architecture

Generally, the MAP sub-module can route the channel signals coming from TIM0 in three ways. First, it is possible to route the whole 49 bits of data coming from channel 0 of module TIM0 (TIM0_CH0) to the TRIGGER signal which is then provided to the DPLL together with the T_VALID signal.

Second, the MAP module can route one of the five signals coming from the module TIM0 (i.e. the signals coming from channel 1 up to channel 5) to the output signal STATE which is then provided to the module DPLL together with the S_VALID signal.

Third, the TRIGGER, T_VALID, STATE and S_VALID signals can be generated out of the TIM Signal Preprocessing (TSPP) subunits. This is done in combination with the Sensor Pattern Evaluation (SPE) sub-module described in **Section 38.23, Sensor Pattern Evaluation (SPE)**.

There, the signal TRIGGER is generated in subunit TSPP0 out of the TIM0 signals coming from channel 0 up to 2.

The signal STATE is generated in subunit TSPP1 out of the TIM signals coming from channel 3 up to channel 5.

This is only done, when the TSSPx subunits are enabled and when the SPEx_NIPD signal is raised by the SPE sub-module. The SPEx_NIPD_NUM signal encodes, which of the 3 TIMx_CHy input signals has been changed. The SPEx_DIR signal is routed through the TSPPx subunit and implements the T_DIR or S_DIR signal.

A third method to provide a direction signal to DPLL is to use TIM0 channel 6 input (TIM0_IN6) and to route it instead of the DIR signal coming from TSSOP0 to the MAP output T_DIR (set TSEL=0)

38.21.2 TIM Signal Preprocessing (TSPP)

The TSPP combines the three 49-bit input streams coming from the TIM0 sub-module and generates one combined 49-bit output stream

TSPPO. The input stream combination is done in the unit Bit Stream Combination (BSC). The architecture of the TSPP is shown in **Figure 38.108**.

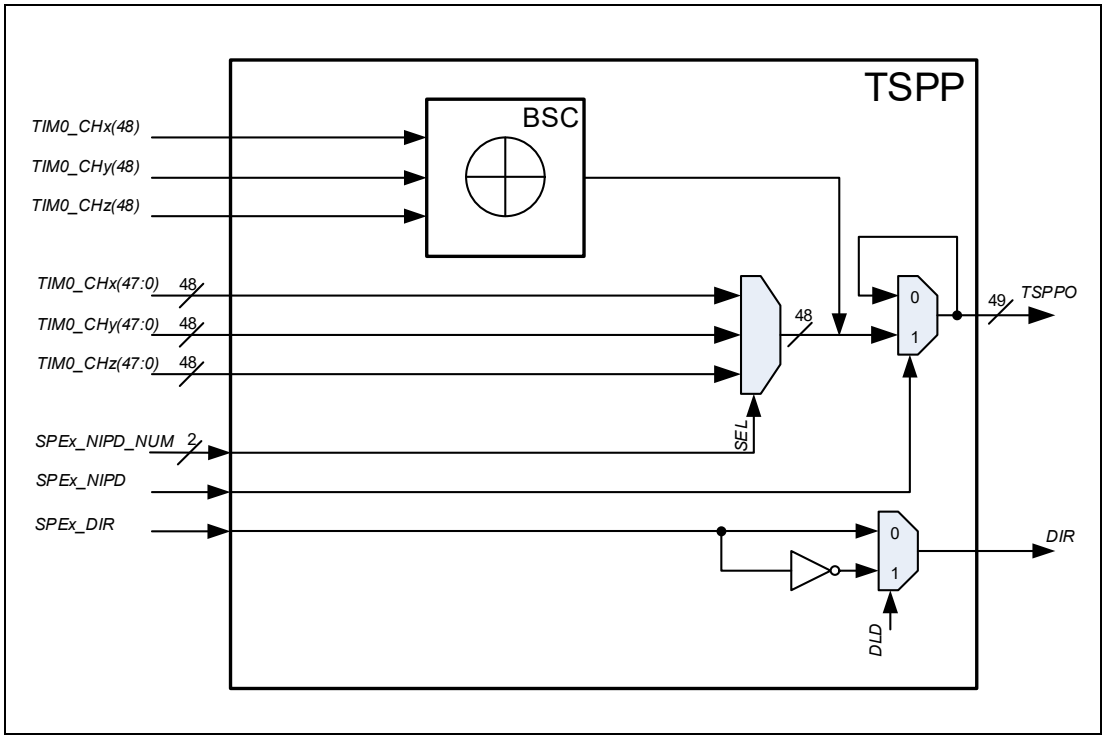

Figure 38.108 TIM Signal Preprocessing (TSPP) subunit architecture

38.21.2.1 Bit Stream Combination

The BSC subunit is used to xor-combine the three most significant bits TIM0_CHx(48), TIM0_CHy(48) and TIM0_CHz(48) of the TIM0 inputs.

The xor-combined signal is merged with the remaining 48 bits of one of the three input signals TIM0_CHx(47 to 0), TIM0_CHy(47 to 0) or TIM0_CHz(47 to 0) the TSPPO signal. The selection is done with the SPEx_NIPD_NUM input signal coming from the SPE sub-module. The action, when the 49 bits are transferred to the TSPPO and the T_VALID or S_VALID signal is raised is determined by the SPEx_NIPD signal coming from the SPE sub-module. The TSPPO output signal generation is shown in the example in **Figure 38.109**.

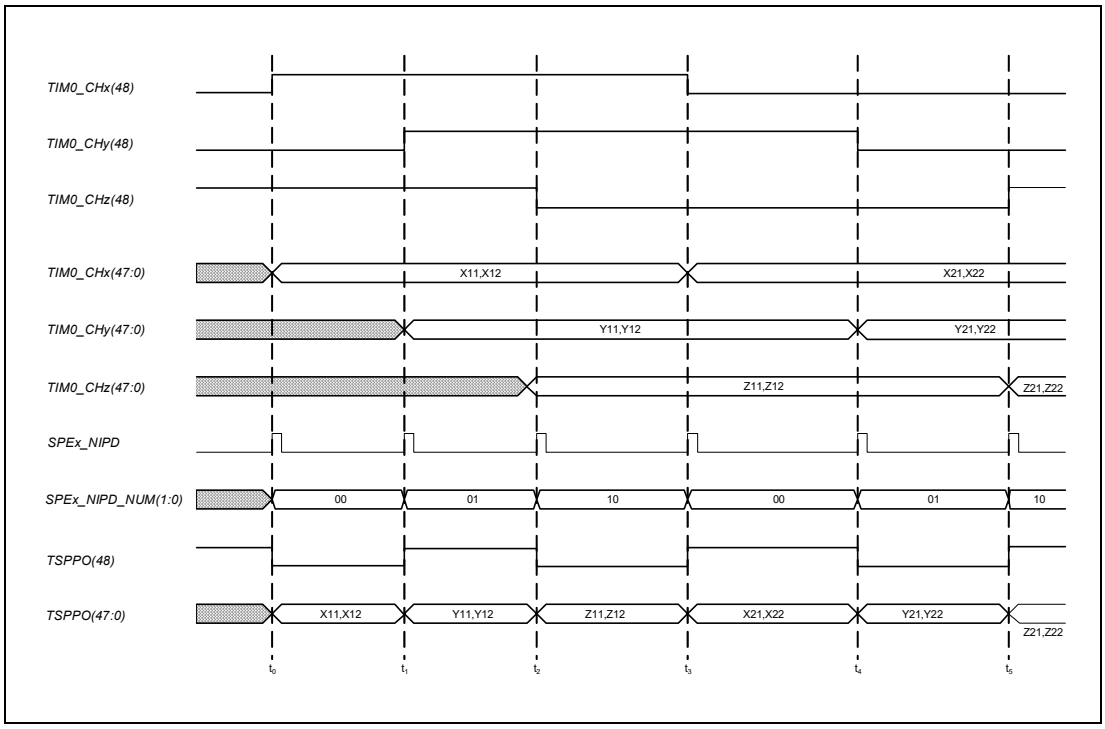

Figure 38.109 TSPP Signal generation for signal TSPPO

The SPEx_NIPD_NUM input signal determines, which data is routed to the TSPPO signal. At the first edge of TIM0_CHx(48) the new data X11 and X12 are routed to TSPPO(47:0). The values X11 and X12 are the two 24-bit values coming from the TIM input channel TIM0_CHx. The next edge is at time t_1 on signal TIM0_CHy(48). Therefore, at time t_1 the TSPPO(48) signal level changes and the TSPPO(47:0) is set to Y11 and Y12 and so forth.

38.21.3 MAP Configuration Registers Overview

MAP contains following configuration registers:

15 to 5	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
4	LSEL	TIM0_IN6 input level selection 0: TIM0_IN6 input level '0' encodes TRIGGER in forward direction. 1: TIM0_IN6 input level '1' encodes TRIGGER in forward direction.
3 to 1	SSL	STATE signal output select. 000_B: TIM0_CH1 selected as STATE output signal. 001_B: TIM0_CH2 selected as STATE output signal. 010_B: TIM0_CH3 selected as STATE output signal. 011_B: TIM0_CH4 selected as STATE output signal. 100_B: TIM0_CH5 selected as STATE output signal. 101_B: TSPP1_TSPPO selected as STATE output signal. 110_B: Same as '000' 111_B: Same as '000'
0	TSEL	TRIGGER signal output select. 0: TIM0_CH0 selected as TRIGGER output signal. 1: TSPP0_TSPPO selected as TRIGGER output signal.

38.22 Digital PLL Module (DPLL)

38.22.1 Overview

The digital PLL (DPLL) sub-module is used for frequency multiplication. The purpose of this module is to get a higher precision of position or value information also in the case of applications with rapidly changed input frequencies. There are two input signals TRIGGER and STATE for which periodic events are processed. The time period between two active events is called an increment. Each increment is divided into a given number of sub increments by pulses called SUB_INC. The resolution of the generated pulses is restricted by the period of the CMU_CLK0 clock or the TS_CLK respectively (see description of the modules TBU, CMU). The input signals TRIGGER and STATE can have the meaning of position information of linear or angle motions, mass flow values, temperature, pressure or level of liquids. By means of the DPLL the load of the CPU can be reduced essentially by relieving it from repeated or periodic standard tasks.

The DPLL has to perform the following tasks:

1. Prediction of the duration of the current increment in chapter {REF:DPLL_1338}
2. Generation of SUB_INC1,2 pulses for up to 2 position counters in normal or emergency mode (see chapter {REF:DPLL_1450})
3. Synchronization of the actual position (under CPU control, see chapter {REF:DPLL_1493})
4. Possibility of seamless switch to emergency mode and back under CPU control, see configuration register DPLL_CTRL_0 at chapter {R- EF:DPLL_5737}
5. Prediction of position and time related events in chapter {REF:DPLL_1383}

38.22.2 Requirements and demarcation

The two input signals TRIGGER and STATE can be sensor signals from the same device or from two independent devices. When they come from the same device the TRIGGER input is typically a more frequent signal and STATE is a less frequent signal. In such a case the STATE signal can support an emergency mode, when no TRIGGER signal is available. There are also applications supported when STATE and TRIGGER are independent signals from different devices. Both input signals are combined with a validation signal T_VALID or S_VALID respectively, which shows the appearance of new data and must result in a data fetch and a start of the correspondent state machine to perform the calculations (see explanation below).

When STATE is a redundant signal of the same device only the TRIGGER input is used to generate the SUB_INC1 pulses in normal mode. There is a configuration possible, called emergency mode, for which the SUB_INC1 pulses are generated using the STATE input signal. The decision to switch in the emergency mode and back is made outside the DPLL. The CPU must switch the configuration bit RMO (reference mode) in the DPLL_CTRL_0 register (see **Section 38.22.18, DPLL Register description**). Because a switch in emergency mode can appear suddenly, the information of the last increment duration of the STATE input up to FULL_SCALE should be stored always as a precaution.

The filtering as well as the combination or choice of the input signals is made in the TIM sub-module (see **Section 38.15, Timer Input Module (TIM)**) by use of a configurable filter algorithm for each slope and signal as well as in the MAP module (see **Section 38.21, TIM0 Input Mapping Module (MAP)**) the right TRIGGER or STATE signal is selected by a multiplexer or in the SPE module (see **Section 38.23, Sensor Pattern Evaluation (SPE)**) different signals are combined to a TRIGGER or STATE signal by using an anti valence operation.

The filter delay value of the signal is transmitted from the TIM module in the FT part of the corresponding signal, because the delay conditions of the signals can change during application.

The filter delays depend also on the filter algorithms used. Only the effective filter delay can be considered in the DPLL.

In order to provide the timing conditions to the DPLL the input trigger signals should have a time stamp (and optional in addition a filter value and a signal level value, as stated above) with an appropriate resolution. The resolution of the time stamps can be either the same resolution as the input time base TBU_TS0 (see **Figure 38.111, DPLL Block Diagram**) or 8 times higher, selected by configuration bits in the DPLL_CTRL_1 register (see **Section 38.22.18.2, DPLL_CTRL_1**). The time base TBU_TS0 is used to predict events in the future, called actions.

At the SUB_INCx outputs a predefined number of pulses between each active slope of the TRIGGER/ STATE signal is generated, when the correspondent pulse generator is enabled by the enable bits SGEx=1 in the DPLL_CTRL_1 register (see **Section 38.22.18.2, DPLL_CTRL_1**).

Dependent on configuration different strategies can be used to correct a wrong pulse number.

The FULL_SCALE range is divided into a fix number of nominal increments. Nominal increments do have the same size. The number of nominal increments in HALF_SCALE is specified in the DPLL_CTRL_0 register (see **Section 38.22.18, DPLL Register description**). For synchronization purposes some TRIGGER / STATE input signals can be suppressed in dependency on the current position. Therefore an increment as duration between two active input events can be either a nominal increment or it can consist of more than one nominal increment. While a true nominal increment starts with an active event a virtual increment (of always nominal size) is an increment which starts with a missing event. Each increment which represents a gap (e.g. for synchronization purposes) consists of exactly one true nominal increment and at least one virtual increment, each of them having the same nominal duration (see figure below).

38.22.3 Input signal courses

Typical input signal courses are shown in the figure below.

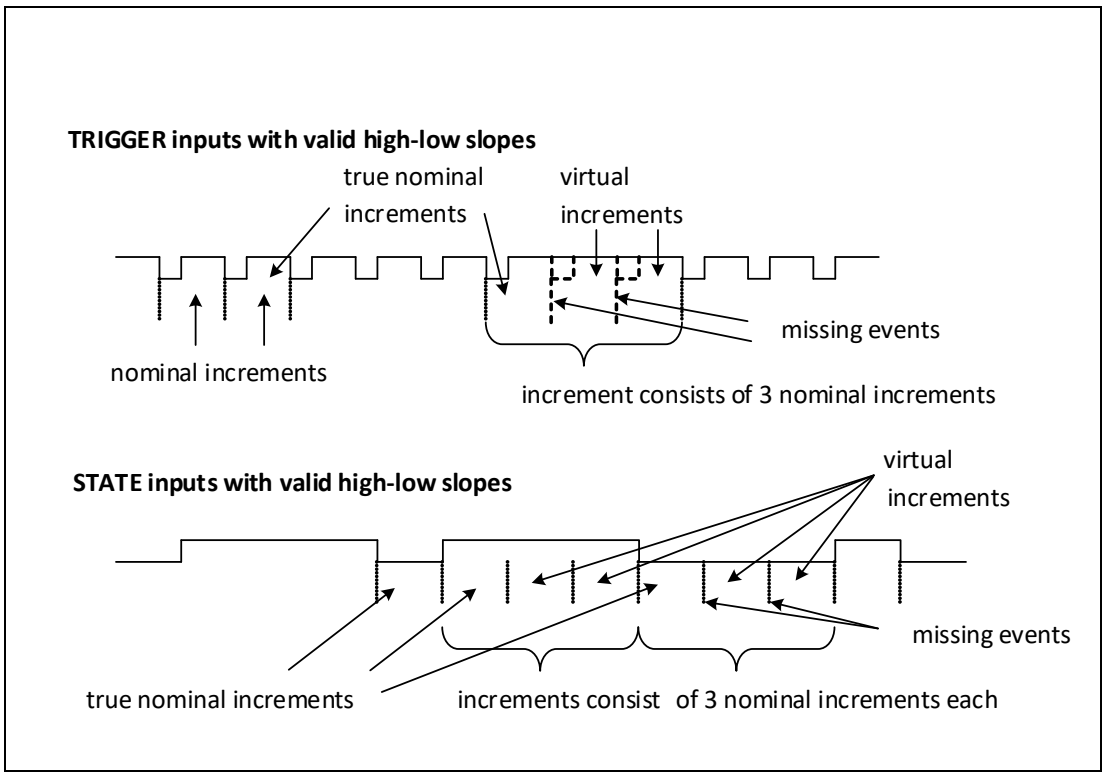

Figure 38.110 Trigger and State Input Signal

38.22.4 Block and interface description

The block description of the DPLL is shown in the following figure.

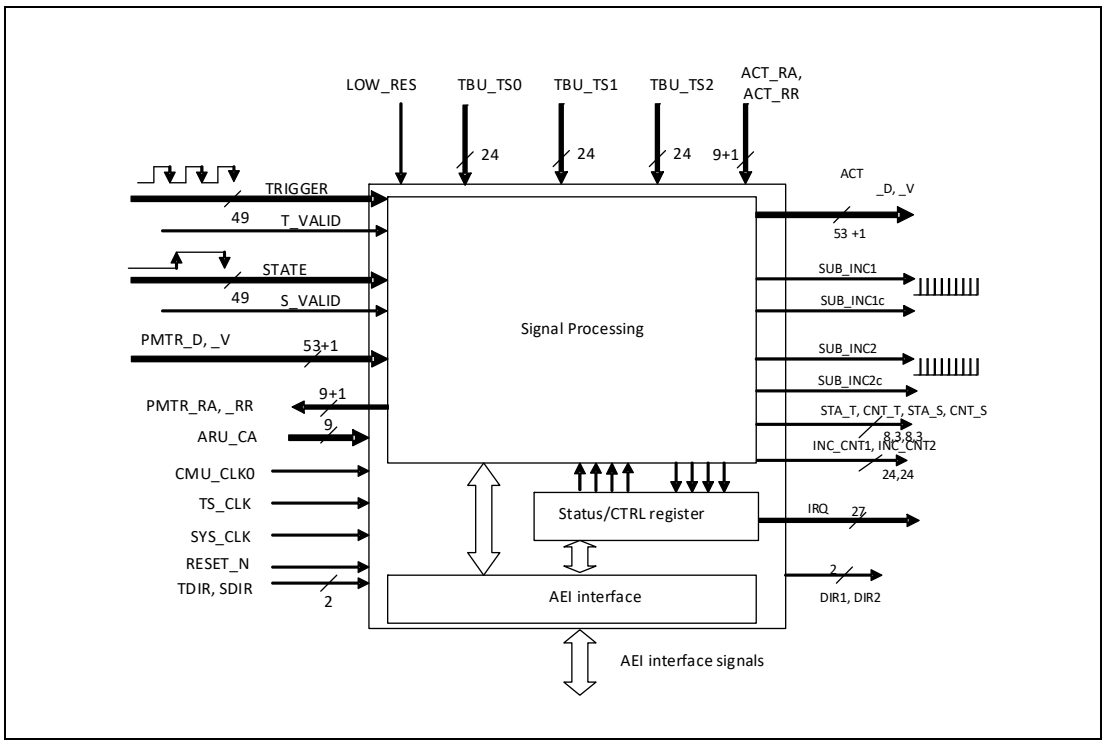

Figure 38.111 DPLL Block Diagram

Table (DPLL_6906) summarizes the interface signals of the DPLL shown by the block diagram above.

Table 38.289 Interface description of DPLL (1/3)

Name	Width	I/O	Description	Comment
TRIGGER	49	I	Normal Signal for triggering DPLL by positions/values Bit(48)= TRIGGER_S Bits(47:24)= TRIGGER_FT Bits(23:0)= TRIGGER_TS	One bit signal value (SV), 24 bits filter delay value info and 24 bits time stamp, filtered in different modes.
T_VALID	1	I	The values of *TRIGGER* are valid	Announces the arrival of a new *TRIGGER* value
STATE	49	I	Assistance signal for synchronization STATE(48)= STATE_S STATE(47:24)= STATE_FT STATE(23:0)= STATE_TS	Replacement of signal *TRIGGER* for emergency situations, or signal from an independent device; bits like above, corresponding
S_VALID	1	I	The values of STATE are valid	Announces the arrival of a new STATE value
PMTR_D	53	I	Position minus time request data, delivered by ARU on request for up to 24 requests PMTR_RR; SV_i=PMTR_D(52:48): ACB bits, directly written to the correspondent DPLL_ACB_j registers PSA[i]=PMTR_D(47:24): position value for action DLA[i]=PMTR_D(23:0) time delay value for action	Data values for calculation of actual Actions; the values are requested by AENi=1[1)] and CAIP=0[2)]; a served request is shown by PMTR_V which signals that valid PMTR data arrived and they are written immediately after that to the corresponding RAM regions and registers; The DLA[i] values must have the same resolution as the TBU_TS0 input.
PMTR_V	1	I	signals a valid PMTR_D value, that means data is delivered on request	when valid: PMTR_D overwrites data in the PSA[i] and DLA[i] registers, also when the corresponding ACT_N[i][3)] bit =1;

Table 38.289 Interface description of DPLL (2/3)

Name	Width	I/O	Description	Comment
ARU_CA	9	I	Channel address; for valid PMTR addresses: demand data by setting PMTR_RR=1 when enabled by AENi=1[1)] and CAIP=0[2)];	counter value of ARU selects PMTR_RA and PMTR_RR when a valid address
PMTR_RA	9	O	read address of PMTR access	reflects ID_PMTR_i according to the selected channel address
PMTR_RR	1	O	read request of PMTR access; suppressed for CAIPi=1 (see DPLL_STATUS register)	reflects the value of the corresponding AENi[1)] bit while the correspondent bit CAIPi=0[2)]
ACT_D	53	O	Output of a time stamp, a position and a control signal for a calculated action; SV_i=ACT_D(52:48): ACB bits, directly written from the correspondent PMTR_D signals; ACT_D(47:24) is the calculated position value PSAC[i] for the action in relation to TBU_TS1 or 2 [6)] and ACT_D(23:0) is the time stamp value TSAC[i] for the action in relation to TBU_TS0 [6)]	Future time stamp with the resolution as TBU_TS0 input, additional position information and additional control bits;
ACT_V	1	O	ACT_D value is available and valid; blocking read access	for a valid action address: ACT_V reflects the shadow value of ACT_N[i][3)] (ACT_N[i] is 1 when new PMTR values are available and the shadow register is updated, when a calculation of the actual PMTR values was done); reset after reading of the ACT_D values
ACT_RA	9	I	ACTION read address;	address bits for selection of all 24 action channels
ACT_RR	1	I	read request of selected action	the action data is demanded from another module
IRQ	27	O	Interrupt request output	Interrupts of DPLL;
SUB_INC1	1	O	Pulse output for *TRIGGER* input filter	sub-position increment provided continuously
SUB_INC2	1	O	Pulse output for *STATE* input filter (when *TRIGGER* and *STATE* are used for 2 independent devices)	sub-position increment provided continuously
SUB_INC1c	1	O	Pulse output for time base unit 1 in compensation mode (can stop in automatic end mode)	sub-position increment related to *TRIGGER* input
SUB_INC2c	1	O	Pulse output for time base unit 2 in compensation mode (can stop in automatic end mode)	sub-position increment related to *STATE* input (when *TRIGGER* and *STATE* are used for 2 independent devices)
TS_CLK	1	I	Time stamp clock	used for generation of the time stamps; this clock is used to generate the SUB_INC1,2 pulses
CMU_CLK0	1	I	CMU clock 0	used for rapid pulse correction of SUB_INC1,2
SYS_CLK	1	I	System clock	High frequency clock
RESET_N	1	I	Asynchronous reset signal	Low active; After Reset he DPLL is available only after performing the RAM reset procedures by the DPLL hardware.
LOW_RES	1	I	low resolution of TBU_TS0 selected; shows which of the 27 bits of TBU_TS0 are connected to the DPLL	LOW_RES=0: TBU_TS0(DPLL)= lower 24 Bits of TBU_TS0(TBU); LOW_RES=1: TBU_TS0(DPLL)= higher 24 Bits of TBU_TS0(TBU); In the case LOW_RES=1 the TS0_HRT and/or TS0_HRS bits can be set [5)]

Table 38.289 Interface description of DPLL (3/3)

Name	Width	I/O	Description	Comment
TBU_TS0	24	I	Actual time stamp from TBU; is needed to decide, if a calculated action is already in the past	24 bit time input, with a resolution of the time stamp clock
TBU_TS1	24	I	Actual position/value stamp 1; for calculation of position stamps (*TRIGGER*/*STATE*)	24 bit pos./val. input, with a resolution of the SUB_INC1 pulses
TBU_TS2	24	I	Actual position/value stamp 2; to be implemented for an additional independent position	ditto for SUB_INC2 for calculation of position stamps (*STATE*) for SMC[5]=RMO[4]=1
TDIR	1	I	Direction of *TRIGGER* input values (TDIR=0 does mean a forward direction and TDIR=1 a backward direction)	direction information from multiple sensors valid only for SMC[5]=1 or IDDS[5]=1
SDIR	1	I	Direction of *STATE* input values (SDIR=0 does mean a forward direction and SDIR=1 a backward direction)	direction information from multiple sensors valid only for SMC[5]=1
DIR1	1	O	Direction information of SUB_INC1 (count forwards for DIR1=0 and backwards for DIR1=1)	count direction of TBU_CH1_BASE; DIR1 changes always after the evaluation of the corresponding valid *TRIGGER* slope and after incrementing/decrementing of the address pointer
DIR2	1	O	Direction information of SUB_INC2 (count forwards for DIR2=0 and backwards for DIR2=1)	count direction of TBU_CH2_BASE; DIR2 changes always after the evaluation of the corresponding valid *STATE* slope and after incrementing/decrementing of the address pointer
STA_T	8	O	Status of state machine TRIGGER	Output to MCS0. Signals accessible via uC interface as well (DPLL_STA)
CNT_T	3	O	Count TRIGGER	Output to MCS0. This reflects the count of active *TRIGGER* slopes (mod8). Signals accessible via uC interface as well (DPLL_STA)
STA_S	8	O	Status of state machine STATE	Output to MCS0. Signals accessible via uC interface as well (DPLL_STA)
CNT_S	3	O	Count STATE	Output to MCS0. This reflects the count of active *STATE* slopes (mod8). Signals accessible via uC interface as well (DPLL_STA)
INC_CNT1	24	O	Increment counter of pulse generator 1 (automatic end mode)	Output to MCS0. Signals accessible via uC interface as well (DPLL_INC_CNT1)
INC_CNT2	24	O	Increment counter of pulse generator 2 (automatic end mode)	Output to MCS0. Signals accessible via uC interface as well (DPLL_INC_CNT2)

38.22.5 DPLL Architecture

38.22.5.1 Purpose of the module

The DPLL generates a predefined number of incremental signal pulses within the period between two events of an input TRIGGER or STATE signal, when the corresponding pulse generator is enabled. The resolution of the pulses is restricted by the frequency of the time stamp clock (TS_CLK). Changes in the period length of the predicted time period of the current increment will result in a change of the pulse frequency in order to get the same number of pulses. This adoption can be performed by DPLL hardware, software or with support of DPLL hardware in different modes. The basic part of a DPLL is to make a prediction of the current period between two TRIGGER and/or STATE signal edges. Disturbances and systematic failures must be considered as well as changes of increment duration caused by acceleration and deceleration of the supervised process. Therefore, a good estimation is to be done using some measuring values from the past. When the process to be predicted takes a steady and differentiable course not only the current increment but also some more increments for the future can be predicted. In utilization of such calculations actions for the future can be predicted.

38.22.5.2 Explanation of the prediction methodology

As already shown in **Section 38.22.1, Overview** the DPLL has to perform different tasks. The basic function for all these tasks is the prediction of the current increment which is based on a relation between increments in the past. Because the relation between two succeeding intervals at a fixed position remains also valid in the case of acceleration or deceleration the prediction of the duration of the current time interval is done by a similarity transformation. Having a good estimation of the current time interval, all the other tasks can be done easily by calculations explained in **Section 38.22.6, Prediction of the current increment duration**.

38.22.5.3 Clock topology

All registers are read using the system clock SYS_CLK. The SUB_INC1,2 pulses generated have in the normal case the highest frequency not higher then CMU_CLK0 or the half of TS_CLK respectively. For individual pulses the frequency can be doubled. All operations can be performed using the system clock.

38.22.5.4 Clock generation

The clock is generated outside the DPLL.

38.22.5.5 Typical frequencies

For the system clock a reasonable clock frequency should be applied to give the DPLL module sufficient computational power to calculate all needed values (prediction of next increment, actions) in time. The typical system clock frequency is in the range from 40 MHz up to 150 MHz.

38.22.5.6 Time stamps and systematic corrections

The time stamps for the input signals TRIGGER and STATE have 24 bits each. These bits represent the value of the 24 bit free running counter running with a clock frequency selected by the configuration of the TBU. Using a typical frequency of 20 MHz the time stamp represents a relative value of time with a resolution of 50 ns.

The input signals have to be filtered. The filter is not part of the DPLL. The time stamps can have a delay caused by the filter algorithm used. There are delayed and undelayed filter algorithms available and the delay value can depend on a time or a position value.

Systematic deviations of TRIGGER inputs can be corrected by a profile, which also considers systematic missing TRIGGER s. The increments containing missing TRIGGER S are divided into the corresponding number of nominal increments whereas the duration of a nominal increment is the greatest divider of all increments duration. For each increment this number of enclosed nominal increments is stored in a profile as NT value for TRIGGER. When the increment is a nominal increment the NT value is 1. For the TRIGGER input the value NT is stored in the ADT_T field in RAM region 2c.

In the case of DPLL_CTRL_0. AMT = 1 the ADT_T[i] values in the RAM region 2c must also contain the adapting information for the TRIGGER signal, which considers for each increment a systematic physical deviation PD from the perfect nominal increment value with a resolution according to the chosen value of MLT+1, which describes the number of SUB_INC1 pulses for a nominal increment.

The value PD for the TRIGGER describes the amount of missing or surplus pulses with a sint13 value, to be added to MLT+1 directly. The correction value is in this way also applicable in the case of missing TRIGGER inputs for the synchronization gaps. In this case the amount of provided SUB_INC1 pulses for a nominal increment (MLT+1) + PD is multiplied by NT. The NT value of the current increment is stored in the variable SYN_T (see NUTC register in **Section 38.22.18.14, DPLL_NUTC**).

In the case of DPLL_CTRL_0.RMO = 1 for DPLL_CTRL_1.SMC =0 (emergency mode) the time stamp of STATE is used to generate the output signal SUB_INC1.

More inaccuracy should be accepted in emergency mode because usually there are only fewer events available for FULL_SCALE according to the value DPLL_CTRL_0.SNU.

For the STATE signal the systematic deviations of the increments can be corrected in the same way as for TRIGGER by profile and adaptation information as described below.

Systematic deviations of STATE inputs can be corrected by a profile, which also considers systematic missing STATE events. The increments containing missing STATEs are divided into the corresponding number of nominal increments whereas the duration of a nominal increment is the greatest divider of all increments duration. For each increment this number of enclosed nominal increments is stored in a profile as NS value for STATE. When the increment is a nominal increment the NS value is 1. For the STATE input the value NS is stored in the ADT_S field in RAM region 1c3.

In the case of DPLL_CTRL_0.AMS = 1 the ADT_S[i] values in the RAM region 1c3 must contain the adapting information for the STATE signal, which considers for each increment a systematic physical deviation PD_S from the perfect nominal increment value with a resolution according to the chosen value of MLS1, which describes the number of SUB_INC1 pulses for a nominal increment (see below).

The number of pulses SUB_INC1 for a nominal STATE increment in emergency mode (for SMC=0) is given by the value of MLS1= (MLT + 1)* (TNU + 1) /(SNU + 1) in order to get the same number of pulses in FULL_SCALE for normal and emergency mode. This value has to be configured by the CPU.

The value PD_S for the STATE describes the amount of missing or surplus pulses with a sint16 value, to be added to MLS1 directly. The correction value is in this way also applicable in the case of missing STATE inputs for the synchronization gaps. In this case the amount of provided SUB_INC1 pulses for a nominal increment MLS1 + PD_S is multiplied by NS. The current NS value is stored in the variable SYN_S (see NUSC register in **Section 38.22.18.15, DPLL_NUSC**).

38.22.5.7 DPLL Architecture overview

As shown in **Figure 38.111, DPLL Block Diagram** the DPLL can process different input signals. The signal TRIGGER is the normal input signal which gives the detailed information of the supervised process. It can be for instance the information of water or other liquid level representing the volume of the liquid, where each millimeter increasing results in a TRIGGER signal generation. In order to get a predefined filling level, without overflow also the inertia of the system must be taken into account. Hence, some delay for closing the inlet valve and also the remaining water amount in the pipe must be considered in order to start the closing action earlier as the filling level will be reached.

A second input signal STATE sends an additional (redundant) information for instance at some centimeters and because of intervals with different distances it gives also information about the system state with the direction of the water flow (in or out), while the TRIGGER signal must not contain information concerning the flow direction. In some applications the inactive slope of TRIGGER can be utilized to transmit direction information. In the case of faults in the TRIGGER signal the STATE signal is to be processed in order to reach the desired value nevertheless, maybe with some loss of accuracy.

The measuring scale can have some systematic failures, because not all millimeter or centimeter distances measured mean the same value. This could be due to changes in the thickness of the measuring cylinder or the inaccurate position of the marks. These systematic failures are well known by the system and for improvement of the prediction the signals ADT_T and ADT_S for the correction of the systematic failures of TRIGGER and STATE respectively are stored in the internal RAM.

The input signals TRIGGER and STATE are represented as a time stamp signal each, which is stored in the 24 bit TS-part of the corresponding signal.

Information concerning the delay of this signal by filtering of disturbances is stored in the 24 bit FT-part of the signal.

In order to establish the relation of time stamps to the actual time the TBU_TS0 ^{2} value is also provided showing the actual time value used for prediction of actions in the future.

After reaching the desired water level the water is filled in a bottle by draining. After that the water filling is repeated. The water level at draining is observed by the same sensor signals (the same number of TRIGGER pulses), but the duration of the draining could be different from the filling time. Both times together form the FULL_SCALE region, while one of them is a HALF_SCALE region, which can differ in time but not in the number of pulses, especially for TRIGGER.

For synchronization purposes some TRIGGER marks can be omitted in order to set the system to a proper synchronization value (maybe before the upper filling value is reached).

In emergency situations, when the TRIGGER signals are missed the STATE signal is used instead of.

The PMTR_i input signals announce the request for a position minus time calculation for up to 24 events.

All 24 events can be activated using the 24 DPLL_CTRL_x.AENi=1 for x=(2,3,4) (action enable) bits. Each of these enable bits are asked by the routing engine for a read access. The corresponding read request is generated by the AENi bit while CAIPx is zero. CAIP1 and CAIP2 are two bits of the DPLL_STATUS register for 12 actions each with the meaning calculation of actions in progress, controlled by the state machine (see **Section 38.22.2, Requirements and demarcation**) for scheduling the operations.

When such a request is serviced by the ARU (in the case CAIPx=0) the values for position and time are written in the corresponding RAM 1a region (0200_H to $025C_H$ for the position value and 0260_H to $02BC_H$ for the delay value), the control bits for the corresponding action are set accordingly. When a

new PMTR value arrives, an old value is overwritten without notice and the shadow bit of ACT_N[i] is cleared while the ACT_N[i] (new action) bit in the DPLL_ACT_STA register is set. The ACT_N[i] is cleared, when the currently calculated action value is in the past. Overwriting of old information is possible without data inconsistency because the read request to ARU is suppressed during action calculations by the CAIP1,2 bits. In this way always the last possible PMTR value is used consistently.

38.22.5.8 DPLL Architecture description

Figure 38.111, DPLL Block Diagram will now be explained in detail in combination with some example configurations of the control registers. There are different configuration bits available which can adopt the DPLL to the use case (see **Section 38.22.18, DPLL Register description**). Let for example in HALF_SCALE the TRIGGER number DPLL_CTRL_0.TNU be $3B_H$ (which is for TNU+1 = 60 decimal that does mean 120 events in FULL_SCALE) and the number of SUB_INC1 pulses between two TRIGGER s DPLL_CTRL_0.MLT be 257_H (this means 600 pulses per TRIGGER event). Than the FULL_SCALE region can be divided into 72000 parts each of them associated with its own SUB_INC1 pulse. For a run through FULL_SCALE all 72000 pulses should appear but maybe with a different pulse frequency between two TRIGGER events. For this example after each 600 pulses at the SUB_INC1 output the next TRIGGER event is to be expected with the corresponding new time stamp.

Missing SUB_INC1 pulses due to acceleration have to be taken into account within the next increment. Not one pulse has to be missed or added because of calculation inaccuracy in average for a sufficient number of FULL_SCALE periods. This means that not one pulse is sent in addition and all missing pulses are to be caught up on afterwards.

For the systematic arrangement of TRIGGER inputs the profile (as already mentioned in **Section 38.22.5.6, Time stamps and systematic corrections** is stored in the RAM region 2c (see **Section 38.22.24.4, DPLL_ADT_T[i]**). In this field the relative position of gaps can be stored in the NT value and also physical deviations in the PD value.

For the consideration of systematic missing TRIGGER s the actual NT value of the profile is stored in the SYN_T bits of the NUTC register (see **Section 38.22.18.14, DPLL_NUTC**).

In normal mode the physical deviation values PD in the ADT_T field could be used to balance the local systematic inaccuracy of the TRIGGER signal. The value of PD (see **Section 38.22.24.4, DPLL_ADT_T[i]**) is the pulse difference in the corresponding nominal increment and does mean the number of sub pulses to be added to the nominal number of pulses. PD is a signed integer value using 13 bits: up to +/–4096 pulses can be added for each increment.

The NT value of the profile ADT_T has the value 1, when a nominal increment is assumed. An integer number greater than 1 shows the number of nominal increments to be considered for a gap. For the actual increment after synchronization the corresponding NT value is stored in SYN_T of the NUTC register.

Using the STATE input there are similar configuration bits available (see **Section 38.22.18, DPLL Register description**). Let for example in HALF_SCALE the STATE number DPLL_CTRL_0.SNU be 0xB (which is for DPLL_CTRL_0.SNU+1 =12 decimal and while DPLL_CTRL_0.SYSF =0 that does mean 24 events in FULL_SCALE). In order to get the same number of SUB_INC1 pulses for FULL_SCALE as above for TRIGGER s the value (DPLL_CTRL_0.ML- T+1)=600 is divided by 2*(DPLL_CTRL_0.SNU+1)=24 and multiplied with 2*(DPLL_CTRL_0.TNU+1)=120. The result 3000 must be stored in MLS1 by the CPU (see **Section 38.22.22.39, DPLL_MLS1**).

For the systematic arrangement of STATE inputs the profile (as already mentioned in **Section 38.22.5.6, Time stamps and systematic corrections** is stored in the RAM region 1c3 (see

Section 38.22.22.54, DPLL_ADT_S[i]). In this field the relative position of gaps can be stored in the NS value and also physical deviations in the PD_S value.

For the consideration of systematic missing TRIGGER s the actual NS value of the profile is stored in the SYN_S bits of the NUSC register (see **Section 38.22.18.15, DPLL_NUSC**).

In emergency mode the physical deviation values PD_S in the ADT_S field could be used to balance the local systematic inaccuracy of the STATE signal. The value of PD_S (see **Section 38.22.22.54, DPLL_ADT_S[i]**) is the pulse difference in the corresponding increment and does mean the number of sub pulses to be added to the nominal number of pulses per increment. PD_S is a signed integer value using 16 bits: up to +/–32768 pulses can be added for each increment.

In emergency mode the physical deviation values PD_S in the ADT_S field could be used to balance the local systematic inaccuracy of the STATE signal. The value of PD_S (see **Section 38.22.22.54, DPLL_ADT_S[i]**) is the pulse difference in the corresponding nominal increment and does mean the number of sub pulses to be added to the nominal number of pulses. PD_S is a signed integer value using 16 bits: up to +/–32768 pulses can be added for each increment.

The NS value of the profile ADT_S has the value 1, when a nominal increment is assumed. An integer number greater than 1 shows the number of nominal increments to be considered for a gap. For the actual increment after synchronization the corresponding NS value is stored in SYN_S of the NUSC register.

38.22.5.9 Block diagrams of time stamp processing.

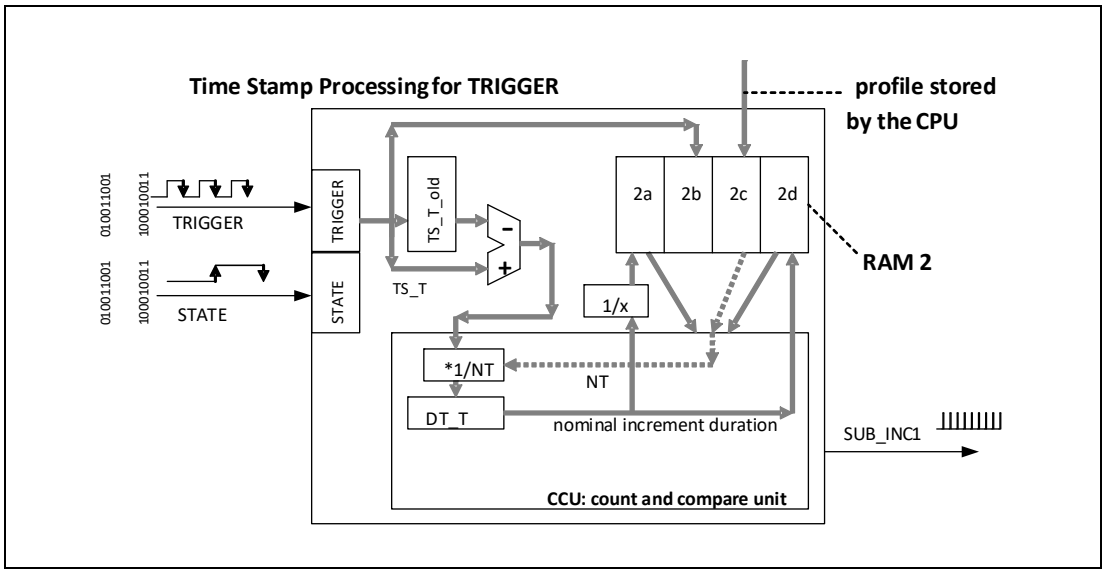

Figure 38.112 Time Stamp Processing Trigger

As shown in the block diagram above the time stamp difference of two succeeding input events is calculated. For the prediction of the current increment duration such values from the past are used. For this purpose the measured and calculated values of the last FULL_SCALE period are stored in the RAM. For the TRIGGER input there are 4 different RAM parts in the RAM region 2: 2a stores the reciprocals of each nominal increment duration RDT_T 2b stores the time stamps of each active input event TSF_T 2c is used for the profile ADT_T and 2d for the nominal increment duration DT_T. Because the prediction is based on the relations of increments in the past this relation can be calculated easily by the multiplication of increment duration values with the reciprocal value of another increment. In order not to be forced to distinguish between gaps and "normal" increments duration also for gaps only the nominal duration and the correspondent reciprocal values are stored in the RAM field. This is possible by consideration of the NT value in the profile: the measured increment duration is divided by NT.

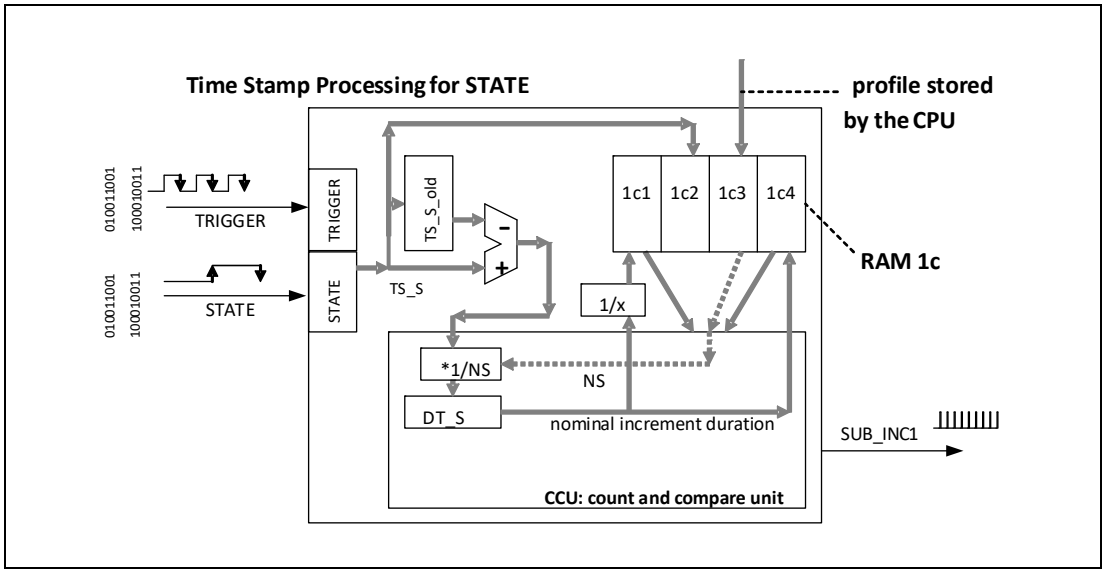

Figure 38.113 Time Stamp Processing State

For the *STATE* input there are also 4 different RAM parts in the RAM region 1c:

1. 1c1 stores the reciprocals of each nominal increment duration RDT_S
2. 1c2 stores the time stamps of each active input event TSF_S
3. 1c3 is used for the profile ADT_S and
4. 1c4 for the nominal increment duration DT_S.

The calculations are performed similar as for the TRIGGER input. The NS value in the profile shows the appearance of a gap.

38.22.5.10 Register and RAM address overview

The address map of the DPLL is divided into register and memory regions as defined in Table (DPLL_1052)[XREF TARGET " (DPLL_1052)] NOT EXIST. The addresses from 0000_H to $00FC_H$ are reserved for registers, from 0100_H to $01FC_H$ is reserved for action registers to serve the ARU at immediately read request. The RAM is divided into 3 independent accessible parts 1a, 1b+c and 2. The part 1a from 0200_H to $037C_H$ is used for PMTR values got from ARU and intermediate calculation values; there is no write access from the CPU possible, while the DPLL is enabled. The RAM 1b part from 0400_H to $05FC_H$ is reserved for RAM variables and the RAM part 1c from 0600_H to $09FC_H$ is used for the STATE signal values. The RAM region 2 from 4000_H to $7FFC_H$ is reserved for the TRIGGER signal values. RAM region 1a has a size of 288 bytes, Ram 1b+c uses 1,125 Kbytes while RAM region 2 is configurable from 1,5 to 12 Kbytes, depending on the number of TRIGGER events in FULL_SCALE. The AOSV_2 register is used to determine the beginning of each part.

The table in (DPLL_1052)[XREF TARGET " (DPLL_1052)] NOT EXIST gives the DPLL Address map overview

Registers are used to control the DPLL and to show its status. Also parameters are stored in registers when useful. The table below shows the addresses for status and control registers as well as values stored in additional registers. The register meaning explained in the register overview (**Section 38.22.11, DPLL Register Memory overview**) while the bit positions of the status and control registers are described in detail in **Section 38.22.18, DPLL Register description**.

Time stamps for TRIGGER and STATE can have either the same resolution as the TBU_TS0 input or 8 times higher. This is configured in the DPLL_CTRL_1 register (see **Section 38.22.18.2, DPLL_CTRL_1**). While the TBU_TS0 is used for action predictions the higher resolution of TRIGGER and STATE inputs can be used for a more accurate pulse generation.

The time stamp fields of TRIGGER and STATE are stored in the corresponding RAM regions in such a way, that for a gap also entries for the virtual increments are provided. This is due to the necessity to calculate time differences between a given number of (real and virtual) input events independent of a gap. Therefore the gap is extended in the RAM fields 2b and 1c2. For all other RAM regions in RAM 2 and RAM 1c the gap is considered as one increment.

For the access to the RAM fields there must be address pointers. When the device starts all address pointers have a zero value and the first measured and calculated values are stored in the beginning of the corresponding RAM field. Because the position of the device is usually unknown at the beginning no profile information can be used. The profile regions must have their own address pointers each which are set by the CPU as soon as the position is known. By setting the appropriate value to the address pointer APT_2C of the TRIGGER profile or APS_1C3 of the STATE profile respectively the synchronization bits in the DPLL_STATUS register SYT or SYS are set respectively. In the following the gap information can be used.

Because the time stamp fields are extended at the gaps there must be additional address pointers for these regions: APT_2B for TRIGGER time stamps and APS_1C2 for STATE time stamps. These address pointers must be incremented by NT or NS respectively when a gap appears.

Table 38.290 Register and RAM address map (1/2)

Addr. range Start	Addr. range End	Value number	Byte #	Content	Indication	Region	RAM size
Addr. range Start	Addr. range End	Value number	Byte #	Content	Indication	Region	RAM size
0x0000	0x0FC	64	256	Register	used/reserved	0	no RAM
0x100	0x1FC	64	192	ACTION registers	direct read from ARU	0	no RAM

Table 38.290 Register and RAM address map (2/2)

Addr. range Start	Addr. range End	Value number	Byte #	Content	Indication	Region	RAM size
0x0200	0x03FC	128	384	PMTR values RAM 1a	CPU R/Pw access, when DPLL disabled; ARU has highest priority	1a with own ports	RAM part 1a: 384 bytes
0x0400	0x05FC	128	384	Variables RAM 1b	R and monitored W access by the CPU	1b	RAM part 1b+c: 1,125 Kbytes
0x0600	0x09FC	256	768	*STATE* data	R and monitored W access by the CPU	1c

0x4600...7000	0x47FC...7FFC	128... 1024	384...3072	DT_T[i]	nom. *TRIGGER* increments	2d	

(1) RAM Region 1

RAM region 1 has a size of 1,5 Kbytes and is used to store variables and parameters as well as the measured and calculated values for increments of STATE. The RAM 1 region is divided into two independent accessible RAM parts (a and b+c) with own ports. The address information is shown in the table above and the detailed description is performed in the following chapters. The RAM 1a is used to store the PMTR values got from ARU and in addition some intermediate calculation results of actions. RAM region 1b is used for variables needed for the prediction of increments, while RAM 1c is used to store time stamps, profile and duration of all the STATE inputs of the last FULL_SCALE region. All variables and values of RAM 1b+c part use a data width of up to 24 bits.

The RAM is to be initialized by the DPLL after HW-reset. All RAM cells must have a zero value after performing the initialize procedure. This is performed when setting The Init_RAM bit in the DPLL_RAM_INI register. The DPLL is only available after finishing this procedure. The initialization progress is shown in the status bits of the same register.

RAM Region 1a:

Used for storage of PMTR values got from ARU; read and write access by the CPU is only possible, when the DPLL is disabled.

The CPU Address range: 0200_H to $03FC_H$

RAM Region 1b:

Usable for intermediate calculations and auxiliary values, data width of 3 bytes used for 24 bit values; A write access to this region results in an interrupt to the CPU, when enabled.

Address range: 0400_H to $05FC_H$

RAM Region 1c :

Values of all STATE increments in FULL_SCALE, data width of 3 bytes used for 24 bit values; A write access to this region results in an interrupt to the CPU, when enabled.

Address range: 0600_H to $09FC_H$

In RAM region 1c there is a difference in the amount of data. While for the RAM regions 1c1, 1c3 and 1c4 there are 2*(SNU+1–SYN_NS) entries for SYSF=0 or 2*(SNU+1) –SYN_NS entries for SYSF=1, for the RAM region 1c2 there are 2*(SNU+1) entries (see DPLL_CTRL_0 and _1 registers). For the latter also the virtual events are considered, that means the gap is divided into equidistant parts each having the same position share as increments without a gap. For that reason the CPU must extend the stored TSF_S[i] values in the RAM region 1c2 before the APS_1C3 is written. The write access to APS_1C3 sets the SYS bit in the DPLL_Status register in order to show the end of the synchronization process. Only when the SYS bit is set the PMTR values can consider more than the last increment duration for the action prediction by setting NUSE to a corresponding value.

NOTE

RAM regions 1b and 1c have a common port.

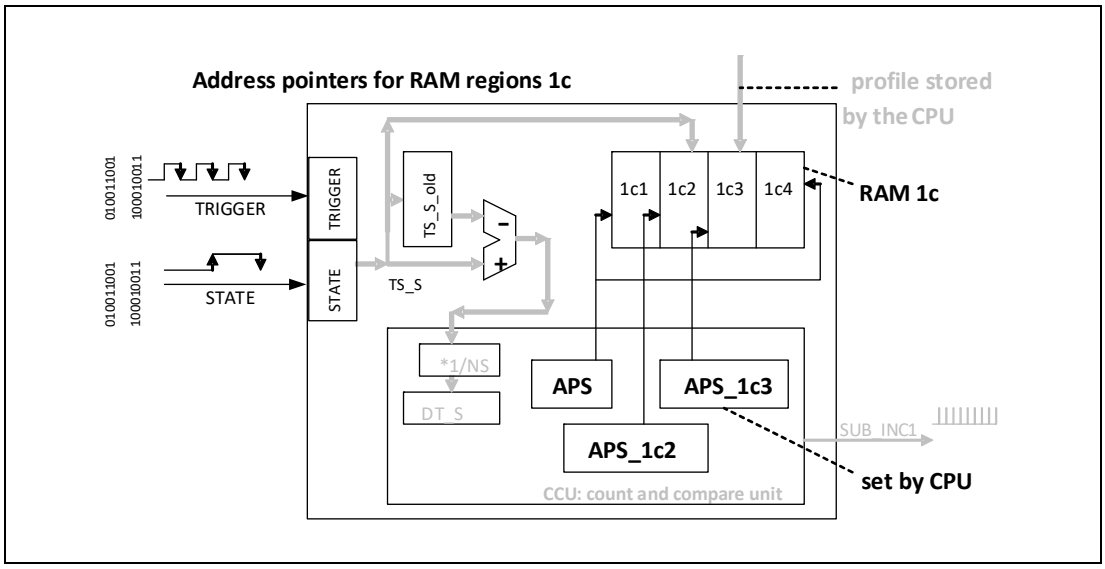

Figure 38.114 Address Pointer for RAM 1c

The address pointers for RAM region 1c are shown in the diagram above. While the address pointer APS points to the RAM regions 1c1 and 1c4, the address pointer APS_1C2 points to the time stamp field in the region 1c2. This is necessary, because in the time stamp field the gaps are extended to the number of nominal increments (see explanation above and also to the synchronization procedure explained in **Section 38.22.8.6, (1) Synchronization description**). The address pointer APS_1C3 is set by the CPU when the position is known and therefore the relation to the other address

pointers is calculated. This setting of this profile address pointer synchronizes the RAM fields to one another. The synchronization is shown in the DPLL_STATUS register (see **Section 38.22.18.30, DPLL_STATUS**) by the SYS bit.

(2) RAM Region 2

The RAM region 2 has a configurable size of 1,5 to 12 Kbytes and is used to store measured and calculated values for increments of TRIGGER. The address information is explained in **Section 38.13, Cluster Configuration Module (CCM)** while the meaning is explained in this chapter.

Because of up to 512 TRIGGER events in HALF_SCALE the fields 2a, b c and d must have up to 1024 storage places each. For 3 Bytes word size this does mean up to 12 Kbyte of RAM region 2.

In order to save RAM size for configurations with less TRIGGER events the RAM is configurable by the offset switch Register OSW ($001C_H$) and the address offset value register of RAM region 2 AOSV_2 (0020_H). The RAM is to be initialized by the DPLL after HW-reset. All RAM cells must have a zero value after performing the initialize procedure. The DPLL is only available after finishing this procedure.

In RAM region 2 there is a difference in the amount of data. While for the RAM regions 2a, 2c and 2d there are 2*(TNU+1–SYN_NT) entries, for the RAM region 2b there are 2*(TNU+1) entries (see **Section 38.22.18.1, DPLL_CTRL_0** and **Section 38.22.18.2, DPLL_CTRL_1**). For the latter also the virtual events are considered, that means the gap is divided into equidistant parts each having the same position share as increments without a gap. For that reason the CPU must extend the stored TSF_T[i] values in the RAM region 2b before the APT_2C is written.

The write access to APT_2C sets the SYT bit in the DPLL_Status register in order to show the end of the synchronization process. Only when the SYT bit is set the PMTR values can consider more than the last increment duration for the action prediction by setting NUTE to a value greater than one.

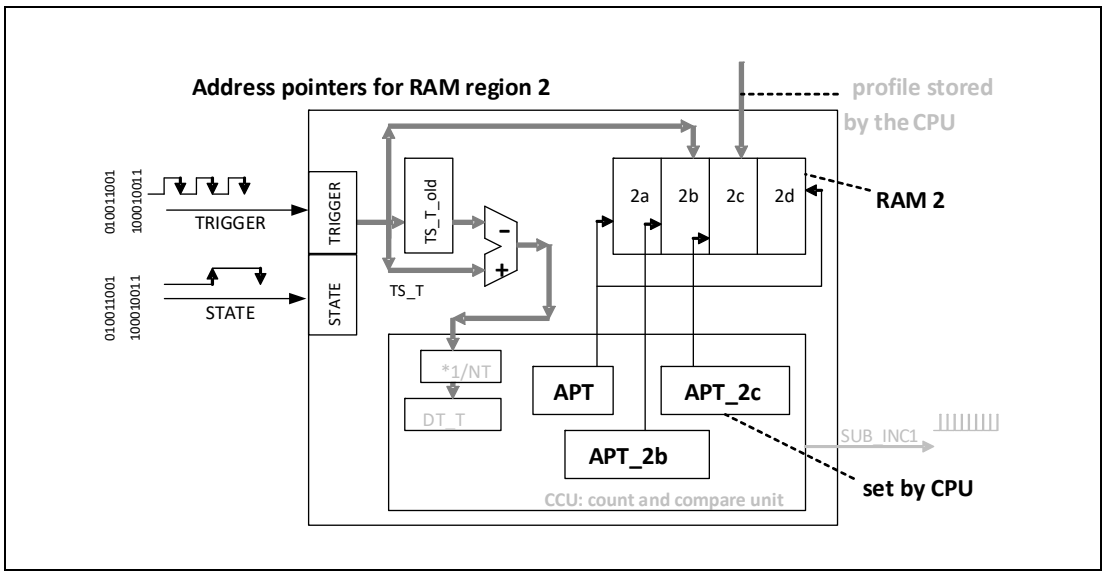

Figure 38.115 Address Pointer for RAM 2

The address pointers for RAM region 2 are shown in the diagram above. While the address pointer APT points to the RAM regions 2a and 2d, the address pointer APT_2B points to the time stamp field in the region 2b. This is necessary, because in the time stamp field the gaps are extended to the number of nominal increments (see explanation above and also to the synchronization procedure explained in **Section 38.22.8.6, (1) Synchronization description**). The address pointer APT_2C is set by the CPU when the position is known and therefore the relation to the other address pointers is calculated. This setting of this profile address pointer synchronizes the RAM fields to one another. The synchronization is shown in the DPLL_STATUS register (see **Section 38.22.18.30, DPLL_STATUS**) by the SYT bit.

38.22.5.11 Software reset and DPLL deactivation

The DPLL module allows different options of deactivation and/or reset. To stop the operation of the DPLL module it is possible to deactivate the DPLL by setting of DPLL_CTRL_1.DEN = 0. This stops the calculations for the generation of the sub increments and the actions. Some control register areas are only configurable in this mode, some but not all register signals are set into an initial state. The RAM memory is not affected by DPLL deactivation at all. The behavior of the DPLL output signals and registers when deactivated is described in this document. The deeper option to reconfigure the DPLL is the use of the software reset. When the DPLL module is deactivated setting DPLL_CTRL_1.SWR

= 1 performs a reset of all DPLL registers and state controllers. The RAM memory is not affected by the software reset at all. After the software reset the DPLL module remains in deactivated state and the control registers must be configured again before operation (activation by DEN = 1) can start again. The RAM modules can be reset (written to all zero) by activation of the memory initialization control bit (INIT_RAM) of the register DPLL_RAM_INI. If the RAM initialization is automatically done after power on reset or not depends on the GTM implementation. A special case is the configuration of the control bit DPLL_CTRL_11.STATE_EXT. If this bit shall be modified during operation a software reset of the DPLL module is strongly recommended. A RAM initialization should also be considered depending on the given application case.

38.22.6 Prediction of the current increment duration

38.22.6.1 The use of increments in the past

Past values to be considered for the prediction of TRIGGER

In order to take into account values of increments for TRIGGER s in the past, the NUTE value is configured to determine the number of past values. In addition the VTN has a value according to the number of virtual increments in the NUTE region. Because gaps come in to the NUTE region or leave it the VTN value must be updated by the CPU until NUTE is set to HALF_SCALE or FULL_SCALE. For the RAM regions 2a and 2d the value NUTE–VTN is to be considered while for the RAM region 2b only the NUTE value is to be considered. This is due to the fact that the time stamp entries in a gap are extended to the number of nominal increments, but duration entries not.

Past values to be considered for the prediction of STATE

In order to take into account values of increments for STATE in the past, the NUSE value is configured to determine the number of past values. In addition the VSN has a value according to the number of virtual increments in the NUSE region. Because gaps come in to the NUSE region or leave it the VSN value must be updated by the CPU until NUSE is set to HALF_SCALE or FULL_SCALE. For the RAM regions 1c1 and 1c4 in the past the value NUSE–VSN is to be considered while for the RAM region 1c2 only the NUSE value is to be considered. This is due to the fact that time stamp entries in a gap are extended to the number of nominal increments, but duration entries not.

38.22.6.2 Increment prediction in Normal Mode and for first PMSM forwards

For the prediction of increments and actions in normal mode the values are calculated as described in the following equations.

The ascending order of calculation must be hold in order not to lose results still needed. It is important for TRIGGER values to calculate and store in the RAM region 2 all values according to equations up to DPLL-14 before DPLL-1a4 to 7, DPLL-1b1 and DPLL-1c1, while the last one overwrites DT_T[i] when NUTE (see **Section 38.22.18.14, DPLL_NUTC**) is set to the FULL_SCALE range. Because the old value of DT_T[i] is also needed for equation DPLL-10 and DPLL-11 this value is stored temporarily at DT_T_ACT as shown by equation **Section 38.22.6.2, (1) Equations DPLL-1a to calculate TRIGGER time stamps** or **Section 38.22.6.2, (2) Equation DPLL-1b to calculate DT_T_ACT (nominal value)** respectively until all prediction calculations are done and after that equation DPLL-1a4 to 7 and DPLL-1b1 updates DT_T[i]: update DT_T[i] after calculations of equation DPLL-14. For p=APT calculates in normal mode.

When using filter information of TRIGGER_FT, selected by IDT=1, it must be distinguished by IFP, if this filter information is time or position related. In order to make possible to perform the automatic resolution corrections of equations (DPLL_10988)[XREF TARGET " (DPLL_10988)] NOT EXIST and (DPLL_10989)[XREF TARGET " (DPLL_10989)] NOT EXIST the filter unit in TIM module must operate using the time stamp clock.

(1) Equations DPLL-1a to calculate TRIGGER time stamps

For calculation of time stamps use the filter delay information and an additional TRIGGER input delay value stored in register TIDEL (initial zero)

TS_T_1 = TRIGGER_TS – TIDEL (DPLL-1a0)

$TS\_T = TS\_T_1$ – FTV_Tx (for IDT=1 and IFP=0) (DPLL-1a1) with

FTV_Tx = FTV_T/8 (for LOW_RES = 1 and TS0_HRT = 0) (DPLL-1a1a)

FTV_Tx = FTV_T (for LOW_RES = 0 or TS0_HRT = 1) (DPLL-1a1b) and

$TS\_T = TS\_T_1$ - FTV_T *(CDT_TX/NMB_T)_old (for IDT=1 and IFP=1) (DPLL-1a2) this can be also calculated using the value of ADD_IN_CALN:

$TS\_T = TS\_T_1$ – FTV_T *(1/ADD_IN_CALN_old) (for IDT=1 and IFP=1) (DPLL-1a3)

For (CDT_TX/NMB_T)_old and (1/ADD_IN_CALN_old) consider values, calculated for the last increment; position related filter values are only considered up to at least 1 ms time between two TRIGGER events. The reciprocal value is stored using a 32 bit fractional part, while only the 24 lower bits are used – for explanation see note (DPLL_10980)[XREF TARGET " (DPLL_10980)] NOT EXIST at DPLL_CTRL_0 register. The value of 1/ADD_IN_CALN_old or (CDT_TX/NMB_T)_old is set to $FFFFFF_H$ in the case of an overflow.

CDT_TX is the predicted duration of the last TRIGGER increment and NMB_T the calculated number of SUB_INC1 events in the last increment, because the new calculations are done by equations DPLL-5 and DPLL-21 for the current increment after that. Therefore in equation (DPL- L_10991)[XREF TARGET " (DPLL_10991)] NOT EXIST the value ADD_IN of the last increment is used (see equation DPLL-25). SYN_T_OLD is the number of TRIGGER events including missing TRIGGERs as specified in the NUTC register for the last increment, with the initial value of 1.

For storage of time stamps in the RAM see also equations DPLL-1a4 ff. after calculation of actions, **Section 38.22.7.5, (1) Equation DPLL-1a4 to update the time stamp values for TRIGGER**.

(2) Equation DPLL-1b to calculate DT_T_ACT (nominal value)

DT_T_ACT= (TS_T – TS_T_OLD)/SYN_T_OLD (DPLL-1b)

For the case SYT=0 (still no synchronization to the profile) the values SYN_T and SYN_T_OLD are still assumed as having the value 1.

Correct the current increment duration value got by equation (DPLL_6911)[XREF TARGET " (DPLL_6911)] NOT EXIST in the case of physical deviations (ADT=1) by DT_T_ACT = DT_T_ACT * (1 – PDC_T + PDC_T –PDC_T) (DPLL-1b1)

with the relative correction value for the last increment

PDC_T = PD_OLD / (MLT+1) (DPLL-1b2) (for SMC=0)

PDC_T = PD_OLD / (MLS1) (for SMC=1) (DPLL-1b3) The term (1 – PDC_T + PDC_T –PDC_T) of equation (DPLL_10998)[XREF TARGET " (DPLL_10998)]NOT EXIST is representing the third order Taylor series of the term 1/(1+PDC_T), which is chosen to reduce the additional time delay due to the more complex computation.

(3) Equation DPLL-1c to calculate RDT_T_ACT (nominal value)

RDT_T_ACT = 1 / DT_T_ACT (DPLL-1c)

(4) Equation DPLL-2a1 to calculate QDT_T_ACT

Relation of the recent last two increment values for APT=p in forward direction (DIR1=0)
QDT_T_ACT = DT_T_ACT * RDT_T[p–1] (DPLL-2a1)

QDT_T_ACT as well as QDT_T[i] have a 24 bit value using a 6 bit integer part and an 18 bit fractional part.

NOTE

QDT_T_ACT uses a 6 bit integer part and an 18 bit fractional part.

(5) Equation DPLL-3 to calculate the error of last prediction

When q = NUTE–VTN considers for the error calculation only the last valid prediction values for DIR1=0: Calculate the error of the last prediction when using only RDT_T_FS1, DT_T[p–q], DT_T[p–q–1] and DT_T[p–1] for the prediction of DT_T[p]:

EDT_T = DT_T_ACT – (DT_T[p–1] * QDT_T[p–q]) (DPLL-3) with

QDT_T[p–q] = DT_T[p–q] * RDT_T[p–q–1] (for FST= 0) (DPLL-2b1)

QDT_T[p–q] = DT_T[p–q] * RDT_T_FS1 (for FST=1) (DPLL-2b2)

FST = 1 has the meaning: NUTE=FULL_SCALE (see **Section 38.22.18.14, DPLL_NUTC**) while QDT_T_ACT as well as QDT_T[i] have a 24 bit value using a 6 bit integer part and an 18 bit fractional part.

NOTE

QDT_T[p – q] uses a 6 bit integer part and an 18 bit fractional part.

(6) Equation DPLL-4 to calculate the weighted average error

for SYT=1 calculate:

MEDT_T := (EDT_T + MEDT_T) / 2(DPLL-4)

(7) Equations DPLL-5 to calculate the current increment value

nominal increment value (for ADT=0):

CDT_TX _nom = (DT_T_ACT + MEDT_T) * QDT_T[p–q+1] (DPLL-5a1)

nominal increment value (for ADT=1):

CDT_TX _nom_corr = CDT_TX _nom * (1 + CDC_T) (DPLL-5a2) with:

CDC_T = PD / (MLT+1) (for SMC=0) (DPLL-5a3)

CDC_T = PD / (MLS1) (for SMC=1) (DPLL-5a4) and

QDT_T[p–q+1] = DT_T[p–q+1] * RDT_T[p–q] (DPLL-2c) (for q > 1) and for q=1 use equation **Section 38.22.6.2, (4) Equation DPLL-2a1 to calculate QDT_T_ACT**.

while QDT_T_ACT as well as QDT_T[i] have a 24 bit value using a 6 bit integer part and an 18 bit fractional part. The CDT_TX_nom value is limited by the relation

CTN_MIN < CDT_TX_nom < CTN_MAX When the calculated value exceeds one of the limits, it is replaced by the corresponding limit value. The expected duration to the next TRIGGER event is:

CDT_TX = CDT_TX _nom * SYN_T (DPLL-5b)(for ADT=0) CDT_TX = CDT_TX _nom_corr * SYN_T
(for ADT=1)

QDT_T[p–q+1] uses a 6 bit integer part and an 18 bit fractional part.

NOTE

In the case of an overflow in equations (DPLL_11005)[XREF TARGET '' (DPLL_11005)] NOT EXIST or (DPLL_11016)[XREF TARGET '' (DPLL_11016)] NOT EXIST set the value to $FFFFFF_H$ and the corresponding CTO bit in the DPLL_STATUS register. In the case of negative values set CDT_TX to 0_H without any effect to the CTO bit.

38.22.6.3 Increment prediction in Emergency Mode and for second PMSM forwards

Note that the ascending order of calculations for STATE and storage of the values in the RAM region 1c must be hold in order not to lose results still needed. The same considerations as done for DT_T_ACT are valid for DT_S_ACT (equation DPLL-6a4...7, DPLL-6b1 and DPLL-6b1): update TD_S[i] only after calculations of equation DPLL-14.

When using filter information of STATE_FT, selected by IDS=1, it must be distinguished by IFP, if this filter information is time or position related. In order to make possible to perform the automatic resolution corrections of equation (DPLL_11019)[XREF TARGET '' (DPLL_11019)] NOT EXIST the filter unit in TIM must operate using the time stamp clock.

(1) Equations DPLL-6a to calculate STATE time stamps

For calculation of time stamps use the filter delay information, the additional STATE input delay value stored in the register SIDEL (initial zero) and use p=APS while DIR2=0:

TS_S_1= STATE_TS-SIDEL (DPLL-6a0)

TS_S = TS_S_1-FTV_Sx (for IDS=1 and IFP=0) (DPLL-6a1) with

FTV_Sx = FTV_S / 8 (for LOW_RES = 1 and TS0_HRS = 0) (DPLL-6a1a)

FTV_Sx = FTV_S (for LOW_RES = 0 or TS0_HRS = 1) (DPLL-6a1b) and

TS_S = TS_S_1- FTV_S * (CDT_SX / NMB_S)_old (for IDS=1 and IFP=1) (DPLL-6a2) this can be also calculated using the value of ADD_IN_CALE:

TS_S = TS_S_1-FTV_S * (1 / ADD_IN_CALE)_old (for IDS=1 and IFP=1) (DPLL-6a3) with see also equations DPLL.6a4 ff. at **Section 38.22.6.2, Increment prediction in Normal Mode and for first PMSM forwards** for TRIGGER.

For (CDT_SX / NMB_S)_old and (1/ADD_IN_CALE)_old consider values, calculated for the last increment; position related filter values are only considered up to at least 1 ms time between two STATE events. The reciprocal value is stored using a 32 bit fractional part, while only the 24 lower bits are used – for explanation see note (DPLL_10980)[XREF TARGET '' (DPLL_10980)] NOT EXIST. The value of 1/ADD_IN_CALE_old or (CDT_SX/NMB_S)_old is set to 0xFFFFFF in the case of an overflow.

NOTE

CDT_SX is the predicted duration of the last STATE increment and NMB_S the calculated number of SUB_INC1 events in the last increment, because the new calculations are done by equations DPLL-10 and DPLL-22 respectively for the current increment after that. Therefore in equation (DPLL_11022)[XREF TARGET '' (DPLL_11022)] NOT EXIST the value ADD_IN of the last increment is used (see equation DPLL-26). SYN_S_OLD is the number of increments including missing STATE s as specified in the NUSC register for the last increment with the initial value of 1. The update to the RAM region 1c4 is done after all related calculations (see equation DPLL-6b1 for this reason).

(2) Equation DPLL-6b to calculate DT_S_ACT (nominal value)

DT_S_ACT= (TS_S – TS_S_OLD) / SYN_S_OLD (DPLL-6b)

For the case SYS=0 (still no synchronization to the profile) the values SYN_S and SYN_S_OLD are still assumed as having the value 1.

Correct the current increment duration value got by equation (DPLL_6917)[XREF TARGET " (DPLL_6917)] NOT EXIST in the case of physical deviations (ADS=1) by

DT_S_ACT = DT_S_ACT * (1 – PDC_S + PDC_S – PDC_S) (DPLL-6b1)

with the relative correction value for the last increment

PDC_S = PD_S_OLD/(MLS1) (DPLL-6b2)(for SMC=0)

PDC_S = PD_S_OLD/(MLS2)(DPLL-6b3) (for SMC=1)

The term (1 – PDC_S + PDC_S – PDC_S) of equation (DPLL_11024)[XREF TARGET " (DPLL_11024)] NOT EXIST is representing the third order Taylor series of the term 1/(1+PDC_S), which is chosen to reduce the additional time delay due to the more complex computation.

(3) Equation DPLL-6c to calculate RDT_S_ACT (nominal value)

RDT_S_ACT = 1 / DT_S_ACT(DPLL-6c)

(4) Equation DPLL-7a1 to calculate QDT_S_ACT

Relation of the last two increment values for APS=p in forward direction (DIR2=0)

QDT_S_ACT = DT_S_ACT * RDT_S[p–1](DPLL-7a1)

QDT_S_ACT as well as QDT_S[i] have a 24 bit value using a 6 bit integer part and an 18 bit fractional part.

NOTE

QDT_S_ACT uses a 6 bit integer part and an 18 bit fractional part.

(5) Equation DPLL-8 to calculate the error of last prediction

With q= NUSE–VSN when using QDT_S[p–q] and DT_S[p–1] for the prediction of DT_S[p]

EDT_S = DT_S_ACT – (DT_S[p–1] * QDT_S[p–q]) (DPLL-8) and with

QDT_S[p–q] = DT_S[p–q] * RDT_S[p–q–1] (for FSS=0) (DPLL-7b1)

QDT_S[p–q] = DT_S[p–q] * RDT_S_FS1 (for FSS=1) (DPLL-7b2)

FSS=1 has the meaning: NUSE=FULL_SCALE (see NUSC register). QDT_S_ACT as well as QDT_S[i] have a 24 bit value using a 6 bit integer part and an 18 bit fractional part.

NOTE

QDT_S[p–q] uses a 6 bit integer part and an 18 bit fractional part.

(6) Equation DPLL-9 to calculate the weighted average error

for SYS=1 calculate:

MEDT_S := (EDT_S + MEDT_S) / 2

(7) Equations DPLL-10 to calculate the current increment (nominal value)

nominal increment value (for ADS=0):

CDT_SX _nom = (DT_S_ACT + MEDT_S) * QDT_S[p–q+1] (DPLL-10a1)

or nominal increment value (for ADS=1):

CDT_SX _nom_corr = CDT_SX _nom * (1+CDC_S) (DPLL-10a2) with: CDC_S = PD / (MLS1) (DPLL-10a3) (for SMC=0)

CDC_S = PD / (MLS2) (DPLL-10a4) (for SMC=1) and

QDT_S[p–q+1] = DT_S[p–q+1] * RDT_S[p–q] (for q>1) (DPLL-7c) and for q=1 use equation (DPLL_11029)[XREF TARGET '' (DPLL_11029)] NOT EXIST. While QDT_S_ACT as well as QDT_S[i] have a 24 bit value using a 6 bit integer part and an 18 bit fractional part.

The CDT_SX_nom value is limited by the relation

CSN_MIN < CDT_SX_nom < CSN_MAX (DPLL-10c) When the calculated value exceeds one of the limits, it is replaced by the corresponding limit value.

The expected duration to the next STATE event is (for ADT=0): CDT_SX = CDT_SX _nom * SYN_T (for ADT=1): CDT_SX = CDT_SX _nom_corr * SYN_S (DPLL-10b)

NOTES

- QDT_S[p–q+1] uses a 6 bit integer part and an 18 bit fractional part.
- In the case of an overflow in equations (DPLL_11036)[XREF TARGET '' (DPLL_11036)] NOT EXIST or (DPLL_11045)[XREF TARGET '' (DPLL_11045)] NOT EXIST set the value to $FFFFFF_H$ and the corresponding CSO bit in the DPLL_STATUS register. In the case of negative values set CDT_SX to 0_H without any effect to the CSO bit. All 5 steps above (DPLL-6 to DPLL-10) are only needed in emergency mode. For the normal mode the calculations of equations DPLL-6 and DPLL-7 are done solely in order to get the values needed for a sudden switch to emergency mode.

38.22.6.4 Increment prediction in Normal Mode and for first PMSM backwards

(1) Equations DPLL-2a2 to calculate QDT_T_ACT backwards

QDT_T_ACT = DT_T_ACT * RDT_T[p+1] (DPLL-2a2)

QDT_T_ACT as well as QDT_T[i] have a 24 bit value using a 6 bit integer part and an 18 bit fractional part.

(2) Equation DPLL-3a to calculate of the error of last prediction

When q = NUTE–VTN and DIR1=1 using only QT_T[p+q] and DT_T[p+1] for the prediction of DT_T[p].

EDT_T = DT_T_ACT – (DT_T[p+1] * QDT_T[p+q] (DPLL-3a) with

QDT_T[p+q] = DT_T[p+q] * RDT_T[p+q+1] for FST=0 (DPLL-2b3)

QDT_T[p+q] = DT_T[p+q] * RDT_T_FS1 for FST=1 (DPLL-2b4)

FST=1 has the meaning: NUTE=FULL_SCALE (see NUTC register). QDT_T_ACT as well as QDT_T[i] have a 24 bit value using a 6 bit integer part and an 18 bit fractional part.

(3) Equation DPLL-4 to calculate the weighted average error

For SYT=1 calculate:
MEDT_T := (EDT_T + MEDT_T) / 2 (DPLL-4)

(4) Equation DPLL-5 to calculate the current increment value

nominal increment value (for ADT=0):
CDT_TX _nom = (DT_T_ACT + MEDT_T) * QDT_T[p+q–1](DPLL-5a5)

nominal increment value (for ADT=1):
CDT_TX _nom_corr = CDT_TX _nom * (1 + CDC_T) (DPLL-5a6)with

CDC_T = PD / (MLT + 1)(DPLL-5a3) (for SMC=0) see (DPLL_11008)[XREF TARGET " (DPLL_11008)] NOT EXIST

CDC_T = PD / (MLS1) (DPLL-5a4)(for SMC=1) see (DPLL_11009)[XREF TARGET " (DPLL_11009)] NOT EXIST and QDT_T[p+q–1] = DT_T[p+q–1] * RDT_T[p+q] (for q>1) (DPLL-2c1) for q=1 use **Section 38.22.6.2, (4) Equation DPLL-2a1 to calculate QDT_T_ACT**

while QDT_T_ACT as well as QDT_T[i] have a 24 bit value using a 6 bit integer part and an 18 bit fractional part. The CDT_TX_nom value is limited by the relation

CTN_MIN < CDT_TX_nom < CTN_MAX (DPLL-5c) When the calculated value exceeds one of the limits, it is replaced by the corresponding limit value. The expected duration to the next TRIGGER event

CDT_TX = CDT_TX _nom * SYN_T (for ADT=0) see (DPLL_11005)[XREF TARGET " (DPLL_11005)] NOT EXIST

CDT_TX = CDT_TX _nom_corr * SYN_T (DPLL-5b) (for ADT=1) see (DPLL_11016)[XREF TARGET " (DPLL_11016)] NOT EXIST

NOTE

In the case of an overflow in equations (DPLL_11005)[XREF TARGET '' (DPLL_11005)] NOT EXIST or (DPLL_11016)[XREF TARGET '' (DPLL_11016)] NOT EXIST set the value to $FFFFFF_H$ and the corresponding CTO bit in the DPLL_STATUS register. In the case of negative values set CDT_TX(_nom) to 0_H.

38.22.6.5 Increment prediction in Emergency Mode and for second PMSM backwards

(1) Equation DPLL-7a2 to calculate QDT_S_ACT backwards

QDT_S_ACT = DT_S_ACT * RDT_S[p+1]

QDT_S_ACT as well as QDT_S[i] have a 24 bit value using a 6 bit integer part and an 18 bit fractional part.

(2) Equation DPLL-8a to calculate the error of the last prediction

While q= NUSE–VSN, use only QDT_S[p+q] and DT_S[p+1] for the prediction of DT_S[p]

EDT_S = DT_S_ACT – (DT_S[p+1] * QDT_S[p+q]) with

QDT_S[p–q] = DT_S[p+q] * RDT_S[p+q+1] (for FSS=0)

QDT_S[p–q] = DT_T[p+q] * RDT_S_FS1 (for FSS=1)

FSS=1 has the meaning: NUSE=FULL_SCALE (see NUSC register). QDT_S_ACT as well as QDT_S[i] have a 24 bit value using a 6 bit integer part and an 18 bit fractional part.

(3) Equation DPLL-9 to calculate the weighted average error

For SYS=1 calculate:

MEDT_S := (EDT_S + MEDT_S) / 2

(4) Equations DPLL-10 to calculate the current increment value

nominal increment value (for ADS=0):

CDT_SX _nom = (DT_S_ACT + MEDT_S) * QDT_S[p+q–1]

or nominal increment value (for ADS=1):

CDT_SX _nom_corr = CDT_SX _nom * (1+CDC_S) with:

CDC_S = PD / (MLS1) (for SMC=0) compare to (DPLL_11039)[XREF TARGET " (DPLL_11039)] NOT EXIST

CDC_S = PD / (MLS2) (for SMC=1) compare to (DPLL_11040)[XREF TARGET " (DPLL_11040)] NOT EXIST.

With QDT_S[p+q–1] = DT_S[p+q–1] * RDT_S[p+q] (for q>1) for q=1 use **Section 38.22.6.2, (4) Equation DPLL-2a1 to calculate QDT_T_ACT**.

While QDT_S_ACT as well as QDT_S[i] have a 24 bit value using a 6 bit integer part and an 18 bit fractional part. The CDT_SX_nom value is limited by the relation

CSN_MIN < CDT_SX_nom < CSN_MAX (compare to (DPLL_11044)[XREF TARGET " (DPLL_11044)] NOT EXIST) When the calculated value exceeds one of the limits, it is replaced by the corresponding limit value.

Then calculate the expected duration to the next STATE event CDT_SX = CDT_SX _nom * SYN_T (for ADT=0) CDT_SX = CDT_SX _nom_corr * SYN_S (for ADT=1) compare to (DPLL_11045)[XREF TARGET " (DPLL_11045)] NOT EXIST

NOTE

In the case of an overflow in equations (DPLL_11036)[XREF TARGET '' (DPLL_11036)] NOT EXIST, (DPLL_11045)[XREF TARGET '' (DPLL_11045)] NOT EXIST set the value to $FFFFFF_H$ and the corresponding CSO bit in the DPLL_STATUS register. In the case of negative values set CDT_SX(_nom) to 0x0. All 5 steps above (DPLL-6 to DPLL-10) are only needed in emergency mode. For the normal mode the calculations of equations DPLL-6 and DPLL-7 are done solely in order to get the values needed for a sudden switch to emergency mode.

38.22.7 Calculations for actions

As already shown for the calculation of the current interval by equations DPLL-1 to DPLL-10 for the prediction of actions a similar calculation is to be done, as shown by the equations DPLL-11. to DPLL-14. The calculation of actions is also needed when the DPLL is used for synchronous motor control applications (SMC=1, see DPLL_CTRL_1 register). For action prediction purposes the measured time periods of the past (one FULL_SCALE back, when the corresponding NUTE or NUSE values are set properly by the CPU) are used. The calculation can be explained by the following assumptions, which are considerably simple:

Take the corresponding increments for prediction in the past and put the sum of it in relation to the increment (DT_T[k], DT_S[k], with ≥ 0, which is represented by the time stamp difference) which is exactly one FULL_SCALE period in the past (DPLL-11 or DPLL-13 respectively). Make a prediction for the coming sum of increments using the current measured increment (DT_T_ACT or DT_S_ACT respectively, that means DPLL-1 or DPLL-6 respectively) and add a weighted average error (DPLL_1347 and DPLL_1554 or DPLL_1361 and DPLL_1362 respectively, calculated for one increment prediction) before multiplication with the relation of equation DPLL-11 or DPLL-13 respectively in order to get the result as described by equations DPLL_6935 or DPLL-14 respectively.

In order to avoid division operations instead of the increment (DT_T[k], DT_S[k], with k > 0) in the past its reciprocal value (RDT_T[k], RDT_S[k], with k > 0) is used, which is stored also in RAM. For the calculation of actions perform always a new refined calculation as long as the resulting time stamp is not in the past. In the other case the TSAC/PSAC values (time/position stamp of action calculated) is set to the time/position stamp of the last input event (TRIGGER/STATE), the ACT_N[i] bit in the DPLL_ACT_STA register is reset, while the corresponding ACT_N[i] bit in the DPLL_ACT_STA_shadow register is set. Each new PMTR_i value will set this ACT_N[i] bit again and reset the correspondent shadow bit until a new calculation is performed.

Make sure that the prediction parameters are chosen such that under all conditions (acceleration/ deceleration) the values of PDT_T, PDT_S and DTA respectively do not exceed the value $FFFFFF_H$. This requirement can limit the predicted position range in the case of very low speed.

Action updates at highest speed

Up to 32 action values can be calculated. For the shortest increment duration (23,4 µs) not all of them can be updated with each active input event. Notice the following conditions and parameters for an estimation of possible results. All time estimation values are given for a system clock frequency of 100 MHz and the assumption, that the calculation of the DPLL is not impeded by a remote read or write access to the DPLL RAMs. Each RAM access is to be considered by an additional delay of about 40 ns ($t_{remote\_RAM\_acces}$, to be described later in detail). When using a different system clock frequency the calculation duration is extended accordingly.

1. Typical time needed for basic operations (RAM update, pointer calculation and SUB_INC generation for normal, emergency mode or one PMSM:
   t_{basic_0} = 9,9 µs.
2. Typical time needed basic operations (RAM update, pointer calculation and SUB_INC generation for two PMSMs:
   t_{basic_1} = 11,0 µs.
3. Typical time needed to calculate one action
   t_{action_i} = 3,7 µs.

NOTE

The above mentioned values are observed worst case values, when the two state machines of TRIGGER and STATE are both in operation.

These values allow the calculation of at least 3 action values for each input event for all specified increments duration. The complete time needed for the basic operation, n action calculations and k remote RAM access operations can be calculated as follows

$t_{complete} = t_{basic\_0/1} + n*t_{action\_i} + k*t_{remote\_RAM\_access}$

Typical applications

Normal and emergency mode For a typical application with the shortest increment duration of 100 µs in normal or emergency mode the calculation of up to 24 action values can be performed for each active input event.

One PMSM For one PMSM and a typical shortest increment time of 39 µs there is the calculation of up to 7 action values possible for each input event.

Two PMSMs with restricted action calculations When only one PMSM uses the action calculation service and the shortest increment duration is 39 µs, there can up to 7 actions served for each active input event.

Two PMSMs with unrestricted action calculations When 2 PMSMs are used and both use the action calculation service at a minimal increment duration of 39 µs there are up to 7 action calculations possible for each of the two engines – that means up to 14 action calculations per increment in average.

38.22.7.1 Action calculations for TRIGGER forwards

valid for RMO=0 or for SMC=1 with p=APT_2B, t=APT, m=NA[i] (part w), mb=NA[i](part b)/1024, NUTE–VTN=q, NUTE=n

NOTE

All 5 steps in equations **Section 38.22.7.1, (1) Equation DPLL-11a1 to calculate the time prediction for an action** (DPLL-11) to (DPLL_6935)[XREF TARGET '' (DPLL_6935)] NOT EXIST are only calculated in normal mode.

(1) Equation DPLL-11a1 to calculate the time prediction for an action

For DIR1=0 and q>m calculate:

PDT_T[i] = (TSF_T[p+m–n] – TSF_T[p–n] + mb* DT_Tx[t–q+1]) * RDT_T[t–q] (DPLL-11a1)with

DT_Tx[t–q+1] = DT_T[t–q+1] for TS0_HRT=0 (DPLL-11b2) compare to (DPLL_11086)[XREF TARGET " (DPLL_11086)] NOT EXIST, (DPLL_11089)[XREF TARGET " (DPLL_11089)] NOT EXIST or DT_Tx[t–q+1] = DT_T[t–q+1]/8 (for TS0_HRT=1) (DPLL-11b3) compare to (DPLL_11087)[XREF TARGET " (DPLL_11087)] NOT EXIST, (DPLL_11090)[XREF TARGET " (DPLL_11090)] NOT EXIST and while the multiplication with mb does mean the fractional part of NA[i].

For SMC=0 and RMO=0 calculate for DIR1=0 all 32 actions in forward direction, if requested; in the case SMC=1 calculate up to 16 actions 0 to 15 in dependence of the TRIGGER input.

(2) Equation DPLL-11a2 to calculate the time prediction for an action

For SYT=1, NUTE= 2*(TNU+1), q>m and DIR1=0 calculate:

PDT_T[i] = (TSF_T[p+m] – TSF_T[p]+ mb* DT_Tx[t–q+1]) * RDT_T[t] (DPLL-11a2) with

DT_Tx[t–q+1] = DT_T[t–q+1] for TS0_HRT=0 (DPLL-11b2)compare to (DPLL_11083)[XREF TARGET " (DPLL_11083)] NOT EXIST, (DPLL_11089)[XREF TARGET " (DPLL_11089)] NOT EXIST or

DT_Tx[t–q+1] = DT_T[t–q+1]/8 (for TS0_HRT=1) (DPLL-11b3)compare to (DPLL_11084)[XREF TARGET " (DPLL_11084)] NOT EXIST, (DPLL_11090)[XREF TARGET " (DPLL_11090)] NOT EXIST

(3) Equation DPLL-11b to calculate the time prediction for an action

for DIR1=0, NUTE–VTN=q, q (< or =) m, n>1 and t=APT:

PDT_T[i] = (m+mb)*DT_Tx[t–q+1] * RDT_T[t–q](DPLL-11b) with

DT_Tx[t–q+1] = DT_T[t–q+1] for TS0_HRT=0 (DPLL-11b2) compare to (DPLL_11086)[XREF TARGET " (DPLL_11086)] NOT EXIST, (DPLL_11083)[XREF TARGET " (DPLL_11083)] NOT EXIST or

DT_Tx[t–q+1] = DT_T[t–q+1]/8 (for TS0_HRT=1)(DPLL-11b3) compare to (DPLL_11084)[XREF TARGET " (DPLL_11084)] NOT EXIST, (DPLL_11087)[XREF TARGET " (DPLL_11087)] NOT EXIST

NOTE

Make the calculations above before updating the TSF_T[i] values according to equations DPLL-1c3 ff.

(4) Equation DPLL-11c to calculate the time prediction for an action

for n=1 (this is always valid for SYT=0)

PDT_T[i] = (m+mb)* DT_T_ax* RDT_T[t–1] (DPLL-11c)with

DT_T_ax = DT_T_ACT for TS0_HRT=0 (DPLL-1a4a) compare to (DPLL_11095)[XREF TARGET " (DPLL_11095)] NOT EXIST, (DPLL_11097)[XREF TARGET " (DPLL_11097)] NOT EXIST or

DT_T_ax = DT_T_ACT/8 (for TS0_HRT=1) (DPLL-1a4b) compare to (DPLL_11098)[XREF TARGET " (DPLL_11098)] NOT EXIST, (DPLL_11102)[XREF TARGET " (DPLL_11102)] NOT EXIST

NOTE

For the relevant last increment add the fractional part of DT_T_ACT as described in NA[i].

(5) Equation DPLL-12 to calculate the duration value until action

DTA[i] = (DT_T_ACT + MEDT_T)* PDT_T[i] (DPLL-12) compare to (DPLL_6941)[XREF TARGET " (DPLL_6941)] NOT EXIST

38.22.7.2 Action calculations for TRIGGER backwards

Valid for RMO=0 or for SMC=1 with p=APT_2B, t=APT, m=NA[i] (part w), mb=NA[i](part b)/1024, q= NUTE–VTN and n=NUTE

For SMC=0 and RMO=0 calculate for DIR1=1 all 32 actions in backward direction for special purposes; in the case SMC=1 calculate up to 16 actions 0 to 15 in dependence of the TRIGGER input.

NOTE

All 5 steps in equations DPLL-11 to (DPLL_6935)[XREF TARGET '' (DPLL_6935)] NOT EXIST are only calculated in normal mode or when SMC=1.

(1) Equation DPLL-11a3 to calculate the time prediction for an action

For DIR1=1 and q>m calculate:

PDT_T[i] = (TSF_T[p–m+n] – TSF_T[p+n] + mb* DT_Tx[t+q–1]) * RDT_T[t+q] (DPLL-11a3) with DT_Tx[t+q–1] = DT_T[t+q–1] for TS0_HRT=0 (DPLL-11b4) or

DT_Tx[t+q–1] = DT_T[t+q–1]/8 for TS0_HRT=1 (DPLL-11b5)

(2) Equation DPLL-11a4 to calculate the time prediction for an action

For SYT=1 and NUTE = 2*(TNU+1), q>m, VTN=2*SYN_NT and hence NUTE–VTN = 2*(TNU+1–SYN_NT) for DIR1=1 PDT_T[i] is:

PDT_T[i] = (TSF_T[p–m] – TSF_T[p]+ mb* DT_Tx[t+q–1]) * RDT_T[t] (DPLL-11a4) with
DT_Tx[t+q–1] = DT_T[t+q–1] for TS0_HRT=0 (DPLL-11b4) or
DT_Tx[t+q–1] = DT_T[t+q–1]/8 for TS0_HRT=1 (DPLL-11b5)

NOTE

Make the calculations above before updating the TSF_T[i] values according to equations DPLL-1c3 ff.

(3) Equation DPLL-11b1 to calculate the time prediction for an action

For NUTE–VTN =q, q (< or =) m the following equation is valid for n>1 and t=APT:

PDT_T[i] = (m+mb)*DT_Tx[t+q–1] * RDT_T[t+q] (DPLL-11b1) with

DT_Tx[t+q–1] = DT_T[t+q–1] for TS0_HRT=0 (DPLL-11b4) or
DT_Tx[t+q–1] = DT_T[t+q–1]/8 for TS0_HRT=1 (DPLL-11b5)

(4) Equation DPLL-11c1 to calculate the time prediction for an action

for n=1 (this is always valid for SYT=0)

PDT_T[i] = (m+mb)* DT_T_ax * RDT_T[t+1] (DPLL-11c1) with

DT_T_ax = DT_T_ACT for TS0_HRT=0 compare to (DPLL_11095)[XREF TARGET '' (DPLL_11095)] NOT EXIST, (DPLL_11092)[XREF TARGET '' (DPLL_11092)] NOT EXIST or

DT_T_ax = DT_T_ACT/8 (for TS0_HRT=1) compare to (DPLL_11093)[XREF TARGET '' (DPLL_11093)] NOT EXIST, (DPLL_11102)[XREF TARGET '' (DPLL_11102)] NOT EXIST

NOTE

For the relevant last increment add the fractional part of DT_T_ACT as described in NA[i].

(5) Equation DPLL-12 to calculate the duration value for an action

DTA[i] = (DT_T_ACT + MEDT_T)* PDT_T[i] compare to (DPLL_6935)[XREF TARGET " (DPLL_6935)] NOT EXIST

Use the results of equations **Section 38.22.6.2, (1) Equations DPLL-1a to calculate TRIGGER time stamps**, **Section 38.22.6.2, (2) Equation DPLL-1b to calculate DT_T_ACT (nominal value)**, **Section 38.22.6.2, (5) Equation DPLL-3 to calculate the error of last prediction** and **Section 38.22.6.2, (6) Equation DPLL-4 to calculate the weighted average error** for the above calculation.

38.22.7.3 Action calculations for STATE forwards

valid for RMO=1 with p=APS_1C2, t=APS, m=NA[i](part w) mb=NA[i](part b)/1024, NUSE–VSN = q and NUSE=n>m

For SMC=0 and RMO=1 calculate for DIR2=0 all 32 actions in forward direction, if requested; in the case SMC=1 and RMO=1 calculate up to 16 actions 16 to 31 in dependence of the STATE input.

NOTE

All 5 steps of equations DPLL-13 to DPLL-14 are only calculated in emergency mode or for SMC=1 in combination with RMO=1.

(1) Equation DPLL-13a1 to calculate the time prediction for an action

For DIR2=0 and q>m calculate:

PDT_S[i] = (TSF_S[p+m–n] – TSF_S[p–n] + mb* DT_Sx[t–q+1] * RDT_S[t–q] (DPLL-13a1) with DT_Sx[t–q+1]= DT_S[t–q+1] for TS0_HRS=0 (DPLL-13b2) or

DT_Sx[t–q+1] = DT_S[t–q+1]/8 for TS0_HRS=1 (DPLL-13b3)

(2) Equation DPLL-13a2 to calculate the time prediction for an action

For SYS=1 and NUSE=2*(SNU+1), q>m, SYSF=0, VSN=2*SYN_NS and hence NUSE–VSN = 2*(SNU+1–SYN_NS) PDT_S[i] is equal to:

PDT_S[i] = (TSF_S[p+m] – TSF_S[p]+ mb*DT_Sx[t–q+1]) * RDT_S[t] (DPLL-13a2) with

DT_Sx[t–q+1] = DT_S[t–q+1] for TS0_HRS=0 (DPLL-13b2) or
DT_Sx[t–q+1] = DT_S[t–q+1]/8 for TS0_HRS=1 (DPLL-13b3)

(3) Equation DPLL-13b to calculate the time prediction for an action

For NUSE –VTN=q, q (< or =) m and n>1:

PDT_S[i] = (m+mb)*DT_Sx[t–q+1] * RDT_S[t–q] (DPLL-13b) with
DT_Sx[t–q+1] = DT_S[t–q+1] for TS0_HRS=0 (DPLL-13b2) or
DT_Sx[t–q+1] = DT_S[t–q+1]/8 for TS0_HRS=1 (DPLL-13b3)

(4) Equation DPLL-13c to calculate the time prediction for an action

for n=1

PDT_S[i] = (m+mb)* DT_S_ax * RDT_S[t–1] (DPLL-13c) with
DT_S_ax = DT_S_ACT for TS0_HRS=0 (DPLL-6a4a) or
DT_S_ax = DT_S_ACT/8 for TS0_HRS=1 (DPLL-6a4b)

(5) Equation DPLL-14 to calculate the duration value for an action

DTA[i] = (DT_S_ACT + MEDT_S)* PDT_S[i] (DPLL-14)

Use the results of DPLL-7, **Section 38.22.6.3, (5) Equation DPLL-8 to calculate the error of last prediction** and **Section 38.22.6.3, (6) Equation DPLL-9 to calculate the weighted average error** for the above calculation

38.22.7.4 Action calculations for STATE backwards

valid for RMO=1 with p=APS_1C2, t=APS, m=NA[i](part w) mb=NA[i](part b)/1024, NUSE–VSN = q and NUSE=n

For SMC=0 and RMO=1 calculate for DIR1=1 all 32 actions in backwards mode for special purposes; in the case SMC=1 and RMO=1 calculate up to 16 actions 16 to 31 in dependence of the STATE input.

NOTE

All 5 steps of equations DPLL-13 to DPLL-14 are only calculated in emergency mode or for SMC=1 in combination with RMO=1.

(1) Equation DPLL-13a3 to calculate the time prediction for an action

For (DIR2= 1 (SMC=1) or DIR1=1 (SMC=0)) and q>m calculate

PDT_S[i] = (TSF_S[p–m+n] – TSF_S[p+n] + mb* DT_Sx[t+q–1]) * RDT_S[t+q] (DPLL-13a3) with
DT_Sx[t+q–1]= DT_S[t+q–1] for TS0_HRS=0 (DPLL-13b4) or
DT_Sx[t+q–1] = DT_S[t+q–1]/8 for TS0_HRS=1 (DPLL-13b5)

(2) Equation DPLL-13a4 to calculate the time prediction for an action

For SYS=1, NUSE=2*(SNU+1), q>m, SYSF=0, VSN=2*SYN_NS and hence NUSE–VSN = 2*(SNU+1–SYN_NS) calculate:

PDT_S[i] = (TSF_S[p–m] – TSF_S[p]+ mb* DT_Sx[t+q–1]) * RDT_S[t] (DPLL-13a4) with
DT_Sx[t+q–1]= DT_S[t+q–1] for TS0_HRS=0 (DPLL-13b4) or

DT_Sx[t+q–1] = DT_S[t+q–1]/8 for TS0_HRS=1 (DPLL-13b5)

(3) Equation DPLL-13b1 to calculate the time prediction for an action

For NUSE–VSN =q, q (< or =) m, NUSE=n and n>1:

PDT_S[i] = m*DT_Sx[t+q–1] * RDT_S[t+q] (DPLL-13b1) with DT_Sx[t+q–1] = DT_S[t+q–1] for TS0_HRS=0 (DPLL-13b4) or DT_Sx[t+q–1] = DT_S[t+q–1]/8 for TS0_HRS=1 (DPLL-13b5)

(4) Equation DPLL-13c1 to calculate the time prediction for an action

for n=1:

PDT_S[i] = (m+mb)* DT_S_ax * RDT_S[t+1] (DPLL-13c1) with
DT_S_ax = DT_S_ACT (for TS0_HRS=0) (DPLL-6a4a) or
DT_S_ax = DT_S_ACT/8 (for TS0_HRS=1) (DPLL-6a4b)

(5) Equation DPLL-14 to calculate the duration value until action

DTA[i] = (DT_S_ACT + MEDT_S)* PDT_S[i] (DPLL-14)

Use the results of DPLL-7, **Section 38.22.6.3, (5) Equation DPLL-8 to calculate the error of last prediction** and **(6), Equation DPLL-9 to calculate the weighted average error** or (DPLL_6929)[XREF TARGET " (DPLL_6929)] NOT EXIST for the above calculation.

38.22.7.5 Update of RAM in Normal and Emergency Mode

After considering the calculations for up to all 24 actions according to equations (DPLL-11, (DPLL_6935)[XREF TARGET " (DPLL_6935)] NOT EXIST), only when going back to state 1 or 21 (because of a new TRIGGER or STATE event, that means when no further PMTR values are to be considered) set time stamp values and duration of increments in the RAM.

(1) Equation DPLL-1a4 to update the time stamp values for TRIGGER

TSF_T[s]=TS_Tx (DPLL-1a4) using the following equations for the determination of TS_Tx

For TS0_HRT=0:

TS_Tx=TS_T (DPLL-1a4w)

DT_T_ax = DT_T_ACT compare to (DPLL_11092)[XREF TARGET " (DPLL_11092)] NOT EXIST, (DPLL_11097)[XREF TARGET " (DPLL_11097)] NOT EXIST

For TS0_HRT=1:

TS_Tx(20:0)=TS_T/8 (DPLL-1a4x)

TS_Tx(23:21)=TBU_TS0_T(23:21) (DPLL-1a4y) for TBU_TS0_T(20:0) > or = TS_Tx(20:0)
TS_Tx(23:21)=TBU_TS0_T(23:21) –1 (DPLL-1a4z) for TBU_TS0_T(20:0) < TS_Tx(20:0)

DT_T_ax = DT_T_ACT/8 compare to (DPLL_11093)[XREF TARGET " (DPLL_11093)] NOT EXIST, (DPLL_11098)[XREF TARGET " (DPLL_11098)] NOT EXIST

NOTE

The combination of values LOW_RES=0 and TS0_HRT=1 is not possible.

Store the time stamp values in the time stamp field according to the address pointer APT_2B=s, but make this update only after the calculation of actions **Section 38.22.7, Calculations for actions** because the old TSF_T[i] values are still needed for these calculations. Note that the address pointer after a gap is still incremented by SYN_T_OLD in that case (see state machine step 1 in **Section 38.22.8.6, Scheduling of the Calculation**).

(2) Equation DPLL-1a5-7 to extend the time stamp values for TRIGGER in forward direction

when SYT=1 and SYN_T_OLD=r>1 and DIR1=0:
TSF_T[s–1] = TSF_T[s] –DT_T_ax (DPLL-1a5)

TSF_T[s–2] = TSF_T[s–1] –DT_T_ax (DPLL-1a6) until

TSF_T[s– r+1] = TSF_T[s– r+2] –DT_T_ax (DPLL-1a7) after the incrementation of the pointer APT_2B by SYN_T_OLD

(3) Equations DPLL-1a5-7 for backward direction

When SYT=1 and SYN_T_OLD=r>1 and DIR1=1

TSF_T[s+1] = TSF_T[s] –DT_T_ax (DPLL-1a5)

TSF_T[s+2] = TSF_T[s+1] –DT_T_ax (DPLL-1a6) until

TSF_T[s+r–1] = TSF_T[s+r–2] –DT_T_ax (DPLL-1a7) after the decrementation of the pointer APT_2B by SYN_T_OLD

(4) Equations DPLL-1b1 and DPLL-1c1 to update the RAM after calculation

DT_T[p] = DT_T_ACT (DPLL-1b1)

save old reciprocal value from RAM before overwriting:

RDT_T_FS1= RDT_T[p] (DPLL-1c1)

after that store new value in RAM

RDT_T[p]= RDT_T_ACT (DPLL-1c2)

Store increment duration and reciprocal value in RAM region 2 in normal mode after calculation of actions only when a new active TRIGG- ER slope is detected and in emergency mode directly after calculation of DT_T_ACT or RDT_T_ACT respectively.

(5) Equation DPLL-6a4 to update the time stamp values for STATE

TSF_S[s]=TS_Sx (DPLL-6a4) using the following equations for the determination of TS_Sx

For TS0_HRS=0:

TS_Sx=TS_S (DPLL-6a4)

DT_S_ax = DT_S_ACT (DPLL-6a4a)

For TS0_HRS=1: TS_Sx(20:0)=TS_S/8 (DPLL-6a4x)

TS_Sx(23:21)=TBU_TS0_S(23:21) (DPLL-6a4y) for TBU_TS0_S(20:0) > or = TS_Sx(20:0)
TS_Sx(23:21)=TBU_TS0_S(23:21) –1 (DPLL-6a4z) for TBU_TS0_S(20:0) < TS_Sx(20:0)

DT_S_ax = DT_S_ACT/8 (DPLL-6a4b)

NOTE

The combination of values LOW_RES=0 and TS0_HRS=1 is not possible.

Store the time stamp value in the time stamp field according to the address pointer APS_1C2=s, but make this update only after the calculation of actions (equations DPLL-13a2, **Section 38.22.7.3, (2) Equation DPLL-13a2 to calculate the time prediction for an action** or DPLL-13a4 **Section 38.22.7.4, (2) Equation DPLL-13a4 to calculate the time prediction for an action**, if applicable) because the old TSF_S[i] values are still needed for these calculations. Note that the address pointer after a gap is still incremented by SYN_S_OLD in that case (see state machine step 21 in **Section 38.22.8.6, Scheduling of the Calculation**).

(6) Equations DPLL-6a5-7 to extend the time stamp values for STATE

When SYS=1 and SYN_S_OLD=r>1 and DIR2=0 or DIR1=0 respectively calculate

TSF_S[s–1] = TSF_S[s] – DT_S_ax (DPLL-6a5)

TSF_S[s–2] = TSF_S[s–1] – DT_S_ax (DPLL-6a6) until TSF_S[s– r+1] = TSF_S[s– r+2] – DT_S_ax (DPLL-6a7)

after incrementation of the pointer APS_2b by SYN_S_OLD

(7) Equations DPLL-6a5-7 for backward direction

When SYS=1 and SYN_S_OLD=r>1 and DIR2=1 or DIR1=1 respectively calculate TSF_S[s+1] = TSF_S[s] – DT_S_ax (DPLL-6a5)

TSF_S[s+2] = TSF_S[s+1] – DT_S_ax (DPLL-6a6) until

TSF_S[s+r–1] = TSF_S[s+r–2] – DT_S_ax (DPLL-6a7)

after the incrementation of the pointer APS_1C2 by SYN_S_OLD

(8) Equations DPLL-6b1 and DPLL-6c2 to update the RAM after calculation

DT_S[p] = DT_S_ACT (DPLL-6b1)

save old reciprocal value from RAM before overwriting:

RDT_S_FS1= RDT_S[p] (DPLL-6c1)

after that store new value in RAM

RDT_S[p] = RDT_S_ACT (DPLL-6c2)

when a new active STATE slope is detected in emergency mode or in normal mode (SMC=RMO=0) directly after calculation of the values above.

Store increment duration and reciprocal value in RAM region 1c in emergency mode after calculation of actions only when a new active STATE slope is detected and in normal mode directly after calculation of DT_S_ACT or RDT_S_ACT respectively.

38.22.7.6 Time and position stamps for actions in Normal Mode

(1) Equation DPLL-15 to calculate the action time stamp

TSAC[i]= DTA[i] – DLA[i] + TS_Tx (for DTA[i] > DLA[i] and DTA[i] – DLA[i] < 800000_H) (DPLL-15a)

TSAC[i]= TS_Tx (for DTA[i] < DLA[i]) (DPLL-15b)

TSAC[i]= $7FFFFF_H$ + TS_Tx (for DTA[i] > DLA[i] and DTA[i] – DLA[i] > $0x7FFFFF_H$) (DPLL-15c)

NOTE

For TS_Tx see equations (DPLL-1a4 and following), **Section 38.22.7.5, (1) Equation DPLL-1a4 to update the time stamp values for TRIGGER**.

The calculation is done after the calculation of the current expected duration value according to equation (DPLL_6941)[XREF TARGET " (DPLL_6941)] NOT EXIST at **Section 38.22.7.2, (5) Equation DPLL-12 to calculate the duration value for an action**. The time stamp of the action can be calculated as shown above in equation DPLL-15 using the delay value of the action and the current time stamp.

(2) Equations DPLL-17 to calculate the position stamp forwards

for DIR1=0 and TS0_HRT=0:

PSAC[i] = PSA[i] – (DLA[i]*RCDT_TX_NOM)*(MLT+1) (DPLL-17) with

RCDT_TX_NOM= (1/CDT_TX_NOM) * SYN_T (DPLL-17a) and
RCDT_TX= 1/CDT_TX (DPLL-17b)

for DIR1=0 and TS0_HRT=1:

PSAC[i] = PSA[i] – (8*DLA[i]*RCDT_TX_NOM)*(MLT+1) (DPLL-17d) with
RCDT_TX_NOM= (1/CDT_TX_NOM) * SYN_T (DPLL-17a) and

RCDT_TX= 1/CDT_TX (DPLL-17b)

replace (MLT+1) in equations (DPLL-17) and (DPLL-17d) by MLS1 for SMC=1

use the calculated value of (DPLL-17b) also for the generation of SUB_INCi and serve the action by transmission of TSAC[i] and PSAC[i] to ACT_D_i. The action is to be updated for each new TRIGGER event until the calculated time stamp is in the past. In this case the values of TSAC[i] and PSAC[i] depend on the DPLL_CTRL_11.ACBU signal. When DPLL_CTRL_11.ACBU = '0': Use the time stamp of the last input event instead of the calculated value and the calculated position stamp of the actual increment as target position value. When DPLL_CTRL_11.ACBU = '1': For ACB_[z][1]= '1': is used as input signal to control if "action in past" shall be checked based on position information. If the position has reached "past" use the calculated position stamp of the actual increment as target position value. For ACB_[z][1]= '0': In this case the PSAC[i] is used as calculated by the DPLL. For ACB_[z][0]= '1': is used as input signal to control if "action in past" shall be checked based on time information. If the time has reached "past" use the time stamp of the last input event instead of the calculated TSAC[i] value. For ACB_[z][0]= '0': In this case the TSAC[i] is used as calculated by the DPLL. Set the corresponding shadow bit in the DPLL_ACT_STA register. Because of the blocking read operation the ACT_D values can be read only once.

(3) Equations DPLL-17 to calculate the position stamp backwards

For DIR1=1 and TS0_HRT=0:

PSAC[i] = PSA[i] + (DLA[i]*RCDT_TX_NOM)*(MLT+1) (DPLL-17c) with

RCDT_TX_NOM= (1/CDT_TX_NOM) * SYN_T (DPLL-17a) and

RCDT_TX= 1/CDT_TX (DPLL-17b)

For DIR1=1 and TS0_HRT=1:

PSAC[i] = PSA[i] + (8*DLA[i]*RCDT_TX_NOM)*(MLT+1) (DPLL-17e) with
RCDT_TX_NOM= (1/CDT_TX_NOM) * SYN_T (DPLL-17a) and

RCDT_TX= 1/CDT_TX (DPLL-17b)

replace (MLT+1) in equations (DPLL-17c) and (DPLL-17e) by MLS1 for SMC=1

use the calculated value of (DPLL-17b) also for the generation of SUB_INCi and serve the action by transmission of TSAC[i] and PSAC[i] to ACT_D_i. The action is to be updated for each new TRIGGER event until the calculated time stamp is in the past. In this case the values of TSAC[i] and PSAC[i] depend on the DPLL_CTRL_11.ACBU signal. When DPLL_CTRL_11.ACBU = '0': Use the time stamp of the last input event instead of the calculated value and the calculated position stamp of the actual increment as target position value. When DPLL_CTRL_11.ACBU

= '1': For ACB_[z][1]= '1': is used as input signal to control if "action in past" shall be checked based on position information. If the position has reached "past" use the calculated position stamp of the actual increment as target position value. For ACB_[z][1]= '0': In this case the PSAC[i] is used as calculated by the DPLL. For ACB_[z][0]= '1': is used as input signal to control if "action in past" shall be checked based on time information. If the time has reached "past" use the time stamp of the last input event instead of the calculated TSAC[i] value. For ACB_[z][0]= '0': In this case the TSAC[i] is used as calculated by the DPLL. Set the corresponding shadow bit in the DPLL_ACT_STA register. Because of the blocking read operation the ACT_D values can be read only once.

38.22.7.7 The use of the RAM

The RAM is used to store the data of the last FULL_SCALE period. The use of single port RAMs is recommended. The data width of the RAM is usual 3 bytes, but could be extended to 4 bytes in future applications. There are 3 different RAMs, each with separate access ports. The RAM 1a is used to store the position minus time requests, got from the ARU. No CPU access is possible to this RAM during operation (when the DPLL is enabled). Ram 1b is used for configuration parameters and variables needed for calculations. Within RAM 1c the values of the STATE events are stored. RAM 1b and RAM 1c do have a common access port and are also marked as RAM 1bc in order to clarify this fact. RAM 2 is used for values of the TRIGGER events. Because of the access of the DPLL internal state machine at the one side and the CPU at the other side the access priority has to be controlled for both RAMs 1bc and 2. The access priority is defined as stated below. The CPU access procedure via AE-interface goes in a wait state (waiting for data valid) while it needs a colliding RAM access during serving a corresponding state machine RAM access. In order not to provoke unexpected behavior of the algorithms the writing of the CPU to the RAM regions 1b, 1c or 2 will be monitored and results in interrupt requests when enabled.

CPU access is specified at follows:

1. CPU has highest priority for a single read/write access. The DPLL algorithm is stalled during external bus RAM accesses.
2. After serving the CPU access to the RAM the DPLL gets the highest RAM access priority for 8 clock cycles. Afterwards continue with 1.

The RAM address space has to be implemented in the address space of the CPU.

38.22.7.8 Time and position stamps for actions in Emergency Mode

(1) Equation DPLL-18 to calculate the action time stamp

TSAC[i]= DTA[i] – DLA[i] + TS_Sx (for DTA[i] > DLA[i] and DTA[i] – DLA[i] < 0x800000) (DPLL-18a) TSAC[i]= TS_Sx (for DTA[i] < DLA[i]) (DPLL-18b)

TSAC[i]= $FFFFF_H$ + TS_Sx (for DTA[i] > DLA[i] and DTA[i] – DLA[i] > $7FFFFF_H$) (DPLL-18c)

NOTE

For TS_Sx see equations (DPLL-6a4 and following), **Section 38.22.7.5, (5) Equation DPLL-6a4 to update the time stamp values for STATE**.

The calculation is done after the calculation of the current expected duration value according to equation DPLL-14 at **Section 38.22.7.3, (5) Equation DPLL-14 to calculate the duration value for an action**. The time stamp of the action can be calculated as shown in equation DPLL-18 using the delay value of the action and the current time stamp.

(2) Equations DPLL-20 to calculate the position stamp forwards

for DIR2=0 or DIR1=0 respectively and TS0_HRS=0: PSAC[i] = PSA[i] – (DLA[i]*RCDT_SX_NOM)*MLS1 (DPLL-20) with
RCDT_SX_NOM= (1/CDT_SX_NOM) * SYN_S (DPLL-20a) and
RCDT_SX= 1/CDT_SX (DPLL-20b)

for DIR2=0 or DIR1=0 respectively and TS0_HRS=1:

PSAC[i] = PSA[i] – (8*DLA[i]*RCDT_SX_NOM)*MLS1 (DPLL-20d) with
RCDT_SX_NOM= (1/CDT_SX_NOM) * SYN_S (DPLL-20a) and
RCDT_SX= 1/CDT_SX (DPLL-20b)

replace MLS1 in equations (DPLL-20) and (DPLL-20d) by MLS2 for (SMC=1 and RMO=1)

use the calculated value of (DPLL-17b) also for the generation of SUB_INCi and serve the action by transmission of TSAC[i] and PSAC[i] to ACT_D_i. The action is to be updated for each new *STATE* event until the calculated time stamp is in the past. In this case the values of TSAC[i] and PSAC[i] depend on the DPLL_CTRL_11.ACBU signal. When DPLL_CTRL_11.ACBU = '0': Use the time stamp of the last input event instead of the calculated value and the calculated position stamp of the actual increment as target position value. When DPLL_CTRL_11.ACBU = '1': For ACB_[z][1]= '1': is used as input signal to control if "action in past" shall be checked based on position information. If the position has reached "past" use the calculated position stamp of the actual increment as target position value. For ACB_[z][1]= '0': In this case the PSAC[i] is used as calculated by the DPLL. For ACB_[z][0]= '1': is used as input signal to control if "action in past" shall be checked based on time information. If the time has reached "past" use the time stamp of the last input event instead of the calculated TSAC[i] value. For ACB_[z][0]= '0': In this case the TSAC[i] is used as calculated by the DPLL. Set the corresponding shadow bit in the DPLL_ACT_STA register. Because of the blocking read operation the ACT_D values can be read only once.

(3) Equations DPLL-20 to calculate the position stamp backwards

For DIR2=1 or DIR1=1 respectively and TS0_HRS=0:

PSAC[i] = PSA[i] + (DLA[i]*RCDT_SX_NOM)*MLS1 (DPLL-20c) with RCDT_SX_NOM= (1/CDT_SX_NOM) * SYN_S (DPLL-20a) and RCDT_SX= 1/CDT_SX (DPLL-20b)

For DIR2=1 or DIR1=1 respectively and TS0_HRS=1:

PSAC[i] = PSA[i] + (8*DLA[i]*RCDT_SX_NOM)*MLS1 (DPLL-20e) with RCDT_SX_NOM= (1/CDT_SX_NOM) * SYN_S (DPLL-20a) and RCDT_SX= 1/CDT_SX (DPLL-20b)

replace MLS1 in equations (DPLL-20c) and (DPLL-20e) by MLS2 for (SMC=1 and RMO=1)

Use the calculated value of (DPLL-20b) also for the generation of SUB_INCi and serve the action by transmission of TSAC[i] and PSAC[i] to ACT_D. The action is to be updated for each new STATE event until the event is in the past. In this case use the time stamp of the last input event instead of the calculated value and the calculated position stamp of the actual increment as target position value. Set the corresponding shadow bit in the DPLL_ACT_STA register. Because of the blocking read operation the ACT_D values can be read only once.

Use the calculated value of (DPLL-17b) also for the generation of SUB_INCi and serve the action by transmission of TSAC[i] and PSAC[i] to ACT_D_i. The action is to be updated for each new STATE event until the calculated time stamp is in the past. In this case the values of TSAC[i] and PSAC[i] depend on the DPLL_CTRL_11.ACBU signal. When DPLL_CTRL_11.ACBU = '0': Use the time stamp of the last input event instead of the calculated value and the calculated position stamp of the actual increment as target position value. When DPLL_CTRL_11.ACBU = '1': For ACB_[z][1]= '1': is used as input signal to control if "action in past" shall be checked based on position information. If the position has reached "past" use the calculated position stamp of the actual increment as target position value. For ACB_[z][1]= '0': In this case the PSAC[i] is used as calculated by the DPLL. For ACB_[z][0]= '1': is used as input signal to control if "action in past" shall be checked based on time information. If the time has reached "past" use the time stamp of the last input event instead of the calculated TSAC[i] value. For ACB_[z][0]= '0': In this case the TSAC[i] is used as calculated by the DPLL. Set the corresponding shadow bit in the DPLL_ACT_STA register. Because of the blocking read operation the ACT_D values can be read only once.

38.22.8 Signal processing

38.22.8.1 Time stamp processing

Signal processing does mean the computation of the time stamps in order to calculate at which time the outputs have to appear. For such purposes the time stamp values have to be stored in the RAM and by calculating the difference between old and new values the duration of the last time interval is determined simply. This difference should be also stored in the RAM in order to see the changes between the intervals by changing the conditions and the speed of the observed process.

38.22.8.2 Count and compare unit

The count and compare unit processes all input signals taking into account the configuration values. It uses a state machine and provides the output signals as described above.

38.22.8.3 Sub pulse generation for SMC=0

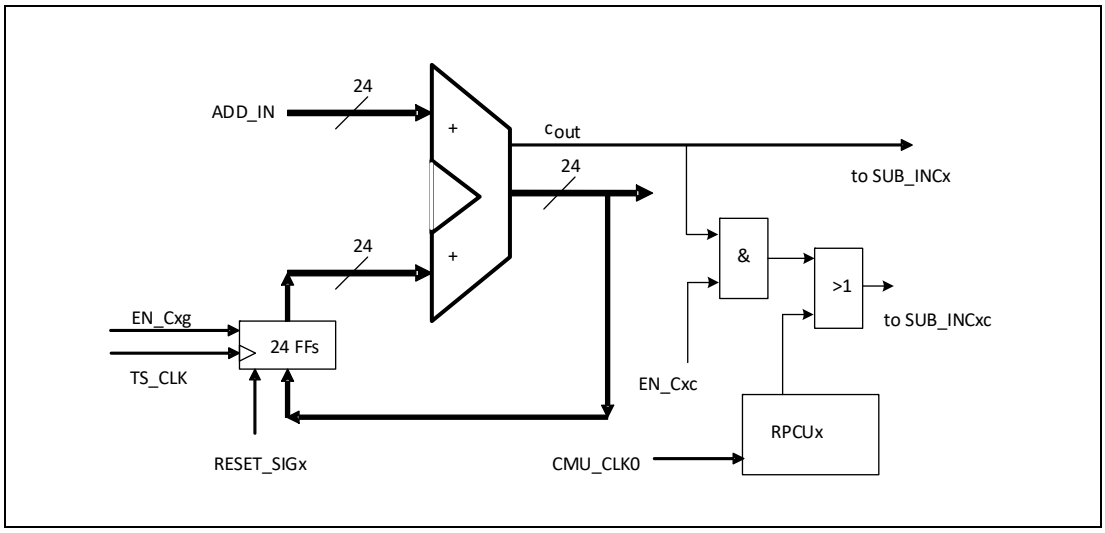

Figure 38.116 Adder for generation of SUB_INCx by the carry c_{out}

NOTE

The SUB_INC generation by the circuit above has the advantage, that the resolution for higher speed values is better as for a simple down counter. After RESET and after EN_Cxg=0 the flip-flops (FFs) should have a zero value. EN_Cxg has to be zero until reliable ADD_IN values are available and the pulse generation starts. This is controlled by the configuration bits SGE1,2 in the DPLL_CONTROL_1 register. The calculated values for the increment prediction using equations (DPLL_11010)[XREF TARGET " (DPLL_11010)] NOT EXIST in **Section 38.22.6.2, (7) Equations DPLL-5 to calculate the current increment value**, (DPLL_11057)[XREF TARGET " (DPLL_11057)] NOT EXIST in **Section 38.22.6.4, (4) Equation DPLL-5 to calculate the current increment value**, (DPLL_11041)[XREF TARGET " (DPLL_11041)] NOT EXIST in **Section 38.22.6.3, (7) Equations DPLL-10 to calculate the current increment (nominal value)** or (DPLL_11077)[XREF TARGET " (DPLL_11077)] NOT EXIST in **Section 38.22.6.5, (4) Equations DPLL-10 to calculate the current increment value** respectively are valid only when at least NUTE>1 TRIGGER values or at least NUSE>1 STATE values are available. For NUTE =1 or NUSE=1 respectively the equations DPLL-25 in **Section 38.22.8.3, (3) Equation DPLL-25 to calculate ADD_IN in normal mode for SMC = 0** and DPLL-26 in **Section 38.22.8.3, (5) Equation DPLL-26 to calculate ADD_IN in emergency mode for SMC = 0** use the actual increment value subtracted by the weighted average error.

The generation of SUB_INC1 pulses depends on the configuration of the DPLL. In automatic end mode the counter INC_CNT1 resets the enable signal EN_C1 when the number of pulses desired is reached. In this case only the uncompensated output SUB_INC1 remains active in order to provide pulses for the input filter unit. In the case of acceleration missing pulses can be determined at the next TRIGGER/STATE event in normal/emergency mode easily. For the correction strategy COA = 0 those missing pulses are sent out with CMU_CLK0 frequency as soon they are determined. During this time period the EN_Cxg remains cleared. After calculation or providing of a new ADD_IN value the FFs are enabled by EN_Cxg. In this way no pulse is lost. The new pulses are sent out afterwards, when INC_CNT1 is set to the desired value, maybe by adding MLT+1 or MLS1 respectively for the new TRIGGER/STATE event.

Because the used DIV procedure of the algorithms results only in integer values, a systematic failure could appear. The pulse generation at SUB_INC1 will stop in automatic end mode when the INC_CNT1 register reaches zero or all remaining pulses at a new increment will be considered in the next calculation. In this way the loss of pulses can be avoided. When a new TRIGGER/STATE appears the value of SYN_T*(MLT+1) or SYN_S*MLS1 respectively is added to INC_CNT1, when SGE1=1. Therefore for FULL_SCALE 2*(TNU+1)*(MLT+1) pulses SUB_INC1 generated, when INC_CNT1 reaches the zero value. The generation of SUB_INC1 pulses has to be done as fast as possible. The calculations for the ADD_IN value must be done first. Therefore all values needed for calculation are to be fetched in a forecast.

(1) Equation DPLL-21 to calculate the number of pulses to be sent in normal mode using the automatic end mode condition

For RMO=0, SMC=0 and DMO=0

NMB_T = ((MLT+1) + PD_store) *SYN_T + MP + MPVAL1 (DPLL-21) with

PD_store = ADT_T[12:0], prefetched during last increment

SYN_T = ADT_T[18:16], prefetched during last increment

MPVAL1 = pulse correction value for PCM1_SHADOW_TRIGGER=1

while the value for PD_store is zero for AMT=0 and the value of MP is zero for COA=0.

In order to get a higher resolution for higher speed a generator for the sub-pulses is chosen using an adder. All missing pulses MP are considered using equation DPLL-21 and are determined by counting the number of pulses of the last increment. The value SYN_T is stored from the last increment using NT of the ADT_T[i] value at RAM region 2c.

(2) Equations DPLL-22–24 to calculate the number of pulses to be sent in emergency mode using the automatic end mode condition for SMC = 0

For RMO=1, SMC=0 and DMO=0; the value for PD_S_store is zero for AMS=0

NMB_S = (MLS1 + PD_S_store) *SYN_S+ MP (DPLL-22) with

MLS1= (MLT+1) * (TNU+1) / (SNU+1) (DPLL-23)

PD_S_store = ADT_S[15:0], prefetched during last increment

SYN_S = ADT_S[21:16], prefetched during last increment MPVAL1 = pulse correction value for PCM1_SHADOW_STATE=1

while the value for PD_S_store is zero for AMS=0 and the value of MP is zero for COA=0

Note that these calculations above in equations DPLL-21 and DPLL-22 are only valid for an automatic end mode (DMO = 0). For calculation of the number of generated pulses a value of 0.5 is added as shown in equations DPLL-25 or DPLL-26 respectively in order to compensate rounding down errors at the succeeding arithmetic operations. Because in automatic end mode the number of pulses is limited by INC_CNT1 it is guaranteed, that not more pulses as needed are generated and in the same way missing pulses are caught up for the next increment.

(3) Equation DPLL-25 to calculate ADD_IN in normal mode for SMC = 0

In normal mode (for RMO=0) calculate in the case LOW_RES=TS0_HRT ADD_IN_CALN= (NMB_T+0.5) *RCDT_TX (DPLL-25) with

RCDT_TX is the 2 time value of the quotient in equation DPLL-17b **Section 38.22.7.6, (3) Equations DPLL-17 to calculate the position stamp backwards**.

In normal mode (for RMO=0) calculate in the case LOW_RES=1 and TS0_HRT=0

ADD_IN_CALN= (NMB_T+0.5) *(RCDT_TX /8) (DPLL-25a) with

RCDT_TX is the 2 time value of the quotient in equation DPLL-17b **Section 38.22.7.6, (3) Equations DPLL-17 to calculate the position stamp backwards**.

For RMO=0 and SMC=0:

ADD_IN_CAL1 = ADD_IN_CALN (DPLL-25b)

LOW_RES=0 and TS0_HRT=1 is not possible. For such a configuration the RCT bit in the DPLL_STATUS register is set together with the ERR bit.

In the automatic end mode (DMO=0) missing pulses should be sent to the input RPCUx (rapid pulse catch up on) in **Figure 38.116**, to be caught up on with CMU_CLK0 (for COA=0). When normal and rapid pulses are generated simultaneously, the SUB_INCx frequency is doubled at this moment in order to count two pulses at the TBU_CHx_BASE register. In order to make the frequency doubling possible, the CMU_CLK0 should be having a frequency which does not exceed half the frequency of TS_CLK. In addition the ADD_IN value should never exceed the value 800000_H. This limitation is only necessary for DMO=0 and COA=0 (see **Section 38.22.18.2, DPLL_CTRL_1**). For the normal mode replace ADD_IN of the ADDER (see **Figure 38.116**) by ADD_IN_CAL1 (when calculated,

DLM=0) or ADD_IN_LD1 (when provided by the CPU, DLM=1). The sub-pulse generation in this case is done by the following calculations using a 24 bit adder with a carry out c_{out} and the following inputs: – ADD_IN the second input is the output of the adder, stored one time stamp clock before.

In order not to complicate the calculation procedure use a Multiplier with a sufficient bit width at the output and use the corresponding shifted output bits.

(4) Enabling of the compensated output for pulses

The c_{out} of the adder influences directly the SUB_INC1 output of the DPLL (see **Figure 38.116**). The compensated output SUB_INCxc is in automatic end mode only enabled by EN_Cxc when INC_CNTx >0.

(5) Equation DPLL-26 to calculate ADD_IN in emergency mode for SMC = 0

In emergency mode (RMO=1) calculate in the case LOW_RES=TS0_HRS ADD_IN_CALE= (NMB_S+0.5)* RCDT_SX (DPLL-26) while

RCDT_SX is the 2 time value of the quotient in equation DPLL-20b **Section 38.22.7.8, (2) Equations DPLL-20 to calculate the position stamp forwards**.

In emergency mode (RMO=1) calculate in the case LOW_RES=1 and TS0_HRS=0 ADD_IN_CALE= (NMB_S+0.5)* RCDT_SX /8 (DPLL-26a) while

RCDT_SX is the 2 time value of the quotient in equation DPLL-20b **Section 38.22.7.8, (2) Equations DPLL-20 to calculate the position stamp forwards**.

For RMO=1 and SMC=0:

ADD_IN_CAL1 = ADD_IN_CALE (DPLL-26b)

LOW_RES=0 and TS0_HRS=1 is not possible. For such a configuration the RCS bit in the DPLL_STATUS register is set together with the ERR bit.

In the automatic end mode (DMO=0) missing pulses should be sent to the input RPCUx (rapid pulse catch up on) in **Figure 38.116**, to be caught up on with CMU_CLK0 (for COA=0). When normal and rapid pulses are generated simultaneously, the SUB_INCx frequency is doubled at this moment in order to count two pulses at the TBU_CHx_BASE register. In order to make the frequency doubling possible, the CMU_CLK0 should be having a frequency which does not exceed half the frequency of the system clock. In addition the ADD_IN value should never exceed the value 0x800000 when the TS_CLK frequency exceeds half the frequency of the system clock. This limitation is only necessary for DMO=0 and COA=0 (see DPLL_CTRL_1 register). For the emergency mode replace ADD_IN of the ADDER (see **Figure 38.116**) by ADD_IN_CAL1 (when calculated, DLM=0) or ADD_IN_LD1 (when provided by the CPU, DLM=1). The sub-pulse generation in this case is done by the following calculations using a 24 bit adder with a carry out c_{one} and the following inputs: – ADD_IN – the second input is the output of the adder, stored one time stamp clock before.

In order not to complicate the calculation procedure use a Multiplier with a sufficient bit width at the output and use the corresponding shifted output bits.

38.22.8.4 Sub pulse generation for SMC = 1

(1) Necessity of two pulse generators

The Adder of **Figure 38.116** must be implemented twice in the case of SMC=1: one for SUB_INC1 controlled by the TRIGGER input and (while RMO=1) one for SUB_INC2, controlled by the STATE input. In the case described in the chapter above for SMC=0 only one Adder is used to generate SUB_INC1 controlled by the TRIGGER in normal mode or by STATE in emergency mode.

(2) Equation DPLL-27 to calculate the number of pulses to be sent for the first device using the automatic end mode condition

For SMC=1 and DMO=0 NMB_T = (MLS1 + PD_store) *SYN_T + MP + MPVAL1 (DPLL-27) with PD_store = ADT_T[12:0],prefetched during last increment SYN_T = ADT_T[18:16], prefetched during last increment MPVAL1 = pulse correction value for PCM1_SHADOW_TRIGGER=1 while the value for PD_store is zero for AMT=0 and for COA=0 use zero instead of the value of MP

(3) Equation DPLL-28 to calculate the number of pulses to be sent for the second device using the automatic end mode condition

for RMO=1, SMC=1 and DMO=0 NMB_S = (MLS2 + PD_S_store) *SYN_S+ MP + MPVAL2 (DPLL-28) with PD_S_store = ADT_S[15:0], prefetched during last increment SYN_S = ADT_S[21:16], prefetched during last increment MPVAL2 = pulse correction value for PCM2_SHADOW_STATE=1 while the value for PD_S_store is zero for AMS=0 and for COA=0 use zero instead of the value of MP

Note that these calculations above in equations DPLL-27 and DPLL-28 are only valid for an automatic end mode (DMO = 0). In addition the number of generated pulses is added by 0.5 as shown in equations DPLL-30 or DPLL-31 respectively in order to compensate rounding down errors at the succeeding division operation. Because in automatic end mode the number of pulses is limited by INC_CNTx it is guaranteed, that not more pulses as needed are generated and in the same way missing pulses are made up for the next increment.

(4) Equation DPLL-30 to calculate ADD_IN for the first device for SMC = 1

The sub-pulse generation in this case is done by the following calculations using a 24 bit adder with a carry out c_{out} and the following inputs:

– ADD_IN – the second input is the (delayed) output of the adder, stored with each time stamp clock. Replace ADD_IN by ADD_IN_CAL1 (when calculated, DLM1=0) or ADD_IN_LD1 (when provided by the CPU, DLM1=1) respectively while:

For SMC=1 and LOW_RES=TS0_HRT ADD_IN_CAL1= (NMB_T+0.5) * RCDT_TX (DPLL-30) When RCDT_TX is the 2 time value of the quotient in equation DPLL-17b **Section 38.22.7.6, (3) Equations DPLL-17 to calculate the position stamp backwards**.

For SMC=1,LOW_RES= 1 and TS0_HRT=0 ADD_IN_CAL1= (NMB_T+0.5) * (RCDT_TX /8) (DPLL-30a) When RCDT_TX is the 2 time value of the quotient in equation DPLL-17b **Section 38.22.7.6, (3) Equations DPLL-17 to calculate the position stamp backwards**.

In order not to complicate the calculation procedure use a Multiplier with a sufficient bit width at the output and use the corresponding shifted output bits.

ADD_IN_CAL1 is a 24 bit integer value. The CDT_TX is the expected duration of current TRIGGER increment. The c_{out} of the adder influences directly the SUB_INC1 output of the DPLL (see **Figure**

38.116). The SUB_INC1 output is in automatic end mode only enabled by EN_C1 when INC_CNT1 >0.

(5) Equation DPLL-31 to calculate ADD_IN for the second device for SMC = 1

Replace ADD_IN by ADD_IN_CAL2 (when calculated, DLM2=0) or ADD_IN_LD2 (when provided by the CPU, DLM2=1) respectively while:

for SMC=1, RMO=1 and LOW_RES=TS0_HRS: ADD_IN_CAL2= (NMB_S+0.5)* RCDT_SX (DPLL-31) When RCDT_SX is the 2 time value of the quotient in equation DPLL-20b **Section 38.22.7.8, (2) Equations DPLL-20 to calculate the position stamp forwards**.

for SMC=1, RMO=1, LOW_RES=1 and TS0_HRS=0: ADD_IN_CAL2= (NMB_S+0.5)* (RCDT_SX /8) (DPLL-31a) When RCDT_SX is the 2 time value of the quotient in equation DPLL-20b **Section 38.22.7.8, (2) Equations DPLL-20 to calculate the position stamp forwards**.

In order not to complicate the calculation procedure use a Multiplier with a sufficient bit width at the output and use the corresponding shifted output bits.

The c_{out} of the adder2 influences directly the SUB_INC2 output of the DPLL (see **Figure 38.116**). The SUB_INC2 output is in automatic end mode only enabled by EN_C2 when **INC_CNT2** >0.

NOTE

Note that after RESET and after EN_Cxc=0 (after stopping in automatic end mode) the flip-flops (FFs) have a zero value and also EN_Cxg has to be zero until reliable ADD_IN values are available and the pulse generation starts. The calculated values for the increment prediction using equations DPLL-2c **Section 38.22.6.2, (7) Equations DPLL-5 to calculate the current increment value**, (DPLL_11057)[XREF TARGET '' (DPLL_11057)] NOT EXIST in chapter **Section 38.22.6.4, (4) Equation DPLL-5 to calculate the current increment value**, (DPLL_11041)[XREF TARGET '' (DPLL_11041)] NOT EXIST in **Section 38.22.6.3, (7) Equations DPLL-10 to calculate the current increment (nominal value)** or (DPLL_11077)[XREF TARGET'' (DPLL_11077)] NOT EXIST in **Section 38.22.6.5, (4) Equations DPLL-10 to calculate the current increment value** respectively are valid only when NUTE>1 or NUSE>1 respectively. For NUTE=1 or NUSE=1 respectively the equations DPLL-30 (see **Section 38.22.8.4, (4) Equation DPLL-30 to calculate ADD_IN for the first device for SMC = 1**) and DPLL-31 (see **Section 38.22.8.4, (5) Equation DPLL-31 to calculate ADD_IN for the second device for SMC = 1**) use the actual increment value subtracted by the weighted average error.

The generation of SUB_INCx pulses depends on the configuration of the DPLL. In automatic end mode the counter INC_CNTx resets the enable signal EN_Cxcu when the number of pulses desired is reached. In this case only the uncompensated outputs SUB_INCx remain active in order to provide pulses for the input filter units. A new TRIGGER or STATE input respectively can reset the FFs and also ADD_IN, especially when EN_Cxc was zero before. In the case of acceleration missing pulses can be determined at the next TRIGGER/STATE event easily. For the correction strategy COA = 0 those missing pulses are sent out with CMU_CLK0 frequency as soon they are determined. After that the pulse counter INC_CNTx should be always zero and the new pulses are sent out afterwards, when INC_CNTx is set to the desired value by adding MLS1 or MLS2 for the new TRIGGER or STATE event respectively.

Because the used DIV procedure of the algorithms results only in integer values, a systematic failure could appear. The pulse generation will stop when the INC_CNTx register reaches zero or all

remaining pulses at a new increment will be considered in the next calculation. In this way the loss of pulses can be avoided.

When a new TRIGGER appears the value of SYN_T*MLS1 is added to INC_CNT1. Therefore for FULL_SCALE 2*(TNU+1)*MLS1 pulses SUB_INC1 generated, when INC_CNT1 reaches the zero value. The generation of SUB_INC1 pulses has to be done as fast as possible.

When a new STATE appears the value of SYN_S*MLS2 is added to INC_CNT2. Therefore for FULL_SCALE 2*(SNU+1)*MLS2 pulses SUB_I- NC2 generated, when INC_CNT2 reaches the zero value. The generation of SUB_INC2 pulses has to be done as fast as possible.

38.22.8.5 Calculation of the Accurate Position Values

All appearing TRIGGER and STATE signals do have a time stamp and a position stamp assigned after the input filter procedure. For the calculation of the exact time stamp the filter values are considered in the calculations of equations **Section 38.22.6.2, (1) Equations DPLL-1a to calculate TRIGGER time stamps** or DPLL-6a **Section 38.22.6.3, (1) Equations DPLL-6a to calculate STATE time stamps** respectively. A corresponding calculation is to be performed for the calculation of position values. The PSTC and PSSC values can be corrected by the CPU, when needed.

After reset, while FTD=0 and no active TRIGGER slope is detected: PSTC = 0 (DPLL-32a)

Calculate the new Position value for each active TRIGGER event: PSTC= PSTC_old + NMB_T_TAR_OLD (DPLL-32b) when FTD=1 and SGE1=1 with PSTC_old is the last PSTC value and NMB_T_old is the number of pulses which are calculated and provided for sending out in the last increment.

After reset, while FSD=0 and no active STATE slope is detected: PSSC= 0 (DPLL-33a)

Calculate the new Position value for each STATE event: PSSC= PSSC_old + NMB_S_TAR_OLD (DPLL-32b) when FSD=1 and SGE1=1 (SMC=0) or SGE2=1 (SMC=1) respectively with PSSC_old is the last PSSC value and NMB_S_old is the number of pulses which are calculated and provided for sending out in the last increment.

38.22.8.6 Scheduling of the Calculation

After enabling the DPLL with each active TRIGGER or STATE event respectively a cycle of operations is performed to calculate all the results shown in detail in the table below **Section 38.22.2, Requirements and demarcation**. A state machine controls this procedure and consists of two parts, the first is triggered by an active slope of the signal TRIGGER, begins at step 1 and ends at step 20 (in normal mode and for SMC=1). The second state machine is controlled by an active slope of the signal STATE, begins at step 21 and ends at step 40 (in emergency mode and also for SMC=RMO=1). Depending on the mode used all 20 steps are executed or already after 2 steps the jump into the initial state is performed, as shown in the state machine descriptions below. For each new extended cycle (without this jump) all prediction values for actions in the case SMC=0 are calculated once more (with maybe improved accuracy because of better parameters) and all pending decisions are made using these new values when transmitted to the decision device.

In (DPLL_6908)[XREF TARGET " (DPLL_6908)] NOT EXIST the steps of the state machine are described. Note that the elaboration of the steps depends on the configuration bits described in the comments. The steps 4 to 17 are only calculated in normal mode (in the state machine explanation below marked yellow in **Section 38.22.2, Requirements and demarcation**), but steps 24 to 37 are only calculated in emergency mode (in the state machine explanation below marked cyan in **Section 38.22.2, Requirements and demarcation**) when SMC=0.

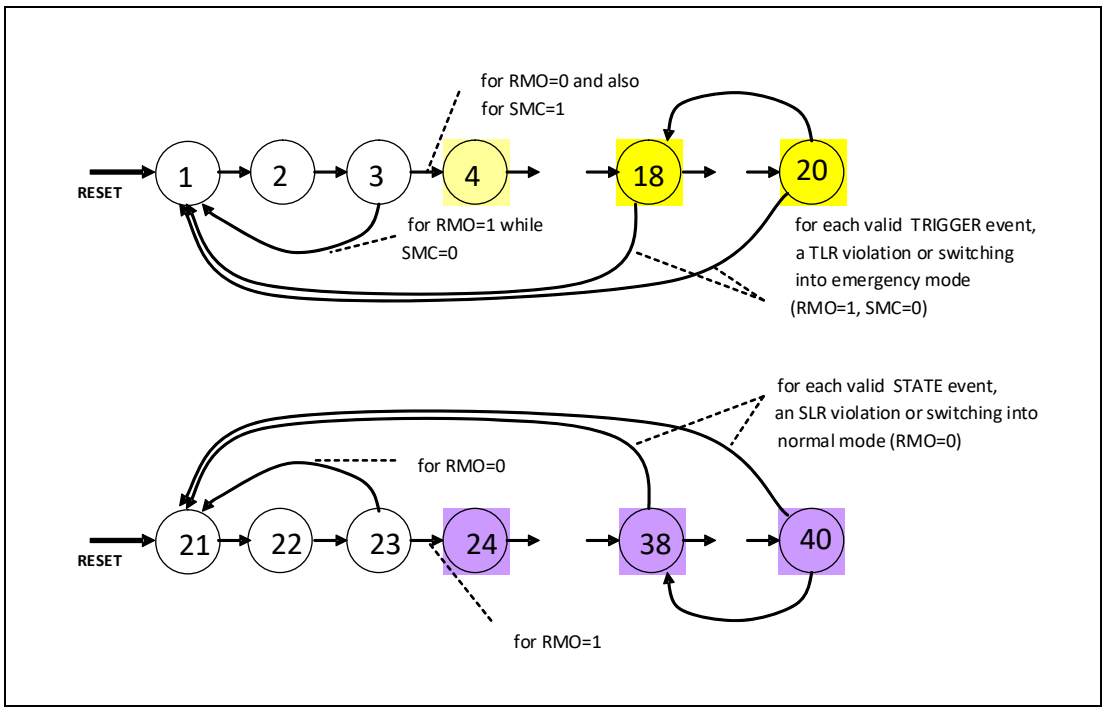

Figure 38.117 State machine partitioning for normal and emergency mode.

(1) Synchronization description

TRIGGER:

The APT (address pointer for duration and reciprocal duration values of TRIGGER increments) is initially set to zero and incremented with each active TRIGGER event. Therefore data are stored in the RAM beginning from the first available value. The actual duration of the last increment is stored at DT_T_ACT. For the prediction of the next increment it is assumed, that the same value is valid as long as NUTE is one.

A missing TRIGGER is assumed, when at least after TOV* DT_T_ACT no active TRIGGER event appears.

The data of equations DPLL-1b1 and DPLL-1c2 **Section 38.22.7.5, (4) Equations DPLL-1b1 and DPLL-1c1 to update the RAM after calculation** are written in the corresponding RAM regions and APT is incremented accordingly up to 2*TNU–2*SYN_NT+1.

The APT_2B (address pointer for the time stamp field of TRIGGER) is initially set to zero and incremented with each active TRIGGER event. When no gap is detected because of the incomplete synchronization process at the beginning, for all TRIGGER events the time stamp values are written in the RAM up to 2*(TNU+1) entries, although only 2*(TNU+1–SYN_NT) events in FULL_SCALE appear. When the current position is detected, the synchronization procedure can be performed as described below: Before the CPU sets the APT_2C address pointer in order to synchronize to the profile, it writes the corresponding increment value for the necessary extension of the RAM region 2b value APT_2B_EXT into the register APT_2B_sync and sets the status bit APT_2C_status. This value can be e.g. 2*SYN_NT, when all gaps in FULL_SCALE already passed the input data stream of TRIGGER, or less than this value, when up to now e.g. only a single gap is to be considered in the data stream stored already in the RAM region 2b. The number of virtual increments to be considered depends on the number of inputs already got. After writing APT_2C by the CPU, with the next TRIGGER event the APT_2B address pointer is incremented (as usual) and then the additional offset value APT_2B_EXT is added to it once (while APT_2B_STATUS=1 and for forward direction). For that reason the APT_2B_STATUS bit is reset after it. The old APT_2B value before adding the offset is stored in the APT_2B_OLD register as information for the CPU where to start the extension procedure. In the following the CPU fills in the time stamp field around the APT_2B_OLD position taking into account the corresponding number of virtual entries stored in the APT_2B_EXT value and the corresponding NT values in the profile. The extension procedure ends when all gaps considered in the APT_2B_EXT value are treated once. In the consequence all storage locations of RAM region 2b up to now do have the corresponding entries. Future gaps are treated by the DPLL. For a backward direction the APT_2C_ext value is subtracted accordingly.

When the CPU writes the APT_2C address pointer the SYT bit is set simultaneously. For SYT=1 in normal mode (SMC=0) the LOCK1 bit is set with the system clock, when the right number of increments between two synchronization gaps is detected by the DPLL. An unexpected missing TRIGGER or an additional TRIGGER between two synchronization gaps does reset the LOCK1 bit in normal mode. In that case the CPU must correct the SUB_INC pulse number and maybe correct the APT_2C pointer. For this purpose the LL1I interrupt can be used.

When SYT is set the calculations of equations DPLL-1 to DPLL-5 are performed accordingly and the values are stored in (and distributed to) the right RAM positions. This includes the multiple time stamp storage by the DPLL for a gap according to equations DPLL-1a5 to 7 forwards **Section 38.22.7.5, (2) Equation DPLL-1a5-7 to extend the time stamp values for TRIGGER in forward direction** or backwards **Section 38.22.7.5, (3) Equations DPLL-1a5-7 for backward direction**. The APT_2B pointer is for that reason incremented or decremented before this operation considering the virtual increments in addition. Note that for the APT and APT_2C pointers the gap is considered as a single increment.

STATE:

The APS (address pointer for duration and reciprocal duration values of STATE) is initially set to zero and incremented with each active STATE event. Therefore data are stored in the RAM field beginning at the first location. The actual duration of the last increment is stored at DT_S_ACT. For the prediction of the next increment it is assumed, that the same value is valid as long as NUSE is one.

A missing STATE is assumed, when at least after SOV* DT_S_ACT no active STATE event appears.

The data of equations DPLL-6b1 and DPLL-6c2 **Section 38.22.7.5, (8) Equations DPLL-6b1 and DPLL-6c2 to update the RAM after calculation** is written in the corresponding RAM regions and APS is incremented accordingly up to 2*SNU–2*SYN_NS+1 (for SYSF=0).

The APS_1C2 (address pointer for the time stamp field of STATE) is initially set to zero and incremented with each active STATE event. When no gap is detected because of the incomplete synchronization process at the beginning, for all STATE events the time stamp values are written in the RAM up to 2*(SNU+1) entries, although (e.g. for SYSF=0) only 2*(SNU+1–SYN_NS) events in FULL_SCALE appear. When the current position is detected, the synchronization procedure can be performed as described below: Before the CPU sets the APS_1C3 address pointer in order to synchronize to the profile, it writes the corresponding increment value APS_1C2_EXT for the necessary extension of the RAM region 1c2 into the register DPLL_APS_SYNC and sets the APS_1C2_STATUS bit there. This value can be e.g. 2*SYN_NS (for SYSF=0) or SYN_NS (for SYSF=1), when all gaps in FULL_SCALE already passed the input data stream of STATE. Also less than this value can be considered, when up to now only a single gap is to be considered in the data stream stored already in the RAM region 1c2. The number of increments to be considered depends on the number of inputs already got. After writing APS_1C3 by the CPU, with the next active STATE slope the APS_1C2 address pointer is incremented (as usual) and then the additional offset value APS_1C2_EXT is added to it once (while APS_1C2_STATUS=1 and forward direction). For that reason the APS_1C2_STATUS bit is reset after it. The old APS_1C2 value is stored in the APS_1C2_OLD register as information for the CPU where to start the extension procedure. In the following the CPU extends the time stamp field beginning from the APS_1C2_OLD position taking into account the corresponding number of virtual entries according to the APS_1C2_EXT value and also the correspondent NS values in the profile. The extension procedure ends when all gaps considered in the APS_1C2_EXT value are treated once. In the consequence all storage locations of RAM region 1c2 up to now do have the corresponding entries. Future gaps are treated by the DPLL. For a backward direction the APS_1C2_EXT value is subtracted accordingly.

When the CPU writes the APS_1C3 address pointer the SYS bit is set simultaneously. For SYS=1 in emergency mode (SMC=0 and DMO=1) the LOCK1 bit is set with the system clock, when the right number of increments between two synchronization gaps is detected by the DPLL. An unexpected missing STATE or an additional STATE between two synchronization gaps does reset the LOCK1 bit in emergency mode. In that case the CPU must correct the SUB_INC1 pulse number and maybe correct the APS_1C3 pointer. For this purpose the LL1I interrupt can be used.

When SYS is set the calculations of equations DPLL-5 to DPLL-10 are performed accordingly and the values are stored in (and distributed to) the right RAM positions. This includes the multiple time stamp storage by the DPLL for a gap according to equations DPLL-6a5 to 7 forwards **Section 38.22.7.5, (6) Equations DPLL-6a5-7 to extend the time stamp values for STATE** or backwards **Section 38.22.7.5, (7) Equations DPLL-6a5-7 for backward direction**. The APS_1C2 pointer is for that reason incremented or decremented before this operation considering the virtual increments in addition. Note that for the APS and APS_2c pointers the gap is considered as a single increment.

SMC=1:

For SMC=1 it is assumed, that the starting position is known by measuring the characteristic of the device. In this way the APT and APT_2C as well the APS and APS_1C3 values are set properly, maybe with an unknown repetition rate. When no gap is to be considered for TRIGGER or STATE signals the APT_2B and APS_1C2 address pointers are set equal to APT or APS respectively. It is assumed, that all missing TRIGGER s and missing STATE s can be also considered from the beginning, when a valid profile with the corresponding adapted values is written in the RAM regions 1c3 and 2c respectively. In that case the TSF_T[i] and TSF_S[i] must be extended by the DPLL according to the profile. Thus the SYT and SYS bits could be set from the beginning and the LOCK1 and LOCK2 bits are set after recognition of the corresponding gaps accordingly. When no gap exists (SYN_NT=0 or SYN_NS=0), the LOCK bits are set immediately. The CPU can correct the APT_2C and APS_1C3 pointer according to the recognized repetition rate later once more without the loss of Lock1,2.

(2) Operation for direction change in normal and emergency mode (SMC = 0)

When for SMC=0 in normal mode a backwards condition is detected for the TRIGGER input signal (e.g. when THMI is not violated), the LOCK1 bit in the DPLL_STATUS register is reset, the NUTE value in NUTC register is set to 1 (the same for NUSE in NUSC). The address pointers APT_2C as described below (and after that decremented for each following active slope of TRIGGER as long as the DIR1 bit shows the backward direction). Notice that in the case of the change of the direction the ITN and ISN bit in the DPLL_STATUS register are reset.

For this transition to the backward direction no change of address pointer APT and APT_2B is necessary.

profile update for TRIGGER when changing direction The profile address pointer APT_2C is changed step by step in order to update the profile information in SYN_T, SYN_T old and PD_store:

1. decrement APT_2C, load SYN_T
2. decrement APT_2C, load SYN_T
3. decrement APT_2C, load SYN_T, PD_store, update SYN_T_OLD
4. decrement APT_2C, make calculations, load SYN_T and PD_store, update SYN_T_OLD and PD_store_old and wait for a new TRIGGER event.

NOTE

The update of SYN_T_OLD and the loading of PD_store can be performed in all steps above. The value of APT_2B needs not to be corrected. For a direction change from backwards to forwards make the same corrections by incrementing APT_2C.

Make calculations does mean: the operation of the state machine starts with the calculations of NMB_T and INC_CNT1 using the actual APT_2C address pointer value, see **Section 38.22.2, Requirements and demarcation**.

The TBU_TB1 value is to be corrected by the number of pulses sent out in the wrong direction mode during the last and current increment. This correction is done by sending out SUB_INC1 pulses for decrementing TBU_TB1 (while DIR1=1).

Save inc_cnt1 value at direction change to inc_cnt1_save. Calculate the new inc_cnt1 value as follows:

1. Stop sending pulses and save inc_cnt1 at the moment of direction change as inc_cnt1_save.

2. Set inc_cnt1 to the target value of the last increment
   nmb_t_tar_old
3. Add the target number of trigger which were calculated for the current increment when this value was already added to inc_cnt1 before the direction change is detected
   + nmb_t_tar
4. Subtract the value of still not sent pulses (remaining value at inc_cnt1_save)
   – inc_cnt1_save
5. Calculate the new target pulses to be sent considering the new values of SYN_T and PD_store and add them:
   + nmb_t_tar_new

This does mean the following equation: inc_cnt1 = nmb_t_tar_old + nmb_t_tar – inc_cnt1_save + nmb_t_tar_new All pulses summarized at inc_cnt1 are sent out by the maximum possible frequency, because no speed information is available for the first increment after changing the direction. Notice that no pulse correction using PCM1 of DPLL_CTRL1 is possible during direction change. When PSTC was incremented/decremented at the active slope and after that the direction change was detected at the same input event, correct PSTC once by – nmb_t_tar_old when changed to backwards + nmb_t_tar_old when changed to forwards in order to compensate the former operation. When the direction information is known before an intended change of PSTC, do not change them. Store the new calculated value nmb_t_tar_new at nmb_t_tar for the correct calculation of PSTC at the next input event.

consequences for STATE With the next active STATE event the direction information is already given. The profile pointer APS_1C3 is to be corrected by a two times decrement in order to point to the profile of the next following increment. In the following it is decremented with each STATE event while DIR1=1. The SYN_S and PD_S_store values must be updated accordingly, including SYN_S_OLD and PD_S_store_old.

Because the right direction is already known when an input event appears, make the following corrections: – decrement APS_1C3, load SYN_S and PD_S_store, update SYN_S_OLD and PD_S_store_old – decrement APS_1C3, make calculations, load SYN_S and PD_S_store, update SYN_S_OLD and PD_S_store_old and wait for a new STATE event. Note: The update of SYN_S_OLD and the loading of PD_S_store can be performed in all steps above. The value of APS_1C2 needs not to be corrected.

When a new STATE event occurs, all address pointers are decremented accordingly as long as DIR1=1.

In emergency mode the pulses are corrected as follows: Save inc_cnt1 value at direction change to inc_cnt1_save. Calculate the new inc_cnt1 value as follows:

1. Stop sending pulses and save inc_cnt1 at the moment of direction change as inc_cnt1_save.
2. Set inc_cnt1 to the target value of the current increment nmb_s_tar Note: In contrast to the normal mode, nmb_s_tar is to be used instead of nmb_s_tar_old, because direction information in emergency mode is only given from the TRIGGER input and occurs of a STATE event independently. That means: The calculations at the last STATE event were done for the correct former direction. In addition still no pulse calculations are performed for the current increment, because the direction change is known at the moment of the recent STATE event. Later direction changes are considered at the next STATE event.
3. Do not add the calculated number of state pulses because no new STATE event occurred.
4. Subtract the value of still not sent target pulses (remaining value at inc_cnt1_save) – inc_cnt1_save

5. Add the new calculated target pulses for the current increment + nmb_s_tar_new when for the calculation all new conditions of PD_S_store and SYN_S are considered. inc_cnt1 = nmb_s_tar_old – inc_cnt1_save + nmb_s_tar_new All pulses summarized at inc_cnt1 are sent out by the maximum possible frequency, because no speed information is available for the first increment after changing the direction. Notice that no pulse correction using PCM1 of DPLL_CTRL1 is possible during direction change. Do not change PSSC and suppress incrementing/decrementing of PSSC at the event directly following to the direction change information. Store the new calculated value nmb_s_tar_new at nmb_s_tar for the correct calculation of PSTC at the next input event.

repeated change to forward direction for TRIGGER The DIR1 bit remains set as long as the THMI value remains none violated for the following TRIGGER events and is reset when for an inactive TRIGGER slope the THMI is violated.

Resetting the DIR1 to 0 results (after repeated reset of LOCK1, ITN, ISN) the opposite correction of the profile address pointer considered.

This does mean two increment operations of the address pointer APS_1C3 including the update of SYN_S and PD_S_store with the automatic update of SYN_S_OLD and PD_S_store_old for STATE and four increment operations of the address pointer APT_2C including the update of SYN_T and PD_store with the automatic update of SYN_T_OLD and PD_store_old for TRIGGER.

The correction of TBU_CH1 is done by sending out the correction pulses with the highest possible frequency at SUB_INC1 while DIR1=0. The number of pulses is calculated as shown above.

consequences for STATE see corrections above. After that the address pointers are incremented again with each following active STATE event as long as DIR1 = 0.

(3) Operation for direction change for TRIGGER (SMC = 1)

When for SMC=1 a backwards condition is detected for the TRIGGER input signal (TDIR=1, resulting in DIR1=1), the LOCK1 bit in the DPLL_STATUS register is reset, the NUTE value in NUTC register is set to 1. The address pointers APT and APT_2C as well as APT_2B are decremented for each active slope of TRIGGER as long as the DIR1 bit shows the backward direction. Notice that in the case of the change of the direction the ITN bit in the DPLL_STATUS register is reset.

profile update for TRIGGER Make the same update steps for the profile address pointer as shown in **Section 38.22.8.6, (2) Operation for direction change in normal and emergency mode (SMC = 0)** : Decrement APT_2C for 2 times with the update of the SYN_T and PD_store values at each step with an automatic update of SYN_T_OLD and PD_store_old:

1. decrement APT_2C, load SYN_T, PD_store, update SYN_T_OLD
2. decrement APT_2C, make calculations, load SYN_T and PD_store, update SYN_T_OLD and PD_store_old and wait for a new TRIGGER event.

In the normal case no correction of wrong pulses sent is necessary, because the direction change is detected by the pattern immediately. Nevertheless a correction is necessary as shown below. In the other case: see treatment of pulses TBU_CH1_BASE in normal mode at **Section 38.22.8.6, (2) Operation for direction change in normal and emergency mode (SMC = 0)**.

Save inc_cntx value at direction change to inc_cnt1_save. Calculate the new inc_cnt1 value as follows: 1. Clear inc_cnt1. 2. Set inc_cnt1 to the target value of the last increment nmb_t_tar Note: In contrast to the normal mode, nmb_t_tar is to be used instead of nmb_t_tar_old, because the direction information

is known before the calculation takes place. 3. Do not add the calculated number of trigger pulses because it is not calculated yet before the direction change information is known. 4. Subtract the value of still not sent pulses (remaining value at inc_cnt1_save) – inc_cnt1_save 5. Add the new calculated target pulses for the current increment + nmb_t_tar_new when for the calculation all new conditions of PD_S_store and SYN_S are considered. inc_cnt1 = nmb_t_tar_old – inc_cnt1_save + nmb_t_tar_new All pulses summarized at inc_cnt1 are sent out by the maximum possible frequency, because no speed information is available for the first increment after changing the direction. Notice that no pulse correction using PCM1 of DPLL_CTRL1 is possible during direction change.

Suppress changing of PSTC for the TRIGGER event when a direction change is detected. Store the new calculated value nmb_t_tar_new at nmb_t_tar for the correct calculation of PSTC at the next input event.

repeated change to forward direction for TRIGGER The DIR1 bit remains set as long as the TDIR bit is set for the following TRIGGER events and is reset when for an active TRIGGER slope the TDIR is zero.

Resetting the DIR1 to 0 results (after repeated reset of LOCK1 and ITN) the opposite correction of the address pointer use. This does mean two increment operations of the address pointer including the update of SYN_T and PD_store.

A complex correction of TBU_CH1_BASE and INC_CNT1 is in the normal case not necessary, when all increments are equal (SYN_NT=0) and no adapt information is used. In this case only the MLS1 value is added to INC_CNT1 in order to back count the value for the last increment. In the other case: see treatment of pulses TBU_CH1_BASE and ICN_CNT1 in normal mode at **Section 38.22.8.6, (2) Operation for direction change in normal and emergency mode (SMC = 0)**.

(4) Operation for direction change for STATE (SMC=1)

When for SMC=1 a backwards condition is detected for the STATE input signal (SDIR=1, resulting in DIR2=1), the LOCK2 bit in the DPLL_STA- TUS register is reset, the NUSE value in NUSC register is set to 1 and the address pointers APS and APS_1C3_f and APS_1C2 are decremented for each active slope of *STATE* as long as the DIR2 bit shows the backward direction.

NOTE

In case of the change of the direction the ISN bit in the DPLL_STATUS register is reset.

For this transition to the backward direction no change of address pointer APS and APS_1C2 is necessary.

profile update for STATE Make the same update steps for the profile address pointer as shown in **Section 38.22.8.6, (2) Operation for direction change in normal and emergency mode (SMC = 0)**: Decrement APS_1C3 for 2 times with the update of the SYN_S, SYN_S_OLD, PD_S_store and PD_S_store_old values at each step:

1. decrement APT_1c3, load SYN_S, PD_S_store, update SYN_S_OLD
2. decrement APT_1c3, make calculations, load SYN_S and PD_S_store, update SYN_S_OLD and PD_S_store_old and wait for a new STATE event.

A complex correction of TBU_CH2_BASE and INC_CNT2 is in the normal case not necessary, when all increments are equal (SYN_NS=0) and no adapt information is used. In this case only the MLS2 value is added to INC_CNT2 in order to back count the value for the last increment. In the other case:

see treatment of pulses TBU_CH1_BASE and ICN_CNT1 in normal mode at **Section 38.22.8.6, (2) Operation for direction change in normal and emergency mode (SMC = 0)**.

For the second PMSM the pulses are corrected as follows: Save inc_cnt2 value at direction change to inc_cnt2_save. Calculate the new inc_cnt2 value as follows:

1. Clear inc_cnt2.
2. Set inc_cnt2 to the target value of the last increment nmb_s_tar Note: In contrast to the normal mode, nmb_s_tar is to be used instead of nmb_s_tar_old, because no new calculation is performed so far.
3. Do not add the calculated number of state pulses because it is not calculated yet before the direction change information is known.
4. Subtract the value of still not sent pulses (remaining value at inc_cnt2_save) – inc_cnt2_save
5. Add the new calculated target pulses for the current increment + nmb_s_tar_new when for the calculation all new conditions of PD_S_store and SYN_S are considered. inc_cnt2 = nmb_s_tar_old– inc_cnt2_save + nmb_s_tar_new All pulses summarized at inc_cnt2 are sent out by the maximum possible frequency, because no speed information is available for the first increment after changing the direction. Notice that no pulse correction using PCM2 of DPLL_CTRL1 is possible during direction change. Do not change PSSC for a STATE event when a direction change is detected. Store the new calculated value nmb_s_tar_new at nmb_s_tar for the correct calculation of PSTC at the next input event.

repeated change to forward direction for STATE The DIR2 bit remains set as long as the SDIR bit is set for the following STATE events and is reset when for an active STATE slope SDIR is zero.

Resetting the DIR2 to 0 results (after repeated reset of LOCK2 and FSD) in the opposite correction of the address pointer use.

After a last decrementing of all address pointers the APS_1C3 is incremented 2 times with a repeated update of SYN_S, SYN_S_OLD and PD_S_store after each increment.

(5) DPLL reaction in the case of non plausible input signals

When the DPLL is synchronized concerning the TRIGGER signal by setting the FTD, SYT and LOCK1 bits in the DPLL_STATUS register, the number of active TRIGGER events between the gaps is to be checked continuously.

When additional events appear while a gap is expected, the LOCK1 bit is reset and the ITN bit in the DPLL_STATUS register is set.

When an unexpected gap appears (missing TRIGGER S), the NUTE value in the NUTC register is set to 1, the LOCK1 bit is reset and the ITN bit in the DPLL_STATUS register is set. The address pointers are incremented with the next active TRIGGER slope accordingly.

The TOR Bit in the DPLL_STATUS register is set, when the time from the last valid TRIGGER event to the next active TRIGGER slope exceeds the value of the last nominal TRIGGER duration multiplied with the value of the TLR register (see **Section 38.22.22.36, DPLL_TLR**). In this case also the TORI interrupt is generated, when enabled.

When in the following the direction DIR1 changes as described in the chapters above the ITN bit in the DPLL_STATUS register is reset, the use of the address pointers APT_2C is switched and the pulse correction takes place as described above.

In all other cases the CPU can interact to leave the unstable state. This can be done by setting the APT_2C address pointer which results in a reset of the ITN bit. In the following NUTE can also be set to higher values.

When the DPLL is synchronized concerning the STATE signal by setting the FSD, SYS and LOCK1 (for SMC=0) or LOCK2 (for SMC=1) bits in the DPLL_STATUS register, the number of active STATE events between the gaps is to be checked continuously.

When additional events appear while a gap is expected or while an unexpected missing STATE event appears, the LOCK1,2 bit is reset and the ISN bit in the DPLL_STATUS register is set.

When an unexpected gap appears for RMO=SMC=1 (missing STATE s for synchronous motor control), the NUSE value in the NUSC register is set to 1, the LOCK2 bit is reset and the ISN bit in the DPLL_STATUS register is set. The address pointers are incremented with the next active STATE slope accordingly.

When the STATE locking range SLR is violated, the state machine 2 will remain in state 21 and the address pointer APS, APS_1C2 and APS_1C3 will remain unchanged until the CPU sets the APS_1C3 accordingly. In this case also the NUSE value in the NUSC register is set to 1. The DPLL stops the generation of the SUB_INC1,2 pulses respectively and will perform no other actions – remaining in step21 of the second state machine. The SOR Bit in the DPLL_STATUS register is set, when the time to the next active STATE slope exceeds the value of the last nominal STATE duration multiplied with the value of the SLR register.

In this case also the SORI interrupt is generated, when enabled.

When in the following the direction DIR2 changes as described in the chapters above the ISN bit in the DPLL_STATUS register is reset, the use of the address pointers APS_1C3 is switched and the pulse correction takes place as described above. In all other cases the CPU must interact to leave the unstable state. This can be done by setting the APS_1C3 address pointers which results in a reset of the ISN bit. In the following NUSE can also be set to higher values.

(6) State description of the State Machine.

Table 38.291 State description of the State Machine Table (1/7)

Step	Description	Comments

Always for DEN=1	for each inactive TRIGGER slope with TEN=1:
	check, if the last active TRIGGER slope was passing the PVT check; only in this case perform the following tasks:
	calculate the time stamp difference ?T to the last active event, store this value at THVAL;
	when THMI >0 is violated (?T < THMI):
	generate TINI interrupt,
	set DIR1=0 (forwards)
	set BWD1=0 (see DPLL_STATUS register)
	else (only for THMI >0):
	set DIR1= 1 (backwards);
	set BWD1=1 (see DPLL_STATUS register)
	after changing the direction correct the pulses WP sent with wrong direction information and send the pulses for the actual increment in addition with highest possible frequency:
	WP=NMB_T-DPLL_INC_CNT1;
	correct INC_CNT1 by addition of 2*WP before sending the correction pulses;
	generate the TISI interrupt;
	
	check THMA, when THMA is violated, generate the TAXI interrupt; go to step 1
	for each inactive STATE slope with SEN=1:
	set DIR2=DIR1
		for SMC=0;
		set DIR1 always after inc./ decr. the address pointers APT, APT_x;
		go to step 1;
		stop output of SUB_INC1 and correct pulses after changing DIR1 after incr./ decr. of APS_x
		set DIR2 always after incr./decr. the address pointers APS, APS_x;
		go to step 1

Always for DEN=1 and (TEN=1 or SEN=1, respectively)	set DIR1=BWD1=TDIR, set DIR2=BWD2=SDIR; for each change of TDIR go to step 1 after performing the following calculations: correct INC_CNT1 correct the pulses (WP, see above) sent with wrong direction information and send the pulses for the actual increment in addition with highest possible frequency. For each change of SDIR go to step 21 after performing the following calculations: update of SYN_S, PD_S_store according to chapter correct INC_CNT1,2 correct the pulses sent with wrong direction information and send the pulses for the actual increment in addition with highest possible frequency.	**for SMC=1**; set the direction bits always after incr./decr. the corresponding address pointers;

Table 38.291 State description of the State Machine Table (2/7)

Step	Description	Comments
1	When DEN = 0 or TEN=0: stay in step 1 until DEN=1, TEN=1 and at least one active *TRIGGER* has been detected (FTD=1); the following steps are performed always (not necessarily in step 1, but also in steps 18 to 20 (when waiting for new PMTR values to be calculated): compare TRIGGER_S with TSL (active slope); **When no active TRIGGER slope appears** and when TS_T_CHECK time is reached: send missing *TRIGGER* INT, also when a gap is expected according to the profile; set MT=1 (missing *TRIGGER* bit) in the DPLL_STATUS register; do not leave the active step, until a valid active *TRIGGER* appears. When an active TRIGGER slope appears check PVT - when the PVT value is violated: generate the PWI interrupt, ignore the *TRIGGER* input and wait for the next active TRIGGER slope (ignore each inactive slope); do not store any value - When the PVT value is fulfilled: store the actual position stamp at PSTM (value at the TRIGGER event) update the RAM region 2 by equation DPLL-1a-c (see chapter) **store the actual INC_CNT1 value at MP1 as missing pulses** *(instead of calculation in step 5)* store all relevant configuration bits **X** of the DPLL_CTRL(0,1) Registers in **shadow** registers and consider them for all corresponding calculations of steps 2 to 20 accordingly; the relevant bits are explained in the registers itself generate the TASI interrupt;	Depending on TSL, TEN, DEN step one is leaving with the next *TRIGGER* input; **Note:** Step 1 is also left in emergency mode when an active *TRIGGER* event appears in order to make a switch back to normal mode possible; _old - values are values valid at the last but one active *TRIGGER* event; for the whole table: use always MLS1 instead of (MLT+1) for the case SMC=1; **dir_crement** does mean: increment for DIR1=0 decrement for DIR1=1 *)replace (MLT+1) by MLS1 for SMC=1 **) NMB_T_TAR is the target value of NMB_T of the last increment (see step 5 ff.) ***) add MPVAL1 once to INC_CNT1, that means only when PCM1=1 ****) **SGE1_delay** is the value of SGE1 delayed by one active TRIGGER event *****) PD_store = 0 for AMT=0 (see DPLL_CTRL_0 register)

	for FTD=0: set PSTC=PSTM
	set FTD (first *TRIGGER* detected)
	do not change PSTC,APT, APT_2B
	for (RMO=0 or SMC=1)
	and SGE1=1: increment INC_CNT1 by (MLT+1)*) +MPVAL1***)
	send SUB_INC1 pulses with highest possible frequency when SGE1=1 and DPLL_CTRL_11.SIP1 = 0.
	for SYT=0 and FTD =1:
	dir_crement APT and APT_2B by one;
	dir_crement for **SGE1_delay******)**=1:** PSTC by NMB_T_TAR**)
	for (RMO=0 or SMC=1) **and SGE1=1**: increment INC_CNT1 by (MLT+1)*) +MPVAL1***)
	
	for SYT=1:
	dir_crement APT, APT_2C**, dir_crement** APT_2B by SYN_T_OLD
	dir_crement for **SGE1_delay******)**=1** PSTC by NMB_T_TAR**)
	for (RMO=0 or SMC=1) **and SGE1=1**: increment INC_CNT1 by SYN_T*((MLT+1)*)+ PD_store)*****) + MPVAL1***)
	PD_store is 0 for AMT=0
	within the DPLL_STATUS register:
	set LOCK1 bit accordingly;	

2	calculate TS_T according to equations DPLL-1a; calculate DT_T_ACT = TS_T - TS_T_OLD calculate RDT_T_ACT calculate QDT_TX according to equation DPLL-2	

Table 38.291 State description of the State Machine Table (3/7)

Step	Description	Comments
3	send CDTI interrupt when NTI_CNT is zero or decrement NTI_CNT when not zero; calculate EDT_T and MEDT_T according to equations DPLL-3 and DPLL-4 for (RMO=1 and SMC=0): update SYN_T, PD_store and go back to step 1	**Note:** There are different behaviors of RM and HW-IP: For the HW-IP the values of SYN_T and PD_store are not updated until a new active TRIGGER slope occurs.
4	calculate CDT_TX according to equation DPLL-5a and b;	for RMO=0 or SMC=1;

5	calculate missing pulses:
	MP1 = INC_CNT1(at the moment of an active TRIGGER slope)
	
	calculate target pulses:
	NMB_T_TAR = ((MLT+1)*) *+ PD_store) *SYN_T + MPVAL1
	(instead of PD_store use zero in the case AMT=0)
		for RMO=0 or SMC=1;
		
		*)replace (MLT+1) by MLS1 for SMC=1;
		
		add MPVAL1 only for PCM=1 and reset PCM1 after that;

6	sent MP with highest possible frequency and set NMB_T = NMB_T_TAR	for RMO=0 or SMC=1, DMO=0 and COA=0
7	calculate the number of pulses to be sent NMB_T = NMB_T_TAR + MP (see equations DPLL-21 or DPLL-27 respectively)	for RMO=0 or SMC=1, DMO=0 and COA=1
8	NMB_T = SYN_T*CNT_NUM_1	for RMO=0 or SMC=1, DMO=1
9	update SYN_T and PD_store;	**Note:** There are different behaviors of RM and HW-IP: For the HW-IP the values of SYN_T and PD_store are not updated until a new active TRIGGER slope occurs.
10	calculate ADD_IN_CAL1 according to equation DPLL-25 and DPLL-25b or DPLL-31 and store this value in RAM use ADD_IN_CAL1 as ADD_IN value for the case DLM=0 use ADD_IN_LD1 as ADD_IN for the case DLM=1, but do this update immediately (without waiting for this step 10); for DMO=DLM=0 and EN_C1u=0: reset the flip-flops in the SUB_INC1 generator; start sending SUB_INC1;	for RMO=0 or SMC=1 for DLM=0 for DLM=1
11	calculate TS_T_CHECK = TS_T + DT_T_ACT *(TOV);	for RMO=0 or SMC=1;
12	automatic setting of actions masking bits in the DPLL_STATUS register: for SMC=0: set CAIP1=CAIP2=1 for SMC=1: set only CAIP1=1	steps 12 to 16 are not valid for the combination: (SMC=0 and RMO=1)
13	for all correspondent actions with ACT_N[i]=1 calculate: NA[i] = (PSA[i] - PSTC)/(MLT+1)*)for forward direction with w= integer part and b = remainder of the division (fractional part); for backward direction use NA[i] = (PSTC - PSA[i])/(MLT+1)*) and consider in both cases the time base overflow in order to get a positive difference	actions 0...11 for SMC=1 actions 0...23 for SMC=0 depending on ACT_N[i] in **DPLL_ACT_STA** register; replace MLT+1 by MLS1 for SMC=1
14	calculate PDT_T[i] and DTA[i] for up to 24 action values according to equations DPLL-11 and DPLL-12;	actions 0...11 for SMC=1 actions 0...23 for SMC=0
15	calculate TSAC[i] according to equation DPLL-15 and PSAC[i] according to equation DPLL-17	actions 0...11 for SMC=1 actions 0...23 for SMC=0
16	automatic resetting of actions masking bits in the DPLL_STATUS register: for SMC=0: set CAIP1=CAIP2=0 for SMC=1: set only CAIP1=0; set the corresponding ACT_N[i] bits in the DPLL_ACT_STA register	Set ACT_N[i] for all enabled actions concerned: 0...11 for SMC=1 0...23 for SMC=0

Table 38.291 State description of the State Machine Table (4/7)

Step	Description	Comments
17	check the relation of the last increment to its predecessor according to the profile and taking into account TOV: set the ITN status bit and reset the corresponding LOCK bit, when not plausible; go to step 18, when no active *TRIGGER* appears for all following steps 18 to 20: go immediately back to step 1, when an active TRIGGER event occurs, interrupt all calculations there and reset all CAIP in that case; when going back to step 1: store TS_T in RAM 2b according to APT_2B; update RAM 2a and RAM 2d	for all conditions
18	wait for a new PMTR value; set the corresponding CAIPx values and go to step 19 in that case	go immediately to step 1 and update the RAM according to step 17 when an active *TRIGGER* event occurs
19	make the requested action calculation according to new PMTR values	go immediately to step 1 and update the RAM according to step 17 when an active *TRIGGER* event occurs
20	reset CAIPx and go back to step 18	go immediately to step 1 and update the RAM according to step 17 when an active *TRIGGER* event occurs
21	When DEN = 0 or SEN=0: make sure that the first active slope of STATE is detected; stay in step 1 until DEN=1, SEN=1 and at least one active *STATE* has been detected (FSD=1); the following steps are performed always (not necessarily in step 21, but also in steps 38 to 40 (when waiting for new PMTR values to be calculated): compare STATE_S with SSL (active slope); for each inactive slope: generate a SISI interrupt; send missing *STATE* INT when TS_S_CHECK time is reached and set MS=1 (missing *STATE* bits) in that case; do not leave step 21 while no active *STATE* appears. When an active *STATE* slope appears: store the actual position stamp at PSSM (value at the STATE event) update RAM by equation DPLL-6a-c (see chapter); **store the actual INC_CNT1/2 at MP1/MP2 respectively as missing pulses** *(instead of calculations in step 25)* store all relevant configuration bits **X** of the DPLL_CTRL(0,1) Registers in **shadow** registers and consider them for all corresponding calculations of steps 22 to 37 accordingly; the relevant bits are explained in the registers itself for FSD=0:	Depending on SSL, SEN, DEN step 21 is leaving with the next *STATE* input; for the steps 22-37: for SMC=1 replace: MLS1 by MLS2, LOCK1 by LOCK2; SUB_INC1 by SUB_INC2; CNT_NUM_1 by CNT_NUM_2; MPVAL1 by MPVAL2; EN_C1u by EN_C2u; **dir_crement** does mean: increment for DIR2=0 decrement for DIR2=1 or DIR1 respectively *) target number of pulses of the last increment (see step 25 ff.) **) add MPVAL1 or MPVAL2 only once, that means as long as PCM1 or PCM2 is set respectively ***) **SGE1_delay** is the value of SGE1 delayed by one active STATE event ****) **SGE2_delay** is the value of SGE2 delayed by one active STATE event *****) PD_S_store = 0 for AMS=0 (see DPLL_CTRL_0 register)

	for **SGE1=1** increment INC_CNT1 by SYN_S*(MLS1 + PD_S_store) + MPVAL1**)
	for RMO=1 and SMC=1: for
	SGE2_delay****)**=1 dir_crement** PSSC by NMB_S_TAR*);
	for **SGE2=1** increment INC_CNT2 by SYN_S*(MLS2 + PD_S_store)*****) +MPVAL2**)
	within the DPLL_STATUS register:
	set LOCK1 or 2 bit accordingly;	

22	calculate TS_S according to equations DPLL-6a; calculate DT_S_ACT = TS_S - TS_S_OLD calculate RDT_S_ACT calculate QDT_SX	
23	send CDSI interrupt; calculate EDT_S and MEDT_S according to equations DPLL-8 and DPLL-9 for RMO=0: go back to step 21 for RMO=0 and update SYN_S and PD_S_store using the current ADT_S[i] values in that case;	**Note:** There are different behaviors of RM and HW-IP: For the HW-IP the values of SYN_S and PD_S_store are not updated until a new active STATE slope occurs.
24	calculate CDT_SX according to equation DPLL-10a and b;	only for RMO=1
25	calculate missing pulses - for TBU_CH1: MP1 = INC_CNT1(active STATE slope) - for TBU_CH2: MP2 = INC_CNT2(active STATE slope) calculate target number of pulses: NMB_S_TAR = (MLS1 + PD_S_store)*SYN_S + PD_S_store +MPVAL1 (for SMC=0) NMB_S_TAR = MLS2* (SYN_S + PD_S_store) + MPVAL2 (for SMC=1) (instead of PD_S_store use zero in the case AMS=0)	only for RMO=1 for SMC=0 instead of MPVAL1 use zero for PCM1=0 for SMC=1 instead of MPVAL2 use zero for PCM2=0; add MPVAL1/2 once to INC_CNT1/2 and reset PCM1/2 after that
26	sent MPx with highest possible frequency and set NMB_S = NMB_S_TAR	only for RMO=1, DMO=0 and COA=0
27	calculate number of pulses to be sent according to DPLL-22 or NMB_S = NMB_S_TAR + MPx	only for RMO=1, DMO=0 and COA=1
28	NMB_S = SYN_S*CNT_NUM_1 (SMC=0) NMB_S = SYN_S*CNT_NUM_2 (SMC=1)	only for RMO=1, DMO=1

Table 38.291 State description of the State Machine Table (6/7)

Step	Description	Comments
29	update SYN_S and PD_S_store;	**Note:** There are different behaviors of RM and HW-IP: For the HW-IP the values of SYN_S and PD_S_store are not updated until a new active STATE slope occurs.
30	calculate ADD_IN_CAL2 according to equation DPLL-26 and DPLL-26b or DPLL-31 respectively and store this value in RAM use ADD_IN_CAL2 as ADD_IN value for the case DLM=0 use ADD_IN_LD2 as ADD_IN for the case DLM=1, but do this update immediately (without waiting for this step 30); for RMO=1, DMO=DLM=0 and EN_C1u=0 (EN_C1u=0): reset the flip-flops in the SUB_INC1 or SUB_INC2 generator respectively; start sending SUB_INC1 / SUB_INC2;	only for RMO=1 for DLM=0 for DLM=1
31	calculate TS_S_CHECK = TS_S + DT_S _ACT * (SOV);	only for RMO=1;
32	automatic setting of actions masking bits in the DPLL_STATUS register: CAIP1 and CAIP2 for SMC=0 only CAIP2 for SMC=1	for RMO=1
33	for all actions with ACT_N[i]=0 calculate: NA[i] = (PSA[i] - PSSC)/MLS1 for forward direction with w = integer part and b = remainder of the division (fractional part) for backward direction use NA[i] = (PSSC - PSA[i])/(MLS1) and consider in both cases the time base overflow in order to get a positive difference use MLS2 as divider in the case of SMC=1	for SMC=0: 24 actions, for SMC=1: 12 actions; depending on ACT_N[i] in **DPLL_ACT_STA** register
34	calculate PDT_S[i] and DTA[i] for up to 24 action values according to equations DPLL-13 and DPLL-14;	only for RMO=1; for SMC=0 actions 0...23 for SMC=1 actions 12...23
35	calculate TSAC[i] according to equation DPLL-18 and PSAC[i] according to equation DPLL-20	for the relevant actions (see above) and RMO=1
36	automatic reset of the actions masking bit CAIP in the DPLL_STATUS register: CAIP1=CAIP2=0 for SMC=0 and only CAIP2=0 for SMC=1 set the corresponding ACT_N[i] bits in the DPLL_ACT_STA register	for the relevant actions (see above) and RMO=1 Set ACT_N[i] and reset ACT_WRi for all enabled actions
37	check the duration of the last increment to its predecessor according to the profile and taking into account SOV: set the ISN status bit and reset the corresponding LOCK bit, when not plausible; go to step 38, when no active *STATE* appears for all following steps 38 to 40: go immediately back to step 21, when an active *STATE* event occurs, interrupt all calculations there and reset all CAIPx in that case; when going back to step 21: store TS_S in RAM 1c2 according to APS_1C2; update RAM 1c1 and RAM 1c4	for all conditions

Table 38.291 State description of the State Machine Table (7/7)

Step	Description	Comments
38	wait for a new PMTR value; set the corresponding CAIPx values and go to step 39 in that case	go immediately to step 21 and update the RAM according to step 37 when an active *STATE* event occurs
39	make the requested action calculation according to new PMTR values	go immediately to step 21 and update the RAM according to step 37 when an active *STATE* event occurs
40	reset CAIP and go back to step 38	go immediately to step 21 and update the RAM according to step 37 when an active *STATE* event occurs

38.22.9 DPLL Interrupt signals

The DPLL provides 27 interrupt lines. These interrupts are shown below.

Table 38.292 DPLL Interrupt Signals

Signal	Description
DPLL_DCGI_IRQ	Direction change
DPLL_SORI_IRQ	*STATE* is out of range
DPLL_TORI_IRQ	*TRIGGER* is out of range
DPLL_CDSI_IRQ	*STATE* duration calculated for last increment
DPLL_CDTI_IRQ	*TRIGGER* duration calculated for last increment
DPLL_TE4_IRQ	*TRIGGER* event interrupt 4 request[3)]
DPLL_TE3_IRQ	*TRIGGER* event interrupt 3 request[3)]
DPLL_TE2_IRQ	*TRIGGER* event interrupt 2 request[3)]
DPLL_TE1_IRQ	*TRIGGER* event interrupt 1 request[3)]
DPLL_TE0_IRQ	*TRIGGER* event interrupt 0 request[3)]
DPLL_LL2_IRQ	Loss of lock interrupt for SUB_INC2 request
DPLL_GL2_IRQ	Get of lock interrupt for SUB_INC2 request
DPLL_E_IRQ	Error interrupt request
DPLL_LL1_IRQ	Loss of lock interrupt for SUB_INC1 request
DPLL_GL1_IRQ	Get of lock interrupt for SUB_INC1 request
DPLL_W1_IRQ	Write access to RAM region 1b or 1c interrupt request
DPLL_W2_IRQ	Write access to RAM region 2 interrupt request
DPLL_PW_IRQ	Plausibility window violation interrupt of *TRIGGER* request
DPLL_TAS_IRQ	*TRIGGER* active slope while NTI_CNT is zero interrupt request
DPLL_SAS_IRQ	*STATE* active slope interrupt request
DPLL_MT_IRQ	Missing *TRIGGER* interrupt request
DPLL_MS_IRQ	Missing *STATE* interrupt request
DPLL_TIS_IRQ	*TRIGGER* inactive slope interrupt request
DPLL_SIS_IRQ	*STATE* inactive slope interrupt request
DPLL_TAX_IRQ	*TRIGGER* maximum hold time violation interrupt request
DPLL_TIN_IRQ	*TRIGGER* minimum hold time violation interrupt request
DPLL_PE_IRQ	DPLL enable interrupt request
DPLL_PD_IRQ	DPLL disable interrupt request

NOTE

TEi_IRQ depends on the TINT value in ADT_T[i]1) and is only active when SYT2) =1.

1. see RAM region 2 explanations; see 19.14
2. see DPLL STATUS register; see 19.12.30
3. see TINT value in the corresponding ADT_T[i] section of RAM region 2; see 19.14.3

38.22.10 MCS to DPLL interface

A reduced AEI interface is implemented in the DPLL, which can only be accessed by the MCS Bus Master interface in the same cluster. The purpose of this interface is to enable a faster interchange of data between the MCS and the DPLL, while enabling a certain control over the DPLL internal state machine.

38.22.10.1 Architecture and organization

The implemented interface has an address width of 4 bits, while the size of the data interface is 24 bits.

The following table shows the implemented AEI addresses from the MCS side. Label RD refers to the label used for the address when reading from the MCS or writing from the DPLL, whereas Label WR refers to the label used for the address when writing from the MCS or reading from the DPLL.

38.22.10.2 General functionality

In order to have a better understanding of the implications when this interface is used, the following working concepts are informally defined here. They refer to the STATE engine operation when DPLL_CTRL_11.STATE_EXT is set.

Update of ram: Operation which stores TSF_S, DT_S_ACTUAL and RDT_S_ACTUAL back to the RAM and reads the profile. Calculation of sub-increments: Calculation of DT_S_ACTUAL, RDT_S_ACTUAL, NMB_S and ADD_IN. Change of direction: Update of profile and its increment or decrement (only in the STATE processor). Calculation of actions (PMT): Where the calculation of PSAC and TSAC is performed (only in state processor).

If DPLL_CTRL_11.STATE_EXT is not set, the DPLL will ignore the data written to this interface from the MCS. The DPLL will not update the interface either and a read done to this interface from the MCS can obtain out-of-date information.

If DPLL_CTRL_11.STATE_EXT is set, some modifications are done to the way that the DPLL module works when using the STATE engine. Up to 128 STATE events can be handled. RAM1c is not used anymore. Instead, the data needed to perform each of the already described operations is fetched from registers in this interface. The data that would have to be written back to RAM1c is also written to this interface. In each of the procedures described above, the DPLL will enter in one or more stalled states, in which it will wait for one or more words to be written to MCS2DPLL_DEB15(STATUS_INFO)

(1) Correspondence between STA_S values and their unlocking keywords

Operation	STA_S value	First Keyword	Second Keyword
Update of ram	00001_001_B	0xE	0x1
Calculation of sub-increments	00010_000_B	0xD	0x2
Calculation of actions	01110_000_B	0xC	0x3
Change of direction	00000_100_B	0xB	0x4
Change of direction	00000_110_B	0xB	0x4

The stalled STATE in the DPLL is freed by writing the upper keywords to MCS2DPLL_DEB15. Note the requirements on DPLL level (described in **Section 38.22.25, MCS to DPLL Configuration Registers Overview**) regarding the data on the interface that has to be written by the MCS program. If this data is incorrectly delivered or the STATE state machine is unlocked before delivery, the proper signal processing of the DPLL cannot be assured.

For the particular case of an update of ram after a virtual increment, the data field TSF_S is not calculated completely by the DPLL STATE processing unit. Instead, the values needed in order to fill this data field are provided (**Section 38.22.7.5, (6) Equations DPLL-6a5-7 to extend the time**

stamp values for STATE and **Section 38.22.7.5, (7) Equations DPLL-6a5-7 for backward direction**)

38.22.10.3 MCS to DPLL Register overview

Table 38.293 MCS to DPLL register overview

Address offset (see Section 38.28)	Common Label	Label RD	Label WR	Details in section
0x0	MCS2DPLL_DEB0	DT_S_P	DT_S_P1	
0x4	MCS2DPLL_DEB1	not used	RDT_S_P1	
0x8	MCS2DPLL_DEB2	TS_SX	RDT_S_PQ1	
0xC	MCS2DPLL_DEB3	DT_SX	DT_S_PQ	
0x10	MCS2DPLL_DEB4	SYN_S_OLD	RDT_S_PQ	
0x14	MCS2DPLL_DEB5	M_DW	DT_S_PQ1	
0x18	MCS2DPLL_DEB6	not used	ADT_S_P	
0x1C	MCS2DPLL_DEB7	RDT_S_P_RD	S_P_RD	
0x20	MCS2DPLL_DEB8	not used	TSF_S_P	
0x24	MCS2DPLL_DEB9	not used	TSF_S_P_MQ	
0x28	MCS2DPLL_DEB10	not used	TSF_S_P_PM_MQ	
0x2C	MCS2DPLL_DEB11	not used	TSF_S_P_PM	
0x30	MCS2DPLL_DEB12	not used	ADT_S_P1	
0x34	MCS2DPLL_DEB13	not used	not used	
0x38	MCS2DPLL_DEB14	not used	not used	
0x3C	MCS2DPLL_DEB15	not used	STATUS_INFO	

38.22.11 DPLL Register Memory overview

The available registers and the size of the RAM area 2 depends on the chosen device. Refer to **Section 38.28, GTM Device 358**.

NOTES

- The registers DPLL_ID_PMTR 24–31 are not available for all devices. Refer to **Section 38.28, GTM Device 358**.
- The values PSA24–31, DLA24–31, NA24–31 and DTA24–31 in RAM 1a are not available for all devices. Refer to **Section 38.28, GTM Device 358**.
- The values PDT_24 to PDT_31 in RAM1b are not available for all devices. Refer to **Section 38.28, GTM Device 358**.
- The registers DPLL_NUSC_EXT1, DPLL_NUSC_EXT2, DPLL_APS_EXT, DPLL_APS_1C3_EXT, DPLL_APS_SYNC_EXT, and DPLL_CTRL_EXT will return AEI_STATUS = b#10 if DPLL_CTRL_11.STATE_EXT is not set.
- For each of the regions, the maximum number of entries is restricted to a value corresponding to the OSS value in the DPLL_OSW register.

The description of registers is beginning at the register DPLL_CTRL_0.

The description of RAM regions is beginning at RAM 1a (see below): Bits 31 down to 24 in each RAM region are not implemented and therefore always read as zero (reserved). Other bits which are declared as reserved are not protected against writing. Reserved address regions are not protected against writing.

The description of the memory region RAM 1a begins with memory element PSA[i]: The RAM region 1a is writable only for DEN=0 (see DPLL_CTRL_1 register).

The description of memory region RAM1b begins with memory element TS_T. The description of memory region RAM1c begins with memory element RDT_S.

The description of register region EXT begins with the register DPLL_TSAC[z]: This is an extension of the normal register region above in order to allow up to 32 action calculations and later specification modifications.

The description of the memory region RAM 2 begins with memory element RDT_T.

38.22.12 DPLL Configuration Registers Overview

DPLL contains following configuration registers:

Table 38.294 Register list (1/2)

Symbol	Register Name	Details in Section
DPLL_CTRL_0	Control Register 0	**38.22.18.1**
DPLL_CTRL_1	Control Register 1	**38.22.18.2**
DPLL_CTRL_2	DPLL Control Register 2 (actions 0-7 enable)	**38.22.18.3**
DPLL_CTRL_3	DPLL Control Register 3 (actions 8-15 enable)	**38.22.18.4**
DPLL_CTRL_4	DPLL Control Register 4 (actions 16-23 enable)	**38.22.18.5**
DPLL_CTRL_5	DPLL Control Register 5 (actions 24-31 enable)	**38.22.18.6**
DPLL_ACT_STA	Action Status Register including Shadow Register	**38.22.18.7**
DPLL_OSW	Offset and Switch old/new Address Register	**38.22.18.8**
DPLL_AOSV_2	Address Offset Register of RAM 2 Regions	**38.22.18.9**
DPLL_APT	DPLL Actual RAM pointer to RAM regions 2a, b and d	**38.22.18.10**
DPLL_APS	DPLL Actual RAM pointer to regions 1c1, 1c2 and 1c4	**38.22.18.11**
DPLL_APT_2C	Actual RAM Pointer Address for Region 2c	**38.22.18.12**
DPLL_APS_1C3	Actual RAM Pointer Address for RAM region 1c3	**38.22.18.13**
DPLL_NUTC	Number of Recent TRIGGER Events used for Calculations	**38.22.18.14**
DPLL_NUSC	Number of Recent STATE Events used for Calculations	**38.22.18.15**
DPLL_NTI_CNT	Number of Active TRIGGER Events to Interrupt	**38.22.18.16**
DPLL_IRQ_NOTIFY	Interrupt Register	**38.22.18.17**
DPLL_IRQ_EN	Interrupt Enable Register	**38.22.18.18**
DPLL_IRQ_FORCINT	Force Interrupt Register	**38.22.18.19**
DPLL_IRQ_MODE	Interrupt Request Mode	**38.22.18.20**
DPLL_EIRQ_EN	Error Interrupt Enable Register	**38.22.18.21**
DPLL_INC_CNT1	DPLL Counter for pulses for TBU_CH1_BASE to be sent in automatic end mode	**38.22.18.22**
DPLL_INC_CNT2	DPLL Counter for pulses for TBU_CH2_BASE to be sent in automatic end mode when SMC=RMO=1	**38.22.18.23**
DPLL_APT_SYNC	DPLL old RAM pointer and offset value for TRIGGER	**38.22.18.24**
DPLL_APS_SYNC	DPLL old RAM pointer and offset value for STATE	**38.22.18.25**
DPLL_TBU_TS0_T	DPLL TBU_CH0_BASE value at last TRIGGER event	**Note:**
DPLL_TBU_TS0_S	DPLL TBU_CH0_BASE value at last STATE event	**38.22.18.27**
DPLL_ADD_IN_LD1	DPLL direct load input value for SUB_INC1	**38.22.18.28**
DPLL_ADD_IN_LD2	DPLL direct load input value for SUB_INC2	**38.22.18.29**
DPLL_STATUS	Status Register	**38.22.18.30**
DPLL_ID_PMTR_[z]	DPLL 9 bit ID information for input signals PMT z 3)	**38.22.18.31**
DPLL_CTRL_0_SHADOW_TRIGGER	DPLL shadow register of DPLL_CTRL_0	**38.22.18.32**
DPLL_CTRL_0_SHADOW_STATE	DPLL shadow register of DPLL_CTRL_0	**38.22.18.33**
DPLL_CTRL_1_SHADOW_TRIGGER	DPLL shadow register of DPLL_CTRL_1	**38.22.18.34**

Table 38.294 Register list (2/2)

Symbol	Register Name	Details in Section
DPLL_CTRL_1_SHADOW_STATE	DPLL shadow register of DPLL_CTRL_1	**38.22.18.35**
DPLL_RAM_INI	Register to control the RAM Initialization	**38.22.18.36**
DPLL_TSAC[z]	Calculated Time Value to start Action z	**38.22.18.37**
DPLL_PSAC[z]	Calculated Position Value to start Action z	**38.22.18.38**
DPLL_ACB_[z]	Control Bits for up to 32 Actions	**38.22.18.39**
DPLL_CTRL_11	Control Register 11	**38.22.18.40**
DPLL_THVAL2	Measured last pulse time from active to inactive slope of TRIGGER after correction of input slope filter delays	**38.22.18.41**
DPLL_TIDEL	TRIGGER input delay	**38.22.18.42**
DPLL_SIDEL	STATE input delay	**38.22.18.43**
DPLL_CTN_MIN	CDT_T_NOM min value	**38.22.18.44**
DPLL_CTN_MAX	CDT_T_NOM max value	**38.22.18.45**
DPLL_CSN_MIN	CDT_S_NOM min value	**38.22.18.46**
DPLL_CSN_MAX	CDT_S_NOM max value	**38.22.18.47**
DPLL_STA	Status of the state machine states	**38.22.18.48**
DPLL_INCF1_OFFSET	Start value of the ADD_IN_ADDER1	**38.22.18.49**
DPLL_INCF2_OFFSET	Start value of the ADD_IN_ADDER2	**38.22.18.50**
DPLL_DT_T_START	Start value of DPLL_DT_T_ACT	**38.22.18.51**
DPLL_DT_S_START	Start value of DPLL_DT_S_ACT	**38.22.18.52**
DPLL_STA_MASK	Notify value for STA_S of register DPLL_STA.	**38.22.18.53**
DPLL_STA_FLAG	Flag according to DPLL_MASK.STA_NOTIFY	**38.22.18.54**
DPLL_INC_CNT1_MASK	Notify value for INC_CNT1 of register DPLL_INC_CNT1	**38.22.18.55**
DPLL_INC_CNT2_MASK	Notify value for INC_CNT2 of register DPLL_INC_CNT2	**38.22.18.56**
DPLL_NUSC_EXT1	Number of Recent STATE Events used for Calculations	**38.22.18.57**
DPLL_NUSC_EXT2	Number of Recent STATE Events used for Calculations	**38.22.18.58**
DPLL_APS_EXT	Actual RAM Pointer Address for STATE	**38.22.18.59**
DPLL_APS_1C3_EXT	Address pointer STATE for RAM region 1c3; Actual RAM pointer address value for ADT_S[i] Initial value: zero (00_H). Actual RAM pointer and synchronization	**38.22.18.60**
DPLL_APS_SYNC_EXT	STATE Time Stamp Field Offset at Synchronization Time	**38.22.18.61**
DPLL_CTRL_EXT	STATE Time Stamp Field Offset at Synchronization Time	**38.22.18.62**

Note 1. This register is not available for all devices. Refer to **Section 38.28, GTM Device 358**.

Note 2. The registers DPLL_ID_PMTR 24-31 are not available for all devices. Refer to **Section 38.28, GTM Device 358**.

38.22.13 RAM Region 1a map description

Memory name	Description	Details in section
PSA[i] (i:0...NOAC-1)	Position/Value request for action i	
DLA[i] (i:0...NOAC-1)	Time to react before PSAi	
NA[i] (i:0...NOAC-1)	Number of TRIGGER/STATE increments to ACTION i	
DTA[i] (i:0...NOAC-1)	Calculated relative time to ACTION i	

Note: The values PSA24-31, DLA24-31, NA24-31 and DTA24-31 in RAM 1a are not available for all devices. Refer to **Section 38.28, GTM Device 358**.

38.22.14 RAM Region 1b map description

Table 38.295 RAM region 1b (1/3)

Memory name	Description	Details in section
TS_T	Actual signal TRIGGER time stamp register TRIGGER_TS	
TS_T_OLD	Previous signal TRIGGER time stamp register TRIGGER_TS_OLD	
FTV_T	Actual signal TRIGGER filter value	
TS_S	Actual signal STATE time stamp register STATE_TS	
TS_S_OLD	Previous signal STATE time stamp register STATE_TS_OLD	
FTV_S	Actual signal STATE filter value	
THMI	TRIGGER hold time min. value	
THMA	TRIGGER hold time max. value	
THVAL	measured last pulse time from active to inactive TRIGGER slope	
TOV	Time out value of TRIGGER, according to the last nominal increment for a missing TRIGGER	
TOV_S	Time out value of STATE, according to the last nominal increment for a missing STATE	
ADD_IN_CAL1	calculated ADD_IN value for SUB_INC1 generation	
ADD_IN_CAL2	calculated ADD_IN value for SUB_INC2 generation	
MPVAL1	missing pulses to be added/subtracted directly to SUB_INC1 and INC_CNT1 once	
MPVAL2	missing pulses to be added/subtracted directly to SUB_INC2 and INC_CNT2 once	
NMB_T_TAR	target number of TRIGGER pulses	
NMB_T_TAR_OLD	target number of TRIGGER pulses	
NMB_S_TAR	target number of STATE pulses	
NMB_S_TAR_OLD	target number of STATE pulses	
RCDT_TX	reciprocal value of expected increment duration (T)	
RCDT_SX	reciprocal value of expected increment duration (S)	
RCDT_TX_NOM	reciprocal value of the expected nominal increment duration (T)	

Table 38.295 RAM region 1b (2/3)

Memory name	Description	Details in section
RCDT_SX_NOM	reciprocal value of the expected nominal increment duration (S)	
RDT_T_ACT	actual reciprocal value of TRIGGER	
RDT_S_ACT	actual reciprocal value of STATE	
DT_T_ACT	Duration of last TRIGGER increment	
DT_S_ACT	Duration of last STATE increment	
EDT_T	Absolute error of prediction for last TRIGGER increment	
MEDT_T	Average absolute error of prediction up to the last TRIGGER increment	
EDT_S	absolute error of prediction for last STATE increment	
MEDT_S	Average absolute error of prediction up to the last STATE increment	
CDT_TX	Expected duration of current TRIGGER increment	
CDT_SX	Expected duration of current STATE increment	
CDT_TX_NOM	Expected nominal duration of current TRIGGER increment (without consideration of missing events)	
CDT_SX_NOM	Expected nominal duration of current STATE increment (without consideration of missing events)	
TLR	TRIGGER locking range value; the TOR bit in the DPLL_STATUS register is set when violated	
SLR	STATE locking range value; the SOR bit is set when violated	
PDT_[i] (i:0...NOAC-1)	predicted time to ACTION i	
MLS1	Calculated number of sub-pulses between two STATE events (to be set by CPU)	
MLS2	Calculated number of sub-pulses between two STATE events (to be set by CPU) for the use when SMC=RMO=1	
CNT_NUM_1	number of sub-pulses of SUB_INC1 in continuous mode, updated by the host only	
CNT_NUM_2	number of sub-pulses of SUB_INC2 in continuous mode, updated by the host only	
PVT	Plausibility value of next active TRIGGER slope	
PSTC	Accurate calculated position stamp of last TRIGGER input;	
PSSC	Accurate calculated position stamp of last STATE input;	
PSTM	Measured position stamp at last active TRIGGER input	
PSTM_OLD	Measured position stamp at last but one active TRIGGER input	
PSSM	Measured position stamp at last active STATE input	

Table 38.295 RAM region 1b (3/3)

Memory name	Description	Details in section
PSSM_OLD	Measured position stamp at last but one active STATE input	
NMB_T	Number of pulses of current increment in normal mode for SUB_INC1 (see equation DPLL-21 or for SMC=1 equation DPLL-27 respectively)	
NMB_S	Number of pulses of current increment in emergency mod for SUB_INC1 (see equation DPLL-22) or in the case SMC=1 for SUB_INC2 (see equation DPLL-28)	

Note: The values PDT_24 to PDT_31 in RAM1b are not available for all devices. Refer to **Section 38.28, GTM Device 358**.

38.22.15 RAM Region 1c map description

Memory name	Description	Details in section
RDT_S[i] (i:0...63)	Part of RAM1c1. Reciprocal value of the corresponding successive increment i, for each true nominal increment.	
TSF_S[i] (i:0...63)	Part of RAM1c2. Time stamp field for state events, for each true nominal increment plus each virtual increment.	
ADT_S[i] (i:0...63)	Part of RAM1c3. Adapt values for the current STATE increment, for each true nominal increment.	
DT_S[i] (i:0...63)	Part of RAM1c4. Uncorrected last increment value of STATE for full scale, for each true nominal increment.	

38.22.16 Register Region EXT description

Register name	Description	Details in
DPLL_TSAC[z] (z:0...NOAC-1)	DPLL calculated action time stamps for action z	
DPLL_PSAC[z] (z:0...NOAC-1)	DPLL calculated action position stamps for action z	
DPLL_ACB_[z] (z:0...(NOAC/4)-1)	DPLL control bits for actions ((4*z)...(4*z)+3)	
DPLL_CTRL_11	DPLL control register	
DPLL_THVAL2	DPLL immediate THVAL value	
DPLL_TIDEL	DPLL additional TRIGGER input delay	
DPLL_SIDEL	DPLL additional STATE input delay	
DPLL_CTN_MIN	CDT_T_NOM minimum value	
DPLL_CTN_MAX	CDT_T_NOM maximum value	
DPLL_CSN_MIN	CDT_S_NOM minimum value	
DPLL_CSN_MAX	CDT_S_NOM maximum value	
DPLL_STA	DPLL state machine status information	
DPLL_INCF1_OFFSET	DPLL ADD_IN_ADDER1 offset for fast pulse generation	
DPLL_INCF2_OFFSET	DPLL ADD_IN_ADDER2 offset for fast pulse generation	
DPLL_DT_T_START	DPLL first value of DPLL_DT_T_ACT for the first increment after setting SIP1 from 0 to 1.	
DPLL_DT_S_START	DPLL first value of DPLL_DT_S_ACT for the first increment after setting SIP2 from 0 to 1.	
DPLL_STA_MASK	DPLL trigger masks for signals DPLL_STA_T and DPLL_STA_S	
DPLL_STA_FLAG	DPLL STA_T/S and INC_CNT1/2 flags	
DPLL_INC_CNT1_MASK	DPLL INC_CNT1 trigger mask	
DPLL_INC_CNT2_MASK	DPLL INC_CNT2 trigger mask	
DPLL_NUSC_EXT1	Extension register number 1 for DPLL_NUSC [4)]	
DPLL_NUSC_EXT2	Extension register number 2 for DPLL_NUSC [4)]	
DPLL_APS_EXT	Extension register for DPLL_APS [4)]	
DPLL_APS_1C3_EXT	Extension register for DPLL_APS_1C3 [4)]	
DPLL_APS_SYNC_EXT	Extension register for DPLL_APS_SYNC [4)]	
DPLL_CTRL_EXT	Extension register for DPLL_CTRL [4)]	

38.22.17 RAM Region 2 map description

Memory name	Description	Details in section
RDT_T[i] (i:0...AOSV_2B/4-1)	Region 2a. Reciprocal value of the corresponding successive increment i, for each true nominal increment.	
TSF_T[i] (i:0...AOSV_2B/4-1)	Region 2b. Time Stamp Field for TRIGGER event i, for each true nominal increment plus each virtual increment.	
ADT_T[i] (i:0...AOSV_2B/4-1)	Region 2c. Adapt values for the current TRIGGER increment i, for each true nominal increment.	
DT_T[i] (i:0...AOSV_2B/4-1)	Region 2d. Uncorrected last increment value of TRIGGER i, for each true nominal increment.	

Note: Note: For each of the regions, the maximum number of entries is restricted to a value corresponding to the OSS value in the DPLL_OSW register.

The description of registers is beginning at the register DPLL_CTRL_0.

The description of RAM regions is beginning at RAM 1a (see below):

Bits 31 down to 24 in each RAM region are not implemented and therefore always read as zero (reserved). Other bits which are declared as reserved are not protected against writing. Reserved address regions are not protected against writing.

The description of the memory region RAM 1a begins with memory element PSA[i]:

The RAM region 1a is writeable only for DEN=0 (see DPLL_CTRL_1 register).

The description of memory region RAM1b begins with memory element TS_T.

The description of memory region RAM1c begins with memory element RDT_S.

The description of register region EXT begins with the register DPLL_TSAC[z]:

This is an extension of the normal register region above in order to allow up to 32 action calculations and later specification modifications.

The description of the memory region RAM 2 begins with memory element RDT_T.

38.22.18 DPLL Register description

38.22.18.1 DPLL_CTRL_0

Access: This register can be read or written in 32-bit units.

Address: <GTM_base> + 28000_H

Value after reset: $003B\ BA57_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	RMO	TEN	SEN	IDT	IDS	AMT	AMS	TNU								
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 38.296 DPLL_CTRL_0 Register Contents (1/3)

Bit Position	Bit Name	Function
31	RMO *1*2	Reference mode; selection of the relevant the input signal for generation of SUB_INC1. See notes {REF:DPLL_5764}, {REF:DPLL_10978}. 0: Normal mode; the signal TRIGGER is used to generate the SUB_INC1 signals 1: Emergency mode for SMC=0; signal STATE is used to generate the SUB_INC1 signals; Double synchronous mode for SMC=1: signal TRIGGER is used to generate the SUB_INC1 signals and STATE is used to generate the SUB_INC2 signals **NOTE** For SMC=0: TRIGGER and STATE are prepared to calculate SUB_INC1. The RMO bit gives a decision only, which of them is used. For changing from normal mode to emergency mode at the following STATE slope (according to the RMO value in the shadow register, see note (DPLL_5764)*[XREF TARGET " (DPLL_5764)] NOT EXIST*) the PSSC value is calculated by PSSC = PSTC. For changing from emergency mode to normal mode at the following TRIGGER slope (according to the RMO value in the shadow register, see note (DPLL_10978)*[XREF TARGET " (DPLL_10978)] NOT EXIST*) the PSTC value is calculated by PSTC = PSSC. In case of no further TRIGGER or STATE events the CPU has to perform the above corrections.
30	TEN	TRIGGER enable. 0: TRIGGER signal is not enabled (no signal considered) 1: TRIGGER signal is enabled
29	SEN	STATE enable. 0: STATE signal is not enabled (no signal considered) 1: STATE signal is enabled
28	IDT *1	Input delay TRIGGER; use of input delay information transmitted in FT part of the TRIGGER signal. See note {REF:DPLL_5764}. 0: Delay information is not used 1: Up to 24 bits of the FT part contain the delay value of the input signal, concerning the corresponding edge

Table 38.296 DPLL_CTRL_0 Register Contents (2/3)

Bit Position	Bit Name	Function
27	IDS *2	Input delay STATE; Use of input delay information transmitted in FT part of the STATE signal. See note {REF:DPLL_10978}. 0: Delay information is not used 1: Up to 24 bits of the FT part contain the delay value of the input signal, concerning the corresponding edge
36	AMT *2	Adapt mode TRIGGER; Use of adaptation information of TRIGGER. See note {REF:DPLL_5764}. 0: No adaptation information for TRIGGER is used 1: Immediate adapting mode; the values for physical deviation PD of ADT_T[i] are considered to calculate the SUB_INC1 pulses in normal mode and for SMC=1
25	AMS	Adapt mode STATE; Use of adaptation information of STATE. See note {REF:DPLL_10978}. 0: No adaptation information is used for STATE 1: Immediate adapting mode; the values for physical deviation PD_S of ADT_S[i] are considered to calculate SUB_INC1 pulses in emergency mode (SMC=0) or SUB_INC2 pulses for SMC=1
24 to 16	TNU*3	TRIGGER number; TNU+1 is number of nominal TRIGGER events in HALF_SCALE (1 to 512). See note {REF:DPLL_10979}. **NOTE** The number of nominal TRIGGER events is the decimal value plus 1. This value can only be written when (RMO=1 and SMC=0) or DEN=0. To make sure that this signal is not changed during a mode change RMO=0 means that the status of RMO=0 must be given before and during writing to the register. Set TSL=00 before changing this value and set RMO=0 only after FULL_SCALE with TSL>0.
15 to 11	SUM*3	STATE number; SNU+1 is number of nominal STATE events in HALF_SCALE (1 to 32). See note {REF:DPLL_10979}. **NOTES** 1. The number of nominal STATE events is the decimal value plus 1. This value can only be written when (RMO=0 and SMC=0) or DEN=0. To make sure that this signal is not changed during a mode change RMO=0 means that the status of RMO=0 must be given before and during writing to the register. Set SSL=00 before changing this value and set RMO=1 only after FULL_SCALE with SSL>0. 2. This register can only be written when DPLL_CTRL_11.STATE_EXT is not set. If DPLL_CTRL_11.STATE_EXT is set, the signal cannot be written, the read value is zero.
10	IFP *1*2*4	Input filter position; value contains position or time related information. See notes {REF:DPLL_5764}, {REF:DPLL_10978}, {REF:DPLL_10980}. 0: TRIGGER_FT and STATE_FT mean time related values, that means the number of time stamp clocks 1: TRIGGER_FT and STATE_FT mean position related values, that means the number of SUB_INC1 (or SUB_INC2 in the case SMC=1) pulses respectively

Table 38.296 DPLL_CTRL_0 Register Contents (3/3)

Bit Position	Bit Name	Function
9 to 0	MLT *1	Multiplier for TRIGGER; MLT+1 is number of SUB_INC1 pulses between two TRIGGER events in normal mode (1 to 1024); See note {REF:DPLL_5764} **NOTES** • For emergency mode the number of SUB_INC1 pulses between two STATE events is calculated by the CPU using the formula MLS1=(MLT+1)* (TNU+1) / (SNU+1) in order to get the same number of SUB_INC1 pulses for FULL_SCALE. This value is stored in RAM at $05C0_H$. Change of MLT by the CPU must result in the corresponding change of MLS1 by the CPU for SMC=0. • The number of MLT events is the binary value plus 1. The value MLT+1 is replaced by MLS1 in the case of SMC=1 (see DPLL_CTRL_1 register) for all relevant calculations.

Note 1. Stored in an independent shadow register for an active TRIGGER event and for DEN = 1.

Note 2. Stored in an independent shadow register for an active STATE event and for DEN = 1.

Note 3. The time between two active STATE or TRIGGER events must be always greater then 23,4 µs; in addition the TS_CLK and the resolution must be chosen such that for each nominal increment the time stamps at the beginning and the end of the increment differ at least in the value of 257

Note 4. For IFP=1 the time between two active TRIGGER or STATE events must be always greater then 2,34 ms and the value x of MLT, MLS1 or MLS2 must be chosen such that the number of time stamp pulses between two SUB_INC events must be less than 65536. This is fulfilled when x is greater than 256.

38.22.18.2 DPLL_CTRL_1

Access: This register can be read or written in 32-bit units.

Address: <GTM_base> + 28004_H

Value after reset: $0000\ 0000_H$

Table 38.297 DPLL_CTRL_1 Register Contents (1/5)

Bit Position	Bit Name	Function
31, 30	TSL	TRIGGER slope select; Definition of active slope for signal TRIGGER each active slope is an event defined by TNU. Set by DEN=0 only. No slope of TRIGGER will be used; 00_B: No slope of TRIGGER will be used; this value makes only sense in emergency mode 01_B: Low high slope will be used as active slope, only inputs with a signal value of "1" will be considered 10_B: High low slope will be used as active slope, only inputs with a signal value of "0" will be considered 11_B: Both slopes will be used as active slopes If DPLL_STATUS.FTD = '0' "level sensitive for first TRIGGER input signal edge" No input signal of TRIGGER will be used; 00_B: No input signal of TRIGGER will be used; this value makes only sense in normal mode 01_B: "high" input signal level will be used as active slope, only inputs with a signal value of "1" will be considered 10_B: "low" input signal level will be used as active slope, only inputs with a signal value of "0" will be considered 11_B: Both input signal levels will be used as active slopes **NOTES** 1. This value can only be written when (RMO=1 and SMC=0) or DEN=0. To make sure that this signal is not changed during a mode change SMC=0 means that the status of SMC=0 must be given before and during writing to the register. 2. Stored in an independent shadow register for an active TRIGGER event and for DEN = 1. 3. Stored in an independent shadow register for an active STATE event and for DEN = 1. 4. Bit is cleared, when transmitted to shadow register

Table 38.297 DPLL_CTRL_1 Register Contents (2/5)

Bit Position	Bit Name	Function
29, 28	SSL	STATE slope select; Definition of active slope for signal STATE each active slope is an event defined by SNU. Set by DEN=0 only. If DPLL_STATUS.FSD = '1' "slope sensitive after detection of first STATE input signal" No slope of STATE will be used; 00_B: No slope of STATE will be used; this value makes only sense in normal mode 01_B: Low high slope will be used as active slope, only inputs with a signal value of "1" will be considered 10_B: High low slope will be used as active slope, only inputs with a signal value of "0" will be considered 11_B: Both slopes will be used as active slopes If DPLL_STATUS.FSD = '0' "level sensitive for first STATE input signal edge" No input signal of STATE will be used; 00_B: No input signal of STATE will be used; this value makes only sense in normal mode 01_B: "high" input signal level will be used as active slope, only inputs with a signal value of "1" will be considered 10_B: "low" input signal level will be used as active slope, only inputs with a signal value of "0" will be considered 11_B: Both input signal levels will be used as active slopes **NOTE** This value can only be written when (RMO=0 and SMC=0) or DEN=0. To make sure that this signal is not changed during a mode change SMC=0 means that the status of SMC=0 must be given before and during writing to the register.
27	SMC	Synchronous Motor Control 0: TRIGGER and STATE inputs are used for a control different to SMC. 1: The TRIGGER input reflects a combined sensor signal for SMC and in the case of RMO=1 also STATE reflects a different combined sensor signal **NOTE** This bit can only be written when the DPLL is disabled.
26	TS0_HRT	Time stamp high resolution TRIGGER 0: The resolution of the used DPLL input TBU_TS0 bits is equal to the TRIGGER input time stamp resolution 1: The TRIGGER input time stamps have a 8 times higher resolution as the TBU_TS0 input **NOTE** This bit can only be written when the DPLL is disabled.
25	TS0_HRS	Time stamp high resolution STATE 0: The resolution of the used DPLL input TBU_TS0 bits is equal to the STATE input time stamp resolution 1: The STATE input time stamps have a 8 times higher resolution as the TBU_TS0 DPLL input **NOTE** This bit can only be written when the DPLL is disabled.

Table 38.297 DPLL_CTRL_1 Register Contents (3/5)

Bit Position	Bit Name	Function
24	SYSF	SYN_NS for FULL_SCALE 0: The SYN_NS value is valid for HALF_SCALE 1: The SYN_NS value is valid for FULL_SCALE The value SYN_NS does mean the sum of all systematic missing STATE events in HALF_SCALE (for SYSF=0) or FULL SCALE (for SYSF=1). **NOTE** This value can only be written when (RMO=0 and SMC=0) or DEN=0. Set SSL=00 before changing this value and set RMO=1 only after FULL_SCALE with SSL>0. To make sure that this signal is not changed during a mode change SMC=0 means that the status of SMC=0 must be given before and during writing to the register.
23	SWR	Software reset 0: No software reset enabled 1: Software reset enabled Resets all register and internal states of the DPLL **NOTE** Setting the SWR bit results only in a software reset when the DPLL is not enabled (DEN=0).
22	LCD	Locking condition definition 0: Locking condition definition is one times missing TRIGGERs as expected by the profile in HALF_SCALE (one gap). 1: Locking condition definition is n–1 times missing TRIGGERs as expected by the profile in HALF_SCALE (one additional tooth) **NOTE** This bit can only be written when the DPLL is disabled and be fixed to zero, when not needed for an implementation.
21 to 16	SYN_NT	Synchronization number of TRIGGER; summarized number of virtual increments in HALF_SCALE. Sum of all systematic missing TRIGGER events in HALF_SCALE; the SYN_NT missing TRIGGER can be divided up to an arbitrary number of blocks. The pattern of events and missing events in FULL_SCALE is shown in RAM region 2c as value NT in addition to the adapted values. The number of stored increments in FULL_SCALE must be equal to 2*(TNU–SYN_NT). This pattern is written by the CPU beginning from a fixed reference point (maybe beginning of the FULL_SCALE region). The relation to the actual increment is established by setting of the profile RAM pointer APT_2C in an appropriate relation to the RAM pointer APT of the actual increment by the CPU. **NOTE** This value can only be written when (RMO=1 and SMC=0) or DEN=0. Set TSL=00 before changing this value and set RMO=0 only after FULL_SCALE with TSL>0. To make sure that this signal is not changed during a mode change SMC=0 means that the status of SMC=0 must be given before and during writing to the register.

Table 38.297 DPLL_CTRL_1 Register Contents (4/5)

Bit Position	Bit Name	Function
15 to 11	SYN_NS	Synchronization number of STATE; summarized number of virtual increments in HALF_SCALE. Sum of all systematic missing STATE events in HALF_SCALE (for SYSF=0) or FULL SCALE (for SYSF=1); the SYN_NS missing STATES can be divided up to an arbitrary number of blocks. The pattern of events and missing events in FULL_SCALE is shown in RAM region 1c3 as value NS in addition to the adapted values. The number of stored increments in FULL_SCALE must be equal to 2*(SNU+1–SYN_NS) for SYSF=0 or 2*(SNU+1)–SYN_NS for SYSF=1. This pattern is written by the CPU beginning from a fixed reference point (maybe beginning of the FULL_SCALE region). The relation to the actual increment is established by setting of the profile RAM pointer APS_1C3 in an appropriate relation to the RAM pointer APS of the actual increment by the CPU. **NOTES** • This value can only be written when (RMO=0 and SMC=0) or DEN=0. Set SSL=00 before changing this value and set RMO=1 only after FULL_SCALE with SSL>0. To make sure that this signal is not changed during a mode change SMC=0 means that the status of SMC=0 must be given before and during writing to the register. • This register can only be written when DPLL_CTRL_11.STATE_EXT is not set. If DPLL_CTRL_11.STATE_EXT is set, the signal cannot be written, the read value is zero.
10	PCM*2, *3	Pulse Correction Mode for SUB_INC2 generation. See notes {REF:DPLL_10981}, {REF:DPLL_10982}. 0: The DPLL does not use the correction value stored in MPVAL2. 1: The DPLL uses the correction value stored in MPVAL2
9	DLM*2	Direct Load Mode for SUB_INC2 generation. See note {REF:DPLL_10981}. 0: The DPLL uses the calculated ADD_IN_CAL value for the SUB_INC2 generation. 1: The ADD_IN_LD value is used for the SUB_INC2 generation and is provided by the CPU; the value remains valid until the CPU writes a new one; the calculated ADD_IN values are stored as ADD_IN_CAL in the RAM at different locations for normal and emergency mode
8	SGE*2	SUB_INC2 generator enable. See note {REF:DPLL_10981}. 0: The SUB_INC2 generator is not enabled. 1: The SUB_INC2 generator is enabled
7	PCM*1, *2, *3	Pulse Correction Mode for SUB_INC1 generation. See notes {REF:DPLL_5804},{REF:DPLL_10981}, {REF:DPLL_10982}. 0: The DPLL does not use the correction value stored in MPVAL1 1: The DPLL uses the correction value stored in MPVAL1 in normal and emergency mode
6	DLM*1, *2	Direct Load Mode for SUB_INC1 generation. See notes {REF:DPLL_5804},{REF:DPLL_10981}. 0: The DPLL uses the calculated ADD_IN_CAL value for the SUB_INC1 generation 1: The ADD_IN_LD value is used for the SUB_INC1 generation and is provided by the CPU; the value remains valid until the CPU writes a new one; the calculated ADD_IN values are stored as ADD_IN_CAL in the RAM at different locations for normal and emergency mode
5	SGE1*1, *2	SUB_INC1 generator enable. See notes {REF:DPLL_5804},{REF:DPLL_10981}. 0: The SUB_INC1 generator is not enabled 1: The SUB_INC1 generator is enabled

Table 38.297 DPLL_CTRL_1 Register Contents (5/5)

Bit Position	Bit Name	Function
4	PIT*1	Plausibility value PVT to next active TRIGGER is time related. See note {REF:DPLL_5804}. 0: The plausibility value is position related (PVT contains the number of SUB_INC1 pulses) 1: The plausibility value is time related (the PVT value is to be multiplied with the duration of the last increment DT_T_ACT and divided by 1024)
3	COA*1, *2	Correction strategy in automatic end mode (DMO=0). See notes {REF:DPLL_5804},{REF:DPLL_10981}. 0: The pulse frequency of the CMU_CLK0 will be used to make up for missing pulses from last increment; the output of the calculated new pulses will start after resetting the FFs in the pulse generation unit. The frequency of CMU_CLK0 should not exceed half the frequency of the system clock (see {REF:DPLL_9427}) 1: Missing pulses of the last increment are distributed evenly to the next increment, calculations are done when the next active input event appears. The number of missing sub-pulses will be determined by the pulse counter difference between the last two active TRIGGER / STATE events respectively; the FFs in the pulse generation unit are not reset before sending new pulses. **NOTE** For SMC=RMO=1: COA is used for SUB_INC1 and SUB_INC2
2	IDDS	Input direction detection strategy in the case of SMC=0. 0: The input direction is detected comparing the THMI value with the duration between active and inactive slope of TRIGGER. 1: The input direction is detected using TDIR input signal also in the case SMC=0. **NOTE** This bit can only be written when the DPLL is disabled and be fixed to zero, when not needed for an implementation. Independent of the value of IDDS is the direction information for TRIGGER in the case SMC=0 always considered at the moment when the inactive slope appears.
1	DEN	DPLL enable. 0: The DPLL is not enabled; Disabling the DPLL will result in a reset state of the DPLL_STATUS register which remains in this state until DEN=1. No DPLL related interrupt will be generated in that case. 1: The DPLL is enabled. **NOTE** The bits 31 down to 0 of the DPLL_STATUS register are cleared, when the DPLL is disabled. Some bits of the control registers can be set only when DEN=0. The protected bits in the DPLL_CTRL_1 register cannot be written when simultaneously DEN is set to 1.
0	DMO*1, *2	DPLL mode select. See notes {REF:DPLL_5804},{REF:DPLL_10981}. 0: Automatic end mode; if the number of pulses for an increment is reached, no further pulse is generated until the next active TRIGGER / STATE is received; in the case of getting a new active TRIGGER / STATE before the defined number of pulses is reached, the pulse frequency is changed according to the conditions described below (COA). 1: Continuous mode; in this mode a difference between the predefined number of pulses and the actual number of generated pulses can influence the pulse frequency by writing a corresponding pulse number into CNT_NUM_1 or CNT_NUM_2 respectively in RAM region 1b.

Note: This value can only be written when (RMO=1 and SMC=0) or DEN=0. To make sure that this signal is not changed during a mode change SMC=0 means that the status of SMC=0 must be given before and during writing to the register.

Note 1. Stored in an independent shadow register for an active TRIGGER event and for DEN = 1.
Note 2. Stored in an independent shadow register for an active STATE event and for DEN = 1.
Note 3. Bit is cleared, when transmitted to shadow register

38.22.18.3 DPLL_CTRL_2

Access: This register can be read or written in 32-bit units.

Address: <GTM_base> + 28008_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 38.298 DPLL_CTRL_2 Register Contents

Bit Position	Bit Name	Function
31 to 24	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
23 to 16	WAD[7:0]	Write control bit of Action_[7:0]. 0: The corresponding AENi bit is not writable 1: The corresponding AENi bit is writable
15 to 8	AEN*[1][7:0]	ACTION_[7:0] enable. 0: The corresponding action is not enabled 1: The corresponding action is enabled
7 to 0	Reserved	When read, the value after reset is returned. When writing, write the value after reset.

Note 1. This bit can be written only if the correspondent WADi Bit is set in the same access. It can be set for debug purposes by CPU also, when DPLL is disabled. The enable bit becomes active only when the DPLL is in operation (DEN=1).

Note: For WADi =1 only the corresponding AENi bits are writable. The AENi bits remain unchanged when the corresponding WADi=0.

38.22.18.4 DPLL_CTRL_3

Access: This register can be read or written in 32-bit units.

Address: <GTM_base> + $2800C_H$

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 38.302 DPLL_ACT_STA Register Contents

Bit Position	Bit Name	Function
31 to 0	ACT_N	New output data values concerning to action i provided 0: No new output data available after a recent PMT request or actual event value is in the past or invalid. 1: Either new PMTR data received or calculation is repeated to be more precise by taking into account new TRIGGER or STATE values **NOTES** 1. ACT_N[i] is set (for AEN[k]=1 and a new valid PMTR), that means when new action data are to be calculated for the correspondent action. After each calculation of the new actions values the ACT_N[i] bit updates the corresponding bit in the connected shadow register. The status of the ACT_N[i] bits in the shadow register is reflected by the corresponding DPLL output signal ACT_V (valid bit). reset together with the corresponding shadow register bit for AEN[k]=0; reset without the corresponding shadow register bit when the calculated event is in the past (the shadow register bit is set, when it was not set before in that case) the corresponding shadow register bit is reset, when new PMTR data are written or when the provided action data are read (blocking read) writable for debugging purposes together with the corresponding shadow register when DEN=0 2. These bits can only be written for test purposes when the DPLL is disabled.

38.22.18.8 DPLL_OSW

Access: This register can be read or written in 32-bit units.

Address: <GTM_base> + $2801C_H$

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	OSS		—	—	—	—	—	—	SWON_T	SWON_S
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R/W	R/W	R	R	R	R	R	R	R	R

Table 38.303 DPLL_OSW Register Contents (1/2)

Bit Position	Bit Name	Function
31 to 10	Reserved	When read, the value after reset is returned.
9, 8	OSS	Offset size of RAM region 2 00_B: Offset size 128 of RAM region 2. 01_B: Offset size 256 of RAM region 2. 10_B: Offset size 512 of RAM region 2. 11_B: Offset size 1024 of RAM region 2. **NOTES** 1. At least 128 and at most 1024 values can be stored in each of the RAM 2 regions a to d accordingly. The value can be set only for DEN=0. The change of the OSS value results in an automatic change of the offset values in the DPLL_AOSV_2 register 2. This value can only be written when the DPLL is disabled.
7 to 2	Reserved	When read, the value after reset is returned.
1	SWON_T	Switch of new TRIGGER; Switch bit for LSB address of TRIGGER. This bit is changed for each write access to TS_T/TS_T_OLD. Using this unchanged address bit SWON_T for any access to TS_T results always in an access to TS_T_OLD. For writing to this address the former old (TS_T_OLD_old) value is overwritten by the new one while the SWON_T bit changes. Thus the former new one is now the old one and the next access is after changing SWON_T directed to this place. Therefore write to TS_T first and after that immediately to FTV_T and PSTM, always before a new TS_T value is to be written. **NOTE** After writing TS_T, FTV_T and PSTM in this order the address pointer AP with LSB(AP)=SWON_T shows for the corresponding address to TS_T_OLD, FTV_T and PSTM while LSB(AP)=/SWON_T results in an access to TS_T, FTV_T_old and PSTM_OLD respectively. The value can be read only. This bit is reset when disabling the DPLL (DEN=0).

Table 38.303 DPLL_OSW Register Contents (2/2)

Bit Position	Bit Name	Function
0	SWON_S	Switch of new STATE; Switch bit for LSB address of STATE. This bit is changed for each write access to TS_S/TS_S_OLD. Using this unchanged address bit SWON_S for any access to TS_S results always in an access to TS_S_OLD. For writing to this address the former old (TS_S_OLD_old) value is overwritten by the new one while the SWON_S bit changes. Thus the former new one is now the old one and the next access is after changing SWON_S directed to this place. Therefore write to TS_S first and after that immediately to FTV_S and PSSM, always before a new TS_S value is to be written. **NOTE** After writing TS_S, FTV_S and PSSM in this order the address pointer AP with LSB(AP)=SWON_S shows for the corresponding address to TS_S_OLD, FTV_S and PSSM while LSB(AP)=/SWON_S results in an access to TS_S, FTV_S_old and PSSM_OLD respectively. The value can be read only. This bit is reset when disabling the DPLL (DEN=0).

38.22.18.9 DPLL_AOSV_2

Access: This register is a read-only register that can be read in 32-bit units.

Address: <GTM_base> + 28020_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	AOSV_2D								AOSV_2C							
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	AOSV_2B								AOSV_2A							
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 38.304 DPLL_AOSV_2 Register Contents (1/2)

Bit Position	Bit Name	Function
31 to 24	AOSV_2D	Address offset value of the RAM 2D region. OS– 0x0: AOSV_2D= 0x06 OS– 0x1: AOSV_2D= 0x0C OS– 0x2: AOSV_2D= 0x18 OS– 0x3: AOSV_2D= 0x30 The value in this field is to be multiplied by 256 (shift left 8 Bits) and added with the start address of the RAM in order to get the start address of RAM region 2d. When the APT value is added to this start address, the current RAM cell DT_Tx is addressed. value is set automatically when OSS in the PPLL_OSW register is set: **NOTES** The offset values are needed to support a scalable RAM size of region 2 from 1,5 Kbytes to 12 Kbytes. The values above must be in correlation with the offset size defined in the OSW register. All offset values are set automatically in accordance to the OSS value in the DPLL_OSW register. This value can be set only for DEN=0.
23 to 16	AOSV_2C	Address offset value of the RAM 2C region. OS– 0x0: AOSV_2C= 0x04 OS– 0x1: AOSV_2C= 0x08 OS– 0x2: AOSV_2C= 0x10 OS– 0x3: AOSV_2C= 0x20 The value in this field is to be multiplied by 256 (shift left 8 Bits) and added with the start address of the RAM in order to get the start address of RAM region 2c. When the APT value is added to this start address, the current RAM cell ADT_Tx is addressed. value is set automatically when OSS in the PPLL_OSW register is set:

Table 38.304 DPLL_AOSV_2 Register Contents (2/2)

Bit Position	Bit Name	Function
15 to 8	AOSV_2B	Address offset value of the RAM 2B region. OS– 0x0: AOSV_2B= 0x02 OS– 0x1: AOSV_2B= 0x04 OS– 0x2: AOSV_2B= 0x08 OS– 0x3: AOSV_2B= 0x10 The value in this field is to be multiplied by 256 (shift left 8 Bits) and added with the start address of the RAM in order to get the start address of RAM region 2b. When the APT value is added to this start address, the current RAM cell TSF_Tx is addressed. value is set automatically when OSS in the PPLL_OSW register is set:
7 to 0	AOSV_2A	Address offset value of the RAM 2A region. OS– 0x0: AOSV_2A= 0x00 OS– 0x1: AOSV_2A= 0x00 OS– 0x2: AOSV_2A= 0x00 OS– 0x3: AOSV_2A= 0x00 The value in this field is to be multiplied by 256 (shift left 8 Bits) and added with the start address of the RAM in order to get the start address of RAM region 2a. When the APT value is added to this start address, the current RAM cell RDT_Tx is addressed. value is set automatically when OSS in the PPLL_OSW register is set:

38.22.18.10 DPLL_APT

Access: This register can be read or written in 32-bit units.

Address: <GTM_base> + 28024_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	APT_2B							
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 38.305 DPLL_APT Register Contents (1/2)

Bit Position	Bit Name	Function
31 to 24	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
23 to 14	APT_2B	Address pointer TRIGGER for RAM region 2b; Actual RAM pointer address value for TSF_T[i] Actual RAM pointer address of TRIGGER events in FULL_SCALE for 2*(TNU+1) TRIGGER periods; this pointer is used for the RAM region 2b. The RAM pointer is initially set to zero. For SYT=1: The pointer APT_2B is incremented by SYN_T_OLD for each active TRIGGER event (simultaneously with APT and APT_2C) for DIR1=0 when an active TRIGGER input appears. For DIR1=1 (backwards) the APT is decremented by SYN_T_OLD. For SYT=0: APT_2B is incremented or decremented by 1. In addition when the APT_2C value is written by the CPU – in order to synchronize the DPLL- with the next active TRIGGER event the APT_2B_EXT value is added/subtracted (while APT_2B_STATUS is one; see DPLL_APT_SYNC register at **Section 38.22.18.24, DPLL_APT_SYNC**). **NOTE** This value can only be written when the WAPT_2B bit is set.
13	WAPT_2B	Write bit for address pointer APT_2B, read as zero. 0: The APT_2B is not writable 1: The APT_2B is writable
12	Reserved	When read, the value after reset is returned. When writing, write the value after reset.

Table 38.305 DPLL_APT Register Contents (2/2)

Bit Position	Bit Name	Function
11 to 2	APT	Address pointer TRIGGER; Actual RAM pointer address value offset for DT_T[i] and RDT_T[i] in FULL_SCALE for 2*(TNU+1–SYN_NT) TRIGGER events. This pointer is used for the RAM region 2 subsections 2a and 2d. The pointer APT is incremented for each active TRIGGER event (simultaneously with APT_2B, APT_2C) for DIR1=0. For DIR1=1 the APT is decremented. The APT offset value is added in the above shown bit position with the subsection address offset of the corresponding RAM region. **NOTES** 1. The APT pointer value is directed to the RAM position, in which the data values are to be written, which corresponds to the last increment. The APT value is not to be changed, when the direction (shown by DIR1) changes, because it points always to a storage place after the considered increment. Changing of DIR1 takes place always after an active TRIGGER event and the resulting increment/decrement. 2. This value can only be written when the WAPT bit is set.
1	WAPT	Write bit for address pointer APT, read as zero. 0: The APT is not writable 1: The APT is writable
0	Reserved	When read, the value after reset is returned. When writing, write the value after reset.

38.22.18.11 DPLL_APS

Access: This register can be read or written in 32-bit units.

Address: <GTM_base> + 28028_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	APS_1C2			
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 38.306 DPLL_APS Register Contents (1/2)

Bit Position	Bit Name	Function
31 to 20	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
19 to 14	APS_1C2	Address pointer STATE for RAM region 1c2; Actual RAM pointer address value for TSF_S[i]. Initial value: zero (0x00). Actual RAM pointer and synchronization position/value of STATE events in FULL_SCALE for up to 64 STATE events but limited to 2*(SNU+1) in normal and emergency mode; this pointer is used for the RAM region 1c2. For SYS=1: APS_1C2 is incremented (decremented) by SYN_S_OLD for each active STATE event and DIR2=0 (DIR2=1). For SYS=0: APT_1c2 is incremented or decremented by 1 respectively. The APS_1C2 offset value is added in the above shown bit position with the subsection offset of the RAM region. In addition when the APS_1C3 value is written by the CPU – in order to synchronize the DPLL- with the next active STATE event the APS_1C2_EXT value is added/subtracted (while APS_1C2_STATUS is one; see DPLL_APT_SYNC register at **Section 38.22.18.25, DPLL_APS_SYNC**). **NOTE** This value can only be written when the WAPS_1C2 bit is set
13	WAPS_1C2	Write bit for address pointer APS_1C2, read as zero. 0: The APS_1C2 is not writable 1: The APS_1C2 is writable
12 to 8	Reserved	When read, the value after reset is returned. When writing, write the value after reset.

Table 38.306 DPLL_APS Register Contents (2/2)

Bit Position	Bit Name	Function
7 to 2	APS	Address pointer STATE; Actual RAM pointer address value for DT_S[i] and RDT_S[i] Actual RAM pointer and synchronization position/value of STATE events in FULL_SCALE for up to 64 STATE events but limited to 2*(SNU+1–SYN_NS) in normal and emergency mode for SYSF=0 or to 2*(SNU+1)–SYN_NS for SYSF=1 respectively; this pointer is used for the RAM region 1c1 and 1c4. APS is incremented (decremented) by one for each active STATE event and DIR2=0 DIR2=1). The APS offset value is added in the above shown bit position with the subsection offset of the RAM region. **NOTES** 1. The APS pointer value is directed to the RAM position, in which the data values are to be written, which correspond to the last increment. The APS value is not to be changed, when the direction (shown by DIR2) changes, because it points always to a storage place after the considered increment. Changing of DIR2 takes place always after an active STATE event and the resulting increment/decrement. 2. This value can only be written when the WAPS bit is set.
1	WAPS	Write bit for address pointer APS, read as zero. 0: The APS is not writable 1: The APS is writable
0	Reserved	When read, the value after reset is returned. When writing, write the value after reset.

38.22.18.12 DPLL_APT_2C

Access: This register can be read or written in 32-bit units.

Address: <GTM_base> + $2802C_H$

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 38.307 DPLL_APT_2C Register Contents

Bit Position	Bit Name	Function
31 to 12	Reserved	When read, the value after reset is returned. When writing, write the value after reset. **NOTES** 1. The APT_2C pointer values are directed to the RAM position of the profile element in RAM region 2c, which correspond to the current increment. For DIR1=0 (DIR1=1) the pointers APT_2C_x are incremented (decremented) by one simultaneously with APT. For SMC=0 the change of DIR1 takes place always after an active TRIGGER event (by evaluation of the inactive slope) and the resulting increment/decrement. In the case SMC=1 the direction change is known before the input event is processed. 2. The correction of the APT_2C pointer differs: for SMC=0 correct 4 times and for SMC=1 correct only 2 times. 3. The APT_2C_x offset value is added in the above shown bit position with the subsection address offset of the corresponding RAM region.
11 to 2	APT_2C	Address pointer TRIGGER for RAM region 2c; Actual RAM pointer address value for ADT_T[i]. Actual RAM pointer address value of TRIGGER adapt events in FULL_SCALE for 2*(TNU+1–SYN_NT) TRIGGER periods depending on the size of the used RAM 2; this pointer is used for the RAM region 2 for the subsection 2c only. The RAM pointer is initially set to zero. The APT_2C value is set by the CPU when the synchronization condition was detected. Within the RAM region 2c initially the conditions for synchronization gaps and adapted values are stored by the CPU.
1, 0	Reserved	When read, the value after reset is returned. When writing, write the value after reset.

38.22.18.13 DPLL_APS_1C3

Access: This register can be read or written in 32-bit units.

Address: <GTM_base> + 28030_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	APS_1C3						—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R	R

Table 38.308 DPLL_APS_1C3 Register Contents

Bit Position	Bit Name	Function
31 to 8	Reserved	When read, the value after reset is returned. When writing, write the value after reset. **NOTES** 1. The APS_1C3 pointer value is directed to the RAM position of the profile element in RAM region 1c2, which corresponds to the current increment. When changing the direction DIR1 or DIR2 respectively, this is always known before an active STATE event is processed. This is because of the pattern recognition in SPE (for PMSM) or because of the direction change recognition by TRIGGER. This direction change results in an automatic increment (forwards) or decrement (backwards) when the input event occurs in addition with a 2 times correction. 2. The APS_1C3_x offset value is added in the above shown bit position with the subsection address offset of the corresponding RAM region. 3. This register is only used when DPLL_CTRL_11.STATE_EXT is not set. If DPLL_CTRL_11.STATE_EXT is set any read/write access to this register will return AEI_STATUS = 10_B.
7 to 2	APS_1C3	Address pointer STATE for RAM region 1c3; Actual RAM pointer address value for ADT_S[i] Initial value: zero (00_H). Actual RAM pointer and synchronization position/value of STATE events in FULL_SCALE for up to 64 STATE events but limited to 2*(SNU+1–SYN_NS) in normal and emergency mode for SYSF=0 or to 2*(SNU+1)–SYN_NS for SYSF=1 respectively; this pointer is used for the RAM region 1c3. The RAM pointer is set by the CPU accordingly, when the synchronization condition was detected.
1, 0	Reserved	When read, the value after reset is returned. When writing, write the value after reset.

Note: Note: The APT_2C pointer values are directed to the RAM position of the profile element in RAM region 2c, which correspond to the current increment. For DIR1=0 (DIR1=1) the pointers APT_2C_x are incremented (decremented) by one simultaneously with APT. For SMC=0 the change of DIR1 takes place always after an active TRIGGER event (by evaluation of the inactive slope) and the resulting increment/decrement. In the case SMC=1 the direction change is known before the input event is processed.

The correction of the APT_2C pointer differs: for SMC=0 correct 4 times and for SMC=1 correct only 2 times.

The APT_2C_x offset value is added in the above shown bit position with the subsection address offset of the corresponding RAM region.

38.22.18.14 DPLL_NUTC

Access: This register can be read or written in 32-bit units.

Address: <GTM_base> + 28034_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	WVTN	WSYN	WNUT	—	—	—	—	VTN						SYN_T_OLD		
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 38.309 DPLL_NUTC Register Contents (1/3)

Bit Position	Bit Name	Function
31	WVTN	Write control bit for VTN; read as zero. 0: The VTN value is not writable 1: The VTN value is writable
30	WSYN	Write control bit for SYN_T and SYN_T_OLD; read as zero. 0: The SYN_T value is not writable 1: The SYN_T value is writable
29	WNUT	Write control bit for NUTE and FST; read as zero. 0: The NUTE value is not writable 1: The NUTE value is writable
28 to 25	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
24 to 19	VTN	Virtual TRIGGER number; number of virtual increments in the current NUTE region This value reflects the number of virtual increments in the current NUTE region; for NUTE=1 this value is zero, when the CPU sets NUTE to a value > 1, it must also set VTN to the correspondent value; for NUTE is set to FULL_SCALE including NUTE=zero (2 modulo 2) the VTN is to be set to 2* SYN_NT. The VTN value is subtracted from the NUTE value in order to get the corresponding APT value for the past; the VTN value is not used for the APT_2B pointer. VTN is to be updated by the CPU when a new gap is to be considered for NUTE or a gap is leaving the NUTE region; for this purpose the TINT values in the profile can be used to generate an interrupt for the CPU at the corresponding positions; no further update of VTN is necessary when NUTE is set to FULL_SCALE. **NOTE** This value can only be written when the WVTN bit is set.

Table 38.309 DPLL_NUTC Register Contents (2/3)

Bit Position	Bit Name	Function
18 to 16	SYN_T_OLD	Number of real and virtual events to be considered for the last increment. This value reflects the NT value of the last but one valid increment, stored in ADT_T[i]; is updated automatically when writing SYN_T. **NOTE** This value is updated by the SYN_T value when the WSYN bit in this register is set.
15 to 13	SYN_T	Number of real and virtual events to be considered for the current increment. This value reflects the NT value of the last valid increment, stored in ADT_T[i]; to be updated after all calculations in step 17 of Table (DPLL_6908)*[XREF TARGET " (DPLL_6908)] NOT EXIST*. **NOTE** This value can only be written when the WSYN bit in this register is set.
12, 11	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
10	FST	FULL_SCALE of TRIGGER; this value is to be set, when NUTE is set to FULL_SCALE. **NOTE** This value can only be written when the WNUT bit is set.

Table 38.309 DPLL_NUTC Register Contents (3/3)

Bit Position	Bit Name	Function
9 to 0	NUTE	Number of recent TRIGGER events used for SUB_INC1 and action calculations modulo 2*(TNUmax+1). 0: The NUTE value is less than FULL_SCALE 1: The NUTE value is equal to FULL_SCALE Number of last nominal increments to be considered for the calculations. No gap is considered in that case for this value, but in the VTN value (see below): This value is set by the CPU, but reset automatically to 1 by a change of direction or loss of LOCK. Each other value can be set by the CPU, maybe Full_SCALE, HALF_SCALE or parts of them. For FULL_SCALE set NUTE= 2*(TNU+1) and for HALF_SCALE NUTE= TNU+1. The relation values QDT_Tx are calculated using NUTE values in the past with its maximum value of 2*(TNU+1). The value zero (in combination with the value FST=1) does mean 2 values in the past. **NOTES** 1. To prevent that inconsistencies between internal pointer in which NUTE is used and the case decision of different prediction method's for prediction of the next event and PMT (position minus time) occur, the NUTE value is stored internally at that point of time when the internal pointers are calculated for the next event cycle. 0 = the NUTE value is less then FULL_SCALE 1 = the NUTE value is equal to FULL_SCALE This value is set by the CPU, but reset automatically to “0” by a change of direction or loss of LOCK. 2. To prevent that inconsistencies between internal pointer in which NUTE is used and the case decision of different prediction method's for prediction of the next event and PMT (position minus time) occur, the NUTE value is stored internally at that point of time when the internal pointers are calculated for the next event cycle 0 = the NUTE value is less then FULL_SCALE 1 = the NUTE value is equal to FULL_SCALE This value is set by the CPU, but reset automatically to “0” by a change of direction or loss of LOCK.

Note: DPLL Number of recent TRIGGER events used for calculations (mod 2*(TNU +1-SYN_NT)).

38.22.18.15 DPLL_NUSC

Access: This register can be read or written in 32-bit units.

Address: <GTM_base> + 28038_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 38.310 DPLL_NUSC Register Contents (1/2)

Bit Position	Bit Name	Function
31	WVSN	Write control bit for VSN; read as zero. 0: The VSN value is not writable 1: The VSN value is writable **NOTE** This register is only used when DPLL_CTRL_11.STATE_EXT is not set. If DPLL_CTRL_11.STATE_EXT is set any read/write access to this register will return AEI_STATUS = 10_B.
30	WSYN	Write control bit for SYN_S and SYN_S_OLD; read as zero. 0: The SYN_S value is not writable 1: The SYN_S value is writable
29	WNUS	Write control bit for NUSE; read as zero. 0: The NUSE value is not writable 1: The NUSE value is writable
28 to 25	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
24 to 19	VSN	Virtual STATE number; number of virtual state increments in the current NUSE region. This value reflects the number of virtual increments in the current NUSE region; for NUSE=1 this value is zero, when the CPU sets NUSE to a value > 1 or zero (2 modulo 2), it must also set VSN to the correspondent value; the VSN value is subtracted from the NUSE value in order to get the corresponding APS value for the past; the VSN value is not used for the APS_1C2 pointer. VSN is to be updated by the CPU when a new gap is to be considered for NUSE or a gap is leaving the NUSE region; for this purpose the SASI interrupt can be used; no further update of VSN is necessary when NUSE is set to FULL_SCALE. **NOTE** This value can only be written when the WVSN bit is set.

Table 38.310 DPLL_NUSC Register Contents (2/2)

Bit Position	Bit Name	Function
18 to 13	SYN_S_OLD	Number of real and virtual events to be considered for the last increment. This value reflects the NS value of the last but one valid increment, stored in ADT_S[i]; is updated automatically when writing SYN_S. **NOTE** This value is updated by the SYN_S value when the WSYN bit in this register is set.
12 to 7	SYN_S	Number of real and virtual events to be considered for the current increment. This value reflects the NS value of the last valid increment, stored in ADT_S[i]; to be updated after all calculations in step 37 of Table (DPLL_6908)*[XREF TARGET " (DPLL_6908)] NOT EXIST*. **NOTE** This value can only be written when the WSYN bit in this register is set.
6	FSS	FULL_SCALE of STATE; this value is to be set, when NUSE is set to FULL_SCALE 0: The NUSE value is less than FULL_SCALE 1: The NUSE value is equal to FULL_SCALE This value is set by the CPU, but reset automatically to 0 by a change of direction or loss of LOCK. **NOTE** This value can only be written when the WNUS bit is set.
5 to 0	NUSE	Number of recent STATE events used for SUB_INCx calculations modulo 2*(SNUmax+1). No gap is considered in that case for this value, but in the VSN value (see below): This register is set by the CPU but reset automatically to 1 by a change of direction or loss of LOCK. Each other value can be set by the CPU, maybe Full_SCALE, HALF_SCALE or parts of them. The relation values QDT_Sx are calculated using NUSE values in the past with its maximum value of 2*SNU+1. **NOTES** 1. To prevent that inconsistencies between internal pointer in which NUSE is used and the case decision of different prediction method's for prediction of the next event and PMT (position minus time) occur, the NUSE value is stored internally at that point of time when the internal pointers are calculated for the next event cycle. 2. This value can only be written when the WNUS bit is set.

38.22.18.16 DPLL_NTI_CNT

Access: This register can be read or written in 32-bit units.

Address: <GTM_base> + $2803C_H$

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 38.312 DPLL_IRQ_NOTIFY Register Contents (1/3)

Bit Position	Bit Name	Function
31 to 28	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
27	DCGI	Direction change interrupt 0: No direction change of TRIGGER is detected 1: Direction change of TRIGGER is detected **NOTE** The interrupt occurs at line number 0.
26	SORI	STATE out of range 0: STATE is not out of range 1: STATE is out of range, the SOR bit in the DPLL_STATUS register is set to 1
25	TORI	TRIGGER out of range interrupt 0: TRIGGER is not out of range 1: TRIGGER is out of range, the TOR bit in the DPLL_STATUS register is set to 1
24	CDSI	Calculation of STATE duration done 0: No Interrupt on calculated STATE duration requested 1: Interrupt on calculated STATE duration requested
23	CDTI	Calculation of TRIGGER duration done, only while NTI_CNT is zero. 0: No Interrupt on calculated TRIGGER duration requested or NTI_CNT is not zero 1: Interrupt on calculated TRIGGER duration requested while NTI_CNT is zero
22	TE4I	TRIGGER event interrupt 4. 0: No Interrupt on TRIGGER event 4 requested 1: Interrupt on TRIGGER event 4 requested
21	TE3I	TRIGGER event interrupt 3. 0: No Interrupt on TRIGGER event 3 requested 1: Interrupt on TRIGGER event 3 requested
20	TE2I	TRIGGER event interrupt 2. 0: No Interrupt on TRIGGER event 2 requested 1: Interrupt on TRIGGER event 2 requested

Table 38.312 DPLL_IRQ_NOTIFY Register Contents (2/3)

Bit Position	Bit Name	Function
19	TE1I	TRIGGER event interrupt 1. 0: No Interrupt on TRIGGER event 1 requested 1: Interrupt on TRIGGER event 1 requested
18	TE0I	TRIGGER event interrupt 0. 0: No Interrupt on TRIGGER event 0 requested 1: Interrupt on TRIGGER event 0 requested
17	LL2I	Loss of lock interrupt for SUB_INC2. 0: The lock loss interrupt is not requested 1: The lock loss interrupt is requested
16	GL2I	Get of lock interrupt, for SUB_INC2. 0: The lock getting interrupt is not requested 1: The lock getting interrupt is requested
15	EI	Error interrupt (see status register bit 31). 0: The error interrupt is not requested 1: The error interrupt is requested
14	LL1I	Loss of lock interrupt for SUB_INC1. 0: The lock loss interrupt is not requested 1: The lock loss interrupt is requested
13	GL1I	Get of lock interrupt, for SUB_INC1. 0: The lock getting interrupt is not requested 1: The lock getting interrupt is requested
12	W1I	Write access to RAM region 1b or 1c interrupt. 0: The RAM write access interrupt is not requested 1: The RAM write access interrupt is requested
11	W2I	RAM write access to RAM region 2 interrupt. 0: The RAM write access interrupt is not requested 1: The RAM write access interrupt is requested
10	PWI	Plausibility window (PVT) violation interrupt of TRIGGER. 0: The plausibility window is not violated 1: The plausibility window is violated
9	TASI	TRIGGER active slope interrupt. 0: No active slope of TRIGGER is detected 1: An active slope of TRIGGER is detected
8	SASI	STATE active slope interrupt. 0: No active slope of STATE is detected 1: An active slope of STATE is detected
7	MTI	Missing TRIGGER interrupt. 0: The missing TRIGGER interrupt is not requested 1: The missing TRIGGER interrupt is requested
6	MSI	Missing STATE interrupt. 0: The missing STATE interrupt is not requested 1: The missing STATE interrupt is requested
5	TISI	TRIGGER inactive slope interrupt. 0: No inactive slope of TRIGGER is detected 1: An inactive slope of TRIGGER is detected **NOTE** The TISI bit is only set for an inactive slope when the preceding active slope was accepted. In the case of suppression of the last active slope by the plausibility check the next inactive slope is to be ignored. No set of TISI is performed in this case.
4	SISI	STATE inactive slope interrupt. 0: No inactive slope of STATE is detected 1: An inactive slope of STATE is detected

Table 38.312 DPLL_IRQ_NOTIFY Register Contents (3/3)

Bit Position	Bit Name	Function
3	TAXI	TRIGGER maximum hold time violation interrupt (dt > THMA > 0). 0: No violation of maximum hold time of TRIGGER is detected 1: A violation of maximum hold time of TRIGGER is detected
2	TINI	TRIGGER minimum hold time violation interrupt (dt ≤ THMI > 0). 0: No violation of minimum hold time of TRIGGER is detected 1: A violation of minimum hold time of TRIGGER is detected
1	PEI	DPLL enable interrupt; announces the switch on of the DEN bit. 0: The DPLL enable interrupt is not requested 1: The DPLL enable interrupt is requested **NOTE** This event is combined with the PDI interrupt to the common PDI + PEI interrupt line number 1.
0	PDI	DPLL disable interrupt; announces the switch off of the DEN bit. 0: The DPLL disable interrupt is not requested 1: The DPLL disable interrupt is requested **NOTE** This event is combined with the PEI interrupt to the common PDI + PEI interrupt line number 1.

Note: All bits in the DPLL_IRQ_NOTIFY register are set permanently until writing a one bit value is performed to the corresponding bit.

38.22.18.18 DPLL_IRQ_EN

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	APT_2B_OLD		—	—	—	—	—	—	—	APT_2B_STATUS	APT_2B_EXT					
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 38.319 DPLL_APT_SYNC Register Contents (1/2)

Bit Position	Bit Name	Function
31 to 24	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
23 to 14	APT_2B_OLD	Address pointer TRIGGER for RAM region 2b at synchronization time; this value is set by the current APT_2B value when the synchronization takes place for the first active TRIGGER event after writing APT_2C but before adding the offset value APT_2B_EXT (that means: when APT_2B_STATUS=1). Address pointer APT_2B value at the moment of synchronization, before the offset value is added, that means the pointer with this value points to the last value before the additional inserted gap
13 to 7	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
6	APT_2B_STATUS	Address pointer 2b status; set by CPU before the synchronization is performed. The value is cleared when the APT_2B_OLD value is written. 0: APT_2B_EXT is not to be considered. 1: APT_2B_EXT has to be considered for time stamp field extension.

Table 38.319 DPLL_APT_SYNC Register Contents (2/2)

Bit Position	Bit Name	Function
5 to 0	APT_2B_EXT	Address pointer 2b extension; this offset value determines, by which value the APT_2B is changed at the synchronization time; set by CPU before the synchronization is performed. This offset value is the number of virtual increments to be inserted in the TSF for an imminent intended synchronization; the CPU sets its value dependent on the gaps until the synchronization time taking into account the considered NUTE value to be set and including the next future increment (when SYN_T_OLD is still 1). When the synchronization takes place, this value is to be added to the APT_2B address pointer (for forward direction, DIR1=0) and the APT_2B_STATUS bit is cleared after it. For backward direction subtract APT_2B_EXT accordingly. This correction is done after updating the RAM TSF with the last TS_T value. **NOTE** When the synchronization is intended and the NUTE value is to be set to FULL_SCALE after it, the APT_2B_EXT value must be set to 2*SYN_NT in order to be able to fill all gaps in the extended TSF_T with the corresponding values by the CPU. When still not all values for FULL_SCALE are available, the APT_2B_EXT value considers only a share according to the corresponding NUTE value to be set after the synchronization.

38.22.18.25 DPLL_APS_SYNC

Access: This register can be read or written in 32-bit units.

Address: <GTM_base> + $280BC_H$

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	APS_1C2_OLD

Table 38.320 DPLL_APS_SYNC Register Contents

Bit Position	Bit Name	Function
31 to 20	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
19 to 14	APS_1C2_OLD	Address pointer STATE for RAM region 1c2 at synchronization time; this value is set by the current APS_1C2 value when the synchronization takes place for the first active STATE event after writing APS_1C3 but before adding the offset value APS_1C2_EXT (that means: when APS_1C2_STATUS=1). Address pointer APS_1C2 value at the moment of synchronization, before the offset value is added, that means the pointer with this value points to the last value before the additional inserted gap
13 to 7	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
6	APS_1C2_STATUS	Address pointer 1c2 status; set by CPU before the synchronization is performed. The value is cleared automatically when the APS_1C2_OLD value is written. 0: APS_1C2_EXT is not to be considered. 1: APS_1C2_EXT has to be considered for time stamp field extension.
5 to 0	APS_1C2_EXT	Address pointer 1c2 extension; this offset value determines, by which value the APS_1C2 is changed at the synchronization time; set by CPU before the synchronization is performed. This offset value is the number of virtual increments to be inserted in the TSF for an imminent intended synchronization; the CPU sets its value dependent on the gaps until the synchronization time taking into account the considered NUSE value to be set and including the next future increment (when SYN_S_OLD is still 1). When the synchronization takes place, this value is to be added to the APS_1C2 address pointer (for forward direction, DIR2=0) and the APT_1c2_status bit is cleared after it. For backward direction subtract APS_1C2_EXT accordingly. **NOTE** When the synchronization is intended and the NUSE value is to be set to FULL_SCALE after it, the APS_1C2_EXT value must be set to SYN_NS (for SYSF=1) or 2*SYN_NS (for SYSF=0) in order to be able to fill all gaps in the extended TSF_S with the corresponding values by the CPU. When still not all values for FULL_SCALE are available, the APS_1C2_EXT value considers only a share according to the NUSE value to be set after the synchronization.

Note: This register is only used when DPLL_CTRL_11.STATE_EXT is not set. If DPLL_CTRL_11.STATE_EXT is set any read/write access to this register will return AEI_STATUS = 10_B.

38.22.18.26 DPLL_TBU_TS0_T

Access: This register can be read or written in 32-bit units.

Address: <GTM_base> + $280C0_H$

Value after reset: $0000\ 0000_H$

Table 38.323 DPLL_ADD_IN_LD1 Register Contents

Bit Position	Bit Name	Function
31 to 24	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
23 to 0	ADD_IN_LD1	Input value for SUB_INC1 generation, given by CPU. This value can be used in normal and emergency mode (SMC=0) as well as for SMC=1. For DLM1 = 1: **NOTES** 1. The value is loaded by the CPU but used by the DPLL only for DLM1=1 (see DPLL_CTRL_1 register). When switching DLM1 to 1, the value in the register is used for the SUB_INC1 generation beginning from the next active TRIGGER or STATE event respectively independently if new values are written by the CPU or not. 2. When a new value is written the output frequency changes according to the given value beginning immediately from the moment of writing. Do not wait for performing step 10 in the state machine for ADD_IN calculations. 3. If the ADD_IN_LD1 value is zero all pulses are sent with the highest possible frequency. For DLM1 = 0: **NOTES** 1. The value loaded by the CPU is stored directly in the internal add_in register which is used to control the sub increment pulse generator directly (see DPLL_CTRL_1 register, DLM1 = 0). 2. When a new ADD_IN_LD1 value is written the output frequency is immediately changed from the moment of writing. The ADD_IN values calculated internally of the DPLL are written to the internal ADD_IN register as well. In the moment when the internal calculation of the ADD_IN values is writing the results into the internal ADD_IN register of the pulse generator the internally calculated ADD_IN values does always have higher priority compared to the values written via the ADD_IN_LD1 register. 3. If the ADD_IN_LD1 value is zero all pulses are sent with the highest possible frequency.

38.22.18.29 DPLL_ADD_IN_LD2

Access: This register can be read or written in 32-bit units.

Address: <GTM_base> + $280CC_H$

Value after reset: $0000\ 0000_H$

	ADD_IN_LD2															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 38.324 DPLL_ADD_IN_LD2 Register Contents

Bit Position	Bit Name	Function
31 to 24	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
23 to 0	ADD_IN_LD2	Input value for SUB_INC2 generation, given by CPU. This value can be used for SMC=1 while RMO=1. For DLM2 = 1: **NOTES** 1. The value is loaded by the CPU but used by the DPLL only for DLM2=1 (see DPLL_CTRL_1 register). When switching DLM2 to 1, the value in the register is used for the SUB_INC2 generation beginning from the next STATE event respectively independently if new values are written by the CPU or not. 2. When a new value is written the output frequency changes according to the given value beginning immediately from the moment of writing. Do not wait for performing step 30 in the state machine for ADD_IN calculations. 3. If the ADD_IN_LD2 value is zero all pulses are sent with the highest possible frequency. For DLM2 = 0: **NOTES** 1. The value loaded by the CPU is stored directly in the internal add_in register which is used to control the sub increment pulse generator directly (see DPLL_CTRL_1 register, DLM2 = 0). 2. When a new ADD_IN_LD2 value is written the output frequency is immediately changed from the moment of writing. The ADD_IN values calculated internally of the DPLL are written to the internal ADD_IN register as well. In the moment when the internal calculation of the ADD_IN values is writing the results into the internal ADD_IN register of the pulse generator the internally calculated ADD_IN values does always have higher priority compared to the values written via the ADD_IN_LD2 register. 3. If the ADD_IN_LD2 value is zero all pulses are sent with the highest possible frequency.

38.22.18.30 DPLL_STATUS

Access: This register can be read or written in 32-bit units.

Address: <GTM_base> + $280FC_H$

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 38.325 DPLL_STATUS Register Contents (1/5)

Bit Position	Bit Name	Function
31	ERR	Error during configuration or operation resulting in unexpected values. 0: when all bits in position 8 to 0 and 10 and 12 are zero 1: when at least one bit in position 8 to 0 or 10 or 12 is one **NOTES** 1. The SOR bit is set, when the time from the last valid STATE event to the next active STATE slope exceeds the value of the last nominal STATE duration multiplied with the value of the SLR register (see **Section 38.22.22.37, DPLL_SLR**) and is reset, when at the current or last active input event a direction change was detected. The SYS bit is not influenced by setting the SOR bit. 2. The TOR bit is set, when the time from the last valid TRIGGER event to the next active TRIGGER slope exceeds the value of the last nominal TRIGGER duration multiplied with the value of the TLR register (see **Section 38.22.22.36, DPLL_TLR**) and is reset, when at the current or last active input event a direction change was detected. The SYT bit is not influenced by setting the TOR bit 3. The DPLL_STATUS register is reset, when the DPLL is disabled (switching DEN from 1 to 0).

Table 38.325 DPLL_STATUS Register Contents (2/5)

Bit Position	Bit Name	Function
30	LOCK1	DPLL Lock status concerning SUB_INC1 0: The DPLL is not locked for TRIGGER M– 0 or SMC=1) or SM– 1) and RM– 1) 1: The DPLL is locked for TRIGGER M– 0 or SMC=1) or SM– 1) and RM– 1) **NOTES** LOCK1 is set: 1. In normal mode (for RMO=SMC=0, LCD=0): Bit is set for an active TRIGGER event when SYT is set and the number of events between two gaps is as expected by the profile (NT values in the ADT_T[i] field) or when SYN_NT=0 and SYT=1. 2. In normal mode (for RMO=SMC=0, LCD=1): Bit is set for an active TRIGGER event when SYT is set and the number of events between two increments without missing TRIGGER (no gap) is as expected by the profile (NT values in the ADT_T[i] field). 3. In emergency mode (for RMO=1 and SMC=0): Bit is set for an active STATE event, when SYS is set and the received events are in correspondence to the profile (NS values in the ADT_S[i] field) for at least two (four in case of direction change) expected missing STATE events or when SYN_NS=0. 4. For SMC=1: Bit is set for an active TRIGGER even when SYT is set and SYN_NT=0 or when SYT is set and the profile stored in the ADT_T[i] field matches once between two gaps. LOCK1 is reset for RMO=SMC=0: 5. When a corresponding missing TRIGGER event occurs while SYN_T=1. This does mean an unexpected missing TRIGGER. 6. When the corresponding input signal TRIGGER is out of locking range TLR, 7. When a corresponding direction change is detected for RMO=1 and SMC=0: 8. When a corresponding missing STATE event occurs while SYN_S=1. This does mean an unexpected missing STATE. 9. When the corresponding input signal STATE is out of locking range TLR for SMC=1: 10. When a corresponding missing TRIGGER event occurs while SYN_T=1. This does mean an unexpected missing TRIGGER. 11. When the corresponding input signal TRIGGER is out of locking range TLR. 12. When a corresponding direction change is detected
29	FTD	First TRIGGER detected. 0: No active TRIGGER event was detected after enabling DPLL 1: At least one active TRIGGER event was detected after enabling DPLL **NOTE** No change of FTD for switching from normal to emergency mode or vice versa.
28	FSD	First STATE detected. 0: Still no active STATE event was detected after enabling DPLL 1: At least one active STATE event was detected after enabling DPLL **NOTE** No change of FSD for switching from normal to emergency mode or vice versa.

Table 38.325 DPLL_STATUS Register Contents (3/5)

Bit Position	Bit Name	Function
27	SYT	Synchronization condition of TRIGGER fixed. This bit is set when the CPU writes to the APT_2C address pointer.
26	SYS	Synchronization condition of STATE fixed. This bit is set when the CPU writes to the APS_1C3 address pointer.
25	LOCK2	DPLL Lock status concerning SUB_INC2 0: The DPLL is not locked concerning STATE for SMC=1 1: The DPLL is locked concerning STATE for SMC=1 **NOTES** 1. Locking of SUB_INC2 appears for RMO=SMC=1: Bit is set, when SYS is set and the number of events between two missing STATE s is as expected by the SYN_S values. 2. LOCK2 is set for SMC=RMO=1: for an active STATE event when SYS is set and SYN_NS=0 or when SYS is set and the profile stored in the ADT_Si field matches once between two gaps. LOCK2 is reset: for SMC=RMO=1 – when a missing STATE event occurs while SYN_S=1. This does mean an unexpected missing STATE. – when the corresponding input signal STATE is out of locking range SLR
24	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
23	BWD1	Backwards drive of SUB_INC1 0: Forward direction 1: Backward direction
22	BWD2	Backwards drive of SUB_INC2 0: Forward direction 1: Backward direction
21	ITN	Increment number of TRIGGER is not plausible; Bit is set when the number of TRIGGERS is different to profile 0: The number of TRIGGER events between synchronization gaps is plausible, a direction change is detected or the address pointer APT_2C is written 1: After setting LOCK1 in normal mode (for SMC=0 or SMC=1) or in emergency mode (only for SMC=0) for missing or additional TRIGGER signals detected; bit is cleared when a direction change is detected or the APT_2C is written
20	ISN	Increment number of STATE is not plausible; Bit is set when the number of STATES is different to profile 0: The number of STATE events between synchronization gaps is plausible, a direction change is detected or the APS_1C3 pointer is written 1: After setting LOCK1 in emergency mode (SMC=0 and RMO=1) or LOCK2 for SMC=RMO=1 missing or additional STATE signals detected; bit is cleared when a direction change is detected or the APS_1C3 is written
19	CAIP1	Calculation of lower half actions in progress 0: Currently no action calculation, new data requests possible 1: Action calculation in progress, no new data requests possible
18	CAIP2	Calculation of upper half actions in progress 0: Currently no action calculation, new data requests possible 1: Action calculation in progress, no new data requests possible
17	CSVT	Current signal value TRIGGER 0: The last TRIGGER_S value was 0 1: The last TRIGGER_S value was 1
16	CSVS	Current signal value STATE 0: The last STATE_S value was 0 1: The last STATE_S value was 1

Table 38.325 DPLL_STATUS Register Contents (4/5)

Bit Position	Bit Name	Function
15	LOW_RES	low resolution of TBU_TS0 is used for DPLL input; this value reflects the input signal LOW_RES 0: The lower 24 Bits of TBU_TS0 are used as input for the DPLL 1: The higher 24 Bits of TBU_TS0 are used as input for the DPLL
14, 13	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
12	RAM2_ERR	DPLL internal access to not configured RAM2 memory space 0: No access to not configured RAM2 memory space 1: Access to not configured RAM2 memory space
11	MT	Missing TRIGGER detected according to TOV 0: No missing TRIGGER detected or a new active TRIGGER slope occurred 1: At least one missing TRIGGER detected after the last active slope
10	TOR	TRIGGER out of range 0: All TRIGGER signal events appear within TLR interval or a direction change was detected 1: At least one TRIGGER signal event is out of TLR;
9	MS	Missing STATE detected according to SOV. 0: No missing STATE detected or a new active STATE slope occurred 1: At least one missing STATE detected after the last active slope
8	SOR	STATE out of range 0: All STATE signal events appear within SLR interval or a direction change was detected 1: At least one STATE signal event is out of SLR;
7	PSE	Prediction space configuration error 0: No prediction space error detected 1: Configured offset value of RAM2 is too small in order to store all TNU+1 values twice in FULL_SCALE
6	RCT	Resolution conflict TRIGGER. Bit is reset, when condition is changed accordingly 0: No resolution conflict detected 1: the TS0_HRT value is set to 1 while LOW_RES=0
5	RCS	Resolution conflict STATE. Bit is reset, when condition is changed accordingly 0: No resolution conflict detected 1: the TS0_HRS value is set to 1 while LOW_RES=0
4	CRO	Calculated Reciprocal value overflow; Bit is set when the calculation of RDT_T_ACT or RDT_S_ACT leads to an overflow 0: No overflow at any reciprocal calculation 1: overflow for at least one reciprocal calculation **NOTE** An overflow in calculation of reciprocal values can occur, when the condition of (DPLL_10979)*[XREF TARGET " (DPLL_10979)] NOT EXIST* is violated. Such an overflow can occur according to the calculations in equations (DPLL_6912)*[XREF TARGET " (DPLL_6912)] NOT EXIST* or (DPLL_6918)*[XREF TARGET " (DPLL_6918)] NOT EXIST*. The overflow is detected when after the calculation and shifting left 32 bits at least one of the bits 31 to 24 is not zero. In that case the corresponding register is set to $FFFFFF_H$.

Table 38.325 DPLL_STATUS Register Contents (5/5)

Bit Position	Bit Name	Function
3	CTO	Calculated TRIGGER duration overflow; Bit is set when equations {REF:DPLL_11005} or {REF:11016} lead to an overflow 0: No overflow at equation {REF:DPLL_11005} or {REF:DPLL_11016} 1: Overflow at equation {REF:DPLL_11005} or {REF:DPLL_11016} **NOTE** When one of the above bits is set the corresponding register contains the maximum value $FFFFFF_H$.
2	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
1	CSO	Calculated STATE duration overflow; Bit is set when equations {REF:DPLL_11036} or {REF:DPLL_11045} lead to an overflow 0: No overflow at equations {REF:DPLL_11036} or {REF:DPLL_11045} 1: Overflow at equations {REF:DPLL_11036} or {REF:DPLL_11045}
0	FPCE	Fast pulse correction error 0: No error at fast pulse correction detected 1: Negative value of MPVAL1/2 used for fast pulse correction mode

Note: Note: Only the values characterized by 1) are stored for an active TRIGGER slope. All other values remain 0. When DEN=0 the relevant bit values of the original register DPLL_CTRL_0 are transferred without any input event at the next system clock. This results in the above reset value.

38.22.18.31 DPLL_ID_PMTR_[z]

Access: This register can be read or written in 32-bit units.

Address: <GTM_base> $4_H \times z + 28100_H$

Value after reset: 0000 $01FE_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 38.327 DPLL_CTRL_0_SHADOW_TRIGGER Register Contents

Bit Position	Bit Name	Function
31	RMO [1)]	Reference mode; selection of the relevant the input signal for generation of SUB_INC1.
30, 29	Reserved	When read, the value after reset is returned.
28	IDT [1)]	Input delay TRIGGER; use of input delay information transmitted in FT part of the TRIGGER signal.
27	Reserved	When read, the value after reset is returned.
26	AMT [1)]	Adapt mode TRIGGER; Use of adaptation information of TRIGGER.
25 to 11	Reserved	When read, the value after reset is returned.
10	IFP [1)]	Input filter position; value contains position or time related information.
9 to 0	MLT [1)]	Multiplier for TRIGGER; MLT+1 is number of SUB_INC1 pulses between two TRIGGER events in normal mode (1...1024);

Note: Only the values characterized by 1) are stored for an active TRIGGER slope. All other values remain 0. When DEN=0 the relevant bit values of the original register DPLL_CTRL_0 are transferred without any input event at the next system clock. This results in the above reset value.

38.22.18.33 DPLL_CTRL_0_SHADOW_STATE

Access: This register is a read-only register that can be read in 32-bit units.

Address: <GTM_base> + $281E4_H$

Value after reset: $0000\ 0000_H$

Table 38.328 DPLL_CTRL_0_SHADOW_STATE Register Contents

Bit Position	Bit Name	Function
31	RMO [1)]	Reference mode; selection of the relevant the input signal for generation of SUB_INC1.
30 to 28	Reserved	When read, the value after reset is returned.
27	IDS [1)]	Input delay STATE; Use of input delay information transmitted in FT part of the STATE signal.
26	Reserved	When read, the value after reset is returned.
25	AMS [1)]	Adapt mode STATE; Use of adaptation information of STATE.
24 to 11	Reserved	When read, the value after reset is returned.
10	IFP [1)]	Input filter position; value contains position or time related information.
9 to 0	Reserved	When read, the value after reset is returned.

Note: Only the values characterized by 2) are stored for an active STATE slope. All other values remain 0. When DEN=0 the relevant bit values of the original register DPLL_CTRL_0 are transferred without any input event at the next system clock.

38.22.18.34 DPLL_CTRL_1_SHADOW_TRIGGER

Access: This register is a read-only register that can be read in 32-bit units.

Address: <GTM_base> + $281E8_H$

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Table 38.331 DPLL_RAM_INI Register Contents

Bit Position	Bit Name	Function
31 to 5	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
4	INIT_RAM	RAM regions 1a, 1b and 2 are to be initialized. 0: Do not start initialization of all RAM regions 1: Start initialization of all RAM regions **NOTES** 1. Setting the INIT_RAM bit results only in a RAM reset when the DPLL is not enabled (DEN=0). 2. Depending on the vendor configuration the connected RAM regions are initialized to zero in the case of a module HW reset or for setting the RST bit in the GTM_RST register. 3. In the case of no RAM initialization it must be ensured that all relevant parameters are configured correctly. Otherwise there is no guarantee to get a predictable behavior.
3	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
2	INIT_2	RAM region 2 initialization in progress 0: No initialization of considered RAM region in progress 1: Initialization of considered RAM region in progress
1	INIT_1BC	RAM region 1b and 1c initialization in progress 0: No initialization of considered RAM region in progress 1: Initialization of considered RAM region in progress
0	INIT_1A	RAM region 1a initialization in progress 0: No initialization of considered RAM region in progress 1: Initialization of considered RAM region in progress

38.22.18.37 DPLL_TSAC[z]

Access: This register can be read or written in 32-bit units.

Address: <GTM_base> + $28E00_H$

Value after reset: $007F\ FFFF_H$

Table 38.334 DPLL_ACB_[z] Register Contents (1/2)

Bit Position	Bit Name	Function
31 to 29	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
28 to 24	ACB_3	Action Control Bits of ACTION_i, reflects ACT_D[i](52:48), i=4*z **NOTES** 1. When DPLL_CTRL_11.ACBU = '0': ACB_3[4:0] are taken as received by ARU interface and are transmitted unchanged as result of action (PMT) calculation. When DPLL_CTRL_11.ACBU = '1': ACB_3[4:2] are taken as received by ARU interface and are transmitted unchanged as result of action (PMT) calculation. ACB_3[1]= '1' is used as input signal to control if "action in past" shall be checked based on position information. ACB_3[1] is written to '1' if action channel has reached "action in past" condition after action has been calculated, written to '0' if action has not reached "past" so far. ACB_3[0] is used as input signal to control if "action in past" shall be checked based on time information. ACB_3[0] is written to '1' if action channel has reached "action in past" condition after action has been calculated, written to '0' if action has not reached "past" so far. 2. This value can only be written via AEI-interface when the DPLL is disabled.
23 to 21	Reserved	When read, the value after reset is returned. When writing, write the value after reset.

Table 38.334 DPLL_ACB_[z] Register Contents (2/2)

Bit Position	Bit Name	Function
20 to 16	ACB_2	Action Control Bits of ACTION_i, reflects ACT_D[i](52:48), i=4*z **NOTES** 1. When DPLL_CTRL_11.ACBU = '0': ACB_2[4:0] are taken as received by ARU interface and are transmitted unchanged as result of action (PMT) calculation. When DPLL_CTRL_11.ACBU = '1': ACB_2[4:2] are taken as received by ARU interface and are transmitted unchanged as result of action (PMT) calculation. ACB_2[1]= '1' is used as input signal to control if "action in past" shall be checked based on position information. ACB_2[1] is written to '1' if action channel has reached "action in past" condition after action has been calculated, written to '0' if action has not reached "past" so far. ACB_2[0] is used as input signal to control if "action in past" shall be checked based on time information. ACB_2[0] is written to '1' if action channel has reached "action in past" condition after action has been calculated, written to '0' if action has not reached "past" so far. 2. This value can only be written via AEI-interface when the DPLL is disabled.
15 to 13	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
12 to 8	ACB_1	Action Control Bits of ACTION_i, reflects ACT_D[i](52:48), i=4*z **NOTES** 1. When DPLL_CTRL_11.ACBU = '0': ACB_1[4:0] are taken as received by ARU interface and are transmitted unchanged as result of action (PMT) calculation. When DPLL_CTRL_11.ACBU = '1': ACB_1[4:2] are taken as received by ARU interface and are transmitted unchanged as result of action (PMT) calculation. ACB_1[1]= '1' is used as input signal to control if "action in past" shall be checked based on position information. ACB_1[1] is written to '1' if action channel has reached "action in past" condition after action has been calculated, written to '0' if action has not reached "past" so far. ACB_1[0] is used as input signal to control if "action in past" shall be checked based on time information. ACB_1[0] is written to '1' if action channel has reached "action in past" condition after action has been calculated, written to '0' if action has not reached "past" so far. 2. This value can only be written via AEI-interface when the DPLL is disabled.
7 to 5	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
4 to 0	ACB_0	Action Control Bits of ACTION_i, reflects ACT_D[i](52:48), i=4*z

Note: When DPLL_CTRL_11.ACBU = '0': ACB_0[4:0] are taken as received by ARU interface and are transmitted unchanged as result of action (PMT) calculation. When DPLL_CTRL_11.ACBU = '1': ACB_0[4:2] are taken as received by ARU interface and are transmitted unchanged as result of action (PMT) calculation. ACB_0[1]= '1' is used as input signal to control if "action in past" shall be checked based on position information. ACB_0[1] is written to '1' if action channel has reached "action in past" condition after action has been calculated, written to '0' if action has not reached "past" so far. ACB_0[0] is used as input signal to control if "action in past" shall be checked based on time information. ACB_0[0] is written to '1' if action channel has reached "action in past" condition after action has been calculated, written to '0' if action has not reached "past" so far.

This value can only be written via AEI-interface when the DPLL is disabled.

38.22.18.40 DPLL_CTRL_11

Access: This register can be read or written in 32-bit units.

Address: <GTM_base> + $28F20_H$

Value after reset: $0000\ 0000_H$

Table 38.335 DPLL_CTRL_11 Register Contents (1/7)

Bit Position	Bit Name	Function
31	WACBU	Write enable for ACB use; the ACB values of PMTR are used to decide if an action is in the past 0: Writing to ACBU is not enabled. 1: Writing to ACBU is enabled. **Note:** Enable writing.
30	WSTATE_EXT	Write enable of STATE_EXT 0: Writing to STATE_EXT is not enabled. 1: Writing to STATE_EXT is enabled.
29	WPCMF2_INCCNT_B	Write enable of PCMF2_INCCNT_B 0: Writing to PCMF2_INCCNT_B is not enabled. 1: Writing to PCMF2_INCCNT_B is enabled.
28	WINCF2	Write enable for INC_CNT2 fast 0: Writing to INCF2 is not enabled 1: Writing to INCF2 is enabled. **Note:** Enable writing.
27	WFSYL2	Write enable for Force Synchronization Loss 2. 0: Writing to FSYL2 is not enabled. 1: Writing to FSYL2 is enabled **Note:** Enable writing.
26	WPCMF2	Write enable for pulse correction mode fast 2 0: Writing to PCMF2 is not enabled 1: Writing to PCMF2 is enabled **Note:** Enable writing.
25	WERZ2	Write enable for error zero 2. 0: Writing to ERZ2 is not enabled 1: Writing to ERZ2 is enabled. **Note:** Enable writing.
24	WSIP2	Write enable for simplified increment prediction 2. 0: Writing to SIP2 is not enabled. 1: Writing to SIP2 is enabled. **Note:** Enable writing.
23	WADS	Write enable of ADS 0: Writing to ADS is not enabled. 1: Writing to ADS is enabled.

Table 38.335 DPLL_CTRL_11 Register Contents (2/7)

Bit Position	Bit Name	Function
22	WADT	Write enable of ADT 0: Writing to ADT is not enabled. 1: Writing to ADT is enabled.
21	WPCMF1_INCCNT_B	Write enable of PCMF1_INCCNT_B 0: Writing to PCMF1_INCCNT_B is not enabled. 1: Writing to PCMF1_INCCNT_B is enabled.
20	WINCF1	Write enable for INC_CNT1 fast 0: Writing to INCF1 is not enabled. 1: Writing to INCF1 is enabled. **Note:** Enable writing
19	WFSYL1	Write enable for Force Synchronization Loss 1. 0: Writing to FSYL1 is not enabled. 1: Writing to FSYL1 is enabled. **Note:** Enable writing.
18	WPCMF1	Write enable for pulse correction mode fast 1 0: Writing to PCM1 is not enabled. 1: Writing to PCM1 is enabled. **Note:** Enable writing.
17	WERZ1	Write enable for error zero 1. 0: Writing to ERZ1 is not enabled. 1: Writing to ERZ1 is enabled. **Note:** Enable writing.
16	WSIP1	Write enable for simplified increment prediction 1. 0: Writing to SIP1 is not enabled. 1: Writing to SIP1 is enabled. **Note:** Enable writing.
15	ACBU	ACB use; the ACB values of PMTR are used to decide if an action is in the past 0: ACB values of PMTR are not considered in DPLL; the decision if an action is in the past is made considering the calculated time value. 1: ACB values of PMTR are considered in DPLL as follows: if ACB[1] = 1, consider if the calculated position value of the corresponding action is in the past. if ACB[0] = 1, consider if the calculated time value of the corresponding action is in the past. ACB[1] and ACB[0] can be set also simultaneously to 1 **NOTE** Return ACB values together with actions as zero, when the actions are in future; set ACB[1]=1, when calculated position value is in the past and the ACB[1] of PMTR was 1. Set ACB[0]=1, when calculated time value is in the past and the ACB[0] of PMTR was 1. The value of ACBU can be only written when WACBU=1.
14	STATE_EXT	Use of STATE engine extension 0: STATE extension is not considered. 1: STATE extension is enabled up to 128 STATE events **NOTE** The STATE_EXT value can be only written when WSTATE_EXT=1 and the DPLL is disabled. See **Section 38.22.10** for a further explanation. If this bit shall be modified during operation a software reset of the DPLL module is strongly recommended. A RAM initialization should also be considered depending on the given application case.

Table 38.335 DPLL_CTRL_11 Register Contents (3/7)

Bit Position	Bit Name	Function
13	PCMF2_INCCNT_B	No increment of INC_CNT2 when PCMF2 active (automatic end mode). 0: Add MPVAL2 value is as well added to the INC_CNT2 when fast pulse correction is done by PCM2 or PCMF2. 1: Do not add MPVAL2 value to the INC_CNT2 register when fast pulse correction is done by PCM2 or PCMF2. This means that just fast pulses are done by decrementing current content of INC_CNT2 register as long as INC_CNT2 is not zero (automatic end mode). The number of pulses (MPVAL2) shall be sufficiently smaller than INC_CNT2 when MPVAL2 is written. **NOTE** The PCMF2_INCCNT_B value can be only written when WPCMF2_INCCNT_B=1.
12	INCF2	INC_CNT2 fast 0: The calculation of a new INC_CNT2 is performed after an active slope was detected and the plausibility check was performed. 1: The calculation of a new INC_CNT2 is prepared before an active slope is detected; the plausibility check is supported by an additional HW checker in order to get the decision earlier and after this decision the pulse generator for SUB_INC2 starts immediately sending out pulses. The calculation of ADD_IN for the SUB_INC generation is performed without adding the 0.5 value to NMB_S in equations DPLL_25 ff. The Signal RESET_SIGx of the pulse generator (see chapter 18.8.3.6) is activated for each new active input slope in order to reset the register values. **NOTE** The INCF2 value can be only written when WINCF2=1.
11	FSYL2	Force Synchronization Loss of LOCK2. 0: No force of synchronization loss. 1: Reset LOCK2, and reset SYS (in emergency mode and for SMC=1). **NOTE** The synchronization loss resets SYS and prevents the use of profiles respectively. The above described effect for FSYL2=1 is only active when WFSYL2=1 simultaneously

Table 38.335 DPLL_CTRL_11 Register Contents (4/7)

Bit Position	Bit Name	Function
10	PCMF2	Pulse correction mode fast for INC_CNT2 0: No fast update of pulses, provided by MPVAL2. 1: When PCM2 is set while PCMF2=1, the pulses provided by MPVAL2 are sent using the rapid pulse generator RPCUx without waiting for a new input event. **NOTE** The fast pulse generation is performed immediately within the current increment. MPVAL2 must be positive integers for the fast pulse correction mode – in the case of negative values the correction is suppressed and the FPCE (fast pulse correction error) bit in the DPLL_STATUS register is set, causing the EI (error interrupt) when enabled. The setting of PCMF2 prevents the transfer of control bits PCM2 to the corresponding shadow registers with an active input event and prevents therefore the distribution of the MPVAL1 values over the current or next increment. The MPVAL2 pulses are sent with the fast clock CMU_CLK0 by the rapid pulse generator RPCUx (see chapter 18.8.3.6 of specification v3.0) triggered in the state 6/26 or 18/38 of the state machines (see chapters 18.8.6.1 and 18.8.6.7 of specification v2.1.0) respectively. The INC_CNT2 is incremented by MPVAL2 respectively. When taken the MPVAL2 value to RPCUx and INC_CNT2 the PCM2 bit is reset immediately and after that also the PCMF2 bit. The value of PCMF2 can be only written when WPCMF2=1. Be careful when using the fast pulse correction during a direction change. Because of sending the correction pulses before, during or after the direction change recognition the result is typically unpredictable. No automatic correction of the fast correction pulses is provided. The necessary corrections must be performed on responsibility of the user.
9	ERZ2	Error is assumed as zero in emergency mode and for the second engine for SMC=1. 0: The MEDT_S value is considered as provided in the corresponding equations. 1: Instead of using MEDT_S the value "0" is used in the corresponding equations. **NOTE** The calculation of EDT_S and MEDT_S is performed independently from the ERZ2 value in all modes without any influence to the MEDT_S value itself. The ERZ2 value influences the use of MEDT_S in emergency mode and for SMC=1 with RMO=1. The value of ERZ2 can be only written when WERZ2=1.
8	SIP2	Simplified increment prediction in emergency mode and for the second engine in the case RMO=1. 0: Increment prediction calculation; the current increment duration CDT_SX is calculated using the relation between increments duration in the past like explained by the corresponding equations. 1: Increment prediction continuation; in this mode for the increment prediction value calculation CDT_SX the value of QDT_S is replaced by 1 for all calculations when NUSE?VSN=1; in the other case the value of SIP2 is ignored and the calculation is performed like for SIP2=0. For the first increment after setting SIP2 from 0 to 1 the value of DT_S_ACT is replaced by the value of the DT_S_START register. This results in a CDT_SX value which is equal to DT_S_START. Notice that this DT_S_START value must be always > 256. **NOTE** The value of SIP2 influences only the increment prediction and error accumulation when NUSE-VSN=1. The calculation of QDT_S itself is not influenced by the SIP2 bit. The value of SIP2 can be only written when WSIP2=1.

Table 38.335 DPLL_CTRL_11 Register Contents (5/7)

Bit Position	Bit Name	Function
7	ADS	Correction of DT_S_ACTUAL, CDT_SX_nom_corr by PD_S 0: No correction of DT_S_ACTUAL, CDT_SX_nom_corr by physical deviation (PD_S) defined in profile of STATE processing unit. 1: Correction of DT_S_ACTUAL, CDT_SX_nom_corr by physical deviation (PD_S) defined in profile of STATE processing unit.
6	ADT	Correction of DT_T_ACTUAL, CDT_TX_nom_corr by PD_T 0: No correction of DT_T_ACTUAL, CDT_TX_nom_corr by physical deviation (PD_T) defined in profile of TRIGGER processing unit. 1: Correction of DT_T_ACTUAL, CDT_TX_nom_corr by physical deviation (PD_T) defined in profile of TRIGGER processing unit.
5	PCMF1_INCCNT_B	No increment of INC_CNT1 when PCMF1 active (automatic end mode). 0: Add MPVAL1 value is as well to the INC_CNT1 when fast pulse correction is done by PCM1 or PCMF1. 1: Do not add MPVAL1 value to the INC_CNT1 register when fast pulse correction is done by PCM1 or PCMF1. This means that just fast pulses are done by decrementing current content of INC_CNT1 register as long as INC_CNT1 is not zero (automatic end mode). The number of pulses (MPVAL1) shall be sufficiently smaller than INC_CNT1 when MPVAL1 is written. **NOTE** The PCMF1_INCCNT_B value can be only written when WPCMF1_INCCNT_B=1.
4	INCF1	INC_CNT1 fast correction 0: The calculation of a new INC_CNT1 is performed after an active slope was detected and the plausibility check was performed. 1: The calculation of a new INC_CNT1 is prepared before an active slope is detected; the plausibility check is supported by an additional HW checker in order to get the decision earlier and after this decision the pulse generator for SUB_INC1 starts immediately sending out pulses The calculation of ADD_IN for the SUB_INC generation is performed without adding the 0.5 value to NMB_T/S in equations DPLL_25 ff. The Signal RESET_SIGx of the pulse generator (see chapter 18.8.3.6) is activated for each new active input slope in order to reset the register values. **NOTE** The INCF1 value can be only written when WINCF1=1. The INCF1 bit should only be written when DPLL_CTRL_1.DEN = '0' (DPLL disabled) to prevent generation of wrong number of sub increments.
3	FSYL1	Force Synchronization Loss of LOCK1. 0: No force of synchronization loss. 1: Reset LOCK1, and reset SYT (in normal mode and for SMC=1) or reset SYS (in emergency mode) **NOTE** The synchronization loss resets SYT/SYS and prevents the use of profiles respectively. The above described effect for FSYL1=1 is only active when WFSYL1=1 simultaneously.

Table 38.335 DPLL_CTRL_11 Register Contents (6/7)

Bit Position	Bit Name	Function
2	PCMF1	Pulse correction mode fast for INC_CNT1 0: No fast update of pulses, provided by MPVAL1. 1: When PCM1 is set while PCMF1=1, the pulses provided by MPVAL1 are sent using the rapid pulse generator RPCUx without waiting for a new input event. **NOTE** The fast pulse generation is performed immediately within the current increment. MPVAL1 must be positive integers for the fast pulse correction mode – in the case of negative values the correction is suppressed and the FPCE (fast pulse correction error) bit in the DPLL_STATUS register is set, causing the EI (error interrupt) when enabled. The setting of PCMF1 prevents the transfer of control bits PCM1 to the corresponding shadow registers with an active input event and prevents therefore the distribution of the MPVAL1 values over the current or next increment. The MPVAL1 pulses are sent with the fast clock CMU_CLK0 by the rapid pulse generator RPCUx (see chapter 18.8.3.6 of specification v3.0) triggered in the state 6/26 or 18/38 of the state machines (see chapters 18.8.6.1 and 18.8.6.7 of specification v2.1.0) respectively. The INC_CNT1 is incremented by MPVAL1 respectively. When taken the MPVAL1 value to RPCUx and INC_CNT1 the PCM1 bit is reset immediately and after that also the PCMF1 bit. The value of PCMF1 can be only written when WPCMF1=1. Be careful when using the fast pulse correction during a direction change. Because of sending the correction pulses before, during or after the direction change recognition the result is typically unpredictable. No automatic correction of the fast correction pulses is provided. The necessary corrections must be performed on responsibility of the user.
1	ERZ1	Error is assumed as zero in normal mode and for the first engine for SMC=1. 0: The MEDT_T value is considered as provided in the corresponding equations. 1: Instead of using MEDT_T the value "0" is used in the corresponding equations. **NOTE** The calculation of EDT_T and MEDT_T is performed independently from the ERZ1 value in all modes without any influence to the MEDT_T value itself. The ERZ1 value influences the use of MEDT_T in normal mode and for SMC=1. The value of ERZ1 can be only written when WERZ1=1.

Table 38.335 DPLL_CTRL_11 Register Contents (7/7)

Bit Position	Bit Name	Function
0	SIP1	Simplified increment prediction in normal mode and for the first engine in the case SMC=1. 0: Increment prediction calculation; the current increment duration CDT_TX is calculated using the relation between increment duration in the past like explained by the corresponding equations. 1: Increment prediction continuation; in this mode for the increment prediction value calculation of CDT_TX the value of QDT_T is replaced by 1 for all calculations when NUTE–VTN=1; in the other case the value of SIP1 is ignored and the calculation is performed like for SIP1=0. For the first increment after setting SIP1 from 0 to 1 the value of DT_T_ACT is replaced by the value of the DT_T_START register. This results in a CDT_TX value which is equal to DT_T_START. Notice that this DT_T_Start value must be always > 256. **NOTES** 1. The value of SIP1 influences only the increment prediction CDT_TX and when NUTE–VTN=1. The calculation of QDT_T itself is not influenced by the SIP1 bit. The value of SIP1 can be only written when WSIP1=1. When SIP1=1 is set the first pulses of the subincrement generator are not generated with highest frequency for the first increment (DPLL_STATUS.ftd = 0, DPLL_CTRL_1.SGE1=1). 2. When SIP1=1 is set the first pulses of the subincrement generator are not generated with highest frequency for the first increment (DPLL_STATUS.ftd=0, DPLL_CTRL_1.SGE1=1).

38.22.18.41 DPLL_THVAL2

Access: This register is a read-only register that can be read in 32-bit units.

Address: <GTM_base> + $28F24_H$

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	THVAL

Table 38.336 DPLL_THVAL2 Register Contents

Bit Position	Bit Name	Function
31 to 24	Reserved	When read, the value after reset is returned.
23 to 0	THVAL	Measured last pulse time from active to inactive slope of TRIGGER after correction of input slope filter delays. **NOTE** This value is available immediately after the inactive slope of TRIGGER. The measured value considers all input slope filter delays. From the received input the corresponding filter delays are subtracted before the time stamp difference of active and inactive slope is calculated.

38.22.18.42 DPLL_TIDEL

Access: This register can be read or written in 32-bit units.

Address: <GTM_base> + $28F28_H$

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 38.343 DPLL_STA Register Contents (1/2)

Bit Position	Bit Name	Function
31 to 24	Reserved	When read, the value after reset is returned.
23 to 21	CNT_S	Count STATE; this reflects the count of active STATE slopes (mod8). This value shows the number of active STATE slopes (mod8) **NOTE** This value allows distinguishing if the above state machine status is consistent to other status values read before or after it.
20	Reserved	When read, the value after reset is returned.
19 to 12	STA_S	Status of STATE state machine; state binary coded This bit field reflects the status of the STATE state machine See **Table 38.345, STA_S bit**. **NOTE** The decimal step number 21 to 40 of the state machine is binary coded from 0x01 to 0x14 respectively using the upper 5 bits (19:15) after subtraction of 20 to the decimal value. The lower 3 bits (14:12) show substates of the corresponding state machine. When the DPLL is disabled this field is 0x000.
11 to 9	CNT_T	Count TRIGGER; this reflects the count of active TRIGGER slopes (mod8). This value shows the number of active TRIGGER slopes (mod8) **NOTE** This value allows distinguishing if the above state machine status is consistent to other status values read before or after it.
8	Reserved	When read, the value after reset is returned.

Table 38.343 DPLL_STA Register Contents (2/2)

Bit Position	Bit Name	Function
7 to 0	STA_T	Status of TRIGGER state machine; state binary coded This bit field reflects the status of the TRIGGER state machine See **Table 38.344, STA_T bit**. **NOTE** The decimal step number 1 to 20 of the state machine is binary coded from 0x01 to 0x14 respectively using the upper 5 bits (7:3). The lower 3 bit (2:0) show substates of the corresponding state machine. When the DPLL is disabled this field is 0x000.

Table 38.344 STA_T bit (1/2)

STA_T(7:3)	STA_T(2:0)	Description/ Monitored action
0	0	Reset state
0	1	Wait, DEN=0
0	2	Calculation of 1/mlt+1, mls1, mls2.
0	3	calculation of direction change issues (pointers and profile update)
0	4	APT_2C is being incremented in normal mode
0	5	APT_2C was incremented 3 times in normal mode, 1 in emergency or SMC=1
0	6	APT_2C was incremented 4 times in normal mode, 2 in emergency or SMC=1
0	7	Update of pointers is finished, perform change of direction operations
1	0	pvt-check
1	1	update of RAM: write RDT_T; DT_T; TSF_T
1	2	loading of profile (syn_t, update syn_t_old) from ADT_T
1	3	TASI-irq, store FTV into RAM1b
1	4	Write PSTC; modify apt, apt_2b; apt_2c (if synchronized); Start fast pulse updates if necessary; Update inc_cnt1;
2	0	Write TS_T to ram1b, calculate dt_t_actual
3	0	update nti_cnt, cdti-irq if nti_cnt=0;
3	1	calculated EDT_T, MEDT_T, RDT_T_actual
4	0	calculate cdt_tx_nom, cdt_tx
5	0	calculate PSTM, rcdt_t, nmb_t_tar, start fast correction of missing pulses (if necessary) for rmo=0 or smc=1.
6	0	calculate nmb_t for rmo=0 or smc=1, dmo=0, coa=0.
7	0	calculate nmb_t for rmo=0 or smc=1, dmo=0, coa=1.
8	0	calculate nmb_t for rmo=0 or smc=1, dmo=1.
9	0	
10	0	calculate add_in_cal1
10	1	write of add_in_cal1 finished, all subincrement calculations done for last active input event
11	0	calculate ts_t_check (MTI-irq), r_add_caln (prepare time stamp calculation (TS_T)) for IDT=IFP=1.
12	0	set caip1,2, action masking bits, action calculation loop control.
13	0	calculate NA(i),
14	0	calculate PDT_T(i)
14	1	calculate DTA(i)

Table 38.344 STA_T bit (2/2)

STA_T(7:3)	STA_T(2:0)	Description/ Monitored action
15	0	calculate TSAC(i)
15	1	calculate PSAC(i)
15	2	action(i) in past condition occurred: assignment of output data.
15	3	action loop control
16	0	wait for new action calculation

Table 38.345 STA_S bit (1/2)

STA_S(7:3)	STA_S(2:0)	Description/ Monitored action
0	0	Reset state
0	1	Wait, DEN=0
0	2	Calculation of 1/mlt+1, mls1, mls2.
0	3	Calculation of direction change issues (pointers and profile update)
0	4	--
0	5	APS_1c3 was incremented once
0	6	APS_1c3 was incremented twice
0	7	Update of pointers is finished, perform change of direction operations
1	0	pvt-check
1	1	update of RAM: write RDT_S; DT_S; TSF_S
1	2	loading of profile (syn_s, update syn_s_old) from ADT_S
1	3	SASI-irq, store FTV into RAM1b
1	4	Write PSSC; modify aps, aps_1c2; aps_1c3 (if synchronized); Start fast pulse updates if necessary; Update inc_cnt1/2;
2	0	Write TS_S to ram1b, calculate dt_s_actual
3	0	update cdsi-irq
3	1	calculate EDT_S, MEDT_S, RDT_S_actual
4	0	calculate cdt_sx_nom, cdt_sx
5	0	calculate PSSM, rcdt_s, nmb_s_tar, start fast correction of missing pulses (if necessary).
6	0	calculate nmb_s for rmo=1 or smc=1, dmo=0, coa=0.
7	0	calculate nmb_s for rmo=1 or smc=1, dmo=0, coa=1.
8	0	calculate nmb_t for rmo=1 or smc=1, dmo=1.
9	0	
10	0	calculate add_in_cal1
10	1	write of add_in_cal1 finished, all subincrement calulations done for last active input event
11	0	calculate ts_s_check (MSI-irq), r_add_caln (prepare time stamp calculation(TS_S)) for IDT=IFP=1.
12	0	set caip1,2, action masking bits, action calculation loop
13	0	calculate NA(i),
14	0	calculate PDT_S(i)
14	1	calculate DTA(i)
15	0	calculate TSAC(i)
15	1	calculate PSAC(i)

Table 38.345 STA_S bit (2/2)

STA_S(7:3)	STA_S(2:0)	Description/ Monitored action
15	2	action(i) in past condition occurred: assignment of output data.
15	3	action loop control
16	0	wait for new action calculation

38.22.18.49 DPLL_INCF1_OFFSET

Access: This register can be read or written in 32-bit units.

Address: <GTM_base> + $28F44_H$

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	DPLL_INCF1_OFFSET

Table 38.350 DPLL_STA_MASK Register Contents

Bit Position	Bit Name	Function
31 to 16	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
15 to 8	STA_NOTIFY_S	Notify value for STA_S of register DPLL_STA. The STA_NOTIFY_S is representing a trigger mask of DPLL_STA.STA_S. When DPLL_STA.STA_S reaches the value of STA_NOTIFY_S the flag DPLL_STA_FLAG.STA_FLAG_S is set to '1' when DPLL_STA.STA_S is leaving the state STA_NOTIFY_S.
7 to 0	STA_NOTIFY_T	Notify value for STA_T of register DPLL_STA. The STA_NOTIFY_T is representing a trigger mask of DPLL_STA.STA_T. When DPLL_STA.STA_T reaches the value of STA_NOTIFY_T the flag DPLL_STA_FLAG.STA_FLAG_T is set to '1' when DPLL_STA.STA_T is leaving the state STA_NOTIFY_T. The signal is visible to MCS0 sub module as part of the special function register.

38.22.18.54 DPLL_STA_FLAG

Access: This register can be read or written in 32-bit units.

Address: <GTM_base> + $28F58_H$

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 38.351 DPLL_STA_FLAG Register Contents

Bit Position	Bit Name	Function
31 to 11	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
10	INC_CNT2_FLAG	Flag according to DPLL_INC_CNT2_MASK.INC_CNT2_NOTIFY The INC_CNT2_FLAG is set to '1' indicating that the signal DPLL_INC_CNT2.INC_CNT2 has left the state defined by the trigger mask of DPLL_INC_CNT2_MASK.INC_CNT2_NOTIFY. The Flag is reset when this bit of the register is written to '1'. The signal is visible to MCS0 sub module as part of the special function register.
9	INC_CNT1_FLAG	Flag according to DPLL_INC_CNT1_MASK.INC_CNT1_NOTIFY The INC_CNT1_FLAG is set to '1' indicating that the signal DPLL_INC_CNT1.INC_CNT1 has left the state defined by the trigger mask of DPLL_INC_CNT1_MASK.INC_CNT1_NOTIFY. The Flag is reset when this bit of the register is written to '1'. The signal is visible to MCS0 sub module as part of the special function register.
8	STA_FLAG_S	Flag according to DPLL_STA_MASK.STA_NOTIFY_S The STA_FLAG_S is set to '1' indicating that the signal DPLL_STA.STA_S has left the state defined by the trigger mask of DPLL_STA_MASK.STA_NOTIFY_S. The Flag is reset when this bit of the register is written to '1'. The signal is visible to MCS0 sub module as part of the special function register.
7 to 1	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
0	STA_FLAG_T	Flag according to DPLL_MASK.STA_NOTIFY_T The STA_FLAG_T is set to '1' indicating that the signal DPLL_STA.STA_T has left the state defined by the trigger mask of DPLL_STA_MASK.STA_NOTIFY_T. The Flag is reset when this bit of the register is written to '1'. The signal is visible to MCS0 sub module as part of the special function register.

38.22.18.55 DPLL_INC_CNT1_MASK

Access: This register can be read or written in 32-bit units.

Address: <GTM_base> + $28F5C_H$

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 38.354 DPLL_NUSC_EXT1 Register Contents

Bit Position	Bit Name	Function
31	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
30	WSYN	Write control bit for SYN_S and SYN_S_OLD; read as zero. 0: The SYN_S value is not writable 1: The SYN_S value is writable
29 to 23	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
22 to 16	SYN_S_OLD	Number of real and virtual events to be considered for the last increment. This value reflects the NS value of the last but one valid increment, stored in ADT_S[i]; is updated automatically when writing SYN_S. **NOTE** This value is updated by the SYN_S value when the WSYN bit in this register is set.
15 to 7	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
6 to 0	SYN_S	Number of real and virtual events to be considered for the current increment. This value reflects the NS value of the last valid increment, stored in ADT_S[i]; to be updated after all calculations in step 37 of Table (DPLL_6908)*[XREF TARGET " (DPLL_6908)] NOT EXIST* **NOTE** This value can only be written when the WSYN bit in this register is set.

Note: This register is only used when DPLL_CTRL_11.STATE_EXT is set. If DPLL_CTRL_11.STATE_EXT is not set any read/write access to this register will return AEI_STATUS = 10_B.

38.22.18.58 DPLL_NUSC_EXT2

Access: This register can be read or written in 32-bit units.

Address: <GTM_base> + $28F68_H$

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	WVSN	—	WNUS	—	—	—	—	—	—	VSN						
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R	R/W	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	FSS	—	—	—	—	—	—	—	—	NUSE						
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 38.355 DPLL_NUSC_EXT2 Register Contents (1/2)

Bit Position	Bit Name	Function
31	WVSN	Write control bit for VSN; read as zero. 0: The VSN value is not writable 1: The VSN value is writable
30	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
29	WNUS	Write control bit for NUSE; read as zero. 0 = the NUSE value is not writeable 1 = the NUSE value is writeable
28 to 23	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
22 to 16	VSN	Virtual STATE number; number of virtual state increments in the current NUSE region. This value reflects the number of virtual increments in the current NUSE region; for NUSE=1 this value is zero, when the CPU sets NUSE to a value > 1 or zero (2 modulo 2), it must also set VSN to the correspondent value; the VSN value is subtracted from the NUSE value in order to get the corresponding APS value for the past; the VSN value is not used for the APS_1C2 pointer. VSN is to be updated by the CPU when a new gap is to be considered for NUSE or a gap is leaving the NUSE region; for this purpose the SASI interrupt can be used; no further update of VSN is necessary when NUSE is set to FULL_SCALE **NOTE** This value can only be written when the WVSN bit is set.
15	FSS	FULL_SCALE of STATE; this value is to be set, when NUSE is set to FULL_SCALE 0: The NUSE value is less than FULL_SCALE 1: The NUSE value is equal to FULL_SCALE This value is set by the CPU, but reset automatically to 0 by a change of direction or loss of LOCK. **NOTE** This value can only be written when the WNUS bit is set.

Table 38.355 DPLL_NUSC_EXT2 Register Contents (2/2)

Bit Position	Bit Name	Function
14 to 7	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
6 to 0	NUSE	Number of recent STATE events used for SUB_INCx calculations modulo 2*(SNUmax+1). No gap is considered in that case for this value, but in the VSN value (see below): This register is set by the CPU but reset automatically to 1 by a change of direction or loss of LOCK. Each other value can be set by the CPU, maybe Full_SCALE, HALF_SCALE or parts of them. The relation values QDT_Sx are calculated using NUSE values in the past with its maximum value of 2*SNU+1. **NOTE** This value can only be written when the WNUS bit is set.

Note: This register is only used when DPLL_CTRL_11.STATE_EXT is set. If DPLL_CTRL_11.STATE_EXT is not set any read/write access to this register will return AEI_STATUS = 10_B.

38.22.18.59 DPLL_APS_EXT

Access: This register can be read or written in 32-bit units.

Bit Position	Bit Name	Function
31 to 21	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
20 to 14	APS_1C2	Address pointer STATE for RAM region 1c2; Actual RAM pointer address value for TSF_S[i]. Initial value: zero (00_H). Actual RAM pointer and synchronization position/value of STATE events in FULL_SCALE for up to 128 STATE events but limited to 2*(SNU+1) in normal and emergency mode; this pointer is used for the RAM region 1c2. For SYS=1: APS_1C2 is incremented (decremented) by SYN_S_OLD for each active STATE event and DIR2=0 (DIR2=1). For SYS=0: APT_1c2 is incremented or decremented by 1 respectively. The APS_1C2 offset value is added in the above shown bit position with the subsection offset of the RAM region. In addition when the APS_1C3 value is written by the CPU – in order to synchronize the DPLL- with the next active STATE event the APS_1C2_EXT value is added/subtracted (while APS_1C2_STATUS is one; see DPLL_APT_SYNC register at **Section 38.22.18.25, DPLL_APS_SYNC**). **NOTE** This value can only be written when the WAPS_1C2 bit is set
13	WAPS_1C2	Write bit for address pointer APS_1C2, read as zero. 0: The APS_1C2 is not writable 1: The APS_1C2 is writable
12 to 9	Reserved	When read, the value after reset is returned. When writing, write the value after reset.

Table 38.356 DPLL_APS_EXT Register Contents (2/2)

Bit Position	Bit Name	Function
8 to 2	APS	Address pointer STATE; Actual RAM pointer address value for DT_S[i] and RDT_S[i] Actual RAM pointer and synchronization position/value of STATE events in FULL_SCALE for up to 128 STATE events but limited to 2*(SNU+1–SYN_NS) in normal and emergency mode for SYSF=0 or to 2*(SNU+1)–SYN_NS for SYSF=1 respectively; See **Section 38.22.10, MCS to DPLL interface**. APS is incremented (decremented) by one for each active STATE event and DIR2=0 DIR2=1). The APS offset value is added in the above shown bit position with the subsection offset of the RAM region. **NOTES** 1. The APS pointer value is directed to the RAM position, in which the data values are to be written, which correspond to the last increment. The APS value is not to be changed, when the direction (shown by DIR2) changes, because it points always to a storage place after the considered increment. Changing of DIR2 takes place always after an active STATE event and the resulting increment/decrement. 2. This value can only be written when the WAPS bit is set.
1	WAPS	Write bit for address pointer APS, read as zero. 0: The APS is not writable 1: The APS is writable
0	Reserved	When read, the value after reset is returned. When writing, write the value after reset.

Note: This register is only used when DPLL_CTRL_11.STATE_EXT is set. If DPLL_CTRL_11.STATE_EXT is not set any read/write access to this register will return AEI_STATUS = 10_B.

38.22.18.60 DPLL_APS_1C3_EXT

Access: This register can be read or written in 32-bit units.

Address: <GTM_base> + $28F3C_H$

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	APS_1C3							—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R

Table 38.357 DPLL_APS_1C3_EXT Register Contents

Bit Position	Bit Name	Function
31 to 9	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
8 to 2	APS_1C3	Address pointer STATE for RAM region 1c3; Actual RAM pointer address value for ADT_S[i] Initial value: zero (0x00). Actual RAM pointer and synchronization position/value of STATE events in FULL_SCALE for up to 128 STATE events but limited to 2*(SNU+1–SYN_NS) in normal and emergency mode for SYSF=0 or to 2*(SNU+1)–SYN_NS for SYSF=1 respectively; this pointer is used for the RAM region 1c3. See **Section 38.22.10, MCS to DPLL interface**. The RAM pointer is set by the CPU accordingly, when the synchronization condition was detected.
1, 0	Reserved	When read, the value after reset is returned. When writing, write the value after reset.

Note 1. The APS_1C3 pointer value is directed to the RAM position of the profile element in RAM region 1c2, which corresponds to the current increment. When changing the direction DIR1 or DIR2 respectively, this is always known before an active STATE event is processed. This is because of the pattern recognition in SPE (for PMSM) or because of the direction change recognition by TRIGGER. This direction change results in an automatic increment (forwards) or decrement (backwards) when the input event occurs in addition with a 2 times correction.

Note 2. The APS_1C3_x offset value is added in the above shown bit position with the subsection address offset of the corresponding RAM region.

Note 3. This register is only used when DPLL_CTRL_11.STATE_EXT is set. If DPLL_CTRL_11.STATE_EXT is not set any read/write access to this register will return AEI_STATUS = 10_B.

38.22.18.61 DPLL_APS_SYNC_EXT

Access: This register can be read or written in 32-bit units.

Address: <GTM_base> + $28F30_H$

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	APS_1C2_OLD						
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	APS_1C2_STATUS	—	—	—	—	—	—	—	—	APS_1C2_EXT						
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 38.358 DPLL_APS_SYNC_EXT Register Contents

Bit Position	Bit Name	Function
31 to 23	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
22 to 16	APS_1C2_OLD	Address pointer STATE for RAM region 1c2 at synchronization time; this value is set by the current APS_1C2 value when the synchronization takes place for the first active STATE event after writing APS_1C3 but before adding the offset value APS_1C2_EXT (that means: when APS_1C2_STATUS=1). Address pointer APS_1C2 value at the moment of synchronization, before the offset value is added, that means the pointer with this value points to the last value before the additional inserted gap
15	APS_1C2_STATUS	Address pointer 1c2 status; set by CPU before the synchronization is performed. The value is cleared automatically when the APS_1C2_OLD value is written. 0: APS_1C2_EXT is not to be considered. 1: APS_1C2_EXT has to be considered for time stamp field extension.
14 to 7	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
6 to 0	APS_1C2_EXT	Address pointer 1c2 extension; this offset value determines, by which value the APS_1C2 is changed at the synchronization time; set by CPU before the synchronization is performed. This offset value is the number of virtual increments to be inserted in the TSF for an imminent intended synchronization; the CPU sets its value dependent on the gaps until the synchronization time taking into account the considered NUSE value to be set and including the next future increment (when SYN_S_OLD is still 1). When the synchronization takes place, this value is to be added to the APS_1C2 address pointer (for forward direction, DIR2=0) and the APT_1c2_status bit is cleared after it. For backward direction subtract APS_1C2_EXT accordingly. **NOTE** When the synchronization is intended and the NUSE value is to be set to FULL_SCALE after it, the APS_1C2_EXT value must be set to SYN_NS (for SYSF=1) or 2*SYN_NS (for SYSF=0) in order to be able to fill all gaps in the extended TSF_S with the corresponding values by the CPU. When still not all values for FULL_SCALE are available, the APS_1C2_EXT value considers only a share according to the NUSE value to be set after the synchronization.

Note: This register is only used when DPLL_CTRL_11.STATE_EXT is set. If DPLL_CTRL_11.STATE_EXT is not set any read/write access to this register will return AEI_STATUS = 10_B.

38.22.18.62 DPLL_CTRL_EXT

Access: This register can be read or written in 32-bit units.

Address: <GTM_base> + $28F34_H$

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	SYN_NS					
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	SNU					
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W

Table 38.359 DPLL_CTRL_EXT Register Contents

Bit Position	Bit Name	Function
31 to 22	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
21 to 16	SYN_NS	Synchronization number of STATE; summarized number of virtual increments in HALF_SCALE Sum of all systematic missing STATE events in HALF_SCALE (for SYSF=0) or FULL SCALE (for SYSF=1); the SYN_NS missing STATES can be divided up to an arbitrary number of blocks. The pattern of events and missing events in FULL_SCALE is shown in RAM region 1c3 as value NS in addition to the adapted values. The number of stored increments in FULL_SCALE must be equal to 2*(SNU+1–SYN_NS) for SYSF=0 or 2*(SNU+1)–SYN_NS for SYSF=1. This pattern is written by the CPU beginning from a fixed reference point (maybe beginning of the FULL_SCALE region). The relation to the actual increment is established by setting of the profile RAM pointer APS_1C3 in an appropriate relation to the RAM pointer APS of the actual increment by the CPU. **NOTES** 1. This value can only be written when the DPLL is disabled. 2. This value can only be written when (RMO=0 and SMC=0) or DEN=0. Set SSL=00 before changing this value and set RMO=1 only after FULL_SCALE with SSL>0.
15 to 6	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
5 to 0	SNU	STATE number; SNU+1 is number of nominal STATE events in HALF_SCALE (1 to 32). **NOTES** 1. This bit can only be written when the DPLL is disabled. 2. The number of nominal STATE events is the decimal value plus 1. This value can only be written when (RMO=0 and SMC=0) or DEN=0. Set SSL=00 before changing this value and set RMO=1 only after FULL_SCALE with SSL>0.

Note: This register is only used when DPLL_CTRL_11.STATE_EXT is set. If DPLL_CTRL_11.STATE_EXT is not set any read/write access to this register will return AEI_STATUS = 10_B.

38.22.19 DPLL RAM Region 1a Value Configuration Registers Overview

DPLL RAM Region 1a value contains following configuration registers:

Table 38.360 Register list

Symbol	Register Name	Details in Section
DPLL_RR1A	DPLL_RR1A	**38.22.20.1**
DPLL_PSA[i]	Position Request for Action i	**38.22.20.2**
DPLL_DLA[i]	Time to React for Action i	**38.22.20.3**
DPLL_NA[i]	Calculated Relative Time to Action i	**38.22.20.4**
DPLL_DTA[i]	Calculated Relative Time to Action i	**38.22.20.5**

38.22.20 DPLL RAM Region 1a value description

NOTE

Bits 31 to 24 of RAM region 1a are not implemented and therefore always read as zero (reserved). Other bits which are declared as reserved are not protected against writing. Unused address regions are not protected against writing when implemented.

38.22.20.1 DPLL_RR1A

Access: This register can be read or written in 32-bit units.

Address: <GTM_base> + 28200_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 38.364 DPLL_NA[i] Register Contents

Bit Position	Bit Name	Function
31 to 24	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
23 to 20	NOT_USED	Not used **NOTE** Must be written to zero.
19 to 10	DW	Number of events to Action_i (integer part, i=0...NOAC–1). **NOTES** 1. Use the maximum value for NA_DW=0x3FF in the case of a calculated value which exceeds the represent able value. 2. This value can only be written when the DPLL is disabled.
9 to 0	DB	Number of events to Action_i (fractional part, i=0...NOAC–1). **NOTE** This value can only be written when the DPLL is disabled.

Note: The NA values for actions 24...31 are not available for devices. Refer to **Section 38.28, GTM Device 358**.

38.22.20.5 DPLL_DTA[i]

Access: This register can be read or written in 32-bit units.

Address: <GTM_base> + 00000_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	DTA

Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 38.365 DPLL_DTA[i] Register Contents

Bit Position	Bit Name	Function
31 to 24	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
23 to 0	DTA	Calculated relative time to ACTION_i (i=0...NOAC–1) **NOTE** This value can only be written when the DPLL is disabled. The DTA value is a positive integer value. When calculations using equations (DPLL_6935)*[XREF TARGET " (DPLL_6935)] NOT EXIST* or DPLL-14 result in a negative value, it is replaced by zero.

38.22.21 DPLL RAM Region 1b and 1c Value Configuration Registers Overview

DPLL RAM Region 1b and 1c value contains following configuration registers:

Table 38.366 Register list (1/2)

Symbol	Register Name	Details in Section
DPLL_TS_T	Actual TRIGGER Time Stamp Value	**38.22.22.1**
DPLL_TS_T_OLD	Previous TRIGGER Time Stamp Value	**38.22.22.2**
DPLL_FTV_T	Actual TRIGGER Filter value	**38.22.22.3**
DPLL_TS_S	Actual STATE Time Stamp Register	**38.22.22.4**
DPLL_TS_S_OLD	Previous STATE Time Stamp Register	**38.22.22.5**
DPLL_FTV_S	Actual STATE Filter Value	**38.22.22.6**
DPLL_THMI	TRIGGER Hold Time Min. Value	**38.22.22.7**
DPLL_THMA	TRIGGER Hold Time Max. Value	**38.22.22.8**
DPLL_THVAL	Measured TRIGGER Hold Time Value	**38.22.22.9**
DPLL_TOV	Time Out Value of Active TRIGGER Slope	**38.22.22.10**
DPLL_TOV_S	Time Out Value of active STATE Slope	**38.22.22.11**
DPLL_ADD_IN_CAL1	Calculated ADD_IN Value for SUB_INC1 Generation	**38.22.22.12**
DPLL_ADD_IN_CAL2	Calculated ADD_IN Value for SUB_INC2 Generation	**38.22.22.13**
DPLL_MPVAL1	Missing Pulses to be Added or Subtracted Directly	**38.22.22.14**
DPLL_MPVAL2	Missing Pulses to be Added or Subtracted Directly	**38.22.22.15**
DPLL_NMB_T_TAR	Target Number of Pulses to be sent in Normal Mode	**38.22.22.16**
DPLL_NMB_T_TAR_OLD	Last but one Target Number of Pulses to be sent in Normal Mode	**38.22.22.17**
DPLL_NMB_S_TAR	Target Number of Pulses to be sent in Emergency Mode	**38.22.22.18**
DPLL_NMB_S_TAR_OLD	Last but one Target Number of Pulses to be sent in Emergency Mode	**38.22.22.19**
DPLL_RCDT_TX	Reciprocal Value of the Expected Increment Duration of TRIGGER	**38.22.22.20**
DPLL_RCDT_SX	Reciprocal Value of the Expected Increment Duration of STATE	**38.22.22.21**
DPLL_RCDT_TX_NOM	Reciprocal Value of the Expected Nominal Increment Duration of TRIGGER	**38.22.22.22**
DPLL_RCDT_SX_NOM	Reciprocal Value of the Expected Nominal Increment Duration of STATE	**38.22.22.23**
DPLL_RDT_T_ACT	Reciprocal Value of the Last Increment of TRIGGER	**38.22.22.24**
DPLL_RDT_S_ACT	Reciprocal Value of the Last Increment of STATE	**38.22.22.25**
DPLL_DT_T_ACT	Duration of the Last TRIGGER Increment	**38.22.22.26**
DPLL_DT_S_ACT	Duration of the Last STATE Increment	**38.22.22.27**
DPLL_EDT_T	Difference of Prediction to Actual Value of the Last TRIGGER Increment	**38.22.22.28**
DPLL_MEDT_T	Weighted Difference of Prediction Errors of TRIGGER	**38.22.22.29**
DPLL_EDT_S	Difference of Prediction to Actual Value of the Last STATE Increment	**38.22.22.30**
DPLL_MEDT_S	Weighted Difference of Prediction Errors of STATE	**38.22.22.31**
DPLL_CDT_TX	Prediction of the Actual TRIGGER Increment Duration	**38.22.22.32**
DPLL_CDT_SX	Prediction of the Actual STATE Increment Duration	**38.22.22.33**

Table 38.366 Register list (2/2)

Symbol	Register Name	Details in Section
DPLL_CDT_TX_NOM	Prediction of the Nominal TRIGGER Increment Duration	**38.22.22.34**
DPLL_CDT_SX_NOM	Prediction of the Nominal STATE Increment Duration	**38.22.22.35**
DPLL_TLR	TRIGGER Locking Range	**38.22.22.36**
DPLL_SLR	STATE Locking Range	**38.22.22.37**
DPLL_PDT_[z]	Projected Increment Sum Relations for Action [z]	**38.22.22.38**
DPLL_MLS1	Calculated Number of Sub-Pulses between two nominal STATE Events for SMC = 0	**38.22.22.39**
DPLL_MLS2	Description: Calculated Number of Sub-Pulses between two nominal STATE Events for SMC=1 and RMO=1	**38.22.22.40**
DPLL_CNT_NUM_1	Counter for number of SUB_INC1 pulses	**38.22.22.41**
DPLL_CNT_NUM_2	Counter for number of SUB_INC2 pulses	**38.22.22.42**
DPLL_PVT	Plausibility Value of Next TRIGGER Slope	**38.22.22.43**
DPLL_PSTC	Actual Calculated Position Stamp of TRIGGER	**38.22.22.44**
DPLL_PSSC	Actual Calculated Position Stamp of STATE	**38.22.22.45**
DPLL_PSTM	Measured Position Stamp at Last TRIGGER Input	**38.22.22.46**
DPLL_PSTM_OLD	Measured Position Stamp at Last but one TRIGGER Input	**38.22.22.47**
DPLL_PSSM	Measured Position Stamp at Last STATE Input	**38.22.22.48**
DPLL_PSSM_OLD	Measured Position Stamp at Last but one STATE Input	**38.22.22.49**
DPLL_NMB_T	Number of Pulses to be sent in Normal Mode	**38.22.22.50**
DPLL_NMB_S	Number of Pulses to be sent in Emergency Mode	**38.22.22.51**
DPLL_RDT_S[i]	Reciprocal Values of the Nominal STATE Increment Duration in FULL_SCALE	**38.22.22.52**
DPLL_TSF_S[i]	Time Stamp Values of the Nominal STATE Events in FULL_SCALE	**38.22.22.53**
DPLL_ADT_S[i]	Adapt and Profile Values of the STATE Increments in FULL_SCALE	**38.22.22.54**
DPLL_DT_S[i]	Nominal STATE Increment Duration in FULL_SCALE	**38.22.22.55**

38.22.22 DPLL RAM Region 1b and 1c value description

NOTE

Bits 31 to 24 of RAM region 1b and 1c are not implemented and therefore always read as zero (reserved). Other bits which are declared as reserved are not protected against writing. Unused address regions are not protected against writing when implemented.

38.22.22.1 DPLL_TS_T

Access: This register can be read or written in 32-bit units.

Address: <GTM_base> + 28400_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	TRIGGER_TS							
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TRIGGER_TS															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 38.367 DPLL_TS_T Register Contents

Bit Position	Bit Name	Function
31 to 24	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
23 to 0	TRIGGER_TS	Time stamp value of the last active TRIGGER input. Measured TRIGGER time stamp **NOTE** The LSB address is determined using the SWON_T value in the OSW register (see **Section 38.22.18.8, DPLL_OSW**).

38.22.22.2 DPLL_TS_T_OLD

Access: This register can be read or written in 32-bit units.

Address: <GTM_base> + 28404_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	TRIGGER_TS_OLD							
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 38.371 DPLL_TS_S_OLD Register Contents

Bit Position	Bit Name	Function
31 to 24	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
23 to 0	STATE_TS_OLD	Time stamp value of the last active STATE input. **NOTE** The LSB address is determined using the SWON_S value in the OSW register (see **Section 38.22.18.8, DPLL_OSW**).

38.22.22.6 DPLL_FTV_S

Access: This register can be read or written in 32-bit units.

Address: <GTM_base> + 28418_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	STATE_FT							
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	STATE_FT															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 38.372 DPLL_FTV_S Register Contents

Bit Position	Bit Name	Function
31 to 24	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
23 to 0	STATE_FT	Filter value of the last active STATE input. Transmitted filter value **NOTE** The LSB address is determined using the SWON_S value in the OSW register (see **Section 38.22.18.8, DPLL_OSW**).

38.22.22.7 DPLL_THMI

Access: This register can be read or written in 32-bit units.

Address: <GTM_base> + 28420_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	NOT_USED							
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	THMI															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 38.373 DPLL_THMI Register Contents

Bit Position	Bit Name	Function
31 to 24	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
23 to 16	NOT_USED	Not used **NOTE** Must be written to zero.
15 to 0	THMI	Minimal time between active and inactive TRIGGER slope (uint16); the time value corresponds to the time stamp clock counts: this does mean the clock selected for the TBU_CH0_BASE (see **Section 38.14.4.2, TBU_CH0_CTRL** register) Set min. value; generate the TINI interrupt in the case of a violation for THMI>0. **NOTE** Typical retention time values after an active slope can be e.g. between 45 µs (forwards) and 90 µs (backwards). When THMI is zero, consider always a THMI violation (forwards).

38.22.22.8 DPLL_THMA

Access: This register can be read or written in 32-bit units.

Address: <GTM_base> + 28424_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	NOT_USED							
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	THMA															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 38.374 DPLL_THMA Register Contents

Bit Position	Bit Name	Function
31 to 24	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
23 to 16	NOT_USED	Not used **NOTE** Must be written to zero.
15 to 0	THMA	Maximal time between active and inactive TRIGGER slope (uint16); the time value corresponds to the time stamp clock counts: this does mean the clock selected for the TBU_CH0_BASE (see **Section 38.14.4.2, TBU_CH0_CTRL** register) Max. value to be set; generate the TAX interrupt in the case of a violation for THMA>0.

38.22.22.9 DPLL_THVAL

Access: This register can be read or written in 32-bit units.

Address: <GTM_base> + 28428_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	THVAL							
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	THVAL															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 38.375 DPLL_THVAL Register Contents

Bit Position	Bit Name	Function
31 to 24	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
23 to 0	THVAL	Measured time from the last active slope to the next inactive TRIGGER slope in time stamp clock counts: this does mean the clock selected for the TBU_CH0_BASE (uint16); The measured value considers all input slope filter delays. From the received input the corresponding filter delays are subtracted before the time stamp difference of active and inactive slope is calculated.

Note: In the case of LOW_RES=1 and TBU_HRT=0 the difference between the time stamps of active and inactive slope is multiplied by 8. The register contains this value.

38.22.22.10 DPLL_TOV

Access: This register can be read or written in 32-bit units.

Address: <GTM_base> + 28430_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	NOT_USED							
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TOV_DW						TOV_DB									
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 38.376 DPLL_TOV Register Contents

Bit Position	Bit Name	Function
31 to 24	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
23 to 16	NOT_USED	Not used **NOTE** Must be written to zero.
15 to 10	TOV_DW	Decision value (integer part) for missing TRIGGER interrupt. TOV(15:0) is to be multiplied with the duration of the last increment and divided by 1024 in order to get the time-out time value for a missing TRIGGER event. **NOTE** For the case of LOW_RES=1 (see **Section 38.22.18.30, DPLL_STATUS** register) consider for the calculation of the time out value the following cases: LOW_RES=1 and DPLL_CTRL_1/TS0_HRT=1: multiply the TBU_TS0 value by 8 LOW_RES=1 and DPLL_CTRL_1/TS0_HRT=0: multiply the TBU_TS0 value by 8 multiply the estimated time point value (using TS_T, dt_t_ACT and TOV) by 8 LOW_RES=0 and DPLL_CTRL_1/TS0_HRT=0: use TBU_TS0 and the estimated time point value unchanged.
9 to 0	TOV_DB	Decision value (fractional part) for missing TRIGGER interrupt.

38.22.22.11 DPLL_TOV_S

Access: This register can be read or written in 32-bit units.

Address: <GTM_base> + 28434_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	NOT_USED							
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	DW						DB									
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 38.377 DPLL_TOV_S Register Contents

Bit Position	Bit Name	Function
31 to 24	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
23 to 16	NOT_USED	Not used **NOTE** Must be written to zero.
15 to 10	DW	Decision value (integer part) for missing STATE interrupt. TOV_S (15:0) is to be multiplied with the duration of the last increment and divided by 1024 in order to get the time-out time value for a missing STATE event. **NOTE** For the case of LOW_RES=1 (see **Section 38.22.18.30, DPLL_STATUS**) consider for the calculation of the time out value the following cases: LOW_RES=1 and DPLL_CTRL_1/TS0_HRS=1: multiply the TBU_TS0 value by 8 LOW_RES=1 and DPLL_CTRL_1/TS0_HRS=0: multiply the TBU_TS0 value by 8 multiply the estimated time point value (using TS_T, dt_s_ACT and SOV) by 8 LOW_RES=0 and DPLL_CTRL_1/TS0_HRS=0: use TBU_TS0 and the estimated time point value unchanged.
9 to 0	DB	Decision value (fractional part) for missing STATE interrupt.

38.22.22.12 DPLL_ADD_IN_CAL1

Access: This register can be read or written in 32-bit units.

Address: <GTM_base> + 28438_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 38.379 DPLL_ADD_IN_CAL2 Register Contents

Bit Position	Bit Name	Function
31 to 24	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
23 to 0	ADD_IN_CAL2	Input value for SUB_INC2 generation, calculated by the DPLL for SMC=RMO=1. Calculated value The update of the ADD_IN value by the calculated value ADD_IN_CAL2 is suppressed for one increment when an unexpected missing STATE (RMO=SMC=1) is detected.

38.22.22.14 DPLL_MPVAL1

Access: This register can be read or written in 32-bit units.

Address: <GTM_base> + 28440_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	SIX1							
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	MPVAL1															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 38.380 DPLL_MPVAL1 Register Contents

Bit Position	Bit Name	Function
31 to 24	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
23 to 16	SIX1	Sign extension for MPVAL1 00_H: MPVAL1 is a positive number FF_H: MPVAL1 is a negative number **NOTE** All bits must be written to either all zeros or all ones.
15 to 0	MPVAL1	Missing pulses for direct correction of SUB_INC1 pulses by the CPU (sint16); Used only for RMO=0 or SMC=1 for the case PCM1=1. Add MPVAL1 once to INC_CNT1 and reset PCM1 after applying once

Note: Do not provide negative values which exceed the amount of NT*(MLT+1) or MLS1 respectively; when considered negative PD values the sum of both (MPVAL1 + NT*PD) should not exceed the amount of NT*(MLT+1) or MLS1 respectively.

38.22.22.15 DPLL_MPVAL2

Access: This register can be read or written in 32-bit units.

Address: <GTM_base> + 28444_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	SIX2							
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	MPVAL2															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 38.381 DPLL_MPVAL2 Register Contents

Bit Position	Bit Name	Function
31 to 24	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
23 to 16	SIX2	Sign extension for MPVAL2 00_H: MPVAL2 is a positive number FF_H: MPVAL2 is a negative number **NOTE** All bits must be written to either all zeros or all ones.
15 to 0	MPVAL2	Missing pulses for direct correction of SUB_INC2 pulses by the CPU (sint16); Used only for SMC=RMO=1 for the case PCM2=1. Add MPVAL2 once to INC_CNT2 and reset PCM2 after applying once **NOTE** Do not provide negative values which exceed the amount of MLS2; when considered negative PD_S values the sum of both (MPVAL2 + NS *PD_S) should not exceed the amount of MLS2.

38.22.22.16 DPLL_NMB_T_TAR

Access: This register can be read or written in 32-bit units.

Address: <GTM_base> + 28448_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	NOT_USED

	RCDT_TX_NOM															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 38.388 DPLL_RCDT_TX_NOM Register Contents

Bit Position	Bit Name	Function
31 to 24	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
23 to 0	RCDT_TX_NOM	Reciprocal value of nominal increment duration *232 while only the lower 24 bits are used. Calculated value; when an overflow occurs in calculation the value is set to $FFFFFF_H$.

38.22.22.23 DPLL_RCDT_SX_NOM

Access: This register can be read or written in 32-bit units.

Address: <GTM_base> + $2846C_H$

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	RCDT_SX_NOM							
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	RCDT_SX_NOM															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 38.389 DPLL_RCDT_SX_NOM Register Contents

Bit Position	Bit Name	Function
31 to 24	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
23 to 0	RCDT_SX_NOM	Reciprocal value of nominal increment duration *232 while only the lower 24 bits are used. Calculated value; when an overflow occurs in calculation the value is set to $FFFFFF_H$.

Note: RCDT_TX_NOM and RCDT_SX_NOM are calculated by the values RCDT_TX and RCDT_SX to be multiplied with SYN_T or SYN_S respectively.

38.22.22.24 DPLL_RDT_T_ACT

Access: This register can be read or written in 32-bit units.

Address: <GTM_base> + 28470_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	RDT_T_ACT							
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	RDT_T_ACT															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 38.390 DPLL_RDT_T_ACT Register Contents

Bit Position	Bit Name	Function
31 to 24	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
23 to 0	RDT_T_ACT	Reciprocal value of last TRIGGER increment *232, only the lower 24 bits are used; the LSB is rounded up when the next truncated bit is 1. Calculated value; when an overflow occurs in calculation the value is set to $FFFFFF_H$ and the CRO bit in the DPLL_STATUS register is set (see **Section 38.22.18.30, DPLL_STATUS**).

38.22.22.25 DPLL_RDT_S_ACT

Access: This register can be read or written in 32-bit units.

Address: <GTM_base> + 28474_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	RDT_S_ACT

Table 38.404 DPLL_PDT_[z] Register Contents

Bit Position	Bit Name	Function
31 to 24	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
23 to 14	DW	Integer part of relation between TRIGGER and STATE increments. Definition of relation values between TRIGGER and STATE increments PDT[i] according to Equations DPLL-11 or DPLL-13 (z:0...NOAC–1).
13 to 0	DB	Fractional part of relation between TRIGGER and STATE increments.

Note: The PDT[z] values for actions i=24...31 are not available for all devices. Refer to **Section 38.28, GTM Device 358**.

38.22.22.39 DPLL_MLS1

Access: This register can be read or written in 32-bit units.

Address: <GTM_base> + $285C0_H$

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	NOT_USED						MLS1	
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

	MLS1															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 38.405 DPLL_MLS1 Register Contents

Bit Position	Bit Name	Function
31 to 24	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
23 to 18	NOT_USED	Not used. **NOTE** Must be written to zero.
17 to 0	MLS1	Number of pulses between two STATE events (to be set and updated by the CPU). For SMC = 0 the value of MLS1 is calculated once by the CPU for fixed values in the DPLL_CTRL_0 register by the formula MLS1 = ((MLT+1) x (TNU+1)/(SNU+1)) and set accordingly. For SMC = 1 the value of MLS1 represents the number of pulses between two nominal TRIGGER events (to be set and updated by the CPU).

38.22.22.40 DPLL_MLS2

Access: This register can be read or written in 32-bit units.

Address: <GTM_base> + $285C4_H$

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	NOT_USED						MLS2	
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 38.409 DPLL_PVT Register Contents

Bit Position	Bit Name	Function
31 to 24	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
23 to 0	PVT	Plausibility value of next active TRIGGER slope. The meaning of the value depends on the value of the PIT value in the DPLL_CTRL_1 register. For PIT = 0: the number of SUB_INC1 pulses to be waited for until a next active TRIGGER event is accepted. For PIT = 1: PVT is to be multiplied with the last nominal increment time DT_T_ACT and divided by 1024 and reduced to a 24 bit value in order to get the time to be waited for until the next active TRIGGER event is accepted. The wait time must be exceeded for an active slope. **NOTE** When an active TRIGGER slope is detected while the wait condition is not fulfilled the interrupt PWI is generated. Note that the SGE1 must be set, when PIT = 0 in order to provide the necessary SUB_INC1 pulses for checking. After an unexpected missing TRIGGER the plausibility check is suppressed for the following increment. In case of direction change the PVT value is automatically set to zero in order to deactivate the check.

38.22.22.44 DPLL_PSTC

Access: This register can be read or written in 32-bit units.

Address: <GTM_base> + $285E0_H$

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	PSTC

Table 38.410 DPLL_PSTC Register Contents

Bit Position	Bit Name	Function
31 to 24	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
23 to 0	PSTC	Calculated position stamp of last TRIGGER input; Value is set by the DPLL and can be updated by the CPU when filter values are to be considered for the exact position (see **Section 38.22.18.30, DPLL_STATUS** and DPLL_CTRL registers for explanation of the status and control bits used). For each active slope of TRIGGER in normal mode when FTD = 0: PSTC is set from actual position value, for the first active TRIGGER event (no filter delay considered) the CPU must update the value once, taking into account the filter value when FTD = 1: PSTC is incremented at each TRIGGER event by SMC = 0: ((MLT+1)+PD) x SYN_T; while PD = 0 for AMT = 0, SMC = 1: (MLS1+PD) x (SYN_T); while PD = 0 for AMT = 0.

38.22.22.45 DPLL_PSSC

Access: This register can be read or written in 32-bit units.

Address: <GTM_base> + $285E4_H$

Value after reset: $0000\ 0000_H$

Table 38.417 DPLL_NMB_S Register Contents

Bit Position	Bit Name	Function
31 to 24	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
23 to 20	NOT_USED	Not used. **NOTE** Must be written to zero.
19 to 0	NMB_S	Number of pulses for STATE; Calculated number of pulses in emergency mode for the current STATE increment. Calculated pulse number.

38.22.22.52 DPLL_RDT_S[i]

Access: This register can be read or written in 32-bit units.

Address: <GTM_base> $4_H \times i + 28600_H$

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	RDT_S							
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	RDT_S															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 38.418 DPLL_RDT_S[i] Register Contents

Bit Position	Bit Name	Function
31 to 24	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
23 to 0	RDT_S	Reciprocal difference time of STATE; nominal reciprocal value of the number of time stamp clocks measured in the corresponding increment x232 while only the lower 24 bits are used; no gap considered. The LSB is rounded up when the next truncated bit is 1. **NOTE** There are 2 x (SNU+1–SYN_NS) entries for SYSF = 0 or 2 x (SNU+1)–SYN_NS entries for SYSF = 1 respectively.

Note: If DPLL_CTRL_11.STATE_EXT is set, this memory range is not used by the DPLL, but emulated outside the DPLL. The DPLL will access the MCS to DPLL interface 19.15 and will expect data to be correctly stored there. This means in fact, that the handling of the RDT_S values has to be done outside, in the MCS integrated in the same cluster.

38.22.22.53 DPLL_TSF_S[i]

Access: This register can be read or written in 32-bit units.

Address: <GTM_base> $4_H \times i + 28700_H$

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

	TSF_S															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 38.419 DPLL_TSF_S[i] Register Contents

Bit Position	Bit Name	Function
31 to 24	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
23 to 0	TSF_S	Time stamp field of STATE; Time stamp value of each active STATE event. **NOTE** There are 2 x (SNU+1) entries.

Note: If DPLL_CTRL_11.STATE_EXT is set, this memory range is not used by the DPLL, but emulated outside the DPLL. The DPLL will access the MCS to DPLL interface 19.15 and will expect data to be correctly stored there. This means in fact, that the handling of the RDT_S values has to be done outside, in the MCS integrated in the same cluster.

38.22.22.54 DPLL_ADT_S[i]

Access: This register can be read or written in 32-bit units.

Address: <GTM_base> $4_H \times i + 28800_H$

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	NOT_USED		NS

Table 38.420 DPLL_ADT_S[i] Register Contents

Bit Position	Bit Name	Function
31 to 24	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
23, 22	NOT_USED	Not used. **NOTE** Must be written to zero.
21 to 16	NS	Number of STATEs; number of nominal STATE parts in the corresponding increment. **NOTE** There are 2 x (SNU+1–SYN_NS) entries for SYSF = 0 or 2 x (SNU+1)–SYN_NS entries for SYSF = 1 respectively.
15 to 0	PD_S	Physical deviation of STATE; Adapt values for each nominal STATE increment in FULL_SCALE (sint16); This value represents the number of pulses to be added to the correspondent nominal increment. The absolute value of a negative PD_S must not exceed MLS1 or MLS2 respectively. The PD value does mean the number of SUB_INC1 pulses per nominal tooth to be added to NS x ((MLS1/2+1)+PD_S);

Note: If DPLL_CTRL_11.STATE_EXT is set, this memory range is not used by the DPLL, but emulated outside the DPLL. The DPLL will access the MCS to DPLL interface 19.15 and will expect data to be correctly stored there. This means in fact, that the handling of the RDT_S values has to be done outside, in the MCS integrated in the same cluster.

38.22.22.55 DPLL_DT_S[i]

Access: This register can be read or written in 32-bit units.

Address: <GTM_base> $4_H \times i + 28900_H$

Value after reset: $0000\ 0000_H$

Table 38.421 DPLL_DT_S[i] Register Contents

Bit Position	Bit Name	Function
31 to 24	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
23 to 0	DT_S	Difference time of STATE; nominal increment duration values for each STATE increment in FULL_SCALE (considering no gap). **NOTE** There are 2 x (SNU+1–SYN_NS) entries for SYSF = 0 or 2 x (SNU+1)–SYN_NS entries for SYSF = 1 respectively.

Note: If DPLL_CTRL_11.STATE_EXT is set, this memory range is not used by the DPLL, but emulated outside the DPLL. The DPLL will access the MCS to DPLL interface 19.15 and will expect data to be correctly stored there. This means in fact, that the handling of the RDT_S values has to be done outside, in the MCS integrated in the same cluster.

38.22.23 DPLL RAM Region 2 Value Configuration Registers Overview

DPLL RAM Region 2 value contains following configuration registers:

Table 38.422 Register list

Symbol	Register Name	Details in Section
DPLL_RR2	DPLL_RR2	**38.22.24.1**
DPLL_RDT_T[i]	Reciprocal Values of the Nominal TRIGGER Increments Duration in FULL_SCALE	**38.22.24.2**
DPLL_TSF_T[i]	Time Stamp Values of the Nominal TRIGGER Increments in FULL_SCALE	**38.22.24.3**
DPLL_ADT_T[i]	Adapt and Profile Values of the TRIGGER Increments in FULL_SCALE	**38.22.24.4**
DPLL_DT_T[i]	Nominal TRIGGER Increments Duration in FULL_SCALE	**38.22.24.5**

38.22.24 DPLL RAM Region 2 value description

NOTE

Bits 31 to 24 of RAM region 2 are not implemented and therefore always read as zero (reserved). Other bits which are declared as reserved are not protected against writing. Unused address regions are not protected against writing when implemented.

38.22.24.1 DPLL_RR2

Access: This register can be read or written in 32-bit units.

Address: <GTM_base> + $2C000_H$

Value after reset: $0000\ 0000_H$

Table 38.424 DPLL_RDT_T[i] Register Contents

Bit Position	Bit Name	Function
31 to 24	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
23 to 0	RDT_T	Reciprocal difference time of TRIGGER; 2 x (TNU+1– SYN_NT) stored values nominal reciprocal value of the number of time stamp clocks measured in the corresponding increment (which is divided by the number of nominal increments); multiplied by x232 while only the lower 24 bits are used; the LSB is rounded up, when the next truncated bit is 1. **NOTE** There are 2 x (TNU+1– SYN_NT) entries. The maximum number of entries is restricted to a value corresponding to the OSS value in the DPLL_OSW register.

Note: The starting index for Memory DPLL_RDT_T[i] in RAM2 is defined by the parameter AOSV_2A in DPLL_AOSV2 Register

38.22.24.3 DPLL_TSF_T[i]

Access: This register can be read or written in 32-bit units.

Address: <GTM_base> $4_H \times i + 00000_H$

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 38.425 DPLL_TSF_T[i] Register Contents

Bit Position	Bit Name	Function
31 to 24	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
23 to 0	TSF_T	Time stamp field of active TRIGGER slopes. **NOTE** There are 2 x (TNU+1) entries. The maximum number of entries is restricted to a value corresponding to the OSS value in the DPLL_OSW register.

Note: The starting index for Memory DPLL_TSF_T[i] in RAM2 is defined by the parameter AOSV_2C in DPLL_AOSV2 Register

38.22.24.4 DPLL_ADT_T[i]

Access: This register can be read or written in 32-bit units.

Address: <GTM_base> $4_H \times i + 00000_H$

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	NOT_USED					NT		
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

R/W	R/W	R/W	R/W	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 38.426 DPLL_ADT_T[i] Register Contents

Bit Position	Bit Name	Function
31 to 24	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
23 to 19	NOT_USED	Not used. **NOTE** Must be written to zero.
18 to 16	NT	Number of TRIGGERs; number of nominal TRIGGER parts in the corresponding increment. **NOTE** There are 2 x (TNU+1– SYN_NT) entries. The maximum number of entries is restricted to a value corresponding to the OSS value in the DPLL_OSW register.
15 to 13	TINT	TRIGGER Interrupt information; Depending on the value up to 7 different interrupts can be generated. In the current version the 5 interrupts TE0_IRQ to TE4_IRQ are supported by TINT = "001", "010", "011", "100", "101" respectively. For the values "000", "110" and "111" no interrupt is generated and no other reaction is performed. The corresponding interrupt is activated, when the TINT value is read by the DPLL together with the other values (PD, NT) according to the profile.
12 to 0	PD	Physical deviation; Adapt values for each nominal TRIGGER increment in FULL_SCALE (sint13); The PD value does mean the number of SUB_INC1 pulses to be added to NT x ((MLT+1)+PD); the absolute value of a negative PD must not exceed (MLT+1) or MLS1 respectively; systematic missing TRIGGER events must be considered for the value of PD;

Note: The starting index for Memory DPLL_ADT_T[i] in RAM2 is defined by the parameter AOSV_2C in DPLL_AOSV2 Register

38.22.24.5 DPLL_DT_T[i]

Access: This register can be read or written in 32-bit units.

Address: <GTM_base> 4_H × i + 00000_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

	DT_T															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 38.427 DPLL_DT_T[i] Register Contents

Bit Position	Bit Name	Function
31 to 24	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
23 to 0	DT_T	Difference time of TRIGGER; increment duration values for each TRIGGER increment in FULL_SCALE divided by the number of nominal increments (nominal value). **NOTE** There are 2 x (TNU+1– SYN_NT) entries. The maximum number of entries is restricted to a value corresponding to the OSS value in the DPLL_OSW register.

Note: The starting index for Memory DPLL_DT_T[i] in RAM2 is defined by the parameter AOSV_2D in DPLL_AOSV2 Register

38.22.25 MCS to DPLL Configuration Registers Overview

MCS to DPLL contains following configuration registers:

Table 38.428 Register list

Symbol	Register Name	Details in Section
MCS2DPLL_DEB0	Data exchange buffer 0	**38.22.26.1**
MCS2DPLL_DEB1	Data exchange buffer 1	**38.22.26.2**
MCS2DPLL_DEB2	Data exchange buffer 2	**38.22.26.3**
MCS2DPLL_DEB3	Data exchange buffer 3	**38.22.26.4**
MCS2DPLL_DEB4	Data exchange buffer 4	**38.22.26.5**
MCS2DPLL_DEB5	Data exchange buffer 5	**38.22.26.6**
MCS2DPLL_DEB6	Data exchange buffer 6	**38.22.26.7**
MCS2DPLL_DEB7	Data exchange buffer 7	**38.22.26.8**
MCS2DPLL_DEB8	Data exchange buffer 8	**38.22.26.9**
MCS2DPLL_DEB9	Data exchange buffer 9	**38.22.26.10**
MCS2DPLL_DEB10	Data exchange buffer 10	**38.22.26.11**
MCS2DPLL_DEB11	Data exchange buffer 11	**38.22.26.12**
MCS2DPLL_DEB12	Data exchange buffer 12	**38.22.26.13**
MCS2DPLL_DEB13	Data exchange buffer 13	**38.22.26.14**
MCS2DPLL_DEB14	Data exchange buffer 14	**38.22.26.15**
MCS2DPLL_DEB15	Data exchange buffer 15	**38.22.26.16**

38.22.26 MCS to DPLL Registers Description

As already mentioned in **Section 38.22.10**, the following registers of the MCS2DPLL interface are exclusively accessible by the MCS instance of cluster 0 and cannot be accessed directly via CPU.

38.22.26.1 MCS2DPLL_DEB0

Access: This register can be read or written in 32-bit units.

Address: <GTM_base> + 00000_H

Value after reset: Undefined

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	DATA							
Value after reset	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
R/W	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	DATA															
Value after reset	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 38.429 MCS2DPLL_DEB0 Register Contents

Bit Position	Bit Name	Function
31 to 24	Reserved	When read, the undefined value is returned. When writing, write "X".
23 to 0	DATA	DATA: Data exchange buffer 0. Actual content depends on whether it is a Read or Write operation from MCS. READ access from MCS: Duration of the last increment DT_S_ACT (19.7.5). This value is updated by the DPLL during the update of ram (STA_S = 0000_1001_B) and is ready to be read when STA_S is modified to 0000_1010_B. WRITE access from MCS: The DPLL expects DT_S[p-1] (19.6.3.5) or DT_S[p+1](19.6.5.2) during the increment prediction (STA_S = 0001_0000_B).

Note: The data write from MCS should be performed between the two writes to MCS2DPLL_DEB15 (MCS2DPLL_STATUS_INFO)

38.22.26.2 MCS2DPLL_DEB1

Access: This register can be read or written in 32-bit units.

Address: <GTM_base> + 00000_H

Value after reset: Undefined

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	DATA							
Value after reset	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
R/W	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	DATA															
Value after reset	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 38.430 MCS2DPLL_DEB1 Register Contents

Bit Position	Bit Name	Function
31 to 24	Reserved	When read, the undefined value is returned. When writing, write "X".
23 to 0	DATA	DATA: Data exchange buffer 1. READ access from MCS: Reads as 0. WRITE access from MCS: The DPLL expects RDT_S[p-1] (19.6.3.4) or RDT_S[p+1](19.6.5.1) during the increment prediction (STA_S = 0001_0000_B) and RDT_S[t-1] (19.7.3) or RDT_S[t+1](19.7.4) during the action calculation (STA_S = 0111_0000_B)

Note: In both cases, the data write from MCS should be performed between the two writes to MCS2DPLL_DEB15 (MCS2DPLL_STATUS_INFO).

38.22.26.3 MCS2DPLL_DEB2

Access: This register can be read or written in 32-bit units.

Address: <GTM_base> + 00000_H

Value after reset: Undefined

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	DATA							
Value after reset	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
R/W	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

	DATA															
Value after reset	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 38.431 MCS2DPLL_DEB2 Register Contents

Bit Position	Bit Name	Function
31 to 24	Reserved	When read, the undefined value is returned. When writing, write "X".
23 to 0	DATA	DATA: Data exchange buffer 2. Actual content depends on whether it is a Read or Write operation from MCS. READ access from MCS: TS_Sx. Use to compute/update the time stamp values for STATE during the update of ram (STA_S = 0000_1001_B) WRITE access from MCS: The DPLL expects RDT_S[p-q-1] (19.6.3.5) or RDT_S[p+q+1] during the increment prediction (STA_S = 0001_0000_B).

Note 1. The data read from MCS should be performed between the two writes to MCS2DPLL_DEB15 (MCS2DPLL_STATUS_INFO).

Note 2. The data write from MCS should be performed between the two writes to MCS2DPLL_DEB15 (MCS2DPLL_STATUS_INFO)

38.22.26.4 MCS2DPLL_DEB3

Access: This register can be read or written in 32-bit units.

Address: <GTM_base> + 00000_H

Value after reset: Undefined

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 38.435 MCS2DPLL_DEB6 Register Contents

Bit Position	Bit Name	Function
31 to 24	Reserved	When read, the undefined value is returned. When writing, write "X".
23 to 0	DATA	Data exchange buffer 6. READ access from MCS: Reads as 0. WRITE access from MCS: The DPLL expects ADT_S[APS_1C2] during the update of RAM (STA_S = 0000_1001_B) and change of direction (STA_S = 0000_0100_B and STA_S = 0000_0110_B)

Note 1. In both cases, the current ADT_S[APS_1C2] value should be stored in the register before unlocking the state machine the second time, i.e.: between the two writes to MCS2DPLL_DEB15 (MCS2DPLL_STATUS_INFO).

Note 2. The format of ADT_S should match the defined in **Section 38.22.22.54, DPLL_ADT_S[i]**.

38.22.26.8 MCS2DPLL_DEB7

Access: This register can be read or written in 32-bit units.

Address: <GTM_base> + 00000_H

Value after reset: Undefined

Table 38.436 MCS2DPLL_DEB7 Register Contents

Bit Position	Bit Name	Function
31 to 24	Reserved	When read, the undefined value is returned. When writing, write "X".
23 to 0	DATA	Data exchange buffer 7. Actual content depends on whether it is a Read or Write operation from MCS. READ access from MCS: Duration of the reciprocal of the last increment RDT_S_ACT. This value is written by the DPLL during the update of ram (STA_S = 0000_1001_B) and is ready to be read when STA_S is modified to 0000_1010_B. WRITE access from MCS: The DPLL expects the reciprocal of the last increment RDT_S[APS] before it is overwritten with RDT_S_ACT during the update of ram (STA_S = 0000_1001_B). For the action calculation, this value is needed as well as RDT_S[t]

Note: During an update of ram, perform the write before unlocking the state machine (STA_S = 0000_1001_B), i.e.: after the first write to MCS2DPLL_DEB15 (MCS2DPLL_STATUS_INFO) but before the second write. During the action calculation, the data write from MCS should be performed between the two writes to MCS2DPLL_DEB15 (MCS2DPLL_STATUS_INFO).

38.23 Sensor Pattern Evaluation (SPE)

38.23.1 Overview

The Sensor Pattern Evaluation (SPE) sub-module can be used to evaluate three hall sensor inputs and together with the TOM module to support the drive of BLDC engines. Thus, the input signals are filtered already in the connected TIM channels. In addition, the SPE sub-module can be used as an input stage to the MAP sub-module if the DPLL should be used to calculate the rotation speed of one or two electric engine(s). The integration of the SPE sub-module into the overall GTM-IP architecture concept is shown in **Figure 38.118**.

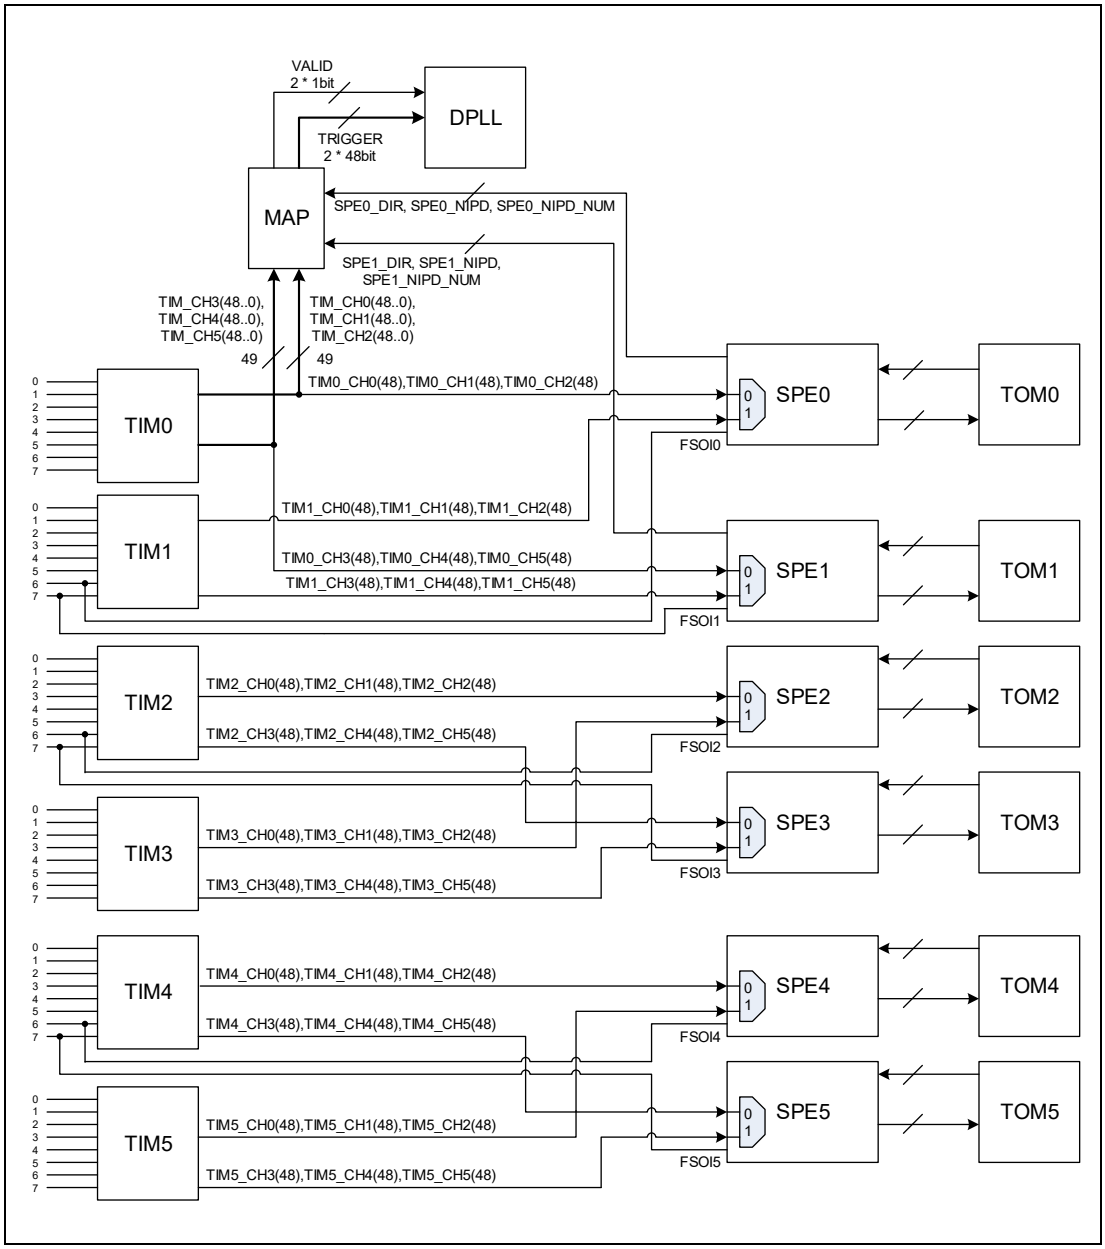

Figure 38.118 SPE sub-module integration concept into GTM-IP

The SPE sub-module can determine a rotation direction out of the combined TIM[i]_CHx(48), TIM[i]_CHy(48) and TIM[i]_CHz(48) signals. On this input signals a pattern match algorithm is applied to generate the SPEx_DIR signal on behalf of the temporal relation between these input

patterns. A possible sample pattern of the three input signals is shown in **Figure 38.119**. In general, the input pattern is programmable within the SPE sub-module.

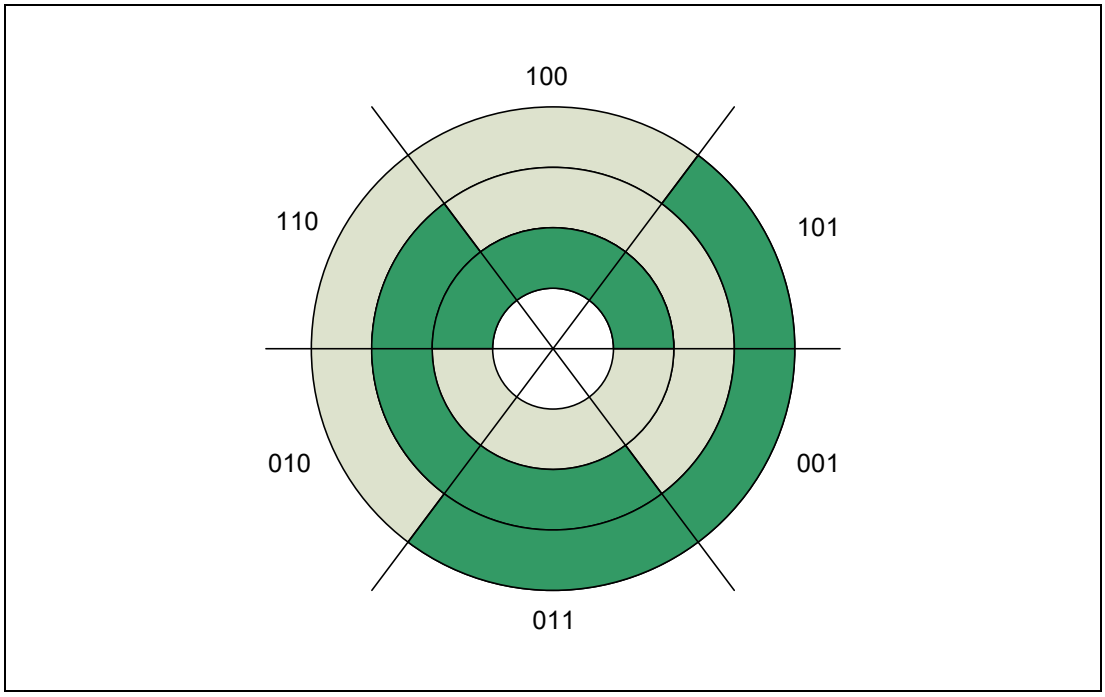

Figure 38.119 SPE Sample input pattern for TIM[i]_CH[x,y,z](48)

In **Figure 38.119** the input signals define the pattern from the input sensors which have a 50% high and 50% low phase. The pattern according to **Figure 38.119** is as follows:

100 110 010 011 001 101 100

where the first bit (smallest circle) represents TIM[i]_CH[x](48), the second bit represents TIM[i]_CH[y](48), and the third bit (greatest circle) represents TIM[i]_CH[z](48).

NOTE

The SPE module expects that with every new pattern only one of the three input signals changes its value.

38.23.2 SPE Sub-module description

The SPE sub-module can handle sensor pattern inputs. Every time if one of the input signals TIM[i]_CH[x](48), TIM[i]_CH[y](48) or TIM[i]_CH[z](48) changes its value, a sample of all three input signals is made. Derived from the sample of the three inputs the encoded rotation direction and the validity of the input pattern sequence is determined and signaled. When a valid input pattern is detected, the SPE sub-module can control the outputs of a dedicated connected TOM sub-module. This connection is shown in **Figure 38.120**.

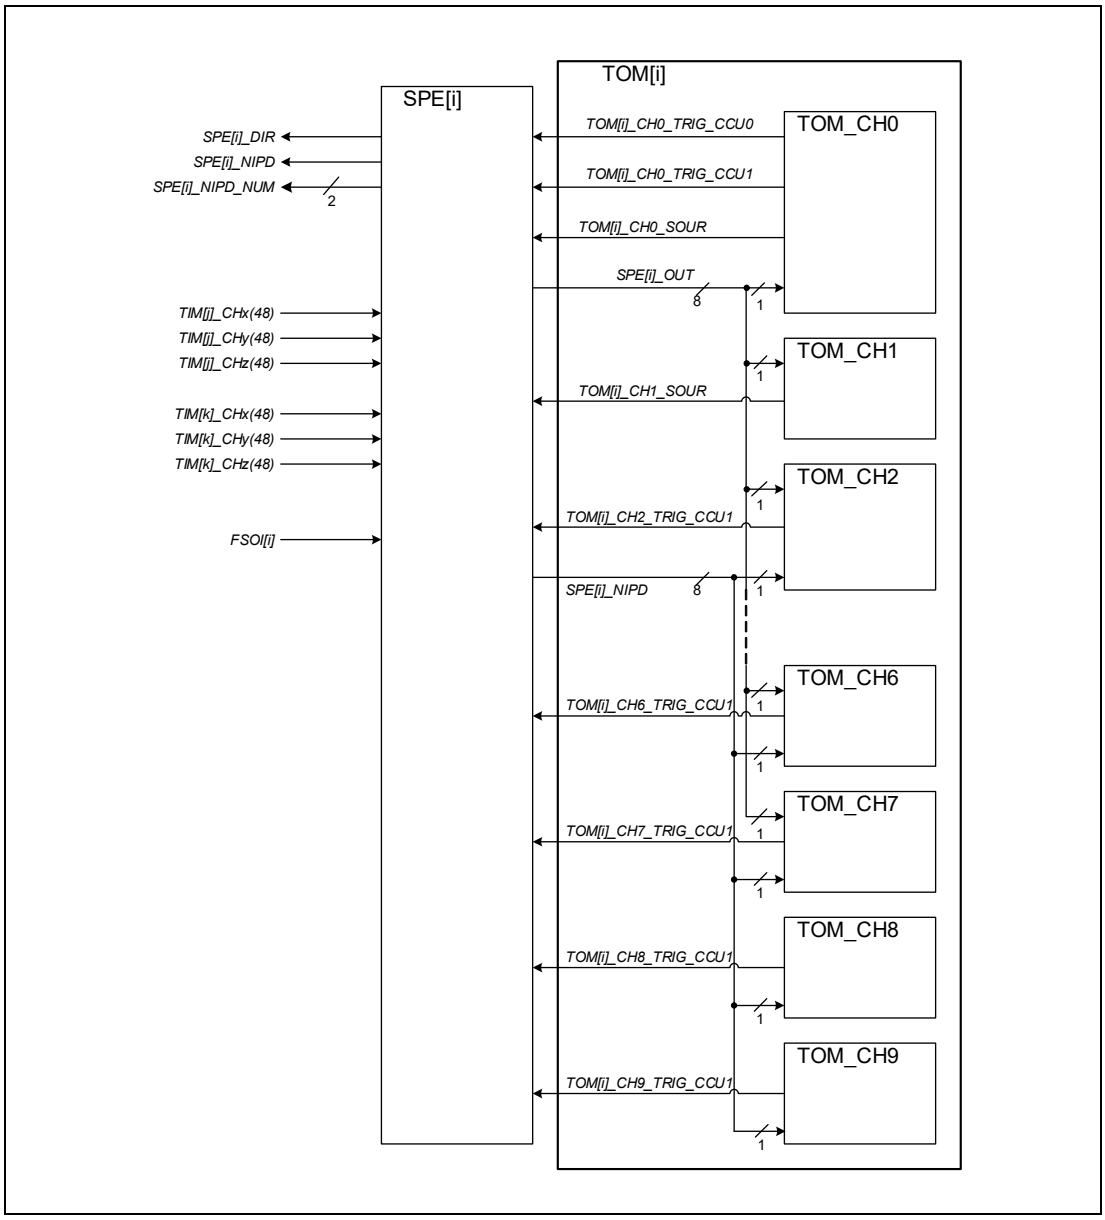

Figure 38.120 SPE to TOM Connections

The TOM[i]_CH0_TRIG_CCU[x] and TOM[i]_CH[x]_SOUR signal lines are used to evaluate the current state of the TOM outputs, whereas the SPE[i]_OUT output vector is used to control the TOM output depending on the new input pattern. The SPE[i]_OUT output vector is defined inside the SPE sub-module in a pattern definition table SPE[i]_OUT_PAT[x]. The internal SPE sub-module architecture is shown in **Figure 38.121**

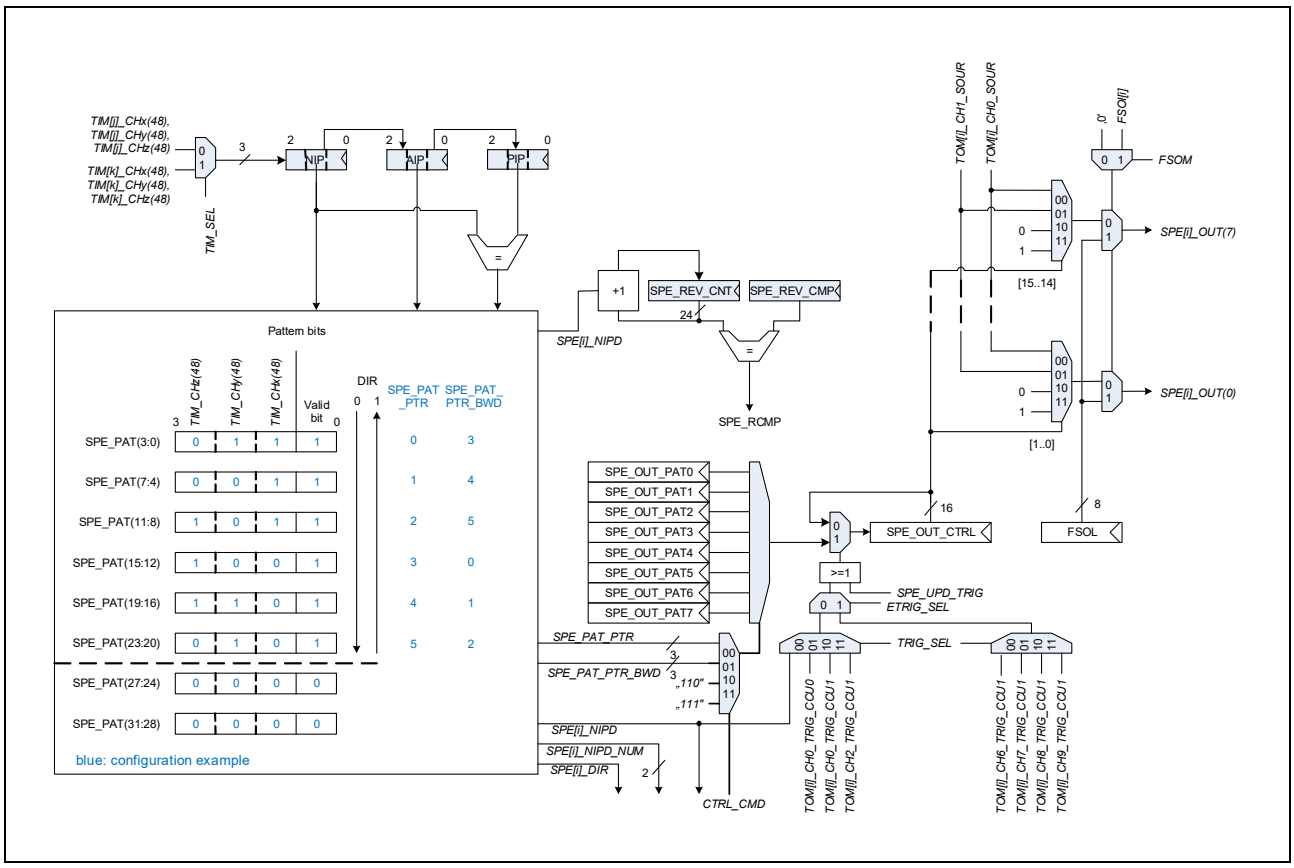

Figure 38.121 SPE Sub-module architecture

The SPE[i]_PAT register holds the valid input pattern for the three input patterns TIM[i]_CH[x](48), TIM[i]_CH[y](48) and TIM[i]_CH[z](48).

The input pattern is programmable. The valid bit shows if the programmed pattern is a valid one. **Figure 38.121** shows the programming of the SPE[i]_PAT register for the input pattern defined in **Figure 38.119**.

The rotation direction is determined by the order of the valid input pattern. This rotation direction defines if the SPE_PAT_PTR is incremented (DIR = 0) or decremented (DIR = 1). Whenever a valid input pattern is detected, the NIPD signal is raised, the SPE_PAT_PTR is incremented/decremented and a new output control signal SPE[i]_OUT(x) is send to the corresponding TOM sub-module.

To command directly the forward or backward rotation the SPE provides with SPE[i]_APT_PTR and SPE[i]_PAT_PTR_BWD two pointers to array SPE[i]_OUT_PAT[z]. Both can point to different values of SPE[i]_OUT_PAT[z] at the same point in time. SPE[i]_APT_PTR is intended to point to the pattern for forward commanding and SPE[i]_PAT_PTR_BWD is intended to point to the pattern for backward commanding. On startup both pointers have to be configured to an initial value that corresponds to different direction depending start pattern of SPE[i]_OUT_PAT[z]. With each valid new input pattern indicated by SPE_NIPD both pointers will be incremented or decremented according to the detected direction. Switching from command forward to command backward can then be done by changing the selected pointer to SPE[i]_OUT_PAT[z] array, i.e. changing SPE_CTRL_CMD in register SPE[i]_CMD from selecting SPE[i]_PAT_PTR to selecting SPE[i]_PAT_PTR_BWD or vice versa. The intended behavior is depicted in the following figure:

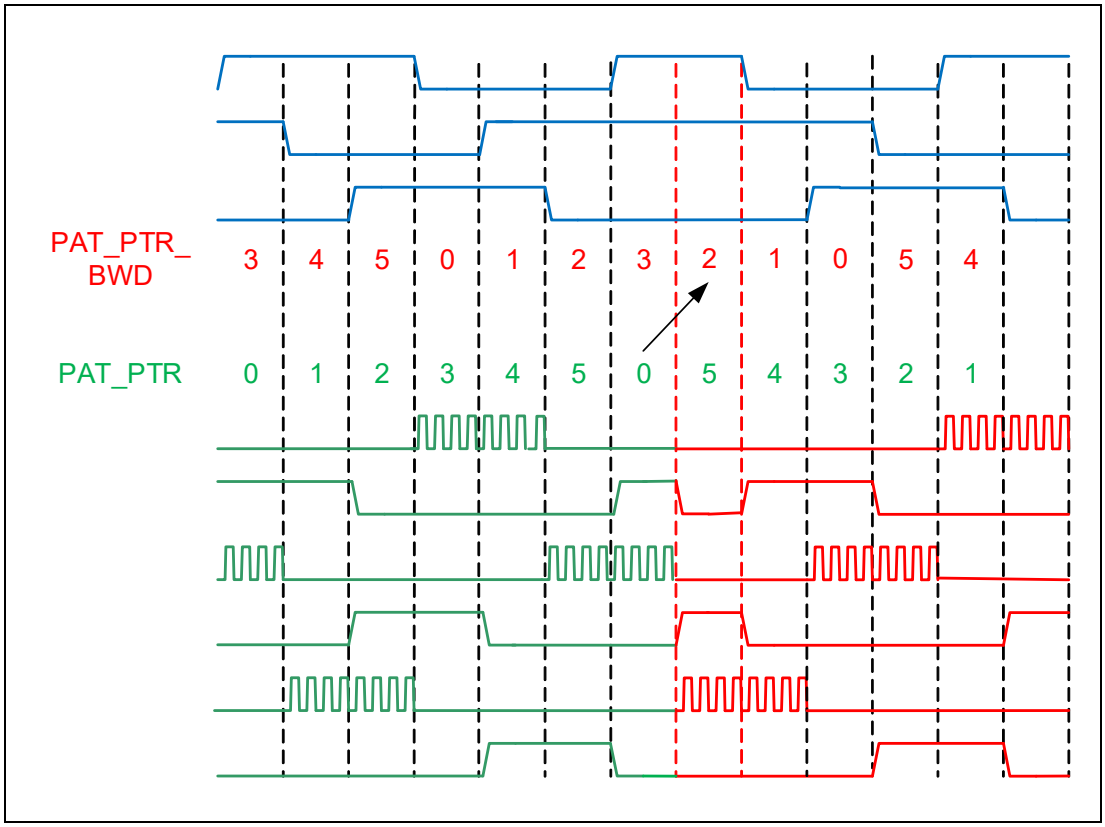

Figure 38.122 SPE forward-backward commanding

With command SPE_CTRL_CMD = 10_B or 11_B a dedicated configurable output pattern configured to the pattern SPE_OUT_PAT6 or SPE_OUT_PAT7 can be commanded to the outputs. An example is the introduction of a SW dead time if switching from pointer SPE[i]_PAT_PTR to SPE[i]_PAT_PTR_BWD or vice versa. E.g. if in SPE[i]_OUT_PAT6 the value 10_B for each output (i.e. set SPE_OUT(n) to 0) is programmed, this can be used as an intermediate step to introduce this 'all off' when switching between SPE[i]_PAT_PTR to SPE[i]_PAT_PTR_BWD or vice versa.

Selectable by TRIG_SEL and ETRIG_SEL the CCU1 trigger of either the TOM channel 2,6,7,8 and 9 can be used together with the SPE module to trigger a delayed update of the SPE_OUT_CTRL register after new input pattern detected by SPE (signaled by SPE[i]_NIPD). To do this, the TOM channel z=2, 6, 7, 8 or 9 has to be configured to work in one-shot mode (set bit OSM in register TOM[i]_CH[z]_CTRL). The SPE trigger of this channel has to be enabled, too (set description of bit SPEM and bit SPE_TRIG in register TOM[i]_CH[z]_CTRL). The SPE module has to be configured to update SPE_OUT_CTRL on TOM[i]_CH[z]_TRIG_CCU1 (set in SPE[i]_CTRL_STAT bits TRIG_SEL to 11_B). Then, on new input detected by SPE, the signal SPE[i]_NIPD triggers the start of the TOM channel z to generates one PWM period by resetting CN0 to 0.

On second PWM edge triggered by CCU1 of TOM channel z, the signal TOM[i]_CH[z]_TRIG_CCU1 triggers the update of SPE_OUT_CTRL.

The update of SPE[i]_OUT_CTRL with the content of one of the SPE_OUT_PAT[z] register can be triggered at any time by writing a 1 to bit SPE_UPD_TRIG in register SPE[i]_CMD.

The regular trigger for update of SPE[i]_OUT_CTRL (commutation trigger) is selected by TRIG_SEL and ETRIG_SEL.

According to **Figure 38.121**, the two input patterns 000_B and 111_B are not allowed combinations and will end in a SPE[i]_PERR interrupt.

These two patterns can be used to determine a sensor input error. A SPE[i]_PERR interrupt will also be raised, if the input patterns occur in a wrong order, e.g. if the pattern 010_B does not follow the pattern 110_B or 011_B.

The register SPE[i]_IN_PAT bit field inside the SPE[i]_CTRL_STAT register is implemented, where the input pattern history is stored by the SPE sub-module. The CPU can determine a broken sensor when the SPE[i]_PERR interrupt occurs by analyzing the bit pattern readable via bit field NIP inside the SPE[i]_CTRL_STAT register. The input pattern in the SPE[i]_CTRL_STAT register is updated whenever a valid edge is detected on one of the input lines TIM[i]_CH[x](48), TIM[i]_CH[y](48) or TIM[i]_CH[z](48). The pattern bit fields are then shifted. The input pattern history generation inside the SPE[i]_CTRL_STAT register is shown in **Figure 38.123**.

Additionally to the sensor pattern evaluation the SPE module also provides the feature of fast shutoff for all TOM channels controlled by the SPE module. The feature is enabled by setting bit FSOM in register SPE[i]_CTRL_STAT. The fast shutoff level itself is defined in the bit field FSOL of register SPE[i]_CTRL_STAT. The TIM input used to trigger the fast shutoff is either TIM channel 6 or TIM channel 7 depending on the TIM instance connected to the SPE module. For details of connections, refer to **Figure 38.118**.

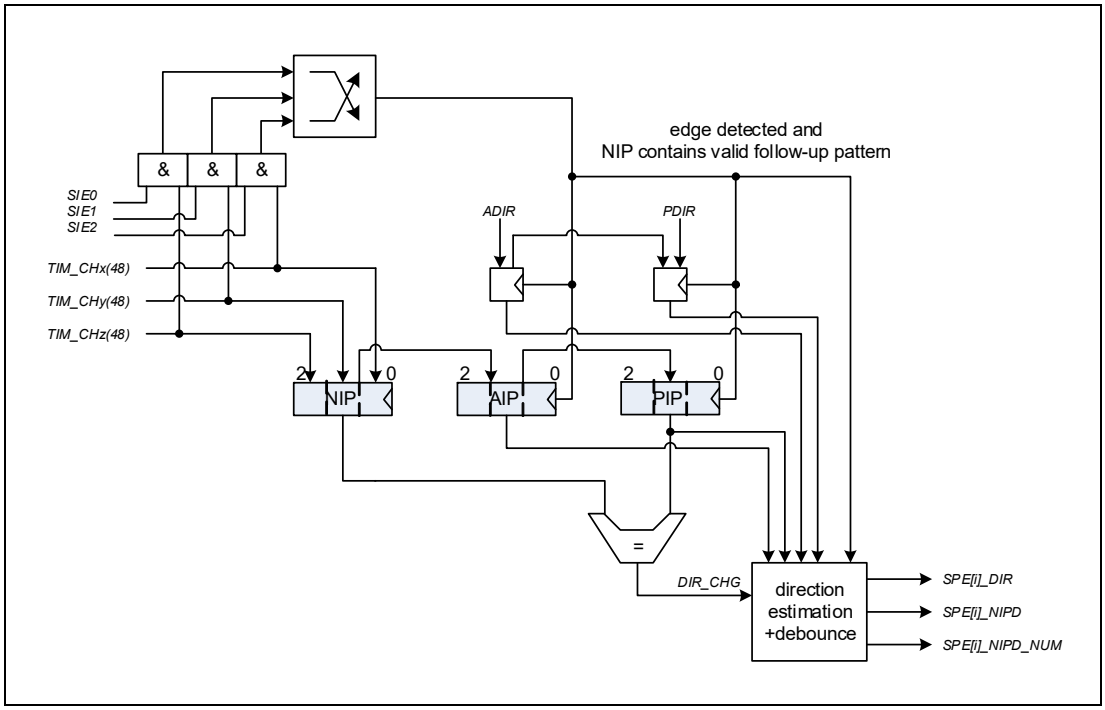

Figure 38.123 SPE[i]_IN_PAT register representation

The CPU can disable one of the three input signals, e.g. when a broken input sensor was detected, by disabling the input with the three input enable bits SIE inside the SPE[i]_CTRL_STAT register.

Whenever at least one of the input signal TIM[i]_CH[x](48), TIM[i]_CH[y](48) or TIM[i]_CH[z](48) changes the SPE sub-module stores the new bit pattern in an internal register NIP (New Input Pattern). If the current input pattern in NIP is the same as in the Previous Input Pattern (PIP) the direction of the engine changed, the SPE[i]_DCHG interrupt is raised, the direction change is stored internally and the pattern in the PIP bit field is filled with the AIP bit field and the AIP bit field is filled with the NIP bit field. The SPE[i]_DIR bit inside the SPE[i]_CTRL_STAT register is toggled and the SPE[i]_DIR signal is changed.

If the SPE encounters that with the next input pattern detected new input pattern NIP the direction change again, the input signal is categorized as bouncing and the bouncing input signal interrupt SPE[i]_BIS is raised.

Immediately after update of register NIP, when the new detected input pattern does not match the PIP pattern (i.e. no direction change was detected), the SPE shifts the value of register AIP to register PIP and the value of register NIP to register AIP. The SPE[i]_NIPD interrupt is raised.

The number of the channel that has been changed and thus leads to the new input pattern is encoded in the signal SPE[i]_NIPD_NUM.

If a sensor error was detected, the CPU has to define upon the pattern in the SPE[i]_CTRL_STAT register, which input line comes from the broken sensor. The faulty signal line has to be masked by the CPU and the SPE sub-module determines the rotation direction on behalf of the two remaining TIM[i]_CH[x] input lines.

The pattern history can be determined by the CPU by reading the two bit fields AIP and PIP of the SPE[i]_CTRL_STAT register. The AIP register field holds the actual detected input pattern at TIM[i]_CH[x](48), TIM[i]_CH[y](48) and TIM[i]_CH[z](48) and the PIP holds the previous detected pattern.

After reset the register NIP, AIP and PIP as well as the register SPE[i]_PAT_PTR and SPE[i]_OUT_CTRL will not contain valid startup values which would allow correct behavior after enabling SPE and detecting the first input patterns. Thus, it is necessary to initialize these register to correct values. To do this, before enabling the SPE, the bit field NIP of register SPE[i]_CTRL_STAT can be read and depending on this value the initialization values for the register AIP, PIP, SPT_PAT_PTR and SPE[i]_OUT_CTRL can be determined.

38.23.2.1 SPE Revolution detection

The SPE sub-module is able to detect and count the number of valid input patterns detected at the specified input ports. This is done with a 24 bit revolution counter SPE_REV_CNT. The counter is incremented by a value of one (1) when a new valid input pattern indicating forward direction is detected. The counter is decremented by a value of one (1) when a new valid input pattern indicating backward direction is detected.

In addition there exists a 24 bit SPE_REV_CMP register. The user can initialize this register with a compare value, where an interrupt SPE[i]_RCMP is raised, when the revolution counter equals the compare value either in forward or backward direction.

Both register may be written by software at any time.

38.23.2.2 SPE Interrupt signals

Signal	Description
SPE[i]_NIPD	SPE New valid input pattern detected.
SPE[i]_DCHG	SPE Rotation direction change detected on behalf of input pattern.
SPE[i]_PERR	SPE Invalid input pattern detected.
SPE[i]_BIS	SPE Bouncing input signal detected at input.
SPE[i]_RCMP	SPE Revolution counter compare value reached.

38.23.3 SPC Configuration Registers Overview

SPC contains following configuration registers:

Table 38.445 Register List

Register name	Description	Details in Section
SPE[i]_CTRL_STAT	SPEi Control status register	**38.23.4.1**
SPE[i]_PAT	SPEi Input pattern definition register.	**38.23.4.2**
SPE[i]_OUT_PAT[z] (z:0...7)	SPEi Output definition register.	**38.23.4.3**
SPE[i]_OUT_CTRL	SPEi output control register	**38.23.4.4**
SPE[i]_REV_CNT	SPEi input revolution counter	**38.23.4.5**
SPE[i]_REV_CMP	SPEi Revolution counter compare value	**38.23.4.6**
SPE[i]_IRQ_NOTIFY	SPEi Interrupt notification register.	**38.23.4.7**
SPE[i]_IRQ_EN	SPEi Interrupt enable register.	**38.23.4.8**
SPE[i]_EIRQ_EN	SPEi Error interrupt enable register.	**38.23.4.9**
SPE[i]_IRQ_FORCINT	SPEi Interrupt generation by software.	**38.23.4.10**
SPE[i]_IRQ_MODE	SPEi Interrupt mode configuration register	**38.23.4.11**
SPE[i]_CTRL_STAT2	SPEi Control status register 2	**38.23.4.12**
SPE[i]_CMD	SPEi Command register	**38.23.4.13**

38.23.4 SPC Configuration Registers Description

38.23.4.1 SPE[i]_CTRL_STAT

Access: This register can be read or written in 32-bit units.

Address: <GTM_base> $80_H \times i + 00800_H$

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	FSOL								ETRIG_SEL	NIP			PDIR	PIP		
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	ADIR	AIP			—	SPE_PAT_PTR			FSOM	TIM_SEL	TRIG_SEL		SIE2	SIE1	SIE0	EN
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 38.446 SPE[i]_CTRL_STAT Register Contents (1/2)

Bit Position	Bit Name	Function
31 to 24	FSOL	Fast Shutoff Level for TOM[i] channel 0 to 7.
23	ETRIG_SEL	Extended trigger selection ETRIG_SEL = 0 TRIG_SEL = 00_B: SPE[i]_NIPD selected TRIG_SEL = 01_B: TOM_CH0_TRIG_CCU0 selected TRIG_SEL = 10_B: TOM_CH0_TRIG_CCU1 selected TRIG_SEL = 11_B: TOM_CH2_TRIG_CCU1 selected ETRIG_SEL = 1 TRIG_SEL = 00_B: TOM_CH6_TRIG_CCU1 selected TRIG_SEL = 01_B: TOM_CH7_TRIG_CCU1 selected TRIG_SEL = 10_B: TOM_CH8_TRIG_CCU1 selected TRIG_SEL = 11_B: TOM_CH9_TRIG_CCU1 selected
22 to 20	NIP	New input pattern that was detected. **NOTE** This bit field mirrors the new input pattern. SPE internal functionality is triggered on each change of this bit field.
19	PDIR	Previous rotation direction. 0: Rotation direction is 0 according to SPE[i]_PAT register. 1: Rotation direction is 1 according to SPE[i]_PAT register.
18 to 16	PIP	Previous input pattern that was detected by a regular input pattern change.
15	ADIR	Actual rotation direction. 0: Rotation direction is 0 according to SPE[i]_PAT register. 1: Rotation direction is 1 according to SPE[i]_PAT register.
14 to 12	AIP	Actual input pattern that was detected by a regular input pattern change.
11	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
10 to 8	SPE_PAT_PTR	Pattern selector for TOM output signals. Actual index into the SPE[i]_OUT_PAT[x] register table. Each register SPE[i]_OUT_PAT[x] is fixed assigned to one bit field IPx_PAT of register SPE[i]_PAT. Thus, the pointer SPE[i]_PAT_PTR represents an index to the selected SPE[i]_OUT_PAT[x] register as well as the actual detected input pattern IPx_PAT. 000_B = SPE[i]_OUT_PAT0 selected.

Table 38.446 SPE[i]_CTRL_STAT Register Contents (2/2)

Bit Position	Bit Name	Function
7	FSOM	Fast Shutoff Mode 0: Fast Shutoff mode disabled. 1: Fast Shutoff mode enabled.
6	TIM_SEL	Select TIM input signal If SPE0 0: TIM0_CH0 to TIM0_CH2 1: TIM1_CH0 to TIM1_CH2 If SPE1 0: TIM0_CH3 to TIM0_CH5 1: TIM1_CH3 to TIM1_CH5 If SPE2 0: TIM2_CH0 to TIM2_CH2 1: TIM3_CH0 to TIM3_CH2 If SPE3 0: TIM2_CH3 to TIM2_CH5 1: TIM3_CH3 to TIM3_CH5 If SPE4 0: TIM4_CH0 to TIM4_CH2 1: TIM5_CH0 to TIM5_CH2 If SPE5 0: TIM4_CH3 to TIM4_CH5 1: TIM5_CH3 to TIM5_CH5
5, 4	TRIG_SEL	Select trigger input signal. ETRIG_SEL = 0 TRIG_SEL = 00_B: SPE[i]_NIPD selected TRIG_SEL = 01_B: TOM_CH0_TRIG_CCU0 selected TRIG_SEL = 10_B: TOM_CH0_TRIG_CCU1 selected TRIG_SEL = 11_B: TOM_CH2_TRIG_CCU1 selected ETRIG_SEL = 1 TRIG_SEL = 00_B: TOM_CH6_TRIG_CCU1 selected TRIG_SEL = 01_B: TOM_CH7_TRIG_CCU1 selected TRIG_SEL = 10_B: TOM_CH8_TRIG_CCU1 selected TRIG_SEL = 11_B: TOM_CH9_TRIG_CCU1 selected **NOTE** In case of ETRIG_SEL=1, according to selected TOM_CH[x]_TRIG_CCU1 signal the configuration bits SPE_TRIG and OSM of register TOM_CH[x]_CTRL have to be set in same TOM channel x to enable the trigger signal generation in one-shot mode.
3 to 1	SIE[2:0]	SPE Input enable for TIM_CHx(48). 0: SPE Input is disabled. 1: SPE Input is enabled. **NOTE** When the input is disabled, a 0 signal is sampled for this input. However, the bit field NIP of this register shows the true value of the input signal.
0	EN	SPE sub-module enable. 0: SPE disabled. 1: SPE enabled.

38.23.4.2 SPE[i]_PAT

Access: This register can be read or written in 32-bit units.

Address: <GTM_base> $80_H \times i + 00804_H$

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	IP7_PAT			IP7_VAL	IP6_PAT			IP6_VAL	IP5_PAT			IP5_VAL	IP4_PAT			IP4_VAL
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 38.447 SPE[i]_PAT Register Contents (1/2)

Bit Position	Bit Name	Function
31 to 29	IP7_PAT	Input pattern 7. See bits 3:1.
28	IP7_VAL	Input pattern 7 is a valid pattern. See bit 0.
27 to 25	IP6_PAT	Input pattern 6. See bits 3:1.
24	IP6_VAL	Input pattern 6 is a valid pattern. See bit 0
23 to 21	IP5_PAT	Input pattern 5. See bits 3:1
20	IP5_VAL	Input pattern 5 is a valid pattern. See bit 0
19 to 17	IP4_PAT	Input pattern 4. See bits 3:1
16	IP4_VAL	Input pattern 4 is a valid pattern. See bit 0
15 to 13	IP3_PAT	Input pattern 3. See bits 3:1
12	IP3_VAL	Input pattern 3 is a valid pattern. See bit 0
11 to 9	IP2_PAT	Input pattern 2. See bits 3:1
8	IP2_VAL	Input pattern 2 is a valid pattern. See bit 0
7 to 5	IP1_PAT	Input pattern 1. See bits 3:1
4	IP1_VAL	Input pattern 1 is a valid pattern. See bit 0
3 to 1	IP0_PAT	Input pattern 0. Bit field defines the first input pattern of the SPE input signals. Bit 1 defines the TIM[i]_CHx(48) input signal. Bit 2 defines the TIM[i]_CHy(48) input signal. Bit 3 defines the TIM[i]_CHz(48) input signal.

Table 38.447 SPE[i]_PAT Register Contents (2/2)

Bit Position	Bit Name	Function
0	IP0_VAL	Input pattern 0 is a valid pattern. 0: Pattern is invalid. 1: Pattern is valid.

NOTE

Only the first block of valid input patterns defines the commutation. All input pattern following the first marked invalid input pattern are ignored.

38.23.4.3 SPE[i]_OUT_PAT[z]

Access: This register can be read or written in 32-bit units.

Address: SPE[i]_OUT_PAT0: <GTM_base> 80_H × i + 00808_H
SPE[i]_OUT_PAT1: <GTM_base> 80_H × i + $0080C_H$
SPE[i]_OUT_PAT2: <GTM_base> 80_H × i + 00810_H
SPE[i]_OUT_PAT3: <GTM_base> 80_H × i + 00814_H
SPE[i]_OUT_PAT4: <GTM_base> 80_H × i + 00818_H
SPE[i]_OUT_PAT5: <GTM_base> 80_H × i + $0081C_H$
SPE[i]_OUT_PAT6: <GTM_base> 80_H × i + 00820_H
SPE[i]_OUT_PAT7: <GTM_base> 80_H × i + 00824_H

Value after reset: $0000\ 0000_H$

	REV_CMP															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 38.451 SPE[i]_REV_CMP Register Contents

Bit Position	Bit Name	Function
31 to 24	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
23 to 0	REV_CMP	Input signal revolution counter compare value The interrupt SPE[i]_RCMP is raised when the SPE[i]_REV_CNT value equals the SPE[i]_REV_CMP register. **NOTES** 1. SPE[i]_RCMP is only raised if an incrementation or decrementation of SPE[i]_REV_CNT is applied, due to an input signal change. 2. Any update of SPE[i]_REV_CNT or SPE[i]_REV_CMP via AEI does not raise a SPE[i]_RCMP interrupt.

38.23.4.7 SPE[i]_IRQ_NOTIFY

Access: This register can be read or written in 32-bit units.

Address: <GTM_base> $80_H \times i + 0082C_H$

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

R/W	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W

Table 38.452 SPE[i]_IRQ_NOTIFY Register Contents (1/2)

Bit Position	Bit Name	Function
31 to 5	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
4	SPE_RCMP	SPE revolution counter match event. 0: No interrupt occurred. 1: New input pattern detected interrupt occurred. **NOTE** This bit will be cleared on a CPU write access of value 1. A read access leaves the bit unchanged.
3	SPE_BIS	Bouncing input signal detected. 0: No interrupt occurred. 1: New input pattern detected interrupt occurred. **NOTE** This bit will be cleared on a CPU write access of value 1. A read access leaves the bit unchanged.
2	SPE_PERR	Wrong or invalid pattern detected at input. 0: No interrupt occurred. 1: New input pattern detected interrupt occurred. **NOTE** This bit will be cleared on a CPU write access of value 1. A read access leaves the bit unchanged.
1	SPE_DCHG	SPE_DIR bit changed on behalf of new input pattern. 0: No interrupt occurred. 1: New input pattern detected interrupt occurred. **NOTE** This bit will be cleared on a CPU write access of value 1. A read access leaves the bit unchanged.

Table 38.452 SPE[i]_IRQ_NOTIFY Register Contents (2/2)

Bit Position	Bit Name	Function
0	SPE_NIPD	New input pattern interrupt occurred. 0: No interrupt occurred. 1: New input pattern detected interrupt occurred. **NOTE** This bit will be cleared on a CPU write access of value 1. A read access leaves the bit unchanged.

38.23.4.8 SPE[i]_IRQ_EN

Access: This register can be read or written in 32-bit units.

Table 38.457 SPE[i]_CTRL_STAT2 Register Contents

Bit Position	Bit Name	Function
31 to 11	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
10 to 8	SPE_PAT_PTR_BWD	Pattern selector for TOM output signals in case of SPE_CTRL_CMD = 01_B (e.g. backward direction). Index into the SPE[i]_OUT_PAT[z] register table in case of SPE_CTRL_CMD = 01_B which may be used for backward direction. Each register SPE[i]_OUT_PAT[x] is fixed assigned to one bit field IPx_PAT of register SPE[i]_PAT. Thus, the pointer SPE[i]_PAT_PTR_BWD represents an index to the selected SPE[i]_OUT_PAT[x] register as well as the actual detected input pattern IPx_PAT. The index pointer SPE_PAT_PTR_BWD is used if SPE_CTRL_CMD = 01_B. The index pointer SPE_PAT_PTR is used if SPE_CTRL_CMD = 00_B (by default). 000_B = SPE[i]_OUT_PAT0 selected.
7 to 0	Reserved	When read, the value after reset is returned. When writing, write the value after reset.

38.23.4.13 SPE[i]_CMD

Access: This register can be read or written in 32-bit units.

Address: <GTM_base> $80_H \times i + 0084C_H$

Value after reset: $0000\ 0000_H$

R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W

Table 38.458 SPE[i]_CMD Register Contents

Bit Position	Bit Name	Function
31 to 17	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
16	SPE_UPD_TRIG	SPE updater trigger 0: No operation 1: Trigger update of SPE_OUT_CTRL with register selected by CTR_CMD multiplexer. **NOTE** This bit is automatically reset to 0.
15 to 2	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
1, 0	SPE_CTRL_CMD	SPE control command 00_B: Use SPE_PAT_PTR as an index pointer to select SPE[i]_OUT_PAT[z] 01_B: Use SPE_PAT_PTR_BWD as an index pointer to select SPE[i]_OUT_PAT[z] 10_B: Select SPE[i]_OUT_PAT6 11_B: Select SPE[i]_OUT_PAT7 **NOTE** On switch between 00_B and 01_B the direction flag will be set according to used pointer.

38.24 Interrupt Concentrator Module (ICM)

38.24.1 Overview

The Interrupt Concentrator Module (ICM) is used to bundle the GTM-IP interrupt lines of the individual sub-modules in a reasonable manner into interrupt groups. By this bundling a smaller amount of interrupt lines is visible at the outside of the GTM-IP.

The individual interrupts of the GTM-IP sub-modules and channels have to be enabled or disabled inside the sub-modules and channels.

The feed through architecture of bundled interrupt lines is used for the sub-modules AEI, ARU, BRC, CMP, SPE, PSM, TIM, DPLL, TOM, ATOM and MCS.

To determine the detailed interrupt source the microcontroller has to read the sub-module/channel interrupt notification register NOTIFY and serve the channel individual interrupt.

NOTE

The interrupts are only visible inside the ICM and in consequence outside of the GTM-IP, when the interrupt is enabled inside the sub-modules themselves.

38.24.2 Bundling

The GTM-IP sub-module individual interrupt sources are connected to the ICM. There, the individual interrupt lines are either feed through and signaled to the outside world or bundled a second time into groups and are then signaled to the outside world.

The ICM interrupt bundling is described in the following sections.

38.24.2.1 GTM Infrastructure Interrupt Bundling

The first interrupt group contains interrupts of the infrastructure and safety components of the GTM. This interrupt group includes therefore interrupt lines coming from the AEI, ARU, BRC, PSM, SPE and CMP sub-modules. In this interrupt group each individual channel of the sub-modules has its own interrupt line to the outside world.

Thus, the active interrupt line can be used by the CPU to determine the GTM-IP sub-module channel that raised the interrupt. The interrupts are also represented in the ICM_IRQG_0 register. This register is typically not read by the CPU, but it is readable.

In addition the interrupt line status for 8 channels of each FIFO are shown in the ICM_IRQG_PSM_0_CI register. Typically, the interrupt source is determined by the corresponding interrupt line and the ICM_IRQG_PSM_0_CI register are typically not read out by the CPU, but they are readable.

In addition the interrupt line status for each SPE are shown in the ICM_IRQG_SPE_CI register. Typically, the interrupt source is determined by the corresponding interrupt line and the ICM_IRQG_SPE_CI register are typically not read out by the CPU, but they are readable.

38.24.2.2 DPLL Interrupt Bundling

The DPLL Interrupt group handles the interrupts coming from the DPLL sub-module of the GTM-IP. Each of the individual DPLL interrupt lines has its own dedicated interrupt line to the outside world. The interrupts are additionally identified in the ICM_IRQG_1 interrupt group register. This register is typically not read out by the CPU, but it is readable.

38.24.2.3 TIM Interrupt Bundling

Inside this group sub-modules which handle GTM-IP input signals are treated. This is the case for the TIM[i] sub-modules. Each TIM sub-module channel is able to generate 6 individual interrupts if enabled inside the TIM channel. These six interrupts are bundled into one interrupt per TIM channel connected to the ICM.

The ICM does no further bundling. Thus, for the GTM-IP 32 interrupt lines TIM[i]_IRQ[y] are provided for the external microcontroller. The channel responsible for the interrupt can be determined by the raised interrupt line.

In addition, the registers ICM_IRQG_2 and ICM_IRQG_3 are mirrors for the TIM sub-module channel interrupts and typically not read out by the CPU, but they are readable.

38.24.2.4 MCS Interrupt Bundling

For complex signal output generation, the MCS sub-modules are used inside the GTM-IP. Each of these MCS sub-modules could have 8 channels with one interrupt line. This interrupt line is connected to the ICM sub-module and is feed through directly to the outside world.

In addition the interrupt line status for the first 8 channels of each MCS is shown in the ICM_IRQG_4 and ICM_IRQG_5 register. The interrupt line status for all used channels of each MCS are shown in the ICM_IRQG_MCS[i]_CI register. Typically, the interrupt source is determined by the corresponding interrupt line and the ICM_IRQ4(/_5) and ICM_IRQG_MCS[i]_CI register are typically not read out by the CPU, but they are readable.

38.24.2.5 TOM and ATOM Interrupt Bundling

For the TOM and ATOM sub-modules, the interrupts are bundled within the ICM sub-module a second time to reduce external interrupt lines. The interrupts are ORed in a manner that one GTM-IP external interrupt line represents two adjacent TOM or ATOM channel interrupts.

For TOM[i] and ATOM[i] the bundling is shown in **Table 38.459**.

Table 38.459 TOM[i] and ATOM[i] the bundling within ICM

TOM[i]-input IRQs	TOM-output IRQs (ORed)	ATOM[i]-input IRQs	ATOM-output IRQs (ORed)
[i]=0..number of TOM's-1		[i]=0..number of ATOM's-1	
TOM[i]_CH0_IRQ	GTM_TOM[i]_IRQ[0]	ATOM[i]_CH0_IRQ	GTM_ATOM[i]_IRQ[0]
TOM[i]_CH1_IRQ		ATOM[i]_CH1_IRQ	
TOM[i]_CH2_IRQ	GTM_TOM[i]_IRQ[1]	ATOM[i]_CH2_IRQ	GTM_ATOM[i]_IRQ[1]
TOM[i]_CH3_IRQ		ATOM[i]_CH3_IRQ	
TOM[i]_CH4_IRQ	GTM_TOM[i]_IRQ[2]	ATOM[i]_CH4_IRQ	GTM_ATOM[i]_IRQ[2]
TOM[i]_CH5_IRQ		ATOM[i]_CH5_IRQ	
TOM[i]_CH6_IRQ	GTM_TOM[i]_IRQ[3]	ATOM[i]_CH6_IRQ	GTM_ATOM[i]_IRQ[3]
TOM[i]_CH7_IRQ		ATOM[i]_CH7_IRQ	
TOM[i]_CH8_IRQ	GTM_TOM[i]_IRQ[4]		
TOM[i]_CH9_IRQ			
TOM[i]_CH10_IRQ	GTM_TOM[i]_IRQ[5]		
TOM[i]_CH11_IRQ			
TOM[i]_CH12_IRQ	GTM_TOM[i]_IRQ[6]		
TOM[i]_CH13_IRQ			
TOM[i]_CH14_IRQ	GTM_TOM[i]_IRQ[7]		
TOM[i]_CH15_IRQ			

The interrupts coming from the TOM[i] sub-modules are registered in the ICM_IRQG_6/ ICM_IRQG_7/ICM_IRQG_8 register. Always two TOM's are bundled in one ICM register, TOM0 and TOM1 are bundled in ICM_IRQG_6. To identify the TOM sub-module channel where the interrupt occurred, the CPU has to read out the ICM_IRQG_6(/_7/_8) register first before it goes to the TOM sub-module channel itself.

The ICM_IRQG_6(/_7/_8) register bits are cleared automatically, when their corresponding interrupt in the sub-module channels is cleared.

The interrupts coming from the ATOM[i] sub-modules are registered in the ICM_IRQG_9/ ICM_IRQG_10/ICM_IRQG_11 register. Always four ATOM's are bundled in one ICM register. ATOM0, ATOM1, ATOM2 and ATOM3 are bundled in ICM_IRQG_9. To identify the ATOM sub-module channel where the interrupt occurred, the CPU has to read out the ICM_IRQG_9(/_10/_11) register first before it goes to the ATOM sub-module channel itself.

The ICM_IRQG_9(/_10/_11) register bits are cleared automatically, when their corresponding interrupt in the sub-module channels is cleared.

In addition the interrupt line status of two 16 channels TOM are shown in each ICM_IRQG_TOM_[k]_CI (k:0 to 2) register, TOM0 and TOM1 are bundled in ICM_IRQG_TOM_0_CI. Typically, the interrupt source is determined by the corresponding interrupt line and the ICM_IRQG_TOM_[k]_CI registers are typically not read out by the CPU, but they are readable.

In addition the interrupt line status of four 8 channels ATOM are shown in each ICM_IRQG_ATOM_[k]_CI (k: 0 to 2) register, ATOM0, ATOM1, ATOM2 and ATOM3 are bundled in ICM_IRQG_ATOM_0_CI. Typically, the interrupt source is determined by the corresponding interrupt line and the ICM_IRQG_ATOM_[k]_CI registers are typically not read out by the CPU, but they are readable.

38.24.2.6 Module Error Interrupt Bundling

The Module Error Interrupt group handles the error interrupts coming from the BRC, FIFO, TIM, MCS, SPE, CMP, DPLL sub-module of the GTM-IP. The Module Error interrupts are additionally identified in the ICM_IRQG_MEI error interrupt group register. This register is typically not read out by the CPU, but it is readable.

In addition, the error interrupt line status for each SPE is shown in the ICM_IRQG_SPE_CEI register. Typically, the error interrupt source is determined by the corresponding interrupt line and the ICM_IRQG_SPE_CEI register are typically not read out by the CPU, but they are readable.

38.24.2.7 FIFO Channel Error Interrupt Bundling

The FIFO Channel Error Interrupt group handles the error interrupts coming from the FIFO channel of the GTM-IP. The FIFO Channel Error interrupts are additionally identified in the ICM_IRQG_CEI0 error interrupt group register. This register is typically not read out by the CPU, but it is readable.

The ICM_IRQG_CEI0 register bits are cleared automatically, when their corresponding error interrupt in the sub-module channel is cleared.

In addition the error interrupt line status for 8 channels of each FIFO are shown in the ICM_IRQG_PSM_0_CEI register. Typically, the error interrupt source is determined by the corresponding interrupt line and the ICM_IRQG_PSM_0_CEI register are typically not read out by the CPU, but they are readable.

38.24.2.8 TIM Channel Error Interrupt Bundling

The TIM Channel Error Interrupt group handles the error interrupts coming from the TIM channel of the GTM-IP. The TIM Channel Error interrupts are additionally identified for the sub-modules TIM0, TIM1, TIM2 and TIM3 in the ICM_IRQG_CEI1 error interrupt group register and for the sub-modules TIM4, TIM5 and TIM6 in the ICM_IRQG_CEI2 error interrupt group register. These register are typically not read out by the CPU, but they are readable.

The ICM_IRQG_CEI1 and ICM_IRQG_CEI2 register bits are cleared automatically, when their corresponding error interrupt in the sub-module channel is cleared.

38.24.2.9 MCS Channel Error Interrupt Bundling

The MCS Channel Error Interrupt group handles the error interrupts coming from the MCS channel of the GTM-IP. All used 8 MCS Channel Error interrupts are additionally identified for each sub-modules MCS[i] in the ICM_IRQG_MCS[i]_CEI error interrupt group register. The first 8 MCS Channel Error interrupts are additionally identified for the sub-modules MCS0, MCS1, MCS2 and MCS3 in the ICM_IRQG_CEI3 error interrupt group register and for the sub-modules MCS4, MCS5, MCS6 and MCS7 in the ICM_IRQG_CEI4 error interrupt group register. These register are typically not read out by the CPU, but they are readable.

The ICM_IRQG_MCS[i]_CEI, ICM_IRQG_CEI3 and ICM_IRQG_CEI4 register bits are cleared automatically, when their corresponding error interrupt in the sub-module channel is cleared.

38.24.2.10 Error Interrupt Cluster Bundling

The Error Interrupt lines of up to 4 clusters are bundled in each ICM_IRQG_CLS_[i]_MEI. Actually each cluster collects one EIRQ of one TIM, MCS, SPE and FIFO. These register are typically not read out by the CPU, but they are readable.

38.24.3 ICM Interrupt Signals

Above table shows the GTM-IP interrupt lines that are visible at the outside of the IP.

Table 38.460 ICM interrupt Signals

Signal	Description
GTM_AEI_IRQ	AEI Shared interrupt
GTM_ARU_IRQ[2:0]	[0]: ARU_NEW_DATA0 Interrupt [1]: ARU_NEW_DATA1 Interrupt [2]: ARU_ACC_ACK Interrupt
GTM_BRC_IRQ	BRC Shared interrupt
GTM_CMP_IRQ	CMP Shared interrupt
GTM_SPE[i]_IRQ	SPE Shared interrupt (i: 0..number of SPE's-1)
GTM_PSM[i]_IRQ[x]	PSM Shared interrupts (x: 0…7) (i: 0..number of PSM's-1)
GTM_DPLL_IRQ[0]	*DPLL_DCGI:* DPLL direction change interrupt
GTM_DPLL_IRQ[1]	*DPLL_EDI;* DPLL enable or disable interrupt
GTM_DPLL_IRQ[2]	*DPLL_TINI:* DPLL *TRIG.* min. hold time (THMI) viol. detected
GTM_DPLL_IRQ[3]	*DPLL_TAXI:* DPLL *TRIG.* max. hold time (THMA) viol. detected
GTM_DPLL_IRQ[4]	*DPLL_SISI:* DPLL *STATE* inactive slope detected
GTM_DPLL_IRQ[5]	*DPLL_TISI:* DPLL *TRIGGER* inactive slope detected
GTM_DPLL_IRQ[6]	*DPLL_MSI:* DPLL Missing *STATE* interrupt
GTM_DPLL_IRQ[7]	*DPLL_MTI:* DPLL Missing *TRIGGER* interrupt
GTM_DPLL_IRQ[8]	*DPLL_SASI:* DPLL *STATE* active slope detected
GTM_DPLL_IRQ[9]	*DPLL_TASI:* DPLL *TRIG.* active slope det. while NTI_CNT is 0
GTM_DPLL_IRQ[10]	*DPLL_PWI:* DPLL Plausibility window (PVT) viol. int. of *TRIG.*
GTM_DPLL_IRQ[11]	*DPLL_W2I:* DPLL Write access to RAM region 2 interrupt
GTM_DPLL_IRQ[12]	*DPLL_W1I:* DPLL Write access to RAM region 1b or 1c int.
GTM_DPLL_IRQ[13]	*DPLL_GL1I:* DPLL Get of lock interrupt for *SUB_INC1*
GTM_DPLL_IRQ[14]	*DPLL_LL1I:* DPLL Lost of lock interrupt for *SUB_INC1*
GTM_DPLL_IRQ[15]	*DPLL_EI:* DPLL Error interrupt
GTM_DPLL_IRQ[16]	*DPLL_GL2I:* DPLL Get of lock interrupt for *SUB_INC2*
GTM_DPLL_IRQ[17]	*DPLL_LL2I:* DPLL Lost of lock interrupt for *SUB_INC2*
GTM_DPLL_IRQ[18]	*DPLL_TE0I:* DPLL *TRIGGER* event interrupt 0
GTM_DPLL_IRQ[19]	*DPLL_TE1I:* DPLL *TRIGGER* event interrupt 1
GTM_DPLL_IRQ[20]	*DPLL_TE2I:* DPLL *TRIGGER* event interrupt 2
GTM_DPLL_IRQ[21]	*DPLL_TE3I:* DPLL *TRIGGER* event interrupt 3
GTM_DPLL_IRQ[22]	*DPLL_TE4I;* DPLL *TRIGGER* event interrupt 4
GTM_DPLL_IRQ[23]	*DPLL_CDTI;* DPLL calculated duration interrupt for *TRIGGER*
GTM_DPLL_IRQ[24]	*DPLL_CDSI;* DPLL calculated duration interrupt for *STATE*
GTM_DPLL_IRQ[25]	*DPLL_TORI; TRIGGER* out of range interrupt
GTM_DPLL_IRQ[26]	*DPLL_SORI; STATE* out of range interrupt
GTM_TIM[i]_IRQ[x]	TIM Shared interrupts (i: 0..number of TIM's-1) (x: 0..7)
GTM_MCS[i]_IRQ[x]	MCS Interrupt for channel x (x: 0…8) (i: 0..number of MCS's-1)
GTM_TOM[i]_IRQ[x]	TOM Shared interrupts for x:0..7 = {ch0||ch1,...,ch14||ch15} (i: 0..number of TOM's-1)
GTM_ATOM[i]_IRQ[x]	ATOM Shared interrupts for x:0..3 = {ch0||ch1,...,ch6||ch7} (i: 0..number of ATOM's-1)
GTM_ERR_IRQ	GTM Error Interrupt

38.24.4 ICM Configuration Registers Overview

ICM contains following configuration registers:

Table 38.461 Register list (1/2)

Symbol	Register Name	Details in Section
ICM_IRQG_0	ICM Interrupt group register covering infrastructural and safety components (ARU, BRC, AEI, PSM0, PSM1, MAP, CMP,SPE)	**38.24.5.1**
ICM_IRQG_1	ICM Interrupt group register covering DPLL	**38.24.5.2**
ICM_IRQG_2	ICM Interrupt group register covering TIM0, TIM1, TIM2, TIM3	**38.24.5.3**
ICM_IRQG_3	ICM Interrupt group register covering TIM4, TIM5, TIM6, TIM7	**38.24.5.4**
ICM_IRQG_4	ICM Interrupt group register covering MCS0 to MCS3 sub-modules	**38.24.5.5**
ICM_IRQG_5	ICM Interrupt group register covering MCS4 to MCS6 sub-modules	**38.24.5.6**
ICM_IRQG_6	ICM Interrupt group register covering GTM-IP output sub-modules TOM0 to TOM1	**38.24.5.7**
ICM_IRQG_7	ICM Interrupt group register covering GTM-IP output sub-modules TOM2 to TOM3	**38.24.5.8**
ICM_IRQG_8	ICM Interrupt group register covering GTM-IP output sub-modules TOM4 to TOM5	**38.24.5.9**
ICM_IRQG_9	ICM Interrupt group register covering GTM-IP output sub-modules ATOM0 to ATOM3	**38.24.5.10**
ICM_IRQG_10	ICM Interrupt group register covering GTM-IP output sub-modules ATOM4 to ATOM7	**38.24.5.11**
ICM_IRQG_11	ICM Interrupt group register covering GTM-IP output sub-modules ATOM8 to ATOM11	**38.24.5.12**
ICM_IRQG_MEI	ICM Interrupt group register for module error interrupt information	**38.24.5.13**
ICM_IRQG_CEI0	ICM Interrupt group register 0 for channel error interrupt information	**38.24.5.14**
ICM_IRQG_CEI1	ICM Interrupt group register 1 for channel error interrupt information	**38.24.5.15**
ICM_IRQG_CEI2	ICM Interrupt group register 2 for channel error interrupt information	**38.24.5.16**
ICM_IRQG_CEI3	ICM Interrupt group register 3 for channel error interrupt information	**38.24.5.17**
ICM_IRQG_CEI4	ICM Interrupt group register 4 for channel error interrupt information	**38.24.5.18**
ICM_IRQG_MCS[i]_CI	ICM Interrupt group MCS i for Channel Interrupt information	**38.24.5.19**
ICM_IRQG_MCS[i]_CEI	ICM Interrupt group MCS i for Channel Error Interrupt information	**38.24.5.20**
ICM_IRQG_SPE_CI	ICM Interrupt group SPE for module Interrupt information	**38.24.5.21**
ICM_IRQG_SPE_CEI	ICM Interrupt group SPE for module Error Interrupt information	**38.24.5.22**
ICM_IRQG_PSM_0_CI	ICM Interrupt group PSM 0 for Channel Interrupt information of FIFO0, FIFO1, FIFO2	**38.24.5.23**
ICM_IRQG_PSM_1_CI	ICM Interrupt group PSM 0 for Channel Error Interrupt information of FIFO0, FIFO1, FIFO2	**38.24.5.24**

Table 38.461 Register list (2/2)

Symbol	Register Name	Details in Section
ICM_IRQG_TOM_[g]_CI	ICM Interrupt group TOM g for Channel Interrupt information of TOMm (m=2*g+(0 to 1))	**38.24.5.25**
ICM_IRQG_ATOM_[g]_CI	ICM Interrupt group ATOM g for Channel Interrupt information of ATOMm (m=4*g+(0 to 3))	**38.24.5.26**
ICM_IRQG_CLS_[g]_MEI	ICM Interrupt group for module Error Interrupt information for each TIMm, MCSm, SPEm, FIFOm (m=4*g+(0 to 3))	**38.24.5.27**

38.24.5 ICM Configuration Registers Description

38.24.5.1 ICM_IRQG_0

Access: This register is a read-only register that can be read in 32-bit units.

Address: <GTM_base> + 00600_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	PSM1_CH7_IRQ	PSM1_CH6_IRQ	PSM1_CH5_IRQ	PSM1_CH4_IRQ	PSM1_CH3_IRQ	PSM1_CH2_IRQ	PSM1_CH1_IRQ	PSM1_CH0_IRQ	PSM0_CH7_IRQ	PSM0_CH6_IRQ	PSM0_CH5_IRQ	PSM0_CH4_IRQ	PSM0_CH3_IRQ	PSM0_CH2_IRQ	PSM0_CH1_IRQ	PSM0_CH0_IRQ
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	SPE5_IRQ	SPE4_IRQ	SPE3_IRQ	SPE2_IRQ	SPE1_IRQ	SPE0_IRQ	CMP_IRQ	AEI_IRQ	BRC_IRQ	ARU_ACC_ACK_IRQ	ARU_NEW_DATA1_IRQ	ARU_NEW_DATA0_IRQ
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 38.462 ICM_IRQG_0 Register Contents (1/2)

Bit Position	Bit Name	Function
31 to 24	PSM1_CH[k]_IRQ	PSM1 shared sub-module channel k interrupt. 0: No interrupt occurred. 1: Interrupt was raised by the corresponding sub-module. **NOTE** Set this bit represents an OR function of the four interrupt sources FIFO_EMPTY, FIFO_FULL, FIFO_LOWER_WM or FIFO_UPPER_WM of FIFO instance 0 channel 0.
23 to 16	PSM0_CH[k]_IRQ	PSM0 shared sub-module channel k interrupt. 0: No interrupt occurred. 1: Interrupt was raised by the corresponding sub-module. **NOTE** Set this bit represents an OR function of the four interrupt sources FIFO_EMPTY, FIFO_FULL, FIFO_LOWER_WM or FIFO_UPPER_WM of FIFO instance 0 channel 0.
15 to 12	Reserved	When read, the value after reset is returned.
11 to 6	SPE[k]_IRQ	SPE[k] shared sub-module interrupt. 0: No interrupt occurred. 1: Interrupt was raised by the corresponding sub-module. **NOTE** Set this bit represents an OR function of the five interrupt sources SPE_NIPD, SPE_DCHG, SPE_PERR, SPE_BIS or SPE_RCMP of SPE instance 0.
5	CMP_IRQ	CMP shared sub-module interrupt. 0: No interrupt occurred. 1: Interrupt was raised by the corresponding sub-module.

Table 38.462 ICM_IRQG_0 Register Contents (2/2)

Bit Position	Bit Name	Function
4	AEI_IRQ	AEI_IRQ interrupt. 0: No interrupt occurred. 1: Interrupt was raised by the corresponding sub-module. **NOTE** Set this bit represents an OR function of the interrupt sources AEI_TO_XPT, AEI_USP_ADDR, AEI_IM_ADDR, AEI_USP_BE, AEIM_USP_ADDR, AEIM_IM_ADDR, AEIM_USP_BE, CLK_EN_ERR or CLK_PER_ERR.
3	BRC_IRQ	BRC shared sub-module interrupt. 0: No interrupt occurred. 1: Interrupt was raised by the corresponding sub-module.
2	ARU_ACC_ACK_IRQ	ARU_ACC_ACK interrupt. 0: No interrupt occurred. 1: Interrupt was raised by the corresponding sub-module.
1	ARU_NEW_DATA1_IRQ	ARU_NEW_DATA1 interrupt. 0: No interrupt occurred. 1: Interrupt was raised by the corresponding sub-module.
0	ARU_NEW_DATA0_IRQ	ARU_NEW_DATA0 interrupt 0: No interrupt occurred. 1: Interrupt was raised by the corresponding sub-module. **NOTE** This bit is only set, when the interrupt is enabled in the interrupt enable register of the corresponding sub-module.

38.24.5.2 ICM_IRQG_1

Access: This register is a read-only register that can be read in 32-bit units.

Address: <GTM_base> + 00604_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	DPLL_SORI_IRQ	DPLL_TORI_IRQ	DPLL_CDSI_IRQ	DPLL_CDTI_IRQ	DPLL_TE4I_IRQ	DPLL_TE3I_IRQ	DPLL_TE2I_IRQ	DPLL_TE1I_IRQ	DPLL_TE0I_IRQ	DPLL_LL2I_IRQ	DPLL_GL2I_IRQ
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 38.463 ICM_IRQG_1 Register Contents (1/3)

Bit Position	Bit Name	Function
31 to 27	Reserved	When read, the value after reset is returned.
26	DPLL_SORI_IRQ	DPLL calculated duration interrupt for state. 0: No interrupt occurred 1: Interrupt was raised by the corresponding sub-module
25	DPLL_TORI_IRQ	DPLL calculated duration interrupt for state. 0: No interrupt occurred 1: Interrupt was raised by the corresponding sub-module
24	DPLL_CDSI_IRQ	DPLL calculated duration interrupt for state. 0: No interrupt occurred 1: Interrupt was raised by the corresponding sub-module
23	DPLL_CDTI_IRQ	DPLL calculated duration interrupt for trigger. 0: No interrupt occurred 1: Interrupt was raised by the corresponding sub-module
22	DPLL_TE4I_IRQ	TRIGGER event interrupt 4. 0: No interrupt occurred 1: Interrupt was raised by the corresponding sub-module
21	DPLL_TE3I_IRQ	TRIGGER event interrupt 3. 0: No interrupt occurred 1: Interrupt was raised by the corresponding sub-module
20	DPLL_TE2I_IRQ	TRIGGER event interrupt 2. 0: No interrupt occurred 1: Interrupt was raised by the corresponding sub-module
19	DPLL_TE1I_IRQ	TRIGGER event interrupt 1. 0: No interrupt occurred 1: Interrupt was raised by the corresponding sub-module
18	DPLL_TE0I_IRQ	TRIGGER event interrupt 0. 0: No interrupt occurred 1: Interrupt was raised by the corresponding sub-module
17	DPLL_LL2I_IRQ	Lost of lock interrupt for SUB_INC2. 0: No interrupt occurred 1: Interrupt was raised by the corresponding sub-module
16	DPLL_GL2I_IRQ	Get of lock interrupt for SUB_INC2. 0: No interrupt occurred 1: Interrupt was raised by the corresponding sub-module

Table 38.463 ICM_IRQG_1 Register Contents (2/3)

Bit Position	Bit Name	Function
15	DPLL_EI_IRQ	Error interrupt 0: No interrupt occurred 1: Interrupt was raised by the corresponding sub-module
14	DPLL_LL1I_IRQ	Lost of lock interrupt for SUB_INC1. 0: No interrupt occurred 1: Interrupt was raised by the corresponding sub-module
13	DPLL_GL1I_IRQ	Get of lock interrupt for SUB_INC1. 0: No interrupt occurred 1: Interrupt was raised by the corresponding sub-module
12	DPLL_W1I_IRQ	Write access to RAM region 1b or 1c interrupt. 0: No interrupt occurred 1: Interrupt was raised by the corresponding sub-module
11	DPLL_W2I_IRQ	Write access to RAM region 2 interrupt. 0: No interrupt occurred 1: Interrupt was raised by the corresponding sub-module
10	DPLL_PWI_IRQ	Plausibility window (PVT) violation interrupt of TRIGGER. 0: No interrupt occurred 1: Interrupt was raised by the corresponding sub-module
9	DPLL_TASI_IRQ	TRIGGER active slope detected while NTI_CNT is zero. 0: No interrupt occurred 1: Interrupt was raised by the corresponding sub-module
8	DPLL_SASI_IRQ	STATE active slope detected. 0: No interrupt occurred 1: Interrupt was raised by the corresponding sub-module
7	DPLL_MTI_IRQ	Missing TRIGGER interrupt. 0: No interrupt occurred 1: Interrupt was raised by the corresponding sub-module
6	DPLL_MSI_IRQ	Missing STATE interrupt. 0: No interrupt occurred 1: Interrupt was raised by the corresponding sub-module
5	DPLL_TISI_IRQ	TRIGGER inactive slope detected interrupt. 0: No interrupt occurred 1: Interrupt was raised by the corresponding sub-module
4	DPLL_SISI_IRQ	STATE inactive slope detected interrupt 0: No interrupt occurred 1: Interrupt was raised by the corresponding sub-module
3	DPLL_TAXI_IRQ	TRIGGER maximum hold time (THMA) violation detected interrupt. 0: No interrupt occurred 1: Interrupt was raised by the corresponding sub-module
2	DPLL_TINI_IRQ	TRIGGER minimum hold time (THMI) violation detected interrupt. 0: No interrupt occurred 1: Interrupt was raised by the corresponding sub-module
1	DPLL_EDI_IRQ	DPLL enable/disable interrupt. 0: No interrupt occurred 1: Interrupt was raised by the corresponding sub-module **NOTE** Set this bit represents an OR function of the two interrupt sources DPLL_PDI or DPLL_PEI.

Table 38.463 ICM_IRQG_1 Register Contents (3/3)

Bit Position	Bit Name	Function
0	DPLL_DCGI_IRQ	TRIGGER direction change detected. 0: No interrupt occurred 1: Interrupt was raised by the corresponding sub-module **NOTE** This bit is only set, when the interrupt is enabled in the interrupt enable register of the corresponding sub-module.

38.24.5.3 ICM_IRQG_2

Access: This register is a read-only register that can be read in 32-bit units.

Address: <GTM_base> + 00608_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

8	TIM_M1_EIRQ	Error interrupt TIM1_EIRQ. See bit 0.
7 to 4	Reserved	When read, the value after reset is returned.
3	FIFO_M0_EIRQ	Error interrupt FIFO0_EIRQ. See bit 0.
2	SPE_M0_EIRQ	Error interrupt SPE0_EIRQ. See bit 0.
1	MCS_M0_EIRQ	Error interrupt MCS0_EIRQ. See bit 0.
0	TIM_M0_EIRQ	Error interrupt TIM0_EIRQ. 0: No error interrupt occurred. 1: Error interrupt was raised by the corresponding sub-module. **NOTE** This bit is only set, when the error interrupt is enabled in the error interrupt enable register of the corresponding sub-module.

38.25 Output Compare Unit (CMP)

38.25.1 Overview

The Output Compare Unit (CMP) is designed for the use in safety relevant applications. The main idea is to have the possibility to duplicate outputs in order to be compared in this unit. Because of the simple EXOR function used it is necessary to ensure the total cycle accurate output behavior of the output modules to be compared. This is given when two neighbored DTM channel (CDTM[n]_DTM[2*i] and CDTM[n]_-DTM[2*i+1]) generate identical signals with phase shift zero at their outputs. This can be reached if they start their output generation at the same time. This start of synchronization is possible by means of the trigger mechanisms TRIG_x provided by the TOM or ATOM as shown in **Section 38.16, Timer Output Module (TOM)** or **Section 38.17, ARU-connected Timer Output Module (ATOM)**. It is not necessary to compare each output channel with each other.

The CMP enables the comparison of 2×24 channels of the CDTM0, CDTM1 and CDTM2 and is restricted to neighbored channels. The first 24 CMP channels are the first 24 DTM channels placed behind TOM0 and TOM1 and the second 24 CMP channels are the first 24 DTM channels placed behind the ATOM0, ATOM1 and ATOM2.

NOTE

When the channels were generated with a higher frequency than the frequency of cluster 1 it is not certain to catch the interrupt in the notify register. Avoid a comparison if frequency is unequal cluster 1 AND (cluster 0 OR cluster 2).

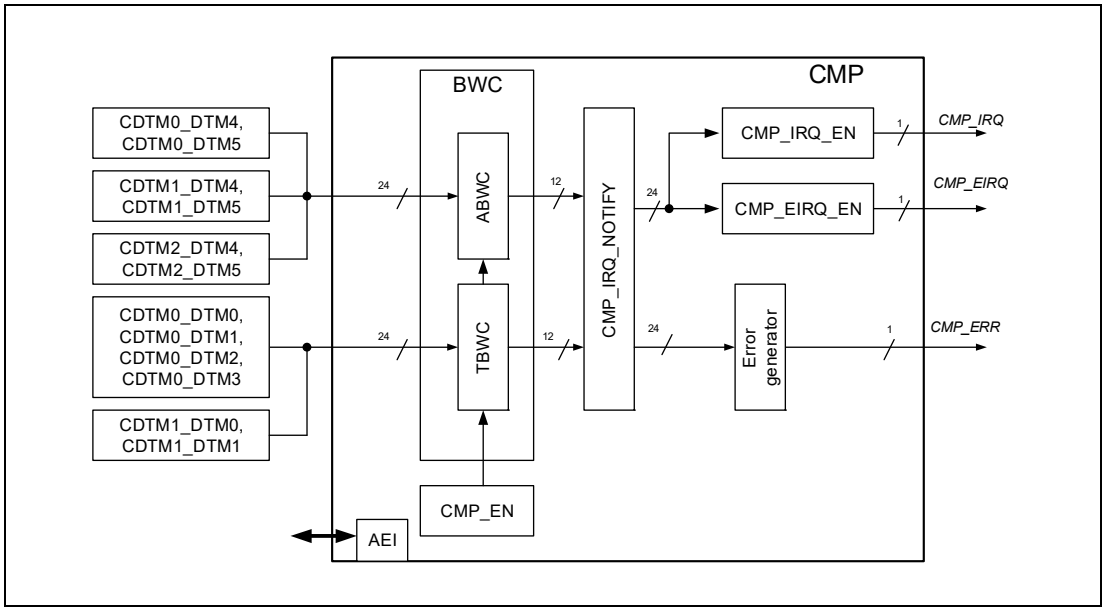

Figure 38.124 Architecture of the Compare Unit

38.25.2 Bitwise Compare Unit (BWC)

The Bitwise Compare Unit ABWC compares in pairs the combinations shown in following table.

Table 38.489 ABWC Compare Unit(1)

ABWC Comparator	Comparator Input 1	Comparator Input 2
ABWC0	CDTM0_DTM4_CH0_OUT	CDTM0_DTM4_CH1_OUT
ABWC1	CDTM0_DTM4_CH2_OUT	CDTM0_DTM4_CH3_OUT
ABWC2	CDTM0_DTM5_CH0_OUT	CDTM0_DTM5_CH1_OUT
ABWC3	CDTM0_DTM5_CH2_OUT	CDTM0_DTM5_CH3_OUT
ABWC4	CDTM1_DTM4_CH0_OUT	CDTM1_DTM4_CH1_OUT
ABWC5	CDTM1_DTM4_CH2_OUT	CDTM1_DTM4_CH3_OUT
ABWC6	CDTM1_DTM5_CH0_OUT	CDTM1_DTM5_CH1_OUT
ABWC7	CDTM1_DTM5_CH2_OUT	CDTM1_DTM5_CH3_OUT
ABWC8	CDTM2_DTM4_CH0_OUT	CDTM2_DTM4_CH1_OUT
ABWC9	CDTM2_DTM4_CH2_OUT	CDTM2_DTM4_CH3_OUT
ABWC10	CDTM2_DTM5_CH0_OUT	CDTM2_DTM5_CH1_OUT
ABWC11	CDTM2_DTM5_CH2_OUT	CDTM2_DTM5_CH3_OUT

The Bitwise Compare Unit TBWC compares in pairs the combinations shown in following table.

Table 38.490 TBWC compare unit

TBWC Comparator	Comparator Input 1	Comparator Input 2
TBWC0	CDTM0_DTM0_CH0_OUT	CDTM0_DTM0_CH1_OUT
TBWC1	CDTM0_DTM0_CH2_OUT	CDTM0_DTM0_CH3_OUT
TBWC2	CDTM0_DTM1_CH0_OUT	CDTM0_DTM1_CH1_OUT
TBWC3	CDTM0_DTM1_CH2_OUT	CDTM0_DTM1_CH3_OUT
TBWC4	CDTM0_DTM2_CH0_OUT	CDTM0_DTM2_CH1_OUT
TBWC5	CDTM0_DTM2_CH2_OUT	CDTM0_DTM2_CH3_OUT
TBWC6	CDTM0_DTM3_CH0_OUT	CDTM0_DTM3_CH1_OUT
TBWC7	CDTM0_DTM3_CH2_OUT	CDTM0_DTM3_CH3_OUT
TBWC8	CDTM1_DTM0_CH0_OUT	CDTM1_DTM0_CH1_OUT
TBWC9	CDTM1_DTM0_CH2_OUT	CDTM1_DTM0_CH3_OUT
TBWC10	CDTM1_DTM1_CH0_OUT	CDTM1_DTM1_CH1_OUT
TBWC11	CDTM1_DTM1_CH2_OUT	CDTM1_DTM1_CH3_OUT

38.25.3 Configuration of the Compare Unit

Because of the restrictions described in the section above the Compare Unit consists of 24 anti valence (EXOR) elements, a select register CMP_EN which selects the corresponding comparisons and a status register CMP_IRQ_NOTIFY which shows and stores each mismatching result, when selected.

For each with CMP_IRQ_EN enabled mismatching error an interrupt signal on CMP_IRQ is generated.

For each with CMP_EIRQ_EN enabled mismatching error an interrupt signal on CMP_EIRQ is generated.

38.25.4 Error Generator

The error generator generates an error signal to be transmitted directly to the MON unit and independently from the CMP_IRQ and CMP_EIRQ. The error is set when in the CMP_IRQ_NOTIFY register at least one bit is set. The CMP_IRQ_NOTIFY bits are not mask able for this purpose.

Additionally CMP_ERR is a primary output port for interrupt actions by CPU itself.

38.25.5 CMP Interrupt Signal

The CMP sub-module has two interrupt signals, one normal interrupt and one error interrupt. The source of both interrupt can be determined by reading the CMP_IRQ_NOTIFY register under consideration of CMP_IRQ_EN register and CMP_EIRQ_EN register. Each source can be forced separately for debug purposes using the interrupt force CMP_IRQ_FORCINT register. CMP_IRQ_MODE configures interrupt output characteristic. All interrupt modes are described in detail in **Section 38.5.5, GTM-IP Interrupt Concept**.

Table 38.491 CMP Interrupt Signal

Signal	Description
CMP_EIRQ	Mismatching interrupt of outputs to be compared, when enabled
CMP_IRQ	Mismatching interrupt of outputs to be compared, when enabled

38.25.6 CMP Configuration Registers Overview

CMP contains following configuration registers:

Table 38.492 Register list

Symbol	Register Name	Details in Section
CMP_EN	CMP comparator enable register	**38.25.7.1**
CMP_IRQ_NOTIFY	CMP event notification register	**38.25.7.2**
CMP_IRQ_EN	CMP interrupt enable register	**38.25.7.3**
CMP_IRQ_FORCINT	CMP interrupt force register	**38.25.7.4**
CMP_IRQ_MODE	CMP interrupt mode configuration register	**38.25.7.5**
CMP_EIRQ_EN	CMP error interrupt enable register	**38.25.7.6**

38.25.7 CMP Configuration Registers Description

38.25.7.1 CMP_EN

Access: This register can be read or written in 32-bit units.

Address: <GTM_base> + 00200_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 38.493 CMP_EN Register Contents (1/2)

Bit Position	Bit Name	Function
31 to 24	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
23	TBWC11_EN	Enable comparator 11 in TBWC (see **Section 38.25.2**). See bit 12.
22	TBWC10_EN	Enable comparator 10 in TBWC (see **Section 38.25.2**). See bit 12.
21	TBWC9_EN	Enable comparator 9 in TBWC (see **Section 38.25.2**). See bit 12.
20	TBWC8_EN	Enable comparator 8 in TBWC (see **Section 38.25.2**). See bit 12.
19	TBWC7_EN	Enable comparator 7 in TBWC (see **Section 38.25.2**). See bit 12.
18	TBWC6_EN	Enable comparator 6 in TBWC (see **Section 38.25.2**). See bit 12.
17	TBWC5_EN	Enable comparator 5 in TBWC (see **Section 38.25.2**). See bit 12.
16	TBWC4_EN	Enable comparator 4 in TBWC (see **Section 38.25.2**). See bit 12.
15	TBWC3_EN	Enable comparator 3 in TBWC (see **Section 38.25.2**). See bit 12.
14	TBWC2_EN	Enable comparator 2 in TBWC (see **Section 38.25.2**). See bit 12.
13	TBWC1_EN	Enable comparator 1 in TBWC (see **Section 38.25.2**). See bit 12.
12	TBWC0_EN	Enable comparator 0 in TBWC (see **Section 38.25.2**). 0: TBWC comparator 0 is disabled. 1: TBWC comparator 0 is enabled.
11	ABWC11_EN	Enable comparator 11 in ABWC (see **Section 38.25.2**). See bit 0.
10	ABWC10_EN	Enable comparator 10 in ABWC (see **Section 38.25.2**). See bit 0.
9	ABWC9_EN	Enable comparator 9 in ABWC (see **Section 38.25.2**). See bit 0.
8	ABWC8_EN	Enable comparator 8 in ABWC (see **Section 38.25.2**). See bit 0.
7	ABWC7_EN	Enable comparator 7 in ABWC (see **Section 38.25.2**). See bit 0.
6	ABWC6_EN	Enable comparator 6 in ABWC (see **Section 38.25.2**). See bit 0.
5	ABWC5_EN	Enable comparator 5 in ABWC (see **Section 38.25.2**). See bit 0.
4	ABWC4_EN	Enable comparator 4 in ABWC (see **Section 38.25.2**). See bit 0.
3	ABWC3_EN	Enable comparator 3 in ABWC (see **Section 38.25.2**). See bit 0.
2	ABWC2_EN	Enable comparator 2 in ABWC (see **Section 38.25.2**). See bit 0.
1	ABWC1_EN	Enable comparator 1 in ABWC (see **Section 38.25.2**). See bit 0.

Table 38.493 CMP_EN Register Contents (2/2)

Bit Position	Bit Name	Function
0	ABWC0_EN	Enable comparator 0 in ABWC (see **Section 38.25.2**). 0: ABWC Comparator 0 is disabled 1: ABWC Comparator 0 is enabled

38.25.7.2 CMP_IRQ_NOTIFY

Access: This register is a read-only register that can be read in 32-bit units.

Address: <GTM_base> + 00204_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	TBWC11	TBWC10	TBWC9	TBWC8	TBWC7	TBWC6	TBWC5	TBWC4
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 38.494 CMP_IRQ_NOTIFY Register Contents (1/2)

Bit Position	Bit Name	Function
31 to 24	Reserved	When read, the value after reset is returned.
23	TBWC11	TOM sub modules outputs bitwise comparator 11 error indication. See bit 12.
22	TBWC10	TOM sub modules outputs bitwise comparator 10 error indication. See bit 12.
21	TBWC9	TOM sub modules outputs bitwise comparator 9 error indication. See bit 12.
20	TBWC8	TOM sub modules outputs bitwise comparator 8 error indication. See bit 12.
19	TBWC7	TOM sub modules outputs bitwise comparator 7 error indication. See bit 12.
18	TBWC6	TOM sub modules outputs bitwise comparator 6 error indication. See bit 12.
17	TBWC5	TOM sub modules outputs bitwise comparator 5 error indication. See bit 12.
16	TBWC4	TOM sub modules outputs bitwise comparator 4 error indication. See bit 12.
15	TBWC3	TOM sub modules outputs bitwise comparator 3 error indication. See bit 12.
14	TBWC2	TOM sub modules outputs bitwise comparator 2 error indication. See bit 12.
13	TBWC1	TOM sub modules outputs bitwise comparator 1 error indication. See bit 12.
12	TBWC0	TOM sub modules outputs bitwise comparator 0 error indication. 0: No error recognized on DTMT sub modules bits 0 and 1 (see **Section 38.25.2**). 1: An error was recognized on corresponding DTMT sub modules bits. **NOTE** This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.
11	ABWC11	Error indication for ABWC11. See bit 0.
10	ABWC10	Error indication for ABWC10. See bit 0.
9	ABWC9	Error indication for ABWC9. See bit 0.
8	ABWC8	Error indication for ABWC8. See bit 0.
7	ABWC7	Error indication for ABWC7. See bit 0.
6	ABWC6	Error indication for ABWC6. See bit 0.
5	ABWC5	Error indication for ABWC5. See bit 0.
4	ABWC4	Error indication for ABWC4. See bit 0.
3	ABWC3	Error indication for ABWC3. See bit 0.

Table 38.494 CMP_IRQ_NOTIFY Register Contents (2/2)

Bit Position	Bit Name	Function
2	ABWC2	Error indication for ABWC2. See bit 0.
1	ABWC1	Error indication for ABWC1. See bit 0.
0	ABWC0	Error indication for ABWC0. 0: No error recognized on DTMA sub modules bits 0 and 1 (see **Section 38.25.2**). 1: An error was recognized on corresponding DTMA sub modules bits. **NOTE** This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.

38.25.7.3 CMP_IRQ_EN

Access: This register can be read or written in 32-bit units.

Address: <GTM_base> + 00208_H

Value after reset: $0000\ 0000_H$

38.26 Monitor Unit (MON)

38.26.1 Overview

The Monitor Unit (MON) is designed for the use in safety relevant applications. The main idea is to have a possibility to supervise common used circuitry and resources. In this way the activity of the clocks is supervised. In addition the characteristics of output signals can be checked in a MCS channel by a re-read-in via TIM and routing to the MCS. When the comparison fails an error signal is generated in MCS and sent to the monitor unit. One error signal per MCS summarizes the errors of all channels. By generating of an activity signal per channel for each such performed comparison, the activity of TIM, ARU and the used clocks is checked implicitly. In addition the ARU cycle time could be also compared in a MCS channel to given values.

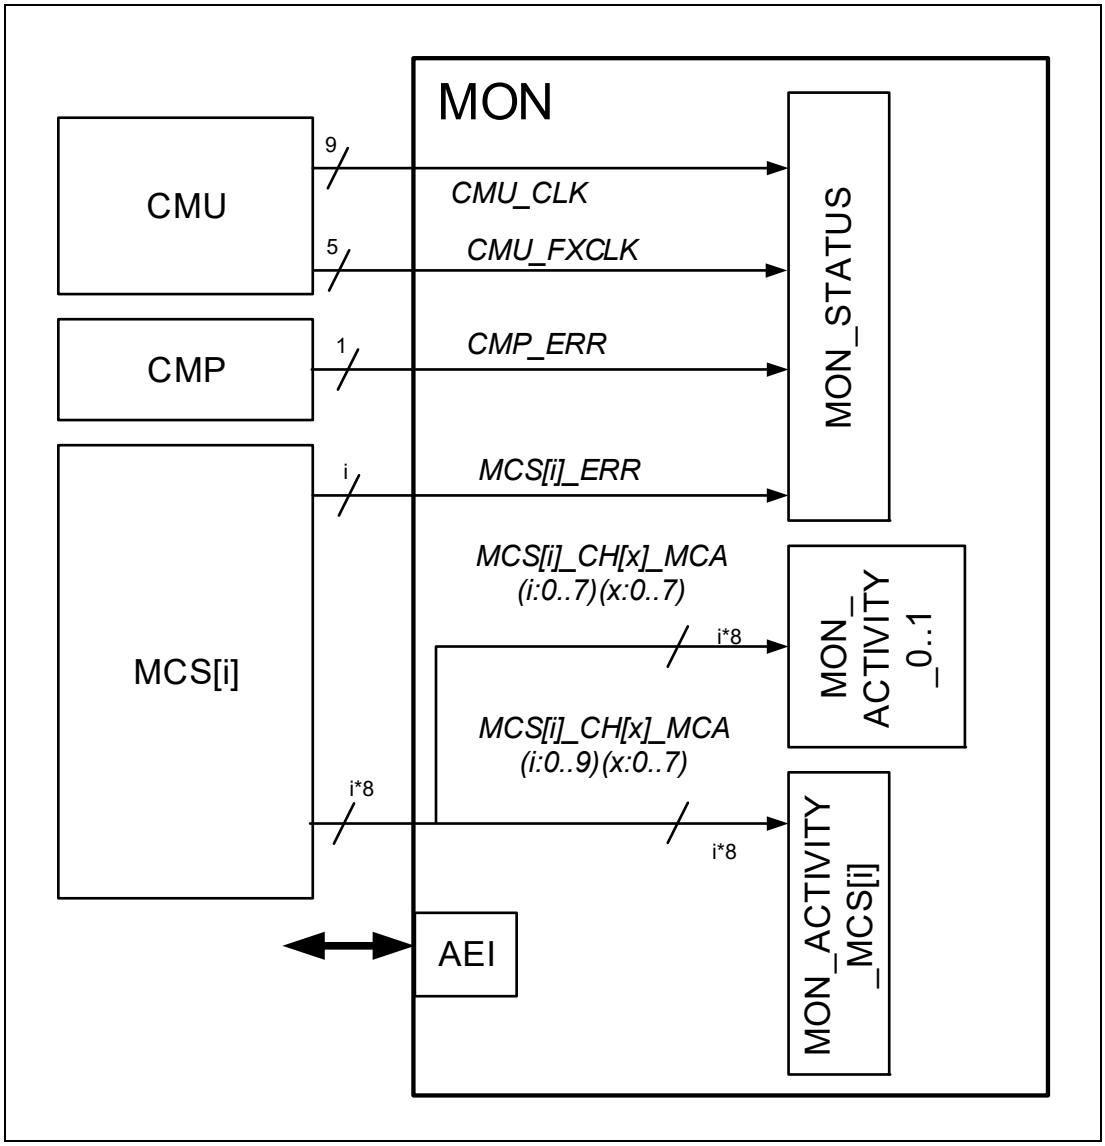

Figure 38.125 MON Block Diagram

38.26.1.1 Realization without Activity Checker of the clock signals

An activity checker of the clock signals used is not needed because these signals are only enables to be used in combination with the system clock. Therefore the clock enables are to be checked to have a high value.

38.26.2 Clock Monitoring

The monitor unit has a connection to each of the 9 clocks CMU_CLK[x] (x = 0 to 8), provided by the CMU. Some of these clocks can be used for special tasks (see **Section 38.12, Clock Management Unit (CMU)**.

In addition the 5 clock inputs of the TOMs CMU_FXCLK[y] (y=0 to 4) are also connected to the MON unit.

The supervising of the clocks is done by scanning for activity of each clock.

A high value is defined as the state to be monitored.

When a high value of the clock enable is detected, the corresponding bit in the status register MON_STATUS is set.

The status register bits are reset by writing a one.

When the register is polled by the CPU and the time between two read accesses is higher than the period of the slowest clock, all bits of the corresponding clocks must have been set.

When polling in shorter time distances, not for all clocks an activity can be shown, although they are still working.

Because of the realization without a select register for the clock signals only the bits of the status register are to be considered for which the clock signal is enabled in the CMU.

38.26.3 CMP error Monitoring

The signal CMP_ERR is to be received directly from module CMP and is set if an error occurred.

38.26.4 Checking the Characteristics of Signals by MCS

By use of the MCS some given properties of signals can be checked. Such signals can be generated output signals of TOM or ATOM channels including DTM function, which are reread in into a TIM and the time stamp information is routed via ARU to the MCS module.

The corresponding MCS signal performs the check according to given properties. In this way signal high or low time as well as signal periods can be checked, also taking into account tolerances. When the check fails a MCS internal error signal is generated and ORed with the error signals of the other channels of the MCS module to a summarized error signal MCS[i]_ERR.

For each MCS a summarized error signal is transmitted to MON and monitored in the MON_STATUS register.

In order to check the execution of the comparison for each MCS channel an activity signal is generated. In the MCS[i]_CH[x]_MCA (i = 0 to 9)(x=0 to 7) vector 8 bits for each MCS[i] (i = 0 to 9) instance are combined. The activity signals are stored in the MON_ACTIVITY_MCS[i] register.

In addition the first 8 bits of MCS0 to 3 are stored in MON_ACTIVITY_0 and the first 8 bits of MCS4 to 7 are stored in MON_ACTIVITY_1. The bits are set by a one signal and reset by writing a one to it (preferably after polling the status of the register).

Because the activity signal shows the execution of a comparison, the involved units for providing the signals and execution of comparison (like TIM, ARU and MCS itself) are checked implicitly to work accordingly. Also the involved clocks and time bases are checked in this way.

38.26.5 Checking ARU Cycle Time

The cycle time of the ARU can be checked, when this is essential for safety purposes. This check can be performed by an MCS channel.

NOTE

The MCS program for measuring the ARU round trip time must add a tolerance value.

The resulting error is reported to the MON unit using the summarized error signal MCS[i]_ERR for each MCS module in addition to an interrupt, generated in MCS. The same signals and status bits are used as in the case of checking the signal characteristics.

The corresponding MCS is programmed to get a fixed data value at address $1FF_H$. The data value is always zero and is not blocked. When getting the access the time stamp value TBU_TS0 is stored in a register. The next time getting the access the new TBU_TS0 value is stored and the difference between both values is compared with a given value. When the comparison fails, an error flag is set in the MCS internal status register, an interrupt is generated and the error signal MCS[i]_ERR is provided.

When the check is performed, an activity signal MCS[i]_CH[x]_MCA (i = 0 to 9)(x = 0 to 7) is provided for each channel x for each MCS[i] (i = 0 to 9) instance together with a summarized interrupt MCS[i]_ERR for each MCS.

The activity signal sets a bit in the MON_ACTIVITY register.

The bits in the MON_ACTIVITY registers are reset by writing a one.

When the check fails, an interrupt is generated and the error signal MCS[i]_ERR is provided for the MON unit.

Figure 38.125 shows the block diagram of the Monitor Unit.

38.26.6 MON Interrupt Signals

The MON sub-module has no interrupt signals.

38.26.7 MON Registers Overview

Following configuration registers are considered in MON sub module

Table 38.499 Register list

Symbol	Register Name	Details in Section
MON_STATUS	Monitor Status register	**38.26.8.1**
MON_ACTIVITY_0	Monitor activity register 0	**38.26.8.2**
MON_ACTIVITY_1	Monitor activity register 1	**38.26.8.3**
MON_ACTIVITY_MCS[z]	Monitor activity register for MCS z	**38.26.8.4**

38.26.8 MON Configuration Registers Description

38.26.8.1 MON_STATUS

Access: This register can be read or written in 32-bit units.

Address: <GTM_base> + 00180_H

Value after reset: $0000\ 4000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 38.500 MON_STATUS Register Contents (1/4)

Bit Position	Bit Name	Function
31 to 30	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
29	MCS9_ERR	Error detected at MCS9 **NOTE** This bit will be readable only.
28	MCS8_ERR	Error detected at MCS8 **NOTE** This bit will be readable only.
27	MCS7_ERR	Error detected at MCS7 **NOTE** This bit will be readable only.
26	MCS6_ERR	Error detected at MCS6 **NOTE** This bit will be readable only.
25	MCS5_ERR	Error detected at MCS5 **NOTE** This bit will be readable only.

Table 38.500 MON_STATUS Register Contents (2/4)

Bit Position	Bit Name	Function
24	MCS4_ERR	Error detected at MCS4 **NOTE** This bit will be readable only.
23	MCS3_ERR	Error detected at MCS3 **NOTE** This bit will be readable only.
22	MCS2_ERR	Error detected at MCS2 **NOTE** This bit will be readable only.
21	MCS1_ERR	Error detected at MCS1 **NOTE** This bit will be readable only.
20	MCS0_ERR	Error detected at MCS0 **NOTE** This bit will be readable only.
19 to 17	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
16	CMP_ERR	Error detected at CMP **NOTE** This bit will be readable only.
15, 13	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
14	ATC_CMU8	CMU_CLK8 activity **NOTES** 1. This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged. 2. Bit is set, when a rising edge is detected at the considered clock.
12	ATC_CMUFX4	CMU_CLKFX4 activity **NOTE** This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.

Table 38.500 MON_STATUS Register Contents (3/4)

Bit Position	Bit Name	Function
11	ATC_CMUFX3	CMU_CLKFX3 activity **NOTE** This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.
10	ATC_CMUFX2	CMU_CLKFX2 activity **NOTE** This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.
9	ATC_CMUFX1	CMU_CLKFX1 activity **NOTE** This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.
8	ATC_CMUFX0	CMU_CLKFX0 activity **NOTE** This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.
7	ACT_CMU7	CMU_CLK7 activity **NOTE** This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.
6	ACT_CMU6	CMU_CLK6 activity **NOTE** This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.
5	ACT_CMU5	CMU_CLK5 activity **NOTE** This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.
4	ACT_CMU4	CMU_CLK4 activity **NOTE** This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.

Table 38.500 MON_STATUS Register Contents (4/4)

Bit Position	Bit Name	Function
3	ACT_CMU3	CMU_CLK3 activity **NOTE** This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.
2	ACT_CMU2	CMU_CLK2 activity **NOTE** This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.
1	ACT_CMU1	CMU_CLK1 activity **NOTE** This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.
0	ACT_CMU0	CMU_CLK0 activity **NOTE** This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.

NOTES

1. Bits 0 to 12 are set, when a rising edge is detected at the considered clock.
2. Bits16 and 20 to 29 are set, when the corresponding unit reports an error.
3. The MCS can be programmed to generate an error, when the comparison of signal values (duty time, cycle time) fails or also when the cycle time of the ARU (checking of the TBU_TS0 between two periodic accesses) is out of the expected range.

38.26.8.2 MON_ACTIVITY_0

Access: This register can be read or written in 32-bit units.

Address: <GTM_base> + 00184_H

Bit Position	Bit Name	Function
31	MCA_7_7	Activity of check performed in module MCS 7 at channel 7. **NOTE** This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.
30	MCA_7_6	Activity of check performed in module MCS 7 at channel 6. **NOTE** This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.
29	MCA_7_5	Activity of check performed in module MCS 7 at channel 5. **NOTE** This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.
28	MCA_7_4	Activity of check performed in module MCS 7 at channel 4. **NOTE** This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.
27	MCA_7_3	Activity of check performed in module MCS 7 at channel 3. **NOTE** This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.

Table 38.502 MON_ACTIVITY_1 Register Contents (2/5)

Bit Position	Bit Name	Function
26	MCA_7_2	Activity of check performed in module MCS 7 at channel 2. **NOTE** This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.
25	MCA_7_1	Activity of check performed in module MCS 7 at channel 1. **NOTE** This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.
24	MCA_7_0	Activity of check performed in module MCS 7 at channel 0. **NOTE** This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.
23	MCA_6_7	Activity of check performed in module MCS 6 at channel 7. **NOTE** This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.
22	MCA_6_6	Activity of check performed in module MCS 6 at channel 6. **NOTE** This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.
21	MCA_6_5	Activity of check performed in module MCS 6 at channel 5. **NOTE** This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.
20	MCA_6_4	Activity of check performed in module MCS 6 at channel 4. **NOTE** This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.
19	MCA_6_3	Activity of check performed in module MCS 6 at channel 3. **NOTE** This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.

Table 38.502 MON_ACTIVITY_1 Register Contents (3/5)

Bit Position	Bit Name	Function
18	MCA_6_2	Activity of check performed in module MCS 6 at channel 2. **NOTE** This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.
17	MCA_6_1	Activity of check performed in module MCS 6 at channel 1. **NOTE** This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.
16	MCA_6_0	Activity of check performed in module MCS 6 at channel 0. **NOTE** This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.
15	MCA_5_7	Activity of check performed in module MCS 5 at channel 7. **NOTE** This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.
14	MCA_5_6	Activity of check performed in module MCS 5 at channel 6. **NOTE** This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.
13	MCA_5_5	Activity of check performed in module MCS 5 at channel 5. **NOTE** This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.
12	MCA_5_4	Activity of check performed in module MCS 5 at channel 4. **NOTE** This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.
11	MCA_5_3	Activity of check performed in module MCS 5 at channel 3. **NOTE** This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.

Table 38.502 MON_ACTIVITY_1 Register Contents (4/5)

Bit Position	Bit Name	Function
10	MCA_5_2	Activity of check performed in module MCS 5 at channel 2. **NOTE** This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.
9	MCA_5_1	Activity of check performed in module MCS 5 at channel 1. **NOTE** This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.
8	MCA_5_0	Activity of check performed in module MCS 5 at channel 0. **NOTE** This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.
7	MCA_4_7	Activity of check performed in module MCS 4 at channel 7. **NOTE** This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.
6	MCA_4_6	Activity of check performed in module MCS 4 at channel 6. **NOTE** This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.
5	MCA_4_5	Activity of check performed in module MCS 4 at channel 5. **NOTE** This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.
4	MCA_4_4	Activity of check performed in module MCS 4 at channel 4. **NOTE** This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.
3	MCA_4_3	Activity of check performed in module MCS 4 at channel 3. **NOTE** This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.

Table 38.502 MON_ACTIVITY_1 Register Contents (5/5)

Bit Position	Bit Name	Function
2	MCA_4_2	Activity of check performed in module MCS 4 at channel 2. **NOTE** This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.
1	MCA_4_1	Activity of check performed in module MCS 4 at channel 1. **NOTE** This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.
0	MCA_4_0	Activity of check performed in module MCS 4 at channel 0. **NOTE** This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.

Note: When not all MCS modules are implemented or the channels are not used for check purposes with supervising, the corresponding activity bits remain zero.

38.26.8.4 MON_ACTIVITY_MCS[z]

Access: This register can be read or written in 32-bit units.

Address: MON_ACTIVITY_MCS0: <GTM_base> + $0018C_H$
MON_ACTIVITY_MCS1: <GTM_base> + 00190_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—								MCA_7	MCA_6	MCA_5	MCA_4	MCA_3	MCA_2	MCA_1	MCA_0
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 38.503 MON_ACTIVITY_MCS[z] Register Contents (1/2)

Bit Position	Bit Name	Function
31 to 8	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
7	MCA_7	Activity of check performed in module MCS z at channel 7. **NOTE** This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.
6	MCA_6	Activity of check performed in module MCS z at channel 6. **NOTE** This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.
5	MCA_5	Activity of check performed in module MCS z at channel 5. **NOTE** This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.
4	MCA_4	Activity of check performed in module MCS z at channel 4. **NOTE** This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.
3	MCA_3	Activity of check performed in module MCS z at channel 3. **NOTE** This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.

Table 38.503 MON_ACTIVITY_MCS[z] Register Contents (2/2)

Bit Position	Bit Name	Function
2	MCA_2	Activity of check performed in module MCS z at channel 2. **NOTE** This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.
1	MCA_1	Activity of check performed in module MCS z at channel 1. **NOTE** This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.
0	MCA_0	Activity of check performed in module MCS z at channel 0. **NOTE** This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.

Note 1. Unused MCA bits are reserved.

Note 2. Read as zero should be written as zero.

38.27 Appendix A

Table 38.504 Register Bit Attributes

Mode	Description
R	Read access
W	Write access
Cr	Clear on read access
Sr	Set on read access
Cw	Clear by write 1 (clears only those bits with value 1)
Sw	Set by write 1 (sets only those bits with value 1)
Aw	Auto clear after write (e.g. trigger something)
Pw	Protected write (separate write enable bit, e.g. init)

Below the bit name in a register table, the attributes “Access Mode” and “Reset Value” of each bit are described with the syntax above.

NOTE

When using Cw or Sw for a bit field e.g. representing a number, a clear/set has to be applied to all bits of the data field, to avoid construction of unintended values different to $00..00_B$ and $11..11_B$.

Table 38.505 Register Reset Value

Mode	Description
0	logic value is 0 after reset
1	logic value is 1 after reset
U	logic value is undefined after reset (0/1, e.g. monitor of external pin)

38.27.1 ARU Write Address Overview

The ARU write address map is specified in **Section 38.28, GTM Device 358**.

38.27.2 GTM Configuration Register Address Map

The addresses of the implemented sub-modules are specified in **Section 38.28, GTM Device 358**.

The start and end address of the configured rams are specified in **Section 38.28, GTM Device 358**.

The full address map of all implemented registers, the start and end addresses of configured rams are recorded in **Section 38.28, GTM Device 358**.

38.27.3 GTM Application Constraints

The ARU write address map is specified in **Section 38.28, GTM Device 358**.

38.27.5 Compatibility Notes

38.27.5.1 DPLL

The following features of DPLL have changed since GTM v3.1.0 release:

1. In case of TORI/SORI the DPLL internal pointer handling is continued and the inc_cnt is not frozen.
2. The acceptance of input signals by configuration of DPLL_CTRL_1.TSL/SSL is extended such that after enabling the by setting DPLL by DPLL_CTRL_1.DEN=1 while DPLL_STATUS.FTD/FSD still '0' the first input signal is treated as level sensitive. In this case the signal level only is used to decide if an input signal is treated as active input signal or not.

38.27.5.2 MCS

Since GTM v2.x following features of MCS have changed:

1. MCS[i]_CTRL was replaced by MCS[i]_CTRL_STAT: MCS[i]_CTRL is obsolete. MCS[i]_CTRL and MCS[i]_CTRL_STAT have different addresses.
2. MCS[i]_RST was replaced by MCS[i]_RESET: MCS[i]_RST is obsolete. MCS[i]_RST and MCS[i]_RESET have different addresses.
3. The new register MCS[i]_CAT contains bits of obsolete register MCS[i]_CTRL
4. The new register MCS[i]_CWT contains bits of obsolete register MCS[i]_CTRL
5. The instruction execution time in accelerated mode compared to a GTM v1.x may be faster due to instruction pre-fetching.
6. On mode switch to SCD_MODE = 0b01 - Round Robin Scheduling - the value of SCD_CH has to be set to appropriate number of tasks. The reset value 0000_b for SCD_CH means that only task 0 is scheduled.

Since GTM v3.1.x following features of MCS have changed:

7. The instruction execution time in accelerated mode compared to a GTM v2.x and v1.x may be different due to increased pipeline depth.

38.28 GTM Device 358

38.28.1 GTM Device 358 Configuration

The **Table 38.508** and **Table 38.509** list the device configuration of device GTM-IP_358.

Table 38.508 GTM-IP_358 Configuration part 1

	Instances	Numbering	Channel
CCM	4	0,1,2,3 fast cluster	
TIM	4	0,1,2,3	All 8

Table 38.509 GTM-IP_358 configuration part 2

	Instances	CDTM Instance Numbering	DTM instances	DTM Instance Numbering
CDTM	4	0,1,2,3	2 DTM each	DTM 4,5

Table 38.510 shows defined constants referenced in GTM-IP_358 3.5.0.2 specification.

Table 38.510 GTM-IP_358 configuration constants

Module	Constant	Value
CCM	NARP	10
CCM	AAW	15
MCFG	MAW	11
MCFG	ERM	0
DPLL	NOAC	32

38.28.2 Reset values of GTM Register

The GTM specification is device independently and some register reset values are undefined and marked with ‘x’.

Reset values of the GTM register are either device depended hardcoded or defined by hardware configuration of silicon vendor.

38.28.2.1 Register reset values device depended hardcoded

Following reset values are device depended hardcoded.

NOTE

The value of GTM_REV changes with every GTM-IP_358 release.

Table 38.511 Device depended hardcoded reset values

Register Name	Reset value
GTM_REV	3583 $50A2_H$
ARU_CADDR_END	0000 0050_H

38.28.2.2 Register reset values defined by hardware configuration of silicon vendor

Following reset values depend on the hardware configuration chosen by silicon vendor.

Table 38.512 hardware configured reset values by silicon vendor

Register Name	Reset value
GTM_BRIDGE_MODE	0400 0000_H
GTM_BRIDGE_PTR1	004X $XXXX_H$
CCM[i]_HW_CONF (i: 0..3)	204F 0039_H
CCM[i]_ATOM_OUT (i = 0,1,2)	FFFF $FFFF_H$
CCM[i]_ATOM_OUT (i = 3)	0000 $FFFF_H$
ATOM[i]_CH[x]_CTRL (x: 0...7)(i: 0…3)	0000 0000_H
ATOM[i]_CH[x]_STAT (x: 0...7)(i: 0…3)	0000 0001_H
MCS[i]_CTRL_STAT (i: 0…3)	0001 0000_H
GTM_IRQ_MODE	0000 0002_H
CMP_IRQ_MODE	0000 0002_H
ARU_IRQ_MODE	0000 0002_H
TIM[i]_CH[x]_IRQ_MODE (x: 0...7)(i: 0…3)	0000 0002_H
ATOM[i]_CH[x]_IRQ_MODE (x: 0...7)(i: 0…3)	0000 0002_H
MCS[i]_CH[x]_IRQ_MODE (x: 0...7)(i: 0…3)	0000 0002_H

38.28.3 AEI write status 10_B to GTM Register under special conditions

Write access to addresses in **Table 38.513** returns status 10_B under special conditions.

Table 38.513 Register which could return status 10_B on AEI write (1/2)

Register name	RegBitModeWrite	unProtected by
ARU ACCESS	Pw	RREQ and WREQ bits are zero
ARU_IRQ_FORCINT	Aw	RF_PROT = 0
ARU_CADDR_END	W	RF_PROT = 0
ATOM[i]_CH[x]_CTRL,11	W	Channel and its output are disabled
ATOM[i]_CH[x]_CTRL,20	W	OSM = 0
ATOM[i]_CH[x]_CTRL,21	Pw	OSM = 1 and bit RST_CCU0 = 0
ATOM[i]_CH[x]_CM0	W	SOMC:serve last compare strategy CCU1 match occurred
ATOM[i]_CH[x]_CM1	Pw	SOMC:serve last compare strategy CCU1 match occurred
ATOM[i]_CH[x]_RDADDR	Pw	Channel is disabled

38.28.7 GTM Register Addresses Mapping Legacy Addresses

The following **Table 38.517** lists all register addresses used by GTM-IP_358 which have additional legacy addresses defined by older GTM Generation.

Table 38.517 GTM Register Addresses Mapping Legacy Addresses (1/3)

Register Label	Register Address	Legacy Register Label	Legacy Address

38.28.8 MCS master interface address map

Each cluster uses the same MCS AEI bus master address map. If a cluster does not contain modules mentioned in the address map, the AEI status signal report a value “10” (illegal module access). The register label names mentioned in the table below equal to the label names in the specification, with exception to the cluster/module index i, which is always omitted in the address map of the MCS bus master interface (e.g. register TIM[i]_CH0_GPR0 is accessible as register TIM_CH0_GPR0 by the MCS of the i-th cluster).

NOTE

The registers CCM[i]_HW_CONF, CCM[i]_AUX_IN_SRC, CCM[i]_EXT_CAP_EN, CCM[i]_TOM_OUT, and CCM[i]_ATOM_OUT are global status and configuration registers that are mirrored from the group of TOP-Level registers to i-cluster. An access to the old GTM addresses are marked with LEG_ (legacy).

38.28.10.2 ARU port partitioning

All GTM sub-modules which are reading from ARU can be connected to one of two ARU read ports. Therefore, it can be read from two different ARU addresses in parallel.

Table 38.521 ARU partitioning

	2 ARU ports	
	ARU-0	ARU-1
ATOM-0	x	
ATOM-1		x
ATOM-2	X	
ATOM-3		X
MCS-0	X	
MCS-1		X
MCS-2	X	
MCS-3		X

38.28.10.3 ARU read ID table

Each ARU connected data destination is defined by a combination of ARU port(ARU- 0 or ARU-1) and an ARU read ID. The two ARU counter are addressing two ARU read IDs in parallel. Depending on ARU mode both counter may have different values at different point in time (i.e. in dynamic routing mode). The maximum ARU round-trip time is determined by value of last ARU read ID. The following table describes the detailed addressing of GTM sub-modules by ARU read IDs.

Table 38.522 ARU read IDs (1/2)

ARU read ID (dec)	ARU-0	ARU-1	ARU read ID (dec)	ARU-0	ARU-1

38.28.11 ATOM

Bit-reversed mode (PCM) in ATOM SOMP is available in the following channels:

Table 38.523 Available PCM in ATOM SOMP mode

Module	Ch-0	Ch-1	Ch-2	Ch-3	Ch-4	Ch-5	Ch-6	Ch-7
ATOM-0	no	yes	no	yes	no	yes	no	yes
ATOM-1	no	yes	no	yes	no	yes	no	yes
ATOM-2	no	yes	no	yes	no	yes	no	yes
ATOM-3	no	yes	no	yes	no	yes	no	yes

38.28.12 GTM Application constraints

If setting up an application on GTM-IP one has to take following constraints into account. Otherwise, the GTM-IP may not be able to fulfill the specified behavior.

Table 38.524 GTM-IP_358 application constraints

#	Module	Description	Required value	Effect, when not considered
1	MCS	Worst Case Execution Time of an N-cycle instruction.	<= 9*N system clock periods	MCS program execution may be too long for the application's requirements.
2	MCS	If MCS scheduling is configured in round robin mode, the MCS features deterministic program execution (the program of MCS channel x does not modify execution time of MCS channel y).		No channel independent execution time.
3	ATOM	If channel is triggered by preceding channel via TRIG_<x-1> signal, the selected CMU_CLK of both channels has to be the same	Identical CMU_CLK	The trigger of preceding channel may be lost
4	TIM	If a TIM channel x uses ARU transfer with enabled TDU, the minimal time T_{IN}between two subsequent measurement cycles has to be greater than the maximum time T_{SAMPLE} between two subsequent ARU read request events on TIM channel x.	$T_{IN} > T_{SAMPLE}$ (FIFO: T_{SAMPLE} = worst case ARU round trip time, MCS: T_{SAMPLE}= max. time between two (N)ARD(I) instructions for TIM channel x)	The ARU destination of TIM channel x cannot distinguish between a measurement cycle overflow and a timeout with subsequent valid measurement cycle.
5	ARU	The ARU round trip time in pure round robin mode is device specific.	(ARU_CADDR_END +1) times system clock periods with ARU_CADDR_END = 80 (default value);	If dynamic mode is activated with CLK_WAIT> 0 the ARU round trip time becomes longer and the value is undefined.

38.28.13 GTM DTM Register Mapping Table

Table 38.525 GTM DTM Register Mapping Table

GTM v2.0 ..V3.0	GTM v3.5

28	2	4	ATOM2
29	2	5	ATOM2
30	3	4	ATOM3
31	3	5	ATOM3

38.28.14 GTM DTMA port mapping Table

Table 38.526 GTM DTMA port mapping Table

gtm_dtma_aux_in[i]	CDTM[n]	CDTM[n]_ DTM[j]
0	0	4
1	0	5
2	1	4
3	1	5
4	2	4
5	2	5
6	3	4
7	3	5

NOTE

In RH850/U2A-EVA Group, gtm_dtma_aux_in[i] pins are fixed to "0".

38.29 Interconnection of GTM-IP

38.29.1 Outputs to ADCJ

GTM outputs can trigger start of ADCJ conversion. The following GTM outputs can be used as ADCJ trigger sources.

- ATOM_OUT
- MCS_IRQ
- TIM_IRQ

Signals specified above are multiplexed together and routed to the ADCJ. Multiplexing scheme is described in **Section 41, Peripheral Interconnect (PIC)**. The GTM can trigger AD groups 0 to 4.

For more information about ADCJ functionality, refer to **Section 43, Analog to Digital Converter (ADCJ)**.

38.29.2 Outputs to ENCA

GTM outputs can trigger the ENCA timer counter capture. The following GTM outputs can be used as ENCA trigger sources.

- ATOM_OUT
- TIM_IRQ

Signals specified above are multiplexed together and routed to the ENCA. The GTM outputs can trigger capture trigger inputs 0 and 1. Multiplexing scheme is described in **Section 41, Peripheral Interconnect (PIC)**.

For more information about ENCA functionality, refer to **Section 40, Encoder Timer A (ENCA)**.

38.29.3 Outputs to PSI5-S

GTM outputs can routed to PSI5-S signals enable, clear, clock and sync pulse signal. The following GTM outputs can be routed to PSI5-S.

- ATOM_OUT

Signals specified above are multiplexed together and routed to the PSI5-S. Multiplexing scheme is described in **Section 41, Peripheral Interconnect (PIC)**. For more information about PSI5-S functionality, refer to **Section 28, Peripheral Sensor Interface 5 S (PSI5S)**.

38.29.4 Outputs to MSPIn

GTM output can be used as hardware triggers for MSPIn's operation. The following GTM outputs can be used.

- MCS_IRQ

Signals specified above are selected by functionality of MSPIn. For more information, refer to **Section 19.5.2.12, MSPInCFGm4 — MSPIn channel Configuration Register m4 (m = 0 to 7)**.

NOTE

In U2A-EVA, it does not support the MCS0 and MCS2 interrupt as MSPI HW trigger.

38.29.5 Peripheral Inputs

Outputs of other peripherals can be connected to GTM inputs. Those outputs are routed to TIM input channels. See **Section 41, Peripheral Interconnect (PIC)** for routing schemes.

38.29.5.1 Inputs from PORT

For GTM inputs of TIM channel, we can select from both alternative pin function of GTM and RLIN3nRX.

If port pin alternative RLIN3nRX function is selected a signal from a micro pin is routed to a corresponding TIM channel. See **Section 41, Peripheral Interconnect (PIC)** for possible routing options to TIM channels.

If port pin alternative GTM function is selected, a signal from a micro pin is routed to a corresponding TIM channel. See **Section 2, Pin Functions** for possible routing options to TIM channels. Whether a signal from a micro pin is used by TIM channel as an input also depends on TIM sub-module configuration inside GTM.

38.29.5.2 Inputs from ADCJ

The following interrupt factors of ADCJ can be routed to TIM input channels.

– End of conversion of ADCJ scan group

38.29.5.3 Input from ENCA

All ENCA interrupt factors can be routed to GTM TIM input channels.

– Encoder input (phase A, B, Z)
– Compare match or capture
– Clear interrupt by ENCA input
– Count clock
– Down-count enable signal

38.29.6 ADC Interface

Results of A/D conversion are stored in ADC_CH[y]_DATA registers (y= 0...31). Either registers 0...15 or registers 16...31 can be used based on GTM_ADCI_CHSELj.CHS. In addition, a register designation is also based on GTMTAG (ADCJ). For more information about GTMTAG configuration, refer to **Section 43, Analog to Digital Converter (ADCJ)**.

It is not possible to send one A/D data to multiple ADC_CH[y]_DATA registers based on GTMTAG. Sending multiple A/D results to a same ADC_CH[y]_DATA register based on GTMTAG is possible but has to be carefully designed to avoid data overwrites.

The data format in ADC_CH[y]_DATA register matches configuration of corresponding A/D channel.

ADC_CH[y]_DATA registers selects the data to be stored from the ADC conversion result.

Table 38.527 Allocation of an ADC_CH[y]_DATA Register and GTMTAG Setting

	ADCJ	
GTM Registers	CHS	GTMTAG[3:0]
ADC_CH0_DATA	0_H	0_H
ADC_CH1_DATA	0_H	1_H

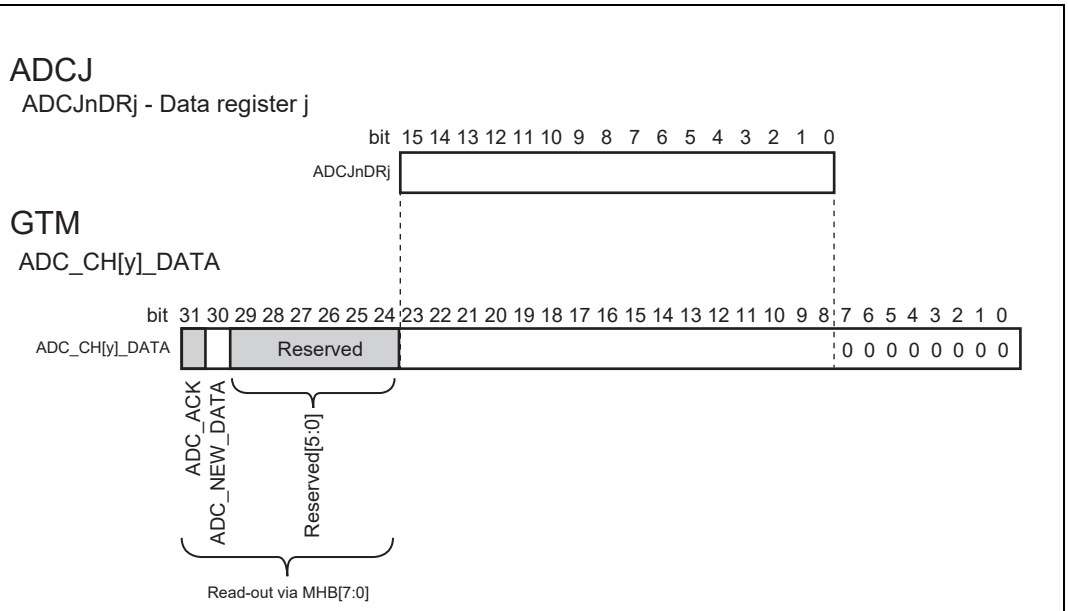
ADC_CH21_DATA	1_H	5_H
ADC_CH22_DATA	1_H	6_H
ADC_CH23_DATA	1_H	7_H
ADC_CH24_DATA	1_H	8_H
ADC_CH25_DATA	1_H	9_H
ADC_CH26_DATA	1_H	A_H
ADC_CH27_DATA	1_H	B_H
ADC_CH28_DATA	1_H	C_H
ADC_CH29_DATA	1_H	D_H
ADC_CH30_DATA	1_H	E_H
ADC_CH31_DATA	1_H	F_H

The figure below shows the bit correspondence between the AD conversion result and the ADCI_CH[y]_DATA register of GTM.



Note: For the transfer formats from ADCJnDRj, refer to **Section 43, Analog to Digital Converter (ADCJ)**.

Figure 38.126 Comparison of AD conversion result with ADC_CH[y]_DATA register of GTM

38.29.7 Safety Mechanism

MCS RAM is protected by ECC function. ECC error of MCS RAM is also reported by MCS channel. For more details about ECC function, refer to **Section 44, Functional Safety**.

38.30 GTM Debug Function

GTM debug feature is as follows.

- Run, break
- Single step execution of MCS
- On-chip breakpoint by:
  - MCS instruction or data access
  - ARU data access
  - TBU counter
- Trace the following with timestamp: (U2A-EVA only)
  - MCS instruction or data access
  - ARU data access
  - TBU counter
  - TIM/ATOM state change

Section 39 Real-Time Clock (RTCA)

This section contains a generic description of Real-Time Clock (RTCA).

First part of this section describes all RH850/U2A-EVA specific properties, such as number of units, register base addresses, etc. Remainder of section describes functions and registers of RTCA.

39.1 Features RTCA for RH850/U2A-EVA

39.1.1 Number of Units and Channels

This microcontroller has following number of RTCA units.

Each RTCA unit has one channel RTCA. “Number of channels” is used with same meaning as “number of units” in this section.

Table 39.1 Number of Units

Product Name	RH850/ U2A-EVA (516 pins)	RH850/ U2A16 (516 pins)	RH850/ U2A16 (373 pins)	RH850/ U2A16 (292 pins)	RH850/ U2A8 (373 pins)	RH850/ U2A8 (292 pins)	RH850/ U2A6 (292 pins)	RH850/ U2A6 (176 pins)	RH850/ U2A6 (156 pins)	RH850/ U2A6 (144 pins)
Number of Units	1 (n = 0)	1 (n = 0)	1 (n = 0)	1 (n = 0)	1 (n = 0)	1 (n = 0)	1 (n = 0)	1 (n = 0)	1 (n = 0)	1 (n = 0)
Name	RTCAn									

Table 39.2 Index

Index	Description
n	Throughout this section, individual RTCA units are identified by index “n” (n = 0); for example, RTCAnCTL0 is RTCAn control register 0.

39.1.2 Register Base Addresses

RTCAn base address is listed in following table.

RTCAn register addresses are given as offsets from base address.

Table 39.3 Register Base Address

Base Address Name	Base Address	Bus Group
<RTCA0_base>	FF99 7000_H	P-Bus Group 2L

39.1.3 Clock Supply

RTCAn clock supply is shown in following table.

Table 39.4 Clock Supply

Unit Name	Unit Clock Name	Supply Clock Name	Description
RTCA0	RTCATCKI	CLKA_RTCA	Macro clock
	PCLK	CLK_LSB	Module clock

39.1.4 Interrupt Requests and Error Notifications

RTCAn interrupt requests are listed in following table.

Table 39.5 Interrupt Requests

Unit Interrupt Signal	Description	Interrupt Number	DMA Trigger Number	Wake up
RTCA0				
INTRTCA01S	1-second interval interrupt	654	—	√
INTRTCA0AL	Alarm interrupt	655	—	√
INTRTCA0R	Fixed interval interrupt	656	—	√

This module has no error notifications.

39.1.5 Reset Sources

RTCAn reset sources are listed in following table. RTCAn is initialized by these reset sources.

Table 39.6 Reset Sources

Unit Name	Register Name	Reset Condition						
		Power On Reset	System Reset 1	System Reset 2	Application Reset	DeepSTOP Reset	Module Reset	JTAG Reset
RTCAn	All registers	√	√	√	—	—	—	—

39.1.6 External Input/Output Signals

External input/output signals of RTCAn are listed below.

Table 39.7 External Input/Output Signals

Unit Signal Name	Description	Alternative Port Pin Signal Name
RTCA0		
RTCAT1HZ	1-Hz pulse output	RTCA0OUT*1

Note 1. RTCA0OUT is connected to TAUJ3. For details, see **Section 34, Timer Array Unit J (TAUJ)**.

39.2 Overview

39.2.1 Functional Overview

Real-Time Clock (RTCA) has following features:

- Count clock selection from 240 kHz to 2.5 MHz
- Counters for years, months, day of month, day of week, hours, minutes, seconds, and a sub-counter. Calendar covers 99 years. Leap years are handled by hardware automatically.
- One Hz pulse output function
- Fixed interval interrupt function
- Alarm interrupt function

39.2.2 Block Diagram

Block diagram shows main components of RTCA.

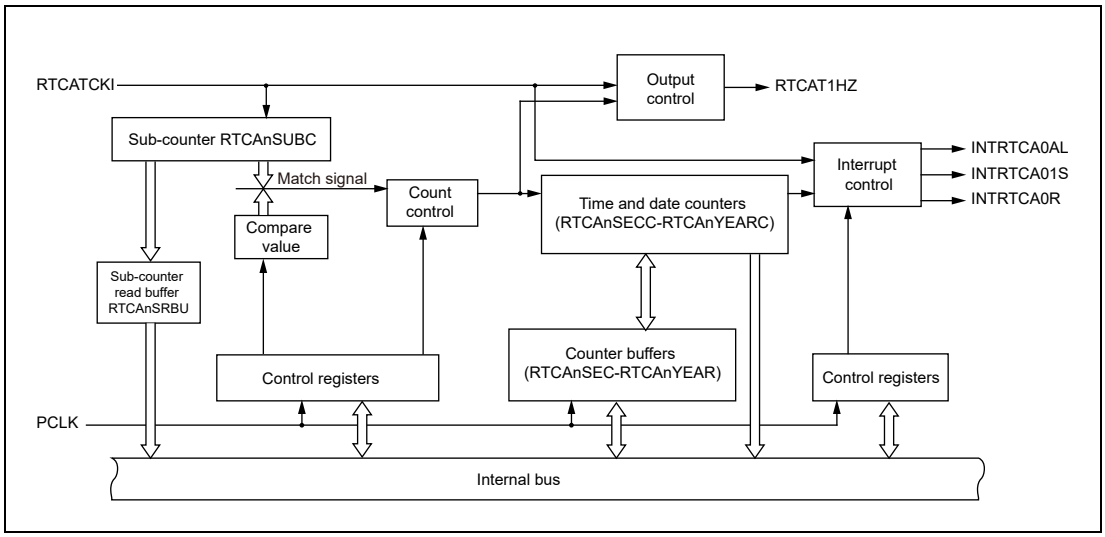


Figure 39.1 Block Diagram of RTCA

39.2.3 Description of Blocks

Real-Time Clock RTCA provides information about present time and date and can generate wake-up signals (interrupts, alarms). This information is derived from count clock RTCATCKI.

Sub-counter

RTCATCKI is input to sub-counter RTCAnSUBC. Sub-counter counts up from 0 until it reaches compare value. Compare value is always defined as frequency of RTCATCKI – 1 (in Hz). Thus, sub-counter overflows after one second. It is then reset to 0 and triggers seconds counter RTCAnSECC (and, if specified, interrupt INTRTCA01S).

Sub-counter can generate a fixed interval interrupt every 0.25 seconds, 0.5 seconds, or 1 second, and a 1-Hz output pulse.

Time and date counters

Counters for minutes, hours, day of week, day of month, months, and years also count up. They have their own overflow limits. If all lower counters overflow, upper counter counts up.

Overflow limit of counter for day of month (RTCAnDAYC) depends on present month (28, 30, or 31 days) and (in February) on year counter RTCAnYEARC (years 0, 4, 8, 12, etc. are considered leap years).

Hours counter RTCAnHOURC can be switched between 12- and 24-hour formats.

Counters for seconds, minutes, hours, day of month, and months can generate a fixed interval interrupt upon overflow (INTRTCA0R).

Counters for minutes, hours, and day of week can also generate an alarm interrupt (INTRTCA0AL), e.g. every Tuesday and Thursday at 10:32.

Counter buffers

All counters can be read directly at any time. Clock signal used to access read/write registers and count clock are usually asynchronous. An overflow of sub-counter during read operation can make all read values obsolete. Therefore, reading counters must be performed using a special procedure. For details, see **Section 39.5.1.3, Reading Clock Counters**.

For reasons of synchronization, counters cannot be written directly.

For reading and writing, all counters are accompanied by buffer registers. Buffer registers provide a synchronized way for reading counters and for setting time and date. When they are used, operation of sub-counter must first be suspended and then re-activated (see also **Section 39.5.1.3, Reading Clock Counters** and **Section 39.5.1.2, Updating Clock Counters**.

RTCAnTIMEC and RTCAnCALC registers and their corresponding buffer registers can be used to check and set time (hours, minutes and seconds) or date (day of week, day of month, month, and year) with one read/write operation.

39.3 Registers

39.3.1 List of Registers

RTCA registers are listed in following table.

<RTCAn_base> is defined in **Section 39.1.2, Register Base Addresses**.

Table 39.8 List of Registers

Module Name	Register Name	Symbol	Address	Access Size	Access Protection	
					PBG	Others
Control registers						
RTCAn	Control register 0	RTCAnCTL0	<RTCAn_base> + 00_H	8	PBG20#10	—
RTCAn	Control register 1	RTCAnCTL1	<RTCAn_base> + 04_H	8	PBG20#10	—
RTCAn	Control register 2	RTCAnCTL2	<RTCAn_base> + 08_H	8	PBG20#10	—
Sub-counter registers						
RTCAn	Sub-count register	RTCAnSUBC	<RTCAn_base> + $0C_H$	32	PBG20#10	—
RTCAn	Sub-count register read buffer	RTCAnSRBU	<RTCAn_base> + 10_H	32	PBG20#10	—
RTCAn	Sub-counter compare register	RTCAnSCMP	<RTCAn_base> + $3C_H$	32	PBG20#10	—
Clock counter and buffer registers						
RTCAn	Seconds count register	RTCAnSECC	<RTCAn_base> + $4C_H$	8	PBG20#10	—
RTCAn	Seconds count buffer register	RTCAnSEC	<RTCAn_base> + 14_H	8	PBG20#10	—
RTCAn	Minute count register	RTCAnMINC	<RTCAn_base> + 50_H	8	PBG20#10	—
RTCAn	Minute count buffer register	RTCAnMIN	<RTCAn_base> + 18_H	8	PBG20#10	—
RTCAn	Hour count register	RTCAnHOURC	<RTCAn_base> + 54_H	8	PBG20#10	—
RTCAn	Hour count buffer register	RTCAnHOUR	<RTCAn_base> + $1C_H$	8	PBG20#10	—
RTCAn	Day of week count register	RTCAnWEEKC	<RTCAn_base> + 58_H	8	PBG20#10	—
RTCAn	Day of week count buffer register	RTCAnWEEK	<RTCAn_base> + 20_H	8	PBG20#10	—
RTCAn	Day count register	RTCAnDAYC	<RTCAn_base> + $5C_H$	8	PBG20#10	—
RTCAn	Day count buffer register	RTCAnDAY	<RTCAn_base> + 24_H	8	PBG20#10	—
RTCAn	Month count register	RTCAnMONC	<RTCAn_base> + 60_H	8	PBG20#10	—
RTCAn	Month count buffer register	RTCAnMONTH	<RTCAn_base> + 28_H	8	PBG20#10	—
RTCAn	Year count register	RTCAnYEARC	<RTCAn_base> + 64_H	8	PBG20#10	—
RTCAn	Year count buffer register	RTCAnYEAR	<RTCAn_base> + $2C_H$	8	PBG20#10	—
Special counter and buffer registers						
RTCAn	Time count register	RTCAnTIMEC	<RTCAn_base> + 68_H	32	PBG20#10	—
RTCAn	Time count buffer register	RTCAnTIME	<RTCAn_base> + 30_H	32	PBG20#10	—
RTCAn	Calendar count register	RTCAnCALC	<RTCAn_base> + $6C_H$	32	PBG20#10	—
RTCAn	Calendar count buffer register	RTCAnCAL	<RTCAn_base> + 34_H	32	PBG20#10	—
Alarm time setting registers						
RTCAn	Alarm minute setting register	RTCAnALM	<RTCAn_base> + 40_H	8	PBG20#10	—
RTCAn	Alarm hour setting register	RTCAnALH	<RTCAn_base> + 44_H	8	PBG20#10	—
RTCAn	Alarm day of week setting register	RTCAnALW	<RTCAn_base> + 48_H	8	PBG20#10	—

39.3.2 Details of RTCA Control Registers

39.3.2.1 RTCAnCTL0 — RTCA Control Register 0

This register controls count operation of sub-counter RTCAnSUBC, format (12-hour/24-hour) of hours counter RTCAnHOURC and alarm hour setting register RTCAnALH, and operation mode.

Access: This register can be read or written in 8-bit or 1-bit units.

Address: <RTCAn_base> + 00_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	RTCAnCE	RTCAnCEST	RTCAnAMPM	RTCAnSLSB	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0
R/W	R/W	R	R/W	R/W	R	R	R	R

Table 39.9 RTCAnCTL0 Register Contents

Bit Position	Bit Name	Function
7	RTCAnCE	Starts/stops sub-counter RTCAnSUBC operation. 0: Stops sub-counter operation. All output pins and all status flags in control register RTCAnCTL2 are cleared. 1: Starts sub-counter operation. sub-counter counts up.
6	RTCAnCEST	Indicates operation enabled/stopped status of sub-counter: 0: Operation stopped status 1: Operation enabled status For details on how to use this status flag, see **Section 39.5.1.1, Initial Setting of RTCA**.
5	RTCAnAMPM	Selects format of hours counter RTCAnHOURC and alarm hour setting register RTCAnALH: 0: 12-hour format (1 to 12, am/pm) 1: 24-hour format (0 to 23, military time) For details on format, see **Table 39.20, 12- and 24-Hour Format**.
4	RTCAnSLSB	Selects operation mode: 0: Setting prohibited 1: Frequency selection mode*1 For details on operation modes, see **Section 39.4, Operation**. Operation mode must not be changed while sub-counter operation is enabled (RTCAnCTL0.RTCAnCEST = 1). For details on initialization of RTCAn, see **Section 39.5.1.1, Initial Setting of RTCA**.
3 to 0	Reserved	When read, the value after reset is returned. When writing, write value after reset.

Note 1. RTCAnSLSB must be set “1” before RTCAnSCMP register setting.

39.3.2.2 RTCAnCTL1 — RTCA Control Register 1

This register controls interrupt request generation and 1-Hz pulse output.

Access: This register can be read or written in 8-bit or 1-bit units.

Address: <RTCAn_base> + 04_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	RTCAnEN1HZ	RTCAnENALM	RTCAnEN1S	RTCAnCT2	RTCAnCT1	RTCAnCT0
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R/W	R/W	R/W	R/W	R/W	R/W

Table 39.10 RTCAnCTL1 Register Contents

Bit Position	Bit Name	Function
7, 6	Reserved	When read, the value after reset is returned. When writing, write value after reset.
5	RTCAnEN1HZ	Enables/stops 1-Hz pulse output (RTCAT1HZ): 0: RTCAT1HZ disabled (RTCAT1HZ is fixed to 0) 1: RTCAT1HZ enabled
4	RTCAnENALM	Enables/disables alarm interrupt request generation (INTRTCA0AL): 0: INTRTCA0AL disabled 1: INTRTCA0AL enabled
3	RTCAnEN1S	Enables/disables 1-second interrupt request generation (INTRTCA01S): 0: INTRTCA01S disabled 1: INTRTCA01S enabled
2 to 0	RTCAnCT[2:0]	Specifies fixed interval interrupt request (INTRTCA0R) setting:

RTCAnCT[2:0]	RTCATINTR Interrupt Request Generation	
	Interval	Timing
000	No interrupt request generation	
001	Every 0.25 seconds	Every 0.25, 0.5, 0.75 and 1 second
010	Every 0.5 seconds	Every 0.5 and 1 second
011	Every second	Every 1 second
100	Every minute	Every 1 minute 00 seconds
101	Every hour	Every 1 hour 00 minutes 00 seconds
110	Every day	Every 1 day 00 hours 00 minutes 00 seconds (i.e., every midnight)
111	Every month	Every 1 month first day 00 hours 00 minutes 00 seconds (i.e., every first midnight of a month)

If settings of RTCAnCT[2:0] are changed while sub-counter operation is enabled (RTCAnCTL0.RTCAnCE = 1), a glitch may be output to INTRTCA0R. Implement appropriate interrupt mask processing procedures.

39.3.2.3 RTCAnCTL2 — RTCA Control Register 2

This register contains status information and controls data transfer from sub-counter RTCAnSUBC to dedicated sub-counter read buffer RTCAnSRBU and operation setting of clock counters (RTCAnSECC to RTCAnYEARC).

Access: This register can be read or written in 8-bit or 1-bit units.

Address: <RTCAn_base> + 08_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	RTCAnWSST	RTCAnRSST	RTCAnRSUB	RTCAnWST	RTCAnWAIT
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R/W	R	R/W

Table 39.11 RTCAnCTL2 Register Contents (1/2)

Bit Position	Bit Name	Function
7 to 5	Reserved	When read, the value after reset is returned. When writing, write value after reset.
4	RTCAnWSST	Indicates whether RTCAnSCMP write operation has been completed: 0: RTCAnSCMP write completed 1: RTCAnSCMP write in progress The write operation ends with next sub-counter overflow. This bit is set (to 1) when RTCAnSCMP is written to while clock counter operation is enabled (RTCAnCE = 1). It is then cleared (to 0) upon completion of RTCAnSCMP write (with next RTCAnSUBC overflow). See **Section 39.5.1.5, Writing to RTCAnSCMP**, for details.
3	RTCAnRSST	Indicates whether value of sub-counter (RTCAnSUBC) has been transferred to sub-count register read buffer (RTCAnSRBU): 0: Transfer in progress, or waiting for a transfer trigger 1: Transfer completed This bit is cleared (transfer is triggered) by RTCAnRSUB=1.This bit is automatically set when transfer is completed. See **Section 39.5.1.4, Reading RTCAnSRBU**, for details.
2	RTCAnRSUB	Triggers transfer of value of sub-counter (RTCAnSUBC) to dedicated read buffer (RTCAnSRBU) or clears transfer state of sub-counter: 0: Transfer status (RTCAnRSST) is cleared. 1: Transfer is triggered. This bit is used to read value of RTCAnSRBU when sub-counter operation is enabled (RTCAnCTL0.RTCAnCE = 1). value of RTCAnSUBC is synchronized with RTCATCKI and loaded to RTCAnSRBU. For details, see **Section 39.5.1.4, Reading RTCAnSRBU**.
1	RTCAnWST	Indicates status of all clock counters (RTCAnSECC to RTCAnYEARC): 0: All clock counters are running. 1: All clock counters are stopped sub-counter is still running. Clock counters must be stopped before reading or writing clock counter values during sub-counter operation (RTCAnCTL0.RTCAnCE = 1). To stop clock counters, set RTCAnWAIT = 1.

Table 39.11 RTCAnCTL2 Register Contents (2/2)

Bit Position	Bit Name	Function
0	RTCAnWAIT	Restarts/stops all clock counters (RTCAnSECC to RTCAnYEARC): 0: Restarts all clock counters either immediately or immediately after clock counter write operation finishes. 1: Stops all clock counters temporarily. Sub-counter is still running. Clock counters must be stopped before reading or writing counter buffers during sub-counter operation (RTCAnCTL0.RTCAnCE = 1). **CAUTION** Only one overflow can be held internally. When two overflows occur, seconds counter is incremented only by one when it is restarted. Thus, procedure must be completed within one second.

39.3.3 Details of RTCA Sub-Counter Registers

39.3.3.1 RTCAnSUBC — RTCA Sub-Count Register

This counter counts 1-second reference time. It operates using count clock RTCATCKI.

Access: This register is a read-only register that can be read in 32-bit units.

Address: <RTCAn_base> + $0C_H$

Value after reset: $0000\ 0000_H$

This register is initialized:

– When write operation is performed to seconds count buffer register (RTCAnSEC) or to time count buffer register (RTCAnTIME) and value is reflected to seconds count register.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	RTCAnSUBC[21:16]					
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

	RTCAnSUBC[15:0]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 39.12 RTCAnSUBC Register Contents

Bit Position	Bit Name	Function
31 to 22	Reserved	When read, the value after reset is returned.
21 to 0	RTCAnSUBC [21:0]	Sub-counter value Sub-counter only operates while RTCAnCTL0.RTCAnCEST = 1.

NOTES

1. This sub-counter operates with RTCATCKI while read operation is clocked by PCLK. Reading this sub-counter during operation (RTCAnCTL0.RTCAnCEST = 1) is asynchronous to RTCATCKI and can lead to wrong results.
   Use sub-count register read buffer (RTCAnSRBU) to read sub-counter value during operation. For details, see **Section 39.5.1.4, Reading RTCAnSRBU**.
2. Count-operation of this sub-counter depends on selected operation mode. See **Section 39.4, Operation**, for details.

39.3.3.2 RTCAnSRBU — RTCA Sub-Count Register Read Buffer

This register is read buffer for sub-counter RTCAnSUBC.

Access: This register is a read-only register that can be read in 32-bit units.

Address: <RTCAn_base> + 10_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	RTCAnSRBU[21:16]					
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

	RTCAnSRBU[15:0]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 39.13 RTCAnSRBU Register Contents

Bit Position	Bit Name	Function
31 to 22	Reserved	When read, the value after reset is returned.
21 to 0	RTCAnSRBU [21:0]	Sub-counter value at time of last RTCAnSUBC read. When RTCAnCTL2.RTCAnRSUB is set to 1, value of RTCAnSUBC is loaded to read buffer in synchronization with RTCATCKI.

NOTE

Perform RTCAnSRBU read according to flow described in **Section 39.5.1.4, Reading RTCAnSRBU**.

39.3.3.3 RTCAnSCMP — RTCA Sub-Counter Compare Register

This register sets compare value of sub-counter RTCAnSUBC in frequency selection mode (RTCAnCTL0.RTCAnSLSB = 1).

When sub-counter values matches value of this register, an overflow signal is output to seconds counter RTCAnSECC and sub-counter is cleared.

Set value for this register according to frequency of input clock RTCATCKI.

Access: This register can be read or written in 32-bit units.
Note following when writing this register during sub-counter operation:
- Previous RTCAnSCMP write must be completed (RTCAnCTL2.RTCAnWSST = 0).
- write operation ends with next sub-counter overflow.

Address: <RTCAn_base> + $3C_H$

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	RTCAnSCMP[21:16]					
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	RTCAnSCMP[15:0]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 39.14 RTCAnSCMP Register Contents

Bit Position	Bit Name	Function
31 to 22	Reserved	When read, the value after reset is returned. When writing, write value after reset.
21 to 0	RTCAnSCMP [21:0]	Sub-counter compare value in frequency selection mode.

Example

Following example illustrates setting of RTCAnSCMP:

- RTCATCKI = 2.5 MHz = 2,500,000 Hz
- RTCAnSCMP = 2,500,000 – 1 = 2,499,999 (decimal code) = $26259F_H$
- Seconds counter RTCAnSECC is triggered when sub-counter value changes from $26259F_H$ to 0_H.

NOTES

1. Operation of RTCA cannot be guaranteed if a value of 3198 (decimal code) or lower is set in this register.
2. Perform RTCAnSCMP write as described in **Section 39.5.1.1, Initial Setting of RTCA** and **Section 39.5.1.5, Writing to RTCAnSCMP**.

39.3.4 Details of RTCA Clock Counter and Buffer Registers

39.3.4.1 RTCAnSECC — RTCA Seconds Count Register

This register is seconds counter. It counts seconds from 00 to 59 in BCD.

This register counts as follows.

- It is triggered by every overflow of sub-counter RTCAnSUBC.

  If sub-counter overflows while seconds counter is stopped (RTCAnCTL2.RTCAnWST = 1), seconds counter behaves as follows:

  – If one sub-counter overflow occurs while seconds counter is stopped, overflow is held internally.
  seconds counter is incremented by one when it is restarted.

  – If two or more overflows occur while seconds counter is stopped, overflow count cannot be held internally.
  seconds counter is incremented by one when it is restarted.

  – If seconds counter was updated while seconds counter is stopped, sub-counter overflow(s) are ignored.

- It outputs an overflow signal when value changes from 59 to 00. Overflow signal triggers minutes counter (RTCAnMINC).

Access: This register is a read-only register that can be read in 8-bit units.

Address: <RTCAn_base> + $4C_H$

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	RTCAnSECC[6:0]						
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R

Table 39.15 RTCAnSECC Register Contents

Bit Position	Bit Name	Function
7	Reserved	When read, the value after reset is returned.
6 to 0	RTCAnSECC [6:0]	Seconds in BCD

NOTES

1. Perform RTCAnSECC read according to flow described in **Section 39.5.1.3, Reading Clock Counters**.
2. A start value can be assigned to this register by writing to seconds count buffer register RTCAnSEC or to clock time setting register RTCAnTIME. See
   - **Section 39.5.1.1, Initial Setting of RTCA**, and
   - **Section 39.5.1.2, Updating Clock Counters**

39.3.4.2 RTCAnSEC — RTCA Seconds Count Buffer Register

This register is a buffer register to read/write seconds counter RTCAnSECC.

Access: This register can be read or written in 8-bit units.

Address: <RTCAn_base> + 14_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	RTCAnSEC[6:0]						
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 39.16 RTCAnSEC Register Contents

Bit Position	Bit Name	Function
7	Reserved	When read, the value after reset is returned. When writing, write the value after reset.
6 to 0	RTCAnSEC [6:0]	Seconds in BCD

NOTES

1. When writing this register, only decimal values between 00 and 59 in BCD are allowed.
2. Perform RTCAnSEC read/write as described in
   - **Section 39.5.1.1, Initial Setting of RTCA,**
   - **Section 39.5.1.2, Updating Clock Counters**, and
   - **Section 39.5.1.3, Reading Clock Counters.**

39.3.4.3 RTCAnMINC — RTCA Minutes Count Register

This register is minutes counter. It counts minutes from 00 to 59 in BCD.

This register counts as follows.

- It is triggered by every overflow of seconds counter RTCAnSECC.
- It outputs an overflow signal when value changes from 59 to 00. Overflow signal triggers hours counter (RTCAnHOURC).

Access: This register is a read-only register that can be read in 8-bit units.

Address: <RTCAn_base> + 50_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	RTCAnMINC[6:0]						
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R

Table 39.17 RTCAnMINC Register Contents

Bit Position	Bit Name	Function
7	Reserved	When read, the value after reset is returned.
6 to 0	RTCAnMINC [6:0]	Minutes in BCD

NOTES

1. Perform RTCAnMINC read according to flow described in **Section 39.5.1.3, Reading Clock Counters**.
2. A start value can be assigned to this register by writing to minutes count buffer register RTCAnMIN or to time count buffer register RTCAnTIME. See
   - **Section 39.5.1.1, Initial Setting of RTCA**, and
   - **Section 39.5.1.2, Updating Clock Counters.**

39.3.4.4 RTCAnMIN — RTCA Minutes Count Buffer Register

This register is a buffer register to read/write minutes counter RTCAnMINC.

Access: This register can be read or written in 8-bit units.

Address: <RTCAn_base> + 18_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	RTCAnMIN[6:0]						
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 39.18 RTCAnMIN Register Contents

Bit Position	Bit Name	Function
7	Reserved	When read, the value after reset is returned. When writing, write value after reset.
6 to 0	RTCAnMIN [6:0]	Minutes in BCD

NOTES

1. When writing this register, only decimal values between 00 and 59 in BCD are allowed.
2. Perform RTCAnMIN read/write as described in
   - **Section 39.5.1.1, Initial Setting of RTCA,**
   - **Section 39.5.1.2, Updating Clock Counters**, and
   - **Section 39.5.1.3, Reading Clock Counters.**

39.3.4.5 RTCAnHOURC — RTCA Hours Count Register

This register is hours counter. It counts hours in BCD. Count range depends on selected hour format. See **Table 39.20, 12- and 24-Hour Format**.

This register counts as follows.

- It is triggered by every overflow of minutes counter RTCAnMINC.
- It outputs an overflow signal when value changes from 23 to 00 (in 24-hour format) or from 31 to 12 (in 12-hour format). Overflow signal triggers two counters:
  - Day of week counter (RTCAnWEEKC)
  - Day of month counter (RTCAnDAYC)

Access: This register is a read-only register that can be read in 8-bit units.

Address: <RTCAn_base> + 54_H

Value after reset: 12_H

Bit	7	6	5	4	3	2	1	0
	—	—	RTCAnHOURC[5:0]					
Value after reset	0	0	0	1	0	0	1	0
R/W	R	R	R	R	R	R	R	R

Table 39.19 RTCAnHOURC Register Contents

Bit Position	Bit Name	Function
7, 6	Reserved	When read, the value after reset is returned.
5 to 0	RTCAnHOURC [5:0]	Hours in BCD. See **Table 39.20, 12- and 24-Hour Format**, for details.

NOTES

1. Perform RTCAnHOURC read according to flow described in **Section 39.5.1.3, Reading Clock Counters**.
2. A start value can be assigned to this register by writing to hours count buffer register RTCAnHOUR or to time count buffer register RTCAnTIME. See
   - **Section 39.5.1.1, Initial Setting of RTCA**, and
   - **Section 39.5.1.2, Updating Clock Counters.**

12- or 24-hour format

Count values of RTCAnHOURC depend on selected hour format.

If 12-hour format is selected (RTCAnCTL0.RTCAnAMPM = 0), bit 5 in RTCAnHOURC register is am/pm indicator:

- RTCAnHOURC[5] = 0: am
- RTCAnHOURC[5] = 1: pm

Following table shows count range of RTCAnHOURC in both 12- and 24-hour format.

Table 39.20 12- and 24-Hour Format

12-Hour Format (RTCAnAMPM = 0)			24-Hour Format (RTCAnAMPM = 1)	
Time	RTCAnHOURC		Time	RTCAnHOURC
0 am	12_H		0	00_H
1 am	01_H		1	01_H
2 am	02_H		2	02_H
3 am	03_H		3	03_H
4 am	04_H		4	04_H
5 am	05_H		5	05_H
6 am	06_H		6	06_H
7 am	07_H		7	07_H
8 am	08_H		8	08_H
9 am	09_H		9	09_H
10 am	10_H		10	10_H
11 am	11_H		11	11_H
0 pm	32_H	↓	12	12_H
1 pm	21_H	pm indicator in 12-hour format: RTCAnHOUR.RTCAnHOUR[5] = 1	13	13_H
2 pm	22_H		14	14_H
3 pm	23_H		15	15_H
4 pm	24_H		16	16_H
5 pm	25_H		17	17_H
6 pm	26_H		18	18_H
7 pm	27_H		19	19_H
8 pm	28_H		20	20_H
9 pm	29_H		21	21_H
10 pm	30_H		22	22_H
11 pm	31_H		23	23_H

39.3.4.6 RTCAnHOUR — RTCA Hours Count Buffer Register

This register is a buffer register to read/write hours counter RTCAnHOURC.

Access: This register can be read or written in 8-bit units.

Address: <RTCAn_base> + $1C_H$

Value after reset: 12_H

Bit	7	6	5	4	3	2	1	0
	—	—	RTCAnHOUR[5:0]					
Value after reset	0	0	0	1	0	0	1	0
R/W	R	R	R/W	R/W	R/W	R/W	R/W	R/W

Table 39.21 RTCAnHOUR Register Contents

Bit Position	Bit Name	Function
7, 6	Reserved	When read, the value after reset is returned. When writing, write value after reset.
5 to 0	RTCAnHOUR [5:0]	Hours in BCD See **Table 39.20, 12- and 24-Hour Format**, for details.

NOTES

1. When writing this register, only following decimal values in BCD are allowed:
   - 12-hour format (RTCAnCTL0.RTCAnAMPM = 0):
     01 to 12 or 21 to 32
   - 24-hour format (RTCAnCTL0.RTCAnAMPM = 1):
     00 to 23
2. Perform RTCAnHOUR read/write as described in
   - **Section 39.5.1.1, Initial Setting of RTCA,**
   - **Section 39.5.1.2, Updating Clock Counters**, and
   - **Section 39.5.1.3, Reading Clock Counters.**

39.3.4.7 RTCAnWEEKC — RTCA Day of Week Count Register

This register is day of week counter. It counts from 0 to 6.

This register counts as follows.

- It is triggered by every overflow of hours counter RTCAnHOURC.

Access: This register is a read-only register that can be read in 8-bit units.

Address: <RTCAn_base> + 58_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	RTCAnWEEKC[2:0]		
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R

Table 39.22 RTCAnWEEKC Register Contents

Bit Position	Bit Name	Function
7 to 3	Reserved	When read, the value after reset is returned.
2 to 0	RTCAnWEEKC [2:0]	Day of week

NOTES

1. Perform RTCAnWEEKC read according to flow described in **Section 39.5.1.3, Reading Clock Counters**.
2. A start value can be assigned to this register by writing to day of week count buffer register RTCAnWEEK or to calendar count buffer register RTCAnCAL. See
   - **Section 39.5.1.1, Initial Setting of RTCA**, and
   - **Section 39.5.1.2, Updating Clock Counters.**

39.3.4.8 RTCAnWEEK — RTCA Day of Week Count Buffer Register

This register is a buffer register to read/write day of week counter RTCAnWEEKC.

There is no particular correspondence between value of RTCAnWEEK and day of week. Set correspondence according to application to be used.

Example: 0 = Sunday, 1 = Monday, …, 6 = Saturday

Access: This register can be read or written in 8-bit units.

Address: <RTCAn_base> + 20_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	RTCAnWEEK[2:0]		
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R/W	R/W	R/W

Table 39.23 RTCAnWEEK Register Contents

Bit Position	Bit Name	Function
7 to 3	Reserved	When read, the value after reset is returned. When writing, write value after reset.
2 to 0	RTCAnWEEK [2:0]	Day of week

NOTES

1. When writing this register, only decimal values between 0 and 6 in BCD are allowed.
2. Perform RTCAnWEEK read/write as described in
   - **Section 39.5.1.1, Initial Setting of RTCA,**
   - **Section 39.5.1.2, Updating Clock Counters**, and
   - **Section 39.5.1.3, Reading Clock Counters.**

39.3.4.9 RTCAnDAYC — RTCA Day of Month Count Register

This register is day of month counter. It counts from 01 to a maximum of 31 in BCD, depending on value of month counter (RTCAnMONC) and year counter (RTCAnYEARC):

- 01 to 31 (January, March, May, July, August, October, December)
- 01 to 30 (April, June, September, November)
- 01 to 29 (February, leap year)
- 01 to 28 (February, non-leap year)

Years 0, 4, 8, 12, etc., are considered leap years.

This register counts as follows.

- It is triggered by every overflow of hours counter RTCAnHOURC.
- It outputs an overflow signal when value changes from 28, 29, 30, or 31 to 01, depending on current month and year. Overflow signal triggers month counter (RTCAnMONC).

Access: This register is a read-only register that can be read in 8-bit units.

Address: <RTCAn_base> + $5C_H$

Value after reset: 01_H

Bit	7	6	5	4	3	2	1	0
	—	—	RTCAnDAYC[5:0]					
Value after reset	0	0	0	0	0	0	0	1
R/W	R	R	R	R	R	R	R	R

Table 39.24 RTCAnDAYC Register Contents

Bit Position	Bit Name	Function
7, 6	Reserved	When read, the value after reset is returned.
5 to 0	RTCAnDAYC [5:0]	Day of month in BCD

NOTES

1. Perform RTCAnDAYC read according to flow described in **Section 39.5.1.3, Reading Clock Counters**.
2. A start value can be assigned to this register by writing to day of month count buffer register RTCAnDAY or to calendar count buffer register RTCAnCAL. See
   - **Section 39.5.1.1, Initial Setting of RTCA**, and
   - **Section 39.5.1.2, Updating Clock Counters.**

39.3.4.10 RTCAnDAY — RTCA Day of Month Count Buffer Register

This register is a buffer register to read/write day of month counter RTCAnDAYC.

Access: This register can be read or written in 8-bit units.

Address: <RTCAn_base> + 24_H

Value after reset: 01_H

Bit	7	6	5	4	3	2	1	0
	—	—	RTCAnDAY[5:0]					
Value after reset	0	0	0	0	0	0	0	1
R/W	R	R	R/W	R/W	R/W	R/W	R/W	R/W

Table 39.25 RTCAnDAY Register Contents

Bit Position	Bit Name	Function
7, 6	Reserved	When read, the value after reset is returned. When writing, write value after reset.
5 to 0	RTCAnDAY [5:0]	Day of month in BCD

NOTES

1. When writing this register, only decimal values between 01 and 31 in BCD are allowed:
   - 01 to 31 (January, March, May, July, August, October, December)
   - 01 to 30 (April, June, September, November)
   - 01 to 29 (February, leap year)
   - 01 to 28 (February, non-leap year)
2. Perform RTCAnDAY read/write as described in
   - **Section 39.5.1.1, Initial Setting of RTCA,**
   - **Section 39.5.1.2, Updating Clock Counters**, and
   - **Section 39.5.1.3, Reading Clock Counters.**

39.3.4.11 RTCAnMONC — RTCA Month Count Register

This register is month counter. It counts month of year, starting from 01 to 12 in BCD.

This register counts as follows.

- It is triggered by every overflow of counter for day of month RTCAnDAYC.
- It outputs an overflow signal when value changes from 12 to 01. Overflow signal triggers year counter (RTCAnYEARC).

Access: This register is a read-only register that can be read in 8-bit units.

Address: <RTCAn_base> + 60_H

Value after reset: 01_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	RTCAnMONC[4:0]
